EXISTENCE OF SOLUTIONS TO THE ELASTOHYDRODYNAMICAL EQUATIONS FOR MAGNETIC RECORDING SYSTEMS*

MICHEL CHIPOT† AND MITCHELL LUSKIN‡

Abstract. The existence of steady-state solutions to the system of nonlinear partial differential equations which are used to model the elastohydrodynamics of magnetic recording systems is demonstrated.

Key words. elastohydrodynamics, Reynolds lubrication equation, nonlinear partial differential equations

AMS(MOS) subject classifications. 35J65, 73J06

1. Introduction. The purpose of this paper is to demonstrate the existence of steady-state solutions under appropriate conditions to the system of nonlinear partial differential equations which are used to model the elastohydrodynamics of magnetic recording systems. There are two components to these mechanical systems: a medium such as a disk pressure which develops in the air bearing between the medium and the recording head causes a deflection in the medium and since the deflection of the medium influences the pressure in the air bearing.

For simplicity, we shall restrict our attention to disk systems. Let $\Omega \subset \mathbb{R}^2$ be the annular region of the disk

$$\Omega = \{ x = (x_1, x_2) \mid R < r < 1 \}$$

where $r = \sqrt{x_1^2 + x_2^2}$ and let $\Gamma \subset \Omega$ be the region where the head is in close proximity to the disk. Thus, we have scaled the spatial variables by the outer radius of the disk. The mathematical model that we use for the transverse displacement of the disk, $u = u(x,t)$, is given by [8], [13]

$$\rho\left(\frac{\partial}{\partial t} + \omega\frac{\partial}{\partial \theta}\right)^2 u = \nabla \cdot (T\nabla u) - \frac{E_p t_p^3}{12(1-\nu^2)}\Delta^2 u - \gamma\left(\frac{\partial}{\partial t} + \omega\frac{\partial}{\partial \theta}\right)u + p - p_a, \tag{1.1}$$

$$x = (x_1, x_2) \in \Omega, \qquad -\infty < t < \infty,$$

where t is time, θ is the angular coordinate in polar coordinates, ρ is area density, ω is the angular speed of rotation of the disk, T is tension, $E_p > 0$ is Young's modulus, t_p is the disk thickness, ν is Poisson's ratio, $\gamma > 0$ is the air damp coefficient, $p = p(x,t)$ is the pressure developed in the air bearing, and p_a is the ambient pressure.

It is reported in [13] that "earlier work has shown that by bonding tensioned flexible recording media to rigid support disks it is possible to have performance features

similar to rigid disks, while retaining the advantages of flexible-media technology." For tensioned flexible recording media, the imposed tension is a scalar constant and the centrifugal tension is insignificant [13]. Thus, we shall take the total tension, T, to be a scalar constant. Since tensioned flexible recording media are bonded to rigid support disks at the inner and outer edge of the media (the support disk rotates with the medium), the appropriate boundary conditions are that the disk is clamped at the edges,

$$u = 0, \qquad r = R, 1, \tag{1.2}$$

and

$$\frac{\partial u}{\partial n} = \frac{\partial u}{\partial r} = 0, \qquad r = R, 1, \tag{1.3}$$

where n is the exterior normal to Ω. More details about tensioned flexible recording media and their advantages with respect to rigid (hard) disks and floppy disks are reported in [11].

The pressure, $p = p(x,t)$, is obtained from the compressible Reynolds lubrication equation [3]–[5], [8], [13]

$$\begin{aligned} &12\mu\frac{\partial(ph)}{\partial t} + 6\mu\mathbf{V}\cdot\nabla(ph) = \nabla\cdot(h^3p\nabla p), && x = (x_1,x_2)\in\Gamma, \\ &p = p_a, && x = (x_1,x_2)\in\partial\Gamma, \end{aligned} \tag{1.4}$$

where μ is the dynamic viscosity of the air, $h = h(x,t)$ is the thickness of the fluid layer between the head and the disk, and $\mathbf{V} = \mathbf{V}(x) = \omega(-x_2, x_1)$ is the velocity of the disk. We extend p to $\Omega - \Gamma$ by $p \equiv p_a$. If $\varphi = \varphi(x)$ represents the transverse coordinate of the head, then

$$h = h(u) = \varphi - u\,. \tag{1.5}$$

It will be convenient to define the dependent variables as functions of Cartesian coordinates, $x = (x_1, x_2)$, and as functions of radial coordinates, (r,θ), in different parts of this paper. However, we will denote the pressure, for example, by $p = p(x,t)$ or by $p = p(r,\theta,t)$. It will always be clear from the context which representation is appropriate.

Since $h = h(u) = \varphi - u$, the system (1.1) and (1.4) is a highly nonlinear, coupled system of partial differential equations. The physical problem requires that the variables be constrained by $p \geq 0$ and $h \geq 0$ ($h < 0$ would mean that a "head crash" has occurred). In this paper, we demonstrate the existence of a steady-state solution to (1.1)–(1.4) provided the parameters satisfy a given inequality. It is not known if there always exists a steady-state solution to the elastohydrodynamical system (1.1) and (1.4). Further, it is not known in general when unique asymptotically stable steady-state solutions exist to the elastohydrodynamical system. We note, though, that it has been demonstrated in [12] that steady-state solutions to (1.1) are asymptotically stable.

These questions of existence, uniqueness, and asymptotic stability for realistic parameter values are of practical interest in the design of magnetic recording systems. "Steady-state" solutions are often found numerically by integrating the time-dependent equations, and it can be difficult to determine whether we have converged

to a steady-state, a slowly varying transient, or a slowly varying periodic solution. In this paper, we show that steady-state solutions do exist for appropriate material constants, design parameters, and operating conditions.

In §2, we shall give some estimates for the steady-state of (1.1). In §3, we shall review the estimates that we have obtained for (1.4) in [5], and we shall give the analysis for the existence of steady-state solutions for the coupled system (1.1) and (1.4). Applications to floppy disk systems and tape systems are also given in §§2 and 3.

We suppose the reader familiar with the usual Sobolev spaces $H^1(\Omega)$, $H^k(\Omega)$, and $H_0^k(\Omega)$, and we refer to [1] for details and notation.

2. The steady-state for the deflection of the rotating disk. In this section, we shall analyze the following steady-state equation for (1.1) to find $u \in H_0^2(\Omega) \cap H^4(\Omega)$ such that

$$\rho\omega^2 \frac{\partial^2 u}{\partial \theta^2} = \nabla \cdot (T \nabla u) - E\Delta^2 u - \gamma\omega \frac{\partial u}{\partial \theta} + p, \qquad x \in \Omega, \tag{2.1}$$

where

$$E \equiv \frac{E_p t_p^3}{12(1-\nu^2)} \tag{2.2}$$

and $p \in L^2(\Omega)$.

Since $p = p(r, \theta)$ is mean square integrable, we have the Fourier expansion

$$p(r,\theta) = \sum_{m=-\infty}^{+\infty} p_m(r) e^{im\theta} \tag{2.3}$$

where the coefficients are given by

$$p_m(r) = \frac{1}{2\pi} \int_0^{2\pi} p(r,\theta) e^{-im\theta}\, d\theta. \tag{2.4}$$

It follows from the orthogonality of $e^{im\theta}$ that

$$\sum_{m=-\infty}^{+\infty} 2\pi \int_R^1 |p_m(r)|^2 r\, dr = \int_0^{2\pi} \int_R^1 |p(r,\theta)|^2 r\, dr\, d\theta < \infty$$

and, hence,

$$\int_R^1 |p_m(r)|^2 r\, dr < \infty.$$

We also assume the solution $u = u(r, \theta)$ to be mean square integrable, and we similarly expand

$$u(r,\theta) = \sum_{m=-\infty}^{+\infty} u_m(r) e^{im\theta}$$

where

$$u_m(r) = \frac{1}{2\pi} \int_0^{2\pi} u(r,\theta) e^{-im\theta}\, d\theta.$$

We again have that

$$\int_0^{2\pi} \int_R^1 |u(r,\theta)|^2 r\, dr\, d\theta = \sum_{m=-\infty}^{+\infty} 2\pi \int_R^1 |u_m(r)|^2 r\, dr < \infty.$$

Now

$$\Delta u = \left(\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial}{\partial r}\right) + \frac{1}{r^2}\frac{\partial^2}{\partial\theta^2}\right)u,$$

so from (2.1) we obtain from matching the coefficient of $e^{im\theta}$ in both sides that

$$-\rho\omega^2 m^2 u_m = T\left(\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial}{\partial r}\right) - \frac{m^2}{r^2}\right)u_m$$

$$- E\left(\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial}{\partial r}\right) - \frac{m^2}{r^2}\right)^2 u_m - i\gamma\omega m u_m + p_m, \tag{2.5}$$

$$u_m = \frac{\partial u_m}{\partial r} = 0, \qquad r = R, 1.$$

Let $\{\varphi_{m,n}(r)\}_{n=1}^{\infty}$ be a complete set of eigenfunctions for the eigenproblem

$$-\left(\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial}{\partial r}\right) - \frac{m^2}{r^2}\right)\varphi_{m,n} + \frac{E}{T}\left(\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial}{\partial r}\right) - \frac{m^2}{r^2}\right)^2 \varphi_{m,n}$$

$$= \lambda_{m,n}\varphi_{m,n}, \qquad R < r < 1, \tag{2.6}$$

$$\varphi_{m,n} = \frac{\partial\varphi_{m,n}}{\partial r} = 0, \qquad r = R, 1,$$

which are normalized by the condition

$$\int_R^1 |\varphi_{m,n}|^2 r dr = 1$$

and where

$$0 < \lambda_{m,1} \le \lambda_{m,2} \le \cdots \le \lambda_{m,n} \le \cdots.$$

Thus, $\lambda_{m,n}$ (respectively, $\varphi_{m,n}$) are critical values (respectively, critical points) of the functional

$$J_m(\varphi) = \int_R^1 \left[\left|\frac{\partial\varphi}{\partial r}\right|^2 + \frac{m^2}{r^2}|\varphi|^2 + \frac{E}{T}\left|\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial\varphi}{\partial r}\right) - \frac{m^2}{r^2}\varphi\right|^2\right] r\, dr$$

subject to the constraints that the real-valued functions, $\varphi(r)$, satisfy

$$\int_R^1 |\varphi|^2 r\, dr = 1,$$

$$\varphi(R) = \varphi(1) = 0,$$

$$\frac{\partial\varphi}{\partial r}(R) = \frac{\partial\varphi}{\partial r}(1) = 0.$$

It can be shown by classical arguments [6] that for $m = 0, \pm 1, \pm 2, \cdots$,

$$\lim_{n \to \infty} \lambda_{m,n} = +\infty. \tag{2.7}$$

We also note that $\lambda_{m,n}$ depends on R, i.e., $\lambda_{m,n} = \lambda_{m,n}(R)$ and that we can obtain from the representation of $\lambda_{m,n}$ as critical values of $J_m(\varphi)$ that $\lambda_{m,n}(R) \geq \lambda_{m,n}(0)$ for $0 \leq R < 1$. Now

$$\int_R^1 \left| \frac{1}{r} \frac{\partial}{\partial r} \left(r \frac{\partial \varphi}{\partial r} \right) - \frac{m^2}{r^2} \varphi \right|^2 r \, dr$$

$$= \int_R^1 \left[\left| \frac{1}{r} \frac{\partial}{\partial r} \left(r \frac{\partial \varphi}{\partial r} \right) \right|^2 + \frac{m^4}{r^4} |\varphi|^2 - \frac{2m^2}{r^3} \frac{\partial}{\partial r} \left(r \frac{\partial \varphi}{\partial r} \right) \varphi \right] r \, dr$$

and since φ satisfies the above boundary conditions it follows from integration by parts that

$$\int_R^1 \frac{m^2}{r^3} \frac{\partial}{\partial r} \left(r \frac{\partial \varphi}{\partial r} \right) \varphi r \, dr$$

$$= -m^2 \int_R^1 \frac{\partial \varphi}{\partial r} \frac{\partial}{\partial r} \left(\frac{\varphi}{r^2} \right) r \, dr$$

$$= -m^2 \int_R^1 r^{-2} \left| \frac{\partial \varphi}{\partial r} \right|^2 r \, dr + 2m^2 \int_R^1 r^{-3} \frac{\partial \varphi}{\partial r} \varphi r \, dr$$

$$= -m^2 \int_R^1 r^{-2} \left| \frac{\partial \varphi}{\partial r} \right|^2 r \, dr + 2m^2 \int_R^1 r^{-4} |\varphi|^2 r \, dr.$$

All the calculations in this paragraph can be used to show that

$$J_m(\varphi) = \int_R^1 \left[\left| \frac{\partial \varphi}{\partial r} \right|^2 + \frac{m^2}{r^2} |\varphi|^2 \right] r \, dr$$

$$+ \frac{E}{T} \int_R^1 \left[\left| \frac{1}{r} \frac{\partial}{\partial r} \left(r \frac{\partial}{\partial r} \varphi \right) \right|^2 + \frac{m^4 - 4m^2}{r^4} |\varphi|^2 + \frac{2m^2}{r^2} \left| \frac{\partial \varphi}{\partial r} \right|^2 \right] r \, dr \tag{2.8}$$

for φ satisfying the imposed boundary conditions.

Classical arguments [6] can also be used to show that

$$\int_R^1 \varphi_{m,n}(r) \varphi_{m,p}(r) r \, dr = \delta_{n,p}.$$

Further, if

$$\int_R^1 |v|^2 r\,dr < \infty,$$

then the expansion

$$v(r) = \sum_{n=1}^{+\infty} v_{m,n}\varphi_{m,n}(r)$$

where

$$v_{m,n} = \int_R^1 v(r)\varphi_{m,n}(r) r\,dr$$

has the properties that

$$\int_R^1 |v|^2 r\,dr = \sum_{n=1}^{+\infty} |v_{m,n}|^2$$

and

$$\int_R^1 \left| v(r) - \sum_{n=1}^{N} v_{m,n}\varphi_{m,n}(r) \right|^2 r\,dr = \sum_{n=N+1}^{+\infty} |v_{m,n}|^2 \to 0$$

as $N \to \infty$. Finally, since

$$J_m(\varphi) \geq \frac{E}{T} \int_R^1 \frac{(m^4 - 4m^2)}{r^4} |\varphi|^2 r\,dr$$

and since

$$J_m(\varphi) \geq \int_R^1 \frac{m^2}{r^2} |\varphi|^2 r\,dr,$$

we have that

$$\lambda_{m,n} \geq \lambda_{m,1} \geq \max\left(\frac{E}{T}(m^4 - 4m^2), m^2 \right). \tag{2.9}$$

These properties of the eigenfunctions $\varphi_{m,n}(r)$ can be used to construct the expansion

$$p(r,\theta) = \sum_{m=-\infty}^{\infty} \sum_{n=1}^{\infty} p_{m,n}\varphi_{m,n}(r) e^{im\theta} \tag{2.10}$$

where

$$p_{m,n} = \frac{1}{2\pi} \int_0^{2\pi} \int_R^1 p(r,\theta)\, e^{-im\theta} \varphi_{m,n}(r) r\,dr.$$

Note that

$$\int_0^{2\pi} \int_R^1 |p|^2 r\,dr\,d\theta = 2\pi \sum_{m=-\infty}^{+\infty} \sum_{n=1}^{+\infty} |p_{m,n}|^2 < \infty.$$

We will now show that there exist unique coefficients, $u_{m,n}$, such that

$$u(r,\theta) = \sum_{m=-\infty}^{+\infty} \sum_{n=1}^{+\infty} u_{m,n}\varphi_{m,n}(r) e^{im\theta} \tag{2.11}$$

is a mean-square integrable solution to (2.1). If we formally substitute the expansions (2.10) and (2.11) into (2.1) we obtain the result that

$$-\rho\omega^2 m^2 u_{m,n} = -T\lambda_{m,n}u_{m,n} - i\gamma\omega m u_{m,n} + p_{m,n}$$

or

$$u_{m,n} = [T\lambda_{m,n} - \rho\omega^2 m^2 + i\gamma\omega m]^{-1} p_{m,n}.$$

So,

$$|u_{m,n}|^2 = [(T\lambda_{m,n} - \rho\omega^2 m^2)^2 + \gamma^2\omega^2 m^2]^{-1} |p_{m,n}|^2.$$

We note that by (2.9)

$$(T\lambda_{m,n} - \rho\omega^2 m^2)^2 + \gamma^2\omega^2 m^2 \geq \begin{cases} T^2\lambda_{0,1}^2 & \text{if } m = 0, \\ \dfrac{\gamma^2 T}{2\rho} & \text{if } m \neq 0,\ T \leq 2\rho\omega^2, \\ \dfrac{T}{2} & \text{if } m \neq 0,\ T > 2\rho\omega^2. \end{cases}$$

Thus,

$$|u_{m,n}|^2 \leq C_1 |p_{m,n}|^2 \tag{2.12}$$

where

$$C_1^{-1} = \min\left(T^2\lambda_{0,1}^2, \frac{\gamma^2 T}{2\rho}, \frac{T}{2}\right).$$

We have thus shown that if $p(r,\theta)$ is mean-square integrable, then the formal solution to (2.1)

$$u(r,\theta) = \sum_{m=-\infty}^{+\infty} \sum_{n=1}^{+\infty} u_{m,n}\varphi_{m,n}(r)e^{im\theta},$$

is unique and by (2.12) satisfies the estimate

$$\int_0^{2\pi}\int_R^1 |u(r,\theta)|^2 r\,dr\,d\theta \leq C_1 \int_0^{2\pi}\int_R^1 |p(r,\theta)|^2 r\,dr\,d\theta. \tag{2.13}$$

Since $\varphi_{m,n}$ satisfies the boundary conditions in (2.6), it follows that $u(r,\theta)$ satisfies (formally) the boundary conditions of (2.1).

Now it follows from (2.6) that $e^{im\theta}\varphi_{m,n}(r)$ are the eigenfunctions of

$$\left[-\Delta + \frac{E}{T}\,\Delta^2\right] e^{im\theta}\varphi_{m,n}(r) = \lambda_{m,n} e^{im\theta}\varphi_{m,n}(r),$$

$$e^{im\theta}\varphi_{m,n}(R) = e^{im\theta}\varphi_{m,n}(1) = 0, \tag{2.14}$$

$$\frac{\partial}{\partial r}[e^{im\theta}\varphi_{m,n}](R) = \frac{\partial}{\partial r}[e^{im\theta}\varphi_{m,n}](1) = 0.$$

Thus, since by integration by parts

$$\int_0^{2\pi}\int_R^1 [T\nabla(e^{im\theta}\varphi_{m,n})\cdot\nabla(e^{iq\theta}\varphi_{q,p}) + E\Delta(e^{im\theta}\varphi_{m,n})\Delta(e^{iq\theta}\varphi_{q,p})]r\,dr\,d\theta$$

$$= \int_0^{2\pi}\int_R^1 [(-T\Delta + E\Delta^2)(e^{im\theta}\varphi_{m,n})]e^{iq\theta}\varphi_{q,p} r\,dr\,d\theta$$

$$= T\lambda_{m,n}\int_0^{2\pi}\int_R^1 (e^{im\varphi}\varphi_{m,n})(e^{iq\theta}\varphi_{q,p})r\,dr\,d\theta$$

$$= 2\pi T\lambda_{m,n}\delta_{m,q}\delta_{n,p},$$

we also have the bound

$$\int_0^{2\pi}\int_R^1 [T|\nabla u|^2 + E|\Delta u|^2]r\,dr\,d\theta = 2\pi T\sum_{m=-\infty}^{+\infty}\sum_{n=1}^{+\infty}\lambda_{m,n}|u_{m,n}|^2$$

$$= 2\pi T\sum_{m=-\infty}^{+\infty}\sum_{n=1}^{+\infty}\frac{\lambda_{m,n}}{[(T\lambda_{m,n} - \rho\omega^2 m^2)^2 + \gamma^2\omega^2 m^2]}|p_{m,n}|^2 \tag{2.15}$$

$$\le 2\pi C_2\sum_{m=-\infty}^{+\infty}\sum_{n=1}^{+\infty}|p_{m,n}|^2 = C_2\int_0^{2\pi}\int_R^1 |p(r,\theta)|^2 r\,dr\,d\theta$$

where by (2.7) and (2.9)

$$C_2 = \max_{m,n}\left[\frac{T\lambda_{m,n}}{(T\lambda_{m,n} - \rho\omega m^2)^2 + \gamma^2 w^2 m^2}\right] < \infty.$$

Since

$$\int_0^{2\pi}\int_R^1 (-T\Delta + E\Delta^2)(e^{im\theta}\varphi_{m,n})\cdot(-T\Delta + E\Delta^2)(e^{iq\theta}\varphi_{q,p})r\,dr\,d\theta$$

$$= \int_0^{2\pi}\int_R^1 (T\lambda_{m,n}e^{im\theta}\varphi_{m,n})(T\lambda_{q,p}e^{iq\theta}\varphi_{q,p})r\,dr\,d\theta$$

$$= 2\pi T^2\lambda_{m,n}\lambda_{q,p}\delta_{m,q}\delta_{n,p},$$

we have the stronger bound

$$\int_0^{2\pi}\int_R^1 |-T\Delta u + E\Delta^2 u|^2 r\,dr\,d\theta = 2\pi T^2 \sum_{m=-\infty}^{+\infty}\sum_{n=1}^{+\infty} \lambda_{m,n}^2 |u_{m,n}|^2$$

$$= 2\pi \sum_{m=-\infty}^{+\infty}\sum_{n=1}^{+\infty} \frac{(T\lambda_{m,n})^2}{(T\lambda_{m,n} - \rho\omega^2 m^2)^2 + \gamma^2\omega^2 m^2} |p_{m,n}|^2 \tag{2.16}$$

$$\leq 2\pi C_3 \sum_{m=-\infty}^{+\infty}\sum_{n=1}^{+\infty} |p_{m,n}|^2$$

$$= C_3 \int_0^{2\pi}\int_R^1 |p(r,\theta)|^2 r\,dr\,d\theta$$

where by (2.7) and (2.9)

$$C_3 = \max\left[\frac{(T\lambda_{m,n})^2}{(T\lambda_{m,n} - \rho\omega^2 m^2)^2 + \gamma^2\omega^2 m^2}\right] < \infty.$$

The inequalities (2.13), (2.15), and (2.16) can be used to show that if $p(r,\theta)$ is mean-square integrable, then the solution $u(r,\theta)$ to (2.1) that we have constructed has the property that all of its partial derivatives of order less than or equal to four are mean-square integrable [1]. Further, this implies that all of the partial derivatives of $u(r,\theta)$ of order less than or equal to two are continuous and that the boundary conditions are satisfied in the classical sense [1].

We review the above results by the following theorem.

THEOREM 2.1. *We suppose that $E_p > 0$, $T > 0$, $\gamma > 0$, and $p \in L^2(\Omega)$. Then there exists a unique solution $u \in H_0^2(\Omega) \cap H^4(\Omega)$ to (2.1). Further, there exist positive constants C_1, C_2, and C_3 such that*

$$\int_\Omega u^2\,dx \leq C_1 \int_\Omega p^2\,dx, \tag{2.17}$$

$$\int_\Omega [T|\nabla u|^2 + E|\Delta u|^2]\,dx \leq C_2 \int_\Omega p^2\,dx, \tag{2.18}$$

$$\int_\Omega |-T\Delta u + E\Delta^2 u|^2\,dx \leq C_3 \int_\Omega p^2\,dx. \tag{2.19}$$

The constants C_1, C_2, and C_3 can be chosen independent of R. Also, the constant C_1, can be chosen independent of ω.

A more detailed analysis of $\lambda_{m,n}$ and the constant C_2 can be used to demonstrate that C_2 is independent of ω for $\rho\omega^2 \leq T$. However, we prefer to give the following elementary proof.

PROPOSITION 2.2. *Assume that*

$$\rho\omega^2 \leq T. \tag{2.20}$$

If $p \in L^2(\Omega)$, then there exists a unique solution to

$$\begin{aligned} &E\Delta^2 u - T\Delta u + \rho\omega^2 \frac{\partial^2 u}{\partial \theta^2} + \gamma\omega \frac{\partial u}{\partial \theta} = p \quad \text{in } \Omega, \\ &u \in H_0^2(\Omega). \end{aligned} \tag{2.21}$$

Moreover, there exists a constant $C_4 = C_4(E)$, independent of ω, such that

$$|u|_{H_0^2(\Omega)} \leq C_4 |p|_{L^2(\Omega)}. \tag{2.22}$$

Proof. This is a straightforward application of the Lax–Milgram theorem. Indeed, consider the weak formulation of (2.21), i.e., set

$$a(u,w) = \int_\Omega E\Delta u \cdot \Delta w + T\nabla u \cdot \nabla w - \rho\omega^2 \frac{\partial u}{\partial \theta} \cdot \frac{\partial w}{\partial \theta} + \gamma\omega \frac{\partial u}{\partial \theta} \cdot w \, dx.$$

Then clearly $a(u,w)$ is a bilinear, continuous form on $H_0^2(\Omega)$. Moreover,

$$\begin{aligned} a(u,u) &= \int_\Omega E\Delta u \cdot \Delta u + T\nabla u \cdot \nabla u - \rho\omega^2 \left(\frac{\partial u}{\partial \theta}\right)^2 + \gamma \frac{w}{2} \frac{\partial}{\partial \theta} u^2 \, dx \\ &= \int_\Omega E\Delta u \cdot \Delta u + T\nabla u \cdot \nabla u - \rho\omega^2 \left(\frac{\partial u}{\partial \theta}\right)^2 dx. \end{aligned} \tag{2.23}$$

(We used the fact that since $\Omega \subset \mathbb{R}^2$, $H_0^2(\Omega) \subset C(\bar{\Omega})$ and $u(r,\theta) = u(r,\theta + 2\pi)$.) Now, recall that

$$\begin{aligned} \frac{\partial u}{\partial \theta} &= \frac{\partial u}{\partial x_1} \cdot \frac{\partial x_1}{\partial \theta} + \frac{\partial u}{\partial x_2} \cdot \frac{\partial x_2}{\partial \theta} \\ &= -r \sin\theta \frac{\partial u}{\partial x_1} + r \cos\theta \frac{\partial u}{\partial x_2}. \end{aligned}$$

Hence, by the Cauchy–Schwarz inequality,

$$\begin{aligned} \left(\frac{\partial u}{\partial \theta}\right)^2 &= r^2 \left(-\sin\theta \frac{\partial u}{\partial x_1} + \cos\theta \frac{\partial u}{\partial x_2}\right)^2 \\ &\leq |\nabla u|^2 \qquad \text{a.e. on } \Omega. \end{aligned}$$

Recalling (2.23) we obtain

$$\begin{aligned} a(u,u) &= \int_\Omega E\Delta u \cdot \Delta u + (T - \rho\omega^2)|\nabla u|^2 \, dx \\ &\geq E \int_\Omega (\Delta u)^2 \, dx. \end{aligned}$$

Since E is assumed to be positive, and since

$$\int_\Omega (\Delta u)^2 \, dx$$

defined on $H_0^2(\Omega)$ is a norm equivalent to the usual one, $a(u, w)$ is a bilinear, continuous, coercive form on $H_0^2(\Omega)$. Now, for $p \in L^2(\Omega)$ it is clear that

$$w \longmapsto \int_\Omega pw \, dx$$

is a continuous linear form on $H_0^2(\Omega)$, so, by the Lax–Milgram theorem there is a unique u in $H_0^2(\Omega)$ satisfying

$$a(u, w) = \int_\Omega pw \, dx \quad \forall w \in H_0^2(\Omega).$$

Moreover, taking $w = u$ in the above equality, we can easily see that (2.22) holds.

It is easy to see that u satisfies (2.21) in the distributional sense. So, we have

$$\Delta^2 u \in L^2(\Omega)$$

since all the other functions appearing in (2.21) are in $L^2(\Omega)$. Hence, by well-known results $u \in H^4(\Omega)$. In particular we recover the fact that the condition

$$u = \frac{\partial u}{\partial r} = 0 \qquad \text{on } \partial\Omega$$

holds in the usual sense (see [1], [7] for details). □

We could have assumed p in the dual of $H_0^2(\Omega)$ and the existence of a weak solution to (2.21) would still have held true.

We note that (2.20) is the condition that (2.21) be elliptic when $E \equiv 0$. In the case that $\gamma \equiv 0$, existence and uniqueness can fail when $\rho\omega^2 > T$. If $\gamma \equiv 0$, then

$$(T\lambda_{m,n} - \rho\omega^2 m^2) u_{m,n} = p_{m,n}.$$

Hence, if $T\lambda_{m,n} = \rho\omega^2 m^2$ for some m, n, then there exist pressures, p, such that (2.21) does not have a solution. One example is clearly

$$p(r, \theta) = e^{im\theta} \varphi_{m,n}(r).$$

Also, in this case ($T\lambda_{m,n} = \rho\omega^2 m^2$ for some m, n) solutions to (2.21) are not unique since if $u(r, \theta)$ is a solution to (2.21), then

$$u(r, \theta) + e^{im\theta} \varphi_{m,n}(r)$$

is also a solution to (2.21). However, Theorem 2.1 guarantees existence and uniqueness when $\gamma > 0$ for all ω.

We note that for the floppy disk, the outer edge is not bonded to a rigid support disk. In this case, the tension depends on r. Furthermore, the radial tension coefficient vanishes at the outer edge [2]. Although clamped plate boundary conditions are appropriate at the inner edge, the plate is free at the outer edge [2]. The head in a floppy disk system does not fly above the medium on an air bearing. In this case, p in (1.1) represents the load on the disk from contact with the head. The analysis given for Proposition 2.2 applies to the floppy disk system if E is sufficiently large. In this case it is no longer true that $\rho\omega^2 \leq T$ everywhere in Ω. However, for $E/\rho\omega^2$ sufficiently large, we can use the inequality

$$\rho\omega^2 \int_\Omega \left(\frac{\partial u}{\partial \theta} \right)^2 dx \leq \frac{E}{2} \int_\Omega (\Delta u)^2 \, dx$$

for $u \in H^2(\Omega)$ and $u = \dfrac{\partial u}{\partial n} = 0$ on the inner edge of the disk.

3. The coupled problem. The steady-state solution of (1.1), (1.4) is

$$E\Delta^2 u - T\Delta u + \rho\omega^2 \frac{\partial^2 u}{\partial \theta^2} + \gamma\omega \frac{\partial u}{\partial \theta} = p - p_a, \qquad \text{in } \Omega, \tag{3.1}$$

$$u \in H_0^2(\Omega),$$

$$\nabla \cdot (h(u)^3 p \nabla p) = 6\mu \mathbf{V} \cdot \nabla(ph(u)), \qquad \text{in}\Gamma, \tag{3.2}$$

$$p = p_a \qquad \text{on } \partial\Gamma,$$

where $\mathbf{V} = \omega(-x_2, x_1)$, $\Omega = \{ x = (x_1, x_2) \mid R < r < 1 \}$.

We shall restrict p so that $p \geq 0$ and set $v = p^2$. The problem then becomes to find (u, v) such that

$$E\Delta^2 u - T\Delta u + \rho\omega^2 \frac{\partial^2 u}{\partial \theta^2} + \gamma\omega \frac{\partial u}{\partial \theta} = \sqrt{v} - \sqrt{v_a}, \qquad \text{in } \Omega, \tag{3.3}$$

$$u \in H_0^2(\Omega),$$

$$\nabla \cdot (h(u)^3 \nabla v) = \omega \mathbf{W} \cdot \nabla(\sqrt{v} \quad h(u)), \qquad \text{in } \Gamma, \tag{3.4}$$

$$v = v_a, \quad \text{on } \partial\Gamma,$$

where we have set $v_a = p_a^2$, $\mathbf{W} = 12\mu(-x_2, x_1)$.

We are going to solve (3.4) in a weak sense. Noting that $\nabla \cdot \mathbf{W} = 0$ we see that if v satisfies (3.4)—say in a classical sense—we have

$$\int_\Omega h(u)^3 \nabla v \cdot \nabla \xi \, dx - \int_\Omega \omega\sqrt{v}\, h(u) \mathbf{W} \cdot \nabla \xi \, dx = 0 \quad \forall \xi \in H_0^1(\Omega), \tag{3.5}$$

$$v = v_a \quad \text{on } \partial\Omega.$$

From the Sobolev embedding theorem [1], [7] we have that

$$H_0^2(\Omega) \subset C(\bar{\Omega})$$

with continuous inclusion. So, for some positive constant C_5 we have that

$$|w|_{L^\infty(\Omega)} \leq C_5 |w|_{H_0^2(\Omega)}, \qquad w \in H_0^2(\Omega).$$

Let us now collect our assumptions. We assume that the function φ (see (1.5)) satisfies

$$\begin{aligned} &\varphi \text{ is a Lipschitz continuous function on } \Gamma, \\ &0 < m \leq \varphi(x) \leq M \quad \text{a.e. for } x \in \Gamma, \end{aligned} \tag{3.6}$$

where m and M are two positive constants.

Assume also that

$$\Gamma \subset \Omega \text{ is a domain of } \mathbf{R}^2 \text{ with Lipschitz boundary;} \tag{3.7}$$

let $|\Gamma|$ denote the Lebesgue measure of Γ and let d denote the smallest width of a strip containing Γ. Then we can prove the following theorem.

THEOREM 3.1. *Let m' be any positive number such that*

$$0 < m' < m.$$

There exists a solution (u, v) of (3.3), (3.4) *if* (3.6) *and* (3.7) *hold and if*

$$\left(\frac{a + \sqrt{a^2 + 4b}}{2}\right) \leq p_a \frac{(m - m')}{C_4 C_5} \tag{3.8}$$

where

$$a = \frac{[12 d\omega\mu(M + m - m')]^2 |\Gamma|^{1/2}}{(m')^6}, \qquad b = a|\Gamma|^{1/2} p_a^2.$$

Proof. Set

$$K_{\mathscr{R}} = \{ v \in L^2(\Gamma) \mid v \geq 0 \text{ a.e. on } \Gamma,\ |v - v_a|_{L^2(\Gamma)} \leq \mathscr{R} \} \tag{3.9}$$

where $\mathscr{R}$ is a positive real number that we will choose later on. It is clear that $K_{\mathscr{R}}$ is a closed convex set of $L^2(\Gamma)$.

For $v \in K_{\mathscr{R}}$ we have

$$\sqrt{v} - \sqrt{v_a} \in L^2(\Omega) \tag{3.10}$$

(v is, of course, supposed to be extended by v_a outside of Γ). Indeed, this is an easy consequence of the inequality

$$|\sqrt{v} - \sqrt{v_a}| \leq \frac{1}{\sqrt{v_a}} |v - v_a|. \tag{3.11}$$

So, by Theorem 2.1 and Proposition 2.2 there exists a unique solution u of

$$\begin{aligned} &E\Delta^2 u - T\Delta u + \rho\omega^2 \frac{\partial^2 u}{\partial\theta^2} + \gamma\omega \frac{\partial u}{\partial\theta} = \sqrt{v} - \sqrt{v_a}, \qquad \text{in } \Omega, \\ &u \in H_0^2(\Omega), \end{aligned} \tag{3.12}$$

and there is a constant $C_4 = C_4(E)$ such that

$$|u|_{H_0^2(\Omega)} \leq \frac{C_4}{\sqrt{v_a}} |v - v_a|_{L^2(\Gamma)} \tag{3.13}$$

(we use here the fact that, by (3.11), we have $|\sqrt{v} - \sqrt{v_a}|_{L^2(\Gamma)} \leq |v - v_a|_{L^2(\Gamma)}/\sqrt{v_a}$). The constant C_4 is independent of ω for $\rho\omega^2 \leq T$. Let m' be any positive number such that

$$0 < m' < m.$$

Let us show first that we can select $\mathscr{R}$ in such a way that

$$h(u) = \varphi - u \geq m' > 0. \tag{3.14}$$

Recall from the Sobolev embedding theorem given above that

$$|u|_{L^\infty(\Omega)} \le C_5 |u|_{H_0^2(\Omega)}$$

$$\le \frac{C_4 C_5}{\sqrt{v_a}} |v - v_a|_{L^2(\Gamma)} \qquad \text{(by (3.13))}.$$

Now, by (3.6), (3.14) will hold if

$$|u|_\infty \le m - m' \tag{3.15}$$

So (3.14) will hold if

$$\frac{C_4 C_5 \mathscr{R}}{\sqrt{v_a}} \le m - m'$$

or, equivalently,

$$\mathscr{R} \le \sqrt{v_a} \frac{(m - m')}{C_4 C_5}. \tag{3.16}$$

Assume that $\mathscr{R}$ has been chosen such that (3.16) holds. Then since $h(u)$ is strictly positive there exists a unique function $\mathscr{T}(v) \ge 0$ which is a solution of

$$\int_\Gamma h(u)^3 \nabla \mathscr{T}(v) \cdot \nabla \xi \, dx - \omega \int_\Gamma \sqrt{\mathscr{T}(v)} h(u) \mathbf{W} \cdot \nabla \xi \, dx = 0, \qquad \forall \xi \in H_0^1(\Omega),$$

$$\mathscr{T}(v) = v_a, \quad \text{on } \Gamma \tag{3.17}$$

(we refer to [5] for a proof of this result).

If we can prove that $\mathscr{T}(v)$ has a fixed point we will be done. First, let us prove that for a suitable choice of $\mathscr{R}$, T maps $K_{\mathscr{R}}$ into itself. Indeed, we already know that $\mathscr{T}(v) \ge 0$. Next, if we take $\xi = \mathscr{T}(v) - v_a$ in (3.17) we get

$$(m')^3 |\nabla(\mathscr{T}(v) - v_a)|^2_{L^2(\Gamma)} \le \int_\Gamma h^3(u) |\nabla(\mathscr{T}(v) - v_a)|^2 \, dx$$

$$= \omega \int_\Gamma h(u) \sqrt{\mathscr{T}(v)} \mathbf{W} \cdot \nabla(\mathscr{T}(v) - v_a) \, dx.$$

Using the Cauchy–Schwarz inequality and recalling (3.6), (3.14) we deduce

$$(m')^3 |\nabla(\mathscr{T}(v) - v_a)|^2_{L^2(\Gamma)} \le 12\omega\mu(M + m - m') |\nabla(\mathscr{T}(v) - v_a)|_{L^2(\Gamma)} \left(\int_\Gamma \mathscr{T}(v) \, dx \right)^{1/2}$$

(note that $\sup_\Gamma |\mathbf{W}| \le 12\mu$). Hence, we have that

$$(m')^3 |\nabla(\mathscr{T}(v) - v_a)|_{L^2(\Gamma)} \le 12\omega\mu(M + m - m') \left(\int_\Gamma \mathscr{T}(v) \, dx \right)^{1/2}$$

$$\le 12\omega\mu(M + m - m') \left\{ \int_\Gamma |\mathscr{T}(v) - v_a| \, dx + |\Gamma| v_a \right\}^{1/2}. \tag{3.18}$$

By the Poincaré inequality,

$$(m')^3|\mathcal{T}(v) - v_a|_{L^2(\Gamma)} \leq d(m')^3|\nabla(\mathcal{T}(v) - v_a)|_{L^2(\Gamma)}$$

$$\leq 12d\omega\mu(M + m - m')\{|\Gamma|^{1/2}|\mathcal{T}(v) - v_a|_{L^2(\Gamma)} + |\Gamma|v_a\}^{1/2} \tag{3.19}$$

where d denotes the smallest width of a strip containing Γ. So, we get

$$|\mathcal{T}(v) - v_a|^2_{L^2(\Gamma)} \leq a|\mathcal{T}(v) - v_a|_{L^2(\Gamma)} + b$$

with

$$a = \frac{[12d\omega\mu(M + m - m')]^2|\Gamma|^{1/2}}{(m')^6}, \qquad b = \frac{[12d\omega\mu(M + m - m')]^2|\Gamma|v_a}{(m')^6} \tag{3.20}$$

and $\mathcal{T}$ maps $K_{\mathcal{R}}$ into itself provided that

$$\left(\frac{a + \sqrt{a^2 + 4b}}{2}\right) \leq \mathcal{R}. \tag{3.21}$$

Assume that (see (3.16))

$$\left(\frac{a + \sqrt{a^2 + 4b}}{2}\right) < \sqrt{v_a}\frac{(m - m')}{C_4C_5} \tag{3.22}$$

then we can select $\mathcal{R}$ such that (3.16) and (3.21) hold. Thus for $v \in K_{\mathcal{R}}$, $\mathcal{T}(v) \in K_{\mathcal{R}}$. Now, from (3.18) it is clear that $\mathcal{T}(K_{\mathcal{R}})$ is relatively compact in $K_{\mathcal{R}}$ (since $H^1(\Omega)$ is compactly embedded in $L^2(\Omega)$, see [7]). So, provided we prove that $\mathcal{T}$ is continuous on $K_{\mathcal{R}}$, by the Schauder fixed point theorem (see [7]) we can conclude the existence of (u, v) satisfying (3.3), (3.5).

To prove the continuity of $\mathcal{T}$ we proceed as follows: let $v_n \in K_{\mathcal{R}}$ be such that $v_n \to v$ in $L^2(\Gamma)$. Let us denote by u_n the solution of (3.3) corresponding to $v = v_n$, and by u the one corresponding to v. From Theorem 2.1 and Proposition 2.2 we derive easily

$$|u_n - u|_{H^2_0(\Omega)} \leq C|(\sqrt{v_n} - \sqrt{v_a}) - (\sqrt{v} - \sqrt{v_a})|_{L^2(\Gamma)}$$

$$\leq C|\sqrt{v_n} - \sqrt{v}|_{L^2(\Gamma)} \leq C\left|\sqrt{|v_n - v|}\right|_{L^2(\Gamma)}$$

$$= C\left(\int_\Gamma |v_n - v|\,dx\right)^{1/2} \leq C|\Gamma|^{1/4}|v_n - v|^{1/2}_{L^2(\Gamma)}.$$

(We used the Cauchy–Schwarz inequality.) Hence $u_n \to u$ in $H^2_0(\Omega)$ and also uniformly on $\bar{\Omega}$. (Recall that $H^2_0(\Omega) \subset C(\bar{\Omega})$ continuously.)

Now, from (3.19) we deduce that for some constant C independent of n we have

$$|\mathcal{T}(v_n)|_{H^1(\Gamma)} \leq C.$$

So we can extract a subsequence n_k from n such that

$$\mathscr{T}(v_{n_k}) \to w \quad \text{in } H^1(\Gamma), \qquad \mathscr{T}(v_{n_k}) \to w \quad \text{in } L^2(\Gamma). \tag{3.23}$$

If we let k go to $+\infty$ in the equality

$$\int_\Gamma h^3(u_{n_k})\nabla\mathscr{T}(v_{n_k})\cdot\nabla\xi - \omega\sqrt{\mathscr{T}(v_{n_k})}h(u_{n_k})\mathbf{W}\cdot\nabla\xi\,dx = 0 \qquad \forall\xi\in H_0^1(\Omega),$$

we obtain (recall that $h^3(u_{n_k}) \to h^3(u)$ uniformly)

$$\begin{aligned} &\int_\Gamma h^3(u)\nabla w\cdot\nabla\xi - \omega\sqrt{w}h(u)\mathbf{W}\cdot\nabla\xi\,dx = 0 \qquad \forall\xi\in H_0^1(\Omega),\\ &w = v_a \qquad \text{on } \partial\Gamma. \end{aligned} \tag{3.24}$$

By uniqueness of the solution of such a problem we have $w = \mathscr{T}(v)$ (see (3.17)). It results from (3.23) that the whole sequence $\mathscr{T}(v_n)$ converges toward $\mathscr{T}(v)$. This proves that $\mathscr{T}(v_n)$ converges toward $\mathscr{T}(v)$. Hence, $\mathscr{T}$ is continuous on $K_{\mathscr{R}}$ and this completes the proof of the theorem.

COROLLARY 3.1. *If ω or $|\Gamma|$ are small enough or m is large enough with M/m fixed and* (3.6) *and* (3.7) *hold, then there exists a solution (u,v) of* (3.3), (3.4).

Proof. Clearly, (3.8) holds for ω or $|\Gamma|$ small enough, all other quantities being kept fixed. Also, (3.8) holds if we set $m' = m/2$ and m is large enough with M/m fixed. □

It should be possible to apply the techniques of this paper to prove results similar to Theorem 3.1 for tape systems. Tape systems are usually modeled by a simplified shell model for the displacement of the tape and the compressible Reynolds lubrication equation for the air bearing [9].

A QUASI-VARIATIONAL INEQUALITY ARISING IN ELASTOHYDRODYNAMICS*

BEI HU†

Abstract. In this paper, a quasi-variational inequality arising in elastohydrodynamic lubrication is studied. In the two-dimensional case modeling a thin fluid film between an elastic ball and a plane, the existence of a smooth solution is proved provided that the viscosity is assumed to be constant. In this case, estimates for the support of the solution are also established and uniqueness of the solution is also proved under some restrictions. In the case where the viscosity is not constant, the existence, regularity, and uniqueness are proved under additional restrictions. Finally, for the one-dimensional problem describing a thin fluid between a rolling cylinder and a plane, the fact that the free boundary consists of at most one point is established in addition to existence and uniqueness.

Key words. variational inequality, free boundary problem, a priori estimates, fixed point

AMS(MOS) subject classifications. 35R35, 35B45, 35B65

1. The model. The lubrication of a ball rolling in the positive x direction gives rise to a variational inequality:

$$-\frac{\partial}{\partial x}\left(\frac{\rho\tilde{h}^3}{12\mu}\frac{\partial\tilde{u}}{\partial x}\right)-\frac{\partial}{\partial y}\left(\frac{\rho\tilde{h}^3}{12\mu}\frac{\partial\tilde{u}}{\partial y}\right)\geq-\frac{\partial}{\partial x}\left(\frac{\rho v\tilde{h}}{2}\right) \tag{1.1}$$

$$\tilde{u}\geq 0 \tag{1.2}$$

$$\tilde{u}\cdot\left[-\frac{\partial}{\partial x}\left(\frac{\rho\tilde{h}^3}{12\mu}\frac{\partial\tilde{u}}{\partial x}\right)-\frac{\partial}{\partial y}\left(\frac{\rho\tilde{h}^3}{12\mu}\frac{\partial\tilde{u}}{\partial y}\right)+\frac{\partial}{\partial x}\left(\frac{\rho v\tilde{h}}{2}\right)\right]=0 \tag{1.3}$$

where $\tilde{u}$ is the pressure, v is the average surface speed ($v>0$), ρ is the density of the liquid which shall be assumed to be constant, $\mu=\mu(\tilde{u})$ is the viscosity coefficient of the liquid, and $\tilde{h}$ is the film thickness which takes the form:

$$\tilde{h}(x,y)=\tilde{k}+\frac{x^2+y^2}{2R}+\frac{2}{\pi E'}\int\frac{\tilde{u}(s,t)dsdt}{\sqrt{(x-s)^2+(y-t)^2}} \tag{1.4}$$

where E' is the effective modulus, and $\tilde{k}$ is a positive constant.

The variational inequality (1.1)–(1.3) (with $\tilde{h}$ a given function) occurs in a simplified model of a lubrication problem (see [2]); the dependence of $\tilde{h}$ on the pressure, as in (1.4), assumes that the ball is elastic; this is the case when the load is large. The system (1.1)–(1.4) forms an elastohydrodynamics lubrication model; for more details see [3], [6]. In this paper, we study the quasi-variational inequality (1.1)–(1.4) in a bounded, but large domain Ω. Since $\tilde{u}$ is small on $\partial\Omega$, it seems natural to impose the boundary condition

$$\tilde{u}=0 \quad \text{on } \partial\Omega. \tag{1.5}$$

If μ is constant, then setting the new variables

$$h=2R\tilde{h},\quad u=\frac{4R}{\pi E'}\tilde{u},\quad k=2R\tilde{k},\quad \lambda=\frac{12\mu v(2R)^3}{\pi E'} \tag{1.6}$$

* Received by the editors August 15, 1988; accepted for publication (in revised form) March 21, 1989.

† School of Mathematics, University of Minnesota, Minneapolis, Minnesota 55455.

we can rewrite (1.1)–(1.5) in the form

$$-\nabla(h^3\nabla u) \geq -\lambda\frac{\partial h}{\partial x} \quad \text{for } (x,y)\in\Omega \tag{1.7}$$

$$u \geq 0 \quad \text{for } (x,y)\in\Omega \tag{1.8}$$

$$u\cdot\left[-\nabla(h^3\nabla u)+\lambda\frac{\partial h}{\partial x}\right]=0 \quad \text{for } (x,y)\in\Omega \tag{1.9}$$

$$u=0 \quad \text{for } (x,y)\in\partial\Omega \tag{1.10}$$

and

$$h(x,y)=k+x^2+y^2+\int_\Omega \frac{u(s,t)dsdt}{\sqrt{(x-s)^2+(y-t)^2}}. \tag{1.11}$$

In §3 we prove the existence of a $C^{1,1}$ solution by using the fixed point theorem; the proof uses some estimates derived in §2. In §4 we take Ω to be a disc with large radius M and obtain some estimates for the support of the solution, i.e., we prove that for some small $\epsilon>0$,

$$u(x,y)>0 \qquad \text{for } -M<x<-\epsilon M. \tag{1.12}$$

In §5 we prove the uniqueness of the solution provided λ is small. In §6 we study the problem (1.7)–(1.11) in the case where

$$\mu=\mu_0 e^{\alpha u}, \qquad \mu_0>0,\ \alpha>0; \tag{1.13}$$

this case is of particular physical interest (see [1], [6]). In [7], by a penalty formulation of the quasi-variational inequality, the existence of $H_0^1(\Omega)$ solution has been proved provided α is small. On the other hand, we are going to prove the existence of a $C^{1,1}$ solution provided α is small (the case $\alpha=0$ is treated in §3).

In §7 we consider a rolling cylinder instead of a rolling ball; the lubrication problem then reduces to a one-dimensional quasi-variational inequality:

$$-\left(\tilde{h}^3\frac{\tilde{u}'}{\mu}\right)' \geq -6v\tilde{h}' \quad \text{for } x\in[-M,M] \tag{1.14}$$

$$\tilde{u}\geq 0 \quad \text{for } x\in[-M,M] \tag{1.15}$$

$$\tilde{u}\cdot\left[-\left(\tilde{h}^3\frac{\tilde{u}'}{\mu}\right)'+6v\tilde{h}'\right]=0 \quad \text{for } x\in[-M,M] \tag{1.16}$$

$$\tilde{u}(\pm M)=0 \tag{1.17}$$

and

$$\tilde{h}=\tilde{k}+\frac{x^2}{2R}+\frac{4}{\pi E'}\int_{-M}^{M}\tilde{u}(s)\log\frac{2M}{|x-s|}ds. \tag{1.18}$$

Setting analogously to (1.6)

$$h=2R\tilde{h}, \quad u=\frac{8R}{\pi E'}\tilde{u}, \quad k=2R\tilde{k}, \quad \lambda=\frac{24\mu_0 v(2R)^3}{\pi E'}, \tag{1.19}$$

the problem, with μ given as in (1.13), reduces to

$$-\left(h^3\frac{u'}{e^{\alpha u}}\right)' \geq -\lambda h' \quad \text{for } x \in [-M, M] \tag{1.20}$$

$$u \geq 0 \quad \text{for } x \in [-M, M] \tag{1.21}$$

$$u \cdot \left[-\left(h^3\frac{u'}{e^{\alpha u}}\right)' + \lambda h'\right] = 0 \quad \text{for } x \in [-M, M] \tag{1.22}$$

$$u(\pm M) = 0 \tag{1.23}$$

and

$$h = k + x^2 + \int_{-M}^{M} u(s) \log \frac{2M}{|x - s|} ds. \tag{1.24}$$

Assuming α to be small, we prove the existence of a $C^{1,1}$ solution. It is also proved that the solution is unique and that the free boundary consists of at most one point provided λ is small.

Numerical work for this case can be found in [1]. In [7], numerical work has been done based on a penalty formulation of the variational inequality.

2. A priori estimates. Later on we shall need some estimates for the solution of the quasi-variational inequality

$$-\nabla(h^3\nabla u) \geq -\lambda N\frac{\partial h}{\partial x} \quad \text{for } (x, y) \in \Omega \tag{2.1}$$

$$u \geq 0 \quad \text{for } (x, y) \in \Omega \tag{2.2}$$

$$u \cdot \left[-\nabla(h^3\nabla u) + \lambda N\frac{\partial h}{\partial x}\right] = 0 \quad \text{for } (x, y) \in \Omega \tag{2.3}$$

$$u = 0 \quad \text{for } (x, y) \in \partial\Omega \tag{2.4}$$

and

$$h = k + N^2(x^2 + y^2) + N\int_{\Omega} \frac{u(s, t)dsdt}{\sqrt{(x - s)^2 + (y - t)^2}} \tag{2.5}$$

where λ, k, N are positive constants, $\lambda \leq \Lambda$, and Ω is a smooth domain in R^2.

Remark. Later on we shall take N to be different constants in the proof of the existence and the estimation of the support of the solution.

LEMMA 2.1. *Assume that* (u, h) *is a solution of* (2.1)-(2.5) *with* $u \in W_0^{1,2}(\Omega)$, $h \in W^{1,2}(\Omega)$. *Then*

$$\int_{\Omega} h^3|\nabla u|^2 dxdy \leq \frac{\lambda^2|\Omega|}{k}N^2. \tag{2.6}$$

Proof. Integrating (2.3) over Ω, we get

$$
\begin{aligned}
\int_\Omega h^3|\nabla u|^2 dxdy &= -\lambda N \int_\Omega u\frac{\partial h}{\partial x} \\
&= \lambda N \int_\Omega h\frac{\partial u}{\partial x} \\
&\le \lambda N \left(\int_\Omega h^2 \left|\frac{\partial u}{\partial x}\right|^2 dxdy\right)^{1/2} \left(\int_\Omega dxdy\right)^{1/2} \\
&\le \frac{\lambda N|\Omega|^{1/2}}{k^{1/2}} \left(\int_\Omega h^3|\nabla u|^2 dxdy\right)^{1/2}
\end{aligned} \tag{2.7}
$$

and hence (2.6) follows. □

Extend u by zero outside Ω. Then $u \in W_0^{1,2}(R^2)$ and, by a change of variables,

$$
h(x,y) = k + N^2(x^2+y^2) + N\int_{R^2} \frac{1}{\sqrt{s^2+t^2}} u(x-s, y-s)dsdt. \tag{2.8}
$$

Thus

$$
\nabla h(x,y) = (2N^2x, 2N^2y) + N\int_{R^2} \frac{1}{\sqrt{s^2+t^2}} \nabla u(x-s, y-t)dsdt. \tag{2.9}
$$

LEMMA 2.2. *Under the assumption of Lemma* 2.1, *we have*

$$
\|\nabla h\|_{L^p(\Omega)} \le CN^2 \tag{2.10}
$$

where $2 < p < \infty$, *and* C *is a constant depending on* Ω , p, *and* Λ.

Proof. Applying Young's inequality (see, for example, [5, Lemma 7.12]) to (2.9), we get

$$
\|\nabla h\|_{L^p(\Omega)} \le C(\Omega)N^2 + C(\Omega, p)N\|\nabla u\|_{L^2(\Omega)}. \tag{2.11}
$$

Since, by (2.6),

$$
k^3 \int_\Omega |\nabla u|^2 dxdy \le \frac{\lambda^2|\Omega|}{k} N^2 \tag{2.12}
$$

and therefore,

$$
\|\nabla u\|_{L^2(\Omega)} \le \left(\frac{\lambda^2|\Omega|}{k^4} N^2\right)^{1/2} = \frac{\lambda|\Omega|^{1/2}}{k^2} N. \tag{2.13}
$$

Substituting this into (2.11), (2.10) follows. □

Setting

$$
f = \frac{3\nabla h}{h}\nabla u - \frac{\lambda N}{h^3}\frac{\partial h}{\partial x}, \tag{2.14}
$$

we can rewrite (2.1)–(2.4) as

$$
-\Delta u \ge f \quad \text{for } (x,y) \in \Omega \tag{2.15}
$$

$$
u \ge 0 \quad \text{for } (x,y) \in \Omega \tag{2.16}
$$

$$
u(-\Delta u - f) = 0 \quad \text{for } (x,y) \in \Omega \tag{2.17}
$$

$$
u = 0 \quad \text{for } (x,y) \in \partial\Omega. \tag{2.18}
$$

LEMMA 2.3. *Under the assumption of Lemma* 2.1, *we have, for any* $2 < p < \infty$,

$$\|u\|_{W^{2,p}(\Omega)} \leq C(\Omega, N, p)\lambda \tag{2.19}$$

$$\|u\|_{W^{2,\infty}(\Omega')} \leq C(\Omega, \Omega', N)\lambda \tag{2.20}$$

$$\|h\|_{W^{1,\infty}(\Omega)} \leq C(\Omega, N) \tag{2.21}$$

$$\|h\|_{W^{2,p}(\Omega')} \leq C(\Omega, \Omega', N) \tag{2.22}$$

where $\Omega' \subset\subset \Omega$, *and the constants in* (2.19)–(2.22) *depend on* k *and* Λ.

Proof. We shall use C to denote various constants depending on Ω and N and use C_p to denote various constants depending on Ω, N, and p.

First let $1 < p < 2$. Then by (2.14)

$$|f|^p \leq C|\nabla h|^p(|\nabla u|^p + \lambda^p). \tag{2.23}$$

Applying Hölder's inequality we get

$$\int_\Omega |f|^p dxdy \leq C\left(\int_\Omega |\nabla h|^{2p/(2-p)} dxdy\right)^{(2-p)/2} \left(\int_\Omega (|\nabla u|^2 + \lambda^2) dxdy\right)^{p/2} \tag{2.24}$$

since $1 < p < 2$, $2 < 2p/(2-p) < \infty$, and by Lemmas 2.1 and 2.2 it then follows that

$$\|f\|_{L^p(\Omega)} \leq C_p\lambda \qquad (1 < p < 2). \tag{2.25}$$

Thus, by L^p estimates for the variational inequality (2.15)–(2.18) give

$$\|u\|_{W^{2,p}(\Omega)} \leq C_p\lambda \qquad (1 < p < 2). \tag{2.26}$$

Using the Sobolev Embedding Theorem we conclude that

$$\|u\|_{W^{1,p}(\Omega)} \leq C_p\lambda \tag{2.27}$$

for any $1 < p < \infty$.

Now from (2.9) and Hölder's inequality it follows that

$$\|\nabla h\|_{L^\infty(\Omega)} \leq C + C\|\nabla u\|_{L^3(\Omega)} \left(\int_{B_K(0)} (s^2 + t^2)^{-3/4} dsdt\right)^{2/3} \tag{2.28}$$

if K is large enough so that $\Omega \subset B_{K/2}(0)$. Using (2.27) it follows that

$$\|\nabla h\|_{L^\infty(\Omega)} \leq C. \tag{2.29}$$

Next, using (2.14), (2.27), and (2.29), we find that

$$\|f\|_{L^p(\Omega)} \leq C_p\lambda \tag{2.30}$$

for any $1 < p < \infty$, and thus by a similar argument as above we obtain the estimate

$$\|u\|_{W^{2,p}(\Omega)} \leq C_p\lambda \tag{2.31}$$

for any $1 < p < \infty$.

To get higher regularity, we differentiate (2.9) using a similar argument as in [5, p. 53–55], and obtain:

$$h_{xx} = 2N^2 + N\int_\Omega \frac{u_{xx}(s,t)dsdt}{\sqrt{(x-s)^2 + (y-t)^2}} - N\int_{\partial\Omega} \frac{u_x(s,t)\cos(\vec{n}, x)}{\sqrt{(x-s)^2 + (y-t)^2}} d\sigma. \tag{2.32}$$

Similar expressions can be derived for h_{xy} and h_{yy}.

By the Sobolev Embedding Theorem and (2.31), it follows that

$$\|u\|_{W^{1,\infty}(\Omega)} \leq C\lambda \tag{2.33}$$

and thus if $(x,y) \in \Omega'$, where $\Omega' \subset\subset \Omega$, then

$$\left| \int_{\partial\Omega} \frac{u_x(s,t)\cos(\vec{n},x)}{\sqrt{(x-s)^2+(y-t)^2}} d\sigma \right| \leq C\lambda. \tag{2.34}$$

Next, applying Young's inequality [5, Lemma 7.12], and using (2.31), (2.34), we conclude that

$$\|h\|_{W^{2,p}(\Omega')} \leq C_p + C_p\|u\|_{W^{2,2}(\Omega)} \leq C_p \quad \text{for any } 2 < p < \infty, \tag{2.35}$$

the constants in (2.35) depend on $dist(\Omega', \partial\Omega)$.

By the Sobolev Embedding Theorem, (2.31), and (2.35), for any $0 < \alpha < 1$ and $\Omega'' \subset\subset \Omega'$,

$$\|h\|_{C^{1,\alpha}(\Omega'')} \leq C' \tag{2.36}$$

and

$$\|u\|_{C^{1,\alpha}(\Omega)} \leq C''\lambda \tag{2.37}$$

where C' depends on α and Ω'' and C'' depends on α. Therefore, using (2.14) it follows that

$$\|f\|_{C^{\beta}(\Omega'')} \leq C'''\lambda \tag{2.38}$$

where C''' depends on β and Ω''. Hence, by elliptic estimates for variational inequalities,

$$\|u\|_{W^{2,\infty}(\Omega''')} \leq C\lambda \tag{2.39}$$

where $\Omega''' \subset\subset \Omega''$, and $0 < \alpha < 1$ (see [4]). □

3. The existence of a solution.

THEOREM 3.1. *Suppose that Ω is a smooth bounded domain, then there exists a solution (u,h) of (1.7)–(1.11) such that*

$$u \in W^{2,p}(\Omega) \cap W^{2,\infty}_{loc}(\Omega), \qquad h \in C^1(\bar{\Omega}) \cap C^{1,\alpha}_{loc}(\Omega) \tag{3.1}$$

for any $2 < p < \infty$ and $0 < \alpha < 1$.

Proof. Take $2 < p < \infty$ (fixed) and let

$$B = W^{1,p}(\Omega) \cap W^{1,2}_0(\Omega). \tag{3.2}$$

For each $u \in B$, define

$$Hu = k + x^2 + y^2 + \int_{\Omega} \frac{u^+(s,t)dsdt}{\sqrt{(x-s)^2+(y-t)^2}}. \tag{3.3}$$

Then, by Hölder's inequality,

$$\|Hu\|_{C^1(\bar{\Omega})} \leq C + C\|u\|_{W^{1,p}(\Omega)} \tag{3.4}$$

$$\|Hu_1 - Hu_2\|_{C^1(\bar{\Omega})} \leq C\|u_1 - u_2\|_{W^{1,p}(\Omega)}. \tag{3.5}$$

Now define Tu to be the solution of (1.7)–(1.10) with $h = Hu$ (it is unique for fixed h).

From (3.4), L^p estimates for the variational inequalities and the compactness of the inclusion $W^{2,p}(\Omega) \to W^{1,p}(\Omega)$, it follows that $T : B \to B$ is compact.

The compactness of T, the uniqueness of the solution of the variational inequality, and (3.5) altogether imply that $T : B \to B$ is continuous.

Next, for any $0 < \sigma < 1$, consider any fixed point u of the operator σT:

$$u = \sigma Tu. \tag{3.6}$$

Notice that since $u/\sigma = Tu$, u is a solution to the following problem:

$$\begin{aligned}
&-\nabla(h^3\nabla u) \geq -\lambda\sigma\frac{\partial h}{\partial x} \quad \text{for } (x,y) \in \Omega \\
&u \geq 0 \quad \text{for } (x,y) \in \Omega \\
&u \cdot \left[-\nabla(h^3\nabla u) + \lambda\sigma\frac{\partial h}{\partial x}\right] = 0 \quad \text{for } (x,y) \in \Omega \\
&u = 0 \quad \text{for } (x,y) \in \partial\Omega
\end{aligned}$$

and

$$h(x,y) = k + x^2 + y^2 + \int_\Omega \frac{u(s,t)dsdt}{\sqrt{(x-s)^2 + (y-t)^2}}. \tag{3.7}$$

Hence by Lemma 2.3 (with $N = 1$),

$$\|u\|_{W^{1,p}(\Omega)} \leq C \tag{3.8}$$

where C is a constant independent of σ.

From this fact and the previous properties of T it follows that the Laray–Schauder fixed point theorem [5, Thm. 10.3] can be applied. Thus, there is a fixed point u for T, that is, there exists a solution (u,h) to the problem (1.7)–(1.11).

Finally by Lemma 2.3,

$$u \in W^{2,\infty}_{loc}(\Omega), \qquad h \in C^{1,\alpha}_{loc}(\Omega), \tag{3.9}$$

and the theorem is proved. □

Remark. If the domain Ω is symmetric with respect to the x-axis, then we may take in (3.2)

$$B = W^{1,p}(\Omega) \cap W^{1,2}_0(\Omega) \cap \{u | u(x,y) = u(x,-y)\} \tag{3.10}$$

and the preceding argument shows that there exists a solution symmetric with respect to y.

4. Estimate on the support. As a simple result of (2.33), we have the following theorem for fixed Ω.

THEOREM 4.1. *For any $\epsilon > 0$, there exists $\lambda_* > 0$ such that if $0 < \lambda < \lambda_*$, then*

$$u(x,y) > 0 \quad \text{for } x < -\epsilon, \ (x,y) \in \Omega. \tag{4.1}$$

Proof. From (2.9) (with N=1) it follows that

$$\begin{aligned} h_x &= 2x + \int_\Omega \frac{u_x(s,t)dsdt}{\sqrt{(x-s)^2+(y-t)^2}} \\ &\equiv 2x + I. \end{aligned} \tag{4.2}$$

By (2.33)

$$\begin{aligned} I &\le C\lambda \int_\Omega \frac{dsdt}{\sqrt{(x-s)^2+(y-t)^2}} \\ &\le C\lambda; \end{aligned} \tag{4.3}$$

hence, for $x < -\epsilon$,

$$h_x < -2\epsilon + C\lambda < 0 \quad \text{for } x < -\epsilon, \ \lambda < \lambda_*, \tag{4.4}$$

provided λ_* is small enough, and hence $u(x,y) > 0$ for $x < -\epsilon$. □

If λ is not small, a similar result still holds if the domain is "large" enough, i.e., $\Omega = B_M(0)$ in (1.7)–(1.11), where M is large. We shall prove the following theorem.

THEOREM 4.2. *For any $\epsilon > 0$, there exists a $K > 0$ such that if $M > K$, then*

$$u(x,y) > 0 \quad \text{for } -M < x < -\epsilon M, \ (x,y) \in B_M(0). \tag{4.5}$$

To prove this theorem, we start with a scaling:

$$u_M(x,y) = u(Mx, My) \quad \text{for } x^2 + y^2 \le 1 \tag{4.6}$$

$$h_M(x,y) = h(Mx, My) \quad \text{for } x^2 + y^2 \le 1. \tag{4.7}$$

A simple calculation shows

$$-\nabla(h_M^3 \nabla u_M) \ge -\lambda M \frac{\partial h_M}{\partial x} \quad \text{for } (x,y) \in B_1 \tag{4.8}$$

and

$$h_M(x,y) = k + M^2(x^2+y^2) + M \int_{B_1} \frac{u(s,t)dsdt}{\sqrt{(x-s)^2+(y-t)^2}}. \tag{4.9}$$

This shows that (u_M, h_M) satisfies (2.1)–(2.5) with $\Omega = B_1(0)$.

It clearly suffices to show that

$$u_M(x,y) > 0 \quad \text{for } -1 < x < -\epsilon \tag{4.10}$$

for M large enough; for simplicity, we drop the subscripts M from u_M and h_M.

Since $h \geq \epsilon^2 M^2$ if $x^2 + y^2 \geq \epsilon^2$, we get from (2.6),

$$\int_{B_1 \setminus B_\epsilon} |\nabla u|^2 dxdy \leq \frac{\lambda^2 \pi}{k\epsilon^6} M^{-4}. \tag{4.11}$$

We shall use C to denote various constants independent of M (although they may depend on ϵ, k, and Λ).

We are going to carry out a proof similar to that in Lemma 2.3, but this time we shall use the fact that $h \geq \epsilon^2 M^2$ if $x^2 + y^2 \geq \epsilon^2$ to find a better estimate on h when $x^2 + y^2 \geq (4\epsilon)^2$.

By Hölder's inequality, for $1 < p < 2$

$$\left\| \frac{\nabla h}{h} \nabla u \right\|_{L^p(B_1 \setminus B_\epsilon)} \leq \frac{1}{\epsilon^2 M^2} \|\nabla h\|_{L^{2p/(2-p)}(B_1 \setminus B_\epsilon)} \|\nabla u\|_{L^2(B_1 \setminus B_\epsilon)}. \tag{4.12}$$

By using (4.11) to estimate ∇u and Lemma 2.2 to estimate ∇h, we get

$$\left\| \frac{\nabla h}{h} \nabla u \right\|_{L^p(B_1 \setminus B_\epsilon)} \leq \frac{1}{\epsilon^2 M^2} (C_p M^2)(CM^{-2}) \leq \frac{C_p}{M^2}. \tag{4.13}$$

By Lemma 2.2, also

$$\begin{aligned} \left\| \frac{\lambda M}{h^3} \frac{\partial h}{\partial x} \right\|_{L^p(B_1 \setminus B_\epsilon)} &\leq \frac{\lambda M}{(\epsilon^2 M^2)^3} \|\nabla h\|_{L^p(B_1)} \\ &\leq (CM^{-5})(C_p M^2) \leq C_p M^{-3}. \end{aligned} \tag{4.14}$$

From (2.14), (4.13), and (4.14), it now follows that

$$\|f\|_{L^p(B_1 \setminus B_\epsilon)} \leq C_p M^{-2} \qquad (1 < p < 2). \tag{4.15}$$

Thus we prove the following lemma.

LEMMA 4.3. *For f defined in* (2.14) (*with $N = M$*),

$$\|f\|_{L^p(B_1 \setminus B_\epsilon)} \leq C_p M^{-2} \quad (1 < p < 2). \tag{4.16}$$

□

Notice that u satisfies the variational inequality

$$-\Delta u \geq f, \quad u \geq 0, \quad u(-\Delta u - f) = 0 \quad \text{in } B_1 \tag{4.17}$$

$$u = 0 \quad \text{on } \partial B_1 \tag{4.18}$$

where f is given by (2.14) (with $N = M$); by Lemmas 4.3, (4.11), and the Poincaré inequality,

$$\|v\|_{L^2(B_1 \setminus B_\epsilon)} \leq \|\nabla v\|_{L^2(B_1 \setminus B_\epsilon)} \quad \text{for } v \in W_0^{1,2}(B_1), \tag{4.19}$$

we get:

$$\|u\|_{L^2(B_1 \setminus B_\epsilon)} \leq CM^{-2} \qquad (1 < p < 2) \tag{4.20}$$

$$\|\nabla u\|_{L^2(B_1 \setminus B_\epsilon)} \leq CM^{-2} \qquad (1 < p < 2) \tag{4.21}$$

$$\|f\|_{L^p(B_1 \setminus B_\epsilon)} \leq C_p M^{-2} \qquad (1 < p < 2). \tag{4.22}$$

LEMMA 4.4. *For* $1 < p < 2$

$$\|u\|_{W^{2,p}(B_1 \setminus B_{2\epsilon})} \le C_p M^{-2} \qquad (1 < p < 2), \tag{4.23}$$

and hence, by the Sobolev Embedding Theorem,

$$\|u\|_{W^{1,p}(B_1 \setminus B_{3\epsilon})} \le C_p M^{-2} \qquad (1 < p < \infty). \tag{4.24}$$

Proof. Take a cutoff function $\zeta \in C^\infty$ so that

$$\begin{aligned} \zeta &= 1 \quad \text{for } 2\epsilon \le \sqrt{x^2+y^2} \le 1 \\ &= 0 \quad \text{for } \sqrt{x^2+y^2} \le \epsilon \end{aligned}$$

and $0 \le \zeta \le 1$. Let $w = \zeta u$. Then

$$\Delta w = u\Delta\zeta + 2\nabla\zeta\nabla u + \zeta\Delta u, \tag{4.25}$$

and w satisfies the variational inequality

$$\begin{aligned} &-\Delta w \ge F \quad \text{for } \epsilon < \sqrt{x^2+y^2} < 1 \\ &w \ge 0 \quad \text{for } \epsilon < \sqrt{x^2+y^2} < 1 \\ &w(-\Delta w - F) = 0 \quad \text{for } \epsilon < \sqrt{x^2+y^2} < 1 \\ &w = 0 \quad \text{for } \sqrt{x^2+y^2} = \epsilon,\ \sqrt{x^2+y^2} = 1 \end{aligned}$$

where

$$F = -u\Delta\zeta - 2\nabla\zeta\nabla u - \zeta f. \tag{4.26}$$

By (4.20)–(4.22), we get

$$\|F\|_{L^p(B_1 \setminus B_\epsilon)} \le C_p M^{-2} \qquad (1 < p < 2). \tag{4.27}$$

Thus by L^p estimates for the variational inequality,

$$\|w\|_{W^{2,p}(B_1 \setminus B_\epsilon)} \le C_p M^{-2} \qquad (1 < p < 2) \tag{4.28}$$

and (4.23) follows. □

Next, we prove the following lemma.

LEMMA 4.5. *There exists a constant* C *such that*

$$\int_{B_1} u(x,y)dxdy \le CM^{-1/5} \tag{4.29}$$

uniformly for large M.

Proof. If (4.29) is not true, then there exists a sequence $M_n \to \infty$ such that

$$\int_{B_1} u_{M_n}(x,y)dxdy > nM_n^{-1/5}. \tag{4.30}$$

Thus

$$\int_{B_1} \frac{u_{M_n}(s,t)}{\sqrt{(x-s)^2+(y-t)^2}} dsdt \ge \frac{1}{2}\int_{B_1} u_{M_n}(x,y)dxdy > \frac{1}{2}nM_n^{-1/5}; \tag{4.31}$$

hence

$$h_{M_n} \geq \frac{1}{2} n M_n^{1-(1/5)} > \frac{n}{2} M_n^{4/5}. \tag{4.32}$$

By Lemma 2.1,

$$\int_{B_1} \left(\frac{n}{2} M_n^{4/5}\right)^3 |\nabla u_{M_n}|^2 dxdy \leq C M_n^2, \tag{4.33}$$

and thus

$$\int_{B_1} |\nabla u_{M_n}|^2 dxdy \leq C n^{-3} M_n^{2-(12/5)} = C n^{-3} M_n^{-2/5}. \tag{4.34}$$

Using Hölder's inequality and (4.19) with $\epsilon \to 0$, we get

$$\begin{aligned} \int_{B_1} u_{M_n}(x,y) dxdy &\leq \pi^{1/2} \|u_{M_n}\|_{L^2(B_1)} \\ &\leq \pi^{1/2} \|\nabla u_{M_n}\|_{L^2(B_1)} \\ &\leq C n^{-3/2} M_n^{-1/5}. \end{aligned} \tag{4.35}$$

From (4.30) and (4.35), it follows that

$$n M_n^{-1/5} < C n^{-3/2} M_n^{-1/5} \tag{4.36}$$

or

$$n < C n^{-3/2} \tag{4.37}$$

which is a contradiction. □

Proof of Theorem 4.2. From (2.9)

$$h_x = 2xM^2 + MI \tag{4.38}$$

where

$$I = \int_{B_1} \frac{u_x(s,t)}{\sqrt{(x-s)^2 + (y-t)^2}} dsdt. \tag{4.39}$$

Take a cutoff function $\zeta \in C^\infty$ such that

$$\begin{aligned} \zeta &= 1 \quad \text{for } \sqrt{x^2+y^2} \geq 3\epsilon \\ &= 0 \quad \text{for } \sqrt{x^2+y^2} \leq 2\epsilon \end{aligned} \tag{4.40}$$

and $0 \leq \zeta \leq 1$. Then

$$\begin{aligned} I &= \int_{B_1} \frac{(u\zeta + u(1-\zeta))_x(s,t)}{\sqrt{(x-s)^2 + (y-t)^2}} dsdt \\ &= \int_{B_1} \frac{(u\zeta)_x(s,t)}{\sqrt{(x-s)^2 + (y-t)^2}} dsdt + \int_{B_1} \frac{(u(1-\zeta))_x(s,t)}{\sqrt{(x-s)^2 + (y-t)^2}} dsdt \\ &\equiv J_1 + J_2. \end{aligned} \tag{4.41}$$

Assume that $(x,y) \in B_1 \setminus B_{4\epsilon}$. Then

$$\sqrt{(x-s)^2+(y-t)^2} \geq \epsilon \quad \text{for } (s,t) \in B_{3\epsilon}. \tag{4.42}$$

Since $u(1-\zeta)=0$ on $\partial B_{3\epsilon}$, no boundary term will appear when we use integration by parts for J_2. Hence

$$\begin{aligned} J_2 &= \int_{B_{3\epsilon}} \frac{(u(1-\zeta))_x(s,t)}{\sqrt{(x-s)^2+(y-t)^2}} dsdt \\ &= -\int_{B_{3\epsilon}} u(1-\zeta)\left(\frac{\partial}{\partial s}\frac{1}{\sqrt{(x-s)^2+(y-t)^2}}\right) dsdt \end{aligned} \tag{4.43}$$

and thus

$$\begin{aligned} |J_2| &\leq C\int_{B_{3\epsilon}} |u| dsdt \\ &\leq CM^{-1/5}, \end{aligned} \tag{4.44}$$

the last inequality is obtained by Lemma 4.5.

By Hölder's inequality

$$\begin{aligned} \|J_1\|_{L^\infty(B_1)} &\leq \|(u\zeta)_x\|_{L^3(B_1\setminus B_{2\epsilon})} \left[\sup_{(x,y)\in B_1} \left\| \frac{1}{\sqrt{(x-\cdot)^2+(y-\cdot)^2}} \right\|_{L^{3/2}(B_1)}\right] \\ &\leq C\|\nabla(u\zeta)\|_{L^3(B_1\setminus B_{2\epsilon})} \end{aligned} \tag{4.45}$$

where the last inequality is obtained by using (4.24).

Thus, by (4.44), (4.45), and (4.21), for $(x,y) \in B_1 \setminus B_{4\epsilon}$

$$|I| \leq |J_1| + |J_2| \leq CM^{-1/5}, \tag{4.46}$$

and thus, for $x \leq -4\epsilon$, we have

$$\begin{aligned} h_x &\leq 2xM^2 + CM^{1-(1/5)} \\ &\leq -8\epsilon M^2 + CM^{2/5} < 0 \end{aligned} \tag{4.47}$$

if $M > K(\epsilon)$, and hence $u(x,y) > 0$ for $x < -4\epsilon$. □

5. Uniqueness. In this section we prove uniqueness provided λ is small. The estimates that we obtained in §§2 and 3 are uniform for λ, that is, the constants C depend only on Λ. Ω will be a fixed smooth domain.

THEOREM 5.1. *There exists $\lambda_1 > 0$ such that the solution of* (1.7)-(1.11) *is unique if $0 \leq \lambda \leq \lambda_1$, where λ_1 depends on Ω and k.*

Proof. We shall use C to denote constants that do not depend on λ.

If (u,h),$(\tilde{u},\tilde{h})$ are two solutions, then we have

$$[-\nabla(h^3\nabla u) + \lambda h_x](\tilde{u}-u) \geq 0 \tag{5.1}$$

$$[-\nabla(\tilde{h}^3\nabla \tilde{u}) + \lambda \tilde{h}_x](u-\tilde{u}) \geq 0. \tag{5.2}$$

Thus

$$\int_\Omega h^3\nabla u\nabla(\tilde{u}-u) \geq \lambda\int_\Omega h(\tilde{u}-u)_x \tag{5.3}$$

$$\int_\Omega \tilde{h}^3\nabla\tilde{u}\nabla(u-\tilde{u}) \geq \lambda\int_\Omega \tilde{h}(u-\tilde{u})_x; \tag{5.4}$$

hence

$$\int_\Omega \{h^3|\nabla(u-\tilde{u})|^2 + (\tilde{h}^3 - h^3)\nabla\tilde{u}\nabla(\tilde{u}-u)\} \leq \lambda \int_\Omega |\nabla(u-\tilde{u})||h-\tilde{h}|. \tag{5.5}$$

Using (2.19) and (2.21), we get

$$\begin{aligned} k^3 \int_\Omega |\nabla(u-\tilde{u})|^2 &\leq C\lambda \int_\Omega |\nabla(u-\tilde{u})||h-\tilde{h}| \\ &\leq C\lambda \|\nabla(u-\tilde{u})\|_{L^2(\Omega)} \|h-\tilde{h}\|_{L^2(\Omega)}. \end{aligned} \tag{5.6}$$

By Young's inequality [5, Lemma 7.12] with $p = q = 2$, we get

$$\|h-\tilde{h}\|_{L^2(\Omega)} \leq C\|u-\tilde{u}\|_{L^2(\Omega)}. \tag{5.7}$$

Now (5.6) and (5.7), together with Poincaré's inequality give:

$$\int_\Omega |\nabla(u-\tilde{u})|^2 \leq C\lambda \|\nabla(u-\tilde{u})\|_{L^2(\Omega)} \|h-\tilde{h}\|_{L^2(\Omega)} \leq C\lambda \int_\Omega |\nabla(u-\tilde{u})|^2. \tag{5.8}$$

Thus, if λ is small, then

$$\int_\Omega |\nabla(u-\tilde{u})|^2 = 0 \tag{5.9}$$

which implies that $u = \tilde{u}$. □

6. The case $\mu = \mu_0 e^{\alpha u}$. In the previous sections we studied the case when the viscosity is constant. We now study the case when the viscosity is given by (1.13). We shall extend all the previous results to this case provided α is small.

Using the transformation

$$w = 1 - e^{-\alpha u}, \tag{6.1}$$

we obtain from (1.1)–(1.5) the variational inequality:

$$-\nabla(h^3\nabla w) \geq -\lambda\alpha h_x \quad \text{for } (x,y) \in \Omega \tag{6.2}$$

$$w \geq 0 \quad \text{for } (x,y) \in \Omega \tag{6.3}$$

$$w[-\nabla(h^3\nabla w) + \lambda\alpha h_x] = 0 \quad \text{for } (x,y) \in \Omega \tag{6.4}$$

$$w = 0 \quad \text{for } (x,y) \in \partial\Omega \tag{6.5}$$

and

$$h(x,y) = k + x^2 + y^2 + \int_\Omega \frac{1}{\alpha}\left(\log \frac{1}{1-w(s,t)}\right) \frac{dsdt}{\sqrt{(x-s)^2 + (y-t)^2}}. \tag{6.6}$$

The main difficulty is to show that $1 - w$ stays uniformly positive. To overcome this difficulty, let us fix $\epsilon \in (0,1)$ and take a cutoff function ζ such that $\zeta \in C^\infty$, $0 \leq \zeta \leq 1$ and

$$\begin{aligned} \zeta(w) &= 1 \quad \text{for } w \leq 1-\epsilon \\ &= 0 \quad \text{for } w \geq 1-\epsilon/2. \end{aligned}$$

Define

$$G(w) = \zeta(w) \log \frac{1}{1-w} \quad \text{for } 0 \le w < \infty; \tag{6.7}$$

then $G \in C^\infty$. Let us take, for instance, $\epsilon = \frac{1}{2}$. Next, instead of (6.6), take

$$h(x,y) = k + x^2 + y^2 + \int_\Omega \frac{1}{\alpha} G(w(s,t)) \frac{dsdt}{\sqrt{(x-s)^2 + (y-t)^2}}. \tag{6.8}$$

Let us consider the system (6.2)–(6.5) and (6.8). From (6.2)–(6.5), it follows that

$$\int_\Omega |\nabla w|^2 dxdy \le \frac{\lambda^2 \alpha^2 |\Omega|}{k^4}. \tag{6.9}$$

Differentiating (6.8), we get

$$\nabla h = 2(x,y) + \int_\Omega G'(w(s,t)) \frac{\nabla w(s,t)}{\alpha} \frac{dsdt}{\sqrt{(x-s)^2 + (y-t)^2}}. \tag{6.10}$$

Note that $|G'(w(s,t))|$ is bounded uniformly, and thus, by Young's inequality [5, Lemma 7.12], we get, for $2 < p < \infty$,

$$\|\nabla h\|_{L^p(\Omega)} \le C + C \|\frac{1}{\alpha} \nabla w\|_{L^2(\Omega)}; \tag{6.11}$$

by (6.9)

$$\|\nabla h\|_{L^p(\Omega)} \le C \tag{6.12}$$

where the constant C is independent of α. Thus, if

$$f = \frac{3\nabla h}{h} \nabla w - \frac{\lambda \alpha}{h^3} \frac{\partial h}{\partial x} \tag{6.13}$$

then, as in the proof of Lemma 2.3 (using (6.9)),

$$\|f\|_{L^p(\Omega)} \le C_p \alpha \lambda \qquad (1 < p < 2). \tag{6.14}$$

From (6.9) and (6.14), it follows by using the L^p estimates for the variational inequality that

$$\|w\|_{W^{2,p}(\Omega)} \le C_p \alpha \lambda \qquad (1 < p < 2) \tag{6.15}$$

Applying the Sobolev Embedding Theorem to (6.15), we obtain

$$w \le C \alpha \lambda \le 1 - \epsilon = \frac{1}{2} \tag{6.16}$$

provided $\alpha\lambda$ is small, and then the expressions (6.8) and (6.6) coincide. The existence, regularity, and uniqueness of the solution now follows as before. Let us summarize the results as follows.

THEOREM 6.1. *There exists a constant $c = c(k, \Omega) > 0$ such that if $0 < \alpha\lambda < c$, then there exists a solution (u, h) such that*

$$u \in W^{2,p}(\Omega) \cap W^{2,\infty}_{loc}(\Omega), \quad h \in C^1(\bar{\Omega}) \cap C^{1,\alpha}_{loc}(\Omega). \tag{6.17}$$

Moreover, there exists a constant $\lambda_1 = \lambda_1(k, \Omega) > 0$ such that if $0 < \alpha\lambda < c$, $0 < \lambda < \lambda_1$, then the solution (u, h) is unique.

7. The one-dimensional problem. Consider the one-dimensional variational inequality:

$$-\left(h^3\frac{u'}{e^{\alpha u}}\right)' \geq -\lambda h' \quad \text{for } x \in [-M, M] \tag{7.1}$$

$$u \geq 0 \quad \text{for } x \in [-M, M] \tag{7.2}$$

$$u \cdot \left[-\left(h^3\frac{u'}{e^{\alpha u}}\right)' + \lambda h'\right] = 0 \quad \text{for } x \in [-M, M] \tag{7.3}$$

$$u(\pm M) = 0 \tag{7.4}$$

and

$$h = k + x^2 + \int_{-M}^{M} u(s) \log \frac{2M}{|x-s|} ds \tag{7.5}$$

where M, λ, and k are positive constants; and α is a positive constant which shall be assumed to be sufficiently small in proving the existence of the solution; both α and λ will be assumed to be sufficiently small in proving the uniqueness of the solution.

Introducing the transformation

$$w = 1 - e^{-\alpha u}, \tag{7.6}$$

as before, we obtain

$$u = \frac{1}{\alpha} \log \frac{1}{1-w}, \tag{7.7}$$

and (7.1)–(7.5) is transformed into the following problem:

$$-(h^3 w')' \geq -\lambda\alpha h' \quad \text{for } x \in [-M, M] \tag{7.8}$$

$$w \geq 0 \quad \text{for } x \in [-M, M] \tag{7.9}$$

$$w[-(h^3 w')' + \lambda\alpha h'] = 0 \quad \text{for } x \in [-M, M] \tag{7.10}$$

$$w(\pm M) = 0 \tag{7.11}$$

and

$$h = k + x^2 + \frac{1}{\alpha} \int_{-M}^{M} \left(\log \frac{1}{1-w(s)}\right) \log \frac{2M}{|x-s|} ds. \tag{7.12}$$

As we did in §6, instead of (7.12), we consider

$$h = k + x^2 + \frac{1}{\alpha} \int_{-M}^{M} (G(w(s))) \log \frac{2M}{|x-s|} ds \tag{7.13}$$

where $G(w)$ is defined in (6.7). The system (7.1)–(7.5) is equivalent to (7.8)–(7.11) and (7.13) if we can establish the bound:

$$w \leq 1 - \epsilon \tag{7.14}$$

but this follows, for small α, from the following lemma.

LEMMA 7.1. *Suppose that* $\lambda \leq \Lambda$. *If* w *satisfies* (7.8)–(7.11), *then*

$$|w(y)| \leq 2M\frac{\lambda\alpha}{k^2} \quad \text{for } |y| \leq M. \tag{7.15}$$

Proof. Integrating (7.10) over $[-M, M]$, we get

$$\begin{aligned} \int_{-M}^{M} h^3|w'|^2 &= -\lambda\alpha\int_{-M}^{M} h'w = \lambda\alpha\int_{-M}^{M} hw' \\ &\leq \lambda\alpha\left(\int_{-M}^{M} h^2|w'|^2\right)^{1/2}(2M)^{1/2} \\ &\leq \frac{\lambda\alpha}{k^{1/2}}(2M)^{1/2}\left(\int_{-M}^{M} h^3|w'|^2\right)^{1/2}, \end{aligned} \tag{7.16}$$

and hence

$$\int_{-M}^{M} h^3|w'|^2 \leq \frac{\lambda^2\alpha^2}{k}(2M). \tag{7.17}$$

It follows that

$$\|w'\|_{L^2[-M,M]} \leq \frac{\lambda\alpha}{k^2}(2M)^{1/2}, \tag{7.18}$$

so that

$$|w(y)| \leq \int_{-M}^{M} |w'(s)|ds \leq (2M)^{1/2}\|w'\|_{L^2[-M,M]}. \tag{7.19}$$

Using (7.18), (7.15) follows. □

Lemma 7.1 tells us that if we choose, for instance, $\epsilon = \frac{1}{2}$, then there exists an $A > 0$ (we may take $A = (k^2/2M)(1-\epsilon) = k^2/4M$) such that

$$w(y) \leq 1 - \epsilon = \frac{1}{2} \quad \text{for } 0 < \alpha\lambda < A, \tag{7.20}$$

and hence (7.12) and (7.13) coincide. Next we shall use constants C to denote various constants depending only on M, k, A, and Λ. Since we are going to use the same method as in §3 to prove existence, care has to be taken so that the constants will not change when we replace λ by $\sigma\lambda$ $(0 \leq \sigma \leq 1)$.

Note that,

$$\lim_{\delta\to 0}\frac{1}{\delta}\log\frac{1}{1-2M\delta/k^2} = \frac{2M}{k^2}. \tag{7.21}$$

and, consequently, by (7.15),

$$\sup_{|s|\leq M}\left|\frac{1}{\alpha}\log\frac{1}{1-w(s)}\right| \leq \lambda\left(\frac{1}{\alpha\lambda}\log\frac{1}{1-2M\alpha\lambda/k^2}\right) \leq C\lambda. \tag{7.22}$$

By (7.12),

$$h \leq C + C\int_{-M}^{M}\log\frac{2M}{|x-s|}ds \leq C. \tag{7.23}$$

To derive an estimate for $w'(x)$ for all x, it suffices to derive an estimate for $w'(x)$ for every interval $[a,b]$ such that $w(a) = w(b) = 0$ and $w(x) > 0$ for $x \in (a,b)$.

By Rolle's theorem, there is a number $c \in (a,b)$ such that $w'(c) = 0$. From (7.10), it follows that

$$h^3(x)w'(x) = \lambda\alpha(h(x) - h(c)). \tag{7.24}$$

And hence, by (7.23),

$$\frac{1}{\alpha}|w'(x)| \le \lambda\left|\frac{h(x) - h(c)}{h^3(x)}\right| \le C\lambda. \tag{7.25}$$

Differentiating (7.13) (which is now the same as (7.12)), we get

$$h'(x) = 2x + \int_{-M}^{M} \frac{1}{\alpha}\frac{w'(s)}{1 - w(s)} \log\frac{2M}{|x - s|}ds, \tag{7.26}$$

and, by (7.20), (7.25),

$$|h'(x)| \le 2M + C\int_{-M}^{M} \log\frac{2M}{|x - s|}ds \le C. \tag{7.27}$$

By (7.10),

$$h^3w'' + 3h^2h'w' = \lambda\alpha h' \quad \text{if } w(x) > 0, \tag{7.28}$$

and thus, by (7.25), (7.27),

$$\sup_{|x|\le M} \frac{1}{\alpha}|w''(x)| \le C\lambda. \tag{7.29}$$

Using these estimates, we can prove the existence of the solution by using the same method as in §3. In the case $\alpha = 0$, we may work with u instead of w. We have proved the following theorem.

THEOREM 7.2. *If α is sufficiently small such that*

$$\frac{2M\lambda\alpha}{k^2} < 1, \tag{7.30}$$

then there exists a solution to (7.1)–(7.5). □

Remark. This condition on α is much more precise than that derived in Theorem 6.1.

Next, we prove that the free boundary consists of at most one free boundary point.

THEOREM 7.3. *There exists $\lambda_0 = \lambda_0(k, M)$ such that if $0 \le \alpha\lambda \le A$, $0 \le \lambda \le \lambda_0$, then there is at most one free boundary point.*

Proof. We can rewrite h' as:

$$h'(x) = 2x + \int_{-M-x}^{M-x} \frac{1}{\alpha}\frac{w'(t + s)}{1 - w(t + s)} \log\frac{2M}{|t|}dt, \tag{7.31}$$

then

$$\begin{aligned} h''(x) &= 2 + \int_{-M}^{M} \frac{1}{\alpha}\left[\frac{w''(s)}{1-w(s)} + \frac{(w'(s))^2}{(1-w(s))^2}\right] \log \frac{2M}{|x-s|} ds \\ &\quad - \frac{1}{\alpha} w'(M) \log \frac{2M}{M-x} + \frac{1}{\alpha} w'(-M) \log \frac{2M}{M+x} \\ &= 2 - I. \end{aligned}$$

By (7.25), (7.29), we get

$$h''(x) \geq 2 - \lambda C_1 \quad \text{for } |x| \leq \frac{M}{2} \tag{7.32}$$

so that if λ is small

$$h''(x) > 0 \quad \text{for } |x| \leq \frac{M}{2}. \tag{7.33}$$

By (7.25), (7.26), if λ is small enough, then

$$h'(x) \geq M - \lambda C_2 > 0 \quad \text{for } x \geq \frac{M}{2} \tag{7.34}$$

$$h'(x) \leq -M + \lambda C_2 < 0 \quad \text{for } x \leq -\frac{M}{2}. \tag{7.35}$$

Take λ_0 so that (7.33)–(7.35) hold for $\lambda \leq \lambda_0$. Then $h'(x)$ has only one zero in $[-M, M]$, say, at $x = d$. Then

$$h'(x) < 0 \quad \text{for } -M \leq x < d \tag{7.36}$$

$$h'(x) > 0 \quad \text{for } d < x \leq M. \tag{7.37}$$

Suppose now that b is the first free boundary point, i.e.,

$$w(x) > 0 \quad \text{for } -M < x < b \tag{7.38}$$

$$w(b) = 0 \quad \text{for } b < M. \tag{7.39}$$

By regularity, $w'(b) = 0$. By (7.36), $w > 0$ on $(-M, d)$. Hence $b \geq d$.

Let us define

$$\begin{aligned} \tilde{w}(x) &= w(x) \quad \text{for } -M \leq x < b \\ &= 0 \quad \text{for } b \leq x \leq M. \end{aligned} \tag{7.40}$$

Since $h'(x) > 0$ for $x > b$, $\tilde{w}$ is also a solution of (7.8)–(7.11). Since the solution is unique (for fixed h), we have $w = \tilde{w}$, and hence b is the only free boundary point. □

We also have uniqueness if λ is small.

THEOREM 7.4. *There exists a number $\lambda_1 > 0$ so that the solution (w, h) to the problem (7.8)–(7.12) is unique provided that $0 \leq \lambda \leq \lambda_1$.*

Proof. The proof is essentially the same as that in Theorem 5.1. It is necessary only to check that

$$\|h - \tilde{h}\|_{L^2[-M,M]} \leq C\lambda \|u - \tilde{u}\|_{L^2[-M,M]} \tag{7.41}$$

which is obviously true. □

Remark. Several problems remain open: the uniqueness of the solution without assuming that λ is small, the shape of the free boundary in the two-dimensional case, and the existence of the solution when $\mu = \mu_0 e^{\alpha u}$ without assuming α small.

Acknowledgments. The problem considered in this paper was suggested by Edward Bissett from General Motor Research Laboratories. The author thanks Professor Avner Friedman for his direction and help while working on this paper.

SUR UNE CLASSE DE FONCTIONNELLES NON CONVEXES ET APPLICATIONS*

RABAH TAHRAOUI†

Abstract. Various questions of physical or mechanical nature are frequently solved by a variational approach. In many situations, minimizers for the total energy associated with the system are being sought. This energy is represented by an integral functional

$$J(v)=\int_\Omega g(x, v, A\,v)\,dx$$

where v is a vectorial function mapping a bounded open subset Ω of $\mathbb{R}^n$ into $\mathbb{R}^m$, and A is a differential operator.

The goal of this paper is closely related to the study of the elastostatic equilibrium for materials whose constitutive laws are nonlinear. In some realistic situations, the shape of the body, the nature of the deformation, or some symmetric arguments require Ω to be an annulus or a disc.

For example, let B be an isotropic and homogeneous body occupying a reference configuration $\mathcal{R}$ before deformation and $\mathcal{R}'$ after deformation

$$x=(x_1, x_2, x_3)\in\mathcal{R}\to x'=x+u(x)\in\mathcal{R}'$$

where $u(x)$ is the displacement function. It is assumed that the deformation is of the form

$$x=(r, \theta, z)\to x'=(u(r), \theta+v(r), z+w(r))$$

where $r=((x_1^2+x_2^2)^{1/2}z=x_3$ and $\theta=\operatorname{arctg}(x_2/x_1)$. The associated energy can be represented by

$$J_1(u)=\int_\Omega g_1(U(|y|, u, \nabla u))\,dy+\lambda\int_\Omega h_1(|y|, u)\,dy$$

where U is a certain function that will be specified later. The function J_1 is, in general, nonconvex; then the direct method of calculus of variations is not applicable. The lack of weak lower sequential semicontinuity does not make it possible to tend toward the limit in minimizing sequences. Despite this, some existence and regularity results are proved by relaxation techniques.

1. Introduction.

L'étude de nombreux phénomènes physiques conduit à la recherche de fonctions minimisant l'énergie interne du système. Cette énergie est en général donnée par des fonctionnelles du type

$$J(v)=\int_\Omega g(x, v, A\,v)\,dx,$$

où $v=(v_1, v_2, \cdots, v_m)$ désigne une fonction définie sur l'ouvert borné Ω de $\mathbb{R}^n$ à valeurs dans $\mathbb{R}^m$, et A est un opérateur différentiel. Une motivation de ce travail est l'étude de l'équilibre élastostatique de certains matériaux dont la loi de comportement est non linéaire (cf. [6], [19], [15], [7]). La géométrie de certains corps et la nature de leur déformation nous imposent de travailler avec Ω à symétrie radiale, i.e., Ω est soit une couronne soit un disque de $\mathbb{R}^2$, de centre zéro: il s'agit, par exemple, de l'étude

* Received by the editors March 1, 1988; accepted for publication (in revised form) February 2, 1989.
† Université de Paris-Sud et Centre, Bâtiment 425, Nationale de Recherche Scientifique, Laboratoire d'Analyse Numérique d'Orsay, Orsay 91405, France and Université de Picardie, U.F.R. Cedex Mathematique et Informatique, Amiens, France.

du déplacement $u=(u_1, u_2, u_3)$ d'un corps B élastique, isotrope, et homogène qui occupe les positions $\mathcal{R}=\Omega\times]-L, +L[$ et $\mathcal{R}'$, respectivement, avant et après déformation:

$$x=(x_1, x_2, x_3)\in\mathcal{R}\to x'=x+u(x)\in\mathcal{R}',$$

on suppose que cette déformation est de la forme

$$x=(r, \theta, z)\to x'=(u(r), \theta+v(r), z+w(r))$$

avec $r=(x_1^2+x_2^2)^{1/2}$ et $z=x_3$; θ désigne l'angle polaire du vecteur $\vec{0}m$ d'extrémité $m=(x_1, x_2)$. Sa densité d'énergie de déformation est supposée de la forme [16] $g_1(U(|y|, u, \nabla u))$ et son énergie totale est

$$(\mathcal{P}_1)\qquad J_1(u)=\int_\Omega g_1(U(|y|, u, \nabla u))\,dy+\lambda\int_\Omega h_1(|y|, u)\,dy$$

où U est une fonction assez spécifique que nous préciserons ultérieurement. De plus, signalons que ces fonctionnelles sont en général non convexes (cf. [9], [5], [1], [10], [6]).

Le modèle de mécanique exposé ci-dessus a fait l'objet d'une étude en [12] avec des hypothèses restrictives par rapport à notre travail. Notre méthode (cf. [4], [17]) est différente de celle mise en oeuvre en [12].

Nous aborderons également l'étude de fonctionnelles plus générales que les précédentes, de la forme

$$(\mathcal{P}_2)\qquad J_2(v)=\int_\Omega g_2(|x|, |\nabla v_1|, \cdots, |\nabla v_m|)+\lambda\int_\Omega h_2(|x|, v)\,dx$$

où $\nabla v=\partial v_j/\partial x_i$, $(1\leqq i\leqq n,\ 1\leqq j\leqq m)$, désigne la matrice gradient de v, et celles du type

$$(\mathcal{P}_3)\qquad J_3(v)=\int_\Omega g_3(Av)\,dx+\int_\Omega h(|x|, v)\,dx$$

où $Av=(A_1v_1, A_2v_2)$ est un opérateur différentiel uniformément elliptique.

Etant donnée une fonctionnelle $J(v)$ semi-continue inférieure faible séquentiellement (s.c.i.f.s.), la méthode directe du calcul des variations consiste à considérer une suite minimisante u_n convergeant vers u, et à passer à la limite dans $J(u_n)$. La s.c.i.f.s. permet alors d'avoir l'inégalité essentielle

$$\underline{\lim}\, J(u_n)\geqq J(u)$$

prouvant ainsi que u réalise le minimum de $J(\cdot)$.

La difficulté majeure que l'on rencontre dans l'étude des fonctionnelles introduites ci-dessus provient de l'absence de semi-continuité inférieure séquentielle faible qui rend inopérante la méthode directe du calcul des variations [9], [8].

Pour la résolution de ces problèmes, nous utilisons l'idée de base contenue dans [3]. La conclusion proviendra d'une analyse fine des conditions d'extrémalité pour obtenir des informations qualitatives sur les solutions des problèmes relaxés correspondants. Cette analyse fine est intimement liée à la structure de chaque problème. Dans cette étude, nous ne présenterons en détail que les points spécifiques aux problèmes abordés ici.

Nous traiterons également dans ce travail la question de l'unicité.

Enfin signalons que ce travail a été annoncé dans [18].

2. Hypothèses et notations du problème ($\mathcal{P}_1$). Pour simplifier l'exposé nous prendrons, d'une part des "fonctions modèles" U de type assez simple mais suffisamment expressives pour la méthode, et nous travaillerons, d'autre part, dans l'espace

fonctionnel $V = H^1(\Omega)$; ce qui nous amène à supposer les hypothèses de croissance convenables sur les fonctions g_1 et h_1. La première est une fonction de $\mathbb{R}$ dans $\mathbb{R}$ régulière, paire telle que

$$0 < \theta_0 \leqq t^{-1} \cdot \frac{dg_1^{**}}{dt}(t) \leqq \theta_1 \quad \forall t, \tag{1}$$

$$a_1 t^2 + b_1 \leqq g_1(t) \leqq a_2 t_2^2 + b_2 \quad \forall t, \tag{2}$$

où a_1 et a_2 sont des constantes positives et g_1^{**} désigne la convexifiée de g_1. La seconde est une fonction régulière de $[a, b] \times \mathbb{R}^3$ dans $\mathbb{R}$ satisfaisant

$$c_1|\eta|^2 + d_1 \leqq h_1(s, \eta) \leqq c_2|\eta|^2 + d_2 \quad \forall (s, \eta), \tag{3}$$

où c_2 est une constante positive et c_1 une constante convenablement choisie;

$$\frac{\partial h_1}{\partial \eta_i}(r, \eta) \leqq 0, \quad i = 2, 3, \quad \forall (r, \eta) \in]a, b[\times \mathbb{R}^3, \tag{4}$$

$$\frac{\partial h_1}{\partial \eta_1}(r, \eta) \equiv 0, \tag{5}$$

$$\frac{\partial h_1}{\partial \eta_3}(r, \eta) + \frac{\partial h_1}{\partial \eta_2}(r, \eta) < 0 \quad \forall (r, \eta) \in]a, b[\times \mathbb{R}^3. \tag{6}$$

La fonction U est supposée de la forme

$$U^2 = U^2(|x|, v, \nabla v) = |\nabla v_1|^2 + \beta^2(|x|, v_1) \cdot |\nabla v_2|^2 + |\nabla v_3|^2$$

où β est une fonction régulière qui vérifie

$$\beta(s, t) \geqq \beta_0 > 0, \tag{7}$$

$$\beta_1(s, t) = \frac{\partial \beta}{\partial s}(s, t) \geqq 0, \tag{8}$$

$$t \cdot \frac{\partial \beta}{\partial t}(s, t) \geqq 0, \; t^{-1} \cdot \frac{\partial \beta}{\partial t}(s, t) < c \quad \text{pour } t \text{ voisin de zéro.} \tag{9}$$

On note:

$$\Gamma_1 = \{x \in \mathbb{R}^2 / |x| = a\}, \qquad \Gamma_2 = \{x \in \mathbb{R}^2 / |x| = b\},$$

$$\Omega = \{x \in \mathbb{R}^2 / a < |x| < b\},$$

$$V_1 = (H_0^1(\Omega)^3 + \varphi, \tag{10}$$

où $\varphi = (\varphi_1, \varphi_2, \varphi_3)$ appartenant à $(H^1(\Omega))^3$ vérifie les conditions aux limites

$$\varphi / \Gamma_1 = \alpha = (\alpha_1, \alpha_2, \alpha_3), \qquad \varphi / \Gamma_2 = \gamma = (\gamma_1, \gamma_2, \gamma_3); \tag{11}$$

les α_i and γ_i sont des constantes supposées vérifier, pour fixer les idées,

$$\delta_i = \gamma_i - \alpha_i > 0, \qquad i = 2, 3, \tag{12}$$

$$\alpha_1 = 0, \qquad \gamma_1 > 0. \tag{13}$$

Nous voulons montrer que le problème

$(\mathscr{P}_1)$ Trouver une solution de $\inf\{J_1(v), v \in V_1\}$

admet au moins une solution, et que cette dernière possède une symétrie radiale. Cette propriété de la solution désirée nous amène à associer à $(\mathscr{P}_1)$ le problème relaxé, en dimension un d'espace:

(π_1) Trouver u dans $\tilde{V}_1$ solution de $\inf\{\tilde{J}_1(v), v \in \tilde{V}_1\}$,

l'espace $\tilde{V}_1$ et la fonctionnelle $\tilde{J}_1$ sont définis par

$$\tilde{V}_1 = \{v \in H^1((a,b))^3 / v_i(a) = \alpha_i,\ v_i(b) = \gamma_i\},$$

$$\tilde{J}_1(v) = \int_a^b r g_1^{**}(V(v))\, dr + \lambda \int_a^b r h_1(r, v)\, dr,$$

où l'on a noté

$$(V(v))^2 = \left(\frac{dv_1}{dr}\right)^2 + \beta^2(r, v_1) \cdot \left(\frac{dv_2}{dr}\right)^2 + \left(\frac{dv_3}{dr}\right)^2.$$

Pour simplifier la présentation nous noterons, si nécessaire, $v' = dv/dr$. Le problème (π_1) admet au moins une solution $u = u_\lambda$. L'idée est de montrer que u vérifie

$$g_1^{**}(V(u(r))) = g_1(V(u(r))) \quad \text{p.p. } r \in]a, b[.$$

Ce sera l'étape 1. L'étape 2 sera consacrée à la régularité de u. Enfin à l'étape 3, nous montrerons que la fonction $\bar{u}(x) = u(|x|)$ est solution de $(\mathscr{P}_1)$.

Etape 1. Cette étape comprend plusieurs propositions.

PROPOSITION 2.1. *On suppose les hypothèses* (1)-(3), (10), *et* (11). *La fonction u solution de* (π_1) *satisfait les relations d'extrémalités suivantes*:

$$r \cdot \frac{g_1^{**\prime}(V)}{V} \cdot u_1' = -p_1, \tag{14}$$

$$r \cdot \frac{g_1^{**\prime}(V)}{V} \beta \cdot \beta_2 \cdot (u_2')^2 + \lambda r \frac{\partial h_1}{\partial \eta_1}(r, u) = -p_1', \tag{15}$$

$$r \cdot \frac{g_1^{**\prime}(V)}{V} \cdot \beta^2 \cdot u_2' = -p_2, \tag{16}$$

$$r \cdot \frac{g_1^{**\prime}(V)}{V} u_3' = -p_3, \tag{17}$$

$$\lambda r \cdot \frac{\partial h_1}{\partial \eta_i}(r, u) = -p_i', \qquad i = 2, 3, \tag{18}$$

où $V = V(u)$, $\beta_2 = \partial\beta/\partial t(r, u_1)$, *et* $g_1^{**\prime}(t) = dg_1^{**}/dt$. *De plus les fonctions* p_i, u_i *appartiennent à* $W^{1,\infty}(a, b)$, $i = 1, 2, 3$.

Démonstration. La preuve de ce résultat s'obtient aisément à partir des équations d'Euler de π_1:

$$-\frac{d}{dr}(r\sigma \cdot u_1') + \lambda r \frac{\partial h_1}{\partial \eta_1}(r, u) + r\sigma \cdot \beta\beta_2 \cdot (u_2')^2 = 0,$$

$$-\frac{d}{dr}(r\sigma \cdot \beta^2 u_2') + \lambda r \frac{\partial h_1}{\partial \eta_2}(r, u) = 0,$$

$$-\frac{d}{dr}(r\sigma u_3') + \lambda r \frac{\partial h_1}{\partial \eta_3}(r, u) = 0.$$

Nous la laissons au lecteur.

Les p_i étant ainsi définies, considérons la fonction de $L^\infty(a, b)$

$$\nu_\lambda(r) = \nu(r) = \left(\frac{p_1}{r}\right)^2 + \left(\frac{p_2}{r\beta}\right)^2 + \left(\frac{p_3}{r}\right)^2;$$

nous avons le résultat suivant.

PROPOSITION 2.2. *Nous supposons* (1)-(8) *et* (10)-(12). *La fonction* $\nu(r)$ *appartient à* $W^{1,\infty}(a, b)$; *de plus, il existe* $\lambda_0 > 0$ *tel que pour tout* λ, $0 < \lambda < \lambda_0$, *on a* $\nu'_\lambda(r) < 0$, $u'_2(r) \geqq 0$, *et* $u'_3(r) \geqq 0$ *p.p.r dans* $]a, b[$.

Démonstration. $\nu(r)$ appartient à $W^{1,\infty}(a, b)$ car p_2^2, p_3^2 appartiennent à $C^1([a, b])$; et $1/\beta^2$ et p_1^2 appartiennent à $W^{1,\infty}(a, b)$. Ainsi, la dérivée au sens des distributions

$$\nu'(r) = \frac{2p_1p'_1}{r^2} + \frac{2p_2p'_2}{r^2\beta^2} + \frac{2p_3p'_3}{r^2} - \frac{2}{r}\left[\left(\frac{p_1}{r}\right)^2 + \left(\frac{p_2}{r\beta}\right)^2 + \left(\frac{p_3}{r}\right)^2\right] - \frac{2(\beta_1 + \beta_2 \cdot u'_1)}{\beta} \cdot \left(\frac{p_2}{r\beta}\right)^2$$

appartient à $L^\infty(a, b)$. Transformons quelque peu cette expression de $\nu'(r)$ à l'aide de (14), (15), et (16); nous obtenons

$$\nu'(r) = \frac{2}{r^2}\left[\frac{p_2p'_2}{\beta_2} + p_3 \cdot p'_3\right] - \frac{2}{r}\left[\left(\frac{p_1}{r}\right)^2 + \left(\frac{p_2}{r\beta}\right)^2 + \left(\frac{p_3}{r}\right)^2\right] - \frac{2\beta_1}{\beta} \cdot \left(\frac{p_2}{r\beta}\right)^2 \tag{19}$$

on voit bien que l'on aura $\nu'(r) < 0$ si l'on montre par exemple que

$$p_3 \cdot p'_3 + \frac{p_2p'_2}{\beta^2} < 0. \tag{20}$$

Remarque 2.1. Les solutions (u_i, p_i), $i = 1, 2, 3$ du système (14)-(18) dépendent du paramètre λ, i.e., que l'on a en fait

$$u_i = u_i^\lambda, \quad p_i = p_i^\lambda, \quad i = 1, 2, 3.$$

On montre aisément les estimations suivantes:

$$\begin{aligned} &\|u_i^\lambda\|'_{L^\infty(a,b)} \leqq c, && i = 1, 2, 3, \\ &\|u_i^\lambda\|_{H^1(a,b)} \leqq c, && i = 1, 2, 3, \\ &\|p_i^\lambda\|_{H^1(a,b)} \leqq c, && i = 1, 2, 3, \end{aligned} \tag{21}$$

où $c = c(g_1, h_1, a, b, \delta_i)$ désigne diverses constantes indépendantes de λ.

Montrons (20). Par une intégration par parties à partir de (16) et (17), on montre les inégalités suivantes:

$$\begin{aligned} 0 < \delta_2 &= u_2(b) - u_2(a) \\ &= -p_2(b)\Sigma_2(b) - \lambda \int_a^b r \frac{\partial h_1}{\partial \eta_2}(r, u) \cdot \Sigma_2 \, dr, \\ 0 < \delta_3 &= u_3(b) - u_3(a) \\ &= -p_3(b)\Sigma_3(b) - \lambda \int_a^b r \frac{\partial h_1}{\partial \eta_3}(r, u) \cdot \Sigma_3 \, dr \end{aligned}$$

où

$$\Sigma_2(r) = \int_a^r \frac{V \cdot ds}{\beta^2 \cdot s \cdot g_1^{**\prime}(V)}, \qquad \Sigma_3(r) = \int_a^r \frac{V \cdot ds}{s \cdot g_1^{**\prime}(V)}.$$

Et ainsi, grâce aux estimations (21), il existe $\lambda_0 > 0$ tel que pour tout λ dans $]0, \lambda_0[$ on a

$$-p_i(b)\Sigma_i(b) > 0, \qquad i = 2, 3,$$

i.e.,

$$p_i(b) < 0, \qquad i = 2, 3;$$

ceci entraîne que les fonctions p_2 et p_3 sont strictement négatives puisque nous avons supposé l'hypothèse (4) à savoir

$$\frac{\partial h_1}{\partial \eta_i}(r, \eta) \leqq 0, \qquad i = 2, 3.$$

Et enfin l'hypothèse (6) entraîne que (20) est vérifié, i.e., $\nu'(r) < 0$. Ainsi s'achève la preuve de la proposition 2.2. □

Remarque 2.2. Une question naturelle se pose: a-t-on une propriété de monotonie pour u_1?

La réponse à la question ci-dessus nous sera donnée par la proposition 2.4.

PROPOSITION 2.3. *Sous les hypothèses* (1) *à* (8) *et* (10) *à* (12), *toute solution u du problème* (π_1) *satisfait*

$$g_1^{**}(V(u(r))) = g_1(V(u(r))) \quad p.p.\ r \in]a, b[.$$

Démonstration. Il suffit de montrer que l'ensemble

$$E = \{r \in]a, b[/ g_1^{**}(V(u(r))) < g_1(V(u(r)))\}$$

est de mesure nulle. Cela se montre, comme dans [17], à l'aide de la propriété suivante de la fonction ν conséquence de la proposition 2.2:

$$|\{r \in [a, b] / \nu(r) = t\}| = 0 \quad \forall t.$$

Remarque 2.3. La fonction ν étant sans palier, il est aisé de voir que l'on a de plus le résultat suivant: s'il existe une partie affine commune aux graphes de g_1 et g_1^{**}, soit par exemple

$$\Delta = \{(t, g_1(t)), t \in \tilde{K}\} \subset \mathbb{R}^2$$

où

$$\tilde{K} = \{t \in \mathbb{R} / g_1'(t) = g_1^{**\prime}(t) = c = \text{constante}\}$$

alors l'ensemble $\{r \in]a, b[/ V(u(r)) \in K\}$ est de mesure nulle. Ainsi "n'interviennent" que les parties strictement convexes du graphes de g_1^{**}.

Cette information nous sera utile pour obtenir un résultat d'unicité (cf. le théorème 2.2).

Revenons maintenant à la monotonie de u_1. Pour cela nous aurons besoin des hypothèses supplémentaires (9) et (13).

PROPOSITION 2.4. *Si l'on suppose que* (9) *et* (13) *ont lieu, alors on a*

$$p_1(r) \leqq 0 \quad \forall r,$$

$$u_1'(r) \geqq 0 \quad p.p.\ r,$$

$$0 \leqq u_1(r) \leqq \gamma_1 \quad \forall r.$$

Démonstration. La fonction u_1 vérifie l'équation

$$-\frac{d}{dr}\left(r\sigma \frac{du_1}{dr}\right) + r\sigma\beta\left(\frac{\beta_2}{u_1}\right)(u_2')^2 \cdot u_1 = 0,$$

$$u_1(a) = 0, \qquad u_1(b) = \gamma_1 > 0,$$

avec $r\sigma \geqq a$, $\theta_0 > 0$, $(u_2')^2 r\sigma\beta \cdot \beta_2 / u_1 \geqq 0$. Le principe du maximum entraîne que l'on a $u_1(r) > 0$ sur $]a, b[$; d'autre part on a par (15) $p_1'(r) \leqq 0$ p.p. r, i.e., que p_1 est décroissant. Et pour montrer que p_1 est négatif nous raisonnerons par l'absurde. Supposons qu'il existe $r_0 \in]a, b]$ tel que $p_1(r) > 0$ $\forall r \in]a, r_0[$; (14) entraîne que l'on a $u_1'(r) \leqq 0$ p.p. $r \in]a, r_0[$ i.e., $u_1(r) \leqq 0$ pour tout r dans $]a, r_0[$. Ceci contredit le principe du maximum. La conclusion suit. □

Remarque 2.4. A travers la preuve de ce résultat il est aisé de voir que si $u_1(a) = \alpha_1 > 0$, il peut exister $r_0 \in]a, b[$ tel que l'on ait

$$u_1'(r) \leqq 0 \quad \text{p.p. sur }]a, r_0[,$$

$$u_1'(r) \geqq 0 \quad \text{p.p. sur }]r_0, b[,$$

$$u_1(r) \geqq 0 \quad \text{sur }]a, b[.$$

Remarque 2.5. Si l'hypothèse (5) n'a plus lieu et si par exemple

$$h_1(r, \eta) = \lambda h(r, \eta_2, \eta_3) + \gamma k(r, \eta_1), \quad 0 < \lambda \leqq \lambda_0, \quad 0 < \gamma \leqq \gamma_0$$

étant deux paramètres réels indépendants, alors le résultat de la proposition 2.2 subsiste pour λ_0 et γ_0 suffisamment petits. En revanche, nous ne pouvons obtenir un résultat de monotonie sur u_1, propriété dont on aura besoin à la § 4 où est traité un exemple issu de l'élasticité.

Etape 2. Régularité de u solution de (π_1). D'après la proposition 2.2, la fonction $\nu(r)$ est continue strictement décroissante. Introduisons, suivant [17], les notations suivantes qui nous seront utiles pour le résultat d'unicité:

$$E(\Lambda) = \left\{ \gamma \in \mathbb{R}^+ \Big/ \frac{dg_1^{**}}{dt}(\gamma) = \Lambda \right\}, \qquad \Lambda \in \mathbb{R}^+,$$

$$a(\Lambda) = \inf\{\gamma, \gamma \in E(\Lambda)\}, \qquad b(\Lambda) = \sup\{\gamma, \gamma \in E(\Lambda)\},$$

$$S = \{\Lambda \in \mathbb{R}^+ / a(\Lambda) < b(\Lambda)\}, \qquad \psi(t) = \frac{dg_1^{**}}{dt}(t).$$

Soit $\Lambda_0 < \Lambda_1 < \Lambda_2 < \cdots < \Lambda_n \cdots$ les éléments de S. La fonction continue

$$\phi(r) = \sqrt{\nu(r)} = \frac{dg_1^{**}}{dt}(V(u(r)))$$

étant strictement décroissante, il existe une suite de nombres réels

$$\{s_k\}_{k=0}^{k=n_1} \subset [a, b]$$

satisfaisant

$$\phi(s_k) = \Lambda_k, \qquad k = 0, 1, \cdots, n_1.$$

D'après la remarque 2.3 la fonction

$$(\psi_{/]b(\Lambda_k), a(\Lambda_{k+1})[})(t)$$

est inversible puisque g_1^{**} est strictement convexe sur $]b(\Lambda_k), a(\Lambda_{k+1})[$. Ainsi:

$$V(u(r)) = [\psi_{/]b(\Lambda_k), a(\Lambda_{k+1})[}]^{-1}(\phi(r))$$

pour tout $s \in]s_k, s_{k+1}[$, i.e., la fonction $V(u(r))$ est continue sur $]s_k, s_{k+1}[$ tout $k = 0, 1, \cdots, n_1$. Ceci prouve à l'aide de (1) et de la proposition 2.2 que $u(r)$ et $\phi(r)$ sont

de classe C^1 sur $]s_k, s_{k+1}[$; donc $V(u(r))$ est C^1 sur $]s_k, s_{k+1}[$; et ainsi de suite on montre que u est C^∞ par morceaux si g_1 et h_1 sont C^∞.

Ainsi, nous venons de démontrer le résultat suivant:

PROPOSITION 2.5. *La fonction u solution de* (π_1) *est* C^∞ *par morceaux si* g_1 *et* h_1 *sont* C^∞.

Etape 3. $\bar{u}(x) = u(|x|)$ est solution de $(\mathcal{P}_1)$.

Comme conséquence des 2 étapes précédentes, on obtient le résultat suivant.

THÉORÈME 2.1. *Sous les hypothèses* (1) *à* (8) *et* (10) *à* (12), *il existe* λ_0 *tel que le problème* $(\mathcal{P}_1)$ *admet, pour tout* λ *dans* $]0, \lambda_0[$, *une solution* $\bar{u}$ *possédant les propriétés suivantes*:

(1) $\bar{u}(x)$ *est radiale*: $\bar{u}(x) = \bar{u}(|x|)$,
(2) $|\nabla \bar{u}(x)| \leqq C$ *p.p.* $x \in \Omega$
(3) $\bar{u}$ *est* C^∞ *par morceaux si* g_1 *et* h_1 *sont* C^∞,
(4) $\bar{u}_2$ *et* $\bar{u}_3$ *sont croissantes le long des rayons.*

De plus si (9) *et* (13) *ont lieu* $\bar{u}_1$ *est croissante le long des rayons.*

Démonstration. Il suffit de voir que $\bar{u}(x) = u(|x|)$ convient. □

Abordons maintenant l'unicité. Rappelons que ce point n'a pas été abordé dans [4] et [17]. Nous avons le résultat suivant.

THÉORÈME 2.2. *On suppose* $\beta(r, t) = \beta(r)$, h *convexe, et* (1)-(8) *et* (12). *Alors* (π_1) *admet une solution unique.*

Démonstration. La preuve de ce résultat nécessite une étape préliminaire: le lemme 2.1. Soient $u \not\equiv \omega$ deux solutions de (π_1). Elles vérifient

$$g_1^{**}(V(u(r))) = g_1(V(u(r))) \quad \text{p.p. } r \in]a, b[,$$

$$g_1^{**}(V(\omega(r))) = g_1(V(\omega(r))) \quad \text{p.p. } r \in]a, b[;$$

pour tout θ dans $[0, 1]$, la fonction $u_\theta = \theta u + (1-\theta)\omega$ solution de (π_1) vérifie la même relation:

$$g_1^{**}(V(u_\theta(r))) = g_1(V(u_\theta(r))) \quad \text{p.p. } r \in]a, b[\quad \forall \theta \in [0, 1]. \tag{22}$$

D'après le résultat de régularité il existe une partition de $]a, b[$ en intervalles $J_k =]s_k s_{k+1}[$, $k = 1, 2, \cdots, n_1$ tels que: $u'(r)$ et $V(u(r))$ soient continues sur J_k pour tout k. Quitte à redécouper les J_k en sous-intervalles, on peut toujours supposer que $\omega'(r)$ et $V(\omega(r))$ sont continues sur J_k pour tout k. Posons alors

$$\mathcal{U}(r, \theta) = V(u_\theta(r))$$

$$= [(u'_{1\theta})^2 + \beta^2(r) \cdot (u'_{2\theta})^2 + (u'_{3\theta})^2]^{1/2}$$

où $u_\theta(r) = \theta u(r) + (1-\theta)\omega(r)$. Il est clair que $\mathcal{U}(r, \theta)$ est continue sur $J_k \times]0, 1[$ à valeurs dans

$$F = \{t \in \mathbb{R}^+ / g_1^{**}(t) = g_1(t)\}.$$

Nous avons le résultat suivant.

LEMME 2.1. *Nous avons* $J_k \cap V(u)^{-1}(I) = J_k \cap V(\omega)^{-1}(I)$ *pour tout* k *et toute composante connexe* I *de* F.

Démonstration. Il suffit de montrer que l'on a

$$[V(u)^{-1}(I_1) \cap J_k] \cap [V(\omega)^{-1}(I_2) \cap J_k] = \varnothing$$

pour tout k et toutes composantes connexes de F, I_1, et I_2 telles que $I_1 \neq I_2$. Nous raisonnerons par l'absurde.

Supposons qu'il existe $k_0 \in [1, \cdots, n_1]$ et deux composantes connexes I_1 et I_2 $(I_1 \neq I_2)$, de F tels que l'ensemble

$$\Omega = V(u)^{-1}(I_1) \cap V(\omega)^{-1}(I_2) \cap J_{k_0}$$

soit non vide; soit $r_0 \in \Omega$; nous avons

$$V(u(r_0)) = \mathcal{U}(r_0, 1) \in I_1, \qquad V(\omega(r_0)) = \mathcal{U}(r_0, 0) \in I_2,$$

et puisque $\mathcal{U}(J_{k_0} \times]0, 1[)$ est connexe, il existe $\theta_0 \in]0, 1[$, δ_1 et δ_2 tels que

$$\mathcal{U}(r_0, \theta_0) \in]\delta_1, \delta_2[\subseteq K$$

où K est le complémentaire de F. Et par continuité il existe un voisinage $\mathcal{V}(r_0)$ tel que

$$\mathcal{U}(r, \theta_0) \in]\delta_1, \delta_2[\quad \forall r \in \mathcal{V}(r_0),$$

c'est à dire

$$g_1(V(u_{\theta_0}(r))) > g_1^{**}(V(u_{\theta_0}(r))) \quad \text{p.p. } r \in \mathcal{V}(r_0)$$

contredisant ainsi (22). Ainsi le lemme 2.1 a lieu. □

Démonstration du théorème 2.2. Si $u \not\equiv \omega$, d'après la remarque 2.3 et le lemme 2.1, il existe $k_0 \in [1, \cdots, n_1]$ tel que

$$\int_{J_{k_0}} g_1^{**}(V(u_{1/2}(r)))\, dr < \frac{1}{2} \int_{J_{k_0}} g_1^{**}(V(u(r)))\, dr + \frac{1}{2} \int_{J_{k_0}} g_1^{**}(V(\omega(r)))\, dr;$$

cette inégalité entraîne la contradiction

$$J_1(u_{1/2}) < \operatorname{Inf}\{J_1(v), v \in V_1\}.$$

Remarque 2.6. Le théorème 2.2 entraîne que la solution radiale de $(\mathcal{P}_1)$ est unique.

3. Hypothèses et notation du problème (P_2). Soit la fonction g_2 de $[a, b] \times \mathbb{R}^2$ dans $\mathbb{R}$, régulière telle que

$$a_1|t|^2 + b_1(r) \leqq g_2(r, t) \leqq a_2|t|^2 + b_2(r) \quad \forall (r, t) \tag{1}$$

où les a_i désignent des constantes positives et les b_i des fonctions $L^\infty(a, b)$. Désignons par $g_2^{**}(r, \cdot)$ la convexifiée de $g_2(r, \cdot)$ par rapport à t, à r fixé, et posons:

$$\mathcal{K} = \{(r, t) \in [a, b] \times \mathbb{R}^2 / g^{**}(r, t) < g_2(r, t)\}. \tag{2}$$

On suppose que, d'une part les composantes connexes $\mathcal{K}_i$ de $\mathcal{K}$, indexées par I, sont au plus dénombrables:

$$\mathcal{K} = \bigcup_{i \in I} \mathcal{K}_i; \tag{3}$$

d'autre part, pour tout i dans I il existe une fonction

$$k_i : (r, t) \in]a, b[\times \mathbb{R}^2 \to k_i(r, t) \in \mathbb{R}$$

affine en t telle que

$$g_2^{**}(r, t) = k_i(r, t) = \sigma_i(r) \cdot t + \xi_i(r) \quad \forall (r, t) \in \mathcal{K}_i \tag{4}$$

où $\sigma_i = (\sigma_i^1, \sigma_i^2)$ sont deux fonctions de $W^{1,\infty}(a, b)$ satisfaisant:

$$\sum_{j=1}^{2} \sigma_i^j(r) \cdot \sigma_i^{j\prime}(r) \geqq 0 \quad \text{p.p. } r \in]a, b[. \tag{5}$$

Cette hypothèse (4), (5) jouera un rôle essentiel dans l'existence. On suppose aussi que g_2 vérifie

$$
\begin{aligned}
&0 < \theta_0 \leqq t_i^{-1} \cdot \frac{\partial g_2^{**}}{\partial t_i}(r, t) \leqq \theta_i(r, t_j) \quad \forall t = (t_1, t_2) \quad \forall i \neq j, \\
&0 \leqq \theta_i(r, t_j) \leqq \gamma_i
\end{aligned} \tag{6}
$$

où θ_0 et γ_i sont des constantes positives:

$$
\begin{aligned}
&g_2(r, t_1, t_2) = g_2(r, \varepsilon_1 t_1, \varepsilon_2 t_2) \quad \forall (r, t), \\
&\varepsilon_1 = \pm 1, \qquad \varepsilon_2 = \pm 1.
\end{aligned} \tag{7}
$$

On se donne une fonction h_2 de $[a, b] \times \mathbb{R}^2$ dans $\mathbb{R}$, régulière telle que

$$
c_1 |\eta|^2 + d_1 \leqq h_2(r, \eta) \leqq c_2 |\eta|^2 + d_2 \quad \forall (r, \eta), \tag{8}
$$

où c_2 est une constante positive et c_1 une constante réelle convenable:

$$
\frac{\partial h_2}{\partial \eta_i}(r, \eta) < 0 \quad \forall (r, \eta), \quad i = 1, 2. \tag{9}
$$

Nous nous proposons alors de résoudre le problème suivant:

$(\mathscr{P}_2)$ Trouver $\bar{u}$ dans V_2 solution de $\inf \{J_2(v), v \in V_2\}$

où

$$
J_2(v) = \int_\Omega g_2(|x|, |\nabla v_1|, |\nabla v_1|)\, dx + \lambda \int_\Omega h_2(|x|, v)\, dx,
$$

$$
V_2 = \{v \in (H^1(\Omega))^2 / v_{i/\Gamma_1} = d_i, v_{i/\Gamma_2} = \beta_i\};
$$

α_i et β_i sont des constantes données, qu'on suppose satisfaisant, pour simplifier, l'inégalité

$$
\alpha_i < \beta_i, \qquad i = 1, 2. \tag{10}
$$

L'idée utilisée pour résoudre $(\mathscr{P}_1)$ reste valable: on part du problème variationnel, en dimension un d'espace, qui est naturellement associé à $(\mathscr{P}_2)$:

(π_2) Trouver $u \in \tilde{V}_2$ solution de $\inf \{\tilde{J}_2(v), v \in \tilde{V}_2\}$

avec

$$
\tilde{J}_2(v) = \int_a^b r g_2^{**}(r, v_1', v_2')\, dr + \lambda \int_a^b r h_2(r, v)\, dr,
$$

$$
\tilde{V}_2 = \{v \in (H^1(a, b))^2 / v_i(a) = \alpha_i, v_i(b) = \beta_i\}.
$$

Ce problème relaxé (π_2) admet au moins une solution $u = u^\lambda$ satisfaisant les relations d'extrémalités

$$
\begin{aligned}
&r \frac{\partial g_2^{**}}{\partial t_i}(r, u') = -p_i \in H^1(a, b), \qquad i = 1, 2, \\
&r\lambda \frac{\partial h_2}{\partial \eta_i}(r, u) = -p_i', \qquad i = 1, 2.
\end{aligned} \tag{11}
$$

Nous allons montrer (comme précédemment) à l'aide des hypothèses (3)-(5) et (9) que pour tout $i \in I$ l'ensemble

$$E_i = \{r \in]a, b[/(r, u'(r)) \in \mathcal{K}_i\}$$

est de mesure nulle, i.e.,

$$g_2^{**}(r, u'(r)) = g_2(r, u'(r)) \quad \text{p.p. } r \in]a, b[.$$

PROPOSITION 3.1. *La solution $u = u^\lambda$ de (π_2) satisfait*

$$u_i' = (u_i^\lambda)' \geqq 0.$$

Démonstration. Pour λ dans $]0, 1]$ on montre les estimations suivantes:

$$\|u_i\|_{H^1} = \|u_i^\lambda\|_{H^1(a,b)} \leqq c, \qquad \|p_i\|_{H^1} = \|p_i^\lambda\|_{H^1(a,b)} \leqq c$$

où c est une constante indépendante de λ. A l'aide d'une intégration par parties à partir de (11) on obtient les relations

$$\begin{aligned} 0 < \delta_i &= u_i(b) - u_i(a) \\ &= -p_i(b)\Sigma_i(b) - \lambda \int_a^b r \frac{\partial h_2}{\partial \eta_i}(r, u) \cdot \Sigma_i(r)\, dr \end{aligned}$$

où Σ_i a pour expression

$$\Sigma_i^\lambda(r) = \Sigma_i(r) = \int_a^r u_i'(s) \cdot \frac{1}{s} \left(\frac{\partial g_2^{**}}{\partial t_i}(s, u') \right)^{-1} ds, \qquad i = 1, 2.$$

On peut alors affirmer l'existence d'un λ_0 dans $]0, 1]$ tel que

$$-p_i^\lambda(b)\Sigma_i^\lambda(b) > 0 \quad \forall \lambda \in]0\lambda_0].$$

Cette inégalité entraîne $p_i(b) < 0$ puisque $\Sigma_i(b)$ est strictement positif à l'aide de (6); ainsi on a

$$p_i(r) < 0 \quad \forall r \in [a, b], \quad i = 1, 2, \tag{12}$$

en vertu de l'hypothèse (9). Par conséquent on peut dire, utilisant l'hypothèse (6), que

$$0 \leqq r \cdot u_i' \cdot \frac{\partial g_2^{**}}{\partial t_i}(r, u') = -p_i \cdot u_i',$$

i.e.,

$$u_i'(r) \geqq 0 \quad \text{p.p. } r \in [a, b], \quad i = 1, 2.$$

Ceci termine la preuve de la proposition. □

PROPOSITION 3.2. *La fonction u vérifie*

$$g_2^{**}(r, u'(r)) = g_2(r, u'(r)) \quad \text{p.p. } r \in]a, b[. \tag{13}$$

Démonstration. Considérons la fonction $\nu(r) = \sum_{i=1}^2 (p_i(r)/r)^2$; à l'aide de (12) et (9) on montre que $\nu'(r) < 0$ p.p. $r \in]a, b[$. Comme pour tout i and I la fonction $\mu_i(r) = \sum_{j=1}^2 (\sigma_i^j)^2$ est croissante, il s'ensuit que l'ensemble $\{r \in]a, b[/\mu_i(r) = \nu(r)\}$ est de mesure nulle; ce qui entraîne que pour tout i dans I l'ensemble $E_i = \{r \in]a, b[/(r, u'(r)) \in \mathcal{K}_i\}$ est de mesure nulle. Ainsi (13) a lieu.

Enfin nous pouvons montrer facilement que u_1 appartient à $W^{1,\infty}(a, b)$. Une conséquence immédiate de ces résultats est le théorème suivant.

THÉORÈME 3.1. *On suppose les hypothèses* (1) *à* (10). *Alors il existe* $\lambda_0 > 0$ *tel que pour tout* λ *dans* $]0, \lambda_0[$ *le problème* $(\mathscr{P}_2)$ *admet au moins une solution* $\bar{u}$. *Cette solution possède les propriétés suivantes*:

(1) $\bar{u}(x)$ *est radiale, i.e.,* $\bar{u}(x) = \bar{u}(|x|)$;

(2) $|\nabla \bar{u}(x)| \leqq c$ *p.p.* $x \in \Omega$;

(3) $\bar{u}_i$ *est monotone le long de chaque rayon.*

Remarque 3.1. Il est possible d'envisager des fonctions g_2 dépendant de r, u, u'; mais cela nécessite des hypothèses supplémentaires qu'il serait fastidieux de décrire ici.

4. Application. Nous considérons un tube T homogène isotrope de section la couronne $C = [0, 2\pi[\times]a, b[$. Nous supposons qu'avant déformation ce corps élastique a ses génératrices parallèles à l'axe $0\vec{z}$:

$$T = C \times [-L, +L] = \{(r, \theta, z) \in]a, b[\times [0, 2\pi] \times [-L, L]\}$$

où nous notons

$$x = (x_1, x_2), \quad r = \sqrt{x_1^2 + x_2^2}, \quad x_1 = r \cos\theta, \quad x_2 = r \sin\theta.$$

Nous nous intéressons aux déformations de la forme

$$(1) \qquad (x, z) = (r, \theta, z) \to (u(r), \theta + v(r), z + w(r)) = (r', \theta', z').$$

D'après [16], [2], les trois invariants principaux du tenseur de Cauchy-Green ont pour expressions:

$$(2) \qquad \begin{aligned} I_1 &= (u')^2 + (uv')^2 + (w')^2 + \left(\frac{u}{r}\right)^2 + 1, \\ I_2 &= (u')^2 + (uv')^2 + \left(\frac{uu'}{r}\right)^2 + \left(\frac{uw'}{r}\right)^2 + \left(\frac{u}{r}\right)^2, \\ I_3 &= \frac{uu'}{r}. \end{aligned}$$

Dans la situation la plus générale, la fonction densité d'énergie de déformation a pour expression (cf. la remarque 3.1)

$$W(I_1, I_2, I_3) = g(r, u, u', v', w').$$

Et dans ce cas la réponse au problème n'est pas simple, notamment à cause de la condition d'invertibilité

$$(3) \qquad \frac{u(r) \cdot u'(r)}{r} > 0.$$

Aussi, pour illustrer simplement ce qui précède, nous allons examiner quelques situations particulières.

Exemple 1. Le cas incompressible. La déformation est de la forme

$$\begin{aligned} &(r, \theta, z) \to (r, \theta + v(r), z + w(r)) \\ &I = I_1 = I_2 = r^2 (v')^2 + (w')^2 + 3, \qquad I_3 = 1, \\ &W(I) = g(\sqrt{I - 3}). \end{aligned}$$

Nous représentons par $U = (v, w)$ le déplacement et par $\partial T = \partial_1 T \cup \partial_2 T$ le bord de T où

$$(4) \qquad \begin{aligned} \partial_1 T &= \{(x, z) / z = \pm L\}, \\ \partial_2 T &= \{(x, z) / |x| = a \text{ ou } |x| = b\}. \end{aligned}$$

Nous supposons que le déplacement est fixé sur $\partial_2 T$:

$$(v, w) = (v_0, w_0) \quad \text{sur } \partial_2 T, \tag{5}$$

et que la traction t est nulle sur $\partial_1 T$:

$$t(x, \pm L) = 0. \tag{6}$$

Alors le problème de l'équilibre élastostatique de T s'écrit: trouver $\bar{u} = (\bar{v}, \bar{w})$ réalisant dans l'espace $V = (H_0^1(C))^2 + (v_0, w_0)$, par exemple, le minimum de la fonctionnelle

$$J(v, w) = \int_C g(\sqrt{I-3})\, de + \lambda \int_C h(|x|, v, w)\, dx \tag{7}$$

où h représente la prise en compte des forces volumiques. Le théorème 2.1 s'applique.

Exemple 2. Le cas faiblement compressible. Nous supposons que la loi de comportement du matériau est telle que son énergie soit de la forme $g(I)$, où

$$\begin{aligned} I^2 &= I_1 - 2I_3 - 1 \\ &= r^2\left[\left(\frac{u}{r}\right)'\right]^2 + r^2\left(\frac{u}{r}\right)^2 (v')^2 + (w')^2. \end{aligned}$$

Remarque 4.1. Des situations particulières du même type ont été envisagées par divers auteurs: dans [13] et [14] par exemple, on considère des densités dépendant uniquement du premier invariant I_1.

Transformons quelque peu l'expression de I en posant

$$\begin{aligned} u(r) &= r + r \cdot y(r) = r(1 + y(r)), \\ I^2 &= r^2(y')^2 + r^2(1+y)^2(v')^2 + (w')^2. \end{aligned}$$

On s'impose les conditions aux limites suivantes:

$$\begin{aligned} &y(a) = 0, \quad \text{i.e., } u(a) = a, \\ &y(b) = y_1 > 0, \quad \text{i.e., } u(b) = b(1+y_1), \\ &v(a) = v_0, \qquad v(b) = v_1, \\ &w(a) = w_0, \qquad w(b) = w_1; \end{aligned} \tag{8}$$

la donnée y_1 sera prise assez petite. Ceci sera justifié plus loin. Il est difficile de contrôler une minoration du terme positif $1 + y(r)$. Aussi nous perturbons la fonctionnelle $J(\cdot)$ par

$$\tilde{J}(y, v, w) = \int_a^b g(\tilde{I}) r\, dr + \lambda \int_a^b h(r, y, v, w) r\, dr \tag{9}$$

où

$$\tilde{I} = r^2(y')^2 + r^2(1 + \sigma_\delta(y))^2 (v')^2 + (w')^2,$$

la fonction $\sigma_\delta(y)$ étant la régularisation classique de $|y|$:

$$\sigma_\delta(y) = \int_0^y \psi_\delta(\theta)\, d\theta,$$

$$\psi_\delta(\theta) = \begin{cases} 1 & \text{si } \theta \geqq \delta, \\ \dfrac{1}{\delta} \cdot \theta & \text{si } \delta > \theta > -\delta, \\ -1 & \text{si } \theta \leqq -\delta, \end{cases}$$

δ étant un paramètre réel, positif assez petit. Il est aisé de voir que l'on peut appliquer les résultats du paragraphe 2 en s'imposant les hypothèses adéquates du théorème 2.1;

et en particulier on obtient que la solution $(\bar{y}, \bar{v}, \bar{w})$ du problème (9), $\inf\{\tilde{J}(y, v, w)/(y, v, w)\}$, vérifie:

$$0 < \bar{y}(r) \leqq y_1 \quad \forall r \in]a, b[,$$

$$\bar{y}'(r) \geqq 0 \quad \text{p.p. } r, \qquad \|\bar{y}'\|_{L^\infty(a,b)} \leqq C_0,$$

ce qui donne bien la condition

$$\frac{uu'}{r} = (1+\bar{y})(1+\bar{y}+r\bar{y}') > 0 \quad \text{p.p. } r.$$

Le modèle de fonction énergie que nous avons considéré est valable pour les matériaux dont le comportement est voisin de celui des matériaux incompressibles (i.e., faiblement compressibles). Il est utile de savoir, lorsque y_1 tend vers zéro, si notre problème (8) "tend" vers le problème incompressible (6), et dans quel sens.

Nous avons le résultat suivant.

PROPOSITION 4.1. *On se donne une suite $y_{1,n} > 0$ tendant vers zéro; et on considère (y_n, v_n, w_n) une solution de* (8). *Alors on a*:

(i) $y_n \to 0$ *uniformément*;

(ii) $\|y_n'\|_{L^\infty(a,b)} \to 0$, $v_n \to \bar{v}$, $w_n \to \bar{w}$ *dans* $H^1(a, b)$ *faible*;

(iii) $(\bar{v}, \bar{w})$ *est solution du problème incompressible* (6);

(iv) $u_n u_n'/r \to 1$ *dans* $L^\infty(a, b)$.

La preuve s'obtient en établissant les estimations adéquates en suivant la même démarche que dans les paragraphes précédents.

Remarque 4.2. La perturbation suivante:

$$\tilde{I} = r^2(y')^2 + r^2(1+|y|)^2(v')^2 + (w')^2 \tag{10}$$

permet également d'obtenir que $\bar{y}$ est positif; cependant elle n'est pas satisfaisante pour notre méthode car $\tilde{I}$ n'est pas différentiable par rapport à y.

Remarque 4.3. Il serait intéressant de savoir si l'on peut passer à la limite quand δ tend vers zéro et obtenir la résolution de notre problème avec (10).

5. Fonctionnelles d'opérateurs elliptiques. Soit Ω un ouvert borné régulier de $\mathbb{R}^n$; on se donne, par exemple, deux opérateurs A_1 et A_2 uniformément elliptiques d'ordre $2m$, à coefficients réguliers, et deux fonctions régulières g_3 de $\Omega \times \mathbb{R}^2$ dans $\mathbb{R}$ et h_3 de $\Omega \times \mathbb{R}^2$ dans $\mathbb{R}$ satisfaisant les hypothèses classiques de croissance suivantes:

$$a_1|t|^p + b_1 \leqq g_3(x, t) \leqq a_2|t|^p + b_2, \qquad 1 < p < +\infty, \tag{1}$$

$$c_1|\eta|^p + d_1 \leqq h_3(x, \eta) \leqq c_2|\eta|^p + d_2; \tag{2}$$

les constantes a_1, a_2, c_2 sont positives; c_1 est un réel convenablement choisi pour assurer la coercitivité du problème considéré. On se donne également les deux opérateurs suivants:

$$A_i = \sum_{\substack{|\alpha|=m \\ |\beta|=m}} (-1)^{|\alpha|} D^\alpha (a_{\alpha\beta}^i D^\beta), \quad a_{\alpha\beta}^i = a_{\beta\alpha}^i, \quad i = 1, 2$$

dont les coefficients sont supposés réguliers. Et on pose

$$K = \{(x, t) \in \Omega \times \mathbb{R}^2 / g_3^{**}(x, t) < g_3(x, t)\}. \tag{3}$$

Nous faisons les hypothèses essentielles suivantes: il existe une famille I, au plus dénombrable de fonctions $\alpha_i = (\alpha_i^1, \alpha_i^2)$ dans $(W^{2m,p}(\Omega))^2$, $\beta_i \in L^\infty(\Omega)$, d'ensembles

$K_i \subset \Omega \times \mathbb{R}^2$ et une constante c tels que

$$K = \bigcup_{i \in I} K_i \quad \forall i \in I,$$

(4)
$$g_{3/K_i}^{**}(x, t) = \alpha_i(x) \cdot t + \beta_i(x) \quad \forall (x, t) \in K_i,$$

(5)
$$\left| A_1\alpha_1(x) + \frac{\partial h_3}{\partial \eta_1}(x, \eta) + c\left(A_2\alpha_2(x) + \frac{\partial h_3}{\partial \eta_2}(x, \eta) \right) \right| > 0 \quad \forall \eta \in \mathbb{R}^2 \quad \text{p.p. } x \in \Omega.$$

Remarque. Une condition du type (5) est donnée dans [4] dans le cas scalaire, régulier et dans [5] dans le cas scalaire non régulier.

Enfin notons par V_3 l'espace $(W^{2m,p}(\Omega) \cap W_0^{m,p}(\Omega))^2 + \varphi$, où φ est une fonction donnée dans $(W^{2m,p}(\Omega))^2$; et soit à minimiser la fonctionnelle

$$J_3(v) = \int_\Omega g_3(x, A_1v_1, A_2v_2)\, dx + \int_\Omega h_3(x, v)\, dx$$

sur l'espace V_3. Alors nous avons le résultat suivant.

THÉORÈME 4.1. *Le problème* $(\mathcal{P}_3)$: $\inf\{J_3(v)/v \in V_3\}$ *admet au moins une solution* $u = (u_1, u_2) \in V_3$.

Idée de la preuve. Le problème relaxé

$$(\mathcal{PR}) \qquad \inf\left\{ \int_\Omega g_3^{**}(x, Av)\, dx + \int_\Omega h_3(x, v)\, dx / v \in V_3 \right\}.$$

admet au moins une solution $u = (u_1, u_2)$ qui vérifient

$$\frac{\partial g^{**}}{\partial t_i}(x, Au) = p_i,$$

$$A_i p_i = \frac{\partial h_3}{\partial \eta_i}(x, u), \qquad i = 1, 2$$

où $p_i \in W^{2m,p}(\Omega)$. Comme dans le cas des problèmes $(\mathcal{P}_1)$ et $(\mathcal{P}_2)$, on montre à l'aide de (4) et (5) que l'ensemble

$$E = \{x \in \Omega / (x, Au(x)) \in K\}$$

est de mesure nulle, i.e., que l'on a

$$g_3^{**}(x, Au(x)) = g_3(x, Au(x)) \quad \text{p.p. } x \in \Omega,$$

montrant ainsi que u est solution de $(\mathcal{P}_3)$. □

Remerciement. Je remercie le référé pour ses remarques qui m'ont permis d'améliorer la présentation de ce travail.

SEMIDISCRETIZATION METHOD FOR THREE-DIMENSIONAL MOTION OF A BINGHAM FLUID*

JONG UHN KIM†

Abstract. By the method of semidiscretization in a time variable, the existence of a strong solution to an initial boundary value problem associated with the three-dimensional motion of a Bingham fluid is established. The main tool used is a discretized version of the variation of constants formula combined with the L^p-theory of the Stokes operator.

Key words. Bingham fluid, semidiscretization method, variation of constants formula, L^p-theory of the Stokes operator

AMS(MOS) subject classifications. 35B10, 35B65, 35K55, 76D99

0. Introduction. In this paper, we present a new result on the existence of solutions of an initial-boundary value problem associated with the motion of a Bingham fluid in a three-dimensional domain. A Bingham fluid is a rigid viscoplastic fluid that is a particular kind of non-Newtonian fluid. This material behaves in a rigid manner when a certain function of stresses does not reach the yield limit; it moves like a Newtonian fluid beyond this limit.

Common examples of Bingham fluids are slurries, drilling muds, oil paints, and toothpaste. Engineering applications (particularly in the chemical and process industries), such as experimental techniques, rolling and extrusion processes, and heat transfer, are discussed in [16], where a list of engineering references will also be found. For the continuum mechanics foundations, see [13].

Since the relation between strains and stresses becomes very different depending on the state of stresses, the motion of a Bingham fluid cannot be described by a single equation. This difficulty was overcome by Duvaut and Lions, who derived a variational inequality that can take care of the unknown interface between rigid medium and fluid zone [3], [4]. They formulated an initial-boundary value problem for a Bingham fluid as follows:

$$(0.1)\qquad (\partial u/\partial t,\, w-u)+a(u,\, w-u)+b(u,\, u,\, w)+J(w)-J(u)\geqq (f,\, w-u)\ \text{in}\ (0,\, T),$$

for each test function w such that $\nabla\cdot w=0$ in Ω and $w=0$ on $\partial\Omega$,

$$(0.2)\qquad \nabla\cdot u=0 \quad \text{in}\ \Omega\times(0,\, T),$$

$$(0.3)\qquad u=0 \quad \text{on}\ \partial\Omega\times[0,\, T],$$

$$(0.4)\qquad u(x,\, 0)=u_0(x) \quad \text{in}\ \Omega.$$

Here, Ω is a bounded domain in $\mathbb{R}^3$ with C^∞ boundary $\partial\Omega$, $u(x,\, t)$ denotes the velocity of the fluid, and $f(x,\, t)$ stands for external force. The density, the yield limit, and the viscosity are assumed to be positive constants. In particular, the density is taken to be

1. We employ the notation:

$$a(u, w) = \sum_{i,j=1}^{3} 2\mu \int_{\Omega} D_{ij}(u) D_{ij}(w)\, dx, \qquad \mu = \text{viscosity},$$

$$D_{ij}(u) = \frac{1}{2}\left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i}\right),$$

$$J(u) = 2g \int_{\Omega} D_{\Pi}(u)^{1/2}\, dx, \qquad g = \text{yield limit},$$

$$D_{\Pi} = \frac{1}{2} \sum_{i,j=1}^{3} D_{ij}(u)^2,$$

$$b(u, v, w) = \sum_{i,j=1}^{3} \int_{\Omega} u_j \frac{\partial v_i}{\partial x_j} w_i\, dx.$$

$(,)$ is a scalar product that will be defined in the next section.

The conservation of momentum is expressed by (0.1) and the condition of incompressibility is given by (0.2).

It is easy to see that (0.1) reduces to the Navier–Stokes equations if the yield limit g vanishes. The nondifferentiable functional $J(\cdot)$ causes a serious mathematical difficulty in addition to the difficulties inherited from the Navier–Stokes equations. This makes the initial boundary value problem very challenging. In the case of laminar flow in a cylindrical pipe, the problem simplifies to a special case, for which the mathematical analysis is complete. This special case also has been used as a typical model in the finite-element analysis of parabolic variational inequalities (see [8] and references therein). We focus on the existence of solutions to the more general problem in a three-dimensional domain.

We will survey known results that have motivated the present investigation.

Duvaut and Lions [3] have proved for the first time the existence of weak solutions of (0.1)–(0.4). The weak solutions according to the definition in [3] and [4] belong to the same function class as the Leray–Hopf weak solutions of the Navier–Stokes equations. For a three-dimensional domain, these weak solutions satisfy a weak version of (0.1) and the uniqueness of weak solutions is an open question.

It is known that for smooth data, there is a local strong solution to the initial-boundary value problem for the Navier–Stokes equations. For the Cauchy problem associated with (0.1) in R^2 or R^3, it is known that strong solutions (local in time in R^3) exist if the data are regular. The result is the same as that for the Navier–Stokes equations (see [9], [14]). For the initial-boundary value problem shown above, a different kind of strong solution was obtained in [3] and [4] in the case of a two-dimensional domain. An analogous result was established in [10] for a three-dimensional domain by assuming that the initial data are stationary states with external force in $L^2(\Omega)^3$. Under the same assumption on the data, Naumann and Wulst [12] obtained a similar result for a variant of a Bingham fluid through a different method. This assumption on the initial data is not satisfied in general even by C^∞ divergence-free vector fields with compact support. Hence, this is not an ordinary regularity assumption and is very restrictive.

The purpose of the present paper is to eliminate this assumption on the initial data. We show that if the initial data are divergence-free vector fields that belong to $L^r(\Omega)^3$, $r > 3$, and whose normal component vanishes on the boundary, there indeed exists at least a local solution regular enough to be unique (see Theorem 2.2). The result is comparable to that of Giga and Miyakawa [7] for the Navier–Stokes equations.

The basic approach for the problem (0.1)-(0.4), initiated by Duvaut and Lions, consists of three steps. The first step is to reduce inequality (0.1) to an equation by substituting a differentiable function with regularizing parameter for $J(\cdot)$. The second step is to obtain a solution for the regularized problem together with uniform estimates independent of the regularizing parameter. The third step is to prove that the limit of a sequence of approximate solutions exists and is a solution of the original problem.

In the second step, we are tempted to use one of two well-known techniques for the Navier-Stokes equations. One such technique is the Galerkin approximation method. For our problem, it seems that we cannot obtain enough estimates independent of the regularizing parameter through this method unless special assumptions are made on the initial data as in [10]. The other method, used in [7], is to set up the variation of the constants formula involving the analytic semigroup generated by the Stokes operator in $L^r(\Omega)^3$ and then to employ the related iteration scheme to find a solution. When we attempt to apply this method to our problem, serious technical difficulties arise. These difficulties can be avoided, however, if we use a discretized version of the variation of the constants formula. The method we will use is basically the semidiscretization method used in [15] to give an alternate proof of the existence of the Leray-Hopf weak solution to the Navier-Stokes equations. While our scheme of discretization is a slight modification of that used in [15], we obtain substantially better estimates by interpreting the scheme as a discretized version of the variation of the constants formula, and we retain all the basic L^2 estimates of [15]. The estimates obtained through this procedure are sufficient for the pointwise convergence of approximating solutions.

Finally we also prove the existence of global solutions and time-periodic solutions by assuming that the initial data and external force are sufficiently small; see Theorems 3.1 and 3.2.

1. Notation and preliminaries. Throughout this paper, Ω denotes a bounded domain in R^3 with C^∞ boundary. We employ the notation defined in the Introduction, as well as the following:

$$\partial_t = \frac{\partial}{\partial t}, \quad \partial_i = \frac{\partial}{\partial x_i} \quad \text{for } 1 = 1, 2, 3, \quad \Delta = \sum_{i=1}^{3} \partial_i^2, \quad \nabla = (\partial_1, \partial_2, \partial_3),$$

$$\nabla \cdot f = \sum_{i=1}^{3} \partial_i f_i \quad \text{for } f = (f_1, f_2, f_3).$$

When E is a Banach space, $L^r(0, T; E)$ is the set of all E-valued strongly measurable L^r functions on $[0, T]$ with the obvious norm. $C(I; E)$ is the set of all E-valued continuous functions on the interval I.

We introduce the following function spaces:

$S = \{\phi \in C_0^\infty(\Omega)^3 : \nabla \cdot \phi = 0 \text{ in } \Omega\}$,

$W^{m,r}(\Omega) = \{v \in L^r(\Omega) : \partial_1^{\alpha_1}\partial_2^{\alpha_2}\partial_3^{\alpha_3} v \in L^r(\Omega), 1 \leqq \alpha_1 + \alpha_2 + \alpha_3 \leqq m\}$,

$W_0^{m,r}(\Omega) =$ the completion of $C_0^\infty(\Omega)$ in $W^{m,r}(\Omega)$,

$W^{-m,r'}(\Omega) =$ the dual of $W_0^{m,r}(\Omega)$, where $1/r' + 1/r = 1$, $1 \leqq r < \infty$,

$X_r =$ the completion of S in $L^r(\Omega)^3$, $1 < r < \infty$,

$V = W_0^{1,2}(\Omega)^3 \cap X_2$,

$V' =$ the dual of V.

$(\ ,\ )$ stands for the duality pairing between V and V'. In particular, if $v \in X_2$ and $w \in V$, then (v, w) coincides with the scalar product of v and w in X_2. We can characterize X_r by

$$X_r = \{v \in L^r(\Omega)^3 : \nabla \cdot v = 0 \text{ in } \Omega \text{ and the normal component of } v \text{ vanishes on } \partial\Omega\}.$$

We let P_r denote the projection from $L^r(\Omega)^3$ onto X_r and write the Stokes operator as

$$A_r = -P_r\Delta \quad \text{for } 1<r<\infty,$$

with the domain

$$\mathcal{D}(A_r) = W^{2,r}(\Omega)^3 \cap W_0^{1,r}(\Omega)^3 \cap X_r.$$

We list some basic properties of A_r. Giga [5] proved that for any $\varepsilon>0$ and $1<r<\infty$, there is a positive constant $C_{\varepsilon,r}$ such that

$$\|(\lambda I + A_r)^{-1}\| \leqq C_{\varepsilon,r}/|\lambda| \tag{1.1}$$

for all $\lambda \in \mathbb{C}$ such that $\lambda \neq 0$ and $|\arg \lambda| \leqq \pi - \varepsilon$, where $\|\cdot\|$ is the norm of a bounded linear operator from X_r into X_r. We also note that zero belongs to the resolvent set of A_r.

Using (1.1), we can define A_r^θ, $0<\theta<1$ by the Dunford integral and the domain of A_r^θ is defined by complex interpolation:

$$\mathcal{D}(A_r^\theta) = [X_r, \mathcal{D}(A_r)]_\theta, \qquad 0 \leqq \theta \leqq 1$$

(see [6]). Since $\mathcal{D}(A_r)$ is compactly embedded into X_r, we have Lemma 1.1.

LEMMA 1.1. *For $0 \leqq \theta_1 < \theta_2 \leqq 1$, the embedding $\mathcal{D}(A_r^{\theta_2}) \subset \mathcal{D}(A_r^{\theta_1})$ is compact.*

Next we obtain some estimates to be used later.

LEMMA 1.2. *Let $1<r<\infty$ and $0 \leqq \alpha \leqq 1$. Then, for any integer $k \geqq 1$ and any $0<\varepsilon \leqq 1$,*

$$\|A_r^\alpha (I+\varepsilon A_r)^{-k}\| \leqq C_{r,\alpha} \exp(-\delta\varepsilon k)/(\varepsilon k)^\alpha, \tag{1.2}$$

where $C_{r,\alpha}$ and δ are positive constants independent of ε and k.

Proof. By virtue of (1.1) and the fact that the resolvent set of A_r contains zero, we can write, for any positive number λ and any integer $k \geqq 2$,

$$-A_r(\lambda I + A_r)^{-k} = \frac{1}{2\pi i}\int_\Gamma z(\lambda - z)^{-k}(zI + A_r)^{-1}\, dz, \tag{1.3}$$

where $\Gamma = \{-\xi + \rho e^{i\theta}: 0 \leqq \rho < \infty\} \cup \{-\xi + \rho e^{-i\theta}: 0 \leqq \rho < \infty\}$ and we choose $\xi > 0$, $\pi/2 < \theta < \pi$ and the orientation of Γ so that Γ is contained in the resolvent set of A_r and $\operatorname{Im}\Gamma$ is increasing along Γ.

It follows from (1.1) and (1.3) that

$$\begin{aligned} \|A_r(\lambda I + A_r)^{-k}\| &\leqq M\int_0^\infty (\lambda + \xi + \rho|\cos\theta|)^{-k}\, d\rho, \\ &\leqq M(\lambda+\xi)^{-k+1}/(k-1), \end{aligned} \tag{1.4}$$

where M denotes positive constants independent of λ and k. Hence, by setting $\varepsilon = 1/\lambda$ and assuming $0<\varepsilon \leqq 1$, we derive

$$\begin{aligned} \|A_r(I+\varepsilon A_r)^{-k}\| &\leqq M(1+\varepsilon\xi)^{-k+1}/\varepsilon(k-1) \\ &\leqq M \exp(-\delta_1\varepsilon k)/(\varepsilon k), \end{aligned} \tag{1.5}$$

where M and δ_1 denote positive constants independent of ε and k. The second inequality in (1.5) is also true for $k=1$, which is easily seen by virtue of (1.1). Since A_r is the infinitesimal generator of a bounded analytic semigroup and the resolvent set of A_r contains zero, it is known that for any integer $k \geqq 1$,

$$\|(\lambda I + A_r)^{-k}\| \leqq M(\lambda + \tilde{\xi})^{-k}, \tag{1.6}$$

where M and $\tilde{\xi}$ are positive constants independent of λ and k. Hence, by setting $\varepsilon = 1/\lambda$, we have

$$\|(I+\varepsilon A_r)^{-k}\| \leqq M(1+\varepsilon\tilde{\xi})^{-k}, \tag{1.7}$$

which, together with the assumption $0<\varepsilon\leqq 1$, yields

$$\|(I+\varepsilon A_r)^{-k}\| \leqq M\exp(-\delta_2\varepsilon k), \tag{1.8}$$

where M and δ_2 are positive constants independent of ε and k. For $0<\alpha<1$, we obtain (1.2) from (1.5) and (1.8) by means of the interpolation inequality.

LEMMA 1.3. *Let $1<r<\infty$ and $0<\alpha\leqq 1$. Then, for any integer $k\geqq 1$ and any $\varepsilon>0$, we have*

$$\|((I+\varepsilon A_r)^{-k}-I)A_r^{-\alpha}\| \leqq C_\alpha(\varepsilon k)^\alpha, \tag{1.9}$$

where C_α is a positive constant independent of ε and k.

Proof. We first note that

$$(I+\varepsilon A_r)^{-1}-I = -\varepsilon A_r(I+\varepsilon A_r)^{-1}, \tag{1.10}$$

which, combined with (1.7), yields

$$\|((I+\varepsilon A_r)^{-1}-I)A_r^{-1}\| \leqq \varepsilon M, \tag{1.11}$$

where M is a positive constant independent of ε. Following [2], we write for $k\geqq 2$

$$((I+\varepsilon A_r)^{-k}-I)A_r^{-1} = ((I+\varepsilon A_r)^{-1}-I)A_r^{-1} + \sum_{j=1}^{k-1}(I+\varepsilon A_r)^{-j}((I+\varepsilon A_r)^{-1}-I)A_r^{-1}. \tag{1.12}$$

Again by (1.7), we derive from (1.12)

$$\|((I+\varepsilon A_r)^{-k}-I)A_r^{-1}\| \leqq M\varepsilon k, \tag{1.13}$$

where M is a positive constant independent of ε and k. Inequality (1.9) is now a simple consequence of (1.7), (1.11), and (1.13) through the interpolation. □

LEMMA 1.4. *Let $v\in X_r$, $1<r<\infty$. Then, for any given $\xi>0$, there is $\delta(\xi, v)>0$ such that for all $\varepsilon>0$ and $k\geqq 1$ satisfying $\varepsilon k\leqq\delta(\xi, v)$,*

$$\|((I+\varepsilon A_r)^{-k}-I)v\|_{X_r} \leqq \xi. \tag{1.14}$$

Proof. Suppose that the assertion above is false. Then there are $\xi>0$, $\{\varepsilon_n\}_{n=1}^\infty$ and $\{k_n\}_{n=1}^\infty$ such that $\varepsilon_n>0$, $k_n\geqq 1$, $\varepsilon_n k_n\to 0$ as $n\to\infty$, and

$$\|((I+\varepsilon_n A_r)^{-k_n}-I)v\|_{X_r} > \xi \quad \text{for all } n. \tag{1.15}$$

It follows from (1.13) that for all $w\in\mathcal{D}(A_r)$,

$$\|((I+\varepsilon_n A_r)^{-k_n}-I)w\|_{X_r} \leqq M\varepsilon_n k_n\|A_r w\|_{X_r} \tag{1.16}$$

where M is a positive constant independent of ε_n, k_n, and w.

In the meantime, (1.7) implies that

$$\|(I+\varepsilon_n A_r)^{-k_n}-I\| \leqq \tilde{M} \quad \text{for all } \varepsilon_n \text{ and } k_n. \tag{1.17}$$

We now choose $w\in\mathcal{D}(A_r)$ such that

$$\|v-w\|_{X_r} \leqq \xi/2\tilde{M}. \tag{1.18}$$

Then we find that

$$\begin{aligned}\|((I+\varepsilon_n A_r)^{-k_n}-I)v\|_{X_r} &\leqq \|((I+\varepsilon_n A_r)^{-k_n}-I)(w-v)\|_{X_r} + M\varepsilon_n k_n\|A_r w\|_{X_r}\\ &\leqq \tfrac{1}{2}\xi + M\varepsilon_n k_n\|A_r w\|_{X_r},\end{aligned} \tag{1.19}$$

which contradicts (1.15) as $\varepsilon_n k_n\to 0$. This concludes the proof. □

We list some properties of the operator $A_r^{\beta} P_r \partial_j$, $j=1,2,3$, that are proved in [7]. Let $1<r<\infty$. Then there is a positive constant C_r such that

$$\|A_r^{-1/2} P_r \partial_j v\|_{X_r} \leqq C_r \|v\|_{L^r(\Omega)^3}, \qquad j=1,2,3, \tag{1.20}$$

for all $v \in W^{1,r}(\Omega)^3$. Hence, $A_r^{-1/2} P_r \partial_j$ can be extended to a bounded linear operator from $L^r(\Omega)^3$ into X_r, $1<r<\infty$. If $3<r<\infty$, $6r/(3+r)<p \leqq r$ and $\delta = \frac{1}{2}+\frac{3}{2}(2/p-1/r)$, then there is a constant $C_{r,p}$ such that

$$\|A_r^{-\delta} P_r \partial_j v\|_{X_r} \leqq C_{r,p} \|v\|_{L^{p/2}(\Omega)^3} \quad \text{for all } v \in W^{1,r}(\Omega)^3. \tag{1.21}$$

Hence, $A_r^{-\delta} P_r \partial_j$ can be extended to a bounded linear operator from $L^{p/2}(\Omega)^3$ into $X_r(\Omega)$, for $3<r<\infty$, $6r/(3+r)<p \leqq r$. If $3<r<\infty$, $0<\nu<3/2r$ and $\delta = 3/2r+\frac{1}{2}-2\nu$, then there is a constant C_r such that for all v, $w \in \mathscr{D}(A_r)$,

$$\|A_r^{-\delta} P_r \sum_{j=1}^{3} \partial_j (v_j w)\|_{X_r} \leqq C_r \|A_r^{\nu} v\|_{X_r} \|A_r^{\nu} w\|_{X_r}, \tag{1.22}$$

where $v=(v_1, v_2, v_3)$.

Hence, the mapping $(v, w) \to A_r^{-\delta} P_r \sum_{j=1}^{3} \partial_j (v_j w)$ can be extended to a bounded bilinear mapping from $\mathscr{D}(A_r^{\nu})^2$ into X_r.

Next we consider the boundary value problem:

$$u - \varepsilon \Delta u + \nabla p = h \quad \text{in } \Omega, \qquad \varepsilon > 0, \tag{1.23}$$

$$\nabla \cdot u = 0 \quad \text{in } \Omega, \tag{1.24}$$

$$u = 0 \quad \text{on } \partial\Omega. \tag{1.25}$$

It is understood that (1.23) and (1.24) hold in the sense of distribution in Ω. If $h = \partial_j v$ and $v \in L^r(\Omega)^3$, $1<r<\infty$, then the unique solution of the problem above in $W_0^{1,r}(\Omega)^3$ can be expressed as

$$u = A_r^{1/2} (I + \varepsilon A_r)^{-1} A_r^{-1/2} P_r \partial_j v. \tag{1.26}$$

Suppose that $3<r<\infty$, $6r/(3+r)<p \leqq r$, $\delta = \frac{1}{2}+\frac{3}{2}(2/p-1/r)$ and that $h = \sum_{j=1}^{3} \partial_j (v_j w)$, where $v=(v_1, v_2, v_3)$ and $v, w \in X_p$. Then, the unique solution in $W_0^{1,p/2}(\Omega)^3$ can be expressed as

$$u = A_r^{\delta} (I + \varepsilon A_r)^{-1} A_r^{-\delta} P_r \sum_{j=1}^{3} \partial_j (v_j w). \tag{1.27}$$

If $3<r<\infty$, $0 \leqq \nu < 3/2r$, $\delta = 3/2r+\frac{1}{2}-2\nu$, and $h = \sum_{j=1}^{3} \partial_j (v_j w)$ with $v, w \in \mathscr{D}(A_r^{\nu})$, then the unique solution in $W_0^{1,r/2}(\Omega)^3$ can be expressed as

$$u = A_r^{\delta} (I + \varepsilon A_r)^{-1} A_r^{-\delta} P_r \sum_{j=1}^{3} \partial_j (v_j w). \tag{1.28}$$

These expressions will be used in the subsequent section. We prove (1.26). Let $h = \partial_j v$ and $v \in L^r(\Omega)^3$, $1<r<\infty$. We choose a sequence $\{v_n\}_{n=1}^{\infty}$ in $W_0^{1,r}(\Omega)^3$ such that v_n converges to v strongly in $L^r(\Omega)^3$. For each n, we write

$$u_n = (I + \varepsilon A_r)^{-1} P_r \partial_j v_n. \tag{1.29}$$

Then $u_n \in \mathscr{D}(A_r)$ and u_n satisfies

$$u_n - \varepsilon \Delta u_n + \nabla p_n = \partial_j v_n \quad \text{in } \Omega \tag{1.30}$$

for some function $p_n \in W^{1,r}(\Omega)$.

We now rewrite (1.29) as

$$u_n = A_r^{1/2} (I + \varepsilon A_r)^{-1} A_r^{-1/2} P_r \partial_j v_n. \tag{1.31}$$

Since $A_r^{-1/2}P_r\partial_j$ is a bounded linear operator from $L^r(\Omega)^3$ into X_r and $A_r^{1/2}(I+\varepsilon A_r)^{-1}$ is a bounded linear operator from X_r into $\mathcal{D}(A_r^{1/2})$, $\{u_n\}_{n=1}^{\infty}$ converges strongly in $\mathcal{D}(A_r^{1/2})$ to

$$u = A_r^{1/2}(I+\varepsilon A_r)^{-1}A_r^{-1/2}P_r\partial_j v. \tag{1.32}$$

From (1.30), we find that u above satisfies

$$u - \varepsilon\Delta u + \nabla p = \partial_j v \tag{1.33}$$

in the sense of distribution in Ω for some scalar function p. Hence, u is a solution of (1.23)-(1.25). The uniqueness of u in $W_0^{1,r}(\Omega)^3$ follows by the duality argument and the existence of the solution in $W_0^{1,r'}(\Omega)^3$, $1/r'+1/r=1$, when $h \in W^{-1,r'}(\Omega)^3$. Now the proof of (1.26) is complete. □

We proceed to prove (1.27). Choose $\{v_n\}_{n=1}^{\infty}$ and $\{w_n\}_{n=1}^{\infty}$ in S such that v_n and w_n converge to v and w, respectively, strongly in X_p. It is apparent that $v_{nj}w_n \in W_0^{1,r}(\Omega)^3$, for $j=1,2,3$, where $v_n=(v_{n1}, v_{n2}, v_{n3})$, and thus, $P_r\partial_j(v_{nj}w_n) = P_{p/2}\partial_j(v_{nj}w_n)$, for $j=1,2,3$.

As above, we write for each n

$$u_n = \sum_{j=1}^{3} A_{p/2}^{1/2}(I+\varepsilon A_{p/2})^{-1}A_{p/2}^{-1/2}P_{p/2}\partial_j(v_{nj}w_n), \tag{1.34}$$

and note that u_n converges to u strongly in $\mathcal{D}(A_{p/2}^{1/2})$, where u is the unique solution in $W_0^{1,p/2}(\Omega)^3$ of (1.23)-(1.25) with $h=\sum_{j=1}^{3}\partial_j(v_j w)$. Rewriting (1.34) as

$$\begin{aligned} u_n &= \sum_{j=1}^{3} (I+\varepsilon A_{p/2})^{-1}P_{p/2}\partial_j(v_{nj}w_n) \\ &= \sum_{j=1}^{3} (I+\varepsilon A_r)^{-1}P_r\partial_j(v_{nj}w_n) \\ &= \sum_{j=1}^{3} A_r^{\delta}(I+\varepsilon A_r)^{-1}A_r^{-\delta}P_r\partial_j(v_{nj}w_n), \end{aligned} \tag{1.35}$$

we derive (1.27) from (1.21) and the fact that u_n converges to u strongly in $\mathcal{D}(A_{p/2}^{1/2})$. The proof of (1.28) is very similar and we omit it.

We use a regularized version of $J(\cdot)$,

$$J_\eta(v) = 2g\int_\Omega (\eta + D_{\mathrm{II}}(v))^{1/2}\,dx, \tag{1.36}$$

where η is a positive number and g is the yield limit. The Gâteaux differential $J_\eta(\cdot)$ is given by

$$(J_\eta'(v), w) = g\int_\Omega \sum_{i,j=1}^{3} (\eta + D_{\mathrm{II}}(v))^{-1/2}D_{ij}(v)D_{ij}(w)\,dx \tag{1.37}$$

for each v, $w \in V$. Since $J_\eta(\cdot)$ is convex, $J_\eta'(\cdot)$ is monotone and

$$J_\eta(v) - J_\eta(w) \geqq (J_\eta'(w), v-w) \tag{1.38}$$

for all v, $w \in V$. We also use the inequality

$$\|(\eta + D_{\mathrm{II}}(v))^{-1/2}D_{ij}(v)\|_{L^\infty(\Omega)} \leqq \sqrt{2} \quad \text{for } i,j=1,2,3 \tag{1.39}$$

for every $\eta > 0$ and $v \in W^{1,1}(\Omega)^3$.

2. Local existence and uniqueness of solutions.

DEFINITION 2.1. A function $u(x, t)$ is called a solution (0.1)-(0.4) on an interval $[0, T)$ if

(i) $u \in L^2(0, T; V)$ and $\partial_t u \in L^2(0, T; V')$;

(ii) (0.1) is satisfied for every $w \in V$, for almost all $t \in (0, T)$;

(iii) $u(x, 0) = u_0(x)$.

Condition (iii) makes sense since (i) implies $u \in C([0, T]; X_2)$, possibly after a modification on a set of measure zero.

This definition of solution is stronger than that of weak solution in [3] and [4]. Our main result is Theorem 2.2.

THEOREM 2.2. *Suppose that* $3 < r < \infty$, $u_0(x) \in X_r$, *and* $f \in L^\infty(0, T; W^{-1,r}(\Omega)^3)$. *Then there is a unique solution* $u(x, t)$ *on an interval* $[0, T^*)$, *where* $0 < T^* \leqq T$. *Furthermore,* $u \in C([0, T^*); X_r)$ *and, for each* $0 < \delta \leqq \frac{1}{2}$, u *is* $\mathscr{D}(A_r^{1/2-\delta})$*-valued locally Hölder continuous on* $(0, T^*)$.

In fact, the assertion above is a consequence of Theorem 2.3.

THEOREM 2.3. *Let* $u_0(x) \in \mathscr{D}(A_r^\nu)$, $f \in L^\infty(0, T; W^{-1,r}(\Omega)^3)$, $0 \leqq \nu \leqq 3/4r$, *and* $3 < r < \infty$. *Then, there is a unique solution* $u(x, t)$ *on an interval* $[0, T_1)$, *where* $0 < T_1 \leqq T$, *and* T_1 *depends only on* ν, r, $\|u_0\|_{\mathscr{D}(A_r^\nu)}$ *and* $\|f\|_{L^\infty(0,T;W^{-1,r}(\Omega)^3)}$. *In particular,* T_1 *is nonincreasing in* $\|u_0\|_{\mathscr{D}(D_r^\nu)}$. *Furthermore,*

$$u \in C([0, T_1]; \mathscr{D}(A_r^\nu)), \tag{2.1}$$

and, for each $0 < \rho < T_1$ *and each* $0 \leqq \alpha < \alpha + \beta < \frac{1}{2} - 3/2r + \nu$,

$$u \in C((0, T_1]; \mathscr{D}(A_r^{\nu+\alpha})), \tag{2.2}$$

$$\|u(s_2) - u(s_1)\|_{\mathscr{D}(A_r^{\nu+\alpha})} \leqq M(s_2 - s_1)^\beta \quad \text{for all } 0 < \rho \leqq s_1 < s_2 < T_1, \tag{2.3}$$

where M *is a positive constant depending on* $r, \rho, \alpha, \beta, \nu$, $\|u_0\|_{\mathscr{D}(A_r^\nu)}$, *and* $\|f\|_{L^\infty(0,T;W^{-1,r}(\Omega)^3)}$.

We will show that Theorem 2.3 implies Theorem 2.2. Let us fix $3 < r < \infty$, $u_0(x) \in X_r$, and $f \in L^\infty(0, T; W^{-1,r}(\Omega)^3)$. Then, by Theorem 2.3 with $\nu = 0$, there is a unique solution u on an interval $[0, T_1)$, and u satisfies (2.1)-(2.3) with $\nu = 0$. Next we show that u is $\mathscr{D}(A_r^{1/2-\delta})$-valued, locally Hölder continuous on $(0, T_1]$ for each $0 < \delta \leqq \frac{1}{2}$. We use the uniqueness of solution and the fact that the solution becomes more regular than the initial datum.

Without loss of generality, let us assume $0 < T_1 < T$. Choose any $0 < \xi < T_1/2$. Then, $u \in C([\xi, T_1]: \mathscr{D}(A_r^\lambda))$ with $\lambda = \min(3/4r, \frac{1}{2}(\frac{1}{2} - 3/2r))$ and

$$\|u\|_{\mathscr{D}(A_r^\lambda)} \leqq M \quad \text{for all } t \in [\xi, T_1] \tag{2.4}$$

for some positive constant M.

For any $s \in [\xi, T_1]$, we can apply Theorem 2.3 with s as initial time, $u(s)$ as an initial datum, and $\nu = \lambda$. We then obtain a solution

$$v_s \in C([s, s+h]; \mathscr{D}(A_r^\lambda)) \cap C([s+\tau, s+h]; \mathscr{D}(A_r^{2\lambda})), \tag{2.5}$$

where $h > 0$ can be chosen independently of s by (2.4) and $\tau = \min(h/2, \xi/2)$. By the uniqueness of solutions, $v_s = u$ on $[s, s+h]$. Hence we can derive that

$$u \in C\left(\left[\xi + \frac{\xi}{2}, T_1\right]; \mathscr{D}(A_r^{2\lambda})\right). \tag{2.6}$$

If $\frac{9}{2} \leqq r$, (2.6) implies

$$u \in C((0, T_1]; \mathscr{D}(A_r^{3/4r})). \tag{2.7}$$

If $3<r<\frac{9}{2}$, we can repeat the same argument until we arrive at (2.7). Next choose any $0<\delta<\frac{1}{2}$ and $0<\rho<T_1/2$. Using $t=\rho/2$ as initial time and $u(\rho/2)$ as an initial datum, we can apply Theorem 2.3 with $\nu=3/4r$ and $\alpha=\max(0, \frac{1}{2}-3/4r-\delta)$ to conclude that u is $\mathscr{D}(A_r^{1/2-\delta})$-valued locally Hölder continuous on $(0, T_1]$. Finally we choose

$$T^*=\sup\{\tilde{T}: T_1\leqq\tilde{T}\leqq T \text{ and there is a solution that is } X_r\text{-valued continuous on } [0, \tilde{T}]\}.$$

By repeating the above argument, we find that u is $\mathscr{D}(A_r^{1/2-\delta})$-valued locally Hölder continuous on $(0, T^*)$. This ends the proof of Theorem 2.2. □

We outline the strategy of proof of Theorem 2.3.

Step 1. We replace $J(\cdot)$ by $J_\eta(\cdot)$. Using the differential $J_\eta'(\cdot)$ and discretizing time variable, we construct a sequence of approximate solutions that are piecewise linear in time. The standard L^2-estimates are obtained as in the case of the Navier-Stokes equations (see [15]). With the aid of the properties of the Stokes operator in L^r, we also obtain L^r estimates independent of η and the meshsize in time variable.

Step 2. It is shown that this sequence of approximate solutions converges to a solution of (0.1)-(0.4) with $J(\cdot)$ replaced by $J_\eta(\cdot)$ as the meshsize tends to zero.

Step 3. We pass η to zero to obtain a solution according to Definition 2.1 and prove the uniqueness of solution.

Throughout this section, we fix $3<r<\infty$ and use the notation

$$A=\mu A_r \quad \text{and} \quad P=P_r.$$

We also suppose that $0\leqq\nu\leqq 3/4r$, $u_0(x)\in\mathscr{D}(A^\nu)$, and $f\in L^\infty(0, T; W^{-1,r}(\Omega)^3)$ are given.

2.1. Construction and estimates of approximate solutions. We choose any positive integer N and set

$$\varepsilon=\frac{T}{N}. \tag{2.8}$$

Define an approximate solution W_N by

$$W_N=\frac{t-k\varepsilon}{\varepsilon}(u_{k+1}-u_k)+u_k \quad \text{for } k\varepsilon\leqq t\leqq(k+1)\varepsilon, \quad k=0, 1, \cdots, N-1, \tag{2.9}$$

where u_0 is the given initial datum and u_{k+1} is determined from the equation

$$(u_{k+1}, \phi)+\varepsilon a(u_{k+1}, \phi)+\varepsilon b(u_k, u_{k+1}, \phi)+\varepsilon(J_\eta'(u_{k+1}), \phi)=(u_k, \phi)+\varepsilon(f_{k+1}, \phi) \tag{2.10}$$

for all $\phi\in S$, $k=0, 1, \cdots, N-1$, where $f_{k+1}=1/\varepsilon\int_{k\varepsilon}^{(k+1)\varepsilon} f\,dt$, for $k=0, 1, \cdots, N-1$, and $(,)$ denotes the duality pairing between V and V'.

LEMMA 2.4. *If $u_k\in X_r$ and $f_{k+1}\in W^{-1,r}(\Omega)^3$, then there is a unique solution u_{k+1} of* (2.10) *in $V\cap W_0^{1,r}(\Omega)^3$.*

Proof. Fix any $u_k\in X_r$ and define a mapping Λ from V into its dual V' such that for every $v, w\in V$,

$$(\Lambda v, w)=(v, w)+\varepsilon a(v, w)+\varepsilon b(u_k, v, w)+\varepsilon(J_\eta'(v), w). \tag{2.11}$$

Since $J_\eta'(\cdot)$ is monotone, it is easily seen that Λ is monotone. Furthermore, Λ is bounded, hemicontinuous and

$$\frac{(\Lambda v, v)}{\|v\|_V}\to\infty \quad \text{as } \|v\|_V\to\infty. \tag{2.12}$$

By virtue of Theorem 2.1 of [11, p. 171], Λ is surjective. Since f_{k+1} can be regarded as

an element of V', there is a function $u_{k+1} \in V$ such that

$$(\Lambda u_{k+1}, w) = (u_k + \varepsilon f_{k+1}, w) \quad \text{for all } w \in V, \tag{2.13}$$

which implies (2.10). Uniqueness follows from the strict monotonicity of Λ. Equation (2.13) implies that

$$\begin{aligned} u_{k+1} - \varepsilon\mu \Delta u_{k+1} + \varepsilon \sum_{j=1}^{3} u_{kj}\partial_j u_{k+1} - \varepsilon g \sum_{j=1}^{3} \partial_j \{(\eta + D_{\Pi}(u_{k+1}))^{-1/2} D_{ij}(u_{k+1})\} \\ + \nabla p = u_k + \varepsilon f_{k+1} \end{aligned} \tag{2.14}$$

holds in the sense of distribution in Ω for some scalar function p, where $u_k = (u_{k1}, u_{k2}, u_{k3})$ and the fourth term is a vector function represented by its ith component.

It remains to prove $u_{k+1} \in W_0^{1,r}(\Omega)^3$. Since $u_{k+1} \in V \subset W_0^{1,2}(\Omega)^3$, it follows that $u_{k+1} \in L^6(\Omega)^3$, and thus $\sum_{j=1}^{3} u_{kj}\partial_j u_{k+1} \in W^{-1,6r/(6+r)}(\Omega)^3$. This, combined with (1.39), yields $u_{k+1} \in W_0^{1,6r/(6+r)}(\Omega)^3$ (see [1]). If $r > 6$, then $W_0^{1,6r/(6+r)}(\Omega) \subset L^{\infty}(\Omega)$, which implies $\sum_{j=1}^{3} u_{kj}\partial_j u_{k+1} \in W^{-1,r}(\Omega)^3$, and hence $u_{k+1} \in W_0^{1,r}(\Omega)^3$. If $r = 6$, then $\sum_{j=1}^{3} u_{kj}\partial_j u_{k+1} \in W^{-1,3}(\Omega)^3$. Consequently, $u_{k+1} \in W_0^{1,3}(\Omega)^3$, which yields $\sum_{j=1}^{3} u_{kj}\partial_j u_{k+1} \in W^{-1,q}(\Omega)^3$, for any $1 \leqq q < 6$. It now follows that $u_{k+1} \in W_0^{1,q}(\Omega)^3$, for any $1 \leqq q < 6$. Thus, $u_{k+1} \in L^{\infty}(\Omega)^3$, which gives $u_{k+1} \in W_0^{1,6}(\Omega)^3$ by the same argument. If $3 < r < 6$, then $W_0^{1,6r/(6+r)}(\Omega) \subset L^{6r/(6-r)}(\Omega)$, and hence $\sum_{j=1}^{3} u_{kj}\partial_j u_{k+1} \in W^{-1,6r/(12-r)}(\Omega)^3$, which yields $u_{k+1} \in W_0^{1,6r/(12-r)}(\Omega)^3$. By induction, we find that $u_{k+1} \in W_0^{1,6r/(6m-(2m-3)r)}(\Omega)^3$, for each positive integer $2 \leqq m \leqq (3r-6)/(2r-6)$. By repeating the same argument, we arrive at $u_{k+1} \in W_0^{1,r}(\Omega)^3$.

Next we substitute u_{k+1} for w in (2.13) and derive

$$\varepsilon \sum_{k=0}^{N-1} \|u_{k+1}\|_V^2 \leqq M, \tag{2.15}$$

$$\|W_N\|_{C([0,T];L^2(\Omega)^3)} \leqq M, \tag{2.16}$$

$$\sum_{k=0}^{N-1} \|u_{k+1} - u_k\|_{L^2(\Omega)^3}^2 \leqq M, \tag{2.17}$$

where M denotes positive constants that are independent of η and N, and that depend only on $\|u_0\|_{L^2(\Omega)^3}$ and $\|f\|_{L^2(0,T;V')}$.

We now proceed to obtain the L^r estimates. Recalling that $0 \leqq \nu \leqq 3/4r$, we find that $u_{k+1} \in \mathcal{D}(A^{\nu})$, for $k = 0, 1, \cdots, N-1$, since $u_{k+1} \in V \cap W_0^{1,r}(\Omega)^3$. By making use of (1.26), (1.28), and (1.39), we can write (2.14) as

$$\begin{aligned} u_{k+1} &= (I + \varepsilon A)^{-1} u_k - \varepsilon A^{1/2+3/2r-2\nu}(I + \varepsilon A)^{-1} A^{-1/2-3/2r+2\nu} P \sum_{j=1}^{3} \partial_j (u_{kj} u_{k+1}) \\ &\quad + \varepsilon A^{1/2}(I + \varepsilon A)^{-1} A^{-1/2} P g \sum_{j=1}^{3} \partial_j \{(\eta + D_{\Pi}(u_{k+1}))^{-1/2} D_{ij}(u_{k+1})\} \\ &\quad + \varepsilon A^{1/2}(I + \varepsilon A)^{-1} A^{-1/2} P f_{k+1}, \end{aligned} \tag{2.18}$$

from which it follows that

$$\begin{aligned} u_k &= (I + \varepsilon A)^{-k} u_0 - \varepsilon \sum_{m=1}^{k} A^{1/2+3/2r-2\nu}(I + \varepsilon A)^{-(k-m+1)} A^{-1/2-3/2r+2\nu} P \sum_{j=1}^{3} \partial_j (u_{(m-1)j} u_m) \\ &\quad + \varepsilon \sum_{m=1}^{k} A^{1/2}(I + \varepsilon A)^{-(k-m+1)} A^{-1/2} P g \sum_{j=1}^{3} \partial_j \{(\eta + D_{\Pi}(u_m))^{-1/2} D_{ij}(u_m)\} \\ &\quad + \varepsilon \sum_{m=1}^{k} A^{1/2}(I + \varepsilon A)^{-(k-m+1)} A^{-1/2} P f_m \quad \text{for } k = 1, \cdots, N. \end{aligned} \tag{2.19}$$

Now we set

$$E_k = \|A^\nu u_k\|_{X_r} \quad \text{for } k = 0, 1, \cdots, N. \tag{2.20}$$

By virtue of (1.2), (1.7), (1.20), (1.22), and (1.39), we derive from (2.19)

$$\begin{aligned} E_k \leqq M_1 + \varepsilon M_2 \sum_{m=1}^{k} (\varepsilon(k-m+1))^{-(1/2+3/2r-\nu)} E_{m-1} E_m \\ + \varepsilon M_3 \sum_{m=1}^{k} (\varepsilon(k-m+1))^{-(1/2+\nu)} \quad \text{for } k = 1, \cdots, N, \end{aligned} \tag{2.21}$$

where M_i's are positive constants independent of η, k, and N. To estimate E_k from (2.21), we observe that

$$\varepsilon \sum_{m=1}^{k} (\varepsilon(k-m+1))^{-(1/2+3/2r-\nu)} \leqq (\varepsilon k)^{1/2-3/2r+\nu} \Big/ \left(\frac{1}{2} - \frac{3}{2r} + \nu\right), \tag{2.22}$$

$$\varepsilon \sum_{m=1}^{k} (\varepsilon(k-m+1))^{-(1/2+\nu)} \leqq (\varepsilon k)^{1/2-\nu} \Big/ \left(\frac{1}{2} - \nu\right). \tag{2.23}$$

We may assume that

$$M_1 \geqq \max(1, E_0) \tag{2.24}$$

and

$$0 < \varepsilon < 1 \quad \text{and} \quad 6M_1 M_2 \varepsilon^{1/2-3/2r+\nu} < \tfrac{1}{2}, \tag{2.25}$$

since we are interested only in large N.

We choose T_1 such that

$$0 < T_1 \leqq T, \tag{2.26}$$

$$M_3 T_1^{1/2-\nu} / (\tfrac{1}{2} - \nu) \leqq \tfrac{1}{2} M_1, \tag{2.27}$$

$$36 M_1 M_2 T_1^{1/2-3/2r+\nu} \Big/ \left(\frac{1}{2} - \frac{3}{2r} + \nu\right) \leqq 1. \tag{2.28}$$

Consequently, we find that if $\varepsilon = T/N < T_1$,

$$E_k \leqq 6M_1 \quad \text{for all } k \text{ such that } \varepsilon(k-1) \leqq T_1, \tag{2.29}$$

from which it follows that

$$\|A^\nu W_N\|_{C([0,T_1];X_r)} \leqq 6M_1, \tag{2.30}$$

for all large N such that $\varepsilon = T/N$ satisfies (2.25) and $\varepsilon < T_1$.

Next we obtain more regular estimates on W_N. Let us fix any ρ such that $0 < 2\rho < T_1$ and choose any s_1 and s_2 such that $\rho \leqq s_1 < s_2 \leqq T_1$. We then take N so large that (2.25) holds and

$$\varepsilon = \frac{T}{N} \leqq \frac{\rho}{2}. \tag{2.31}$$

Then there are positive integers k and n such that

$$k\varepsilon \leqq s_1 < (k+1)\varepsilon, \tag{2.32}$$

$$n\varepsilon \leqq s_2 < (n+1)\varepsilon. \tag{2.33}$$

We now choose any α and β such that

$$0<\alpha<\alpha+\beta<\frac{1}{2}-\frac{3}{2r}+\nu. \tag{2.34}$$

Then $u_m\in\mathscr{D}(A^{\nu+\alpha})$, for $m=1,\cdots,N$, since $u_m\in V\cap W_0^{1,r}(\Omega)^3$, for $m=1,\cdots,N$. To estimate $\|A^{\nu+\alpha}(W_N(s_2)-W_N(s_1))\|_{X_r}$, we treat three different cases separately.

In estimates (2.35)–(2.46), M denotes positive constants independent of η, ε, k, n, s_1, and s_2.

Case 1. $n-k\geqq 2$. According to (2.19), we write

$$\begin{aligned}
A^{\nu+\alpha}(u_n-u_k)=&A^{\alpha}((I+\varepsilon A)^{-n}-(I+\varepsilon A)^{-k})A^{\nu}u_0\\
&-\varepsilon\sum_{m=1}^{k}A^{\alpha+\beta+1/2+3/2r-\nu}((I+\varepsilon A)^{-(n-m+1)}\\
&-(I+\varepsilon A)^{-(k-m+1)})A^{-\beta}A^{-1/2-3/2r+2\nu}P\sum_{j=1}^{3}\partial_j(u_{(m-1)j}u_m)\\
&-\varepsilon\sum_{m=k+1}^{n}A^{\alpha+1/2+3/2r-\nu}\\
&\cdot(I+\varepsilon A)^{-(n-m+1)}A^{-1/2-3/2r+2\nu}P\sum_{j=1}^{3}\partial_j(u_{(m-1)j}u_m)\\
&+\varepsilon\sum_{m=1}^{k}A^{\alpha+\nu+1/2+\beta}((I+\varepsilon A)^{-(n-m+1)}\\
&-(I+\varepsilon A)^{-(k-m+1)})A^{-1/2-\beta}P\\
&\cdot\left(f_m+g\sum_{j=1}^{3}\partial_j\{(\eta+D_\Pi(u_m))^{-1/2}D_{ij}(u_m)\}\right)\\
&+\varepsilon\sum_{m=k+1}^{n}A^{\alpha+\nu+1/2}(I+\varepsilon A)^{-(n-m+1)}A^{-1/2}P\\
&\cdot\left(f_m+g\sum_{j=1}^{3}\partial_j\{(\eta+D_\Pi(u_m))^{-1/2}D_{ij}(u_m)\}\right)
\end{aligned} \tag{2.35}$$

and estimate each term on the right-hand side.

$$\begin{aligned}
&\|A^{\alpha}((I+\varepsilon A)^{-n}-(I-\varepsilon A)^{-k})A^{\nu}u_0\|_{X_r}\\
&\quad\leqq\|A(I+\varepsilon A)^{-k}((I+\varepsilon A)^{-(n-k)}-I)A^{-(1-\alpha)}A^{\nu}u_0\|_{X_r}\\
&\quad\leqq\frac{M}{\varepsilon k}(\varepsilon(n-k))^{1-\alpha}\|A^{\nu}u_0\|_{X_r}\leqq\frac{M}{\rho}(s_2-s_1)^{1-\alpha}\quad\text{using (1.2) and (1.9),}
\end{aligned} \tag{2.36}$$

$$\begin{aligned}
&\varepsilon\sum_{m=1}^{k}\|A^{\alpha+\beta+1/2+3/2r-\nu}(I+\varepsilon A)^{-(k-m+1)}((I+\varepsilon A)^{-(n-k)}-I)A^{-\beta}\\
&\qquad\cdot A^{-1/2-3/2r+2\nu}P\sum_{j=1}^{3}\partial_j(u_{(m-1)j}u_m)\|_{X_r}\\
&\quad\leqq M(\varepsilon(n-k))^{\beta}\sum_{m=1}^{k}\varepsilon(\varepsilon(k-m+1))^{-(\alpha+\beta+1/2+3/2r-\nu)}E_{m-1}E_m,\\
&\qquad\qquad\text{using (1.2), (1.9), (1.22), and (2.20),}\\
&\quad\leqq M(\varepsilon(n-k))^{\beta}(\varepsilon k)^{1-(\alpha+\beta+1/2+3/2r-\nu)}/\{1-(\alpha+\beta+\tfrac{1}{2}+3/2r-\nu)\}\\
&\quad\leqq M(s_2-s_1)^{\beta}T_1^{1-(\alpha+\beta+1/2+3/2r-\nu)}\quad\text{using (2.29),}
\end{aligned} \tag{2.37}$$

$$\varepsilon \sum_{m=k+1}^{n} \|A^{\alpha+1/2+3/2r-\nu}(I+\varepsilon A)^{-(n-m+1)}A^{-1/2-3/2r+2\nu}P \sum_{j=1}^{3} \partial_j(u_{(m-1)j}u_m)\|_{X_r}$$

$$\leqq M \sum_{m=k+1}^{n} \varepsilon(\varepsilon(n-m+1))^{-(\alpha+1/2+3/2r-\nu)}E_{m-1}E_m \tag{2.38}$$

$$\leqq M(s_2-s_1)^{1/2-\alpha-3/2r+\nu},$$

$$\varepsilon \sum_{m=1}^{k} \|A^{\alpha+\nu+1/2+\beta}((I+\varepsilon A)^{-(n-m+1)}-(I+\varepsilon A)^{-(k-m+1)})A^{-\beta}A^{-1/2}P$$

$$\cdot\left(f_m+g\sum_{j=1}^{3}\partial_j\{(\eta+D_\Pi(u_m))^{-1/2}D_{ij}(u_m)\}\right)\|_{X_r} \tag{2.39}$$

$$\leqq M(\varepsilon(n-k))^{\beta}\sum_{m=1}^{k}\varepsilon(\varepsilon(k-m+1))^{-(\alpha+\nu+1/2+\beta)}$$

$$\leqq M(s_2-s_1)^{\beta}T_1^{1/2-(\alpha+\nu+\beta)} \quad \text{using (1.2), (1.9), and (1.39),}$$

$$\varepsilon \sum_{m=k+1}^{n} \left\| A^{\alpha+\nu+1/2}(I+\varepsilon A)^{-(n-m+1)}A^{-1/2}P \right.$$

$$\left. \cdot\left(f_m+g\sum_{j=1}^{3}\partial_j\{(\eta+D_\Pi(u_m))^{-1/2}D_{ij}(u_m)\}\right)\right\|_{X_r}$$

$$\leqq M\sum_{m=k+1}^{n}\varepsilon(\varepsilon(n-m+1))^{-(\alpha+\nu+1/2)} \tag{2.40}$$

$$\leqq M(\varepsilon(n-k))^{1-(\alpha+\nu+1/2)}$$

$$\leqq M(s_2-s_1)^{1/2-\alpha-\nu}.$$

Combining the above estimates, we have

$$\|A^{\alpha+\nu}(u_n-u_k)\|_{X_r} \leqq \frac{M}{\rho}(s_2-s_1)^{1-\alpha}+MT_1^{1/2+\nu-\alpha-\beta-3/2r}(s_2-s_1)^{\beta}$$

$$+M(s_2-s_1)^{1/2+\nu-\alpha-3/2r}+MT_1^{1/2-\alpha-\nu-\beta}(s_2-s_1)^{\beta} \tag{2.41}$$

$$+M(s_2-s_1)^{1/2-\alpha-\nu}$$

$$\leqq M(s_2-s_1)^{\beta}.$$

Similarly, we can also obtain

$$\|A^{\alpha+\nu}(u_{n+1}-u_{k+1})\|_{X_r} \leqq M(s_2-s_1)^{\beta}, \tag{2.42}$$

$$\|A^{\alpha+\nu}(u_{k+1}-u_k)\|_{X_r} \leqq M\varepsilon^{\beta}. \tag{2.43}$$

Since $s_1=k\varepsilon+\lambda_1\varepsilon$, $s_2=n\varepsilon+\lambda_2\varepsilon$ with $0\leqq\lambda_1<1$, $0\leqq\lambda_2<1$, and $s_2-s_1>\varepsilon$,

$$\|A^{\alpha+\nu}(W_N(s_2)-W_N(s_1))\|_{X_r} \leqq (1-\lambda_2)\|A^{\alpha+\nu}(u_n-u_k)\|_{X_r}$$

$$+\lambda_2\|A^{\alpha+\nu}(u_{n+1}-u_{k+1})\|_{X_r}+|\lambda_2-\lambda_1|\,\|A^{\alpha+\nu}(u_{k+1}-u_k)\|_{X_r} \tag{2.44}$$

$$\leqq M(s_2-s_1)^{\beta}.$$

Case 2. $n=k+1$. In this case, $s_1=(k+1)\varepsilon-\lambda_1\varepsilon$ and $s_2=(k+1)\varepsilon+\lambda_2\varepsilon$, where $0\leqq\lambda_2<1$, $0<\lambda_1\leqq 1$ and $s_2-s_1=(\lambda_1+\lambda_2)\varepsilon$. Hence, (2.43) yields

$$
\begin{aligned}
\|A^{\alpha+\nu}(W_N(s_2)-W_N(s_1))\|_{X_r} &\leqq \|A^{\alpha+\nu}((1-\lambda_2)u_{k+1}+\lambda_2 u_{k+2}) \\
&\quad -A^{\alpha+\nu}(\lambda_1 u_k+(1-\lambda_1)u_{k+1})\|_{X_r} \\
&\leqq \lambda_1\|A^{\alpha+\nu}(u_{k+1}-u_k)\|_{X_r}+\lambda_2\|A^{\alpha+\nu}(u_{k+2}-u_{k+1})\|_{X_r} \\
&\leqq (\lambda_1+\lambda_2)M\varepsilon^{\beta}=M\varepsilon^{\beta}\frac{s_2-s_1}{\varepsilon}=M(s_2-s_1)^{\beta}\left(\frac{s_2-s_1}{\varepsilon}\right)^{1-\beta} \\
&\leqq 2^{1-\beta}M(s_2-s_1)^{\beta}\leqq M(s_2-s_1)^{\beta}.
\end{aligned}
\tag{2.45}
$$

Case 3. $n=k$. Using $0<s_2-s_1<\varepsilon$ and (2.43), we have

$$
\begin{aligned}
\|A^{\alpha+\nu}(W_N(s_2)-W_N(s_1))\|_{X_r} &= \frac{s_2-s_1}{\varepsilon}\|A^{\alpha+\nu}(u_{k+1}-u_k)\|_{X_r} \\
&\leqq M(s_2-s_1)^{\beta}\left(\frac{s_2-s_1}{\varepsilon}\right)^{1-\beta} \\
&\leqq M(s_2-s_1)^{\beta}.
\end{aligned}
\tag{2.46}
$$

On account of (2.44)-(2.46), we conclude that if $\varepsilon=T/N$ satisfies (2.25) and (2.31), then

$$
\|A^{\alpha+\nu}(W_N(s_2)-W_N(s_1))\|_{X_r}\leqq M(s_2-s_1)^{\beta} \quad \text{for } \rho\leqq s_1<s_2\leqq T_1. \tag{2.47}
$$

Through an analogous procedure, we can also derive

$$
\|A^{\alpha+\nu}W_N(s)\|_{X_r}\leqq M \quad \text{for } \rho\leqq s\leqq T_1. \tag{2.48}
$$

In (2.47) and (2.48), M stands for positive constants independent of η, ε, s_1, and s_2, and dependent on α, β, ν, ρ, T_1, $\|A^{\nu}u_0\|_{X_r}$, and $\|f\|_{L^{\infty}(0,T;W^{-1,r}(\Omega)^3)}$.

2.2. Convergence as the time meshsize tends to zero. In this section, we prove that the approximate solution W_N defined by (2.9) converges to a solution of the regularized problem as $N\to\infty$. We recall that $0\leqq\nu\leqq 3/4r$, $u_0(x)\in\mathscr{D}(A^{\nu})$, and $f\in L^{\infty}(0,T;W^{-1,r}(\Omega)^3)$, and that T_1 was chosen according to (2.26)-(2.28).

LEMMA 2.5. *The sequence* $\{W_N\}_{N=1}^{\infty}$ *is precompact in* $C([0,T_1];\mathscr{D}(A^{\nu}))$.

Proof. First we fix a positive integer N_0 such that $T/N_0<T_1$ and $\varepsilon=T/N_0$ satisfies (2.25). Let $t^*\in(0,T_1]$ be given. Then, we can choose an integer $N^*\geqq N_0$ and a positive number ρ so that $2\rho<t^*\leqq T_1$ and $\varepsilon=T/N\leqq\rho/2$, for all $N\geqq N^*$. By virtue of (2.48), it is evident that $\{W_N(t^*)\}_{N=N^*}^{\infty}$ is precompact in $\mathscr{D}(A^{\nu})$ and, consequently, $\{W_N(t^*)\}_{N=N_0}^{\infty}$ is precompact in $\mathscr{D}(A^{\nu})$. Furthermore, it follows from (2.47) that $\{W_N\}_{N=N^*}^{\infty}$ is equicontinuous at $t=t^*$ where each W_N is regarded as a continuous function from $[0,T_1]$ into $\mathscr{D}(A^{\nu})$. Thus, $\{W_N\}_{N=N_0}^{\infty}$ is equicontinuous at t^*. Next we show that $\{W_N\}_{N=N_0}^{\infty}$ is equicontinuous at $t=0$. Let us recall that $W_N(0)=u_0$ for every N, and derive an analogue of (2.21) from (2.19):

$$
\begin{aligned}
\|A^{\nu}(u_k-u_0)\|_{X_r} &\leqq \|((I+\varepsilon A)^{-k}-I)A^{\nu}u_0\|_{X_r} \\
&\quad +\varepsilon M_2\sum_{m=1}^{k}(\varepsilon(k-m+1))^{-(1/2+3/2r-\nu)}E_{m-1}E_m \\
&\quad +\varepsilon M_3\sum_{m=1}^{k}(\varepsilon(k-m+1))^{-(1/2+\nu)} \quad \text{for } k=1,\cdots,N,
\end{aligned}
\tag{2.49}
$$

where M_2 and M_3 are the same as in (2.21). Let any $\zeta > 0$ be given. By assuming $N \geqq N_0$ and combining Lemma 1.4, (2.22), (2.23), (2.29), and (2.49), we can find a positive number δ depending on ζ and u_0, but independent of η, N, and k such that $\varepsilon k \leqq \delta$ implies

$$\|A^{\nu}(u_k - u_0)\|_{X_r} \leqq \zeta. \tag{2.50}$$

Using this δ, we set

$$\tilde{\delta} = \min\left(\frac{\delta}{2}, \frac{\delta}{2}\frac{\zeta}{7M_1}\right), \tag{2.51}$$

where M_1 is the same as in (2.29); see also (2.24).

If $N \geqq N_0$, $N \geqq 2T/\delta$, and $0 \leqq s \leqq \tilde{\delta}$, then (2.50) gives

$$\|A^{\nu}(W_N(s) - u_0)\|_{X_r} \leqq \zeta. \tag{2.52}$$

If $N \geqq N_0$, $N < 2T/\delta$, and $0 \leqq s \leqq \tilde{\delta}$, then $\varepsilon = T/N > \delta/2 \geqq \tilde{\delta}$ and

$$\begin{aligned} \|A^{\nu}(W_N(s) - u_0)\|_{X_r} &\leqq \frac{s}{\varepsilon}\|A^{\nu}(u_1 - u_0)\|_{X_r} \\ &\leqq \frac{s}{\varepsilon} 7M_1 \quad \text{by (2.24) and (2.29),} \\ &\leqq \zeta \quad \text{by (2.51).} \end{aligned} \tag{2.53}$$

We now conclude that for any given $\zeta > 0$, there is $\tilde{\delta} > 0$ independent of η and N such that

$$\|A^{\nu}(W_N(s) - u_0)\|_{X_r} \leqq \zeta \quad \text{for all } s \in [0, \tilde{\delta}] \text{ and all } N \geqq N_0. \tag{2.54}$$

Hence, $\{W_N\}_{N=N_0}^{\infty}$ is equicontinuous at $t = 0$. According to the Ascoli Theorem, $\{W_N\}_{N=N_0}^{\infty}$ is precompact in $C([0, T_1]; \mathcal{D}(A^{\nu}))$ and so is $\{W_N\}_{N=1}^{\infty}$. This completes the proof of Lemma 2.5. □

We can now extract a subsequence still denoted by $\{W_N\}$ such that for some function u

$$\lim_{N\to\infty} W_N = u \tag{2.55}$$

in the norm of $C([0, T_1]; \mathcal{D}(A^{\nu}))$.

LEMMA 2.6. *The limit u in* (2.55) *satisfies*

$$u \in L^2(0, T_1; V), \qquad \partial_t u \in L^2(0, T_1; V'), \tag{2.56}$$

$$u(x, 0) = u_0(x), \tag{2.57}$$

$$(\partial_t u, w - u) + a(u, w - u) + b(u, u, w) + J_{\eta}(w) - J_{\eta}(u) \geqq (f, w - u) \tag{2.58}$$

for all $w \in V$, for almost all $t \in (0, T_1)$. Furthermore, it holds that for any $0 < \rho < T_1$ and α, β satisfying (2.34),

$$\|u(s)\|_{\mathcal{D}(A^{\alpha+\nu})} \leqq M \quad \text{for } \rho \leqq s \leqq T_1, \tag{2.59}$$

$$\|u(s_2) - u(s_1)\|_{\mathcal{D}(A^{\alpha+\nu})} \leqq M(s_2 - s_1)^{\beta} \quad \text{for } \rho \leqq s_1 < s_2 \leqq T_1, \tag{2.60}$$

where M denotes positive constants independent of η, s, s_1, and s_2, and dependent on α, β, ν, ρ, T_1, $\|u_0\|_{\mathcal{D}(A^{\nu})}$, and $\|f\|_{L^{\infty}(0,T;W^{-1,r}(\Omega)^3)}$.

Proof. Equation (2.57) is obvious since $W_N(0)=u_0$, for each N. By virtue of (2.47), (2.48), and Lemma 1.1, we can use the Ascoli Theorem to obtain (2.59) and (2.60). Next let us fix a positive integer N_0 such that $T/N_0<T_1$ and $\varepsilon=T/N_0$ satisfies (2.25).

Then, it follows from (1.39), (2.14), (2.15), and (2.29) that for $N\geqq N_0$ and $T/N\leqq\rho<T_1$,

$$\|W_N\|_{L^2(\rho,T_1;V)}\leqq M, \tag{2.61}$$

$$\|\partial_t W_N\|_{L^2(\rho,T_1;V')}\leqq M, \tag{2.62}$$

where M denotes positive constants independent of η, ρ, and N. Consequently, (2.55) implies that for each $0<\rho<T_1$,

$$W_N\to u \quad \text{weakly in } L^2(\rho, T_1; V) \quad \text{as } N\to\infty, \tag{2.63}$$

$$\partial_t W_N\to\partial_t u \quad \text{weakly in } L^2(\rho, T_1; V') \quad \text{as } N\to\infty, \tag{2.64}$$

and consequently,

$$\|u\|_{L^2(0,T_1;V)}\leqq M, \tag{2.65}$$

$$\|\partial_t u\|_{L^2(0,T_1;V')}\leqq M, \tag{2.66}$$

where M stands for positive constants independent of η.

We proceed to prove (2.58).

Let us define

$$U_N(t)=u_{k+1} \quad \text{for } k\varepsilon\leqq t<(k+1)\varepsilon, \qquad k=0,1,\cdots,N-1, \tag{2.67}$$

$$U_N^*(t)=u_k \quad \text{for } k\varepsilon\leqq t<(k+1)\varepsilon, \qquad k=0,1,\cdots,N-1, \tag{2.68}$$

$$F_N(t)=f_{k+1} \quad \text{for } k\varepsilon\leqq t<(k+1)\varepsilon, \qquad k=0,1,\cdots,N-1. \tag{2.69}$$

Then it is proved in [15, p. 329] that as $N\to\infty$,

$$F_N\to f \quad \text{strongly in } L^2(0, T; V'), \tag{2.70}$$

$$W_N-U_N\to 0 \quad \text{strongly in } L^2(0, T; X_2). \tag{2.71}$$

Likewise, by using (2.17), it is easy to see that

$$W_N-U_N^*\to 0 \quad \text{strongly in } L^2(0, T; X_2). \tag{2.72}$$

Furthermore, it follows from (2.15) and (2.29) that

$$\|U_N\|_{L^2(0,T;V)}\leqq M \quad \text{for all } N, \tag{2.73}$$

$$\|W_N\|_{L^2(\rho,T;V)}\leqq M \quad \text{for all } \rho,\ N \text{ such that } T/N\leqq\rho<T, \tag{2.74}$$

$$\|U_N^*\|_{L^\infty(0,T_1;X_r)}\leqq M \quad \text{for all } N\geqq N_0, \tag{2.75}$$

where M stands for positive constants independent of η, ρ, and N.

Consequently, (2.55) implies that as $N\to\infty$

$$U_N\to u \quad \text{strongly in } L^2(0, T_1; X_2), \tag{2.76}$$

$$U_N^*\to u \quad \text{strongly in } L^2(0, T_1; X_2), \tag{2.77}$$

$$U_N\to u \quad \text{weakly in } L^2(0, T_1; V), \tag{2.78}$$

which, together with (2.73) and (2.75), give

$$U_{Nj}^*U_N\to u_j u \quad \text{weakly in } L^2(0, T_1; L^2(\Omega)^3) \tag{2.79}$$

for $j=1,2,3$, where $U_N^*=(U_{N1}^*, U_{N2}^*, U_{N3}^*)$ and $u=(u_1, u_2, u_3)$.

Next it follows from (2.10) that for each N,

$$\int_0^{T_1} (\partial_t W_N, \psi)\, dt + \int_0^{T_1} a(U_N, \psi)\, dt + \int_0^{T_1} b(U_N^*, U_N, \psi)\, dt + \int_0^{T_1} (J_\eta'(U_N), \psi)\, dt = \int_0^{T_1} (F_N, \psi)\, dt, \tag{2.80}$$

for all $\psi \in L^2(0, T_1; V)$. By making use of (1.38) and the fact that $U_N \in L^2(0, T; V)$, we infer that for each N,

$$\begin{aligned} &\int_0^{T_1} (\partial_t W_N, \psi - U_N)\, dt + \int_0^{T_1} a(U_N, \psi - U_N)\, dt \\ &\quad + \int_0^{T_1} b(U_N^*, U_N, \psi)\, dt + \int_0^{T_1} (J_\eta(\psi) - J_\eta(U_N))\, dt \\ &\quad \geqq \int_0^{T_1} (F_N, \psi - U_N)\, dt \end{aligned} \tag{2.81}$$

for all $\psi \in L^2(0, T_1; V)$. We next observe that for $k\varepsilon \leqq t < (k+1)\varepsilon$, $k = 0, 1, \cdots, N-1$,

$$(\partial_t W_N, U_N - W_N) = \frac{1}{\varepsilon}\left(1 - \frac{1}{\varepsilon}(t - k\varepsilon)\right) \|u_{k+1} - u_k\|_{X_2}^2 \geqq 0, \tag{2.82}$$

and hence,

$$\begin{aligned} \int_0^{T_1} (\partial_t W_N, U_N)\, dt &= \int_0^{T_1} (\partial_t W_N, W_N)\, dt + \int_0^{T_1} (\partial_t W_N, U_N - W_N)\, dt \\ &\geqq \int_0^{T_1} (\partial_t W_N, W_N)\, dt \\ &= \frac{1}{2} \|W_N(T_1)\|_{X_2}^2 - \frac{1}{2} \|u_0\|_{X_2}^2. \end{aligned} \tag{2.83}$$

Accordingly, we use (2.55), (2.65), and (2.66) to deduce

$$\begin{aligned} \liminf_{N\to\infty} \int_0^{T_1} (\partial_t W_N, U_N)\, dt &\geqq \liminf_{N\to\infty} \int_0^{T_1} (\partial_t W_N, W_N)\, dt \\ &= \frac{1}{2} \|u(T_1)\|_{X_2}^2 - \frac{1}{2} \|u_0\|_{X_2}^2 \\ &= \int_0^{T_1} (\partial_t u, u)\, dt. \end{aligned} \tag{2.84}$$

By virtue of (2.78) and (2.79), we see that

$$\liminf_{N\to\infty} \int_0^{T_1} J_\eta(U_N)\, dt \geqq \int_0^{T_1} J_\eta(u)\, dt, \tag{2.85}$$

$$\liminf_{N\to\infty} \int_0^{T_1} a(U_N, U_N)\, dt \geqq \int_0^{T_1} a(u, u)\, dt, \tag{2.86}$$

$$\lim_{N\to\infty} \int_0^{T_1} b(U_N^*, U_N, \psi)\, dt = \int_0^{T_1} b(u, u, \psi)\, dt \quad \text{for each } \psi \in L^2(0, T_1; V). \tag{2.87}$$

Combining (2.64), (2.70), and (2.84)-(2.87), we can pass $N \to \infty$ in (2.81) to arrive at

$$\begin{aligned} &\int_0^{T_1} (\partial_t u, \psi - u)\, dt + \int_0^{T_1} a(u, \psi - u)\, dt + \int_0^{T_1} b(u, u, \psi)\, dt \\ &\quad + \int_0^{T_1} (J_\eta(v) - J_\eta(u))\, dt \\ &\quad \geqq \int_0^{T_1} (f, \psi - u)\, dt \end{aligned} \tag{2.88}$$

for every $\psi \in L^2(0, T_1; V)$. By the same argument as in [4], (2.88) implies (2.58). This ends the proof of Lemma 2.6. □

2.3. Convergence as η tends to zero. For each $\eta > 0$, we denote by u_η the function in Lemma 2.6 to signify its dependence on η. We will show that u_η converges to a solution of (0.1)-(0.4) as η tends to zero. Since T_1 was chosen according to (2.26)-(2.28), T_1 is independent of η and nonincreasing in $\|u_0\|_{\mathcal{D}(A^\nu)}$.

LEMMA 2.7. *The set $\{u_\eta\}_{\eta>0}$ is precompact in $C([0, T_1]; \mathcal{D}(A^\nu))$.*

Proof. By (2.54) and (2.55), it is easily seen that $\{u_\eta(t)\}_{\eta>0}$ is equicontinuous at $t = 0$. Inequalities (2.59) and (2.60) imply that $\{u_\eta(t)\}_{\eta>0}$ is precompact in $\mathcal{D}(A^\nu)$ and equicontinuous at each $0 < t \leqq T_1$. Now we apply the Ascoli theorem to conclude the proof. □

Let us extract a sequence still denoted by $\{u_\eta\}$ such that for some function u,

$$\lim_{\eta \to 0} u_\eta = u \tag{2.89}$$

in the norm of $C([0, T_1]; \mathcal{D}(A^\nu))$.

LEMMA 2.8. *The limit function u in* (2.89) *is a solution of* (0.1)-(0.4) *on the interval* $[0, T_1)$. *Furthermore, it holds that for any $0 < \rho < T_1$ and α, β satisfying* (2.34),

$$\|u(s)\|_{\mathcal{D}(A^{\alpha+\nu})} \leqq M \quad \text{for } \rho \leqq s \leqq T_1, \tag{2.90}$$

$$\|u(s_2) - u(s_1)\|_{\mathcal{D}(A^{\alpha+\nu})} \leqq M(s_2 - s_1)^\beta \quad \text{for } \rho \leqq s_1 < s_2 \leqq T_1, \tag{2.91}$$

where M denotes positive constants independent of s, s_1, and s_2, and dependent on α, β, ν, ρ, T_1, $\|u_0\|_{\mathcal{D}(A^\nu)}$, and $\|f\|_{L^\infty(0,T;W^{-1,r}(\Omega)^3)}$.

Proof. Since the positive constants denoted by M in (2.59) and (2.60) are independent of η, we use Lemma 1.1 and the Ascoli Theorem to derive (2.90) and (2.91). Meanwhile, (2.65), (2.66), and (2.89) yield

$$u_\eta \to u \quad \text{weakly in } L^2(0, T_1; V), \tag{2.92}$$

$$\partial_t u_\eta \to \partial_t u \quad \text{weakly in } L^2(0, T_1; V'), \tag{2.93}$$

and thus

$$\begin{aligned} \liminf_{\eta \to 0} \int_0^{T_1} J_\eta(u_\eta)\, dt &\geqq \liminf_{\eta \to 0} \int_0^{T_1} J(u_\eta)\, dt \\ &\geqq \int_0^{T_1} J(u)\, dt. \end{aligned} \tag{2.94}$$

Now, by the same argument as in the proof of Lemma 2.6, we can show that u satisfies (0.1) for every $w \in V$, for almost all $t \in (0, T_1)$. We omit the details.

2.4. Conclusion of the proof of Theorem 2.3. It remains to establish the uniqueness of solution. Let u be the solution obtained in Lemma 2.8, and let $\tilde{u}$ be another solution on $[0, T_1)$ according to Definition 2.1. Then, we have

$$(\partial_t(u-\tilde{u}), u-\tilde{u}) + a(u-\tilde{u}, u-\tilde{u}) \leqq b(u, u, \tilde{u}) + b(\tilde{u}, \tilde{u}, u), \tag{2.95}$$

for almost all $t \in (0, T_1)$.

As in [11, p. 85], we have

$$\begin{aligned} |b(u, u, \tilde{u}) + b(\tilde{u}, \tilde{u}, u)| &= |b(u-\tilde{u}, u-\tilde{u}, u)| \\ &\leqq M\|u\|_{X_r}\|u-\tilde{u}\|_{X_2}^{2/s}\|u-\tilde{u}\|_V^{1+3/r}, \end{aligned} \tag{2.96}$$

where $2/s + 3/r = 1$ and M is a positive constant. Since $u \in C([0, T_1]; X_r)$, we combine (2.95), (2.96), and the Hölder inequality to deduce

$$(\partial_t(u-\tilde{u}), u-\tilde{u}) \leqq M\|u-\tilde{u}\|_{X_2}^2, \tag{2.97}$$

for almost all $t \in (0, T_1)$.

It now follows that $u = \tilde{u}$ on $[0, T_1]$.

This and Lemma 2.8 complete the proof of Theorem 2.3. □

Finally, we remark that if $T_1 < T$, then the solution can be extended to a larger interval by means of Theorem 2.3 itself. Let us choose

$$T^* = \sup\{\tilde{T}: T_1 \leqq \tilde{T} \leqq T \text{ and there is a solution that is } \mathscr{D}(A^\nu)\text{-valued continuous on } [0, \tilde{T}]\}. \tag{2.98}$$

Then, $u \in C([0, T_1]; \mathscr{D}(A^\nu))$ can be extended to $u \in C([0, T^*); \mathscr{D}(A^\nu))$. If $T^* < T$,

$$\lim_{t \to T^*-} \|u(t)\|_{\mathscr{D}(A^\nu)} = \infty. \tag{2.99}$$

In this case, it is not known whether there is a solution (according to Definition 2.1) defined on an interval $[0, T^{**})$, $T^{**} > T^*$.

3. Global existence. Our assertion on the existence of global solution is Theorem 3.1.

THEOREM 3.1. *Let*

$$3 < \frac{6r}{r+3} < p < r \quad \text{and} \quad \lambda = \frac{r-(2r/p)}{r-2}.$$

There is a positive number C such that if $u_0 \in X_r$ and $f \in L^\infty(0, \infty; W^{-1,r}(\Omega)^3)$ satisfy

$$(\|u_0\|_{X_2} + \|f\|_{L^\infty(0,\infty;V')})^{2(1-\lambda)}(1 + \|u_0\|_{X_r} + \|f\|_{L^\infty(0,\infty;W^{-1,r}(\Omega)^3)})^\lambda \leqq C, \tag{3.1}$$

then there is a unique solution u according to Definition 2.1 on the interval $[0, T)$, for any $0 < T < \infty$. Furthermore, $u \in C([0, \infty); X_r)$ and, for each $0 < \delta \leqq \frac{1}{2}$, u is $\mathscr{D}(A^{1/2-\delta})$-valued and locally Hölder continuous on $(0, \infty)$.

The idea of proof is to choose any $T > 0$ and establish the existence of solution u on $[0, T]$ together with the estimate of $\sup_{t \in [0,T]} \|u(t)\|_{X_r}$. Under assumption (3.1), it will be shown that this estimate is independent of T, and hence the time interval can be extended indefinitely with the aid of the uniqueness of solutions.

Proof. We will follow the scheme of § 2.1. Choose any $T > 0$ and any positive integer N. As before, we set $\varepsilon = T/N$. Let us write

$$G_k = \|u_k\|_{X_2} \quad \text{for } k = 0, 1, \cdots, N, \tag{3.2}$$

$$\Theta_1 = \operatorname{ess\,sup}_{t \geqq 0} \|f(t)\|_{V'}. \tag{3.3}$$

By substituting u_{k+1} for ϕ in (2.10), we can derive

$$G_{k+1}^2 - G_k^2 + \varepsilon C_1 G_{k+1}^2 \leqq \varepsilon C_2 \Theta_1^2 \quad \text{for } k = 0, 1, \cdots, N-1, \tag{3.4}$$

where C_1 and C_2 are positive constants dependent only on Ω and μ. Since we are interested only in small ε, we may assume

$$0 < \varepsilon < \min\left(1, \frac{1}{2C_1}\right). \tag{3.5}$$

It then follows from (3.4) that

$$\begin{aligned} G_k^2 &\leqq (1+\varepsilon C_1)^{-k} G_0^2 + \varepsilon C_2 \Theta_1^2 \sum_{m=1}^{k} (1+\varepsilon C_1)^{-m}, \\ &\leqq G_0^2 \exp(-\delta_1 \varepsilon k) + \frac{C_2}{C_1} \Theta_1^2 \quad \text{for } k = 1, \cdots, N, \end{aligned} \tag{3.6}$$

where δ_1 is a positive number independent of ε, k, and T.

We will obtain a new estimate of $E_k = \|u_k\|_{X_r}$: we are considering the case $\nu = 0$ in (2.20).

Recalling that $3 < 6r/(r+3) < p < r$, we set

$$b = \frac{1}{2} + \frac{3}{2}\left(\frac{2}{p} - \frac{1}{r}\right) \tag{3.7}$$

and rewrite (2.19) by using (1.27) as

$$\begin{aligned} u_k &= (I+\varepsilon A)^{-k} u_0 - \varepsilon \sum_{m=1}^{k} A^b (I+\varepsilon A)^{-(k-m+1)} A^{-b} P \sum_{j=1}^{3} \partial_j (u_{(m-1)j} u_m) \\ &+ \varepsilon \sum_{m=1}^{k} A^{1/2} (I+\varepsilon A)^{-(k-m+1)} A^{-1/2} P g \sum_{j=1}^{3} \partial_j \{(\eta + D_\Pi(u_m))^{-1/2} D_{ij}(u_m)\} \\ &+ \varepsilon \sum_{m=1}^{k} A^{1/2} (I+\varepsilon A)^{-(k-m+1)} A^{-1/2} P f_m \quad \text{for } k = 1, \cdots, N. \end{aligned} \tag{3.8}$$

By means of (1.2), (1.20), (1.21), (1.39), and the inequality

$$\|h\|_{L^p(\Omega)} \leqq \|h\|_{L^2(\Omega)}^{1-\lambda} \|h\|_{L^r(\Omega)}^{\lambda} \quad \text{for all } h \in L^r(\Omega) \quad \text{where } \lambda = \frac{r-(2r/p)}{r-2}, \tag{3.9}$$

we deduce

$$\begin{aligned} E_k &\leqq C_3 \exp(-\delta_2 \varepsilon k) E_0 + C_4 \varepsilon \sum_{m=1}^{k} \exp(-\delta_3 \varepsilon (k-m+1)) \\ &\quad \cdot (\varepsilon(k-m+1))^{-b} G_{m-1}^{1-\lambda} G_m^{1-\lambda} E_{m-1}^{\lambda} E_m^{\lambda} \\ &\quad + C_5 \varepsilon \sum_{m=1}^{k} \exp(-\delta_4 \varepsilon (k-m+1)) (\varepsilon(k-m+1))^{-1/2} (\Theta_2 + C_6), \end{aligned} \tag{3.10}$$

where $\Theta_2 = \operatorname{ess\,sup}_{t \geqq 0} \|f(t)\|_{W^{-1,r}(\Omega)^3}$, and C_i's and δ_i's are positive constants independent of η, ε, k, T, E_m's, G_m's, Θ_1, and Θ_2.

Let us set

$$C_7 = C_4 \int_0^\infty \exp(-\delta_3 s) s^{-b}\, ds, \tag{3.11}$$

$$C_8 = C_5 \int_0^\infty \exp(-\delta_4 s) s^{-1/2}\, ds, \tag{3.12}$$

$$C_9 = \max(1, C_3, C_8), \tag{3.13}$$

$$M_1 = \max(1, E_0, \Theta_2 + C_6), \tag{3.14}$$

$$M_2 = 4C_9 M_1. \tag{3.15}$$

We then choose $\zeta > 0$ such that

$$C_4 \zeta^{2(1-\lambda)} M_2^{\lambda} \leqq \tfrac{1}{3}, \tag{3.16}$$

$$C_7 \zeta^{2(1-\lambda)} M_2^{\lambda} \leqq \tfrac{1}{6}, \tag{3.17}$$

and suppose that

$$G_0 + \left(\frac{C_2}{C_1}\right)^{1/2} \Theta_1 \leqq \zeta. \tag{3.18}$$

Then, by virtue of (3.6),

$$G_k \leqq \zeta \quad \text{for all } k = 0, 1, \cdots, N. \tag{3.19}$$

We proceed to show by induction

$$E_k \leqq M_2 \quad \text{for all } k = 0, \cdots, N. \tag{3.20}$$

It is obvious that $E_0 \leqq M_2$ and $M_2 \geqq 4$.

If $E_m \leqq M_2$, for $m = 0, \cdots, k-1$, then by (3.10), (3.16), and (3.17), we have

$$E_k \leqq 2C_9 M_1 + \tfrac{1}{6} M_2 + \tfrac{1}{3} E_k^{\lambda}. \tag{3.21}$$

If $E_k \leqq 1$, then $E_k \leqq M_2$.

If $E_k > 1$, then (3.21) yields

$$\tfrac{2}{3} E_k \leqq 2C_9 M_1 + \tfrac{1}{6} M_2 \tag{3.22}$$

and hence $E_k \leqq M_2$. This proves (3.20).

Now we can choose a proper positive constant C in (3.1), subject to the constants above, independent of u_0 and f so that (3.1) guarantees (3.16)–(3.18), from which (3.20) follows. The remainder of the proof of Theorem 3.1 can be carried out precisely in the same manner as in the previous section, and we omit it. □

Next we present a result on the asymptotic behavior of solutions when the external force f is time-periodic. Our assertion is given in Theorem 3.2.

THEOREM 3.2. *Suppose that f is L-periodic in time and that u_0 and f satisfy* (3.1) *and*

$$(\|u_0\|_{X_2} + \Theta_1)^d (1 + \|u_0\|_{X_r} + \Theta_2)^{1-d} \leqq \tilde{C}, \tag{3.23}$$

where Θ_1, Θ_2 are the same as above, and d, $\tilde{C}$ are positive constants that will be determined below. Then the solution $u(x, t)$ of the theorem above converges to an L-periodic solution as $t \to \infty$. More precisely, there is a function $u_L(x, t)$ satisfying (0.1) *on* $(-\infty, \infty)$ *such that*

$$u_L \in L^2(0, L; V) \quad \text{and} \quad \partial_t u_L \in L^2(0, L; V'), \tag{3.24}$$

$$u_L(t) = u_L(t + L) \quad \text{for all } t \in (-\infty, \infty), \tag{3.25}$$

$$\|u(t) - u_L(t)\|_{X_2} \leqq M \exp(-\omega t) \quad \text{for all } t \geqq 0, \tag{3.26}$$

where M and ω are positive constants, and for each $0 < \delta \leqq \frac{1}{2}$, u_L is a Hölder continuous $\mathscr{D}(A^{1/2-\delta})$-valued function on $(-\infty, \infty)$.

Proof. The method of proof is similar to that of Theorem 4.2 of [10]. Let $u(x, t)$ be the global solution obtained in Theorem 3.1. Then, by setting $w = 0$ in (0.1), we have

$$\frac{1}{2}\frac{d}{dt}\|u\|_{X_2}^2 + a(u, u) \leqq (f, u) \quad \text{for almost all } t \in (0, \infty), \tag{3.27}$$

from which it follows that

$$\|u\|_{X_2}^2 \leqq \|u_0\|_{X_2}^2 \exp(-\omega_1 t) + C_{10} \operatorname*{ess\,sup}_{t \geqq 0} \|f(t)\|_{V'}^2, \tag{3.28}$$

where ω_1 and C_{10} are positive constants depending on Ω and μ. We next define

$$v_k(x, t) = u(x, t + kL) \quad \text{for } k = 0, 1, 2, \cdots. \tag{3.29}$$

Then, each v_k satisfies (0.1) on the interval $(-kL, \infty)$ and it is easily seen that

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}\|v_k - v_0\|_{X_2}^2 + C_{11}\|v_k - v_0\|_V^2 &\leqq |b(v_k - v_0, v_k - v_0, v_0)| \\ &\leqq C_{12}\|v_0\|_{L^3(\Omega)^3}\|v_k - v_0\|_V^2 \\ &\leqq C_{13}\|v_0\|_{X_2}^d \|v_0\|_{X_r}^{1-d}\|v_k - v_0\|_V^2 \\ &\qquad \text{for almost all } t \in (0, \infty), \end{aligned} \tag{3.30}$$

where C_{11}, C_{12}, and C_{13} are positive constants depending only on Ω and μ, and d is a number satisfying $d/2 + (1-d)/r = \frac{1}{3}$.

In the meantime, it follows from (3.20) that

$$\|v_0(t)\|_{X_r} = \|u(t)\|_{X_r} \leqq C_{14}(1 + E_0 + \Theta_2) \quad \text{for all } t \geqq 0, \tag{3.31}$$

where C_{14} is a positive constant independent of E_0 and Θ_2. By virtue of (3.28) and (3.31), we can choose a positive number $\tilde{C}$ in (3.23) so that (3.23) implies

$$C_{13}\|v_0(t)\|_{X_2}^d \|v_0(t)\|_{X_r}^{1-d} \leqq \tfrac{1}{2}C_{11} \quad \text{for all } t \geqq 0. \tag{3.32}$$

Hence, under conditions (3.1) and (3.23), we obtain from (3.30)

$$\frac{d}{dt}\|v_k - v_0\|_{X_2}^2 + C_{11}\|v_k - v_0\|_V^2 \leqq 0 \quad \text{for almost all } t \in (0, \infty), \tag{3.33}$$

which yields

$$\|v_k - v_0\|_{X_2} \leqq C_{15} \exp(-\omega_2 t) \quad \text{for all } t \geqq 0 \text{ and all } k \geqq 0, \tag{3.34}$$

where C_{15} and ω_2 are positive constants.

Now we find that

$$\begin{aligned} \|v_{k+m}(t) - v_m(t)\|_{X_2} &= \|v_k(t + mL) - v_0(t + mL)\|_{X_2} \\ &\leqq C_{15} \exp(-\omega_2 mL) \quad \text{for all } t \geqq 0 \text{ and all } k, m \geqq 0. \end{aligned} \tag{3.35}$$

Consequently, $\{v_k\}_{k=0}^{\infty}$ is a Cauchy sequence in $C([0, \infty); X_2)$. Let u_L be its limit. By the same argument as in [10], u_L satisfies (0.1) and (3.24)–(3.26). We omit the remaining details.

Acknowledgment. I thank Professors K. Hannsgen and R. Wheeler for their support. I am also grateful to the referee for constructive criticism.

GLOBAL BIFURCATION OF STEADY-STATE SOLUTIONS ON A BIOCHEMICAL SYSTEM*

CHUNQING LU†

Abstract. The differential equation $u''-(u/k\beta^2(u^2+2\varepsilon u+4k\varepsilon^2))=0$ with the boundary conditions $u(0)=u(1)=1$ governs the steady-state solutions from a mono-enzyme membrane model. It is proved that for a given $k>0$ there are at most three solutions for all $\varepsilon>0$ and for all $\beta>0$, and that there exists an $\varepsilon_*=\varepsilon_*(k)$, a value of ε, at which a pitchfork bifurcation occurs in the corresponding reaction-diffusion equations.

Key words. steady state, pitchfork, global bifurcation

AMS(MOS) subject classification. 92A09

1. Introduction. A model describing the diffusion and reaction of a substrate in a mono-enzymatic artificial membrane was established by Thomas (see Kernevez and Thomas [5]). The biochemical system is a membrane with the enzyme uricase linked to a support. The substrate is uric acid, and the cosubstrate is oxygen. The substrate and cosubstrate diffuse only within the membrane and they react in the presence of the enzyme (they are not parts of the membrane). The stoichiometric equation is:

$$\text{uric acid} + \text{oxygen} \xrightarrow{\text{uricase}} \text{allantoin} + \text{other products.}$$

Let $S=S(x, t)$ be the concentration of the substrate of the membrane. Then it satisfies the following reaction-diffusion equation:

$$S_t - D_S S_{xx} + R(S) = 0, \tag{1.1}$$

together with boundary conditions

$$S = S_0 \quad \text{at } x=0 \quad \text{and} \quad x = L \text{ (membrane thickness)},$$

and the given initial condition, where D_S is the coefficient of diffusion, a constant, and

$$R(S) = V_M S/[k_S + S(1+S/k_{SS})]$$

is the rate of the reaction where k_S is the Michaelis constant, k_{SS} the inhibition constant of S for the enzyme, and V_M is the maximal value of the reaction rate. Nondimensionalizing the equation, we obtain the following partial differential equation:

$$s_t - s_{xx} + \sigma F(s) = 0, \quad 0<x<1, \quad t>0 \tag{1.2}$$

with boundary conditions

$$s(0, t) = s(1, t) = s_0, \tag{1.2'}$$

and the given initial data $s(x, 0)$, where $s=S/k_S$ and $F(s)=s/(1+s+ks^2)$, and $\sigma=(V_M/k_S)(L^2/D_S)$, $k=k_S/k_{SS}$, and $s_0=S_0/k_S$ are positive constants. Then the steady-state equation associated with (1.2)-(1.2') is the two-point boundary value problem:

$$-s''+\sigma F(s)=0, \qquad 0<x<1, \tag{1.3}$$

$$s(0)=s(1)=s_0. \tag{1.3'}$$

Kernevez [4] showed that there exist at least three solutions for (1.3)-(1.3′) for large σ and for some s_0. In 1976, Brauner and Nicolaenko [1] studied the stability of the multiple steady-state solutions using the Crandall-Rabinowitz theorem for large σ based on the assumption that there are at most three solutions without a proof. In 1985, Lu [7] gave a rigorous proof: given $k>0$, there exists an $s_{0*}=s_{0*}(k)$ such that if $s_0>s_{0*}$, then there are at most three solutions for any $\sigma>0$. Lu also indicated that the method can also be applied to the case for large σ. In this paper, Lu continues his work of [6] and [7], and studies the global bifurcation for all s_0 and $\sigma>0$ for given k to prove that a pitchfork bifurcation point exists in the system.

Biologically, the results will explain that multiple stable steady states and a hysteresis phenomenon occur in a very simple biochemical system, such as this one, where diffusion and enzyme reaction interact, because s_0 is very large compared with the membrane thickness L. Mathematically, questions about numbers and stability of steady-state solutions of reaction-diffusion equations depend heavily upon their nonlinear terms, and there is no general way to handle them. Smoller and Wasserman [9] studied a case in which the nonlinearity is a polynomial. Hastings and McLeod [2] dealt with an exponential nonlinearity. In this paper, we consider a different nonlinearity from theirs—a class of rational functions.

2. Main results. We again apply the changes of variables used in [6] and [7]:

$$u(x)=s_0^{-1}s(x),\quad \beta=s_0\sigma^{-1/2},\quad \varepsilon=(2ks_0)^{-1}.$$

Then the given steady-state equation takes the form:

$$-u''+\frac{u}{k\beta^2(u^2+2\varepsilon u+4k\varepsilon^2)}=0,\qquad 0<x<1, \tag{2.1}$$

$$u(0)=u(1)=1, \tag{2.1′}$$

and the reaction-diffusion equation becomes

$$\frac{\partial u}{\partial t}-\frac{\partial^2 u}{\partial x^2}+\frac{u}{k\beta^2(u^2+2\varepsilon u+4k\varepsilon^2)}=0,\quad 0<x<1,\quad t>0, \tag{2.2}$$

$$u(0,t)=u(1,t)=1,\qquad t>0, \tag{2.2′}$$

$$u(x,0)\text{ given.} \tag{2.2″}$$

The main results are the following three theorems.

THEOREM 1. *For any given $k>0$, there exist at most three solutions of* (2.1)-(2.1′) *for all positive β and ε.*

THEOREM 2. *For any given $k>0$, there exists an $\varepsilon_*=\varepsilon_*(k)$, a value of ε, such that for each $\varepsilon<\varepsilon_*$ there is a pair (β_1,β_2) depending on ε and k such that* (2.1)-(2.1′) *has exactly three solutions for $\beta\in(\beta_1,\beta_2)$, and only one solution for $\varepsilon\geqq\varepsilon_*$ and for any $\beta>0$.*

THEOREM 3. *Suppose that ε_* is chosen as in Theorem 2. If $\varepsilon>\varepsilon_*$, then the unique solution of* (2.1)-(2.1′) *is stable to* (2.2)-(2.2″); *if $\varepsilon\in(0,\varepsilon_*)$ and* (2.1)-(2.1′) *has three solutions, then two of them are stable and the other unstable.*

Remark 1. Let $u(x)$ be any solution of (2.1)-(2.1′) and $u(x,t)$ a solution of (2.2)-(2.2″). If for any given $\alpha>0$ there exists a $\delta>0$ such that $\|u(x,t)-u(x)\|<\alpha$ for all $t>0$ as long as $\|u(x,0)-u(x)\|<\delta$, then $u(x)$ is called stable to (2.2)-(2.2″); otherwise, it is unstable, where $\|\cdot\|$ is the C-norm.

Remark 2. It is observed from Theorems 2 and 3 that when the initial boundary value problem (2.2)-(2.2″) is treated as a local flow in a certain function space (cf. [10]), ε_* is a bifurcation point at which a pitchfork bifurcation occurs.

Remark 3. Because of the practical background of the equations, all parameters appearing in the u-equations are positive. Also, we assume that all solutions studied in the paper are positive as well. The existence of such solutions has been proved in [7].

3. Proofs of Theorems 1 and 2. We need some lemmas.

LEMMA 1. *If* $u(x)$ *solves* (2.1)-(2.1′), *then* $u(\frac{1}{2})=0$.

Proof. Multiply (2.1) by u', and then integrate both sides. This yields

$$\frac{[u'(x)]^2}{2}=\frac{1}{k\beta^2}\int_{u(1/2)}^{u(x)}\frac{u\,du}{u^2+2\varepsilon u+4k\varepsilon^2}+\frac{[u'(\frac{1}{2})]^2}{2}. \tag{3.1}$$

Then $u'(0)^2=u'(1)^2$. Since $u>0$, $u''>0$ and u is convex. Then $u'(0)=-u'(1)$. Let $x=\frac{1}{2}+z$ and $v(z)=u(\frac{1}{2}+z)$. Then $v(z)$ satisfies (2.1) in $(-\frac{1}{2},\frac{1}{2})$ with $v(-\frac{1}{2})=v(\frac{1}{2})=1$, and $v'(\frac{1}{2})=-v'(-\frac{1}{2})$. It is observed that $w(z)=v(-z)$ is also a solution of (2.1) with the same initial values as v. By the uniqueness of $v(z)$, $v(z)=v(-z)$, implying that $u'(\frac{1}{2})=0$.

Lemma 1 implies that the number of steady-state solutions will be determined by the number of values of $u(\frac{1}{2})$, which must satisfy certain conditions. To determine such conditions, as in [7], denote $u(\frac{1}{2})=1/y$, solve $u'(x)$ from (3.1), and integrate the obtained equation. Then introduce the change of variable: $\varepsilon+u=(\varepsilon+(1/y))e^{t^2}$. It follows that

$$2\left(\varepsilon+\frac{1}{y}\right)\int_0^v te^{t^2}\left[\ln\frac{(1+\varepsilon y)^2e^{2t^2}+(4k-1)\varepsilon^2y^2}{(1+\varepsilon y)^2+(4k-1)\varepsilon^2y^2}-2\varepsilon y\int_1^{(1+\varepsilon y)e^{t^2}-\varepsilon y}\frac{ds}{(s+\varepsilon y)^2+(4k-1)\varepsilon^2y^2}\right]^{-1/2}dt=\frac{1}{2\beta\sqrt{k}}, \tag{3.2}$$

where $v=v(\varepsilon,y)=(\ln(\varepsilon+1)-\ln(\varepsilon+1/y))^{1/2}$. We denote the function on the left-hand side of (3.2), the so-called response function, by $f(y;\varepsilon)$. In this paper it may be written as f or $f(y)$ depending on the context. Thus, the number of multiple steady states will be uniquely determined by the number of solutions of the function equation $f(y;\varepsilon)=(2\beta\sqrt{k})^{-1}$. Denote

$$G=G(y,t,s)=\ln\frac{(1+\varepsilon y)^2e^{2t^2}+(4k-1)\varepsilon^2y^2}{(1+\varepsilon y)^2+(4k-1)\varepsilon^2y^2}-2\varepsilon y\int_1^{(1+\varepsilon y)e^{t^2}-\varepsilon y}\frac{ds}{(s+\varepsilon y)^2+(4k-1)\varepsilon^2y^2}, \tag{3.3}$$

and $H=H(y,\varepsilon)=G(y,V(y,\varepsilon),\varepsilon)$. Then (3.2) becomes

$$f(y;\varepsilon)=2\left(\varepsilon+\frac{1}{y}\right)\int_0^v te^{t^2}G^{-1/2}\,dt. \tag{3.4}$$

Hence,

$$\frac{\partial f}{\partial y}=\frac{1+\varepsilon}{(1+\varepsilon y)yH^{1/2}}-\frac{2}{y^2}\int_0^v te^{t^2}G^{-1/2}\,dt-\left(\varepsilon+\frac{1}{y}\right)\int_0^v te^{t^2}G^{-3/2}\frac{\partial G}{\partial y}\,dt, \tag{3.5}$$

$$\begin{aligned}\frac{\partial^2 f}{\partial y^2}=&-\frac{2(1+\varepsilon)}{(1+\varepsilon y)y^2H^{1/2}}-\frac{1+\varepsilon}{2(1+\varepsilon y)yH^{3/2}}\left(\frac{\partial H}{\partial y}+\frac{\partial G}{\partial y}\bigg|_{t=v}\right)\\&+\frac{4}{y^3}\int_0^v te^{t^2}G^{-1/2}\,dt+\frac{3(1+\varepsilon y)}{2y}\int_0^v te^{t^2}G^{-5/2}\left(\frac{\partial G}{\partial y}\right)^2dt\\&+\int_0^v te^{t^2}G^{-3/2}\left(\frac{2}{y^2}\frac{\partial G}{\partial y}-\frac{1+\varepsilon y}{y}\frac{\partial^2 G}{\partial y^2}\right)dt.\end{aligned} \tag{3.6}$$

Since $\partial f/\partial y$ and $\partial^2 f/\partial y^2$ are too complicated, we introduce an auxiliary function $P = P(y;\varepsilon) = (1+\varepsilon y)^3 y((\partial^2 f/\partial y^2)+(2/y)(\partial f/\partial y))$.

For the remaining lemmas in this section, we present analytic proofs in detail only for $k=\frac{1}{4}$, because the proof for general k would be very tedious, as is pointed out in [6]. Also, the numerical results in [4] give good evidence that all properties of the response functions $f(y;\varepsilon)$ are demonstrated by the following lemmas. In the case $k=\frac{1}{4}$,

$$P = \frac{\varepsilon(y-2)-1}{yH^{3/2}} + 6\varepsilon^2 \int_0^v te^{t^2}(1-e^{-t^2})^2 G^{-5/2}\,dt. \tag{3.7}$$

LEMMA 2. *Function P has a unique zero in $(1,\infty)$ for any ε.*

Proof. It is observed from (3.7) that $P>0$ for $y \geqq (2+\varepsilon^{-1})$ and $\lim_{y\to 1^+} H(y:\varepsilon)=0$, and hence $\mathrm{Lim}_{y\to 1^+} P(y;\varepsilon) = -\infty$. This proves the existence of zeros of P in $(1,\infty)$. To see the uniqueness, we differentiate P with respect to y once:

$$\begin{aligned}\frac{\partial P}{\partial y} &= \frac{1+2\varepsilon}{y^2 H^{3/2}} + \frac{3\{\varepsilon^2(y-1)^2-(1+\varepsilon)[\varepsilon(y-2)-1]\}}{(1+\varepsilon y)^2 y^2(1+\varepsilon)H^{5/2}} \\ &\quad + \frac{30\varepsilon^3}{(1+\varepsilon y)^2}\int_0^v te^{t^2}(1-e^{-t^2})^3 G^{-7/2}\,dt.\end{aligned} \tag{3.8}$$

Then $\partial P/\partial y > 0$ for $y \in (1, 2+\varepsilon^{-1})$. The conclusion of the lemma follows readily.

We now proceed with the proof of Theorem 1. We mean that a function $Q(x)$ has a wiggle at a critical point $x=x_0$, or that x_0 is a wiggle-point of Q, if there exists a $\delta>0$ such that $Q'(x)<0$ ($Q'(x)>0$) for $x\in(x_0-\delta, x_0)$ and $Q'(x)>0$ ($q'(x)<0$) for $x\in(x_0, x_0+\delta)$. Therefore, to prove Theorem 1, we ought to show that $f(y;\varepsilon)$ is either monotonic or so-called "S-shaped," i.e., having two wiggles. We prove this by contradiction. Since $f(1;\varepsilon)=0$ and $f(y;\varepsilon)\to\infty (y\to\infty)$, f must be a function with an even number of wiggles. Suppose that f is neither monotonic nor does it have two wiggles. Then it must have at least four wiggles. Without loss of generality we assume that f has exactly four wiggles. Let the leftmost wiggle-point be x_1 at which f takes the local maximum and $f''\leqq 0$; the remaining wiggle-points in turn are $x_2<x_3<x_4$. By Lemma 2, given ε, there is at most one zero among $f''(x_i)$ $(i=1,2,3,4)$. We consider two subcases about $f''(x_i)$: (1) neither of them is zero; (2) only one is zero. If case (1) holds, then $f''(x_i)<0$ and $P(x_i)<0$ for $i=1,3$, and $f''(x_j)>0$ and $P(x_j)>0$ for $j=2,4$, which contradicts Lemma 2. If case (2) holds, say $f''(x_1)=0$, then $P(x_1)=0$. However, the fact that $f''(x_2)>0$ and $f''(x_3)<0$ implies $P(x_2)>0$ and $P(x_3)<0$. Again, it violates Lemma 2. Similarly, we can prove that it is impossible for any of the $f''(x_j)(j=2,3,4)$ to become zero. This means the previous assumption that f has at least four wiggles is wrong. The proof of Theorem 1 is complete.

The remaining lemmas are concerned with the proof of Theorem 2.

LEMMA 3. *There exists an ε_0, a value of ε, such that $f(y;\varepsilon)$ is a function with two wiggles for $\varepsilon\in(0,\varepsilon_0)$.*

LEMMA 4. *$f(y;0)$ is a function with exactly one wiggle, and takes its maximum at $x_0=2+\alpha$, where α is a constant.*

LEMMA 5. *Let α be chosen as in Lemma 4. Then $f'(y;\varepsilon)>0$ for all $y>1$ and for all $\varepsilon \geqq 1/\alpha$.*

Lemma 3 is the main result of [6].

Proof of Lemma 4. Elementary calculations show that

$$f(y;0) = \frac{\sqrt{2}}{y}\int_0^{\sqrt{\ln y}} e^{t^2}\,dt, \tag{3.9}$$

$$f'(y;0)=\frac{1}{y\sqrt{2\ln y}}-\frac{\sqrt{2}}{y^2}\int_0^{\sqrt{\ln y}} e^{t^2}\,dt, \tag{3.10}$$

$$f''(y;0)=\frac{-2}{y^2\sqrt{2\ln y}}-\frac{\sqrt{2}}{4y^2(2\ln y)^{3/2}}+\frac{2\sqrt{2}}{y^3}\int_0^{\sqrt{\ln y}} e^{t^2}\,dt. \tag{3.11}$$

Let $\Delta=\Delta(y)=f'(y;0)+2f'(y;0)/y$. Then $\Delta<0$ for all $y>1$, which means that $f''<0$ wherever $f'=0$; hence $f(y;0)$ is a function with only one wiggle at $x=x_0$, and takes the global maximum at x_0. Furthermore,

$$\begin{aligned} 2\sqrt{2\ln 2}\,f'(2;0) &= 1-\sqrt{\ln 2}\int_0^{\sqrt{\ln 2}} e^{t^2}\,dt \\ &= 1-\sqrt{\ln 2}\int_0^{\sqrt{\ln 2}} \sum_0^{\infty}\frac{t^{2n}}{n!}\,dt \\ &> 1-\left\{\ln 2+\frac{(\ln 2)^2}{3}+\frac{(\ln 2)^3}{10}\sum_0^{\infty}\left[\frac{\ln 2}{4}\right]^n\right\}. \end{aligned} \tag{3.12}$$

Using $\ln 2<0.7$, we obtain $2\sqrt{2\ln 2}\,f'(2;0)>0.09$, and hence $f(2;0)>0$. Similarly, we prove $f'(e;0)<0$. Therefore, the wiggle-point of $f(y;0)$, $x_0=2+\alpha$ for some $\alpha\in(0,e-2)$. This proves the lemma.

Proof of Lemma 5. Differentiating $f'(y;\varepsilon)$ with respect to ε yields

$$\frac{\partial^2 f}{\partial\varepsilon\partial y}=\frac{2(y-1)}{(1+\varepsilon y)^3 yH^{3/2}}+\frac{6\varepsilon}{(1+\varepsilon y)^3}\int_0^{v} te^{t^2}(1-e^{-t^2})^2G^{-5/2}\,dt. \tag{3.13}$$

It is seen from (3.13) that given $y>1$, $f'(y;\varepsilon)$ increases as ε does. Thus $f'(y;\varepsilon)>0$ for $y\in(1,2+\alpha]$ and for all $\varepsilon>0$, because $f'(y;0)>0$ for $y\in(1,2+\alpha)$ by the preceding lemma. If $y>2+\alpha$, then $y>2+\varepsilon^{-1}$, and hence $P(y;\varepsilon)>0$. Therefore, $f'(y;\varepsilon)>0$ for $y>2+\alpha$, for otherwise $f'\leqq 0$ leads $f''>0$; i.e., f would reach its minimum first on the left, which is impossible. This proves Lemma 5.

The geometrical meaning of Theorem 2 is as follows. There exists a value of ε, $\varepsilon_*>0$ such that $f(y;\varepsilon)$ has exactly two wiggles for $\varepsilon\in(0,\varepsilon_*)$, and that $f'(y;\varepsilon)\geqq 0$ for $\varepsilon\geqq\varepsilon_*$. To prove this, we define two subsets M and N on the real line as follows:

$$M=\{\varepsilon\,|\,f(y;\varepsilon)\text{ with only two wiggles for all }y>1\}, \tag{3.14}$$

$$N=\{\varepsilon\,|\,\varepsilon>0\text{ and }f'(y;\varepsilon)<0\text{ for some }y>1\}. \tag{3.14'}$$

LEMMA 6. *M is an open interval, and $M=N$.*

Proof. We first prove $M=N$. It is trivial that $M\subset N$ by the definition about the wiggle-point. Take an $\varepsilon\in N$, so that $f'(y';\varepsilon)<0$ for some $y'>1$. Since $f'(y;\varepsilon)\to\infty$ as $y\to 1+$ and $f(y;\varepsilon)\to\infty$ as $y\to\infty$, therefore $f'(y^-;\varepsilon)>0$ and $f'(y^+;\varepsilon)<0$ for some y^- and y^+, where $1<y^-<y'<y^+$. This leads us to the fact that f has at least two wiggles. Then, from the proof of Theorem 1, such $\varepsilon\in M$; hence $N\subset M$. Obviously, N is open and so is M. Also, M is nonempty and bounded from Lemmas 3 and 5. Note that the complement of N, $N^{\subset}=\{\varepsilon\,|\,f'(y;\varepsilon)\geqq 0\text{ for all }y>1\}$ is a continuum because $\varepsilon'\in N^{\subset}$ implies that $(\varepsilon',\infty)\subset N^{\subset}$ by $\partial^2 f/\partial\varepsilon\partial y>0$ from (3.13). Therefore, M is an open interval containing $(0,\varepsilon_0)$, where ε_0 is given by Lemma 3. This proves the lemma.

Now set $\varepsilon_*=\operatorname{Sup} M$. We see from the proof of Lemma 6 that $\varepsilon_*\in N^{\subset}$ and $f'(y;\varepsilon)\geqq 0$ for all $\varepsilon\geqq\varepsilon_*$, and that $\varepsilon\in M$ and f has exactly two wiggles for $\varepsilon<\varepsilon_*$. In fact, the next lemma shows that ε_* bifurcates the numbers of the steady-state solutions.

LEMMA 7. *$f'(y;\varepsilon)>0$ for all $\varepsilon>\varepsilon_*$, and $f'(y;\varepsilon)$ has a unique zero y_** (cf. Fig. 1).

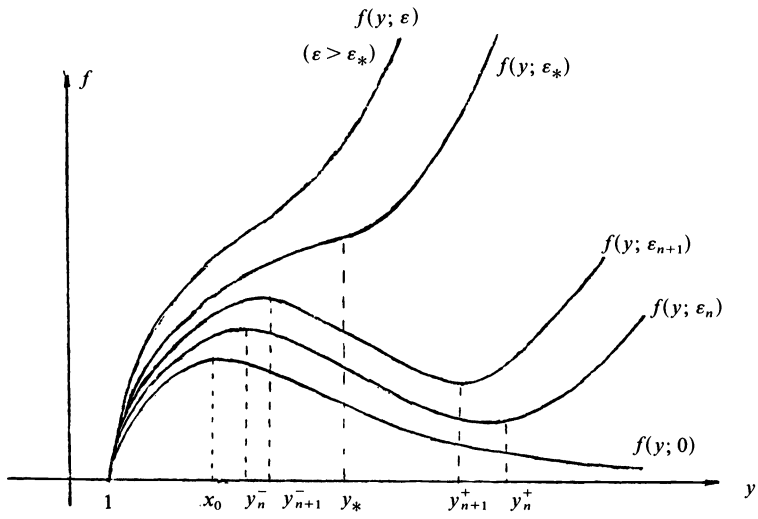

FIG. 1

Proof. Take a monotonically increasing sequence $\{s_n\}$ $n = 1, 2 \cdots$ such that $\varepsilon_n \uparrow \varepsilon_*$ as $n \to \infty$. Let $y_n^- < y_n^+$ be the two wiggle-points of $f(y;\varepsilon_n)$. Then $f'(y_n^-;\varepsilon_n) = f'(y_n^+;\varepsilon_n) = 0$, $f''(y_n^-;\varepsilon_n) \leqq 0$ and $f''(\varepsilon_n^+;\varepsilon_n) \leqq 0$ for all n. Also, $f'(y_{n+1}^-;\varepsilon_n) < 0$ and $f'(y_{n+1}^+;\varepsilon_n) < 0$ by $\partial^2 f/\partial\varepsilon\,\partial y > 0$. Thus $[y_n^-, y_n^+] \supset [y_{n+1}^-, y_{n+1}^+]$; hence there exist $y_*^- \leqq y_*^+$ such that $y_n^- \uparrow y_*^-$ and $y_n^+ \uparrow y_*^+$ as $n \to \infty$. Since f' and f'' are continuous on any subsets of the $y-\varepsilon$ plane, $[y', y''] \times [\varepsilon', \varepsilon'']$ where y', y'', ε', and ε'' are arbitrary real numbers, $f'(y_n^-;\varepsilon_n) \to f'(y_*^-;\varepsilon_*)$ and $f'(y_n^+;\varepsilon_n) \to f'(y_*^-;\varepsilon_*)$ as $n \to \infty$. Therefore $f'(y;\varepsilon_*)$ has zeros y_*^- and y_*^+. Next we prove the uniqueness of the zero by contradiction. Suppose that y_1 is the leftmost zero of $f'(y;\varepsilon_*)$, and y_2 the nearest zero to y_1. Then $f''(y_1;\varepsilon_*) \leqq 0$. If $f''(y_1;\varepsilon_*) < 0$, then $f'(y_1;\varepsilon_*) = 0$ implies $f' < 0$ for some $y > y_1$; hence $\varepsilon_* \in N$. This violates $\varepsilon_* \notin M$. If $f''(y_1;\varepsilon_*) = 0$, then $f''(y_2;\varepsilon_*) > 0$ by Lemma 2, and hence $f' < 0$ for some $y < y_2$. Again, it violates $s_* \notin M$. The lemma is proved.

Since $\partial^2 f/\partial\varepsilon\,\partial y > 0$, $f'(y;\varepsilon) > 0$ for all $\varepsilon > \varepsilon_*$ and for all $y > 1$. For $\varepsilon \in (0, \varepsilon_*)$, let $y_-(\varepsilon) < y_+(\varepsilon)$ be the two wiggle-points. We set $\beta_1 = [2\sqrt{k} f(y_-;\varepsilon)]^{-1}$ and $\beta_2(\varepsilon) = [2\sqrt{k} f(y_+;\varepsilon)]^{-1}$. Then the conclusions of Theorem 2 follow immediately.

4. Proof of Theorem 3. We will use the Morse Index Theorem to investigate the eigenvalue problem. For convenience, let $Q = Q(u) = \sigma F(u)$, where $F(u)$ is given in § 1. In this paper we use the following definition.

DEFINITION. A number λ and a nontrivial function $v(x)$ are called an eigenvalue and an eigenfunction (corresponding to λ) associated with $u(x)$, a solution of (2.1)-(2.1'), respectively, if they satisfy the following boundary value problem:

$$v'' - Q_u v = \lambda v, \qquad 0 < x < 1, \tag{4.1}$$

$$v(0) = v(1) = 0. \tag{4.1'}$$

It is well known that there exists a unique positive eigenfunction on $[0, 1]$, and that the corresponding eigenvalue is real and simple (cf. [8]). They are called fundamental or principal eigenfunction and eigenvalue. In this paper we always mean such eigenfunction and eigenvalue. Also, it is known that the parabolic partial differential equation (2.2)-(2.2') may be treated as a local flow in a certain function space W, and that the steady-state solution $u(x)$ is stable for $\lambda < 0$, and unstable for $\lambda > 0$ in the sense of Lyapunov.

Given $u(x)$, a solution of (2.1)-(2.1'), we introduce an operator $L=(d^2/dx^2)-Q_u$ on W. Define $L[v]=v''-Q_uv$ for $v\in W$. Then the Morse index of L on the interval $(0, 1]$ equals the number of positive eigenvalues associated with $u(x)$. Therefore, $u(x)$ is stable when the index is zero; $u(x)$ is unstable when the index is 1.

Remark. Suppose that $w(x)\in W$ and satisfies

$$L[w]=0, \qquad 0<x<1, \tag{4.2}$$

$$w(0)=0, \qquad w'(0)\neq 0. \tag{4.2'}$$

Then the number of zeros of functions of this kind on the interval $(0, 1]$ does not depend on choices of $w(x)$. We now introduce the Morse Index Theorem in this simple case.

MORSE INDEX THEOREM. *The Morse Index of the operator L is finite and equal to the number of zeros of any function $w(x)$ satisfying* (4.2)-(4.2') (*cf.* [3]).

To apply the Morse Index Theorem we construct the following functions:

$$w(x)=\begin{cases} u'(x)\displaystyle\int_0^x (u')^{-2}\,dt, & 0\leqq x<\tfrac{1}{2}, \\ u'(x)\left[A+\displaystyle\int_1^x (u')^{-2}\,dt\right], & \tfrac{1}{2}\leqq x<1, \end{cases} \tag{4.3}$$

where

$$A=\frac{2}{u''(\frac{1}{2})}\left[\frac{1}{u'(0)}+\int_0^{1/2}\frac{u'(\frac{1}{2})-u''(t)}{[u'(t)]^2}\,dt\right]. \tag{4.4}$$

It can be proved that $w(x)$ given by (4.3) is a C^2 function and satisfies (4.2)-(4.2'). All we need is to compute their zeros for different cases of $u(x)$.

LEMMA 8. *The number of zeros on* $(0, 1]$ *of* $w(x)$ *given by* (4.3) *is at most one. It is zero for* $A<0$, *and one for* $A>0$.

LEMMA 9. *Suppose that* $u(x)$ *solves* (2.1)-(2.1') *and* $u(\frac{1}{2})=1/y$. *If* $f'(y;\varepsilon)\neq 0$, *then* $u(x)$ *is nondegenerate, i.e., the eigenvalue of the operator L is nonzero. Furthermore, if* $f'(y;\varepsilon)>0$, *then* $u(x)$ *is stable; if* $f'(y;\varepsilon)<0$, *then* $u(x)$ *is unstable.*

Proof of Lemma 8. Since the solutions of (2.1)-(2.1') we studied are positive, $u''(x)>0$; hence $u'(x)<0$ in $[0, \frac{1}{2})$ and $u'(x)>0$ in $(\frac{1}{2}, 1]$. We observe from (4.3) that if $A<0$, then $w(x)<0$ for all $x\in(0, 1]$, and that if $A>0$, then $w(1)=Au'(1)>0$ implies that $w(x)$ has at least one zero on $(\frac{1}{2}, 1]$. On the other hand, since the function $\{A+\int_1^x [u'(t)]^{-2}\,dt\}$ is monotonically increasing and $u'>0$ for $x\in(\frac{1}{2}, 1]$, $w(x)$ has at most one zero on $(\frac{1}{2}, 1]$. This proves the lemma.

Proof of Lemma 9. For simplicity, let $M(u)=\int Q(u)\,du$. Then the response function $f(y;\varepsilon)$ becomes

$$f(y;\varepsilon)=\frac{1}{\beta}\int_{1/y}^1 \frac{du}{\sqrt{M(u)-M(1/y)}}. \tag{4.5}$$

Denote $u(\frac{1}{2})=\eta$ $(=1/y)$ and $T(\eta)=\beta f(1/\eta;\varepsilon)$. Then

$$T(\eta)=\int_0^{1-\eta}\frac{ds}{\sqrt{M(s+\eta)-M(\eta)}}, \tag{4.6}$$

$$T'(\eta) = -\frac{1}{\sqrt{M(1)-M(\eta)}} - \int_\eta^1 \frac{M'(u)-M'(\eta)}{2[\sqrt{M(u)-M(\eta)}]^3}\,du$$

$$= \sqrt{2}\left[-\frac{1}{u'(1)} - \int_{1/2}^1 \frac{u''(t)-u''(\tfrac{1}{2})}{[u'(t)]^2}\,dt\right] \tag{4.7}$$

$$= \sqrt{2}\left[\frac{1}{u'(0)} + \int_0^{1/2} \frac{u''(\tfrac{1}{2})-u''(t)}{[u'(t)]^2}\,dt\right],$$

because $u'' = Q(u)$ and $u'^2 = 2[M(u)-M(\eta)]$. It turns out from (4.4) that

$$A = \frac{\sqrt{2}\,T'(\eta)}{u''(\tfrac{1}{2})} = -\frac{\sqrt{2}\,\beta f'(y;\varepsilon)}{u''(\tfrac{1}{2})y^2}. \tag{4.8}$$

We have checked that $L[w]=0$ and $L[u']=0$, and that u' and w are linearly independent on $(0,1)$. Therefore, the general solution of the second-order differential equation $L[z]=0$ can be expressed by $z = c_1u' + c_2w$, where c_1 and c_2 are arbitrary constants. Suppose that $Y(0)=Y(1)=0$ and $L[Y]=0$. Then $Y\equiv 0$ on $[0,1]$ by the uniqueness of the solution of $L[z]=0$, which implies that the eigenvalue of L is nonzero. If $f'>0$, then $A<0$ by (4.8), and the Morse Index is zero by Lemma 8. Hence, by the Morse Index Theorem, the eigenvalue of L is negative. Therefore, $u(x)$ is stable. Similarly, if $f'<0$, then $u(x)$ is unstable.

The proof of Theorem 2 has already shown that (i) if $\varepsilon > \varepsilon_*$ then $f'(y;\varepsilon)>0$ for all $y \geqq 1$ and hence the unique steady-state solution is stable; (ii) if $0<\varepsilon<\varepsilon_*$ and $\beta \in (\beta_1, \beta_2)$, then there are three solutions u_1, u_2, and u_3 of (2.1)-(2.1′). Let $u_i(\frac{1}{2}) = 1/y_i$ $(i=1,2,3)$; hence $f'(y_j;\varepsilon)>0$ for $j=1,3$ and $f'(y_2;\varepsilon)<0$. By Lemma 9, we prove Theorem 3 immediately.

We can apply the Conley Index Theory to get more information about the global structure of the multiple steady states. It is seen that the Conley Index of u_2, $h(u_2)=\Sigma^1$, is a pointed circle, and the Conley Index of u_j, $h(u_j)=\Sigma^0$, is a pointed zero sphere $(j=1,3)$. Then there exist solutions v_1 and v_2 of (2.2)-(2.2′) connecting u_2 to u_1 and u_2 to u_3, respectively [10, Thm. 22.33], namely, $v_1(x,t)\to u_1(x)$ and $v_2(x,t)\to u_3(x)$ as $t\to\infty$, $v_1(x,t)\to u_2(x)$ and $v_2(x,t)\to u_2(x)$ as $t\to-\infty$ uniformly on $[0,1]$. Suppose that $u_*(x,t)$ solves (2.2)-(2.2′) with $u_*(x,0)=u_*(x)$. We claim that if $u_2(x)<u_*(x)<u_1(x)$ for $x\in(0,1)$, then u_* lies in the stable manifold of u_1, i.e., $u_*(x,t)\to u_1(x)$ as $t\to\infty$, while if $u_3(x)<u_*(x)<u_2(x)$ for $x\in(0,1)$, then u_* lies in the stable manifold of u_3. To see this, suppose, for example, that $u_1(x)>u_*(x)>u_2(x)$ for $x\in(0,1)$. Then $u_1(x)>u_*(x,t_0)>u_2(x)$ for some $t_0>0$ and $x\in(0,1)$, and it follows that $\partial u_*(0,t_0)/\partial x<0$ (because $u_*(x,t_0)<u_1<1$ and $u_*(0,t_0)=1$), and $\partial u_*(1,t_0)/\partial x>0$. Thus if v_1 is the solution connecting u_2 to u_1, then by the fact that $v_1(x,t)\to u_2$ as $t\to-\infty$ uniformly on $[0,1]$ we see that $v_1(x,t_0-t_1)<u_*(x,t_0)$ for some $t_1>0$. Let $w(x,t)\equiv v_1(x,t-t_1)$. Then $w(0,t)=w(1,t)=1$ and $w(x,t_0)<u_*(x,t_0)$. By the comparison theorem we obtain $w(x,t)<u_*(x,t)$ for all $t\geqq t_0$ and for $x\in(0,1)$. Meanwhile, $w(x,t)\to u_1(x)$ uniformly as $t\to\infty$, so that the same is true for $u_*(x,t)$; in other words, u_* lies in the stable manifold of u_1. In the same way, we can prove that if $u_3<u_*<u_2$, then u_* lies in the stable manifold of u_3.

We can also investigate the stability using the maximum principle to prove that the region of attraction of u_1 includes all initial distributions $v(x,0)$ satisfying $u_2(x)<v(x,0)\leqq 1$, while that of u_3 includes all $v(x,0)$ satisfying $\underline{u}(x)\leqq v(x,0)<u_2(x)$, where $\underline{u}(x) = (\cosh(x-\frac{1}{2})/2k\beta\varepsilon)/(\cosh(1/4k\beta\varepsilon)$ is a lower solution of (2.1) (cf. [7]). This is illustrated in Fig. 2.

SINGULAR LIMIT ANALYSIS OF STABILITY OF TRAVELING WAVE SOLUTIONS IN BISTABLE REACTION-DIFFUSION SYSTEMS*

Y. NISHIURA†, M. MIMURA†, H. IKEDA‡, AND H. FUJII§

Abstract. The stability properties of the traveling front solutions to bistable reaction-diffusion systems in which there are big differences in both the diffusion rates and the reaction rates between two species are studied. In contrast to the scalar case, this bistable system has multiple existence of traveling waves in the appropriate region of parameters. Each wave can be constructed by using a singular perturbation method, and its stability or instability is determined by a simple algebraic quantity appearing in its construction: namely, the sign of the Jacobian of inner and outer matching conditions. The singular limit approach (which is quite different from formal limiting arguments) adopted in this paper is rigorous and very useful in the study of stability problems of singularly perturbed solutions.

Key words. stability, traveling wave, singular perturbation, reaction-diffusion system

1. Introduction.

Bistable media are one of the basic machineries that create a variety of propagating patterns. Especially, traveling front waves describing the transition from one stable state to the other are the most essential and interesting ones for such media. For a two-component model system, we meet the following equations:

$$(P)_{\varepsilon,\tau} \qquad \begin{aligned} \varepsilon\tau u_t &= \varepsilon^2 u_{zz} + f(u, v), \\ v_t &= v_{zz} + g(u, v), \end{aligned} \qquad (t, z) \in (0, \infty) \times \mathbf{R}.$$

Here ε and τ are real parameters, where $\varepsilon\tau$ and ε/τ are, respectively, the ratios of the rates of reaction and diffusion of the quantities u and v. Suppose that ε is sufficiently small. When τ is of the order ε, the diffusion rates of u and v are of the same order, but u reacts much faster than v. On the other hand, when τ is of order $1/\varepsilon$, u reacts with the same order as v, although there is a big difference between the diffusion rates of u and v. The qualitative information about f and g is depicted in Fig. 1: f is a cubic-like function, and $g = 0$ intersects with $f = 0$ at three points $E_\pm$ and E_0.

Note that E_+ and E_- are stable constant solutions of $(P)_{\varepsilon,\tau}$. It is natural to expect the existence of traveling fronts connecting E_- to E_+. For such an existence problem, we know at least numerically that, when $\tau = O(\varepsilon)$, there occurs a multiple existence of traveling front solutions. On the other hand, when $\tau = O(1/\varepsilon)$, there is one solution [9] that is proved to be stable in [11]. We can imagine from this that a certain transition process might happen to the structure of solutions when τ varies between two extreme values. In fact, Ikeda, Mimura, and Nishiura [10] have recently studied the case $\tau = O(1)$, where there are differences in *both* reaction and diffusion rates between u and v, namely, u reacts much faster than v but diffuses much slower than v. It is noteworthy that the number of traveling fronts connecting E_- to E_+ depends crucially on the parameter τ. More precisely, on the one hand, there exists a unique traveling front solution for large τ and, on the other hand, there exist at least three solutions for small τ. In fact, when f and g are specified, respectively, as

$$f(u, v) = u(1-u)(u-a) - v \quad \text{and} \quad g(u, v) = u - \gamma v \tag{1.1}$$

with constants a and γ, Fig. 2 shows a typical situation of the dependency of traveling

front solutions on τ. This contrasts with the scalar reaction-diffusion equation of bistable type (see, e.g., Fife and McLeod [6]) where the front solution is always *unique* and *stable.* Multiple existence of traveling front solutions is also shown by Rinzel and Terman [16] for the bistable FitzHugh-Nagumo system with piecewise nonlinearity.

The aim of this paper is twofold concerning the stability properties of traveling front solutions of $(P)_{\varepsilon,\tau}$ when ε is sufficiently small and $\tau = O(1)$. First, we clarify the stability properties of the front solutions by using the Singular Limit Eigenvalue Problem (SLEP) method originated in [13] (see Theorems 3.1 and 3.2). Second, in Theorem 4.1 we give an alternative form of the stability criterion of Theorems 3.1 and 3.2, which essentially stems from the *geometrical* nature of the construction of singular limit traveling front solutions in § 2. Loosely speaking, our results can be summarized as follows.

MAIN THEOREM. *The linearized eigenvalue problem at a traveling front solution has a unique real simple eigenvalue besides the translation free zero eigenvalue and the rest of the spectrum lies strictly inside of the left halfplane independently of the parameters ε and τ. This critical eigenvalue is obtained as a zero of a scalar equation called the* SLEP *equation (see* (3.68) *and* (3.69)), *and its sign determines the stability of the traveling front, namely, positive (respectively, negative) means unstable (respectively, asymptotically stable in the orbital sense). Moreover, the sign of the critical eigenvalue is equal to that of the Jacobian of the C^1-matching conditions for outer and inner solutions of a singularly perturbed traveling front wave (see* (2.16) *and* (4.25)).

The last statement is close to the spirit of Evans' works [3], [4], which relate the stability of nerve pulse to the intersecting manner of stable and unstable manifolds. This geometrical interpretation of the stability criterion is very useful in a practical sense. Namely, when we construct a lowest-order approximation to a traveling front solution as $\varepsilon \downarrow 0$, we can judge its stability *simultaneously.* In fact, by looking at the schematic diagram Fig. 2, we can say from the construction of each solution that, except for the limit point, the upper and the lower branch are stable, while the middle one is unstable. This is quite reasonable from a bifurcation point of view. The details will be shown in § 4.

The idea of the SLEP method is to derive a limiting linearized eigenvalue problem as $\varepsilon \downarrow 0$ without losing information coming from the transition layer. It turns out that a Dirac point mass (in the one-dimensional case) appears in the limit of $\varepsilon \downarrow 0$ after an appropriate scaling, and the coefficient of it is determined by the global geometrical quantities of f and g. After some computation, the whole problem is reduced to solving a transcendental equation, or more geometrically, to finding intersection points of a straight line and a convex curve, which tells us the limiting location of dangerous eigenvalues to the stability (see (3.69)). See [12]-[15] for the details of the SLEP method and its applications.

What we would like to emphasize in this paper is that the singular limit analysis as $\varepsilon \downarrow 0$ (which is essentially different from $\varepsilon = 0$) sheds light on the world of $\varepsilon > 0$.

Finally, Jones and Gardner [17] have notified us that a topological approach may work to solve the same stability problem as above.

We impose the following assumptions on the nonlinearities of f and g (see Fig. 1).

(A0) f and g are smooth functions of u and v on some open set Q in $\mathbf{R}^2$.

(A1) $f = 0$ is S-shaped and consists of three branches $u = h_-(v)$, $h_0(v)$, and $h_+(v)$ $(h_-(v) \leqq h_0(v) \leqq h_+(v))$, while $g = 0$ intersects once with each branch at $E_- = (u_-, v_-)$, E_0, and $E_+ = (u_+, v_+)$ $(v_- < v_+)$, respectively, as in Fig. 1. The signs of f and g are both negative in the upper region of the curves $f = 0$ and $g = 0$.

(A2) $J(v) \equiv \int_{h_-(v)}^{h_+(v)} f(u, v)\, du$ has a unique isolated zero at $v^* \in (v_{\min}, v_{\max})$.

(A3) $f_u(h_\pm(v), v) < 0$ for $v \in [v_-, v_+]$,

$g(h_-(v), v) < 0 < g(h_+(v), v)$ for $v \in (v_-, v_+)$,

$g_v(h_\pm(v), v) < 0$ for $v = v_\pm$,

$$\frac{\partial(f, g)}{\partial(u, v)}(h_\pm(v), v) > 0 \quad \text{for } v \in [v_-, v_+].$$

(A4) $f_v(u, v) < 0$ for $(u, v) \in \{(u, v) \mid h_-(v) \leqq u \leqq h_+(v),\ v_- \leqq v \leqq v_+\}$,

$g_u(u, v) > 0$ at $(u, v) = (u_\pm, v_\pm)$.

Remark 1.1. The assumption for the sign of $(\partial(f, g)/\partial(u, v))(h_\pm(v), v)$ is equivalent to

$$\frac{d}{dv} g(h_\pm(v), v) < 0 \quad \text{for } v \in [v_-, v_+],$$

since, from $f(h_\pm(v), v) = 0$,

$$\frac{d}{dv} g(h_\pm(v), v) = \left. \frac{f_u g_v - f_v g_u}{f_u} \right|_{(u,v)=(h_\pm(v),v)}$$

holds.

Throughout this paper, we will use the following function spaces and notation. Let $I = \mathbf{R}_-$, $\mathbf{R}_+$ or $\mathbf{R}$, ρ, and σ be positive numbers, and let n be a nonnegative integer;

$$X^n_{\rho,\sigma}(I) \equiv \left\{ u \in C^n(I) \;\middle|\; \|u\|_{X^n_{\rho,\sigma}(I)} \equiv \sum_{i=0}^{n} \sup_{x \in I} \left| e^{\rho|x|} \left(\sigma \frac{d}{dx} \right)^i u(x) \right| < \infty \right\},$$

$$C_{\text{unif}}(I) \equiv \{u \mid u \text{ is bounded and uniformly continuous on } I\},$$

$$\mathbf{C}_{\text{unif}}(I) \equiv C_{\text{unif}}(I) \times C_{\text{unif}}(I),$$

$$H^n_\rho(I) \equiv \left\{ u \in H^n(I) \;\middle|\; \|u\|_{H^n_\rho(I)} \equiv \left\{ \sum_{i=0}^{n} \int_I \left| e^{\rho|x|} \left(\frac{d}{dx} \right)^i u(x) \right|^2 dx \right\}^{1/2} < \infty \right\}$$

where $H^n(I)$ is the usual Sobolev space on I;

$$L^2_\rho(I) \equiv H^0_\rho(I),$$

$$(H^n_\rho)^*(I) \equiv \text{the dual space of } H^n_\rho(I),$$

$\langle \cdot, \cdot \rangle$; L^2 inner product. $\langle \cdot, \cdot \rangle_x$ is also used to specify the independent variable;

$$\mathbf{C}_\mu \equiv \{\lambda \in \mathbf{C} \mid \operatorname{Re} \lambda > -\mu,\ \mu \in \mathbf{R}_+\},$$

$\sigma_e(\mathscr{L})$ identically equals the set of the essential spectrum of the operator $\mathscr{L}$; $C^n_{\text{c.u.}}(I)$ identically equals the uniform convergence on any compact subset of I in $C^n(I)$-sense.

2. Construction of traveling front solutions. In this section we will summarize the existence results of traveling front solutions studied in the previous paper [10]. Introducing the traveling coordinate $x = z + ct$, we find that traveling front solutions with velocity c satisfy

$$\begin{aligned} &\varepsilon^2 u_{xx} - \varepsilon c \tau u_x + f(u, v) = 0, \\ &v_{xx} - c v_x + g(u, v) = 0, \end{aligned} \qquad x \in \mathbf{R} \tag{2.1}$$

with boundary conditions

$$u(\pm\infty) = u_\pm, \qquad v(\pm\infty) = v_\pm. \tag{2.2}$$

To avoid the phase ambiguity, we impose the following condition on $u(x)$:

$$u(0) = \alpha \tag{2.3}$$

where α is an arbitrarily fixed value in some interval (see § 2.2). Moreover, we put

$$v(0) = \beta \tag{2.4}$$

for $\beta \in (v_-, v_+)$, which will be determined later.

We divide the whole interval $\mathbf{R}$ into two subintervals $\mathbf{R}_-$ and $\mathbf{R}_+$. First, fix c and β arbitrarily, and look for solutions $(u_\pm, v_\pm)$ of the following boundary value problem on each subinterval $\mathbf{R}_\pm$ with the aid of outer and inner approximations:

$$\begin{aligned} &\varepsilon^2(u_\pm)_{xx} - \varepsilon c\tau(u_\pm)_x + f(u_\pm, v_\pm) = 0, \\ &(v_\pm)_{xx} - c(v_\pm)_x + g(u_\pm, v_\pm) = 0, \\ &u_\pm(\pm\infty) = u_\pm, \qquad u_\pm(0) = \alpha, \\ &v_\pm(\pm\infty) = v_\pm, \qquad v_\pm(0) = \beta. \end{aligned} \qquad x \in \mathbf{R}_\pm, \tag{2.5}_\pm$$

Second, we derive two relations between c and β through C^1-matching of the outer and inner solutions of $(2.5)_\pm$ at $x = 0$, respectively, and construct singular limit solutions by taking the intersection of these two relations. Finally, using a singular limit solution, we obtain a solution (u, v) of (2.1), (2.2) for some $c = c(\varepsilon)$ (see Fig. 3).

2.1. Outer solutions. Fig. 3 shows that the derivatives of $u_\pm(x)$ are moderate in the region away from a layer position. Therefore, the solutions of the following limiting equations of $(2.5)_\pm$ as $\varepsilon \downarrow 0$ could become good approximations there:

$$\begin{aligned} &f(u_\pm, v_\pm) = 0, \\ &(v_\pm)_{xx} - c(v_\pm)_x + g(u_\pm, v_\pm) = 0, \qquad x \in \mathbf{R}_\pm, \\ &v_\pm(\pm\infty) = v_\pm, \qquad v_\pm(0) = \beta. \end{aligned} \tag{2.6}_\pm$$

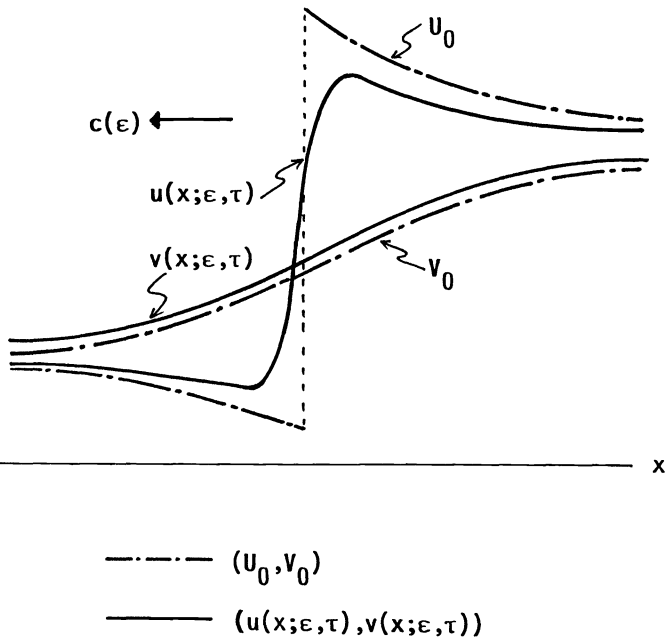

FIG. 3. *The profile of a traveling front solution* $(u(x; \varepsilon, \tau), v(x; \varepsilon, \tau))$ *and its outer solution* (U_0, V_0).

As particular solutions of the first equation, we take $u_\pm = h_\pm(v_\pm)$ (see (A1)). Substituting this into the second equation, we see that $(2.6)_\pm$ is reduced to

$$(2.7)_\pm \qquad \begin{aligned} &(V_\pm)_{xx} - c(V_\pm)_x + g(h_\pm(V_\pm), V_\pm) = 0, \qquad x \in \mathbf{R}_\pm, \\ &V_\pm(\pm\infty) = v_\pm, \qquad V_\pm(0) = \beta. \end{aligned}$$

LEMMA 2.1. *For any fixed $c \in \mathbf{R}$ and $\beta \in (v_-, v_+)$, there exist unique strictly monotone increasing solutions $V_0^\pm(x; c, \beta)$ of $(2.7)_\pm$ satisfying*

$$|V_0^\pm(x; c, \beta) - v_\pm| \in X^2_{\mu(c),1}(\mathbf{R}_\pm)$$

where $\mu(c) = \min\{\mu_-(c), \mu_+(c)\}$ and $\mu_\pm(c)$ are positive roots of $\mu_\pm^2 - c\mu_\pm + (d/dv)g(h_\pm(v_\pm), v_\pm) = 0$. Moreover, $V_0^\pm(x; c, \beta)$ are continuous with respect to $(c, \beta) \in \mathbf{R} \times (v_-, v_+)$ in the $X^2_{\mu(c),1}(\mathbf{R}_\pm)$-topology and satisfy

$$(2.8) \qquad \frac{\partial}{\partial c}\left[\frac{d}{dx} V_0^-(0; c, \beta) - \frac{d}{dx} V_0^+(0; c, \beta)\right] > 0$$

and

$$(2.9) \qquad \frac{\partial}{\partial \beta}\left[\frac{d}{dx} V_0^-(0; c, \beta) - \frac{d}{dx} V_0^+(0; c, \beta)\right] > 0.$$

LEMMA 2.2. (outer matching condition). *For any fixed $c \in \mathbf{R}$, there uniquely exists $\beta = \beta_0(c) \in C^1(\mathbf{R})$ satisfying*

$$\frac{d}{dx} V_0^-(0; c, \beta_0(c)) - \frac{d}{dx} V_0^+(0; c, \beta_0(c)) = 0,$$

which is a strictly monotone decreasing function of $c \in \mathbf{R}$ and converges to $v_\pm$ as $c \to \mp\infty$, respectively. Moreover, for $v^* \in (v_-, v_+)$,

$$I(v^*) \gtreqless 0 \quad \text{if and only if} \quad \beta_0(0) \gtreqless v^*$$

where $I(\beta) = \int_{v_-}^{\beta} g(h_-(v), v)\, dv + \int_{\beta}^{v_+} g(h_+(v), v)\, dv$.

We define $U_0^\pm(x; c, \beta)$ by

$$U_0^\pm(x; c, \beta) = h_\pm(V_0^\pm(x; c, \beta)), \qquad x \in \mathbf{R}_\pm.$$

We denote the C^1-matching *outer solution* on the whole line by

$$(2.10)_a \qquad V_0(x; c) \equiv \begin{cases} V_0^-(x; c, \beta_0(c)), & x \in \mathbf{R}_-, \\ V_0^+(x; c, \beta_0(c)), & x \in \mathbf{R}_+ \end{cases}$$

and

$$(2.10)_b \qquad U_0(x; c) \equiv \begin{cases} h_-(V_0^-(x; c, \beta_0(c))), & x \in \mathbf{R}_-, \\ h_+(V_0^+(x; c, \beta_0(c))), & x \in \mathbf{R}_+ \end{cases}$$

(see Fig. 3.)

2.2. Inner solutions. Since the outer solutions $U_0^\pm(x; c, \beta)$ do not satisfy the boundary condition at $x = 0$, we must remedy them in a neighborhood of $x = 0$. For this purpose, it is convenient to introduce the stretched variable $y = x/\varepsilon$. Substituting $(U_0^\pm + W_0^\pm, V_0^\pm)$ into $(2.5)_\pm$ with remedy terms $W_0^\pm(y)$, and putting $\varepsilon = 0$, we obtain the following problems for $W_0^\pm$:

$$(2.11)_\pm \qquad \begin{aligned} &(W_0^\pm)_{yy} - c\tau(W_0^\pm)_y + f(h_\pm(\beta) + W_0^\pm, \beta) = 0, \qquad y \in \mathbf{R}_\pm, \\ &W_0^\pm(0) = \alpha - h_\pm(\beta), \\ &W_0^\pm(\pm\infty) = 0 \end{aligned}$$

where β and α are arbitrarily fixed constants satisfying $\beta \in (v_-, v_+)$ and $\alpha \in (h_-(\beta), h_+(\beta))$. That is, the inner transition layer is stretched on the whole line and connects $h_-(\beta)$ to $h_+(\beta)$.

LEMMA 2.3 (Fife and McLeod [6]). *For any fixed $\beta \in [v_-, v_+]$, consider the following problem*:

$$\begin{aligned} &W_{yy} - cW_y + f(W, \beta) = 0, \qquad y \in \mathbf{R}, \\ &W(\pm\infty) = h_\pm(\beta), \qquad W(0) = \alpha. \end{aligned} \tag{2.12}$$

Then there exists $c = c_0(\beta)$ such that (2.12) *has a unique strictly monotone increasing solution $W(y; c_0(\beta), \beta)$ satisfying*

$$|W(y; c_0(\beta); \beta) - h_\pm(\beta)| \in X^2_{\sigma_\pm(\beta),1}(\mathbf{R}_\pm)$$

where

$$\sigma_\pm(\beta) = [\mp c_0(\beta) + \sqrt{(c_0(\beta))^2 - 4f_u(h_\pm(\beta), \beta)}]/2$$

and

$$c_0(\beta) \gtreqless 0 \quad \textit{if and only if } J(\beta) \gtreqless 0.$$

It is almost clear from Lemma 2.3 that the derivatives of W_0^+ and W_0^- are matched at $x = 0$ if and only if c is equal to $c_0(\beta)/\tau$.

LEMMA 2.4 (inner matching condition). *For any fixed $\beta \in [v_-, v_+]$, let*

$$c_I(\beta; \tau) \equiv c_0(\beta)/\tau. \tag{2.13}$$

Then there exists $\delta_0 > 0$ such that for any fixed $(\hat{c}, \hat{\beta}) \in \Lambda_{\delta_0} \equiv \{(\hat{c}, \hat{\beta}) \,|\, |\hat{c} - c_I(\beta; \tau)| + |\hat{\beta} - \beta| \leqq \delta_0\}$, $(2.11)_\pm$ have unique strictly monotone increasing solutions $W_0^\pm(y; \tau, \hat{c}, \hat{\beta})$ satisfying

$$|W_0^\pm(y; \tau, \hat{c}, \hat{\beta}) - h_\pm(\hat{\beta})| \in X^2_{\sigma_\pm(\tau),1}(\mathbf{R}_\pm)$$

where $\sigma_\pm(\tau) = \inf_{(\hat{c},\hat{\beta}) \in \Lambda_{\delta_0}} \sigma_\pm(\tau; \hat{c}, \hat{\beta})$ with

$$\sigma_\pm(\tau; c, \beta) \equiv [\mp c\tau + \sqrt{(c\tau)^2 - 4f_u(h_\pm(\beta), \beta)}]/2.$$

Furthermore, $W_0^\pm(y; \tau, \hat{c}, \hat{\beta})$ are continuous with respect to $(\hat{c}, \hat{\beta}) \in \Lambda_{\delta_0}$ in the $X^2_{\sigma_\pm(\tau),1}(\mathbf{R}_\pm)$-topology and

$$\frac{d}{dy} W_0^-(0; \tau, c_I(\beta; \tau), \beta) - \frac{d}{dy} W_0^+(0; \tau, c_I(\beta; \tau), \beta) = 0, \tag{2.14}$$

$$\frac{\partial}{\partial c}\left[\frac{d}{dy} W_0^-(0; \tau, c_I(\beta; \tau), \beta) - \frac{d}{dy} W_0^+(0; \tau, c_I(\beta; \tau), \beta)\right] > 0, \tag{2.15}_a$$

$$\frac{\partial}{\partial \beta}\left[\frac{d}{dy} W_0^-(0; \tau, c_I(\beta; \tau), \beta) - \frac{d}{dy} W_0^+(0; \tau, c_I(\beta; \tau), \beta)\right] > 0. \tag{2.15}_b$$

Remark 2.1. It follows from (2.14) and (2.15) that $(d/d\beta)c_I(\beta, \tau) (= (1/\tau) \times (d/d\beta)c_0(\beta))$ is strictly negative for $\beta \in [v_-, v_+]$. Therefore there exists an inverse function of (2.13), say $\beta = \beta_I(c; \tau)$, that is strictly decreasing for $c \in (c_I(v_+; \tau), c_I(v_-; \tau))$.

Remark 2.2. The definition domain for β can be extended to $(v_{\min}, v_{\max})$ in Lemma 2.4, since Lemma 2.3 holds for $\beta \in (v_{\min}, v_{\max})$.

2.3. Singular limit traveling front solutions. It is clear that the lowest-order approximations $(U_0^\pm(x; c, \beta) + W_0^\pm(x; \tau, c, \beta), V_0^\pm(x; c, \beta))$ of $(2.5)_\pm$ are matched at $x = 0$ in the C^0-sense. To construct an exact solution for small positive ε on the whole

line $\mathbf{R}$, the singular perturbation method requests C^1-continuity of these approximations so that their derivatives must be matched at $x=0$ in the C^0-sense. Thus, we impose the following conditions on $(W_0^{\pm}, V_0^{\pm})$:

$$\begin{aligned}&\Phi_0(\tau, c, \beta) \equiv \frac{d}{dy} W_0^-(0; \tau, c, \beta) - \frac{d}{dy} W_0^+(0; \tau, c, \beta) = 0,\\ &\Psi_0(c, \beta) \equiv \frac{d}{dx} V_0^-(0; c, \beta) - \frac{d}{dx} V_0^+(0; c, \beta) = 0.\end{aligned} \tag{2.16}$$

It turns out from Lemmas 2.2 and 2.4 that the above relations are equivalent to the conditions:

$$\beta = \beta_0(c) \tag{2.17}$$

and

$$c = c_0(\beta)/\tau. \tag{2.18}$$

From Remark 2.1, the latter is equivalent to

$$\beta = \beta_I(c; \tau). \tag{2.19}$$

Note that both β_0 and β_I are C^1-functions and strictly decreasing as in Fig. 4 (see also Remark 2.2). Geometrically, the solution set for (2.16) is represented by the intersection points of two curves $\beta = \beta_0(c)$ and $\beta = \beta_I(c; \tau)$.

For any given $\tau > 0$, let (c^*, β^*) be an arbitrary intersection point of (2.17) and (2.19). Define $(u_0(x; \varepsilon, \tau), v_0(x; \varepsilon, \tau))$ by

$$u_0(x; \varepsilon, \tau) = \begin{cases} U_0^-(x; c^*, \beta^*) + W_0^-\left(\dfrac{x}{\varepsilon}; \tau, c^*, \beta^*\right), & x \in \mathbf{R}_-, \\ U_0^+(x; c^*, \beta^*) + W_0^+\left(\dfrac{x}{\varepsilon}; \tau, c^*, \beta^*\right), & x \in \mathbf{R}_+ \end{cases} \tag{2.20}_a$$

and

$$v_0(x; \varepsilon, \tau) = \begin{cases} V_0^-(x; c^*, \beta^*), & x \in \mathbf{R}_-, \\ V_0^+(x; c^*, \beta^*), & x \in \mathbf{R}_+. \end{cases} \tag{2.20}_b$$

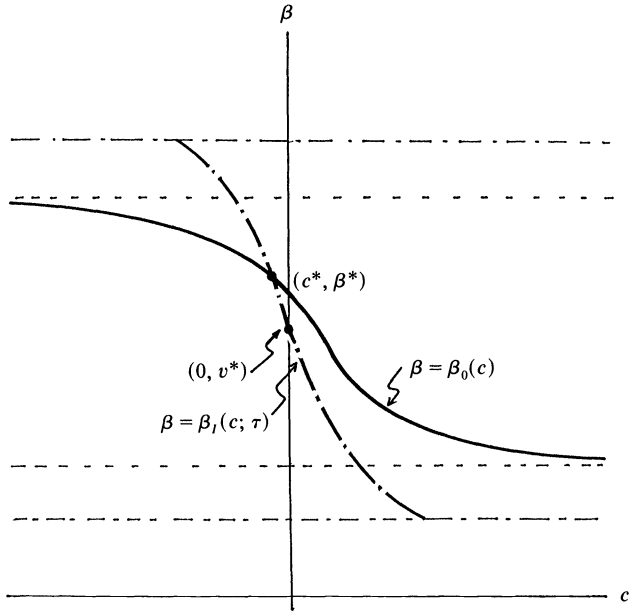
We call $(u_0(x; \varepsilon, \tau), v_0(x; \varepsilon, \tau))$ a *singular limit traveling front solution* of (2.1)-(2.3) with the *singular limit velocity* c^*.

The following theorem shows that the number of the singular limit traveling front solutions varies depending on τ and the location of v^* (see (A2)).

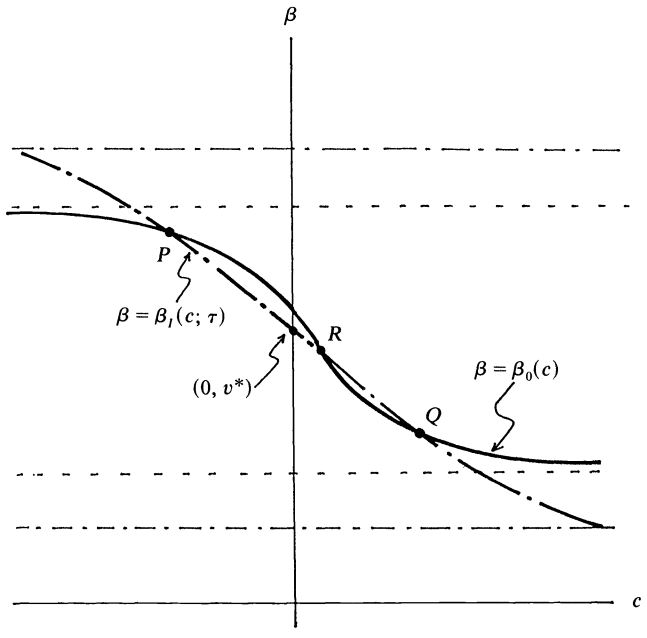
THEOREM 2.1. *Suppose that* (A0)-(A4) *hold. When* $v^* \in (v_-, v_+)$, (2.1)-(2.3) *has three singular limit traveling front solutions for small* τ *and has only one for large* τ. (*See Fig.* 2.) *On the other hand, when* $v^* \in (v_{\min}, v_{\max}) \backslash (v_-, v_+)$, *it has only one for both small and large* τ.

2.4. Traveling front solutions for $\varepsilon > 0$. Using a singular limit traveling front solution as an approximation, we can construct the exact solution of (2.1)-(2.3) with the aid of the standard singular perturbation method. Let (c^*, β^*) be an arbitrary intersection point of (2.17) and (2.19), and assume that

$$\frac{\partial(\Phi_0, \Psi_0)}{\partial(c, \beta)} \neq 0 \quad \text{at } (c^*, \beta^*), \tag{2.21}$$



(a) τ: large



(b) τ: small

FIG. 4. *The graphs of outer and inner matching conditions and their intersections. For large τ they have a unique intersection, but for small τ they have three intersecting points.*

which is equivalent to the following:

(2.22) The two curves of C^1-matching conditions $\beta=\beta_0(c)$ and $\beta=\beta_I(c;\tau)$ intersect with each other *transversally* at (c^*,β^*).

First we fix τ, c, and β and construct exact solutions of $(2.5)_\pm$ on each subinterval $\mathbf{R}_\pm$ for sufficiently small ε, which we denote by $(u^\pm(x;\varepsilon,\tau,c,\beta), v^\pm(x;\varepsilon,\tau,c,\beta))$ (see Lemma 3.2 of [10]), and then match these solutions at $x=0$ in C^1-sense. For this purpose, we define two functions Φ and Ψ as follows:

$$\begin{aligned}\Phi(\varepsilon,\tau,c,\beta)&\equiv\varepsilon\frac{d}{dx}u^-(0;\varepsilon,\tau,c,\beta)-\varepsilon\frac{d}{dx}u^+(0;\varepsilon,\tau,c,\beta),\\ \Psi(\varepsilon,\tau,c,\beta)&\equiv\frac{d}{dx}v^-(0;\varepsilon,\tau,c,\beta)-\frac{d}{dx}v^+(0;\varepsilon,\tau,c,\beta),\end{aligned}\tag{2.23}$$

and determine c and β as functions of ε such that

$$\Phi(\varepsilon,\tau,c,\beta)=0=\Psi(\varepsilon,\tau,c,\beta)\tag{2.24}$$

hold. Noting that Φ, Ψ, and their first derivatives with respect to c and β are uniformly continuous for $\varepsilon>0$, we can extend them continuously up to $\varepsilon=0$. Letting $\varepsilon=0$, (2.23) is reduced to (2.16), i.e.,

$$\Phi(0,\tau,c,\beta)=\Phi_0(\tau,c,\beta),\qquad \Psi(0,\tau,c,\beta)=\Psi_0(c,\beta).\tag{2.25}$$

As before, for any fixed $\tau>0$, let (c^*,β^*) be an arbitrary solution of (2.25). Recalling the nondegenerate condition (2.21), we easily see that

$$\frac{\partial(\Phi,\Psi)}{\partial(c,\beta)}\neq 0\tag{2.26}$$

holds at $(\varepsilon,\tau,c,\beta)=(0,\tau,c^*,\beta^*)$. Thus we can apply the Implicit Function Theorem to (2.24). That is, there is $\varepsilon_0>0$ such that there exist continuous functions $c(\varepsilon;\tau)$ and $\beta(\varepsilon;\tau)$ satisfying (2.24) for $\varepsilon\in[0,\varepsilon_0)$ and $\lim_{\varepsilon\downarrow 0}c(\varepsilon;\tau)=c^*$ and $\lim_{\varepsilon\downarrow 0}\beta(\varepsilon;\tau)=\beta^*$. We have reached the goal.

THEOREM 2.2. *Suppose that* (A0)-(A4) *hold and that, for a given* $\tau>0$, *the curves* (2.17) *and* (2.19) *intersect transversally at* (c^*,β^*). *Then, for any* $\varepsilon\in(0,\varepsilon_0)$ *there exists a traveling front solution* $(u(x;\varepsilon,\tau),v(x;\varepsilon,\tau))\in X^2_{\rho,\varepsilon}(\mathbf{R})\times X^2_{\rho,1}(\mathbf{R})$ *of the problem* (2.1)-(2.3), *satisfying*

$$\|u(\cdot;\varepsilon,\tau)-u_0(\cdot;\varepsilon,\tau)\|_{X^1_{\rho,\varepsilon}(\mathbf{R})}+\|v(\cdot;\varepsilon,\tau)-v_0(\cdot;\varepsilon,\tau)\|_{X^1_{\rho,1}(\mathbf{R})}\to 0$$

as $\varepsilon\downarrow 0$. *Furthermore, the velocity* $c(\varepsilon;\tau)$ *converges to the singular velocity* c^* *as* $\varepsilon\downarrow 0$.

We simply denote this solution by $\mathcal{U}^\varepsilon=(u^\varepsilon,v^\varepsilon)$.

COROLLARY 2.1. *Suppose that* (A0)-(A4) *hold and fix* ε *to be sufficiently small. When* $v^*\in(v_-,v_+)$, (2.1)-(2.3) *has three traveling front solutions for small* τ *and has only one for large* τ. *On the other hand, when* $v^*\in(v_{\min},v_{\max})\backslash(v_-,v_+)$, *it has only one for both small and large* τ.

Let us specify f and g as (1.1). Then the solution structure is revealed for all τ as in Fig. 2.

Finally, we show the asymptotic behavior of the stretched traveling front solutions of Theorem 2.2 on any compact interval as $\varepsilon\downarrow 0$, which plays an important role in the next section.

LEMMA 2.5. *Let* $(u^\varepsilon, v^\varepsilon) = (u(x;\varepsilon,\tau), v(x;\varepsilon,\tau))$ *be a traveling front solution obtained in Theorem* 2.2, *and let* $(\tilde{u}^\varepsilon, \tilde{v}^\varepsilon)$ *be the stretched solution of* $(u^\varepsilon, v^\varepsilon)$, *namely,* $(\tilde{u}^\varepsilon, \tilde{v}^\varepsilon) \equiv (u(\varepsilon y;\varepsilon,\tau), v(\varepsilon y;\varepsilon,\tau))$. *Then we have*

$$\lim_{\varepsilon \downarrow 0} (\tilde{u}^\varepsilon, \tilde{v}^\varepsilon) = (W(y; c_0(\beta^*), \beta^*), \beta^*) \quad \text{in } C^2_{\text{c.u.}}(\mathbf{R})\text{-sense} \tag{2.27}$$

where $W(y; c_0(\beta^*), \beta^*)$ *is the unique monotone increasing solution of* (2.12).

Proof. By using (2.20) and Theorem 2.2, we can easily show (2.27). So we leave the details to the reader. See also Lemma 1.1 of [13].

Remark 2.3. Note that (2.27) contains the following result:

$$\lim_{\varepsilon \downarrow 0} \frac{d}{dy} \tilde{u}^\varepsilon = \frac{d}{dy} W(y; c_0(\beta^*), \beta^*) \quad \text{in } C^1_{\text{c.u.}}(\mathbf{R})\text{-sense.}$$

The following result is a direct consequence of Lemma 2.5.

COROLLARY 2.2. *Let* $F(u, v)$ *be a smooth function of* u *and* v. *Then, the composite function* $F(\tilde{u}^\varepsilon, \tilde{v}^\varepsilon)$ *satisfies*

$$\lim_{\varepsilon \downarrow 0} F(\tilde{u}^\varepsilon, v^\varepsilon) = F(W(y; c_0(\beta^*), \beta^*), \beta^*) \quad \text{in } C^2_{\text{c.u.}}(\mathbf{R})\text{-sense.}$$

We close this section by presenting a lemma on the embedding properties of the Hilbert space $H^1_\rho(\mathbf{R})$.

LEMMA 2.6. *The Hilbert space* $H^1_\rho(\mathbf{R})$ $(\rho > 0)$ *satisfies the following properties*:

(i) $H^1_\rho(\mathbf{R})$ *is continuously embedded in* $C_{\text{unif}}(\mathbf{R})$.

(ii) *A bounded set in* $H^1_\rho(\mathbf{R})$ $(\rho > 0)$ *is precompact in* $L^2_{\rho'}(\mathbf{R})$ *for* $0 < \rho' < \rho$.

Proof. Taking an expanding sequence of compact intervals that converges to the whole line, and applying the diagonal arguments with the Sobolev Embedding Theorem on a compact interval, we can prove two claims without difficulty by virtue of the exponential weight function in the definition of $H^1_\rho(\mathbf{R})$.

3. Criterion for the stability of traveling front solutions. In this section, we will study the stability of the traveling fronts obtained in the previous section. If we consider the linearized equations of $(P)_{\varepsilon,\tau}$ around the specified traveling front solutions, the spectrum of the resulting linearized problem consists of two parts; the essential spectrum and isolated eigenvalues. It is proved later that the former one is not dangerous (see Proposition 3.1) but the latter one is crucial to the stability (see Lemma 3.9 and Theorem 3.2). In § 3.3 we clarify the limiting location of the real isolated eigenvalues as $\varepsilon \downarrow 0$, which varies depending on the parameter τ. Finally, we show in § 3.4 that the limiting analysis in § 3.3 is valid for small but positive ε.

3.1. Linearized problem and preliminaries. Let us take an arbitrary traveling front solution $\mathcal{U}^\varepsilon \equiv (u^\varepsilon, v^\varepsilon)$ of (2.1)-(2.3). Recall that when τ is arbitrarily fixed, the velocity c is determined as a function of ε with the singular limit velocity $c^* = \lim_{\varepsilon \downarrow 0} c(\varepsilon)$. The original evolutional system $(P)_{\varepsilon,\tau}$ takes the following form after using the traveling coordinate $x = z + c(\varepsilon)t$ and shifting the origin to $\mathcal{U}^\varepsilon$:

$$\begin{pmatrix} \varepsilon\tau & 0 \\ 0 & 1 \end{pmatrix} \frac{\partial}{\partial t} \begin{pmatrix} \hat{u} \\ \hat{v} \end{pmatrix} = \mathcal{L}^\varepsilon \begin{pmatrix} \hat{u} \\ \hat{v} \end{pmatrix} + H(\hat{u}, \hat{v}) \tag{$\hat{P}$}_{\varepsilon,\tau}$$

where

$$\begin{pmatrix} \hat{u} \\ \hat{v} \end{pmatrix} \equiv \begin{pmatrix} u \\ v \end{pmatrix} - \begin{pmatrix} u^\varepsilon \\ v^\varepsilon \end{pmatrix}, \qquad \mathcal{L}^\varepsilon \equiv \begin{pmatrix} L^\varepsilon & f^\varepsilon_v \\ g^\varepsilon_u & M^\varepsilon \end{pmatrix}$$

with

$$L^\varepsilon \equiv \varepsilon^2 \frac{d^2}{dx^2} - c(\varepsilon)\varepsilon\tau \frac{d}{dx} + f_u^\varepsilon, \qquad M^\varepsilon \equiv \frac{d^2}{dx^2} - c(\varepsilon)\frac{d}{dx} + g_v^\varepsilon,$$

and

$$H(\hat{u}, \hat{v}) \equiv \begin{pmatrix} f(u, v) - f(u^\varepsilon, v^\varepsilon) - f_u^\varepsilon \hat{u} - f_v^\varepsilon \hat{v} \\ g(u, v) - g(u^\varepsilon, v^\varepsilon) - g_u^\varepsilon \hat{u} - g_v^\varepsilon \hat{v} \end{pmatrix}.$$

Here $f_u^\varepsilon, f_v^\varepsilon, g_u^\varepsilon$, and g_v^ε denote, respectively, the partial derivatives of f and g evaluated at $\mathcal{U}^\varepsilon$. The corresponding linearized eigenvalue problem is given by

$$(LP)_{\varepsilon,\tau} \qquad \mathcal{L}^\varepsilon \begin{pmatrix} w \\ z \end{pmatrix} \equiv \begin{bmatrix} L^\varepsilon & f_v^\varepsilon \\ g_u^\varepsilon & M^\varepsilon \end{bmatrix}, \qquad \begin{pmatrix} w \\ z \end{pmatrix} = \lambda \begin{pmatrix} \varepsilon\tau & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} w \\ z \end{pmatrix}.$$

The underlying space for $(\hat{P})_{\varepsilon,\tau}$ and $(LP)_{\varepsilon,\tau}$ can be taken as $\mathbf{X}_1 \equiv \mathbf{C}_{\text{unif}}(\mathbf{R})$ with

$$D(\mathcal{L}^\varepsilon) = \{\mathbf{U} = (w, z)^t \mid \mathbf{U}, \mathbf{U}_x, \mathbf{U}_{xx} \in \mathbf{X}_1\}. \tag{3.1}$$

Using the standard arguments, we can show that $\mathcal{L}^\varepsilon$ becomes a sectorial operator (see, for example, Henry [8]) and the spectral distribution of $\mathcal{L}^\varepsilon$ determines the nonlinear stability (or instability) in $\mathbf{X}_1^\alpha$-topology, where $\mathbf{X}_1^\alpha$ denotes the Banach space associated with the fractional power of $\mathcal{L}^\varepsilon$, namely,

$$\mathbf{X}_1^\alpha \equiv D((-\mathcal{L}^\varepsilon + \kappa I)^\alpha) \tag{3.2}$$

for an appropriate positive constant κ and $\alpha \in [0, 1)$ with the usual graph norm. Although the choice of the underlying space might be a problem of taste depending on the phenomena described by the model systems, $\mathbf{C}_{\text{unif}}(\mathbf{R})$ seems to have a natural topology for reaction-diffusion systems. Another choice is, for example, $L^2(\mathbf{R})$; however, in this case, the initial perturbation must satisfy some sort of decaying property at infinity. Nevertheless, it should be noted that there are no essential differences among underlying spaces as far as the discrete spectrum of $(LP)_{\varepsilon,\tau}$ is concerned, since the associated eigenfunctions decay exponentially as $|x| \to \infty$. Taking this advantage, we will look for the eigenfunctions in $H_\rho^1(R)$ $(\subset \mathbf{L}^2(\mathbf{R}))$ instead of $\mathbf{C}_{\text{unif}}(\mathbf{R})$, which is more convenient for our purposes. In view of $(LP)_{\varepsilon,\tau}$, we see that it becomes highly degenerated as $\varepsilon \downarrow 0$: the highest order of L^ε vanishes, and each coefficient in $\mathcal{L}^\varepsilon$ has a discontinuous point at the layer position in this limit. Therefore, it is not clear in advance what kind of singular behaviors and degeneracies will occur for eigenvalues as well as eigenfunctions in the limit of $\varepsilon \downarrow 0$. As we will see in § 3.3, the SLEP method is very useful in solving these problems, and it has worked nicely in various other problems (see Nishiura and Fujii [13], [14], Nishiura [12], and Nishiura and Mimura [15]).

In the remaining part of this section, we will present several preliminaries used to derive the SLEP equation in the next section. Hereafter we simply write c instead of $c(\varepsilon)$. The main thing is to clarify the spectral behavior of the singular Sturm–Liouville eigenvalue problem:

$$\begin{aligned} &L^\varepsilon \phi = \zeta \phi, \\ &\phi \in D(L^\varepsilon) \equiv \{\phi \mid \phi, \phi_x, \phi_{xx} \in C_{\text{unif}}(\mathbf{R})\}. \end{aligned} \tag{3.3}$$

Let ζ_0^ε and ϕ_0^ε be the principal eigenvalue and its eigenfunction of (3.3) satisfying

$\|\phi_0^\varepsilon\|_{L^2(\mathbf{R})} = 1$, respectively. It is convenient to introduce the stretched problem of (3.3):

$$\tilde{L}^\varepsilon \tilde{\phi} \equiv \left(\frac{d^2}{dy^2} - c\tau\frac{d}{dy} + \tilde{f}_u^\varepsilon\right)\tilde{\phi} = \zeta\tilde{\phi}, \tag{3.4}$$

$$\tilde{\phi} \in D(\tilde{L}^\varepsilon) \equiv \{\tilde{\phi} \mid \tilde{\phi}, \tilde{\phi}_y, \tilde{\phi}_{yy} \in C_{\text{unif}}(\mathbf{R})\}$$

where $y \equiv x/\varepsilon$ is a stretched variable and $\tilde{f}_u^\varepsilon$ is defined by $\tilde{f}_u^\varepsilon \equiv f_u(\tilde{u}^\varepsilon, \tilde{v}^\varepsilon)$. The L^2-normalized principal eigenfunction $\hat{\phi}_0^\varepsilon$ of (3.4) is defined by

$$\hat{\phi}_0^\varepsilon \equiv \sqrt{\varepsilon}\ \tilde{\phi}_0^\varepsilon = \sqrt{\varepsilon}\ \phi_0^\varepsilon(\varepsilon y). \tag{3.5}$$

Of course, the eigenvalues for (3.4) remain the same by stretching.

Remark 3.1. In general, the existence of the discrete spectrum for (3.3) is not trivial, however, we will show in the proof of Lemma 3.2 that there exists the principal eigenvalue of (3.3), which tends to zero as $\varepsilon \downarrow 0$, and that the associated eigenfunction decays exponentially as $|x| \to +\infty$.

Recalling Corollary 2.2, we see that the limiting form of the potential term $\tilde{f}_u^\varepsilon$ becomes

$$\lim_{\varepsilon \downarrow 0} \tilde{f}_u^\varepsilon = f_u(W(y; c_0(\beta^*), \beta^*), \beta^*) \quad \text{in } C^2_{\text{c.u.}}\text{-sense.}$$

We denote this limiting function by $\tilde{f}_u^*$. Therefore, the limiting Sturm–Liouville problem of (3.4) becomes

$$\tilde{L}^*\tilde{\phi} \equiv \left(\frac{d^2}{dy^2} - c^*\tau\frac{d}{dy} + \tilde{f}_u^*\right)\tilde{\phi} = \zeta\phi, \tag{3.6}$$

$$\tilde{\phi} \in D(\tilde{L}^*) = D(\tilde{L}^\varepsilon).$$

Remark 3.2. Differentiating (2.12) with respect to y for $c = c_0(\beta^*)$ $(= c^*\tau)$, we see that the limiting problem (3.6) has zero eigenvalue and the associated eigenfunction is given by $W_y(y; c_0(\beta^*), \beta^*)$.

Formally, the adjoint problem for (3.3) is given by

$$(L^\varepsilon)^* \phi^* = \zeta^* \phi^*, \qquad \phi^* \in D(L^\varepsilon)^* = D(L^\varepsilon) \tag{3.7}$$

where

$$(L^\varepsilon)^* \equiv \varepsilon^2 \frac{d^2}{dx^2} + c\varepsilon\tau\frac{d}{dx} + f_u^\varepsilon.$$

Apparently, the stretched adjoint problem is defined by

$$(\tilde{L}^\varepsilon)^* \tilde{\phi}^* = \zeta^* \tilde{\phi}^* \tag{3.8}$$

where

$$(\tilde{L}^\varepsilon)^* \equiv \frac{d^2}{dy^2} + c\tau\frac{d}{dy} + \tilde{f}_u^\varepsilon$$

with the same definition domain as (3.4). We denote by $\phi_0^{\varepsilon *}$ (respectively, $\hat{\phi}_0^{\varepsilon *} \equiv \sqrt{\varepsilon}\ \phi_0^{\varepsilon *}(\varepsilon y)$) the L^2-normalized principal eigenfunction of (3.7) (respectively, (3.8)) associated with the principal eigenvalue $\zeta^* = \zeta_0^\varepsilon$. Applying the change of dependent variables from ϕ (respectively, ϕ^*) to $\psi \equiv e^{-(c\tau/2\varepsilon)x}\phi$ (respectively, $\psi \equiv e^{(c\tau/2\varepsilon)x}\phi^*$), it is easily seen that (3.3) (respectively, (3.7)) is converted to the formal self-adjoint operator:

$$L_s^\varepsilon \psi \equiv \left[\varepsilon^2 \frac{d^2}{dx^2} + \left\{f_u^\varepsilon - \left(\frac{c\tau}{2}\right)^2\right\}\right]\psi = \zeta\psi. \tag{3.9}$$

Remark 3.3. Since the element in $D(L^\varepsilon)$ has no decaying property near $\pm\infty$, the formal adjoint operator of L^ε is not defined as (3.7). Therefore, at the present stage, it is not appropriate to call (3.7) the adjoint problem for (3.3). However, as we will see in the proof of Lemma 3.2, the eigenfunctions in $C_{\text{unif}}(\mathbf{R})$ of (3.3) (or (3.4)) decay exponentially as $|x|\to\infty$ (or $|y|\to\infty$), which may justify the above abuse. In fact, we will see that the problem (3.3) (or (3.7)) is equivalent to (3.9) in $L^2(\mathbf{R})$, as far as isolated eigenvalues are concerned.

Remark 3.4. There exists a one-to-one correspondence between the isolated eigenvalues and their eigenfunctions of L^ε and those of $(L^\varepsilon)^\#$. Namely, suppose (ζ, ϕ) (respectively, $(\zeta, \tilde{\phi})$) is an eigenpair of (3.3) (respectively, (3.4)); then $(\zeta, e^{-c\tau x/\varepsilon}\phi)$ (respectively, $(\zeta, e^{-c\tau y}\tilde{\phi})$) becomes an eigenpair of (3.7) (respectively, (3.8)). Note that eigenvalues are unchanged.

The principal eigenfunction of (3.4) and the y-derivative of the stretched u-component of the traveling front solution converge to the stretched inner layer solution as follows.

LEMMA 3.1. *Let ϕ_0^ε (respectively, $\phi_0^{\varepsilon *}$) be the L^2-normalized principal eigenfunction of L^ε (respectively, $(L^\varepsilon)^\#$), and let $\hat{\phi}_0^\varepsilon$ (respectively, $\hat{\phi}_0^{\varepsilon *}$) be the L^2-normalized stretched function of ϕ_0^ε (respectively, $\phi_0^{\varepsilon *}$), namely, $\hat{\phi}_0^\varepsilon = \sqrt{\varepsilon}\,\phi_0^\varepsilon(\varepsilon y)$ (respectively, $\hat{\phi}_0^{\varepsilon *} = \sqrt{\varepsilon}\,\phi_0^{\varepsilon *}(\varepsilon y)$). Then it holds that*

(i) $\lim_{\varepsilon\downarrow 0} \hat{\phi}_0^\varepsilon$ *(respectively,* $\tilde{u}_y^\varepsilon$*)* $= \gamma W_y(y; c_0(\beta^*), \beta^*)$ *(respectively,* $W_y(y; c_0(\beta^*), \beta^*)$*) in* $C^2_{\text{c.u.}}(\mathbf{R})$*-sense,*

(ii) $\lim_{\varepsilon\downarrow 0} \hat{\phi}_0^{\varepsilon *} = \gamma^\# W_y^\#(y; c_0(\beta^*), \beta^*)$ *in* $C^2_{\text{c.u.}}(\mathbf{R})$*-sense*

where γ and $\gamma^\#$ are the positive normalized constants given by

$$\gamma = \| W_y(y; c_0(\beta^*), \beta^*)\|_{L^2}^{-1} \quad \text{and} \quad \gamma^\# = \| W_y^\#(y; c_0(\beta^*), \beta^*)\|_{L^2}^{-1},$$

respectively, with $W_y^\#(y; c_0(\beta^*), \beta^*) \equiv e^{-c_0(\beta^*)\tau y} W_y(y; c_0(\beta^*), \beta^*)$.

Proof. In view of the construction of $(u^\varepsilon, v^\varepsilon)$ (see § 2, Ikeda, Mimura, and Nishiura [10]), and Remark 3.4, we can prove the above lemma as in Lemma 1.3 of Nishiura and Fujii [13].

LEMMA 3.2 (spectral properties of L^ε). *The essential spectrum of* (3.3) *is contained in the union of the left regions inside or at the boundaries of the two parabolas*:

$$\text{Re}\,\zeta = -(\text{Im}\,\zeta)^2/(\tau c)^2 + \alpha_\pm \tag{3.10}$$

where $\alpha_\pm = \lim_{x\to\pm\infty} f_u^\varepsilon < 0$. *The spectrum lying outside the above region consists of real isolated eigenvalues, and they have a strictly negative upper bound $-\mu_0$ for small ε except the principal eigenvalue ζ_0^ε, where μ_0 is a positive constant independent of ε. The principal eigenvalue ζ_0^ε is the unique critical eigenvalue of* (3.3) *(i.e., it approaches zero as $\varepsilon\downarrow 0$) and behaves as*

$$\zeta_0^\varepsilon = \hat{\zeta}_0(\varepsilon)\varepsilon \quad \text{as } \varepsilon\downarrow 0 \tag{3.11}$$

where $\hat{\zeta}_0(\varepsilon)$ is a continuous function of ε up to $\varepsilon = 0$ satisfying

$$\hat{\zeta}_0^* \equiv \lim_{\varepsilon\downarrow 0} \hat{\zeta}_0(\varepsilon) = -\left\{ c^*(\beta^* - v_-) - \int_{-\infty}^{0} g(U_0, V_0)\,dx \right\} \frac{dc_0(\beta^*)}{d\beta} > 0 \tag{3.12}$$

where (U_0, V_0) is the outer solution defined in (2.10) *and $c_0(\beta)$ is the inner velocity defined in Lemma* 2.3. (See Fig. 5.)

Proof. (i) Location of the essential spectrum. Since the traveling front solutions $\mathcal{U}^\varepsilon$ converge to the critical point with exponential order as $|x|\to\infty$, the coefficient f_u^ε of (3.3) becomes an asymptotically negative constant as $|x|\to\infty$. It is known (see, for example, Henry [8]) that the location of the essential spectrum $\sigma_e(L^\varepsilon)$ for such an

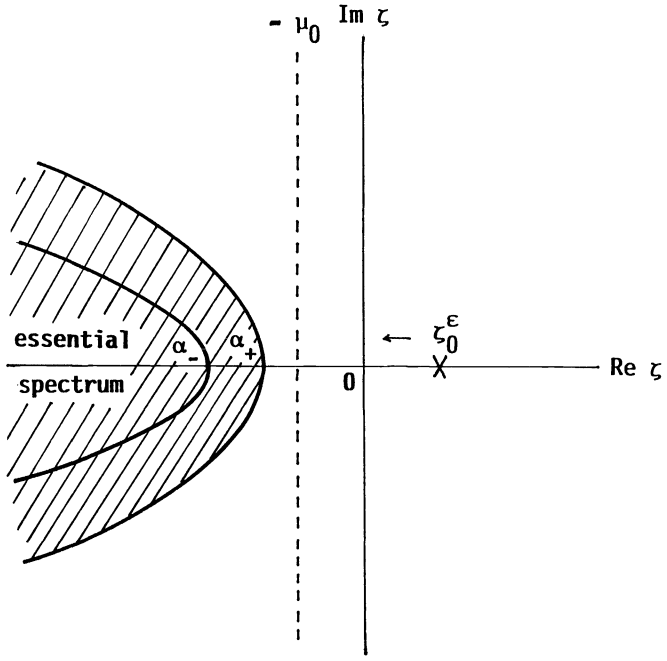


FIG. 5. *Spectral behavior of the singular Sturm–Liouville operator* L^ε.

operator as L^ε is contained in the union of the left regions inside or the boundaries of the following curves:

$$S_\pm = \{\zeta \mid -\varepsilon^2\gamma^2 - ic\varepsilon\tau\gamma + \alpha_\pm - \zeta = 0,\ -\infty < \gamma < \infty\} \tag{3.13}$$

where $\lim_{x\to\pm\infty} f_u^\varepsilon = \alpha_\pm$. It is easy to see that the sets $S_\pm$ are two parabolas in $\mathbf{C}$ defined by

$$\operatorname{Re}\zeta = -(\operatorname{Im}\zeta)^2/(c\tau)^2 + \alpha_\pm. \tag{3.14}$$

Note that the above two parabolas are uniformly bounded away from the imaginary axis for small ε.

(ii) Location of the isolated eigenvalues. Let ζ lie outside the union of the left regions inside or the boundaries of $S_\pm$. Suppose that such a ζ belongs to the spectrum of (3.3); then it must be an isolated eigenvalue. First, we will show that the associated eigenfunction must decay exponentially as $|x| \to \infty$. To do this, it suffices to consider the limiting first-order systems of (3.3) as $x \to \pm\infty$:

$$\frac{d}{dx}\begin{pmatrix}\phi\\ \phi_x\end{pmatrix} = \begin{pmatrix}0 & 1/\varepsilon\\ (-\alpha_\pm+\zeta)/\varepsilon & c\tau/\varepsilon\end{pmatrix}\begin{pmatrix}\phi\\ \phi_x\end{pmatrix}. \tag{3.15}_\pm$$

The eigenvalues of the matrix of the right-hand side are given by

$$\frac{c\tau}{2\varepsilon} \pm \frac{1}{2}\sqrt{\left(\frac{c\tau}{\varepsilon}\right)^2 + \frac{4}{\varepsilon^2}(-\alpha_\pm+\zeta)}. \tag{3.16}$$

Here we denote by $\frac{1}{2}\sqrt{(c\tau/\varepsilon)^2 + (4/\varepsilon^2)(-\alpha_\pm+\zeta)}$ the complex number whose real part is greater than $|c|\tau/2\varepsilon$. Note that the numbers in (3.16) become pure imaginary numbers if and only if ζ lies on the parabolic curves $S_\pm$ (see (3.13)). Since we assume that ζ is outside the parabolic regions, the real parts of (3.16) are not equal to zero. Therefore,

the real parts of two eigenvalues of (3.16) have the opposite sign. Suppose ζ is an eigenvalue and ϕ is the associated eigenfunction of (3.3) in $C_{\text{unif}}(\mathbf{R})$. Then it is well known from the general theory (see, for example, Coddington and Levinson [1]) that ϕ has the same asymptotic behaviors as those of solutions of $(3.15)_{\pm}$ when $x \to \pm\infty$. Namely, ϕ must decay exponentially as

$$|\phi| \simeq \exp\left\{\frac{c\tau}{2\varepsilon} \mp r_{\pm}(\zeta)\right\} x \quad \text{as } x \to \pm\infty \tag{3.17}$$

where $r_{\pm}(\zeta)$ are defined by

$$r_{\pm}(\zeta) \equiv \frac{1}{2} \operatorname{Re} \sqrt{\left(\frac{c\tau}{\varepsilon}\right)^2 + \frac{4}{\varepsilon^2}(-\alpha_{\pm} + \zeta)} \qquad \left(> \frac{|c|\tau}{2\varepsilon}\right). \tag{3.18}$$

Now let us apply the change of independent variables from ϕ to ψ as

$$\psi \equiv e^{-(c\tau/2\varepsilon)x}\phi. \tag{3.19}$$

Then, (3.3) is converted to the self-adjoint form (3.9). Note that the eigenvalues are invariant. It follows from (3.17) and (3.18) that ψ also decays exponentially strictly faster than $O(\exp(-(|c|\tau/2\varepsilon)|x|))$ in both directions $x \to \pm\infty$. Conversely, it is clear that any eigenvalue of (3.9) is real and the corresponding eigenfunction that belongs to $L^2(\mathbf{R})$ must decay exponentially as $|x| \to +\infty$. Therefore, it is easily seen that there is a *one-to-one correspondence* of the isolated eigenvalues between the problem (3.3) in $C_{\text{unif}}(\mathbf{R})$ and the problem (3.9) and $L^2(\mathbf{R})$. In fact they are exactly the same. Thus we can conclude that the eigenvalues of (3.3) are real and the associated eigenfunctions decay as does (3.17).

Next we will show the existence of the principal eigenvalue ζ_0^{ε}, and that the remaining eigenvalues (if they exist) are strictly smaller than ζ_0^{ε} up to $\varepsilon = 0$. It is convenient to consider this problem in the self-adjoint form (3.9) in $L^2(\mathbf{R})$. The principal eigenvalue ζ_0^{ε} is characterized by the maximum value of the variational problem:

$$\max Q^{\varepsilon}(\psi, \psi) \equiv \max\left\{-\varepsilon^2\langle\psi_x, \psi_x\rangle + \left\langle\left\{f_u^{\varepsilon} - \left(\frac{c\tau}{2}\right)^2\right\}\psi, \psi\right\rangle\right\} \tag{3.20}$$

where ψ varies in $H^1(\mathbf{R})$ satisfying $\|\psi\|_{L^2(\mathbf{R})} = 1$.

First note that ${}^{\mathcal{T}}u_x^{\varepsilon} = (u_x^{\varepsilon}, v_x^{\varepsilon})$ satisfies $(LP)_{\varepsilon,\tau}$ with $\lambda = 0$. Therefore, applying the same change of variables as (3.19) to u_x^{ε}, we find that $\psi^{\varepsilon} \equiv e^{-(c\tau/2\varepsilon)x}u_x^{\varepsilon}$ satisfies $L_s^{\varepsilon}\psi^{\varepsilon} + f_v^{\varepsilon}\, e^{-(c\tau/2\varepsilon)x}v_x^{\varepsilon} = 0$. Thus $\bar{\psi}^{\varepsilon} \equiv \psi^{\varepsilon}/\|\psi^{\varepsilon}\|_{L^2(\mathbf{R})}$ satisfies

$$Q^{\varepsilon}(\bar{\psi}^{\varepsilon}, \bar{\psi}^{\varepsilon}) = \langle -f_v^{\varepsilon}\, e^{-(c\tau/2\varepsilon)x}v_x^{\varepsilon}/\|\psi^{\varepsilon}\|_{L^2(\mathbf{R})}, \bar{\psi}^{\varepsilon}\rangle.$$

In view of Lemma 3.1 and the construction of $(u^{\varepsilon}, v^{\varepsilon})$, we see that $\langle -f_v^{\varepsilon}\, e^{-(c\tau/2\varepsilon)x}v_x^{\varepsilon}, \bar{\psi}^{\varepsilon}\rangle$ is uniformly bounded for any small ε and that $\|\psi^{\varepsilon}\|_{L^2(\mathbf{R})} = O(1/\sqrt{\varepsilon})$. Hence, $Q^{\varepsilon}(\bar{\psi}^{\varepsilon}, \bar{\psi}^{\varepsilon})$ satisfies

$$Q^{\varepsilon}(\bar{\psi}^{\varepsilon}, \bar{\psi}^{\varepsilon}) \geqq -c\sqrt{\varepsilon}$$

for some positive constant c that is strictly larger than the supremum of the essential spectrum (see (3.10)). This implies the existence of the isolated principal eigenvalue ζ_0^{ε}. Let ψ_0^{ε} attain the maximum value; then $|\psi_0^{\varepsilon}|$ also attains the same value. Therefore we can take ψ_0^{ε} to be nonnegative. Moreover, noting that $\psi_0^{\varepsilon} \in H^2(\mathbf{R})$, ψ_0^{ε} is strictly positive (so is the principal eigenfunction ϕ_0^{ε} $(\equiv e^{(c\tau/2\varepsilon)x}\psi_0^{\varepsilon})$ of (3.3)), since if $\psi(x) = 0 = \psi'(x)$ at some point, ψ becomes identically zero. Let $\bar{\zeta}^{\varepsilon}$ be an arbitrary eigenvalue of (3.9) and let ψ^{ε} be an associated eigenfunction; then it holds that

$$\varepsilon^2 \int_{-\infty}^{\infty} (\psi_0^{\varepsilon})^2 \left\{\frac{d}{dx}\left(\frac{\psi^{\varepsilon}}{\psi_0^{\varepsilon}}\right)\right\}^2 dx = \zeta_0^{\varepsilon} - \bar{\zeta}^{\varepsilon}. \tag{3.21}$$

Apparently, $\zeta_0^\varepsilon \geqq \bar{\zeta}^\varepsilon$ holds. Suppose $\bar{\zeta}^\varepsilon = \zeta_0^\varepsilon$; then it follows from (3.21) that $\psi^\varepsilon / \psi_0^\varepsilon =$ const., which implies that ζ_0^ε is a simple eigenvalue. Now we will show that all the other eigenvalues are strictly below the principal eigenvalue ζ_0^ε up to $\varepsilon = 0$. Namely, there exists a positive constant μ_0 independent of ε such that

$$\zeta_0^\varepsilon - \bar{\zeta}^\varepsilon \geqq \mu_0 > 0 \tag{3.22}$$

holds for any eigenvalue $\bar{\zeta}^\varepsilon$ $(\neq \zeta_0^\varepsilon)$ and small ε. To show (3.22), it is convenient to introduce the stretched variable

$$y = \frac{x}{\varepsilon}. \tag{3.23}$$

Then (3.9) becomes

$$\tilde{L}_s^\varepsilon \tilde{\psi} \equiv \left[\frac{d^2}{dy^2} + \left\{ \tilde{f}_u^\varepsilon - \left(\frac{c\tau}{2} \right)^2 \right\} \right] \tilde{\psi} = \zeta \tilde{\psi}. \tag{3.24}$$

Let $\hat{\psi}_0^\varepsilon$ be defined by

$$\hat{\psi}_0^\varepsilon \equiv \sqrt{\varepsilon}\, \psi_0^\varepsilon(\varepsilon y). \tag{3.25}$$

Then $\hat{\psi}_0^\varepsilon$ is the principal eigenfunction of (3.24) with $\|\hat{\psi}_0^\varepsilon\|_{L^2(\mathbf{R})} = 1$. Similarly, $\hat{\psi}^\varepsilon$ is defined to be $\sqrt{\varepsilon}\, \psi^\varepsilon(\varepsilon y)$. Formula (3.21) can be rewritten as

$$\int_{-\infty}^{\infty} (\hat{\psi}_0^\varepsilon)^2 \left\{ \frac{d}{dy} \left(\frac{\hat{\psi}^\varepsilon}{\hat{\psi}_0^\varepsilon} \right) \right\}^2 dy = \zeta_0^\varepsilon - \bar{\zeta}^\varepsilon. \tag{3.26}$$

Suppose the claim (3.22) does not hold. Then we can find a sequence $\varepsilon_n \downarrow 0$ as $n \uparrow \infty$ such that there exists another eigenvalue $\zeta_1^{\varepsilon_n}$ satisfying

$$\lim_{n \uparrow \infty} \zeta_0^{\varepsilon_n} = \lim_{n \uparrow \infty} \zeta_1^{\varepsilon_n}. \tag{3.27}$$

Here we use the fact that ζ_0^ε remains bounded for small ε. We can assume without loss of generality that $\zeta_1^{\varepsilon_n}$ is the second eigenvalue of (3.9) (or (3.3)). Let us denote by ψ_1^ε (or $\hat{\psi}_1^\varepsilon$ in y variable) the corresponding normalized eigenfunction to ζ_1^ε. Note the following orthogonal property:

$$\langle \psi_1^\varepsilon, \psi_0^\varepsilon \rangle_x = 0 \quad \text{and} \quad \langle \hat{\psi}_1^\varepsilon, \hat{\psi}_0^\varepsilon \rangle_y = 0. \tag{3.28}$$

Here we need Sublemma 3.1.

SUBLEMMA 3.1. *There exist a subsequence* $\{\varepsilon_{n'}\}$, *of* $\{\varepsilon_n\}$, *and two functions* $\hat{\psi}_0^\infty$ *and* $\hat{\psi}_1^\infty$ *in* $H^2(\mathbf{R})$ *such that*

$$\lim_{n' \uparrow \infty} \hat{\psi}_i^{\varepsilon_{n'}} = \hat{\psi}_i^\infty \quad \text{in } H^2(\mathbf{R})\text{-sense for } i = 0, 1.$$

Proof. Noting that both eigenfunctions decay exponentially as $|x| \to \infty$, it can be shown that both families of functions remain bounded in $H_\rho^1(\mathbf{R})$ for an appropriate $\rho > 0$. Using Lemma 2.6 and (3.24), we can easily reach the conclusion. The details are left to the reader.

Substituting the results of Sublemma 3.1 and (3.27) into (3.26), we see in the limit of $\varepsilon_{n'} \downarrow 0$ that

$$\int_{-\infty}^{\infty} (\hat{\psi}_0^\infty)^2 \left\{ \frac{d}{dy} \left(\frac{\hat{\psi}_1^\infty}{\hat{\psi}_0^\infty} \right) \right\}^2 dy = 0. \tag{3.29}$$

This implies that $\hat{\psi}_1^\infty$ is a constant multiple of $\hat{\psi}_0^\infty$. However, this contradicts the orthogonal property (3.28), which is also valid for $\hat{\psi}_0^\infty$ and $\hat{\psi}_1^\infty$. This completes the proof of (3.22).

Finally, we will prove the asymptotic behavior of the principal eigenvalue ζ_0^ε when $\varepsilon \downarrow 0$. The basic fact is that zero is an eigenvalue of $\mathscr{L}^\varepsilon$ and the associated eigenfunction is given by the spatial derivative of $\mathscr{U}^\varepsilon$ as has been seen before. Namely, it holds that

$$L^\varepsilon u_x^\varepsilon + f_v^\varepsilon v_x^\varepsilon = 0, \qquad g_u^\varepsilon u_x^\varepsilon + M^\varepsilon v_x^\varepsilon = 0. \tag{3.30}$$

Using the stretched variable y, this becomes

$$\tilde{L}^\varepsilon \tilde{u}_y^\varepsilon + \tilde{f}_v^\varepsilon v_y^\varepsilon = 0, \qquad \tilde{g}_u^\varepsilon \tilde{u}_y^\varepsilon + \tilde{M}^\varepsilon v_y^\varepsilon = 0 \tag{3.31}$$

where

$$\tilde{L}^\varepsilon = \frac{d^2}{dy^2} - c\tau \frac{d}{dy} + \tilde{f}_u^\varepsilon, \quad \tilde{M}^\varepsilon = \frac{1}{\varepsilon^2}\frac{d^2}{dy^2} - \frac{c}{\varepsilon}\frac{d}{dy} + \tilde{g}_v^\varepsilon, \quad \tilde{u}_y^\varepsilon = \frac{d}{dy} u^\varepsilon(\varepsilon y),$$

and so on. Recalling the construction of $\mathscr{U}^\varepsilon = (u^\varepsilon, v^\varepsilon)$ (see § 2), we see that both $\tilde{u}_y^\varepsilon$ and $\tilde{v}_y^\varepsilon$ decay exponentially as $|y| \to \infty$. The adjoint operator $(\tilde{L}^\varepsilon)^* \equiv d^2/dy^2 + c\tau(d/dy) + \tilde{f}_u^\varepsilon$ has the same principal eigenvalue ζ_0^ε and the corresponding eigenfunction $\hat{\phi}_0^{\varepsilon *}$ is given by $e^{-c\tau y}\hat{\phi}_0^\varepsilon$ (see Remark 3.4). Multiplying $\hat{\phi}_0^{\varepsilon *}$ to the first equation of (3.31), after integration by parts we obtain

$$\langle \tilde{u}_y^\varepsilon, (\tilde{L}^\varepsilon)^* \hat{\phi}_0^{\varepsilon *} \rangle + \langle \tilde{f}_v^\varepsilon \tilde{v}_y^\varepsilon, \hat{\phi}_0^{\varepsilon *} \rangle = 0.$$

Since $(\tilde{L}^\varepsilon)^* \hat{\phi}_0^{\varepsilon *} = \zeta_0^\varepsilon \hat{\phi}_0^{\varepsilon *}$, we have

$$\zeta_0^\varepsilon = \frac{\langle -\tilde{f}_v^\varepsilon \tilde{v}_y^\varepsilon, \hat{\phi}_0^{\varepsilon *} \rangle}{\langle \tilde{u}_y^\varepsilon, \hat{\phi}_0^{\varepsilon *} \rangle}. \tag{3.32}$$

On the other hand, $\tilde{v}^\varepsilon$ satisfies

$$\frac{1}{\varepsilon^2}\frac{d^2}{dy^2}\tilde{v}^\varepsilon - \frac{c}{\varepsilon}\frac{d}{dy}\tilde{v}^\varepsilon + g(\tilde{u}^\varepsilon, \tilde{v}^\varepsilon) = 0.$$

Integrating this with respect to y, we have

$$\tilde{v}_y^\varepsilon = \varepsilon \left\{ c(\tilde{v}^\varepsilon - \tilde{v}^\varepsilon(-\infty)) - \varepsilon \int_{-\infty}^{y} g(\tilde{u}^\varepsilon, \tilde{v}^\varepsilon)\, dy \right\}. \tag{3.33}$$

Substituting (3.33) into (3.32), we obtain

$$\zeta_0^\varepsilon = \varepsilon \left\langle -\tilde{f}_v^\varepsilon \left\{ c(\tilde{v}^\varepsilon - v_-) - \varepsilon \int_{-\infty}^{y} g(\tilde{u}^\varepsilon, \tilde{v}^\varepsilon)\, dy \right\}, \hat{\phi}_0^{\varepsilon *} \right\rangle \Big/ \langle \tilde{u}_y^\varepsilon, \hat{\phi}_0^{\varepsilon *} \rangle. \tag{3.34}$$

By using Lemma 3.1 and Corollary 2.2, the numerator and the denominator of (3.34) have the following limits as $\varepsilon \downarrow 0$:

$$\begin{aligned} &\lim_{\varepsilon \downarrow 0} \left\langle \left\{ c(\tilde{v}^\varepsilon - v_-) - \varepsilon \int_{-\infty}^{y} g(\tilde{u}^\varepsilon, \tilde{v}^\varepsilon)\, dy \right\} (-\tilde{f}_v^\varepsilon), \hat{\phi}_0^{\varepsilon *} \right\rangle \\ &= \left\{ c^*(V_0(0) - v_-) - \int_{-\infty}^{0} g(U_0, V_0)\, dx \right\} \cdot \lim_{\varepsilon \downarrow 0} \langle -\tilde{f}_v^\varepsilon, \hat{\phi}_0^{\varepsilon *} \rangle \qquad (3.35) \\ &= \left\{ c^*(\beta^* - v_-) - \int_{-\infty}^{0} g(U_0, V_0)\, dx \right\} \langle -f_v(W, \beta^*), \gamma^* W_y^* \rangle \end{aligned}$$

and

$$\lim_{\varepsilon \downarrow 0} \langle \tilde{u}_y^\varepsilon, \hat{\phi}_0^{\varepsilon *} \rangle = \langle W_y, \gamma^* W_y^* \rangle. \tag{3.36}$$

Recall that $W(y; c_0(\beta), \beta)$ satisfies (see Lemma 2.3)

$$\frac{d^2}{dy^2} W - c_0(\beta) \frac{d}{dy} W + f(W, \beta) = 0.$$

Differentiating this with respect to β, we have

$$\frac{d^2}{dy^2} W_\beta - c_0(\beta) \frac{d}{dy} W_\beta + f_u(W, \beta) W_\beta - \frac{d}{d\beta} c_0(\beta) \frac{d}{dy} W + f_v(W, \beta) = 0. \tag{3.37}$$

Taking the inner product with $W_y^\#$ on both sides of (3.37) and using the fact that $W_y^\#$ satisfies

$$\frac{d^2}{dy^2} W_y^\# + c_0(\beta) \frac{d}{dy} W_y^\# + f_u(W, \beta) W_y^\# = 0,$$

we obtain for $\beta = \beta^*$

$$-\frac{d}{d\beta} c_0(\beta) \langle W_y, W_y^\# \rangle + \langle f_v(W, \beta^*), W_y^\# \rangle = 0. \tag{3.38}$$

Substituting (3.35), (3.36), and (3.38) into (3.34), we can conclude that

$$\lim_{\varepsilon \downarrow 0} \frac{\zeta_0^\varepsilon}{\varepsilon} = -\frac{d}{d\beta} c_0(\beta) \left\{ c(\beta^* - v_-) - \int_{-\infty}^{0} g(U_0, V_0)\, dx \right\},$$

which is strictly positive from Remark 2.1 and the strict monotonicity of V_0, i.e.,

$$\frac{d}{dy} V_0(0) = c^*(\beta^* - v_-) - \int_{-\infty}^{0} g(U_0, V_0)\, dx > 0.$$

This completes the proof of Lemma 3.2.

3.2. Location of the essential spectrum. In this section we will consider the location of the essential spectrum of $(LP)_{\varepsilon,\tau}$. It is known that there are several different kinds of definitions for the essential spectrum. Here we adopt the definition employed in Goldberg [7] (see also Henry [8]). However, it should be noted that even if we take a different one, we can obtain the same a priori bound as in Proposition 3.1, since it is known that $\sup \sigma_e\{(LP)_{\varepsilon,\tau}\}$ does not depend on the choice of the definitions (see, for example, Edmunds and Evans [2]). Our goal is the following.

PROPOSITION 3.1. *For a given $\tau > 0$, there exists a positive constant δ_e independent of ε and τ such that*

$$\operatorname{Re}\{\sigma_e(LP)_{\varepsilon,\tau}\} \leqq -\delta_e < 0$$

holds for small ε.

Proof. The location of the essential spectrum is determined by the following sets:

$$S_\pm = \{\lambda \mid \det(-\mu^2 D - i\mu M + N_\pm - \lambda B) = 0, -\infty < \mu < \infty\} \tag{3.39}$$

where

$$D = \begin{pmatrix} \varepsilon^2 & 0 \\ 0 & 1 \end{pmatrix}, \qquad M = \begin{pmatrix} c\varepsilon\tau & 0 \\ 0 & c \end{pmatrix}$$

$$N_\pm = \begin{pmatrix} \alpha_\pm & \beta_\pm \\ \gamma_\pm & \delta_\pm \end{pmatrix} \equiv \lim_{x \to \pm\infty} \begin{pmatrix} f_u^\varepsilon & f_v^\varepsilon \\ g_u^\varepsilon & g_v^\varepsilon \end{pmatrix}, \qquad B = \begin{pmatrix} \varepsilon\tau & 0 \\ 0 & 1 \end{pmatrix}.$$

It is clear that

$$\det(-\mu^2 D - i\mu M + N_\pm - \lambda B) = \begin{vmatrix} -\mu^2\varepsilon^2 - i\mu c\varepsilon\tau + \alpha_\pm - \varepsilon\tau\lambda & \beta_\pm \\ \gamma_\pm & -\mu^2 - i\mu c + \delta_\pm - \lambda \end{vmatrix} = 0$$

becomes

$$\varepsilon\tau\lambda^2 - \{-(\varepsilon\tau+\varepsilon^2)\mu^2 + (\alpha_\pm + \varepsilon\tau\delta_\pm) - 2i\mu c\varepsilon\tau\}\lambda + (\mu^2\varepsilon^2 + i\mu c\varepsilon\tau - \alpha_\pm)(\mu^2 + i\mu c - \delta_\pm) - \beta_\pm\gamma_\pm = 0.$$

The roots of this equation are given by

$$\lambda = \frac{1}{2\varepsilon\tau}[-(\varepsilon\tau+\varepsilon^2)\mu^2 + (\alpha_\pm + \varepsilon\tau\delta_\pm) - 2i\mu c\varepsilon\tau \pm \sqrt{\Theta}]$$

where

$$\Theta \equiv \{(\varepsilon\tau+\varepsilon^2)\mu^2 - (\alpha_\pm + \varepsilon\tau\delta_\pm)\}^2 - 4(\mu c\varepsilon\tau)^2 + 4i\mu c\varepsilon\tau\{(\varepsilon\tau+\varepsilon^2)\mu^2 - (\alpha_\pm + \varepsilon\tau\delta_\pm)\} - 4\varepsilon\tau\{(\mu^2\varepsilon^2 - \alpha_\pm + i\mu c\varepsilon\tau)(\mu^2 - \delta_\pm + i\mu c) - \beta_\pm\gamma_\pm\}.$$

After some computation, we have

$$\operatorname{Re}\Theta = \{(\varepsilon\tau-\varepsilon^2)\mu^2 + (\alpha_\pm - \varepsilon\tau\delta_\pm)\}^2 + 4\varepsilon\tau\beta_\pm\gamma_\pm, \qquad \operatorname{Im}\Theta = 0.$$

Therefore,

$$\lambda = \frac{1}{2\varepsilon\tau}[-(\varepsilon\tau+\varepsilon^2)\mu^2 + (\alpha_\pm + \varepsilon\tau\delta_\pm) - 2i\mu c\varepsilon\tau \pm \sqrt{\{(\varepsilon\tau-\varepsilon^2)\mu^2 + (\alpha_\pm - \varepsilon\tau\delta_\pm)\}^2 + 4\varepsilon\tau\beta_\pm\gamma_\pm}]. \tag{3.40}$$

We will compute the supremum of the real part of (3.40) when μ varies in $\mathbf{R}$, which gives us the upper bound of the essential spectrum. Suppose the inside of the $\sqrt{\ }$-part of (3.40) takes the minus sign or zero; then it is clear that

$$\operatorname{Re}\lambda \leqq \frac{1}{2\varepsilon\tau}[-(\varepsilon\tau+\varepsilon^2)\mu^2 + (\alpha_\pm + \varepsilon\tau\delta_\pm)]. \tag{3.41}$$

It is obvious that the right-hand side of (3.41) is majorized by

$$\frac{1}{2\varepsilon\tau}\alpha_\pm + \frac{1}{2}\delta_\pm, \tag{3.42}$$

which is apparently strictly negative uniformly for small ε and $\tau > 0$ from (A3). On the other hand, if the inside of the $\sqrt{\ }$-part takes the plus sign, we need to take it into account. Without loss of generality, it suffices to consider the case where the $\sqrt{\ }$-part becomes a real number, namely,

$$\{(\varepsilon\tau-\varepsilon^2)\mu^2 + (\alpha_\pm - \varepsilon\tau\delta_\pm)\}^2 + 4\varepsilon\tau\beta_\pm\gamma_\pm \quad (\geqq 0).$$

In this case, it follows from $\beta_\pm\gamma_\pm < 0$ (see (A4)) that

$$\begin{aligned}\operatorname{Re}\lambda &= \frac{1}{2\varepsilon\tau}[-(\varepsilon\tau+\varepsilon^2)\mu^2 + (\alpha_\pm + \varepsilon\tau\delta_\pm) \pm \sqrt{\{(\varepsilon\tau-\varepsilon^2)\mu^2 + (\alpha_\pm - \varepsilon\tau\delta_\pm)\}^2 + 4\varepsilon\tau\beta_\pm\gamma_\pm}] \\ &\leqq \frac{1}{2\varepsilon\tau}[-(\varepsilon\tau+\varepsilon^2)\mu^2 + (\alpha_\pm + \varepsilon\tau\delta_\pm) + |(\varepsilon\tau-\varepsilon^2)\mu^2 + (\alpha_\pm - \varepsilon\tau\delta_\pm)|].\end{aligned} \tag{3.43}$$

According to the sign of the inside of $|\cdot|$, (3.43) becomes

$$\text{(3.44)}\qquad \operatorname{Re}\lambda \leqq \begin{cases} \dfrac{1}{2\varepsilon\tau}\{-2\varepsilon^2\mu^2+2\alpha_\pm\} = -\dfrac{\varepsilon}{\tau}\mu^2+\dfrac{1}{\varepsilon\tau}\alpha_\pm \leqq \dfrac{1}{\varepsilon\tau}\alpha_\pm, \\ \dfrac{1}{2\varepsilon\tau}\{-2\varepsilon\tau\mu^2+2\varepsilon\tau\delta_\pm\} = -\mu^2+\delta_\pm \leqq \delta_\pm. \end{cases}$$

Thus we see from (3.44) that

$$\text{(3.45)}\qquad \operatorname{Re}\lambda \leqq \max\left\{\frac{1}{\varepsilon\tau}\alpha_\pm, \delta_\pm\right\}.$$

Combining the results (3.42) and (3.45), we can derive the conclusion of Proposition 3.1. Note that we can take $-\delta_e$ to be $\max\{\alpha_\pm, \frac{1}{2}\delta_\pm\}$ when ε is assumed to be taken smaller than τ^{-1} (i.e., $\varepsilon\tau<1$).

3.3. The SLEP equation and the behavior of the isolated eigenvalues in the singular limit. We will study the location of the isolated eigenvalues and their dependency on τ. As has been shown in § 3.2, the essential spectrum of $\mathscr{L}^\varepsilon$ is strictly bounded away from the imaginary axis, so that the stability properties of the traveling front solutions depend solely on the behavior of the isolated eigenvalues. In fact as we will see later, some of the isolated eigenvalues really cross the imaginary axis, and therefore we must track their behavior rather than try to obtain a priori bounds for them. The main difficulty in doing so is that, when $\varepsilon \downarrow 0$, the eigenfunctions associated with those dangerous eigenvalues do not remain in the usual function space such as $\mathbf{C}_{\text{unif}}(\mathbf{R})$ or $\mathbf{L}^2(\mathbf{R})$. The eigenfunctions actually fall into the measure space (a point measure for the one-dimensional case). However, the SLEP method enables us to overcome this difficulty and control these eigenvalues uniformly for small ε.

First, we will study the asymptotic behavior of the eigenfunctions as $|x|\to+\infty$. Since the traveling front solution $\mathscr{U}^\varepsilon$ approaches the equilibrium states E_+ and E_- with the exponential order as $|x|\to\infty$, the asymptotic behavior of the eigenfunctions for large $|x|$ can be described by the limiting constant coefficient system of $(LP)_{\varepsilon,\tau}$:

$$\text{(3.46)}_\pm\qquad \begin{aligned} &\left(\varepsilon^2\frac{d^2}{dx^2}-c\varepsilon\tau\frac{d}{dx}+\alpha_\pm\right)w+\beta_\pm z = \varepsilon\tau\lambda w, \\ &\gamma_\pm w+\left(\frac{d^2}{dx^2}-c\frac{d}{dx}+\delta_\pm\right)z = \lambda z \end{aligned}$$

where $\alpha_\pm = \lim_{x\to\pm\infty} f_u^\varepsilon = f_u(E_\pm)$, $\beta_\pm = f_v(E_\pm)$, $\gamma_\pm = g_u(E_\pm)$, and $\delta_\pm = g_v(E_\pm)$. It follows from (A3) that

$$\text{(3.47)}\qquad \alpha_\pm<0 \quad\text{and}\quad \det_\pm \equiv \alpha_\pm\delta_\pm-\beta_\pm\gamma_\pm>0.$$

It suffices to consider the + case only and, for notational simplicity, we omit the subscript + hereafter. We rewrite $(3.46)_\pm$ in the form

$$\text{(3.48)}_a\qquad \begin{aligned} &\varepsilon\frac{dw}{dx}=\xi, \qquad \varepsilon\frac{d\xi}{dx}=c\tau\xi-\alpha w-\beta z+\varepsilon\tau\lambda w, \\ &\frac{dz}{dx}=\eta, \qquad \frac{d\eta}{dx}=c\eta-\gamma w-\delta z+\lambda z \end{aligned}$$

or in a vector form

$$\frac{d}{dx}\begin{pmatrix} w \\ \xi \\ z \\ \eta \end{pmatrix} = \begin{pmatrix} 0 & 1/\varepsilon & 0 & 0 \\ -\alpha/\varepsilon + \tau\lambda & c\tau/\varepsilon & -\beta/\varepsilon & 0 \\ 0 & 0 & 0 & 1 \\ -\gamma & 0 & -\delta+\lambda & c \end{pmatrix}\begin{pmatrix} w \\ \xi \\ z \\ \eta \end{pmatrix} \tag{3.48}_b$$

$$\equiv M_\lambda^{\varepsilon,\tau,c}\begin{pmatrix} w \\ \xi \\ z \\ \eta \end{pmatrix}.$$

The eigenvalues of the matrix of $M_\lambda^{\varepsilon,\tau,c}$ determine the asymptotic behavior of the eigenfunctions. The characteristic polynomial with the unknown κ becomes

$$\kappa^2\left(\kappa - \frac{c\tau}{\varepsilon}\right)(\kappa - c) - \kappa\left(\kappa - \frac{c\tau}{\varepsilon}\right)(\lambda - \delta) - \kappa(\kappa - c)\left(\tau\lambda - \frac{\alpha}{\varepsilon}\right)\Big/\varepsilon - \frac{\beta\gamma}{\varepsilon^2} + \left(\tau\lambda - \frac{\alpha}{\varepsilon}\right)(\lambda - \delta)/\varepsilon = 0. \tag{3.49}$$

Examining the roots of (3.49), we have Proposition 3.2.

PROPOSITION 3.2. *Assume that* λ *belongs to*

$$\{\lambda \in \mathbf{C} \mid \operatorname{Re}\lambda > \det/\alpha\}. \tag{3.50}$$

The eigenvalues of the matrix $M_\lambda^{\varepsilon,\tau,c}$ *are divided into two classes. One is of the order* $O(1)$ *and the other is of the order* $O(1/\varepsilon)$ *as* $\varepsilon \downarrow 0$, *each of which consists of two eigenvalues with positive and negative* Re*-parts, respectively*:

(i) *The* $O(1)$*-class consists of two eigenvalues, say* $\kappa_\pm^1$, *which remain finite in the limit* $\varepsilon \downarrow 0$. *Their principal parts are given by*

$$\kappa_\pm^1 \equiv \frac{c}{2} \pm \sqrt{\frac{c^2}{4} - \frac{\det}{\alpha} + \lambda} + O(\varepsilon) \tag{3.51}$$

with $\operatorname{Re}\kappa_\pm^1 \gtrless 0$.

(ii) *The* $O(1/\varepsilon)$*-class has two eigenvalues, say* $\kappa_\pm^\varepsilon$, *which diverge with order* $1/\varepsilon$ *as* $\varepsilon \downarrow 0$. *The principal parts of them are given by*

$$\kappa_\pm^\varepsilon \equiv \tfrac{1}{2}(c\tau \pm \sqrt{(c\tau)^2 - 4\alpha})/\varepsilon + O(1) \tag{3.52}$$

with $\operatorname{Re}\kappa_\pm^\varepsilon \gtrless 0$.

The eigenvectors associated with the above eigenvalues are denoted by $\Xi_\pm^1$ and $\Xi_\pm^\varepsilon$, respectively. If we need to distinguish the eigenvalues and the eigenvectors at E_+ and E_-, we add + or − after the superscript one or ε such as $\kappa_\pm^{1+}$, $\Xi_\pm^{\varepsilon-}$.

Remark 3.5. Let λ satisfy

$$\operatorname{Re}\lambda > -\hat{\mu} \equiv \max\left\{\frac{\det_+}{\alpha_+}, \frac{\det_-}{\alpha_-}\right\}; \tag{3.53}$$

then, it is clear from the above proposition that, at both E_+ and E_-, (3.49) has two eigenvalues with positive real parts of the orders $O(1)$ and $O(1/\varepsilon)$ and two eigenvalues with negative real parts of the same property.

Proof of Proposition 3.2. (i) Multiplying ε^2 to (3.49) gives

$$\alpha\kappa^2 - c\alpha\kappa + (\alpha\delta - \beta\gamma) - \alpha\lambda + O(\varepsilon) = 0. \tag{3.54}$$

The two roots of the principal part of (3.54) are both simple under (3.50), leading to (3.51) with the aid of the Implicit Function Theorem.

(ii) Introducing the new unknown $\hat{\kappa}$ by $\kappa = \hat{\kappa}/\varepsilon$ and then multiplying (3.49) by ε^4, we have

$$\hat{\kappa}^2(\hat{\kappa}^2 - c\tau\hat{\kappa} + \alpha) + O(\varepsilon) = 0. \tag{3.55}$$

The two roots of the equation $\hat{\kappa}^2 - c\tau\hat{\kappa} + \alpha = 0$ are simple. Therefore, by using the Implicit Function Theorem again, we obtain (3.52). Since (3.49) is of fourth order, the above four solutions are all roots of it. The sign properties of the real parts, i.e., $\operatorname{Re}\kappa_{\pm}^1 \gtrless 0$ and $\operatorname{Re}\kappa_{\pm}^{\varepsilon} \gtrless 0$, can be shown by a simple computation under the assumption (3.50).

Proposition 3.2 clearly shows that if we suppose there is an isolated eigenvalue satisfying (3.53) with the eigenfunction Ψ in $\mathbf{C}_{\mathrm{unif}}(\mathbf{R})$, then Ψ *must* decay with the exponential order as $|x| \to \infty$. This guarantees us that later we will be able to work in much more comfortable Hilbert space $H_{\rho}^1(\mathbf{R})$ for the isolated eigenvalues.

Now we return to the problem $(LP)_{\varepsilon,\tau}$:

$$L^{\varepsilon}w + f_v^{\varepsilon}z = \varepsilon\tau\lambda w, \qquad g_u^{\varepsilon}w + M^{\varepsilon}z = \lambda z \tag{$(LP)_{\varepsilon,\tau}$}$$

where λ is an isolated eigenvalue and ${}^t(w, z)$ is the associated eigenfunction. In view of Proposition 3.2, we may think that it seems to be appropriate to regard the mapping of the left-hand side of $(LP)_{\varepsilon,\tau}$ to be the one from $X_{\rho,\varepsilon}^2(\mathbf{R}) \times X_{\rho,1}^2(\mathbf{R})$ to $X_{\rho,1}^0(\mathbf{R}) \times X_{\rho,1}^0(\mathbf{R})$. However, our basic strategy is to find the nice limiting eigenvalue problem from which the necessary information for positive ε can be easily extracted. Unfortunately, the above setting for function spaces is not fit for this purpose, since it turns out that eigenfunctions associated with the isolated eigenvalues are no longer usual functions in the limit $\varepsilon \downarrow 0$. More precisely, their w-components approach the Dirac point measure after some scaling, and, at the same time, z-components tend to smooth functions except the jump discontinuity of the first x-derivative at the layer position. Therefore, it is necessary to replace the above function spaces by weaker ones with the decaying property. For this purpose, we first convert $(LP)_{\varepsilon,\tau}$ into a single equation with respect to z by solving the first equation of $(LP)_{\varepsilon,\tau}$ with respect to w, and then we put a new appropriate function space for z, namely, $H_{\rho}^1(\mathbf{R})$ which is valid up to $\varepsilon \downarrow 0$. The following lemma is needed for this procedure.

LEMMA 3.3. *For small ε, it holds that*

$$\frac{\zeta_0^{\varepsilon}}{\varepsilon\tau} \notin \sigma\{(LP)_{\varepsilon,\tau}\}.$$

Proof. We can prove this in a similar way to that of Lemma 2.1 in [13], so we leave the details to the reader.

Owing to Lemmas 3.2 and 3.3, we can solve the first equation of $(LP)_{\varepsilon,\tau}$ with respect to w for $\lambda \in \mathbf{C}_{\hat{\mu}}$ (see Remark 3.5 for the definition of $\hat{\mu}$):

$$w = (L^{\varepsilon} - \varepsilon\tau\lambda)^{-1}(-f_v^{\varepsilon}z). \tag{3.56}$$

For later use, we decompose (3.56) into two parts

$$(L^{\varepsilon} - \varepsilon\tau\lambda)^{-1}(\cdot) = \frac{1}{\zeta_0^{\varepsilon} - \varepsilon\tau\lambda} P^{\varepsilon}(\cdot) + (L^{\varepsilon} - \varepsilon\tau\lambda)^{\dagger}(\cdot) \tag{3.57}_a$$

where P^{ε} is the projection operator on the principal eigenfunction of L^{ε} defined by

$$P^{\varepsilon}(\cdot) \equiv \langle \cdot, \phi_0^{\varepsilon *} \rangle \phi_0^{\varepsilon}, \tag{3.57}_b$$

and $(L^\varepsilon - \varepsilon\tau\lambda)^\dagger$ is the remaining part of the resolvent, i.e.,

$$(L^\varepsilon - \varepsilon\tau\lambda)^\dagger(\cdot) \equiv (L^\varepsilon - \varepsilon\tau\lambda)^{-1}(\cdot) - \frac{1}{\zeta_0^\varepsilon - \varepsilon\tau\lambda} P^\varepsilon(\cdot). \tag{3.57}_c$$

Remark 3.6. In view of Lemma 3.1 and $(3.57)_c$ (see also Lemma 3.4), it is easy to see that

$$\|(L^\varepsilon - \varepsilon\tau\lambda)^\dagger\|_{\mathscr{L}(X,X)} \leqq M, \tag{3.58}$$

holds for any small ε and $\lambda \in \mathbf{C}_{\hat{\mu}}$ with M being an appropriate positive constant independent of ε. Here the underlying space X is $L^2_\rho(\mathbf{R})$ $(\rho \geqq 0)$ and $\mathscr{L}(X, X)$ denotes the set of bounded linear operators from X to X.

Substituting (3.56) into the second equation of $(LP)_{\varepsilon,\tau}$ we have a closed eigenvalue problem with respect to z:

$$M^\varepsilon z + \frac{g_u^\varepsilon}{\zeta_0^\varepsilon - \varepsilon\tau\lambda} P^\varepsilon(-f_v^\varepsilon z) + g_u^\varepsilon (L^\varepsilon - \varepsilon\tau\lambda)^\dagger(-f_v^\varepsilon z) = \lambda z. \tag{3.59}$$

The core of the SLEP method consists of the following two key lemmas, which characterize the asymptotic behaviors of the second and the third terms of the left-hand side of (3.59).

LEMMA 3.4 (the first key lemma). *Let $F(u, v)$ be a smooth function of u and v. Then it holds that*

$$(L^\varepsilon - \varepsilon\tau\lambda)^\dagger(F^\varepsilon h) \xrightarrow[\varepsilon \downarrow 0]{} F^* h / f_u^* \quad \textit{strongly in } L^2_\rho\textit{-sense}$$

for any function $h \in L^2_\rho(\mathbf{R}) \cap L^\infty(\mathbf{R})$, $\tau \in \mathbf{R}_+$, and $\lambda \in \mathbf{C}_{\hat{\mu}}$, where $F^\varepsilon \equiv F(u^\varepsilon, v^\varepsilon)$ and $F^* = F(U_0, V_0)$. Moreover, the convergence is uniform on a bounded set in $\mathbf{C}_{\hat{\mu}} \times H^1_{\rho_1}(\mathbf{R})$ $(\rho_1 > \rho \geqq 0)$ with respect to (λ, h).

Proof. We can prove this in the spirit of the proof of Lemma 2.2 in Nishiura and Fujii [13] with the aid of Lemma 2.6. So we leave the details to the reader.

LEMMA 3.5 (the second key lemma). *It holds that*

(a) $$\lim_{\varepsilon \downarrow 0} \frac{-f_v^\varepsilon}{\sqrt{\varepsilon}} \phi_0^{\varepsilon *} = k_1^* \delta_0 \quad \textit{in } (H^1_\rho)^\#(\mathbf{R})\textit{-sense}$$

(b) $$\lim_{\varepsilon \downarrow 0} \frac{g_u^\varepsilon}{\sqrt{\varepsilon}} \phi_0^\varepsilon = k_2^* \delta_0$$

where $\delta_0 = \delta(x)$ is the Dirac δ-function at $x = 0$, and k_i^* $(i = 1, 2)$ are positive constants given by

$$k_1^* = -\gamma^\# \langle W_y, W_y^\# \rangle \frac{d}{d\beta} c_0(\beta^*) > 0,$$

$$k_2^* = \gamma\{g(h_+(\beta^*), \beta^*) - g(h_-(\beta^*), \beta^*)\} > 0.$$

Proof. With the aid of Lemma 3.1 and (3.38), we can prove this in a way similar to that of Lemma 2.3 in Nishiura and Fujii [13], so we omit it.

Now we are ready to derive the singular limit eigenvalue problem of (3.59). First we rewrite the second term of (3.59) through ε-scaling:

$$\frac{g_u^\varepsilon}{\zeta_0^\varepsilon - \varepsilon\tau\lambda} P^\varepsilon(-f_v^\varepsilon z) = \frac{\langle z, -f_v^\varepsilon \phi_0^{\varepsilon *}/\sqrt{\varepsilon} \rangle}{\zeta_0^\varepsilon/\varepsilon - \tau\lambda} g_u^\varepsilon \phi_0^\varepsilon / \sqrt{\varepsilon}\,.$$

Using the above two key lemmas and Lemma 3.2, we see that, as $\varepsilon \downarrow 0$, (3.59) becomes

$$\frac{d^2}{dx^2} z - c^* \frac{d}{dx} z + \frac{k^*}{\hat{\zeta}_0^* - \tau\lambda} \langle z, \delta_0 \rangle \delta_0 + \frac{\det^*}{f_u^*} z = \lambda z, \qquad z \in H_\rho^1(\mathbf{R}) \tag{3.60}$$

where $k^* = k_1^* k_2^*$, $\det^* \equiv f_u^* g_v^* - f_v^* g_u^*$, $f_u^* \equiv f_u(U_0, V_0)$, and so on. Here, of course, (3.60) should be written in a weak form; however, for notational simplicity, we write it in a classical form. We call (3.60) *the* SLEP *differential equation* of $(LP)_{\varepsilon,\tau}$. The formal adjoint equation to (3.60) is given by

$$\frac{d^2}{dx^2} z^\# + c^* \frac{d}{dx} z^\# + \frac{k^*}{\hat{\zeta}_0^* - \tau\lambda} \langle z^\#, \delta_0 \rangle \delta_0 + \frac{\det^*}{f_u^*} z^\# = \lambda z^\#, \qquad z^\# \in (H_\rho^1)^\#(\mathbf{R}). \tag{3.61}$$

Without loss of generality, we can take

$$\langle z, \delta_0 \rangle = 1 \tag{3.62}$$

as a normalization for z, since if $\langle z, \delta_0 \rangle = 0$, z becomes identically zero. Under (3.62), (3.60) is equivalent to

$$\frac{d^2}{dx^2} z^\pm - c^* \frac{d}{dx} z^\pm + \frac{\det^*}{f_u^*} z^\pm = \lambda z^\pm, \qquad z^\pm \in H_\rho^1(\mathbf{R}_\pm), \tag{3.63}_a$$

$$z^+(0) = z^-(0), \tag{3.63}_b$$

$$\frac{dz^+}{dx}(0) - \frac{dz^-}{dx}(0) = -\frac{k^*}{\hat{\zeta}_0^* - \tau\lambda}. \tag{3.63}_c$$

It is clear that z^+ and z^- are smooth functions of x on $\mathbf{R}_+$ and $\mathbf{R}_-$, respectively. The task is to find λ such that the associated solutions of $(3.63)_a$ and $(3.63)_b$ satisfy the jump condition $(3.63)_c$ with respect to the first derivative.

Let us convert the SLEP differential equation (3.60) into the equivalent transcendental equation, which is much easier to deal with. We first introduce the inverse of the following differential operator $T_\lambda^{\varepsilon,\tau,c}$; $H_\rho^1(\mathbf{R}) \to (H_\rho^1)^\#(\mathbf{R})$,

$$T_\lambda^{\varepsilon,\tau,c} \equiv -\frac{d^2}{dx^2} + c\frac{d}{dx} - g_u^\varepsilon (L^\varepsilon - \varepsilon\tau\lambda)^\dagger (-f_v^\varepsilon \cdot) - g_v^\varepsilon + \lambda \tag{3.64}_a$$

through the associated bilinear form

$$\begin{aligned} B_\lambda^{\varepsilon,\tau,c}(z_1, z_2) = {} & \langle (z_1)_x, (z_2)_x \rangle + c\langle (z_1)_x, z_2 \rangle \\ & - \langle g_u^\varepsilon (L^\varepsilon - \varepsilon\tau\lambda)^\dagger (-f_v^\varepsilon z_1), z_2 \rangle + \langle (\lambda - g_v^\varepsilon) z_1, z_2 \rangle \end{aligned} \tag{3.64}_b$$

for $z_1, z_2 \in H_\rho^1(\mathbf{R})$. Recall that c is not an independent parameter but a function of ε with $c^* = \lim_{\varepsilon \to 0} c(\varepsilon)$.

LEMMA 3.6. *There exist positive constants ε_0 and ρ such that the differential operator (in the generalized sense) $T_\lambda^{\varepsilon,\tau,c}: H_\rho^1(\mathbf{R}) \to (H_\rho^1)^\#(\mathbf{R})$ is uniformly invertible for $0 \leqq \varepsilon \leqq \varepsilon_0$, τ in a bounded set in $\mathbf{R}_+$, and $\lambda \in \mathbf{C}_{\hat{\mu}}$, where $\hat{\mu}$ is a positive constant stated in Remark 3.5. We denote this inverse operator by $K_\lambda^{\varepsilon,\tau,c}: (H_\rho^1)^\#(\mathbf{R}) \to H_\rho^1(\mathbf{R})$. Moreover, $K_\lambda^{\varepsilon,\tau,c}$ depends on τ and λ analytically, and depends on ε continuously up to $\varepsilon = 0$ in operator norm sense, respectively.*

Proof. We can prove this lemma in a way parallel to that of Lemma 3.1 of Nishiura and Fujii [13], so we leave the details to the reader.

Applying the operator $K_\lambda^{\varepsilon,\tau,c}$ to (3.59), we have

$$z = \frac{\langle -f_v^\varepsilon z, \phi_0^{\varepsilon *}/\sqrt{\varepsilon}\rangle}{\zeta_0^\varepsilon/\varepsilon - \tau\lambda} K_\lambda^{\varepsilon,\tau,c}\left(g_u^\varepsilon \frac{\phi_0^\varepsilon}{\sqrt{\varepsilon}}\right), \tag{3.65}$$

which shows that z is a constant multiple of $K_\lambda^{\varepsilon,\tau,c}(g_u^\varepsilon(\phi_0^\varepsilon/\sqrt{\varepsilon}))$, namely, for a constant α

$$z = \alpha K_\lambda^{\varepsilon,\tau,c}\left(g_u^\varepsilon \frac{\phi_0^\varepsilon}{\sqrt{\varepsilon}}\right) \in H_\rho^1(\mathbf{R}). \tag{3.66}$$

Substituting (3.66) into (3.65), we see that the nontrivial solution z of (3.65) exists if and only if λ satisfies the algebraic-like equation

$$\frac{\zeta_0^\varepsilon}{\varepsilon} - \tau\lambda = \left\langle K_\lambda^{\varepsilon,\tau,c}\left(g_u^\varepsilon \frac{\phi_0^\varepsilon}{\sqrt{\varepsilon}}\right), -f_v^\varepsilon \frac{\phi_0^{\varepsilon *}}{\sqrt{\varepsilon}}\right\rangle. \tag{3.67}$$

We set

$$\mathcal{F}(\lambda;\varepsilon,\tau,c) \equiv \frac{\zeta_0^\varepsilon}{\varepsilon} - \tau\lambda - \left\langle K_\lambda^{\varepsilon,\tau,c}\left(g_u^\varepsilon \frac{\phi_0^\varepsilon}{\sqrt{\varepsilon}}\right), -f_v^\varepsilon \frac{\phi_0^{\varepsilon *}}{\sqrt{\varepsilon}}\right\rangle = 0. \tag{3.68}$$

This is the basic relation among ε, τ, c, and λ in the sense that the behaviors of isolated eigenvalues with respect to ε (including $\varepsilon = 0$), τ, and c are governed by (3.68). Recalling Lemma 3.1, the left-hand side of (3.67) is defined continuously up to $\varepsilon = 0$. On the other hand, in view of Lemmas 3.5 and 3.6, the right-hand side of (3.67) is also well defined up to $\varepsilon = 0$. Therefore (3.68) holds uniformly for small ε up to $\varepsilon = 0$. Thus, the limiting equation of (3.68) as $\varepsilon \downarrow 0$ is given by

$$\mathcal{F}(\lambda;0,\tau,c^*) \equiv \hat{\zeta}_0^* - \tau\lambda - k^*\langle K_\lambda^{*,\tau,c^*}\delta_0, \delta_0\rangle = 0. \tag{3.69}$$

We call (3.69) *the* SLEP *equation* of $(LP)_{\varepsilon,\tau}$. The great advantage of the SLEP equation is that not only the limiting location of isolated eigenvalues but also the behaviors of those for positive ε can be obtained from (3.69) by applying a *usual* Implicit Function Theorem to it at $\varepsilon = 0$. This is due to the nice limiting characterization as in Lemmas 3.4 and 3.5.

We first analyze the SLEP equation (3.69), and then we will return to (3.68) in the next section. The following lemma enables us to concentrate on the study of the behavior of *real* eigenvalues of (3.69).

LEMMA 3.7. *For a given $\tau > 0$, there exists a positive constant μ_1 (which may depend on τ) such that the* SLEP *equation* (3.69) *does not have complex isolated eigenvalues in the region $\mathbf{C}_{\mu_1}$.*

Proof. See the Appendix for the proof.

The real eigenvalues of (3.69) have a simple geometrical interpretation, namely, they are the intersection points between the straight line $S(\lambda;\tau,c^*) \equiv \hat{\zeta}_0^* - \tau\lambda$ and the curve

$$G(\lambda;\tau,c^*) \equiv k^*\langle K_\lambda^{*,\tau,c^*}\delta_0, \delta_0\rangle. \tag{3.70}$$

G satisfies the following properties as a function of λ.

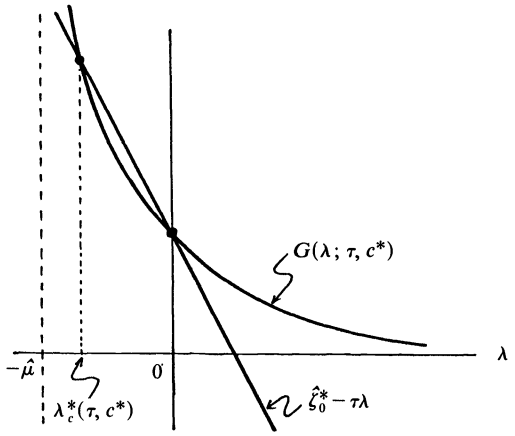
LEMMA 3.8. *$G(\lambda;\tau,c^*)$ is a strictly decreasing and convex function of real λ for $\lambda > -\hat{\mu}$ and satisfies the following*:

(i) $G(0;\tau,c^*) = \hat{\zeta}_0^*$,

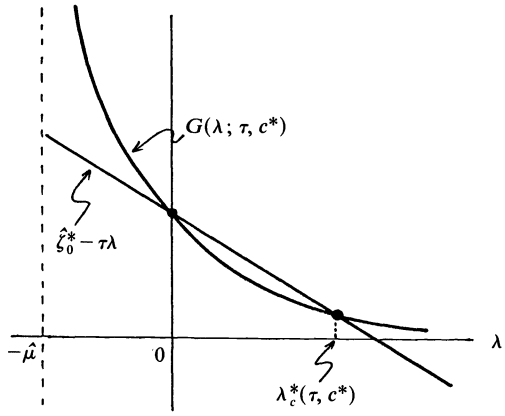
(ii) $\lim_{\lambda\to+\infty} G(\lambda;\tau,c^*) = 0$.

See Fig. 6.

Proof. We can prove this, except property (i), exactly in the same manner as the proof of Lemma 3.3 in Nishiura and Mimura [15], so we leave the details to the reader.



(a) $-\tau < \frac{d}{d\lambda} G(0; \tau, c^*)$ (stable)



(b) $-\tau > \frac{d}{d\lambda} G(0; \tau, c^*)$ (unstable)

FIG. 6. *The limiting location of the critical eigenvalue of* $(LP)_{\varepsilon,\tau}$ *is represented as an intersecting point of two curves* $G(\lambda; \tau, c^*)$ *and* $\hat{\zeta}_0^* - \tau\lambda$, *which becomes negative (respectively, positive) when* $-\tau <$ (*respectively*, $>$)$(d/d\lambda)G(0; \tau, c^*)$.

As for the property (i), this is a direct consequence of the translation invariance property. In fact, the spatial derivative of the traveling front solution $\mathcal{U}_x^\varepsilon = (u_x^\varepsilon, v_x^\varepsilon)$ is an eigenfunction of $(LP)_{\varepsilon,\tau}$ with $\lambda = 0$ for any small ε. Therefore the SLEP equation (3.69) must also have a zero eigenvalue, implying the property (i).

It is easily seen from Lemma 3.8 that there are exactly *two* intersection points including the multiplicity between S and G: as is expected, one is the zero eigenvalue

that comes from the translation invariance (see Lemma 3.8(i)), and the other is called the (real) *critical eigenvalue.* We denote this critical eigenvalue by $\lambda_c^*(\tau, c^*)$ or simply $\lambda_c^*(\tau)$. In view of Fig. 6 and Lemma 3.8, we easily see the following lemma.

LEMMA 3.9. *There exists a unique real critical eigenvalue* $\lambda = \lambda_c^*(\tau, c^*)$ *and its sign is determined as follows*:

$$\lambda_c^*(\tau, c^*) \gtreqless 0 \quad \text{if and only if} \quad -\tau \gtreqless \frac{d}{d\lambda} G(\lambda; \tau, c^*)\Big|_{\lambda=0}.$$

From Lemmas 3.7 and 3.9, and Proposition 3.1, we can conclude the following stability properties of traveling front solutions in the singular limit sense.

THEOREM 3.1 (linearized stability in the singular limit sense). *Let* $\mathcal{U}^\varepsilon = (u^\varepsilon, v^\varepsilon)$ *be a traveling front solution of* $(P)_{\varepsilon,\tau}$ *with the asymptotic velocity* c^* *as* $\varepsilon \downarrow 0$. *Then, its singular limit traveling front solution is*

$$\left.\begin{matrix} \textit{stable} \\ \textit{marginally stable} \\ \textit{unstable} \end{matrix}\right\} \quad \text{if and only if} \quad -\tau \gtreqless \frac{d}{d\lambda} G(\lambda; \tau, c^*)\Big|_{\lambda=0},$$

respectively. Here the terms stable, unstable, and marginally stable are used in the linearized sense; for example, stable means that all the spectrum have strictly negative real parts except the zero eigenvalue associated with the translation invariance.

3.4. Stability of the traveling front solutions for positive ε. In the previous section, we have studied the stability properties of the traveling front solutions in the singular limit sense. Namely, we have derived the SLEP equation (3.69), which tells us the limiting location of the real critical eigenvalue, and have given a criterion for the stability of traveling fronts (see Theorem 3.1). The great advantage of the SLEP method is that stability properties for positive ε can be obtained directly from (3.69) by using a *usual* Implicit Function Theorem, despite the fact that the linearized problem $(LP)_{\varepsilon,\tau}$ and the associated eigenfunctions behave in a singular manner as $\varepsilon \downarrow 0$.

Generically speaking, stability properties are preserved when ε becomes positive. The only exceptional case is the third one (the marginal case) in Theorem 3.1 where stability properties as well as existence for positive ε become more delicate problems. The discussions of the details for this case are postponed to a forthcoming paper where we have a nice qualitative description about what happens to the tangential case in a structurally stable manner when we look at the behavior of the solution *branch* in (τ, c)-space rather than looking at just one particular solution.

The location of eigenvalues of $(LP)_{\varepsilon,\tau}$ for positive ε is determined by (3.68), i.e.,

$$\mathcal{F}(\lambda; \varepsilon, \tau) = \frac{\zeta_0^\varepsilon}{\varepsilon} - \tau\lambda - \left\langle K_\lambda^{\varepsilon,\tau,c}\left(g_u^\varepsilon \frac{\phi_0^\varepsilon}{\sqrt{\varepsilon}}\right), -f_v^\varepsilon \frac{\phi_0^{\varepsilon *}}{\sqrt{\varepsilon}}\right\rangle = 0. \tag{3.68}$$

We can analyze this equation as a perturbation of the SLEP equation (3.69). We use the simple notation $\lambda_c^*(\tau)$ as a critical eigenvalue of (3.69) (see Lemma 3.9).

LEMMA 3.10. *The real critical eigenvalue* $\lambda_c^*(\tau)$ *of* (3.69) *can be extended uniquely to the solution* $\lambda_c^\varepsilon(\tau)$ *of* $\mathcal{F}(\lambda; \varepsilon, \tau) = 0$ *for small* ε, *where* $\lambda_c^\varepsilon(\tau)$ *is real and continuous with respect to* ε *satisfying*

$$\lim_{\varepsilon \downarrow 0} \lambda_c^\varepsilon(\tau) = \lambda_c^*(\tau).$$

Moreover, there exists a positive constant μ_2 *such that there are no real solutions of* $\mathcal{F}(\lambda; \varepsilon, \tau) = 0$ *in* $\mathbf{C}_{\mu_2}$ *for small* ε *except* $\lambda_c^\varepsilon(\tau)$ *and the zero eigenvalue coming from the translation invariance property.*

Proof. Recall that $\mathcal{F} = \mathcal{F}(\lambda; \varepsilon, \tau)$ is analytic with respect to λ in $\mathbf{C}_{\hat{\mu}}$ and continuous with respect to ε up to $\varepsilon = 0$. Since $\lambda = 0$ is always a solution of $\mathcal{F} = 0$ because of the translation invariance property, $\mathcal{F}$ can be decomposed as

$$\mathcal{F}(\lambda; \varepsilon, \tau) = \lambda H(\lambda; \varepsilon, \tau)$$

where H depends on $(\lambda; \varepsilon, \tau)$ in a similar way as $\mathcal{F}$ and H is real-valued for real λ. The critical eigenvalue $\lambda_c^*(\tau)$ of the SLEP equation (3.69) is a solution of $H(\lambda; 0, \tau) = 0$, namely,

$$H(\lambda_c^*(\tau); 0, \tau) = 0. \tag{3.71}$$

When $\lambda_c^*(\tau) \neq 0$, it follows from Lemmas 3.8 and 3.9 that the straight line S and the convex curve G intersect each other transversally at $\lambda = \lambda_c^*(\tau)$, which implies that

$$\frac{\partial \mathcal{F}}{\partial \lambda}(\lambda_c^*(\tau); 0, \tau) = \lambda_c^*(\tau) \frac{\partial H}{\partial \lambda}(\lambda_c^*(\tau); 0, \tau) \neq 0.$$

Therefore, it holds that

$$\frac{\partial H}{\partial \lambda}(\lambda_c^*(\tau); 0; \tau) \neq 0. \tag{3.72}$$

When $\lambda_c^*(\tau) = 0$ (the tangential case), it holds that

$$\frac{\partial \mathcal{F}}{\partial \lambda}(0; 0, \tau) = 0.$$

However, after some computation we have

$$\frac{\partial^2 \mathcal{F}}{\partial \lambda^2}(0; 0, \tau) = 2 \frac{\partial H}{\partial \lambda}(0; 0, \tau) = -2k^* \langle K_0^{*, \tau, c^*})^3 \delta_0, \delta_0 \rangle < 0.$$

Thus, (3.72) holds whether or not $\lambda_c^*(\tau) = 0$. Combining (3.71) with (3.72) and applying the Implicit Function Theorem to $H = 0$ (if necessary, we extend H to the negative ε continuously), we obtain the unique real critical eigenvalue $\lambda = \lambda_c^{\varepsilon}(\tau)$ of $\mathcal{F} = 0$ satisfying $\lim_{\varepsilon \downarrow 0} \lambda_c^{\varepsilon}(\tau) = \lambda_c^*(\tau)$.

Noting Lemma 3.9 and the uniqueness property of the Implicit Function Theorem, the latter part of Lemma 3.10 can be proved by contradiction without difficulty. Therefore we leave the details to the reader.

Lemma 3.10 is essential for judging the stability properties, since we have the following a priori bound for the remaining spectrum.

LEMMA 3.11. *Both the essential spectrum and the nonreal isolated eigenvalues of* $(LP)_{\varepsilon, \tau}$ *are uniformly bounded away from the imaginary axis for small* ε. *Namely, suppose that* λ *belongs to the above spectrum*; *then it holds that*

$$\lambda \notin \mathbf{C}_{\mu_3}, \tag{3.73}$$

for a positive constant μ_3 *independent of small* ε.

Proof. For the essential spectrum, this result is already proved in Proposition 3.1. For complex eigenvalues, we first show the following sublemma.

SUBLEMMA 3.1. *Suppose that* $\lambda \in \mathbf{C}_{\hat{\mu}}$ *is an isolated eigenvalue of* (3.68) (*for the definition of* $\hat{\mu}$, *see Remark* 3.5); *then for small* ε *it satisfies*

$$|\lambda| \leqq M_1$$

where M_1 *is a positive constant independent of* ε.

Proof. In view of Remark 3.6 and Lemma 3.6, we can easily prove by contradiction that there does not exist a divergent sequence of eigenvalues in $\mathbf{C}_{\hat{\mu}}$ of (3.68) as $\varepsilon \downarrow 0$. The details are left to the reader.

Using this sublemma, we will prove (3.73) for complex eigenvalues by contradiction. Suppose that there does not exist such a μ_3 for any small ε. It follows from Sublemma 3.1 that we can find a sequence of complex eigenvalues $\{\lambda_{\varepsilon_n}\}_{n\geqq 1}$ ($\operatorname{Im}\lambda_{\varepsilon_n} \neq 0$) of (3.68) with $\varepsilon_n \downarrow 0$ as $n \uparrow \infty$, which converges to λ_* satisfying the SLEP equation (3.69) with $\operatorname{Re}\lambda_* \geqq 0$. By recalling Lemma 3.7, the only possibility is that λ_* is equal to one of the real eigenvalues of (3.69). However, in the view of Lemma 3.10 and its proof, we see that both eigenvalues $\lambda_c^*(\tau)$ and the zero of (3.69) are uniquely extended as *real* solutions of (3.68), which is a contradiction and completes the proof of Lemma 3.11.

Except in the tangential case, i.e., $\lambda_c^*(\tau) = 0$, we can conclude the following from Lemmas 3.10 and 3.11.

THEOREM 3.2. *Let $\mathcal{U}^\varepsilon$ be a traveling front solution of $(P)_{\varepsilon,\tau}$ with the limiting velocity $c^* = \lim_{\varepsilon \downarrow 0} c(\varepsilon)$ constructed in § 2. Then, for small ε, $\mathcal{U}^\varepsilon$ is*

(i) *Asymptotically orbital stable in $\mathbf{C}_{\text{unif}}(\mathbf{R})$-topology if*

$$-\tau < \frac{d}{d\lambda} G(\lambda; \tau, c^*)\Big|_{\lambda=0} = -k^*\langle (K_0^{*,\tau,c^*})^2 \delta_0, \delta_0\rangle, \tag{3.74}$$

or

(ii) *Unstable if*

$$-\tau > \frac{d}{d\lambda} G(\lambda; \tau, c^*)\Big|_{\lambda=0} = -k^*\langle (K_0^{*,\tau,c^*})^2 \delta_0, \delta_0\rangle. \tag{3.75}$$

Proof of Theorem 3.2. It is clear from Lemmas 3.9 and 3.10 that the inequality $\tau >$ (respectively, $<$) $-(d/d\lambda)G(\lambda; \tau, c^*)|_{\lambda=0}$ implies the unique existence of the negative (respectively, positive) eigenvalue $\lambda_c^\varepsilon(\tau)$ for small ε. The simplicity of this critical eigenvalue $\lambda_c^\varepsilon(\tau)$ and the zero eigenvalue associated with the translation invariance can be proved in an analogous way to that of Theorem 4.1 of Nishiura and Mimura [13]. Therefore we omit the details. Thus, noting Lemma 3.11, we obtain the conclusion of Theorem 3.2.

4. Relation between stability and the sign of the Jacobian of matching conditions. In the previous section, we have obtained a stability criterion in which the location of the unique real critical eigenvalue is determined via comparison of slopes at the origin of two curves of the SLEP equation. In this section we will show that the stability criterion in Theorem 3.2 corresponds exactly to the *sign* of the Jacobian $\partial(\Phi_0, \Psi_0)/\partial(c, \beta)$, where Φ_0 and Ψ_0 are the functions used in C^1-matching conditions for singular limit solutions in § 2. In other words, the intersecting manner of two curves $\beta = \beta_0(c)$ and $\beta = \beta_I(c)$, associated with $\Phi_0 = 0$ and $\Psi_0 = 0$, respectively, determines the stability properties of traveling front solutions.

This not only gives us a clear geometrical interpretation of the stability criterion, but also has a useful practical application. In fact, when we construct the singular limit solutions, we can also judge their stabilities simultaneously. To prove this relation, we will prepare three lemmas: the first one deals with the formula of $(d/dc)\beta_0(c)$; similarly, $(d/dc)\beta_I(c)$ is computed in the second one; and, finally, in the third lemma a relation between the coefficient of the SLEP equation and the depth of the jump $j(\beta)$ at $\beta = \beta^*$ (see (4.1)) is given.

We introduce the following notation for later use:

$$G_\pm(V) \equiv g(h_\pm(V), V), \tag{4.1}_a$$

$$(4.1)_b \qquad G_\beta(V) \equiv \begin{cases} G_+(V) & \text{for } \beta \leqq V < v_{\max}, \\ G_-(V) & \text{for } v_{\min} < V < \beta, \end{cases}$$

and

$$(4.1)_c \qquad j(\beta) \equiv G_+(\beta) - G_-(\beta).$$

LEMMA 4.1. *Let $\beta = \beta_0(c)$ be the relation for β and c (see Lemma 2.2) where the outer equation $(2.7)_\pm$ for v has a unique C^1-matching solution $V_0(x; c)$ (see (2.10)). Then it holds that*

$$(4.2) \qquad \frac{d}{dc}\beta_0(c) = -j(\beta_0(c))^{-1}\left\{c(\beta_0(c) - v_-) - \int_{-\infty}^{0} g(U_0, V_0)\, dx\right\}^2 \langle z_0, z_0^* \rangle$$

where $U_0 \equiv h_{\beta_0(c)}(V_0)$, and z_0 (respectively, z_0^*) is given by $(d/dx) \cdot V_0(x; c)/(d/dx)V_0(0; c)$ (respectively, $e^{-cx}z_0$). Moreover, if $(c, \beta_0(c))$ is an intersection point with $\beta = \beta_I(c)$, then z_0 (respectively, z_0^*) is the limiting z-component of the eigenfunction associated with the translation free zero eigenvalue of $(LP)_{\varepsilon,\tau}$ (respectively, the adjoint problem $(LP)^*_{\varepsilon,\tau}$) under the normalization $z_0(0) = 1$ (respectively, $z_0^*(0) = 1$).

Proof. For arbitrary $c \in \mathbf{R}$, the outer solution V_0 matched in C^1-sense at the origin exists uniquely for $\beta = \beta_0(c)$ and satisfies the following equation (see Lemma 2.2):

$$(4.3) \qquad \frac{d^2}{dx^2}V_0 - c\frac{d}{dx}V_0 + G_{\beta_0(c)}(V_0) = 0.$$

Although (4.3) should be written in a weak form due to the jump discontinuity of $G_{\beta_0(c)}(\cdot)$ at the origin, we write it in a classical form for notational simplicity. Note that the C^1-matched solution V_0 of (4.3) can be regarded as a function of the velocity c; $V_0 = V_0(x; c)$. We rewrite (4.3) as

$$(4.4) \qquad \frac{d^2}{dx^2}V_0 - c\frac{d}{dx}V_0 + j(\beta_0(c))H_{\beta_0(c)}(V_0) + \hat{G}_{\beta_0(c)}(V_0) = 0$$

where $H_{\beta_0(c)}(\cdot)$ denotes the Heaviside function with unit jump at $\beta_0(c)$, and $\hat{G}_{\beta_0(c)}(\cdot) \equiv G_{\beta_0(c)}(\cdot) - j(\beta_0(c))H_{\beta_0(c)}(\cdot)$, which is a continuous function of x. Note that $H_{\beta_0(c)}(V_0(x))$ is the Heaviside function with unit jump at $x = 0$ as a function of x. Differentiating (4.4) with respect to x, we obtain

$$(4.5) \qquad \frac{d^2}{dx^2}(V_0)_x - c\frac{d}{dx}(V_0)_x + j(\beta_0(c))\delta_0(x) + \frac{d}{dV}\hat{G}_{\beta_0(c)}(V_0)(V_0)_x = 0.$$

On the other hand, differentiating (4.4) with respect to c, we have

$$\begin{aligned} &\frac{d^2}{dx^2}\dot{V}_0 - c\frac{d}{dx}\dot{V}_0 - \frac{d}{dx}V_0 + \frac{dj}{d\beta}(\beta_0(c))H_{\beta_0(c)}(V_0)\dot{\beta}_0(c) \\ &\quad - j(\beta_0(c))(V_0)_x(0)^{-1}\delta_0(x)\dot{\beta}_0(c) + j(\beta_0(c))\delta_0(x)\dot{V}_0 \\ &\quad + \frac{d}{d\beta}\hat{G}_{\beta_0(c)}(V_0)\dot{\beta}_0(c) + \frac{d}{dV}\hat{G}_{\beta_0(c)}(V_0)\dot{V}^0 = 0, \end{aligned} \qquad (4.6)$$

where $\cdot$ means c-differentiation. In view of (4.5), it is easily seen that $(V_0)^*_x = e^{-cx}(V_0)_x$ satisfies

$$(4.7) \qquad \frac{d^2}{dx^2}(V_0)^*_x + c\frac{d}{dx}(V_0)^*_x + j(\beta_0(c))\delta_0(x) + \frac{d}{dV}\hat{G}_{\beta_0(c)}(V_0)^*_x = 0.$$

This is apparently the adjoint equation of (4.5). Multiplying $(V_0)_x^{\#}$ to (4.6) on both sides, after integration by parts we obtain

$$
\begin{aligned}
&-\langle (V_0)_x, (V_0)_x^{\#}\rangle + \left\{ \left\langle \frac{dj}{d\beta}(\beta_0(c)) H_{\beta(c)}(V_0), (V_0)_x^{\#} \right\rangle \right. \\
&\qquad -\langle j(\beta_0(c))(V_0)_x(0)^{-1}\delta_0(x), (V_0)_x^{\#}\rangle \\
&\qquad \left. + \left\langle \frac{d}{d\beta}\hat{G}_{\beta_0(c)}(V_0), (V_0)_x^{\#} \right\rangle \right\} \dot{\beta}_0(c) = 0.
\end{aligned} \tag{4.8}
$$

We will show the following equality:

$$
\left\langle \frac{dj}{d\beta}(\beta_0(c)) H_{\beta_0(c)}(V_0), (V_0)_x^{\#} \right\rangle + \left\langle \frac{d}{d\beta}\hat{G}_{\beta_0(c)}(V_0), (V_0)_x^{\#} \right\rangle = 0. \tag{4.9}
$$

Making the Newton quotient of $\hat{G}_\beta$, we see that

$$
\begin{aligned}
\left\langle \frac{\hat{G}_{\beta+\Delta\beta}(V_0) - \hat{G}_\beta(V_0)}{\Delta\beta}, (V_0)_x^{\#} \right\rangle &= \frac{1}{\Delta\beta}\int_{x_\beta}^{x_{\beta+\Delta\beta}} \{\hat{G}_{\beta+\Delta\beta}(V_0) - \hat{G}_\beta(V_0)\}\cdot (V_0)_x^{\#}\, dx \\
&\quad - \frac{1}{\Delta\beta}\{j(\beta+\Delta\beta) - j(\beta)\}\int_{x_{\beta+\Delta\beta}}^{\infty} (V_0)_x^{\#}\, dx
\end{aligned} \tag{4.10}
$$

where x_β denotes the value of x where V_0 becomes β. Here, for definiteness, we only consider the case of $\Delta\beta > 0$. Note that x_β is uniquely defined because of the monotonicity of $V_0(x)$. Since $|\hat{G}_{\beta+\Delta\beta}(V_0(x)) - \hat{G}_\beta(V_0(x))| \leqq \max_{\beta'\in[\beta,\beta+\Delta\beta]} |j(\beta') - j(\beta)| \leqq$ const. $\Delta\beta$ and $x_{\beta+\Delta\beta}$ tends to x_β as $\Delta\beta \to 0$, the first term of the right-hand side of (4.10) goes to zero when $\Delta\beta \to 0$. Therefore, it follows from (4.10) that

$$
\left\langle \frac{d}{d\beta}\hat{G}_\beta(V_0), (V_0)_x^{\#} \right\rangle = -\frac{dj}{d\beta}\int_{x_\beta}^{\infty} (V_0)_0^{\#}\, dx,
$$

which shows (4.9) at $\beta = \beta_0(c)$. Substituting (4.9) into (4.8) and noting that $(V_0)_x = (V_0)_x^{\#}(0)$, we have

$$
\dot{\beta}_0(c) = -\frac{\langle (V_0)_x, (V_0)_x^{\#}\rangle}{j(\beta_0(c))} = -j(\beta_0(c))^{-1}((V_0)_x(0))^2\langle z_0, z_0^{\#}\rangle \tag{4.11}
$$

where z_0 (respectively, $z_0^{\#}$) is defined by $(V_0)_x/(V_0)_x(0)$ (respectively, $(V_0)_x^{\#}/(V_0)_x^{\#}(0)$). Let us compute the value of $(V_0)_x(0)$. Integrating (4.3) from $-\infty$ to 0, we obtain

$$
(V_0)_x(0) = c\{V_0(0) - v_-\} - \int_{-\infty}^{0} G_{\beta_0(c)}(V_0(x))\, dx.
$$

Since $x = 0$ is the switching point from the left branch $h_-(v)$ to the right one $h_+(v)$, and $V_0(0) = \beta_0(c)$, this becomes

$$
(V_0)_x(0) = c\{\beta_0(c) - v_-\} - \int_{-\infty}^{0} g(U_0, V_0)\, dx. \tag{4.12}
$$

Substituting this into (4.11), we obtain (4.2).

The last claim of Lemma 4.1 is clear from the fact that the x-derivative of the traveling front solution becomes an eigenfunction associated with the zero eigenvalue of $(LP)_{\varepsilon,\tau}$ for any small ε.

In view of Lemmas 2.3 and 2.4, the inner layer solutions were defined by solutions of the following stretched scalar equation:

$$W_{yy} - c\tau W_y + f(W, \beta) = 0, \qquad W(\pm\infty) = h_\pm(\beta),\ W(0) = \alpha \tag{4.13}$$

where $c = c_0(\beta)/\tau$ for any $\beta \in (v_-, v_+)$. By recalling Remark 2.1, the inner relation $c = c_0(\beta)/\tau$ can be solved with respect to β as $\beta = \beta_I(c)$. Here, of course, β_I depends also on τ; however, for simplicity, we do not write the τ-dependency explicitly. Therefore the solution of (4.13) can be regarded as a function of c for any fixed τ.

LEMMA 4.2. *Let $\beta = \beta_I(c)$ $(= \beta_I(c; \tau))$ be the inverse function of the inner C^1-matching condition $c = c_0(\beta)/\tau$ in Lemma* 2.4. *Then, it holds that*

$$\dot{\beta}_I(c) = \tau \Big/ \frac{d}{d\beta} c_0(\beta_I(c)). \tag{4.14}$$

Proof. Differentiating (4.13) with respect to c, we have

$$\dot{W}_{yy} - c\tau\dot{W}_y - \tau W_y + f_u(W, \beta_I(c))\dot{W} + f_v(W, \beta_I(c))\dot{\beta}_I(c) = 0 \tag{4.15}$$

where $\cdot$ means c-differentiation as before. On the other hand, differentiating (4.13) with respect to y, it is easily seen that W_y satisfies

$$\frac{d^2}{dy^2} W_y - c\tau \frac{d}{dy} W_y + f_u(W, \beta_I(c)) W_y = 0. \tag{4.16}$$

Therefore, $W_y^\# \equiv e^{-c\tau y} W_y$ satisfies

$$\frac{d^2}{dy^2} W_y^\# + c\tau \frac{d}{dy} W_y^\# + f_u(W, \beta_I(c)) W_y^\# = 0. \tag{4.17}$$

Note that both W_y and $W_y^\#$ decay exponentially as $|y| \to +\infty$ (see Lemma 2.3). Taking the inner product with $W_y^\#$ on both sides of (4.15) and using (4.17), after integration by parts we obtain

$$-\tau\langle W_y, W_y^\#\rangle + \dot{\beta}_I(c)\langle f_v(W, \beta_I(c)), W_y^\#\rangle = 0. \tag{4.18}$$

When we recall the relation (3.38), it follows from (4.18) that

$$\dot{\beta}_I(c) = \tau \Big/ \frac{d}{d\beta} c_0(\beta_I(c)),$$

which proves (4.14).

Now let (c^*, β^*) be an arbitrary transversal intersection point between $\beta = \beta_0(c)$ and $\beta = \beta_I(c)$, and $\mathcal{U}^\varepsilon = (u^\varepsilon, v^\varepsilon)$ be the corresponding traveling front solution. As we have remarked before, the spatial derivative $\mathcal{U}_x^\varepsilon = (u_x^\varepsilon, v_x^\varepsilon)$ satisfies $(LP)_{\varepsilon,\nu}$ with $\lambda = 0$ for any small ε. Therefore the SLEP differential equation (3.60) must also have zero eigenvalue and the z-component of the associated eigenfunction, under the normalization $\langle z_0, \delta_0\rangle = 1$, is given by

$$z_0 = \frac{k^*}{\hat{\zeta}_0^*} K_0^{*,\tau,c^*}\delta_0. \tag{4.19}$$

Recall that c^* is the limiting velocity of $\mathcal{U}^\varepsilon$ as $\varepsilon \downarrow 0$. Also noting that $z_0^\#$ $(= e^{-c^* x} z_0)$ is a kernel function of the adjoint problem (3.61), we see that it is represented by

$$z_0^\# = \frac{k^*}{\hat{\zeta}_0^*} K_0^{*,\tau,-c^*}\delta_0. \tag{4.20}$$

On the other hand, recalling that v^ε remains as a $C^1(\mathbf{R})$-function up to $\varepsilon = 0$, we see that v_x^ε converges to $(V_0)_x$. In view of (4.5) and Lemma 3.6, $(V_0)_x$ is represented by

$$(V_0)_x = j(\beta^*) K_0^{*,\tau,c^*} \delta_0. \tag{4.21}$$

Here we use the fact that $d\hat{G}_{\beta^*}/dV(V_0) = \det^*/f_u^*$ and $\beta^* = \lim_{\varepsilon \downarrow 0} v^\varepsilon(0)$. It is clear that z_0 $(=\lim_{\varepsilon \downarrow 0}(v_x^\varepsilon / v_x^\varepsilon(0)))$ and $(V_0)_x / \langle (V_0)_x, \delta_0 \rangle$ must coincide with each other. Thus in view of (4.19) and (4.21), we see that the following relation holds among the numbers k^*, $\hat{\zeta}_0^*$, and $j(\beta^*)$.

LEMMA 4.3. *Let (c^*, β^*) be an arbitrary intersection point of $\beta = \beta_0(c)$ and $\beta = \beta_I(c)$. Then it holds that*

$$\frac{j(\beta^*)}{(V_0)_x(0)} = \frac{k^*}{\hat{\zeta}_0^*}. \tag{4.22}$$

As has been seen in § 2, the singular limit traveling front solutions can be constructed by finding the intersection points between $\beta = \beta_0(c)$ and $\beta = \beta_I(c)$. We will show that the manner of intersection of these two curves is exactly equivalent to the sign of the real critical eigenvalue in Theorem 3.1. In other words, the inequalities $\dot{\beta}_I(c) \lesseqgtr \dot{\beta}_0(c)$ at $c = c^*$ are equivalent to those in Theorem 3.1. Our goal is the following.

THEOREM 4.1 (stability and matching conditions). *For a given $\tau > 0$, let (c^*, β^*) be an arbitrary intersection point of outer and inner relation curves $\beta = \beta_0(c)$ and $\beta = \beta_I(c)$ in § 2. Then, the inequalities*

$$\dot{\beta}_I(c^*) \gtreqless \dot{\beta}_0(c^*) \qquad \left(\cdot = \frac{d}{dc}\right) \tag{4.23}$$

are equivalent to

$$-\tau \gtreqless \frac{d}{d\lambda} G(\lambda; \tau, c^*)\Big|_{\lambda = 0} = -k^* \langle (K_0^{*,\tau,c^*})^2 \delta_0, \delta_0 \rangle, \tag{4.24}$$

which determine the stability properties of the traveling front solution. Moreover, the inequalities (4.23) (*or* (4.24)) *are equivalent to the sign of the Jacobian of C^1-matching conditions* $(\Phi_0(c, \beta; \tau), \Psi_0(c, \beta)) = (0, 0)$ (*see* § 2), *namely,*

$$\frac{\partial(\Phi_0, \psi_0)}{\partial(c, \beta)} \gtreqless 0 \quad \text{at } (c^*, \beta^*). \tag{4.25}$$

Proof. Using Lemmas 4.1 and 4.2, the inequalities (4.23) can be rewritten as

$$-\tau \gtreqless \frac{dc_0(\beta^*)}{d\beta} j(\beta^*)^{-1} \left\{ c^*(\beta^* - v_-) - \int_{-\infty}^{0} g(U_0, V_0)\, dx \right\}^2 \langle z_0, z_0^\# \rangle. \tag{4.26}$$

Recalling the formula (3.12) for $\hat{\zeta}_0^*$ and using Lemma 4.3 and (4.12), (4.26) becomes

$$-\tau \gtreqless -\frac{(\hat{\zeta}_0^*)^2}{k^*} \langle z_0, z_0^\# \rangle. \tag{4.27}$$

Substituting the expressions (4.19) and (4.20) into (4.27), we have

$$-\tau \gtreqless -k^* \langle K_0^{*,\tau,c^*} \delta_0, K_0^{*,\tau,-c^*} \delta_0 \rangle = -k^* \langle (K_0^{*,\tau,c^*}, \delta_0)^2, \delta_0 \rangle, \tag{4.28}$$

which is clearly equivalent to (4.24). Finally, we will prove the equivalence to (4.25). Rewriting the Jacobian as

$$\frac{\partial(\Phi_0, \Psi_0)}{\partial(c, \beta)} = \frac{\partial \Phi_0}{\partial \beta} \frac{\partial \Psi_0}{\partial \beta} \left\{ \frac{\partial \Phi_0 / \partial c}{\partial \Phi_0 / \partial \beta} - \frac{\partial \Psi_0 / \partial c}{\partial \Psi_0 / \partial \beta} \right\},$$

we see from the formula of derivative of the implicit function that, at the intersection point (c^*, β^*) of $\beta = \beta_0(c)$ and $\beta = \beta_I(c)$, it holds that

$$\left.\frac{\partial(\Phi_0, \Psi_0)}{\partial(c, \beta)}\right|_{(c,\beta)=(c^*,\beta^*)} = \frac{\partial \Phi_0}{\partial \beta}\frac{\partial \Psi_0}{\partial \beta}(\dot{\beta}_I(c^*) - \dot{\beta}_0(c^*)). \tag{4.29}$$

This combined with (2.9) and $(2.15)_b$ proves the last claim of Theorem 4.1.

Example 3.1. Suppose that $\beta = \beta_0(c)$ and $\beta = \beta_I(c)$ intersect each other as in Fig. 4(b). The traveling front solutions corresponding to P and Q (respectively, R) are stable (respectively, unstable).

Appendix. *Proof of Lemma* 3.7. The basic idea of the proof is essentially contained in the proof of Theorem 3.1 of Nishiura and Mimura [15]. However, it should be noted that $\hat{\zeta}_0^*$ and $G(\lambda; \tau, c^*)$ (see (3.12) and (3.70)) depend on the parameter τ, which is a different point from the case treated in [15].

For a given $\tau = \tau_0$, we must show the nonexistence of the complex eigenvalues in $\mathbf{C}_{\mu_1}$ for the SLEP equation (see (3.96) and (3.70)):

$$\mathcal{F}(\lambda; 0, \tau_0, c^*) = \hat{\zeta}_0^* - \tau_0\lambda - G(\lambda; \tau_0, c^*) = 0. \tag{1}$$

The strategy is that we consider the following modified equation of (1):

$$\tilde{\mathcal{F}}(\lambda; \tau) = \hat{\zeta}_0^* - \tau\lambda - G(\lambda; \tau_0, c^*) = 0, \tag{2}$$

namely, the coefficient of the second term of (1) is not fixed to be τ_0 and all the remaining terms are exactly the same as before. We study the behavior of the solutions of (2) when τ varies in $\mathbf{R}_+$, and prove the lemma by contradiction. For this purpose, we prepare four lemmas, the proofs of which will be given in the last part. First it follows from Lemma 3.8 that $\lambda = 0$ is always a solution of (2) and there exists a unique value $\tau = \tau_c$ (which depends on τ_0) such that the straight line $\hat{\zeta}_0^* - \tau_c\lambda$ is tangent to the convex curve $G(\lambda; \tau_0, c^*)$ at $\lambda = 0$. The first lemma describes the behavior of solutions of (2) near $(\tau, \lambda) = (\tau_c, 0)$ as follows.

LEMMA A1. *Equation* (2) *has exactly two solutions near* $(\tau, \lambda) = (\tau_c, 0)$. *One is the zero solution* $(\lambda \equiv 0)$, *which is independent of* τ, *and the other is the real solution* $\lambda \equiv \hat{\lambda}(\tau)$ *with* $\hat{\lambda}(\tau_c) = 0$, *which behaves, near* $\tau = \tau_c$, *as does*

$$\hat{\lambda}(\tau) \simeq -C_T(\tau - \tau_c) \tag{3}$$

where C_T *is a positive constant given by*

$$C_T \equiv \frac{1}{k^*\langle (K_0^{*,\tau_0,c^*})^3 \delta_0, \delta_0\rangle}.$$

Besides the zero solution, $\hat{\lambda}(\tau)$ *is a unique zero of* (2) *in an appropriate complex neighborhood of* $\lambda = 0$.

Remark A1. When $\tau \neq \tau_c$, it holds that $\partial\tilde{\mathcal{F}}/\partial\lambda(\hat{\lambda}(\tau); \tau) \neq 0$ at the unique nonzero real solution $\lambda = \hat{\lambda}(\tau)$ of (2).

The next lemma shows the uniqueness of solutions of (2) on the imaginary axis.

LEMMA A2. *Suppose there exists a solution of* (2) *that crosses the imaginary axis when* τ *varies. Then it must be a real one and must coincide with the solution* $\hat{\lambda}(\tau)$ *in Lemma* A1. *Therefore, there are no complex solutions with* Im-*part* $\neq 0$ *that cross the imaginary axis.*

The following lemma shows that a complex solution of (2) can always be extended uniquely as a function of τ.

LEMMA A3. *Let* (λ_1, τ_1) *be a solution of* (2) *in* $\mathbf{C}_{\hat{\mu}} \times \mathbf{R}_+$. *If* $\operatorname{Im} \lambda_1 \neq 0$, *then it holds that*

$$\frac{\partial \tilde{\mathcal{F}}}{\partial \lambda}(\lambda_1; \tau) \neq 0.$$

Finally, the next lemma shows the nonexistence of solutions of (2) for large τ.

LEMMA A4. *There exist positive constants* τ_s *and* μ_s *such that there are no solutions of* (2) *in* $\mathbf{C}_{\mu_s}$ *for* $\tau \geqq \tau_s$ *except the simple zero solution.*

Now we are ready to prove Lemma 3.7 by contradiction. Suppose that Lemma 3.7 is not true; then we can find a nonreal solution $\lambda_0(\tau_0)$ of (1) with $\operatorname{Re}(\lambda_0(\tau_0)) \geqq 0$. Here we use the fact that $\lambda = 0$ is not an accumulation point of solutions of (1), which can be easily checked by using the properties of G (see Lemma 3.8) and the proof of Lemma A1. Note that τ_0 must be strictly smaller than τ_s in Lemma A4. Regarding $\lambda_0(\tau_0)$ as a special solution of (2) for $\tau = \tau_0$, we trace its behavior when τ varies. We denote by $\lambda_0(\tau)$ the solution of (2), which is a continuation of $\lambda_0(\tau_0)$ as τ varies. In view of Lemma A3, $\lambda_0(\tau_0)$ is uniquely continued as far as it remains a nonreal solution. When τ increases, we see from Lemma A4 that $\lambda_0(\tau)$ must cross the imaginary axis before τ reaches τ_s. However, owing to Lemma A2, $\lambda_0(\tau)$ cannot cross the imaginary axis. Therefore $\lambda_0(\tau)$ must fall into the real solution of (2) before it reaches the imaginary axis. But we see from Lemma A1 and Remark A1 that this is not possible, which is a contradiction and completes the proof.

Proof of Lemma A1. It is clear from Lemma 3.8(i) that $\lambda = 0$ is always a solution of (2) independent of τ. Therefore, since $\tilde{\mathcal{F}}$ is analytic with respect to λ, $\tilde{\mathcal{F}}$ can be rewritten locally near $\lambda = 0$ in the following form:

$$\tilde{\mathcal{F}}(\lambda; \tau) = \lambda \tilde{H}(\lambda; \tau) \tag{4}$$

where $\tilde{H}$ is a smooth function with respect to all variables. After some computation, we obtain

$$\frac{\partial^2 \tilde{\mathcal{F}}}{\partial \lambda^2}(0; \tau_c) = -2k^* \langle (K_0^{*, \tau_0, c^*})^3 \delta_0, \delta_0 \rangle < 0. \tag{5}$$

Since $\partial^2 \tilde{\mathcal{F}} / \partial \lambda^2 (0; \tau_c) = 2 \partial \tilde{H} / \partial \lambda (0, \tau_c)$, it follows from (5) that

$$\frac{\partial \tilde{H}}{\partial \lambda}(0; \tau_c) = -k^* \langle (K_0^{*, \tau_0, c^*})^3 \delta_0, \delta_0 \rangle < 0. \tag{6}$$

This implies via the Implicit Function Theorem that $\tilde{H} = 0$ has a unique solution $\lambda = \hat{\lambda}(\tau)$ in an appropriate complex neighborhood of $\lambda = 0$ with $\hat{\lambda}(\tau_c) = 0$. It also holds that

$$\left. \frac{d\hat{\lambda}(\tau)}{d\tau} \right|_{\tau = \tau_c} = -\frac{\partial \tilde{H} / \partial \tau (0; \tau_c)}{\partial \tilde{H} / \partial \lambda (0; \tau_c)} = -\frac{1}{k^* \langle (K_0^{*, \tau_0, c^*})^3 \delta_0, \delta_0 \rangle}, \tag{7}$$

which completes the proof of Lemma A1.

Proof of Lemma A2. We will show that the origin $(\lambda = 0)$ is the unique solution on the imaginary axis of (2). The real and imaginary parts of (2) are given by

$$\hat{\zeta}_0^* - \tau \lambda_R - A(\lambda_R, (\lambda_I)^2) = 0, \tag{8}_a$$

$$B(\lambda_R, (\lambda_I)^2) - \tau = 0 \tag{8}_b$$

where $\lambda = \lambda_R + i\lambda_I$, and A and B are smooth functions of λ_R $(> -\hat{\mu})$ and $(\lambda_I)^2 \geqq 0$ defined by

$$(9)_a \qquad A(\lambda_R, (\lambda_I)^2) = k^*\langle \hat{I}K_{\lambda_R}\delta_0, \delta_0\rangle,$$

$$(9)_b \qquad B(\lambda_R, (\lambda_I)^2) = k^*\langle \hat{I}K_{\lambda_R}^2\delta_0, \delta_0\rangle.$$

Here $K_{\lambda_R}: (H_\rho^1)^* \to H_\rho^1$ is the inverse operator of

$$T_{\lambda_R} \equiv -\frac{d^2}{dx^2} - c^*\frac{d}{dx} - \frac{\det^*}{f_u^*} + \lambda_R \quad \text{and} \quad \hat{I} = \{I + (\lambda_I)^2 K_{\lambda_R}^2\}^{-1}: H_\rho^1 \to H_\rho^1.$$

The following results are useful, the proofs of which are left to the reader (see also Lemma 3.2 of Nishiura and Mimura [15]).

SUBLEMMA A1.

(i) $\dfrac{\partial A}{\partial(\lambda_I)^2} < 0$ *and* $\dfrac{\partial B}{\partial(\lambda_I)^2} < 0,$

(ii) $\lim\limits_{|\lambda_I| \uparrow \infty} A = 0$ *and* $\lim\limits_{|\lambda| \uparrow \infty} B = 0,$

(iii) $\dfrac{\partial B}{\partial \lambda_R} < 0$ *for* $\lambda_R > -\hat{\mu},$

(iv) $B(\lambda_R, 0) = -\dfrac{d}{d\lambda_R} A(\lambda_R, 0).$

Let us set $\lambda_R = 0$ in (8) and $B_0 = B(0, 0)$. It follows from Sublemma A1(i) that $(8)_b$ can be solved uniquely with respect to $(\lambda_I)^2$ as a function of τ for $\tau \leqq B_0$. We denote it by $(\lambda_I)^2(\tau)$. Note that $(\lambda_I)^2(\tau)$ is a strictly decreasing function of τ with $(\lambda_I)^2(B_0) = 0$ and $\lim_{\tau \to 0} (\lambda_I)^2(\tau) = +\infty$. Substituting this into $(8)_a$, we have a scalar equation of τ $(\leqq B_0)$:

$$(10) \qquad \hat{\zeta}_0^* - A(0, (\lambda_I)^2(\tau)) = 0.$$

In view of Sublemma A1(i), we see that $A(0, (\lambda_I)^2(\tau))$ is a strictly monotone increasing function of τ. Therefore (10) has a unique solution, if it exists. On the other hand, we already know that $\lambda = 0$ is a special solution of (8) coming from the translation invariance, which shows that $\tau = B_0$ is a unique zero of (10). Thus, all the eigenvalues that cross the imaginary axis must go through the origin. Recalling the local uniqueness of the zero solution of (2) in some complex neighborhood (see Lemma A1), we see that $\hat{\lambda}(\tau)$ is the unique solution of (2) which crosses the imaginary axis as τ varies.

Proof of Lemma A3. This can be done in the spirit of the proof of Proposition 3.1 of Nishiura and Mimura [15]. So we leave the details to the reader.

Proof of Lemma A4. First note that, from Sublemma A1(i) and (iii), B is a strictly decreasing function λ_R and $(\lambda_I)^2$. Let $\tau_s \equiv B(-\hat{\mu}/2, 0)$. Then, in view of $(8)_b$, we see that there are no complex eigenvalues in the region $\mathrm{Re}\,\lambda \geqq -\mu_1/2$ for $\tau \geqq \tau_s$. Recalling Sublemma A1(iv) and $A(\lambda_R, 0) \equiv G(\lambda_R; \tau_0, c^*)$ (see (3.70)), we see that $-\tau_s$ is the slope of the convex curve $G(\lambda; \tau_0, c^*)$ at $\lambda = -\hat{\mu}/2$. A simple geometric consideration implies that there are no real eigenvalues λ satisfying $\lambda \geqq -\hat{\mu}/2$ for $\tau \geqq \tau_s$. Combining these results, we can conclude Lemma A4 with $-\mu_s = \max\{-\mu_1/2, -\delta_e\}$ for $\tau \geqq \tau_s$ (see Proposition 3.1 for the definition of δ_e).

TRAVELLING WAVE SOLUTIONS TO A SEMILINEAR DIFFUSION SYSTEM*

J. ESQUINAS† AND M. A. HERRERO†

Abstract. This paper considers the semilinear system

$$\text{(S)}\qquad \begin{aligned} &u_t - u_{xx} + v^p = 0,\\ &v_t - v_{xx} + u^q = 0,\\ &-\infty < x < +\infty, \qquad t > 0 \end{aligned}$$

with $p > 0$ and $q > 0$, and looks for nonnegative and nontrivial travelling wave solutions to (S): $u(x, t) = \varphi(ct - x)$, $v(x, t) = \psi(ct - x)$ possessing sharp fronts, i.e., such that $\varphi(\xi) = \psi(\xi) = 0$ for $\xi \leqq \xi_0$ and some finite ξ_0, which after a phase shift can always be assumed to be located at the origin. These solutions are called finite travelling waves (FTW). Here it is shown that if $pq < 1$, for any real c there exists an FTW that is unique up to phase translations and unbounded, whereas no FTW exists if $pq \geqq 1$. The asymptotic wave profiles near the front as well as far from it are also determined.

1. Introduction.

In this paper we will consider the system

$$\text{(1.1)}\qquad \begin{aligned} &u_t - u_{xx} + v^p = 0,\\ &v_t - v_{xx} + u^q = 0,\\ &-\infty < x < +\infty, \qquad t > 0 \end{aligned}$$

where p and q are positive real numbers. More precisely, we are interested in the existence of nonnegative *finite travelling waves* (FTW). By a *travelling wave* of (1.1) with speed c we mean a solution $(u(x, t), v(x, t))$ defined in

$$S = \{(x, t): -\infty < x < +\infty, t > 0\}$$

of the form

$$\text{(1.2)}\qquad u(x, t) = \varphi(ct - x), \qquad v(x, t) = \psi(ct - x)$$

where $\varphi(\xi)$ and $\psi(\xi)$ are nonnegative and different from zero, $\varphi, \psi \in \mathscr{C}^2(-\infty, +\infty)$, and $\varphi(\xi), \psi(\xi) \to 0$ as $\xi \to -\infty$ and are nondecreasing in ξ. Here φ and ψ are the respective wave profiles, and c may be any real number. If $\varphi(\xi) = \psi(\xi) = 0$ when $\xi \leqq \xi_0$ for some real ξ_0 we say that (u, v) is a *finite travelling wave.* In this case the line $x = ct - \xi_0$ is a front separating the region $P_+(u, v) = \{(x, t): u > 0, v > 0\}$ from the one where $u = v = 0$. Clearly, $P_+(u, v)$ expands in time when $c > 0$ and recedes if $c < 0$, to remain stationary for $c = 0$. In the context of scalar heat conduction problems the two first cases are referred to as the onset of heating and cooling waves, respectively.

There exists a wide literature on reaction-diffusion systems and their stationary states (cf., for instance, [A], [S], and references therein), and, in particular, on the existence of travelling waves to them (see [AW], [F], [FM], [BNS], [CL], [H], [T],

and the references therein). Here we will concern ourselves with one of the simplest cases of semilinear systems exhibiting a nontrivial coupling involving zeroth-order terms, but the techniques employed extend to a wide class of diffusion-absorbing problems. See in this context the remark at the end of § 4.

Let us proceed to describe our results. As the nonlinear terms v^p, u^q are monotone and unbounded for nonnegative values of u and v, no travelling wave can be expected that connects zero to a positive constant state. Thus our FTW will be unbounded, a fact already observed in nonlinear heat conduction problems in the scalar case (cf. [M], [HV]). We first obtain a necessary and sufficient condition for FTW's to exist in terms of p and q, namely, Theorem 1 below.

THEOREM 1. *There exist finite travelling wave solutions of* (1.1) *if and only if*

$$pq < 1. \tag{1.3}$$

Moreover, if (1.3) *holds, for any real c there exists an* FTW *moving with speed c, and the corresponding wave profiles* φ *and* ψ *are unique up to translations in space and time.*

We will assume henceforth that (1.3) holds, and proceed to derive the asymptotic wave profiles near the front (which we may assume to be located at $\xi = ct - x = 0$) as well as for large values of ξ. To this end, we recall some notation. We say that $f(\xi)$ and $g(\xi)$ are equivalent as $\xi \to \xi_0$ (finite or infinite), and write $f(\xi) \approx g(\xi)$ as $\xi \to \xi_0$, if $\lim_{\xi \to \xi_0} (f(\xi)/g(\xi)) = 1$. We then have Theorem 2.

THEOREM 2. *Assume that* $pq < 1$ *and for any real c, let* (φ, ψ) *be the* FTW *propagating with speed c obtained in Theorem* 1. *Then the following hold.*

(i) *For any real c, we have*

$$\varphi(\xi) \approx A\xi^{\alpha} \text{ and } \varphi(\xi) \approx B\xi^{\beta} \text{ as } \xi \to 0^+, \text{ where} \tag{1.4}$$

$$\alpha = \frac{2(1+p)}{1-pq}, \qquad \beta = \frac{2(1+q)}{1-pq},$$

$$A^{1-pq} = ((\beta(\beta-1))^p \alpha(\alpha-1))^{-1}, \qquad B = A^q(\beta(\beta-1))^{-1}.$$

(ii) *If* $c < 0$, *then*

$$\varphi(\xi) \approx C\xi^{\gamma} \text{ and } \psi(\xi) \approx D\xi^{\delta} \text{ as } \xi \to \infty, \text{ where} \tag{1.5}$$

$$\gamma = \frac{1+p}{1-pq}, \qquad \delta = \frac{1+q}{1-pq},$$

$$C^{1-pq} = ((-c)^{1+p}\delta^p\gamma)^{-1}, \qquad D = C^q((-c)\delta)^{-1}.$$

(iii) *If* $c > 0$, *the asymptotics for* $\xi \to \infty$ *depend on the values of p and q as follows*:

If $p < 1$, $q < 1$ *then* $\varphi(\xi) \approx M_1 e^{c\xi}$, $\psi(\xi) \approx N_1 e^{c\xi}$, *where* (1.6a)

$$M_1^{1-pq} = \frac{1}{(c^2(1-q))^p c^2(1-p)}, \qquad N_1 = \frac{M_1^q}{c^2(1-q)};$$

If $p < 1$, $q = 1$ *then* $\varphi(\xi) \approx M_2 e^{c\xi}$, $\psi(\xi) \approx N_2 \xi e^{c\xi}$, *where* (1.6b)

$$M_2^{1-p} = \frac{1}{c^{p+1}} \int_0^{\infty} s^p e^{c(p-1)s}\, ds, \qquad N_2 = \frac{M_2}{c};$$

If $p < 1$, $q > 1$ *then* $\varphi(\xi) \approx M_3 e^{c\xi}$, $\psi(\xi) \approx N_3 e^{cq\xi}$, *where* (1.6c)

$$M_3^{1-pq} = \frac{1}{(c^2(q-1)q)^p c^2(1-pq)}, \qquad N_3 = \frac{M_3^q}{c^2(q-1)q}.$$

The cases $p>1$, $q<1$ and $p>1$, $q=1$ are obtained by changing the coefficients in (1.6b, c) *in an obvious way.*

Let us remark briefly on the estimates above. First, when we look for solutions of the form (1.2), (1.1) is reduced to an ordinary differential equation (ODE) system in the variable $\xi = ct - x$, namely,

$$\varphi'' = c\varphi' + \psi^p, \qquad \psi'' = c\psi' + \varphi^q. \tag{1.7}$$

When $c=0$ (i.e., in the case of stationary waves), (1.7) has an explicit solution given by

$$\varphi(\xi) = A\xi^\alpha, \quad \psi(\xi) = B\xi^\beta, \quad \alpha, \beta, A, B, \text{ as in (1.4).} \tag{1.8}$$

Therefore (1.4) shows that, regardless of the wave-speed c, the first-order asymptotics of FTW's near $\xi=0$ is precisely that of the stationary solutions (1.8). As for the behaviour when $\xi\to\infty$, consider beginning with the case $c<0$ and try formally the asymptotic expansion

$$\varphi(\xi) = C\xi^\gamma + \cdots, \quad \psi(\xi) = D\xi^\delta + \cdots, \quad \xi \gg 0.$$

Substituting this into (1.7) yields

$$\begin{aligned} C\gamma(\gamma-1)\xi^{\gamma-2} &= cC\gamma\xi^{\gamma-1} + D^p\xi^{\delta p} + \cdots, \\ D\delta(\delta-1)\xi^{\delta-2} &= cD\delta\xi^{\delta-1} + C^q\xi^{\gamma q} + \cdots \end{aligned} \tag{1.9}$$

so that, neglecting the terms on the left of (1.9) and matching those on the right, we obtain the values listed in (1.5). We call the wave profiles thus determined to be of an *absorptive nature*, since constants C, D, δ, γ in (1.5) are those corresponding to the explicit FTW solution of the simplified absorbing system obtained from (1.1) by dropping the terms u_{xx}, v_{xx} there.

When $c>0$ we expect the leading behaviour at infinity to be influenced indeed by the heatlike part of (1.1). For instance, if $p<1$ and $q>1$, trying in (1.7) $\varphi(\xi)\approx P e^{\mu\xi}$ and $\psi(\xi)\approx Q e^{\nu\xi}$ leads to

$$P\mu^2 e^{\mu\xi} = cP\mu\, e^{\mu\xi} + Q^p\, e^{p\nu\xi} + \cdots, \tag{1.10a}$$

$$Q\nu^2 e^{\nu\xi} = cQ\nu\, e^{\nu\xi} + P^q\, e^{\mu q\xi} + \cdots. \tag{1.10b}$$

Considering then the three terms in (1.10b) as of the same order yields $\nu = \mu q$, whereas matching the first two in (1.10a) gives us $\mu = c$. We then obtain $\nu = cq$, $\mu = c$ and the third term in (1.10a) is of lower order as $\xi\to\infty$. These are the wave behaviours stated in (1.6c), except for the coefficients P, Q, which remain to be obtained. A similar analysis can be performed for the remaining cases, always yielding the exponential-like estimates for φ and ψ listed in (1.6). Because of the influence of the parabolic part of (1.1), we call these behaviours of *diffusive* type, in contrast wih those obtained in (1.4), (1.5).

As to the precedents of this paper, we should first mention the work [RK], where the authors considered the general scalar equation

$$u_t = a(u^m)_{xx} - bu^p + k(u^n)_x, \qquad a, m, n, b, p, k > 0 \tag{1.11}$$

and used formal perturbation theory (as in the remarks just made above), to describe all the possible asymptotic behaviours of waves occurring in (1.11) in terms of the different parameters therein. See also [PP], where the onset of FTW for another kind of degenerate diffusion equation is analyzed in a similar way. Later, in [HV], a rigorous justification of the results conjectured in [RK] was provided for the case $k=0$; negative

values of m and p were also allowed. The methods employed involve phase space and comparison arguments. We have resorted to different techniques here, since the natural phase space associated with (1.7) is four-dimensional, and therefore rather unwieldy. Basically, existence is obtained by a fixed-point argument in whose formulation the asymptotic behaviours predicted by perturbation theory play a crucial role (cf. § 3). As to uniqueness, it follows from a general ODE argument as explained in § 2 below.

From the results in [RK] and [HV] it follows, in particular, that for the equation

$$u_t = a(u^m)_{xx} - bu^p, \quad a, b > 0, \quad m, p > -1 \tag{1.12}$$

only three asymptotic behaviours of FTW's are possible, there named as *absorptive*, *diffusive*, and *stationary*. These are illustrated by explicit solutions easily obtained by dropping, respectively, the second, third, and first terms in (1.12) (cf. [HV, § 2]). In particular, for the semilinear equation

$$u_t - u_{xx} + u^p = 0, \tag{1.13}$$

FTW's $u(x, t) = \varphi(ct - x)$ exist for positive values of p if and only if $p < 1$. Their behaviour is stationary ($\varphi(\xi) \approx A_1 \xi^{(2/1-p)}$ near the front $\xi \equiv ct - x = 0$, and absorptive ($\varphi(\xi) \approx A_2 \xi^{(1/1-p)}$ or diffusive ($\varphi(\xi) \approx A_3 e^{c\xi}$) as $\xi \to \infty$, according, respectively, to whether $c < 0$ or $c > 0$. Here A_1 and A_2, are positive constants, A_2 depends on c but A_1 does not, and their explicit values are determined, for instance, by trying a formal perturbation expansion. On the other hand,

$$A_3 = \left(\frac{1}{c^2(1-p)}\right)^{(1/1-p)},$$

as can be seen by repeating the arguments in § 4 below. The reader will notice the analogy between these results and the discussion following Theorems 1 and 2 above, although several diffusive behaviours are possible for (1.1) depending on the values of p and q.

Higher-order wave asymptotics can also be obtained from our techniques. As an example, we derive a two-term expansion for FTW's near the fronts.

THEOREM 3. *Let $pq < 1$, and for any real c let $u_c(x, t) = \varphi(ct - x)$, $v_c(x, t) = \psi(ct - x)$ be the solution obtained in Theorems 1 and 2. Then, for $ct - x$ positive and close enough to zero,*

$$u_c(x, t) \approx A(ct - x)^{\alpha} + A_1(ct - x)^{\alpha+1} + \cdots, \tag{1.14}$$

$$v_c(x, t) \approx B(ct - x)^{\beta} + B_1(ct - x)^{\beta+1} + \cdots \tag{1.15}$$

where A, B, α, β are as in Theorem 2 and

$$A_1 = \frac{cA(p(\alpha - 1) + \beta + 1)}{(\alpha + 1)(\beta + 1) - pq(\beta - 1)(\alpha - 1)}, \tag{1.16}$$

$$B_1 = \frac{cB\beta + qA^{q-1}A_1}{\beta(\beta + 1)}. \tag{1.17}$$

Note that the wave-speed c, which is not reflected in the first-order approximation near the front, does appear when second-order terms are considered.

We conclude this Introduction with the plan of the paper. Some preliminaries, as well as uniqueness and nonexistence results, are gathered in § 2. Section 3 is devoted to existence and asymptotics of cooling waves ($c < 0$) under the necessary condition $pq < 1$. Section 4 covers the case $c > 0$.

2. Preliminaries. Nonexistence when $pq \geqq 1$. Uniqueness. A finite travelling wave to (1.1) can be described as a nontrivial, nonnegative solution to the ODE system

$$\begin{aligned} &\varphi, \psi \in C^2[0, \infty), \\ &\varphi''(\xi) = c\varphi'(\xi) + \psi(\xi)^p \quad \text{for } \xi > 0, \\ &\psi''(\xi) = c\psi'(\xi) + \varphi(\xi)^q \quad \text{for } \xi > 0 \end{aligned} \tag{2.1}$$

together with conditions

$$\varphi(\xi) = \varphi'(\xi) = \psi(\xi) = \psi'(\xi) = 0 \quad \text{for } \xi \leqq 0. \tag{2.2}$$

If such a solution exists, the following representation formulas hold:

$$\varphi(\xi) = \int_0^\xi \left(\frac{e^{c(\xi-s)}-1}{c}\right) \psi(s)^p \, ds, \tag{2.3a}$$

$$\psi(\xi) = \int_0^\xi \left(\frac{e^{c(\xi-s)}-1}{c}\right) \varphi(s)^q \, ds, \tag{2.3b}$$

$$\varphi'(\xi) = \int_0^\xi e^{c(\xi-s)} \varphi(s)^p \, ds, \tag{2.3c}$$

$$\psi'(\xi) = \int_0^\xi e^{c(\xi-s)} \varphi(s)^q \, ds. \tag{2.3d}$$

Indeed, (2.3c, d) can be obtained just by differentiating in the first two equations above. Now, substituting (2.3b) into (2.3a), we get

$$\varphi(\xi) = \int_0^\xi \left(\frac{e^{c(\xi-t)}-1}{c}\right) \left[\int_0^t \left(\frac{e^{c(t-s)}-1}{c}\right) \varphi(s)^q \, ds\right]^p dt. \tag{2.4}$$

Therefore, finding FTW's amounts to obtaining nontrivial solutions to the integral equation (2.4).

We now state a nonexistence result.

LEMMA 2.1. *There are no* FTW's *when* $pq \geqq 1$.

Proof. Let us show that $\varphi(\xi) = \psi(\xi) \equiv 0$ if $pq \geqq 1$. If $p \geqq 1$, and $q \geqq 1$, the conclusion follows at once from standard uniqueness results. As to the general case, we will argue by contradiction. By (2.3c, d) both φ and ψ are monotone nondecreasing, and once they are different from zero they always stay positive. Without loss of generality, we may then assume $\varphi(\xi) > 0$, $\psi(\xi) > 0$ for $\xi > 0$. Then from (2.4) we deduce

$$\varphi(\xi) \leqq \varphi(\xi)^{pq} F(\xi) \tag{2.5}$$

where

$$F(\xi) = \int_0^\xi \left(\frac{e^{c(\xi-t)}-1}{c}\right) \left[\int_0^t \left(\frac{e^{c(t-s)}-1}{c}\right) ds\right]^p dt$$

so that, in particular, $F(\xi) \to 0$ as $\xi \to 0$. Now the contradiction follows, since by (2.5), $\varphi(\xi)^{1-pq}$ should go to zero as $\xi \to 0$, which is impossible. □

Uniqueness up to phase shift is contained in the following lemma.

LEMMA 2.2. *Suppose that* (φ_1, ψ_1) *and* (φ_2, ψ_2) *are nontrivial solutions of* (2.1), (2.2). *Then for some real* η *we have* $\varphi_2(\xi) = \varphi_1(\xi - \eta)$ *and* $\psi_2(\xi) = \psi_1(\xi - \eta)$.

Proof. The argument involves two steps.

(i) Any pair of different nontrivial solutions (φ_1, ψ_1) and (φ_2, ψ_2) is ordered, i.e., $\varphi_1(\xi) < \varphi_2(\xi)$ and $\psi_1(\xi) < \psi_2(\xi)$ or $\varphi_1(\xi) > \varphi_2(\xi)$ and $\psi_1(\xi) > \psi_2(\xi)$ for $\xi > 0$.

Actually, it suffices to show the result for φ_1 and φ_2, since the corresponding statement for ψ_1, ψ_2 then follows from (2.3b). To begin with, if supp $\varphi_1 \subset$ supp φ_2 and supp $\varphi_1 \neq$ supp φ_2, (2.3a, b) yield $\varphi_1(\xi) > \varphi_2(\xi)$ for all $\xi > 0$. Therefore we have only to deal with the case

$$\varphi_1(0) = \varphi_2(0), \quad \varphi_1(\xi) > 0, \quad \varphi_2(\xi) > 0 \quad \text{for all } \xi > 0.$$

We then argue by contradiction as follows. Assume that there exists $\xi_0 > 0$ such that $\varphi_1(\xi_0) = \varphi_2(\xi_0)$. Then there exists $\eta > 0$ such that, for any $\xi \leqq \xi_0$,

$$\varphi_{1,\eta}(\xi) \leqq \varphi_2(\xi)$$

where

$$\varphi_{1,\eta}(\xi) = \begin{cases} 0 & \text{if } \xi \leqq \eta, \\ \varphi_1(\xi - \eta) & \text{if } \xi \geqq \eta. \end{cases}$$

Note that for arbitrary $\eta \geqq 0$, $(\varphi_\eta(\xi), \psi_\eta(\xi))$ is a solution of (2.1) provided $(\varphi(\xi), \psi(\xi))$ is also. Now we set $\mu_0 = \inf\{\eta > 0: \varphi_{1,\eta}(\xi) \leqq \varphi_2(\xi) \text{ for } \xi \leqq \xi_0\}$. If $\mu_0 > 0$, there exists $\bar{\xi} \geqq \mu_0$ such that

$$\varphi_{1,\mu_0}(\bar{\xi}) = \varphi_2(\bar{\xi}).$$

In this case we define

$$\mu_1 = \inf\{\xi \leqq \bar{\xi}: \varphi_{1,\mu_0}(\xi) = \varphi_2(\xi)\}.$$

Clearly, $\mu_1 \geqq \mu_0 > 0$. We would then have

$$\varphi_{1,\mu_0}(\xi) < \varphi_2(\xi) \quad \text{if } 0 < \xi < \mu_1, \tag{2.6}$$

$$\varphi_{1,\mu_0}(\mu_1) = \varphi_2(\mu_1) \tag{2.7}$$

but in view of (2.3c) and (2.6), $\varphi_{1,\mu_0}(\mu_1) < \varphi_2(\mu_1)$, so that (2.7) cannot hold. Thus $\mu_0 = 0$ and $\varphi_1(\xi) \leqq \varphi_2(\xi)$ for all $\xi \leqq \xi_0$. Interchanging the roles of φ_1 and φ_2 we deduce $\varphi_1(\xi) = \varphi_2(\xi)$ and the proof of (i) is complete.

(ii) Now let (φ_1, ψ_1) and (φ_2, ψ_2) be two nontrivial solutions of (2.1), (2.2). Without loss of generality, we may assume $\varphi_1(\xi) > \varphi_2(\xi)$ for $\xi > 0$. Since $\varphi_2 \not\equiv 0$, there exists $\eta > 0$ such that $\varphi_{1,\eta}(\xi) < \varphi_2(\xi)$ for $\xi > 0$. Now set

$$\eta_0 = \inf\{\eta: \varphi_{1,\eta}(\xi) < \varphi_2(\xi) \text{ for } \xi > 0\}.$$

If $\eta_0 = 0$, $\varphi_1(\xi) = \varphi_2(\xi)$ so that we may assume $\eta_0 > 0$. Then $\varphi_{1,\delta}(\xi) < \varphi_2(\xi) < \varphi_{1,\varepsilon}(\xi)$ for any δ, ε such that $0 < \varepsilon < \eta_0 < \delta$ and $\xi > 0$, and this implies that $\varphi_2(\xi) = \varphi_{1,\eta_0}(\xi)$. The corresponding result for ψ_1, ψ_2 now follows from (2.3b). □

3. Proofs of Theorems 1 and 2. The case $c < 0$. From now on we assume $pq < 1$ and look for a nontrivial solution to the integral equation for φ obtained in § 2, namely,

$$\varphi(\xi) = \int_0^\xi \left(\frac{e^{c(\xi - t)} - 1}{c}\right)\left[\int_0^t \left(\frac{e^{c(t-s)} - 1}{c}\right)\varphi(s)^q \, ds\right]^p dt. \tag{3.1}$$

To this end a fixed-point argument will be employed. We begin with the case $c < 0$, an assumption to be retained throughout this section.

Let us consider a function $h(\xi) \in \mathscr{C}^2[0, \infty) \cap \mathscr{C}^\infty(0, \infty)$ such that $h(\xi) > 0$ for $\xi > 0$ and

$$h(\xi) = \begin{cases} \xi^\alpha & \text{with } \alpha = \dfrac{2(1+p)}{1-pq} \quad \text{if } \xi \leqq 1, \\ \xi^\beta & \text{with } \beta = \dfrac{1+p}{1-pq} \quad \text{if } \xi \geqq 2. \end{cases} \tag{3.2}$$

Then (3.1) will be solved if we can find a function $\varphi(\xi)=h(\xi)f(\xi)$ such that $f(\xi)>0$ for $\xi>0$, $f\in C^2[0,\infty)$, and f is a fixed point for the operator

$$(3.3)\qquad (Tf)(\xi)=\frac{1}{h(\xi)}\int_0^{\xi}\left(\frac{e^{c(\xi-t)}-1}{c}\right)\left[\int_0^{t}\left(\frac{e^{c(t-s)}-1}{c}\right)(h(s)f(s))^q\,ds\right]^p dt$$

in the Banach space

$$(3.4)\qquad E=((C[0,\infty];\mathbb{R}),\|\ \|_\infty)$$

defined as the space of continuous functions in the Alexandroff compactified set $[0,\infty]$ corresponding to the semiaxis $[0,\infty)$, endowed with the supremum norm. We now have Lemma 3.1.

LEMMA 3.1. *T maps E into E. In particular, for any function $f\in E$,*

$$(3.5)\qquad (Tf)(0)=\frac{f(0)^{pq}}{M}\quad \textit{with } M=((1+\alpha q)(2+\alpha q))^p\alpha(\alpha-1),$$

$$(3.6)\qquad (Tf)(\infty)=\frac{f(\infty)^{pq}}{N}\quad \textit{with } N=(-c)^{1+p}(1+\beta q)^p\beta$$

where $f(\infty)=\lim_{x\to\infty}f(x)$, and α,β are as in (3.2).

Proof. It suffices to show (3.5), (3.6). When $\xi>0$ is close to zero, we have

$$\frac{e^{c(\xi-t)}-1}{c}\approx(\xi-t)\quad \text{for } 0\leqq t\leqq\xi,$$

$$f(\xi)\approx f(0)$$

so that for $\xi\approx 0$ (cf. (3.2), (3.3))

$$\begin{aligned}(Tf)(\xi)&\approx\xi^{-\alpha}\int_0^{\xi}(\xi-t)\left[\int_0^{t}(t-s)s^{\alpha q}f(0)^q\,ds\right]^p dt\\&=\xi^{-\alpha}f(0)^{pq}((1+\alpha q)(2+\alpha q))^{-p}\int_0^{\xi}(\xi-t)t^{p(\alpha q+2)}\,dt\\&=f(0)^{pq}((1+\alpha q)(2\alpha q))^{-p}(\alpha(\alpha-1))^{-1}.\end{aligned}$$

This gives (3.5). As for (3.6), we remark that since $c<0$, we have, for fixed $\xi_0>1$ and $\xi\gg\xi_0$,

$$\begin{aligned}(Tf)(\xi)&\approx\xi^{-\beta}\int_{\xi_0}^{\xi}\left(\frac{e^{c(\xi-t)}-1}{c}\right)\left[\int_{\xi_0}^{t}\left(\frac{e^{c(t-s)}-1}{c}\right)s^{\beta q}f(s)^q\,ds\right]^p dt\\&\approx\xi^{-\beta}f(\infty)^{pq}\int_{\xi_0}^{\xi}\left(\frac{-1}{c}\right)\left[\int_{\xi_0}^{t}\left(\frac{-1}{c}\right)s^{\beta q}\,ds\right]^p dt,\end{aligned}$$

whence comes the result. □

LEMMA 3.2. *T is continuous, and transforms bounded sets of E into bounded sets of E. In particular, there holds*

$$(3.7)\qquad \|Tf\|_\infty\leqq\|f\|_\infty^{pq}\|TI\|_\infty\quad \textit{where } I(\xi)=1 \textit{ for any } \xi\geqq 0.$$

The proof of this result is straightforward.

We want to show next that T transforms bounded sets into bounded and equicontinuous sets, when restricted to a suitable domain $K\subset E$, which consists of those functions $f\in E$ such that

$$(3.8a)\qquad f(\xi)\geqq 0\quad \text{for any } \xi\in[0,\infty);$$

(3.8b) $\|f\|_\infty \leqq k_1 f(0)$, $\|f\|_\infty \leqq k_2 f(\infty)$, where

$$k_1 = \max\left((M\|TI\|_\infty)^{(1/1-pq)}, 1\right), \qquad k_2 = \max\left((N\|TI\|_\infty)^{(1/1-pq)}, 1\right),$$

M and N being the constants in (3.5), (3.6), and I being the constant function in (3.7);

(3.8c) For any $\varepsilon > 0$ we have

$$(1-\varepsilon)f(0) \leqq f(x) \leqq (1+\varepsilon)f(0) \quad \text{if } x < \delta(\varepsilon),$$

$$(1-\varepsilon)f(\infty) \leqq f(x) \leqq (1+\varepsilon)f(\infty) \quad \text{if } x > N(\varepsilon)$$

where

$$\delta(\varepsilon) = \sup\left(x: (1-\varepsilon)^{1-pq} \leqq \frac{(TI)(x)}{(TI)(0)} \leqq (1+\varepsilon)^{1-pq}\right),$$

$$N(\varepsilon) = \inf\left(x: (1-\varepsilon)^{1-pq} \leqq \frac{(TI)(x)}{(TI)(\infty)} \leqq (1+\varepsilon)^{1-pq}\right).$$

We have thus defined a cone (i.e., a closed, convex set K in the Banach space E such that (i) $\lambda f \in K$ for any $\lambda \geqq 0$ if $f \in K$, and (ii) for any $f \in E$, $f \not\equiv 0$, at least one of the functions f, $(-f)$ does not lie in K). This set is nonempty, since both the trivial function and $I(x)$ in (3.7) are in K. We now have Lemma 3.3.

LEMMA 3.3. $T(K) \subset K$.

Proof. Let $f \in K$. It is clear that $(Tf)(\xi) \geqq 0$ for any $\xi \in [0, \infty)$. Furthermore, by (3.5) and (3.8b)

$$\|Tf\|_\infty \leqq \|f\|_\infty^{pq} \|TI\|_\infty \leqq k_1^{pq} f(0)^{pq} \|TI\|_\infty = k_1^{pq} M \|TI\|_\infty (Tf)(0)$$

so that we have $\|Tf\|_\infty \leqq k_1 (Tf)(0)$ as soon as we impose

$$k_1 \geqq (M\|TI\|_\infty)^{(1/1-pq)}.$$

Actually equality would suffice for our purposes at this point; however, the fact that $k_1 \geqq 1$ will play a role in a later result. Similarly, we see that $\|Tf\|_\infty \leqq k_2 (Tf)(\infty)$.

Now take $x < \delta(\varepsilon)$ with $\delta(\varepsilon)$ given in (3.8c) and use this last property applied to f to get

$$(Tf)(\xi) \leqq f(0)^{pq}(1+\varepsilon)^{pq}(TI)(\xi)$$

so that by (3.5)

$$\begin{aligned}(Tf)(\xi) &\leqq M(1+\varepsilon)^{pq}(TI)(\xi)(Tf)(0) \\ &= (1+\varepsilon)^{pq}(TI)(\xi)((TI)(0))^{-1}(Tf)(0)\end{aligned}$$

and since $(TI)(\xi)((TI)(0))^{-1} \leqq (1+\varepsilon)^{1-pq}$ in the interval under consideration, the conclusion follows. The corresponding estimate at infinity is arrived at analogously. □

LEMMA 3.4. *T transforms bounded sets in K into bounded and equicontinuous sets in K.*

Proof. The first statement in the lemma has already been listed in Lemma 3.2. On the other hand, proving equicontinuity away from $\xi = 0$ and $\xi = +\infty$ is immediate: actually, it is not necessary to restrict T to the cone K at this stage. As for the cases $\xi = 0, +\infty$, they follow at once from (3.8c) since $TK \subset K$. □

Let us summarize. So far, we have shown that T given in (3.3) is a bounded, completely continuous operator that maps the cone K defined in (3.8) into itself. By the classical Schauder Theorem (cf, for instance, [K]), T has at least a fixed point $f(\xi)$. This is not enough, however, since $f(\xi)$ may vanish identically. Our next step is then Lemma 3.5.

LEMMA 3.5. *T has a nontrivial fixed point in K.*

Proof. For $n = 1, 2, \cdots$ we define

$$T_n(f) = T\left(f + \frac{I}{n}\right)$$

where $I(x)$ is given in (3.7). Now, since $k_1 \geqq 1$ and $k_2 \geqq 1$, the function $f + I/n$ belongs to K provided that $f \in K$, and it is easy to see that for any fixed n, T_n is a nonnegative, bounded, and completely continuous operator from K into K. Furthermore, since

$$\| TI \|_\infty \geqq \min\left(TI(0), TI(\infty)\right) = \min\left(\frac{1}{M}, \frac{1}{N}\right) \equiv a_0 > 0,$$

we have

$$\| T_n f \|_\infty \geqq \left\| T\frac{I}{n} \right\|_\infty \geqq \frac{a_0}{n^{pq}} > 0. \tag{3.9}$$

Then a variant of Schauder's theorem (cf. [K, p. 242]) states that for any $r_0 > 0$, there exist $\lambda_n > 0$ and $g_n \in K$ such that

$$T_n g_n = \lambda_n g_n, \tag{3.10}$$

$$\| g_n \|_\infty = r_0. \tag{3.11}$$

Write $\mu_n = (\lambda_n)^{-1}$. It then follows from (3.9) that

$$g_n(\xi) = \mu_n T_n g_n(\xi) = \mu_n T\left(g_n(\xi) + \frac{I(\xi)}{n}\right) \geqq \mu_n T\left(\frac{I(\xi)}{n}\right)$$

whence

$$\begin{aligned} g_n(\xi) = \mu_n T_n g_n(\xi) &= \mu_n T\left(g_n(\xi) + \frac{I(\xi)}{n}\right) \geqq \mu_n T\left(g_n(\xi)\right) \\ &\geqq \mu_n T\left(\mu_n T\left(\frac{I(\xi)}{n}\right)\right) = \mu_n^{1+pq} n^{-(pq)^2} T^2 I(\xi). \end{aligned} \tag{3.12}$$

Iterating (3.12), we deduce that for any $m = 1, 2, \cdots$

$$g_n(\xi) \geqq (\mu_n^{1+pq+\cdots+(pq)^m}) n^{-pq^{(m+1)}} T^{m+1} I(\xi)$$

so that

$$r_0 = \| g_n \|_\infty \geqq (\mu_n^{1+pq+\cdots+(pq)^m}) n^{-pq^{(m+1)}} \| T^{m+1} I \|_\infty. \tag{3.13}$$

On the other hand, by (3.5)

$$\| T^2 I \|_\infty = \| T(TI) \|_\infty \geqq T(TI(0)) = T\left(\frac{1}{M}\right) = (M^{1+pq})^{-1}.$$

Thus for any $m \geqq 1$

$$\| T^{m+1} I \|_\infty \geqq (M^{1+pq+\cdots+(pq)^m})^{-1}. \tag{3.14}$$

Putting together (3.13) and (3.14) we get

$$r_0 = \|g_n\|_\infty \geqq (M^{1+pq+\cdots+(pq)^m})^{-1} n^{-pq^{(m+1)}} (\mu_n^{1+pq+\cdots+(pq)^m}). \tag{3.15}$$

We now let $m \to \infty$ in (3.15) for fixed n. As $pq < 1$, this gives

$$r_0 \geqq (M^{(1/(1-pq))})^{-1} \mu_n^{(1/(1-pq))}. \tag{3.16}$$

The next step consists of passing to the limit in (3.10). By (3.11), the sequence $\{g_n + I/n\}$, $n = 1, 2, \cdots$ is bounded. As T is completely continuous, we have that, up to a subsequence also labelled with n,

$$T\left(g_n + \frac{I}{n}\right) \to g \quad \text{as } n \to \infty \tag{3.17}$$

for some $g \in K$ with $0 < \|g\|_\infty < \infty$. On the other hand, by (3.16) and again up to a subsequence, we get

$$\mu_n \to \mu_0 < \infty \quad \text{as } n \to \infty. \tag{3.18}$$

Now from (3.10), (3.17), and (3.18) we conclude that, along a suitable subsequence,

$$g_n \to \mu_0 g \quad \text{as } n \to \infty. \tag{3.19}$$

Therefore, using (3.17) and (3.19), we get

$$g = \lim_{n\to\infty} T\left(g_n + \frac{I}{n}\right) = \lim_{n\to\infty} T(g_n) = T(\mu_0 g),$$

i.e.,

$$g = T(\mu_0 g) = \mu_0^{pq} T(g)$$

and then the function $f = \mu_0^{-(pq/(1-pq))} g$ is the required fixed point, since it satisfies $f = Tf$. □

Note that, since $\|f\|_\infty \neq 0$, it follows from (3.8c) that $f(0)$ and $f(\infty)$ are both positive. In particular, from (3.5), (3.6) we conclude that $f(0)^{1-pq} = M^{-1}$, $f(\infty)^{1-pq} = N^{-1}$ with M, N as in Lemma 3.1. This gives the asymptotic estimates corresponding to φ (1.4), (1.5) of Theorem 2. Those corresponding to ψ follow, for instance, from (2.3b). □

4. The case $c > 0$. Our next step consists in obtaining the corresponding results for expanding waves, i.e., for the case $c > 0$. Since the arguments very much parallel those in § 3, we just stress the new relevant points and sketch the rest of the proof. To begin with, instead of $h(\xi)$ in (3.2) we consider three positive functions $z_i(\xi) \in \mathscr{C}^2[0, \infty)$, $i = 1, 2, 3$ such that $z_i(\xi) = \xi^\alpha$ with $\alpha = 2(1+p)/(1-pq)$ if $\xi \leqq 1$ and

$$z_i(\xi) = \begin{cases} e^{c\xi} & \text{if } \xi \geqq 2, \quad i = 1, \\ \xi e^{c\xi} & \text{if } \xi \geqq 2, \quad i = 2, \\ e^{c\xi} & \text{if } \xi \geqq 2, \quad i = 3. \end{cases} \tag{4.1}$$

We now define nonnegative operators $T_{i,q}$ acting on E (cf. (3.4)) as follows:

$$(T_{i,q} f)(\xi) = \frac{1}{z_i(\xi)} \int_0^\xi \left(\frac{e^{c(\xi-t)} - 1}{c}\right) \left[\int_0^t \left(\frac{e^{c(t-s)} - 1}{c}\right) z_i^q(s) f(s)^q \, ds\right]^p dt$$

where $i = 1$ if $p < 1$, $i = 2$ if $p = 1$, and $i = 3$ if $p > 1$. Then we have Lemma 4.1.

LEMMA 4.1. *T_i maps E into E for $i=1,2,3$. In particular, for any $f\in E$,*

$$(T_{i,q}f)(0)=\frac{f(0)^{pq}}{M} \quad \textit{with } M \textit{ given in } (3.5) \quad \textit{and} \quad i=1,2,3, \tag{4.2}$$

$$(T_{1,q}f)(\infty)=f(\infty)\frac{1}{(c^2(1-q))^p c^2(1-p)} \quad \textit{if } q<1, \tag{4.3a}$$

$$(T_{1,q}f)(\infty)=f(\infty)^p\frac{1}{c^{p+1}}\int_0^{+\infty} s^p\, e^{c(p-1)s}\,ds \quad \textit{if } q=1, \tag{4.3b}$$

$$(T_{1,q}f)(\infty)=f(\infty)^{pq}\frac{1}{(c^2(q-1)q)^p c^2(1-pq)} \quad \textit{if } q>1. \tag{4.3c}$$

Proof. Condition (4.2) has already been obtained in (3.5). As for (4.3), we note that since

$$\int_0^{\xi}\left(\frac{e^{c(\xi-t)}-1}{c}\right)e^{cqt}\,dt=\frac{e^{cq\xi}}{c^2q(q-1)}-\frac{e^{c\xi}}{c^2(q-1)}+\frac{1}{c^2q},$$

we have for $\xi\gg 0$

$$\left[\int_0^{\xi}\left(\frac{e^{c(\xi-t)}-1}{c}\right)e^{cqt}\,dt\right]^p\approx\begin{cases}\dfrac{e^{cp\xi}}{(c^2(1-q))^p} & \text{if } q<1,\\[2ex] \dfrac{\xi^p\, e^{cp\xi}}{c^p} & \text{if } q=1,\\[2ex] \dfrac{e^{cpq\xi}}{(c^2q(q-1))^p} & \text{if } q>1,\end{cases} \tag{4.4}$$

and then (4.3) follows by elementary calculus. □

To conclude the proof of Theorem 2, it suffices to repeat the fixed-point arguments in § 3 with some obvious modifications. In particular, for $p<1$ operators $T_{1,q}$ are to be considered as acting on the cones $K_{i,q}$, obtained by replacing (TI) by $(T_{1,q}I)$ in (3.8). □

Proof of Theorem 3. It will suffice to obtain (1.14) and (1.16), since the corresponding results for $v_c(x,t)$ are similar. To proceed, we recall that in Theorem 2 we have shown that

$$\varphi(\xi)=\xi^{\alpha}f(\xi) \quad \text{for } \xi>0, \quad \xi\approx 0 \tag{4.5}$$

where

$$f(\xi)=(Tf)(\xi), \tag{4.6}$$

T being the operator defined in (3.3), (3.4). Since $f(\xi)\in\mathscr{C}^2$, we have that

$$f(\xi)=f(0)+f'(0)\xi+O(\xi^2) \quad \text{as } \xi\approx 0, \tag{4.7}$$

whence

$$A_1=f'(0)=\lim_{\xi\to 0^+}\left(\frac{1}{\xi}((Tf)(\xi)-A)\right). \tag{4.8}$$

To compute A_1 we expand the quantity in the braces above up to second-order terms and then pass to the limit. For $t \approx 0$, we compute

$$\int_0^t \left(\frac{e^{c(t-s)}-1}{c}\right) s^{\alpha q} f(s)^q \, ds$$

$$\approx \int_0^t \left((t-s)+\frac{c}{2}(t-s)^2\right) s^{\alpha q} A^q \left(1+\frac{A_1 s}{A}\right)^q ds$$

$$\approx \int_0^t \left((t-s)+\frac{c}{2}(t-s)^2\right) s^{\alpha q} (A^q + qA^{q-1}A_1)\, ds$$

$$\approx \frac{A^q t^\beta}{\beta(\beta-1)} + \frac{t^{\beta+1}A^{q-1}}{\beta(\beta+1)}\left(\frac{cA}{\beta-1}+qA_1\right)$$

where β is given in (1.4). It then follows that

$$\int_0^\xi \left(\frac{e^{c(\xi-t)}-1}{c}\right)\left[\int_0^t \left(\frac{e^{c(t-s)}-1}{c}\right) s^{\alpha q} f(s)^q \, ds\right]^p dt$$

$$\approx \frac{A^{pq}\xi^\alpha}{(\beta(\beta-1))^p \alpha(\alpha-1)} + \frac{A^{pq}\xi^{\alpha+1}}{(\beta(\beta-1))^p \alpha(\alpha+1)}$$

$$\cdot \left(\frac{c(p(\alpha-1)+\beta+1)}{(\alpha-1)(\beta+1)} + \frac{pqA^{-1}A_1(\beta-1)}{\beta+1}\right)$$

so that, taking into account (1.4), we conclude that for $\xi > 0$, $\xi \approx 0$,

$$\frac{1}{\xi}((Tf)(\xi)-A) \approx \frac{Ac(p(\alpha-1)+\beta+1)+pqA_1(\alpha-1)(\beta-1)}{(\alpha+1)(\beta+1)}. \tag{4.9}$$

The results follow from (4.8) and (4.9). □

We conclude with a few remarks. First we observe that, for the waves (u_c, v_c) obtained previously, we have

$$\lim_{ct-x\to 0^+} \left(\frac{\partial u_c(ct-x)/\partial t}{\partial u_c(ct-x)/\partial x}\right) = -c, \tag{4.10}$$

which is the equation satisfied at the front of u_c. Indeed, a similar result holds for v_c. Note that relation (4.10) can be arrived at in a formal way as follows. For $\varepsilon > 0$, write $x_\varepsilon(t)$ to denote the level line $u(x_\varepsilon(t), t) = \varepsilon$. Then differentiating with respect to t yields

$$\frac{\partial u}{\partial x}\frac{dx_\varepsilon}{dt} + \frac{\partial u}{\partial t} = 0,$$

which, if we let $\varepsilon \to 0$, suggest the following equation for the level line $x_0(t)$, where $u(x_0(t), t) = 0$:

$$\frac{dx_0}{dt} = -\frac{\partial u/\partial t}{\partial u/\partial x}$$

where the quantity on the right is computed at the curve $x_0(t)$. This is precisely (4.10) in the case of waves (u_c, v_c).

Next we consider the limit case $pq = 1$. We already know that there are no FTW's in this case. However, travelling waves exist, although they are not unique. More precisely, we have Lemma 4.2.

LEMMA 4.2. *Assume* $pq=1$. *Then for any real* c *there exist* $\theta>0$, $\chi>\max(0, c)$ *such that, for any* $P>0$,

$$\varphi(\xi)=Pe^{\theta\xi}, \qquad \psi(\xi)=\frac{p^q e^{\chi\xi}}{\chi(\chi-c)}$$

is a monoparametric family of solutions to (1.7) *satisfying*

$$\varphi(\xi), \psi(\xi)\to\infty \quad \text{as } \xi\to\infty,$$

$$\varphi(\xi), \psi(\xi)\to 0 \quad \text{as } \xi\to-\infty.$$

Proof. We just try $\varphi=Pe^{\theta\xi}$, $\psi=Qe^{\chi\xi}$ in (1.7). This leads to

$$\begin{aligned} P\theta(\theta-c)\,e^{\theta\xi}&=Q^p\,e^{\chi p\xi},\\ Q\chi(\chi-c)\,e^{\chi\xi}&=P^q\,e^{\theta q\xi} \end{aligned} \tag{4.11}$$

where we impose

$$\theta=\chi p, \qquad \chi=\theta q. \tag{4.12}$$

Note that this yields no further information on θ or χ, since $pq=1$. Matching the corresponding coefficients in (4.11), we get $P\theta(\theta-c)=Q^p$, $Q\chi(\chi-c)=P^q$ whence

$$P\theta(\theta-c)=\left(\frac{P^q}{\chi(\chi-c)}\right)^p=\frac{P}{(\chi(\chi-c))^p}$$

and using (4.12) we deduce

$$\chi p(\chi p-c)(\chi(\chi-c))^p=1.$$

When $p=q=1$ this reads $\chi^2(\chi-c)^2=1$, which always has a positive solution for $\chi\geqq\max(0, c)$. As to the general case, we may assume, for instance, that $p>1$, and then $F_p(\chi)=\chi p(\chi p-c)(\chi(\chi-c))^p$ also has a positive root for $\chi\geqq\max(0, c)$. The corresponding values of θ are then obtained by (4.12), and for fixed $P>0$ the associated $Q=Q(P)$ is determined from (4.11). □

As a final remark, we observe that the methods in this paper apply to other types of semilinear diffusion-absorption systems. For instance, consider the following example:

$$\begin{aligned} &u_t-u_{xx}+(uv)^p=0,\\ &v_t-v_{xx}+(uv)^q=0,\\ &-\infty<x<\infty,\ t>0, \qquad p, q>0. \end{aligned} \tag{4.13}$$

Searching for waves $u_c(x, t)=\varphi(ct-x)$, $v_c(x, t)=\varphi(ct-x)$ in (4.13) we are led to the ODE system

$$\varphi''=c\varphi'+(\varphi\psi)^p, \qquad \psi''=c\psi'+(\varphi\psi)^q. \tag{4.14}$$

Now the analogue to (1.3), i.e., the condition for FTW's to exist, is

$$p+q<1.$$

As before, formal perturbation methods suggest the asymptotic behaviour of the waves.

For instance, in the case $c<0$, we have

$$\varphi(\xi)\approx\begin{cases}A_1\xi^{\alpha_1} & \text{with } \alpha_1=\dfrac{2(1-q+p)}{1-(p+q)} \quad \text{if } \xi\approx 0,\\ A_2\xi^{\alpha_1/2} & \text{if } \xi\gg 0,\end{cases}$$

$$\psi(\xi)\approx\begin{cases}B_1\xi^{\beta_1} & \text{with } \beta_1=\dfrac{2(1-p+q)}{1-(p+q)} \quad \text{if } \xi\approx 0,\\ B_2\xi^{\beta_1/2} & \text{if } \xi\gg 0\end{cases}$$

where A_1, A_2, B_1, B_2 are positive constants depending on p and q.

Results corresponding to Theorems 1-3 can now be proved with some minor modifications. We just mention that, because of the structure of (4.14), it is convenient to get the fixed-point argument for the variable $z(\xi)=\varphi(\xi)\psi(\xi)$, for which the formula analogous to (2.4) reads

$$z(\xi)=\left[\int_0^\xi\left(\frac{e^{c(\xi-t)}-1}{c}\right)z(t)^p\,dt\right]\left[\int_0^\xi\left(\frac{e^{c(\xi-t)}-1}{c}\right)z(t)^q\,dt\right].$$

SPATIALLY OSCILLATORY STEADY STATES OF TUBULAR CHEMICAL REACTORS*

ROGER ALEXANDER†

Abstract. The equations governing the nonadiabatic tubular chemical reactor have as many low-conversion steady-state solutions as are wanted, if the coefficient of heat transfer from reactor to cooling jacket is sufficiently large, and if the activation energy is large. These steady states exhibit no reaction zone: temperature and reactant concentration do not deviate much from their inlet values. The temperature profiles are oscillatory in these steady states; the most oscillatory profile can be computed by the method of averaging.

Key words. chemical reactors, multiple steady states, averaging method

AMS(MOS) subject classifications. 80A32, 34B15

1. Introduction. In this paper we show that the axial dispersion model of the nonadiabatic tubular reactor can have arbitrarily many steady states, provided that two constants occurring in the governing equations are sufficiently large.

The steady states of the reactor are solutions of a boundary value problem for the temperature T and reacting species concentration C. In these equations the reactor length has been normalized to unity. Constants H, M, B, D, β, γ are explained below. The equations are:

$$
\begin{aligned}
&\frac{1}{H}T''-T'-\beta(T-1)+BDC\,e^{-\gamma/T}=0, && 0<x<1,\\
&T'-H(T-1)=0, && x=0,\\
&T'=0, && x=1,\\
&\frac{1}{M}C''-C'-D\,e^{-\gamma/T}C=0, && 0<x<1,\\
&C'-M(C-1)=0, && x=0,\\
&C'=0, && x=1.
\end{aligned}
\tag{1.1}
$$

Consult [VA] for a detailed derivation, or [A2] for an explanatory sketch; here we merely indicate the meaning of the parameters:

H, M—Péclet numbers for heat and mass, respectively,

β—coefficient of heat transfer between reactor tube and cooling jacket,

B—heat release of chemical reaction,

D—Damköhler number,

γ—activation energy.

As far as the author knows, no one has proved that (1.1) can have more than three solutions. However, formal asymptotic methods and numerical bifurcation analysis have made it "well known" that there can be up to seven steady states when the activation energy is large. This result, and the difficulties the equations pose for a rigorous analysis, are discussed in the survey [A2].

Kapila and Poore [KP] have constructed formal asymptotic solutions to (1.1). We are interested here in *one* of the types of solution described by them, the "low-conversion" steady state. Such a solution exhibits no "reaction zone"; instead T and C remain close to their inlet values throughout the reactor.

In this paper we show that (1.1) can have an arbitrary number of low-conversion steady-state solutions, provided that the reactor parameters are in a suitable range. These solutions exhibit temperature profiles in the form of oscillations that grow slowly in amplitude as the reactor is traversed from inlet to outlet. Note that these solutions occur in addition to the six other types of steady states, identified by Kapila and Poore, that may be present.

This paper extends previous work of the author [A1] in two crucial respects. First, in [A1] multiple solutions are found for an approximating equation—what is called here the "decoupled equation" for the temperature.

Here we derive the *same* multiplicity results for the original equation (1.1) as for the decoupled equation.

The second improvement over [A1] is the use of the method of averaging to obtain a more precise count of the number of solutions. In the previous paper, a simple differential inequality is used to give a lower bound on solution multiplicity.

Formally, the limit $\gamma \to \infty$ yields the "nonreacting" solution: $T = C = 1$ everywhere. We take γ finite but large, and use it as a microscope to find "low-conversion" solutions—solutions with T and C near 1 throughout the reactor.

Into (1.1) we substitute

$$T = 1 + \gamma^{-1} y, \quad C = 1 + \gamma^{-1} z, \quad D = \gamma^{-1} \lambda e^{\gamma}$$

to obtain an equivalent boundary problem for (y, z):

$$\frac{1}{H} y'' - y' - \beta y + B\lambda (1 + \gamma^{-1} z) \exp\left[\frac{y'}{1 + \gamma^{-1} y}\right] = 0, \qquad 0 < x < 1, \tag{1.2}$$

$$y' - Hy = 0 \quad \text{at } x = 0, \tag{1.2$_0$}$$

$$y' = 0 \quad \text{at } x = 1, \tag{1.2$_1$}$$

$$\frac{1}{M} z'' - z' - \gamma^{-1} \lambda \exp\left[\frac{y}{1 + \gamma^{-1} y}\right] z = \lambda \exp\left[\frac{y}{1 + \gamma^{-1} y}\right], \qquad 0 < x < 1, \tag{1.3}$$

$$z' - Mz = 0 \quad \text{at } x = 0, \tag{1.3$_0$}$$

$$z' = 0 \quad \text{at } x = 1. \tag{1.3$_1$}$$

In (1.3), z is the solution of a linear boundary problem with coefficients depending on y. On the other hand, we expect z to influence y only weakly, for it appears multiplied by γ^{-1} in the equation for y, and γ is large.

It is worth emphasizing that (1.2)-(1.3) are *equivalent* to the original system of (1.1)—they do not represent the first term in an expansion in inverse powers of γ.

Replace the coefficient $(1 + \gamma^{-1} z)$ in (1.2) by 1 to obtain the "decoupled equation" for y:

$$\frac{1}{H} y'' - y' - \beta y + B\lambda \exp\left[\frac{y}{1 + \gamma^{-1} y}\right] = 0, \qquad 0 < x < 1,$$

$$y' - Hy = 0 \quad \text{at } x = 0, \tag{1.4}$$

$$y' = 0 \quad \text{at } x = 1.$$

In § 2 we study this problem. We show that it has many solutions when β is large and $\gamma^{-1}\beta$ is small. We establish the oscillatory character of those solutions and derive bounds on them. Phase-plane methods have been used before to investigate multiple steady states (see [MA]). In § 3 we return to the coupled problem, and show that to each solution $\tilde{y}$ of (1.4) corresponds a solution (y, z) of (1.2)-(1.3) with y near $\tilde{y}$; moreover, distinct solutions of (1.4) yield distinct solutions of (1.2)-(1.3). Section 4 summarizes some further points and unanswered questions. Some calculations are relegated to the Appendices.

2. The decoupled y-equation. Begin by writing (1.4) as a boundary value problem for a first-order system. Let

$$y_1 = y, \qquad y_2 = y'.$$

This gives

$$y_1' = y_2, \qquad y_2' = H\left\{y_2 + \beta y_1 - B\lambda \exp\left[\frac{y_1}{1+\gamma^{-1}y_1}\right]\right\}, \tag{2.1}$$

and the boundary conditions

$$y_2(0) - Hy_1(0) = 0, \qquad y_2(1) = 0. \tag{2.2}$$

Let the parameters H, B, λ be fixed in what follows. It is shown in Appendix A that if $\beta/B\lambda > e$ and $\gamma^{-1}\beta$ is small, then the system of (2.1) has three critical points $(y_1, y_2) = (\alpha_j, 0)$, $j = 0, 1, 2$:

$$\alpha_0 = \frac{B\lambda}{\beta} + O(\beta^{-2}),$$

$$\alpha = \alpha_1 = \log\frac{\beta}{B\lambda} + \log\log\frac{\beta}{B\lambda} + o(1),$$

$$\alpha_2 = \frac{B\lambda}{\beta}\, e^{\gamma}(1 + O(\gamma^2 e^{-\gamma})).$$

The critical points $(\alpha_0, 0)$ and $(\alpha_2, 0)$ are always saddles. We will write α for α_1—this is the pivot of our analysis. Appendix A shows as well that the critical point $(\alpha, 0)$ is an unstable spiral point provided

$$\frac{\alpha}{(1+\gamma^{-1}\alpha)^2} > 1 + \frac{H}{4\beta} \qquad (\alpha = \alpha_1).$$

This condition holds when β^{-1} and $\gamma^{-1}\beta$ are small enough, for any fixed choice of H, B, and λ.

Let us write $y(x; \eta) := (y_1(x; \eta), y_2(x; \eta))^T$ for the solution of the differential equations (2.1) subject to the initial conditions

$$y_1(0) = \eta, \qquad y_2(0) = H\eta.$$

This y satisfies the first boundary condition of (2.2). It remains to determine η so that the second boundary condition of (2.2), $y_2(1; \eta) = 0$, is satisfied. We show that there are many such η.

Keeping in mind the geometry of trajectories near the spiral point, use the rule

$$\hat{\theta}(x; \eta) = \arctan\frac{y_2(x; \eta)}{y_1(x; \eta) - \alpha}$$

to determine $\hat{\theta}$ depending continuously on both variables $x \geqq 0$, $\eta \geqq 0$, understanding that

$$\pi \geqq \hat{\theta}(0; \eta) \geqq 0.$$

Solutions of the decoupled equation and boundary conditions correspond to values of η for which

$$\hat{\theta}(1; \eta) = k\pi, \qquad k \in \mathbf{Z}.$$

It is easy to see from the vector field that

$$\hat{\theta}(1; 0) > \pi. \tag{2.3}$$

We will establish Lemma 2.1.

LEMMA 2.1. *There are numbers $\bar{\eta}$ and Y with $\alpha < \bar{\eta} < Y = \alpha + \log\log\sqrt{\beta/B\lambda} + o(1)$ such that*

$$\hat{\theta}(1; \bar{\eta}) > -\pi.$$

The bulk of this section is devoted to the proof of the next lemma.

LEMMA 2.2. *There is a number η^* with $0 < \eta^* < \bar{\eta}$ such that*

$$\hat{\theta}(1; \eta^*) < -\omega + O(1), \qquad \omega \sim (\beta \log \beta)^{1/2}.$$

The multiplicity result then follows directly from (2.3) and Lemmata 2.1 and 2.2 by an application of the continuous dependence of solutions on initial conditions and the Intermediate Value Theorem.

THEOREM. *Let N be the greatest integer less than ω/π. Then for each integer $k = 1, 0, -1, \cdots, -N$ there is a number η'_k satisfying*

$$0 < \eta'_k < \eta^*, \qquad \hat{\theta}(1; \eta'_k) = k\pi;$$

for each integer $k = -1, -2, \cdots, -N$ there is a number η''_k satisfying

$$\eta^* < \eta''_k < \bar{\eta}, \qquad \hat{\theta}(1; \eta''_k) = k\pi.$$

Since ω may be made arbitrarily large by making β^{-1} and $\gamma^{-1}\beta$ small, the decoupled equation (2.1) with boundary conditions (2.2) can have an arbitrary, finite number of solutions.

This is the argument of [A1], refined so as not to give away half the solutions. The proof of Lemma 2.1 yields the following corollary.

COROLLARY TO LEMMA 2.1. *There is a constant independent of β, γ such that*

$$\max_{\substack{0 \leqq x \leqq 1 \\ 0 \leqq \eta \leqq \bar{\eta}}} |y_1(x; \eta)| \leqq \text{const } Y.$$

This bound will be useful in the construction of solutions of the coupled equations in § 3.

Finally, we note that [A1] works with the simplified nonlinear reaction rate e^y instead of the "exact" form $\exp[y/(1+\gamma^{-1}y)]$. This makes no essential difference because γ is large and the argument y is restricted to the range $0 \leqq y \leqq Y$.

Proof of Lemma 2.1 *and its corollary.* We will determine $Y > \alpha$ such that the right branch of the stable manifold of the saddle $(\alpha_0, 0)$ crosses the y_1-axis between $(\alpha, 0)$ and $(Y, 0)$. Inspection of the vector field and uniqueness of solutions then shows that $y_2(x; Y)$ decreases monotonically to zero and remains negative thereafter. This proves the result.

To determine Y, consider the conservative system

$$y_1' = y_2, \qquad y_2' = H\beta\left(y_1 - \frac{B\lambda}{\beta}\exp\left[\frac{y_1}{1+\gamma^{-1}y_1}\right]\right). \tag{2.4}$$

Define the potential V by

$$-V'(y) = H\beta\left(y - \frac{B\lambda}{\beta}\exp\left[\frac{y}{1+\gamma^{-1}y}\right]\right), \qquad V(0) = 0.$$

Consider the Hamiltonian function

$$K(y_1, y_2) = \tfrac{1}{2}y_2^2 + V(y_1).$$

Differentiation along a solution of (2.1) yields

$$\frac{d}{dx}K(y_1, y_2) = Hy_2^2 \geqq 0$$

with the inequality being strict everywhere but on the y_1-axis.

The level curve

$$K(y_1, y_2) = K(\alpha_0, 0) \tag{2.5}$$

is a saddle-loop for the conservative system (2.4). We have Proposition 2.1.

PROPOSITION 2.1. *K is a Lyapunov function for the system* (2.1), *run backward in x. Every point inside the saddle-loop* (2.5) *tends under* (2.1) *to the spiral* $(\alpha, 0)$ *as* $x \to -\infty$. *In particular, the right branch of the stable manifold of the saddle* $(\alpha_0, 0)$ *spirals into* $(\alpha, 0)$ *as* $x \to -\infty$.

Proof [H]. If we call $(Y, 0)$ the vertex of the saddle-loop equation (2.5) for the conservative system, then the right branch of the stable manifold of the saddle $(\alpha_0, 0)$ first crosses the y_1 axis for negative x at a point between $(\alpha, 0)$ and $(Y, 0)$. The approximation to Y is computed in Appendix B. There we show that

$$\begin{aligned} Y &= \log\frac{\beta}{B\lambda} + 2\log\log\frac{\beta}{B\lambda} - \log 2 + o(1) \\ &= \alpha + \log\log\sqrt{\beta/B\lambda} + o(1). \end{aligned}$$

If we follow the right branch of the stable manifold of the saddle backward in x beyond its crossing of the y_1-axis we find its first crossing of the line of initial conditions at a point we will call $(\bar{\eta}, H\bar{\eta})$. Note that $\bar{\eta} < Y$.

Proof of Lemma 2.2. To begin, change to local coordinates about the spiral point $(\alpha, 0)$. Appendix C gives the boundary problem (2.1), (2.2) in terms of new variables (u_1, u_2):

$$\begin{pmatrix} u_1' \\ u_2' \end{pmatrix} = \begin{bmatrix} H/2 & \omega \\ -\omega & H/2 \end{bmatrix}\begin{pmatrix} u_1 \\ u_2 \end{pmatrix} + Q\omega N(u_1)\begin{pmatrix} 0 \\ 1 \end{pmatrix}, \tag{2.6}$$

$$u_2(0) = \frac{H}{2\omega}u_1(0) + \frac{H\alpha}{\omega}, \qquad u_2(1) = -\frac{H}{2\omega}u_1(1). \tag{2.7}$$

In these equations the parameters ω and Q satisfy

$$\omega \sim \sqrt{\beta\log\beta}, \qquad Q \sim 1$$

when β^{-1} and $\gamma^{-1}\beta$ are small. The nonlinear function N satisfies $N(0) = N'(0) = 0$.

What makes this problem interesting is that the coefficient of the nonlinear term is large while the neighborhood of the origin in which we need a good approximate

solution is small: we will see that unlimited multiplicity of solutions is tied to $\omega \to \infty$, but ω is the coefficient of the nonlinear term of (2.6).

Introduce the polar coordinates

$$u_1 = r\cos\theta, \qquad u_2 = r\sin\theta.$$

Equation (2.6) becomes

$$\begin{aligned} r' &= \frac{H}{2} r - Q\omega \sin\theta\, N(r\cos\theta), \\ \theta' &= -\omega\left(1 + \frac{Q\cos\theta}{r} N(r\cos\theta)\right). \end{aligned} \tag{2.8}$$

The boundary conditions, expressed in terms of the angle

$$\psi = \tan^{-1}(H/2\omega),$$

are

$$\begin{aligned} r(0) &= H\frac{\alpha}{\omega}\csc(\theta(0)-\psi)\Big/\sqrt{1+\left(\frac{H}{2\omega}\right)^2}, \\ \tan\theta(1) &= -\tan\psi = -\frac{H}{2\omega}. \end{aligned} \tag{2.9}$$

We seek the initial point of the trajectory that wraps around the spiral point the maximum number of times, starting from the line of initial conditions (2.9). Change dependent and independent variables by

$$t = \omega x; \qquad \text{write "}\cdot\text{" for } \frac{d}{dt};$$

$$R(t) = \omega^{1/2} r(t/\omega), \qquad \Theta(t) = \theta(t/\omega).$$

This change of variables makes (2.8) into

$$\begin{aligned} \dot{R} &= \frac{H}{2\omega} R - Q\omega^{1/2} \sin\Theta\, N(\omega^{-1/2} R\cos\Theta), \\ \dot{\Theta} &= -1 - \frac{\omega^{1/2} Q\cos\Theta}{R} N(\omega^{-1/2} R\cos\Theta). \end{aligned}$$

Finally, the substitution $\Theta(t) = \varphi(t) - t$ puts the equation into a form suitable for averaging:

$$\begin{aligned} \dot{R} &= \frac{H}{2\omega} R - \omega^{1/2} Q\sin(\varphi - t) N(\omega^{-1/2} R\cos(\varphi - t)), \\ \dot{\varphi} &= -\omega^{1/2}\frac{Q}{R}\cos(\varphi - t) N(\omega^{-1/2} R\cos(\varphi - t)). \end{aligned} \tag{2.10}$$

The boundary conditions are

$$\begin{aligned} R(0) &= \frac{H}{\sqrt{1+\left(\frac{H}{2\omega}\right)^2}} \frac{\alpha}{\omega^{1/2}} \csc(\varphi(0) - \psi), \\ &\tan(\varphi(\omega) - \omega) + \tan\psi = 0. \end{aligned} \tag{2.11}$$

For the averaging computation, we expand (2.10) in powers of $\omega^{-1/2}$:

$$(\dot{R}, \dot{\varphi})^T = \omega^{-1/2} f(t, R, \varphi) + \omega^{-1} g(t, R, \varphi) + \omega^{-3/2} p(t, R, \varphi, \omega^{-1/2}).$$

The analytical forms of f, g, p are computed in Appendix D. Each of f, g, p is 2π-periodic in t, and the time-average of f is zero:

$$f^0(R, \varphi) = \int_0^{2\pi} f(t, R, \varphi)\, dt = 0.$$

This fortunate cancellation allows us to compute an approximate solution valid (i.e., with error $O(\omega^{-1/2})$) for $0 \leqq t \leqq \omega$, that is, for the entire interval $0 \leqq x \leqq 1$. This follows from Theorem 3.9.1 of [SV]. It is shown in Appendix D that the solution of (2.10) with the initial condition (2.11) is approximated to within an error of $O(\omega^{-1/2})$ for $0 \leqq t \leqq \omega$ by the solution of

$$\begin{aligned} &\frac{d\bar{R}}{dt} = \omega^{-1} \frac{H}{2} \bar{R}, \qquad && \bar{R}(0) = R(0), \\ &\frac{d\bar{\varphi}}{dt} = \omega^{-1} E \bar{R}^2, && \bar{\varphi}(0) = \varphi(0). \end{aligned} \tag{2.12}$$

(E is a constant defined by (D4).)

Solve these equations, using the given initial conditions, to find

$$\begin{aligned} R(\omega) &= e^{H/2} R(0) + O(\omega^{-1/2}), \\ \varphi(\omega) &= \bar{\varphi}(\omega) + O(\omega^{-1/2}) \\ &= \varphi(0) + E(e^H - 1) \cdot \frac{H}{1 + (H/2\omega)^2} \frac{\alpha^2}{\omega} \csc^2(\varphi(0) - \psi) + O(\omega^{-1/2}). \end{aligned}$$

Undoing the substitutions then gives, for the solution of (2.8) subject to initial conditions (2.9),

$$\begin{aligned} r|_{x=1} &= e^{H/2} \frac{H}{\sqrt{1 + (H/2\omega)^2}} \frac{\alpha}{\omega} \csc(\theta(0) - \psi) + O(\omega^{-1/2}), \\ \theta|_{x=1} &= \theta(0) - \omega + \frac{EH(e^H - 1)}{1 + (H/2\omega)^2} \frac{\alpha^2}{\omega} \csc^2(\theta(0) - \psi) + O(\omega^{-1/2}). \end{aligned} \tag{2.13}$$

This approximation is valid as long as $r(0) = O(\omega^{-1/2})$. If we choose $\theta(0)$ to minimize the leading terms in this approximation to $\theta(1)$ we find that

$$\theta(0) = \psi + O\left[\left(\frac{\alpha^2}{\omega}\right)^{1/3}\right]$$

gives the approximation

$$\min \theta(1) = -\omega + O\left[\left(\frac{\alpha^2}{\omega}\right)^{1/3}\right] + O(\omega^{-1/2}).$$

For this choice of θ we have

$$r(0) = O\left(\frac{\alpha^{1/2}}{\omega^{2/3}}\right)$$

so that the approximation is valid.

This says that the trajectory, which starts on the line of initial conditions with $\theta(0)=\theta_{\min}$, winds $[\omega/2\pi]$ times clockwise around the spiral point. In the original coordinate system (y_1, y_2) this corresponds to a point η^* with the property asserted in the statement of Lemma 2.2.

3. The coupled equations. Now we show that the multiplicity results of § 2 hold for the full system (1.2)-(1.3). To begin, we note that if y is known then z is determined.

LEMMA 3.1. *Let $y \in C[0,1]$ be given. Then the boundary value problem for z, (1.3), has a unique solution.*

Proof. Write $q(x)=\gamma^{-1}\lambda \exp(h(y(x)))$. The difference of two solutions of (1.3) satisfies

$$\frac{1}{M}z''-z'-q(x)z=0$$

with the same (homogeneous) boundary conditions. Multiply this equation by $-z$ and integrate from zero to 1; integrate by parts and use the boundary conditions to get

$$0=\frac{1}{2}[z^2(1)+z^2(0)]+\frac{1}{M}\int_0^1 (z')^2\,dx+\int_0^1 qz^2\,dx.$$

Since $q>0$, this shows that $z=0$.

For $f\in C[0,1]$ write $\|f\|$ for $\max_{0\leqq x\leqq 1}|f(x)|$. We next bound $\|z\|$ in terms of bounds on y.

LEMMA 3.2. *Let Y be a positive constant. Then there are positive constants $\gamma_0=\gamma_0(\lambda, Y)$ and C such that for any $y\in C[0,1]$ with $0\leqq y(x)\leqq Y$ for $0\leqq x\leqq 1$, the solution z of (1.3) is bounded by*

$$\|z\|\leqq C\lambda\, e^{Y}$$

provided $\gamma\geqq\gamma_0$.

Proof. The solution z of

$$\begin{aligned}&\frac{1}{M}z''-z'=f(x), \qquad 0<x<1,\\ &z'(0)-Mz(0)=0,\\ &z'(1)=0\end{aligned}\tag{3.1}$$

is

$$z(x)=-\int_0^x f(\xi)\,d\xi-e^{Mx}\int_x^1 e^{-M\xi}f(\xi)\,d\xi.$$

A short calculation shows that $\|z\|\leqq\|f\|$. The solution z of (1.3) solves (3.1) with

$$f=\lambda \exp[h(y)](1+\gamma^{-1}z).$$

If $0\leqq y\leqq Y$ then $0\leqq h(y)<Y$, so that

$$\|z\|\leqq\lambda\, e^{Y}(1+\gamma^{-1}\|z\|).$$

Thus if $\gamma^{-1}\lambda\, e^{Y}<1$, then

$$\|z\|\leqq(1-\gamma^{-1}\lambda\, e^{Y})^{-1}\lambda\, e^{Y}$$

and the lemma follows.

Next we use this estimate to show that the solution of (1.3) depends Lipschitz continuously on the coefficient y, provided $0\leqq y\leqq Y$.

LEMMA 3.3. *If* $Y>0$, $y_1, y_2 \in C[0,1]$, *if* z_1 (*respectively*, z_2) *is the solution of* (1.3) *with* $y=y_1$ (*respectively*, $y=y_2$), *if* $0 \leqq y_k(x) \leqq Y$, $k=1,2$, *and if* $\gamma \geqq \gamma_0$, *then*

$$\|z_1-z_2\| \leqq (1-\gamma^{-1}\lambda\, e^Y)^{-1}(1+\gamma^{-1}C\lambda\, e^Y)\lambda\, e^Y \|y_1-y_2\|.$$

Proof. Subtract the equations for z_1 and z_2. Then

$$\frac{1}{M}(z_1-z_2)''-(z_1-z_2)' = \lambda(e^{h(y_1)}-e^{h(y_2)})+\gamma^{-1}\lambda(e^{h(y_1)}z_1-e^{h(y_2)}z_2)$$

$$= \lambda(e^{h(y_1)}-e^{h(y_2)})+\gamma^{-1}\lambda(e^{h(y_1)}-e^{h(y_2)})z_1+\gamma^{-1}\lambda\, e^{h(y_2)}(z_1-z_2),$$

and z_1-z_2 satisfies the boundary conditions. By Lemma 3.2, $\|z_1\| \leqq C\lambda e^Y$. The function $\exp[h(y)]$ is Lipschitz continuous in y for $0 \leqq y \leqq Y$ with Lipschitz constant e^Y. By the proof of Lemma 3.2,

$$\|z_1-z_2\| \leqq \lambda\, e^Y \|y_1-y_2\| + \gamma^{-1}\lambda\, e^Y \|y_1-y_2\| C\lambda\, e^Y + \gamma^{-1}\lambda\, e^Y \|z_1-z_2\|$$

and the lemma follows.

Next we estimate a Lipschitz constant for the dependence of the solution y of (1.2) on z regarded as a coefficient. It is nearly evident from the form of the equations that if y_1, y_2 are solutions of (1.2) with coefficients $z=z_1$ and $z=z_2$, respectively, and with the same initial data, then we have an estimate of the form

$$\|y_1-y_2\| \leqq \text{const}\ \gamma^{-1}\|z_1-z_2\|. \tag{3.2}$$

We could next combine this result with Lemma 3.3 to set up a convergent iterative scheme to solve the coupled boundary value problems (1.2)-(1.3). However, the constant—obtained in (3.2) from a direct application of the Gronwall inequality to (1.2)—would contain a term of the form $\exp(\exp\sqrt{\beta})$, and our iteration could be shown to converge only for enormously large γ. Therefore we localize (1.2) at the spiral point $(\alpha, 0)$ and obtain an estimate like (3.2) with a somewhat better constant.

Recall from Appendix C the change of variables localizing (1.4) at the spiral point

$$\begin{bmatrix} y-\alpha \\ y' \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ H/2 & \omega \end{bmatrix}\begin{bmatrix} u \\ v \end{bmatrix}. \tag{3.3}$$

Apply the same change of variables to (1.2). If (y_k, y_k') corresponds to (u_k, v_k), $k=1,2$, under this change of variables—here subscripts indicate different solutions rather than components of a vector—then $u_1-u_2=y_1-y_2$ and we can estimate u_1-u_2 instead. The following proposition gives the resulting estimate.

PROPOSITION 3.1. *Consider the initial value problems* $k=1,2$:

$$\begin{aligned} &\frac{1}{H}y_k''-y_k'-\beta y_k+B\lambda(1+\gamma^{-1}z_k)\exp[h(y_k)]=0, \\ &y_k(0)=\eta, \\ &y_k'(0)=H\eta. \end{aligned} \tag{3.4}$$

Assume $0<\eta<\bar{\eta}$, $\|z_k\| \leqq C\lambda\, e^Y$ *for* $k=1,2$, *and that* γ *is sufficiently large. Then* $\|y_k\| < Y$ *for* $k=1,2$ *and there is a constant* c *such that*

$$\|y_1-y_2\| \leqq \gamma^{-1}Q\omega c \log\beta \exp[Q\omega\, e^{H/2}c\log\beta(1+\gamma^{-1}C\lambda\, e^Y)]\|z_1-z_2\|.$$

Use the change of variables (3.3) to transform (3.4) to

$$\begin{bmatrix} u_k' \\ v_k' \end{bmatrix} = A\begin{bmatrix} u_k \\ v_k \end{bmatrix} - Q\omega(N(u_k)+\gamma^{-1}z_kF(u_k))\begin{bmatrix} 0 \\ 1 \end{bmatrix}, \qquad k=1,2 \tag{3.5$_k$}$$

with appropriate initial conditions, as in Appendix C. Subtract (3.5_2) from (3.5_1) to obtain for the difference variables $(u, v) = (u_1 - u_2, v_1 - v_2)$:

$$\begin{aligned} \begin{bmatrix} u' \\ v' \end{bmatrix} &= A\begin{bmatrix} u \\ v \end{bmatrix} - Q\omega\{N(u_1) - N(u_2) + \gamma^{-1}[z_1F(u_1) - z_2F(u_2)]\}\begin{bmatrix} 0 \\ 1 \end{bmatrix}, \\ \begin{bmatrix} u \\ v \end{bmatrix}(0) &= \begin{bmatrix} 0 \\ 0 \end{bmatrix}. \end{aligned} \tag{3.6}$$

Now use the variation of parameters formula to get

$$\begin{bmatrix} u \\ v \end{bmatrix}(x) = -Q\omega \int_0^x e^{A(x-s)} W(s) \begin{bmatrix} 0 \\ 1 \end{bmatrix} ds,$$

in which W denotes the expression in curly brackets in (3.6). Now $u(x)$ is just the first component of the right-hand side, and we get

$$u(x) = -Q\omega \int_0^x e^{H(x-s)/2} \sin \omega(x-s)\, W(s)\, ds. \tag{3.7}$$

Write $N_k = N(u_k)$, $F_k = F(u_k)$; then

$$W = N_1 - N_2 + \gamma^{-1}[z_1(F_1 - F_2) + F_2(z_1 - z_2)]. \tag{3.8}$$

LEMMA 3.4. *There is a constant c such that $c \log \beta$ is a Lipschitz constant for N and F and a bound for F for $u \leqq Y - \alpha$.*

This follows from the forms of N and F derived in Appendix C, and from (B2) for Y. Next, by the bounds on y when $\gamma^{-1} = 0$ derived in § 2, the assumed bounds on η and $\|z_k\|$, $k = 1, 2$, and continuous dependence, it follows that $y_k < Y$ and thus $u_k < Y - \alpha$. Insert the Lipschitz conditions for N and F into (3.8) to obtain Lemma 3.5.

LEMMA 3.5. $|W(s)| \leqq c \log \beta(1 + \gamma^{-1} C\lambda\, e^Y)|u(s)| + \gamma^{-1} c \log \beta \|z_1 - z_2\|$, *and consequently*

$$|u(x)| \leqq Q\omega\, e^{H/2} \cdot c \log \beta(1 + \gamma^{-1} C\lambda\, e^Y) \int_0^x |u(s)|\, ds + \gamma^{-1} c \log \beta Q\omega\, e^{H/2} \|z_1 - z_2\|.$$

The estimate of Proposition 3.1 now follows by the Gronwall inequality [H].

PROPOSITION 3.2. *Let η be given, $0 < \eta < \bar{\eta}$. There is a unique ζ, $0 < \zeta < C\lambda\, e^Y$ such that the solution of the coupled equations* (1.2)-(1.3) *subject to the initial conditions*

$$\begin{aligned} y(0) &= \eta, \qquad y'(0) = H\eta, \\ z(0) &= \zeta, \qquad z'(0) = M\zeta, \end{aligned} \tag{3.9}$$

satisfies the second boundary condition for z: $z'(1) = 0$.

Proof. Construct sequences $\{y_k\}_{k=0}^{\infty}$ and $\{z_k\}_{k=0}^{\infty}$ as follows. Let $z_0 = 0$, and let y_0 be the solution of (1.2) with $z = z_0$ there, subject to the initial conditions (3.9). Then for each $k = 1, 2, \cdots$, let z_k be the (unique) solution of the boundary value problem (1.3) with $y = y_{k-1}$ there, and y_k the solution of the initial value problem (1.2), (3.9) with $z = z_k$. By Lemma 3.2 and Proposition 3.1 we have $\|z_k\| \leqq C\lambda\, e^Y$, $\|y_k\| \leqq Y$, $k \geqq 0$. Combine the estimates of Lemma 3.3 and Proposition 3.1 to get the estimate

$$\|y_{k+1} - y_k\| \leqq \gamma^{-1} C(\beta, H, B, \lambda) \|y_k - y_{k-1}\|.$$

A similar estimate holds for z. Thus if γ is sufficiently large, the y_k and z_k converge uniformly; the limiting pair (y, z) satisfy the differential equations (1.2)-(1.3), the initial conditions (3.9) for y, and the boundary conditions (1.3_0) for z.

COROLLARY. *The coupled boundary value problem* (1.2)-(1.3) *has as many solutions with* $0 \leqq y(0) \leqq \bar{\eta}$ *as has the decoupled equation* (1.4).

Proof. It is enough to show that (2.3) and the analogues of Lemmata 2.1 and 2.2 continue to hold when y is taken to be the solution of the coupled system. The angle $\tilde{\theta}$ is well defined: the polar radius r is bounded away from zero along solutions of the decoupled equation that start on the initial conditions. For sufficiently large γ this is still true for the solution of the full equation. Thus $\hat{\theta}$ is well defined, and the stated conclusions are valid by continuous dependence.

4. Comments.

(1) The estimate following (3.7) can probably be improved. The integral should be $O(\omega^{-1})$ unless W oscillates with frequency ω—but in that case the amplitude of W should be quite small.

(2) The leading term in the asymptotic expansion of θ, (2.13), is unimodular. If θ itself were indeed unimodular, then Lemma 2.1 would give an exact count of the number of solutions. Possibly, this could be answered by computing the solution of the variational equation by the method of averaging.

(3) The question of the stability of the steady states found here remains open.

Appendix A. Locate and classify critical points of the decoupled y-equation. The critical points of (2.1) are given by

$$\text{(A1)} \qquad y_2 = 0, \qquad y_1 = \frac{B\lambda}{\beta} \exp\left[\frac{y_1}{1+\gamma^{-1}y_1}\right].$$

Since γ is large, we expect the second equation to have two roots near the roots of

$$y = \frac{B\lambda}{\beta} e^y$$

when this has two roots, namely, when $B\lambda/\beta < 1/e$. In what follows we will choose successively large $\gamma = \gamma_0(\beta)$, with $\beta/\gamma_0(\beta) \to 0$ as $\beta \to \infty$; the expression $O(f(\beta))$ will mean "with a constant independent of γ, for all $\gamma > \gamma_0(\beta)$." For all results prior to § 3, it suffices to take $\gamma_0(\beta) = \beta^2$.

Iterate (A1) to obtain the first root

$$\text{(A2)} \qquad \alpha_0 = \frac{B\lambda}{\beta}\left(1 + \frac{B\lambda}{\beta} + O(\beta^{-2})\right).$$

Next, take logarithms in (A1):

$$\text{(A3)} \qquad \frac{y}{1+\gamma^{-1}y} = \log\frac{\beta}{B\lambda} + \log y.$$

Let $G = \beta/B\lambda$. Iterate the last equation, bearing in mind that γ is large; conclude that

$$\text{(A4)} \qquad \alpha \equiv \alpha_1 = \log G + \log\log G + \frac{\log\log G}{\log G} + O\left(\frac{\log\log\beta}{\log\beta}\right)^2.$$

This critical point takes a central role in the analysis that follows. We will always call it simply α.

The third critical point plays no role in this work, for the solutions that interest us will obey $0 \leqq y(x) \leqq Y$, with Y a β-dependent constant slightly larger than α. For

completeness, we give the third critical point. Rearrange (A3) to get

$$\log y = -\log G + \frac{y}{1+\gamma^{-1}y}$$

$$= -\log G + \frac{\gamma}{1+y^{-1}\gamma}.$$

We seek a root α_2 near $(B\lambda/\beta)\, e^{\gamma}$. Iterating now for $\log y$ gives

$$\alpha_2 = \frac{B\lambda}{\beta}\, e^{\gamma}(1+O(\gamma^2\, e^{-\gamma})).$$

Of course this is enormous compared to α.

Let us now classify the critical points. Denote the term in the exponential by

(A5) $$h(y) = \frac{y}{1+\gamma^{-1}y}.$$

Then a short calculation shows that the Jacobian of the system (2.1) at a critical point is given by

$$J(\alpha_j, 0) = \begin{bmatrix} 0 & 1 \\ H\beta(1-\alpha_j h'(\alpha_j)) & H \end{bmatrix}.$$

(This calculation uses the fact that (A1) holds for $y_1 = \alpha_j$.) The determinant is negative, and we have a saddle, for $(\alpha_0, 0)$ and $(\alpha_2, 0)$. The determinant is positive at $(\alpha, 0) = (\alpha_1, 0)$. At this point the discriminant $(\operatorname{Tr} J)^2 - 4 \det J$ is negative, and we have an unstable spiral, when the inequality

$$\alpha h'(\alpha) - 1 > \frac{H}{4\beta}$$

holds. Since $h'(y) = (1+\gamma^{-1}y)^{-2}$, this inequality holds as soon as β is large enough for any fixed H, B, λ; recall that α is given by (A4) and $\gamma^{-1}\beta$ is small.

Appendix B. The conservative system. Consider the potential energy function $V(y, \gamma^{-1})$ defined by

$$V'(y, \gamma^{-1}) = H\left(B\lambda \exp\left[\frac{y}{1+\gamma^{-1}y}\right] - \beta y\right),$$

$$V(0) = 0.$$

For the special case $\gamma^{-1} = 0$ we have explicitly

$$V(y, 0) = H\left(B\lambda(e^{y}-1) - \frac{\beta}{2}y^2\right).$$

The saddle-loop for the conservative system (2.4) crosses the y_1-axis at the point $(Y, 0)$ defined by

(B1) $$V(Y, \gamma^{-1}) = V(\alpha_0, \gamma^{-1}).$$

We determine Y for $\gamma^{-1} = 0$; then the Y for finite γ differs from this by $O(\gamma^{-1}\log\beta)$. We have to solve the following equation, from (B1) and the approximation (A2) for α_0:

$$H\left(B\lambda(e^{Y}-1) - \frac{\beta}{2}Y^2\right) = \frac{H}{2}\frac{(B\lambda)^2}{\beta} + O(\beta^{-2}).$$

This leads to

$$Y = \log\left(\frac{\beta Y^2}{2B\lambda} + 1 + O(\beta^{-1})\right)$$

$$= \log\frac{\beta}{B\lambda} + 2\log Y - \log 2 + O(\beta^{-1}),$$

and the solution is given by

$$Y = \log\frac{\beta}{B\lambda} + 2\log\log\frac{\beta}{B\lambda} - \log 2 + o(1)$$

$$= \alpha + \log\log\frac{\beta}{B\lambda} - \log 2 + o(1)$$

$$= \alpha + \log\log\sqrt{\beta/B\lambda} + o(1).$$

In addition, we find that the saddle-loop crosses the line of initial conditions at point η:

$$K(\eta, H\eta) = K(\alpha_0, 0).$$

The equation for the "large" solution leads to

$$\frac{H^2}{2}\eta^2 + H\left(B\lambda(e^\eta - 1) - \frac{\beta}{2}\eta^2\right) = O(\beta^{-1})$$

or

$$\eta = \log\left(\frac{\beta - H}{2B\lambda}\eta^2 + 1 + O(\beta^{-1})\right)$$

$$= \log\left(\frac{\beta}{B\lambda}\cdot\eta^2\cdot\frac{1 - H/\beta}{2} + 1 + O(\beta^{-1})\right)$$

and we find that $\eta = Y + O(\beta^{-1})$.

Appendix C. Localization at the spiral point. Translate the origin to the spiral point in (1.4) by the substitution

$$y_1 = w_1 + \alpha, \qquad y_2 = w_2$$

and get

$$\begin{pmatrix} w_1' \\ w_2' \end{pmatrix} = \begin{pmatrix} w_2 \\ H\{w_2 + \beta(w_1 + \alpha) - (B\lambda/\beta)\exp[h(\alpha + w_1)]\} \end{pmatrix}$$

$$= \begin{bmatrix} 0 & 1 \\ H\beta(1 - \alpha h'(\alpha)) & H \end{bmatrix}\begin{pmatrix} w_1 \\ w_2 \end{pmatrix}$$

$$-H\alpha\beta\left(\exp\left[\frac{h'(\alpha)w_1}{1 + (\gamma^{-1}w_1)/(1 + \gamma^{-1}\alpha)}\right] - h'(\alpha)w_1 - 1\right)\begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$

The Jacobian at the spiral point is

$$J(\alpha) = \begin{bmatrix} 0 & 1 \\ H\beta(1 - \alpha h'(\alpha)) & H \end{bmatrix}$$

with complex eigenvalues given by

$$\frac{H}{2} \pm i\omega, \qquad \omega^2 = H\beta(\alpha h'(\alpha) - 1) - \frac{H^2}{4}.$$

Perform a linear change of coordinates with the matrix S,

$$S = \begin{bmatrix} 1 & 0 \\ H/2 & \omega \end{bmatrix},$$

whose columns are the real and imaginary parts of an eigenvector for $H/2 + i\omega$; substitute

$$\begin{bmatrix} w_1 \\ w_2 \end{bmatrix} = S \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \begin{bmatrix} u_1 \\ (H/2)u_1 + \omega u_2 \end{bmatrix};$$

and obtain the system

$$\begin{pmatrix} u_1' \\ u_2' \end{pmatrix} = \begin{bmatrix} H/2 & \omega \\ -\omega & H/2 \end{bmatrix} \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} - Q\omega N(u_1) \begin{bmatrix} 0 \\ 1 \end{bmatrix}. \tag{C1}$$

Here we set

$$Q := \frac{H\alpha\beta}{\omega^2} = \frac{1}{h'(\alpha) - (1/\alpha)(1 + (H/4\beta))} = 1 + O(\alpha^{-1}),$$

$$N(u) := \exp\left[\frac{h'(\alpha)u}{1 + (\gamma^{-1}u)/(1 + \gamma^{-1}\alpha)}\right] - h'(\alpha)u - 1 \tag{C2}$$

is the nonlinearity. Note that when γ, β are large we have $Q \sim 1$; note further that $N(0) = N'(0) = 0$.

By following the coordinate changes in the boundary conditions we find in the new variables the line of initial conditions

$$u_2(0) = \frac{H}{2\omega} u_1(0) + \frac{H\alpha}{\omega}, \tag{C3}$$

and the line of final conditions

$$u_2(1) = -\frac{H}{2\omega} u_1(1). \tag{C4}$$

We can also perform the same change of variables for y in (1.2) with the coefficient z. We obtain

$$\begin{bmatrix} u_1 \\ u_2 \end{bmatrix}' = \begin{bmatrix} H/2 & \omega \\ -\omega & H/2 \end{bmatrix} \begin{pmatrix} u_1 \\ v_2 \end{pmatrix} - Q\omega(N(u_1) + \gamma^{-1} z F(u_1)) \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

with N as before and F given by

$$F(u) = \exp\left[\frac{h'(\alpha)u}{1 + (\gamma^{-1}u)/(1 + \gamma^{-1}\alpha)}\right].$$

Appendix D. Averaging computations. We begin by expanding the vector field of (2.10) in powers of $\omega^{-1/2}$. For this we require the Taylor expansion of the nonlinear

function N defined by (C2). Let

$$\sigma = \frac{\gamma^{-1}}{1+\gamma^{-1}\alpha}, \qquad k = h'(\alpha) = (1+\gamma^{-1}\alpha)^{-2},$$

the function h being defined by (A5). Then

$$N(u) = N_2u^2 + N_3u^3 + O(u^4) \tag{D1}$$

with

$$N_2 = \frac{k^2}{2} - \sigma k, \qquad N_3 = \frac{k^3}{6} - \sigma k^2 + \sigma^2 k.$$

We note that $N_2 = \frac{1}{2} + O(\gamma^{-1}\alpha)$, $N_3 = \frac{1}{6} + O(\gamma^{-1}\alpha)$. This illustrates the earlier remark that replacing $h(y)$ by y in the exponential throughout makes no essential difference.

Inserting the expansion (D1) for N into (2.10) leads to

$$\begin{aligned} \dot{R} &= -\omega^{-1/2}QR^2N_2\cos^2(\varphi - t)\sin(\varphi - t) \\ &\quad + \omega^{-1}\left(\frac{H}{2}R - QR^3N_3\cos^3(\varphi - t)\sin(\varphi - t)\right) + O(\omega^{-3/2}), \\ \dot{\varphi} &= -\omega^{-1/2}QRN_2\cos^3(\varphi - t) - \omega^{-1}QR^2N_3\cos^4(\varphi - t) + O(\omega^{-3/2}). \end{aligned} \tag{D2}$$

Define

$$f(t, R, \varphi) = -QN_2\begin{pmatrix} R^2\cos^2(\varphi - t)\sin(\varphi - t) \\ R\cos^3(\varphi - t) \end{pmatrix},$$

$$g(t, R, \varphi) = \begin{pmatrix} (H/2)R - QR^3N_3\cos^3(\varphi - t)\sin(\varphi - t) \\ -QR^2N_3\cos^4(\varphi - t) \end{pmatrix}.$$

Then (D2) may be written

$$(\dot{R}, \dot{\varphi})^T = \omega^{-1/2}f(t, R, \varphi) + \omega^{-1}g(t, R, \varphi) + \omega^{-3/2}p(t, R, \varphi, \omega^{-1/2})$$

with $\omega^{-3/2}p$ being the remainder in Taylor's formula. The functions f, g, p are 2π-periodic in t and the average of f vanishes:

$$f^0(R, \varphi) = \frac{1}{2\pi}\int_0^{2\pi} f(\tau, R, \varphi)\, d\tau = 0.$$

Define

$$v^1(t, R, \varphi) = \int_0^t f(\tau, R, \varphi)\, d\tau - \frac{1}{2\pi}\int_0^{2\pi}\int_0^t f(\tau, R, \varphi)\, d\tau\, dt,$$

$$f^1(t, R, \varphi) = D_{(R,\varphi)}f(t, R, \varphi)v^1(t, R, \varphi)$$

and let f^{10} and g^0 be the respective mean values over a period of f^1 and g. By Theorem 3.9.1 of [SV], the solution of (2.10) with initial conditions $R(0) = R_0$, $\varphi(0) = \varphi_0$ is approximated with an error that is $O(\omega^{-1/2})$ for $0 \leqq t \leqq \omega$ by the solution of

$$\begin{aligned} &\frac{d}{dt}(\bar{R}, \bar{\varphi})^T = \omega^{-1}(f^{10}(\bar{R}, \bar{\varphi}) + g^0(\bar{R}, \bar{\varphi})), \\ &(\bar{R}(0), \bar{\varphi}(0)) = (R_0, \varphi_0). \end{aligned} \tag{D3}$$

We now compute v^1, f^1, f^{10}, and g^0:

$$v^1(t, R, \varphi) = -QRN_2 \begin{pmatrix} \int_0^t R\cos^2(\varphi-\tau)\sin(\varphi-\tau)\,d\tau - \text{Mean value} \\ \int_0^t \cos^3(\varphi-\tau)\,d\tau - \text{Mean value} \end{pmatrix}$$

$$= -QRN_2 \begin{pmatrix} \frac{1}{3}R\cos^3(\varphi-\tau)_0^t - \text{Mean value} \\ -\sin(\varphi-\tau)_0^t + \frac{1}{3}\sin^3(\varphi-\tau)_0^t - \text{Mean value} \end{pmatrix}$$

$$= -QRN_2 \begin{pmatrix} \frac{1}{3}R\cos^3(\varphi-t) - \frac{1}{3}R\cos^3\varphi - \text{Mean value} \\ -\sin(\varphi-t) + \sin\varphi + \frac{1}{3}\sin^3(\varphi-t) - \frac{1}{3}\sin^3\varphi - \text{Mean value} \end{pmatrix}$$

$$= -QRN_2 \begin{pmatrix} \frac{R}{3}\cos^3(\varphi-t) \\ -\sin(\varphi-t) + \frac{1}{3}\sin^3(\varphi-t) \end{pmatrix}.$$

Next,

$$f^1 = D_{(R,\varphi)} f \cdot v^1$$

$$= Q^2N_2^2R \begin{pmatrix} 2R\cos^2(\varphi-t)\sin(\varphi-t) & R^2[\cos(\varphi-t) - 3\sin^2(\varphi-t)\cos(\varphi-t)] \\ \cos^3(\varphi-t) & -3R\cos^2(\varphi-t)\sin(\varphi-t) \end{pmatrix}$$

$$\cdot \begin{pmatrix} \frac{R}{3}\cos^3(\varphi-t) \\ -\sin(\varphi-t) + \frac{1}{3}\sin^3(\varphi-t) \end{pmatrix}$$

$$= Q^2N_2^2R$$

$$\cdot \begin{pmatrix} R^2\left(\frac{2}{3}\cos^5(\varphi-t)\sin(\varphi-t) + \cos(\varphi-t)(1-3\sin^2(\varphi-t))\sin(\varphi-t)\left(\frac{1}{3}\sin^2(\varphi-t) - 1\right)\right) \\ R\left(\frac{1}{3}\cos^6(\varphi-t) + 3\cos^2(\varphi-t)\sin^2(\varphi-t) - \cos^2(\varphi-t)\sin^4(\varphi-t)\right) \end{pmatrix}.$$

To compute f^{10}, observe that the first component of f^1 has mean value zero. Hence

$$f^{10}(R, \varphi) = \frac{5}{12}Q^2N_2^2R^2\begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$

Next,

$$g^0(R, \varphi) = \begin{pmatrix} \frac{H}{2}R \\ -\frac{3}{8}QN_3R^2 \end{pmatrix}.$$

So the averaged equations are

$$\frac{d\bar{R}}{dt} = \omega^{-1}\frac{H}{2}\bar{R}, \qquad \bar{R}(0) = R_0,$$

$$\frac{d\bar{\varphi}}{dt} = \omega^{-1}E\bar{R}^2, \qquad \bar{\varphi}(0) = \varphi_0, \tag{D4}$$

$$E = \frac{5}{12}Q^2N_2^2 - \frac{3}{8}QN_3 = \frac{1}{24} + O(\alpha^{-1}).$$

Acknowledgments. It is a pleasure to thank Jim Murdock for useful discussions, and H. F. Weinberger for his hospitality at the Institute for Mathematics and its Applications, University of Minnesota, Minneapolis, Minnesota.

INERTIAL MANIFOLDS AND MULTIGRID METHODS*

R. TEMAM†

Abstract. This article presents an analogy existing between the concepts of approximate inertial manifolds in dynamical systems theory and multigrid methods in numerical analysis. In view of the large-time approximation of dissipative evolution equations in a turbulent regime, a new algorithm is proposed and studied that combines some ideas and concepts of inertial manifolds and multigrid methods. This article emphasizes theoretical questions. More practical (computational) questions will be investigated elsewhere.

Key words. inertial manifolds, attractors, partial differential equations, approximation, multigrid methods

AMS(MOS) subject classifications. 35K60, 65N05

Introduction. Two theories have developed in parallel during the last years with different objectives; namely, the theory of inertial manifolds that has emerged from the study of dynamical systems and the theory of multigrid methods in numerical analysis. Although these two theories seem very far apart, our aim here is to show that they have some underlying ideas in common and to investigate the relation between them.

Multigrid methods concern the numerical solution of partial differential equations by finite differences or finite elements using two (or more) mesh grids, one finer and one coarser. The main observation constituting the starting point of the theory is that a simple iterative method is sufficient to determine the high-frequency components of the solution, but that further effort is needed to solve the low-frequency components (see [B], [H], [Mc], and the references therein).

In dynamical systems theory the objective is to study the long-term behavior of the solutions of an evolution equation. When the equation is dissipative all solutions converge as $t \to \infty$ to a complicated set $\mathscr{A}$, the global attractor, which may be fractal. This set embodies the large-time dynamics of the equation, corresponding to all sorts of regimes, including the turbulent ones. Although this set may be fairly complicated, in general it has finite dimension. Inertial manifolds are smooth finite-dimensional manifolds that are invariant by the flow, contain the global attractor, and attract all the orbits at an exponential rate. All dissipative systems are not known to possess an inertial manifold, but the related concept of approximate inertial manifolds has been introduced and applies to a broad class of dissipative systems (see [FST1], [FST2], [FNST1], [FNST2], [CFNT], [MS], [T4], and the references therein). Now, in essence, inertial and approximate inertial manifolds correspond to an exact (or approximate) interaction law between small and large wavelengths. When an orbit lies on the inertial manifold the small wavelengths are, at each instant of time, an explicit function of the large wavelengths, this correlating function being the equation of the manifold. And of course, an orbit starting outside the manifold converges to it exponentially fast, and thus soon, after an initial period, the interaction law between small and large wavelengths goes into effect.

In previous articles (see [FMT], [T5], [MT1], [MT2], [JRT]), we have shown how we can construct effective numerical algorithms by using approximate inertial manifolds, in the context of spectral and finite-element methods. Our object in this

article is to present and study similar algorithms in the case of finite differences. Here we naturally meet the methodology of multigrid methods: the large wavelength components of the flow are based on the coarse grid, while the small wavelength components are based on the fine grid. Let us mention, however, that despite this analogy, the questions that we address here are quite different from those addressed in the multigrid literature. The multigrid literature emphasizes more the linear part of the equation, while here we are more interested in the nonlinear terms: following ideas derived from inertial manifolds and dynamical systems theory, our object here is to describe in an approximate way the nonlinear interaction of small wavelengths based on the finer grid and large wavelengths based on the coarser grid.

For the sake of simplicity we will devote this article to some specific situations and examples, but our results apply to much more general situations. We consider a class of nonlinear evolution equations for which the linear elliptic part corresponds to a Dirichlet problem in a square. In § 1 we describe our space discretization procedure based on the use of the *incremental unknowns*. We are given two grids in the square, the fine and coarse grids; the discretization is simply the five-point discretization of the Laplace operator on the fine grid. However, instead of considering the usual nodal values for the unknown function, we will consider the incremental unknowns on the fine grid. They consist of the nodal values on the coarse grid and, on the points of the fine grids not belonging to the coarse one, the unknown is the increment to an interpolate value of the neighboring coarse points. We are not aware of any explicit use of the incremental unknowns in numerical analysis.[1] The material presented in § 1 is, however, very simple and necessary for the rest of the article.

In § 2 we present, at the level of linear elliptic problems, the appropriate variational setting for the use of the incremental unknowns. The variational framework for finite-difference discretization of linear elliptic problems was introduced by Céa [C]. Although the variational framework is very well suited for finite elements, and its use is routine in this case, it is not indispensable and is less used in the context of finite differences. We will see that it is very appropriate here, at least for the theoretical part of the work; we will recall and present the necessary material in § 2.

In § 3 we present the nonlinear equations that we study. An abstract equation and three specific equations related to the Navier–Stokes equations and to reaction-diffusion equations are presented. As previously mentioned, our results apply to general equations, but we refrain here from considering general equations and concentrate on the specific examples. In § 4 we implement the spatial discretization of the problem using two different grids and the incremental unknowns, and implement the algorithm based on inertial manifolds and multigrid methods (the IMG algorithm). The stability, consistency, and convergence of the algorithm are investigated in § 5, which relies extensively on the use of energy methods. Finally, in § 6 we consider a full discretized version of the IMG algorithm, i.e., one involving space and time discretization. We consider an explicit time discretization scheme and restrict ourselves to a *linear problem*. Indeed, another advantage of the IMG algorithm appears already, at the level of a linear evolution equation, in the form of an improved stability condition; namely, the stability condition is that corresponding to the coarse mesh instead of that corresponding to the fine mesh.

In this article we have emphasized simple equations and theoretical aspects in connection with dynamical systems. In subsequent works we intend to consider more general equations; and we intend to describe in more detail and in a more practical

[1] They appear in a hidden way in the multigrid methods through the restriction and prolongation operators.

form the computational aspects of the algorithm. Other related forms of the algorithm will also be considered; see in particular [T8].

1. Matricial structure of the problem. In this section we introduce the incremental unknowns and show their use in the solution of finite-difference problems. We consider successively one- and two-dimensional problems.

1.1. The one-dimensional case. For the sake of simplicity we start with the model one-dimensional problem:

$$-\frac{d^2u}{dx^2}=f \quad \text{in } (0,1), \qquad u(0)=u(1)=0. \tag{1.1}$$

For $N\in\mathbb{N}$, we consider the fine grid corresponding to the discretization mesh $h=1/2N$ and the coarse grid corresponding to the discretization mesh $2h=1/N$. The coarse gridpoints are the points $2jh$, $j=0,\cdots,N$ ($j=0$ and N correspond to the boundary points); the fine gridpoints are the points jh, $j=0,\cdots,2N$ (see Fig. 1.1). We write $f_j=f(jh)$, $u_j\simeq u(jh)$ and, on the fine grid, we write the usual finite difference scheme

$$-\frac{1}{h^2}(u_{j+1}-2u_j+u_{j-1})=f_j, \quad j=1,\cdots,2N-1, \quad u_0=u_{2N}=0. \tag{1.2}$$

The incremental unknowns consist of the numbers u_{2j}, $j=1,\cdots,N-1$, corresponding to the approximate values at the points $2jh$, and of the numbers

$$\bar{u}_{2j+1}=u_{2j+1}-\tfrac{1}{2}(u_{2j}+u_{2j+2}), \qquad j=0,\cdots,N-1, \tag{1.3}$$

corresponding to the increments from the average values at the neighbors, at the points $(2j+1)h$, $j=0,\cdots,N-1$. We easily infer from (1.2) that

$$\bar{u}_{2j+1}=\frac{h^2}{2}f_{2j+1}, \qquad j=0,\cdots,N-1, \tag{1.4}$$

$$\frac{1}{4h^2}\{2u_{2j}-u_{2j-2}-u_{2j+2}\}-\frac{1}{2}\{\bar{u}_{2j-1}+\bar{u}_{2j+1}\}=\frac{1}{2}f_{2j}, \qquad j=1,\cdots,N-1. \tag{1.5}$$

If we take (1.4) into account, (1.5) becomes

$$\frac{1}{4h^2}\{2u_{2j}-u_{2j-2}-u_{2j+2}\}=\frac{1}{2}f_{2j}+\frac{1}{4}\{f_{2j-1}+f_{2j+1}\}, \qquad j=1,\cdots,N-1. \tag{1.6}$$

The key point for the nonlinear analysis hereafter is that the incremental values are small. This is transparent in (1.4), which shows that

$$\bar{u}_{2j+1}=O(h^2). \tag{1.7}$$

In matricial form, we write (1.2) as

$$\tilde{A}\tilde{U}=\tilde{b}, \tag{1.8}$$

FIG. 1.1. *Coarse gridpoints* (○) *and fine gridpoints* (×, ○) *on* $(0,1)$ *for* $N=5$.

where $\tilde{U} = (u_1, \cdots, u_{2N-1})^t$, $\tilde{b} = (f_1, \cdots, f_{2N-1})^t$, and $\tilde{A} = (1/h^2)T$, T being the usual tridiagonal matrix

$$T = \begin{pmatrix} 2 & -1 & & & 0 \\ -1 & \ddots & \ddots & & \\ & \ddots & \ddots & & -1 \\ 0 & & & -1 & 2 \end{pmatrix}.$$

We may reorder $\tilde{U}$, $\tilde{b}$ into their coarse and fine components:

$$U = (U_c, U_f)^t, \qquad b = (b_c, b_f)^t,$$

$$U_c = (u_2, \cdots, u_{2N-2})^t, \qquad U_f = (u_1, u_3, \cdots, u_{2N-1})^t,$$

$$b_c = (f_2, \cdots, f_{2N-2})^t, \qquad b_f = (f_1, f_3, \cdots, f_{2N-1})^t,$$

and rewrite (1.8) as

$$AU = b, \tag{1.9}$$

this time with

$$A = \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix},$$

$A_{11} = (2/h^2)I_{N-1}$, $A_{22} = (2/h^2)I_N$, where I_j is the jth-dimensional unit matrix and A_{12} is an $(N-1) \times N$ matrix:

$$A_{12} = A_{21} = -\frac{1}{h^2} B_N,$$

$$B_N = \begin{pmatrix} 1 & 1 & & & \\ & \ddots & \ddots & & 0 \\ & 0 & & & \\ & & & 1 & 1 \end{pmatrix}.$$

Using the incremental unknowns, we then replace U by $\hat{U} = (U_c, U_i)^t$,

$$U = S\hat{U}, \tag{1.10}$$

$$S = \begin{pmatrix} I_{N-1} & 0 \\ \frac{1}{2}B_N^t & I_N \end{pmatrix}, \qquad S^{-1} = \begin{pmatrix} I_{N-1} & 0 \\ -\frac{1}{2}B_N^t & I_N \end{pmatrix}.$$

We infer from (1.9) that $AS\hat{U} = b$ or

$$\hat{A}\hat{U} = \hat{b}, \tag{1.11}$$

with $\hat{A} = S^tAS$, $\hat{b} = S^tb$. Like A, the matrix $\hat{A}$ is symmetric positive definite.

1.2. The two-dimensional case. Although some steps of the procedure will now be less transparent, we will proceed in exactly the same way for the two-dimensional case. We consider the Dirichlet problem

$$-\Delta u = f \quad \text{in } \Omega, \qquad u = 0 \quad \text{on } \partial\Omega \tag{1.12}$$

in the square $\Omega = (0, 1)^2$ and its five-point discretization. As above, for $N \in \mathbb{N}$, we set $h = 1/2N$, $2h = 1/N$ and consider the fine grid corresponding to the mesh h, and the

coarse grid corresponding to the mesh $2h$ in both directions. For $i, j = 0, \cdots, 2N$, we write $f_{ij} = f(ih, jh)$ and $u_{ij} \simeq u(ih, jh)$ is the approximate value of $u(ih, jh)$. The fine gridpoints are the points (ih, jh), $i = 1, \cdots, 2j-1$, $j = 1, \cdots, 2j-1$, and the coarse gridpoints are the points $(2ih, 2jh)$, $i = 1, \cdots, N-1$, $j = 1, \cdots, N-1$.

The discrete equations read

$$\frac{1}{h^2}(2u_{i,j} - u_{i-1,j} - u_{i+1,j}) + \frac{1}{h^2}(2u_{i,j} - u_{i,j-1} - u_{i,j+1}) = f_{ij}, \tag{1.13}$$

$$1 \leqq i, \qquad j \leqq 2N-1.$$

Usually we number the unknowns u_{ij} in a sequential order, say from left to right and from top to bottom, and reinterpret (1.13) as a system similar to (1.8). We may also, as for (1.9), reorder the nodes in a different way, with the coarse gridpoints first[2] (numbered from left to right and from top to bottom), then the rest of the fine gridpoints numbered in the same way.[3] We write

$$U = (U_c, U_f)^t, \qquad b = (b_c, b_f)^t,$$

and we then have an analogue of (1.9):

$$AU = b, \tag{1.14}$$

with a matrix A that will not be made explicit here.

At this point we introduce the incremental unknowns: they are made first of the coarse grid nodal values $u_{2i,2j}$, $i, j = 1, \cdots, N-1$. Then, at the noncoarse gridpoints, the incremental unknowns are defined as follows (see Fig. 1.3):

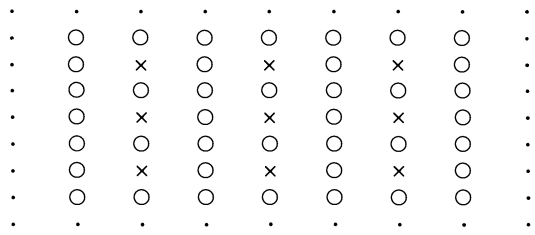

FIG. 1.2. *Coarse gridpoints* (×) *and fine gridpoints* (×, ○) *on the square* $(0, 1)^2$ *for* $N = 4$.

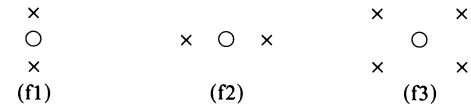

FIG. 1.3. *Noncoarse gridpoints of type* (f1), (f2), *or* (f3).

[2] See points × in Fig. 1.2.

[3] See points ○ in Fig. 1.2. In fact, a more subtle numbering of the noncoarse gridpoints (×) is desirable; this question will be addressed elsewhere.

—Fine gridpoints of type (f1), those at the middle of two vertical coarse gridpoints. The incremental unknown is then

$$\bar{u}_{2i+1,2j} = u_{2i+1,j} - \tfrac{1}{2}(u_{2i,j} + u_{2i+2,j}), \qquad i = 0, \cdots, N-1, \quad j = 1, \cdots, N-1. \tag{1.15}$$

—Fine gridpoints of type (f2), those at the middle of two horizontal coarse gridpoints. The incremental unknown at such a point reads

$$\bar{u}_{2i,2j+1} = u_{2i,2j+1} - \tfrac{1}{2}(u_{2i,2j} + u_{2i,2j+2}), \qquad i = 1, \cdots, N-1, \quad j = 0, \cdots, N-1. \tag{1.16}$$

—Fine gridpoints of type (f3), the rest of the noncoarse gridpoints. They are at the center of a square of edge $2h$, the vertices of which are coarse gridpoints (or boundary points). In this case we introduce the incremental unknown

$$\bar{u}_{2i+1,2j+1} = u_{2i+1,2j+1} - \tfrac{1}{4}(u_{2i,2j} + u_{2i,2j+2} + u_{2i+2,2j} + u_{2i+2,2j+2}), \qquad i, j = 0, \cdots, N-1. \tag{1.17}$$

Note that in (1.15)-(1.17), $u_{\alpha\beta} = 0$ if α or $\beta = 0$ or $2N$; of course the corresponding unknowns disappear then.

Let $\bar{U}_f$ denote the incremental unknowns defined by (1.15)-(1.17) and let $\hat{U} = (U_c, \bar{U}_f)$ be the new unknowns. We have

$$U = S\hat{U}, \tag{1.18}$$

where the matrix S, as well as its inverse, is easily derived from (1.15)-(1.17). Then (1.14) yields

$$\hat{A}\hat{U} = \hat{b} \tag{1.19}$$

with $\hat{A} = S^t A S$ and $\hat{b} = S^t b$.

The explicit form of $\hat{A}$ is less transparent here than in dimension 1. It is also less transparent that the incremental values $\bar{U}_f$ are small as in (1.4); however, this will be proved in § 2 by using the variational approach.

2. Variational framework. The variational formulation of (1.11) is well known. We introduce the Sobolev space $V = H_0^1(\Omega)$ endowed with its scalar product

$$a(u, v) = ((u, v)) = \int_\Omega \text{grad } u.\text{grad } v \, dx$$

and we look for $u \in V$ such that

$$a(u, v) = (f, v) \quad \forall v \in V, \tag{2.1}$$

where (f, v) is the $L^2(\Omega)$-scalar product of f and v:

$$(f, v) = \int_\Omega fv \, dx.$$

We denote by $\|\cdot\|$ and $|\cdot|$ the V and L^2 norms corresponding to the scalar products $((\cdot, \cdot))$, $(\cdot, \cdot)$, respectively.

We now recall briefly the variational framework corresponding to the finite-difference scheme (1.12) (see [C]). For the mesh $h = 1/2N$, we introduce the space V_h, which consists of step functions $u_h, v_h, \cdots$, that are constants on the squares centered at $(ih, (i+1)h) \times (jh, (j+1)h)$, $i, j = 0, \cdots, 2N-1$ of edge h and that vanish

if i or $j = 0$ or $2N-1$. The space V_h is spanned by the basis functions w_{hM}, $M = (ih, jh)$, $i, j = 1, \cdots, 2N-2$, which are equal to 1 in the square $[ih, (i+1)h) \times [jh, (j+1)h)$ and which vanish outside this square. Thus

$$u_h(x) = \sum_{M \in \mathring{\Omega}_h} u_h(M) w_{hM}(x), \qquad x \in \Omega; \tag{2.2}$$

$\mathring{\Omega}_h$ is the set of points (ih, jh), $i, j = 1, \cdots, 2N-2$, and we denote by Ω_h the set of points (ij, jh), $i, j = 0, \cdots, 2N$.

We introduce the finite-difference operators ∇_{1h}, ∇_{2h}:

$$\nabla_{ih}\varphi(x) = \frac{1}{h}(\varphi(x + he_i) - \varphi(x)),$$

$e_1 = (1, 0)$, $e_2 = (0, 1)$ and we endow V_h with the scalar product

$$((u_h, v_h))_h = \sum_{i=1}^{2} (\nabla_{ih} u_h, \nabla_{ih} v_h),$$

where $(\cdot, \cdot)$ is as before the scalar product in $L^2(\Omega)$. We set $\|\cdot\|_h = \{((\cdot, \cdot))_h\}^{1/2}$ and observe that $\|\cdot\|_h$ and $|\cdot|$ are Hilbert norms on V_h. The discrete analogue of (2.1) is the following variational problem:

(2.3) Find $u_h \in V_h$ such that $((u_h, v_h))_h = (f, v_h)$, for all $v_h \in V_h$.

Setting $u_h(M) = u_{ij}$ for $M = (ih, jh) \in \mathring{\Omega}_h$, it can easily be shown that (2.3) is equivalent to the system of equations (1.12) with the only difference that here f_{ij} is an average value of f:

$$f_{ij} = \frac{1}{h^2} \int_{ih}^{(i+1)h} \int_{jh}^{(j+1)h} f(x)\, dx. \tag{2.4}$$

Now there is no objection to considering the mesh $2h = 1/N$ and the corresponding space V_{2h} spanned by the basis functions $w_{2h,M}$, $M \in \mathring{\Omega}_{2h}$, where $w_{2h,M}$ and $\mathring{\Omega}_{2h}$ are defined exactly as before. We are not interested here in the analogue of (2.3) in V_{2h}. Rather we are interested in an appropriate rewriting of (2.3). We observe that $V_{2h} \subset V_h$ and write

$$V_h = V_{2h} \oplus W_h, \tag{2.5}$$

where W_h is the space spanned by the functions w_{hM}, $M \in \mathring{\Omega}_h \backslash \mathring{\Omega}_{2h}$. We thus obtain a basis of V_h consisting of the $w_{2h,M}$, $M \in \mathring{\Omega}_{2h}$, and the w_{hM}, $M \in \mathring{\Omega}_h \backslash \mathring{\Omega}_{2h}$. The previously used basis of V_h or V_{2h} is called the natural basis, while this basis of V_h induced by that of V_{2h} will be called the *induced basis.*

We now write the decomposition of an element $u_h \in V_h$ corresponding to (2.5):

$$u_h = y_h + z_h, \quad y_h \in V_{2h}, \quad z_h \in W_h, \tag{2.6}$$

and try to identify y_h and z_h, on a square $[2ih, 2(i+1)h[\times [2jh, 2(j+1)h[$ of vertex $M_1 = (2ih, 2jh)$, as in Fig. 2.1.

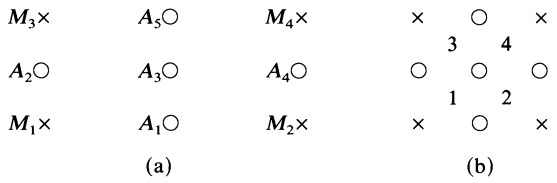

FIG. 2.1. *Subdivision of a coarse grid square into four fine grid squares.*

We have

$$w_{2h,M_1} = w_{hM_1} + \sum_{i=1}^{3} w_{hA_i}.$$

Hence

$$u_h = \sum_{M \in \mathring{\Omega}_h} u_h(M) w_{hM} \tag{2.7}$$

is equal on this square to

$$u_h(M_1) w_{hM_1} + \sum_{i=1}^{3} u_h(A_i) w_{hA_i} = u_h(M_1) w_{2hM_1} + \sum_{i=1}^{3} (u_h(A_i) - u_h(M_1)) w_{hA_i}.$$

We conclude that y_h is the coarse grid component

$$y_h = \sum_{M \in \mathring{\Omega}_{2h}} u_h(M) w_{2hM}, \tag{2.8}$$

and

$$\begin{aligned} z_h = \sum_{M \in \Omega_h} \{ & (u_h(M + he_1) - u_h(M)) w_{h,M+he_1} \\ & + (u_h(M + he_2) - u_h(M)) w_{h,M+he_2} \\ & + (u_h(M + he_1 + he_2) - u_h(M)) w_{h\,M+he_1+he_2} \}. \end{aligned} \tag{2.9}$$

The components of z_h in the basis of W_h described before are thus the incremental quantities of the form

$$u_h(A_1) - u_h(M_1), \quad u_h(A_2) - u_h(M_1), \quad u_h(A_3) - u_h(M_1). \tag{2.10}$$

We will then call z_h the *incremental component* of u_h and y_h its *coarse grid component.* Let us observe that

$$z_h(M) = 0 \quad \forall M \in \Omega_{2h}, \quad \forall z_h \in W_h. \tag{2.11}$$

Remark 2.1. These incremental values of u_h are not those used in § 1. A different basis of V_h leading to cumbersome computations must be used to recover the incremental unknowns mentioned in § 1. For the sake of simplicity we will pursue the analysis with incremental values (2.10) and decompositions (2.5)-(2.6), (2.8)-(2.9). However, for all practical purposes, we advocate the use of the incremental unknowns of § 1, which are much more convenient in effective computations.

We now return to the approximate problem, namely (2.3). Using the decomposition (2.5), (2.6) we write $u_h = y_h + z_h$ and observe that (2.3) is equivalent to

$$\begin{aligned} ((y_h + z_h, \tilde{y}_h))_h &= (f, \tilde{y}_h) \quad \forall \tilde{y}_h \in V_{2h}, \\ ((y_h + z_h, \tilde{z}_h))_h &= (f, \tilde{z}_h) \quad \forall \tilde{z}_h \in W_h. \end{aligned} \tag{2.12}$$

Of course, replacing v_h by u_h in (2.3) we obtain the usual a priori estimates:

$$\|u_h\|_h^2 = (f, u_h). \tag{2.13}$$

Thanks to the discrete Poincaré inequality (see [C] or [T2]),

$$|u_h| \leqq c_1 \|u_h\|_h, \tag{2.14}$$

where c_1 is independent of h, we find

$$\begin{aligned} \|u_h\|_h^2 &\leqq |f|\,|u_h| \leqq c_1 |f|\,\|u_h\|_h, \\ \|u_h\|_h &\leqq c_1 |f|. \end{aligned} \tag{2.15}$$

We can also obtain (2.13) by replacing $\tilde{y}_h$ by y_h in the first equation of (2.12) and $\tilde{z}_h$ by z_h in the second equation of (2.12), and adding the resulting relations.

Our aim is now to show that (2.15) in fact yields two separate a priori estimates for y_h and z_h.

Let us admit temporarily the following lemmas, which will be proved below.

LEMMA 2.1 (Strong Cauchy-Schwarz inequality). *We have the enhanced Cauchy-Schwarz inequality*:

$$|((y_h, z_h))_h| \leqq \frac{\sqrt{3}}{2} \|y_h\|_h \|z_h\|_h \quad \forall y_h \in V_{2h}, \quad \forall z_h \in W_h. \tag{2.16}$$

LEMMA 2.2.

$$\|y_h\|_h^2 = 2\|y_h\|_{2h}^2 \quad \forall y_h \in V_{2h}. \tag{2.17}$$

LEMMA 2.3 (Strong Poincaré inequality in W_h). *We have the following strong Poincaré inequality for functions in* W_h:

$$|z_h| \leqq h\|z_h\|_h \quad \forall z_h \in W_h. \tag{2.18}$$

If we admit these lemmas, then

$$\begin{aligned} \|u_h\|_h^2 &= \|y_h + z_h\|_h^2 \\ &= \|y_h\|_h^2 + \|z_h\|_h^2 + 2((y_h, z_h))_h \\ &\geqq \|y_h\|_h^2 + \|z_h\|_h^2 - \sqrt{3}\|y_h\|_h \|z_h\|_h \\ &\geqq \left(1 - \frac{\sqrt{3}}{2}\right)\{\|y_h\|_h^2 + \|z_h\|_h^2\} \\ &\geqq \frac{1}{8}\{\|y_h\|_{2h}^2 + \|z_h\|_h^2\} \end{aligned} \tag{2.19}$$

and (2.15) yields

$$\|y_n\|_{2h}^2 + \|z_h\|_h^2 \leqq 8c_1^2|f|^2. \tag{2.20}$$

Finally, using (2.18) and (2.20),

$$|z_h|^2 \leqq 8h^2c_1^2|f|^2. \tag{2.21}$$

We have thus proved the following analogue of (1.7).

PROPOSITION 2.1. *The incremental component* z_h *of* u_h *is small in the* L^2*-norm*:

$$|z_h| \leqq 4hc_1|f|. \tag{2.22}$$

We conclude this section by proving Lemmas 2.1–2.3.

Proof of Lemma 2.1. We must show that

$$\int_\Omega \nabla_h y_h \nabla_h z_h \, dx \leqq \frac{\sqrt{3}}{2}\left(\int_\Omega |\nabla_h y_h|^2 \, dx\right)^{1/2}\left(\int_\Omega |\nabla_h z_h|^2 \, dx\right)^{1/2}, \tag{2.23}$$

where $\nabla_h = (\nabla_{1h}, \nabla_{2h})$. It suffices to show (2.23) with Ω replaced by a typical coarse grid square $\mathcal{R}$ as in Fig. 2.1; (2.22) would then follow by summation for the different $\mathcal{R}$'s and utilization of the Schwarz inequality in the integrals.

For the sake of simplicity in the notation we set $y_h(M_i) = m_i$ and $z_h(A_i) = p_i$, and recall that $z_h(M_i) = 0$ for all i (see (2.11)). The function y_h is constant on the square $\mathcal{R}$ of Fig. 2.1(a) and its value is m_1. The function z_h is constant on each of the four

subsquares $\mathcal{R}_1, \cdots, \mathcal{R}_4$ numbered as shown in Fig. 2.1(b); on $\mathcal{R}_1$, $z_h = 0$, on $\mathcal{R}_2$, $z_h = p_1$, on $\mathcal{R}_3$, $z_h = p_2$, and on $\mathcal{R}_4$, $z_h = p_3$.

Now the computation is straightforward:

—On $\mathcal{R}_1$, $\nabla_h y_h = 0$, $\nabla_h z_h = \frac{1}{h}(p_1, p_2)$,

—On $\mathcal{R}_2$, $\nabla_h y_h = \frac{1}{h}(m_2 - m_1, 0)$, $\nabla_h z_h = \frac{1}{h}(-p_1, p_3 - p_1)$,

—On $\mathcal{R}_3$, $\nabla_h y_h = \frac{1}{h}(0, m_3 - m_1)$, $\nabla_h z_h = \frac{1}{h}(p_3 - p_2, -p_2)$,

—On $\mathcal{R}_4$, $\nabla_h y_h = \frac{1}{h}(m_2 - m_1, m_3 - m_1)$, $\nabla_h z_h = \frac{1}{h}(p_4 - p_3, p_5 - p_3)$.

Then

$$\int_{\mathcal{R}} |\nabla_h y_h|^2 \, dx = 2\{(m_2 - m_1)^2 + (m_3 - m_1)^2\}, \tag{2.24}$$

$$\int_{\mathcal{R}} |\nabla_h z_h|^2 \, dx = 2(p_1^2 + p_2^2) + (p_3 - p_1)^2 + (p_3 - p_2)^2 + (p_4 - p_3)^2 + (p_5 - p_3)^2, \tag{2.25}$$

$$\begin{aligned}
&\int_{\mathcal{R}} \nabla_h y_h \nabla_h z_h \, dx \\
&= -p_1(m_2 - m_1) - p_2(m_3 - m_1) + (m_2 - m_1)(p_4 - p_3) + (m_3 - m_1)(p_5 - p_3) \\
&= (m_2 - m_1)(p_4 - p_3 - p_1) + (m_3 - m_1)(p_5 - p_3 - p_2) \\
&\leqq \{2(m_2 - m_1)^2 + 2(m_3 - m_1)^2\}^{1/2} \cdot \left\{\frac{1}{2}(p_4 - p_3 - p_1)^2 + \frac{1}{2}(p_5 - p_3 - p_2)^2\right\}^{1/2} \\
&\leqq \left(\int_{\mathcal{R}} |\nabla_h y_h|^2 \, dx\right)^{1/2} \cdot \left\{\frac{3}{4}(p_4 - p_3)^2 + \frac{3}{4}(p_5 - p_3)^2 + \frac{3}{2}p_1^2 + \frac{3}{2}p_2^2\right\}^{1/2} \\
&\leqq \frac{\sqrt{3}}{2}\left(\int_{\mathcal{R}} |\nabla_h y_h|^2 \, dx\right)^{1/2} \left(\int_{\mathcal{R}} |\nabla_h z_h|^2 \, dx\right)^{1/2}.
\end{aligned}$$

Proof of Lemma 2.2. We use the same notation as in Lemma 2.1 and observe that $\nabla_{2h} y_h$ is constant in $\mathcal{R}$ and equal to $(1/2h)(m_2 - m_1, m_3 - m_1)$. Hence

$$\int_{\mathcal{R}} |\nabla_{2h} y_h|^2 \, dx = (m_2 - m_1)^2 + (m_3 - m_1)^2,$$

and it suffices to compare this to (2.24).

Proof of Lemma 2.3. Using the notation of Lemma 2.1, it suffices to prove that

$$\int_{\mathcal{R}} (z_h)^2 \, dx \leqq h^2 \int_{\mathcal{R}} |\nabla_h z_h|^2 \, dx. \tag{2.26}$$

The right-hand side of this inequality is given by (2.25) and the left-hand side is equal to

$$\begin{aligned}
h^2(p_1^2 + p_2^2 + p_3^2) &\leqq h^2\{2p_1^2 + 2p_2^2 + (p_3 - p_1)^2 + (p_3 - p_2)^2\} \\
&\leqq h^2 \int_{\mathcal{R}} |\nabla_h z_h|^2 \, dx.
\end{aligned}$$

Remark 2.2. Although here we emphasize the case $\Omega = (0, 1)^2$, let us observe that the framework and results extend to the case where Ω is any bounded domain of $\mathbb{R}^2$. In this case the mesh h can be any vector (h_1, h_2) of $\mathbb{R}^2$, $h_i > 0$, and we consider the mesh $\mathcal{R}_h$ consisting of the points $jh = (j_1 h_1, j_2 h_2)$, $j_i \in \mathbb{Z}$. We denote by $\sigma_h(M)$ the rectangle centered at M of edges h_1, h_2, and

$$\sigma_h^1(M) = \sigma_h(M) \cup \sigma_h(M + h_1 e_1) \cup \sigma_h(M + h_2 e_2).$$

Then

$$\mathring{\Omega}_h = \{M \in \mathcal{R}_h, \sigma_h^1(M) \subset \Omega\},$$
$$\Omega_h = \{M \in \mathcal{R}, \sigma_h(M) \subset \Omega\},$$

and for $M \in \Omega_h$, w_{hM} is the characteristic function of $\sigma_h(M)$. We define V_h as the space spanned by the w_{hM}, $M \in \mathring{\Omega}_h$, and $V_{2h} \subset V_h$ is defined in the same way for $2h = (2h_1, 2h_2)$. The finite difference operators ∇_{ih} are defined by

$$\nabla_{ih}\varphi(x) = \frac{1}{h_i}(\varphi(x + h_i e_i) - \varphi(x)).$$

We still have (2.5) with W_h defined exactly as above. All the results extend without any modification. Lemmas 2.1 and 2.2 are still valid, and in Lemma 2.3 we replace (2.18) by

$$\begin{aligned} |z_h| &\leqq \max(h_1, h_2)\|z_h\|_h \\ &\leqq (h_1^2 + h_2^2)^{1/2}\|z_h\|_h, \end{aligned} \tag{2.27}$$

and (2.22) is modified accordingly:

$$|z_h| \leqq 2 \max(h_1, h_2) c_1 |f|. \tag{2.28}$$

3. A class of nonlinear evolution equations. Let H be a Hilbert space endowed with the scalar product $(\cdot, \cdot)$ and the norm $|\cdot|$. We consider an evolution equation of the form

$$\frac{du}{dt} + Au + R(u) = 0 \tag{3.1}$$

with

$$R(u) = B(u) + C(u) + f. \tag{3.2}$$

The unknown function u is a map from $\mathbb{R}_+$ (or some interval of $\mathbb{R}$) into H. The operator A is linear self-adjoint unbounded in H with domain $D(A)$. We assume that A is positive closed and that A^{-1} is compact. The powers A^s of A for $S \in \mathbb{R}$ are defined and map $D(A^s)$ into H, and $D(A^s)$ is a Hilbert space for the norm $|A^s \cdot|$. We set $V = D(A^{1/2})$ and we denote by $\|\cdot\| = |A^{1/2} \cdot|$ the norm on V; $\nu > 0$ is given.

The nonlinear term $R(u)$ satisfies (3.2), where $B(u) = B(u, u)$; $B(\cdot, \cdot)$ is a bilinear continuous operator from $V \times V$ into V'; C is a linear operator from V into H and $f \in H$. We denote by b the trilinear continuous form on V given by

$$b(u, v, w) = \langle B(u, v), w \rangle \quad \forall u, v, w \in V,$$

and we assume that

$$b(u, v, v) = 0 \quad \forall u, v \in V, \tag{3.3}$$

$$|b(u, v, w)| \leqq c_2 |u|^{1/2}\|u\|^{1/2}\|v\||w|^{1/2}\|w\|^{1/2} \quad \forall u, v, w \in V, \tag{3.4}$$

$$|Cu| \leqq c_3\|u\| \quad \forall u \in V, \tag{3.5}$$

where c_2, c_3 like the quantities c_i appearing subsequently are positive constants. In addition, we require that B maps $V \times D(A)$ into H and

$$|B(u, v)| \leqq c_4 |u|^{1/2} \|u\|^{1/2} \|v\|^{1/2} |Av|^{1/2} \quad \forall u, v \in D(A), \tag{3.6}$$

$$|B(u, v)| \leqq c_5 |u|^{1/2} |Au|^{1/2} \|v\| \quad \forall u, v \in D(A). \tag{3.7}$$

Finally, we require $\nu A + C$ to be positive, i.e., there exists $\alpha > 0$ such that

$$((\nu A + C)u, u) \geqq \alpha \|u\|^2 \quad \forall u \in V. \tag{3.8}$$

Under the hypotheses above, we infer from classical results that the initial value problem consisting of (3.1) and

$$u(0) = u_0 \tag{3.9}$$

has a unique solution $u = u(t)$ defined for all $t > 0$ and such that

$$u \in \mathscr{C}(\mathbb{R}_+; H) \cap L^2(0, T; V) \quad \forall T > 0. \tag{3.10}$$

Moreover, if $u_0 \in V$, then

$$u \in \mathscr{C}(\mathbb{R}_+; V) \cap L^2(0, T; D(A)) \quad \forall T > 0. \tag{3.11}$$

Remark 3.1. As usual, we can rewrite (3.1), (3.2) in a weak (variational) form that will be appropriate for the treatment below, namely,

$$\frac{d}{dt}(u, v) + a(u, v) + b(u, u, v) + (Cu, v) = (f, v) \quad \forall v \in V, \tag{3.12}$$

where

$$a(u, v) = (Au, v). \tag{3.13}$$

We may assume for simplicity that

$$a(u, v) = \nu((u, v)), \qquad \nu > 0, \tag{3.14}$$

but this is not essential.

The abstract equation considered here includes, in particular, several dissipative evolution equations and the two-dimensional Navier–Stokes equations; however, we do not want to consider such a complicated equation here, and we will now give some simpler equations satisfying these hypotheses.

Example 1. Let Ω be an open-bounded set in $\mathbb{R}^2$ with boundary $\partial\Omega$. We consider the evolution problem (of Burgers type):

$$\frac{\partial u}{\partial t} - \Delta u + a_1 \frac{\partial u}{\partial x_1} + a_2 \frac{\partial u}{\partial x_2} + u \frac{\partial u}{\partial x_1} = f, \quad x \in \Omega, \quad t > 0, \tag{3.15}$$

$$u = 0 \quad \text{on } \partial\Omega, \tag{3.16}$$

$$u(x, 0) = u_0(x), \qquad x \in \Omega. \tag{3.17}$$

Here a_1, a_2 are given in $L^\infty(\Omega)$ and $f \in L^2(\Omega)$. We take $H = L^2(\Omega)$, $V = H_0^1(\Omega)$, $A = -\Delta$ with Dirichlet boundary conditions:

$$B(u, v) = u \frac{\partial v}{\partial x_1}, \qquad Cu = a_1 \frac{\partial u}{\partial x_1} + a_2 \frac{\partial u}{\partial x_2}.$$

It is easy to check that all the hypotheses are satisfied.

Example 2. This is an example of an integral Burgers type equation. Everything else being unchanged, we now consider

$$B(u, v) = \left(\int_\Omega u(\xi)\, d\xi \right) \frac{\partial v}{\partial x_1}.$$

All the hypotheses above are satisfied.

Example 3. This last example is a system close to the Navier-Stokes equations but without the pressure term and the incompressibility condition; and the nonlinear (inertial) term is modified as in [T1]. Let Ω be an open-bounded set of $\mathbb{R}^2$ with boundary $\partial\Omega$. The function $u = (u_1, u_2)$ maps $\Omega \times (0, T)$ into $\mathbb{R}^2$ and satisfies

$$\frac{\partial u}{\partial t} - \nu \Delta u + (u \cdot \nabla) u + \frac{1}{2} (\operatorname{div} u) u = f, \quad x \in \Omega, \quad t > 0, \tag{3.18}$$

$$u = 0 \quad \text{on } \partial\Omega, \tag{3.19}$$

$$u(x, 0) = u_0(x). \tag{3.20}$$

We take $H = L^2(\Omega)^2$, $V = H_0^1(\Omega)^2$, $D(A) = \{H_0^1(\Omega) \cap H^2(\Omega)\}^2$, $A = -\nu\Delta$, $C = 0$, and

$$B(u, v) = (u \cdot \nabla) v + \tfrac{1}{2} (\operatorname{div} u) v.$$

All the hypotheses are satisfied.

4. Spatial discretization. The IMG algorithm. In this section we present the IMG algorithm, which combines the ideas and concepts on inertial manifolds and those on multigrid methods. We start by describing the spatial discretization of (3.1) (or (3.12)) in a way suitable for our purpose. We then give an estimate on the incremental component of the solution, which is a partial justification for the IMG algorithm. Finally, we describe the IMG algorithm itself.

4.1. Spatial discretization. For the spatial discretization of (3.1), (3.12), we are traditionally given a family of finite-dimensional spaces $V_h \subset H$ endowed with a Hilbert scalar product and norm $((\cdot, \cdot))h$, $\|\cdot\|_h$. The parameter h is a discretization parameter. For Galerkin methods, and particularly for finite-element methods, $V_h \subset V$ and it is required that $\cup_h V_h$ is dense in V. For finite differences, as shown in § 2, the space V_h is not a subspace of V and the hypotheses are slightly more involved; they will not be recalled here (see, however, § 5).

For the spatial discretization of (3.12), we then consider a function u_h from $\mathbb{R}_+$ into V_h, which satisfies

$$\frac{d}{dt}(u_h, v_h) + a_h(u_h, v_h) + b_h(u_h, u_h, v_h) + (C_h u_h, v_h) = (f, v_h) \quad \forall v_h \in V_h, \tag{4.1}$$

where a_h, v_h, and C_h are appropriate approximations of a, v, and C. Of course, the second step in the numerical approximation of (3.1), (3.12) is the time discretization of (4.1), but we emphasize the spatial discretization here.

4.2. Incremental unknowns. As in § 2, we now consider two values of the discretization parameter, h and $2h$, and the corresponding approximating spaces V_h and V_{2h}. It is assumed that $V_{2h} \subset V_h$ and, more precisely, we write as in (3.5)

$$V_h = V_{2h} \oplus W_h. \tag{4.2}$$

Any $u_h \in V_h$ is decomposed into

$$u_h = y_h + z_h, \tag{4.3}$$

where y_h is called the coarse grid component of u_h and z_h is called the incremental component of u_h. We assume the following properties, which have been proved in § 2 when $V = H_0^1(\Omega)$ and $\Omega = (0, 1)^2$:

$$|((y_h, z_h))_h| \leqq (1-\delta)\|y_h\|_h \|z_h\|_h \quad \forall y_h \in V_{2h}, \quad \forall z_h \in W_h, \tag{4.4}$$

where $0 < \delta < 1$ is independent of h, and

$$S_1(h)|z_h| \leqq \|z_h\|_h \quad \forall z_h \in W_h, \tag{4.5}$$

where $S_1(h) \to \infty$ as $h \to 0$.

We now use the decomposition (4.3) of u_h and it is straightforward that (4.1) is equivalent to the following system for y_h, z_h:

$$\left(\frac{d}{dt}(y_h + z_h), \tilde{y}_h\right) + a_h(y_h + z_h, \tilde{y}_h) + b_h(y_h + z_h, y_h + z_h, \tilde{y}_h) + (C_h(y_h + z_h), \tilde{y}_h) = (f, \tilde{y}_h) \quad \forall \tilde{y}_h \in V_{2h}, \tag{4.6}$$

$$\left(\frac{d}{dt}(y_h + z_h), \tilde{z}_h\right) + a_h(y_h + z_h, \tilde{z}_h) + b_h(y_h + z_h, y_h + z_h, \tilde{z}_h) + (C_h(y_h + z_h), \tilde{z}_h) = (f, \tilde{z}_h) \quad \forall \tilde{z}_h \in W_h. \tag{4.7}$$

This is just a rewriting of the natural spatial discretization scheme (4.1) corresponding to V_h. However, as a partial justification for the IMG algorithm described below, we want to show now that the incremental component z_h is small for h small.

4.3. Estimate on the incremental component. To derive a priori estimates we must assume that a_h, b_h, C_h satisfy some hypotheses similar to those on a, b, C (see (3.3)-(3.8)). We assume here that

$$b_h(u_h, v_h, v_h) = 0 \quad \forall u_h, v_h \in V_h, \tag{4.8}$$

$$|b_h(u_h, v_h, w_h)| \leqq c_6 |u_h|^{1/2} \|u_h\|_h^{1/2} \|v_h\| \, |w_h|^{1/2} \|w_h\|_h^{1/2} \quad \forall u_h, v_h, w_h \in V_h, \tag{4.9}$$

$$|a_h(u_h, v_h)| \leqq c_7 \|u_h\|_h \|v_h\|_h, \qquad |C_h u_h| \leqq c_8 \|u_h\|_h \quad \forall u_h, v_h \in V_h, \tag{4.10}$$

$$a_h(u_h, u_h) + (C_h u_h, u_h) \geqq \alpha_1 \|u_h\|_h^2 \quad \forall u_h \in V_h, \tag{4.11}$$

$$|u_h|_h \leqq c_9 \|u_h\|_h \quad \forall u_h \in v_h, \tag{4.12}$$

where c_6-c_9 and α_1 are independent of h ($\alpha_1 > 0$).

As usual, a priori estimates on u_h are obtained by replacing v_h by $u_h (= u_h(t))$ in (4.1). It is equivalent to replacing $\tilde{y}_h$ by $y_h (= y_h(t))$ in (4.6) and $\tilde{z}_h$ by $z_h (= z_h(t))$ in (4.7) and adding the equations that we obtain. Thanks to (4.8) we find

$$\frac{1}{2}\frac{d}{dt}|u_h|^2 + a_h(u_h, u_h) + (C_h u_h, u_h) = (f, u_h).$$

Using (4.11) and (4.12), we can then write

$$\frac{1}{2}\frac{d}{dt}|u_h|^2+\alpha_1\|u_h\|_h^2\leqq|f||u_h|$$

$$\leqq c_9|f|\,\|u_h\|_h$$

$$\leqq\frac{\alpha_1}{2}\|u_h\|_h^2+\frac{c_9^2}{2\alpha_1}|f|^2,$$

$$\frac{d}{dt}|u_h|^2+\alpha_1\|u_h\|_h^2\leqq\frac{c_9^2}{\alpha_1}|f|^2, \tag{4.13}$$

$$\frac{d}{dt}|u_h|^2+\frac{\alpha_1}{c_8^2}|u_h|^2\leqq\frac{c_9^2}{\alpha_1}|f|^2. \tag{4.14}$$

The last inequality yields a uniform estimate of u_h in $\mathscr{C}(\mathbb{R}_+;H)$:

$$|u_h(t)|^2\leqq|u_h(0)|^2\exp\left(-\frac{\alpha_1}{c_9^2}t\right)+\frac{c_8^2c_9^2}{\alpha_1^2}|f|^2\quad\forall t>0. \tag{4.15}$$

Returning to (4.13) we find, for any $T>0$

$$\frac{1}{T}\int_0^T\|u_h\|^2\,dt\leqq\frac{1}{T\alpha_1}|u_h(0)|^2+\frac{c_9^2}{\alpha_1^2}|f|^2\leqq K_1. \tag{4.16}$$

Separate estimates can be obtained for y_h and z_h by using (4.4). Indeed,

$$\|u_h\|^2=\|y_h+z_h\|_h^2$$

$$=\|y_h\|_h^2+\|z_h\|_h^2+2((y_h,z_h))_h \tag{4.17}$$

$$\geqq 2\delta(\|y_h\|_h^2+\|z_h\|_h^2),$$

and hence

$$\frac{1}{T}\int_0^T(\|y_h\|_h^2+\|z_h\|_h^2)\,dt\leqq\frac{K_1}{2\delta}. \tag{4.18}$$

Then, using (4.5), we obtain that z_h is small in the following sense (at least):

$$\frac{1}{T}\int_0^T|z_h|^2\,dt\leqq\frac{K_1}{2\delta}(S_1(h))^{-2}. \tag{4.19}$$

We can derive further a priori estimates on z_h, but they involve more complicated computations and will not be given here.

4.4. The IMG algorithm. The algorithm that we now present stems from the the theory of dynamical systems, the idea being to approximate the universal attractor describing the long-term behavior of the solutions of (3.1), (3.2). A partial justification of this algorithm lies in the fact that some of the terms involving z_h in (4.6), (4.7) are small and thus can be neglected. We refer the reader to [FMT] and [T5], [T6] for further justification.

The algorithm that we consider is the following: $u_h=y_h+z_h$ is an approximation of u different from that above and, in particular, y_h, z_h are no longer the same as in (4.6), (4.7).

We look for $u_h = y_h + z_h$, satisfying

$$\left(\frac{dy_h}{dt}, \tilde{y}_h\right) + a_h(y_h + z_h, \tilde{y}_h) + b_h(y_h, y_h, \tilde{y}_h) + b_h(y_h, z_h, \tilde{y}_h) + b_h(z_h, y_h, \tilde{y}_h) + (C_h(y_h + z_h), \tilde{y}_h) = (f, \tilde{y}_h) \quad \forall \tilde{y}_h \in V_{2h}, \tag{4.20}$$

$$a_h(y_h + z_h, \tilde{z}_h) + b_h(y_h, y_h, \tilde{z}_h) + (C_h(y_h + z_h), \tilde{z}_h) = (f, \tilde{z}_h) \quad \forall \tilde{z}_h \in W_h, \tag{4.21}$$

$$(y_h(0), \tilde{y}_h) = (u_0, \tilde{y}_h) \quad \forall \tilde{y}_h \in V_{2h}. \tag{4.22}$$

Theoretical questions including the existence of y_h, z_h will be studied in § 5. For the moment we conclude this section with some general comments.

We rewrite (4.21) in the form

$$a_h(z_h, \tilde{z}_h) + (C_h z_h, \tilde{z}_h) = -a_h(y_h, \tilde{z}_h) - b_h(y_h, y_h, \tilde{z}_h) - (C_h y_h, \tilde{z}_h) + (f, \tilde{z}_h) \quad \forall \tilde{z}_h \in W_h. \tag{4.23}$$

It then follows from the Lax-Milgram Theorem and hypothesis (4.11) that, at each instant of time, $z_h = z_h(t)$ is uniquely determined as a function of $y_h = y_h(t)$ and of the other data:

$$z_h(t) = \Phi_h(y_h(t)). \tag{4.24}$$

By inserting this expression of z_h in (4.20), we find the following equation for y_h:

$$\left(\frac{dy_h}{dt}, \tilde{y}_h\right) + a_h(y_h + \Phi_h(y_h), \tilde{y}_h) + b_h(y_h, y_h, \tilde{z}_h) + b_h(y_h, \Phi_h(y_h), \tilde{z}_h) + b_h(\Phi_h(y_h), y_h, \tilde{y}_h) + (C_h(y_h + \Phi_h(y_h)), \tilde{y}_h) = (f, \tilde{y}_h) \quad \forall \tilde{y}_h \in V_{2h}. \tag{4.25}$$

We observe that, setting $\Phi_h = 0$ in (4.25), (4.22), we recover exactly the approximation based on V_{2h}. Hence (4.25) gives a V_{2h} approximation of y_h, perturbed by some "small terms" $z_h = \Phi_h(y_h)$. The solution u_h of the IMG algorithm lies on the manifold $\mathcal{M}_h$ of V_h of equation

$$z_h = \Phi_h(y_h). \tag{4.26}$$

The dimension of this manifold is that of V_{2h}. Note that, with a usual V_{2h} discretization ($z_h = 0$), the solution $u_h = y_h$ would lie in V_{2h}; and with a V_h-discretization as in (4.1) (or (4.6), (4.7)), the solution u_h could be a priori anywhere in V_h. Here the solution lies on the manifold $\mathcal{M}_h$ of V_h whose dimension is that of V_{2h}. As in [T5] for the case of spectral methods, it is expected that the IMG algorithm provides a V_h-accuracy, with a V_{2h}-complexity of computation.

Remark 4.1. Although we restricted ourselves to two discretization meshes h and $2h$, we could as well consider two discretization meshes h and dh, $d \in \mathbb{N}$ fixed ($= 2, 3, 4, \cdots$). All the developments above would be still valid without any modification; we only need to extend (4.4), (4.15) (i.e., Lemmas 2.1 and 2.3) to this case.

5. Convergence of the algorithm. Our aim is now to prove the convergence of the algorithm presented in § 4. We do not make any attempt at generality and, strictly speaking, the convergence result hereafter applies to the three examples described in § 3. However, the methodology is general, and with appropriate hypotheses—including in particular the so-called consistency hypotheses that specify how a_h, b_h, C_h, v_h approximate a, b, C, V—the result applies to the general equation (3.1), (3.12) and to even more general situations.

THEOREM 5.1. *The hypotheses are those above, u_0 is given in H, and $u = u(t)$ is the solution of* (3.1), (3.9). *For every fixed h, the solution $u_h = y_h + z_h$ of* (4.20)-(4.22) *exists and is uniquely defined for all $t > 0$. When $h \to 0$, u_h converges to u in the following sense:*

(5.1) *$y_h \to u$ in $L^p(0, T; H)$ strongly for all $T > 0$ and all p, $1 \leqq p < \infty$, $\nabla_h u_h \to \nabla u$ in $L^2(\Omega \times (0, T))$ strongly, for all $T > 0$.*

(5.2) *$z_h \to 0$ in $L^p(0, T; H)$ strongly for all $T > 0$ and all p, $1 \leqq p < \infty$, $\nabla_h z_h \to 0$ in $L^2(\Omega \times (0, T))$ strongly, for all $T > 0$.*

(5.3) *$y_h \to u$ and $z_h \to 0$ in $L^\infty(\mathbb{R}_+; H)$ weak-star.*

The proof of Theorem 5.1 is given below. It comprises several steps, the first ones being devoted to the derivation of a priori estimates.

5.1. A priori estimates I. We start by deriving a priori estimates for y_h and z_h. They are similar to those derived in (4.18), (4.19) for the usual discretization procedure.

The system of equations (4.20)-(4.22) is equivalent to (4.25) and (4.22), the expression of Φ_h being given by (4.24). Since Φ_h is a simple (quadratic) function, the existence of y_h (and thus z_h) on some interval of time $[0, T_h)$ follows readily from classical theorems on differential equations. The fact that y_h and z_h are defined for all $t > 0$ (i.e., $T_h = +\infty$) will follow from the a priori estimates below.

We replace $\tilde{y}_h$ by y_h $(= y_h(t))$ in (4.20) and $\tilde{z}_h$ by z_h $(= z_h(t))$ in (4.21) and we add the equations that we obtain. We find

$$\frac{1}{2}\frac{d}{dt}|y_h|^2 + a_h(y_h + z_h, y_h + z_h) + (C_h(y_h + z_h), y_h + z_h) = (f, y_h + z_h). \tag{5.4}$$

We have used (4.8) and its consequence

$$b_h(\varphi_h, \psi_h, \theta_h) = -b_h(\varphi_h, \theta_h, \psi_h) \quad \forall \varphi_h, \psi_h, \theta_h \in V_h. \tag{5.5}$$

Thanks to (4.11) we then have

$$\begin{aligned}
\frac{1}{2}\frac{d}{dt}|y_h|^2 + \alpha_1\|y_h + z_h\|_h^2 &= (f, y_h + z_h) \\
&\leqq |f||y_h + z_h| \quad \text{(by the Schwarz inequality and (4.12))} \\
&\leqq c_9|f|\,\|y_h + z_h\|_h \\
&\leqq \frac{\alpha_1}{2}\|y_h + z_h\|_h^2 + \frac{c_9^2}{2\alpha_1}|f|^2,
\end{aligned}$$

$$\frac{d}{dt}|y_h|^2 + \alpha_1\|y_h + z_h\|_h^2 \leqq \frac{c_9^2}{\alpha_1}|f|^2. \tag{5.6}$$

Using (4.4) as in (4.17) and again using (4.11), we obtain

$$\frac{d}{dt}|y_h|^2 + 2\alpha_1\delta(\|y_h\|_h^2 + \|z_h\|_h^2) \leqq \frac{c_9^2}{\alpha_1}|f|^2, \tag{5.7}$$

$$\frac{d}{dt}|y_h|^2 + \frac{2\alpha_1\delta}{c_9^2}|y_h|^2 \leqq \frac{c_9^2}{\alpha_1}|f|^2. \tag{5.8}$$

We infer from (5.8) and from Gronwall's Lemma the following estimate on y_h:

$$|y_h(t)|^2 \leqq |y_h(0)|^2 \exp\left(-\frac{2\alpha_1\delta}{c_9^2}t\right) + \frac{c_9^4}{2\alpha_1^2\delta}|f|^2. \tag{5.9}$$

This shows that y_h remains bounded, and y_h is defined for all $t>0$ (i.e., $T_h=+\infty$). Furthermore, since by (4.22)

$$|y_h(0)|\leqq|u_0|, \tag{5.10}$$

we have a time-uniform estimate for y_h that is independent of h:

(5.11) y_h remains in a bounded set of $L^\infty(\mathbb{R}_+;H)$ as $h\to 0$.

As we have already mentioned, (4.23) and (4.24) imply that z_h too is defined for all $t>0$. By integration of (5.7) between zero and T ($T>0$ fixed), we then deduce that

$$\frac{1}{T}\int_0^T(\|y_h\|_h^2+\|z_h\|_h^2)\,dt\leqq\frac{1}{2\alpha_1\delta T}|y_h(0)|^2+\frac{c_9^2}{2\alpha_1\delta T}|f|^2. \tag{5.12}$$

This implies that

(5.13) For every $T>0$ fixed, the norms of y_h and z_h in $L^2(0,T;V_h)$ remain bounded as $h\to 0$.

By use of (4.5) this yields

(5.14) For every $T>0$ fixed, the norm of $\{S_1(h)\}z_h$ in $L^2(0,T;H)$ remains bounded as $h\to 0$.

Remark 5.1. We note that due to the term $1/T$ in front of the integral in the left-hand side of (5.12), this inequality yields slightly more than (5.13). More generally, we can integrate (5.7) between t and $t+T$ (t, $T>0$ fixed); using (5.9) and (5.10) we then find

$$\begin{aligned}\frac{1}{T}\int_0^{t+T}(\|y_h\|_h^2+\|z_h\|_h^2)\,ds&\leqq\frac{1}{2\alpha_1\delta T}|y_h(t)|^2+\frac{c_9^2}{2\alpha_1^2\delta}|f|^2\\&\leqq\frac{1}{2\alpha_1\delta T}|y_h(0)|^2\exp\left(-\frac{2\alpha_1\delta}{c_9^2}t\right)+\left(\frac{c_9^4}{4\alpha_1^3\delta^2T}+\frac{c_9^2}{2\alpha_1^2\delta}\right)|f|^2,\end{aligned} \tag{5.15}$$

$$\frac{1}{T}\int_t^{t+T}(\|y_h\|_h^2+\|z_h\|_h^2)\,ds\leqq\frac{1}{2\alpha_1\delta T}|u_0|^2+\left(\frac{c_9^4}{4\alpha_1^3\delta^2T}+\frac{c_9^2}{2\alpha_1^2\delta}\right)|f|^2.$$

This estimate independent of h is valid for all $t>0$, $T>0$. Of course (5.15) also implies an analogue of (5.14).

Remark 5.2. We recall that in the case where V_h is the discrete analogue of $H_0^1(\Omega)$ as in § 2, i.e., for the five-point discretization of the Laplace operator, then

$$\|y_h\|_h^2=\int_\Omega|\nabla_h y_h|^2\,dx,$$

$$\int_0^T\|y_h(t)\|_h^2\,dt=\int_0^T\int_\Omega|\nabla_h y_h(x,t)|^2\,dx\,dt.$$

Therefore (5.13) is an estimate in $L^2(\Omega\times(0,T))$, independent of h, for the discrete analogue of the gradient of y_h and z_h.

5.2. A priori estimates II. The following a priori estimates give some improvements that are not essential but are useful. We first restrict ourselves to the framework of § 2 (i.e., to Examples 1–3 of § 3). Since V_h is finite-dimensional, the norms of V_h are equivalent; thus (2.14) (or (4.12)) can be supplemented by another inequality:

$$\|u_h\|_h\leqq S_2(h)|u_h|\quad\forall u_h\in V_h, \tag{5.16}$$

where $S_2(h) \to \infty$ as $h \to 0$. In the situation of § 2 the computation of $S_2(h)$ is easy and we find

$$S_2(h) = \frac{2\sqrt{2}}{h}. \tag{5.17}$$

Now we set $\tilde{z}_h = z_h$ $(= z_h(t))$ in (4.23) and (4.8)-(4.11):

$$a_h(z_h, z_h) + (C_h z_h, z_h) = -a_h(y_h, z_h) - b_h(y_h, y_h, z_h) - (C_h y_h, z_h) + (f, z_h),$$

$$\alpha_1 \|z_h\|_h^2 \leqq c_7 \|y_h\|_h \|z_h\|_h + c_8 \|y_h\|_h |z_h| + c_6 |y_h| \|y_h\|_h \|z_h\|_h + |f||z_h|$$

$$\leqq (c_7 + c_8 S_1(h)^{-1} + c_6 |y_h|) \|y_h\|_h \|z_h\|_h + S_1(h)^{-1} |f| \|z_h\|_h \quad \text{(because of (4.5))}.$$

Again using (4.5) and (5.16), we find

$$|z_h| \leqq (\alpha_1 S_1(h))^{-1} (c_7 + c_8 S_1(h)^{-1} + c_6 |y_h|) \|y_h\|_h + \frac{1}{\alpha_1} (S_1(h))^{-3} |f|$$

$$\leqq \frac{1}{\alpha_1} \frac{S_2(h)}{S_1(h)} (c_7 + c_8 S_1(h)^{-1} + c_6 |y_h|) |y_h| + \frac{1}{\alpha_1} (S_1(h))^{-2} |f|.$$

Owing to the expression of $S_1(h)$ in (2.18) $(S_1(h) = h^{-1})$ and to the expression of $S_2(h)$ in (5.17), we have

$$\frac{S_2(h)}{S_1(h)} \leqq 2\sqrt{2}. \tag{5.18}$$

Finally, thanks to (5.11), we conclude that

(5.19) z_h remains in a bounded set of $L^\infty(\mathbb{R}_+; H)$ as $H \to 0$.

5.3. Passage to the limit. The passage to the limit $h \to 0$ relies on fairly standard methods. We will only sketch this step of the proof; the reader is referred to [T2] for the details in related situations.

Thanks to (5.11), (5.13), Remark 5.2, (5.14), and (5.19), there exists a subsequence (still denoted h) and there exists u:

$$u \in L^\infty(\mathbb{R}_+; H) \cap L^2(0, T; V) \quad \forall T > 0, \tag{5.20}$$

such that for $h \to 0$

$$\begin{aligned} &y_h \to u \text{ in } L^\infty(\mathbb{R}_+; H) \text{ weak-star,} \\ &\nabla_h y_h \to \nabla u \text{ in } L^2(\Omega \times (0, T)) \text{ weakly} \quad \forall T > 0, \end{aligned} \tag{5.21}$$

$$\begin{aligned} &z_h \to 0 \text{ in } L^\infty(\mathbb{R}_+; H) \text{ weak-star,} \\ &\nabla_h z_h \to 0 \text{ in } L^2(\Omega \times (0, T)) \text{ weakly} \quad \forall T > 0. \end{aligned} \tag{5.22}$$

We infer from (5.14) and (5.19) that

$$z_h \to 0 \text{ in } L^p(0, T; H) \text{ strongly} \quad \forall 1 \leqq p < \infty, \quad \forall T > 0. \tag{5.23}$$

Also, by using a compactness argument recalled below, we can improve (5.21) and show that

$$y_h \to u \text{ in } L^p(0, T; H) \text{ strongly} \quad \forall 1 \leqq p < \infty, \quad \forall T > 0 \quad \text{as } h \to 0. \tag{5.24}$$

Using the convergences (5.21)-(5.24) we can then pass to the limit in (4.20)-(4.22), following classical methods. At the limit we find that u is solution of (3.12) (or (3.1)) and (3.9). Since the solution to this problem is unique, we see by a contradiction argument that the convergences (5.21)-(5.24) hold for the whole sequence h.

Finally, for the strong convergence of the derivatives we consider the restriction operators r_h (see [C], [T2]) that map V into V_h and such that

$$\begin{aligned} &r_h u \to u && \text{in } L^2(0, T; H) \text{ strongly,} \\ &\nabla_h r_h u \to \nabla u && \text{in } L^2(0, T; H) \text{ strongly.} \end{aligned} \tag{5.25}$$

We then consider the following expression, where $u_h = y_h + z_h$:

$$X_h = \frac{1}{2}|y_h(T) - u(T)|^2 + \int_0^T \cdot \{a_h(u_h - r_h u, u_h - r_h u) + (C_h(u_h - r_h u, (C_h(u_h - r_h u), u_h - r_h u)u_h - r_h u)\}\, dt.$$

We have $X_h = X_h^1 + X_h^2 + X_h^3$:

$$X_h^1 = \frac{1}{2}|y_h(T)|^2 + \int_0^T \{a_h(u_h, u_h) + (C_h u_h, u_h)\}\, dt$$

$$= \frac{1}{2}|y_h(0)|^2 + \int_0^T (f, u_h)\, dt \quad \text{(by (5.4))};$$

it is clear that, for $h \to 0$,

$$X_h^1 \to X^1 = \frac{1}{2}|u_0|^2 + \int_0^T (f, u)\, dt;$$

$$X_h^2 = -(y_h(T), u(T)) - 2\int_0^T \{a_h(u_h, r_h u) + (C_h u_h, r_h u)\}\, dt;$$

as $h \to 0$, X_h^2 converges to

$$X^2 = -|u(T)|^2 - 2\int_0^T \{a(u, u) + (Cu, u)\}\, dt,$$

$$X^2 = -2X^1,$$

$$X_h^3 = \frac{1}{2}|u(T)|^2 + \int_0^T \{a_h(r_h u, r_h u) + (C_h r_h u, r_h u)\}\, dt.$$

Thanks to (5.25), when $h \to 0$, X_h^3 converges to $-\frac{1}{2}X^2 = X^1$.

Finally X_h converges to zero and thanks to (4.11) we conclude that

$$\int_0^T \|u_h - r_h u\|_h^2\, dt \to 0 \quad \text{as } h \to 0.$$

We denote by $\tilde{y}_h(t)$ and $\tilde{z}_h(t)$ the components of $(r_h u)(t)$ on V_{2h} and W_h. Using again (4.4) as in (4.17), we find

$$\int_0^T \|y_h - \tilde{y}_h\|_h^2\, dt \to 0 \quad \text{as } h \to 0,$$

$$\int_0^T \|z_h - \tilde{z}_h\|_h^2\, dt \to 0 \quad \text{as } h \to 0.$$

The conclusion follows then from the easy to prove fact that the incremental component $\tilde{z}_h$ of $r_h u$ converges to zero as $h \to 0$.

The proof of Theorem 5.1 is complete after we prove (5.24).

5.4. Compactness. The strong convergence result in (5.24) is shown by using a compactness theorem. The most appropriate here is that in [T3]. To apply this compactness result, we observe (see, for instance, [T2]) that the set

$$\{\varphi_h \in H,\ \|\varphi_h\|_h \leqq 1\} \tag{5.26}$$

is relatively compact in $H = L^2(\Omega)$. Furthermore we must estimate, for $r>0$ fixed,

$$\int_0^T |y_h(t+r)-y_h(t)|^2\,dt. \tag{5.27}$$

By integration of (4.20) we find[4]

$$\begin{aligned}(y_h(t+r)-y_h(t),\tilde{y}_h)+a_h\left(\int_t^{t+r} u_h(s)\,ds,\tilde{y}_h\right)+\left(C_h\int_t^{t+r} u_h(s)\,ds,\tilde{y}_h\right)\\ +\left(\int_t^{t+r} B_h(y_h(s))+B_h(y_h(s),z_h(s))+B_h(z_h(s),y_h(s))\,ds,\tilde{y}_h\right)\\ =\left(\int_t^{t+r} f(s)\,ds,\tilde{y}_h\right).\end{aligned}$$

We then set $\tilde{y}_h = y_h(t+r)-y_h(t)$ and integrate the resulting equation with respect to t. This gives

$$\int_0^T |y_h(t+r)-y_h(t)|^2\,dt \leqq \sum_{j=1}^{6} I_j$$

with

$$\begin{aligned}I_1&=\left|\int_0^T a_h\left(\int_t^{t+r} u_h(s)\,ds, y_h(t+r)-y_h(t)\right)dt\right|\\ &\leqq r^{1/2}c_7\left(\int_0^{T+r}\|u_h(s)\|_h^2\,ds\right)^{1/2}\left(\int_0^T \|y_h(t+r)-y_h(t)\|_h\,dt\right)\\ &\leqq cr^{1/2},\end{aligned}$$

where here and below c is independent of r and h;

$$\begin{aligned}I_2&=\left|\int_0^T\left(C_h\int_t^{t+r} u_h(s)\,ds, y_h(t+r)-y_h(t)\right)dt\right|\\ &\leqq c_8 r^{1/2}\left(\int_0^{T+r}\|u_h(s)\|_h^2\,ds\right)^{1/2}\left(\int_0^T |y_h(t+r)-y_h(t)|\,dt\right)\\ &\leqq cr^{1/2},\end{aligned}$$

$$\begin{aligned}I_3&=\left|\int_0^T\left(\int_t^{t+r} B_h(y_h(s))\,ds, y_h(t+r)-y_h(t)\right)dt\right|\\ &\leqq c_6\int_0^T\left(\int_t^{t+r}|y_h(s)|\,\|y_h(s)\|_h\,ds\right)\|y_h(t+r)-y_h(t)\|_h\,dt \quad \text{(from (4.9) and (5.5))}\\ &\leqq c_6 r^{1/2}|y_h|_{L^\infty(\mathbb{R}_+;H)}\left(\int_0^T\|y_h(s)\|_h^2\,ds\right)^{1/2}\cdot\left(\int_0^T\|y_h(t+r)-y_h(t)\|_h\,dt\right)\\ &\leqq cr^{1/2}.\end{aligned}$$

[4] $B_h(\varphi_h)=B_h(\varphi_h,\varphi_h)$, where $B_h(\cdot,\cdot)$ is the bilinear mapping from $V_h\times V_h$ into V_h defined by $(B_h(\varphi_h,\psi_h),\theta_h)=b_h(\varphi_h,\psi_h,\theta_h)$, for all $\varphi_h,\psi_h,\theta_h\in V_h$.

The two other terms involving B_h and denoted I_4, I_5 are estimated similarly. Finally,

$$I_6 = \left| \int_0^T \left(\int_t^{t+r} f(s)\, ds, y_h(t+r) - y_h(t) \right) dt \right|$$
$$\leqq r^{1/2} \left(\int_0^{T+r} |f(s)|^2\, ds \right)^{1/2} \left(\int_0^T |y_h(t+r) - y_h(t)|_h\, dt \right)$$
$$\leqq c r^{1/2}.$$

In conclusion (5.27) is bounded by $cr^{1/2}$ and tends to zero as $r \to 0$, uniformly with respect to h. As is shown in [T3] this, together with (5.26), ensures (5.24).

Remark 5.3. The extension of Theorem 5.1 to more general examples than those of § 3 necessitate the following hypotheses:

(i) $S_2(h)/S_1(h)$ is bounded by a constant independent of h (see (5.16) and (5.18)).

(ii) The consistency hypotheses specifying how a_h, b_h, C_h, and V_h approximate a, b, C, and V.

(iii) The definition of a restriction operator r_h mapping V into V_h and such that (5.25) holds.

For example, in the case of the Dirichlet problem in a bounded domain Ω of $\mathbb{R}^2$ with meshes h_1, h_2 different in both directions, as in Remark 2.1, then

$$S_1(h) = 2c_1 \{\max(h_1, h_2)\}^{-1}$$

(see Remark 2.1); an easy computation shows that

$$S_2(h) = \sqrt{2} \left(\frac{1}{h_1^2} + \frac{1}{h_2^2} \right)^{1/2}.$$

Hence (i) is satisfied if h_1/h_2 remains bounded from above and below.

6. Improved stability. One of the advantages produced by the IMG algorithm is an improved stability condition when discretizations in space and time are both performed and an explicit time-discretization scheme is used. Since this improvement is already transparent in the linear case we will restrict ourselves to the linear case and replace b, C, b_h, C_h by 0. Without any loss of generality we can also set $f = 0$; finally for simplicity we take

$$\begin{aligned} &a(u, v) = \nu((u, v)), \qquad \nu > 0, \\ &a_h(u_h, v_h) = \nu((u_h, v_h))_h. \end{aligned} \tag{6.1}$$

After discretization in time by an explicit scheme the IMG algorithm (4.20)-(4.22) now leads to the construction of two sequences of elements of V_h:

$$\begin{aligned} &y_h^n \in V_{2h}, && n \geqq 0, \\ &z_h^n \in W_h, && n \geqq 0, \\ &u_h^n = y_h^n + z_h^n \in V_h, && n \geqq 0. \end{aligned}$$

These elements are defined recursively. We first define y_h^0 by setting as in (4.22):

$$(y_h^0, \tilde{y}_h) = (u_0, \tilde{y}_h) \quad \forall \tilde{y}_h \in V_{2h}. \tag{6.2}$$

When y_h^n is known, $n \geqq 0$, we define z_h^n and y_h^{n+1} as follows:

$$\frac{1}{k}(y_h^{n+1} - y_h^n, \tilde{y}_h) + a_h(y_h^n + z_h^n, \tilde{y}_h) = 0 \quad \forall \tilde{y}_h \in V_{2h}, \tag{6.3}$$

$$a_h(y_h^n + z_h^n, \tilde{z}_h) = 0 \quad \forall \tilde{z}_h \in W_h. \tag{6.4}$$

Here $T>0$ is fixed, $M\in\mathbb{N}$ is given and $k=T/M$ is the time discretization mesh. We rewrite (6.4) as

$$a_h(z_h^n,\tilde{z}_h)=-a_h(y_h^n,\tilde{z}_h)\quad\forall\tilde{z}_h\in W_h \tag{6.5}$$

and we infer easily the existence and uniqueness of $z_h^n\in W_h$ satisfying (4.3)-(4.4) from the Lax-Milgram Theorem. Once z_h^n (and y_h^n) are known, (6.3) readily determines $y_h^{n+1}\in V_{2h}$. The construction can then continue.

The stability condition arises when we try to determine a priori estimates on the sequences y_h^n, z_h^n. For the a priori estimates we replace $\tilde{y}_h$ by y_h^n in (6.3) and $\tilde{z}_h$ by z_h^n in (6.4). We have

$$2(y_h^{n+1}-y_h^n,y_h^n)=|y_h^{n+1}|^2-|y_h^n|^2-|y_h^{n+1}-y_h^n|^2.$$

Thus,

$$|y_h^{n+1}|^2-|y_h^n|^2-|y_h^{n+1}-y_h^n|^2+2k\nu((u_h^n,y_h^n))_h=0, \tag{6.6}$$

$$\nu((u_h^n,z_h^n))_h=0, \tag{6.7}$$

and by adding (6.6) to $2k$ times (6.7) we find

$$|y_h^{n+1}|^2-|y_h^n|^2+2k\nu\|u_h^n\|_h^2=|y_h^{n+1}-y_h^n|^2. \tag{6.8}$$

To estimate the right-hand side of (6.8) we replace $\tilde{y}_h$ by $k(y_n^{n+1}-y_h^n)$ in (6.3) and we obtain

$$\begin{aligned}|y_h^{n+1}-y_h^n|^2&=-k\nu((u_h^n,y_h^{n+1}-y_h^n))_h\\&\leqq k\nu\|u_h^n\|_h\|y_h^{n+1}-y_h^n\|_h.\end{aligned}$$

Now we can use *the analogue of* (5.16) *in* V_{2h}:

$$\|\varphi_h\|_h\leqq S_2(2h)|\varphi_h|\quad\forall\varphi_h\in V_{2h},$$

and this leads to

$$\begin{aligned}&|y_h^{n+1}-y_h^n|^2\leqq k\nu S_2(2h)\|u_h^n\|_h|y_h^{n+1}-y_h^n|,\\&|y_h^{n+1}-y_h^n|^2\leqq(k\nu S_2(2h))^2\|u_h^n\|_h^2.\end{aligned} \tag{6.9}$$

We compare (6.8) and (6.9) and write:

$$|y_h^{n+1}|^2-|y_h^n|^2+2k\nu(1-\tfrac{1}{2}k\nu(S_2(2h))^2)\|u_h^n\|_h^2\leqq 0\quad\forall n\geqq 0. \tag{6.10}$$

We can deduce the desired a priori estimates from (7.10) provided k, h satisfy the *stability condition*

$$\tfrac{1}{2}k\nu(S_2(2h))^2<1, \tag{6.11}$$

or more precisely

$$\tfrac{1}{2}k\nu(S_2(2h))^2\leqq 1-\theta, \tag{6.12}$$

for some θ, $0<\theta<1$. If we replace $S_2(2h)$ by its expression from (5.17), (6.11) becomes

$$\frac{k\nu}{h^2}<1. \tag{6.13}$$

If instead of (6.2)-(6.4) we consider the traditional explicit finite-difference scheme in V_h, we obtain the stability condition

$$\tfrac{1}{2}k\nu(S_2(h))^2<1,$$

i.e.,

$$\frac{k\nu}{h^2} < \frac{1}{4}.$$

In conclusion, the IMG *algorithm allows a time-step four times larger than the usual explicit finite-difference scheme* and yields a similar result with essentailly four times fewer computations. Of course the IMG algorithm as depicted in (6.3), (6.4) is not fully explicit since the determination of z_h^n from (6.5) is implicit. However, we must remember that the z_h^n are small increments and therefore their determination can be made in a very rudimentary way.

A more complete analysis of the time-discretized version of the IMG algorithm in the context of nonlinear equations will be performed elsewhere, but we thought that it would be useful to indicate here another partial justification of the IMG algorithm.

THE BIFURCATION OF HOMOCLINIC AND PERIODIC ORBITS FROM TWO HETEROCLINIC ORBITS*

S.-N. CHOW†, B. DENG‡, AND D. TERMAN§

Abstract. Conditions are found for a unique homoclinic or periodic orbit to bifurcate from a heteroclinic loop for autonomous ordinary differential equations. This leads to a codimension 2 unfolding of a heteroclinic loop. This approach, based on an idea developed by Šil'nikov, reduces the problem to the study of bifurcation equations. The result is applied to various types of traveling wave solutions of the FitzHugh-Nagumo equations with a cubic nonlinear term.

Key words. heteroclinic orbit, homoclinic orbit, periodic orbit, Šil'nikov solution, exponential expansion, strong λ-lemma, Lyapunov-Schmidt reduction, bifurcation equation

1. Introduction. This paper is concerned with the creation of homoclinic and periodic orbits from a pair of heteroclinic orbits of differential equations of the form

$$\dot{x} = f(x, \alpha), \quad x \in \mathbb{R}^N, \quad \alpha \in \mathbb{R}^2. \tag{1.1}$$

We assume that $a, b \in \mathbb{R}^N$ are hyperbolic equilibria of (1.1) for all α. By a heteroclinic solution from a to b we mean a solution $\Gamma(t)$ of (1.1) that satisfies

$$\lim_{t \to -\infty} \Gamma(t) = a \quad \text{and} \quad \lim_{t \to +\infty} \Gamma(t) = b.$$

A homoclinic solution to a is a solution of (1.1) that satisfies

$$\lim_{|t| \to \infty} \Gamma(t) = a.$$

In this paper we demonstrate that a bifurcation of homoclinic solutions must take place at a value α_0 for which there exists a pair of heteroclinic solutions from a to b and from b to a, if certain generic conditions are satisfied. Moreover, if we assume that in a parameter space there are two curves c_{ab} and c_{ba} that cross transversely at α_0 and correspond to $a \to b$ and $b \to a$ heteroclinic solutions, respectively, then we show that there are two curves c_{aa} and c_{bb} in parameter space emanating from α_0 that correspond to homoclinic solutions. The curve c_{aa} will be tangent to c_{ab} at α_0, and c_{bb} will be tangent to c_{ba} at α_0. We also consider the existence of periodic solutions of (1.1). We prove that the curves c_{aa} and c_{bb} form the boundary of a sector Λ; a periodic solution of (1.1) exists for precisely those values of α in Λ.

The motivation of this work comes from the study of reaction-diffusion equations. These are equations of the form

$$U_t = DU_{xx} + F(U, \lambda) \tag{1.2}$$

where $U \in \mathbb{R}^N$, D is a nonnegative diagonal matrix, and $\lambda \in \mathbb{R}$ is a parameter. A traveling wave solution of (1.2) is a solution of the form $U(x, t) = V(z)$, $z = x + \theta t$. That is, it corresponds to solutions that appear to be traveling with constant shape and velocity. We are interested in traveling wave solutions of (1.2) that connect two rest points of (1.2). Assume that A, $B \in \mathbb{R}^N$ satisfies $F(A, \lambda) = F(B, \lambda) = \mathcal{O}$ for all λ. Here, $\mathcal{O}$ is the origin in $\mathbb{R}^N$. We consider traveling wave solutions of (1.2) that satisfy

$$\lim_{z \to -\infty} V(z) = A \quad \text{and} \quad \lim_{z \to +\infty} V(z) = B.$$

Note that a traveling wave solution satisfies the following system of ordinary differential equations:

$$DV'' - \theta V' + F(V, \lambda) = 0.$$

If we let $V' = W$, then this is equivalent to the first-order system

$$V' = W, \qquad DW' = \theta W - F(V, \lambda) \tag{1.3}$$

together with the boundary conditions

$$\lim_{z \to -\infty} (V(z), W(z)) = (A, \mathcal{O}) \quad \text{and} \quad \lim_{z \to +\infty} (V(z), W(z)) = (B, \mathcal{O}).$$

Hence, the problem of proving the existence of a traveling wave solution of (1.2) reduces to finding a heteroclinic solution of (1.3). Note that the speed θ is a parameter in (1.3). Hence, (1.3) depends on two parameters and is a special case of (1.1).

Many systems possess a variety of traveling wave solutions. A given system may have, for a given value of parameters, traveling fronts, pulses, multiple pulses, and periodic solutions. If a given system does have many traveling wave solutions, then the existence of some of them (the traveling fronts, perhaps) may be easy to prove, while the existence of others (pulses, perhaps) may be more difficult to prove. Our results demonstrate that the more complicated waves can arise as bifurcations of the simpler waves. In § 6 we present an example to illustrate this point.

The proofs of our results are based on an idea of Šil'nikov [8], [11], [12]. It begins with a Poincaré return map on certain proper cross sections of the heteroclinic orbits. With Šil'nikov's change of variables for these Poincaré maps, the problem reduces to a two-parameter family of transcendental equations. The uniqueness of homoclinic and periodic orbits follows from an Implicit Function Theorem argument. The existence of homoclinic and periodic orbits is derived from certain bifurcation equations that arise from the transcendental equations.

A precise statement of our results is given in § 2. In § 3 we define Poincaré maps on certain proper cross sections and explain the idea of Šil'nikov's change of variables for these Poincaré maps. In § 4 we prove the uniqueness of the homoclinic and periodic orbits. In § 5 we derive the bifurcation equations for the existence of the homoclinic and periodic orbits, and then prove the main results. In § 6 we show how our results apply to the FitzHugh-Nagumo equations.

We point out that we can weaken considerably the generic hypothesis of the results presented in this paper and still conclude that there exists a bifurcation of homoclinic orbits. In [3] we prove such a result. This result is described at the end of § 2. Of course, under the weaker hypotheses we cannot expect to obtain the detailed description of the nature of the bifurcating orbits obtained in this paper.

2. Statement of the main result. In this section we will first introduce the main hypotheses (H1)-(H8), and then state our main theorem. We also state our main theorem in [3] for comparison.

Consider a system of ordinary differential equations with parameter α

$$\dot{z} = F(z, \alpha) \tag{2.1}$$

where $z = (z^{(1)}, \cdots, z^{(d)}) \in \mathbb{R}^d$ and $\alpha = (\alpha_1, \alpha_2) \in \mathbb{R}^2$. We assume that (2.1) has two distinct hyperbolic equilibria a_1 and a_2 for all α. We also assume that when $\alpha = (0, 0)$, (2.1) has a heteroclinic orbit Γ_{12} from a_1 to a_2 and another heteroclinic orbit Γ_{21} from a_2 to a_1.

Let $C_i = C_i(\alpha) = DF(a_i, \alpha)$, $i = 1, 2$, where D is the differentiation operator with respect to z. Let $\sigma_i = \sigma_i(\alpha)$ be the spectrum of C_i, i.e.,

$$\sigma_i(\alpha) = \{\lambda \in \mathbb{C} \mid \lambda \text{ is an eigenvalue of } C_i\}. \tag{2.2}$$

Let $\sigma_i^+ = \sigma_i^+(\alpha)$ and $\sigma_i^- = \sigma_i^-(\alpha)$ be defined as follows:

$$\sigma_i^+(\alpha) = \sigma_i \cap \{\lambda \in \mathbb{C} \mid \operatorname{Re} \lambda > 0\} \tag{2.3}$$

$$\sigma_i^-(\alpha) = \sigma_i \cap \{\lambda \in \mathbb{C} \mid \operatorname{Re} \lambda < 0\}. \tag{2.4}$$

It is clear from the hyperbolicity of equilibria a_i, $i = 1, 2$ and the existence of heteroclinic orbits Γ_{12} and Γ_{21} that for $\alpha = (0, 0)$,

$$\sigma_i^+ \neq \varnothing, \qquad \sigma_i^- \neq \varnothing, \tag{2.5}$$

and

$$\sigma_i = \sigma_i^+ \cup \sigma_i^-. \tag{2.6}$$

Let $\mu_i = \mu_i(\alpha)$ with

$$\mu_i(\alpha) = \min_{\lambda \in \sigma_i^+} \operatorname{Re} \lambda. \tag{2.7}$$

Then (2.4) and (2.5) imply

$$\mu_i > 0. \tag{2.8}$$

First, we consider two conditions on the eigenvalues that are not required in [3].

(H1) μ_i is a simple real eigenvalue for C_i for $i = 1, 2$ and

$$\mu_i < \min_{\lambda \in \sigma_i^+ - \{\mu_i\}} \operatorname{Re} \lambda, \qquad i = 1, 2, \tag{2.9}$$

(H2) $$\mu_i < -\max_{\lambda \in \sigma_i^-} \operatorname{Re} \lambda, \qquad i = 1, 2.$$

For many problems of homoclinic bifurcations, hypotheses (H1) and (H2) play a crucial role in determining the bifurcation structure. For example, it is well known that if the first eigenvalue of σ^+ is a pair of complex eigenvalues rather than a simple real one as in (H1), then the system has an invariant set carrying the Bernoulli shift (see Šil'nikov [18]). Also, if the largest eigenvalue of σ^- is real and simple and if its absolute value is equal to the first eigenvalue of σ^+ (this will violate (H2)), then in any small neighborhood of the homoclinic orbit the periodic orbits are no longer unique for small $\alpha = 0$. Furthermore, double-periodic and double-homoclinic orbits may occur in the latter case (see Yanagida [16] and Chow, Deng, and Fiedler [17]). However, as we will show, if (H1) and (H2) are satisfied in addition to other hypotheses, then the bifurcations of homoclinic and periodic orbits from the heteroclinic loop $\Gamma_{12} \cup \Gamma_{21}$ are unique.

Let $m_i > 0$ and $n_i > 0$ be the dimensions of the stable and unstable manifolds of a_i, respectively. As in [3], we assume the following hypothesis.

(H3) $m_1 = m_2 = m$ and $n_1 = n_2 = n$.

Because of (H3) it is well known (see Hale and Lin [6] and Palmer [9]) that the continuation of heteroclinic orbits $\Gamma_{12}(\Gamma_{21})$ occurs generically in a codimension-1 submanifold in the space of vector fields. This implies that (H4)-(H6) are all generic.

(H4) Γ_{12} and Γ_{21} are in general position:

$$\text{codim span}\{T_pW_1^u, T_pW_2^s\} = 1, \qquad p \in \Gamma_{12},$$

$$\text{codim span}\{T_pW_2^u, T_pW_1^s\} = 1, \qquad p \in \Gamma_{21},$$

where W_i^u and W_i^s denote the stable and unstable manifolds of a_i for $i = 1, 2$ at $\alpha = (0, 0)$, and T_pW denotes the tangent space of a given manifold W at basepoint p.

We also assume that there are two smooth curves intersecting transversally in the parameter spaces that correspond to the smooth branches of heteroclinic orbits from a_1 to a_2 and from a_2 to a_1, respectively. Thus, up to a change of coordinates in parameter space, we assume the following hypothesis.

(H5) Equation (2.1) has a smooth branch of heteroclinic orbits Γ_{α_1} from a_1 to a_2 with $(\alpha_1, 0) \in \mathbb{R}^2$ and $\Gamma_0 = \Gamma_{12}$. Equation (2.1) has a smooth branch of heteroclinic orbit Γ_{α_2} from a_2 to a_1 with $(0, \alpha_2) \in \mathbb{R}^2$ and $\Gamma_0 = \Gamma_{21}$.

The next hypothesis (H6) is related to the transverse crossing of the stable and unstable manifolds as parameters vary. To be more precise, let $W_i^s(\alpha)$ and $W_i^u(\alpha)$ denote the stable and unstable manifolds of a_i, $i = 1, 2$ for (2.1) at α. Clearly, $W_i^s(0, 0) = W_i^s$ and $W_i^u(0, 0) = W_i^u$, where W_i^s and W_i^u are as in (H4). Let Σ_1 be an arbitrary and small $(d-1)$-dimensional cross section such that Σ_1 intersects Γ_{12} at exactly one point, and Σ_1 is transverse to the flow of (2.1) for $\alpha = (0, 0)$. Let $M_1^u = M_1^u(\alpha)$ and $M_2^s = M_2^s(\alpha)$ be connected components of $W_1^u(\alpha) \cap \Sigma_1$ and $W_2^s(\alpha) \cap \Sigma_1$, respectively, satisfying that M_1^u and M_2^s vary continuously with α near $\alpha = 0$ and

$$M_1^u(0) \cap M_2^s(0) = \Gamma_{12} \cap \Sigma_1. \tag{2.10}$$

Let $d_1 = d_1(\alpha_1, \alpha_2)$ be the distance between M_1^u and M_2^s defined by

$$d_1(\alpha_1, \alpha_2) = \inf |z_1 - z_2| \qquad \text{with } z_1 \in M_1^u \quad \text{and} \quad z_2 \in M_2^s. \tag{2.11}$$

Similarly, we can choose a proper cross section Σ_2 transverse to Γ_{21} and their distance $d_2 = d_2(\alpha_1, \alpha_2)$. It is easy to see that hypothesis (H5) implies

$$d_1(\alpha_1, 0) = 0. \tag{2.12}$$

Similarly, we have

$$d_2(0, \alpha_2) = 0. \tag{2.13}$$

We assume hypothesis (H6).

(H6) W_1^u and W_2^s, and W_2^u and W_1^s intersect transversally in the following sense:

$$\lim_{\alpha_2 \to 0} \frac{d_1(0, \alpha_2)}{|\alpha_2|} \neq 0 \quad \text{and} \quad \lim_{\alpha_1 \to 0} \frac{d_2(\alpha_1, 0)}{|\alpha_1|} \neq 0.$$

Note that (H6) implies $d_1(0, \alpha_2)$ has the same order as $|\alpha_2|$. This is certainly a generic assumption. The conditions here appear weaker than the usual conditions on the transverse crossing of stable and unstable manifolds. In § 5 we will see that together with the other hypotheses, (H6) does imply the transverse crossing in the usual sense. Indeed, the Melnikov functions in $\mathbb{R}^2$ are precisely the distances d_1 and d_2. Also, from (2.11) we know that d_1 depends on the choice of cross section Σ_1. However, it is not difficult to see that because the map induced by the flow of (2.1) from one cross section to another is a diffeomorphism, assumption (H6) is actually independent of the choice of cross sections.

It is clear that hypotheses (H4)-(H6) are concerned with the global structure of the stable and unstable manifolds. The following two hypotheses, (H7) and (H8), however, are concerned with both the global and local structure of the unstable manifolds near the equilibria. It is shown in Deng [5] that they are generic assumptions.

(H7) Γ_{12} is tangent to an eigenvector of $C_1(0)$ for the eigenvalue $\mu_1(0)$ as $t \to -\infty$; Γ_{21} is tangent to an eigenvector of $C_2(0)$ for the eigenvalue $\mu_2(0)$ as $t \to -\infty$.

Hypothesis (H8) is concerned with the inclination behavior of the global unstable manifold of one equilibrium near the other equilibrium. This has to do with the local strong unstable manifold W_i^{uu} of a_i that is $(n-1)$-dimensional and is tangent at a_i to the linear subspace spanned by the eigenvectors of C_i corresponding to the eigenvalues $\lambda \in \sigma_i^+ - \{\mu_i\}$. To be more precise, let (x, y) be local coordinates of points in a sufficiently small neighborhood U_i of a_i such that $x = 0$ and $y = 0$ correspond to the subspaces spanned by eigenvectors of $\lambda \in \sigma_i^+$ and $\lambda \in \sigma_i^-$, respectively. In particular, choose the $y^{(1)}$-axis as the direction of an eigenvector for the principal eigenvalue μ_i of C_i. Then W_i^{uu} can be expressed as the graph of a smooth function h^{uu} of the variable $\hat{y} = (y^{(2)}, \cdots, y^{(n)})$ that parameterizes the strong unstable eigenvector subspace of eigenvalues $\lambda \in \sigma_i^+ - \{\mu_i\}$.

DEFINITION. An $(n-1)$-dimensional smooth manifold D^{n-1} having nonempty intersection with the stable manifold W_i^s satisfies the *strong inclination property* if for every $\varepsilon > 0$ there is a $T(\varepsilon) > 0$ such that for every $t \geqq T(\varepsilon)$ the connected component of the image D_t^{n-1} in U_i under the time t mapping of the solutions with initial data from D^{n-1} can be expressed as the graph of a smooth function h_t of the same argument $\hat{y}$ as h^{uu} satisfying $\|h_t - h^{uu}\|_{C^1} < \varepsilon$, where $\|\cdot\|_{C^1}$ denotes the usual C^1 norm.

It is shown in Deng [5] that this strong inclination property holds true for a generic family of such D^{n-1}. The corresponding result is referred to as the strong λ-lemma for D^{n-1} in [5]. Now, let $M_1^u(0)$ and $M_2^u(0)$ be as in (2.10) and (H6). They are $(n-1)$-dimensional and intersect $W_2^s(0)$ and $W_1^s(0)$ at a single point, respectively. We assume hypothesis (H8).

(H8) $M_1^u(0)$ and $M_2^u(0)$ satisfy the strong inclination property (cf. Fig. 2.1).

Note that by Deng [5], (H7) is equivalent to $\Gamma_{12} \cap W_1^{uu} = \varnothing$ and $\Gamma_{21} \cap W_2^{uu} = \varnothing$. Also, due to the group property of the flow, it is not difficult to see that (H8) is independent of the choice of the cross section Σ_1 and Σ_2 in the definitions of M_1^u and M_2^u. Together with (H4), hypothesis (H8) will enable us to choose a one-dimensional subspace complementary to the $(d-2)$-dimensional subspace of span $\{T_p W_2^s(0), T_p M_1^u(0)\}$ in $T_p \Sigma_1 = \mathbb{R}^{d-1}$ at $p = W_2^s(0) \cap M_1^u(0) = \Gamma_{12} \cap \Sigma_1$. We will see that if Σ_1 is sufficiently close to the equilibrium a_2, then this complementary subspace can be chosen approximately to be the eigenvector subspace of the principal positive eigenvalue $\mu_2(0)$ for $C_2(0)$ provided (H8) is satisfied. All this will be done in §§ 4 and 5. As shown by the following main result, a system satisfying the eigenvalue conditions

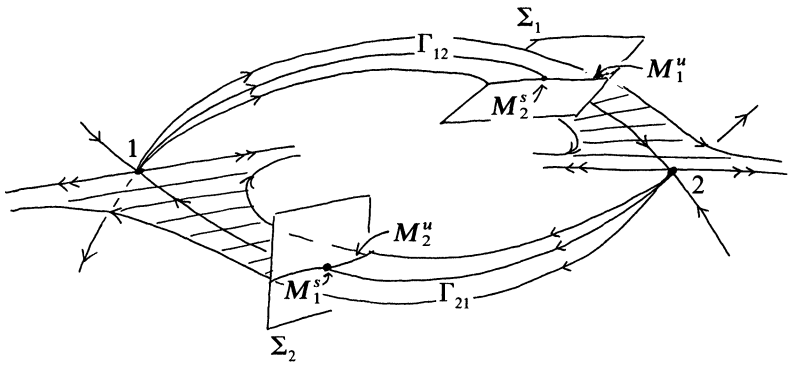

FIG. 2.1

(H1)-(H3) as well as the strong inclination properties (H7) and (H8) is analogous to the classical system considered by Šil'nikov in [12] which has a homoclinic orbit and satisfies conditions (H1), (H2), (H7), and (H8).

THEOREM 2.1. *Suppose F is C^k with $k \geqq 4$ and* (H1)-(H8) *are satisfied. Then there exists a small neighborhood $N \subset \mathbb{R}^d$ of $\Gamma_{12} \cup \Gamma_{21} \cup \{a_1, a_2\}$, a small neighborhood $V \subset R^2$ of $\alpha = (0, 0)$, and a nonsingular change of parameters $\varepsilon = c(\alpha)$, $\varepsilon \in E = c(V)$, such that the following holds true.*

(a) *There exist smooth functions $\varepsilon_1 = k_1(\varepsilon_2)$ defined for $\varepsilon_2 > 0$, $(\varepsilon_1, \varepsilon_2) \in E$, and $\varepsilon_2 = k_2(\varepsilon_1)$ defined for $\varepsilon_1 > 0$, $(\varepsilon_1, \varepsilon_2) \in E$ such that if*

$$\mathscr{C}_1 = \{\varepsilon \in E \mid \varepsilon_1 = k_1(\varepsilon_2),\ \varepsilon_2 > 0\}$$

and

$$\mathscr{C}_2 = \{\varepsilon \in E \mid \varepsilon_2 = k_2(\varepsilon_1),\ \varepsilon_1 > 0\},$$

then, for $i = 1, 2$, (2.1) *has a homoclinic orbit $\gamma \subset N$ to a_i with parameter α if and only if $\varepsilon = c(\alpha) \in \mathscr{C}_i$. Moreover, for each α with $c(\alpha) \in \mathscr{C}_i$, γ is unique in N. Furthermore,*

$$(\varepsilon_1, 0) = c((\alpha_1, 0)) \quad \text{and} \quad (0, \varepsilon_2) = c((0, \alpha_2)), \tag{2.14}$$

$$\lim_{\varepsilon_2 \to 0^+} k_1(\varepsilon_2) = \lim_{\varepsilon_1 \to 0^+} k_2(\varepsilon_1) = 0, \tag{2.15}$$

$$\lim_{\varepsilon_2 \to 0^+} \frac{dk_1}{d\varepsilon_2}(\varepsilon_2) = \lim_{\varepsilon_1 \to 0^+} \frac{dk_2}{d\varepsilon_1}(\varepsilon_1) = 0. \tag{2.16}$$

(b) *Let*

$$\Lambda = \{\varepsilon = (\varepsilon_1, \varepsilon_2) \in E \mid \text{either } \varepsilon_1 > 0 \text{ or } \varepsilon_2 > 0, \tag{2.17}$$
$$\varepsilon_1 > k_1(\varepsilon_2) \text{ if } \varepsilon_2 > 0, \text{ and } \varepsilon_2 > k_2(\varepsilon_1) \text{ if } \varepsilon_1 > 0\}.$$

Then, (2.1) *has a periodic orbit $\gamma \subset N$ at parameter α if and only if $c(\alpha) \in \Lambda$. Finally, for each parameter α with $c(\alpha) \in \Lambda$, γ is the unique periodic orbit in N.*

Figure 2.2 is the bifurcation diagram for Theorem 2.1.

As we mentioned in the Introduction, we can weaken the hypotheses of Theorem 2.1 and still prove the existence of bifurcating homoclinic orbits. In [3] we prove the following result.

THEOREM 2.2. *Suppose F is C^2 and hypotheses* (H3)-(H6) *are satisfied. Then there is a continuous map $\kappa : (0, 1] \to \mathbb{R}^2$ such that for each $s \in (0, 1]$,* (2.1) *has a homoclinic orbit to a_1 for $\alpha = \kappa(s)$. If $s_1 \neq s_2$, then the corresponding connections are not the same. Moreover, $\lim_{s \to 0^+} \kappa(s) = (0, 0)$. Finally, the same conclusion applies to a_2.*

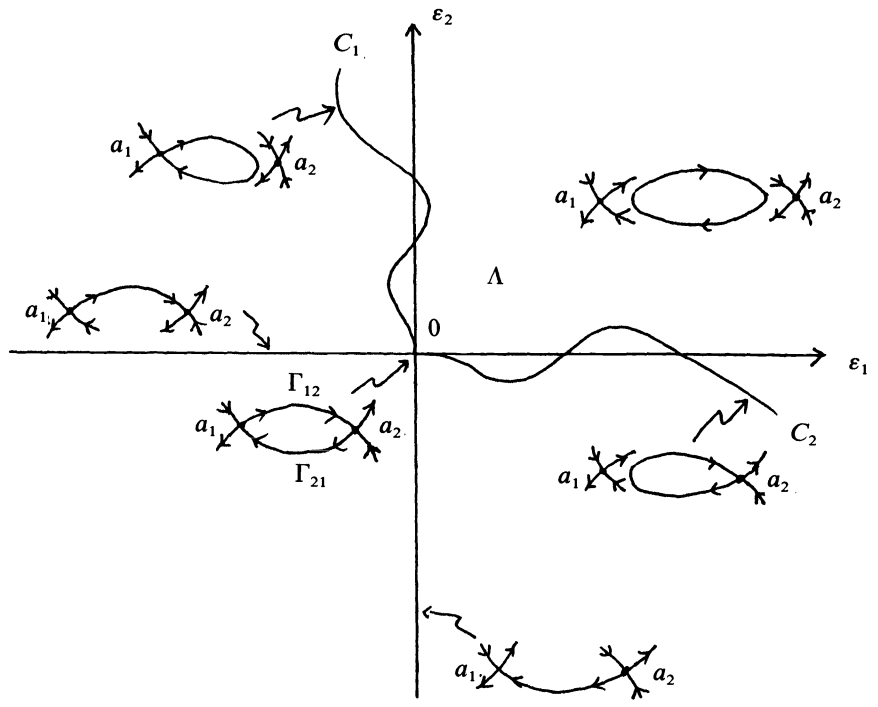

FIG. 2.2

Remark 2.3. The eigenvalue conditions (H1) and (H2) and the strong inclination properties (H7) and (H8) are required for the implicit function principle argument in this paper, which results in the uniqueness of the homoclinic and periodic orbits bifurcating from the loop $\Gamma_{12} \cup \Gamma_{21}$. These conditions are not required in Theorem 2.2. Theorem 2.2 asserts the bifurcation of homoclinic orbits must take place even though uniqueness is not claimed. The importance of Theorem 2.2 as well as its topological approach presented in [3] is to help us understand better the structure of vector fields near a codimension-2 bifurcation point at which a heteroclinic loop $\Gamma_{12} \cup \Gamma_{21}$ takes place. It tells us that this bifurcation point is precisely located at the intersection of the closures of two codimension-1 bifurcation branches on which the homoclinic bifurcations take place. Similar topological structures near a vector field that represents higher than codimension-2 bifurcation points at which a heteroclinic loop takes place should also be expected. As suggested by Theorem 2.2, this has to do with a further relaxation on the condition of equal dimensionality $\dim W_1^s = \dim W_2^s = m$ and $\dim W_1^u = \dim W_2^u = n$ required by both Theorems 2.1 and 2.2. Also note that the vector fields in Theorem 2.2 are assumed to be only C^2.

3. Poincaré maps and Šil'nikov's change of variables. A natural approach to this bifurcation problem is through the study of Poincaré maps for the loop $\Gamma_{12} \cup \Gamma_{21} \cup \{a_1, a_2\}$. To do this we need a result by Deng [5].

THEOREM 3.1. *Suppose that the system of ordinary differential equations with parameter* α,

$$\begin{aligned} \dot{x} &= A(\alpha)x + f(x, y, \alpha), \\ \dot{y} &= B(\alpha)y + g(x, y, \alpha), \end{aligned} \qquad x \in \mathbb{R}^m, \quad y \in \mathbb{R}^n, \quad \alpha \in \mathbb{R}^2 \tag{3.1}$$

satisfies the following hypotheses:

(H9) *The matrix functions* $A = A(\alpha) \in \mathbb{R}^{m\times n}$, $B = B(\alpha) \in \mathbb{R}^{n\times n}$ *and the vector functions* $f = f(x, y, \alpha)$, $g = g(x, y, \alpha)$ *are* C^k *with* $k \geqq 3$,

(H10) $f(0, y, \alpha) = 0, \qquad g(x, 0, \alpha) = 0,$

$Df(0, 0, \alpha) = 0, \qquad Dg(0, 0, \alpha) = 0$

where D *is the differentiation operator with respect to* $z = (x, y)$,

(H11) B *has the following form*:

$$B = \begin{bmatrix} \mu(\alpha) & 0 \\ 0 & B_1(\alpha) \end{bmatrix} \tag{3.2}$$

and satisfies

$$0 < \mu(\alpha) < \min_{\lambda \in \sigma(B_1(\alpha)) - \{\mu(\alpha)\}} \operatorname{Re} \lambda, \tag{3.3}$$

$$0 < \mu(\alpha) < -\min_{\lambda \in \sigma(A(\alpha))} \operatorname{Re} \lambda. \tag{3.4}$$

Then there exist sufficiently small constants $\delta_0 > 0$ *and* α_0 *such that for every* $s \geqq 0$, $|x_0| \leqq \delta_0$, $|y_1| \leqq \delta_0$, *and* $|\alpha| \leqq \alpha_0$, (3.1) *has a unique solution* $x(t) = x(t; s, x_0, y_1, \alpha)$, $y(t) = y(t; s, x_0, y_1, \alpha)$ *satisfying*

$$x(0) = x_0, \qquad y(s) = y_1, \tag{3.5}$$

$$|x(t)| \leqq 2\delta_0, \quad |y(t)| \leqq 2\delta_0, \quad 0 \leqq t \leqq t_0 \tag{3.6}$$

where $t_0 > s$ *is some constant depending on* δ, s, x_0, *and* y_1. *Furthermore, as functions of* t, s, x_0, y_1 *and* α *the solution* $(x, y)(t; s, x_0, y_1, \alpha)$ *is* C^k *and* C^{k+1} *in* t. *Also, there exist constants* $K_0 \geqq 1$ *and* $\bar{\nu} > 0$, *which depend only on* $\mu(\alpha)$ *and* $\lambda(\alpha)$, *and a* C^{k-2} *function* $\varphi = \varphi(x_0, y_1, \alpha) \in \mathbb{R}^n$ *such that*

$$\sum_{j=0}^{k-1} |D^j x(s; s, x_0, y_1, \alpha)| \leqq K_0 e^{-\lambda(\alpha)s}, \tag{3.7}$$

$$\sum_{j=0}^{k-2} |D^j (e^{\mu(\alpha)s} y(0; s, x_0, y_1, \alpha) - \varphi(x_0, y_1, \alpha))| \leqq K_0 e^{-\nu s} \tag{3.8}$$

where D^j *is the differentiation operator of order* j *in* (s, x_0, y_1, α). *Moreover, the function* φ *satisfies*

$$D\varphi(0, 0, \alpha) = \begin{bmatrix} 0 & \cdots & 0 & 1 & 0 & \cdots & 0 \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 \end{bmatrix}_{n\times d} \tag{3.9}$$

where D *is the first-order differentiation operator in* (x_0, y_1). *Finally, the local strong unstable manifold* W^{uu}_{loc} *can be expressed as follows*:

$$\{(0, y) \mid \varphi^{(1)}(0, y, \alpha) = 0, |y| \leqq \delta_0\} = W^{uu}_{\text{loc}} \tag{3.10}$$

where $\varphi = (\varphi^{(1)}, \cdots, \varphi^{(n)})$.

Remark 3.2. (a) Note that if $s = 0$, then $x(t) = x(t; 0, x_0, y_1, \alpha)$, $y(t) = y(t; 0, x_0, y_1, \alpha)$ is the unique solution of the initial value problem $x(0) = x_0$, $y(0) = y_0$ with $y_0 = y_1$ for (3.1). This kind of boundary value problem was first introduced by Šil'nikov [11] for the study of the structure of flows near a homoclinic orbit.

(b) We will not need the exponential estimates (3.7) and (3.8) in Theorem 3.1 in this section. However, they are useful in later sections. In particular, the estimate (3.8) is extremely important and is equivalent to writing $y(0; s, x_0, y_1, \alpha) = \varphi(x_0, y_1, \alpha)e^{-\mu(\alpha)s} + R(s, x_0, y_1, \alpha)$ with a C^{k-2} function R all of whose derivatives up to order $k-2$ are exponentially bounded by $K_0 e^{-(\mu(\alpha)+\bar{\nu})s}$. This decomposition of $y(0)$ is referred to as an exponential expansion in [5].

(c) The properties (3.9) and (3.10) on the coefficient function φ for the exponential expansion will be used later to construct a one-dimensional subspace complementary to the span$\{T_p W_2^s(0), T_p M_1^u(0)\}$ in $T_p\Sigma_1 = \mathbb{R}^{d-1}$ at $p = W_2^s(0) \cap M_1^u(0) = \Gamma_{12} \cap \Sigma_1$ mentioned earlier when (H8) on the strong inclination property for $M_1^u(0)$ was introduced.

To apply Theorem 3.1, we first observe that by a smooth change of variables in a small neighborhood U_i of a_i, (2.1) is C^k conjugate in U_i to equations in the following form:

$$\begin{aligned} \dot{x} &= A_i(\alpha)x + f_i(x, y, \alpha), \\ \dot{y} &= B_i(\alpha)y + g_i(x, y, \alpha), \end{aligned} \qquad x \in \mathbb{R}^m, \quad y \in \mathbb{R}^n, \quad \alpha \in \mathbb{R}^2. \tag{3.11}$$

Here A_i, B_i, f_i, g_i and C^{k-1}, and f_i and g_i satisfy (H10) for $i = 1, 2$. Furthermore, (H1) and (H2) imply that A_i and B_i satisfy (H11). Thus, Theorem 3.1 is applicable to (3.11) for $i = 1$ and 2. It is not difficult to see that we may choose a single δ_0 from Theorem 3.1 such that the conclusions hold true for (3.11) for $i = 1$ and 2. We will use this δ_0 to define several cross sections to the loop $\Gamma_{12} \cup \Gamma_{21} \cup \{a_1, a_2\}$ and to the maps along them.

Since the discussion in the following few paragraphs applies to both a_1 and a_2, we will treat only a_1 and, therefore, suppress all the subscripts of a. Also, we will suppress the parameter α if doing so does not cause confusion.

First, we specify some notation used in this paper. Let $p \in W_{\text{loc}}^s \cap \{\Gamma_{12} \cup \Gamma_{21}\}$ and $q \in W_{\text{loc}}^u \cap \{\Gamma_{12} \cup \Gamma_{21}\}$. Write

$$p = (\bar{x}_0, 0), \qquad q = (0, \bar{y}_1). \tag{3.12}$$

By (H7), we may choose $\bar{y}_1 = (\bar{y}_1^{(1)}, \cdots, \bar{y}_1^{(n)})$ to satisfy

$$\bar{y}_1^{(1)} = \delta_0. \tag{3.13}$$

For simplicity, we assume that

$$\bar{x}_0^{(1)} = \delta_0 \tag{3.14}$$

where $\bar{x}_0 = (\bar{x}_0^{(1)}, \cdots, \bar{x}_0^{(m)})$. We remark that (3.14) will not be used in any proof and therefore is not essential. Let $\delta_0 > \delta_1 > 0$ and $\delta_0 > \delta_2 > 0$ be arbitrary small constants, and

$$\Sigma^s(\delta_1) = \{(x, y) | x^{(1)} = \delta_0, |x - \bar{x}_0| < \delta_1, |y| < \delta_1\}, \tag{3.15}$$

$$\Sigma^u(\delta_2) = \{(x, y) | y^{(1)} = \delta_0, |x| < \delta_2, |y - \bar{y}_0| < \delta_2\}. \tag{3.16}$$

Note that for sufficiently small δ_2, (H1) implies that $\Sigma^u = \Sigma^u(\delta_2)$ is transverse to the flow of (2.1). For simplicity, we assume, without loss of generality, that $\Sigma^s = \Sigma^s(\delta_1)$ is also transverse to the flow of (3.1) for small δ_1. Again, we emphasize that the forms (3.14) and (3.15) are merely for simplicity in our discussion and will not be used in our proof. Let $z(t) = z(t; z_0)$ denote the solution of (3.11) with initial data $z(0) = z_0$, and let $z = (x, y)$.

Next, we define a local map near the equilibrium by the flow. Define

$$\begin{aligned} \sigma^s = \{(x_0, y_0) \in \Sigma^s \,|\, &\exists s = s(x_0, y_0) \text{ such that } z(t; z_0) \notin \Sigma^u \\ &\text{for } 0 \leqq t < s \text{ and } z(s; z_0) \in \Sigma^u, \text{ where } z_0 = (x_0, y_0)\}. \end{aligned} \tag{3.17}$$

It is not difficult to see that since Σ^s and Σ^u are transverse to the flow of (3.11), δ_1 and δ_2 can be chosen so small that the function $s: \sigma^s \to \mathbb{R}$, which represents the first time needed for the trajectory starting from σ^s to reach Σ^u, is well defined and continuously differentiable. Define

$$\pi: \sigma^s \to \Sigma^u \tag{3.18}$$

$$(x_0, y_0) \to z(s; z_0) \text{ with } s = s(x_0, y_0) \text{ and } z_0 = (x_0, y_0).$$

Obviously, π is a diffeomorphism onto its image. Let

$$\sigma^u = \pi(\sigma^s) \tag{3.19}$$

(see Fig. 3.1).

Applying the same arguments (3.12), (3.15)-(3.19) to (3.11) for $i = 1$ and 2, we obtain the following points, maps, etc.: p_i, q_i, δ_{i1}, δ_{i2}, Σ_i^s, Σ_i^u, σ_i^s, σ_i^u, and $\pi_i: \sigma_i^s \to \sigma_i^u$, $i = 1, 2$.

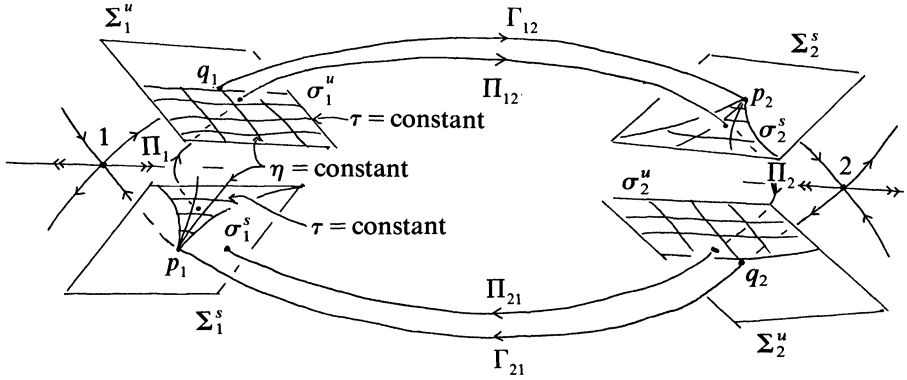

FIG. 3.1

Next, we define a global map near Γ_{12} by following the flow. Since q_1 and p_2 are on Γ_{12}, there exists a unique $t_1 > 0$ such that $z(t; q_1) \notin \Sigma_2^s$ for $0 \leqq t < t_1$ and $z(t_1; q_1) = p_2$. Hence, by the Implicit Function Theorem, for every $(x_0, y_0) \in \Sigma_1^u$ sufficiently close to q_1, there exists a unique time $t_2 = t_2(x_0, y_0) > 0$, such that $z(t; z_0) \notin \Sigma_2^s$ for all $0 \leqq t < t_2$, $z_0 = (x_0, y_0)$, and $z(t_2; z_0) \in \Sigma_2^s$, that is, the first time for the trajectory to hit Σ_2^s. It is easy to see that we can choose δ_{12} sufficiently small so that $t_2(x_0, y_0)$ is smoothly defined for all $(x_0, y_0) \in \Sigma_1^u$ and remains close to the constant t_1. Define

$$\pi_{12}: \Sigma_1^u \to \Sigma_2^s \tag{3.20}$$

$$(x_0, y_0) \to z(t_2, z_0) \text{ with } t_2 = t_2(x_0, y_0) \text{ and } z_0 = (x_0, y_0).$$

Obviously, π_{12} is a diffeomorphism. Similarly, for a sufficiently small δ_{22}, we can define $\pi_{21}: \Sigma_2^u \to \Sigma_1^s$.

Note that if

$$\pi_{12}(\sigma_1^u) \subset \sigma_2^s \tag{3.21}$$

then, a Poincaré return map $\pi = \pi_{21} \cdot \pi_{12} \cdot \pi_{12} \cdot \pi_1$: $\sigma_1^s \to \Sigma_1^s$ is well defined. Since we can always expect that (3.21) holds true for certain subset $\tilde{\sigma}_1^u \subset \sigma_1^u$, a map

$$\pi_{11} = \pi_{21} \cdot \pi_2 \cdot \pi_{12} \cdot \pi_1: \tilde{\sigma}_1^s \to \Sigma_1^s \tag{3.22}$$

is always well defined. π_{11} is called a Poincaré map. Similarly, we may obtain the other Poincaré map π_{22} (cf. Fig. 3.1).

Now, the following discussion is devoted to the relation between the periodic points of π_{11} and the reduced equivalent equations. Naturally, a periodic orbit near $\Gamma_{12} \cup \Gamma_{21}$ corresponds to a periodic point of either π_{11} or π_{22}. Intuitively, the structure of $\tilde{\sigma}_1^s$ is more complicated than that of σ_1^s. Thus, instead of studying the fixed points of the Poincaré map π_{11} on $\tilde{\sigma}_1^s$, we consider the following equations:

$$\begin{aligned} &\pi_{12} \cdot \pi_1(z_1) = z_2, \\ &\pi_{21} \cdot \pi_2(z_2) = z_1, \end{aligned} \qquad z_1 \in \sigma_1^s, \quad z_2 \in \sigma_2^s. \tag{3.23}$$

It is obvious that the existence of fixed points for π_{11} is equivalent to the existence of solutions z_1 and z_2 to (3.23). However, when we examine (3.17) and (3.18) for π_1 (equivalently, π_2), we find several difficulties. First, since $p_1 \in \Gamma_{21}$ is on the local stable manifold of a_1, by (3.17) p_1 must not be in σ_1^s. Second, due to the hyperbolicity of the equilibrium a_1, the time $s_1 = s_1(x_0, y_0)$ needed for a point on the orbit to travel from σ_1^s to σ_1^u approaches infinity as $(x_0, y_0) \to p_2$. Moreover, the definitions for π_1 and π_2 reveal few properties with which we can analyze (3.23). Usually, if we can find a local change of variables near each a_1 and a_2 such that under the new variables the nonlinear equation (3.1) becomes a system of linear equations in U_1 and U_2 then these problems will be dramatically simplified. This so-called C^1-linearization approach is indeed quite common in literature. Our hypotheses (H1) and (H2) on the eigenvalues are not sufficient to obtain such a C^1-linearization in general. The approach to overcome these difficulties is through a change of variables only on σ_1^s and σ_2^s. This idea is due to Šil'nikov.

Let Δ_1 be a $(d-1)$-dimensional open set. Let $\rho_1 \colon \Delta_1 \to \sigma_1^s$ be a diffeomorphism onto its image. Then ρ_1 is called a *change of variables* in σ_1^s. Let $\rho_{11} = \pi_1 \cdot \rho_1 \colon \Delta_1 \to \sigma_i^u$. Similarly, we may have a change of variables ρ_2, in σ_2^s. The purpose of such changes of variables is to make the local maps ρ_{11} and ρ_{22} tractable. Before we introduce the Šil'nikov changes of variables, we note the following simple facts.

It is easy to see that to find solutions z_1 and z_2 to (3.23) it suffices to find solutions to the following equations:

$$\begin{aligned} &\pi_{12} \cdot \rho_{11}(\zeta_1) = \rho_2(\zeta_2), \\ &\pi_{21} \cdot \rho_{22}(\zeta_2) = \rho_1(\zeta_1), \end{aligned} \qquad \zeta_1 \in \Delta_1, \quad \zeta_2 \in \Delta_2. \tag{3.24}$$

However, the existence of solutions to (3.24) is only a sufficient condition for the existence of solutions to (3.23). But we will see that by restricting periodic orbits of (2.1) to a sufficiently small neighborhood N of $\Gamma_{12} \cup \Gamma_{21} \cup \{a_i, a_2\}$, we can guarantee that the condition for the existence of solutions to (3.24) in some subsets $\hat{\Delta}_1 \subset \Delta_1$ and $\hat{\Delta}_2 \subset \Delta_2$ is both sufficient and necessary for the existence of certain types of periodic orbits in N. This is to be explained as follows.

In this paper, a small neighborhood N of $\Gamma_{12} \cup \Gamma_{21} \cup \{a_1, a_2\}$ satisfies

$$N \cap L_i^s \subset \Sigma_i^s, \qquad i = 1, 2 \tag{3.25}$$

where $L_i^s = \{(x, y) \in U_i \mid x^{(1)} = \delta_0, |x| \leqq \delta_0, |y| \leqq \delta_0\}$. Let

$$\hat{\Sigma}_i^s = N \cap \Sigma_i^s, \qquad i = 1, 2, \tag{3.26}$$

$$\hat{\sigma}_i^s = \hat{\Sigma}_i^s \cap \sigma_i^s, \qquad i = 1, 2. \tag{3.27}$$

Let γ be a periodic (homoclinic) orbit in N; then γ is called a *K-periodic (homoclinic) orbit* if the number of points in the set $\gamma \cap \hat{\sigma}_1^s (\gamma \cap \operatorname{cl} \hat{\sigma}_1^s)$ is exactly K. Certainly, for a K-periodic (homoclinic) orbit γ in N the number of points in $\gamma \cap \hat{\sigma}_2^s (\gamma \cap \operatorname{cl} \hat{\sigma}_2^s)$ is also equal to K. Moreover, if N is so small that

$$\hat{\sigma}_i^s \subset \rho_i(\Delta_i), \qquad i = 1, 2, \tag{3.28}$$

then there exists a K-periodic orbit γ in N, say $K=1$, if and only if (3.24) has solutions $\zeta_1 \in \hat{\Delta}_1$ and $\zeta_2 \in \hat{\Delta}_2$ where

$$\hat{\Delta}_i = \rho_i^{-1}(\hat{\sigma}_i^s), \qquad i=1,2. \tag{3.29}$$

We will put these observations into a lemma. Before doing so, we note that all definitions for maps and sets as above extend immediately to the perturbed system of (2.1) with a small parameter α. Thus, from now on we allow the arguments of π_1, π_2, π_{12}, ρ_2, ρ_{11}, ρ_{22}, etc. to include the parameter α. But we write σ_1^s instead of $\sigma_1^s(\alpha)$, and so on.

LEMMA 3.3. *Let σ_i^s, σ_i^u, π_i, $i=1,2$ be defined as in* (3.17)-(3.19). *Let π_{12}, π_{21} be defined as in* (3.20). *Let ρ_i, $i=1,2$ be a smooth map satisfying that for every α, $\rho_i(\cdot,\alpha):\Delta_i(\alpha)\to\sigma_i^s(\alpha)$ is a diffeomorphism onto its images. Let*

$$\rho_{ii}(\cdot,\alpha)=\pi_i(\rho_i(\cdot,\alpha),\alpha):\Delta_i(\alpha)\to\sigma_i^u(\alpha), \qquad i=1,2. \tag{3.30}$$

Then the following statements hold true:

(a) *For each small α there exist a small neighborhood N of $\Gamma_{12}\cup\Gamma_{21}\cup\{a_1,a_2\}$ and a K-periodic orbit γ in N if and only if the equations*

$$\begin{aligned}&\pi_{12}(\rho_{11}(\zeta_i^{(j)},\alpha),\alpha)=\rho_2(\zeta_2^{(j)},\alpha),\\ &\pi_{21}(\rho_{22}(\zeta_2^{(j)},\alpha),\alpha)=\rho_1(\zeta_1^{(j+1)},\alpha),\end{aligned} \qquad j=0,1,2,\cdots(\mathrm{mod}\ K) \tag{3.31}$$

have a solution

$$\zeta_i^{(j)}\in\hat{\Delta}_i(\alpha), \qquad i=1,2, \quad j=0,1,2,\cdots(\mathrm{mod}\ K) \tag{3.32}$$

where $\hat{\Delta}_i$, $i=1,2$, are as in (3.29).

(b) *For each small α there exists a small neighborhood N of $\Gamma_{12}\cup\Gamma_{21}\cup\{a_1,a_2\}$ and a K-homoclinic orbit γ to a_1 in N if and only if*

$$\begin{aligned}&\pi_{12}((0,y),\alpha)=\rho_2(\zeta_2^{(0)},\alpha),\\ &\pi_{21}(\rho_{22}(\zeta_2^{(j)},\alpha))=\rho_1(\zeta_1^{(j+1)},\alpha),\\ &\pi_{12}(\rho_{11}(\zeta_1^{(j+1)},\alpha),\alpha)=\rho_2(\zeta_2^{(j+1)},\alpha), \qquad j=0,1,2,\cdots(\mathrm{mod}\ K-1),\\ &\pi_{21}(\rho_{22}(\zeta_2^{(K-1)},\alpha),\alpha)=(x,0),\end{aligned} \tag{3.33}$$

have a solution with

$$\begin{aligned}&(0,x)\in\hat{\Sigma}_1^s(\alpha), \qquad (0,y)\in\hat{\Sigma}_1^u(\alpha),\\ &\zeta_i^{(j)}\in\hat{\Delta}_i(\alpha), \qquad i=1,2, \quad j=0,1,2,\cdots(\mathrm{mod}\ K-1)\end{aligned} \tag{3.34}$$

where $\hat{\Sigma}_1^s(\alpha)=\Sigma_1^s\cap N$ and $\hat{\Sigma}_1^u(\alpha)=\Sigma_1^u\cap N$.

Remark 3.4. (a) A statement similar to (b) of Lemma 3.3 holds true for homoclinic orbits to a_2. (b) An immediate consequence of this lemma is that to find periodic or homoclinic orbits near Γ we can first solve (3.31) and (3.33) without the constraints (3.32) and (3.34) associated with the small neighborhood N and then construct a neighborhood N independent of α such that (3.32) or (3.34) holds true.

We now introduce the changes of variables ρ_1 and ρ_2. Let $s_0>0$ be a constant. Let $\Delta_i=\Delta_i(s_0)$, $i=1,2$, be defined by

$$\Delta_i(s_0)=\{\zeta\in\mathbb{R}^{d-1}\mid \zeta=(s,x_0,y_1),\ s>s_0,\ (x_0,0)\in\Sigma_i^s,\ (0,y_1)\in\Sigma_i^u\}. \tag{3.35}$$

Let $(x,y)(t)=(x,y)(t;s,x_0,y_1,\alpha)$ be the solution of (3.11) satisfying (3.5). Define for every small α and $i=1,2$,

$$\rho_i(\cdot,\alpha):\Delta_i\to\Sigma_i^s \quad \text{with } (s,x_0,y_1)\to(x,y)(0). \tag{3.36}$$

We have the following lemma.

LEMMA 3.5. *There exists sufficiently large $S_0 > 0$ such that for all $s_0 > S_0$, ρ_i, defined by* (3.36), *defines a change of variables in σ_i^s. Moreover, the corresponding local map ρ_{ii}, defined by* (3.30), *is given by*

$$\rho_{ii}(\cdot, \alpha): \Delta_i \to \sigma_i^u \quad \text{with } (s, x_0, y_1) \to (x, y)(s) \tag{3.37}$$

where $i = 1, 2$.

Proof. It is obvious from Lemma 3.1 that ρ_i is differentiable. The exponential estimates in (3.7) and (3.8) imply that we can choose a sufficiently large $S_0 > 0$ such that $|y(0)| < \delta_{11}$ and $|x(s)| < \delta_{12}$ for all $s > s_0 \geqq S_0$ and $(s, x_0, y_1) \in \Delta_i$. Since both $(x, y)(0) \in \Sigma_i^s$ and $(x, y)(s) \in \Sigma_i^u$ are on the same orbit of (2.1), it follows from the definitions (3.17) and (3.18) for π_i, that $(x, y)(0) \in \sigma_i^s(\alpha)$ and $\pi_i(x(0), y(0), \alpha) = (x, y)(s) \in \sigma_i^u(\alpha)$. This, together with (3.30) implies (3.37).

To show that $\rho_i(\cdot, \alpha)$ is a diffeomorphism, recall the smooth scalar function s in the definitions (3.17) and (3.18) for the local map π_i. Note that

$$\bar{\rho}: \rho_i(\Delta_i, \alpha) \to \Delta_i$$

$$(x_0, y_0) \to (s, x_0, y(s; 0, x_0, y_0, \alpha)) \text{ with } s = s(x_0, y_0),$$

is actually the inverse for $\rho(\cdot, \alpha)$. Since $\bar{\rho}$ is also differentiable, $\rho(\cdot, \alpha)$ must be a local diffeomorphism. □

4. Uniqueness of homoclinic and periodic orbits. According to Lemma 3.3 and (b) of Remark 3.4, it suffices to consider (3.31) and (3.33) in the new variables in Δ_1 and Δ_2 introduced by (3.35) and (3.36). In this section, we will use these equations and prove the uniqueness of periodic and homoclinic orbits near $\Gamma_{12} \cup \Gamma_{21} \cup \{a_1, a_2\}$ (Proposition 4.1). To do so, we first rewrite the coordinates for Σ_i^s, Σ_i^u and Δ_i in some equivalent forms. Throughout this section, $i = 1$ or 2.

Since for all $(x, y) \in \Sigma_i^s$, $x^{(1)} = \delta_0$, there exists an obvious correspondence $(x, y) \leftrightarrow (\xi, y)$ with

$$\xi = (x^{(2)} - \bar{x}_{i0}^{(2)}, \cdots, x^{(m)} - \bar{x}_{i0}^{(m)}) \in \mathbb{R}^{m-1} \tag{4.1}$$

where $p_i = (\bar{x}_{i0}, 0)$ is as in (3.12). Note that $(\xi, y) \in \mathbb{R}^{d-1}$ and

$$\Sigma_i^s = \{(\xi, y) \in \mathbb{R}^{d-1} \,|\, |\xi| < \delta_{i1}, |y| < \delta_{1i}\}. \tag{4.2}$$

Similarly, let

$$\eta = (y^{(2)} - \bar{y}_{i1}^{(2)}, \cdots, y^{(n)} - \bar{y}_{i1}^{(n)}) \in \mathbb{R}^{n-1} \tag{4.3}$$

where $q_i = (0, \bar{y}_{i1})$ is as in (3.12). Then, (3.16) can be expressed as

$$\Sigma_i^u = \{(x, \eta) \in \mathbb{R}^{d-1} \,|\, |x| < \delta_{i2}, |\eta| < \delta_{i2}\} \tag{4.4}$$

(cf. Fig. 3.1).

Under the new variables (ξ, y) and (x, η) for Σ_i^s and Σ_i^u, respectively, $\pi_{12}: \Sigma_1^u \to \Sigma_2^s$ can be expressed as

$$\begin{aligned} \xi &= P_1(x, \eta, \alpha), \\ y &= Q_1(x, \eta, \alpha), \end{aligned} \qquad (x, \eta) \in \Sigma_1^u \tag{4.5}$$

where $\pi_{12} = (P_1, Q_1)$ is a diffeomorphism. Similarly, we have $\pi_{21} = (P_2, Q_2)$: $\Sigma_2^u \to \Sigma_1^s$.

In view of these changes of variables, the following correspondence is also a valid change of variables for both Δ_1 and Δ_2:

$$(s, x, y) \to (\tau, \xi, \eta) \tag{4.6}$$

where $(s, x, y) \in \Delta_i$ is as in (3.35), x and ξ, and y and η are related through (4.1) and (4.3), respectively, and

$$\tau = e^{-\mu(\alpha)s}. \tag{4.7}$$

Hence, (3.35) for Δ_i can be expressed as

$$\Delta_i = \{(\tau, \xi, \eta) \in \mathbb{R}^{d-1} \mid 0 < \tau < \tau_0, |\xi| < \delta_{i1}, |\eta| < \delta_{i2}\} \tag{4.8}$$

where

$$\tau_0 = e^{-\mu(\alpha)s_0}. \tag{4.9}$$

Note that Δ_i depends on the parameter α, which is suppressed for simplicity of notation.

In the new variables for Δ_i, let

$$X(\tau, \xi, \eta, \alpha) = x(s; s, x_0, y_1, \alpha), \tag{4.10}$$

$$Y(\tau, \xi, \mu, \alpha) = y(0; s, x_0, y_1, \alpha), \tag{4.11}$$

and

$$\psi(\xi, \eta, \alpha) = \varphi(x_0, y_1, \alpha) \tag{4.12}$$

where the solution $(x, y)(t) = (x, y)(t; s, x_0, y_1, \alpha)$ and the function φ are as in Theorem 3.1, and (τ, ξ, η) and (s, x_0, y_1) are related by (4.6) and (4.7). It is not difficult to see that from (3.7), (3.5), (4.7), (4.10)-(4.12) there exists a smooth function $R = R(\tau, \xi, \eta, \alpha)$ such that

$$\left| \frac{\partial}{\partial \tau} D^j X \right| = O(\tau^\nu), \tag{4.13}$$

$$Y = \tau\psi(\xi, \eta, \alpha) + R(\tau, \xi, \eta, \alpha), \tag{4.14}$$

$$\psi(\xi, \eta, \alpha) = \delta_0 \begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix} + O(|\xi| + |\eta|)\delta_0 \tag{4.15}$$

and

$$\left| \frac{\partial}{\partial \tau} D^j R \right| = O(\tau^\nu). \tag{4.16}$$

Here, the differentiation operator D^j involves derivatives only with respect to ξ, η and α, $j \leqq k-3$, and the constant ν satisfies

$$0 < \nu < \min\left\{ \frac{\lambda(\alpha)}{\mu(\alpha)} - 1, \frac{\bar{\nu}}{\mu(\alpha)} \right\}, \qquad |\alpha| \ll 1 \tag{4.17}$$

where λ is as in (3.6) and $\bar{\nu}$ is as in (3.8). To avoid confusion, we write X_i, Y_i, ψ_i, and R_i to denote the functions in (4.10), (4.11), (4.12), and (4.14), respectively, from Δ_i.

An important observation from (4.13)-(4.16) is that the functions X and Y can be C^1 extended to $\tau \leqq 0$. For simplicity, let X and Y denote such extensions in the extended region:

$$\tilde{\Delta}_i = \{(\tau, \xi, \eta) \in \mathbb{R}^{d-1} \mid |\tau| < \tau_0, |\xi| < \delta_{i1}, |\eta| < \delta_{i2}\}. \tag{4.18}$$

Obviously,

$$\Delta_i = \tilde{\Delta}_i \cap \{(\tau, \xi, \eta) \in \mathbb{R}^{d-1} \mid \tau > 0\}. \tag{4.19}$$

Note that both Δ_i and $\tilde{\Delta}_i$ depend on α. But, for the simplicity of notation, it is suppressed from the arguments.

Now, let us consider (3.31) and (3.33) for the periodic and homoclinic orbits near $\Gamma_{12} \cup \Gamma_{21}$. Let $K \geqq 1$, and $\zeta \in (\Delta_1 \times \Delta_2)^K$ with

$$\zeta = (\tau_1^0, \xi_1^0, \eta_1^0, \tau_2^0, \xi_2^0, \eta_2^0, \cdots, \tau_i^{K-1}, \xi_1^{K-1}, \eta_1^{K-1}, \tau_2^{K-1}, \xi_2^{K-1}, \eta_2^{K-1}). \tag{4.20}$$

Let

$$X_i^j = X(\tau_i^j, \xi_i^j, \eta_i^j, \alpha) \quad \text{and} \quad Y_i^j = Y(\tau_i^j, \xi_i^j, \eta_i^j, \alpha) \tag{4.21}$$

where

$$(\tau_i^j, \xi_i^j, \eta_i^j) \in \Delta_i, \qquad i = 1, 2, \quad j = 0, 1, 2, \cdots. \tag{4.22}$$

Then, it is not difficult to see that in the new variables τ, ξ, and η, equation (3.31) for periodic orbits is equivalent to

$$\Phi(\zeta, \alpha) = 0 \tag{4.23}$$

where

$$\Phi(\zeta, \alpha) = \begin{pmatrix} -\xi_2^j + P_1(X_1^j, \eta_1^j, \alpha) \\ -Y_2^j + Q_1(X_1^j, \eta_1^j, \alpha) \\ -\xi_1^{j+1} + P_2(X_2^j, \eta_2^j, \alpha) \\ -Y_1^{j+1} + Q_2(X_2^j, \eta_2^j, \alpha) \end{pmatrix}, j = 0, 1, 2, \cdots (\text{mod } K). \tag{4.24}$$

In particular, the estimates (4.13) and (4.16), (4.21), and (4.24) imply that (3.33) for the K-homoclinic orbits to a_1 is actually equivalent to (4.23) with $\zeta \in (\tilde{\Delta}_1 \times \tilde{\Delta}_2)^K$ satisfying

$$\tau_1^0 = 0, \quad (0, \xi_1^0, \eta_1^0) \in \tilde{\Delta}_1, \quad (\tau_2^0, \xi_2^0, \eta_2^0) \in \Delta_2 \tag{4.25}$$

and

$$(\tau_i^j, \xi_i^j, \eta_i^j) \in \Delta_i, \qquad i = 1, 2, \quad j = 1, 2, \cdots, K-1. \tag{4.26}$$

This shows that we only need to treat (4.23) uniformly in the extended domain $(\tilde{\Delta}_1 \times \tilde{\Delta}_2)^K$ for both the homoclinic and periodic orbits. Moreover, due to the following results (Theorem 4.2) on the uniqueness of periodic and homoclinic orbits in a small neighborhood N, we will see that we actually only have to consider (4.23) with $K = 1$. In this case, the correspondence between a solution $(\tau_1, \xi_1, \eta_1, \tau_2, \xi_2, \eta_2)$ of $\Phi = 0$ and an orbit are as follows:

(a) $\tau_1 = \tau_2 = 0$ corresponds to the heteroclinic loop from a_1 to a_2 and from a_2 to a_1,

(b) $\tau_1 = 0$ and $\tau_2 > 0$ corresponds to a homoclinic orbit from a_1 to a_1,

(c) $\tau_1 > 0$ and $\tau_2 = 0$ corresponds to a homoclinic orbit from a_2 to a_2,

(d) $\tau_1 > 0$ and $\tau_2 > 0$ corresponds to a periodic orbit.

In this section we will show that $\Phi = 0$ always has a unique solution for small α in the extended domain by Implicit Function Theorem arguments. However, it is obvious to see that the existence of solutions to $\Phi = 0$ does not always imply the

constraints $\tau_1 \geqq 0$ and $\tau_2 \geqq 0$ as required. Therefore, to get $\tau_1 \geqq 0$ and $\tau_2 \geqq 0$ for certain parameters, we need to derive some bifurcation equations from (4.23). This is to be done in the next section. We now have our results (Proposition 4.1 and Theorem 4.2) on the uniqueness of homoclinic and periodic orbits near $\Gamma_{12} \cup \Gamma_{21} \cup \{a_1, a_2\}$.

PROPOSITION 4.1. *Suppose* (2.1) *satisfies* (H1)-(H3) *and* (4.23) *satisfies the following conditions in the extended domain* $(\tilde{\Delta}_1 \times \tilde{\Delta}_2)^K$:

(4.27) *If* $\zeta^* = (\tau_1^*, \xi_1^*, \eta_1^*, \tau_2^*, \xi_2^*, \eta_2^*) \in \Delta_1 \times \Delta_2$ *is a solution to* (4.23), *with* $K = 1$, *then* $(\zeta^*, \cdots, \zeta^*) \in (\tilde{\Delta}_1 \times \tilde{\Delta}_2)^K$ *is also a solution to* (4.23) *with* $K > 1$.

(4.28) *For every small* α, *with* $K = 1$, (4.29) *has a unique solution* ζ^*.

(4.29) *For every small* α *and every* $K > 1$, *the solution of* (4.23) *in* $(\tilde{\Delta}_1 \times \tilde{\Delta}_2)^K$ *is unique.*

Then, for every small α *there exists at most one periodic or homoclinic orbit near* $\Gamma_{12} \cap \Gamma_{21} \cup \{a_1, a_2\}$, *but not both. Moreover, only simple* $(K = 1)$ *periodic or homoclinic orbits can exist.*

Proof. Suppose there exist two orbits γ_1 and γ_2, each of which is a periodic or homoclinic orbit. Then, there exist $K_1 \geqq 1$ and $K_2 \geqq 1$ such that (4.23) has a solution ζ_1^* for K_1 and ζ_2^* for K_2 with ζ_1^* satisfying either (4.22), or (4.25) and (4.26). Let $\zeta^* \in \tilde{\Delta}_1 \times \tilde{\Delta}_2$ be the solution to (4.23) with $K = 1$ guaranteed by the hypothesis (4.28). Then, hypotheses (4.27) and (4.29) imply

$$\zeta_i^* = (\zeta^*, \cdots, \zeta^*) \in (\tilde{\Delta}_1 \times \tilde{\Delta}_2)^{K_i}, \qquad i = 1, 2. \tag{4.30}$$

This implies that ζ^* must satisfy either (4.22), or (4.25) and (4.26). That is, there exists a simple periodic or homoclinic orbit near $\Gamma_{12} \cup \Gamma_{21} \cup \{a_1, a_2\}$. Furthermore, (4.30) forces K_1, $K_2 = 1$, and $\zeta_1^* = \zeta_2^* = \zeta^*$. This completes the proof. □

Finally, we have Theorem 4.2.

THEOREM 4.2. *Suppose that hypotheses* (H1)-(H4), (H7), *and* (H8) *are satisfied. Then there exists a neighborhood* N *of* $\Gamma_{12} \cup \Gamma_{21} \cup \{a_1, a_2\}$ *and a neighborhood* O *if* $\alpha = 0$ *such that for all small* α, *there exists at most one homoclinic or periodic orbit in* N, *but not both. Moreover, only simple* $(K = 1)$ *homoclinic or periodic orbits can exist.*

Proof. Note that (4.27)-(4.29) and Remark 3.4(b) of Lemma 3.3 imply the existence of such a neighborhood N. Hence, to prove the theorem it suffices to verify (4.27)-(4.29).

Condition (4.27) simply follows the definition (4.24) for Φ. To verify (4.28) and (4.29), we apply the Implicit Function Theorem to (4.23).

Let $K = 1$. Then $\zeta = (\tau_1^0, \xi_1^0, \eta_1^0, \tau_2^0, \xi_2^0, \eta_2^0) \in \mathbb{R}^{2(d-1)}$. The existence of Γ_{12} and Γ_{21} when $\alpha = 0$ implies that

$$\Phi(0, 0) = 0. \tag{4.31}$$

Since Φ is C^1, a simple calculation together with the eigenvalue conditions (H1) and (H2) implies

$$\frac{\partial \Phi}{\partial \zeta}(0, 0) = \begin{bmatrix} 0 & 0 & \partial P_{10}/\partial \eta & 0 & -I_{m-1} & 0 \\ 0 & 0 & \partial Q_{10}/\partial \eta & -\psi_{20} & 0 & 0 \\ 0 & -I_{m-1} & 0 & 0 & 0 & \partial P_{20}/\partial \eta \\ -\psi_{10} & 0 & 0 & 0 & 0 & \partial Q_{20}/\partial \eta \end{bmatrix}$$

where $\partial P_{i0}/\partial \eta = \partial P_i/\partial \eta$ $(0, 0, 0)$, $\partial Q_{i0}/\partial \eta = \partial Q_i/\partial \eta$ $(0, 0, 0)$, $\psi_{i0} = \psi_i$ $(0, 0, 0)$, and $i = 1, 2$. This matrix becomes diagonal through permutation, making the first two column

blocks into the last two column blocks. Then, it is easy to have

$$\det \frac{\partial \Phi}{\partial \zeta}(0,0) = (-1)^m \det\left[\frac{\partial Q_{10}}{\partial \eta}, \psi_{20}\right] \det\left[\frac{\partial Q_{20}}{\partial \eta}, \psi_{10}\right]. \tag{4.32}$$

We will show that (4.32) does not vanish.

Observe that the column vectors of the $(d-1)\times(d-2)$ matrix

$$M_1 = \begin{bmatrix} \partial P_{10}/\partial \eta & -I_{m-1} \\ \partial Q_{10}/\partial \eta & 0 \end{bmatrix} \tag{4.33}$$

span the subspace

$$\operatorname{span}\{T_p W_2^s, T_p W_1^u\} \cap T_p \Sigma_2^s \tag{4.34}$$

where $p = \Gamma_{12} \cap \Sigma_2^s$ is as in (3.12). This is because $T_p W_2^s = \mathbb{R}^m \times \{0\}$ and $T_p W_1^u = \operatorname{Im}(D_y \pi_{12}(0,0)) \times \operatorname{span}\{T_p \Gamma_{12}\}$. Since W_2^s and W_1^u are in general position (see (H5)) and Σ_2^s is transverse to Γ_{12}, we have

$$\operatorname{rank} M_1 = d-2. \tag{4.35}$$

Moreover, if δ_0 is as in Theorem 3.1, then, by (3.10) and (4.15) and the strong inclination property (H8), the vector $(0, \psi_{20}) = (0, \psi_2(0,0,0)) \in \mathbb{R}^{d-1}$ is complementary to the intersection of $\operatorname{span}\{T_p W_2^s, T_p W_1^u\}$ with $T_p \Sigma_2^s$. This implies

$$\operatorname{rank}\left[M_1, \begin{bmatrix} 0 \\ \psi_{20} \end{bmatrix}\right]_{(d-1)\times(d-1)} = d-1 \tag{4.36}$$

and thus,

$$\det\left[M_1, \begin{bmatrix} 0 \\ \psi_{20} \end{bmatrix}\right] = (-1)^{(n+1)(m-1)} \det\left[\frac{\partial Q_{10}}{\partial \eta}, \psi_{20}\right] \neq 0. \tag{4.37}$$

Similarly, we can show that

$$\det\left[\frac{\partial Q_{20}}{\partial \eta}, \psi_{10}\right] \neq 0. \tag{4.38}$$

We now conclude from (4.32) that

$$\det \frac{\partial \Phi}{\partial \zeta}(0,0) \neq 0. \tag{4.39}$$

It follows from the Implicit Function Theorem that there exist neighborhoods O of $\xi = 0 \in \tilde{\Delta}_1 \times \tilde{\Delta}_2$ and V of $\alpha = (0,0)$ in $\mathbb{R}^2$, and a C^1 function $\zeta^* = \zeta^*(\alpha)$, $\alpha \in V$, with $\zeta^*(\alpha) \in O$ for all $\alpha \in V$ and

$$\zeta^*(0) = 0 \tag{4.40}$$

such that ζ^* is the unique solution to (4.23). Note that by the Implicit Function Theorem, we also have that

$$\det \frac{\partial \Phi}{\partial \zeta}(\zeta, \alpha) \neq 0, \qquad \zeta \in O, \quad \alpha \in V. \tag{4.41}$$

This proves (4.28).

Next, we verify (4.29). Let $K > 1$ and consider (4.23) in $(\tilde{\Delta}_1 \times \tilde{\Delta}_2)^K$. The same reasoning as for (4.31) yields

$$\Phi(0,0) = 0. \tag{4.42}$$

Also, since Φ is C^1, simple calculation yields

$$\det\frac{\partial\Phi}{\partial\zeta}(0,0)=\begin{vmatrix} 0 & 0 & * & 0 & -I & 0 & & & & & & \\ 0 & 0 & * & * & 0 & 0 & & & & & & \\ & & & 0 & 0 & * & 0 & -I & 0 & & & \\ & & & 0 & 0 & * & * & 0 & 0 & & & \\ & & & & & & & & 0 & 0 & * & 0 & -I & 0 \\ & & & & & & & & 0 & 0 & * & * & 0 & 0 \\ 0 & -I & 0 & & & & & & & & & 0 & 0 & * \\ * & 0 & 0 & & & & & & & & & 0 & 0 & * \end{vmatrix} \tag{4.43}$$

where all nonspecified entries are zero. Similarly, by permutation we obtain a diagonal matrix such that every block of the form

$$\begin{bmatrix} * & 0 & -I \\ * & * & 0 \end{bmatrix}$$

in the diagonal is one of the following:

$$\begin{bmatrix} \partial P_{i0}/\partial\eta & 0 & -I_{m-1} \\ \partial Q_{i0}/\partial\eta & -\psi_{j0} & 0 \end{bmatrix}, \qquad i,j=1,2, \quad i\neq j.$$

By direct computation

$$\det\frac{\partial\Phi}{\partial\zeta}(0,0)=(-1)^m\left(\det\left[\frac{\partial Q_{10}}{\partial\eta},\psi_{20}\right]\cdot\det\left[\frac{\partial Q_{20}}{\partial\eta},\psi_{10}\right]\right)^K\neq 0 \tag{4.44}$$

because of (4.37) and (4.38). Moreover, it is not hard to see that (4.41) implies

$$\det\frac{\partial\Phi}{\partial\zeta}(\zeta,\alpha)=0, \qquad \zeta\in O^k, \quad \alpha\in V. \tag{4.45}$$

Hence, by the Implicit Function Theorem, equation (4.23) with $K>1$ has a unique solution $\zeta^*=\zeta^*(\alpha)$ for every $\alpha\in V$, ζ^* is C^1, and $\zeta^*(\alpha)\in O^k$ for all $\alpha\in V$. This proves (4.29). □

5. Bifurcation equations and proof of Theorem 2.1. From Theorem 4.2 it follows that a homoclinic or periodic orbit must satisfy

$$\Phi(\zeta,\alpha)=0, \quad \zeta\in\hat{\Delta}_1\times\hat{\Delta}_2, \quad \alpha\in\mathbb{R}^2 \tag{5.1}$$

with $\zeta=(\tau_1,\xi_1,\eta_1,\tau_2,\xi_2,\eta_2)$, $\tau_i\in\mathbb{R}$, $\xi_i\in\mathbb{R}^{m-1}$, $\eta_i\in\mathbb{R}^{n-1}$, and

$$\Phi(\zeta,\alpha)=\begin{pmatrix} -\xi_2+P_1(X_1,\eta_1,\alpha) \\ -Y_2+Q_1(X_1,\eta_1,\alpha) \\ -\xi_1+P_2(X_2,\eta_2,\alpha) \\ -Y_1+Q_2(X_2,\eta_2,\alpha) \end{pmatrix}. \tag{5.2}$$

Here, $X_i=X(\tau_i,\xi_i,\eta_i,\alpha)$, $Y_i=Y(\tau_i,\xi_i,\eta_i)\in\hat{\Delta}_i$, and (P_i,Q_i) are as in § 4. Recall, from the discussion given before Proposition 4.1, that the existence of homoclinic and periodic solutions is equivalent to the existence of solutions $\zeta\in\hat{\Delta}_1\times\hat{\Delta}_2$ of (5.1) satisfying

$$\tau_1\geqq 0, \quad \tau_2\geqq 0, \quad \tau_1+\tau_2\neq 0. \tag{5.3}$$

Also, a solution ζ of (5.1) with $\tau_1=\tau_2=0$ corresponds to the existence of a heteroclinic loop. Hence, the modified condition of (5.3):

$$\tau_1\geqq 0 \quad \text{and} \quad \tau_2\geqq 0 \tag{5.4}$$

for solutions ζ of (5.1) is equivalent to the existence of a homoclinic, periodic, or heteroclinic loop near $\Gamma_{12} \cup \Gamma_{21} \cup \{a_1, a_2\}$. From Theorem 4.2 it follows that any solution to (5.1) for $\alpha \in V$ must be $\zeta^* = \zeta^*(\alpha) = (\tau_1^*, \xi_1^*, \eta_1^*, \tau_2^*, \xi_2^*, \eta_2^*) \in O$, where O, V, and ζ^* are as in (4.40). Therefore, we need to verify that there exists a subset $\bar{\Lambda} \subset V$ such that

$$\zeta^* \in \Omega \quad \text{if and only if } \alpha \in \bar{\Lambda}, \tag{5.5}$$

where

$$\Omega = O \cap \{\zeta \in \hat{\Delta}_1 \times \hat{\Delta}_2 \mid \zeta = (\tau_1, \zeta_1, \eta_1, \tau_2, \xi_2, \eta_2),\ \tau_1 \geqq 0,\ \tau_2 \geqq 0\}. \tag{5.6}$$

This will be true if the mapping $h: \alpha \to (\tau_1^*(\alpha), \tau_2^*(\alpha)) \in \mathbb{R}^2$ is a diffeomorphism near $\alpha = 0$. Indeed, this is what we will prove in this section.

It is difficult to prove the nonsingularity of the mapping h by directly working with τ_1^*, τ_2^* and (5.1). Instead, we solve (5.1) in a way different from § 4 so that the correspondence between τ_1^*, τ_2^* and α can be easily determined through some bifurcation equations. To do so, we need the following notation. For $y = (y^{(1)}, \cdots, y^{(n)}) \in \mathbb{R}^n$, let

$$\hat{y} = (y^{(2)}, \cdots, y^{(n)}) \in \mathbb{R}^{n-1}. \tag{5.7}$$

For $z = (x, y) \in \mathbb{R}^{m-1} \times \mathbb{R}^n$, let

$$\hat{z} = (x, \hat{y}) \in \mathbb{R}^{m-1} \times \mathbb{R}^{n-1}. \tag{5.8}$$

Let

$$\Phi_i = \begin{pmatrix} -\xi_j + P_i(X_i, \eta_i, \alpha) \\ -Y_j + Q_i(X_i, \eta_i, \alpha) \end{pmatrix}, \qquad i, j = 1, 2, \quad i \neq j \tag{5.9}$$

where X_i and Y_i are as in (5.2). Then, for Φ defined by (5.2), we have

$$\Phi = \begin{pmatrix} \Phi_1 \\ \Phi_2 \end{pmatrix}. \tag{5.10}$$

We first solve the equation

$$\Phi_1(\zeta, \alpha) = 0 \tag{5.11}$$

where Φ_1 is as in (5.9). The existence of Γ_{12} and Γ_{21} at $\alpha = 0$ implies

$$\Phi_1(0, 0) = 0. \tag{5.12}$$

Also, by (H5), the existence of the heteroclinic orbit Γ_{α_1} for $\alpha = (\alpha_1, 0)$ implies that (5.11) always has solutions η_1 and ξ_2 for $\tau_1 = \tau_2 = 0$ and $\alpha = (\alpha_1, 0)$. That is,

$$Q_1(0, \eta_1, (\alpha_1, 0)) = 0 \quad \text{for some } |\eta_1| \ll 1. \tag{5.13}$$

Also, let $\hat{\Phi}_1$ be given by (5.8). Then, from (5.12), we have that

$$\hat{\Phi}_1(0, 0) = 0. \tag{5.14}$$

In addition, similarly to the computation for (4.32), it is easy to see that

$$\frac{\partial \Phi_1}{\partial(\eta_1, \xi_2)}(0, 0) = \begin{bmatrix} \partial P_{10}/\partial \eta & -I_{m-1} \\ \partial Q_{10}/\partial \eta & 0 \end{bmatrix} = M_1 \tag{5.15}$$

where M_1, $\partial P_{10}/\partial \eta$, and $\partial Q_{10}/\partial \eta$ are as in (4.33). Thus, (4.35) implies

$$\operatorname{rank} \frac{\partial \Phi_1}{\partial(\eta_1, \xi_2)}(0, 0) = d - 2. \tag{5.16}$$

Moreover, it is not difficult to see from (H8) of the strong inclination property and (5.15) that

$$\operatorname{rank} \frac{\partial \hat{\Phi}_1}{\partial(\eta_1, \xi_2)}(0,0) = d-2. \tag{5.17}$$

Hence, by (5.14), (5.17), and the Implicit Function Theorem, there exist C^1 functions $a = a(z, \alpha) \in \mathbb{R}^{n-1}$ and $b = b(z, \alpha) \in \mathbb{R}^{m-1}$, defined for $z \in \mathbb{R}^d$, $\alpha \in \mathbb{R}^2$ with $|z| \ll 1$, $|\alpha| \ll 1$, such that

$$\hat{\Phi}_1(\zeta, \alpha) = 0, \quad |\zeta| \ll 1, \quad |\alpha| \ll 1, \tag{5.18}$$

if and only if $\zeta = \zeta_*(\chi, \alpha)$, where

$$\zeta_* = (\tau_1, \xi_1, \eta_1, \tau_2, \xi_2, \eta_2) \quad \text{with } \eta_1 = a(\chi, \alpha) \text{ and } \xi_2 = b(\chi, \alpha), \tag{5.19}$$

and

$$\chi = (\tau_1, \xi_1, \tau_2, \eta_2).$$

Moreover, the Implicit Function Theorem implies that

$$a(0,0) = 0 \quad \text{and} \quad b(0,0) = 0. \tag{5.20}$$

Now, by substituting $\zeta = \zeta_*(\chi, \alpha)$ into the remaining equation, the full system of equation (5.11) is equivalent to the equation

$$\Phi_1^{(m)}(\zeta_*(\chi, \alpha), \alpha) = 0. \tag{5.21a}$$

Next, we will derive an equation equivalent to (5.21a). To do so, we first note some properties for the solution of (5.18). It is easy to see from (5.9) and (5.18) that when $\tau_1 = \tau_2 = 0$, the solutions $\eta_1 = a(\chi, \alpha)|_{\tau_1=\tau_2=0}$ and $\xi_2 = b(\chi, \alpha)|_{\tau_1=\tau_2=0}$ do not depend on ξ_1 and η_2. Thus

$$a_\alpha = a(\chi, \alpha)|_{\tau_1=\tau_2=0} \quad \text{and} \quad b_\alpha = b(\chi, \alpha)_{\tau_1=\tau_2=0} \tag{5.21b}$$

are functions of the variable α alone. This observation is very important. Obviously, we also have

$$a - a_\alpha = O(|\tau_1| + |\tau_2|) \quad \text{and} \quad b - b_\alpha = O(|\tau_1| + |\tau_2|). \tag{5.22}$$

Moreover, when $\tau_1 = \tau_2 = 0$, (5.18) implies

$$\begin{pmatrix} -b_\alpha + P_{1\alpha} \\ \hat{Q}_{1\alpha} \end{pmatrix} = \hat{\Phi}(\zeta_*(\chi, \alpha), \alpha)\Big|_{\tau_1=\tau_2=0} = 0 \tag{5.23}$$

where $P_{1\alpha} = P_1(0, a_\alpha, \alpha)$ and $Q_{1\alpha} = Q_1(0, a_\alpha, \alpha)$. In particular,

$$\hat{Q}_{1\alpha} = 0, \qquad |\alpha| \ll 1. \tag{5.24}$$

Let $\partial P_{1\alpha}/\partial \eta = \partial P_1/\partial \eta\ (0, a_\alpha, \alpha)$, $\partial Q_{1\alpha}/\partial \eta = \partial Q_1/\partial \eta\ (0, a_\alpha, \alpha)$ and

$$M_{1\alpha} = \begin{bmatrix} \partial P_{1\alpha}/\partial \eta & -I_{m-1} \\ \partial Q_{1\alpha}/\partial \eta & 0 \end{bmatrix}. \tag{5.25}$$

Then, by continuous dependence on α, by (5.15), and by (5.16), we have

$$\operatorname{rank} M_{1\alpha} = d-2. \tag{5.26}$$

In particular, by (5.17), we have

$$\operatorname{rank} \frac{\partial Q_{1\alpha}}{\partial \eta} = n-1. \tag{5.27}$$

Now, by (5.18), (5.24), and (5.25), a simple computation yields

$$\det\left[M_{1\alpha}, \Phi_1(\zeta_*, \alpha) - M_{1\alpha}\begin{pmatrix} a-a_\alpha \\ b \end{pmatrix}\right] = (-1)^{mn-1} \det\left[\frac{\partial Q_{1\alpha}}{\partial \eta}\right] \Phi_1^{(m)}(\zeta_*, \alpha). \tag{5.28}$$

Hence, (5.27) and (5.28) imply that the full system of equation (5.21b) is equivalent to the following equation:

$$\det\left[M_{1\alpha}, \Phi_1(\zeta_*, \alpha) - M_{1\alpha}\begin{pmatrix} a-a_\alpha \\ b \end{pmatrix}\right] = 0 \tag{5.29}$$

where $a = a(\chi, \alpha)$, $b = b(\chi, \alpha)$, $\zeta^* = \zeta_*(\chi, \alpha)$, and a_α are as in (5.19) and (5.21a).

To simplify (5.29) further, we expand (P_1, Q_1) at $(x, \eta) = (0, a_\alpha)$ and ψ_2 at $(\xi, \eta) = (b_\alpha, 0)$, respectively. Thus, by (5.22) we obtain

$$\begin{pmatrix} P_1(X_1, a, \alpha) \\ Q_1(X_1, a, \alpha) \end{pmatrix} = \begin{pmatrix} P_{1\alpha} \\ Q_{1\alpha} \end{pmatrix} + \frac{\partial(P_1, Q_1)}{\partial(x, \eta)}(0, a_\alpha, \alpha)\begin{pmatrix} X_1 \\ a-a_\alpha \end{pmatrix} + O(|\tau_1|^2 + |\tau_2|^2), \tag{5.30}$$

$$\psi_2(b, \eta_2) = \psi_{2\alpha} + O(|\eta_2| + |\tau_1| + |\tau_2|) \tag{5.31}$$

where $\psi_{2\alpha} = \psi_2(b_\alpha, 0)$. Also, from (5.31), (4.14), and (4.16) we have

$$Y_2(\tau_2, b, \eta_2, \alpha) = \psi_{2\alpha}\tau_2 + O(|\eta_2|\,|\tau_2| + |\tau_1|^{1+\nu} + |\tau_2|^{1+\nu}) \tag{5.32}$$

where $\nu > 0$ is as in (4.16). Now, substituting (5.30) with $X_1 = X(\tau_1, \xi_1, a, \alpha)$ and (5.32) into (5.29), from (4.15) we obtain

$$\begin{aligned} &-\det\left[M_{1\alpha}, \begin{pmatrix} 0 \\ \psi_{2\alpha} \end{pmatrix}\right]\tau_2 + \det\left[M_{1\alpha}, \begin{pmatrix} P_{1\alpha} \\ Q_{1\alpha} \end{pmatrix}\right] \\ &\quad + O(|\eta_2|\,|\tau_2| + |\tau_1|^{1+\nu} + |\tau_2|^{1+\nu}) = 0. \end{aligned} \tag{5.33}$$

Note that by the continuous dependence on α and (4.36),

$$\det\left[M_{1\alpha}, \begin{pmatrix} 0 \\ \psi_{2\alpha} \end{pmatrix}\right] \neq 0, \qquad |\alpha| \ll 1. \tag{5.34}$$

Hence, (5.33) can be further simplified to

$$\tau_2 = c_2(\alpha_1, \alpha_2) + O(|\eta_2|\,|\tau_2| + \tau_1|^{1+\nu} + |\tau_2|^{1+\nu}) \tag{5.35}$$

where

$$c_2(\alpha_1, \alpha_2) = \det\left[M_{1\alpha}, \begin{pmatrix} P_{1\alpha} \\ Q_{1\alpha} \end{pmatrix}\right] \Big/ \det\left[M_{1\alpha}, \begin{pmatrix} 0 \\ \psi_{2\alpha} \end{pmatrix}\right]. \tag{5.36}$$

PROPOSITION 5.1. *In addition to* (H1)-(H4), (H7), *and* (H8) *as in Theorem* 4.2, *suppose* (H5) *and* (H6) *are also satisfied. Then for sufficiently small* α

$$c_2(\alpha_1, 0) = 0 \tag{5.37}$$

and

$$\frac{\partial c_2}{\partial \alpha_2}(0, 0) \neq 0 \tag{5.38}$$

where c_2 *is given by* (5.36).

Proof. If $\tau_1 = \tau_2 = 0$, then

$$\Phi_1(\zeta, \alpha)|_{\tau_1=\tau_2=0} = \begin{pmatrix} -\xi_2 + P_1(0, \eta_2, \alpha) \\ Q_1(0, \eta_2, \alpha) \end{pmatrix}. \tag{5.39}$$

Moreover, (5.11) and (5.35) are equivalent. Thus, (5.13) and (5.35) imply (5.37). To prove (5.38), we first conclude from (5.22) that

$$\det\left[M_{1\alpha}, \begin{pmatrix} P_{1\alpha} \\ Q_{1\alpha} \end{pmatrix}\right] = (-1)^{mn-1} \det\left[\frac{\partial Q_{1\alpha}}{\partial \eta}\right] Q_{1\alpha}^{(1)}. \tag{5.40}$$

Since $(0, a_\alpha) \in W_1^u(\alpha)$, $\pi_{12}(0, a_\alpha, \alpha) = (P_{1\alpha}, Q_{1\alpha}) \in W_1^u(\alpha)$. Hence, (5.24) and (2.11) with $M_1^u(\alpha) = \{\pi_{12}(0, \eta, \alpha) \,|\, |\eta| \ll 1\} \subset \Sigma_2^s$ and $M_2^s(\alpha) = \{(x, 0) \,|\, |x| \ll 1\} \subset \Sigma_2^s$, imply that

$$0 \leqq d_1(\alpha_1, \alpha_2) \leqq \inf_{z \in M_2^s(\alpha)} |(P_{1\alpha}, Q_{1\alpha}) - z| \leqq |Q_{1\alpha}^{(1)}|. \tag{5.41}$$

Moreover, by (H5)

$$0 < d_1(0, \alpha_2) \quad \text{for } \alpha_2 \neq 0. \tag{5.42}$$

This and (5.41) imply $Q_{1\alpha}^{(1)}$ at $\alpha = (0, \alpha_2)$ with $\alpha_2 \neq 0$ being nonzero. Suppose, $Q_{1\alpha}^{(1)} > 0$ for $\alpha = (0, \alpha_2)$, $\alpha_2 > 0$. Then, we conclude from the transverse crossing hypothesis (H6) and (5.41) that

$$0 < \lim_{\alpha_2 \to 0^+} \frac{d_1(0, \alpha_2)}{\alpha_2} \leqq \lim_{\alpha_2 \to 0^+} \frac{Q_{1\alpha}^{(1)}}{\alpha_2}, \qquad \alpha = (0, \alpha_2). \tag{5.43}$$

Since (5.37), (5.40), and (5.27) also imply $Q_{1\alpha}^{(1)} = 0$ when $\alpha = (0, \alpha_2)$, it follows that

$$\lim_{\alpha_2 \to 0^+} \frac{Q_{1\alpha}^{(1)}}{\alpha_2} = \frac{\partial Q_{1\alpha}^{(1)}}{\partial \alpha_2}\bigg|_{\alpha=0}, \qquad \alpha = (0, \alpha_2). \tag{5.44}$$

Now, it is easy to see that (5.38) follows from the quotient rule of differentiation, (5.40), (5.43), and (5.44). □

Now, from Proposition 5.1 and (5.35) we have the following lemma.

LEMMA 5.2. *Suppose hypotheses* (H1)-(H8) *are satisfied. Then there exist a* C^1 *function* $c_2 = c_2(\alpha_1, \alpha_2)$ *satisfying* (5.37) *and a* C^1 *function* $r_2 = r_2(\tau_1, \xi_1, \tau_2, \eta_2, \alpha)$ *satisfying*

$$|r_2| = O(|\eta_2||\tau_2| + |\tau_1|^{1+\nu} + |\tau_2|^{1+\nu}) \tag{5.45}$$

with $\nu > 0$ *such that* (5.11) *has a solution* $\zeta = (\tau_1, \xi_1, \eta_1, \tau_2, \xi_2, \eta_2)$ *with* $|\zeta| \ll 1$ *and* $|\alpha| \ll 1$ *if and only if*

$$\tau_2 = c_2(\alpha_1, \alpha_2) + r_2(\tau_1, \xi_1, \tau_2, \eta_2, \alpha). \tag{5.46}$$

Note that by applying Lemma 5.2 to equation $\Phi_2(\zeta, \alpha) = 0$, there also exist C^1 functions $c_1 = c_1(\alpha_1, \alpha_2)$ and $r_1 = r_1(\tau_2, \xi_2, \tau_1, \eta_1, \alpha)$ such that equation $\Phi_2(\zeta, \alpha) = 0$ is equivalent to

$$\tau_1 = c_1(\alpha_1, \alpha_2) + r_1(\tau_2, \xi_2, \tau_1, \eta_1, \alpha). \tag{5.47}$$

In particular, by the proof of Theorem 4.2, if $\zeta^*(\alpha) = (\tau_1^*, \xi_1^*, \eta_1^*, \tau_2^*, \xi_2^*, \eta_2^*)(\alpha)$ solves (5.1), it must also satisfy (5.46) and (5.47) by Lemma 5.2. That is,

$$\begin{aligned} \tau_1^* &= c_1(\alpha_1, \alpha_2) + r_1(\tau_1^*, \xi_1^*, \tau_2^*, \eta_2^*, \alpha) \\ \tau_2^* &= c_2(\alpha_1, \alpha_2) + r_2(\tau_2^*, \xi_2^*, \tau_1^*, \eta_1^*, \alpha). \end{aligned} \tag{5.48}$$

These equations are considered as *bifurcation equations* for (5.1). Now, we can easily derive the following from (5.48).

Proof of Theorem 2.1. Without loss of generality, let $V \subset \mathbb{R}^2$ be the same as in Theorem 4.2. Since $|\zeta^*(\alpha)| = O(|\alpha|)$, (5.45) and (5.48) imply that

$$\tau_1^* = c_1(\alpha_1, \alpha_2) + O(|\alpha|^{1+\nu}), \qquad \tau_2^* = c_2(\alpha_1, \alpha_2) + O(|\alpha|^{1+\nu}). \tag{5.49}$$

In addition, (5.37) and (5.38) imply that the change of parameters

$$\varepsilon = c(\alpha) = (c_1(\alpha_1, \alpha_2), c_2(\alpha_1, \alpha_2)) \tag{5.50}$$

is nonsingular in V and satisfies (2.14) of Therorem 2.1. This and (5.49) imply that

$$\frac{\partial(\tau_1^*, \tau_2^*)}{\partial(\varepsilon_1, \varepsilon_2)}\bigg|_{\varepsilon=0} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}. \tag{5.51}$$

That is the map $h: \varepsilon \to (\tau_1^*, \tau_2^*)$, which is a local diffeomorphism. Thus $\bar{\Lambda}$ in (5.5) and (5.6) is now given as $h^{-1}(\{\tau_1^* \geqq 0, \tau_2^* \geqq 0\})$. In particular, the boundary $h^{-1}(\{\tau_1^* = 0, \tau_2^* > 0\})$ of $\bar{\Lambda}$ corresponds to a unique homoclinic orbit to a_1 and is given as follows:

$$0 = \varepsilon_1 + O(|\varepsilon|^{1+\nu})$$

by (5.49). It is obvious that this boundary curve, corresponding to $\mathscr{C}_1$ in our theorem, and (2.15) and (2.16) follow immediately. The interior of $\bar{\Lambda}$ yields (2.17). This completes the proof. □

6. Application. Consider the FitzHugh-Nagumo equations

$$u_t = u_{xx} + f(u) - w, \qquad w_t = \varepsilon(u - \gamma w). \tag{6.1}$$

We refer the readers to [4], [7], [10], and [13] for more details on these equations. In (6.1) ε and γ are positive constants with $0 < \varepsilon \ll 1$. For $f(u)$, we take

$$f(u) = u(1-u)(u-a), \qquad 0 < a < \tfrac{1}{2}.$$

A traveling wave solution of (6.1) is a bounded, nonconstant solution of the form

$$(u(x, t), w(x, t)) = (U(z), W(z)), \qquad z = x + \theta t, \quad \theta = \text{constant}. \tag{6.2}$$

By substituting (6.2) into (6.1), (U, W) satisfies the following system of ordinary differential equations:

$$U' = V, \quad V' = \theta V - f(U) + W, \quad W' = \varepsilon(U - \gamma W)/\theta. \tag{6.3}$$

If γ is large enough, then there exist three rest points as shown in Fig. 6.1.

In what follows we let $\varphi = (\mathscr{E}_1, \mathscr{E}_2)$ be the point of intersection shown in Fig. 6.1, and $\mathscr{E} = (\mathscr{E}_1, 0, \mathscr{E}_2)$ the corresponding rest point of (6.3). We take $\mathscr{O} = (0, 0, 0)$ as another rest point.

By a pulse we mean a solution $\Gamma_{\mathscr{O}} = \Gamma_{\mathscr{O}}(z)$ of (6.3) that satisfies

$$\lim_{|z| \to +\infty} \Gamma_{\mathscr{O}}(z) = \mathscr{O}.$$

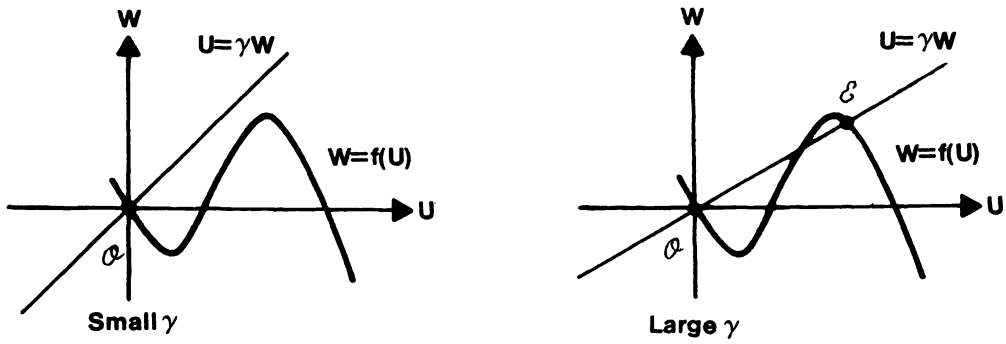

FIG. 6.1

By an $\mathscr{E}$-pulse $\Gamma_{\mathscr{E}}$ we mean a solution that satisfies

$$\lim_{|z|\to+\infty} \Gamma_{\mathscr{E}}(z) = \mathscr{E}.$$

By a front wave Γ_F we mean a solution that satisfies

$$\lim_{z\to+\infty} \Gamma_F(z) = \mathscr{E} \quad \text{and} \quad \lim_{z\to-\infty} \Gamma_F(z) = \mathscr{O}.$$

By a back wave Γ_B we mean a solution that satisfies

$$\lim_{z\to+\infty} \Gamma_B(z) = \mathscr{O} \quad \text{and} \quad \lim_{z\to-\infty} \Gamma_B(z) = \mathscr{E}.$$

Throughout this discussion we assume that $0 < \varepsilon \ll 1$. The relevant parameters are then γ and the wave speed θ. It has been shown (see [1], [10]) that there exist constants $0 < \gamma_1 < \gamma_2 < \gamma_3$ such that we have the following:

(1) If $\gamma_1 < \gamma$ and $0 < \varepsilon \ll 1$, then a front wave Γ_F exists for some θ, say $\theta_F(\gamma)$.

(2) If $\gamma_1 < \gamma < \gamma_3$ and $0 < \varepsilon \ll 1$, then a back wave Γ_B exists for some θ, say $\theta_B(\gamma)$.

(3) In the limit $\varepsilon \to 0$, the graphs of these differentiable functions $\theta_F(\gamma)$ and $\theta_B(\gamma)$ are approximately shown in Fig. 6.2.

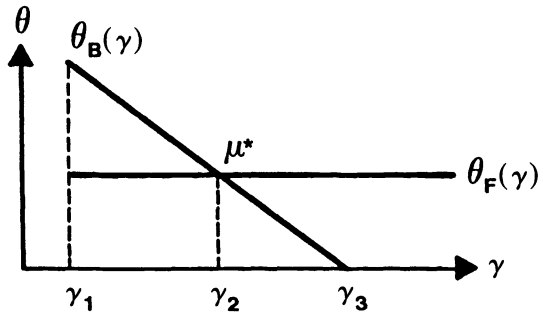

FIG. 6.2

These two curves cross precisely at $\gamma = \gamma_2$, in the limit $\varepsilon \to 0$. For ε small, but not zero, the curves $\theta_B(\gamma)$ and $\theta_F(\gamma)$ have the same qualitative features as shown in Fig. 6.2. For γ close to γ_1, $\theta_B(\gamma) > \theta_F(\gamma)$, while for γ close to γ_3, $\theta_B(\gamma) < \theta_F(\gamma)$. Hence there must exist $\mu^* = (\gamma^*(\varepsilon), \theta^*(\varepsilon))$ where the two curves cross.

It is not difficult to show that when $0 < \varepsilon \ll 1$, the linearizations of (5.3) at $\mathscr{O}$ and $\mathscr{E}$ have two negative eigenvalues and one positive eigenvalue. One of the negative eigenvalues is zero in the limit $\varepsilon \to 0$ while the other two stay uniformly away from zero as $\varepsilon \to 0$. Thus, (H1)-(H3) are satisfied only for the time-reverse system of (6.3). Hypothesis (H4) follows easily from (1)-(3) above. Hypothesis (H5) is always true for systems in $\mathbb{R}^3$. As mentioned earlier (H6)-(H8) are generic (see Fig. 6.3). We can verify these conditions do hold for (6.3) using the singular perturbation description of the wave (see [1] and [10]). Thus, Theorem 2.1 is applicable for the time-reverse system of (6.3).

Let $\theta_{\mathscr{O}}$ and $\theta_{\mathscr{E}}$ denote the pulse and ε-pulse curves in parameter space. Then, by Theorem 2.1 there are four possibilities for the location of the sector Λ that corresponds to the periodic orbits. However, Λ is determined by the following results taken from [1] and [10] together with the relative positions of θ_F, θ_B, $\theta_{\mathscr{O}}$, and $\theta_{\mathscr{E}}$ of Theorem 2.1:

(1) The front speed exceeds the pulse speed for the same γ;

(2) When both a front and back exist, a pulse exists only if the back speed exceeds the front speed. The corresponding statements also hold for ε-pulses (see Fig. 6.4).

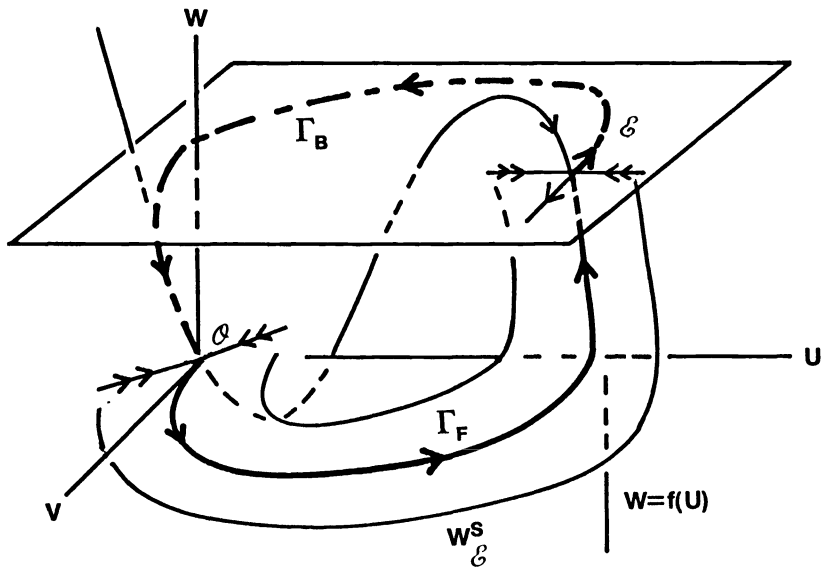

FIG. 6.3

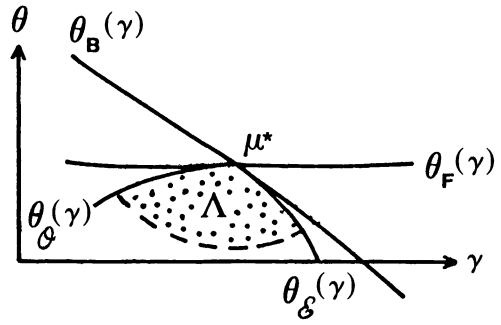

FIG. 6.4

The important consequence of this result is that for γ near γ_2 there exist infinitely many periodic waves traveling at speeds always exceeded by the pulse speed. This result is also contained in [1].

LIPSCHITZ CONTINUOUS METRIC SELECTIONS IN $C_0(T)$*

WU LI†

Abstract. This paper gives an intrinsic characterization of those finite-dimensional subspaces G of $C_0(T)$ whose metric projections P_G have Lipschitz continuous selections. It is also proved that P_G has a Lipschitz continuous selection if and only if P_G is Lipschitz continuous.

Key words. Lipschitz continuity of metric projection, Lipschitz continuous selection of metric projection, Hausdorff strong unicity, extremal signature

AMS(MOS) subject classifications. 41A50, 41A65

1. Introduction. The problems concerning the existence of various continuous metric selections have received much attention in recent years. The existence of continuous metric selections is essential for finding stable algorithms to compute best approximations (cf. [24], [30]-[32]). Also, the existence of Lipschitz continuous metric selections and continuous metric selections will help us to determine the proximinality of certain tensor product subspaces in multivariate approximation (cf. [18] and "Sitting Duck Theorem" in [5], [19]). For finite-dimensional subspaces G of $C_0(T)$, the behavior of the metric projections P_G has been deeply investigated (cf. [8] and [23] for surveys). Nürnberger, Sommer, and Li (cf. [15], [17], [23], [8]) found several intrinsic characterizations of the existence of continuous selections for P_G. It was proved in [12] and [14], by Fischer and Li independently, that the almost lower semicontinuity of P_G is equivalent to the existence of a continuous selection for P_G. In [16], Li gives an intrinsic characterization of the lower semicontinuity of P_G. In [20], Lin generalizes a result by Deutsch [7] and establishes an intrinsic characterization of the existence of linear selections for P_G. Thus, as far as the various continuities of P_G are concerned, there is still one interesting question remaining: What are intrinsic characterizations of those G whose metric projections P_G have Lipschitz continuous selections (or whose P_G are Lipschitz continuous)?

In this paper, we will give the question above a complete answer. Before we go into detail, we introduce some notation.

Let T be a locally compact Hausdorff space and let $C_0(T)$ be the Banach space of real-valued continuous functions f on T that vanish at infinity, i.e., for any $\varepsilon > 0$, the set $\{t \in T: |f(t)| \geqq \varepsilon\}$ is compact. The norm of $f \in C_0(T)$ is defined as follows:

$$\|f\| = \sup\{|f(t)|: t \in T\}.$$

For $G \subset C_0(T)$, the metric projection from $C_0(T)$ to G is defined as

$$P_G(f) = \{g \in G: \|f - g\| = d(f, G)\},$$

where

$$d(f, G) = \inf\{\|f - p\|: p \in G\}.$$

Recall [13] that P_G is called Hausdorff strongly unique at $f \in C_0(T)$ if there is a constant $\lambda(f) > 0$ such that

$$\|f - g\| \geqq d(f, G) + \lambda(f) \cdot d(g, P_G(f)), \qquad g \in G.$$

* Received by the editors October 14, 1987; accepted for publication (in revised form) October 24, 1988.
† Department of Mathematics, Pennsylvania State University, University Park, Pennsylvania 16802.

P_G is said to be uniform Hausdorff strongly unique if there is a constant $\lambda > 0$ such that

$$\|f-g\| \geqq d(f, G)+\lambda \cdot d(g, P_G(f)), \quad f \in C_0(T), \quad g \in G.$$

Remember that P_G is called Lipschitz continuous if there is a constant $\lambda > 0$ such that

$$H(P_G(f), P_G(h)) \leqq \lambda \cdot \|f-h\|, \qquad f, h \in C_0(T),$$

where

$$H(P_G(f), P_G(h)) = \max \{\sup \{d(g, P_G(f)): g \in P_G(h)\},$$
$$\sup \{d(p, P_G(h)): p \in P_G(f)\}\}.$$

We say that P_G has a Lipschitz continuous selection if there exists a Lipschitz continuous mapping Q from $C_0(T)$ to G such that $Q(f) \in P_G(f)$ for each $f \in C_0(T)$.

Now we can state our main results.

THEOREM 1.1. *Suppose that G is a finite-dimensional subspace of $C_0(T)$. Then the following are mutually equivalent:*

(i) *P_G is uniform Hausdorff strongly unique;*

(ii) *P_G is Lipschitz continuous;*

(iii) *P_G has a Lipschitz continuous selection;*

(iv) *$T \backslash Z(g)$ is compact for every $g \in G$, where $Z(g) = \{t \in T: g(t) = 0\}$.*

COROLLARY 1.2. *Suppose $c_0 = C_0(\mathbb{N})$ and G is a finite-dimensional subspace of c_0. Then the following are mutually equivalent:*

(1) *P_G is uniformly Hausdorff strongly unique;*

(2) *P_G is Lipschitz continuous;*

(3) *P_G has a Lipschitz continuous selection;*

(4) *There is $n \geqq 1$ such that $g(i) = 0$, $i \geqq n$, $g \in G$.*

Remark 1.3. Cline [6] knew that, for a compact T with finite points and a Haar subspace G of $C(T)$, P_G is Lipschitz continuous (cf. also [1]). Cline [6] also proved that for a compact T with infinite points and a Haar subspace G of $C(T)$, P_G is Lipschitz continuous only if $\dim G = 1$. The converse was proved by Berdyshev [2] (cf. also [28]). Respess and Cheney [28] extended Cline's result and proved that P_G has a Lipschitz continuous selection only if $\dim G = 1$, provided that G has Haar property at a neighborhood of a cluster point of T. We can easily derive these results by using Theorem 1.1. When T is compact, Berdyshev [2] also has some characterizations of P_G being Lipschitz continuous.

Remark 1.4. In general, there are one-dimensional subspaces of $C_0(T)$ for which the metric projections P_G have no continuous selections [3]. But for any finite-dimensional subspace G of c_0, P_G is lower semicontinuous (lsc) (cf. [4] or [16]). However, Corollary 1.2 implies that, in general, the lower semicontinuity of P_G is not equivalent to the Lipschitz continuity of P_G. Also, Corollary 1.2 implies that there is a one-dimensional subspace G of c_0 such that P_G is lsc but P_G has no Lipschitz continuous selection. It is interesting to note that metric projections in $L_1(T, \mu)$ have quite different features. Contrary to the phenomena mentioned above, for any one-dimensional subspace G of $L_1(T, \mu)$, P_G is lsc if and only if P_G is Lipschitz continuous and P_G has a continuous selection if and only if P_G has a Lipschitz continuous selection [9].

Remark 1.5. The idea of Hausdorff strong uniqueness is introduced in [13] to characterize the lower semicontinuity of P_G and is a natural generalization of the strong uniqueness of best approximations in $C_0(T)$ introduced by Newman and Shapiro [21]. However, it is interesting to note that the uniform Hausdorff strong uniqueness

may also be considered as a natural generalization of the $1\frac{1}{2}$-ball property introduced by Yost [33], since G has the $1\frac{1}{2}$-ball property if and only if [11]

$$\|f-g\| = d(f, G)+d(g, P_G(f)) \quad \text{for any } f\in C_0(T), \quad g\in G.$$

Some results in [33] have been generalized by Park [25] to the case that P_G is uniform Hausdorff strongly unique. Also, Park [25], [26] gives an example of a one-dimensional subspace G of $C[a, b]$ such that P_G is uniform Hausdorff strongly unique but G does not have the $1\frac{1}{2}$-ball property.

Remark 1.6. That (i) implies (ii) in Theorem 1.1 is the special case of Park's results [25] or [26]. By using the Steiner point, we can show that if P_G is Lipschitz continuous, then P_G has a Lipschitz continuous selection (cf. [10], [27]). Thus (ii) implies (iii).

Since a subset A of $\mathbb{N}$ is compact if and only if A is a finite subset of $\mathbb{N}$, Corollary 1.2 follows immediately from Theorem 1.1. By Remark 1.6, we need to show only that (iii) implies (ii), which in turn implies (i). In § 2 we give some properties of extremal signatures of G that will play an important role in this paper. In § 3 we show that (iii) implies (iv). In § 4 we study the structure of G that satisfies (iv). In § 5 we prove that (iv) implies (i).

2. Extremal signatures. A signature σ on T is a mapping from T to $\{-1, 0, 1\}$ such that $\{t\in T: \sigma(t)\neq 0\} =: \operatorname{supp}\sigma$ is a nonempty finite set. Extremal signatures were introduced by Rivlin and Shapiro [29] to characterize elements in $P_G(f)$. For an equivalent definition of extremal signatures see [17], [29].

DEFINITION 2.1. An extremal signature σ of G is a signature on T such that if $g\in G$ satisfies $\sigma(t)g(t)\geqq 0$, for $t\in\operatorname{supp}\sigma$, then $\operatorname{supp}\sigma\subset Z(g)$. A primitive extremal signature σ of G is an extremal signature of G such that

$$\dim G|_{\operatorname{supp}\sigma} = \dim G|_{\operatorname{supp}\sigma\setminus\{t\}} = \operatorname{card}(\operatorname{supp}\sigma)-1 \quad \text{for } t\in\operatorname{supp}\sigma.$$

Now we list some properties of extremal signatures of G that will be used in this paper.

LEMMA 2.2 (Rivlin and Shapiro [29]). *Suppose $f\in C_0(T)\setminus G$ and $g\in G$. Then $g\in P_G(f)$ if and only if there is a primitive extremal signature σ of G such that*

$$f(t)-g(t) = \sigma(t)\|f-g\| \quad \text{for } t\in\operatorname{supp}\sigma.$$

LEMMA 2.3. *Suppose that σ is an extremal signature of G. Then $P_{G|_{\operatorname{supp}\sigma}}(\sigma|_{\operatorname{supp}\sigma}) = \{0\}$ and there is a constant $\lambda(\sigma)>0$ such that*

$$\max\{\sigma(t)g(t): t\in\operatorname{supp}\sigma\}\geqq\lambda(\sigma)\cdot\max\{|g(t)|: t\in\operatorname{supp}\sigma\} \quad \text{for } g\in G.$$

LEMMA 2.4. *Suppose $B\subset T$. Then $\operatorname{card}(B)>\dim G|_B$ if and only if there is an extremal signature σ with $\operatorname{supp}\sigma\subset B$, where $\operatorname{card}(B)$ denotes the cardinal number of the set B.*

LEMMA 2.5. *If σ_1 is an extremal signature of G and σ_2 is an extremal signature of $G(\operatorname{supp}\sigma_1) := \{g\in G: \operatorname{supp}\sigma_1\subset Z(g)\}$, then*

$$\sigma(t) = \begin{cases}\sigma_1(t), & t\in\operatorname{supp}\sigma_1,\\ \sigma_2(t), & t\in T\setminus\operatorname{supp}\sigma_1,\end{cases}$$

is an extremal signature of G.

Lemmas 2.3–2.5 are results in § 2 of [17]. By Lemmas 2.4 and 2.5 we can establish the following auxiliary lemma, which will be used in the proof that (iii) implies (iv) in Theorem 1.1.

LEMMA 2.6. *Suppose* $B \subset T$ *and* $\operatorname{card}(B) > \dim G|_B$. *Then there is an extremal signature* σ *of* G *such that* $\operatorname{supp}\sigma \subset B$ *and*

$$\dim G(\operatorname{supp}\sigma)|_B = \operatorname{card}(B\backslash Z(G(\operatorname{supp}\sigma))),$$

where $G(\operatorname{supp}\sigma) = \{g \in G: \operatorname{supp}\sigma \subset Z(g)\}$.

Proof. We prove this lemma by induction on $\dim G$. Assume that Lemma 2.6 is true if $\dim G \leqq s$, where $s \geqq 0$. Now suppose $\dim G = s+1$. If $\dim G|_B = \operatorname{card}(B\backslash Z(G))$, then there is $t_0 \in B \cap Z(G)$, since $\dim G|_B < \operatorname{card}(B)$. Obviously,

$$\sigma(t) = \begin{cases} 1, & t = t_0, \\ 0, & t \in T\backslash\{t_0\} \end{cases}$$

is an extremal signature of G and

$$\begin{aligned} \dim G(\operatorname{supp}\sigma)|_B &= \dim G(t_0)|_B = \dim G|_B \\ &= \operatorname{card}(B\backslash Z(G)) = \operatorname{card}(B\backslash Z(G(\operatorname{supp}\sigma))), \end{aligned}$$

since $G(\operatorname{supp}\sigma) = G$. Thus, without loss of generality, we may assume

$$\dim G|_B \neq \operatorname{card}(B\backslash Z(G)). \tag{2.1}$$

Since $\dim G|_B = \dim G|_{B\backslash Z(G)} \leqq \operatorname{card}(B\backslash Z(G))$, (2.1) implies

$$\dim G|_{B\backslash Z(G)} < \operatorname{card}(B\backslash Z(B)). \tag{2.2}$$

By Lemma 2.4, there is an extremal signature σ_1 of G with $\operatorname{supp}\sigma_1 \subset B\backslash Z(G)$. Set $G^* = G(\operatorname{supp}\sigma_1)$. Then $\dim G^* \leqq \dim G - 1 \leqq s$. Since $\dim G^*|_B \leqq \dim G|_B < \operatorname{card}(B)$, by the inductive hypothesis, there is an extremal signature σ_2 of G^* such that

$$\operatorname{supp}\sigma_2 \subset B, \qquad \dim G^*(\operatorname{supp}\sigma_2)|_B = \operatorname{card}(B\backslash Z(G^*(\operatorname{supp}\sigma_2))).$$

Define

$$\sigma(t) = \begin{cases} \sigma_1(t), & t \in \operatorname{supp}\sigma_1, \\ \sigma_2(t), & t \in T\backslash\operatorname{supp}\sigma_1. \end{cases}$$

By Lemma 2.5, σ is an extremal signature of G. Since

$$\operatorname{supp}\sigma = \operatorname{supp}\sigma_1 \cup \operatorname{supp}\sigma_2,$$

we obtain that

$$\operatorname{supp}\sigma \subset B, \tag{2.3}$$

$$\begin{aligned} \dim G(\operatorname{supp}\sigma)|_B &= \dim G^*(\operatorname{supp}\sigma_2)|_B \\ &= \operatorname{card}(B\backslash Z(G^*(\operatorname{supp}\sigma_2))) = \operatorname{card}(B\backslash Z(G(\operatorname{supp}\sigma))). \end{aligned} \tag{2.4}$$

Formulae (2.3) and (2.4) show that σ is the required extremal signature of G.

3. Proof of (iii) implying (iv). Suppose that P_G has a Lipschitz continuous selection Q. If (iv) in Theorem 1.1 fails to be true, then there is $g^* \in G$ such that $\operatorname{supp}(g^*) = T\backslash Z(g^*)$ is not compact. Set

$$T_k = \{t \in T: 0 < |g^*(t)| < 1/k\}, \qquad k \geqq 1.$$

If for some k, T_k is a finite set, then

$$\operatorname{supp}(g^*) = \{t \in T: |g^*(t)| \geqq \varepsilon\}, \tag{3.1}$$

where

$$\varepsilon = \min\{|g^*(t)|: t \in T_k\} > 0. \tag{3.2}$$

Formulae (3.1) and (3.2) imply that supp (g^*) is compact. This contradicts our assumption that supp (g^*) is not compact. Thus, for each $k \geqq 1$, T_k is an infinite set. Since $T_k \supset T_{k+1}$, $k \geqq 1$, we have

$$0 \leqq \dim G|_{T_{k+1}} \leqq \dim G|_{T_k} \leqq \dim G < +\infty, \qquad k \geqq 1,$$

i.e., $\{\dim G|_{T_k}\}_{k=1}^{\infty}$ is a bounded decreasing sequence. So, there is $r \geqq 0$ such that

$$\lim_{k\to\infty} \dim G|_{T_k} = r. \tag{3.3}$$

Since $\dim G|_{T_k}$ are integers, (3.3) implies that there is $N > 0$ such that

$$\dim G|_{T_k} = \dim G|_{T_N} = r, \qquad k \geqq N. \tag{3.4}$$

It follows from (3.4) that

$$\begin{aligned} \dim G(T_k) &= \dim G - \dim G|_{T_k} \\ &= \dim G - \dim G|_{T_N} = \dim G(T_N), \qquad k \geqq N, \end{aligned} \tag{3.5}$$

where $G(T_k) = \{g \in G\colon T_k \subset Z(g)\}$. By (3.5) and $G(T_k) \supset G(T_N)$ for $k \geqq N$, we obtain

$$G(T_k) = G(T_N), \qquad k \geqq N. \tag{3.6}$$

For each $k \geqq N$, since T_k is an infinite set, by Lemma 2.6 there is an extremal signature σ_k of G such that

$$\operatorname{supp} \sigma_k \subset T_k, \tag{3.7}$$

$$\operatorname{card}(T_k \backslash Z(G_k)) \leqq \dim G_k \leqq \dim G < +\infty, \tag{3.8}$$

where

$$G_k = \{g \in G\colon \operatorname{supp} \sigma_k \subset Z(g)\}. \tag{3.9}$$

It follows from (3.7) and (3.9) that

$$G_k \supset G(T_N), \qquad k \geqq N. \tag{3.10}$$

Set

$$\varepsilon_k = \min\{|g^*(t)|\colon t \in T_k \backslash Z(G_k)\}. \tag{3.11}$$

By (3.8), $\varepsilon_k > 0$. By (3.11) and the definition of T_k, we obtain

$$T_n \cap (T_k \backslash Z(G_k)) = \varnothing, \quad n > 1/\varepsilon_k, \quad n \geqq k,$$

i.e.,

$$T_n \subset Z(G_k), \quad n > 1/\varepsilon_k, \quad n \geqq k. \tag{3.12}$$

Formula (3.12) implies

$$G(T_n) \supset G_k, \quad n > 1/\varepsilon_k, \quad n \geqq k. \tag{3.13}$$

It follows from (3.6), (3.10), and (3.13) that

$$G_k = G(T_N), \qquad k \geqq N. \tag{3.14}$$

Since supp σ_k is a finite set and T_k is open, there are open sets W_k and V_k such that

$$\operatorname{supp} \sigma_k \subset V_k \subset \bar{V}_k \subset W_k \subset \bar{W}_k \subset T_k, \qquad \bar{W}_k \text{ is compact,}$$

where $\bar{A}$ denotes the closure of set A. Now, by using Tietze's extension theorem, we can construct f_k, $h_k \in C_0(T)$ such that

$$
\begin{aligned}
&f_k(t) = \sigma_k(t), \qquad t \in \operatorname{supp} \sigma_k,\\
&\|f_k\| = 1,\\
&f_k(t) = 0, \qquad t \in T \setminus V_k;\\
&h_k(t) = g^*(t), \qquad t \in \bar{V}_k,\\
&\|h_k\| = \max\{|g^*(t)|: t \in \bar{V}_k\} < 1/k,\\
&h_k(t) = 0, \qquad t \in T \setminus W_k.
\end{aligned}
$$

Let $0 < \alpha < \min\{\frac{1}{2}, \frac{1}{2}\|g^*\|\}$. Then

$$
\begin{aligned}
1 &= \max\{|f_k(t)|: t \in \operatorname{supp} \sigma_k\}\\
&= \max\{|f_k(t) + \alpha h_k(t) - \alpha g^*(t)|: t \in \operatorname{supp} \sigma_k\}\\
&\leqq \|f_k + \alpha h_k - \alpha g^*\|\\
&\leqq \max\{\max\{|f_k(t)|: t \in \bar{V}_k\}, \max\{\alpha |h_k(t) - g^*(t)|: t \in \bar{W}_k\}\}\\
&\leqq \max\{1, \alpha(\|h_k\| + \|g^*\|)\}\\
&\leqq \max\{1, \alpha(1/k + \|g^*\|)\} \leqq 1, \qquad k \geqq N,
\end{aligned}
$$

i.e.,

$$
\|f_k + \alpha h_k - \alpha g^*\| = 1. \tag{3.15}
$$

By (3.15) and the construction of f_k, h_k, we get

$$
\begin{aligned}
&f_k(t) = \sigma_k(t) = \sigma_k(t)\|f_k\| \quad \text{for } t \in \operatorname{supp} \sigma_k,\\
&f_k(t) + \alpha h_k(t) - \alpha g^*(t) = \sigma_k(t) = \sigma_k(t)\|f_k - \alpha h_k - \alpha g^*\| \quad \text{for } t \in \operatorname{supp} \sigma_k.
\end{aligned}
$$

If $g \in P_G(f_k)$, then

$$
|\sigma_k(t) - g(t)| = |f_k(t) - g(t)| \leqq \|f_k\| = 1 \quad \text{for } t \in \operatorname{supp} \sigma_k.
$$

By Lemma 2.3, $g|_{\operatorname{supp}\sigma_k} \in P_{G|_{\operatorname{supp}\sigma k}}(\sigma|_{\operatorname{supp}\sigma_k})$ and $g(t) = 0$ for $t \in \operatorname{supp} \sigma_k$, i.e.,

$$
P_G(f_k) \subset G_k, \qquad k \geqq N. \tag{3.16}
$$

Similarly, we can obtain

$$
P_G(f_k + \alpha h_k) - \alpha g^* = P_G(f_k + \alpha h_k - \alpha g^*) \subset G_k, \qquad k \geqq N. \tag{3.17}
$$

Thus, by (3.14), for the Lipschitz continuous selection Q of P_G, we have

$$
\begin{aligned}
&Q(f_k) \in G(T_N), \qquad k \geqq N,\\
&Q(f_k + \alpha h_k) - \alpha g^* \in G(T_N), \qquad k \geqq N.
\end{aligned}
$$

So, for $k \geqq N$,

$$
\begin{aligned}
\alpha \cdot \max\{|g^*(t)|: t \in T_N\} &= \max\{|Q(f_k, t) - Q(f_k + \alpha h_k, t)|: t \in T_N\}\\
&\leqq \|Q(f_k) - Q(f_k + \alpha h_k)\| \leqq \lambda \cdot \|f_k - f_k - \alpha h_k\| \qquad (3.18)\\
&= \lambda \cdot \alpha \cdot \|h_k\| < \lambda \cdot \alpha / k,
\end{aligned}
$$

where $\lambda > 0$ is the constant in the definition of Lipschitz continuity of Q. It follows from (3.18) that

$$0 < \max\{|g^*(t)|: t \in T_N\} < \lambda/k, \qquad k \geqq N,$$

which is impossible. The contradiction shows that (iii) implies (iv) in Theorem 1.1.

4. An equivalent form of (iv). We first assume that G satisfies (iv) in Theorem 1.1. Set

$$\operatorname{supp}(G) = \{t \in T: g(t) \neq 0 \text{ for some } g \in G\}.$$

We define a relation on $\operatorname{supp}(G)$ as follows:

$$x \sim y \quad \text{iff } \dim G|_{\{x,y\}} = 1,$$

where $x, y \in \operatorname{supp}(G)$. Then it is easy to check that "$\sim$" is an equivalence relation on $\operatorname{supp}(G)$. Let

$$\mathscr{X} = \{[x]: x \in \operatorname{supp}(G)\},$$

where $[x]$ denotes the equivalence class of x.

LEMMA 4.1. $\operatorname{supp}(G)$ *is compact and open.*

Proof. Suppose $G = \operatorname{span}\{g_i\}_1^r$. Then

$$\operatorname{supp}(G) = \bigcup_{i=1}^{r} \operatorname{supp}(g_i),$$

where $\operatorname{supp}(g_i) = \{t \in T: g_i(t) \neq 0\}$. By the continuity of g_i, $\operatorname{supp}(g_i)$ is open; by (iv) and $\operatorname{supp}(g_i) = T \backslash Z(g_i)$, $\operatorname{supp}(g_i)$ is compact. Thus, $\operatorname{supp}(G)$ is open and compact.

LEMMA 4.2. $[x]$ *is open and compact for each* $x \in \operatorname{supp}(G)$.

Proof. Let $\{g_i\}_1^s \subset G$ such that

$$\operatorname{span}\{g_i\}_1^s = \{g \in G: g(x) = 0\} =: G(x).$$

Since $y \in Z(G(x)) \cap \operatorname{supp}(G)$ if and only if $y \in \operatorname{supp}(G)$ and $\dim G|_{\{x,y\}} = 1$, where $Z(G(x)) = T \backslash \operatorname{supp}(G(x))$, we obtain

$$[x] = \operatorname{supp}(G) \cap Z(G(x)). \tag{4.1}$$

Since $Z(G(x)) = \{t \in T: g(t) = 0 \text{ for all } g \in G(x)\}$ is closed, $[x]$ is a closed subset of the compact set $\operatorname{supp}(G)$. So, $[x]$ is compact. On the other hand, by (iv), $Z(g_i) = T \backslash \operatorname{supp}(g_i)$ is open for each $1 \leqq i \leqq s$, so $Z(G(x)) = Z(\operatorname{span}\{g_i\}_1^s) = \bigcap_{i=1}^s Z(g_i)$ is open. By Lemma 4.1 and (4.1), we have that $[x]$ is open. Thus, $[x]$ is open and compact.

LEMMA 4.3. $\mathscr{X}$ *is a finite set.*

Proof. Assume the contrary, i.e., $\mathscr{X}$ is an infinite set. Then there are $\{x_k\}_1^\infty \subset \operatorname{supp}(G)$ such that

$$[x_i] \neq [x_j], \quad i \neq j, \quad i, j \geqq 1. \tag{4.2}$$

By Lemma 4.1, $\operatorname{supp}(G)$ is compact. Let $x^* \in \operatorname{supp}(G)$ be a cluster point of $\{x_k\}_1^\infty$. Since, by Lemma 4.2, $[x^*]$ is open, we obtain that $[x^*] \cap \{x_k\}_1^\infty$ is an infinite set. Let $i \neq j$, $x_i, x_j \in [x^*]$. Then

$$[x_i] = [x^*] = [x_j],$$

which contradicts (4.2). So, $\mathscr{X}$ is finite.

THEOREM 4.4. *Suppose that G is a finite-dimensional subspace of $C_0(T)$. Then the following are equivalent*:

(a) *$T\backslash Z(g)$ is compact for every $g \in G$;*

(b) *There are open and compact subsets $\{A_i\}_1^n$ such that*

$$\bigcup_{i=1}^{n} A_i = \operatorname{supp}(G), \tag{4.3}$$

and for $1 \leqq i, j \leqq n$,

$$\dim G|_{A_i \cup A_j} = 1 \quad \text{only if } i = j. \tag{4.4}$$

Proof. Part (a) implies (b). By Lemma 4.3, there are $\{x_i\}_1^n \subset \operatorname{supp}(G)$ such that

$$[x_i] \neq [x_j], \quad i \neq j, \quad 1 \leqq i, \quad j \leqq n, \tag{4.5}$$

$$\bigcup_{i=1}^{n} [x_i] = \bigcup_{x \in \operatorname{supp}(G)} [x] = \operatorname{supp}(G). \tag{4.6}$$

But $\dim G|_{[x_i] \cup [x_j]} = 1$ implies $[x_i] = [x_j]$. So, by (4.5), we get

$$\dim G|_{[x_i] \cup [x_j]} = 1 \quad \text{iff } i = j. \tag{4.7}$$

From (4.1) we obtain

$$G(x) = \{g \in G: g|_{[x]} \equiv 0\} =: G([x]), \qquad x \in \operatorname{supp}(G). \tag{4.8}$$

Hence, by (4.8) we get

$$1 = \dim G|_{\{x\}} = \dim G - \dim G(x) = \dim G - \dim G([x]) = \dim G|_{[x]}, \quad x \in \operatorname{supp}(G). \tag{4.9}$$

It follows that

$$\dim G|_{[x_i]} = 1, \qquad 1 \leqq i \leqq n. \tag{4.10}$$

Now, (4.6), (4.7), (4.10), and Lemma 4.2 ensure that (b) holds for $A_i = [x_i]$, $1 \leqq i \leqq n$.

Part (b) implies (a). By (4.4), we know that for any $g \in G$, $Z(g) \cap A_i \neq \varnothing$ implies $A_i \subset Z(g)$. Thus, for any $g \in G$, there is a subset J of $\{i\}_1^n$ such that $T\backslash Z(g) = \bigcup_{i \in J} A_i$ is compact.

5. Proof of (iv) implying (i). To prove that (iv) implies (i), we need several lemmas.

LEMMA 5.1. *For any $B \subset T$, there is a constant $\lambda(B) > 0$ such that*

$$d(g, G(B)) \leqq \lambda(B) \|g\|_B, \qquad g \in G,$$

where $\|g\|_B = \sup\{|g(t)|: t \in B\}$.

Proof. Let $\{g_i\}_1^r \subset G$ be such that $G|_B = \operatorname{span}\{g_i|_B\}_1^r$ and $\{g_i|_B\}_1^r$ is linearly independent. Let

$$G^* = \operatorname{span}\{g_i\}_1^r.$$

Then it is not difficult to check that $\|\cdot\|_B$ and $d(\cdot, G(B))$ are two norms on G^*. Since any two norms on a finite-dimensional space are equivalent, there is a constant $\lambda(B) > 0$ such that

$$d(g^*, G(B)) \leqq \lambda(B) \|g^*\|_B, \qquad g^* \in G^*. \tag{5.1}$$

Now let $g \in G$. Since $G^*|_B = G|_B$, there is $g^* \in G^*$ such that

$$g|_B = g^*|_B, \tag{5.2}$$

i.e.,

$$g - g^* \in G(B). \tag{5.3}$$

By (5.1)-(5.3) we get

$$d(g, G(B)) = d(g^*, G(B)) \leqq \lambda(B)\|g^*\|_B = \lambda(B) \cdot \|g\|_B, \qquad g \in G.$$

LEMMA 5.2. *Suppose $f \in C_0(T)$, $T = B_1 \cup B_2$, $B_1 \subset Z(G)$, and $G^* = G|_{B_2}$. If there is a positive constant α_1 such that*

$$\|f-g\| \geqq d(f|_{B_2}, G^*) + \alpha_1 \cdot d(g|_{B_2}, P_{G^*}(f|_{B_2})), \qquad g \in G, \tag{5.4}$$

then for every $g \in G$,

$$\|f-g\| \geqq d(f, G) + \left(\frac{\alpha_1}{2}\right) \cdot d(g, P_G(f)). \tag{5.5}$$

Proof. Suppose $g \in G$ and

$$\|f-g\| = d(f, G) + \mu. \tag{5.6}$$

If $\mu \leqq 0$, $g \in P_G(f)$ and (5.5) is trivial. So we may assume $\mu > 0$. Let $g^* \in G$ such that $g^*|_{B_2} \in P_{G^*}(f|_{B_2})$ and

$$d(g|_{B_2}, P_{G^*}(f|_{B_2})) = \|g - g^*\|_{B_2}. \tag{5.7}$$

For $0 < \lambda \leqq 1$, we claim

$$\|f - g^* + \lambda(g^* - g)\|_{B_2} \leqq d(f|_{B_2}, G^*) + \lambda \cdot (d(f, G) - d(f|_{B_2}, G^*) + \mu). \tag{5.8}$$

In fact, if (5.8) fails to be true, then there is $t_\lambda \in B_2$ such that

$$|f(t_\lambda) - g^*(t_\lambda) + \lambda(g^*(t_\lambda) - g(t_\lambda))| > d(f|_{B_2}, G^*) + \lambda \cdot \mu^*, \tag{5.9}$$

where

$$\mu^* = d(f, G) - d(f|_{B_2}, G^*) + \mu > 0.$$

Since $|f(t_\lambda) - g^*(t_\lambda)| \leqq d(f|_{B_2}, G^*) < d(f|_{B_2}, G^*) + \lambda \cdot \mu^*$, by (5.9), we obtain

$$|f(t_\lambda) - g^*(t_\lambda) + \lambda(g^*(t_\lambda) - g(t_\lambda))| = \varepsilon_\lambda(f(t_\lambda) - g^*(t_\lambda)) + \lambda|g^*(t_\lambda) - g(t_\lambda)|, \tag{5.10}$$

where $\varepsilon_\lambda = \operatorname{sign}(g^*(t_\lambda) - g(t_\lambda))$. Thus, by (5.9) and (5.10), we have

$$\begin{aligned}
\|f-g\| &\geqq \varepsilon_\lambda(f(t_\lambda) - g(t_\lambda)) \\
&= \varepsilon_\lambda(f(t_\lambda) - g^*(t_\lambda)) + |g^*(t_\lambda) - g(t_\lambda)| \\
&> \varepsilon_\lambda(f(t_\lambda) - g^*(t_\lambda)) + \frac{1}{\lambda} d(f|_{B_2}, G^*) + \lambda\mu^* - \varepsilon_\lambda(f(t_\lambda) - g^*(t_\lambda)) \\
&= \left(1 - \frac{1}{\lambda}\right) \varepsilon_\lambda \cdot (f(t_\lambda) - g^*(t_\lambda)) + \frac{1}{\lambda} d(f|_{B_2}, G^*) + \mu^* \\
&\geqq \left(1 - \frac{1}{\lambda}\right) \|f - g^*\|_{B_2} + \frac{1}{\lambda} d(f|_{B_2}, G^*) + \mu^* \\
&= \left(1 - \frac{1}{\lambda}\right) d(f|_{B_2}, G^*) + \frac{1}{\lambda} d(f|_{B_2}, G^*) + \mu^* \\
&= d(f, G) + \mu,
\end{aligned}$$

which contradicts (5.6). The contradiction shows that our claim (5.8) is true.

Set $\lambda^* = 1 - \mu/\mu^*$. Then, by (5.8), we get

$$\begin{aligned}\|f - g^* + \lambda^*(g^* - g)\| &\leqq d(f|_{B_2}, G^*) + \lambda^* \cdot \mu^* \\ &= d(f|_{B_2}, G^*) + \mu^* - \mu = d(f, G),\end{aligned}$$

i.e.,

$$g^* + \lambda^*(g - g^*) \in P_G(f).$$

So,

$$d(g, P_G(f)) \leqq \|g - g^* - \lambda^*(g - g^*)\| = (1 - \lambda^*)\|g - g^*\|. \tag{5.11}$$

We discuss two cases.

Case (a). $d(g|_{B_2}, P_{G^*}(f|_{B_2})) \geqq 2(\mu^* - \mu)/\alpha_1$.

By the hypothesis, we have

$$\begin{aligned}\|f - g\| &\geqq d(f|_{B_2}, G^*) + \alpha_1 \cdot d(g|_{B_2}, P_{G^*}(f|_{B_2})) \\ &\geqq d(f|_{B_2}, G^*) + \mu^* - \mu + \frac{\alpha_1}{2} \cdot d(g|_{B_2}, P_{G^*}(f|_{B_2})) \\ &= d(f, G) + \frac{\alpha_1}{2} \cdot d(g|_{B_2}, P_{G^*}(f|_{B_2})).\end{aligned} \tag{5.12}$$

Since $T = B_1 \cup B_2$, $B_1 \subset Z(G)$, and $G^* = G|_{B_2}$, it is easy to verify that

$$P_{G^*}(f|_{B_2}) \subset P_G(f)|_{B_2}, \tag{5.13}$$

$$d(g|_{B_2}, P_G(f)|_{B_2}) = d(g, P_G(f)). \tag{5.14}$$

It follows from (5.12)-(5.14) that

$$\|f - g\| \geqq d(f, G) + \frac{\alpha_1}{2} \cdot d(g, P_G(f)).$$

Case (b). $d(g|_{B_2}, P_{G^*}(f|_{B_2})) < 2(\mu^* - \mu)/\alpha_1$.

By (5.7) and $T \setminus B_2 \subset B_1 \subset Z(G)$, we have

$$d(g|_{B_2}, P_{G^*}(f|_{B_2})) = \|g - g^*\|_{B_2} = \|g - g^*\|. \tag{5.15}$$

It follows from (5.15), (5.11), and the hypothesis that

$$\begin{aligned}d(g, P_G(f)) &\leqq (1 - \lambda^*)\|g - g^*\| \\ &= d(g|_{B_2}, P_{G^*}(f|_{B_2})) \cdot \mu/\mu^* \\ &\leqq 2 \cdot (\mu^* - \mu) \cdot \mu/(\mu^* \cdot \alpha_1) \\ &\leqq 2\mu/\alpha_1.\end{aligned} \tag{5.16}$$

By (5.6) and (5.16), we obtain

$$\|f - g\| \geqq d(f, G) + \frac{\alpha_1}{2} \cdot d(g, P_G(f)).$$

Thus, we have proved that (5.5) holds for any $g \in G$.

LEMMA 5.3. *Suppose* $f \in C_0(T)$, $T = B_1 \cup B_2$, *and* $G^* = G(B_1)|_{B_2}$. *If there are positive constants* α_1, α_2 *such that*

$$\|f - g\| \geqq d(f, G) + \alpha_1 \cdot d(g|_{B_1}, P_G(f)|_{B_1}), \qquad g \in G, \tag{5.17}$$

$$\|f-g-g^*\| \geqq d(f-g|_{B_2}, G^*)+\alpha_2 \cdot d(g^*|_{B_2}, P_{G^*}(f-g|_{B_2})), \quad g \in P_G(f), \quad g^* \in G^*, \tag{5.18}$$

then

$$\|f-g\| \geqq d(f, G)+\alpha_3 \cdot d(g, P_G(f)), \qquad g \in G, \tag{5.19}$$

where $\alpha_3=\min\{\alpha_2/4, \alpha_1 \cdot \alpha_2/[2 \cdot \lambda(B_1) \cdot (\alpha_2+2)]\}$ *and* $\lambda(B_1)$ *is any constant that satisfies*

$$d(g, G(B_1)) \leqq \lambda(B_1) \cdot \|g\|_{B_1}, \qquad g \in G.$$

Proof. Suppose $g \in G$. Let $g_1 \in P_G(f)$ such that

$$\|g-g_1\|_{B_1}=d(g|_{B_1}, P_G(f)|B_1). \tag{5.20}$$

By Lemma 5.1, there is a positive constant $\lambda(B_1)$ such that

$$d(p, G(B_1)) \leqq \lambda(B_1)\|p\|_{B_1}, \qquad p \in G. \tag{5.21}$$

By (5.20) and (5.21), there is $g_2 \in G(B_1)$ such that

$$\|g-g_1-g_2\|=d(g-g_1, G(B)) \leqq \lambda(B_1)\|g-g_1\|_{B_1}=\lambda(B_1)d(g|_{B_1}, P_G(f)|_{B_1}). \tag{5.22}$$

Now we discuss two cases.

Case (a). $d(g|_{B_1}, P_G(f)|_{B_1}) \leqq \alpha_2 \cdot d(g, P_G(f))/[2 \cdot \lambda(B_1) \cdot (\alpha_2+2)]$.

By (5.18) and Lemma 5.2, we get

$$\|f-g_1-g_2\| \geqq d(f-g_1, G(B_1))+\frac{\alpha_2}{2} \cdot d(g_2, P_{G(B_1)}(f-g_1)). \tag{5.23}$$

Since $g_1 \in P_G(f)$, we have

$$d(f-g_1, G(B))=d(f, G), \tag{5.24}$$

$$P_{G(B_1)}(f-g_1) \subset P_G(f-g_1)=P_G(f)-g_1. \tag{5.25}$$

It follows from (5.23)-(5.25) that

$$\begin{aligned}\|f-g_1-g_2\| &\geqq d(f, G)+\frac{\alpha_2}{2} d(g_2, P_G(f)-g_1) \\ &= d(f, G)+\frac{\alpha_2}{2} d(g_1+g_2, P_G(f)).\end{aligned} \tag{5.26}$$

Since $d(g, P_G(f)) \geqq d(g_1+g_2, P_G(f))-\|g-g_1-g_2\|$, (5.22) and (5.26) imply

$$\begin{aligned}\|f-g\| &\geqq \|f-g_1-g_2\|-\|g-g_1-g_2\| \\ &\geqq d(f, G)+\frac{\alpha_2}{2} d(g, P_G(f))-\left(1+\frac{\alpha_2}{2}\right) \cdot \|g-g_1-g_2\| \\ &\geqq d(f, G)+\frac{\alpha_2}{2} d(g, P_G(f))-\lambda(B_1) \cdot \left(1+\frac{\alpha_2}{2}\right) \cdot d(g|_{B_1}, P_G(f)|_{B_1}).\end{aligned} \tag{5.27}$$

Now it follows from (5.27) and the hypothesis that

$$\|f-g\| \geqq d(f, G)+\frac{\alpha_2}{4} d(g, P_G(f)). \tag{5.28}$$

Case (b). $d(g|_{B_1}, P_G(f)|_{B_1}) > \alpha_2 \cdot d(g, P_G(f))/[2 \cdot \lambda(B_1) \cdot (\alpha_2+2)]$.

By (5.17) and the hypothesis, we obtain

$$\begin{aligned} \|f-g\| &\geqq d(f, G)+\alpha_1 \cdot d(g|_{B_1}, P_G(f)|_{B_1}) \\ &\geqq d(f, G)+\alpha_1\alpha_2 \cdot d(g, P_G(f))/[2 \cdot \lambda(B_1) \cdot (\alpha_2+2)]. \end{aligned} \tag{5.29}$$

Thus, for $\alpha_3 = \min\{\alpha_2/4, \alpha_1 \cdot \alpha_2/[2 \cdot \lambda(B_1) \cdot (\alpha_2+2)]\}$, by (5.28) and (5.29), (5.19) holds.

From now on, we will always assume that G satisfies (iv) in Theorem 1.1. By Theorem 4.4, there are open and compact subsets $\{A_i\}_1^n$ such that

$$\bigcup_{i=1}^{n} A_i = \operatorname{supp}(G), \tag{5.30}$$

and for $1 \leqq i, j \leqq n$,

$$\dim G|_{A_i \cup A_j} = 1 \quad \text{iff } i = j. \tag{5.31}$$

For convenience, denote

$$A(I) = \bigcup_{i \in I} A_i, \qquad I \subset \{1, 2, \cdots, n\}. \tag{5.32}$$

To give a lower-bounded estimation of Hausdorff strongly unique constants, we need some structural constants of G. By (5.31), there are $g_i \in G$ such that

$$G|_{A_i} = \operatorname{span}\{g_i|_{A_i}\}, \qquad 1 \leqq i \leqq n. \tag{5.33}$$

Since $g_i(t) \neq 0$ for $t \in A_i$ and A_i is compact, we obtain

$$\alpha_i =: \|g_i\|_{A_i}/\min\{|g_i(t)|: t \in A_i\} < \infty, \qquad 1 \leqq i \leqq n. \tag{5.34}$$

Define

$$1 \leqq \alpha = \max\{\alpha_i: 1 \leqq i \leqq n\} < \infty. \tag{5.35}$$

For any $g \in G$, if $g|_{A_i} \not\equiv 0$, then $g|_{A_i} = \lambda_i g_i|_{A_i}$ with $\lambda_i \neq 0$. So,

$$\|g\|_{A_i}/\min\{|g(t)|: t \in A_i\} = \alpha_i \leqq \alpha, \qquad g \in G \text{ with } \|g\|_{A_i} \neq 0. \tag{5.36}$$

Set

$$\mathcal{T} = \{I \subset \{i\}_1^n: \dim G|_{A(I)} = \dim G|_{A(I\setminus\{j\})} = \operatorname{card}(I) - 1 \text{ for } j \in I\}.$$

For $I \in \mathcal{T}$, it is easy to check that $\|\cdot\|_{A(I)}$ and $\|\cdot\|_{A(I\setminus\{j\})}$, $j \in I$, are norms on $G|_{A(I)}$. Since any two norms on $G|_{A(I)}$ are equivalent, there is a constant $\beta(I) > 0$ such that

$$\|g\|_{A(I\setminus\{j\})} \geqq \beta(I) \cdot \|g\|_{A(I)}, \quad g \in G, \quad j \in I \in \mathcal{T}. \tag{5.37}$$

Define

$$1 \geqq \beta = \min\{\beta(I): I \in \mathcal{T}\} > 0, \tag{5.38}$$

since $\mathcal{T}$ is a finite set. By Lemma 5.1, for $\varnothing \neq I \subset \{i\}_1^n$, there are constants $\gamma(I)$ such that

$$d(g, G(A(I))) \leqq \gamma(I)\|g\|_{A(I)}, \quad g \in G, \quad I \subset \{i\}_1^n. \tag{5.39}$$

Define

$$1 \leqq \gamma = \max\{\gamma(I): I \subset \{i\}_1^n\} < \infty. \tag{5.40}$$

The constants α, β, γ are essential in estimating the lower bound of Hausdorff strongly unique constants of P_G.

LEMMA 5.4. *For any primitive extremal signature σ of G and any real number $\lambda \geqq 0$, we have*

$$\|\lambda\sigma - g\|_{\operatorname{supp}\sigma} \geqq \|\lambda\sigma\|_{\operatorname{supp}\sigma} + (\beta/\alpha)\|g\|_{\operatorname{supp}\sigma}, \qquad g \in G. \tag{5.41}$$

Proof. Since $\beta/\alpha \leqq 1$, (5.41) is trivial if $\lambda = 0$. So, we may assume

$$\lambda > 0.$$

Set $G^* = G|_{\operatorname{supp}\sigma}$, $\sigma^* = \sigma|_{\operatorname{supp}\sigma}$, $\operatorname{supp}\sigma = \{t_i\}_0^m$. By Definition 2.1 and Lemma 2.3, we obtain that

$$P_{G^*}(\lambda\sigma^*) = \lambda P_{G^*}(\sigma^*) = \{0\}, \tag{5.42}$$

$$\dim G^* = \dim G|_{\{t_i\}_0^m} = \dim G|_{\{t_i\}_0^m \setminus \{t_j\}} = m, \qquad 0 \leqq j \leqq m. \tag{5.43}$$

It is trivial that

$$|\lambda\sigma^*(t)| = \|\lambda\sigma^*\|, \qquad t \in \operatorname{supp}\sigma = \{t_i\}_0^m. \tag{5.44}$$

So, it follows from (5.42)-(5.44) and Theorem 1.3 of [22] that

$$\|\lambda\sigma^* - g^*\| \geqq \|\lambda\sigma^*\| + \eta \cdot \|g^*\|, \qquad g^* \in G^*, \tag{5.45}$$

where

$$\eta = \min\{1/\|p_i^*\| : 0 \leqq i \leqq m\} \tag{5.46}$$

and p_i^* are the unique functions in G^* such that

$$p_i^*(t_j) = \operatorname{sign}(\lambda\sigma^*(t_j)) = \sigma^*(t_j), \quad 0 \leqq i, \quad j \leqq m, \quad j \neq i. \tag{5.47}$$

Choose $p_i \in G$ such that

$$p_i|_{\operatorname{supp}\sigma} = p_i^*, \qquad 0 \leqq i \leqq m. \tag{5.48}$$

Let $\{k_i : 0 \leqq i \leqq m\} \subset \{1, \cdots, n\}$ such that

$$t_i \in A_{k_i}, \qquad 0 \leqq i \leqq m. \tag{5.49}$$

By (5.31), (5.43), and (5.49), we obtain

$$\dim G|_{\cup_{i=0}^m A_{k_i}} = \dim G|_{\cup_{i=0}^m A_{k_i} \setminus A_{k_j}} = m, \qquad 0 \leqq j \leqq m. \tag{5.50}$$

By (5.47), (5.48), and (5.36), we can derive that

$$\|p_i\|_{A_{k_j}} \leqq \alpha \cdot |p_i(t_j)| = \alpha \cdot |p_i^*(t_j)| = \alpha, \quad 0 \leqq i, \quad j \leqq m, \quad i \neq j. \tag{5.51}$$

Now we discuss two cases.

Case (a). $m = 1$.

By (5.50) and (5.31), $A_{k_0} = A_{k_1}$. So, it follows from (5.51) that

$$\|p_i^*\| = \|p_i\|_{\{t_0, t_1\}} \leqq \|p_i\|_{A_{k_i}} \leqq \alpha, \qquad i = 0, 1.$$

So,

$$\eta \geqq \min\{1/\|p_i^*\| : i = 0, 1\} \geqq 1/\alpha. \tag{5.52}$$

Case (b). $m > 1$.

By (5.50) and $m > 1$, we obtain that for $I = \{k_i : 0 \leqq i \leqq m\}$,

$$\dim G|_{A(I)} = \dim G|_{A(I \setminus \{j\})} = \operatorname{card}(I) - 1 = m, \qquad j \in I;$$

i.e., $I \in \mathcal{T}$. It follows from (5.51) that

$$\|p_i\|_{A(I \setminus \{k_i\})} \leqq \alpha, \qquad 0 \leqq i \leqq m. \tag{5.53}$$

By (5.53), (5.37), and (5.38), we get

$$\|p_i\|_{A(I)} \leqq \|p_i\|_{A(I\setminus\{k_i\})}/\beta \leqq \alpha/\beta, \qquad 0 \leqq i \leqq m.$$

Thus,

$$\begin{aligned} \eta &\geqq \min\{1/\|p_i^*\|: 0 \leqq i \leqq m\} = \min\{1/\|p_i\|_{\operatorname{supp}\sigma}: 0 \leqq i \leqq m\} \\ &\geqq \min\{1/\|p_i\|_{A(I)}: 0 \leqq i \leqq m\} \geqq \beta/\alpha. \end{aligned} \tag{5.54}$$

Since $\beta \leqq 1$, (5.52) and (5.54) imply

$$\eta \geqq \beta/\alpha. \tag{5.55}$$

So, by (5.45) and (5.55), we obtain that for any $g \in G$,

$$\begin{aligned} \|\lambda\sigma - g\|_{\operatorname{supp}\sigma} &= \|\lambda\sigma^* - g|_{\operatorname{supp}\sigma}\| \\ &\geqq \|\lambda\sigma^*\| + \eta \cdot \|g|_{\operatorname{supp}\sigma}\| \geqq \|\lambda\sigma^*\| + (\beta/\alpha)\|g|_{\operatorname{supp}\sigma}\| \\ &= \|\lambda\sigma\|_{\operatorname{supp}\sigma} + (\beta/\alpha) \cdot \|g\|_{\operatorname{supp}\sigma}. \end{aligned}$$

This shows that (5.41) holds.

5.1. Proof that (iv) implies (i) in Theorem 1.1. We prove that (iv) implies (i) by induction on dim G. The conclusion is trivial if dim $G = 0$. Assume that for any subspace M with dim $M \leqq s$, if M satisfies (iv), then P_M is uniform Hausdorff strongly unique. Now suppose that G satisfies (iv) and dim $G = s+1$.

Let $T^* = \operatorname{supp}(G)$, $G^* = G|_{T^*}$. Set

$$G_I = G^*(A(I))|_{T^*\setminus A(I)}, \qquad \varnothing \neq I \subset \{i\}_1^n.$$

Since $G_1 \subsetneqq G^*$ and T^* is compact, we obtain that G_I satisfies (iv) and dim $G_I \leqq$ dim $G^* - 1 \leqq$ dim $G - 1 = s$. By the inductive hypothesis, P_{G_I} is uniform Hausdorff strongly unique, i.e., there is a positive constant $\eta(I) > 0$ such that

$$\|h - p\| \geqq d(h, G_I) + \eta(I) \cdot d(p, P_{G_I}(h)), \quad h \in C(T^*\setminus A(I)), \quad p \in G_I.$$

Since $\{i\}_1^n$ has only finitely many different subsets, we have

$$\eta =: \min\{\eta(I): \varnothing \neq I \subset \{i\}_1^n\} > 0.$$

Obviously, for any nonempty set $I \subset \{i\}_1^n$,

$$\|h - p\| \geqq d(h, G_I) + \eta \cdot d(p, P_{G_I}(h)), \quad p \in G_I, \quad h \in C(T^*\setminus A(I)). \tag{5.56}$$

Now we claim

$$\|f - g\| \geqq d(f, G) + \lambda \cdot d(g, P_G(f)), \quad g \in G, \quad f \in C_0(T), \tag{5.57}$$

where

$$\lambda = \min\{\eta/8, \beta \cdot \eta/[\alpha^2 \cdot \gamma \cdot 4(\eta+2)]\}.$$

First assume $f^* = f|_{T^*} \in C(T^*)\setminus G^*$. By Lemma 2.2, there are $g^* \in P_{G^*}(f^*)$ and a primitive extremal signature σ of G^* such that

$$f^*(t) - g^*(t) = \sigma(t)\|f^* - g^*\| = \sigma(t)d(f^*, G^*), \qquad t \in \operatorname{supp}\sigma. \tag{5.58}$$

By Lemma 5.4, (5.58) implies that

$$\begin{aligned} \|f^* - p\| &\geqq \|f^* - p\|_{\operatorname{supp}\sigma} \\ &= \|f^* - g^* - (p - g^*)\|_{\operatorname{supp}\sigma} \\ &= \|d(f^*, G^*)\sigma - (p - g^*)\|_{\operatorname{supp}\sigma} \\ &\geqq \|d(f^*, G^*)\sigma\|_{\operatorname{supp}\sigma} + (\beta/\alpha)\|p - g^*\|_{\operatorname{supp}\sigma}, \qquad p \in G^*. \end{aligned} \tag{5.59}$$

Let $J=\{i\colon \operatorname{supp}\sigma\cap A_i\neq\varnothing\}$. Then for any $p\in G^*$,

$$\begin{aligned}\|p\|_{A(J)}&=\max\{\|p\|_{A_i}\colon i\in I\}\\ &\leqq\max\{\alpha\cdot\|p\|_{A_i\cap\operatorname{supp}\sigma}\colon i\in I\}\\ &\leqq\alpha\cdot\|p\|_{\operatorname{supp}\sigma}.\end{aligned}\tag{5.60}$$

It follows from (5.59) and (5.60) that

$$\|f^*-p\|\geqq d(f^*,G^*)+(\beta/\alpha^2)\cdot\|p-g^*\|_{A(J)},\qquad p\in G^*.\tag{5.61}$$

Formula (5.61) implies that $P_{G^*}(f^*)|_{A(J)}=\{g^*|_{A(J)}\}$. Thus, (5.61) is equivalent to

$$\|f^*-p\|\geqq d(f^*,G^*)+(\beta/\alpha^2)\cdot d(p|_{A(J)},P_{G^*}(f^*)|_{A(J)}),\qquad p\in G^*.\tag{5.62}$$

By (5.39) and (5.40),

$$d(p,G^*(A(J)))\leqq\gamma\cdot\|p\|_{A(J)},\qquad p\in G^*.\tag{5.63}$$

It follows from (5.56) that

$$\begin{aligned}\|h-p\|\geqq d(h|_{T^*\setminus A(J)},G_J)+\eta\cdot d(p|_{T^*\setminus A(J)},P_{G_J}(h)),\\ h\in C_0(T^*),\qquad p\in G_J.\end{aligned}\tag{5.64}$$

By (5.62)–(5.64) and Lemma 5.3, we get

$$\|f^*-g\|\geqq d(f^*,G^*)+\lambda^*d(g,P_{G^*}(f^*)),\qquad g\in G^*,\tag{5.65}$$

where

$$\lambda^*=\min\{\eta/4,\beta\cdot\eta/[\alpha^2\cdot\gamma\cdot 2(\eta+2)]\}.$$

If $f^*\in G^*$, then (5.65) is trivial. So (5.65) holds for any $f\in C_0(T)$. It follows from (5.65) and Lemma 5.2 that

$$\|f-p\|\geqq d(f,G)+\left(\frac{\lambda^*}{2}\right)\cdot d(p,P_G(f)),\qquad p\in G.$$

Thus, we have proved (5.57), since $\lambda=\lambda^*/2$. So, P_G is uniform Hausdorff strongly unique, i.e., (iv) implies (i) in Theorem 1.1.

JUSTIFICATION OF MATCHING WITH THE TRANSITION EXPANSION OF VAN DER POL'S EQUATION*

A. D. MacGILLIVRAY†

Abstract. The analysis of the relaxation oscillations of Van der Pol's equation presents an especially challenging test of the formal techniques of the method of matched asymptotic expansions for solving singular perturbation problems. The formal analysis is described in Kevorkian and Cole's monograph [J. Kevorkian and J. D. Cole, "Perturbation Methods in Applied Mathematics", Springer-Verlag, Berlin, New York, 1981], which explains why the inner and outer expansions must necessarily be supplemented by a third "transition" expansion in order to obtain a uniformly valid approximation beyond $O(1)$ on a complete half-period. Kevorkian and Cole carry out the construction and delicate matching of several terms in the expansions. The present paper mathematically justifies their formal results to $O(\varepsilon^{1/3})$, and is the first such proof for any transition expansion. Partly for this reason, but also because the idea underlying the proof has been and will be applied to other singular perturbation problems, this paper is intended to be a contribution to the study of asymptotic methods rather than merely to the theory of Van der Pol's equation.

Key words. singular perturbation, rigorous matching, Van der Pol, matched asymptotic expansions

AMS(MOS) subject classifications. 34C15, 34E15

1. Introduction.

This paper presents a mathematical justification of terms in the transition asymptotic expansion of relaxation oscillations of Van der Pol's equation, written as

$$\varepsilon \frac{d^2y}{dt^2} + (1-y^2)\frac{dy}{dt} + y = 0.$$

It also justifies matching these terms with the leading terms in the inner and outer asymptotic expansions. The construction of these terms and their formal (i.e., non-rigorous) matching is explained in complete detail in Kevorkian and Cole's well-known monograph [4].

Van der Pol's equation is, of course, a canonical example that has long been used in texts, exposition, and research. As an example illustrating the method of matched asymptotic expansions in solving singular perturbation problems, it provides an especially stringent test of that method because three principal asymptotic expansions are required, and the formal matching among them is an extremely delicate matter. It is not surprising that the mathematical justification also presents some challenges. Our analysis is believed to be the only justification of validity and matching of a transition asymptotic expansion for any nontrivial problem (and not merely the Van der Pol problem).

The present work extends the work of MacGillivray [8], [9], which presents a complete mathematical justification of the formal result by demonstrating that the leading terms of the inner and outer expansions, as constructed by Kevorkian and Cole [4], give $O(1)$ approximations to the solution, as ε tends to zero, on explicit domains of uniform validity that overlap. The extension by the present analysis justifies the assertion that the first two terms of the transition expansion and the leading terms of the inner and outer expansions give $O(\varepsilon^{1/3})$ approximations to the solution, as $\varepsilon \to 0$, on explicit domains of validity that overlap; see Fig. 1.

The question of how to organize this paper was difficult. I wanted to describe certain aspects of what Littlewood called the "dramatic fine structure of solutions"

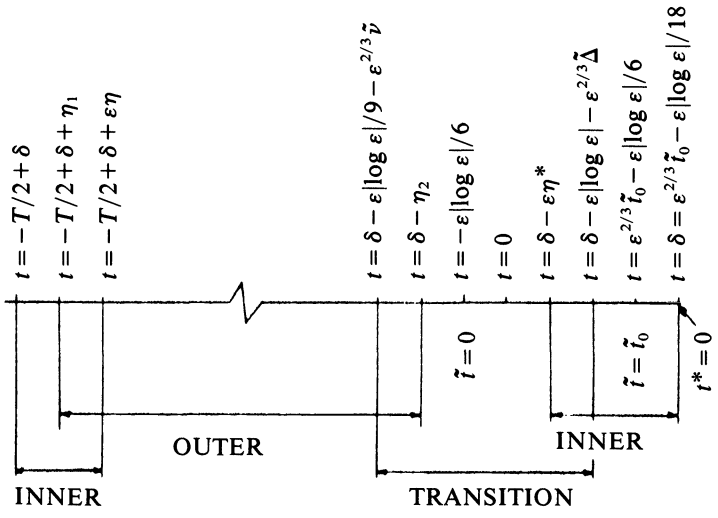

FIG. 1.

[7, p. 13], but sometimes detailed computations can get out of hand. (Littlewood describes his last paper on Van der Pol's equation as "The Monster" [7, p. 16]). However, the proofs include enough guideposts to enable the interested or skeptical reader to fill in some or all of the desired details. I hope I have achieved a balance between brevity and verbosity, but in any case, detailed proofs are available upon request from the author (MacGillivray [10], [11]).

The organization of the paper is as follows: Propositions 1–11 are presented in § 3, and lead to Theorem A, which is the first of four main theorems. Theorem A asserts that the first two terms of the transition expansion approximate the solution to $O(\varepsilon^{1/3})$ on an explicit domain of uniform validity. In § 4, the analysis begins with an application of Kaplun's Extension Theorem and, after five more propositions, concludes with Theorem B, which asserts an explicit domain of validity for the inner expansion to $O(\varepsilon^{1/3})$. The three propositions in § 5 lead to Theorem C, which gives an explicit domain of uniform validity of the outer expansion as an $O(\varepsilon^{1/3})$ approximation. In § 6, Theorem D collects these results together, completing the mathematical justification of the method of matched asymptotic expansions for this problem. It is worth mentioning that an interesting feature in the proofs is the recurring pairwise interaction between the expansions that is undoubtedly related in some way to the formal matching procedures.

The analysis of this and the two previous papers enables us to examine some formal techniques of asymptotic analysis from a different vantage point and thereby possibly enhance the understanding not only of how certain techniques work, but also why they work. This view has been highlighted by recent work on "fingering problems." Langer [6], for example, discusses one of these problems for which a straightforward perturbation analysis led to seemingly reasonable results. These were accepted as correct for many years, but Langer shows them to be incorrect. See also the review paper by Saffman [14].

For the sake of completeness, we give a short list of works devoted specifically to the analysis of Van der Pol's equation: Cartwright [1], Dorodnicyn [2], Haag [3], Pontryagin, Mishchenko, and coworkers; see [12], Stoker [15]. A recent paper by Storti and Rand [16] applies much of the formal analysis (including the transition expansion)

of Kevorkian and Cole to strongly coupled relaxation oscillators. Finally, we mention the book by O'Malley [13] and the review paper by Lagerstrom and Casten [5] to supplement Kevorkian and Cole's book [4] as references on singular perturbation problems and asymptotic expansions.

2. Notation and other preliminaries. In the next section we present the analysis that leads to Theorem A, which proves that the first two terms of the transition expansion constructed by Kevorkian and Cole [4] approximate the exact solution uniformly on an explicit interval as $\varepsilon \to 0$. We will use many results from Kevorkian and Cole's formal analysis as well as from MacGillivray [8], [9]. We assume the reader is familiar with the method of matched asymptotic expansions as developed in [4].

Recall Van der Pol's equation in the form

$$\varepsilon \frac{d^2y}{dt^2} + (1-y^2)\cdot\frac{dy}{dt} + y = 0. \tag{1}$$

We impose the same initial conditions as in [4]:

$$y(\delta) = 0, \tag{2}$$

$$y'(\delta) < 0 \tag{3}$$

where

$$\delta = \delta(\varepsilon) = \varepsilon^{2/3}\tilde{t}_0 - \frac{\varepsilon|\ln \varepsilon|}{18}, \tag{4}$$

with $\tilde{t}_0 = 2.3381\cdots$ being the absolute value of the first zero of the Airy function. The stretched inner variable t^* and transition variable $\tilde{t}$ are defined by the following expressions [4]:

$$\varepsilon t^* = t - \delta, \tag{5}$$

$$\varepsilon^{2/3}\tilde{t} = t + \frac{\varepsilon|\log \varepsilon|}{6}. \tag{6}$$

The relationships among t, t^*, and $\tilde{t}$ are shown schematically in Fig. 1.

We introduce the function $R(\tilde{t}; \varepsilon)$, and recall from [8], [9], the functions $r(t^*; \varepsilon)$ and $h(t; \varepsilon)$, all defined as corrections to terms in the asymptotic expansions constructed formally in [4]. They are

$$y(t; \varepsilon) = g_0(t^*) + r(t^*; \varepsilon), \tag{7}$$

$$y(t; \varepsilon) = u_0(t) + h(t; \varepsilon), \qquad t \leqq 0, \tag{8}$$

$$y(t; \varepsilon) = 1 + \varepsilon^{1/3} f_1(\tilde{t}) + \varepsilon^{1/3} R(\tilde{t}; \varepsilon), \qquad \tilde{t} < \tilde{t}_0. \tag{9}$$

$g_0(t^*)$ is defined in [4, form. 2.6.23), corrected:

$$\frac{1}{3}\ln(1-g_0) - \frac{1}{(1-g_0)} - \frac{1}{3}\ln(g_0+2) = t^*, \tag{10}$$

and $r(t^*; \varepsilon)$ satisfies (MacGillivray [8])

$$\frac{d^2r}{dt^{*2}} = \left(-\frac{dg_0}{dt^*}\right)\cdot(2g_0+r)r + (1-g_0^2-2rg_0-r^2)\frac{dr}{dt^*} - \varepsilon y. \tag{11}$$

$u_0(t)$ is defined in [4, form. (2.6.10)]:

$$\log u_0 - (u_0^2-1)/2 = t, \qquad t \leqq 0, \tag{12}$$

and $h(t;\varepsilon)$ satisfies (MacGillivray [9])

$$\varepsilon\frac{d^2h}{dt^2}=(1-y^2)\frac{dh}{dt}+\frac{(1+u_0y)h}{(u_0^2-1)}+\frac{\varepsilon u_0(1+u_0^2)}{(u_0^2-1)^3}. \tag{13}$$

Kevorkian and Cole construct $f_1(\tilde{t})$ using the Airy function. The reader is referred to their book for details, including their sketch of the graph of f_1 [4, Fig. 2.6.4]. Our Fig. 2 shows a careful plot of $-f_1(\tilde{t})$. $R(\tilde{t};\varepsilon)$ satisfies

$$\begin{aligned}\frac{d^2R}{d\tilde{t}^2}&=-2(R+f_1)\frac{dR}{d\tilde{t}}-2R\frac{df_1}{d\tilde{t}}-\varepsilon^{1/3}\\&\quad\cdot\left\{(f_1+R)+(f_1+R)^2\frac{dR}{d\tilde{t}}+(f_1+R)^2\frac{df_1}{d\tilde{t}}\right\}.\end{aligned} \tag{14}$$

It is proved in MacGillivray [9] that

$$y(t)=u_0+o(1)\quad\text{as }\varepsilon\to 0, \tag{15}$$

uniformly on any interval of the form

$$[-T/2+\mu_1(\varepsilon)+\delta,\ -\mu_2(\varepsilon)+\delta] \tag{16}$$

where

$$\varepsilon\ll\mu_i\ll 1,\qquad i=1,2 \tag{17}$$

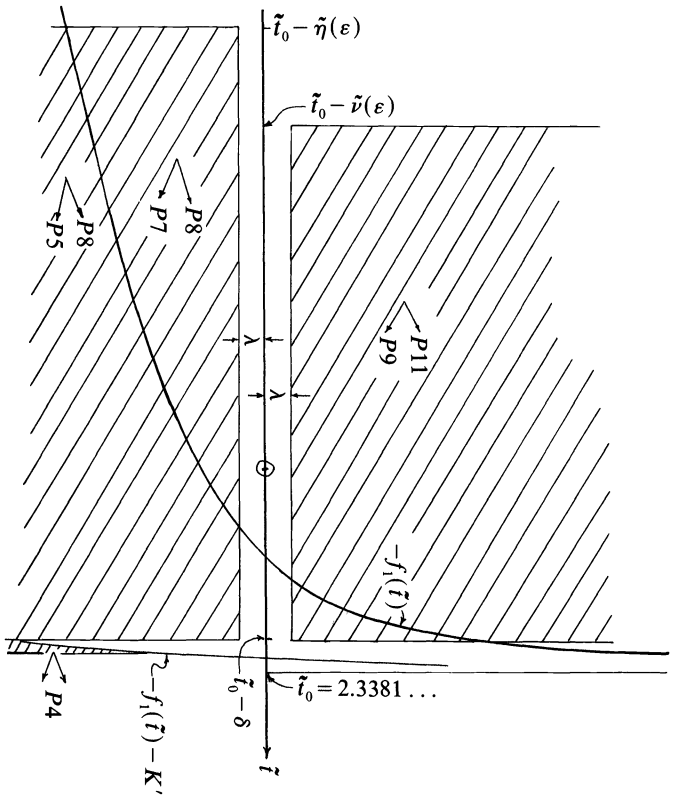

FIG. 2.

and where $T = T(\varepsilon)$, the period of oscillation, is calculated to be

$$T = 3 - 2\log 2 + o(1) \quad \text{as } \varepsilon \to 0 \tag{18}$$

in agreement with the well-known classical result.

MacGillivray [8] has proved that

$$y(t) = g_0(t^*) + O(\varepsilon^{1/3}) \quad \text{as } \varepsilon \to 0 \tag{19}$$

uniformly on the interval

$$t^* \in [-\varepsilon^{-1/3}/2,\ \varepsilon^{-2/3}]. \tag{20}$$

Stated otherwise, there exists a constant K such that for all sufficiently small ε and all t^* satisfying (20),

$$|y(t^*) - g_0(t^*)| < K\varepsilon^{1/3}. \tag{21}$$

Because $y(t;\ \varepsilon)$ is an odd periodic function, we have the further result

$$y(t) = -g_0(t^* + T/2\varepsilon) + O(\varepsilon^{1/3}) \tag{22}$$

uniformly on the interval

$$t^* \in \left[\frac{-T}{2\varepsilon} - \frac{\varepsilon^{-1/3}}{2},\ \frac{-T}{2\varepsilon} + \varepsilon^{-2/3}\right]. \tag{23}$$

The interval $t \in [-T/2 + \delta,\ \delta]$, is contained in the union of the three intervals (16), (20), (23) if ε is sufficiently small. Thus formulas (15), (19), and (22) together provide a complete $O(1)$ description of $y(t;\ \varepsilon)$ over a complete half-period, and hence for all t by odd periodic extension.

3. Analysis of the transition asymptotic expansion. The idea behind the following analysis is to construct regions in the $(y,\ t)$ plane that are "forbidden" to the solution. Consequently, the proofs often proceed by setting up contradiction arguments. These proofs have a strong geometric appeal, and so the reader may find Fig. 2 a useful guide. Notice the short line segments that appear in the crosshatched regions. The location of the tail of a line segment represents the point $(\tilde{t},\ R(\tilde{t}))$ and the sign of the slope of the line segment corresponds to the sign of $R'(\tilde{t})$. Beside each line segment is the number of the proposition that proves the corresponding $R(\tilde{t})$ and $R'(\tilde{t})$ is forbidden if ε is sufficiently small.

PROPOSITION 1. *Choose* $\alpha \in (0,\ \frac{1}{4}]$. *Then* $\Delta > 0$ *can be chosen to satisfy the following*:

(i) $\Delta < \frac{1}{2}$,

(ii) $(1+\alpha)/(\tilde{t} - \tilde{t}_0) < f_1(\tilde{t}) < (1-\alpha)/(\tilde{t} - \tilde{t}_0)$ *for all* $\tilde{t} \in [\tilde{t}_0 - \Delta,\ \tilde{t}_0]$,

(iii) $-(1+\alpha)/(\tilde{t} - \tilde{t}_0)^2 < f_1'(\tilde{t}) < -(1-\alpha)/(\tilde{t} - \tilde{t}_0)^2$ *for all* $\tilde{t} \in [\tilde{t}_0 - \Delta,\ \tilde{t}_0)$,

(iv) $1/\Delta > K$, *where* K *is defined in* (21).

Proof. Inequalities (ii), (iii) follow from [4, forms. (2.6.58); (2.6.59), corrected].

PROPOSITION 2. *Let* Δ *be as in Proposition* 1. *Then, for all sufficiently small* ε, *the following properties hold*:

(i) $R(\tilde{t}_0 - \Delta/2) > -f_1(\tilde{t}_0 - \Delta/2) - K'$ *for some constant* K',

(ii) $R(\tilde{t}_0 - \Delta) < -f_1(\tilde{t}_0 - \Delta)$ (*strict inequality*),

(iii) $R(\tilde{t}_0 - \varepsilon^{1/6}) = o(\varepsilon^{-1/6})$,

(iv) $R(\tilde{t}_0 - \varepsilon^{1/3}|\log \varepsilon|) \to \infty$ *as* $\varepsilon \to 0$,

(v) $R(\tilde{t}) + f_1(\tilde{t}) > -19\varepsilon^{-1/3}/(20|\log \varepsilon|)$ *for* $\tilde{t} \in [\tilde{t}_0 - \Delta,\ \tilde{t}_0 - \varepsilon^{1/3}|\log \varepsilon|]$.

Proof. Using (5), (6), (19), and (20), we can readily show

$$y(t;\ \varepsilon) = g_0\left((\tilde{t} - \tilde{t}_0)\varepsilon^{-1/3} - \frac{|\log \varepsilon|}{9}\right) + O(\varepsilon^{1/3}) \tag{24}$$

uniformly for $\tilde{t} \in [\tilde{t}_0 - \Delta, \tilde{t}_0)$. From [4, form. (2.6.24)],

$$g_0(t^*) = 1 + \frac{1}{t^*} - \frac{\log(-t^*)}{(3t^{*2})} + \cdots \quad \text{as } t^* \to -\infty, \tag{25}$$

so that (24) can be rewritten as

$$y(t;\varepsilon) = 1 + \frac{1+o(1)}{(\tilde{t}-\tilde{t}_0)\varepsilon^{-1/3} - \dfrac{|\log\varepsilon|}{9}} + O(\varepsilon^{1/3}). \tag{26}$$

Thus,

$$\varepsilon^{1/3}(f_1(\tilde{t}) + R(\tilde{t})) = \frac{\varepsilon^{1/3}(1+o(1))}{(\tilde{t}-\tilde{t}_0)\dfrac{1-\varepsilon^{1/3}|\log\varepsilon|}{9(\tilde{t}-\tilde{t}_0)}} + O(\varepsilon^{1/3}). \tag{27}$$

Recalling the definition of K in (21), we easily show that

$$-\frac{4}{\Delta} < f_1\left(\tilde{t}_0 - \frac{\Delta}{2}\right) + R\left(\tilde{t}_0 - \frac{\Delta}{2}\right) < 0, \tag{28}$$

$$-\frac{4}{\Delta} < f_1(\tilde{t}_0 - \Delta) + R(\tilde{t}_0 - \Delta) < 0, \tag{29}$$

and (i) and (ii) follow immediately, with $K' = 4/\Delta$.

To prove (iii), simply substitute $\tilde{t} = \tilde{t}_0 - \varepsilon^{1/6}$ into (26) and use the following result from [4]:

$$f_1(\tilde{t}) = \frac{1}{(\tilde{t}-\tilde{t}_0)} - \frac{\tilde{t}_0(\tilde{t}-\tilde{t}_0)}{3} + O((\tilde{t}-\tilde{t}_0)^2) \quad \text{as } \tilde{t} \to \tilde{t}_0. \tag{30}$$

Part (iv) is proved in a similar fashion. The proof of (v) also depends on (21) and (30) and is the result of a straightforward computation.

PROPOSITION 3. *For all sufficiently small ε, the amplitude $y(t)$ is positive on the interval $\tilde{t} \in [\tilde{t}_0 - \varepsilon^{-2/3}/2, \tilde{t}_0)$ and, in addition, $R(\tilde{t}_0 - \varepsilon^{-2/3}/2)$ is positive.*

Proof. $y(t)$ is positive between its zeros at $t = \delta - T/2$ and $t = \delta$. Writing this interval in terms of $\tilde{t}$ using (6), a short computation shows the interval $\tilde{t} \in [\tilde{t}_0 - \varepsilon^{-2/3}/2, \tilde{t}_0)$ lies within it, provided ε is sufficiently small. This verifies the first part of the proposition.

To prove the second part, first note that the point $\tilde{t} = \tilde{t}_0 - \varepsilon^{-2/3}/2$ corresponds to $t = -\frac{1}{2} + o(1)$, which is well within the domain of uniform validity of $u_0(t)$; see (15) and (16). Thus it follows that

$$1 + \varepsilon^{1/3}\left[f_1\left(\tilde{t}_0 - \frac{\varepsilon^{-2/3}}{2}\right) + R\left(\tilde{t}_0 - \frac{\varepsilon^{-2/3}}{2}\right)\right] = u_0\left(-\frac{1}{2}\right) + o(1). \tag{31}$$

From [4, form. (2.6.50)],

$$\begin{aligned} f_1\left(\tilde{t}_0 - \frac{\varepsilon^{-2/3}}{2}\right) &= \sqrt{\left(\frac{\varepsilon^{-2/3}}{2} - \tilde{t}_0\right)} + \cdots \\ &= \varepsilon^{-1/3}\left(\frac{1}{\sqrt{2+o(1)}}\right) \quad \text{as } \varepsilon \to 0. \end{aligned} \tag{32}$$

Thus

$$R\left(\tilde{t}_0-\frac{\varepsilon^{-2/3}}{2}\right)=\varepsilon^{-1/3}\left(-\frac{1}{\sqrt{2+o(1)}}+u_0\left(-\frac{1}{2}\right)-1\right). \tag{33}$$

It is a trivial matter to estimate $u_0(-\frac{1}{2})$ numerically from (12):

$$u_0(-\tfrac{1}{2})=1.7333\cdots. \tag{34}$$

Substituting (34) into (33) leads immediately to the verification of the second part of the proposition.

PROPOSITION 4. *Let Δ be chosen as in Proposition* 1, *and K' as in Proposition* 2. *Then for all sufficiently small ε,*

$$R(\tilde{t})\geqq -f_1(\tilde{t})-K' \quad \textit{for } \tilde{t}\in\left[\tilde{t}_0-\varepsilon^{-2/3},\ \tilde{t}_0-\frac{\Delta}{2}\right]. \tag{35}$$

Proof. It is easy to show, using part (i) of Proposition 2, and Proposition 3, that, if ε is sufficiently small, $R(\tilde{t})$ exceeds $-f_1(\tilde{t})-K'$ when $\tilde{t}=\tilde{t}_0-\Delta/2$ and when $\tilde{t}=\tilde{t}_0-\varepsilon^{-2/3}/2$. Making the tentative assumption that the conclusion of the proposition is false implies the existence of $\tilde{t}_1$, $\tilde{t}_2$, we have

$$\tilde{t}_0-\frac{\varepsilon^{-2/3}}{2}<\tilde{t}_1<\tilde{t}_2<\tilde{t}_0-\frac{\Delta}{2}$$

such that

$$R(\tilde{t}_1)+f_1(\tilde{t}_1)=R(\tilde{t}_2)+f_1(\tilde{t}_2)=-K',$$

$$R(\tilde{t})+f_1(\tilde{t})<-K' \quad \text{for } \tilde{t}\in(\tilde{t}_1,\tilde{t}_2).$$

This leads immediately to a $\tilde{t}_3\in(\tilde{t}_1,\tilde{t}_2)$, where y lies between zero and unity and where y' is zero. Such a point lies on a phase plane trajectory that spirals toward the origin as $\tilde{t}\to-\infty$, and is therefore not on the limit cycle. This contradiction completes the proof.

PROPOSITION 5. *Let $1\ll\tilde{\eta}(\varepsilon)\ll\varepsilon^{-2/3}/2$, let $\lambda>0$ be given, and let Δ be as in Proposition* 1. *Then, for all sufficiently small ε, there exists no $\tilde{t}_1\in[\tilde{t}_0-\tilde{\eta},\ \tilde{t}_0-\Delta]$ for which $R(\tilde{t}_1)\leqq-\lambda$, $R(\tilde{t}_1)\leqq-f_1(\tilde{t}_1)$, and $R'(\tilde{t}_1)\leqq 0$.*

Proof. Assume tentatively that such a $\tilde{t}_1$ exists, and note that for any $\tilde{t}\in[\tilde{t}_0-\tilde{\eta},\ \tilde{t}-\Delta/2]$ for which $R(\tilde{t})\leqq-\lambda$, $R(\tilde{t})\leqq-f_1(\tilde{t})$, and $R'(\tilde{t})\leqq 0$, Proposition 4 and (14) imply

$$\frac{d^2R}{d\tilde{t}^2}\leqq 2\lambda\left(\frac{df_1}{d\tilde{t}}\right)-\varepsilon^{1/3}(f_1+R)^2\left(\frac{dR}{d\tilde{t}}\right)+o(\tilde{\eta}^{-1/2}) \tag{36}$$

for all sufficiently small ε.

From the text above equation (2.6.50) in [4], we find $f_1'(\tilde{t})=\sqrt{(-\tilde{t})}+\cdots$ as $\tilde{t}\to-\infty$. Since $|f_1'|$ is an increasing function, it follows directly that

$$\left|\frac{df_1}{d\tilde{t}}\right|\geqq\left(\frac{\tilde{\eta}^{-1/2}}{2}\right)(1+o(1)) \quad \text{for } \tilde{t}\in[\tilde{t}_0-\tilde{\eta},\ \tilde{t}_0).$$

Thus

$$\frac{d^2R}{d\tilde{t}^2}\leqq-2\lambda\left(\frac{\tilde{\eta}^{-1/2}}{2}\right)(1+o(1))-\varepsilon^{1/3}(f_1+R)^2\left(\frac{dR}{d\tilde{t}}\right), \tag{37}$$

assuming the conditions above (36) hold. It is easy now to use a continuation argument to verify that on the interval $(\tilde{t}_1, \tilde{t}_0-\Delta/2)$ we have

$$R'(\tilde{t})<0, \quad R(\tilde{t})<-\lambda, \quad R(\tilde{t})<-f_1(\tilde{t}).$$

On the interval $[\tilde{t}_0-\Delta, \tilde{t}_0-\Delta/2]$, $R(\tilde{t})$ is bounded. Thus, if ε is sufficiently small, the two terms containing $R'(\tilde{t})$ in (14) combine to give a negative contribution. The remaining terms in the braces being bounded yields

$$\frac{d^2R}{d\tilde{t}^2}\leqq -2\lambda|f_1'(\tilde{t}_0-\Delta)|+o(1) \tag{38}$$

on the interval $[\tilde{t}_0-\Delta, \tilde{t}_0-\Delta/2]$. Two integrations yield

$$R'(\tilde{t})<-2\lambda|f_1'(\tilde{t}_0-\Delta)|\cdot(1+o(1))\cdot(\tilde{t}-\tilde{t}_0+\Delta), \tag{39}$$

$$R(\tilde{t})<-\lambda-2\lambda|f_1'(\tilde{t}_0-\Delta)|\cdot(1+o(1))\cdot\frac{(\tilde{t}-\tilde{t}_0+\Delta)^2}{2} \tag{40}$$

on $(\tilde{t}_0-\Delta, \tilde{t}_0-\Delta/2]$.

Let

$$\kappa=\left(\frac{3\lambda\Delta^2}{32}\right)|f_1'(\tilde{t}_0-\Delta)|. \tag{41}$$

Then (39), (40) give

$$R\left(\tilde{t}_0-\frac{\Delta}{2}\right)<\frac{\kappa}{\left(\tilde{t}_0-\frac{\Delta}{2}\right)-\tilde{t}_0}, \tag{42}$$

$$R'\left(\tilde{t}_0-\frac{\Delta}{2}\right)<\frac{-\kappa}{\left[\left(\tilde{t}_0-\frac{\Delta}{2}\right)-\tilde{t}_0\right]^2}. \tag{43}$$

Now as long as

$$R(\tilde{t})\leqq\frac{\kappa}{\tilde{t}-\tilde{t}_0}, \tag{44}$$

$$R'(\tilde{t})\leqq\frac{-\kappa}{(\tilde{t}-\tilde{t}_0)^2} \tag{45}$$

remain valid to the right of $\tilde{t}=\tilde{t}_0-\Delta/2$, both (f_1+R) and R' will remain negative. Then estimate (v) in Proposition 2, together with properties (ii), (iii) in Proposition 1, leads, after a straightforward computation, to the conclusion that as long as (44) and (45) remain valid to the right of $\tilde{t}_0-\Delta/2$, $\tilde{t}<\tilde{t}_0$,

$$\frac{d^2R}{d\tilde{t}^2}\leqq\left[\frac{2\kappa}{(\tilde{t}-\tilde{t}_0)^3}\right]\{(2-2\alpha+\kappa)\cdot(1+o(1))\}+o(1), \tag{46}$$

which is negative if ε is sufficiently small. Furthermore, the quantity within the braces exceeds unity if ε is sufficiently small, and an obvious continuation argument leads to the conclusion that (44), (45) remain valid on $[\tilde{t}_0-\Delta/2, \tilde{t}_0-\varepsilon^{1/3}|\log\varepsilon|]$. This contradicts (iv) of Proposition 2, if ε is sufficiently small, completing the proof.

COROLLARY. *The conclusion of Proposition* 5 *remains true if* $\tilde{\eta}(\varepsilon)$ *is replaced by* $\tilde{\eta}(\varepsilon)+1$.

PROPOSITION 6. *If ε is sufficiently small, $R(\tilde{t})$ cannot have a minimum in the region bounded by*

$$-f_1(\tilde{t}) \leqq R(\tilde{t}) \leqq -\lambda \quad \text{and} \quad \tilde{t}_0 - \varepsilon^{-2/3} \leqq \tilde{t} \leqq \tilde{t}_0 - \Delta.$$

Proof. If we assume tentatively the existence of such a minimum at $\tilde{t}_1$, then at $\tilde{t}_1$ we show easily that

$$\frac{d^2R}{d\tilde{t}^2} \leqq -2R\left(\frac{df_1}{d\tilde{t}}\right) - \varepsilon^{1/3}[(f_1+R)+(f_1+R)f_1(\tilde{t}_1)\cdot f_1'(\tilde{t}_1)]. \tag{47}$$

From what precedes equation (2.6.50) in [4], we find

$$f_1(\tilde{t}) = \sqrt{(-\tilde{t})} + \cdots \quad \text{and} \quad f_1'(\tilde{t}) = \frac{-1}{2\sqrt{(-\tilde{t})}} + \cdots \tag{48}$$

as $\tilde{t} \to -\infty$. Then there exists a $\tilde{\tau}$ such that for $\tilde{t} \leqq \tilde{t}_0 - \tilde{\tau}$,

$$f_1(\tilde{t}) < (1+\alpha)\sqrt{(-\tilde{t})} \quad \text{and} \quad f_1'(\tilde{t}) > -(1+\alpha)[2\sqrt{(-\tilde{t})}]. \tag{49}$$

Two easy computations (one if $\tilde{t}_1 < \tilde{t}_0 - \tilde{\tau}$, and the other if $\tilde{t}_1 \in [\tilde{t}_0 - \tilde{\tau}, \tilde{t}_0 - \Delta]$) yield $R''(\tilde{t}_1) < 0$ if ε is sufficiently small, a contradiction.

PROPOSITION 7. *Let $\tilde{\eta}$, λ, and Δ be as in Proposition 5. Then, for all sufficiently small ε, there exists no $\tilde{t}_1 \in [\tilde{t}_0 - \tilde{\eta}, \tilde{t}_0 - \Delta]$ for which*

$$-f_1(\tilde{t}_1) \leqq R(\tilde{t}_1) < -\lambda \quad \text{and} \quad R'(\tilde{t}_1) \leqq 0. \tag{50}$$

Proof. Assume tentatively such a $\tilde{t}_1$ exists. An obvious continuation argument leads to the conclusion that as long as $R(\tilde{t}) \geqq -f_1(\tilde{t})$ to the right of $\tilde{t}_1$, $R'(\tilde{t})$ will be negative and lie below $-\lambda$. Clearly (see Fig. 2) this cannot persist indefinitely, and the graph of $R(\tilde{t})$ must enter the region $R \leqq -f_1(\tilde{t})$, $R \leqq -\lambda$, $\tilde{t}_0 - \tilde{\eta} \leqq \tilde{t} \leqq \tilde{t}_0 - \Delta$ with a nonpositive slope. Proposition 5 then yields the desired contradiction.

COROLLARY. *The conclusion of Proposition 7 remains true if $\tilde{\eta}$ is replaced by $\tilde{\eta}+1$.*

PROPOSITION 8. *Let $\tilde{\eta}$, λ, and Δ be as in Proposition 5 Then, if ε is sufficiently small, there exists no $\tilde{t}_2 \in [\tilde{t}_0 - \tilde{\eta}, \tilde{t}_0 - \Delta]$ for which*

$$R'(\tilde{t}_2) > 0 \quad \text{and} \quad R(\tilde{t}_2) \leqq -\lambda. \tag{51}$$

Proof. Assume tentatively such a $\tilde{t}_2$ exists. It follows from the corollary to Proposition 5 and the proof of Proposition 6 that

$$R'(\tilde{t}_0 - \tilde{\eta}) > 0 \quad \text{and} \quad R(\tilde{t}_0 - \tilde{\eta}) \leqq -\lambda. \tag{52}$$

There are two cases, depending on whether $R(\tilde{t}_0 - \tilde{\eta}) \geqq -f_1(\tilde{t}_0 - \tilde{\eta})$ or not. If $R(\tilde{t}_0 - \tilde{\eta}) \geqq -f_1(\tilde{t}_0 - \tilde{\eta})$, then, as $\tilde{t}$ decreases, $R(\tilde{t})$ cannot drop below $-f_1(\tilde{t})$ on the interval $[\tilde{t}_0 - \tilde{\eta} - 1, \tilde{t}_0 - \tilde{\eta}]$ and still be on the limit cycle (recall $R(\tilde{t}_0 - \varepsilon^{-2/3}/2)$ is positive) and so

$$R(\tilde{t}_0 - \tilde{\eta} - 1) \geqq -f_1(\tilde{t}_0 - \tilde{\eta} - 1). \tag{53}$$

The same conclusion holds if the other alternative, $R(\tilde{t}_0 - \tilde{\eta}) < -f_1(\tilde{t}_0 - \tilde{\eta})$, is assumed. To show this, note that $R'(\tilde{t}_0 - \tilde{\eta}) < -f_1'(\tilde{t}_0 - \tilde{\eta})$ if ε is sufficiently small, since otherwise we would not be on the limit cycle. Then as long as

$$R(\tilde{t}) \leqq -f_1(\tilde{t}) \quad \text{and} \quad R'(\tilde{t}) \leqq -f_1'(\tilde{t}) \tag{54}$$

to the left of $\tilde{t}_0 - \tilde{\eta}$, we show with the help of Proposition 4 that

$$\frac{d^2R}{d\tilde{t}^2} \leqq 2f_1\left(\frac{df_1}{d\tilde{t}}\right) + O(\varepsilon^{1/3}), \tag{55}$$

and estimates (48) then give

$$\frac{d^2R}{d\tilde{t}^2} \leqq \{2\sqrt{(\tilde{t}_0-\tilde{\eta})(1+o(1))}\}\left\{\frac{-1}{2\sqrt{(\tilde{t}_0-\tilde{\eta})}}(1+o(1))\right\}+O(\varepsilon^{1/3}). \tag{56}$$

Thus if ε is sufficiently small,

$$\frac{d^2R}{d\tilde{t}^2} \leqq -\frac{1}{3} \tag{57}$$

as long as (54) holds to the left of $\tilde{t}_0-\tilde{\eta}$. This implies

$$R'(\tilde{t}_0-\tilde{\eta}-1) > -f_1'(\tilde{t}_0-\tilde{\eta}-1) \tag{58}$$

if ε is sufficiently small, which in turn implies (53) (for otherwise the trajectory is not the limit cycle). At this stage it has been established that for ε sufficiently small,

$$-f_1(\tilde{t}_0-\tilde{\eta}-1) \leqq R(\tilde{t}_0-\tilde{\eta}-1) < -\lambda, \tag{59a}$$

$$R'(\tilde{t}_0-\tilde{\eta}-1) > 0. \tag{59b}$$

Now, to be on the limit cycle trajectory, $R(\tilde{t}) \geqq -f_1(\tilde{t})$ for all $\tilde{t} \in [\tilde{t}_0-\varepsilon^{-2/3}/2,\ \tilde{t}_0-\tilde{\eta}-1]$. However, from the proof of Proposition 6, $R'(\tilde{t})$ remains positive to the left of $\tilde{t}_0-\tilde{\eta}-1$ at least until $\tilde{t}_0-\varepsilon^{-2/3}/2$ is reached, forcing $R(\tilde{t}_0-\varepsilon^{-2/3}/2) < -\lambda$. This contradicts Proposition 3.

So far it has been shown that if ε is sufficiently small, no part of the graph of $R(\tilde{t})$ can appear in the region $R \leqq -\lambda$, $\tilde{t}_0-\tilde{\eta} \leqq \tilde{t} \leqq \tilde{t}_0-\Delta$. The next three propositions explore the region $R \geqq \lambda$.

PROPOSITION 9. *Let λ, Δ be as in Proposition 5, and let $\tilde{\nu} = \tilde{\nu}(\varepsilon)$ satisfy $\Delta \ll \tilde{\nu} \ll \varepsilon^{-1/3}$. Then, for all sufficiently small ε, there exists no $\tilde{t}_1 \in [\tilde{t}_0-\tilde{\nu},\ \tilde{t}_0-\Delta]$ for which*

$$R(\tilde{t}_1) \geqq \lambda \quad \textit{and} \quad R'(\tilde{t}_1) \leqq 0. \tag{60}$$

Proof. Assume tentatively that such a $\tilde{t}_1$ exists, and note that wherever R' is nonpositive, (14) gives

$$\frac{d^2R}{d\tilde{t}^2} \geqq -2(R+f_1)\left(\frac{dR}{d\tilde{t}}\right)-2R\left(\frac{df_1}{d\tilde{t}}\right)-\varepsilon^{1/3}(f_1+R). \tag{61}$$

The idea of the proof is to show R' is negative for all $\tilde{t} < \tilde{t}_1$; this would contradict the fact that y is periodic. We begin by showing $d^2R/d\tilde{t}^2$ is positive on the interval $[\tilde{t}_0-2\tilde{\nu},\ \tilde{t}_1)$. Since the first term on the right of (61) has factor $dR/d\tilde{t}$, we need only show that the second factor dominates the third. Specifically, we can easily show that at any $\tilde{t}$ in the interval $[\tilde{t}_0-2\tilde{\nu},\ \tilde{t}_1)$ at which $R(\tilde{t}) \geqq \lambda$,

$$|\varepsilon^{1/3}(f_1+R)| < \frac{1}{2}\left|2R\left(\frac{df_1}{d\tilde{t}}\right)\right| \tag{62}$$

for all sufficiently small ε. Having shown this dominance, an obvious continuation argument leads to the conclusion that for all sufficiently small ε,

$$\frac{dR}{d\tilde{t}} < 0 \quad \text{and} \quad R(\tilde{t}) > \lambda \quad \text{on } [\tilde{t}_0-2\tilde{\nu},\ \tilde{t}_1). \tag{63}$$

If ε sufficiently small,

$$f_1(\tilde{t})+R(\tilde{t}) > 0 \quad \text{and} \quad f'(\tilde{t}) \leqq -\frac{3}{8\sqrt{(\tilde{t}_0-\tilde{t})}} \quad \text{on } [\tilde{t}_0-2\tilde{\nu},\ \tilde{t}_0-\tilde{\nu}] \tag{64}$$

so that

$$\frac{d^2R}{d\tilde{t}^2} > \left(\frac{3\lambda}{8}\right)(\tilde{t}_0 - \tilde{t})^{-1/2}, \qquad \tilde{t} \in [\tilde{t}_0 - 2\tilde{\nu}, \tilde{t}_0 - \tilde{\nu}], \tag{65}$$

and an integration gives

$$R'(\tilde{t}_0 - 2\tilde{\nu}) \leqq -\left(\frac{3\lambda}{4}\right)\left(1 - \frac{1}{\sqrt{2}}\right)(2\tilde{\nu})^{1/2}. \tag{66}$$

Thus the first term in (61) dominates the third term when $\tilde{t} = \tilde{t}_0 - 2\tilde{\nu}$. Again an easy continuation argument can be applied to the left of $\tilde{t}_0 - 2\tilde{\nu}$ to conclude $R'(\tilde{t})$ is negative for all $\tilde{t} < \tilde{t}_1$, which implies the contradiction mentioned near the beginning of the proof.

PROPOSITION 10. *Let $\tilde{\nu} = \tilde{\nu}(\varepsilon)$ again satisfy $\Delta \ll \tilde{\nu} \ll \varepsilon^{-1/3}$ with Δ, λ as in Proposition 5. If there is a $\tilde{t}_1 \in [\tilde{t}_0 - \tilde{\nu}, \tilde{t}_0 - \Delta]$ for which $R(\tilde{t}_1) \geqq \lambda$ and $R'(\tilde{t}_1) > 0$, then, provided ε is sufficiently small, $R(\tilde{t}) > \lambda$ and $R'(\tilde{t}) > 0$ for all $\tilde{t} \in (\tilde{t}_1, \tilde{t}_0) \subset [\tilde{t}_0 - \tilde{\nu}, \tilde{t}_0)$. In addition there exists λ' which depends on λ and Δ but is independent of sufficiently small ε such that*

$$R'\left(\tilde{t}_0 - \frac{\Delta}{2}\right) \geqq \lambda'. \tag{67}$$

Proof. Assume such a $\tilde{t}_1$ exists. From Proposition 9 we conclude immediately that $R(\tilde{t}_0 - \Delta) > \lambda$ and $R'(\tilde{t}_0 - \Delta) > 0$. To prove these inequalities on $[\tilde{t}_0 - \Delta, \tilde{t}_0)$ note that from (ii) of Proposition 2, $R'(\tilde{t}_0 - \Delta) < -f_1(\tilde{t}_0 - \Delta)$. From this it follows that

$$R(\tilde{t}) < -f_1(\tilde{t}) \quad \text{and} \quad R'(\tilde{t}) < -f_1'(\tilde{t}) \quad \text{on } [\tilde{t}_0 - \Delta, \tilde{t}_0), \tag{68}$$

for otherwise the trajectory is not the limit cycle. The information above used in (14) leads directly to

$$\frac{d^2R}{d\tilde{t}^2} > -2R\left(\frac{df_1}{d\tilde{t}}\right) \quad \text{on } [\tilde{t}_0 - \Delta, \tilde{t}_0), \tag{69}$$

from which the conclusion $R(\tilde{t}) > \lambda$, $R'(\tilde{t}) > 0$ on $(\tilde{t}_1, \tilde{t}_0)$ follows immediately. To complete the proof simply integrate (69) from $\tilde{t}_0 - \Delta$ to $\tilde{t}_0 - \Delta/2$. The result is

$$R'\left(\tilde{t}_0 - \frac{\Delta}{2}\right) > \lambda |f_1'(\tilde{t}_0 - \Delta)| \left(\frac{\Delta}{2}\right) \equiv \lambda'. \tag{70}$$

The next proposition proves that $\tilde{t}_1$ as described in Proposition 10 cannot exist.

PROPOSITION 11. *Let $\tilde{\nu}$ be as in Proposition 10, and let Δ and λ be as in Proposition 5. Let λ' be defined by (70). Then, for all sufficiently small ε, there is no $\tilde{t}_1 \in [\tilde{t}_0 - \tilde{\nu}, \tilde{t}_0 - \Delta]$ for which $R(\tilde{t}_1) \geqq \lambda$ and $R'(\tilde{t}_1) > 0$.*

Proof. Assume tentatively that such a $\tilde{t}_1$ exists. From Proposition 10,

$$R\left(\tilde{t}_0 - \frac{\Delta}{2}\right) > \lambda \quad \text{and} \quad R'\left(\tilde{t}_0 - \frac{\Delta}{2}\right) > \lambda' \tag{71}$$

for all sufficiently small ε. From (71) there exists κ_0, independent of ε, such that

$$\kappa_0 R\left(\tilde{t}_0 - \frac{\Delta}{2}\right) > -f_1\left(\tilde{t}_0 - \frac{\Delta}{2}\right) - \frac{1}{2f_1'\left(\tilde{t}_0 - \frac{\Delta}{2}\right)}, \tag{72}$$

$$\kappa_0 R'\left(\tilde{t}_0 - \frac{\Delta}{2}\right) \geqq -f_1'\left(\tilde{t}_0 - \frac{\Delta}{2}\right) \tag{73}$$

for all sufficiently small ε. Now multiply (69) by κ_0:

$$\frac{d^2(\kappa_0 R)}{d\tilde{t}^2} > -2(\kappa_0 R)\left(\frac{df_1}{d\tilde{t}}\right), \qquad \tilde{t} \in \left[\tilde{t}_0 - \frac{\Delta}{2}, \tilde{t}_0\right) \tag{74}$$

and add it to the equation satisfied by f_1 [4, p. 75]. The result is the inequality

$$\frac{d^2(\kappa_0 R + f_1)}{d\tilde{t}^2} > -2(\kappa_0 R + f_1)\left(\frac{df_1}{d\tilde{t}}\right) - 1, \qquad \tilde{t} \in \left[\tilde{t}_0 - \frac{\Delta}{2}, \tilde{t}_0\right). \tag{75}$$

Inequalities (72) and (73) imply that at $\tilde{t}_0 - \Delta/2$, $d^2(\kappa_0 R + f_1)/d\tilde{t}^2$ is positive and that $d(\kappa_0 R + f_1)/d\tilde{t}$ is positive on some interval to the right of $\tilde{t}_0 - \Delta/2$, so $\kappa_0 R + f_1$ is increasing. f_1', on the other hand, is negative and decreasing. A continuation argument then yields

$$\kappa_0 R(\tilde{t}) + f_1(\tilde{t}) > 0 \quad \text{for all } \tilde{t} \in \left[\tilde{t}_0 - \frac{\Delta}{2}, \tilde{t}_0\right). \tag{76}$$

In particular,

$$R(\tilde{t} - \varepsilon^{1/6}) > \frac{\varepsilon^{-1/6}(1 + o(1))}{\kappa_0} \tag{77}$$

where (30) has been used. But (77) contradicts (iii) of Proposition 2, so $\tilde{t}_1$ cannot exist if ε is sufficiently small.

The first main result can now be proved.

THEOREM A. *Let Δ be any positive number and let $\tilde{\nu} = \tilde{\nu}(\varepsilon)$ satisfy*

$$\Delta \ll \tilde{\nu}(\varepsilon) \ll \varepsilon^{-1/3}. \tag{78}$$

Then

$$y(t) = 1 + \varepsilon^{1/3} f_1(\tilde{t}) + o(\varepsilon^{1/3}) \tag{79}$$

uniformly for

$$\tilde{t} \in [\tilde{t}_0 - \tilde{\nu}, \tilde{t}_0 - \Delta]. \tag{80}$$

Proof. Let λ be any positive number, and note that, with no loss of generality, we can assume Δ satisfies the conditions in Proposition 1. Note also that $\tilde{\nu} \ll \varepsilon^{-1/3} \ll \varepsilon^{-2/3}$, and so $\tilde{\nu}$ can replace $\tilde{\eta}$. From Propositions 5, 7-9, and 11,

$$|R(\tilde{t})| < \lambda \quad \text{for } \tilde{t} \in [\tilde{t}_0 - \tilde{\nu}, \tilde{t}_0 - \Delta] \tag{81}$$

for all sufficiently small ε. That is,

$$R(\tilde{t}) = o(1) \quad \text{for } \tilde{t} \in [\tilde{t}_0 - \tilde{\nu}, \tilde{t}_0 - \Delta] \tag{82}$$

and from (9) the result follows.

4. Inner expansion analysis. We begin with a summary of results proved in [8] concerning the leading term of the inner asymptotic expansion. Recall $r(t^*)$ is defined in (7).

PROPOSITION 12.

(a) $|y(t; \varepsilon)| < 3$ *if* $\varepsilon < \frac{1}{15}$,

(b) $dr/dt^*(0) < 0$,

(c) $r(t^*) \geqq 0$ *for* $t^* \in [-\varepsilon^{-1/3}/2, 0]$,

(d) $y(t; \varepsilon) = g_0(t^*) + O(\varepsilon^{1/3})$,

uniformly for $t^* \in [-\varepsilon^{-1/3}/2, +\varepsilon^{-2/3}]$.

The next proposition extends the domain of uniform validity of the transition expansion declared in Theorem A, and is an immediate consequence of Kaplun's Extension Theorem [4], [5].

PROPOSITION 13. *Let* $\tilde{\nu} = \tilde{\nu}(\varepsilon)$ *be as in Theorem* A. *Then there exists* $\tilde{\Delta} = \tilde{\Delta}(\varepsilon)$ *such that* $\tilde{\Delta} \to 0+$ *as* $\varepsilon \to 0$ *and such that*

$$y(t;\varepsilon) = 1 + \varepsilon^{1/3} f_1(\tilde{t}) + o(\varepsilon^{1/3}) \tag{83}$$

uniformly for $\tilde{t} \in [\tilde{t}_0 - \tilde{\nu},\ \tilde{t}_0 - \tilde{\Delta}]$. *Furthermore, without loss of generality, we can assume*

$$\frac{\varepsilon^{1/3}|\log \varepsilon|}{\tilde{\Delta}^2} \to 0 \quad \text{as } \varepsilon \to 0. \tag{84}$$

PROPOSITION 14.

$$\frac{dr}{dt^*}(0) = o(\varepsilon^{1/3}). \tag{85}$$

Proof. Tentatively assume γ is a positive constant and that there are arbitrarily small ε-values for which

$$\frac{dr}{dt^*} < -\gamma\varepsilon^{1/3}; \tag{86}$$

throughout the proof assume ε is chosen from this set. It is easily shown that for ε sufficiently small,

$$r'(-1) < \frac{-\gamma\varepsilon^{1/3}}{4}, \tag{87}$$

$$r(-1) > \frac{\gamma\varepsilon^{1/3}}{2}. \tag{88}$$

If ε is sufficiently small, $-\varepsilon^{2/3} > -\gamma\varepsilon^{1/3}/4$, and for such ε denote by t_1^* the first t^*-value to the left of -1, where dr/dt^* has increased to $-\varepsilon^{2/3}$. Kevorkian and Cole establish asymptotic properties for $g_0(t^*)$ which imply the existence of constants C_1, C_2, C_3 such that if $t^* \leqq -1$,

$$g_0(t^*) \geqq C_1, \tag{89}$$

$$g_0'(t^*) < \frac{-C_2}{t^{*2}}, \tag{90}$$

$$1 - (g_0(t^*))^2 < \frac{2C_3}{(-t^*)}. \tag{91}$$

These and (a) of Proposition 12 used in (11) give

$$\frac{d^2r}{dt^{*2}} > \frac{2C_1C_2}{t^{*2}} + \left(\frac{2C_3}{(-t^*)}\right) \cdot \left(\frac{dr}{dt^*}\right) - 3\varepsilon, \qquad t^* \in [t_1^*, -1], \tag{92}$$

and at t_1^* it is necessary that the left side of (92) be nonpositive. Hence, after multiplying the right side of (92) by $(t_1^*)^2$, there results a quadratic in t_1^*, and t_1^* must be at least as negative as the negative root of the quadratic. Assuming γ is small enough to ensure

$$\frac{3\gamma C_1C_2}{C_3^2} < 1, \tag{93}$$

elementary computations yield

$$t_1^* < \left(\frac{-3C_1C_2\gamma}{8C_3}\right)\varepsilon^{-1/3}. \tag{94}$$

Relating t^*-values and $\tilde{t}$-values with (5) and (6), it is readily seen that $\tilde{t}_0-\tilde{\Delta}$ lies to the right of t_1^* if ε is sufficiently small, and hence at the t^*-value corresponding to $\tilde{t}_0-\tilde{\Delta}$, dr/dt^* is more negative than $-\varepsilon^{2/3}$ and r is at least as positive as $\gamma\varepsilon^{1/3}/2$. Now use the asymptotic behavior of $g_0(t^*)$ as recorded by Kevorkian and Cole [4, form. (2.6.24)]—see (25), and evaluate g_0 at the t^* corresponding to $\tilde{t}_0-\tilde{\Delta}$:

$$g_0\left(-\varepsilon^{-1/3}\tilde{\Delta}\left[1+\frac{\varepsilon^{1/3}|\log\varepsilon|}{9\tilde{\Delta}}\right]\right)=1+\left(\frac{\varepsilon^{1/3}}{-\tilde{\Delta}}\right)\left\{1+O\left(\frac{\varepsilon^{1/3}|\log\varepsilon|}{9\tilde{\Delta}}\right)\right\}+O\left\{\frac{\log|-\varepsilon^{1/3}\tilde{\Delta}(1+o(1))|}{[\varepsilon^{-1/3}\tilde{\Delta}(1+o(1)]^2}\right\}. \tag{95}$$

With (84), this leads to

$$\begin{aligned} y(\tilde{t}=\tilde{t}_0-\tilde{\Delta}) &= 1-\frac{\varepsilon^{1/3}}{\tilde{\Delta}}+o(\varepsilon^{1/3})+r(\tilde{t}=\tilde{t}_0-\tilde{\Delta}) \\ &> 1-\frac{\varepsilon^{1/3}}{\tilde{\Delta}}+\frac{\gamma\varepsilon^{1/3}}{2}+o(\varepsilon^{1/3}). \end{aligned} \tag{96}$$

On the other hand, from Proposition 13 and (30),

$$\begin{aligned} y(\tilde{t}=\tilde{t}_0-\tilde{\Delta}) &= 1+\varepsilon^{1/3}f_1(\tilde{t}_0-\tilde{\Delta})+o(\varepsilon^{1/3}) \\ &= 1-\frac{\varepsilon^{1/3}}{\tilde{\Delta}}+o(\varepsilon^{1/3}). \end{aligned} \tag{97}$$

Comparing (96) and (97) yields the needed contradiction and the proposition is proved.

PROPOSITION 15. *Let $t_{\tilde{\Delta}}^*$ denote the t^*-value corresponding to $\tilde{t}=\tilde{t}_0-\tilde{\Delta}$. Then*

$$r(t^*)=o(\varepsilon^{1/3}) \tag{98}$$

uniformly for $t^*\in[t_{\tilde{\Delta}}^*, 0]$.

Proof. The proof is similar to that of Proposition 14. Thus, let γ denote a positive constant and assume tentatively the existence of $t_1^*\in[t_{\tilde{\Delta}}^*, 0]$, where $r(t_1^*)\geqq\gamma\varepsilon^{1/3}$. Then the Mean Value Theorem produces a $t_\alpha^*\in(t_{\tilde{\Delta}}^*, 0)$, where $r'(t_\alpha^*)$ is at least as negative as $(\gamma\varepsilon^{1/3})/(2t_{\tilde{\Delta}}^*)$, and hence (recall $t_{\tilde{\Delta}}^*=-\varepsilon^{-1/3}\tilde{\Delta}(1+o(1))$) for all sufficiently small ε,

$$r'(t_\alpha^*)<-\varepsilon^{2/3}, \tag{99}$$

and of course

$$r'(t_\alpha^*)>\gamma\varepsilon^{1/3}/2. \tag{100}$$

The remainder of the proof is essentially like that of Proposition 14.

COROLLARY. *Let $\eta^*=o(\varepsilon^{-1/3})$. Then*

$$y=g_0(t^*)+o(\varepsilon^{1/3}) \tag{101}$$

uniformly for $t^*\in[-\eta^*, 0]$.

Proof. In the proof of Proposition 15, replace $\tilde{\Delta}$ by $\max\{\varepsilon^{1/3}\eta^*, \tilde{\Delta}\}$.

We now turn our attention to the behavior of $r(t^*)$ to the right of $t^*=0$. The goal is to sharpen the estimate of Proposition 6 in [8].

PROPOSITION 16. *Let $1\ll\eta\ll\varepsilon^{-2/3}$. Then both $r(t^*)$ and $r'(t^*)$ are $o(\varepsilon^{1/3})$ uniformly for $t^*\in[0, \eta]$.*

Proof. As in [8], begin with the identities

$$\frac{dr}{dt^*}-(1-g_0^2)r=\frac{dr}{dt^*}(0)+\int_0^{t^*}\left\{-\left(\frac{dg_0}{d\nu}\right)r^2-\varepsilon y-[2g_0+r]r\left(\frac{dr}{d\nu}\right)\right\}d\nu, \tag{102}$$

$$\begin{aligned} r(t^*)=&\left(\frac{dr}{dt^*}(0)\right)\left\{\exp\int_0^{t^*}(1-g_0^2)\,ds\right\}\int_0^{t^*}\left\{\exp\left[-\int_0^{\xi}(1-g_0^2)\,ds\right]\right\}d\xi \\ &+\left\{\exp\int_0^{t^*}(1-g_0^2)\,ds\right\}\int_0^{t^*}\left\{\exp\left[-\int_0^{\xi}(1-g_0^2)\,ds\right]\right\} \\ &\cdot\left\{\int_0^{\xi}\left[-\left(\frac{dg_0}{d\nu}\right)r^2-\varepsilon y(2g_0+r)r\left(\frac{dr}{d\nu}\right)\right]d\nu\right\}\Bigg\}d\xi \end{aligned} \tag{103}$$

At $t^*=0$, both r and r' are $o(\varepsilon^{1/3})$, and this estimate certainly cannot be destroyed on any finite interval due to the presence of products of r and r' in the integrands. Choose the finite interval to be $[0, 4]$. So,

$$r(t^*)=o(\varepsilon^{1/3}), \tag{104}$$

$$r'(t^*)=o(\varepsilon^{1/3}), \tag{105}$$

uniformly on $[0, 4]$.

To continue these estimates to the right of $t^*=4$, multiply (11) by dr/dt^*:

$$\begin{aligned} \frac{d}{dt^*}\left(\frac{dr}{dt^*}\right)^2=&-3\left(\frac{dr}{dt^*}\right)^2+\left(\frac{dr}{dt^*}\right) \\ &\cdot\left[-(2g_0')\cdot(2g_0+r)r+(-2(y^2-1)+3)\left(\frac{dr}{dt^*}\right)-2\varepsilon y\right]. \end{aligned} \tag{106}$$

If the expression in the square braces were absent from (106), then $|dr/dt^*|$ would decay exponentially fast and the $o(\varepsilon^{1/3})$ estimate for $r(4)$, $r'(4)$ would persist for all $t^*>4$. The task is thus to control the term in the square braces, at least until t^* reaches η. To this end, let k denote any positive constant and choose ε small enough to ensure neither $|r(4)|$ nor $|r'(4)|$ exceeds $k\varepsilon^{1/3}/2$. Then, for as long as

$$|r(t^*)|\leqq 2k\varepsilon^{1/3}, \tag{107}$$

$$|r'(t^*)|\leqq k\varepsilon^{1/3} \tag{108}$$

hold to the right of $t^*=4$, simple computations yield

$$\left(\frac{dr}{dt^*}\right)^2<(k\varepsilon^{1/3})^2. \tag{109}$$

(To arrive at (109), use (a) and (d) of Proposition 12, together with the facts that g_0 is within .001 of -2 and $g_0'(t^*)$ has magnitude smaller than .001 for $t^*\geqq 4$.) Thus the weak inequalities (107), (108) imply the strict inequality (109), so it is now only necessary to exclude the possibility that equality in (107) occurs at some t^*-value in $[4, \eta]$. Assume tentatively that $r(t^*)$ reaches $2k\varepsilon^{1/3}$ for the first time at $t^*=t_2^*$, and denote by t_1^* the last t^*-value previous to t_2^* that $r=0$, or $t_1^*=4$, whichever is greater. (The case $r(t_2^*)=-2k\varepsilon^{1/3}$ is considered below.)

Observe that on any subinterval of $[t_1^*, t_2^*]$ where $r'(t^*)$ happens to be as large as $5\varepsilon/3$, it is easily shown that if ε is sufficiently small, the expression in the braces in

(106) is negative, and from this it follows immediately that if dr/dt^* ever exceeds $5\varepsilon/3$ on $[t_1^*, t_2^*]$ it must do so at t_1^*. Now integrate the inequality, obtained from (106),

$$\frac{d}{dt^*}\left(\frac{dr}{dt^*}\right)^2 < -3\left(\frac{dt}{dt^*}\right)^2 \tag{110}$$

for as long as $dr/dt^* \geqq 5\varepsilon/3$ on $[t_1^*, t_2^*]$. The trivial computation yields

$$\begin{aligned} r(t^*) &\leqq r(t_1^*) + r'(t_1^*)\frac{2}{3}\left[1 - \exp\left(\frac{-3(t^* - t_1^*)}{2}\right)\right] \\ &< \frac{3k\varepsilon^{1/3}}{2}. \end{aligned} \tag{111}$$

Obviously, once dr/dt^* has dropped to $5\varepsilon/3$, it can never again equal $5\varepsilon/3$, and so any further increase in r on the interval $[t_1^*, t_2^*]$ is limited to $5\varepsilon/3 \cdot (t_2^* - t_1^*)$, and this cannot exceed $5\varepsilon/3 \cdot \eta$. Consequently,

$$\begin{aligned} r(t_2^*) &\leqq \frac{3k\varepsilon^{1/3}}{2} + \frac{5\varepsilon}{3}\eta \\ &< 2k\varepsilon^{1/3} \end{aligned} \tag{112}$$

if ε is sufficiently small. This contradicts the definition of t_2^*.

It is even easier to prove that $r(t^*) > -2k\varepsilon^{1/3}$ for $t^* \in [4, \eta]$ since if r, r' are both nonpositive, all the terms in the braces of (106) are nonpositive.

It has now been shown that for arbitrary positive k, (107), (108) are valid for all $t^* \in [4, \eta]$, provided ε is sufficiently small. Combining this with the result on the interval $[0, 4]$ completes the proof.

From the corollary to Proposition 15 and from Proposition 16 we have the following theorem.

THEOREM B. *Let* $0 \ll \eta^* \ll \varepsilon^{-1/3}$ *and* $0 \ll \eta \ll \varepsilon^{-2/3}$. *Then*

$$y = g_0(t^*) + o(\varepsilon^{1/3}) \tag{113}$$

uniformly for $-\eta^* \leqq t^* \leqq \eta$.

5. Outer expansion analysis. In this section we prove that the leading term of the outer asymptotic expansion, $u_0(t)$, gives an $O(\varepsilon^{1/3})$ approximation to y on an explicit domain of uniform validity.

PROPOSITION 17. *Let* $\varepsilon^{2/3} \ll \eta_2 \leqq \varepsilon^{1/3}$. *Then*

$$y(\delta - \eta_2) = u_0(\delta - \eta_2) + o(\varepsilon^{1/3}), \tag{114}$$

$$h(t) \leqq o(\varepsilon^{1/3}) \quad \textit{uniformly on} \left[\frac{-T}{2} + \delta, \delta - \eta_2\right]. \tag{115}$$

Proof. If ε is sufficiently small, $\delta - \eta_2$ is in the domain of uniform validity of the transition expansion; see Theorem A, (4), and (6). An elementary computation involving the asymptotic behavior of f_1 (see (32)) gives

$$y(\delta - \eta_2) = 1 + \varepsilon^{1/3}(\varepsilon^{-2/3}\eta_2 - \tilde{t}_0)^{1/2} + o(\varepsilon^{1/3}). \tag{116}$$

On the other hand, the asymptotic behavior of u_0 described by Kevorkian and Cole's equation [4, eq. (2.6.15)] yields

$$y(\delta - \eta_2) = 1 + \varepsilon^{1/3}(\varepsilon^{-2/3}\eta_2 - \tilde{t}_0)^{1/2} + o(\varepsilon^{1/3}) + h(-\eta_2 + \delta). \tag{117}$$

Combining (116) and (117) yields (114).

To show h is bounded above by $o(\varepsilon^{1/3})$ uniformly on $[-T/2+\delta, -\eta_2+\delta]$, note $y(-T/2+\delta)=0$ and $u_0(-T/2+\delta)>0$, so $h(T/2+\delta)$ is negative. It is now easy to show that the assumptions that $h(\delta-\eta_2)$ is nonnegative and that h exceeds $h(\delta-\eta_2)$ anywhere on the interval lead to a contradiction. If $h(\delta-\eta_2)$ is negative, a similar argument shows $h(t)$ is negative on $[-T/2+\delta, \delta-\eta_2]$. This completes the proof.

The next two propositions give a proof of a classical result. The method of proof in Proposition 19 is used in Proposition 20.

PROPOSITION 18.

$$T \leqq (3-2\log 2)+o(\varepsilon^{1/3}). \tag{118}$$

Proof. Only those small ε-values for which $-T/2 > -\frac{3}{2}+\log 2$ need be considered. Let Δt_ε satisfy

$$|\log \varepsilon| \leqq \frac{\Delta t_\varepsilon}{\varepsilon} \ll \varepsilon^{-2/3}. \tag{119}$$

From Theorem B and the antiperiodic behavior of the oscillations, and equation (2.6.72) of [4], there follows

$$\begin{aligned} y\left(\frac{-T}{2}+\delta+\Delta t_\varepsilon\right) &= -g_0\left(\frac{\Delta t_\varepsilon}{\varepsilon}\right)+o(\varepsilon^{1/3}) \\ &= 2+o(\varepsilon^{1/3}), \end{aligned} \tag{120}$$

and thus

$$h\left(\frac{-T}{2}+\delta+\Delta t_\varepsilon\right) = 2+o(\varepsilon^{1/3})-u_0\left(\frac{-T}{2}+\delta+\Delta t_\varepsilon\right). \tag{121}$$

Noting that u_0' is increasing on the interval between $-\frac{3}{2}+\log 2$ and $-T/2+\delta+\Delta t_\varepsilon$, that $u_0'(-\frac{3}{2}+\log 2)=-\frac{2}{3}$, and that $u_0(-\frac{3}{2}+\log 2)=2$, we can easily show with the Mean Value Theorem that

$$h\left(\frac{-T}{2}+\delta+\Delta t_\varepsilon\right) > o(\varepsilon^{1/3})+\frac{2}{3}\left[\left(\frac{-T}{2}+\delta+\Delta t_\varepsilon\right)-\left(-\frac{3}{2}+\log 2\right)\right]. \tag{122}$$

Now use (115) to complete the proof.

PROPOSITION 19.

$$T \leqq (3-2\log 2)+o(\varepsilon^{1/3}). \tag{123}$$

Proof. Assume tentatively that there is a positive constant γ and a set $E(\gamma)$ of ε-values which contains arbitrarily small values of ε for which

$$\frac{-T}{2} < -\frac{3}{2}+\log 2-\frac{\gamma\varepsilon^{1/3}}{2}. \tag{124}$$

Let

$$t_\varepsilon = \frac{-T}{2}+\delta+\Delta t_\varepsilon. \tag{125}$$

Then from (121),

$$h(t_\varepsilon) = 2+o(\varepsilon^{1/3})-u_0(t_\varepsilon). \tag{126}$$

If ε is sufficiently small,

$$t_\varepsilon < -\frac{3}{2}+\log 2-\frac{7\gamma\varepsilon^{1/3}}{16} \tag{127}$$

and since $u_0(-\frac{3}{2}+\log 2)=2$, (127) and (126) imply the existence of a positive constant k that is *independent of* ε *for all sufficiently small* ε, such that

$$h(t_\varepsilon)\leqq -k\varepsilon^{1/3}; \tag{128}$$

that is, h is negative and bounded away from zero by $O(\varepsilon^{1/3})$. The method of proof proceeds by showing that h continues to be negative and bounded away from zero to the right of t_ε, even penetrating the region of uniform validity of the transition expansion. But estimates from the latter prevent h from being negative and bounded away from zero by $O(\varepsilon^{1/3})$, thus proving the proposition.

To prove that (128) implies that h continues to be negative and bounded away from zero by $O(\varepsilon^{1/3})$, it is necessary to use technical details that are straightforward computations, and only a proof outline will be given. Begin with the differential equation for h written in the form

$$\begin{aligned}\frac{d^2h}{dt^2}=&-\left(\frac{1}{\varepsilon}\right)(y^2-1)\frac{dh}{dt}+\left(\frac{1}{2\varepsilon}\right)\frac{(1+u_0y)h}{(u_0^2-1)}\\&+\left(\frac{1}{2\varepsilon}\right)\frac{(1+u_0y)h}{(u_0^2-1)}\left\{1+\frac{u_0(1+u_0^2)2\varepsilon}{(u_0^2-1)^2h}\right\}\end{aligned} \tag{129}$$

and note first that Proposition 16, together with the exponential decay of g_0', implies $h'(t_\varepsilon)$ is bounded above by $o(\varepsilon^{-2/3})$. Thus, if $h'(t_\varepsilon)>\varepsilon^{1/3}$, we use the first term on the right side of (129) (which is approximately $-3h'/\varepsilon$) to show $h'(t)$ drops to $\varepsilon^{1/3}$ so fast that h is still negative and bounded away from zero by $O(\varepsilon^{1/3})$. Further, the t-value where h' reaches $\varepsilon^{1/3}$ is, like t_ε, on the left of and bounded away from $-\frac{3}{2}+\log 2$ by $O(\varepsilon^{1/3})$.

Now continue, and with the help of the second term on the right side of (129), show that h' drops to zero and becomes negative in a time interval of $O(\varepsilon)$. Thus, if h' was not negative at t_ε, it becomes so at a t-value that is, like t_ε itself, on the left of and bounded away from $-\frac{3}{2}+\log 2$ by $O(\varepsilon^{1/3})$. And clearly h is still negative and bounded away from zero by $O(\varepsilon^{1/3})$. Obviously, $h'(t)$ remains negative as long as the term in the braces of (129) remains positive, so the last step is to follow the sign of the term in the braces.

Note that $u_0(t)$ decreases to $u_0(0)=1$, as t increases. This leads to the conclusion that the term in the braces remains positive as long as

$$\frac{5\varepsilon}{(u_0-1)^2|h|}\leqq 1. \tag{130}$$

It turns out that the estimates above lead to the conclusion

$$h(t)\leqq\frac{-k\varepsilon^{1/3}}{4} \tag{131}$$

at least until (130) fails. It has been shown [9, eq. 50] that $t>-(u_0-1)^2$ when $-\frac{3}{2}+\log 2\leqq t<0$. It follows that (130) remains valid at least until

$$t=\frac{-20\varepsilon^{2/3}}{k}, \tag{132}$$

if ε is sufficiently small, and so the tentative assumption implies (131) holds for

$$t\in\left[t_\varepsilon,\frac{-20\varepsilon^{2/3}}{k}\right]. \tag{133}$$

However, consider the t-value corresponding to $\tilde{t} = \tilde{t}_0 - \tilde{\nu}$, where $\tilde{\nu}$ is defined in Theorem A. That is, $t = \varepsilon^{2/3}(\tilde{t}_0 - \tilde{\nu}) - \varepsilon|\log \varepsilon|/6$. It is easily verified from (79) that

$$y(\tilde{t} = \tilde{t}_0 - \tilde{\nu}) = 1 + \varepsilon^{1/3}(-\tilde{t}_0 + \tilde{\nu})^{1/2} + o(\varepsilon^{1/3}), \tag{134}$$

and from (6), (8), and the small-t behavior of u_0 that

$$y\left(t = \varepsilon^{2/3}(\tilde{t}_0 - \tilde{\nu}) - \frac{\varepsilon|\log \varepsilon|}{6}\right) = 1 + \varepsilon^{1/3}(-\tilde{t}_0 + \tilde{\nu})^{1/2} + o(\varepsilon^{1/3}) + h\left(\tilde{t}_0 - \tilde{\nu} - \frac{\varepsilon|\log \varepsilon|}{6}\right). \tag{135}$$

Thus

$$h\left(\varepsilon^{2/3}(\tilde{t}_0 - \tilde{\nu}) - \frac{\varepsilon|\log \varepsilon|}{6}\right) = o(\varepsilon^{1/3}),$$

contradicting (131), since $t = \varepsilon^{2/3}(\tilde{t}_0 - \tilde{\nu}) - \varepsilon|\log \varepsilon|/6$ is obviously in the interval (133) when ε is sufficiently small.

THEOREM C. *Let $\eta_1(\varepsilon)$, $\eta_2(\varepsilon)$ satisfy*

$$\varepsilon|\log \varepsilon| \leqq \eta_1 \ll \varepsilon^{1/3} \quad \textit{and} \quad \varepsilon^{2/3} \ll \eta_2 \ll \varepsilon^{1/3}. \tag{136}$$

Then

$$y(t; \varepsilon) = u_0(t) + o(\varepsilon^{1/3}) \tag{137}$$

uniformly for

$$t \in \left[\frac{-T}{2} + \delta + \eta_1, \delta - \eta_2\right]. \tag{138}$$

Proof. From Proposition 16, $\delta + \eta_1$ is in the domain where $r(t^*) = o(\varepsilon^{1/3})$ and where $g_0(t^*) = 2 + o(\varepsilon^{1/3})$. Using the antiperiodic behavior of y gives

$$y\left(\frac{-T}{2} + \delta + \eta_1\right) = 2 + o(\varepsilon^{1/3}). \tag{139}$$

Using $T = 3 - 2\log 2 + o(\varepsilon^{1/3})$ gives

$$y\left(\frac{-T}{2} + \delta + \eta_1\right) = 2 + o(\varepsilon^{1/3}) + h\left(\frac{-T}{2} + \delta + \eta_1\right), \tag{140}$$

and so

$$h\left(\frac{-T}{2} + \delta + \eta_1\right) = o(\varepsilon^{1/3}).$$

Next let k denote any positive constant and assume tentatively that h falls below $-k\varepsilon^{1/3}$ on the interval (138). Because of (139) and (114) there must be a t-value between $-T/2 + \delta + \eta_1$ and $\delta - \eta_2$, where h is less than $-k\varepsilon^{1/3}$ and where h' vanishes. The continuation argument of Proposition 19 is now applied and the same contradiction reached; the theorem is proved.

6. Summary. There remains the pleasant and easy task of collecting together the results of Theorems A–C, to confirm that together the explicit domains of validity of

the terms of the inner, outer, and transition expansions studied above indeed overlap in such a way as to cover the half period $t \in [-T/2+\delta, \delta]$. All domains are expressed in terms of the outer variable t, and are shown schematically in Fig. 1.

THEOREM D. *Let $\tilde{\Delta}$ be as defined in Proposition* 13, *and let η, η_1, η_2, $\tilde{\nu}$, and η^* satisfy*

(a) $\varepsilon|\log \varepsilon| \ll \eta_1 \ll \varepsilon\eta \ll \varepsilon^{1/3}$,

(b) $\varepsilon^{2/3} \ll \eta_2 \ll \varepsilon^{2/3}\tilde{\nu} + \varepsilon|\log \varepsilon|/9 \ll \varepsilon^{1/3}$,

(c) $\sqrt{\varepsilon^{5/3}|\log \varepsilon|} \ll \varepsilon^{2/3}\tilde{\Delta} + \varepsilon|\log \varepsilon|/9 \ll \varepsilon\eta^* \ll \varepsilon^{2/3}$.

Then, uniformly and within an $o(\varepsilon^{1/3})$ error, y is approximated by the following expressions:

$$-g_0\left(t^* + \frac{T}{2\varepsilon}\right) \quad \text{for } t \in \left[\frac{-T}{2} + \delta, \frac{-T}{2} + \delta + \varepsilon\eta\right], \tag{141}$$

$$u_0(t) \quad \text{for } t \in \left[\frac{-T}{2} + \delta + \eta_1, \delta - \eta_2\right], \tag{142}$$

$$1 + \varepsilon^{1/3} f_1(\tilde{t}) \quad \text{for } t \in \left[\delta - \frac{\varepsilon|\log \varepsilon|}{9} - \varepsilon^{2/3}\tilde{\nu}, \delta - \frac{\varepsilon|\log \varepsilon|}{9} - \varepsilon^{2/3}\tilde{\Delta}\right], \tag{143}$$

$$g_0(t^*) \quad \text{for } t \in [\delta - \varepsilon\eta^*, \delta]. \tag{144}$$

Proof. If η satisfies (a) and if η^* satisfies (c), then (141) and (144) follow immediately from Theorem B; of course, a translation, based on the antiperiodicity of y, is needed for (141). If η_1, η_2 satisfy (a) and (b), then (142) follows from Theorem C. Finally, if $\tilde{\nu}$ satisfies (b) then (143) follows from Theorem A. Obviously the intervals in (141) through (144) overlap and their union is $[-T/2+\delta, \delta]$.

UNIFORM ASYMPTOTIC EXPANSIONS OF A CLASS OF INTEGRALS IN TERMS OF MODIFIED BESSEL FUNCTIONS, WITH APPLICATION TO CONFLUENT HYPERGEOMETRIC FUNCTIONS*

N. M. TEMME†

Abstract. The integral

$$F_\lambda(z,\alpha)=\int_0^\infty t^{\lambda-1}\,e^{-zt-\alpha/t}f(t)\,dt$$

is considered for large values of the real parameter z; α and λ are uniformity parameters in $[0,\infty)$. The asymptotic expansion is given in terms of the modified Bessel function $K_\lambda(2\sqrt{\alpha z})$. The asymptotic nature of the expansion is discussed and error bounds are constructed for the remainders in the expansions. An example is given for confluent hypergeometric or Whittaker functions. In this example the integrals are transformed to standard forms and the mappings are investigated.

Key words. uniform asymptotic expansions of integrals, modified Bessel function, confluent hypergeometric function, Whittaker function, construction of error bounds, transformation to standard form

AMS(MOS) subject classifications. 41A60, 30E15, 33A20

1. Introduction.

We consider integrals of the form

$$F_\lambda(z,\alpha)=\int_0^\infty t^{\lambda-1}\,e^{-zt-\alpha/t}f(t)\,dt, \tag{1.1}$$

which reduces to a modified Bessel function in the case that f is a constant. We have

$$2(\alpha/z)^{\lambda/2}K_\lambda(2\sqrt{\alpha z})=\int_0^\infty t^{\lambda-1}\,e^{-zt-\alpha/t}\,dt. \tag{1.2}$$

The integral in (1.1) is considered with $\alpha,\ \lambda\geqq 0$ and large positive values of z. We aim to derive asymptotic expansions for $F_\lambda(z,\alpha)$ that hold uniformly with respect to both α and λ in the interval $[0,\infty)$. To handle the transition of the case $\alpha=0$ to $\alpha>0$, the modified Bessel function (1.2) is needed. Observe that when $\alpha=0$ the essential singularity in the integrand of (1.1) disappears and that (1.1) becomes a more familiar Laplace integral, which can be expanded by using Watson's lemma.

First we consider fixed values of λ. To describe the asymptotic features we introduce the positive number β defined by

$$\beta=\sqrt{\alpha/z}. \tag{1.3}$$

The saddle points of $\exp(-zt+\alpha/t)$ are located at $t=\pm\beta$. When β is bounded away from zero, we can use the familiar Laplace method, since at the point $t=\beta$ the integrand has the form of a Gaussian function. When, however, $\alpha\to 0$, that is, $\beta\to 0$, the internal saddle point coalesces with the point $t=0$, where the argument of the exponential function has a pole. In addition, there is an algebraic singularity (if $\lambda\neq 1$), but the influence of the essential singularity due to the pole is more significant. Observe that in the limit $\alpha=0$, as mentioned earlier, the pole disappears; also, both saddle points coalesce with the pole. These asymptotic features are typical for certain integrals defining Bessel functions. For this reason the modified Bessel function in (1.2) serves

* Received by the editors May 5, 1988; accepted for publication (in revised form) February 27, 1989.

as a basic approximant in the uniform asymptotic expansions in this paper. In § 4 we show how an integral with the same phenomena can be transformed into the standard form (1.1).

The integral in (1.1) is the simplest case with the asymptotic features described above, especially when the parameters are in the indicated intervals. We apply the results to a confluent hypergeometric function. By allowing different intervals of integration, say a contour in the complex plane, we can also consider negative values of α. Then the ordinary Bessel function $J_\nu(z)$ shows up. This case is more difficult, but the applications are very interesting in the theory of special functions.

Consider as an analogue of (1.1) a loop integral in the form

$$G_\lambda(z,\alpha)=\frac{1}{2\pi i}\int_{-\infty}^{(0^+)} t^{-\lambda-1}\,e^{zt+\alpha/t}f(t)\,dt. \tag{1.4}$$

This notation means that the contour of integration starts from $-\infty$, arg $t=-\pi$, describes a circle counterclockwise around the origin, and returns to $-\infty$, arg $t=+\pi$. The integral (1.4) has the modified Bessel function $I_\lambda(2\sqrt{\alpha z})$ as approximant. When $f=1$ we have

$$G_\lambda(z,\alpha)=(z/\alpha)^{\lambda/2}I_\lambda(2\sqrt{\alpha z}). \tag{1.5}$$

When α is negative this function is an ordinary J-Bessel function. In [2] and [6] integrals of the type (1.4) are treated and the method is used for obtaining a uniform expansion of Laguerre polynomials. We plan to return to this problem in a future paper.

The starting point (1.1) is of interest since it has a real interval of integration. Thus the transformation to the standard form (1.1) involves a real mapping. This makes the first steps of the analysis rather simple, since we do not need to trace the transformed contour in the complex plane. For studying the asymptotic nature of the expansion, we use complex variables, however.

The plan of the paper is as follows. In § 2 we construct a series expansion based on an integration by parts procedure, and we give estimates for the remainder in the expansion. In § 3 we consider an expansion that is based on expanding f at the internal saddle point. In § 4 we give an application to confluent hypergeometric functions. In § 5 the parameter λ is considered as a second uniformity parameter in $[0,\infty)$, and again we apply the methods on a confluent hypergeometric function. Especially, we pay attention to the mappings needed for a transformation to the standard form.

Terminology. We call a parameter *fixed* when it does not depend on the parameters z, α, λ. $\Re z=x$, $\Im z=y$ are the real and imaginary part of $z=x+iy$.

2. An integration by parts procedure. The procedure of this section takes into account both saddle points $\pm\beta$ of the exponential function (where β is given in (1.3)), although $-\beta$ lies outside the interval of integration. For this reason we assume that f is also defined at negative values of its argument, and that f is sufficiently smooth for the operations to be used here. Further conditions on f will be given later.

2.1. Construction of the formal series. The first step is the representation

$$f(t)=a_0+b_0(t-\beta)+(t-\beta^2/t)g(t), \tag{2.1}$$

where a_0, b_0 follow from substitution of $t=\pm\beta$. We have

$$a_0=f(\beta),\qquad b_0=\frac{1}{2\beta}[f(\beta)-f(-\beta)].$$

Inserting (2.1) into (1.1) we obtain

$$F_\lambda(z,\alpha)=a_0A_\lambda(z,\beta)+b_0B_\lambda(z,\beta)+F_\lambda^{(1)}(z,\alpha),$$

where A_λ, B_λ are combinations of the modified Bessel functions introduced in (1.2). It is straightforward to verify that

$$A_\lambda(z,\beta)=2\beta^\lambda K_\lambda(2\beta z), \quad B_\lambda(z,\beta)=2\beta^{\lambda+1}[K_{\lambda+1}(2\beta z)-K_\lambda(2\beta z)]. \tag{2.2}$$

An integration by parts gives

$$\begin{aligned} F_\lambda^{(1)}(z,\alpha) &= -\frac{1}{z}\int_0^\infty t^\lambda g(t)\, d\exp(-z(t+\beta^2/t)) \\ &= \frac{1}{z}\int_0^\infty t^{\lambda-1}\exp(-z(t+\beta^2/t))f_1(t)\,dt \end{aligned}$$

with

$$f_1(t)=t^{1-\lambda}\frac{d}{dt}[t^\lambda g(t)]=\lambda g(t)+tg'(t).$$

We see that $zF_\lambda^{(1)}(z,\alpha)$ is of the same form as $F_\lambda(z,\alpha)$. The above procedure can now be applied to $zF_\lambda^{(1)}(z,\alpha)$, and we obtain for (1.1) the formal expansion

$$F_\lambda(z,\alpha)\sim A_\lambda(z,\beta)\sum_{s=0}^\infty a_s z^{-s}+B_\lambda(z,\beta)\sum_{s=0}^\infty b_s z^{-s} \quad \text{as } z\to\infty, \tag{2.3}$$

where we define inductively $f_0=f$, $g_0=g$ and for $s=1,2,\cdots$

$$\begin{aligned} &f_s(t)=t^{1-\lambda}\frac{d}{dt}[t^\lambda g_{s-1}(t)]=a_s+b_s(t-\beta)+\left(t-\frac{\beta^2}{t}\right)g_s(t), \\ &a_s=f_s(\beta), \qquad b_s=\frac{1}{2\beta}[f_s(\beta)-f_s(-\beta)]. \end{aligned} \tag{2.4}$$

Remark 2.1. As mentioned earlier, for this procedure we need function values of f and derivatives at negative values, although the integral (1.1) is defined only for t-values in $[0,\infty)$. When we consider analytic functions f, as we do later, we assume that f is analytic in a domain Ω in the complex plane that contains the real line. When, however, f is supposed to belong to $C^k[0,\infty)$, we assume in the above procedure that f has been smoothly continued on $(-\infty,0]$.

2.2. The remainder of the expansion. We introduce a remainder for the expansion in (2.3) by writing

$$F_\lambda(z,\alpha)=A_\lambda(z,\beta)\sum_{s=0}^{n-1} a_s z^{-s}+B_\lambda(z,\beta)\sum_{s=0}^{n-1} b_s z^{-s}+z^{-n}R_n, \tag{2.5}$$

where $n=0,1,\cdots$. When $n=0$ the sums are empty and $R_0=F_\lambda(z,\alpha)$. The integration by parts procedure yields for R_n the representation

$$R_n=\int_0^\infty t^{\lambda-1}\exp\left(-z\left(\frac{t+\beta^2}{t}\right)\right)f_n(t)\,dt, \tag{2.6}$$

where f_n is defined by (2.4).

When a bound for $|f_n(t)|$ is available, say,

$$|f_n(t)|\leqq M_n, \qquad t\geqq 0, \quad n=0,1,\cdots, \tag{2.7}$$

then a bound for R_n reads

$$|R_n|\leqq M_n A_\lambda(z,\beta). \tag{2.8}$$

Since f_n depends on β, the quantity M_n may also depend on β. It follows that for bounded values of β, say $\beta \in [0, \beta_0]$, β_0 fixed and finite, the estimate (2.8) of the remainder R_n shows the asymptotic nature of the expansion (2.5), provided that (2.7) is satisfied.

We must point out that, in general, it is rather difficult to find realistic numbers M_n in order to obtain sharp estimates in (2.8). Also, the estimate in (2.7) is rather global, since it takes into account values of f_n in the complete interval $[0, \infty)$.

A sharper and more realistic bound for R_n may be obtained as follows. Let

$$w_\sigma(t) = \exp\{\sigma(t+\beta^2/t-2\beta)\}, \qquad t>0, \quad \sigma \geqq 0. \tag{2.9}$$

Observe that $w_\sigma(\beta)=1$ and that when $\sigma>0$

$$\lim_{t\to 0} w_\sigma(t) = \lim_{t\to+\infty} w_\sigma(t) = +\infty.$$

We assume that we can assign quantities σ_n and M_n, which may depend on β and which satisfy

$$\sigma_n \geqq 0, \qquad M_n \geqq 1+\varepsilon_n, \qquad \varepsilon_n \text{ fixed and positive,} \tag{2.10}$$

such that for all $t>0$ we have

$$|f_n(t)| \leqq M_n |f_n(\beta)| w_{\sigma_n}(t). \tag{2.11}$$

Then instead of (2.8) we obtain

$$|R_n| \leqq M_n |f_n(\beta)| \tilde{A}_\lambda(z,\beta), \qquad z>\sigma_n, \tag{2.12}$$

where

$$\tilde{A}_\lambda(z,\beta) = A_\lambda(z-\sigma_n,\beta)\, e^{-2\beta\sigma_n}. \tag{2.13}$$

When $f_n(\beta)=0$ a slight modification is needed. The idea about this approach is that in (2.11) function values outside a neighborhood of $t=\beta$ may be estimated very roughly, and that the integral, which results after inserting the right-hand side of (2.11) into (2.6), can be written in terms of one of the approximants in front of the series in (2.5).

A possible approach to computing M_n and σ_n of (2.11) is to start with trial values of M_n satisfying (2.10). Then we compute

$$\sigma_n = \sup_{t\geqq 0} \tilde{f}_n(t), \qquad \beta \text{ fixed in } [0,\infty),$$

where

$$\tilde{f}_n(t) = \frac{\ln|f_n(t)/[M_n f_n(\beta)]|}{t+\beta^2/t-2\beta}, \qquad t\neq\beta, \quad f_n(\beta)\neq 0.$$

Observe that the function defined in (2.13) satisfies

$$\tilde{A}_\lambda(z,\beta)/A_\lambda(z,\beta) = 1+o(1) \quad \text{as } z\to\infty,$$

uniformly with respect to $\beta \in [0,\infty)$. This follows from (2.2) and well-known asymptotic relations for the Bessel function.

3. Expansion at the internal saddle point. In the expansion (2.3) we have used function values of f at the negative saddle point $-\beta$. These values appear in the coefficients a_s, b_s of the expansion. The form of the expansion is very attractive, since only two special functions arise, and also since the parameters β and z are nicely

separated in both series. Although the expansion (2.3) has a canonical form, there remains the drawback that the function f must be defined at $(-\infty, 0]$ in order to obtain for β a uniformity domain $[0, \infty)$. For example, it is not possible to obtain such a uniformity domain when $f(t) = 1/(t+1)$. In this section we only expand the function f at the internal saddle point, and we formulate further conditions on f in order to obtain an optimal domain for β.

3.1. The functions $Q_s(\zeta)$ and $\tilde{Q}_s(\zeta)$. We expand f in the form

$$f(t) = \sum_{s=0}^{\infty} a_s(\beta)(t-\beta)^s, \qquad a_s = \frac{f^{(s)}(\beta)}{s!}. \tag{3.1}$$

Substituting (3.1) in (1.1), we obtain after interchanging the order of summation and integration the formal result

$$F_\lambda(z, \alpha) \sim z^{-\lambda} \sum_{s=0}^{\infty} a_s(\beta) Q_s(\zeta) z^{-s}, \qquad \text{as } z \to \infty, \tag{3.2}$$

where

$$Q_s(\zeta) = \zeta^{\lambda+s} \int_0^{\infty} t^{\lambda-1}(t-1)^s e^{-\zeta(t+1/t)}\, dt, \tag{3.3}$$

$$\zeta = \beta z. \tag{3.4}$$

The functions $Q_s(\zeta)$ can be expressed in terms of the modified Bessel functions defined in (1.2). It is easily verified that

$$Q_s(\zeta) = 2\zeta^{\lambda+s} \sum_{r=0}^{s} (-1)^{s-r} \binom{s}{r} K_{\lambda+r}(2\zeta). \tag{3.5}$$

On the other hand, integrating by parts in (3.3), we obtain the recursion relation

$$Q_{s+2} = (s+\lambda+1-2\zeta)Q_{s+1} + \zeta(2s+\lambda+1)Q_s + s\zeta^2 Q_{s-1}, \qquad s = 0, 1, 2, \cdots. \tag{3.6}$$

For proving the asymptotic properties of (3.2) it is useful to introduce the functions

$$\tilde{Q}_s(\zeta) = \zeta^{\lambda+s} \int_0^{\infty} t^{\lambda-1}|t-1|^s e^{-\zeta(t+1/t)}\, dt. \tag{3.7}$$

By applying Laplace's method it is found that for large positive values of ζ

$$\tilde{Q}_s(\zeta) \sim \zeta^{\lambda+(s-1)/2} e^{-2\zeta} \Gamma\left(\frac{s+1}{2}\right), \qquad s = 0, 1, 2, \cdots. \tag{3.8}$$

Furthermore, we have when z is fixed

$$\lim_{\beta \to 0} \tilde{Q}_s(\zeta) = \Gamma(\lambda+s).$$

3.2. Error bounds and interpretation of the expansion. We introduce a remainder in the expansion (3.2) by writing

$$f(t) = \sum_{s=0}^{n-1} a_s(\beta)(t-\beta)^s + R_n(t, \beta)(t-\beta)^n, \qquad n = 0, 1, 2, \cdots. \tag{3.9}$$

Then we obtain for (3.2)

$$F_\lambda(z, \alpha) = z^{-\lambda}\left[\sum_{s=0}^{n-1} a_s(\beta) Q_s(\zeta) z^{-s} + E_n(z, \alpha) z^{-n}\right], \tag{3.10}$$

where

$$E_n(z,\alpha)=z^{\lambda+n}\int_0^\infty t^{\lambda-1}(t-\beta)^n R_n(t,\beta)\exp\left(-z\left(\frac{t+\beta^2}{t}\right)\right)dt. \tag{3.11}$$

Let f be analytic in a connected domain Ω of the complex plane; Ω may depend on β, and we assume that the radius of convergence R_β of the expansion (3.1) satisfies the condition

$$R_\beta \geqq \rho(1+\beta)^\kappa, \qquad \beta\geqq 0 \qquad (\rho,\kappa \text{ fixed}, \rho>0, \kappa\geqq\tfrac{1}{2}). \tag{3.12}$$

This condition says that the distance between the singularities of f and the point $t=\beta$ should be of order $\mathcal{O}(\beta^\kappa)$, uniformly with respect to $\beta\in[0,\infty)$. When $\kappa<\frac{1}{2}$ the singularities of f are too close to the saddle point. Furthermore, we assume that f has the following growth condition in Ω: there is a real fixed number p such that

$$\sup_{t\in\Omega}(1+|t|)^{-p}|f(t)| \tag{3.13}$$

is bounded for $\beta\in[0,\infty)$.

The coefficients $a_s(\beta)$ of (3.1) can be written as

$$a_s(\beta)=\frac{1}{2\pi i}\int_{C_r}\frac{f(t)}{(t-\beta)^{s+1}}\,dt, \tag{3.14}$$

where C_r is a circle with centre β and radius $r(1+\beta)^\kappa$; r may depend on β, but should be uniformly bounded away from zero and small enough to keep C_r inside Ω. Using (3.14) we obtain the following form of Cauchy's inequality

$$|a_s(\beta)|\leqq r^{-s}M_r(\beta)(1+\beta)^{-s\kappa}, \tag{3.15}$$

where

$$M_r(\beta)=\sup_{t\in C_r}|f(t)|. \tag{3.16}$$

In the next theorem we introduce an asymptotic sequence $\{\phi_s\}$, which is constructed on the basis of the estimates in (3.7) and (3.15). For the concept of asymptotic scale and (generalized) asymptotic expansion we refer to [4, p. 25].

THEOREM 3.1. *Let* $\zeta=\beta z$, $\kappa\geqq\frac{1}{2}$, *and let*

$$\phi_s=\phi_s(z,\beta)=M_r(\beta)(1+\beta)^{-s\kappa}(1+\zeta)^{\lambda+(s-1)/2}\,e^{-2\zeta}z^{-s}, \qquad s=0,1,2,\cdots. \tag{3.17}$$

Then $\{\phi_s\}$ *is an asymptotic scale as* $z\to\infty$, *uniformly with respect to* $\beta\in[0,\infty)$.

Proof.

$$\frac{\phi_{s+1}}{\phi_s}=(1+\beta)^{-\kappa}\sqrt{\zeta+1}\,z^{-1}\leqq\frac{1}{\sqrt{z}} \quad \text{if } z\geqq 1. \tag{3.18}$$

Now we write the expansion (3.2) in the notation

$$z^\lambda F_\lambda(z,\alpha)\sim\sum_{s=0}^\infty a_s(\beta)Q_s(\zeta)z^{-s}; \qquad \{\phi_s\} \quad \text{as } z\to\infty, \tag{3.19}$$

and we have the following theorem.

THEOREM 3.2. *The expansion* (3.19) *is a uniform asymptotic expansion as* $z\to\infty$, *uniformly with respect to* $\beta\in[0,\infty)$.

Proof. According to the definition of generalized (uniform) asymptotic expansions, we have to prove

$$z^{-n}E_n(z,\beta)=\mathcal{O}(\phi_n),\qquad n=0,1,2,\cdots, \tag{3.20}$$

as $z\to\infty$, uniformly with respect to $\beta\in[0,\infty)$. The interval of integration in (3.11) is split up as follows

$$[0,\infty)=\Delta_-\cup[t_-,t_+]\cup\Delta_+, \tag{3.21}$$

where

$$\Delta_-=[0,t_-],\qquad \Delta_+=[t_+,\infty),\qquad t_\pm=\beta\pm r_1(1+\beta)^\kappa,\qquad 0<r_1<r,\quad r_1\text{ fixed}, \tag{3.22}$$

with r as in (3.14). When t_- happens to be negative, we replace it by 0. For $t\in[t_-,t_+]$ we can write

$$R_n(t,\beta)=\frac{1}{2\pi i}\int_{C_r}\frac{f(\tau)}{(\tau-t)(\tau-\beta)^n}\,d\tau, \tag{3.23}$$

with C_r as in (3.14). If $\tau\in C_r$, we have $|\tau-t|\geqq(r-r_1)(1+\beta)^\kappa$. Thus we obtain as in (3.15)

$$|R_n(t,\beta)|\leqq\frac{M_r(\beta)(1+\beta)^{-n\kappa}}{r^{n-1}(r-r_1)}. \tag{3.24}$$

Hence z^λ times the integral over $[t_-,t_+]$ in (3.11) gives a contribution which is bounded by

$$\begin{aligned}&\frac{z^\lambda M_r(\beta)(1+\beta)^{-n\kappa}}{r^{n-1}(r-r_1)}\int_{t_-}^{t_+}t^{\lambda-1}|t-\beta|^n\exp\left(-z\left(\frac{t+\beta^2}{t}\right)\right)dt\\&\quad=M_r(\beta)(1+\beta)^{-n\kappa}z^{-n}\tilde{Q}_n(\zeta)\mathcal{O}(1)\quad\text{as } z\to\infty,\end{aligned} \tag{3.25}$$

uniformly with respect to $\beta\in[0,\infty)$. Using (3.7), (3.8), and (3.17), we conclude that

$$z^{-n}E_n(z,\alpha)=I_-+I_++\mathcal{O}(\phi_n)\quad\text{as } z\to\infty, \tag{3.26}$$

uniformly with respect to $\beta\in[0,\infty)$, where $I_\pm$ are the contributions to (3.11) from $\Delta_\pm$. For $t\in\Delta_\pm$ we write

$$(t-\beta)^nR_n(t,\beta)=f(t)-\sum_{s=0}^{n-1}a_s(\beta)(t-\beta)^s,$$

and the proof is finished when we have shown that

$$z^\lambda\int_{\Delta_\pm}t^{\lambda-1}\,e^{-z(t+\beta^2/t)}\,g(t)\,dt=\mathcal{O}(\phi_n)\quad\text{as } z\to\infty, \tag{3.27}$$

uniformly with respect to $\beta\in[0,\infty)$, where $g(t)$ is $|f(t)|$ or $|a_s(t-\beta)^s|(0\leqq s\leqq n-1)$. In fact, it is possible to prove that

$$I_\pm\sim 0;\qquad\{\phi_s\}\quad\text{as } z\to\infty, \tag{3.28}$$

uniformly with respect to $\beta\in[0,\infty)$. That is, $I_\pm$ are asymptotically equal to zero with respect to the scale $\{\phi_s\}$. The proof of (3.28) is similar to that given for another type of integral in [5, Lemma 3.3] and will not be repeated here. □

The above theorem gives only an order estimate in terms of ϕ_n for the remainder defined in (3.11) and gives an interpretation of the asymptotic nature of the expansions (3.2) and (3.19). To obtain a numerical upper bound for $E_n(z,\lambda)$ we proceed as in

the previous section. Since $f(t)$ satisfies the growth condition (3.13), it is possible to find numbers M_n, σ_n satisfying (2.10), such that

$$|R_n(t,\beta)| \leqq M_n |a_n(\beta)| w_{\sigma_n}(t), \qquad 0<t<\infty. \tag{3.29}$$

Using this in (3.11), we obtain the bound

$$|E_n(z,\lambda)| \leqq M_n |a_n(\beta)|\, e^{-2\beta\sigma_n} \tilde{Q}_n(\zeta-\beta\sigma_n), \qquad z>\sigma_n. \tag{3.30}$$

When $a_n(\beta)$ happens to vanish as a function of $\beta \in [0,\infty)$, this approach needs a slight modification.

4. Application to confluent hypergeometric functions. We start with the confluent hypergeometric function defined by

$$\Gamma(a)U(a,b,x) = \int_0^\infty u^{a-1}(1+u)^{b-a-1}\, e^{-xu}\, du. \tag{4.1}$$

We consider a as the large parameter and x as a uniformity parameter in $[0,\infty)$; b is a fixed real parameter. We take $b \leqq 1$; the relation

$$U(a,b,x) = x^{1-b}U(a+1-b, 2-b, x)$$

can be used when $b>1$.

4.1. Transformation to the standard form. First we give a simple intermediate transformation. The function $[u/(u+1)]^a$ assumes its maximal value (on $[0,\infty)$) at $u=\infty$. This function controls the asymptotic behaviour of the integrand and, hence, we transform it to an exponential function by writing $u/(u+1)=\exp(-w)$. Then (4.1) becomes

$$\Gamma(a)U(a,1-\lambda,x) = \int_0^\infty w^{\lambda-1} \exp\left(-aw - \frac{x}{e^w-1}\right) \tilde{f}(w)\, dw, \tag{4.2}$$

where

$$\tilde{f}(w) = \left[\frac{1-e^{-w}}{w}\right]^{\lambda-1}. \tag{4.3}$$

We transform (4.2) into (1.1) with the help of the transformation

$$w + \frac{\nu}{e^w-1} = t + \frac{\beta^2}{t} + A, \tag{4.4}$$

where $\nu = x/a$ and β, A are to be determined. We compute them on the following condition on the mapping: the critical points of the w-function in (4.4) must correspond with the critical points of the t-function. Critical points are $\pm w_0$, $\pm t_0$, where

$$t_0 = \beta, \qquad w_0 = \cosh^{-1}(1+\nu/2) = \ln\left(1+\frac{\nu+W_0}{2}\right), \qquad W_0 = \sqrt{\nu^2+4\nu}. \tag{4.5}$$

It follows that

$$A = -\frac{\nu}{2}, \qquad \beta = \frac{w_0+\sinh w_0}{2} = \frac{1}{2}\ln\left(1+\frac{\nu+W_0}{2}\right) + \frac{1}{4}W_0. \tag{4.6}$$

From the simple differential equation

$$\frac{d\beta}{d\nu} = \frac{1}{4}\sqrt{(\nu+4)/\nu}$$

and a Taylor expansion of the right-hand side, it follows that β^2 of (4.4) is an analytic function of ν, at least in the disc $|\nu|<4$. Conversely, ν is an analytic function of β^2 in some neighborhood of the origin. These domains can be extended to domains containing $[0,\infty)$.

With these values of A, β the mapping $w\mapsto t$ is regular at $w=\pm w_0$ and at $w=0$. In fact it is regular in $\mathbb{R}$ and as a conformal mapping in a large domain Ω of the complex plane. We have the correspondences

$$t(\pm\infty)=\pm\infty, \qquad t(\pm w_0)=\pm\beta, \qquad t(0)=0. \tag{4.7}$$

More details on the mapping are given in the next subsection.

Using transformation (4.4) in (4.2), we arrive at the standard form

$$F_\lambda(z,\alpha)=\Gamma(a)\,e^{-x/2}U(a,b,x)=\int_0^\infty t^{\lambda-1}\,e^{-zt-\alpha/t}f(t)\,dt, \tag{4.8}$$

with $z=a$, $\alpha=z\beta^2$, $\lambda=1-b$, β defined in (4.6) with $\nu=x/a$, and

$$f(t)=\left(\frac{1-e^{-w}}{t}\right)^{\lambda-1}\frac{dw}{dt}, \qquad \frac{dw}{dt}=\left(\frac{e^w-1}{t}\right)^2\frac{t^2-\beta^2}{(e^w-1)^2-\nu e^w}. \tag{4.9}$$

The function $t(w)$ defined in (4.4) is an odd function of w. This easily follows from rewriting (4.4) in the form

$$\frac{1}{2}\nu+w+\frac{\nu}{e^w-1}=t+\frac{\beta^2}{t}. \tag{4.10}$$

After these preparations the expansion of (3.2) can be constructed. The expansion holds uniformly with respect to $\beta\in[0,\infty)$; that is, uniformly with respect to $x\in[0,\infty)$.

The asymptotic nature of the expansion follows from combining (3.20) and (3.17). For this particular case we can derive an upper bound for $M_r(\beta)$ of (3.16). The t-values on the circle are written as $t=\beta+\tau\sqrt{\beta+1}$, with $|\tau|=r$, r fixed. When β and ν are large, we derive from (4.6) $\beta=\nu/4+\ln\sqrt{\nu}+\mathcal{O}(1)$. So, for large values of β, we obtain (using (4.10)) $t+\beta^2/t-\nu/2=w+\nu/(e^w-1)=\ln\nu+\tau^2+\mathcal{O}(1)$. That is, $w\sim\ln\nu$. Then it follows from (4.9) that $f(t)=\mathcal{O}(\beta^{1/2-\lambda})$, $t\in C_r$. Consequently, we can find a fixed number K, such that

$$M_r(\beta)\leqq K(\beta+1)^{1/2-\lambda}, \qquad \beta\in[0,\infty). \tag{4.11}$$

To conclude this subsection, we give the first coefficient $a_0(\beta)$ of (3.2). A few calculations based on (4.9) and l'Hôpital's rule yield

$$\left.\frac{dw}{dt}\right|_{t=\pm\beta}=\sqrt{2\tanh(w_0/2)/\beta}.$$

So we obtain

$$a_0(\beta)=\sqrt{2\tanh(w_0/2)/\beta}\left(\frac{1-e^{-w_0}}{\beta}\right)^{\lambda-1}. \tag{4.12}$$

4.2. Analytical properties of the mapping (4.4). We now consider the mapping (4.4) in more detail. We restrict w to the strip

$$H=\{w\,|\,\Re w\in\mathbb{R},\,\Im w\in[-\pi,\pi]\}, \tag{4.13}$$

and we prove the following.

THEOREM 4.1. *Let Ω be the image of H under the mapping $w\mapsto t$ defined in* (4.4). *Let $\nu\in[0,\infty)$ and let A, β be defined by* (4.6). *Then $t(w,\beta)$ is analytic in H.*

In the following proof we show that $t(w,\beta)$ and $w(t,\beta)$ are analytic in a fixed neighborhood of $(0,0)$. Accordingly, we concentrate on small (complex) values of the parameters. For remaining values the proof is much easier. For instance, when β is bounded away from zero, the critical points $t=\pm\beta$ and the pole at $t=0$ of the right-hand side of (4.4) are well separated. The preparations for applying the Implicit Function Theorem mentioned below are more straightforward then.

Proof. From (4.6) it follows that

$$w_0=\beta[1+o(1)], \qquad \nu=\beta^2[1+o(1)] \quad \text{as } \beta\to 0.$$

Recall that $t(w)$ is an odd function of w (see (4.10)). We introduce a function $y=y(w,\beta)$ by writing

$$t=w\left[\frac{\beta}{w_0}+(w^2-w_0^2)y\right]. \tag{4.14}$$

This matches the points $w=0\Leftrightarrow t=0$ and also the critical points $w=\pm w_0\Leftrightarrow t=\pm\beta$; y is an even function of w and should vanish with β. Substituting (4.14) in (4.10), we obtain

$$\frac{\nu t}{w}\frac{\phi(w)-\phi(w_0)}{w^2-w_0^2}+\frac{\beta}{w_0}\left(1-\frac{\beta}{w_0}\right)+(w^2-w_0^2)\left(1-\frac{2\beta}{w_0}\right)y-w^2(w^2-w_0^2)^2y^2=0,$$

where $\phi(w)=w/(\exp w-1)-1+w/2$. We expand

$$\frac{\phi(w)-\phi(w_0)}{w^2-w_0^2}=\sum_{s=1}^{\infty}b_s(w^2-w_0^2)^{s-1}, \qquad b_1=\frac{\beta-w_0}{\nu w_0}.$$

Since $\phi(w)$ is analytic if $|w|<2\pi$, the series converges if β and w are small. Finally, we obtain the equation $F(y,w,\beta)=0$, where F is given by

$$\frac{\nu\beta}{w_0}\sum_{s=2}^{\infty}b_s(w^2-w_0^2)^{s-2}+\nu y\sum_{s=1}^{\infty}b_s(w^2-w_0^2)^{s-1}+\left(1-\frac{2\beta}{w_0}\right)y-w^2y^2.$$

The series represents analytic functions of w, w_0. When β is small, w_0 is an analytic function of β (see (4.6)). Hence, F is analytic in a fixed neighborhood of $(0,0,0)$, $F(0,0,0)=0$, and $F_y(0,0,0)=-1$. After these preparations we can use an Implicit Function Theorem (see, for instance, [1, p. 36]) and solve for $y(w,\beta)$; it is analytic in a fixed neighborhood of $(0,0)$. By using (4.14) it follows that the same holds for $t(w,\beta)$. □

The first terms in the expansion

$$t(w,\beta)=c_1(\beta)w+c_3(\beta)w^3+\cdots$$

easily follow from (4.10). We have

$$c_1(\beta)=\frac{\beta^2}{\nu}, \qquad c_3(\beta)=\frac{c_1^2+\dfrac{\beta^2}{6}-c_1-\dfrac{\nu c_1}{4}}{\nu}.$$

THEOREM 4.2. *The mapping* (4.4) *is univalent in H.*

Proof. First we show that the mapping is univalent on

$$\mathscr{L}_+=\{w=u+iv\,|\,u\in\mathbb{R},\ v=\pi\},$$

which is the upper part of the boundary ∂H of H. We write $t=re^{i\theta}$. The image of $\mathscr{L}_+$ in the t-plane is defined by the equations

$$\pi=r\sin\theta\left(1-\frac{\beta^2}{r^2}\right), \quad \Psi(u)=\Phi(\theta), \tag{4.15}$$

where

$$\Psi(u)=\nu/2+u-\nu/(e^u+1), \qquad \Phi(\theta)=r\cos\theta\left(1+\frac{\beta^2}{r^2}\right).$$

The first equation in (4.15) defines a curve given by

$$r(\theta)=\frac{\pi+\sqrt{\pi^2+4\beta^2\sin^2\theta}}{2\sin\theta}, \qquad 0<\theta<\pi.$$

It follows that $r>\pi/\sin\theta$. Furthermore, we have

$$\Psi(-\infty)=\Phi(\pi)=-\infty, \qquad \Psi(+\infty)=\Phi(0)=+\infty.$$

The function $\Psi(u)$ is one-to-one on $\mathbb{R}$. The same is true for $\Phi(\theta)$ on $(0,\pi)$, but the proof requires a little extra work. We have, using the first equation in (4.15),

$$\frac{dr}{d\theta}=-\frac{r\cos\theta(r^2-\beta^2)}{\sin\theta(r^2+\beta^2)}.$$

It follows that

$$\frac{d\Phi(\theta)}{d\theta}=-\frac{\sin\theta(r^2+\beta^2)}{r^3}\left[r^2+\left(\frac{dr}{d\theta}\right)^2\right], \tag{4.16}$$

which shows that $\Phi(\theta)$ is one-to-one on $(0,\pi)$. We infer that for each value $u\in\mathbb{R}$ we can find one and only one value $\theta\in(0,\pi)$, such that $\Psi(u)=\Phi(\theta)$, and, hence, one and only one value $r(\theta)$. Since $t(w)$ is an odd function of w (see (4.10)), the mapping $w\mapsto t$ is one-to-one on ∂H. When $\Re w\to\pm\infty$ we have $w\sim t$. Hence the mapping $t(w)$ is also one-to-one as $w\to\infty$, $w\in H$. We now consider a large closed rectangle $ABCD$ of which upper side AB and lower side CD are finite parts of ∂H, and BC and AD are far away to the right and to the left, respectively. From the above arguments it is not difficult to conclude that the mapping is univalent on BC, AD, and on the whole Jordan curve $ABCDA$, provided that the vertical sides are far away. Then we use a well-known result of complex function theory, which says that consequently the mapping is also univalent in the interior of rectangle $ABCD$, since it is analytic there. See [3, Vol. II, p. 118]. We can take the finite rectangle as large as we please. Thus the result also holds for H. □

For the uniform expansion of (4.8) we take Ω as the image of the strip H under the mapping $w\mapsto t$. From $f(t)$ defined in (4.9) it follows that (3.13) is bounded in Ω if $p=1-\lambda$ and that $M_r(\beta)$ of (3.16) is well defined. There remains to show that the radius of convergence R_β of the series in (3.1) satisfies (3.12). It appears that we must take $\kappa=\frac{1}{2}$. In fact, we show that Ω contains a disc around β with radius $\rho\sqrt{\beta+1}$ (ρ fixed), for all $\beta\geqq 0$. The points of intersection of the circle with radius r around the point $t=\beta$ with the curve defined by the first equation of (4.15) are governed by the equations (we write $t=\sigma+i\tau$)

$$(\sigma-\beta)^2+\tau^2=r^2, \qquad \pi=\tau\left(1-\frac{\beta^2}{\sigma^2+\tau^2}\right), \qquad \tau>\pi.$$

When we require that the circle is tangent at the curve we have the extra condition

$$\frac{\sigma-\beta}{\tau}=\frac{2\sigma(\tau-\pi)^2}{\pi\beta^2+2\tau(\tau-\pi)^2}.$$

This equation is obtained by equating $d\tau/d\sigma$ of both equations and eliminating $\tau^2+\sigma^2$ by using the second one. For large values of β the solution of these three equations reads

$$\tau=\pi+a\sqrt{\beta}[1+o(1)], \qquad \sigma=\beta+b\sqrt{\beta}[1+o(1)], \qquad r=c\sqrt{\beta}[1+o(1)],$$

with $a=b=\sqrt{\pi/2}$, $c=\sqrt{\pi}$.

This shows that Ω is large enough to apply Theorem 3.2. From a further analysis it follows that the value $\kappa=\frac{1}{2}$ is best possible in this case. Apart from the real critical points $\pm w_0$ given in (4.5), which are regular points for the mapping, we have other ones located at $\pm w_0\pm 2\pi ni$, $n=1, 2, \cdots$. For large values of β those are mapped at a distance $\mathcal{O}(\sqrt{\beta})$ from the critical point $t=\beta$.

Remark 4.1. The behaviour of $f(t)$ of (4.9) in the left half-plane $\Re t<0$ is quite different from that in $\Re t>0$, except when $\lambda=1$. Consequently, the approach of § 2 is less attractive. See also Remark 2.1.

Remark 4.2. When $b=\frac{1}{2}$, (4.1) is a parabolic cylinder function, and the functions $Q_s(\zeta)$ defined in (3.3), (3.5) are elementary functions ($\lambda=\frac{1}{2}$). Then (3.2) gives an expansion of the parabolic cylinder function $D_\nu(z)$, as $\nu\to-\infty$, which is uniformly valid with respect to $z\in[0,\infty)$.

5. A second uniformity parameter. In this section we consider (1.1) with λ as a second uniformity parameter in $[0,\infty)$. Thus we take further advantage of the fact that the modified Bessel function is a function of two variables. In this case it is convenient to put the reciprocal gamma function in front of the integral. So, now we write

$$F_\lambda(z,\alpha)=\frac{1}{\Gamma(\lambda)}\int_0^\infty t^{\lambda-1}\,e^{-zt-\alpha/t}f(t)\,dt. \tag{5.1}$$

In [5] we considered (5.1) with $\alpha=0$, again with $z\to\infty$ and λ as a uniformity parameter in $[0,\infty)$. In [6] we applied the present method for a loop integral (without proofs) to the case of Laguerre polynomials.

We write $\lambda=\mu z$. The critical points of the integrand are now defined as the points where the derivative of $t+\beta^2/t-\mu\ln t$ vanishes. This gives the real critical points

$$t_\pm=\frac{\mu\pm T}{2}, \qquad T=\sqrt{\mu^2+4\beta^2}. \tag{5.2}$$

Observe that also in this case one of the real saddle points is outside the interval of integration, and that the "phase function" that is used to compute the critical points has a logarithmic singularity at $t=0$. The two critical points coincide with this singularity when β and μ both vanish. At the same moment, however, the logarithmic singularity disappears.

First we construct an expansion by using the integration by parts procedure of § 2. The modification of (2.1) is

$$f(t)=c_0+d_0(t-t_+)+(t-\mu-\beta^2/t)h(t). \tag{5.3}$$

Using this in (5.1) we obtain, after repeating the procedure,

$$F_\lambda(z,\alpha)=C(z,\beta,\mu)\sum_{s=0}^{n-1}c_sz^{-s}+D(z,\beta,\mu)\sum_{s=0}^{n-1}d_sz^{-s}+z^{-n}R_n. \tag{5.4}$$

The functions in front of the series are again combinations of Bessel functions as in (2.2). We have

$$C(z,\beta,\mu)=\frac{2\beta^\lambda}{\Gamma(\lambda)}K_\lambda(2\beta z), \qquad D(z,\beta,\mu)=\frac{2\beta^\lambda}{\Gamma(\lambda)}[\mu K_{\lambda+1}(2\beta z)-t_+K_\lambda(2\beta z)].$$

The coefficients c_s, d_s follow from the recursion relation

$$f_0(t)=f(t), \qquad f_s(t)=t\frac{d}{dt}h_{s-1}(t)=c_s+d_s(t-t_+)+\left(t-\mu-\frac{\beta^2}{t}\right)h_s(t),$$

$$c_s=f_s(t_+), \qquad d_s=\frac{f(t_+)-f(t_-)}{t_+-t_-}.$$

The remainder R_n in (5.4) can be written in the form

$$R_n=\frac{1}{\Gamma(\lambda)}\int_0^\infty t^{\lambda-1}\,e^{-zt-\alpha/t}f_n(t)\,dt.$$

A bound can be constructed by using constants σ_n, M_n satisfying (2.10), and using a function

$$w_\sigma(t)=\exp\left(\sigma\left(t+\frac{\beta^2}{t}-\mu\ln t-t_+-\frac{\beta^2}{t_+}+\mu\ln t_+\right)\right)$$

such that, as in (2.11), for all $t>0$

$$|f_n(t)|\leqq M_n|f_n(t_+)|w_{\sigma_n}(t).$$

Then we obtain

$$|R_n|\leqq M_n|f_n(t_+)|\tilde{C}(z,\beta,\mu), \qquad z>\sigma_n,$$

where

$$\tilde{C}(z,\beta,\mu)=C(z-\sigma_n,\beta,\mu)\exp\left(-\sigma_n\left(t_++\frac{\beta^2}{t_+}-\mu\ln t_+\right)\right).$$

When $f_n(t_+)=0$, a slight modification is needed. An optimal value of σ_n follows from the method described in § 2.2.

The analogue of the expansion of § 3 is obtained by substituting

$$f(t)=\sum_{s=0}^{n-1}c_s(\beta,\mu)(t-t_+)^s+R_n(t,\beta,\mu)(t-t_+)^n, \qquad c_s=\frac{f^{(s)}(t_+)}{s!}. \tag{5.5}$$

So we obtain

$$F_\lambda(z,\alpha)=z^{-\lambda}\left[\sum_{s=0}^{n-1}c_s(\beta,\mu)P_sz^{-s}+E_n(z,\alpha,\lambda)z^{-n}\right], \tag{5.6}$$

where

$$E_n(z,\alpha,\lambda)=z^{\lambda+n}\int_0^\infty t^{\lambda-1}(t-t_+)^nR_n(t,\beta,\mu)\exp\left(-z\left(\frac{t+\beta^2}{t}\right)\right)dt,$$

$$P_s=\frac{z^{\lambda+s}}{\Gamma(\lambda)}\int_0^\infty t^{\lambda-1}(t-t_+)^s\exp\left(-z\left(\frac{t+\beta^2}{t}\right)\right)dt$$

$$=\frac{2z^{\lambda+s}\beta^\lambda}{\Gamma(\lambda)}\sum_{r=0}^{s}\binom{s}{r}(-t_+)^{s-r}\beta^rK_{\lambda+r}(2\beta z).$$

A recursion relation for P_s follows from the above integral representation.

$$\tilde{P}_s=\frac{z^{\lambda+s}}{\Gamma(\lambda)}\int_0^\infty t^{\lambda-1}|t-t_+|^s\exp\left(-z\left(\frac{t+\beta^2}{t}\right)\right)dt$$

$$\sim\frac{\eta^{\lambda+(s-1)/2}}{\Gamma(\lambda)}\exp\left(-\eta\left(1+\frac{\beta^2}{t_+^2}\right)\right)\left[\frac{\beta^2+t_+^2}{2t_+^2}\right]^{-(s+1)/2}\Gamma\left(\frac{s+1}{2}\right) \quad \text{as } \eta\to\infty, \tag{5.7}$$

where $\eta = zt_+$. Since z is the large parameter, η is large if at least one of the uniformity parameters β, μ is bounded away from zero.

The coefficients c_s and the remainder R_n can be written as

$$c_s(\beta,\mu)=\frac{1}{2\pi i}\int_{C_r}\frac{f(\tau)}{(\tau-t_+)^s}\,d\tau, \qquad R_n(t,\beta,\mu)=\frac{1}{2\pi i}\int_{C_r}\frac{f(\tau)}{(\tau-t)(\tau-t_+)^n}\,d\tau,$$

where C_r is a circle around t_+ with radius $r(1+t_+)^\kappa$, $\kappa \geqq \frac{1}{2}$, $r>0$. We accept that f depends on both uniformity parameters β, μ, and we assume that the domain of analyticity Ω is large enough to contain such a circle for all β, $\mu \geqq 0$.

As in § 3 we have the following theorems. The quantity $M_r(\beta,\mu)$ is defined as in (3.16); we also assume that (3.13) is bounded for all β, $\mu \in [0,\infty)$.

THEOREM 5.1. *Let $\eta = zt_+$, $\kappa \geqq \frac{1}{2}$, and let for $s = 1, 2, \cdots$*

$$\chi_s=\frac{M_r(\beta,\mu)}{\Gamma(\lambda)z^s}\,\frac{(1+\eta)^{(s-1)/2}}{(1+t_+)^{s\kappa}}\exp\left(-\eta\left(1+\frac{\beta^2}{t_+^2}\right)\right)\left[\frac{\beta^2+t_+^2}{2t_+^2}\right]^{-(s+1)/2}. \tag{5.8}$$

Then $\{\chi_s\}$ is an asymptotic scale as $z\to\infty$, uniformly with respect to β, $\mu \in [0,\infty)$.

THEOREM 5.2. *The expansion*

$$z^\lambda F_\lambda(z,\alpha)\sim\sum_{s=0}^{\infty}c_s(\beta,\mu)P_s z^{-s}; \qquad \{\chi_s\} \quad \text{as } z\to\infty, \tag{5.9}$$

is a uniform asymptotic expansion as $z\to\infty$, uniformly with respect to β, $\mu \in [0,\infty)$.

A bound for the remainder E_n of (5.6) can be constructed by combining the methods used for (3.30) and the above estimate for the remainder of (5.4).

5.1. Application to a confluent hypergeometric function. Our starting point is (cf. (4.2))

$$\frac{\Gamma(a)}{\Gamma(\lambda)}U(a,1-\lambda,x) =\frac{1}{\Gamma(\lambda)}\int_0^\infty \exp\left(-z\left[-\mu\ln(1-e^{-w})+w+\frac{\nu}{e^w-1}\right]\right)\frac{dw}{1-e^{-w}}, \tag{5.10}$$

with $z=a$, $\mu=\lambda/z$, $\nu=x/z$. The real critical points of the "phase function" are

$$w_\pm=\ln\left(1+\frac{\mu+\nu\pm W}{2}\right), \qquad W=\sqrt{(\mu+\nu)^2+4\nu}. \tag{5.11}$$

The transformation to the standard form (5.1) reads

$$-\mu\ln(e^w-1)+(\mu+1)w+\frac{\nu}{e^w-1}=t+\frac{\beta^2}{t}-\mu\ln t+A; \tag{5.12}$$

A, β are determined by substituting $w_\pm$ and $t_\pm$, where $t_\pm$ are the critical points defined in (5.2). We have the correspondences

$$t(\pm\infty)=\pm\infty, \qquad t(w_\pm)=t_\pm, \qquad t(0)=0.$$

Observe that the introduction of a second parameter (here in the form of μ) does not require a third constant in the equation (5.12). It has the same number of constants as (4.4). In fact, in order to obtain a regular mapping $w\mapsto t$, the constants multiplying the log-functions in the left- and right-hand side of (5.12) must be the same. We assume that the log-functions take their principal branches.

Elimination of A from the two equations (5.12) (with $w=w_{\pm}$, $t=t_{\pm}$) gives a relation for the unknown parameter β in terms of μ, ν:

$$(\mu+1)\ln\frac{2+\mu+\nu+W}{2+\mu+\nu-W}-\mu\ln\frac{W+\mu+\nu}{W-\mu-\nu}+W=2T-\mu\ln\frac{T+\mu}{T-\mu}. \tag{5.13}$$

By considering $\mu\in[0,\infty)$ as a fixed parameter, we obtain a more transparent relation for $\beta(\nu)$ in the form of a differential equation:

$$\frac{d\beta(\nu)}{d\nu}=\frac{\beta W}{2\nu T},\qquad \beta(0)=0. \tag{5.14}$$

The value of A follows from (5.12) by substituting $w=w_+$, $t=t_+$. We have

$$A=(\mu+1)w_+-\mu\ln\frac{\mu+\nu+W}{\mu+T}-\frac{\mu+\nu-W}{2}-T.$$

Using (5.13), we can eliminate $W/2-T$ and we obtain

$$A=\frac{1}{2}\left[(\mu+1)\ln(\mu+1)+\mu\ln\frac{\beta^2}{\nu}-\mu-\nu\right]. \tag{5.15}$$

The transformation (5.12) is discussed in the next subsection. By using it in (5.10) we obtain the standard form (5.1):

$$F_\lambda(z,\alpha)=\frac{e^{zA}\Gamma(a)}{\Gamma(\lambda)}U(a,1-\lambda,x)=\frac{1}{\Gamma(\lambda)}\int_0^\infty t^{\lambda-1}e^{-zt-\alpha/t}f(t)\,dt,$$

where $z=a$, $\alpha=z\beta^2$; β^2 follows from (5.13) with $\mu=\lambda/z$, $\nu=x/z$. Furthermore,

$$f(t)=\frac{t}{1-e^{-w}}\frac{dw}{dt}=\frac{e^w(e^w-1)}{t}\,\frac{t^2-\mu t-\beta^2}{(e^w-1)^2-(\mu+\nu)(e^w-1)-\nu}. \tag{5.16}$$

The first coefficient of (5.9) equals $f(t_+)$. A few computations give

$$c_0(\beta,\mu)=e^{w_+/2}\sqrt{T/W}.$$

The function f satisfies $f(t)\sim t$ as $t\to+\infty$, whereas f is exponentially small at $-\infty$. This time we can also derive an expansion based on (5.4).

5.2. Analytical properties of the mapping (5.12). The mapping $w\mapsto t$ defined in (5.12) is one-to-one on the strip H given in (4.13). First we prove this property for the boundary. The proof is similar to that for Theorem 4.2. The equations for the image of the upper part of ∂H are given by (cf. (4.15))

$$\pi=r\sin\theta\left(1-\frac{\beta^2}{r^2}\right)-\mu\theta,\qquad \Psi(u)=\Phi(\theta),$$

where

$$\Psi(u)=-A+(\mu+1)u-\frac{\nu}{e^u+1},\qquad \Phi(\theta)=r\cos\theta\left(1+\frac{\beta^2}{r^2}\right)-\mu\ln r.$$

It follows that the image is given by

$$r(\theta)=\frac{\mu\theta+\pi+\sqrt{(\mu\theta+\pi)^2+4\beta^2\sin^2\theta}}{2\sin\theta},\qquad 0<\theta<\pi.$$

The function $\Psi(u)$ is one-to-one on $\mathbb{R}$. When we compute $d\Phi(\theta)/d\theta$, we find the same expression as in (4.16). As in Theorem 4.2, we conclude that the mapping is univalent on the boundary for all β, $\mu\in[0,\infty)$.

It remains to show that the mapping is analytic inside H. The interesting question is: Is $t(w)$ analytic at $t=0$, $t=w_{\pm}$, uniformly with respect to the parameters ν, μ? Especially interesting are small values of the parameters, since then the critical points coalesce with the pole and log-singularity at $w=0$. When one of the parameters is bounded away from the origin, the critical points $w_{\pm}$ are well separated. In that case the problem is simpler. Here we prove that $t(w, \nu, \mu)$ is analytic for complex values of the three arguments in a fixed neighborhood of $(0, 0, 0)$. The proof follows the idea of § 4.2.

First we have the following theorem.

THEOREM 5.1. *$\beta^2=\beta^2(\nu, \mu)$ defined by (5.13) is an analytic function of ν, μ.*

Proof. As remarked earlier, we concentrate on small values of the parameters. For $\mu=0$ the relation between ν and β is given in (4.6), and we have mentioned there that $\beta^2(\nu, 0)$ is analytic in the domain of interest. On the other hand, we have the expansion

$$\beta^2(\nu, \mu) \sim c_1(\mu)\nu + c_2(\mu)\nu^2 + c_3(\mu)\nu^3 + \cdots \quad \text{as } \nu \to 0.$$

The coefficients c_s are analytic functions of μ. The first few easily follow from (5.13):

$$c_1(\mu) = e^{(\mu+1)\ln(\mu+1)/\mu - 1} = 1 + \frac{1}{2}\mu - \frac{1}{24}\mu^2 + \mathcal{O}(\mu^3) \quad \text{as } \mu \to 0,$$

$$c_2(\mu) = \frac{c_1(\mu)[\mu + 2 - 2c_1(\mu)]}{\mu^2} = \frac{1}{12} + \mathcal{O}(\mu) \quad \text{as } \mu \to 0.$$

Next we observe that the quantity T of (5.2) is singular at $\beta^2=-\mu^2/4$ and that W of (5.11) has singular points at $\nu=\nu_0$, $\nu=\nu_1$, where

$$\nu_0 = -(\mu+2) + 2\sqrt{\mu+1}, \qquad \nu_1 = -(\mu+2) - 2\sqrt{\mu+1}. \tag{5.17}$$

It is obvious that the singularities at $-\mu^2/4$, ν_0 must correspond. That is, a necessary condition for β^2 to be regular for small values of $|\mu|$ is $\beta^2(\nu_0, \mu) = -\mu^2/4$. Note that $\nu_0 \sim -\mu^2/4$ as $\mu \to 0$ and that (5.13) is satisfied when we substitute $T=W=0$.

We "remove" the singularity at $\nu=\nu_0$ from (5.13), and we introduce a function $X=X(q, \mu)$ by writing

$$\frac{T+\mu}{T-\mu}\,\frac{W-\mu-\nu}{W+\mu+\nu} = \frac{1+\sqrt{q}\,X}{1-\sqrt{q}\,X}, \qquad q = \nu - \nu_0. \tag{5.18}$$

In other words,

$$\sqrt{q}\,X = \frac{\mu W - (\nu+\mu)T}{WT - \mu(\mu+\nu)}, \qquad T = \mu[W + (\nu+\mu)\sqrt{q}\,X]/D, \tag{5.19}$$

$$D = \nu + \mu + \sqrt{q}\,XW.$$

Now we can rewrite (5.13) in the form $K+L+M=0$, with

$$K = (W-2T)D = W(\nu-\mu) + \sqrt{q}\,X(\nu^2 + 4\nu - \mu^2),$$

$$L = D(\mu+1)\ln\frac{2+\mu+\nu+W}{2+\mu+\nu-W} = D(\mu+1)\ln\frac{1+\sqrt{q}\,Z}{1-\sqrt{q}\,Z},$$

$$M = D\mu\ln\frac{T+\mu}{T-\mu}\,\frac{W-\mu-\nu}{W+\mu+\nu} = D\mu\ln\frac{1+\sqrt{q}\,X}{1-\sqrt{q}\,X},$$

where

$$Z=\frac{\sqrt{\nu-\nu_1}}{2+\mu+\nu}=\frac{\sqrt{q+\nu_0-\nu_1}}{q+2+\mu+\nu_0}.$$

We expand $K+L+M$ in powers of q. A first observation is that $F(q, X, \mu):=(K+L+M)/\sqrt{q}$ is a function of q, X, μ, the factor $\sqrt{q}$ being completely removed. We expand F in powers of q. We have

$$F(q, X, \mu)=F_0+F_1q+F_2q^2+\cdots,$$

where $F_s(X, \mu)$ do not explicitly depend on q (or ν). We compute

$$F_0=(\nu_0-\mu)\sqrt{\nu_0-\nu_1}-2\mu(\nu_0+\mu)X+\frac{2\sqrt{\nu_0-\nu_1}(\nu_0+\mu)(\mu+1)}{2+\mu+\nu_0}+2\mu(\nu_0+\mu)X.$$

It appears that $F_0(X, \mu)\equiv 0$, and that, hence, we can continue with the equation $G(q, X, \mu):=F/q=F_1+F_2q+\cdots=0$. We claim that the equation $G(q, X, \mu)=0$ can be solved for $X=X(q, \mu)$, and that X is analytic for small values of both arguments. By calculating some limits, it follows from (5.18) or (5.19) that $X(0, 0)=-\frac{1}{2}$. This is used to show that $G(0, -\frac{1}{2}, 0)=F_1(0, 0)=0$. In order to apply an Implicit Function Theorem (see [1, p. 36]), we need to show that G is analytic in a neighborhood of $(0, -\frac{1}{2}, 0)$ and that $G(0, -\frac{1}{2}, 0)=0$, $G_X(0, -\frac{1}{2}, 0)\neq 0$. It is straightforward to verify that $G(q, X, \mu)$ is analytic in a neighborhood of $(0, -\frac{1}{2}, 0)$. Furthermore, $G_X(0, -\frac{1}{2}, 0)=\partial F_1/\partial X=4$ at $(X, \mu)=(-\frac{1}{2}, 0)$. We have shown that we can solve the equation $G=0$ and that the solution $X(q, \mu)$ is analytic in a fixed neighborhood of $(0, 0)$.

It remains to show that β^2 is analytic. We consider T of (5.2) given in the middle of (5.19). We are done when we have shown that μ/D is bounded away from zero when μ is small, since then we can divide the denominator of T by μ. From the above result it follows that we can expand

$$X(q, \mu)=X_0(q)+X_1(q)\mu+\cdots,$$

where the coefficients X_s are analytic functions of q. From the first equation of (5.19) we compute $X_0=-1/\sqrt{\nu-\nu_1}=-1/\sqrt{\nu+4}$. Hence

$$D=\nu+\mu+(\nu-\nu_0)\sqrt{\nu-\nu_1}\,X_0+\mathcal{O}(\mu)=\mathcal{O}(\mu)$$

as $\mu\to 0$. It now follows that T^2 is an analytic function of q, μ in a fixed neighborhood of $(0, 0)$, and, consequently, that β^2 is analytic. This proves the theorem. □

Remark 5.1. It is possible to base a proof on the differential equation (5.14). The condition $\beta(0)=0$ is not enough to prove the theorem, since the ratio β^2/ν (at $\nu=0$) turns out to be undefined. Requiring that this ratio equals $c_1(\mu)$ is sufficient, however.

In Theorem 4.1 we expanded the functions of (4.10) at the critical points $\pm w_0$, and in (4.14) we used a representation of t in which y can be viewed as a part of the complete expansion. In fact, (4.14) is a change of variables. In the present case we expand at the critical points $w_\pm$, and the expansions have the form

$$\psi(w)=\sum_{k=0}^{\infty}[a_k+wb_k]V^k, \qquad V=V(w)=(w-w_-)(w-w_+). \tag{5.20}$$

When ψ is sufficiently smooth, the coefficients a_k, b_k are uniquely defined. The first

few are given by

$$a_0=\frac{\psi_-w_+-\psi_+w_-}{w_+-w_-}, \qquad b_0=\frac{\psi_+-\psi_-}{w_+-w_-},$$

$$a_1=\frac{b_0w_0-\psi'_+w_--\psi'_-w_+}{(w_+-w_-)^2}, \qquad b_1=\frac{\psi'_++\psi'_--2b_0}{(w_+-w_-)^2},$$

where $w_0=w_++w_-$, and $\psi_+=\psi(w_+)$, etc. For analytic functions the coefficients can be represented as Cauchy-type integrals. We have

$$(5.21)\quad a_k=\frac{1}{2\pi i}\int_C (w-w_0)V^{-k-1}(w)\psi(w)\,dw, \qquad b_k=\frac{1}{2\pi i}\int_C V^{-k-1}(w)\psi(w)\,dw,$$

where C is a contour around the two critical points; ψ must be analytic inside C and continuous on C. This can be verified by substituting a new variable $w=v+w_0/2$. Then we have

$$\psi(w)=f\left(v+\frac{w_0}{2}\right)=\sum c_kV^k+v\sum b_kV^k, \qquad c_k=a_k+\frac{1}{2}w_0b_k.$$

By separating odd and even parts (with respect to v), and representing c_k, b_k as Cauchy integrals in the V-plane, we arrive at (5.21). (Note that a circle around the origin in the w-plane is traversed twice in the V-plane.) For MacLaurin series the domain of convergence is a disc. For expansions as in (5.20) the domain of convergence is defined by $|V(w)|<|V(w_s)|$, where w_s is a singularity of ψ; this domain is bounded by a Cassini's oval with foci at $w_\pm$. See also [7, Exercise 24, p. 149].

The parameter t of (5.12) is represented in the form

$$(5.22)\qquad t=w[B+Cw+V(w)y],$$

where B, C do not depend on w, and we require that the points $\{w_-, 0, w_+\}$ correspond with $\{t_-, 0, t_+\}$. This gives for B, C the values

$$(5.23)\qquad B=\frac{w_+^2t_--w_-^2t_+}{w_+w_-(w_+-w_-)}, \qquad C=\frac{t_+w_--t_-w_+}{w_-w_+(w_+-w_-)}.$$

The critical points $w_\pm$, $t_\pm$ are not analytic for small values of the parameters. However, we have the following lemma.

LEMMA 5.1. *B, C, w_+w_-, $w_0=w_++w_-$ are analytic functions of μ, ν in a fixed neighborhood of $(0,0)$. Moreover, $B=1+o(1)$, $C=o(1)$ near $(0,0)$.*

Proof. We use the notation of Theorem 5.1. We have $w_0=\ln(1+\mu)$ and the product w_+w_- is an even function of W. So the singularity in $W=\sqrt{q}\sqrt{\nu-\nu_1}$ is removed when we expand w_+w_- in powers of W. Using (5.2), we can write

$$(5.24)\qquad 2C=-\frac{\mu}{w_+w_-}\left[1-\frac{T\ln(1+\mu)/\mu}{w_+-w_-}\right].$$

We introduce a parameter η by writing

$$\beta^2=\nu[E+(\nu-\nu_0)\eta], \qquad E=-\frac{\mu^2}{4\nu_0}=-\frac{\nu_1}{4}.$$

Then we have $T=2\sqrt{q}\sqrt{E+\nu\eta}$; $\eta=\eta(\nu,\mu)$ is analytic in a neighborhood of $(0,0)$. Next we use $w_+-w_-=\ln[(1+\sqrt{q}Z)/(1-\sqrt{q}Z)]$. Since the factor $\sqrt{q}$ can be removed, we infer that the fraction $T/(w_+-w_-)$ is regular. It is easily verified that the expression

between square brackets in (5.24) vanishes when $\nu \to 0$ and that $w_+ w_- = -\nu F$, where $F = F(\nu, \mu)$ is analytic at $(0, 0)$, with $F = 1 + \mathcal{O}(\nu + \mu)$, as $\nu, \mu \to 0$. This proves that C is analytic at $(0, 0)$; the factor μ in the first fraction of (5.24) takes care of the vanishing of C at $(0, 0)$. A more detailed analysis shows that $C \sim -\mu/24$, $\mu \to 0$, $\nu = 0$. The proof for B now follows from the representation $B + w_0 C = (t_+ - t_-)/(w_+ - w_-) = T/(w_+ - w_-)$. At $\nu = 0$ this expression reduces to $\mu/\ln(\mu + 1) = 1 + \mathcal{O}(\mu)$, as $\mu \to 0$. □

COROLLARY 5.1. *Let ψ of* (5.20) *be analytic in a domain containing the points $w_\pm$. Then the coefficients a_k, b_k are analytic functions of the parameters μ, ν.*

Proof. This follows from the fact that sum and product of $w_\pm$ occur in $V(w)$ and that the Cauchy-type integrals in (5.21) are analytic functions of $w_+ + w_-$ and $w_+ w_-$. □

After these preparations we are ready to consider the following theorem.

THEOREM 5.2. *The function $t(w, \nu, \mu)$ defined by* (5.12), *with β^2 defined in* (5.13), *is analytic in a fixed neighborhood of* $(0, 0, 0)$.

Proof. We write (5.12) in the form

$$F(t, w, \mu, \nu) = tH(w) - S(t) = 0, \tag{5.25}$$

where

$$H(w) = -\mu \ln \frac{e^w - 1}{w} + (\mu + 1)w + \frac{\nu}{e^w - 1} - A, \qquad S(t) = t^2 + \beta^2 - \mu t \ln \frac{t}{w}. \tag{5.26}$$

Using (5.22) we can consider F as a function of w, with two known parameters μ, ν, and one unknown parameter y. We expand F as in (5.20):

$$F = \sum_{k=0}^{\infty} [u_k + w v_k] V^k(w), \tag{5.27}$$

where the coefficients u_k, v_k do not depend on w and t; they do depend on y, however. The first coefficients are

$$\begin{aligned}
u_0 &= -C^2 b^2 a - C^2 a^2 - aB^2 - 2aBCb + f_0 B + g_0 aC - \beta^2 \\
&\quad + \mu a(Cc_0 + Bd_0 + Cbd_0), \\
v_0 &= -2aBC - C^2 b^3 - bB^2 + f_0 C + g_0 B - 2C^2 ab - 2b^2 BC + g_0 bC \\
&\quad + \mu(Cad_0 + Bc_0 + Cbc_0 + bBd_0 + Cb^2 d_0), \\
u_1 &= -B^2 - C^2 b^2 - 2aBy - 2Cbay - 2C^2 a + f_0 y + f_1 B - 2BCb + g_0 C + g_1 aC \\
&\quad + \mu(aBd_1 + Cbad_1 + Cac_1 + Cc_0 + Bd_0 + Cbd_0 + ayd_0), \\
v_1 &= -2bBy - 2Cb^2 y - 2BC - 2Cay - 2C^2 b + g_0 y + f_1 C + g_1 B + g_1 bC \\
&\quad + \mu(bBd_1 + Cb^2 d_1 + Bc_1 + Cad_1 + Cbc_1 + Cd_0 + yc_0 + byd_0), \\
u_2 &= -ay^2 + g_1 C + f_2 B + f_1 y - 2By + g_2 aC - C^2 - 2Cby \\
&\quad + \mu(Cac_2 + aBd_2 + Bd_1 + Cc_1 + yd_0 + Cbd_1 + Cbad_2 + ayd_1), \\
v_2 &= g_2 bC - by^2 + g_1 y - 2Cy + g_2 B + f_2 C \\
&\quad + \mu(Cb^2 d_2 + byd_1 + Cbc_2 + Cad_2 + Bc_2 + bBd_2 + yc_1 + Cd_1),
\end{aligned}$$

where a, b are defined by $w^2 = a + bw + V(w)$, i.e., $a = -w_+ w_-$, $b = w_+ + w_-$ and the coefficients c_k, d_k, f_k, g_k occur in the expansions

$$wH(w) = f_0 + g_0 w + f_1 V + g_1 wV + f_2 V^2 + g_2 wV^2 + \cdots,$$

$$\ln \frac{t}{w} = c_0 + d_0 w + c_1 V + d_1 wV + c_2 V^2 + d_2 wV^2 + \cdots.$$

The coefficients u_0, v_0 vanish identically. This can be verified by straightforward manipulations. It also follows from the observation that the representation (5.22) can be viewed as a truncated expansion for t, in which the first coefficients B, C are defined properly. If more coefficients D, E, $\cdots$ had been included in y (and defined properly), more and more coefficients u_k, v_k would vanish identically. When using (5.22), only a few coefficients will vanish. Although u_1, v_1 contain the parameter y (also via c_1, d_1), these coefficients vanish too. Again, this can be verified by straightforward manipulations.

It follows that we can proceed with the equation $G=0$, where

$$G=G(y, w, \mu, \nu)=\frac{F(t, w, \mu, \nu)}{V^2(w)}.$$

The coefficient u_2 contains a term $-2By$, with B given in (5.23). From Lemma 5.1, it follows that B is bounded away from zero when the parameters μ, ν are small. The remaining contributions to u_2 containing the parameter y tend to zero as μ, $\nu \to 0$. All coefficients u_k, v_k are analytic functions of μ, ν, and the convergent infinite series (including coefficients v_2 and higher) represents a function of y, w, μ, ν that is analytic in a neighborhood of $(0, 0, 0, 0)$. Consequently, since $\partial G(0, 0, 0, 0)/\partial y = -2$, we can solve for y and this solution is an analytic function of w, μ, ν in a fixed neighborhood of $(0, 0, 0)$. The same holds for t given in (5.22). □

Remark 5.3. A simpler version ($\mu = 0$) of the above theorem is considered in Theorem 4.1. Another simpler version ($\nu = 0$) is given by [5, Thm. 2.1].

We still have to show that Ω (the image of strip H of (4.13) under the mapping $w \mapsto t$ defined in (5.12)) is large enough to contain a disc around t_+ with radius $\rho(1+t_+)^\kappa$, $\kappa \geqq \frac{1}{2}$, ρ fixed. It is not difficult to verify that when $\beta > \mu$ the proof runs as in § 4.2. If μ is much larger than β, the situation improves, and we can take $\kappa = 1$.

We conclude by computing a bound for the quantity $M_r(\beta, \mu)$ used in (5.8), and defined as in (3.16). The t-values on the circle C_r are written as $t = t_+ + \tau\sqrt{t_+ + 1}$, with $|\tau| = r$, r fixed. We assume that at least one of the parameters ν, μ is large. We have

$$t+\frac{\beta^2}{t}-\mu \ln t \sim t_+ + \frac{\beta^2}{t_+}-\mu \ln t_+ + \frac{T(1+t_+)}{t_+(\mu+T)}\tau^2 + \mathcal{O}(t_+^{-1}).$$

We denote the factor multiplying τ^2 by q. Observe that, roughly speaking, q belongs to the interval $[\frac{1}{2}, 1]$. Using this in (5.12), we obtain

$$q\tau^2 \sim -\mu \ln \frac{e^w-1}{e^{w_+}-1} + (\mu+1)(w-w_+) + \nu\left[\frac{1}{e^w-1}-\frac{1}{e^{w_+}-1}\right].$$

Denoting the right-hand side by $\psi(w)$, we see that $\psi(w_+) = \psi'(w_+) = 0$. A few computations give

$$\psi''(w_+) = 1 + \frac{2(\nu+W)}{(\nu+\mu+w)^2} = 1 + o(1).$$

To solve the equation $\psi(w) = q\tau^2$ we expand $\psi(w_+ + v) = \frac{1}{2}v^2\psi''(w_+) + \cdots$. We can take the fixed number r as small as we please. Then the solution of the above equation reads $w \sim w_+ + \tau\sqrt{2q}$. Using this in (5.16), we infer that $f(t) \sim 4\sqrt{t_+}/\tau$, under the condition that $t \in C_r$ and that at least one of the parameters ν, μ is large. Consequently, we can find a fixed number K, such that

$$M_r(\beta, \mu) \leqq K\sqrt{1+t_+}/r, \qquad \nu, \mu \in [0, \infty).$$

AN ASYMPTOTIC PROBLEM IN DERANGEMENT THEORY*

J. GILLIS†, MOURAD E. H. ISMAIL‡, AND T. OFFER†

Abstract. N elements, divided into sets of respective cardinalities $\{n_1, n_2, \cdots, n_a\}$, k sets of each size, where $N = k\sum_{i=1}^{a} n_i$, are given. The probability is considered that a random permutation of the N elements is a derangement, i.e., that it leaves none of the elements in the set to which it belonged initially. In particular, an asymptotic estimate of this probability as $k \to \infty$ is obtained.

It is known that the number of possible derangements can be represented by an integral involving products of Laguerre polynomials. The probability is obtained by asymptotic evaluation of a more general integral, involving the generalized Laguerre polynomials $L_n^{(\alpha)}(x)$, of which the integral required here is a special case.

Key words. derangement, Laguerre polynomials, asymptotic

AMS(MOS) subject classifications. primary 05A05; secondary 26C05

1. Introduction. Given finite sets, of respective cardinalities $\{n_1, n_2, \cdots, n_a\}$, k sets of each size, we consider permutations of the entire set of $k\sum_{i=1}^{a} n_i$ elements. A permutation will be called a derangement if none of the elements is left in the set to which it initially belonged. Our main purpose is to estimate asymptotically, as $k \to \infty$, the probability that a random permutation of the elements is a derangement.

Let $D_k(n_1, n_2, \cdots, n_a)$ denote the total number of possible derangements and let $P_k(n_1, \cdots, n_a)$ denote the probability of a permutation being a derangement. It is clear that

$$P_k(n_1, \cdots, n_a) = D_k(n_1, \cdots, n_a) \Big/ \left(k \sum_{i=1}^{a} n_i\right)!. \tag{1.1}$$

Now it is known ([1, p. 135], [2, p. 4]) that

$$D_k(n_1, \cdots, n_a) = \prod_{i=1}^{a} \{(-1)^{n_i} n_i!\}^k \int_0^\infty \left\{\prod_{i=1}^{a} L_{n_i}(x)\right\}^k e^{-x}\, dx \tag{1.2}$$

where $L_n(x)$ denotes the Laguerre polynomial

$$L_n(x) = \sum_{m=0}^{n} (-1)^m \binom{n}{m} \frac{x^m}{m!}. \tag{1.3}$$

Since neither $D_k(n_1, \cdots, n_a)$ nor $P_k(n_1, \cdots, n_a)$ have closed-form expressions, integral representations such as (1.2) are useful for several reasons. First, we can use (1.2) and the recurrence relations for Laguerre polynomials to derive recurrence relations for $D_k(n_1, \cdots, n_a)$. For a number of such recurrence relations, some of which seem difficult to prove from direct combinatorial considerations, see [2, p. 142]. Second, an integral representation such as (1.2) proves the positivity of the linearization of products of $\{(-1)^n L_n(x)\}$, and hence the existence of a discrete convolution structure associated with $\{(-1)^n L_n(x)\}$. Third, as we will see in this paper, (1.2) can be used to estimate the size of the D_k's or P_k's for large k. We write

$$s_r = \sum_{i=1}^{a} n_i^r \qquad (r = 1, 2, \cdots), \tag{1.4}$$

and so

$$P_k(n_1, \cdots, n_a) = (-1)^{ks_1}\left(\prod_{i=1}^{a} n_i!\right)^k \{(s_1k)!\}^{-1} \int_0^\infty \left\{\prod_{i=1}^{a} L_{n_i}(x)\right\}^k e^{-x}\, dx. \tag{1.5}$$

We will show that, as $k \to \infty$,

$$P_k(n_1, \cdots, n_a) = \exp\left(-\frac{s_2}{s_1}\right)\left\{1 - \frac{s_1(2s_3 - s_2) - s_2^2}{2s_1^3 k} + O(k^{-2})\right\}. \tag{1.6}$$

It follows, in particular, that in the special case $a = 1$,

$$\lim_{k\to\infty} P_k(n_1) = e^{-n_1}, \tag{1.7}$$

a result previously obtained by Askey, Ismail, and Rashed [1, p. 5], though the method of proof there does not seem to extend to the case $a > 1$.

The limiting relation (1.7) is interesting because it shows that $P_k(n_1) \sim (P_k(1))^{n_1}$, i.e., the probability of having a derangement of type $n_1, n_1, \cdots, n_1$ (k times), $k \to \infty$, is asymptotically equal to that of having n_1 independent copies of the classical derangement problem with $k \to \infty$. Now (1.6), which we will prove, is more interesting because it shows that

$$\{P_k(n_1, n_2, \cdots, n_a)\}^{s_1} \sim \prod_{i=1}^{a} \{P_k(n_i)\}^{n_i},$$

a surprising result with an obvious combinatorial interpretation.

Equation (1.6) will follow from the asymptotic estimation, as $k \to \infty$, of the integral in (1.2). However, we will begin by examining a more general integral, namely,

$$I(\alpha) = \int_0^\infty \left\{\prod_{i=1}^{a} (-1)^{n_i} L_{n_i}^{(\alpha)}(x)\right\}^k x^\alpha e^{-x}\, dx \tag{1.8}$$

where the $L_{n_i}^{(\alpha)}$ are generalized Laguerre polynomials defined (for $\alpha > -1$) by

$$L_n^{(\alpha)}(x) = \sum_{m=0}^{n} (-1)^m \binom{n+\alpha}{n-m} \frac{x^m}{m!}. \tag{1.9}$$

It is not known whether the integrals $I(\alpha)$ of (1.8) are nonnegative for $\alpha > -1$. When $\alpha = 0$ the nonnegativity of $I(\alpha)$ follows from the combinatorial interpretation of [2]. The nonnegativity of $I(\alpha)$ for $\alpha \neq 0$ is difficult to prove because each Laguerre polynomial $L_n^\alpha(x)$ in the integrand has n simple zeros in the range of integration. It will be shown that, for large k,

$$I(\alpha) = (2\pi)^{1/2}(ks_1)^{ks_1+\alpha+1/2}\left\{\prod_{i=1}^{a} n_i!\right\}^{-k} \exp\left\{-ks_1 - \frac{s_2 + \alpha s_1}{s_1}\right\}\left\{1 + \frac{h}{k} + O(k^{-2})\right\} \tag{1.10}$$

where

$$h = \{(1 + 12\alpha + 18\alpha^2)s_1^2 - 12s_1s_3 + 6s_2^2 + 6(\alpha+1)s_1s_2\}/12s_1^3.$$

In particular,

$$\begin{aligned} I(0) = (2\pi)^{1/2}(ks_1)^{ks_1+1/2}&\left\{\prod_{i=1}^{a} n_i!\right\}^{-k} \exp\left\{-ks_1 - \frac{s_2}{s_1}\right\} \\ &\cdot\left\{1 - \frac{1}{12ks_1} - \frac{s_1(2s_3 - s_2) - s_2^2}{2ks_1^3} + O(k^{-2})\right\}. \end{aligned} \tag{1.11}$$

Now,

$$P_k(n_1, \cdots, n_a) = \left\{ \prod_{i=1}^{a} n_i ! \right\}^k \{(ks_1)!\}^{-1} I(0) \quad \text{(by (1.5))}$$

$$= (2\pi)^{1/2} (ks_1)^{ks_1+1/2} \{(ks_1)!\}^{-1}$$

$$\cdot \left\{ 1 - \frac{1}{12ks_1} - \frac{s_1(2s_3 - s_2) - s_2^2}{2ks_1^3} + O(k^{-2}) \right\} \tag{1.12}$$

$$\cdot \exp\left\{ -ks_1 - \frac{s_2}{s_1} \right\},$$

while, by Stirling's Formula,

$$(ks_1)! = (2\pi)^{1/2} (ks_1)^{ks_1+1/2} \exp(-ks_1) \left\{ 1 + \frac{1}{12ks_1} + O(k^{-2}) \right\}. \tag{1.13}$$

Estimate (1.6) now follows immediately from (1.12) and (1.13). It remains to establish (1.10).

2. Proof of (1.10). We will use the Laplace approach (cf. [4, p. 81]), writing

$$I(\alpha) = \int_0^\infty e^{f(x)}\, dx \tag{2.1}$$

where

$$f(x) = k \sum_{i=1}^{a} \ln\{(-1)^{n_i} L_{n_i}^{(\alpha)}(x)\} + \alpha \ln x - x. \tag{2.2}$$

It will turn out that interest centres entirely on large values of x, where $(-1)^{n_i} L_{n_i}^{(\alpha)}(x) > 0$, and we may therefore ignore questions about logarithms of negative quantities.

2.1. Maximum of the integral. Let $Q(x) = \prod_{i=1}^{a} \{(-1)^{n_i} L_{n_i}^{(\alpha)}(x)\}$. Then

$$f(x) = k \ln Q(x) + \alpha \ln x - x$$

and so the extremals of $f(x)$ are to be sought among the roots of the equation

$$(x - \alpha) Q(x) = kxQ'(x). \tag{2.3}$$

This is a polynomial equation of degree $s_1 + 1$. It is clear that, for large k, there will be a root close to $x = 0$, and $s_1 - 1$ roots close to those of $Q'(x)$, all bounded independently of k. On the other hand, if

$$Q(x) = a_0 x^{s_1} + a_1 x^{s_1-1} + \cdots,$$

then (2.3) becomes

$$kx(s_1 a_0 x^{s_1-1} + \cdots) = (x - \alpha)(a_0 x^{s_1} + a_1 x^{s_1-1} + \cdots),$$

i.e.,

$$a_0 x^{s_1+1} - \{(ks_1 + \alpha) a_0 - a_1\} x^{s_1} + \cdots = 0$$

so that the sum of all $(s_1 + 1)$ roots is $ks_1 + \alpha - a_1/a_0$. It follows that the remaining root will be

$$x_0 = ks_1 + O(1). \tag{2.4}$$

For large k this will clearly be the largest root and it is easily verified that $f(x)$ will attain its global maximum there. It remains to estimate x_0 more precisely.

For any fixed $\alpha > -1$, write

$$v_n(x) = L_n^{(\alpha)\prime}(x)/L_n^{(\alpha)}(x); \tag{2.5}$$

then (2.3) becomes

$$k \sum_{i=1}^{a} v_{n_i}(x) = 1 - \frac{\alpha}{x}. \tag{2.6}$$

But $y = L_n^{(\alpha)}(x)$ satisfies the differential equation ([3, p. 781])

$$xy'' + (\alpha + 1 - x)y' + ny = 0 \tag{2.7}$$

and hence v_n satisfies

$$x(v_n' + v_n^2) + (\alpha + 1 - x)v_n + n = 0. \tag{2.8}$$

However, $L_n^{(\alpha)}(x)$ is a polynomial of degree n, and so v_n must be of the form

$$\frac{n}{x} + O\left(\frac{1}{x^2}\right)$$

for large x. We deduce, by successive approximation in (2.8), that

$$v_n(x) = \frac{n}{x} + \frac{n(n+\alpha)}{x^2} + \frac{n(n+\alpha)(2n+\alpha-1)}{x^3} + O(x^{-4}). \tag{2.9}$$

It follows that

$$V(x) = \sum_{i=1}^{a} v_{n_i}(x) = \frac{s_1}{x} + \frac{s_2 + \alpha s_1}{x^2} + \frac{c}{x^3} + O(x^{-4}) \tag{2.10}$$

where

$$c = 2s_3 + (3\alpha - 1)s_2 + \alpha(\alpha - 1)s_1. \tag{2.11}$$

Equation (2.6) now becomes

$$1 - \frac{\alpha}{x} = k\left(\frac{s_1}{x} + \frac{s_2 + \alpha s_1}{x^2} + \frac{c}{x^3} \cdots\right). \tag{2.12}$$

Starting from (2.4) we obtain, by successive approximation in (2.12),

$$x_0 = ks_1 + \frac{s_2 + 2\alpha s_1}{s_1} + \frac{t}{ks_1^3} + O(k^{-2}) \tag{2.13}$$

where

$$t = 2s_1s_3 - s_2^2 - s_1s_2 - \alpha(\alpha + 1)s_1^2. \tag{2.14}$$

2.2. Taylor expansion of $f(x)$ about $x = x_0$. Since

$$f'(x) = kV(x) + \frac{\alpha}{x} - 1 \tag{2.15}$$

it follows that, for $r \geqq 2$,

$$f^{(r)}(x_0) = kV^{(r-1)}(x_0) + (-1)^{r-1}(r-1)!\,\alpha x_0^{-r}. \tag{2.16}$$

Substituting in (2.16) from (2.10) and (2.13) we get, after some manipulation,

$$f(x)=f(x_0)-A(x-x_0)^2+B(x-x_0)^3-C(x-x_0)^4\cdots \tag{2.17}$$

where

$$\begin{aligned} A&=-\frac{1}{2}f''(x_0)=\frac{1}{2ks_1}\left\{1-\frac{\alpha}{ks_1}+\frac{t}{k^2s_1^4}+O(k^{-3})\right\},\\ B&=\frac{1}{6}f'''(x_0)=\frac{1}{3k^2s_1^2}\left\{1-\frac{2\alpha}{ks_1}+\frac{3t}{k^2s_1^4}+O(k^{-3})\right\}, \qquad (2.18)\\ C&=-\frac{1}{24}f^{(iv)}(x_0)=\frac{1}{4k^3s_1^3}\left\{1-\frac{3\alpha}{ks_1}+\frac{6t}{k^2s_1^4}+O(k^{-3})\right\}. \end{aligned}$$

2.3. Estimation of $e^{f(x_0)}$. By (2.2),

$$e^{f(x_0)}=x_0^{\alpha}\,e^{-x_0}\left\{\prod_{i=1}^{a}(-1)^{n_i}L_{n_i}^{(\alpha)}(x_0)\right\}^k. \tag{2.19}$$

We write

$$(-1)^nL_n^{(\alpha)}(x)=\frac{x^n}{n!}G_n(x) \tag{2.20}$$

where

$$G_n(x)=1-\frac{n(n+\alpha)}{x}+\frac{n(n-1)(n+\alpha)(n+\alpha-1)}{2x^2}+O(x^{-3})$$

so that

$$\ln G_n(x_0)=-\frac{n(n+\alpha)}{x_0}-\frac{n(n+\alpha)(2n+\alpha-1)}{2x_0^2}+O(x_0^{-3}), \tag{2.21}$$

and hence

$$\begin{aligned} \prod_{i=1}^{a}(-1)^{n_i}L_{n_i}^{(\alpha)}&=x_0^{s}\left\{\prod_{i=1}^{a}n_i!\right\}^{-1}\\ &\quad\cdot\exp\left\{-\frac{s_2+\alpha s_1}{x_0}-\frac{2s_3+(3\alpha-1)s_2+\alpha(\alpha-1)s_1}{2x_0^2}+O(x_0^{-3})\right\},\\ e^{f(x_0)}&=x_0^{\alpha}\,e^{-x_0}\left\{\prod_{i=1}^{a}(-1)^{n_i}L_{n_i}(x)\right\}^k\\ &=x_0^{ks_1+\alpha}\left\{\prod_{i=1}^{a}n_i!\right\}^{-k} \qquad (2.22)\\ &\quad\cdot\exp\left\{-x_0-\frac{k(s_2+\alpha s_1)}{x_0}-\frac{k[2s_3+(3\alpha-1)s_2+\alpha(\alpha-1)s_1]}{2x_0^2}+O(kx_0^{-3})\right\}. \end{aligned}$$

Substituting from (2.13) we get, after some manipulation,

$$e^{f(x_0)}=x_0^{ks_1+\alpha}\left\{\prod_{i=1}^{a}n_i!\right\}^{-k}\exp\left\{-ks_1-\frac{2s_2+3\alpha s_1}{s_1}-\frac{g}{2ks_1^3}+O(k^{-2})\right\} \tag{2.23}$$

where

$$g=6s_1s_3-4s_2^2-3(\alpha+1)s_1s_2-\alpha(5\alpha+3)s_1^2.$$

But

$$x_0 = ks_1\left\{1+\frac{s_2+2\alpha s_1}{ks_1^2}+\frac{t}{k^2 s_1^4}+O(k^{-3})\right\}$$

and so

$$\ln\left(\frac{x_0}{ks_1}\right)=\frac{s_2+2\alpha s_1}{ks_1^2}+\frac{2t-(s_2+2\alpha s_1)^2}{2k^2 s_1^4}+O(k^{-3}) \tag{2.24}$$

whence

$$(ks_1+\alpha)\ln\left(\frac{x_0}{ks_1}\right)=\frac{s_2+2\alpha s_1}{s_1}+\frac{p}{2ks_1^3}+O(k^{-2}) \tag{2.25}$$

where

$$p = 4s_1s_3-3s_2^2-2(\alpha+1)s_1s_2-2\alpha(\alpha+1)s_1^2, \tag{2.26}$$

$$\left(\frac{x_0}{ks_1}\right)^{ks_1+\alpha}=\exp\left\{\frac{s_2+2\alpha s_1}{s_1}+\frac{p}{2ks_1^3}+O(k^{-2})\right\}. \tag{2.27}$$

From (2.23) and (2.27) we get

$$e^{f(x_0)}=(ks_1)^{ks_1+\alpha}\left\{\prod_{i=1}^{a} n_i!\right\}^{-k}\exp\left\{-ks_1-\frac{s_2+\alpha s_1}{s_1}-\frac{q}{2ks_1^3}+O(k^{-2})\right\} \tag{2.28}$$

where

$$q = 2s_1s_3-s_2^2-(\alpha+1)s_1s_2-\alpha(3\alpha+1)s_1^2. \tag{2.29}$$

2.4. Estimation of $\int_0^\infty e^{f(x)-f(x_0)}\,dx$. It follows from (2.17) that the integral can be estimated by

$$\begin{aligned}\int_{-x_0}^{\infty} e^{-Au^2+Bu^3-Cu^4}\,du &= \left(\int_{-\infty}^{\infty}-\int_{-\infty}^{-x_0}\right)e^{-Au^2+Bu^3-Cu^4}\,du \\ &= X-Y \quad \text{(say)}.\end{aligned} \tag{2.30}$$

We begin by estimating Y:

$$\begin{aligned}0<Y&=\int_{-\infty}^{-x_0} e^{-Au^2+Bu^3-Cu^4}\,du \\ &<\int_{-\infty}^{-x_0} e^{-Au^2}\,du \quad \text{since } A, B, C, \text{ are all positive} \\ &=\int_{x_0}^{\infty} e^{-Au^2}\,du.\end{aligned} \tag{2.31}$$

But for large k, $x_0 > ks_1$, by (2.13), and hence

$$\begin{aligned}0<Y&<\int_{ks_1}^{\infty} e^{-Au^2}\,du \\ &= A^{-1/2}\,\mathrm{Erfc}\,(ks_1A^{1/2}) \\ &\sim (2ks_1)^{1/2}\,\mathrm{Erfc}\,(\sqrt{ks_1/2}) \quad \text{by (2.18)} \\ &\sim 2\pi^{-1/2}\exp(-ks_1/2)\end{aligned} \tag{2.32}$$

(cf. [3, p. 298].

To estimate X we write $v^2 = Au^2 - Bu^3 + Cu^4$ leading to

$$u = av + \beta v^2 + \gamma v^3 \cdots \tag{2.33}$$

where

$$\alpha = A^{-1/2}, \qquad \gamma = \tfrac{1}{8}A^{-7/2}(5B^2 - 4AC). \tag{2.34}$$

We then get

$$\begin{aligned} X &\sim \int_{-\infty}^{\infty} e^{-v^2}\, du \\ &= \int_{-\infty}^{\infty} e^{-v^2} \frac{du}{dv}\, dv \\ &= \int_{-\infty}^{\infty} e^{-v^2}(\alpha + 3\gamma v^2 + \cdots)\, dv \\ &\sim \sqrt{\pi}(\alpha + 3\gamma/2) \\ &= \frac{1}{16}\sqrt{\pi}\, A^{-7/2}(16A^3 + 15B^2 - 12AC). \end{aligned} \tag{2.35}$$

Substituting again from (2.18), we obtain

$$\int_0^{\infty} \exp\{f(x) - f(x_0)\}\, dx = \sqrt{2\pi k s_1}\left\{1 + \frac{1+6\alpha}{12ks_1} + O(k^{-2})\right\}. \tag{2.36}$$

2.5. Proof of (1.10) and (1.6). It follows from (2.1) that

$$\begin{aligned} I(\alpha) &= e^{f(x_0)} \int_0^{\infty} e^{f(x)-f(x_0)}\, dx \\ &= (ks_1)^{ks_1+\alpha}\left\{\prod_{i=1}^{a} n_i!\right\}^{-k} \exp\left\{-ks_1 - \frac{s_2+\alpha s_1}{s_1} - \frac{q}{2ks_1^3} + O(k^{-2})\right\} \\ &\quad \cdot \sqrt{2\pi k s_1}\left\{1 + \frac{1+6\alpha}{12ks_1} + O(k^{-2})\right\} \quad \text{by (2.28) and (2.36)} \\ &= (2\pi)^{1/2}(ks_1)^{ks_1+\alpha+1/2}\left\{\prod_{i=1}^{a} n_i!\right\}^{-k} \exp\left\{-ks_1 - \frac{s_2+\alpha s_1}{s_1}\right\} \\ &\quad \cdot \left\{1 + \frac{(1+6\alpha)s_1^2 - 6q}{12ks_1^3} + O(k^{-2})\right\} \\ &= (2\pi)^{1/2}(ks_1)^{ks_1+\alpha+1/2}\left\{\prod_{i=1}^{a} n_i!\right\}^{-k} \exp\left\{-ks_1 - \frac{s_2+\alpha s_1}{s_1}\right\}\left\{1 + \frac{h}{k} + O(k^{-2})\right\}, \end{aligned}$$

i.e., (1.10).

Equation (1.6) now follows as shown in § 1, (1.12), and (1.13).

3. Some numerical results. Table 1 may give some idea as to the accuracy of approximation (1.6) for even quite small values of k. All results are correct to the fourth decimal place.

THETA FUNCTION GENERALIZATIONS OF SOME CONSTANT TERM IDENTITIES IN THE THEORY OF RANDOM MATRICES*

P. J. FORRESTER†

Abstract. The probability distribution for the location of the eigenvalues in Dyson's unitary random matrix ensembles is generalized to involve theta functions. At three special values of a parameter, corresponding to Dyson's orthogonal, unitary, and symplectic ensembles, the normalization constant of the probability distribution is calculated. The results can be viewed as giving the constant term in the Laurent expansion of the multivariable function $\prod_{k\neq l=1}^{N}(1-w_k/w_l)^{\Gamma/2}(q^2w_k/w_l;\,q^2)_\infty^\Gamma$ for $\Gamma=1$, 2, and 4.

Key words. random matrix ensembles, constant term identities, q-series

AMS(MOS) subject classifications. 26B99, 26C99

1. Introduction and summary. The probability distribution for N points on a line

$$P_{N\Gamma}(x_1, x_2, \cdots, x_N)\,dx_1\,dx_2\cdots dx_N \tag{1.1}$$

where

$$P_{N\Gamma}=C_{N\Gamma}^{-1}\left\{\prod_{1\leqq j<k\leqq N}|\theta_1(\pi(x_k-x_j)/L,\,q)|\right\}^\Gamma \tag{1.2}$$

is a natural generalization of a distribution first studied by Dyson [5]. In (1.2)

$$\begin{aligned}\theta_1(z,q)&=-i\sum_{n=-\infty}^{\infty}(-1)^n q^{(n+1/2)^2}e^{2i(n+1/2)z}\\&=2q^{1/4}\sin z\prod_{n=1}^{\infty}(1-q^{2n}e^{2iz})(1-q^{2n}e^{-2iz})(1-q^{2n})\end{aligned} \tag{1.3}$$

and $C_{N\Gamma}$ denotes the normalization constant. Dyson's probability distribution is reclaimed in the $q\to 0$ limit of (1.2), this representing the eigenvalue distribution function of three ensembles of unitary random matrices (with $\pi x/L$ identified as the phase θ) at the special couplings $\Gamma=1$, 2, and 4. These three ensembles are directly related to the three classical groups: orthogonal, unitary, and symplectic [6].

For general $q<1$, (1.2) has three further physical interpretations. First, $P_{N\Gamma}$ represents (up to a constant) the Boltzmann factor of the classical one-component plasma with the logarithmic potential, interacting on a line with doubly periodic boundary conditions. To see this, we observe that the function

$$\Phi(x,y)=\frac{1}{2\pi LW}\sum_{\substack{m,n=-\infty\\(m,n)\neq(0,0)}}^{\infty}\frac{e^{2\pi i(mx/L+ny/W)}}{(m/L)^2+(n/W)^2} \tag{1.4}$$

satisfies the two-dimensional Poisson equation

$$\nabla^2\Phi(x,y)=-2\pi\delta(\mathbf{x}) \tag{1.5}$$

and is periodic in x and y (periods L and W), respectively. It has been shown by Glasser [9] that (1.4) can be summed to give

$$\Phi(x,y)=\frac{\pi y^2}{(LW)}-\log\left|\theta_1\left(\pi\left(\frac{x}{L}+\frac{iy}{L}\right),\,e^{-\pi W/L}\right)\right|+\text{const.} \tag{1.6}$$

* Received by the editors July 25, 1988; accepted for publication (in revised form) March 1, 1989.

Thus with

$$q = e^{-\pi W/L}, \quad \Gamma = e^2/k_B T, \quad \text{and } y \text{ fixed} \tag{1.7}$$

where e denotes the magnitude of the charges, the plasma interpretation of (1.2) follows immediately.

The second physical interpretation of (1.2) is as the ground state wavefunction of a quantum many-body problem. This observation is due to Sutherland [14] who showed that $P_{N\Gamma}$ satisfies the Schrödinger equation

$$P_{N\Gamma}^{-1} \sum_{j=1}^{N} \frac{\partial^2 P_{N\Gamma}}{\partial (x_j)^2} = V - E_0 \tag{1.8}$$

where

$$\begin{aligned} V - E_0 = & \sum_{1 \leqq j < k \leqq N} (\Gamma^2 N(\phi^2(x_k - x_j) + \phi'(x_k - x_j)) - 2\Gamma(\Gamma - 1)\phi'(x_k - x_j)) \\ & + \Gamma^2 N(N-1)(N-2)\eta/L. \end{aligned} \tag{1.9}$$

In (1.9)

$$\phi(x) = \frac{\pi \theta_1'(\pi x/L, q)}{L\theta_1(\pi x/L, q)} \tag{1.10}$$

and

$$\eta = -\frac{\pi^2 L}{6} \frac{\theta_1'''(0)}{\theta_1'(0)}. \tag{1.11}$$

In the large L (thermodynamic) limit, the potential V can be written as two parts: the one-dimensional Coulomb potential (with periodic boundary conditions, period L)

$$V_0(x) = \Gamma^2 \left(-\frac{4N}{LW^2}|x| + \frac{4Nx^2}{L^2 W^2} \right) \tag{1.12}$$

and a short-range potential

$$V_1(x) = \Gamma^2 \frac{4Nx}{LW^2} \left(\frac{|x|}{x} - \coth\left(\frac{x}{W} \right) \right) + \frac{2\Gamma(\Gamma - 1)}{W^2} \frac{1}{\sinh^2 (x/W)}. \tag{1.13}$$

(Note that our πW is denoted r in [14].)

The third physical interpretation of (1.2) follows from the observation that when multiplied by a suitable function of the nome q, P_{N1} satisfies the N-dimensional heat equation (see (2.18) below). Further, suppose $q = e^{-4\pi^2 Dt/L^2}$, D denoting the diffusion constant. Then the function $g_N(q)\psi$ in (2.18) represents the probability that N walkers undergoing Brownian motion, initially equally spaced on a circle of circumference length L, arrive at the points $x_1, \cdots, x_N$ in time t without their paths intersecting one another. Walkers whose paths cannot intersect have been termed vicious in [7].

In this paper we address the problem of evaluating the normalization $C_{N\Gamma}$ in (1.2), which is given by the N-dimensional integration

$$C_{N\Gamma} = \left(\prod_{l=1}^{N} \int_0^L dx_l \right) \left\{ \prod_{1 \leqq j < k \leqq N} |\theta_1(\pi(x_k - x_j)/L; q)| \right\}^{\Gamma}. \tag{1.14}$$

An interesting alternative representation can be obtained by using the product form of θ_1 given in (1.3), and noting

$$|2 \sin (a-b)|^2 = (1 - e^{2i(a-b)})(1 - e^{-2i(a-b)}). \tag{1.15}$$

The integrand now consists of simple factors that can all be expanded in a multivariable Laurent series in terms of the $e^{2\pi i x_j/L} j = 1, \cdots, N$. Clearly, the only term that would give a nonzero contribution to the integral is the constant term (CT), which is independent of all the $e^{2\pi i x_j/L}$ (but of course still dependent on q). Writing

$$w_j = e^{2\pi i x_j/L} \tag{1.16}$$

we thus have

$$C_{N\Gamma} = L^N (q^2; q^2)_\infty^{\Gamma N(N-1)/2} q^{\Gamma N(N-1)/8} K_{N\Gamma} \tag{1.17}$$

where

$$K_{N\Gamma} = \mathrm{CT} \prod_{\substack{k,l=1 \\ k \neq l}}^{N} \left(1 - \frac{w_k}{w_l}\right)^{\Gamma/2} \left(q^2 \frac{w_k}{w_l}; q^2\right)_\infty^{\Gamma}, \tag{1.18}$$

the symbol CT denoting the constant term in the Laurent expansion (q is regarded as a constant). In (1.17) and (1.18) we have introduced the notation

$$(z; q)_\infty = \prod_{n=0}^{\infty} (1 - zq^n). \tag{1.19}$$

The Laurent expansion in (1.18) is to be constructed by applying the binomial theorem to each individual factor. In general, this will give a formal series, since convergence will only occur when $|w_k| = 1$, $k = 1, 2, \cdots, N$. The cases $\Gamma = 2m$, m a positive integer, are the only exceptions; the Laurent expansion is then convergent for all $w_k \neq 0$.

If $q = 0$, the right-hand side of (1.18) reduces to

$$\mathrm{CT} \prod_{\substack{k,l=1 \\ k \neq l}}^{N} \left(1 - \frac{w_k}{w_l}\right)^{\Gamma/2}, \tag{1.20}$$

which was first considered by Dyson [5]. On the basis of three exact evaluations ($\Gamma = 1$, 2, and 4), (1.20) was conjectured to equal

$$\frac{(\Gamma N/2)!}{(\Gamma/2)!^N}. \tag{1.21}$$

This was subsequently proved by Wilson [17].

Although the identity equating (1.20) and (1.21) has been extensively generalized in a number of directions ([1]-[4], [12]; [10] gives a comprehensive account of pre-1984 literature), none of these works give the value of (1.18). Below we will provide two new constant term identities that give the evaluation of (1.18) for $\Gamma = 1$, 2 and 4.

We find

$$K_{N1} = \frac{N!}{(q^2; q^2)^{(N-1)}} \begin{cases} \dfrac{1}{\pi^{(N-1)/2}} \displaystyle\prod_{j=1}^{(N-1)/2} \sum_{n=-\infty}^{\infty} \frac{q^{2Nn^2+4nj}}{Nn+j}, & N \text{ odd}, \\ \dfrac{1}{\pi^{N/2}} \displaystyle\prod_{j=1}^{N/2} \sum_{n=-\infty}^{\infty} \frac{q^{2Nn^2+4n(j-1/2)}}{Nn+j-1/2}, & N \text{ even}, \end{cases} \tag{1.22}$$

$$K_{N2} = \frac{N!}{(q^2; q^2)_\infty^{2(N-1)}} \frac{(q^{4N}; q^{4N})_\infty^N}{(q^4; q^4)_\infty}, \tag{1.23}$$

$$K_{N4} = \frac{2^N N!}{(q^2; q^2)_\infty^{4N-1}} \prod_{j=0}^{N-1} \sum_{n=-\infty}^{\infty} \left(2nN + j + \frac{1}{2}\right) q^{4Nn^2+4n(j+1/2)}. \tag{1.24}$$

The remainder of the paper consists of three parts. First, we study an identity due to Sutherland [15], which is extended to calculate a previously unspecified proportionality constant. Second, we apply generalizations of integration techniques used in the theory of random matrices [13] to deduce the identity (3.17) from which (1.22) and (1.24) follow. Third, an identity of Macdonald [11] for the root system A_N is used to derive (1.23).

2. Some determinant identities. The following result has been derived (but not formally proved) by Sutherland [15].

THEOREM 2.1. *Let N be odd and $f_N(q)$ be some yet-to-be-determined function of the nome q. With the notation*

$$\psi(x_1, \cdots, x_N; q) = \prod_{1 \leqq k < l \leqq N} \theta_1(\pi(x_l - x_k); q) \tag{2.1}$$

we have

$$f_N(q)\psi(x_1, \cdots, x_N; q) = \int_0^1 d\gamma \det[\theta_3(\pi(x_j + \gamma - l/N); q^{1/N})]_{j,l=1,\cdots,N}. \tag{2.2}$$

The θ_1 function is defined by (1.3) *while*

$$\theta_3(z; q) = \sum_{n=-\infty}^{\infty} q^{n^2} e^{2iz}. \tag{2.3}$$

(This is the notation of Whittaker and Watson [16].)

Proof. Both the left-hand side (LHS) and right-hand side (RHS) of (2.2) are antisymmetric functions of $x_1, \cdots, x_N$ that vanish whenever $x_k = x_{k'}$, $k, k' = 1, 2, \cdots, N$ $(k \neq k')$. It thus suffices to check that both sides of (2.2) are the same function of x_1 with $x_2, \cdots, x_N$ regarded as fixed. We do this by studying the periodicity properties of each side.

From the definitions (1.3) and (2.2), and noting N is odd, it is immediately obvious that both the LHS and RHS are periodic under the translation $x_1 \mapsto x_1 + 1$. Now write $q = e^{\pi i \tau}$, where $\mathrm{Im}(\tau) > 0$, and consider the periodicity of both sides under the mapping $x_1 \mapsto x_1 + \tau$. Since

$$\theta_1(\pi(x + \tau); q) = -q^{-1} e^{-2\pi i x} \theta_1(\pi x; q) \tag{2.4}$$

the LHS remains the same apart from a factor

$$q^{-(N-1)} e^{-2\pi i x_1 (N-1)} \prod_{l=2}^{N} e^{2\pi i x_l}. \tag{2.5}$$

After deleting the minus sign prefactor, (2.4) holds with θ_1 replaced by θ_3. Thus, after replacing x_1 by $x_1 + \tau$, the lth term of the first row of the determinant in (2.2) can be written

$$q^{-(N-1)^2/N} e^{-2\pi i (x_1 + \gamma - l/N)(N-1)} \theta_3(\pi(x_1 + \gamma + \tau/N - l/N), q^{1/N}). \tag{2.6}$$

On the other hand, according to (2.4), the lth term of the jth row $(j = 2, \cdots, N)$ can be written as follows:

$$q^{1/N} e^{2\pi i (x_j + \gamma - l/N)} \theta_3(\pi(x_j + \gamma + \tau/N - l/N), q^{1/N}). \tag{2.7}$$

If in the first row we note that $e^{2\pi i l(N-1)/N} = e^{-2\pi i l/N}$, a common factor of $e^{-2\pi i l/N}$ can be removed from the lth column (the product from $l = 1, \cdots, N$ of such a factor

equals 1). Furthermore, removing obvious common factors from each row of the determinant, the RHS becomes

$$q^{-(N-1)}\, e^{-2\pi i x_1 (N-1)} \left(\prod_{l=2}^{N} e^{2\pi i x_l} \right) \cdot \int_0^1 d\gamma \, \det\left[\theta_3(\pi(x_j + \gamma + \tau/N - l/N); q^{1/N}) \right]_{j,l=1,\cdots,N}. \tag{2.8}$$

The integral is in fact the same as the RHS of (2.2) since the line integral along the path $\gamma + i \operatorname{Im}(\tau)/N$, $0 \leqq \gamma \leqq 1$, is the same as that along the unit interval $0 \leqq \gamma \leqq 1$, by Cauchy's theorem and the periodicity of the integral. Comparing (2.5) and (2.8), we see that the periodicity factors under the transformation $x_1 \mapsto x_1 + \tau$ of the LHS and RHS are the same.

Finally, consider the ratio RHS/LHS. From the above results, this is a doubly periodic function with periods π and τ. Furthermore, since the zeros of both the LHS and RHS are simple and occur at $x_1 = x_2, \cdots, x_N$ (mod π and mod τ), we have that RHS/LHS is a doubly periodic entire function, and thus by Liouville's theorem is a constant. Hence we have the result (2.2). □

The corresponding result for N even (which is not given in [13]) is Theorem 2.2.

THEOREM 2.2. *Let $g_N(q)$ be some yet to be determined function of q. Then for N even*

$$g_N(q)\psi(x_1, \cdots, x_N; q) = \int_0^1 d\gamma \, \det\left[\theta_1\left(\pi\left(x_j + \gamma - \frac{l}{N} \right); q^{1/N} \right) \right]_{j,l=1,\cdots,N} \tag{2.9}$$

where ψ is as defined in (2.1).

The proof is very similar to that above, so it will not be given here.

2.1. Calculating the proportionality constants. Let us now take up the problem of calculating $f_N(q)$ and $g_N(q)$ in (2.2) and (2.9). We have Theorem 2.3.

THEOREM 2.3. *The proportionality constants in* (2.2) *and* (2.9) *are given by*

$$f_N(q) = g_N(q) = N^{N/2} q^{-(N-1)(N-2)/24} (q^2; q^2)_\infty^{-(N-1)(N-2)/2}. \tag{2.10}$$

Proof. We will make use of an identity of Macdonald [11] (see also Andrews [1]) that states

$$\mathrm{CT}\left\{ \prod_{1 \leqq j < k \leqq N} \left(\frac{w_j}{w_k}; q \right)_\infty \left(q \frac{w_k}{w_j}; q \right)_\infty \right\} = \frac{1}{(q; q)_\infty^{N-1}}. \tag{2.11}$$

The product on the LHS of (2.11) is simply related to (2.1). Using (1.3) and the notation (1.16), we see

$$\prod_{1 \leqq j < k \leqq N} \left(\frac{w_j}{w_k}; q \right)_\infty \left(q \frac{w_k}{w_j}; q \right)_\infty = i^{N(N-1)/2} q^{-N(N-1)/8} (q^2; q^2)^{-N(N-1)/2} \cdot \left(\prod_{k=1}^{N} e^{\pi i (N-2k+1) x_k} \right) \psi(x_1, \cdots, x_N; q). \tag{2.12}$$

To proceed further we must specify the parity of N. Let us suppose N is even. Our strategy is to substitute for ψ according to (2.9) and integrate from zero to 1 for each x_k, $k = 1, \cdots, N$ (which is equivalent to calculating the constant term). Since the constant term of the LHS is given by (2.11), the only unknown will be $g_N(q)$, which will thus be specified.

Note that by expanding the determinant in (2.9) row-by-row according to the series definition of θ_1, and using the definition of a determinant as a sum over permutations, we have

$$\begin{aligned}\left(\prod_{k=1}^{N}\int_0^1 dx_k\, e^{\pi i(N-2k+1)x_k}\right)\psi(x_1,\cdots,x_N;q)\\ =g_N^{-1}(q)(-i)^N\sum_{n_1=-\infty}^{\infty}\cdots\sum_{n_N=-\infty}^{\infty}\left(\prod_{j=1}^{N}(-1)^{n_j}q^{(n_j+1/2)^2/N}\right)\\ \cdot\sum_{P=1}^{N!}\varepsilon(P)\int_0^1 d\gamma\left(\prod_{j=1}^{N}\exp\left(2\pi i(\gamma-P(j)/N)(n_j+1/2)\right)\right.\\ \left.\cdot\int_0^1 dx_j\exp\left(2\pi i x_j(n_j+N/2+1-j)\right)\right).\end{aligned}\tag{2.13}$$

In the integral over x_j the only nonzero term is when

$$n_j=j-1-N/2,\qquad j=1,2,\cdots,N\tag{2.14}$$

and so the RHS of (2.13) becomes

$$g_N^{-1}(q)q^{(N^2-1)/12}\sum_{P=1}^{N!}\varepsilon(P)\prod_{j=1}^{N}\exp\left(-2\pi iP(j)(j-(N+1)/2)/N\right).\tag{2.15}$$

The sum over permutations in (2.15) is by definition equal to

$$\det\left[\exp\left(-2\pi ik(j-(N+1)/2)/N\right)\right]_{j,k=1,\cdots,N}.\tag{2.16}$$

Multiplying this determinant by its complex conjugate gives N^N, so up to a phase of unit modulus, (2.16) is equal to $N^{N/2}$. To determine the phase, we note from van der Monde's determinant expansion that (2.16) is equal to

$$\prod_{1\leqq k<j\leqq N}\left(e^{\pi i(y_j-y_k)}-e^{-\pi i(y_j-y_k)}\right),\qquad y_j=-\frac{j}{N},\tag{2.17}$$

which says immediately that the phase of (2.16) is $(-i)^{N(N-1)/2}$ and so comparison of (2.11) and (2.15) gives the evaluation of $g_N(q)$ in (2.10). An analogous argument, using (2.2) instead of (2.9), gives the same result for $f_N(q)$. □

As an aside, we note a different proof of the following remarkable result due to Sutherland [15].

THEOREM 2.4. *With $q=e^{\pi i\tau}$ and $g_N(q)\psi$ given by* (2.10) *and* (2.1),

$$\sum_{j=1}^{N}\frac{\partial^2}{\partial(x_j)^2}\left(g_N(q)\psi\right)=4\pi iN\frac{\partial}{\partial\tau}\left(g_N(q)\psi\right)\tag{2.18}$$

and similarly for $f_N(q)\psi$. That is, the functions $g_N(q)\psi$ and $f_N(q)\psi$ satisfy the N-dimensional heat equation.

Proof. We simply note that the RHS of the identity (2.9) obeys (2.18). The partial derivatives can be performed row-by-row in the determinant, and the identity follows immediately from the fact that a single θ_1 function satisfies the one-dimensional heat equation, so that

$$\frac{\partial^2}{\partial(x_j)^2}\theta_1(\pi(x_j-x_k);q)=4\pi i\frac{\partial}{\partial\tau}\theta_1(\pi(x_j-x_k);q).\tag{2.19}$$

□

Remark. Sutherland [15] has provided a different derivation of (2.18) based on the Schrödinger equation (1.8). This approach can also be used to specify the proportionality constants $g_N(q)$ and $f_N(q)$, but this was not carried through in [15].

2.2. A confluent form of the determinant identities. Consider the identity (2.9). Let $N = N_1 + 2N_2$, where N_1 is even. Write $x_{N_1+2p-1} = y_p$, $p = 1, 2, \cdots, N_2$ and take the limit $x_{N_1+2p} \to y_p$. By first dividing both sides by

$$\prod_{p=1}^{N_2} (x_{N_1+2p} - y_p) \tag{2.20}$$

and subtracting the (N_1+2p-1)th row of the determinant from the (N_1+2p)th row, we obtain

$$\begin{aligned} &g_{N_1+2N_2}(q)(\theta_1'(0,q))^{N_1}\phi(x_1,\cdots,x_{N_1},y_1,\cdots,y_{N_2};q) \\ &= \int_0^1 d \left| \left[\begin{array}{c} \theta_1(\pi(x_j+\gamma-l/(N_1+2N_2)); q^{1/(N_1+2N_2)}) \\ \theta_1(\pi(y_\alpha+\gamma-l/(N_1+2N)); q^{1/(N_1+2N_2)}) \\ \theta_1'(\pi(y_\alpha+\gamma-l/(N_1+2N_2)); q^{1/(N_1+2N_2)}) \end{array} \right]_{\substack{j=1,\cdots,N_1 \\ \alpha=1,\cdots,N_2 \\ l=1,\cdots,N_1+2N_2}} \right| \end{aligned} \tag{2.21}$$

In (2.21) we have introduced the notation

$$\begin{aligned} &\phi(x_1,\cdots,x_{N_1},y_1,\cdots,y_{N_2};q) \\ &= \prod_{1\le j<k\le N_1} \theta_1(\pi(x_k-x_j);q) \prod_{j=1}^{N_2}\prod_{k=1}^{N_1} \theta_1^2(\pi(y_j-x_k);q) \\ &\quad \cdot \prod_{1\le j<k\le N_2} \theta_1^4(\pi(y_k-y_j);q) \end{aligned} \tag{2.22}$$

and the first entry in the determinant holds true for the first N_1 rows ($j = 1, \cdots, N_1$), while the rows $N_1+2\alpha-1$ are given by the second term, and the rows $N_1+2\alpha$ by the third term.

3. The constant term identities. We are now in a position to evaluate the following multidimensional integrals (or equivalently, calculate the following constant term identities):

$$\begin{aligned} I_1 &\equiv \left(\prod_{j=1}^{N}\int_0^1 dx_j\right)\left(\prod_{k=1}^{N_2}\int_0^1 dy_k\right)|\phi(x_1,\cdots,x_{N_1},y_1,\cdots,y_{N_2};q)| \\ &= q^{N_1(N_1-1)/8+N_1N_2/2+N_2(N_2-1)/2}(q^2;q^2)_\infty^{N_1(N_1-1)/2+2N_1N_2+2N_2(N_2-1)} X_{N_1,N_2} \end{aligned} \tag{3.1}$$

where

$$\begin{aligned} X_{N_1,N_2} = \mathrm{CT}\Bigg\{ &\prod_{\substack{k,l=1 \\ k\ne l}}^{N_1} \left(1-\frac{w_k}{w_l}\right)^{1/2}\left(q^2\frac{w_k}{w_l};q^2\right)_\infty \prod_{k=1}^{N_1}\prod_{\alpha=1}^{N_2}\left(1-\frac{w_k}{z_\alpha}\right)\left(1-\frac{z_\alpha}{w_k}\right) \\ &\cdot \left(q^2\frac{w_k}{z_\alpha};q^2\right)_\infty^2\left(q^2\frac{z_\alpha}{w_k};q^2\right)_\infty^2 \prod_{\substack{\alpha,\beta=1 \\ \alpha\ne\beta}}^{N_2}\left(1-\frac{z_\alpha}{z_\beta}\right)^2\left(q^2\frac{z_\alpha}{z_\beta};q^2\right)_\infty^4 \Bigg\} \end{aligned} \tag{3.2}$$

and

$$\begin{aligned} I_2 &\equiv \left(\prod_{j=1}^{N}\int_0^1 dx_j\right)|\psi(x_1,\cdots,x_N)|^2 \\ &= q^{N(N-1)/4}(q^2;q^2)^{N(N-1)} K_{N2} \end{aligned} \tag{3.3}$$

where, from the notation (1.18),

$$K_{N2} = \mathrm{CT} \prod_{\substack{k,l=1 \\ k\neq l}}^{N} \left(1-\frac{w_k}{w_l}\right)\left(q^2\frac{w_k}{w_l};\, q^2\right)_\infty^2. \tag{3.4}$$

In (3.1) and (3.3), ϕ and ψ are given by (2.22) and (2.1), respectively.

3.1. Further identities for ψ and ϕ. To evaluate (3.1) and (3.3) we must further transform the identities (2.9) and (2.21). The key step (again due to Sutherland [15]) is to expand the determinants row-by-row using (1.3) to obtain a formula analogous to (2.13).

In (2.9) we multiply the resulting expression by

$$i^{-N(N-1)/2}N^{-N}/2 \det\left[e^{2\pi i l(k-1/2)/N}\right]_{\substack{l=1,2,\cdots,N \\ k=-N/2,\cdots,N/2-1}}. \tag{3.5}$$

According to the discussion between (2.15) and (2.18), (3.5) is equal to unity. The multiplication gives

$$\begin{aligned} &g_N(q)\psi(x_1,\cdots,x_N;q) \\ &\quad = i^{-N(N-1)/2}N^{-N/2}q^{(N^2-1)/12} \\ &\qquad \cdot \int_0^1 d\gamma \det\left[e^{2\pi i x_j(k+1/2)}\theta_3(\pi N(x_j+\gamma)+\pi\tau(k+\tfrac{1}{2}),\, q^N)\right]_{\substack{j=1,2,\cdots,N \\ k=-N/2,\cdots,N/2-1}}. \end{aligned} \tag{3.6}$$

The kth and k'th ($k\neq k'$) member of each row j are now orthogonal on the interval [0, 1].

The procedure of multiplying by a determinant of the form (3.3) (this time of dimension N_1+2N_2), allows the following result to be deduced from (2.21):

(3.7)

$$\begin{aligned} &g_{N_1+2N_2}(q)(\theta_1'(0,q))^{N_2}\phi(x_1,\cdots,x_{N_1},y_1,\cdots,y_{N_2};q) \\ &= i^{-N_1/2}(N_1+2N_2)^{-(N_1+2N_2)/2}q^{[(N_1+2N_2)]^2-1]/12} \\ &\quad \cdot \int_0^1 d\gamma \det\begin{bmatrix} e^{2\pi i x_j(k+1/2)}\theta_3(\pi(N_1+2N_2)(x_j+\gamma)+\pi\tau(k+\frac{1}{2});\, q^{(N_1+2N_2)}) \\ e^{2\pi i y_j(k+1/2)}\theta_3(\pi(N_1+2N_2)(y_\alpha+\gamma)+\pi\tau(k+1/2);\, q^{(N_1+2N_2)}) \\ e^{2\pi i y_j(k+1/2)}\theta_3'(\pi(N_1+2N_2)(y_\alpha+\gamma)+\pi\tau(k+1/2);\, q^{(N_1+2N_2)}) \end{bmatrix}_{\substack{j=1,\cdots,N_1 \\ \alpha=1,\cdots,N_2 \\ k=N_2-N_1/2,\cdots, \\ N_2+N_1/2-1}} \end{aligned}$$

Here we have adopted the same convention of ordering the rows in the determinant as in (2.21).

3.2. Evaluation of I_1. To perform the integration in (3.1) we use an extension of the method of integration over alternate variables [13] used to compute I_1 in the $q\to 0$ limit by Forrester in [8].

The integrand in (3.1) is symmetric in $x_1,\cdots,x_N$ so the ordering

$$0\leqq x_1<x_2<\cdots<x_N\leqq 1 \tag{3.8}$$

can be made provided we multiply by $N!$. For the integrand we substitute the identity (3.7). From the structure of the determinant in (3.7), the integration over x_1 from zero to x_2 can be performed by integrating each term in the first row. Next integrate over

x_3 from x_2 to x_4 by integrating every term in the third row. Since

$$\int_{x_2}^{x_4} dx = \int_0^{x_4} dx - \int_0^{x_2} dx \tag{3.9}$$

we see that by adding the first row to the third, the integration can be taken from zero to x_4. Proceeding in this fashion until $x_1, x_3, \cdots, x_{N_1-1}$ have been integrated over gives for the kth entry of the $(2j-1)$th row $(j=1, 2, \cdots, N_1/2)$

$$\int_0^{x_{2j}} dx\, e^{2\pi i x(k+1/2)} \theta_3\left(\pi(N_1+2N_2)(x+\gamma)+\pi\tau\left(k+\frac{1}{2}\right); q^{(N_1+2N_2)}\right). \tag{3.10}$$

The integrand is now symmetric in $x_2, x_4, \cdots x_{N_1}$ so the ordering implicit in (3.8) can be removed, provided we divide by $(N_1/2)!$. Next we write the determinant as a sum over permutations, and write each of the θ-functions in series form. Ordering the permutations $P(2l) > P(2l-1)$, $l=1, 2, \cdots, N_1/2+N_2$ gives the expression

$$\begin{aligned} I_1 = {} & 2^{-N_1/2+N_2}\pi^{-N_1/2}(N_1+2N_2)^{-(N_1+2N_2)/2} q^{[(N_1+2N_2)^2-1]/12} \\ & \cdot g_{N_1+2N_2}^{-1}(q)(\theta_1'(0,q))^{-N_2} \sum_{n_1=\infty}^{\infty} \cdots \sum_{n_{N_1+2N_2}=-\infty}^{\infty} \sum_{P(2l)>P(2l-1)} \varepsilon(P) \\ & \cdot \prod_{k=1}^{N_1/2} \left(\frac{1}{(N_1+2N_2)n_{P(2k)}+P(2k)+\frac{1}{2}} - \frac{1}{(N_1+2N_2)n_{P(2k-1)}+P(2k-1)+\frac{1}{2}} \right) \\ & \cdot \prod_{j=1}^{N_2} ((N_1+2N_2)(n_{P(2k)}-n_{P(2k-1)})+P(2k)-P(2k-1)) \\ & \cdot \int_0^1 d\gamma \prod_{l=1}^{N_1/2+N_2} q^{(N_1+2N_2)(n_{P(2l)}^2+n_{P(2l-1)}^2)+2n_{P(2l-1)}(P(2l-1)+1/2)+2n_{P(2l)}(P(2l)+1/2)} \\ & \cdot \int_0^1 dx \exp(2\pi i(x+\gamma)[(N_1+2N_2)(n_{P(2l-1)}+n_{P(2l)})+P(2l)+P(2l-1)+1] \end{aligned} \tag{3.11}$$

where for each $l=1, 2, \cdots, N_1+2N_2$

$$P(l) \in \{-N_1/2-N_2, -N_1/2-N_2+1, \cdots, N_1/2+N_2-1\}. \tag{3.12}$$

From the integration over x in (3.11) and the allowed values of $P(l)$ in (3.12), we see immediately that the only nonzero terms in (3.11) occur when, for each $l=1, 2, \cdots, N_1/2+N_2$,

$$n_{P(2l-1)} = -n_{P(2l)}, \tag{3.13}$$

$$P(2l) = Q(l), \qquad P(2l-1) = -Q(l)-1 \tag{3.14}$$

where

$$Q(l) \in \{0, 1, \cdots, N_1/2+N_2-1\}. \tag{3.15}$$

Since the index on the sum over the n's is arbitrary, we are free to relabel and write $n_{P(j)} = n_j$ in all cases. Furthermore, all permutations given by (3.14) have even parity. Hence (3.11) reduces to

$$\begin{aligned} I_1 = {} & \pi^{-N_1/2}(N_1+2N_2)^{-(N_1+2N_2)/2} q^{((N_1+2N_2)^2-1)/12} g_{N_1+2N_2}^{-1}(q)(\theta_1'(0,q))^{-N_2} \\ & \cdot \sum_{Q=1}^{(N_1/2+N_2)!} \prod_{k=1}^{N_1/2} \sum_{n=-\infty}^{\infty} \frac{q^{2(N_1+2N_2)n^2+4(Q(k)+1/2)n}}{(N_1+2N_2)n+Q(k)+\frac{1}{2}} \\ & \cdot \prod_{j=1}^{N_2} \sum_{m=-\infty}^{\infty} \left[(N_1+2N_2)m + Q\left(\frac{N_1}{2}+j\right)+\frac{1}{2} \right] q^{2(N_1+2N_2)m^2+4(Q(N_1/2+j)+1/2)m}. \end{aligned} \tag{3.16}$$

We observe that the sum over permutations can be formed by the multiplication into series of a product expansion of a polynomial. Substituting (3.16) into (3.1) and using (2.10) and the product expansion of $\theta_1'(0, q)$, we have thus derived the following result.

THEOREM 3.1. *Let N_1 be even, and X_{N_1,N_2} be given by* (3.2). *Then*

$$X_{N_1,N_2} = \pi^{-N_1/2}(q^2; q^2)_\infty^{-N_1-4N_2+1}\left(\frac{N_1}{2}+N_2\right)!\Big/\left[\left(\frac{N_1}{2}\right)!N_2!\right]$$

(3.17)

$$\cdot\left\{\textit{coefficient of } \xi^{N_1/2} \textit{ in the expansion of } \prod_{k=0}^{N_1/2+N_2-1}(A(k; q)+\xi B(k; q))\right\}$$

where

$$A(k; q) = \sum_{n=-\infty}^{\infty}\left[(N_1+2N_2)n+k+\frac{1}{2}\right]q^{2(N_1+2N_2)n^2+4(k+1/2)n} \tag{3.18}$$

and

$$B(k; q) = \sum_{n=-\infty}^{\infty}\frac{q^{2(N_1+2N_2)n^2+4(k+1/2)n}}{(N_1+2N_2)n+k+\frac{1}{2}}. \tag{3.19}$$

The results (1.22) (N even) and (1.24) follow immediately from (3.17) by choosing $N_2 = 0$ and $N_1 = 0$, respectively. The result (1.22) for N odd can be derived from the analogue of (3.17) with N_1 odd (the necessary identity is the same as (3.17)-(3.19), except that the quantity $N_1/2$ in (3.17) is replaced by $(N_1-1)/2$, and in (3.18) and (3.19), $(k+\frac{1}{2})$ is replaced by k).

3.3. Evaluation of I_2. The constant term K_{N2} in (3.3) can be most expediently evaluated by use of the identity

$$\prod_{1\le j<k\le N}\left(\frac{w_k}{w_j}; q^2\right)_\infty\left(q^2\frac{w_j}{w_k}; q^2\right)_\infty$$

(3.20)

$$= \frac{1}{(q^2; q^2)_\infty^{N-1}}\sum_{Y_{\{m_j\}}}\sum_{P=1}^{N!}\varepsilon(P)\prod_{l=1}^{N}q^{Nm_l^2+(N+1-2P(l))m_l}w_l^{Nm_l+l-P(l)}$$

where

$$Y_{\{m_j\}} = \left\{(m_1, \cdots, m_N): \sum_{j=1}^{N} m_j = 0,\ m_j \in \mathbf{Z} \text{ each } j = 1, \cdots, N\right\}. \tag{3.21}$$

This identity is due to Macdonald [11] and relates to the root system A_N. In the present context (for N even), (3.20) follows immediately from (3.6). To see this, rewrite the LHS of (3.6) using the product expansion of the θ_1 function (3.1), and rewrite the RHS by expanding the determinant row-by-row using the series expansion (2.3) and integrating over γ.

From (3.3) and (3.20) we see

$$K_{N2} = \frac{1}{(q^2; q^2)^{2N-2}}\sum_{Y_{\{m_j\}}}\sum_{Y_{\{n_j\}}}\sum_{P=1}^{N!}\sum_{Q=1}^{N!}\varepsilon(P)\varepsilon(Q)\prod_{l=1}^{N}w_l^{N(m_l-n_l)-(P(l)-Q(l))}$$

(3.22)

$$\cdot\prod_{l=1}^{N}q^{N(m_l^2+n_l^2)+(N+1-P(l))m_l+(N+1-Q(l))n_l}.$$

Since

$$P(l), Q(l) \in \{1, 2, \cdots, N\} \tag{3.23}$$

the only constant terms in (3.22) occur when

$$P(l) = Q(l) \quad \text{and} \quad m_l = n_l, \quad l = 1, \cdots, N. \tag{3.24}$$

All permutations P then give the same contribution, so we can choose $P(l) = l$ provided we multiply by $N!$. Hence

$$K_{N2} = \frac{N!}{(q^2;q^2)^{2N-2}} \sum_{Y_{\{m_j\}}} \prod_{l=1}^{N} q^{2Nm_l^2+2(N+1-l)m_l}$$
$$= \frac{N!}{(q^2;q^2)^{2N-2}} \int_0^1 d\alpha \prod_{k=1}^{N} \theta_3(\pi\alpha + \pi\tau(N+1-2k); q^{2N}). \tag{3.25}$$

The second line of (3.25) follows from the first by using the series expansion (2.3).

From the product expansion of θ_3 we have

$$\prod_{k=1}^{N} \theta_3(\pi\alpha + \pi\tau(N+1-2k); q^{2N}) = \frac{(q^{4N};q^{4N})_\infty^N}{(q^4;q^4)_\infty} \theta_3(\pi\alpha; q^2). \tag{3.26}$$

Thus the integration over α can be done at once to yield the desired result (1.23).

Acknowledgment. I thank the referee for pointing out that (3.20) can be found in [11].

THE BOUNDARY LAYER FOR THE REISSNER–MINDLIN PLATE MODEL*

DOUGLAS N. ARNOLD† AND RICHARD S. FALK‡

Abstract. The structure of the solution of the Reissner–Mindlin plate equations is investigated, emphasizing its dependence on the plate thickness. For the transverse displacement, rotation, and shear stress, asymptotic expansions in powers of the plate thickness are developed. These expansions are uniform up to the boundary for the transverse displacement, but for the other variables there is a boundary layer. Rigorous error bounds are given for the errors in the expansions in Sobolev norms. As applications, new regularity results for the solutions and new estimates for the difference between the Reissner–Mindlin solution and the solution to the biharmonic equation are derived. Boundary conditions for a clamped edge are considered for most of the paper, and the very similar case of a hard simply-supported plate is discussed briefly at the end. Other boundary conditions will be treated in a forthcoming paper.

Key words. Reissner, Mindlin, plate, boundary layer

1. Introduction.

The Reissner–Mindlin model describes the deformation of a plate subject to a transverse loading in terms of the transverse displacement of the midplane and the rotation of fibers normal to the midplane [9], [10]. This linear model, as well as its generalization to shells, is frequently used for plates and shells of small to moderate thickness. Specifically, let Ω denote the region in $\mathbb{R}^2$ occupied by the midsection of the plate and ω and ϕ the transverse displacement of Ω and the rotation of the fibers normal to Ω, respectively. The Reissner–Mindlin model for the bending of a clamped isotropic elastic plate in equilibrium determines ω and ϕ as the solution of the partial differential equations

$$-\mathbf{div}\, C\, \mathcal{E}(\phi) - \lambda\bar{t}^{-2}(\mathbf{grad}\,\omega - \phi) = 0, \tag{1.1}$$

$$-\lambda\bar{t}^{-2}\,\mathrm{div}(\mathbf{grad}\,\omega - \phi) = g, \tag{1.2}$$

in Ω and the boundary conditions

$$\phi = 0,\ \omega = 0, \tag{1.3}$$

on $\partial\Omega$. Here $g\bar{t}^3$ is the transverse load force density per unit area, $\bar{t}$ is the plate thickness, $\lambda = Ek/2(1+\nu)$ with E the Young's modulus, ν the Poisson ratio, and k the shear correction factor, $\mathcal{E}(\phi)$ is the symmetric part of the gradient of ϕ, and the fourth-order tensor C is defined by

$$C\mathcal{T} = D\left[(1-\nu)\mathcal{T} + \nu\,\mathrm{tr}(\mathcal{T})\mathcal{I}\right], \quad D = \frac{E}{12(1-\nu^2)},$$

for any 2×2 matrix $\mathcal{T}$ ($\mathcal{I}$ denotes the 2×2 identity matrix). Note that the load has been scaled so that the solution tends to a nonzero limit as $\bar{t}$ tends to zero. The Dirichlet boundary conditions (1.3) model a plate which experiences no displacement along its lateral edge. This is commonly referred to as a clamped edge (which is the terminology we adopt here), although the terms welded or built-in are perhaps more descriptive.

The Reissner–Mindlin model is an alternative to the biharmonic model for plate bending. The biharmonic model gives the transverse displacement as the solution to the boundary value problem

$$D\,\Delta^2 \omega_0 = g \quad \text{in } \Omega, \quad \omega_0 = \partial\omega_0/\partial n = 0 \quad \text{on } \partial\Omega. \tag{1.4}$$

With our scaling of the load function, the solution ω_0 is independent of the plate thickness. By contrast, the solution of the Reissner–Mindlin model depends in a complex way on the plate thickness. It is the purpose of this paper to investigate the structure of solution in its dependence on $\bar{t}$.

We shall develop asymptotic expansions with respect to $\bar{t}$ for ω and $\boldsymbol{\phi}$ (as well as other quantities associated with the solution such as the shear stress). The expansions are of the following forms[1]

$$\omega \sim \omega_0 + \bar{t}^2\omega_2 + \bar{t}^3\omega_3 + \cdots,$$
$$\boldsymbol{\phi} \sim \boldsymbol{\phi}_0 + \bar{t}^2(\boldsymbol{\phi}_2 + \chi\boldsymbol{\Phi}_0) + \bar{t}^3(\boldsymbol{\phi}_3 + \chi\boldsymbol{\Phi}_1) + \cdots.$$

Here the functions ω_i and $\boldsymbol{\phi}_i$, the interior expansion functions, are independent of $\bar{t}$. The functions $\boldsymbol{\Phi}_i$ are boundary correctors. They depend on $\bar{t}$ only through the quantity $\rho/\bar{t}$, where ρ is the distance of a point of Ω from the boundary. More specifically,

$$\boldsymbol{\Phi}_i = \hat{\boldsymbol{\Phi}}_i(\rho/\bar{t}, \theta)$$

where θ is a coordinate which roughly gives arclength along the boundary (see § 2), and the function $\hat{\boldsymbol{\Phi}}_i(\eta, \theta)$ has the form of a polynomial with respect to η times $\exp(-\sqrt{12k}\eta)$. Thus $\boldsymbol{\Phi}_i$ represents a boundary layer function, which essentially lives in a strip of width $\bar{t}$ around the boundary. Finally, χ is a cutoff function which is independent of $\bar{t}$ and identically equal to unity in a neighborhood of $\partial\Omega$.

In §§ 3 and 6 we construct all terms of these expansions. Here we summarize the results for the principal terms. The function ω_0 is the solution to the biharmonic problem above, ω_2 solves

$$D\,\Delta^2 \omega_2 = \frac{-1}{6k(1-\nu)}\,\Delta g \quad \text{in } \Omega, \quad \omega_2 = 0, \quad \frac{\partial\omega_2}{\partial n} = \frac{-1}{6k(1-\nu)}\frac{\partial}{\partial n}\,\Delta\omega_0 \quad \text{on } \partial\Omega,$$

and ω_3 solves

$$D\,\Delta^2 \omega_3 = 0 \quad \text{in } \Omega, \quad \omega_3 = 0, \quad \frac{\partial\omega_3}{\partial n} = \frac{-1}{12\sqrt{3k^3}(1-\nu)}\frac{\partial^2}{\partial s^2}\,\Delta\omega_0 \quad \text{on } \partial\Omega.$$

[1] In order not to introduce unnecessary distractions, in this introduction we use a slightly different notation than in the following sections. The ω_i and $\boldsymbol{\phi}_i$ of this section are $\lambda^{-i/2}$ times the corresponding quantities used in the remaining sections, and $\hat{\boldsymbol{\Phi}}_{i-2}(\eta, \theta)$ here is $\lambda^{-i/2}$ times $\hat{\boldsymbol{\Phi}}_{i-2}(\sqrt{\lambda}\eta, \theta)$ used later.

For the expansion of ϕ, we have $\phi_0 = \mathbf{grad}\,\omega_0$, $\phi_2 = \mathbf{grad}\,\psi$, where

$$\Delta^2 \psi = 0 \quad \text{in } \Omega, \qquad \psi = \frac{1}{6k(1-\nu)}\Delta\omega_0, \quad \frac{\partial\psi}{\partial n} = 0 \quad \text{on } \partial\Omega,$$

and

$$\hat{\boldsymbol{\Phi}}_0(\eta,\theta) = -\frac{\exp(-\sqrt{12k}\eta)}{6k(1-\nu)}\frac{\partial}{\partial s}\Delta\omega_0(0,\theta)\boldsymbol{s},$$

where $\boldsymbol{s} = \boldsymbol{s}(\theta)$ is the unit tangent vector to $\partial\Omega$.

We prove a priori estimates for all terms of the expansions in § 4, and establish error bounds for the remainders in § 5. With these results, we may easily investigate the regularity of solutions of the Reissner–Mindlin system and their limit as $\bar{t} \to 0$. Supposing that g is sufficiently smooth, we have the following estimates, in which the constant C depends on g, Ω, and the elastic constants, but is independent of $\bar{t}$. Here $\|\cdot\|_s$ and $|\cdot|_s$ denote the norms in the Sobolev spaces $H^s(\Omega)$ and $H^s(\partial\Omega)$ (see § 2).

The transverse displacement ω is regular uniformly in $\bar{t}$, but the regularity of the rotation $\boldsymbol{\phi}$ is limited by the boundary layer:

$$\|\omega\|_s \le C, \qquad \|\boldsymbol{\phi}\|_s \le C\bar{t}^{\min(0,5/2-s)}, \qquad s \in \mathbb{R}.$$

Thus all derivatives of ω remain bounded uniformly in L^2 as $\bar{t} \to 0$, while for $\boldsymbol{\phi}$, the second derivatives remain bounded in L^2, but higher derivatives will in general blow up as $\bar{t} \to 0$.

The quantity $\boldsymbol{\zeta} := \lambda\bar{t}^{-2}(\mathbf{grad}\,\omega - \boldsymbol{\phi})$, which is related to the shear stress, is often of interest. From the above expansions we get

$$\lambda^{-1}\boldsymbol{\zeta} \sim \mathbf{grad}\,\omega_2 - \boldsymbol{\phi}_2 - \chi\boldsymbol{\Phi}_0 + t(\mathbf{grad}\,\omega_3 - \boldsymbol{\phi}_3 - \chi\boldsymbol{\Phi}_1) + \cdots,$$

so it has a stronger boundary layer. Indeed, $\boldsymbol{\zeta}$ is not uniformly bounded in H^s for $s > \frac{1}{2}$:

$$\|\boldsymbol{\zeta}\|_s \le C\bar{t}^{\min(0,1/2-s)}, \quad s \in \mathbb{R}.$$

Of course, the boundary layer does not limit the regularity of $\boldsymbol{\phi}$ or $\boldsymbol{\zeta}$ at a positive distance from $\partial\Omega$ nor does it affect the smoothness of their restrictions to $\partial\Omega$. Thus

$$\|\boldsymbol{\phi}\|_{H^s(\Omega_c)} + |\boldsymbol{\phi}|_s + \|\boldsymbol{\zeta}\|_{H^s(\Omega_c)} + |\boldsymbol{\zeta}|_s \le C, \qquad s \in \mathbb{R},$$

for any compact subdomain Ω_c of Ω.

In the limit as $\bar{t} \to 0$, each of the variables ω, $\boldsymbol{\phi}$, and $\boldsymbol{\zeta}$ tends in L^2 to the leading terms of its asymptotic expansions. The number of derivatives which converge and the rate of convergence may be determined by examining the first neglected interior and boundary terms of the expansions. We get, for each $s \in \mathbb{R}$, that

$$\begin{aligned}
&\|\omega - \omega_0\|_s \le C\bar{t}^2,\\
&\|\boldsymbol{\phi} - \boldsymbol{\phi}_0\|_s \le C\bar{t}^{\min(2,5/2-s)},\\
&\|\boldsymbol{\zeta} - \lambda(\mathbf{grad}\,\omega_2 - \boldsymbol{\phi}_2)\|_s \le C\bar{t}^{\min(1/2,1/2-s)}.
\end{aligned}$$

Note that for $\boldsymbol{\phi}$ and $\boldsymbol{\zeta}$, the rate of convergence depends on the Sobolev norm under consideration. For each of the variables, taking more terms from the expansions increases the rates of convergence. For example,

$$\|\omega - \omega_0 - \bar{t}^2\omega_2\|_s \le C\bar{t}^3, \qquad \|\boldsymbol{\phi} - \boldsymbol{\phi}_0 - \bar{t}^2(\boldsymbol{\phi}_2 + \chi\boldsymbol{\Phi}_0)\|_s \le C\bar{t}^{\min(3,7/2-s)}.$$

Taking sufficiently many terms in the expansions gives approximations of any desired algebraic order of convergence in $\bar{t}$ in any desired Sobolev space (provided g is sufficiently regular).

It is also possible to use the asymptotic expansion to derive estimates in function spaces other than H^s. Thus for example, we show at the end of § 5 that

$$\|\phi\|_{W^s_\infty} \leq C\bar{t}^{\min(0,2-s)},$$

and, in particular, that $\|\phi\|_{W^2_\infty}$ is uniformly bounded. Note that this is a better estimate than we would get applying the Sobolev Embedding Theorem directly to the estimates for ϕ in H^s. It is also easy to show that

$$\|\omega - \omega_0\|_{L^\infty} \leq C\bar{t}^2, \qquad \|\phi - \phi_0\|_{L^\infty} \leq C\bar{t}^2,$$

but ζ does not in general converge in $L^\infty(\Omega)$.

The Reissner–Mindlin model is discussed in many places (under various names), although not very much attention has been devoted to the boundary layer behavior. The existence of a boundary layer is noted in [6, Chaps. 8.9–8.10] and [11, Chap. 3.5]. Assiff and Yen [2] also note the existence of a boundary layer, and use separation of variable techniques to compute the exact solution to the equations on a circular plate with a special load. This calculation exhibits the boundary layer, and may be taken as an example of our theory. Häggblad and Bathe recently studied the boundary layer in more general situations via formal techniques and numerical experiments in [7]. They also consider the effect of corners, which is not treated here. In [6], [11], and [7], the authors emphasize a reformulation of the Reissner–Mindlin system consisting of a biharmonic equation for ω (with different right-hand side than (1.4)), and a singularly perturbed Laplacian for $\operatorname{rot}\phi$. These equations are coupled through somewhat complicated boundary conditions, however, and we have preferred not to use them. As far as we know, the explicit form of the asymptotic expansions and error bounds for them are new.

2. Notation and preliminaries. The letter C denotes a generic constant, not necessarily the same in each occurrence. We assume that Ω is a smooth, bounded, and simply-connected domain in $\mathbb{R}^2$. The $L^2(\Omega)$ and $L^2(\partial\Omega)$ inner products are denoted by $(\cdot,\cdot)$ and $\langle\cdot,\cdot\rangle$ respectively. We shall use the usual L^2-based Sobolev spaces $H^s(\Omega)$ and $H^s(\partial\Omega)$, $s \in \mathbb{R}$, with norms denoted by $\|\cdot\|_s$ and $|\cdot|_s$. The reader is referred to [8] for precise definitions of these spaces and their properties, of which we recall only a few here. For $s \geq 0$, H^{-s} may be identified with the dual of $\mathring{H}^s$, the closure of C_0^∞ in H^s. If $s \geq 0$, $n \geq i \geq 0$ are real numbers, then the interpolation inequality

$$\|g\|^n_{s+i} \leq C\|g\|^{n-i}_s \|g\|^i_{s+n} \tag{2.1}$$

holds. If $g \in L^2(\Omega)$ and $\Delta^{-1} g$ denotes the unique function in $H^2(\Omega) \cap \mathring{H}^1(\Omega)$ whose Laplacian is equal to g, then

$$C^{-1}\|\Delta^{-1} g\|_{s+2} \leq \|g\|_s \leq C\|\Delta^{-1} g\|_{s+2}, \qquad s \geq 0,$$

where the constant C may depend on s and Ω, but not on g. In other words, $g \mapsto \|\Delta^{-1} g\|_{s+2}$ defines an equivalent norm on $H^s(\Omega)$ for $s \geq 0$. This is also true for $s = -1$, but slightly different negative norms are needed to extend this shift theorem

to other negative values. We define $|||g|||_s = \|\Delta^{-1} g\|_{s+2}$ for $g \in L^2(\Omega)$ and all real s. Then $|||\cdot|||_s$ is equivalent to the ordinary Sobolev norm $\|\cdot\|_s$ for $s \geq 0$ and $s = -1$. For $s = -2$, $|||\cdot|||_s$ is equivalent to the norm in the dual space of $H^2(\Omega) \cap \mathring{H}^1(\Omega)$. The norm $|||\cdot|||$ can be identified for other values of s as well, but this is not necessary for our purposes. From (2.1) we have

$$|||g|||_{s+i}^n \leq C|||g|||_s^{n-i}|||g|||_{s+n}^i,$$

valid for all real $s \geq -2$, $n \geq i \geq 0$. We shall make frequent use of this fact to bound sums of the form $\sum_{i=0}^n t^i|||g|||_{s+i}$ by a multiple of the sum of the first and last terms.

We also require the quotient space $H^s(\Omega)/\mathbb{R}$. An element $p \in H^s(\Omega)/\mathbb{R}$ is a coset consisting of all functions in $H^s(\Omega)$ differing from a fixed function by a constant. The quotient norm is given by

$$\|p\|_{s/\mathbb{R}} = \min_{q \in p} \|q\|_s.$$

In fact, $\|p\|_{s/\mathbb{R}} = \|p_0\|_s$ where p_0 is the unique function in the coset p having mean value zero.

We use boldface type to denote 2-vector-valued functions, operators whose values are vector-valued functions, and spaces of vector-valued functions. Script type is used in a similar way for 2×2-matrix objects. Thus, for example, $\operatorname{div}\boldsymbol{\psi} \in L^2(\Omega)$ for $\boldsymbol{\psi} \in \boldsymbol{H}^1(\Omega)$, while $\mathbf{div}\,\mathcal{T} \in \boldsymbol{L}^2(\Omega)$ for $\mathcal{T} \in \mathcal{H}^1(\Omega)$. Finally, we use various standard differential operators:

$$\mathbf{grad}\, r = \begin{pmatrix} \partial r/\partial x \\ \partial r/\partial y \end{pmatrix}, \qquad \operatorname{div}\boldsymbol{\psi} = \frac{\partial \psi_1}{\partial x} + \frac{\partial \psi_2}{\partial y},$$

$$\mathbf{div}\begin{pmatrix} t_{11} & t_{12} \\ t_{21} & t_{22} \end{pmatrix} = \begin{pmatrix} \partial t_{11}/\partial x + \partial t_{12}/\partial y \\ \partial t_{21}/\partial x + \partial t_{22}/\partial y \end{pmatrix},$$

$$\mathbf{curl}\, p = \begin{pmatrix} -\partial p/\partial y \\ \partial p/\partial x \end{pmatrix}, \qquad \operatorname{rot}\boldsymbol{\psi} = \frac{\partial \psi_1}{\partial y} - \frac{\partial \psi_2}{\partial x}.$$

Note that these differential operators annihilate constants, and consequently induce operators on the quotient space $H^s(\Omega)/\mathbb{R}$ for each s. We denote the induced operator in the same way as the original. Thus, for example, if $p \in H^1(\Omega)/\mathbb{R}$, $\mathbf{curl}\, p$ denotes the element of $\boldsymbol{L}^2$ obtained by applying the curl to any element in the coset p.

In our analysis, we rely on an equivalent formulation of the Reissner–Mindlin plate equations, suggested by Brezzi and Fortin [3]. This formulation is derived by using the Helmholtz theorem to decompose the scaled transverse shear stress vector:

$$\boldsymbol{\zeta} := \lambda \bar{t}^{\,-2}(\mathbf{grad}\,\omega - \boldsymbol{\phi}) = \mathbf{grad}\, r + \mathbf{curl}\, p, \qquad r \in \mathring{H}^1(\Omega), \quad p \in H^1(\Omega)/\mathbb{R}. \tag{2.2}$$

Setting $t^2 = \bar{t}^{\,2}/\lambda$, one finds

$$-\Delta r = g, \tag{2.3}$$

$$-\mathbf{div}\, C\, \mathcal{E}(\boldsymbol{\phi}) - \mathbf{curl}\, p = \mathbf{grad}\, r, \tag{2.4}$$

$$-\operatorname{rot}\boldsymbol{\phi} + t^2 \Delta p = 0, \tag{2.5}$$

$$-\Delta\omega = -\operatorname{div}\boldsymbol{\phi} - t^2 \Delta r, \tag{2.6}$$

with the boundary conditions

$$r = 0, \qquad \boldsymbol{\phi} = 0, \qquad \frac{\partial p}{\partial n} = 0, \qquad \omega = 0. \tag{2.7}$$

Note that r satisfies a Dirichlet problem for Poisson's equation, which decouples from the other three equations. Once r has been determined, $\boldsymbol{\phi}$ and p may be computed from (2.4) and (2.5) and their boundary conditions, and then ω is determined by a second Dirichlet problem for Poisson's equation. Thus all the difficulties of the problem have been concentrated in the system (2.4)–(2.5) for $\boldsymbol{\phi}$ and p. When $t = 0$, this system of partial differential equations is very similar to the Stokes equations. For positive t, these two equations represent a singularly perturbed Stokes-like system.

It is easy to check that this reformulation is equivalent to the usual Reissner–Mindlin formulation (cf. [3] or [1]). That is, if $(\omega, \boldsymbol{\phi}) \in H^1(\Omega) \times \boldsymbol{H}^1(\Omega)$ solves (1.1)–(1.3) and $(r, p) \in \mathring{H}^1(\Omega) \times H^1(\Omega)/\mathbb{R}$ are defined (uniquely) by (2.2), then (2.3)–(2.7) are satisfied, and, conversely, if $(\omega, \boldsymbol{\phi}, p, r) \in H^1(\Omega) \times \boldsymbol{H}^1(\Omega) \times H^1(\Omega)/\mathbb{R} \times H^1(\Omega)$ solves (2.3)–(2.7) then (1.1)–(1.3) hold.

To describe the boundary layer for the Reissner–Mindlin plate, we shall employ the standard technique of making a change of variable in a neighborhood of the boundary. Let $(X(\theta), Y(\theta))$, $\theta \in [0, L)$, be a parametrization of $\partial\Omega$ by arclength, and let Ω_0 be a normal tubular neighborhood of $\partial\Omega$ in Ω. Then, for each point $z = (x, y) \in \Omega_0$ there is a unique nearest point $z_0 \in \partial\Omega$. Let θ denote the arclength parameter, with counterclockwise orientation, corresponding to z_0 and $\rho = |z - z_0|$ the distance from the point z to the boundary. Since Ω_0 is a tubular neighborhood of $\partial\Omega$, the correspondence $(x, y) \mapsto (\rho, \theta)$ is a diffeomorphism between Ω_0 and $(0, \rho_0) \times \mathbb{R}/L$ for some $\rho_0 > 0$. Explicitly, $x = X(\theta) - \rho Y'(\theta)$, $y = Y(\theta) + \rho X'(\theta)$. A simple computation shows that the Jacobian of the transformation from (x, y) coordinates to (ρ, θ) coordinates on Ω_0 is given by $1 - \kappa(\theta)\rho$, where κ denotes the curvature of $\partial\Omega$. With these definitions, the unit outward normal and counterclockwise unit tangent vectors are given by

$$\boldsymbol{n} = -\operatorname{\mathbf{grad}} \rho = -\operatorname{\mathbf{curl}} \theta, \quad \boldsymbol{s} = \operatorname{\mathbf{grad}} \theta = -\operatorname{\mathbf{curl}} \rho \quad \text{on } \partial\Omega.$$

We use tildes to denote the corresponding change of variables for functions, i.e.,

$$\tilde{f}(\rho, \theta) := f(x, y).$$

We shall also use the stretched variable $\hat{\rho} = \rho/t$. Circumflexes denote the corresponding change of variables

$$\hat{f}(\hat{\rho}, \theta) := \tilde{f}(\rho, \theta) = f(x, y).$$

3. An asymptotic expansion of the solution. We now turn to the construction of an asymptotic expansion with respect to the scaled thickness $t = \bar{t}/\sqrt{\lambda}$ of the solution of the Reissner–Mindlin clamped plate model using the formulation given in (2.3)–(2.7). Clearly r does not depend on t, so we begin, in this section, with the expansion of $\boldsymbol{\phi}$ and p. In § 6 we consider the expansion of ω and the shear stress.

Our immediate goal is to develop approximations of $\boldsymbol{\phi}$ and p by sums of the form

$$\boldsymbol{\phi}(x, y) \sim \boldsymbol{\phi}^I(x, y) + \boldsymbol{\phi}^B(x, y) := \sum_{i=0}^{\infty} t^i \boldsymbol{\phi}_i(x, y) + t^2 \tilde{\chi}(\rho) \sum_{i=0}^{\infty} t^i \hat{\boldsymbol{\Phi}}_i(\hat{\rho}, \theta),$$

$$p(x, y) \sim p^I(x, y) + p^B(x, y) := \sum_{i=0}^{\infty} t^i p_i(x, y) + t \tilde{\chi}(\rho) \sum_{i=0}^{\infty} t^i \hat{P}_i(\hat{\rho}, \theta),$$

where $\tilde{\chi}(\rho)$ is a smooth cutoff function which is identically one for $0 \leq \rho \leq \rho_0/3$ and which is identically zero for $\rho > 2\rho_0/3$. (The power of t multiplying the second sum in each expansion was chosen in anticipation of the results that follow.) In this section we shall calculate formally in order to motivate appropriate definitions of the interior expansion functions $\boldsymbol{\phi}_i$ and p_i, and the boundary correctors $\hat{\boldsymbol{\Phi}}_i$ and $\hat{P}_i$. In the next section we derive some estimates for these functions, and in § 5 we give rigorous bounds for the errors in the asymptotic expansions.

Now $\boldsymbol{\phi} \in \boldsymbol{H}^1(\Omega)$ and $p \in H^1(\Omega)/\mathbb{R}$ are uniquely determined by the equations

$$\begin{aligned} &-\mathbf{div}\, C\,\mathcal{E}(\boldsymbol{\phi}) - \mathbf{curl}\, p = \mathbf{grad}\, r \quad \text{in } \Omega, \\ &-\operatorname{rot} \boldsymbol{\phi} + t^2 \Delta p = 0 \ (\operatorname{mod} \mathbb{R}) \quad \text{in } \Omega, \\ &\boldsymbol{\phi} = 0, \quad \frac{\partial p}{\partial n} = 0 \quad \text{on } \partial\Omega. \end{aligned}$$

In writing the second equation modulo $\mathbb{R}$ we mean that $\boldsymbol{\phi}$ and p are to be determined with $-\operatorname{rot} \boldsymbol{\phi} + t^2 \Delta p$ equal to an unspecified constant function. In fact if we integrate this equation using the divergence theorem, it follows that if $\boldsymbol{\phi}$ and p also satisfy the boundary conditions, then the constant must vanish. Thus, although the equation modulo $\mathbb{R}$ is formally weaker than (2.5), in fact together with the other equation and the boundary conditions, we have an equivalent problem to (2.4), (2.5), (2.7). The reason for introducing this complication is that it is more convenient to define an asymptotic expansion that satisfies the second equation only up to an additive constant.

Formally, $(\boldsymbol{\phi}^I, p^I)$ will be determined such that

$$-\mathbf{div}\, C\,\mathcal{E}(\boldsymbol{\phi}^I) - \mathbf{curl}\, p^I = \mathbf{grad}\, r \quad \text{in } \Omega, \tag{3.1}$$

$$-\operatorname{rot} \boldsymbol{\phi}^I + t^2 \Delta p^I = 0 \ (\operatorname{mod} \mathbb{R}) \quad \text{in } \Omega, \tag{3.2}$$

$$\boldsymbol{\phi}^I = -\boldsymbol{\phi}^B \quad \text{on } \partial\Omega, \tag{3.3}$$

and $(\boldsymbol{\phi}^B, p^B)$ will be determined such that

$$-\mathbf{div}\, C\,\mathcal{E}(\boldsymbol{\phi}^B) - \mathbf{curl}\, p^B = 0 \quad \text{in } \Omega, \tag{3.4}$$

$$-\operatorname{rot} \boldsymbol{\phi}^B + t^2 \Delta p^B = 0 \quad \text{in } \Omega, \tag{3.5}$$

$$\frac{\partial p^B}{\partial n} = -\frac{\partial p^I}{\partial n} \quad \text{on } \partial\Omega. \tag{3.6}$$

Inserting the series expansions for $\boldsymbol{\phi}^I$, p^I, and $\boldsymbol{\phi}^B$ in the first boundary value problem and equating coefficients of corresponding powers of t, we obtain the boundary value problems defining the interior expansion functions $\boldsymbol{\phi}_i$ and p_i:

$$-\mathbf{div}\, C\,\mathcal{E}(\boldsymbol{\phi}_i) - \mathbf{curl}\, p_i = \begin{cases} \mathbf{grad}\, r & \text{for } i = 0, \\ 0 & \text{for } i > 0, \end{cases} \tag{3.7}$$

$$-\operatorname{rot} \boldsymbol{\phi}_i = \begin{cases} 0 \ (\operatorname{mod} \mathbb{R}) & \text{for } i = 0, 1, \\ -\Delta p_{i-2} \ (\operatorname{mod} \mathbb{R}) & \text{for } i \geq 2, \end{cases} \tag{3.8}$$

and the boundary conditions

$$\phi_i = \begin{cases} 0 & \text{for } i = 0, 1, \\ -\Phi_{i-2} & \text{for } i \geq 2. \end{cases} \tag{3.9}$$

In fact, (3.8) can be replaced by the simpler equation

$$\operatorname{rot} \phi_i = 0 \pmod{\mathbb{R}}. \tag{3.10}$$

To see this, apply rot to (3.7). Using simple calculus identities, we get that

$$-\frac{E}{24(1+\nu)} \Delta \operatorname{rot} \phi_i + \Delta p_i = 0.$$

It then follows from (3.8) that $\Delta p_i = 0$ for $i = 0, 1$ and, for $i \geq 2$,

$$\Delta p_i = \frac{E}{24(1+\nu)} \Delta^2 p_{i-2}.$$

By induction, $\Delta p_i = 0$ for all i. We thus use the system (3.7), (3.10), (3.9) to define the interior expansion functions. This system is essentially the Stokes equations and admits a unique solution in $\boldsymbol{H}^1(\Omega) \times L^2(\Omega)/\mathbb{R}$ (see Lemma 4.2 below). Note that the implied constant in (3.10) is uniquely determined by compatibility between this equation and the boundary conditions in (3.9). We also remark that the right-hand side of all three equations vanishes for $i = 1$, so $\phi_1 = 0$ and $p_1 = 0$.

To obtain the defining equations for the boundary correctors, we transform the system (3.4)–(3.6) to ρ-θ coordinates. The equation for $\tilde{\phi}^B$ and $\tilde{p}^B$ corresponding to (3.4) is

$$\tilde{\mathcal{A}}_0 \frac{\partial^2 \tilde{\phi}^B}{\partial \rho^2} + \tilde{\mathcal{A}}_1 \frac{\partial^2 \tilde{\phi}^B}{\partial \rho \partial \theta} + \tilde{\mathcal{A}}_2 \frac{\partial \tilde{\phi}^B}{\partial \rho} + \tilde{\mathcal{A}}_3 \frac{\partial^2 \tilde{\phi}^B}{\partial \theta^2} + \tilde{\mathcal{A}}_4 \frac{\partial \tilde{\phi}^B}{\partial \theta} + \tilde{\boldsymbol{A}}_5 \frac{\partial \tilde{p}^B}{\partial \rho} + \tilde{\boldsymbol{A}}_6 \frac{\partial \tilde{p}^B}{\partial \theta} = 0, \tag{3.11}$$

where

$$\mathcal{A}_0 = -D \begin{pmatrix} (\rho_x)^2 + (1-\nu)(\rho_y)^2/2 & (1+\nu)\rho_x\rho_y/2 \\ (1+\nu)\rho_x\rho_y/2 & (\rho_y)^2 + (1-\nu)(\rho_x)^2/2 \end{pmatrix},$$

$$\mathcal{A}_1 = -D \begin{pmatrix} 2\theta_x\rho_x + (1-\nu)\theta_y\rho_y & (1+\nu)(\theta_y\rho_x + \theta_x\rho_y)/2 \\ (1+\nu)(\theta_y\rho_x + \theta_x\rho_y)/2 & 2\theta_y\rho_y + (1-\nu)\theta_x\rho_x \end{pmatrix},$$

$$\mathcal{A}_2 = -D \begin{pmatrix} \rho_{xx} + (1-\nu)\rho_{yy}/2 & (1+\nu)\rho_{xy}/2 \\ (1+\nu)\rho_{xy}/2 & \rho_{yy} + (1-\nu)\rho_{xx}/2 \end{pmatrix},$$

$$\mathcal{A}_3 = -D \begin{pmatrix} (\theta_x)^2 + (1-\nu)(\theta_y)^2/2 & (1+\nu)\theta_x\theta_y/2 \\ (1+\nu)\theta_x\theta_y/2 & (\theta_y)^2 + (1-\nu)(\theta_x)^2/2 \end{pmatrix},$$

$$\mathcal{A}_4 = -D \begin{pmatrix} \theta_{xx} + (1-\nu)\theta_{yy}/2 & (1+\nu)\theta_{xy}/2 \\ (1+\nu)\theta_{xy}/2 & \theta_{yy} + (1-\nu)\theta_{xx}/2 \end{pmatrix},$$

$$\boldsymbol{A}_5 = -\operatorname{\mathbf{curl}} \rho, \quad \boldsymbol{A}_6 = -\operatorname{\mathbf{curl}} \theta.$$

Note that

$$\boldsymbol{A}_5 = \boldsymbol{s}, \quad \boldsymbol{A}_6 = \boldsymbol{n} \quad \text{on } \partial\Omega.$$

In ρ-θ coordinates (3.5) becomes

$$-\tilde{\boldsymbol{A}}_5 \cdot \frac{\partial \tilde{\boldsymbol{\phi}}^B}{\partial \rho} - \tilde{\boldsymbol{A}}_6 \cdot \frac{\partial \tilde{\boldsymbol{\phi}}^B}{\partial \theta} + t^2 \left(\frac{\partial^2 \tilde{p}^B}{\partial \rho^2} + \tilde{A}_7 \frac{\partial \tilde{p}^B}{\partial \rho} + \tilde{A}_8 \frac{\partial^2 \tilde{p}^B}{\partial \theta^2} + \tilde{A}_9 \frac{\partial \tilde{p}^B}{\partial \theta} \right) = 0, \tag{3.12}$$

where

$$A_7 = \Delta \rho, \quad A_8 = |\mathbf{grad}\, \theta|^2, \quad A_9 = \Delta \theta.$$

In deriving (3.12), we use the facts that $|\mathbf{grad}\, \rho| = 1$ and $\mathbf{grad}\, \rho \cdot \mathbf{grad}\, \theta = 0$. The boundary condition (3.6) becomes

$$\frac{\partial \tilde{p}^B}{\partial \rho} = \widetilde{\frac{\partial p^I}{\partial n}} \quad \text{on } \partial\Omega. \tag{3.13}$$

The exact form of the coefficient functions in (3.11) and (3.12) is not essential. However, the coefficients $\tilde{\mathcal{A}}_0$ and $\tilde{\boldsymbol{A}}_5$ have some properties which will prove important.

LEMMA 3.1. *The matrix-valued function $\tilde{\mathcal{A}}_0(\rho, \theta)$ and the vector-valued function $\tilde{\boldsymbol{A}}_5(\rho, \theta)$ are independent of ρ. Moreover for each fixed θ, $\tilde{\mathcal{A}}_0$ is symmetric negative definite and $\tilde{\boldsymbol{A}}_5$ is a unit eigenvector of $\tilde{\mathcal{A}}_0$ with eigenvalue $-D(1-\nu)/2$.*

Proof. That these coefficients are independent of ρ follows from the observation that $\widetilde{\partial\rho/\partial x}$ and $\widetilde{\partial\rho/\partial y}$ depend on θ but not on ρ. The second sentence is easily verified using the fact that $|\mathbf{grad}\, \rho| = 1$. □

The remaining coefficients are in general functions of both ρ and θ and to obtain the boundary layer equations, we expand them in Taylor series about $\rho = 0$. That is, we define operators $\mathcal{A}_i^j(\theta)$ by the formal Taylor series expansions:

$$\tilde{\mathcal{A}}_i(\rho, \theta) = \sum_{j=0}^{\infty} \frac{\rho^j}{j!} \tilde{\mathcal{A}}_i^j(\theta), \qquad i = 1, 2, 3, 4,$$

and define $\tilde{\boldsymbol{A}}_6^j$ and $\tilde{A}_i^j$, $i = 7, 8, 9$, similarly. Formally inserting these expansions in (3.11) and at the same time making the change of variable $\rho = t\hat{\rho}$ gives

$$\begin{aligned} &t^{-2} \hat{\mathcal{A}}_0 \frac{\partial^2 \hat{\boldsymbol{\phi}}^B}{\partial \hat{\rho}^2} + t^{-1} \left[\hat{\mathcal{A}}_1^0 \frac{\partial^2 \hat{\boldsymbol{\phi}}^B}{\partial \hat{\rho} \partial \theta} + \hat{\mathcal{A}}_2^0 \frac{\partial \hat{\boldsymbol{\phi}}^B}{\partial \hat{\rho}} + \hat{\boldsymbol{A}}_5 \frac{\partial \hat{p}^B}{\partial \hat{\rho}} \right] \\ &\quad + \sum_{j=0}^{\infty} t^j \left[\frac{\hat{\rho}^{j+1}}{(j+1)!} \left(\hat{\mathcal{A}}_1^{j+1} \frac{\partial^2 \hat{\boldsymbol{\phi}}^B}{\partial \hat{\rho} \partial \theta} + \hat{\mathcal{A}}_2^{j+1} \frac{\partial \hat{\boldsymbol{\phi}}^B}{\partial \hat{\rho}} \right) \right. \\ &\qquad \left. + \frac{\hat{\rho}^j}{j!} \left(\hat{\mathcal{A}}_3^j \frac{\partial^2 \hat{\boldsymbol{\phi}}^B}{\partial \theta^2} + \hat{\mathcal{A}}_4^j \frac{\partial \hat{\boldsymbol{\phi}}^B}{\partial \theta} + \hat{\boldsymbol{A}}_6^j \cdot \frac{\partial \hat{p}^B}{\partial \theta} \right) \right] = 0. \end{aligned} \tag{3.14}$$

Similarly (3.12) becomes:

$$\begin{aligned} &-t^{-1} \hat{\boldsymbol{A}}_5 \cdot \frac{\partial \hat{\boldsymbol{\phi}}^B}{\partial \hat{\rho}} - \hat{\boldsymbol{A}}_6^0 \cdot \frac{\partial \hat{\boldsymbol{\phi}}^B}{\partial \theta} + \frac{\partial^2 \hat{p}^B}{\partial \hat{\rho}^2} \\ &\quad + \sum_{j=0}^{\infty} t^{j+1} \left[-\frac{\hat{\rho}^{j+1}}{(j+1)!} \hat{\boldsymbol{A}}_6^{j+1} \cdot \frac{\partial \hat{\boldsymbol{\phi}}^B}{\partial \theta} + \frac{\hat{\rho}^j}{j!} \left(\hat{A}_7^j \frac{\partial \hat{p}^B}{\partial \hat{\rho}} + t \hat{A}_8^j \frac{\partial^2 \hat{p}^B}{\partial \theta^2} + t \hat{A}_9^j \frac{\partial \hat{p}^B}{\partial \theta} \right) \right] = 0. \end{aligned} \tag{3.15}$$

We now calculate the differential equations determining the boundary correctors by inserting the series expansions for ϕ^B and p^B (defined at the beginning of this section) in (3.14) and (3.15) and equating coefficients of corresponding powers of t. Neglecting the cutoff function χ, we obtain from (3.14) the equations

$$\hat{\mathcal{A}}_0 \frac{\partial^2 \hat{\boldsymbol{\Phi}}_0}{\partial \hat{\rho}^2} + \hat{\boldsymbol{A}}_5 \frac{\partial \hat{P}_0}{\partial \hat{\rho}} = 0,$$

$$\hat{\mathcal{A}}_0 \frac{\partial^2 \hat{\boldsymbol{\Phi}}_1}{\partial \hat{\rho}^2} + \hat{\boldsymbol{A}}_5 \frac{\partial \hat{P}_1}{\partial \hat{\rho}} + \hat{\mathcal{A}}_1^0 \frac{\partial^2 \hat{\boldsymbol{\Phi}}_0}{\partial \hat{\rho} \partial \theta} + \hat{\mathcal{A}}_2^0 \frac{\partial \hat{\boldsymbol{\Phi}}_0}{\partial \hat{\rho}} + \hat{\boldsymbol{A}}_6^0 \frac{\partial \hat{P}_0}{\partial \theta} = 0,$$

and, for $i = 2, 3, \cdots$,

$$\hat{\mathcal{A}}_0 \frac{\partial^2 \hat{\boldsymbol{\Phi}}_i}{\partial \hat{\rho}^2} + \hat{\boldsymbol{A}}_5 \frac{\partial \hat{P}_i}{\partial \hat{\rho}} + \hat{\mathcal{A}}_1^0 \frac{\partial^2 \hat{\boldsymbol{\Phi}}_{i-1}}{\partial \hat{\rho} \partial \theta} + \hat{\mathcal{A}}_2^0 \frac{\partial \hat{\boldsymbol{\Phi}}_{i-1}}{\partial \hat{\rho}} + \hat{\boldsymbol{A}}_6^0 \frac{\partial \hat{P}_{i-1}}{\partial \theta}$$
$$+ \sum_{j=0}^{i-2} \left[\frac{\hat{\rho}^{j+1}}{(j+1)!} \left(\hat{\mathcal{A}}_1^{j+1} \frac{\partial^2 \hat{\boldsymbol{\Phi}}_{i-2-j}}{\partial \hat{\rho} \partial \theta} + \hat{\mathcal{A}}_2^{j+1} \frac{\partial \hat{\boldsymbol{\Phi}}_{i-2-j}}{\partial \hat{\rho}} + \hat{\boldsymbol{A}}_6^{j+1} \frac{\partial \hat{P}_{i-2-j}}{\partial \theta} \right) \right.$$
$$\left. + \frac{\hat{\rho}^j}{j!} \left(\hat{\mathcal{A}}_3^j \frac{\partial^2 \hat{\boldsymbol{\Phi}}_{i-2-j}}{\partial \theta^2} + \hat{\mathcal{A}}_4^j \frac{\partial \hat{\boldsymbol{\Phi}}_{i-2-j}}{\partial \theta} \right) \right] = 0.$$

Introducing the convention $\hat{\boldsymbol{\Phi}}_i = 0$, $\hat{P}_i = 0$ for $i < 0$, we may write these three equations as

$$\hat{\mathcal{A}}_0 \frac{\partial^2 \hat{\boldsymbol{\Phi}}_i}{\partial \hat{\rho}^2} + \hat{\boldsymbol{A}}_5 \frac{\partial \hat{P}_i}{\partial \hat{\rho}} = -\hat{\boldsymbol{F}}_i(\hat{\rho}, \theta), \qquad i \in \mathbb{N}, \tag{3.16}$$

where

$$\hat{\boldsymbol{F}}_i(\hat{\rho}, \theta) = \sum_{j=0}^{i-1} \frac{\hat{\rho}^j}{j!} \left(\hat{\mathcal{A}}_1^j \frac{\partial^2 \hat{\boldsymbol{\Phi}}_{i-1-j}}{\partial \hat{\rho} \partial \theta} + \hat{\mathcal{A}}_2^j \frac{\partial \hat{\boldsymbol{\Phi}}_{i-1-j}}{\partial \hat{\rho}} + \hat{\mathcal{A}}_3^j \frac{\partial^2 \hat{\boldsymbol{\Phi}}_{i-2-j}}{\partial \theta^2} \right.$$
$$\left. + \hat{\mathcal{A}}_4^j \frac{\partial \hat{\boldsymbol{\Phi}}_{i-2-j}}{\partial \theta} + \hat{\boldsymbol{A}}_6^j \frac{\partial \hat{P}_{i-1-j}}{\partial \theta} \right).$$

Similarly, from (3.15), we obtain

$$-\hat{\boldsymbol{A}}_5 \cdot \frac{\partial \hat{\boldsymbol{\Phi}}_i}{\partial \hat{\rho}} + \frac{\partial^2 \hat{P}_i}{\partial \hat{\rho}^2} = \hat{G}_i(\hat{\rho}, \theta) :=$$
$$- \sum_{j=0}^{i-1} \frac{\hat{\rho}^j}{j!} \left(-\hat{\boldsymbol{A}}_6^j \cdot \frac{\partial \hat{\boldsymbol{\Phi}}_{i-1-j}}{\partial \theta} + \hat{A}_7^j \frac{\partial \hat{P}_{i-1-j}}{\partial \hat{\rho}} + \hat{A}_8^j \frac{\partial^2 \hat{P}_{i-2-j}}{\partial \theta^2} + \hat{A}_9^j \frac{\partial \hat{P}_{i-2-j}}{\partial \theta} \right), \tag{3.17}$$
$$i \in \mathbb{N}.$$

Inserting the asymptotic expansions for p^I and p^B in (3.13), changing variables from ρ to $\hat{\rho}$, and matching powers, we obtain the boundary conditions

$$\frac{\partial \hat{P}_i}{\partial \hat{\rho}}(0, \theta) = \widetilde{\frac{\partial p_i}{\partial n}}(0, \theta), \qquad i \in \mathbb{N}. \tag{3.18}$$

Finally, in order to determine the boundary correctors uniquely, we also impose the conditions at infinity

$$\lim_{\hat{\rho}\to\infty} \hat{\boldsymbol{\Phi}}_i(\hat{\rho},\theta) = 0, \quad \lim_{\hat{\rho}\to\infty} \hat{P}_i(\hat{\rho},\theta) = 0. \tag{3.19}$$

We remark that (3.17) is to be satisfied exactly, rather than up to an additive constant (as was (3.10)). Similarly, because of the boundary condition at infinity, we have specified $\hat{P}_i$ completely, not just up to an additive constant as was the case for p_i. Once the boundary correctors $\hat{\boldsymbol{\Phi}}_k$ and $\hat{P}_k$ for $k < i$ and the interior expansion function p_i are known, we may view (3.16)–(3.19) as a boundary value problem in ordinary differential equations in which the independent variable is $\hat{\rho}$, the unknowns are $\hat{\boldsymbol{\Phi}}_i$ and $\hat{P}_i$, and θ plays the role of a parameter. As we shall see (in Theorem 3.3), this problem has a unique solution. Therefore we can recursively determine all the interior expansion functions and boundary correctors as follows. First we determine $(\boldsymbol{\phi}_0, p_0)$ by (3.7), (3.10), and (3.9). Then we determine $(\hat{\boldsymbol{\Phi}}_0, \hat{P}_0)$ by (3.16)–(3.19) (the right-hand sides of (3.16) and (3.17) being zero and the right-hand side of (3.18) being known). Then $(\boldsymbol{\phi}_1, p_1)$ is uniquely determined by (3.7), (3.10), and (3.9), and so forth. Thus we have proved the following theorem.

THEOREM 3.2. *There exist functions $\boldsymbol{\phi}_i(x,y)$, $p_i(x,y)$ on Ω and $\hat{\boldsymbol{\Phi}}_i(\hat{\rho},\theta)$, $\hat{P}_i(\hat{\rho},\theta)$ on $\hat{\Omega}_0$, $i \in \mathbb{N}$, unique except that p_i is determined only up to an additive constant, which satisfy the boundary value problems* (3.7), (3.10), (3.9) *and* (3.16)–(3.19).

The Stokes-like boundary value problem (3.7), (3.10), (3.9) is well posed, but, of course, we cannot in general determine its solution in closed form, even if r were known in closed form. (However, the regularity of solutions to this problem is well understood—cf. Lemma 4.2.) The system (3.16)–(3.19) can, in principle, be solved in closed form. For example, the solution for $i = 0$ is

$$\hat{P}_0(\hat{\rho},\theta) = -\frac{1}{c}\widehat{\frac{\partial p_0}{\partial n}}(0,\theta)e^{-c\hat{\rho}}, \qquad \hat{\boldsymbol{\Phi}}_0(\hat{\rho},\theta) = \hat{\boldsymbol{A}}_5(\theta)\widehat{\frac{\partial p_0}{\partial n}}(0,\theta)e^{-c\hat{\rho}}, \tag{3.20}$$

where $c = [24(1+\nu)/E]^{1/2}$. (We show that this is the only solution in the proof of Theorem 3.3.)

The following theorem gives the form of the solution for general i. In particular, it states that $\hat{\boldsymbol{\Phi}}_i$ and $\hat{P}_i$ are polynomials in $\hat{\rho}$ times the decaying exponential $e^{-c\hat{\rho}}$.

THEOREM 3.3. *For each $i \in \mathbb{N}$, the system* (3.16)–(3.19) *has a unique solution $(\hat{\boldsymbol{\Phi}}_i, \hat{P}_i)$. Moreover there exist smooth functions $\boldsymbol{\alpha}_{ijkl}(\theta)$ and $\alpha_{ijkl}(\theta)$ depending only on i, the domain Ω, and the plate constants E and ν such that*

$$\hat{\boldsymbol{\Phi}}_i(\hat{\rho},\theta) = e^{-c\hat{\rho}} \sum_{k=0}^{i}\sum_{j=0}^{i}\sum_{l=0}^{i-j} \boldsymbol{\alpha}_{ijkl}(\theta)\hat{\rho}^k \frac{\partial^l}{\partial\theta^l}\widehat{\frac{\partial p_j}{\partial n}}(0,\theta),$$

$$\hat{P}_i(\hat{\rho},\theta) = e^{-c\hat{\rho}} \sum_{k=0}^{i}\sum_{j=0}^{i}\sum_{l=0}^{i-j} \alpha_{ijkl}(\theta)\hat{\rho}^k \frac{\partial^l}{\partial\theta^l}\widehat{\frac{\partial p_j}{\partial n}}(0,\theta).$$

The proof, an exercise in ordinary differential equations based on the form of the coefficients of (3.16)–(3.17) as given in Lemma 3.1, is given in the Appendix.

This completes the construction of the interior and boundary layer asymptotic expansions. In the next section we bound the individual terms of the series and determine how nearly the finite sums satisfy the differential systems which motivated their definitions. Then, in § 5, we prove error bounds for the finite sums of the expansions.

4. A priori estimates. We begin this section by deriving a priori bounds on the boundary correctors using Theorem 3.3.

THEOREM 4.1 (A PRIORI ESTIMATES FOR BOUNDARY CORRECTORS). *Let i be a nonnegative integer. There exists a constant C depending only on the domain Ω, the elastic constants E and ν, and s and i, such that*

$$|\boldsymbol{\Phi}_i|_s + |P_i|_s \le C \sum_{j=0}^{i} \left| \frac{\partial p_j}{\partial n} \right|_{s+i-j}, \qquad s \in \mathbb{R},$$

$$\|\boldsymbol{\Phi}_i\|_{s,\Omega_0} + \|P_i\|_{s,\Omega_0} \le C t^{1/2-s} \sum_{j=0}^{i} \sum_{m=0}^{s} t^m \left| \frac{\partial p_j}{\partial n} \right|_{m+i-j}, \qquad s \in \mathbb{N}.$$

Proof. The first estimate follows from Theorem 3.3 by setting $\hat{\rho} = 0$ and using the triangle inequality. We now consider the second inequality. To establish the bound for $\boldsymbol{\Phi}_i$, we change to (ρ, θ) coordinates and seek bounds on the integrals

(4.1)
$$\left[\int_0^L \int_0^{\rho_0} |\partial^{s-m+k} \tilde{\boldsymbol{\Phi}}_i / \partial \rho^{s-m} \partial \theta^k|^2 |1 - \kappa(\theta)\rho| \, d\rho \, d\theta \right]^{1/2}, \qquad 0 \le m \le s, \quad 0 \le k \le m.$$

Now $\tilde{\boldsymbol{\Phi}}_i$ is a sum of terms of the form

(4.2)
$$\boldsymbol{\alpha}(\theta) \exp(-c\rho/t) f(\rho/t) \frac{\partial^l}{\partial \theta^l} \widetilde{\frac{\partial p_j}{\partial n}}(0, \theta), \qquad \boldsymbol{\alpha} \text{ smooth, } f \text{ polynomial, } j \le i, \; l \le i - j.$$

The $L^2(\Omega_0)$ norm of (4.2) is bounded by $Ct^{1/2} |\partial p_j / \partial n|_l$, since

$$\int_0^{\rho_0} |\exp(-c\rho/t) f(\rho/t)|^2 \, d\rho \le t \int_0^{\infty} |\exp(-c\hat{\rho}) f(\hat{\rho})|^2 \, d\hat{\rho}.$$

Applying $\partial^{s-m+k} / \partial \rho^{s-m} \partial \theta^k$ to (4.2) gives t^{m-s} times a sum of terms of the same form except that l may be as large as $i - j + k \le m + i - j$. Thus (4.1) is bounded by $Ct^{1/2} \sum_{j=0}^{i} t^{m-s} |\partial p_j / \partial n|_{m+i-j}$. Summing over $m = 0, 1, \cdots, s$ gives the desired bound for $\tilde{\boldsymbol{\Phi}}_i$, and that for P_i is proved identically. □

We next summarize the basic regularity properties of the Stokes-like system which defines the interior expansion functions.

LEMMA 4.2. *Let $s \in \mathbb{N}$, $f \in H^s(\Omega) \cap \mathring{H}^1(\Omega)$, $g \in H^s(\Omega)/\mathbb{R}$, and $\boldsymbol{l} \in \boldsymbol{H}^{s+1/2}(\partial\Omega)$ be given. Then there exist unique $\boldsymbol{\psi} \in \boldsymbol{H}^{s+1}(\Omega)$, $q \in H^s(\Omega)/\mathbb{R}$ satisfying the partial differential equations*

$$-\mathbf{div}\, C\, \mathcal{E}(\boldsymbol{\psi}) - \mathbf{curl}\, q = \mathbf{grad}\, f, \tag{4.3}$$

$$-\operatorname{rot} \boldsymbol{\psi} = g \pmod{\mathbb{R}}, \tag{4.4}$$

and the boundary conditions

$$\boldsymbol{\psi} = \boldsymbol{l}.$$

Moreover, there exists a constant C depending only on s, E, ν, and Ω such that

$$\|\boldsymbol{\psi}\|_{s+1} + \|q\|_{s/\mathbb{R}} \leq C(\|f\|_s + \|g\|_{s/\mathbb{R}} + |\boldsymbol{l}|_{s+1/2}).$$

Remarks. 1. The restriction that the forcing function in (4.3) be the gradient of an $\mathring{H}^1(\Omega)$ function is sufficient for our purposes and allows us to avoid some technical points concerning duals of Sobolev spaces and trace operators with values in negative order spaces. 2. If we replace $\mathbf{div}\, C\,\mathcal{E}(\boldsymbol{\psi})$ with Δ then the simple change of variables $(\psi_1, \psi_2) \to (\psi_2, -\psi_1)$ converts (4.3), (4.4) to a generalized Stokes system, and this result is well known [5]. Here we give a proof which works for general C based on regularity results for the biharmonic.

Proof. Written in weak form, the boundary value problem is to find $\boldsymbol{\psi} \in \boldsymbol{H}^1(\Omega)$ such that $\boldsymbol{\psi} = \boldsymbol{l}$ on $\partial\Omega$ and $q \in L^2(\Omega)/\mathbb{R}$ satisifying

$$\begin{aligned}(C\,\mathcal{E}(\boldsymbol{\psi}), \mathcal{E}(\boldsymbol{\mu})) - (q, \operatorname{rot} \boldsymbol{\mu}) &= -(f, \operatorname{div} \boldsymbol{\mu}) \\ -(\operatorname{rot} \boldsymbol{\psi}, v) &= (g, v)\end{aligned}$$

for all $\boldsymbol{\mu} \in \mathring{H}^1(\Omega)$ and all $v \in L^2(\Omega)$ of mean value zero. Existence and uniqueness of a solution in $\boldsymbol{H}^1(\Omega) \times L^2(\Omega)/\mathbb{R}$ is proved just as for the generalized Stokes equations, e.g., by applying Brezzi's theorem [4]. The estimate for $s = 0$ follows from the same argument. To establish the estimate with $s \geq 1$, we apply the Helmholtz decomposition to $\boldsymbol{\psi}$ to get $\boldsymbol{\psi} = \mathbf{grad}\, z + \mathbf{curl}\, b$, with $z \in \mathring{H}^1(\Omega)$, $b \in H^1(\Omega)/\mathbb{R}$. From (4.4) we get

$$\Delta b = g \pmod{\mathbb{R}} \quad \text{in } \Omega,$$

with boundary conditions $\partial b/\partial n = \boldsymbol{l} \cdot \boldsymbol{s}$. Taking the divergence of equation (4.3) gives

$$-D\,\Delta^2 z = \Delta f \quad \text{in } \Omega,$$

with boundary conditions $z = 0$, $\partial z/\partial n = \boldsymbol{l} \cdot \boldsymbol{n} + \partial b/\partial s$. Applying regularity results for the biharmonic problem and the Laplacian, we obtain

$$\begin{aligned}\|b\|_{s+2/\mathbb{R}} &\leq C(\|g\|_{s/\mathbb{R}} + + |\boldsymbol{l}|_{s+1/2}), \\ \|z\|_{s+2} &\leq C(\|\,\Delta f\|_{s-2} + |\boldsymbol{l}|_{s+1/2} + |\partial b/\partial s|_{s+1/2}) \\ &\leq C(\|f\|_s + |\boldsymbol{l}|_{s+1/2} + \|b\|_{s+2/\mathbb{R}}) \\ &\leq C(\|f\|_s + |\boldsymbol{l}|_{s+1/2} + \|g\|_{s/\mathbb{R}}).\end{aligned}$$

The bound for $\boldsymbol{\psi}$ now follows directly by the triangle inequality and the bound for q then follows from (4.3). □

We now use the previous two theorems to obtain estimates for the interior expansion functions.

THEOREM 4.3 (A PRIORI ESTIMATES FOR INTERIOR EXPANSION FUNCTIONS). *Let $\boldsymbol{\phi}_i$ and p_i be the interior expansion functions. Then for all $s \geq 0$ and $i \in \mathbb{N}$, there exists a constant C such that*

$$\|\boldsymbol{\phi}_i\|_{s+1} + \|p_i\|_{s/\mathbb{R}} \leq C|||g|||_{s+i-2}.$$

Proof. Since $-\Delta r = g$ and r vanishes on $\partial\Omega$, we have

$$\|r\|_s \leq C|||g|||_{s-2}. \tag{4.5}$$

Thus, it suffices to prove that

$$\|\phi_i\|_{s+1} + \|p_i\|_{s/\mathbb{R}} \le C\|r\|_{s+i}. \tag{4.6}$$

We prove this first for $s \in \mathbb{N}$ by induction on i. For $i = 0$, we get this immediately from the defining equations (3.7), (3.10), (3.9), and Lemma 4.2. As already noted $\phi_1 = p_1 = 0$, so (4.6) holds for $i = 1$ also. For $i \ge 2$, we apply Lemma 4.2, Theorem 4.1, and the trace theorem to obtain

$$\|\phi_i\|_{s+1} + \|p_i\|_{s/\mathbb{R}} \le C|\boldsymbol{\Phi}_{i-2}|_{s+1/2} \le C\sum_{j=0}^{i-2}\left|\frac{\partial p_j}{\partial n}\right|_{s-3/2+i-j} \le C\sum_{j=0}^{i-2}\|p_j\|_{s+i-j}.$$

Application of the inductive hypothesis completes the proof of (4.6) for integer s. The proof for noninteger s now follows by a standard interpolation argument. □

COROLLARY 4.4. *For $s \ge -\frac{3}{2}$ and $i \in \mathbb{N}$, there exists a constant C such that*

$$\left|\frac{\partial p_i}{\partial s}\right|_s + \left|\frac{\partial p_i}{\partial n}\right|_s + |\boldsymbol{\Phi}_i|_s + |P_i|_s \le C|||g|||_{s+i-1/2}.$$

Proof. As remarked in the previous section, p_i is harmonic for all i. Consequently, the trace inequality

$$\left|\frac{\partial p_i}{\partial s}\right|_s + \left|\frac{\partial p_i}{\partial n}\right|_s \le C\|p_i\|_{s+3/2/\mathbb{R}}$$

holds for all s, so the bounds on p_i follow easily from the theorem. The bounds on $\boldsymbol{\Phi}_i$ and P_i then follow from Theorem 4.1. □

We now combine Theorems 4.1 and 4.3 to obtain an essential result for the derivation of error bounds for the boundary layer expansion.

THEOREM 4.5 (A PRIORI ESTIMATES FOR BOUNDARY CORRECTORS). *Let i, k, l, n, and s be nonnegative integers and define functions $\boldsymbol{f}$ and f on Ω_0 by*

$$\tilde{\boldsymbol{f}} = \left(\frac{\rho}{t}\right)^k t^l \frac{\partial^{l+n}}{\partial\rho^l\partial\theta^n}\tilde{\boldsymbol{\Phi}}_i, \qquad \tilde{f} = \left(\frac{\rho}{t}\right)^k t^l \frac{\partial^{l+n}}{\partial\rho^l\partial\theta^n}\tilde{P}_i.$$

Then there exists a constant C depending only on the domain Ω, the elastic constants E and ν, and i, k, l, n, and s, such that

$$\|\boldsymbol{f}\|_{s,\Omega_0} + \|f\|_{s,\Omega_0} \le C(t^{1/2-s}|||g|||_{i+n-1/2} + t^{1/2}|||g|||_{s+i+n-1/2}).$$

Proof. Note that, if in (4.2) we differentiate with respect to $\hat{\rho}$ (i.e., differentiate with respect to ρ and multiply by t), we obtain something of the same form. The same is true if we multiply by $\hat{\rho}$. If we differentiate with respect to θ we obtain a sum of two terms of the same form, with one higher order of differentiation on $\widetilde{\partial p_j/\partial n}$. Hence, reasoning just as in the proof of Theorem 4.1, we obtain

$$\|f\|_{s,\Omega_0} + \|\boldsymbol{f}\|_{s,\Omega_0} \le Ct^{1/2-s}\sum_{j=0}^{i}\sum_{m=0}^{s} t^m\left|\frac{\partial p_j}{\partial n}\right|_{m+i+n-j}.$$

An application of Corollary 4.4 completes the proof. □

We now consider the partial sums given by

$$\phi_m^I(x,y) = \sum_{i=0}^{m} t^i \phi_i(x,y), \qquad p_m^I(x,y) = \sum_{i=0}^{m} t^i p_i(x,y),$$

$$\phi_m^B(x,y) = t^2 \tilde{\chi}(\rho) \sum_{i=0}^{m} t^i \hat{\Phi}_i(\hat{\rho},\theta), \quad p_m^B(x,y) = t\tilde{\chi}(\rho) \sum_{i=0}^{m} t^i \hat{P}_i(\hat{\rho},\theta).$$

Note that while Φ_i and P_i are only defined on the tubular neighborhood Ω_0 of $\partial\Omega$, ϕ_m^B and p_m^B are defined on all of Ω because of the cutoff function χ. By construction, (ϕ_m^I, p_m^I) and (ϕ_m^B, p_m^B) should almost satisfy the boundary value problems (3.1)–(3.3) and (3.4)–(3.6), respectively. We now make precise to what extent this is true.

For the interior expansion this is easy. The following theorem follows directly from (3.7), (3.10), (3.9).

THEOREM 4.6 (BOUNDARY VALUE PROBLEM FOR THE INTERIOR EXPANSION). *Let $m \in \mathbb{N}$. The finite interior expansion $(\phi_m^I, p_m^I) \in \boldsymbol{H}^1(\Omega) \times H^1(\Omega)/\mathbb{R}$ satisfies the boundary value problem*

$$\begin{aligned} &-\mathbf{div}\, C\,\mathcal{E}(\phi_m^I) - \mathbf{curl}\, p_m^I = \mathbf{grad}\, r \quad \text{in } \Omega, \\ &-\operatorname{rot} \phi_m^I + t^2 \Delta p_m^I = 0 \ (\operatorname{mod} \mathbb{R}) \quad \text{in } \Omega, \\ &\phi_m^I = -\phi_{m-2}^B \quad \text{on } \partial\Omega. \end{aligned}$$

For the boundary expansion, it follows from (3.18) that the boundary condition

$$\frac{\partial p_m^B}{\partial n} = -\frac{\partial p_m^I}{\partial n} \quad \text{on } \partial\Omega \tag{4.7}$$

is satisfied exactly, but for the differential equations the situation is more complicated. Define the residuals $\boldsymbol{R}_m$ and R_m by the equations:

$$-\mathbf{div}\, C\,\mathcal{E}(\phi_m^B) - \mathbf{curl}\, p_m^B = \boldsymbol{R}_m \quad \text{in } \Omega, \tag{4.8}$$

$$-\operatorname{rot} \phi_m^B + t^2 \Delta p_m^B = R_m \quad \text{in } \Omega. \tag{4.9}$$

The following theorem shows that these residuals are indeed of high order with respect to t.

THEOREM 4.7 (BOUNDARY VALUE PROBLEM FOR THE BOUNDARY LAYER EXPANSION). *Let $m \in \mathbb{N}$. The finite boundary layer expansion $(\phi_m^B, p_m^B) \in \boldsymbol{H}^1(\Omega) \times H^1(\Omega)$ satisfies the boundary value problem (4.7)–(4.9), with the following bounds valid for the forcing functions $\boldsymbol{R}_m$, R_m:*

$$\begin{aligned} &\|\boldsymbol{R}_m\|_s \le C(t^{m+3/2-s}\|g\|_{m+1/2} + t^{m+5/2}\|g\|_{m+s+3/2}), \qquad s = -1, 0, \cdots, \\ &\|R_m\|_s \le C(t^{m+5/2-s}\|g\|_{m+1/2} + t^{m+7/2}\|g\|_{m+s+3/2}), \qquad s \in \mathbb{N}. \end{aligned}$$

Proof. It suffices to prove the theorem with the right-hand sides replaced by

$$Ct^{m+3/2-s} \sum_{i=0}^{s+1} t^i \|g\|_{m+1/2+i} \text{ and } Ct^{m+5/2-s} \sum_{i=0}^{s+1} t^i \|g\|_{m+1/2+i},$$

respectively. In addition to the portion of the residual due to truncating the series after finitely many terms, we must consider the contributions from two other sources, namely the replacement of the coefficients by Taylor polynomial approximations and the suppression of the cutoff function χ. Because of the presence of the cutoff function χ in the definitions of ϕ_m^B and p_m^B, it is easy to see that the residuals $\boldsymbol{R}_m$ and R_m will vanish for $\rho \geq \rho_0$, i.e., in $\Omega \setminus \Omega_0$. In Ω_0, after changing to $(\hat\rho, \theta)$ variables, we have (cf. (3.11))

$$\hat{\boldsymbol{R}}_m = t^{-2}\hat{\boldsymbol{A}}_0 \frac{\partial^2 \hat\phi_m^B}{\partial \hat\rho^2} + t^{-1}\left(\hat{\boldsymbol{A}}_1 \frac{\partial^2 \hat\phi_m^B}{\partial \hat\rho \partial\theta} + \hat{\boldsymbol{A}}_2 \frac{\partial \hat\phi_m^B}{\partial \hat\rho}\right) + \hat{\boldsymbol{A}}_3 \frac{\partial^2 \hat\phi_m^B}{\partial\theta^2} + \hat{\boldsymbol{A}}_4 \frac{\partial \hat\phi_m^B}{\partial\theta}$$
$$+ t^{-1}\hat{\boldsymbol{A}}_5 \frac{\partial \hat p_m^B}{\partial \hat\rho} + \hat{\boldsymbol{A}}_6 \frac{\partial \hat p_m^B}{\partial\theta} = \tilde\chi(\rho)\hat{\boldsymbol{R}}_m^1 + \hat{\boldsymbol{R}}_m^2,$$

where

$$\hat{\boldsymbol{R}}_m^1 = \sum_{i=0}^{m} t^i \left(\hat{\boldsymbol{A}}_0 \frac{\partial^2 \hat{\boldsymbol{\Phi}}_i}{\partial \hat\rho^2} + \hat{\boldsymbol{A}}_5 \frac{\partial \hat P_i}{\partial \hat\rho}\right)$$
$$+ \sum_{i=0}^{m+1} t^i \left(\hat{\boldsymbol{A}}_1 \frac{\partial^2 \hat{\boldsymbol{\Phi}}_{i-1}}{\partial\hat\rho\partial\theta} + \hat{\boldsymbol{A}}_2 \frac{\partial \hat{\boldsymbol{\Phi}}_{i-1}}{\partial\hat\rho} + \hat{\boldsymbol{A}}_3 \frac{\partial^2 \hat{\boldsymbol{\Phi}}_{i-2}}{\partial\theta^2} + \hat{\boldsymbol{A}}_4 \frac{\partial \hat{\boldsymbol{\Phi}}_{i-2}}{\partial\theta} + \hat{\boldsymbol{A}}_6 \frac{\partial \hat P_{i-1}}{\partial\theta}\right)$$
$$+ t^{m+2}\left(\hat{\boldsymbol{A}}_3 \frac{\partial^2 \hat{\boldsymbol{\Phi}}_m}{\partial\theta^2} + \hat{\boldsymbol{A}}_4 \frac{\partial \hat{\boldsymbol{\Phi}}_m}{\partial\theta}\right),$$
$$\hat{\boldsymbol{R}}_m^2 = \tilde\chi'(\rho)\left[\sum_{i=0}^{m} t^i \left(2\hat{\boldsymbol{A}}_0 \frac{\partial \hat{\boldsymbol{\Phi}}_i}{\partial\hat\rho} + \hat{\boldsymbol{A}}_5 \hat P_i\right) + \sum_{i=0}^{m+1} t^i \left(\hat{\boldsymbol{A}}_1 \frac{\partial \hat{\boldsymbol{\Phi}}_{i-1}}{\partial\theta} + \hat{\boldsymbol{A}}_2 \hat{\boldsymbol{\Phi}}_{i-1}\right)\right]$$
$$+ \tilde\chi''(\rho) \sum_{i=0}^{m} t^i \hat{\boldsymbol{A}}_0 \hat{\boldsymbol{\Phi}}_i,$$

and we have again used the convention that terms with negative indices vanish. Now for any $k \geq -1$

$$\tilde{\boldsymbol{A}}_1(\rho,\theta) = \sum_{j=0}^{k} \frac{\rho^j}{j!} \tilde{\boldsymbol{A}}_1^j(\theta) + \rho^{k+1} \bar{\boldsymbol{A}}_1^{k+1}(\rho,\theta)$$

where

$$\bar{\boldsymbol{A}}_1^{k+1}(\rho,\theta) = \begin{cases} \displaystyle\int_0^1 \frac{\partial^{k+1}\tilde{\boldsymbol{A}}_1}{\partial\rho^{k+1}}(s\rho,\theta)\frac{(1-s)^k}{k!}\,ds, & k \geq 0, \\ \tilde{\boldsymbol{A}}_1(\rho,\theta), & k = -1. \end{cases}$$

The other coefficients admit similar Taylor expansions (except for $\tilde{\boldsymbol{A}}_0$ and $\tilde{\boldsymbol{A}}_5$ which are functions of θ only). Substituting these expansions for $k = m - i$ and using $\rho = t\hat\rho$, we get

$$\hat{\boldsymbol{R}}_m^1 = \sum_{i=0}^{m} t^i \left(\hat{\boldsymbol{A}}_0 \frac{\partial^2 \hat{\boldsymbol{\Phi}}_i}{\partial\hat\rho^2} + \hat{\boldsymbol{A}}_5 \frac{\partial \hat P_i}{\partial\hat\rho}\right) + \sum_{i=0}^{m+1} t^i \sum_{j=0}^{m-i} \frac{(t\hat\rho)^j}{j!}\left(\hat{\boldsymbol{A}}_1^j \frac{\partial^2 \hat{\boldsymbol{\Phi}}_{i-1}}{\partial\hat\rho\partial\theta} + \hat{\boldsymbol{A}}_2^j \frac{\partial \hat{\boldsymbol{\Phi}}_{i-1}}{\partial\hat\rho}\right.$$
$$\left. + \hat{\boldsymbol{A}}_3^j \frac{\partial^2 \hat{\boldsymbol{\Phi}}_{i-2}}{\partial\theta^2} + \hat{\boldsymbol{A}}_4^j \frac{\partial \hat{\boldsymbol{\Phi}}_{i-2}}{\partial\theta} + \hat{\boldsymbol{A}}_6^j \frac{\partial \hat P_{i-1}}{\partial\theta}\right)$$

$$
\begin{aligned}
&+\sum_{i=0}^{m+1} t^i(t\hat{\rho})^{m-i+1}\left(\hat{\mathcal{A}}_1^{m-i+1}\frac{\partial^2\hat{\boldsymbol{\Phi}}_{i-1}}{\partial\hat{\rho}\partial\theta}+\hat{\mathcal{A}}_2^{m-i+1}\frac{\partial\hat{\boldsymbol{\Phi}}_{i-1}}{\partial\hat{\rho}}\right.\\
&\qquad\left.+\hat{\mathcal{A}}_3^{m-i+1}\frac{\partial^2\hat{\boldsymbol{\Phi}}_{i-2}}{\partial\theta^2}+\hat{\mathcal{A}}_4^{m-i+1}\frac{\partial\hat{\boldsymbol{\Phi}}_{i-2}}{\partial\theta}+\hat{\boldsymbol{A}}_6^{m-i+1}\frac{\partial\hat{P}_{i-1}}{\partial\theta}\right)\\
&+t^{m+2}\left(\hat{\mathcal{A}}_3\frac{\partial^2\hat{\boldsymbol{\Phi}}_m}{\partial\theta^2}+\hat{\mathcal{A}}_4\frac{\partial\hat{\boldsymbol{\Phi}}_m}{\partial\theta}\right)\\
=&\sum_{i=0}^{m} t^i\left[\hat{\mathcal{A}}_0\frac{\partial^2\hat{\boldsymbol{\Phi}}_i}{\partial\hat{\rho}^2}+\hat{\boldsymbol{A}}_5\frac{\partial\hat{P}_i}{\partial\hat{\rho}}+\sum_{j=0}^{i}\frac{\hat{\rho}^j}{j!}\left(\hat{\mathcal{A}}_1^j\frac{\partial^2\hat{\boldsymbol{\Phi}}_{i-j-1}}{\partial\hat{\rho}\partial\theta}+\hat{\mathcal{A}}_2^j\frac{\partial\hat{\boldsymbol{\Phi}}_{i-j-1}}{\partial\hat{\rho}}\right.\right.\\
&\qquad\left.\left.+\hat{\mathcal{A}}_3^j\frac{\partial^2\hat{\boldsymbol{\Phi}}_{i-j-2}}{\partial\theta^2}+\hat{\mathcal{A}}_4^j\frac{\partial\hat{\boldsymbol{\Phi}}_{i-j-2}}{\partial\theta}+\hat{\boldsymbol{A}}_6^j\frac{\partial\hat{P}_{i-j-1}}{\partial\theta}\right)\right]\\
&+t^{m+1}\sum_{i=0}^{m+1}\hat{\rho}^{m-i+1}\left(\hat{\mathcal{A}}_1^{m-i+1}\frac{\partial^2\hat{\boldsymbol{\Phi}}_{i-1}}{\partial\hat{\rho}\partial\theta}+\hat{\mathcal{A}}_2^{m-i+1}\frac{\partial\hat{\boldsymbol{\Phi}}_{i-1}}{\partial\hat{\rho}}\right.\\
&\qquad\left.+\hat{\mathcal{A}}_3^{m-i+1}\frac{\partial^2\hat{\boldsymbol{\Phi}}_{i-2}}{\partial\theta^2}+\hat{\mathcal{A}}_4^{m-i+1}\frac{\partial\hat{\boldsymbol{\Phi}}_{i-2}}{\partial\theta}+\hat{\boldsymbol{A}}_6^{m-i+1}\frac{\partial\hat{P}_{i-1}}{\partial\theta}\right)\\
&+t^{m+2}\left(\hat{\mathcal{A}}_3\frac{\partial^2\hat{\boldsymbol{\Phi}}_m}{\partial\theta^2}+\hat{\mathcal{A}}_4\frac{\partial\hat{\boldsymbol{\Phi}}_m}{\partial\theta}\right),
\end{aligned}
$$

where we have used the identity $\sum_{i=0}^{m}\sum_{j=0}^{m-i}F(i,j)=\sum_{i=0}^{m}\sum_{j=0}^{i}F(i-j,j)$ to obtain the second equality. Now the term in brackets vanishes by construction (cf. (3.16)). Thus

$$
\begin{aligned}
\hat{\boldsymbol{R}}_m^1=&\,t^{m+1}\sum_{i=0}^{m+1}\hat{\rho}^{m-i+1}\left(\hat{\mathcal{A}}_1^{m-i+1}\frac{\partial^2\hat{\boldsymbol{\Phi}}_{i-1}}{\partial\hat{\rho}\partial\theta}+\hat{\mathcal{A}}_2^{m-i+1}\frac{\partial\hat{\boldsymbol{\Phi}}_{i-1}}{\partial\hat{\rho}}\right.\\
&\left.+\hat{\mathcal{A}}_3^{m-i+1}\frac{\partial^2\hat{\boldsymbol{\Phi}}_{i-2}}{\partial\theta^2}+\hat{\mathcal{A}}_4^{m-i+1}\frac{\partial\hat{\boldsymbol{\Phi}}_{i-2}}{\partial\theta}+\hat{\boldsymbol{A}}_6^{m-i+1}\frac{\partial\hat{P}_{i-1}}{\partial\theta}\right)\\
&+t^{m+2}\left(\hat{\mathcal{A}}_3\frac{\partial^2\hat{\boldsymbol{\Phi}}_m}{\partial\theta^2}+\hat{\mathcal{A}}_4\frac{\partial\hat{\boldsymbol{\Phi}}_m}{\partial\theta}\right),
\end{aligned}
$$

or

$$
\begin{aligned}
\hat{\boldsymbol{R}}_m^1=&\,t^{m+1}\left[\sum_{j=0}^{m}\hat{\rho}^j\left(\hat{\mathcal{A}}_1^j\frac{\partial^2\hat{\boldsymbol{\Phi}}_{m-j}}{\partial\hat{\rho}\partial\theta}+\hat{\mathcal{A}}_2^j\frac{\partial\hat{\boldsymbol{\Phi}}_{m-j}}{\partial\hat{\rho}}+\hat{\mathcal{A}}_3^j\frac{\partial^2\hat{\boldsymbol{\Phi}}_{m-j-1}}{\partial\theta^2}\right.\right.\\
&\left.\left.+\hat{\mathcal{A}}_4^j\frac{\partial\hat{\boldsymbol{\Phi}}_{m-j-1}}{\partial\theta}+\hat{\boldsymbol{A}}_6^j\frac{\partial\hat{P}_{m-j-1}}{\partial\theta}\right)+t\left(\hat{\mathcal{A}}_3\frac{\partial^2\hat{\boldsymbol{\Phi}}_m}{\partial\theta^2}+\hat{\mathcal{A}}_4\frac{\partial\hat{\boldsymbol{\Phi}}_m}{\partial\theta}\right)\right].
\end{aligned}
\tag{4.10}
$$

A similar computation gives $\hat{R}_m=\tilde{\chi}(\rho)\hat{R}_m^1+\hat{R}_m^2$, where

$$
\begin{aligned}
\hat{R}_m^1=&\,t^{m+2}\left[\sum_{j=0}^{m}\hat{\rho}^j\left(-\hat{\boldsymbol{A}}_6^j\cdot\frac{\partial\hat{\boldsymbol{\Phi}}_{m-j}}{\partial\theta}+\hat{\mathcal{A}}_7^j\frac{\partial\hat{P}_{m-j}}{\partial\hat{\rho}}+\hat{\mathcal{A}}_8^j\frac{\partial^2\hat{P}_{m-j-1}}{\partial\theta^2}\right.\right.\\
&\left.\left.+\hat{\mathcal{A}}_9^j\frac{\partial\hat{P}_{m-j-1}}{\partial\theta}\right)+t\left(\hat{\mathcal{A}}_8\frac{\partial^2\hat{P}_m}{\partial\theta^2}+\hat{\mathcal{A}}_9\frac{\partial\hat{P}_m}{\partial\theta}\right)\right]
\end{aligned}
$$

and

$$\hat{R}_m^2 = \tilde{\chi}'(\rho)\left[t\sum_{i=0}^{m} t^i\left(-\hat{A}_5\hat{\boldsymbol{\Phi}}_i + 2\frac{\partial \hat{P}_i}{\partial \hat{\rho}}\right) + t\sum_{i=0}^{m+1} t^i \hat{P}_{i-1}\right] + \tilde{\chi}''(\rho)t\sum_{i=0}^{m} t^i \hat{P}_i.$$

It suffices to show that the desired bounds are satisfied by each of the terms $\boldsymbol{R}_m^1$, $\boldsymbol{R}_m^2$, R_m^1, and R_m^2. The bounds on $\|\boldsymbol{R}_m^1\|_s$ and $\|R_m^1\|_s$, $s \geq 0$, follow from the expressions for the residuals just computed and Theorem 4.5.

We next bound $\|\boldsymbol{R}_m^2\|_s$ and $\|R_m^2\|_s$, $s \geq 0$. Using the expressions for $\hat{\boldsymbol{\Phi}}_i$ and $\hat{P}_i$ given in Theorem 3.3, we can write $\boldsymbol{R}_m^2$ and R_m^2 as a sum of terms all with a common factor of $e^{-c\hat{\rho}}$. Now, because of the presence of the factors $\tilde{\chi}'$ and $\tilde{\chi}''$ in the definitions of $\boldsymbol{R}_m^2$ and R_m^2, each of these terms vanishes for $\rho \leq \rho_0/3$. On the region where $\rho \geq \rho_0/3$

$$e^{-c\hat{\rho}} \leq K_j\left(\frac{c\rho_0}{3}\right)^{-j} t^j =: C_j t^j$$

with $K_j := \max_{x\geq 0} x^j e^{-x} < \infty$, for *any* desired power j. Using this result, referring to the expressions given in Theorem 3.3, and applying Corollary 4.4, it is not difficult to show that for any j and suitable C

$$\|\boldsymbol{R}_m^2\|_s \leq Ct^j\|g\|_{m+s+1/2}, \qquad \|R_m^2\|_s \leq Ct^j\|g\|_{m+s-1/2}. \tag{4.11}$$

Finally, we establish the first estimate when $s = -1$. First we note that

$$\hat{\mathcal{A}}_1^j = \frac{1}{j!}\hat{\mathcal{A}}_1^j + t\hat{\rho}\hat{\mathcal{A}}_1^{j+1}.$$

Substituting this and analogous expressions for $\hat{\mathcal{A}}_2^j$, $\hat{\mathcal{A}}_3^j$, $\hat{\mathcal{A}}_4^j$, and $\hat{\boldsymbol{A}}_6^j$ in (4.10) we get

$$\hat{\boldsymbol{R}}_m^1 = \hat{\boldsymbol{R}}_m^{11} + \hat{\boldsymbol{R}}_m^{12} + \hat{\boldsymbol{R}}_m^{13},$$

where

$$\hat{\boldsymbol{R}}_m^{11} = t^{m+1}\left[\sum_{j=0}^{m}\frac{\hat{\rho}^j}{j!}\left(\hat{\mathcal{A}}_1^j\frac{\partial^2\hat{\boldsymbol{\Phi}}_{m-j}}{\partial\hat{\rho}\partial\theta} + \hat{\mathcal{A}}_2^j\frac{\partial\hat{\boldsymbol{\Phi}}_{m-j}}{\partial\hat{\rho}} + \hat{\mathcal{A}}_3^j\frac{\partial^2\hat{\boldsymbol{\Phi}}_{m-j-1}}{\partial\theta^2} + \hat{\mathcal{A}}_4^j\frac{\partial\hat{\boldsymbol{\Phi}}_{m-j-1}}{\partial\theta} + \hat{\boldsymbol{A}}_6^j\frac{\partial\hat{P}_{m-j-1}}{\partial\theta}\right)\right],$$

$$\hat{\boldsymbol{R}}_m^{12} = t^{m+2}\hat{\mathcal{A}}_3\frac{\partial^2\hat{\boldsymbol{\Phi}}_m}{\partial\theta^2},$$

and

$$\hat{\boldsymbol{R}}_m^{13} = t^{m+2}\left[\sum_{j=0}^{m}\hat{\rho}^{j+1}\left(\hat{\mathcal{A}}_1^{j+1}\frac{\partial^2\hat{\boldsymbol{\Phi}}_{m-j}}{\partial\hat{\rho}\partial\theta} + \hat{\mathcal{A}}_2^{j+1}\frac{\partial\hat{\boldsymbol{\Phi}}_{m-j}}{\partial\hat{\rho}} + \hat{\mathcal{A}}_3^{j+1}\frac{\partial^2\hat{\boldsymbol{\Phi}}_{m-j-1}}{\partial\theta^2} + \hat{\mathcal{A}}_4^{j+1}\frac{\partial\hat{\boldsymbol{\Phi}}_{m-j-1}}{\partial\theta} + \hat{\boldsymbol{A}}_6^{j+1}\frac{\partial\hat{P}_{m-j-1}}{\partial\theta}\right) + \hat{\mathcal{A}}_4\frac{\partial\hat{\boldsymbol{\Phi}}_m}{\partial\theta}\right]. \tag{4.12}$$

By (3.16)

$$\hat{\boldsymbol{R}}_m^{11} = -t^{m+1}\left(\hat{\mathcal{A}}_0 \frac{\partial^2 \hat{\boldsymbol{\Phi}}_{m+1}}{\partial \hat{\rho}^2} + \hat{\boldsymbol{A}}_5 \frac{\partial \hat{P}_{m+1}}{\partial \hat{\rho}}\right),$$

or

$$\tilde{\boldsymbol{R}}_m^{11} = -t^{m+2}\left(\hat{\mathcal{A}}_0 t \frac{\partial^2 \tilde{\boldsymbol{\Phi}}_{m+1}}{\partial \rho^2} + \hat{\boldsymbol{A}}_5 \frac{\partial \tilde{P}_{m+1}}{\partial \rho}\right).$$

Therefore, for any $\boldsymbol{\psi} \in \mathring{H}^1(\Omega)$,

(4.13)

$$\begin{aligned}(\chi \boldsymbol{R}_m^{11}, \boldsymbol{\psi}) &= -t^{m+2}\int_0^L\int_0^{\rho_0} \tilde{\chi}(\rho)\left(\hat{\mathcal{A}}_0 t \frac{\partial^2 \tilde{\boldsymbol{\Phi}}_{m+1}}{\partial \rho^2} + \hat{\boldsymbol{A}}_5 \frac{\partial \tilde{P}_{m+1}}{\partial \rho}\right)\tilde{\boldsymbol{\psi}}(\rho,\theta)[1-\kappa(\theta)\rho]\,d\rho d\theta \\ &= t^{m+2}\int_0^L\int_0^{\rho_0}\left(\hat{\mathcal{A}}_0 t \frac{\partial \tilde{\boldsymbol{\Phi}}_{m+1}}{\partial \rho} + \hat{\boldsymbol{A}}_5 \tilde{P}_{m+1}\right)\frac{\partial}{\partial \rho}\left\{\tilde{\chi}(\rho)\tilde{\boldsymbol{\psi}}(\rho,\theta)[1-\kappa(\theta)\rho]\right\} d\rho d\theta.\end{aligned}$$

Applying the Schwarz inequality and Theorem 4.5 gives

$$(\chi \boldsymbol{R}_m^{11}, \boldsymbol{\psi}) \le C t^{m+5/2}\|g\|_{m+1/2}\|\boldsymbol{\psi}\|_1, \tag{4.14}$$

or, since $\boldsymbol{\psi}$ was arbitrary,

$$\|\chi \boldsymbol{R}_m^{11}\|_{-1} \le C t^{m+5/2}\|g\|_{m+1/2}.$$

Similarly,

$$\begin{aligned}(\chi \boldsymbol{R}_m^{12}, \boldsymbol{\psi}) &= t^{m+2}\int_0^L\int_0^{\rho_0} \tilde{\chi}(\rho)\hat{\mathcal{A}}_3 \frac{\partial^2 \tilde{\boldsymbol{\Phi}}_m}{\partial \theta^2}\tilde{\boldsymbol{\psi}}(\rho,\theta)[1-\kappa(\theta)\rho]\,d\rho d\theta \\ &= -t^{m+2}\int_0^L\int_0^{\rho_0} \tilde{\chi}(\rho)\hat{\mathcal{A}}_3 \frac{\partial \tilde{\boldsymbol{\Phi}}_m}{\partial \theta}\frac{\partial}{\partial \theta}\left\{\tilde{\boldsymbol{\psi}}(\rho,\theta)[1-\kappa(\theta)\rho]\right\} d\rho d\theta,\end{aligned}$$

whence

$$\|\chi \boldsymbol{R}_m^{12}\|_{-1} \le C t^{m+5/2}\|g\|_{m+1/2}.$$

Finally, applying Theorem 4.5 directly to (4.12) and (4.11), respectively, we get

$$\|\chi \boldsymbol{R}_m^{13}\|_{-1} \le C\|\boldsymbol{R}_m^{13}\|_0 \le C t^{m+5/2}\|g\|_{m+1/2},$$

and

$$\|\boldsymbol{R}_m^2\|_{-1} \le \|\boldsymbol{R}_m^2\|_0 \le C t^{m+5/2}\|g\|_{m+1/2}.$$

Since $\boldsymbol{R}_m = \chi \boldsymbol{R}_m^{11} + \chi \boldsymbol{R}_m^{12} + \chi \boldsymbol{R}_m^{13} + \boldsymbol{R}_m^2$, the last three equations imply

$$\|\boldsymbol{R}_m\|_{-1} \le C t^{m+5/2}\|g\|_{m+1/2},$$

as desired. □

5. Error estimates. Let

$$\begin{aligned}\boldsymbol{\phi}_n^E &= \boldsymbol{\phi} - \boldsymbol{\phi}_n^I - \boldsymbol{\phi}_{n-2}^B \\ &= \boldsymbol{\phi} - [\boldsymbol{\phi}_0 + t\boldsymbol{\phi}_1 + \cdots + t^n\boldsymbol{\phi}_n + \chi(t^2\boldsymbol{\Phi}_0 + t^3\boldsymbol{\Phi}_1 + \cdots + t^n\boldsymbol{\Phi}_{n-2})], \\ p_n^E &= p - p_n^I - p_{n-2}^B \\ &= p - [p_0 + tp_1 + \cdots + t^n p_n + \chi(tP_0 + t^2P_1 + \cdots + t^{n-1}P_{n-2})].\end{aligned}$$

Thus $\boldsymbol{\phi}_n^E$ and p_n^E denote the errors in the asymptotic expansions up to order roughly n. Since $\boldsymbol{\phi}_1$ and p_1 vanish,

$$\boldsymbol{\phi}_0^E = \boldsymbol{\phi}_1^E = \boldsymbol{\phi} - \boldsymbol{\phi}_0, \qquad p_0^E = p_1^E = p - p_0.$$

In this section we derive rigorous error bounds for $\boldsymbol{\phi}_n^E$ and p_n^E. In Theorem 5.1 we bound the error in $\boldsymbol{H}^1(\Omega)\times L^2(\Omega)/\mathbb{R}$ and in Theorem 5.2 we bound the error in higher order Sobolev norms.

THEOREM 5.1 (ERROR ESTIMATES FOR $\boldsymbol{\phi}$ AND p IN ENERGY NORM). *There exists a constant C independent of t such that*

$$\|\boldsymbol{\phi}_1^E\|_1 + \|p_1^E\|_{0/\mathbb{R}} + t\|\operatorname{\mathbf{grad}} p_1^E\|_0 \le Ct^{3/2}\|g\|_{-1/2}$$

and for $n \ge 2$

$$\|\boldsymbol{\phi}_n^E\|_1 + \|p_n^E\|_{0/\mathbb{R}} + t\|\operatorname{\mathbf{grad}} p_n^E\|_0 \le C(t^{n+1/2}\|g\|_{n-3/2} + t^{n+3/2}\|g\|_{n-1/2}).$$

Proof. It follows easily from (2.4), (2.5), (2.7), Theorem 4.6, and (4.7)–(4.9) that $(\boldsymbol{\phi}_n^E, p_n^E)$ satisfy the partial differential equations

$$-\operatorname{\mathbf{div}} C\,\mathcal{E}(\boldsymbol{\phi}_n^E) - \operatorname{\mathbf{curl}} p_n^E = -\boldsymbol{R}_{n-2}, \tag{5.1}$$

$$-\operatorname{rot}\boldsymbol{\phi}_n^E + t^2\,\Delta p_n^E = -R_{n-2} \pmod{\mathbb{R}}, \tag{5.2}$$

and the boundary conditions

$$\boldsymbol{\phi}_n^E = 0, \qquad \frac{\partial p_n^E}{\partial n} = -t^{n-1}\frac{\partial p_{n-1}}{\partial n} - t^n\frac{\partial p_n}{\partial n}. \tag{5.3}$$

Writing these equations variationally, we get for all $\boldsymbol{\psi} \in \mathring{\boldsymbol{H}}^1(\Omega)$ and $q \in L^2(\Omega)$ with mean value zero,

$$\begin{aligned}&(C\,\mathcal{E}(\boldsymbol{\phi}_n^E), \mathcal{E}(\boldsymbol{\psi})) - (\operatorname{\mathbf{curl}} p_n^E, \boldsymbol{\psi}) = -(\boldsymbol{R}_{n-2}, \boldsymbol{\psi}), \\ &(\boldsymbol{\phi}_n^E, \operatorname{\mathbf{curl}} q) + t^2(\operatorname{\mathbf{grad}} p_n^E, \operatorname{\mathbf{grad}} q) = (R_{n-2}, q) - t^{n+1}\langle \partial p_{n-1}/\partial n + t\partial p_n/\partial n, q\rangle.\end{aligned} \tag{5.4}$$

Now let

$$\bar{p}_n^E = p_n^E - \frac{1}{\operatorname{meas}\Omega}\int_\Omega p_n^E\,dx$$

denote the difference between p_n^E and its mean value. Choosing $\boldsymbol{\psi} = \boldsymbol{\phi}_n^E$ and $q = \bar{p}_n^E$ and adding the equations, we obtain

$$\begin{aligned}&(C\,\mathcal{E}(\boldsymbol{\phi}_n^E), \mathcal{E}(\boldsymbol{\phi}_n^E)) + t^2(\operatorname{\mathbf{grad}} p_n^E, \operatorname{\mathbf{grad}} p_n^E) \\ &\qquad = -(\boldsymbol{R}_{n-2}, \boldsymbol{\phi}_n^E) + (R_{n-2}, \bar{p}_n^E) - t^{n+1}\langle \partial p_{n-1}/\partial n + t\partial p_n/\partial n, \bar{p}_n^E\rangle.\end{aligned}$$

Applying Korn's inequality and standard estimates, we thus obtain

$$\|\boldsymbol{\phi}_n^E\|_1^2 + t^2\|\operatorname{\mathbf{grad}} p_n^E\|_0^2 \le C(\|\boldsymbol{R}_{n-2}\|_{-1}\|\boldsymbol{\phi}_n^E\|_1 + \|R_{n-2}\|_0\|p_n^E\|_{0/\mathbb{R}} \cdot + t^{n+1}(|\partial p_{n-1}/\partial n|_0 + t|\partial p_n/\partial n|_0)|\bar{p}_n^E|_0).$$

Now

$$|\bar{p}_n^E|_0 \le C\|\bar{p}_n^E\|_0^{1/2}\|\bar{p}_n^E\|_1^{1/2} \le C(t^{-1/2}\|p_n^E\|_{0/\mathbb{R}} + t^{1/2}\|\operatorname{\mathbf{grad}} p_n^E\|_0),$$

so the last term in the previous estimate may be bounded by

$$Ct^{n+1/2}(|\partial p_{n-1}/\partial n|_0 + t|\partial p_{n-1}/\partial n|_0)(\|p_n^E\|_{0/\mathbb{R}} + t\|\operatorname{\mathbf{grad}} p_n^E\|_0).$$

Now choose $\boldsymbol{\psi} \in \mathring{\boldsymbol{H}}^1(\Omega)$ satisfying

$$\operatorname{rot}\boldsymbol{\psi} = \bar{p}_n^E, \qquad \|\boldsymbol{\psi}\|_1 \le C\|p_n^E\|_{0/\mathbb{R}}.$$

(The existence of $\boldsymbol{\psi}$ follows from Lemma 4.2.) From the first variational equation, we obtain

$$\begin{aligned}\|p_n^E\|_{0/\mathbb{R}}^2 &= (p_n^E, \bar{p}_n^E)\\ &= (\boldsymbol{C}\,\boldsymbol{\mathcal{E}}(\boldsymbol{\phi}_n^E), \boldsymbol{\mathcal{E}}(\boldsymbol{\psi})) + (\boldsymbol{R}_{n-2}, \boldsymbol{\psi})\\ &\le C\|\boldsymbol{\psi}\|_1(\|\boldsymbol{\phi}_n^E\|_1 + \|\boldsymbol{R}_{n-2}\|_{-1}),\end{aligned}$$

and so

$$\|p_n^E\|_{0/\mathbb{R}} \le C(\|\boldsymbol{\phi}_n^E\|_1 + \|\boldsymbol{R}_{n-2}\|_{-1}).$$

Combining all these results and using the arithmetic-geometric mean inequality, we obtain

$$\begin{aligned}&\|\boldsymbol{\phi}_n^E\|_1 + \|p_n^E\|_{0/\mathbb{R}} + t\|\operatorname{\mathbf{grad}} p_n^E\|_0\\ &\qquad \le C\left[\|\boldsymbol{R}_{n-2}\|_{-1} + \|R_{n-2}\|_0 + t^{n+1/2}|\partial p_{n-1}/\partial n|_0 + t^{n+3/2}|\partial p_n/\partial n|_0\right].\end{aligned}$$

Note that if $n = 1$, the right-hand side reduces to $Ct^{3/2}|\partial p_0/\partial n|_0$. The theorem follows immediately from this estimate, Corollary 4.4, and Theorem 4.7. □

We now turn to the derivation of error estimates in higher norms.

THEOREM 5.2 (ERROR ESTIMATES FOR $\boldsymbol{\phi}$ AND p IN HIGHER NORMS). *Let $s \ge 2$ be an integer. Then*

$$\|\boldsymbol{\phi}_1^E\|_s + t\|p_1^E\|_{s/\mathbb{R}} \le C(t^{5/2-s}\|g\|_{-1/2} + t\|g\|_{s-2})$$

and for $n \ge 2$

$$\|\boldsymbol{\phi}_n^E\|_s + t\|p_n^E\|_{s/\mathbb{R}} \le C(t^{n+3/2-s}\|g\|_{n-3/2} + t^{n+1}\|g\|_{n+s-2}).$$

Proof. By standard regularity results for the Dirichlet problem for plane elasticity and (5.1),

$$\|\boldsymbol{\phi}_n^E\|_s \le C\|\operatorname{\mathbf{div}} \boldsymbol{C}\,\boldsymbol{\mathcal{E}}(\boldsymbol{\phi}_n^E)\|_{s-2} \le C(\|\operatorname{\mathbf{grad}} p_n^E\|_{s-2} + \|\boldsymbol{R}_{n-2}\|_{s-2}). \tag{5.5}$$

Using regularity for the Neumann problem for the Laplacian and (5.2) and (5.3), we similarly obtain

$$\|p_n^E\|_{s/\mathbb{R}} \le C\left(\|\Delta p_n^E\|_{s-2/\mathbb{R}} + \left|\frac{\partial p_n^E}{\partial n}\right|_{s-3/2}\right)$$
$$\le C\left(t^{-2}\|\operatorname{rot}\boldsymbol{\phi}_n^E\|_{s-2} + t^{-2}\|R_{n-2}\|_{s-2} + t^{n-1}\left|\frac{\partial p_{n-1}}{\partial n}\right|_{s-3/2} + t^n\left|\frac{\partial p_n}{\partial n}\right|_{s-3/2}\right).$$

Combining these results and using Corollary 4.4 and Theorem 4.7, we get for $n \ge 1$, $s \ge 2$,

$$\|\boldsymbol{\phi}_n^E\|_s + t\|p_n^E\|_{s/\mathbb{R}} \le C\left(\|\mathbf{grad}\, p_n^E\|_{s-2} + \|\boldsymbol{R}_{n-2}\|_{s-2} + t^{-1}\|\operatorname{rot}\boldsymbol{\phi}_n^E\|_{s-2}\right.$$
$$\left. + t^{-1}\|R_{n-2}\|_{s-2} + t^n\left|\frac{\partial p_{n-1}}{\partial n}\right|_{s-3/2} + t^{n+1}\left|\frac{\partial p_n}{\partial n}\right|_{s-3/2}\right)$$
$$\le C(\|p_n^E\|_{s-1/\mathbb{R}} + t^{-1}\|\boldsymbol{\phi}_n^E\|_{s-1} + t^{n+3/2-s}\|g\|_{n-3/2}$$
$$+ t^{n+1/2}\|g\|_{n+s-5/2} + t^n\|g\|_{n+s-3} + t^{n+1}\|g\|_{n+s-2}).$$

Since $\boldsymbol{R}_{-1}$, R_{-1}, and p_1 vanish, for $n = 1$ we can simplify this result to

$$\|\boldsymbol{\phi}_1^E\|_s + t\|p_1^E\|_{s/\mathbb{R}} \le C(\|p_1^E\|_{s-1/\mathbb{R}} + t^{-1}\|\boldsymbol{\phi}_1^E\|_{s-1} + t\|g\|_{s-2}).$$

Thus

$$\|\boldsymbol{\phi}_n^E\|_s + t\|p_n^E\|_{s/\mathbb{R}}$$
$$\le \begin{cases} C(\|p_1^E\|_{s-1/\mathbb{R}} + t^{-1}\|\boldsymbol{\phi}_1^E\|_{s-1} + t\|g\|_{s-2}), & n = 1, \\ C(\|p_n^E\|_{s-1/\mathbb{R}} + t^{-1}\|\boldsymbol{\phi}_n^E\|_{s-1} + t^{n+3/2-s}\|g\|_{n-3/2} + t^{n+1}\|g\|_{n+s-2}), & n \ge 2. \end{cases}$$

For $s = 2$, the theorem follows from this relation and Theorem 5.1. We can complete the proof using this relation and a simple induction on s. □

As a consequence of Theorems 5.1, 5.2, and 4.3, we easily obtain bounds on $\boldsymbol{\phi}$ and p.

THEOREM 5.3 (BOUNDS ON $\boldsymbol{\phi}$ AND p).

$$\|\boldsymbol{\phi}\|_s \le C(t^{5/2-s}\|g\|_{-1/2} + t\|g\|_{s-2} + |||g|||_{s-3}), \qquad s = 1, 2, \cdots,$$
$$\|p\|_{s/\mathbb{R}} \le C(t^{3/2-s}\|g\|_{-1/2} + |||g|||_{s-2}), \qquad s \in \mathbb{N}.$$

Proof. From Theorems 5.1 and 5.2 we have

$$\|p_1^E\|_{s/\mathbb{R}} \le C(t^{3/2-s}\|g\|_{-1/2} + |||g|||_{s-2}), \qquad s \in \mathbb{N}.$$

By Theorem 4.3,

$$\|p_0\|_{s/\mathbb{R}} \le C|||g|||_{s-2}.$$

Applying the triangle inequality, we obtain

$$\|p\|_{s/\mathbb{R}} \le \|p_1^E\|_{s/\mathbb{R}} + \|p_0\|_{s/\mathbb{R}} \le C(t^{3/2-s}\|g\|_{-1/2} + |||g|||_{s-2}).$$

A similar argument gives the estimate on ϕ. □

We may use the interpolation property of the Sobolev norms to obtain bounds on $\|\phi_n^E\|_s$ and $\|p_n^E\|_s$ for noninteger s similar to those given in Theorems 5.1 and 5.2 for integer s. In particular we have

$$\begin{aligned}\|\phi_1^E\|_{5/2} &\le C(\|\phi_1^E\|_2\|\phi_1^E\|_3)^{1/2}\\ &\le C[(t^{1/2}\|g\|_{-1/2}+t\|g\|_0)(t^{-1/2}\|g\|_{-1/2}+t\|g\|_1)]^{1/2}\\ &\le C(\|g\|_{-1/2}+t^{3/2}\|g\|_1)\end{aligned}$$

and, similarly,

$$\begin{aligned}\|p_1^E\|_{3/2/\mathbf{R}} &\le C(\|p_1^E\|_{1/\mathbf{R}}\|p_1^E\|_{2/\mathbf{R}})^{1/2}\\ &\le C[t^{1/2}\|g\|_{-1/2}(t^{-1/2}\|g\|_{-1/2}+\|g\|_0)]^{1/2}\\ &\le C(\|g\|_{-1/2}+t^{1/2}\|g\|_0).\end{aligned}$$

Combining with Theorem 4.3 as above, we get

$$\|\phi\|_{5/2} \le C(\|g\|_{-1/2}+t^{3/2}\|g\|_1), \tag{5.6}$$

$$\|p\|_{3/2/\mathbf{R}} \le C(\|g\|_{-1/2}+t^{1/2}\|g\|_0). \tag{5.7}$$

In general, however, higher norms of ϕ and p do not remain bounded as $t \to 0$.

Thus far our estimates have all been in the L^2-based Sobolev spaces H^s. In closing this section, we note that our asymptotic expansions and error estimates can be used to study the dependence of the solution on t in many other function spaces as well, for example in the L^p-based Sobolev spaces W_p^s or the Hölder spaces $C^{m,\alpha}$. To determine the behavior of the norm $\|\phi\|_{W_\infty^s}$ with respect to t, for example, we may write $\phi = \phi_n^E + \phi_n^I + \phi_{n-2}^B$. Now, assuming g is sufficiently smooth, $\|\phi_n^E\|_{n+3/2}$ is bounded uniformly in t. Hence, if n is sufficiently large ($n > s - \frac{1}{2}$ in this case), then the Sobolev Embedding Theorem implies that $\|\phi_n^E\|_{W_\infty^s}$ is bounded uniformly. Each of the interior expansion functions is bounded in all the H^s spaces, so $\|\phi_n^I\|_{W_\infty^s}$ is also bounded uniformly. Thus the behavior of ϕ is determined by that of $\phi_{n-2}^B = \chi(t^2\Phi_0+t^3\Phi_1+\cdots+t^n\Phi_{n-2})$. Since we have quite explicit expressions for the boundary correctors (Theorem 3.3), it is not difficult to determine the behavior of ϕ_{n-2}^B. We see that $\|\phi_{n-2}^B\|_{W_\infty^s} = O(t^{2-s})$. Thus

$$\|\phi\|_{W_\infty^s} = O(t^{\min(2-s,0)}).$$

Estimates of other quantities, including the errors in the partial sums of the asymptotic expansions can be derived similarly. With a little effort we can get a bound which indicates explicitly the dependence of the norm on the load function g as well. However, we do not expect that the required regularity on g in these estimates (and in some of the previous ones as well) is optimal.

6. Asymptotic expansion of the transverse displacement and shear. In the previous sections we obtained and justified an asymptotic expansion for the rotation variable ϕ. We now turn to the other primitive variable, ω, and obtain an expansion for it. In contrast to ϕ, we will see that ω has no boundary layer.

Define the auxiliary variable $v = \omega - t^2 r$. Clearly $v = 0$ on $\partial\Omega$ and, from (2.6), $\Delta v = \operatorname{div} \phi$. Then, taking the divergence of (2.4) and substituting (2.3), we easily compute that $D\Delta^2 v = D\Delta \operatorname{div} \phi = g$. Next, note that $\mathbf{grad}\, v = \mathbf{grad}\, w - t^2\, \mathbf{grad}\, r = \phi + t^2\, \mathbf{curl}\, p$. Since ϕ vanishes on $\partial\Omega$,

$$\frac{\partial v}{\partial n} = -t^2 \frac{\partial p}{\partial s} \quad \text{on } \partial\Omega.$$

Thus v is completely characterized as the solution of a certain Dirichlet problem for the biharmonic operator, and it is easy to see how to expand it in powers of t. For $i \in \mathbb{N}$, define v_i by the biharmonic problem

$$D\Delta^2 v_i = \begin{cases} g, & i = 0, \\ 0, & i \geq 1, \end{cases} \quad \text{in } \Omega,$$

$$v_i = 0, \quad \partial v_i/\partial n = \begin{cases} 0, & i = 0, 1, \\ -\partial p_0/\partial s, & i = 2 \\ -\partial p_{i-2}/\partial s - \partial P_{i-3}/\partial s, & i \geq 3, \end{cases} \quad \text{on } \partial\Omega.$$

The coefficients in the asymptotic expansion of ω are then given by

$$\omega_i = \begin{cases} v_i, & i \neq 2, \\ v_2 + r, & i = 2. \end{cases}$$

Note that ω_0 satisfies the boundary value problem

$$D\Delta^2 \omega_0 = g \quad \text{in } \Omega, \qquad \omega_0 = \frac{\partial \omega_0}{\partial n} = 0 \quad \text{on } \partial\Omega.$$

It is useful to express the first terms of the expansions for w and ϕ in terms of ω_0. First of all, there is a simple relation between ω_0 and ϕ_0.

THEOREM 6.1.

$$\phi_0 = \mathbf{grad}\, \omega_0.$$

Proof. From (3.10) and (3.9), it follows that $\phi_0 = \mathbf{grad}\, \mu$ for some $\mu \in \mathring{H}^2(\Omega)$. Inserting in (3.7) and taking the divergence gives

$$D\Delta^2 \mu = -\Delta r = g.$$

Comparing with the defining equations for ω_0, we see that $\mu = \omega_0$. □

Clearly $\omega_1 = v_1 = 0$ and $\omega_2 = v_2 + r$, where

$$\Delta^2 v_2 = 0 \quad \text{in } \Omega, \qquad v_2 = 0, \quad \partial v_2/\partial n = -\partial p_0/\partial s \quad \text{on } \partial\Omega, \tag{6.1}$$

$$\Delta r = -g \quad \text{in } \Omega, \qquad r = 0 \quad \text{on } \partial\Omega. \tag{6.2}$$

Now, from (3.7),

$$\frac{\partial p_0}{\partial s} = \mathbf{div}\, C\, \mathcal{E}(\phi_0) \cdot \boldsymbol{n} + \frac{\partial r}{\partial n} = D\frac{\partial \Delta \omega_0}{\partial n} + \frac{\partial r}{\partial n}. \tag{6.3}$$

$$\frac{\partial p_0}{\partial n} = -\mathbf{div}\, C\, \mathcal{E}(\phi_0) \cdot \boldsymbol{s} = -D\frac{\partial \Delta \omega_0}{\partial s}. \tag{6.4}$$

Using (6.3) in (6.1) and combining with (6.2), we get

$$\Delta^2 \omega_2 = -\Delta g \quad \text{on } \Omega, \qquad \omega_2 = 0, \quad \frac{\partial \omega_2}{\partial n} = -D\frac{\partial \Delta \omega_0}{\partial n},$$

which is a biharmonic problem for ω_2. From the definitions, $\omega_3 = v_3$ is a biharmonic function vanishing on $\partial\Omega$ with $\partial\omega_3/\partial n = -\partial P_0/\partial s$ (since $p_1 = 0$). Using (3.20) and (6.4) to simplify the latter boundary condition gives the following biharmonic problem for ω_3:

$$\Delta^2 \omega_3 = 0 \quad \text{in } \Omega, \qquad \omega_3 = 0, \quad \frac{\partial \omega_3}{\partial n} = -\frac{D}{c}\frac{\partial^2}{\partial s^2}\Delta\omega_0 \quad \text{on } \partial\Omega.$$

Turning to the expansion for $\boldsymbol{\phi}$, the expression for $\boldsymbol{\Phi}_0$ in (3.20) becomes, in light of (6.4),

$$\hat{\boldsymbol{\Phi}}_0(\hat{\rho}, \theta) = -D\frac{\partial \widehat{\Delta \omega_0}}{\partial s}(0, \theta) e^{-c\hat{\rho}} \boldsymbol{s}. \tag{6.5}$$

To determine $\boldsymbol{\phi}_2$, we note from (3.10) that $\operatorname{rot} \boldsymbol{\phi}_2$ is constant. Since

$$\int_\Omega \operatorname{rot} \boldsymbol{\phi}_2 = -\int_{\partial\Omega} \boldsymbol{\phi}_2 \cdot \boldsymbol{s} = \int_{\partial\Omega} \boldsymbol{\Phi}_0 \cdot \boldsymbol{s} = 0,$$

$\operatorname{rot} \boldsymbol{\phi}_2 = 0$ and $\boldsymbol{\phi}_2 = \mathbf{grad}\, \psi$ for some function ψ. Substituting in (3.7) and taking the divergence shows that ψ is biharmonic. Then the boundary conditions $\mathbf{grad}\, \psi = -\boldsymbol{\Phi}_0$ on $\partial\Omega$ determine ψ modulo $\mathbb{R}$ and $\boldsymbol{\phi}_2$ completely. In light of (6.5), the boundary conditions on ψ become

$$\psi = D\Delta\omega_0 \pmod{\mathbb{R}}, \quad \partial\psi/\partial n = 0 \quad \text{on } \partial\Omega.$$

We now obtain a priori estimates for the ω_i and error estimates for the finite sums of the expansion.

THEOREM 6.2 (A PRIORI ESTIMATES FOR THE ω_i). *Let $i \in \mathbb{N}$, $s \geq 2$. Then*

$$\|\omega_i\|_s \leq C |||g|||_{s+i-4}.$$

Proof. This follows easily from regularity for the biharmonic equation, Corollary 4.4, and (4.5). □

Let $\omega_n^E = \omega - \sum_{i=0}^n t^i \omega_i$ denote the error in the partial sums of the asymptotic expansion

$$\omega \sim \sum_{i=0}^{\infty} t^i \omega_i.$$

The next theorem bounds the error in expansion. Note that the order of the error is the same in all Sobolev norms, reflecting the fact that ω does not involve a boundary layer.

THEOREM 6.3 (ERROR ESTIMATES FOR ω). *For $n = 1, 2, \cdots$ and $s = 1, 2, \cdots$*

$$\|\omega_n^E\|_s \leq C(t^{n+1}\|g\|_{n+s-3} + t^{n+s+1}\|g\|_{n+2s-3}).$$

Proof. Set $v_n^E = v - \sum_{i=0}^n t^i v_i$. Note that $\omega_n^E = v_n^E$ for $n > 1$, and $\omega_1^E = v_1^E + t^2 r$, so it suffices to prove the theorem with ω_n^E replaced by v_n^E.

Now

$$D\,\Delta^2 v_n^E = 0 \quad \text{in } \Omega,$$
$$v_n^E = 0 \quad \text{on } \partial\Omega,$$

and

$$\begin{aligned}\frac{\partial v_n^E}{\partial n} &= -t^2 \frac{\partial}{\partial s}(p - p_{n-2}^I - p_{n-3}^B) \\ &= -t^2 \frac{\partial}{\partial s}\left(p_{n+s-1}^E + \sum_{i=n-1}^{n+s-1} t^i p_i + \sum_{i=n-1}^{n+s-2} t^i P_{i-1}\right).\end{aligned}$$

Thus, using regularity results for the biharmonic problem,

$$\begin{aligned}\|v_n^E\|_s &\le C \left|\frac{\partial v_n^E}{\partial n}\right|_{s-3/2} \\ &\le Ct^2 \left(\|p_{n+s-1}^E\|_{s/\mathbf{R}} + \sum_{i=n-1}^{n+s-1} t^i \|p_i\|_{s/\mathbf{R}} + \sum_{i=n-1}^{n+s-2} t^i |P_{i-1}|_{s-1/2}\right).\end{aligned}$$

Applying Theorem 5.1 or 5.2, Theorem 4.3, and Corollary 4.4, we get

$$\begin{aligned}\|v_n^E\|_s &\le Ct^2 \left(t^{n-1/2}\|g\|_{n+s-5/2} + t^{n+s-1}\|g\|_{n+2s-3} + \sum_{i=n-1}^{n+s-1} t^i \|g\|_{i+s-2}\right) \\ &\le C(t^{n+1}\|g\|_{n+s-3} + t^{n+s+1}\|g\|_{n+2s-3}),\end{aligned}$$

as desired. □

Using a similar argument, we can also obtain regularity estimates for ω in $H^s(\Omega)$ uniform with respect to t.

THEOREM 6.4. *For $s = 2, 3, \cdots$ there exists a constant C independent of t such that*

$$\|\omega\|_s \le C(\|g\|_{s-4} + t^2\|g\|_{s-2}), \quad s = 2, 3,$$
$$\|\omega\|_s \le C(\|g\|_{s-4} + t^s\|g\|_{2s-4}), \quad s \ge 4.$$

Proof. Using standard regularity results for the biharmonic problem and (4.5), we get

$$\|\omega\|_s \le \|v\|_s + t^2\|r\|_s \le C(\|g\|_{s-4} + t^2|\partial p/\partial s|_{s-3/2} + t^2\|g\|_{s-2}). \tag{6.6}$$

When $s \ge 4$, we substitute $p = \sum_{i=0}^{s-2} t^i p_i + \chi \sum_{i=0}^{s-4} t^{i+1} P_i + p_{s-2}^E$, into (6.6) and apply Corollary 4.4 and Theorem 5.2 to estimate the right-hand side, obtaining

$$\|\omega\|_s \le C\left(\|g\|_{s-4} + \sum_{i=0}^{s-2} t^{i+2}\|g\|_{s+i-2} + \sum_{i=0}^{s-4} t^{i+3}\|g\|_{s+i-1} + t^{1/2}\|g\|_{s-7/2}\right),$$

which gives the desired result.

When $s = 2$ or $s = 3$, we substitute $p = p_0 + p_1^E$ into (6.6) and complete the proof with a similar argument. □

Recall that the scaled transverse shear stress is given by $\boldsymbol{\zeta} = t^{-2}(\mathbf{grad}\,\omega - \boldsymbol{\phi})$, which we decomposed as $\mathbf{grad}\,r + \mathbf{curl}\,p$. We can obtain an asymptotic expansion for the shear stress from either of these expressions, in the former case noting a cancellation due to Theorem 6.1. Thus, formally,

$$\begin{aligned}\boldsymbol{\zeta} &\sim (\mathbf{grad}\,\omega_2 - \boldsymbol{\phi}_2) + t(\mathbf{grad}\,\omega_3 - \boldsymbol{\phi}_3) + \cdots - \chi(\boldsymbol{\Phi}_0 + t\boldsymbol{\Phi}_1 + \cdots)\\ &\sim (\mathbf{grad}\,r + \mathbf{curl}\,p_0) + t^2\,\mathbf{curl}\,p_2 + t^3\,\mathbf{curl}\,p_3 + \cdots + \chi(t\,\mathbf{curl}\,P_0 + t^2\,\mathbf{curl}\,P_1 + \cdots).\end{aligned}$$

In light of our previous results, it is straightforward to bound the individual terms in either of these expansions as well as the remainders when the expansions are terminated. Here we content ourselves with determining the regularity of the shear stress vector and its dependence on t.

THEOREM 6.5. *Let $s \geq -1$ be an integer. Then there exists a constant C independent of t such that*

$$\|\boldsymbol{\zeta}\|_s \leq C(t^{1/2-s}\|g\|_{-1/2} + |||g|||_{s-1}).$$

Proof. This follows immediately from Theorem 5.3 and (4.5). □

Similar bounds hold in the noninteger order Sobolev spaces. In particular,

$$\|\boldsymbol{\zeta}\|_{1/2} \leq C(\|g\|_{-1/2} + t^{1/2}\|g\|_0),$$

as follows immediately from (4.5) and (5.7). In general $\|\boldsymbol{\zeta}\|_s$ will blow up as $t \to 0$ if $s > 1/2$. Thus the shear stress evidences a rather strong boundary layer.

7. Hard simply-supported boundary conditions. Two sets of boundary conditions are commonly used with the Reissner–Mindlin equations to model a simply-supported plate. Boundary conditions for a hard simply-supported plate are

$$M_n\boldsymbol{\phi} = 0, \quad \boldsymbol{\phi}\cdot\boldsymbol{s} = 0, \quad w = 0,$$

where $M_n\boldsymbol{\phi} = \boldsymbol{n}^t\mathcal{C}\,\mathcal{E}(\boldsymbol{\phi})\boldsymbol{n}$, or, in (ρ,θ) coordinates,

$$\widetilde{M_n\boldsymbol{\phi}} = D\left(-\frac{\partial\tilde{\boldsymbol{\phi}}}{\partial\rho}\cdot\boldsymbol{n} + \nu\frac{\partial\tilde{\boldsymbol{\phi}}}{\partial\theta}\cdot\boldsymbol{s}\right).$$

(For a soft simply-supported plate the condition $\boldsymbol{\phi}\cdot\boldsymbol{s} = 0$ is replaced by $\boldsymbol{s}^t\mathcal{C}\,\mathcal{E}(\boldsymbol{\phi})\boldsymbol{n} = 0$. Thus, in both cases the lateral edge of the undisplaced plate is not permitted to displace vertically. In the soft case a vertical fiber on the lateral edge is permitted to rotate freely, while in the hard case it may only rotate in the plane normal to the edge. The soft conditions would seem to be easier to realize in practice.)

The boundary layer analysis for the hard simply-supported plate, which we consider in this section, is very similar to that for the clamped plate. The soft simply-supported plate has a significantly stronger boundary layer which will be investigated in a subsequent paper.

The only difference in the asymptotic expansions themselves for the hard simply-supported Reissner–Mindlin plate and the clamped plate is that the boundary conditions for the problems defining the interior expansion functions must be modified. All

the major estimates for the expansion functions and all the error analysis carries over. However, at a few places in the analysis additional terms must be considered. In this section we indicate very briefly these additional considerations.

As in the case of the clamped plate, we use the decomposition of the shear stress vector, given by formula (2.2). We then obtain the reformulation of (2.3)–(2.6), where the boundary conditions (2.7) are replaced by:

$$r = 0, \quad \boldsymbol{\phi} \cdot \boldsymbol{s} = 0, \quad M_n \boldsymbol{\phi} = 0, \quad \partial p / \partial n = 0, \quad w = 0.$$

The forms of the asymptotic expansions for $\boldsymbol{\phi}$ and p are the same as those given in § 3 for the clamped plate, and the interior approximations satisfy the same partial differential equations (3.7), (3.10), but the boundary conditions (3.9) are replaced by

$$\boldsymbol{\phi}_i \cdot \boldsymbol{s} = \begin{cases} 0, & i = 0, 1, \\ -\hat{\boldsymbol{\Phi}}_{i-2} \cdot \boldsymbol{s}, & i \geq 2, \end{cases}$$

and

$$M_n \boldsymbol{\phi}_i = \begin{cases} 0, & i = 0, \\ D(\partial \hat{\boldsymbol{\Phi}}_0 / \partial \hat{\rho}) \cdot \boldsymbol{n}, & i = 1, \\ D[(\partial \hat{\boldsymbol{\Phi}}_{i-1} / \partial \hat{\rho}) \cdot \boldsymbol{n} - \nu (\partial \hat{\boldsymbol{\Phi}}_{i-2} / \partial \theta) \cdot \boldsymbol{s}], & i \geq 2. \end{cases}$$

The boundary correctors are again defined by (3.16)–(3.19). Thus, the analysis in § 3 remains valid. In particular, Theorem 3.3 still holds and the formula for the first boundary corrector is again (3.20). It follows immediately that $M_n \boldsymbol{\phi}_1 = 0$ on $\partial\Omega$ and hence $\boldsymbol{\phi}_1 = 0$, $p_1 = 0$.

To bound the errors in the asymptotic expansions, we need analogues of the results proved in § 4. From the form of the boundary correctors (given in Theorem 3.3), we get immediately that

$$|\boldsymbol{\Phi}_i|_s + t \left| \frac{\partial \boldsymbol{\Phi}_i}{\partial n} \right|_s \leq C \sum_{j=0}^{i} \left| \frac{\partial p_j}{\partial n} \right|_{s+i-j}, \tag{7.1}$$

for all $s \in \mathbb{R}$, $i \in \mathbb{N}$. To estimate the interior expansion functions we use the following analogue of Lemma 4.2.

LEMMA 7.1. *Let $s \in \mathbb{N}$, $f \in H^s(\Omega) \cap \mathring{H}^1(\Omega)$, $g \in H^s(\Omega)/\mathbb{R}$, $k \in H^{s+1/2}(\partial\Omega)$, and $l \in H^{s-1/2}(\partial\Omega)$ be given. Then there exist unique $\boldsymbol{\psi} \in \boldsymbol{H}^{s+1}(\Omega)$, $q \in H^s(\Omega)/\mathbb{R}$ satisfying the partial differential equations*

$$-\operatorname{\mathbf{div}} \boldsymbol{C}\, \boldsymbol{\mathcal{E}}(\boldsymbol{\psi}) - \operatorname{\mathbf{curl}} q = \operatorname{\mathbf{grad}} f, \tag{7.2}$$

$$-\operatorname{rot} \boldsymbol{\psi} = g \pmod{\mathbb{R}}, \tag{7.3}$$

and the boundary conditions

$$\boldsymbol{\psi} \cdot \boldsymbol{s} = k, \qquad M_n \boldsymbol{\psi} = l.$$

Moreover, there exists a constant C depending only on s, E, ν, and Ω such that

$$\|\boldsymbol{\psi}\|_{s+1} + \|q\|_{s/\mathbb{R}} \leq C(\|f\|_s + \|g\|_{s/\mathbb{R}} + |k|_{s+1/2} + |l|_{s-1/2}).$$

Proof. The weak form of the boundary value problem is to find $\boldsymbol{\psi} \in \boldsymbol{H}^1(\Omega)$ such that $\boldsymbol{\psi} \cdot \boldsymbol{s} = k$ on $\partial\Omega$ and $q \in L^2(\Omega)/\mathbb{R}$ satisifying

$$\begin{aligned}(\mathcal{C}\,\mathcal{E}(\boldsymbol{\psi}), \mathcal{E}(\boldsymbol{\mu})) - (q, \operatorname{rot} \boldsymbol{\mu}) &= -(f, \operatorname{div} \boldsymbol{\mu}) + \langle l, \boldsymbol{\mu} \cdot \boldsymbol{n} \rangle, \\ -(\operatorname{rot} \boldsymbol{\psi}, v) &= (g, v),\end{aligned}$$

for all $\boldsymbol{\mu} \in \boldsymbol{H}^1(\Omega)$ such that $\boldsymbol{\mu} \cdot \boldsymbol{s} = 0$ on $\partial\Omega$ and all $v \in L^2(\Omega)$ of mean value zero. Existence and uniqueness of a solution in $\boldsymbol{H}^1(\Omega) \times L^2(\Omega)/\mathbb{R}$ is proved just as for the generalized Stokes equations, e.g., by applying Brezzi's theorem [4]. The estimate for $s = 0$ follows from the same argument. To establish the claimed regularity for $s \geq 1$, we apply the Helmholtz decomposition to $\boldsymbol{\psi}$ to get $\boldsymbol{\psi} = \mathbf{grad}\, z + \mathbf{curl}\, b$, with $z \in \mathring{H}^1(\Omega)$, $b \in H^1(\Omega)/\mathbb{R}$. Now, it suffices to show that

$$\|b\|_{s+2/\mathbb{R}} + \|z\|_{s+2} \leq C(\|f\|_s + \|g\|_{s/\mathbb{R}} + |k|_{s+1/2}), \quad s \in \mathbb{N},$$

since this gives the estimate on $\boldsymbol{\psi}$ immediately, and that on q then follows from (7.2).

From (7.3) we have

$$\Delta b = g \pmod{\mathbb{R}} \quad \text{in } \Omega,$$

with boundary conditions $\partial b/\partial n = k$, so the desired bound on b follows from regularity for the Neumann problem for Laplace's equation. We prove the desired estimate for z by induction on s. The case $s = 0$ follows from the bound on $\|\boldsymbol{\psi}\|_1$ since $z = \operatorname{div} \boldsymbol{\psi}$. Thus we assume that s is a positive integer.

Let $w = D\,\Delta z + f$. Since

$$\begin{aligned}M_n(\mathbf{grad}\, z) &= D\left[\Delta z - (1-\nu)\left(\frac{\partial^2 z}{\partial s^2} + \kappa \frac{\partial z}{\partial n}\right)\right], \\ M_n(\mathbf{curl}\, b) &= D(1-\nu)\left(-\frac{\partial}{\partial s}\frac{\partial b}{\partial n} + \kappa \frac{\partial b}{\partial s}\right),\end{aligned}$$

the boundary conditions for $\boldsymbol{\psi}$ imply that

$$w - f = D\,\Delta z = l + D(1-\nu)(\partial^2 z/\partial s^2 + \kappa \partial z/\partial n + \partial k/\partial s - \kappa \partial b/\partial s) \quad \text{on } \partial\Omega,$$

or, since z and f vanish on $\partial\Omega$,

$$w = l + D(1-\nu)(\kappa \partial z/\partial n + \partial k/\partial s - \kappa \partial b/\partial s) \quad \text{on } \partial\Omega.$$

Now, taking the divergence of equation (7.2) gives

$$-D\,\Delta^2 z = \Delta f \quad \text{in } \Omega.$$

so w is harmonic. Applying regularity for the Dirichlet problem for Laplace's equation then gives

$$\begin{aligned}\|w\|_s &\leq C(|\partial z/\partial n|_{s-1/2} + |\partial k/\partial s|_{s-1/2} + |\partial b/\partial s|_{s-1/2}) \\ &\leq C(\|z\|_{s+1} + |k|_{s+1/2} + \|b\|_{s+1/\mathbb{R}}) \\ &\leq C(\|z\|_{s+1} + |k|_{s+1/2} + \|g\|_{s/\mathbb{R}}).\end{aligned}$$

Finally z satisfies

$$-\Delta z = D^{-1}(f - w) \quad \text{in } \Omega, \qquad z = 0 \quad \text{on } \partial\Omega,$$

so another application of regularity for the Dirichlet problem shows that

$$\|z\|_{s+2} \le C(\|f\|_s + \|w\|_s) \le C(\|f\|_s + \|g\|_{s/\mathbf{R}} + |k|_{s+1/2} + \|z\|_{s+1}),$$

and the proof is completed by induction. □

Using this result and (7.1), it follows that Theorem 4.3 holds also in the hard simply-supported case, and then that Theorem 4.5 also remains valid.

Turning to the finite interior and boundary expansions, Theorem 4.6 and Theorem 4.7 hold as before. However, in order to prove the analogue of Theorem 5.1, we need a slight refinement of the estimate of $\|\boldsymbol{R}_m\|_{-1}$.

THEOREM 7.2. *If $\boldsymbol{\psi} \in \boldsymbol{H}^1(\Omega)$ satisfies $\boldsymbol{\psi} \cdot \boldsymbol{s} = 0$ on $\partial\Omega$ and $m \in \mathbb{N}$, then*

$$\left|(\boldsymbol{R}_m, \boldsymbol{\psi}) - t^{m+3}\left\langle D\frac{\partial \boldsymbol{\Phi}_{m+1}}{\partial n} \cdot \boldsymbol{n}, \boldsymbol{\psi} \cdot \boldsymbol{n}\right\rangle\right| \le Ct^{m+5/2}\|g\|_{m+1/2}\|\boldsymbol{\psi}\|_1.$$

Proof. The proof is very close to that of the H^{-1} estimate in Theorem 4.7. The only difference is that instead of (4.14) we must show that

$$\left|(\chi \boldsymbol{R}_m^{11}, \boldsymbol{\psi}) - t^{m+3}\left\langle D\frac{\partial \boldsymbol{\Phi}_{m+1}}{\partial n} \cdot \boldsymbol{n}, \boldsymbol{\psi} \cdot \boldsymbol{n}\right\rangle\right| \le Ct^{m+5/2}\|g\|_{m+1/2}\|\boldsymbol{\psi}\|_1 \tag{7.4}$$

(which is the same as (4.14) for $\boldsymbol{\psi} \in \mathring{\boldsymbol{H}}^1(\Omega)$). Since $\boldsymbol{\psi}$ does not vanish on the boundary, when we integrate by parts in (4.13) we get a boundary term:

$$\begin{aligned}(\chi \boldsymbol{R}_m^{11}, \boldsymbol{\psi}) &= t^{m+2}\int_0^L\int_0^{\rho_0}\left(\hat{\mathcal{A}}_0 t\frac{\partial \tilde{\boldsymbol{\Phi}}_{m+1}}{\partial \rho} + \hat{\boldsymbol{A}}_5 \tilde{P}_{m+1}\right)\frac{\partial}{\partial \rho}\left\{\tilde{\chi}(\rho)\tilde{\boldsymbol{\psi}}(\rho,\theta)[1-\kappa(\theta)\rho]\right\} d\rho d\theta \\ &\qquad - t^{m+2}\left\langle \mathcal{A}_0 t\frac{\partial \boldsymbol{\Phi}_{m+1}}{\partial n} - \boldsymbol{A}_5 P_{m+1}, \boldsymbol{\psi}\right\rangle.\end{aligned}$$

Now $\boldsymbol{A}_5 \cdot \boldsymbol{\psi} = \boldsymbol{s} \cdot \boldsymbol{\psi} \equiv 0$ and $\mathcal{A}_0\boldsymbol{\psi} = \mathcal{A}_0\boldsymbol{n}(\boldsymbol{\psi} \cdot \boldsymbol{n}) = -D\boldsymbol{n}(\boldsymbol{\psi} \cdot \boldsymbol{n})$, so

$$\left\langle \mathcal{A}_0 t\frac{\partial \boldsymbol{\Phi}_{m+1}}{\partial n} - \boldsymbol{A}_5 P_{m+1}, \boldsymbol{\psi}\right\rangle = -t\left\langle D\frac{\partial \boldsymbol{\Phi}_{m+1}}{\partial n} \cdot \boldsymbol{n}, \boldsymbol{\psi} \cdot \boldsymbol{n}\right\rangle.$$

The proof of inequality (7.4) and the remainder of the theorem now proceed just as in Theorem 4.7. □

Defining $\boldsymbol{\phi}_n^E$ and p_n^E as in § 5, we see that they again satisfy the partial differential equations (5.1) and (5.2). The boundary conditions now become

$$\boldsymbol{\phi}_n^E \cdot \boldsymbol{s} = 0, \qquad M_n\boldsymbol{\phi}_n^E = t^{n+1}D\frac{\partial \boldsymbol{\Phi}_{n-1}}{\partial n} \cdot \boldsymbol{n}, \qquad \frac{\partial p_n^E}{\partial n} = -t^{n-1}\frac{\partial p_{n-1}}{\partial n} - t^n\frac{\partial p_n}{\partial n},$$

and the variational equation (5.4) which enters the proof of Theorem 5.1 thus becomes

$$(C\,\mathcal{E}(\boldsymbol{\phi}_n^E), \mathcal{E}(\boldsymbol{\psi})) - (\mathbf{curl}\, p_n^E, \boldsymbol{\psi}) = -(\boldsymbol{R}_{n-2}, \boldsymbol{\psi}) + t^{n+1}D\left\langle \frac{\partial \boldsymbol{\Phi}_{n-1}}{\partial n} \cdot \boldsymbol{n}, \boldsymbol{\psi} \cdot \boldsymbol{n}\right\rangle,$$

valid for ψ with vanishing tangential component on $\partial\Omega$. We bounded the right-hand side of this equation in Theorem 7.2. This is the only additional consideration in establishing Theorem 5.1 in the hard simply-supported case.

The higher-order estimates in Theorem 5.2 also carry over to the present case, but again there is an additional term to be bounded because ϕ_n^E does not vanish on $\partial\Omega$. The bound for $\|\phi_n^E\|_s$ given in (5.5) must be modified to include the additional term

$$t^{n+1}\left|\frac{\partial \Phi_{n-1}}{\partial n}\cdot \boldsymbol{n}\right|_{s-3/2}.$$

In view of (7.1) and Theorem 4.3, this term is easily bounded by $t^n\|g\|_{s+n-3}$, which is no larger than other terms which were treated in the proof of Theorem 5.2. Of course, once Theorems 4.3, 5.1, and 5.2 are established, the regularity results given in Theorem 5.3 follow.

An asymptotic expansion and regularity results for the transverse displacement and the shear stress can be developed as in § 6. Naturally the boundary conditions in the defining problems for the expansion functions are changed. The boundary conditions on ϕ and p imply that $v = \omega - t^2 r$ satisfies, in addition to the differential equation $D\,\Delta^2 v = g$, the boundary conditions

$$v = 0, \qquad (1-\nu)\partial^2 v/\partial n^2 + \nu\,\Delta\, v = t^2(1-\nu)\kappa\partial p/\partial s \quad \text{on } \partial\Omega,$$

where κ denotes the curvature of $\partial\Omega$. It is then clear how to define the regular expansion for v and hence ω, and all the analysis of § 6 carries over easily.

Appendix. In this appendix we give the proof of Theorem 3.3 concerning the existence, uniqueness, and form of the solution of the boundary value problems defining the boundary correctors.

Proof. Differentiating (3.17) with respect to $\hat\rho$, we obtain

$$-\hat{\boldsymbol{A}}_5\cdot\frac{\partial^2\hat{\boldsymbol{\Phi}}_i}{\partial\hat\rho^2}+\frac{\partial^3\hat P_i}{\partial\hat\rho^3}=\frac{\partial\hat G_i(\hat\rho,\theta)}{\partial\hat\rho}.$$

Multiplying (3.16) by $\hat{\mathcal{A}}_0^{-1}$ and taking the inner product with $\hat{\boldsymbol{A}}_5$, we obtain

$$\hat{\boldsymbol{A}}_5\cdot\frac{\partial^2\hat{\boldsymbol{\Phi}}_i}{\partial\hat\rho^2}+\hat{\boldsymbol{A}}_5^t\hat{\mathcal{A}}_0^{-1}\hat{\boldsymbol{A}}_5\frac{\partial\hat P_i}{\partial\hat\rho}=-\hat{\boldsymbol{A}}_5^t\hat{\mathcal{A}}_0^{-1}\hat{\boldsymbol{F}}_i(\hat\rho,\theta).$$

Adding these equations and observing from Lemma 3.1 that $\hat{\boldsymbol{A}}_5^t\hat{\mathcal{A}}_0^{-1}\hat{\boldsymbol{A}}_5=-c^2$, we get

$$\frac{\partial^3\hat P_i}{\partial\hat\rho^3}-c^2\frac{\partial\hat P_i}{\partial\hat\rho}=-\hat{\boldsymbol{A}}_5^t\hat{\mathcal{A}}_0^{-1}\hat{\boldsymbol{F}}_i(\hat\rho,\theta)+\frac{\partial\hat G_i(\hat\rho,\theta)}{\partial\hat\rho}=:\hat H_i. \tag{8.1}$$

The general solution of the associated homogeneous equation is $c_1(\theta)+c_2(\theta)e^{-c\hat\rho}+c_3(\theta)e^{c\hat\rho}$, with the functions c_i arbitrary. Now if we have two solutions to (3.16)–(3.19), then the difference in the values of $\hat P_i$ must be of this form. Applying (3.19) implies that c_1 and c_3 vanish, and then the homogeneous form of (3.18) implies that c_2 vanishes. Thus there can be at most one function $\hat P_i$ satisfying (3.16)–(3.19). Once $\hat P_i$ is known, $\hat{\boldsymbol{\Phi}}_i$ is determined up to the addition of a function linear in $\hat\rho$ by (3.16).

In light of (3.19), $\hat{\boldsymbol{\Phi}}_i$ is uniquely determined. Thus we have shown that there can be at most one solution $(\hat{\boldsymbol{\Phi}}_i, \hat{P}_i)$ to (3.16)–(3.19).

Let us say that a scalar-valued function $\hat{Q}(\hat{\rho}, \theta)$ is of type (m, i) if

$$\hat{Q}(\hat{\rho}, \theta) = e^{-c\hat{\rho}} \sum_{k=0}^{m} \sum_{j=0}^{i} \sum_{l=0}^{i-j} \alpha_{jkl}(\theta) \hat{\rho}^k \frac{\partial^l}{\partial \theta^l} \widetilde{\frac{\partial p_j}{\partial n}}(0, \theta)$$

for some smooth functions $\alpha_{jkl}(\theta)$. A vector-valued function is of type (m, i) if all components are. We claim that there is a solution $(\hat{\boldsymbol{\Phi}}_i, \hat{P}_i)$ to (3.16)–(3.19) which is of of type (i, i). We will establish the claim by induction on i, thereby completing the proof of the theorem. The solution given in (3.20) verifies the claim for $i = 0$. Now suppose that $(\hat{\boldsymbol{\Phi}}_j, \hat{P}_j)$ is of type (j, j) for $j = 0, 1, \cdots, i-1$. It follows easily from their respective definitions (just after (3.16) and in (3.17) and (8.1)) that $\hat{\boldsymbol{F}}_i$, $\hat{G}_i$, and $\hat{H}_i$ are of type $(i-1, i)$. It is then elementary to see that the differential equation (8.1) has a unique solution of type (i, i) satisfying the boundary condition (3.18). Next, there is a unique function $\hat{\boldsymbol{\Phi}}_i$ of type (i, i) satisfying (3.16). Together (3.16), (8.1), and the decay at infinity of $\hat{\boldsymbol{\Phi}}_i$, $\hat{G}_i$, and the $\hat{\rho}$-derivatives of $\hat{P}_i$ imply (3.17). Thus $(\hat{\boldsymbol{\Phi}}_i, \hat{P}_i)$ satisfy (3.16)–(3.19) and are of the desired form. This completes the induction.

A SINGULAR PERTURBATION ANALYSIS OF REVERSE BIASED *pn*-JUNCTIONS*

CHRISTIAN SCHMEISER†

Abstract. A two-dimensional version of the drift-diffusion model for stationary flow of charge carriers in semiconductor devices is considered. It consists of a system of three elliptic equations that is singularly perturbed for large applied biases. For the case of a *pn*-junction diode under strong reverse bias, an approximating problem, which includes a free-boundary problem for the potential and a mixed elliptic-hyperbolic problem for the analysis of current flow, is derived. The solvability of this formal limit problem is proved.

Key words. semiconductors, drift-diffusion model, singular perturbations

AMS(MOS) subject classifications. 35B25, 35R35

1. Introduction.

In this paper we consider the system

$$\Delta\psi = n - p - C(x), \tag{1.1a}$$

$$\varepsilon\nabla n - n\nabla\psi = \varepsilon J_n, \qquad \operatorname{div} J_n = 0, \tag{1.1b}$$

$$-\varepsilon\nabla p - p\nabla\psi = \varepsilon J_p, \qquad \operatorname{div} J_p = 0 \tag{1.1c}$$

for $x \in \Omega \subset \mathbb{R}^2$, where Ω is a bounded simply-connected domain with Lipschitz boundary representing the semiconductor part of an electronic device. The scaling that leads to (1.1) (see [13]) is valid for large applied biases. The dimensionless parameter ε is small and positive in this case. The Poisson equation (1.1a) determines the electrostatic potential ψ and thus the electric field $E = -\nabla\psi$. The term $-n+p+C(x)$ on the right-hand side is the space charge density with contributions from the negatively charged free electrons (density n), the positively charged holes (density p), and a fixed distribution of charges $C(x)$ called the doping profile. The equations in (1.1b, c) represent a convection-diffusion model for the electron and hole current densities J_n and J_p, and current continuity.

We consider (1.1) subject to mixed Dirichlet-Neumann boundary conditions. Dirichlet conditions are given at contacts (disjoint, connected boundary segments, closed with respect to $\partial\Omega$) and homogeneous Neumann conditions at the remaining insulating part of the boundary.

A semiconductor device is specified by the doping profile and the number and location of contacts. We consider a *pn*-junction diode, where Ω splits into a *p*-region Ω_1 where $C(x) < 0$ holds and an *n*-region Ω_2 where $C(x) > 0$ holds. Ω_1 and Ω_2 are separated by the *pn*-junction Γ. The following technical assumptions will be used:

(A1) Γ is a smooth curve that meets $\partial\Omega$ under right angles. In neighborhoods of the points where Γ meets $\partial\Omega$, the boundary is given by straight line segments.

(A2) The doping profile is smooth in $\Omega_1 \cup \Omega_2$ and has jump discontinuities at Γ. $|C(x)| \geqq \gamma > 0$ holds.

A diode has two contacts C_1, $C_2 \subset \partial\Omega$ with $C_1 \subset \partial\Omega_1$ and $C_2 \subset \partial\Omega_2$. We assume the following:

(A3) The closure $\bar{\Gamma}$ of the *pn*-junction does not intersect the contacts C_1 and C_2.

A typical example for the device geometry is depicted in Fig. 1.1.

We consider (1.1) subject to the boundary conditions

$$\psi|_{C_1} = 0, \qquad \psi|_{C_2} = \alpha,$$

$$n|_{C_1,C_2} = \tfrac{1}{2}(C + \sqrt{C^2 + 4\delta^4})|_{C_1,C_2}, \tag{1.2}$$

$$p|_{C_1,C_2} = \tfrac{1}{2}(-C + \sqrt{C^2 + 4\delta^4})|_{C_1,C_2},$$

$$\nabla\psi \cdot \nu|_{\partial\Omega_N} = \nabla n \cdot \nu|_{\partial\Omega_N} = \nabla p \cdot \nu|_{\partial\Omega_N} = 0 \tag{1.3}$$

where $\partial\Omega_N = \partial\Omega \backslash (C_1 \cup C_2)$ denotes the insulating boundary segments and ν the unit outward normal.

The parameter α represents the applied voltage with $\alpha > 0$ in the case of large reverse bias. The Dirichlet data for n and p are obtained from the assumptions of vanishing space charge ($n - p - C = 0$) and thermal equilibrium ($np = \delta^4$) at the contacts. The thermal equilibrium equation represents a mass-action law, where δ^2 is the scaled intrinsic number of the semiconductor (see [15] for details). In practical applications δ^2 takes small values because densities (such as the intrinsic number) are scaled by the maximal value of the doping profile, which usually is much larger than the intrinsic carrier density.

Several existence proofs for (1.1)-(1.3) can be found in the literature (see [11] and [12] and references therein). An application of Theorem 3.2.1 in [11] yields Theorem 1.1.

THEOREM 1.1. *Problem* (1.1)-(1.3) *has a solution* $(\psi, n, p) \in (H^1(\Omega) \cap L^\infty(\Omega))^3$ *that satisfies*

$$-\varepsilon\beta \leqq \psi \leqq \alpha + \varepsilon\beta \quad \text{in } \Omega$$

where

$$\beta := 2 \ln [(\|C\|_{L^\infty(\Omega)} + \sqrt{\|C\|^2_{L^\infty(\Omega)} + 4\delta^4})/2\delta^2]$$

holds.

Although β tends to infinity as $\delta \to 0$, the product $\varepsilon\beta$ is usually small compared to unity. This suggests an asymptotic analysis of (1.1)-(1.3) for $\varepsilon \to 0$. Theorem 1.1

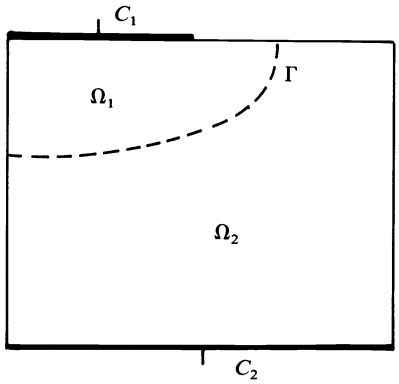

FIG. 1.1. *Device geometry.*

shows that the potential is bounded uniformly in ε. For a rigorous analysis of the limit $\varepsilon \to 0$ additional a priori estimates of this kind would be necessary. However, the existence result on which Theorem 1.1 is based does not provide sufficiently sharp bounds.

In [4] Caffarelli and Friedman treated related problems. The main difference from (1.1)-(1.3) is a modification of the boundary conditions that allows for a rigorous analysis of a simplified problem.

Similar results for one-dimensional problems have been developed in a series of papers by Brezzi et al. [1]-[3]. The analysis of the present work is based on the formal methods of singular perturbation theory.

Although the modified boundary conditions in the above-mentioned papers do not allow for an analysis of current flow, the limiting behavior of the potential is obtained. Under appropriate assumptions ψ is shown to converge to the solution of the variational inequality

$$\psi_0 \in K_\alpha : \int_\Omega \nabla\psi_0 \nabla(v-\psi_0)\,dx \geqq \int_\Omega C(x)(v-\psi_0)\,dx \quad \forall v \in K_\alpha \tag{1.4}$$

where

$$K_\alpha := \{\psi \in H^1(\Omega) : \psi|_{C_1} = 0,\ \psi|_{C_2} = \alpha,\ 0 \leqq \psi \leqq \alpha \text{ a.e. in } \Omega\} \tag{1.5}$$

holds. Inequality (1.4) can be interpreted as a double obstacle problem for the deformation ψ of a membrane. The membrane lies between the obstacles represented by $\psi = 0$ and $\psi = \alpha$ and is fixed to the lower obstacle along C_1 and to the upper obstacle along C_2. In this context $C(x)$ is a transversal force pushing downward in Ω_1 and upward in Ω_2.

Without being derived as a limit of (1.1)-(1.3), the double obstacle problem (1.4) has already been formulated as a model for the potential distribution in [7] and [10]. It can be motivated by the reduced equations

$$\Delta\psi_0 = n_0 - p_0 - C(x), \qquad n_0 \nabla\psi_0 = p_0 \nabla\psi_0 = 0 \tag{1.6}$$

and the estimates in Theorem 1.1.

For the carrier densities n_0 and p_0 the reduced system implies

$$n_0 - p_0 - C(x) = 0 \quad \text{in } Z \cup A$$

where Z and A denote the coincidence sets

$$Z := \{x \in \Omega : \psi_0(x) = 0\},$$

$$A := \{x \in \Omega : \psi_0(x) = \alpha\},$$

$$n_0 = p_0 = 0 \quad \text{in } N = \Omega \setminus (Z \cup A).$$

In the physical literature the noncoincidence set N is called the depletion region, as it is depleted of charge carriers, or the space charge region.

The equations above are not sufficient for characterizing the limiting charge carrier and current densities. For a one-dimensional situation the limiting problem has been completed by Schmeiser [13]. It is the main purpose of the present work to extend these results to the two-dimensional case.

The formulation of the limit problem requires certain topological properties of the sets Z, A, and N that are proved in § 2 to hold for α small enough.

In § 3 we introduce asymptotic expansions in powers of ε for the solution that allow us to formulate equations determining the current flow. It turns out that in the

space charge region N the flow is purely convective and governed by a hyperbolic system, whereas diffusion is significant in Z and A, where a system of elliptic equations has to be solved. A proof of existence of a locally unique solution of the coupled problem for small δ^4 is the main result of § 3.

2. The double obstacle problem. This section is concerned with an analysis of problem (1.4) for small values of α. Standard results for variational inequalities [8] yield Theorem 2.1.

THEOREM 2.1. (A) *Problem* (1.4) *has a unique solution* ψ_0 *that is Hölder continuous. Besides,* $\psi_0 \in W^{2,p}(\Omega')$ *holds for any* $p < \infty$ *and for any subdomain* Ω' *of* Ω *whose closure does not contain critical boundary points, i.e.,* (a) *points where* $\partial\Omega$ *is not smooth, and* (b) *edges of the contacts where Dirichlet and Neumann boundary conditions meet.*

$$\text{(B)} \qquad \Delta\psi_0 + C(x) \leqq 0 \quad \text{a.e. in } Z \cup N,$$

$$\Delta\psi_0 + C(x) \geqq 0 \quad \text{a.e. in } A \cup N.$$

A direct consequence of (B) is Corollary 2.1.

COROLLARY 2.1. $Z \subset \bar{\Omega}_1$, $A \subset \bar{\Omega}_2$, $\Gamma \subset \bar{N}$. By continuity of ψ_0, Z and A are closed, and thus, N is open relative to Ω. A refinement of the last result in Corollary 2.1 is Lemma 2.1.

LEMMA 2.1. $\Gamma \subset N$.

Proof. Suppose $x_0 \in \Gamma \cap A$. The smoothness of Γ and the continuity of ψ_0 imply the existence of a ball $B_R(y) \subset \Omega_1 \cap N$ with $x_0 \in \partial B_R(y)$ (see Fig. 2.1). We have

(a) $\Delta\psi_0 = -C(x) > 0$ in $B_R(y)$,

(b) $\alpha = \psi_0(x_0) > \psi_0(x)$ for $x \in B_R(y)$,

(c) ψ_0 continuous.

Application of Lemma 3.4 in [6] leads to

$$\nabla\psi_0(x_0) \cdot \nu > 0$$

where ν is the outward unit normal on $\partial B_R(y)$. This is in contradiction to $\nabla\psi_0 = 0$ in A. Analogously we prove $\Gamma \cap Z = \{\ \}$, which completes the proof.

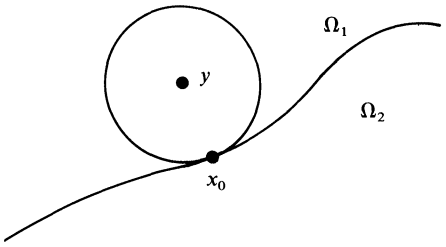

FIG. 2.1

The lemma immediately implies $\Gamma_Z \subset \Omega_1$, $\Gamma_A \subset \Omega_2$ for the free boundaries Γ_Z separating Z and N and Γ_A separating A and N. From the smoothness of $C(x)$ in $\Omega_1 \cup \Omega_2$ we obtain smoothness of Γ_Z and Γ_A by standard results (see [5], [8]).

For the analysis of the following section we will need Z, A, and N to be connected. For Z and A this cannot be expected to hold in general. But we have Lemma 2.2.

LEMMA 2.2. *N is connected.*

Proof. By the above results there is a component N_Γ of N with $\Gamma \subset N_\Gamma$. Assume the existence of an additional component $\tilde{N} \subset \Omega_1$. We have

$$\Delta\psi_0 = -C(x) > 0 \quad \text{in } \tilde{N},$$
$$\psi_0 = 0 \quad \text{or} \quad \nabla\psi_0 \cdot \nu = 0 \quad \text{on } \partial\tilde{N},$$

which implies $\psi_0 \leqq 0$ in $\tilde{N}$ by the maximum principle. This is in contradiction to $\psi_0 > 0$ in N. Analogously we show that there does not exist an additional component of N in Ω_2. Thus, $N = N_\Gamma$, which completes the proof.

In [13] we have shown that Γ_Z and Γ_A converge to Γ as $\alpha \to 0$ in the one-dimensional case. In the following this result is extended to two dimensions.

We define

$$\Omega_\rho := \{x \in \Omega : d(x, \Gamma) < \rho\}.$$

With $s(x) := d(x, \Gamma)$ we have

$$s \in C^2(\Omega_{\rho_0}) \quad \text{for some } \rho_0 > 0,$$
$$|\nabla s| = 1, \quad \Delta s \geqq -M \quad \text{in } \Omega_{\rho_0} \quad \text{for some } M > 0$$

by assumption (A1).

THEOREM 2.2. *Let α be small enough so that $\rho = (2\alpha(M\rho_0 + 1)/\gamma)^{1/2} \leq \rho_0$ holds. Then $N \subset \Omega_\rho$ holds.*

Remark. The theorem is a mathematical version of the statement, "The width of the depletion region is proportional to the square root of the applied bias," which is well known in the engineering literature (see [16]) for the case of abrupt junctions. The result could be extended to graded junctions where the doping profile smoothly changes sign across Γ and, accordingly, $\gamma > 0$ with the required properties does not exist. In this case the width of the depletion region is $O(\alpha^{1/3})$ for small values of α.

Proof. Let us deal with the part of N lying in Ω_1 first. We define a comparison function by

$$w(x) := \begin{cases} 0, & x \in \Omega_1 \setminus \Omega_\rho, \\ \alpha(1 - s(x)/\rho)^2, & x \in \Omega_1 \cap \Omega_\rho. \end{cases}$$

Obviously, $w \in C^1(\Omega_1)$, $w \geqq 0$ in Ω_1, $w|_{C_1} = 0$, $w|_\Gamma = \alpha$ holds. Besides, we have for $x \in \Omega_1 \cap \Omega_\rho$

$$\Delta w(x) = 2\alpha/\rho^2[(s - \rho)\Delta s + |\nabla s|^2]$$
$$\leqq \frac{\gamma}{M\rho_0 + 1}[(\rho - s)M + 1]$$
$$\leqq \gamma \frac{\rho M + 1}{\rho_0 M + 1} \leqq \gamma \leqq -C(x),$$

and for $x \in \Omega_1 \setminus \Omega_\rho$

$$\Delta w(x) = 0 < -C(x).$$

This shows that w is a supersolution of the equation $\Delta w + C(x) = 0$ in Ω_1. A comparison principle as in [8] implies

$$\psi_0 \leqq w \quad \text{in } \Omega_1,$$

and thus, $\psi_0 = 0$ in $\Omega_1 \setminus \Omega_\rho$. Similarly, it can be shown that $\psi_0 = \alpha$ in $\Omega_2 \setminus \Omega_\rho$ holds, which completes the proof.

COROLLARY 2.2. *$\psi_0 \in W^{2,p}(\Omega)$ for $p < \infty$ and for α small enough.*

Proof. $\psi_0 = 0$ or $\psi_0 = \alpha$ in neighborhoods of critical boundary points by Theorem 2.2 and assumption (A1). The result now follows by Theorem 2.1.

Theorem 2.2 shows that the free boundaries meet $\partial\Omega$ within the Neumann segments for α small enough.

LEMMA 2.3. (a) *If $\partial\Omega$ is smooth in a neighborhood of a point x_0 where one of the free boundaries meets $\partial\Omega_N$, then the angle between the free boundary and $\partial\Omega_N$ at x_0 is $\pi/2$.*

(b) $\nabla\psi_0/|\nabla\psi_0|$ *is orthogonal to the free boundaries.*

Proof. (a) A locally orthogonal smooth coordinate transformation moves x_0 to the origin and a neighborhood of x_0 in Ω to $\{x_2>0\}\cap B_R(0)$, where (x_1, x_2) are the new coordinates. (See Fig. 2.2.). The extension of ψ_0 to $B_R(0)$ as an even function of x_2 is the solution of a variational inequality in $B_R(0)$. The smoothness of the free boundary that follows from standard results, and its symmetry with respect to the x_1-axis, imply the conclusion of the lemma.

(b) Let $x_0\in\Omega$ lie on Γ_Z. Then ψ_0 is smooth in a neighborhood of x_0 in N by elliptic regularity. As in the proof of (a) we transform this neighborhood to $\{x_2>0\}\cap B_R(0)$. We have $\psi_0(x_1, x_2)=x_2{}^2 f(x_1, x_2)$ with f smooth because $\psi_0=0$ for $x_2<0$ and $\psi_0\in C^1(B_R)$. Assumption (A2) and the fact that ψ_0 satisfies $\Delta\psi_0+C(x)=0$ in N imply

$$f(x_1, 0)\geqq\tilde{\gamma}>0.$$

If we use this, straightforward computation shows

$$\lim_{x_2\to 0}\nabla\psi_0/|\nabla\psi_0|=(0, 1),$$

which is the desired result. It can be extended to points where Γ_Z meets the boundary by reflection as in the proof of Lemma 2.3. Points on Γ_A are treated analogously.

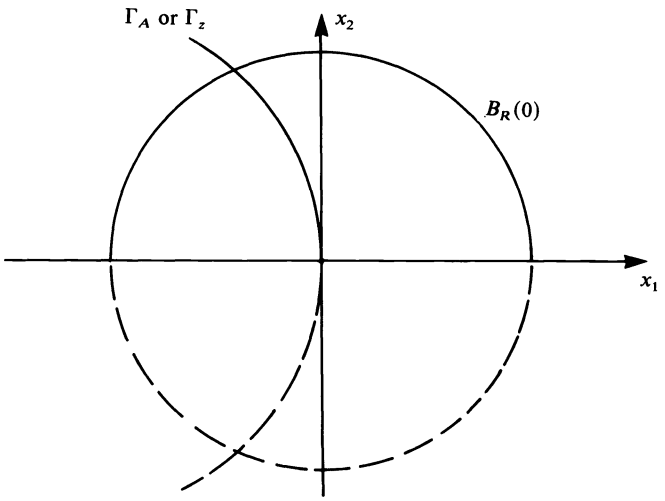

FIG. 2.2

The remaining part of this section is devoted to a more detailed analysis of the solution of (1.4) for small α. With the substitution $\psi_0=\alpha\phi$, (1.4) changes to

$$\phi\in K_1:\ \alpha\int_\Omega\nabla\phi\nabla(v-\phi)\,dx\geqq\int_\Omega C(x)(v-\phi)\,dx\quad\forall v\in K_1 \tag{2.1}$$

where K_1 is defined as in (1.5). This is a singularly perturbed variational inequality. The reduced problem obtained by formally setting $\alpha = 0$ in (2.1) does not have a solution. This difficulty can be overcome by considering a larger solution space. Lions [9] treated problems where the reduced variational inequality is governed by a bilinear form that is coercive in the enlarged space. As this is not possible in our situation, we guarantee solvability by choosing the larger space such that K_1 becomes bounded. Our choice is $L^2(\Omega)$ and the reduced problem is defined as

$$\bar{\phi} \in \bar{K}_1 : 0 \geqq \int_\Omega C(x)(v - \bar{\phi})\, dx \quad \forall v \in \bar{K}_1 \tag{2.2}$$

where $\bar{K}_1$ is the closure of K_1 in $L^2(\Omega)$. Obviously (2.2) has the unique solution

$$\bar{\phi} = \begin{cases} 0 & \text{a.e. in } \Omega_1, \\ 1 & \text{a.e. in } \Omega_2. \end{cases} \tag{2.3}$$

From the proof of Theorem 2.2 we obtain a validity result for the formal approximation $\bar{\phi}$.

LEMMA 2.4. *For the solutions ϕ of* (2.1) *and $\bar{\phi}$ of* (2.2)

$$\|\phi - \bar{\phi}\|_{L^p(\Omega)} = O(\alpha^{1/2p}) \quad \text{as } \alpha \to 0$$

holds for $p \geqq 1$.

Proof. For the function $w(x)$ defined in the proof of Theorem 2.2 we have

$$|\phi(x) - \bar{\phi}(x)| \leqq w/\alpha \quad \text{a.e. in } \Omega_1.$$

This implies

$$\begin{aligned} \|\phi - \bar{\phi}\|_{L^p(\Omega_1)} &\leqq \left(\int_{\Omega_1 \cap \Omega_\rho} (1 - s(x)/\rho)^{2p}\, dx \right)^{1/p} \\ &\leqq (\text{meas } (\Omega_1 \cap \Omega_\rho))^{1/p} = O(\alpha^{1/2p}). \end{aligned}$$

Similarly we obtain

$$\|\phi - \bar{\phi}\|_{L^p(\Omega_2)} = O(\alpha^{1/2p}),$$

which completes the proof.

Obviously, $\bar{\phi}$ is not smooth enough for a uniformly valid approximation. To improve on that we introduce a correction layer at Γ. Considering a local change of variables

$$(x_1, x_2) \to (r, s)$$

where

$$s(x) = \begin{cases} -d(x, \Gamma) & \text{in } \Omega_1, \\ d(x, \Gamma) & \text{in } \Omega_2, \end{cases}$$

we introduce the fast variable $\sigma = s/\sqrt{\alpha}$ and the σ-interval $I = (-\sqrt{2(M\rho_0 + 1)/\gamma}, \sqrt{2(M\rho_0 + 1)/\gamma})$ (compare with Theorem 2.2). Then the layer problem is given by the one-dimensional variational inequality:

$$\hat{\phi} \in \tilde{K} : \int_I \hat{\phi}_\sigma (v_\sigma - \hat{\phi}_\sigma)\, d\sigma \geqq \int_I C(r, \sigma)(v - \hat{\phi})\, d\sigma \quad \forall v \in \tilde{K}$$

where $\tilde{K}$ is defined by

$$\begin{aligned} \tilde{K} = \{ \hat{\phi} \in H^1(I) : \hat{\phi}(-\sqrt{2(M\rho_0 + 1)/\gamma}) = 0, \\ \hat{\phi}(\sqrt{2(M\rho_0 + 1)/\gamma}) = 1, 0 \leqq \hat{\phi} \leqq 1 \}. \end{aligned}$$

The one-dimensional variational inequality has been treated in [13]. It is easy to show that the free boundaries are located in the interior of I and that $\hat{\phi}$ is strictly monotonically increasing between them.

A formal approximation of the solution of (2.1) is defined by

$$\phi_{as} = \begin{cases} \bar{\phi} & \text{in } \Omega \backslash \Omega_\rho, \\ \hat{\phi} & \text{in } \Omega_\rho. \end{cases}$$

THEOREM 2.3. $\|\phi - \phi_{as}\|_{H^1(\Omega)} = O(\alpha^{1/4})$.

Proof. By assumptions (A1), (A2) it is straightforward to show that ϕ_{as} solves the variational inequality

$$(2.4) \quad \phi_{as} \in K_1: \alpha \int_\Omega \nabla \phi_{as}(v - \phi_{as})\, dx \geqq \int_\Omega (C(x) + \alpha g(x))(v - \phi_{as})\, dx \quad \forall v \in K_1$$

where $\|g\|_{L^\infty(\Omega)}$ is bounded independently of α. For $w = \phi - \phi_{as}$ we get from Lemma 2.4 and the definition of ϕ_{as}

$$(2.5) \qquad \|w\|_{L^p(\Omega)} = O(\alpha^{1/2p}).$$

If we set $v = \phi_{as}$ in (2.1) and $v = \phi$ in (2.4), the sum of the resulting inequalities reads

$$-\alpha \int_\Omega |\nabla w|^2\, dx \geqq \alpha \int_\Omega g(x) w\, dx.$$

This implies

$$\|\nabla w\|^2_{L^2(\Omega)} \leqq \|g\|_{L^\infty(\Omega)} \|w\|_{L^1(\Omega)} = O(\alpha^{1/2})$$

by Hölder's inequality, the boundedness of $g(x)$, and (2.5) with $p = 1$. Combining this estimate with (2.5) ($p = 2$) completes the proof.

Finally, we state two assumptions that are needed in the following section:

(A4) Z and A are connected.

(A5) $\nabla \psi_0 / |\nabla \psi_0|$ is Lipschitz in N.

Since both assumptions are satisfied by the formal approximations constructed above, the author conjectures that they are satisfied for α small enough, although a proof of this conjecture is not available.

3. Analysis of current flow. By formally setting $\varepsilon = 0$ in (1.1) and considering the solution of (1.4) we obtain the equations

$$(3.1a) \qquad n_0 - p_0 - C(x) = 0 \qquad \text{in } Z \cup A,$$

$$(3.1b) \qquad n_0 = p_0 = 0 \qquad \text{in } N,$$

$$(3.1c) \qquad \operatorname{div} J_{n0} = \operatorname{div} J_{p0} = 0 \qquad \text{in } \Omega,$$

which are not sufficient for the computation of n_0, p_0, J_{n0}, and J_{p0}. It is a standard procedure in perturbation theory to derive additional equations by introducing asymptotic expansions for the solution and equating coefficients of higher-order terms (see [14], [18]). We make the ansatz

$$w = w_0 + \varepsilon w_1 + O(\varepsilon^2)$$

where w stands for any of the solution components. Substitution in (1.1b, c) and comparison of coefficients of ε leads to

$$\nabla n_0 - n_0 \nabla \psi_1 - n_1 \nabla \psi_0 = J_{n0},$$
$$-\nabla p_0 - p_0 \nabla \psi_1 - p_1 \nabla \psi_0 = J_{p0}.$$

With (3.1) and our knowledge about ψ_0 we arrive at

$$J_{n0} = -n_1 \nabla \psi_0, \qquad J_{p0} = -p_1 \nabla \psi_0 \quad \text{in } N, \tag{3.2}$$

$$\begin{aligned} J_{n0} &= \nabla n_0 - n_0 \nabla \psi_1 \\ J_{p0} &= -\nabla p_0 - p_0 \nabla \psi_1 \end{aligned} \quad \text{in } Z \cup A. \tag{3.3}$$

Our next aim is to eliminate ψ_1 from (3.1a), (3.3). In [13] this is done by introducing the slow variable np. As the resulting problem is difficult to handle in the two-dimensional case, we instead introduce the change of variables

$$n_0 = e^{\psi_1} u, \qquad p_0 = e^{-\psi_1} v.$$

If we use (3.1a) for eliminating ψ_1, (3.3) changes to

$$\begin{aligned} J_{n0} &= \frac{C + \sqrt{C^2 + 4uv}}{2u} \nabla u \\ J_{p0} &= -\frac{-C + \sqrt{C^2 + 4uv}}{2v} \nabla v \end{aligned} \quad \text{in } Z \cup A. \tag{3.4}$$

Substituting (3.2) and (3.4) in (3.1c) yields the system

$$\operatorname{div}(n_1 \nabla \psi_0) = \operatorname{div}(p_1 \nabla \psi_0) = 0 \quad \text{in } N, \tag{3.5a}$$

$$\operatorname{div}\left(\frac{C + \sqrt{C^2 + 4uv}}{2u} \nabla u\right) = \operatorname{div}\left(\frac{-C + \sqrt{C^2 + 4uv}}{2v} \nabla v\right) = 0 \quad \text{in } Z \cup A, \tag{3.5b}$$

which is elliptic in $Z \cup A$ and hyperbolic in N.

Note that the computation of the current densities J_{n0}, J_{p0} in N necessitates the determination of the $O(\varepsilon)$ corrections n_1 and p_1 of the charge carrier densities. For singular singularly perturbed problems, it is typical to have to deal with terms of different orders simultaneously.

The formulation of the problem is completed by prescribing boundary conditions at $\partial\Omega$ and interface conditions at Γ_Z and Γ_A (see Fig. 3.1). As ψ_0 satisfies the original

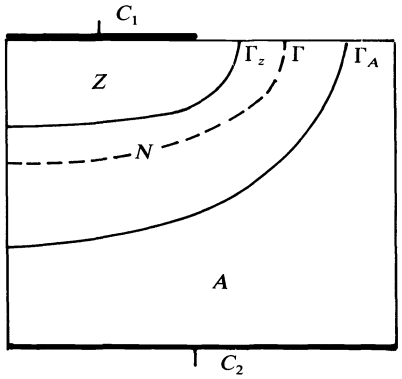

FIG. 3.1

boundary conditions for ψ, homogeneous boundary conditions for the correction ψ_1 are required. This leads to

$$u|_{C_1,C_2} = \tfrac{1}{2}(C + \sqrt{C^2+4\delta^4})|_{C_1,C_2},$$
$$v|_{C_1,C_2} = \tfrac{1}{2}(-C + \sqrt{C^2+4\delta^4})|_{C_1,C_2}, \tag{3.6a}$$

$$\nabla u \cdot \nu, \nabla v \cdot \nu|_{(\partial Z \cup \partial A)\cap \partial\Omega_N} = 0. \tag{3.6b}$$

Since the characteristics of (3.5a) are parallel to $\partial N \cap \partial\Omega_N$, we do not need any boundary conditions there. At the interfaces Γ_Z and Γ_A, we obviously require continuity of the normal components of the current densities

$$[J_{n0} \cdot \nu]_{\Gamma_Z,\Gamma_A} = [J_{p0} \cdot \nu]_{\Gamma_Z,\Gamma_A} = 0 \tag{3.6c}$$

where $[\,\cdot\,]_S$ denotes the jump of a quantity across the curve S and ν stands for the unit normal to $\Gamma_Z(\Gamma_A)$ pointing outward from $Z(A)$. The above-mentioned observation that np is a slow variable leads to the condition $[n_0 p_0]_{\Gamma_Z,\Gamma_A} = 0$.

By requiring the concentrations to be nonnegative, we see from (3.1) that only p_0 has a jump discontinuity at Γ_Z and only n_0 has a jump discontinuity at Γ_A. This implies that for u and v

$$u|_{\Gamma_Z} = 0, \qquad v|_{\Gamma_A} = 0. \tag{3.6d}$$

The reduced solution is determined completely by solving (3.5), (3.6).

Before starting to analyze the reduced problem we mention that the jumps of p_0 at Γ_Z and n_0 at Γ_A can be smoothed by layer solutions. They are obtained by introducing fast local coordinates along Γ_Z and Γ_A. This leads to a system of ordinary differential equations on $\mathbb{R}$ that has been analyzed in [13].

As a preliminary step in the discussion of the reduced problem we consider the hyperbolic equations (3.5a). As $\nabla\psi_0$ vanishes at Γ_Z and Γ_A, the solutions n_1 and p_1 have singularities there in the case of nonvanishing current densities. It has been demonstrated in [13] that, despite these singularities, matching to layer solutions can be carried out. The following lemma shows that

$$n_1, p_1 = O(|\nabla\psi_0|^{-1})$$

holds close to Γ_Z and Γ_A. From the proof of Lemma 2.3 we see that $|\nabla\psi_0|$ is a possible choice of a local variable there. Written in the fast variable $\xi = |\nabla\psi_0|/\sqrt{\varepsilon}$, $O(\sqrt{\varepsilon}/\xi)$-contributions result from n_1 and p_1; these can be matched to algebraically decaying layer solutions of order $O(\sqrt{\varepsilon})$. The current flow through N is analyzed in Lemma 3.1.

LEMMA 3.1. *Let the operator* $S: H^{1/2}(\Gamma_Z) \to H^{1/2}(\Gamma_A)$ *be defined by*

$$S(f) := n\nabla\psi_0 \cdot \nu|_{\Gamma_A}$$

where n is the solution of

$$\operatorname{div}(n\nabla\psi_0) = 0 \quad \text{in } N,$$
$$n\nabla\psi_0 \cdot \nu|_{\Gamma_Z} = f.$$

Then S is a bounded and boundedly invertible linear operator.

Proof. We introduce $\hat{n} = n|\nabla\psi_0|$, which must solve the Cauchy problem

$$\operatorname{div}(\hat{n}\nabla\psi_0/|\nabla\psi_0|) = 0 \quad \text{in } N,$$
$$\hat{n}|_{\Gamma_Z} = f$$

because $\nabla\psi_0 \cdot \nu/|\nabla\psi_0||_{\Gamma_Z} = 1$ by Lemma 2.3(b). Assumption (A5) implies existence and uniqueness of $\hat{n}$.

We define the mapping $\phi : \Gamma_Z \to \Gamma_A$ by following characteristics starting at $x \in \Gamma_Z$ until they leave N at $\phi(x) \in \Gamma_A$. It is another consequence of assumption (A5) that ϕ is a diffeomorphism.

Let $x(s)$ denote a parametrization of Γ_Z by arclength. An application of the divergence theorem to the region bounded by the segment between $x(s)$ and $x(s+h)$ on Γ_Z, the characteristics starting at $x(s)$ and $x(s+h)$, and the segment between $\phi(x(s))$ and $\phi(x(s+h))$ on Γ_A yields

$$\int_s^{s+h} f(x(\sigma))\, d\sigma = -\int_s^{s+h} S(f)(\phi(x(\sigma)))|\phi_x \dot{x}|\, d\sigma.$$

By letting $h \to 0$ we obtain the representation

$$f(x) = -S(f)(\phi(x))|\phi_x \dot{x}|$$

for the inverse of S. A final application of assumption (A5) and Lemma 2.3(b) implies $|\phi_x \dot{x}| > 0$, which completes the proof.

Remark. The space $H^{1/2}$ was chosen only for convenience in the proof of Theorem 3.1 below. Obviously the result also holds for other function spaces.

Using Lemma 3.1 and introducing $u|_A = e^w$, $v|_Z = e^z$, we must still solve a system of four coupled elliptic boundary value problems:

$$\operatorname{div}\left(\frac{2e^z}{-C+\sqrt{C^2+4ue^z}}\nabla u\right) = 0 \quad \text{in } Z,$$

(3.7a)
$$u|_{C_1} = \left.\frac{2\delta^4}{-C+\sqrt{C^2+4\delta^4}}\right|_{C_1}, \qquad u|_{\Gamma_Z} = 0,$$

$$\nabla u \cdot \nu|_{\partial\Omega_N \cap \partial Z} = 0,$$

$$\operatorname{div}\left(\frac{C+\sqrt{C^2+4e^w v}}{2}\nabla w\right) = 0 \quad \text{in } A,$$

(3.7b)
$$\frac{C+\sqrt{C^2+4e^w v}}{2}\nabla w \cdot \nu|_{\Gamma_A} = S\left(\frac{2e^z}{-C+\sqrt{C^2+4ue^z}}\nabla u \cdot \nu|_{\Gamma_Z}\right),$$

$$w|_{C_2} = \left.\ln\frac{C+\sqrt{C^2+4\delta^4}}{2}\right|_{C_2}, \qquad \nabla w \cdot \nu|_{\partial\Omega_N \cap \partial A} = 0;$$

$$\operatorname{div}\left(\frac{2e^w}{C+\sqrt{C^2+4e^w v}}\nabla v\right) = 0 \quad \text{in } A,$$

(3.7c)
$$v|_{C_2} = \left.\frac{2\delta^4}{C+\sqrt{C^2+4\delta^4}}\right|_{C_2}, \qquad v|_{\Gamma_A} = 0,$$

$$\nabla v \cdot \nu|_{\partial\Omega_N \cap \partial A} = 0;$$

$$\operatorname{div}\left(\frac{-C+\sqrt{C^2+4ue^z}}{2}\nabla z\right) = 0 \quad \text{in } Z,$$

(3.7d)
$$\frac{-C+\sqrt{C^2+4ue^z}}{2}\nabla z \cdot \nu|_{\Gamma_Z} = S^{-1}\left(\frac{2e^w}{C+\sqrt{C^2+4e^w v}}\nabla v \cdot \nu|_{\Gamma_A}\right),$$

$$z|_{C_1} = \left.\ln\frac{-C+\sqrt{C^2+4\delta^4}}{2}\right|_{C_1}, \qquad \nabla z \cdot \nu|_{\partial\Omega_N \cap \partial Z} = 0.$$

LEMMA 3.2. For $\delta^4 = 0$, problem (3.7) has a unique solution (u_0, v_0, w_0, z_0) that satisfies

$$u_0 = v_0 = 0, \tag{3.8a}$$

$$w_0 \in H^1(A) \cap H^2(A'), \qquad z_0 \in H^1(Z) \cap H^2(Z'),$$

$$\ln \gamma \leqq w_0, \qquad z_0 \leqq \ln (\|C\|_{L^\infty(\Omega)}) \tag{3.8b}$$

for all subdomains Z' and A' of Z and A, respectively, that do not contain critical boundary points as defined in Theorem 2.1.

Remark. Note that H^2-regularity holds in neighborhoods of Γ_Z and Γ_A whose endpoints can be considered critical boundary points for the problem (3.5), (3.6).

Proof. The maximum principle applied to problems (3.7a, c) immediately implies the estimates

$$0 \leqq u, v \leqq \frac{2\delta^4}{\gamma + \sqrt{\gamma^2 + 4\delta^4}},$$

of which (3.8a) is a direct consequence. Thus, problems (3.7b, d) for $\delta^4 = 0$ reduce to

$$\begin{aligned} &\operatorname{div}(|C|\nabla w_0) = 0 \quad \text{in } A, \\ &w_0|_{C_2} = \ln(|C|)|_{C_2}, \qquad \nabla w_0 \cdot \nu|_{\partial A \setminus C_2} = 0; \end{aligned} \tag{3.7b}_0$$

$$\begin{aligned} &\operatorname{div}(|C|\nabla z_0) = 0 \quad \text{in } Z, \\ &z_0|_{C_1} = \ln(|C|)|_{C_1}, \qquad \nabla z_0 \cdot \nu|_{\partial Z \setminus C_1} = 0. \end{aligned} \tag{3.7d}_0$$

Again applying the maximum principle, we get solutions $w_0 \in H^1(A) \cap L^\infty(A)$, $z_0 \in H^1(Z) \cap L^\infty(Z)$ and estimates (3.8b). Elliptic regularity implies $w_0 \in H^2(A')$, $z_0 \in H^2(Z')$ for A', Z', which, in addition to the requirements in the statement of the lemma, do not contain the endpoints of Γ_A and Γ_Z.

In the neighborhood of an endpoint $x_0 \in \partial\Omega$ of Γ_A we employ a local coordinate transformation as in the proof of Lemma 2.3. There it was shown that the extension of Γ_A to the exterior of Ω by reflection is smooth. The extension of w_0 to the exterior as an even function with respect to $\partial\Omega$ satisfies an elliptic equation and homogeneous Neumann conditions at the extended Γ_A. Thus, elliptic regularity results can be applied in a neighborhood of x_0, giving H^2-regularity of w_0 there. Treating endpoints of Γ_Z analogously we obtain $w_0 \in H^2(A')$, $z_0 \in H^2(Z')$ for A', Z' as in the statement of the lemma.

To facilitate the subsequent analysis we make the following additional regularity assumptions:

(A6) $w_0 \in W^{1,6}(A)$, $z_0 \in W^{1,6}(Z)$.

(A7) Let $f_0 \in L^{3/2}(\Omega)$ and $f_1, f_2 \in L^3(\Omega)$ hold.
Then the solution of

$$\begin{aligned} &\Delta w = f_0 + \operatorname{div}((f_1, f_2)) \quad \text{in } \Omega, \\ &w|_{C_1, C_2} = w_D, \qquad \nabla w \cdot \nu|_{\partial\Omega_N} = 0 \end{aligned}$$

for smooth Dirichlet data w_D is in $W^{1,3}(\Omega)$ and satisfies

$$\|w\|_{W^{1,3}(\Omega)} \leqq c_1 + c_2(\|f_0\|_{L^{3/2}(\Omega)} + \|f_1\|_{L^3(\Omega)} + \|f_2\|_{L^3(\Omega)}).$$

The validity of the above assumptions requires a certain behavior of $\partial\Omega$ close to critical boundary points. Differential equations such as those in (A7) occur when the divergence terms appearing in (3.7) are expanded, and lower-order terms are considered as data.

THEOREM 3.1. *For δ^4 small enough, problem* (3.7) *has a solution* (u, v, w, z) *in the Banach space*

$$B = [(W^{1,3}(Z) \cap H^2(Z')) \times (W^{1,3}(A) \cap H^2(A'))]^2$$

satisfying

$$\|(u-u_0, v-v_0, w-w_0, z-z_0)\|_B = O(\delta^4)$$

where Z', A' are as in Lemma 3.2.

Proof. We introduce the errors

$$\delta^4\tilde{u} = u-u_0, \quad \delta^4\tilde{v} = v-v_0, \quad \delta^4\tilde{w} = w-w_0, \quad \delta^4\tilde{z} = z-z_0.$$

By linearization we rewrite (3.7) as

$$\operatorname{div}\left(\frac{e^{z_0}}{|C|}\nabla\tilde{u} + f_1\right) = 0 \quad \text{in } Z,$$

(3.9a)
$$\tilde{u}|_{C_1} = \left.\frac{2}{-C+\sqrt{C^2+4\delta^4}}\right|_{C_1}, \qquad \tilde{u}|_{\Gamma_Z} = 0,$$

$$\nabla\tilde{u}\cdot\nu|_{\partial\Omega_N\cap\partial Z} = 0;$$

$$\operatorname{div}\left(|C|\nabla\tilde{w} + \frac{e^{w_0}}{|C|}\tilde{v}\nabla w_0 + f_2\right) = 0 \quad \text{in } A,$$

(3.9b)
$$\left(|C|\nabla\tilde{w} + \frac{e^{w_0}}{|C|}\tilde{v}\nabla w_0\right)\cdot\nu|_{\Gamma_A} = S\left(\frac{e^{z_0}}{|C|}\nabla\tilde{u}\cdot\nu|_{\Gamma_Z}\right) + f_3,$$

$$\tilde{w}|_{C_2} = \delta^{-4}\ln\left.\frac{C+\sqrt{C^2+4\delta^4}}{2C}\right|_{C_2}, \qquad \nabla\tilde{w}\cdot\nu|_{\partial\Omega_N\cap\partial A} = 0;$$

$$\operatorname{div}\left(\frac{e^{w_0}}{|C|}\nabla\tilde{v} + f_4\right) = 0 \quad \text{in } A,$$

(3.9c)
$$\tilde{v}|_{C_2} = \left.\frac{2}{C+\sqrt{C^2+4\delta^4}}\right|_{C_2}, \qquad \tilde{v}|_{\Gamma_A} = 0,$$

$$\nabla\tilde{v}\cdot\nu|_{\partial\Omega_N\cap\partial A} = 0;$$

$$\operatorname{div}\left(|C|\nabla\tilde{z} + \frac{e^{z_0}}{|C|}\tilde{u}\nabla z_0 + f_5\right) = 0 \quad \text{in } Z,$$

(3.9d)
$$\left(|C|\nabla\tilde{z} + \frac{e^{z_0}}{|C|}\tilde{u}\nabla z_0\right)\cdot\nu|_{\Gamma_Z} = S^{-1}\left(\frac{e^{w_0}}{|C|}\nabla\tilde{v}\cdot\nu|_{\Gamma_A}\right) + f_6,$$

$$\tilde{z}|_{C_1} = \delta^{-4}\ln\left.\frac{-C+\sqrt{C^2+4\delta^4}}{-2C}\right|_{C_1}, \qquad \nabla\tilde{z}\cdot\nu|_{\partial\Omega_N\cap\partial Z} = 0$$

where the operators

$$f_1, f_5 : B \to (L^3(Z)\cap H^1(Z'))^2,$$
$$f_2, f_4 : B \to (L^3(A)\cap H^1(A'))^2,$$
$$f_3 : B \to H^{1/2}(\Gamma_A), \qquad f_6 : B \to H^{1/2}(\Gamma_Z)$$

can easily be seen to be Lipschitz with $O(\delta^4)$ Lipschitz constants. The proof employs the trace theorem and the continuous imbedding $W^{1,3} \subset\subset L^\infty$. Theorem 3.1 follows by a contraction mapping argument if we can show solvability of the linear problem where the f_i are considered as inhomogeneities.

Solvability in $H^1(A)(H^1(Z))$ of (3.9a, c) is immediate. H^2-regularity away from critical boundary points follows as in the proof of Lemma 3.2. For proving $W^{1,3}$-regularity we rewrite the differential equation in (3.9a) as

$$\Delta\tilde{u} = \nabla(|C|/e^{z_0})f_1 - \operatorname{div}(|C|/e^{z_0}f_1) - |C|/e^{z_0}\nabla(e^{z_0}/|C|)\nabla\tilde{u}.$$

Using the estimates

$$\|\nabla(|C|/e^{z_0})f_1\|_{L^{3/2}(Z)} \leqq \|\nabla(|C|/e^{z_0})\|_{L^3(Z)}\|f_1\|_{L^3(Z)} \leqq c\|f_1\|_{L^3(Z)}$$

$$\||C|/e^{z_0}f_1\|_{L^3(Z)} \leqq c\|f_1\|_{L^3(Z)},$$

$$\||C|/e^{z_0}\nabla(e^{z_0}/|C|)\nabla\tilde{u}\|_{L^{3/2}(Z)} \leqq \||C|/e^{z_0}\|_{L^\infty(Z)}\|\nabla(e^{z_0}/|C|)\|_{L^6(Z)}\|\nabla\tilde{u}\|_{L^2(Z)} \leqq c\|\nabla\tilde{u}\|_{L^2(Z)}$$

where we applied assumption (A6) and the Hölder inequality, we obtain $\tilde{u} \in W^{1,3}(Z)$ and continuous dependence on the data from assumption (A7). For $\tilde{v}$ we proceed analogously.

Considering $\tilde{u}$ and $\tilde{v}$ as data in (3.9b, d) we see that these problems can obviously be solved. If we note that the trace theorem (see, e.g., [17]) guarantees a sufficiently smooth extension of the Neumann data into the interior of Z and A, respectively, the required regularity can be shown similarly to the treatment of $\tilde{u}$ and $\tilde{v}$.

Thus the proof of Theorem 3.1 is complete.

STABILITY OF STEADY STATES FOR PREY-PREDATOR DIFFUSION EQUATIONS WITH HOMOGENEOUS DIRICHLET CONDITIONS*

YOSHIO YAMADA†

This paper is dedicated to Hiroshi Fujita on the occasion of his 60th *birthday.*

Abstract. This paper concerns a system of reaction-diffusion equations that describes the evolution of population densities of a prey species u and a predator species v inhabiting the same bounded domain. Under homogeneous Dirichlet boundary conditions, asymptotic stability properties of nonnegative steady states are discussed. The corresponding steady-state problem has nonnegative solutions of three different types; the trivial solution $(0, 0)$, the semitrivial solutions $(u, 0)$, $(0, v)$ with u, v positive, and a positive solution (u, v) with both components positive. Stability properties of the trivial and semitrivial solutions are determined completely. The stability and uniqueness of positive solutions are also studied. This method is based on spectral analysis, comparison principle, and bifurcation theory.

Key words. reaction-diffusion equations, positive steady state, asymptotic stability, bifurcation, prey-predator system

AMS(MOS) subject classifications. primary 35K55; secondary 35B32, 35B40

1. Introduction. In this paper we study the following system of reaction-diffusion equations:

$$\begin{aligned} u_t &= d_1\Delta u + au + uf(u, v), \\ v_t &= d_2\Delta v + bv + vg(u, v), \end{aligned} \tag{1.1}$$

for $x = (x_1, x_2, \cdots, x_N) \in \Omega$ and $t > 0$, where Δ is the Laplacian, and Ω is a bounded domain in R^N with smooth boundary Γ. In (1.1), d_1 and d_2 are positive diffusion constants, a and b are some constants, and the interaction between u and v is determined by f and g. These equations are supplemented by homogeneous Dirichlet boundary conditions

$$u = v = 0 \quad \text{for } (x, t) \in \Gamma \times (0, \infty). \tag{1.2}$$

Systems such as (1.1) arise in mathematical ecology and describe the evolution of population densities of two interacting species that inhabit the same region Ω undergoing simple diffusion. We study (1.1) as a model of prey-predator systems. Let u and v be population densities of a prey and a predator species, respectively. The constant a in (1.1) represents the birth rate of u and is assumed to be positive. Similarly, the constant b represents the birth rate of v, but we do not require its positivity. The functions f and g, reflecting the dynamics of the prey-predator interaction between u and v, are assumed to fulfill the following conditions:

(A.1) $f(u, v)$ is a C^1-function of $(u, v) \in [0, \infty) \times [0, \infty)$ such that $f(0, 0) = 0$ and $f_v(u, v) < 0$ for all $(u, v) \in [0, \infty) \times [0, \infty)$.

(A.2) $g(u, v)$ is a C^1-function of $(u, v) \in [0, \infty) \times [0, \infty)$ such that $g(0, 0) = 0$ and $g_u(u, v) > 0$ for all $(u, v) \in [0, \infty) \times [0, \infty)$.

† Department of Mathematics, Waseda University, Ohkubo 3-4-1, Shinjuku, Tokyo, 160 Japan.

Moreover, we impose the following self-limiting assumptions on f and g:

(A.3) $f(u, 0)$ is strictly monotone decreasing in $u \geqq 0$ and $\lim_{u\to\infty} f(u, 0) = -\infty$.

(A.4) $g(0, v)$ is strictly monotone decreasing in $v \geqq 0$ and $\lim_{v\to\infty} g(u, v) = -\infty$ for each $u \geqq 0$.

According to (A.3) and (A.4), each species can control its growth rate in the absence of the other species. Boundary condition (1.2) means that the habitat Ω is surrounded by hostile environment for both species.

Our purpose is to study the asymptotic behavior of nonnegative solutions for (1.1)-(1.2). In connection with this study, we are interested in finding all nonnegative steady-state solutions for (1.1)-(1.2) and deciding their stability. Related problems have been discussed by many authors; for prey-predator systems with Dirichlet conditions, see, e.g., [1]-[5], [8], [9], [14]-[16]. Especially, Blat and Brown [1] have studied nonnegative steady-state solutions for (1.1)-(1.2) in the case where

$$f(u, v) = -a_1 u - a_2 v, \qquad g(u, v) = b_1 u - b_2 v, \tag{1.3}$$

for some positive constants a_1, a_2, b_1, and b_2. By making use of decoupling and global bifurcation techniques, they have constructed nonnegative steady-state solutions, including positive ones. Recently, their existence results have been sharpened by Dancer [8], [9] with the use of degree theory. Indeed, necessary and sufficient conditions are established for the existence of positive steady-state solutions. (See also Li [16].)

However, it seems that stability properties of steady states have not yet been completely understood. In this direction, we refer the reader to the work of Conway, Gardner, and Smoller [4], [5], who have discussed the change of stability of nonnegative steady states for similar problems in the case $N = 1$.

We will indicate our main results on the stability of nonnegative steady states as well as on their structure. For the sake of simplicity, we choose f and g of form (1.3) and take a and b as bifurcation parameters. As in Fig. 1, the (a, b) parameter space is divided into four regions I, II, III, and IV defined by positive constants a^*, b^* and monotone C^1-functions $\bar{a}$, $\bar{b}$. Curves C_1 and C_2 are defined by $b = \bar{b}(a)$ and $a = \bar{a}(b)$, respectively. Besides the trivial solution $(0, 0)$, the stationary problem for (1.1)-(1.2) has two semitrivial solutions as nonnegative steady states: $(u^*, 0)$ for $a > a^*$ and $(0, v^*)$ for $b > b^*$. When (a, b) lies in I, $(0, 0)$ is a global attractor for (1.1)-(1.2); that is, all nonnegative solutions of (1.1)-(1.2) converge to $(0, 0)$ as $t \to \infty$. As a increases across a^* for each fixed b, then $(u^*, 0)$ bifurcates from $(0, 0)$. For $(a, b) \in$ II, $(u^*, 0)$ is a global attractor to (1.1)-(1.2) with nonnegative initial data, whereas $(0, 0)$ loses its stability. Another semitrivial solution $(0, v^*)$ existing for $b > b^*$ has similar stability properties when $(a, b) \in$ III. As a result, $(0, 0)$, $(u^*, 0)$, and $(0, v^*)$, respectively, possess I, II, and III as their global stability regions, so that there are no positive steady states for $(a, b) \in \text{I} \cup \text{II} \cup \text{III}$. When (a, b) lies in IV, these trivial and semitrivial solutions become unstable and a positive steady-state solution $(\bar{u}, \bar{v})$ appears as a secondary bifurcation from $(u^*, 0)$ or $(0, v^*)$. Especially, $(\bar{u}, \bar{v})$ is locally stable for $(a, b) \in$ IV restricted in a neighborhood of $C_1 \cup C_2$.

The content of this paper is as follows. In § 2 we collect some preliminary results about asymptotic and stability properties for related single reaction-diffusion equations. In § 3 we carry out spectral analysis for trivial and semitrivial steady-state solutions of (1.1)-(1.2). Section 4 is devoted to the study of global attractivity of trivial and semitrivial solutions, where the comparison principle is a basic tool. By the local bifurcation theory due to Crandall and Rabinowitz [6], [7], it is shown in § 5 that positive steady-state solutions bifurcate from two semitrivial ones and that they are

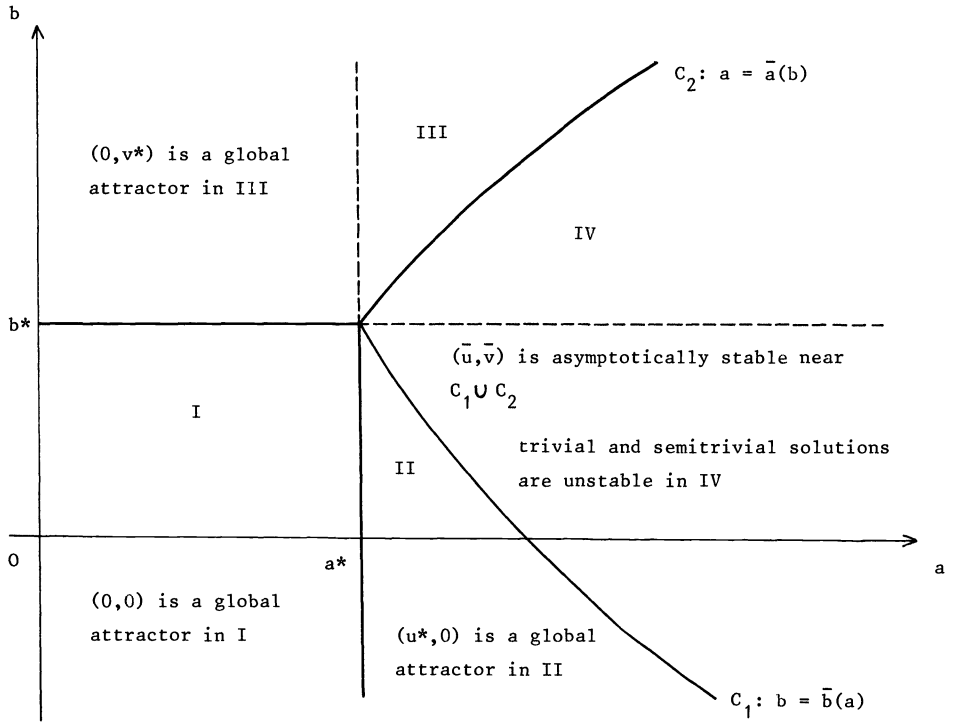

FIG. 1

locally stable. According to global bifurcation theory, these bifurcating solutions are connected to each other by a branch of positive steady-state solutions. In § 6 we carry out bifurcation and stability analysis near $(a, b) = (a^*, b^*)$ to get more information about the branch of positive solutions.

The analysis in the present paper concentrates on reaction-diffusion systems of prey-predator type. However, most of the methods developed in §§ 3, 5, and 6 are also valid for studying reaction-diffusion systems of competition type.

Notation. The usual norms of the spaces $L^p(\Omega)$ for $1 \leqq p < \infty$ and $C(\bar{\Omega})$ are defined by

$$\|u\|_p^p = \int_\Omega |u(x)|^p \, dx, \qquad \|u\|_\infty = \max_{x \in \bar{\Omega}} |u(x)|.$$

In particular, we denote by $(\cdot, \cdot)_2$ the inner product of $L^2(\Omega)$. For any integer k, let $W^{k,p}(\Omega)$ be the Sobolev space of functions $u: \Omega \to R$ such that u and its distributional derivatives up to order k belong to $L^p(\Omega)$. The completion of $C_0^\infty(\Omega)$ with respect to the $W^{k,p}(\Omega)$-norm is denoted by $\mathring{W}^{k,p}(\Omega)$.

2. Some preliminaries for single reaction-diffusion equations. In this section we collect some results about single reaction-diffusion equations that are required later.

Consider the following initial boundary value problem:

$$\begin{aligned} &w_t = d\Delta w + \alpha(x)w + (c + h(w))w \quad \text{in } \Omega \times (0, \infty), \\ &w = 0 \qquad\qquad\qquad\qquad\qquad\quad \text{on } \Gamma \times (0, \infty), \end{aligned} \tag{2.1}$$

where d is a positive constant, α is a $C^{\mu}(\bar{\Omega})$-function with $\mu > 0$, and c is a parameter moving over $(-\infty, \infty)$. We assume that

(H) $h:[0,\infty)\to(-\infty,0]$ is a strictly monotone decreasing function of class $C^1([0,\infty))$ such that $h(0)=0$ and $\lim_{w\to\infty} h(w)=-\infty$.

Let $p > N$ and set $X = L^p(\Omega)$. We define a closed linear operator A in X with domain $D(A)$ by

$$Au = -d\Delta w \quad \text{for } w \in D(A) \equiv W^{2,p}(\Omega) \cap \mathring{W}^{1,p}(\Omega).$$

It is well known that $-A$ generates an analytic semigroup $\{e^{-tA}\}_{t\geqq 0}$ and that the solution w of (2.1) with $w(0) = w_0$ satisfies

$$w(t) = e^{-tA}w_0 + \int_0^t e^{-(t-s)A}\tilde{h}(w(s))\,ds, \tag{2.2}$$

where $\tilde{h}(w) = (\alpha + c + h(w))w$.

Let w_0 be any nonnegative function of class $C(\bar{\Omega})$ and let $w(x, t; w_0)$ denote the solution of (2.1) with $w(0) = w_0$. By virtue of (H), we can choose $M > 0$ such that $h(M) + c + \|\alpha\|_{\infty} = 0$. Then the comparison theorem (see, e.g., Protter and Weinberger [17]) yields an a priori estimate

$$0 \leqq w(x, t; w_0) \leqq \max\{\|w_0\|_{\infty}, M\}, \tag{2.3}$$

which assures that the solution w of (2.1) exists globally in time. Moreover, using (2.3) and the smoothing effect of parabolic equations, we can see from (2.2) that, for any $0 \leqq \alpha < 1$, the solution orbit $\{w(t; w_0);\ t \geqq 1\}$ is relatively compact in $D(A^{\alpha})$ equipped with graph norm of A^{α} (see Henry [10, Thm. 3.3.6]). Here we observe that

$$D(A^{\alpha}) \subset C^1(\bar{\Omega}) \quad \text{if } 1 + N/p < 2\alpha, \tag{2.4}$$

where injection is continuous and compact (see, e.g., [10, Thms. 1.4.8 and 1.6.1]). In what follows, we fix α satisfying $(p+N)/2p < \alpha < 1$. Define the ω-limit set $\omega(w_0)$ associated with the solution orbit $\{w(t; w_0);\ t \geqq 0\}$ by

$$\begin{aligned}\omega(w_0) = \{w^*;\ &\text{there exists a sequence } \{t_n\}\uparrow\infty \\ &\text{such that } w(t_n; w_0) \to w^* \text{ in } D(A^{\alpha})\};\end{aligned} \tag{2.5}$$

then it is nonempty, connected, and invariant [10, Thm. 4.3.3]. Furthermore, (2.1) is gradient-like with respect to the functional

$$E(w) = \int_{\Omega} \{d|\nabla w(x)|^2/2 - (\alpha(x) + c)w(x)^2/2 - H(w(x))\}\,dx,$$

where $H'(w) = wh(w)$, so that E is a Lyapunov function on $D(A^{\alpha})$, that is, $dE(w(t; w_0))/dt \leqq 0$. Therefore,

$$\omega(w_0) \subset \{w^* \in D(A^{\alpha});\ w^* \text{ is a nonnegative steady-state solution of (2.1)}\} \tag{2.6}$$

[10, Thm. 4.3.4]; so that any $w^* \in \omega(w_0)$ satisfies

$$\begin{aligned} &-d\Delta w - \alpha w = (c + h(w))w \quad \text{and} \quad w \geqq 0 \quad \text{in } \Omega, \\ &w = 0 \qquad\qquad\qquad\qquad\qquad\qquad\quad \text{on } \Gamma. \end{aligned} \tag{2.7}$$

Let ζ_0 be the least eigenvalue for

$$-d\Delta w - \alpha w = \zeta w \quad \text{in } \Omega \quad \text{and} \quad w = 0 \quad \text{on } \Gamma. \tag{2.8}$$

It is well known that, if $c \leqq \zeta_0$, then $w \equiv 0$ is the only solution of (2.7), whereas if $c > \zeta_0$, then (2.7) has a unique positive solution w^* (see, e.g., Blat and Brown [1]). Thus we are able to show the following proposition in the standard manner with use of the comparison technique (see, e.g., [5, Prop. 2.1]).

PROPOSITION 2.1. *Let w be the solution of* (2.1) *with $w(\cdot\,, 0) = w_0$, where $w_0 (\not\equiv 0)$ is a nonnegative function of class $C(\bar{\Omega})$.*

(i) *If $c \leqq \zeta_0$, then $\lim_{t\to\infty} w(\cdot\,, t) = 0$ in $C(\bar{\Omega})$.*

(ii) *If $c > \zeta_0$, then $\lim_{t\to\infty} w(\cdot\,, t) = w^*(c)$ in $C(\bar{\Omega})$, where $w^*(\cdot\,; c)$ is a unique positive solution of* (2.7).

We will investigate some properties related to $w^*(c)$ for $c > \zeta_0$. The linearized operator $L(c): X \to X$ of (2.7) about $w^*(c)$ is given by

$$L(c)w = Aw - \alpha w - cw - (wh(w))'(w^*(c))w \quad \text{with } D(L(c)) = D(A),$$

where $(wh(w))' = d(wh(w))/dw$. As is well known, the spectrum $\sigma(L(c))$ of $L(c)$ consists of eigenvalues that lie on the real axis. Furthermore, we can prove the following lemma.

LEMMA 2.2. *For each $c > \zeta_0$, all eigenvalues of $L(c)$ are positive.*

Proof. It suffices to follow the arguments used by Ito [11, Lemma A.1] (see also Blat and Brown [2, Lemma 2.1]). □

LEMMA 2.3. *For each $c > \zeta_0$, $L(c)$ has a bounded inverse $L(c)^{-1}$. Moreover,*

$$L(c)^{-1} f > 0 \quad \text{in } \Omega$$

for all f $(\not\equiv 0) \in X$ satisfying $f \geqq 0$ almost everywhere in Ω.

Proof. If follows from Lemma 2.2 that $L(c)$ is invertible in X. For each nonnegative $f \in X$, put $w = L(c)^{-1} f$ and decompose it as $w = w^+ - w^-$, where $w^+ = \max\{w, 0\}$ and $w^- = -\min\{w, 0\}$. Since w satisfies

$$-d\Delta w - \{\alpha + c + (wh(w))'(w^*(c))\}w = f \quad \text{in } \Omega \tag{2.9}$$

with $w = 0$ on Γ, multiplying (2.9) by $-w^-$ and integrating the resulting expression over Ω, we can derive

$$0 \geqq -\int_\Omega f w^- \, dx = \int_\Omega [d|\nabla w^-|^2 - \{\alpha + c + (wh(w))'(w^*(c))\}(w^-)^2] \, dx$$

$$\geqq \nu_0 \int_\Omega (w^-)^2 \, dx,$$

where ν_0 is the least eigenvalue of $L(c)$, which is positive by Lemma 2.2. Thus, $w^- \equiv 0$; so that $w \geqq 0$ almost everywhere in Ω. The strict positivity of w in Ω follows from the strong maximum principle. □

Finally, we state the dependence of $w^*(c)$ on c.

LEMMA 2.4. (i) $\operatorname{Lim}_{c\to\zeta_0} w^*(c) = 0$ *uniformly in $\bar{\Omega}$.*

(ii) *The mapping $c \to w^*(c)$ is of class $C^1((\zeta_0, \infty); D(A))$ and the Fréchet derivative of w^* with respect to c, which is denoted by w_c^*, satisfy*

$$w_c^*(c) > 0 \quad \text{in } \Omega \quad \text{for } c > \zeta_0.$$

For the proof, see [2, Lemma 2.2] or [11, Lemma A.3].

3. Spectral analysis. We first give existence and regularity results of global solutions for (1.1)-(1.2) with nonnegative initial data.

For $p > n$, set $\mathbf{X} = \{L^p(\Omega)\}^2$, $\mathbf{Y} = \{W^{2,p}(\Omega) \cap \mathring{W}^{1,p}(\Omega)\}^2$ and define a closed linear operator $\mathbf{A}$ in $\mathbf{X}$ by

$$\mathbf{A}\begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} A_1 u \\ A_2 v \end{pmatrix} \quad \text{for} \begin{pmatrix} u \\ v \end{pmatrix} \in D(\mathbf{A}) \equiv \mathbf{Y},$$

where $A_1 u = -d_1 \Delta u$ and $A_2 v = -d_2 \Delta v$. Since $-\mathbf{A}$ generates an analytic semigroup $\{\exp(-t\mathbf{A})\}_{t \geqq 0}$ in $\mathbf{X}$, the initial value problem for (1.1), (1.2) can be treated as that for an abstract evolution equation (see § 2).

Then the global solvability theorem reads as follows.

PROPOSITION 3.1. *Let u_0, v_0 be nonnegative functions of class $C(\bar{\Omega})$. Then there exists a unique solution (u, v) of* (1.1), (1.2) *with $(u(0), v(0)) = (u_0, v_0)$ in the class $C([0, \infty); \mathbf{X}) \cap C^1((0, \infty); D(\mathbf{A}))$. Moreover,*

$$0 \leqq u(x, t) \leqq m_1 \quad \text{and} \quad 0 \leqq v(x, t) \leqq m_2 \tag{3.1}$$

for $(x, t) \in \Omega \times [0, \infty)$ with some positive constants m_1, m_2.

Proof. Since the local solvability and uniqueness can be derived in the standard manner, to obtain the global solvability it suffices to show (3.1) (see, e.g., Rothe [19, Thm. 1]). In view of the forms in (1.1), it is easy to see from the comparison theorem that

$$u \geqq 0 \quad \text{and} \quad v \geqq 0 \tag{3.2}$$

as long as the solution (u, v) exists. Hence, by (A.1),

$$u_t \leqq d_1 \Delta u + u(a + f(u, 0)). \tag{3.3}$$

Since we can choose $M_a > 0$ satisfying $a + f(M_a, 0) = 0$ by (A.3), application of the comparison theorem to (3.3) yields

$$u \leqq \max\{\|u_0\|_\infty, M_a\} \equiv m_1. \tag{3.4}$$

Therefore, because of (3.4) and (A.2), we can show

$$v_t \leqq d_2 \Delta v + v(b + g(m_1, v)). \tag{3.5}$$

As in the derivation of (3.4), it follows from (3.5) that

$$v \leqq \max\{\|v_0\|_\infty, N_b\} \equiv m_2, \tag{3.6}$$

where N_b is a positive constant satisfying $b + g(m_1, N_b) = 0$ (use (A.4)). Thus (3.1) is derived from (3.2), (3.4), and (3.6). □

Usually, the asymptotic behavior of global solutions is closely related to the stability analysis of the corresponding stationary problem. So we consider

$$-d_1 \Delta u - au = uf(u, v) \quad \text{in } \Omega, \tag{3.7}$$

$$-d_2 \Delta v - bv = vg(u, v) \quad \text{in } \Omega, \tag{3.8}$$

$$u = v = 0 \quad \text{on } \Gamma, \tag{3.9}$$

with additional condition

$$u \geqq 0 \quad \text{and} \quad v \geqq 0 \quad \text{in } \Omega. \tag{3.10}$$

Besides the *trivial solution* $(0, 0)$, the stationary problem above may have solutions of two different types; *semitrivial solutions* $(u, 0)$, $(0, v)$ with u and v positive and *positive solution* (u, v) with both components positive. The existence of semitrivial

solutions follows from Proposition 2.1. Indeed, if we denote by λ_0 (>0) the least eigenvalue of

$$-\Delta u = \lambda u \quad \text{in } \Omega, \qquad u = 0 \quad \text{on } \Gamma, \tag{3.11}$$

then Proposition 2.1, together with (A.1) and (A.3), yields the existence of a (unique) positive function $u^*(a)$ satisfying

$$-d_1\Delta u^* - au^* = u^* f(u^*, 0) \quad \text{in } \Omega, \qquad u^* = 0 \quad \text{on } \Gamma, \tag{3.12}$$

for $a > d_1\lambda_0$; so that $(u^*(a), 0)$ clearly satisfies (3.7)-(3.10). Similarly, there is another semitrivial solution $(0, v^*(b))$ for $b > d_2\lambda_0$, where $v^*(b)$ is the unique positive solution of

$$-d_2\Delta v^* - bv^* = v^* g(0, v^*) \quad \text{in } \Omega, \qquad v^* = 0 \quad \text{on } \Gamma. \tag{3.13}$$

We now investigate the (local) stability of these trivial and semitrivial solutions by examining the spectrum of the corresponding linearized operator. Recall that any solution $(\bar{u}, \bar{v})$ of (3.7)-(3.9) is said to be *asymptotically stable* if the spectrum of the linearized operator of (3.7)-(3.9) at $(\bar{u}, \bar{v})$ lies in the right-hand side of the imaginary axis. If there are some points in the spectrum with negative real parts, we say that $(\bar{u}, \bar{v})$ is *unstable*. (For details, see Kielhöfer [13, Thms. 4.1, 4.2] or Henry [10, Thms. 5.1.1, 5.1.3].)

The linearized operator of (3.7)-(3.9) at $(0, 0)$ is given by

$$\mathbf{L}_0(a, b) = \begin{pmatrix} A_1 - a & 0 \\ 0 & A_2 - b \end{pmatrix}, \tag{3.14}$$

whose spectrum consists of eigenvalues. Clearly, we have Theorem 3.2.

THEOREM 3.2. *Set*

$$a^* = d_1\lambda_0 \quad \textit{and} \quad b^* = d_2\lambda_0. \tag{3.15}$$

The trivial solution is asymptotically stable if $a < a^*$ and $b < b^*$ and unstable if $a > a^*$ or $b > b^*$.

We proceed to the spectral analysis of the semitrivial solutions. The linearized operator of (3.7)-(3.9) at $(u^*(a), 0)$ produces the closed operator $\mathbf{L}_1(a, b)$ in $\mathbf{X}$ given by

$$\mathbf{L}_1(a, b) = \begin{pmatrix} L_1(a) & -u^*(a) f_v(u^*(a), 0) \\ 0 & L_2(a, b) \end{pmatrix} \tag{3.16}$$

with $D(\mathbf{L}_1) = \mathbf{Y}$, where $L_1(a)u = A_1 u - au - (uf)_u(u^*(a), 0)u$ and $L_2(a, b)v = A_2 v - bv - g(u^*(a), 0)v$. By the Riesz-Schauder theory, the spectrum $\sigma(\mathbf{L}_1(a, b))$ of $\mathbf{L}_1(a, b)$ consists of real eigenvalues and

$$\sigma(\mathbf{L}_1(a, b)) = \sigma(L_1(a)) \cup \sigma(L_2(a, b))$$

(cf. [11, Lemma 3.5] or [5, Thm. 2.7]). By Lemma 2.2, $\sigma(L_1(a))$ lies on the positive real axis. Moreover, $\sigma(L_2(a, b))$ lies on the real axis and the least eigenvalue $\nu_2(a, b)$ is characterized as

$$\nu_2(a, b) = \bar{b}(a) - b, \tag{3.17}$$

with

$$\bar{b}(a) = \inf\{d_2\|\nabla v\|_2^2 - (g(u^*(a), 0)v, v)_2;\ v \in \mathring{W}^{1,2}(\Omega),\ \|v\|_2 = 1\}. \tag{3.18}$$

Therefore, the stability of $(u^*(a), 0)$ is stated as follows.

THEOREM 3.3. *Define* (a^*, b^*) *by* (3.15) *and* $\bar{b}$ *by* (3.18). *Let* $a \geqq a^*$. *Then* $(u^*(a), 0)$ *is asymptotically stable if* $\bar{b}(a) > b$ *and unstable if* $\bar{b}(a) < b$.

For later use we will collect some properties of $\bar{b}$.

LEMMA 3.4. *The function* $\bar{b}$ *defined by* (3.18) *satisfies the following*:

(i) $\bar{b} \in C([a^*, \infty))$ *and* $\bar{b}(a^*) = b^*$.

(ii) $\bar{b} \in C^1((a^*, \infty))$ *and* $\bar{b}'(a) < 0$.

(iii) If $f_u(0, 0) < 0$, *then* $\lim_{a \to a^*} \bar{b}'(a) = g_u(0, 0)/f_u(0, 0) < 0$.

Proof. We follow the idea used by Ito [11, Lemma A.4] to prove (i) and (ii). Since $\bar{b}(a)$ is the least eigenvalue of

$$-d_2 \Delta v - g(u^*(a), 0)v = \mu v \quad \text{in } \Omega, \qquad v = 0 \quad \text{on } \Gamma,$$

we may take the corresponding eigenfunction $\psi(a)$ such that $\|\psi(a)\|_2 = 1$ and $\psi(a) > 0$ in Ω. The infimum in (3.18) is attained by $\psi(a)$, so that

$$\begin{aligned} \bar{b}(a+h) &= d_2 \|\nabla \psi(a+h)\|_2^2 - (g(u^*(a+h), 0)\psi(a+h), \psi(a+h))_2 \\ &\leqq d_2 \|\nabla \psi(a)\|_2^2 - (g(u^*(a+h), 0)\psi(a), \psi(a))_2 \\ &= \bar{b}(a) - (\{g(u^*(a+h), 0) - g(u^*(a), 0)\}\psi(a), \psi(a))_2. \end{aligned} \tag{3.19}$$

The similar inequality is valid if a and $a+h$ are exchanged. Hence

$$|\bar{b}(a+h) - \bar{b}(a)| \leqq \|g(u^*(a+h), 0) - g(u^*(a), 0)\|_\infty. \tag{3.20}$$

Thus the assertion of (i) follows from (3.20) and Lemma 2.4. To prove (ii), we observe that (3.20), together with (ii) of Lemma 2.4, implies the local Lipschitz continuity of $\bar{b}$ on (a^*, ∞). Hence making use of (3.19), divide $\bar{b}(a+h) - \bar{b}(a)$ by $h > 0$ ($h < 0$) and let $h \to 0$; then

$$\bar{b}'(a) = -\int_\Omega g_u(u^*(a), 0) u_a^*(a) \psi(a)^2 \, dx \tag{3.21}$$

for almost every $a \in (a^*, \infty)$. In (3.21), $a \to u^*(a)$ is continuously differentiable in $C(\bar{\Omega})$ by Lemma 2.4 and $a \to \psi(a)$ is continuous in $L^2(\Omega)$ by the perturbation result of Kato [12, Chap. 4, § 5]. Thus the right-hand side of (3.21) is continuous in a, so that (3.21) holds true for all $a \in (a^*, \infty)$. In view of (A.2) and Lemma 2.4, the negativity of $\bar{b}'$ easily follows from (3.21).

We prove (iii) with use of the identity (3.21). Let φ_0 be the eigenfunction of (3.11) corresponding to the least eigenvalue λ_0; so that we can take φ_0 satisfying $\varphi_0 > 0$ in Ω and $\|\varphi_0\|_2 = 1$. By (i) of Lemma 2.4, it is possible to show that

$$\lim_{a \to a^*} g_u(u^*(a), 0) = g_u(0, 0) \quad \text{in } C(\bar{\Omega}). \tag{3.22}$$

Moreover, by the result of Kato [12],

$$\lim_{a \to a^*} \psi(a) = \varphi_0 \quad \text{in } L^2(\Omega). \tag{3.23}$$

It remains to derive the dependence of u_a^* on a. Since $u^*(a)$ is the unique nontrivial solution of (3.12) for $a > a^*$, we make use of the local bifurcation theory of Crandall and Rabinowitz [7, Lemma 1.1] to get an expression of $u^*(a)$ near $a = a^*$. Set $X = L^p(\Omega)$ and $Y = W^{2,p}(\Omega) \cap \mathring{W}^{1,p}(\Omega)$. Define the operator $F: Y \times R \to X$ by

$$F(u; a) = A_1 u - au - uf(u, 0).$$

Clearly, $F(0; a)=0$ and $F_u(0; a^*)=A_1-a^*$; so that $\dim N(A_1-a^*)=$ codim $R(A_1-a^*)=1$, where the null space and range space of a linear operator L are denoted by $N(L)$ and $R(L)$. Moreover,

$$F_{ua}(0; a^*)\varphi_0=-\varphi_0\notin R(A_1-a^*).$$

Therefore, applying Lemma 1.1 of [7], we obtain functions $(w(s), a(s))\in C^1([-s_0, s_0]; X\times R)$, where s_0 is a sufficiently small number, with the following properties: (a) $w(0)=0$ and $a(0)=a^*$; (b) $F(u(s), a(s))=0$, where $u(s)=s(\varphi_0+w(s))$ and $w(s)\in R(A_1-a^*)\cap Y$. The uniqueness of nontrivial solutions for (3.12) near $a=a^*$ (see [7, Lemma 1.1]) implies

$$u^*(a(s))=s(\varphi_0+w(s)). \tag{3.24}$$

Now observe that

$$\begin{aligned}0&=(F(s(\varphi_0+w(s)); a(s)), \varphi_0)_2\\&=-s(a(s)-a^*)-s((\varphi_0+w(s))f(s(\varphi_0+w(s)), 0), \varphi_0)_2\end{aligned}$$

because $\|\varphi_0\|_2=1$ and $w(s)\in R(A_1-a^*)$. Hence

$$a(s)-a^*=-((\varphi_0+w(s))f(s(\varphi_0+w(s)), 0), \varphi_0)_2;$$

so

$$\frac{da}{ds}(0)=-f_u(0, 0)\|\varphi_0\|_3^3. \tag{3.25}$$

Since it follows from (3.24) and (3.25) that

$$u_a^*(a^*)=\varphi_0/a_s(0)=-\varphi_0(f_u(0, 0)\|\varphi_0\|_3^3)^{-1}, \tag{3.26}$$

identity (3.21), together with (3.22), (3.23), and (3.26), gives

$$\lim_{a\to a^*}\bar{b}'(a)=\frac{g_u(0, 0)}{f_u(0, 0)}. \qquad \square$$

The stability analysis for $(0, v^*(b))$ can be carried out in the same way as that for $(u^*(a), 0)$. The linearized operator $\mathbf{L}_2(a, b)$: $\mathbf{X}\to\mathbf{X}$ of (3.7)-(3.9) at $(0, v^*(b))$ is given by

$$\mathbf{L}_2(a, b)=\begin{pmatrix}L_3(a, b) & 0\\ -v^*(b)g_u(0, v^*(b)) & L_4(b)\end{pmatrix}$$

with $D(\mathbf{L}_2(a, b))=\mathbf{Y}$, where $L_3(a, b)u=A_1u-au-f(0, v^*(b))u$ and $L_4(b)v=A_2v-bv-(vg)_v(0, v^*(b))v$. The spectrum

$$\sigma(\mathbf{L}_2(a, b))=\sigma(L_3(a, b))\cup\sigma(L_4(b))$$

is composed of only real eigenvalues. By Lemma 2.2, the least eigenvalue of $L_4(b)$ is positive. To characterize the least eigenvalue $\nu_3(a, b)$ of $L_3(a, b)$, we introduce the following function (cf. (3.18)):

$$\bar{a}(b)=\inf\{d_1\|\nabla u\|_2^2-(f(0, v^*(b))u, u)_2;\ u\in\mathring{W}^{1,2}(\Omega), \|u\|_2=1\}. \tag{3.27}$$

Since $\nu_3(a, b)=\bar{a}(b)-a$, the stability of $(0, v^*(b))$ reads as follows.

THEOREM 3.5. *Let $b\geqq b^*$. If $\bar{a}$ is defined by* (3.27), *then $(0, v^*(b))$ is asymptotically stable if $a<\bar{a}(b)$ and unstable if $a>\bar{a}(b)$.*

Finally, we state some properties of the function $\bar{a}$, which can be shown in the same way as Lemma 3.4.

LEMMA 3.6. *The function* $\bar{a}$ *defined by* (3.27) *satisfies*

(i) $\bar{a} \in C([b^*, \infty))$ *and* $\bar{a}(b^*) = a^*$;

(ii) $\bar{a} \in C^1((b^*, \infty))$ *and* $\bar{a}'(b) > 0$;

(iii) *If* $g_v(0, 0) < 0$, *then*

$$\lim_{b \to b^*} \bar{a}'(b) = f_v(0, 0)/g_v(0, 0) > 0.$$

4. Stability analysis via the comparison principle. In § 3 we discussed the linearized stability of trivial and semitrivial steady-state solutions. More information about their stability properties can be derived via the comparison principle.

Though Theorem 3.2 means merely the local stability of $(0, 0)$, its global attractivity holds in the following sense.

THEOREM 4.1. *If* $a \leqq a^*$ *and* $b < b^*$, *then every nonnegative solution of* (1.1), (1.2) *converges to* $(0, 0)$ *uniformly in* $\bar{\Omega}$ *as* $t \to \infty$.

Proof. By the nonnegativity of u and (A.1),

$$u_t \leqq d_1 \Delta u + au + uf(u, 0) \quad \text{in } \Omega \times (0, \infty).$$

Let U be the solution of

$$\begin{aligned} &U_t = d_1 \Delta U + aU + Uf(U, 0) && \text{in } \Omega \times (0, \infty), \\ &U = 0 && \text{on } \Gamma \times (0, \infty), \\ &U(\cdot, 0) = u(\cdot, 0) \geqq 0 && \text{in } \Omega. \end{aligned} \tag{4.1}$$

The comparison theorem for parabolic equations implies $0 \leqq u \leqq U$ and Proposition 2.1 ensures that $U(\cdot, 0) \to 0$ uniformly in $\bar{\Omega}$ as $t \to \infty$. Therefore,

$$\lim_{t \to \infty} u(\cdot, t) = 0 \quad \text{uniformly in } x \in \bar{\Omega}. \tag{4.2}$$

Because of (4.2) we can show that, for any $\varepsilon > 0$, there exists T_ε such that

$$v_t \leqq d_2 \Delta v + (b + \varepsilon)v + vg(0, v) \quad \text{in } \Omega \times [T_\varepsilon, \infty).$$

Since $b + \varepsilon \leqq b^*$ for sufficiently small ε, Proposition 2.1, together with the comparison theorem, enables us to show that

$$\lim_{t \to \infty} v(\cdot, t) = 0 \quad \text{uniformly in } x \in \bar{\Omega}, \tag{4.3}$$

as in the derivation of (4.2). Thus (4.2) and (4.3) yield the assertion. □

Before studying the global attractivity of $(u^*(a), 0)$ or $(0, v^*(b))$, we put some additional conditions on f and g:

$$f(0, v) \geqq f(u, v) \quad \text{for all } u, v \geqq 0, \tag{A.5}$$

$$g(u, 0) \geqq g(u, v) \quad \text{for all } u, v \geqq 0. \tag{A.6}$$

THEOREM 4.2. *In addition to* (A.1)-(A.4), *assume* (A.6). *If* $a > a^*$ *and* $\bar{b}(a) > b$, *then every nonnegative solution* (u, v) *of* (1.1), (1.2) *with* $u(\cdot, 0) \not\equiv 0$ *satisfies*

$$\lim_{t \to \infty} (u(\cdot, t), v(\cdot, t)) = (u^*(a), 0) \quad \textit{uniformly in } \bar{\Omega}. \tag{4.4}$$

Proof. We employ the same method, based on the comparison theorem, as that used by Conway, Gardner, and Smoller [5, Thm. 2.3] (see also [4]). Note that the solution U of (4.1) satisfies

$$\lim_{t\to\infty} U(\cdot, t) = u^*(a) \quad \text{uniformly in } \bar{\Omega}$$

by Proposition 2.1. Therefore, in view of $u \leqq U$, we can show that

$$\limsup_{t\to\infty} u(\cdot, t) \leqq u^*(a) \quad \text{uniformly in } \bar{\Omega}. \tag{4.5}$$

This fact, together with (A.2) and (A.6), assures that, for any $\varepsilon > 0$, there is T_ε such that

$$\begin{aligned} v_t &\leqq d_2\Delta v + (b+\varepsilon)v + vg(u^*(a), v) \\ &\leqq d_2\Delta v + (b+\varepsilon)v + vg(u^*(a), 0) \end{aligned}$$

in $\Omega \times [T_\varepsilon, \infty)$. Here we recall that the least eigenvalue of $-d_2\Delta - g(u^*(a), 0)$ with homogeneous Dirichlet condition is $\bar{b}(a)$ (see (3.18)). Since $b+\varepsilon < \bar{b}(a)$ if $\varepsilon > 0$ is sufficiently small, it follows from the comparison theorem that

$$\lim_{t\to\infty} v(\cdot, t) = 0 \quad \text{uniformly in } \bar{\Omega}. \tag{4.6}$$

Having established (4.6), we return to the first equation of (1.1). For any $\varepsilon > 0$,

$$u_t \geqq d_1\Delta u + (a-\varepsilon)u + uf(u, 0) \quad \text{in } \Omega \times [T'_\varepsilon, \infty)$$

with some $T'_\varepsilon > 0$. If ε is sufficiently small so that $d_1\lambda_0 < a - \varepsilon$, Proposition 2.1 enables us to deduce that

$$\liminf_{t\to\infty} u(\cdot, t) \geqq u^*(a-\varepsilon) \quad \text{uniformly in } \Omega. \tag{4.7}$$

Letting $\varepsilon \downarrow 0$ in (4.7) and using (4.5), we have

$$\lim_{t\to\infty} u(\cdot, t) = u^*(a) \quad \text{uniformly in } \Omega. \tag{4.8}$$

Thus (4.6) and (4.8) accomplish the proof. □

When (A.5) is assumed in place of (A.6), it is possible to show the global attractivity of $(0, v^*(b))$ along the same line as Theorem 4.2.

THEOREM 4.3. *In addition to* (A.1)-(A.4), *assume* (A.5). *If* $b \geqq b^*$ *and* $\bar{a}(b) > a$, *then every nonnegative solution of* (1.1), (1.2) *with* $v(\cdot, 0) \not\equiv 0$ *satisfies*

$$\lim_{t\to\infty} (u(\cdot, t), v(\cdot, t)) = (0, v^*(b)) \quad \textit{uniformly in } \bar{\Omega}.$$

Remark 4.1. We summarize our stability results of §§ 3 and 4 in the (a, b) parameter space (see Fig. 1). Assume that (A.1)-(A.6) are imposed on f and g. (Observe that f and g defined by (1.3) satisfy (A.1)-(A.6).) Theorems 4.1-4.3 ensure that $(0, 0)$, $(u^*(a), 0)$, and $(0, v^*(b))$ become global attractors for (1.1), (1.2) when (a, b) lies in regions I, II, and III, respectively. Therefore, there are no positive steady states for $(a, b) \in \text{I} \cup \text{II} \cup \text{III}$. This fact agrees with the result of Li [16], who has discussed prey-predator systems by setting almost the same assumptions as (A.1)-(A.6). Finally, we should say that, by Theorems 3.2, 3.3, and 3.5, trivial and semitrivial steady states are unstable if $(a, b) \in \text{IV}$.

5. Analysis of the stationary problem by bifurcation theory. In the subsequent sections we study positive steady states for (1.1), (1.2). There are several results on their existence; [1]-[3], [5], [8], [9], and [16]. Among them, Li [16, Thms. 1, 2] (cf.

Dancer [8], [9]) has established necessary and sufficient conditions for prey-predator diffusion systems (similar to ours) by using the degree theory. According to his work, it will be shown that, under assumptions (A.1)-(A.6), stationary problem (3.7)-(3.10) has a positive solution if and only if all the trivial and semitrivial solutions are unstable; that is, (a, b) satisfies $a > \bar{a}(b)$ and $b > \bar{b}(a)$. However, the stability of positive steady states is still an open problem. We will discuss their stability with use of the bifurcation theory, although most of the existence parts are already known.

It is now convenient to restate our preceding results from the standpoint of bifurcation theory (see Fig. 1). When a (respectively, b) is regarded as a bifurcation parameter, $(u^*(a), 0)$ (respectively, $(0, v^*(b))$) appears as a primary bifurcation from $(0, 0)$ at $a = a^*$ (respectively $b = b^*$) and the stability changes there. Moreover, $(u^*(a), 0)$ and $(0, v^*(b))$ lose their stability, when (a, b) crosses the C_1-curve and the C_2-curve, respectively. Therefore, positive solutions of (3.7)-(3.9) will be realized as secondary bifurcations from $(u^*(a), 0)$ or $(0, v^*(b))$. See the works of Blat and Brown [1]-[3] and Conway, Gardner, and Smoller [4], [5], where some bifurcation techniques are used.

We first discuss the secondary bifurcation from $(u^*(a), 0)$. Let $a > a^*$ be fixed and regard b as a parameter. Define a nonlinear operator $\mathbf{F}: \mathbf{Y} \times R \to \mathbf{X}$ by

$$\mathbf{F}(U; b) = \begin{pmatrix} A_1 u - au - uf(u, v) \\ A_2 v - bv - vg(u, v) \end{pmatrix} \quad \text{for } U = \begin{pmatrix} u \\ v \end{pmatrix} \in \mathbf{Y}. \tag{5.1}$$

Clearly, $\mathbf{F}(U^*; b) = 0$, where $U^* = {}^t(u^*(a), 0)$. As in the proof of Lemma 3.4, we employ the results of Crandall and Rabinowitz [7] to show bifurcation at $b = \bar{b}(a)$. In what follows, we sometimes write $\bar{b}$ in place of $\bar{b}(a)$. The Fréchet derivative of $\mathbf{F}(U; b)$ with respect to U at $(U, b) = (U^*, \bar{b})$ is given by

$$\mathbf{F}_U(U^*; \bar{b}) = \mathbf{L}_1(a, \bar{b}), \tag{5.2}$$

where $\mathbf{L}_1(a, b)$ is defined by (3.16). We will verify the assumptions of Lemma 1.1 of [7].

LEMMA 5.1. (i) $\dim N(\mathbf{F}_U(U^*; \bar{b}(a))) = 1$ *and* $N(\mathbf{F}_U(U^*; \bar{b}(a))) = \{{}^t(\varphi_1, \varphi_2)\}$ *with* $\varphi_1 < 0$, $\varphi_2 > 0$ *in* Ω *and* $\|\varphi_2\|_2 = 1$.

(ii) $\operatorname{codim} R(\mathbf{F}_u(U^*; \bar{b}(a))) = 1$. *Moreover,* ${}^t(h_1, h_2) \in R(\mathbf{F}_U(U^*; \bar{b}(a)))$ *if and only if* $(h_2, \varphi_2)_2 = 0$.

(iii)

$$\mathbf{F}_{Ub}(U^*; \bar{b}(a)) \begin{pmatrix} \varphi_1 \\ \varphi_2 \end{pmatrix} \notin R(\mathbf{F}_U(U^*; \bar{b}(a))).$$

Proof. In view of (5.2), we examine $N(\mathbf{L}_1(a, \bar{b}))$ and $R(\mathbf{L}_1(a, \bar{b}))$. Recall that zero is the least eigenvalue of $L_2(a, \bar{b})$ (see (3.17)), so that $\dim N(\mathbf{L}_1(a, \bar{b})) = 1$ because of the invertibility of $L_1(a)$ by Lemma 2.3. Let ${}^t(\varphi_1, \varphi_2) \in N(\mathbf{L}_1(a, \bar{b}))$. Then

$$L_1(a)\varphi_1 = u^*(a) f_v(u^*(a), 0)\varphi_2, \qquad L_2(a, \bar{b})\varphi_2 = 0.$$

Since φ_2 does not change sign, we may take φ_2 such that $\varphi_2 > 0$ in Ω and $\|\varphi_2\|_2 = 1$. By (A.1),

$$u^*(a) f_v(u^*(a), 0)\varphi_2 < 0 \quad \text{in } \Omega,$$

which, together with Lemma 2.3, implies

$$\varphi_1 = L_1(a)^{-1}(u^*(a) f_v(u^*(a), 0)\varphi_2) < 0 \quad \text{in } \Omega.$$

Thus we have shown (i).

If ${}^t(h_1, h_2)$ is in $R(\mathbf{L}_1(a, \bar{b}))$, there must be a solution (u, v) of

$$L_1(a)u - u^*(a) f_v(u^*(a), 0)v = h_1, \qquad L_2(a, \bar{b})v = h_2.$$

It is well known that the second equation has a solution v if and only if $(h_2, \varphi_2) = 0$. For such a solution v, the first equation has a unique solution u because of the invertibility of $L_1(a)$. Thus (ii) has been proved.

Finally, we observe that

$$\mathbf{F}_{Ub}(U^*; \bar{b})\begin{pmatrix}\varphi_1\\ \varphi_2\end{pmatrix} = \begin{pmatrix}0\\ -\varphi_2\end{pmatrix}.$$

Hence the assertion of (iii) easily follows from (ii). □

We are ready to prove the following bifurcation result.

THEOREM 5.2. *In addition to* (A.1)-(A.4), *assume* (A.6). *Let* $a > a^*$ *be fixed. Then there exists a positive number* δ *such that, for every* $b \in (\bar{b}(a), \bar{b}(a) + \delta)$, *there is a solution* $(\underline{u}, \underline{v})$ *of* (3.7)-(3.10) *with the following properties*:

(a) $u^*(a) > \underline{u} > 0$ *and* $\underline{v} > 0$ *in* Ω.

(b) $(\underline{u}, \underline{v})$ *is the only nontrivial solution of* (3.7)-(3.10) *near* $(u^*(a), 0)$.

(c) $(\underline{u}, \underline{v})$ *is asymptotically stable.*

Proof. We will prove this theorem along the same line as Conway, Gardner, and Smoller [5, Thm. 3.5] by applying the bifurcation theory of Crandall and Rabinowitz [7].

Because of Lemma 5.1, all the assumptions of Lemma 1.1 in [7] are satisfied, so that there exist a positive number s_0 and continuously differentiable functions ${}^t(w_1, w_2): (-s_0, s_0) \to \mathbf{Y}$ and $\beta: (-s_0, s_0) \to R$ with the following properties:

(i) $\beta(0) = 0$.

(ii) ${}^t(w_1(s), w_2(s)) \in R(\mathbf{L}_1(a, \bar{b}))$ and $w_1(0) = w_2(0) = 0$.

(iii) If

$$\begin{aligned} &\underline{u}(s) = u^*(a) + s(\varphi_1 + w_1(s)), \ \underline{v}(s) = s(\varphi_2 + w_2(s)),\\ &b(s) = \bar{b} + \beta(s), \end{aligned} \tag{5.3}$$

where φ_1, φ_2 are given in Lemma 5.1, then $\mathbf{F}(\underline{U}(s); b(s)) = 0$ with $\underline{U}(s) = {}^t(\underline{u}(s), \underline{v}(s))$; and

(iv) $(\underline{U}(s), b(s))$ is the unique nontrivial solution of $\mathbf{F}(U; b) = 0$ in a neighborhood of $(U^*, \bar{b})$.

This fact implies the existence of a nontrivial solution of (3.7)-(3.9) when (a, b) lies near the C_1-curve defined by $b = \bar{b}(a)$. Since $\varphi_1 < 0$ and $\varphi_2 > 0$ in Ω by Lemma 5.1, it follows from (5.3) that

$$u^*(a) > \underline{u}(s) > 0 \quad \text{and} \quad \underline{v}(s) > 0 \quad \text{in } \Omega$$

for sufficiently small $s > 0$.

As a next step, we will discuss the linearized stability of $(\underline{u}(s), \underline{v}(s))$. Let $\pi(s)$ denote the principal eigenvalue of $\mathbf{F}_U(\underline{U}(s); b(s))$. According to Theorem 1.16 of [7],

$$\lim_{s \to 0} \{-sb'(s)(\partial \nu_2 / \partial b)(a, \bar{b}) / \pi(s)\} = 1,$$

where $\nu_2(a, b)$ is defined by (3.17). Therefore,

$$\pi(s) = s\beta'(s)(1 + o(1)) \quad \text{for sufficiently small } s > 0. \tag{5.4}$$

We will show

$$\beta'(0) > 0 \tag{5.5}$$

to see the asymptotic stability of $(\underline{u}(s), \underline{v}(s))$ for sufficiently small $s > 0$. (Moreover, (5.5) tells us the direction of the bifurcation; $b(s) > \bar{b}$ for small $s > 0$.) Now

$\mathbf{F}(\underline{U}(s); b(s)) = 0$ implies that

$$L_2(a, \bar{b})\underline{v}(s) - \beta(s)\underline{v}(s) - \underline{v}(s)\{g(\underline{u}(s), \underline{v}(s)) - g(u^*(a), 0)\} = 0. \tag{5.6}$$

Since $\varphi_2 \in N(L_2(a, \bar{b}))$ and $(\underline{v}(s), \varphi_2)_2 = s$ by Lemma 5.1, taking the $L^2(\Omega)$-inner product of (5.4) with φ_2 leads to

$$\beta(s) = -((\varphi_2 + w_2(s))\{g(\underline{u}(s), \underline{v}(s)) - g(u^*(a), 0)\}, \varphi_2)_2. \tag{5.7}$$

Differentiation of (5.7) with respect to s gives

$$\beta'(0) = -\int_\Omega \{g_u(u^*(a), 0)\varphi_1 + g_v(u^*(a), 0)\varphi_2\}\varphi_2^2\, dx. \tag{5.8}$$

Thus (5.5) follows from (5.8) because $\varphi_1 < 0$ and $\varphi_2 > 0$ by Lemma 5.1, $g_u(u^*(a), 0) > 0$ by (A.2), and $g_v(u^*(a), 0) \leqq 0$ by (A.6).

The assertions of this theorem will be derived from the above results by regarding b as a bifurcation parameter rather than s (use (5.5)). □

The preceding argument is valid for studying the secondary bifurcation from $(0, v^*(b))$ at C_2-curve defined by $a = \bar{a}(b)$. Let $b > b^*$ be fixed and regard a as a bifurcation parameter. We define a mapping $\mathbf{G}: \mathbf{Y} \times R \to \mathbf{X}$ by

$$\mathbf{G}(V; a) = \begin{pmatrix} A_1 u - au - uf(u, v) \\ A_2 v - bv - vg(u, v) \end{pmatrix} \quad \text{for } V = \begin{pmatrix} u \\ v \end{pmatrix} \in \mathbf{Y}.$$

Clearly, $\mathbf{G}(V^*; a) = 0$ for all $a \geqq 0$ with $\mathbf{V}^* = {}^t(0, v^*(b))$. Correspondingly to Lemma 5.1, it is possible to show the following lemma.

LEMMA 5.3. (i) $\dim N(\mathbf{G}_V(V^*; \bar{a}(b))) = 1$ *and* $N(\mathbf{G}_V(V^*; \bar{a}(b))) = \{{}^t(\psi_1, \psi_2)\}$ *with* $\psi_1 > 0$ *and* $\psi_2 > 0$ *in* Ω *and* $\|\psi_1\|_2 = 1$.

(ii) $\operatorname{codim} R(\mathbf{G}_V(V^*; \bar{a}(b))) = 1$. *Moreover,* ${}^t(h_1, h_2) \in R(\mathbf{G}_v(V^*; \bar{a}(b)))$ *if and only if* $(h_1, \psi_1)_2 = 0$.

(iii) $$\mathbf{G}_{Va}(V^*; \bar{a}(b))\begin{pmatrix} \psi_1 \\ \psi_2 \end{pmatrix} \notin R(\mathbf{G}_V(V^*; \bar{a}(b))).$$

The following theorem can be shown in the same manner as Theorem 5.2 with the use of Lemma 5.3.

THEOREM 5.4. *In addition to* (A.1)-(A.4), *assume* (A.5). *Let* $b > b^*$ *be fixed. Then there exists a positive number* δ *such that, for every* $a \in (\bar{a}(b), \bar{a}(b) + \delta)$, *there exists a solution* $(\bar{u}, \bar{v})$ *of* (3.7)-(3.10) *that satisfies*:

(a) $\bar{u} > 0$ *and* $\bar{v} > v^*(b)$ *in* Ω.

(b) $(\bar{u}, \bar{v})$ *is the only nontrivial solution of* (3.7)-(3.10) *near* $(0, v^*(b))$.

(c) $(\bar{u}, \bar{v})$ *is asymptotically stable.*

Sketch of proof. Owing to Lemma 5.3, the bifurcation theory of Crandall and Rabinowitz yields the existence of a positive number s_0 and continuously differentiable functions ${}^t(w_1, w_2)$: $(-s_0, s_0) \to \mathbf{Y}$ and α: $(-s_0, s_0) \to R$ satisfying (i) $\alpha(0) = 0$; (ii) ${}^t(w_1(s), w_2(s)) \in R(\mathbf{G}_V(V^*; \bar{a}))$ and $w_1(0) = w_2(0) = 0$; and (iii) if

$$\bar{u}(s) = s(\psi_1 + w_1(s)), \qquad \bar{v}(s) = v^*(b) + s(\psi_2 + w_2(s)),$$
$$a(s) = \bar{a} + \alpha(s),$$

where ψ_1 and ψ_2 are as given in Lemma 5.3, then $\mathbf{G}(\bar{V}(s); a(s)) = 0$ with $\bar{V}(s) = {}^t(\bar{u}(s), \bar{v}(s))$. Therefore, in view of (iii), it is easy to show (a) because of the positivity of ψ_1 and ψ_2. In studying the asymptotic stability of $(\bar{u}(s), \bar{v}(s))$, it is essential to know the sign of $\alpha'(0)$. After some calculations, we can show that

$$\alpha'(0) = -\int_\Omega (f_u(0, v^*(b))\psi_1 + f_v(0, v^*(b))\psi_2)\psi_1^2\, dx \tag{5.9}$$

(cf. (5.8)). Hence (A.1), (A.5), and Lemma 5.3 enable us to see $\alpha'(0)>0$, which completes the proof. □

Theorems 5.2 and 5.4 assure the existence, uniqueness, and stability of positive solutions when $(a, b)\in$ IV lies in a neighborhood of C_1 or C_2 curve (see Fig. 1). To study the general case, we follow the argument of Ito [11, Thm. 5.1] based on the global bifurcation result of Rabinowitz [18] (see [1, Thm. 3.3]). Then it is possible to show Theorem 5.5.

THEOREM 5.5. *Assume* (A.1)-(A.6) *and let* $a>a^*$ *be fixed. Then there exists a branch of positive solutions of* (3.7)-(3.9) *that bifurcates from* $(u^*(a), 0)$ *at* $b=\bar{b}(a)$ *and meets with* $(0, v^*(b))$ *at* $b=(\bar{a})^{-1}(a)$, *where* $(\bar{a})^{-1}$ *is the inverse function of* $\bar{a}$.

Thus we have obtained a fairly clear understanding of the set of solutions for (3.7)-(3.10) and their stability properties. For example, consider the case $a>a^*$. Theorem 4.2 implies that $(u^*(a), 0)$ is a global attractor for (1.1), (1.2) if $b<\bar{b}(a)$. As b becomes larger than $\bar{b}(a)$, $(u^*(a), 0)$ loses its stability, and a positive solution, which is stable when b is near $\bar{b}(a)$, bifurcates from $(u^*(a), 0)$ at $b=\bar{b}(a)$ (Theorem 5.2). Such a positive solution exists for $\bar{b}(a)<b<(\bar{a})^{-1}(a)$ (Theorem 5.5), is stable when b is near $(\bar{a})^{-1}(a)$, and becomes identical with $(0, v^*(b))$ at $b=(\bar{a})^{-1}(a)$ (Theorem 5.4). By Theorem 4.3, $(0, v^*(b))$ is a global attractor for (1.1), (1.2) whenever b is larger than $(\bar{a})^{-1}(a)$.

6. Bifurcation from a double eigenvalue. In this section we discuss stability properties of positive solutions for (3.7)-(3.9) in the case when $(a, b)\in$ VI lies in a neighborhood of (a^*, b^*) $(\equiv(d_1\lambda_0, d_2\lambda_0))$.

The operator $\mathbf{L}_0(a, b)$ defined by (3.14) has zero as a double eigenvalue for $(a, b)=(a^*, b^*)$. We will derive appropriate expressions of positive solutions by simultaneously regarding a, b as bifurcation parameters. Throughout this section we assume, in addition to (A.1)-(A.6), that

$$f_u(0,0)<0 \quad \text{and} \quad g_v(0,0)<0. \tag{A.7}$$

Define a nonlinear mapping $\mathbf{H}:\mathbf{Y}\times R\to\mathbf{X}$ by

$$\mathbf{H}(U; a, b)=\begin{pmatrix} A_1u-au-uf(u,v)\\ A_2v-bv-vg(u,v)\end{pmatrix} \quad \text{for } U=\begin{pmatrix}u\\v\end{pmatrix}\in\mathbf{Y}. \tag{6.1}$$

Then $\mathbf{H}(0; a, b)=0$ for all a, b and $\mathbf{H}_U(0; a^*, b^*)=\mathbf{L}_0(a^*, b^*)$. In what follows, we simply write $\mathbf{L}_0$ in place of $\mathbf{L}_0(a^*, b^*)$. Clearly, dim $N(\mathbf{L}_0)=$ codim $R(\mathbf{L}_0)=2$. We can take $\{\Phi_1, \Phi_2\}\in N(\mathbf{L}_0)$ with

$$\Phi_1=\begin{pmatrix}\varphi_0\\0\end{pmatrix} \quad \text{and} \quad \Phi_2=\begin{pmatrix}0\\\varphi_0\end{pmatrix}, \tag{6.2}$$

where φ_0 is the eigenfunction of (3.11) corresponding to λ_0 and satisfies $\varphi_0>0$ in Ω and $\|\varphi_0\|_2=1$. Moreover,

$$\begin{pmatrix}h_1\\h_2\end{pmatrix}\in R(\mathbf{L}_0) \quad \text{if and only if } (h_1, \varphi_0)_2=(h_2, \varphi_0)_2=0. \tag{6.3}$$

For $U={}^t(u, v)\in\mathbf{X}$, we define

$$\mathbf{P}U=(u, \varphi_0)_2\Phi_1+(v, \varphi_0)_2\Phi_2$$

and decompose $\mathbf{X}$ as $\mathbf{X}=\mathbf{X}_1+\mathbf{X}_2$ with $\mathbf{X}_1=\mathbf{P}\mathbf{X}$ and $\mathbf{X}_2=(\mathbf{I}-\mathbf{P})\mathbf{X}$. Similarly, $\mathbf{Y}$ is decomposed as $\mathbf{Y}=\mathbf{Y}_1+\mathbf{Y}_2$ with $\mathbf{Y}_1=\mathbf{P}\mathbf{Y}$ and $\mathbf{Y}_2=(\mathbf{I}-\mathbf{P})\mathbf{Y}$. Then $\mathbf{X}_1=\mathbf{Y}_1=N(\mathbf{L}_0)$, $\mathbf{X}_2=R(\mathbf{L}_0)$, and $\mathbf{Y}_2=R(\mathbf{L}_0)\cap\mathbf{Y}$.

We will look for solutions of $\mathbf{H}(U; a, b) = 0$ in the form

$$U = s\{\cos\omega\Phi_1 + \sin\omega\,\Phi_2 + W\} \quad \text{with } w = {}^t(w_1, w_2) \in \mathbf{Y}_2, \tag{6.4}$$

where s and ω are parameters. Since positive solutions are concerned, we restrict ω to $(0, \pi/2)$. Let $\omega \in (0, \pi/2)$ be fixed for the time being. We define a nonlinear mapping $\mathbf{K}(W, \alpha, \beta; s): \mathbf{Y}_2 \times R \times R \times R \to \mathbf{X}$ by

$$\begin{aligned}\mathbf{K}(W, \alpha, \beta; s) &= s^{-1}\mathbf{H}(s(\cos\omega\Phi_1 + \sin\omega\Phi_2 + W); a^* + \alpha, b^* + \beta) \\ &= \mathbf{L}_0 W - \begin{pmatrix}\alpha(\varphi_0\cos\omega + w_1)\\ \beta(\varphi_0\sin\omega + w_2)\end{pmatrix} \\ &\quad - \begin{pmatrix}(\varphi_0\cos\omega + w_1)f(\tilde{u}, \tilde{v})\\ (\varphi_0\sin\omega + w_2)g(\tilde{u}, \tilde{v})\end{pmatrix}\end{aligned} \tag{6.5}$$

for $W = {}^t(w_1, w_2)$ with $\tilde{u} = s(\varphi_0\cos\omega + w_1)$ and $\tilde{v} = s(\varphi_0\sin\omega + w_2)$. Clearly, $\mathbf{K}$ is a C^1-mapping from $\mathbf{Y}_2 \times R \times R \times R$ to $\mathbf{X}$ satisfying $\mathbf{K}(0, 0, 0; 0) = 0$. The Fréchet derivative of $\mathbf{K}$ with respect to (W, α, β) at $(W, \alpha, \beta, s) = (0, 0, 0, 0)$ is the linear mapping

$$(\hat{W}, \hat{\alpha}, \hat{\beta}) \to \mathbf{L}_0\hat{W} - (\hat{\alpha}\cos\omega)\Phi_1 - (\hat{\beta}\sin\omega)\Phi_2,$$

which is an isomorphism from $\mathbf{Y}_2 \times R \times R$ to $\mathbf{X}$. Therefore, the Implicit Function Theorem implies the existence of continuously differentiable functions $(\tilde{W}(s), \tilde{\alpha}(s), \tilde{\beta}(s))$, defined for sufficiently small $|s|$, that satisfy (i) $\tilde{W}(0) = 0$, $\tilde{\alpha}(0) = \tilde{\beta}(0) = 0$ and (ii) $\mathbf{K}(\tilde{W}(s), \tilde{\alpha}(s), \tilde{\beta}(s); s) = 0$. Hence, if we set

$$\begin{aligned}&u(s) = s(\varphi_0\cos\omega + \tilde{w}_1(s), \qquad \tilde{v}(s) = s(\varphi_0\sin\omega + \tilde{w}_2(s)), \\ &\tilde{a}(s) = a^* + \tilde{\alpha}(s), \qquad \tilde{b}(s) = b^* + \tilde{\beta}(s),\end{aligned} \tag{6.6}$$

then $(\tilde{U}(s), \tilde{a}(s), \tilde{b}(s))$ with $\tilde{U}(s) = {}^t(\tilde{u}(s), \tilde{v}(s))$ becomes a nontrivial solution of $\mathbf{H}(U; a, b) = 0$. Especially, since $(\tilde{w}_i(s), \varphi_0)_2 = 0$ for $i = 1, 2$, it follows from $\mathbf{H}(\tilde{U}(s); \tilde{a}(s), \tilde{b}(s)) = 0$ that

$$\tilde{\alpha}(s)\cos\omega = -((\varphi_0\cos\omega + \tilde{w}_1(s))f(\tilde{u}(s), \tilde{v}(s)), \varphi_0)_2, \tag{6.7}$$

$$\tilde{\beta}(s)\sin\omega = -((\varphi_0\sin\omega + \tilde{w}_2(s))g(\tilde{u}(s), \tilde{v}(s)), \varphi_0)_2. \tag{6.8}$$

Differentiating (6.7) and (6.8) with respect to s, after some calculations we can derive

$$\tilde{\alpha}'(0) = -(f_u(0, 0)\cos\omega + f_v(0, 0)\sin\omega)\|\varphi_0\|_3^3, \tag{6.9}$$

$$\tilde{\beta}'(0) = -(g_u(0, 0)\cos\omega + g_v(0, 0)\sin\omega)\|\varphi_0\|_3^3, \tag{6.10}$$

so that

$$\begin{aligned}\lim_{s\to 0}\frac{\tilde{b}(s) - b^*}{\tilde{a}(s) - a^*} &= \lim_{s\to 0}\frac{\tilde{\beta}(s)}{\tilde{\alpha}(s)} \\ &= \frac{g_u(0, 0)\cos\omega + g_v(0, 0)\sin\omega}{f_u(0, 0)\cos\omega + f_v(0, 0)\sin\omega}.\end{aligned} \tag{6.11}$$

If the right-hand side of (6.11) is denoted by $l(\omega)$, then $l(\omega)$ is an increasing function of $\omega \in (0, \pi/2)$ such that

$$\lim_{\omega\to 0} l(\omega) = \frac{g_u(0, 0)}{f_u(0, 0)} \quad \text{and} \quad \lim_{\omega\to\pi/2} l(\omega) = \frac{g_v(0, 0)}{f_v(0, 0)}. \tag{6.12}$$

Now we recall some properties of C_1- and C_2-curves near (a^*, b^*). The C_1 curve, defined by $b = \bar{b}(a)$, satisfies

$$\lim_{a\to a^*}\frac{d\bar{b}}{da}(a) = \frac{g_u(0, 0)}{f_u(0, 0)} \tag{6.13}$$

by Lemma 3.4(iii), and the C_2-curve, defined by $a=\bar{a}(b)$, satisfies

$$\lim_{a\to a^*}\frac{d(\bar{a})^{-1}}{da}(a)=\frac{g_v(0,0)}{f_v(0,0)} \tag{6.14}$$

by Lemma 3.6(iii). In view of (6.12)-(6.14), we can conclude that, for each $\omega\in(0,\pi/2)$ sufficiently close to zero, the solution $(\tilde{u}(s),\tilde{v}(s))$ constructed as above coincides with the positive solution bifurcating from $(u^*(a),0)$ at the C_1-curve (see Theorem 5.2); and that, for each $\omega\in(0,\pi/2)$ sufficiently close to $\pi/2$, $(u(s),v(s))$ coincides with the positive solution bifurcating from $(0,v^*(b))$ at the C_2-curve (see Theorem 5.4). Thus we may see that the expression (6.6), for sufficiently small $s>0$, represents a branch of positive solutions of (3.7)-(3.10) that connects the bifurcating positive solution from the C_1-curve with that from the C_2-curve.

We will discuss the asymptotic stability of $(\tilde{u}(s),\tilde{v}(s))$ by the spectral analysis for $\mathbf{H}_U(\tilde{U}(s);\tilde{a}(s),\tilde{b}(s))$ along the idea of [6], [7]. Observe that the principal eigenvalue of $\mathbf{H}_U(\tilde{U}(0);\tilde{a}(0),\tilde{b}(0))=\mathbf{L}_0$ is zero with multiplicity 2. Hence, it suffices to examine the behavior near $s=0$ for (possibly two) eigenvalues $\zeta(s)$ such that

$$\mathbf{H}_U(\tilde{U}(s);\tilde{a}(s),\tilde{b}(s))U=\zeta(s)U \tag{6.15}$$

with $\zeta(0)=0$. We will look for eigenfunctions U in the form

$$U=\Phi_1+p\Phi_2+W,\qquad W\in Y_2, \tag{6.16}$$

where p and W are to be determined later. Substitution of (6.16) into (6.15) yields the following equivalent problem:

$$\mathbf{L}_0W-\mathbf{M}(s)W-(I-\mathbf{P})\mathbf{N}(s)(\Phi_1+p\Phi_2+W)-\zeta W=0, \tag{6.17}$$

$$-\tilde{\alpha}(s)-(\mathbf{N}(s)(\Phi_1+p\Phi_2+W),\Phi_1)_2-\zeta=0, \tag{6.18}$$

$$-\tilde{\beta}(s)p-(\mathbf{N}(s)(\Phi_1+p\Phi_2+W),\Phi_2)_2-\zeta p=0, \tag{6.19}$$

where

$$\mathbf{M}(s)=\begin{pmatrix}\alpha(s) & 0\\ 0 & \tilde{\beta}(s)\end{pmatrix},$$

$$\mathbf{N}(s)=\begin{pmatrix}(uf)_u(\tilde{u}(s),\tilde{v}(s)) & (uf)_v(\tilde{u}(s),\tilde{v}(s))\\ (vg)_u(\tilde{u}(s)),\tilde{v}(s)) & (vg)_v(\tilde{u}(s),\tilde{v}(s))\end{pmatrix}.$$

By (6.9) and (6.10),

$$\begin{aligned}\tilde{\alpha}(s)&=-s(f_u(0,0)\cos\omega+f_v(0,0)\sin\omega)\|\varphi_0\|_3^3+o(s),\\ \tilde{\beta}(s)&=-s(g_u(0,0)\cos\omega+g_v(0,0)\sin\omega)\|\varphi_0\|_3^3+o(s),\end{aligned} \tag{6.20}$$

for sufficiently small $s\geqq 0$. Moreover, some calculations give

$$\begin{aligned}(\mathbf{N}(s)\Phi_1,\Phi_1)_2&=s(2f_u(0,0)\cos\omega+f_v(0,0)\sin\omega)\|\varphi_0\|_3^3+o(s),\\ (\mathbf{N}(s)\Phi_2,\Phi_1)_2&=sf_v(0,0)\cos\omega\|\varphi_0\|_3^3+o(s),\\ (\mathbf{N}(s)\Phi_1,\Phi_2)_2&=sg_u(0,0)\sin\omega\|\varphi_0\|_3^3+o(s),\\ (\mathbf{N}(s)\Phi_2,\Phi_2)_2&=s(g_u(0,0)\cos\omega+2g_v(0,0)\sin\omega)\|\varphi_0\|_3^3+o(s).\end{aligned} \tag{6.21}$$

We first solve (W,ζ) from (6.17) and (6.18) as functions of s and p. From the Implicit Function Theorem there exist continuously differentiable functions $(W(s;p),\zeta(s;p))$, defined for small $s\geqq 0$, with the following properties:

(i) $(W(0;p),\zeta(0;p))=(0,0)$;

(ii) $(W(s;p),\zeta(s;p))$ satisfies (6.17) and (6.18);

(iii) $\|W(s;p)\|_{Y_2}\leqq Cs(1+|p|)$ and $|\zeta(s;p)|\leqq Cs(1+|p|)$ with some $C>0$.

Therefore, it follows from (6.18), with use of (6.20) and (6.21), that

$$\begin{aligned}\zeta(s;p) = &-sp(f_v(0,0)\cos\omega\|\varphi_0\|_3^3 + o(1))\\ &-s(f_u(0,0)\cos\omega\|\varphi_0\|_3^3 + o(1)).\end{aligned} \tag{6.22}$$

Moreover, since $(W(s;p), \zeta(s;p))$ must satisfy (6.19), we are led to the following equation:

$$\begin{aligned}0 &= -\zeta(s;p)p - \tilde{\beta}(s)p - (\mathbf{N}(s)(\Phi_1 + p\Phi_2 + W(s;p)), \Phi_2)_2\\ &= sp^2\{f_v(0,0)\cos\omega\|\varphi_0\|_3^3 + o(1)\}\\ &\quad + sp\{f_u(0,0)\cos\omega\|\varphi_0\|_3^3 - g_v(0,0)\sin\omega\|\varphi_0\|_3^3 + o(1)\}\\ &\quad - s\{g_u(0,0)\sin\omega\|\varphi_0\|_3^3 + o(1)\}.\end{aligned}$$

Hence,

$$\begin{aligned}&p^2\{f_v(0,0)\cos\omega + o(1)\} + p\{f_u(0,0)\cos\omega - g_v(0,0)\sin\omega + o(1)\}\\ &\quad - \{g_u(0,0)\sin\omega + o(1)\} = 0,\end{aligned}$$

so that we can find two continuous functions $p_\pm(s)$ such that

$$\begin{aligned}p_\pm(s) = (2f_v(0,0)\cos\omega)^{-1}&[(g_v(0,0)\sin\omega - f_u(0,0)\cos\omega)\\ &\pm\{(f_u(0,0)\cos\omega - g_v(0,0)\sin\omega)^2\\ &\quad + 4f_v(0,0)g_u(0,0)\sin\omega\cos\omega\}^{1/2}] + o(1).\end{aligned} \tag{6.23}$$

Substitution of (6.23) into (6.22) gives two eigenvalues $\zeta_\pm(s)$ such that

$$\begin{aligned}\zeta_\pm(s) = -2^{-1}s&[f_u(0,0)\cos\omega + g_v(0,0)\sin\omega\\ &\pm\{(f_u(0,0)\cos\omega - g_v(0,0)\sin\omega)^2\\ &\quad + 4f_v(0,0)g_u(0,0)\sin\omega\cos\omega\}^{1/2}] + o(s).\end{aligned}$$

Since it is easy to see $\operatorname{Re}\zeta_\pm(s) > 0$ for sufficiently small $s > 0$, the spectrum of $\mathbf{H}_U(\tilde{U}(s); \tilde{a}(s), \tilde{b}(s))$ lies in the right half-plane of $\mathbf{C}$. Thus we have shown the following result.

THEOREM 6.1. *If $(a, b) \in$ IV lies in a neighborhood of (a^*, b^*), then there exists a solution of* (3.7)-(3.10), *which is positive and asymptotically stable.*

Remark 6.1. If we take f and g of the form (1.3), then all assumptions (A.1)-(A.7) are fulfilled. Therefore, our results can be summarized as in § 1 (see Fig. 1) and improve on those of Blat and Brown [1]. Especially, the stability properties of the trivial and semitrivial steady-state solutions are completely determined.

Remark 6.2. Our stability analysis developed in this paper is valid with slight modification even if some of (A.1)-(A.7) are replaced by other suitable conditions. For example, it is possible to study the stability of positive steady states for reaction-diffusion systems such as the Holling-Tanner model (see [2]) or the competition model.

PATTERN FORMATION IN HETEROGENEOUS REACTION-DIFFUSION-ADVECTION SYSTEMS WITH AN APPLICATION TO POPULATION DYNAMICS*

S.-I. EI† AND M. MIMURA†

Abstract. Heterogeneous reaction-diffusion-advection equations are proposed for studying pattern formation due to spatial heterogeneity. The equations contain a small parameter ε, indicating the ratio of the diffusion and advection rates and the reaction rate. Two-timing methods in the limit $\varepsilon \downarrow 0$ make it possible to reduce the original partial differential equation problem to the approximating ordinary differential equation problem, so that asymptotic states of solutions can be investigated. As an application to population dynamics, population models of the Lotka-Volterra type are considered for studying the effect of spatial heterogeneity on development of spatial and temporal distributions of individuals.

Key words. pattern formation due to heterogeneities, two-timing method

AMS(MOS) subject classifications. 34A05, 92A15

1. Introduction. To theoretically understand spatial and temporal distributions of ecological populations, there have been proposed a large number of mathematical models that essentially include two terms, such as dispersal and growth and/or death. As one of these models, we have the following reaction-diffusion-advection system:

$$\frac{\partial u}{\partial t} + \operatorname{div} J = f(u), \quad t > 0, \quad x \in \Omega, \tag{1.1}$$

where

$$u = (u_1, u_2, \cdots, u_n), \qquad f(u) = (f_1(u), f_2(u), \cdots, f_n(u)),$$
$$J = J(u) = -(d_1 \nabla u_1 + u_1 \nabla e_1, d_2 \nabla u_2 + u_2 \nabla e_2, \cdots, d_n \nabla u_n + u_n \nabla e_n),$$

and Ω is a bounded domain in $\mathbb{R}^N$. Here u_i is the population density of the ith species at time t and position x, with the diffusion rate d_i, the tactic advection ∇e_i, and the growth term f_i. We conveniently write $(d_1, d_2, \cdots, d_n)$ and $(e_1, e_2, \cdots, e_n)$ as d and e, respectively. Usually d, e, and f depend on t, x, and u. The flux J consists of two dispersal processes: the normal random movement of individuals, and the directed movement toward the favorable region (or, on the contrary, from the unfavorable one). If e is constant, namely, if the advection term is absent, J is reduced to the usual diffusive flux. The boundary condition to (1.1) is

$$\langle \nu, J \rangle = 0_n, \quad t > 0, \quad x \in \partial\Omega \tag{1.2}$$

where $\langle , \rangle$ is an inner product, ν is the outward normal vector on the boundary $\partial\Omega$, and 0_n is the n-dimensional zero vector. This condition ecologically implies that there is no population flow through the boundary $\partial\Omega$.

The scalar case of (1.1), (1.2) ($n = 1$) has been widely investigated when the advection term is absent and the growth term f depends only on u. The resulting problem of (1.1), (1.2) is

$$\frac{\partial u}{\partial t} = \operatorname{div}(d(x)\nabla u) + f(u), \qquad t > 0, \quad x \in \Omega \tag{1.3}$$

with the boundary condition

$$\frac{\partial u}{\partial \nu}=0, \quad t>0, \quad x\in\partial\Omega. \tag{1.4}$$

For (1.3), (1.4), there are interesting results on existence, stability and bifurcation properties of nonconstant stationary solutions [1], [10], [11], [14]-[16], [22], [33], [39]. The most noteworthy result is that when the domain Ω is convex, any stable nonconstant stationary solutions do not exist if d is constant, but possibly exist due to suitable heterogeneities of $d(x)$. In application points of view, a class of equations such as (1.1) has been discussed by various investigators in population genetics [7], [8], in population dynamics [12], [25], [26], [29] and in neurobiology [20], [30], [31].

To our knowledge, there has not yet been any full and systematic analysis for the system of equations of (1.1) ($n\geqq 2$) to study the effect of spatial heterogeneity on solutions, except for several works including [13], [37]. Under such circumstances, Shigesada [34] has dealt with the extreme case, where the rate of dispersal is sufficiently large compared with that of growth. This restriction is required by the ecological situation such that the dispersal processes take place daily, while the growth process takes place only once or twice a year. Under this assumption, (1.1) is written as

$$\frac{\partial u}{\partial t}+\operatorname{div} J=\varepsilon f, \quad t>0, \quad x\in\Omega \tag{1.1}_\varepsilon$$

with a small parameter ε. By using the two-time-scale (two-timing) method, approximating ordinary differential equations can be formally derived from $(1.1)_\varepsilon$, (1.2) as $\varepsilon\downarrow 0$ [34]. Although this reduction of partial differential equations (PDEs) to ordinary differential equations (ODEs) is formal, we can obtain much information on the time development of solutions of $(1.1)_\varepsilon$, (1.2) by studying the corresponding ODEs. Recently, Ei and Mimura [5] and Ei [4] have shown that this reduction is valid for all t up to $O(1/\varepsilon)$, and that in some situations it is valid for all $t\in[0,\infty)$. Such reduction methods for infinite-dimensional dynamical systems to finite-dimensional dynamical systems are among the most recent interesting topics in the analysis of dynamical systems (see [2] and [9], for instance).

Let us show one population model equation, described by $(1.1)_\varepsilon$, (1.2), which represents competition between two species in the one-dimensional heterogeneous habitat. It is given by

$$\begin{aligned}
&\frac{\partial u_1}{\partial t}=\frac{\partial}{\partial x}\left(d_1\frac{\partial u_1}{\partial x}+u_1\dot{e}_1\right)+\varepsilon\left(r_1-\frac{\alpha_1u_1+\beta_1u_2}{K_1}\right)u_1,\\
&\frac{\partial u_2}{\partial t}=\frac{\partial}{\partial x}\left(d_2\frac{\partial u_2}{\partial x}+u_2\dot{e}_2\right)+\varepsilon\left(r_2-\frac{\beta_2u_1+\alpha_2u_2}{K_2}\right)u_2,\\
&\qquad\qquad\qquad\qquad\qquad\qquad t>0, \qquad x\in\Omega\equiv(0,1)
\end{aligned} \tag{1.5}_\varepsilon$$

with

$$d_i\frac{\partial u_i}{\partial x}+u_i\dot{e}_i=0, \quad t>0, \quad x\in\partial\Omega \quad (i=1,2), \tag{1.6}$$

where $\dot{e}_i=(de_i/dx)$ $(i=1,2)$ and (r_1, r_2) is the intrinsic growth rate, (α_1, α_2) and (β_1, β_2) are, respectively, the intraspecific and interspecific competition rates between the two species, and (K_1, K_2) is the carrying capacity. Here we assume that all the parameters are positive constants, leaving e_i and K_i $(i=1,2)$ to be functions of x. We

specify that $K_i(x)$ $(i=1,2)$ be humped as shown in Fig. 1, where x_i is the maximum point of $K_i(x)$ $(i=1,2)$, and consider the effect of the heterogeneities of $K_i(x)$ on the stability of spatial distributions of the two competing species. To do so, we introduce one parameter $\theta = x_2 - x_1$ that indicates the distance between the most favorable regions of the two competing species. We assume that e_i satisfies

$$e_i(x) = -\gamma \log K_i(x)$$

with a positive constant γ $(i=1,2)$. This relation implies that each species tends to migrate toward the higher gradient of its carrying capacity in Ω. This requirement seems to be phenomenologically reasonable. We show numerically the time development of (u_1, u_2) of $(1.5)_\varepsilon$, (1.6) for the same initial distributions. When $\theta = 0$, u_1 exists while u_2 is extinct (Fig. 2(a)). When $\theta = 0.2$, u_2 exists while u_1 is extinct (Fig. 2(b)). On the other hand, when $\theta = 0.4$, the situation changes so that u_1 and u_2 can coexist (Fig. 2(c)). These simulations suggest that stable spatial distributions of the competing species strongly depend on the heterogeneous carrying capacities. Mathematically speaking, bifurcation phenomena may possibly occur when θ varies.

Motivated by these phenomena, we are interested in pattern formation of solutions of $(1.1)_\varepsilon$, (1.2). Especially, we study the dependency of spatial heterogeneities of J and f on solutions.

In § 2, we apply the two-timing method to the PDE problem $(1.1)_\varepsilon$, (1.2) and derive the approximating ODE problem ((2.8), (2.9)) in the limit $\varepsilon \downarrow 0$. The validity of this method is also shown. In § 3, we study existence and stability problems of stationary solutions as well as periodic solutions of $(1.1)_\varepsilon$, (1.2). We emphasize here that not only existence but also stability of such solutions of the PDE problem generically inherit from those of the approximating ODE problem. In § 4, we give proofs of the theorems shown in § 3. Finally, in § 5, as an application of our procedure, we study the qualitative behavior of solutions of the specified model $(1.5)_\varepsilon$, (1.6) when θ varies. Further application to population models with spatially heterogeneous environments will be reported in [6].

2. Reduction of PDE problems to the approximating ODE problems. In this section, we apply the two-timing method ([33], for instance) to the following initial boundary value problem to $(1.1)_\varepsilon$ with a small parameter ε:

$$\frac{\partial u}{\partial t} + \operatorname{div} J = \varepsilon f(x, u), \quad t > 0, \quad x \in \Omega, \tag{2.1}_\varepsilon$$

$$\langle \nu, J \rangle = 0_n, \quad t > 0, \quad x \in \partial\Omega, \tag{2.2}$$

$$u(0, x) = \xi(x), \qquad x \in \bar{\Omega}, \tag{2.3}$$

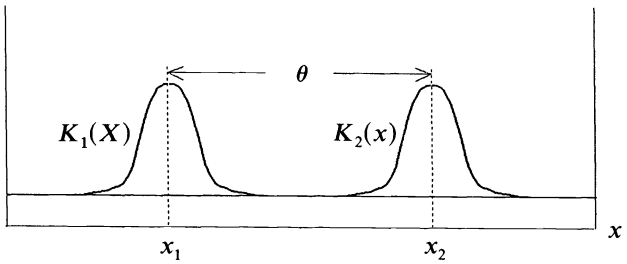

FIG. 1. *Graph of heterogeneous carrying capacity* K_i $(i=1,2)$.

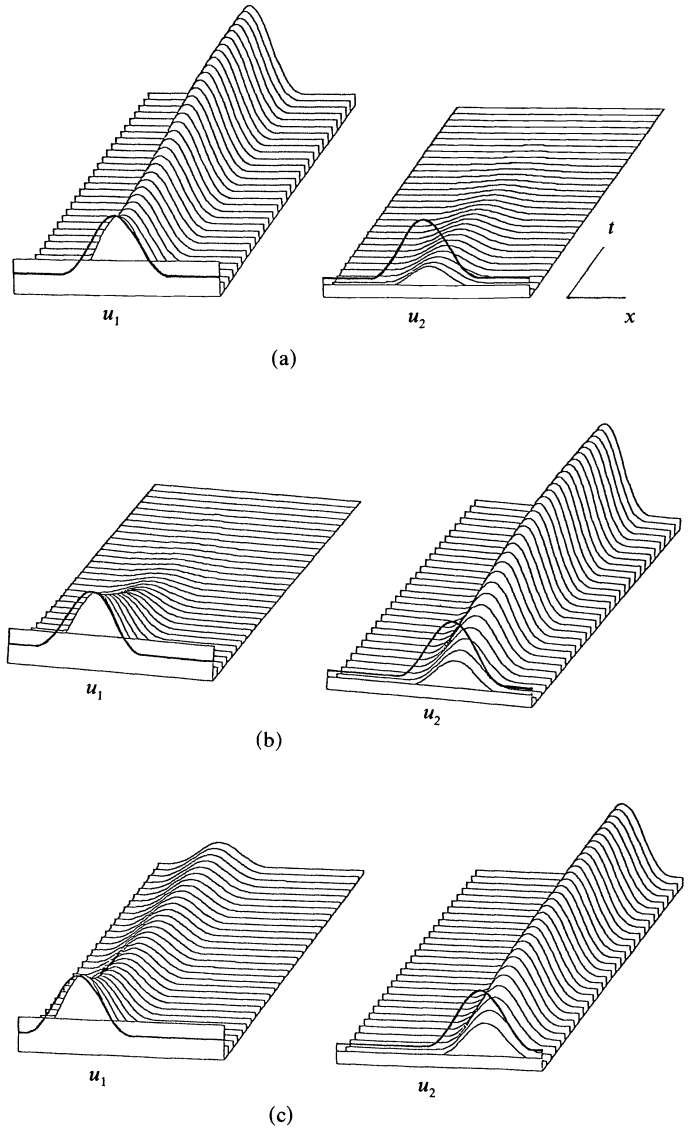

FIG. 2. *Time development of solutions of* $(1.5)_\varepsilon$, (1.6) *with the same initial condition for the suitably specified parameters (see* (4.5), (4.6) *and* $\varepsilon = 0.1$) *when* θ *varies*: (a) $\theta = 0$, (b) $\theta = 0.2$, (c) $\theta = 0.4$. *In each figure, bold lines denote the functional forms of* $K(x)$.

where $\xi = (\xi_1, \xi_2, \cdots, \xi_n)$, Ω is a bounded domain in $\mathbb{R}^N$ with sufficiently smooth boundary $\partial\Omega$, and e and f are smooth functions in every argument. Here we assume that

(A) d is a positive constant and e is a function of x only.

When ε is sufficiently small, namely, when the dispersal proceeds much faster than the dynamics, we can imagine that the spatial distributions of individuals are governed by the dispersal process as the initial stage and then are followed by the dynamical process as the second stage. Such time development of solutions requires us to introduce two different timescales t and τ $(=\varepsilon t)$. We now attempt to find solutions of $(2.1)_\varepsilon$, (2.2) in the form

$$u(t, x; \varepsilon) = u_0(t, \tau, x) + \varepsilon u_1(t, \tau, x) + O(\varepsilon^2). \tag{2.4}$$

With the relation $\partial/\partial t = \partial/\partial t + \varepsilon(\partial/\partial\tau)$, inserting (2.4) into $(2.1)_\varepsilon$-(2.3) and equating coefficients of like powers of ε, we obtain

$$\begin{aligned} &\frac{\partial}{\partial t} u_0 + \operatorname{div} J_0 = 0, \quad t>0, \quad x\in\Omega, \\ &\langle \nu, J_0\rangle = 0_n, \quad t>0, \quad x\in\partial\Omega, \end{aligned} \tag{2.5}$$

where $J_0 = J(u_0)$. Similarly,

$$\begin{aligned} &\frac{\partial}{\partial t} u_1 + \frac{\partial}{\partial \tau} u_0 + \operatorname{div} J_1 = f(x, u_0), \quad t>0, \quad x\in\Omega, \\ &\langle \nu, J_1\rangle = 0_n, \quad t>0, \quad x\in\partial\Omega, \end{aligned} \tag{2.6}$$

where $J_1 = J(u_1)$. Let $\varphi(x)$ be the stationary solution of (2.5) with $\int_\Omega \varphi(x)\,dx = 1_n$, where 1_n is the n-dimensional vector whose components are all 1. Then we find that there is a function $U(\tau) = (U_1, U_2, \cdots, U_n)(\tau)$ such that

$$\lim_{t\to\infty} u_0(t, \tau, x) = U(\tau)\cdot\varphi(x) \tag{2.7}$$

for a uniquely determined φ. Here, for $x = (x_1, x_2, \cdots, x_n)$ and $y = (y_1, y_2, \cdots, y_n)$, $x\cdot y$ means the vector $(x_1y_1, x_2y_2, \cdots, x_ny_n)$. Similarly, $V\cdot x$ means the set $\{v\cdot x \in \mathbb{R}^n \mid v\in V\}$ for $x\in\mathbb{R}^n$ and a set V in $\mathbb{R}^n$. Here $U(\tau)$ is determined as follows. Integrating (2.6) over Ω, we have

$$\frac{\partial}{\partial t}\int_\Omega u_1(t, \tau, x)\,dx + \frac{dU}{d\tau} = \int_\Omega f(x, u_0(t, \tau, x))\,dx. \tag{2.8}$$

Suppose that for any fixed τ, $u_1(t, \tau, x)$ is bounded for all $t>0$, or equivalently, $\partial/\partial t\int_\Omega u_1(t, \tau, x)\,dx \to 0$ as $t\to\infty$ (Ei [4]). Then, when $t\to\infty$, (2.8) reduces to the following ODE of U only:

$$\frac{dU}{d\tau} = F(U), \qquad \tau>0, \tag{$2.9)_1$}$$

where $F(U) = \int_\Omega f(x, U\cdot\varphi(x))\,dx = (F_1(U), F_2(U), \cdots, F_n(U))$. Since $\partial/\partial t\int_\Omega \cdot u_0(t, \tau, x)\,dx = 0_n$ by (2.5), we have $\int_\Omega u_0(0, \tau, x)\,dx = U(\tau)$. Therefore, by $u_0(0, 0, x) = \xi(x)$, the initial condition to $(2.9)_1$ is

$$U(0) = \int_\Omega \xi(x)\,dx. \tag{$2.9)_2$}$$

Thus the initial value problem for $U(\tau)$ is formulated as (2.9).

Remark 2.1. If (2.7) is valid, the spatial and temporal distributions of solutions of $(2.1)_\varepsilon$-(2.3) for large time t could be governed by $\varphi(x)$ and $U(\tau)$, respectively.

Remark 2.2. If $e_i(x)$ are all constant, that is, if $\nabla e_i(x)\equiv 0$, then $\varphi_i(x) = 1/|\Omega|$, so that $F_i(U) = 1/|\Omega|\int_\Omega f_i(x, U_1/|\Omega|, \cdots, U_n/|\Omega|)\,dx$. This case has already been discussed by Conway, Hoff, and Smoller [3], Yu [37], and Hale [13].

We omit the construction of $u_0(t, \tau, x)$, because it is shown in Ei [4]. However, we should note here that it is not unique. One explicit form is $u_0(t, \tau, x) = w(t, x) + U(\tau)\cdot\varphi(x)$, where $w(t, x)$ is the solution of

$$\begin{aligned} &\frac{\partial w}{\partial t} + \operatorname{div} J(w) = 0_n, \quad t>0, \quad x\in\Omega, \\ &w(0, x) = \xi(x) - \int_\Omega \xi(x)\,dx\cdot\varphi(x), \qquad x\in\bar{\Omega}. \end{aligned} \tag{2.10}$$

Next we briefly mention the validity of $u_0(t, \tau, x)$ as an approximation to the exact solution $u(t, x; \varepsilon)$ of $(2.1)_\varepsilon$-(2.3). We first introduce some notation. Let $C^0(\Omega; \mathbb{R}^n)$ be the Banach space consisting of all bounded continuous functions over Ω with the norm $\|u\|_0 = \sup_{x\in\Omega} |u(x)|$ for $u \in C^0(\Omega; \mathbb{R}^n)$ and $\operatorname{dist}\{V_1, V_2\} = \inf\{\|x-y\|_0 | x \in V_1, y \in V_2\}$ for two closed sets V_1, V_2 in $C^0(\Omega; \mathbb{R}^n)$. Similarly, $C^k(\Omega; \mathbb{R}^n)$ denotes the Banach space consisting of all k-times continuously differentiable functions over Ω with the norm $\|u\|_k = \sum_{i=0}^k \sup_{x\in\Omega} |D^i u(x)|$. When a finite-dimensional space can be considered as a subspace of $C^0(\Omega; \mathbb{R}^n)$, we identify the Euclidean norm of the finite-dimensional space with the restriction of $\|\cdot\|_0$ to the space, say $|\cdot|$, because all norms of a finite-dimensional space are equivalent to each other. Similarly, we use the same symbol $\operatorname{dist}\{V_1, V_2\}$ even if V_1 and V_2 are subsets of the finite-dimensional space.

Let $\pi(\tau; \Xi)$ be a solution of $(2.9)_1$ with the initial condition

$$U(0) = \Xi \in \mathbb{R}^n. \tag{2.11}$$

DEFINITION. We call a closed bounded set Γ in $\mathbb{R}^n$ an *exponentially stable attractor* of π if there exist an open bounded set $V (\supset \Gamma)$ in $\mathbb{R}^n$ and constants $M_0 > 0$, $\alpha > 0$ such that

$$\operatorname{dist}(\pi(\tau; \xi), \Gamma) \leqq M_0 e^{-\alpha\tau} \operatorname{dist}(\xi, \Gamma)$$

for any $\xi \in V$ and any $\tau > 0$.

THEOREM 2.1 [4]. *If $\pi(\tau; \int_\Omega \xi(x)\, dx)$ converges, as $\tau \to \infty$, to some exponentially stable attractor Γ, then there exist constants $\varepsilon_1 > 0$ and $C_1 > 0$ such that for any $\varepsilon \in (0, \varepsilon_1]$ a solution of $(2.1)_\varepsilon$-(2.3) $u(t, x; \varepsilon)$ exists for all t and*

$$\operatorname{dist}\{u(t, \cdot; \varepsilon), \Gamma \cdot \varphi(\cdot)\} \leqq C_1 \varepsilon$$

for sufficiently large t.

Theorem 2.1 indicates that if the initial value $\int_\Omega \xi(x)\, dx$ of $(2.9)_1$ is contained in the attractive region of Γ, then $u(t, \cdot; \varepsilon)$ eventually enters an ε-neighborhood of $\Gamma \cdot \varphi(\cdot)$ in $C^0(\Omega; \mathbb{R}^n)$.

As a special case, if Γ consists of either only one equilibrium or only one periodic orbit of $(2.9)_1$, Theorem 2.1 can be stated as follows.

COROLLARY 2.1 [4]. *In addition to the assumptions of Theorem 2.1, assume that Γ is an equilibrium of $(2.9)_1$. Then there exist constants $\varepsilon_1 > 0$ and $C_1 > 0$ such that*

$$\|u(t, \cdot; \varepsilon) - u_0(t, \varepsilon t, \cdot)\|_0 \leqq C_1 \varepsilon$$

uniformly for any $\varepsilon \in (0, \varepsilon_1]$ and any $t \in [0, \infty)$.

COROLLARY 2.2 [4]. *In addition to the assumptions of Theorem 2.1, assume that Γ is a periodic orbit of $(2.9)_1$. Then, there exist constants $\varepsilon_1 > 0$, $\eta \in (0, 1)$, and $C_1 > 0$ such that*

$$\operatorname{dist}\left\{u(t, \cdot; \varepsilon), \bigcup_{s\geqq 0} u_0(s, \varepsilon s, \cdot)\right\} \leqq C_1 \varepsilon^\eta$$

uniformly for any $\varepsilon \in (0, \varepsilon_1]$ and any $t \in [0, \infty)$.

The results above indicate that the solution $u(t, x; \varepsilon)$ of $(2.1)_\varepsilon$-(2.3) asymptotically enters an ε-neighborhood of the lowest approximation $u_0(t, \varepsilon t, x)$ in suitable function spaces. However, these do not reveal the behavior of the solution in that neighborhood. That is, even if Γ consists of a unique periodic orbit, for instance, we cannot say whether $(2.1)_\varepsilon$, (2.2) also has a unique periodic solution such that the solution $u(t, x; \varepsilon)$ tends to it as $t \to \infty$.

In the next section, we study the relation between the asymptotic states of solutions of (2.9) and $(2.1)_\varepsilon$, (2.2) when ε is sufficiently small.

3. Asymptotic states of $u(t, x; \varepsilon)$. In this section, to study asymptotic states of $u(t, \cdot; \varepsilon)$ of $(2.1)_\varepsilon$, (2.2), we are concerned with the existence and stability of stationary solutions as well as periodic solutions.

DEFINITION. Let π_e and $\pi_p = \{\pi_p(\tau)\}$ be an equilibrium and a periodic orbit of $(2.9)_1$, respectively. Consider the linearized equation of $(2.9)_1$ about π_e or π_p:

$$\frac{dy}{d\tau} = F_U y, \tag{3.1}$$

where $F_U = dF/dU$. We call π_e a *nondegenerate* equilibrium if $F_U(\pi_e)$ has no zero eigenvalue, and call π_p a *nondegenerate* periodic orbit if the characteristic multiplier 1 is an isolated simple eigenvalue of the period map of (3.1).

THEOREM 3.1. *If π_e is a nondegenerate equilibrium of $(2.9)_1$, there is a constant $\varepsilon_0 > 0$ such that $(2.1)_\varepsilon$, (2.2) has a unique stationary solution $\bar{u}(x; \varepsilon)$ for $|\varepsilon| < \varepsilon_0$ which satisfies $\bar{u}(\cdot; \varepsilon) \in C((-\varepsilon_0, \varepsilon_0); C^0(\Omega; \mathbb{R}^n))$ and $\lim_{\varepsilon \downarrow 0} \bar{u}(x; \varepsilon) = \pi_e \cdot \varphi(x)$ uniformly in $x \in \Omega$.*

THEOREM 3.2. *Suppose that π_e is a nondegenerate equilibrium of $(2.9)_1$ and that $\bar{u}(\cdot; \varepsilon)$ is a unique stationary solution associated with π_e as shown in Theorem 3.1. Let L_ε be a linearized operator of $(2.1)_\varepsilon$, (2.2) about $\bar{u}(\cdot; \varepsilon)$. Then there exist $\varepsilon_1 > 0$, $C_1 > 0$, and $\alpha > 0$ such that the spectrum of L_ε consists of two spectral sets $\sigma_1(\varepsilon)$, $\sigma_2(\varepsilon)$ satisfying $\sigma_1(\varepsilon) \subset \{\lambda \in \mathbb{C} \,|\, |\lambda| \leqq C_1 \varepsilon\}$ and $\sigma_2(\varepsilon) \subset \{\lambda \in \mathbb{C} \,|\, \operatorname{Re} \lambda < -\alpha\}$ for $0 < \varepsilon \leqq \varepsilon_1$. For any $\lambda(\varepsilon) \in \sigma_1(\varepsilon)$, there is some $\lambda_0 \in \sigma(F_U(\pi_e))$ such that $\lim_{\varepsilon \downarrow 0} \lambda(\varepsilon)/\varepsilon = \lambda_0$ and its converse also holds, where $\sigma(F_U(\pi_e))$ denotes the spectrum of $F_U(\pi_e)$.*

For this theorem, (i) L_ε has n eigenvalues in an ε-neighborhood of the origin; (ii) by the suitable ε-scaling, these eigenvalues coincide with those of $F_U(\pi_e)$.

THEOREM 3.3. *If the nondegenerate equilibrium π_e is asymptotically stable, $\bar{u}(x; \varepsilon)$ associated with π_e is also asymptotically stable for sufficiently small $\varepsilon > 0$. Moreover, it has an attractive region V, which is independent of ε, in $C^0(\Omega; \mathbb{R}^n)$.*

Similar results hold for the case of the nondegenerate periodic orbit.

THEOREM 3.4. *If π_p is a nondegenerate periodic orbit with period τ_0, there is $\varepsilon_0 > 0$ such that $(2.1)_\varepsilon$, (2.2) has a periodic solution $P(t, x; \varepsilon)$ with period t_ε for $0 < \varepsilon < \varepsilon_0$ which satisfies*

$$\lim_{\varepsilon \downarrow 0} \operatorname{dist} \{P(t, \cdot; \varepsilon), \pi_p \cdot \varphi(\cdot)\} = 0 \quad \text{for } 0 \leqq t \leqq t_\varepsilon,$$

$$\lim_{\varepsilon \downarrow 0} \varepsilon t_\varepsilon = \tau_0.$$

THEOREM 3.5. *Suppose that π_p is a nondegenerate periodic orbit and that $P(t, x; \varepsilon)$ is a periodic solution of $(2.1)_\varepsilon$, (2.2) associated with π_p as shown in Theorem 3.4. Let $U_\varepsilon(t)$ be a period map of $P(t, x; \varepsilon)$ in $(2.1)_\varepsilon$, (2.2). Then, there exist $\varepsilon_1 > 0$ and $C_i > 0$ $(i = 1, 2, 3)$ such that the spectrum of $U_\varepsilon(t)$ consists of two spectral sets $\sigma_1(\varepsilon)$, $\sigma_2(\varepsilon)$ satisfying $\sigma_1(\varepsilon) \subset \{\lambda \in \mathbb{C} \,|\, C_1 \leqq |\lambda| \leqq C_2\}$ and $\sigma_2(\varepsilon) \subset \{\lambda \in \mathbb{C} \,|\, |\lambda| \leqq C_3 \varepsilon\}$ for $0 < \varepsilon \leqq \varepsilon_1$. For any $\lambda(\varepsilon) \in \sigma_1(\varepsilon)$, there is some characteristic multiplier λ_0 of (3.1) such that $\lim_{\varepsilon \downarrow 0} \lambda(\varepsilon) = \lambda_0$ and its converse also holds.*

Remark 3.1. The spectrum of $U_\varepsilon(t)$ is independent of t because of the compactness of $U_\varepsilon(t)$.

THEOREM 3.6. *Assume π_p is nondegenerate and the spectrum of the period map of (3.1) (except 1) lies in $\{|\lambda| < \delta\}$ for some $\delta < 1$. Then $P(t, x; \varepsilon)$ associated with π_p is*

orbitally asymptotically stable for sufficiently small $\varepsilon > 0$. Moreover, it has an attractive region V that is independent of ε, in $C^0(\Omega; \mathbb{R}^n)$.

These results imply that asymptotic states of solutions of PDE problems derive from those of the approximating ODE problems except for degenerate cases. Consequently, the asymptotic behavior of solutions of the PDE problem can be generically investigated by studying the ODE problems.

Let θ be a parameter indicating the heterogeneities of circumstances for individuals in ecology. Then problem $(2.1)_\varepsilon$, (2.2) is written as

$$\frac{\partial u}{\partial t} + \operatorname{div} J(u; \theta) = \varepsilon f(x, u; \theta), \quad t > 0, \quad x \in \Omega, \tag{3.2}_\varepsilon$$

$$\langle \nu, J(u; \theta) \rangle = 0_n, \quad t > 0, \quad x \in \partial\Omega, \tag{3.3}$$

and the stationary solution $\varphi(x)$ of (2.5) as $\varphi(x; \theta)$.

The approximating ODE becomes

$$\frac{dU}{d\tau} = F(U; \theta), \qquad \tau > 0 \tag{3.4}$$

with a parameter θ. For a study of pattern formation due to spatial inhomogeneity, we are interested in bifurcation problems of $(3.2)_\varepsilon$, (3.3) with respect to θ. Suppose that solution structures of (3.4) can be globally analyzed with respect to θ. Then Theorems 3.1–3.6 imply that the regular (i.e., nondegenerate) branch for θ of (3.4) extends to that of the PDE problem $(3.2)_\varepsilon$, (3.3). However, we should note that these theorems do not give any information to degenerate cases such as bifurcation points or limiting points. It is expected that the global picture of asymptotic states for PDE problems will be generically deformed from that of associated ODE problems. These imperfection problems are now in progress.

4. Proofs. Let B be the Banach space $C^0(\Omega; \mathbb{R}^n)$ with sup-norm $\|\cdot\|_0$ and let A be the operator defined by $Au = -\operatorname{div} J(u)$ with domain $D(A) = \{u \in W^{2,N+1}(\Omega; \mathbb{R}^n) \mid Au \in B \text{ and } \langle \nu, J(u) \rangle = 0_n \text{ on } x \in \partial\Omega\}$. $\mathscr{L}(B)$ denotes the Banach space of bounded linear operators from B into itself with operator norm $\|\cdot\|$. Then A is a generator of an analytic semigroup in B with the spectrum $\sigma(A) = \{0 = \lambda_0 > \lambda_1 > \lambda_2 > \cdots\}$ (Stewart [36]), $\operatorname{Ker} A = \mathbb{R}^n \cdot \varphi$, and the projection $Q: B \to \operatorname{Ker} A$ is given by $Qu = \int_\Omega u(x)\, dx \cdot \varphi$ for $u \in B$. Under this notation, $F(U)$ in $(2.9)_1$ is represented by

$$F(U) \cdot \varphi(\cdot) = Qf(\cdot, U \cdot \varphi(\cdot)) \quad \text{for } U \in \mathbb{R}^n \tag{4.1}$$

and problem $(2.1)_\varepsilon$, (2.2), (2.3) is written as the initial value problem in B:

$$\begin{aligned} &\frac{du}{dt} = Au + \varepsilon f(u), \qquad t > 0, \\ &u(0) = \xi, \end{aligned} \tag{4.2}$$

where $f(u)(\cdot)$ denotes $f(\cdot, u)$, so that $f(u)$ is a smooth function from B into itself. Here we give other notation used in this section: $\sigma(\mathscr{L})$ denotes the spectrum of $\mathscr{L}$ if $\mathscr{L}$ is a closed operator in B; Id is the identity in B; $P = \mathrm{Id} - B$; $B_1 = QB$; $B_2 = PB$; I_i is the identity in B_i $(i = 1, 2)$, respectively; E is a unit matrix in $\mathbb{R}^n$; M and a are constants such that $\|e^{tA}P\| \leqq M e^{-at}$ for $t \geqq 0$; C and C_i $(i = 1, 2, \cdots)$ are constants independent of sufficiently small $\varepsilon > 0$.

Proof of Theorem 3.1. The stationary problem (2.1), (2.2) is written as

$$0 = Au + \varepsilon f(u). \tag{4.3}$$

We define u_1 and u_2 by $u_1 = Qu$ and $u_2 = Pu$, and we decompose (4.3) into

$$0 = Qf(u_1+u_2), \qquad 0 = Au_2 + \varepsilon Pf(u_1+u_2). \tag{4.4}$$

By (4.1), the nondegeneracy of π_e is equivalent to $\det (Qf_u(\pi_e \cdot \varphi)|_{B_1}) \neq 0$, so that by the standard Lyapunov-Schmidt method, we see that (4.4) has a solution $(\bar{u}_1(\varepsilon), \bar{u}_2(\varepsilon))$ with $(\bar{u}_1(0), \bar{u}_2(0)) = (\pi_e \cdot \varphi, 0)$ (see Theorem 3 of Ei and Mimura [5], for instance). □

Proof of Theorem 3.2. Let $\bar{u}(\varepsilon)(\cdot) = \bar{u}(\cdot\,; \varepsilon)$ $(|\varepsilon| \leqq \varepsilon_0)$ be the stationary solution of (4.3) satisfying $\bar{u}(0)(\cdot) = \pi_e \cdot \varphi(\cdot)$. Then the linearized operator L_ε of (4.2) about $\bar{u}(\varepsilon)$ is described by $L_\varepsilon = A + \varepsilon f_u(\bar{u}(\varepsilon))$. Consider the equation

$$(\lambda - L_\varepsilon)u = v \tag{4.5}$$

for $\lambda \in \mathbb{C}$ and $v \in B$. Putting $u_1 = Qu$, $u_2 = Pu$ and $v_1 = Qv$, $v_2 = Pv$, we have a pair of equations equivalent to (4.5):

$$\lambda u_1 - \varepsilon Qf_u(\bar{u}(\varepsilon))(u_1+u_2) = v_1, \tag{4.6}_1$$

$$\lambda u_2 - A_2 u_2 - \varepsilon Pf_u(\bar{u}(\varepsilon))(u_1+u_2) = v_2, \tag{4.6}_2$$

where A_2 is the operator that is restricted to B_2, which is invertible in B_2. Let α be a constant satisfying $0 > -\alpha > \lambda_1$. Then, if λ satisfies $\operatorname{Re}\lambda > -\alpha$ and $\varepsilon > 0$ is sufficiently small, $(4.6)_2$ is solvable on u_2 and it is written as

$$u_2 = G(\lambda, \varepsilon)(v_2 + \varepsilon Pf_u(\bar{u}(\varepsilon))), \tag{4.7}$$

where $G_1(\lambda, \varepsilon) = (\lambda I_2 - A_2 - \varepsilon Pf_u(\bar{u}(\varepsilon)))^{-1}$. Substituting (4.7) into $(4.6)_1$, we have

$$\{\lambda I_1 - \varepsilon Qf_u(\bar{u}(\varepsilon))(I_1 + \varepsilon G(\lambda, \varepsilon)Pf_u(\bar{u}(\varepsilon)))\}u_1 = v_1 + \varepsilon Qf_u(\bar{u}(\varepsilon))G(\lambda, \varepsilon)v_2. \tag{4.8}$$

Since $\bar{u}(\varepsilon)$ and $G_1(\lambda, \varepsilon)$ are uniformly bounded for sufficiently small $\varepsilon > 0$, there is a constant $C_0 > 0$ such that $\|Qf_u(\bar{u}(\varepsilon))(I_1 + \varepsilon G_1(\lambda, \varepsilon)Pf_u(\bar{u}(\varepsilon)))\| \leqq C_0$. Hence, if λ satisfies $|\lambda| > C_1\varepsilon$ for some $C_1 > C_0$ and sufficiently small $\varepsilon > 0$, (4.8) is solvable on u_1. Consequently, there are positive constants C_1 and ε_1 such that if λ satisfies $|\lambda| \geqq C_1\varepsilon$ and $\operatorname{Re}\lambda > -\alpha$ for $0 < \varepsilon \leqq \varepsilon_1$, λ is an element of $\rho(L_\varepsilon)$. This implies that the spectrum $\sigma(L_\varepsilon)$ consists of two spectral sets $\sigma_1(\varepsilon)$, $\sigma_2(\varepsilon)$ such that $\sigma_1(\varepsilon) \subset \{\lambda \in \mathbb{C} \,|\, |\lambda| \leq C_1\varepsilon\}$ and $\sigma_2(\varepsilon) \subset \{\lambda \in \mathbb{C} \,|\, \operatorname{Re}\lambda < -\alpha\}$.

We consider the spectrum contained in $\sigma_1(\varepsilon)$ for $0 < \varepsilon \leqq \varepsilon_1$. Since L_ε has the compact resolvent, $\sigma_1(\varepsilon)$ consists only of isolated eigenvalues with finite multiplicity. Putting $\lambda' = \lambda/\varepsilon$ for $\lambda \in \sigma_1(\varepsilon)$, we consider the following eigenvalue problem:

$$(\varepsilon\lambda' - L_\varepsilon)u = 0,$$

which is equivalent to

$$\lambda' u_1 - Qf_u(\bar{u}(\varepsilon))(u_1+u_2) = 0, \tag{4.9}_1$$

$$\varepsilon\lambda' u_2 - A_2 u_2 - \varepsilon Pf_u(\bar{u}(\varepsilon))(u_1+u_2) = 0, \tag{4.9}_2$$

where $u_1 = Qu$ and $u_2 = Pu$. Since $(4.9)_2$ is solvable on u_2, we obtain

$$u_2 = \varepsilon G_2(\lambda', \varepsilon)Pf_u(\bar{u}(\varepsilon))u_1, \tag{4.10}$$

where $G_2(\lambda', \varepsilon) = (\varepsilon\lambda' I_2 - A_2 - \varepsilon Pf_u(\bar{u}(\varepsilon)))^{-1}$. After substituting (4.10) into $(4.9)_1$, we see $G_3(\lambda', \varepsilon)u_1 = 0$, where $G_3(\lambda', \varepsilon) = \{\lambda' I_1 - Qf_u(\bar{u}(\varepsilon))(I_1 + \varepsilon G_2(\lambda', \varepsilon)Pf_u(\bar{u}(\varepsilon)))\}$. Here $G_3(\lambda', \varepsilon)$ is a matrix in the finite-dimensional space B_1, so that it suffices to investigate zeros of $g_\varepsilon(\lambda') = \det G_3(\lambda', \varepsilon)$. Let $D_1 = \{\lambda \in \mathbb{C} \,|\, |\lambda| < C_1\}$. $g_\varepsilon(\lambda')$ is an analytic function of λ', and as $\varepsilon \downarrow 0$, it converges to $g_0(\lambda') = \det(\lambda' I_1 - Qf_u(\pi_e \cdot \varphi)|_{B_1}) = \det(\lambda' E - F_U(\pi_e))$ uniformly on $\bar{D}_1$. We may assume that $g_\varepsilon(\lambda')$ and $g_0(\lambda')$ are not zero on ∂D_1, so that the proof is complete by use of the theorem of Hurwitz. □

Proof of Theorem 3.3. From Theorem 3.2, it is obvious that $\bar{u}(\varepsilon)$ is asymptotically stable for sufficiently small $\varepsilon > 0$. We show only that $\bar{u}(\varepsilon)$ has an attractive region independent of small $\varepsilon > 0$.

Under the assumption of Theorem 3.3, it is proved by Lemma 5.1 of Ei and Mimura [5] that there exist positive constants β, θ $(0 < \theta < \pi/2)$, ε_2, and C such that for $0 < \varepsilon < \varepsilon_2$, the sector $S_\varepsilon = \{\lambda \in \mathbb{C} \,|\, |\arg(\lambda - \beta\varepsilon)| < \pi/2 + \theta,\ \lambda \neq \beta\varepsilon\}$ is contained in $\rho(L_\varepsilon)$ and

$$\|(\lambda - L_\varepsilon)^{-1}\| \leqq \frac{C}{|\lambda - \beta\varepsilon|} \quad \text{for all } \lambda \in S_\varepsilon \tag{4.11}$$

holds. By transforming t into τ $(=\varepsilon t)$, (4.2) becomes

$$\frac{du}{d\tau} = \frac{1}{\varepsilon} Au + f(u) \tag{4.12}$$

and the linearized operator about $\bar{u}(\varepsilon)$ becomes $1/\varepsilon L_\varepsilon$ $(=1/\varepsilon A + f_u(\bar{u}(\varepsilon)))$. Let $S = \{\lambda \in \mathbb{C} \,|\, |\arg(\lambda - \beta)| < \pi/2 + \theta,\ \lambda \neq \beta\}$. Then by (4.11), we have $\|(\lambda - 1/\varepsilon L_\varepsilon)^{-1}\| \leqq C/|\lambda - \beta|$ for all $\lambda \in S$, implying that $\|e^{\tau L_\varepsilon/\varepsilon}\| \leqq C_2 e^{-\beta\tau}$ for some $C_2 > 0$ independent of ε satisfying $0 < \varepsilon \leqq \varepsilon_2$. Thus it turns out that $\bar{u}(\varepsilon)$ of (4.12) has an attractive region V independent of sufficiently small $\varepsilon > 0$. □

Proof of Theorem 3.4.

LEMMA 4.1. *For a given constant $C_0 > 0$, there is $\varepsilon_0 > 0$ such that* (4.2) *has an invariant manifold $\mathcal{M}_\varepsilon$ for $|\varepsilon| < \varepsilon_0$ which is represented as $\mathcal{M}_\varepsilon = \{u_1 + h(u_1, \varepsilon) \,|\, u_1 \in D_0\}$, with $D_0 = \{u_1 \in B_1 \,|\, |u_1| < C_0\}$. h satisfies $h(\cdot, \cdot) \in C^1(D_0 \times (-\varepsilon_0, \varepsilon_0); B_2)$, $\|h(u_1, \varepsilon)\| \leqq C_1\varepsilon$, and $\|h_u(u_1, \varepsilon)\| \leqq C_1\varepsilon$ for some $C_1 > 0$.*

Proof. Problem (4.2) is rewritten as follows:

$$\frac{du_1}{dt} = \varepsilon Q f(u_1 + u_2), \qquad \frac{du_2}{dt} = A_2 u_2 + \varepsilon P f(u_1 + u_2), \tag{4.13}$$

where $u_1 = Qu$ and $u_2 = Pu$. Noting $\|e^{tA_2}\| = \|e^{tA} P\| \leqq M e^{-at}$, we can prove this lemma in a standard manner (cf. Carr [2]), so we omit the proof. □

By Lemma 4.1, we find that the dynamics of (4.13) on the invariant manifold $\mathcal{M}_\varepsilon$ is reduced to that of $du_1/dt = \varepsilon Q f(u_1 + h(u_1, \varepsilon))$, or equivalently,

$$\frac{du_1}{d\tau} = Q f(u_1 + h(u_1, \varepsilon)), \tag{4.14}_\varepsilon$$

where $\tau = \varepsilon t$. Since $\pi_e(\tau) \cdot \varphi(\cdot)$ is a nondegenerate periodic solution of $(4.14)_0$ ($\varepsilon = 0$ in $(4.14)_\varepsilon$) with period τ_0, it is shown by Theorem 8.3.2 of Henry [18] that there exists a periodic solution $\tilde{P}(\tau; \varepsilon)$ with period τ_ε for sufficiently small ε such that $\tau_\varepsilon \to \tau_0$ and $\operatorname{dist}\{\tilde{P}(\tau; \varepsilon)(\cdot), \pi_p \cdot \varphi(\cdot)\} \to 0$ as $\varepsilon \downarrow 0$. Therefore the definition of $P(t, \cdot; \varepsilon) = \tilde{P}(\varepsilon t; \varepsilon)(\cdot)$ completes the proof. □

Remark 4.1. We note that $(4.14)_\varepsilon$ is reduced to $(2.9)_1$ as $\varepsilon \downarrow 0$. This implies that $(2.9)_1$ constructed by the two-timing method is the lowest approximation to $(4.14)_\varepsilon$ on the invariant manifold $\mathcal{M}_\varepsilon$.

Proof of Theorem 3.5. We define $P(t, \cdot; \varepsilon)$ by $P(t; \varepsilon)(\cdot)$ and consider the linearized equation of (4.2) about $P(t; \varepsilon)$:

$$\frac{du}{dt} = (A + \varepsilon f_u(P(t; \varepsilon)))u. \tag{4.15}$$

Let $T_\varepsilon(t, s)$ be the evolutional operator of (4.15), that is, $T_\varepsilon(t, s)u_0$ gives a solution of (4.15) with $u(s) = u_0$. Then the period map $U_\varepsilon(s)$ of $P(t; \varepsilon)$ is given by $U_\varepsilon(s) = T_\varepsilon(s + t_\varepsilon, t_\varepsilon)$.

LEMMA 4.2. *There exist* $\varepsilon_1>0$ *and* $C_1>0$ *such that* $\|PU_\varepsilon(s)\|\leqq C_1\varepsilon$ *for* $0<\varepsilon<\varepsilon_1$ *and* $s\geqq 0$.

Proof. Equation (4.15) is equivalent to

$$\frac{du_1}{dt}=\varepsilon Qf_u(P(t;\varepsilon))(u_1+u_2), \tag{4.16}_1$$

$$\frac{du_2}{dt}=A_2u_2+\varepsilon Pf_u(P(t;\varepsilon))(u_1+u_2), \tag{4.16}_2$$

where $u_1=Qu$ and $u_2=Pu$. Let $u(s)=u_0$ with $\|u_0\|_0\leqq 1$. Then, as is done in Lemma 6.6 of Ei [4], we can show that there exist $\varepsilon_2>0$ and $C_2>0$ such that $\|u_2(s+t)-e^{tA_2}Pu_0\|_0\leqq C_2\varepsilon$ for $0<\varepsilon<\varepsilon_2$, so that we have

$$\|u_2(s+t)\|_0\leqq C_2\varepsilon+Me^{-at}\|u_0\|_0. \tag{4.17}$$

Since the inequality $t_\varepsilon\geqq C_3/\varepsilon$ holds for some $C_3>0$, we see that

$$\|u_2(s+t_\varepsilon)\|_0=\|PU_\varepsilon u_0\|_0\leqq C_2\varepsilon+Me^{-aC_3/\varepsilon}\leqq C_4\varepsilon$$

for some $C_4>0$. The estimate above holds uniformly for u_0 ($\|u_0\|_0\leqq 1$), which gives the proof. □

Suppose $\|PU_\varepsilon(s)\|\leqq C_1\varepsilon$ for $0<\varepsilon<\varepsilon_1$ and consider the equation $(\lambda-U_\varepsilon(s))u=v$, or equivalently

$$\lambda u_1-QU_\varepsilon(s)(u_1+u_2)=v_1, \tag{4.18}_1$$

$$\lambda u_2-PU_\varepsilon(s)(u_1+u_2)=v_2, \tag{4.18}_2$$

where $u_1=Qu$, $u_2=Pu$ and $v_1=Qv$, $v_2=Pv$. If λ satisfies $|\lambda|>C_2\varepsilon$ for some C_2 with $C_2>C_1$, then $(4.18)_2$ is solvable on u_2 and we have

$$u_2=(\lambda-PU_\varepsilon(s))^{-1}(v_2-PU_\varepsilon(s)u_1), \tag{4.19}$$

$$\|(\lambda-PU_\varepsilon(s))^{-1}\|\leqq\frac{C_3}{|\lambda|} \tag{4.20}$$

for some $C_3>0$. Substituting (4.19) into $(4.18)_1$, we see

$$(\lambda-QU_\varepsilon(s)Q+QU_\varepsilon(s)(\lambda-PU_\varepsilon(s))^{-1}PU_\varepsilon(s))u_1=k_1, \tag{4.21}$$

where $k_1=v_1-QU_\varepsilon(s)(\lambda-PU_\varepsilon(s))^{-1}v_2$. Let $\Pi(\tau)$ be the periodic map of π_p in

$$\frac{du_1}{d\tau}=Qf_u(\pi_p(\tau)\cdot\varphi)u_1 \quad \text{for } u_1\in B_1,$$

which is the same equation as (3.1). Since $\|QU_\varepsilon(s)Q-\pi(\varepsilon s)\|\to 0$ as $\varepsilon\downarrow 0$, there exist C_i $(i=4,5,6)$ such that $\sigma(QU_\varepsilon(s)Q)\subset\{\lambda\in\mathbb{C}\,|\,C_4<|\lambda|<C_5\}$ and such that, for any λ satisfying $|\lambda|\leqq C_4$ or $|\lambda|\geqq C_5$, $(\lambda-QU_\varepsilon(s)Q)^{-1}$ exists with $\|(\lambda-QU_\varepsilon(s)Q)^{-1}\|\leqq C_6$. Hence there exists $C_7>0$ such that

$$\|(\lambda-QU_\varepsilon(s)Q)^{-1}QU_\varepsilon(s)(\lambda-PU_\varepsilon(s))^{-1}PU_\varepsilon(s)\|\leqq\frac{C_7\varepsilon}{|\lambda|}\leqq\frac{C_7}{C_2}$$

for λ satisfying $C_2\varepsilon<|\lambda|\leqq C_4$ or $|\lambda|\geqq C_5$. Taking C_2 such that $C_2>C_7$, we see that (4.21) is solvable on u_1 when $\varepsilon>0$ is sufficiently small, that is, $\{\lambda\in\mathbb{C}\,|\,C_2\varepsilon<|\lambda|\leqq C_4$ or $|\lambda|\geqq C_5\}$ is in $\rho(U_\varepsilon(s))$, which gives the proof of the first half of this theorem.

LEMMA 4.3. $\|U_\varepsilon(s)-\pi(\varepsilon s)Q\|\to 0$ *as* $\varepsilon\downarrow 0$.

Proof. From (4.17), we suppose that there exists a positive constant C_8 such that

$$\|u_2(s+t)\|_0\leqq C_8(\varepsilon+e^{-at}) \tag{4.22}$$

uniformly for u_0 with $\|u_0\|_0 \leqq 1$. Let $\bar{T}_\varepsilon(t, s)$ be the evolutional operator of

$$\frac{du}{dt} = \varepsilon Q f_u(P(t; \varepsilon))u \tag{4.23}$$

and let $\bar{U}_\varepsilon(s)$ be the period map, that is, $\bar{U}_\varepsilon(s) = \bar{T}_\varepsilon(s + t_\varepsilon, s)$. Then $\|\bar{T}_\varepsilon(t, s)\|$ is bounded for $t_\varepsilon \geqq t \geqq s \geqq 0$ and $\bar{U}_\varepsilon(s)Q \to \pi(\varepsilon s)Q$ as $\varepsilon \downarrow 0$. Equation $(4.16)_1$ implies that

$$u_1(s + t_\varepsilon) = \bar{U}_\varepsilon(s)Qu_0 + \varepsilon \int_s^{s+t_\varepsilon} \bar{T}_\varepsilon(s + t_\varepsilon, \sigma)Qf_u(P(\sigma; \varepsilon))u_2(\sigma)\, d\sigma. \tag{4.24}$$

From (4.22) we have

$$\begin{aligned} \|u_1(s + t_\varepsilon) - \bar{U}_\varepsilon(s)Qu_0\|_0 &= \|QU_\varepsilon(s)u_0 - \bar{U}_\varepsilon(s)Qu_0\|_0 \\ &\leqq \varepsilon \int_s^{s+t_\varepsilon} C_9(\varepsilon + e^{-a\sigma})\, d\sigma \\ &\leqq \varepsilon C_9\left(\varepsilon t_\varepsilon + \frac{1}{a}\right) \\ &\leqq \varepsilon C_{10} \end{aligned} \tag{4.25}$$

for some C_9 and C_{10}. Hence

$$\begin{aligned} \|U_\varepsilon(s) - \Pi(\varepsilon s)Q\| &\leqq \|QU_\varepsilon(s) - \bar{U}_\varepsilon(s)Q\| \\ &\quad + \|\bar{U}_\varepsilon(s)Q - \Pi(\varepsilon s)Q\| + \|PU_\varepsilon(s)\| \to 0 \end{aligned} \tag{4.26}$$

as $\varepsilon \downarrow 0$. □

We consider the spectrum contained in $\sigma_1(\varepsilon)$. Noting that $\sigma(U_\varepsilon(s)) = \sigma_1(\varepsilon) \cup \sigma_2(\varepsilon)$ such that $\sigma_1(\varepsilon) \subset \{\lambda \in \mathbb{C} \mid C_4 < |\lambda| < C_5\}$ and $\sigma_2(\varepsilon) \subset \{\lambda \in \mathbb{C} \mid |\lambda| \leqq C_2\varepsilon\}$, we define a projection corresponding to $\sigma_1(\varepsilon)$ by $Q_\varepsilon(s)$, that is, $Q_\varepsilon(s) = 1/2\pi i \int_\Gamma (\lambda - U_\varepsilon(s))^{-1}\, d\lambda$, where Γ is a closed curve enclosing $\sigma_1(\varepsilon)$ with $C_2\varepsilon < |\gamma| < C_4$ or $|\gamma| > C_5$ for any $\gamma \in \Gamma$. Let $B_\varepsilon(s) = Q_\varepsilon(s)B$ and $I_\varepsilon(s)$ be the identity in $B_\varepsilon(s)$. Since $U_\varepsilon(s)$ has a compact resolvent, $\sigma_1(\varepsilon)$ consists only of isolated eigenvalues with finite multiplicity. Hence $B_\varepsilon(s)$ is a finite-dimensional space, and it suffices to investigate the zeros of $g_{\varepsilon,s}(\lambda) = \det(\lambda I_\varepsilon(s) - Q_\varepsilon(s)U_\varepsilon(s))$. From Lemma 4.3 and $Q = 1/2\pi i \int_\Gamma (\lambda - \pi(\varepsilon s)Q)^{-1}\, d\lambda$, we have $\|Q_\varepsilon(s) - Q\| \to 0$ as $\varepsilon \downarrow 0$, so that $g_{\varepsilon,s}(\lambda)$ converges to $g_0(\lambda) = \det(\lambda I_1 - Q\Pi(0)Q) = \det(\lambda I_1 - \Pi(0))$ uniformly for λ satisfying $C_4 \leqq |\lambda| \leqq C_5$. Since $g_{\varepsilon,s}(\lambda)$ and $g_0(\lambda)$ are analytic functions of λ and $g_0(\lambda) \neq 0$ on Γ, the theorem of Hurwitz completes the proof. □

Proof of Theorem 3.6. If we transform t into $\tau\ (= \varepsilon t)$, (4.15) becomes

$$\frac{du}{d\tau} = \left(\frac{1}{\varepsilon}A + \varepsilon f_u(\tilde{P}(\tau; \varepsilon))\right)u, \tag{4.27}$$

where $\tilde{P}(\tau; \varepsilon)$ is a periodic solution with period τ_ε associated with $\pi_p \cdot \varphi$ as shown in the proof of Theorem 3.4. Let $\tilde{T}_\varepsilon(\tau, s)$ and $\tilde{U}_\varepsilon(s)$ be the evolutional operator and the period map of (4.27), respectively. Then we remark that $\tilde{T}_\varepsilon(\varepsilon t, \varepsilon s) = T_\varepsilon(t, s)$ and $\tilde{U}_\varepsilon(\varepsilon s) = U_\varepsilon(s)$ hold, where $T_\varepsilon(t, s)$ and $U_\varepsilon(s)$ are the evolutional operator and the period map of (4.15), respectively. From (4.22) and (4.25), we see that there exists $C_{11} > 0$ such that

$$\|\tilde{T}(\tau, s)\| \leqq C_{11} \tag{4.28}$$

for all $\tau \geqq s \geqq 0$. Then, in a way similar to the proof of Theorem 7.2.3 of Henry [18], we can prove that there exist $C_{12} > 0$ and $\delta > 0$ independent of sufficiently small $\varepsilon > 0$ such that

$$\|\tilde{T}(\tau, s)u\|_0 \leqq C_{12}\, e^{-\delta(\tau - s)}\|u\|_0 \tag{4.29}$$

for $\tau \geqq s$ and $u \in B_\varepsilon^1(s)$, where $B_\varepsilon^1(s)$ is a subspace invariant under $\tilde{U}(s)$, $\sigma(\tilde{U}(s)|_{B_\varepsilon^1}) = \sigma(\tilde{U}(s))\backslash\{1\}$. The estimates (4.28) and (4.29) imply this proof. □

5. Application to two-competing species models. In the previous section, we have found that when ε is sufficiently small, the qualitative property of solutions of PDE problem $(2.1)_\varepsilon$, (2.2) is similar to those of ODE problem $(2.9)_1$, if they are nondegenerate.

In this section, as an application of our procedure, we consider the two-competing-species model already proposed as $(1.5)_\varepsilon$, (1.6) in § 1. For this model, we introduced a parameter θ in some interval Θ indicating the distance between the maximum points of $K_1(x)$ and $K_2(x)$. Here, to make clear the dependence on θ, we write the carrying capacity $K(x)$ as $K(x; \theta)$ and the stationary solution $\varphi(x)$ of (2.5) as $\varphi(x; \theta)$. Then, applying our procedure to $(1.5)_\varepsilon$, we obtain the following approximating ODE with the parameter θ:

$$\begin{aligned} \frac{dU_1}{d\tau} &= (r_1 - a_1(\theta)U_1 - b_1(\theta)U_2)U_1, \\ \frac{dU_2}{d\tau} &= (r_2 - b_2(\theta)U_1 - a_2(\theta)U_2)U_2, \end{aligned} \tag{5.1}$$

where

$$a_i(\theta) = \alpha_i \int_\Omega \frac{\varphi_i^2(x; \theta)}{K_i(x; \theta)}\,dx, \qquad b_i(\theta) = \beta_i \int_\Omega \frac{\varphi_1(x; \theta)\varphi_2(x; \theta)}{K_i(x; \theta)}\,dx$$

for $i = 1, 2$. The asymptotic states of solutions to (5.1) can be studied by phase-plane analysis, namely, the global structure of equilibria of (5.1) is completely known with respect to θ.

Let us show one example. We choose

$$\begin{aligned} K_1(x; \theta) &= \begin{cases} \dfrac{3}{5} \cdot \cos 4\pi\left(x + \dfrac{\theta}{2}\right) + 1 & \left(-\dfrac{\theta}{2} + \dfrac{1}{4} < x < -\dfrac{\theta}{2} + \dfrac{3}{4}\right), \\ \dfrac{2}{5} & \text{otherwise}, \end{cases} \\ K_2(x; \theta) &= \begin{cases} \dfrac{3}{5} \cdot \cos 4\pi\left(x - \dfrac{\theta}{2}\right) + 1 & \left(\dfrac{\theta}{2} + \dfrac{1}{4} < x < \dfrac{\theta}{2} + \dfrac{3}{4}\right), \\ \dfrac{2}{5} & \text{otherwise}. \end{cases} \end{aligned} \tag{5.2}$$

By noting that $x_1 = -(\theta/2) + \frac{1}{2}$ and $x_2 = \theta/2 + \frac{1}{2}$, we find that θ varies in the interval $\Theta = [0, \frac{1}{2}]$. We specify d, r, α, β, and γ as

$$\begin{aligned} &d = (d_1, d_2) = (1, 1), \quad r = (1, 1), \quad \alpha = (1, 1), \\ &\beta = (1.5, 1.2), \qquad \gamma = 1.6, \end{aligned} \tag{5.3}$$

respectively.

First we consider the case when the dispersal is ignored, so that $(1.5)_\varepsilon$ is formally reduced to the ODE system with parameters x and θ:

$$\begin{aligned} \frac{du_1}{dt} &= \varepsilon\left(r_1 - \frac{\alpha_1 u_1 + \beta_1 u_2}{K_1(x; \theta)}\right)u_1, \\ \frac{du_2}{dt} &= \varepsilon\left(r_2 - \frac{\beta_1 u_1 + \alpha_2 u_2}{K_2(x; \theta)}\right)u_2. \end{aligned} \tag{5.4}$$

A simple calculation shows that the parameters in (5.4) are chosen so as to have *no* stable coexistence equilibrium for any $x \in \bar{\Omega}$ and $\theta \in \Theta$. In ecological terms, this situation indicates the competitive exclusion between the two species as long as they do not migrate. Under this situation, we have the following problem. If they migrate in a heterogeneous habitat, is it possible for them to coexist? For this problem, the approximating ODE system (5.1) works well.

First, consider the case when the advection is ignored, that is, $\gamma = 0$. We easily find that the stationary solutions of $(1.5)_\varepsilon$ with $\varepsilon = 0$ and of (1.6) are $\varphi(x; \theta) \equiv (1, 1)$, which is independent of θ, so that the approximating ODE system is also independent of θ. Phase-plane analysis shows the global picture of equilibria of (5.1) in Fig. 3. The ecological interpretation is that if the two competing species move with diffusion only, they never coexist even if the heterogeneous habitat encourages a favorably segregated pattern for them.

Next, consider the case when the advection term is present, say $\gamma = 1.6$. Figure 4 shows the global bifurcation pictures for θ, where there are two critical values θ_* ($\simeq 0.15$) and θ^* ($\simeq 0.27$) such that *three* qualitatively different asymptotic states appear for $0 < \theta < \theta_*$, $\theta_* < \theta < \theta^*$, and $\theta_* < \theta < \frac{1}{2}$. The stable coexistence equilibrium exists for $\theta_* < \theta < \frac{1}{2}$. Theorems 3.1-3.3 say that there is a stable stationary coexistence solution of $(1.5)_\varepsilon$, (1.6). That is, coexistence of the competing species occurs due to incorporation of spatial heterogeneity and tactical migration (see [34]). Thus, from Fig. 4, the reader can now completely understand why three different asymptotic states of solutions appear for suitable θ as in Fig. 2.

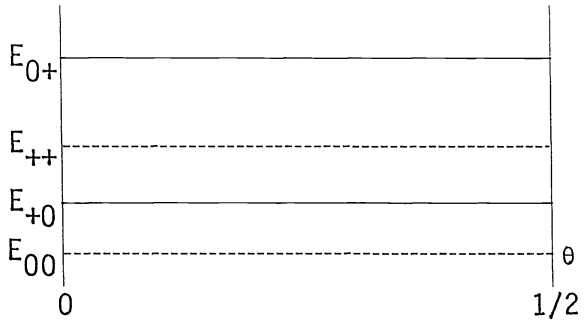

FIG. 3. *Global structure of equilibria of* (4.4) *when* $\gamma = 0$. $E_{00} = (0, 0)$, $E_{+0} = (r_1/a_1, 0)$, $E_{0+} = (0, r_2/a_2)$, *and* E_{++} *is the coexistence equilibrium.* —— *is the stable branch.* - - - *is the unstable branch.*

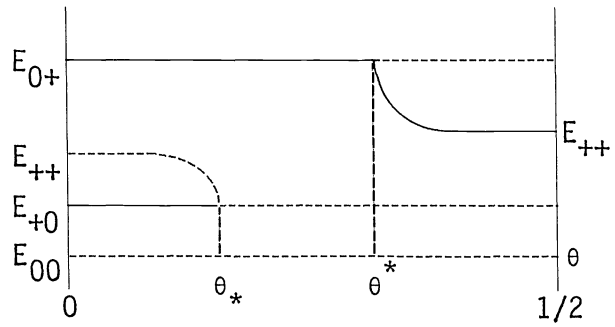

FIG. 4. *Global structure of equilibria of* (4.4) *when* $\gamma = 1.6$.

There remains one interesting problem. Our theorems do not discuss bifurcation points $\theta = \theta_*$ and $\theta = \theta^*$. This analysis, with further applications to the multispecies model, will be reported in [6].

Acknowledgment. We are grateful to Miss T. Yamanoue for numerically computing the problems $(1.5)_\varepsilon$, (1.6) with (5.2) and (5.3).

THE STEFAN PROBLEM WITH A KINETIC CONDITION AT THE FREE BOUNDARY*

XIE WEIQING†

Abstract. This paper considers a class of one-dimensional solidification problems, in which a kinetic undercooling is incorporated into the temperature condition at the interface. A model problem with linear kinetic law is considered. This study indicates that the presence of a kinetic term at the interface can prevent finite-time blowup even though supercooling (superheating) exists. The mathematical effects of the kinetic term are discussed.

Key words. kinetic undercooling, Stefan problem, supercooled

AMS(MOS) subject classifications. 35K05, 35R35, 80A20

1. Introduction. Mathematical models of solidification that include interface kinetics effects have been considered for quite some time (see [1], [2], and references therein). This class of free boundary problems, which arise in a number of physical situations, is that of nonequilibrium problems, in which the phase-change temperature is dependent on the velocity of the front at which the phase change occurs (for more physical problems, see [3]-[6] and references therein). Here we study a model problem with linear kinetic law at the interface in the one-dimensional case. Specifically, let the curve $x=s(t)$ with $s(0)=b$ $(0<b<1)$ be defined as the interface that separates the liquid and solid phases. With u denoting temperature (scaled so that it vanishes at equilibrium), we may write the system of equations as

$$u_t = k_L u_{xx} \quad \text{in } Q_1=\{(x,t)/\ 0<x<s(t), 0<t\leqq T\}, \tag{1.1}$$

$$u_t = k_S u_{xx} \quad \text{in } Q_2=\{(x,t)/\ s(t)<x<1, 0<t\leqq T\}, \tag{1.2}$$

and on the interface $x=s(t)$ as

$$u^- = u^+ = u^I, \tag{1.3}$$

$$k_L u_x^- - k_S u_x^+ = -L\dot{s}(t), \tag{1.4}$$

$$u^I = \varepsilon \dot{s}(t), \tag{1.5}$$

$$s(0)=b, \qquad 0<b<1, \tag{1.6}$$

where k_L and k_S are thermal diffusivities of a liquid and a solid, respectively, $L\neq 0$ is the latent heat, ε is a constant, and the superscripts + and − denote, respectively, the right-hand and left-hand limits with respect to the spatial variable x. These equations are subject to the initial and boundary conditions

$$u(x,0)=\phi_1(x), \qquad 0\leqq x\leqq b, \tag{1.7}$$

$$u(x,0)=\phi_2(x), \qquad b\leqq x\leqq 1, \tag{1.8}$$

$$u(i-1,t)=f_i(t), \qquad t\geqq 0 \quad (i=1,2). \tag{1.9}$$

For the discussion below, we will also denote problem (1.1)-(1.9) as problem (P).

In the absence of the interface kinetics effects (i.e., when the coefficient $\varepsilon=0$), this problem is known as the Stefan problem, which has been widely studied and for which the mathematical results are fairly well understood.

The model in which the coefficient ε is nonzero has been considered by Coriell and Parker in [3], where the shape stability has been carried out for the effects of linear kinetic and of square kinetic law (i.e., $\varepsilon \dot{s} = u^2$) when temperature u satisfies Laplace's equation, in place of the time-dependent diffusion equation (see also the references in [3]). This has also been generalized by Coriell and Sekerka [4], who discuss the morphological stability of a planar solid-liquid interface during unidirectional solidification of a binary alloy. Crowley [5] has described several physical situations in which two kinds of nonequilibrium problems occur; those that arise in the modeling of alloy solidification in certain regimes, and those that arise in the study of condensed-phase flame propagation in which the reaction zone is thin. Visintin [7] has studied the latter problem using a variational approach, but has only been able to establish the existence of a generalized solution.

Our objective in this paper is to understand the mathematical effects of the kinetic term for the above model problem in the classical framework. The results here are completely parallel to the results that have been proved for the standard Stefan problem, but without sign restriction on the boundary and initial data that may lead to the finite-time blowup for the Stefan problem in certain circumstances. This indicates that the interface kinetics effect may regularize the problem, at least in the one-dimensional case, in such a way that it can stop blowup, even if supercooling (superheating) exists.

In § 2 we give the existence proof via a fixed-point argument. Section 3 establishes the uniqueness of the solution. Section 4 discusses the regularity of the free boundary (also for temperature $u(x, t)$), and the C^∞-regularity is proved by repeating the "bootstrap" process. Last, in § 5, we retrieve the solution of the Stefan problem by taking the limit $\varepsilon \to 0$, with sign restriction on the boundary and initial data and an additional assumption about the free boundary.

2. Existence of a solution of problem (P). In this section we establish the existence of problem (P), (1.1)-(1.9). A definition of a classical solution $(s(t); u(x, t))$ is defined in the usual sense, which satisfies

(i) $s \in C^1(0, T)$.

Denoting by $Q_T \equiv Q \equiv (0, 1) \times (0, T)$ and by u_i the restrictions to Q_i of $u(x, t)$,

(ii) $u_i(x, t) \in C(\bar{Q}_i) \cap C^{2,1}(Q_i)$,

$u_{ix} \in C(\bar{Q}_i \backslash \{x = i-1\})$, $\quad i = 1, 2,$

and (1.1)-(1.9), the functions $\phi_i(x)$ and $f_i(t)$ $(i = 1, 2)$ in (1.7)-(1.9) satisfy

$$f_i(t) \in C^1(\mathbb{R}^1) \cap L^\infty(\mathbb{R}^1), \quad \phi_1(x) \in C^1[0, b], \quad \phi_2(x) \in C^1[b, 1] \tag{2.1}$$

and the consistency conditions

$$f_1(0) = \phi_1(0), \quad f_2(0) = \phi_2(1), \quad \phi_1(b) = \phi_2(b). \tag{2.2}$$

To prove the existence result, we use a fixed-point argument.

Let $K(T_0, M) = \{s(t) \in C^1[0, T_0] / s(0) = b, 0 < s(t) < 1, |\dot{s}| \leqq M\}$, where M is a fixed constant to be specified below and T_0 is small enough so that

$$MT_0 \leqq \min\{b, 1-b\}. \tag{2.3}$$

For simplicity, we first consider the case in which the constants ε and L are positive.

For any given $s(t) \in \bar{K}(T_0, M)$, there exists a unique solution $u(x, t)$ of problem (1.1)-(1.3), (1.6)-(1.9), and

$$k_L u_x^-(s(t), t) - k_S u_x^+(s(t), t) + \frac{L}{\varepsilon} u(s(t), t) = 0 \tag{2.4}$$

(see, e.g., [8], [9]). With this choice of $u(x, t)$, we define the mapping F such that $Fs = h$ with

$$h(t) = b + \frac{1}{\varepsilon}\int_0^t u(s(\tau), \tau; s(t))\, d\tau, \tag{2.5}$$

where $u(x, t; s(t))$ is a solution of problems (1.1)-(1.3), (1.6)-(1.9), and (2.4) corresponding to the given interface $x = s(t)$.

If we can show that F has a fixed point that belongs in $K(T_0, M)$, then from (2.5) and (2.4), it follows that (1.4) and (1.5) are satisfied. Thus $(s(t), u(x, t))$ will then form a solution of problem (P).

To show that F maps $\bar{K}(T_0, M)$ into itself, we observe that $h(t)$ is again in $C^1[0, T]$ and $h(0) = b$ because $u(x, t)$ is a classical solution of (1.1)-(1.3), (1.6)-(1.9), and (2.4). Note that a straightforward application of maximum principle yields the estimate

$$\|u(x, t)\|_{0, Q_{T_0}} \leqq M_0 \equiv \max\,(\|\phi_i\|_0, \|f_i\|_0, i = 1, 2). \tag{2.6}$$

If we take $M = M_0/\varepsilon$, then by (2.5) we have $h(t) \in K(T_0, M)$. This means the mapping F is from $\bar{K}(T_0, M)$ into itself.

We next show that F is a continuous mapping. To do this, suppose $s^n(t), s(t) \in \bar{K}$ $(n = 1, 2, \cdots)$, $s^n \to s$ uniformly on $[0, T_0]$. Define $u^n(x, t)$, $u(x, t)$ to be the solution of problem (1.1)-(1.3), (1.6)-(1.9), (2.4) corresponding to the boundary $x = s^n(t)$, $x = s(t)$, respectively. We first prove that $u^n(x, t) \to u(x, t)$ in $C(\bar{Q}_{T_0})$.

Since the $u^n(x, t)$ is bounded uniformly, which is also the generalized solution of the problem

$$u_t - (K(x, t)u_x + a(x, t)u)_x + a(x, t)u_x = 0 \quad \text{in } Q_{T_0}, \tag{2.7}$$

with boundary and initial conditions (1.7)-(1.9) in the sense of [10], where

$$K(x, t) = \begin{cases} k_L, \\ k_S, \end{cases} \qquad a(x, t) = \begin{cases} 0 & \text{in } Q_1^n = \{0 < x \leqq s^n(t), 0 < t < T_0\}, \\ -L/\varepsilon & \text{in } Q_2^n = \{s^n(t) < x < 1, 0 < t < T_0\}, \end{cases} \tag{2.8}$$

then $u^n(x, t)$ has uniform Hölder constants on $\bar{Q}_{T_0}$ [10]. Thus there is a subsequence (which we also denote by $u^n(x, t)$) converging in $C(\bar{Q}_{T_0})$ to some function $u(x, t)$. Any region Q' bounded away from the interface $x = s(t)$ and parabolic boundary Γ of Q_{T_0} is also bounded away from $x = s^n(t)$ for n sufficiently large. The uniform bounds on higher derivatives of $u^n(x, t)$ in Q' allow us to pass to the limit to conclude that u satisfies (1.1), (1.2).

To prove (2.4), we note that the $u^n(x, t)$ satisfy

$$\int\int_{Q_{T_0}} [u_t^n \xi + K(x, t)u_x^n \xi_x + a(x, t)u^n \xi_x + a(x, t)u_x^n \xi]\, dx\, dt = 0$$

for all smooth $\xi(x, t)$ vanishing in a neighbourhood of Γ. Passing to the limit as $n \to \infty$ we have the same equality for u. As $\xi(x, t)$ is arbitrary and (1.1), (1.2), integrating by parts and noting that $s(t) \in \bar{K}(T_0, M)$ can show that (2.4) holds.

The uniqueness of the solution $u(x, t)$ of the boundary value problem (1.1)-(1.3), (1.6)-(1.9), (2.4) for given interface follows by standard methods (see, e.g., [8]). Then the limit function $u(x, t)$ of $u^n(x, t)$ is a solution of problem (1.1)-(1.3), (1.6)-(1.9), (2.4) corresponding to the interface $x = s(t)$; this implies that $u^n(x, t) \to u(x, t)$ in $C(\bar{Q}_{T_0})$.

We now prove $F(s^n) \to F(s)$ in $C[0, T_0]$, denoting by $\alpha(t) = \min(s^n(t), s(t))$ and by $u(x, t; \beta(t))$ the solution of (1.1)-(1.3), (1.6)-(1.9), (2.4) corresponding to the interface $x = \beta(t)$.

Then

$$
\begin{aligned}
F(s^n) - F(s) = & \frac{1}{\varepsilon} \int_0^t [u^n(s^n(\tau), \tau; s^n(t)) - u^n(\alpha(\tau), \tau; s^n(t))]\, d\tau \\
& + \frac{1}{\varepsilon} \int_0^t [u^n(\alpha(\tau), \tau; s^n(t)) - u(\alpha(\tau), \tau; s(t))]\, d\tau \\
& + \frac{1}{\varepsilon} \int_0^t [u(\alpha(\tau), \tau; s(t)) - u(s(\tau), \tau; s(t))]\, d\tau \\
\equiv & I_1^n + I_2^n + I_3^n .
\end{aligned} \tag{2.9}
$$

From the Hölder estimates of $u^n(x, t)$ and $u(x, t)$ on $\bar{Q}_{T_0}$ we get

$$
|I_i^n| \leqq \frac{M\alpha}{\varepsilon} \|s^n - s\|_{C[0, T_0]} \qquad (i = 1, 3), \tag{2.10}
$$

and the Dominated Convergence Theorem implies that

$$
|I_2^n| \to 0 \quad \text{as } n \to \infty \tag{2.11}
$$

because $u^n(x, t; s^n(t)) \to u(x, t; s(t))$ in $C(\bar{Q}_{T_0})$.

Hence, from (2.9)-(2.11), we get the continuity of the mapping F.

We have thus proved that the mapping F has a fixed point $\bar{K}(T_0, M)$ by the Schauder fixed-point theorem. The fixed point is also in $K(T_0, M)$. This gives a solution of problem (P) in $0 < t \leqq T_0$.

Noting that $u(x, T_0) \in C^1[0, s(T_0)] \cap C^1[s(T_0), 1]$ and (2.6), we can continue the process step by step to construct a global solution of problem (P) in $0 < t \leqq T$ by the same argument as that given above, where "global" means that either $T = \infty$ and $0 < s(t) < 1$ for $t < \infty$, or $T < +\infty$ and $\lim_{t \to T^-} s(t) = 0$ or 1. Thus the existence is proved for positive ε and L.

The method demonstrated above can clearly be extended to the case of negative ε and L.

In the case of $\varepsilon L < 0$, we note that the solution of (1.1)-(1.3), (1.6)-(1.9), (2.4) for given interface $s(t) \in \bar{K}(T_0, M)$ is also a generalized solution of problem (2.7), (1.7)-(1.9) in the sense of [10]. We then can obtain the L^∞-norm estimate of the solution $u(x, t)$, which may depend on $\|\phi_i\|_{L^\infty}$, $\|f_i\|_{L^\infty}$ $(i = 1, 2)$, ε, L, and T, but not on the interface $s(t)$ [10]. Using the same method as stated above we can prove the existence of a classical solution in $0 < t \leqq T_0$. We are careful to note also that the L^∞-norm estimate for $u(x, t)$ holds for any $T > 0$ for which (1.1)-(1.3), (1.6)-(1.9), (2.4) has a solution (and not just for the small T_0 for which existence is assured, as above). We then can extend the solution in $0 < t \leqq T_0$, step by step, to a global one; "global" here refers to existence either for all times $t \geqq 0$ or until the free boundary hits one of the fixed sides $x = 0$ or $x = 1$.

3. Uniqueness. We now prove the uniqueness of problem (1.1)-(1.9). Note that problem (1.1)-(1.9) corresponds to the Stefan problem if $\varepsilon = 0$; the uniqueness of the weak solution and hence of the classical solution has been proved by Oleinik [11]. Here we consider the uniqueness of solution of (1.1)-(1.9) when $\varepsilon \neq 0$.

We first derive some estimates for the solution of (1.1)-(1.9) for discussion below.

By a direct calculation of the integrals $\int_0^T d/dt \int_0^1 u^2\,dx\,dt$ and $\int_0^T d/dt \int_0^1 ku_x^2\,dx\,dt$ and using the boundary and interface conditions, we have

$$\begin{aligned}(3.1)\quad &\sup_{0\leqq t\leqq T}\int_0^1 u^2(x,t)\,dx+2\iint_{Q_1\cup Q_2} ku_x^2\,dx\,dt\\ &=\int_0^1 \phi^2(x)\,dx-\frac{2L}{\varepsilon}\int_0^T (u^I)^2\,dt-2\int_0^T (k_L f_1(t)u_x(0,t)-k_S f_2(t)u_x(1,t))\,dt,\end{aligned}$$

$$\begin{aligned}(3.2)\quad &\int_0^1 ku_x^2(x,T)\,dx+2\iint_{Q_1\cup Q_2} k^2u_{xx}^2\,dx\,dt\\ &=\int_0^1 k(\dot\phi(x))^2\,dx+2\int_0^T (k_L u_x^- u_t^- - k_S u_x^+ u_t^+)\,dt\\ &=\int_0^T (k_L(u_x^-)^2-k_S(u_x^+)^2)\dot s\,dt-2\int_0^T (k_L u_x(0,t)\dot f_1(t)-k_S u_x(1,t)\dot f_2(t))\,dt.\end{aligned}$$

Note that by (1.3)–(1.5) on $x=s(t)$, the second term on the right-hand side of (3.2) is equal to

$$-\frac{2L}{\varepsilon}\int_0^T u^I\frac{d}{dt}u^I-2\int_0^T (k_L(u_x^-)^2-k_S(u_x^+)^2)\dot s\,dt.$$

Then we get

$$\begin{aligned}(3.3)\quad \int_0^1 ku_x^2(x,T)\,dx+2\iint_{Q_1\cup Q_2} k^2u_{xx}^2\,dx\,dt &=\int_0^1 k(\dot\phi(x))^2\,dx-\frac{L}{\varepsilon}(u^2(s(T),T)-\phi^2(b))\\ &\quad-\int_0^T (k_L(u_x^-)^2-k_S(u_x^+)^2)\dot s\,dt\\ &\quad-2\int_0^T (k_L u_x(0,t)\dot f_1(t)-k_S u_x(1,t)\dot f_2(t))\,dt\end{aligned}$$

from (3.3), (3.4), and using the inequality below [12],

$$\|u_x(\cdot,T)\|^2_{L^\infty(a,b)}\leqq c\|u_{xx}\|_{L^2(a,b)}\|u_x\|_{L^2(a,b)},$$

we can derive

$$(3.4)\qquad \sup_{0\leqq t\leqq T}\int_0^1 ku_x^2(x,t)\,dx+\iint_{Q_1\cup Q_2}(ku_x^2+k^2u_{xx}^2)\,dx\,dt\leqq C,$$

where constant C depends on ε, L, T, $\|\phi_i\|_{H^1}$, $\|f_i\|_{H^1(0,T)}$ $(i=1,2)$, and $\delta=\min\{s(t),1-s(t),0\leqq t\leqq T\}$.

To prove the uniqueness, let $(s(t);u(x,t))$ and $(\underset{\sim}{s}(t);\underset{\sim}{u}(x,t))$ be two solutions in some time interval $0<t<T_1$, such that for some positive constant $\delta>0$,

$$\delta\leqq s(t),\qquad \underset{\sim}{s}(t)\leqq 1-\delta\quad\text{as } 0<t\leqq T_1,$$

we can prove that $s(t)=\underset{\sim}{s}(t)$, $u(x,t)=\underset{\sim}{u}(x,t)$ in $[0,T_1]$.

Define the new space variable ξ by

$$(3.5)\qquad \xi=\alpha(x,s(t)),$$

where the function $\alpha(x,s)$ as defined in $[0,1]\times[\delta,1-\delta]$ satisfies [13]

$$(3.6)\qquad \alpha(i,s)=i,\quad (i=0,1),\quad \alpha(s,s)=\tfrac12,\quad \alpha_x(s,s)=1\quad\text{as } \delta\leqq s\leqq 1-\delta,$$

$$(3.7)\qquad \alpha_x(x,s)\geqq\alpha_0>0,\quad |D^\beta\alpha|\leqq c\quad(|\beta|\leqq 3)\quad\text{in } [0,1]\times[\delta,1-\delta],$$

where α_0 and c are positive constants.

Then (3.5) determines x as a function of ξ and t, and the function $v(\xi, t)$, described by

$$v(\xi, t) = u(x, t), \tag{3.8}$$

is defined on $Q_T \equiv Q$ for any $0 < T < T_1$.

Setting

$$Q^- = (0, \tfrac{1}{2}) \times (0, T), \quad Q^+ = (\tfrac{1}{2}, 1) \times (0, T), \quad Q = Q^- \cup Q^+ \tag{3.9}$$

and noting that $u_x = v_\xi \alpha_x$, $u_{xx} = v_{\xi\xi}(\alpha_x)^2 + v_\xi \alpha_{xx}$, and $u_t = v_t + v_\xi \alpha_s \dot{s}(t)$, we find that the function $v(\xi, t)$ satisfies the system

$$v_t - k_L(\alpha_x)^2 v_{\xi\xi} = v_\xi(k_L \alpha_{xx} - \alpha_s \dot{s}(t)) \quad \text{in } Q^-, \tag{3.10}$$

$$v_t - k_S(\alpha_x)^2 v_{\xi\xi} = v_\xi(k_S \alpha_{xx} - \alpha_s \dot{s}(t)) \quad \text{in } Q^+, \tag{3.11}$$

$$v^-(\tfrac{1}{2}, t) = v^+(\tfrac{1}{2}, t) = \varepsilon \dot{s}(t), \qquad t > 0, \tag{3.12}$$

$$k_L v_\xi^-(\tfrac{1}{2}, t) - k_S v_\xi^+(\tfrac{1}{2}, t) = -L\dot{s}(t), \qquad t > 0, \tag{3.13}$$

and the initial and boundary conditions

$$v(\xi, 0) = \phi(\xi), \qquad 0 \leqq \xi \leqq 1, \tag{3.14}$$

$$v(i-1, t) = f_i(t), \quad i = 1, 2, \quad t \geqq 0, \tag{3.15}$$

where $\phi(\xi) = \phi_1$ if $\xi \in [0, \frac{1}{2}]$ and $\phi(\xi) = \phi_2$ if $\xi \in [\frac{1}{2}, 1]$; the superscripts + and − denote, respectively, the right-hand and left-hand limits with respect to the variable ξ.

Similarly, define $w(\xi, t) = \underset{\sim}{y}(x, t)$ with $\xi = \alpha(x, \underset{\sim}{s}(t))$. Then $w(\xi, t)$ satisfies a system similar to that satisfied by $v(\xi, t)$.

Now define

$$k = \begin{cases} k_L & \text{in } Q^-, \\ k_S & \text{in } Q^+, \end{cases} \tag{3.16}$$

$$z(\xi, t) = v(\xi, t) - w(\xi, t). \tag{3.17}$$

Then $z(\xi, t)$ satisfies the following system:

$$z_t - k(\alpha_x)^2 z_{\xi\xi} = g \quad \text{in } \underset{\sim}{Q}, \tag{3.18}$$

$$z^-(\tfrac{1}{2}, t) = z^+(\tfrac{1}{2}, t) = \varepsilon(\dot{s} - \dot{\underset{\sim}{s}}), \qquad t > 0, \tag{3.19}$$

$$k_L z_\xi^-(\tfrac{1}{2}, t) - k_S z_\xi^+(\tfrac{1}{2}, t) = -L(\dot{s} - \dot{\underset{\sim}{s}}), \qquad t > 0, \tag{3.20}$$

where

$$g = \begin{cases} g_1 & \text{in } Q^-, \\ g_2 & \text{in } Q^+, \end{cases} \tag{3.21}$$

$$g_1 = (k_L(\alpha_x)^2 - k_L(\underset{\sim}{\alpha}_x)^2) w_{\xi\xi} + (k_L \alpha_{xx} - \alpha_s \dot{s}) z_\xi + [(k_L \alpha_{xx} - \alpha_s \dot{s}) - (k_L \underset{\sim}{\alpha}_{xx} - \underset{\sim}{\alpha}_s \dot{\underset{\sim}{s}})] w_\xi, \tag{3.22}$$

$$g_2 = (k_S(\alpha_x)^2 - k_S(\underset{\sim}{\alpha}_x)^2) w_{\xi\xi} + (k_S \alpha_{xx} - \alpha_s \dot{s}) z_\xi + [(k_S \alpha_{xx} - \alpha_s \dot{s}) - (k_S \underset{\sim}{\alpha}_{xx} - \underset{\sim}{\alpha}_s \dot{\underset{\sim}{s}})] w_\xi \tag{3.23}$$

with $\underset{\sim}{\alpha} = \alpha(x, \underset{\sim}{s})$.

From (3.18) we get

$$\iint_{\underset{\sim}{Q}} z(z_t - k(\alpha_x)^2 z_{\xi\xi})\, d\xi\, dt = \iint_{\underset{\sim}{Q}} gz\, d\xi\, dt. \tag{3.24}$$

Note that

$$|g_i| \leqq c[|z_\xi| + |\dot{s} - \dot{\underset{\sim}{s}}| + |s - \underset{\sim}{s}| + |w_{\xi\xi}||s - \underset{\sim}{s}|] \qquad (i = 1, 2) \tag{3.25}$$

and the lower bound of the left-hand side of (3.24) is

$$\frac{1}{2}\int_0^1 z^2(\xi, T)\,d\xi + c\iint_{\underset{\sim}{Q}} (z_\xi)^2\,d\xi\,dt - c\iint_{\underset{\sim}{Q}} |z||z_\xi|\,d\xi\,dt, \tag{3.26}$$

while the right-hand side term of (3.24) is bounded by

$$\begin{aligned} &c\iint_{\underset{\sim}{Q}} (|z||z_\xi| + |\dot{s}-\dot{\underset{\sim}{s}}||z| + |s-\underset{\sim}{s}||z| + |w_{\xi\xi}||s-\underset{\sim}{s}||z|)\,d\xi\,dt \\ &\leqq c\left\{\int_0^T |\dot{s}-\dot{\underset{\sim}{s}}|^2\,dt + \eta\iint_{\underset{\sim}{Q}} ((z_\xi)^2 + (w_{\xi\xi})^2|s-\underset{\sim}{s}|^2)\,d\xi\,dt\right. \\ &\qquad \left. + c(\eta)\iint_{\underset{\sim}{Q}} z^2\,d\xi\,dt\right\}. \end{aligned} \tag{3.27}$$

The first term on the right-hand side of (3.27) is bounded by

$$\begin{aligned} c\int_0^T \frac{1}{\varepsilon^2} z^2\left(\frac{1}{2}, t\right) dt &\leqq \frac{c}{\varepsilon^2}\int_0^T \|z(\cdot, t)\|_{L^\infty}^2\,dt \\ &\leqq \eta\iint_{\underset{\sim}{Q}} (z_\xi)^2\,d\xi\,dt + c(\eta)\iint_{\underset{\sim}{Q}} z^2\,d\xi\,dt. \end{aligned} \tag{3.28}$$

Noting also that $\iint_{\underset{\sim}{Q}} |w_{\xi\xi}|^2\,d\xi\,dt \leqq c$ because of estimate (3.4), we have

$$\begin{aligned} \eta\iint_{\underset{\sim}{Q}} |w_{\xi\xi}|^2|s-\underset{\sim}{s}|^2\,d\xi\,dt &= \eta\int_0^T \left(\int_0^1 w_{\xi\xi}^2\,d\xi\right)|s-\underset{\sim}{s}|^2\,dt \\ &\leqq \frac{\eta}{\varepsilon}\int_0^T \left(\int_0^1 w_{\xi\xi}^2\,d\xi\right)\left(\int_0^t z^-\left(\frac{1}{2}, \tau\right)d\tau\right)^2 dt \\ &\leqq \frac{c\eta}{\varepsilon}\int_0^T \left(\int_0^1 w_{\xi\xi}^2\,d\xi\right)\int_0^t (\|z_\xi(\cdot, \tau)\|_{L^2(0,1/2)}^2 \\ &\quad + \|z(\cdot, \tau)\|_{L^2(0,1)}^2)\,d\tau\,dt \\ &\leqq \frac{c\eta}{\varepsilon}\iint_{\underset{\sim}{Q}} w_{\xi\xi}^2\,d\xi\,dt\left(\iint_{\underset{\sim}{Q}} (z^2 + z_\xi^2)\,d\xi\,dt\right). \end{aligned} \tag{3.29}$$

From (3.26)–(3.29) and choosing η sufficiently small, we get

$$\frac{1}{2}\int_0^1 z^2(\xi, \tau)\,d\xi + c\iint_{\underset{\sim}{Q}} z_\xi^2\,d\xi\,dt \leqq c\int_0^T\int_0^1 z^2(\xi, t)\,d\xi\,dt.$$

This implies that

$$\int_0^1 z^2(\xi, \tau)\,d\xi = 0$$

so that $z \equiv 0$ on Q and consequently $v(\xi, t) = w(\xi, t)$, $s(t) = \underset{\sim}{s}(t)$. Thus the uniqueness is proved.

4. Regularity of the solution. We now discuss the regularity of the solution for problem (P). Recall that, for the ordinary Stefan problem, the free boundary is always infinitely differentiable on the time interval in which existence is assured [14], [15]. Here the same result is proved for the problem with linear interface kinetics (1.5).

To prove the regularity of the free boundary, we consider a neighbourhood of the free boundary $x=s(t)$ for $0<t<T$, where $[0, T]$ is the time interval in which the solution of problem (P) exists with $\min\{s(t), 1-s(t), 0\leqq t\leqq T\}>0$.

Choose $\delta>0$ so small that the region

$$N=\{(x, t)/\ s(t)-\delta<x<s(t)+\delta, 0<t<T\}$$

lies in Q_T. Change the variable to

$$\xi=x-s(t) \tag{4.1}$$

and let $v(\xi, t)=u(\xi+s(t), t)$ for $(\xi, t)\in N_1$, where $(s(t), u(x, t))$ is the unique solution of problem (P), $N_1=\{(\xi, t)/-\delta<\xi<\delta, 0<t<T\}$.

Then $v(\xi, t)$ satisfies the following system:

$$v_t-k_{\mathrm{L}}v_{\xi\xi}=\dot{s}(t)v_\xi, \quad -\delta<\xi<0, \quad 0<t<T, \tag{4.2}$$

$$v_t-k_{\mathrm{S}}v_{\xi\xi}=\dot{s}(t)v_\xi, \quad 0<\xi<\delta, \quad 0<t<T, \tag{4.3}$$

$$v(\xi, 0)=\underset{\sim}{\phi}(\xi), \quad -\delta\leqq\xi\leqq\delta, \tag{4.4}$$

$$v^-(0, t)=v^+(0, t)=\varepsilon\dot{s}(t), \quad 0<t<T, \tag{4.5}$$

$$k_{\mathrm{L}}v_\xi^-(0, t)-k_{\mathrm{S}}v_\xi^+(0, t)=-\dot{s}(t) \quad 0<t<T. \tag{4.6}$$

We assume, without loss of generality, that $k_{\mathrm{L}}\geqq k_{\mathrm{S}}$ and define the following two functions:

$$w(\xi, t)=v(\xi, t)-v(-\underset{\sim}{k}\xi, t), \tag{4.7}$$

$$\underset{\sim}{w}(\xi, t)=v(\xi, t)+\underset{\sim}{k}v(-\underset{\sim}{k}\xi, t), \tag{4.8}$$

where

$$\underset{\sim}{k}=(k_{\mathrm{S}}/k_{\mathrm{L}})^{1/2}\leqq 1. \tag{4.9}$$

Then $w(\xi, t)$ satisfies

$$w_t-k_{\mathrm{L}}w_{\xi\xi}=\dot{s}(t)(v_\xi(\xi, t)-v_\xi(-\underset{\sim}{k}\xi, t)) \quad \text{in } N_1^-, \tag{4.10}$$

$$w(0, t)=0, \quad 0\leqq t\leqq T, \tag{4.11}$$

$$w(\xi, 0)=\underset{\sim}{\phi}_1(\xi)-\underset{\sim}{\phi}_2(-\underset{\sim}{k}\xi), \quad -\delta\leqq\xi\leqq 0, \tag{4.12}$$

and $\underset{\sim}{w}(\xi, t)$ satisfies

$$\underset{\sim}{w}_t-k_{\mathrm{L}}\underset{\sim}{w}_{\xi\xi}=\dot{s}(t)(v_\xi(\xi, t)+\underset{\sim}{k}v_\xi(-\underset{\sim}{k}\xi, t)) \quad \text{in } N_1^-, \tag{4.13}$$

$$k_{\mathrm{L}}\left(\underset{\sim}{w}_\xi(0, t)+\frac{1}{(\underset{\sim}{k}+1)\varepsilon}\underset{\sim}{w}(0, t)\right)=0, \quad 0\leqq t\leqq T, \tag{4.14}$$

$$\underset{\sim}{w}(\xi, 0)=\underset{\sim}{\phi}_1(\xi)+\underset{\sim}{k}\underset{\sim}{\phi}_2(-\underset{\sim}{k}\xi), \quad -\delta\leqq\xi\leqq 0, \tag{4.15}$$

where $N_1^-=\{(\xi, t)/-\delta<\xi<0, 0<t<T\}$. Note that the functions on the right-hand side of (4.10), (4.13) belong to L^∞. According to the local parabolic L^p-estimates for the problem with the Dirichlet boundary condition and the problem with directional derivative [10], we have

$$\|w, \underset{\sim}{w}\|_{W_p^{2,1}(N_2)}\leqq C, \tag{4.16}$$

where $p>1$ is arbitrarily constant, for any interior domain N_2, the boundary of which contains a segment $\xi=0$. We choose $p>1$ suitable large such that

$$w_\xi,\ \underset{\sim}{w}_\xi \in C^{\alpha,\alpha/2}(\bar{N}_2), \tag{4.17}$$

where $0<\alpha<1$ [10].

Note that, from (4.7) and (4.8),

$$v(\xi,t)=\frac{1}{\underset{\sim}{k}+1}(\underset{\sim}{k}w(\xi,t)+\underset{\sim}{w}(\xi,t)), \tag{4.18}$$

$$v(-\underset{\sim}{k}\xi,t)=\frac{1}{\underset{\sim}{k}+1}(\underset{\sim}{w}(\xi,t)-w(\xi,t)), \tag{4.19}$$

and hence $v_\xi(\xi,t)\in C^{\alpha,\alpha/2}(\overline{N_3^-})\cap C^{\alpha,\alpha/2}(\overline{N_3^+})$, where N_3^- is a domain of the form $(-\delta,0)\times(\eta,T)$ and N_3^+ is its reflection in the line $\xi=0$. By (4.6) we have $\dot{s}(t)\in C^{\alpha/2}(0,T)$, and so the functions on the right-hand sides of (4.10), (4.13) are now $C^{\alpha,\alpha/2}(\overline{N_3^-})$. Then, according to the parabolic Schauder estimates [10], [16] for (4.10), (4.13), we have

$$w(\xi,t),\ \underset{\sim}{w}(\xi,t)\in C^{2+\alpha,(2+\alpha)/2}(\overline{N_4^-}),$$

where N_4^- is an interior domain of N_3^-, the boundary of which contains a segment of the $\xi=0$ axis; and so $w_\xi(\xi,t)$, $\underset{\sim}{w}_\xi(\xi,t)\in C^{1+\alpha,(1+\alpha)/2}(\overline{N_4^-})$. Using (4.18), (4.19), and (4.6), we find that the functions on the right-hand side of (4.10), (4.13) are $C^{1+\alpha,(1+\alpha)/2}(\overline{N_4^-})$.

This "bootstrap" process may now be continually repeated, each time to derive better estimates on the derivatives of w, $\underset{\sim}{w}$ and therefore of $s(t)$, $V(\xi,t)$, $v(-\underset{\sim}{k}\xi,t)$, all the way up to the $\xi=0$ axis for any $t>0$. Hence $s(t)$ is infinitely differentiable in the time interval $0<t<T$.

By standard parabolic regularity theory [12], [17], we can also obtain that $u(x,t)$ is infinitely differentiable in $Q_1\cup\{x=s(t),\ t>0\}$ and $Q_2\cup\{x=s(t),\ t>0\}$.

5. The limit process as $\varepsilon\to 0$. We now discuss the limit process for ε when sign restrictions are imposed on ε, L, and boundary and initial data. This means we will henceforth assume that

$$f_1(t)>0,\quad f_2(t)<0,\quad \phi_1(x)\geqq 0,\quad \phi_2(x)\leqq 0, \tag{5.1}$$

where $\phi_1(b)=\phi_2(b)=0$ and ε, L are positive constants.

We will retrieve the solution of the standard Stefan problem by taking the limit $\varepsilon\to 0^+$ in the classical sense, and this only with an additional restriction about monotonicity (nondecreasing) of the free boundary.

We recall from previous sections that problem (1.1)-(1.9) possesses a unique classical solution and note that the solution $(s_\varepsilon(t);\ u_\varepsilon(x,t))$ $(\varepsilon>0)$ satisfies

$$u_\varepsilon(s_\varepsilon(t),t)=\varepsilon\dot{s}_\varepsilon(t), \tag{5.2}$$

$$Ls_\varepsilon(t)=L_b+\int_0^1\phi(x)\,dx-\int_0^1 u_\varepsilon(x,t)\,dx-\int_0^t(k_L u_{\varepsilon_x}(0,\tau)-k_S u_{\varepsilon_x}(1,\tau))\,d\tau \tag{5.3}$$

and estimates (2.6). To pass the limit $\varepsilon\to 0$ in the classical sense, we need to derive some a priori estimates for the solution $(s_\varepsilon(t);\ u_\varepsilon(x,t))$, which is independent of ε.

Using the method employed in [8], we can derive an estimate of $(1/\varepsilon)u_\varepsilon(s_\varepsilon(t),t)$ that is independent of ε. This is done by comparing the function $v(x,t)$, which satisfies (1.1)-(1.3), (1.7)-(1.9), and the interface condition $v=0$. Note carefully that

$v_x^{\pm}(s_\varepsilon(t), t) < 0$ by the maximum principle and that the lower bound of $v_x^-(s_\varepsilon(t), t)$ can be estimated by using the auxiliary function method that is independent of ε [9]; this is derived from the crucial assumption about nondecreasing of the free boundary.

Consider the function $(1/\varepsilon)(u_\varepsilon - v)$ and suppose that p_0 is a positive maximum point of that function. Then p_0 must belong to $\{(x, t)/\ x = s_\varepsilon(t), 0 < t \leqq T\}$, $(u_{\varepsilon_x}^- - v_x^-)(p_0) > 0$, and $(u_{\varepsilon_x}^+ - v_x^+)(p_0) < 0$ by the strong maximum principle. Furthermore, we have

$$\begin{aligned} \max_{Q_T} \frac{L}{\varepsilon}(u_\varepsilon - v) &= \frac{L}{\varepsilon}(u_\varepsilon - v)(p_0) = \frac{L}{\varepsilon} u_\varepsilon(p_0) \\ &= -k_L(u_{\varepsilon_x}^- - v_x^-)(p_0) + k_S(u_{\varepsilon_x}^+ - v_x^+)(p_0) - k_L v_x^-(p_0) + k_S v_x^+(p_0) \\ &\leqq -k_L v_x^-(p_0) \leqq B \quad \text{(independent of } \varepsilon); \end{aligned} \tag{5.4}$$

this implies that

$$|\dot{s}_\varepsilon(t)| \leqq C, \tag{5.5}$$

where C is a constant that is independent of ε. From (3.1) and (3.3) and using (5.5), we have

$$\begin{aligned} &\sup_{0 \leqq t \leqq T} \int_0^1 u_\varepsilon^2(x, t)\, dx + \int_0^1 k u_{\varepsilon_x}^2(x, T)\, dx + 2 \iint_{Q_1 \cup Q_2} k^2 u_{\varepsilon_{xx}}^2\, dx\, dt \\ &\leqq C \Big[\|\phi\|_{H^1(0,1)}^2 + \|f_1\|_{H^1(0,T)}^2 + \|f_2\|_{H^1(0,T)}^2 \\ &\qquad + \int_0^T (\|u_{\varepsilon_x}(\cdot, t)\|_{L^2(0, s_\varepsilon(t))}^2 + \|u_{\varepsilon_x}(\cdot, t)\|_{L^2(s_\varepsilon(t), 1)}^2)\, dt \Big] \\ &\leqq C \Big[\|\phi\|_{H^1(0,1)}^2 + \|f_1\|_{H^1(0,T)}^2 + \|f_2\|_{H^1(0,T)}^2 + \eta \iint_{Q_1 \cup Q_2} u_{\varepsilon_{xx}}^2\, dx\, dt \\ &\qquad + c(\eta) \int_0^T \int_0^1 u_{\varepsilon_x}^2\, dx\, dt \Big]. \end{aligned} \tag{5.6}$$

Then we derive

$$\begin{aligned} &\sup_{0 \leqq t \leqq T} \int_0^1 (u_\varepsilon^2(x, t) + u_{\varepsilon_x}^2(x, t))\, dx + \iint_{Q_1 \cup Q_2} (u_{\varepsilon_x}^2 + u_{\varepsilon_{xx}}^2)\, dx\, dt \\ &\qquad \leqq C(T, \|\phi\|_{H^1(0,1)}^2 + \|f_i\|_{H^1(0,T)}^2 (i = 1, 2)). \end{aligned} \tag{5.7}$$

We can then get the solution of the Stefan problem via compactness arguments, and possibly take subsequences. Indeed, in the light of estimates (5.5) and (5.7), there exist a couple $(s(t); u(x, t))$ with $s(t) \in C^{0,1}[0, T]$ and $u \in C^{\alpha, \alpha/2}(\bar{Q}_T)$ $(0 < \alpha < 1)$, such that $s_\varepsilon \to s$ uniformly in $C[0, T]$ and $u_\varepsilon \to u$ uniformly in $C(\bar{Q}_T)$; moreover, $(s(t); u(x, t))$ satisfying (1.1), (1.2), (1.7)-(1.9), and (5.2), (5.3) imply, respectively,

$$u = 0 \quad \text{on } x = s(t), \tag{5.8}$$

$$Ls(t) = b + \int_0^1 \phi(x)\, dx - \int_0^t u(x, t)\, dx + \int_0^t (k_L u_x(0, \tau) - k_S u_x(1, \tau))\, d\tau. \tag{5.9}$$

Note that $s(t) \in C^{0,1}[0, T]$ and then $u_x \in C(\bar{Q}_1) \cap C(\bar{Q}_2)$; then (5.8) implies the Stefan condition (1.4).

Our demonstration above also indicates that we can retrieve the solution of the one-phase Stefan problem by taking $\varepsilon \to 0^+$ without any additional restrictions (the

monotonicity of the free boundary, in fact, holds automatically in this case). Note that from (3.1), (3.3), we can get

$$\sup_{0\leqq t\leqq T}\int_0^{s_\varepsilon(t)} u_{\varepsilon_x}^2(x,t)\,dx+\int_0^T\int_0^{s_\varepsilon(t)}(u_{\varepsilon_x}^2+u_{\varepsilon_{xx}}^2)\,dx\,dt\leqq C, \tag{5.10}$$

where the constant C depends only on the known data, but not on ε.

By the interpolation inequality [12], $\|f\|^2_{L^\infty(a,b)}\leqq C\|f_x\|_{L^2(a,b)}\|f\|_{L^2(a,b)}$, (5.10) implies that

$$\int_0^T \|u_{\varepsilon_x}(\cdot,t)\|^4_{L^\infty(0,s_\varepsilon(t))}\,dt\leqq C,$$

and then $\|\dot{s}_\varepsilon(t)\|_{L^4(0,T)}\leqq C$, where the constant C is independent of ε. With the above estimates at hand, we can easily get the solution of the one-phase Stefan problem via compactness arguments.

It is perhaps also worth noting that, in general, without the restriction (5.1), it may not always be expected to pass the limit $\varepsilon\to 0$ because the finite-time blowup might, in fact, occur for the supercooled (superheated) Stefan problem in certain circumstances (see, e.g., [18]-[20]).

Acknowledgments. I thank Dr. J. R. Ockendon for his helpful advice and encouraging discussions during the preparation of this paper. I am also very grateful to the referees for suggesting several improvements and pointing out misprints in the original version of the manuscript.

SEMIGROUP THEORY AND NUMERICAL APPROXIMATION FOR EQUATIONS IN LINEAR VISCOELASTICITY*

R. H. FABIANO† AND K. ITO‡

Abstract. The following abstract integro-differential equation

$$\ddot{u}(t) + A\left[Eu(t) - \int_{-r}^{0} g(s)u(t+s)\,ds\right] = f(t)$$

is considered on a Hilbert space. Such equations arise in the modeling of linear viscoelastic beams. The equation is reformulated as an abstract Cauchy problem, and several approximation schemes are discussed. Well-posedness and convergence results are given in the context of linear semigroup theory. Results of numerical eigenvalue calculations for various approximation schemes are discussed.

Key words. integro–differential equation, linear semigroup theory

AMS(MOS) subject classifications. 45K05, 65M60, 73F99

1. Introduction.

We consider the following integro-differential equation:

$$\ddot{u}(t) + A\left[Eu(t) - \int_{-r}^{0} g(s)u(t+s)\,ds\right] = f(t). \tag{1.1}$$

Here A is a positive definite, self-adjoint unbounded operator on a Hilbert space H, and $f(t)$ is an H-valued function. Also, E is a positive constant (a stiffness coefficient in applications to linear viscoelasticity) and $g(s)$ is a "history kernel" which is further characterized below. In §2, we formulate the equation as an abstract Cauchy problem and prove well-posedness. This abstract framework is useful for the construction and convergence analysis of approximation schemes for (1.1). It can be seen that an approximation scheme for this type of equation involves discretization of the spatial variable (finite elements, for example) together with an appropriate approximation scheme for the resulting delay equation (we consider the so-called averaging scheme of Banks and Burns [1] and a newer scheme recently developed by Ito and Kappel [10].) In §3, we discuss this approach to approximation, and prove a convergence result using the Trotter–Kato semigroup approximation theorem.

The results here extend those of [2]. Our theory allows for a singularity at the origin in the kernel $g(s)$, while in [2] it is required that $g(s)$ be bounded. Less importantly, there is a possibly restrictive technical condition in the convergence proof of [2] which we do not require.

One of our motivations for studying (1.1) is that this type of equation arises in the modeling of linear viscoelastic beams (see [4]–[9]). The abstract framework that

we consider is especially useful for the applications to parameter identification and control problems for viscoelastic models. (We do not discuss these applications here; see [2], [3]). It is also of interest to investigate the damping induced by the assumption of Boltzmann viscoelasticity in modeling the motion of a beam. This is related to the behavior of the eigenvalues. In the purely elastic model (no damping) the eigenvalues of the underlying dynamical system lie on the imaginary axis. A good indication of the damping behavior in the viscoelastic model is the location of the eigenvalues in the left halfplane. In §4, we calculate these eigenvalues, and we also discuss the convergence behavior of the approximation schemes developed in §3. In addition, we consider a new approximation scheme based on a variation of the averaging scheme in which a nonuniform mesh is used. The theoretical convergence arguments for this scheme, which are similar to those used for the averaging scheme, are not included here. However, we do include some numerical examples for this scheme to illustrate the fast convergence which we have observed.

2. An abstract Cauchy problem. In this section we reformulate (1.1) as an abstract Cauchy problem and prove well-posedness. First we establish some preliminary ideas. Assume V and H are Hilbert spaces and $V \subset H$ with continuous dense injection. Let V^* denote the strong dual space of V. We identify H with its dual, so that $V \subset H = H^* \subset V^*$. The dual product $\langle \phi, \psi \rangle_{V,V^*}$ on $V \times V^*$ is the unique extension by the continuity of the scalar product $\langle \phi, \psi \rangle_H$ of H restricted to $V \times H$. Consider a symmetric sesquilinear form σ on V such that

$$|\sigma(u,v)| \leq C|u|_V\,|v|_V \quad \text{for } u,v \in V \tag{2.1}$$

$$\sigma(u,u) \geq \omega |u|_V^2 \quad \text{for } u \in V \tag{2.2}$$

where $\omega > 0$. Let $A \in \mathcal{L}(V, V^*)$ be defined by

$$\sigma(u,v) = \langle Au, v \rangle_{V^*,V} \quad \text{for all } u,v \in V. \tag{2.3}$$

It then follows from [16, Thm. 2.2.3] that the restriction of A on H with

$$\operatorname{dom}(A) = \{u \in V : Au \in H\}, \tag{2.4}$$

where we will use the same symbol A for such a restriction, defines a positive definite and self-adjoint operator on H, $\operatorname{dom}(A^{1/2}) = V$, and

$$\sigma(u,v) = \langle A^{1/2}u, A^{1/2}v \rangle \quad \text{for } u,v \in V.$$

Thus, V can be equipped with the scalar product $\langle u, v \rangle_V = \sigma(u, v,)$.

Given $r \in [-\infty, 0)$ consider the second-order equation in H

$$\ddot{u}(t) + A\left(Eu(t) - \int_{-r}^{0} g(\theta)u(t+\theta)\,d\theta\right) = f(t) \tag{2.5}$$

where E is a positive constant, $t \to f(t)$ is an H-valued integrable function, and we assume $g > 0$ and $g' \geq 0$ on $(-r, 0)$, and g is integrable with

$$\alpha = E - \int_{-r}^{0} g(\theta)\,d\theta > 0. \tag{2.6}$$

An example is

$$g(\theta) = \frac{ce^{\gamma\theta}}{|\theta|^p} \tag{2.7}$$

where $c > 0$ and $0 \leq p < 1$ and $\gamma > 0$.

Next, let $W = L_g^2(-r, 0; V)$ be the Hilbert space of all V-valued, square integrable functions defined on the measure space $([-r, 0], \text{Borel sets}, g\,d\theta)$, equipped with norm

$$|w|_W^2 = \int_{-r}^{0} g(\theta)|w(\theta)|_V^2\,d\theta. \tag{2.8}$$

Let Z denote the Hilbert space $V \times H \times W$ equipped with norm

$$|(u, v, w)|_Z^2 = \alpha|u|_V^2 + |v|_H^2 + \int_{-r}^{0} g(\theta)|w(\theta)|_V^2\,d\theta. \tag{2.9}$$

Motivated by the state-space formulations found in [6] and [17], we define for $t \geq 0$

$$\begin{aligned} v(t) &= \dot{u}(t) \\ w(t, \theta) &= u(t) - u(t + \theta), \qquad -r \leq \theta \leq 0. \end{aligned} \tag{2.10}$$

Then $z = (u, v, w) \in Z$ formally satisfies

$$\frac{d}{dt}z(t) = \mathcal{A}z(t) + \text{col}[0, f(t), 0] \tag{2.11}$$

where

$$\mathcal{A}z = \left(v, -A\left(\alpha u + \int_{-r}^{0} g(\theta)w(\theta)\,d\theta\right), v + \frac{d}{d\theta}w\right) \tag{2.12}$$

for $z = (u, v, w) \in Z$.

Thus (1.1) has been reformulated as the abstract Cauchy problem (2.11). Next we use the Lumer–Phillips theorem [13] to show that $\mathcal{A}$ generates a C_0-semigroup on Z.

THEOREM 2.1. *The linear operator $\mathcal{A}$ on Z, defined by* (2.12) *with domain*

$$\text{dom}(\mathcal{A}) = \left\{ \begin{array}{l} (u, v, w) \in Z : v \in V \\ \dot{w} \in L_g^2(-r, 0; V), \quad w(0) = 0, \\ \alpha u + \int_{-r}^{0} g(\theta)w(\theta)\,d\theta \in \text{dom}(A) \end{array} \right\} \tag{2.13}$$

generates a C_0-semigroup $S(t)$ on Z.

Proof. First we argue the dissipativeness. For $z = (u, v, w) \in \text{dom}(\mathcal{A})$

$$\begin{aligned} \langle \mathcal{A}z, z\rangle &= \alpha\langle u, v\rangle_V - \left\langle A\left(\alpha u + \int_{-r}^{0} g(\theta)w(\theta)\,d\theta\right), v\right\rangle_{V^*, V} \\ &\quad + \int_{-r}^{0} g(\theta)\langle v + Dw, w\rangle_V\,d\theta \\ &= \int_{-r}^{0} g(\theta)\langle Dw, w\rangle_V\,d\theta \end{aligned}$$

where

$$D\phi = \frac{d}{d\theta}\phi \quad \text{with } \operatorname{dom}(D) = \{\phi \in W : D\phi \in W \text{ and } \phi(0) = 0\} \tag{2.14}$$

and we used $\langle u, v\rangle_V = \sigma(u, v) = \langle Au, v\rangle_{V^*,V}$ for $u, v \in V$. Let us consider for $\epsilon > 0$ and $R < r$,

$$\begin{aligned} I_{\epsilon,R} &= \int_{-R}^{-\epsilon} \frac{1}{2} g(\theta) \frac{d}{d\theta} |w(\theta)|_V^2 \, d\theta \\ &= \frac{1}{2} g(-\epsilon)|w(-\epsilon)|_V^2 - \frac{1}{2} g(-R)|w(-R)|_V^2 - \frac{1}{2}\int_{-R}^{-\epsilon} g'(\theta)|w(\theta)|_V^2 \, d\theta \\ &\le \frac{1}{2} g(-\epsilon)|w(-\epsilon)|_V^2 . \end{aligned} \tag{2.15}$$

Since $w(-\epsilon) = w(0) - \int_{-\epsilon}^0 Dw(\theta)\, d\theta = -\int_{-\epsilon}^0 Dw(\theta)\, d\theta$, by the Cauchy–Schwarz inequality

$$|w(-\epsilon)|_V^2 \le \int_{-\epsilon}^0 \frac{d\theta}{g(\theta)} \int_{-\epsilon}^0 g(\theta)|Dw|_V^2 \, d\theta.$$

Note that $g(-\epsilon)\int_{-\epsilon}^0 d\theta/g(\theta) = \int_{-\epsilon}^0 g(-\epsilon)/g(\theta)\, d\theta \le \epsilon$. Thus, we obtain

$$I_{\epsilon,R} \le \epsilon \int_{-\epsilon}^0 g(\theta)|Dw|_V^2 \, d\theta,$$

and this implies for $z \in \operatorname{dom}(\mathcal{A})$ that

$$\langle \mathcal{A}z, z\rangle = \lim_{\epsilon \downarrow 0, R \uparrow r} I_{\epsilon,R} \le 0. \tag{2.16}$$

Next we will show that $(\lambda I - \mathcal{A})\operatorname{dom}(\mathcal{A}) = Z$ for $\operatorname{Re}\lambda > 0$. The equation $(\lambda I - \mathcal{A})z = (\phi, \psi, h)$ is written as

$$\lambda u - v = \phi \in V \tag{2.17}$$

$$\lambda v + A\left(\alpha u + \int_{-r}^0 g(\theta) w(\theta)\, d\theta\right) = \psi \in H \tag{2.18}$$

$$\lambda w - v - Dw = h \quad \text{and} \quad w(0) = 0. \tag{2.19}$$

From (2.19), we obtain

$$w(\theta) = \int_\theta^0 e^{\lambda(\theta-\xi)}\,(v + h(\xi))\, d\xi .$$

From (2.17), $v = \lambda u - \phi$. Substituting these into (2.18), we have

$$\lambda^2 u + A\left[\alpha u + \int_{-r}^0 g(\theta) \int_\theta^0 e^{\lambda(\theta-\xi)}\,(\lambda u - \phi + h(\xi))\, d\xi\, d\theta\right] = \psi + \lambda\phi,$$

or

$$\begin{aligned} &\left[\lambda^2 + A\left(E - \int_{-r}^0 e^{\lambda\theta} g(\theta)\, d\theta\right)\right] u \\ &\qquad = \psi + \lambda\phi + \int_{-r}^0 e^{\lambda\theta} g(\theta) \int_\theta^0 e^{-\lambda\xi} A\,(\phi - h(\xi))\, d\xi\, d\theta \end{aligned} \tag{2.20}$$

where we used $\int_\theta^0 \lambda e^{\lambda(\theta-\xi)}\,d\xi = 1-e^{\lambda\theta}$. Note that the right-hand side of (2.20) belongs to V^*. Thus, if we define

$$\Delta(\lambda) = \lambda^2 I + A\left(E - \int_{-r}^0 e^{\lambda\theta} g(\theta)\,d\theta\right) \in \mathcal{L}(V, V^*),$$

then $\lambda \in \rho(\mathcal{A})$ if and only if $\Delta^{-1}(\lambda) \in \mathcal{L}(V^*, V)$. For fixed $\lambda \in \mathcal{C}$ consider the sesquilinear form μ on V:

$$\begin{aligned}\mu(u,v) &= \langle \Delta(\lambda)u, v\rangle_{V^*,V} \\ &= \lambda^2\langle u, v\rangle_H + \left(E - \int_{-r}^0 e^{\lambda\theta}\, g(\theta)\,d\theta\right)\sigma(u,v) \quad \text{for } u, v \in V.\end{aligned} \tag{2.21}$$

Then, for some constant C

$$|\mu(u,v)| \le C|u|_V\,|v|_V \quad \text{for } u, v \in V,$$

and for $\lambda = a + bi$ with $a > 0$

$$\operatorname{Re}\mu(u,u) \ge (a^2 - b^2)|u|_H^2 + \alpha|u|_V^2 \quad \text{for } u \in V.$$

Thus, it follows from [15, Thm. 3.2.A] that if $\lambda > 0$, then $\Delta^{-1}(\lambda) \in \mathcal{L}(V^*, V)$.

Since Z is a Hilbert space, it follows from [13, Thm. 1.4.6] that $\operatorname{dom}(\mathcal{A})$ is dense in Z. Therefore the theorem follows from the Lumer–Phillips theorem. □

3. Approximation schemes. In this section we consider the construction of approximation schemes for (2.11)–(2.12), and we give convergence arguments based on the Trotter–Kato theorem (see [13]). Construction of these schemes involves choosing finite-dimensional subspaces of the state space Z and an approximation of the state operator $\mathcal{A}$. It can be seen that this involves two stages—the spatial variable, which includes the spaces H and V and the operator A, and the delay variable, which includes the space W and the operator D. We assume r is a fixed positive constant. For the spatial variable let V^N be any sequence of finite-dimensional subspaces of V. We assume the following approximation condition:

(C1) for any $\phi \in V$, there exists a sequence $\phi^N \in V^N$ such that $|\phi^N - \phi|_V \to 0$ as $n \to \infty$.

P_H^N and P_V^N will denote the orthogonal projection of H and V onto V^N, respectively. Let us define continuous linear operators $A^N : V^N \to V^N$ by

$$\langle A^N x, y\rangle_H = \sigma(x,y) \quad \text{for } x, y \in V^N. \tag{3.1}$$

Thus, the spaces V^N complete the discretization of the spatial variable in the sense that they give finite-dimensional subspaces of V and H, and (3.1) defines an approximation of the operator A. This is often equivalent to simply choosing a standard finite element scheme. We consider next the discretization of the delay variable. There are many approximation schemes available for delay equations, and we shall consider the so-called averaging scheme (see [1]) and a newer spline-based scheme recently developed by Ito and Kappel (see [10]). What is involved in any case is the discretization

of the delay interval $[-r, 0]$ and an approximation of the differential operator D. To proceed, let B_i^M, $i = 1, \cdots, M$ be the usual first-order spline elements corresponding to the mesh $\theta_j^M = -jr/M$, $j = 0, \cdots, M$; i.e.,

$$B_i^M(\theta) = \begin{cases} \frac{M}{r}\left(\theta - \theta_{i+1}^M\right) & \text{for } \theta_{i+1}^M \le \theta \le \theta_i^M \\ \frac{M}{r}\left(\theta_{i-1}^M - \theta\right) & \text{for } \theta_i^M \le \theta \le \theta_{i-1}^M \\ 0 & \text{elsewhere,} \end{cases}$$

and put $E_i^M = \chi_{[\theta_i^M, \theta_{i-1}^M)}$, $i = 1, \cdots, M$. Here, $\chi_{[a,b)}$ denotes the usual characteristic function on the interval $[a, b)$. For each integer N, M, we define the following subspaces of $W = L_g^2(-r, 0; V)$:

$$\widetilde{W}^{N,M} = \left\{ w \in W \mid w = \sum_{i=1}^{M} b_i^M B_i^M,\ b_i^M \in V^N \right\}$$

(3.2)

$$W^{N,M} = \left\{ w \in W \mid w = \sum_{i=1}^{M} a_i^M E_i^M,\ a_i^M \in V^N \right\}.$$

Let $P_g^{N,M}$ be the orthogonal projection of W onto $W^{N,M}$. Then we have the following convergence result for the orthogonal projections.

LEMMA 3.1. *$P_g^{N,M} h \to h$ for all $h \in W$.*

Proof. It follows from arguments used in Theorem 2.1 that D is dissipative in W and range $(I - D) = W$. Hence it follows from [13, Thm. 1.4.6] that

$$\operatorname{dom}(D) = \{w \in W : Dw \in W \text{ and } w(0) = 0\}$$

is dense in W. If $w \in \operatorname{dom}(D)$ then $g|w|_V^2$ is uniformly bounded on $[-r, 0]$. In fact, for $\theta \le \hat{\theta}$

$$\begin{aligned} g(\theta)|w(\hat{\theta})|_V^2 &= g(\theta)\Big|\int_{\hat{\theta}}^{0} Dw\, d\xi\Big|_V^2 \\ &\le \int_{\hat{\theta}}^{0} \frac{g(\theta)}{g(\xi)}\, d\xi \int_{\hat{\theta}}^{0} g|Dw|_V^2\, d\xi \le r|Dw|_W^2. \end{aligned}$$

Similarly, $\operatorname{dom}(D^2)$ is dense in W and for $\theta \le \hat{\theta}$

$$g(\theta)|Dw(\hat{\theta})|_V^2 \le r|D^2 w|_W^2 \quad \text{for } w \in \operatorname{dom}(D^2).$$

For $w \in \operatorname{dom}(D^2)$, define

$$w^{N,M}(\theta) = \sum_{i=1}^{M} w^N(\theta_{i-1}^M) E_i^M(\theta), \quad \text{where } w^N = P_V^N w.$$

Note that

$$w^N(\theta) = P_V^N w(\theta) = P_V^N \int_0^{\theta} Dw d\xi = \int_0^{\theta} P_V^N Dw d\xi.$$

Thus, $DP_V^N w = P_V^N Dw$ for $w \in \mathrm{dom}(D)$ so that if $w \in \mathrm{dom}(D^2)$, then $w^N \in \mathrm{dom}(D^2)$ and $|D^2 w^N|_W \leq |D^2 w|_W$. Hence for $w \in \mathrm{dom}(D^2)$,

$$\left|w - P_g^{N,M} w\right|_W \leq |w - w^{N,M}|_W \leq |w - w^N|_W + |w^N - w^{N,M}|_W$$

where the first term of the right-hand side tends to zero as $N \to \infty$ by the dominated convergence theorem. By the mean value theorem, for $\theta \in \left(\theta_i^M, \theta_{i-1}^M\right)$, $i = 1, \cdots, M$, there exists $\xi(\theta) \in \left(\theta, \theta_{i-1}^M\right)$ such that

$$w^N(\theta) - w^{N,M}(\theta) = Dw^N(\xi)\left(\theta - \theta_{i-1}^M\right).$$

Thus

$$\begin{aligned} |w^N - w^{N,M}|_W^2 &\leq \sum_{i=1}^M \int_{\theta_i^M}^{\theta_{i-1}^M} g(\theta)\, |Dw^N(\xi)|_V^2 \left(\theta - \theta_{i-1}^M\right)^2 d\theta \\ &\leq \frac{M}{3} r\, |D^2 w^N|_W^2 \left(\frac{r}{M}\right)^3. \end{aligned}$$

Hence for $w \in \mathrm{dom}(D^2)$

$$\left|w - P_g^{N,M} w\right|_W \to 0 \quad \text{as } N, M \to \infty.$$

Since $\mathrm{dom}(D^2)$ is dense in W and $|P_g^{N,M}| \leq 1$, this implies that $P_g^{N,M} \to I$, strongly in W. □

In order to define approximations of the operator D, consider the sesquilinear form $a^{N,M}$ on $\widetilde{W}^{N,M} \times W^{N,M}$ defined by

$$a^{N,M}\left(w^{N,M}, h^{N,M}\right) = \int_{-r}^0 \left\langle Dw^{N,M}, h^{N,M}\right\rangle_V g(\theta)\, d\theta \tag{3.3}$$

for $w^{N,M} \in \widetilde{W}^{N,M}$ and $h^{N,M} \in W^{N,M}$. Since $a^{N,M}$ is continuous, there exists a linear operator $\widetilde{D}^{N,M} : \widetilde{W}^{N,M} \to W^{N,M}$ such that

$$a^{N,M}\left(w^{N,M}, h^{N,M}\right) = \left\langle \widetilde{D}^{N,M} w^{N,M}, h^{N,M}\right\rangle_W.$$

Note that $D\widetilde{W}^{N,M} = W^{N,M}$. Hence a simple calculation shows that $\widetilde{D}^{N,M}$ is given by

$$\widetilde{D}^{N,M} w^{N,M} = \frac{M}{r} \sum_{i=1}^M \left(b_{i-1}^M - b_i^M\right) E_i^M \tag{3.4}$$

for $w^{N,M} = \sum_{i=1}^M b_i^M B_i^M$, $b_i^M \in V^N$, where $b_0^M = 0$. We will consider two isomorphisms $i_k^{N,M} : \widetilde{W}^{N,M} \to W^{N,M}$, $k = 1, 2$, defined by

$$i_1^{N,M} w^{N,M} = \sum_{i=1}^M b_i^M E_i^M \tag{3.5}$$

and

$$i_2^{N,M} w^{N,M} = \sum_{i=1}^M \frac{b_{i-1}^M + b_i^M}{2} E_i^M. \tag{3.6}$$

We define the operators $D_k^{N,M} : W^{N,M} \to W^{N,M}$ by $D_k^{N,M} = \tilde{D}^{N,M}(i_k^{N,M})^{-1}$, $k = 1, 2$. It will be apparent that the operators $D_1^{N,M}$ and $D_2^{N,M}$ correspond to the averaging scheme and the spline-based scheme, respectively. We can now complete the construction of our finite-dimensional approximation schemes for (2.11)–(2.12). Specifically, define the finite-dimensional state space $Z^{N,M} = V^N \times V^N \times W^{N,M}$, and let $P_Z^{N,M} : Z \to Z^{N,M}$ be the corresponding orthogonal projection. Letting $z^{N,M}(t) = (u^N(t), v^N(t), w^{N,M}(t))$, we consider the following differential equation on $Z^{N,M}$:

$$\frac{d}{dt} z^{N,M}(t) = \mathcal{A}_k^{N,M} z^{N,M}(t) + \operatorname{col}\left(0, P_H^N f(t), 0\right) \tag{3.7}$$

where

$$z^{N,M}(0) = \left(P_V^N u(0), P_H^N v(0), P_g^{N,M} w(0)\right).$$

Here the operator $\mathcal{A}_k^{N,M} : Z^{N,M} \to Z^{N,M}$ is defined by

$$\mathcal{A}_k^{N,M} z^{N,M} = \begin{pmatrix} v^N \\ -A^N\left(\alpha u^N + \int_{-r}^0 g(\theta) w^{N,M}(\theta)\, d\theta\right) \\ v^N + D_k^{N,M} w^{N,M} \end{pmatrix} \tag{3.8}$$

and the norm of $Z^{N,M}$ is induced from the Z-norm defined by (2.9).

In the next two subsections we prove a semigroup convergence result for each of the schemes (corresponding to $k = 1, 2$).

3.1. Averaging scheme. The isomorphism $i_1^{N,M}$ defined by (3.5) corresponds to the so-called averaging approximation considered in [1]. Recall that $S(t)$ is the C_0-semigroup generated by the operator $\mathcal{A}$. Let $S_1^{N,M}(t) : Z^{N,M} \to Z^{N,M}$ be the semigroup generated by $\mathcal{A}_1^{N,M}$. We intend to use the Trotter–Kato theorem (see [13]) to show that $S_1^{N,M}(t) P_Z^{N,M} \xrightarrow{s} S(t)$ as $N, M \to \infty$ (see Theorem 3.4 below). We will need the following two lemmas. The first is a uniform (in N and M) dissipativeness result for the operators $\mathcal{A}_1^{N,M}$, and the second is a resolvent convergence result for the operators $D_1^{N,M}$.

LEMMA 3.2. *$\mathcal{A}_1^{N,M}$ is dissipative in $Z^{N,M}$.*

Proof. For $z^{N,M} = (u^N, v^N, w^{N,M}) \in Z^{N,M}$ with $w^{N,M} = \sum_{i=1}^M a_i^M E_i^M$,

$$\begin{aligned}
\langle \mathcal{A}_1^{N,M} z^{N,M}, z^{N,M} \rangle_Z &= \alpha\sigma(u^N, v^N) - \sigma\left(\alpha u^N + \int_{-r}^0 g(\theta) w^{N,M}(\theta)\, d\theta, v^N\right) \\
&\quad + \int_{-r}^0 \left\langle v^N + \sum_{i=1}^M \frac{M}{r}\left(a_{i-1}^M - a_i^M\right) E_i^M, w^{N,M} \right\rangle_V g(\theta)\, d\theta \\
&= \sum_{i=1}^M \frac{M}{r} \left\langle a_{i-1}^M - a_i^M, a_i^M \right\rangle_V g_i^M,
\end{aligned}$$

where $a_0^M = 0$ and $g_i^M = \int_{\theta_i^M}^{\theta_{i-1}^M} g(\theta)\,d\theta$, $\quad i = 1, \cdots, M$.

Continuing, we have

$$\begin{aligned}\left\langle \mathcal{A}_1^{N,M} z^{N,M}, z^{N,M} \right\rangle_Z &= \frac{1}{2}\sum_{i=1}^{M} \frac{M}{r} g_i^M \left(\left|a_{i-1}^M\right|_V^2 - \left|a_i^M - a_{i-1}^M\right|_V^2 - \left|a_i^M\right|_V^2 \right) \\ &= -\frac{1}{2}\sum_{i=1}^{M-1} \frac{M}{r}\left(g_i^M - g_{i+1}^M\right)\left|a_i^M\right|_V^2 - \frac{1}{2}\frac{M}{r} g_M^M \left|a_M^M\right|_V^2 \\ &\quad - \frac{1}{2}\sum_{i=1}^{M} \frac{M}{r} g_i^M \left|a_i^M - a_{i-1}^M\right|_V^2 \le 0,\end{aligned}$$

since $g_i^M \ge g_{i+1}^M$ for $1 \le i \le M-1$. □

LEMMA 3.3. *For $\lambda > 0, (\lambda I - D_1^{N,M})^{-1} P_g^{N,M} h \to (\lambda I - D)^{-1} h$ for all $h \in W$.*

Proof. It follows from the arguments in Lemma 3.2 that $D_1^{N,M}$ is dissipative in $W^{N,M}$ so that $|(\lambda I - D_1^{N,M})^{-1}|_W \le 1/\lambda$ for $\lambda > 0$.

Let us define the sesquilinear form a on $\mathrm{dom}(D) \times W$ by

$$a(w,h) = \int_{-r}^{0} \langle Dw, h\rangle_V\, g(\theta)\,d\theta \quad \text{for } w \in \mathrm{dom}(D) \text{ and } h \in W. \tag{3.9}$$

For $\lambda > 0$, let $w = (\lambda I - D)^{-1} h$ and $w^{N,M} = (\lambda I - D_1^{N,M})^{-1} P_g^{N,M} h$ for $h \in W$, or equivalently $(\lambda I - D)w = h$ and $(\lambda I - D_1^{N,M}) w^{N,M} = P_g^{N,M} h$. Then, we must show that $|w - w^{N,M}|_W \to 0$ as $N, M \to \infty$. We have

$$\lambda\langle w, \gamma\rangle - a(w,\gamma) = \langle h, \gamma\rangle$$

for all $\gamma \in W$ and

$$\begin{aligned}&\lambda\left\langle i_1^{N,M} \widetilde{w}^{N,M}, \gamma^{N,M}\right\rangle - a^{N,M}\left(\widetilde{w}^{N,M}, \gamma^{N,M}\right) \\ &\qquad = \langle h, \gamma^{N,M}\rangle\end{aligned}$$

for all $\gamma^{N,M} \in W^{N,M}$, where $\widetilde{w}^{N,M} = (i_1^{N,M})^{-1} w^{N,M} = \sum_{i=1}^{M} a_i^M B_i^M$. Choosing $\gamma = \gamma^{N,M}$ in the first equation, we obtain for every $\widehat{w}^{N,M} \in \widetilde{W}^{N,M}$

$$\begin{aligned}&\lambda\left\langle i_1^{N,M}\left(\widehat{w}^{N,M} - \widetilde{w}^{N,M}\right), \gamma^{N,M}\right\rangle_W - a^{N,M}\left(\widehat{w}^{N,M} - \widetilde{w}^{N,M}, \gamma^{N,M}\right) \\ &\quad = a\left(w, \gamma^{N,M}\right) - a^{N,M}\left(\widehat{w}^{N,M}, \gamma^{N,M}\right) - \lambda\left\langle w - i_1^{N,M}\widehat{w}^{N,M}, \gamma^{N,M}\right\rangle_W\end{aligned}$$

for all $\gamma^{N,M} \in W^{N,M}$.

Let us choose $\widehat{w}^{N,M} \in \widetilde{W}^{N,M}$ as

$$\widehat{w}^{N,M} = \int_0^{\theta} P_g^{N,M}(Dw)\,d\xi. \tag{3.10}$$

Then

$$a\left(w, \gamma^{N,M}\right) - a^{N,M}\left(\widehat{w}^{N,M}, \gamma^{N,M}\right) = \int_{-r}^{0} \left\langle Dw - P_g^{N,M}(Dw), \gamma^{N,M}\right\rangle g(\theta)\,d\theta = 0$$

for all $\gamma^{N,M} \in w^{N,M}$. Using this and the fact that

$$i_1^{N,M}\left(\lambda i_1^{N,M} - \widetilde{D}^{N,M}\right)^{-1} = \left(\lambda I - D_1^{N,M}\right)^{-1} \quad \text{for } \lambda > 0,$$

it follows that

$$\left|i_1^{N,M}(\hat{w}^{N,M}-\tilde{w}^{N,M})\right|_W \le \left|P_g^{N,M}\left(w-i_1^{N,M}\hat{w}^{N,M}\right)\right|_W. \tag{3.11}$$

Moreover, we have

$$\left|w-i_1^{N,M}\hat{w}^{N,M}\right|_W \le \left|\int_0^\theta \left(Dw-P_g^{N,M}(Dw)\right)d\xi\right|_W + \left|i_1^{N,M}\hat{w}^{N,M}-\hat{w}^{N,M}\right|_W.$$

But

$$\begin{aligned}\left|\int_0^\theta \left(Dw-P_g^{N,M}(Dw)\right)d\xi\right|_W^2 &\le \int_{-r}^0 g(\theta)\int_\theta^0 \frac{d\xi}{g(\xi)}\left|Dw-P_g^{N,M}Dw\right|_W^2\\ &\le \frac{r^2}{2}\left|Dw-P_g^{N,M}Dw\right|_W^2 \to 0\end{aligned}$$

as $N, M \to \infty$. Also,

$$\begin{aligned}\left|i_1^{N,M}\hat{w}^{N,M}-\hat{w}^{N,M}\right|_W^2 &\le \sum_{i=1}^M \int_{\theta_i^M}^{\theta_{i-1}^M} g(\theta)\left(\theta-\theta_i^M\right)^2\left|\xi_i^M\right|_V^2 d\theta\\ &\le \left(\frac{r}{M}\right)^2 |Dw|_W^2 \to 0 \quad \text{as } M\to\infty\end{aligned}$$

where $P_g^{N,M}(Dw)=\sum_{i=1}^M \xi_i^M E_i^M$. Hence, $|i_1^{N,M}\hat{w}^{N,M}-w|_W \to 0$ as $N, M \to \infty$. It then follows from (3.11) that

$$\left|w^{N,M}-i_1^{N,M}\hat{w}^{N,M}\right|_W \to 0$$

so that

$$|w-w^{N,M}|_W \le \left|w^{N,M}-i_1^{N,M}\hat{w}^{N,M}\right|_W + \left|w-i_1^{N,M}\hat{w}^{N,M}\right|_W \to 0$$

as $N, M \to \infty$. □

Now we can state and prove the main result of this section.

THEOREM 3.4. *For all* $z \in Z$

$$S_1^{N,M}(t)P_Z^{N,M}z \to S(t)z \quad \text{as } N,\ M\to\infty$$

uniformly on bounded t-intervals.

Proof. In Lemma 3.2 we showed that the stability hypothesis of the Trotter–Kato theorem is satisfied. It remains for us to show convergence of $\left(\lambda I-\mathcal{A}_1^{N,M}\right)^{-1}P_Z^{N,M}z$ to $(\lambda I-\mathcal{A})^{-1}z$ for $\lambda > 0$. To do this, let $z=(\phi,\psi,h)\in Z$, and let $P_Z^{N,M}z = (\phi^N,\psi^N,h^{N,M})\in Z^{N,M}$. Also, let

$$(u,v,w)=(\lambda I-\mathcal{A})^{-1}z,$$

and

$$(u^N,v^N,w^{N,M})=\left(\lambda I-\mathcal{A}_1^{N,M}\right)^{-1}P_Z^{N,M}z.$$

Then, recalling (2.17)–(2.21), it follows that

$$w(\theta) = \int_\theta^0 e^{\lambda(\theta-\xi)}(v + h(\xi))\, d\xi, \qquad v = \lambda u - \phi,$$

and u satisfies

$$\mu(u,\chi) = \langle \psi + \lambda\phi, \chi\rangle_H + \sigma\left(\int_{-r}^0 g(\theta)(\lambda I - D)^{-1}(\phi - h(\theta))\, d\theta, \chi\right)$$

for all $\chi \in V$. Here μ is defined by (2.21). Following a similar analysis for the operator $\mathcal{A}_1^{N,M}$, we have

$$\lambda u^N - v^N = \phi^N \tag{3.12a}$$

$$\lambda v^N + A^N\left(\alpha u^N + \sum_{i=1}^M g_i^M a_i^M\right) = \psi^N \tag{3.12b}$$

$$\lambda a_i^M - v^N - \frac{M}{r}\left(a_{i-1}^M - a_i^M\right) = h_i^M, \qquad i = 1, \cdots, M \tag{3.12c}$$

where $w^{N,M} = \sum_{i=1}^M a_i^M E_i^M$ and $h^{N,M} = \sum_{i=1}^M h_i^M E_i^M$.

From (3.12c),

$$\left(\lambda + \frac{M}{r}\right) a_i^M = \frac{M}{r} a_{i-1}^M + v^N + h_i^M, \qquad i = 1, \cdots, M,$$

or

$$a_i^M = \left(1 + \frac{r}{M}\lambda\right)^{-1}\left[a_{i-1}^M + \frac{r}{M}\left(v^N + h_i^M\right)\right] \quad \text{with } a_0^M = 0.$$

By induction,

$$a_i^M = \sum_{j=1}^i \left(1 + \frac{r}{M}\lambda\right)^{j-i-1} \frac{r}{M}\left(v^N + h_j^M\right). \tag{3.13}$$

From (3.12a), $v^N = \lambda u^N - \phi^N$, and substituting these into (3.12b), we obtain

$$\lambda^2 u^N + A^N\left(\alpha u^N + \lambda \sum_{i=1}^M g_i^M \sum_{j=1}^i \left(1 + \frac{r}{M}\lambda\right)^{j-i-1} \frac{r}{M} u^N\right)$$
$$= \psi^N + \lambda\phi^N + \sum_{i=1}^M g_i^M A^N \sum_{j=1}^i \left(1 + \frac{r}{M}\lambda\right)^{j-i-1} \frac{r}{M}\left(\phi^N - h_j^M\right).$$

Here, $(1 + \frac{r}{M}\lambda)^{-1}\frac{r}{M}\lambda\sum_{j=1}^i (1 + \frac{r}{M}\lambda)^{j-i} = 1 - (1 + \frac{r}{M}\lambda)^{-i}$. Thus we have

$$\begin{aligned}\Delta_1^{N,M} u^N &= \psi^N + \lambda\phi^N \\ &\quad + A^N \int_{-r}^0 g(\theta)\left(\lambda I - D_1^{N,M}\right)^{-1}\left(\phi^N - h^{N,M}\right) d\theta\end{aligned} \tag{3.14}$$

where $\Delta_1^{N,M} \in \mathcal{L}(V^N, V^N)$ is given by

$$\Delta_1^{N,M} = \lambda^2 I + A^N\left(E - \sum_{i=1}^M g_i^M \left(1 + \frac{r}{M}\lambda\right)^{-i}\right). \tag{3.15}$$

Next note that if we define

$$e_1^M(\lambda\theta) = \sum_{i=1}^{M} \left(1 + \frac{r}{M}\lambda\right)^{-i} E_i^M(\theta), \tag{3.16}$$

then $|e^{\lambda\theta} - e_1^M(\lambda\theta)| \to 0$ as $M \to \infty$, uniformly on $[-r, 0]$ (see [11]). For each $M \geq 1$, define the sesquilinear form μ_1^M on V by

$$\mu_1^M(u, v) = \lambda^2 \langle u, v\rangle_H + \left(E - \int_{-r}^{0} g(\theta) e_1^M(\lambda\theta)\, d\theta\right) \sigma(u, v)$$

for $u, v \in V$. Then

$$\left|\mu_1^M(u, v) - \mu(u, v)\right| \leq \left(\int_{-r}^{0} g(\theta) \left|e^{\lambda\theta} - e_1^M(\lambda\theta)\right| d\theta\right) |u|_V |v|_V \tag{3.17}$$

and

$$\mu_1^M(u, u) \geq \lambda^2 |u|_H^2 + \alpha |u|_V^2 \quad \text{for all } u \in V. \tag{3.18}$$

Finally, from (3.14)–(3.15), we can write down the following equation for u^N:

$$\mu_1^M(u^N, \chi^N) = \langle \psi^N + \lambda\phi^N, \chi^N\rangle_H + \sigma\left(\int_{-r}^{0} g(\theta) \left(\lambda I - D_1^{N,M}\right)^{-1} (\phi^N - h^{N,M})\, d\theta, \chi^N\right)$$

for all $\chi^N \in V^N$.

Now, to finish the proof it is sufficient to show that $u^N \to u$. If we set $\hat{u}^N = P_V^N u$, then it is sufficient to show that $|\hat{u}^N - u^N|_V \to 0$. We have

$$\begin{aligned} \mu_1^M(\hat{u}^N - u^N, \chi^N) &= \mu_1^M(\hat{u}^N, \chi^N) - \mu_1^M(u, \chi^N) \\ &\quad + \mu_1^M(u, \chi^N) - \mu(u, \chi^N) + \lambda \langle \phi - \phi^N, \chi^N\rangle_H \\ &\quad + \sigma\left(\int_{-r}^{0} g(\theta) \left((\lambda I - D)^{-1}(\phi - h) - \left(\lambda I - D_1^{N,M}\right)^{-1} \right.\right. \\ &\qquad \left.\left. \cdot (\phi^N - h^{N,M})\right) d\theta, \chi^N\right) \end{aligned} \tag{3.19}$$

for all $\chi^N \in V^N$. It then follows from (3.17)–(3.19) that for $\lambda \geq 0$

$$\begin{aligned} \alpha |\hat{u}^N - u^N|_V &\leq \lambda^2 |u - \hat{u}^N|_H + \lambda |\phi - \phi^N|_H + K |u - \hat{u}^N|_V \\ &\quad + \left(\int_{-r}^{0} g(\theta)\, d\theta\right) \left(\sup_{\theta \in [-r,0]} \left|e^{\lambda\theta} - e_1^M(\lambda\theta)\right| |u|_V \right. \\ &\quad \left. + \left|(\lambda I - D)^{-1}(\phi - h) - \left(\lambda I - D_1^{N,M}\right)^{-1} P_g^{N,M}(\phi - h)\right|_W\right) \end{aligned}$$

where K is independent of N and M.

It thus follows from Lemma 3.3 that $|\hat{u}^N - u^N|_V \to 0$ as $N, M \to \infty$, so that for all $z \in Z$,

$$\left|\left(\lambda I - \mathcal{A}_1^{N,M}\right)^{-1} P_Z^{N,M} z - (\lambda I - \mathcal{A})^{-1} z\right|_Z \to 0$$

as $N, M \to \infty$. The result follows from the Trotter–Kato theorem. □

3.2. Spline-based scheme. The isomorphism $i_2^{N,M}$ defined by (3.6) leads to the scheme developed in [10]. Let $S_2^{N,M}(t) : Z^{N,M} \to Z^{N,M}$ be the semigroup generated by $\mathcal{A}_2^{N,M}$. The proof of convergence of $S_2^{N,M}(t)z \to S(t)z$ for $z \in Z$ will be parallel to one for $S_1^{N,M}(t)z$, given in §3.1.

LEMMA 3.5. *$\mathcal{A}_2^{N,M}$ is dissipative in $Z^{N,M}$.*

Proof. Let $z^{N,M} = (u^N, v^N, w^{N,M})$, where $w^{N,M} = \sum_{i=1}^M a_i^M E_i^M$ and where $(i_2^{N,M})^{-1} w^{N,M} = \tilde{w}^{N,M} = \sum_{i=1}^M b_i^M B_i^M$. We have

$$\begin{aligned}
&\langle \mathcal{A}_2^{N,M} z^{N,M}, z^{N,M} \rangle_Z \\
&\quad = \alpha\sigma(u^N, v^N) - \sigma\left(\alpha u^N + \int_{-r}^0 g(\theta) w^{N,M}(\theta)\, d\theta, v^N\right) \\
&\qquad + \int_{-r}^0 \left\langle v^N + \sum_{i=1}^M \left(b_{i-1}^M - b_i^M\right) \frac{M}{r} E_i^M, w^{N,M} \right\rangle_V g(\theta)\, d\theta \\
&\quad = \sum_{i=1}^M \left(\frac{M}{2r}\right) \left\langle \left(b_{i-1}^M - b_i^M\right), \left(b_{i-1}^M + b_i^M\right) \right\rangle_V g_i^M \\
&\quad = \sum_{i=1}^M \frac{1}{2} \left(\frac{M}{r}\right) g_i^M \left(\left|b_{i-1}^M\right|_V^2 - \left|b_i^M\right|_V^2 \right) \\
&\quad = -\frac{1}{2} \sum_{i=1}^{M-1} \left(\frac{M}{r}\right) \left(g_i^M - g_{i+1}^M\right) \left|b_i^M\right|_V^2 - \frac{1}{2} \left(\frac{M}{r}\right) g_M^M \left|b_M^M\right|_V^2 \le 0
\end{aligned}$$

where $a_i^M = (b_{i-1}^M + b_i^M)/2$, $1 \le i \le M$, $b_0^M = 0$, and $g_{M+1}^M = 0$. The result follows. □

Before proceeding to the main convergence result of this section, we discuss some preliminary calculations for the resolvent $\left(\lambda I - \mathcal{A}_2^{N,M}\right)^{-1}$. Consider the equation for $z^{N,M} = (u^N, v^N, w^{N,M}) \in Z^{N,M}$ given by

$$\lambda z^{N,M} - \mathcal{A}_2^{N,M} z^{N,M} = (\phi^N, \psi^N, h^{N,M}) \in Z^{N,M},$$

or equivalently

$$\lambda u^N - v^N = \phi^N \tag{3.20a}$$

$$\lambda v^N + A^N \left(\alpha u^N + \sum_{i=1}^M g_i^M a_i^M\right) = \psi^N \tag{3.20b}$$

$$\lambda \left(\frac{b_{i-1}^M + b_i^M}{2}\right) - v^N - \frac{M}{r} \left(b_{i-1}^M - b_i^M\right) = h_i^M, \quad i = 1, \cdots, M \tag{3.20c}$$

where from (3.6), $\widetilde{w}^{N,M} = \sum_{i=1}^{M} b_i^M B_i^M$ and $w^{N,M} = i_2^{N,M}\widetilde{w}^{N,M} = \sum_{i=1}^{M}((b_{i-1}^M + b_i^M)/2)\, E_i^M$ (i.e., $a_i^M = (b_{i-1}^M + b_i^M)/2, \quad i = 1, \cdots, M$) and $b_0^M = 0$. From (3.20c)

$$\left(\frac{\lambda}{2} + \frac{M}{r}\right) b_i^M = \left(\frac{M}{r} - \frac{\lambda}{2}\right) b_{i-1}^M + v^N + h_i^M,$$

or

$$b_i^M = \left(1 - \frac{r}{2M}\lambda\right)\left(1 + \frac{r}{2M}\lambda\right)^{-1} b_{i-1}^M + \frac{r}{M}\left(1 + \frac{r}{2M}\lambda\right)^{-1}(v^N + h_i^M), \qquad 1 \le i \le M.$$

By induction

$$b_i^M = \frac{r}{M}\left(1 + \frac{r}{2M}\lambda\right)^{-1} \sum_{j=1}^{i} \left(\frac{1 - \frac{r}{2M}\lambda}{1 + \frac{r}{2M}\lambda}\right)^{i-j} \left(v^N + h_j^M\right).$$

From (3.20a), $v^N = \lambda u^N - \phi^N$ and substituting these into (3.20b) we obtain

$$\lambda^2 u^N + A^N\left(Eu^N - \sum_{i=1}^{M} g_i^M \left(1 + \frac{r}{2M}\lambda\right)^{-1}\left(\frac{1 - \frac{r}{2M}\lambda}{1 + \frac{r}{2M}\lambda}\right)^{i-1} u^N\right) = \psi^N + \lambda\phi^N + A^N \int_{-r}^{0} g(\theta)\left(\lambda I - D_2^{N,M}\right)^{-1}(\phi^N - h^{N,M})\, d\theta$$

where we used

$$a_i^M = \frac{b_{i-1}^M + b_i^M}{2}$$

and

$$\frac{1}{2}\left(\sum_{j=1}^{i} x^{i-j} + \sum_{j=1}^{i-1} x^{i-1-j}\right) = \frac{1 - \left(\frac{1+x}{2}\right) x^{i-1}}{1 - x} = \left(\frac{r}{M}\lambda\right)^{-1}\left(1 + \frac{r}{2m}\lambda\right) - \left(\frac{r}{M}\lambda\right)^{-1}\left(\frac{1 - \frac{r}{2M}\lambda}{1 + \frac{r}{2M}\lambda}\right)^{i-1}, \qquad 1 \le i \le M,$$

(with $x = (1 - r\lambda/2m)/(1 + r\lambda/2m)$).

Thus, we have

$$\Delta_2^{N,M} u^N = \psi^N + \lambda\phi^N + A^N \int_{-r}^{0} g(\theta)\left(\lambda I - D_2^{N,M}\right)^{-1}(\phi^N - h^{N,M})\, d\theta \tag{3.21}$$

where $\Delta_2^{N,M} \in \mathcal{L}(V, V^*)$ is given by

$$\Delta_2^{N,M} = \lambda^2 I + A^N \left(E - \sum_{i=1}^{M} g_i^M \left(1 + \frac{r}{2M}\lambda\right)^{-1} \left(\frac{1 - \frac{r}{2M}\lambda}{1 + \frac{r}{2M}\lambda}\right)^{i-1} \right). \tag{3.22}$$

Hence, it is easy to show that $\lambda \in \rho(\mathcal{A}_2^{N,M})$ if and only if $(\Delta_2^{N,M})^{-1}$ exists. We can now state the main result of this section.

THEOREM 3.6. *For all* $z \in Z$

$$S_2^{N,M}(t) P_Z^{N,M} z \to S(t) z \quad \text{as } N, M \to \infty$$

uniformly on bounded t-intervals.

Proof. From Lemma 3.5, if $\lambda > 0$, then $\lambda \in \rho(\mathcal{A}_2^{N,M})$ and $|(\lambda I - \mathcal{A}_2^{N,M})^{-1}|_Z \leq \frac{1}{\lambda}$, $\lambda > 0$. Next, note that for $w = (\lambda I - D)^{-1} h$, $h \in W$, $\lambda > 0$,

$$\begin{aligned} \left| i_2^{N,M} \widehat{w}^{N,M} - \widehat{w}^{N,M} \right|_W^2 &\leq \sum_{i=1}^{M} \int_{\theta_i^M}^{\theta_{i-1}^M} g(\theta) \left(\theta - \frac{\theta_{i-1}^M + \theta_i^M}{2}\right) \left|\xi_i^M\right|_V^2 \, d\theta \\ &\leq \left(\frac{r}{2m}\right)^2 |Dw|_W^2 \to 0 \quad \text{as } M \to \infty \end{aligned}$$

where $\widehat{w}^{N,M}$ is given by (3.10) and $P_g^{N,M}(Dw) = \sum_{i=1}^{M} \xi_i^M E_i^M$. Hence, arguments similar to those in the proof of Lemma 3.3 allow us to show

$$\left(\lambda I - D_2^{N,M}\right)^{-1} P_g^{N,M} h \to (\lambda I - D)^{-1} h \quad \text{as } N, M \to \infty$$

for all $h \in W$. Note that for each $\lambda > 0$

$$\left| e^{\lambda\theta} - \sum_{i=1}^{M} \left(1 + \frac{r}{2m}\lambda\right)^{-1} \left(\frac{1 - \frac{r}{2m}\lambda}{1 + \frac{r}{2m}\lambda}\right)^{i-1} E_i^M \right| \to 0$$

uniformly on $[-r, 0]$. If we define the sesquilinear form μ_2^M on V by

$$\mu_2^M(u, v) = \lambda^2 \langle u, v \rangle + \left(E - \int_{-r}^{0} g(\theta) e_2^M(\lambda\theta) \, d\theta \right) \sigma(u, v)$$

for $u, v \in V$, then

$$\begin{aligned} \left| \mu_2^M(u, v) - \mu(u, v) \right| &\leq \left(\int_{-r}^{0} g(\theta) \left| e^{\lambda\theta} - e_2^M(\lambda\theta) \right| \, d\theta \right) |u|_V \, |v|_V \\ &= \epsilon_2(\lambda) |u|_V \, |v|_V \end{aligned}$$

where

$$e_2^M(\lambda\theta) = \sum_{i=1}^{M} \left(1 + \frac{r}{2m}\lambda\right)^{-1} \left(\frac{1 - \frac{r}{2m}\lambda}{1 + \frac{r}{2m}\lambda}\right)^{i-1} E_i^M$$

and $\epsilon_2(\lambda) \to 0$ as $M \to \infty$. Thus, using the exact same arguments as in the proof of Theorem 3.4, we can show that for all $z \in Z$ and $\lambda > 0$

$$\left| \left(\lambda I - \mathcal{A}_2^{N,M}\right)^{-1} P_Z^{N,M} z - (\lambda I - \mathcal{A})^{-1} z \right|_Z \to 0$$

as $N, M \to \infty$. Now, the theorem follows from the Trotter–Kato theorem. □

4. Numerical results. In this section we apply the approximation results developed above to a specific example. In particular, we consider the following model for transverse vibrations of a cantilevered linear viscoelastic beam:

$$\frac{\partial^2 u}{\partial t^2}(t,x) + \frac{\partial^2}{\partial x^2}\left[Eu_{xx}(t,x) - \int_{-r}^{0} g(s)u_{xx}(t+s,x)\,ds\right] = f(t,x) \tag{4.1}$$

where $0 < x < 1$, $t \geq 0$, and

$$u(t,0) = 0, \qquad \left[Eu_{xx}(t,x) - \int_{-r}^{0} g(s)u_{xx}(t+s,x)\,ds\right]\Bigg|_{x=1} = 0,$$

$$u_x(t,0) = 0, \qquad \frac{\partial}{\partial x}\left[Eu_{xx}(t,x) - \int_{-r}^{0} g(s)u_{xx}(t+s,x)\,ds\right]\Bigg|_{x=1} = 0.$$

Here $u(t,x)$ is the transverse displacement at time t and position x of a vibrating beam. Assume that $g(s) = \alpha e^{\beta s}/\sqrt{-s}$. It has been observed that such exponentially decaying kernels with a singularity at $s = 0$ provide a reasonable model for many viscoelastic structures (see [7], [9]). For this example we fix the parameter values in the model to be $E = 40$, $r = 1$, $\alpha = 10$, and $\beta = 5$. Define the Hilbert spaces

$$H = L_2(0,1)$$

and

$$V = \{v \in H^2(0,1) : v(0) = 0 = v'(0)\},$$

and the following sesquilinear form on $V \times V$:

$$\sigma(u,v) = \langle u'', v'' \rangle_H . \tag{4.2}$$

Then if we set $u(t) = u(t,\cdot)$, we can write (4.1) in the form of (1.1) and apply the theory we have developed for (1.1).

The first step in the approximation scheme is the construction of the finite-dimensional spaces $V^N \subset V$. For a positive integer N and partition $\{x_i\}_{i=0}^N$, $x_i = i/N$, of $[0,1]$, let S_3^N denote the set of cubic splines with knots at the x_i. Let $\{B_i^N\}_{i=1}^{N+1}$ be the standard cubic B-spline basis of S_3^N (see [14]). The set S_3^N is not contained in V, but we can define basis elements h_i^N which satisfy $h_i^N(0) = d/dx\, h_i^N(0) = 0$. That is, define

$$h_1^N = 2B_1^N - B_0^N + 2B_{-1}^N$$

and

$$h_i^N = B_i^N, \quad i = 2, \cdots, N+1.$$

Let $V^N = \operatorname{span}\{h_i^N\}_{i=1}^{N+1}$. The approximation scheme is completed with either of the delay discretizations described in §3. Hence we are led to finite-dimensional ordinary differential equations of the form

$$\dot{z}^{N,M}(t) = \mathcal{A}_k^{N,M} z^{N,M}(t) + \operatorname{col}\left(0, P_H^N f(t,x), 0\right) \tag{4.3}$$

where $k = 1$ or 2 corresponds to the choice of delay discretization.

Returning to consideration of the original equation (4.1), note that the eigenvalues of this viscoelastic system (that is, the eigenvalues of $\mathcal{A}$) are the solutions λ of the characteristic equation (recall $\Delta(\lambda)$ in §2)

$$\lambda^2 + \omega_j\left(E - \int_{-r}^{0} g(s)e^{\lambda s}\,ds\right) = 0. \tag{4.4}$$

Here $-\omega_j$, $j = 1, 2, \cdots$, are the eigenvalues of the operator A which is determined by (2.3) and (4.2). It is well known that $\omega_j = c_j^4$, where c_j, $j = 1, 2, \cdots$, are the roots of the frequency equation

$$\cos c \cdot \cosh c + 1 = 0. \tag{4.5}$$

Note that $c_j \approx (j - \frac{1}{2})\pi$ as $j \to \infty$. Note also that for the case $g(s) \equiv 0$, the solutions $\lambda_\pm$ of (4.4) are given by $\lambda_\pm = \pm i\sqrt{\omega E}$. Naturally we expect this since the case $g \equiv 0$ corresponds to no damping (i.e., perfectly elastic system). Now (4.5) and (4.4) can be solved to high accuracy numerically using Newton's method. In Table 1 we note the effect of viscoelastic damping by comparing the eigenvalues of the damped and undamped systems for the first five modes.

TABLE 1

	Undamped	Damped
Mode 1	$0 \pm 22.2372i$	$-0.69475 \pm 21.4162i$
Mode 2	$0 \pm 139.3583i$	$-1.86160 \pm 137.4791i$
Mode 3	$0 \pm 390.2074i$	$-3.13974 \pm 387.1056i$
Mode 4	$0 \pm 764.6508i$	$-4.30433 \pm 760.3019i$
Mode 5	$0 \pm 1264.0226i$	$-5.61023 \pm 1258.2092i$

Next we compare the efficacy of the two approximation schemes by observing the rate of convergence, as $N, M \to \infty$, of the eigenvalues of $A_k^{N,M}$ to the eigenvalues of $\mathcal{A}$. Actually, we fix $N = 9$, which from finite element theory gives a good approximation of the eigenvalues corresponding to the first four undamped modes. In Tables 2 and 3 we observe the behavior of these eigenvalues as M increases. We note that convergence is "frequency dependent," i.e., larger values of M are required for higher mode eigenvalues. After extensive numerical experiments, it appears that the scheme based upon the delay approximation of Ito and Kappel converges about twice as fast as the AVE scheme.

We turn finally to an idea which, from a computational point of view, may well be the most important contribution of this paper. When using the schemes discussed above for control and identification problems, large values of N and M may be required

in order that the finite-dimensional system gives a good enough approximation to the infinite-dimensional system to be useful for the intended application. However, for N and M too large the computational burden may be unreasonable. Thus we were led to consider an alternative scheme in which a "nonuniform" mesh is used. More specifically, we discretize the interval $[-r, 0]$ according to the mesh θ_j^M, where $\theta_0^M = 0$, $\theta_M^M = -r$, and θ_j^M, $j = 1, 2, \cdots, M-1$ is defined so that

$$\int_{\theta_j^M}^{\theta_{j-1}^M} g(s)\, ds = \frac{c}{M}, \qquad j = 1, \cdots, M-1.$$

Here $c = \int_{-r}^{0} g(s)\, ds$. Thus the mesh is distributed according to the "mass" of the function $g(s)$. In our example this amounts to a greater concentration of mesh elements in the immediate "past history" than in the far "past history." Note that, using this mesh, we have (recall 3.15)

$$\Delta_1^{N,M} = \lambda^2 I + A^N \left(E - \sum_{i=1}^{M} \frac{c}{M} \prod_{j=1}^{i} \left(1 + \lambda \alpha_j^M\right)^{-1} \right)$$

where $\alpha_j^M = \theta_{j-1}^M - \theta_j^M$.

Because $g(s) \in L_1(-r, 0)$, it can be shown that all of the convergence arguments used for the "uniform" mesh can be suitably modified so as to hold for this nonuniform mesh. In fact, for the AVE scheme, these arguments can be found in [12]. What we gain with this new scheme, however, is a much faster rate of convergence. In Tables 4 and 5 we observe eigenvalue convergence just as in Tables 2 and 3, except now with the nonuniform mesh. Again, the scheme of Ito and Kappel performs slightly better than the AVE scheme, but the important feature is the comparison of Tables 4 and 5 with Tables 2 and 3. For example, the value $M = 8$ for the nonuniform mesh compares favorably to the value $M = 400$ for the uniform mesh. This is a significant improvement and this scheme should prove useful for the applications to control and identification mentioned above. Finally we note that the improved rate of convergence with the nonuniform mesh is as yet only a numerical observation. However, we are working on a theoretical justification of this observation.

DIFFERENTIABILITY PROPERTIES OF SOLUTIONS OF THE EQUATION $-\varepsilon^2\Delta u + ru = f(x,y)$ IN A SQUARE*

H. HAN† AND R. B. KELLOGG‡

Abstract. A singularly-perturbed, elliptic boundary value problem is considered in a square. A theory of corner singularities for a 90° angle that takes account of lower-order terms in the equation is developed. In the case $r(x,y) \equiv$ const., an asymptotic expansion of the solution is obtained that can be differentiated termwise and which displays both the corner singularities and the boundary and corner layers of the solution.

Key words. singular perturbations, boundary layers, asymptotic [Aanalysis, corner layers

1. Introduction.

The solution of an elliptic boundary value problem possesses as much smoothness as the coefficients of the equation, the data of the problem, and the boundary of the domain permit. For example, if the domain has corners, and is therefore not smooth, the solution has corner singularities and derivatives of the solution become infinite near these corners. If the highest order terms in the equation have a small parameter that alters the balance between the ellipticity and the other terms in the equation, the solution may have a boundary layer, a region of rapid transition near the boundary of the domain. In this paper we study in a simple example a problem that contains both corner singularities and boundary layers.

We consider the equation in the title in the unit square Ω with u specified on the boundary Γ. It is known that the solution $u(x,y,\varepsilon)$ has singularities near each of the four vertices of Ω. It is also known that, for small ε, $u(x,y,\varepsilon)$ has a boundary layer behavior near Γ. We seek a joint asymptotic expansion of $u(x,y,\varepsilon)$ as $(x,y) \to$ a vertex of Ω and as $\varepsilon \to 0$ that displays the singular behavior of u in the two limits.

Butuzov [1] has already given an asymptotic expansion of u for small ε. This expansion, which serves as our starting point, contains boundary layer terms for each of the four sides of Ω, and "corner layer" terms for each of the four vertices of Ω. Butuzov has also established the uniform validity of the expansion by giving a uniform bound for the remainder in $\bar{\Omega}$. Our concern is with the differentiability of the Butuzov expansion. The importance of this lies in the fact that if the boundary data is continuous, the solution u is continuous in $\bar{\Omega}$. The corner singularities in u occur in the *derivatives* of u, starting with the second derivatives which have logarithmic singularities near the vertices of Ω. If we want to understand the interaction of the corner singularities and the boundary layer, we must obtain asymptotic expansions of the derivatives of u.

Our main result is that in the case $r(x,y) \equiv$ const.\ the Butuzov expansion can be differentiated termwise to provide an asymptotic expansion of derivatives of the

solution. As a consequence of our analysis, we write the expansion in a form that shows explicitly both the traditional corner singularities and the boundary and corner layers of the solution.

In §2 we develop the Butuzov expansion. Section 3 contains a discussion of corner singularities on the square Ω. Grisvard [2] gives an exposition of this theory, especially for the Laplace operator. In this theory, there are constructed certain linear functionals of the data of a problem whose nonvanishing guarantees the presence of corner singularities in the solution of the problem. Each linear functional is associated with a vertex of the domain. In the case of the Laplace operator, when the angle of the vertex is $\pi/2$, the corresponding linear functionals are local; that is, they depend only on the data and the derivatives of the data at the vertex. We construct the appropriate linear functionals for the operator $Mu = -\Delta u + pu_x + qu_u + ru$ on the square Ω. In the construction, we pay particular attention to the effect of the lower-order terms. We find that if the coefficients p, q, r are not constant, the higher-order linear functionals are not, in general, local. In §4 we give our results on the derivatives of u.

We let $D^m u(x, y)$ denote a generic derivative of order m of u. When appropriate, we use subscripts to indicate the independent variables that are being differentiated. We let $C^{m,\alpha}(S)$ denote the usual Holder space of functions of differentiability class m, and whose mth order derivatives are Holder continuous with exponent α in a set S. When $S = \bar{\Omega}$ we simply write $C^{k,\alpha}$.

2. The Butuzov expansion. We consider the singularly perturbed elliptic boundary value problem

$$Lu \equiv -\varepsilon^2 \Delta u + r(x, y)u = f \quad \text{in } \Omega, \tag{2.1a}$$

$$u(s, 0) = g_s(s),\ u(s, 1) = g_n(s),\ u(0, s) = g_w(s),\ u(1, s) = g_e(s), \quad s \in [0, 1], \tag{2.1b}$$

where $\Omega = (0, 1) \times (0, 1)$. The functions r, f are assumed to be smooth in $\bar{\Omega}$ and $r(x, y) > 0$. We let $r_{\min} > 0$ denote the minimum value of $r(x, y)$ in $\bar{\Omega}$, and we let $a > 0$ denote a constant with $a < r_{\min}$. The boundary data g_l, h_l are assumed to be smooth in $[0, 1]$ and to satisfy the compatibility conditions $g_s(0) = g_w(0)$, $g_s(1) = g_e(0)$, etc. The asymptotic analysis of the solution of (2.1) is complicated by the fact that the domain Ω does not have a smooth boundary. Nevertheless, Butuzov [1] has given an asymptotic expansion of the solution with an arbitrary number of terms, and has provided an estimate for the remainder in the expansion. The expansion of Butuzov contains "boundary layer functions," whose role is to correct discrepancies between the boundary data and the boundary values of the reduced problem on the four sides of Ω, and "corner layer functions," whose role is to correct discrepancies between the boundary data and the boundary values of the reduced problem near the four vertices of Ω. In this section we describe the Butuzov asymptotic expansion, and we give a bound for the remainder in the expansion.

We start with the "outer expansion." For this, define $u_0(x, y) = f(x, y)/r(x, y)$, $u_1(x, y) = 0$, and $u_i(x, y) = \Delta u_{i-2}(x, y)/r(x, y)$ for $i \geq 2$. Thus, $u_i = 0$ for i odd and

$$Lu_i = -\varepsilon^2 \Delta u_i + \Delta u_{i-2}, \quad i = 2, 4, \cdots. \tag{2.2}$$

We set

$$U_{2n}(x, y) = \sum_{i=0}^{2n} \varepsilon^i u_i(x, y).$$

Then from (2.2) we have

$$LU_{2n} = f - \varepsilon^{2n+2}\Delta u_{2n}. \tag{2.3}$$

From (2.3) we see that $L(u - U_{2n}) = O(\varepsilon^{2n+2})$. Unfortunately, $u - U_{2n}$ is not small on Γ. The boundary layer functions, which we now define, are designed to correct this discrepancy in the boundary data of $u - U_{2n}$.

We introduce a stretched variable η, defined by $\eta = y/\varepsilon$. We note the formula

$$Lv(x,\eta) = -\varepsilon^2 v_{xx}(x,\eta) - v_{\eta\eta}(x,\eta) + r(x,y)v(x,\eta).$$

We make a formal expansion of the equation $Lv = 0$ into powers of ε, and equate to zero the coefficients of ε^i, to define a sequence of functions $v_0, v_1, \cdots$, as follows.

$$\begin{aligned} &-v_{0,\eta\eta} + r_0(x)v_0 = 0, \\ &-v_{1,\eta\eta} + r_0(x)v_1 = -\eta r_1(x)v_0, \\ &-v_{i,\eta\eta} + r_0(x)v_i = v_{i-2,xx} - \sum_{l=0}^{i-1} \eta^{i-l} r_{i-l}(x)v_l, \quad i = 2, \cdots, 2n. \end{aligned} \tag{2.4a}$$

The functions $r_i(x)$ are defined to be the coefficients in the Taylor series expansion of $r(x,y)$ in the variable y:

$$r(x,y) = \sum_{i=0} y^i r_i(x).$$

The equations (2.4a) are a sequence of ordinary differential equations that are used to recursively determine $v_0, v_1, \cdots$. We must specify boundary conditions to complete the determination of the v_i. We specify the boundary conditions

$$\begin{aligned} &v_0(x,0) = g_s(x) - u_0(x,0), \quad v_0(x,\eta) \to 0 \quad \text{as } \eta \to \infty, \\ &v_i(x,0) = -u_i(x,0), \quad v_i(x,\eta) \to 0 \quad \text{as } \eta \to \infty, \quad i = 1, 2, \cdots. \end{aligned} \tag{2.4b}$$

It is easy to see from the positivity of $r_0(x)$ that (2.4a,b) has a solution $v_i(x,\eta)$, and that the functions v_i satisfy

$$|D_{x\eta}^m v_i(x,\eta)| \le c_m e^{-a\eta}, \qquad m = 0, 1, \cdots, \tag{2.5}$$

where the constant c_m depends on the data of (2.1) and its derivatives. The constant $a \in (0, r_{\min})$. We also note the formulas

$$\begin{aligned} Lv_0(x,\eta) &= -\varepsilon^2 v_{0,xx}(x,\eta) + [r(x,y) - r_0(x)]v_0(x,\eta), \\ Lv_1(x,\eta) &= -\varepsilon^2 v_{1,xx}(x,\eta) + r(x,y)v_1(x,\eta) - r_0(x)v_1(x,\eta) - \eta r_1(x)v_0(x,\eta), \\ Lv_i(x,\eta) &= -\varepsilon^2 v_{i,xx}(x,\eta) + v_{i-2,xx}(x,\eta) + r(x,y)v_i(x,\eta) \\ &\quad - \sum_{l=0}^{i} \eta^{i-l} r_{i-l}(x)v_l(x,\eta), \qquad i \ge 2. \end{aligned}$$

We set

$$V_{2n}(x,\eta) = \sum_{i=0}^{2n} \varepsilon^i v_i(x,\eta).$$

We then have

$$\begin{aligned} LV_{2n}(x,\eta) = &-\varepsilon^{2n+2} v_{2n,xx}(x,\eta) - \varepsilon^{2n+1} v_{2n-1,xx}(x,\eta) \\ &+ \sum_{i=0}^{2n} \varepsilon^i v_i(x,\eta) \left\{ r(x,y) - \sum_{k=0}^{2n-i} y^k r_k(x) \right\}, \end{aligned} \tag{2.6a}$$

$$V_{2n}(x,0) = g_s(x) - U_{2n}(x,0), \tag{2.6b}$$

$$|D_{x\eta}^m V_{2n}(x,\eta)| \le c_m e^{-a\eta}, \quad m = 0,1,\cdots. \tag{2.6c}$$

In a manner similar to the construction of the v_i, we define a stretched variable $\xi = x/\varepsilon$, and we define functions $w_i(\xi,y)$ and $W_{2n}(\xi,y) = \sum_{i=0}^{2n} \varepsilon^i w_i(\xi,y)$. Also, we define stretched variables $\bar\eta = (1-y)/\varepsilon$ and $\bar\xi = (1-x)/\varepsilon$, and we define boundary layer functions $\bar v_i(x,\bar\eta)$ and $\bar w_i(\bar\xi,y)$ as above. We also define functions $\bar V_{2n}(x,\bar\eta)$ and $\bar W_{2n}(\bar\xi,y)$. These functions satisfy equations analogous to (2.6). Then we find that the remainder, $u - U_{2n} - V_{2n} - W_{2n} - \bar V_{2n} - \bar W_{2n}$, is not small near the four vertices of Ω. We introduce corner layer functions to correct this discrepancy in the boundary data near the corners.

Consider a function $z^1(\xi,\eta)$ of the stretched variables (ξ,η). Note that

$$Lz^1(\xi,\eta) = -z^1_{\xi\xi} - z^1_{\eta\eta} + r(x,y)z^1.$$

We make a formal expansion of the equation $Lz^1 = 0$ into powers of ε, and equate to zero the coefficients of ε^i, to define a sequence of functions $z_i^1(\xi,\eta)$. In defining the functions z_i^1 we shall require the Taylor series expansion of $r(\varepsilon\xi,\varepsilon\eta)$ in powers of ε. We write this expansion as

$$r(\varepsilon\xi,\varepsilon\eta) = \sum_{i=0} \varepsilon^i \rho_i^1(\xi,\eta),$$

where $\rho_0^1 = r(0,0)$, $\rho_1^1 = r_x(0,0)\xi + r_y(0,0)\eta$, and in general $\rho_i^1(\xi,\eta)$ is a homogeneous polynomial of degree i. With this, the functions $z_i^1(\xi,\eta)$ are defined by

$$\begin{aligned} &-z^1_{0,\xi\xi} - z^1_{0,\eta\eta} + \rho_0^1 z_0^1 = 0, \\ &-z^1_{i,\xi\xi} - z^1_{i,\eta\eta} + \rho_0^1 z_i^1 = -\sum_{l=0}^{i-1} \rho_{i-l}^1 z_l^1, \quad i = 1,\cdots,2n. \end{aligned} \tag{2.7a}$$

We use the boundary conditions

$$\begin{aligned} &z_i^1(\xi,0) = -w_i(\xi,0), \qquad 0 \le i \le 2n, \\ &z_i^1(0,\eta) = -v_i(0,\eta), \qquad 0 \le i \le 2n, \\ &z_i^1(\xi,\eta) \to 0 \qquad \text{as } \xi,\eta \to \infty. \end{aligned} \tag{2.7b}$$

We note that the boundary data in (2.7b) are compatible at the origin:

$$w_i(0,0) - v_i(0,0) = \begin{cases} g_s(0) - g_w(0) = 0, & i = 0, \\ 0, & i > 0. \end{cases}$$

It can be shown that (2.7a,b) has a unique solution z_i^1 which satisfies

$$|z_i^1(\xi,\eta)| \le ce^{-a\rho}, \quad 0 \le \xi,\eta \le \infty, \tag{2.8a}$$

$$|D_{\xi\eta}^m z_i^1(\xi,\eta)| \le ce^{-a\rho}, \quad \rho \ge 1, \tag{2.8b}$$

where we have set $\rho = (\xi^2+\eta^2)^{1/2}$. The restriction $\rho \ge 1$ in (2.8b) is to avoid the possible corner singularities in these functions at the origin. These corner singularities will be discussed at the end of §3. We also note the formulas

$$Lz_0^1(\xi,\eta) = [r(x,y) - \rho_0^1(\xi,\eta)]z_0^1(\xi,\eta),$$

$$Lz_i^1(\xi,\eta) = r(x,y)z_i^1(\xi,\eta) - \sum_{j=0}^{i} \rho_{i-j}^1(\xi,\eta)z_j^1(\xi,\eta).$$

We set

$$Z_{2n}^1(\xi,\eta) = \sum_{i=0}^{2n} \varepsilon^i z_i^1(\xi,\eta).$$

We then have

$$LZ_{2n}^1(\xi,\eta) = \sum_{i=0}^{2n} \varepsilon^i z_i^1(\xi,\eta) \left\{ r(x,y) - \sum_{j=0}^{2n-i} \varepsilon^j \rho_j^1(\xi,\eta) \right\}, \tag{2.9a}$$

$$Z_{2n}^1(\xi,0) = -W_{2n}(\xi,0), \qquad Z_{2n}^1(0,\eta) = -V_{2n}(0,\eta), \tag{2.9b}$$

$$|Z_{2m}^1(\xi,\eta)| \le ce^{-a(\xi+\eta)}. \tag{2.9c}$$

We also define corner layer functions $z_i^2(\bar{\xi},\eta)$, $z_i^3(\xi,\bar{\eta})$, and $z_i^4(\bar{\xi},\bar{\eta})$, respectively, at the other three corners, $(1,0)$, $(0,1)$, and $(1,1)$ of Ω. These functions satisfy equations similar to (2.7a,b), and the corresponding sums, Z_{2n}^l, $l = 2,3,4$, satisfy equations similar to (2.9).

Using the functions defined above, the asymptotic expansion $\tilde{u}_{2n}$ of Butuzov is defined to be

$$\tilde{u}_{2n} = U_{2n} + V_{2n} + W_{2n} + \bar{V}_{2n} + \bar{W}_{2n} + \sum_{l=1}^{4} Z_{2n}^l. \tag{2.10}$$

We let $R_{2n} = u - \tilde{u}_{2n}$ denote the remainder in the asymptotic expansion.

We have the theorem of Butuzov.

THEOREM 2.1. *Let u solve* (2.1a,b). *There is a constant $c_n > 0$ that is independent of ε such that*

$$|u(x,y) - \tilde{u}_{2n}(x,y)| \le c_n \varepsilon^{2n+1}.$$

Proof. We examine the boundary value problem satisfied by R_{2n}. From (2.3) we have $|L(u - U_{2n})| \le c\varepsilon^{2n+2}$. Since

$$\left| r(x,y) - \sum_{k=0}^{2n-i} y^k r_k(x) \right| \le cy^{2n-i+1} = c\varepsilon^{2n-i+1}\eta^{2n-i+1},$$

the inequalities in (2.6) give

$$|LV_{2n}(x,\eta)| \le c\varepsilon^{2n+1} + c\varepsilon^{2n+1} \sum_{i=0}^{2n} \eta^{2n-i+1} e^{-a\eta} \le c\varepsilon^{2n+1}.$$

Similar inequalities hold for the other terms that appear in the definition of $\tilde{u}_{2n}$. Hence

$$|LR_{2n}(x,y)| \le c\varepsilon^{2n+1}, \qquad (x,y) \in \Omega. \tag{2.11}$$

To examine the size of R_{2n} on $\partial\Omega$ we consider the typical side $y = 0$. From (2.6) we have

$$u(x,0) - U_{2n}(x,0) - V_{2n}(x,0) = 0.$$

From (2.9) we have

$$Z_{2n}^1(\xi,0) + W_{2n}(\xi,0) = 0,$$

and similarly,

$$Z^2_{2n}(\bar{\xi},0) + \bar{W}_{2n}(\bar{\xi},0) = 0.$$

Hence

$$R_{2n}(x,0) = -\bar{V}_{2n}(x,1/\varepsilon) - Z^3_{2n}(\xi,1/\varepsilon) - Z^4_{2n}(\bar{\xi},1/\varepsilon). \tag{2.12}$$

From the exponential decay of these functions, $|R_{2n}(x,0)| \leq c\exp(-a/\varepsilon) \leq \varepsilon^{2n+1}$. Reasoning in a similar manner on the other sides of Ω, we obtain

$$|R_{2n}(x,y)| \leq c\exp(-a/\varepsilon) \leq c\varepsilon^{2n+1}, \qquad (x,y) \in \partial\Omega. \tag{2.13}$$

Using (2.11), (2.13), and the maximum principle for the operator L, we obtain the result. □

Using the exponential decay of the boundary layer functions, we may differentiate both sides of (2.12) an arbitrary number of times with respect to x and obtain

$$|D^m_x R_{2n}(x,0)| \leq ce^{-a/\varepsilon}. \tag{2.14}$$

Similar inequalities hold on the other three sides of Ω. These inequalities will be used in §4.

It is useful to interpret the expansion (2.9) in terms of the asymptotic analysis of a function of three variables. We are concerned with the solution $u(x,y,\varepsilon)$ of (2.1) in a neighborhood of $x = y = \varepsilon = 0$. The function $\tilde{u}_{2n}$ is defined by (2.9) as the sum of functions of fewer variables: the functions u_i, which are independent of ε, the functions v_i, which depend on $(x, y/\varepsilon)$, the functions z^1_i, which depend on $(x/\varepsilon, y/\varepsilon)$, etc. The asymptotic analysis of u has thus been reduced to an asymptotic analysis of functions of fewer independent variables.

3. Compatibility conditions. On a domain with a smooth boundary, the solution of an elliptic boundary value problem has an amount of differentiability that is determined by the differentiability of the data. If the boundary of the domain is *piecewise smooth*, as for example, a polygon, this is no longer the case. In addition to the differentiability of the data, some auxiliary conditions are also required to guarantee the differentiability of the solution. These auxiliary conditions are expressed by the vanishing of certain linear functionals of the data. The theory that leads to these auxiliary conditions is presented in Grisvard [2]. In this section we present this theory in the case of the square Ω, and with special regard for the effect of the lower-order terms. We find that in the case of constant coefficients, the linear functionals are local, and the vanishing of the linear functionals may be regarded as a statement of compatibility between the boundary data at a vertex and the differential equation at that vertex. It is this fact that enables the analysis in the paper to be carried out. If the coefficients of the equation are not constant, the linear functionals are not in general local functions of the data.

We develop the linear functionals and the compatibility conditions for the boundary value problem

$$Mu \equiv -\Delta u + p(x,y)u_x + q(x,y)u_y + r(x,y)u = f \quad \text{in } \Omega, \tag{3.1a}$$

$$u(s,0) = g_s(s), u(s,1) = g_n(s), u(0,s) = g_w(s), u(1,s) = g_e(s), \quad s \in [0,1]. \tag{3.1b}$$

We suppose that the coefficients and data of the problem are smooth. We let Ω^0 be the set $\partial\Omega$ with the four vertices excluded.

A sequence of linear functionals, $\bar{\Lambda}_0(f,g), \bar{\Lambda}_1(f,g), \cdots$, is defined by

$$\bar{\Lambda}_0(f,g) = g_s(0) - g_w(0),$$
$$\bar{\Lambda}_1(f,g) = g_s''(0) + g_w''(0) + f(0,0),$$
$$\bar{\Lambda}_2(f,g) = g_s^{(4)}(0) - g_w^{(4)}(0) + D_x^2 f(0,0) - D_y^2 f(0,0),$$

and, in general,

$$\bar{\Lambda}_k(f,g) = g_s^{(2k)}(0) + (-1)^{k+1} g_w^{(2k)}(0) + \sum_{i=1}^{k} (-1)^{i-1} D_x^{2(k-i)} D_y^{2(i-1)} f(0,0). \tag{3.2}$$

We also write $\bar{\Lambda}_k = \bar{\Lambda}_k^{(1)}$, and in a similar way we define linear functionals $\bar{\Lambda}_k^{(l)}$, $l = 2,3,4$, at the other three vertices of Ω. $\bar{\Lambda}_k^{(l)}(f,g)$ is defined only if f and g possess sufficient regularity. It is convenient to define a space $X_{k,\alpha}$ of pairs (f,g) such that $f \in C^{k-2,\alpha}(\bar{\Omega})$, $g_s \in C^{k,\alpha}([0,1])$, and similarly for the other three sides of Ω. $X_{k,\alpha}$ is a Banach space with the corresponding norm. $\bar{\Lambda}_j^{(l)}$ is a bounded linear functional on $X_{2k,\alpha}$ for $j \le k$.

The linear functionals $\bar{\Lambda}_k^{(l)}$ pertain to the Poisson equation on Ω. Sometimes we shall need to apply $\bar{\Lambda}_k^{(l)}$ to the data generated by a function u. For this, we let γu denote the boundary values of u. Then $\bar{\Lambda}_k^{(l)}(-\Delta u, \gamma u)$ refers to the value of $\bar{\Lambda}_k^{(l)}$ on the data generated by the function u. Volkov [3] has analyzed the regularity of solutions of the Poisson equation, and the results are presented in Grisvard [2]. From these sources we cite the following theorem.

THEOREM 3.1. *Let u solve the problem $-\Delta u = f$ in Ω with boundary conditions* (3.1b). *Let $k \ge 1$ and suppose $(f,g) \in X_{2k,\alpha}$. Then the solution $u \in C^{2k,\alpha}(\bar{\Omega})$ if and only if*

$$\bar{\Lambda}_j^{(l)}(f,g) = 0, \qquad 0 \le j \le k, \quad 1 \le l \le 4. \tag{3.3}$$

If, furthermore, $(f,g) \in X_{2k+1,\alpha}$, the solution $u \in C^{2k+1,\alpha}(\bar{\Omega})$ if and only if (3.3) *holds.*

We want to apply this result to the problem (3.1). For this, let f and g be given, let u be the solution of (3.1), and set $F = f - ru - pu_x - qu_y$. We then define linear functionals $\Lambda_k^{(l)}(f,g)$ by

$$\Lambda_k^{(l)}(f,g) = \bar{\Lambda}_k^{(l)}(F,g).$$

As above, $\Lambda_k^{(l)}(Mu, \gamma u)$ provides the value of u on the data generated by the function u. In the case $l = 1$ we write $\Lambda_k(f,g)$ for $\Lambda_k^{(l)}(f,g)$.

The problem of determining whether $\Lambda_k(f,g)$ is well defined is a little tricky and is best settled by an inductive argument. Suppose the data $(f,g) \in X_{2,\alpha}$, and suppose further that $\bar{\Lambda}_0^{(l)}(f,g) = 0$ for $l = 1,2,3,4$. That is, suppose the boundary data are compatible at the four vertices of Ω. Then it turns out that the solution u of (3.1) lies in $C^{1,\alpha}(\bar{\Omega})$. Hence $(F,g) \in X_{2,\alpha}$, so $\Lambda_1^{(l)}(f,g) = \bar{\Lambda}_1^{(l)}(F,g)$ is a bounded linear functional on $X_{2,\alpha}$. The next linear functional, $\Lambda_2^{(l)}(f,g)$, is well defined only if $\Lambda_1^{(l)}(f,g) = 0$, and in an inductive argument, $\Lambda_k^{(l)}(f,g)$ is well defined only if $\Lambda_j^{(l)}(f,g) = 0$ for $j = 1,2,\cdots,k-1$ and $l = 1,2,3,4$. This reasoning is the content of the following theorem.

THEOREM 3.2. *Suppose* $(f,g) \in X_{2,\alpha}$, *and suppose* $\Lambda_0^{(l)}(f,g) = 0$ *for* $l = 1,2,3,4$. *Then the solution* u *of* (3.1) *lies in* $C^{1,\alpha}(\bar{\Omega})$. *If* $(f,g) \in X_{2k,\alpha}$ *and* $u \in C^{2k-1,\alpha}(\bar{\Omega})$, *the linear functionals* $\Lambda_j^{(l)}(f,g)$, $j = 1,2,\cdots,k$ *are well defined and* $\Lambda_j^{(l)}(f,g) = 0$ *for* $j = 1,2,\cdots,k-1$. *We have* $\Lambda_k^{(l)}(f,g) = 0$ *for* $l = 1,2,3,4$ *if and only if* $u \in C^{2k,\alpha}(\bar{\Omega})$. *If, further,* $(f,g) \in X_{2k+1,\alpha}$ *and* $\Lambda_k^{(l)}(f,g) = 0$ *for* $l = 1,2,3,4$, *then* $u \in C^{2k+1,\alpha}(\bar{\Omega})$.

Proof. Suppose $(f,g) \in X_{2,\alpha}$. Since the boundary data are compatible at the vertices of Ω, g may be extended in Ω to a function $\phi \in C^{2,\alpha}(\bar{\Omega})$. Then $v = u - \phi$ satisfies a problem of the form (3.1) with zero boundary data. A reflection argument shows that $v \in C^{1,\alpha}(\bar{\Omega})$, so $u \in C^{1,\alpha}(\bar{\Omega})$. Now suppose $(f,g) \in X_{2k,\alpha}$ and $u \in C^{2k-1,\alpha}(\bar{\Omega})$. Then $F \in C^{2k-2,\alpha}(\bar{\Omega})$, so $(F,g) \in X_{2k,\alpha}$, so $\Lambda_j^{(l)}(f,g)$ is well defined for $j = 1,\cdots,k$. Again since $u \in C^{2k-1,\alpha}(\bar{\Omega})$, from Theorem 3.1 we have $\Lambda_j^{(l)}(f,g) = \bar{\Lambda}_j^{(l)}(F,g) = 0$, $j = 1,\cdots,k-1$. From Theorem 3.1, $\Lambda_k^{(l)}(f,g) = \bar{\Lambda}_k^{(l)}(F,g) = 0$ for $l = 1,2,3,4$ if and only if $u \in C^{2k,\alpha}(\bar{\Omega})$. If $(f,g) \in X_{2k+1,\alpha}$ and $\Lambda_k^{(l)}(f,g) = 0$ for $l = 1,2,3,4$, then since $u \in C^{2k,\alpha}(\bar{\Omega})$, $F \in C^{2k-1,\alpha}(\bar{\Omega})$. Hence $(F,g) \in X_{2k-1,\alpha}$, so from Theorem 3.1, $u \in C^{2k+1,\alpha}(\bar{\Omega})$. □

From its definition we note that $\bar{\Lambda}_k^{(l)}(f,g)$ is a local functional of (f,g) in that the value of the functional only depends on the values of f and g and their derivatives at a certain point, the lth vertex of Ω. This is what enables the well definedness of $\bar{\Lambda}_k^{(l)}$ to depend only on the smoothness of f and g, and not on the vanishing of the preceding functionals. If M has constant coefficients the functionals $\Lambda_k^{(l)}$ can be reformulated to be local functionals, and to be well defined regardless of the vanishing of the previous functionals. This is established in Lemma 3.1.

LEMMA 3.1. *Suppose* M *has constant coefficients. Then there are bounded linear functionals* $\tilde{\Lambda}_k^{(l)}$ *on* $X_{2k,\alpha}$, $l = 1,2,3,4$, *such that* $\tilde{\Lambda}_k^{(l)}(f,g)$ *depends only on the values and derivatives of* f *and* g *at the* l*th vertex of* Ω, *and such that if* $k \geq 1$ *and* $(f,g) \in X_{2k,\alpha}$, *the solution* u *of* (3.1) *is in* $C^{2k,\alpha}(\bar{\Omega})$ *if and only if*

$$\tilde{\Lambda}_j^{(l)}(f,g) = 0, \qquad 0 \leq j \leq k, \quad 1 \leq l \leq 4. \tag{3.4}$$

If (3.4) *hold and if, furthermore,* $(f,g) \in X_{2k+1,\alpha}$, *then* $u \in C^{2k+1,\alpha}(\bar{\Omega})$.

Proof. The definition of the linear functionals $\tilde{\Lambda}_k^{(l)}$ involves a formal differentiation of (3.1). We take the case $l = 1$ and we write $\tilde{\Lambda}_k$ instead of $\tilde{\Lambda}_k^{(1)}$. Let u be the solution of (3.1) and suppose that $u \in C^{2k-1,\alpha}(\bar{\Omega})$. From Theorem 3.2, $\Lambda_j^{(l)}(f,g) = 0$ for all l and for $0 \leq j \leq k-1$. From (3.2) we see that $\Lambda_k(f,g) = \bar{\Lambda}_k(F,g)$ involves derivatives of u of order $\leq 2k-1$ of u evaluated at $(0,0)$. Also from (3.2), each derivative of even order of u occurring in $\bar{\Lambda}_k(F,g)$ is of the form $D_x^{2\mu}D_y^{2\nu}u(0,0)$. From the boundary conditions, $D_x^j u(0,0) = g_s^j(0)$, $D_y^j u(0,0) = g_w^j(0)$. By successive differentiations of (3.1a) and evaluations at $(0,0)$ we find that any odd order derivative of u, evaluated at $(0,0)$, may be written in terms of the values and derivatives of f, g_s, and g_w at $(0,0)$. Similarly, it may be shown that any even order derivative of u of the above form, when evaluated at $(0,0)$, may be written in terms of the values and derivatives of f, g_s, and g_w at $(0,0)$. If these expressions for the derivatives of u at $(0,0)$ are substituted into the formula for $\bar{\Lambda}_k(F,g)$, we obtain a new linear functional, denoted $\tilde{\Lambda}_k(f,g)$, which depends explicitly on the values and derivatives of f and g at $(0,0)$, and which is a bounded functional on $X_{2k,\alpha}$. By the construction, $\tilde{\Lambda}_k(f,g) = \Lambda_k(f,g)$ if $u \in C^{2k-1,\alpha}(\bar{\Omega})$. Hence (3.4) holds if and only if $u \in C^{2k,\alpha}(\bar{\Omega})$. □

If the coefficients of M are not constant, this reformulation of the linear functionals will not, in general, be possible. To see this, consider for example the case $l = 1$. If u satisfies (3.1a,b) and is smooth at $(0,0)$ we have $F = f - rg_s - pg'_s - qg'_w$ at (0,0), so

$$\tilde{\Lambda}_1(f,g) = g''_s(0) - p(0,0)g'_s(0) - r(0,0)g_s(0) + g''_w(0) - q(0,0)g'_w(0) + f(0,0). \tag{3.5}$$

A similar result holds for the other vertices, so $\Lambda_1^{(l)}$ can be reformulated to be a local functional, even if the coefficients are variable. To calculate $\Lambda_2^{(1)}(f,g)$ we must obtain formulas for F_{xx} and F_{yy} at $(0,0)$. In particular, we must obtain a formula for $(pu_x)_{yy} = pu_{xyy} + 2p_y u_{xy} + p_{yy}u_x$ at (0,0). There seems to be no formula for $u_{xy}(0,0)$ in terms of the data f, g_s, g_w and their derivatives evaluated at the origin. Hence the linear functional $\Lambda_2^{(1)}$ is not, in general, a local functional. If the operator M has no first derivative terms, so $p = q = 0$, then the functionals $\Lambda_2^{(l)}$ can be reformulated to be local functionals. In this case, since $F = f - ru$, if u is smooth at $(0,0)$, $F_{xx} = f_{xx} - rg''_s - 2r_x g'_s - r_{xx}g_s$ at $(0,0)$ and similarly for F_{yy}, so we may set

$$\begin{aligned}\tilde{\Lambda}_2(f,g) = {} & g_s^{(4)}(0) - g_w^{(4)}(0) + D_x^2 f(0,0) - D_y^2 f(0,0) \\ & - r(0,0)g''_s(0) - 2r_x(0,0)g'_s(0) - r_{xx}(0,0)g_s(0) \\ & - r(0,0)g''_w(0) - 2r_y(0,0)g'_w(0) - r_{yy}(0,0)g_w(0).\end{aligned} \tag{3.6}$$

In this case, however, Λ_3 involves $r_{xy}(0,0)u_{xy}(0,0)$ and so is not, in general, a local functional.

If the solution u of (3.1) does not satisfy the compatibility conditions, we can use Theorem 3.2 to obtain estimates for the derivatives of u near the corners. For this, we introduce singular functions associated with the corners. Let (r,θ) denote polar coordinates, and let

$$\psi_k(x,y) = r^{2k}\theta\cos 2k\theta + r^{2k}(\ln r)\sin 2k\theta.$$

This function arises from taking the imaginary part of the analytic function $(x + iy)^{2k}\ln(x+iy)$. Therefore we have $\psi_k(x,0) = 0, \psi_k(0,y) = (-1)^k(\pi/2)y^{2k}$ and $\Delta\psi_k = 0$. It is easily seen that $\psi_k \in C^{2k-1,\alpha}(\bar{\Omega})$ for any $\alpha < 1$ but $D^{2k}\psi_k$ is not bounded. Hence $\Lambda_i(M\psi_k, \gamma\psi_k)$ is well defined for $i \le k$, $\Lambda_i(M\psi_k,\gamma\psi_k) = 0$ for $i < k$, and $\Lambda_k(M\psi_k,\gamma\psi_k) \neq 0$. In fact, $\Lambda_k(M\psi_k,\gamma\psi_k) = \bar{\Lambda}_k(0,\gamma\psi_k) = -(\pi/2)(2k)!$. We also write $\psi_k = \psi_k^1$, and in a similar way we construct singular functions ψ_k^l, $l = 2,3,4$ at the other vertices of Ω. The only singularity of ψ_k^l is at the lth vertex of Ω. Collecting these facts and using Theorem 3.2, we obtain the following lemma.

LEMMA 3.2. *$\Lambda_i^{(j)}(M\psi_k^l, \gamma\psi_k^l)$ is well defined for $i \le k$, vanishes for $i < k$, and satisfies*

$$\Lambda_k^{(j)}(M\psi_k^l,\gamma\psi_k^l) = \begin{cases} a_k^l = -(\pi/2)(2k)!, & j = l, \\ 0, & j \neq l. \end{cases} \tag{3.7}$$

The derivatives of ψ_k^1 satisfy the inequalities

$$|D^m\psi_k^1(x,y)| \le \begin{cases} c, & m < 2k, \\ c[1 + |\ln r|], & m = 2k, \\ cr^{-(m-2k)}, & m > 2k. \end{cases}$$

and similar inequalities hold for the other vertices.

We use the singular functions to obtain bounds on the derivatives of u. This is done, in the following theorem, by establishing a recursive set of adjustments to

the solution u, subtracting off the singular part. In the case of constant coefficients, we could use the localized linear functionals $\tilde{\Lambda}_k^{(l)}$, and a recursive definition of the adjustments to the solution would not be necessary.

THEOREM 3.3. *There are bounded linear functionals $\Psi_i^{(l)}$ on $X_{2i,\alpha}$ such that if $(f,g) \in X_{2k+1,\alpha}$, if u is the solution of* (3.1), *and if v_k is defined by*

$$u = \sum_{l=1}^{4} \sum_{i=1}^{k} \Psi_i^{(l)}(f,g)\psi_i^l + v_k,$$

then $v_k \in C^{2k+1,\alpha}$ and $||v_k||_{C^{2k+1,\alpha}} \leq c||(f,g)||_{X_{2k+1,\alpha}}$. The derivatives of u of order up to $2k+1$ satisfy the inequalities

$$|D^m u(x,y)| \leq \begin{cases} c, & m = 1, \\ c[1 + |\ln r|], & m = 2, \\ cr^{-(m-2)}, & 2 < m \leq 2k+1, \end{cases} \tag{3.8}$$

which are valid in a neighborhood of the origin. Similar inequalities hold at the other vertices of Ω.

Proof. The linear functionals are defined in a recursive fashion, and the proof is by induction. From Theorem 3.2, $u \in C^{1,\alpha}(\bar{\Omega})$ and the linear functionals $\Lambda_1^{(l)}(f,g)$ are well defined. Set $v_0 = u$. Suppose, by induction, that $\Psi_j^{(l)}$ and v_j have been defined for $j = 0, \cdots, i-1$ with $v_{i-1} \in C^{2i-1,\alpha}$. Thus, $\Lambda_j^{(l)}(Mv_{i-1}, \gamma v_{i-1}) = 0$ for $j \leq i-1$ and $\Lambda_i^{(l)}(Mv_{i-1}, \gamma v_{i-1})$ is well defined. Let

$$\Psi_i^{(l)}(f,g) = \Lambda_i^{(l)}(Mv_{i-1}, \gamma v_{i-1})/a_i^l.$$

Then

$$|\Psi_i^{(l)}(f,g)| \leq c||(Mv_{i-1}, \gamma v_{i-1})||_{X_{2i,\alpha}} \leq c_1||(f,g)||_{X_{2i,\alpha}}.$$

Also,

$$v_i = v_{i-1} - \sum_{l=1}^{4} \Psi_i^{(l)}(f,g)\psi_i^l,$$

so $\Lambda_i^{(l)}(MV_i, \gamma v_i) = 0$. Since $\Lambda_j^{(l)}(M\psi_i^l, \gamma\psi_i^l) = 0$ for $j < i$, $\Lambda_j^{(l)}(Mv_i, \gamma v_i) = 0$ for $j \leq i$. Hence $v_i \in C^{2i+1,\alpha}$ and the induction is complete. Inequality (3.8) now follows from (3.7) and the bounds for $D^m v_k(x,y)$. □

4. Expansion of the derivatives. In this section, we consider the asymptotic expansion of the derivatives of u. It is found that, in the case $r(x,y) \equiv$ const., the desired asymptotic expansion of $D^m u$ can be obtained by differentiating the Butuzov expansion. The analysis proceeds by studying the derivatives of the remainder R_{2n} in the Butuzov expansion. For this, we set $M = \varepsilon^{-2}L$ and apply the compatibility conditions developed in §3. In (2.10) all the functions on the right are smooth except possibly the Z_{2n}^l, and Z_{2n}^l is smooth at all vertices of Ω except possibly the lth vertex. Hence

$$\Lambda_k^{(l)}(M\tilde{u}_{2n}, \gamma\tilde{u}_{2n}) = \Lambda_k^{(l)}(MZ_{2n}^l, \gamma Z_{2n}^l). \tag{4.1}$$

We first require some information concerning the corner layer functions z_i^l. We state the result only in the case $l = 1$.

LEMMA 4.1. *For some $c > 0$, $a > 0$,*

$$|D^m_{\xi\eta} z^1_i(\xi,\eta)| \le \begin{cases} ce^{-a\rho}, & m = 1, \\ c[1 + |\ln \rho|]e^{-a\rho}, & m = 2, \\ c\rho^{-(m-2)}e^{-a\rho} & m \ge 3. \end{cases}$$

If $r(x,y) \equiv$ const., there are constants a_{ik} such that $\tilde{\Lambda}_k(Mz^1_i, \gamma z^1_i) = a_{ik}/\varepsilon^{2k}$.

Proof. From (2.7) we know that z^1_i is smooth for $\xi > 0$, $\eta > 0$, and the only possible singularity is at the origin. We consider z^1_i as being defined by a boundary value problem in the unit square. Using (3.8) to estimate $D^m z^1_i$ for $\rho \le 1$, and using (2.8b) for $\rho > 1$, we obtain the first assertion. Now suppose $r(x,y) \equiv$ const. Let $f_i(\xi,\eta)$ denote the right side of (2.7a), and let $F_i = Mz_i$. Then $F_i = \varepsilon^{-2}Lz_i = -z_{i,xx} - z_{i,yy} + \varepsilon^{-2} r z_i = -\varepsilon^{-2} f_i$. Note also that $D^k_x z_i(x,0) \sim \varepsilon^{-k}$, $D^k_y z_i(0,y)) \sim \varepsilon^{-k}$. A computation then shows that $\tilde{\Lambda}_k(Mz^1_i, \gamma z^1_i)$ is a homogeneous function of ε, and the degree of homogeneity is ε^{-2k}, so we obtain the second assertion. □

Although in general the derivatives of R_{2n} are not bounded in $\bar{\Omega}$, the derivatives of LR_{2n} are bounded in $\bar{\Omega}$. This fact is important in our analysis. The next lemma provides bounds for these derivatives.

LEMMA 4.2. *Suppose $r(x,y) \equiv$ const. For $m \le 2n+1$, $|D^m_{xy} LR_{2n}| \le c\varepsilon^{2n+1-m}$.*

Proof. From (2.11) the result is true for $m = 0$. From (2.3), $|D^m_{xy} L(u - U_{2n})| \le c\varepsilon^{2n+2}$. Since $D_y = \varepsilon^{-1} D_\eta$, $|D^m_{xy} v(x,\eta)| \le c\varepsilon^{-m} |D^m_{x\eta} v(x,\eta)|$. Using (2.6), we get

$$|D^m_{xy} LV_{2n}(x,\eta)| \le c\varepsilon^{2n+1-m}, \qquad m \le 2n+1.$$

Similar results hold for the other boundary layers. From (2.9), $LZ_{2n} = 0$, and similarly for the other corner layers. Combining these estimates, we obtain the result. □

We now have the following lemma.

LEMMA 4.3. *Suppose $r \equiv$ const. Then if $2k < 2n+1$, $\Lambda^{(l)}_k(MR_{2n}, \gamma R_{2n}) = 0$.*

Proof. We give the proof in the case $l = 1$. Since $u = \tilde{u}_{2n} + R_{2n}$, we use (4.1) to get

$$\varepsilon^{k+1}\Lambda_k(Mu, \gamma u) = \varepsilon^{k+1}\Lambda_k(MZ^1_{2n}, \gamma Z^1_{2n}) + \varepsilon^{k+1}\Lambda_k(MR_{2n}, \gamma R_{2n}). \tag{4.3}$$

Since $r \equiv$ const., we may use the linear functional $\tilde{\Lambda}_k$ given by Lemma 3.1. A computation shows that $\tilde{\Lambda}_k(Mu, \gamma u)$ is a polynomial in ε^{-1} of degree $\le k+1$, and from Lemma 3.1 we note that the coefficients of the polynomial are linear combinations of the derivatives $D^i_x g_s(0)$ and $D^i_y g_w(0)$ for $0 \le i \le 2k$, and the derivatives $D^i_{xy} f(0,0)$ for $0 \le i \le 2(k-1)$. Furthermore, each derivative $D^i_{xy} f(0,0)$ that appears in $\tilde{\Lambda}_k(f,g)$ appears in the coefficient of $\varepsilon^{-(2k-i)}$. Hence the left side of (4.3) is a polynomial of degree $\le k+1$ in ε with coefficients that depend only on the data f and g. From Lemma 4.1, $\varepsilon^{k+1}\tilde{\Lambda}_k(MZ^1_{2n}, \gamma Z^1_{2n})$ is a sum of powers ε^j with $-k+1 \le j \le 2n-k+1$. The coefficients of ε^j in this expression depend only on the data f and g. We now estimate $h_k(\varepsilon) = \varepsilon^{k+1}\tilde{\Lambda}_k(MR_{2n}, \gamma R_{2n})$. As we have seen, h_k may be written as a polynomial in ε with coefficients depending on ε. These coefficients are linear combinations of the derivatives $D^i_x R_{2n}(x,0)$ evaluated at $x = 0$, $0 \le i \le 2k$, the derivatives $D^i_y R_{2n}(0,y)$ evaluated at $y = 0$, $0 \le i \le 2k$, and the derivatives $D^i_{xy} LR_{2n}(0,0)$, $0 \le i \le 2(k-1)$. From (2.14) and the analogous inequalities on the other sides of Ω, the derivatives of the boundary values of R_{2n} are exponentially small. The derivatives of $LR_{2n}(0,0)$ that appear in $h_k(\varepsilon)$ appear in the form $\varepsilon^{i-k+1} D^i_{xy} LR_{2n}$, and from Lemma 4.2, these terms are bounded by $c\varepsilon^{2n+2-k}$. Hence we have proved

$$|h_k(\varepsilon)| \le c\varepsilon^{2n+2-k}. \tag{4.4}$$

Hence if $k+1 < 2n+2-k$, $h_k(\varepsilon)$ vanishes more quickly than the other two terms appearing in (4.3). Since h_k is an analytic function of ε, we must have $h_k(\varepsilon) \equiv 0$. The proof in the case of other l is similar. □

We now have the following lemma.

LEMMA 4.4. *Let κ, μ, and ν be nonnegative integers with $\mu+\nu \le m$ and $2\kappa \le \mu$. Then $\varepsilon^2 D_x^\mu D_y^\nu R$ may be written as a linear combination of $\varepsilon^2 D_x^{\mu-2\kappa} D_y^{\nu+2\kappa} R$, derivatives of R of order $\le \mu+\nu-2$, and derivatives of LR of order $\le \mu+\nu-2$. The coefficients appearing in the linear combination depend only on r and its derivatives, and in particular are independent of ε.*

Proof. The proof follows from successive differentiations of the equation $-\varepsilon^2 R_{xx} - \varepsilon^2 R_{yy} + rR = LR$ and an examination of the linear combinations of derivatives of R of order $\mu+\nu$ that are obtained. □

The next lemma gives bounds for the solution of a mixed boundary value problem associated with the operator L, with the dependence of the constants on ε made explicit.

LEMMA 4.5. *Let $R \in C^2(\bar{\Omega})$, and let $c > 0$ be such that $|LR(x,y)| \le c$ on $\bar{\Omega}$, and on each of the four sides of Ω either $R \le c$ or $|\partial R/\partial n| \le c/\varepsilon$. Then $|R(x,y)| \le 8c \max\{1, 1/r_{\min}\}$, where $r_{\min} > 0$ denotes the minimum value of r.*

Proof. Set

$$T(x,y) = 2c[4 - e^{-x/\varepsilon} - e^{-(1-x)/\varepsilon} - e^{-y/\varepsilon} - e^{-(1-y)/\varepsilon}].$$

Then a computation shows that $LT \ge cr_{\min}$ in $\bar{\Omega}$, $T(x,0) \ge c$, $T_y(x,0) \ge c/\varepsilon$, and similarly for the other three sides of Ω. Applying the maximum principle to the function $\max\{1, 1/r_{\min}\}T \pm R$, we obtain the result. □

Using these lemmas, we give the desired results for the derivatives of $\tilde{u}_{2n}$.

THEOREM 4.1. *Suppose $r(x,y) \equiv$ const., and let u be the solution of (2.1). Let $n \ge 2$. Then there is a constant $c > 0$, independent of ε, such that for $m \le 2n+1$,*

$$|D_{xy}^m R_{2n}(x,y)| = |D_{xy}^m u(x,y) - D_{xy}^m \tilde{u}_{2n}(x,y)| \le c\varepsilon^{2n+1-m}.$$

Proof. From Lemma 4.3, $\Lambda_k^{(l)}(MR_{2n}, \gamma R_{2n}) = 0$ for $k \le n$. Hence from Theorem 3.2, $R_{2n} \in C^{2n+1,\alpha}(\bar{\Omega})$, so $D_{xy}^m R_{2n}$ is continuous in $\bar{\Omega}$ for $m \le 2n+1$. The proof is by induction on m. From Theorem 2.1 the result is true for $m = 0$. To continue, let $m > 0$ and suppose the inequality is true for all orders of differentiation less than m. Let $S = D_{xy}^m R_{2n}$. To estimate S we will apply the maximum principle to a boundary value problem satisfied by S. For this we must estimate LS and the right-hand sides in the boundary conditions that we will impose on S. It is easily seen that $D_{xy}^m LR_{2n} - LD_{xy}^m R_{2n}$ is a linear combination of derivatives of R_{2n} of order less than m. Hence, by induction and Lemma 4.2,

$$|LS(x,y)| \le c\varepsilon^{2n+1-m}. \tag{4.5}$$

The boundary conditions which we impose on S depend on the particular derivative that is being estimated. Note first that from (2.14) and the analogous inequalities on the other three sides of Ω,

$$\begin{aligned} &|D_x^k R_{2n}(x,0)| \le ce^{-a/\varepsilon}, \qquad |D_x^k R_{2n}(x,1)| \le ce^{-a/\varepsilon}, \\ &|D_y^k R_{2n}(0,y)| \le ce^{-a/\varepsilon}, \qquad |D_y^k R_{2n}(1,y)| \le ce^{-a/\varepsilon}. \end{aligned} \tag{4.6}$$

Let $S = D_x^\mu D_y^\nu R_{2n}$, where $\mu+\nu = m$. The boundary value problem that we associate with S depends on the parity of μ and ν. Suppose, for example, that μ is even and

ν is odd, so m is odd. In this case, for the boundary value problem satisfied by S we impose Dirichlet conditions on the vertical sides of Ω and Neumann conditions on the horizontal sides of Ω. Using Lemma 4.4, we write S as a linear combination of $D_y^m R_{2n}$, and of derivatives of R_{2n} and LR_{2n} of order $\leq m-2$, where the coefficients of the latter derivatives are bounded by $c\varepsilon^{-2}$. We evaluate this relation on a vertical side of Ω. We use the inequality (4.6) to bound $D_y^m R_{2n}$, and (4.5) and the inductive assumption to bound the other terms in the linear combination. We obtain

$$|S(0,y)| \leq c\varepsilon^{2n+1-m}, \qquad |S(1,y)| \leq c\varepsilon^{2n+1-m}. \tag{4.7}$$

Similarly, we write $S_y = D_x^\mu D_y^{\nu+1} R_{2n}$ as a linear combination of $D_x^{m+1} R_{2n}$, and of derivatives of R_{2n} and LR_{2n} of order $\leq m-1$, where the coefficients of the latter derivatives are bounded by $c\varepsilon^{-2}$. We evaluate this relation on a horizontal side of Ω. We use the inequality (4.6) to bound $D_x^{m+1} R_{2n}$, and (4.5) and the inductive assumption to bound the other terms in the linear combination. We obtain

$$|S_y(x,0)| \leq c\varepsilon^{2n-m}, \qquad |S_y(x,1)| \leq c\varepsilon^{2n-m}. \tag{4.8}$$

Using (4.5), (4.7), (4.8), and Lemma 4.5, we obtain $|S(x,y)| \leq c\varepsilon^{2n+1-m}$. If μ is odd and ν is even, we assign Dirichlet conditions to the horizontal sides of Ω and Neumann conditions to the vertical sides of Ω. If μ and ν are both even, Dirichlet conditions are assigned to all the sides of Ω, and if μ and ν are both odd, Neumann conditions are assigned to all the sides of Ω. The reasoning is similar in all these cases. If $r(x,y) \not\equiv$ const., we use the reformulation of Λ_k for $k = 1, 2$ given in (3.5) and (3.6). From these formulas we obtain Lemma 4.1 for $k = 1, 2$, and then we obtain Lemma 4.3. The rest of the proof of (4.5) follows as before, so in the general case we obtain (4.5) for $k = 1, 2$. □

It is natural to ask whether Theorem 4.1 holds in the case $r(x,y) \not\equiv$ const. We conjecture that the result holds for $m \leq 5$, but that for $m > 5$ the Butuzov expansion must be modified to obtain an asymptotic expansion of $D^m u$. The question is not studied further here.

It is of interest to combine the corner expansion (3.7) given in §3 with the boundary layer expansion provided by (2.10). Since the outer expansion U_{2n} is smooth, and the boundary layer expansions V_{2n}, W_{2n}, etc., are smooth, and since a consequence of Lemma 4.3 is that R_{2n} is smooth, it follows that the corner singularities of u at the lth vertex of Ω are contained in the corner layer terms z_i^l of $\tilde{u}_{2n}$. To analyze these corner singularities we may use the expansion (3.7). It is useful here to introduce singular functions that are specifically adapted to the operator N that defines the corner layer functions:

$$Nz(\xi,\eta) \equiv -z_{\xi\xi}(\xi,\eta) - z_{\eta\eta}(\xi,\eta) + r(0,0)z(\xi,\eta).$$

We define singular functions $\chi_k(\xi,\eta)$ as the solution to the problem

$$\begin{aligned} &-\Delta\chi_k + r(0,0)\chi_k = 0, \qquad \xi > 0, \quad \eta > 0, \\ &\chi_k(\xi,0) = 0, \qquad \chi_k(0,\eta) = \eta^{2k}, \\ &\chi_k \to 0 \quad \text{as } \rho \to \infty. \end{aligned} \tag{4.9}$$

Considered as a function on the unit square in the $\xi\eta$ plane, χ_k has a singularity only at the origin and

$$\Lambda_i(N\chi_k, \gamma\chi) \text{ is } \begin{cases} = 0, & i < k, \\ \neq 0, & i = k, \\ \text{not defined}, & i > k. \end{cases} \tag{4.10}$$

It may be shown that χ_k satisfies the inequalities

$$|D^l\chi_k(\xi,\eta)| \le \begin{cases} ce^{-r(0,0)\rho}, & l < 2k, \\ c[1+|\ln\rho|]e^{-r(0,0)\rho}, & l = 2k, \\ c\rho^{-(l-2k)}e^{-r(0,0)\rho}, & l > 2k. \end{cases} \tag{4.11}$$

Using these functions, we write the singular expansion of $z_i^1(\xi,\eta)$ as

$$z_i^1(\xi,\eta) = \sum_{k=1}^{m} \Lambda_k(Nz_i^1, \gamma z_i^1)\chi_k(\xi,\eta) + \zeta_m^1(\xi,\eta). \tag{4.12}$$

The remainder, ζ_m^1 has $2m+1$ continuous derivatives in the positive quadrant $\xi \ge 0$, $\eta \ge 0$ and satisfies

$$|D^l\zeta_k^1(\xi,\eta)| \le ce^{-r(0,0)\rho}, \qquad 0 \le l \le 2m+1. \tag{4.13}$$

We also write $\chi_k^{(1)}(\xi,\eta) = \chi_k(\xi,\eta)$, and in a similar manner we define singular functions $\chi_k^{(l)}$ pertaining to the other vertices of Ω.

We now formulate a result that expresses the interaction between the corner singularities of the problem and the singular perturbation behavior of the problem.

THEOREM 4.2. *Let u be the solution of* (2.1). *Suppose $r(x,y) \equiv$ const. Then*

$$u(x,y) = \sum_{l=1}^{4}\sum_{k=1}^{m} a_k^l(\varepsilon)\chi_k^{(l)} + V_{2n} + W_{2n} + \bar{V}_{2n} + \bar{W}_{2n} + S_m(x,y,\varepsilon), \tag{4.14}$$

where $a_k(\varepsilon)$ is a polynomial in ε of degree $2n$, and where the remainder S_m satisfies

$$|D^l S_m(x,y,\varepsilon)| \le c, \qquad 0 \le l \le 2m+1.$$

Proof. Inserting (4.12) into (2.10) we obtain (4.14) where

$$a_k^l(\varepsilon) = \sum_{i=0}^{2n} \varepsilon^i \Lambda_k^{(l)}(Nz_i^l, \gamma z_i^l),$$

$$S_j(x,y,\varepsilon) = U_{2n} + R_{2n} + \sum_{i,l} \varepsilon^i \zeta_i^l.$$

The inequality then follows from the properties of the functions that form S_m. □

As a corollary of Theorem 4.2, we obtain bounds on the derivatives of u that display both the parameter ε and the distance to the nearest corner of Ω. To state these bounds we define distance functions d_v and d_s measuring the distance to the nearest vertex of Ω and the nearest side of $\bar{\Omega}$ respectively by

$$d_v(x,y)^2 = \min\{x^2+y^2,\ (1-x)^2+y^2,\ x^2+(1-y)^2,\ (1-x)^2+(1-y)^2\}$$

$$d_s(x,y) = \min\{x, y, 1-x, 1-y\}.$$

We then have the following corollary.

COROLLARY. *Let u be the solution of* (2.1). *Suppose that $r(x,y) \equiv$ const. Then we have*

$$|D_{xy}^m u(x,y)| \le c + c\varepsilon^{-m}e^{-ad_s(x,y)/\varepsilon} + \begin{cases} ce^{-ad_v/\varepsilon}, & m = 1, \\ c[1+|\ln(d_v/\varepsilon)|]e^{-ad_v/\varepsilon}, & m = 2, \\ c(d_v/\varepsilon)^{-(m-2)}e^{-ad_v/\varepsilon} & m \ge 3. \end{cases}$$

Proof. The result follows from Theorem 4.2 and the bounds on the derivatives of the various functions that have been established. □

CONVEX FUNCTION OF A MEASURE OBTAINED BY HOMOGENIZATION*

FRANÇOISE DEMENGEL† AND TANG QI‡

Abstract. This paper defines and studies convex functions of a homogenized measure. These types of mathematical objects are Γ limit of integral functionals which depend on the deformation of the displacement of a material. This work has been done in view of its applications to homogenization in perfect plasticity.

Key words. integration theory via linear functionals, operations with distributions, yield criteria

AMS(MOS) subject classifications. 28C05, 46F10, 73E05

Introduction. This paper states mathematical results necessary for studying the homogenization for one kind of material, namely, elastic perfect plastic, for Hencky's law.

The theory of homogenization consists in assuming that the domain Ω occupied by the considered material is composed of a great number of identical cells of size ε. For $\varepsilon > 0$, P_ε is defined as the prehomogenized corresponding displacement problem, and P_ε^* as the stress problem. By letting ε tend to zero the domain Ω becomes almost homogeneous and the question is, in what sense P_ε converges to the homogenized problem, which will be defined later.

Variational mechanical problems for nonhomogeneous materials other than plasticity have been studied with theories of homogenization (cf. [3], [4]), but the functionals used were coercives on reflexive spaces. The main difficulty here lies in the fact that the "prehomogenized" energies are bounded only in L^1. This has motivated this first theoretical part. The homogenized energy $\int \bar{\Psi}(u)$ is defined not only as a functional, but also as the integral on the open set Ω *of a measure.* We show in § 1 that $\bar{\Psi}(u)$ is a measure that is absolutely continuous with respect to the measure $|e^D(u)|+|\operatorname{div} u|^2$. As Buttazo and Dal Mazo [4] did for homogenization of coercive problems on H^1, we state in § 2, the existence of a punctual function, called homogenized and denoted Ψ_{hom}, such that

$$\langle \bar{\Psi}(u), \varphi \rangle = \int \Psi_{\text{hom}}(e(u)(x))\varphi(x)\, dx,$$

when u is sufficiently regular (for example, for u in $H^1(\Omega)$). Moreover, Ψ_{hom} satisfies

$$c_0(|\xi^D|+|\operatorname{tr}\xi|^2-1) \leqq \Psi_{\text{hom}}(\xi) \leqq c_1(|\xi^D|+|\operatorname{tr}\xi|^2+1).$$

The theory of convex function of a measure, studied in [11] and [12], then allows the measure $\Psi_{\text{hom}}(e(u))$ to be defined when u belongs to $U(\Omega)=\{u \in L^1(\Omega),\ (u_{i,j}+u_{j,i})/2 \in M^1(\Omega)$, for all $i,j \in [1, N]$ and div $u \in L^2(\Omega)\}$. The central result of this paper then consists of showing that the measure $\Psi_{\text{hom}}(e(u))$ *coincides with* $\bar{\Psi}(u)$; in other words, the formula just above may be extended in a certain sense to functions of $U(\Omega)$:

$$\langle \bar{\Psi}(u), \varphi \rangle = \langle \Psi_{\text{hom}}(e(u)), \varphi \rangle.$$

This result will be crucial for stating (see [9]) the convergence of prehomogenized problems towards the homogenized one.

We conclude by giving an "explicit" expression of Ψ_{hom}, and by determining the convex set K_{hom}, which is the domain of $(\Psi_{\text{hom}})^* = (\Psi^*)_{\text{hom}}$. These results have been obtained before by Bouchitté [3], [2] for the gradient and by Tang Qi [19] for the strains, but our method seems to be more direct and uses the properties of convex functions of a measure.

1. The homogenized measure $\bar{\Psi}(u)$ for u in $U(\Omega)$. Let Ω be an open bounded set of $\mathbb{R}^N$, $N \geqq 2$, and let E be the space of symmetric tensors of order two on $\mathbb{R}^N$. When ξ belongs to E, its deviator ξ^D is defined by $\xi^D = \xi - (\text{tr } \xi / N)\,\text{Id}$, where $\text{tr } \xi = \sum_{i=1}^N \xi_{ii}$. We denote by Y the open N-simplex $]0, 1[^N$, and we suppose that Ψ is measurable and Y-periodic with respect to the first variable, convex in relation to the second one, and verifying that

$$\Psi \text{ is nonnegative}, \qquad \Psi(x, 0) = 0. \tag{1.1}$$

There exist some positive constants c_0, c_1, such that for every $\xi \in E$, for all $x \in \mathbb{R}^N$,

$$c_0(|\xi^D| + (\text{tr } \xi)^2 - 1) \leqq \Psi(x, \xi) \leqq c_1(|\xi^D| + (\text{tr } \xi)^2 + 1). \tag{1.2}$$

A useful consequence of (1.2) and the convexity of Ψ is the following. If $\text{tr } \xi = \text{tr } \eta$, then

$$|\Psi(x, \xi) - \Psi(x, \eta)| \leqq C_1(|\xi^d - \eta^d|). \tag{1.3}$$

We denote for a real $\varepsilon > 0$ by Ψ_ε the function

$$\Psi_\varepsilon(x, \varepsilon) = \Psi\left(\frac{x}{\varepsilon}, \xi\right). \tag{1.4}$$

Now we give more notation. $e(u)$ will denote for u in L^1 the deformation of u, i.e.,

$$e(u)_{ij} = \frac{u_{i,j} + u_{j,i}}{2} \quad \forall i, j \in [1, N] \tag{1.5}$$

(where the derivatives are taken in the sense of distributions). We define the spaces:

$$LU(\Omega) = \{u \in L^1(\Omega),\ e(u) \in L^1(\Omega, E),\ \text{div } u \in L^2(\Omega)\}, \tag{1.6}$$

$$U(\Omega) = \{u \in L^1(\Omega),\ e(u) \in M^1(\Omega, E),\ \text{div } u \in L^2(\Omega)\} \tag{1.7}$$

where $M^1(\Omega, E)$ denotes the space of bounded measures on Ω that take their values in E. Let us finally recall the characterization of Γ-limits (cf. [7], [8], [1]). If (X, τ) is a topological space satisfying the first axiom of countability, F_h is a sequence of functions from X into $\bar{\mathbb{R}}$, and u is an element of X, then

$$\lambda^- = \Gamma^- \underline{\lim}_{\substack{h \to 0 \\ v \to u}} F_h(v)$$

if and only if, for every sequence u_h converging to u in (X, τ),

(i) $\lambda^- \leqq \underline{\lim}\, F_h(u_h)$;

(ii) There exists a sequence u_h converging to u in (X, τ) such that $\lambda^- = \underline{\lim}\, F_h(u_h)$.

In a similar manner we define the $\Gamma\,\overline{\lim}$, by replacing $\underline{\lim}$ by $\overline{\lim}$ in the inequalities above. It is easy to see that $\Gamma^-\,\underline{\lim}\, F_h$ and $\Gamma^-\,\overline{\lim}\, F_h$ exist, since they may also be defined as

$$\Gamma^-\,\underline{\lim}\, F_h(u) = \inf_{v_h \to u} \left\{ \underline{\lim}_{h \to 0} F_h(v_h) \right\},$$

$$\Gamma^-\,\overline{\lim}\, F_h(u) = \inf_{v_h \to u} \left\{ \overline{\lim}_{h \to 0} F_h(v_h) \right\}.$$

A sequence F_h is said to be Γ convergent in u if and only if $(\Gamma^- \underline{\lim})\, F_h(u) = (\Gamma^- \overline{\lim}\, F_h)(u)$.

In the following definitions we will take $X = L^p(\Omega)$, where p is fixed in $]1, N/N-1[$ endowed with its strong topology.

Let us take φ in $\mathscr{C}(\bar{\Omega})$,[1] $\varphi \geqq 0$, u in $U(\Omega)$, and define the functional

$$F_\varepsilon(v, \varphi) = \begin{cases} \displaystyle\int \Psi\left(\frac{x}{\varepsilon}, e(v)\right)\varphi(x)\, dx & \text{if } v \in LU(\Omega), \\ +\infty & \text{if not} \end{cases} \tag{1.8}$$

[2]

and the following Γ-limit:

$$\langle \bar{\Psi}^-(u), \varphi\rangle = \Gamma^-(L^p) \underline{\lim_{\substack{\varepsilon \mapsto 0 \\ v \mapsto u}}} F_\varepsilon(v, \varphi) < +\infty, \qquad \langle \bar{\Psi}^+(u), \varphi\rangle = \Gamma^- \overline{\lim}\, F_\varepsilon(v, \varphi). \tag{1.9}$$

In the result above (Theorem 1.1(i)) we will see that the Γ limit of $F_\varepsilon(u, \varphi)$ exists for a subsequence, for every u, and $\varphi \geqq 0$, in $C(\bar{\Omega})$. We will then restrict to this subsequence and denote by $\langle \bar{\Psi}(u), \varphi\rangle$ the corresponding Γ limit.

THEOREM 1.1. (i) *There exists a subsequence ε' for which $\bar{\Psi}^-(u) = \bar{\Psi}^+(u) = \bar{\Psi}(u)$ for every u in $U(\Omega)$. Moreover, $\bar{\Psi}(u)$ may be extended as a bounded measure on Ω, absolutely continuous with respect to $|e^D(u)| + (\operatorname{div} u)^2$.*

(ii) *$\bar{\Psi}$ is a convex function of u.*

Proof. (i) We begin to show that for every u in $U(\Omega)$, $\bar{\Psi}^-(u)$ and $\bar{\Psi}^+(u)$ are Lipschitz with respect to $\varphi \geqq 0$ in $\mathscr{C}(\bar{\Omega})$. We proceed toward that aim in several steps. For convenience we give them only for $\bar{\Psi}^-(u)$, the changes for $\bar{\Psi}^+(u)$ being obvious.

Step 1. For every $\varphi \in \mathscr{C}(\bar{\Omega})$, $\varphi \geqq 0$,

$$\lim_{n \to +\infty} \left\langle \bar{\Psi}^-(u), \operatorname{Sup}\left(\varphi, \frac{1}{n}\right)\right\rangle = \langle \bar{\Psi}^-(u), \varphi\rangle.$$

Step 2. For every φ_1 and φ_2 in $\mathscr{C}^1(\bar{\Omega})$, φ_1 and $\varphi_2 \geqq 0$, we have

$$|\langle \bar{\Psi}^-(u), \varphi_1\rangle - \langle \bar{\Psi}^-(u), \varphi_2\rangle| \leqq C_2(u)|\varphi_1 - \varphi_2|_\infty.$$

Suppose for now that steps 1 and 2 have been proved, assume that φ_1 and φ_2 have been proved, and take φ_1 and φ_2 in $\mathscr{C}(\bar{\Omega})$, φ_1 and $\varphi_2 \geqq 0$. Define $\varphi_i^n = \operatorname{Sup}(\varphi_i, 1/n)$, for $i = 1, 2$. There exists $\bar{\varphi}_i^n \in \mathscr{C}^1(\bar{\Omega})$, $|\bar{\varphi}_i^n - \varphi_i^n| \leqq 1/2n$. Then $\theta_i^n = \bar{\varphi}_i^n - 1/2n$ verifies

$$0 \leqq \theta_i^n \leqq \varphi_i^n \leqq \theta_i^n + \frac{1}{n},$$

and then by step 1,

$$\begin{aligned} \langle \bar{\Psi}^-(u), \varphi_1\rangle &\leqq \langle \bar{\Psi}^-(u), \varphi_1^n\rangle \\ &\leqq \left\langle \bar{\Psi}^-(u), \theta_1^n + \frac{1}{n}\right\rangle \end{aligned}$$

(because $\langle \bar{\Psi}^-(u), \cdot\rangle$ is obviously increasing with respect to $\varphi \geqq 0$).

---

[1] The definition and results that follow are also valid for $\varphi \in \mathscr{C}(\Omega)$, φ bounded.

[2] It is well known that $LU(\Omega) \subset L^q(\Omega)$, for all $q \in [1, N/N-1]$.

By step 2 we then obtain

$$\langle\bar{\Psi}^-(u),\varphi_1\rangle \leqq \langle\bar{\Psi}^-(u),\theta_2^n\rangle + \left|\theta_1^n+\frac{1}{n}-\theta_2^n\right|_\infty$$
$$\leqq \langle\bar{\Psi}^-(u),\varphi_2^n\rangle + |\varphi_1^n-\varphi_2^n|_\infty + \frac{2}{n}$$
$$\leqq \langle\bar{\Psi}^-(u),\varphi_2\rangle + \frac{C_2(u)}{2n} + \frac{2}{n} + |\varphi_1-\varphi_2|_\infty.$$

n being arbitary, this proves the desired result, by changing φ_1 in φ_2.

Proof of step 1. Take $\delta>0$ and $\varphi\geqq 0$ in $\mathscr{C}(\Omega)$, $\delta<|\varphi|_\infty/2$. We easily have $\langle\bar{\Psi}^-(u),\varphi\rangle\leqq\langle\bar{\Psi}^-(u),\sup(\delta,\varphi)\rangle$. Let us take

$$\theta_\delta = \begin{cases} 1 & \text{on } \{x,\varphi(x)\geqq 2\delta\},\\ 0 & \text{on } \{x,\varphi(x)\leqq\delta\},\end{cases}$$

$0\leqq\theta_\delta\leqq 1$, $|\nabla\theta_\delta|_\infty\leqq C_3(\delta)$, $\theta_\delta\in\mathscr{C}^1(\Omega)$, and let $u_\varepsilon^\delta\in LU(\Omega)$,

$$\int\psi\left(\frac{x}{\varepsilon},e(u_\varepsilon^\delta)(x)\right)\varphi\leqq\langle\bar{\Psi}^-(u),\varphi\rangle+\delta,\qquad |u_\varepsilon^\delta-u|_{L^p}\leqq\frac{\delta}{C_3(\delta)}.$$

Now Theorem 3.4 of [21] shows that there exists $\bar{u}_\varepsilon^\delta\in LU(\Omega)$,

$$\left|\int_\Omega|e(\bar{u}_\varepsilon^\delta)|-\int_\Omega|e(u)|\right|\leqq\delta,$$
$$|\operatorname{div}\bar{u}_\varepsilon^\delta-\operatorname{div}u|_2\leqq\delta,$$
$$|\bar{u}_\varepsilon^\delta-u|_{L^p}\leqq\frac{\delta}{C_3(\delta)}.$$

Let us define $w_\varepsilon=u_\varepsilon\theta+\bar{u}_\varepsilon(1-\theta)$. (We drop the dependence on δ.) We have $w_\varepsilon\mapsto u$ in $L^p(\Omega)$, and $e(w_\varepsilon)=e(u_\varepsilon)\theta+e(\bar{u}_\varepsilon)(1-\theta)+(u_\varepsilon-\bar{u}_\varepsilon)\otimes\nabla\theta$. By a technical result of Giaquinta and Modica [14], there exists $z_\varepsilon\in W^{1,p}(\Omega)$ such that

$$\operatorname{div}z_\varepsilon=-\operatorname{tr}((u_\varepsilon-\bar{u}_\varepsilon)\otimes\nabla\theta),$$
$$z_{\varepsilon|\Gamma}=-\frac{1}{\Gamma}\int_\Omega\operatorname{tr}(u_\varepsilon-\bar{u}_\varepsilon)\otimes\nabla\theta,$$
$$|z_\varepsilon|_{W^{1,p}}\leqq C_4|(u_\varepsilon-\bar{u}_\varepsilon)\otimes\nabla\theta|_{L^p(\Omega)}\leqq C_4\delta$$

where the constant C_4 above depends only on N, Ω, and p.

We now define $v_\varepsilon=w_\varepsilon+z_\varepsilon$. We have

$$e(v_\varepsilon)=e(u_\varepsilon)\theta+(1-\theta)e(\bar{u}_\varepsilon)+e^D(z_\varepsilon)+((u_\varepsilon-\bar{u}_\varepsilon)\oplus\nabla\theta)^D$$

and then

$$\operatorname{div}v_\varepsilon=\theta_\delta\operatorname{div}u_\varepsilon+(1-\theta_\delta)\operatorname{div}\bar{u}_\varepsilon$$

so $v_\varepsilon\to v$ in $L^p(\Omega)$ and $v_\varepsilon\in LU(\Omega)$:

$$\int_\Omega|e(v_\varepsilon)-\theta e(u_\varepsilon)-(1-\theta)e(\bar{u}_\varepsilon)|=\int_\Omega|e^D(v_\varepsilon)-\theta e^D(u_\varepsilon)-(1-\theta)e^D(\bar{u}_\varepsilon)|$$
$$\leqq|e(z_\varepsilon)+\nabla\theta\otimes(u_\varepsilon-\bar{u}_\varepsilon)|_{L^1}$$
$$\leqq(C_4+1)\delta\,(\text{meas. }\Omega)^{1-1/p}$$
$$\leqq C_5\delta.$$

And then, using (1.3)

$$|\Psi(x)-\Psi(y)| \leqq C_1|x^D - y^D|,$$

$$\begin{aligned}\int \Psi\left(\frac{x}{\varepsilon}, e(v_\varepsilon)\right) \mathrm{Sup}\,(\varphi,\delta) &\leqq \int \Psi\left(\frac{x}{\varepsilon}, e(u_\varepsilon)\theta + (1-\theta)e(\bar{u}_\varepsilon)\right) \mathrm{Sup}\,(\varphi,\delta)\\ &\quad + C_5(u)\delta(|\varphi|_\infty + \delta)\\ &\leqq \int_{\varphi \geqq \delta} \Psi\left(\frac{x}{\varepsilon}, e(u_\varepsilon)\right)\theta_\delta\varphi + \int_{\varphi \leqq 2\delta} \Psi\left(\frac{x}{\varepsilon}, e(\bar{u}_\varepsilon)\right)\\ &\quad \cdot (1-\theta)\,\mathrm{Sup}\,(\varphi,\delta) + C_5\delta(|\varphi|_\infty + \delta)\\ &\leqq \int \Psi\left(\frac{x}{\varepsilon}, e(u_\varepsilon)\right)(x)\varphi + 2\delta C_1\\ &\quad \cdot \left(\int (|e^D(\bar{u}_\varepsilon)| + |\mathrm{div}\,\bar{u}_\varepsilon|^2) + \mathrm{meas.}\,\Omega\right) + C_5\delta(|\varphi|_\infty + \delta)\end{aligned}$$

and then

$$\langle \bar{\Psi}^-(u), \mathrm{Sup}\,(\varphi,\delta)\rangle \leqq \langle \bar{\Psi}^-(u), \varphi\rangle + 2\delta C_1(\|u\|_{LU(\Omega)} + \delta + \mathrm{meas.}\,\Omega) + C_5\delta(|\varphi|_\infty + \delta).$$

This implies the desired result, δ being arbitrary.

Proof of step 2. We want then to show that for every u in $U(\Omega)$, $\bar{\Psi}^-(u)$ and $\bar{\Psi}^+(u)$ are Lipschitz with respect to φ, when $\varphi \in W^{1,\infty}(\Omega)$, for the norm of $\mathscr{C}(\Omega)$. Toward that aim, let $\delta > 0$ be given, φ_1 and φ_2 in $W^{1,\infty}(\Omega)$, $\varphi_1, \varphi_2 \geqq 0$, and let u_ε be in $LU(\Omega)$, such that $u_\varepsilon \mapsto u$ in $L^p(\Omega)$ and

$$\underline{\lim} \int \Psi\left(\frac{x}{\varepsilon}, e(u_\varepsilon)\right)(x)\varphi_1(x) \leqq \langle \bar{\Psi}^-(u), \varphi_1\rangle + \delta.$$

By Theorem (3.4) of [21], there exists $\bar{u}_\varepsilon \in LU(\Omega)$, $\bar{u}_\varepsilon \mapsto u$ in $L^p(\Omega)$, $\mathrm{div}\,\bar{u}_\varepsilon \mapsto \mathrm{div}\,u$ in $L^2(\Omega)$ and $\int_\Omega |e^D(\bar{u}_\varepsilon)| \mapsto \int_\Omega |e^D(u)|$. (We will denote it for convenience as the tight convergence in $U(\Omega)$.) We define $\theta = \inf(1, (\varphi_1/(\varphi_2+\delta)))$. It is easy to see that $\theta \in W^{1,\infty}$. Define $w_\varepsilon = u_\varepsilon\theta + \bar{u}_\varepsilon(1-\theta)$. We have $w_\varepsilon \mapsto u$ in $L^p(\Omega)$, and $e(w_\varepsilon) = e(u_\varepsilon)\theta + e(\bar{u}_\varepsilon)(1-\theta) + (u_\varepsilon - \bar{u}_\varepsilon)\otimes\nabla\theta$. By a technical result of Giaquinta and Modica [14], there exists $z_\varepsilon \in W^{1,p}(\Omega)$ such that

$$\begin{aligned}&\mathrm{div}\, z_\varepsilon = -\mathrm{tr}\,((u_\varepsilon - \bar{u}_\varepsilon)\otimes\nabla\theta),\\ &z_{\varepsilon|\Gamma} = -\frac{1}{\Gamma}\int_\Omega \mathrm{tr}\,(u_\varepsilon - \bar{u}_\varepsilon)\otimes\nabla\theta,\\ &|z_\varepsilon|_{W^{1,p}} \leqq C_4|(u_\varepsilon - \bar{u}_\varepsilon)\otimes\nabla\theta|_{L^p(\Omega)}\end{aligned}$$

where the constant above depends only on N, Ω, and p. Since $(u_\varepsilon - \bar{u}_\varepsilon) \mapsto 0$ in L^p, we may choose ε sufficiently small to have

$$|z_\varepsilon|_{W^{1,p}} \leqq C_4\delta.$$

We now define $v_\varepsilon = w_\varepsilon + z_\varepsilon$. We have

$$\begin{aligned}\int_\Omega |e(v_\varepsilon) - \theta e(u_\varepsilon) - (1-\theta)e(\bar{u}_\varepsilon)| &= \int_\Omega |e^D(v_\varepsilon) - \theta e^D(u_\varepsilon) - (1-\theta)e^D(\bar{u}_\varepsilon)|\\ &\leqq |e(z_\varepsilon) + \nabla\theta\otimes(u_\varepsilon - v_\varepsilon)|_{L^1}\\ &\leqq (C_4+1)\delta(\mathrm{meas.}\,\Omega)^{1-1/p}\\ &\leqq C_5\delta.\end{aligned}$$

Then, by (1.3),

$$|\Psi(x)-\Psi(y)| \leqq C_1|x^D-y^D|,$$

$$\int \Psi\left(\frac{x}{\varepsilon}, e(v_\varepsilon)\right)\varphi_2 \leqq \int \Psi\left(\frac{x}{\varepsilon}, e(u_\varepsilon)\theta+(1-\theta)e(\bar{u}_\varepsilon)\right)\varphi_2 + C_5\delta|\varphi_2|.$$

This implies

$$\begin{aligned}\langle\bar{\Psi}^-(u), \varphi_2\rangle &\leqq \underline{\lim} \int \Psi\left(\frac{x}{\varepsilon}, e(v_\varepsilon)\right)\varphi_2 \\ &\leqq \underline{\lim} \int \Psi\left(\frac{x}{\varepsilon}, e(u_\varepsilon)\right)\theta\varphi_2 + \int \Psi\left(\frac{x}{\varepsilon}, e(\bar{u}_\varepsilon)\right)(1-\theta)\varphi_2 + C_5\delta|\varphi_2|_\infty.\end{aligned}$$

We now remark that $\theta\varphi_2 \leqq \varphi_1$ and obtain

$$\begin{aligned}\langle\bar{\Psi}^-(u), \varphi_2\rangle &\leqq \underline{\lim} \int \Psi\left(\frac{x}{\varepsilon}, e(u_\varepsilon)\right)\varphi_1 + \overline{\lim} \int \Psi\left(\frac{x}{\varepsilon}, e(\bar{u}_\varepsilon)\right)(1-\theta)\varphi_2 + C_5\delta|\varphi_2| \\ &\leqq \langle\bar{\Psi}^-(u), \varphi_1\rangle + C_1\,\overline{\lim} \int_\Omega (|e^D(\bar{u}_\varepsilon)| + (\operatorname{div}\bar{u}_\varepsilon)^2+1)(|\varphi_2-\varphi_1|_\infty+\delta) \\ &\quad + C_5\delta|\varphi_2|_\infty \\ &\leqq \bar{\Psi}^-(u, \varphi_1) + C_1\int_\Omega (|e^D(u)| + (\operatorname{div} u)^2+1)|\varphi_2-\varphi_1|_\infty + C_6\delta.\end{aligned}$$

Since δ is arbitrary, we obtain that

$$\bar{\Psi}^-(u, \varphi_2) \leqq \bar{\Psi}^-(u, \varphi_1) + C_1\|u\|_{LU(\Omega)}|\varphi_2-\varphi_1|_\infty$$

where $\|u\|_{LU(\Omega)} = \int_\Omega (|e^D(u)| + (\int_\Omega (\operatorname{div} u)^2)^{1/2}$.

This ends the proof of Steps 1 and 2 and thus of the Lipschitz property of $\bar{\Psi}^-$. The analogous is true for $\bar{\Psi}^+$, following the same arguments. Now let $\mathscr{D} = \{\varphi_i\}$ be a countable dense subset in $\mathscr{C}_0^+(\Omega)$. Fix j in $\mathbb{N}$; there exists a subsequence $\sigma_j(\varepsilon)$ such that the corresponding $F_{\sigma_j}(\cdot, \varphi_j)$ are Γ-convergent. (This is a consequence of a Buttazzo compacity result, since L^p possesses a countable base.) By a diagonal process we then obtain that there exists a subsequence $\sigma(\varepsilon)$ such that for every u in $\mathscr{U}(\Omega)$, we have

$$\begin{aligned}\langle\bar{\Psi}^+(u), \varphi_j\rangle &= \langle\bar{\Psi}^-(u), \varphi_j\rangle \\ &= \Gamma_- \lim_{\substack{\varepsilon\to 0 \\ v\mapsto u}} \int \Psi\left(\frac{x}{\sigma(\varepsilon)}, e(v)(x)\right)\varphi_j(x).\end{aligned}$$

Then take u in $U(\Omega)$ and φ in $\mathscr{C}(\bar{\Omega})$, $\varphi \geqq 0$, for all $\varepsilon > 0$; there exists φ_j in $\mathscr{D}$, such that $|\varphi_j - \varphi|_\infty < \varepsilon/C_1(u)$. We then have

$$\begin{aligned}|\langle\bar{\Psi}^-(u), \varphi\rangle - \langle\bar{\Psi}^+(u), \varphi\rangle| &\leqq |\langle\bar{\Psi}^-(u), \varphi\rangle - \langle\bar{\Psi}^-(u), \varphi_j\rangle| + |\langle\bar{\Psi}^+(u), \varphi\rangle - \langle\bar{\Psi}^+(u), \varphi_j\rangle| \\ &\leqq 2C_1(u)|\varphi-\varphi_j|_\infty \\ &\leqq 2\varepsilon.\end{aligned}$$

With ε being arbitrary, this implies that for the subsequence $\sigma(\varepsilon)$, $\langle\bar{\Psi}^-(u), \varphi\rangle = \langle\bar{\Psi}^+(u), \varphi\rangle$, for every φ in $\mathscr{C}(\bar{\Omega})$, $\varphi \geqq 0$. We denote the common value $\bar{\Psi}^-(u) = \bar{\Psi}^+(u)$ by $\bar{\Psi}(u)$. Now let us show that $\bar{\Psi}(u)$ may be extended as a bounded measure on Ω.

For the first time we show the additivity of $\bar{\Psi}(u)$ on $W^{1,\infty}(\Omega)$. Let $\varphi_i \geqq 0$ $(i=1,2)$ be in $W^{1,\infty}(\Omega)$, and u_ε be in $LU(\Omega)$, such that $u_\varepsilon \mapsto u$ in $L^1(\Omega)$, $\int \Psi(x/\varepsilon, e(u_\varepsilon))(\varphi_1+\varphi_2)(x) \to \langle \bar{\Psi}(u), \varphi_1+\varphi_2\rangle$. By the definition of Γ^- limits,

$$\langle \bar{\Psi}(u), \varphi_i\rangle \leqq \underline{\lim}_{\varepsilon\mapsto 0} \int \Psi\left(\frac{x}{\varepsilon}, e(u_\varepsilon)\right)\varphi_i \quad \text{for } i=1,2,$$

and then $\sum_i \langle \bar{\Psi}(u), \varphi_i\rangle \leqq \langle \bar{\Psi}(u), \varphi_1+\varphi_2\rangle$. For the reverse inequality, with $\delta>0$ being given, let $u_\varepsilon^{i\delta}$ be in $LU(\Omega)$, such that $u_\varepsilon^{i\delta}$ tends to u in $L^1(\Omega)$ and $\int \Psi(x/\varepsilon, e(u_\varepsilon^{i\delta}))\varphi_i \leqq \langle \bar{\Psi}(u), \varphi_i\rangle + \delta$, for $i=1, 2$, and $\bar{u}_\varepsilon$ as in the proof of the Lipschitz property of $\bar{\Psi}$, and define

$$u_\varepsilon = \sum_{i=1,2} \frac{\varphi_i u_\varepsilon^{i\delta}}{\sum_i \varphi_i + \delta} + \frac{\delta \bar{u}_\varepsilon}{\sum_i \varphi_i + \delta}.$$

It is easy to see that $u_\varepsilon \in LD(\Omega)$ and that $u_\varepsilon \to u$ in $L^p(\Omega)$. The calculus of $e(u_\varepsilon)$ gives

$$e(u_\varepsilon) = \sum_i \theta_i e(u_\varepsilon^{i\delta}) + \frac{\delta}{\sum_i \varphi_i + \delta} e(\bar{u}_\varepsilon) + (u_\varepsilon^1 - \bar{u}_\varepsilon) \oplus \nabla\theta + (u_\varepsilon^2 - \bar{u}_\varepsilon) \oplus \theta_2$$

where $\theta_i = \varphi_i/(\sum_i \varphi_i + \delta)$ for $i=1,2$.

By the technical result of Giaquinta and Modica [14] already cited, let w_ε be in $W^{1,p}(\Omega)$, such that

$$\begin{aligned}
&\operatorname{div} w_\varepsilon = \operatorname{tr} \lambda_\varepsilon,\\
&w_\varepsilon \cdot n_{|\gamma} = -1/|\Gamma| \int_\Omega \operatorname{tr} \lambda_\varepsilon,\\
&|w_\varepsilon|_{W^{1,p}} \leqq C_4 |(u_\varepsilon^1 - \bar{u}_\varepsilon) \otimes \nabla\theta_1|_{L^p} + |(u_\varepsilon^2 - \bar{u}_\varepsilon) \otimes \theta_2|_{L^p}.
\end{aligned}$$

We may choose ε sufficiently small in order to have the last quantity on the right above less than δ. We then define $v_\varepsilon = u_\varepsilon + w_\varepsilon$. We have $v_\varepsilon \mapsto u$ in $L^p(\Omega)$, and

$$\begin{aligned}
|e(v_\varepsilon) - \theta_1 e(u_\varepsilon^1) - \theta_2 e(u_\varepsilon^2)| &= |e^D(v_\varepsilon) - \theta_1 e^D(u_\varepsilon^1) - \theta_2 e^D(u_\varepsilon^2)|\\
&\leqq |e(w_\varepsilon)| + |(1-\theta_1-\theta_2)e(\bar{u}_\varepsilon)| + |\nabla\theta_1 \otimes (u_\varepsilon^1 - \bar{u}_\varepsilon)| + |\nabla\theta_2 \otimes (u_\varepsilon^2 - \bar{u}_\varepsilon)|.
\end{aligned}$$

We get

$$\begin{aligned}
\langle \bar{\Psi}(u), \varphi_1+\varphi_2\rangle &\leqq \underline{\lim} \int \Psi\left(\frac{x}{\varepsilon}, \theta_1 e(u_\varepsilon^1) + \theta_2 e(u_\varepsilon^2)\right)(\varphi_1+\varphi_2) + (C_2+2)\delta|\varphi_1+\varphi_2+\delta|_\infty\\
&\quad + \left(\int_\Omega |e^D(\bar{u}_\varepsilon)| + (\operatorname{div} \bar{u}_\varepsilon)^2\right)\delta\\
&\leqq \underline{\lim} \int \Psi\left(\frac{x}{\varepsilon}, \theta_1 e(u_\varepsilon^1)\right)(\varphi_1+\varphi_2)\\
&\quad + \overline{\lim} \int \Psi\left(\frac{x}{\varepsilon}, \theta_2 e(u_\varepsilon^2)\right)(\varphi_1+\varphi_2) + C_6\delta\\
&\leqq \langle \bar{\Psi}(u), \varphi_1\rangle + \langle \bar{\Psi}(u), \varphi_2\rangle + C_6\delta.
\end{aligned}$$

With δ being arbitrary, this ends the proof of additivity for $\bar{\Psi}(u)$ on $W^{1,\infty}(\Omega) \cap \mathscr{C}^+(\Omega)$, and then on $\mathscr{C}^+(\bar{\Omega})$, by density, since $\bar{\Psi}(u)$ is Lipschitz with respect to φ for the usual norm of $\mathscr{C}(\bar{\Omega})$.

We now extend $\bar{\Psi}(u)$ to $\mathscr{C}(\Omega)$ by setting

$$\langle \bar{\Psi}(u), \varphi\rangle = \langle \bar{\Psi}(u), \varphi_1\rangle - \langle \bar{\Psi}(u), \varphi_2\rangle \tag{1.10}$$

where $\varphi = \varphi_1 - \varphi_2$ is every decomposition of φ in the difference of two nonnegative functions in $\mathscr{C}^+(\bar{\Omega})$. That this does not depend on the decomposition of φ is a consequence of $\bar{\Psi}(u)$'s additivity. Let us now show that $\bar{\Psi}(u)$ is absolutely continuous with respect to $|e^D(u)| + (\operatorname{div} u)^2$. For that purpose, we use a result of approximation in [21]. For u in $U(\Omega)$, there exists u_ε in $LU(\Omega)$, u_ε tends to u in $L^1(\Omega)$, $|e^D(u_\varepsilon)| \mapsto |e^D(u)|$ tightly on Ω, and $\operatorname{div} u_\varepsilon \mapsto \operatorname{div} u$ in $L^2(\Omega)$. By definition of $\bar{\Psi}(u)$,

$$\begin{aligned} \langle \bar{\Psi}(u), \varphi \rangle &\leqq \underline{\lim} \int \Psi\left(\frac{x}{\varepsilon}, e(u_\varepsilon)\right)\varphi \\ &\leqq \underline{\lim} \int c_1(|e^D(u_\varepsilon)| + (\operatorname{div} u_\varepsilon)^2 + 1)\varphi \qquad (1.11) \\ &= \int c_1(|e^D(u)| + (\operatorname{div} u)^2 + 1)\varphi. \end{aligned}$$

(ii) It is easy to show that $\bar{\Psi}$ is a convex function with respect to u. Take φ in $\mathscr{C}_0(\Omega)$, $\varphi \geqq 0$, a real t in $[0,1]$, and functions u_ε^i in $LU(\Omega)$, with u_ε^i tending to u^i in $L^p(\Omega)$ $(i = 1, 2)$ such that $\int \Psi(x/\varepsilon, e(u_\varepsilon^i))\varphi \mapsto \langle \bar{\Psi}(u^i), \varphi \rangle$. By the convergence of $tu_\varepsilon^1 + (1-t)u_\varepsilon^2$ toward u in $L^1(\Omega)$ and the properties of the Γ-limit,

$$\begin{aligned} \langle \bar{\Psi}(tu^1 + (1-t)u^2), \varphi \rangle &\leqq \underline{\lim} \int \Psi\left(\frac{x}{\varepsilon}, te(u_\varepsilon^1) + (1-t)e(u_\varepsilon^2)\right)\varphi \\ &\leqq \overline{\lim} \int t\Psi\left(\frac{x}{\varepsilon}, e(u_\varepsilon^1)\right)\varphi + \overline{\lim} \int (1-t)\Psi\left(\frac{x}{\varepsilon}, e(u_\varepsilon^2)\right)\varphi \\ &= t\langle \bar{\Psi}(u^1), \varphi \rangle + (1-t)\langle \bar{\Psi}(u^2), \varphi \rangle. \end{aligned}$$

PROPOSITION 1.1. *Let u be in $LU(\Omega)$. There exists u_ε in $LU(\Omega)$, u_ε tends to u tightly in $LU(\Omega)$, $u_\varepsilon = u_{|\Gamma}$, and*

$$\int_\Omega \Psi\left(\frac{x}{\varepsilon}, e(u_\varepsilon)\right) \to \int_\Omega \bar{\Psi}(u).$$

COROLLARY. *For u in $LU(\Omega)$, there exists u_ε in $LU(\Omega)$, $u_\varepsilon \mapsto u$ tightly in $LU(\Omega)$, $u_\varepsilon = u_{|\Gamma}$ and $\Psi(x/\varepsilon, e(u_\varepsilon)) \mapsto \bar{\Psi}(u)$ tightly on Ω.*

Proof. Assume that u belongs to $LU(\Omega)$. We are going to show that for every $\delta > 0$ there exists $u_{\varepsilon,\delta}$ in $LU(\Omega)$, such that

$$|u_{\varepsilon,\delta} - u|_1 < \delta, \qquad (1.12)$$

$$\int_\Omega \Psi\left(\frac{x}{\varepsilon}, e(u_{\varepsilon,\delta})\right) \leqq \int_\Omega \bar{\Psi}(u) + \delta, \qquad (1.13)$$

$$u_{\varepsilon,\delta} = u_{|\Gamma}. \qquad (1.14)$$

Let us show (1.12)-(1.14). For $\delta > 0$ given, let κ_δ be a compact subset in Ω such that $\int_{\Omega \setminus \kappa_\delta} |e(u)| < \delta$ and a function φ_δ in $\mathscr{C}_0(\Omega)$, $\varphi_\delta = 1$ on κ_δ, $0 \leqq \varphi_\delta \leqq 1$. By definition of $\int_\Omega \bar{\Psi}(u)$, there exists $v_{\varepsilon,\delta}$ in $LU(\Omega)$ such that

$$\int_\Omega |v_{\varepsilon,\delta} - u|_p < \frac{\delta}{|\nabla \varphi_\delta|_\infty},$$

$$\int_\Omega \Psi\left(\frac{x}{\varepsilon}, e(v_{\varepsilon\delta})\right) \leqq \int_\Omega \bar{\Psi}(u) + \delta.$$

This last inequality and (1.2) imply that $v_{\varepsilon\delta}$ is bounded in $LU(\Omega)$ and then is weakly convergent toward u in $U(\Omega)$. We define $z_{\varepsilon,\delta}=\varphi_\delta v_{\varepsilon,\delta}+(1-\varphi_\delta)u$. By the result of Giaquinta and Modica [14], let $w_{\varepsilon,\delta}$ be in $W^{1,p}$ for some $p\in]1, N/N-1[$

$$\operatorname{div}\tilde{w}_{\varepsilon\delta}=\nabla\varphi_\delta\cdot(v_{\varepsilon\delta}-u)-\frac{1}{|\Omega|}\int_\Omega(\nabla\varphi_\delta\cdot(v_{\varepsilon\delta}-u)),$$

$$\tilde{w}_{\varepsilon\delta}=0_{|\Gamma},$$

$$|\tilde{w}_{\varepsilon\delta}|_{W^{1,p}}\leqq 2c|(\nabla\varphi_\delta)(v_{\varepsilon\delta}-u)|_p$$

and define $u_{\varepsilon\delta}=v_{\varepsilon\delta}-w_{\varepsilon\delta}$; $\operatorname{div}u_\varepsilon=\varphi_\delta\operatorname{div}v_{\varepsilon\delta}+(1-\varphi_\delta)\operatorname{div}u+(1/|\Omega|)\int_\Omega\nabla\varphi_\delta\cdot(v_{\varepsilon\delta}-u)$ tends to $\operatorname{div}u$ in $L^2(\Omega)$. Let us calculate $e(u_\varepsilon)$:

$$\begin{aligned}e(u_\varepsilon)&=\varphi_\delta e(v_{\varepsilon\delta})+(1-\varphi_\delta)e(u)+(\nabla\varphi_\delta)\otimes(v_{\varepsilon\delta}-u)-e(w_{\varepsilon\delta})\\&=\varphi_\delta e(v_{\varepsilon\delta})+(1-\varphi_\delta)e(u)+[\nabla\varphi_\delta\otimes(v_{\varepsilon\delta}-u)]^D-e^D(w_{\varepsilon\delta})\\&\quad+\frac{1}{|\Omega|}\left(\int_\Omega\nabla\varphi_\delta\cdot(v_{\varepsilon\delta}-u)\right)\mathrm{Id}.\end{aligned}$$

Using the convexity of Ψ and (1.2) and (1.3), we get

$$\begin{aligned}\psi\left(\frac{x}{\varepsilon},e(u_\varepsilon)\right)&\leqq\int_\Omega\varphi_\delta\Psi\left(\frac{x}{\varepsilon},e(v_{\varepsilon\delta})\right)+\int_\Omega(1-\varphi_\delta)\Psi\left(\frac{x}{\varepsilon},e(u)\right)\\&\quad+C_1\left|\int_\Omega|e^D(\tilde{w}_{\varepsilon\delta})|+\int_\Omega|\nabla\varphi_\delta\otimes(v_{\varepsilon\delta}-u)^D|\right|\\&\quad+C_1\left[\frac{1}{N|\Omega|}\int_\Omega\nabla\varphi_\delta\cdot(v_{\varepsilon\delta}-u)\right]^2|\Omega|\\&\leqq\int_\Omega\bar{\Psi}(u)+\delta+\int_{\Omega\setminus\kappa_\delta}|e(u)|+C_1\left[2C\delta+\delta+\frac{1}{N^2}\delta^2|\Omega|\right]\\&\leqq\int_\Omega\bar{\Psi}(u)+C_2\delta,\end{aligned}$$

which ends the proof of Proposition 1.1.

Proof of the corollary. Let u be in $LU(\Omega)$ and u_ε as in Proposition 1.1. Since u_ε is tightly convergent toward u, $\Psi(x/\varepsilon, e(u_\varepsilon))$ is (due to (1.2)) a bounded sequence in $L^1(\Omega)$, we may then extract from it a subsequence, still denoted u_ε such that $\Psi(x/\varepsilon, e(u_\varepsilon))\mapsto\nu$ vaguely. By the definition of the Γ-limit $\bar{\Psi}(u)$, we have for every φ in $\mathscr{C}^0(\Omega)$, $\varphi\geqslant 0$,

$$\begin{aligned}\langle\bar{\Psi}(u),\varphi\rangle&\leqslant\underline{\lim}\int\Psi\left(\frac{x}{\varepsilon},e(u_\varepsilon)(x)\right)\varphi(x)\,dx\\&=\int\nu\varphi,\end{aligned}$$

and then $\bar{\Psi}(u)\leqslant\nu$. On the other hand, by lower semicontinuity we have an open set

$$\begin{aligned}\int\nu&\leqslant\underline{\lim}\int\Psi\left(\frac{x}{\varepsilon},e(u_\varepsilon)(x)\right)\varphi(x)\,dx\\&=\int\bar{\Psi}(u)\end{aligned}$$

(by definition of u_ε). We finally obtain $\nu = \bar{\Psi}(u)$; thus every subsequence of $\Psi(x/\varepsilon, e(u_\varepsilon)(x))$ converges to $\nu = \bar{\Psi}(u)$ and then all the sequence tends to it.

Furthermore, we will need the following locally Lipschitz result for $\bar{\Psi}$. Let $\mathcal{O}$ be an open set in Ω. We denote for u in $LU(\Omega)$ by $\|u\|_\partial$ the quantity $\|u\|_\mathcal{O} = \int_\mathcal{O} |e^D(u)| + (\int_\mathcal{O} |\text{div } u|^2)^{1/2}$. We then have the following result.

PROPOSITION 1.2. *For every $R>0$ and for every $(u, v) \in LU(\Omega)$ subject to $\int_\Omega |e^D(v)| + (\text{div } v)^2$ less than R, for every $\mathcal{O}$ an open set in Ω, we have*

$$\left| \int_\mathcal{O} (\bar{\Psi}(u) - \bar{\Psi}(v)) \right| \leqq C_1(3R+4)\|u-v\|_\mathcal{O}. \tag{1.15}$$

Proof.

- Suppose first that $\|u-v\|_\mathcal{O} > 1$. Then

$$\begin{aligned} \left| \int_\mathcal{O} (\bar{\Psi}(u) - \bar{\Psi}(v)) \right| &\leqq \int_\mathcal{O} (\bar{\Psi}(u) + \bar{\Psi}(v)) \\ &\leqq 2C_1(R+1) \\ &\leqq \|u-v\|_\mathcal{O} 2C_1(R+1). \end{aligned}$$

- Assume now that $0 < \|u-v\|_\mathcal{O} \leqq 1$ and define $w = u + (v-u)/(\|u-v\|_\mathcal{O})$; we have $v = u + \|u-v\|_\mathcal{O}(w-u)$, and by the convexity of $\bar{\Psi}$,

$$\begin{aligned} \bar{\Psi}(v) - \bar{\Psi}(u) &\leqq \|u-v\|_\mathcal{O}(\bar{\Psi}(w) - \bar{\Psi}(u)) \\ &\leqq \|u-v\|_\mathcal{O}(|\bar{\Psi}(w)| + |\bar{\Psi}(u)|) \\ &\leqq \|u-v\|_\mathcal{O}(3C_1R+4) \end{aligned}$$

$$\left[\text{because } \int_\mathcal{O} \bar{\Psi}(w) \leqq C_1 \left(\int_\mathcal{O} |e^D(w)| + \int |\text{div } w|^2 \right) \right.$$

$$\leqq C_1 \left(\int_\mathcal{O} |e^D(u)| + 1 + 2((\text{div } u)^2 + 1) \right)$$

$$\left. \leqq C_1(2R+3) \right].$$

By changing u and v we get the desired result.

- We finally deal with the case where $\|u-v\|_\mathcal{O} = 0$, and show that $\int_\mathcal{O} (\bar{\Psi}(u) - \bar{\Psi}(v)) = 0$. Toward that aim, by the definition of $\int_\mathcal{O} \bar{\Psi}(v)$, let φ_δ be in $\mathcal{C}_0(\Omega)$, $0 \leqq \varphi_\delta \leqq 1$, with a compact support in Ω, such that $\int_\mathcal{O} \bar{\Psi}(v)(1-\varphi_\delta) < \delta$. Also, let u_ε be in $LU(\Omega)$, subject to $u_\varepsilon \to u$ in $L^p(\Omega)$, and $\int \Psi(x/\varepsilon, e(u_\varepsilon)(x))\varphi_\delta \to \int \bar{\Psi}(u)\varphi_\delta$. The sequence $u_\varepsilon + v - u$ converges toward v, and then

$$\begin{aligned} \langle \bar{\Psi}(v), \varphi_\delta \rangle &\leqq \underline{\lim} \int \Psi\left(\frac{x}{\varepsilon}, e(u_\varepsilon + v - u)\right)(x)\varphi_\delta \\ &\leqq \underline{\lim} \int \Psi\left(\frac{x}{\varepsilon}, e(u_\varepsilon)(x)\right)\varphi_\delta(x)\, dx + C_1 \int (|e^D(v-u)| + |\text{div } (v-u)|^2)\varphi_\delta \\ &\leqq \int_\mathcal{O} \bar{\Psi}(u)\varphi_\delta + 0 \\ &\leqq \int_\mathcal{O} \bar{\Psi}(u). \end{aligned} \tag{1.16}$$

with δ being arbitrary, we obtain the desired conclusion by changing u and v.

We conclude this section by giving two useful results. One is a lemma of "commutativity" of $\bar{\Psi}$ with translation, which is due to the periodicity of Ψ. The other may be considered as a Jensen's inequality for the measure $\bar{\Psi}(u)$.

LEMMA 1.1. *Assume that u belongs to $U(\Omega)$, φ is in $\mathscr{C}_0(\Omega)$, and $y \in \mathbb{R}^N$ is such that $|y| < d(\mathrm{Supp}\ \varphi, \partial\Omega)$. Then*

$$\langle \bar{\Psi}(u)(\cdot - y), \varphi\rangle = \langle \bar{\Psi}(u), \varphi(\cdot + y)\rangle. \quad [3] \tag{1.17}$$

Proof. We will obtain (1.17) by showing the inequality

$$\langle \bar{\Psi}(u)(\cdot - y), \varphi\rangle \leqq \langle \bar{\Psi}(u), \varphi(\cdot + y)\rangle$$

for φ in $\mathscr{C}_0(\Omega) \cap W^{1,\infty}(\Omega)$, $\varphi \geqq 0$, and y, $|y| < d(\mathrm{Supp}\ \varphi, \partial\Omega)$; the reverse is obtained by considering the functions $u(\cdot + y)$ and $\varphi(\cdot - y)$ in place of u and φ. So let φ and y be as above. The function $\varphi(\cdot + y)$ is nonnegative in $\mathscr{C}_0(\Omega)$. Let us then take u_ε in $LU(\Omega)$, u_ε tending to u in L^1 strongly, and $\int \Psi(x/\varepsilon, e(u_\varepsilon)(x))\varphi(x+y)\,dx \to \langle \bar{\Psi}(u), \varphi(\cdot + y)\rangle$. Let $y_\varepsilon^i = [y_i/\varepsilon]$.[4] We easily have that $y_\varepsilon = (y_\varepsilon)_i \in \mathbb{Z}^N$, $\varepsilon \vec{y}_\varepsilon \mapsto \vec{y}$, $|\varepsilon \vec{y}_\varepsilon| < d(\mathrm{Supp}^t \cdot \varphi, \partial\Omega)$, and we let $\bar{u}_\varepsilon$ be in $LU(\Omega)$, $\bar{u}_\varepsilon \to u$ in $LU(\Omega)$ tightly, and $\theta_\varepsilon = \varphi(\cdot + y_1)/(\delta + \varphi(\cdot + \varepsilon y_\varepsilon))$. For ε sufficiently small, θ_ε is less than 1. We define $v_\varepsilon = \theta_\varepsilon u_\varepsilon + (1 - \theta_\varepsilon) v_\varepsilon$ and $\tilde{u}_\varepsilon = v_\varepsilon + w_\varepsilon$ in a way we have already used twice:

$$\begin{aligned}
&\operatorname{div} w_\varepsilon = -\operatorname{tr}(u_\varepsilon - v_\varepsilon) \otimes \nabla \theta_\varepsilon, \\
&w_{\varepsilon|\Gamma} = -\frac{1}{|\Gamma|} \int \operatorname{tr}(u_\varepsilon - v_\varepsilon) \otimes \nabla \theta_\varepsilon, \\
&|w_\varepsilon|_{W^{1,p}} \leqq C |\operatorname{tr}(u_\varepsilon - v_\varepsilon) \otimes \nabla \theta_\varepsilon|_{L^p}.
\end{aligned}$$

It is easy to see that $|\nabla \theta_\varepsilon|_\infty$ is bounded independently with respect to ε, and then we may choose ε sufficiently small to obtain $|w_\varepsilon|_{W^{1,p}} \leqq \delta$. By definition of Γ-limits, we may write, since $\tilde{u}_\varepsilon \to u$ in L^p and $\tilde{u}_\varepsilon(\cdot - \varepsilon y_\varepsilon) \mapsto u(\cdot - y)$:

$$\begin{aligned}
\langle \bar{\Psi}(u(\cdot - y)), \varphi\rangle &\leqq \underline{\lim} \int \Psi\left(\frac{x}{\varepsilon}, e(\tilde{u}_\varepsilon)(x - \varepsilon y_\varepsilon)(\varphi(x))\right) \\
&\leqq \underline{\lim} \int \Psi\left(\frac{x + \varepsilon y_\varepsilon}{\varepsilon}, e(\tilde{u}_\varepsilon)(x)(\varphi(x) + \varepsilon y_\varepsilon)\right) \\
&\leqq \underline{\lim} \int \Psi\left(\frac{x}{\varepsilon}, e(u_\varepsilon)(x)\theta_\varepsilon(x)(\varphi(x) + \varepsilon y_\varepsilon)\right) \\
&\quad + \overline{\lim} \int \Psi\left(\frac{x}{\varepsilon}, e(\bar{u}_\varepsilon)(x)(1 - \theta_\varepsilon)(x)\varphi(x + \varepsilon y_\varepsilon)\right) \\
&\quad + \overline{\lim}\, C_1 \int (|e^D(w_\varepsilon)| + |\nabla \theta_\varepsilon \otimes (u_\varepsilon - \bar{u}_\varepsilon)|)\varphi(x + \varepsilon y_\varepsilon) \\
&\leqq \underline{\lim} \int \Psi\left(\frac{x}{\varepsilon}, e(u_\varepsilon)(x)\right)\varphi(x + y) + C_1\delta \\
&\quad + C_1 \int (|e^D(u)| + (\operatorname{div} u)^2) \sup_x |\varphi(x + \varepsilon y_\varepsilon) - \varphi(x + y)| \\
&\leqq 2C_1\delta + \langle \bar{\Psi}(u), \varphi(\cdot - y)\rangle.
\end{aligned}$$

With δ being arbitrary, we have the result of the lemma.

[3] For a measure ν we define its shifted $\nu(\cdot + y)$ by $\langle \nu(\cdot + y), \varphi\rangle = \langle \nu(\cdot), \varphi(\cdot - y)\rangle$ for all φ in $\mathscr{C}_0(\Omega)$, $y < d(\mathrm{Supp}\ \varphi, \partial\Omega)$.

[4] For a real ξ, $[\xi]$ denotes the entire part of ξ.

We now give a result that we will need in proving the fundamental result of Theorem 2.1 in the next section.

PROPOSITION 1.3. *Let ρ be in $\mathscr{C}_0^\infty(\mathscr{R}^N)$, $\rho \geqq 0$, $\int \rho = 1$, and φ in $\mathscr{C}_0(\Omega)$, $\varphi \geqq 0$, such that*

$$\mathrm{Supp}^t \cdot \varphi + \mathrm{Supp}^t \cdot \rho \subset \Omega.$$

Then for all u in $U(\Omega)$,

$$\langle \bar{\Psi}(u * \rho), \varphi \rangle \leqq \langle \rho * \bar{\Psi}(u), \varphi \rangle.$$

Proof. With $\delta > 0$ being given, let us define $(\Omega_i^\delta)_i$ a partition of Ω into disjointed universally measurable sets, such that meas. $(\Omega_i^\delta) < \delta$. Using the Mean Value Theorem on Ω_i^δ, we are allowed to choose y_i^δ in Ω_i^δ, such that $\rho(y_i^\delta) = 1/|\Omega_i^\delta| \int_{\Omega_i^\delta} \rho(x)\, dx$, so the equality $\sum_i |\Omega_i^\delta| \rho(y_i^\delta) = 1$ holds. It is well known that the function $u^\delta = \sum_i |\Omega_i^\delta| \rho(y_i^\delta) u(\cdot - y_i^\delta)$ is strongly convergent towards $\rho * u$ in $L^1(\Omega)$, so by lower semicontinuity of the Γ-limit, and using the convexity of $\bar{\Psi}$, we have

$$\begin{aligned} \langle \bar{\Psi}(\rho * u), \varphi \rangle &\leqq \varliminf_{\delta \mapsto 0} \langle \bar{\Psi}(u^\delta), \varphi \rangle \\ &\leqq \varliminf_{\delta \mapsto 0} \sum_i |\Omega_i^\delta| \rho(y_i^\delta) \langle \bar{\Psi}(u(\cdot - y_i^\delta)), \varphi \rangle. \end{aligned}$$

We now apply Lemma 1.1 for $y = y_i^\delta$, and use the uniform convergence of $\sum_i |\Omega_i^\delta| \rho(y_i^\delta) \varphi(\cdot + y_i^\delta)$ toward $\check{\rho} * \varphi$, to obtain

$$\begin{aligned} \langle \bar{\Psi}(\rho * u), \varphi \rangle &\leqq \varliminf_{\delta \mapsto 0} \sum_i |\Omega_i^\delta| \rho(y_i^\delta) \varphi(\cdot + y_i^\delta) \\ &= \varliminf_{\delta \mapsto 0} \left\langle \bar{\Psi}(u), \sum_i |\Omega_i^\delta| \rho(y_i^\delta) \varphi(\cdot + y_i^\delta) \right\rangle \\ &= \langle \bar{\Psi}(u), \check{\rho} * \varphi \rangle. \end{aligned}$$

With the left-hand side of the inequality above being nothing but $\langle \rho * \bar{\Psi}(u), \varphi \rangle$, this ends the proof of (i).

2. Integral representation of $\bar{\Psi}(u)$. In this section we want to show the existence of a function Ψ_{hom}, defined on E, such that for all φ in $\mathscr{C}_0(\Omega)$ we have

$$\langle \bar{\Psi}(u), \varphi \rangle = \int \Psi_{\mathrm{hom}}(e(u)(x)) \varphi(x)\, dx$$

when u is sufficiently regular (C^1, for example). The convexity of Ψ_{hom} and its behavior at infinity will permit us, using the theory of convex function of a measure (cf. [11], [12]), to define the measure $\Psi_{\mathrm{hom}}(e(u))$ when u belongs to $U(\Omega)$. The central result of this section will be that

$$\Psi_{\mathrm{hom}}(e(u)) = \bar{\Psi}(u)$$

for every u in $U(\Omega)$.

The existence of the punctual function Ψ_{hom} is a consequence of Proposition 2.1 below.

PROPOSITION 2.1. *There exists a function h on $\mathbb{R}^N \times E$, measurable with respect to x and uniformly locally Lipschitz with respect to the second variable, such that*

$$\langle \bar{\Psi}(u), \varphi \rangle = \int h(x, e(u)(x)) \varphi(x)\, dx \tag{2.1}$$

for every u in $LU(\Omega)$.

Proof. This proof borrows ideas from Lemma 4.1 of [4]. Inequality (1.11) implies, for every $u \in LU(\Omega)$, that $\bar{\Psi}(u)$ is absolutely continuous with respect to the Lebesgue measure. We then denote by h_u the function in $L^1(\Omega)$ defined by

$$\langle \bar{\Psi}(u), \varphi \rangle = \int h_u(x)(\varphi(x))\, dx.$$

Let $\mathcal{P}$ be the set of functions of the form $\xi \cdot x$ where ξ belongs to E, with coordinates in $\mathbb{Q}$. There exists a subset M in Ω, such that meas. $(\Omega - M) = 0$, which verifies the following. If $x \in M$ and $u \in \mathcal{P}$, we define

$$h(x, \xi) = \lim_{\delta \mapsto 0} \frac{1}{|B(x, \delta)|} \int_{B(x,\delta)} h_u(x)\, dx$$

where $u = \xi \cdot x \cdot h$ may be extended to E by continuity. It is clear that $h(x, \cdot)$ is a convex function. Moreover, by (1.11) we have

$$\begin{aligned} |h(x, \xi)| &\leqq \lim_{\delta \mapsto 0} \frac{1}{|B(x, \delta)|} \int_{B(x,\delta)} \bar{\Psi}(u) \\ &\leqq C_1(|e^D(u)| + (\operatorname{div} u)^2 + 1) \\ &\leqq C_1(|\xi^D| + (\operatorname{tr} \xi)^2 + 1). \end{aligned}$$

Then, as in the proof of Proposition 1.2, the functional $\int_A h(x, e(u)(x))\, dx$ verifies the local Lipschitz Property (1.15), where $\bar{\Psi}(u)$ and $\bar{\Psi}(v)$ are replaced by $h(\cdot, e(u)(\cdot))$ and $h(\cdot, e(v)(\cdot))$. Let us then take $u \in LU(\Omega)$, $\delta > 0$, and (A_k) some open disjoint subsets subject to $\cup \overline{A_k} = \Omega$ and meas. $(\partial A_k) = 0$, $(\xi_k)_k \in E$ with rational coordinates, such that

$$\int_\Omega \left| e^D(u) - \sum_k \xi_k^D \chi_{A_k} \right| + \left(\int_\Omega \left[\operatorname{div} u - \sum_k (\operatorname{tr} \xi_k) \chi_{A_k} \right]^2 \right)^{1/2} < \delta.$$

Let us note that we may choose the ξ_k to have in addition

$$\sum_k (|\xi_k^D| + (\operatorname{tr} \xi_k)^2)(\text{meas. } A_k) \leqq \int_\Omega (|e^D(u)| + |\operatorname{div} u|^2) = R.$$

We then obtain

$$\begin{aligned} \left| \int_\Omega h(x, e(u)) - \sum \int_{A_k} h(x, \xi_k) \right| &\leqq \sum \left| \int_{A_k} h(x, e(u)) - h(x, \xi_k) \right| \\ &\leqq \left(\sum_k \int_{A_k} |e^D(u) - \sum \xi_k^D \chi_{A_k}| \right. \\ &\qquad \left. + \left(\int_\Omega \left(\operatorname{div} u - \sum (\operatorname{tr} \xi_k) \chi_{A_k} \right)^2 \right)^{1/2} \right) C_1(3R + 4)\delta. \end{aligned}$$

Now we denote by v_k a function in $LU(\Omega)$, such that $v_k(x)|_{A_k} = \xi_k \cdot x|_{A_k}$, which verifies $\int_\Omega |e^D(v_k)| + |\operatorname{div} v_k|^2 \leqq R$. By Proposition 1.2 for $\bar{\Psi}$ and by using meas. $\partial A_k = 0$, we may write

$$\left| \int_{A_k} \bar{\Psi}(u) - \bar{\Psi}(v_k) \right| \leqq C_1(3R + 4) \| u - v_k \|_{A_k}.$$

Furthermore, by summing on k:

$$\left| \int_\Omega \bar{\Psi}(u) - \sum_k \int_{A_k} \bar{\Psi}(v_k) \right| \leqq C_1(3R + 4)\delta$$

using the fact that $\int_{A_k} \bar{\Psi}(v_k) = \int_{A_k} h(x, \xi_k)$, we have finally obtained that

$$\left| \int_\Omega \bar{\Psi}(u) - \int_\Omega h(x, e(u)(x)) \right| \leqq C_1(3R+4)2\delta.$$

with δ being arbitrary, this ends the proof of Proposition 2.1.

PROPOSITION 2.2. *The function h defined in Proposition 2.1 does not depend on $x \in \mathbb{R}^N$. In other words, there exists a function Ψ_{hom}, defined on E such that*

$$\langle \bar{\Psi}(u), \varphi \rangle = \int \Psi_{\text{hom}}(e(u)(x))\varphi(x)\, dx \tag{2.2}$$

for every u in $LU(\Omega)$.

Proof. It suffices to show that h is locally constant with respect to the first variable. Let φ be in $\mathscr{C}_0(\Omega)$, and y, $|y| < d(\text{Supp } \varphi, \partial\Omega)$. By using Proposition 2.1 and Lemma 1.1 we get

$$\begin{aligned} \int h(x+y, e(u)(x))\varphi(x)\, dx &= \int h(x, e(u_{-y})(x))\varphi_{-y}(x)\, dx \\ &= \langle \bar{\Psi}(u_{-y}), \varphi_{-y} \rangle \\ &= \langle \bar{\Psi}(u), \varphi_{-y+y} \rangle \\ &= \langle \bar{\Psi}(u), \varphi \rangle. \end{aligned}$$

□

Now we want to show that the integral representation formula of $\bar{\Psi}$ may be extended to the u's in $U(\Omega)$. In other words, we want to show Theorem 2.1.

THEOREM 2.1. *Assume that u belongs to $U(\Omega)$; then for every φ in $\mathscr{C}_0(\Omega)$,*

$$\langle \bar{\Psi}(u), \varphi \rangle = \langle \Psi_{\text{hom}}(e(u)), \varphi \rangle \tag{2.3}$$

where $\Psi_{\text{hom}}(e(u))$ is taken as function of a measure (cf. [11], [12]).

Proof. To show (2.3) let us first remark that

$$\Psi_{\text{hom}}(e(u)) \geqq \bar{\Psi}(u).$$

Indeed, by an approximation result that we have used already [21], there exists u_n in $LU(\Omega)$, u_n tends to u in $L^1(\Omega)$, and $\Psi_{\text{hom}}(e(u_n)) \to \Psi_{\text{hom}}(e(u))$ vaguely. Propositions 2.1 and 2.2 give, for φ in $\mathscr{C}_0(\Omega)$,

$$\langle \bar{\Psi}(u_n), \varphi \rangle = \int \Psi_{\text{hom}}(e(u_n))(x)\varphi(x)\, dx,$$

so by lower semicontinuity of the Γ-limits,

$$\begin{aligned} \langle \bar{\Psi}(u), \varphi \rangle &\leqq \underline{\lim} \langle \bar{\Psi}(u_n), \varphi \rangle \\ &= \underline{\lim} \int \Psi_{\text{hom}}(e(u_n)(x))\varphi(x)\, dx \\ &= \int \Psi_{\text{hom}}(e(u)(x))\varphi(x)\, dx. \end{aligned}$$

For the reverse inequality let us take $\varphi \geqq 0$, φ in $\mathscr{C}_0(\Omega)$, $n \in \mathbb{N}$, such that $1/n < d(\text{Supp } \varphi, \partial\Omega)$ and $\rho_n(x) = n^N \rho(nx)$, where ρ is in $\mathscr{C}_0^\infty(\mathbb{R}^N)$, $\int \rho = 1$, $0 \leqq \rho \leqq 1$, $u_n = \rho_n * u$. It is shown in [11] that u_n tends to u and $\int \Psi_{\text{hom}}(e(u_n))\varphi$ tends to $\int_\Omega \Psi_{\text{hom}}(e(u))\varphi$.

Using Proposition 1.3, we then write

$$\begin{aligned}\int \Psi_{\text{hom}}(e(u))\varphi &= \lim_{n\to+\infty} \int \Psi_{\text{hom}}(e(u_n)(x))\varphi(x)\,dx \\ &= \lim_{n\to+\infty} \langle \bar{\Psi}(u_n), \varphi\rangle \\ &= \lim_{n\to+\infty} \langle \bar{\Psi}(\rho_n * u), \varphi\rangle \\ &\leqq \underline{\lim}_{n\to+\infty} \langle \rho_n * \bar{\Psi}(u), \varphi\rangle.\end{aligned}$$

From the classical fact that $\rho_n * \bar{\Psi}(u)$ is vaguely convergent toward $\bar{\Psi}(u)$, the conclusion follows.

Let us remark that it is now possible to extend the approximation result in Proposition 1.2 to the u's in $U(\Omega)$. This may be written as follows.

PROPOSITION 2.3. *Assume that u belongs to $U(\Omega)$. Then there exists u_ε in $LU(\Omega)$, such that*

$$\begin{aligned}&u_\varepsilon \to u \quad \text{in } L^1(\Omega),\\ &u_\varepsilon = u_{|\Gamma},\\ &\operatorname{div} u_\varepsilon \to \operatorname{div} u \quad \text{in } L^2(\Omega) \text{ weakly},\\ &\int \Psi\left(\frac{x}{\varepsilon}, e(u_\varepsilon)\right) \to \int \Psi_{\text{hom}}(e(u)).\end{aligned}$$

Proof. Let $\delta > 0$ be given, and u be in $U(\Omega)$. By an approximation result in [21], there exists v in $LU(\Omega)$ such that $|v-u| < \delta$, $|\operatorname{div} v - \operatorname{div} u|_{L^2(\Omega)} < \delta$, $|\int_\Omega |e^D(u)| - |e^D(v)|| \leqq \delta$, $v = u_{|\Gamma}$, and $|\int \Psi_{\text{hom}}(e(v)) - \Psi_{\text{hom}}(e(u))| < \delta$. By applying Proposition 1.2 to v, we obtain the desired result.

3. An explicit expression of Ψ_{hom}. This section is devoted to the explicit expression of Ψ_{hom} for a particular subsequence. It involves a new method that uses "lower semicontinuity" for convex functions of a measure. The expression we find is

$$\Psi_{\text{hom}}(\xi) = \inf_{u \in LU_{\text{per}}(Y)} \int \Psi(x, \xi + e(u)) \tag{3.1}$$

where $LU_{\text{per}}(Y)$ will be defined later. Formula (3.1) has been given by Tang Qi [19] and Bouchitte [3] for the gradient, but their proofs use, respectively, penalization and dual methods. Before showing (3.1), we need some preliminaries on periodic measures that we did not find in the literature (but they must exist!).

3.1. Preliminaries on periodic measures.

DEFINITION 3.1. We denote by $M^1_{\text{per}}(Y)$ the space of the measures μ in $\mathbb{R}^N$ that verify the property

$$\int_{\mathbb{R}^N} \mu\varphi = \int \mu\varphi_{\vec{j}} \tag{3.2}$$

for every φ continuous with a compact support in Y, $\vec{j} \in \mathbb{Z}^N$, and where $\varphi_{\vec{j}}(x) = \varphi(x + \vec{j})$.

Remark 3.1. Of course, a measure in $M^1_{\text{per}}(Y)$ that is not identically zero cannot be a bounded measure on $\mathbb{R}^N$.

Remark 3.2. This notion coincides with that of usual periodicity when μ is a function. Moreover, $\mu \in M^1_{\text{per}}(Y) \Rightarrow |\mu| \in M^1_{\text{per}}(Y)$.

Remark 3.3. μ is a Y-periodic measure if and only if it is a Y-periodic distribution and also a measure. The if part directly results from Definition 3.1; the only if part is a consequence of Proposition 3.1(i).

PROPOSITION 3.1. (i) *Formula* (3.3) *may be extended to functions* φ *in* $\mathscr{C}(\mathbb{R}^N, X)$, *Y periodic, in the sense that*

$$\int_Y \mu \cdot \varphi = \int_{Y+\vec{j}} \mu \cdot \varphi \quad \textit{for all } \vec{j} \textit{ in } \mathbb{Z}^N.$$

(ii) $$\int_B |\mu| = \int_{B+\vec{j}} |\mu|,$$

for every Borel subset B in $\mathbb{R}^N$, *and for all* $\vec{j}$ *in* $\mathbb{Z}^N$.

Proof. (i) Using Remark 3.2, we may assume that μ is nonnegative. Let us then take a nonnegative function φ in $\mathscr{C}(\mathbb{R}^N, X)$ that is Y-periodic, and a function Ψ in $\mathscr{C}_0(\mathbb{R}^N)$ with compact support in Y, $0 \leqq \Psi \leqq \varphi$, such that $\int_Y \mu\varphi \leqq \int_Y \mu\Psi + \delta$. By applying (1.26) and remarking that $\Psi_{-\vec{j}}$ belongs to $\mathscr{C}_0(Y+\vec{j})$ and $\Psi_{-\vec{j}} \leqq \varphi_{-\vec{j}} = \varphi$, we have

$$\begin{aligned}\int_Y \mu\varphi &\leqq \int_{\mathbb{R}^N} \mu\Psi + \delta \\ &= \int_{\mathbb{R}^N} \mu\Psi_{\vec{j}} + \delta \\ &\leqq \int_{Y+\vec{j}} \mu\varphi + \delta.\end{aligned}$$

The reverse inequality may of course be shown by the same process.

(ii) We begin to show (3.4) when B is a subset of Y and first of all when B is open. We assume once more that μ is nonnegative, $\mathcal{O}$ is an open set in Y, δ is a positive number, and φ is in $\mathscr{C}_0(Y)$, $0 \leqq \varphi \leqq 1_\Omega$ and $\int_{\mathcal{O}} \mu\varphi \geqq \int_{\mathcal{O}} \mu - \delta$. The function $\varphi_{\vec{j}}$ is in $\mathscr{C}_0(\mathcal{O}\backslash\vec{j})$, $0 \leqq \varphi_{\vec{j}} \leqq 1_{\mathcal{O}\backslash\vec{j}}$ so that

$$\begin{aligned}\int_{\mathcal{O}\backslash\vec{j}} \mu &\geqq \int \mu\varphi_{\vec{j}} \\ &= \int \mu\varphi \\ &\geqq \int_{\mathcal{O}} \mu - \delta\end{aligned}$$

with δ being arbitrary, we get the half part of (3.4) for $\mathcal{O}$. By changing $\mathcal{O}$ in $\mathcal{O}+\vec{j}$ and $\vec{j}$ in $-\vec{j}$, we obtain the desired result. Now let K be a compact subset of Y, a positive number, and a function φ in $\mathscr{C}_0(Y)$, $\varphi = 1$ on K such that

$$\int \mu\varphi \leqq \int_{K^\mu} + \delta.$$

The function $\varphi_{+\vec{j}}$ is compactly supported in $Y\backslash\vec{j}$ and $\varphi_{\vec{j}} = 1$ on $K\backslash\vec{j}$. So by definition of $\int_{K\backslash\vec{j}} \mu$

$$\int_{K\backslash\vec{j}} \mu \leqq \int \mu\varphi_{\vec{j}} = \int \mu\varphi \leqq \int_K \mu + \delta.$$

With δ being arbitrary, we get

$$\int_{K\setminus\vec{j}} \mu \leqq \int_K \mu$$

and by a now classical argument

$$\int_K \mu = \int_{K\setminus\vec{j}} \mu.$$

Finally, let us consider a Borel subset B in Y. By definition of $\mu(B)$,

$$\mu(B) = \inf_{\mathcal{O}\supset B} \mu(\mathcal{O}).$$

So let $\mathcal{O}$ be an open subset in Y such that $\mathcal{O}\supset B$ and $\mu(\mathcal{O})\leqq\mu(B)+\delta$. The open set $\mathcal{O}\setminus\vec{j}$ contains $B\setminus\vec{j}$; thus

$$\begin{aligned}\mu(B\setminus\vec{j}) &\leqq \mu(\mathcal{O}\setminus\vec{j})\\ &= \mu(\mathcal{O})\\ &\leqq \mu(B)+\delta.\end{aligned}$$

With δ being arbitrary and by the usual process, we obtain

$$\mu(B) = \mu(B\setminus\vec{j}).$$

Let us now deal with the general case of a Borel set in $\mathbb{R}^N$. It is easy to find a partition $(B_i)_{i\in\mathbb{N}}$ of B in Borel subsets in $\mathbb{R}^N$, and $\vec{j}_i$ in $\mathbb{Z}^N$ such that $B_i\setminus\vec{j}_i\subset Y$. By the additivity of μ on disjoint measurable sets and by the result above for measurable subsets in Y, we get

$$\begin{aligned}\mu(B) &= \sum_i \mu(B_i)\\ &= \sum \mu(B_i-\vec{j}_i)\\ &= \sum \mu((B_i-\vec{j}_i)+(\vec{j}+\vec{j}_i))\\ &= \sum \mu(B_i+\vec{j})\\ &= \mu(B+\vec{j}).\end{aligned} \tag{3.3}$$

PROPOSITION 3.2. *Assume that* $\mu\in M^1_{\text{per}}(Y)$, $\vec{y}\in\,]0,1[^N$ *is such that* $\int_{\partial(y+Y)}|\mu|=0$, *and define* $]0,1\}_i$ *as*

$$]0,1\}_i = \begin{cases}]0,1] & \text{if } y_i>0,\\ ]0,1[& \text{if } y_i=0.\end{cases} \tag{3.4}$$

Then

$$\int_{\vec{y}_0+Y}\mu = \int_{\prod_i]0,1\}_i}\mu. \tag{3.5}$$

Proof. We prove (3.5) by induction on N. For $N=1$ we have to show that for $\alpha\in\,]0,1]$ and for μ in $M^1_{\text{per}}(]0,1[)$, such that $\int_{\{\alpha\}}|\mu|=0$,

$$\int_{]\alpha,\alpha+1[}\mu = \int_{]0,1]}\mu.$$

Toward that aim we write, using Proposition 3.2(ii),

$$\int_{]\alpha,\alpha+1[} \mu = \int_{]0,1]} \mu + \int_{]1,\alpha+1[} \mu$$
$$= \int_{]0,1]} \mu + \int_{]0,\alpha[} \mu$$

and, since μ has no mass on α,

$$\int_{]0,\alpha+1[} \mu = \int_{]0,\alpha[} \mu + \int_{]\alpha,\alpha+1[} \mu.$$

So we get (3.5) for $N=1$. Now let us suppose that (3.5) has been proved for all ν in $M^1_{\text{per}}(]0,1[^{N-1})$, and let μ be in $M^1_{\text{per}}(]0,1[^N)$, and $\vec{y}$ in $]0,1[^N$. We define $\mu_N \in M^1_{\text{per}}(]0,1[)$ by

$$\mu_N(\cdot) = \int_{\vec{y}_N+]0,1[^{N-1}} \mu(x_1, \cdots, x_{N+1})$$

(where $\vec{y}_N = \vec{y} - Y_N \vec{e}_N$). By applying (3.5) to μ_N for $N=1$ we obtain

$$\int_{\vec{y}_N+]0,1[^N} \mu = \int_{\vec{y}_N+]0,1[} \mu_N = \int_{]0,1]} \mu_N$$
$$= \int_{\prod]y_i,y_{i+1}[\times]0,1\}_N} \mu(x_1, \cdots, x_N)$$
$$= \int_{\prod_{1\le i\le N-1}]y_i,y_{i+1}[} \left[\int_{]0,1\}_N} \mu(x_1, \cdots, x_N) \right].$$

Let us now define the measure ν in $M^1_{\text{per}}(]0,1[^{N-1})$ by the formula

$$\langle \nu, \varphi \rangle = \int \mu \varphi(x_1, \cdots, x_{N-1}) \otimes 1_{]0,1[}$$

for every φ in $\mathscr{C}_0(]0,1[^N)$. By applying the induction hypothesis to ν we get

$$\int_{\prod_{1\le i\le N-1}]y_i,y_{i+1}[} \nu = \int_{\prod_{1\le i\le N-1}]0,1]} \nu$$
$$= \int_{\prod_{1\le i\le N-1}]0,1\}_i} \int_{]0,1\}_N} \nu$$
$$= \int_{\prod_{1\le i\le N-1}]0,1\}_i} \mu,$$

which ends the proof of Proposition 3.2.

Remark 3.4. Assume that Ψ is a continuous function defined on X, which is at most linear at infinity, i.e., $|\Psi(\xi)| \le k_1(1+|\xi|)$, for all $\xi \in X$, and such that $\Psi_\infty(\xi) = \lim_{t\to+\infty} (\Psi(t\xi)/t)$ exists in X. Then $\Psi(\mu)$ may be defined as in [14] and [15] by the formula

$$\Psi(\mu) = \Psi \circ g\, dx + \Psi_\infty(\mu^s),$$

where $\mu = g\, dx + \mu^s$ is the Lebesgue decomposition of μ, μ^s being singular. When μ is Y-periodic it is obvious that g and μ^s are Y-periodic, so $\Psi(\mu)$ is too. The same result still holds if we assume that Ψ is convex but not necessarily at most linear at infinity (see [12]) and may be obtained by the use of a duality formula [12]. We now give a result of the approximation in $M^1(Y)$, for a topology related to Ψ.

PROPOSITION 3.3. *Let Ψ be a convex function greater than or equal to zero that is at most linear at infinity, and let μ be in $M^1_{\text{per}}(Y)$. Then there exists u_n in $\mathscr{C}^\infty(\mathbb{R}^N)$, Y periodic, such that*

$$|u_n| \to |\mu| \quad \text{vaguely on } \mathbb{R}^N,$$

$$\Psi(u_n) \to \Psi(\mu) \quad \text{vaguely on } \mathbb{R}^N,$$

$$\int_Y |u_n| \to \int_{Y_1} |\mu|, \qquad \int_Y \Psi(u_n) \to \int_{Y_1} \Psi(\mu)$$

where $Y_1 =]0, 1[^N$.

Proof. Let ρ be in $\mathscr{C}_0^\infty(]-1, +1[^N)\rho \geqq 0, \int \rho = 1, \rho(0) = 1, m \in \mathbb{N}, \rho_m(x) = m^N \rho(mx)$, and $u_m = \rho_m * \mu$. It is easy to see by the definition of $M^1_{\text{per}}(Y)$ that $\rho_m * \mu$ is Y-periodic. Moreover, $|\rho_m * \mu|$ is vaguely convergent toward μ, and by Lemma 2.3 in [11], $\Psi(u_m)$ is vaguely convergent to $\Psi(\mu)$ on $\mathbb{R}^N$. Now let y_0 be in $]0, 1[^N$, such that $\int_{\partial(y_0+Y)} |\mu| = 0$; we have

$$\int_Y \Psi(u_m) = \int_{y_0+Y} \Psi(u_m) \to \int_{y_0+Y} \psi(\mu) = \int_{Y_1} \Psi(\mu),$$

$$\int_Y |u_m| = \int_{y_0+Y} |u_m| \to \int_{y_0+Y} |\mu| = \int_{Y_1} |\mu|,$$

which ends the proof of Proposition 3.3.

3.2. An explicit expression of Ψ_{hom}. The convex set K_{hom}. In this section we give an explicit calculation method of the function Ψ_{hom} for a particular subsequence $\sigma(\varepsilon)$, namely, the sequence $1/n$.

Let us now give several definitions:

$$LU_{\text{per}}(Y) = \{u \in LU_{\text{loc}}(\mathbb{R}^N),\ u(x + \vec{j}) = u(x),$$
$$\text{for almost every } x \text{ in } \mathbb{R}^N \text{ and } \vec{j} \text{ in } \mathbb{Z}^N\};$$

$$BD_{\text{per}}(Y) = \{u \in BD_{\text{loc}}(\mathbb{R}^N),\ u(x + \vec{j}) = u(x)$$
$$\text{for almost every } x \text{ in } \mathbb{R}^N \text{ and } \vec{j} \text{ in } \mathbb{Z}^N\};$$

$$U_{\text{per}}(Y) = \{u \in BD_{\text{per}}(Y),\ \text{div } u \in L^2(\mathbb{R}^N)\}.$$

The internal and external traces for functions of BD, LU, U have been defined by Suquet [17] and Temam [21]. We remark that functions of $LU_{\text{per}}(Y)$ must not have discontinuities on ∂Y. On the contrary, functions of $BD_{\text{per}}(Y)$ are allowed to have one, although the Y-periodicity implies that the external trace $\gamma_+ u$ on some face of Y must be equal to the internal trace $\gamma_- u$ on the opposite face (functions in $U_{\text{per}}(Y)$ must verify, in addition, $u \cdot n^+ = u \cdot n^- / \partial Y$.

By the study made in the first two sections, we know that there exists a subsequence $\sigma(1/n)$ (which we will denote $1/n$ for simplicity) for which the functionals $F_{1/n}(v, \cdot)$ are Γ-convergent to the measure $\Psi_{\text{hom}}(e(u))$, for all $v_n \mapsto u$ in $U(\Omega)$. To show the expression of Ψ_{hom} given in the introduction of § 3, we will need the three lemmas below. Note that the expression found for $\Psi_{\text{hom}}(\xi)$ does not depend on σ. We then may say that the entire sequence $F_{1/n}(\cdot, \varphi)$ is Γ-convergent toward $\Psi_{\text{hom}}(e(u))$.

LEMMA 3.1. *Assume that $\xi \in E$, and define the problem*

$$\inf P_{\text{hom}}(\xi) = \inf_{u \in LU_{\text{per}}(Y)} \left\{ \frac{1}{|Y|} \int_{Y_1} \Psi_{\text{hom}}(\xi + e(u)) \right\}.$$

Then

$$\inf P_{\text{hom}}(\xi) = \Psi_{\text{hom}}(\xi).$$

LEMMA 3.2. *Let $P_n(\xi)$ be the variational problem defined as*

$$\inf P_n(\xi) = \inf_{u \in LU_{\text{per}}(Y)} \left\{ \frac{1}{|Y|} \int_Y \Psi(nx, \xi + e(u)) \right\}.$$

Then

$$\inf P_n(\xi) = \inf P_1(\xi) \quad \forall n \in \mathbb{N}.$$

LEMMA 3.3.

$$\underline{\lim}_{n \to +\infty} \inf P_n(\xi) = \overline{\lim}_{n \to +\infty} \inf P_n(\xi)$$
$$= \inf P_{\text{hom}}.$$

Equation (3.1) follows obviously from these three lemmas. It remains to show them.

Proof of Lemma 3.1. (i) Let ξ be in E and u in $LU_{\text{per}}(Y)$. The equality $\int_Y e(u) = 0$, and the convexity of Ψ_{hom} imply that

$$\Psi_{\text{hom}}(\xi) = \Psi_{\text{hom}} \left\{ \int_Y (\xi + e(u)) \right\}$$
$$\leqq \int_Y \Psi_{\text{hom}}(\xi + e(u))$$
$$= \int_Y \Psi_{\text{hom}}(\xi + e(u)).$$

The reverse inequality is obtained by setting $u = 0$ in the infimum.

(ii) We may suppose without loss of generality that $\xi = 0$. Let u be in $LU_{\text{per}}(Y)$, and u_m as in the proof of Proposition 3.3, i.e., $u_m \in LU_{\text{per}}(Y) \cap \mathscr{C}^\infty(\mathbb{R}^N)$, u_m tends to u in $L^1_{\text{loc}}(\mathbb{R}^N)$, and $|e(u_m)| \to |e(u)|$ vaguely on $\mathbb{R}^N$. By Lemma (2.2) of [14], $\Psi_{\text{hom}}(e(u_m))$ is vaguely convergent toward $\Psi_{\text{hom}}(e(u))$ on $\mathbb{R}^N$. By taking $\vec{y}_0$ such that $\int_{\partial(y_0+Y)} |e(u)| = 0$, we obtain that

$$\int_{Y_1} \Psi_{\text{hom}}(e(u)) = \int_{(y_0+Y)} \Psi_{\text{hom}}(e(u))$$
$$= \lim_{m \to +\infty} \int_{(y_0+Y)} \Psi_{\text{hom}}(e(u_m))$$
$$= \lim_{m \to +\infty} \int_Y \Psi_{\text{hom}}(e(u_m)).$$

Proof of Lemma 3.2. A first step consists of showing that $\inf P_1(\xi) = \inf P_n(\xi)$ for every $n \in \mathbb{N}$. With $\delta > 0$ being given and u_n in $LU_{\text{per}}(Y)$ such that

$$\int_Y \Psi(nx, e(u_n(x) + \xi)\, dx \leqq \inf P_n(\xi) + \delta,$$

we define the function u by the formula

$$u(x) = \frac{1}{n^2} \sum_{1 \leqq j \leqq N} \sum_{0 \leqq i \leqq n-1} u_n\left(\frac{1}{n}(x + i_j)\right).$$

u belongs to $U_{\text{per}}(Y)$, and

$$e(u)(x)=\frac{1}{n^3}\sum_j\sum_i e(u_n)\left(\frac{1}{n}(x+i_j)\right).$$

Since u is admissible for P_1, using the convexity of Ψ, its Y-periodicity, and $Y=\bigcup_j (1/n)(Y+i_j)$, $i_j \leqq n-1$, valid for all $n\in\mathbb{N}$, we get

$$\begin{aligned}
\inf P_1(\xi) &\leqq \int_Y \Psi(x, e(u)(x)+\xi)\\
&\leqq \sum \frac{1}{n^3}\int_Y \Psi\left(x, e(u_n)\left(\frac{1}{n}(x+\vec{i})\right)+\xi\right) dx\\
&= \sum \frac{1}{n^3}\int_{(Y+\vec{i})/n} \Psi[n(x-\vec{i}), e(u_n)(x)+\xi]\, dx\\
&= \sum \int_{(Y+\vec{i})/n} \Psi(nx, e(u_n)(x))\, dx\\
&= \int_Y \Psi(nx, e(u_n)(x)+\xi)\, dx\\
&\leqq \inf P_n(\xi)+\delta.
\end{aligned}$$

For the reverse inequality, let u be in $LU_{\text{per}}(Y)$ so that $\int_Y \Psi(x, e(u)(x)+\xi)\, dx \leqq \inf P_1(\xi)$, and define $u_n(x)=(1/n)u(nx)$. u_n is in $LU_{\text{loc}}(\mathbb{R}^N)$, $(1/n)Y$-periodic, and then Y is admissible as a period, so it is admissible for P_n and we may write

$$\begin{aligned}
\inf P_n(\xi) &\leqq \int_Y \Psi(nx, e(u_n)(x)+\xi)\, dx\\
&= \int_Y \Psi(nx, e(u)(nx)+\xi)\, dx\\
&= \frac{1}{n^3}\int_{nY} \Psi(x, e(u)(x)+\xi)\, dx\\
&= \int_Y \Psi(x, e(u)(x)+\xi)\, dx\\
&\leqq \inf P_1(\xi)+\delta.
\end{aligned}$$

Lemma 3.2 is then proved.

Proof of Lemma 3.3. We first show that $\inf P_{\text{hom}}(\xi) \geqq \overline{\lim}\, \inf P_n(\xi)$. Let u be in $LU_{\text{per}}(Y)$, such that $\int_Y \Psi_{\text{hom}}(e(u)+\xi) \leqq \inf P_{\text{hom}}(\xi)+\delta$. By Proposition 1.2 in § 1, there exists $v_n \in LU(Y)$, $v_n \mapsto u+\xi\cdot x$ in $U(\Omega)$, $\int_Y \Psi(nx, e(v_n)(x)) \mapsto \int_Y \Psi_{\text{hom}}(e(u)+\xi)$, $v_{n|\partial\gamma} = u+\xi\cdot x_{|\partial\gamma}$. Then $u_n = v_n - \xi\cdot x_{|\partial\gamma} = u_{|\partial\gamma}$ and may be extended by periodicity to $\mathbb{R}^N$ as a function of $LU_{\text{per}}(Y)$. We then have

$$\begin{aligned}
\overline{\lim}\, \inf P_n(\xi) &\leqq \overline{\lim} \int_Y \Psi(nx, e(u_n)(x)+\xi)\\
&= \int_Y \Psi_{\text{hom}}(e(u)(x)+\xi)\\
&\leqq \inf P_{\text{hom}}(\xi)+\delta.
\end{aligned}$$

For the reverse inequality, $\delta > 0$ being given, let u_n be in $LU_{\text{per}}(Y)$ such that

$$\frac{1}{|Y|}\int_Y \Psi(nx, e(u_n)(x)+\xi) \leqq \inf P_n + \delta.$$

This implies that $e(u_n)$ is bounded in L^1 and that div u_n is bounded in $L^2(\Omega)$. With u_n being periodic, there exists a constant c_n such that $(u_n - c_n)$ is bounded in $LU_{\text{loc}}(\mathbb{R}^N)$. We may extract from it a subsequence, still denoted $u_n - c_n$, such that

$$(u_n - c_n) \to u \quad \text{in } U_{\text{loc}}(\mathbb{R}^N) \text{ weakly},$$

u being, of course, periodic.

Since $e(u)$ is a bounded periodic measure, there exists $\vec{x}_0, x_0^i \neq 0$, for all i, such that $\int_{\partial\{\vec{x}_0+Y\}} |e(u)| = 0$, which means that u does not present a discontinuity across the boundary of $\vec{x}_0 + Y$. Then, using the properties of Y-periodic measures, we get

$$\begin{aligned}\int_{Y_1} \Psi_{\text{hom}}(e(u)+\xi) &= \int_{\vec{x}_0+Y} \Psi_{\text{hom}}(e(u)+\xi) \\ &\leqq \underline{\lim} \int_{x_0+Y} \Psi(nx, e(u_n)(x)+\xi)\, dx \\ &= \underline{\lim} \int_Y \Psi(nx, e(u_n)(x)+\xi)\, dx,\end{aligned}$$

and then

$$\Psi_{\text{hom}}(\xi) = \inf P_{\text{hom}} \leqq \underline{\lim} \inf P_n.$$

The explicit expression of $\Psi_{\text{hom}}(\xi)$ permits us, first, to find again the explicit expression of Ψ^*_{hom}, and second, to show the equality

$$(\Psi_{\text{hom}})_\infty = (\Psi_\infty)_{\text{hom}} \tag{3.6}$$

where Ψ_∞ denotes the asymptotic function of Ψ. An explicit calculation of Ψ^*_{hom} has been given in [2], [19]; we calculate it by starting from the previous form of Ψ_{hom} and using convex analysis techniques (see Ekeland and Temam [13] for the details of the calculations):

$$\begin{aligned}\Psi^*_{\text{hom}}(\eta) &= \operatorname*{Sup}_\xi \left\{ \xi\cdot\eta - \inf_{u\in LU_{\text{per}}(Y)} \left\{ \int_Y \Psi(x, e(u)+\xi) \right\} \right\} \\ &= -\inf_{\xi, u\in LU_{\text{per}}(Y)} \left\{ \int_Y \Psi(x, e(u)+\xi) - \xi\cdot\eta \right\} \\ &= -\operatorname*{Sup}_{\substack{\text{div } \sigma = 0 \\ \int_Y \sigma = 0 \\ \sigma \in L^2_{\text{per}}(Y) \\ (\sigma+\eta)^D \in K^D(x)}} \left\{ -\int_Y \Psi^*(x, \sigma+\eta) \right\}\end{aligned}$$

$$\Psi^*_{\text{hom}}(\eta) = \inf_{\substack{\text{div } \alpha = 0 \\ \int_Y \sigma = 0}} \left\{ \int_Y \Psi^*(x, \sigma+\eta) \right\}. \tag{3.7}$$

This also gives a rather precise description of the convex set K_{hom}:

$$K_{\text{hom}} = \text{Dom } \Psi^*_{\text{hom}} = \left\{ \eta, \exists \sigma \in L^2_{\text{per}}(Y), (\sigma+\eta)^D \in K^D(x), \int_Y \sigma = 0, \text{div } \sigma = 0 \right\} \tag{3.8}$$

where $K^D(x) = K(x) \cap \{\sigma, \text{tr } \sigma = 0\}$.

3.3. The functions $(\Psi_{\text{hom}})_\infty$ and $(\Psi_\infty)_{\text{hom}}$. In this section, the results of §§ 1 and 2 concerning Ψ are extended to functions that do not satisfy (1.1) and (1.2); moreover, the equality $(\Psi_{\text{hom}})_\infty = (\Psi_\infty)_{\text{hom}}$ is shown. It permits us to prove the approximation result (3.11), which is not obvious.

Let us recall that when Ψ is convex and continuous, its asymptotic function Ψ_∞ is defined as

$$\Psi_\infty(\xi) = \lim_{t \to +\infty} \frac{\Psi(t\xi)}{t}.$$

If Ψ satisfies (1.2), the domain of Ψ_∞ is the space of deviators $E^D = \{\xi \in E, \operatorname{tr} \xi = 0\}$ and Ψ_∞ verifies $\Psi_\infty(x, 0) = 0$, and when ξ belongs to E^D,

$$C_0|\xi^D| \leqq \Psi_\infty(x, \xi) \leqq C_1|\xi^D|.$$

We define the spaces

$$LU^0(\Omega) = \{u \in LU(\Omega), \operatorname{div} u = 0\}, \qquad U^0(\Omega) = \{u \in U(\Omega), \operatorname{div} u = 0\}$$

and the analogues of $\bar{\Psi}^-(u)$, $\bar{\Psi}^+(u)$:

$$\langle \bar{\Psi}^-_\infty(u)\varphi \rangle = \Gamma^-(L^p) \varliminf_{\substack{\varepsilon \to 0 \\ v \to u}} F_{\infty\varepsilon}(u, \varphi), \tag{3.9}$$

$$\langle \bar{\Psi}^+_\infty(u), \varphi \rangle = \Gamma^-(L^p) \varlimsup_{\varepsilon \to 0} F_{\infty\varepsilon}(u, \varphi) \tag{3.10}$$

where $\varphi \geqq 0$ is in $\mathscr{C}(\bar{\Omega})$ and

$$F_{\infty\varepsilon}(v, \varphi) = \begin{cases} \displaystyle\int \Psi_\infty\left(\frac{x}{\varepsilon}, e(v_\varepsilon)(x)\right) \varphi(x)\, dx & \text{if } u_\varepsilon \in LU^0(\Omega), \\ +\infty & \text{if not,} \end{cases}$$

and we have the analogue of Theorem 1.1.

THEOREM. (i) *There exists a subsequence ε' for which $\bar{\Psi}^-_\infty(u) = \bar{\Psi}^+_\infty(u) = \bar{\Psi}_\infty(u)$ for every u in $U^0(\Omega)$; $\bar{\Psi}_\infty(u)$ may be extended as a bounded measure on Ω, absolutely continuous with respect to $|e^D(u)|$.*

(ii) *$\bar{\Psi}_\infty$ is a convex function of u and verifies*

$$|\bar{\Psi}_\infty(u) - \bar{\Psi}_\infty(v)| \leqq C_1|e^D(u) - e^D(v)|.$$

Proof. The proof follows that of Theorem 1.1, and the changes it brings are obvious if we use at each step the approximant $\bar{u}_\varepsilon$, the following result of approximation, also stated in [21]. Let Ω be an open C^1 bounded set of $\mathbb{R}^N$; for every u in $U^0(\Omega)$ there exists $\bar{u}_\varepsilon$ in $C^1(\Omega, E) \cap L^1(\Omega, E)$ such that

$$\bar{u}_\varepsilon \to u \quad \text{in } L^1(\Omega),$$

$$|e^D(\bar{u}_\varepsilon)| \to |e^D(u)| \quad \text{tightly on } \Omega,$$

$$\operatorname{div} \bar{u}_\varepsilon = 0,$$

$$\bar{u}_\varepsilon = u_{|\Gamma}.$$

This is the main argument used to prove the approximation result below. It is left to the reader:

(3.11) Let u be in $LU^0(\Omega)$. There exists u_ε in $LU^0(\Omega)$, u_ε tends to u in $U(\Omega)$, $u_\varepsilon = u_{|\Gamma}$, and $\int_\Omega \Psi_\infty(x/\varepsilon, e(u_\varepsilon)) \to \int_\Omega \bar{\Psi}_\infty(u)$.

Following the argument in Proposition 2.1, it is easy to show that there exists a punctual function that we denote $(\Psi_\infty)_{\text{hom}}$, of domain E^D such that

$$\langle \bar{\Psi}_\infty(u), \varphi \rangle = \int (\Psi_\infty)_{\text{hom}}(e(u))(x)\varphi(x)\, dx$$

for every u in $LU^0(\Omega)$, φ in $\mathscr{C}_0(\Omega)$; of course, the results in Theorem 2.1 and Proposition 2.3 are still valid for $\Psi_\infty(u)$ when u belongs to $LU^0(\Omega)$.

We may give an explicit form of $(\Psi_\infty)_{\text{hom}}$. For $\xi \in E^D$ it is

$$(\Psi_\infty)_{\text{hom}}(\xi) = \inf_{u \in LU_{\text{per}}(Y)} \left(\int_Y \Psi_\infty(x, \xi + e(u)) \right). \tag{3.12}$$

Note that the domain of the function in the right member of (3.12) is E^D. Indeed, the infimum must be taken for u verifying $\operatorname{tr} \xi + \operatorname{div} u = 0$. But $u \in LU_{\text{per}}(Y)$ implies that $\int_Y \operatorname{div} u = 0$, and then $\operatorname{tr} \xi = \int_Y \operatorname{tr} \xi = \int_Y \operatorname{tr} \xi + \operatorname{div} u = 0$.

To show (3.12), we proceed as we did for Ψ (the analogues of Lemmas 3.1–3.3 are true and may be proved by adapting the arguments used already).

Now we will prove the following:

$$(\Psi_{\text{hom}})_\infty = (\Psi_\infty)_{\text{hom}}. \tag{3.13}$$

The left member of (3.13) makes sense because it is the asymptotic function of Ψ_{hom}. Moreover, (1.2) yields that $\Psi_{\text{hom}}(\xi)$ is "quadratic" with respect to $\operatorname{tr} \xi$, and "linear" with respect to $|\xi^D|$, and then $\operatorname{dom} (\Psi_{\text{hom}})_\infty = E^D$. Since $(\Psi_{\text{hom}})_\infty$ and $(\Psi_\infty)_{\text{hom}}$ are lower semicontinuous and proper, it suffices to show that their conjugates coincide. We have

$$\begin{aligned}(\Psi_{\text{hom}})^*_\infty(\eta) &= \sup_{\xi \in E^D} \left\{ \eta \cdot \xi - \inf_{\substack{u \in LU_{\text{per}}(Y) \\ \operatorname{div} u = 0}} \left(\int_Y \Psi_\infty(x, \xi + e(u)) \right) \right\} \\ &= - \inf_{\substack{\xi \in E^D \\ u \in LU^0_{\text{per}}(Y)}} \left\{ \int_Y \Psi_\infty(x, \xi + e(u)) - \eta \cdot \xi \right\}.\end{aligned}$$

These calculations are rather technical, although classical in the theory of duality (cf. Ekeland and Temam [13]). We obtain

$$\Psi^*_{\text{hom}}(\eta) = \sup_{\substack{\exists \sigma \in L^2_{\text{per}}(Y) \\ \operatorname{div} \sigma = 0 \text{ in } \mathbb{R}^N \\ \int_Y \sigma^D = 0 \\ (\sigma + \eta)^D \in K^D}} \{0\} = \chi_{\overline{K_{\text{hom}}}}(\eta)$$

where $\overline{K_{\text{hom}}} = \{\eta, \exists \sigma \in L^2_{\text{per}}(\chi), \operatorname{div} \sigma = 0 \text{ in } \mathbb{R}^N, \int_Y \sigma^D = 0, (\sigma(x) + \eta)^D \in K^D(x)\}$.

Let us note that $\overline{K_{\text{hom}}} = K_{\text{hom}}$. First, we obviously have $K_{\text{hom}} \subset \overline{K_{\text{hom}}}$. Second, take η in $\overline{K_{\text{hom}}}$, and $\sigma \in L^2_{\text{per}}(Y)$, such that $\operatorname{div} \sigma = 0$ in $\mathbb{R}^N$, $\int_Y \sigma^D = 0$, $(\sigma(x) + \eta)^D \in K^D(x)$. Then $\sigma_{1ij} = (\sigma_{ij} - \int_Y \operatorname{tr} \sigma \delta_{ij})$ verifies $\sigma_1 \in L^2_{\text{per}}(Y)$, $\operatorname{div} \sigma_1 = 0$, $\int_Y \sigma_1 = 0$, $(\sigma + \eta)^D \in K^D(x)$, and thus $\eta \in K_{\text{hom}}$. We have finally obtained that

$$(\Psi_{\text{hom}})_\infty = (\Psi_\infty)_{\text{hom}}.$$

In particular, for u in $U^0(\Omega)$, there exists $u_\varepsilon \in LU(\Omega)$, $\operatorname{div} u_\varepsilon = 0$, $u_\varepsilon \to u$ in $L^1(\Omega)$, $u_\varepsilon = u_{|\Gamma}$ such that

$$\int_\Omega \left(\Psi_\infty\left(\frac{x}{\varepsilon}, e(u_\varepsilon) \right)(x)\, dx \right) \to \int_\Omega (\Psi_{\text{hom}})_\infty(e(u)).$$

This result will be important to study the relations between the prehomogenized limit analysis problems and the homogenized one in [9]. □

In [9] we apply these mathematical results to homogenization in plasticity. The displacement problem for a nonhomogeneous, elastic, perfect plastic material made with a great number of identical cells of size ε may be written in the following variational form:

$$\inf_{\substack{u\in H^1\\ u=u_0|\Gamma_0}} \left\{ \int_\Omega \psi\left(\frac{x}{\varepsilon}, e(u)\right) - \lambda \int_\Omega fu - \lambda \int_{\Gamma_1} Fu \right\}$$

where $u_0 \in H^{1/2}(\Gamma)$, $u_0 = \chi_{\Gamma_0} u_0$, f is the body force ($f \in L^{N/(N-1)}$), F is the boundary force ($F \in L^\infty(\Gamma_1)$), and λ is a real parameter; Ψ is the energy functional that verifies the assumptions in § 1. In [9] we show that when λ is less than a positive limit load λ_0, which we define precisely, then inf P_ε converges toward the homogenized problem

$$\inf_{\substack{u\in H^1(\Omega)\\ u=u_0|\Gamma_0}} \left\{ \int_\Omega \psi_{\text{hom}}(e(u)) - \lambda \int_\Omega fu - \lambda \int_{\Gamma_1} Fu \right\}$$

where ψ_{hom} is the function defined in § 1.

Appendix. Let us give a concrete mechanical example for which the formulas found in § 3 give an explicit description of the homogenized convex set, and of Ψ_{hom}. Suppose that k_{ij} is a divergence-free function, with $k_{ii} = 0$, $k_{12}(x_1, x_2, x_3) = k_1(x_3)$, $k_{13}(x_1, x_2, x_3) = k_2(x_2)$, $k_{23}(x_1, x_2, x_3) = k_3(x_1)$, k_1, k_2, k_3 being periodic of period 1. We assume in addition that

$$0 < \alpha_0 \leqq \sum_j |k_{ij}(x)| \leqq \alpha_1 < +\infty.$$

We have div $(k) = 0$ and $K(x)$ is defined as

$$K(x) = \{\sigma, |\sigma_{ij}^D|(x) \leqq k_{ij}(x)\}.$$

By the formula following (3.7) in § 3, K_{hom} is defined as $K_{\text{hom}} = \{\eta \in E, \exists \sigma \in L^2_{\text{per}}(Y), \int_Y \sigma = 0, \text{ div } \sigma = 0, \text{ and } \sigma + \eta \in K\}$. We will show that

$$K_{\text{hom}} = \left\{ \eta \in E, |\eta_{ij}^D| \leqq \int_Y (k_{ij})(x) \right\}.$$

Toward that aim, we denote by $\overline{K_{\text{hom}}}$ the right member in the equality above; we begin by showing that $K_{\text{hom}} \subset \overline{K_{\text{hom}}}$. Thus suppose that $\eta \in K_{\text{hom}}$, and that σ verifies $\sigma \in L^2_{\text{per}}(Y)$, $\int_Y \sigma = 0$, $\sigma + \eta \in K$, and div $\sigma = 0$. We have

$$|\eta_{ij}^D| = \left| \int_Y (\sigma + \eta)_{ij}^D \right| \leqq \int_Y |(\sigma + \eta)_{ij}^D| \leqq \int_Y k_{ij}(x)$$

and then $\eta \in \overline{K_{\text{hom}}}$. Conversely, if η is such that $|\eta_{ij}^D| \leqq \int_Y k_{ij}(x)$, let α_{ij} be $\eta_{ij}^D / \int_Y k_{ij}(x)$; we have $|\alpha_{ij}| \leqq 1$ for all ij, and we define $\sigma_{ij} = \alpha_{ij} k_{ij} - \eta_{ij}^D$. We have $\int_Y \sigma_{ij} = 0$ $(\sigma + \eta)_{ij}^D = (\sigma_{ij} + \eta_{ij}^D)(x) = \alpha_{ij} k_{ij}(x) \leqq k_{ij}(x)$, and div $\sigma = 0$; this implies that $\eta \in K_{\text{hom}}$.

Suppose now that

$$\text{(A1)} \qquad \Psi^*(x, \xi) = \begin{cases} \frac{1}{2}\alpha (\text{tr } \xi)^2 & \text{if } \xi^D \in K^D(x), \\ +\infty & \text{if not} \end{cases}$$

where α is some positive constant. Then $\Psi(x, \cdot)$ satisfies the hypothesis in § 1. Let us calculate Ψ^*_{hom}. Using (3.7) we have

$$\text{(A2)} \qquad \Psi^*_{\text{hom}}(\xi) = \inf_{\substack{\text{div } \sigma = 0\\ \int_Y \sigma = 0\\ (\xi+\sigma)^D \in K^D(x)}} \left(\frac{1}{2} \alpha \int_Y (\text{tr } (\xi + \sigma))^2 \right).$$

Let us show that

$$\Psi^*_{\text{hom}}(\xi)=\begin{cases}\frac{1}{2}\alpha(\operatorname{tr}\xi)^2 & \text{if } |\xi^D_{ij}|\leqq\int_Y k_{ij}(x),\\ +\infty & \text{if not.}\end{cases}$$

Since the two sides of (A2) are infinite when $\xi\notin K_{\text{hom}}$, we may suppose that $\xi\in K_{\text{hom}}$. By setting $\sigma=0$ in the right-hand side of (A2) we get that

$$\Psi^*_{\text{hom}}(\xi)\leqq\tfrac{1}{2}\alpha(\operatorname{tr}\xi)^2.$$

Now Jensen's inequality yields

$$\frac{1}{2}\alpha\left(\int_Y(\operatorname{tr}(\xi+\sigma))\right)^2\leqq\frac{1}{2}\int_Y\alpha(\operatorname{tr}(\xi+\sigma))^2$$

and then, with $\int_Y\operatorname{tr}\sigma=0$,

$$\frac{1}{2}\alpha\int_Y(\operatorname{tr}(\xi))^2\leqq\inf_{\substack{\sigma\\ \int_Y\sigma=0}}\left(\frac{1}{2}\int_Y\operatorname{tr}(\xi+\sigma)^2\right)$$

$$=\Psi^*_{\text{hom}}(\xi).$$

We have finally obtained the desired result, and are able to calculate Ψ_{hom}:

$$\Psi_{\text{hom}}(\xi)=\frac{1}{2\alpha}(\operatorname{tr}\xi)^2+\sum_{ij}\left(\int_Y k_{ij}(x)\right)|\xi^D_{ij}|.$$

Acknowledgments. The authors thank the referee for remarks and advice, and G. Bouchitte, François Murat, and Colette Picard for fruitful discussions on this subject.

SOME NONLINEAR WEAK ERGODIC THEOREMS*

ROGER D. NUSSBAUM†

Abstract. Let C be a cone with nonempty interior in a Banach space and, for $j \geqq 1$, let $f_j : \mathring{C} \to \mathring{C}$ be a sequence of maps. It is frequently assumed that each f_j is homogeneous of degree 1 and order-preserving with respect to the partial ordering induced by C; but it is not assumed that $f_j(C-\{0\}) \subset \mathring{C}$. If $F_m = f_m f_{m-1} \cdots f_1$, the composition of the first m f_j, and if d denotes Hilbert's projective metric, then theorems (usually called weak ergodic theorems in the population biology literature) can be proved ensuring that, for all x and y in $\mathring{C}$, $\lim_{m\to\infty} d(F_m(x), F_m(y)) = 0$ and (if C is normal) $\lim_{m\to\infty} \|(F_m(x)/\|F_m(x)\|) - (F_m(y)/\|F_m(y)\|)\| = 0$. If $u \in \mathring{C}$ is fixed and assumptions on the f_j are strengthened, it can be proved that for every $z \in \mathring{C}$ there exists $\lambda(x) > 0$ such that $\lim_{m\to\infty} \|F_m(x) - \lambda(x) F_m(u)\| = 0$. These theorems are applied to the case where $C = \{x \in \mathbb{R}^n : x_i \geqq 0 \text{ for } 1 \leqq i \leqq n\}$ and where the maps f_j belong to a class M arising in the theory of "means and their iterations" and in certain problems from population biology.

Key words. Hilbert's projective metric, nonlinear weak ergodic theorems, cones, nonlinear cone maps, positive linear operators

AMS(MOS) subject classifications. 47A35, 47B55, 47H07, 47H09

1. Preliminaries. In an effort to make this paper self-contained, we begin by recalling some definitions and theorems from the literature. By a cone C (with vertex at 0) in a Banach space X we mean a closed, convex subset C of X such that (a) $tC \subset C$ for all $t \geqq 0$ and (b) if $x \in C - \{0\}$, then $-x \notin C$. A cone induces a partial ordering on X by

$$x \leqq y \quad \text{if and only if } y - x \in C.$$

Two elements $x, y \in C$ will be called "comparable" if there exist positive reals α and β such that

$$\alpha x \leqq y \leqq \beta x, \qquad \alpha, \beta > 0.$$

If x and y in C are comparable, we follow Bushell [6] and define

$$M(y/x) = \inf\{\beta > 0 : y \leqq \beta x\}, \tag{1.1}$$

$$m(y/x) = \sup\{\alpha > 0 : \alpha x \leqq y\}. \tag{1.2}$$

If $u \in C - \{0\}$, C_u will denote the set of elements of C that are comparable to u. If u is an element of the interior of C, C_u is the interior of C. In general C_u satisfies all properties of a cone except closedness.

Associated to the set C_u is a natural normed linear space E_u,

$$E_u = \{x \in X : \text{there exists } \alpha > 0 \text{ such that } -\alpha u \leqq x \leqq \alpha u\}.$$

For $x \in E_u$, we define a norm $|x|_u$ by

$$|x|_u = \inf\{\alpha > 0 : -\alpha u \leqq x \leqq \alpha u\}.$$

A cone C in a Banach space X is called "normal" if there exists a constant M such that

$$\|x\| \leqq M\|y\|$$

for all $x, y \in C$ such that $x \leqq y$. A cone C is "total" if the closure of the linear span of C equals X. If C is a cone, C^* will always denote the set of continuous linear functionals $\psi \in X^*$ such that $\psi(x) \geqq 0$ for all $x \in C$. It is not hard to see that if C is a total cone, then C^* is a cone.

The basic technical tool we will use in this paper is the so-called "Hilbert's projective metric" d. If C is a cone in a Banach space X and $u \in C - \{0\}$, then for $x, y \in C_u$, define $\beta = M(y/x)$, $\alpha = m(y/x)$, and

$$d(x, y) = \log\left(\frac{\beta}{\alpha}\right), \tag{1.3}$$

$$\bar{d}(x, y) = \log(\max(\beta, \alpha^{-1})). \tag{1.4}$$

We can easily prove (see [6]) that the projective metric d satisfies all properties of a metric except that $d(y, x) = 0$ if and only if $y = \lambda x$ for some $\lambda > 0$. On the other hand, $\bar{d}$, which was introduced by Thompson [36], is a metric on C_u. If $\Sigma = \{x \in C_u : \|x\| = 1\}$, (Σ, d) is a metric space, and it is natural to ask if (Σ, d) is complete. It is proved in [37] that (Σ, d) is complete if and only if

$$\sup\{\|x\| : 0 \leqq x \leqq u\} < \infty, \tag{1.5}$$

and (1.5) is satisfied if and only if E_u is a complete normed linear space. Also, one can show that $(C_u, \bar{d})$ is complete if and only if (1.5) is satisfied. It should be noted that the results in [37] are closely related to much earlier theorems of Thompson [36] and Birkhoff (see Theorem 5 in [5] and Remark 1.1 in [25]). Notice also that if $\psi \in C^*$ and $\psi(u) > 0$ and

$$\Sigma_\psi = \{x \in C_u : \psi(x) = 1\},$$

then (Σ_ψ, d) is complete if and only if (Σ, d) is complete, because (Σ_ψ, d) and (Σ, d) are isometric.

If $K = \{x \in \mathbb{R}^n : x_i \geqq 0 \text{ for } 1 \leqq i \leqq n\}$, K will be called the "standard cone in $\mathbb{R}^n$." Obviously, K is normal, so if $\Sigma_1 = \{x \in \mathring{K} : \sum_{i=1}^n x_i = 1\}$ or $\Sigma_2 = \{x \in \mathring{K} : x_1 = 1\}$, the remarks above show that (Σ_1, d) and (Σ_2, d) are complete.

We also need to recall some results about positive linear operators. Suppose that C is a cone in a Banach space X and that $L : X \to X$ is a bounded linear operator such that $L(C) \subset C$. Assume that Lx and Ly are comparable for all $x, y \in C$ such that $Lx \neq 0$ and $Ly \neq 0$ and define a number $\Delta(L)$, the "projective diameter of $L(C) - \{0\}$" by

$$\Delta(L) = \sup\{d(Lx, Ly) : x, y \in C, Lx \neq 0 \text{ and } Ly \neq 0\}. \tag{1.6}$$

If $Lx = 0$ for all $x \in C$, we define $\Delta(L) = 0$. If L is as above and $\Delta(L) < \infty$ we shall say that "L has finite projective diameter."

If $x, y \in C - \{0\}$ are not comparable, define $d(x, y) = \infty$. If $x, y \in C - \{0\}$ and $M(y/x) < \infty$, define

$$\operatorname{osc}(y/x) = M(y/x) - m(y/x). \tag{1.7}$$

If $M(y/x) = \infty$, define $\operatorname{osc}(y/x) = \infty$. If L is a bounded linear operator such that $L(C) \subset C$ and Lx and Ly are nonzero and comparable for all $x, y \in C - \{0\}$, define

$$k(L) = \inf\{k > 0 : d(Lx, Ly) \leqq k d(x, y) \text{ for all } x, y \in C - \{0\}\},$$

$$N(L) = \inf\{\lambda > 0 : \operatorname{osc}(Ly/Lx) \leqq \lambda \operatorname{osc}(y/x) \text{ for } x, y \in C - \{0\}\}.$$

It is easy to see that $k(L) \leqq 1$ and $N(L) \leqq 1$. However, if $\Delta(L) < \infty$, results of Birkhoff [4], [5] and Hopf [19], with refinements of Ostrowski [27], Bauer [2], Bushell [6], [7], and others [20], [37] imply that

$$N(L) = k(L) = \tanh\left(\frac{\Delta(L)}{4}\right) < 1. \tag{1.8}$$

As a particular example, note that if K is the standard cone in $\mathbb{R}^n$ and L is an $n \times n$ matrix, all of whose entries are positive, then $\Delta(L) < \infty$. In fact, it is not hard to prove that $\Delta(L) = \sup_{i,j} d(Le_i, Le_j)$, where e_i, $1 \leqq i \leqq n$, is the standard basis of $\mathbb{R}^n$. From this observation and (1.8) we derive an explicit formula (see [6], [35]) for $\Delta(L)$ and $k(L)$.

If C is a cone and $D \subset C$, a map $f: D \to C$ will be called nonexpansive with respect to d if

$$d(f(x), f(y)) \leqq d(x, y) \quad \text{for all } x, y \in D. \tag{1.9}$$

We have the obvious modification for $\bar{d}$. A map $f: D \to C$ will be called "order-preserving" if $f(x) \leqq f(y)$ for all $x, y \in D$ such that $x \leqq y$. The map f will be called "homogeneous of degree 1" on D if

$$f(tx) = tf(x) \quad \text{for all } t > 0 \quad \text{and} \quad x \in D \quad \text{such that } tx \in D,$$

and will be called "subhomogeneous" on D if $f(tx) \geqq tf(x)$ for all t, $0 < t \leqq 1$, and $x \in D$ such that $tx \in D$. It is an easy exercise that if $u \in C - \{0\}$, $D = C_u$ and $f: D \to D$ is order preserving and homogeneous of degree 1, then f is nonexpansive with respect to d: see [6], [25], [29]. Thompson [36] observed that, if $f: C_u \to C_u$ is subhomogeneous and order-preserving, then f is nonexpansive with respect to $\bar{d}$. Potter [29] observed that, for $\psi \in C^*$ with $\psi(u) > 0$, the restriction of f to $\Sigma_\psi = \{x \in C_u: \psi(x) = 1\}$ is nonexpansive with respect to d.

Now suppose that C is a cone in a Banach space X, $u \in C - \{0\}$, and S is a collection of maps $f: C_u \to C_u$. In most of this paper we will assume that f is order preserving and homogeneous of degree 1 for every $f \in S$. Suppose that $f_j \in S$, $1 \leqq j < \infty$, is a sequence of functions in S and define

$$F_n = f_n f_{n-1} f_{n-2} \cdots f_1 \tag{1.10}$$

for $n \geqq 1$. We are interested in finding further conditions ensuring that for all $x, y \in C_u$,

$$\lim_{n \to \infty} d(F_n(x), F_n(y)) = 0. \tag{1.11}$$

Such results are called "weak ergodic theorems" in the population biology literature [11], [17]. The linear theory is well understood: see the excellent survey article [11] by Cohen. If (1.5) is satisfied, it is known (see eq. (1.20a) in [25]) that there exists a constant M such that

$$\begin{aligned} &\|x - y\| \leqq M[\exp(d(x, y)) - 1] \quad \text{for all } x, y \in \Sigma, \\ &\Sigma = \{x \in C_u: \|x\| = 1\}. \end{aligned} \tag{1.12}$$

Using (1.12) we can see that if (1.5) and (1.11) hold and the functions f_j are homogeneous of degree 1, then

$$\lim_{n \to \infty} \|F_n(x)\| F_n(x)\|^{-1} - F_n(y)\| F_n(y)\|^{-1}\| = 0. \tag{1.13}$$

Note that if (1.5) is satisfied, $C \cap E_u$ is a normal cone with nonempty interior C_u in the Banach space E_u, so by working in E_u we can assume that C is normal with nonempty interior.

In fact, the question we are asking is motivated by a particular class of maps $\mathcal{M}$ defined on the interior of the standard cone K in $\mathbb{R}^n$, so we recall the definition of $\mathcal{M}$ (see [24], the Introduction to [25], and § 4 of [23]). Recall that a probability vector σ is a vector $\sigma \in K$ such that $\sum_{i=1}^{n} \sigma_i = 1$. If r is a real number and σ a probability vector, define $M_{r\sigma} : \mathring{K} \to \mathbb{R}$ by

$$M_{r\sigma}(x) = \left(\sum_{i=1} \sigma_i x_i^r \right)^{1/r}.$$

If $r = 0$, define

$$M_{0\sigma}(x) = \prod_{i=1}^{n} x_i^{\sigma_i}.$$

Such maps, of course, have an extensive classical theory, described in [18]. For $1 \leqq i \leqq n$, let Γ_i be a finite collection of ordered pairs (r, σ), with r a real number and σ a probability vector. For $(r, \sigma) \in \Gamma_i$ let $c_{ir\sigma}$ be a positive real number and define $f_i : \mathring{K} \to (0, \infty)$ by

$$f_i(x) = \sum_{(r,\sigma)\in\Gamma_i} c_{ir\sigma} M_{r\sigma}(x). \tag{1.14}$$

Define f_i to be the ith component of a map $f : \mathring{K} \to \mathring{K}$. If $f : \mathring{K} \to \mathring{K}$ can be written in this form, we will write $f \in M$. If f can be written as in (1.14) in such a way that $r \geqq 0$ for all $(r, \sigma) \in \Gamma_i$ and $1 \leqq i \leqq n$, we say that $f \in M_+$; if f can be written as in (1.14) such that $r < 0$ for all $(r, \sigma) \in \Gamma_i$ and $1 \leqq i \leqq n$, we say that $f \in M_-$. Note that if f is a linear map such that $f(\mathring{K}) \subset \mathring{K}$, then $f \in M_+ \cap M_-$. We define $\mathcal{M}(\mathcal{M}_+, \mathcal{M}_-)$ to be the smallest set of maps $f : \mathring{K} \to \mathring{K}$ such that $\mathcal{M} \supset M (\mathcal{M}_+ \supset M_+, \mathcal{M}_- \supset M_-)$ and $\mathcal{M}(\mathcal{M}_+, \mathcal{M}_-)$ is closed under addition of functions, composition of functions, and multiplication by positive scalars. The class $\mathcal{M}$ arises in the theory of "means and their iterations"; see [1], [12], [15], [23]-[26]. It is proved in [26] (this is not hard) that if $f \in \mathcal{M}$, then f extends continuously to K and $f | \mathring{K}$ is C^∞. We will see that establishing weak ergodic theorems may already be nontrivial when $S = \mathcal{M}$ and $C = K$. Existing nonlinear weak ergodic theorems as, for example, in the work of Fujimoto and Krause [16], are frequently inapplicable. On the other hand, we have not attempted to give an all-inclusive abstract framework: there are examples to which our general theorems are not directly applicable but which can be handled with theorems from [16].

2. Some nonlinear weak ergodic theorems. The following definition will play a crucial role in our subsequent work.

DEFINITION 2.1. Let C be a cone in a Banach space X and D a subset of C such that all elements of D are comparable. Suppose that $f_j : D \to D$, $j \geqq 1$, is a sequence of maps and define $F_m = f_m f_{m-1} \cdots f_1$ to be the composition of the first m functions f_j, $1 \leqq j \leqq m$. We say that $\langle f_j \rangle$ has "the bounded orbit property" (with respect to Hilbert's projective metric) if for every $x \in D$, there exist $y \in D$ and $R > 0$ (possibly depending on x) such that

$$d(F_m(x), y) \leqq R \quad \text{for all } m \geqq 1.$$

If each of the functions f_j is nonexpansive with respect to d, it is an easy exercise (left to the reader) to prove that $\langle f_j \rangle$ has the bounded orbit property if and only if there exist $x_0, y_0 \in D$ and $R_0 > 0$ such that

$$d(F_m(x_0), y_0) \leqq R_0 \quad \text{for all } m \geqq 1.$$

If $D = C_u$ for some $u \in C - \{0\}$ and each of the functions $f_j : D \to D$ in Definition 2.1 is homogeneous of degree 1 and order-preserving, select $\psi \in C^*$ such that $\psi(u) > 0$ and define $\Sigma_\psi = \{x \in C_u : \psi(x) = 1\}$ and $h_j : D \to D$ by

$$h_j(x) = f_j(x)/\psi(f_j(x)).$$

It is another easy exercise (again left to the reader) to prove that $\langle h_j \rangle$ satisfies the bounded orbit property if and only if $\langle f_j \rangle$ does. The maps h_j can also be considered maps of $D_1 = \Sigma_\psi$ to itself and $\langle h_j \rangle$ satisfies the bounded orbit property on D_1 if and only if $\langle h_j \rangle$ satisfies the bounded orbit property on D.

Suppose that C is a cone with nonempty interior in a finite-dimensional Banach space X and $f : \mathring{C} = D \to \mathring{C}$ is homogeneous of degree 1 and order-preserving. We can define $f_j = f$ for all $j \geqq 1$ and ask whether $\langle f_j \rangle$ satisfies the bounded orbit property with respect to d. It is a special case of results in § 4 of [25] that $\langle f_j \rangle$ satisfies the bounded orbit property if and only if f has an eigenvector $v \in \mathring{C}$ (so $f(v) = \lambda v$). Note that if f extends continuously to C, it certainly has an eigenvector in $C - \{0\}$, but the question of whether f has an eigenvector in $\mathring{C}$ may be quite subtle, even if $f \in \mathscr{M}_-$. The reader is referred to [25], [26] for further details. Even the simple-looking four-dimensional map $f \in M_-$ in [34] requires some care. For a complete, rigorous analysis see [26].

We will need the following simple geometrical lemma to prove our first weak ergodic theorem.

LEMMA 2.1. *Let C be a cone in a Banach space X and let S be a subset of C. Assume that all elements of S are comparable and that there exists $\rho > 0$ such that $d(x, y) \leqq \rho$ for all $x, y \in S$. If $w \in C$ and $w = x_1 + x_2$ for points $x_1, x_2 \in S$, we have that $x_1 \geqq \lambda w$ or $x_2 \geqq \lambda w$, where $\lambda = \frac{1}{2} \exp(-\rho)$.*

Proof. Suppose that $w = x_1 + x_2$ as above and that $d(x_1, x_2) = \tau \leqq \rho$. It suffices to prove that

$$x_1 \geqq \mu w \quad \text{or} \quad x_2 \geqq \mu w \quad \text{where } \mu = \tfrac{1}{2} \exp(-\tau).$$

It follows easily from the definition of Hilbert's projective metric that

$$d(x_1, w) \leqq \tau \quad \text{and} \quad d(x_2, w) \leqq \tau. \tag{2.1}$$

In fact, we have strict inequality in (2.1) if $\tau > 0$. Formulae (2.1) imply that there exist positive constants α_j and β_j for $j = 1, 2$ such that

$$\alpha_j w \leqq x_j \leqq \beta_j w \quad \text{and} \quad (\beta_j/\alpha_j) \leqq \exp(\tau). \tag{2.2}$$

Assume that $\alpha_j < \mu$ for $j = 1$ and $j = 2$. Then we obtain

$$x_j \leqq \beta_j w = (\alpha_j/\mu)\mu(\beta_j/\alpha_j) w \leqq c_j w, \tag{2.3}$$

where

$$c_j = (\tfrac{1}{2})(\alpha_j/\mu) < \tfrac{1}{2}. \tag{2.4}$$

By adding (2.3) for $j = 1$ and $j = 2$ we obtain

$$w = x_1 + x_2 \leqq (c_1 + c_2) w = cw. \tag{2.5}$$

Since the constant c in (2.5) is less than 1, we have a contradiction, and therefore it must be true that $\alpha_1 \geqq \mu$ or $\alpha_2 \geqq \mu$. □

We will actually use Lemma 2.1 in the following less general version.

LEMMA 2.2. *Let C be a cone in a Banach space X and let $A : X \to X$ be a bounded linear operator such that $A(C) \subset C$ and A has finite projective diameter (so $\Delta(A) < \infty$*

for $\Delta(A)$ as in (1.6)). *Then if $z \in C$ and $z = x + y$ for $x, y \in C$, we have $Ax \geqq \lambda Az$ or $Ay \geqq \lambda Az$, where*

$$\lambda = (\tfrac{1}{2}) \exp(-\Delta(A)).$$

Proof. In the notation of Lemma 2.1, define S by

$$S = \{Ax: x \in C \text{ and } Ax \neq 0\}, \tag{2.6}$$

so the diameter ρ of S with respect to Hilbert's projective metric is $\Delta(A)$. If $Ax = 0$ or $Ay = 0$ for x and y as in the statement of the lemma, the result is obvious. Otherwise, if we define $w = Az$, $x_1 = Ax$, and $x_2 = Ay$, Lemma 2.2 follows immediately from Lemma 2.1. □

With these preliminaries we can establish our first weak ergodic theorem. In reading the statement of Theorem 2.1 below, recall that if A and B are linear maps and C is a cone, we say that $A \leqq B$ (in the partial ordering induced by C) if $A(x) \leqq B(x)$ for all $x \in C$.

THEOREM 2.1. *Let C be a cone with nonempty interior in a Banach space X and for each $j \geqq 1$ let $f_j: \mathring{C} \to \mathring{C}$ be a map that is order-preserving and homogeneous of degree 1. For $m \geqq 1$ let $F_m = f_m f_{m-1} \cdots f_1$ denote the composition of the first m maps f_j and let F_0 denote the identity. Assume that there exist $u \in \mathring{C}$, an integer $p \geqq 1$, a real number $R > 0$, and a sequence of bounded linear operators $A_i: X \to X$, $i \geqq 1$, with the following properties*:

(a) *For every $j \geqq 1$, f_j is continuously Fréchet differentiable on $B_R(F_{j-1}(u))$, where $B_R(y) = \{x \in \mathring{C}: d(x, y) < R\}$.*

(b) *The operator A_i satisfies $A_i(\mathring{C}) \subset (\mathring{C})$ for all $i \geqq 1$.*

(c) *If $g_j = f_{jp} f_{jp-1} \cdots f_{jp-p+1}$ and $G_m = g_m g_{m-1} \cdots g_1 = F_{mp}$, then $g_j'(x) \geqq A_j$ for all $x \in B_R(G_{j-1}(u))$ and all $j \geqq 1$.*

(d) *There exists a positive constant k such that $A_j(G_{j-1}(u)) \geqq k g_j(G_{j-1}(u))$ for $j \geqq 1$.*

If A_j has finite projective diameter, let $\Delta(A_j)$ be the projective diameter as in (1.6), *and otherwise define $\Delta(A_j) = \infty$ and $\exp(-\Delta(A_j)) = 0$. Then if we have that*

$$\lim_{N \to \infty} \sum_{j=1}^{N} \exp(-\Delta(A_j)) = \infty, \tag{2.7}$$

it follows that

$$\lim_{m \to \infty} d(F_m(x), F_m(y)) = 0 \quad \text{for all } x, y \in \mathring{C}. \tag{2.8}$$

Also, if C is normal, (1.13) *is satisfied for all $x, y \in \mathring{C}$. In particular, if $A_j = A$ for all $j \geqq 1$ and $\Delta(A) < \infty$, then* (2.8) *is satisfied.*

Proof. By the triangle inequality it suffices to prove (2.8) for all $x \in \mathring{C}$ and for $y = u$. As has already been noted, each map f_j is nonexpansive with respect to d, so for any $x \in \mathring{C}$, $d(F_m(x), F_m(u))$ is a monotonic decreasing sequence of reals. Thus to prove (2.8) it suffices to prove that

$$\lim_{j \to \infty} d(G_j(x), G_j(u)) = 0 \quad \text{for all } x \in \mathring{C}. \tag{2.9}$$

Fix a number R_1, $0 < R_1 < R$, and suppose we can prove that there exists a sequence of numbers λ_j with $0 < \lambda_j \leqq 1$, such that if $d(y, G_j(u)) \leqq R_1$, $j \geqq 0$, then

$$d(g_{j+1}(y), g_{j+1}(G_j(u))) \leqq \lambda_{j+1} d(y, G_j(u)), \tag{2.10}$$

$$\lim_{N \to \infty} \prod_{j=m}^{N} \lambda_j = 0 \quad \text{for any } m \geqq 1. \tag{2.11}$$

Repeated application of (2.10) and (2.11) then implies that if $d(G_{m-1}(x), G_{m-1}(u)) \leqq R_1$ for some $m \geqq 1$, then

$$d(G_N(x), G_N(u)) \leqq \left(\prod_{j=m}^{N} \lambda_j \right) \quad \text{for all } N \geqq m,$$

which establishes (2.9) in the case $d(x, u) \leqq R_1$.

If $d(y, G_{j-1}(u)) = \rho > R_1$, Proposition 1.9 in [25] implies that there exists y_1 on the line segment connecting y to $G_{j-1}(u)$ such that

$$d(y, y_1) = \rho - R_1 \quad \text{and} \quad d(y_1, G_{j-1}(u)) = R_1. \tag{2.12}$$

Using the nonexpansivity of g_j and (2.10) we obtain from (2.12) that

$$d(g_j(y), G_j(u)) \leqq \rho - R_1 + \lambda_j R_1. \tag{2.13}$$

If $\rho \leqq R_2$, $R_2 > R_1$, we obtain from (2.13) that

$$d(g_j(y), G_j(u)) \leqq \mu_j d(y, G_{j-1}(u)), \tag{2.14}$$

where

$$\mu_j = [R_2 - (1-\lambda_j)R_1]R_2^{-1}. \tag{2.15}$$

Formula (2.14) was proved under the assumption that $R_1 < \rho \leqq R_2$, but because $\mu_j \geqq \lambda_j$, the equation holds for $\rho \leqq R_2$.

If $d(x, u) \leqq R_2$, the nonexpansive property of G_j implies that

$$d(G_j(x), G_j(u)) \leqq R_2 \quad \text{for all } j \geqq 0.$$

Thus by repeated applications of (2.14) we obtain

$$d(G_N(x), G_N(u)) \leqq \left(\prod_{j=1}^{N} \mu_j \right) d(x, u),$$

so (2.9) will follow if we can prove that

$$\lim_{N\to\infty} \left(\prod_{j=1}^{N} \mu_j \right) = 0. \tag{2.16}$$

If $\lambda_j \leqq \frac{1}{2}$ for infinitely many indices j, we can easily see that there exists a constant $c < 1$ such that $0 \leqq \mu_j \leqq c$ for infinitely many indices c and (2.16) will be satisfied. Thus we can assume that $\frac{1}{2} < \lambda_j \leqq 1$ for $j \geqq m$, so $\frac{1}{2} < \mu_j \leqq 1$ for $j \geqq m$. Under these conditions it is well known and easily checked that

$$\lim_{N\to\infty} \prod_{j=m}^{N} \lambda_j = 0 \Leftrightarrow \sum_{j=m}^{\infty} -\log(\lambda_j) = \infty \Leftrightarrow \sum_{j=m}^{\infty} (1-\lambda_j) = \infty,$$

$$\lim_{N\to\infty} \prod_{j=m}^{N} \mu_j = 0 \Leftrightarrow \sum_{j=m}^{\infty} -\log(\mu_j) = \infty \Leftrightarrow \sum_{j=m}^{\infty} (1-\mu_j) = \infty.$$

Because $(1-\mu_j) = (R_1/R_2)(1-\lambda_j)$, the equations above imply that (2.16) is satisfied.

Thus it suffices to prove that (2.10) and (2.11) can be satisfied. For a fixed $\psi \in C^* - \{0\}$ it suffices (by homogeneity) to define $u_j = G_j(u)/\psi(G_j(u))$ and to prove that

$$d(g_{j+1}(u_j), g_{j+1}(y)) \leqq \lambda_{j+1} d(y, u_j)$$

for all y such that $\psi(y) = 1$ and $d(y, u_j) \leqq R_1 < R$. Recall (see Lemma 4.1 in [25] or argue directly) that

$$V_{R_1}(u_j) = \{y: d(y, u_j) \leqq R_1\}$$

is convex. For notational convenience, define $G_{j+1} = g$, $A_{j+1} = A$, and $u_j = v$ and let α and β be positive numbers such that

$$\alpha v \leqq y \leqq \beta v \quad \text{and} \quad \log(\beta/\alpha) = \rho = d(y, v).$$

The normalization $\psi(y) = \psi(v) = 1$ implies that $\alpha \leqq 1$ and $\beta \geqq 1$. If we define

$$w_t = (1-t)(\alpha v) + ty \quad \text{and} \quad z_t = (1-t)y + t(\beta v), \quad 0 \leqq t \leqq 1,$$

we obtain

$$g(y) - g(\alpha v) = \int_0^1 g'(w_t)(y - \alpha v)\, dt,$$

$$g(\beta v) - g(y) = \int_0^1 g'(z_t)(\beta v - y)\, dt.$$

If we recall that $g'(z_t) \geqq A$, we obtain from the preceding two equations that

$$\alpha g(v) + A(y - \alpha v) \leqq g(y) \leqq \beta g(v) - A(\beta v - y). \tag{2.17}$$

Note that

$$A(y - \alpha v) + A(\beta v - y) = (\beta - \alpha)Av,$$

so Lemma 2.2 implies that there exists a positive constant $\gamma = \gamma_{j+1} = (\frac{1}{2}) \exp(-\Delta(A_{j+1}))$ such that

$$A(y - \alpha v) \geqq \gamma(\beta - \alpha)Av \quad \text{or} \quad A(\beta v - y) \geqq \gamma(\beta - \alpha)Av.$$

For definiteness we assume that

$$A(y - \alpha v) \geqq \gamma(\beta - \alpha)Av. \tag{2.18}$$

The proof in the other case is essentially the same.

Next, remember that we assume the existence of a positive constant k, independent of $j \geqq 0$, such that

$$A(v) = A_{j+1}(u_j) \geqq kg(v) = kg_{j+1}(u_j). \tag{2.19}$$

If we use (2.17)-(2.19) we obtain

$$\alpha g(v) + k\gamma(\beta - \alpha)g(v) \leqq g(y) \leqq \beta g(v), \tag{2.20}$$

where $\log(\beta/\alpha) = d(y, v)$ and $\gamma = (\frac{1}{2}) \exp(-\Delta(A_{j+1}))$. Formula (2.20) implies that $k\gamma \leqq 1$ and

$$d(g(v), g(y)) \leqq \log\left(\frac{\beta}{\alpha + k\gamma(\beta - \alpha)}\right). \tag{2.21}$$

If we define $s = \beta/\alpha$, with $1 \leqq s \leqq \exp(R_1)$, and recall that $d(v, y) = \log(s)$, we obtain from (2.21) that $d(g(v), g(y)) = d(g_{j+1}(u_j), g_{j+1}(y)) \leqq \lambda_{j+1} d(u_j, y)$, where

$$\lambda_{j+1} = \sup_{1 < s \leqq \exp(R_1)} \frac{\varphi_1(s)}{\varphi_2(s)}, \tag{2.22}$$

with $\varphi_1(s) = \log[s(1 + k\gamma(s-1))^{-1}]$ and $\varphi_2(s) = \log(s)$.

Because $\varphi_j(1) = 0$, the generalized mean value theorem implies that for each s, $1 < s \leqq \exp(R_1)$, there exists σ with $1 < \sigma < s$ such that

$$\varphi_1(s)/\varphi_2(s) = \varphi_1'(\sigma)/\varphi_2'(\sigma) = (1 - k\gamma)(1 + k\gamma(\sigma - 1))^{-1}, \tag{2.23}$$

so

$$\lambda_{j+1} = 1 - \left(\frac{k}{2}\right) \exp\left(-\Delta(A_{j+1})\right). \tag{2.24}$$

The same sort of argument that we have used already proves that

$$\lim_{N\to\infty} \prod_{j=m}^{N} \lambda_j = 0 \quad \text{for every } m \geqq 1$$

if and only if (2.7) is satisfied.

This completes the proof of (2.8); the remaining assertions of the theorem are straightforward and left to the reader. □

Remark 2.1. Let hypotheses and notation be as in Theorem 2.1. However, do not assume condition (d), and suppose that $\langle g_j \rangle$ satisfies the bounded orbit property. Then condition (d) is equivalent to the following condition (d′):

(d′) There exists a positive constant k_1 such that

$$A_j(u) \geqq k_1 g_j(u) \quad \text{for all } j \geqq 1.$$

We will prove that (d′) implies (d); the opposite implication is proved similarly. If u_j is as defined in the proof of Theorem 2.1, the bounded orbit hypothesis implies that there exist positive constants c_j and d_j, $j \geqq 1$, such that

$$c_j u_0 \leqq u_j \leqq d_j u_0 \quad \text{and} \quad d_j / c_j \leqq M,$$

where M is a constant independent of j. It follows that

$$c_j g_{j+1}(u_0) \leqq g_{j+1}(u_j) \leqq d_j g_{j+1}(u_0),$$

$$c_j A_{j+1}(u_0) \leqq A_{j+1}(u_j) \leqq d_j A_{j+1}(u_0).$$

If we use these inequalities and hypothesis (d′) we find that

$$g_{j+1}(u_j) \leqq d_j g_{j+1}(u_0) \leqq k_1^{-1} d_j A_{j+1}(u_0) \leqq k_1^{-1} \left(\frac{d_j}{c_j}\right) A_{j+1}(u_j)$$

$$\leqq k_1^{-1} M A_{j+1}(u_j),$$

which is equivalent to hypothesis (d).

It may be unclear how we can expect to find operators A_j such as those in Theorem 2.1. The next corollary shows that under mild assumptions a scalar multiple of $g_j'(G_{j-1}(u))$ can serve as A_j.

COROLLARY 2.1. *Let C be a cone with nonempty interior in a Banach space X, and let $f_j : \mathring{C} \to \mathring{C}$, $j \geqq 1$, be a sequence of maps that are order-preserving and homogeneous of degree* 1. *For a fixed $p \geqq 1$, let g_j and G_m be as defined in Theorem* 2.1, *and assume that there exist $r > 0$ and $u \in \mathring{C}$ such that f_j is C^1 on $B_r(F_{j-1}(u))$ for all $j \geqq 1$, where $B_r(x) = \{y \in \mathring{C} : d(y, x) < r\}$. Define $u_j = G_j(u)/\|G_j(u)\|$ and assume that there exist positive constants c and $\rho \leqq r$ such that, if $d(x, u_{j-1}) < \rho$ and $j \geqq 1$, then*

$$g_j'(x) \geqq c g_j'(u_{j-1}). \tag{2.25}$$

Finally, assume that the operators $B_j = g_j'(G_{j-1}(u)) = g_j'(u_{j-1})$ satisfy

$$\sum_{j=1}^{\infty} \exp\left(-\Delta(B_j)\right) = \infty, \tag{2.26}$$

where $\Delta(B_j)$ *is given by* (1.6) *if* B_j *has finite projective diameter, and that they satisfy* $\exp(-\Delta(B_j)) = 0$ *otherwise. Then it follows that*

$$\lim_{n\to\infty} d(F_n(x), F_n(y)) = 0 \quad \text{for all } x, y \in \mathring{C}.$$

If C *is normal,* (1.13) *is also satisfied for all* $x, y \in \mathring{C}$.

Proof. Define $A_j = cB_j$ for c as in (2.25). It suffices to prove that the hypotheses of Theorem 2.1 are satisfied. Formula (2.25) implies (taking $\rho = R$) that hypothesis (c) of Theorem 2.1 is satisfied.

Because g_i is order-preserving, B_i and $A_i = cB_i$ are also order-preserving, so $A_i(C) \subset C$. The homogeneity of g_i implies that

$$g_i(u_{i-1}) = B_i(u_{i-1}) \in \mathring{C}, \tag{2.27}$$

and using (2.27) and the order-preserving property of A_i we conclude that $A_i(\mathring{C}) \subset \mathring{C}$. Thus hypothesis (b) of Theorem 2.1 is satisfied. Hypothesis (d) of Theorem 2.1 also follows directly from (2.27). Finally, because $\Delta(cB_i) = \Delta(B_i)$, (2.7) is equivalent to (2.26). □

The homogeneity of the functions f_j in Theorem 2.1 plays less of a role than it might at first seem to. We illustrate this by stating a result that follows by essentially the same argument as Theorem 2.1. First, we need a lemma proved by Potter (see [29]) in the case where the function g is defined, order-preserving, and subhomogeneous on *all* of $\mathring{C}$.

LEMMA 2.3. (Compare [29].) *Let* C *be a cone with nonempty interior in a Banach space* X, *and for* $\psi \in C^* - \{0\}$ *and* $\lambda > 1$ *define* $\Sigma = \{x \in \mathring{C}: \psi(x) = 1\}$ *and* $D = \{x \in \mathring{C}: \lambda^{-1} < \psi(x) < \lambda\}$. *Assume that* $f: D \to \mathring{C}$ *is order-preserving and subhomogeneous on* D. *Then* $f|\Sigma$ *is nonexpansive with respect to Hilbert's projective metric* d, *so* $d(f(x), f(y)) \leqq d(x, y)$ *for all* $x, y \in \Sigma$.

Proof. If x_0 and x_1 are points in Σ with $d(x_0, x_1) = \rho$, define $x_s = (1-s)x_0 + sx_1$. For a given integer $n > 1$, it follows from Proposition 1.9 in [25] that there are real numbers s_j, with $s_j < s_{j+1}$ for $0 \leqq j < n$ and $s_0 = 0$ and $s_n = 1$ and (writing $y_j = x_{s_j}$)

$$d(y_j, y_{j+1}) = \rho n^{-1} \quad \text{for } 0 \leqq j < n.$$

Note that in general $s_j \neq jn^{-1}$.

Choose n so large that $\rho n^{-1} < \lambda$. It suffices to prove that

$$d(f(y_j), f(y_{j+1})) \leqq d(y_j, y_{j+1}) = \rho n^{-1}, \tag{2.28}$$

for then the triangle inequality gives

$$d(f(x_0), f(x_1)) \leqq \sum_{j=0}^{n-1} d(f(y_j), f(y_{j+1})) \leqq n(\rho n^{-1}) = d(x_0, x_1).$$

For a fixed j select numbers α and β so that

$$\alpha y_j \leqq y_{j+1} \leqq \beta y_j \quad \text{and} \quad \log\left(\frac{\beta}{\alpha}\right) = \rho n^{-1}. \tag{2.29}$$

Because $\psi(y_j) = \psi(y_{j+1}) = 1$, we easily obtain from (2.29) that $0 < \alpha \leqq 1 \leqq \beta$ and $\alpha^{-1} \leqq \rho n^{-1} < \lambda$ and $\beta < \rho n^{-1} < \lambda$. It follows that the points αy_j, $\beta^{-1} y_{j+1}$, y_j, and y_{j+1} all lie in D. By using the subhomogeneity and the order-preserving property of f on D we find that

$$\alpha f(y_j) \leqq f(\alpha y_j) \leqq f(y_{j+1}) \quad \text{and} \quad \beta^{-1} f(y_{j+1}) \leqq f(\beta^{-1} y_{j+1}) \leqq f(y_j),$$

so

$$d(f(y_j), f(y_{j+1})) \leqq \log\left(\frac{\beta}{\alpha}\right).$$

□

We can now give a version of Theorem 2.1 for order-preserving, subhomogeneous operators. Once we know Lemma 2.3, the proof of the next theorem follows by essentially the same argument as in Theorem 2.1 and is left to the reader.

THEOREM 2.2. *Let C be a cone with nonempty interior in a Banach space X and for fixed $\psi \in C^* - \{0\}$ and $\lambda > 1$ define $D = \{x \in \mathring{C}: \lambda^{-1} < \psi(x) < \lambda\}$ and $\Sigma = \{x \in \mathring{C}: \psi(x) = 1\}$. Suppose that $g_j: D \to \mathring{C}$, $j \geqq 1$, is a sequence of order-preserving, subhomogeneous maps and define*

$$h_j(x) = g_j(x)/\psi(g_j(x)),$$

with $H_m = h_m h_{m-1} \cdots h_1$ and H_0 equal to the identity. For some $u \in \Sigma$ define $u_j = H_j(u)$ and assume that there exists $R > 0$ and a sequence of bounded linear operators A_j, $j \geqq 1$, such that:

(a) *g_j is continuously Fréchet differentiable on $B_R(u_{j-1}) \cap D$ for all $j \geqq 1$, where $B_R(y) = \{x \in \mathring{C}: d(x, y) < R\}$.*

(b) *$A_i(\mathring{C}) \subset \mathring{C}$ for all $i \geqq 1$ and $g_i'(x) \geqq A_i$ for all $x \in B_R(u_{i-1}) \cap D$ and $i \geqq 1$.*

(c) *There exists a positive constant k such that $A_j(u_{j-1}) \geqq k g_j(u_{j-1})$ for all $j \geqq 1$.*

If we have

$$\lim_{N \to \infty} \sum_{j=1}^{N} \exp(-\Delta(A_j)) = \infty,$$

where $\Delta(A_j)$ is given by (1.6), *then it follows that*

$$\lim_{n \to \infty} d(H_n(x), H_n(y)) = 0 \quad \text{for all } x, y \in \Sigma,$$

and

$$\lim_{n \to \infty} \|H_n(x) - H_n(y)\| = 0 \quad \text{for all } x, y \in \Sigma$$

if C is normal.

Remark 2.2. Note that in the statement of Theorem 2.2 there is no integer p analogous to the one in the statement of Theorem 2.1. If we assume that the g_j satisfy a "ray-preserving property" as in [16], then

$$\{g_j(tx): t > 0\} \subset \{s g_j(x): s > 0\} \quad \text{for } j \geqq 1 \quad \text{and} \quad x \in \Sigma.$$

Then if $G_m = g_m g_{m-1} \cdots g_1$, we can verify (see [16]) that

$$G_m(x)/\psi(G_m(x)) = H_m(x).$$

Using this fact we can then give a version of Theorem 2.2 that directly generalizes Theorem 2.1. Without the ray-preserving property there seems to be no necessary connection between G_m and H_m.

However, the assumption of the ray-preserving property for order-preserving, subhomogeneous operators can be restrictive. To see this, suppose that $f_j: \mathring{C} \to \mathring{C}$, $j = 1, 2$, is order-preserving and $f_j(tx) = t^{\lambda_j} f_j(x)$ for $0 < t \leqq 1$ and $x \in \mathring{C}$, where $0 < \lambda_j \leqq 1$. Then f_j is subhomogeneous, order-preserving, and ray-preserving. However, $f = f_1 + f_2$ is subhomogeneous and order-preserving, but not ray-preserving unless $\lambda_1 = \lambda_2$.

Remark 2.3. In [16], Fujimoto and Krause have obtained weak ergodic theorems for ray-preserving maps of the standard cone $K = \{x \in \mathbb{R}^n: x_i \geqq 0 \text{ for } 1 \leqq i \leqq n\}$ into itself. If $\Gamma = \{x \in K: \psi(x) = 1\}$ ($\psi \in K^* - \{0\}$) and $f_j: K \to K$, $j \geqq 1$, is a sequence of maps for which we want to establish a weak ergodic theorem, then the assumption of "uniform pointwise boundedness" in Theorem 4 of [16] (assuming, for simplicity that $r = 1$ in the statement of that theorem) implies that there exist $a, b \in \mathring{K}$ such that

$$a \leqq f_j(x)/\psi(f_j(x)) = h_j(x) \leqq b \quad \text{for all } x \in \Gamma. \tag{2.30}$$

Formula (2.30) (or its analogue for $r \geqq 1$) implies that $h_j : \Gamma \cap \mathring{K} \to \Gamma \cap \mathring{K}$, $j \geqq 1$, satisfies the bounded orbit property with respect to d, but uniform pointwise boundedness represents a less general condition than the bounded orbit property does. In particular, if $f_j \in \mathcal{M}$ for $j \geqq 1$, many examples of interest do not satisfy (2.30) or even the condition that $f_j(K - \{0\}) \subset \mathring{K}$, but they may satisfy the bounded orbit property. Of course (see § 4 of [16]), there are also many examples where the uniform pointwise boundedness assumption is satisfied.

Remark 2.4. The reader will note that the bounded orbit property is not assumed in Theorem 2.1, Corollary 2.1, or Theorem 2.2. Nevertheless, the bounded orbit property plays a crucial role: to verify the hypotheses of Corollary 2.1 or Theorem 2.2 for examples of interest, we will typically have to verify the bounded orbit property.

In the framework of Theorem 2.1 it is natural to ask if a stronger conclusion can be obtained. Does there exist $v \in \mathring{C}$ such that

$$\lim_{n\to\infty} d(F_n(x), v) = 0 \quad \text{and} \quad \lim_{n\to\infty} \| F_n(x)/\|F_n(x)\| - v\| = 0 \quad \text{for all } x \in \mathring{C}?$$

A similar question can be asked for Theorem 2.2. Such results are called "strong ergodic theorems" in [11]. As we now show, such a theorem can be derived easily from Theorem 2.1.

THEOREM 2.3. *Let C be a cone with nonempty interior in a Banach space X and $f_j : \mathring{C} \to \mathring{C}$, $j \geqq 1$, a sequence of maps that are homogeneous of degree 1 and order-preserving. Assume that there exists $v \in \mathring{C}$, $\|v\| = 1$, such that*

$$\lim_{j\to\infty} d(f_j(v), v) = 0, \tag{2.31}$$

where d denotes Hilbert's projective metric. Assume there exists $R > 0$, an integer $p \geqq 1$, and a sequence of bounded linear operators A_j, $j \geqq 1$, with the following properties:

(a) *If g_j is defined as in Theorem 2.1, g_j is continuously Fréchet differentiable on $B_R(v) = \{x \in \mathring{C} : d(x, v) < R\}$ for all $j \geqq 1$.*

(b) *For all $x \in B_R(v)$ and all $j \geqq 1$ we have $g_j'(x) \geqq A_j$.*

(c) *The operators A_j satisfy $A_j(\mathring{C}) \subset \mathring{C}$, A_j has finite projective diameter $\Delta(A_j)$, and*

$$\sup\{\Delta(A_j) : j \geqq 1\} < \infty. \tag{2.32}$$

(d) *There exists a positive constant k such that $A_j(v) \geqq k g_j(v)$ for all $j \geqq 1$. Then it follows that $\lim_{n\to\infty} d(F_n(x), v) = 0$ for all $x \in \mathring{C}$, and $\lim_{n\to\infty} \|F_n(x)/\|F_n(x)\| - v\| = 0$ if C is normal.*

Proof. By using the triangle inequality and the nonexpansiveness of f_j we can verify that

$$d(g_j(v), v) \leqq \sum_{i=jp-p+1}^{jp} d(f_i(v), v),$$

so

$$\lim_{j\to\infty} d(g_j(v), v) = 0.$$

We claim that to prove the theorem it suffices to prove that

$$\lim_{n\to\infty} d(G_n x, v) = \lim_{n\to\infty} d(F_{np} x, v) = 0 \quad \text{for all } x \in \mathring{C}. \tag{2.33}$$

To see this, note that the triangle inequality and the nonexpansiveness of the f_j imply that for $np < m < np + p$,

$$d(F_m x, v) \leqq d(F_{np} x, v) + \sum_{j=0}^{m-np-1} d(f_{m-j} v, v). \tag{2.34}$$

Formulae (2.31), (2.33), and (2.34) imply that

$$\lim_{m\to\infty} d(F_m x, v) = 0 \quad \text{for all } x \in \mathring{C}.$$

Thus it suffices to work with g_j and G_j.

Select a fixed number R_1, $0 < R_1 < R$, and define $V_{R_1}(v) = \{z: d(z, v) \leqq R_1\}$. Essentially the same argument used in the proof of Theorem 2.1 actually shows that for all $x, y \in V_{R_1}(v)$,

$$d(g_j(x), g_j(y)) \leqq c_j d(x, y),$$

where $c_j = [1 - (k/2)\, e^{-R_1} \exp(-\Delta(A_j))]$. (Note the extra factor e^{-R_1} in c_j; this is unnecessary if x or y equals v.) Because we assume that $\Delta(A_j)$ is bounded above, we have

$$\sup\{c_j: j \geqq 1\} = c < 1.$$

Now select any number ε, $0 < \varepsilon < R_1$, and suppose that $x \in V_\varepsilon(v)$, so $d(x, v) \leqq \varepsilon$. Then we obtain

$$\begin{aligned} d(g_j(x), v) &\leqq d(g_j(x), g_j(v)) + d(g_j(v), v) \\ &\leqq c\varepsilon + d(g_j(v), v). \end{aligned}$$

It follows that there exists an integer $m = m(\varepsilon)$ such that

$$g_j(V_\varepsilon(v)) \subset V_\varepsilon(v) \quad \text{for } j \geqq m(\varepsilon).$$

We now apply Theorem 2.1. For $m = m(\varepsilon)$ as above, define $\varphi_i(x) = g_{m+i}(x)$ and $\Phi_j = \varphi_j \varphi_{j-1} \cdots \varphi_1$. The sequence φ_j, $j \geqq 1$, satisfies the bounded orbit property; in fact, $\Phi_j(v) \in V_\varepsilon(v)$ for all $j \geqq 1$. It is also easy to check that all the hypotheses of Theorem 2.1 are satisfied, so

$$\lim_{j\to\infty} d(\Phi_j(y), \Phi_j(v)) = 0 \quad \text{for all } y \in \mathring{C}.$$

Taking $y = G_m(x)$ for $x \in \mathring{C}$, we conclude that

$$\lim_{j\to\infty} d(G_{j+m}(x), \Phi_j(v)) = 0 \quad \text{for all } x \in \mathring{C}.$$

Since $\Phi_j(v) \in V_\varepsilon(v)$ for all $j \geqq 1$, we conclude that for any fixed $x \in \mathring{C}$ there exists n such that

$$d(G_j(x), v) < 2\varepsilon \quad \text{for all } j \geqq n.$$

Since $\varepsilon > 0$ can be taken as small as desired, the proof is complete. □

Remark 2.5. Suppose that $f: \mathring{C} \to \mathring{C}$ is a map and $f(v) = \lambda v$ for some $v \in \mathring{C}$. Assume that $f_j: \mathring{C} \to \mathring{C}$, $j \geqq 1$, is a sequence of maps as in Theorem 2.3 and that for every $x \in \mathring{C}$ we have

$$\lim_{j\to\infty} d(f_j(x), f(x)) = 0.$$

Then it is certain that $\lim_{j\to\infty} d(f_j(v), v) = 0$, which provides a situation where we can find a vector v as in Theorem 2.3. However, such a vector v may well exist even if the functions f_j do not converge to a function f.

Remark 2.6. Essentially the same argument as in Theorem 2.3 can be extended, as in Theorem 2.2, to the case of order-preserving maps that are subhomogeneous. Details are left to the reader.

Under the hypotheses of Theorem 2.1, it is natural to ask if, for every given $x \in \mathring{C}$, there exists a positive number $\gamma = \gamma(x)$ such that

$$\lim_{n\to\infty} \|F_n(x) - \gamma F_n(u)\| = 0.$$

If $f_j = f$ for all $j \geqq 1$ and $f(u) = u$, this question is considered at length in § 3 of [25]. Before considering the general case it is convenient to prove a simple lemma.

LEMMA 2.4. *Let C be a normal cone with nonempty interior in a Banach space X. If $u \in \mathring{C}$ and R, c_1, and c_2 are positive reals, define V by*

$$V = \{x \in \mathring{C}: d(x, u) \leqq R \text{ and } c_1 \leqq \|x\| \leqq c_2\},$$

where d denotes Hilbert's projective metric. Then there exists $\rho > 0$ so that, for every $x \in V$,

$$\{z \in X: \|z - x\| < \rho\} \subset \mathring{C}.$$

Proof. If $x \in V$, there exist positive numbers α and β such that

$$\alpha u \leqq x \leqq \beta u \quad \text{and} \quad \beta\alpha^{-1} \leqq e^R. \tag{2.35}$$

By the definition of normality there exists a constant M so that if $0 \leqq x \leqq y$ then

$$\|x\| \leqq M\|y\|. \tag{2.36}$$

Combining (2.35) and (2.36) gives

$$\alpha\|u\| \leqq M\|x\| \leqq Mc_2 \quad \text{and} \quad c_1 \leqq \|x\| \leqq M\beta\|u\|. \tag{2.37}$$

Formulae (2.35) and (2.37) imply that

$$(c_1/M\|u\|)\, e^{-R} \leqq \alpha \quad \text{and} \quad \beta \leqq (Mc_2/\|u\|)\, e^R.$$

Thus there exists a number $\gamma \geqq 1$, independent of $x \in V$, such that

$$\gamma^{-1}u \leqq x \leqq \gamma u. \tag{2.38}$$

Because $\gamma^{-1}u \in \mathring{C}$, there exists $\rho > 0$ such that $\gamma^{-1}u + z \in \mathring{C}$ for all $z \in X$ with $\|z\| < \rho$, and (2.38) then implies that $x + z \in \mathring{C}$ for all $x \in V$ and all z with $\|z\| < \rho$. □

If C is a cone with nonempty interior in a Banach space X, $x \in \mathring{C}$ and $\{y: \|y - x\| < \rho\} \subset \mathring{C}$, then we can easily prove that for $\|y - x\| < \rho$ we have

$$(\rho - \|y - x\|)\rho^{-1}x \leqq y \leqq (\rho + \|y - x\|)\rho^{-1}x. \tag{2.39}$$

THEOREM 2.4. *Let notation and assumptions be as in Theorem 2.1. Assume also that $\langle f_j \rangle$ satisfies the bounded orbit property, that C is normal, and that*

$$\sup\{\|F_m(u)\|: m \geqq 0\} < \infty \quad \textit{and} \quad \inf\{\|F_m(u)\|: m \geqq 0\} > 0. \tag{2.40}$$

Then for every $x \in \mathring{C}$ there exists a positive number $\gamma = \gamma(x)$ such that

$$\lim_{m\to\infty} \|F_m(x) - \gamma F_m(u)\| = 0. \tag{2.41}$$

The map $x \to \gamma(x)$ is homogeneous of degree 1, order-preserving, and continuous.

Proof. It is known (see [32]) that there exists an equivalent norm on X whose restriction to C is order-preserving. Thus we can assume that if $0 \leqq x \leqq y$, then $\|x\| \leqq \|y\|$.

For a fixed $x \in \mathring{C}$, define numbers α_n and β_n by

$$\alpha_n = m(F_n(x)/F_n(u)) \quad \text{and} \quad \beta_n = M(F_n(x)/F_n(u)),$$

so

$$\alpha_n F_n(u) \leqq F_n(x) \leqq \beta_n F_n(u). \tag{2.42}$$

Applying f_{n+1} to (2.42) we find that

$$\alpha_n F_{n+1}(u) \leqq F_{n+1}(x) \leqq \beta_n F_{n+1}(u),$$

and we conclude from this inequality that

$$\alpha_n \leqq \alpha_{n+1}, \quad \beta_{n+1} \leqq \beta_n, \quad \alpha_n \leqq \beta_n \quad \text{for all } n, \tag{2.43}$$

so $\lim_{n\to\infty} \alpha_n = \alpha$ and $\lim_{n\to\infty} \beta_n = \beta$.

If we can prove that $\alpha = \beta$, we can define $\gamma(x) = \beta$ and (by normality of the cone) it is evident from (2.42) that (2.41) is satisfied. Furthermore, the homogeneity and order-preserving properties of $\gamma(x)$ follow immediately from the formula

$$\gamma(x) = \lim_{n\to\infty} M(F_n(x)/F_n(u)).$$

Because γ is homogeneous of degree 1 and order-preserving, we can easily derive from (2.39) that γ is continuous.

Theorem 2.1 implies that

$$\lim_{n\to\infty} \|F_n(x)\|F_n(x)\|^{-1} - F_n(u)\|F_n(u)\|^{-1}\| = 0, \tag{2.44}$$

and (2.42) gives

$$\alpha_n \leqq \gamma_n = \|F_n(x)\|/\|F_n(u)\| \leqq \beta_n. \tag{2.45}$$

Formulae (2.40) and (2.45) imply that $\|F_n(x)\|$ is bounded above and below by positive reals. Using the fact that $\|F_n(x)\|$ is bounded above, we obtain from (2.44)

$$\lim_{n\to\infty} \|F_n(x) - \gamma_n F_n(u)\| = \lim_{n\to\infty} \varepsilon_n = 0. \tag{2.46}$$

We now use Lemma 2.4. The bounded orbit property implies that there exists $R > 0$ such that

$$d(\gamma_n F_n(u), u) = d(F_n(u), u) \leqq R \quad \text{for all } n \geqq 1.$$

Furthermore, as already noted, there exist positive reals c_1 and c_2 such that

$$c_1 \leqq \gamma_n \|F_n(u)\| = \|F_n(x)\| \leqq c_2.$$

Thus Lemma 2.3 implies that there exists $\rho > 0$ such that if $\|z - \gamma_n F_n(u)\| < \rho$ for some $n \geqq 0$, then $z \in \mathring{C}$. If ε_n is defined as in (2.46), then (2.39) implies that if $\varepsilon_n < \rho$ for $n \geqq N$, then for $n \geqq N$,

$$[(\rho - \varepsilon_n)\rho^{-1}]\gamma_n F_n(u) \leqq F_n(x) \leqq [(\rho + \varepsilon_n)\rho^{-1}]\gamma_n F_n(u). \tag{2.47}$$

It follows that

$$0 \leqq \beta_n - \alpha_n \leqq (\rho + \varepsilon_n)\rho^{-1}\gamma_n - (\rho - \varepsilon_n)\rho^{-1}\gamma_n = 2\varepsilon_n \rho^{-1}\gamma_n,$$

and we conclude (using (2.46) and the fact γ_n is bounded) that

$$\lim_{n\to\infty} (\beta_n - \alpha_n) = 0. \qquad \square$$

As an easy corollary of Theorem 2.4 we mention the following result, a slightly weaker version of which has been proved by Cohen in [12]. Of course, in this simple situation it is also possible to give an elementary, direct proof, so the following corollary is meant only as an illustration of Theorem 2.4.

COROLLARY 2.2. (Compare [12].) *Let* $K = \{(x_1, x_2) \in \mathbb{R}^2 : x_i \geqq 0 \text{ for } i = 1, 2\}$. *Let* λ_j, $j \geqq 1$, *be a sequence of real numbers such that* $0 \leqq \lambda_j \leqq 1$, *and for each* $j \geqq 1$ *define*

$$f_j : \mathring{K} \to \mathring{K} \quad \text{by} \quad f_j(x_1, x_2) = ((1-\lambda_j)x_1 + \lambda_j x_2, x_1^{1-\lambda_j} x_2^{\lambda_j})$$

and define $F_n = f_n f_{n-1} \cdots f_1$. *Then for each* $x = (x_1, x_2) \in \mathring{K}$, *there exists* $\gamma = \gamma(x) > 0$ *such that*

$$\lim_{n\to\infty} F_n(x) = (\gamma, \gamma).$$

Proof. Let $u = (1, 1)$ so $f_j(u) = u$ for all $j \geqq 1$. Thus f_j, $j \geqq 1$, satisfies the bounded orbit property in Theorem 2.1 and (2.40) in Theorem 2.4. The functions f_j are clearly all order-preserving, homogeneous of degree 1, and C^1 on $\mathring{K}$. For a fixed $R > 0$, define

$$A_j = e^{-R} \begin{pmatrix} 1-\lambda_j & \lambda_j \\ 1-\lambda_j & \lambda_j \end{pmatrix}.$$

It is easy to check that $f_j'(x) \geqq A_j$ for all x with $d(x, u) \leqq R$ and

$$A_j(u) \geqq e^{-R} f_j(u) = e^{-R} u.$$

Also, A_j has one-dimensional range, so $\Delta(A_j) = 0$. If we take $p = 1$ (in the notation of Theorem 2.1), we thus see that all hypotheses of Theorems 2.1 and 2.4 are satisfied, so the conclusion of the corollary follows from Theorem 2.4. □

The preceding theorems typically make some assumption of differentiability. These assumptions are motivated by the applications we have in mind and can certainly be weakened. The hypotheses of Theorem 2.1 represent only a convenient way to obtain the estimates in (2.10) and (2.11). To illustrate this point we mention the following theorem, whose proof is essentially the first part of the proof of Theorem 2.1. Details are left to the reader.

THEOREM 2.5. *Let* C *be a cone with nonempty interior in a Banach space* X. *Let* Σ *be a subset of* $\mathring{C}$ *and* $S = \{y \in \mathring{C} : \|y\| = 1\}$ *and assume that for each* $y \in S$ *there is a unique positive number* $\lambda = \lambda(y)$ *such that* $\lambda y \in \Sigma$. *Suppose that the* $h_j : \Sigma \to \Sigma$, $j \geqq 1$, *is a sequence of maps and that there exists* $u \in \Sigma$ *such that if* $H_m = h_m h_{m-1} \cdots h_1$ (*the composition of the first* m *functions* h_j) *and* H_0 *denotes the identity, then*

$$d(h_m(x), H_m(u)) \leqq d(x, H_{m-1}(u)) \quad \text{for all } x \in \Sigma \quad \text{and} \quad m \geqq 1.$$

(*Here* d *denotes Hilbert's projective metric.*) *In addition, assume that there exist* $R > 0$ *and a sequence of reals* λ_j, $j \geqq 1$, *such that* $0 \leqq \lambda_j \leqq 1$ *for all* j,

$$d(h_m(x), H_m(u)) \leqq \lambda_m d(x, H_{m-1}(u)) \quad \text{for all } x \in \Sigma \text{ with } d(x, H_{m-1}(u)) \leqq R, \text{ and}$$

$$\lim_{N\to\infty} \prod_{j=m}^{N} \lambda_j = 0 \quad \text{for all } m \geqq 1.$$

It then follows that for every $x \in \Sigma$,

$$\lim_{n\to\infty} d(H_n(x), H_n(u)) = 0.$$

3. Applications: verifying the bounded orbit property. In this section we show how the results of § 2 can be applied in the case where $f_j \in M$ for all $j \geqq 1$, M being the class defined in § 1. We shall show that the main difficulty lies in verifying the bounded orbit property with respect to d. If $f_j \in M_+$ for all $j \geqq 1$, we will give reasonably general conditions ensuring that the bounded orbit property is satisfied. As we have already noted in § 2, if $f_j \in M_-$ for all $j \geqq 1$, verifying the bounded orbit property can be a difficult problem even when $f_j = f$ for all $j \geqq 1$.

We begin with some needed notation and definitions. We will always denote by K the standard cone in $\mathbb{R}^n$,

$$K = \{x \in \mathbb{R}^n : x_i \geqq 0 \text{ for } 1 \leqq i \leqq n\}. \tag{3.1}$$

If $f_j \in M$ is a sequence of functions for $j \geqq 1$, we will denote by f_{ji}, $1 \leqq i \leqq n$, the ith component of the function $f_j : \mathring{K} \to \mathring{K}$. By definition of M, there is a finite collection Γ_{ji} of ordered pairs (r, σ), r a real number and σ a probability vector, and positive real numbers $c_{jir\sigma}$ for $(r, \sigma) \in \Gamma_{ji}$, such that

$$f_{ji}(x) = \sum_{(r,\sigma)\in\Gamma_{ji}} c_{jir\sigma} M_{r\sigma}(x). \tag{3.2}$$

Because $(x^r)^{1/r} = x$, the set Γ_{ji} described above may not be uniquely determined by the function f_{ji}. However, we will need some control of the size of the numbers r, which appear in (3.2). Thus we make the following definitions. Suppose that $\phi \in M$ so ϕ_i, the ith component of ϕ, can be written

$$\phi_i(x) = \sum_{(r,\sigma)\in G_i} c_{ir\sigma} M_{r\sigma}(x), \tag{3.3}$$

where G_i is a finite collection of ordered pairs (r, σ), r a real number and σ a probability vector, and $c_{ir\sigma} > 0$. If $\phi \in M_+$, the sets G_i can be chosen so that $r \geqq 0$ for all $(r, \sigma) \in G_i$.

DEFINITION 3.1. If $\phi \in M$, we define $\mu(\phi)$ by

$$\begin{aligned} \mu(\phi) = \inf\{\mu > 0 &: \phi_i(x) \text{ can be expressed as in (3.3),} \\ &\text{and } |r| \leqq \mu \text{ for all } (r, \sigma) \in G_i \text{ and for } 1 \leqq i \leqq n\}. \end{aligned} \tag{3.4}$$

If $\phi \in M_+$, we define $\nu(\phi)$ by

$$\begin{aligned} \nu(\phi) = \inf\{\nu > 0 &: \phi_i(x) \text{ can be expressed as in (3.3),} \\ &\text{and } 0 \leqq r \leqq \nu \text{ for all } (r, \sigma) \in G_i \text{ and for } 1 \leqq i \leqq n\}. \end{aligned} \tag{3.5}$$

If C is a cone in a Banach space X and A and B are bounded linear maps of X to X, we will say that $A \leqq B$ if $(B - A)(C) \subset C$; the ordering depends on C. If $A(C) \subset C$ and $B(C) \subset C$, we will say that A and B are comparable if there exist positive numbers c_1 and c_2 such that

$$c_1 A \leqq B \leqq c_2 A.$$

If $C = K$ and $X = \mathbb{R}^n$, then bounded linear maps are $n \times n$ matrices, $A = (a_{ij}) \leqq B = (b_{ij})$ if and only if $a_{ij} \leqq b_{ij}$ for all i, j. If $a_{ij} \geqq 0$ and $b_{ij} \geqq 0$ for all i, j, A and B are comparable if and only if there exist positive reals c_1 and c_2 such that

$$c_1 a_{ij} \leqq b_{ij} \leqq c_2 a_{ij} \quad \text{for all } i, j.$$

Our next lemma is easy, but we give a proof for completeness.

LEMMA 3.1. *Assume that C is a cone in a Banach space X and that $A, B : X \to X$ are bounded linear operators such that $A(C) \subset C$ and $B(C) \subset C$. Assume that A and B are comparable; then there exist positive reals c_1 and c_2 such that*

$$c_1 A \leqq B \leqq c_2 A. \tag{3.6}$$

If A has finite projective diameter $\Delta(A)$ (see (1.6)), then B has finite projective diameter and

$$\Delta(B) \leqq \Delta(A) + 2 \log (c_2/c_1). \tag{3.7}$$

Proof. If x and y are any two elements of C such that Bx and By are nonzero, then by using (3.6) we see that Ax and Ay are nonzero. By definition of finite projective diameter, it follows that there exist positive reals α and β such that

$$\alpha A(x) \leqq A(y) \leqq \beta A(x) \quad \text{and} \quad \log(\beta/\alpha) \leqq \Delta(A). \tag{3.8}$$

By using (3.6) repeatedly we obtain from (3.8) that

$$\alpha(c_1/c_2)B(x) \leqq B(y) \leqq \beta(c_2/c_1)B(x), \tag{3.9}$$

which implies that

$$d(Bx, By) \leqq 2\log(c_2/c_1) + \log(\beta/\alpha). \tag{3.10}$$

Formulae (3.8) and (3.10) yield (3.7). □

In [26] it is proved that if $f \in \mathcal{M}$ (see § 1 for definitions), then f is C^∞ on $\mathring{K}$ and $f'(x)$ and $f'(y)$ are comparable for all $x, y \in \mathring{K}$ (this is not hard). We need a more precise version of this fact, relating the sizes of $f'(x)$ and $f'(y)$, when $f \in M$.

LEMMA 3.2. *Let K denote the standard cone in $\mathbb{R}^n$* (see (3.1)), *let $v = (1, 1, \cdots, 1)$ be the vector all of whose components are* 1, *and define $\psi \in K^*$ by*

$$\psi(x) = \sum_{i=1}^{n} x_i.$$

Suppose that $f: \mathring{K} \to \mathring{K}$ is homogeneous of degree 1 *and order-preserving. If $x \in \mathring{K}$, $\psi(x) = n$, and $d(x, v) \leqq R$ (d denotes Hilbert's projective metric), then*

$$e^{-R} f(v) \leqq f(x) \leqq e^{R} f(v). \tag{3.11}$$

If $f \in M$ and $\mu(f) < \gamma$ (see Definition 3.1), *then for all $x \in \mathring{K}$ such that $d(x, v) \leqq R$,*

$$\exp(-R(\gamma+1)) f'(v) \leqq f'(x) \leqq \exp(R(\gamma+1)) f'(v), \tag{3.12}$$

where $f'(x)$ denotes the Jacobian matrix at x.

Proof. If $\psi(x) = n = \psi(v)$ and $\alpha = m(x/v)$ and $\beta = M(x/v)$, we must have $\alpha \leqq 1 \leqq \beta$; and if $d(x, v) \leqq R$, then

$$\beta/\alpha \leqq e^R. \tag{3.13}$$

Formula (3.13) implies that $\beta \leqq e^R$ and $\alpha \geqq e^{-R}$ (since $\alpha \leqq 1 \leqq \beta$), and (3.11) follows from the homogeneity and order-preserving properties of f.

If $f \in M$, $\mu(f) < \gamma$, and f_i denotes the ith component of $f(x)$, then we can write

$$f_i(x) = \sum_{(r,\sigma) \in G_i} c_{ir\sigma} M_{r\sigma}(x), \qquad |r| < \gamma \quad \text{for } (r, \sigma) \in G_i. \tag{3.14}$$

Here G_i is a finite collection of ordered pairs (r, σ) with $r \in \mathbb{R}$ and σ a probability vector and $c_{ir\sigma} > 0$ for $(r, \sigma) \in G_i$, $1 \leqq i \leqq n$. If $d(x, v) \leqq R$ we have

$$e^{-R} \leqq x_j/x_k \leqq e^R \quad \text{for all } j, k. \tag{3.15}$$

A calculation implies that for $d(x, v) \leqq R$,

$$\frac{\partial M_{r\sigma}}{\partial x_j}(x) = \sigma_j [x_j (M_{r\sigma}(x))^{-1}]^{r-1}. \tag{3.16}$$

Recall that $M_{r\sigma}$ is an order-preserving map on $\mathring{K}$ for any real number r and that (3.15) implies that

$$e^{-R} x_j v \leqq x \leqq e^R x_j v.$$

Using this we conclude that for $d(x, v) \leqq R$ we have

$$e^{-R} \leqq x_j(M_{r\sigma}(x))^{-1} \leq e^R;$$

(3.16) then implies that

$$\sigma_j e^{-R|r-1|} \leqq \frac{\partial M_{r\sigma}}{\partial x_j}(x) \leqq \sigma_j e^{R|r-1|}. \tag{3.17}$$

Because $|r| < \gamma$ for all r such that $(r, \sigma) \in G_i$, we conclude from (3.17) that

$$\exp(-R(\gamma+1)) \sum_{(r,\sigma)\in G_i} c_{ir\sigma}\sigma_j \leqq \frac{\partial f_i}{\partial x_j}(x) \leqq \exp(R(\gamma+1)) \sum_{(r,\sigma)\in G_i} c_{ir\sigma}\sigma_j. \tag{3.18}$$

Of course (3.18) is equivalent to

$$\exp(-R(\gamma+1)) \frac{\partial f_i}{\partial x_j}(v) \leqq \frac{\partial f_i}{\partial x_j}(x) \leqq \exp(R(\gamma+1)) \frac{\partial f_i}{\partial x_j}(v),$$

which implies (3.2). □

We can now state a weak ergodic theorem for functions $f_j \in M$. In the statement of the following theorem recall that a nonnegative $n \times n$ matrix B is called "primitive" if there exists $p \geqq 1$ such that B^p has all positive entries.

THEOREM 3.1. *Let K be the standard cone in $\mathbb{R}^n$ (see (3.1)) and suppose that for $j \geqq 1$, $f_j \in M$, where M is the class of maps of $\mathring{K}$ into itself defined in § 1. Assume that $\mu(f_j) < \gamma < \infty$ for all $j \geqq 1$ (see Definition 3.1). If $v = (1, 1, \cdots, 1)$, suppose also that there exist an $n \times n$ primitive matrix B and an $n \times n$ matrix A such that $B \leqq f_j'(v) \leqq A$ for all $j \geqq 1$. Finally, assume that $\langle f_j \rangle$ satisfies the bounded orbit property with respect to Hilbert's projective metric d (see Definition 2.1). Then if $F_k = f_k f_{k-1} \cdots f_1$,*

$$\lim_{k\to\infty} d(F_k(x), F_k(v)) = 0 \quad \textit{for all } x \in \mathring{K},$$

$$\lim_{k\to\infty} \| F_k(x)\|F_k(x)\|^{-1} - F_k(v)\|F_k(v)\|^{-1}\| = 0 \quad \textit{for all } x \in \mathring{K}.$$

Proof. Select an integer $p \geqq 1$ such that B^p has all positive entries, and for this p let G_k and g_k be as defined in Theorem 2.1. The bounded orbit property implies that $\{F_k(x): k \geqq 0\}$ has finite projective diameter for any $x \in \mathring{K}$. In particular, there exists $R > 0$ such that

$$\{F_k(v): k \geqq 0\} \subset B_R(v) = \{z: d(z, v) < R\}. \tag{3.19}$$

For notational convenience, define

$$v_k = F_k(v) \quad \text{and} \quad u_k = G_k(u)/\|G_k(u)\|.$$

Because each f_j is nonexpansive with respect to d we see that if $x \in B_R(v_k)$, then for $j \geqq 1$ we have

$$f_{k+j} f_{k+j-1} \cdots f_{k+1}(x) \in B_R(v_{k+j}) \subset B_{2R}(v). \tag{3.20}$$

If $x \in B_R(u_k) = B_R(G_k(u))$, then by using (3.20) and the chain rule we see that

$$g_{k+1}'(x) = f_{kp+p}'(y_1) f_{kp+p-1}'(y_2) \cdots f_{kp+1}'(y_p), \tag{3.21}$$

where $y_1, y_2, \cdots, y_p$ are points in $B_{2R}(v)$ that depend on x and the maps f_j.

We now use Lemma 3.2 and (3.21) to conclude that

$$\exp(-p(\gamma+1)(2R)) f_{jp}'(v) f_{jp-1}'(v) \cdots f_{jp-p+1}'(v) \leqq g_j'(x),$$

$$g_j'(x) \leqq \exp(p(\gamma+1)(2R)) f_{jp}'(v) f_{jp-1}'(v) \cdots f_{jp-p+1}'(v)$$

for all $x \in B_R(u_{j-1})$, $j \geqq 1$. It follows that for some $c_1 > 0$ we have

$$\exp(-2p(\gamma+1)R)B^p \leqq g_j'(x) \leqq c_1 \exp(2p(\gamma+1)R)B^p \quad \text{for all } x \in B_R(u_{j-1}). \tag{3.22}$$

By using (3.22) we see that there exists a positive real number c, independent of j, such that

$$g_j'(x) \geqq c g_j'(u_{j-1}) \quad \text{for all } j \geqq 1, \quad x \in B_R(u_{j-1}),$$

which is (2.25).

If we define $B_j = g_j'(u_{j-1})$, then (3.22) and Lemma 3.1 imply that

$$\Delta(B_j) \leqq 4p(\gamma+1)R + \Delta(B^p),$$

so

$$\sum_{j=1}^{\infty} \exp(-\Delta(B_j)) = \infty.$$

The conclusions of Theorem 3.1 now follow directly from Corollary 2.1. □

As an immediate consequence of Theorems 3.1 and 2.4 we obtain the following result.

COROLLARY 3.1. *Let the notation and assumptions be as in Theorem* 3.1. *In addition, assume that there exists* $u \in \mathring{K}$ *such that* (2.40) *is satisfied. Then for each* $x \in \mathring{K}$ *there exists* $\gamma = \gamma(x) > 0$ *such that*

$$\lim_{m\to\infty} \| F_m(x) - \gamma F_m(u) \| = 0,$$

and $x \to \gamma(x)$ *is continuous, order-preserving, and homogeneous of degree* 1.

Similarly, by using Lemmas 3.1 and 3.2, we can derive the following corollary of Theorem 2.3. Details are left to the reader.

COROLLARY 3.2. *Let notation and assumptions be as in Theorem* 3.1. *Assume that there exists* $w \in K$ *such that*

$$\lim_{j\to\infty} d(f_j(w), w) = 0.$$

Then it follows that for all $x \in \mathring{K}$,

$$\lim_{k\to\infty} d(F_k(x), w) = 0 \quad \textit{and} \quad \lim_{k\to\infty} \| F_k(x) \| F_k(x) \|^{-1} - w \| = 0.$$

If σ is a probability vector and $x \in \mathring{K}$, we will use the notation

$$x^{\sigma} = \prod_{j=1} x_j^{\sigma_j}, \tag{3.23}$$

where x_j and σ_j are the jth components of x and σ, respectively. If $x, y \in \mathring{K}$ we will also use the notation

$$\log(x) = (\log(x_1), \log(x_2), \cdots, \log(x_n)) \quad \text{and} \quad y \cdot \log(x) = \sum_{j=1}^{n} y_j \log(x_j).$$

If $\langle f_k \rangle$ is a sequence of maps, order-preserving and homogeneous of degree 1, of $\mathring{K}$ into itself, verifying the bounded orbit property may be difficult. However, we now show that if $f_{ki}(x)$ can be bounded below in a suitable way by cx^{σ}, where $c > 0$, σ is a probability vector, and both c and σ may depend on k and i, then we can prove that $\langle f_k \rangle$ satisfies the bounded orbit property with respect to d. This idea has already been used in § 4 of [23] for the case where $f_k = f$ for all $k \geqq 1$.

Our next lemma is a slight variant of Lemma 4.1 in [23]. Since the argument is the same, the proof is left to the reader.

LEMMA 3.3. *Suppose that K is the standard cone in $\mathbb{R}^n$ and f and g are maps of $\mathring{K}$ into itself. Suppose that A is a nonnegative $n \times n$ matrix with no zero rows; suppose also that if $a_{ij} > 0$, then there exist a positive constant c and a probability vector σ (σ depends on i and j) such that $\sigma_j \geqq \eta > 0$ (where σ_j denotes the jth component of σ) and*

$$f_i(x) = \text{the } i\text{th component of } f(x) \geqq cx^{\sigma} \quad \text{for all } x \in \mathring{K}.$$

The constants c and η are assumed independent of i and j. Similarly, suppose that B is a nonnegative $n \times n$ matrix with no zero rows and that if $b_{ij} > 0$, then there exist a positive constant d and a probability vector τ such that $\tau_j \geqq \theta > 0$ and

$$g_i(y) \geqq dy^{\tau} \quad \text{for all } y \in \mathring{K}.$$

Here d and θ are assumed independent of i and j, but τ may depend on i and j. Then BA is an $n \times n$ nonnegative matrix with no zero rows, and if the entry in row i, column j of BA is nonzero, there exists a probability vector μ such that

$$g_i(f(x)) \geqq \lambda x^{\mu} \quad \text{for all } x \in \mathring{K},$$

where $\lambda \geqq cd$ and $\mu_j \geqq \theta\eta$.

In the statement of the following theorem, recall that $f_{ki}(x)$ denotes the ith component of a map $f_k : \mathring{K} \to \mathring{K}$.

THEOREM 3.2. *Let K denote the standard cone in $\mathbb{R}^n$ and suppose that $f_k : \mathring{K} \to \mathring{K}$, $k \geqq 1$, is a sequence of maps that are order-preserving and homogeneous of degree 1. Let $A = (a_{ij})$ be an $n \times n$ nonnegative, primitive matrix. If $a_{ij} > 0$, assume that there exist $c > 0$ and $\delta > 0$ (independent of i, j, and $k \geqq 1$) and a probability vector σ with $\sigma_j \geqq \delta$ (σ may depend on i, j, and k) such that*

$$f_{ki}(x) \geqq cx^{\sigma} \quad \text{for all } x \in \mathring{K}.$$

If $v = (1, 1, \cdots, 1)$, assume that there exists a constant c_2 such that $f_k(v) \leqq c_2 v$ for all $k \geqq 1$. Then $\langle f_k \rangle$ satisfies the bounded orbit property with respect to Hilbert's projective metric d, and for every $u \in \mathring{K}$, there exists $R > 0$ such that

$$d(F_k(u), u) \leqq R \quad \text{for all } k \geqq 1.$$

Proof. Let F_k be as defined in Theorem 2.1 and select $p \geqq 1$ such that all entries of A^p are positive. For any fixed $k \geqq 0$, define $g : \mathring{K} \to \mathring{K}$ by

$$g = f_{k+p} f_{k+p-1} \cdots f_{k+1}. \tag{3.24}$$

By applying Lemma 3.3 $(p-1)$ times and recalling that A^p has all positive entries, we see that for any i, j with $1 \leqq i, j \leqq n$ there exists a probability vector σ (depending on i, j, k, and p) with $\sigma_j \geqq \delta^p = \eta$ (σ_j = the jth component of σ) and

$$g_i(x) = \text{the } i\text{th component of } g(x) \geqq c^p x^{\sigma} \quad \text{for all } x \in \mathring{K}. \tag{3.25}$$

Suppose that $x \in \mathring{K}$ and $d(x, v) \leqq R$, and select j so that

$$x_j = M(x/v) = M. \tag{3.26}$$

If $m = m(x/v)$, we obtain from (3.25) and (3.26) that

$$g_i(x) \geqq c^p x^{\sigma} \geqq c^p M^{\sigma_j} m^{1-\sigma_j} \geqq c^p (M/m)^{\eta} m = c^p M^{\eta} m^{1-\eta}. \tag{3.27}$$

In deriving (3.27) we use $M/m \geqq 1$.

On the other hand, we assume that $f_j(v) \leqq c_2 v$ for all j, so

$$g(v) \leqq c_2^p v. \tag{3.28}$$

Because $x \leqq Mv$ we conclude from (3.28) that

$$g_s(x) \leqq c_2^p M \quad \text{for } 1 \leqq s \leqq n. \tag{3.29}$$

Combining (3.27) and (3.29) we conclude that

$$d(g(x), v) \leqq p \log\left(\frac{c_2}{c}\right) + (1-\eta)\log\left(\frac{M}{m}\right) \leqq p \log\left(\frac{c_2}{c_1}\right) + (1-\eta)R. \tag{3.30}$$

It follows from (3.30) that there exist a real number λ, $0 < \lambda < 1$, and a number R_1, both independent of k in the definition of g, such that

$$d(g(x), v) \leqq \lambda R \quad \text{if } d(x, v) \leqq R \quad \text{and} \quad R \geqq R_1. \tag{3.31}$$

We can also assume that R_1 is so large that

$$d(F_j(v), v) < R_1 \quad \text{for } 1 \leqq j < p. \tag{3.32}$$

In general we can write F_m for $m \geqq p$ in the form

$$F_m = g_1 g_2 \cdots g_t F_j, \tag{3.33}$$

where $0 \leqq j < p$ and each g_i in (3.33) is assumed to be of the form given by (3.24) for some $k \geqq 0$. Since every g as in (3.24) maps $B_{R_1}(v)$ into itself and since $F_j(v) \in B_{R_1}(v)$ for $0 \leqq j < p$, we conclude that $F_m(v) \in B_{R_1}(v)$ for all $m \geqq 1$. □

With the aid of Theorems 3.1 and 3.2 we can give a more concrete weak ergodic theorem.

THEOREM 3.3. *Let K denote the standard cone in $\mathbb{R}^n$ (see (3.1)) and let $\langle f_k \rangle$, $k \geqq 1$, be a sequence of maps such that $f_k \in M_+$ for all $k \geqq 1$. Assume that $\mu(f_k) < \rho < \infty$ for all $k \geqq 1$ (see Definition 3.1). Let $v = (1, 1, \cdots, 1)$ denote the vector all of whose components equal 1 and assume that there exists an $n \times n$ nonnegative, primitive matrix B such that*

$$f_k'(v) \geqq B \quad \text{for all } k \geqq 1. \tag{3.34}$$

Assume that there exists $\beta_2 > 0$ such that

$$f_k(v) \leqq \beta_2 v \quad \text{for all } k \geqq 1. \tag{3.35}$$

Then we have that for all $x \in \mathring{K}$

$$\lim_{k\to\infty} d(F_k(x), F_k(v)) = 0,$$

$$\lim_{k\to\infty} \|F_k(x)\|F_k(x)\|^{-1} - F_k(v)\|F_k(v)\|^{-1}\| = 0.$$

If there exists $u \in \mathring{K}$ such that

$$\sup\{\|F_k(u)\| : k \geqq 1\} < \infty \quad \text{and} \quad \inf\{\|F_k(u)\| : k \geqq 1\} > 0,$$

then for every $x \in \mathring{K}$ there exists $\gamma = \gamma(x) > 0$ such that

$$\lim_{k\to\infty} \|F_k(x) - \gamma F_k(u)\| = 0.$$

If there exists $w \in \mathring{K}$ such that

$$\lim_{j\to\infty} d(f_j(w), w) = 0,$$

then for every $x \in \mathring{K}$,

$$\lim_{k\to\infty} d(F_k(x), w) = 0.$$

Proof. The existence of a matrix A as in Theorem 3.1 follows from (3.35) and the equation $f_k'(v)(v)=f_k(v)$. Thus, by virtue of Theorem 3.1 and Corollaries 3.1 and 3.2, it suffices to prove that the sequence $\langle f_k\rangle$ satisfies the bounded orbit property. We establish the bounded orbit property by using Theorem 3.2.

First note that, because f_k is homogeneous of degree 1,

$$f_k(v)=f_k'(v)(v)\geqq Bv;$$

therefore there exist positive constants β_1 and β_2 so that

$$\beta_1 v\leqq f_k(v)\leqq \beta_2 v \quad \text{for all } k\geqq 1. \tag{3.36}$$

If we write

$$f_{ki}(x)=\sum_{(r,\sigma)\in\Gamma_{ki}} c_{kir\sigma}M_{r\sigma}(x), \quad 1\leqq i\leqq n, \quad k\geqq 1,$$

we can assume $r\geqq 0$ for $(r,\sigma)\in\Gamma_{ki}$ (because $f_k\in M_+$). Formula (3.36) implies that

$$\beta_1\leqq f_{ki}(v)=c_{ki}=\sum_{(r,\sigma)\in\Gamma_{ki}} c_{kir\sigma}\leqq\beta_2. \tag{3.37}$$

It is a classical result (see [18]) that $M_{r\sigma}(x)\geqq M_{0\sigma}(x)$ for $r\geqq 0$, so

$$f_{ki}(v)\geqq c_{ki}\sum_{(r,\sigma)\in\Gamma_{ki}} c_{kir\sigma}c_{ki}^{-1}M_{0\sigma}(x). \tag{3.38}$$

If we apply log to both sides of (3.38) and use the concavity of log we obtain

$$\log f_{ki}(x)\geqq(\log c_{ki})+\left(\sum_{(r,\sigma)\in\Gamma_{ki}} c_{kir\sigma}c_{ki}^{-1}\sigma\right)\cdot(\log x). \tag{3.39}$$

If we define a probability vector τ_{ki} by

$$\tau_{ki}=\sum_{(r,\sigma)\in\Gamma_{ki}} c_{kir\sigma}c_{ki}^{-1}\sigma, \tag{3.40}$$

we obtain from (3.37), (3.39), and (3.40) that

$$f_{ki}(x)\geqq c_{ki}x^{\tau_{ki}}\geqq\beta_1 x^{\tau_{ki}}. \tag{3.41}$$

Denote by b_i the ith row of the matrix B. A simple calculation shows that the ith row of the Jacobian matrix $f_k'(v)$ is $c_{ki}\tau_{ki}$, so by the hypotheses of our theorem we have that

$$\tau_{ki}\geqq c_{ki}^{-1}b_i\geqq\beta_2^{-1}b_i. \tag{3.42}$$

If $B=(b_{ij})$, define a positive number δ by

$$\delta=\inf\{b_{ij}\beta_2^{-1}\colon b_{ij}>0\}.$$

Then it follows from (3.41) and (3.42) that if $b_{ij}>0$, the jth component of τ_{ki} in (3.41) is greater than or equal to δ. Since β_1 and δ are independent of i, j and $k\geqq 1$, Theorem 3.2 implies that $\langle f_k\rangle$ satisfies the bounded orbit property. □

Remark 3.1. Note that, for functions f_k that satisfy the hypotheses of Theorem 3.3, it can easily happen that f_k does not map certain nonzero points in the boundary of K into the interior of K and that the diameter (with respect to Hilbert's projective metric d) of $\{f_k(x)\colon x\in\mathring{K}\}$ is *not* finite. Both of these phenomena are illustrated by the simple arithmetic-geometric mean map

$$f_k(x)=f(x)=\left(\frac{x_1+x_2}{2},\ \sqrt{x_1x_2}\right).$$

In addition, both phenomena are typical of many examples of interest. For example, suppose that $x_k = F_k(x)$, where F_k is as in Theorem 3.3. More generally, for $f_k \in M_+$, we can define $\tilde{f}_k$ by

$$\tilde{f}_k(x) = \mu_k(x) f_k(x),$$

where $\mu_k(x)$ is a positive scalar function of x. If we define $\tilde{F}_k = \tilde{f}_k \tilde{f}_{k-1} \cdots \tilde{f}_1$ and $x_k = \tilde{F}_k(x)$ and $x_0 = x$, it is easy to see that

$$\tilde{F}_k(x) = \lambda_k(x) F_k(x), \qquad \lambda_k(x) = \prod_{j=1}^{k} \mu_j(x_{j-1}).$$

Here $\lambda_k(x)$ is a positive scalar, and the presence of $\lambda_k(x)$ does not affect the validity of the first part of Theorem 3.3, because Hilbert's projective metric does not distinguish points on rays. In this terminology, x may represent an initial "population vector" (so that the j-component of x represents the number of members of the population in class j) and $x_k = \tilde{F}_k(x)$ may represent the population vector at time k. Under reasonable assumptions on the biological model, we expect f_k to vanish at certain nonzero points on the boundary of K. Note, however, that if f_k is linear and irreducible, f_k does not vanish on nonzero points of the boundary of K. This point indicates a drawback of linear weak ergodic theorems in population biology.

ON BERNSTEIN-SZEGÖ ORTHOGONAL POLYNOMIALS ON SEVERAL INTERVALS*

FRANZ PEHERSTORFER†

Abstract. Let $l\in\mathbb{N}$, $a_1<a_2<\cdots<a_{2l}$, $E_l=\bigcup_{k=1}^{l}[a_{2k-1},a_{2k}]$, $H(x)=\prod_{k=1}^{2l}(x-a_k)$ and let $\rho_\nu(x)=c\prod_{k=1}^{\nu^*}(x-w_k)^{\nu_k}$ be a real polynomial with $w_k\notin\operatorname{int}(E_l)$ for $k=1,\cdots,\nu^*$ and $\nu_k=1$ if w_k is a boundary point of E_l. For given ρ_ν and $\varepsilon=(\varepsilon_1,\cdots,\varepsilon_{\nu^*})$, $\varepsilon_k\in\{-1,1\}$, the following linear functional on $\mathbb{P}$, $\mathbb{P}$ denoting the space of real polynomials, is defined:

$$\Psi_{H,\rho_\nu,\varepsilon}(p)=\int_{E_l}p(x)\frac{\sqrt{-H(x)}}{\rho_\nu(x)}\operatorname{sgn}\left(-\prod_{k=1}^{l}(x-a_{2k-1})\right)dx$$

$$+\sum_{k=1}^{\nu^*}(1-\varepsilon_k)\sum_{j=1}^{\nu_k}\mu_{j,k}p^{(j-1)}(w_k)$$

where $\mu_{j,k}$'s are certain numbers. Polynomials orthogonal with respect to the (not necessarily positive definite) linear functional $\Psi_{H,\rho_\nu,\varepsilon}$ are characterized. Those polynomials are given the name Bernstein-Szegö orthogonal polynomials on several intervals. Special attention is given to the most interesting case $\varepsilon=(1,\cdots,1)$.

Key words. orthogonal polynomial, associated polynomial, several intervals, Bernstein-Szegö weight function, point measure

1. Introduction and notation.

Let $l\in\mathbb{N}$, $a_k\in\mathbb{R}$ for $k=1,\cdots,2l$, $a_1<a_2<\cdots<a_{2l}$ and put

$$E_l=\bigcup_{k=1}^{l}[a_{2k-1},a_{2k}],\qquad H(x)=\prod_{k=1}^{2l}(x-a_k),$$

$$\frac{1}{h(x)}=\begin{cases}\operatorname{sgn}\left(\prod_{k=1}^{l}(x-a_{2k-1})\right)\Big/\sqrt{-H(x)} & \text{for } x\in E_l,\\ 0 \quad \text{elsewhere.}\end{cases}$$

R and S denote polynomials with leading coefficient 1 of degree r, respectively, s, that satisfy the relation

$$R(x)S(x)=H(x)$$

and ρ_ν denotes a real polynomial of degree ν that has no zero in E_l, i.e.,

$$\rho_\nu(x)=c\prod_{k=1}^{\nu^*}(x-w_k)^{\nu_k}$$

where $c\in\mathbb{R}\setminus\{0\}$, $\nu^*\in\mathbb{N}_0$, $\nu_k\in\mathbb{N}$ for $k=1,\cdots,\nu^*$, $\nu=\sum_{k=1}^{\nu^*}\nu_k$, $w_k\in\mathbb{C}\setminus E_l$, for $k=1,\cdots,\nu^*$, and the w_k's are real or appear in pairs of complex numbers. Furthermore, we set

$$\rho_{\nu,k}(x)=\rho_\nu(x)/(x-w_k)^{\nu_k}\quad\text{for } k=1,\cdots,\nu^*,$$

$$\Xi_{\nu^*}=\{(\varepsilon_1,\cdots,\varepsilon_{\nu^*}):\varepsilon_k\in\{-1,+1\}\quad\text{for } k=1,\cdots,\nu^*\}.$$

For given R, ρ_ν, and $\varepsilon \in \Xi_{\nu^*}$ we define the following linear functionals on the space of real polynomials $\mathbb{P}$:

$$L_{R,\rho_\nu,\varepsilon}(p) = \sum_{k=1}^{\nu^*} \frac{1-\varepsilon_k}{(\nu_k-1)!} \left(\frac{pR}{\rho_{\nu,k}\sqrt{H}}\right)^{(\nu_k-1)}(w_k) \quad \text{for } p \in \mathbb{P}, \tag{1.1}$$

$$\Psi_{R,\rho_\nu,\varepsilon}(p) = \int p \frac{R}{\rho_\nu h}\, dx + L_{R,\rho_\nu,\varepsilon}(p) \quad \text{for } p \in \mathbb{P} \tag{1.2}$$

where we make the additional assumption that $\varepsilon_{k+1} = \varepsilon_k$ if w_k and w_{k+1} are complex conjugate and where that branch of $\sqrt{H}$ is chosen (see Lemma 1) that is analytic on $\mathbb{C}\setminus E_l$ and satisfies

$$\operatorname{sgn}\sqrt{H(y)} = \operatorname{sgn} \prod_{k=1}^{l} (y - a_{2k-1}) \quad \text{for } y \in \mathbb{R}\setminus E_l.$$

Here $g^{(j)}$ denotes the jth derivative of g. Instead of $\Psi_{1,\rho,\varepsilon}$ we write $\Psi_{\rho,\varepsilon}$.

In this paper we study polynomials $p_n = x^n + \cdots$, $n \in \mathbb{N}$, which are orthogonal with respect to $\Psi_{R,\rho_\nu,\varepsilon}$, i.e., which satisfy

$$\Psi_{R,\rho_\nu,\varepsilon}(x^j p_n) = 0 \quad \text{for } j = 0, \cdots, \tilde{n}$$

where $\tilde{n} \geqq n-1$. Let us note that $\tilde{n} > n-1$ is possible since the linear functional need not be definite. It is not difficult to demonstrate (see Lemma 2) that for given R, ρ_ν, ε there exists a unique sequence of so-called basic integers (i_n), $i_0 := 0 < i_1 < i_2 < \cdots$, with $i_{n+1} \leqq i_n + \nu + l$ and a unique sequence of polynomials $p_{i_n} = x^{i_n} + \cdots$, $n \in \mathbb{N}_0$, such that

$$\Psi_{R,\rho_\nu,\varepsilon}(x^j p_{i_n}) = 0 \quad \text{for } j = 0, \cdots, i_{n+1}-2, \tag{1.3}$$

$$\Psi_{R,\rho_\nu,\varepsilon}(x^{i_{n+1}-1} p_{i_n}) \neq 0, \tag{1.4}$$

and the p_{i_n}'s satisfy a recurrence relation of the type

$$p_{i_n}(x) = d_{i_n}(x) p_{i_{n-1}}(x) - \lambda_{i_n} p_{i_{n-2}}(x) \quad \text{for } n \in \mathbb{N} \tag{1.5}$$

where $\lambda_{i_n} \in \mathbb{R}\setminus\{0\}$, $d_{i_n} \in \mathbb{P}_{i_n - i_{n-1}}$ (as usual, $\mathbb{P}_n$ denotes the set of polynomials of degree at most n), $p_{i_0} = 1$, and $p_{i_{-1}} = 0$. If the functional $\Psi_{R,\rho_\nu,\varepsilon}$ can be represented in the form

$$\Psi_{R,\rho_\nu,\varepsilon}(p) = \int p\, d\psi_{R,\rho_\nu,\varepsilon} \tag{1.6}$$

where $\psi_{R,\rho_\nu,\varepsilon}$ is a (not necessarily positive) measure, we write also, instead of (1.3), that $p_{i_n} \perp \mathbb{P}_{i_{n+1}-2}$ with respect to $d\psi_{R,\rho_\nu,\varepsilon}$, respectively, with respect to $R/\rho_\nu h$, if $L_{R,\rho_\nu,\varepsilon} = 0$, i.e., if $\varepsilon_k = 1$ for $k = 1, \cdots, \nu^*$. Obviously, (1.6) holds if all zeros of ρ_ν are simple and real. The orthogonality condition in this case becomes

$$\int_{E_l} \frac{x^j p_{i_n}(x)}{\rho_\nu(x)} \sqrt{\frac{\prod_{\mu\in J}|x-a_\mu|}{\prod_{\mu\in K\setminus J}|x-a_\mu|}} \operatorname{sgn}\left(\prod_{\mu\in I}(x-a_\mu)\right) \operatorname{sgn}\left(\prod_{\mu\in J}(x-a_\mu)\right) dx$$

$$+ \sum_{k=1}^{\nu^*} \frac{(1-\varepsilon_k)}{\rho_\nu'(w_k)} \sqrt{\frac{\prod_{\mu\in J}(w_k-a_\mu)}{\prod_{\mu\in K\setminus J}(w_k-a_\mu)}}\, w_k^j p_{i_n}(w_k) = 0 \quad \text{for } j = 0, \cdots, i_{n+1}-2 \tag{1.7}$$

where $K = \{1, 2, \cdots, 2l\}$, $I = \{1, 3, 5, \cdots, 2l-1\}$ and $J \subset K$. If $\psi_{R,\rho_\nu,\varepsilon}$ from (1.6) is a positive measure, i.e., if $\Psi_{R,\rho_\nu,\varepsilon}$ is positive definite, then it follows from (1.6) and (1.3) that the sequence of basic integers (i_n) satisfies $i_n = n$ for $n \in \mathbb{N}$, which implies that the recurrence relation (1.5) becomes

$$p_n(x) = (x-\alpha_n) p_{n-1}(x) - \lambda_n p_{n-2}(x) \quad \text{for } n \in \mathbb{N}. \tag{1.8}$$

For the case where (p_n) satisfies a recurrence relation of the form (1.8) with $\lambda_n \neq 0$ for $n \in \mathbb{N}$ (i.e., for the case where $i_n = n$ for $n \in \mathbb{N}$), we define the so-called associated polynomials $(p_n^{(j)})_{n \in \mathbb{N}_0}$ of order $j, j \in \mathbb{N}_0$, by

$$p_n^{(j)}(x) = (x - \alpha_{n+j}) p_{n-1}^{(j)}(x) - \lambda_{n+j} p_{n-2}^{(j)} \quad \text{for } n \in \mathbb{N} \tag{1.9}$$

with $p_0^{(j)} = 1$ and $p_{-1}^{(j)} = 0$.

To state our results we need the following additional notation. For $p \in \mathbb{P}$ let

$$p_{R,\rho_\nu,\varepsilon}^{[1]}(z) = \Psi_{R,\rho_\nu,\varepsilon}\left(\frac{p(z) - p(x)}{z - x}\right) \tag{1.10}$$

where it is understood that $\Psi_{R,\rho_\nu,\varepsilon}$ operates on x. The index R,ρ_ν,ε is omitted if there is no possibility of confusion. Note that $p_n^{[1]}$, $n \in \mathbb{N}$, is, up to a constant, the associated polynomial of degree $n-1$ of order 1 if $\Psi_{R,\rho_\nu,\varepsilon}$ is definite and if p_n denotes the corresponding orthogonal polynomial with leading coefficient 1. ∂p denotes the exact degree of $p \in \mathbb{P}$. Henceforth p_n, p_{i_n}, q_m, q_{i_m} denote polynomials of degree n, i_n, m, i_m, respectively with leading coefficient 1.

For the single interval case, say $[-1, +1]$, $\Psi_{R,\rho_\nu,\varepsilon}$ with $\varepsilon = (1, 1, \cdots, 1)$ is of the type

$$\int_{-1}^{+1} . (1-x)^\alpha (1+x)^\beta / \rho_\nu(x)\, dx \quad \text{where } \alpha, \beta \in \{-\tfrac{1}{2}, \tfrac{1}{2}\}. \tag{1.11}$$

Polynomials orthogonal with respect to such weight functions have been studied by Bernstein [5] and Szegö [25, pp. 31-33] and are now known under those authors' names. These polynomials also play an important role in L^p- and Chebyshev approximation on $[-1, +1]$ (see [1, pp. 249-254] and [6]). Since $\Psi_{R,\rho_\nu,\varepsilon}$ can be considered a generalization of (1.11), we call polynomials orthogonal with respect to $\Psi_{R,\rho_\nu,\varepsilon}$ Bernstein-Szegö polynomials on several intervals. Another extension of the Bernstein-Szegö orthogonal polynomials for a more general class of weight functions than that given in (1.11) has been given by Nevai [26].

Polynomials orthogonal on two intervals with respect to R/h, their recursion coefficients, and their close connection with polynomials deviating least from zero on two intervals with respect to the maximum, respectively, the L^1-, norm are investigated by Peherstorfer in [21] and [22]. For the representation of L^1-minimal polynomials on several intervals in terms of polynomials orthogonal with respect to R/h, see [20]. Using elliptic, respectively, Abelian, functions, polynomials orthogonal with respect to particular weight functions of the type (1.7), without point measure, have been studied by Achieser and Tomčuk [2], [3], Nuttall and Singh [18, § 5], [19, § 4.3.1-§4.3.4], and Magnus [17, § 4].

In [13] Geronimus (see also [11]) has shown that polynomials satisfying a three-term recurrence relation with periodic recursion coefficients are orthogonal on a set of several intervals with respect to a functional of the type $\Psi_{H,\rho,\varepsilon}$. Polynomials orthogonal to certain special weight functions of the type above have been given by Ismail [15], very recently by Geronimo and Van Assche [12, Remark 7], and by Peherstorfer [23]. In this paper we do not use elliptic, respectively, Abelian, functions, and our approach, and our results as well, are different from those given in the above-mentioned papers.

This paper is organized as follows. In § 2 we list and discuss the main results of the paper. Section 3 contains all the preliminary results. In the remaining sections the listed results of § 2 are proved.

Finally, we would like to mention that, based on the characterization of the orthogonal polynomials in § 2, we will show in a forthcoming paper how to obtain a

nonlinear recurrence relation for the recursion coefficients of the polynomials orthogonal with respect to $\Psi_{R,\rho,\varepsilon}$, and we will give a necessary and sufficient condition for the periodicity of the recursion coefficients of orthogonal polynomials.

2. Statement of results. The first main result is Theorem 1.

THEOREM 1. *Let $n \in \mathbb{N}$ be such that $n \geqq \max\{\nu+1-l, (\nu+1-r)/2\}$, put $m = n+r-l$, and suppose that $p_n \in \mathbb{P}_n$ satisfies*

$$Rp_n^2 = Sq_m^2 + \rho_\nu \tag{2.1}$$

where $q_m \in \mathbb{P}_m$. Furthermore, assume that p_n and q_m have no common zero and that at the zeros w_k of ρ_ν

$$Rp_n(w_k) = \varepsilon_k \sqrt{H(w_k)}\, q_m(w_k) \quad \text{for } k = 1, \cdots, \nu^*$$

where $\varepsilon_k \in \{-1, +1\}$, and set $\varepsilon = (\varepsilon_1, \cdots, \varepsilon_{\nu^*})$. Then the following propositions hold:

$$\text{(a)} \quad \Psi_{R,\rho_\nu,\varepsilon}(x^j p_n) = 0 \text{ for } j = 0, \cdots, n+l-2;$$

$$\text{(b)} \quad \Psi_{S,\rho_\nu,\varepsilon}(x^j q_m) = 0 \text{ for } j = 0, \cdots, m+l-2; \tag{2.2}$$

$$\text{(c)} \quad q_m(z) = \int \frac{(Rp_n)(z) - (Rp_n)(x)}{z-x} \frac{dx}{h(x)};$$

and, if $m > \nu - l$,

$$p_n(z) = \int \frac{(Sq_m)(z) - (Sq_m)(x)}{z-x} \frac{dx}{h(x)}, \tag{2.3}$$

$$\text{(d)} \quad q_m(z) = \begin{cases} \displaystyle\int \frac{p_n(z)-p_n(x)}{z-x} \frac{R(x)}{h(x)}\, dx & \text{if } r < l, \\ \displaystyle\int \frac{p_n(z)-p_n(x)}{z-x} \frac{R(x)}{h(x)}\, dx + p_n(z) & \text{if } r = l. \end{cases}$$

COROLLARY 1. *Suppose that the assumptions of Theorem 1 are fulfilled and that $\rho_\nu = \tilde{\rho}_{\nu-\mu} g_\mu$, where $\mu \in \{0, \cdots, \nu\}$. Furthermore, assume that w_{k_j}, $j = 1, \cdots, \nu^* - \mu^*$, are the zeros of $\tilde{\rho}_{\nu-\mu}$ and put $\tilde{\varepsilon} = (\varepsilon_{k_1}, \cdots, \varepsilon_{k_{\nu^*-\mu^*}})$. Then*

$$\Psi_{R,\tilde{\rho}_{\nu-\mu},\tilde{\varepsilon}}(x^j p_n) = 0 \quad \text{for } j = 0, \cdots, n+l-2-\mu,$$

$$\Psi_{S,\tilde{\rho}_{\nu-\mu},\tilde{\varepsilon}}(x^j q_m) = 0 \quad \text{for } j = 0, \cdots, m+l-2-\mu.$$

In particular, $p_n \perp \mathbb{P}_{n+l-2-\nu}$ ($q_m \perp \mathbb{P}_{m+l-2-\nu}$) with respect to R/h (S/h).

The next corollary shows how to construct a polynomial ρ for a given polynomial p_n such that p_n is orthogonal with respect to $\Psi_{\rho,\varepsilon}$.

COROLLARY 2. *Let $p_n \in \mathbb{P}_n$. Put*

$$q_m(z) = \int \frac{p_n(z)-p_n(x)}{z-x} \frac{dx}{h(x)} \quad \text{and} \quad \rho = p_n^2 - Hq_m^2.$$

Furthermore, suppose that p_n and q_m have no common zero and that at the zeros w_k of ρ

$$p_n(w_k) = \varepsilon_k \sqrt{H(w_k)}\, q_m(w_k).$$

Then $\rho \in \mathbb{P}_{n+l-1}$ and

$$\Psi_{\rho,\varepsilon}(x^j p_n) = 0 \quad \text{for } j = 0, \cdots, n+l-2.$$

In view of Theorem 1 the question arises: under which conditions does $\Psi_{R,\rho_\nu,\varepsilon}(p) = \int p(R/\rho_\nu h)\, dx$ for $p \in \mathbb{P}$? We give the answer for the special case $R = 1$ only, since the conditions become rather complicated in the general case.

THEOREM 2. *Let $n \in \mathbb{N}$, $n \geqq \max\{l, \nu\}$ and suppose that $p_n \in \mathbb{P}_n$ satisfies*

$$p_n^2 - Hq_m^2 = \rho_\nu \tag{2.1}$$

where p_n and q_m, $q_m \in \mathbb{P}_m$, have no common zero. $p_n \perp \mathbb{P}_{n+l-2}$ with respect to $1/\rho_\nu h$ if and only if all zeros of p_n and q_m are simple and are in $\operatorname{int}(E_l)$ and the zeros of p_n and $\prod_{k=2}^{l}(x-a_{2k-1})q_m$ interlace strictly.

The next theorem shows that the sufficiency conditions of Theorem 1 are also necessary. For Theorem 3 compare also [17, p. 161].

THEOREM 3. *Let i_n be a basic integer with respect to $\Psi_{R,\rho_\nu,\varepsilon}$ and suppose that $i_{n+1} + i_n + r \geqq \nu + l + 1$. Furthermore, let $v \in \mathbb{P}_{\nu-1}$ and $u \in \mathbb{P}_{r-(l+\nu)}$ be such that at the zeros w_k of $\rho_\nu(x) = \prod_{k=1}^{\nu^*}(x-w_k)^{\nu_k}$*

$$v^{(j)}(w_k) = \varepsilon_k (R/\sqrt{H})^{(j)}(w_k) \quad \text{for } j = 0, \cdots, \nu_k - 1, \tag{2.4}$$

$$R(z)/\rho_\nu(z)\sqrt{H(z)} = u(z) + O(z^{-1})$$

and put

$$Y = u\rho_\nu + v.$$

Then the following propositions hold:

(a) $$Rp_{i_n}^2 - S(Yp_{i_n} + \rho_\nu p_{i_n}^{[1]})^2 = \rho_\nu g_{(i_n)}$$

where $g_{(i_n)} \in \mathbb{P}_{i_n+l-i_{n+1}}$ and $g_{(i_n)}$ has leading coefficient $2\Psi_{R,\rho_\nu,\varepsilon}(x^{i_{n+1}-1}p_{i_n})$.

(b) *Y is of the form*

$$Y(z) = \int \frac{R(z)-R(x)}{z-x}\frac{dx}{h(x)} - \Psi_{R,\rho_\nu,\varepsilon}\left(\frac{\rho_\nu(z)-\rho_\nu(x)}{z-x}\right).$$

(c) *If $i_{n+1} \geqq \nu + 1$, then*

$$\Psi_{S,\rho_\nu,\varepsilon}(x^j(Yp_{i_n} + \rho_\nu p_{i_n}^{[1]})) = 0 \quad \text{for } j = 0, \cdots, i_{n+1} + r - l - 2.$$

Notation. Let (i_n) be a sequence of basic integers with respect to $\Psi_{R,\rho_\nu,\varepsilon}$ and let Y be defined as in Theorem 3. We put

$$q_{i_m} = Yp_{i_n} + \rho_\nu p_{i_n}^{[1]} \tag{2.5}$$

where $i_m = i_n + r - l$. Note that, in view of Theorem 3 and Theorem 1, (i_m) is a sequence of basic integers with respect to $\Psi_{S,\rho_\nu,\varepsilon}$ for those m satisfying $i_{m+1} \geqq \nu + 1 + r - l$ and that the q_{i_m}'s satisfy the same recurrence relation as the p_{i_n}'s.

As an easy consequence of Theorem 3 we obtain that a polynomial orthogonal with respect to $\Psi_{R,\rho,\varepsilon}$ satisfies a second-order differential equation. Using different methods, this fact has been proved by several authors [4], [10], [14].

COROLLARY 3. *Suppose that the assumptions of Theorem 3 are fulfilled and let p_{i_n}, ρ_ν, $g_{(i_n)}$, Y be such as in Theorem 3. Put $N = R\rho_\nu g_{(i_n)}$ and $\mu = \partial g_{(i_n)}$. Assume that Rp_{i_n} and q_{i_m} have no common zero.*

(a) *There is an $u \in \mathbb{P}_{l+\nu+\mu-1}$ such that $Ruq_{i_m} = -N'Rp_{i_n}/2 + N(Rp_{i_n})'$.*

(b) *$y = Rp_{i_n}/\sqrt{N}$ satisfies the differential equation $2G(x)y'' + G(x)y' + 2y = 0$, where $G = -H(N/Ru)^2$.*

Note that the differential equation of Corollary 3(b) is not of Sturm–Liouville type, since G depends on p_{i_n}.

The next theorem and corollary show how to make those polynomials orthogonal with respect to $\Psi_{R,\rho_\nu\tilde{\rho}_\mu,\sigma}$ if we know all polynomials $(p_{i_n})_{n\in\mathbb{N}}$ and one polynomial $\tilde{p}_j$ orthogonal with respect to $\Psi_{R,\rho_\nu,\varepsilon}$, respectively, $\Psi_{R,\tilde{\rho}_\mu,\tilde{\varepsilon}}$, where $\sigma = (\varepsilon_1, \cdots, \varepsilon_{\nu^*}, \pm\tilde{\varepsilon}_1, \cdots, \pm\tilde{\varepsilon}_{\mu^*})$.

THEOREM 4. *Let (i_n) be the sequence of basic integers with respect to $\Psi_{R,\rho_\nu,\varepsilon}$ and suppose that $i_{n+1}+i_n+r \geqq \nu+l+1$. Assume that*

$$u_j^2 - Hv_k^2 = \tilde{\rho}_\mu \tag{2.6}$$

where the polynomials $u_j = x^j + \cdots \in \mathbb{P}_j$ and $v_k = x^k + \cdots \in \mathbb{P}_k$ have no common zero, $2j > \mu$, and at the zeros $\tilde{w}_\kappa$ of $\tilde{\rho}_\mu$

$$u_j(\tilde{w}_\kappa) = \tilde{\varepsilon}_\kappa \sqrt{H(\tilde{w}_\kappa)}\, v_k(\tilde{w}_\kappa) \quad \text{for } \kappa = 1, \cdots, \mu^*,$$

$\tilde{\varepsilon}_\kappa \in \{-1, +1\}$. Furthermore, put

$$P_{i_n+j} = u_j p_{i_n} + S v_k q_{i_m} \quad \text{and} \quad Q_{i_m+j} = u_j q_{i_m} + R v_k p_{i_n}, \tag{2.7}$$

$$\tilde{P}_{i_n+\mu-j} = u_j p_{i_n} - S v_k q_{i_m} \quad \text{and} \quad \tilde{Q}_{i_m+\mu-j} = u_j q_{i_m} - R v_k p_{i_n} \tag{2.8}$$

where $i_m = i_n + r - l$. Then the following propositions hold:

(a) $$\Psi_{R,\rho_\nu\tilde{\rho}_\mu,\sigma}(x^\lambda P_{i_n+j}) = 0 \quad \text{for } \lambda = 0, \cdots, i_{n+1}+j-2$$

$$\Psi_{S,\rho_\nu\tilde{\rho}_\mu,\sigma}(x^\lambda Q_{i_m+j}) = 0 \quad \text{for } \lambda = 0, \cdots, i_{m+1}+j-2$$

where $\sigma = (\varepsilon_1, \cdots, \varepsilon_{\nu^*}, \tilde{\varepsilon}_1, \cdots, \tilde{\varepsilon}_{\mu^*})$.

(b) *If $2i_n + \mu + r > 2j + \nu$ then $\tilde{P}_{i_n+\mu-j}$, respectively, $\tilde{Q}_{i_m+\mu-j}$, is a polynomial of degree $i_n+\mu-j$, respectively, $i_m+\mu-j$, with leading coefficient $\tilde{K}$, where $\tilde{K}$ is the leading coefficient of $\tilde{\rho}_\mu$, that satisfies for $i_{n+1} > \nu+j$*

$$\Psi_{R,\rho_\nu\tilde{\rho}_\mu,\sigma}(x^\lambda \tilde{P}_{i_n+\mu-j}) = 0 \quad \text{for } \lambda = 0, \cdots, i_{n+1}+\mu-j-2,$$

respectively,

$$\Psi_{S,\rho_\nu\tilde{\rho}_\mu,\tilde{\sigma}}(x^\lambda \tilde{Q}_{i_m+\mu-j}) = 0 \quad \text{for } \lambda = 0, \cdots, i_{m+1}+\mu-j-2$$

where $\tilde{\sigma} = (\varepsilon_1, \cdots, \varepsilon_{\nu^*}, -\tilde{\varepsilon}_1, \cdots, -\tilde{\varepsilon}_{\mu^*})$.

(c) *The polynomials P_{i_n+j}, $\tilde{P}_{i_n+\mu-j}$, Q_{i_m+j}, and $\tilde{Q}_{i_m+\mu-j}$ satisfy the same recurrence relation with respect to i_n as the polynomials p_{i_n} for $i_{n+1}+i_n+r \geqq \nu+l+1$.*

Since in general not $\tilde{\rho}_\mu$, but $\tilde{\rho}_\mu g$, $g \in \mathbb{P}_{l-1}$, has a representation of the form (2.6), let us state the following corollary.

COROLLARY 4. *Suppose that the assumptions of Theorem 4 are fulfilled. In addition, assume that $i_n = n$ for $n \in \mathbb{N}_0$ and that $\tilde{\rho}_\mu = \bar{\rho}_{\mu-\tau} g$, where $\bar{\rho}_{\mu-\tau}$, $g \in \mathbb{P}$ and $\partial g = \tau$. Then for each $n \geqq \nu+\mu-j$ there are τ numbers $c_{0,n}, \cdots, c_{\tau,n}$, such that*

$$\bar{P}_{n+j} := \sum_{\kappa=0}^{\tau} c_{\kappa,n} P_{n+j+\kappa}/g \quad \text{and} \quad \bar{Q}_{m+j} := \sum_{\kappa=0}^{\tau} c_{\kappa,n} Q_{m+j+\kappa}/g$$

are polynomials of degree at most $n+j$, respectively, $m+j$, that satisfy

$$\Psi_{R,\rho_\nu\bar{\rho}_{\mu-\tau},\delta}(x^\lambda \bar{P}_{n+j}) = 0 \quad \text{for } \lambda = 0, \cdots, n+j-1,$$

$$\Psi_{S,\rho_\nu\bar{\rho}_{\mu-\tau},\delta}(x^\lambda \bar{Q}_{m+j}) = 0 \quad \text{for } \lambda = 0, \cdots, m+j-1$$

where $\delta = (\varepsilon_1, \cdots, \varepsilon_{\nu^*}, \bar{\varepsilon}_1, \cdots, \bar{\varepsilon}_{(\mu-\tau)^*})$.

Concerning the single interval case $[-1, +1]$, we obtain from Theorem 4 the corollary below.

COROLLARY 5. *Let* $E_1=[-1,1]$ *and let* $t_\nu(z)=\prod_{\kappa=1}^{\nu^*}(z-z_\kappa)^{\nu_\kappa}$ *and* $\tilde{t}_\mu(z)=\prod_{\kappa=1}^{\mu^*}(z-z_\kappa)^{\mu_\kappa}$, *where* $|z_\kappa|<1$, *respectively,* $|\tilde{z}_\kappa|>1$ *for* $\kappa=1,\cdots,\nu^*$, *respectively,* $\kappa=1,\cdots,\mu^*$, *and put*

$$\sum_{\kappa=0}^{\nu+\mu} d_\kappa z^\kappa = t_\nu(z)\tilde{t}_\mu(z),$$

$$\rho_\nu(x)=|t_\nu(e^{i\phi})|^2 \quad \textit{and} \quad \tilde{\rho}_\mu(x)=|\tilde{t}_\mu(e^{i\phi})|^2$$

$x=\cos\phi$, $\phi\in[0,\pi]$. *Then for* $n\geqq\nu+\mu$

$$\Psi_{\rho_\nu\tilde{\rho}_\mu,\sigma}\left(x^\lambda\sum_{\kappa=0}^{\nu+\mu} d_\kappa T_{n-(\nu+\mu)+\kappa}\right)=0 \quad \textit{for } \lambda=0,\cdots,n-1$$

and for $n>\nu+\mu$

$$\Psi_{x^2-1,\rho_\nu\tilde{\rho}_\mu,\sigma}\left(x^\lambda\sum_{\kappa=0}^{\nu+\mu} d_\kappa U_{n-1-(\nu+\mu)+\kappa}\right)=0 \quad \text{for } \lambda=0,\cdots,n-2$$

where $\sigma=(\sigma_1,\cdots,\sigma_{\nu^*+\mu^*})$ *is such that*

$$\sigma_\kappa=\begin{cases}1 & \textit{at the zeros of } \rho_\nu,\\ -1 & \textit{at the zeros of } \tilde{\rho}_\mu.\end{cases}$$

As usual the polynomials T_n, *respectively,* U_n, $n\in\mathbb{N}$, *denote the Chebyshev polynomials of degree n of first, respectively, second, kind on* $[-1,+1]$.

Remark. In Corollary 5 we have excluded the case that the polynomials t_ν, respectively, $\tilde{t}_\mu$, have zeros on the circumference $|z|=1$. The reason is the following simple fact. If $\sum_{\kappa=0}^{\nu} d_\kappa z^\kappa$, $d_\kappa\in\mathbb{R}$, has the complex conjugate zeros $e^{i\tilde{\phi}}$, $e^{-i\tilde{\phi}}$ then $\sum_{\kappa=0}^{\nu} d_\kappa T_{n-\nu+\kappa}(\sum_{\kappa=0}^{\nu} d_\kappa U_{n-1-\nu+\kappa})$ and $\rho_\nu(x)=|\sum_{\kappa=0}^{\nu} d_\kappa e^{i\kappa\phi}|^2$ have the common zero $\tilde{x}=\cos\tilde{\phi}$.

Let us note that, by a well-known result of Fejér and Riesz, each polynomial ρ_ν that is positive on $[-1,+1]$ can be represented uniquely in the form ($x=\cos\phi$, $\phi\in(0,\pi)$)

$$\rho_\nu(x)=c\left|\prod_{\kappa=1}^{\nu}(z-z_\kappa)\right|^2=\tilde{c}\left|\prod_{\kappa=1}^{\nu}(1-zz_\kappa)\right|^2$$

where c, $\tilde{c}\in\mathbb{R}^+$, and $|z_\kappa|<1$ for $\kappa=1,\cdots,\nu$. Note that the second equality gives the unique representation of ρ_ν by a polynomial of degree at most ν with all its zeros outside of the open unit disk.

Applying Corollary 5 to $z-b$, respectively, $(z-b-\sqrt{b^2+1})(z-b+\sqrt{b^2+1})$, $b\in\mathbb{R}$, we get the orthogonality properties of U_n-bU_{n-1}, respectively, $U_n-2bU_{n-1}-U_{n-2}$, given by Chihara [8], [7, p. 205] (see also [29]). Note that there is a misprint in [7, form. (13.6)]. The denominator $1+b^2-t$ in (13.6) should be replaced by $1+b^2-t^2$. From a different point of view, the single interval case has also been considered by Geronimus [13] and by Dombrowski and Nevai [28].

Next let us determine that functional to which the associated polynomials are orthogonal.

THEOREM 5. *Let* $(p_{i_n})_{n\in\mathbb{N}_0}$ *be orthogonal with respect to* $\Psi_{R,\rho_\nu,\varepsilon}$ *and suppose that the basic integers* (i_n) *satisfy* $i_n=n$ *for each* $n\in\mathbb{N}_0$. *Let* $j\in\mathbb{N}$, $2j-2>\nu+l-r$, $k=j+r-l$, *and let*

$$Rp_{j-1}^2-Sq_{k-1}^2=\rho_\nu g_{(j-1)} \tag{2.9}$$

where at the zeros $z_{\kappa,j-1}$, $\kappa=1,\cdots,l^*-1$, *of* $g_{(j-1)}$

$$(Rp_{j-1})(z_{\kappa,j-1})=\delta_{\kappa,j-1}(\sqrt{H}q_{k-1})(z_{\kappa,j-1}),\qquad \kappa=1,\cdots,l^*-1.$$

Furthermore, we put for $n\in\mathbb{N}_0$

$$C_{n+l}^{(j)}=(Rp_{n+j}p_{j-1}-Sq_{n+k}q_{k-1})/K_j\rho_\nu,$$

$$D_n^{(j)}=(q_{n+k}p_{j-1}-p_{n+j}q_{k-1})/K_j\rho_\nu$$

where $K_j=\prod_{\mu=1}^{j}\lambda_\mu$ *and* $\lambda_1=\Psi_{R,\rho_\nu,\varepsilon}(1)$.

(a) $D_n^{(j)}=p_n^{(j)}$ *for* $n\in\mathbb{N}_0$.

(b) $C_{n+l}^{(j)}$, $n\in\mathbb{N}_0$, *are polynomials of degree* $n+l$ *with leading coefficient* 1 *that satisfy the recurrence relation*

$$C_{n+l}^{(j)}(x)=(x-\alpha_{n+j})C_{n+l-1}^{(j)}(x)-\lambda_{n+j}C_{n+l-2}^{(j)}(x)\quad \text{for } n\geqq 2.$$

(c) *The polynomials* $C_{n+l}^{(j)}$, *respectively,* $p_n^{(j)}$, $n\in\mathbb{N}_0$, *are orthogonal with respect to* $\Psi_{g_{(j-1)},-\delta_{j-1}}$, *respectively,* $\Psi_{H,g_{(j-1)},-\delta_{j-1}}$.

Remark. If $\Psi_{R,\rho_\nu,\varepsilon}$ is positive definite, then (if we use the facts that $R/\rho_\nu h>0$ by (1.2) and $R\rho_\nu g_{(j-1)}>0$ on int (E_l) by (2.9)), $g_{(j-1)}$ has exactly one zero in each interval $[a_{2\kappa}, a_{2\kappa+1}]$, $\kappa=1,\cdots,l-1$.

Finally, we describe the location of the zeros of p_n and q_m if $\Psi_{\rho,\varepsilon}$ can be represented by a positive absolutely continuous measure.

THEOREM 6. *Assume that* $1/h\rho_\nu>0$ *on* E_l *and let* $\rho_\nu(x)=\prod_{k=1}^{\mu}(x-w_k)v(x)$, *where* $a_2<w_1<w_2<\cdots<w_\mu<a_{2l-1}$ *and* v *is a polynomial that is positive on* $[a_1, a_{2l}]$. *Let* ρ_1, ρ_2 *be polynomials such that* $\rho_1\rho_2=\prod_{k=1}^{\mu}(x-w_k)$ *and that* ρ_1, *respectively,* ρ_2, *vanishes at the first, third, etc., respectively second, fourth, etc., zero of* ρ_ν *in* (a_{2j}, a_{2j+1}), $j=1,\cdots,l-1$. *Furthermore, suppose that* $n\geqq\max\{\nu+1-l,\ (\nu+1-r)/2\}$ *and that,* $m=n+r-l$,

$$p_n^2-Hq_m^2=\rho_\nu g_{(n)} \tag{2.10}$$

where $g_{(n)}\in\mathbb{P}_{l-1}$ *and* p_n *and* q_m *have no common zero. Then* $p_n\perp\mathbb{P}_{n-1}$ ($q_m\perp\mathbb{P}_{m-1}$) *with respect to* $1/\rho_\nu h$ (h/ρ_ν) *if and only if all zeros of* p_n *and* q_m *are in* (a_1, a_{2l}), p_n *and* q_m *have at most one zero in each interval* (a_{2j}, a_{2j+1}), $j=1,\cdots,l-1$, *and the zeros of* $\rho_1 q_m$ *and* $\rho_2 p_n$ *interlace strictly.*

3. Preliminary results. To prove our results we need several lemmas. Lemma 1 plays an important role.

LEMMA 1. *Let* $t\in\mathbb{P}_l$ *with leading coefficient* 1.

(a) *For* $z\in\mathbb{C}\setminus E_l$

$$\int\frac{t(x)}{z-x}\frac{dx}{h(x)}=\begin{cases}\dfrac{t(z)}{\sqrt{H(z)}} & \text{if } \partial t\leqq l-1,\\[2ex] \dfrac{t(z)}{\sqrt{H(z)}}-1 & \text{if } \partial t=l\end{cases}$$

where that branch of $\sqrt{\ }$ *is chosen for which*

$$\lim_{z\to\infty}\frac{z^l}{\sqrt{H(z)}}=1.$$

(b) *If* $y \in \mathbb{R}\setminus E_l$ *and* $\partial t \leqq l-1$, *then*

$$\int \frac{t(x)}{y-x}\frac{dx}{h(x)} = \frac{t(t)}{\sqrt{H(y)}} = \frac{t(y)\operatorname{sgn}\prod_{k=1}^{l}(y-a_{2k-1})}{\sqrt{|H(y)|}}.$$

(c) $$\int x^j \frac{dx}{h(x)} = \begin{cases} 0 & \text{for } j = 0, \cdots, l-2, \\ 1 & \text{for } j = l-1. \end{cases}$$

Proof. (a) First let us consider the case $\partial t \leqq l-1$. Put

$$C = \bigcup_{k=1}^{2l-1} (a_k, a_{k+1}),$$

$$F(z) = t(z)/\sqrt{H(z)} = t(z)/\sqrt{|H(z)|}\, e^{i(\arg H(z))/2} \text{ for } z \in \mathbb{C}\setminus E_l,$$

$$F^+(x) = \lim_{z\to x \text{ on } C^+} F(z) \quad \text{and} \quad F^-(x) = \lim_{z\to x \text{ on } C^-} F(z)$$

where $z \to x$ on $C^{\pm}$ means that $x \in C$, $|z-x| \to 0$ and $\operatorname{Im} z \gtrless 0$. From Theorem 4.1 and p. 495 of [16] it follows that

$$F(z) = \frac{1}{2\pi i}\int_C \frac{F^-(x)-F^+(x)}{z-x}\,dx \quad \text{for } z \in \mathbb{C}\setminus[a_1, a_{2l}].$$

Since by simple calculation

$$\lim_{z\to x \text{ on } C^{\pm}} \arg H(z) = \pm(2l-k)\pi \quad \text{for } x \in (a_k, a_{k+1}), \quad k \in \{0, \cdots, 2l\}$$

where $a_0 := -\infty$ and $a_{2l+1} := \infty$, we obtain

$$F^-(x)-F^+(x) = \frac{t(x)}{\sqrt{|H(x)|}}\left[\lim_{z\to x \text{ on } C^-} e^{-i(\arg H(z))/2} - \lim_{z\to x \text{ on } C^+} e^{-i(\arg H(z))/2}\right]$$

$$= \frac{t(x)}{\sqrt{|H(x)|}} \begin{cases} 2i(-1)^{l-k} & \text{for } x \in (a_{2k-1}, a_{2k}), \quad k \in \{1, \cdots, l\}, \\ 0 & \text{for } x \in (a_{2k}, a_{2k+1}), \quad k \in \{1, \cdots, l-1\}, \end{cases}$$

which proves (a) for $\partial t \leqq l-1$ and $z \in \mathbb{C}\setminus[a_1, a_{2l}]$. Observing that both functions

$$\int \frac{t(x)}{z-x}\frac{dx}{h(x)} \quad \text{and} \quad t(z)/\sqrt{H(z)}$$

are analytic on $\mathbb{C}\setminus E_l$, it follows by the Identity Theorem that equality holds for $z \in \mathbb{C}\setminus E_l$.

If $\partial t = l$ we get, setting

$$F_1(z) = F(z) - 1,$$

that

$$\lim_{z\to\infty} F_1(z) = 0.$$

If we proceed as above the assertion follows.

(b) We obtain by calculation that for $y \in (a_{2k}, a_{2k+1})$, $k \in \{0, \cdots, l\}$,

$$\lim_{z\to y} t(z)/\sqrt{H(z)} = (-1)^{l-k} t(y)/\sqrt{|H(y)|},$$

which, in conjunction with (a), gives the assertion.

Part (c) follows immediately by series expansion of $1/\sqrt{H(z)}$ at $z = \infty$.

Next let us state some facts on polynomials orthogonal with respect to a linear functional. The following two lemmas are essentially known (see [27] and [30]).

LEMMA 2. *Let $K \in \mathbb{N}_0$ and let c be a real linear functional on $\mathbb{P}$ with*

$$c(x^j) = 0 \quad \text{for } j = 0, \cdots, K-1 \text{ and } c(x^K) \neq 0.$$

Assume that there does not exist $t \in \mathbb{P}$ such that $c(x^j t) = 0$ for all $j \in \mathbb{N}_0$. Then the following propositions hold:

(a) *There exists a unique sequence of so-called basic integers i_n, $n \in \mathbb{N}_0$, $i_0 := 0 < i_1 < i_2 < \cdots$ and a sequence of polynomials $p_{i_n}(x) = x^{i_n} + \cdots$ such that for $n \in \mathbb{N}_0$*

$$c(x^j p_{i_n}) = 0 \quad \text{for } j = 0, \cdots, i_{n+1} - 2 \text{ and } c(x^{i_{n+1}-1} p_{i_n}) \neq 0.$$

(b) *The polynomials p_{i_n} satisfy a recurrence relation of the form*

$$p_{i_{n+1}}(x) = d_{i_{n+1}}(x) p_{i_n}(x) - \lambda_{i_{n+1}} p_{i_n}(x) \quad \text{for } n \in \mathbb{N} \tag{3.1}$$

where $d_{i_{n+1}} \in \mathbb{P}_{i_{n+1}-i_n}$, $\lambda_{i_{n+1}} \in \mathbb{R} \setminus \{0\}$ and $p_0(x) = 1$.

(c) *The associated polynomials*

$$p_{i_n}^{[1]}(z) = c\left(\frac{p_{i_n}(z) - p_{i_n}(x)}{z - x}\right)$$

satisfy the same recurrence relation as the p_{i_n}'s. Note that $p_{i_n}^{[1]} \in \mathbb{P}_{i_n - 1 - K}$.

(d) $p_{i_n} p_{i_{n+1}}^{[1]} - p_{i_{n+1}} p_{i_n}^{[1]} = c(x^{i_{n+1}-1} p_{i_n})$ *for* $n \in \mathbb{N}$.

Proof. Part (a) follows from [27, Props. 1.14, 1.17].

(b) Representing $p_{i_{n+1}}$ in the form $p_{i_{n+1}} = \sum_{j=0}^{n} e_{i_{j+1}} p_{i_j}$, where $e_{i_{j+1}} \in \mathbb{P}_{i_{j+1}-i_j}$, and using the orthogonality property of the polynomials p_{i_j} gives the assertion.

Part (c) follows with the help of (3.1).

(d) From (3.1) we get that for $n \in \mathbb{N}$

$$\lambda_{i_{n+1}} = c(x^{i_{n+1}-1} p_{i_n}) / c(x^{i_n - 1} p_{i_{n-1}}). \tag{3.2}$$

Since, again by the recurrence relation of p_{i_n} and $p_{i_n}^{[1]}$,

$$p_{i_n} p_{i_{n+1}}^{[1]} - p_{i_{n+1}} p_{i_n}^{[1]} = \lambda_{i_{n+1}} (p_{i_{n-1}} p_{i_n}^{[1]} - p_{i_n} p_{i_{n-1}}^{[1]}),$$

the assertion follows with the help of (3.2) by induction arguments.

LEMMA 3. *Suppose that the assumptions of Lemma 2 are fulfilled, put $c_j = c(x^j)$ for $j \in \mathbb{N}_0$, and assume that $\sum_{j=0}^{\infty} c_j z^{-(j+1)}$ converges for sufficiently large $|z|$. Furthermore, let $n \geqq K+1$, $p_n(z) = z^n + \cdots \in \mathbb{P}_n$, $q \in \mathbb{P}_{n-1-K}$, and $\mu \in \mathbb{N}$. Then*

$$\frac{q(z)}{p_n(z)} = \sum_{j=0}^{n+\mu-2} c_j z^{-(j+1)} + O(z^{-(n+\mu)}) \tag{3.3}$$

if and only if

$$c(x^j p_n) = 0 \quad \text{for } j = 0, 1, \cdots, \mu - 2,$$

$$q(z) = c\left(\frac{p_n(z) - p_n(x)}{z - x}\right).$$

Proof. Sufficiency. Since

$$\begin{aligned} \frac{c((p_n(z) - p_n(x))/(z-x))}{p_n(z)} &= c\left(\frac{1}{z-x}\right) - \frac{c(p_n/(z-x))}{p_n(z)} \\ &= c\left(\frac{1}{z-x}\right) - \frac{1}{z^\mu p_n(z)} c\left(\frac{x^{\mu-1} p_n}{1 - (x/z)}\right) \end{aligned}$$

where in the last equality we have used the orthogonality property of p_n, the sufficiency part is proved.

Necessity. Since p_n has leading coefficient 1 and $c_K \neq 0$, it follows that $\partial q = n-1-K$. If we set

$$p_n(x) = \beta_0 x^n + \beta_1 x^{n-1} + \cdots + \beta_n,$$

it follows immediately from (3.3) that

$$\sum_{k=0}^{n} c_{n+j-k}\beta_k = 0 \quad \text{for } j = 0, \cdots, \mu-2,$$

which is obviously equivalent to

$$c(x^j p_n) = 0 \quad \text{for } j = 0, \cdots, \mu-2.$$

Since, by the sufficiency part,

$$c\left(\frac{p_n(z)-p_n(x)}{z-x}\right) - q(z) = p_n(z)O(z^{-(n+\mu)}) = O(z^{-\mu}),$$

the lemma is proved.

LEMMA 4. *There exists an* $M \in \mathbb{R}^+$ *such that* (1.1) *holds for* $p := 1/(z-x)$, $z \in \{z \in \mathbb{C}: |z| > M\}$, *where* $L_{R,\rho_\nu,\varepsilon}$ *operates on* x.

Proof. Since $L_{R,\rho_\nu,\varepsilon}$ is of the form $\kappa := \max_{1 \leqq k \leqq \nu^*} \nu_k$,

$$L_{R,\rho_\nu,\varepsilon}(p) = \sum_{j=0}^{\kappa} \sum_{k=1}^{\nu^*} \mu_{j,k} p^{(j)}(w_k),$$

we get, setting $M_1 = \max_{j,k} |\mu_{j,k}|$ and $M = \max\{1, \max_k |w_k|\}$, that for $j > \kappa$

$$|L_{R,\rho_\nu,\varepsilon}(x^j)| \leqq j(j-1)\cdots(j-\kappa)M^j M_1 \nu^*(\kappa+1).$$

Thus

$$L_{R,\rho_\nu,\varepsilon}\left(\frac{1}{z-x}\right) = \sum_{j=0}^{\infty} L_{R,\rho_\nu,\varepsilon}(x^j) z^{-j-1} \quad \text{uniformly for } |z| > M. \tag{3.4}$$

Using Leibniz's formula we get by (1.1) that the series is equal to

$$\sum_{k=1}^{\nu^*} \frac{1-\varepsilon_k}{(\nu_k-1)!} \sum_{\mu=0}^{\nu_k-1} \binom{\nu_k-1}{\mu} \left(\frac{R}{\rho_{\nu,k}\sqrt{H}}\right)^{(\nu_k-1-\mu)}(w_k) \sum_{j=0}^{\infty} \frac{(x^j)^{(\mu)}(w_k)}{z^{j+1}}.$$

Taking into consideration the fact that for $|w_k/z| < 1$

$$\left(\frac{1}{z-x}\right)^{(\mu)}(w_k) = \sum_{j=0}^{\infty} \frac{(x^j)^{(\mu)}(w_k)}{z^{j+1}}$$

the assertion is proved.

DEFINITION 1 (see [24]). We say that a function f has n sign changes on a set X if there are $n+1$ points $\{x_i | i = 1, \cdots, n+1, x_i < x_{i+1}\}$ in X so that $f(x_i)(-1)^i > 0 (< 0)$. $S(f, X)$ denotes the number of sign changes on X.

LEMMA 5. *Let* $m \in \mathbb{N}_0$, $v \in L^1(E_l)$ *and let* $p_n = x^n + \cdots \in \mathbb{P}$. *If* $S(v, E_l) = m$ *and* $p_n \perp \mathbb{P}_{n-1+j}$, $j \in \mathbb{N}_0$, *on* E_l *with respect to* v, *then* $j \leqq m$ *and* p_n *has at least* $n+j-m$ *simple zeros in* $\operatorname{int}(E_l)$.

Proof. First we demonstrate that $j \leqq m$. Assuming that $j > m$ and choosing a $t \in \mathbb{P}_m$ such that

$$t \operatorname{sgn} v \geqq 0 \quad \text{on } E_l,$$

we get

$$\int_{E_l} p_n^2 tv\,dx > 0,$$

which is a contradiction to the orthogonality property of p_n.

Now suppose that p_n has $k < n+j-m$ simple zeros in int (E_l). Then p_n is of the form

$$p_n(x) = f_k(x)g(x)$$

where f_k, $g \in \mathbb{P}$ and $g \geqq 0$ on E_l. Since

$$\int_{E_l} x^i f_k g v\,dx = \int_{E_l} x^i p_n v\,dx = 0 \quad \text{for } i = 0, \cdots, n-1+j,$$

we get

$$f_k \perp \mathbb{P}_{k-1+(n+j-k)} \quad \text{on } E_l \text{ with respect to } gv.$$

Using the fact that

$$S(gv, E_l) = S(v, E_l) = m,$$

in view of the first part we obtain that

$$n+j-k \leqq m,$$

which is a contradiction to the assumption.

Remark. Observing that

$$\Psi_{R,\rho_\nu,\varepsilon}(\rho_\nu p) = \int_{E_l} \frac{pR}{h}\,dx \quad \text{for } p \in \mathbb{P},$$

with the help of Lemma 5 we get that two basic integers i_n, i_{n+1}, $n \in \mathbb{N}_0$, with respect to $\Psi_{R,\rho_\nu,\varepsilon}$, satisfy $i_{n+1} \leqq i_n + \nu + l$. Moreover, taking into account (3.4), Lemmas 2 and 3 can be applied to $\Psi_{R,\rho_\nu,\varepsilon}$.

4. Proofs of Theorems 1 and 3 and Corollaries 1–3. In this section we omit, because of abbreviation, the indices of p_n, p_{i_n}, q_m, $\cdots$, ρ_ν, respectively.

Proof of Theorem 1. (c) from (2.1) we get that

$$\frac{q(z)}{Rp(z)} = \frac{1}{\sqrt{H(z)}} + O(z^{-(2n+r+l-\nu)}), \tag{4.1}$$

which, in conjunction with Lemmas 3 and 1(a), gives

$$Rp \perp \mathbb{P}_{n+l-2-\nu} \quad \text{with respect to } 1/h \tag{4.2}$$

and that q is of the form (2.2).

From (4.1) it follows that

$$\frac{(Sq)(z)}{p(z)} = \sqrt{H(z)} + O(z^{-(2n+r+l-\nu)+2l}),$$

which implies, in view of $n+l = m+s$, that

$$\frac{p(z)}{Sq(z)} = \frac{1}{\sqrt{H(z)}} + O(z^{-(2m+s+l-\nu)}). \tag{4.3}$$

Hence

$$Sq \perp \mathbb{P}_{m+l-2-\nu} \quad \text{with respect to } 1/h, \tag{4.4}$$

and p is of the form (2.3).

(a) Since each $t \in \mathbb{P}_{n+l-2}$ can be represented in the form $t = u\rho + v$, where $u \in \mathbb{P}_{n+l-2-\nu}$ and $v \in \mathbb{P}_{\nu-1}$, it follows from (4.2) and the fact that $L_{R,\rho,\varepsilon}(u\rho p) = 0$ that

$$\Psi_{R,\rho,\varepsilon}(tp) = \Psi_{R,\rho,\varepsilon}(vp) = \int \frac{v}{\rho} pR \frac{dx}{h} + L_{R,\rho,\varepsilon}(vp).$$

Thus it remains to show that

$$\int \frac{v}{\rho} pR \frac{dx}{h} = \sum_{k=1}^{\nu^*} \frac{(\varepsilon_k - 1)}{(\nu_k - 1)!} \left(\frac{vpR}{\rho_k \sqrt{H}} \right)^{(\nu_k - 1)} (w_k).$$

Partial fraction expansion gives, for $v \in \mathbb{P}_{\nu-1}$,

$$\frac{v(x)}{\rho(x)} = \sum_{k=1}^{\nu^*} \sum_{j=1}^{\nu_k} \frac{A_{k,j}}{(x - w_k)^j}$$

where

$$A_{k,j} = \left(\frac{v}{\rho_k} \right)^{(\nu_k - j)} (w_k)/(\nu_k - j)!. \tag{4.5}$$

Since by Lemma 1(a) and (2.2)

$$\int \frac{(Rp)(x)}{x - z} \frac{dx}{h(x)} = \int \frac{(Rp)(x) - (Rp)(z)}{x - z} \frac{dx}{h(x)} + (Rp)(z) \int \frac{1}{x - z} \frac{dx}{h(x)}$$

$$= q(z) - \frac{(Rp)(z)}{\sqrt{H(z)}},$$

we deduce that for $z \in \mathbb{C} \setminus E_l$

$$j! \int \frac{(Rp)(x)}{(x - z)^{j+1}} \frac{dx}{h(x)} = q^{(j)}(z) - \left(\frac{Rp}{\sqrt{H}} \right)^{(j)} (z). \tag{4.6}$$

Taking into account the fact that p and q have no common zero, we obtain from (2.1) that

$$q^{(j)}(w_k) = \varepsilon_k \left(\frac{Rp}{\sqrt{H}} \right)^{(j)} (w_k) \quad \text{for } j = 0, \cdots, \nu_k - 1.$$

Thus, with the help of (4.5), (4.6), and Leibniz's formula, we get

$$\int \frac{v(x)}{\rho(x)} (Rp)(x) \frac{dx}{h(x)} = \sum_{k=1}^{\nu^*} \sum_{j=1}^{\nu_k} A_{k,j} \int \frac{(Rp)(x)}{(x - w_k)^j} \frac{dx}{h(x)}$$

$$= \sum_{k=1}^{\nu^*} \sum_{j=1}^{\nu_k} A_{k,j} (\varepsilon_k - 1) \left(\frac{Rp}{\sqrt{H}} \right)^{(j-1)} (w_k)/(j-1)!$$

$$= \sum_{k=1}^{\nu^*} (\varepsilon_k - 1) \left(\frac{vRp}{\rho_k \sqrt{H}} \right)^{(\nu_k - 1)} (w_k),$$

which is the desired result.

Part (b) can be demonstrated analogously.

Part (d) follows immediately from the relation

$$\int \frac{(Rp)(z)-(Rp)(x)}{z-x}\frac{dx}{h(x)} = p(z)\int \frac{R(z)-R(x)}{z-x}\frac{dx}{h(x)} + \int \frac{p(z)-p(x)}{z-x}\frac{R(x)}{h(x)}\,dx,$$

part (c), and Lemma 1(c).

Proof of Corollary 1. Let us consider the simplest case:

$$\rho = \tilde{\rho}(x - w_{k^*}).$$

Observing that

$$\tilde{\rho}_k(x) = \begin{cases} \rho_k(x)/(x-w_{k^*}) & \text{for } k \neq k^*, \\ \rho_{k^*}(x) & \text{for } k = k^*, \end{cases}$$

we get, since by Leibniz's formula for $\nu_{k^*} > 1$

$$\frac{(1-\varepsilon_{k^*})}{(\nu_{k^*}-1)!}\left(\frac{(x-w_{k^*})f}{\rho_{k^*}}\right)^{(\nu_{k^*}-1)}(w_{k^*}) = \frac{(1-\varepsilon_{k^*})}{(\nu_{k^*}-2)!}\left(\frac{f}{\rho_{k^*}}\right)^{(\nu_{k^*}-2)}(w_{k^*}),$$

that for $f \in \mathbb{P}$

$$\Psi_{R,\rho,\varepsilon}((x-w_{k^*})f) = \Psi_{R,\tilde{\rho},\tilde{\varepsilon}}(f).$$

Since, by Theorem 1,

$$\Psi_{R,\rho,\varepsilon}((x-w_{k^*})tp) = 0 \quad \text{for all } t \in \mathbb{P}_{n+l-3}$$

the assertion is proved for the simplest case. The corollary now follows by induction arguments.

Proof of Corollary 2. Since

$$\frac{q(z)}{p(z)} = \frac{1}{\sqrt{H(z)}} - \frac{1}{p(z)}\int \frac{p(x)}{z-x}\frac{dx}{h(x)} = \frac{1}{\sqrt{H(z)}} + O(z^{-(n+1)})$$

it follows that

$$p^2 - Hq^2 = O(z^{n+l-1}),$$

which, in view of Theorem 1, proves the assertion.

Proof of Theorem 3. (a) Since Y satisfies (2.4) and the relation

$$\frac{R(z)/\sqrt{H(z)} - Y(z)}{\rho(z)} = O(z^{-1}),$$

we deduce that

$$G(z) := \frac{R(z)/\sqrt{H(z)} - Y(z)}{\rho(z)} - \sum_{k=1}^{\nu^*}\sum_{j=1}^{\nu_k}\frac{A_{k,j}}{(z-w_k)^j}$$

where

$$(\nu_k - j)!A_{k,j} = [(R/\sqrt{H} - Y)/\rho_k]^{(\nu_k - j)}(w_k) \tag{4.7}$$

is analytic on $\mathbb{C}\backslash E_l$ and of order $O(z^{-1})$. Using Theorem 4.1 and p. 495 of [16], we get that

$$G(z)=\int \frac{1}{z-x}\frac{R(x)}{\rho(x)h(x)}\,dx. \tag{4.8}$$

Since, by Lemma 4 for sufficiently large $|z|$,

$$L_{R,\rho,\varepsilon}\left(\frac{1}{z-x}\right)=\sum_{k=1}^{\nu^*}(1-\varepsilon_k)\sum_{j=1}^{\nu_k}\frac{(R/\rho_k\sqrt{H})^{(\nu_k-j)}(w_k)}{(\nu_k-j)!(z-w_k)^j}$$

we obtain from (4.7) and (4.8) that ($|z|$ sufficiently large)

$$\begin{aligned}\frac{R(z)/\sqrt{H(z)}-Y(z)}{\rho(z)}&=\int\frac{1}{z-x}\frac{R(x)}{\rho(x)h(x)}\,dx+L_{R,\rho,\varepsilon}\left(\frac{1}{z-x}\right)\\&=\Psi_{R,\rho,\varepsilon}\left(\frac{1}{z-x}\right).\end{aligned}$$

Hence, by the orthogonality property of p,

$$\frac{p^{[1]}(z)}{p(z)}=\frac{R(z)/\sqrt{H(z)}-Y(z)}{\rho(z)}+O(z^{-(i_n+i_{n+1})}) \tag{4.9}$$

from which it follows that

$$\sqrt{H(z)}(Yp+\rho p^{[1]})(z)=(Rp)(z)+O(z^{l+\nu-i_{n+1}}). \tag{4.10}$$

Squaring this relation, we obtain that for $i_{n+1}+i_n+r\geqq\nu+l+1$

$$S(z)(Yp+\rho p^{[1]})^2(z)=Rp^2(z)+O(z^{l+\nu+i_n-i_{n+1}}).$$

Since Y satisfies (2.4), it follows that

$$Rp^2-S(Yp+\rho p^{[1]})^2=\rho g$$

where $g\in\mathbb{P}_{i_n+l-i_{n+1}}$.

Observing that the $O(\ )$ part of (4.9) is of the form

$$O(z^{-(i_n+i_{n+1})})=(-\Psi_{R,\rho,\varepsilon}(x^{i_{n+1}-1}p_{i_n}))z^{-(i_n+i_{n+1})}+O(z^{-(i_n+i_{n+1}+1)}),$$

we find that g has the given leading coefficient.

Part (c) follows immediately from Theorem 1 and Corollary 1.

(b) In view of Lemma 2 and the remark at the end of § 3, we can choose an $n\in\mathbb{N}$ such that $i_{n+1}\geqq\nu+1$. Then on the one hand, setting $\Psi_{R,\rho,\varepsilon}=\Psi$, we get

$$\begin{aligned}\Psi\left(\frac{\rho(z)p(z)-\rho(x)p(x)}{z-x}\right)&=\rho(z)\Psi\left(\frac{p(z)-p(x)}{z-x}\right)+\Psi\left(\frac{\rho(z)-\rho(x)}{z-x}p(x)\right)\\&=\rho(z)p^{[1]}(z)\end{aligned}$$

and on the other hand,

$$\begin{aligned}\Psi\left(\frac{\rho(z)p(z)-\rho(x)p(x)}{z-x}\right)&=p(z)\Psi\left(\frac{\rho(z)-\rho(x)}{z-x}\right)+\Psi\left(\frac{p(z)-p(x)}{z-x}\rho(x)\right)\\&=p(z)\Psi\left(\frac{\rho(z)-\rho(x)}{z-x}\right)+\int\frac{p(z)-p(x)}{z-x}\frac{R(x)}{h(x)}\,dx\\&=p(z)\left[\Psi\left(\frac{\rho(z)-\rho(x)}{z-x}\right)-\int\frac{R(z)-R(x)}{z-x}\frac{dx}{h(x)}\right]\\&\qquad+\int\frac{(Rp)(z)-(Rp)(x)}{z-x}\frac{dx}{h(x)},\end{aligned}$$

which, with the help of (a) and Theorem 1(c), gives the assertion.

Proof of Corollary 3. (a) Since Rp and q have no common zero and since

$$(Rp)^2 - Hq^2 = R\rho g,$$

it follows that $N = R\rho g > 0$ on int (E_l). Differentiating the relation

$$(RpN^{-1/2})^2 - H(qN^{-1/2})^2 = 1, \tag{4.11}$$

we get that at the zeros of q

$$(RpN^{-1/2})' = N^{-3/2}[-N'Rp/2 + (Rp)'N] = 0. \tag{4.12}$$

Thus there is a $\tilde{u} \in \mathbb{P}_{r+l+\nu+\mu-1}$ such that

$$\tilde{u}q = -N'Rp/2 + (Rp)'N,$$

which proves (a).

(b) From (4.11), (4.12), and (a) it follows that

$$y^2 + G(x)(y')^2 = 1.$$

Differentiating this relation, we have part (b).

5. Proofs of Theorems 4 and 5 and Corollaries 4 and 5. The following lemma plays a crucial role in what follows.

LEMMA 6. *Let*

$$R = AB, \quad S = CD \quad \text{and} \quad \tilde{R} = AD, \quad \tilde{S} = CB \tag{5.1}$$

where $A, B, C, D \in \mathbb{P}$, $RS = \tilde{R}\tilde{S} = H$ *and* B *and* D *have no common zero. Furthermore, assume that the polynomials* e_n, f_m, g_j, h_k *have the following properties*:

$$Re_n^2 - Sf_m^2 = \rho_\nu \tag{5.2}$$

where $2n + r > \nu$, e_n *and* f_m *have no common zero, and at the zeros* w_k *of* ρ_ν

$$Re_n(w_\kappa) = \varepsilon_k \sqrt{H(w_k)} f_m(w_\kappa) \quad \text{for } \kappa = 1, \cdots, \nu^*, \tag{5.3}$$

$$\tilde{R}g_j^2 - \tilde{S}h_k^2 = \tilde{\rho}_\mu \tag{5.4}$$

where $2j + \tilde{r} > \mu$, g_j *and* h_k *have no common zero, and at the zeros* $\tilde{w}_\kappa$ *of* $\tilde{\rho}_\mu$

$$\tilde{R}g_j(\tilde{w}_\kappa) = \tilde{\varepsilon}_\kappa \sqrt{H(\tilde{w}_\kappa)} h_k(\tilde{w}_\kappa) \quad \text{for } \kappa = 1, \cdots, \mu^*. \tag{5.5}$$

Then the following propositions hold:

(a) $BD(Ae_ng_j \pm Cf_mh_k)^2 - AC(Df_mg_j \pm Be_nh_k)^2 = \rho_\nu \tilde{\rho}_\mu$, *where at the zeros* w_κ *of* ρ_ν

$$BD(Ae_ng_j \pm Cf_mh_k)(w_\kappa) = \varepsilon_\kappa \sqrt{H(w_k)} (Df_mg_j \pm Be_nh_k)(w_\kappa),$$

and at the zeros $\tilde{w}_\kappa$ *of* $\tilde{\rho}_\mu$

$$BD(Ae_ng_j \pm Cf_mh_k)(\tilde{w}_\kappa) = \pm \tilde{\varepsilon}_\kappa \sqrt{H(\tilde{w}_\kappa)} (Df_mg_j \pm Be_nh_k)(\tilde{w}_\kappa).$$

(b) *If* $2n + \mu + (r - \tilde{r}) > 2j + \nu$, *then* $Ae_ng_j - Cf_mh_k$, *respectively,* $Df_mg_j - Be_nh_k$, *is of degree* $n - j + \mu - \partial D$, *respectively,* $m - j + \mu - \partial A$, *and both polynomials have leading coefficient* $\tilde{K}$, *where* $\tilde{K}$ *is the leading coefficient of* $\tilde{\rho}_\mu$.

Proof. (a) Simple calculation gives

$$BD(Ae_ng_j \pm Cf_mh_k)^2 - AC(Df_mg_j \pm Be_nh_k)^2 = (\tilde{R}g_j^2 - \tilde{S}h_k^2)(Re_n^2 - Sf_m^2) = \rho_\nu \tilde{\rho}_\mu.$$

Since, in view of (5.1) and (5.3) at the zeros w_κ of ρ_ν,

$$BDAe_ng_j = \varepsilon_\kappa \sqrt{H} f_m Dg_j \quad \text{and} \quad BDCf_mh_k = \varepsilon_\kappa \sqrt{H} e_n Bh_k,$$

and in view of (5.1) and (5.5),

$$BDAe_n g_j = \tilde{\varepsilon}_\kappa \sqrt{H}\, h_k Be_n \quad \text{and} \quad BDCf_m h_k = \tilde{\varepsilon}_\kappa \sqrt{H}\, g_j Df_m,$$

part (a) follows.

(b) From (5.2), respectively, (5.4), we derive that for $2n+r>\nu$

$$(f_m\sqrt{H})(z) = (Re_n)(z) - (K/2)z^{-(n-\nu)} + O(z^{-(n-\nu+1)}), \tag{5.6}$$

respectively, that for $2j+\tilde{r}>\mu$

$$(h_k\sqrt{H})(z) = (\tilde{R}g_j)(z) - (\tilde{K}/2)z^{-(j-\mu)} + O(z^{-(j-\mu+1)}), \tag{5.7}$$

where K, respectively, $\tilde{K}$, denotes the leading coefficient of ρ_ν, respectively, $\tilde{\rho}_\mu$.

Multiplying (5.6) and (5.7) and observing that

$$H = ABCD, \quad R\tilde{R} = A^2BD, \quad n+j+\partial A = m+k+\partial C, \quad m+j+\partial D = n+k+\partial B,$$

we get

$$Ae_n g_j - Cf_m h_k = (\tilde{K}/2)z^{n+\mu+\partial A-(j+\tilde{r})} + \text{lower terms in } z,$$

respectively,

$$Df_m g_j - Be_n h_k = (K/2)z^{m+\mu+\partial D-(j+\tilde{r})} + \text{lower terms in } z,$$

which gives part (b).

Proof of Theorem 4. (a) By Theorem 3 we have for $i_{n+1}+i_n+r>\nu+l$

$$Rp_{i_n}^2 - Sq_{i_m}^2 = \rho_\nu g_{(i_n)}$$

where $\partial g_{(i_n)} = l+i_n-i_{n+1}$, and at the zeros w_κ of ρ_ν

$$Rp_{i_n}(w_\kappa) = \varepsilon_\kappa \sqrt{H(w_\kappa)}\, q_{i_m}(w_\kappa) \quad \text{for } \kappa = 1, \cdots, \nu^*.$$

From Lemma 6 we obtain that

$$RP_{i_n+j}^2 - SQ_{i_m+j}^2 = \rho_\nu \tilde{\rho}_\mu g_{(i_n)}$$

and that

$$RP_{i_n+j}(w_\kappa) = \varepsilon_\kappa \sqrt{H(w_k)}\, Q_{i_m+j}(w_\kappa) \quad \text{and} \quad RP_{i_n+j}(\tilde{w}_\kappa) = \tilde{\varepsilon}_\kappa \sqrt{H(\tilde{w}_\kappa)}\, Q_{i_m+j}(\tilde{w}_\kappa)$$

for $\kappa = 1, \cdots, \nu^*$, respectively, $\kappa = 1, \cdots, \mu^*$.

Applying Theorem 1 and Corollary 1 gives part (a). Part (b) can be proved analogously. Part (c) follows immediately from the definition of $P_{i_n+j}, \cdots$, and Lemma 2(c).

Proof of Corollary 4. Let (l_i) be the sequence of basic integers with respect to $\Psi_{R,\rho_\nu\bar{\rho}_{\mu-\tau},\delta}$ and let $i^* \in \mathbb{N}_0$ be such that $l_{i^*} \leqq n+j \leqq l_{i^*+1}-1$. Then $gp_{l_{i^*}}$ can be represented in the form

$$gp_{l_{i^*}} = \sum_{\kappa=0}^{\tau+l_{i^*}} c_{\kappa,n}P_\kappa = \sum_{\kappa=l_{i^*+1}-1}^{\tau+l_{i^*}} c_{\kappa,n}P_\kappa$$

where the last equality follows from Theorem 4(a) and the fact that $gp_{l_{i^*}} \perp \mathbb{P}_{l_{i^*+1}-2}$ with respect to $\Psi_{R,\rho_\nu\bar{\rho}_{\mu-\tau}g,\varepsilon}$. Hence the corollary is proved for $\bar{P}_{n+j}$.

Concerning $\bar{Q}_{m+j}$, we observe that in view of (2.6) and (2.7)

$$Rv_k \sum_{\kappa=0}^{\tau} c_{\kappa,n}P_{n+j+\kappa} = u_j \sum_{\kappa=0}^{\tau} c_{\kappa,n}Q_{m+j+\kappa} - \bar{\rho}_{\mu-\tau}g \sum_{\kappa=0}^{\tau} c_{\kappa,n}q_{m+\kappa}.$$

Since, by (2.6), u_j does not vanish at the zeros of g, we obtain that $\bar{Q}_{m+j} \in \mathbb{P}_{m+j}$. The assertion now follows from Theorem 4(a).

Proof of Corollary 5. First let us demonstrate that the assertion holds for $\mu = 0$. Since t_ν has all zeros in the open unit disk it follows that

$$(\operatorname{Re}\{t_\nu(e^{i\varphi})\})^2 + \sin^2\varphi(\operatorname{Im}\{t_\nu(e^{i\varphi})\}/\sin\varphi)^2 = \rho_\nu(\cos\varphi) > 0, \tag{5.8}$$

from which we get by the orthogonality property (Theorem 1) that the polynomials $\operatorname{Re}\{t_\nu(e^{i\varphi})\}$ and $\operatorname{Im}\{t_\nu(e^{i\varphi})\}/\sin\varphi$, $x = \cos\varphi$, have ν, respectively, $\nu - 1$, simple zeros in $(-1, +1)$ that, because of (5.8), separate each other. Using the well-known fact that $T_n(x) = \operatorname{Re} e^{in\varphi}$, respectively, $U_{n-1}(x) = \operatorname{Im} e^{in\varphi}/\sin\varphi$, $n \in \mathbb{N}$, is orthogonal with respect to $1/\sqrt{1-x^2}$, respectively, $\sqrt{1-x^2}$, on $[-1, +1]$ we obtain from Theorem 4(a) combined with Theorem 2 that

$$\operatorname{Re}\{t_\nu(e^{i\varphi})\} \operatorname{Re} e^{in\varphi} + (x^2-1)\frac{\operatorname{Im}\{t_\nu(e^{i\varphi})\}}{\sin\varphi}\frac{\operatorname{Im} e^{in\varphi}}{\sin\varphi} = \operatorname{Re}\{e^{in\varphi}t_\nu(e^{i\varphi})\},$$

respectively,

$$\operatorname{Re}\{t_\nu(e^{i\varphi})\}\frac{\operatorname{Im} e^{in\varphi}}{\sin\varphi} + \frac{\operatorname{Im}\{t_\nu(e^{i\varphi})\}}{\sin\varphi}\operatorname{Re} e^{in\varphi} = \frac{\operatorname{Im}\{e^{in\varphi}t_\nu(e^{i\varphi})\}}{\sin\varphi},$$

is orthogonal with respect to $\Psi_{\rho_\nu(1,1,\cdots,1)}$, respectively, $\Psi_{x^2-1,\rho_\nu(1,1,\cdots,1)}$. Hence the assertion is proved for $\mu = 0$.

Using the relations

$$(\operatorname{Re}\{\tilde{t}_\mu(e^{-i\varphi})\})^2 + \sin^2\varphi\left(\frac{\operatorname{Im}\tilde{t}_\mu(e^{-i\varphi})}{\sin\varphi}\right)^2 = \tilde{\rho}_\mu(\cos\varphi)$$

and, setting $\kappa = \mu + \nu$,

$$\operatorname{Re}\{\tilde{t}_\mu(e^{-i\varphi})\} \operatorname{Re}\{e^{i(n-\kappa)\varphi}t_\nu(e^{i\varphi})\} + \sin^2\varphi\frac{\operatorname{Im}\{\tilde{t}_\mu(e^{-i\varphi})\}}{\sin\varphi}\frac{\operatorname{Im}\{e^{i(n-\kappa)\varphi}t_\nu(e^{i\varphi})\}}{\sin\varphi}$$
$$= \operatorname{Re}\{e^{i(n-\kappa)\varphi}t_\nu(e^{i\varphi})\tilde{t}_\mu(e^{i\varphi})\},$$

we get the assertion from the first part of the proof and Theorem 4(b).

Proof of Theorem 5. (a) Using (2.5) and relation (10) of [9], we get that

$$q_{n+k}p_{j-1} - p_{n+j}q_{k-1} = \rho_\nu(p^{[1]}_{n+j}p_{j-1} - p^{[1]}_{j-1}p_{n+j})$$
$$= \rho_\nu\left(\prod_{i=1}^{j}\lambda_i\right)p_n^{(j)},$$

which proves (a).

(b), (c). In view of Lemma 6 and (2.9) we have for $j \in \mathbb{N}_0$

$$(Rp_{n+j}p_{j-1} - Sq_{n+k}q_{k-1})^2 - H(q_{n+k}p_{j-1} - p_{n+j}q_{k-1})^2 = \rho_\nu^2 g_{(j-1)}g_{(n+j)}, \tag{5.9}$$

with

$$(Rp_{n+j}p_{j-1} - Sq_{n+k}q_{k-1})(z_{\kappa,j-1})$$
$$= -\delta_{\kappa,j-1}(\sqrt{H}(q_{n+k}p_{j-1} - p_{n+j}q_{k-1}))(z_{\kappa,j-1}) \quad \text{for } \kappa = 1, \cdots, l^* - 1. \tag{5.10}$$

From (5.9) and (a) we obtain that $\partial C^{(j)}_{n+l} = n + l$. Since, in view of (2.5), $(p_{n+j})_{n\in\mathbb{N}_0}$ and $(q_{n+k})_{n\in\mathbb{N}_0}$ satisfy the recurrence relation

$$y_n = (x - \alpha_{n+j})y_{n-1} - \lambda_{n+j}y_{n-2},$$

part (b) follows. Part (c) follows immediately from (5.9), (5.10), and Theorem 1.

6. Proofs of Theorems 2 and 6. In the following we put

$$p = p_n, \quad q = q_m, \quad \rho = \rho_\nu.$$

Proof of Theorem 2. Set

$$u(x) = \prod_{j=2}^{l} (x - a_{2j-1}).$$

Necessity. From Theorem 1 and Lemma 5 it follows that all zeros of p and q are simple and lie in int (E_l). Now let

$$x_1 < x_2 < \cdots < x_n$$

denote the zeros of p. Since, by (2.1'), $\rho > 0$ on int (E_l), we get that $u/\rho h > 0$ on int (E_l). Taking into account that, in view of Theorem 1, $p \perp \mathbb{P}_{n-1}$ with respect to $u/\rho h$, we obtain by Gaussian quadrature formula that

$$\int \frac{tu}{h\rho}\, dx = \sum_{j=1}^{n} \lambda_j t(x_j) \quad \text{for all } t \in \mathbb{P}_{2n-1'}$$

where $\lambda_j \in \mathbb{R}^+$. Hence

$$\int tu \frac{dx}{h} = \sum_{j=1}^{n} \lambda_j \rho(x_j) t(x_j) \quad \text{for all } t \in \mathbb{P}_{2n-1-\nu}. \tag{6.1}$$

Since, by Theorem 1(c) and Corollary 1,

$$u(z)q(z) = \int \frac{u(z)p(z) - u(x)p(x)}{z - x} \frac{dx}{h(x)},$$

we get with the help of (6.1) that at a zero x_{j^*} of p

$$u(x_{j^*})q(x_{j^*}) = \lambda_{j^*}\rho(x_{j^*})p'(x_{j^*}),$$

which implies that uq and p have strictly interlacing zeros. Thus the necessity part is proved.

Sufficiency. Since all zeros of p and q are simple and are in int (E_l), and since the zeros of p and uq interlace strictly, we get that p and $(x - a_1)uq$ have the same number of sign changes in each interval $[a_{2j-1}, a_{2j})$, $j = 1, \cdots, l$, which implies that

$$\operatorname{sgn} p(x) = \operatorname{sgn} \prod_{j=1}^{l} (x - a_{2j-1}) \operatorname{sgn} q(x) \quad \text{for } x \in \mathbb{R} \setminus E_l.$$

Hence we obtain from (2.1) and Lemma 1(b) that at the real zeros w_k of ρ

$$p(w_k) = \sqrt{H(w_k)}\, q(w_k).$$

Thus it remains to show that at the complex zeros w_j of ρ

$$p(w_j) = \sqrt{H(w_j)}\, q(w_j). \tag{6.2}$$

Since on the one hand, by partial fraction expansion,

$$\frac{(uq)(z)}{p(z)} = \sum_{j=1}^{n} \frac{\lambda_j}{z - x_j}, \qquad \lambda_j \in \mathbb{R}^+$$

and on the other hand, by Lemma 1(a),

$$\frac{u(z)}{\sqrt{H(z)}} = \int \frac{u(x)}{z - x} \frac{dx}{h(x)},$$

we obtain with the help of the relations

$$\operatorname{Im}\{1/(z-x_j)\} \gtrless 0 \quad \text{for } \operatorname{Im} z \gtrless 0, \qquad u/h > 0 \quad \text{on int}(E_l)$$

and that

$$\operatorname{sgn} \operatorname{Im}\{(uq)(z)/p(z)\} = \operatorname{sgn} \operatorname{Im}\{u(z)/\sqrt{H(z)}\} \quad \text{for } z \in \mathbb{C}\backslash\mathbb{R},$$

which implies that (6.2) holds at the zeros of ρ.

Proof of Theorem 6. Since $1/h\rho > 0$ on E_l it follows that ρ_1 has in each interval (a_{2j}, a_{2j+1}), $j = 1, \cdots, l-1$, exactly one zero more than ρ_2. Hence

$$\partial\rho_1 = \partial\rho_2 + l - 1 \quad \text{and} \quad \partial(\rho_1 q) = \partial(\rho_2 p) - 1.$$

Furthermore, we deduce that the zeros of ρ_1 and $\prod_{j=2}^{l-1}(x-a_{2j})\rho_2$ interlace strictly, which gives, in conjunction with the relation

$$\operatorname{sgn}\sqrt{H(x)} = \begin{cases} -\operatorname{sgn}\prod_{j=2}^{l-1}(x-a_{2j}) & \text{for } x \in [a_1, a_{2l}]\backslash E_l, \\ \operatorname{sgn}\prod_{j=2}^{l-1}(x-a_{2j}) & \text{for } x \in \mathbb{R}\backslash[a_1, a_{2l}], \end{cases} \tag{6.3}$$

that at the zeros $w_{k,1}$ of ρ_1

$$\operatorname{sgn}\sqrt{H(w_{k,1})}\operatorname{sgn}\rho_2(w_{k,1}) = -\operatorname{sgn}\rho_1'(w_{k,1}) \tag{6.4}$$

and at the zeros $w_{k,2}$ of ρ_2

$$\operatorname{sgn}\rho_1(w_{k,2}) = \operatorname{sgn}\sqrt{H(w_{k,2})}\operatorname{sgn}\rho_2'(w_{k,2}). \tag{6.5}$$

Necessity. Since $1/\rho h > 0$ it is well known (see, e.g., [7]), that the zeros of p and $p^{[1]}$ interlace strictly. Hence we get from Theorem 3(b) that at the zeros x_k of p

$$\operatorname{sgn} q(x_k) = \operatorname{sgn}\rho(x_k)\operatorname{sgn}p^{[1]}(x_k) = \operatorname{sgn}\rho(x_k)\operatorname{sgn}p'(x_k),$$

which implies immediately that

$$\operatorname{sgn}(\rho_1 q)(x_k) = \operatorname{sgn}(\rho_2 p)'(x_k).$$

Since, by Theorem 1,

$$p(w_k) = \sqrt{H(w_k)}q(w_k) \quad \text{for } k = 1, \cdots, \mu,$$

we obtain from (6.5) that at the zeros $w_{k,2}$ of ρ_2

$$\operatorname{sgn}(\rho_1 q)(w_{k,2}) = \operatorname{sgn}(\rho_2 p)'(w_{k,2}),$$

which proves the necessity part.

Sufficiency. From the interlacing property of $\rho_1 q$ and $\rho_2 p$ it follows that at the zeros $w_{k,2}$ of ρ_2

$$\operatorname{sgn}(\rho_1 q)(w_{k,2}) = \operatorname{sgn}\rho_2'(w_{k,2})\operatorname{sgn}p(w_{k,2})$$

and at the zeros $w_{k,1}$ of ρ_1

$$\operatorname{sgn}(\rho_2 p)(w_{k,1}) = -\operatorname{sgn}\rho_1'(w_{k,1})\operatorname{sgn}q(w_{k,1}),$$

which implies, by (6.4) and (6.5), that

$$\operatorname{sgn}p(w_k) = \operatorname{sgn}\sqrt{H(w_k)}\operatorname{sgn}q(w_k) \quad \text{for } k = 1, \cdots, \mu. \tag{6.6}$$

Using the fact that

$$\operatorname{sgn} q(x) = \operatorname{sgn} \sqrt{H(x)} \operatorname{sgn} p(x) \quad \text{for } x \in \mathbb{R}\backslash[a_1, a_{2l}],$$

we find with the help of (2.10) that at all real zeros w of ρ

$$p(w) = \sqrt{H(w)}\, q(w). \tag{6.7}$$

Since p and q have at most one zero in each interval (a_{2j}, a_{2j+1}), $j = 1, \cdots, l-1$, and since the zeros of $\rho_1 q$ and $\rho_2 p$ are strictly interlacing, we can choose exactly one zero $w_{k_j,1}$ of ρ_1 from each interval (a_{2j}, a_{2j+1}), $j = 1, \cdots, l-1$, such that the zeros of $\tilde{\rho}_1 q$ and p interlace strictly, where

$$\tilde{\rho}_1(x) = \prod_{j=1}^{l-1} (x - w_{k_j,1}).$$

If we proceed as in the proof of the sufficiency part of Theorem 2, it follows that (6.7) holds also at the complex conjugate zeros of ρ, which proves the theorem.

Acknowledgments. The author thanks the referees for valuable comments, for pointing out an error in the original version of the manuscript, and for bringing papers [26], [28], and [29] to his attention.

ZEROS OF TRANSFORMED POLYNOMIALS*

A. ISERLES† AND S. P. NØRSETT†

Abstract. Transformations that map polynomials with zeros in a certain interval into polynomials with zeros in another interval are considered here. By using the theory of bi-orthogonal polynomials, a general technique for the construction of such transformations is developed. Finally, a list of 16 different transformations formed by using the authors' technique is presented.

Transformations of this type have already been applied in numerical analysis, approximation theory, and real analysis.

Key words. orthogonal polynomials, hypergeometric functions, bi-orthogonal polynomials, q-hypergeometric functions, zeros of polynomials

1. Introduction.

Let D and E be two real intervals that need not be distinct. The theme of this paper is transformations that map polynomials whose zeros all lie in D into polynomials with all zeros in E.

Many nontrivial instances of such transformations are known ([Marden, 1966], [Pólya and Szegö, 1976]). Probably the most important are due to Pólya and Schur [1914]: Let the transformation T be defined as

$$T\left\{\sum_{k=0}^{m} p_k x^k\right\} = \sum_{k=0}^{m} \alpha_k p_k x^k, \tag{1.1}$$

where $\{\alpha_k\}_{k=0}^{\infty}$ is a given real sequence (called a *multiplier sequence*). Then, given that all the zeros of $p(x)=\Sigma p_k x^k$ are real, all the zeros of Tp will also be always real if and only if the function $f(z)=\sum_{k=0}^{\infty}(1/k!)\alpha_k z^k$ is of the form

$$f(z) = c\, e^{dz} z^n \prod_{l=1}^{N}\left(1+\frac{z}{z_l}\right), \tag{1.2}$$

where n is a nonnegative integer, N is either a nonnegative integer or infinity, $c\in\mathscr{R}$, $d\geqq 0$, $z_l>0$ for all $1\leqq l\leqq N$ and $\sum_{l=1}^{N} z_l^{-1}<\infty$. See also [Hille, 1962], [Pólya and Szegö, 1976], as well as the extension of these transformations for complex $D=E$ by Craven and Csordas [1983].

In the present paper we introduce a mechanism for generation of numerous transformations of similar type. It is based on the theory of bi-orthogonal polynomials that has been recently developed by the authors [Iserles and Nørsett, 1988]. This mechanism, as well as relevant elements of the theory of bi-orthogonal polynomials, is described in § 2. By using our mechanism and further algebraic manipulation, we introduce sixteen transformations in §§ 3-6. These transformations are listed below, with names ("Jacobi," "Laguerre," etc.) given for identification purposes. The reason for these names will become clear in the sequel. We use throughout the standard notation for Pochhammer symbols $(a)_m$:

$$(a)_0 := 1, \qquad a\in\mathscr{C};$$
$$(a)_m := (a)_{m-1}(a+m-1), \qquad m\geqq 1,$$

and for Gauss-Heine symbols $(a;\rho)_m$:

$$(a;\rho)_0 := 1, \qquad a, \rho \in \mathscr{C},$$
$$(a;\rho)_m := (a;\rho)_{m-1}(1-a\rho^{m-1}), \qquad m \geqq 1.$$

Zero-mapping transformations.

1. *Jacobi transformation.*

$$T\left\{\sum_{k=0}^{m} r_k(x)_k\right\} = \sum_{k=0}^{m} (-1)^k(-\alpha-m)_k x^k (1-x)^{m-k} r_k,$$
$$\alpha > 1, \quad D = (0,\infty), \quad E = (0,1).$$

2. *Laguerre transformation.*

$$T\left\{\sum_{k=0}^{m} r_k(x)_k\right\} = \sum_{k=0}^{m} r_k x^k, \qquad D = E = (0,\infty).$$

3. *Meixner transformation.*

$$\lambda > 0, \quad T\left\{\sum_{k=0}^{m} q_k x^k\right\} = \sum_{k=0}^{m} (-1)^k(-x)_k(\lambda+x)_{m-k}\lambda^k q_k, \quad D = (0,\lambda), \quad E = (0,\infty).$$

4. *Charlier transformation.*

$$T\left\{\sum_{k=0}^{m} q_k x^k\right\} = \sum_{k=0}^{m} (-1)^k(-x)_k q_k, \qquad D = E = (0,\infty).$$

5. *Krawtchouk transformation.*

$$\eta \geqq m, \quad T\left\{\sum_{k=0}^{m} q_k x^k\right\} = \sum_{k=0}^{m} (-x)_k(x-\eta)_{m-k} q_k, \quad D = E = (0,\infty).$$

6. *Wall transformation.*

$$T\left\{\sum_{k=0}^{m} s_k(x;\rho)_k\right\} = \sum_{k=0}^{m} (\rho^{m-k}\alpha;\rho)_k(\alpha x;\rho)_{m-k} s_k x^k,$$
$$\rho \in (0,1), \quad \alpha \in (-1,1), \quad D = E = (0,1).$$

7. *Llaw tranformation.*

$$\rho > 1, \quad T\left\{\sum_{k=0}^{m} (-x;\rho)_k s_k\right\} = \sum_{k=0}^{m} s_k x^k, \quad D = (0,\infty), \quad E = (1,\infty).$$

8. *q-Krawtchouk transformation.*

$$T\left\{\sum_{k=0}^{m} (-x\rho^N;\rho)_k s_k\right\} = \sum_{k=0}^{m} s_k(\rho^{m-N-k};\rho)_k(\rho^{-N}x;\rho)_{m-k} x^k,$$
$$N \geqq m, \quad \rho \in (0,1), \quad D = (0,\infty), \quad E = (0,1).$$

9. *Wigert transformation.*

$$T\left\{\sum_{k=0}^{m} t_k x^k(-\alpha\rho^{-m+1}x,\rho)_{m-k}\rho^{-(3/2)k^2}\right\} = \sum_{k=0}^{m} t_k x^k,$$
$$\alpha < 1, \quad \alpha \neq 0, \quad \rho \in (0,1), \quad D = E = (0,\infty).$$

10. Γ_1 *transformation.*

$$\lambda > 0, \quad T\left\{\sum_{k=0}^{m} r_k(x)_k\right\} = \sum_{k=0}^{m} (-1)^k(-x)_k\lambda^{m-k} r_k, \quad D = E = (0,\infty).$$

11. Γ_2 *transformation.*

$$a, b>0, \quad T\left\{\sum_{k=0}^{m} u_k(x-m)_k\right\} = \sum_{k=0}^{m} \frac{(-1)^k}{(a)_k(b)_k} u_{m-k}(-x)_k, \quad D=E=(0,\infty).$$

12. Γ_3 *transformation.*

$$T\left\{\sum_{k=0}^{m} r_k(x)_k\right\} = \sum_{k=0}^{m} (-1)^k(-m-\alpha+1)_k(-x)_k(x-N)_{m-k}r_k,$$

$$\alpha>0, \quad N\in\mathscr{Z}, \quad N\geqq m, \quad D=E=(0,\infty).$$

13. Γ_4 *transformation.*

$$T\left\{\sum_{k=0}^{m} r_k(x)_k\right\} = \sum_{k=0}^{m} (-1)^k(\beta-m)_k(-x)_k(x+\alpha)_{m-k}r_k,$$

$$\alpha, \beta>0, \quad \beta\notin\mathscr{Z}, \quad D=(0,\beta), \quad E=(0,\infty).$$

14. $q-\Gamma_1$ *transformation.*

$$\alpha, \rho\in(0,1), \quad T\left\{\sum_{k=0}^{m} w_k(\alpha x\rho^k;\rho)_{m-k}\right\} = \sum_{k=0}^{m} \frac{w_k x^k}{(\alpha;\rho)_k}, \quad D=E=(0,1).$$

15. $q-\Gamma_2$ *transformation.*

$$T\left\{\sum_{k=0}^{m} (-1)^k\rho^{kN-(k-1)k}(\rho^{-N};\rho)_k(\alpha;\rho)_k\left(-\frac{x}{\alpha}\rho^{N-m};\rho\right)_{m-k} v_k\right\} = \sum_{k=0}^{m} v_k \prod_{j=0}^{k-1}(x-\rho^j),$$

$$\alpha>\rho^{-N+1}, \quad \rho\in(0,1), \quad m\leqq N, \quad N\in\mathscr{Z}, \quad D=E=(0,1).$$

16. $q-\Gamma_3$ *transformation.*

$$T\left\{\sum_{k=0}^{m} (x;\rho)_k(x\rho^{\alpha+k+1};\rho)_{m-k}v_k\right\} = \sum_{k=0}^{m} \rho^{-(N+1+\alpha)k}(\rho^{-N+k};\rho)_{m-k}v_k \prod_{j=0}^{k-1}(x-\rho^j),$$

$$\alpha>0, \quad \rho\in(0,1), \quad m\leqq N, \quad N\in\mathscr{Z}, \quad D=E=(0,1).$$

An alternative technique for generating transformations with predictable behaviour of zeros can be developed from the work of Al-Salam and Ismail [1976] on *convolution-orthogonal polynomials*: Let ψ be a Laplace transform of a nonnegative function and assume that it is analytic (this assumption can be somewhat relaxed) and with nonzero derivatives at the origin. Then the transformation

$$T\left\{\sum_{k=0}^{m} q_k x^k\right\} = \sum_{k=0}^{m} \frac{q_k}{\psi^{(k)}(0)}(-x)_k \tag{1.3}$$

maps polynomials with real zeros into polynomials with real zeros. Full details of the proof and examples are reported in [Iserles, Nørsett, and Saff, 1988]. Note that a straightforward application of (1.3) generalises our Charlier transformation.

Some applications of results from the present paper feature in [Iserles and Saff, 1987]. Further mechanisms for generation of "zero-mapping" transformations are described in [Iserles and Saff, 1989] and [Iserles, Nørsett, and Saff, 1988].

2. A mechanism for generation of transformations. We commence this section by reviewing pertinent elements of the theory of bi-orthogonal polynomials from [Iserles and Nørsett, 1988].

Let $\pi_m[x]$ denote the set of all mth degree polynomials. Given a one-parametric family of distributions $\varphi(x, \mu)$, $x \in E$, $\mu \in D$, where D and E are intervals, we define the mth *bi-orthogonal polynomial* $p_m(x; \mu_1, \mu_2, \cdots, \mu_m)$ as a monic member of $\pi_m[x]$ that satisfies the conditions

$$\int_E p(x; \mu_1, \cdots, \mu_m)\, d\varphi(x, \mu_l) = 0, \qquad l = 1, 2, \cdots, m.$$

Here $\mu_1, \cdots, \mu_m$ are distinct points in D.

We denote the moments of φ by I_k, $k \geqq 0$:

$$I_k(\mu) := \int_E x^k\, d\varphi(x, \mu), \quad k \geqq 0, \quad \mu \in D,$$

and define the function $D_m(\mu_1, \cdots, \mu_m)$ by $D_0 \equiv 1$:

$$D_m(\mu_1, \cdots, \mu_m) := \det \begin{pmatrix} I_0(\mu_1), & I_1(\mu_1), & \cdots, & I_{m-1}(\mu_1) \\ \vdots & \vdots & & \vdots \\ I_0(\mu_m), & I_1(\mu_m), & \cdots, & I_{m-1}(\mu_m) \end{pmatrix}, \tag{2.1}$$

$$m \geqq 0, \quad \mu_1, \cdots, \mu_m \in D.$$

The mth *generator* of φ is defined as

$$H_m(\mu; \mu_1, \cdots, \mu_m) := \int_E p(x; \mu_1, \cdots, \mu_m)\, d\varphi(x, \mu), \qquad \mu \in D. \tag{2.2}$$

THEOREM 1. (a) *Bi-orthogonal polynomials exist and are unique for all* $m \geqq 1$ *and all distinct* $\mu_1, \cdots, \mu_m \in D$ *if and only if* $D_m(\mu_1, \cdots, \mu_m) \neq 0$ *for all* $m \geqq 1$ *and distinct* $\mu_1, \cdots, \mu_m \in D$.

(b) *If the last condition is satisfied then*

$$p_m(x; \mu_1, \cdots, \mu_m) = \frac{1}{D_m(\mu_1, \cdots, \mu_m)} \det \begin{pmatrix} I_0(\mu_1), & I_1(\mu_1), & \cdots, & I_m(\mu_1) \\ \vdots & \vdots & & \vdots \\ I_0(\mu_m), & I_1(\mu_m), & \cdots, & I_m(\mu_m) \\ 1, & x, & \cdots, & x^m \end{pmatrix}, \tag{2.3}$$

$$H_m(\mu; \mu_1, \cdots, \mu_m) = \frac{D_{m+1}(\mu_1, \cdots, \mu_m, \mu)}{D_m(\mu_1, \cdots, \mu_m)}.$$

Let φ be of the form $d\varphi(x, \mu) = \omega(x, \mu)\, d\alpha(x)$, where α is a distribution in x, independent of μ. We say that φ has the *interpolation property* if

$$E_m \begin{pmatrix} x_1, \cdots, x_m \\ \mu_1, \cdots, \mu_m \end{pmatrix} := \det \begin{pmatrix} \omega(x_1, \mu_1), & \cdots, & \omega(x_1, \mu_m) \\ \vdots & & \vdots \\ \omega(x_m, \mu_1), & \cdots, & \omega(x_m, \mu_m) \end{pmatrix} \neq 0$$

for all $m \geqq 1$, distinct $x_1, \cdots, x_m \in E$ and distinct $\mu_1, \cdots, \mu_m \in D$.

THEOREM 2. *If* φ *possesses the interpolation property then each* $p_m(\cdot; \mu_1, \cdots, \mu_m)$ *has* m *distinct zeros in the interval* E.

The stage is now set for the introduction of our "zero-mapping" transformations. Let us assume that the conditions of Theorem 1 hold, that the p_m's are known explicitly and that φ possesses the interpolation property.

For every distinct $\mu_1, \cdots, \mu_m \in D$ we have a unique $p_m(\cdot; \mu_1, \cdots, \mu_m)$. This defines a mapping from distinct m-tuples in D^m into mth-degree monic polynomials. Let $q_m(x) := \prod_{k=1}^{m} (x - \mu_k)$. Then, by the same token, we have a mapping

$$Tq_m = p_m(\cdot; \mu_1, \cdots, \mu_m) \tag{2.4}$$

of monic mth-degree polynomials into themselves, with the property that each polynomial with distinct zeros in D is mapped into a polynomial with distinct zeros in E.

Moreover, let us assume that $p_m(\cdot; \mu_1, \cdots, \mu_m)$ remain well defined even if some μ_k's coalesce and that p_m does not vanish at the endpoints of E. Then Theorem 3 follows at once.

THEOREM 3. *The mapping T maps polynomials with all zeros in D into polynomials with all zeros in E. Moreover, polynomials with distinct zeros are mapped into polynomials with distinct zeros.*

Thus, our method of constructing transformations consists of the following set stages:

(a) Choose $d\varphi(x, \mu) = \omega(x, \mu)\, d\alpha(x)$. Verify the existence and uniqueness conditions of Theorem 1 (i.e., *regularity* in the terminology of Iserles and Nørsett [1988]).

(b) Verify the satisfaction of the interpolation property.

(c) Derive bi-orthogonal polynomials $p_m(x; \mu_1, \cdots, \mu_m)$ in an explicit form.

(d) Verify that the polynomials remain well defined for all $\mu_1, \cdots, \mu_m \in D$, regardless of distinctness, and that they do not vanish at the endpoints of E.

In practice, an extra stage is sometimes useful:

(e) Bring the transformation T, by standard algebraic manipulation, into a "nicer" form.

Of the first four stages, typically only (b) and (c) present interesting problems (nothing general can be said, of course, about stage (e)). To verify the interpolation property we exploit its connection with total positivity [Iserles and Nørsett, 1988] and standard results on totally positive systems, cf. [Karlin and Studden, 1966]. A formula for an explicit form of the bi-orthogonal polynomials that correspond to a fairly general set of distributions will be presented later in this section. First, however, we provide an example that elucidates some familiar results.

Let ψ be any distribution in $D = (0, \infty)$ and set $\varphi(x, \mu) := \psi(x/\mu)$, $x \in E = (0, \infty)$, $\mu \in D$. Then [Iserles and Nørsett, 1988] φ is regular and

$$p_m(x; \mu_1, \cdots, \mu_m) = c_m \sum_{k=0}^{m} \frac{q_k}{c_k} x^k,$$

where $\sum_{k=0}^{m} q_k x^k = \prod_{k=1}^{m} (x - \mu_k)$ and $c_k := \int_0^\infty x^k\, d\psi(x)$, $k \geqq 0$, are the moments of ψ. Thus (dividing by $c_m > 0$),

$$T\left\{\sum_{k=0}^{m} q_k x^k\right\} = \sum_{k=0}^{m} \frac{q_k}{c_k} x^k,$$

a Pólya–Schur transformation with the multiplier sequence $\{1/c_k\}_{k=0}^{\infty}$.

Let $\psi(x) = -e^{-x}$. Then $d\varphi(x, \mu) = (1/\mu) \exp(-x/\mu)\, dx$; hence $\omega(x, \mu) = \exp(-x/\mu)$ and the interpolation property follows [Karlin and Studden, 1966]. This produces the transformation

$$T\left\{\sum_{k=0}^{m} q_k x^k\right\} = \sum_{k=0}^{m} \frac{1}{k!} q_k x^k \tag{2.5}$$

that maps positive zeros into positive zeros (note that the Pólya–Schur result refers to real zeros being mapped into real zeros, but it is trivial that if the zeros of $q(x)$ are,

in addition, positive, then so are the zeros of Tq, where T has been defined in (1.1) and $\{\alpha_k\}$ satisfies the Pólya-Schur conditions).

Another choice of ψ is the Stieltjes-Wigert distribution [Chihara, 1978]:

$$d\varphi(x,\mu)=\frac{\sigma}{\mu\sqrt{\pi}}e^{-\sigma^2(\log(x/\mu))^2}\,dx,$$

where $\sigma>0$. Let $\alpha=\exp(-1/(4\sigma^2))\in(0,1)$. Then

$$c_k=\alpha^{-(k+1)^2},\qquad k\geqq 0.$$

The interpolation property is valid, since

$$\omega(x,\mu)=\frac{\sigma}{\mu\sqrt{\pi}}e^{-\sigma^2((\log x)^2+(\log\mu)^2)}x^{2\sigma^2\log\mu}$$

and $\tilde{\omega}(x,\mu):=x^{2\sigma^2\log\mu}$ satisfies the interpolation property.

Standard manipulation produces the transformation

$$T\left\{\sum_{k=0}^{m}q_kx^k\right\}=\sum_{k=0}^{m}\alpha^{k^2}q_kx^k, \tag{2.6}$$

that maps positive zeros into positive zeros.

Finally, let $\psi(x)=\int_0^x\tau^\beta(1-\tau)^n\,d\tau$, $0\leqq x\leqq 1$; $\psi(x)\equiv n!/(\beta+1)_{n+1}$, $1\leqq x$, where $\beta>-1$ and n is a nonnegative integer. It is proved in [Iserles and Nørsett, 1988] that, although the interpolation property is invalid, the bi-orthogonal polynomial $p_m(\cdot;\mu_1,\cdots,\mu_m)$ has m distinct zeros in $(0,\infty)$. Hence our analysis holds and the transformation

$$T\left\{\sum_{k=0}^{m}q_kx^k\right\}=\sum_{k=0}^{m}\frac{(\beta+n+2)_k}{(\beta+1)_k}q_kx^k \tag{2.7}$$

maps positive zeros into positive zeros. Note that

$$\alpha_k=\frac{(\beta+n+2)_k}{(\beta+1)_k},\qquad k\geqq 0,$$

implies that

$$f(z):=\sum_{k=0}^{\infty}\frac{1}{k!}\alpha_kz^k={}_1F_1\left[\begin{matrix}\beta+n+2;\\ \beta+1;\end{matrix}z\right]$$

(see [Rainville, 1967] or [Slater, 1966] for exposition of hypergeometric functions). Thus by the first Kummer identity

$$f(z)=e^z\,{}_1F_1\left[\begin{matrix}-n-1;\\ \beta+1;\end{matrix}-z\right]=\frac{(n+1)!}{(1+\beta)_{n+1}}L_{n+1}^{(\beta)}(-z)\,e^z,$$

where $L_m^{(\alpha)}$ is a Laguerre polynomial [Szegö, 1975]. Thus, f is of the form (1.2) and $\{\alpha_k\}$ is a multiplier sequence.

Mappings (2.5) and (2.6) are well known [Pólya and Schur, 1914], [Pólya and Szegö, 1976],whereas the mapping (2.7) can be equivalently derived by techniques based on the Gauss-Lucas theorem [Marden, 1966].

We now present an explicit form of bi-orthogonal polynomials for a general family of distributions.

Let $\boldsymbol{\rho} = \{\rho_k\}_{k=0}^{\infty}$ be any family of monic polynomials, such that $\rho_k \in \pi_k(x)$, $0 \leqq k$. We set

$$I_k(\mu, \boldsymbol{\rho}) = \int_E \rho_k(x)\, d\varphi(x, \mu), \quad k \geqq 0, \quad \mu \in D.$$

It is easy to see that if the $I_k(\mu)$'s are replaced by $I_k(\mu, \boldsymbol{\rho})$'s in the definition of $Dm(\mu_1, \cdots, \mu_m)$ the determinant remains intact—this follows from the monicity of the ρ_k's and elementary operations on the columns of the underlying matrix. Likewise, the $I_k(\mu)$'s and x^l's can be replaced by $I_k(\mu, \boldsymbol{\rho})$'s and $\rho_l(x)$'s in (2.3). This extra generality will be useful in the next sections, mainly the choice $\rho_k(x) = (-1)^k(-x)_k$, $k \geqq 0$.

Given a real interval D, we consider two infinite families of linear functions $g_k(\mu) = \alpha_k + \beta_k\mu$, $h_k(\mu) = \gamma_k + \delta_k\mu$, $0 \leqq k$, such that $h_k(\mu) \neq 0$, $k \geqq 0$, $\mu \in D$, and $\alpha_k\delta_l - \beta_k\gamma_l \neq 0$, $0 \leqq k \leqq l$. We focus our attention on distributions with generalized moment functions of the form

$$I_k(\mu, \boldsymbol{\rho}) = \prod_{j=0}^{k-1} \frac{g_j(\mu)}{h_j(\mu)}, \qquad k \geqq 1,$$

$$I_0(\mu, \boldsymbol{\rho}) \equiv 1.$$

LEMMA 4. *If such a distribution exists then it is regular.*

Proof. Let

$$z_k^{(m)}(\mu) := \prod_{j=0}^{k-1} g_j(\mu) \prod_{j=k}^{m-2} h_j(\mu), \qquad k = 0, \cdots, m-1.$$

Note that $z_k^{(m)} \in \pi_{j-1}(\mu)$, with leading coefficient $\prod_{j=0}^{k-1} \beta_j \prod_{j=k}^{m-2} \delta_j$. It follows that

$$I_k(\mu, \boldsymbol{\rho}) = \frac{z_k^{(m)}(\mu)}{\prod_{j=0}^{m-2} h_j(\mu)}, \quad k \geqq 0, \quad \mu \in D,$$

$$D_m(\mu_1, \cdots, \mu_m) = \frac{1}{\prod_{l=1}^{m} \prod_{j=0}^{m-2} h_j(\mu_l)}\, V_m(\mu_1, \cdots, \mu_m), \qquad m \geqq 1,$$

where

$$V_m(\mu_1, \cdots, \mu_m) := \det \begin{pmatrix} z_0^{(m)}(\mu_1), & z_1^{(m)}(\mu_1), & \cdots, & z_{m-1}^{(m)}(\mu_1) \\ \vdots & \vdots & & \vdots \\ z_0^{(m)}(\mu_m), & z_1^{(m)}(\mu_m), & \cdots, & z_{m-1}^{(m)}(\mu_m) \end{pmatrix}.$$

To prove regularity, it is sufficient to demonstrate that $V_m(\mu_1, \cdots, \mu_m) \neq 0$ for all $m \geqq 1$ and distinct $\mu_1, \cdots, \mu_m \in D$. Note that the matrix of V_m can be brought into a Vandermonde form by elementary column operations; thus

$$V_m(\mu_1, \cdots, \mu_m) = C \prod_{1 \leqq k < l \leqq m} (\mu_l - \mu_k), \tag{2.8}$$

C independent of $\mu_1, \cdots, \mu_m$—a process that breaks down if the matrix is singular, but then, of course, (2.8) is true with $C = 0$.

We will now derive explicitly the constant C. Since $V_m(\mu_1, \cdots, \mu_{m-1}, \mu) \in \pi_{m-1}[\mu]$ and $V_m(\mu_1, \cdots, \mu_{m-1}, \mu_l) = 0$, $l = 1, \cdots, m-1$, it follows that

$$V_m(\mu_1, \cdots, \mu_m) = C_m(\mu_1, \cdots, \mu_{m-1}) \prod_{l=1}^{m-1} (\mu_m - \mu_l).$$

Moreover, by introspection,

$$C_m(\mu_1, \cdots, \mu_{m-1}) = \det \begin{pmatrix} z_0^{(m)}(\mu_1), & z_1^{(m)}(\mu_1), & \cdots, & z_{m-1}^{(m)}(\mu_1) \\ \vdots & \vdots & & \vdots \\ z_0^{(m)}(\mu_{m-1}), & z_1^{(m)}(\mu_{m-1}), & \cdots, & z_{m-1}^{(m)}(\mu_{m-1}) \\ \sigma_0^{(m)} & \sigma_1^{(m)}, & \cdots, & \sigma_{m-1}^{(m)} \end{pmatrix}, \tag{2.9}$$

where $\sigma_k^{(m)} := \prod_{j=0}^{k-1} \beta_j \prod_{j=k}^{m-2} \delta_j$ is the leading coefficient of $z_k^{(m)}$.

We assume first that $\delta_k \neq 0$, $k = 0, \cdots, m-2$, multiply each kth column by β_{k-1}/δ_{k-1} and subtract it from the $(k+1)$st column. Since

$$\sigma_k^{(m)} - \frac{\beta_{k-1}}{\delta_{k-1}} \sigma_{k-1}^{(m)} = 0,$$

$$z_k^{(m)}(\mu_l) - \frac{\beta_{k-1}}{\delta_{k-1}} z_{k-1}^{(m)}(\mu_l) = \frac{\alpha_{k-1}\delta_{k-1} - \beta_{k-1}\gamma_{k-1}}{\delta_{k-1}} \prod_{j=0}^{k-2} g_j(\mu_l) \prod_{j=k}^{m-2} h_j(\mu_l),$$

$$l = 1, \cdots, m-1, \qquad k = 1, \cdots, m-1;$$

zeros are inserted into the bottom row, save for the first element, and, expanding in that row,

$$C_m(\mu_1, \cdots, \mu_{m-1}) = (-1)^{m-1} \prod_{k=0}^{m-2} (\alpha_k\delta_k - \beta_k\gamma_k)/\delta_k \times \det \begin{pmatrix} \tilde{z}_0(\mu_1), & \cdots, & \tilde{z}_{m-2}(\mu_1) \\ \vdots & & \vdots \\ \tilde{z}_0(\mu_{m-1}), & \cdots, & \tilde{z}_{m-2}(\mu_{m-1}) \end{pmatrix},$$

$$\tilde{z}_k(\mu) := \prod_{j=0}^{k-1} g_j(\mu) \prod_{j=k+1}^{m-2} h_j(\mu).$$

Let $h_j^{(l)}(\mu) := h_{j+l}(\mu)$, $l, j \geqq 0$ and let $V_m^{(l)}(\mu_1, \cdots, \mu_m)$ be the determinant which is obtained by replacing h_j by $h_j^{(l)}$ in the definition of V_m, leaving the g_js intact. Hence $V_m^{(0)} \equiv V_m$ and

$$C_m(\mu_1, \cdots, \mu_{m-1}) = (-1)^{m-1} \prod_{k=0}^{m-2} \frac{\alpha_k\delta_k - \beta_k\gamma_k}{\delta_k} V_{m-1}^{(1)}(\mu_1, \cdots, \mu_{m-1}).$$

It follows that $V_m^{(0)}$ obeys the recurrence

$$V_m^{(0)}(\mu_1, \cdots, \mu_m) = (-1)^{m-1} \prod_{k=0}^{m-2} \frac{\alpha_k\delta_k - \beta_k\gamma_k}{\delta_k} \prod_{l=1}^{m-1} (\mu_m - \mu_l) V_{m-1}^{(1)}(\mu_1, \cdots, \mu_{m-1})$$

and, by induction,

$$V_m^{(0)}(\mu_1, \cdots, \mu_m) = (-1)^{ms - 1/2s(s+1)} \left\{ \prod_{l=0}^{s-1} \prod_{k=l}^{m-2} \frac{\alpha_{k-l}\delta_k - \beta_{k-l}\gamma_l}{\delta_k} \right\} \times \left\{ \prod_{l=m+1-s}^{m} \prod_{k=1}^{l-1} (\mu_l - \mu_k) \right\} V_{m-s}^{(s)}(\mu_1, \cdots, \mu_{m-s}), \qquad s = 0, \cdots, m-1.$$

In particular, setting $s = m-1$ yields

$$V_m(\mu_1, \cdots, \mu_m) = (-1)^{1/2(m-1)m} \left\{ \prod_{l=0}^{m-2} \prod_{k=l}^{m-2} \frac{\alpha_{k-l}\delta_k - \beta_{k-l}\gamma_l}{\delta_k} \right\} \prod_{1 \leqq k < l \leqq m} (\mu_l - \mu_k) \neq 0,$$

since $\alpha_n\delta_k - \beta_n\gamma_k \neq 0$ for all $n \leqq k$. This proves regularity, subject to $\delta_k \neq 0$, $k \geqq 0$.

It is obvious from the method of proof how to allow vanishing δ_k's: if $\delta_n = 0$, say, then $\sigma_k^{(m)} = 0$ for all $k \leqq n$. The elimination in (2.9) can then be carried out by using a pivot on the bottom right corner. Although the value of $C_m(\mu_1, \cdots, \mu_m)$ changes, this quantity remains nonzero and the lemma is true. □

Having proved existence and uniqueness of the underlying bi-orthogonal polynomials, it is easy to furnish an explicit formula.

LEMMA 5. *Let*

$$q_m(x) := \prod_{k=1}^{m} (x - \mu_k) = \sum_{k=0}^{m} d_k z_k^{(m+1)}(x) = \sum_{k=0}^{m} d_k \prod_{j=0}^{k-1} g_j(x) \prod_{j=k}^{m-1} h_j(x).$$

Then

$$p_m(x; \mu_1, \cdots, \mu_m) = \frac{1}{d_m} \sum_{k=0}^{m} d_k \rho_k(x).$$

Proof. With the above form of p_m,

$$H_m(\mu) = \int_E p_m(x; \mu_1, \cdots, \mu_m)\, d\varphi(x, \mu) = \frac{1}{d_m} \sum_{k=0}^{m} d_k I_k(\mu; \boldsymbol{\rho})$$

$$= \frac{1}{d_m} \left(\prod_{j=0}^{m-1} h_j^{-1}(\mu) \right) \sum_{k=0}^{m} d_k z_k^{(m+1)}(\mu) = q_m(\mu);$$

hence $H_m(\mu_l) = 0$, $l = 1, 2, \cdots, m$, and the bi-orthogonality conditions are satisfied. □

We now have the following theorem.

THEOREM 6. *Let $\varphi(x, \mu)$, $x \in E$ be a distribution for every $\mu \in D$, such that*

$$I_k(\mu, \boldsymbol{\rho}) = \prod_{j=0}^{k-1} \frac{g_j(\mu)}{h_j(\mu)}, \qquad k = 0, 1, \cdots,$$

where $\boldsymbol{\rho}$ is given, g_j, h_j, $j = 0, 1, \cdots$, are linear and g_k/h_l are bounded and monotone for all $k = 0, \cdots, l$. Then, given that φ possesses the interpolation property, the transformation

$$T\left\{ \sum_{k=0}^{m} d_k \prod_{j=0}^{k-1} g_j(x) \prod_{j=k}^{m-1} h_j(x) \right\} = \sum_{k=0}^{m} d_k \rho_k(x)$$

maps polynomials whose zeros are all in D into polynomials with zeros all in cl E.

Proof. The proof follows as a straightforward consequence of Theorem 3 and Lemmata 4 and 5 upon noting that $h_k(\mu) \neq 0$, $\mu \in D$, $\alpha_k\delta_l - \beta_k\gamma_l \neq 0$, $0 \leqq k \leqq l$, is equivalent to the boundedness and monotonicity of g_k/h_l for all $0 \leqq k \leqq l$. □

The last theorem can be typically strengthened, cl E being replaced by E, upon showing that, under the stipulated conditions, $\sum_{k=0}^{m} d_k\rho_k$ cannot vanish at the endpoints of E.

The main problem rests in the identification of distributions with the desired generalised moments. Although these moments bear certain resemblance to those connected with Hahn-type orthogonal polynomials [Andrews and Askey, 1985], a characterisation of the underlying distributions is unknown.

Fortunately, it is frequently possible to identify such distributions. For example, the distributions $d\varphi(x, \mu) = \psi(x/\mu)$, that were introduced earlier in this section, correspond to $\rho_k(x) = x^k$, $k \geqq 0$, $g_0(\mu) \equiv 1$, $g_k(\mu) = (c_k/c_{k-1})\mu$, $k \geqq 1$, $h_k(u) \equiv 1$, $k \geqq 0$, where $c_k = \int_0^\infty x^k \, d\psi(x)$, $k \geqq 0$.

In the next four sections we introduce many further distributions that satisfy the conditions of Theorem 6.

3. Transformations of hypergeometric type. In this section we present five transformations that are related to distributions that induce familiar sets of orthogonal polynomials. All these sets involve hypergeometric functions, motivating our classification. The explicit form of the bi-orthogonal polynomials has been derived in the first four cases in [Iserles and Nørsett, 1988].

Jacobi transformation. Let $d\varphi(x, \mu) = x^{\mu-1}(1-x)^\alpha \, dx$, $\alpha > -1$, $D = (0, \infty)$, $E = (0, 1)$. Thus

$$I_k(\mu) = \frac{(\mu)_k}{(\alpha+\mu+1)_k}, \qquad k \geqq 0,$$

and $g_k(\mu) = k+\mu$, $h_k(\mu) = \alpha+k+1+\mu$, $k \geqq 0$, $g_l h_k' - h_k g_l' \equiv k-l+1+\alpha \neq 0$, $0 \leqq l \leqq k$. Thus Theorem 7 follows.

THEOREM 7. *The transformation*

$$T\left\{\sum_{h=0}^{m} (x)_k(\alpha+1+k+x)_{m-k} d_k\right\} = \sum_{k=0}^{m} d_k x^k, \qquad \alpha > -1, \tag{3.1}$$

maps polynomials with positive zeros into polynomials with zeros in $(0, 1)$.

Proof. The interpolation property is valid [Iserles and Nørsett, 1988]. Thus, the conditions of Theorem 6 are satisfied and it is only necessary to verify that no zeros are possible at the endpoints. But let

$$q(x) := \sum_{k=0}^{m} (x)_k(\alpha+1+k+x)_{m-k} d_k.$$

Then $d_0 = q(0)$, $\sum_{k=0}^m d_k$ is the coefficient of x^m in q and neither quantity may vanish. □

The transformations (3.1) can be recast in a more convenient form.

LEMMA 8. *Let*

$$q(x) = \sum_{k=0}^{m} (x)_k(\alpha+1+k+x)_{m-k} d_k = \sum_{k=0}^{m} (x)_k r_k. \tag{3.2}$$

Then $d_k = (1/(\alpha+1)_m)(-1)^k \sum_{j=0}^k \binom{m-j}{k-j}(-m-\alpha)_j r_j$, $k = 0, \cdots, m$.

Proof. It is enough to show that, with the stipulated values of $d_0, \cdots, d_m$, (3.2) is true for $m+1$ different values of x. We choose $x_n = -n$, $n = 0, \cdots, m$. Then

$$q(-n) = n! \sum_{k=0}^{n} \frac{(-1)^k}{(n-k)!} r_k$$

and

$$
\begin{aligned}
n!\sum_{k=0}^{n}\frac{(-1)^k}{(n-k)!}(\alpha+1+k-n)_{m-k}d_k
&=(-1)^m\frac{n!}{(-\alpha-m)_n}\sum_{k=0}^{n}(-1)^k\frac{(-\alpha)_{n-k}}{(n-k)!}\sum_{j=0}^{k}\binom{m-j}{k-j}(-m-\alpha)_j r_j\\
&=\frac{(-1)^m n!}{(-\alpha-m)_n}\sum_{j=0}^{n}\frac{(m-j)!}{(n-j)!}(-m-\alpha)_j r_j\sum_{k=j}^{n}(-1)^k\binom{n-j}{k-j}\frac{(-\alpha)_{n-k}}{(m-k)!}\\
&=\frac{(-1)^{m-n}n!}{(-\alpha-m)_n}\sum_{j=0}^{n}\frac{(m-j)!}{(n-j)!}(-m-\alpha)_j r_j\sum_{k=0}^{n-j}(-1)^k\binom{n-j}{k}\frac{(-\alpha)_k}{(m-n+k)!}\\
&=\frac{(-1)^{m-n}n!}{(-\alpha-m)_n}\sum_{j=0}^{n}\frac{(m-j)!(-m-\alpha)_j}{(n-j)!(m-n)!}r_j\,{}_2F_1\left[\begin{matrix}-n+j,-2;\\ m-n+1;\end{matrix}1\right]\\
&=\frac{(-1)^{m-n}n!}{(-\alpha-m)_n}\sum_{j=0}^{n}\frac{(m-j)!(-m-\alpha)_j}{(n-j)!(m-n)!}r_j\frac{(m-n+1+\alpha)_{n-j}}{(m-n+1)_{n-j}}\\
&=n!\sum_{j=0}^{n}\frac{(-1)^j}{(n-j)!}r_j=q(-n),
\end{aligned}
$$

where we have used the Vandermonde theorem to sum up the hypergeometric function with a unit argument. □

We now discard the factor of $((\alpha+1)_m)^{-1}$ to obtain the following theorem.

THEOREM 7A. *The transformation*

$$T\left\{\sum_{k=0}^{m}(x)_k r_k\right\}=\sum_{k=0}^{m}(-1)^k(-m-\alpha)_k x^k(1-x)^{m-k}r_k,\qquad \alpha>-1,$$

maps polynomials with positive zeros into polynomials with zeros in $(0, 1)$.

Proof. The proof follows immediately from (3.1) and Lemma 8, upon noting that (without the common factor of $((\alpha+1)_m)^{-1}$)

$$
\begin{aligned}
\sum_{k=0}^{m}d_k x^k&=\sum_{k=0}^{m}(-1)^k\sum_{j=0}^{k}\binom{m-j}{k-j}(-m-\alpha)_j r_j x^k\\
&=\sum_{j=0}^{m}(-1)^j(-m-\alpha)_j x^j r_j\sum_{k=0}^{m-j}(-1)^k\binom{m-j}{k}x^k\\
&=\sum_{j=0}^{m}(-1)^j(-m-\alpha)_j x^j(1-x)^{m-j}r_j.
\end{aligned}
$$

□

Laguerre transformation. Let $d\varphi(x,\mu)=(1/\Gamma(\mu))x^{\mu-1}e^{-x}\,dx$, $D=E=(0,\infty)$. The interpolation property holds by [Iserles and Nørsett, 1988]. Moreover,

$$I_k(\mu)=(\mu)_k,\qquad k\geqq 0;$$

hence $g_k(\mu)=k+\mu$, $h_k(\mu)\equiv 1$, $g_l'h_k-g_kh_k'\equiv 1$ for all $0\leqq l\leqq k$. Thus, by Theorem 6 and as migration of zeros to the boundary of E can be easily excluded, we obtain the following theorem.

THEOREM 9. *The transformation*

$$T\left\{\sum_{k=0}^{m}(x)_k r_k\right\}=\sum_{k=0}^{m}r_k x^k$$

maps polynomials with positive zeros into polynomials with positive zeros.

Meixner transformation. Let $d\varphi(x,\mu)=(1-\mu/\lambda)^{-\lambda}\mu^x\,d\psi(x)$, $D=(0,\lambda)$, $E=(0,\infty)$, where ψ is a step function with jumps of $(\lambda)_k/(k!\lambda^k)$ at $k=0, 1, \cdots$. Here λ is a positive constant. We set $\rho_k(x):=(-1)^k(-x)_k$, $k\geqq 0$. Hence

$$I_k(\mu,\boldsymbol{\rho})=(\lambda)_k\left(\frac{\mu}{\lambda-\mu}\right)^k,\qquad k\geqq 0,$$

and $g_k=(1+k/\lambda)\mu$, $h_k=1-\mu/\lambda$, $g_l'h_k-g_lh_k'=1+l/\lambda\neq 0$, $0\leqq l\leqq k$. The interpolation property is again valid [Iserles and Nørsett, 1988].

By referring to Theorem 6, we at once have Theorem 10 below.

THEOREM 10. *Let λ be a positive constant. Then the transformation*

$$T\left\{\sum_{k=0}^{m} d_k(\lambda)_k x^k(\lambda-x)^{m-k}\right\}=\sum_{k=0}^{m}(-1)^k(-x)_k d_k \tag{3.3}$$

maps polynomials with zeros in $(0,\lambda)$ into polynomials with positive zeros.

Proof. It only remains to verify that $p(x)=\sum_{k=0}^{m}(-1)^k(-x)_k d_k$ does not vanish at the endpoints. Let

$$q(x)=\sum_{k=0}^{m} d_k(\lambda)_k x^k(\lambda-x)^{m-k}.$$

Then $p(0)=\lambda^{-m}q(0)\neq 0$ and, for $x\gg 0$, $p(x)\simeq d_m=\lambda^{-m}q(\lambda)/(\lambda)_m\neq 0$. □

Transformation (3.3) can easily be reformulated.

THEOREM 10A. *Let λ be a positive constant. Then the transformation*

$$T\left\{\sum_{k=0}^{m} q_k x^k\right\}=\sum_{k=0}^{m}(-1)^k(-x)_k(\lambda+x)_{m-k}\lambda^k q_k$$

maps polynomials with zeros in $(0,\lambda)$ into polynomials with positive zeros.

Proof. Given constants $q_0,\cdots,q_m$, set

$$d_k=\frac{1}{(\lambda)_k}\sum_{j=0}^{k}\binom{m-j}{k-j}\lambda^k q_j,\qquad k=0,\cdots,m.$$

Then

$$\begin{aligned}\sum_{k=0}^{m} d_k(\lambda)_k x^k(\lambda-x)^{m-k}&=\sum_{k=0}^{m}\sum_{j=0}^{k}\binom{m-j}{k-j}\lambda^k q_j x^k(\lambda-x)^{m-k}\\&=\sum_{j=0}^{m}\lambda^j q_j x^j\sum_{k=0}^{m-j}\binom{m-j}{k}x^k(\lambda-x)^{m-j-k}\\&=\lambda^m\sum_{j=0}^{m} q_j x^j\end{aligned} \tag{3.4}$$

and, by using the Vandermonde theorem [Rainville, 1967],

$$\begin{aligned}\sum_{k=0}^{m}(-1)^k(-x)_k d_k&=\sum_{k=0}^{m}(-1)^k\frac{(-x)_k}{(\lambda)_k}\sum_{j=0}^{k}\binom{m-j}{k-j}\lambda^j q_j\\&=\sum_{j=0}^{m}(-1)^j\lambda^j q_j\sum_{k=0}^{m-j}(-1)^k\binom{m-j}{k}\frac{(-x)_{k+j}}{(\lambda)_{k+j}}\\&=\sum_{j=0}^{m}(-1)^j\lambda^j q_j\frac{(-x)_j}{(\lambda)_j}\,{}_2F_1\left[\begin{matrix}-m+j,-x+j;\\ \lambda+j;\end{matrix}1\right]\\&=\sum_{j=0}^{m}(-1)^j\lambda^j q_j\frac{(-x)_j(\lambda+x)_{m-j}}{(\lambda)_j(\lambda+j)_{m-j}}\\&=\frac{1}{(\lambda)_m}\sum_{j=0}^{m}(-1)^j q_j\lambda^j(-x)_j(\lambda+x)_{m-j}.\end{aligned} \tag{3.5}$$

The theorem now follows by comparing (3.4) and (3.5) with (3.3). □

Charlier transformation. Now $d\varphi(x,\mu)=e^{-\mu}\mu^x\,d\psi(x)$, $D=E=(0,\infty)$, where ψ is a step function with jumps of $1/k!$ at $k=0,1,\cdots$. Again, it is possible to prove that all the conditions of Theorem 6 are satisfied. However, it is easier to take advantage

of the fact that the present distribution is a limiting case of the one connected with the Meixner transformation as $\lambda \to \infty$.

THEOREM 11. *The transformation*

$$T\left\{\sum_{k=0}^{m} q_k x^k\right\} = \sum_{k=0}^{m} (-1)^k q_k (-x)_k$$

maps polynomials with positive zeros into polynomials with positive zeros.

As we have already mentioned in § 1, the last result can be alternatively proved by using the convolution-orthogonality theory of Al-Salam and Ismail [1976].

Krawtchouk transformation. Let $d\varphi(x, \mu) = (1+\mu)^{-\eta}\mu^x\, d\psi(x)$, $D = E = (0, \infty)$, where $\eta \geqq 1$ and ψ is a step function with jumps of $(-1)^k(-\eta)_k/k!$ at $k = 0, 1, \cdots$. Note that, strictly speaking, φ is not a distribution—the jumps may be negative for $k > \eta$. However, as long as we confine our attention to $k \leqq \eta$ the theory of § 2 remains valid.

Let $\delta_k = (-1)^k(-x)_k$, $k = 0, 1, \cdots$. Then

$$\begin{aligned} I_k(x, \boldsymbol{\rho}) &= (-1)^k(1+\mu)^{-\eta} \sum_{l=0}^{\infty} (-1)^l(-l)_k \frac{(-\eta)_l}{l!}\mu^l \\ &= (-1)^k(-\eta)_k(1+\mu)^{-\eta}\mu^k \sum_{l=0}^{\infty} \frac{(-1)^l}{l!}(-\eta+k)_l\mu^l \\ &= (-1)^k(1+\mu)^{-\eta}\mu^k\, {}_1F_0\left[\begin{matrix}-\eta+k;\\ -;\end{matrix} -\mu\right] \\ &= (-1)^k\mu^k(1+\mu)^{-k}, \qquad k = 0, 1, \cdots. \end{aligned}$$

Thus $g_k = (\eta - k)x$, $h_k = 1 + x$, $g_l'h_k - g_lh_k' = \eta - l \neq 0$, $l = 0, \cdots, k$, $k = 0, 1, \cdots, [\eta] - 1$.

φ possesses the interpolation property—the proof follows easily from [Iserles and Nørsett, 1988]. We again use Theorem 6 to prove Theorem 12 below.

THEOREM 12. *Let $1 \leqq m \leqq \eta$. Then the transformation*

$$T\left\{\sum_{k=0}^{m} d_k(-1)^k(-\eta)_k x^k(1+x)^{m-k}\right\} = \sum_{k=0}^{m} d_k(-1)^k(-x)_k \tag{3.6}$$

maps polynomials with positive zeros into polynomials with positive zeros.

Proof. It is only necessary to demonstrate that $p(x) = \Sigma(-1)^k d_k(-x)_k$ may not vanish at the endpoints. Let $q(x) = \Sigma(-1)^k d_k(-\eta)_k x^k(1+x)^{m-k}$. Then

$$p(0) = d_0 = q(0) \neq 0, \quad p(x) \simeq d_m x^m \simeq (-1)^m q(x)/(-\eta)_m \neq 0, \quad x \gg 0$$

and the theorem is true. □

Transformation (3.6) can be recast as below.

THEOREM 12A. *Let $1 \leqq m \leqq \eta$. Then the transformation*

$$T\left\{\sum_{k=0}^{m} q_k x^k\right\} = \sum_{k=0}^{m} (-x)_k(x-\eta)_{m-k} q_k$$

maps polynomials with positive zeros into polynomials with positive zeros.

Proof. Set

$$\sum_{k=0}^{m} d_k(-1)^k(-\eta)_k x^k(1+x)^{m-k} = \sum_{k=0}^{m} q_k x^k.$$

Changing the variable into $y = x/(1+x)$ yields

$$\begin{aligned} \sum_{k=0}^{m} d_k(-1)^k(-\eta)_k y^k &= \sum_{k=0}^{m} q_k y^k(1-y)^{m-k} \\ &= \sum_{k=0}^{m} (-1)^k \left(\sum_{l=0}^{k} (-1)^l \binom{m-l}{k-l} q_l\right) y^k; \end{aligned}$$

hence

$$d_k = \frac{1}{(-\eta)_k} \sum_{l=0}^{k} (-1)^l \binom{m-l}{k-l} q_l, \qquad k = 0, \cdots, m.$$

Consequently,

$$\begin{aligned}\sum_{k=0}^{m} d_k (-1)^k (-x)_k &= \sum_{k=0}^{m} \frac{(-1)^k}{(-\eta)_k} (-x)_k \sum_{l=0}^{k} (-1)^l \binom{m-l}{k-l} q_l \\ &= \sum_{l=0}^{m} q_l \frac{(-x)_l}{(-\eta)_l} {}_2F_1\left[\begin{matrix}-m+l, -x+l; \\ -\eta+l;\end{matrix} 1\right] \\ &= \frac{1}{(-\eta)_m} \sum_{l=0}^{m} q_l (-x)_l (x-\eta)_{m-l},\end{aligned}$$

where, as before, the Vandermonde theorem has been used to sum the hypergeometric series with unit argument.

Comparison with (3.6) furnishes the proof. □

4. Transformations of q-hypergeometric type. As notation for q-hypergeometric functions varies (cf. [Andrews and Askey, 1985], [Exton, 1983], [Slater, 1966]), we wish to clarify that, throughout this paper,

$${}_p\Phi_q\left[\begin{matrix}a_1, \cdots, a_p; \\ b_1, \cdots, b_q;\end{matrix} \rho, x\right] := \sum_{k=0}^{\infty} \frac{(a_1; \rho)_k (a_2; \rho)_k \cdots (a_p; \rho)_k}{(b_1; \rho)_k (b_2; \rho)_k \cdots (b_q; \rho)_k} \frac{x^k}{(\rho; \rho)_k},$$

$$[\rho]_n := (\rho; \rho)_n, \quad n = 0, 1, \cdots,$$

$$\begin{bmatrix} m \\ n \end{bmatrix} := \frac{[\rho]_m}{[\rho]_n [\rho]_{m-n}}, \quad n = 0, \cdots, m.$$

Wall transformation. Let α be any number in $(-1, 1)$. We set

$$d\varphi(x, \mu) = \frac{(\mu; \rho)_\infty}{(\alpha\mu; \rho)_\infty} x^{\log \mu / \log \rho} \, d\psi(x), \qquad D = E = (0, 1),$$

where $\rho \in (0, 1)$ and ψ is a step function with jumps of $(\alpha; \rho)_k / [\rho]_k$ at ρ^k, $k = 0, 1, \cdots$. We note at once that the interpolation property is valid: $d\varphi(x, \mu)/d\psi(x) = \omega(x, \mu) = C(\mu) x^{\log \mu / \log \rho}$, where $C \neq 0$ is independent of x. But

$$\det \begin{pmatrix} x_1^{\nu_1}, & x_1^{\nu_2}, & \cdots, & x_1^{\nu_m} \\ \vdots & \vdots & & \vdots \\ x_m^{\nu_1}, & x_m^{\nu_2}, & \cdots, & x_m^{\nu_m} \end{pmatrix} \neq 0$$

for all distinct $x_1, \cdots, x_m > 0$ and distinct $\nu_1, \cdots \nu_m \in \mathcal{R}$, hence φ possesses the interpolation property.

The moments of φ can be evaluated by summing the ${}_1\Phi_0$ function with the Heine formula [Slater, 1966]:

$$\begin{aligned} I_k(\mu) &= \frac{(\mu; \rho)_\infty}{(\alpha\mu; \rho)_\infty} \sum_{l=0}^{\infty} \rho^{kl} \mu^l \frac{(\alpha; \rho)_l}{[\rho]_l} \\ &= \frac{(\mu; \rho)_\infty}{(\alpha\mu; \rho)_\infty} {}_1\Phi_0\left[\begin{matrix}\alpha; \\ -;\end{matrix} \rho, \mu\rho^k\right] = \frac{(\mu; \rho)_k}{(\alpha\mu; \rho)_k}, \qquad k = 0, 1, \cdots. \end{aligned}$$

Hence $g_k = 1 - \rho^k x$, $h_k = 1 - \alpha\rho^k x$, $g_l' h_k - g_l h_k' = \alpha\rho^k - \rho^l \neq 0$ (since $\alpha \in (-1, 1)$, $\rho \in (0, 1)$) for all $l = 0, \cdots, k$, $k = 0, 1, \cdots$. We are within the conditions of Theorem 6, and consequently, Theorem 13 follows.

THEOREM 13. *Let* $\alpha \in (-1, 1)$, $\rho \in (0, 1)$. *The transformation*

$$T\left\{\sum_{k=0}^{m} d_k(x;\rho)_k(\alpha x\rho^k;\rho)_{m-k}\right\} = \sum_{k=0}^{m} d_k x^k \tag{4.1}$$

maps polynomials with zeros in $(0, 1)$ *into polynomials with zeros in* $(0, 1)$.

Proof. Again, it is enough to demonstrate that $p(x) = \sum d_k x^k$ does not vanish at the endpoints. But

$$p(0) = \frac{1}{(\alpha;\rho)_m} q(1), \qquad p(1) = q(0),$$

where $q(x) = \sum d_k(x;\rho)_k(\alpha x\rho^k;\rho)_{m-k}$ and the theorem follows. □

As in § 3, the main effort is in recasting the transformation (4.1) into an equivalent form.

LEMMA 14. *Let*

$$q(x) = \sum_{k=0}^{m} d_k(x;\rho)_k(\alpha x\rho^k;\rho)_{m-k} = \sum_{k=0}^{m} s_k(x;\rho)_k.$$

Then

$$d_k = \sum_{l=0}^{k} (-1)^{k-l} \begin{bmatrix} m-l \\ k-l \end{bmatrix} \rho^{1/2(k-l)(k-l-1)} \frac{\alpha^{k-l} s_l}{(\alpha;\rho)_{m-l}}, \qquad k = 0, 1, \cdots, m.$$

Proof. With the above values of $d_0, \cdots, d_m$,

$$\begin{aligned}
q(\rho^{-n}) &= (-1)^n [\rho]_n (\alpha;\rho)_{m-n} \sum_{l=0}^{n} (-1)^l \frac{[\rho]_{m-l}\alpha^{n-l}s_l}{(\alpha;\rho)_{m-l}} \rho^{-1/2((n+1)n-(l+1)l)} \\
&\quad \times \sum_{k=l}^{n} (-1)^k \frac{(\rho/\alpha;\rho)_{n-k}}{[\rho]_{k-l}[\rho]_{m-l}[\rho]_{n-k}} \rho^{1/2(k^2-k-2l)} \\
&= [\rho]_n (\alpha;\rho)_{m-n} \sum_{l=0}^{n} (-1)^l \frac{[\rho]_{m-l}}{[\rho]_{n-l}} \frac{\alpha^{n-l}s_l\rho^{-n+(1/2)l(l+1)-nl}}{[\rho]_{m-n}(\alpha;\rho)_{m-l}} \\
&\quad \times \sum_{k=0}^{n-l} (-1)^k \begin{bmatrix} n-l \\ k \end{bmatrix} \frac{(\rho/\alpha;\rho)_k}{(\rho^{m-n+1};\rho)_k} \rho^{(1/2)k(k+1)-(n-l)} \\
&= [\rho]_n (\alpha;\rho)_{m-n} \sum_{l=0}^{n} (-1)^l \begin{bmatrix} m-l \\ n-l \end{bmatrix} \frac{\alpha^{n-l}s_l\rho^{-n+(1/2)l(l+1)-nl}}{(\alpha;\rho)_{m-l}} \\
&\quad \times {}_2\Phi_1\left[\begin{matrix} \rho^{-n+l}, \rho/\alpha; \\ \rho^{-m+n+1}; \end{matrix} \rho, \rho\right] \\
&= [\rho]_n (\alpha;\rho)_{m-n} \sum_{l=0}^{n} (-1)^l \begin{bmatrix} m-l \\ n-l \end{bmatrix} \frac{\alpha^{n-l}s_l\rho^{-n+(1/2)l(l+1)-nl}}{(\alpha;\rho)_{m-l}} \\
&\quad \times \frac{(\alpha\rho^{m-n};\rho)_{n-l}}{(\rho^{m-n+1};\rho)_{n-l}} \rho^{n-l}\alpha^{-n+l} \\
&= \sum_{l=0}^{n} (-1)^l \frac{[\rho]_n}{[\rho]_{n-l}} \rho^{(1/2)l(l-1)-nl} s_l \\
&= \sum_{l=0}^{m} s_l(\rho^{-n};\rho)_l, \qquad n = 0, 1, \cdots, m.
\end{aligned}$$

Note the use of the q-analogue of the Vandermonde theorem [Slater, 1966], [Exton, 1983] to sum up the ${}_2\Phi_1$ function with argument ρ.

Since two mth degree polynomials that coincide at $m+1$ distinct points must be identical, the lemma follows. □

THEOREM 13A. *Let $\alpha \in (-1, 1)$, $\rho \in (0, 1)$. The transformation*

$$T\left\{\sum_{k=0}^{m} s_k(x; \rho)_k\right\} = \sum_{k=0}^{m} s_k(\alpha\rho^{m-k}; \rho)_k x^k (\alpha x; \rho)_{m-k}$$

maps polynomials with zeros in $(0, 1)$ into polynomials with zeros in $(0, 1)$.

Proof. We substitute $d_0, \cdots, d_m$ from the last lemma into (4.1) and use the Heine theorem [Slater, 1966]:

$$\begin{aligned}(\alpha; \rho)_m \sum_{k=0}^{m} d_k x^k &= \sum_{l=0}^{m} (\alpha\rho^{m-l}; \rho)_l s_l \sum_{k=l}^{m} (-1)^{k-l} \begin{bmatrix} m-l \\ k-l \end{bmatrix} \alpha^{k-l} x^k \rho^{1/2(k-l)(k-l-1)} \\ &= \sum_{l=0}^{m} (\alpha\rho^{m-l}; \rho)_l s_l x^l \, {}_1\Phi_0\left[\begin{matrix} \rho^{-m+l}; \\ -; \end{matrix} \rho, \rho^{m-l}\alpha x\right] \\ &= \sum_{l=0}^{m} (\alpha\rho^{m-l}; \rho)_l s_l x^l \frac{(\alpha x; \rho)_\infty}{(\alpha x \rho^{m-l}, \rho)_\infty} \\ &= \sum_{l=0}^{m} s_l (\alpha\rho^{m-l}; \rho)_l x^l (\alpha x; \rho)_{m-l}\end{aligned}$$

and the theorem follows. □

Llaw transformation. The present transformation is, in a sense, a "reverse" Wall transformation—hence the name. Let $\rho > 1$ and

$$f(z) := {}_0\Phi_0\left[\begin{matrix} -; \\ -; \end{matrix} \rho, z\right].$$

f is an entire function and

$$f\left(\frac{z}{\rho}\right) - f(z) = \sum_{k=1}^{\infty} \frac{\rho^{-k} z^k}{[\rho]_{k-1}} = \rho^{-1} z f\left(\frac{z}{\rho}\right).$$

Hence $f(z) = (1 - z/\rho) f(z/\rho)$ and, by induction,

$$f(z) = \left(\frac{z}{\rho}; \rho^{-1}\right)_s f(\rho^{-s} z), \qquad s \geqq 0.$$

Let $s \to \infty$. Since $\rho > 1$, $\rho^{-s} z \to 0$, thus $f(0) = 1$ implies that

$$f(z) = \left(\frac{z}{\rho}; \rho^{-1}\right)_\infty. \tag{4.2}$$

Now let

$$d\varphi(x, \mu) = \frac{1}{(-\rho^{-1}\mu; \rho^{-1})_\infty} x^{\log \mu / \log \rho} \, d\psi(x), \quad D = (0, \infty), \quad E = (1, \infty),$$

where ψ is a step function with the positive jumps of $(-1)^k/[\rho]_k$ at ρ^k, $k = 0, 1, \cdots$ We have by (4.2)

$$I_k(\mu) = \frac{1}{(-\rho^{-1}\mu; \rho^{-1})_\infty} {}_0\Phi_0\left[\begin{matrix} -; \\ -; \end{matrix} \rho, -\mu\rho^k\right] = (-\mu; \rho)_k, \qquad k = 0, 1, \cdots.$$

Thus $g_k = 1 + \rho^k x$, $h_k \equiv 1$, $g_l' h_k - g_l h_k' = \rho^l \neq 0$, $l = 0, \cdots, k$, $k = 0, 1, \cdots$.

THEOREM 15. *Let $\rho > 1$. The transformation*

$$T\left\{\sum_{k=0}^{m} s_k(-x;\rho)_k\right\} = \sum_{k=0}^{m} s_k x^k$$

maps polynomials with positive zeros into polynomials with zeros in $(1,\infty)$.

Proof. As the interpolation property is valid by an argument identical to that for the Wall transformation, we are within the conditions of Theorem 6. The polynomial $p(x)=\sum s_k x^k$ cannot vanish at 1 or ∞:

$$p(1)=\sum s_k = q(0),$$
$$p(x)\simeq s_m x^m \simeq \rho^{-1/2(m-1)m} q(x), \qquad x \gg 0,$$

where $q(x)=\sum s_k(-x;\rho)_u$. Hence zeros of p cannot migrate to the endpoints of E and the proof is complete. □

q-Krawtchouk transformation. Let *integer* $N \geqq 1$ be given. Like the Krawtchouk transformation, the q-analogue is valid only for a limited range of m, namely $m \leqq N$. We set

$$d\varphi(x,\mu) = \frac{(-\mu\rho^N;\rho)_\infty}{(-\mu;\rho)_\infty} x^{\log\mu/\log\rho}\, d\psi(x), \quad \rho\in(0,1), \quad D=(0,\infty), \quad E=(0,1),$$

where ψ is a step function with jumps of $(-1)^k\rho^{kN}(\rho^{-N};\rho)_k/[\rho]_k$ at ρ^k, $k=0,1,\cdots N$. Note that the jumps are positive for all $k=0,\cdots,N$. The interpolation property is again valid. The moments are obtained by exploiting the Heine formula [Slater, 1966]:

$$I_k(\mu) = \frac{(-\mu\rho^N;\rho)_\infty}{(-\mu;\rho)_\infty}\, {}_1\Phi_0\left[\begin{matrix}\rho^{-N};\\ -;\end{matrix}\rho, -\mu\rho^{N+k}\right]$$
$$= \frac{(-\mu\rho^N;\rho)_k}{(-\mu;\rho)_k}, \qquad k=0,1,\cdots.$$

Therefore $g_k = 1+\rho^{N+k}x$, $h_k = 1+\rho^k x$, $g_l'h_k - g_l h_k' = \rho^{N+k}-\rho^l \neq 0$, $l=0,\cdots,k$, $k=0,1,\cdots,N$, and all the conditions of Theorem 6 hold.

THEOREM 16. *Let $\rho\in(0,1)$. The transformation*

$$T\left\{\sum_{k=0}^{m} d_k(-x\rho^N;\rho)_k(-\rho^k x;\rho)_{m-k}\right\} = \sum_{k=0}^{m} d_k x^k, \qquad m\leqq N \tag{4.3}$$

maps polynomials with positive zeros into polynomials with zeros in $(0,1)$.

Proof. The proof follows by demonstrating, similarly to past proofs, that zeros cannot migrate to the endpoints of E. □

To reformulate (4.3), we note the similarity with (4.1). By setting $y := -x\rho^N$, $\alpha=\rho^{-N}$ we obtain

$$\sum_{k=0}^{m} d_k(y;\rho)_k(\alpha y\rho^k;\rho)_{m-k} = \sum_{k=0}^{m} s_k(y;\rho)_k,$$

where $d_0,\cdots,d_m$ are given in Lemma 14. An immediate consequence of the method of proof of Theorem 13A is Theorem 16A below.

THEOREM 16A. *Let $\rho\in(0,1)$. The transformation*

$$T\left\{\sum_{k=0}^{m} s_k(-x\rho^N;\rho)_k\right\} = \sum_{k=0}^{m} s_k(\rho^{m-N-k};\rho)_k x^k(\rho^{-N}x;\rho)_{m-k}$$

maps polynomials with positive zeros into polynomials with zeros in $(0,1)$.

Wigert transformation. The distribution

$$d\varphi(x,\mu)=\frac{\rho^{1/2(1+\mu)^2}}{\sqrt{-2\pi\log\rho}}(-\alpha\rho^{\mu};\rho)_\infty\left(\frac{\alpha}{x}\rho^{-1/2};\rho\right)_\infty x^\mu e^{1/2((\log x)^2/\log\rho)}\,dx,$$

$u\in\mathcal{R}$, $E=(0,\infty)$, $\rho\in(0,1)$, $\alpha<1$, features (with $\mu=0$) in the definition of Stieltjes-Wigert polynomials [Chihara, 1978].

Let

$$G(\sigma):=\int_0^\infty x^\sigma e^{1/2((\log x)^2/\log\rho)}\,dx.$$

Changing the variable $t=\log x$ yields

$$\begin{aligned}G(\sigma)&=\int_{-\infty}^{\infty}\exp\left((\sigma+1)t+\frac{1}{2}\frac{t^2}{\log\rho}\right)dt\\&=\sqrt{-2\log\rho}\,\rho^{-1/2(\sigma+1)^2}\int_{-\infty}^{\infty}e^{-t^2}\,dt\\&=\sqrt{-2\pi\log\rho}\,\rho^{-1/2(\sigma+1)^2}.\end{aligned}$$

Next, let

$$F(\nu):=\int_0^\infty x^\nu\left(\frac{\alpha}{x}g^{-1/2};\rho\right)_\infty e^{1/2((\log x)^2/\log\rho)}\,dx,\qquad \nu\geqq 0.$$

Since

$$\sum_{n=0}^{\infty}(-1)^n\frac{\rho^{(1/2)n(n-2)}}{[\rho]_n}z^n=(\rho^{-1/2}z;\rho)_\infty,\qquad z\in\mathcal{C}$$

[Slater, 1966], it follows that

$$\begin{aligned}F(\nu)&=\sum_{n=0}^{\infty}(-1)^n\frac{\rho^{(1/2)n(n-2)}\alpha^n}{[\rho]_n}G(\nu-n)\\&=\rho^{-1/2(\nu+1)^2}\sqrt{-2\pi\log\rho}\sum_{n=0}^{\infty}\frac{(-\rho^\nu\alpha)^n}{[\rho]_n}\\&=\rho^{-1/2(\nu+1)^2}\sqrt{-2\pi\log\rho}\;{}_0\Phi_0\left[\begin{matrix}-\\-\end{matrix};\rho,-\rho^\nu\alpha\right]\\&=\rho^{-1/2(\nu+1)^2}\sqrt{-2\pi\log\rho}\,\frac{1}{(-\rho^\nu\alpha;\rho)_\infty}.\end{aligned}$$

Thus,

$$\begin{aligned}I_k(\mu)&=\rho^{1/2(1+\mu)^2}\frac{(-\alpha\rho^\mu;\rho)_\infty}{\sqrt{-2\pi\log\rho}}F(\mu+k)=(-\rho^\mu\alpha;\rho)_k\rho^{-k\mu-(1/2)k(k+2)}\\&=(-\eta\alpha;\rho)_k\eta^{-k}\rho^{-(1/2)k(k+2)},\qquad k=0,1,\cdots,\end{aligned}$$

where $\eta:=\rho^\mu$. Henceforth we will use η, rather than μ—thus, $D=(0,\infty)$. As a function of η, I_k is of the form $\prod_{j=0}^{k-1}(g_j(\eta)/h_j(\eta))$, where $g_k=1+\alpha\rho^k\eta$, $h_k=\rho^{k+3/2}\eta$, $g_l'h_k-g_lh_k'=-\rho^{k+3/2}(1-\alpha\rho^l)\neq 0$, $l=0,\cdots,k$, $k=0,1,\cdots$ (since $\alpha<1$, $\rho\in(0,1)$).

The interpolation property holds, since

$$d\phi(x,\mu)=C_1(x)C_2(\mu)x^\mu\,dx;$$

all that matters for the interpolation property is x^{μ}. Thus, all the conditions of Theorem 6 are satisfied and we have Theorem 17.

THEOREM 17. *Let $\alpha < 1$, $\rho \in (0, 1)$. The transformations*

$$T\left\{\sum_{k=0}^{m} d_k x^{m-k}(-\alpha x;\rho)_k \rho^{1/2(m-k)(m+k-2)}\right\} = \sum_{k=0}^{m} d_k x^k, \tag{4.4}$$

$$T\left\{\sum_{k=0}^{m} t_k x^k(-\alpha\rho^{-m+1}x;\rho)_{m-k}\rho^{-(1/2)k^2}\right\} = \sum_{k=0}^{m} t_k x^k \tag{4.5}$$

map polynomials with positive zeros into polynomials with positive zeros.

Proof. Equation (4.4) is a straightforward consequence of Theorem 6—again it is easy to verify that zeros do not migrate to the endpoints. Equation (4.5) follows from (4.4) by reversing the summation and replacing x by $\rho^{m-1}x$. □

5. Transformations of gamma type. The theme common to all four transformations in this section is the appearance of the gamma function in the distribution φ.

Γ_1 *transformation.* Let $\alpha \in (0, 1)$ and

$$d\varphi(x, \mu) = (1-\alpha)^{\mu}\frac{\Gamma(x+\mu)}{\Gamma(\mu)}\,d\psi(x), \qquad D = E = (0, \infty),$$

where the step function ψ has jumps of $\alpha^k/k!$ at $k = 0, 1, \cdots$.

LEMMA 18. *The distribution φ possesses the interpolation property.*

Proof. It is enough to show that $\Gamma(x+\mu)$ is strictly totally positive [Karlin and Studden, 1966]:

$$d\varphi(x, \mu) = C(\mu)\Gamma(x+\mu)\,d\psi(x),$$

where C and ψ make no difference to interpolation property.

Let $f(x, t)$, $g(t, y)$, $x \in (a_1, b_1)$, $t \in (c, d)$, $y \in (a_2, b_2)$, be two strictly totally positive functions and let $\phi(t)$, $t \in (c, d)$, be a distribution. Then also

$$h(x, y) := \int_c^d f(x, t)g(t, y)\,d\phi(t), \quad x \in (a_1, b_1), \quad y \in (a_2, b_2) \tag{5.1}$$

is strictly totally positive [Pólya and Szegö, 1976].

We set $a_1 = a_2 = c = 0$, $b_1 = b_2 = d = \infty$, $f(x, t) = t^x$, $g(t, y) = t^y$, $\phi(t) = (1/t)\,e^{-t}\,dt$. Thus,

$$h(x, y) = \int_0^{\infty} e^{-t}t^{x+y-1}\,dt = \Gamma(x+y)$$

is strictly totally positive and, consequently, φ possesses the interpolation property.

Let $\rho_k = (-1)^k(-x)_k$, $k = 0, 1, \cdots$. Then

$$I_k(\mu, \boldsymbol{\rho}) = (-1)^k(1-\alpha)^{\mu}\sum_{l=0}^{\infty}\frac{1}{l!}(-l)_k(\mu)_l\alpha^l$$

$$= (1-\alpha)^{\mu}(\mu)_k\alpha^k\,{}_1F_0\left[\begin{matrix}\mu+k;\\ -;\end{matrix}\ \alpha\right] = \left(\frac{\alpha}{1-\alpha}\right)^k(\mu)_k = \lambda^k(\mu)_k, \qquad k = 0, 1, \cdots,$$

where $\lambda := \alpha/(1-\alpha) > 0$. Thus, $g_k = \lambda(k+x)$, $h_k \equiv 1$, $g_l'h_k - g_lh_k' \equiv \lambda > 0$, $l = 0, \cdots, k$, $k = 0, 1, \cdots$. We are within the conditions of Theorem 6; consequently Theorem 19 follows.

THEOREM 19. *Let $\lambda > 0$. The transformation*

$$T\left\{\sum_{k=0}^{m} r_k(x)_k\right\} = \sum_{k=0}^{m} (-1)^k(-x)_k\lambda^{m-k}r_k \tag{5.2}$$

maps polynomials with positive zeros into polynomials with positive zeros.

Proof. The statement of the theorem is true for

$$T\left\{\sum_{k=0}^{m} d_k\lambda^k(x)_k\right\} = \sum_{k=0}^{m} (-1)^k d_k(-x)_k;$$

it is trivial that zeros cannot migrate to the endpoints of E. Form (5.2) follows when we set $r_k = \lambda^k d_k$, $k = 0, \cdots, m$. □

Γ_2 *transformation.* Let $a, b > 0$ and

$$d\varphi(x, \mu) = \frac{\Gamma(\mu - a)\Gamma(\mu - b)}{\Gamma(\mu - a - b)\Gamma(\mu + x)}\, d\psi(x), \quad D = (a + b, \infty), \quad E = (0, \infty),$$

where ψ is a step function with jumps of $(a)_k(b)_k/k!$ at $k = 0, 1, \cdots$. We assume for the time being that $\mu - a - b$ is not an integer—this assumption will be lifted later.

LEMMA 20. *φ possesses the interpolation property.*

Proof. It is enough to demonstrate that the beta function $B(x, \mu)$ is strictly totally positive:

$$d\varphi(x, \mu) = \frac{\Gamma(\mu - a)\Gamma(\mu - b)}{\Gamma(\mu - a - b)\Gamma(\mu)} \frac{1}{\Gamma(x)}\, d\psi(x) = C_1(\mu)C_2(x)B(x, \mu)\, d\psi(x).$$

This follows easily from (5.1) by setting $f(x, t) = t^{x-1}$, $g(t, y) = (1 - t)^{y-1}$, $\phi(t) = t$, $a_1 = 0$, $b_1 = \infty$, $a_2 = a + b$, $b_2 = \infty$, $c = 0$, $d = 1$, since

$$B(x, y) = \int_0^1 t^{x-1}(1 - t)^{y-1}\, dt$$

[Rainville, 1967]. □

Next we evaluate $I_k(\mu, \boldsymbol{\rho})$, where $\rho_k = (-1)^k(-x)_k$, $k = 0, 1, \cdots$. To this purpose we use a standard formula [Rainville, 1967] to sum up ${}_2F_1$ with the unit argument

$$\begin{aligned} I_k(\mu, \boldsymbol{\rho}) &= (-1)^k \frac{\Gamma(\mu - a)\Gamma(\mu - b)}{\Gamma(\mu - a - b)\Gamma(\mu)} \sum_{l=0}^{\infty} \frac{(-l)_k(a)_l(b)_l}{l!(\mu)_l} \\ &= \frac{\Gamma(\mu - a)\Gamma(\mu - b)}{\Gamma(\mu - a - b)\Gamma(\mu + k)} (a)_k(b)_k\, {}_2F_1\left[\begin{matrix} a+k, b+k; \\ \mu+k; \end{matrix} 1\right] \\ &= \frac{(-1)^k(a)_k(b)_k}{(-\mu + a + b + 1)_k}, \qquad k = 0, 1, \cdots. \end{aligned}$$

To simplify matters, we change the parameter: $\mu' := \mu - a - b$, $D' = (0, \infty)$. Hence

$$I_k(\mu, \boldsymbol{\rho}) = (-1)^k \frac{(a)_k(b)_k}{(-\mu + 1)_k}, \qquad k = 0, 1, \cdots$$

(use of an identical symbol I_k should cause no confusion). Note that μ is not allowed, for the time being, to be an integer.

We have $g_k=(a+k)(b+k)$, $h_k=x-k-1$, $g_l'h_k-g_lh_k'=-(a+l)(b+l)\neq 0$, $l=0,\cdots,k$, $k=0,1,\cdots$.

THEOREM 21. *Let $a, b>0$. The transformation*

$$T\left\{\sum_{k=0}^{m} u_k(x-m)_k\right\}=\sum_{k=0}^{m}\frac{(-1)^k u_{m-k}}{(a)_k(b)_k}(-x)_k \tag{5.3}$$

maps polynomials with positive zeros into polynomials with positive zeros.

Proof. First, we note that μ may attain all values in $(0,\infty)$—our restriction to noninteger values is hereby lifted. This is permissible, since bi-orthogonal polynomials exist, by continuity, for all choice of distinct $\mu_1,\cdots,\mu_m>0$. Thus, all the conditions of Theorem 6 hold and the transformation

$$T\left\{\sum_{k=0}^{m} d_k(a)_k(b)_k(x-m)_{m-k}\right\}=\sum_{k=0}^{m}(-1)^k d_k(-x)_k \tag{5.4}$$

maps polynomials with positive zeros into polynomials with positive zeros: migration of zeros to the endpoints of E is excluded in what should be by now a standard way.

To obtain (5.3) we set

$$u_k := d_{m-k}(a)_{m-k}(b)_{m-k}, \qquad k=0,1,\cdots,m,$$

in (5.4). □

Γ_3 *transformation.* Let α be a positive constant and N be a natural number. We set

$$d\varphi(x,\mu)=\frac{\Gamma(x+\mu)}{(\alpha+\mu)_N\Gamma(\mu)}\,d\psi(x),$$

where the step function ψ jumps $\binom{N}{k}(\alpha)_{N-k}$ at $k=0,1,\cdots,N$. As in the case of the Krawtchouk and the q-Krawtchouk transformations, we confine our attention to $m=1,\cdots,N$.

The interpolation property holds, by a proof identical to that of Lemma 18.

Let $\rho_k := (-1)^k(-x)_k$, $k=0,1,\cdots$.

$$\begin{aligned} I_k(\mu,\boldsymbol{\rho}) &= \frac{N!}{(\alpha+\mu)_N}\sum_{l=k}^{N}\frac{(\mu)_l(\alpha)_{N-l}}{(l-k)!(N-l)!} \\ &= \frac{N!(\mu)_k(\alpha)_{N-k}}{(\alpha+\mu)_N(N-k)!}\,{}_2F_1\left[\begin{matrix}-N+k,\mu+k;\\ -\alpha-N+k+1;\end{matrix}1\right] \\ &= \frac{N!(\mu)_k(\alpha+k+\mu)_{N-k}}{(\alpha+\mu)_N(N-k)!} \\ &= \frac{N!}{(N-k)!}\frac{(\mu)_k}{(\alpha+\mu)_k}, \qquad k=0,1,\cdots,N. \end{aligned}$$

Again, all the conditions of Theorem 6 are satisfied: $g_k=(N-k)(x+k)$, $h_k=\alpha+k+x$, $g_l'h_k-g_lh_k'=\alpha(N-k)\neq 0$, $l=0,\cdots,k$, $k=0,\cdots,N-1$.

THEOREM 22. *Let $\alpha>0$, $N\in\mathscr{Z}$, $\mathscr{N}\geqq 1$. The transformation*

$$T\left\{\sum_{k=0}^{m}\frac{d_k}{(N-k)!}(x)_k(x+\alpha+k)_{m-k}\right\}=\sum_{k=0}^{m}(-1)^k d_k(-x)_k, \qquad m\leqq N, \tag{5.5}$$

maps polynomials with positive zeros into polynomials with positive zeros.

By using Lemma 8, we can recast (5.5) into a different form.

THEOREM 22A. *Let $\alpha>0$, $N\in\mathscr{Z}$, $N\geqq 1$. The transformation*

$$T\left\{\sum_{k=0}^{m} r_k(x)_k\right\}=\sum_{k=0}^{m}(-1)^k r_k(-m-\alpha+1)_k(-x)_k(x-N)_{m-k},\qquad m\leqq N,$$

maps polynomials with positive zeros into polynomials with positive zeros.

Proof. As a consequence of Lemma 8,

$$\sum_{k=0}^{m}\frac{d_k}{(N-k)!}(x)_k(x+\alpha+k)_{m-k}=\sum_{k=0}^{m} r_k(x)_k$$

holds with

$$d_k=(-1)^k\frac{(N-k)!}{(\alpha)_m}\sum_{j=0}^{k}\binom{m-j}{k-j}(-m-\alpha+1)_j r_j,\qquad k=0,\cdots,m.$$

Thus, by the Vandermonde theorem,

$$\begin{aligned}\sum_{k=0}^{m}(-1)^k d_k(-x)_k&=\frac{1}{(\alpha)_m}\sum_{j=0}^{m}(-m-\alpha+1)_j r_j\sum_{k=j}^{m}\binom{m-j}{k-j}(N-k)!\,(-x)_k\\&=\frac{1}{(\alpha)_m}\sum_{j=0}^{m}(N-j)!(-m-\alpha+1)_j r_j(-x)_j\,{}_2F_1\left[\begin{matrix}-m+j,-x+j;\\-N+j;\end{matrix}1\right]\\&=(-1)^m\frac{(N-m)!}{(\alpha)_m}\sum_{j=0}^{m}(-1)^j r_j(-m-\alpha+1)_j(-x)_j(x-N)_{m-j}\end{aligned}$$

and the proof follows. □

Γ_4 *transformation.* Let α, $\beta>0$, with β a noninteger. We set

$$d\varphi(x,\mu)=\frac{\Gamma(\beta)\Gamma(\alpha+\beta-\mu)\Gamma(x+\mu)}{\Gamma(\beta-\mu)\Gamma(\alpha+\beta)\Gamma(\mu)}\,d\psi(x),\quad D=(0,\beta),\quad E=(0,\infty),$$

where the step function ψ has jumps of $(\alpha)_k/(k!(\alpha+\beta)_k)$ at $k=0,1,\cdots$.

The interpolation property follows easily from Lemma 18, whereas the moments are obtained by using the Vandermonde theorem:

$$\begin{aligned}\rho_k&:=(-1)^k(-x)_k,\qquad k=0,1,\cdots,\\I_k(\mu,\boldsymbol{\rho})&=(-1)^k\frac{\Gamma(\beta)\Gamma(\alpha+\beta-\mu)}{\Gamma(\beta-\mu)\Gamma(\alpha+\beta)}\sum_{l=0}^{\infty}\frac{(-l)_k}{l!}\frac{(\alpha)_l(\mu)_l}{(\alpha+\beta)_l}\\&=\frac{\Gamma(\beta)\Gamma(\alpha+\beta-\mu)}{\Gamma(\beta-\mu)\Gamma(\alpha+\beta)}\frac{(\alpha)_k(\mu)_k}{(\alpha+\beta)_k}\,{}_2F_1\left[\begin{matrix}\alpha+k,\mu+k;\\\alpha+\beta+k;\end{matrix}1\right]\\&=\frac{(\alpha)_k(\mu)_k}{(\alpha+\beta)_k}\frac{\Gamma(\beta)\Gamma(\alpha+\beta-\mu)}{\Gamma(\beta-\mu)\Gamma(\alpha+\beta)}\frac{\Gamma(\alpha+\beta+k)\Gamma(\beta-\mu-k)}{\Gamma(\beta)\Gamma(\alpha+\beta-\mu)}\\&=(-1)^k\frac{(\alpha)_k(\mu)_k}{(-\beta+\mu+1)_k},\qquad k=0,1,\cdots.\end{aligned}$$

Thus $g_k=(\alpha+k)(k+x)$, $h_k=\beta-k-1-x$, $g_l'h_k-g_lh_k'=(\alpha+l)(\beta-k-1+l)\neq 0$ (since β is not an integer), $l=0,\cdots,k$, $k=0,1,\cdots$. All the conditions of Theorem 6 hold, migration of zeros to the boundary of E is prevented, and we have the following theorem.

THEOREM 23. *Let α, $\beta > 0$, β a noninteger. The transformation*

$$T\left\{\sum_{k=0}^{m} d_k(\alpha)_k(x)_k(\beta-m-x)_{m-k}\right\} = \sum_{k=0}^{m}(-1)^k d_k(-x)_k \tag{5.6}$$

maps polynomials with zeros in $(0, \beta)$ into polynomials with positive zeros.

To reformulate (5.6) we require the following lemma, which bears much similarity to Lemma 8.

LEMMA 24. *Let γ be neither zero nor a negative integer. Then*

$$\sum_{k=0}^{m} e_k(x)_k(\gamma-x)_{m-k} = \sum_{k=0}^{m} r_k(x)_k \tag{5.7}$$

implies that

$$e_k = \sum_{l=0}^{k}\binom{m-l}{k-l}\frac{r_l}{(\gamma+l)_{m-l}}, \qquad k=0,1,\cdots,m. \tag{5.8}$$

Proof. Let

$$q_1(x) := \sum_{k=0}^{m} e_k(x)_k(\gamma-x)_{m-k}, \qquad q_2(x) := \sum_{k=0}^{m} r_k(x)_k. \qquad \square$$

To prove (5.7), it is enough to demonstrate that $q_1(-n) = q_2(-n)$, $n = 0, 1, \cdots, m$, where the coefficients of q_1 and q_2 are linked via (5.8). But

$$\begin{aligned}
\frac{1}{n!}q_1(-n) &= \sum_{k=0}^{n}(-1)^k\frac{e_k}{(n-k)!}(\gamma+n)_{m-k} \\
&= \sum_{k=0}^{n}\frac{(-1)^k}{(n-k)!}(\gamma+n)_{m-k}\sum_{l=0}^{k}\binom{m-l}{k-l}\frac{r_l}{(\gamma+l)_{m-l}} \\
&= \sum_{l=0}^{n}(-1)^l\frac{(m-l)!}{(\gamma+l)_{m-l}}r_l\sum_{k=0}^{n-l}(-1)^k\frac{(\gamma+n)_{m-l-k}}{k!(n-l-k)!(m-l-k)!} \\
&= \sum_{l=0}^{n}(-1)^l\frac{(\gamma+n)_{m-l}}{(\gamma+l)_{m-l}(n-l)!}r_l\sum_{k=0}^{n-l}(-1)^k\binom{n-l}{k}\frac{(-m+l)_k}{(-\gamma-n-m+l+1)_k} \\
&= \sum_{l=0}^{n}(-1)^l\frac{(\gamma+n)_{m-l}}{(\gamma+l)_{m-l}(n-l)!}r_l\,{}_2F_1\left[\begin{matrix}-n+l,-m+l;\\ -\gamma-n-m+1;\end{matrix}1\right] \\
&= \sum_{l=0}^{n}(-1)^l\frac{r_l}{(n-l)!}\frac{(\gamma+n)_{m-l}(-\gamma-n+1)_{n-l}}{(\gamma+l)_{m-l}(-\gamma-n-m+l+1)_{n-l}}.
\end{aligned}$$

Thus, as

$$(\gamma+n)_{m-l}(-\gamma-n+1)_{n-l} = (\gamma+l)_{m-l}(-\gamma-n-m+l+1)_{n-l}, \qquad l=0,\cdots,n,$$

we have

$$q_1(-n) = n!\sum_{l=0}^{n}(-1)^l\frac{r_l}{(n-l)!} = q_2(-n), \qquad n=0,1,\cdots,m,$$

and the proof follows. $\square$

THEOREM 23A. *Let α, $\beta > 0$, β a noninteger. The transformation*

$$T\left\{\sum_{k=0}^{m} r_k(x)_k\right\} = \sum_{k=0}^{m}(-1)^k(\beta-m)_k r_k(-x)_k(\alpha+x)_{m-k}$$

maps polynomials with zeros in $(0, \beta)$ into polynomials with positive zeros.

Proof. We set $e_k := (\alpha)_k d_k$, $k = 0, \cdots, m$, $\gamma = \beta - m$ in (5.7). Note that γ is a noninteger. Thus, by (5.7), if

$$\sum_{k=0}^{m} d_k(\alpha)_k(x)_k(\beta - m - x)_{m-k} = \sum_{k=0}^{m} r_k(x)_k, \tag{5.9}$$

then $d_0, \cdots, d_m$ and $r_0, \cdots, r_m$ are linked via (5.8). Moreover,

$$\begin{aligned}
\sum_{k=0}^{m} (-1)^k d_k(-x)_k &= \sum_{k=0}^{m} (-1)^k \frac{(-x)_k}{(\alpha)_k} \sum_{l=0}^{k} \binom{m-l}{k-l} \frac{r_l}{(\beta - m + l)_{m-l}} \\
&= \sum_{l=0}^{m} (-1)^l \frac{(-x)_l r_l}{(\beta - m + l)_{m-l}(\alpha)_l} {}_2F_1\left[\begin{matrix} -m+l, -x+l; \\ \alpha+l; \end{matrix} 1\right] \\
&= \sum_{l=0}^{m} (-1)^l \frac{(-x)_l r_l}{(\beta - m + l)_{m-l}(\alpha)_l} \frac{(\alpha + x)_{m-l}}{(\alpha + l)_{m-l}} \\
&= \frac{1}{(\alpha)_m(\beta - m)_m} \sum_{l=0}^{m} (-1)^l (\beta - m)_l r_l (-x)_l (\alpha + x)_{m-l}.
\end{aligned} \tag{5.10}$$

The proof follows when we compare (5.9) and (5.10) with (5.6). □

6. Transformations of q-gamma type. There are several q-analogues of the gamma function [Exton, 1983]. In this section we consider distributions that include the function

$$\Gamma_\rho(z) := \frac{1}{(z; \rho)_\infty}, \qquad \rho, z \in C. \tag{6.1}$$

q-Γ_1 transformation. Let $\rho, \alpha \in (0, 1)$,

$$d\varphi(x, \mu) = \frac{(\alpha; \rho)_\infty (\mu; \rho)_\infty}{(\alpha\mu; \rho)_\infty (\mu x; \rho)_\infty} d\psi(x), \qquad D = E = (0, 1),$$

where ψ jumps $\alpha^k/[\rho]_k$ at ρ^k, $k = 0, 1, \cdots$. Thus,

$$\begin{aligned}
I_k(\mu) &= \frac{(\alpha; \rho)_\infty (\mu; \rho)_\infty}{(\alpha\mu; \rho)_\infty} \sum_{l=0}^{\infty} \frac{\alpha^l \rho^{kl}}{[\rho]_l (\mu\rho^l; \rho)_\infty} \\
&= \frac{(\alpha; \rho)_\infty}{(\alpha\mu; \rho)_\infty} \sum_{l=0}^{\infty} \frac{(\mu; \rho)_l}{[\rho]_l} \alpha^l \rho^{kl} = \frac{(\alpha; \rho)_\infty}{(\alpha\mu; \rho)_\infty} {}_1\Phi_0\left[\begin{matrix} \mu; \\ -; \end{matrix} \rho, \alpha\rho^k\right].
\end{aligned}$$

We sum the ${}_1\Phi_0$ series by the Heine theorem [Slater, 1966]:

$$I_k(\mu) = \frac{(\alpha; \rho)_\infty}{(\alpha\mu; \rho)_\infty} \frac{(\alpha\mu\rho^k; \rho)_\infty}{(\alpha\rho^k; \rho)_\infty} = \frac{(\alpha; \rho)_k}{(\alpha\mu; \rho)_k}, \qquad k = 0, 1, \cdots.$$

Thus, $g_k(x) \equiv 1 - \alpha\rho^k$, $h_k(x) = 1 - \alpha\rho^k x$, $g_l' h_k - g_l h_k' = \alpha\rho^k(1 - \alpha\rho^l) \neq 0$, $l = 0, \cdots, k$, $k = 0, 1, \cdots$.

LEMMA 25. *For every $\rho \in (0, 1)$ the function $\Gamma_\rho(x\mu)$ is strictly totally positive for all $0 < x, \mu < \infty$.*

Proof. Since $|\rho| < 1$, the Euler theorem [Slater, 1966] and (6.1) imply that

$$\Gamma_\rho(x\mu) = {}_0\Phi_0\left[\begin{matrix} -; \\ -; \end{matrix} \rho, x\mu\right] = \sum_{k=0}^{\infty} \frac{(\mu x)^k}{[\rho]_k}. \tag{6.2}$$

Let

$$f(x, t) = x^{\log t/\log \rho}, \quad g(t, y) = y^{\log t/\log \rho}, \quad 0 < x, y < \infty, \quad 0 < t < 1.$$

Clearly, both f and g are strictly totally positive. Moreover, let ϕ be a step function with jumps of $1/[\rho]_k$ at ρ^k, $k=0, 1, \cdots$. Thus, by (6.2),

$$\Gamma_\rho(x\mu)=\int_0^1 f(x, t)g(t, \mu)\, d\phi(t)$$

and strict total positivity follows from (5.1). □

THEOREM 26. *Let α, $\rho \in (0, 1)$. The transformation*

$$T\left\{\sum_{k=0}^{m} w_k(\alpha x\rho^k; \rho)_{m-k}\right\}=\sum_{k=0}^{m}\frac{w_k}{(\alpha; \rho)_k}x^k \tag{6.3}$$

maps polynomials with zeros in $(0, 1)$ into polynomials with zeros in $(0, 1)$.

Proof. Since all the conditions of Theorem 6 are satisfied, the transformation

$$T\left\{\sum_{k=0}^{m} d_k(\alpha; \rho)_k(\alpha\rho^k x; \rho)_{m-k}\right\}=\sum_{k=0}^{m} d_k x^k$$

maps polynomials with zeros in $(0, 1)$ into polynomials with zeros in $(0, 1)$—it is again trivial that zeros cannot migrate to the boundary.

Form (6.3) follows when we set $w_k=(\alpha; \rho)_k d_k$, $k=0, 1, \cdots, m$. □

An alternative form of (6.3) can be obtained by changing the basis of moments: Let $\rho_k(x)=\prod_{l=0}^{k-1}(x-\rho^l)=x^k(1/x; \rho)_k$, $k=0, 1, \cdots$. Then by the Heine theorem [Slater, 1966],

$$I_k(\mu; \boldsymbol{\rho})=\frac{(\mu; \rho)_\infty(\alpha; \rho)_\infty(-1)^k\alpha^k}{(\alpha\mu; \rho)_\infty(\mu\rho^k; \rho)_\infty}\,{}_1\Phi_0\left[\begin{matrix}\mu\rho^k;\\ -;\end{matrix}\rho, \alpha\right]$$

$$=(-1)^k\rho^{1/2(k-1)k}\alpha^k\frac{(\mu; \rho)_k}{(\alpha\mu; \rho)_k}, \qquad k=0, 1, \cdots.$$

Thus $g_k(x)=-\alpha\rho^k(1-\rho^k x)$, $h_k(x)=1-\alpha\rho^k x$, $h_l' g_k - h_l g_k' = -\alpha\rho^l(\alpha\rho^k-\rho^l)\neq 0$, $l=0, \cdots, k$, $k=0, 1, \cdots$, all the conditions of Theorem 6 are valid, and we have Theorem 26A.

THEOREM 26A. *Let α, $\rho \in (0, 1)$. The transformation*

$$T\left\{\sum_{k=0}^{m}(-1)^k\rho^{1/2(k-1)k}d_k(x; \rho)_k(\alpha\rho^k x; \rho)_{m-k}\right\}=\sum_{k=0}^{m} d_k\prod_{l=0}^{k-1}(x-\rho^l)$$

maps polynomials with zeros in $(0, 1)$ into polynomials with zeros in $(0, 1)$.

q-Γ_2 transformation. Let $\rho \in (0, 1)$, N be a natural number, $\alpha > \rho^{-N+1}$, and

$$d\varphi(x, \mu)=\frac{\alpha^{-N}(-\mu x; \rho)_\infty}{(-\mu\rho^N; \rho)_\infty(-(\mu/\alpha); \rho)_N}\, d\psi(x), \quad D=(0, \infty), \quad E=(0, 1),$$

where ψ jumps $(\rho^{-N}; \rho)_k(\alpha; \rho)_k\rho^k/[\rho]_k > 0$ at ρ^k, $k=0, 1, \cdots, N$.

LEMMA 27. *φ possesses the interpolation property.*

Proof. It is sufficient to prove that $(-\mu x; \rho)_\infty$ is strictly totally positive for all $x, \mu \in (0, 1)$. By (4.2),

$$(-\mu x; \rho)_\infty={}_0\Phi_0\left[\begin{matrix}-;\\ -;\end{matrix}\rho^{-1}, -\mu x\rho^{-1}\right]=\sum_{k=0}^{\infty}(-1)^k\frac{(\mu x\rho^{-1})^k}{[\rho^{-1}]_k}.$$

The proof now proceeds along the lines of the proof of Lemma 25, the distribution ϕ

being replaced by a step function with jumps of $(-1)^k/[\rho^{-1}]_k > 0$ ($[\rho^{-1}]_k = (\rho^{-1}, \rho^{-1})_k$), $k = 0, 1, \cdots$, at ρ^{-k} and the interval of integration being $(1, \infty)$. □

Let $\rho_k(x) = \prod_{l=0}^{k-1}(x-\rho^l)$, $k = 0, 1, \cdots$. Then for all $k = 0, \cdots, N$

$$I_k(\mu, \boldsymbol{\rho}) = \frac{(-1)^k \alpha^{-N} \rho^{1/2(k-1)k}}{(-\mu\rho^N; \rho)_\infty (-(\mu/\alpha); \rho)_N} \sum_{l=k}^{\infty} \frac{(-\mu\rho^l; \rho)_\infty (\rho^{-N}; \rho)_l (\alpha; \rho)_l}{[\rho]_{l-k}} \rho^l$$

$$= (-1)^k \rho^{1/2(k+1)k} \frac{\alpha^{-N}(-\mu\rho^k; \rho)_\infty (\rho^{-N}; \rho)_k (\alpha; \rho)_k}{(-\mu\rho^N; \rho)_\infty (-(\mu/\alpha); \rho)_N} {}_2\Phi_1\left[\begin{matrix}\rho^{-N+k}, \alpha\rho^k; \\ -\mu\rho^k;\end{matrix} \rho, \rho\right].$$

We sum the ${}_2\Phi_1$ series up with the Vandermonde q-analogue [Slater, 1966]:

$$I_k(\mu, \boldsymbol{\rho}) = (-1)^k \rho^{1/2(k+1)k} \frac{\alpha^{-N}(-\mu\rho^k; \rho)_\infty (\rho^{-N}; \rho)_k (\alpha; \rho)_k}{(-\mu\rho^N; \rho)_\infty (-(\mu/\alpha); \rho)_N} \frac{(-(\mu/\alpha); \rho)_{N-k} \alpha^{N-k} \rho^{k(N-k)}}{(-\mu\rho^k; \rho)_{N-k}}$$

$$= (-1)^k \alpha^{-k} \rho^{-1/2(k-1)k + Nk} \frac{(\rho^{-N}; \rho)_k (\alpha; \rho)_k}{(-(\mu/\alpha)\rho^{N-k}; \rho)_k}$$

$$= (-1)^k \frac{\rho^k}{\mu^k} \frac{(\rho^{-N}; \rho)_k (\alpha; \rho)_k}{(-(\alpha/\mu)\rho^{-N+1}; \rho)_k}, \qquad k = 0, 1, \cdots, N.$$

Hence $g_k(x) \equiv -\rho(1-\rho^{-N+k})(1-\alpha\rho^k)$, $h_k(x) = \alpha\rho^{-N+k+1} + x$, $g_l' h_k - g_l h_k' \neq 0$, $l = 0, \cdots, k$, $k = 0, 1, \cdots, N-1$. All the conditions of Theorem 6 are satisfied, leading to Theorem 28.

THEOREM 28. *Let $\rho \in (0, 1)$, $\alpha > \rho^{-N+1}$, $m = 1, 2, \cdots, N$. The transformation*

$$T\left\{\sum_{k=0}^{m} (-1)^k d_k \rho^{kN - 1/2(k-1)k} \alpha^{m-k} (\alpha; \rho)_k (\rho^{-N}; \rho)_k \left(-\frac{x}{\alpha}\rho^{N-m}; \rho\right)_{m-k}\right\}$$

$$= \sum_{k=0}^{m} d_k \prod_{l=0}^{k-1} (x-\rho^l)$$

maps polynomials with positive zeros into polynomials with zeros in $(0, 1)$.

Note that, in the last theorem, we were unable to exclude migration of zeros to the endpoints of E.

q-Γ_3 transformation. Let N be a natural number, $\rho \in (0, 1)$, and $\alpha > \rho^{-N+1}$. We set

$$d\varphi(x, \mu) = \frac{(\alpha; \rho)_N (\mu; \rho)_\infty \mu^{-N}}{((\alpha/\mu); \rho)_N (\mu x; \rho)_\infty} d\psi(x), \qquad D = E = (0, 1),$$

where ψ has jumps of $(\rho^{-N}; \rho)_k \rho^k / ([\rho]_k (\alpha; \rho)_k) > 0$ at ρ^k, $k = 0, 1, \cdots, N$. Again $\rho_k(x) := \prod_{l=0}^{k-1}(x-\rho^l)$, $k = 0, 1, \cdots$. Hence,

$$I_k(\mu, \boldsymbol{\rho}) = \frac{(\alpha; \rho)_N (\mu; \rho)_\infty \mu^{-N}}{((\alpha/\mu); \rho)_N} (-1)^k \rho^{1/2(k-1)k} \sum_{l=k}^{N} \frac{(\rho^{-N}; \rho)_l \rho^l}{[\rho]_{l-k} (\mu\rho^l; \rho)_\infty (\alpha; \rho)_l}$$

$$= \frac{(-1)^k \mu^{-N} \rho^{(1/2)k(k+1)} (\alpha; \rho)_N (\rho^{-N}; \rho)_k (\mu; \rho)_k}{((\alpha/\mu); \rho)_N (\alpha; \rho)_k} {}_2\Phi_1\left[\begin{matrix}\rho^{-N+k}, \mu\rho^k; \\ \alpha\rho^k;\end{matrix} \rho, \rho\right]$$

$$= \frac{(-1)^k \mu^{-N} \rho^{(1/2)k(k+1)} (\alpha; \rho)_N (\rho^{-N}; \rho)_k (\mu; \rho)_k}{((\alpha/\mu); \rho)_N (\alpha; \rho)_k} \times \frac{((\alpha/\mu); \rho)_{N-k} \mu^{N-k} \rho^{k(N-k)}}{(\alpha\rho^k; \rho)_{N-k}}$$

$$= \frac{(\rho^{-N}; \rho)_k (\mu; \rho)_k}{((\mu/\alpha)\rho^{-N+1}; \rho)_k} \left(\frac{\rho}{\alpha}\right)^k, \qquad k = 0, 1, \cdots, N.$$

Consequently, $g_k(x)=\rho(1-\rho^{-N+k})(1-x\rho^k)$, $h_k(x)\equiv\alpha(1-(x/\alpha)\rho^{-N+k+1})$, $g_l'h_k-g_lh_k'\neq 0$, $l=0,\cdots,k$, $k=0,\cdots,N-1$, and, since it follows from Lemma 25 that φ possesses the interpolation property, all the conditions of Theorem 6 hold. This furnishes our last transformation.

THEOREM 29. *Let* $\rho\in(0,1)$, $\alpha>\rho^{-N+1}$, $m=1,2,\cdots,N$. *The transformation*

$$T\left\{\sum_{k=0}^{m} d_k\rho^k(\rho^{-N};\rho)_k(x;\rho)_k\alpha^{m-k}\left(\frac{x}{\alpha}\rho^{-N+k+1};\rho\right)_{m-k}\right\}=\sum_{k=0}^{m} d_k\prod_{l=0}^{k-1}(x-\rho^l)$$

maps polynomials with zeros in $(0,1)$ *into polynomials with zeros in* $(0,1)$.

Note that, again, the last theorem does not prevent zeros being mapped to the endpoints of E.

Acknowledgments. The authors greatly benefited from discussing transformations and bi-orthogonality with numerous colleagues. Special mention and thanks go to Phil Davis (Brown University), Bill Gragg (Naval Postgraduate School), Mourad Ismail (University of South Florida), Ted Rivlin (IBM), Ed Saff (University of South Florida), and Gil Strang (MIT).

A SUMMATION THEOREM FOR HYPERGEOMETRIC SERIES VERY-WELL-POISED ON G_2*

ROBERT A. GUSTAFSON†

Abstract. An analogue of Bailey's ${}_6\psi_6$ summation theorem is proved for basic hypergeometric series that are very well poised on the Lie algebra G_2. As a limiting case, a new proof of the Macdonald identity associated to the affine root system of type G_2 is obtained. A summation theorem for ordinary hypergeometric series that are very well poised on G_2 is proved by Carlson's theorem.

Key words. hypergeometric series, basic hypergeometric series, summation theorem, Lie algebra G_2

AMS(MOS) subject classifications. 33A75, 33A30, 33A35

1. Introduction and statement of results. This paper is a sequel to the paper [10] entitled "The Macdonald identities for affine root systems of classical type and hypergeometric series very-well-poised on semisimple Lie algebras." We will prove an analogue of Bailey's ${}_6\psi_6$ summation theorem [5] for very-well-poised series on the complex Lie algebra G_2 [10] associated to the full co-root lattice of G_2 and to the seven-dimensional irreducible representation of G_2 of highest weight λ_1, where λ_1 is the first fundamental weight [7, App.]. A limiting case of this summation theorem is the Macdonald identity [15] associated to the affine root system of type G_2. The method is similar to that used by Andrews [1] to deduce the Jacobi triple product identity as a limit of the ${}_6\psi_6$ summation theorem and by Milne [17] in his proof of the Macdonald identities for the affine root systems of type A_l.

Before stating the main theorem, we need to define some notation. For convenience, let q be a real number, $0<q<1$. If $c\in\mathbb{C}$ and n is a positive integer, then the q-rising factorial is defined by

$$[c]_n=(1-c)(1-cq)\cdots(1-cq^{n-1}),\qquad [c]_\infty=\prod_{k=0}^{\infty}(1-cq^k).$$

For $n\in\mathbb{Z}$, define

$$[c]_n=[c]_\infty/[cq^n]_\infty.$$

We have

$$[c]_{-n}=\frac{(-1)^n q^{(n+1)n/2}}{[qc^{-1}]_n c^n}$$

for all $n\in\mathbb{Z}$.

Similarly, the ordinary rising factorial is defined by

$$(c)_n=\Gamma(c+n)/\Gamma(c)$$

for $n\in\mathbb{Z}$ and $c\in\mathbb{C}$.

In § 2 we will prove the following fundamental theorem.

THEOREM 1.1. Let $z=(z_1,z_2,z_3)\in\mathbb{C}^3$ *and* $a_i,b_i\in\mathbb{C}$ *for* $i=1,2$. Let $\varphi_i=\varepsilon_i-\frac{1}{3}(\varepsilon_1+\varepsilon_2+\varepsilon_3)$ *for* $i=1,2,3$, *where* $\varepsilon_i\in\mathbb{C}^3$ *is the standard triple with* 1 *in the ith entry*

† Department of Mathematics, Texas A&M University, College Station, Texas 77843 and Indian Statistical Institute, 203 Barrackpore Trunk Road, Calcutta 700 035, India.

and zero in the other entries. Let L be the lattice in $\mathbb{C}^3$ generated by φ_1, φ_2, φ_3, i.e., $L=\sum_{i=1}^{3}\mathbb{Z}\varphi_i$. Note that $\varphi_1+\varphi_2+\varphi_3=0$. Finally, let

$$c_i=\begin{cases} a_i & \text{for } i=1,2,\\ qb_{i-2}^{-1} & \text{for } i=3,4.\end{cases} \tag{1.2}$$

Then we have

$$\begin{aligned} t=\sum_{(t_1,t_2,t_3)\in L}\Bigg\{ & q^{t_1+2t_2-3t_3}\left(\frac{1-q^{-2z_1-2t_1+z_2+t_2+z_3+t_3}}{1-q^{-2z_1+z_2+z_3}}\right)\\ & \cdot\left(\frac{1-q^{z_1+t_1-2z_2-2t_2+z_3+t_3}}{1-q^{z_1-2z_2+z_3}}\right)\left(\frac{1-q^{-z_1-t_1-z_2-t_2+2z_3+2t_3}}{1-q^{-z_1-z_2+2z_3}}\right)\\ & \cdot\left(\frac{1-q^{z_1+t_1-z_2-t_2}}{1-q^{z_1-z_2}}\right)\left(\frac{1-q^{-z_1-t_1+z_3+t_3}}{1-q^{-z_1+z_3}}\right)\left(\frac{1-q^{-z_2-t_2+z_3+t_3}}{1-q^{-z_2+z_3}}\right)\\ & \cdot\prod_{i=1}^{2}\prod_{\substack{1\le j,k\le 3\\ j\ne k}}\frac{[a_iq^{z_j-z_k}]_{t_j-t_k}}{[b_iq^{z_j-z_k}]_{t_j-t_k}}\Bigg\} \end{aligned} \tag{1.3}$$

$$\begin{aligned} =\frac{[q]_\infty^2\left[q\prod_{i=1}^{4}c_i^{-1}\right]_\infty\prod_{1\le i\le j\le 4}[q(c_ic_j)^{-1}]_\infty\prod_{1\le i<j<k\le 4}[q(c_ic_jc_k)^{-1}]_\infty}{\left[q\prod_{i=1}^{4}c_i^{-2}\right]_\infty\prod_{i=1}^{4}[qc_i^{-1}]_\infty\prod_{i=1}^{4}\prod_{\substack{1\le j,k\le 3\\ j\ne k}}[c_1^{-1}q^{1+z_j-z_k}]_\infty}\\ \cdot\prod_{i=1}^{3}\{[q^{1+3z_i-z_1-z_2-z_3}]_\infty[q^{1-3z_i+z_1+z_2+z_3}]_\infty\}\\ \cdot\prod_{\substack{1\le j,k\le 3\\ j\ne k}}[q^{1+z_j-z_k}]_\infty, \end{aligned}$$

where $|q^{-3}\prod_{i=1}^{2}(b_i/a_i)^2|<1$ for convergence and none of the denominators on both sides of (1.3) *vanish.*

Remark 1.4. We may assume that $z_1+z_2+z_3=0$ in Theorem 1.1 as this case implies the general result. With this restriction and in the notation of [10], the series on the left-hand side of (1.3) is denoted by

$${}_2\psi_2\left(G_2;\lambda_1;L;\begin{matrix}a_1, & a_2\\ b_1, & b_2\end{matrix};z;q;(1,\cdots,1)\right),$$

where L is the full co-root lattice for G_2.

COROLLARY 1.5 (Macdonald [15]). *With notation as in Theorem* 1.1, *we have*

$$\begin{aligned} \sum_{t\in L}\Bigg\{ & q^{t_1+2t_2-3t_3}\frac{(1-q^{-2z_1-2t_1+z_2+t_2+z_3+t_3})}{(1-q^{-2z_1+z_2+z_3})}\\ & \cdot\frac{(1-q^{z_1+t_1-2z_2-2t_2+z_3+t_3})(1-q^{-z_1-t_1-z_2-t_2+2z_3+2t_3})}{(1-q^{z_1-2z_2+z_3})(1-q^{-z_1-z_2+2z_3})}\\ & \cdot\frac{(1-q^{z_1+t_1-z_2-t_2})(1-q^{-z_1-t_1+z_3+t_3})(1-q^{-z_2-t_2+z_3+t_3})}{(1-q^{z_1-z_2})(1-q^{-z_1+z_3})(1-q^{-z_2+z_3})}\\ & \cdot q^{\sum_{1\le j<k\le 3}\{4(z_j-z_k)(t_j-t_k)+2(t_j-t_k)^2\}}\Bigg\} \end{aligned} \tag{1.6}$$

$$=[q]_\infty^2\prod_{i=1}^{3}[q^{1+3z_i-z_1-z_2-z_3}]_\infty[q^{1-3z_i+z_1+z_2+z_3}]_\infty\prod_{\substack{1\le j,k\le 3\\ j\ne k}}[q^{1+z_j-z_k}]_\infty.$$

Proof. Let $a_i \to \infty$ and $b_i \to 0$ for $i = 1, 2$ in (1.3). Then the argument in Theorem 7.1 of [10] shows that (1.6) is equivalent to the Macdonald identity (Theorem 8.7 of [15]) for G_2.

In § 3 we will prove the limiting case ($q \to 1$) of Theorem 1.1.

THEOREM 1.7. *Let $z = (z_1, z_2, z_3) \in \mathbb{C}^3$ and $\alpha_i, \beta_i \in \mathbb{C}$ for $i = 1, 2$. Let L be defined as in Theorem* 1.1. *Let*

$$\gamma_i = \begin{cases} \alpha_i & \text{for } i = 1, 2, \\ 1 - \beta_{i-2} & \text{for } i = 3, 4. \end{cases} \tag{1.8}$$

Then we have

$$\begin{aligned} &\sum_{t=(t_1,t_2,t_3)\in L} \left\{ \left(\frac{-2z_1 - 2t_1 + z_2 + t_2 + z_3 + t_3}{-2z_1 + z_2 + z_3} \right) \right. \\ &\quad \cdot \left(\frac{z_1 + t_1 - 2z_2 - 2t_2 + z_3 + t_3}{z_1 - 2z_2 + z_3} \right) \left(\frac{-z_1 - t_1 - z_2 - t_2 + 2z_3 + 2t_3}{-z_1 - z_2 + 2z_3} \right) \\ &\quad \cdot \left(\frac{z_1 + t_1 - z_2 - t_2}{z_1 - z_2} \right) \left(\frac{-z_1 - t_1 + z_3 + t_3}{-z_1 + z_3} \right) \left(\frac{-z_2 - t_2 + z_3 + t_3}{-z_2 + z_3} \right) \\ &\quad \left. \cdot \prod_{i=1}^{2} \prod_{\substack{1 \le j,k \le 3 \\ j \ne k}} \frac{(\alpha_i + z_j - z_k)_{t_j - t_k}}{(\beta_i + z_j - z_k)_{t_j - t_k}} \right\} \\ &= \frac{\Gamma\left(1 - 2\sum_{i=1}^{4} \gamma_i\right) \prod_{i=1}^{4} \Gamma(1 - \gamma_i) \prod_{i=1}^{4} \prod_{\substack{1 \le j,k \le 3 \\ j \ne k}} \Gamma(1 - \gamma_i + z_j - z_k)}{\Gamma\left(1 - \sum_{i=1}^{4} \gamma_i\right) \prod_{1 \le i \le j \le 4} \Gamma(1 - \gamma_i - \gamma_j) \prod_{1 \le i < j < k \le 4} \Gamma(1 - \gamma_i - \gamma_j - \gamma_k)} \\ &\quad \cdot \left\{ \prod_{i=1}^{3} \Gamma(1 + 3z_i - z_1 - z_2 - z_3) \right. \\ &\quad \left. \cdot \Gamma(1 - 3z_i + z_1 + z_2 + z_3) \prod_{\substack{1 \le j,k \le 3 \\ j \ne k}} \Gamma(1 + z_j - z_k) \right\}^{-1}, \end{aligned} \tag{1.9}$$

where $\operatorname{Re}(2\sum_{i=1}^{2}(\beta_i - \alpha_i)) > 3$ *for convergence and the poles of both sides of* (1.9) *are avoided.*

We hope that Theorem 1.1 will have application in the theory of partitions of multidimensional analogues (see [1], [2]). It seems likely that families of orthogonal polynomials in two variables will be associated to these summation theorems (see [3], [4], [8], and [19]).

The results of this paper provide evidence that there may be summation theorems for very-well-poised hypergeometric series associated to the exceptional simple Lie algebras over $\mathbb{C}$ or, alternatively, to affine root systems of exceptional type. Limiting cases of these summation theorems should give the Macdonald identities for affine root systems of exceptional type.

There is a problem in extending the methods of this paper to the other exceptional Lie algebras (or affine root systems). In order to find the corresponding difference equations there need to be sufficiently large numbers of numerator and denominator parameters a_i and b_i. For these other exceptional Lie algebras (or affine root systems) there does not appear to be a sufficient number of parameters to produce the required difference equation.

2. Proof of Theorem 1.1. We begin the proof of identity (1.3) by first showing that the series on the left-hand side of (1.3) converges whenever $|q^{-3}\prod_{i=1}^{2}(b_i/a_i)^2|<1$ and none of the denominators vanish. With notation as in Theorem 1.1, let Φ be the root system of type G_2 (see [7, App.]) with a partial ordering and W the Weyl group of G_2, $W\approx\mathfrak{D}_6$, the dihedral group of order 12. Let $\rho=\frac{1}{2}\sum_{\alpha>0}\alpha$. Using the Weyl denominator formula for G_2 (see [12]), the left-hand side of (1.3) can be rewritten as

$$\sum_{t\in L}\left\{q^{-\rho(t)}\prod_{\alpha>0}\frac{(1-q^{\alpha(z+t)})}{(1-q^{\alpha(z)})}\prod_{i=1}^{2}\prod_{\substack{1\leqq j,k\leqq 3\\ j\neq k}}\frac{[a_iq^{z_j-z_k}]_{t_j-t_k}}{[b_iq^{z_j-z_k}]_{t_j-t_k}}\right\}$$

$$=\left(\prod_{\alpha>0}(1-q^{-\alpha(z)})\right)^{-1}\sum_{t\in L}\sum_{w\in W}\tag{2.1}$$

$$\cdot\left\{\varepsilon(w)q^{-w\rho(t+z)}\prod_{i=1}^{2}\prod_{\substack{1\leqq j,k\leqq 3\\ j\neq k}}\frac{[a_iq^{z_j-z_k}]_{t_j-t_k}}{[b_iq^{z_j-z_k}]_{t_j-t_k}}\right\}$$

where $\varepsilon(w)$ is the sign of the Weyl group element $w\in W$ and $t=(t_1,t_2,t_3)$ and $z=(z_1,z_2,z_3)$ in the notation of Theorem 1.1.

Let $t\in L$ and $t=n_1\varphi_1+n_2\varphi_2+n_3\varphi_3$ for some choice of n_1, n_2, $n_3\in\mathbb{Z}$. Suppose

$$n_{\sigma(1)}\geqq n_{\sigma(2)}\geqq n_{\sigma(3)},$$

where σ is a permutation of $\{1,2,3\}$. Let $l_1=n_{\sigma(1)}-n_{\sigma(2)}$ and $l_2=n_{\sigma(2)}-n_{\sigma(3)}$. Since $\varphi_1+\varphi_2+\varphi_3=0$, then we have

$$t=l_1\varphi_{\sigma(1)}+l_2(-\varphi_{\sigma(3)})\tag{2.2}$$

with l_1, $l_2\geqq 0$. It follows that

$$\prod_{i=1}^{2}\prod_{\substack{1\leqq j,k\leqq 3\\ j\neq k}}\frac{[a_iq^{z_j-z_k}]_{t_j-t_k}}{[b_iq^{z_j-z_k}]_{t_j-t_k}}$$

$$=\prod_{i=1}^{2}\left\{\frac{[a_iq^{z_{\sigma(1)}-z_{\sigma(2)}}]_{l_1}[a_iq^{z_{\sigma(2)}-z_{\sigma(1)}}]_{-l_1}}{[b_iq^{z_{\sigma(1)}-z_{\sigma(2)}}]_{l_1}[b_iq^{z_{\sigma(2)}-z_{\sigma(1)}}]_{-l_1}}\right.\tag{2.3}$$

$$\left.\cdot\frac{[a_iq^{z_{\sigma(2)}-z_{\sigma(3)}}]_{l_2}[a_iq^{z_{\sigma(3)}-z_{\sigma(2)}}]_{-l_2}[a_iq^{z_{\sigma(1)}-z_{\sigma(3)}}]_{l_1+l_2}[a_iq^{z_{\sigma(3)}-z_{\sigma(1)}}]_{-l_1-l_2}}{[b_iq^{z_{\sigma(2)}-z_{\sigma(3)}}]_{l_2}[b_iq^{z_{\sigma(3)}-z_{\sigma(2)}}]_{-l_2}[b_iq^{z_{\sigma(1)}-z_{\sigma(3)}}]_{l_1+l_2}[b_iq^{z_{\sigma(3)}-z_{\sigma(1)}}]_{-l_1-l_2}}\right\}.$$

From (2.1)-(2.3) we see that the left-hand side of (1.3) converges absolutely if we can show for all $\sigma\in S_3$ and $w\in W$ the absolute convergence of the following series:

$$\sum_{\substack{t=l_1\varphi_{\sigma(1)}-l_2\varphi_{\sigma(3)}\\ l_1,l_2\geqq 0}}q^{-w\rho(t+z)}\prod_{i=1}^{2}\left\{\frac{[a_iq^{z_{\sigma(1)}-z_{\sigma(2)}}]_{l_1}[a_iq^{z_{\sigma(2)}-z_{\sigma(1)}}]_{-l_1}}{[b_iq^{z_{\sigma(1)}-z_{\sigma(2)}}]_{l_1}[b_iq^{z_{\sigma(2)}-z_{\sigma(1)}}]_{-l_1}}\frac{[a_iq^{z_{\sigma(2)}-z_{\sigma(3)}}]_{l_2}}{[b_iq^{z_{\sigma(2)}-z_{\sigma(3)}}]_{l_2}}\right.\tag{2.4}$$

$$\left.\cdot\frac{[a_iq^{z_{\sigma(3)}-z_{\sigma(2)}}]_{-l_2}}{[b_iq^{z_{\sigma(3)}-z_{\sigma(2)}}]_{-l_2}}\frac{[a_iq^{z_{\sigma(1)}-z_{\sigma(3)}}]_{l_1+l_2}}{[b_iq^{z_{\sigma(1)}-z_{\sigma(3)}}]_{l_1+l_2}}\frac{[a_iq^{z_{\sigma(3)}-z_{\sigma(1)}}]_{-l_1-l_2}}{[b_iq^{z_{\sigma(3)}-z_{\sigma(1)}}]_{-l_1-l_2}}\right\}.$$

We will use the ratio test to show the convergence of (2.4).

Let d_u be the $t=u$ term in the series (2.4). Consider

$$\frac{d_{(t+\varphi_{\sigma(1)})}}{d_t}=q^{-w\rho(\varphi_{\sigma(1)})}\prod_{i=1}^{2}\left\{\left(\frac{1-a_iq^{z_{\sigma(1)}-z_{\sigma(2)}+l_1}}{1-b_iq^{z_{\sigma(1)}-z_{\sigma(2)}+l_1}}\right)\left(\frac{1-b_iq^{z_{\sigma(2)}-z_{\sigma(1)}-l_1-1}}{1-a_iq^{z_{\sigma(2)}-z_{\sigma(1)}-l_1-1}}\right)\right.$$

$$\left.\cdot\left(\frac{1-a_iq^{z_{\sigma(1)}-z_{\sigma(3)}+l_1+l_2}}{1-b_iq^{z_{\sigma(1)}-z_{\sigma(3)}+l_1+l_2}}\right)\left(\frac{1-b_iq^{z_{\sigma(3)}-z_{\sigma(1)}-l_1-l_2-1}}{1-a_iq^{z_{\sigma(3)}-z_{\sigma(1)}-l_1-l_2-1}}\right)\right\}\tag{2.5}$$

$$= q^{-w\rho(\varphi_{\sigma(1)})}\left(\frac{b_1b_2}{a_1a_2}\right)^2 M(l_1, l_2),$$

where

$$M(l_1, l_2) = \prod_{i=1}^{2}\left\{\left(\frac{1-a_iq^{z_{\sigma(1)}-z_{\sigma(2)}+l_1}}{1-b_iq^{z_{\sigma(1)}-z_{\sigma(2)}+l_1}}\right)\left(\frac{1-b_i^{-1}q^{z_{\sigma(1)}-z_{\sigma(2)}+l_1+1}}{1-a_i^{-1}q^{z_{\sigma(1)}-z_{\sigma(2)}+l_1+1}}\right)\right.$$
$$\left.\cdot\left(\frac{1-a_iq^{z_{\sigma(1)}-z_{\sigma(3)}+l_1+l_2}}{1-b_iq^{z_{\sigma(1)}-z_{\sigma(3)}+l_1+l_2}}\right)\left(\frac{1-b_i^{-1}q^{z_{\sigma(1)}-z_{\sigma(3)}+l_1+l_2+1}}{1-a_i^{-1}q^{z_{\sigma(1)}-z_{\sigma(3)}+l_1+l_2+1}}\right)\right\}.$$

There is a similar formula for $d_{t-\varphi_{\sigma(3)}}/d_t$.

By choosing l_1 and l_2 sufficiently large, we can make $|M(l_1, l_2)|$ as close to 1 as desired, with a corresponding statement for $d_{t-\varphi_{\sigma(3)}}/d_t$. Hence by the ratio test for multiple series, the series (2.4) will converge if

$$|q^{-w\rho(\varphi_{\sigma(1)})}(b_1b_2)^2/(a_1a_2)^2| < 1, \qquad |q^{w\rho(\varphi_{\sigma(3)})}(b_1b_2)^2/(a_1a_2)^2| < 1.$$

Now $\rho = -\varepsilon_1 - 2\varepsilon_2 + 3\varepsilon_3$, where ε_i is the standard basis vector in $\mathbb{C}^3$ and $w\rho = \pm(-\varepsilon_{\tau(1)} - 2\varepsilon_{\tau(2)} + 3\varepsilon_{\tau(3)})$ for some permutation $\tau \in S_3$. It follows that for all $w \in W$ and $\sigma \in S_3$ we have

$$|q^{-w\rho(\varphi_{\sigma(1)})}| \leqq q^{-3}, \qquad |q^{w\rho(\varphi_{\sigma(3)})}| \leqq q^{-3}.$$

Hence the original series on the left-hand side of identity (1.3) will converge whenever

$$|q^{-3}(b_1b_2)^2/(a_1a_2)^2| < 1$$

and denominators do not vanish.

To prove Theorem 1.1 we will show that both sides of (1.3) satisfy a q-difference equation in the parameters c_i, $1 \leqq i \leqq 4$. If for some $i \neq j$, c_ic_j equals 1, we will show that (1.3) reduces to an identity equivalent to a special case of the summation theorem for multilateral hypergeometric series that are very well poised on the Lie algebra of type A_1 [9], [10]. By means of this special evaluation of (1.3) and the q-difference equation, the general result follows by induction and analytic continuation of the parameters c_i.

DEFINITION 2.6. If $f(c_j)$ is a function of the variable c_j, then

$$(R_jf)(c_j) = f(c_jq).$$

LEMMA 2.7. *Let $f(c_1, \cdots, c_4, z) = f$ be the left-hand side of the right-hand side of* (1.3). *Then f satisfies the q-difference equation* (*where we assume that* $\prod_{1\leqq i<j\leqq 4}(c_i - c_j) \times (c_ic_j - 1) \neq 0$):

$$\sum_{i=1}^{4}\prod_{\substack{l=1\\ l\neq i}}^{4}\frac{c_i}{(c_l - c_i)(c_lc_i - 1)}\prod_{\substack{1\leqq j,k\leqq 3\\ j\neq k}}(1 - c_lq^{z_j - z_k})(R_lf) = f. \tag{2.8}$$

Proof. That the left-hand side of (1.3) satisfies the q-difference equation (2.8) is essentially the same proof as in Lemmas 5.3. and 6.3 of [10]. We give the proof below.

For any i, $1 \leqq i \leqq 4$, we define

$$d_i(m) = c_i^m + c_i^{6-m} \quad \text{for } 0 \leqq m < 3, \tag{2.9a}$$

$$d_i(3) = c_i^3. \tag{2.9b}$$

Consider the determinant

$$\sum_{\sigma\in S_4}\varepsilon(\sigma)\prod_{i=0}^{3}d_{\sigma(i+1)}(i) = \left(\prod_{i=1}^{4}c_i^3\right)\sum_{(\sigma,t)\in S_4\times T}\left\{\varepsilon(\sigma)\prod_{i=1}^{4}c_{\sigma(i)}^{(l+1-i)t_i}\right\}, \tag{2.10}$$

where $T=\{(t_1,\cdots,t_4)|t_i\in\{1,-1\}$ for $1\leqq i\leqq 4$ and $\sum_{i=1}^4 t_i\equiv 0 \pmod 4\}$. From the Weyl denominator formula for the root system of type D_4 [12], we find that the right hand side of (2.10) equals

$$\begin{aligned}(2.11)\qquad &\prod_{i=1}^4 c_i^3 \prod_{1\leqq i<j\leqq 4}[((c_i/c_j)^{1/2}-(c_j/c_i)^{1/2})((c_ic_j)^{1/2}-(c_ic_j)^{-1/2})]\\ &=\prod_{1\leqq i<j\leqq 4}(c_i-c_j)(c_ic_j-1).\end{aligned}$$

More generally, we have that the determinant

$$(2.12)\qquad \sum_{\sigma\in S_4}\left\{\varepsilon(\sigma)d_{\sigma(1)}(m)\prod_{i=1}^3 d_{\sigma(i+1)}(i)\right\}$$

vanishes unless $m=0$, in which case it equals $\prod_{1\leqq i<j\leqq 4}(c_i-c_j)(c_ic_j-1)$. By expanding the determinant (2.12) along the first column and using the Weyl denominator formula for the root system of type D_3, we find (2.12) equals

$$(2.13)\qquad \sum_{l=1}^4(-1)^{l-1}d_l(m)\prod_{\substack{i=1\\ i\neq l}}^4(c_i)\prod_{\substack{1\leqq i<j\leqq 4\\ i,j\neq l}}(c_i-c_j)(c_ic_j-1).$$

Dividing (2.13) by $\prod_{1\leqq i<j\leqq 4}(c_i-c_j)(c_ic_j-1)$, we obtain the identity

$$(2.14)\qquad \sum_{l=1}^4 d_l(m)\prod_{\substack{i=1\\ i\neq l}}^4\frac{c_i}{(c_l-c_i)(c_lc_i-1)}=\begin{cases}0 & \text{if } 1\leqq m\leqq 3,\\ 1 & \text{if } m=0.\end{cases}$$

Now let ψ denote the left-hand side of (1.3). For any l, $1\leqq l\leqq 4$, consider

$$\begin{aligned}(2.15)\qquad R_l(\psi)=\sum_{t\in L}&\prod_{\substack{1\leqq j,k\leqq 3\\ j\neq k}}\left(\frac{1-c_lq^{z_j+t_j-z_k-t_k}}{1-c_lq^{z_j-z_k}}\right)\\ &\cdot q^{-\rho(t)}\prod_{\alpha>0}\left(\frac{1-q^{\alpha(z+t)}}{1-q^{\alpha(z)}}\right)\prod_{i=1}^2\prod_{\substack{1\leqq j,k\leqq 3\\ j\neq k}}\frac{[a_iq^{z_j-z_k}]_{t_j-t_k}}{[b_iq^{z_j-z_k}]_{t_j-t_k}}\Bigg\},\end{aligned}$$

with notation as in (2.1):

$$\begin{aligned}R_l(\psi)=\sum_{t\in L}\Bigg\{&\sum_{m=0}^3(-1)^m[d_l(m)e_m(q^{z_j+t_j-z_k-t_k})]/\prod_{\substack{1\leqq j,k\leqq 3\\ j\neq k}}(1-c_lq^{z_j-z_k})\\ &\cdot q^{-\rho(t)}\prod_{\alpha>0}\left(\frac{1-q^{\alpha(z+t)}}{1-q^{\alpha(z)}}\right)\prod_{i=1}^2\prod_{\substack{1\leqq j,k\leqq 3\\ j\neq k}}\frac{[a_iq^{z_j-z_k}]_{t_j-t_k}}{[b_iq^{z_j-z_k}]_{t_j-t_k}}\Bigg\},\end{aligned}$$

where $e_m(q^{z_j+t_j-z_k-t_k})$ is the elementary symmetric function of degree m in the variables $q^{z_j+t_j-z_k-t_k}$, $1\leqq j\neq k\leqq 3$. Note that $e_m(q^{z_j+t_j-z_k-t_k})=e_{6-m}(q^{z_j+t_j-z_k-t_k})$ for $0\leqq m\leqq 3$ and $e_0(q^{z_j+t_j-z_k-t_k})\equiv 1$.

It follows that

$$\begin{aligned}&\sum_{l=1}^4\left\{\prod_{\substack{i=1\\ i\neq l}}^4\frac{c_i}{(c_l-c_i)(c_lc_i-1)}\prod_{\substack{1\leqq j,k\leqq 3\\ j\neq k}}(1-c_lq^{z_j-z_k})(R_l\psi)\right\}\\ &\quad=\sum_{t\in L}\sum_{m=0}^3\sum_{l=1}^4\left\{d_l(m)\prod_{\substack{i=1\\ i\neq l}}^4\frac{c_i}{(c_l-c_i)(c_lc_i-1)}(-1)^me_m(q^{z_j+t_j-z_k-t_k})\right.\end{aligned}$$

$$\cdot q^{-\rho(t)} \prod_{\alpha>0} \left(\frac{1-q^{\alpha(z+t)}}{1-q^{\alpha(z)}} \right) \prod_{i=1}^{2} \prod_{\substack{1\leqq j,k\leqq 3 \\ j\neq k}} \frac{[a_i q^{z_j-z_k}]_{t_j-t_k}}{[b_i q^{z_j-z_k}]_{t_j-t_k}} \Bigg\} \tag{2.16}$$

$$= \sum_{t\in L} q^{-\rho(t)} \prod_{\alpha>0} \left(\frac{1-q^{\alpha(z+t)}}{1-q^{\alpha(z)}} \right) \prod_{i=1}^{2} \prod_{\substack{1\leqq j,k\leqq 3 \\ j\neq k}} \frac{[a_i q^{z_j-z_k}]_{t_j-t_k}}{[b_i q^{z_j-z_k}]_{t_j-t_k}}$$

$$= \psi$$

by (2.14). Thus the left-hand side of (1.3) satisfies the q-difference equation (2.8).

Let Q denote the right-hand side of (1.3). For any l, $1\leqq l\leqq 4$, consider

$$R_l(Q) = Q\cdot(1-q^{-1}c_l^{-2}) \prod_{i=1}^{4} (1-c_l^{-1}c_i^{-1})$$

$$\cdot \frac{\displaystyle\prod_{j,k\neq l,1\leqq j<k\leqq 4} (1-c_l^{-1}c_j^{-1}c_k^{-1})(1-\prod_{i=1}^{4} c_i^{-1})}{(1-c_l^{-1})(1-q^{-1}\prod_{i=1}^{4} c_i^{-2})(1-\prod_{i=1}^{4} c_i^{-2}) \displaystyle\prod_{1\leqq j,k\leqq 3, j\neq k} (1-c_l^{-1}q^{z_j-z_k})}. \tag{2.17}$$

Thus, to show that Q satisfies the q-difference equation (2.8), we are reduced to verifying the identity

$$\sum_{l=1}^{4} \frac{c_l^3}{\displaystyle\prod_{i=1,i\neq l}^{4} (c_l-c_i)} (1-q^{-1}c_l^{-2})(1+c_l^{-1}) \prod_{\substack{1\leqq j<k\leqq 4 \\ j,k\neq l}} (1-c_l^{-1}c_j^{-1}c_k^{-1})$$

$$= \left(1-q^{-1}\prod_{i=1}^{4} c_i^{-2}\right)\left(1+\prod_{i=1}^{4} c_i^{-1}\right). \tag{2.18}$$

If $\{X_1, \cdots, X_n\}$ is a set of variables, then

$$e_k(X_1, \cdots, X_n) = \sum_{1\leqq i_1<i_2<\cdots<i_k\leqq n} X_{i_1}X_{i_2}\cdots X_{i_k}$$

is the elementary symmetric function of degree k. We have

$$\prod_{\substack{1\leqq j<k<4 \\ j,k\neq l}} (1-c_l^{-1}c_j^{-1}c_k^{-1}) = \sum_{m=0}^{3} (-1)^m c_l^{-m} e_m(c_j^{-1}c_k^{-1}), \tag{2.19}$$

where $e_m(c_j^{-1}c_k^{-1})$ is the elementary symmetric function of degree m in the variables $\{c_j^{-1}c_k^{-1} \mid 1\leqq j<k\leqq 4; j, k\neq l\}$. We can also write

$$\begin{aligned} &e_0(c_j^{-1}c_k^{-1}) = 1, \\ &e_1(c_j^{-1}c_k^{-1}) = e_2(c_j^{-1}), \\ &e_2(c_j^{-1}c_k^{-1}) = e_1(c_j^{-1}) \prod_{\substack{i=1 \\ i\neq l}}^{4} (c_i)^{-1}, \\ &e_3(c_j^{-1}c_k^{-1}) = \prod_{\substack{i=1 \\ i\neq l}}^{4} (c_i)^{-2}, \end{aligned} \tag{2.20}$$

where the elementary symmetric functions on the right-hand sides of (2.20) are in the variables $\{c_j^{-1} \mid 1\leqq j\leqq 4, j\neq l\}$. Note that $e_3(c_j^{-1}) = \prod_{i=1;i\neq l}^{4} (c_i)^{-1}$ and $e_4(c_j^{-1}) = 0$. We also have

$$c_l^{-1}e_m(c_j^{-1}) = e_{m+1}(c_1^{-1}, c_2^{-1}, c_3^{-1}, c_4^{-1}) - e_{m+1}(c_j^{-1}), \tag{2.21}$$

where $0 \leqq m \leqq 3$, and $e_m(c_j^{-1})$ and $e_{m+1}(c_j^{-1})$ are functions in the variables $\{c_j^{-1} \mid 1 \leqq j \leqq 4, j \neq l\}$. It follows that

$$\sum_{m=0}^{3} (-1)^m c_l^{-m} e_m(c_j^{-1}c_k^{-1}) = 1 - e_3 + c_l e_4 + e_2 e_4 - c_l e_3 e_4 + c_l^2 e_4^2 - c_l^{-1} e_4^2, \tag{2.22}$$

where the symmetric functions on the right-hand side of (2.22) are in the variables $c_1^{-1}, c_2^{-1}, c_3^{-1}, c_4^{-1}$ and on the left-hand side of (2.22) are in the variables $\{c_j^{-1}c_k^{-1} \mid 1 \leqq j < k \leqq 4; j, k \neq l\}$.

To calculate the left-hand side of (2.18), we will need an important lemma due to Louck and Biedenharn [14] (see also [11]).

LEMMA 2.23. *Let $X_1, \cdots, X_n$ be arbitrary distinct complex numbers, of any non-negative integer, and $h_l(X)$ the lth homogeneous symmetric function of $X_1, \cdots, X_n$. We then have*

$$\sum_{i=1}^{n} (X_i)^q \prod_{\substack{s=1 \\ s \neq i}}^{n} (X_s - X_i)^{-1} = (-1)^{n-1} h_{q-n+1}(X).$$

Note that $h_k(X) \equiv 0$ if $k < 0$ and $h_0(X) \equiv 1$.

Using the identity

$$c_l^3 \prod_{\substack{i=1 \\ i \neq l}}^{4} (c_l - c_i)^{-1} = -\prod_{\substack{i=1 \\ i \neq l}}^{4} \left(\frac{c_i^{-1}}{c_l^{-1} - c_i^{-1}} \right), \tag{2.24}$$

we substitute identities (2.19) and (2.22) into the left-hand side of (2.18). Thus the left-hand side of (2.18) equals

$$\begin{aligned}
&\sum_{l=1}^{4} \frac{c_l^3}{\prod_{i=1; i=l}^{4} (c_l - c_i)} (1 - q^{-1}c_l^{-2})(1 + c_l^{-1})\{1 - e_3 + c_l e_4 + e_2 e_4 - c_l e_3 e_4 + c_l^2 e_4^2\} \\
&\quad - \sum_{l=1}^{4} \frac{c_l^3}{\prod_{i=1, i \neq l}^{4} (c_l - c_i)} (1 + c_l^{-1} - q^{-1}c_l^{-2}) c_l^{-1} e_4^2 + \sum_{l=1}^{4} \frac{(-q^{-1}c_l^{-3}) e_4^3}{\prod_{i=1, i \neq l}^{4} (c_l^{-1} - c_i^{-1})} \\
&= 1 - e_3(c_i^{-1}) + h_1(c_i) e_4(c_i^{-1}) + e_4(c_i^{-1}) + e_2(c_i^{-1}) e_4(c_i^{-1}) \\
&\quad - h_1(c_i) e_3(c_i^{-1}) e_4(c_i^{-1}) - e_3(c_i^{-1}) e_4(c_i^{-1}) + h_2(c_i) e_4^2(c_i^{-1}) \\
&\quad + h_1(c_i) e_4^2(c_i^{-1}) - q^{-1} e_4^2(c_i^{-1}) - q^{-1} e_4^3(c_i^{-1}),
\end{aligned} \tag{2.25}$$

where the symmetric functions e_k on the left-hand side of (2.25) are in the variables c_i^{-1}, $1 \leqq i \leqq 4$, and on the right-hand side of (2.25) the symmetric functions $h_k(c_i)$ and $e_k(c_i^{-1})$ are in the variables c_i and c_i^{-1}, $1 \leqq i \leqq 4$, respectively.

Note that $h_1(c_i) e_4(c_i^{-1}) = e_3(c_i^{-1})$, with notation as above. A simple case of the Jacobi-Trudi identity [16] is $h_2(c_i) = e_1^2(c_i) - e_2(c_i)$. Since $h_1(c_i) = e_1(c_i)$ and $e_2(c_i) e_4(c_i^{-1}) = e_2(c_i^{-1})$, this implies $h_2(c_i) e_4^2(c_i^{-1}) = e_3^2(c_i^{-1}) - e_2(c_i^{-1}) e_4(c_i^{-1})$, with notation as above. Hence, the right-hand side of (2.25) equals

$$\begin{aligned}
&1 - e_3 + e_3 + e_4 + e_2 e_4 - e_3^2 - e_3 e_4 + e_3^2 - e_2 e_4 + e_3 e_4 - q^{-1} e_4^2 - q^{-1} e_4^3 \\
&\quad = 1 + e_4 - q^{-1} e_4^2 - q^{-1} e_4^3,
\end{aligned} \tag{2.26}$$

where all symmetric functions are in the variables c_i^{-1}, $1 \leqq i \leqq 4$. The right-hand side of (2.26) equals the right-hand side of (2.18). This completes the proof of (2.18), and also the proof of Lemma 2.7. In other words, both sides of (1.3) satisfy the same q-difference equation (2.8).

To complete the proof of (1.3) we need to consider a special evaluation of the series on the left-hand side of (1.3).

LEMMA 2.27. *Assume* $|q^{-3}\prod_{i=1}^{2}(b_i/a_i)^2| < 1$ *and none of the denominators on both sides of* (1.3) *vanish; then* (1.3) *is valid whenever* $c_i c_j = 1$ *for some* $i \neq j$, $1 \leqq i, j \leqq 4$.

Proof. Let $p_j : \mathbb{C}^3 \to \mathbb{C}$, $1 \leqq j \leqq 3$, be linear functionals such that for all $X = (X_1, X_2, X_3) \in \mathbb{C}^3$ we have $p_1(X) = X_1 - X_2$, $p_2(X) = X_2 - X_3$, and $p_3(X) = X_3 - X_1$. For $z = (z_1, z_2, z_3)$ as in (1.3), define $p_1(z) = z_1 - z_2 = u_1$, $p_2(z) = z_2 - z_3 = u_2$, and $p_3(z) = z_3 - z_1 = u_3$. Similarly, for $t = (t_1, t_2, t_3) \in L$, define $p_1(t) = t_1 - t_2 = y_1$, $p_2(t) = t_2 - t_3 = y_2$, and $p_3(t) = t_3 - t_1 = y_3$. For the generators φ_1, φ_2, φ_3 of L, we have the following:

$$p_1(\varphi_1) = 1, \quad p_1(\varphi_2) = -1, \quad p_1(\varphi_3) = 0,$$

$$p_2(\varphi_1) = 0, \quad p_2(\varphi_2) = 1, \quad p_2(\varphi_3) = -1,$$

$$p_3(\varphi_1) = -1, \quad p_3(\varphi_2) = 0, \quad p_3(\varphi_3) = 1.$$

Hence for $t \in L$ and $t = n_1\varphi_1 + n_2\varphi_2 + n_3\varphi_3$, we have

$$p_1(t) = n_1 - n_2 = y_1, \quad p_2(t) = n_2 - n_3 = y_2, \quad p_3(t) = n_3 - n_1 = y_3.$$

If $t = n_1'\varphi_1 + n_2'\varphi_2 + n_3'\varphi_3$, then $n_1 - n_2 = n_1' - n_2' = y_1$, $n_2 - n_3 = n_2' - n_3' = y_2$, and $n_3 - n_1 = n_3' - n_1' = y_3$. Conversely, given any triple $(y_1, y_2, y_3) \in \mathbb{Z}^3$ such that $y_1 + y_2 + y_3 = 0$, let $t = -y_3\varphi_1 + y_2\varphi_2$. Then we have $p_1(t) = -y_3 - y_2 = y_1$, $p_2(t) = y_2$, and $p_3(t) = y_3$. It follows that there is a one-to-one correspondence between elements $t \in L$ and triples $(y_1, y_2, y_3) \in \mathbb{Z}^3$ such that $y_1 + y_2 + y_3 = 0$.

Consequently, in the above notation we may rewrite the left-hand side of (1.3) as follows:

$$\begin{aligned}\sum_{\substack{y_1,y_2,y_3=-\infty \\ y_1+y_2+y_3=0}}^{\infty} \Bigg\{ & q^{y_1+3y_2}\left(\frac{1-q^{u_3+y_3-u_1-y_1}}{1-q^{u_3-u_1}}\right) \\ & \cdot\left(\frac{1-q^{u_1+y_1-u_2-y_2}}{1-q^{u_1-u_2}}\right)\left(\frac{1-q^{u_3+y_3-u_2-y_2}}{1-q^{u_3-u_2}}\right)\left(\frac{1-q^{u_1+y_1}}{1-q^{u_1}}\right) \\ & \cdot\left(\frac{1-q^{u_3+y_3}}{1-q^{u_3}}\right)\left(\frac{1-q^{-u_2-y_2}}{1-q^{-u_2}}\right)\prod_{i=1}^{4}\prod_{j=1}^{3}\frac{[c_i q^{u_j}]_{y_j}}{[qc_i^{-1}q^{u_j}]_{y_j}}\Bigg\}.\end{aligned} \tag{2.28}$$

Now let us assume for some $i \neq j$, $1 \leqq i, j \leqq 4$, that $c_i = c_j^{-1} = q^{u_i}$. Suppose that $c_4 = c_3^{-1} = q^{u_3}$. The proof is similar in the other cases. Then (2.28) reduces to the following:

$$\sum_{\substack{y_1,y_2=-\infty \\ y_1+y_2=0}}^{\infty} \left\{\left(\frac{q^{u_1+y_1}-q^{u_2+y_2}}{q^{u_1}-q^{u_2}}\right)\prod_{i,j=1}^{2}\frac{[c_i q^{u_j}]_{y_j}}{[qc_i^{-1}q^{u_j}]_{y_j}}\right\}. \tag{2.29}$$

Expression (2.29) is a basic hypergeometric series that is very well poised on A_1 (or $SU(2)$), i.e., a classical ${}_6\psi_6$ series. Its sum is evaluated as a special case of theorem 1.15 of [9]. (This case is simply a reformulation of Bailey's ${}_6\psi_6$ sum [5].) We find that

(2.29) equals

$$\frac{[q]_\infty[q^{1+u_1-u_2}]_\infty[q^{1+u_2-u_1}]_\infty\prod_{i,k=1}^{2}[qc_i^{-1}c_k^{-1}]_\infty}{[q(c_1c_2)^{-2}]_\infty\prod_{i,k=1}^{2}[qc_i^{-1}q^{u_k}]_\infty[qc_i^{-1}q^{-u_k}]_\infty} \tag{2.30}$$

$$\cdot\,[q^{1+u_1+u_2}(c_1c_2)^{-1}]_\infty[q^{1-u_1-u_2}(c_1c_2)^{-1}]_\infty.$$

Expression (2.30) equals the right-hand side of (1.3) in the case $c_4 = c_3^{-1} = q^{u_3}$.

We will now eliminate the restriction that $c_4 = c_3^{-1} = q^{u_3}$ and simply require that $c_4 = c_3^{-1}$. Let ψ and Q be the left- and right-hand sides, respectively, of (1.3). Define $\Phi(z) = Q^{-1}\psi$ as a function of $z = (z_1, z_2, z_3)$, where $z_1 + z_2 + z_3 = 0$. We have the following lemma.

LEMMA 2.31 [10, Lemma 3.15]. *$\Phi(z)$ is a constant for all z such that $z_1 + z_2 + z_3 = 0$.*

Proof. This lemma is an immediate consequence of Lemma 3.15 of [10]. It is only necessary to verify that

$$\prod_{\alpha>0}\alpha(z)^2 = 2\sum_{\substack{1\le j,k\le 3\\ j\ne k}}(z_j - z_k)^2$$

with notation as in (2.1). This can be done without much difficulty.

As a consequence of Lemma 2.31, it follows that since (1.3) is valid for $c_4 = c_3^{-1} = q^{u_3}$, it must also be valid for $c_4 = c_3^{-1}$ regardless of u_3. More generally, (1.3) is valid whenever $c_ic_j = 1$ for some $i \ne j$, $1 \le i, j < 4$. This completes the proof of Lemma 2.27.

Using the special evaluation in Lemma 2.27 as a starting point, we will prove (1.3) by induction. Assume that $c_1c_3 = q^{-k_1}$ and $c_2c_4 = q^{-k_2}$, where k_1 and k_2 are nonnegative integers. Furthermore, assume temporarily that $c_ic_j^{-1} \ne q^l$ for any integer l and all i, j such that $1 \le i \ne j \le 4$. Let $k = k_1 + k_2$. The assumption $k \ge 0$ guarantees the convergence of the series on the left-hand side of (1.3). Now assume that (1.3) is valid for all such c_i with $0 \le k \le N$ for some integer N. Consider the case $k = N+1$. If $k_1 = 0$ or $k_2 = 0$, then (1.3) is a consequence of Lemma 2.27. If both k_1 and k_2 are positive, then (1.3) follows from the induction hypothesis and Lemma 2.7. By induction this proves that (1.3) is valid whenever $c_ic_{i+2} = q^{-k_i}$, $i = 1,2$, for all nonnegative integers k_i (assuming no denominators vanish).

Both sides of (1.3) are analytic functions in the variables c_i^{-1}, $1 \le i \le 4$. In each variable c_i^{-1}, (1.3) is satisfied on a set of points with a limit point in the domain of convergence. By analytic continuation, (1.3) is valid for all c_i, $1 \le i \le 4$, in the domain of convergence $|q^{-3}\prod_{i=1}^{2}(b_i/a_i)^2| < 1$. We also eliminate the assumption that $c_ic_j^{-1} \ne q^l$ by analytic continuation. This completes the proof of Theorem 1.1.

Remark 2.32. It should be mentioned that the analytic continuation argument used here is related to one used by Ismail [13] in an elementary proof of Ramanujan's ${}_1\psi_1$ summation theorem. Milne [18] gives a generalization of Ismail's argument for basic hypergeometric series in $U(n)$.

3. Proof of Theorem 1.7. In this section we will prove Theorem 1.7. We first prove the convergence condition $\mathrm{Re}(2\sum_{i=1}^{2}(\beta_i - \alpha_i)) > 3$ for the series in (1.9). Then we will prove (1.9) by taking the limit as $q \to 1$ of a terminating case of Theorem 1.1. An application of Carlson's theorem [6, p. 39] gives the general result.

To show the convergence of the series in (1.9), we follow an argument similar to the proof of the convergence of the series in (1.3). Given $t \in L$ such that $t = n_1\varphi_1 + n_2\varphi_2 + n_3\varphi_3$ with $n_1, n_2, n_3 \in \mathbb{Z}$, then there is a permutation σ of $\{1, 2, 3\}$ such that $t = l_1\varphi_{\sigma(1)} - l_2\varphi_{\sigma(3)}$, where $l_1 = n_{\sigma(1)} - n_{\sigma(2)}$ and $l_2 = n_{\sigma(2)} - n_{\sigma(3)}$ with $l_1, l_2 \ge 0$. As in

(2.3), it follows that

$$\prod_{i=1}^{2}\prod_{\substack{1\leqq j,k\leqq 3\\ j\neq k}}\frac{(\alpha_j+z_j-z_k)_{t_j-t_k}}{(\beta_i+z_j-z_k)_{t_j-t_k}}$$

$$=\prod_{i=1}^{2}\left\{\frac{(\alpha_i+z_{\sigma(1)}-z_{\sigma(2)})_{l_1}(\alpha_i+z_{\sigma(2)}-z_{\sigma(1)})_{-l_1}}{(\beta_i+z_{\sigma(1)}-z_{\sigma(2)})_{l_1}(\beta_i+z_{\sigma(2)}-z_{\sigma(1)})_{-l_1}}\right.$$

$$\cdot\frac{(\alpha_i+z_{\sigma(2)}-z_{\sigma(3)})_{l_2}(\alpha_i+z_{\sigma(3)}-z_{\sigma(2)})_{-l_2}}{(\beta_i+z_{\sigma(2)}-z_{\sigma(3)})_{l_2}(\beta_i+z_{\sigma(3)}-z_{\sigma(2)})_{-l_2}}$$

(3.1)

$$\left.\cdot\frac{(\alpha_i+z_{\sigma(1)}-z_{\sigma(3)})_{l_1+l_2}(\alpha_i+z_{\sigma(3)}-z_{\sigma(1)})_{-l_1-l_2}}{(\beta_i+z_{\sigma(1)}-z_{\sigma(3)})_{l_1+l_2}(\beta_i+z_{\sigma(3)}-z_{\sigma(1)})_{-l_1-l_2}}\right\}$$

$$=\prod_{i=1}^{2}\left\{\frac{(\alpha_i+z_{\sigma(1)}-z_{\sigma(2)})_{l_1}(1-\beta_i+z_{\sigma(1)}-z_{\sigma(2)})_{l_1}}{(\beta_i+z_{\sigma(1)}-z_{\sigma(2)})_{l_1}(1-\alpha_i+z_{\sigma(1)}-z_{\sigma(2)})_{l_1}}\right.$$

$$\cdot\frac{(\alpha_i+z_{\sigma(2)}-z_{\sigma(3)})_{l_2}(1-\beta_i+z_{\sigma(2)}-z_{\sigma(3)})_{l_2}}{(\beta_i+z_{\sigma(2)}-z_{\sigma(3)})_{l_2}(1-\alpha_i+z_{\sigma(2)}-z_{\sigma(3)})_{l_2}}$$

$$\left.\cdot\frac{(\alpha_i+z_{\sigma(1)}-z_{\sigma(3)})_{l_1+l_2}(1-\beta_i+z_{\sigma(1)}-z_{\sigma(3)})_{l_1+l_2}}{(\beta_i+z_{\sigma(1)}-z_{\sigma(3)})_{l_1+l_2}(1-\alpha_i+z_{\sigma(1)}-z_{\sigma(3)})_{l_1+l_2}}\right\}.$$

With t as above, also observe that

$$|(z_1+t_1-z_2-t_2)(-z_1-t_1+z_3+t_3)(-z_2-t_2+z_3+t_3)|$$

(3.2a)

$$\leqq k_1(l_1+1)(l_2+1)(l_1+l_2+1),$$

$$|(-2z_1-2t_1+z_2+t_2+z_3+t_3)(z_1+t_1-2z_2-2t_2+z_3+t_3)$$

(3.2b)

$$\cdot(-z_1-t_1-z_2-t_2+2z_3+2t_3)|\leqq k_2(l_1+l_2+1)^3$$

for some constants k_1, $k_2\geqq 0$.

From (3.1) and (3.2a, b) we see that the series in identity (1.9) converges absolutely if, for all $\sigma\in S_3$, the following series converges absolutely:

(3.5)

$$\sum_{l_1,l_2\geqq 0}(l_1+1)(l_2+1)(l_1+l_2+1)^4$$

$$\cdot\prod_{i=1}^{2}\left\{\frac{(\alpha_i+z_{\sigma(1)}-z_{\sigma(2)})_{l_1}}{(\beta_i+z_{\sigma(1)}-z_{\sigma(2)})_{l_1}}\right.$$

(3.3)

$$\cdot\frac{(1-\beta_i+z_{\sigma(1)}-z_{\sigma(2)})_{l_1}(\alpha_i+z_{\sigma(2)}-z_{\sigma(3)})_{l_2}(1-\beta_i+z_{\sigma(2)}-z_{\sigma(3)})_{l_2}}{(1-\alpha_i+z_{\sigma(1)}-z_{\sigma(2)})_{l_1}(\beta_i+z_{\sigma(2)}-z_{\sigma(3)})_{l_2}(1-\alpha_i+z_{\sigma(2)}-z_{\sigma(3)})_{l_2}}$$

$$\left.\cdot\frac{(\alpha_i+z_{\sigma(1)}-z_{\sigma(3)})_{l_1+l_2}(1-\beta_i+z_{\sigma(1)}-z_{\sigma(3)})_{l_1+l_2}}{(\beta_i+z_{\sigma(1)}-z_{\sigma(3)})_{l_1+l_2}(1-\alpha_i+z_{\sigma(1)}-z_{\sigma(3)})_{l_1+l_2}}\right\}.$$

Using the classical identity

$$\lim_{n\to\infty}\frac{n^X\Gamma(n)}{\Gamma(n+X)}=1,\tag{3.4}$$

then the series (3.3) converges absolutely if and only if the following series converges absolutely:

$$\sum_{l_1,l_2\geqq 0}\frac{(l_1+1)(l_2+1)(l_1+l_2+1)^4}{(l_1+l_2+1)^{2(\beta_1+\beta_2-\alpha_1-\alpha_2)}}\prod_{i=1}^{2}$$

$$\cdot\left\{\frac{(\alpha_i+z_{\sigma(1)}-z_{\sigma(2)})_{l_1}}{(\beta_i+z_{\sigma(1)}-z_{\sigma(2)})_{l_1}}\,\frac{(1-\beta_i+z_{\sigma(1)}-z_{\sigma(2)})_{l_1}(\alpha_i+z_{\sigma(2)}-z_{\sigma(3)})_{l_2}(1-\beta_i+z_{\sigma(2)}-z_{\sigma(3)})_{l_2}}{(1-\alpha_i+z_{\sigma(1)}-z_{\sigma(2)})_{l_1}(\beta_i+z_{\sigma(2)}-z_{\sigma(3)})_{l_2}(1-\alpha_i+z_{\sigma(2)}-z_{\sigma(3)})_{l_2}}\right\}.$$

Assuming that $\operatorname{Re}(2\sum_{i=1}^{2}(\beta_i-\alpha_i))>3$ and using (3.4) again, then the series (3.5) converges absolutely if the following series converges absolutely:

$$\left\{\sum_{l_1\geqq 0}\frac{(l_1+1)^2}{l_1^{2(\beta_1+\beta_2-\alpha_1-\alpha_2)}}\right\}\cdot\left\{\sum_{l_2\geqq 0}\frac{(l_2+1)^2}{l_2^{2(\beta_1+\beta_2-\alpha_1-\alpha_2)}}\right\}. \tag{3.6}$$

The convergence of (3.6) is implied by the assumption $\operatorname{Re}(2\sum_{i=1}^{2}(\beta_i-\alpha_i))>3$. Therefore under the same assumption the series in (1.9) converges absolutely.

We will now prove Theorem 1.7. The proof is quite similar to that of Theorems 8.3 and 8.9 of [10]. Set

$$\alpha_i=-\alpha_i'+z_i-z_{i+1}, \tag{3.7a}$$

$$\beta_i=1+\beta_i'+z_i-z_{i+1} \tag{3.7b}$$

for $i=1,2$. We will assume that

$$\operatorname{Re}(\alpha_i'),\ \operatorname{Re}(\beta_i')\geqq 0 \tag{3.8a}$$

for $i=1,2$ and

$$z_j\in\mathbb{R},\qquad 0\leqq z_j<\tfrac{1}{4} \tag{3.8b}$$

for $1\leqq j\leqq 4$. Then for a nonnegative integer r and $1\leqq j,\ k\leqq 3$, $j\neq k$, we have

$$\left|\frac{-\alpha_i'+z_i-z_{i+1}+z_j-z_k+r}{1+\alpha_i'-z_i+z_{i+1}+z_j-z_k+r}\right|<1 \tag{3.9}$$

for $i=1,2$ and a similar relation for β_i'. It follows that

$$\prod_{\substack{1\leqq j,k\leqq 3\\ j\neq k}}|(-\alpha_i'+z_i-z_{i+1}+z_j-z_k)_{t_j-t_k}|<1 \tag{3.10}$$

for $i=1,2$ and $t\in L$, with a similar relation for β_i'. Hence if we choose some α_i', $1\leqq i\leqq 2$, and fix all other parameters α_j', $j\neq i$, and β_1', β_2', z_1, z_2, and z_3, then we have

$$\operatorname{Re}(2(\beta_1+\beta_2-\alpha_j))=\operatorname{Re}(4+2(\beta_1'+\beta_2'+\alpha_j'))>3. \tag{3.11}$$

By a slight modification of the argument above showing convergence of the series in (1.9), it follows that the series in (1.9) is uniformly and absolutely convergent for $\operatorname{Re}(\alpha_i')\geqq 0$ and is regular and bounded in the variable α_i' for $\operatorname{Re}(\alpha_i')\geqq 0$.

Using Stirling's formula

$$\Gamma(a+s)=\sqrt{2\pi}\,s^{a+s-1/2}e^{-s}\left(1+O\left(\frac{1}{s}\right)\right)$$

as $s\to\infty$ in $S_\theta=\{s\colon|\arg s|<\theta\}$, $0<\theta<\pi$, and $a,\ s\in\mathbb{C}$, we can show that under conditions (3.8a, b) the right-hand side of (1.9) is regular and of polynomial growth in the region $\operatorname{Re}(\alpha_i')\geqq 0$ as a function of the variable α_i'. There is a similar statement if we choose the parameter β_i', $1\leqq i\leqq 2$, and fix the other parameters β_j', $j\neq i$, and α_1', α_2', z_1, z_2, and z_3. Subject to (3.8a, b), the series on the left-hand of (1.9) will be regular and bounded in the region $\operatorname{Re}(\beta_i')\geqq 0$ as a function of the variable β_i'. Also the right-hand side of (1.9), as a function of β_i', will be regular and of polynomial growth in this region.

Now set

$$a_j=q^{-k_j+z_j-z_{j+1}},\qquad b_j=q^{1+n_j+z_j-z_{j+1}}$$

for $j=1,2$ in (1.3), where the k_j and n_j are nonnegative integers. Then the left-hand side of (1.3) reduces to a finite sum of nonzero terms as the series terminates in both

directions in all summation indices. Similarly, the right-hand side of (1.3) reduces to a quotient of finite products. Taking the limit of (1.3) as $q \to 1$ with these assumptions, we obtain the special case of (1.9), where $\alpha_j' = k_j$ and $\beta_j' = n_j$ for $j = 1, 2$ and nonnegative integers k_j and n_j.

With assumptions as in (3.8a, b), we choose a parameter α_i', $1 \leqq i \leqq 2$, and fix the other parameters, subject to the conditions $\alpha_j' = k_j$ for $j \neq i$ and $\beta_j' = n_j$ for $j = 1, 2$, where the k_j and n_j are nonnegative integers. Let F be the difference between the left- and right-hand sides of (1.9). (The choice of sign is unimportant.) We view F as a function of α_i', as regular in the region $\mathrm{Re}(\alpha_i') \geqq 0$, and as vanishing when $\alpha_i' = 0, 1, 2, \cdots$. By Carlson's theorem [6, p. 39], F is identically zero as a function of α_i'. Repeating this procedure for the parameters α_j' and β_j' successively, we remove the restrictions that $\alpha_j' = k_j$ and $\beta_j' = n_j$ for nonnegative integers k_j and n_j. Finally, by analytic continuation the restrictions on the parameters z_j, $1 \leqq j \leqq l$, are removed. It follows that F vanishes identically as a function of all the parameters α_j', β_j', and z_j, when it is defined and converges. This completes the proof of Theorem 1.7.

ERROR BOUNDS FOR A UNIFORM ASYMPTOTIC EXPANSION OF THE LEGENDRE FUNCTION $Q_n^{-m}(\cosh z)$ *

C. L. FRENZEN†

Abstract. For fixed m with $m+\frac{1}{2}>0$, an asymptotic expansion for large n is obtained for the Legendre function $Q_n^{-m}(\cosh z)$ that is uniformly valid for z in the unbounded interval $[0,\infty)$. This method is based on an integral representation of the function. The coefficients in the expansion satisfy a recurrence relation, and simple computable bounds are provided for the error terms associated with the expansion.

Key words. error bound, uniform asymptotic expansion, Legendre function

AMS(MOS) subject classifications. primary 41A60, 33A45

1. Introduction. Recently several authors have obtained asymptotic expansions of Legendre functions directly from their integral representations. The derivation of these expansions provides an alternative to Olver's differential equation approach, which gives asymptotic expansions of $P_n^{-m}(\cosh z)$ and $Q_n^m(\cosh z)$ for large n and fixed $m\geqq 0$ that are uniformly valid for z in a *complex* domain containing the interval $[0,\infty)$ [3, Chap. 12, §§ 12, 13]. Olver also provides numerical bounds for the error terms associated with these expansions.

Ursell [7] has given an alternative derivation of these expansions from integral representations of the Legendre functions, and has presented a new method for constructing error bounds. His bounds, though, are not computable and are valid only for bounded *complex* z. Starting from an integral representation Shivakumar and Wong [6] give an asymptotic expansion of $P_n^{-m}(\cosh z)$ for real z and fixed m, $m+\frac{1}{2}>0$, and construct error bounds comparable to those given by Olver, *computable* and uniformly valid for z in the infinite interval $[0,\infty)$. Although it is capable of deriving an asymptotic expansion for the other Legendre function $Q_n^{-m}(\cosh z)$, their method could not provide error bounds.

In this paper, we provide computable error bounds for an asymptotic expansion of $Q_n^{-m}(\cosh z)$ obtained from an integral representation. These bounds are uniformly valid for z in the infinite interval $[0,\infty)$. Our expansion differs from, but is equivalent to, those given by Olver [3, p. 465] and Ursell [7]. More precisely, we show that for $m+\frac{1}{2}>0$, $n-m+1>0$, and for any positive integer p

$$e^{mi\pi}Q_n^{-m}(\cosh z)=\left(\frac{z}{\sinh z}\right)^{1/2}\left[\sum_{\nu=0}^{p-1} d_\nu(z)\frac{K_{m+\nu}(uz)}{u^{m+\nu}}+\varepsilon_p(z,u)\right] \tag{1.1}$$

where $u=n+\frac{1}{2}$ and $K_\nu(z)$ is the modified Bessel function. The coefficients $d_\nu(z)$ are analytic functions of z, and can be obtained recursively. The first three are given by

$$d_0(z)=1,\qquad d_1(z)=\frac{\Gamma(m+\frac{3}{2})}{\Gamma(m+\frac{1}{2})}\left(m-\frac{1}{2}\right)\frac{z\coth z-1}{2z}, \tag{1.2}$$

$$d_2(z)=\frac{\Gamma(m+\frac{5}{2})}{\Gamma(m+\frac{3}{2})}\left\{\frac{1}{6}\left(m-\frac{1}{2}\right)\left[1+\frac{3}{z^2}-\frac{3}{z}\coth z\right]+\frac{1}{8}\left(m-\frac{1}{2}\right)\left(m-\frac{3}{2}\right)\left(\frac{(1-z\coth z)^2}{z^2}\right)\right\}.$$

The error term $\varepsilon_p(z,u)$ satisfies the inequality

$$|\varepsilon_p(z,u)|\leqq\frac{\Gamma(m+p+\frac{1}{2})}{\Gamma(m+\frac{1}{2})}\left(\frac{2z}{2+z}\right)^p M_p\frac{K_{m+p}(uz)}{u^{m+p}} \tag{1.3}$$

* Received by the editors September 6, 1988; accepted for publication March 23, 1989.

† Department of Mathematics, Southern Methodist University, Dallas, Texas 75275. Present address, Department of Mathematics, Naval Postgraduate School, Monterey, California 93943. This research was supported in part by National Science Foundation grant DMS-8718941.

for $-\frac{1}{2}<m\leqq\frac{1}{2}$, and

$$|\varepsilon_p(z,u)|\leqq\frac{\Gamma(m+p+\frac{1}{2})}{\Gamma(m+\frac{1}{2})}\left(\frac{2z}{2+z}\right)^p M_p\, e^{-(m-1/2)z}\,\frac{K_{m+p}([u-(m-\frac{1}{2})]z)}{[u-(m-\frac{1}{2})]^{m+p}} \tag{1.4}$$

for $m>\frac{1}{2}$, where $0\leqq z<\infty$ and $n>-\frac{1}{2}$. Note that since $n-m+1>0$, $u-(m-\frac{1}{2})>0$. M_p is a computable constant independent of u and z, and the first three are

$$\begin{aligned} M_1&=|m-\tfrac{1}{2}|, \qquad M_2=\frac{|m-\frac{1}{2}|}{2}+\frac{|m-\frac{1}{2}||m-\frac{3}{2}|}{2}\\ M_3&=\frac{|m-\frac{1}{2}|}{6}+\frac{|m-\frac{1}{2}||m-\frac{3}{2}|}{2}+\frac{|m-\frac{1}{2}||m-\frac{3}{2}||m-\frac{5}{2}|}{6}. \end{aligned} \tag{1.5}$$

Regarding the form of the bound in (1.4), later we show that for $m>\frac{1}{2}$,

$$1<e^{-(m-1/2)z}\,\frac{K_{p+m}([u-(m-\frac{1}{2})]z)}{K_{p+m}(uz)}\leqq\left[\frac{u}{u-(m-\frac{1}{2})}\right]^{p+m} \tag{1.6}$$

for z in $[0,\infty)$. Equation (1.6) implies that

$$e^{-(m-1/2)z}K_{p+m}([u-(m-\tfrac{1}{2})]z)=K_{p+m}(uz)(1+o(1)) \tag{1.7}$$

uniformly for z in $[0,\infty)$ as $u\to\infty$.

Expansion (1.1) can be rearranged to agree with those obtained by Olver and Ursell, but, in doing so, the simple estimate for the remainder given in (1.3) and (1.4) is lost. A comparison of our results with those of Olver and a discussion of our bounds is given in the final section of this paper.

2. Derivation of the expansion. For $m+\frac{1}{2}>0$ and $u-m+\frac{1}{2}>0$ we have the integral representation [1, § 3.7]

$$e^{mi\pi}Q_n^{-m}(\cosh z)=\left(\frac{\pi}{2}\right)^{1/2}\frac{(\sinh z)^{-m}}{\Gamma(m+\frac{1}{2})}\int_z^\infty e^{-ut}(\cosh t-\cosh z)^{m-1/2}\,dt \tag{2.1}$$

where $u=n+\frac{1}{2}$. As in [6], we first obtain a series expansion for the integrand in (2.1). Beginning with the result [8, Form. (3), p. 140]

$$\left(\frac{2}{\pi z}\right)^{1/2}\cos\sqrt{z^2-2z\theta}=\sum_{m=0}^{\infty}\frac{\theta^m}{m!}J_{m-1/2}(z) \tag{2.2}$$

valid for all complex θ and z, we replace z by iz and θ by $i\theta$ in (2.2) to obtain

$$\left(\frac{2}{\pi z}\right)^{1/2}\cosh\sqrt{z^2-2z\theta}=\sum_{m=0}^{\infty}\frac{(-1)^m}{m!}\theta^m I_{m-1/2}(z). \tag{2.3}$$

Here $J_\nu(z)$ and $I_\nu(z)$ are the Bessel functions of the first kind and the modified Bessel function, respectively, and $J_\nu(iz)=e^{\nu\pi i/2}I_\nu(z)$. Putting $z^2-2z\theta=t^2$ in (2.3) and recalling that

$$I_{-1/2}(z)=\left(\frac{2}{\pi z}\right)^{1/2}\cosh z, \qquad I_{1/2}(z)=\left(\frac{2}{\pi z}\right)^{1/2}\sinh z$$

then yields

$$\cosh t-\cosh z=\frac{\sinh z}{2z}(t^2-z^2)\sum_{\nu=0}^{\infty}\phi_\nu(z)(t^2-z^2)^\nu \tag{2.4}$$

where $\phi_0(z)=1$ and

$$\phi_\nu(z)=\frac{1}{2^\nu(\nu+1)!}\frac{I_{\nu+1/2}(z)}{z^\nu I_{1/2}(z)}, \qquad \nu\geqq 1. \tag{2.5}$$

Note from (2.5) and the asymptotic behavior of $I_\nu(z)$ as $z\to\infty$ (see [3, p. 251)] that

$$\phi_\nu(z)=O(z^{-\nu}) \qquad (z\to\infty). \tag{2.6}$$

The expression

$$(\cosh t-\cosh z)^{m-1/2}=\left(\frac{\sinh z}{2z}\right)^{m-1/2}(t^2-z^2)^{m-1/2}\sum_{\nu=0}^{\infty}\psi_\nu(z)(t^2-z^2)^\nu \tag{2.7}$$

now follows immediately for t sufficiently close to z, where the coefficients $\psi_\nu(z)$ satisfy the recurrence relation

$$\psi_{\nu+1}(z)=\sum_{j=0}^{\nu}\left[\left(m-\frac{1}{2}\right)-\frac{j}{\nu+1}\left(m+\frac{1}{2}\right)\right]\phi_{\nu+1-j}(z)\psi_j(z), \tag{2.8}$$

$\nu=0, 1, 2, \cdots$, with $\psi_0(z)=1$ (see [4]). As in [6],

$$\psi_1(z)=-\frac{1}{4}\left(m-\frac{1}{2}\right)\frac{1-z\coth z}{z^2}, \tag{2.9}$$

$$\begin{aligned}\psi_2(z)=&\frac{1}{24}\left(m-\frac{1}{2}\right)\left[\frac{1}{z^2}\left(1+\frac{3}{z^2}\right)-\frac{3}{z^3}\coth z\right]\\&+\frac{1}{32}\left(m-\frac{1}{2}\right)\left(m-\frac{3}{2}\right)\left(\frac{1-z\coth z}{z^2}\right)^2.\end{aligned} \tag{2.10}$$

Note from (2.6) and (2.8) that

$$\psi_\nu(z)=O(z^{-\nu}) \qquad (z\to\infty). \tag{2.11}$$

We now introduce the remainder $\Delta_p(z, t)$ defined by

$$\left(\frac{\cosh t-\cosh z}{t^2-z^2}\frac{2z}{\sinh z}\right)^{m-1/2}=\sum_{\nu=0}^{p-1}\psi_\nu(z)(t^2-z^2)^\nu+(t^2-z^2)^p\Delta_p(z, t), \qquad t\geqq z. \tag{2.12}$$

Inserting (2.12) into (2.1) and using the formula (see [8, § 6.3, p. 185])

$$K_\nu(uz)=\frac{\pi^{1/2}(2z)^{-\nu}u^\nu}{\Gamma(\nu+\frac{1}{2})}\int_z^\infty e^{-ut}(t^2-z^2)^{\nu-1/2}\,dt, \tag{2.13}$$

then yields

$$e^{mi\pi}Q_n^{-m}(\cosh z)=\left(\frac{z}{\sinh z}\right)^{1/2}\left[\sum_{\nu=0}^{p-1}d_\nu(z)\frac{K_{m+\nu}(uz)}{u^{m+\nu}}+\varepsilon_p(z, u)\right] \tag{2.14}$$

where

$$\varepsilon_p(z, u)=\frac{\pi^{1/2}}{(2z)^m\Gamma(m+\frac{1}{2})}\int_z^\infty e^{-ut}(t^2-z^2)^{p+m-1/2}\Delta_p(z, t)\,dt. \tag{2.15}$$

The coefficient $d_\nu(z)$ is given explicitly by

$$d_\nu(z)=\frac{\Gamma(m+\nu+\frac{1}{2})}{\Gamma(m+\frac{1}{2})}(2z)^\nu\psi_\nu(z) \tag{2.16}$$

(see (1.2)). Note from (2.1) and (2.12) that when $m=\frac{1}{2}$, $d_j(z)$ and $\varepsilon_j(z,u)$ are both zero for all $j\geqq 1$.

In the following sections we will show that, for $-\frac{1}{2}<m\leqq\frac{1}{2}$,

$$|\Delta_p(z,t)|\leqq\frac{M_p}{(2+z)^p},\qquad t\geqq z, \tag{2.17}$$

while for $m>\frac{1}{2}$

$$|\Delta_p(z,t)|\leqq\frac{M_p}{(2+z)^p}\,e^{(t-z)(m-1/2)},\qquad t\geqq z \tag{2.18}$$

where M_p is a computable constant independent of u and z explicitly given in (4.10). The first three are given in (1.5), the desired estimates in (1.3) and (1.4) now follow from (2.13), (2.15), (2.17), and (2.18).

3. Some preliminary results. To establish the estimates in (2.17) and (2.18) we will study the function

$$\sigma(z,t)=\frac{2z}{\sinh z}\left(\frac{\cosh t-\cosh z}{t^2-z^2}\right) \tag{3.1}$$

for $t\geqq z$, with $\sigma(z,z)=1$.

LEMMA 1. *For $t\geqq z$,*

$$\begin{aligned}&(\sigma(z,t))^{m-1/2}\leqq 1,\qquad -\tfrac{1}{2}<m\leqq\tfrac{1}{2},\\ &(\sigma(z,t))^{m-1/2}\leqq e^{(t-z)(m-1/2)},\qquad m>\tfrac{1}{2}.\end{aligned} \tag{3.2}$$

Proof. From the identity

$$\frac{\cosh t-\cosh z}{t^2-z^2}=\frac{1}{2}\,\frac{\sinh\left(\frac{t+z}{2}\right)}{\left(\frac{t+z}{2}\right)}\cdot\frac{\sinh\left(\frac{t-z}{2}\right)}{\left(\frac{t-z}{2}\right)}, \tag{3.3}$$

it follows that

$$\sigma(z,t)=\left(\frac{z}{\sinh z}\,\frac{\sinh\left(\frac{t+z}{2}\right)}{\left(\frac{t+z}{2}\right)}\right)\left(\frac{\sinh\left(\frac{t-z}{2}\right)}{\left(\frac{t-z}{2}\right)}\right). \tag{3.4}$$

Each term in parentheses in (3.4) is greater than or equal to one for $t\geqq z$, yielding the first inequality in (3.2). For the second, we again use (3.3) to conclude

$$\sigma(z,t)=(e^t)\left(\frac{z}{\sinh z}\right)\left(\frac{1-e^{-(t+z)}}{t+z}\right)\left(\frac{1-e^{-(t-z)}}{t-z}\right). \tag{3.5}$$

Since the function $(1-e^{-\theta})/\theta$ decreases monotonically from one for θ in $[0,\infty)$, for $t\geqq z$ (3.5) implies

$$\sigma(z,t)\leqq(e^t)\left(\frac{z}{\sinh z}\right)\left(\frac{1-e^{-2z}}{2z}\right)=e^{t-z}, \tag{3.6}$$

and this gives the second inequality in (3.2). □

From (2.4) it follows that σ is a function of t^2-z^2. Denoting this function by G and putting $x=t^2-z^2$ with $x\geqq 0$ for $t\geqq z$, we have

$$\begin{aligned}\sigma(z,t)=G(x)&\equiv\sum_{\nu=0}^{\infty}\phi_\nu(z)x^\nu\\&=\frac{2z}{\sinh z}\,\frac{\cosh\sqrt{z^2+x}-\cosh z}{x}.\end{aligned}\tag{3.7}$$

In what follows it will be convenient to *temporarily* replace z by $\sqrt{z}$ in studying G. Consequently, x becomes t^2-z, where $t\geqq\sqrt{z}$. After we have obtained the required results we will again replace $\sqrt{z}$ by z. So, from (3.7) we will study the function

$$G(x)=\frac{2\sqrt{z}}{\sinh\sqrt{z}}\,\frac{\cosh\sqrt{z+x}-\cosh\sqrt{z}}{x}=\sum_{\nu=0}^{\infty}\phi_\nu(\sqrt{z})x^\nu,\qquad x\geqq 0.\tag{3.8}$$

Equation (3.8) implies that

$$G(x)=\frac{2\sqrt{z}}{\sinh\sqrt{z}}\sum_{k=0}^{\infty}h^{(k+1)}(z)\frac{x^k}{(k+1)!}\tag{3.9}$$

where $h(z)=\cosh\sqrt{z}$ and the Maclaurin series expansion of $\cosh\sqrt{z+x}$ has been used.

LEMMA 2. *With* $h(z)=\cosh\sqrt{z}$, $r=0,1,2,\cdots$, *and* $z\geqq 0$,

$$h^{(r+1)}(z)h^{(r+1)}(z)>h^{(r)}(z)h^{(r+2)}(z).\tag{3.10}$$

Proof. With

$$h(z)=\cosh\sqrt{z}=\sum_{k=0}^{\infty}\frac{z^k}{(2k)!}\tag{3.11}$$

and

$$\frac{d^r}{dz^r}z^k=\frac{\Gamma(k+1)}{\Gamma(k-r+1)}z^{k-r},\tag{3.12}$$

we have

$$\begin{aligned}h^{(r)}(z)&=\sum_{k=r}^{\infty}\frac{\Gamma(k+1)}{\Gamma(k-r+1)}\,\frac{z^{k-r}}{\Gamma(2k+1)}\\&=\sum_{j=0}^{\infty}\frac{\Gamma(r+j+1)}{\Gamma(j+1)}\,\frac{z^j}{\Gamma(2(r+j)+1)}\\&=\frac{\pi^{1/2}}{2^{2r}}\sum_{j=0}^{\infty}\frac{z^j}{2^{2j}j!\Gamma(r+j+\frac{1}{2})}\end{aligned}\tag{3.13}$$

where the duplication formula for the gamma function has been used in the last equality in (3.13). From the latter equation it follows that $h^{(r)}(0)>0$, while

$$\begin{vmatrix}h^{(r)}(0) & h^{(r+1)}(0)\\ h^{(r+1)}(0) & h^{(r+2)}(0)\end{vmatrix}=\frac{\pi}{2^{4r+4}\Gamma(r+\frac{1}{2})\Gamma(r+\frac{3}{2})}\left[\frac{1}{r+\frac{3}{2}}-\frac{1}{r+\frac{1}{2}}\right]<0\tag{3.14}$$

for $r=0,1,2,\cdots$, where the vertical lines in (3.14) indicate a determinant. These results can be combined by writing

$$\varepsilon_k\begin{vmatrix}h^{(r)}(0)&\cdots&h^{(r+k)}(0)\\ h^{(r+k)}(0)&\cdots&h^{(r+2k)}(0)\end{vmatrix}>0,\quad k=0,1,\quad r=0,1,2,3,\cdots\tag{3.15}$$

where $\varepsilon_0=1$, $\varepsilon_1=-1$. We now employ the following result from Theorem 8.4 of [2, p. 84].

LEMMA. *Suppose $f(z)$ has a power series expansion about the origin that is convergent for $|z|<\rho$. If $f(z)$ satisfies*

$$\varepsilon_k\begin{vmatrix} f^{(r)}(0) & f^{(r+1)}(0) & \cdots & f^{(r+k)}(0) \\ f^{(r+1)}(0) & & \cdots & f^{(r+k+1)}(0) \\ \vdots & & & \vdots \\ f^{(r+k)}(0) & & \cdots & f^{(r+2k)}(0) \end{vmatrix}>0$$

for $r=0,1,2,\cdots$, $k=0,1,2,\cdots,n$, where $\varepsilon_0,\varepsilon_1,\cdots,\varepsilon_n$ is a prescribed sequence of plus or minus signs, then

$$\varepsilon_k\begin{vmatrix} f^{(r)}(z) & f^{(r+1)}(z) & \cdots & f^{(r+k)}(z) \\ f^{(r+1)}(z) & & \cdots & f^{(r+k+1)}(z) \\ \vdots & & & \vdots \\ f^{(r+k)}(z) & & \cdots & f^{(r+2k)}(z) \end{vmatrix}>0$$

for $0\leqq z<\rho$, $k=0,1,2,\cdots,n$, $r=0,1,2,\cdots$.

With $\rho=\infty$, $n=1$, $f(z)=h(z)=\cosh\sqrt{z}$, $\varepsilon_0=1$, $\varepsilon_1=-1$, the above lemma and (3.15) allow us to conclude that

$$-\begin{vmatrix} h^{(r)}(z) & h^{(r+1)}(z) \\ h^{(r+1)}(z) & h^{(r+2)}(z) \end{vmatrix}>0 \tag{3.16}$$

for $z\geqq 0$, $r=0,1,2,\cdots$, and this is (3.10). □

Inequality (3.10) implies

$$\frac{h^{(r+2)}(z)}{h^{(r+1)}(z)}<\frac{h^{(r+1)}(z)}{h^{(r)}(z)}$$

for $z\geqq 0$, $r=0,1,2,\cdots$, so that

$$\frac{h^{(r+k+1)}(z)}{h^{(r+k)}(z)}<\frac{h^{(r+k)}(z)}{h^{(r+k-1)}(z)}<\cdots<\frac{h^{(l+1)}(z)}{h^{(l)}(z)}<\cdots<\frac{h^{(2)}(z)}{h^{(1)}(z)} \tag{3.17}$$

for $z\geqq 0$, $r>0$, and $k\geqq 1$. In (3.17) the product of the first k terms on the left (setting $l=r+1$) is strictly less than the product of the last k terms on the right (setting $l=k$). Canceling numerators and denominators and admitting the possibility that $r=0$ or $k=0$ then implies

$$\frac{h^{(r+k+1)}(z)}{h^{(r+1)}(z)}\leqq\frac{h^{(k+1)}(z)}{h^{(1)}(z)} \tag{3.18}$$

for $z\geqq 0$, $r\geqq 0$, and $k\geqq 0$.

Let

$$A_r(z)=(r+1)\phi_r(\sqrt{z}) \tag{3.19}$$

where ϕ_r is defined in (2.5). The inequality in (3.18) now gives the following result for G defined in (3.8).

LEMMA 3. *For all $z>0$, $\xi\geqq 0$ and $r=0,1,2,\cdots$*

$$\frac{G^{(r)}(\xi)}{r!\,G(\xi)}\leqq A_r(z) \tag{3.20}$$

where $A_r(z)$ is given in (3.19).

Proof. From (3.9) and (3.12),

$$G^{(r)}(\xi)=\sum_{k=0}^{\infty}\frac{h^{(r+k+1)}(z)}{r+k+1}\frac{\xi^k}{k!}, \tag{3.21}$$

while from (3.8) and (3.9) it follows that, since $h^{(1)}(z)=\sinh\sqrt{z}/2\sqrt{z}$,

$$\frac{h^{(r+1)}(z)}{h^{(1)}(z)}=(r+1)!\,\phi_r(\sqrt{z})=r!\,A_r(z). \tag{3.22}$$

Therefore

$$\frac{G^{(r)}(\xi)}{r!\,G(\xi)}=A_r(z)\frac{\sum_{k=0}^{\infty}\frac{1}{r+k+1}\frac{h^{(r+k+1)}(z)}{h^{(r+1)}(z)}\frac{\xi^k}{k!}}{\sum_{k=0}^{\infty}\frac{1}{k+1}\frac{h^{(k+1)}(z)}{h^{(1)}(z)}\frac{\xi^k}{k!}}. \tag{3.23}$$

By (3.18) the series in the denominator on the right-hand side of (3.23) is a majorant of the series in the numerator, and this gives (3.20). □

Finally, we establish some upper bounds for $A_r(z)$. From (3.19) and (2.5)

$$A_r(z)=(r+1)\phi_r(\sqrt{z})=\frac{I_{r+1/2}(\sqrt{z})}{r!(2\sqrt{z})^r I_{1/2}(\sqrt{z})}. \tag{3.24}$$

Because $I_{r+1/2}(\sqrt{z})\leqq I_{1/2}(\sqrt{z})$ (see [3, p. 251]), it follows from (3.24) that

$$A_r(z)\leqq\frac{1}{r!(2\sqrt{z})^r}. \tag{3.25}$$

From the power series definition of $I_\nu(z)$ [3, p. 60] and the result

$$\frac{\Gamma(r+1)}{\Gamma(r+s+\frac{3}{2})}\leqq\frac{1}{\Gamma(s+\frac{3}{2})},$$

for $r=0,1,2,\cdots$, $s=0,1,2,\cdots$, an argument similar to that for (3.23) applied to (3.24) yields the following inequality:

$$A_r(z)\leqq\frac{1}{2^{2r}(r!)^2}. \tag{3.26}$$

For $0\leqq\sqrt{z}\leqq 2$, $2+\sqrt{z}\leqq 4$ and (3.26) implies

$$A_r(z)\leqq\frac{1}{(2+\sqrt{z})^r(r!)^2}. \tag{3.27}$$

For $\sqrt{z}\geqq 2$, $2\sqrt{z}\geqq 2+\sqrt{z}$ and (3.25) implies

$$A_r(z)\leqq\frac{1}{(2+\sqrt{z})^r r!}. \tag{3.28}$$

Together, (3.27) and (3.28) give

$$A_r(z)\leqq\frac{1}{(2+\sqrt{z})^r r!}, \tag{3.29}$$

for all $z\geqq 0$, $r=0,1,2,\cdots$.

4. Proof of (2.17) and (2.18). Changing z to $\sqrt{z}$ in (2.12) and recalling the definition of G in (3.8) gives

$$(G(x))^{m-1/2}=\sum_{\nu=0}^{p-1}\psi_\nu(\sqrt{z})x^\nu+x^p r_p(\sqrt{z},x),\qquad x\geqq 0 \tag{4.1}$$

where

$$r_p(\sqrt{z},x)=\Delta_p(\sqrt{z},\sqrt{x+z}). \tag{4.2}$$

We now use di Bruno's formula for the nth derivative of a composite function (see, for example, [5, p. 34]):

$$\frac{d^p}{dx^p}f(g(x))=\sum_{k=1}^{p}f^{(k)}(g(x))A_{pk}(g^{(1)}(x),g^{(2)}(x),\cdots,g^{(p)}(x)),\qquad p\geqq 1 \tag{4.3}$$

where $f^{(k)}$ denotes the kth derivative of f and the coefficients A_{pk} (which do not depend on f) are given by the formula

$$A_{pk}(g^{(1)}(x),\cdots,g^{(p)}(x))=\sum\frac{p!}{m_1!m_2!\cdots m_p!}\left(\frac{g^{(1)}(x)}{1!}\right)^{m_1}\cdots\left(\frac{g^{(p)}(x)}{p!}\right)^{m_p}. \tag{4.4}$$

The summation in (4.4) extends over all nonnegative integers $m_1, m_2, \cdots, m_p$ satisfying

$$m_1+m_2+\cdots+m_p=k,\qquad m_1+2m_2+\cdots+pm_p=p. \tag{4.5}$$

Taylor's theorem applied to (4.1) now implies that there exists a ξ between zero and x such that

$$\begin{aligned} r_p(\sqrt{z},x)&=\frac{1}{p!}\frac{d^p}{ds^p}((G(s))^{m-1/2})\Big|_{s=\xi}\\ &=\frac{1}{p!}\sum_{k=1}^{p}\frac{\Gamma(m+\frac{1}{2})}{\Gamma(m+\frac{1}{2}-k)}(G(\xi))^{m-1/2-k}A_{pk}(G^{(1)}(\xi),\cdots,G^{(p)}(\xi)) \end{aligned} \tag{4.6}$$

where (4.3) and (3.12) have been employed. From (4.4) and (4.5), (4.6) can be written as

$$\begin{aligned} r_p(\sqrt{z},x)&=(G(\xi))^{m-1/2}\sum_{k=1}^{p}\\ &\cdot\left(\frac{\Gamma(m+\frac{1}{2})}{\Gamma(m+\frac{1}{2}-k)}\sum\frac{\left(\frac{G^{(1)}(\xi)}{1!G(\xi)}\right)^{m_1}\left(\frac{G^{(2)}(\xi)}{2!G(\xi)}\right)^{m_2}\cdots\left(\frac{G^{(p)}(\xi)}{p!G(\xi)}\right)^{m_p}}{m_1!m_2!\cdots m_p!}\right) \end{aligned} \tag{4.7}$$

where, for each k, the inner sum in (4.7) sums over the solutions of (4.5). From (3.20) and (3.29)

$$\left(\frac{G^{(r)}(\xi)}{r!G(\xi)}\right)^{m_r}\leqq(A_r(z))^{m_r}\leqq\frac{1}{(r!)^{m_r}}\frac{1}{(2+\sqrt{z})^{rm_r}}. \tag{4.8}$$

Using (4.8) and (4.5) in the inner sum in (4.7) and taking absolute values then implies

$$|r_p(\sqrt{z},x)|\leqq\frac{(G(\xi))^{m-1/2}}{(2+\sqrt{z})^p}M_p \tag{4.9}$$

where

$$M_p = \sum_{k=1}^{p} \left(\left| \frac{\Gamma(m+\frac{1}{2})}{\Gamma(m+\frac{1}{2}-k)} \right| \sum \frac{\left(\frac{1}{1!}\right)^{m_1}\left(\frac{1}{2!}\right)^{m_2}\cdots\left(\frac{1}{p!}\right)^{m_p}}{m_1!\,m_2!\cdots m_p!} \right), \tag{4.10}$$

with, as before, the inner sum satisfying (4.5). The first three M_p's are given in (1.5). Noting that $0 \leqq \xi \leqq x$ in (4.9) and that $x = t^2 - z$, there exists some t_1, $\sqrt{z} \leqq t_1 \leqq t$, so that $\xi = t_1^2 - z$. With (3.7) and (4.2), (4.9) becomes

$$|\Delta_p(\sqrt{z}, t)| \leqq \frac{(\sigma(\sqrt{z}, t_1))^{m-1/2}}{(2+\sqrt{z})^p} M_p. \tag{4.11}$$

Now replace $\sqrt{z}$ by z. If $-\frac{1}{2} < m \leqq \frac{1}{2}$, then (3.2) in Lemma 1 gives (2.17). On the other hand, if $m > \frac{1}{2}$, the fact that $t \geqq t_1$ implies

$$\sigma(z, t_1) = G(t_1^2 - z^2) \leqq G(t^2 - z^2) = \sigma(z, t), \tag{4.12}$$

since G is an increasing function by (3.8). Lemma 1, (4.11), and (4.12) then yield (2.18).

5. Proof of (1.6) and comparison with Olver's result. From [8, p. 206], with $x > 0$,

$$K_\nu(x) = \left(\frac{\pi}{2x}\right)^{1/2} \frac{e^{-x}}{\Gamma(\nu+\frac{1}{2})} \int_0^\infty e^{-t} t^{\nu-1/2} \left(1+\frac{t}{2x}\right)^{\nu-1/2} dt, \tag{5.1}$$

so that, for $z > 0$,

$$K_{p+m}(uz) = \left(\frac{\pi}{2uz}\right)^{1/2} \frac{e^{-uz}}{\Gamma(p+m+\frac{1}{2})} \int_0^\infty e^{-t} t^{p+m-1/2} \left(1+\frac{t}{2uz}\right)^{p+m-1/2} dt, \tag{5.2}$$

while

$$e^{-(m-1/2)z} K_{p+m}\left(\left[u-\left(m-\frac{1}{2}\right)\right]z\right) = \left(\frac{\pi}{2[u-(m-\frac{1}{2})]z}\right)^{1/2} \frac{e^{-uz}}{\Gamma(p+m+\frac{1}{2})} \cdot \int_0^\infty e^{-t} t^{p+m-1/2} \left(1+\frac{t}{2[u-(m-\frac{1}{2})]z}\right)^{p+m-1/2} dt. \tag{5.3}$$

From (5.2) and (5.3) it follows that for $m > \frac{1}{2}$

$$1 < e^{-(m-1/2)z} \frac{K_{p+m}([u-(m-\frac{1}{2})]z)}{K_{p+m}(uz)}. \tag{5.4}$$

Since, for $\nu > 0$,

$$K_\nu(z) \sim \tfrac{1}{2}\Gamma(\nu)(\tfrac{1}{2}z)^{-\nu} \qquad (z \to 0) \tag{5.5}$$

[3, p. 252], (5.4) holds for z in $[0, \infty)$. Multiplying both sides of (5.2) by $(uz)^{p+m}$ and both sides of (5.3) by $[u-(m-\frac{1}{2})]^{p+m}$ implies

$$(uz)^{p+m} K_{p+m}(uz) > ([u-(m-\tfrac{1}{2})]z)^{p+m}\, e^{-(m-1/2)z} K_{p+m}([u-(m-\tfrac{1}{2})]z), \tag{5.6}$$

or

$$\frac{e^{-(m-1/2)z} K_{p+m}([u-(m-\frac{1}{2})]z)}{K_{p+m}(uz)} < \left(\frac{u}{u-(m-\frac{1}{2})}\right)^{p+m}. \tag{5.7}$$

As $z \to 0^+$, the inequality in (5.7) becomes an equality (see (5.5)). When we take this possibility into account, (5.4) and (5.7) give (1.6) for $m > \frac{1}{2}$ and z in $[0, \infty)$.

It is difficult to compare our result to earlier ones. Ursell's bounds [7] break down when z becomes unbounded. Olver [3, p. 465] provides a uniform asymptotic expansion with error bounds for $Q_n^m(\cosh z)$ for large n, fixed $m \geqq 0$, and z in a complex domain containing $[0, \infty)$, whereas we have provided a uniform asymptotic expansion with error bounds for $Q_n^{-m}(\cosh z)$ for large n, fixed $m+\frac{1}{2}>0$, and z in $[0, \infty)$. Although the connection formula (see [3, p. 178])

$$Q_n^{-m}(\cosh z) = e^{-2m\pi i}\frac{\Gamma(n-m+1)}{\Gamma(n+m+1)}Q_n^m(\cosh z) \tag{5.8}$$

relates $Q_n^{-m}(\cosh z)$ and $Q_n^m(\cosh z)$ the presence of the gamma function ratio makes it difficult to compare our bound with Olver's. Additionally, Olver's expansion involves only two Besssel functions, K_m and K_{m+1}, while our expansion involves all the Bessel functions K_{m+p}, $p = 0, 1, 2, \cdots$. Our expansion can be rearranged to agree with Olver's, but the simplicity of the error estimates (1.3), (1.4) is then lost. As in [6], our coefficients $d_\nu(z)$ (given in (2.16)) are simple to calculate, and because $d_\nu(z) = O(z^\nu)$, $(z \to 0)$, our expansion is useful for small z.

Perhaps the best we can do to compare the two expansions is to take the one-term approximation that each gives when, in our expansion, $-m \geqq 0$. This occurs when $-\frac{1}{2} < m \leqq 0$, so if we substitute $-m$ into Olver's expansion, with $0 \leqq -m < \frac{1}{2}$, we can compare the two (see [6] for a similar comparison). In this case, the one-term approximation obtained from our expansion is (see (1.1) and (1.3) with $p = 1$)

$$e^{mi\pi}Q_n^{-m}(\cosh z) = \left(\frac{z}{\sinh z}\right)^{1/2}\left[\frac{K_m(uz)}{u^m} + \varepsilon_1(z, u)\right] \tag{5.9}$$

where

$$|\varepsilon_1(z, u)| \leqq \frac{2z}{2+z}\left|m^2 - \frac{1}{4}\right|\frac{K_{m+1}(uz)}{u^{m+1}}. \tag{5.10}$$

Substituting $-m \geqq 0$ into the one-term approximation obtained from Olver's expansion gives (see [3, eqs. (12.13)-(12.15), with $p = 0$, p. 465])

$$e^{m\pi i}Q_n^{-m}(\cosh z) = \frac{1}{1+\delta_1}\left(\frac{z}{\sinh z}\right)^{1/2}\left[\frac{K_m(uz)}{u^m} + \frac{\eta_{1,2}(u, z^2)}{u^m}\right] \tag{5.11}$$

where we have used the fact that $K_{-m}(uz) = K_m(uz)$ [3, p. 252]. In (5.11) δ_1 is a constant satisfying

$$|\delta_1| \leqq \lambda_1(-m)\frac{|m^2-\frac{1}{4}|}{2u}\exp\left[\lambda_1(-m)\frac{|m^2-\frac{1}{4}|}{2u}\right] \tag{5.12}$$

and

$$\frac{|\eta_{1,2}(u, z^2)|}{u^m} \leqq \lambda_1(-m)K_m(uz)\exp\left[\frac{\lambda_1(-m)}{u}V_{z,\infty}\{zB_0^{-m}(z^2)\}\right]\frac{V_{z,\infty}\{zB_0^{-m}(z^2)\}}{u^{m+1}} \tag{5.13}$$

where

$$\lambda_1(-m) = \sup_{x\in(0,\infty)}\{2xI_{-m}(x)K_m(x)\}, \tag{5.14}$$

$$zB_0^{-m}(z^2) = \frac{-(m^2-\frac{1}{4})}{2}\left(\coth z - \frac{1}{z}\right), \tag{5.15}$$

and

$$V_{z,\infty}\{zB_0^{-m}(z^2)\} = \frac{|m^2-\frac{1}{4}|}{2}\int_z^\infty \left(\frac{1}{t^2}-\frac{1}{(\sinh t)^2}\right) dt. \tag{5.16}$$

Note that

$$V_{0,\infty}\{zB_0^{-m}(z^2)\} = \frac{|m^2-\frac{1}{4}|}{2}. \tag{5.17}$$

Olver assumes that $u = n+\frac{1}{2}$ is large enough so that $|\delta_1|<1$. To ensure this, from (5.12) it is sufficient to require that

$$\lambda_1(-m)\frac{|m^2-\frac{1}{4}|}{2u} < 0.567. \tag{5.18}$$

Since $V_{z,\infty}\{zB_0^{-m}(z^2)\} \leqq V_{0,\infty}\{zB_0^{-m}(z^2)\}$, from (5.17) and (5.18) it follows that

$$\exp\left[\frac{\lambda_1(-m)}{u} V_{z,\infty}\{zB_0^{-m}(z^2)\}\right] < 2. \tag{5.19}$$

With (5.19), (5.13) may be written as

$$\frac{|\eta_{1,2}(u,z^2)|}{u^m} \leqq 2\lambda_1(-m)K_m(uz)\frac{V_{z,\infty}\{zB_0^{-m}(z^2)\}}{u^{m+1}}. \tag{5.20}$$

Because of the presence of the variational operator (5.16) in Olver's bound (5.20), and the presence of the factor $2z/2+z$ in our bound (5.10), Olver's bound is more effective for large z while our bound is more effective for small z. To see this, note that for fixed m with $-\frac{1}{2}<m\leqq 0$, $\lambda_1(m)$ and $(1+\delta_1)^{-1}$ are constants. First, suppose $uz>1$. From [3, p. 250],

$$K_{m+1}(uz) = O\left(\left(\frac{\pi}{2uz}\right)^{1/2} e^{-uz}\right), \qquad K_m(uz) = O\left(\left(\frac{\pi}{2uz}\right)^{1/2} e^{-uz}\right). \tag{5.21}$$

Since $|m^2-\frac{1}{4}|>0$, (5.16) and (5.17) imply that

$$\frac{2z}{2+z} = o(V_{z,\infty}\{zB_0^{-m}(z^2)\}) \qquad (z\to 0^+). \tag{5.22}$$

Consequently, for small enough z, the bound in (5.10) is better than the bound in (5.20). However, when z is large, $V_{z,\infty}\{zB_0^{-m}(z^2)\} = O(1/z)$ while $2z/(2+z) = O(1)$ and the situation is reversed. Now suppose that $uz\leqq 1$. If z is small, from (5.5) with $(m+1)>0$,

$$\frac{2z}{2+z} K_{m+1}(uz) = O\left(\frac{2^m\Gamma(m+1)}{u^{m+1}z^m}\right). \tag{5.23}$$

For small z the variational operator (5.16) is $O(1)$, and for $-m>0$ (5.5) again gives

$$V_{z,\infty}\{zB_0^{-m}(z^2)\}K_m(uz) = O\left(\frac{2^{-m-1}\Gamma(-m)}{(uz)^{-m}}\right), \tag{5.24}$$

while if $-m=0$ (from [3, p. 252]),

$$V_{z,\infty}\{zB_0^{-m}(z^2)\}K_m(uz) = O(-\ln(uz)). \tag{5.25}$$

Because $m+1>-m$ (since $m>-\frac{1}{2}$), and $-m\geqq m$ (since $m\leqq 0$), comparing (5.23), (5.24), and (5.25) reveals that for small z the bound in (5.10) is more effective than

the bound in (5.20). On the other hand, if z is large and $uz \leqq 1$ (which is possible since $u = n + \frac{1}{2} > 0$ is all we require), then

$$\frac{2z}{2+z} K_{m+1}(uz) = O\left(\frac{2^m \Gamma(m+1)}{(uz)^{m+1}}\right). \tag{5.26}$$

When $-m > 0$,

$$V_{z,\infty}\{zB_0^{-m}(z^2)\} K_m(uz) = O\left(\frac{2^{-m-1}\Gamma(-m)}{(uz)^{-m} z}\right), \tag{5.27}$$

while if $-m = 0$, then

$$V_{z,\infty}\{zB_0^{-m}(z^2)\} K_m(uz) = O\left(\frac{-\ln(uz)}{z}\right). \tag{5.28}$$

Since $uz \leqq 1$, $(m+1) > -m$ and z is large, (5.26)-(5.28) indicate that for large z the bound in (5.20) is better than the bound in (5.10).

To conclude, as in [6] we can assess the bounds in (1.3) and (1.4) for all m by examining the ratio $R_p^{-m}(z, u)$ of these bounds to the first neglected term $d_p(z) K_{m+p}(uz)/u^{m+p}$. If $m = \frac{1}{2}$ the expansion truncates after the first term and all the rest are zero; see the remark following (2.16). If $-\frac{1}{2} < m < \frac{1}{2}$, using (1.3) and canceling a common factor gives

$$R_p^{-m}(z, u) = \frac{M_p (2z)^p/(2+z)^p}{(2z)^p \psi_p(z)} \tag{5.29}$$

where $\psi_p(z)$ is defined recursively in (2.8), $\psi_1(z)$ and $\psi_2(z)$ being given in (2.9) and (2.10). The above ratio is interesting because it leads to a comparison between the maximum absolute value of the error bound for z in $[0, \infty)$ and the maximum absolute value of the first neglected term for z in $[0, \infty)$; bounded z poses no problems. For any specific m satisfying $-\frac{1}{2} < m < \frac{1}{2}$ the maximum value of $(2z)^p |\psi_p(z)|$ in $[0, \infty)$ can be computed numerically. Since $\psi_p(z)$ is analytic in $[0, \infty)$ and $\psi_p(z) = O(z^{-p})$ as $z \to \infty$, this value is a finite nonzero number. On the other hand, the maximum value of $(2z)^p/(2+z)^p$ in $[0, \infty)$ is 2^p. Letting $\tilde{R}_p^{-m}$ denote the ratio of the maxima of the absolute values of the numerator and the denominator in (5.29) over $[0, \infty)$, it follows that $\tilde{R}_p^{-m}$ is finite for each $p \geqq 1$. It is also evident from (5.29) that the error bound in (1.3) mimics the behavior of the first neglected term near both $z = 0$ and $z = \infty$.

For $m > \frac{1}{2}$, the ratio of the bound in (1.4) to the first neglected term is

$$\begin{aligned} R_p^{-m}(z, u) = &\left(\frac{M_p (2z)^p/(2+z)^p}{(2z)^p \psi_p(z)}\right)\left(\frac{e^{-(m-1/2)z} K_{p+m}([u-(m-\frac{1}{2})]z)}{K_{p+m}(uz)}\right) \\ &\cdot \left(\frac{u}{u-(m-\frac{1}{2})}\right)^{m+p}. \end{aligned} \tag{5.30}$$

By (1.6) the middle factor in (5.30) is finite for all z in $[0, \infty)$ and all $p \geqq 1$ and the same is also true for the last factor. By the previous argument, the ratio of the maxima of the absolute values of the numerator and denominator in the first factor in (5.30) over $[0, \infty)$ is also finite for each $p \geqq 1$. Furthermore, from (5.30) and (1.6) it follows that the error bound in (1.4) mimics the behavior of the first neglected term near both $z = 0$ and $z = \infty$.

Finally, we remark that the presence of factors like $[u-(m-\frac{1}{2})]^{-(m+p)}$ in the error bound (1.4) frequently occurs in asymptotics (see [3, p. 89, (9.02)], for example), and serves here as a reminder that two competing exponential factors appear in the integrand

of the integral representation (2.1), one growing like $e^{(m-1/2)t}$ for $m > \frac{1}{2}$, the other decaying like e^{-ut}.

FUNCTIONAL INEQUALITIES FOR COMPLETE ELLIPTIC INTEGRALS AND THEIR RATIOS*

G. D. ANDERSON,† M. K. VAMANAMURTHY,‡ AND M. VUORINEN§

Abstract. Some functional inequalities satisfied by complete elliptic integrals of the first kind are obtained. These inequalities are sharp and generalize the functional identity of Landen. A related inequality is given for certain quotients of such integrals.

Key words. complete elliptic integral, quasiconformal mapping, functional inequality, Teichmüller ring, Grötzsch ring

AMOS(MOS) subject classifications. primary 33A25, 33A70; secondary 30C60

1. Introduction.

For $0<r<1$ the functions

$$K(r)=\int_0^{\pi/2}(1-r^2\sin^2 t)^{-1/2}\,dt,\quad K'(r)=K(r'),\quad r'=\sqrt{1-r^2}, \tag{1.1}$$

$$E(r)=\int_0^{\pi/2}(1-r^2\sin^2 t)^{1/2}\,dt,\quad E'(r)=E(r'),\quad r'=\sqrt{1-r^2} \tag{1.2}$$

are known as complete elliptic integrals of the first and second kind, respectively [BF], [Bo], [BB2], and their values are listed in standard tables (e.g., [AS], [Fr]). The special combinations

$$\mu(r)=\frac{\pi}{2}\frac{K'(r)}{K(r)},\quad \gamma(s)=\frac{2\pi}{\mu(r)},\quad r=\frac{1}{s} \tag{1.3}$$

are particularly important in quasiconformal analysis (cf. [LV]).

The elliptic integral $K(r)$ satisfies the following basic identities due to Landen [BF, #163.01, 164.02] (cf. [WW, p. 507]):

$$K\left(\frac{2\sqrt{r}}{1+r}\right)=(1+r)K(r),\qquad K\left(\frac{1-r}{1+r}\right)=\frac{1}{2}(1+r)K'(r), \tag{1.4}$$

while the function $\mu(r)$ satisfies the identities

$$\mu(r)\mu(\sqrt{1-r^2})=\frac{\pi^2}{4},\quad \mu(r)\mu\left(\frac{1-r}{1+r}\right)=\frac{\pi^2}{2},\quad \mu(r)=2\mu\left(\frac{2\sqrt{r}}{1+r}\right) \tag{1.5}$$

(cf. [LV, Forms. (2.7), (2.9), (2.3), pp. 60, 61]). The first identity in (1.5) follows directly from definition (1.1), while the other two follow from (1.4). It is also well known that

$$\log\frac{1}{r}<\mu(r)<\log\frac{4}{r} \tag{1.6}$$

for $0<r<1$ [LV, Form. (2.10), p. 61].

In this paper we study some properties of the functions $K(r)$ and $\mu(r)$. These special functions are important in the theory of quasiconformal mappings in the plane [LV] and in n-space [AVV1]-[AVV4], [Vu2]. In the present paper we prove certain functional inequalities for $K(r)$ and $\mu(r)$ by analytic arguments (mainly well-known properties of $K(r)$). Our work is motivated in part by certain functional inequalities, valid for higher-dimensional analogues of $\mu(r)$, which were proved in [Vu1] by geometric arguments. Our main results are as follows.

THEOREM 1.7. *For $r, a, b \in (0,1)$, the functions $K(r)$, $K'(r)$ satisfy the functional inequalities*

$$K(\sqrt{r}) < (1+r)K(r), \tag{1.8}$$

$$(1+r)K'(r) < 2K'(\sqrt{r}), \tag{1.9}$$

$$K\left(\frac{2\sqrt[4]{ab}}{\sqrt{(1+a)(1+b)}}\right) \leqq (1+\sqrt{ab})K(\sqrt{ab}), \tag{1.10}$$

$$2K'\left(\frac{2\sqrt[4]{ab}}{\sqrt{(1+a)(1+b)}}\right) \geqq (1+\sqrt{ab})K'(\sqrt{ab}). \tag{1.11}$$

There is equality in (1.10) *and* (1.11) *if and only if $a=b$, while* (1.8) *and* (1.9) *hold with equality at $r=0,1$, respectively, and* (1.9) *is asymptotically sharp at $r=0$.*

THEOREM 1.12. *For $a, b \in (0,1)$,*

$$\mu(a)+\mu(b) \leqq \mu\left(\frac{ab}{(1+\sqrt{1-a^2})(1+\sqrt{1-b^2})}\right) \leqq 2\mu(\sqrt{ab}).$$

In each case equality holds if and only if $a=b$.

Throughout this paper, for $t \in [0,1]$, t' will denote $\sqrt{1-t^2}$, as in (1.1) and (1.2). When the argument of the function is clear, we will frequently write K, K' and E, E' instead of $K(r)$, $K'(r)$ and $E(r)$, $E'(r)$. We will follow the relatively standard notation of [LV].

2. Properties of the function $K(r)$. The following differentiation formulas will be useful in our work.

LEMMA 2.1. *For $0<r<1$,*

$$(1) \qquad \frac{d}{dr}\frac{K'(r)}{K(r)} = \frac{-\pi}{2rr'^2K(r)^2},$$

$$(2) \qquad \mu'(r) = \frac{-\pi^2}{4rr'^2K(r)^2},$$

where $K(r)$, $\mu(r)$ are as in (1.1) *and* (1.3), *respectively.*

Proof. Formula (1) appears in [C, p. 217] and [E, p. 445]. It may also be obtained from the differentiation formula for $K(r)$ ([BF, #710.00], [Bo, p. 21]) and Legendre's relation ([BF, #110.10], [Bo, p. 25]). Formula (2) follows immediately from (1) and (1.3). □

THEOREM 2.2. *As a function of r,*

(1) *$K(r)$ is strictly increasing from $(0,1)$ onto $(\pi/2, \infty)$. Moreover, $f_1(r) \equiv K(r)+c\log r$ is increasing if and only if $c \geqq 0$; there is no c for which $f_1(r)$ is decreasing.*

(2) *$K(r)+\log r'$ is strictly decreasing from $(0,1)$ onto $(\log 4, \pi/2)$, and $K(r)+GG(\pi/4)\log r'$ is strictly increasing from $(0,1)$ onto $(\pi/2, \infty)$. Moreover, $f_2(r) \equiv K(r)+c\log r'$ is increasing if and only if $c \leqq \pi/4$ and decreasing if and only if $c \geqq 1$.*

(3) *$r'K(r)^2$ is strictly decreasing from $[0,1)$ onto $(0, \pi^2/4]$.*

(4) *Let* $f(r) = r' \exp(r^2K/(E - r'^2K))$, $0 < r < 1$, *and* $f(0) = e^2$, $f(1) = 4$. *Then* f *is strictly decreasing from* $[0, 1]$ *onto* $[4, e^2]$. *In particular, for* $0 < r < 1$,

$$4 < r' \exp(r^2K/(E - r'^2K)) < e^2,$$

and these bounds are sharp as r *tends to one, zero, respectively.*

(5) $K(r)/\log(4/r')$ *is strictly decreasing from* $(0, 1)$ *onto* $(1, \pi/\log 16)$, *and* $K(r)/\log(e^2/r')$ *is strictly increasing from* $(0, 1)$ *onto* $(\pi/4, 1)$. *Moreover,* $f_3(r) \equiv K(r)/\log(c/r')$ *is strictly decreasing if and only if* $0 < c \leqq 4$ *and strictly increasing if and only if* $c \geqq e^2$. *In particular, for* $0 < r < 1$,

$$\log(4/r') \leqq K(r) \leqq (\pi/\log 16)\log(4/r'),$$

$$(\pi/4)\log(e^2/r') \leqq K(r) \leqq \log(e^2/r').$$

(6) $r \exp(\pi K'/2K)$ *is strictly decreasing from* $(0, 1)$ *onto* $(1, 4)$.

(7) $r^{-2}(E - r'^2K)$ *is strictly increasing from* $(0, 1)$ *onto* $(\pi/4, 1)$.

(8) $K(r)K'(r)$ *is strictly decreasing on* $(0, 1/\sqrt{2}]$ *and strictly increasing on* $[1/\sqrt{2}, 1)$.

(9) $K(r)^{-2} + K'(r)^{-2}$ *has its absolute maximum on* $(0, 1)$ *at* $1/\sqrt{2}$.

Proof. The first statement in part (1) follows directly from definition (1.1). For the stronger statement we note by [BF, #710.00] that $f_1(r)$ is increasing on $(0, 1)$

$$\Leftrightarrow (E - r'^2K)/(rr'^2) + c/r \geqq 0, \qquad 0 < r < 1$$

$$\Leftrightarrow -c \leqq \inf\{(E - r'^2K)/r'^2 : 0 < r < 1\} = 0$$

$$\Leftrightarrow c \geqq 0.$$

Similarly, $f_1(r)$ cannot be decreasing since this would require $c \leqq -\sup\{(E - r'^2K)/r'^2 : 0 < r < 1\} = -\infty$.

The first monotonicity property in (2) was proved in [AV, Form. (2)], and from this the limits $f_2(0+)$ and $f_2(1-)$ when $c = \pi/4$ are clear. For the rest of (2) we note that $f_2'(r) \geqq 0$ on $(0, 1)$

$$\Leftrightarrow (E - r'^2K)/(rr'^2) - cr/r'^2 \geqq 0, \qquad 0 < r < 1$$

$$\Leftrightarrow c \leqq \inf\{(E - r'^2K)/r^2 : 0 < r < 1\} = \pi/4$$

and $f_2'(r) \leqq 0$

$$\Leftrightarrow c \geqq \sup\{(E - r'^2K)/r^2 : 0 < r < 1\} = 1 \text{ [AV, Form. (1)]}.$$

For (3), let $f(r) = r'K(r)^2$. By [BF, #710.00] we may write $f'(r) = K(r)g(r)/(rr')$, where $g(r) \equiv (E - r'^2K) + (E - K)$. But it is easy to see that $g(0) = 0$ and $g'(r) = rK - rE/r'^2 < 0$ on $(0, 1)$ [BF, #710.04, 710.05], hence $f'(r) < 0$ on $(0, 1)$. Clearly $f(0) = \pi^2/4$ and $f(1-) = 0$.

In part (4), if we let $g(r) = \log f(r)$ we get, after simplification [BF], $g'(r) = rK(E - r'^2K)^{-2}[(E - r'^2K) - (K - E)]$. Since $(E - r'^2K) = 0 = (K - E)$ when $r = 0$ and since $(d/dr)[(E - r'^2K) - (K - E)] = r'^{-2}(r'^2K - E) < 0$, it follows that $g'(r) < 0$ on $(0, 1)$ and that f is decreasing. The limit $f(0+) = e^2$ follows from [AV, Form. (1)]. For $f(1-) = 4$ it is sufficient to prove that $\lim_{r\to 1}[r^2/(E - r'^2K) - 1]K = 0$, since by [BF, #112.01] we know that $\lim_{r\to 1} r'\, e^K = 4$. First, as r tends to 1,

$$h(r) \equiv \left[\frac{r^2}{E - r'^2K} - 1\right]K = \frac{r^2}{E - r'^2K}\left[1 - \frac{E - r'^2K}{r^2}\right]K \sim [r^2 - E + r'^2K]K$$

by [AV, p. 62, line 1]. But $r'^2K^2 \to 0$ as $r \to 1$ by (3). So $h(r) \sim (r^2 - E)K$ as $r \to 1$. Then, by l'Hôpital's rule, [BF, #710], [AV, Form. (1)], and (3) we have

$$(r^2 - E)K = \frac{r^2 - E}{1/K} \sim \frac{2r - (E-K)/r}{-K^{-2}(E - r'^2K)/(rr'^2)} = \frac{[2 - (E-K)/r^2]r'^2K^2}{-(E - r'^2K)/r^2}$$

$$\sim [(E-K)/r^2 - 2](r'K)^2 \sim -r'^2K^3 = -\frac{(r'K^2)^2}{K} \to 0.$$

Parts (6) and (7) and the first monotonicity property in (5) were proved in (1), (3), and (4), respectively, of [AV]. The assertions about $K(r)/\log(e^2/r')$ in (5) follow from the properties of $K(r)/\log(4/r')$. The remainder of (5) follows from (4) since $f_3'(r) \leqq 0$ on (0, 1)

$$\Leftrightarrow (\log(c/r'))^2 f_3'(r) = (\log(c/r'))(E - r'^2K)/(rr'^2) - rK/r'^2 \leqq 0, \qquad 0 < r < 1$$

$$\Leftrightarrow c \leqq \inf\{r' \exp((r^2K)/(E - r'^2K)) : 0 < r < 1\} = 4,$$

and

$$f_3'(r) \geqq 0, \qquad 0 < r < 1 \Leftrightarrow c \geqq \sup\{r' \exp(r^2K/(E - r'^2K)) : 0 < r < 1\} = e^2.$$

For (8), by [BF, #710.00] we have

$$\frac{d}{dr}(K(r)K'(r)) = \frac{1}{rr'^2}[F(r) - F(r')],$$

where

$$F(r) = K'(E - r'^2K) = r^2K' \int_0^{\pi/2} \frac{\cos^2 t}{\sqrt{1 - r^2 \sin^2 t}}\, dt.$$

It follows from (3) that $r'^2K(r)$ is strictly decreasing on [0, 1), and hence that $r^2K'(r)$ is strictly increasing there. Thus $F(r)$, as the product of two positive strictly increasing functions, is strictly increasing on (0, 1). Hence $F(r) - F(r')$ is negative when $0 < r < 1/\sqrt{2}$ and positive when $1/\sqrt{2} < r < 1$.

Finally, for (9), let $G(r) = K(r)^{-2} + K'(r)^{-2}$, $0 < r < 1$. Then by [BF, #710.00] we have

$$G'(r) = \frac{-2}{rr'^2}\left[\frac{E - r'^2K}{K^3} - \frac{E' - r^2K'}{K'^3}\right],$$

which is zero when $r = 1/\sqrt{2}$. It is easy to see that $G'(r) = 0$ if and only if

$$\frac{r^2K'^3}{r'^2K^3} = \frac{\int_0^{\pi/2} ((\cos^2 t)/\sqrt{1 - r'^2 \sin^2 t})\, dt}{\int_0^{\pi/2} ((\cos^2 t)/\sqrt{1 - r^2 \sin^2 t})\, dt}.$$

But the right side of this last equation is obviously decreasing for $r \in (0, 1)$, while by (3) the left side is increasing there. Since $G(0+) = G(1-) = 4/\pi^2 \approx 0.4053 < 0.5818 \approx 2/K(1/\sqrt{2})^2 = G(1/\sqrt{2})$, we have $\max_{0<r<1} G(r) = G(1/\sqrt{2})$. □

COROLLARY 2.3. *For* $0 < r < 1$, $K(r) \leqq (\pi/2)\log(e/r')$.

Proof. From 2.2(5) we have

$$K(r) - \frac{\pi}{2}\log\left(\frac{e}{r'}\right) \leqq \frac{\pi}{\log 16}\log\frac{4}{r'} - \frac{\pi}{2}\log\frac{e}{r'} = \frac{\pi \log(1/r')}{\log 16}(1 - \log 4) < 0. \qquad \square$$

Remarks 2.4. (1) Theorem 2.2(3) is a best possible result, in the sense that if $c > 0$ then $f(r) \equiv r'K(r)^{2+c}$ is not monotone on [0, 1). For we can then show that $f'(r) = K^{1+c}g(r)/(rr')$, where $g(r) \equiv -r^2K + (2+c)(E - r'^2K)$. Moreover, $g'(r) = rh(r)/r'^2$, where $h(r) \equiv (c+1)r'^2K - E$. Then $h(0) = c\pi/2 > 0$ and $h(1) = -1 < 0$. Thus there exists $\delta > 0$ such that $f'(r) > 0$ on $(0, \delta)$ and $f'(r) < 0$ on $(1 - \delta, 1)$.

(2) By combining Theorem 2.2(5) with the first transformation in (1.4) we may easily show that K satisfies the inequality

$$K(r) \geqq \frac{1}{1+r} \log\left(4\frac{1+r}{1-r}\right), \qquad 0<r<1. \tag{2.5}$$

This procedure may be repeated; the second time, for example, it leads to the inequality

$$K(r) \geqq \frac{2}{(1+\sqrt{r})^2} \log\left(2\frac{1+\sqrt{r}}{1-\sqrt{r}}\right), \qquad 0<r<1. \tag{2.6}$$

2.7. *Proof of Theorem* 1.7. First we note that $\sqrt{r}<2\sqrt{r}/(1+r)$ for $r\in(0,1)$. Then since K is strictly increasing on $[0,1)$, (1.8) follows from the first identity in (1.4). Since K' is strictly decreasing on $(0,1]$, the second identity in (1.4) implies (1.9). The equality statements for (1.8) and (1.9) follow from the fact that $K(0)=\pi/2=K'(1)$, while the assertion about asymptotic sharpness is a consequence of [BF, #112.01].

For (1.10) we first observe that $(1+a)(1+b)\geqq(1+\sqrt{ab})^2$ for $a, b>0$. Then it follows from the first identity in (1.4) that

$$K\left(\sqrt{\frac{4\sqrt{ab}}{(1+a)(1+b)}}\right) \leqq K\left(\frac{2\sqrt[4]{ab}}{1+\sqrt{ab}}\right) = (1+\sqrt{ab})K(\sqrt{ab}). \tag{2.8}$$

Again, since K' is decreasing and $(1+a)(1+b)\geqq(1+\sqrt{ab})^2$ for $a, b>0$, we have by (1.4)

$$K'\left(\frac{2\sqrt[4]{ab}}{\sqrt{(1+a)(1+b)}}\right) \geqq K'\left(\frac{2\sqrt[4]{ab}}{1+\sqrt{ab}}\right) = K\left(\frac{1-\sqrt{ab}}{1+\sqrt{ab}}\right) = \frac{1+\sqrt{ab}}{2} K'(\sqrt{ab}).$$

Since K is strictly increasing, there is equality in (1.10) if and only if the first two arguments in (2.8) are equal, and it is easy to show that this occurs if and only if $a=b$. Similarly, there is equality in (1.11) if and only if $a=b$. □

COROLLARY 2.9. *For* $a, b\in(0,1)$,

$$\frac{(1+a')(1+b')}{2(1+a'b')} < \frac{K(ab/((1+a')(1+b')))}{K(ab/(1+a'b'))} < 1.$$

Proof. The upper bound is trivial since $(1+a')(1+b')>1+a'b'$. For the lower bound, we have

$$K\left(\frac{ab}{(1+a')(1+b')}\right) = K\left(\frac{\sqrt{(1-a')(1-b')}}{\sqrt{(1+a')(1+b')}}\right) > K\left(\frac{(1-a')(1-b')}{(1+a')(1+b')}\right),$$

and the second identity in (1.4) yields

$$\begin{aligned} K\left(\frac{(1-a')(1-b')}{(1+a')(1+b')}\right) &= K\left(\frac{1-(a'+b')/(1+a'b')}{1+(a'+b')/(1+a'b')}\right) \\ &= \frac{1}{2}\left(1+\frac{a'+b'}{1+a'b'}\right) K'\left(\frac{a'+b'}{1+a'b'}\right) \\ &= \frac{1}{2}\frac{(1+a')(1+b')}{1+a'b'} K\left(\frac{ab}{1+a'b'}\right). \end{aligned}$$

□

3. Properties of the function μ. In [AVV3] we obtained some properties of the n-dimensional analogue of μ for all $n\geqq 2$. Now, using the explicit formula for $\mu(r)$ in (1.3), we obtain some stronger properties for the case $n=2$.

3.1. *Proof of Theorem* 1.12. The second inequality is a special case of [AVV3, Form. (1.24)]. Next, by [AVV3, Form. (1.22)] and the third identity in (1.5) we have

$$\mu\left(\frac{2\sqrt{r}}{1+r}\right)+\mu\left(\frac{2\sqrt{s}}{1+s}\right)\leqq\mu(\sqrt{rs}).$$

Setting $a=2\sqrt{r}/(1+r)$ and $b=2\sqrt{s}/(1+s)$ then gives the first inequality.

Since this argument shows that the theorem is equivalent to [AVV3, Form. (1.22)] when $n=2$, it is sufficient to prove the equality statement for [AVV3, Form. (1.22)] with $n=2$. But by the third identity in (1.5) we have, with $a=\cos(2x)$, $b=\cos(2y)$, $x, y\in[0, \pi/4]$,

$$\mu(a)+\mu(b)=2\mu(\sqrt{ab})\Leftrightarrow\sqrt{(1+a')(1+b')}+\sqrt{(1-a')(1-b')}=2$$
$$\Leftrightarrow\cos(x-y)=1\Leftrightarrow x=y\Leftrightarrow a=b. \qquad \square$$

Remark 3.2. Alternatively, we could prove Theorem 1.12 by using derivatives of elliptic integrals.

THEOREM 3.3. *For* $0<r<1$,

$$\mu(r^2)\mu\left(\left(\frac{1-r}{1+r}\right)^2\right)=\pi^2 \tag{3.4}$$

and for each integer $k\geqq 2$,

$$2^{k-1}\pi^2<\mu(r^{2^k})\mu\left(\left(\frac{1-r}{1+r}\right)^{2^k}\right)<2^{2k-1}\pi^2. \tag{3.5}$$

The first bound in (3.5) *is asymptotically sharp as r tends either to zero or to one.*

Proof. First, by the third and second identities in (1.5),

$$\mu(r^2)\mu\left(\left(\frac{1-r}{1+r}\right)^2\right)=2\mu(r^2)\mu\left(\frac{1-r^2}{1+r^2}\right)=\pi^2.$$

Next, suppose $k=2$. Then by (1.5), (3.4), and the fact that μ is strictly decreasing we have

$$\mu(r^4)\mu\left(\left(\frac{1-r}{1+r}\right)^4\right)=2\mu(r^4)\mu\left(\frac{(1-r^2)^2}{1+6r^2+r^4}\right)>2\mu(r^4)\mu\left(\left(\frac{1-r^2}{1+r^2}\right)^2\right)=2\pi^2.$$

Next, for the upper bound, from Theorem 1.12 and (3.4) we get

$$\mu(r^4)\mu\left(\left(\frac{1-r}{1+r}\right)^4\right)\leqq 4\mu(r^2)\mu\left(\left(\frac{1-r}{1+r}\right)^2\right)=4\pi^2<8\pi^2.$$

Now suppose that $n=2^k$, where $k\geqq 2$ is an integer for which (3.5) is true. Then by the third identity in (1.5)

$$\mu\left(\left(\frac{1-r}{1+r}\right)^{2n}\right)=2\mu\left(\frac{2(1-r^2)^n}{(1+r)^{2n}+(1-r)^{2n}}\right)>2\mu\left(\left(\frac{1-r^2}{1+r^2}\right)^n\right),$$

since

$$\binom{2n}{2l}\geqq\binom{n}{l}$$

for $0\leqq l\leqq n$ with equality only if $l=0$ or n. The first inequality in (3.5) now follows by the second identity in (1.5) and by mathematical induction.

Finally, for the upper bound in (3.5) we again use induction:

$$\mu(r^{2n})\mu\left(\left(\frac{1-r}{1+r}\right)^{2n}\right)=\mu((r^n)^2)\mu\left(\left(\left(\frac{1-r}{1+r}\right)^n\right)^2\right)\leqq 2\mu(r^n)\cdot 2\mu\left(\left(\frac{1-r}{1+r}\right)^n\right)$$
$$\leqq 4\cdot 2^{2k-1}\pi^2$$
$$=2^{2(k+1)-1}\pi^2.$$

The asymptotic limits are a consequence of [AVV3, Lemma 2.6(2), (4)]. □

THEOREM 3.6. *If $0<r<1$ and $m=2^k$, where $k\geqq 2$ is an integer, then*

$$m<\frac{\mu(((1-r)/(1+r))^m)}{\mu((1-r^m)/(1+r^m))}<m^2.$$

Proof. The proof follows by (3.5) and the second identity in (1.5). □

THEOREM 3.7. *For $0<r<1$, $r'\log(4/r)<\mu(r)<\log(4/r)$. These estimates are sharp as r tends to zero.*

Proof. The second estimate is contained in (1.6). The first follows from Theorem 2.2(3),(5), which says that

$$\frac{\mu(r)}{r'\log(4/r)}=\frac{\pi}{2r'K(r)}\frac{K'(r)}{\log(4/r)}$$

is strictly increasing from $(0,1)$ onto $(1,\infty)$. □

COROLLARY 3.8. *For $a, b\in(0,1)$,*

$$\mu(a)<2\mu(\sqrt{a}), \tag{3.9}$$

$$\mu(\sqrt{ab})\leqq 2\mu\left(\frac{2\sqrt[4]{ab}}{\sqrt{(1+a)(1+b)}}\right). \tag{3.10}$$

There is equality in (3.10) if and only if $a=b$.

Proof. For (3.9), divide (1.9) by (1.8). For (3.10), divide (1.11) by (1.10). The equality in (3.10) follows from the third identity in (1.5). □

4. Properties of the graph of μ. The following lemma will be needed in this section.

LEMMA 4.1. *Let $g:[0,1]\to[0,\infty)$ be continuous and (strictly) convex with $g(0)=0$, and let g be differentiable on $(0,1)$. Then $g(r)/r$ is (strictly) increasing on $(0,1]$.*

Proof. By the Mean Value Theorem,

$$\frac{d}{dr}\left(\frac{g(r)}{r}\right)=\frac{1}{r}\left(g'(r)-\frac{g(r)}{r}\right)=\frac{1}{r}(g'(r)-g'(r_1))\geqq 0,$$

where $0<r_1<r$. □

The function introduced in the next lemma behaves very much like μ (cf. [AVV3, Lemma 2.6, Cor. 2.8] as well as Theorem 4.3 below) and will be useful in the study of μ.

LEMMA 4.2. *For $0<r<1$ let $m(r)\equiv(2/\pi)r'^2K(r)K'(r)$. Then:*

(1) *$m(r)+\log r$ is a strictly decreasing concave function from $(0,1)$ onto $(0,\log 4)$.*
(2) *$m(r)/\log(1/r)$ is strictly increasing from $(0,1)$ onto $(1,\infty)$.*
(3) *$m(r)/\log(4/r)$ is strictly decreasing from $(0,1)$ onto $(0,1)$.*
(4) *$(\log(4/r)-m(r))/r$ is strictly increasing from $(0,1)$ onto $(0,\infty)$.*
(5) *$\log(1/r)<m(r)<r'\log(4/r)<\mu(r)<\log(4/r)$.*

Proof. For (1) let $f(r)=m(r)+\log r$. Then by differentiation [BF, #710.00] and by Legendre's relation [BF, #110.10] we have

$$-f'(r)=\frac{4}{\pi r}K'(K-E)=\frac{4}{\pi}rK'\int_0^{\pi/2}\frac{\sin^2 t}{\sqrt{1-r^2\sin^2 t}}\,dt,$$

which is positive and increasing on $(0, 1)$, while $f(1-)=0$ by Theorem 2.2 and [BF, #111.02]. Moreover, by [BF, #112.01] or [Bo, p. 21, Form. (20)] and the fact that

$$\frac{2}{\pi} r'^2 K - 1 = -r^2 + O(r^2)$$

([BF, #900.00], [Bo, p. 21]), we have

$$f(0+) = \frac{2}{\pi} \lim_{r\to 0} r'^2 K(K' + \log r) + \lim_{r\to 0} \left(\log \frac{1}{r}\right)\left(\frac{2}{\pi} r'^2 K - 1\right) = \log 4.$$

For part (2), setting $g(r) = m(r)/\log(1/r)$, differentiating, and using Legendre's relation [BF, #110.10] we get

$$\frac{\pi}{2} r \left(\log \frac{1}{r}\right)^2 g'(r) = \left(2E'K - \frac{\pi}{2}\right) F(r),$$

where

$$F(r) \equiv \log r + \frac{r'^2 KK'}{2E'K - \pi/2}.$$

Similarly, by [BF, #710.00, 710.02, 110.10],

$$F'(r) = \frac{2KK'}{r} \frac{(K-E)E' - r^2 KK'}{(2E'K - \pi/2)^2},$$

where

$$(K-E)E' - r^2 KK' \leqq r^2 K(E' - K') < 0$$

since $K - E < r^2 K$ and $E' < K'$ on $(0, 1)$ [BF, #110.06, 110.07]. Thus $F'(r) < 0$, so that $F(r) > F(1) = 0$ for $0 < r < 1$. Since $2E'K > \pi$, this implies that $g'(r) > 0$ on $(0, 1)$. The limit as r tends to zero follows from [BF, #111.02, 112.01]; the limit as r tends to one follows from l'Hôpital's rule.

From (1) it follows that $\log(4/r) - m(r)$ is a strictly increasing and convex function from $(0, 1)$ onto $(0, \log 4)$. Then (3) follows when we divide by $\log(4/r)$, and (4) follows from Lemma 4.1.

Finally, because of (2), (1.6), and Theorem 3.7, we need only prove the second inequality in (5). For this we define $f(r) = \log(4/r) - (2/\pi) r' KK'$. Then writing

$$f(r) = -(K' - \log(4/r)) + K'(1-r') + r'K'(1 - (2/\pi)K)$$

and using Theorem 2.2(2) and [BF, #900.00] gives $f(0+) = 0$, while

$$f'(r) = -\frac{1}{r} + \frac{1}{rr'} + \frac{2K'}{\pi rr'}[(K-E) - (E - r'^2 K)]$$

by [BF, #710.00] and Legendre's relation. With $g(r) \equiv (K-E) - (E - r'^2 K)$, we have $g(0) = 0$ and

$$g'(r) = \frac{r}{r'^2} - rK = \frac{r}{r'^2}(E - r'^2 K) > 0.$$

Thus $g(r) > 0$ on $(0, 1)$, hence $f'(r) > 0$ on $(0, 1)$, and (5) follows. □

THEOREM 4.3. (1) *The function $\mu(r)$ is strictly decreasing, has exactly one inflection point on $(0, 1)$ and satisfies $\mu'(0+) = -\infty = \mu'(1-)$.*

(2) *The function $g(r) \equiv \mu(r) + \log r$ is strictly decreasing and concave on $(0, 1)$ and satisfies $g'(0+) = 0$, $g'(1-) = -\infty$.*

(3) *The function $h(r) \equiv \mu(r) + \log(r/r')$ is strictly increasing and convex on $(0, 1)$ and satisfies $h'(0+) = 0$, $h'(1-) = \infty$.*

(4) *The function* $\mu(r)/\log(1/r)$ *is strictly increasing but is neither convex nor concave on* $(0,1)$.

(5) *The function* $\mu(r)/\log(4/r)$ *is strictly decreasing and concave on* $(0,1)$.

(6) *The function* $1/\mu(r)$ *is strictly increasing and has exactly one inflection point on* $(0,1)$.

Proof. The monotonicity in parts (1), (2), and (6) is well known ([LV, Lemma 6.3], [G1, Lemma 6], [A, §§ 8, 9]; cf. [AVV3, Proof of Lemma 2.6(1)]), and in the others it follows from [AVV3, Lemma 2.6]. The limits $\mu'(0+) = -\infty = \mu'(1-)$ follow immediately from Lemma 2.1 and Theorem 2.2. Next, let $f(r) = r(1-r^2)K(r)^2$ be the denominator function in the formula for $\mu'(r)$ in Lemma 2.1. By [BF, #710.00],

$$f'(r) = K(r)[-(1+r^2)K(r)+2E(r)],$$

where E is as in (1.2). Then by [BF, #111.02, 111.03, 111.05] or [Bo, p. 20] we have $f'(0+) = \pi^2/4$ and $f'(1-) = -\infty$. The intermediate value theorem implies that there exists at least one $r_0 \in (0,1)$ such that $f'(r_0) = 0 = \mu''(r_0)$, and there is at most one such r_0 because $f'(r)/K(r)$ is strictly decreasing. Thus μ is convex on $(0, r_0]$ and concave on $[r_0, 1)$.

For part (2), using Lemma 2.1 and [BF, #112.01] (cf. [Bo, p. 21]), we see that $g'(1-) = -\infty$, while Lemma 2.1, [BF, #710.00], l'Hôpital's rule, and [BF, #710.05] give

$$\lim_{r\to 0} g'(r) = \lim_{r\to 0} \frac{4}{\pi^2 r}(E(r)-K(r)) = \lim_{r\to 0} \frac{-4rE(r)}{\pi r'^2} = 0.$$

Then by Lemma 2.1, [BF, #710.00], and the fact that $K(r) \geqq \pi/2$,

$$g''(r) \leqq \frac{\pi^2}{4r^2r'^4K^3}[(-2+r^2-r^4)K+2E].$$

Let $F(r) = (-2+r^2-r^4)K+2E$. Then $F(0) = 0$ by [BF, #111.02], while

$$r'^2F'(r) = -r[E-r'^2K+r^2(E+3r'^2K)] < 0$$

by [AV, Form. (1)].

The limits in part (3) follow from part (2). Next, by Lemma 2.1,

$$h'(r) = \frac{1}{rr'^2}\left(\frac{-\pi^2}{4K(r)^2}+1\right) > 0, \qquad 0<r<1,$$

since $K(r) > \pi/2$. For convexity it is sufficient to show that $G(r) \equiv (1-\pi^2/(4K(r)^2))/r$ is increasing. It is easy to show that $G'(r) > 0$ if and only if $(2E(r)-r'^2K(r))-4K(r)^3r'^2/\pi^2 > 0$. But this follows from Theorem 2.2 and the fact that

$$r\frac{d}{dr}(2E(r)-r'^2K(r)) = E(r)-r'^2K(r) > 0$$

for $0<r<1$ [BF, #710.04, 710.02]. Hence part (3) follows.

Next, for part (4),

$$\frac{d}{dr}\left(\frac{\mu(r)}{\log(1/r)}\right) = \frac{\pi^2((2/\pi)r'^2KK'-\log(1/r))}{4rr'^2K^2(\log(1/r))^2}.$$

By Lemma 4.2(1) this has limit ∞ as r tends to zero, while Lemma 4.2(2) and Theorem 2.2 show that it tends to ∞ as r tends to one; thus part (4) follows.

For part (5) we write

$$-\frac{d}{dr}\left(\frac{\mu(r)}{\log(4/r)}\right) = \frac{\pi^2}{4}\frac{1}{r'^2K^2(\log(4/r))^2}\cdot\frac{\log(4/r)-(2/\pi)rr'^2KK'}{r},$$

which is increasing by Theorem 2.2 and Lemma 4.2(4).

Finally, for part (6), by Lemma 2.1 and [BF, #710.00] we have

$$\frac{d^2}{dr^2}\frac{1}{\mu(r)}=\frac{2\pi}{r^2r'^4K'(r)^3}[2E'(r)-r'^2K'(r)].$$

Since $2E'(r)-r'^2K'(r)$ is a strictly increasing function from $(0,1)$ onto $(-\infty,\pi)$, part (6) follows by the intermediate value theorem. □

Remarks 4.4. (1) The monotonicity of the function in Theorem 4.3(3) is stated by Gehring in [G2].

(2) Although $\mu(r)$ has been shown above to be neither convex nor concave on $(0,1)$, we now establish the interesting fact that the function $\mu(1/s)$ is concave and its reciprocal is convex on $(1,\infty)$.

THEOREM 4.5. *As functions of s on* $(1,\infty)$:

(1) $\mu(1/s)$ *is concave*;

(2) $g(s)\equiv\mu(1/s)/\log s$ *is convex*;

(3) $h(s)\equiv\mu(1/s)/\log(4s)$ *is concave.*

Proof. For part (1), let $f(s)=\mu(r)$, where $s=1/r$. Then by Lemma 2.1,

$$f'(s)=\frac{\pi^2 r}{4r'^2K(r)^2};$$

by Theorem 2.2 this is an increasing function of r, hence a decreasing function of s.

For part (2), set $r=1/s$ and $F(r)=g(s)$. Then

$$-g'(s)=-F'(r)\frac{dr}{ds}=\frac{\pi^2 r((2/\pi)r'^2KK'-\log(1/r))}{4r'^2K^2(\log(1/r))^2}$$

$$=\frac{\pi^2 r}{4r'^2K^2\log(1/r)}\left[\frac{(2/\pi)r'^2KK'}{\log(1/r)}-1\right],$$

which, by Lemma 4.2(2), is increasing as a function of r, and hence is decreasing as a function of s.

For part (3), set $r=1/s$ and $G(r)=h(s)$. Then

$$h'(s)=G'(r)\frac{dr}{ds}=\frac{\pi^2 r(\log(4/r)-(2/\pi)r'^2KK')}{4r'^2K^2(\log(4/r))^2},$$

which, by Theorem 2.2 and Lemma 4.2(1), is increasing as a function of r and hence decreasing as a function of s. □

LEMMA 4.6. *Let* $f\colon I\to(0,\infty)$ *be twice differentiable and concave on some interval* $I\subset R^1$. *Then* $1/f$ *is convex on* I.

Proof. Let $g(x)=1/f(x)$. Then

$$g''(x)=\frac{2(f'(x))^2}{f(x)^3}-\frac{f''(x)}{(f(x))^2}\geqq 0$$

since $f''(x)\leqq 0$. □

COROLLARY 4.7. *The function* $\gamma(s)$ *is decreasing and strictly convex on* $(1,\infty)$.

Proof. The proof is an immediate consequence of Theorem 4.5(1) and Lemma 4.6. □

Next we obtain estimates for $\mu(r)$ that improve on the inequalities

$$\log((1+\sqrt{r'})^2/r)<\mu(r)<\log(2(1+r')/r) \tag{4.8}$$

due to Lehto and Virtanen [LV, p. 62].

THEOREM 4.9. *For* $0<r<1$,

$$\frac{1}{2}\log\frac{1+\sqrt{r'}+2\sqrt[4]{r'}}{1-\sqrt{r'}}<\mu(r)<\frac{1}{2}\log\frac{1+\sqrt{r'}+\sqrt{2(1+r')}}{1-\sqrt{r'}}.$$

Proof. By means of a Möbius transformation we may map the plane Grötzsch ring $B^2\setminus[0, r]$ onto the symmetric ring $D = B^2(R)\setminus[-1, 1]$, where $R = (1+r')/r$, and by conformal invariance we have $\mu(r) = \operatorname{mod} D$. Next, the function $w = \frac{1}{2}(\zeta + 1/\zeta)$ maps the circular annulus $A = \{\zeta: 1 < |\zeta| < \rho\}$ conformally onto the elliptical ring $E(\rho)$ consisting of the set $\{w = u+iv: u^2/(\rho+1/\rho)^2 + v^2/(\rho-1/\rho)^2 < \frac{1}{4}\}$ minus a slit $[-1, 1]$ in the u-axis. If we take $\rho_1 + 1/\rho_1 = 2R = \rho_2 - 1/\rho_2$, we have $E(\rho_1) \subset D \subset E(\rho_2)$, and hence $\operatorname{mod} E(\rho_1) < \mu(r) < \operatorname{mod} E(\rho_2)$. Solving for ρ_1 and ρ_2 in terms of R and using conformal invariance we obtain

$$\log \frac{1+r'+\sqrt{2r'(1+r')}}{r} < \mu(r) < \log \frac{1+r'+\sqrt{2(1+r')}}{r}. \tag{4.10}$$

As in [LV] we may improve (4.10) by combining these inequalities with the third identity in (1.5), which is equivalent to $\mu(r) = \frac{1}{2}\mu((1-r')/(1+r'))$. In doing this we obtain the desired estimates. It follows from the elementary inequalities $(1+x)^2 < 2(1+x^2)$ and $(1+x^2)^3 < (1+x)^2(1+x^4)$ for all $x \in (0, 1)$ that the upper and lower estimates, respectively, in the theorem are better than those in (4.8). □

4.11. *Figures.* To illustrate some of the results in this paper, we computed $\mu(r)$ numerically for $0 < r < 1$, using the recursive method of Gauss [BB2], [To] (cf. [Tr], [As]). Figures 1-3 show graphs of several functions related to μ that illustrate Theorems 4.3 and 4.5.

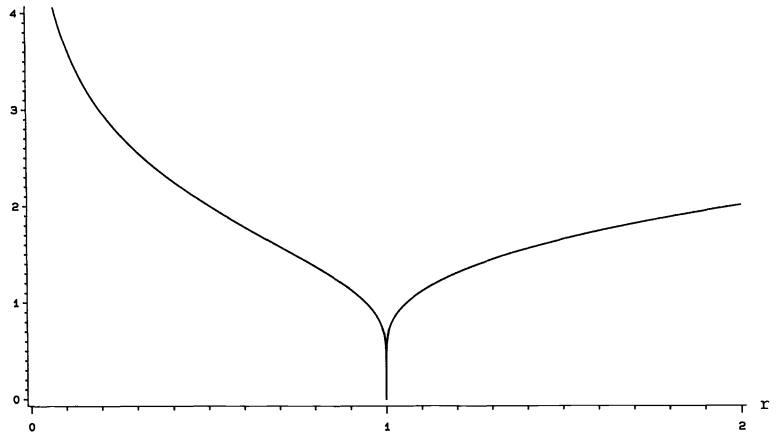

FIG. 1. $\mu(r)$, $0 < r \leqq 1$, *and* $\mu(1/r)$, $r > 1$.

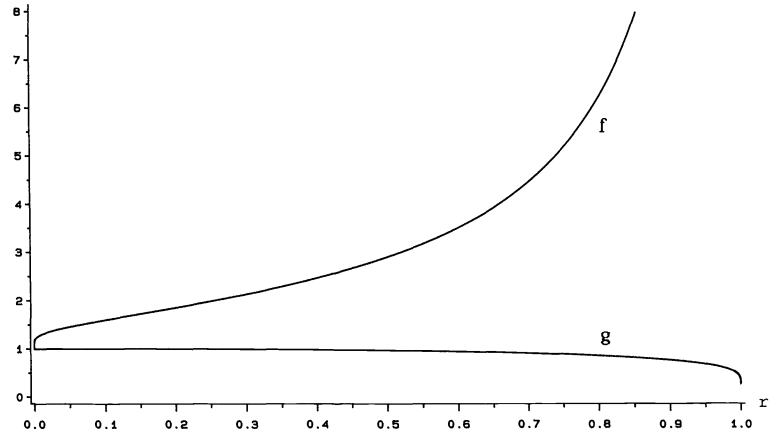

FIG. 2. $f(r) = \mu(r)/\log(1/r)$, $g(r) = \mu(r)/\log(4/r)$, $0 < r < 1$.

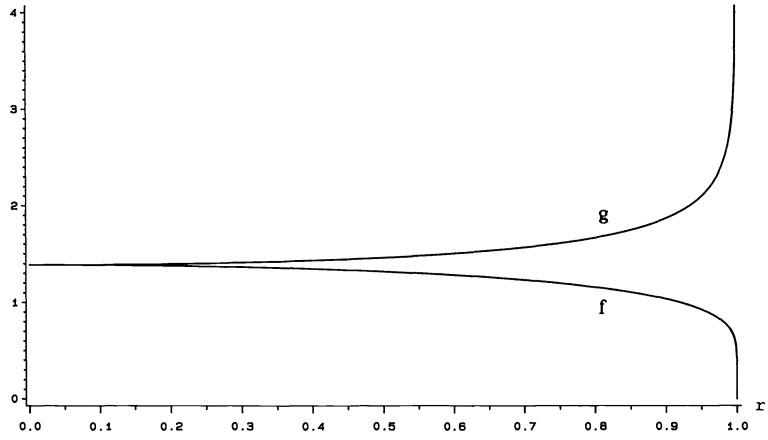

FIG. 3. $f(r)=\mu(r)+\log r$, $g(r)=\mu(r)+\log(r/r')$.

5. Properties of the Teichmüller capacity. The conformal capacity of the Teichmüller extremal ring is denoted here by $\tau(t)$, $t>0$. It is related to the capacity of the plane Grötzsch ring (see (1.3)) by the functional identity [G1, § 18]

$$\gamma(s)=2\tau(s^2-1). \tag{5.1}$$

In this section we study inequalities and limits for ratios of such Teichmüller capacities.

THEOREM 5.2. *For $1<A<\infty$ let $f(s)=\tau(s)/\tau(As)$ for all $s\in(0,\infty)$. Then f is strictly increasing on $(0,1/\sqrt{A}]$ and strictly decreasing on $[1/\sqrt{A},\infty)$ with $\lim_{s\to 0} f(s)=1=\lim_{s\to\infty} f(s)$. Consequently, $1\leqq f(s)\leqq f(1/\sqrt{A})$ for all $s\in(0,\infty)$.*

Proof. If we set $a=1/\sqrt{s+1}$, $b=1/\sqrt{As+1}$, then by (5.1) and the fact that μ is strictly decreasing we have $f(s)=\mu(b)/\mu(a)>1$.

Next, it follows easily from Lemma 2.1 that

$$\mu^2(a)f'(s)=\frac{\pi^3a^2}{16(1-a^2)K^2(a)K^2(b)}[K(a)K'(a)-K(b)K'(b)].$$

In the case where $0<s<1/A$, i.e., $1/\sqrt{2}<b<a$, it follows from Theorem 2.2(8) that $f'(s)>0$, so that f increases. If $1<s<\infty$, i.e., $0<b<a<1/\sqrt{2}$, then by the same theorem we have $f'(s)<0$, so that f is decreasing on $[1,\infty)$.

Finally, we consider the interval $[1/A,1]$. We note first that, by the definition of f and the first identity in (1.5),

$$f(1/A)=\frac{\mu(1/\sqrt{2})}{\mu(\sqrt{A/(A+1)})}=\frac{\mu(1/\sqrt{A+1})}{\mu(1/\sqrt{2})}=f(1).$$

Hence by the Mean Value Theorem there exists $s_0\in(1/A,1)$ such that $f'(s_0)=0$. Since $A>1$, $f'(s_0)=0$ if and only if $K(a)K'(a)=K(b)K'(b)$ if and only if $b=a'$ if and only if $s_0=1/\sqrt{A}$. Thus f has a unique critical point $s_0=1/\sqrt{A}\in(1/A,1)$, and hence $f(s_0)$ is either the maximum or minimum of $f(s)$ for $s\in[1/A,1]$.

We need only compare $f(s_0)$ with $f(1)=f(1/A)$. Setting $x=\sqrt{A}>1$, by (1.5) we have

$$f(s_0)=f\left(\frac{1}{x}\right)=\frac{\mu(1/\sqrt{x+1})}{\mu(\sqrt{x(x+1)})}=\frac{4}{\pi^2}(\mu(1/\sqrt{x+1}))^2=\frac{4}{\pi^2}(\mu(y))^2,$$

where $y = 1/\sqrt{x+1} \in (0, 1/\sqrt{2})$. Next,

$$f(1) = \frac{\mu(1/\sqrt{A+1})}{\mu(1/\sqrt{2})} = \frac{2}{\pi}\mu(1/\sqrt{x^2+1}) = \frac{2}{\pi}\mu(z),$$

where $z = 1/\sqrt{x^2+1}$. We let

$$g(x) = \frac{\mu^2(1/\sqrt{x+1})}{\mu(1/\sqrt{x^2+1})} = \frac{\mu^2(y)}{\mu(z)},$$

noting that $0 < z \leqq y \leqq 1/\sqrt{2}$ for $x \in [1, \infty)$. Clearly $g(1) = \pi/2$, and we need only prove that g is increasing on $[1, \infty)$. Differentiating and simplifying, we get

$$\mu^2(z)g'(z) = \frac{\pi^3}{8}\frac{K'(y)}{x^2K^3(y)K^2(z)}[K(z)K'(z) - K(y)K'(y)],$$

which is positive since $0 < z < y < 1/\sqrt{2}$ for all $x \in (1, \infty)$. Hence g is increasing on $[1, \infty)$, $g(x) > g(1) = \pi/2$ for all $x \in (1, \infty)$, and we conclude that $f(1/\sqrt{A}) > f(1) = f(1/A)$. If f' were negative at some point of $(1/A, 1/\sqrt{A})$, then by continuity f' would have another zero in this interval. This contradiction shows that f is strictly increasing on $[1/A, 1/\sqrt{A}]$. Similarly, f is strictly decreasing on $[1/\sqrt{A}, 1]$.

Finally, the limit as s tends to zero follows from (5.1) and [AVV3, Lemma 2.6(4)], and the limit as s tends to ∞ follows from (5.1) and [AVV3, Lemma 2.6(2)]. □

Remark 5.3. Theorem 5.2 enables us to replace the numerical bound 1.172 in [LeVu, § 1.2] by the exact constant $\tau(1/\sqrt{2})/\tau(\sqrt{2}) = (4/\pi^2)\mu^2(\sqrt{\sqrt{2}-1}) = 1.1712\cdots$.

6. Concluding remarks. Complete elliptic integrals have been tabulated and compared to other functions during the past century (cf. [LF, pp. 208–213]). The usual comparison function for $K(r)$ is $\log(4/\sqrt{1-r^2})$, and we relate our results to some earlier recent work on this topic.

In 1984 Borwein and Borwein [BB1, p. 356, Prop. 2] proved that

$$\left| K(r) - \log\frac{4}{\sqrt{1-r^2}} \right| \leqq 4(1-r^2)K(r). \tag{6.1}$$

In 1985 Carlson and Gustafson [CG, p. 1072, Form. (1.1)] went on to show that

$$1 < \frac{K(r)}{\log(4/\sqrt{1-r^2})} < \frac{4}{(3+r^2)} \tag{6.2}$$

for $r \in (0, 1)$. Note that the quantity between the absolute value bars in (6.1) is positive by Theorem 2.2(2) and that (6.2) yields the following improved upper bound for it:

$$0 < K(r) - \log\frac{4}{\sqrt{1-r^2}} \leqq \frac{1-r^2}{3+r^2}\log\frac{4}{\sqrt{1-r^2}} \leqq \frac{1-r^2}{3+r^2}K(r). \tag{6.3}$$

Remarks 6.4. (1) Theorem 2.2(5) strengthens the Carlson–Gustafson inequality (6.2) for $0 \leqq r < \sqrt{(4/\pi)\log 16 - 3} = 0.728\cdots$.

(2) Some computational work that we have done supports the validity of the following conjecture, which is motivated by (6.2):

$$\frac{9}{8+r^2} < \frac{K(r)}{\log(4/\sqrt{1-r^2})} < \frac{9.2}{8+r^2}$$

for $0 < r < 1$.

(3) For $0 < r < 1$, the double inequality

$$1 + \frac{r^2(1-r^2)}{12-2r^2} < \frac{K(r)}{\log(4/\sqrt{1-r^2})} < \frac{10.2}{9+r^2}$$

is true. The upper bound is due to J. S. Frame [F] in private communication, and the lower bound is contained in the referee's report of this paper.

THE PLATE PARADOX FOR HARD AND SOFT SIMPLE SUPPORT*

I. BABUŠKA† AND J. PITKÄRANTA‡

Abstract. This paper studies the plate-bending problem with hard and soft simple support. It shows that in the case of hard support, the plate paradox, which is known to occur in the Kirchhoff model, is also present in the three-dimensional model and the Reissner-Mindlin model. The paradox consists of the fact that, on a sequence of convex polygonal domains converging to a circle, the solutions of the corresponding plate-bending problems with a fixed uniform load do not converge to the solution of the limit problem. The paper also shows that the paradox is not present when soft simple support is assumed. Some practical aspects are briefly discussed.

Key words. plates, Kirchhoff model, Reissner-Mindlin model, simply supported plate, plate paradox

AMS(MOS) subject classifications. 35J50, 35J55, 73C20, 73C99

1. Introduction. The Kirchhoff model of a plate is usually accepted as a good approximation to the three-dimensional model for thin plates. In the case of simply supported polygonal plates, however, the Kirchhoff model is known to suffer from unphysical phenomena that can lead to a large error of the model in some situations. In particular, the following paradox, referred to below as the plate paradox, occurs [2], [4]. Consider a sequence $\{\omega_n\}$ of convex polygonal domains approaching a circle. For each n, let w_n be the transverse deflection corresponding to the Kirchhoff model of the plate-bending problem, where the plate occupying the region ω_n is simply supported on $\partial\omega_n$ and is subject to a uniform load $p(x) \equiv 1$. Furthermore, let w_c be the solution to the limit problem, i.e., that on the circle. Then as $n \to \infty$, the sequence $\{w_n\}$ converges pointwise, but the limit w_∞ is different from w_c. For example, at the center of the circle the error of w_∞ is about 40 percent. Some other related plate paradoxes are given in [14], [15]. Practical implications occur, for example, in the finite-element method when the domain is approximated by a polygon with sidelength $h \to 0$. For further aspects see also [8], [18], [21], [23], and [25].

It is often assumed that the plate paradox is caused by the assumption of vanishing vertical shear strains that is implicit in the Kirchhoff model. This has been supported, e.g., by a note (see [3]) that the paradox is not present when the Reissner-Mindlin model instead of the Kirchhoff model is used. The aim of this paper is to locate the source of the paradox more precisely. We show that it is the way the *boundary conditions* are imposed in the Kirchhoff model that causes the paradox, and not the overall assumption of vanishing shear strains.

In the three-dimensional model of the plate, the boundary condition of simple support is typically imposed by requiring that the vertical component of the displacement (or at least its average in the vertical direction) vanish on the edge of the plate. On the other hand, the Kirchhoff model effectively imposes the more restrictive condition that all tangential displacements must vanish on the edge. Of course, it is

also possible to impose such "hard" boundary conditions in other plate models, e.g., in the Reissner–Mindlin model (cf. [22]) or in the three-dimensional model itself. We show that in such a case, *the plate paradox occurs* in both the Reissner–Mindlin model and in the three-dimensional model. On the other hand, we also show that *the paradox does not occur* in these models in case of "soft" support, where only the vertical displacements are restricted on the edge of the plate. Hence, we are led to the conclusion that the paradox is caused by the hard boundary conditions that are intrinsic in the Kirchhoff model.

Our results are based on energy estimates relating the three-dimensional model and the Reissner–Mindlin model to the Kirchhoff model. Such estimates can be derived by combining the energy and complementary energy principles associated to the plate-bending problem. They were, in fact, applied early by Morgenstern [16], [17] to prove that the Kirchhoff model is the correct asymptotic limit of the three-dimensional model as the thickness of the plate tends to zero. Although the assumption of a smooth domain is implicit in Morgenstern's work, we can easily extend the analysis techniques of [16] to more general situations. In particular, we show here that in a sequence of convex polygonal domains converging to a circle, the relative error of the Kirchhoff model, when compared to the three-dimensional model with *hard* support, is uniformly of order $\mathcal{O}(h^{1/2})$ in the energy norm, where h is the thickness of the plate. Moreover, by similar techniques we show that the gap between Reissner–Mindlin and Kirchhoff models is uniformly of order $\mathcal{O}(h)$ under the same assumptions. Finally, we show that on a smooth domain, the three models are at most $\mathcal{O}(h^{1/2})$ apart. Hence we conclude that the plate paradox must occur in the hard-support models if h is fixed and sufficiently small.

Let us mention that our results are in parallel with recent benchmark calculations [7]. These calculations confirm, in particular, that the error of the Kirchhoff model with respect to the three-dimensional model is primarily due to the assumed hard boundary conditions on simply supported polygonal plates. For example, in the case of a uniformly loaded square plate of thickness $h = \text{side length}/100$, the relative error of the Kirchhoff model in energy norm is approximately 11 percent when compared to the three-dimensional model with soft support, and approximately 2 percent when compared to the hard-support model [7]. This example also shows that the error of the Kirchhoff model may be quite large even for relatively thin plates of simple shape.

The results above show that imposing various boundary conditions that are seemingly close, such as hard and soft simple support, can influence the solution in the entire domain and not only in the boundary layer. Very likely such effects also occur for other boundary conditions for both plates and shells. Therefore, since *any* boundary condition is an idealization of reality, finding the "correct" boundary conditions is an important and sometimes difficult part of building a dimensionally reduced model. For example, both soft and hard simple support can be poor approximations of the real "simple" support.

The plan of the paper is as follows. Section 2 gives the preliminaries and basic formulations of the plate problems. Section 3 elaborates on the variational formulations of the plate problems and presents various energy estimates. Section 4 addresses the problem of the plate paradox. Finally, Appendices A, B, and C present some auxiliary results needed in §§ 3 and 4.

2. Preliminaries. Consider an elastic plate of thickness h that occupies the region $\Omega = \omega \times (-h/2, h/2)$, where $\omega \in \mathbb{R}^2$ is a Lipschitz bounded domain. We assume that the plate is subject to given normal tractions p (i.e., the load) on $\omega \times \{-h/2\}$ and

$\omega \times \{h/2\}$ and that it is simply supported on $\partial\omega \times (-h/2, h/2)$ in such a way that if $\underline{u} = (u_1, u_2, u_3)$ is the displacement field, then

$$u_3(x) = 0, \qquad x \in \partial\omega \times \left(-\frac{h}{2}, \frac{h}{2}\right) \tag{2.1}$$

and the other two conditions are natural boundary conditions describing homogenous (zero) components of tractions. Later this condition will be called the soft simple support. If we assume for the moment that no other geometric boundary conditions other than (2.1) are imposed, the plate-bending problem can be formulated as follows. Find the displacement field $\underline{u}_0$ that minimizes the quadratic functional of the total energy

$$\begin{aligned} F(\underline{u}) = \frac{1}{2}\int_\Omega \left\{\lambda(\operatorname{div}\underline{u})^2 + \mu \sum_{i,j=1}^{3} [\varepsilon_{ij}(\underline{u})]^2\right\} dx_1\, dx_2\, dx_3 \\ - \int_\omega p \frac{1}{2}\left[u_3\left(\cdot, \frac{h}{2}\right) + u_3\left(\cdot, -\frac{h}{2}\right)\right] dx_1\, dx_2 \end{aligned} \tag{2.2}$$

in the Sobolev space $[H^1(\Omega)]^3$ under the boundary condition (2.1). Here $\underline{\varepsilon} = \{\varepsilon_{ij}\}_{i,j=1}^3$, $\varepsilon_{ij} = \frac{1}{2}((\partial u_i/\partial x_j) + (\partial u_j/\partial x_i))$ is the strain tensor, and λ and μ are the Lamé coefficients of the material, i.e.,

$$\lambda = \frac{E\nu}{(1+\nu)(1-2\nu)}, \qquad \mu = \frac{E}{1+\nu},$$

where E is the Young modulus and ν is the Poisson ratio, $0 \leqq \nu \leqq \frac{1}{2}$. We also assume that the surface traction p is symmetrically distributed with regard to the planar surfaces of the plate, i.e., we consider a pure bending problem.

So far we have assumed a special model of simple support based on simple geometric constraint (2.1). Of course there are many other possibilities. Later we will discuss another model—of hard simple support—and will discuss the effects of these models of simple support on the solution.

It is well known that if $h/\operatorname{diam}(\omega)$ is small, the three-dimensional plate-bending problem can be formulated in various dimensionally reduced forms (see, e.g., [1], [11], [22]). Here we consider two representatives of such formulations that are used in practice: the Kirchhoff model and the Reissner-Mindlin model (cf. [22] and the references therein).

In general, when ω is fixed and $h \to 0$, the three-dimensional formulation and the dimensionally reduced models converge to the same limit, provided that the load p is appropriately scaled (see below). Hence for sufficiently thin plates the models give practically the same solutions. However, as will be seen later, what is "sufficiently thin" can depend strongly on ω, i.e., the convergence can be very slow in some situations.

In the Kirchhoff model, we approximate the three-dimensional solution as

$$\underline{u}_0(x_1, x_2, x_3) \cong \left(-x_3 \frac{\partial w_K}{\partial x_1}(x_1, x_2), -x_3 \frac{\partial w_K}{\partial x_2}(x_1, x_2), w_K(x_1, x_2)\right),$$

where w_K minimizes the energy

$$F_K(w) = \frac{1}{2}\int_\omega \left\{\nu(\Delta w)^2 + (1-\nu)\sum_{i,j=1}^{2}\left(\frac{\partial^2 w}{\partial x_i \partial x_j}\right)^2\right\} dx_1\, dx_2 - \int_\omega fw\, dx_1\, dx_2 \tag{2.3}$$

in the Sobolev space $H^2(\omega)$ under the boundary condition

$$w = 0 \quad \text{on } \partial\omega. \tag{2.4}$$

Here f is related to p as

$$f=\frac{p}{D}, \qquad D=\frac{Eh^3}{12(1-\nu^2)}. \tag{2.5}$$

When comparing different plate models with fixed ω and variable h we will assume below that f (and not p) is fixed. This ensures that the different models have the same (nontrivial) limit as $h\to 0$. For example, defining the average transverse deflection in the three-dimensional model as

$$w_0=\frac{1}{h}\int_{-h/2}^{h/2} u_3(\cdot, x_3)\,dx_3,$$

we can show (under fairly general assumptions on ω (see [10], [11], [16], [17], and § 3 below) that $\|w_0-w_K\|_{L_2(\omega)}\to 0$ as $h\to 0$.

In the Reissner–Mindlin model, we approximate $\underline{u}_0$ by

$$\underline{u}_0(x_1, x_2, x_3)\approx(-x_3\theta_{R,1}(x_1, x_2), -x_3\theta_{R,2}(x_1, x_2), w_R(x_1, x_2)),$$

where $(w_R, \underline{\theta}_R)$ minimizes the energy

$$\begin{aligned} F_R(w, \underline{\theta}) &= \frac{1}{2}\int_\omega \left\{\nu(\operatorname{div}\underline{\theta})^2+(1-\nu)\sum_{i,j=1}^{2}[\varepsilon_{ij}(\underline{\theta})]^2\right\} dx_1\,dx_2 \\ &\quad +\frac{1}{2}\left(\frac{\kappa}{h^2}\right)\int_\omega |\underline{\theta}-\underline{\nabla} w|^2\,dx_1\,dx_2-\int_\omega fw\,dx_1\,dx_2 \end{aligned} \tag{2.6}$$

in the Sobolev space $[H^1(\omega)]^3$ under the boundary condition (2.4). Here $\kappa=6(1-\nu)\kappa_0$, where $\kappa_0=O(1)$ is an additional shear correction factor that may take various values in practice.

We point out that the Kirchhoff approximation to $\underline{u}_0$ satisfies, in addition to (2.1), the boundary condition

$$(u_1t_1+u_2t_2)(x)=0, \qquad x\in\partial\omega\times\left(-\frac{h}{2}, \frac{h}{2}\right), \tag{2.7}$$

where $\underline{t}=(t_1, t_2)$ denotes the tangent to $\partial\omega$. This suggests that we should also consider the original plate-bending problem under such more restrictive geometric boundary conditions. Below we refer to the boundary conditions (2.1) and (2.7) and their counterpart in the Reissner–Mindlin model, i.e., (2.4) together with

$$\theta_1t_1+\theta_2t_2=0 \quad \text{on } \partial\omega, \tag{2.8}$$

as hard simple support in contrast to conditions (2.1) and (2.4), which we refer to as soft simple support. Hence, when using the Kirchhoff model we have in mind hard (not soft) simple support. Later we will show that the incapacity of the Kirchhoff model to represent soft simple support can be a severe deficiency of the model on polygonal domains.

3. Variational formulations of the plate-bending problem. Energy estimates. In §§ 3.1–3.3 and in the related Appendix A, we summarize first some basic characteristics of variational formalisms and energy principles associated to the plate-bending problem in its various forms. These results are basically known, but we present them here for the reader's convenience. In § 3.4 we prove some energy estimates relating the Kirchhoff model to both the Reissner–Mindlin model and the three-dimensional model, using the results of the previous subsections.

We assume that the plate occupies the region $\Omega = \omega \times (-h/2, h/2)$, where ω is a Lipschitz bounded domain. Our particular interest is in the cases where ω is either a convex polygon or a smooth domain.

We denote by $H^s(\omega)$, respectively, $H^s(\Omega)$, the usual Sobolev spaces with index $s > 0$. The seminorm and norm of the spaces $[H^s(\omega)]$ or $[H^s(\omega)]^k$ are denoted by $|\cdot|_{s,\omega}$ and $\|\cdot\|_{s,\omega}$, respectively, $|\cdot|_{s,\Omega}$ and $\|\cdot\|_{s,\Omega}$. By $(\cdot,\cdot)$ we mean the inner product of $[L_2(\omega)]^k$ or $[L_2(\Omega)]^k$, and by $\langle\cdot,\cdot\rangle$ the pairing of a space and its dual. The dual space of $H_0^1(\omega)$ will often be needed below and is denoted by $H^{-1}(\omega)$.

3.1. The three-dimensional model. Let us denote by N the space of horizontal rigid displacements of the plate

$$N = \{(\alpha_1 x_1 + \alpha_3 x_2, \alpha_2 x_2 - \alpha_3 x_1, 0),\ \alpha_i \in \mathbb{R},\ i = 1, 2, 3\}.$$

We define the space of (geometrically) admissible displacements in the case of soft simple support as

$$U = \left\{ \underline{u} \in [H^1(\Omega)]^3 \colon u_3 = 0 \text{ on } \partial\omega \times \left(-\frac{h}{2}, \frac{h}{2}\right),\ (\underline{u}, \underline{v}) = 0\ \ \forall \underline{v} \in N \right\} \tag{3.1a}$$

and in the case of hard simple support as

$$U = \left\{ \underline{u} \in [H^1(\Omega)]^3 \colon u_3 = t_1 u_1 + t_2 u_2 = 0 \text{ on } \partial\omega \times \left(-\frac{h}{2}, \frac{h}{2}\right),\ (\underline{u}, \underline{v}) = 0\ \ \forall \underline{v} \in N \right\}. \tag{3.1b}$$

(For simplicity, here we also remove all the horizontal rigid displacements in case of hard support.) Furthermore, we let $\mathcal{H}$ stand for the space of stress or strain tensors defined as

$$\mathcal{H} = \{\underline{\sigma} = (\sigma_{ij})_{i,j=1}^3 \colon \sigma_{ij} \in L_2(\Omega),\ \sigma_{ij} = \sigma_{ji}\},$$

and introduce a linear mapping $S \colon \mathcal{H} \to \mathcal{H}$ representing a scaled stress-strain relationship of a linear elastic material:

$$(S\underline{\tau})_{i,j} = D^{-1}[\lambda \operatorname{tr}(\underline{\tau})\delta_{ij} + \mu\tau_{ij}],$$

where λ and μ are the Lamé coefficients and the scaling factor D is as in (2.5). Then S is one to one and

$$(S^{-1}\underline{\tau})_{i,j} = \frac{D}{E}[(1+\nu)\tau_{ij} - \nu \operatorname{tr}(\underline{\tau})\delta_{ij}]. \tag{3.2}$$

Moreover, S and S^{-1} are self-adjoint if $\mathcal{H}$ is supplied with the natural inner product

$$(\underline{\sigma}, \underline{\tau})_{\mathcal{H}} = \sum_{i,j=1}^{3} (\sigma_{ij}, \tau_{ij}).$$

Let us further define the bilinear forms

$$\mathcal{A}(\underline{u}, \underline{v}) = (\underline{\varepsilon}(\underline{u}), S\underline{\varepsilon}(\underline{v}))_{\mathcal{H}}, \qquad \underline{u}, \underline{v} \in U,$$
$$\mathcal{B}(\underline{\sigma}, \underline{\tau}) = (\underline{\sigma}, S^{-1}\underline{\tau})_{\mathcal{H}}, \qquad \underline{\sigma}, \underline{\tau} \in \mathcal{H},$$

and the linear functional

$$Q(\underline{v}) = \frac{1}{2}\int_\omega f\left[v_3\left(\cdot, \frac{h}{2}\right) + v\left(\cdot, -\frac{h}{2}\right)\right] dx_1\, dx_2,$$

where it is assumed that $f \in L_2(\omega)$, to imply that Q is a bounded linear functional on U (by standard trace inequalities).

In the notation above, the *energy principle* states that the displacement field $\underline{u}_0$ due to the load $f=(p/D)\in L_2(\omega)$ is determined as the solution to the following minimization problem. Find $\underline{u}_0\in U$ that minimizes in U the functional

$$\mathcal{F}(\underline{u})=\tfrac{1}{2}\mathcal{A}(\underline{u},\underline{u})-Q(\underline{u}).$$

The existence and uniqueness of $\underline{u}_0$ is due to the following coercivity inequality, known as the Korn inequality (cf. [19]).

LEMMA 3.1. *If U is defined by* (3.1a), *there is a positive constant c such that*

$$\mathcal{A}(\underline{u},\underline{u})\geqq c\|\underline{u}\|^2_{1,\Omega},\qquad \underline{u}\in U. \tag{3.3}$$

We point out that the constant in (3.3) depends on ω (and h), although it is positive for any given Lipschitz domain. In Appendix B we show that the constant in (3.3) remains uniformly positive over a certain family of domains, a result needed in § 5 below.

Given f and the corresponding displacement field $\underline{u}_0$, let $\underline{\sigma}_0=S\underline{u}_0$ be the corresponding (scaled) stress field. The pair $(\underline{u},\underline{\sigma})=(\underline{u}_0,\underline{\sigma}_0)$ is then the solution to the following variational problem. Find $(\underline{u},\underline{\sigma})\in U\times\mathcal{H}$ such that

$$\mathcal{B}(\underline{\sigma},\underline{\tau})-(\underline{\varepsilon}(\underline{u}),\underline{\tau})_{\mathcal{H}}=0,\qquad \underline{\tau}\in\mathcal{H}, \tag{3.4a}$$

$$(\underline{\sigma},\underline{\varepsilon}(\underline{v}))=Q(\underline{v}),\qquad \underline{v}\in U. \tag{3.4b}$$

It can be easily verified following [5] and [9] (see Appendix A) that the solution to (3.4) exists and is unique.

Finally, we mention that according to the *complementary energy principle*, $\underline{\sigma}_0$ is found alternatively as the solution to the following minimization problem [19]. Find $\underline{\sigma}_0\in\mathcal{H}$ that minimizes in $\mathcal{H}$ the functional

$$\mathcal{G}(\underline{\sigma})=\tfrac{1}{2}\mathcal{B}(\underline{\sigma},\underline{\sigma})$$

under the constraint (3.4b).

In § 4 below we need the following corollary of the two energy principles (cf. [16]).

LEMMA 3.2. *For any $(\underline{u},\underline{\sigma})\in U\times\mathcal{H}$ such that $\underline{\sigma}$ satisfies* (3.4b), *the following identity holds*:

$$\tfrac{1}{2}\mathcal{A}(\underline{u}_0-\underline{u},\underline{u}_0-\underline{u})+\tfrac{1}{2}\mathcal{B}(\underline{\sigma}_0-\underline{\sigma},\underline{\sigma}_0-\underline{\sigma})=\mathcal{F}(\underline{u})+\mathcal{G}(\underline{\sigma}).$$

Proof. It follows from the energy principle that

$$\mathcal{A}(\underline{u}_0,\underline{v})=Q(\underline{v}),\qquad \underline{v}\in U,$$

and from the complementary energy principle that

$$\mathcal{B}(\underline{\sigma}_0,\underline{\tau})=0,\qquad \underline{\tau}\in\mathcal{H}\colon(\underline{\tau},\underline{\varepsilon}(\underline{v}))_{\mathcal{H}}=Q(\underline{v})\quad\forall\underline{v}\in U.$$

Therefore, in particular, $\mathcal{A}(\underline{u}_0,\underline{u})=Q(\underline{u})$ and $\mathcal{B}(\underline{\sigma}_0,\underline{\sigma})=\mathcal{B}(\underline{\sigma}_0,\underline{\sigma}_0)$, and hence

$$\begin{aligned}\tfrac{1}{2}\mathcal{A}(\underline{u}_0-\underline{u},\underline{u}_0-\underline{u})+\tfrac{1}{2}\mathcal{B}(\underline{\sigma}_0-\underline{\sigma},\underline{\sigma}_0-\underline{\sigma})&=[\tfrac{1}{2}\mathcal{A}(\underline{u},\underline{u})-\mathcal{A}(\underline{u}_0,\underline{u})+\tfrac{1}{2}\mathcal{B}(\underline{\sigma},\underline{\sigma})]\\&\quad+[\tfrac{1}{2}\mathcal{A}(\underline{u}_0,\underline{u}_0)+\tfrac{1}{2}\mathcal{B}(\underline{\sigma}_0,\underline{\sigma}_0)-\mathcal{B}(\underline{\sigma}_0,\underline{\sigma})]\\&=[\mathcal{F}(\underline{u})+\mathcal{G}(\underline{\sigma})]+[\tfrac{1}{2}\mathcal{A}(\underline{u}_0,\underline{u}_0)-\tfrac{1}{2}\mathcal{B}(\underline{\sigma}_0,\underline{\sigma}_0)]\\&=\mathcal{F}(\underline{u})+\mathcal{G}(\underline{\sigma}).\end{aligned}$$

□

3.2. The Reissner–Mindlin model. In the Reissner-Mindlin model geometrically admissible displacements $(w,\underline{\theta})$ span the space $H^1_0(\omega)\times V$, where either

$$V=[H^1(\omega)]^2 \tag{3.5a}$$

or

$$V=\{\underline{\theta}\in[H^1(\omega)]^2:\ t_1\theta_1+t_2\theta_2=0 \text{ on } \partial\omega\} \tag{3.5b}$$

corresponding to soft and hard boundary conditions, respectively. We let $\mathcal{K}$ stand for the space of momentum and curvature tensors:

$$\mathcal{K}=\{\underline{m}=(m_{ij})_{i,j=1}^2,\ m_{ij}\in L_2(\omega),\ m_{12}=m_{21}\},$$

and supply $\mathcal{K}$ with the natural inner product

$$(\underline{m},\underline{k})_{\mathcal{K}}=\sum_{i,j=1}^{2}(m_{ij},k_{ij}).$$

Furthermore, we introduce the linear mapping $T:\mathcal{K}\to\mathcal{K}$ as defined by

$$(T\underline{k})_{ij}=\nu\,\mathrm{tr}\,(\underline{k})\delta_{ij}+(1-\nu)k_{ij},\qquad \underline{k}\in\mathcal{K}.$$

The inverse of T is given by

$$(T^{-1}\underline{k})_{ij}=\frac{1}{1-\nu}k_{ij}-\frac{\nu}{1+\nu}\,\mathrm{tr}\,(\underline{k})\delta_{ij}, \tag{3.6}$$

and obviously T and T^{-1} are self-adjoint.

Finally we introduce the bilinear forms

$$\mathcal{A}_R(w,\underline{\theta};z,\underline{\varphi})=(\underline{\varepsilon}(\underline{\theta}),T\underline{\varepsilon}(\underline{\varphi}))+\left(\frac{\kappa}{h^2}\right)(\underline{\theta}-\underline{\nabla}w,\underline{\varphi}-\underline{\nabla}z),\quad w,z\in H_0^1(\omega),\quad \underline{\theta},\underline{\varphi}\in V,$$

$$\mathcal{B}_R(\underline{m},\underline{\gamma};\underline{k},\underline{\zeta})=(\underline{m},T^{-1}\underline{k})_{\mathcal{K}}+\left(\frac{h^2}{\kappa}\right)(\underline{\gamma},\underline{\zeta}),\quad \underline{m},\underline{k}\in\mathcal{K},\quad \underline{\gamma},\underline{\zeta}\in[L_2(\omega)]^2,$$

where $\underline{\varepsilon}(\underline{\theta})=(\varepsilon_{ij}(\underline{\theta}))_{i,j=1}^2$ and κ are as in (2.6).

In the notation above, the Reissner–Mindlin formulation of the plate-bending problem, as stated according to the energy principle, is to find the pair $(w_R,\underline{\theta}_R)\in H_0^1(\omega)\times V$ that minimizes in $H_0^1(\omega)\times V$ the functional

$$\mathcal{F}_R(w,\underline{\theta})=\tfrac{1}{2}\mathcal{A}_R(w,\underline{\theta};w,\underline{\theta})-\langle f,w\rangle$$

for a given $f\in H^{-1}(\omega)$.

The existence and uniqueness of $(w_R,\underline{\theta}_R)$ is the consequence of the following lemma, which is proved in Appendix B in slightly more general form (see Lemma B.2 of Appendix B).

LEMMA 3.3. *There is a positive constant c such that*

$$(\underline{\varepsilon}(\underline{\theta}),T\underline{\varepsilon}(\underline{\theta}))_{\mathcal{K}}+\|\underline{\theta}-\underline{\nabla}w\|_{0,\omega}^2\geqq c(\|\underline{\theta}\|_{1,\omega}^2+\|w\|_{1,\omega}^2),$$
$$\underline{\theta}\in[H^1(\omega)]^2,\quad w\in H_0^1(\omega).$$

Remark 3.1. Regarding the validity of Lemma 3.3 uniformly over a sequence of domains, see Appendix B. (Such a result is needed in § 5 below.)

The analogy of the variational formulation (3.4) is stated for the Reissner–Mindlin model as follows. Find $(w,\underline{\theta},\underline{m},\underline{\gamma})\in H_0^1(\omega)\times V\times\mathcal{K}\times[L_2(\omega)]^2$ such that

$$(\underline{m},T^{-1}\underline{k})_{\mathcal{K}}-(\underline{\varepsilon}(\underline{\theta}),\underline{k})_{\mathcal{K}}=0,\qquad \underline{k}\in\mathcal{K}, \tag{3.7a}$$

$$(h^2/\kappa)(\underline{\gamma},\underline{\zeta})-(\underline{\theta}-\underline{\nabla}w,\zeta)=0,\qquad \underline{\zeta}\in[L_2(\omega)]^2, \tag{3.7b}$$

$$(\underline{m},\underline{\varepsilon}(\underline{\varphi}))_{\mathcal{K}}+(\underline{\gamma},\underline{\varphi})=0,\qquad \underline{\varphi}\in V, \tag{3.7c}$$

$$-(\underline{\gamma},\underline{\nabla}z)=\langle f,z\rangle,\qquad z\in H_0^1(\omega). \tag{3.7d}$$

The (unique; see Appendix A) solution to this problem is $(w_R, \underline{\theta}_R, \underline{\underline{m}}_R, \underline{\gamma}_R)$, where $\underline{\underline{m}}_R = T\underline{\underline{\varepsilon}}(\underline{\theta}_R)$ and $\underline{\gamma}_R = (\kappa/h^2)(\underline{\theta}_R - \underline{\nabla} w_R)$ have the physical meaning of momentum and (vertical) shear stress field, respectively, both being scaled by a factor D^{-1}.

Finally we note that the pair $(\underline{\underline{m}}_R, \underline{\gamma}_R)$ can be obtained alternatively as the solution to the following minimization problem (the complementary energy principle). Find $(\underline{\underline{m}}_R, \underline{\gamma}_R) \in \mathcal{H} \times [L_2(\omega)]^2$ that minimizes in $\mathcal{H} \times [L_2(\omega)]^2$ the functional

$$\mathcal{G}_R(\underline{\underline{m}}, \underline{\gamma}) = \tfrac{1}{2}\mathcal{B}_R(\underline{\underline{m}}, \underline{\gamma}; \underline{\underline{m}}, \underline{\gamma})$$

under the constraints (3.7c, d).

Upon combining the two energy principles we obtain, in analogy with Lemma 3.2, the following lemma.

LEMMA 3.4. *For any* $(w, \theta) \in H_0^1(\omega) \times V$ *and for any* $(\underline{\underline{m}}, \underline{\gamma}) \in \mathcal{H} \times [L_2(\omega)]^2$ *satisfying* (3.7c, d) *the following identity holds*:

$$\tfrac{1}{2}\mathcal{A}_R(w_R - w, \underline{\theta}_R - \underline{\theta}; w_R - w, \underline{\theta}_R - \underline{\theta}) + \tfrac{1}{2}\mathcal{B}_R(\underline{\underline{m}}_R - \underline{\underline{m}}, \underline{\gamma}_R - \underline{\gamma}; \underline{\underline{m}}_R - \underline{\underline{m}}, \underline{\gamma}_R - \underline{\gamma}) = \mathcal{F}_R(w, \underline{\theta}) + \mathcal{G}_R(\underline{\underline{m}}, \underline{\gamma}).$$

3.3. The Kirchhoff model. Upon introducing the space

$$W = \{z \in H^2(\omega): z = 0 \text{ on } \partial\omega\},$$

we formulate the plate-bending problem according to the Kirchhoff model as follows. Given $f \in W'$ (=dual space of W), find $w_K \in W$ that minimizes in W the energy functional

$$\mathcal{F}_K(w) = \tfrac{1}{2}(\underline{\underline{\varepsilon}}(\underline{\nabla} w), T\underline{\underline{\varepsilon}}(\underline{\nabla} w))_{\mathcal{H}} - \langle f, w\rangle,$$

where T and $(\cdot, \cdot)_{\mathcal{H}}$ are the same as in the Reissner–Mindlin model. The existence and uniqueness of $w_{\mathcal{H}}$ in the consequence of the coercivity inequality

$$(\underline{\underline{\varepsilon}}, (\underline{\nabla} w), T\underline{\underline{\varepsilon}}(\underline{\nabla} w))_{\mathcal{H}} \geqq c\|w\|_{2,\omega}^2, \qquad w \in W,$$

which itself is an easy consequence of Lemma 3.3. Note that $w_{\mathcal{H}}$ is uniquely defined, in particular, if $f \in H^{-1}(\omega)$, and note also that the pair $(w_K, \underline{\theta}_K)$, where $\underline{\theta}_K = \underline{\nabla} w_K$, minimizes the Reissner functional $\mathcal{F}_R$ over the subspace $Z \subset H_0^1(\omega) \times V$ defined by

$$Z = \{(w, \underline{\theta}) \in W \times V: \theta = \underline{\nabla} w\}.$$

For the Kirchhoff model, the analogy of the mixed variational formulation (3.7) is the following. Given $f \in W'$, find $(w, \underline{\theta}, \underline{\underline{m}}, \underline{\gamma}) \in W \times V \times \mathcal{H} \times V'$ (where V' is the dual space of V) such that

$$(\underline{\underline{m}}, T^{-1}\underline{\underline{k}})_{\mathcal{H}} - (\underline{\underline{\varepsilon}}(\underline{\theta}), \underline{\underline{k}})_{\mathcal{H}} = 0, \qquad \underline{\underline{k}} \in \mathcal{H}, \tag{3.8a}$$

$$\langle \underline{\theta} - \underline{\nabla} w, \underline{\zeta}\rangle = 0, \qquad \underline{\zeta} \in V', \tag{3.8b}$$

$$(\underline{\underline{m}}, \underline{\underline{\varepsilon}}(\underline{\varphi}))_{\mathcal{H}} + \langle \underline{\gamma}, \underline{\varphi}\rangle = 0, \qquad \underline{\varphi} \in V, \tag{3.8c}$$

$$-\langle \underline{\gamma}, \underline{\nabla} z\rangle = \langle f, z\rangle, \qquad z \in W. \tag{3.8d}$$

LEMMA 3.5. *The variational problem* (3.8) *is well posed and the unique solution is* $(w, \underline{\theta}, \underline{\underline{m}}, \underline{\gamma}) = (w_K, \underline{\theta}_K, \underline{\underline{m}}_K, \underline{\gamma}_K)$, *where* $\underline{\theta}_K = \underline{\nabla} w_K$, $\underline{\underline{m}}_K = T\underline{\underline{\varepsilon}}(\underline{\theta}_K)$, *and* $\underline{\gamma}_K$ *is defined by* (3.8c), *i.e.*,

$$\langle \underline{\gamma}_K, \underline{\varphi}\rangle = -(\underline{\underline{m}}_K, \underline{\underline{\varepsilon}}(\underline{\varphi}))_{\mathcal{H}}, \qquad \underline{\varphi} \in V. \tag{3.9}$$

Proof. If $(w, \underline{\theta}, \underline{\underline{m}}, \underline{\gamma}) = (w_K, \underline{\theta}_K, \underline{\underline{m}}_K, \underline{\gamma}_K)$, (3.8a–c) hold trivially. Moreover, since w_K minimizes $\mathcal{F}_K$ in W, we have $(\underline{\underline{m}}_K, \underline{\underline{\varepsilon}}(\underline{\nabla} z))_{\mathcal{H}} = (\underline{\underline{\varepsilon}}(\underline{\nabla} w_K), T\underline{\underline{\varepsilon}}(\underline{\nabla} z))_{\mathcal{H}} = \langle f, z\rangle$ for all $z \in W$; so, by (3.9), (3.8d) holds as well. The well-posedness is proved in Appendix A. □

Remark 3.2. Note that although w_K, $\underline{\theta}_K$, and $\underline{\underline{m}}_K$ obviously do not depend on the way the space V is defined in (3.5), $\underline{\gamma}_K$ certainly does (see below). Hence in this (somewhat weak) sense the "soft" and "hard" formulations are still separate even in the Kirchhoff model.

We need below the following specific result related to the case where ω is a convex polygon.

LEMMA 3.6. *Let w_K be defined as above assuming that ω is a convex polygon and that $f \in H^{-1}(\omega)$. Furthermore, let $\rho \in H_0^1(\omega)$ and $\psi \in H_0^1(\omega)$ be such that*

$$(\underline{\underline{\nabla}}\rho, \underline{\underline{\nabla}}\xi) = (\psi, \xi), \qquad \xi \in H_0^1(\omega), \tag{3.10a}$$

$$(\underline{\underline{\nabla}}\psi, \underline{\underline{\nabla}}\xi) = \langle f, \xi\rangle, \qquad \xi \in H_0^1(\omega). \tag{3.10b}$$

Then $\rho = w_K$ and $\psi = -\Delta w_K$.

Proof. From (3.10a, b) it is obvious that $\psi = -\Delta\rho \in H_0^1(\omega)$, so it suffices to show that $\rho = w_K$. First, since $\psi \in H^1(\omega)$ and since ω is a convex polygon, it follows from (3.10a) that $\rho \in H^2(\omega)$ and $\rho \in H^3(\tilde{\omega})$, $\tilde{\bar{\omega}} \subset \bar{\omega} - UA_i$, A_i being the vertices of ω; i.e., $\rho \in W$ (cf. [13]). Moreover, since $\rho = \Delta\rho = 0$ almost everywhere on $\partial\omega$ and since $\partial\omega$ consists of straight-line segments only, it follows that $\partial^2\rho/\partial t^2 = \partial^2\rho/\partial n^2 = 0$ almost everywhere on $\partial\omega$. Therefore, and noting also that $\partial z/\partial t = 0$ almost everywhere on $\partial\omega$ if $z \in W$, integrating by parts shows that

$$\begin{aligned}(\underline{\underline{\nabla}}\psi, \underline{\underline{\nabla}}z) &= -(\underline{\underline{\nabla}}(\Delta\rho), \underline{\underline{\nabla}}z) = -\nu(\underline{\underline{\nabla}}(\Delta\rho), \underline{\underline{\nabla}}z) - (1-\nu)\sum_{i,j=1}^{2}\left(\frac{\partial^3\rho}{\partial x_i \partial^2 x_j^2}, \frac{\partial z}{\partial x_i}\right)\\ &= (\underline{\underline{\varepsilon}}(\underline{\underline{\nabla}}\rho), T\underline{\underline{\varepsilon}}(\underline{\underline{\nabla}}z)) - \int_{\partial\omega}\left[\nu\Delta\rho + (1-\nu)\frac{\partial^2\rho}{\partial n^2}\right]\frac{\partial z}{\partial n}\,ds\\ &= (\underline{\underline{\varepsilon}}(\underline{\underline{\nabla}}\rho), T\underline{\underline{\varepsilon}}(\underline{\underline{\nabla}}z)), \qquad z \in W.\end{aligned}$$

Hence, by (3.10b), $(\underline{\underline{\varepsilon}}(\underline{\underline{\nabla}}\rho), T\underline{\underline{\varepsilon}}(\nabla z)) = \langle f, z\rangle$, for all $z \in W$, so ρ minimizes $\mathscr{F}_K$ in W and accordingly, $\rho = w_K$. □

We can now prove the following result that will be needed in the next subsection.

LEMMA 3.7. *Let ω be either a convex polygon or a smooth domain, and let $(w, \underline{\theta}, \underline{\underline{m}}, \underline{\gamma}) = (w_K, \underline{\theta}_K, \underline{\underline{m}}_K, \underline{\gamma}_K) \in W \times V \times \mathscr{K} \times V'$ be the solution to (3.8) for a given $f \in H^{-1}(\omega)$, and with V defined by (3.5b). Then $\underline{\gamma}_K = -\underline{\underline{\nabla}}(\Delta w_K) \in [L_2(\omega)]^2$ and $(w_K, \underline{\theta}, \underline{\underline{m}}_K, \underline{\gamma}_K)$ is a solution to (3.7) with $h = 0$ in (3.7b). Moreover, if ω is a convex polygon, then $\|\underline{\gamma}_K\|_{0,\omega} = \|f\|_{-1,\omega}$, where*

$$\|f\|_{-1,\omega} = \sup_{z \in H_0^1(\omega)} \frac{\langle f, z\rangle}{|z|_{1,\omega}},$$

and if ω is a smooth domain, then $\|\underline{\gamma}_K\|_{0,\omega} \leqq C\|f\|_{-1,\omega}$, where C depends on ω.

Proof. If $\underline{\gamma}_K \in [L_2(\omega)]^2$ and $f \in H^{-1}(\omega)$, it follows from a simple closure argument that (3.8) remains valid if W is replaced by V and if $\langle\cdot,\cdot\rangle$ on the left side is replaced by $(\cdot,\cdot)$. To prove that $\underline{\gamma}_K = -\underline{\underline{\nabla}}(\Delta w_K)$, we integrate by parts in (3.9) to obtain

$$\begin{aligned}\langle\underline{\gamma}_K, \underline{\varphi}\rangle &= -\int_\omega \underline{\underline{\nabla}}(\Delta w_K)\cdot\underline{\varphi}\,dx_1\,dx_2 + \int_{\partial\omega}\left[\nu\Delta w_K + (1-\nu)\frac{\partial^2 w_K}{\partial n^2}\right]\underline{\varphi}\cdot\underline{n}\,ds\\ &\quad + \int_{\partial\omega}(1-\nu)\frac{\partial^2 w_K}{\partial n \partial t}\underline{\varphi}\cdot\underline{t}\,ds, \qquad \underline{\varphi} \in V.\end{aligned}$$

Here the first boundary integral vanishes because $\nu\Delta w + (1-\nu)(\partial^2 w/\partial n^2) = 0$ on $\partial\omega$ is the natural boundary condition associated to the problem of minimizing $\mathscr{F}_K$, and the

second boundary integral vanishes since $\underline{\varphi} \cdot \underline{t} = 0$, $\underline{\varphi} \in V$, assuming that V is defined by (3.5b). Hence $\underline{\gamma}_K = -\underline{\nabla}(\Delta w_K)$. On the other hand, from (3.10) we have $\underline{\gamma}_K \in [L_2(\omega)]^2$, and from the well-posedness of (3.8) we see that indeed $\underline{\gamma}_K = -\underline{\nabla}(\Delta w_K)$.

Having verified that $\underline{\gamma}_K = -\underline{\nabla}(\Delta w_K)$, we conclude from Lemma 3.6 that $\underline{\gamma}_K = \underline{\nabla}\psi$, where $\psi \in H_0^1(\omega)$ satisfies (3.10b), so $\|\underline{\gamma}_K\|_{0,\omega} = \|f\|_{-1,\omega}$ as asserted. Finally, if ω is a smooth domain, a standard elliptic regularity estimate implies that $\|\underline{\gamma}_K\|_{0,\omega} \leqq C\|w\|_{3,\omega} \leqq C_1\|f\|_{-1,\omega}$. □

Remark 3.3. It is essential for our results in the next section that when ω is a convex polygon, $\|\underline{\gamma}_K\|_{0,\omega}$ is bounded by $\|f\|_{-1,\omega}$ independently of ω, in contrast to the smooth domain, where the constant depends on ω.

3.4. Energy estimates in case of hard support. Let us define the energy norms

$$|||\underline{u}, \underline{\sigma}|||^2 = \mathcal{A}(\underline{u}, \underline{u}) + \mathcal{B}(\underline{\sigma}, \underline{\sigma}), \qquad (\underline{u}, \underline{\sigma}) \in U \times \mathcal{H},$$

$$|||w, \underline{\theta}, \underline{m}, \underline{\gamma}|||_R^2 = \mathcal{A}_R(w, \underline{\theta}; w, \underline{\theta}) + \mathcal{B}_R(\underline{m}, \underline{\gamma}; \underline{m}, \underline{\gamma}),$$

$$(w, \underline{\theta}, \underline{m}, \underline{\gamma}) \in H_0^1(\omega) \times V \times \mathcal{K} \times [L_2(\omega)]^2,$$

where the bilinear forms are as defined in §§ 3.1 and 3.2. Then by Lemma 3.2 we have the identity

$$|||\underline{u}_0 - \underline{u}, \underline{\sigma}_0 - \underline{\sigma}|||^2 = |||\underline{u}, \underline{\sigma}|||^2 - 2Q(\underline{u}) \tag{3.11}$$

whenever $\underline{u} \in U$ and $\underline{\sigma} \in \mathcal{H}$ satisfies the constraint (3.4b). Similarly, by Lemma 3.4,

$$|||w_R - w, \underline{\theta}_R - \underline{\theta}, \underline{m}_R - \underline{m}, \underline{\gamma}_R - \underline{\gamma}|||_R^2 = |||w, \underline{\theta}, \underline{m}, \underline{\gamma}|||_R^2 - 2\langle f, w\rangle, \tag{3.12}$$

where $(w, \underline{\theta}) \in H_0^1(\omega) \times V$ and $(\underline{m}, \underline{\gamma}) \in \mathcal{K} \times [L_2(\omega)]^2$ satisfies constraints (3.7c, d).

Let us first apply (3.12) to estimate the gap between the Reissner "quadruple" $(w_R, \underline{\theta}_R, \underline{m}_R, \underline{\gamma}_R)$ and the Kirchhoff "quadruple" $(w_K, \underline{\theta}_K, \underline{m}_K, \underline{\gamma}_K)$. By Lemma 3.7, the choice $(w, \underline{\theta}, \underline{m}, \underline{\gamma}) = (w_K, \underline{\theta}_K, \underline{m}_K, \underline{\gamma}_K)$ is legitimate in (3.12) under the assumptions that ω is either a convex polygon or a smooth domain; $f \in H^{-1}(\omega)$; and V is defined by (3.5b), i.e., the case of hard support. Upon simplifying the right side of (3.12), in this case we obtain the identity

$$|||w_R - w_K, \underline{\theta}_R - \underline{\theta}_K, \underline{m}_R - \underline{m}_K, \underline{\gamma}_R - \underline{\gamma}_K|||_R^2 = (h^2/\kappa)\|\underline{\gamma}_K\|_{0,\omega}^2,$$

which together with Lemma 3.7 leads to the following theorem.

THEOREM 3.1. *Let ω be either* (a) *a convex polygon or* (b) *a smooth domain, let $f \in H^{-1}(\omega)$, and let $(w_R, \underline{\theta}_R, \underline{m}_R, \underline{\gamma}_R)$ and $(w_K, \underline{\theta}_K, \underline{m}_K, \underline{\gamma}_K)$ be the solution to* (3.7) *and* (3.8), *respectively, where V is defined by* (3.5b). *Then in case* (a) *we have the identity*

$$|||w_R - w_K, \underline{\theta}_R - \underline{\theta}_K, \underline{m}_R - \underline{m}_K, \underline{\gamma}_R - \underline{\gamma}_K|||_R^2 = (h^2/\kappa)\|f\|_{-1,\omega}^2,$$

where $\|f\|_{-1,\omega}$ is defined as in Lemma 3.7, *and in case* (b) *the estimate*

$$|||w_R - w_K, \underline{\theta}_R - \underline{\theta}_K, \underline{m}_R - \underline{m}_K, \underline{\gamma}_R - \underline{\gamma}_K|||_R^2 = C(h^2/\kappa)\|f\|_{-1,\omega}^2,$$

where C depends on ω.

Remark 3.4. It is easy to verify that

$$|||w_R - w_K, \underline{\theta}_R - \underline{\theta}_K, \underline{m}_R - \underline{m}_K, \underline{\gamma}_R - \underline{\gamma}_K|||_R^2 \geqq E_K - E_R,$$

where E_R and E_K stand for the total energy of the plate in the Kirchhoff and Reissner–Mindlin models, respectively, i.e.,

$$E_K = \mathcal{F}_R(w_K, \underline{\theta}_K) = -\tfrac{1}{2}\langle f, w_K\rangle, \qquad E_R = \mathcal{F}_R(w_R, \underline{\theta}_R) = -\tfrac{1}{2}\langle f, w_R\rangle.$$

In particular, if ω is a convex polygon, Theorem 3.1 and Lemma 3.6 lead to the relative estimate

$$(E_K - E_R)/E_K \leqq C(\omega, f, \nu)h^2/\kappa_0,$$

where κ_0 is the shear correction factor, and

$$C(\omega, f, \nu) = -\frac{1}{6(1-\nu)} \frac{\int_\omega \Delta w_K f \, dx_1 \, dx_2}{\int_\omega w_K f \, dx_1 \, dx_2}.$$

For example, if ω is the unit square and $f(x) \equiv 1$, then $C(\omega, f, \nu) = 3.440428/(1-\nu)$.

Remark 3.5. In case of soft boundary conditions, constraint (3.7c) is more restrictive and rules out the choice $(\underline{\underline{m}}, \underline{\gamma}) = (\underline{\underline{m}}_K, \underline{\gamma}_K)$ in (3.12). It is still possible to find $(\tilde{\underline{\underline{m}}}_K, \tilde{\underline{\gamma}}_K) \in \mathcal{H} \times [L_2(\omega)]^2$, which is close to $(\underline{\underline{m}}_K, \underline{\gamma}_K)$ away from the boundary and satisfies all the required constraints [16]. With such a construction, it is possible to show that if both f and ω are sufficiently smooth, then

$$|||w_R - w_K, \underline{\theta}_R - \underline{\theta}_K, \underline{\underline{m}}_R - \tilde{\underline{\underline{m}}}_K, \underline{\gamma}_R - \tilde{\underline{\gamma}}_K|||_R^2 \leqq C(\omega, f)h.$$

For other estimates of this type see also [11], the references therein, and [20].

Next, we apply (3.11) to bound the difference between the three-dimensional solution and the Kirchhoff solution. To this end, we need to construct a three-dimensional extension $(\underline{u}_K, \underline{\underline{\sigma}}_K) \in U \times \mathcal{H}$ of the Kirchhoff solution $(w_K, \underline{\theta}_K, \underline{\underline{m}}_K, \underline{\gamma}_K)$. Following [16] we define $\underline{u}_K \in U$ as

$$\underline{u}_K = (-x_3\theta_{K,1}, -x_3\theta_{K,2}, w_K + \tfrac{1}{2}x_3^2\psi), \tag{3.13}$$

and $\underline{\underline{\sigma}}_K \in \mathcal{H}$ as

$$\begin{aligned} &\sigma_{K,ij} = -\alpha x_3 m_{K,ij}, && i,j = 1,2, \\ &\sigma_{K,i3} = \alpha(\tfrac{1}{2}x_3^2 - \tfrac{1}{8}h^2)\gamma_{K,i}, && i = 1,2, \\ &\sigma_{K,33} = \alpha(-\tfrac{1}{6}x_3^3 + \tfrac{1}{8}h^2 x_3)f, \end{aligned} \tag{3.14}$$

where $\alpha = 12/h^3$ and $\psi \in H_0^1(\omega)$ is so far unspecified. It is easy to check that $\underline{\underline{\sigma}}_K$ satisfies (3.4b) as far as U is defined by (3.1b), so (3.11) applies with the choice $(\underline{u}, \underline{\underline{\sigma}}) = (\underline{u}_K, \underline{\underline{\sigma}}_K)$ in this case. After a short computation, the right side of (3.11) can then be expressed as

$$\begin{aligned} |||\underline{u}_K, \underline{\underline{\sigma}}_K|||^2 - 2Q(\underline{u}_K) = &\frac{(1-\nu)^2}{1-2\nu} \int_\omega \left(\psi + \frac{\nu}{1-\nu}\Delta w_K\right)^2 dx_1 \, dx_2 \\ &+ \frac{3(1-\nu)}{160} h^2 \int_\omega |\nabla\psi|^2 \, dx_1 \, dx_2 \\ &+ \frac{1}{5(1-\nu)} h^2 \int_\omega (|\underline{\gamma}_K|^2 + \nu \Delta w_K f) \, dx_1 \, dx_2 \\ &+ \frac{17}{1680(1-\nu^2)} h^4 \int_\omega f^2 \, dx_1 \, dx_2 - \frac{1}{4} h^2 \int_\omega \psi f \, dx_1 \, dx_2. \end{aligned}$$

Now if ω is a convex polygon, the choice $\psi = (\nu/(1-\nu))\Delta w_K$ is legitimate and leads—recall also that $\|\gamma_K\|_{0,\omega}^2 = -\int_\omega \Delta w_K f \, dx_1 \, dx_2 = \|f\|_{-1,\omega}^2$ (see Lemmas 3.6 and 3.7)—to the identity

$$|||\underline{u}_K, \underline{\underline{\sigma}}_K|||^2 - 2Q(\underline{u}_K) = \frac{32 + 8\nu + 3\nu^2}{160(1-\nu)} h^2 \|f\|_{-1,\omega}^2 + \frac{17}{1680(1-\nu^2)} h^4 \int_\omega f^2 \, dx_1 \, dx_2.$$

On the other hand, if ω is a smooth domain, we can still find for any $\delta > 0$ a $\psi \in H_0^1(\omega)$ so that

$$\int_\omega \left(\psi - \frac{\nu}{1-\nu}\Delta w_K\right)^2 dx_1\, dx_2 \leqq C\delta\nu^2 \|\Delta w_K\|_{1,\omega}^2, \tag{3.15a}$$

$$\int_\omega |\nabla\psi|^2\, dx_1\, dx_2 \leqq C\delta^{-1}\nu^2 \|\Delta w_K\|_{1,\omega}^2. \tag{3.15b}$$

Since $\|\Delta w_K\|_{1,\omega} \leqq C(\omega)\|f\|_{-1,\omega}$, we obtain in this case, choosing $\delta = \sqrt{1-2\nu}\, h$, the estimate

$$|||\underline{u}_K, \underline{\underline{\varrho}}_K|||^2 - 2Q(\underline{u}_K) \leqq C(\omega)\frac{\nu^2 h^2}{\sqrt{1-2\nu}}\|f\|_{-1,\omega}^2 + \frac{17h^4}{1680(1-\nu^2)}\|f\|_{0,\omega}^2.$$

We thus conclude the following theorem.

THEOREM 3.2. *Assume that ω is either* (a) *a convex polygon or* (b) *a smooth domain. Let $f \in L_2(\omega)$, let $(\underline{u}_0, \underline{\underline{\varrho}}_0) \in U \times \mathcal{H}$ be the solution to* (3.4) *with U defined by* (3.1b), *and let $(\underline{u}_K, \underline{\underline{\varrho}}_K)$ be defined by* (3.13)-(3.14), *where $(w_K, \underline{\theta}_K, \underline{\underline{m}}_K, \underline{\gamma}_K) \in W \times V \times \mathcal{H} \times V'$ is the solution to* (3.8) *with V defined by* (3.5b), *and either $\psi = (\nu/(1-\nu))\Delta w_K$ (case* (a)) *or ψ satisfies* (3.15a, b) *with $\delta = \sqrt{1-2\nu}\, h$ (case* (b)). *Then in case* (a) *we have the identity*

$$|||\underline{u}_0 - \underline{u}_K, \underline{\underline{\varrho}}_0 - \underline{\underline{\varrho}}_K|||^2 = C_1(\nu)h^2\|f\|_{-1,\omega}^2 + C_2(\nu)h^4\|f\|_{0,\omega}^2$$

and in case (b) *the estimate*

$$|||\underline{u}_0 - \underline{u}_K, \underline{\underline{\varrho}}_0 - \underline{\underline{\varrho}}_K|||^2 \leqq C(\omega)[C_3(\nu)h + h^2]\|f\|_{-1,\omega}^2 + C_2(\nu)h^4\|f\|_{0,\omega}^2,$$

where $\|f\|_{-1,\omega}$ is defined as in Lemma 3.7 *and*

$$C_1(\nu) = \frac{32 + 8\nu + 3\nu^2}{160(1-\nu)}, \quad C_2(\nu) = \frac{17}{1680(1-\nu^2)}, \quad C_3(\nu) = \frac{\nu^2}{\sqrt{1-2\nu}}.$$

Remark 3.6. In the case of soft boundary conditions it is possible to show that, if ω is smooth and f is sufficiently smooth, then

$$|||\underline{u}_0 - \underline{u}_K, \underline{\underline{\varrho}}_0 - \underline{\underline{\tilde{\varrho}}}_K|||^2 \leqq C(\omega, f)[1 + C_3(\nu)]h,$$

where $\underline{\underline{\tilde{\varrho}}}_K$ is close to $\underline{\underline{\varrho}}_K$ away from the boundary strip $\partial\omega \times (-h/2, h/2)$ [11], [16].

4. The plate paradox. Let $\omega_0 \subset \mathbb{R}^2$ be the unit circular domain with the center at the origin, i.e.,

$$\omega^{[0]} = \{(x_1, x_2): r^2 = x_1^2 + x_2^2 < 1\}.$$

Furthermore, let $\omega^{[n]}$, $n = 1, 2, \cdots$, be the sequence of regular $(n+3)$-polygons such that

$$\bar{\omega}^{[n]} \subset \omega^{[n+1]} \subset \bar{\omega}^{[n+1]} \subset \omega^{[0]},$$

$$\omega^{[n]} \to \omega^{[0]} \quad \text{as } n \to \infty$$

in the sense that for any $x \in \omega^{[0]}$ there is $n(x) > 0$ such that $x \in \omega^{[n]}$ for all $n > n(x)$. Finally, let $\Omega^{[n]} = \omega^{[n]} \times (-h/2, h/2)$ and $\Omega^{[0]} = \omega^{[0]} \times (-h/2, h/2)$.

Assume now that the unit load is imposed, i.e., $f = p/D = 1$ (see § 2). Then for fixed thickness h there exist the unique solutions $\underline{u}_0^{[n]}$, $(w_R^{[n]}, \underline{\varrho}_R^{[n]})$, and $w_K^{[n]}$, $n = 0, 1, 2, \cdots$, corresponding, respectively, to the three-dimensional, Reissner-Mindlin, and Kirchhoff formulations of the plate-bending problem with either hard or soft

simple support. In § 4.1 we will show that $w_K^{[n]} \to w_K^{[\infty]} \neq w_K^{[0]}$ and give explicit expressions for $w_K^{[\infty]}$ and $w_K^{[0]}$. This is the plate paradox in the Kirchhoff model pointed out in [7] and [3]. In § 4.2 we will show that this paradox also occurs in the Reissner-Mindlin model and in the three-dimensional formulation in case of *hard simple support.* Finally, in § 4.3 we show that the paradox *does not occur* in the Reissner-Mindlin and three-dimensional formulations where soft simple support is imposed. This has been briefly noted in [3].

The results clearly show that seemingly minor changes in the boundary conditions can lead to a significant change of the solution on $\Omega^{[n]}$, respectively, $\omega^{[n]}$, when n is large. In fact, we will see that there can be significant changes already when $n = 1$.

The main question we will address below in this section is whether, as $n \to \infty$,

$$\underline{u}^{[n]} \to \underline{u}^{[0]} \quad \text{for the three-dimensional formulation,}$$

$$(w_R^{[n]}, \underline{\theta}_R^{[n]}) \to (w_R^{[0]}, \underline{\theta}_R^{[0]}) \quad \text{for the Reissner-Mindlin model,}$$

$$w_k^{[n]} \to w_k^{[0]} \quad \text{for the Kirchhoff model.}$$

4.1. The plate paradox for the Kirchhoff model. We have shown in Lemma 3.6 that for $n = 1, 2, \cdots$, $w_k^{[n]} = \rho^{[n]}$, and $-\Delta w_k^{[n]} = \psi^{[n]}$, where $\rho^{[n]}$ and $\psi^{[n]}$ satisfy (3.10a, b).

THEOREM 4.1. *Let* $\rho^{[\infty]}, \psi^{[\infty]} \in H_0^1(\omega^{[0]})$ *be such that*

$$(\underline{\nabla}\rho^{[\infty]}, \underline{\nabla}\xi) = (\psi^{[\infty]}, \xi), \qquad \xi \in H_0^1(\omega^{[0]}), \tag{4.1a}$$

$$(\underline{\nabla}\psi^{[\infty]}, \underline{\nabla}\xi) = \langle f, \xi \rangle, \qquad \xi \in H_0^1(\omega^{[0]}) \tag{4.1b}$$

with $f = 1$. *Then as* $n \to \infty$

$$\|\psi^{[n]} - \psi^{[\infty]}\|_{H^1(\omega^{[0]})} \to 0, \qquad \|\varphi^{[n]} - \rho^{[\infty]}\|_{H^1(\omega^{[0]})} \to 0.$$

Here we understand that $\psi^{[n]}$ *and* $\varphi^{[n]}$ *extend by zero from* $\omega^{[n]}$ *to* $\omega^{[0]}$.

Proof. Let P_n denote the orthogonal projection of $H_0^1(\omega^{[0]})$ onto the subspace $H_0^{1,n}(\omega^{[0]})$ defined by

$$H^{1,n}(\omega^{[0]}) = \{u \in H_0^1(\omega^{[0]}) \colon u = 0 \text{ on } \omega^{[0]} - \omega^{[n]}\}$$

and let $\hat{\psi}^{[n]}$ and $\hat{\rho}^{[n]}$ denote the extension of $\psi^{[n]}$ and $\rho^{[n]}$, respectively, by zero onto $\omega^{[0]}$. Then $\hat{\psi}^{[n]} = P_n \psi^{[\infty]}$ by (4.1b). From Theorem C.1 in Appendix C, it then follows immediately that $\hat{\psi}^{[n]} \to \psi^{[\infty]}$ in $H_0^1(\omega^{[0]})$. From (4.1a) we then see that $\rho^{[n]} - P_n \rho^{[\infty]} \to 0$ in $H_0^1(\omega^{[0]})$, and therefore, by the same argument, that $\hat{\rho}^{[n]} \to \rho^{[\infty]}$ in $H_0^1(\omega^{[0]})$. □

Let us now characterize $\hat{\rho}^{[0]} = w_K^{[0]}$ and $\rho^{[\infty]} = w_K^{[\infty]}$ more explicitly. To this end, note first that $\rho^{[\infty]}$ is the solution to the problem

$$\Delta\Delta\rho^{[\infty]} = 1 \qquad \text{on } \omega^{[0]}, \tag{4.2a}$$

$$\rho^{[\infty]} = \Delta\rho^{[\infty]} = 0 \quad \text{on } \partial\omega^{[0]}. \tag{4.2b}$$

On the other hand, it is easy to see that $\rho^{[0]}$ is the solution of the problem

$$\Delta\Delta\rho^{[0]} = 1 \quad \text{on } \omega^{[0]}, \tag{4.3a}$$

$$\rho^{[0]} = 0 \qquad \text{on } \partial\omega^{[0]}, \tag{4.3b}$$

$$\nu\Delta\rho^{[0]} + (1-\nu)\frac{\partial^2 \rho^{[0]}}{\partial n^2} = 0. \tag{4.3c}$$

Here (4.3c) is the standard boundary condition for the simply supported circular plate (see, e.g., [24, p. 554]). Solutions (4.2) and (4.3) show that

$$\rho^{[\infty]} = C_1^{[\infty]} + C_2^{[\infty]} r^2 + C_3^{[\infty]} r^4, \qquad \rho^{[0]} = C_1^{[0]} + C_2^{[0]} r^2 + C_3^{[0]} r^4,$$

where $r^2 = x_1^2 + x_2^2$,

$$C_3^{[\infty]} = C_3^{[0]} = \frac{1}{64},$$

and C_1, C_2 are determined from the boundary conditions. By simple computation we get

$$\rho^{[0]}(0,0) = w_K^{[0]}(0,0) = \frac{1}{64}\frac{5+\nu}{1+\nu}, \tag{4.4a}$$

$$\rho^{[\infty]}(0,0) = w_K^{[\infty]}(0,0) = \frac{3}{64}, \tag{4.4b}$$

and hence for $\nu = 0.3$ we have

$$\frac{w_K^{[0]}(0,0)}{w_K^{[\infty]}(0,0)} = 1.36,$$

i.e., the gap between $w_K^{[0]}$ and $w_K^{[\infty]}$ is 36 percent at the origin. Analogously, for $\nu = 0.3$,

$$\frac{\|w_K^{[0]} - w_K^{[\infty]}\|_{0,\omega^{[0]}}}{\|w_K^{[\infty]}\|_{0,\omega^{[0]}}} = 0.287.$$

Remark 4.1. We have assumed that $\omega^{[n]}$ were regular polygons. As the proof shows, (4.5b) also holds when $\{\omega^{[n]}\}$ is an arbitrary sequence of *convex* polygons such that $\omega^{[n]} \to \omega^{[0]}$ in the sense described above.

It is essential, however, that $\omega^{[n]}$ are convex polygons. If we replace $\omega^{[n]}$ by $\hat{\omega}^{[n]}$, where $\hat{\omega}^{[n]}$ are nonconvex polygons as shown in Fig. 4.1, then [15] shows that $\hat{\omega}^{[\infty]}$

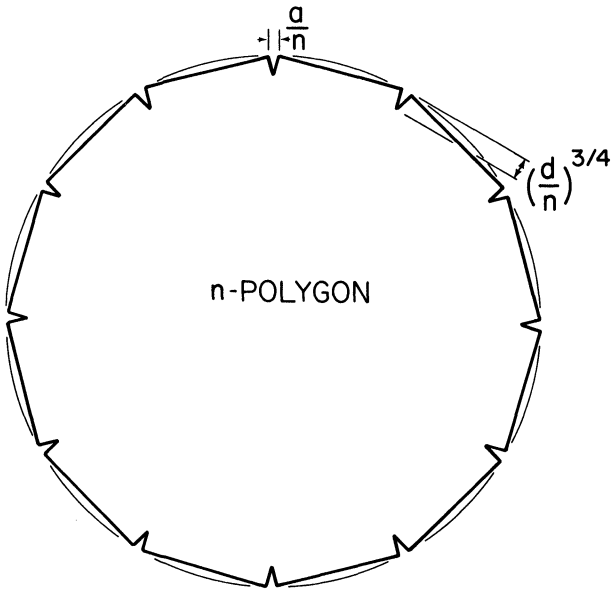

FIG. 4.1. *A nonconvex polygon* $\omega^{[n]}$.

satisfies

$$\Delta\Delta\hat{\omega}^{[\infty]} = 1 \qquad \text{in } \omega^{[0]},$$

$$\hat{\omega}^{[\infty]} = \frac{\partial\hat{\omega}^{[\infty]}}{\partial n} = 0 \qquad \text{in } \partial\omega^{[0]},$$

and hence

$$\hat{\omega}^{[\infty]}(0,0) = \frac{1}{64}. \tag{4.4c}$$

4.2. The plate paradox for the three-dimensional and Reissner–Mindlin models. We will analyze in detail the case of Reissner-Mindlin model only. The case of the three-dimensional formulation can be dealt with analogously.

THEOREM 4.2. *Let h be fixed and sufficiently small, and let $w_R^{[n]}$ be the Reissner-Mindlin solution on $\omega^{[n]}$ corresponding to unit load $f = 1$ on $\omega^{[n]}$ and hard simple support on $\partial\omega^{[n]}$, $n = 0, 1, 2, \cdots$. Then if $w_R^{[n]}$ is extended by zero onto $\omega^{[0]}$, we have*

$$\|w_R^{[n]} - \omega_R^{[0]}\|_{1,\omega^{[0]}} \geqq \alpha > 0,$$

$$\left| \int_{\omega^{[0]}} (w_R^{[n]} - w_R^{[0]})\, dx_1\, dx_2 \right| \geqq \alpha > 0$$

for all $n \geqq n_0$, n_0 large enough.

Proof. By Theorem 3.1 we have

$$|||w_R^{[n]} - w_K^{[n]}, \underline{\theta}_R^{[n]} - \underline{\theta}_K^{[n]}, \underline{m}_R^{[n]} - \underline{m}_K^{[n]}, \underline{\gamma}_R^{[n]} - \underline{\gamma}_K^{[n]}|||_R^2 \leqq h^2/\kappa \|f\|_{-1,\omega^{[n]}}^2,$$

$$|||w_R^{[0]} - w_K^{[0]}, \underline{\theta}_R^{[0]} - \underline{\theta}_K^{[0]}, \underline{m}_R^{[0]} - \underline{m}_K^{[0]}, \underline{\gamma}_R^{[0]} - \underline{\gamma}_K^{[0]}|||_R^2 \leqq Ch^2/\kappa \|f\|_{-1,\omega^{[0]}}^2.$$

Note that $\|f\|_{-1,\omega^{[n]}} \leqq C_0$ independently of n. Using Lemma 3.3 and Theorem B.3, we see that

$$[\|w_R^{[n]} - w_K^{[n]}\|_{1,\omega^{[n]}}^2 + \|\underline{\theta}_R^{[n]} - \underline{\theta}_K^{[n]}\|_{1,\omega^{[n]}}^2] \leqq Ch^2,$$

$$[\|w_R^{[0]} - w_K^{[0]}\|_{1,\omega^{[0]}}^2 + \|\underline{\theta}_R^{[0]} - \underline{\theta}_K^{[0]}\|_{1,\omega^{[0]}}^2] \leqq Ch^2,$$

where C is independent of n and h. On the other hand, we have by Theorem 4.1,

$$\|w_K^{[n]} - w_K^{[\infty]}\|_{1,\omega^{[0]}} \to 0 \quad \text{as } n \to \infty,$$

$$\|w_K^{[\infty]} - w_K^{[0]}\|_{1,\omega^{[0]}} > 0.$$

This shows that for sufficiently small h there is $\alpha > 0$ such that $\|w_R^{[0]} - w_R^{[n]}\|_{1,\omega^{[n]}} \geqq \alpha > 0$ for all $n > n_0$.

Realizing that (in our case for $f = 1$)

$$E_R^{[n]} = -\int_{\omega^{[n]}} w_R^{[n]}\, dx_1\, dx_2, \qquad E_R^{[0]} = -\int w_R^{[0]}\, dx_1\, dx_2,$$

$$E_K^{[n]} = -\int w_K^{[n]}\, dx_1\, dx_2, \qquad E_R^{[0]} = -\int w_K^{[0]}\, dx_1\, dx_2,$$

we also have

$$\left| \int (\omega_R^{[0]} - w_R^{[n]})\, dx_1\, dx_2 \right| \geqq \alpha > 0 \quad \text{as } n > n_0. \qquad \square$$

Using Theorem 3.2 and analogous arguments, we get Theorem 4.3.

THEOREM 4.3. *Let h be fixed and sufficiently small and let $\underline{u}_0^{[n]} = (u_{01}^{[n]}, u_{02}^{[n]}, u_{03}^{[n]})$ be the three-dimensional solution of the plate-bending problem on $\Omega^{[n]}$ corresponding to*

the load $p = D$ and hard simple support, $n = 0, 1, 2, \cdots$. Then if $u_{03}^{[n]}$ is extended by zero onto $\Omega^{[0]}$, we have

$$\|u_{03}^{[n]} - u_{03}^{[0]}\|_{1,\Omega^{[0]}} \geqq \alpha > 0,$$

$$\left| \int_{\omega^{[0]}} \left(u_{03}^{[n]}\left(x_1, x_2, \frac{h}{2}\right) + u_{03}^{[0]}\left(x_1, x_2, \frac{h}{2}\right)\right) dx_1\, dx_2 \right| \geqq \alpha > 0$$

for all $n \geqq n_0$, n_0 sufficiently large.

Theorems 4.2 and 4.3 show that hard simple support leads not only to the paradox in the Kirchhoff model but also to those in the three-dimensional formulation and the Reissner–Mindlin model. (In § 4.3 we will show that the paradox occurs neither in the three-dimensional formulation nor in the Reissner–Mindlin model when the simple soft support is imposed.)

The proof employs the fact that the Kirchhoff model approximates very well the Reissner–Mindlin and three-dimensional formulations for the *hard* support. This shows that the circular plate and polygonal plate solutions are far apart in the entire region and not only in the area close to the boundary, where boundary layer effects occur.

The results above show that plausibly unimportant changes in the boundary conditions could lead to significant changes in the solution through the entire region even if the three-dimensional linear elasticity model is used. We expect that the paradox will also occur in nonlinear formulations. For engineering implications of effects of this type we refer to [6].

4.3. The "nonparadox" in case of soft simple support. In this section we will prove that, in contrast to hard simple support, the solution on $\omega^{[n]}$ converges to the solution on $\omega^{[0]}$ for both the Reissner–Mindlin and the three-dimensional plate model. This is in obvious contrast to hard simple support. We will elaborate in detail on the case of the Reissner–Mindlin model. The analysis of the three-dimensional model is analogous.

Let us denote

$$\mathscr{D}_n = \omega^{[n+1]} - \omega^{[n]}, \qquad n = 1, 2, \cdots,$$

$$\mathscr{D}_0 = \omega^{[1]},$$

$$\mathscr{D}_n^0 = \omega^{[0]} - \omega^{[n]}, \qquad n = 1, 2, \cdots$$

(see Fig. 4.2).

Let $L = (L_2(\omega^{[0]})^3$, $\underline{u} = (w, \underline{\theta}) \in L$ and

$$\mathscr{S}_0 = \{\underline{u} \in L\colon w \in H_0^1(\omega^{[0]}),\ \underline{\theta} \in (H^1(\omega^{[0]}))^2\},$$

$$\mathscr{S}_n = \{u \in L\colon w \in H_0^1(\omega^{[0]}),\ w = 0 \text{ on } \mathscr{D}_n^0,\ \underline{\theta} \in (H^1(\omega^{[0]})^2)\},$$

$$\mathscr{T}_n = \{u \in L\colon w \in H_0^1(\omega^{[0]}),\ \underline{\theta} \in (H^1(\omega^{[n]}))^2,\ \underline{\theta} \in (H^1(\mathscr{D}_m))^2,\ m = n, n+1, \cdots\},$$

$$\mathscr{L}_{n,m} = \{u \in L\colon w \in H_0^1(\omega^{[0]}),\ w = 0 \text{ on } \mathscr{D}_n^0,$$

$$\underline{\theta} \in (H^1(\omega^{[m]}))^2,\ \underline{\theta} \in (H^1(\mathscr{D}_j))^2,\ j = m, m+1, \cdots\}.$$

We have $\mathscr{S}_n \subset \mathscr{S}_0$, $\mathscr{S}_0 \subset \mathscr{T}_n$, and

$$\mathscr{L}_{n,m} \supset \mathscr{S}_n, \qquad \mathscr{L}_{n,m} \subset \mathscr{T}_m.$$

All the spaces are embedded in $\mathscr{T}_1$. Furthermore, let

$$Z_n = \{u \in L\colon w \in H^1(\omega^{[n]}),\ \underline{\theta} \in (H^1(\omega^{[n]})^2\},$$

$$\mathring{Z}_n = \{u \in Z_n\colon w \in H_0^1(\omega^{[n]})\},$$

$$\mathscr{A}_R^0(w, \underline{\theta}; z, \underline{\varphi}) = \sum_{i=0}^{\infty} \mathscr{A}_R^{\mathscr{D}_i}(\underline{u}, \underline{v}),$$

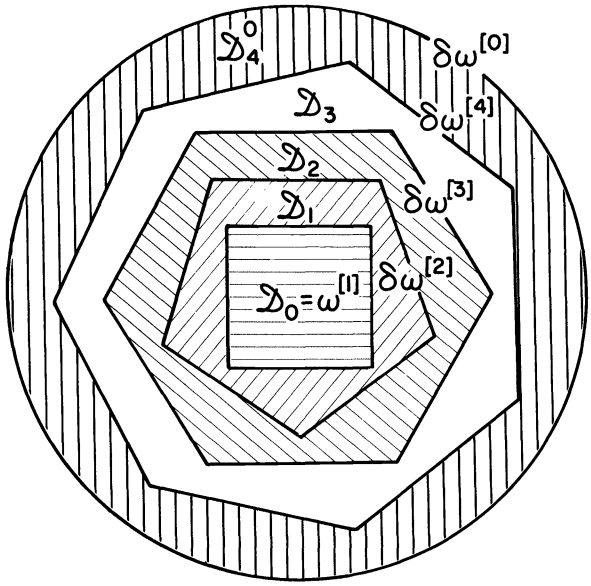

FIG. 4.2. *The configuration of the domains* $\mathcal{D}_n$, $\mathcal{D}_0$, $\mathcal{D}'_n$.

where $\mathcal{A}_R^{\omega}$ is given in § 3.2 for the region ω and $\mathcal{A}_R^{\mathcal{D}^i}$ has the same form but is integrated only over $\mathcal{D}^i$. Analogously we define $\mathcal{A}_R^{\omega^{[n]}}$, etc. Finally, we supply $\mathcal{T}_1$ with the norm

$$\|\underline{u}\|^2 = \sum_{i=0}^{\infty} \mathcal{A}_R^{\mathcal{D}^i}(\underline{u}, \underline{u}).$$

To see that $\|\cdot\|$ is indeed a norm, assume that $\underline{u} = (w, \underline{\theta}) \in \mathcal{T}_1$ and $\|\underline{u}\| = 0$. Then, since the first term in the expression for $\mathcal{A}_R^{\mathcal{D}^i}$ is the same as in the case of plane elasticity (where θ_1, θ_2 play the role of the displacements), we have on $\mathcal{D}_j$, $\theta_1 = a_j + c_j x_2$, $\theta_2 = b_j - c_j x_1$, and because $\|\underline{\theta} - \nabla w\|_{0,\mathcal{D}_j} = 0$ we get $c_j = 0$. Hence $w = d_j + a_j x_1 + b_j x_2$ on $\mathcal{D}_j$, and so, because $w \in H_0^1(\omega^{[0]})$ we get $w = 0$ and $a_j = b_j = 0$, $j = 0, 1, 2, \cdots$ (see also Appendix B). Hence $\underline{u} = 0$ and accordingly, $\|\cdot\|$ is a norm on $\mathcal{T}_1$.

For $\underline{u} \in Z_n$ let $\|\underline{u}\|^2_{R,\omega^{[n]}} = \mathcal{A}_R^{\omega^{[n]}}(\underline{u}, \underline{u})$. Then by Theorem B.1 in Appendix B,

$$\inf_{abc} \|\theta_1 - (a + cx_2), \theta_2 - (b - cx_1)\|_{1,\omega^{[n]}} \leqq C_n \|u\|_{R,\omega^{[n]}}, \tag{4.5a}$$

$$\inf_{abcd} \|w - (d + ax_1 + bx_2 + cx_1 x_2)\|_{1,\omega^{[n]}} \leqq C_n \|u\|_{R,\omega^{[n]}}. \tag{4.5b}$$

Here C_n depends in general on $\omega^{[n]}$.

Assume now that for an $n_0 > 0$

(4.6a) f has compact support in $\omega^{[n_0]}$,

$$\int_{\omega^{[n_0]}} f\,dx_1\,dx_2 = \int_{\omega^{[n_0]}} fx_1\,dx_1\,dx_2 = \int_{\omega^{[n_0]}} fx_2\,dx_1\,dx_2 = \int_{\omega^{[n_0]}} fx_1 x_2\,dx_1\,dx_2 = 0 \tag{4.6b}$$

and that $n > n_0$, $m > n_0$. Then for $\underline{u} \in \mathcal{T}_n$, $n \geqq n_0$,

$$\left| \int_{\omega^{[0]}} fw\,dx_1\,dx_2 \right| = \left| \int_{\omega^{[n_0]}} fw\,dx_1\,dx_2 \right| \leqq C_{n_0} \|u\|.$$

Hence for $n, m \geqq n_0$ there exist unique

$$\underline{u}(\mathcal{S}_n) \in \mathcal{S}_n, \quad \underline{u}(\mathcal{T}_n) \in \mathcal{T}_n, \quad \underline{u}(\mathcal{L}_{n,m}) \in \mathcal{L}_{n,m}, \quad \underline{u}(\mathring{\mathcal{Z}}_n) \in \mathring{\mathcal{Z}}_m$$

such that

$$t_R^0(\underline{u}(\mathcal{S}_n), \underline{v}) = \int_{\omega^{[0]}} fz \, dx_1 \, dx_2 \quad \forall v \in (z, \underline{\varphi}) \in \mathcal{S}_n$$

and analogously for $u(\mathcal{T}_n)$, $u(\mathcal{L}_{n,m})$, $u(\mathring{\mathcal{Z}}_n)$. Obviously $\underline{u}(\mathcal{S}_0) = \underline{u}_R^{[0]}$ and $\underline{u}(\mathring{\mathcal{Z}}_n) = \underline{u}_R^{[n]}$, and $\underline{u}(\mathcal{L}_{n,m}) = \underline{u}(\mathring{\mathcal{Z}}_n)$ on $\omega^{[n]}$ and is zero on $\mathcal{D}_n^0$.

Using Theorem C.1 we get

(4.7a) $$\underline{u}_R^{[0]} = \underline{u}(\mathcal{S}_0) = \underline{u}(\mathcal{S}_n) + \underline{\rho}(\mathcal{S}_0, \mathcal{S}_n),$$

(4.7b) $$\|\underline{u}(\mathcal{S}_0)\|^2 = \|\underline{u}(\mathcal{S}_n)\|^2 + \|\underline{\rho}(\mathcal{S}_0, \mathcal{S}_n)\|^2,$$

(4.7c) $$\|\underline{\rho}(\mathcal{S}_0, \mathcal{S}_n)\| \to 0 \quad \text{as } n \to \infty;$$

(4.8a) $$\underline{u}(\mathcal{T}_n) = \underline{u}(\mathcal{S}_0) + \underline{\rho}(\mathcal{T}_n, \mathcal{S}_0),$$

(4.8b) $$\|\underline{u}(\mathcal{T}_n)\|^2 = \|\underline{u}(\mathcal{S}_0)\|^2 + \|\underline{\rho}(\mathcal{T}_n, \mathcal{S}_0)\|^2,$$

(4.8c) $$\|\underline{\rho}(\mathcal{T}_n, \mathcal{S}_0)\| \to 0 \quad \text{as } n \to \infty;$$

(4.9a) $$\underline{u}(\mathcal{L}_{n,m}) = \underline{u}(\mathcal{S}_n) + \underline{\rho}(\mathcal{L}_{n,m}, \mathcal{S}_n),$$

(4.9b) $$\|\underline{u}(\mathcal{L}_{n,m})\|^2 = \|\underline{u}(\mathcal{S}_n)\|^2 + \|\underline{\rho}(\mathcal{L}_{n,m}, \mathcal{S}_n)\|^2,$$

(4.9c) $$\|\underline{\rho}(\mathcal{L}_{n,m}, \mathcal{S}_n)\| \to 0 \quad \text{as } m \to \infty;$$

(4.10a) $$\underline{u}(\mathcal{T}_m) = \underline{u}(\mathcal{L}_{n,m}) + \underline{\rho}(\mathcal{T}_m, \mathcal{L}_{n,m}),$$

(4.10b) $$\|\underline{u}(\mathcal{T}_m)\|^2 = \|\underline{u}(\mathcal{L}_{n,m})\|^2 + \|\underline{\rho}(\mathcal{T}_m, \mathcal{L}_{n,m})\|^2,$$

(4.10c) $$\|\underline{\rho}(\mathcal{T}_m, \mathcal{L}_{n,m})\| \to 0 \quad \text{as } n \to \infty.$$

Now let $\varepsilon > 0$ and $n > \max(n(\varepsilon), n_0)$. Then we have

$$\|\underline{\rho}(\mathcal{S}_0, \mathcal{S}_n)\|^2 < \varepsilon, \qquad \|\underline{\rho}(\mathcal{T}_n, \mathcal{S}_0)\|^2 < \varepsilon.$$

Using (4.7)-(4.10) we get

$$\begin{aligned}\|\underline{u}(\mathcal{S}_0)\|^2 + \|\underline{\rho}(\mathcal{T}_m, \mathcal{S}_0)\|^2 &= \|\underline{u}(\mathcal{T}_m)\|^2 = \|\underline{u}(\mathcal{L}_{n,m})\|^2 + \|\underline{\rho}(\mathcal{T}_m, \mathcal{L}_{n,m})\|^2 \\ &= \|\underline{u}(\mathcal{S}_n)\|^2 + \|\underline{\rho}(\mathcal{L}_{n,m}, \mathcal{S}_n)\|^2 + \|\underline{\rho}(\mathcal{T}_n, \mathcal{L}_{n-n})\|^2 \\ &= \|\underline{u}(\mathcal{S}_n)\|^2 - \|\underline{\rho}(\mathcal{S}_0, \mathcal{S}_n)\|^2 + \|\underline{\rho}(\mathcal{L}_{n,m}, \mathcal{S}_n)\|^2 \\ &\quad + \|\underline{\rho}(\mathcal{T}_m, \mathcal{L}_{n,m})\|^2\end{aligned}$$

and hence for $n, m \geqq \max(n(\varepsilon), n_0)$

$$\|\underline{\rho}(\mathcal{T}_m, \mathcal{S}_0)\|^2 + \|\underline{\rho}(\mathcal{S}_0, \mathcal{S}_n)\|^2 = \|\underline{\rho}(\mathcal{L}_{n,m}, \mathcal{S}_n)\|^2 + \|\underline{\rho}(\mathcal{T}_m, \mathcal{L}_{n,m})\|^2 \leqq 2\varepsilon,$$

which yields

$$\|\underline{\rho}(\mathcal{L}_{n,n}, \mathcal{S}_n)\|^2 \leqq 2\varepsilon.$$

Therefore

$$\underline{u}(\mathcal{S}_0) - \underline{u}(\mathcal{L}_{n,n}) = \underline{u}(\mathcal{S}_0) - \underline{u}(\mathcal{S}_n) + \underline{u}(\mathcal{S}_n) - \underline{u}(\mathcal{L}_{n,n}) = \underline{\rho}(\mathcal{S}_0, \mathcal{S}_n) - \underline{\rho}(\mathcal{L}_{n,n}, \mathcal{S}_n)$$

and hence

$$\|\underline{u}(\mathcal{S}_0) - \underline{u}(\mathcal{L}_{n,n})\| \leqq \varepsilon^{1/2} + \sqrt{2\varepsilon} \leqq C\varepsilon^{1/2}.$$

Because, as above, $\underline{u}(\mathcal{L}_{n,n}) = \underline{u}_R^{[n]}$ on $\omega^{[n]}$, and zero on $\mathcal{D}_n^0$, $\underline{u}_R^{[n]} \to \underline{u}_R^{[0]}$ in the space $\mathcal{T}_1$ or in any $\mathcal{T}_m$ for m fixed.

Remark 4.2. Note that until now we have not used Theorem B.3 (Appendix B), but only Theorem B.1.

So far we have assumed that f satisfies (4.6). Let us now study the general case. Assume that $f \in L_2(\omega^{[0]})$.

Let us first note that if $\underline{u} = (w, \theta) \in \mathscr{L}_{n,n}$, then $w \in H_0^1(\omega^{[0]})$ and

$$\|w\|_{1,\omega^{[n]}} = \|w\|_{1,\omega^{[n]}} \leqq C\|\underline{u}\| \tag{4.11}$$

with C independent of n because of Theorem B.3.

For $0 < \Delta < \frac{1}{2}$ we denote

$$R_\Delta = \{(x_1, x_2): x_1^2 + x_2^2 > 1 - \Delta\},$$
$$\partial R_\Delta = \{(x_1, x_2): x_1^2 + x_2^2 = 1 - \Delta\}.$$

Then

$$\|w\|_{0,R_\Delta} \leqq C\Delta \|w\|_{1,\omega^{[0]}} \leqq C\Delta\|u\|,$$
$$\|w\|_{0,\partial R_\Delta} \leqq C\Delta^{1/2}\|w\|_{1,\omega^{[0]}} \leqq C\Delta^{1/2}\|u\|.$$

Now let

$$f_\Delta = \begin{cases} f & \text{on } R_\Delta, \\ 0 & \text{on } \omega^{[0]} - R_\Delta, \end{cases}$$
$$g_\Delta = (a + bx_1 + cx_2 + dx_1x_2)\mathscr{O}_\Delta,$$

where $\mathscr{O}_\Delta$ is the Dirac function concentrated on ∂R_Δ and a, b, c, d are such that $f_\Delta + g_\Delta$ satisfies (4.6).

For $n > n_{1,\Delta}$ such that $\bar{\bar{R}}_\Delta \subset \omega^{[n_{1,\Delta}]}$, let $\underline{u}_\Delta(\mathscr{L}_{n,n})$ and $\underline{u}_\Delta(\mathscr{S}_0)$ be the solutions when instead of f the function f_Δ is used. Then we get

$$\|\underline{u}_\Delta(\mathscr{L}_{n,n}) - \underline{u}(\mathscr{L}_{n,n})\| \leqq C\Delta^{1/2},$$
$$\|\underline{u}_\Delta(\mathscr{S}_0) - \underline{u}(\mathscr{S}_0)\| \leqq C\Delta^{1/2},$$

where C is independent of n and Δ but, in general, depends on f. Hence we can select Δ so that $C\Delta^{1/2} < \varepsilon$. Furthermore, we have shown

$$\|\underline{u}_\Delta(\mathscr{L}_{n,n}) - \underline{u}_\Delta(\mathscr{S}_0)\| < \varepsilon$$

for all $n \geqq n_1(\varepsilon)$ and therefore

$$\|\underline{u}(\mathscr{L}_{n,n}) - \underline{u}(\mathscr{S}_0)\| < 3\varepsilon$$

for all $n \geqq n_1(\varepsilon)$. Since $\underline{u}(\mathscr{S}_0) = \underline{u}_R^{[0]}$ and $\underline{u}(\mathscr{L}_{n,n}) = \underline{u}_R^{[n]}$, we get

$$\|\underline{u}_R^{[0]} - \underline{u}_R^{[n]}\| \to 0 \quad \text{as } n \to \infty.$$

Here $\underline{u}_R^{[n]} = (w_R^{[n]}, \underline{\theta}_R^{[n]})$ is understood to be extended by zero on $\mathscr{D}_n^0$ and $\|\cdot\|$ is the norm in $\mathscr{T}_1$ (note that $w_R^{[n]} \in H_0^1(\omega^{[0]})$, but $\underline{\theta}_R^{[n]} \notin H^1(\omega^{[0]})$ although $\theta_R^{[n]} \subset H^1(\omega^{[n]})$). Because the functions in $H^1(\omega^{[0]})$ with compact support are dense in $H_0^1(\omega^0)$, there is $\bar{w}^{[n]} \in H_0^1(\omega^{[n]})$ such that $\|w^{[0]} - \bar{w}^{[n]}\| \leqq \varepsilon$ for all $n \geqq n_2(\varepsilon)$. Hence with $\bar{\underline{u}}^{[n]} = (\bar{w}^{[n]}, \underline{\theta}_R^{[n]})$ we get

$$\|\bar{\underline{u}}^{[n]} - \underline{u}_R^{[0]}\| \to 0 \quad \text{as } n \to \infty.$$

Hence, using Theorem B.2 (Appendix B), we have

$$\|w_R^{[n]} - w_R^{[0]}\|^2_{H^1(\omega^{[n]})} + \|\underline{\theta}^{[n]} - \underline{\theta}_R^{[0]}\|^2_{H^1(\omega^{[n]})} \to 0 \quad \text{as } n \to \infty.$$

In summary, we have proved Theorem 4.4 below.

THEOREM 4.4. *Let* $f \in L_2(\omega^{[0]})$ *and let* $u_R^{[n]} = (w_R^{[n]}, \underline{\theta}_R^{[n]})$, *respectively,* $u_R^{[0]} = (w_R^{[0]}, \underline{\theta}_R^{[0]})$, *be the Reissner-Mindlin solution on* $\omega^{[n]}$, *respectively,* $\omega^{[0]}$, *for soft simple support and fixed h. Then*

$$\|w_R^{[n]} - w_R^{[0]}\|_{H^1(\omega^{[n]})} + \|\underline{\theta}_R^{[n]} - \underline{\theta}_R^{[0]}\|_{H^1(\omega^{[n]})} \to 0 \quad \text{as } n \to \infty.$$

We see that in contrast to the hard support there is no plate paradox when the soft support is imposed. Hence soft simple support is physically more natural than hard simple support.

Remark 4.3. In Theorem 4.2 we assumed that $f \in L_2(\omega^{[0]})$ while the solutions $\underline{u}_R^{[0]}$ and $\underline{u}_R^{[n]}$ were defined for any $f \in H^{-1}(\omega^{[0]})$, respectively, $f \in H^{-1}(\omega^{[n]})$. If f has compact support, then Theorem 4.4 also holds for $f \in H^{-1}(\omega^{[0]})$. We can weaken the assumptions on f in Theorem 4.4, e.g., so that $f \in H^{\alpha}(\omega^{[0]})$, $\alpha > -\frac{1}{2}$, but the proof will not hold for $f \in H^{-1}(\omega^{[0]})$.

Remark 4.4. We have assumed that $\omega^{[n]}$ is the sequence of regular polygons. This assumption was used only when we were using Theorem B.3. Hence Theorem 4.4 holds for any regular family of domains (see Appendix B). If f satisfies (4.6), then there is no need for regularity (see Remark 4.2) of the family of domains under consideration and Theorem 4.4 holds in the full generality.

Remark 4.5. We have assumed in Theorem 4.5 that $h > 0$ is fixed (i.e., independent of n). We could also consider a two-parameter family of problems where both n and h vary. Then, for n fixed and $h \to 0$, $\underline{u}_R^{[n]} \to \underline{u}_K^{[n]}$ (and hence for $h \to 0$ the difference between soft and hard support disappears). Hence, combining the results of this section with § 4.2, we see that

$$\lim_{n\to\infty} \lim_{h\to 0} \underline{u}_R^{(n)} \neq \lim_{h\to 0} \lim_{n\to\infty} \underline{u}_R^{(n)}.$$

In a way analogous to the proof of Theorem 4.4, we can prove Theorem 4.5.

THEOREM 4.5. *Let h be fixed and* $\underline{u}^{[0]}$, *respectively* $\underline{u}^{[n]}$, *be the solution of the three-dimensional plate problem on* $\Omega^{[0]}$, *respectively,* $\Omega^{[n]}$, *with soft simple support. Assume that the load* $p \in L_2(\omega^{[0]})$. *Then*

$$\|\underline{u}^{[0]} - \underline{u}^{[n]}\|_{1,\Omega^{[n]}} \to 0$$

as $n \to \infty$.

Remark 4.6. Remarks 4.3–4.5 are also valid for the three-dimensional plate model.

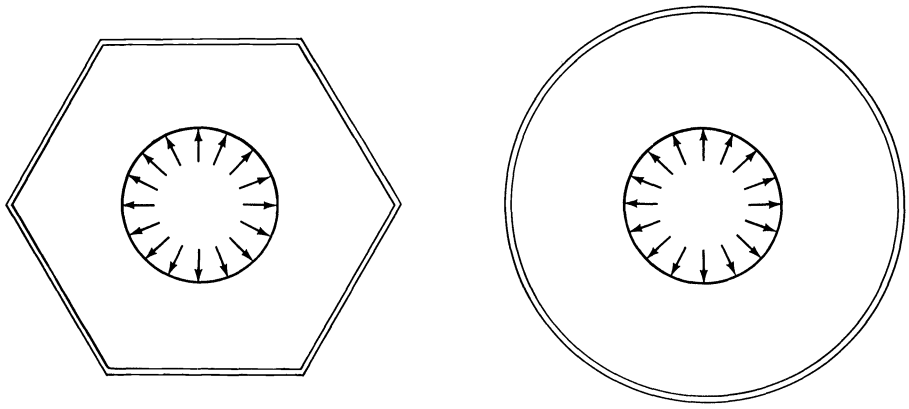
4.4. Some additional considerations. As we have seen, the Kirchhoff model (biharmonic equation) leads to paradoxical behavior for hard simple support. The same mathematical formulation also describes other problems and hence leads to the same paradoxical behavior.

As an example, we mention the problem of a reinforced tube shown in Fig. 4.3a, b. The reinforcement is attached by an unextendable tape to the exterior surface. Here we have the paradox that the stress caused by hydrostatic pressure is different for the polygonal and circular outer surfaces.

Analogous examples can very likely be found in fields other than elasticity where the problem reduces to the biharmonic (or polyharmonic) equation.

We have shown the paradoxical behavior for $n \to \infty$ and h relatively large compared with $1/n$ (see Remark 4.5). Hence the question arises of how large will be the difference between hard and soft support in three-dimensional formulation for n fixed and $h \to 0$. To this end we consider a square plate with sidelength equal to 1. In Table 4.1 we give the values of

$$\left[\frac{|E_{\text{SOFT}} - E_{\text{HARD}}|}{|E_{\text{SOFT}}|}\right]^{1/2} = \eta(h), \qquad \left[\frac{|E_{\text{HARD}} - E_K|}{|E_{\text{HARD}}|}\right]^{1/2} = \xi(h).$$



(a) (b)

FIG. 4.3. *Reinforced polygonal and circular tubes.*

TABLE 4.1

Percent	$h = 0.1$	$h = 0.01$
η	34.68	11.69
ξ	20.21	2.03

Here by E_{SOFT} and E_{HARD} we denote the (three-dimensional) plate energy for soft and hard support, and by E_K, the plate energy of the Kirchhoff model for the Poisson ratio $\nu = 0$ (see also [7]).

Appendix A. Well-posedness of variational problems (3.4), (3.7), and (3.8). We use the following basic theorem (see [18]).

THEOREM A.1. *Let H be a Hilbert space and $\mathcal{B}$ be a bilinear form on $H \times H$ that satisfies*

$$\text{(A0)} \qquad \mathcal{B}(u, v) = \mathcal{B}(v, u), \qquad u, v \in H,$$

$$\text{(A1)} \qquad |\mathcal{B}(u, v)| \leqq C\|u\|_H \|v\|_H, \qquad u, v \in H,$$

$$\text{(A2)} \qquad \sup_{\substack{v \in H \\ \|v\|_H = 1}} \mathcal{B}(u, v) \geqq c\|u\|_H \quad \forall u \in H,$$

where C and c are positive constants. Then if F is any bounded linear functional on H, there is a unique $u \in H$ satisfying

$$\text{(A3)} \qquad \mathcal{B}(u, v) = F(v), \qquad v \in H.$$

In applying Theorem A.1 to problems (3.4), (3.7), and (3.8), we choose the following notation.

(a) The three-dimensional model (3.4):

$$H = U \times \mathcal{H},$$

$$\mathcal{B}(\underline{u}, \underline{\sigma}; \underline{v}, \underline{\tau}) = (\underline{\sigma} S^{-1} \underline{\tau})_{\mathcal{H}} - (\underline{\varepsilon}(\underline{u}), \underline{\tau})_{\mathcal{H}} - (\underline{\sigma}, \underline{\varepsilon}(\underline{v}))_{\mathcal{H}},$$

$$F(\underline{v}, \underline{\tau}) = -Q(\underline{v}).$$

(b) The Reissner-Mindlin model (3.7):

$$H = H_0^1(\omega) \times V \times \mathcal{K} \times [L_2(\omega)]^2,$$

$$\mathcal{B}(w, \underline{\theta}, \underline{\underline{m}}, \underline{\gamma}; z, \underline{\varphi}, \underline{\underline{k}}, \underline{\zeta}) = (\underline{\underline{m}}, T^{-1}\underline{\underline{k}})_{\mathcal{K}} - (\underline{\underline{\varepsilon}}(\underline{\theta}), \underline{\underline{k}})_{\mathcal{K}} - (\underline{\underline{\varepsilon}}(\underline{\varphi}), \underline{\underline{m}})_{\mathcal{K}} - (\underline{\theta} - \underline{\nabla} w, \underline{\zeta}) - (\underline{\varphi} - \underline{\nabla} z, \underline{\gamma}) + (h^2/\kappa)(\underline{\gamma}, \underline{\zeta}),$$

$$F(z, \underline{\varphi}, \underline{\underline{k}}, \underline{\zeta}) = -\langle f, z\rangle.$$

(c) The Kirchhoff model (3.8):

$$H = W \times V \times \mathcal{K} \times V',$$

$$\mathcal{B}(w, \underline{\theta}, \underline{\underline{m}}, \underline{\gamma}; z, \underline{\varphi}, \underline{\underline{k}}, \underline{\zeta}) = (\underline{\underline{m}}, T^{-1}\underline{\underline{k}})_{\mathcal{K}} - (\underline{\underline{\varepsilon}}(\underline{\theta}), \underline{\underline{k}})_{\mathcal{K}} - (\underline{\underline{\varepsilon}}(\underline{\varphi}), \underline{\underline{m}})_{\mathcal{K}} - \langle \underline{\theta} - \underline{\nabla} w, \underline{\zeta}\rangle - \langle \underline{\varphi} - \underline{\nabla} z, \underline{\gamma}\rangle,$$

$$F(z, \underline{\varphi}, \underline{\underline{k}}, \underline{\zeta}) = -\langle f, z\rangle.$$

Then in each case, $\mathcal{B}$ is symmetric, F is a bounded linear functional on H, and the variational problem takes the general form (A3). Thus it suffices to show that (A1) and (A2) hold.

THEOREM A.2. *Assume that ω is a bounded Lipschitz domain and that the parameters ν, h, and κ satisfy*

$$0 \leqq \nu < \tfrac{1}{2}, \quad \bar{h} \leqq h \leqq \bar{h}^{-1}, \quad \bar{\kappa} \leqq \kappa \leqq \bar{\kappa}^{-1},$$

where $\bar{h} > 0$ and $\bar{\kappa} > 0$ are given. Then in each of the three cases above there are constants $C = C(\bar{h}, \bar{\kappa})$ and $c = c(\omega, \bar{h}, \bar{\kappa})$ such that (A1) *and* (A2) *hold.*

Proof. In view of (3.2) and (3.6) the mappings $S^{-1}: \mathcal{H} \to \mathcal{H}$ and $T^{-1}: \mathcal{K} \to \mathcal{K}$ are uniformly bounded in the assumed range of ν. It then follows easily that the assertion concerning (A1) holds, so let us concentrate on showing that (A2) is true.

(a) The three-dimensional model. Let $(\underline{u}, \underline{\underline{\sigma}}) \in U \times \mathcal{H}$ be given and let

$$(\underline{\underline{\sigma}}_0)_{ij} = \tfrac{1}{3} \operatorname{tr}(\underline{\underline{\sigma}}) \delta_{ij}, \qquad i, j = 1, 2, 3.$$

Then $\|\underline{\underline{\sigma}}\|_{\mathcal{H}}^2 = \|\underline{\underline{\sigma}} - \underline{\underline{\sigma}}_0\|_{\mathcal{H}}^2 + \frac{1}{3}\|\operatorname{tr}(\underline{\underline{\sigma}})\|_{0,\Omega}^2$ and it follows from (3.2) that

$$(\underline{\underline{\sigma}}, S^{-1}\underline{\underline{\sigma}})_{\mathcal{H}} = \frac{D}{E}\{(1+\nu)\|\underline{\underline{\sigma}} - \underline{\underline{\sigma}}_0\|_{\mathcal{H}}^2 + (1-2\nu)\|\underline{\underline{\sigma}}_0\|_{\mathcal{H}}^2\}$$

(A4)

$$\geqq \frac{h^3}{12}\|\underline{\underline{\sigma}} - \underline{\underline{\sigma}}_0\|_{\mathcal{H}}^2 \qquad (0 \leqq \nu \leqq \tfrac{1}{2}).$$

We use the following lemma, which is related to the well-posedness of the Stokes problem. For the proof see [12].

LEMMA A.1. *There exists $\underline{v}_0 \in U$ and a constant C_1 depending on ω and $\bar{h}$ such that the following inequalities hold*:

$$\|\underline{v}_0\|_{1,\Omega} \leqq C_1 \|\operatorname{tr}(\underline{\underline{\sigma}})\|_{0,\Omega},$$

$$(\operatorname{div} \underline{v}_0, \operatorname{tr}(\underline{\underline{\sigma}})) \geqq \|\operatorname{tr}(\underline{\underline{\sigma}})\|_{0,\Omega}^2.$$

With $\underline{v}_0$ as in Lemma A.1 we now set $(\underline{v}, \underline{\underline{\tau}}) = (-\underline{u} - \delta \underline{v}_0, \underline{\underline{\sigma}} - \delta^2 \underline{\underline{\varepsilon}}(\underline{u}))$, where δ is a constant to be specified shortly. Then by (A4), the inequality $(\tau_1, \tau_2)_{\mathcal{H}} \leqq (s/2)\|\tau_1\|_{\mathcal{H}}^2 + (1/2s)\|\tau_2\|_{\mathcal{H}}^2$ $(s > 0)$, and Lemma 3.1, we have that

$$\begin{aligned}
\mathcal{B}(\underline{u}, \underline{\underline{\sigma}}; \underline{v}, \underline{\underline{\tau}}) &= (\underline{\underline{\sigma}}, S^{-1}\underline{\underline{\sigma}})_{\mathcal{H}} + \tfrac{1}{3}\delta(\operatorname{tr}(\underline{\underline{\sigma}}), \operatorname{div} \underline{v}_0) \\
&\quad + \delta(\underline{\underline{\sigma}} - \underline{\underline{\sigma}}_0, \underline{\underline{\varepsilon}}(\underline{v}_0)) + \delta^2\|\underline{\underline{\varepsilon}}(\underline{u})\|_{\mathcal{H}}^2 - \delta^2(\underline{\underline{\sigma}}, S^{-1}\underline{\underline{\varepsilon}}(\underline{u}))_{\mathcal{H}} \\
&\geqq (\tfrac{1}{12}\bar{h}^3 - C_2\delta - C_3\delta^2)\|\underline{\underline{\sigma}} - \underline{\underline{\sigma}}_0\|_{\mathcal{H}}^2 + (\tfrac{1}{6}\delta - C_4\delta^2)\|\operatorname{tr}(\underline{\underline{\sigma}})\|_{0,\Omega}^2 + c_1\delta^2\|\underline{u}\|_{1,\Omega}^2 \\
&\geqq \min\{\tfrac{1}{12}\bar{h}^3 - C_2\delta - C_3\delta^2, \tfrac{1}{2}\delta - 3C_4\delta^2, c_1\delta^2\}(\|\underline{u}\|_{1,\Omega}^2 + \|\underline{\underline{\sigma}}\|_{\mathcal{H}}^2).
\end{aligned}$$

Thus, choosing δ to be a sufficiently small positive number, we have found $(\underline{v}, \underline{\tau}) \in U \times \mathcal{H}$ such that $\|\underline{v}, \underline{\tau}\|_H \leqq C\|\underline{u}, \underline{\varrho}\|_H$ and $\mathcal{B}(\underline{u}, \underline{\varrho}; \underline{v}, \underline{\tau}) \geqq c\|\underline{u}, \underline{\varrho}\|_H^2$, where C and c depend only on ω and $\bar{h}$. Hence (A2) is true in case (a) with c depending on ω and $\bar{h}$.

(b) The Reissner-Mindlin model. Given $(w, \underline{\theta}, \underline{\underline{m}}, \underline{\gamma}) \in H_0^1(\omega) \times V \times \mathcal{H} \times [L_2(\omega)]^2$, let $(z, \underline{\varphi}, \underline{\underline{k}}, \underline{\zeta}) = (-w, -\underline{\theta}, \underline{\underline{m}} - \delta \underline{\underline{\varepsilon}}(\underline{\theta}), \underline{\gamma} - \delta(\underline{\theta} - \underline{\nabla} w))$, where δ is a constant to be specified. Then noting that by (3.6), $(\underline{\underline{m}}, T^{-1}\underline{\underline{m}}) \geqq \|\underline{\underline{m}}\|_{\mathcal{H}}^2/(1+\nu)$, and recalling Lemma 3.3, we have

$$\begin{aligned}
\mathcal{B}(w, \underline{\theta}, \underline{\underline{m}}, \underline{\gamma}; z, \underline{\varphi}, \underline{\underline{k}}, \underline{\zeta}) &= (\underline{\underline{m}}, T^{-1}\underline{\underline{m}})_{\mathcal{H}} + \left(\frac{h^2}{\kappa}\right)\|\underline{\gamma}\|_{0,\omega}^2 + \delta\|\underline{\underline{\varepsilon}}(\underline{\theta})\|_{\mathcal{H}}^2 - \delta(\underline{\underline{m}}, T^{-1}\underline{\underline{\varepsilon}}(\underline{\theta}))_{\mathcal{H}} \\
&\quad + \delta\|\underline{\theta} - \underline{\nabla} w\|_{0,\omega}^2 - \delta\left(\frac{h^2}{\kappa}\right)(\underline{\gamma}, \underline{\theta} - \underline{\nabla} w) \\
&\geqq \left(\frac{1}{1+\nu} - C_1\delta\right)\|\underline{\underline{m}}\|_{\mathcal{H}}^2 + \frac{1}{2}\delta\|\underline{\underline{\varepsilon}}(\underline{\theta})\|_{\mathcal{H}}^2 + \frac{1}{2}\delta\|\underline{\theta} - \underline{\nabla} w\|_{0,\omega}^2 \\
&\quad + \left(\frac{h^2}{\kappa}\right)\left(1 - C_2\delta\frac{h^2}{\kappa}\right)\|\underline{\gamma}\|_{0,\omega}^2 \\
&\geqq \min\left\{\frac{1}{1+\nu} - C_1\delta, c_1\delta, \frac{h^2}{\kappa}\left(1 - C_2\delta\frac{h^2}{\kappa}\right)\right\}\|w, \underline{\theta}, \underline{\underline{m}}, \underline{\gamma}\|_H^2.
\end{aligned}$$

Thus if δ is small enough we have found $(z, \underline{\varphi}, \underline{\underline{k}}, \underline{\zeta}) \in H$ such that $\|z, \underline{\varphi}, \underline{\underline{k}}, \underline{\zeta}\|_H \leqq C\|w, \underline{\theta}, \underline{\underline{m}}, \underline{\gamma}\|_H$ and $\mathcal{B}(w, \underline{\theta}, \underline{\underline{m}}; z, \underline{\varphi}, \underline{\underline{k}}, \underline{\zeta}) \geqq c\|w, \underline{\theta}, \underline{\underline{m}}, \underline{\gamma}\|_H^2$, where the constants depend only on ω, $\bar{h}$, and $\bar{\kappa}$. These prove the assertion in case (b).

(c) The Kirchhoff model. Given $(w, \underline{\theta}, \underline{\underline{m}}, \underline{\gamma}) \in H$, let $(z, \underline{\varphi}, \underline{\underline{k}}, \underline{\zeta}) = (-w, -\underline{\theta} - \delta\underline{\varphi}_0, \underline{\underline{m}} - \delta\underline{\underline{\varepsilon}}(\underline{\theta}), \underline{\gamma} - \delta\underline{\zeta}_0)$, where $\underline{\varphi}_0 \in V$ and $\underline{\zeta}_0 \in V'$ are defined so as to satisfy

$$\begin{aligned}
&\|\underline{\varphi}_0\|_{1,\omega} = \|\underline{\gamma}\|_{V'}, \qquad \langle \underline{\gamma}, \underline{\varphi}_0\rangle = \|\underline{\gamma}\|_{V'}^2, \\
&\|\underline{\zeta}_0\|_{V'} = \|\underline{\theta} - \underline{\nabla} w\|_{1,\omega}, \qquad \langle \underline{\theta} - \underline{\nabla} w, \underline{\zeta}_0\rangle = \|\underline{\theta} - \underline{\nabla} w\|_{1,\omega}^2,
\end{aligned}$$

which obviously is possible. As in case (b), we then find that for a sufficiently small δ, $\|z, \underline{\varphi}, \underline{\underline{k}}, \underline{\zeta}\|_H \leqq C\|w, \underline{\theta}, \underline{\underline{m}}, \underline{\gamma}\|_H$ and $\mathcal{B}(w, \underline{\theta}, \underline{\underline{m}}, \underline{\gamma}; z, \underline{\varphi}, \underline{\underline{k}}, \underline{\zeta}) \geqq c\|w, \underline{\theta}, \underline{\underline{m}}, \underline{\gamma}\|_H^2$, where C and c depend only on ω, and so the assertion follows in case (c).

Appendix B. The Korn inequality. Let ω be a bounded Lipschitz domain and define the seminorm

$$|\underline{\theta}|_{E(\omega)} = \left\{\int_\omega \sum_{i,j=1}^{2} |\varepsilon_{ij}(\underline{\theta})|^2 \, dx_1 \, dx_2\right\}^{1/2}, \qquad \underline{\theta} \in (H^1(\omega))^2,$$

where $\varepsilon_{ij}(\underline{\theta}) = \frac{1}{2}(\partial\theta_i/\partial x_j + \partial\theta_j/\partial x_i)$, and let

$$|\underline{u}|_{R,\omega}^2 = |\underline{\theta}|_{E(\omega)}^2 + \|\underline{\theta} - \underline{\nabla} w\|_{0,\omega}^2, \quad \underline{u} = (w, \underline{\theta}), \quad w \in H^1(\omega), \quad \underline{\theta} \in (H^1(\omega))^2.$$

THEOREM B.1. *There is a constant C depending only on ω such that for any $\underline{\theta} \in [H^1(\omega)]^2$*

$$\text{(B1)} \qquad \inf_{abc}\{\|\theta_1 - a - bx_2\|_{1,\omega}^2 + \|\theta_2 - c + bx_1\|_{1,\omega}^2\} \leqq C|\underline{\theta}|_{E(\omega)}^2,$$

$$\text{(B2)} \qquad \inf_{abcd}\|w - (a + bx_1 + cx_2 + dx_1x_2)\|_{H^1(\omega)} \leqq C|\underline{u}|_{R,\omega}.$$

Proof. Inequality (B1) follows immediately from the Korn inequality for plane elasticity (see [19]). Inequality (B2) follows from (B1).

LEMMA B.1. *There exists a constant C depending on ω such that for any $(w, \underline{\theta}) \in [H^1(\omega)]^3$*

$$\|w\|^2_{1,\omega} + \|\underline{\theta}\|^2_{1,\omega} \leqq C\left\{|\underline{u}|^2_{R,\omega} + \int_{\partial\omega} w^2\, ds\right\}.$$

Proof. We apply the standard contradiction argument. If the assertion is not true, there is a sequence $\{w_n, \underline{\theta}_n\}$ such that

$$\|w_n, \underline{\theta}_n\|_{1,\omega} = 1,$$

$$\|\underline{\theta}_n\|_{E(\omega)} \to 0,$$

$$\|\underline{\theta}_n - \underline{\underline{\nabla}} w_n\|_{0,\omega} \to 0, \qquad \int_{\partial\omega} w_n^2\, ds \to 0$$

as $n \to \infty$. Then by Theorem B.1, $\{\underline{\theta}_n\}$ contains a subsequence (which we denote once more by $\{\underline{\theta}_n\}$) such that $\underline{\theta}_n \to (a - bx_2, c + bx_1)$ in $[H^1(\omega)]^2$. Furthermore, since $\|\theta_n - \nabla w_n\|_{0,\omega} \to 0$, there is another subsequence (once more denoted by $\{\underline{\theta}_n, w_n\}$) so that $w_n \to w$ in $H^1(\omega)$. Hence $b = 0$ and $w = ax_1 + cx_2 + d$. Because $\int w_n^2\, ds \to 0$ we get $a = c = d = 0$, contradicting the assumption $\|w_n, \underline{\theta}_n\|_{1,\omega} = 1$. □

We immediately get Theorem B.2.

THEOREM B.2. *There exists a constant C depending only on ω such that for any $\underline{u} = (w, \underline{\theta}) \in H^1_0(\omega) \times [H^1(\omega)]^2$*

$$\|w\|^2_{1,\omega} + \|\underline{\theta}\|_{1,\omega} \leqq C|\underline{u}|^2_{R,\omega}. \tag{B3}$$

Let us now consider a family $\mathcal{F} = \{\omega\}$ of Lipschitz bounded domains. The family will be called *regular* if there is a (uniform) constant C so that (B3) holds for all $\omega \in \mathcal{F}$.

Let us now consider a special family of domains. Let $\omega^{[0]}$ be a unit circle and $\omega^{[n]}$ be a sequence of regular $n+3$-polygons such that

$$\bar{\omega}^{[n]} \subset \bar{\omega}^{[n+1]} \subset \bar{\omega}^{[n+1]} \subset \omega^{[0]},$$

$$\omega^{[n]} \to \omega^{[0]} \quad \text{as } n \to \infty$$

in the sense that for any $x \in \omega^{[0]}$ there is $n(x) > 0$ such that $x \in \omega^{[n]}$ for all $n > n(x)$. We let $\mathcal{F}_0 = \{\omega^{[0]}, \omega^{[1]}, \omega^{[2]}, \cdots\}$.

THEOREM B.3. *The family $\mathcal{F}_0$ is a regular family of domains and hence there exists $C > 0$ such that*

$$\|w\|^2_{1,\omega^{[n]}} + \|\underline{\theta}\|^2_{1,\omega^{[n]}} \leqq C|\underline{u}|^2_{R,\omega^{[n]}}$$

for any $\underline{u} = (w, \underline{\theta}) \in H^1_0(\omega^{[n]}) \times [H^1(\omega^{[n]})]^2$, $n = 0, 1, 2, \cdots$.

Proof. For $n > n_0$ the $\omega^{[n]}$ are star-shaped domains and

$$\partial\omega^{[n]} = \{(x_1, x_2): x_1 = \rho_n(\theta)\cos\theta, x_2 = \rho_n(\theta)\sin\theta, 0 \leqq \theta \leqq 2\pi\},$$

where $\rho_n(\theta) \to 1$ and $\rho_n'(\theta) \to 0$ uniformly. Let Q_n be the one-to-one map of $\omega^{[n]}$ onto $\omega^{[0]}$ defined by

$$Q_n(\rho(\theta)\cos\theta, \rho(\theta)\sin\theta) = (\rho(\theta)\cos\theta, \rho(\theta)\sin\theta) \quad \text{for } \rho(\theta) \leqq \frac{1}{2}$$

$$= \left(\frac{1}{2}\frac{\rho(\theta) - (\frac{1}{2})}{\rho_n(\theta) - (\frac{1}{2})} + \frac{1}{2}\right)\cos\theta$$

$$= \left(\frac{1}{2}\frac{\rho(\theta) - (\frac{1}{2})}{\rho_n(\theta) - (\frac{1}{2})} + \frac{1}{2}\right)\sin\theta \quad \text{for } \rho(\theta) > \frac{1}{2}.$$

If $Q_n(x_1, x_2) = (\xi_1, \xi_2)$ then we have $\xi_1 = \xi_1^{[n]}(x_1, x_2)$, $\xi_2^{[n]} = \xi_2(x_1, x_2)$, $x_1 = x_1^{[n]}(\xi_1, \xi_2)$, $x_2 = x_2^{[n]}(\xi_1, \xi_2)$, and $\xi_i^{[n]} \to x_i$, $(\partial\xi_i/\partial x_j) \to \delta_{ij}$, $x_i^{[n]} \to \xi_i$, $(\partial x_i/\partial\xi_j) \to \delta_{ij}$, $i, j = 1, 2$ as $n \to \infty$, uniformly with respect to $(x_1, x_2) \in \omega^{[n]}$ and $(\xi_1, \xi_2) \in \omega^{[0]}$. Let $\underline{u} = (w, \underline{\theta}) \in H_0^1(\omega^{[n]}) \times (H^1(\omega^{[n]}))^2$ and let

$$\bar{u} = (\bar{w}, \bar{\underline{\theta}}), \qquad \bar{\underline{u}}(\xi_1, \xi_2) = \underline{u}(x_1(\xi_1, \xi_2), x_2(\xi_1, \xi_2)).$$

Then $\bar{\underline{u}} \in H_0^1(\omega^{[0]}) \times (H^1(\omega^{[0]})^2)$ and by Theorem B.2 we have

$$\|\bar{w}\|_{1,\omega^{[0]}}^2 + \|\underline{\theta}\|_{1,\omega^{[0]}}^2 \leqq C|\bar{\underline{u}}|_{R,\omega^{[0]}}^2$$

and also

$$\|\bar{w}\|_{1,\omega^{[0]}} = \|w\|_{1,\omega^{[n]}}(1 + o(1)),$$

$$\|\bar{\underline{\theta}}\|_{1,\omega^{[0]}} = \|\underline{\theta}\|_{1,\omega^{[n]}}(1 + o(1)),$$

$$|\bar{\underline{u}}|_{R,\omega^{[0]}} = |\underline{u}|_{R,\omega^{[n]}} + o(1)(\|w\|_{1,\omega^{[n]}} + \|\underline{\theta}\|_{1,\omega^{[n]}})$$

as $n \to \infty$. Hence

$$\|w\|_{1,\omega^{[n]}}^2(1 + o(1)) + \|\underline{\theta}\|_{1,\omega^{[n]}}^2(1 + o(1)) \leqq C[|\underline{u}|_{R,\omega^{[n]}}^2 + o(1)(\|w\|_{1,\omega^{[n]}}^2 + \|\underline{u}\|_{1,\omega^{[n]}}^2)].$$

From this we see that for $n > n_0$ the family is a regular one. Using Theorem B.2, we then see that the whole family $\mathscr{F}_0$ is regular. □

Appendix C. A projection theorem.

THEOREM C.1. *Let H be a Hilbert space, let $\{H_n\}$ and $\{K_n\}$ be sequences of closed subspaces of H such that $H_n \subset H_{n+1}$ and $K_n \supseteq K_{n+1}$, $n = 1, 2, \cdots$, and let*

$$H_0 = \overline{\bigcup_n H_n} \quad \text{and} \quad K_0 = \bigcap_n K_n.$$

Furthermore, let P_n and Q_n, respectively, P_0, Q_0, be orthogonal projections onto H_n and K_n, respectively, H_0, K_0. Then for any $u \in H$

$$\|P_n u - P_0 u\| \to 0, \qquad \|Q_n u - Q_0 u\| \to 0$$

as $n \to \infty$.

Proof. First observe that $\|Q_{n+1}u\| = \|Q_{n+1}Q_n u\| \leqq \|Q_n u\|$, so $\|Q_n u\| \to q \geqq 0$ monotonically. Furthermore,

$$\|Q_n u - Q_{n+j}u\| = \|Q_n u\|^2 - 2(Q_n u, Q_{n+j}u) + \|Q_{n+j}\|^2 = \|Q_n u\|^2 - \|Q_{n+j}u\|^2,$$

so $\{Q_n u\}$ is a Cauchy sequence. So $Q_n u \to v$ and $v \in K_n$ for all n. Hence $v \in K_0$ and since $(v, w) = \lim_{n\to\infty}(Q_n u, w) = \lim_{n\to\infty}(u, Q_n w) = (u, w)$ for all $w \in K_0$, it follows that $v = Q_0 u$.

Let us now consider the projection operator $I - P_n = \tilde{Q}_n$. Then $\tilde{Q}_n$ projects H onto H_n^1 and $H_w^1 \supset H_{n+1}^1$. Hence $\tilde{Q}_n u = u - P_n u \to u - v \in \bigcap H_n^1$. So $P_n u \to v \in H_0$ and by the same argument as before, $v = P_0 u$. □

A BIDIMENSIONAL ELECTROMAGNETIC PROBLEM*

MICHEL CROUZEIX† AND JEAN DESCLOUX‡

Abstract. Electric alternating currents running in a system of infinite cylindrical parallel conductors generate an electromagnetic field, which is defined by a potential $\varphi : \mathbb{R}^2 \to \mathbb{C}$. φ is harmonic in the exterior domain and satisfies a Helmholtz equation in the cross sections of the conductors. The asymptotic properties of φ as the frequency tends to infinity, in particular the boundary layers due to the skin effect, are studied.

Key words. electromagnetic fields, asymptotic behaviour, boundary layer, skin effect, Helmholtz equation

AMS(MOS) subject classifications. 35J05, 35B25, 35B40

1. Introduction. This paper has been motivated by the numerical simulation of the electromagnetic casting process (EMC). When the ingot is sufficiently long, the electromagnetic part of the problem reduces to the search of a complex potential φ in $\mathbb{R}^2$, of class C^1, with logarithmic behaviour at infinity, satisfying the conditions

$$\Delta\varphi + 2i\alpha^2(\varphi + C_k) = 0 \quad \text{in } \Omega_k, \quad 1 \leqq k \leqq N, \qquad \Delta\varphi = 0 \quad \text{in } \bar{\Omega}^c; \tag{1.1}$$

here $\Omega_k \subset \mathbb{R}^2$, $1 \leqq k \leqq N$, are the cross sections in the x_1, x_2 plane of cylindrical electric conductors in which runs a current with angular frequency ω; $2\alpha^2 = \mu_0\sigma\omega$ is a real constant where μ_0 is the magnetic permeability of the air and σ the conductivity; i is the imaginary unit and the C_k's are given complex constants.

Our initial purpose was to find a fast, accurate, and reliable numerical algorithm for solving problem (1.1). We have been led to a theoretical study of problem (1.1), partly independent of our original aim, which is the subject of this paper. We shall report on the numerical aspects in a forthcoming paper.

Maybe because of the problem's particular character, we have found few references in the literature relative to problem (1.1). All of them [2], [4] are essentially concerned with numerical, practical, or theoretical questions.

In § 2, we introduce some notation and recall a few basic mathematical tools and results. We feel it is necessary to construct with some detail our mathematical model; this is the object of § 3. In § 4, because of their physical and mathematical relevance, we define two specific problems, closely related to (1.1), which are studied in the remaining parts of the paper.

For many applications, in particular for the EMC process, the coefficient α is large and we can observe a very pronounced skin effect in the conductors, i.e., the electric current $j = 2i\alpha^2(\varphi + C_k)$ almost vanishes in Ω_k except in a thin layer in the neighborhood of $\partial\Omega_k$. This is a serious difficulty for numerical computations, in particular, since we are specially interested in the fields (current, induction, Laplace forces) in the conductors. For this reason in §§ 5-7 we analyse the behaviour of φ for large α. Section 5 gives some global estimates for the rate of convergence of φ to a limit function φ_∞, as α tends to infinity. Section 6 contains more refined local estimates. In § 7 we construct a simple and accurate boundary layer approximation of φ in the neighborhood of smooth parts of $\partial\Omega_k$. All these results are rather satisfactory and complete except in the neighborhoods of corners of $\partial\Omega_k$ for which many improvements

* Received by the editors February 29, 1988; accepted for publication (in revised form) May 26, 1989.

remain to be done; in particular, we have not succeeded in getting a simple picture of the singularity of φ at a corner for large α.

As a consequence of Proposition 7.2, it follows that, along regular parts of $\partial\Omega_k$, φ satisfies approximatively a Robin-type boundary condition. In § 8 we show how this property can be used, in the case where the $\partial\Omega_k$'s have no corner, for defining an approximation of φ, which can be computed easily.

2. Notation and some basic tools. An element of $\mathbb{R}^2$ is denoted by $x=(x_1, x_2)$; $|x|^2=x_1^2+x_2^2$. $B(x,\delta)$ is the open ball with center x and radius δ. ∂_1 and ∂_2 are the partial derivatives with respect to x_1 and x_2 and $\vec{\nabla}=(\partial_1,\partial_2)$. For $m\geqq 0$, ∂_1^m and ∂_2^m are the mth derivatives with respect to x_1 and x_2. For $\Lambda\subset\mathbb{R}^2$, $\bar{\Lambda}$ is the closure of Λ, $\partial\Lambda$ is the boundary of Λ and χ_Λ is the characteristic set of Λ. For a function $v:\Lambda\to\mathbb{C}$, $\bar{v}$ is the complex conjugate of v, and $\partial v/\partial n$ denotes the exterior normal derivative. For $\Lambda\subset\mathbb{R}^2$ open, the symbols $L^p(\Lambda)$, $H^m(\Lambda)$, $W^{m,p}(\Lambda)$ (Sobolev spaces), $C^m(\Lambda)$, $C_0^m(\Lambda)$, $C^{m,\beta}(\Lambda)$ (the mth derivatives are β Hölder continuous, $0<\beta<1$) and the corresponding norms $\|\cdot\|_{L^p(\Lambda)},\cdots$, have their usual meanings for complex-valued functions. We will also use the spaces $L^p_{\mathrm{loc}}(\Lambda),\cdots$ and $L^p(\partial\Lambda)\cdots$.

For an open set $\Lambda\subset\mathbb{R}^2$, $\partial\Lambda$ is piecewise C^∞ if $\partial\Lambda$ is composed of a finite number of closed arcs that are C^∞ and if for each interior angle γ at corners we have $0<\gamma<2\pi$; furthermore, we impose the condition $\partial\Lambda=\partial\bar{\Lambda}$.

Let $\Lambda\subset\mathbb{R}^2$ be an open connected set such that Λ^c is bounded and let $\Phi\neq\varnothing$ be an open bounded subset of Λ. We define

$$W_0^1(\Lambda)=\left\{v:\Lambda\to\mathbb{C}\;\middle|\;\frac{v}{(1+|x|)\ln(2+|x|)}\in L^2(\Lambda):\partial_l v\in L^2(\Lambda),\ l=1,2\right\}, \tag{2.1}$$

$$\|v\|^2_{W_0^1(\Lambda)}=\|v\|^2_{L^2(\Phi)}+\|\partial_1 v\|^2_{L^2(\Lambda)}+\|\partial_2 v\|^2_{L^2(\Lambda)}. \tag{2.2}$$

For a study of the space $W_0^1(\Lambda)$, we can consult, for example, [6]. In particular, we have the following proposition.

PROPOSITION 2.1. (a) *$W_0^1(\Lambda)$ is a complete space for the norm $\|\cdot\|_{W_0^1(\Lambda)}$.*

(b) *$C_0^\infty(\mathbb{R}^2)$ is dense in $W_0^1(\mathbb{R}^2)$.*

(c) *If $\partial\Lambda$ is piecewise C^∞, then $W_0^1(\Lambda)=\{v_{|\Lambda}\mid v\in W_0^1(\mathbb{R}^2)\}$.*

(d) $1\in W_0^1(\Lambda)$, $\ln(1+|x|)\notin W_0^1(\mathbb{R}^2)$.

The following result of potential theory is classical.

PROPOSITION 2.2. *Let v be an harmonic complex function on the open domain $\Lambda\subset\mathbb{R}^2$ with bounded complement. We suppose that $v(x)=O(\ln|x|)$ as $|x|\to\infty$. Then there exist complex constants d and e such that*

$$v(x)=d\ln|x|+e+O(|x|^{-1}),$$
$$\partial_1^k\partial_2^l v(x)=d\,\partial_1^k\partial_2^l\ln|x|+O(|x|^{-(k+l+1)}),\qquad k+l\geqq 1.$$

The next trace estimate will play an important role in § 5.

PROPOSITION 2.3. *Let $\Lambda\subset\mathbb{R}^2$ be an open domain such that $\partial\Lambda$ is piecewise C^∞. Then there exists a constant c independent of $v\in H^1(\Lambda)$ such that*

$$\|v\|^2_{L^2(\partial\Lambda)}\leqq c\|v\|_{H^1(\Lambda)}\|v\|_{L^2(\Lambda)}. \tag{2.3}$$

Proof. By a classical imbedding theorem (see, for example, [1]), for any $w\in L^1(\Lambda)$ such that $\partial_l w\in L^1(\Lambda)$, $l=1,2$, we have $\|w\|_{L^1(\partial\Lambda)}\leqq c\{\|w\|_{L^1(\Lambda)}+\|\partial_1 w\|_{L^2(\Lambda)}+\|\partial_2 w\|_{L^1(\Lambda)}\}$, where c is some generic constant. We apply this result to $w=v^2$ and by Schwarz's inequality we obtain

$$\begin{aligned}(\|v\|_{L^2(\partial\Lambda)})^2&\leqq c\{\|v\|^2_{L^2(\Lambda)}+\|v\|_{L^2(\Lambda)}(\|\partial_1 v\|_{L^2(\Lambda)}+\|\partial_2 v\|_{L^2(\omega)})\}\\&\leqq c\|v\|_{L^2(\Lambda)}\|v\|_{H^1(\Lambda)}.\end{aligned}$$

□

3. Mathematical model. In $\mathbb{R}^3$ we consider a system of N cylindrical conductors parallel to the x_3 axis in an alternating electromagnetic field. We denote by $\Omega_1, \Omega_2, \cdots, \Omega_N \subset \mathbb{R}^2$ their cross sections, which we suppose are bounded in the x_1, x_2 plane, and set $\Omega = \cup\, \Omega_k$. Let $\vec{j}$, E, and H be, respectively, the tridimensional complex current, the electric field, and the magnetic field. We introduce the following assumptions:

(3.1) (a) $\vec{E}(x_1, x_2, x_3, t) = E(x_1, x_2)\, e^{-i\omega t}\, \vec{e}_3$ in the conductors,

(3.2) (b) $\vec{H}(x_1, x_2, x_3, t) = H_1(x_1, x_2)\, e^{-i\omega t}\, \vec{e}_1 + H_2(x_1, x_2)\, e^{-i\omega t}\, \vec{e}_2$ in $\mathbb{R}^3$,

(3.3) (c) $\vec{j} = \sigma \vec{E}$ in the conductors, $\vec{j} = 0$ outside the conductors,

(3.4) (d) $\partial_t \vec{H} + 1/\mu_0 \overrightarrow{\text{rot}}\, E = 0$ in the conductors,

(3.5) (e) $\overrightarrow{\text{rot}}\, \vec{H} = \vec{j}$ in $\mathbb{R}^3$,

(3.6) (f) $\text{div}\, \vec{H} = 0$ in $\mathbb{R}^3$.

Let us be precise and comment on these hypotheses. i is the complex unit; ω is the angular frequency; t is the time; μ_0 is the magnetic permeability in the vacuum; $\vec{e}_1$, $\vec{e}_2$, $\vec{e}_3$ are the unit vectors along the coordinate axis. Assumption (3.1) is assumed to be valid only in the conductors; supposing (3.1) is valid in $\mathbb{R}^3$ is physically not realistic (see Sommerfeld [7]) and would lead to mathematical contradictions. In (3.3), we suppose that the electric conductivity σ is the same positive constant for all conductors; in fact, all results contained in this paper can be extended without difficulty to the case where the conductivity is constant in each conductor but different from one to another. Assumptions (3.4)-(3.6) are standard Maxwell's equations where in (3.5) we have neglected the displacement currents, which is legitimate for moderate frequencies. Finally, we observe that all fields are x_3 independent and can be considered as mapping from $\mathbb{R}^2$ into $\mathbb{C}$ or $\mathbb{C}^2$.

From (3.1), (3.3), there exists $j : \mathbb{R}^2 \to \mathbb{C}$ such that

$$\begin{aligned} &\vec{j}(x_1, x_2, x_3, t) = j(x_1, x_2)\, e^{-i\omega t}\, \vec{e}_3, \quad \text{and} \\ &j(x) = \sigma E(x) \quad \text{for } x \in \Omega, \qquad j(x) = 0 \quad \text{for } x \in \Omega^c, \end{aligned} \tag{3.7}$$

where $x = (x_1, x_2) \in \mathbb{R}^2$. From (3.6) and (3.2) follows the existence of a potential φ in $\mathbb{R}^2$ such that

$$(H_1(x), H_2(x)) = \overrightarrow{\text{rot}}\, \varphi(x) = (\partial_2 \varphi(x), -\partial_1 \varphi(x)), \qquad x \in \mathbb{R}^2 \tag{3.8}$$

where $\overrightarrow{\text{rot}}$ denotes here the bidimensional vector curl. By using in particular (3.1), (3.4), (3.7), and (3.8), we obtain

$$\overrightarrow{\text{rot}}\, (i\omega\mu_0\sigma\varphi - j) = 0 \quad \text{in } \Omega_k, \quad k = 1, 2, \cdots, N;$$

this implies the existence of constants $C_k \in \mathbb{C}$ such that

$$j = i\omega\mu_0\sigma(\varphi + C_k) \quad \text{in } \Omega_k, \quad k = 1, 2, \cdots, N. \tag{3.9}$$

By (3.2), (3.5), (3.7), and (3.8), we have

$$-\Delta\varphi = j \quad \text{in } \mathbb{R}^2; \tag{3.10}$$

finally, with (3.7), (3.9), we obtain

$$-\Delta\varphi = i\omega\mu_0\sigma\chi\varphi + f \quad \text{in } \mathbb{R}^2 \tag{3.11}$$

where χ is the characteristic function of Ω and $f = i\omega\mu_0\sigma C_k$ in Ω_k, $f = 0$ in Ω^c.

For physical reasons, it is natural to impose on φ a behaviour at most logarithmic at infinity. By Proposition 2.2 there exist constants d and $e \in \mathbb{C}$ such that

$$\varphi(x) = d \ln |x| + e + O(|x|^{-1}) \quad \text{as } |x| \to \infty. \tag{3.12}$$

Without restriction of generality, we can further impose the constraint $e = 0$ since the physical fields are independent of e.

On the basis of equations (3.11), (3.12) with the condition $e = 0$, we are now in the position of formulating the mathematical problem we will study.

Let $\Omega = \bigcup_k \Omega_k \subset \mathbb{R}^2$; we suppose

(3.13) (a) Ω_k is a bounded connected open set, $1 \leqq k \leqq N$;

(3.14) (b) $\bar{\Omega}_k \cap \bar{\Omega}_l = \varnothing$ for $k \neq l$; $\partial\Omega$ is piecewise C^∞.

For given constants $C_k \in \mathbb{C}$, $k = 1, 2, \cdots, N$, our basic mathematical problem will be to find $\varphi \in L^2_{\text{loc}}(\mathbb{R}^2)$ such that

$$-\Delta\varphi = 2i\alpha^2 \chi_\Omega \varphi + f \quad \text{in distribution in } \mathbb{R}^2, \tag{3.15}$$

$$\varphi(x) = d \ln |x| + O(|x|^{-1}) \quad \text{as } |x| \to \infty, \tag{3.16}$$

where χ_Ω is the characteristic function of Ω, $f = 2i\alpha^2 C_k$ in Ω_k, $f = 0$ in Ω^c and $\alpha^2 = \omega\mu_0\sigma/2 > 0$; in (3.16) $d \in \mathbb{C}$ is an unknown constant.

From potential theory (see, for example, Nedelec [6]), it follows that problem (3.15), (3.16) is equivalent to the following integral problem. For given constants $C_k \in \mathbb{C}$, find $\varphi \in L^2(\Omega)$ such that

$$\varphi(x) = \frac{-i\alpha^2}{\pi} \int_\Omega \ln |\xi - x| \varphi(\xi)\, d\xi - \frac{1}{2\pi} \int_\Omega \ln |\xi - x| f(\xi)\, d\xi. \tag{3.17}$$

Our first basic result is contained in the following.

PROPOSITION 3.1. *Problem* (3.15), (3.16) *has one and only one solution. Furthermore,* $\varphi \in W^{2,p}_{\text{loc}}(\mathbb{R}^2)$, *for any* $1 \leqq p < \infty$, $\varphi \in C^{1,\beta}(\mathbb{R}^2)$ *for any* $0 < \beta < 1$, *and* $\varphi \in C^\infty(\Omega \cup \bar{\Omega}^c)$.

Proof. For proving the existence and uniqueness of the solution, it suffices, by the Fredholm alternative, to verify that, for $f = 0$, (3.17) admits only the trivial solution; we multiply (3.17) by $\bar{\varphi}(x)$ and integrate over Ω; we then remark that the left member of the resulting equation is real, whereas the right member is purely imaginary. Standard regularity results for the Laplacian operator show that $\varphi \in C^\infty(\Omega \cup \bar{\Omega}^c)$ and $\varphi \in W^{2,p}_{\text{loc}}(\mathbb{R}^2)$; therefore $\varphi \in C^{1,\beta}_{\text{loc}}(\mathbb{R}^2)$; Proposition 2.2 implies that, in fact, $\varphi \in C^{1,\beta}(\mathbb{R}^2)$, $0 < \beta < 1$. □

For a solution of (3.15), (3.16), we introduce the notion of total current defined by

$$J = \int_\Omega j(x)\, dx. \tag{3.18}$$

Since $2\alpha^2 = \omega\mu_0\sigma$, we obtain by (3.9)

$$J = 2\alpha^2 i \sum_{k=1}^{N} \int_{\Omega_k} (\varphi + C_k)(x)\, dx. \tag{3.19}$$

Furthermore, we have the following relation.

PROPOSITION 3.2. *Let* φ *be the solution of* (3.15), (3.16). *Then*

$$J = -2\pi d.$$

Proof. By Proposition 2.2, we have $d\varphi/dn = d/R + O(R^{-2})$. Integrating relation (3.10) on $B(0, R)$, we obtain the desired result by using Green's formula and (3.18). □

Remark 3.1. In our model, we have neglected the displacement currents, which supposes α is not too large. On another side, most of the results of this paper concern asymptotic relations as $\alpha \to \infty$. Besides their intrinsic mathematical interest, these asymptotic relations are physically relevant in many concrete situations for a large range of values of α.

4. Two particular cases of physical importance. In simulating the industrial process of electromagnetic casting (EMC), we have encountered the following particular case of the situation described in the preceding section. For each $1 \leqq k \leqq N$, there exists $1 \leqq l \leqq N$ such that Ω_k and Ω_l are symmetric with respect to the axis Ox_2; furthermore $C_k = -C_l$; k may be equal to l in which case $C_k = 0$. The constants C_k are obtained from the specifications of the EMC installation. By uniqueness of the solution of problem (3.15), (3.16), it follows that $\varphi(-x_1, x_2) = -\varphi(x_1, x_2)$ for all $(x_1, x_2) \in \mathbb{R}^2$, which implies that $d = 0$ in (3.16). As a consequence of Propositions 2.1, 2.2, and 3.1, $\varphi \in W_0^1(\mathbb{R}^2)$, so that by (3.15) φ satisfies the variational equation

$$\int_{\mathbb{R}^2} \vec{\nabla}\varphi \cdot \vec{\nabla}\bar{v} - 2i\alpha^2 \int_\Omega \varphi\bar{v} = \int_\Omega f\bar{v} \quad \forall v \in W_0^1(\mathbb{R}^2). \tag{4.1}$$

For mathematical convenience, we generalize the above situation somewhat and consider the following problem. For given sets Ω_k satisfying (3.13), (3.14) and for given constants $C_k \in \mathbb{C}$, $1 \leqq k \leqq N$, find $\varphi \in W_0^1(\mathbb{R}^2)$ such that

$$\int_{\mathbb{R}^2} \vec{\nabla}\varphi \cdot \vec{\nabla}\bar{v} - 2i\alpha^2 \int_\Omega \varphi\bar{v} = \int_\Omega f\bar{v} \quad \forall v \in W_0^1(\mathbb{R}^2), \tag{4.2}$$

where $\Omega = \cup_{k=1}^N \Omega_k$, $f = 2i\alpha^2 C_k$ on Ω_k, $f = 0$ in Ω^c.

We will study problem (4.2) in detail in the next sections. However, we immediately remark that, by Propositions 2.1 and 2.2, a solution φ of (4.2) will behave at infinity as $e + O(|x|^{-1})$, and consequently will be a solution of the original problem (3.15), (3.16) if and only if the constant $e = 0$.

Another situation of interest is the case of a single conductor so that $\Omega = \Omega_1$. In this context, however, the total current J defined in (3.18) appears as a data and the constant C_1 as an unknown. By Proposition 3.2, the relevant problem then reads as follows. For given $J \in \mathbb{C}$, find $\varphi \in L^2_{\text{loc}}(\mathbb{R}^2)$ and $\xi \in \mathbb{C}$ such that

$$-\Delta\varphi = 2i\alpha^2 \chi_\Omega(\varphi + \xi) \quad \text{in distribution in } \mathbb{R}^2, \tag{4.3}$$

$$\varphi(x) = \frac{J}{2\pi} \ln|x| + O(|x|^{-1}) \quad \text{as } |x| \to \infty. \tag{4.4}$$

In (4.4), the constant J is immaterial; furthermore, from a mathematical point of view, the number of conductors is of little importance. In the next sections we will consider the following problem. For given Ω_k, $1 \leqq k \leqq N$ satisfying (3.13), (3.14), find $\varphi \in L^2_{\text{loc}}(\mathbb{R}^2)$ and $\xi \in \mathbb{C}$ such that

$$-\Delta\varphi = 2i\alpha^2 \chi_\Omega(\varphi + \xi) \quad \text{in distribution in } \mathbb{R}^2, \tag{4.5}$$

$$\varphi(x) = \ln|x| + O(|x|^{-1}) \quad \text{as } |x| \to \infty. \tag{4.6}$$

We conclude this section by two remarks.

Remark 4.1. The single conductor problem (4.3), (4.4) can be generalized in a natural way for the case of several conductors: we prescribe the current J_k for each of them. By (3.5), this leads to the following problem.

For given $J_k \in \mathbb{C}$, $1 \leqq k \leqq N$, find $\varphi \in L^2_{\text{loc}}(\mathbb{R}^2)$ and the constants $C_k \in \mathbb{C}$, $1 \leqq k \leqq N$, such that (3.15), (3.16) are satisfied under the constraint

$$2i\alpha^2 \int_{\Omega_k} (\varphi + C_k)(x)\, dx = J_k, \qquad 1 \leqq k \leqq N.$$

Clearly, by (3.15), the total current J will be the sum of the J_k. This problem, which is mentioned in the literature [2], possesses one and only one solution. To a large extent its study, in particular the convergence when $\alpha \to \infty$, can be reduced to that of problems (4.2) and (4.5), (4.6). For the sake of simplicity, we will not consider it in the following.

The problems of solving (3.15), (3.16) for given constants C_k on one side and for given J_k on another are strongly related. Suppose we have solved (3.15), (3.16) for $C_j = 1$, $C_l = 0$ if $l \neq j$, $1 \leqq j \leqq N$; then the problem for given J_k reduces to a linear system of N equations that can be proved to possess a unique solution.

Remark 4.2. We can object that the problem introduced in Remark 4.1 is not physical if the total current J does not vanish; in particular, this will always be the case for the situation of the single conductor. The following argument shows that this difficulty can be overcome. To this end, we add to the system an auxiliary conductor Ω_{N+1} for which we prescribe a current equal to $-J$; we then translate it in a given direction. Let b denote the distance between the origin and the center of gravity of Ω_{N+1}, and let φ_b and φ be the solutions of the auxiliary and of the original problems, respectively. It is then possible to show that, for any fixed α and for any fixed bounded domain Λ, we have $\|\varphi_b - \varphi\|_{H^1(\Lambda)} = O(1/b)$.

5. Global asymptotic estimates. As mentioned in the Introduction, we are interested in situations with pronounced skin effect in the conductors. It is then natural to consider what happens if we let the angular frequency ω tend to infinity; since $2\alpha^2 = \mu_0 \sigma \omega$, this amounts to letting the parameter $\alpha \to \infty$. Unfortunately, in problem (3.15), (3.16), for exceptional domains Ω, d may become unbounded as α tends to infinity; see Remark 5.2 below. For this reason, we will treat problems (4.2) and (4.5), (4.6). To insist on the dependence on α, we will sometimes use the notation φ_α, ξ_α, $\cdots$ instead of φ, ξ, $\cdots$. We begin with problem (4.2).

PROPOSITION 5.1. *Problem* (4.2) *has one and only one solution. Furthermore,* $\varphi \in C^{1,\beta}(\mathbb{R}^2) \cap W^{2,p}_{\text{loc}}(\mathbb{R}^2)$, *for all* $0 < \beta < 1$, $1 \leqq p < \infty$, *and there exists a constant* $e \in \mathbb{C}$ *such that*

$$\varphi(x) = e + O(|x|^{-1}) \quad \text{as } |x| \to \infty.$$

Proof. Multiplying (4.2) by $(1+i)$, we see that the left member then defines a continuous and coercive form on $W^1_0(\mathbb{R}^2)$ defined in § 2; existence and uniqueness follows by the Lax-Milgram Lemma. Regularity follows from the fact that φ satisfies (3.15). The asymptotic relation as $|x| \to \infty$ can be deduced from Propositions 2.1 and 2.2. □

We now introduce the function φ_∞, candidate for the limit of φ_α when $\alpha \to \infty$.

LEMMA 5.1. *In connection with problem* (4.2), *there exists a unique function* $\varphi_\infty \in W^1_0(\mathbb{R}^2)$ *such that* $\varphi_\infty = -C_k$ *in* Ω_k *and* $\Delta\varphi_\infty = 0$ *in* $\bar{\Omega}^c$. *Furthermore,* $d\varphi_\infty/dn \in L^2(\partial\Omega)$, *where* $d\varphi_\infty/dn$ *is the normal derivative, exterior to* Ω, *of the restriction of* φ *to* $\bar{\Omega}^c$.

Proof. It suffices to find $\varphi \in W^1_0(\bar{\Omega}^c)$ such that $\Delta\varphi = 0$ and $\varphi = -C_k$ on $\partial\Omega_k$. This problem can be reduced to a problem of the following form. Find $\sigma \in G$ such that $\int_{\bar{\Omega}^c} \nabla\sigma \cdot \nabla\bar{v} = \int_{\bar{\Omega}^c} g\bar{v}$ for all $v \in G$, where g is a bounded function with bounded support and $G = \{v \in W^1_0(\bar{\Omega}^c) \mid v = 0 \text{ on } \partial\Omega\}$; we remark that the Dirichlet form is coercive on

G and apply the Lax-Milgram Lemma. That $d\varphi/dn \in L^2(\partial\Omega)$ is a consequence of the fact that $\partial\Omega$ is piecewise C^∞ (see Grisvard [3]). □

PROPOSITION 5.2. *Let φ_α be the solution of problem* (4.2), *and let φ_∞ be defined by Lemma* 5.1. *Then asymptotically, as $\alpha \to \infty$, we have*

(a) $\|\varphi_\alpha - \varphi_\infty\|_{W_0^1(\mathbb{R}^2)} = O(\alpha^{-1/2})$,

(b) $\|\varphi_\alpha - \varphi_\infty\|_{L^2(\Omega)} = O(\alpha^{-3/2})$,

(c) $\|\varphi_\alpha - \varphi_\infty\|_{L^2(\partial\Omega)} = O(\alpha^{-1})$,

(d) $\|\vec{\nabla}\varphi_\alpha\|_{L^2(\partial\Omega)} = O(1)$.

Proof. Set $\eta = \varphi_\alpha - \varphi_\infty$. We have

$$-\Delta\eta - 2i\alpha^2\eta = 0 \quad \text{in } \Omega, \qquad -\Delta\eta = 0 \quad \text{in } \bar{\Omega}^c. \tag{5.1}$$

By Proposition 5.1 and Lemma 5.1, $\eta \in W_0^1(\mathbb{R}^2)$ but its normal derivative on $\partial\Omega$ has a jump that is equal to $d\varphi_\infty/dn$. We multiply both equations of (5.1) by $\bar{\eta}$, integrate, respectively, on Ω and $\bar{\Omega}^c$, use Green's formula, and add the resulting relations; we get

$$\int_{\mathbb{R}^2} |\vec{\nabla}\eta|^2 - 2i\alpha^2 \int_\Omega |\eta|^2 = -\int_{\partial\Omega} \frac{d\varphi_\infty}{dn}\,\bar{\eta}. \tag{5.2}$$

Let us take the modulus in (5.2). The left member is bounded from below by

$$(\|\vec{\nabla}\eta\|^2_{L^2(\mathbb{R}^2)} + 2\alpha^2\|\eta\|^2_{L^2(\Omega)})/2 \geqq (\|\eta\|^2_{W_0^1(\mathbb{R}^2)} + \|\alpha\eta\|^2_{L^2(\Omega)})/2$$

if $\alpha \geqq 1$ and if we set $\Lambda = \mathbb{R}^2$, $\Phi = \Omega$ in (2.2). As far as the right member is concerned, by Propositions 2.3 and Lemma 5.1 we can write

$$\left|\int_{\partial\Omega} \frac{d\varphi_\infty}{dn}\,\bar{\eta}\right|^2 \leqq \left\|\frac{d\varphi_\infty}{dn}\right\|^2_{L^2(\partial\Omega)} \|\eta\|^2_{L^2(\partial\Omega)} \leqq c\|\eta\|_{H^1(\Omega)}\|\eta\|_{L^2(\Omega)}$$

$$\leqq \frac{c}{\alpha}(\|\eta\|^2_{W_0^1(\mathbb{R}^2)} + \|\alpha\eta\|^2_{L^2(\Omega)}),$$

where c is a generic constant independent of α; parts (a) and (b) follow immediately. By Proposition 2.3, part (c) is a consequence of parts (a) and (b). By (5.1) and part (b) we obtain that $\|\Delta\eta\|_{L^2(\Omega)} = O(\alpha^{1/2})$, and consequently $\|\Delta\varphi_\alpha\|_{L^2(\mathbb{R}^2)} = O(\alpha^{1/2})$; since (part (a)) $\|\varphi_\alpha\|_{W_0^1(\mathbb{R}^2)} = O(1)$, we conclude by standard elliptic regularity results that $\|\varphi_\alpha\|_{H^2(\Omega)} = O(\alpha^{1/2})$. Consider a particular Ω_k and set $\zeta = \varphi_\alpha + C_k$; from the above results we have $\|\zeta\|_{H^2(\Omega_k)} = O(\alpha^{1/2})$ and $\|\zeta\|_{H^1(\Omega_k)} = O(\alpha^{-1/2})$; applying Proposition 2.3 to $\partial_l\zeta$, we obtain $\|\partial_l\zeta\|_{L^2(\partial\Omega)} = O(1)$, $l = 1, 2$; this proves part (d) of Proposition 5.2. □

Next we consider problem (4.5), (4.6). Let $\zeta \in C^\infty(\mathbb{R}^2)$ such that $\zeta(x) = 0$ for $|x| \leqq a$ and $\zeta(x) = 1$ for $|x| \geqq a+1$; a is a fixed number chosen in such a way that $\Omega \subset B(0, a-1)$. $g(x) = \Delta(\zeta(x)\ln|x|)$ is then a $C^\infty(\mathbb{R}^2)$ function, with bounded support and vanishing on Ω. By using variational methods as in the proofs of Proposition 5.1 and Lemma 5.1, we define uniquely w_α and $w_\infty \in W_0^1(\mathbb{R}^2)$ by the requirements

$$-\Delta w_\alpha = 2i\alpha^2\chi_\Omega w_\alpha + g \quad \text{in distribution in } \mathbb{R}^2, \tag{5.3}$$

$$w_\infty = 0 \quad \text{in } \Omega, \quad -\Delta w_\infty = g \quad \text{in distribution in } \bar{\Omega}^c. \tag{5.4}$$

By Propositions 2.1 and 2.2, there exist ξ_α and $\xi_\infty \in \mathbb{C}$ such that

$$w_\alpha(x) = \xi_\alpha + O(|x|^{-1}), \qquad w_\infty(x) = \xi_\infty + O(|x|^{-1}). \tag{5.5}$$

Now set

$$\varphi_\alpha = \zeta\ln|x| + w_\alpha - \xi_\alpha, \qquad \varphi_\infty = \zeta\ln|x| + w_\infty - \xi_\infty. \tag{5.6}$$

PROPOSITION 5.3. (a) *Problem* (4.5), (4.6) *possesses a unique solution* $(\varphi_\alpha, \xi_\alpha)$; φ_α *belongs to* $C^{1,\beta}(\mathbb{R}^2) \cap W^{2,p}_{\text{loc}}(\mathbb{R}^2)$, *for any* β, p *with* $0 < \beta < 1$, $1 \leqq p < +\infty$.

(b) *There exist a unique function* φ_∞ *and a unique constant* $\xi_\infty \in \mathbb{C}$ *satisfying the properties*: $\varphi_\infty \in H^1_{\mathrm{loc}}(\mathbb{R}^2)$, $\varphi_\infty = -\xi_\infty$ *on* Ω, φ_∞ *is harmonic on* $\bar{\Omega}^c$, $\varphi_\infty(x) = \ln|x| + O(|x|^{-1})$ *as* $|x| \to \infty$.

(c) $(\varphi_\alpha, \xi_\alpha)$ *and* $(\varphi_\infty, \xi_\infty)$ *are given by* (5.5), (5.6).

Proof. We only check part (a). Direct calculations show that $(\varphi_\alpha, \xi_\alpha)$, as defined by (5.5), (5.6), is the solution of problem (4.5), (4.6). Suppose it has two solutions and denote their difference by (v, η). Then, by Propositions 2.1 and 2.2, $v \in W^1_0(\mathbb{R}^2)$ and satisfies the equation $-\Delta v = 2i\alpha^2(v+\eta)$, which implies $v = -\eta$ on $\mathbb{R}^2$; since $v(x) = O(|x|^{-1})$ as $|x| \to \infty$, we get $\eta = 0$. Regularity results follow as in the proof of Proposition 3.1. □

We now study the convergence of φ_α toward φ_∞. The arguments of the proof of Proposition 5.2 apply to w_α and w_∞; in fact, as is easily checked, Proposition 5.2 is valid when we replace φ_α and φ_∞ by w_α and w_∞, respectively. By (5.6), it remains to estimate the term $(\xi_\alpha - \xi_\infty)$. To this aim, consider the domain $B(0, r)\backslash\bar{\Omega}$ for r large enough. By Green's formula, we obtain

$$\int_{\partial\Omega} \left\{ (w_\alpha - w_\infty) \frac{d\varphi_\infty}{dn} - \varphi_\infty \frac{d(w_\alpha - w_\infty)}{dn} \right\} = \int_{\partial B(0,r)} \left\{ (w_\alpha - w_\infty) \frac{d\varphi_\infty}{dn} - \varphi_\infty \frac{d(w_\alpha - w_\infty)}{dn} \right\}, \tag{5.7}$$

where the normal is exterior to Ω and $B(0, r)$. We use the asymptotic behaviours of φ_∞, w_α and w_∞ as $|x| \to \infty$. Standard arguments show that $\int_{\partial\Omega} \varphi_\infty \, d(w_\alpha - w_\infty)/dn = -\xi_\infty \int_{\partial\Omega} d(w_\alpha - w_\infty)/dn = 0$; furthermore, as $r \to \infty$, the right-hand side of (5.7) converges to $2\pi(\xi_\alpha - \xi_\infty)$. It follows from above that

$$|\xi_\alpha - \xi_\infty| = \left| \frac{1}{2\pi} \int_{\partial\Omega} (w_\alpha - w_\infty) \frac{d\varphi_\infty}{dn} \right| \leqq \frac{1}{2\pi} \left\| \frac{d\varphi_\infty}{dn} \right\|_{L^2(\partial\Omega)} \| w_\alpha - w_\infty \|_{L^2(\partial\Omega)} = O(\alpha^{-1}).$$

Summarizing this discussion, we have Proposition 5.4.

PROPOSITION 5.4. *Let* $(\varphi_\alpha, \xi_\alpha)$ *and* $(\varphi_\infty, \xi_\infty)$ *be given by Proposition* 5.3. *Then*:

(a) $\| \varphi_\alpha - \varphi_\infty \|_{W^1_0(\mathbb{R}^2)} = O(\alpha^{-1/2})$,

(b) $\| \varphi_\alpha - \varphi_\infty + (\xi_\alpha - \xi_\infty) \|_{L^2(\Omega)} = O(\alpha^{-3/2})$,

(c) $\| \varphi_\alpha - \varphi_\infty \|_{L^2(\partial\Omega)} = O(\alpha^{-1})$,

(d) $\| \vec{\nabla} \varphi_\alpha \|_{L^2(\partial\Omega)} = O(1)$,

(e) $|\xi_\alpha - \xi_\infty| = O(\alpha^{-1})$.

Remark 5.1. The estimates of Propositions 5.2 and 5.4 are identical except for part (b).

The next result, which is probably not optimal, will not be used later; we quote it without proof.

PROPOSITION 5.5. *Let* φ_α *and* φ_∞ *be defined either by Proposition* 5.2 *or Proposition* 5.3. *Then*

$$\| \varphi_\alpha - \varphi_\infty \|_{L^\infty(\mathbb{R}^2)} = O(\alpha^{-1/2}).$$

The following estimate, difficult and certainly not optimal, concerns the convergence of the normal derivative as $\alpha \to \infty$. We will prove it at the end of § 6.

PROPOSITION 5.6. *Let* φ_α *and* φ_∞ *be defined either by Proposition* 5.2 *or Proposition* 5.3. *Then* $\| \vec{\nabla}(\varphi_\alpha - \varphi_\infty) \|_{L^1(\partial\Omega)} = O((\alpha / \ln \alpha)^{-1/2})$.

We conclude this section by an example and a remark.

Example 5.1. The system consists of one conductor with circular section, i.e., $\Omega = B(0, R)$. For the nonphysical problem (4.2) we obtain the trivial solution $\varphi_\alpha = \varphi_\infty = -C_1$ on $\mathbb{R}^2$. More interesting is problem (4.5), (4.6) which we now consider. Here

$\varphi_\alpha(x) = \varphi_\infty(x) = \ln|x|$ for $|x| \geqq R$ and $\varphi_\infty(x) = -\xi_\infty = \ln R$ for $|x| \leqq R$, whereas, for $|x| \leqq R$, φ_α is of the form

$$\varphi_\alpha(x) = -\xi_\alpha + a_\alpha J_0((1+i)\alpha|x|). \tag{5.8}$$

In (5.8), J_0 denotes the Bessel function of order zero; the complex constants ξ_α and a_α are determined by imposing the continuity of φ_α and of its normal derivative on $\partial\Omega$. Explicit calculations using the asymptotic expansions of Bessel functions show that all estimates of Proposition 5.4 are optimal.

Remark 5.2. For $\Omega = B(0, R)$, let $(\varphi_\alpha, \xi_\alpha)$ be the solution of problem (4.5), (4.6) and $\tilde{\varphi}_\alpha$ be the solution of the initial problem (3.15), (3.16) with $C_1 = 1$. Clearly, $\tilde{\varphi}_\alpha = (1/\xi_\alpha)\varphi_\alpha$. By Proposition 5.4 and the above discussion of Example 5.1, $\lim_{\alpha\to\infty} \xi_\alpha = \xi_\infty = -\ln R$ and $\tilde{\varphi}_\alpha(x) = (1/\xi_\alpha)\ln|x|$ for $|x| \geqq R$. If $R = 1$, there is no possible convergence of $\tilde{\varphi}_\alpha$ as $\alpha \to \infty$ on any subset of $\bar{\Omega}^c$. In fact, for any Ω, there exists one and only one domain homothetic to Ω for which the same phenomenon occurs with $C_k = 1$, $k = 1, 2, \cdots, N$.

6. Some local estimates. In this section φ_α and φ_∞ will denote the functions defined either in Proposition 5.2 or in Proposition 5.3.

We first note that if $\Lambda \subset \mathbb{R}^2$ is a bounded open set such that $\bar{\Lambda}$ does not contain any corner of $\partial\Omega$, then for any m we have that φ_α and φ_∞ belong to $H^m(\Lambda \cap \Omega)$ and to $H^m(\Lambda \cap \bar{\Omega}^c)$. Loosely speaking, the restrictions of φ_α and φ_∞ to $\bar{\Omega}$ or to Ω^c are C^∞ except at the corners of $\partial\Omega$. These properties are consequences of standard regularity results for elliptic equations. To investigate properties in the neighborhood of $\partial\Omega$, we introduce the following local transformation of coordinates. Let $\Gamma \subset \partial\Omega$ be a smooth arc. One of its endpoints, say P, can be a corner of $\partial\Omega$. Γ admits the parametrization $(\gamma_1(t), \gamma_2(t))$ where t is the arclength parameter such that P corresponds to $t = 0$. With $\vec{n} = (n_1(t), n_2(t))$ denoting, as usual, the unit normal exterior to Ω, we set

$$(x_1, x_2) = (\gamma_1(\xi_2), \gamma_2(\xi_2)) + \xi_1(n_1(\xi_2), n_2(\xi_2)). \tag{6.1}$$

As is well known, (ξ_1, ξ_2) defines a local orthogonal curvilinear system of coordinates, the metric of which is given by the quadratic form

$$d\xi_1^2 + s^2(\xi_1, \xi_2)\, d\xi_2^2, \qquad s(\xi_1, \xi_2) = 1 + \frac{\xi_1}{R(\xi_2)}; \tag{6.2}$$

$R(\xi_2)$ is the radius of curvature of Γ, where $R(\xi_2) > 0$ if Ω is "convex" at the point of Γ with parameter $t = \xi_2$. We will denote by D_1^l and D_2^l the lth partial derivatives with respect to ξ_1 and ξ_2, respectively, so that, for example, the scalar product of two gradients is given by

$$\vec{\nabla} u \cdot \vec{\nabla} v = D_1 u \cdot D_1 v + D_2 u \cdot D_2 v / s^2. \tag{6.3}$$

To P, endpoint of Γ, or to any Q interior point of Γ, we associate an open rectangle T as shown in Figs. 6.1 and 6.2. In particular we suppose the following:

(a) The system of coordinates (ξ_1, ξ_2) is defined and regular in $\bar{T}$.

(b) $T \cap \Omega = \{x \in T \mid \xi_1 < 0\}$ and $T \cap \bar{\Omega}^c = \{x \in T \mid \xi_1 > 0\}$ are nonempty and satisfy the cone condition.

(c) $P \in \bar{T}$ or $Q \in T$.

LEMMA 6.1. *Let T be a rectangle as defined above and let $\theta : \mathbb{R}^2 \to \mathbb{R}_+$ be a function such that θ, $\partial_1\theta$, and $\partial_2\theta$ belong to $L^\infty(\mathbb{R}^2)$ and $\theta = 0$ in T^c. Then for any $m = 1, 2, 3, \cdots$, we have as α tends to infinity:*

(a) $\|\theta^m D_2^m(\varphi_\alpha - \varphi_\infty)\|_{W_0^1(\mathbb{R}^2)} = O(\alpha^{-1/2})$,

(b) $\|\theta^m D_2^m(\varphi_\alpha - \varphi_\infty)\|_{L^2(\Omega)} = O(\alpha^{-3/2})$,

(c) $\|\theta^m D_2^m(\varphi_\alpha - \varphi_\infty)\|_{L^2(\partial\Omega)} = O(\alpha^{-1})$.

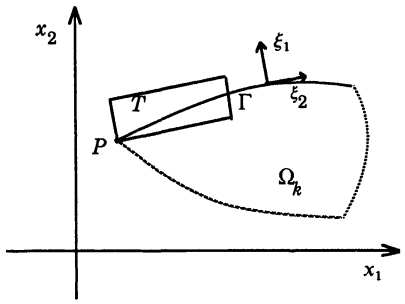

FIG. 6.1.

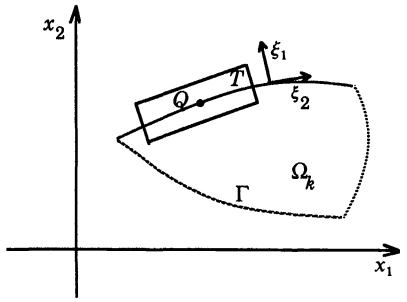

FIG. 6.2

Proof. We will prove Lemma 6.1 only for $m=1$ and for φ_α, φ_∞ defined by Proposition 5.2. The estimates relative to $m \geqq 2$ can be obtained with similar arguments by an induction process. The situation corresponding to Proposition 5.3 is treated easily by considering the function $\varphi_\alpha - \varphi_\infty + \xi_\alpha - \xi_\infty$; see Proposition 5.4(b). We start as in the proof of Proposition 5.2 with $\eta = \varphi_\alpha - \varphi_\infty$. Multiplying (5.1) by $v \in C_0^\infty(T)$, we obtain after integration by parts

$$\int_{\mathbb{R}^2} \vec{\nabla}\eta \cdot \vec{\nabla} v - 2i\alpha^2 \int_\Omega \eta v = -\int_{\partial\Omega} \frac{d\varphi_\infty}{dn} v. \tag{6.4}$$

In the coordinates (ξ_1, ξ_2), by using in particular (6.3), (6.4) becomes

$$\int_{\mathbb{R}^2} (sD_1\eta D_1 v + s^{-1} D_2 \eta D_2 v) - 2i\alpha^2 \int_{\tilde{\Omega}} s\eta v = -\int_{\mathbb{R}} D_1\varphi_\infty(0, \xi_2) v(0, \xi_2)\, d\xi_2 \tag{6.5}$$

where $\tilde{\Omega}$ is the image of $T \cap \Omega$ in the (ξ_1, ξ_2) plane. We set $v = -D_2 w$ in (6.5), where $w \in C_0^\infty(\tilde{T})$ and $\tilde{T}$ is the image of T in the (ξ_1, ξ_2) plane; after integration by parts, we obtain

$$\begin{aligned} &\int_{\mathbb{R}^2} (sD_1 D_2 \eta D_1 w + s^{-1} D_2^2 \eta D_2 w) - 2i\alpha^2 \int_{\tilde{\Omega}} sD_2 \eta w \\ &= -\int_{\mathbb{R}} D_1 D_2 \varphi_\infty(0, \xi_2) w(0, \xi_2)\, d\xi_2 \\ &\quad - \int_{\mathbb{R}^2} (D_2 s D_1 \eta D_1 w + D_2(s^{-1}) D_2 \eta D_2 w) + 2i\alpha^2 \int_{\tilde{\Omega}} D_2 s \eta w. \end{aligned} \tag{6.6}$$

In a first step, we assume that $\theta \in C_0^\infty(T)$, therefore we can set $w = \theta z$ with $z \in C_0^\infty(\tilde{T})$; after some elementary calculations, with $\Psi = D_2\eta = D_2(\varphi_\alpha - \varphi_\infty)$, we get

$$
\begin{aligned}
&\int_{\mathbb{R}^2} (sD_1(\theta\Psi)D_1 z + s^{-1}D_2(\theta\Psi)D_2 z) - 2i\alpha^2 \int_{\tilde{\Omega}} s\theta\Psi z \\
&\quad = -\int_{\mathbb{R}} \theta D_1 D_2\varphi_\infty(0, \xi_2)\, z(0, \xi_2)\, d\xi_2 \\
&\quad\quad - \int_{\mathbb{R}^2} (D_2 s D_1\eta D_1(\theta z) + D_2(s^{-1})D_2\eta D_2(\theta z)) + 2i\alpha^2 \int_{\tilde{\Omega}} D_2 s\eta\theta z \\
&\quad\quad + \int_{\mathbb{R}^2} \{sD_1\theta(\Psi D_1 z - zD_1\Psi) + s^{-1}D_2\theta(\Psi D_2 z - zD_2\Psi)\}.
\end{aligned}
\tag{6.7}
$$

From classical results of regularity $\theta D_1 D_2\varphi_\infty(0, \xi_2) \in C^\infty(\partial\Omega)$; therefore it follows from (6.7) that

$$
\mathscr{L}(\theta\Psi) \equiv -[D_1(sD_1) + D_2(s^{-1}D_2)](\theta\Psi) \in H^{-1}(\tilde{T});
$$

since $\theta\Psi$ has a compact support included in $\tilde{T}$, we deduce from the hypoellipticity of $\mathscr{L}$ that $\theta\Psi \in H_0^1(\tilde{T})$. Then by density we can set $z = \theta\bar{\Psi}$ in (6.7). In the last term of the right member, we replace $\theta\bar{\Psi}D\Psi$ by $\bar{\Psi}D(\theta\Psi) - \Psi\bar{\Psi}D\theta$; we use Proposition 2.3 and Proposition 5.2(a),(b) and obtain the estimate

$$
\begin{aligned}
&|\|\theta\Psi\|^2_{W_0^1(\mathbb{R}^2)} - 2i\alpha^2\|\theta\Psi\|^2_{L^2(\Omega)}| \\
&\leqq C\|\theta D_1 D_2\varphi_\infty\|_{L^2(\partial\Omega)}(\|\theta\Psi\|_{L^2(\Omega)}\|\theta\Psi\|_{H^1(\Omega)})^{1/2} + C\alpha^{-1/2}\|\theta^2\Psi\|_{W_0^1(\mathbb{R}^2)} \\
&\quad + C\alpha^{1/2}\|\theta^2\Psi\|_{L^2(\Omega)} + C\|\vec{\nabla}\theta\|_{L^\infty(\mathbb{R}^2)}(\alpha^{-1/2}\|\theta\Psi\|_{W_0^1(\mathbb{R}^2)} + \alpha^{-1}\|\vec{\nabla}\theta\|_{L^\infty(\mathbb{R}^2)})
\end{aligned}
\tag{6.8}
$$

where C is a generic constant independent of α and θ.

From results of Grisvard [3], $\delta D_1 D_2\varphi_\infty \in L^2(\partial\Omega)$, where $\delta(x)$ denotes the distance from x to the corners of $\partial\Omega$; clearly, $|\theta(x)| \leqq \delta(x)\|\vec{\nabla}\theta\|_{L^\infty(\mathbb{R}^2)}$ and $\|\theta D_1 D_2\varphi_\infty\|_{L^2(\partial\Omega)} \leqq C\|\vec{\nabla}\theta\|_{L^\infty(\mathbb{R}^2)}$. After a convenient treatment of the terms $\theta^2\Psi$ in (6.8) and by using classical inequalities, we obtain for C independent of α and θ

$$
\|\theta\vec{\nabla}\Psi\|_{L^2(\mathbb{R}^2)} \leqq C\alpha^{-1/2}\|\vec{\nabla}\theta\|_{L^\infty(\mathbb{R}^2)}, \qquad \|\theta\Psi\|_{L^2(\Omega)} \leqq C\alpha^{-3/2}\|\vec{\nabla}\theta\|_{L^\infty(\mathbb{R}^2)};
\tag{6.9}
$$

this proves parts (a) and (b) of Lemma 6.1 when $\theta \in C_0^\infty(T)$; part (c) follows from Proposition 2.3.

Now we consider the case where $\theta(x) = g(x) =$ distance from x to ∂T if $x \in T$ and $\theta(x) = 0$ if $x \in T^c$; then we can find a sequence of $\theta_n \in C_0^\infty(T)$ such that

$$
\theta_n \text{ converges to } g \text{ everywhere, and } \|\vec{\nabla}\theta_n\|_{L^\infty(\mathbb{R}^2)} \leqq \left(1 + \frac{1}{n}\right)\|\vec{\nabla}g\|_{L^\infty(\mathbb{R}^2)}.
$$

We obtain (6.9) for $\theta = g$ as the limit for $\theta = \theta_n$ by using the Lebesgue Theorem. The general situation is treated easily by noting that $|\theta(x)| \leqq g(x)\|\vec{\nabla}\theta\|_{L^\infty(\mathbb{R}^2)}$. □

LEMMA 6.2. *Let $\Lambda \subset \bar{\Omega}^c$ be an open bounded set. Then*

$$
\|\varphi_\alpha - \varphi_\infty\|_{L^2(\Lambda)} = O(\alpha^{-1}).
$$

Proof. Set $\eta = \varphi_\alpha - \varphi_\infty$ and let $w \in W_0^1(\bar{\Omega}^c)$ satisfy the relations

$$
\Delta w = \eta\chi_\Lambda \quad \text{in } \bar{\Omega}^c, \qquad w = 0 \quad \text{on } \partial\Omega,
\tag{6.10}
$$

where χ_Λ is the characteristic function of Λ. By Grisvard's regularity results [3], there exists a constant c, independent of η, such that $\|dw/dn\|_{L^2(\partial\Omega)} \leqq c\|\eta\|_{L^2(\Lambda)}$. Let r_0 be such that $\Omega \cup \Lambda \subset B(0, r_0)$. By Green's formula, we have for $r > r_0$

$$\|\eta\|^2_{L^2(\Lambda)} = \int_{\Omega^c \cap B(0,r)} \eta \Delta w = -\int_{\partial\Omega} \eta \frac{dw}{dn} + \int_{\partial B(0,r)} \left(\eta \frac{dw}{dn} - w\frac{d\eta}{dn}\right). \tag{6.11}$$

η and w belong to $W^1_0(\mathbb{R}^2)$ and are harmonic in $(\bar{B}(0, r_0))^c$. By Propositions 2.1 and 2.2, these functions and their normal derivatives behave, respectively, as do $O(1)$ and $O(|x|^{-2})$ as $|x|$ tends to infinity; we conclude that the second term of the right-hand side of (6.11) vanishes. Lemma 6.2 then follows from (6.11) and from Proposition 5.2(c) or Proposition 5.4(c). □

PROPOSITION 6.1. *Let $\Lambda \subset \bar{\Omega}^c$ be an open bounded set such that $\bar{\Lambda}$ contains no corner of $\partial\Omega$. Then for any $m = 0, 1, 2, \cdots$, we have*

$$\|\varphi_\alpha - \varphi_\infty\|_{H^m(\Lambda)} = O(\alpha^{-1}).$$

Proof. We remark that by Lemma 6.1(c) we have the estimate $\|\varphi_\alpha - \varphi_\infty\|_{H^m(\Gamma)} = O(\alpha^{-1})$ for any $m = 0, 1, 2, \cdots$ and any $\Gamma \subset \partial\Omega$ such that $\bar{\Gamma}$ contains no corner of $\partial\Omega$. Together with standard regularity results and Lemma 6.2, this implies Proposition 6.1. □

As an immediate consequence of the important Proposition 6.1, we have, for example, the following corollary.

COROLLARY 6.1. *For $\Gamma \subset \partial\Omega$ such that $\bar{\Gamma}$ contains no corner of $\partial\Omega$ and for any $m = 0, 1, 2, \cdots$, we have*

$$\|\vec{\nabla}(\varphi_\alpha - \varphi_\infty)\|_{H^m(\Gamma)} = O(\alpha^{-1}).$$

We conclude this section with the proof of Proposition 5.6. By Corollary 6.1, it suffices to prove Proposition 5.6 when we replace $\partial\Omega$ by a small arc Γ one endpoint of which is a corner; we can assume that $\Gamma \subset T \cap \partial\Omega$, where T is a rectangle as shown in Fig. 6.1. We use Proposition 5.2(a), Proposition 5.4(a), and Lemma 6.1(a) with $m = 1$ and $\theta = g$, where $g(x) = 0$ if $x \in T^c$ and $g(x)$ is the distance from x to ∂T if $x \in T$. We immediately deduce the relations $\|gD_1D_2\eta\|_{L^2(T)} = O(\alpha^{-1/2})$ and $\|gD_2^2\eta\|_{L^2(T)} = O(\alpha^{-1/2})$; from this last estimate and the fact that η is harmonic in $\bar{\Omega}^c$, we obtain that $\|gD_1^2\eta\|_{L^2(T\cap\bar{\Omega}^c)} = O(\alpha^{-1/2})$; then we can conclude that

$$\|g\partial_l\eta\|_{H^1(T\cap\bar{\Omega}^c)} = O(\alpha^{-1/2}), \qquad l = 1, 2. \tag{6.12}$$

Setting $w = \partial_l\eta$ and $\Lambda = T \cap \bar{\Omega}^c$, we have by a classical imbedding theorem and Schwarz's inequality

$$\begin{aligned} \|g|w|^2\|_{L^1(\partial\Lambda)} &\leqq C\left\{\|g|w|^2\|_{L^1(\Lambda)} + \sum_{j=1}^{2} \|\partial_j(g|w|^2)\|_{L^1(\Lambda)}\right\} \\ &\leqq C\left\{\|g\|_{L^\infty(\mathbb{R}^2)}\|w\|^2_{L^2(\Lambda)}\right. \\ &\qquad \left. + \sum_{j=1}^{2} (2\|\partial_j(gw)\|_{L^2(\Lambda)}\|w\|_{L^2(\Lambda)} + \|\partial_j g\|_{L^\infty(\Lambda)}\|w\|^2_{L^2(\Lambda)})\right\}. \end{aligned} \tag{6.13}$$

Since $\|w\|_{L^2(\Lambda)} = O(\alpha^{-1/2})$, it follows by (6.12) that the right-hand side of (6.13) is $O(\alpha^{-1})$; furthermore, we observe that along Γ, the arclength parameter ξ_2 is $O(g)$; consequently, we have obtained the estimate

$$\|\xi_2^{1/2}w\|_{L^2(\Gamma)} = O(\alpha^{-1/2}). \tag{6.14}$$

For $0<\gamma<1$, we can write $|w| = \xi_2^{(\gamma-1)/2}[\xi_2^{1/2}|w|]^{1-\gamma}|w|^{\gamma}$ so that by Hölder's inequality we obtain

$$\|w\|_{L^1(\Gamma)} \leqq \|\xi_2^{(\gamma-1)/2}\|_{L^2(\Gamma)}(\|\xi_2^{1/2}w\|_{L^2(\Gamma)})^{1-\gamma}\|w\|_{L^2(\Gamma)}^{\gamma}. \tag{6.15}$$

By Propositions 5.2(d) and 5.4(d), we know that $\|w\|_{L^2(\Gamma)}$ is uniformly bounded with respect to α; from (6.15) with $\gamma = 1/\ln\alpha$, we readily obtain the final estimate:

$$\|\partial_l(\varphi_\alpha - \varphi_\infty)\|_{L^1(\Gamma)} = \|w\|_{L^1(\Gamma)} = O((\alpha/\ln\alpha)^{-1/2}), \qquad l=1,2. \qquad \square$$

7. A boundary layer approximation. As in the previous section, φ_α will denote here the function defined either in Proposition 5.2 or Proposition 5.3. Our purpose is to study the behaviour of φ_α for large α in a conductor section Ω_k. We fix k, $1 \leqq k \leqq N$ and set $\Lambda = \Omega_k$. Furthermore, we set $\eta_\alpha = \eta = \varphi_\alpha + C_k$ for problem (4.2) and $\eta_\alpha = \eta = \varphi_\alpha + \xi$ for problem (4.5), (4.6).

We first remark that η_α satisfies in Λ the following Helmholtz homogeneous equation:

$$\Delta\eta_\alpha + 2i\alpha^2\eta_\alpha = 0 \quad \text{in } \Lambda. \tag{7.1}$$

It is well known that $F(x,y) = (1/4i)H_0^1((1+i)\alpha|x-y|)$ is a fundamental solution of this Helmholtz equation where H_0^1 is a Hankel function. It follows that η_α admits for $x \in \Lambda$ the representation

$$\eta_\alpha(x) = \int_{\partial\Lambda}\left\{\eta_\alpha(y)\frac{d}{dn_y}F(x,y) - F(x,y)\frac{d\eta_\alpha(y)}{dn_y}\right\}d\mu(y). \tag{7.2}$$

Then, by Propositions 5.2, 5.4, and by the asymptotic expansion formulae of the Hankel functions (see, for example, [5]), we immediately deduce the following proposition.

PROPOSITION 7.1. *Let $x \in \Lambda$ and d be the distance of x to $\partial\Lambda$. There exists a constant C_{mn} such that for $\alpha \geqq 1/d$ we have*

$$|\partial_1^m\partial_2^n\eta_\alpha(x)| \leqq C_{mn}\alpha^{m+n}\frac{e^{-\alpha d}}{\sqrt{\alpha d}}, \qquad m, n = 0, 1, 2, \cdots.$$

Now consider a smooth arc $\Gamma \subset \partial\Lambda$ such that the endpoints of Γ are not corners of $\partial\Lambda$. With the system of coordinates (ξ_1, ξ_2) introduced by (6.1), Γ is the set of points $(0, \xi_2)$, $0 \leqq \xi_2 \leqq \xi_{02}$. Furthermore, there exists $\delta > 0$ such that $V = \{x \mid -\delta < \xi_1 < 0,\ 0 < \xi_2 < \xi_{02}\} \subset \Lambda$ and such that the distance of the points of ∂V corresponding to $\xi_1 = -\delta$ to $\partial\Lambda$ is equal to δ. We define in $\bar{V}$ an approximate u_α of η_α by the relation

$$u_\alpha(\xi_1, \xi_2) = \frac{1}{\sqrt{s(\xi_1, \xi_2)}}e^{(1-i)\alpha\xi_1}\eta_\alpha(0, \xi_2), \tag{7.3}$$

where s is given by (6.2). We remark that $u_\alpha = \eta_\alpha$ on Γ.

As in § 6, D_1^l and D_2^l denote the partial derivatives of order l with respect to ξ_1 and ξ_2, whereas $R = R(\xi_2)$ is the radius of curvature of Γ.

PROPOSITION 7.2. *For any $m = 0, 1, 2, \cdots$ we have*

(a) $\|D_2^m(\eta_\alpha - u_\alpha)\|_{L^\infty(\bar{V})} = O(\alpha^{-3})$,

(b) $\|D_2^m D_1(\eta_\alpha - u_\alpha)\|_{L^\infty(\bar{V})} = O(\alpha^{-2})$.

Proof. We consider only the case $m = 0$, since the treatment of the general situation needs essentially the same tools. We use the expression of the Laplace operator in the (ξ_1, ξ_2) system of coordinates and write (7.1) in $\tilde{\Lambda}$, image of Λ in the (ξ_1, ξ_2) plane. Setting $w = \eta_\alpha - u_\alpha$, after some calculations we obtain

$$D_1(sD_1w) + 2i\alpha^2 sw = z, \tag{7.4}$$

$$z(\xi_1, \xi_2) = -D_2\left(\frac{1}{s}D_2\eta\right)(\xi_1, \xi_2) - \eta(0, \xi_2)\frac{e^{(1-i)\alpha\xi_1}}{4s^{3/2}(\xi_1, \xi_2)R^2(\xi_2)}. \tag{7.5}$$

From Lemma 6.1(b) and Proposition 6.1, we easily deduce that we have, uniformly with respect to $0 \leqq \xi_2 \leqq \xi_{02}$,

$$\|D_2^l \eta(\cdot, \xi_2)\|_{L^2(-\delta,0)} = O(\alpha^{-3/2}), \quad l = 1, 2, \quad |\eta(0, \xi_2)| = O(\alpha^{-1}). \tag{7.6}$$

Then (7.5) and (7.6) imply that

$$\|z(\cdot, \xi_2)\|_{L^2(-\delta,0)} = O(\alpha^{-3/2}) \quad \text{uniformly for } 0 \leqq \xi_2 \leqq \xi_{02}. \tag{7.7}$$

For ξ_2 fixed, we multiply (7.4) by $\bar{w}$; after an integration by parts, since $w(0, \xi_2) = 0$, we obtain

$$\left| -\int_{-\delta}^{0} s|D_1 w|^2 \, d\xi_1 + 2i\alpha^2 \int_{-\delta}^{0} s|w|^2 \, d\xi_1 \right| \leqq \|z(\cdot, \xi_2)\|_{L^2(-\delta,0)} \|w(\cdot, \xi_2)\|_{L^2(-\delta,0)} + |sw D_1 w(-\delta, \xi_2)|; \tag{7.8}$$

by (7.3), (7.6), and Proposition 7.1, the second term of the right-hand member of (7.8) is $O(e^{-\alpha\delta})$. Then (7.7) and (7.8) imply the estimate $\|w\|_{L^2(-\delta,0)} = O(\alpha^{-7/2})$ and $\|D_1 w\|_{L^2(-\delta,0)} = O(\alpha^{-5/2})$; with (7.4) and (7.7) we have, furthermore, $\|D_1^2 w\|_{L^2(-\delta,0)} = O(\alpha^{-3/2})$. We conclude by standard arguments. □

Remark 7.1. Results similar to those of Proposition 7.1 can be derived by directly using the Helmholtz equation (7.1) instead of the integral representation (7.2). This method is more complicated but can be generalized to the situation where α is variable, i.e., the conductivity is not constant.

Remark 7.2. Suppose that in the definition (7.3) of u_α we replace $s(\xi_1, \xi_2)$ by 1; then in Proposition 7.2 we lose one order, i.e., $O(\alpha^{-3})$ and $O(\alpha^{-2})$ are replaced, respectively, by $O(\alpha^{-2})$ and $O(\alpha^{-1})$.

Remark 7.3. Because of the exponential decay of η_α and u_α in the boundary layer, L^2 estimates are better than those for L^∞. From the proof of Proposition 7.2 we obtain, for example,

$$\|\eta_\alpha - u_\alpha\|_{L^2(V)} = O(\alpha^{-7/2}), \qquad \|\eta_\alpha - u_\alpha\|_{H^1(V)} = O(\alpha^{-5/2}). \tag{7.9}$$

8. An approximation of φ_α in $\bar{\Omega}^c$ satisfying a Robin boundary condition. Our purpose is to define a "cheap" approximation of φ_α. For the sake of briefness, we will consider only problem (4.2); problem (4.5), (4.6) can be treated in a similar way. To insure the validity of this approximation we must introduce a severe restriction on the regularity of Ω; in fact, we will suppose that

(8.1) $\partial\Omega$ is of class C^∞.

Let φ_α be the solution of problem (4.2). Suppose we know φ_α or an approximation Ψ_α of φ_α on $\partial\Omega$. Then, because of hypothesis (8.1), the results of § 7 allow us to define an explicit and simple approximation of φ_α in Ω.

Consider Proposition 7.2(b) with $m = 1$ and $\bar{V}$ being replaced by $\bar{V} \cap \partial\Omega$. Since $\eta_\alpha = \varphi_\alpha + C_k$, by (7.3) we immediately obtain the following proposition.

PROPOSITION 8.1. *Let φ_α be the solution of problem* (4.2) *and assume hypothesis* (8.1). *Then*

$$\left\| \frac{d\varphi_\alpha}{dn} - z_\alpha(\varphi_\alpha + C_k) \right\|_{L^\infty(\partial\Omega_k)} = O(\alpha^{-2}), \qquad 1 \leqq k \leqq N,$$

where $z_\alpha = (1-i)\alpha - 1/(2R)$ and R is the radius of curvature of $\partial\Omega_k$. □

Proposition 8.1 shows that φ_α satisfies approximately a Robin boundary condition on $\partial\Omega$. This leads us to introduce the following exterior problem. Find $\Psi_\alpha \in W_0^1(\bar{\Omega}^c)$

such that

$$\Delta\Psi_\alpha = 0 \quad \text{in } \bar{\Omega}^c, \qquad \frac{d\Psi_\alpha}{dn} = z_\alpha(\Psi_\alpha + C_k) \quad \text{on } \partial\Omega_k, \quad 1 \leqq k \leqq N, \tag{8.2}$$

where the unit normal $\vec{n}$ on $\partial\Omega$ is exterior to Ω.

PROPOSITION 8.2. *Let φ_α be the solution of problem* (4.2) *and assume hypothesis* (8.1). *Then*

(a) *Problem* (8.2) *has one and only one solution,*

(b) $\|\varphi_\alpha - \Psi_\alpha\|_{W_0^1(\bar{\Omega}^c)} = O(\alpha^{-5/2})$,

(c) $\|\varphi_\alpha - \Psi_\alpha\|_{L^2(\partial\Omega)} = O(\alpha^{-3})$.

Proof. Problem (8.2) admits the following variational formulation:

$$\int_{\Omega^c} \vec{\nabla}\Psi_\alpha \cdot \vec{\nabla} v + \int_{\partial\Omega} z_\alpha \Psi_\alpha v = -\sum_{k=1}^{N} C_k \int_{\partial\Omega_k} z_\alpha v \quad \forall v \in W_0^1(\bar{\Omega}^c). \tag{8.3}$$

Point (a) follows from (8.3) as an application of the Lax-Milgram Lemma. Set $w_\alpha = \Psi_\alpha - \varphi_\alpha$. Since $\varphi_\alpha \in W_0^1(\bar{\Omega}^c)$ and is harmonic in $\bar{\Omega}^c$, from 8.3 we obtain

$$\int_{\Omega^c} \vec{\nabla} w_\alpha \cdot \vec{\nabla} v + \int_{\partial\Omega} z_\alpha w_\alpha v = \sum_{k=1}^{N} \int_{\partial\Omega_k} \left(\frac{d\varphi_\alpha}{dn} - z_\alpha(\varphi_\alpha + C_k) \right) v \quad \forall v \in W_0^1(\bar{\Omega}^c). \tag{8.4}$$

We set $v = \bar{w}_\alpha$ in (8.4) and recall that $z_\alpha = (1-i)\alpha - 1/(2R)$; we take the imaginary part of this relation and obtain the estimate (c) by Proposition 8.1; replacing (8.4) with $v = \bar{w}_\alpha$ we conclude that $\|\nabla w_\alpha\|_{L^2(\bar{\Omega}^c)} = O(\alpha^{-5/2})$; together with part (c), this proves part (b). □

Remark 8.1. In addition to those shown in Proposition 8.2, other estimates can be obtained. For example, with some extra calculations, we can prove that

$$\|\varphi_\alpha - \Psi_\alpha\|_{L^\infty(\partial\Omega)} = O(\alpha^{-3}). \tag{8.5}$$

Furthermore, it is possible to extend φ_α to $\mathbb{R}^2$ by the boundary layer approximation introduced in § 7 and produce estimates relative to Ω. We will not pursue this. On one hand, these estimates are direct corollaries of the preceding ones or can be obtained by using the same tools; on the other hand, due to the very restrictive hypothesis (8.1), they are of limited interest.

Remark 8.2. Numerical tests show that for many practical applications, Ψ_α gives a very satisfactory approximation of φ_α if $\partial\Omega$ is regular. If $\partial\Omega$ has corners, the definition (8.2) of Ψ_α is still meaningful; however, we get only very poor theoretical error estimates, which are confirmed by numerical experiments.

Remark 8.3. If $\partial\Omega$ has corners, Proposition 8.1 is still valid when we replace $L^2(\partial\Omega_k)$ by $L^\infty(\Gamma)$ where Γ is a closed part of $\partial\Omega_k$ without singularities. In a forthcoming paper, we shall present successful numerical computations obtained with a method that takes advantage of this fact.

CONJECTURE ON THE STRUCTURE OF SOLUTIONS OF THE RIEMANN PROBLEM FOR TWO-DIMENSIONAL GAS DYNAMICS SYSTEMS*

TONG ZHANG† AND YUXI ZHENG‡

Abstract. Two-dimensional flow of polytropic gas with initial data being constant in each quadrant is considered. Under the assumption that each jump in initial data outside of the origin projects exactly one planar wave of shocks, centered rarefaction waves, or slip planes, it is proved that only 16 combinations of initial data are reasonable. For each combination, a conjecture on the structure of the solution in the whole space $t>0$ is given.

Key words. Riemann problem, shock, rarefaction waves, slip plane, selfsimilar solution, rarefactive pseudostationary flow

AMS(MOS) subject classifications. primary 35L65, 35L67; secondary 65M99

1. Introduction. Using the experiences of researching the Riemann problem and interactions of waves for one-dimensional gas dynamics systems [1]-[7], two-dimensional scalar conservation laws [8], two-dimensional steady flows [9], [10], and the regular reflection and Mach reflection [12], we consider the Riemann problem of two-dimensional gas dynamic systems. Both isentropic and adiabatic flow are considered.

The isentropic flow is modeled by the following system:

$$\begin{aligned} &\rho_t+(\rho u)_x+(\rho v)_y=0,\\ &(\rho u)_t+(\rho u^2+p)_x+(\rho uv)_y=0, \quad p=A\rho^\gamma, \quad \gamma>1, \quad A>0,\\ &(\rho v)_t+(\rho uv)_x+(\rho v^2+p)_y=0 \end{aligned} \tag{1.1}$$

and adiabatic flow,

$$\begin{aligned} &\rho_t+(\rho u)_x+(\rho v)_y=0,\\ &(\rho u)_t+(\rho u^2+p)_x+(\rho uv)_y=0,\\ &(\rho v)_t+(\rho uv)_x+(\rho v^2+p)_y=0,\\ &\left(\rho\left(e+\frac{u^2+v^2}{2}\right)\right)_t+\left(\rho u\left(h+\frac{u^2+v^2}{2}\right)\right)_x+\left(\rho v\left(h+\frac{u^2+v^2}{2}\right)\right)_y=0,\\ &e=\frac{p}{(\gamma-1)\rho}, \qquad h=e+\frac{p}{\rho}, \end{aligned} \tag{1.1$'$}$$

where ρ, (u, v), p denote density, velocity and pressure, respectively, and γ and A are constants.

The Riemann problems are defined, respectively, as follows:

$$(\rho, p, u, v)|_{t=0}=(\rho_i, p_i, u_i, v_i)\equiv ①, \tag{1.2$'$}$$

or in the ith quadrant of (x, y) plane $(i=1, 2, 3, 4)$,

$$(\rho, p, u, v)|_{t=0}=(\rho_i, p_i, u_i, v_i)\equiv ①, \tag{1.2$'$}$$

where ① are constant states.

Let us consider the selfsimilar solutions $(\rho, u, v)=(\rho(\xi, \eta), u(\xi, \eta), v(\xi, \eta))$ or $(\rho, p, u, v)=(\rho(\xi, \eta), p(\xi, \eta), u(\xi, \eta), v(\xi, \eta))$ $(\xi=x/t, \eta=y/t)$, called pseudostationary flow; then (1.1) or (1.1)′ changes, respectively, to

$$\begin{aligned} &-\xi\rho_\xi+(\rho u)_\xi-\eta\rho_\eta+(\rho v)_\eta=0,\\ &-\xi(\rho u)_\xi+(\rho u^2+p)_\xi-\eta(\rho u)_\eta+(\rho uv)_\eta=0,\\ &-\xi(\rho v)_\xi+(\rho uv)_\xi-\eta(\rho v)_\eta+(\rho v^2+p)_\eta=0, \end{aligned} \tag{1.3}$$

or

$$\begin{aligned} &-\xi\rho_\xi+(\rho u)_\xi-\eta\rho_\eta+(\rho v)_\eta=0,\\ &-\xi(\rho u)_\xi+(\rho u^2+p)_\xi-\eta(\rho u)_\eta+(\rho uv)_\eta=0,\\ &-\xi(\rho v)_\xi+(\rho uv)_\xi-\eta(\rho v)_\eta+(\rho v^2+p)_\eta=0,\\ &-\xi\left(\rho\left(e+\frac{u^2+v^2}{2}\right)\right)_\xi+\left(\rho u\left(h+\frac{u^2+v^2}{2}\right)\right)_\xi-\eta\left(\rho\left(e+\frac{u^2+v^2}{2}\right)\right)_\eta\\ &\quad+\left(\rho v\left(h+\frac{u^2+v^2}{2}\right)\right)_\eta=0, \end{aligned} \tag{1.3}′$$

and the Riemann problems change to boundary value problems at the infinity, i.e.,

$$(\rho, u, v) \text{ or } (\rho, p, u, v)\to\begin{cases}①\\②\\③\\④\end{cases} \text{ as } \xi^2+\eta^2\to\infty\begin{cases}\xi>0, & \eta>0,\\ \xi<0, & \eta>0,\\ \xi<0, & \eta<0,\\ \xi>0, & \eta<0.\end{cases}$$

We seek the solution in the whole (ξ, η) plane.

It is easy to show that the pseudostationary flow is transonic and must be supersonic at the infinity for bounded solutions. Considering the infinity as a Cauchy support, we construct the solution from infinity. The data at infinity are four constant states with four jumps. Solving these four jumps in the neighborhood of infinity, we obtain four planar waves, parallel to the coordinate axis, each of which consists, generally speaking, of three planar waves: a backward rarefaction wave $\tilde{R}$ or shock $\tilde{S}$, a slip line J, and a forward rarefaction wave $\vec{R}$ or shock $\vec{S}$. For simplicity, we assume that each jump of the data can be connected by exactly one planar wave of $\vec{R}$, $\vec{S}$, or J. Thus, in the neighborhood of infinity, the solution consists of four planar waves of R, S, and J, besides the four constant states. The problem will be classified according to the different combinations of these four waves. In § 3 we prove that only 16 cases of combinations are needed to be considered; six cases do not involve J, and 10 do involve J. Then we discuss the problem case by case in §§ 4–6. After some analysis, calculation, and demonstration, we get a conjecture on the structure of the solution in the whole (ξ, η) plane for each case.

We extend the supersonic planar flows coming from infinity along the stream lines. They should stop at a boundary of supersonic flow if they do not interact; otherwise they stop at the point where they interact. For the latter case, we solve the interaction of planar waves up to the boundary of supersonic flow, which consists of sonic curves, shocks, and slip lines. The boundary bounds a bounded domain of subsonic flow. Many beautiful structures appear in the solutions. When we solve the interaction of planar rarefaction waves, we must seek the global continuous solution of a Goursat problem with sonic points as the ends of its support, a problem of

degenerate hyperbolic system. When we solve the interaction of shocks, we meet the problem of reflection of an oblique shock, and the regular reflection and Mach reflection appear. To determine the subsonic flow we need to deal with a problem of a degenerate elliptic system with free boundary. Slip lines are more fascinating. They should end with a spiral [13]-[15] as they enter into the subsonic flow. In summary, the two-dimensional Riemann problem gathers many interesting open problems. Maybe there is a long way to go to solve all of these problems using pure analytical methods, but it is possible to check them by computation first.

DEFINITION. The pseudostationary flow is called rarefactive if the density is nonincreasing along the stream lines in the flow.

In summary, our conjecture on the solutions can be described as follows. The solutions are piecewise smooth except for a spiral of slip lines, and they consist of constant states, continuous rarefaction waves, shocks, and slip lines. There are no compressive continuous waves. These properties are similar to those of the one-dimensional case.

However, shocks may have bifurcation points and may vanish somewhere continuously. There is a subsonic domain in the flow, the boundary of which consists of sonic curves, slip lines, and/or shocks. The stream lines must go into the subsonic domain and focus at a node if there is no slip line in the domain; otherwise they may end with a spiral. All these features are substantially different from those of the one-dimensional case.

In addition, we have two conjectures for general pseudostationary flow as follows. (1) The pseudostationary flow is continuous on the whole plane if and only if it is continuous and rarefactive in a neighborhood of infinity. (2) The pseudostationary flow is smooth (i.e., C^1) on the whole plane if and only if it is a constant state.

2. Preliminaries.

2.1. Characteristics and standard forms. After simple calculation, the systems (1.3) and (1.3)′ can, for smooth solutions, be reduced to

$$\begin{pmatrix} U & \rho & 0 \\ p'/\rho & U & 0 \\ 0 & 0 & U \end{pmatrix}\begin{pmatrix} \rho_\xi \\ U_\xi \\ V_\xi \end{pmatrix}+\begin{pmatrix} V & 0 & \rho \\ 0 & V & 0 \\ p'/\rho & 0 & V \end{pmatrix}\begin{pmatrix} \rho_\eta \\ U_\eta \\ V_\eta \end{pmatrix}+\begin{pmatrix} 2\rho \\ U \\ V \end{pmatrix}=0,\tag{2.1}$$

[1]

and

$$\begin{pmatrix} U & 0 & \rho & 0 \\ 0 & 1 & \rho U & 0 \\ 0 & 0 & 0 & \rho U \\ 0 & U & \gamma p & 0 \end{pmatrix}\begin{pmatrix} \rho_\xi \\ p_\xi \\ U_\xi \\ V_\xi \end{pmatrix}+\begin{pmatrix} V & 0 & 0 & \rho \\ 0 & 0 & \rho V & 0 \\ 0 & 1 & 0 & \rho V \\ 0 & V & 0 & \gamma p \end{pmatrix}\begin{pmatrix} \rho_\eta \\ p_\eta \\ U_\eta \\ V_\eta \end{pmatrix}+\begin{pmatrix} 2\rho \\ \rho U \\ \rho V \\ 2\gamma p \end{pmatrix}=0,\tag{2.1}'$$

where $(U, V)=(u-\xi, v-\eta)$, which is called pseudovelocity. Their characteristic equations are

$$(V-\lambda U)[(V-\lambda U)^2-c^2(1+\lambda^2)]=0,$$

$$(V-\lambda U)^2[(V-\lambda U)^2-c^2(1+\lambda^2)]=0,$$

where $c=\sqrt{p'(\rho)}$ (isentropic) or $\sqrt{\gamma p/\rho}$ (adiabatic), which is called sound speed. So,

[1] It is symmetric when $p=\rho^3/3$.

either

$$V-\lambda U=0, \quad \text{i.e. } \lambda=\lambda_0\equiv\frac{V}{U} \text{ (pseudoflow characteristic),}$$

or

$$(V-\lambda U)^2=c^2(1+\lambda^2), \tag{2.2}$$

i.e.,

$$\lambda=\lambda_\pm\equiv\frac{UV\pm\sqrt{c^2(U^2+V^2-c^2)}}{U^2-c^2} \quad \text{(pseudowave or } \lambda \text{ characteristics),} \tag{2.3}$$

$$=\frac{V^2-c^2}{VU\mp\sqrt{c^2(U^2+V^2-c^2)}} \tag{2.4}$$

which are

real and distinct if and only if $U^2+V^2>c^2$ (supersonic),
real and the same if and only if $U^2+V^2=c^2$ (sonic),
complex conjugate if and only if $U^2+V^2<c^2$ (subsonic).

Obviously, bounded solutions (ρ, u, v) must be pseudosupersonic in the neighborhood of infinity.

There are three families of characteristic lines defined by

$$\frac{d\eta}{d\xi}=\lambda_i(\rho, U, V) \qquad (i=0, +, -),$$

which are called flow or $\lambda_\pm$ characteristic lines, respectively, in the supersonic domain for a given solution $(\rho(\xi, \eta), u(\xi, \eta), v(\xi, \eta))$. The flow characteristic lines, which are called stream lines also, can be oriented so that they come from the infinity. The $\lambda_\pm$ characteristic lines can never be tangent to the stream lines.

There are only stream lines in the subsonic flow.

The more interesting thing is the sonic curve. The $\lambda_\pm$ characteristic lines are tangent to each other at and only at sonic points and are perpendicular to the stream line there. What is the relation between the sonic curve and the $\lambda_\pm$ characteristic lines? In which cases will they coincide, contact, be perpendicular, or only intersect?

Let us deduce system (2.1) and (2.1)′ to characteristic form. The left eigenvectors corresponding to λ_0, $\lambda_\pm$ are, respectively,

$$l_0\|(0, U, V), \qquad l_\pm\|(V-\lambda_\pm U, \lambda_\pm\rho, -\rho),$$

$$l'_{01}\|(c^2, 0, 0, -1), \quad l'_{02}\|(0, U, V, 0), \qquad l'_\pm\|(0, \lambda_\pm c^2, -c^2, V-\lambda_\pm U).$$

The characteristic forms are

$$(c^2/\rho, U, V)\left(\frac{\partial}{\partial\xi}+\lambda_0\frac{\partial}{\partial\eta}\right)\begin{pmatrix}\rho\\U\\V\end{pmatrix}+(U+\lambda_0 V)=0, \tag{2.5}$$

$$\left(\pm\frac{\sqrt{c^2(U^2+V^2-c^2)}}{\rho}, -V, U\right)\left(\frac{\partial}{\partial\xi}+\lambda_\pm\frac{\partial}{\partial\eta}\right)\begin{pmatrix}\rho\\U\\V\end{pmatrix}+(\lambda_\pm U-V)=0; \tag{2.6}$$

(2.5)′ $\left(\frac{\partial}{\partial\xi}+\lambda_0\frac{\partial}{\partial\eta}\right)(p\rho^{-\gamma})=0$ (i.e., the smooth wave must be isentropic along each stream line),

$$\frac{1}{\rho}\left(\frac{\partial}{\partial\xi}+\lambda_0\frac{\partial}{\partial\eta}\right)p+\left(\frac{\partial}{\partial\xi}+\lambda_0\frac{\partial}{\partial\eta}\right)\left(\frac{U^2+V^2}{2}\right)+(U+\lambda_0 V)=0,$$

(2.6)′ $$\left(\pm\frac{\sqrt{c^2(U^2+V^2-c^2)}}{\rho c^2},-V,U\right)\left(\frac{\partial}{\partial\xi}+\lambda_\pm\frac{\partial}{\partial\eta}\right)\begin{pmatrix}p\\U\\V\end{pmatrix}+(\lambda_\pm U-V)=0.$$

The first-order system (2.5)-(2.6) consists of a quasilinear equation (2.5) and a mixed-type system of quasilinear equations (2.6). System (2.5)′-(2.6)′ is a hyperbolic system (2.5)′ coupled with a mixed-type system (2.6)′. It is well known that systems (2.5)-(2.6) and (2.5)′-(2.6)′ are both linearly degenerate for the flow characteristic and convex (genuinely nonlinear) for wave characteristic families.

2.2. Discontinuities. It is well known that along the discontinuity line $\eta=\eta(\xi)$, the Rankine-Hugoniot condition should be true, i.e.,

(2.7)
$$\begin{aligned}&[\rho U]\,d\eta=[\rho V]\,d\xi,\\&[\rho U^2+p]\,d\eta=[\rho UV]\,d\xi,\\&[\rho UV]\,d\eta=[\rho V^2+p]\,d\xi;\end{aligned}$$

(2.7)′
$$\begin{aligned}&[\rho U]\,d\eta=[\rho V]\,d\xi,\\&[\rho U^2+p]\,d\eta=[\rho UV]\,d\xi,\\&[\rho UV]\,d\eta=[\rho V^2+p]\,d\xi,\\&\left[\rho U\left(h+\frac{U^2+V^2}{2}\right)\right]d\eta=\left[\rho V\left(h+\frac{U^2+V^2}{2}\right)\right]d\xi,\end{aligned}$$

where $[Q]\equiv Q-Q_0$, i.e., the jump of Q across the discontinuity. Solving (2.7), we obtain either the linear discontinuity

(2.8)
$$\begin{aligned}&\frac{d\eta}{d\xi}=\frac{V}{U}=\frac{V_0}{U_0}\equiv\sigma_0\\&[\rho]=0\end{aligned}\qquad\text{(slip line)}$$

or nonlinear discontinuity

(2.9) $$\frac{d\eta}{d\xi}=\frac{U_0V_0\pm\sqrt{\bar c^2(U_0^2+V_0^2-\bar c^2)}}{U_0^2-\bar c^2}=-\frac{U-U_0}{V-V_0}\equiv\sigma_\pm,$$

(2.10) $$\rho_0(U_0\sigma_\pm-V_0)(V-V_0)=p-p_0,$$

where $\bar c^2=(\rho/\rho_0)([p]/[\rho])$. For the case of adiabatic flow, the only difference is that (2.8) is replaced by $[p]=0$ and the following equation should be added to (2.9) and (2.10):

(2.11) $$\frac{p}{p_0}=\frac{(\gamma+1)\rho-(\gamma-1)\rho_0}{(\gamma+1)\rho_0-(\gamma-1)\rho}>0.$$

It is easy to show that the nonlinear discontinuity can never be tangent to the stream line or the $\lambda_\pm$ characteristic lines. We call the compressive nonlinear discontinuity a shock or a shock wave.

2.3. Planar elementary waves and their sonic curve and characteristic lines. Planar elementary waves $(\rho(\xi), u(\xi), v(\xi))$ or $(\rho(\xi), p(\xi), u(\xi), v(\xi))$ involve:

(i) Constant states: $(\rho, u, v) = \text{const.}$ or $(\rho, p, u, v) = \text{const.}$

(ii) Backward and forward rarefaction waves:

$$\tilde{\tilde{R}}(\xi): \begin{cases} \xi = \lambda_{\mp} \equiv u \mp c, \\ \dfrac{du}{d\rho} = \mp \dfrac{c}{\rho}, \\ dv = 0, \end{cases} \quad \text{or} \quad \begin{cases} \xi = \lambda_{\mp} \equiv u \mp c, \\ \dfrac{du}{d\rho} = \mp \dfrac{c}{\rho}, \\ dv = 0, \\ d(p\rho^{-\gamma}) = 0 \quad \text{(i.e., } \tilde{\tilde{R}}(\xi) \text{ must be isentropic).} \end{cases}$$

(iii) Backward and forward shock waves:

$$\tilde{\tilde{S}}(\xi): \begin{cases} \xi = \sigma_{\mp} = u_l \mp \sqrt{\dfrac{\rho_r [p]}{\rho_l [\rho]}}, \\ \dfrac{[u]}{[\rho]} = \mp \sqrt{\dfrac{1}{\rho_r \rho_l} \dfrac{[p]}{[\rho]}}^2, \\ [V] = 0, \\ \rho_l \lesseqgtr \rho_r \quad \text{(entropy condition),} \end{cases}$$

or

$$\tilde{\tilde{S}}(\xi): \begin{cases} \xi = \sigma_{\mp} = u_l \mp \sqrt{\dfrac{\rho_r}{\rho_l} \dfrac{[p]}{[\rho]}}, \\ \dfrac{[u]}{[\rho]} = \mp \sqrt{\dfrac{1}{\rho_r \rho_l} \dfrac{[p]}{[\rho]}}^2, \\ [v] = 0, \\ \dfrac{p_l}{p_r} = \dfrac{(\gamma+1)\rho_l - (\gamma-1)\rho_r}{(\gamma+1)\rho_r - (\gamma-1)\rho_l} > 0, \\ p_l \lesseqgtr p_r \Leftrightarrow \rho_l \lesseqgtr \rho_r \quad \text{(entropy condition).} \end{cases}$$

(iv) Slip lines:

$$J(\xi): \begin{cases} \xi = u_l = u_r, \\ [\rho] = 0, \end{cases} \quad \text{or} \quad \begin{cases} \xi = u_l = u_r, \\ [p] = 0. \end{cases}$$

Let us consider their sonic curve and characteristic lines.

(i) Constant state $(\rho, u, v) = (\rho_0, u_0, v_0)$ or $(\rho, p, u, v) = (\rho_0, p_0, u_0, v_0)$. Their sonic curve is a circle:

$$(\xi - u_0)^2 + (\eta - v_0)^2 = c_0^2.$$

The flow is subsonic inside the circle and supersonic outside the circle. The stream lines satisfy

$$\frac{d\eta}{d\xi} = \frac{\eta - v_0}{\xi - u_0}.$$

[2] This is equivalent to $u_l \mp \sqrt{(\rho_r/\rho_l)([p]/[\rho])} = u_r \mp \sqrt{(\rho_l/\rho_r)([p]/[\rho])}$.

Integrating it, we obtain

$$\frac{\eta - v_0}{\xi - u_0} = \text{const.},$$

which are all rays starting from infinity and focusing at the center of the sonic circle.

The wave characteristic lines satisfy

$$\frac{d\eta}{d\xi} = \lambda_{\pm},$$

where $\lambda_{\pm}$ satisfy

$$[(\eta - v_0) - \lambda_{\pm}(\xi - u_0)]^2 = c_0^2(1 + \lambda_{\pm}^2).$$

Differentiating them along their own characteristic lines, we obtain

$$-2[(\eta - v_0) - \lambda_{\pm}(\xi - u_0)](\xi - u_0)\frac{d\lambda_{\pm}}{d\xi} = 2\lambda_{\pm}c_0^2\frac{d\lambda_{\pm}}{d\xi};$$

i.e.,

$$\pm\sqrt{c_0^2[(\xi - u_0)^2 + (\eta - v_0)^2 - c_0^2]}\,\frac{d\lambda_{\pm}}{d\xi} = 0,$$

so

$$\frac{d\lambda_{\pm}}{d\xi} = 0,$$

which means the wave characteristic lines are straight lines. Because they are perpendicular to the stream lines at the sonic circle, they must be the tangent lines of the

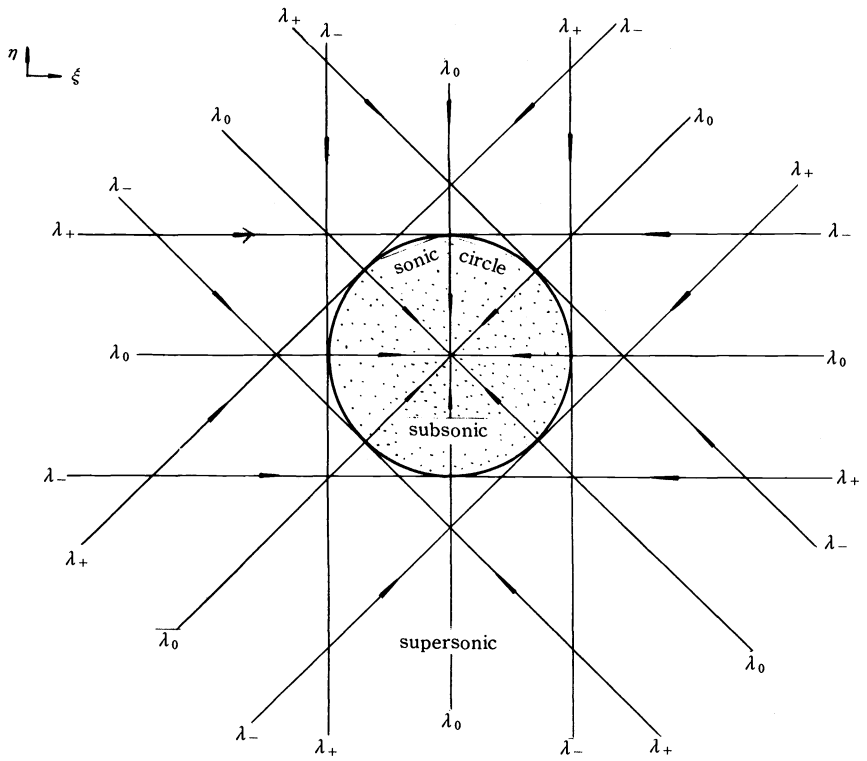

FIG. 2.1

circle. It is easy to establish that the clockwise rays correspond to λ_- and the counterclockwise rays correspond to λ_+. We can orient them so that they come from infinity and end at the sonic circle (Fig. 2.1).

(ii) $\vec{R}(\xi)_{2,1}$ connecting ② and ① (Figs. 2.2 and 2.3):

$$\vec{R}(\xi)_{2,1}:\begin{cases}\xi = u+\sqrt{p'(\rho)}, & (\xi_2 \equiv u_2+c_2 \leqq \xi \leqq u_1+c_1 \equiv \xi_1),\\ u = u_1+\displaystyle\int_{\rho_1}^{\rho}\frac{\sqrt{p'(\rho)}}{\rho}\,d\rho, & (0 \leqq \rho_2 \leqq \rho \leqq \rho_1),\\ v = v_1.\end{cases}$$

The sonic curve is a straight segment

$$\eta = v_1 \qquad (\xi_2 \leqq \xi \leqq \xi_1),$$

which we call the sonic stem.

The stream lines satisfy

$$\frac{d\eta}{d\xi} = \frac{\eta - v_1}{\sqrt{p'(\rho)}}$$

and we have

$$\frac{d\xi}{d\rho} = \frac{du}{d\rho}+\frac{1}{2}\frac{p''(\rho)}{\sqrt{p'(\rho)}} = \frac{\sqrt{p'}}{\rho}+\frac{1}{2}\frac{p''(\rho)}{\sqrt{p'(\rho)}} = \frac{\sqrt{A\gamma}}{2}(\gamma+1)\rho^{(\gamma-3)/2},$$

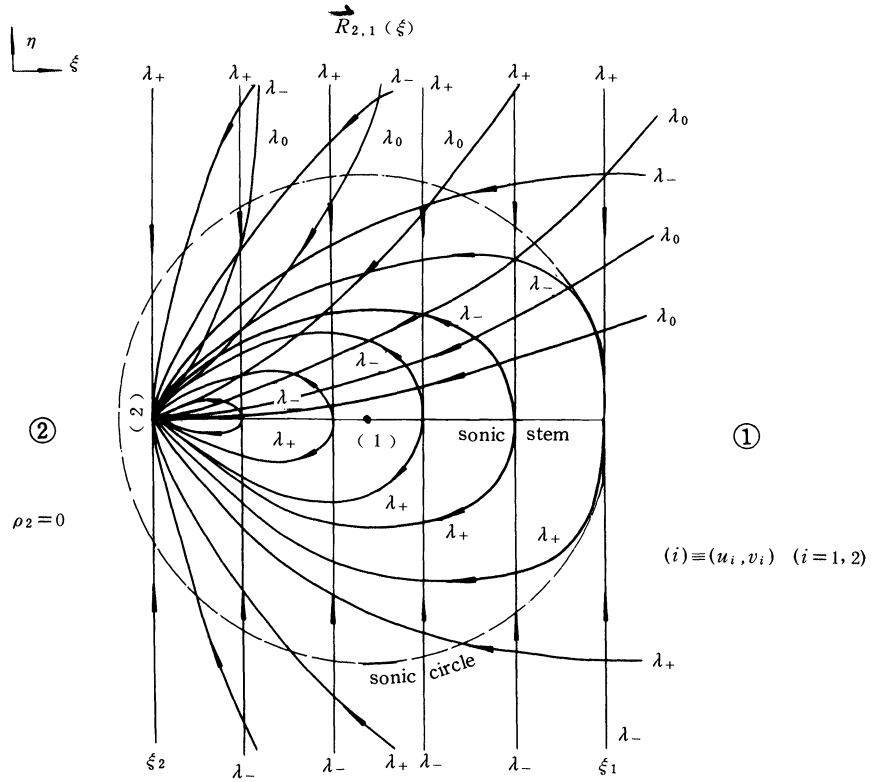

FIG. 2.2

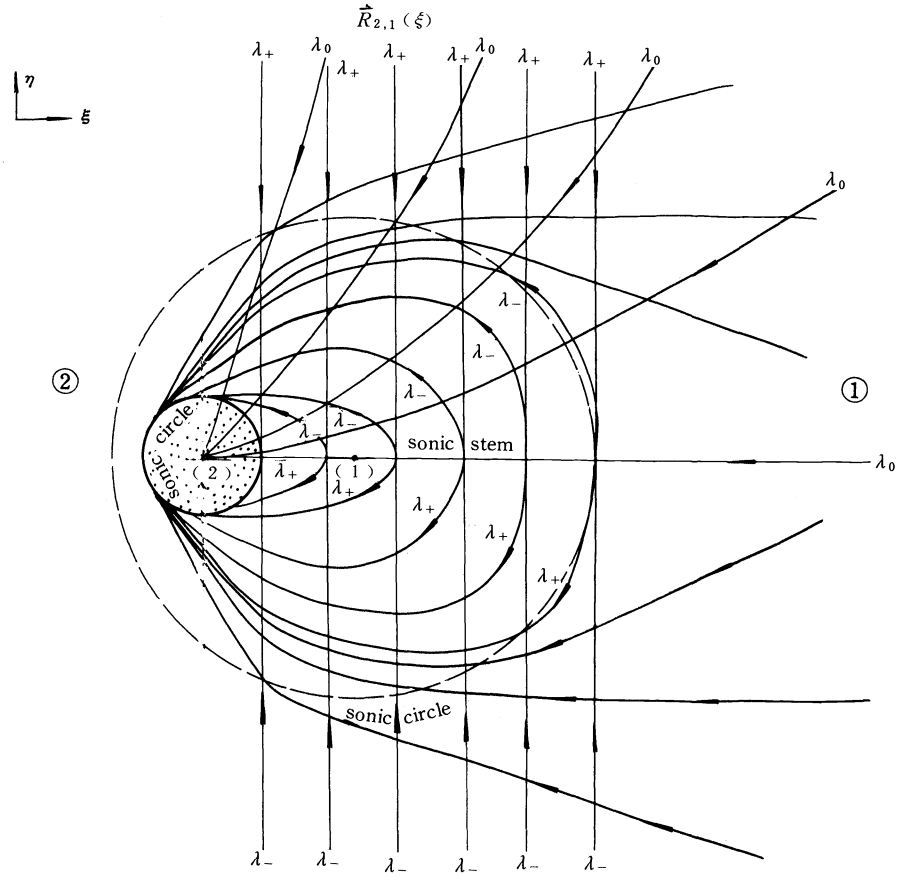

FIG. 2.3

so

$$\frac{d\eta}{d\rho}=\frac{(\gamma+1)(\eta-v_1)}{2\rho}.$$

Integrating them, we get

$$\xi-u_1=\sqrt{A\gamma}\rho_1^{(\gamma-1)/2}+\sqrt{A\gamma}\,\frac{\gamma+1}{\gamma-1}(\rho^{(\gamma-1)/2}-\rho_1^{(\gamma-1)/2}),$$

$$\eta-v_1=c\rho^{(\gamma+1)/2}(=c(\xi-u_2)^{(\gamma+1)/(\gamma-1)} \text{ if } \rho_2=0),$$

where c is an arbitrary constant. The sonic stem is located on the stream line $c=0$ and is perpendicular to the $\lambda_\pm$ characteristic lines there. Here the situation is totally different from that of constant states where the sonic curve is tangent to the $\lambda_\pm$ characteristic lines. The other stream lines are symmetric about it and all intersect at point (u_2, v_2). (Figure 2.2 is for $\rho_2=0$, Fig. 2.3 is for $\rho_2>0$. We use (i) to denote the point (u_i, v_i).)

The $\lambda_\pm$ characteristic lines satisfy

$$\frac{d\eta}{d\xi}=\lambda_\pm,$$

where

$$\lambda_+ = \infty, \quad \lambda_- = \frac{(\eta - v_1)^2 - p'}{2\sqrt{p'}(\eta - v_1)}, \quad (\eta > v_1),$$

$$\lambda_+ = \frac{(\eta - v_1)^2 - p'}{2\sqrt{p'}(\eta - v_1)}, \quad \lambda_- = \infty, \quad (\eta < v_1).$$

We need only to consider

$$\frac{d\eta}{d\xi} = \frac{(\eta - v_1)^2 - p'}{2\sqrt{p'}(\eta - v_1)}.$$

As $d\xi = ((2p' + p'')/(2\rho\sqrt{p'}))\, d\rho$, we have

$$\frac{d(\eta - v_1)^2}{d\rho} = \frac{\gamma + 1}{2\rho}[(\eta - v_1)^2 - \gamma\rho^{\gamma - 1}].$$

Integrating it, we get

$$(\eta - v_1)^2 = \rho^{(\gamma+1)/2}\left(c - \frac{\gamma(\gamma+1)}{\gamma - 3}\rho^{(\gamma-3)/2}\right) \qquad (\gamma \neq 3)$$

or

$$(\eta - v_1)^2 = \rho^2(c - \ln \rho) \qquad (\gamma = 3).$$

All of the $\lambda_\pm$ characteristic lines focus at (u_2, v_2) (see Fig. 2.2).

If ② is not a vacuum ($\rho_2 > 0$), then the sonic curves and characteristic lines of ②, $\vec{R}_{2,1}(\xi)$, and ① are as pictured in Fig. 2.3. Figure 2.3 can be made by combining Figs. 2.1 and 2.2. The sonic curve is made of the sonic circle of ② and the sonic stem of $\vec{R}_{2,1}(\xi)$. The sonic circle of ① is located in $\xi \leqq \xi_1$; therefore it is an imaginary one.

(iii) $\vec{S}_{2,1}(\xi)$ connecting ② and ① (Fig. 2.4):

$$\vec{S}_{2,1}(\xi): \begin{cases} \xi = \sigma_+ = u_2 + \sqrt{\dfrac{\rho_1}{\rho_2} p'_{12}} = u_1 + \sqrt{\dfrac{\rho_2}{\rho_1} p'_{12}}, \\ v_2 = v_1, \\ \rho_2 > \rho_1 \Leftrightarrow u_2 > u_1, \end{cases}$$

or

$$\vec{S}_{2,1}(\xi): \begin{cases} \xi = \sigma_+ = u_2 + \sqrt{\dfrac{\rho_1}{\rho_2} p'_{12}} = u_1 + \sqrt{\dfrac{\rho_2}{\rho_1} p'_{12}}, \\ v_2 = v_1, \\ \dfrac{p_2}{p_1} = \dfrac{(\gamma+1)\rho_2 - (\gamma-1)\rho_1}{(\gamma+1)\rho_1 - (\gamma-1)\rho_2} > 0, \\ p_2 > p_1 \Leftrightarrow \rho_2 > \rho_1 \Leftrightarrow u_2 > u_1, \end{cases}$$

where $p'_{12} \equiv (p_2 - p_1)/(\rho_2 - \rho_1)$.

Obviously, $u_2 + c_2 > \sigma_+ > u_1 + c_1$, $\sigma_+ > u_2$, which means that the sonic circle of ① is located in $\xi < \sigma_+$ (so, it is an imaginary one), and the sonic circle of ② is divided into two parts by the shock (so, it is partly imaginary). The characteristic lines of ① and ② are determined by these two sonic circles, respectively.

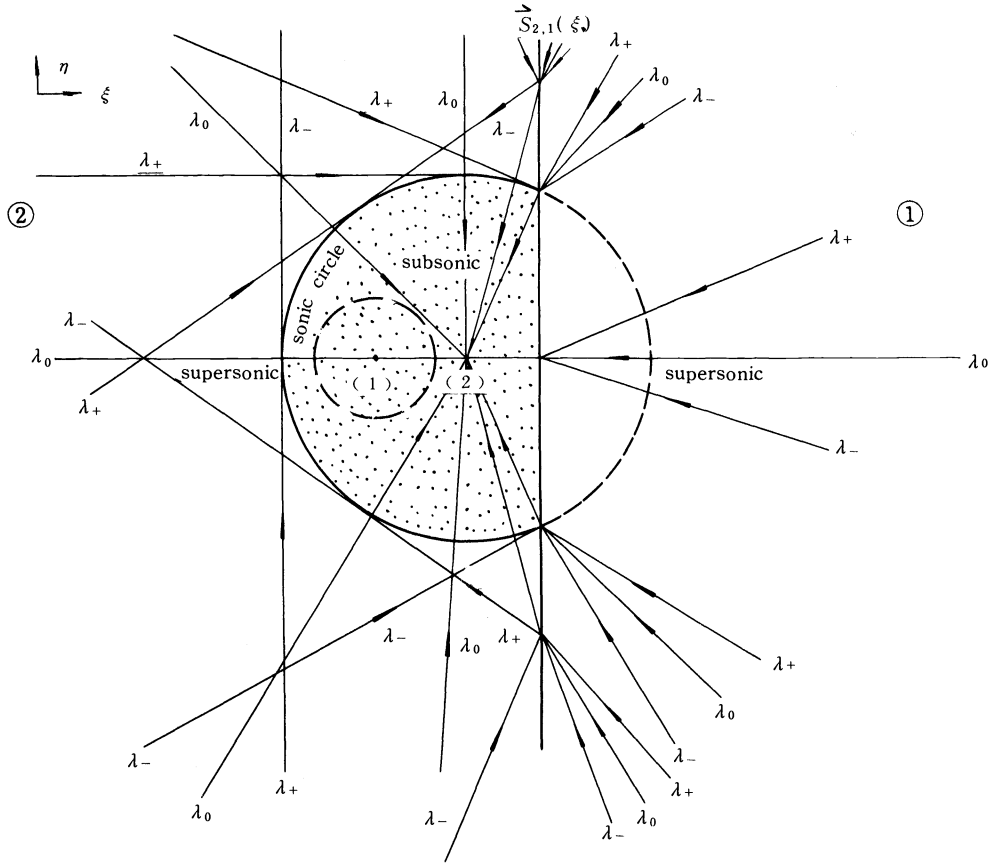

FIG. 2.4

(iv) $J_{2,1}(\xi)$ connecting ② and ① (Fig. 2.5):

$$J_{2,1}(\xi):\begin{cases}\xi = u_2 = u_1,\\ \rho_2 = \rho_1,\end{cases} \quad \text{or} \quad \begin{cases}\xi = u_2 = u_1,\\ p_2 = p_1.\end{cases}$$

It seems that we cut the constant states along the stream line $\xi = u_1 = u_2$ into two parts, and slip them up or down.

Completely analogously, we can deal with the remaining planar elementary waves along the other directions.

3. Classification. Under our assumptions, there are only four planar elementary waves besides the constant states in a neighborhood of infinity.

We now analyze which combinations of these four waves are possible.

We consider the combination where J does not appear first. Thus $\rho_i \neq \rho_j$ $(i \neq j,\ i, j = 1, 2, 3, 4)$. It is easy to show that there are only the following three combinations of ρ_i's:

$$\begin{array}{ccc} \rho_2 < \rho_1 & \rho_2 < \rho_1 & \rho_2 < \rho_1 \\ \vee \quad \vee & \wedge \quad \vee & \vee \quad \vee \\ \rho_3 < \rho_4 & \rho_3 > \rho_4 & \rho_2 > \rho_4 \end{array}$$

and that all other combinations of ρ_i's can be reduced to the three above by coordinate transformations.

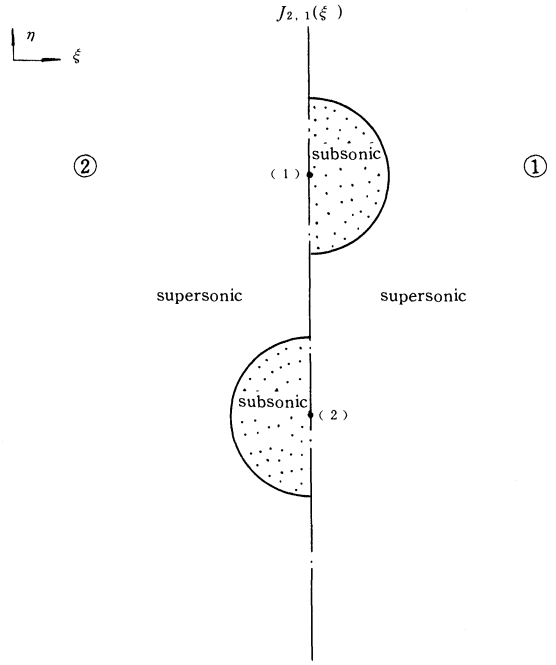

FIG. 2.5

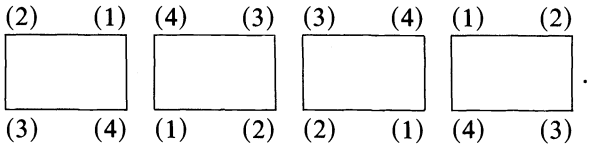
For each of the above three possible combinations of ρ_i's, there are only two further possibilities:

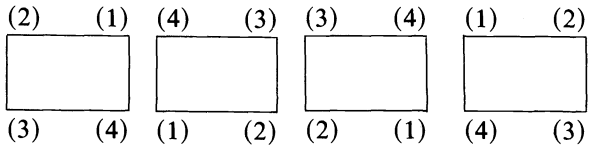
$$\rho_2 < \rho_1, \qquad u_2 < u_1: \vec{R}(\xi),$$

$$\rho_2 < \rho_1, \qquad u_2 > u_1: \tilde{S}(\xi).$$

It is easy to show that $(\xi, \eta) = (i) \equiv (u_i, v_i)$ $(i = 1, 2, 3, 4)$ must be located on the four corners of a rectangle, and there are only four possibilities as follows:



Combining all facts mentioned above, we have the following table:



$\rho_2 < \rho_1$	$\vec{R}$	$\tilde{S}$	$\vec{R}$	$\tilde{S}$
$\vee \quad \vee$	$\vec{R} \quad \vec{R}$	$\tilde{S} \quad \tilde{S}$	$\tilde{S} \quad \tilde{S}$	$\vec{R} \quad \vec{R}$
$\rho_3 < \rho_4$	$\vec{R}$	$\tilde{S}$	$\vec{R}$	$\tilde{S}$
$\rho_2 < \rho_1$	$\vec{R}$	$\tilde{S}$	$\vec{R}$	$\tilde{S}$
$\wedge \quad \vee$	$\tilde{R} \quad \vec{R}$	$\vec{S} \quad \tilde{S}$	$\vec{S} \quad \tilde{S}$	$\tilde{R} \quad \vec{R}$
$\rho_3 > \rho_4$	$\tilde{R}$	$\vec{S}$	$\tilde{R}$	$\vec{S}$

$\rho_2 < \rho_1$	$\vec{R}$	$\tilde{S}$	$\vec{R}$	$\tilde{S}$
$\vee \quad \vee$	$\vec{R} \quad \vec{R}$	$\tilde{S} \quad \tilde{S}$	$\tilde{S} \quad \tilde{S}$	$\vec{R} \quad \vec{R}$
$\rho_3 > \rho_4$	$\tilde{R}$	$\vec{S}$	$\tilde{R}$	$\vec{S}$

But the bottom set of combinations are impossible. In fact, taking as an example, $\vec{R}\overset{\vec{R}}{\tilde{R}}\vec{R}$, we have

$$v_1 = v_2, \quad v_2 - v_3 = \int_{\rho_3}^{\rho_2} \frac{\sqrt{p'}}{\rho}\, d\rho, \quad v_3 = v_4, \quad v_4 - v_1 = \int_{\rho_1}^{\rho_4} \frac{\sqrt{p'}}{\rho}\, d\rho;$$

thus

$$\int_{\rho_3}^{\rho_4} \frac{\sqrt{p'}}{\rho}\, d\rho = \int_{\rho_4}^{\rho_1} \frac{\sqrt{p'}}{\rho}\, d\rho,$$

which is obviously impossible.

For $\tilde{S}\overset{\tilde{S}}{\vec{S}}\tilde{S}$, we have

$$v_1 = v_2, \quad v_2 - v_3 = \sqrt{\frac{1}{\rho_2\rho_3} p'_{23}(\rho_2 - \rho_3)}, \quad v_3 = v_4, \quad v_4 - v_1 = \sqrt{\frac{1}{\rho_1\rho_4} p'_{14}(\rho_1 - \rho_4)};$$

thus

$$\sqrt{\frac{1}{\rho_2\rho_3} p'_{23}(\rho_2 - \rho_3)} = \sqrt{\frac{1}{\rho_1\rho_4} p'_{14}(\rho_1 - \rho_4)},$$

which is also easily shown to be impossible.

Analogously, the remaining cases are impossible. □

Obviously, the two columns to the right of the table are similar (i.e., coordinate rotations can transform one to the other); therefore there are only six cases that do not involve J: two for four R's, two for four S's, and two for two R's and two S's.

Now, we consider cases involving J.

(1) Four J's. There are only four subcases (Fig. 3.1). The two rows are similar in the figure. Therefore there are only two subcases.

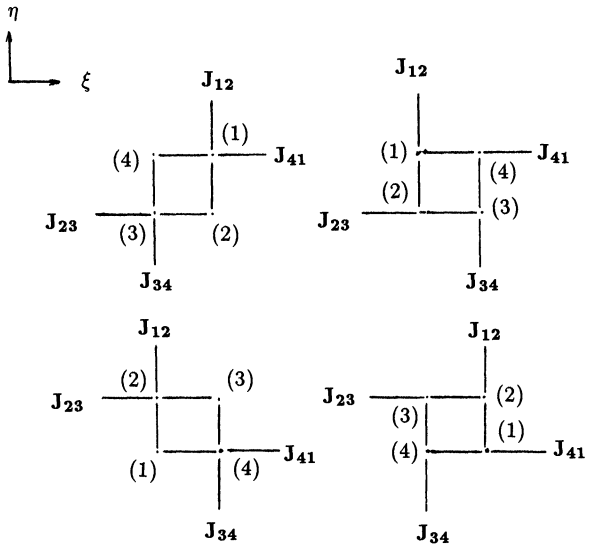


FIG. 3.1

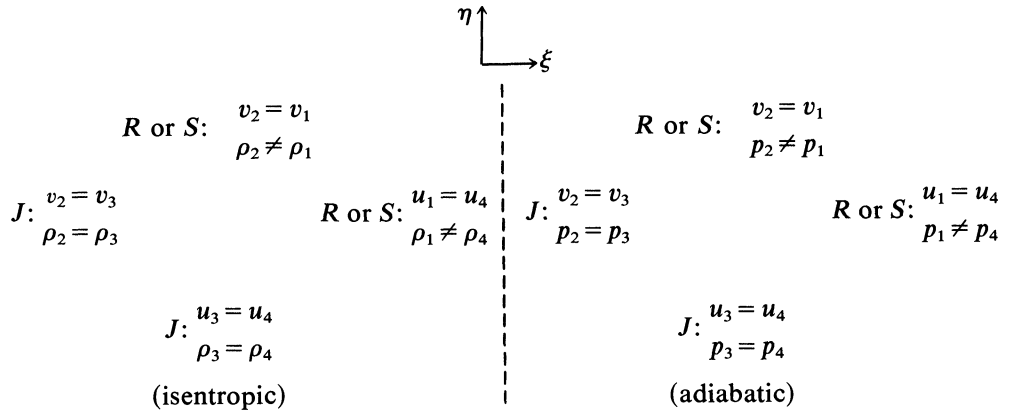
(2) Three J's. From three J's we know that $\rho_1=\rho_2=\rho_3=\rho_4$ (isentropic) or $p_1=p_2=p_3=p_4$ (adiabatic), which contradicts the fourth wave.

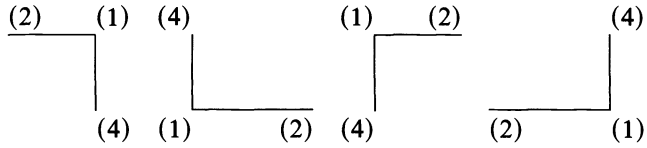
(3) Two J's.

(i) Two J's are neighbors. Without loss of generality, we assume that the two J's are in the directions of $-\xi$ and $-\eta$. We need to find out the wave types in the other two directions.

Observe the following table:



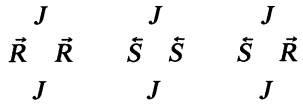
We have (1) = (3), and $\rho_2=\rho_3=\rho_4$ (isentropic) or $p_2=p_3=p_4$ (adiabatic). Thus



$\rho_2=\rho_4<\rho_1$	(isentropic)	$\vec{R}$	$\tilde{S}$	$\tilde{S}$	$\vec{R}$
or		$J\ \vec{R}$	$J\ \tilde{S}$	$J\ \vec{R}$	$J\ \tilde{S}$
$p_2=p_4<p_1$	(adiabatic)	J	J	J	J
$\rho_2=\rho_4>\rho_1$	(isentropic)	$\tilde{R}$	$\vec{S}$	$\vec{S}$	$\tilde{R}$
or		$J\ \tilde{R}$	$J\ \vec{S}$	$J\ \tilde{R}$	$J\ \vec{S}$
$p_2=p_4>p_1$	(adiabatic)	J	J	J	J

The two columns to the right are similar, so there are only six cases.

(ii) Two J's are not neighbors. It is easy to show that there are only three cases:

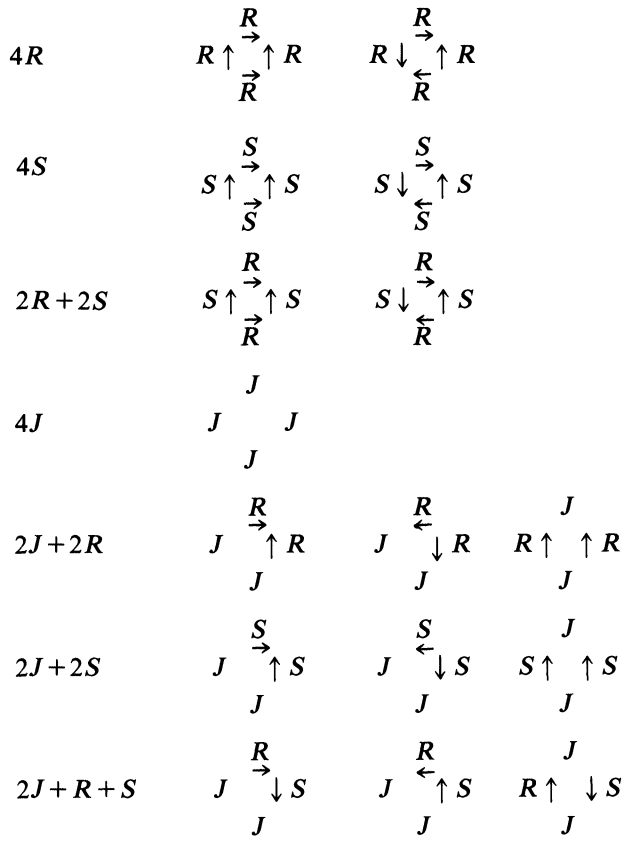


(4) One J:

$$J:\ u_2=u_1$$
$$R \text{ or } S:\ u_2=u_3 \qquad R \text{ or } S:\ u_1=u_4$$
$$R \text{ or } S:\ u_3\neq u_4.$$

It is obviously impossible.

In sum, we have 16 cases that need to be considered as follows:



We discuss them case by case in the forthcoming sections.

4. Four rarefaction waves. These must be isentropic. There are two cases.

(1) Four $\vec{R}$'s. The sonic circles and the sonic stems of $\vec{R}$'s are pictured in Fig. 4.1. The inequalities of ρ_i are

$$\rho_3 < \begin{matrix}\rho_2 \\ \rho_4\end{matrix} < \rho_1.$$

From

$$u_1 - u_2 = \int_{\rho_2}^{\rho_1} (\sqrt{p'}/\rho)\, d\rho, \qquad v_1 - v_2 = 0,$$

$$u_2 - u_3 = 0, \qquad v_2 - v_3 = \int_{\rho_3}^{\rho_2} (\sqrt{p'}/\rho)\, d\rho,$$

$$u_3 - u_4 = \int_{\rho_4}^{\rho_3} (\sqrt{p'}/\rho)\, d\rho, \qquad v_3 - v_4 = 0,$$

$$u_4 - u_1 = 0, \qquad v_4 - v_1 = \int_{\rho_1}^{\rho_4} (\sqrt{p'}/\rho)\, d\rho,$$

$v_3 = v_4$
$\rho_3 < \rho_4$

FIG. 4.1

we have

$$\int_{\rho_3}^{\rho_4} \frac{\sqrt{p'}}{\rho}\, d\rho = \int_{\rho_2}^{\rho_1} \frac{\sqrt{p'}}{\rho}\, d\rho, \qquad \int_{\rho_3}^{\rho_2} \frac{\sqrt{p'}}{\rho}\, d\rho = \int_{\rho_4}^{\rho_1} \frac{\sqrt{p'}}{\rho}\, d\rho.$$

Obviously, they are equivalent, and we call them compatibility conditions.

The system is strictly hyperbolic at infinity. We consider infinity as a Cauchy support. The data at the support are four constant states with four jumps. Solving them, we obtain a continuous rarefactive solution consisting of four constant states and four $\vec{R}$'s in the neighborhood of infinity. Extending the solution along stream lines, we should stop at either point P where two $\vec{R}$'s meet as $\vec{R}_{1,2}(\xi)$, ① and $\vec{R}_{4,1}(\eta)$, or the sonic curves as $\vec{R}_{2,3}(\eta)$, ③ and $\vec{R}_{4,3}(\xi)$ (Fig. 4.1). $\vec{R}_{1,2}(\xi)$ and $\vec{R}_{4,1}(\eta)$ meet at P before they reach their sonic curves. The boundary of $\vec{R}_{1,2}(\xi)$ should be the λ_- characteristic line extending from P. It penetrates $\vec{R}_{1,2}(\xi)$ and goes into ② with positive slope, and therefore it goes into $\vec{R}_{2,3}(\eta)$ without intersecting its sonic stem and then goes into ③ (Fig. 4.2). Analogously, we can extend the λ_+ characteristic line from P to go through $\vec{R}_{4,1}(\eta)$, ④ and $\vec{R}_{3,4}(\xi)$, and into ③.

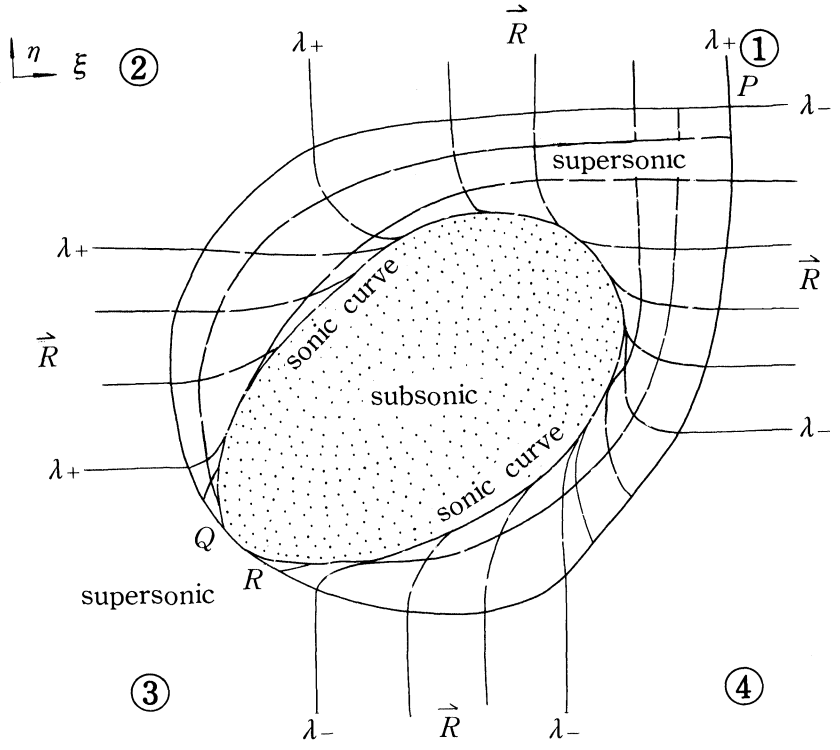

FIG. 4.2

There are two cases:

(a) These two characteristic lines extending from P become tangent to the sonic circle of ③ at Q and R, respectively, before they interact (Fig. 4.2). The λ_- characteristic line $\widehat{PQ}$ and the λ_+ characteristic line $\widehat{PR}$ form a Goursat problem. Q and R, the ends of the supports, are sonic points. We conjecture that this Goursat problem has a unique supersonic rarefactive continuous solution up to a sonic curve connecting Q and R

(but different from the arc $\widehat{QR}$) as its boundary. This sonic boundary, which is an envelope of the $\lambda_{\pm}$ characteristic lines, and the arc $\widehat{QR}$ of the sonic circle of ③ bound a domain. In this domain we conjecture that there exists a unique global subsonic continuous solution with a node of stream lines in it.

(b) Two λ characteristic lines intersect before they contact the sonic circle of ③. Our conjecture concerning the configuration of the solution is shown in Fig. 4.3.

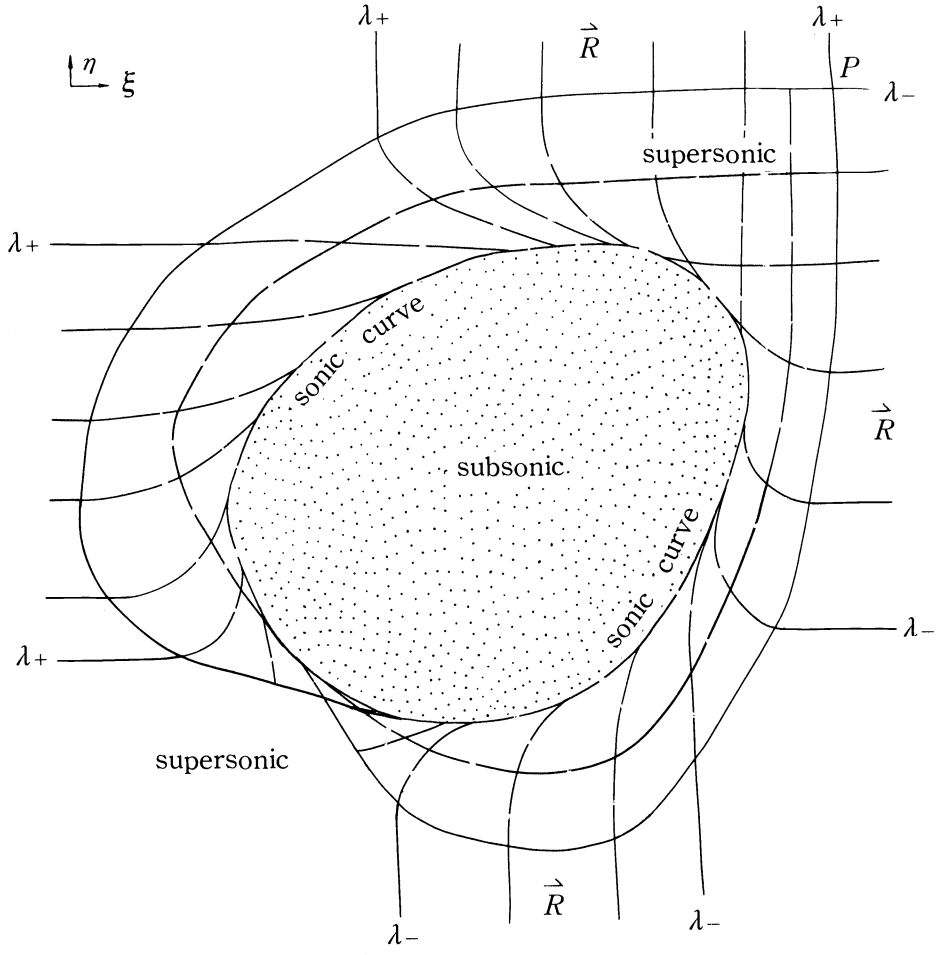

FIG. 4.3

There is an internal boundary, outside which the flow is supersonic and rarefactive. The boundary is the envelope of the λ characteristic lines. Inside the boundary, the flow is subsonic and rarefactive with a node of stream lines.

(2) Two $\vec{R}$'s and two $\tilde{R}$'s. It is pictured in Fig. 4.4. The inequalities of ρ_i are

$$\rho_3 > \frac{\rho_2}{\rho_4} < \rho_1.$$

The compatibility conditions are

$$\int_{\rho_2}^{\rho_3} \frac{\sqrt{p'}}{\rho}\, d\rho = \int_{\rho_4}^{\rho_1} \frac{\sqrt{p'}}{\rho}\, d\rho, \qquad \int_{\rho_2}^{\rho_1} \frac{\sqrt{p'}}{\rho}\, d\rho = \int_{\rho_4}^{\rho_3} \frac{\sqrt{p'}}{\rho}\, d\rho.$$

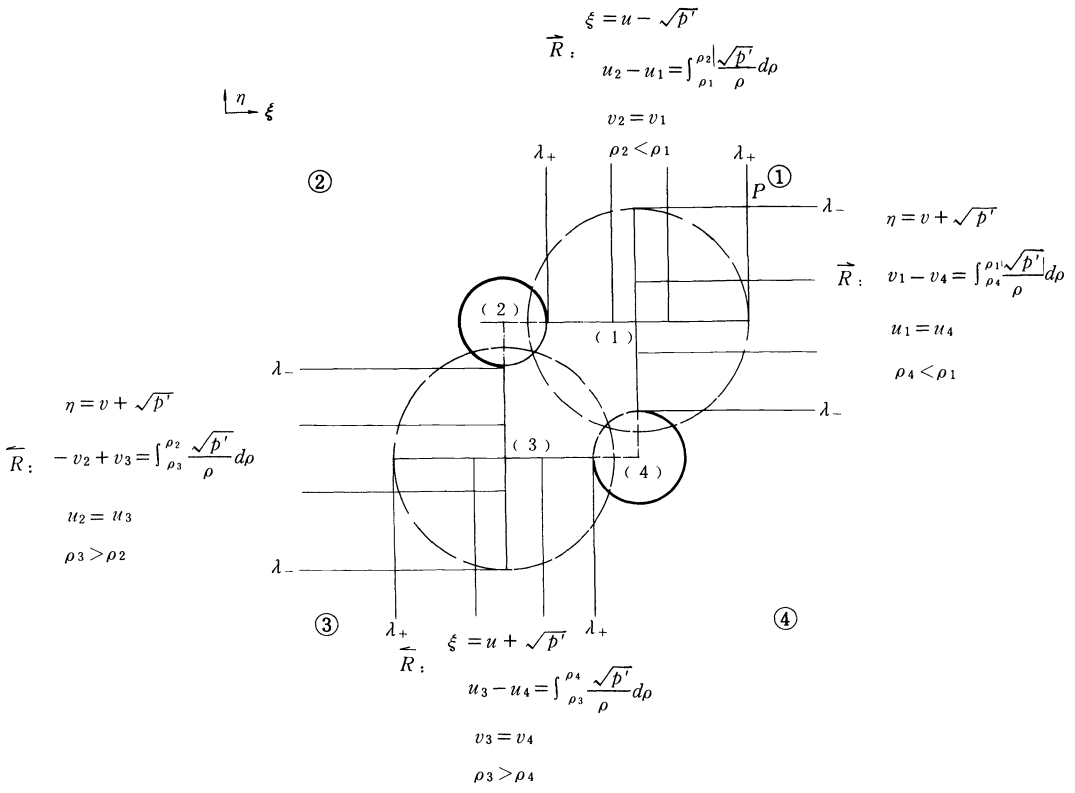

FIG. 4.4

It is easy to know from them that $\rho_2 = \rho_4$, $\rho_1 = \rho_3$; then $u_1 - u_2 = v_1 - v_4$. Thus Fig. 4.4 is symmetric to $\eta - \xi = -u_1 + v_1$ and $\xi + \eta = u_2 + v_2$. $\vec{R}_{1,2}$ and $\vec{R}_{1,4}$ meet at P. $\tilde{R}_{2,3}$ and $\tilde{R}_{4,3}$ meet at P'. Extend the following:

λ_- characteristic line from P to go through $\vec{R}_{1,2}$ and into ②,
λ_+ characteristic line from P to go through $\vec{R}_{1,4}$ and into ④,
λ_- characteristic line from P' to go through $\tilde{R}_{2,3}$ and into ②,
λ_+ characteristic line from P' to go through $\tilde{R}_{4,3}$ and into ④.

The $\lambda_\pm$ characteristic lines from P and P' in ② are either tangent to the sonic circle of ② before they meet, or they meet before they are tangent to the sonic circle of ②. The situation is analogous to ④. The configuration of solutions are conjectured as shown in Figs. 4.5 and 4.6.

There is a simple correspondence between two-dimensional pseudostationary flow and one-dimensional unstationary flow as follows. The stream line corresponds to $x =$ constant in the one-dimensional case where x is a Lagrangian coordinate. Infinity corresponds to $t = 0$ in the one-dimensional case, and the node of stream lines corresponds to $t = \infty$ in the one-dimensional case.

In addition, we have two conjectures for general pseudostationary flow as follows: (1) The pseudostationary flow is continuous on the whole plane if and only if it is continuous and rarefactive in a neighborhood of infinity. (2) The pseudostationary flow is smooth on the whole plane if and only if it is a constant state.

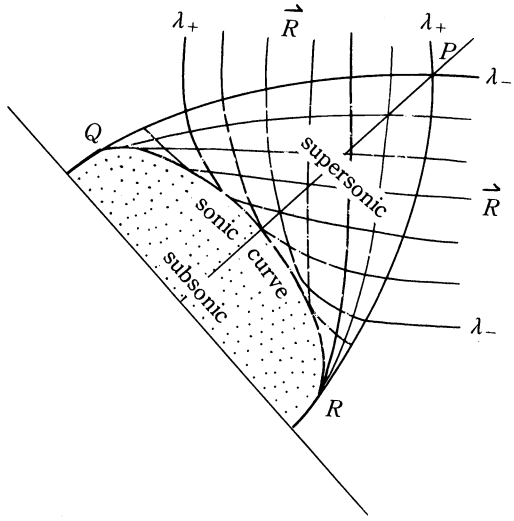

FIG. 4.5

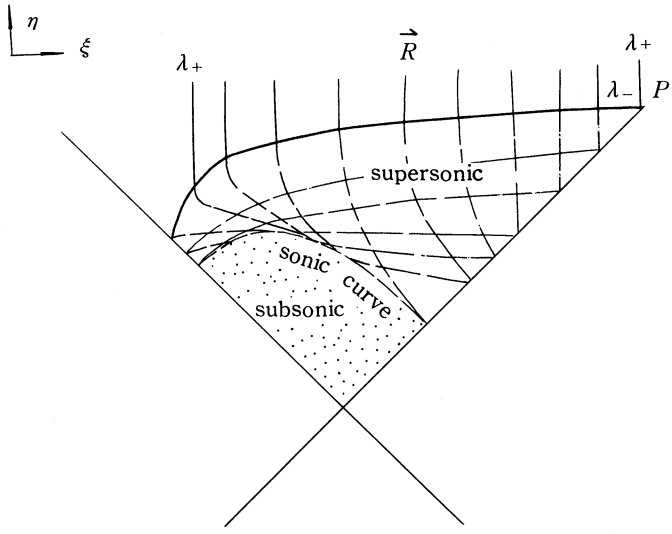

FIG. 4.6

5. Four shocks. There are two cases.

(1) Four $\vec{S}$'s (Fig. 5.1). The entropy conditions are

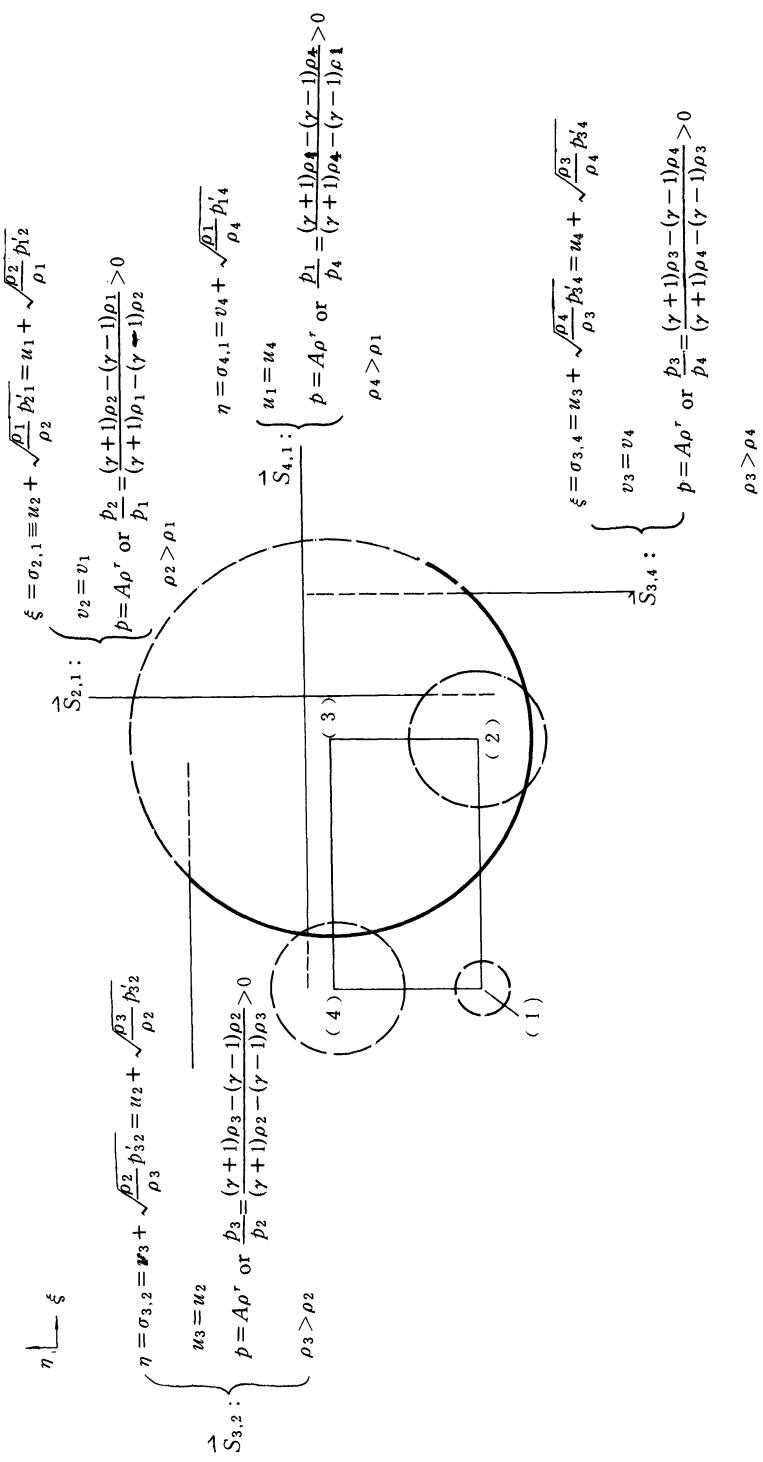
$$\rho_3 > \frac{\rho_2}{\rho_4} > \rho_1.$$

The compatibility conditions are

$$\sqrt{\frac{1}{\rho_1\rho_2}\,p'_{12}(\rho_2-\rho_1)} = \sqrt{\frac{1}{\rho_3\rho_4}\,p'_{34}(\rho_3-\rho_4)},$$

$$\sqrt{\frac{1}{\rho_4\rho_1}\,p'_{41}(\rho_4-\rho_1)} = \sqrt{\frac{1}{\rho_3\rho_2}\,p'_{32}(\rho_3-\rho_2)}.$$

They are not equivalent.



η
ξ
$\hat{S}_{2,1}$:
$\xi = \sigma_{2,1} \equiv u_2 + \sqrt{\frac{\rho_1}{\rho_2}}\, p'_{21} = u_1 + \sqrt{\frac{\rho_2}{\rho_1}}\, p'_{12}$
$v_2 = v_1$
$p = A\rho^r$ or $\frac{p_2}{p_1} = \frac{(\gamma+1)\rho_2 - (\gamma-1)\rho_1}{(\gamma+1)\rho_1 - (\gamma-1)\rho_2} > 0$
$\rho_2 > \rho_1$
$\hat{S}_{4,1}$:
$\eta = \sigma_{4,1} = v_4 + \sqrt{\frac{\rho_1}{\rho_4}}\, p'_{14}$
$u_1 = u_4$
$p = A\rho^r$ or $\frac{p_1}{p_4} = \frac{(\gamma+1)\rho_1 - (\gamma-1)\rho_4}{(\gamma+1)\rho_4 - (\gamma-1)\rho_1} > 0$
$\rho_4 > \rho_1$
$\hat{S}_{3,2}$:
$\eta = \sigma_{3,2} = v_3 + \sqrt{\frac{\rho_2}{\rho_3}}\, p'_{32} = u_2 + \sqrt{\frac{\rho_3}{\rho_2}}\, p'_{32}$
$u_3 = u_2$
$p = A\rho^r$ or $\frac{p_3}{p_2} = \frac{(\gamma+1)\rho_3 - (\gamma-1)\rho_2}{(\gamma+1)\rho_2 - (\gamma-1)\rho_3} > 0$
$\rho_3 > \rho_2$
$\hat{S}_{3,4}$:
$\xi = \sigma_{3,4} = u_3 + \sqrt{\frac{\rho_4}{\rho_3}}\, p'_{34} = u_4 + \sqrt{\frac{\rho_3}{\rho_4}}\, p'_{34}$
$v_3 = v_4$
$p = A\rho^r$ or $\frac{p_3}{p_4} = \frac{(\gamma+1)\rho_3 - (\gamma-1)\rho_4}{(\gamma+1)\rho_4 - (\gamma-1)\rho_3} > 0$
$\rho_3 > \rho_4$
(1)
(2)
(3)
(4)

FIG. 5.1

We can prove that

$$\sigma_{1,2}<\sigma_{3,4}, \qquad \sigma_{1,4}<\sigma_{2,3}.$$

In fact, it is equivalent to proving that

$$\frac{\rho_1}{\rho_2}p'_{12}<\frac{\rho_4}{\rho_3}p'_{34}, \qquad \frac{\rho_1}{\rho_4}p'_{14}<\frac{\rho_2}{\rho_3}p'_{23}.$$

Making use of the compatibility conditions, we see this is equivalent to proving that

$$\rho_1\rho_3<\rho_2\rho_4.$$

Put

$$\rho_3=x\rho_1, \quad \rho_2=y\rho_1, \quad \rho_4=z\rho_1;$$

then our problem reduces to proving that

$$x<yz$$

under entropy conditions

$$x>\frac{y}{z}>1$$

and compatibility conditions

$$\frac{(x^\gamma-z^\gamma)(x-z)}{xz}=\frac{(y^\gamma-1)(y-1)}{y} \quad \text{(isentropic)}$$

or

$$\frac{(x-z)^2}{xz}\cdot\frac{(\gamma+1)z-(\gamma-1)}{(\gamma+1)z-(\gamma-1)x}=\frac{(y-1)^2}{y}\cdot\frac{(\gamma+1)-(\gamma-1)z}{(\gamma+1)-(\gamma-1)y} \quad \text{(adiabatic)}$$

with

$$(\gamma+1)-(\gamma-1)y>0, \qquad (\gamma+1)-(\gamma-1)z>0.$$

For isentropic flow, put

$$f(x)\equiv(x^\gamma-z^\gamma)(x-z)y-xz(y^\gamma-1)(y-1).$$

It is easy to check that

$$F(z)<0,$$
$$f(yz)=y(y^\gamma-1)(y-1)z^2(z^{\gamma-1}-1)>0,$$
$$f''(x)=\gamma yx^{\gamma-2}[(\gamma+1)x-(\gamma-1)z]>0.$$

So, when $f(x)=0$, we have $x<yz$.

For adiabatic flow, put

$$f(x)\equiv(x-z)^2[(\gamma+1)z-(\gamma-1)]y[(\gamma+1)-(\gamma-1)y]$$
$$-xz[(\gamma+1)z-(\gamma-1)x](y-1)^2[(\gamma+1)-(\gamma-1)z].$$

It is easy to check that

$$f(z)<0,$$
$$f(yz)=yz^2(y-1)^2[(\gamma+1)-(\gamma-1)y](\gamma-1)(z^2-1)>0,$$
$$f''(x)=(\gamma-1)z(y-1)^2[(\gamma+1)-(\gamma-1)z]$$
$$+2[(\gamma+1)z-(\gamma-1)]y[(\gamma+1)-(\gamma-1)y]>0.$$

So, when $f(x)=0$, we have $x<yz$. □

Thus, $\vec{S}_{2,3}(\eta)$ intersects the sonic circle of ③ before it meets other shocks. The same is true for $\vec{S}_{3,4}(\xi)$. $\vec{S}_{2,3}(\eta)$, ③ and $\vec{S}_{3,4}(\xi)$ should stop at the sonic circle of ③ (Fig. 5.2). Across the circle, the flow should be subsonic and the shocks should be

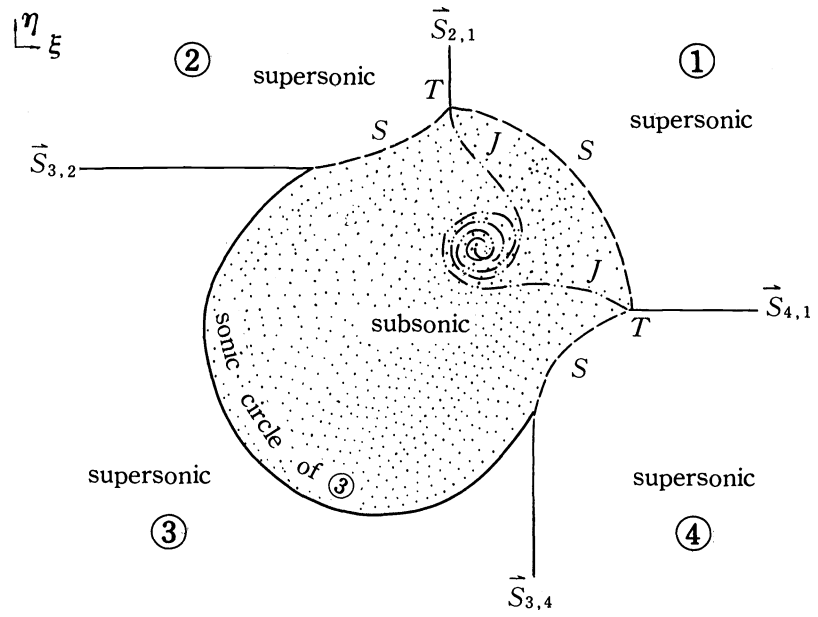


FIG. 5.2

bent to intersect the other two shocks $\vec{S}_{2,1}(\xi)$ and $\vec{S}_{1,4}(\eta)$, respectively. The curved shock with ② on one side must be convex with respect to (u_2, v_2). The intersection points T of shocks should have a triple shock configuration. The shocks from two triple points T will match together smoothly. The flow behind them should be subsonic and, in front of them, supersonic. The slip lines coming from the T's are linear jumps. There are no entropy conditions for slip lines. They should end with spirals in the subsonic flow. The subsonic flow and its free boundary of shocks as well as the triple points should be determined simultaneously.

(2) Two $\vec{S}$'s and two $\tilde{S}$'s (Fig. 5.3). The entropy conditions are

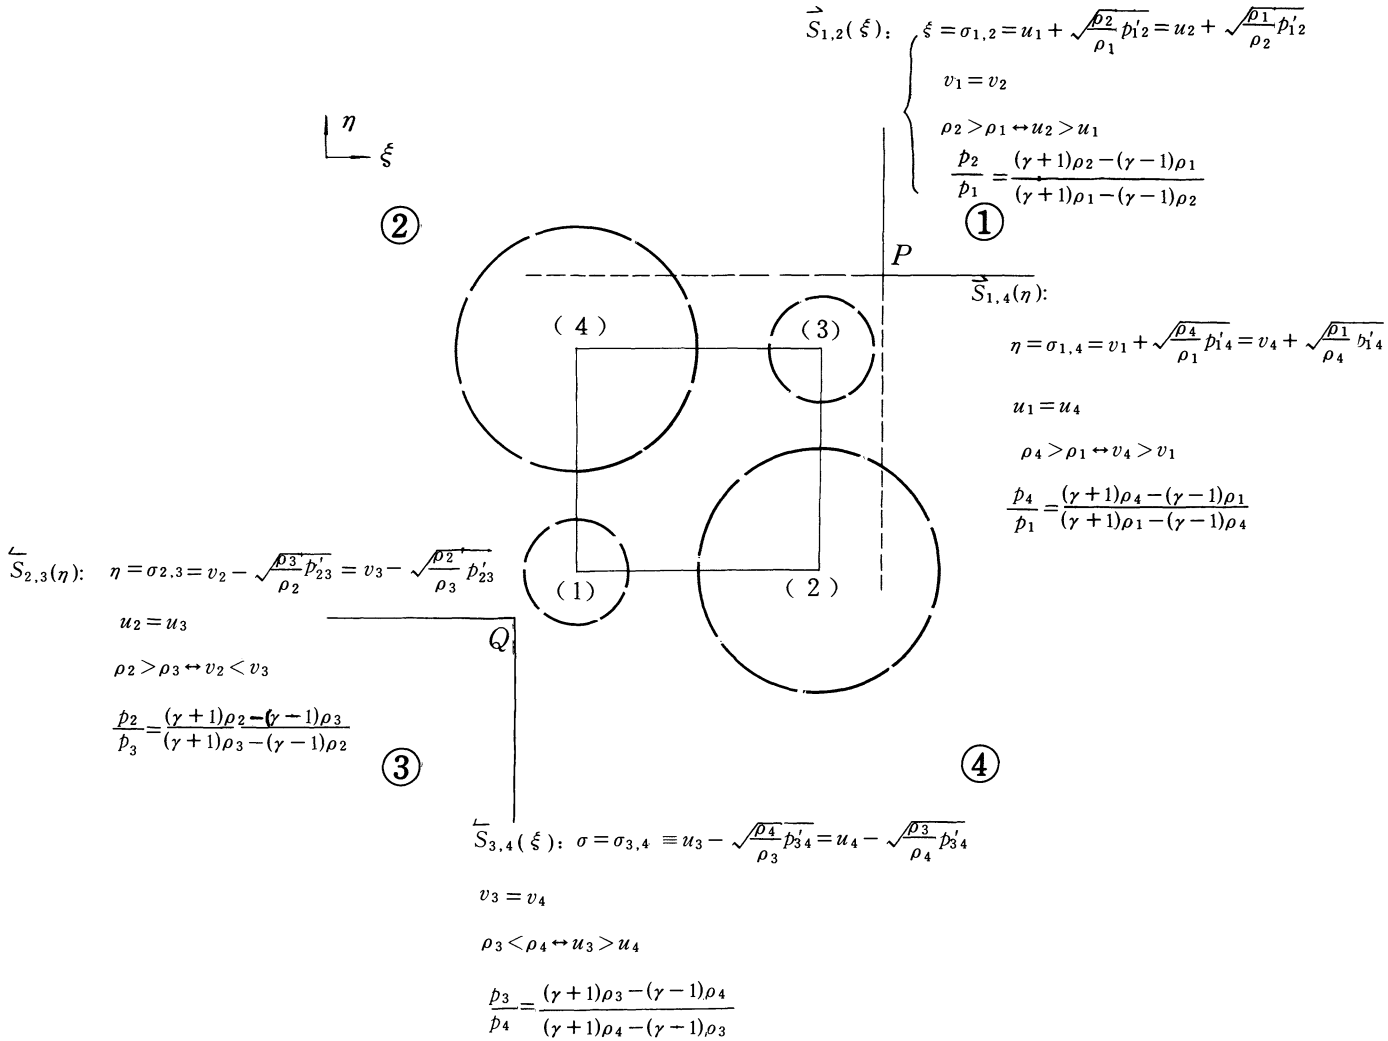
$$\rho_1 \lessgtr \frac{\rho_2}{\rho_4} \gtrless \rho_3.$$

The compatibility conditions are

$$\sqrt{\frac{1}{\rho_1\rho_2}p'_{12}}(\rho_1-\rho_2)=\sqrt{\frac{1}{\rho_3\rho_4}p'_{34}}(\rho_3-\rho_4), \qquad \sqrt{\frac{1}{\rho_2\rho_3}p'_{23}}(\rho_3-\rho_2)=\sqrt{\frac{1}{\rho_1\rho_4}p'_{14}}(\rho_1-\rho_4)$$

from which we know that $\rho_1=\rho_3$, $\rho_2=\rho_4$; then $u_2-u_1=v_3-v_2$ and Fig. 5.3 is symmetric to $\xi+\eta=u_2+v_2$ and $\xi-\eta=u_1-v_1$.

Obviously, $\sigma_{1,2}>\sigma_{3,4}$ and $\sigma_{1,4}>\sigma_{2,3}$, so we consider the intersection point P of $\vec{S}_{1,2}$ and $\vec{S}_{1,4}$. Both ② and ④ may be subsonic, sonic, or supersonic with respect to P. If ② and ④ are subsonic at P, we should go back to their sonic circle, and $\vec{S}_{1,2}$ and $\vec{S}_{1,4}$ should be bent from there. We conjecture the structure of the solution as in Fig. 5.4.



$\overrightarrow{S}_{1,2}(\xi)$: $\xi=\sigma_{1,2}=u_1+\sqrt{\frac{p_2}{\rho_1}}p'_{12}=u_2+\sqrt{\frac{p_1}{\rho_2}}p'_{12}$

FIG. 5.3

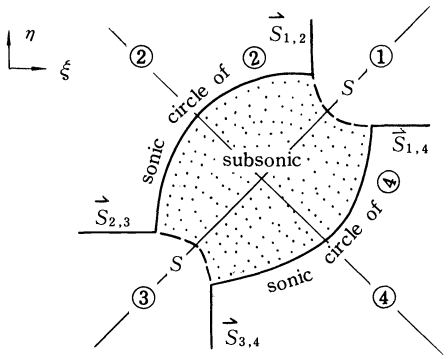

FIG. 5.4

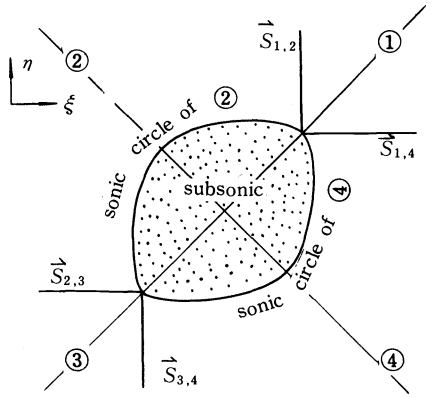

FIG. 5.5

If ② and ④ are sonic at P, the structure of the solution should be as shown in Fig. 5.5.

If ② and ④ are supersonic at P, the problem is just the same as the reflection of an oblique shock in steady flow at P, since the straight line through P and Q is a stream line. But it is not the diffraction of a planar shock around a compressive corner because the two symmetric axes, two stream lines, are perpendicular to each other. By the way, it is easy to prove that ② and ④ are supersonic at P when $1<\gamma\leqq 3$.

There are two possibilities as follows.

In the case of adiabatic flow, if

$$(*)\qquad \sqrt[3]{-\frac{q}{2}+\sqrt{\frac{q^2}{4}+\frac{p^3}{27}}}+\sqrt[3]{-\frac{q}{2}+\sqrt{\frac{q^2}{4}+\frac{p^3}{27}}}\leqq 2,$$

where

$$p=\frac{3ac-b^2}{3a^2}<0,\quad q=\frac{2b^3-9abc+27a^2d}{27a^3}<0,\quad a=\zeta^2>0,$$

$$b=-\zeta\{(3\zeta-2)+(\gamma-1)(\zeta-1)[(\gamma+1)(\zeta-1)+2]\}<0,$$

$$c=-(\zeta-1)[2(\gamma+1)\zeta(\zeta-1)+(\zeta+1)]<0,$$

$$d=-(\zeta-1)^2<0,\qquad \zeta=\rho_2/\rho_1,$$

the structure of the solution is regular reflection [12] (Fig. 5.6).

If the state (denoted by ⑤) behind the reflection shock at P is subsonic or sonic, there is a curved reflection shock that connects the supersonic flow and subsonic flow, otherwise the reflection shock is a straight line until it reaches the sonic circle of constant state ⑤. Then the subsonic flow should be bounded by the sonic circle of ⑤, the curved reflection shock S, as well as the two perpendicular stream lines.

If condition (*) is violated, the structure of the solution should be Mach reflections as shown in Fig. 5.7. There are several subcases: simple Mach reflection if ⑤ is sonic or subsonic; complex Mach reflection if ⑤ is supersonic and the sonic circle of ⑤ intersects with J; and double Mach reflection if ⑤ is supersonic but the sonic circle of ⑤ does not intersect with J. It seems that there is no spiral because of symmetry, but the spiral should appear after perturbation [13]-[15] (Fig. 5.8).

This phenomenon reflects the instability of two-dimensional flow.

$$\rho_3 > \begin{matrix}\rho_2 \\ \rho_4\end{matrix} < \rho_1$$

and

$$\int_{\rho_2}^{\rho_1} \frac{\sqrt{p'}}{\rho}\,d\rho = \int_{\rho_4}^{\rho_3} \frac{\sqrt{p'}}{\rho}\,d\rho, \qquad \sqrt{\frac{1}{\rho_3\rho_2}\,p'_{32}(\rho_3-\rho_2)} = \sqrt{\frac{1}{\rho_1\rho_4}\,p'_{14}(\rho_1-\rho_4)}.$$

The shock $\vec{S}_{2,3}$ must meet the sonic circle of ② first; then it penetrates $\vec{R}_{1,2}$ and goes into ① to intersect $\tilde{S}_{14}$ and forms a triple point. The new shock coming from the triple point continues on to penetrate $\vec{R}_{3,4}$ and enters ③ to intersect $\vec{S}_{2,3}$ and forms another triple point. This triple point on $\vec{S}_{2,3}$ may not be the sonic point we started with, so we modify the structure by starting at a (triple) point that is also the end point of the shock coming from $\tilde{S}_{1,4}$. Therefore we conjecture that the structure of the solution is as shown in Fig. 6.4.

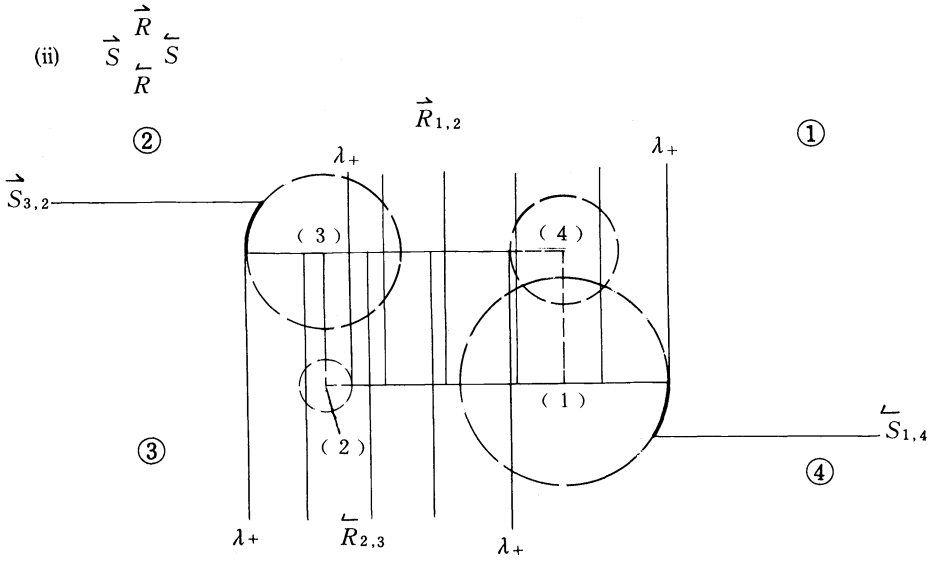

FIG. 6.3

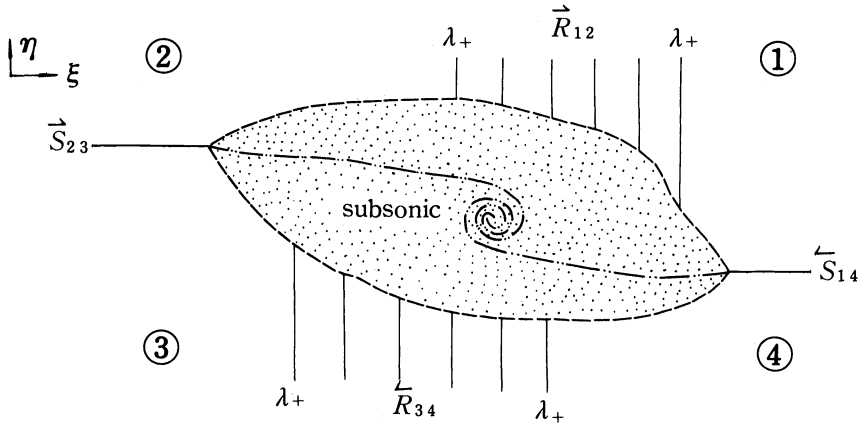

FIG. 6.4

7. The cases involving slip lines.

(1) Four J's. There are only two subcases (Fig. 7.1). For both we have

$$u_1 = u_2, \quad u_3 = u_4, \quad v_2 = v_3, \quad v_4 = v_1,$$

$$\rho_1 = \rho_2 = \rho_3 = \rho_4 \quad \text{(isentropic)} \quad \text{or} \quad p_1 = p_2 = p_3 = p_3 \quad \text{(adiabatic)}.$$

In the first subcase (Fig. 7.2), J_{41}, ④, and J_{34} should stop at the sonic circle of ④. It is easy to see that the slip line having constant state ③ at one side must be a straight line through point (3). So J_{34} cannot be bent to be a boundary between ③ and a subsonic flow. We conjecture that there is a free boundary of shock that starts tangentially to the λ-characteristic at the intersection point of $J_{3,4}$ and the sonic circle

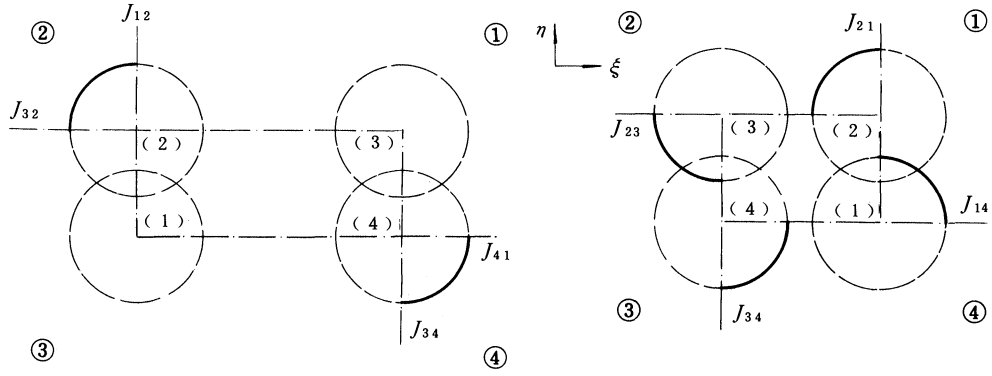

FIG. 7.1

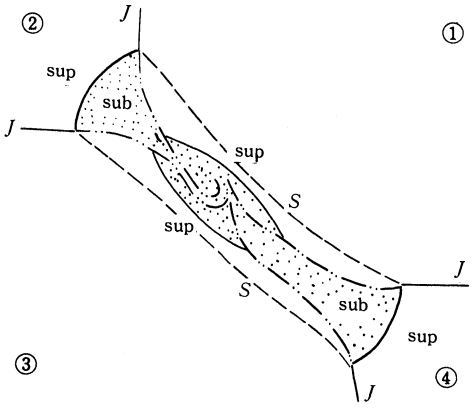

FIG. 7.2

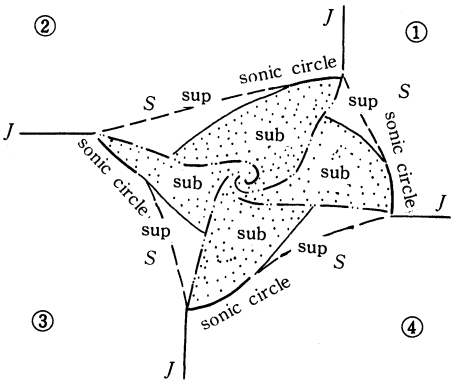

FIG. 7.3

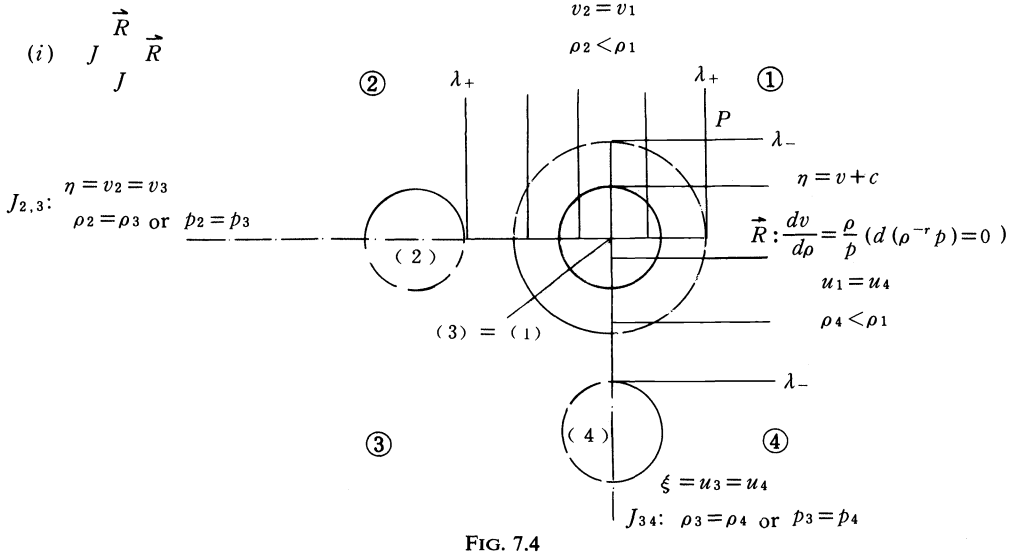

FIG. 7.4

of ④ and ends tangentially to the λ_+ characteristic at the intersection point of $J_{3,2}$ and the sonic circle of ②. This shock wave connects ③ to a nonconstant supersonic flow, which becomes subsonic in the central region gradually by itself or through the slip lines. The structure is similar in the upper right region. The slip lines end with spirals in the subsonic region.

In the second subcase, as the undetermined shocks should be out of their corresponding sonic circles and end tangentially at the circles, we conjecture that the solution is as shown in Fig. 7.3.

(2) Two J's.

(a) Two J's are neighbors.

(i) $J_J^{\vec{R}}\vec{R}$ (Fig. 7.4). Figure 7.4 is symmetric to $\xi-\eta=u_1-v_1$. It is a combination of Figs. 4.4 and 7.1. Our conjecture of the solution is shown in Fig. 7.5.

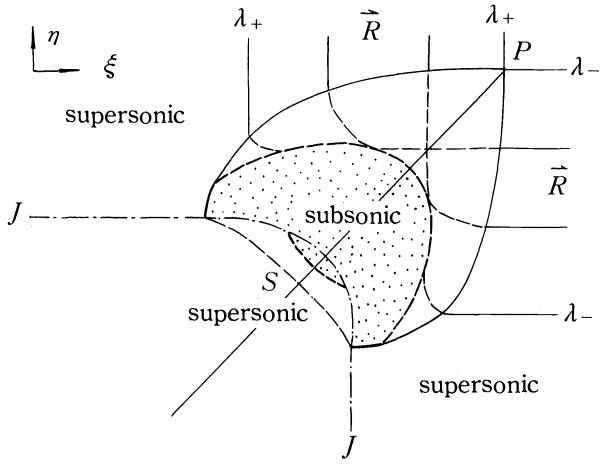

FIG. 7.5

(ii) $J_J^{\tilde{R}}\tilde{R}$ (Fig. 7.6). Figure 7.6 is symmetric to $\xi-\eta=u_1-v_1$. We have $\rho_1<\rho_2=\rho_3=\rho_4$, $(u_1, v_1)=(u_3, v_3)$. Solve $\tilde{R}_{12}$, ①, and $\tilde{R}_{14}$ to $\lambda_\mp$ through $p_\mp$, ① to $\widehat{Q_-Q_+}$. These curves and undetermined shock $\widehat{P_-P_+}$ bound a domain inside which there is a subsonic domain as shown in Fig. 7.7.

(iii) $J_J^{\vec{S}}\vec{S}$ (Fig. 7.8). We have $\rho_1=\rho_2=\rho_4>\rho_3$. Figure 7.8 is symmetric to $\xi-\eta=u_1-v_1$, and it is a combination of the upper right part of Fig. 5.3 and the lower left part of the first part of Fig. 7.1. The solutions are combinations of parts of Figs. 5.4–5.7 and 7.2.

(iv) $J_J^{\tilde{S}}\tilde{S}$ (Fig. 7.9). We have $\rho_1>\rho_2=\rho_3=\rho_4$. It is a combination of parts of Figs. 5.1 and 7.1. The solution is a combination of parts of Figs. 5.2 and 7.2.

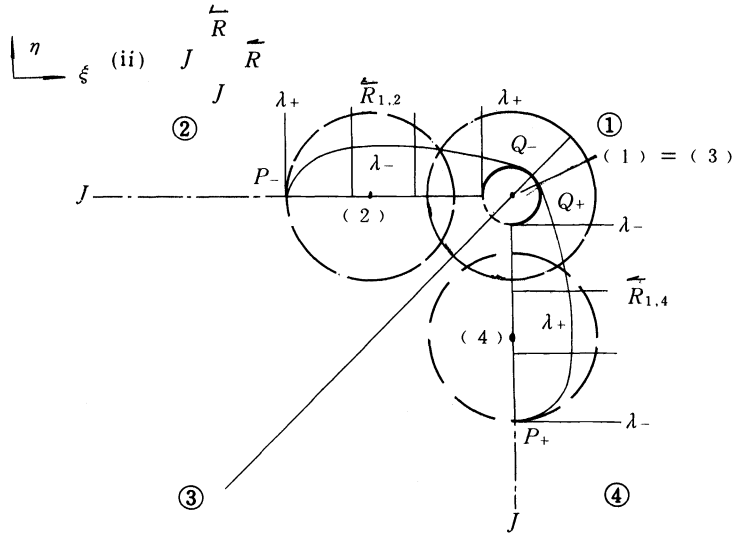

FIG. 7.6

(v) $J^{\vec{R}}_{J}\tilde{S}$ (Fig. 7.10). We have $\rho_2=\rho_3=\rho_4<\rho_1$ and $(u_1, v_1)=(u_3, v_3)$. It is a combination of parts of Figs. 6.1 and 7.1. The solution is a combination of parts of Figs. 6.2 and 7.2 (Fig. 7.11).

(vi) $J^{\vec{S}}_{J}\tilde{R}$ (Fig. 7.12). We have $\rho_1<\rho_2=\rho_3=\rho_4$. It is a combination of parts of Figs. 6.3 and 7.1. The solution (Fig. 7.13) is a combination of parts of Figs. 6.4 and 7.2.

(b) Two J's are not neighbors.

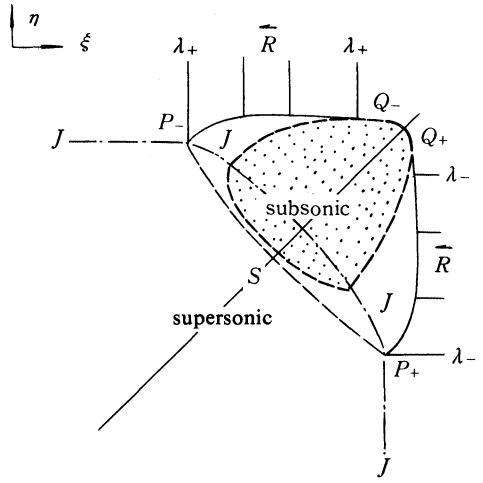

FIG. 7.7

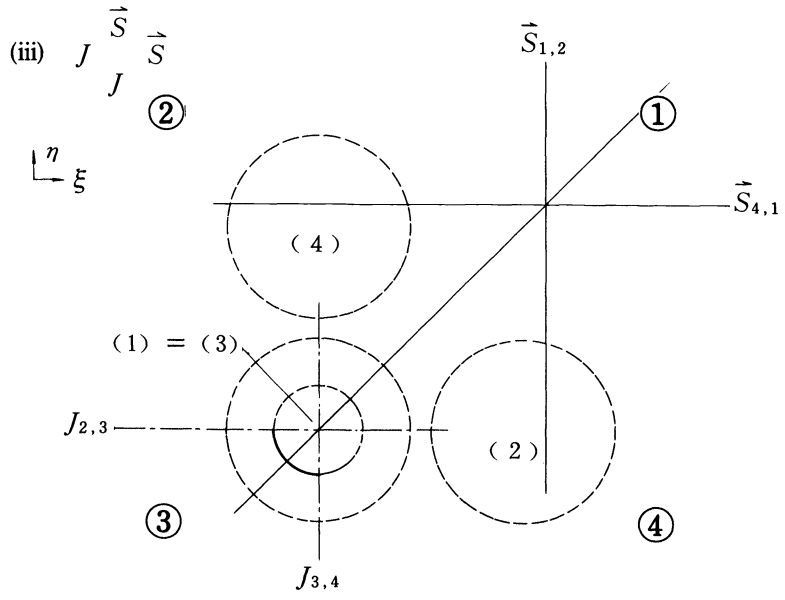

FIG. 7.8

(i) $\vec{R}\overset{J}{J}\vec{R}$ (Fig. 7.14). Cut the $\vec{R}$ along the sonic stem into two parts, then slip them up or down. ① should stop at point P. A shock should start from P continuously at the side of ② and be tangent to the λ_- characteristic there. The shock should be convex with respect to point (2), so it will go into $\vec{R}_{23}$ and then penetrate $\vec{R}_{23}$ into ③; then it will be tangent to the sonic circle of ③ and will vanish there continuously (Fig. 7.15). Analogously, ③ should stop at point Q. A shock should start from Q continuously

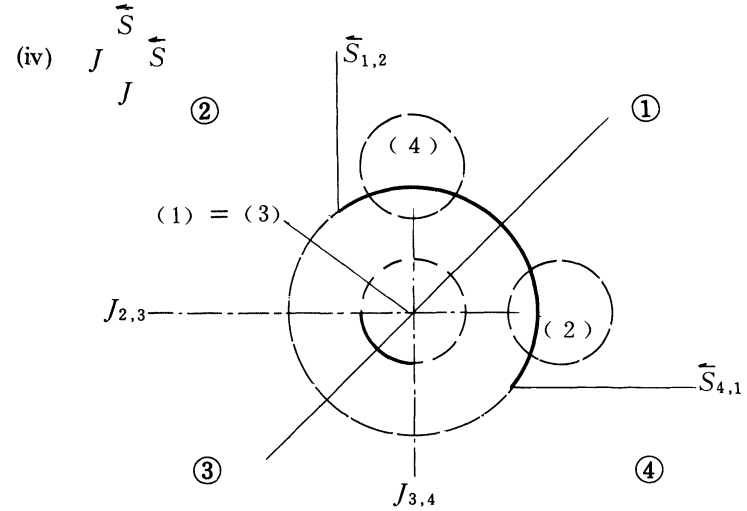

FIG. 7.9

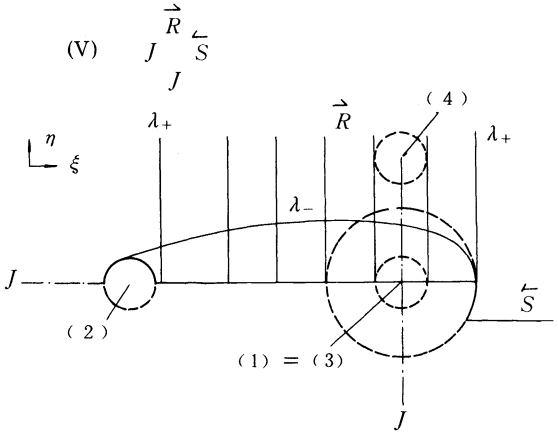

FIG. 7.10

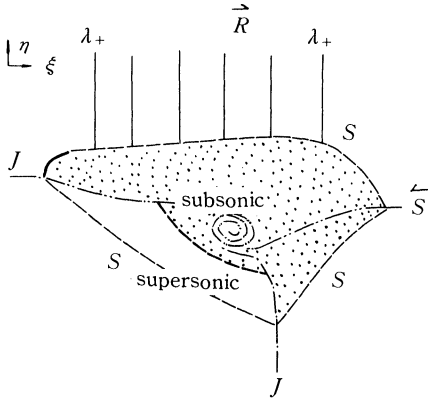

FIG. 7.11

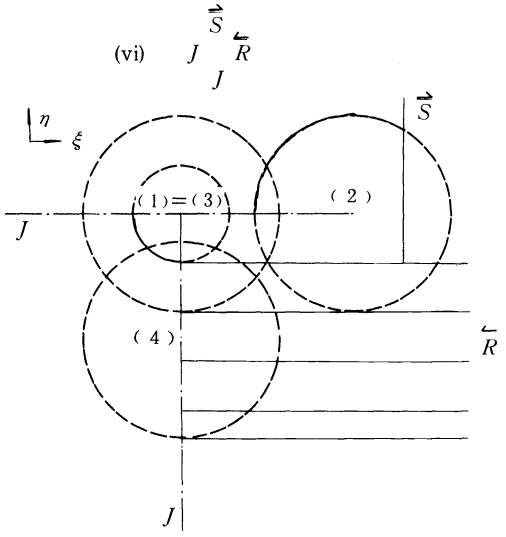

FIG. 7.12

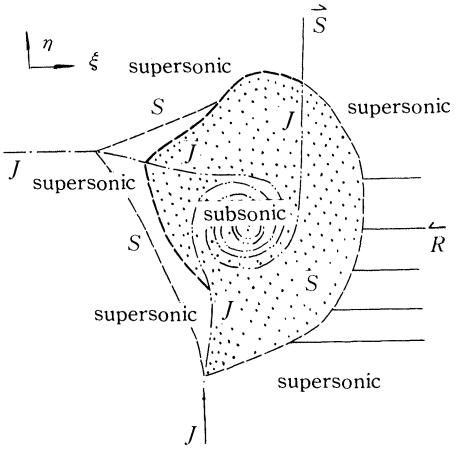

FIG. 7.13

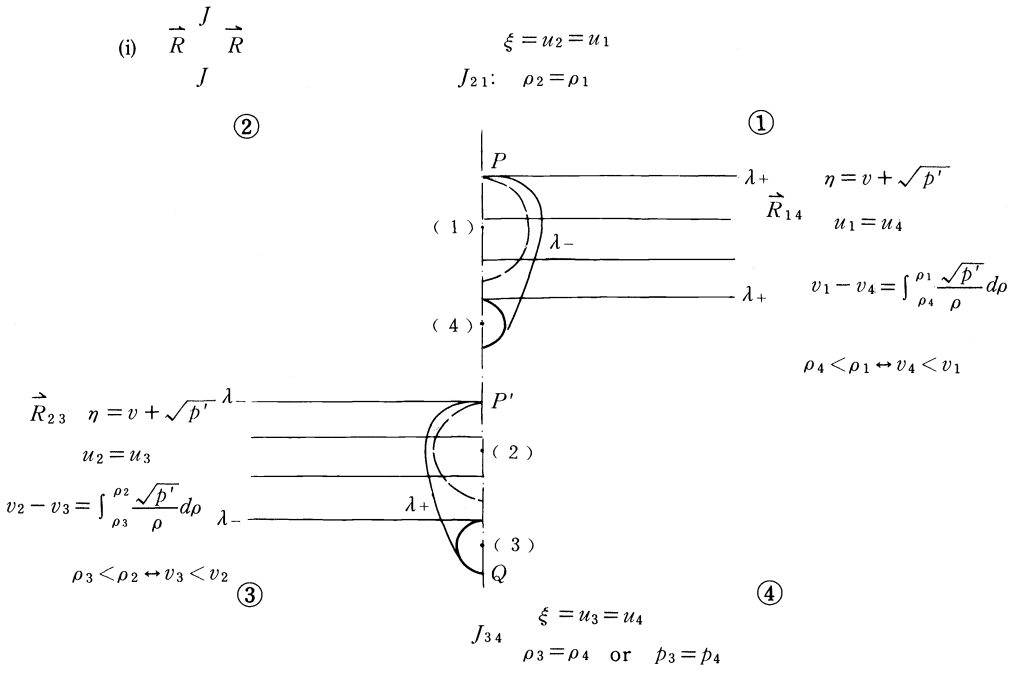

FIG. 7.14

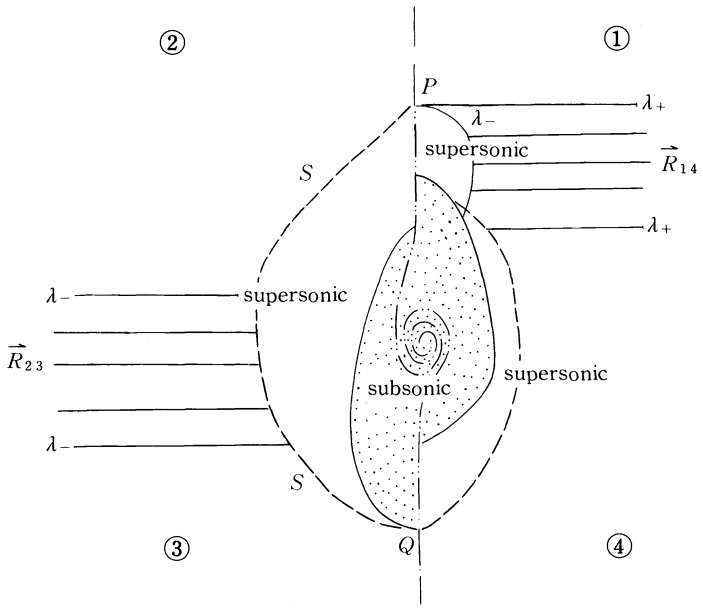

FIG. 7.15

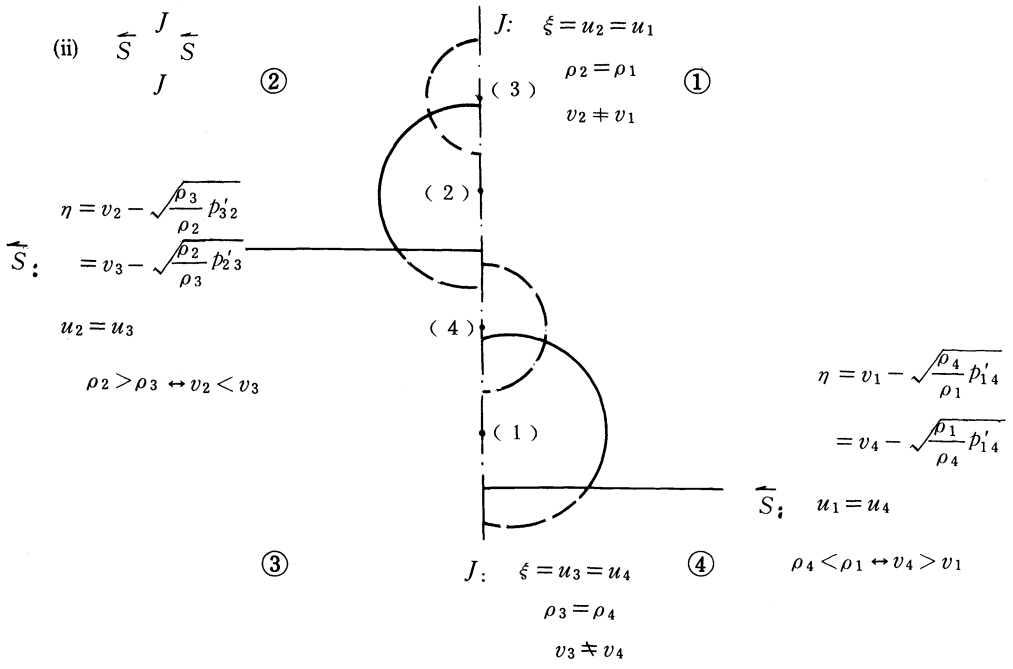

FIG. 7.16

at the side of ④ and be tangent to the λ_+ characteristic there. The shock should be convex with respect to point (4), be tangent to the sonic curve somewhere, and vanish there continuously. There is a subsonic region inside these two shocks and the J's end with spirals in this region (Fig. 7.15).

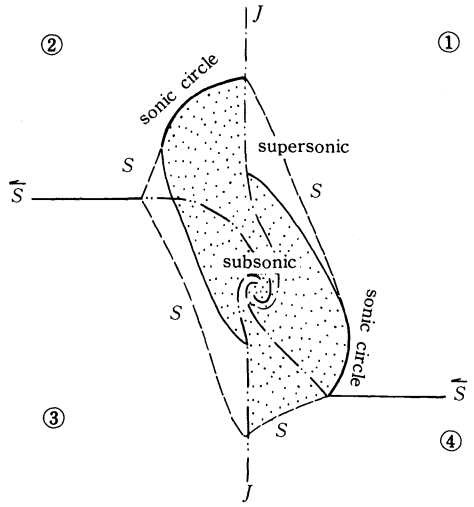

FIG. 7.17

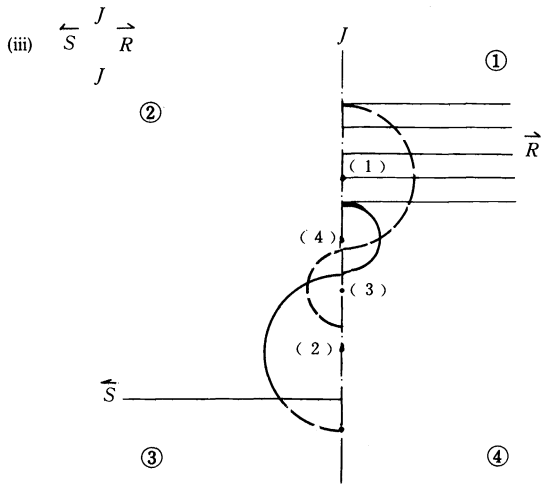

FIG. 7.18

(ii) $\tilde{S}\overset{J}{}_{J}\tilde{S}$ (Fig. 7.16). Divide $\tilde{S}$ along the vertical stream line into two parts, then slip them apart (Fig. 7.16).

We conjecture that the solution is as shown in Fig. 7.17.

(iii) $\tilde{S}\overset{J}{}_{J}\vec{R}$ (Fig. 7.18). Take a half of (i) and half of (ii), and piece them together along the slip line (Fig. 7.18).

We conjecture that the solution is as shown in Fig. 7.19.

ON THE ENSKOG EQUATION WITH LARGE INITIAL DATA*

LEIF ARKERYD†

Abstract. This paper is concerned with the Enskog equation with large initial data in L^1, where the high density factor is constant. As a preliminary step, existence and uniqueness is first studied in full physical space and in a box with periodic boundary conditions under the restriction of bounded velocities, by the use of a priori estimates in the norm $\int (\sup_{0\le t\le T} f(x+tv, v, t)|)\, dx\, dv$. Global existence and uniqueness for small data and unbounded velocities is an easy consequence of this step. The rest of the paper is devoted to the central topic: global existence, regularity, and uniqueness for large initial data in full physical space for the case of unbounded velocities, provided all v-moments are initially finite. Here the more detailed structure of the collision operator is exploited in the a priori estimates.

Key words. Enskog equation, global results, well-posedness, regularity

AMS(MOS) subject classification. 76P05

1. Introduction. The Enskog equation [8] is a quite successful model of transport phenomena in moderately dense gases [9]. This paper studies the initial value problem for the Enskog equation with large L^1 initial data. Previous large data results include global existence in L^1 for one space dimension [5] and two space dimensions [1]. Existence in arbitrary dimension for small data was also obtained in [6], and for large data in [2], [7], and [10]. The averaging argument used there gives no information about, e.g., uniqueness or regularity. The present paper, on the other hand, uses a contraction mapping suitable for extracting detailed information about the solutions.

Let v', v'_* be the velocities after collision of two molecules having precollisional velocities v, v_*, and with v', v'_* also depending on the directional variable u belonging to the unit sphere ∂B. In a suitable coordinate system the Enskog collision operator can be written

$$Q(f,f) = \sigma^2 \int_{\partial B\times R^3} (f'f'_*\chi^- - ff_*\chi^+) S(v, v_*, u)\, dv_*\, du,$$

with

$$(v-v_*, u)_+ = S(v, v_*, u) = \max(0, (v-v_*, u)).$$

The arguments of f', f'_*, f, f_* are (x, v'), $(x-\sigma u, v'_*)$, (x, v), and $(x+\sigma u, v_*)$, where $v' = v - u(v-v_*, u)$ and $v'_* = v_* + u(v-v_*, u)$. The Enskog equation, depending on the variables $(x, v, t) \in R^3\times R^3\times R_+$, is

$$\frac{\partial}{\partial t} f + v\cdot \nabla_x f = Q(f,f). \tag{1.1}$$

The high-density factors $\chi^\pm$ in the original Enskog paper [8] are functions of the local density $\int f(\cdot, v, \cdot)\, dv$ at $(x\pm\sigma u/2, t)$. A later modification that formally satisfies some entropy bound takes $\chi^\pm$ as a function of the local density at (x, t) and $(x\pm\sigma u, t)$. The present paper considers only the simplified case of $\chi^\pm$ = constant, commonly known as the Enskog–Boltzmann equation, and for which a strict proof of an H-theorem is known ([7]; see also (1.4) below). The extension to the case of a variable high-density

factor must await a strict proof of an H-theorem in that case. For further information on the various forms of the Enskog equation as well as an extensive bibliography, see [3].

This paper starts with a study of existence and uniqueness in the case of bounded velocities by contraction mappings and by conservation properties. For this, mass and moments of second order are assumed to exist initially. The symmetry properties of the collision operator then imply that these quantities are bounded on any bounded time interval. This can be used to control the higher moments of interest in estimates of the type

$$\|f\| \leqq c\|f\| + \delta.$$

Here $0 < c < 1$, and the smallness of δ is controlled independently of the velocity bounds. From such estimates, a priori bounds and local convergence of the approximations with respect to the $\|\cdot\|$-norm are obtained in the unbounded velocity case. Certain uniformity features of the estimates, together with entropy estimates in the unbounded case, lead to the global results. The following regularity discussion depends on similar estimates and bases its control of the moments of the derivatives on the control of the moments of f.

The plan of the paper is as follows. The Introduction continues with a description of the problem. Section 2 is a preliminary study of the case of bounded velocities. Global small-data existence and uniqueness for unbounded velocities is a simple consequence. Section 3 contains some useful estimates independent of the velocity cutoffs. In § 4 the global existence and uniqueness theorem for unbounded velocities is proved. Finally, the regularity properties of those solutions are studied in § 5.

Denote by L_r the space of measurable functions f on $\Omega = R^3 \times R^3$ with $(1 + |v|^r) f(x, v) \in L^1(\Omega)$. Set $|v|_M = \max(|v|, 1)$. The norm $\int_{R^3} |v|_M^r |f(x, v)|\, dx\, dv$ is written $\|\cdot\|_r$, and the positive cone in L_r is L_r^+. Let $L_{r,T}$ be the space of measurable functions on $\Omega \times [0, T]$ with

$$\operatorname*{ess\,sup}_{0 \leqq t \leqq T} |f(x + vt, v, t)| \in L_r,$$

and denote the $\|\cdot\|_r$-norm of this ess sup by $\|\cdot\|_{r,T}$. The use of such norms was introduced into nonlinear kinetic theory by Toscani in a discrete velocity setting [11].

Consider (1.1) for $t > 0$ and regard the left-hand side as a directional derivative $D_t f^{\#}$ along $f^{\#}(x, v, t) = f(x + vt, v, t)$. Take $f_0 = f(0+)$ as initial condition with $f_0 \in L_r^+$ for all $r \in R$. The aim of the paper is to study (1.1) with such initial conditions globally in time also for large f_0.

Starting with the Caflisch paper [4], the different influences of the low and high velocities on the evolution have sometimes been analysed by a corresponding splitting of the density function. Here we will use one such splitting well adapted to the present problem and similar ones in kinetic theory. For that purpose set

$$f_{i0}(x, v) = \min(f_0(x, v), w) \quad \text{for } |x|^2 \leqq w^2, \quad |v|^2 \leqq w^2,$$

and set $f_{i0}(x, v) = 0$ otherwise. Introduce

$$f_i^{\#}(x, v, t) = f_{i0}(x, v), \quad f_e = f - f_i, \quad f_{e0} = f_0 - f_{i0},$$

and $\mathcal{B}^{\#}$ as w times the characteristic function of $\operatorname{supp} f_{i0}$. The equation for f_e is

$$D_t f_e^{\#} = Q(f_i + f_e, f_i + f_e)^{\#}, \qquad t > 0,$$

with initial condition $f_e(0+) = f_{e0}$. Throughout the paper C denotes various constants.

The proofs will use the energy bound

$$\int v^2 f(x, v, t)\, dx\, dv \leqq \int v^2 f_0(x, v)\, dx\, dv, \tag{1.2}$$

a bound of the second x-moment due to J. Polewczak [10]:

$$\int (x - tv)^2 f(x, v, t)\, dx\, dv \leqq \int x^2 f_0(x, v)\, dx\, dv, \tag{1.3}$$

and an entropy bound due to Cercignani [7]:

$$\begin{aligned} &\int f(x, v, t) \log f(x, v, t)\, dx\, dv \\ &\quad \leqq \int f_0(x, v) \log f_0(x, v)\, dx\, dv + \frac{1}{2}\left(\int f_0(x, v)\, dx\, dv\right)^2. \end{aligned} \tag{1.4}$$

(I am grateful to C. Cercignani for giving me access to this result before its publication.) The proofs of (1.2)-(1.4) hold in a formal sense for solutions of (1.1) provided that

$$(1 + v^2 + x^2) f_0, \qquad f_0 \log f_0 \in L^1.$$

Estimates (1.2) and (1.3) can be carried out strictly on various approximations of (1.1) and follow in that way in the limit for the solutions of (1.1) to be constructed below in this paper. The case of (1.4) is treated in the proof of Theorem 4.1. By straightforward computation (1.2)-(1.4) imply

$$\int x^2 f(x, v, t)\, dx\, dv \leqq 2 \int x^2 f_0(x, v)\, dx\, dv + 4t^2 \int v^2 f_0\, dx\, dv, \tag{1.5}$$

$$\begin{aligned} &\int_{f > w} f(x, v, t)\, dx\, dv \\ &\quad \leqq (\log w)^{-1}\left(\int f_0(x, v) \log f_0(x, v)\, dx\, dv + \frac{1}{2}\left(\int f_0(x, v)\, dx\, dv\right)^2\right. \\ &\qquad + (4t^2 + 1) \int v^2 f_0(x, v)\, dx\, dv + \int \exp(-v^2 - x^2)\, dx\, dv \\ &\qquad \left. + 2 \int x^2 f_0(x, v)\, dx\, dv\right). \end{aligned} \tag{1.6}$$

2. Existence and uniqueness in the case of bounded velocities. This section contains a preliminary analysis of the Enskog equation for bounded velocities, i.e., with the collision operator

$$Q^j(f, g) = \sigma^2 \int_{R^3} \int_{\partial B} (f' f'_* - f f_*) W_j S\, dv_*\, du,$$

where $W_j = 1$ if $v^2 + v_*^2 \leqq 2^{2j}$, and $W_j = 0$ otherwise. The relevant Enskog equation in integral form is $A^j f = f$, where

$$(A^j f)^{\#} = f_0 + \int_0^t Q^j(f, f)^{\#}(s)\, ds.$$

In view of § 4, consider for a fixed (large) time interval $[0, T_1]$ in the case where $2^j > 2w$, w being such that the right-hand side in (1.6) with $t = T_1$ is bounded from above by $(512)^{-1}$. That implies

$$\int_{|v|>w} |v| f_0(x, v)\, dx\, dv < 256^{-1}, \qquad \|f_{e0}\|_1 < 128^{-1}. \tag{2.1}$$

(The powers of $\frac{1}{2}$ introduced here and below are chosen for convenience instead of the usual cumbersome statements of the type "there is a small enough constant independent of... such that the following estimate holds," where... usually stands for a couple of lines describing what particular variables and expressions the constant should be independent of.)

Denote by $\mathcal{M}(\delta)$ the set of all measurable subsets $M \subset R^6$ such that for almost every $v \in R^3$ the set M_v of those x for which $(x, v) \in M$ has measure less than δ. Define

$$\mathcal{S}(\delta, F) = \sup_{\mathcal{M}(\delta)} \int_M |F(x, v)|\, dx\, dv.$$

Integrals of the following type will appear in the estimates of the collision operator:

$$\int_0^T ds \int_{R^3} \int_{\partial B} F(y + s(v - v_*) + \sigma u, v_*)(v - v_*, u)_+ \sigma^2 W_j\, dv_*\, du. \tag{2.2}$$

Since the Jacobian of the change of variables $\sigma^2(v - v_*, u)_+\, ds\, du \to dx$ equals 1, they can be bounded by $\mathcal{S}(\delta, F)$ for $\delta = T 2^{j+1} \pi \sigma^2$.

An estimate concerning the function f_i of § 1 will be needed.

LEMMA 2.1.

$$\sigma^2 \int_0^T ds \int |v|_M^r f_i^{\#}(x, v, s) f_i^{\#}(x + s(v - v_*) + \sigma u, v_*, s) S\, dx\, dv\, dv_*\, du$$

$$\leqq \mathcal{S}(2w\pi\sigma^2 T, f_{i0}) \|f_{i0}\|_r.$$

Proof. Use (2.2) and note that $|v - v_*| \leqq 2w$ on the support of the integrand.

LEMMA 2.2. *If $g \in L^+_{r,T}$ and $T > 0$, then*

$$\sigma^2 \int_0^T ds \int |v|_M^r g^{\#}(x, v, s) g^{\#}(x + s(v - v_*) + \sigma u, v_*, s) S\, dx\, dv\, dv_*\, du \leqq \|g\|_{r,T} \|g\|_{0,T}.$$

Proof. The proof follows from

$$\int dv_* \int \sigma^2\, du \int_0^T ds\, g^{\#}(x + s(v - v_*) + \sigma u, v_*, s) S \leqq \|g\|_{0,T}.$$

THEOREM 2.3. *Suppose $f_0(1 + v^2 + x^2) \in L^+_0$, $f_0 \log f_0 \in L_0$. Then, locally in time, the equation $A^j f = f$ has a unique solution $f^j \in L^+_0$ that conserves mass, first v-moments, and energy, and satisfies* (1.3).

Proof. The following approximations will be shown to converge to a solution of $A^j f = f$ on some open neighborhood of $t = 0$. With $f_0 = 0$ and

$$L_j f_n(t) = \sigma^2 \int_0^t ds \int f_n(x + vs + \sigma u, v_*, s)\, W_j S\, dv_*\, du,$$

define inductively for $n \in N$:

$$f_{n+1}^{\#}(t) = f_0 \exp(-L_j f_n(t)) + \int_0^t ds \exp(-L_j f_n(t) + L_j f_n(s))$$

(2.3)

$$\times \int (f'_n f'_{n*})^{\#}(s) \sigma^2 W_j S \, dv_* \, du.$$

Then

$$f_{n+1}^{\#}(t) = f_0 + \int_0^t ds \int (f'_n f'_{n*} - f_{n+1} f_{n*})^{\#}(s) \sigma^2 W_j S \, dv_* \, du.$$

In particular, the perturbation

$$_e f_{n+1}^{\#} = f_{n+1}^{\#} - f_i^{\#}$$

satisfies

$$_e f_{n+1}^{\#}(t) = f_{e0} + \int_0^t ds \int (f'_i f'_{i*} + f'_{ie} f'_{n*} + {}_e f'_n f'_{i*} + {}_e f'_{ne} f'_{n*}$$

$$- f_i f_{i*} - f_{ie} f_{n*} - {}_e f_{n+1} f_{i*} - {}_e f_{n+1} {}_e f_{n*})^{\#}(s) \sigma^2 W_j S \, dv_* \, du = f_{e0} + \mathcal{I}_1 + \cdots + \mathcal{I}_8.$$

Here $\mathcal{I}_1, \cdots, \mathcal{I}_8$ are the eight terms of the collision operator in the given order. This expression gives an $\|\cdot\|_{0,T}$-estimate for f_{n+1}.

By Lemma 2.1 the integral of $|\mathcal{I}_1| + |\mathcal{I}_5|$ is bounded from above by $2\mathcal{S}(2w\pi\sigma^2 T, f_{i0}) \|f_{i0}\|_0$.

The corresponding integral of $|\mathcal{I}_4| + |\mathcal{I}_8|$ is, by Lemma 2.2, bounded by

$$\|_e f_n\|_{0,T} (\|_e f_n\|_{0,T} + \|_e f_{n+1}\|_{0,T}). \tag{2.4}$$

After a change of variables in $\int |\mathcal{I}_2|$, $\int |\mathcal{I}_3|$, each of the integrals of $|\mathcal{I}_2|$, $|\mathcal{I}_3|$, $|\mathcal{I}_6|$ can be bounded by

$$\int_0^T ds \int f_i(x + vs, v, s) |_e f_n(x + vs + \sigma u, v_*, s)| \sigma^2 W_j S \, dv \, dv_* \, dx \, du.$$

As in the proof of Lemma 2.1, this in turn is bounded by

$$\mathcal{S}(2^{j+1} \pi \sigma^2 T, f_{i0}) \|_e f_n\|_{0,T}.$$

In the same way the integral of $|\mathcal{I}_7|$ is bounded by

$$\mathcal{S}(2^{j+1} \pi \sigma^2 T, f_{i0}) \|_e f_{n+1}\|_{0,T}.$$

It follows that

$$\begin{aligned} \|_e f_{n+1}\|_{0,T} \leqq{} & \|f_{e0}\|_0 + 2\mathcal{S}(2w\pi\sigma^2 T, f_{i0}) \|f_{i0}\|_0 \\ & + (\|_e f_n\|_{0,T} + \|_e f_{n+1}\|_{0,T} + 3\mathcal{S}(2^{j+1} \pi \sigma^2 T, f_{i0})) \|_e f_n\|_{0,T} \\ & + \mathcal{S}(2^{j+1} \pi \sigma^2 T, f_{i0}) \|_e f_{n+1}\|_{0,T}. \end{aligned}$$

Choose T so that $\mathcal{S}(2^{j+1} \pi \sigma^2 T, \mathcal{B}) < 16^{-1}$, and $2\mathcal{S}(2w\pi\sigma^2 T, \mathcal{B}) \|\mathcal{B}\|_0 < 128^{-1}$. It follows that $\|_e f_n\|_{0,T} \leqq 16^{-1}$ for $n \in N$. Moreover, for the same value of T,

$$\begin{aligned} \|_e f_{n+1} - {}_e f_{m+1}\|_{0,T} \leqq{} & 3\mathcal{S}(2^{j+1} \pi \sigma^2 T, f_{i0}) \|_e f_n - {}_e f_m\|_{0,T} \\ & + \mathcal{S}(2^{j+1} \pi \sigma^2 T, f_{i0}) \|_e f_{n+1} - {}_e f_{m+1}\|_{0,T} \\ & + (\|_e f_n\|_{0,T} + \|_e f_m\|_{0,T} + \|_e f_{m+1}\|_{0,T}) \|_e f_n - {}_e f_m\|_{0,T} \\ & + \|_e f_n\|_{0,T} \|_e f_{n+1} - {}_e f_{m+1}\|_{0,T} \\ \leqq{} & 8^{-1} \|_e f_{n+1} - {}_e f_{m+1}\|_{0,T} + \tfrac{3}{8} \|_e f_n - {}_e f_m\|_{0,T}. \end{aligned}$$

Hence $({}_e f_n)_0^\infty$ is Cauchy in the $\|\cdot\|_{0,T}$-norm. Denote the limit by f_e^j. It follows that the equation $A^j f = f$ has a unique, nonnegative solution $f^j = f_i + f_e^j$ on $[0, T]$ with the $\|\cdot\|_{0,T}$-norm bounded. The time-integrated gain and loss terms

$$\int_0^T ds \int f^{j\prime} f_*^{j\prime} \sigma^2 W_j S \, dv_* \, du, \qquad \int_0^T ds \int f^j f_*^j \sigma^2 W_j S \, dv_* \, du$$

each belong to L_0, so on $[0, T]$ it follows that the usual change of variable proof can be applied to prove that the mass, v-moments, and energy of f_0 are conserved by f^j, and that (1.3) holds.

Remark. (i) In fact, the proof does not require $v^2 f_0 \in L^1$.

(ii) The proof implies stability. If $(f_{0k})_N$ converges to f_0 in L^1, and if $(\int x^2 f_{0k} \, dx \, dv)_N$ is uniformly bounded, then $(f_k^j(\cdot, t))_N$ converges to $f^j(\cdot, t)$ in L^1 on $[0, T]$.

(iii) The theorem holds with the same proof for a periodic x-domain, and for both types of domain for the symmetrized Enskog equation. (The symmetrized equation uses the whole ∂B as a u-domain in Q and the same v', v_*' for $\pm u$ together with $S(v, v_*, u) = |(v - v_*, u)|$.) Just as in the Boltzmann equation, the H-function $\int f^j(x, v, t) \log f^j(x, v, t) \, dx \, dv$ is nonincreasing for the symmetrized Enskog equation, which in turn implies existence for all $t > 0$.

(iv) If $\|f_0\|_0$ is small enough (e.g., less than 128^{-1}), then a shortened version of the proof above, using only the term (2.4) and the physical space R^3, shows that the full Enskog equation (1.1) without velocity cutoff has a global, unique solution conserving mass and v-moments, and having nonincreasing energy.

3. Bounds for the moments of the collision term. Let f_i (depending on f_0) be as defined in § 1.

LEMMA 3.1. *Suppose that* $w 2^{-k} \leqq \delta \ll \eta \ll 1$, *and that* $g \in L_{r,T}^+$. *Then the following estimate holds*:

$$\sigma^2 \int_0^T dt \int_{|v| \geqq 2^{k+1}} dv |v|_M^r \int (f_i' g_*' + g' f_{i*}')^{\#} S \, dv_* \, du \, dx$$
$$\leqq C\{(1-\delta)^{-r} \eta^2 + (1 + \eta^2 - \delta^2)^{-r/2}\} \|g\|_{r,T}.$$

Here C depends on w but not on f_0, k, or T.

Proof. This is the first of several computations using a splitting of the domain of integration into parts related to the relevant properties of the integrand. The $f_i' g_*'$ and $g' f_{i*}'$-terms can be treated analogously so only the $f_i' g_*'$-term is discussed. Under the present hypotheses,

$$|v'| \leqq w \leqq \delta 2^k < \delta |v|$$

if $(x, v') \in \operatorname{supp} f_i'$. Set $\chi_j(v) = 1$ for $2^j \leqq |v| \leqq 2^{j+1}$, and $\chi_j(v) = 0$ otherwise.

For $j > k$ consider first the part of the domain of integration where $v \in \operatorname{supp} \chi_j$ and $|v_*| < \eta |v|$. From the conservation of first moments and energy for the mapping $(v, v_*) \to (v', v_*')$, it follows that

$$|v - v_*'| < (\eta + \delta)|v|, \qquad |v_*'| > (1 - \delta)|v|.$$

Recall that

$$|f_i(x + tv, v', t)| \leqq w \quad \text{if } |x + t(v - v')| \leqq w, \quad |v'| \leqq w,$$

and $f_i = 0$ otherwise. If

$$G_T(x, v) = \sup_{0 \leqq t \leqq T} |g^{\#}(x, v, t)|,$$

then

$$|g(x-\sigma u+tv, v'_*, t)| \leqq G_T(x-\sigma u+t(v-v'_*), v'_*).$$

This together with a change of variables $x \to x-\sigma u+t(v-v'_*)$, followed by an integration with respect to t, x, v'_*, u, and v' in that order, gives an upper bound for the present part of the integral, namely,

$$C(1-\delta)^{-r}\eta^2\|(\chi_{j-1}+\chi_j+\chi_{j+1})g\|_{r,T}. \tag{3.1}$$

Here η^2 comes from the angular contribution, and C depends linearly on w^5 but does not depend on j or T.

Consider next for $v \in \operatorname{supp} \chi_j$ the remaining part of the integral, i.e., the part with $|v_*| > \eta|v|$. Then

$$|v|^r \leqq (1+\eta^2-\delta^2)^{-r/2}|v'_*|^r,$$

and if $v'_* \in \operatorname{supp} \chi_{j+n}$ with $n \geqq 2$, in addition

$$|v|^r \leqq 2^{-(n-1)r}|v'_*|^r.$$

It follows that this part of the integral can be bounded by

$$\begin{aligned}&(1+\eta^2-\delta^2)^{-r/2}3^{-1}2^3\pi w^5\sigma^2 \int (\chi_j(v'_*)+\chi_{j+1}(v'_*))G_T(x, v'_*)|v'_*|^r\,dx\,dv'_*\,du \\ &+\sum_{n\geqq 2} 2^{-(n-1)r}3^{-1}2^3\pi w^5\sigma^2 \int G_T(x, v'_*)|v'_*|^r\chi_{n+j}(v'_*)\,dx\,dv'_*\,du.\end{aligned} \tag{3.2}$$

Finally, sum (3.1) and (3.2) for $j > k$, and note that

$$\sum_{n\geqq 1} 2^{-nr} \leqq C(1+\eta^2-\delta^2)^{-r/2}.$$

The lemma follows from here.

When we keep the notation of Lemma 3.1, the remaining integral will be estimated next.

LEMMA 3.2.

$$\begin{aligned}&\sigma^2 \int_0^T dt \int_{|v|\leqq 2^{k+1}} dv|v|_M^r \int (f'_i g'_* + g' f'^{*}_i)^{\#} S\,dv_*\,du\,dx \\ &\quad \leqq 2^{r/2+1}\mathscr{S}(T2^{k+3}\pi\sigma^2, F_{iT}|v|_M^r)\|g\|_{r,T} + 2^{-r+1}\|f_i\|_{0,T}\|g\|_{r,T}.\end{aligned}$$

Proof. As in Lemma 3.1 it is enough to consider the $f'_i g'_*$-term. Split the domain of integration into two subdomains, $|v'_*| < 2^{k+2}$ and $|v'_*| \geqq 2^{k+2}$. As in the proof of Lemma 2.1 the first integral gives a contribution bounded by

$$2^{r/2}\mathscr{S}(T2^{k+3}\pi\sigma^2, F_{iT}|v|_M^r)\|g\|_{r,T}.$$

Substitute $|v|_M$ by $|v_*|_M/2$ in the second integral and argue as in the proof of Lemma 2.2 to get the bound

$$2^{-r}\|f_i\|_{0,T}\|g\|_{r,T}.$$

LEMMA 3.3. *For $g, p \in L^+_{r,T}$ and $0 < \delta \ll 1$, set $G_T = \sup_{t\leqq T} g^{\#}(t)$, $P_T = \sup p^{\#}(t)$. The following estimate holds*:

$$\begin{aligned}&\sigma^2 \int_0^T dt \int g' p'_* |v|^r S\,dv_*\,dv\,du\,dx \\ &\quad \leqq (1+(1-\delta)^{-r}+\varepsilon\delta^{-1/2}2^{r/2})(\|g\|_{t,T}\|p\|_{1/2,T}+\|g\|_{1/2,T}\|p\|_{r,T}) \\ &\qquad +2^{r/2}(\mathscr{S}(\mu, G_T)\|p\|_{r,T}+\mathscr{S}(\mu, P_T)\|g\|_{r,T}),\end{aligned}$$

where $\mu = T2\pi\varepsilon^{-2}\sigma^2$.

Proof. The proof uses a splitting of the domain of integration. By the proof of Lemma 2.2 the integral over that part of the domain where

$$|v'| \geqq |v| \quad \text{or} \quad |v'_*| \geqq |v|$$

can be bounded by

$$(\|g\|_{r,T}\|p\|_{0,T} + \|p\|_{r,T}\|g\|_{0,T}).$$

In the same way the integral over the set where

$$|v'| \leqq \delta|v|, \quad (1-\delta^2)^{1/2}|v| \leqq |v'_*| \leqq |v| \quad \text{or} \quad |v'_*| \leqq \delta|v|, \quad (1-\delta^2)^{1/2}|v| \leqq |v'| \leqq |v|$$

can be bounded by

$$(1-\delta)^{-r}(\|g\|_{r,T}\|p\|_{0,T} + \|g\|_{0,T}\|p\|_{r,T}).$$

Also, the integral over the set where

$$\delta|v| < |v'| < |v|, \quad \delta|v| < |v'_*| < |v|, \quad |v| > \varepsilon^{-2}$$

can be bounded by

$$2^{r/2}\varepsilon\delta^{-1/2}(\|g\|_{r,T}\|p\|_{1/2,T} + \|g\|_{1/2,T}\|p\|_{r,T}).$$

Finally, in the remaining domain $|v| \leqq \varepsilon^{-2}$, and $|v'|, |v'_*| \leqq |v|$. Analogously to the proof of Lemma 2.1 this part can be bounded by

$$2^{r/2}(\mathscr{S}(\mu, G_T)\|p\|_{r,T} + \mathscr{S}(\mu, P_T)\|g\|_{r,T}).$$

This completes the proof of the lemma.

LEMMA 3.4. *Suppose* $g, p \in L^+_{r,T}$, *and* $0 < \delta \ll 1$. *Then the following estimates hold*:

$$\begin{aligned} \sigma^2 \int_0^T dt \int g' p'_* (|v|^r_M + |v_*|^r_M) S \, dv_* \, du \, dv \, dx \\ \leqq 2^{r/2+1}\varepsilon^2\|g\|_{r+1,T}\|p\|_{r,T} + 2\|g\|_{0,T}\|p\|_{r,T} \\ + 2(1-\delta)^{-r}\|g\|_{0,T}\|p\|_{r,T} + \varepsilon^{-2r}\delta^{-r}2^{r/2+1}\mathscr{S}(\delta^{-1}\mu, G_T)\|p\|_{r,T}, \end{aligned} \tag{3.3}$$

$$\begin{aligned} \sigma^2 \int_0^T dt \int g p_* (|v|^r_M + |v_*|^r_M) S \, dv_* \, dv \, du \, dx \\ \leqq 2\varepsilon^2\|g\|_{r+1,T}\|p\|_{r,T} + 2\varepsilon^{-2r}\mathscr{S}(\mu, G_T)\|p\|_{r,T} + 2\|g\|_{0,T}\|p\|_{r,T}. \end{aligned} \tag{3.4}$$

Here $\mu = T2\pi\varepsilon^{-2}\sigma^2$.

Proof. First consider (3.3) for $|v|^r_M$. As in the proof of the previous lemmas, the integral over that part of the domain where $|v'| \geqq \varepsilon^{-2}$ or $|v'_*| \geqq |v|$ can be bounded by

$$2^{r/2}\varepsilon^2\|g\|_{r+1,T}\|p\|_{r,T} + \|g\|_{0,T}\|p\|_{r,T}. \tag{3.5}$$

In the rest of the domain $|v'| \leqq \varepsilon^{-2}$ and $|v'_*| \leqq |v|$. If $|v'| < \delta|v|$, then $|v| \geqq |v'_*| > (1-\delta)|v|$, and the integral can be bounded by

$$(1-\delta)^{-r}\|g\|_{0,T}\|p\|_{r,T}. \tag{3.6}$$

If $|v'| > \delta|v|$ and $|v'| \leqq \varepsilon^{-2}$, $|v'_*| \leqq |v|$, then $|v'_*| \leqq \varepsilon^{-2}\delta^{-1}$, and the integral can be bounded by

$$\varepsilon^{-2r}\delta^{-r}2^{r/2+1}\mathscr{S}(\delta^{-1}\mu, G_T)\|p\|_{r,T}. \tag{3.7}$$

Now (3.3) for $|v|^r_M$ follows from (3.5)-(3.7). The proof of (3.3) for $|v_*|^r_M$ and of (3.4) is similar.

4. Global existence and uniqueness in the case of unbounded velocities. In this section the solution f of the full Enskog equation of § 1 will be obtained as a strong L^1-limit of the solutions f^j from Theorem 2.3 when the physical space is R^3. The main result is Theorem 4.1.

THEOREM 4.1. *Suppose that* $(1+|v|)^r f_0$ *belongs to* L_0^+ *for all* $r \geqq 0$, *and that* $x^2 f_0$, $f_0 \log f_0$ *belong to* L_0. *Then the Enskog equation has a unique solution* f *on* R_+ *with* $\|f\|_{r,T} < \infty$ *for* r, $T > 0$, *with mass and first v-moments conserved, and satisfying* (1.2)–(1.4).

Let $[0, T_1]$ be a (large) time interval and choose w, so that (2.1) holds. Set

$$(A_j' f)^{\#}(t) = f_{e0} \exp(-L_j f_i(t)) + \int_0^t \exp(-L_j f_i(t) + L_j f_i(s)) \cdot \left((Q^j(f_i+f, f_i+f)^{\#}(s) + \int \sigma^2 (ff_{i*})^{\#}(s) W_j S \, du \, dv \right) ds.$$

The function $f_e^j = f^j - f_i$ satisfies $f_e^j = A_j' f_e^j$ for $t > 0$.

LEMMA 4.2. *For any* $f \in L_{2,T}$ *with*

$$\sup_{t \leqq T} \int |f(x, v, t)| |v|_M^2 \, dx \, dv \leqq 4 \int f_0(x, v) |v|_M^2 \, dx \, dv$$

the following estimate holds:

$$\|A_j' f\|_{r,T} \leqq \|f_{e0}\|_r + 4\mathcal{S}(2w\pi\sigma^2 T, f_{i0}) \|f_{i0}\|_r + 4\|f\|_{0,T} \|f\|_{r,T} + CT\|f_0\|_2, \qquad 0 \leqq r \leqq 1.$$

Here the constant C *is independent of* j *and depends only on* w.

Proof. The collision operator in A_j' is

$$Q^j(f_i+f, f_i+f) + \int \sigma^2 (ff_{i*}) W_j S \, du \, dv_*$$

$$= \int \{f_i' f_{i*}' - f_i f_{i*} + f_i' f_*' + f' f_{i*}' - f_i f_* + f' f_* - ff_*\} \sigma^2 W_j S \, dv_* \, du \tag{4.1}$$

$$= \mathcal{I}_1 + \cdots + \mathcal{I}_7,$$

where $\mathcal{I}_1, \cdots, \mathcal{I}_7$ are the seven terms of the collision operator in the given order. The exponential factor in A_j' is bounded from above by 1.

By Lemma 2.1 the resulting integral of $|\mathcal{I}_1| + |\mathcal{I}_2|$ is bounded from above by

$$4\mathcal{S}(2w\pi\sigma^2 T, f_{i0}) \|f_{i0}\|_r. \tag{4.2}$$

By Lemma 2.2 the corresponding integral of $|\mathcal{I}_6| + |\mathcal{I}_7|$ is bounded by

$$4\|f\|_{0,T} \|f\|_{r,T}. \tag{4.3}$$

It is easy to see that the integrals of $|\mathcal{I}_3|$, $|\mathcal{I}_4|$, and $|\mathcal{I}_5|$—after a change of variables in the first two—can be bounded by

$$2 \int_0^T dt \int |v|_M^r |v_*|_M^r f_i(x + vt, v, t) |f(x + vt + \sigma u, v_*, t)| \sigma^2 S \, dv \, dv_* \, dx \, du$$

$$\leqq \sigma^2 w^6 2^4 \pi^2 3^{-1} \int |f(x, v_*, t)| \, |v_*|_M^2 \, dx \, dv_* \, dt.$$

By hypothesis this is bounded by

$$\sigma^2 w^6 2^6 \pi^2 3^{-1} T \int f_0(x, v)|v|_M^2 \, dx\, dv = CT\|f_0\|_2, \tag{4.4}$$

where C depends only on w. The lemma follows from (4.2)-(4.4).

Next choose $T<1$ so that

$$CT\|f_0\|_2 < 256^{-1}, \qquad \mathscr{S}(2w\pi\sigma^2 T, \mathscr{B})(4\|\mathscr{B}\|_{r,T}+1) < 256^{-1}.$$

Note that this condition on T depends on w but not on j. It is an easy consequence of Lemma 4.2 that the solution f^j of Theorem 2.3 exists on $[0, T]$ for every j, and that

$$\|f_e^j\|_{1,T} \leqq 32^{-1}.$$

The same results then hold when f_0 is replaced by any function g such that (1.2)-(1.4) are satisfied by $f(\cdot, t) = g$, $t \leqq T_1$.

Set $F_{T'}^j = \sup_{t\leqq T'} f^{j\#}(t)$, $F_{eT'}^j = \sup_{t\leqq T'} |f_e^{j\#}(t)|$.

LEMMA 4.3. *Given $\delta > 0$, there are $\tilde{T} \leqq T$ and $\mu > 0$ depending on w and f_0, but not on j, such that*

$$\mathscr{S}(\mu, F_{eT'}^j) \leqq \delta, \qquad T' \leqq \tilde{T}.$$

Proof. Evidently the lemma holds if $F_{e\tilde{T}}^j$ is replaced by $\mathscr{B}$. Also $F_{eT'}^j \leqq \mathscr{B} + F_{T'}^j$. So it is enough to consider $F_{T'}^j$:

$$F_{T'}^j \leqq f_0 + \int_0^{T'} ds \int (f^{j\prime} f_*^{j\prime})^{\#} \sigma^2 W_j S \, dv_* \, du$$

$$\leqq f_0 + \int_0^{T'} ds \{f_i' f_{i*}' + |f_i' f_{e*}^{j\prime}| + |f_e^{j\prime} f_{i*}'| + |f_e^{j\prime} f_{e*}^{j\prime}|\}^{\#} \sigma^2 W_j S \, dv_* \, du = \mathscr{I}_1' + \cdots + \mathscr{I}_5'.$$

Evidently the j-independent terms $\mathscr{I}_1'$ and $\mathscr{I}_2'$ satisfy the lemma. By the proof of (4.4), and with $\tilde{T}$ small enough, the lemma holds for $\mathscr{I}_3' + \mathscr{I}_4'$. Finally, for $\mu = 2^{k+2}\pi\sigma^2\tilde{T}$,

$$\int_\Omega \mathscr{I}_5' \, dx\, dv = \int_\Omega \int_0^{T'} \int |f_e^{j\prime} f_{e*}^{j\prime}|^{\#} \sigma^2 W_j S \, dx\, dv\, dv_*\, du\, ds$$

$$\leqq 2^{-k+2} \|f_e^j\|_{1,T'} \|f_e^j\|_{0,T'} + \int_0^{T'} \int |f_e^j f_{e*}^j| \sigma^2 W_{2k} S \, dx\, dv\, dv_*\, du\, ds$$

$$\leqq 2^{-k+2} \|f_e^j\|_{1,T'} \|f_e^j\|_{0,T} + \sup_{\mathscr{M}(\mu)} \int_M |F_{eT'}^j| \, dx\, dv \|f_e^j\|_{0,T'}.$$

Integrating the inequality shown above for $F_{eT'}^j$ over M, taking the supremum over all $M \in \mathscr{M}(\mu)$, and moving the last term to the left-hand side gives

$$\sup_{\mathscr{M}(\mu)} 2^{-1} \int_M F_{eT'}^j \, dx\, dv \leqq \sup_{\mathscr{M}(\mu)} \int_M f_{i0} \, dx\, dv$$

$$+ \sup_{\mathscr{M}(\mu)} \int_M (\mathscr{I}_1' + \mathscr{I}_2' + \mathscr{I}_3' + \mathscr{I}_4') \, dx\, dv + 2^{-k-8}. \tag{4.5}$$

For $\delta > 0$ given, μ, k, and $\tilde{T}$ can be so chosen that for $T' \leqq \tilde{T}$, each of the six terms to the right in (4.5) can be bounded by $\delta/12$. This implies the statement of the lemma.

Remark. If $0 \leqq t \leqq T_1$ and (1.2)-(1.4) are satisfied by $f(\cdot, t) = g$, then f_0 can be replaced by g in Lemma 4.3, and $\tilde{T}$ can be chosen independently of g and t for $0 \leqq t \leqq T_1$.

LEMMA 4.4. *Let $f \in L_{r,T}$ and set $F_T = \sup_{t \leqq T} f^{\#}(t)$. The following estimate holds:*

$$\begin{aligned}\|A_j' f\|_{r,T} \leqq \|f_{e0}\|_r &+ 2^{r/2+2}\mathscr{S}(2w\pi\sigma^2 T, \mathscr{B})\|f_{i0}\|_r \\ &+ C\{(1-\delta)^{-r}\eta^2 + (1+\eta^2-\delta^2)^{-r/2} + 2^{r/2+2}\mathscr{S}(2^{k+3}\pi\sigma^2 T, \mathscr{B}|v|_M^r) \\ &\quad + 2^{-r}\tilde{w} + 2^{r/2+1}\mathscr{S}(2\pi\varepsilon^{-2}\sigma^2 T, F_T)\}\|f\|_{r,T} \\ &+ (3 + 2(1-\delta)^{-r} + \varepsilon\delta^{-1/2}2^{r/2+1})\|f\|_{1/2,T}\|f\|_{r,T}, \qquad r \geqq 1.\end{aligned}$$

Here $w2^{-k} \leqq \delta \ll \eta \ll 1$, $\tilde{w} = w^7\pi^2\sigma^2 9^{-1}2^5$, and the constant C depends only on w.

Proof. As in the proof of Lemma 4.2 the exponential factor in A_j' is bounded by 1, and the integral of $|\mathscr{I}_1| + |\mathscr{I}_2|$ is bounded by

$$2^{r/2+2}\mathscr{S}(2w\pi\sigma^2 T, f_{i0})\|f_{i0}\|_r. \tag{4.6}$$

The integral of $|\mathscr{I}_3| + |\mathscr{I}_4|$ can, by Lemmas 3.1 and 3.2, be bounded by

$$C\{(1-\delta)^{-r}\eta^2 + (1+\eta^2-\delta^2)^{-r/2} + 2^{r/2+1}\mathscr{S}(2^{k+3}\pi\sigma^2 T, f_{i0}|v|_M^r) + 2^{-r}\tilde{w}\}\|f\|_{r,T}. \tag{4.7}$$

Here C depends only on w, and $w2^{-k} \leqq \delta \ll \eta \ll 1$.

The domain of integration for $|\mathscr{I}_5|$ can be split into two parts, $|v_*| \leqq 2^k$ and $|v_*| > 2^k$, and the integral bounded by

$$\{\mathscr{S}(2^{k+3}\pi\sigma^2 T, f_{i0}|v|_M^r) + w^r 2^{-rk}\tilde{w}\}\|f\|_{r,T}. \tag{4.8}$$

By Lemma 3.3 the integral of $|\mathscr{I}_6|$ can be bounded by

$$\{(2 + 2(1-\delta)^{-r} + \varepsilon\delta^{-1/2}2^{r/2+1})\|f\|_{1/2,T} + 2^{r/2+1}\mathscr{S}(\mu, F_T)\}\|f\|_{r,T}, \tag{4.9}$$

where $\mu = T2\pi\varepsilon^{-2}\sigma^2$. Finally, the integral of $|\mathscr{I}_7|$ can be bounded by

$$\|f\|_{r,T}\|f\|_{0,T}. \tag{4.10}$$

The lemma follows from (4.6)-(4.10), since $f_{i0} \leqq \mathscr{B}$, and $w2^{-k} < 2^{-1}$.

A final lemma, which follows next, requires some further w-dependent conditions on T, which are needed for estimates of $A_j' f_e^j$ in the equation $f_e^j = A_j' f_e^j$ using Lemma 4.4. Namely, in Lemma 4.4 choose in turn η suitably small, $r = r_0$ suitably large, δ suitably small, k suitably large, ε suitably small, and $\tilde{T}$ from Lemma 4.3 (all choices only depending on w), so that for $T \leqq \tilde{T}$

$$0.5\|f_e^j\|_{r_0,T} \leqq \|f_{e0}\|_{r_0} + 256^{-1},$$

with r_0 and $\tilde{T}$ depending only on w and not on j. Moreover, r_0 and $\tilde{T}$ can be chosen so that also

$$\|f_e^j\|_{r_0-1,T} \leqq 2(\|f_{e0}\|_{r_0-1} + 256^{-1}),$$

with r_0 and $\tilde{T}$ depending only on w. In the same way, note that for $r > r_0$, $\tilde{T}_r$ depending only on w and r can be chosen so that for $T_r \leqq \tilde{T}_r$

$$\begin{aligned}\|f_e^j\|_{r-1,T_r} &\leqq 2(\|f_{e0}\|_{r-1} + 256^{-1}), \\ \|f_e^j\|_{r,T_r} &\leqq 2(\|f_{e0}\|_r + 256^{-1}).\end{aligned} \tag{4.11}$$

As above, $\tilde{T}$ and $\tilde{T}_r$ can be chosen independent of t and of $f_0 = g$, when (1.2)-(1.4) are satisfied by $f(\cdot, t) = g$, $0 \leqq t \leqq T_1$.

LEMMA 4.5. $\lim_{j\to\infty} \sup_{j' \geqq j} \|A_{j'}' f_e^{j'} - A_j' f_e^{j'}\|_{r-1,T_r} = 0$.

Proof. Take $2^{j-1} \geqq w$ and $j' > j$. Then

$$|\exp(-L_{j'} f_i(t)) - \exp(-L_j f_i(t))|$$

equals zero, if $|v|^2 < 2^{2j} - w^2$. Otherwise it is bounded by 1. It follows that

$$\|A'_{j'}f_e^{j'} - A'_j f_e^{j'}\|_{r-1,T_r}$$

$$\leqq \int_{|v|>2^{j-1}} f_{e0}(x,v)|v|^{r-1}\,dx\,dv + \int_{|v|>2^{j-1}} dv \int_0^{T_r} ds \int |v|^{r-1}|Q^{j'}(f^{j'}, f^{j'})^{\#}(s)|$$

$$+ \sigma^2 \int (f_e^{j'} f_{i*})^{\#}(s)\, W_{j'} S\,du\,dv_*\,dv\,dx + \int_0^{T_r} ds \int (|f'_i f_{e*}^{j'\prime}| + |f_e^{j'\prime} f'_{i*}|$$

$$+ |f_i f_{e*}^{j'}| + |f_e^{j'\prime} f_{e*}^{j'\prime}| + |f_e^{j'} f_{e*}^{j'}|)|v|_M^{r-1}(W_{j'} - W_j) S\sigma^2\,du\,dv\,dv_*\,dx.$$

Evidently the limit when $j \to \infty$ is zero for the first term and the $f_i f_{i*}$-terms. The other terms are bounded by

$$2^{-j+r/2+2}\|f_e^{j'}\|_{r,T_r}(\|f_i\|_{0,T_r} + \|f_e^{j'}\|_{0,T_r}) \leqq 2^{-j+r/2+3}(\|f_{e0}\|_r + 256^{-1})(2\|f_0\|_0 + 32^{-1}).$$

This tends to zero when $j \to \infty$.

Proof of Theorem 4.1. The values of r_0 and $\tilde{T}_r$ given before Lemma 4.5 will be used. First the Cauchy property of the sequence (f_e^j) will be proved in $L_{r-1,\tilde{T}}$ for some $\tilde{T}$ with $0 < \tilde{T} \leqq \tilde{T}_r$ when $r = r_0$. Consider for $j' > j$

$$\begin{aligned} \|f_e^{j'} - f_e^j\|_{r-1,T'} &= \|A'_{j'}f_e^{j'} - A'_j f_e^j\|_{r-1,T'} \\ &\leqq \|A'_{j'}f_e^{j'} - A'_j f_e^{j'}\|_{r-1,T'} + \|A'_j f_e^{j'} - A'_j f_e^j\|_{r-1,T'}. \end{aligned} \tag{4.12}$$

It is enough to estimate the right side of (4.12) by a term equal to a small multiple (less than 1) of $\|f_e^{j'} - f_e^j\|_{r-1,T'}$ plus a term tending to zero when $j \to \infty$.

By the same reasoning as in the proof of Lemma 4.4, the term $\|A'_j f_e^{j'} - A'_j f_e^j\|_{r-1,T'}$ can be bounded by

(4.13)

$$C\{(1-\delta)^{-r}\eta^2 + (1+\eta^2-\delta^2)^{-r/2} + 2^{r/2+2}\mathcal{S}(2^{k+3}\pi\sigma^2 T, \mathcal{B}|v|_M^r) + 2^{-r+1}\tilde{w}\}\|f_e^{j'} - f_e^j\|_{r-1,T'}$$

$$+ \left\| \sigma^2 \int_0^t ds \int \{|f_e^{j'\prime} f_{e*}^{j'\prime} - f_e^{j\prime} f_{e*}^{j\prime}| + |f_e^{j'} f_{e*}^{j'} - f_e^j f_{e*}^j|\}^{\#} W_{j'} S\,du\,dv_* \right\|_{r-1,T'}.$$

Here the constants k, η, and δ have the values given before Lemma 4.5. By Lemma 3.4 the last term in (4.13) can be bounded by

$$\begin{aligned} &\|f_e^{j'} - f_e^j\|_{r-1,T'}\{2^{r/2+2}\varepsilon^2(\|f_e^{j'}\|_{r,T'} + \|f_e^j\|_{r,T'}) \\ &\quad + (4 + 2(1-\delta)^{1-r})(\|f_e^{j'}\|_{0,T'} + \|f_e^j\|_{0,T'}) \\ &\quad + (\mathcal{S}(\delta^{-1}\mu, F_{eT'}^{j'}) + \mathcal{S}(\delta^{-1}\mu, F_{eT'}^j))2^{r/2+2}\varepsilon^{-2r}\delta^{-r}\}, \end{aligned} \tag{4.14}$$

where $\mu = T'2\pi\varepsilon^{-2}\sigma^2$. The factor $2^{r/2+2}\varepsilon^2(\|f_e^{j'}\|_{r,T'} + \|f_e^j\|_{r,T'})$ can be made arbitrarily small by a suitable choice of ε.

Note that if we construct a solution f successively on small subintervals with the same length $\tilde{T}_{r_0}$ and in $[0, T_1]$, then (4.11) gives a uniform upper bound when $T \leqq T_1$ of $\|f\|_{r,T}$, and of $\|f_e^j\|_{r,T_r}$ when f^j has initial value $f(T)$. This upper bound can be inserted instead of $\|f_e^{j'}\|_{r,T'}$, $\|f_e^j\|_{r,T'}$, and ε can be chosen once and for all on $[0, T_1]$. Then by Lemma 4.3 for a small enough $T' = \tilde{T} > 0$ depending only on w, the factor

$$\varepsilon^{-2r}\delta^{-r}2^{r/2+2}(\mathcal{S}(\delta^{-1}\mu, F_{e\tilde{T}}^{j'}) + \mathcal{S}(\delta^{-1}\mu, F_{e\tilde{T}}^j))$$

can be made suitably small, again uniformly on $[0, T_1]$ with respect to f^j with initial value $f(T)$, $0 \leqq T \leqq T_1$. Therefore the estimates (4.13), (4.14) imply

$$\|A'_{j'}f_e^{j'} - A'_j f_e^j\|_{r-1,\tilde{T}} \leqq \|f_e^{j'} - f_e^j\|_{r-1,\tilde{T}}/2,$$

which inserted into (4.12) gives

$$\|f_e^{j'}-f_e^j\|_{r-1,\tilde{T}} \leqq \|f_e^{j'}-f_e^j\|_{r-1,\tilde{T}}/2+\|A_j^l f_e^{j'}-A_j^l f_e^{j'}\|_{r-1,\tilde{T}}.$$

By Lemma 4.5 this implies that the sequence (f_e^j) is Cauchy in the $\|\cdot\|_{r-1}$-norm for $t \leqq \tilde{T}$. It follows that the limit f_e has $(1+|v|^{r-1})f_e(x, v, t)$ in $L^1(\Omega)$ for $t \leqq \tilde{T}$, and that the sum $f=f_i+f_e$ is the unique solution in L^+_{r-1} of

$$(f_i+f_e)^{\#}(t)=f_0+\int_0^t Q(f_i+f_e, f_i+f_e)^{\#}(s)\,ds, \qquad t \leqq \tilde{T}.$$

Moreover, f conserves mass and v-moments and satisfies (1.2) and (1.3) for $t \leqq \tilde{T}=\tilde{T}_{r_0}$.

Next, given $r \geqq r_0$, $f(\cdot, t)$ has finite $\|\cdot\|_r$-norm for $0 \leqq t \leqq \tilde{T}_r$ by (4.11). It follows from the local part of the regularity proof below in Theorem 5.2 that locally around $t=0$ and for r large enough, the solution conserves the x-differentiability of the initial value with respect to the r-norm. By this x-differentiability, the same type of argument implies that the solution conserves the v-differentiability of the initial value locally around $t=0$. From here the formal argument in the proof of the entropy bound (1.4) holds in a strict sense for sufficiently smooth initial values. The initial value f_0 of the present theorem can be approximated by smooth ones, so the continuous dependence of the solution on the initial value in any $\|\cdot\|_{r,T}$-norm then implies (1.4) for the solution f with initial value f_0 on $[0, \tilde{T}_r]$. From here, since $f(\cdot, \tilde{T}_r)$ satisfies (1.2)–(1.4), the same estimate now applies on $[\tilde{T}_r, 2\tilde{T}_r]$, and by induction on $[0, \tilde{T}_{r_0}]$. Also, $\|f(\cdot, \tilde{T}_{r_0})\|_r$ is finite for all r, and $f(\cdot, \tilde{T}_{r_0})$ satisfies (1.2)–(1.4). The whole construction can now be repeated on $[\tilde{T}_{r_0}, 2\tilde{T}_{r_0}]$, and by induction on $[0, T_1]$. Hence there exists a unique solution with all the desired properties on $[0, T_1]$. But T_1 is arbitrary, so the solution exists on R_+. This completes the proof of the theorem.

5. Regularity. The solutions of the Enskog equation shown above retain the regularity properties of the initial value f_0.

THEOREM 5.1. *If $f \in \bigcap_{r\geqq 0} C_0(R_+, L_r)$, with $\|f\|_{r,T}<\infty$ for r, $T>0$, is the solution of the Enskog equation with initial value f_0, where $D^\alpha f_0 \in \bigcap_{r\geqq 0} L_r$ for $|\alpha| \leqq k$, then $D^\alpha f \in \bigcap_{r\geqq 0} C_0(R_+, L_r)$ for $|\alpha| \leqq k$.*

To prove this final result the following technical lemma is needed.

LEMMA 5.2. *Suppose that $f \in \bigcap_{r\geqq 0} C_0(R_+, L_r)$, with $\|f\|_{r,T}<\infty$ for r, $T>0$. Take $T_1>0$ and define*

$$\mathscr{L}g(x, v, t)=\int g(x+tv+\sigma u, v_*, t)S\,dv_*\,du.$$

There is $r_1>r_0$, such that for $r \geqq r_1$, $0 \leqq t_0 \leqq T_1$, and $g \in \bigcap_{r\geqq 0} C_0([0, T_1], L_r)$, with $\|g\|_{r,T}<\infty$ for r, $T>0$, the mapping

$$g \to -\int_{t_0}^t \mathscr{L}g(x, v, \tau)\,d\tau f^{\#}(x, v, t_0)\exp\left(-\int_{t_0}^t \mathscr{L}f(x, v, \tau)\,d\tau\right)-\int_{t_0}^t ds\int_s^t \mathscr{L}g(x, v, \tau)\,d\tau$$

$$\cdot \exp\left(-\int_s^t \mathscr{L}f(x, v, \tau)\,d\tau\right)\int (f'f'_*)^{\#}S\sigma^2\,du\,dv_* \tag{5.1}$$

$$+\int_{t_0}^t ds\exp\left(-\int_s^t \mathscr{L}f(x, v, \tau)\,d\tau\right)\int (f'g'_*+g'f'_*)^{\#}S\sigma^2\,du\,dv_*$$

is strictly contracting (constant of contraction less than 1) in the norm $\int_\Omega \sup_{A_{t_0}}|g^{\#}(x, v, s)|\,|v|_M^r\,dx\,dv$, for some $T_{t_0}>0$. Here

$$A_{t_0}=[t_0-T_{t_0}, t_0+T_{t_0}]\cap[0, T_1].$$

Proof. Set $G_T(\cdot) = \sup_{[0,T]} |g^{\#}(\cdot, t)|$, $F_T = \sup_{[0,T]} f^{\#}(\cdot, t)$. The following estimates hold for the various terms of the mapping (5.1) with $t_0 = 0$. For

$$\int_0^T ds \int |v|_M^r f_0(x, v)|g^{\#}(x + s(v - v_*) + \sigma u, v_*, t)|\sigma^2 S\, dx\, dv\, dv_*\, du$$

estimate separately the part of the domain of integration where $\max(|v|, |v_*|) \leqq 2^k$, and the rest of the domain. With $\mu = 2^{k+1}\sigma^2\pi T$ this gives an upper bound

$$2^{-k+1}(\|g\|_{1,T}\|f_0\|_r + \|g\|_{0,T}\|f_0\|_{r+1}) + \mathcal{S}(\mu, f_0|v|_M^r)\|g\|_{0,T}. \tag{5.2}$$

For

$$\int_0^T ds \int (|v|_M^r + |v_*|_M^r) f^{\#}(x, v', s) \cdot |g^{\#}(x + s(v' - v'_*) - \sigma u, v'_*, s)|\sigma^2 S\, dx\, dv\, dv_*\, du, \tag{5.3}$$

consider first the $|v|_M^r$-term. The integral over the subdomain where $\max(|v'|, |v'_*|) \leqq 2^k$ can be bounded from above by

$$2^{r/2}\mathcal{S}(\mu, F_T|v|_M^r)\|g\|_{r,T}. \tag{5.4}$$

The subdomain where $|v'| > 2^k$ gives the upper bound

$$2^{r/2+2-k}\|f\|_{r+1,T}\|g\|_{r,T}. \tag{5.5}$$

Finally, as in the proof of Lemmas 3.1 and 3.2, the subdomain where $|v'| \leqq 2^k$, $|v'_*| > 2^k$ gives the upper bound

$$\begin{aligned} &C((1-\delta)^{-r}\sigma^2 + (1 + \eta^2 - \delta^2)^{-r/2})\|f\|_{0,T}\|g\|_{r,T} \\ &\quad + (2^{r/2}\mathcal{S}(2^{\nu+3}\sigma^2\pi T, F_T|v|_M^r) + 2^{-r+1}\|f\|_{0,T})\|g\|_{r,T}. \end{aligned} \tag{5.6}$$

Here $2^{k-\nu} \leqq \delta \ll \eta \ll 1$. The following upper bound for the same term can be obtained similarly:

$$\begin{aligned} &C(1-\delta)^{-r}\eta^2\|f\|_{0,T}\|g\|_{r,T} + C(1 + \eta^2 - \delta^2)^{-r/2}2^{-\nu}\|g\|_{r+1,T}\|f\|_{0,T} \\ &\quad + 2^{r/2}\mathcal{S}(2^{\nu+3}\sigma^2\pi T, F_T|v|_M^r)\|g\|_{r,T}. \end{aligned} \tag{5.7}$$

The $|v_*|_M^r$-term gives the same contributions, so an upper bound for (5.3) is

$$\begin{aligned} &\{2^{r/2}\mathcal{S}(\mu, F_T|v|_M^r) + 2^{r/2+2-k}\|f\|_{r+1,T} + C((1-\delta)^{-r}\eta^2 + (1 + \eta^2 - \delta^2)^{-r/2})\|f\|_{0,T} \\ &\quad + (2^{r/2}\mathcal{S}(2^{\nu+1}\sigma^2\pi T, F_T|v|_M^r) + 2^{-r+1}\|f\|_{0,T})\}\|g\|_{r,T}. \end{aligned} \tag{5.8}$$

Next consider the term

$$\begin{aligned} &\int_0^T ds \int_s^T \int g^{\#}(x + \tau(v - \bar{v}_*) + \sigma\bar{u}, \bar{v}_*, \tau)\sigma^2 S\, d\tau\, d\bar{u}\, d\bar{v}_* \\ &\quad \cdot \int f^{\#}(x + s(v - v'), v', s) f^{\#}(x + s(v - v'_*) - \sigma u, v'_*, s)\sigma^2 S|v|_M^r\, dx\, dv\, dv_*\, du. \end{aligned} \tag{5.9}$$

Here

$$\int_s^T \int g^{\#}(x + \tau(v - \bar{v}_*) + \sigma\bar{u}, \bar{v}_*, \tau)\sigma^2 S\, d\tau\, d\bar{u}\, d\bar{v}_* \leqq \|g\|_{0,T}. \tag{5.10}$$

Arguing as in the proof of (5.8) but using (5.7) instead of (5.6), we get the following bound for (5.9):

$$\|g\|_{0,T}\{2^{r/2}\mathscr{S}(\mu, F_T|v|_M^r)\|f\|_{r,T}+2^{r/2+2-k}\|f\|_{r+1,T}\|f\|_{r,T}$$

$$+C(1-\delta)^{-r}\eta^2\|f\|_{0,T}\|f\|_{r,T}+C(1+\eta^2-\delta^2)^{-r/2}2^{-\nu}\|f\|_{r+1,T}\|f\|_{0,T} \tag{5.11}$$

$$+2^{r/2}\mathscr{S}(2^{\nu+3}\sigma^2\pi T, F_T|v|_M^r)\|f\|_{r,T}\}.$$

The terms in (5.1) can be bounded by (5.2), (5.8), or (5.11). In (5.2) with r given choosing k large and then T sufficiently small, the coefficient of $\|g\|_{1,T}$ can be made less than $\frac{1}{4}$. Note that this also can be made to hold if $\|f\|_{r+1,T}$ and $\|f_0\|_r$ are replaced by $\|f\|_{r+1,T_1}$ and $\|g\|_{0,T}$ and $\|g\|_{1,T}$ is replaced by $\|g\|_{r,T}$. Moreover, $\mathscr{S}(\mu, f_0|v|_M^r)$ can be replaced by $\mathscr{S}(\mu, f^{\#}(t_0)|v|_M^r)$ for $T=T_{t_0}$ sufficiently small.

In (5.8) choose, in turn, η suitably small, $r\geqq r_1$ with r_1 suitably large, δ suitably small, k suitably large, ν suitably large (for (5.6)), and T suitably small to make the coefficient of $\|g\|_{r,T}$ less than $\frac{1}{4}$. Again this can be made to hold if $\|f\|_{r+1,T}$ and $\|f\|_{0,T}$ are replaced by $\|f\|_{r+1,T_1}$, $\|f\|_{0,T_1}$, and $\mathscr{S}(\cdots F_T\cdots)$ by $\mathscr{S}(\cdots P_{t_0}\cdots)$, where $P_{t_0}=\sup_{A_{t_0}} f^{\#}(t)$ for a small enough T_{t_0}. In the same way, given r, T_{t_0} can be chosen so small that in (5.11) the coefficient of $\|g\|_{0,T}$ can be made less than $\frac{1}{4}$. From here the lemma follows.

Proof of Theorem 5.1. Given $T_1>0$ it is enough to find $r_k>0$ so that the theorem holds on $[0, T_1]$ for $r\geqq r_k$ and $|\alpha|\leqq k$. Consider first the case $k=1$, and take $D^\alpha=\partial_{x_1}$, $D^\alpha=\partial_{x_2}$, or $D^\alpha=\partial_{x_3}$. It follows by the contraction properties of Lemma 5.2 that, for some $T_r>0$ depending on r, the equation

$$g^{\#}(x, v, t)$$

$$=\left(D^\alpha f_0-f_0\int_0^t \mathscr{L}g(x, v, \tau)\,d\tau\right)\exp\left(-\int_0^t \mathscr{L}f(x, v, \tau)\,d\tau\right)$$

$$+\int_0^t ds\exp\left(-\int_s^t \mathscr{L}f(x, v, \tau)\,d\tau\right)\left\{\int (f'g'_*+g'f'_*)^{\#}\sigma^2 S\,dx\,dv\,dv_*\,du\right\} \tag{5.12}$$

$$-\int_0^t ds\left(\int_s^t \mathscr{L}g(x, v, \tau)\,d\tau\right)\exp\left(-\int_s^t \mathscr{L}f(x, v, \tau)\,d\tau\right)f'f'_*\sigma^2 S\,dx\,dv\,dv_*\,du$$

has a unique solution with $\|g\|_{r,T_r}<\infty$ belonging to $C_0([0, T_1], L_r)$ for $r\geqq r_1$.

Similarly, the difference quotient $\Delta^\alpha f/\Delta x_\alpha$, which solves an equation related to (5.12), can be shown to converge to g in the $\|\cdot\|_{r,T}$-norm when $\Delta x_\alpha\to 0$. Hence $D^\alpha f\in C_0([0, T_1], L_r)$ and $\|D^\alpha f\|_{r,T_r}<\infty$. From here, by the same argument, kth-order differentiability holds locally around $t=0$. In this part of the proof, given r, only the bounds on $\|f\|_{r+1,T_r}$ were used to obtain the contracting properties of Lemma 5.2. For that reason this part of the proof can be used as part of the proof of Theorem 4.5.

Next use Lemma 5.1 in its full force and repeat the argument above with $T_r=T_1$ and $k=1$. It follows that $D^\alpha f\in C_0([0, T_1], L_r)$ for $|\alpha|=1$. Since $T_1>0$ is arbitrary the theorem is proved for $k=1$. Provided the theorem holds for derivatives of order less than or equal to $k-1$, repeating the argument gives the theorem for kth-order derivatives.

Acknowledgment. The author thanks J. Polewczak for pointing out a mistake in an earlier version of the paper.

EXISTENCE OF STEADY-STATE SOLUTIONS FOR A ONE-PREDATOR–TWO-PREY SYSTEM*

NELA LAKOŠ†

Abstract. This paper discusses the existence of strictly positive solutions (in all three components) of the three-dimensional system of elliptic partial differential equations subject to Dirichlet boundary conditions, and models the situation in which a predator feeds on two-prey species. Results are obtained by the use of degree theory in cones, positive operators, and sub- and supersolution techniques.

Key words. predator-prey, competing species, system, bifurcation, degree, positive solutions, existence

AMS(MOS) subject classifications. 35J65, 92A17

0. Introduction. In this paper we study the three-dimensional system

$$\begin{aligned} -\Delta u &= u(a-u-cv-dz), \\ -\Delta v &= v(e+fu-v+gz), \\ -\Delta z &= z(\alpha-\beta u-\gamma v-z) \quad \text{in } \Omega, \\ u &= v = z = 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{0.1}$$

whose solutions are in fact steady-state (time-independent) solutions of a parabolic system. Here, Ω is a domain in $\mathfrak{R}^N$, with a smooth boundary. u, v, and z represent the population densities of certain species that co-inhabit the region Ω. u and z compete for the same food and are prey for the predator species v. All the parameters in (0.1) are assumed to be positive constants, except for e, which is also allowed to be negative. In the absence of one of the species, (0.1) reduces to a two-dimensional subsystem, either of competing species type ($v \equiv 0$) or of predator-prey type ($u \equiv 0$ or $z \equiv 0$). Solutions of either two-dimensional system are called extinction-state solutions of (0.1). Our goal is to establish sufficient conditions for the existence of componentwise strictly positive solutions of (0.1) (which we simply call positive solutions).

In § 2, we review some results obtained by various authors, of whom we mention a few—Leung [L1], Blat and Brown [BB], Dancer [D2], [D3]—who consider the existence of positive solutions of two-dimensional systems of both types. We also review (in modified form) results obtained by Cosner and Lazer [CL], Cantrell and Cosner [CC], McKenna and Walter [MW], and Leung [L2], regarding the uniqueness of positive solutions for competing species systems, and we obtain similar results for the predator-prey situation.

In § 3 we assume conditions under which the predator-prey subsystem ($z \equiv 0$) has a unique positive solution $(\bar{u}, \bar{v})$, and obtain a connected set (as α is varied) of positive solutions of (0.1) bifurcating from the branch $\{(\alpha, (\bar{u}, \bar{v}, 0)), \alpha \geqq 0\}$.

In § 4, we assume conditions under which the competing species subsystem has a unique positive solution $(\bar{u}, \bar{z})$ and, using e as a bifurcation parameter, we obtain a connected set of positive solutions of (0.1) bifurcating from the set $\{(e, (\bar{u}, 0, \bar{z})), e \geqq \nu\}$. As a consequence, we obtain our main result, Theorem 4.8.

Our main tool is degree theory with respect to cones and positive operator techniques, which were used by Dancer for the two-dimensional systems. We also use

sub- and supersolution techniques and variational characterization of eigenvalues, which are main tools in [CL].

The referee has informed us that some existence results for three species models were obtained by Korman and Leung [KL].

1. Preliminaries. Let λ_1 be the principle eigenvalue of

$$\begin{aligned} -\Delta\phi &= \lambda\phi \quad \text{in } \Omega, \\ \phi &= 0 \qquad \text{on } \partial\Omega. \end{aligned} \tag{1.1}$$

Let $m(x) \in C(\bar{\Omega})$ be such that $m(x_0) > 0$, for some $x_0 \in \Omega$. Then, by Theorem 1 of [HK], the boundary value problem

$$\begin{aligned} -\Delta\phi &= \lambda m\phi \quad \text{in } \Omega, \\ \phi &= 0 \qquad \text{on } \partial\Omega, \end{aligned} \tag{1.2}$$

has a principal eigenvalue, $\lambda_1(m) > 0$ and it is the only positive eigenvalue of (1.2) with a positive eigenfunction.

For every $p > 0$ such that $m + p > 0$ in Ω, define an operator $L_p := (-\Delta + p)^{-1}(m + p)$. Here $m + p$ denotes the Nemytskii operator associated with a function $m + p$; $(-\Delta + p)^{-1}$ denotes an inverse under Dirichlet boundary conditions; and $(-\Delta + p)^{-1}: C_0(\bar{\Omega}) \to C_0(\bar{\Omega})$ is a compact positive linear operator. Hence, L_p is the positive compact operator on $C_0(\bar{\Omega})$ and is irreducible (see [Sc, p. 269]), and therefore the spectral radius $r(L_p)$ is positive. $r(L_p)$ is also the only eigenvalue of L_p with a positive eigenfunction, by Theorem 3.2 of [Sc] (Krein-Rutman).

LEMMA 1.1. *If* $\lambda_1(m) = 1$, *then* $r(L_p) = 1$.

Proof. If $\lambda_1(m) = 1$, then there exists $\phi > 0$ such that (1.2) holds for $\lambda = 1$. This implies that $\phi = L_p\phi$. Therefore, $r(L_p) = 1$. □

Let $m, n \in C(\bar{\Omega})$ be such that $m < n$. Let $L_m = (-\Delta + p)^{-1}(m + p)$ and $L_n = (-\Delta + p)^{-1}(n + p)$.

LEMMA 1.2. $r(L_m) < r(L_n)$.

Proof. It is easy to show that $r(L_m) \leqq r(L_n)$. Assume that $r(L_m) = r(L_n) = r$. By the Krein-Rutman Theorem there exist $\varphi > 0$ and $\psi > 0$ such that $L_m\varphi = r\varphi$ and $L_n\psi = r\psi$ in Ω, and $\varphi = \psi = 0$ on $\partial\Omega$. This implies that

$$-\Delta r\varphi + pr\varphi = (m + p)\varphi \quad \text{in } \Omega, \tag{1.3}$$

$$-\Delta r\psi + pr\psi = (n + p)\psi \quad \text{in } \Omega. \tag{1.4}$$

Multiplying (1.3) by ψ and (1.4) by φ, then integrating over Ω and subtracting them, we obtain

$$0 = \int_\Omega (m - n)\varphi\psi \, dx < 0,$$

a contradiction. □

Consider the boundary value problem

$$\begin{aligned} -\Delta\phi &= \phi(a - \phi) \quad \text{in } \Omega, \\ \phi &= 0 \qquad \text{on } \partial\Omega. \end{aligned} \tag{1.5}$$

LEMMA 1.3. (i) *If* $a \leqq \lambda_1$, *then* (1.5) *has no nontrivial positive solution.*

(ii) *If* $a > \lambda_1$, *then there exists a unique positive solution* ϕ_a *of* (1.5) *and* $0 < \phi_a < a$. *Also,* $a < b$ *implies that* $\phi_a < \phi_b$.

Proof. See [BB, pp. 22–23] for the proof.

For $a > \lambda_1$ and $0 < k(<1)$, consider

$$\begin{aligned} -\Delta\phi &= \phi(a \pm k\phi_a - \phi) && \text{in } \Omega, \\ \phi &= 0 && \text{on } \partial\Omega. \end{aligned} \tag{1.6}$$

LEMMA 1.4. *$(1 \pm k)\phi_a$ is a unique positive solution of* (1.6).

Proof. The existence part is obvious. Assume there exists $u > 0$ such that (1.6) holds and $u \neq (1+k)\phi_a$. Let $\phi = (u - (1+k)\phi_a)$. Then ϕ satisfies the following boundary value problem

$$\begin{aligned} -\Delta\phi &= \phi(a - u - \phi_a) && \text{in } \Omega, \\ \phi &= 0 && \text{on } \partial\Omega. \end{aligned} \tag{1.7}$$

Then

$$\int_\Omega [-\Delta\phi - \phi(a - u - \phi_a)]\phi \, dx = 0. \tag{1.8}$$

On the other hand, since $\phi_a > 0$ is a solution of (1.5), it follows that for the eigenvalue problem

$$\begin{aligned} -\Delta\psi - \psi(a - \phi_a) &= \lambda\psi && \text{in } \Omega, \\ \psi &= 0 && \text{on } \partial\Omega, \end{aligned} \tag{1.9}$$

zero is the lowest eigenvalue. It follows, due to variational characterization of the lowest eigenvalue (see [CH]), that

$$\int_\Omega [-\Delta\psi - \psi(a - \phi_a)]\psi \, dx \geqq 0 \quad \forall \psi \in C_0^2(\bar{\Omega}). \tag{1.10}$$

Formula (1.10), in particular, holds for ϕ. Now, (1.8) implies that $\int_\Omega u\phi^2 \, dx \leqq 0$, which is a contradiction. □

2. Two-species systems. In this section, we review some results for two-species systems. First, we consider the system modeling the one-predator–one-prey situation:

$$\begin{aligned} -\Delta u &= u(a - u - cv), \\ -\Delta v &= v(e + fu - v) && \text{in } \Omega, \\ u &= v = 0 && \text{on } \partial\Omega. \end{aligned} \tag{2.1}$$

For the proof of the following theorem, see [BB] or [D2].

THEOREM 2.1. *Assume that $a > \lambda_1$ and $e > \lambda_1$. For* (2.1) *there always exist two solutions, $(\phi_a, 0)$ and $(0, \phi_e)$. Let a^* be such that $\lambda_1(a^* - c\phi_e) = 1$. If $0 < c < 1$, then there exists a positive solution, (u, v), such that $u > 0$ and $v > 0$, for all $a \in (a^*, \infty)$, $(a^* \in (\lambda_1, e))$.*

Let

$$K = \frac{c^2 + f^2(1+f)^2}{(4+2cf)(1 - c(1+f))},$$

$$L = \frac{c^2 + f^2(1+f)^2}{4+2cf} + c(1+f).$$

It is easy to see that $0 < K < 1$ if and only if $0 < L < 1$.

Assume that $0 < K < 1$, $e > \lambda_1$ and define $\underline{a} := \inf\{a \in [\lambda_1, e];\ \phi_a \geqq L\phi_e\}$, and $\bar{a} := \sup\{a \in [e, \infty];\ K\phi_a \leqq \phi_e\}$. If we also assume that $a \in [\underline{a}, \bar{a}]$, the following lemma holds.

LEMMA 2.2. *Let* (u, v) *be a solution of* (2.1) *such that* $u>0$ *and* $v>0$. *Then* $u<\phi_a$ *and* $\phi_e<v<(1+f)\phi_e$. *If* $a\geqq e$, *then* $u\geqq(1-c(1+f))\phi_a$ *and if* $a\leqq e$, *then* $u\geqq(1-(c(1+f)/L))\phi_a$.

Proof. It has been proved in [D2] that $v\geqq\phi_e$ and $u\leqq\phi_a$. Since $v=0$ on $\partial\Omega$ and in Ω we have that $-\Delta v=v(e+fu-v)\leqq v(e+f\phi_a-v)$, it follows that v is a subsolution for (1.6). Since any big enough constant is a supersolution, Theorem 4.1 of [S] and Lemma 1.4 imply that $v\leqq(1+f)\phi_e$.

Assume that $a\geqq e$. Since $u=0$ on $\partial\Omega$ and in Ω we have that $-\Delta u=u(a-u-cv)\geqq u(a-u-c(1+f)\phi_a)$, it follows that u is a supersolution of (1.6), with $k=c(1+f)$. On the other hand, by the maximum principle (see [GT]) there exists an $\varepsilon>0$ such that $\varepsilon\phi_a<u$ and $\varepsilon<(1-c(1+f))$. Since we have that $-\Delta(\varepsilon\phi_a)=\varepsilon\phi_a(a-\phi_a)\leqq\varepsilon\phi_a(a-(\varepsilon+c(1+f)))\phi_a=\varepsilon\phi_a(a-c(1+f)\phi_a-\varepsilon\phi_a)$ in Ω and $\varepsilon\phi_a=0$ on $\partial\Omega$, $\varepsilon\phi_a$ is a subsolution of (1.6). Theorem 4.1 of [S] and Lemma 1.4 imply that $u\geqq(1-c(1+f))\phi_a$. We argue similarly for the case $a\leqq e$, the only difference being that $-\Delta u=u(a-u-cv)>u(a-u-c(1+f)\phi_e)\geqq u(a-u-(c(1+f)/L)\phi_a)$, in Ω. □

THEOREM 2.3. *If* $a\in[\underline{a}, \bar{a}]$, *there exists a unique positive solution* $(\bar{u}, \bar{v})$ *of* (2.1) *such that* $\bar{u}>0$ *and* $\bar{v}>0$.

Proof. Assume that there exist two different solutions (u_1, v_1) and (u_2, v_2) of (2.1) such that $u_i, v_i>0$, $i=1, 2$, for some $a\in[\underline{a}, \bar{a}]$. Let $p=u_1-u_2$, $q=v_1-v_2$. It is easy to check that (2.1) implies the following:

$$-\Delta p=p(a-u_1-cv_1)-u_2p-cu_2q,$$

$$-\Delta q=q(e+fu_1-v_1)+fv_2p-v_2q \quad \text{in } \Omega,$$

$$p=q=0, \quad \text{on } \partial\Omega.$$

Therefore,

$$\int_\Omega[-\Delta p-p(a-u_1-cv_1)]p\,dx+\int_\Omega(u_2p+cu_2q)p\,dx=0, \tag{2.2}$$

$$\int_\Omega[-\Delta q-q(e+fu_1-v_1)]q\,dx+\int_\Omega(v_2q-fv_2p)q\,dx=0. \tag{2.3}$$

Since (u_1, v_1) is a solution of (2.1), zero is the lowest eigenvalue for the following two eigenproblems:

$$-\Delta\phi-\phi(a-u_1-cv_1)=\alpha\phi \quad \text{in } \Omega,$$

$$\phi=0 \quad \text{on } \partial\Omega,$$

$$-\Delta\psi-\psi(e+fu_1-v_1)=\beta\psi \quad \text{in } \Omega,$$

$$\psi=0 \quad \text{on } \partial\Omega.$$

Arguing as in the proof of Lemma 1.4, we get that the first terms in both (2.2) and (2.3) are nonnegative. Therefore,

$$\int_\Omega(u_2p^2+(cu_2-fv_2)pq+v_2q^2)\,dx\leqq 0. \tag{2.4}$$

We would like to show that $D:=(cu_2-fv_2)^2-4u_2v_2<0$. That would prove that the

form in (2.4) is positive definite and imply that $p \equiv q \equiv 0$. In the case $a \geqq e$,

$$D = c^2u_2^2 + f^2v_2 - (4+2cf)u_2v_2 < c^2\phi_a^2 + f^2(1+f)^2\phi_a^2 - (4+2cf)(1-c(1+f))\phi_a\phi_e$$
$$\leqq [c^2 + f^2(1+f)^2 - (4+2cf)(1-c(1+f))K]\phi_a^2 = 0.$$

In the case where $a \leqq e$,

$$D < c^2\phi_e^2 + f^2(1+f)^2\phi_e^2 - (4+2cf)(1-(c(1+f)/L))\phi_a\phi_e$$
$$\leqq (c^2 + f^2(1+f)^2 - (4+2cf)(L-c(1+f))]\phi_e^2 = 0. \qquad \square$$

Next, we consider the two competing species system:

$$\begin{aligned} -\Delta u &= u(a-u-dz), \\ -\Delta z &= z(\alpha - \beta u - z) \quad \text{in } \Omega, \\ u &= z = 0 \quad \text{on } \partial\Omega. \end{aligned} \tag{2.5}$$

It is clear that the first part of Theorem 2.1 holds for (2.5), as well. Assume that $a > \lambda_1$, $d < 1$, $\beta < 1$, and let

$$R = \frac{d^2+\beta^2}{(4-2\,d\beta)(1-d)} + \beta, \qquad Q = \frac{d^2+\beta^2}{(4-2\,d\beta)(1-\beta)} + d.$$

Assume that $0 < R < 1$ (this, obviously, implies that $0 < Q < 1$), and define $\alpha_1 := \inf\{\alpha \geqq \lambda_1,\ \phi_\alpha \geqq R\phi_a\}$, $\alpha_2 := \sup\{\alpha \geqq \lambda_1,\ Q\phi_\alpha \leqq \phi_a\}$. Assume that $d(1+\beta)/(1+d) < (a-\lambda_1)/a$. For the proof of the following theorem, see [L].

THEOREM 2.4. *Assume that* $\alpha \in (\lambda_1 + \beta a,\ (a-\lambda_1)/d)$. *Then there exists a positive solution* (u, z), *of* (2.5), *such that* $u > 0$ *and* $z > 0$.

LEMMA 2.5. *Assume that* $\alpha \in [\alpha_1, \alpha_2]$. *Then for any solution* (u, z) *of* (2.5), *such that* $u > 0$, $z > 0$, *the following holds. If* $\alpha \leqq a$, *then* $(1-d)\phi_a \leqq u \leqq \phi_a$, $(1-(\beta/R))\phi_\alpha \leqq z \leqq \phi_\alpha$; *if* $\alpha \geqq a$, *then* $(1-(d/Q))\phi_a \leqq u \leqq \phi_a$, $(1-\beta)\phi_\alpha \leqq z \leqq \phi_\alpha$.

Proof. Since $-\Delta u = u(a-u-dz) \geqq u(a-u-d\phi_\alpha)$, in the case $\alpha \geqq a$ we get that $-\Delta u \geqq u(a-u-(d/Q)\phi_a)$. In the case where $\alpha \leqq a$ we get that $-\Delta u \geqq u(a-u-d\phi_a)$. Since $-\Delta z = z(\alpha - \beta u - z) \geqq z(\alpha - \beta\phi_\alpha - z)$, in the case $\alpha \geqq a$ we get that $-\Delta z \geqq z(\alpha - \beta\phi_\alpha - z)$; in the case where $\alpha \leqq a$ we get that $-\Delta z \geqq z(\alpha - (\beta/R)\phi_\alpha - z)$. The rest follows, as in the proof of Lemma 2.2. $\square$

THEOREM 2.6. *If* $\alpha \in [\alpha_1, \alpha_2] \cap (\lambda_1 + \beta a,\ (a-\lambda_1)/d)$, *there exists a unique positive solution* $(\bar{u}, \bar{z})$ *of* (2.5) *such that* $\bar{u} > 0$ *and* $\bar{z} > 0$.

Proof. Assume that there exist two different solutions (u_1, z_1) and (u_2, z_2) such that $u_i > 0$, $z_i > 0$, $i = 1, 2$. Let $p = u_1 - u_2$, $q = z_1 - z_2$. Then

$$\begin{aligned} -\Delta p &= p(a-u_1-dz_1) - u_2p - du_2q, \\ -\Delta q &= q(\alpha - \beta u_1 - z_1) - \beta z_2 p - z_2 q \quad \text{in } \Omega, \\ p &= q = 0 \quad \text{on } \partial\Omega. \end{aligned}$$

As in the proof of Theorem 2.3, this implies that

$$\int_\Omega (u_2p^2 + (du_2 + \beta z_2)pq + z_2q^2)\,dx \leqq 0. \tag{2.6}$$

Let $\bar{D} = (du_2 + \beta z_2)^2 - 4u_2z_2$. Lemma 2.5 implies that $\bar{D} < 0$, which then implies that the form in (2.6) is positive definite. Therefore (2.6) can hold only for $p \equiv q \equiv 0$. $\square$

3. Three-species system with α as bifurcation parameter. In this section, we study the problem (0.1) and assume that all the parameters are fixed positive constants, except for α, which will serve as bifurcation parameter. We will deal with two different sets of assumptions:

$$\lambda_1 < e \leqq a \leqq \bar{a},$$

$$\beta + \gamma(1+f+g) \leqq K, \tag{3.1}$$

$$d + c(1+f+g) < 1,$$

$$\lambda_1 < \underline{a} \leqq a \leqq e,$$

$$\beta + \gamma(1+f+g) \leqq L, \tag{3.2}$$

$$d + c(1+f+g) \leqq L.$$

$\underline{a}$, $\bar{a}$, L, K were defined in the previous section. All the results will be stated for (3.1), and statements in parentheses will refer to (3.2). In the absence of parentheses, the result holds for both cases.

LEMMA 3.1. *Let* (u, v, z) *be a solution of* (0.1), *such that* $u, v, z \geqq 0$. *Then*

(i) $u \leqq \phi_a$;

(ii) $v \leqq (1+f+g)\phi_\eta$, $\eta = \max\{\alpha, a, e\}$; *if* $v \not\equiv 0$, $\phi_e \leqq v$;

(iii) $z \leqq \phi_\alpha$ *and if* $z \not\equiv 0$ *and* $\alpha \geqq a, e$, *then* $(1-[\beta+\gamma(1+f+g)])\phi_\alpha \leqq z$.

Proof. We proceed as in the proof of Lemma 2.5. The crucial inequalities are:

(ii) $$-\Delta v = v(e+fu+gz-v) \leqq v(e+f\phi_a+g\phi_\alpha-v) \leqq v(\eta+(f+g)\phi_\eta-v);$$

(iii) $$-\Delta z = z(\alpha-\beta u-\gamma v-z) \geqq z(\alpha-\beta\phi_a-\gamma(1+f+g)\phi_\alpha-z)$$

$$= z(\alpha-[\beta+\gamma(1+f+g)]\phi_\alpha-z).$$ □

We now establish an appropriate setting that will enable us to transform problem (0.1) into a fixed-point equation. To this end, let $E = [C_0(\bar{\Omega})]^3$, be a Banach space with the norm $\|u\| = \|(u_1, u_2, u_3)\| = \max\{\|u_i\|_0,\ i = 1, 2, 3\}$. Let $P = [C_0(\bar{\Omega})^+]^3$ be a cone of positive functions in E. For all $\alpha > 0$, define a set $T_\alpha \subset P$ by $T_\alpha := \{(u, v, z) \in P,\ u \leqq 2a,\ v \leqq 2\eta(1+f+g),\ z \leqq 2\alpha\}$. By Lemma 3.1, all positive solutions of (0.1) lie in the interior (with respect to relative topology on P) of T_α. Also, there exists a continuous, nondecreasing function of α, $p(\alpha)$, such that $a-u-cv-dz+p(\alpha) > 0$, $e+fu-v+gz+p(\alpha) > 0$, $\alpha-\beta u-\gamma v-z+p(\alpha) > 0$, for all $(u, v, z) \in T_\alpha$. This enables us to define $A(\alpha, \cdot)$, an operator on T_α, by

$$A(\alpha, (u, v, z)) := (-\Delta+p(\alpha))^{-1}(u(a-u-cv-dz+p(\alpha)), v(e+fu-v+gz+p(\alpha)),$$

$$z(\alpha-\beta u-\gamma v-z+p(\alpha))). \tag{3.3}$$

$A(\alpha, \cdot)$: $T_\alpha \to P$; it is completely continuous and Fréchet differentiable, and fixed points of $A(\alpha, \cdot)$ are solutions of (0.1). Since we are interested in positive solutions of (0.1), we will study equations of the form

$$A(\alpha, (u, v, z)) = (u, v, z) \tag{3.4}$$

instead of (0.1), i.e., we will study fixed points of a one-parameter family of completely continuous maps. This family, A: $T \to P$, where $T = \bigcup_{\alpha \geqq 0}\{\alpha\} \times T_\alpha$, $T \subset \mathfrak{R}^+ \times P$, is a

completely continuous map. Therefore, the solution set S of (3.4) defined by

$$S := \{(\alpha, (u, v, z)) \in T, A(\alpha, (u, v, z)) = (u, v, z)\}$$

is locally compact.

Let $\delta = 1/d(1-[\beta+\gamma(1+f+g)])$ and let α^* be such that $\lambda_1(\alpha^* - \gamma\phi_e) = 1$.

LEMMA 3.2. *If $\alpha \geqq a\delta (\alpha \geqq e\delta)$ or $\alpha \leqq \alpha^*$, then $A(\alpha, \cdot)$ has no fixed point with all three components nontrivial.*

Proof. Assume that $\alpha \leqq \alpha^*$ and that there exists $(u, v, z) \in T_\alpha$, a fixed point of $A(\alpha, \cdot)$ such that $u > 0$, $v > 0$, and $z > 0$. Let $p = p(\alpha)$. Since $z = (-\Delta+p)^{-1}(\alpha - \beta u + \gamma v - z + p)z$, it follows that $r((-\Delta+p)^{-1}(\alpha - \beta u - \gamma v - z + p)) = 1$. On the other hand,

$$\alpha - \beta u - \gamma v - z < \alpha - \gamma v < \alpha - \gamma\phi_e \leqq \alpha^* - \gamma\phi_e. \tag{3.5}$$

Also, Lemma 1.1 implies that $r((-\Delta+p)^{-1}(\alpha^* - \gamma\phi_e + p)) = 1$. Now, (3.5) and Lemma 1.2 imply that $r((-\Delta+p)^{-1}(\alpha - \beta u - \gamma v - z + p)) < 1$, which is a contradiction.

Let $\alpha \geqq a\delta$ and let $(u, v, z) \in T_\alpha$, $u > 0$, $v > 0$, $z > 0$, be a fixed point of $A(\alpha, \cdot)$. Since $a - u - cv - dz + p < a - u - d(1-\beta-\gamma(1+f+g))\phi_\alpha + p = a - u - 1/\delta\phi_\alpha + p$, and $u = (-\Delta+p)^{-1}(a - u - cv - dz + p)u$, it follows that

$$u \leqq (-\Delta+p)^{-1}\left(a - u - \frac{1}{\delta}\phi_\alpha + p\right)u. \tag{3.6}$$

This implies that $r((-\Delta+p)^{-1}(a - u - 1/\delta\phi_\alpha + p)) \geqq 1$, by definition of spectral radius. On the other hand,

$$\begin{aligned} a - u - \frac{1}{\delta}\phi_\alpha < a - \frac{1}{\delta}\phi_\alpha &= \frac{1}{\delta}(a\delta - \phi_\alpha) \\ &< \alpha - \phi_\alpha. \end{aligned}$$

Arguing as in the previous case, we get

$$r\left((-\Delta+p)^{-1}\left(a - u - \frac{1}{\delta}\phi_\alpha + p\right)\right) < r((-\Delta+p)^{-1}(\alpha - \phi_\alpha + p)) = 1,$$

a contradiction.

In the case $\lambda_1 < a \leqq e$ and $\alpha \geqq e\delta$, the crucial inequalities are

$$\begin{aligned} u &= (-\Delta+p)^{-1}(a - u - cv - dz + p)u \\ &\leqq (-\Delta+p)^{-1}\left(e - u - \frac{1}{\delta}\phi_\alpha + p\right)u, \end{aligned}$$

$$e - u - \frac{1}{\delta}\phi_\alpha < \frac{1}{\delta}(e\delta - \phi_\alpha) < \alpha - \phi_\alpha. \qquad \square$$

Let $(\bar{u}, \bar{v})$ be a unique positive solution of (2.1) such that $\bar{u} > 0$ and $\bar{v} > 0$, guaranteed by Theorem 2.3.

LEMMA 3.3. *There exists a unique $\bar{\alpha} > 0$ such that*

$$r((-\Delta + p(\bar{\alpha}))^{-1}(\bar{\alpha} - \beta\bar{u} - \gamma\bar{v} + p(\bar{\alpha}))) = 1, \tag{3.7}$$

$\bar{\alpha} \in (\alpha^*, e) (\bar{\alpha} \in (\alpha^*, a))$. Also, $r((-\Delta + p(\alpha))^{-1}(\alpha - \beta\bar{u} - \gamma\bar{v} + p(\alpha)))$ is less than 1, if $\alpha < \bar{\alpha}$, and greater than 1, if $\bar{\alpha} < \alpha$.

Proof. If $\alpha \leqq \alpha^*$, then $\alpha - \beta\bar{u} - \gamma\bar{v} < \alpha - \gamma\phi_e \leqq \alpha^* - \gamma\phi_e$. Arguing as in Lemma 3.2, we get that

$$r((-\Delta + p(\alpha))^{-1}(\alpha - \beta\bar{u} - \gamma\bar{v} + p(\alpha))) < r((-\Delta + p(\alpha))^{-1}(\alpha^* - \gamma\phi_e + p(\alpha))) = 1.$$

If $\alpha \geqq e$, then

$$\begin{aligned}\alpha - \beta\bar{u} - \gamma\bar{v} &> \alpha - \beta\phi_a - \gamma(1+f)\phi_e > e - (\beta + \gamma(1+f))\phi_a \\ &\geqq e - \frac{\beta + \gamma(1+f)}{K}\phi_e \\ &\geqq e - \phi_e.\end{aligned}$$

This implies that $r((-\Delta + p(\alpha))^{-1}(\alpha - \beta\bar{u} - \gamma\bar{v} + p(\alpha))) > 1$. (In the case where $\lambda_1 < a \leqq e$ and $\alpha \geqq a$, the crucial inequalities are

$$\begin{aligned}\alpha - \beta\bar{u} - \gamma\bar{v} &> \alpha - \beta\phi_a - \gamma(1+f)\phi_e > \alpha - (\beta + \gamma(1+f))\phi_e \\ &> a - \frac{\beta + \gamma(1+f)}{L}\phi_a > a - \phi_a.)\end{aligned}$$

Let $r(\alpha)$: $\mathfrak{R}^+ \to \mathfrak{R}^+$ be defined by

$$r(\alpha) := r((-\Delta + p(\alpha))^{-1}(\alpha - \beta\bar{u} - \gamma\bar{v} + p(\alpha))).$$

Then Theorem 4.3.1 and § 4.3.5 of [K] imply that $r(\alpha)$ is a continuous function. Since $r(\alpha^*) < 1$ and $r(e) > 1$ ($r(a) > 1$), it follows that there exists an $\bar{\alpha} \in (\alpha^*, e)$, ($\bar{\alpha} \in (\alpha^*, a)$), such that $r(\bar{\alpha}) = 1$, i.e., (3.7) holds. Assume there exists α', $\alpha' \neq \bar{\alpha}$ such that $r(\alpha') = 1$. Then there exist $\phi > 0$ and $\psi > 0$ such that (1.2) holds, respectively, for $m = \bar{\alpha} - \beta\bar{u} - \gamma\bar{v}$ and $n = \alpha' - \beta\bar{u} - \gamma\bar{v}$. It follows that $\int_\Omega -\Delta\phi \cdot \psi \, dx = \int_\Omega m\psi\phi \, dx$ and $\int_\Omega -\Delta\psi \cdot \phi \, dx = \int_\Omega n\psi\phi \, dx$. Subtracting these two equalities, we get that $0 = \int_\Omega (m-n)\phi\psi \, dx \neq 0$, which is a contradiction.

Since $\bar{\alpha}$ is the only value of α such that $r(\alpha) = 1$, and since $r(\alpha)$ is a continuous function and $r(\alpha^*) < 1$, $r(e) > 1$ ($r(a) > 1$), it follows that $r(\alpha) < 1$ if $\alpha < \bar{\alpha}$, and that $r(\alpha) > 1$ if $\alpha > \bar{\alpha}$. □

Remark 3.4. Let L_α be the linearization of $A(\alpha, \cdot)$ at the point $(\bar{u}, \bar{v}, 0) \in T_\alpha$. ($(\bar{u}, \bar{v}, 0)$ is, obviously, a fixed point of $A(\alpha, \cdot)$.) Then

$$\begin{aligned}L_\alpha(l, k, h) = (-\Delta + p(\alpha))^{-1}((a - 2\bar{u} - c\bar{v} + p(\alpha))l - c\bar{u}k - d\bar{u}h, f\bar{v}l \\ + (e + f\bar{u} - 2\bar{v} + p(\alpha))k + g\bar{v}h, (\alpha - \beta\bar{u} - \gamma\bar{v} + p(\alpha))h).\end{aligned}$$

Next, we would like to compute the fixed-point index of $A(\alpha, \cdot)$ at the point $(\bar{u}, \bar{v}, 0)$ relative to the cone P. Let $i(A(\alpha, \cdot), y)$ denote the fixed-point index of $A(\alpha, \cdot)$ at y with respect to the cone P.

LEMMA 3.5. *$i(A(\alpha, \cdot), (\bar{u}, \bar{v}, 0))$ is equal to zero if $\alpha > \bar{\alpha}$, and equal to ± 1 if $\alpha < \bar{\alpha}$.*

Proof. We will use the notation from [D1]. Let $y = (\bar{u}, \bar{v}, 0)$. Then $W_y = C_0(\bar{\Omega}) \times C_0(\bar{\Omega}) \times C_0(\bar{\Omega})^+$. First we have to show that L_α has no eigenvector in W_y corresponding to eigenvalue 1. Assume, on the contrary, that there exists $(l, k, h) \in W_y$ such that

$$L_\alpha(l, k, h) = (l, k, h). \tag{3.8}$$

Assume that $h \not\equiv 0$. Equation (3.8) implies that $(-\Delta + p(\alpha))^{-1}(\alpha - \beta\bar{u} - \gamma\bar{v} + p(\alpha))h = h$, and therefore, $r((-\Delta + p(\alpha))^{-1}(\alpha - \beta\bar{u} - \gamma\bar{v} + p(\alpha))) = 1$. This contradicts the assumption that $\alpha \neq \bar{\alpha}$. Hence $h \equiv 0$. If $l \not\equiv 0 \not\equiv k$, then (3.8) implies that $-\Delta l - (a - 2\bar{u} - c\bar{v})l + c\bar{u}k = 0$, and $-\Delta k - f\bar{v}l - (e + f\bar{u} - 2\bar{v})k = 0$, in Ω, and $l = k = 0$, on $\partial\Omega$. Multiplying the

first equality by l, and the second by k and then integrating over Ω, we get

$$\int_\Omega [-\Delta l \cdot l - (a - \bar{u} - c\bar{v})l^2]\, dx + \int_\Omega [\bar{u}l^2 + c\bar{u}kl]\, dx = 0,$$

$$\int_\Omega [-\Delta k \cdot k - (e + f\bar{u} - \bar{v})k^2]\, dx + \int_\Omega [\bar{v}k^2 - f\bar{v}lk]\, dx = 0.$$

Arguing as in the proof of Lemma 2.5, we get that

$$\int_\Omega [\bar{u}l^2 + \bar{v}k^2 + (c\bar{u} - f\bar{v})lk]\, dx \leqq 0.$$

The form above is equal to the form in (2.4), which is positive definite. Hence $l \equiv k \equiv 0$.

Following the notation of [D1], we find that $S_y = C_0(\bar{\Omega}) \times C_0(\bar{\Omega}) \times \{0\}$. Let $M = \{0\} \times \{0\} \times C_0(\bar{\Omega})$. Then M is a closed complement of S_y in E. Let Π be the projection onto M, and let M_α denote the restriction of L_α to M. Then $\Pi \circ M_\alpha = (-\Delta + p(\alpha))^{-1}(\alpha - \beta\bar{u} - \gamma\bar{v} + p(\alpha))$. Now, Theorem 1 (with Remark 2) and Lemma 2 (with Remark 3) of [D1] imply that $i(A(\alpha, \cdot), (\bar{u}, \bar{v}, 0)) = i(L_\alpha, 0, S_y) = \pm 1$, if $\alpha < \bar{\alpha}$, and $i(A(\alpha, \cdot), (\bar{u}, \bar{v}, 0)) = 0$, if $\alpha > \bar{\alpha}$. □

Let $C_0 = \{(\alpha, (\bar{u}, \bar{v}, 0)), \alpha \geqq 0\}$. Then $C_0 \subset S$; it is a continuum (a closed, connected set) in S, and therefore in $\Re^+ \times P$.

LEMMA 3.6. *$\bar{\alpha}$ is a bifurcation point for* (3.4) *with respect to C_0. It is the only one.*

Proof. Assume that $\bar{\alpha}$ is not a bifurcation point for C_0. Then there exists an interval $[B, C]$ such that $\bar{\alpha} \in [B, C]$ and an open set, U, $U \subset [B, C] \times P \cap T$ (in relative topology) such that $\bar{U} \cap S = [B, C] \times \{(\bar{u}, \bar{v}, 0)\}$ and $\partial U \cap S = \varnothing$. Let $U_\alpha = \{(u, v, z), (\alpha, (u, v, z)) \in U\}$. Then, by the general homotopy invariance property of the fixed-point index (see [A, Thm. 11.3]), $i(A(B, \cdot), U_B) = i(A(C, \cdot), U_C)$. On the other hand, by the excision property and definition of local index (see [A, p. 659]), $i(A(B, \cdot), U_B) = i(A(B, \cdot), (\bar{u}, \bar{v}, 0)) = \pm 1$, and $i(A(C, \cdot), U_C) = i(A(C, \cdot), (\bar{u}, \bar{v}, 0)) = 0$, since $B < \bar{\alpha}$, and $C > \bar{\alpha}$, which is a contradiction.

Assume that there exists another bifurcation point α, $\alpha \neq \bar{\alpha}$. Then there exists a sequence in $S \setminus C_0$, $\{(\alpha_n, (u_n, v_n, z_n)), n \in \aleph\}$ such that $\alpha_n \to \alpha$, $u_n \to \bar{u}$, $v_n \to \bar{v}$, $z_n \to 0$. Also, there exists $N \in \aleph$ such that $u_n > 0$, $v_n > 0$, for all $n \geqq N$.

Assume that $z_n = 0$, for some $n \geqq N$. Then (u_n, v_n) is a solution of (2.1) and therefore $u_n = \bar{u}$, $v_n = \bar{v}$, and hence $(\alpha_n, (u_n, v_n, z_n)) \in C_0$, contrary to the assumption. So, $z_n > 0$ for all $n \geqq N$. The following holds:

$$\frac{z_n}{\|z_n\|} = (-\Delta)^{-1}\left(\frac{z_n}{\|z_n\|}(\alpha_n - \beta u_n - \gamma v_n - z_n)\right), \qquad n \geqq N. \tag{3.9}$$

The sequence on the right-hand side converges for some subsequence (which we relabel as the original one), since $(-\Delta)^{-1}$ is a compact operator and the sequence in the parentheses is bounded. Therefore, the left-hand side of (3.9) converges also, to some z of norm 1. Passing to the limit in (3.9), we get that $z = (-\Delta)^{-1}(z(\alpha - \beta\bar{u} - \gamma\bar{v}))$, which implies that $z = (-\Delta + p(\alpha))^{-1}(\alpha - \beta\bar{u} - \gamma\bar{v} + p(\alpha))z$, and by Lemma 3.3, it follows that $\alpha = \bar{\alpha}$, contrary to the assumption. □

Let $\Sigma = (S \setminus C_0) \cup \{(\bar{\alpha}, (\bar{u}, \bar{v}, 0))\}$. Σ is a closed subset of S, by Lemma 3.6.

LEMMA 3.7. *Σ contains an unbounded continuum $\tilde{C}$, bifurcating from C_0 at $\bar{\alpha}$.*

Proof. Let $\tilde{C}$ be the component of Σ containing $(\bar{\alpha}, (\bar{u}, \bar{v}, 0))$. Assume that $\tilde{C}$ is bounded. Then there exists $\mu > \bar{\alpha}$ such that $\tilde{C} \subset [0, \mu] \times P \cap T$ and $\tilde{C} \cap \{\mu\} \times T_\mu = \varnothing$. Let $X = S \cap [0, \mu] \times P$. X is obviously a compact topological space. Let $Y = \tilde{C} \cup C_0 \cap X$, $Z = S \cap (\{\mu\} \times P \cup \{0\} \times P) \setminus Y$. Then Y and Z are nonempty, disjoint, closed subsets

of X (for example $(\mu, (0, \phi_e, 0)) \in Z$). By Whyburn's Lemma (see [W]) there exist two compact sets V and W, such that $Y \subset V$, $Z \subset W$, $V \cap W = \emptyset$, $V \cup W = X$. This implies that there exists an open set U in $[0, \mu] \times P$, such that $U \supset V \supset Y$, $U \cap W = \emptyset$ and $\partial U \cap S = \emptyset$. Therefore, $i(A(\alpha, \cdot), U_\alpha)$ is well defined for all $\alpha \in [0, \mu]$, and it is constant (with respect to α) by the homotopy invariance principle (see [A, Thm. 11.3]). On the other hand, $i(A(\mu, \cdot), U_\mu) = i(A(\mu, \cdot), (\bar{u}, \bar{v}, 0)) = 0$, since $\mu > \bar{\alpha}$. Therefore, $i(A(0, \cdot), U_0) = 0$. Since $i(A(0, \cdot), (\bar{u}, \bar{v}, 0)) = \pm 1$, it follows that $\tilde{C} \cap \{0\} \times P \neq \emptyset$. Let $(0, (u, v, z)) \in \tilde{C} \cap \{0\} \times P$. If $z \not\equiv 0$, then (3.2) implies that $-\Delta z = -z(\beta u + \gamma v + z)$, in Ω and $z = 0$, on $\partial\Omega$, which contradicts the maximum principle. Hence $z \equiv 0$. Therefore, (u, v) is a solution of (2.1), different from $(\bar{u}, \bar{v})$. So, at least one of the components must be zero. It cannot be v, since $\tilde{C}$ is a continuum and positive v-components are bounded away from zero. So, $u \equiv 0$, and $v = \phi_e$. Since $\tilde{C} \cap \{0\} \times P = \{(0, (0, \phi_e, 0))\}$, $\tilde{C}$ must contain the whole unbounded continuum $\{(\alpha, (0, \phi_e, 0)), \alpha \geqq 0\}$, contrary to the assumption. □

LEMMA 3.8. *Let C be the component of $\tilde{C} \cap [0, a] \times P$ ($\tilde{C} \cap [0, e] \times P$), containing $(\bar{\alpha}, (\bar{u}, \bar{v}, 0))$. Then*

(i) *$u > 0$, $v > 0$, $z > 0$, for all $(\alpha, (u, v, z)) \in C \setminus \{(\bar{\alpha}, (\bar{u}, \bar{v}, 0))\}$;*

(ii) *$C \cap [0, \alpha^*] \times P = \emptyset$;*

(iii) *$C \cap \{\alpha\} \times P \neq \emptyset$, for all $\alpha \in [\bar{\alpha}, a]$, ($[\bar{\alpha}, e]$).*

Proof. Part (i) must hold for some neighborhood of $(\bar{\alpha}, (\bar{u}, \bar{v}, 0))$ in C. Take any $(\alpha, (u, v, z)) \in S$ such that $\alpha \leqq a$ and $u > 0$. Since $-\Delta u = u(a - u - cv - dz) \geqq u(a - u - c(1+f+g)\phi_a - d\phi_\alpha) \geqq u(a - u - [c(1+f+g) + d]\phi_a)$, in Ω and $u = 0$ on $\partial\Omega$, it follows, as in the proof of Lemma 2.2, that

$$u \geqq (1 - [c(1+f+g) + d])\phi_a. \tag{3.10}$$

Assume that (i) does not hold. Then there exists $(\alpha, (u, v, z)) \in C$ such that either $u \equiv 0$, or $v \equiv 0$, or $z \equiv 0$. Assume that $u \equiv 0$. Then (3.10) implies that $u \equiv 0$, for all $(\alpha(u, v, z)) \in C$, since C is a continuum, which is a contradiction. Assume that $v \equiv 0$. Then $v \equiv 0$, for all $(\alpha, (u, v, z)) \in C$, since for positive v, $v > \phi_e$ and C is a continuum. This is, again, a contradiction. If $z \equiv 0$, then $u = \bar{u}$, $v = \bar{v}$ and, therefore $\alpha = \bar{\alpha}$, which proves (i). Part (ii) follows from Lemma 3.2 and (iii) follows from Lemmas 3.3 and 3.7. □

4. Three-species system with e as bifurcation parameter. In this section we assume that all the parameters in (0.1) are fixed positive constants, except for e. Since we follow the approach of the previous section, we try to avoid repetition by omitting or sketching the proofs only. We assume the following:

$$\begin{aligned} &a > \lambda_1, \\ &d, \beta, d\frac{1+\beta}{1+d} < \frac{a-\lambda_1}{a}, \\ &0 < R < 1, \\ &\alpha \in [\alpha_1, \alpha_2] \cap \left(\lambda_1 + \beta a, \frac{a-\lambda_1}{d}\right), \\ &\beta + \gamma(1+f+g) < R, \qquad d + c(1+f+g) < Q. \end{aligned} \tag{4.1}$$

All the constants in (4.1) have been defined in § 2. Let E and P be as in the previous section. Let $\nu = \lambda_1 - 2\alpha/R$. Since Lemma 3.1 holds, the set $T_e \subset P$, defined below, for all $e \in [\nu, \infty)$, contains in its interior all the positive solutions of (0.1):

$$T_e := \{(u, v, z) \in P, u \leqq 2a, v \leqq 2\eta(1+f+g), z \leqq 2\alpha\}, \qquad \eta = \max\{\alpha, a, e\}.$$

Let $p(e)$ be a continuous, nondecreasing function on $[\nu, \infty)$, such that $a-u-cv-dz+p(e)>0$, $e+fu-v+gz+p(e)>0$, $\alpha-\beta u-\gamma v-z+p(e)>0$, for all $(u, v, z)\in T_e$. Define an operator $A(e, \cdot)$ on T_e by (3.3), by writing $p(e)$ instead of $p(\alpha)$. We consider a one-parameter family of fixed-point equations on $T:=\bigcup_{e\geqq\nu}\{e\}\times T_e$:

$$A(e, (u, v, z))=(u, v, z). \tag{4.2}$$

A solution set S of (4.2), defined by $S:=\{(e, (u, v, z))\in T, A(e, (u, v, z))=(u, v, z)\}$, is locally compact.

LEMMA 4.1. *Let (u, v, z) be a solution of* (4.2). *Then $e\geqq\alpha/\gamma$ implies that $z\equiv 0$, and $e\geqq a/c$ implies that $u\equiv 0$.*

Proof. Let (u, v, z) be a solution of (4.2) such that $e\geqq\alpha/\gamma$ and $z>0$. Then $r((-\Delta+p(e))^{-1}(\alpha-\beta u-\gamma v-z+p(e)))=1$. On the other hand, $\alpha-\beta u-\gamma v-z<\alpha-\gamma\phi_e=\gamma(\alpha/\gamma-\phi_e)\leqq\gamma(e-\phi_e)\leqq e-\phi_e$, which implies a contradiction.

If (u, v, z) is a solution of (4.2) such that $e\geqq a/c$ and $u>0$, then $r((-\Delta+p(e))^{-1}(a-u-cv-dz+p(e)))=1$. On the other hand, $a-u-cv-dz<a-c\phi_e=c((a/c)-\phi_e)\leqq c(e-\phi_e)\leqq e-\phi_e$, which implies a contradiction. □

LEMMA 4.2. *Assume that $e\leqq\min\{a, \alpha\}$ and let (u, v, z) be a solution of* (4.2) *such that $u>0$ and $z>0$. Then*

$$z\geqq\left(1-\frac{\beta+\gamma(1+f+g)}{R}\right)\phi_\alpha \quad \textit{and} \quad u\geqq\left(1-\frac{d+c(1+f+g)}{Q}\right)\phi_a.$$

Proof. We argue as in the proof of Lemma 2.2. The main inequalities are

$$\begin{aligned}-\Delta z&=z(\alpha-\beta u-\gamma v-z)\geqq z(\alpha-(\beta+\gamma(1+f+g))\phi_\eta-z)\\&\geqq z(\alpha-((\beta+\gamma(1+f+g))/R)\phi_\alpha-z),\end{aligned}$$

and

$$\begin{aligned}-\Delta u&=u(a-u-cv-dz)>u(a-u-(d+c(1+f+g))\phi_\eta)\\&\geqq u(a-u-((d+c(1+f+g))/Q)\phi_a).\end{aligned}$$

□

Let $(\bar u, \bar z)$ be a unique positive solution of (2.5), guaranteed by Theorem 2.6.

LEMMA 4.3. *There exists a unique $\bar e\in[\nu, \infty)$ such that*

$$r(\bar e):=r((-\Delta+p(\bar e))^{-1}(\bar e+f\bar u+g\bar z+p(\bar e)))=1.$$

Also, $r(e)<1$ for $e<\bar e$, and $r(e)>1$ for $e>\bar e$.

Proof. Let $e=\lambda_1-(f/R+g)\alpha$. Then

$$e+f\bar u+g\bar z<e+f\phi_a+g\phi_\alpha<e+((f/R+g)\phi_\alpha<e+(f/R)+g)\alpha=\lambda_1.$$

Arguing as in Lemma 3.3, we get that $r((-\Delta+p(e))^{-1}(e+f\bar u+g\bar z+p(e)))<1$.

On the other hand, for $e=\lambda_1$ we get that $r((-\Delta+p(e))^{-1}(e+f\bar u+g\bar z+p(e)))>1$. The rest follows as in the proof of Lemma 3.3. □

As in the previous section, we would like to compute the fixed-point index of $A(e, \cdot)$ at the point $(\bar u, 0, \bar z)$, relative to the cone P, as the parameter e is varied. To prove the following, we proceed step by step as in the proof of Lemma 3.5.

LEMMA 4.4. *$i(A(e, \cdot), (\bar u, 0, \bar z))$ is equal to ± 1 if $e<\bar e$, and is equal to zero if $e>\bar e$.*

Let $C_0=\{(e, (\bar u, 0, \bar z)), e\geqq\nu\}$. $C_0\subset S$ is a continuum in S and in $[\nu, \infty)\times P$.

LEMMA 4.5. *$\bar e$ is a bifurcation point for* (4.2) *with respect to C_0. It is the only one.*

Proof. Follow the proof of Lemma 3.6. □

Let $\Sigma=(S\backslash C_0)\cup\{(\bar e, (\bar u, 0, \bar z))\}$. Lemma 4.5 implies that Σ is a closed subset of S.

LEMMA 4.6. *Σ contains an unbounded continuum $\tilde C$ bifurcating from C_0 at $\bar e$.*

Proof. We proceed as in the proof of Lemma 3.7. Let $\tilde C$ be the component of Σ containing $(\bar e, (\bar u, 0, \bar z))$. Assume that $\tilde C$ is bounded. Then there exists $\mu>e$ such that

$\tilde{C} \subset [\nu, \mu] \times P$ and $\tilde{C} \cap \{\mu\} \times P = \emptyset$. Let $X = S \cap [\nu, \mu] \times P$, $Y = \tilde{C} \cup C_0 \cap X$, $Z = S \cap (\{\mu\} \times P \cup \{\nu\} \times P) \setminus Y$. Arguing as in the proof of Lemma 3.7, we can find an open set U in $[\nu, \mu] \times P$ such that $Y \subset U$, $\bar{U} \cap Z = \emptyset$, and $\partial U \cap S = \emptyset$. So, $i(A(e, \cdot), U_e)$ is well defined for all $e \in [\nu, \mu]$ and constant with respect to e. It follows that $i(A(\mu, \cdot), U_\mu) = i(A(\mu, \cdot), (\bar{u}, 0, \bar{z})) = 0$, since $\mu > \bar{e}$. Therefore, $i(A(\nu, \cdot), U_\nu) = 0$. Since $i(A(\nu, \cdot), (\bar{u}, 0, \bar{z})) = \pm 1$, and $U_\nu \cap S = (\tilde{C} \cap \{\nu\} \times P) \cup \{(\nu, (\bar{u}, 0, \bar{z}))\}$, it follows that $\tilde{C} \cap \{\nu\} \times P \neq \emptyset$. Let $(\nu, (u, v, z)) \in \tilde{C} \cap \{\nu\} \times P$. If $v \not\equiv 0$, then $-\Delta v = v(\nu + fu - v + gz) \leqq -v^2$ in Ω, and $v \equiv 0$ on $\partial\Omega$. This contradicts the maximum principle (see [GT]). Since $v \equiv 0$, it follows that (u, z) is a solution of (2.5), and therefore $u \equiv 0$ or $z \equiv 0$. So, $\tilde{C} \cap \{\nu\} \times P$ contains either $(\nu, (0, 0, 0))$, $(\nu, (0, 0, \phi_\alpha))$ or $(\nu, (\phi_a, 0, 0))$. In either case, $\tilde{C}$ must contain a whole unbounded continuum, for example, $\{(e, (0, 0, 0)), e \geqq \nu\}$, contrary to the assumption. □

LEMMA 4.7. *Let C be the component of $\tilde{C} \cap [\nu, \min\{a, \alpha\}] \times P$, containing $\{(\bar{e}, (\bar{u}, 0, \bar{z}))\}$. Then*

(i) *$u > 0$, $v > 0$, $z > 0$ for all $(e, (u, v, z)) \in C \setminus \{(\bar{e}, (\bar{u}, 0, \bar{z}))\}$;*

(ii) *$C \cap \{e\} \times P \neq \emptyset$ for all $e \in (\bar{e}, \min\{a, \alpha\}]$.*

Proof. Part (i) must hold in some neighborhood of $(\bar{e}, (\bar{u}, 0, \bar{z}))$ in C. Lemma 4.2 implies that $u > 0$ and $z > 0$ for all $(e, (u, v, z)) \in C \setminus \{(\bar{e}, (\bar{u}, 0, \bar{z}))\}$. Then $v > 0$, since (u, z) solves (2.5). Part (ii) is obvious. □

Lemmas 4.7 and 3.8 imply the following theorem.

THEOREM 4.8. *Assume that* (3.1) *or* (3.2) *holds. Then there exists a positive solution of* (0.1) *for all $\alpha \in (\bar{\alpha}, \max\{a, e\})$. If* (4.1) *holds instead, the same is true for all $e \in (\bar{e}, \min\{a, \alpha\})$.*

By Lemma 3.3, $\bar{\alpha} \in (\alpha^*, \min\{a, e\})$ and an estimate for $\bar{e}$ is provided by the following remark.

Remark 4.9. Let ω be an eigenfunction of (1.1) associated with λ_1, such that $\|\omega\| = 1$, $\omega > 0$. Define $\kappa := \int_\Omega \omega^3\, dx / \int_\Omega \omega^2\, dx$. The following estimate holds:

$$\bar{e} < \lambda_1[1 - \kappa(a - \lambda_1)(f(Q - d) + g(R - \beta))].$$

Proof. Let $\xi = f(Q - d) + g(R - \beta)$. Then, there exists a unique e such that

$$r((-\Delta + p(e))^{-1}(e + \xi\phi_a + p(e))) = 1. \tag{4.3}$$

We can prove this by arguing as in the proof of Lemma 3.3. Since $e + f\bar{u} + g\bar{z} > e + f(1 - d/Q)\phi_a + g(1 - \beta/R)\phi_\alpha > e + (f(Q - d) + g(R - \beta))\phi_a = e + \xi\phi_a$, it follows that $r((-\Delta + p(e))^{-1}(e + f\bar{u} + g\bar{z} + p(e))) > 1$, and, therefore, that $e > \bar{e}$. Equality (4.3) implies that there exists $\varphi > 0$ such that $-\Delta\varphi = (e + \xi\phi_a)\varphi$, in Ω and $\varphi = 0$, on $\partial\Omega$. Arguing as in the proof of Lemma 1.4, we infer that $0 \leqq \int_\Omega [-\Delta\omega \cdot \omega - \omega^2(e + \xi\phi_a)]\, dx = \int_\Omega [\lambda_1\omega^2 - e\omega^2 - \xi\phi_a\omega^2]\, dx$. Therefore,

$$e \int_\Omega \omega^2\, dx \leqq \lambda_1 \int_\Omega \omega^2\, dx - \xi \int_\Omega \phi_a\omega^2\, dx. \tag{4.4}$$

On the other hand, $\phi_a \geqq \lambda_1(a - \lambda_1)\omega$ (see [CL, pp. 1128–1129]). This and (4.4) imply that

$$e \leqq \lambda_1 - \xi\lambda_1(a - \lambda_1) \int_\Omega \omega^3\, dx \Big/ \int_\Omega \omega^2\, dx.$$

Since $\bar{e} < e$, we get that $\bar{e} < \lambda_1(1 - \xi\kappa(a - \lambda_1))$, from which it follows that $\bar{e}$ is negative, for a big enough. □

CONTACT MAPS AND INDUCED DIFFERENTIAL EQUATIONS*

HENRY HERMES†

Abstract. The goal of this paper is to examine constructive ways of generating solutions of partial differential equations (pde's) by the use of associated ordinary differential equations (ode's). Specifically, the classical method of Cauchy characteristics for first-order pde's is examined from the Cartan geometric viewpoint, i.e., as a method of extension via a contact (or Cauchy-characteristic) vector field on a submanifold determined by the equation in an appropriate jet bundle. Contact vector fields generate *contact transformations*, which are self maps of a jet bundle with induced cotangent space maps preserving the contact structure. *Contact maps*, or immersions, from one jet bundle to another with induced maps carrying contact structures in a specified manner are introduced. Contact transformations transform pde's to pde's; a contact map can induced an ordinary differential equation from a pde. For example, a contact map that induces a sixth-order, linear ode from the classical Burgers' pde is constructed. The final goal is to examine extending Cauchy data for second- or higher-order pde's via nonautonomous "Cauchy vector fields" on the jet bundles of the equations induced by contact maps.

AMS(MOS) subject classifications. 35A30, 58G37

Introduction. Our goal is to consider constructive ways of obtaining solutions of partial differential equations (pde's) by use of associated ordinary differential equations (ode's). The usual method of solving an initial value problem for a first-order pde is to extend the data along Cauchy characteristics, i.e., via the flow of a "Cauchy characteristic vector field" on the appropriate jet bundle associated with the equation. For a first-order equation, such a vector field can be explicitly constructed and will locally extend any (noncharacteristic) initial data to a solution. It is known that Cauchy characteristic vector fields do not exist on the jet bundles associated with pde's of order 2 or more. Our goal is to extend initial data for such equations via the flows arising from nonautonomous ode's on the associated jet bundle.

To be more specific, let $x=(x_1, x_2)\in\mathbb{R}^2$, $u^{(1)}=(u, u_{x_1}, u_{x_2})$ and $(x, u^{(1)})$ denote local coordinates on the jet bundle $J^1(\mathbb{R}^2, \mathbb{R}^1)$. Consider a first-order pde $\Delta(x, u^{(1)})=0$, i.e., $\Delta: J^1(\mathbb{R}^2, \mathbb{R}^1)\to\mathbb{R}^1$, and let M_Δ denote the manifold on which $\Delta=0$. Typical Cauchy data would be to prescribe a map $t\to x(t)\in\mathbb{R}^2$ and data $u(x(t))=u_0(t)$, $\partial u(x(t))/\partial x_1=p_1(t)$, $\partial u(x(t))/\partial x_2=p_2(t)$ where the compatibility conditions $u_0'(t)=p_1(t)x_1'(t)+p_2(t)x_2'(t)$ and $\Delta(x(t), u_0(t), p_1(t), p_2(t))=0$ must hold. In classical language this was expressed by calling $t\to v(t)=(x_1(t), x_2(t), u_0(t), p_1(t), p_2(t))\in M_\Delta$ an *initial strip*; in modern language v is called a *one-graph* in M_Δ. Geometrically, we picture v as defining a one-dimensional section of M_Δ. A parametric representation of a solution is obtained by extending the one-graph $t\to v(t)$ via the flow of Cauchy characteristics. Specifically, we construct a vector field V on $J^1(\mathbb{R}^2, \mathbb{R}^1)$, tangent to M_Δ, and with solution through q denoted $(\exp sV)(q)$, such that $\bar{v}(t, s)=(\exp sV)(v(t))$ is a one-graph giving a two-dimensional section of M_Δ from which the solution is obtained. In general, this geometric method of Cartan no longer works for higher-order equations $\Delta: J^k(\mathbb{R}^m, \mathbb{R}^1)\to\mathbb{R}^1$, $k\geqq 2$.

Section 1 introduces notation and summarizes basic results on k-graphs, contact transformations, and Cartan's geometrical viewpont of pde's. Section 2 introduces contact maps and their induced equations. Briefly, a kth-order pde in m independent variables, denoted $\Delta(x, u^{(k)}) = 0$, will be viewed as defining a submanifold M_Δ in the jet bundle $J^k(\mathbb{R}^m, \mathbb{R}^1)$. A contact transformation F is a self-diffeomorphism of $J^k(\mathbb{R}^m, \mathbb{R}^1)$ with induced cotangent space map F^* preserving the contact structure (i.e., if $\Omega^k(\mathbb{R}^m, \mathbb{R}^1)$ denotes the module of contact forms on $J^k(\mathbb{R}^m, \mathbb{R}^1)$, then $F^*\Omega^k = \Omega^k$). Form $F(M_\Delta)$, a new submanifold that may be viewed as defining an induced equation. Solutions of the latter are related to solutions of the former via F^{-1}. Example 1.3 will illustrate this classical use of contact transformations. A *contact map* F will be an immersion of one jet bundle $J^k(\mathbb{R}^m, \mathbb{R}^1)$ to another, say $J^l(\mathbb{R}^p, \mathbb{R}^q)$, $p \leqq m$, such that $F^*\Omega^l(\mathbb{R}^p, \mathbb{R}^q) \supset \Omega^k(\mathbb{R}^m, \mathbb{R}^1)$. Again, $F(M_\Delta)$ gives an induced equation, in particular, if $p = 1$ this will be an induced ordinary differential equation. If ψ is a solution of the induced equation, then F^{-1} of the graph of the lth prolongation of ψ (i.e., $\mathrm{pr}^{(l)}\,\psi$) gives a p-section (denote it $t \to v(t)$) of M_Δ, which is a k-graph. Thus there exist maps $x : \mathbb{R}^p \to \mathbb{R}^m$ and $w : \mathbb{R}^m \to \mathbb{R}^1$ such that $v(t) = (x(t), \mathrm{pr}^{(k)}\, w(x(t)))$ and $\Delta(x(t), \mathrm{pr}^{(k)}\, w(x(t))) = 0$. In this sense, w satisfies the pde Δ along the curve (submanifold) $t \to x(t)$. If $p = m-1$, i.e., $t = (t_1, \cdots, t_{m-1})$, then $t \to v(t)$ is a k-graph in M_Δ with image an $(m-1)$-dimensional section, and hence serves as Cauchy data for the pde $\Delta = 0$. The theory, to here, is illustrated by Example 2.2, which is Burgers' equation having $M_\Delta \subset J^2(\mathbb{R}^2, \mathbb{R}^1)$. We give a contact map $F : J^2(\mathbb{R}^2, \mathbb{R}^1) \to J^6(\mathbb{R}^1, \mathbb{R}^1)$ such that the induced equation is a linear, sixth-order, ordinary differential equation. Solutions of this linear ode readily provide appropriate Cauchy data for the pde.

Next, Theorem 1 gives conditions that, when satisfied, yield a vector field whose flow (when transverse) extends *any* k-graph $v : \mathbb{R}^q \to M_\Delta \subset J^k(\mathbb{R}^m, \mathbb{R}^n)$ to a k-graph $\bar{v} : \mathbb{R}^{q+1} \to M_\Delta$. As mentioned, if $k = 1$, this is classical, the vector field V is a contact vector field, indeed the Cauchy characteristic vector field. This is illustrated in Example 2.4. In general, the conditions of Theorem 1 cannot be satisfied for $k \geqq 2$. In § 3 we consider extensions via the flow of nonautonomous ode's. In particular, we consider the case $k = 2$ and a specific contact map $F : J^2(\mathbb{R}^2, \mathbb{R}^1) \to J^6(\mathbb{R}^1, \mathbb{R}^1)$. Here the induced equation associated with any second-order pde $\Delta : J^2(\mathbb{R}^2, \mathbb{R}^1) \to \mathbb{R}^1$ will be (in general) a sixth-order ode. We choose to do the extension in the jet bundle of the induced equation. If $\tau \to v(\tau) \in M_\Delta$ is a two-graph in $J^2(\mathbb{R}^2, \mathbb{R}^1)$ and $\gamma(\tau) = F \circ v(\tau)$, Theorem 2 gives conditions that, when satisfied, lead to a system of ode's on $J^6(\mathbb{R}^1, \mathbb{R}^1)$ such that their solution, denoted $s \to \phi(s, q)$, $\phi(0, q) = q$, satisfies $F^{-1} \circ \phi(s, \gamma(\tau))$ is a two-graph in M_Δ, which yields a parametric solution to the equation $\Delta = 0$ with initial data given by v.

Recent results in higher symmetries, conservation laws, and the Hamiltonian structure of partial differential equations have led to a rebirth and extension (in modern terminology) of the methods of Lie, Cartan [7], [5], and Vessiot [6]. These methods have also been instrumental in certain aspects of control theory [2], [3]. The rapid expansion of this subject has made much of the literature inaccessible to the non-specialist. Our goal here is to make the exposition as self-contained as possible (at the expense of generality) and to stress specific examples. Our notation is consistent with that in [5]. Certainly, a large part of this paper may be regarded as expository.

1. Graph maps and contact transformations. Local coordinates for a jet bundle $J^k(\mathbb{R}^m, \mathbb{R}^1)$ will be written as $(x, u^{(k)})$ where $x = (x_1, \cdots, x_m)$ and $u^{(k)} = (u, u_{x_1}, \cdots, u_{x_m}, u_{x_1x_1}, \cdots)$, i.e., subscripts to represent all partial derivatives through order k. As a specific example, local coordinates for $J^2(\mathbb{R}^2, \mathbb{R}^1)$ are $(x, u^{(2)}) =$

$(x_1, x_2, u, u_{x_1}, u_{x_2}, u_{x_1x_1}, u_{x_1x_2}, u_{x_2x_2})$. If $w:\mathbb{R}^m \to \mathbb{R}^1$ its kth prolongation, denoted $\mathrm{pr}^{(k)}w$, is defined as

$$\mathrm{pr}^{(k)}\, w(x) = (w(x), w_{x_1}(x), \cdots, w_{x_1x_1}(x), \cdots),$$

where here subscripts denote actual partial derivatives, and all partial derivatives through order k appear.

Given a differential equation $\Delta(x, u^{(k)}) = 0$, $x \in \mathbb{R}^m$, we consider $\Delta: J^k(\mathbb{R}^m, \mathbb{R}^1) \to \mathbb{R}^1$ and if this map has Jacobian of rank 1, then

$$M_\Delta = \{(x, u^{(k)}) \in J^k(\mathbb{R}^m, \mathbb{R}^1): \Delta(x, u^{(k)}) = 0\}$$

is a submanifold of codimension 1 in $J^k(\mathbb{R}^m, \mathbb{R}^1)$.

Example 1.1 (Burgers' equation).

$$\Delta(x, u^{(2)}) = u_{x_1} - uu_{x_2} - u_{x_2x_2}. \tag{1.1}$$

Here M_Δ is a seven-dimensional manifold in the eight-dimensional $J^2(\mathbb{R}^2, \mathbb{R}^1)$. A necessary and sufficient condition that a smooth function $w:\mathbb{R}^2 \to \mathbb{R}^1$ be a solution of $\Delta = 0$ is that the graph of $\mathrm{pr}^{(2)}\, w$ lies in M_Δ, i.e., $x \to (x, \mathrm{pr}^{(2)}\, w(x)) = (i, \mathrm{pr}^{(2)}\, w)(x) \in M_\Delta$. On the other hand, if $x \to (i, y)(x) = (x_1, x_2, y_1(x), \cdots, y_6(x)) \in M_\Delta$ we certainly cannot conclude that y_1 is a solution of $\Delta = 0$. Indeed, $x \to (i, y)(x) = (x_1, x_2, x_1^2 + x_2, 2x_1 + x_2, 1, 2, 0, 2x_1 - x_1^2) \in M_\Delta$ but clearly $y(x) \neq \mathrm{pr}^{(2)}\, w(x)$ for any $w:\mathbb{R}^2 \to \mathbb{R}^1$ since $\partial y_1(x)/\partial x_1 \neq y_2(x)$ as is necessary.

DEFINITION. For $p \leq m$, a map $v:\mathbb{R}^p \to J^k(\mathbb{R}^m, \mathbb{R}^1)$ is a *k-graph* if there exist maps $x:\mathbb{R}^p \to \mathbb{R}^m$, $w:\mathbb{R}^m \to \mathbb{R}^1$ such that $v(s) = (x(s), \mathrm{pr}^{(k)}\, w(x(s)))$, $s \in \mathbb{R}^p$. If x is an immersion, the image of v gives (locally) a p-dimensional section of $J^k(\mathbb{R}^m, \mathbb{R}^1)$.

Remark 1.1. The terminology k-graph stems from the standard case where $v:\mathbb{R}^m \to J^k(\mathbb{R}^m, \mathbb{R}^1)$ has the form $v(x) = (x, y(x)) = (i, y)(x)$ with the values $y(x)$ in the fibre above x. Here the image of v is the graph of y, and it is traditional to call y a k-graph if there exist $w:\mathbb{R}^m \to \mathbb{R}^1$ such that $y(x) = \mathrm{pr}^{(k)}\, w(x)$. This would be the nonparametric case: the above definition includes both the parametric case and a domain $\mathbb{R}^p$ with $p \leqq m$.

The conditions that partial derivatives match correctly in order that $v:\mathbb{R}^p \to J^k(\mathbb{R}^m, \mathbb{R}^1)$ be a k-graph are encoded in the module of contact forms, denoted $\Omega^k(\mathbb{R}^m, \mathbb{R}^1)$, on $j^k(\mathbb{R}^m, \mathbb{R}^1)$.

Example 1.2. The contact module $\Omega^2(\mathbb{R}^2, \mathbb{R}^1)$ is the module generated by the three one-forms:

$$\omega^1 = u_{x_1}\, dx_1 + u_{x_2}\, dx_2 - du, \qquad \omega^2 = u_{x_1x_1}\, dx_1 + u_{x_1x_2}\, dx_2 - du_{x_1},$$
$$\omega^3 = u_{x_1x_2}\, dx_1 + u_{x_2x_2}\, dx_2 - du_{x_2}$$

over the ring of smooth, real-valued, functions on $J^2(\mathbb{R}^2, \mathbb{R}^1)$.

PROPOSITION 1.1 (Gardner [1, Prop. 2.4]). *Let π denote projection of $J^k(\mathbb{R}^m, \mathbb{R}^1)$ onto $\mathbb{R}^m$, $p \leqq m$ and $v:\mathbb{R}^p \to J^k(\mathbb{R}^m, \mathbb{R}^1)$ be such that $\pi \circ v:\mathbb{R}^p \to \mathbb{R}^m$ is an immersion. Then a necessary and sufficient condition that v be a k-graph (locally) is that $v^*\Omega^k(\mathbb{R}^m, \mathbb{R}^1) = \{0\}$.*

The proof is exactly as that given by Gardner in [1] where he considered $v:\mathbb{R}^m \to J^k(\mathbb{R}^m, \mathbb{R}^1)$ with $\pi \circ v$ a diffeomorphism. This was used only to ensure that $\pi \circ v$ is locally one-to-one, hence his proof suffices for Proposition 1.1 as stated above.

Remark 1.2. In the nonparametric case where $v:\mathbb{R}^m \to J^k(\mathbb{R}^m, \mathbb{R}^1)$ has the form $v(x) = (i, y)(x)$ with $y(x)$ in the fibre above x, we have $\pi \circ v(x) = x$, i.e., the condition $\pi \circ v$, an immersion, is automatic.

In summary, and for convenience for later reference, we now have Proposition 1.2.

PROPOSITION 1.2. *Let $\Delta: J^k(\mathbb{R}^m, \mathbb{R}^1) \to \mathbb{R}^1$ be a given differential equation with Jacobian of rank 1 so M_Δ is well defined. If $v:\mathbb{R}^p \to M_\Delta \subset J^k(\mathbb{R}^m\mathbb{R}^1)$, $p \leqq m$, is such that*

$\pi \circ v$ is an immersion and $v^*\Omega^k(\mathbb{R}^m, \mathbb{R}^1) = \{0\}$, then there exist maps $x: \mathbb{R}^p \to \mathbb{R}^m$, $w: \mathbb{R}^m \to \mathbb{R}^1$ such that for $t \in \mathbb{R}^p$ (locally),

(a) $v(t) = (x(t), \operatorname{pr}^{(k)} w(x(t)))$.

(b) $\Delta(x(t), \operatorname{pr}^{(k)} w(x(t))) = 0$.

DEFINITION. A local diffeomorphism $F: J^k(\mathbb{R}^m, \mathbb{R}^1) \to J^k(\mathbb{R}^m, \mathbb{R}^1)$ is a *contact transformation* if F maps k-graphs into k-graphs, or equivalently, if its induced map on the cotangent bundle preserves the contact structure, i.e., $F^*\Omega^k(\mathbb{R}^m, \mathbb{R}^1) \subset \Omega^k(\mathbb{R}^m, \mathbb{R}^1)$.

Next we give a classical use of a contact transformation to "linearize" a nonlinear differential equation. The example is meant to motivate the concept of contact map and induced equation, which will follow.

Example 1.3. Consider $F: J^1(\mathbb{R}^1, \mathbb{R}^1) \to J^1(\mathbb{R}^1, \mathbb{R}^1)$ with (x, y, y') local coordinates in the domain and $(t, \sigma, \dot{\sigma})$ local coordinates in the range. Specifically, $t = F_1(x, y, y') = y'$, $\sigma = F_2(x, y, y') = y - xy'$, and $\dot{\sigma} = F_3(x, y, y') = -x$. Then F is a contact transformation (the Legendre transformation). To verify, $\Omega^1(\mathbb{R}^1, \mathbb{R}^1)$ is generated by $\omega(t, \sigma, \dot{\sigma}) = \dot{\sigma}dt - d\sigma$, hence (in local coordinates) $\omega(F^{-1}(t, \sigma, \dot{\sigma})) = (-x, -1, 0)$ and $F^*\omega = (-x, -1, 0)(\partial(F_1, F_2, F_3)/\partial(x, y, y')) = (y', -1, 0) = \omega(x, y, y')$ as required.

Next, consider the differential equation

$$\Delta(x, y, y') = x + \sum_{i=1}^{5} c_i (y')^i$$

where $c_1, \cdots, c_5$ are arbitrary constants. Here M_Δ is a two-manifold in $J^1(\mathbb{R}^1, \mathbb{R}^1)$, as is $F(M_\Delta)$. Indeed, the induced (or transformed) equation is

$$\tilde{\Delta}(t, \sigma, \dot{\sigma}) = -\dot{\sigma} + \sum_{i=1}^{5} c_i t^i$$

and $F(M_\Delta) = \{(t, \sigma, \dot{\sigma}): \tilde{\Delta} = 0\}$. Here, the induced equation is trivially integrated, i.e., $\psi(t) = k + \sum_{i=1}^{5} c_i t^{i+1}/(i+1)$ is its general solution. Then $t \to (i, \operatorname{pr}^{(1)} \psi)(t) \in F(M_\Delta)$ is a one-graph in $J^1(\mathbb{R}^1, \mathbb{R}^1)$. Its preimage $t \to v(t) = F^{-1}(t, \psi(t), \dot{\psi}(t)) = (-\dot{\psi}(t)), \psi(t) - t\dot{\psi}(t), t)$ is a one-section of M_Δ, which is a one-graph. Proposition 1.2 applies when $\dot{\psi}(t) \neq 0$, in which case we have the parametric representation of a solution of $\Delta = 0$ given by $x(t) = -\dot{\psi}(t)$, $y(t) = \psi(t) - t\dot{\psi}(t)$. Furthermore, with $t \to x(t)$ as above, Proposition 1.2 not only assures the existence of the nonparametric solution $w: \mathbb{R}^1 \to \mathbb{R}^1$ (in general difficult to find) but also gives the information that $w(x(t)) = \psi(t) - t\dot{\psi}(t)$, $w'(x(t)) = t$.

Remark 1.3. A coordinate change in $\mathbb{R}^m$ induces a contact transformation on $J^k(\mathbb{R}^m, \mathbb{R}^1)$ and, more generally, any self-diffeomorphism of $\mathbb{R}^m \times \mathbb{R}^1$ induces, by prolongation, a contact transformation of $J^k(\mathbb{R}^m, \mathbb{R}^1)$. (See [5] for the explicit construction.) Furthermore, a result of Bäcklund shows every contact transformation of $J^k(\mathbb{R}^m, \mathbb{R}^n)$ with $n \geqq 2$ is of this form, i.e., a prolongation of a self-diffeomorphism of $\mathbb{R}^m \times \mathbb{R}^n$ (see [7]). Two partial differential equations that can be transformed into each other via a local coordinate change in the underlying space should certainly be considered equivalent. A broader equivalence is that provided by the group of contact transformations in the appropriate jet bundle, a classification problem studied by Lie at the turn of the century.

2. Contact maps. Contact transformations are self-maps of a jet bundle, whereas contact maps may be from one jet bundle to another.

DEFINITION. An immersion $F: J^k(\mathbb{R}^m, \mathbb{R}^n) \to J^l(\mathbb{R}^p, \mathbb{R}^q)$ is a *contact map* if $F^*\Omega^l(\mathbb{R}^p, \mathbb{R}^q) \supset \Omega^k(\mathbb{R}^m, \mathbb{R}^n)$.

The motivation is as follows. Given a differential equation Δ with $M_\Delta \subset J^k(\mathbb{R}^m, \mathbb{R}^n)$ and contact map $F: J^k(\mathbb{R}^m, \mathbb{R}^n) \to J^l(\mathbb{R}^p, \mathbb{R}^q)$ we again have an induced equation

described by $F(M_\Delta)$. Suppose ψ is a solution of this induced equation, i.e., $t \to (i, \mathrm{pr}^{(l)}\psi)(t) \in F(M_\Delta)$. Let $v(t) = F^{-1}((i, \mathrm{pr}^{(l)}\psi)(t))$; so (locally) $t \to v(t) \in M_\Delta$ is a p-section of M_Δ. Then $(i, \mathrm{pr}^{(l)}\psi) = F \circ v$ and since $t \to (i, \mathrm{pr}^{(l)}\psi)(t)$ is an l-graph, $\{0\} = (i, \mathrm{pr}^{(l)}\psi)^*\Omega^l(\mathbb{R}^p, \mathbb{R}^q) = v^*F^*\Omega^l(\mathbb{R}^p, \mathbb{R}^q)$. But $F^*\Omega^l(\mathbb{R}^p, \mathbb{R}^q) \supset \Omega^k(\mathbb{R}^m, \mathbb{R}^n)$, hence $v^*\Omega^k = \{0\}$, i.e., $t \to v(t)$ is a k-graph in M_Δ to which we can, in general, apply Proposition 1.2.

The major portion of this section will deal with specific examples. Methods for the construction of contact transformations are well known, [7, §§ 2.3, 2.4]. No similar general results are known (at this time) for contact maps.

Our first goal is to construct a contact map $F: J^2(\mathbb{R}^2, \mathbb{R}^1) \to J^6(\mathbb{R}^1, \mathbb{R}^1)$, both jet bundles of dimension 8. When accomplished, the induced equation associated with *any* second-order pde in two independent variables, will be a sixth-order ode. The particular contact map we will exhibit is constructed to have a linear induced equation associated to the Burgers equation.

The generators of $\Omega^2(\mathbb{R}^2, \mathbb{R}^1)$, denoted ω^1, ω^2, ω^3, are exhibited in Example 1.2. Choose local coordinates for $J^6(\mathbb{R}^1, \mathbb{R}^1)$ as $(t, \sigma, \sigma^{(1)}, \sigma^{(2)}, \sigma^{(3)}, \sigma^{(4)}, \sigma^{(5)}, \sigma^{(6)})$. Then generators of $\Omega^6(\mathbb{R}^1, \mathbb{R}^1)$ are:

$$\nu^1 = \sigma^{(1)}\,dt - d\sigma, \qquad \nu^2 = \sigma^{(2)}\,dt - d\sigma^{(1)},$$
$$\nu^3 = \sigma^{(3)}\,dt - d\sigma^{(2)}, \qquad \nu^4 = \sigma^{(4)}\,dt - d\sigma^{(3)},$$
$$\nu^5 = \sigma^{(5)}\,dt - s\sigma^{(4)}, \qquad \nu^6 = \sigma^{(6)}\,dt - d\sigma^{(5)}.$$

A direct attempt to find F such that $F^*\Omega^6 \supset \Omega^2$ leads to an extremely complicated set of partial differential equations for the components of F, aggravated by the fact that Ω^2 has three generators "to be covered." The construction is more tractable in the dual setting.

For X a vector field, say on $J^k(\mathbb{R}^m, \mathbb{R}^n)$, and ω a one-form, let $\langle \omega, X \rangle$ denote the standard, bilinear pairing of the cotangent bundle $T^*J^k(\mathbb{R}^m, \mathbb{R}^n)$ and tangent bundle $TJ^k(\mathbb{R}^m, \mathbb{R}^n)$. Dual to $\Omega^k(\mathbb{R}^m, \mathbb{R}^n)$ is a distribution (or module) sometimes called the Vesiot distribution:

$$\Lambda^k(\mathbb{R}^m, \mathbb{R}^n) = \{X \in TJ^k(\mathbb{R}^m, \mathbb{R}^n) \colon \langle \omega, X \rangle = 0, \qquad \omega \in \Omega^k(\mathbb{R}^m, \mathbb{R}^n)\}.$$

As before, F^* denotes an induced cotangent space map, whereas F_* will denote the induced tangent space map.

PROPOSITION 2.1. *Let $F: J^2(\mathbb{R}^2, \mathbb{R}^1) \to J^6(\mathbb{R}^1, \mathbb{R}^1)$ be an immersion and restrict attention to a neighborhood where F is one-to-one. Then $\Omega^2(\mathbb{R}^2, \mathbb{R}^1) \subset F^*\Omega^6(\mathbb{R}^1, \mathbb{R}^1)$ if and only if $\Lambda^6(\mathbb{R}^1, \mathbb{R}^1) \subset F_*\Lambda^2(\mathbb{R}^2, \mathbb{R}^1)$.*

Proof. (a) Suppose $\Omega^2 \subset F^*\Omega^6$ but $\Lambda^6 \not\subset F_*\Lambda^2$. Then there exist $X \in \Lambda^6$ and a one-form ν such that (i) $\langle \nu, X \rangle = 0$, and (ii) $\langle \nu, F_*\Lambda^2 \rangle = \{0\}$. But (i) implies $\nu \notin \Omega^6$, whereas (ii) yields $\langle F_*\nu, \Lambda^2 \rangle = \{0\}$ or $F^*\nu \in \Omega^2$. But F^* is one-to-one, hence $\nu \in \Omega^6$, a contradiction.

(b) Suppose $\Lambda^6 \subset F_*\Lambda^2$ but $\Omega^2 \not\subset F^*\Omega^6$. Then there exist $\omega \in \Omega^2$ and a vector field Y such that (i) $\langle \omega, Y \rangle \neq 0$, and (ii) $\langle F^*\Omega^6, Y \rangle = \{0\}$. But (ii) implies that $F_*Y \in \Lambda^6$ or $Y \in \Lambda^2$, which means $\langle \omega, Y \rangle = 0$ contradicting (i). □

As mentioned, the advantage of the use of Proposition 2.1 in our case is one of dimension, i.e., $\Lambda^6(\mathbb{R}^1, \mathbb{R}^1)$ has only two generators, specifically,

$$X^1 = \frac{\partial}{\partial x_1} + u\frac{\partial}{\partial x_2} + u_{x_1}\frac{\partial}{\partial u} + u_{x_2}\frac{\partial}{\partial u_{x_1}} + u_{x_1x_1}\frac{\partial}{\partial u_{x_2}} + u_{x_1x_2}\frac{\partial}{\partial u_{x_1x_1}} + u_{x_2x_2}\frac{\partial}{\partial u_{x_1x_2}},$$

$$X^2 = \frac{\partial}{\partial u_{x_2x_2}}.$$

The generators of $\Lambda^2(\mathbb{R}^2, \mathbb{R}^1)$ are

$$Y^1 = \frac{\partial}{\partial \sigma^{(4)}}, \quad Y^2 = \frac{\partial}{\partial \sigma^{(5)}}, \quad Y^3 = \frac{\partial}{\partial \sigma^{(6)}},$$

$$Y^4 = \frac{\partial}{\partial t} + \sigma^{(2)} \frac{\partial}{\partial \sigma^{(1)}} + \sigma^{(4)} \frac{\partial}{\partial \sigma^{(2)}} + \sigma^{(5)} \frac{\partial}{\partial \sigma^{(3)}},$$

$$Y^5 = \frac{\partial}{\partial \sigma} + \sigma^{(3)} \frac{\partial}{\partial \sigma^{(1)}} + \sigma^{(5)} \frac{\partial}{\partial \sigma^{(2)}} + \sigma^{(6)} \frac{\partial}{\partial \sigma^{(3)}}.$$

We seek a local diffeomorphism $F: J^2(\mathbb{R}^2, \mathbb{R}^1) \to J^6(\mathbb{R}^1, \mathbb{R}^1)$ such that for smooth functions $\alpha_1, \cdots, \alpha_5$ and $\beta_1, \cdots, \beta_5$

$$\sum_{i=1}^{5} \alpha_i F_* Y^i = X^1, \qquad \sum_{i=1}^{5} \beta_i F_* Y^i = X^2. \tag{2.1}$$

We next give a solution to (2.1).

Example 2.1. *A contact map* $F: J^2(\mathbb{R}^2, \mathbb{R}^1) \to J^6(\mathbb{R}^1, \mathbb{R}^1)$.

$$\begin{aligned} &t = F_1(x, u^{(2)}) = x_1, \quad \sigma = F_2 = -x_2, \quad \sigma^{(1)} = F_3 = u, \quad \sigma^{(2)} = F_4 = u_{x_1} - uu_{x_2}, \\ &\sigma^{(3)} = F_5 = u_{x_1x_1} - u_{x_1}u_{x_2} + uu_{x_2}^2 - 2uu_{x_1x_2} + u^2 u_{x_2x_2}, \\ &\sigma^{(4)} = F_6 = u_{x_2}, \quad \sigma^{(5)} = F_7 = u_{x_1x_2} - uu_{x_2x_2}, \quad \sigma^{(6)} = F_8 = u_{x_2x_2}. \end{aligned} \tag{2.2}$$

For completeness, the (irrelevant) values α_i, β_i needed to verify that (2.1) holds are

$$\begin{aligned} \alpha_1 &= -(u_{x_2}^2 - 2u_{x_1x_2} + 2uu_{x_2x_2})(u_{x_1} - uu_{x_2}) - u_{x_2}(u_{x_1x_1} - uu_{x_1x_2}) \\ &\quad + (u_{x_1} - 2uu_{x_2})(u_{x_1x_2} - uu_{x_2x_2}) + 2uu_{x_2x_2} + 2uu_{x_1}u_{x_2x_2} - 2u^2u_{x_2}u_{x_2x_2} + u_{x_2}, \\ \alpha_2 &= u_{x_1}u_{x_2x_2} - uu_{x_2}u_{x_2x_2} + u_{x_2x_2}, \quad \alpha_3 = 0, \quad \alpha_4 = 1, \quad \alpha_5 = u, \\ \beta_1 &= u^2, \quad \beta_2 = u, \quad \beta_3 = 1, \quad \beta_4 = 0, \quad \beta_5 = 0. \end{aligned}$$

$F^{-1}: J^6(\mathbb{R}^1, \mathbb{R}^1) \to J^6(\mathbb{R}^2, \mathbb{R}^1)$ is, locally,

$$\begin{aligned} &x_1 = t, \quad x_2 = -\sigma, \quad u = \sigma^{(1)}, \quad u_{x_1} = \sigma^{(2)} + \sigma^{(1)}\sigma^{(4)}, \quad u_{x_2} = \sigma^{(4)}, \\ &u_{x_1x_1} = \sigma^{(3)} + \sigma^{(4)}\sigma^{(2)} + 2\sigma^{(1)}\sigma^{(5)} - 1(\sigma^{(1)})^2\sigma^{(6)}, \\ &u_{x_1x_2} = \sigma^{(5)} + \sigma^{(6)}, \qquad u_{x_2x_2} = \sigma^{(6)}. \end{aligned} \tag{2.3}$$

Example 2.2 (Application of F, as above, to Burgers' equation). With $\Delta(x, u^{(2)}) = u_{x_1} - uu_{x_2} - u_{x_2x_2}$ the induced equation (using (2.2)) is

$$\sigma^{(6)}(t) - \sigma^{(2)}(t) = 0. \tag{2.4}$$

We may readily write a basis for the solution space of the linear induced equation. If ψ denotes any solution

$$t \to v(t) = F^{-1}((i, \operatorname{pr}^{(6)} \psi)(t)) \tag{2.5}$$

is a two-graph in M_Δ. Using F^{-1}, computing shows that $\pi \circ v(t) = (t, -\psi(t))$ and this gives an immersion in $\mathbb{R}^2$, hence Proposition 1.2 applies. In particular, we know that the map $x: \mathbb{R}^1 \to \mathbb{R}^2$ is $(x(t)) = (t, -\psi(t))$ and there exists $w: \mathbb{R}^2 \to \mathbb{R}^2$ such that $\Delta(x(t), \operatorname{pr}^{(2)} w(x(t))) = 0$. While w may be difficult to find, from F^{-1} and (2.5) we do know that $w(x(t)) = \psi^{(1)}(t)$, $w_{x_1}(x(t)) = \psi^{(2)}(t) + \psi^{(1)}(t)\psi^{(4)}(t)$, etc. In short, for any solution ψ of the induced equation (2.4), $v(t)$ as given in (2.5) defines appropriate "Cauchy data" for an initial value problem for the Burgers equation.

Example 2.3. *A contact map* $F: J^1(\mathbb{R}^2, \mathbb{R}^1) \to J^3(\mathbb{R}^1, \mathbb{R}^1)$. Choose $(x, u^{(1)}) = (x_1, x_2, u, u_{x_1}, u_{x_2})$ as local coordinates for $J^1(\mathbb{R}^2, \mathbb{R}^1)$ and $(t, \sigma, \sigma', \sigma'', \sigma''')$ as local coordinates for $J^3(\mathbb{R}^1, \mathbb{R}^1)$. Then $\Omega^1(\mathbb{R}^2, \mathbb{R}^1)$ is generated by $\omega = u_{x_1}\, dx_1 + u_{x_2}\, dx_2 - du$, whereas $\Omega^3(\mathbb{R}^1, \mathbb{R}^1)$ has $\nu^1 = \sigma' dt - d\sigma$, $\nu^2 = \sigma'' dt - d\sigma'$, $\nu^3 = \sigma''' dt - d\sigma''$ as generators. Since $\Omega^1(\mathbb{R}^2, \mathbb{R}^1)$ has but one generator, Proposition 2.1 should not be used, i.e., we proceed directly to seeking a map F and smooth functions α_1, α_2, α_3 such that $\omega = \sum_1^3 \alpha_i F^* \nu^i = F^*(\sum_1^3 \alpha_i \nu^i)$. Explicitly, if the components of F are denoted as $F_i(x, u^{(1)})$, then we require (in coordinate form)

$$\begin{aligned} &(\alpha_1 F_3 + \alpha_2 F_4 + \alpha_3 F_5, -\alpha_1, -\alpha_2, -\alpha_2, -\alpha_3, 0) \\ &\qquad (\partial(F_1, \cdots, F_5)/\partial(x, u^{(1)})) = (u_{x_1}, u_{x_2}, -1, 0, 0). \end{aligned} \tag{2.6}$$

A solution of (2.6) is

$$\begin{aligned} &t = F_1(x, u^{(1)}) = x_1, \quad \sigma = F_2 = x_2, \quad \sigma' = F_3 = u + u_{x_2}, \\ &\sigma'' = F_4 = -u_{x_2}, \qquad \sigma''' = F_5 = u_{x_1} + u_{x_2} + u u_{x_2} + u_{x_2}^2. \end{aligned} \tag{2.7}$$

The corresponding (irrelevant) values of the coefficient functions in (2.6) are $\alpha_1 = -u_{x_2}$, $\alpha_2 = \alpha_3 = 1$. An easy calculation gives F^{-1} as

$$x_1 = t, \quad x_2 = \sigma, \quad u = \sigma' + \sigma'', \quad u_{x_1} = \sigma''' + \sigma'' + \sigma'\sigma'', \quad u_{x_2} = -\sigma''. \tag{2.8}$$

We next address the problem of extending a k-graph $v: \mathbb{R}^p \to J^k(\mathbb{R}^m, \mathbb{R}^n)$, $p < m$, to a k-graph $\bar{v}: \mathbb{R}^m \to J^k(\mathbb{R}^m, \mathbb{R}^n)$, with the requirement that if the graph of v is in M_Δ, then this also is true for the graph of $\bar{v}$.

Extensions of *k*-graphs. For V a vector field on $J^k(\mathbb{R}^m, \mathbb{R}^n)$ we denote its flow map at time s, initiating from initial data q at $s = 0$, by $(\exp sV)(q)$ and for fixed s, let $(\exp sV): J^k(\mathbb{R}^m, \mathbb{R}^n) \to J^k(\mathbb{R}^m, \mathbb{R}^n)$ denote the flow-induced diffeomorphism. If ω is a one-form, $L_V\omega$ denotes its Lie derivative with respect to V. For generality, we now consider a system of several, say r, kth-order partial differential equations in m independent and n dependent variables, i.e., $\Delta = (\Delta_1, \cdots, \Delta_r): J^k(\mathbb{R}^m, \mathbb{R}^n) \to \mathbb{R}^r$.

DEFINITION. A vector field V on $J^k(\mathbb{R}^m, \mathbb{R}^n)$ is a *Cauchy characteristic vector field* for the pde system $\Delta: J^k(\mathbb{R}^m, \mathbb{R}^n) \to \mathbb{R}^r$ if

(a) $V\Delta = 0$ on M_Δ, i.e., V is tangent to M_Δ.

(b) $L_V \Omega^k(\mathbb{R}^m, \mathbb{R}^n) \subseteq \Omega^k(\mathbb{R}^m, \mathbb{R}^n)$ on M_Δ (i.e., V is a contact vector field, see Remark 2.1).

(c) $\langle \omega, V \rangle = 0$ on M_Δ for $\omega \in \Omega^k(\mathbb{R}^m, \mathbb{R}^n)$.

Properties show that V is a classical symmetry generator for Δ. Property (c) ensures (as will be shown) that for fixed $q \in M_\Delta$ the map $s \to (\exp sV)(q)$ is a k-graph. The reason for the terminology is that if $\Delta: J^1(\mathbb{R}^m, \mathbb{R}^1) \to \mathbb{R}^1$, i.e., is a first-order pde, a characteristic vector field V of Δ determines the classical characteristic equations.

THEOREM 1 (Extension via Cauchy characteristics). *Assume that* $\Delta: J^k(\mathbb{R}^m, \mathbb{R}^n) \to \mathbb{R}^r$ *defines a system of partial differential equations with Jacobian of rank r so* $M_\Delta = \{(x, u^{(k)}) \in J^k: \Delta = 0\}$ *is (locally) a submanifold. For* $t \in \mathbb{R}^p$ *let* $t \to v(t) \in M_\Delta$ *be a k-graph with image a p-section in* M_Δ, $p < m$, *and (again)* $\pi: J^k(\mathbb{R}^m, \mathbb{R}^n) \to \mathbb{R}^m$ *is projection. If V is a Cauchy characteristic vector field for* Δ *and if the map*

$$(t, s) \to \bar{v}(t, s) = (\exp sV)(v(t))$$

is such that $\pi \circ \bar{v}$ *is an immersion (roughly speaking the orbits of V are transverse to the graph of v), then* $\bar{v}$ *defines a* $(p+1)$ *section of* M_Δ, *which is a k-graph extension of V.*

Proof. Since V is tangent to M_Δ and the graph of v lies in M_Δ, it follows that $\bar{v}$ takes values in M_Δ. Also $\bar{v}(t, 0) = v(t)$ showing $\bar{v}$ extends v, whereas $\pi \circ v$, an immersion, ensures the image of $\bar{v}$ is a $(p+1)$-section of M_Δ when the image of v is a p-section.

Let $(\exp sV)^*$ denote the cotangent space map induced by the (fixed s) diffeomorphism $p \to (\exp sV)(p)$, let v_1 denote the map $t \to \bar{v}(t, s)$ with s fixed, and let v_2 denote the map $s \to \bar{v}(t, s)$ with t fixed. It suffices to show that $v_i^* \Omega^k(\mathbb{R}^m, \mathbb{R}^n) = \{0\}$, $i = 1, 2$.

First, $v_1^* \Omega^k = v^*(\exp sV)^* \Omega^k = v^* \Omega^k = \{0\}$, which uses the fact that V is a contact vector field, i.e., $(\exp sV)^* \Omega^k = \Omega^k$, and that v was given as a k-graph, i.e., $v^* \Omega^k = \{0\}$.

Finally, noting that $(\partial/\partial s)(\exp sV)(v(t)) = V((\exp sV)(v(t)))$, we have $v_2^* \Omega^k = \langle \Omega^k, V \rangle$. But $\bar{v}$, hence also v_2, takes values only on M_Δ and by (b), $\langle \Omega^k, V \rangle = \{0\}$ on M_Δ. Thus $\pi \circ \bar{v}$ is an immersion and $\bar{v}^* \Omega^k = \{0\}$. The conclusion now follows from Proposition 1.1. □

Remark 2.1. V is a *contact vector field* on $J^k(\mathbb{R}^m, \mathbb{R}^n)$ if for small $|s|$, $q \to (\exp sV)(q)$ is a contact transformation, i.e., $(\exp sV)^* \Omega^k \subset \Omega^k$ or equivalently that its Lie derivative satisfy $L_V \Omega^k \subseteq \Omega^k$. As will be shown in Example 2.4, an underlying key to the Cauchy characteristics for first-order pde's is the fact that the general form of a contact vector field on $J^1(\mathbb{R}^m, \mathbb{R}^1)$ is known. For $J^k(\mathbb{R}^m, \mathbb{R}^n)$, special contact vector fields, sometimes called banal vector fields (see [7]), can be constructed as prolongations of vector fields on $\mathbb{R}^m \times \mathbb{R}^n$. Specifically, let X be a vector field on $\mathbb{R}^m \times \mathbb{R}^n$. Then for small $|s|$, $(\exp sX)$ maps the graph of a function $w: \mathbb{R}^m \to \mathbb{R}^n$ to the graph of a function $\tilde{w}$ (possibly with restricted domain). The kth prolongation of X, denoted $\mathrm{pr}^{(k)} X$, is defined as the vector field on $J^k(\mathbb{R}^m, \mathbb{R}^n)$ such that $(\exp s(\mathrm{pr}^{(k)} X))$ takes the graph of $\mathrm{pr}^{(k)} w$ to the graph of $\mathrm{pr}^{(k)} \tilde{w}$. This shows that $\mathrm{pr}^{(k)} X$ is a (local) contact vector field, i.e., its flow maps k-graphs to k-graphs. For the explicit construction of $\mathrm{pr}^{(k)} X$ see [5]. These banal vector fields are too restrictive to have use in Theorem 1, even in the case $k = 1$. (See Remark 2.3.)

Example 2.4 (Classical Cauchy characteristics as an application of Theorem 1). Consider the pde $\Delta = 0$ where

$$\Delta(x, u^{(1)}) = u_{x_1} + u_{x_2}^2. \tag{2.9}$$

Clearly, the Jacobian of Δ, as a map from $J^1(\mathbb{R}^2, \mathbb{R}^1)$ to $\mathbb{R}^1$, has rank 1 so M_Δ is well defined. For purposes of illustration we first construct an initial data one-graph $t \to v(t) \in M_\Delta$ via the use of the induced equation generated by the contact map $F: J^1(\mathbb{R}^2, \mathbb{R}^1) \to J^3(\mathbb{R}^1, \mathbb{R}^1)$ given in Example 2.3. Since $\Delta = F_5 + F_3 F_4 + F_4 + F_4^2$, the induced equation is

$$\sigma''' + \sigma' \sigma'' + \sigma'' + (\sigma'')^2 = 0. \tag{2.10}$$

This equation is highly nonlinear, but it is an ordinary differential equation. We may verify, for example, that $\psi(t) = e^{-t}$ is a solution. Let ψ denote an arbitrary solution of (2.10). Then

$$v(t) = F^{-1}((i, \mathrm{pr}^{(3)} \psi)(t)) = (t, \psi(t), \psi'(t) + \psi''(t), -(\psi''(t))^2, -\psi''(t)) \tag{2.11}$$

and $t \to v(t)$ gives a one-section of $M_\Delta \subset J^1(\mathbb{R}^2, \mathbb{R}^1)$, which is a one-graph. In the classical terminology (e.g., [4, p. 39]), the image of v is called an *initial strip manifold* and it is well known that we can extend v, locally, to a solution of $\Delta = 0$ by the method of characteristics. The relationship between this and Theorem 1 follows.

We next extend v via Theorem 1. Let $f: J^1(\mathbb{R}^2, \mathbb{R}^1) \to \mathbb{R}^1$ be an arbitrary smooth function. The general form of a contact vector field on $J^1(\mathbb{R}^2, \mathbb{R}^1)$ is

$$V = -f_{u_{x_1}} \frac{\partial}{\partial x_1} - f_{u_{x_2}} \frac{\partial}{\partial x_2} + (f - u_{x_1} f_{u_{x_1}} - u_{x_2} f_{u_{x_2}}) \frac{\partial}{\partial u} + (f_{x_1} + u_{x_1} f_u) \frac{\partial}{\partial u_{x_1}} + (f_{x_2} + u_{x_2} f_u) \frac{\partial}{\partial u_{x_2}}.$$

(i) The condition that V be tangent to M_Δ, i.e., $V\Delta = 0$ on M_Δ, is

$$f_{x_1} + u_{x_1} f_u + 2u_{x_2}(f_{x_2} + u_{x_2} f_u) = 0 \quad \text{when } u_{x_1} = -u_{x_2}^2$$

or

$$f_{x_1} - 2f_{x_2}u_{x_2} - f_u u_{x_2}^2 = 0.$$

As in the calculation of symmetry generators (which is exactly this step; see [5]) this requires $f_{x_1} = 0$, $f_{x_2} = 0$, $f_u = 0$ on M_Δ, i.e., we will consider

$$f = f(u_{x_1}, u_{x_2}). \tag{2.12}$$

(ii) The condition $\langle \omega, V \rangle = 0$ on M_Δ requires

$$f = 0 \quad \text{on } M_\Delta. \tag{2.13}$$

Conditions (2.12), (2.13) are simultaneously satisfied by the choice $f = \Delta = u_{x_1} + u_{x_2}^2$ giving

$$V = -\frac{\partial}{\partial x_1} - 2u_{x_2}\frac{\partial}{\partial x_2} - u_{x_2}^2\frac{\partial}{\partial u}. \tag{2.14}$$

Finally, since V is a contact vector field, $L_V\Omega^2 \subset \Omega^2$ and V, as given by (2.14), is a Cauchy characteristic vector field.

Remark 2.2. The generalization of the above construction to $\Delta: J^1(\mathbb{R}^m, \mathbb{R}^1) \to \mathbb{R}^1$ is immediate, i.e., the known form of a Cauchy characteristic vector field for Δ is

$$V = -\sum_1^m \left(\frac{\partial \Delta}{\partial u_{x_i}}\right)\frac{\partial}{\partial u_{x_i}} - \left(\sum_1^m u_{x_i}\frac{\partial \Delta}{\partial u_{x_i}}\right)\frac{\partial}{\partial u} + \sum_1^m \left(\frac{\partial \Delta}{\partial x_i} + u_{x_i}\frac{\partial \Delta}{\partial u}\right)\frac{\partial}{\partial u_{x_i}}.$$

Continuing with Example 2.4, if ψ is a solution of the induced equation (e.g., $\psi(t) = e^{-t}$) and $v(t) = F^{-1} \circ \psi(t)$, then

$$\begin{aligned}\bar{v}(t, s) &= (\exp sV)(v(t)) \\ &= (t - s, \psi(t) + 2\psi''(t)s, \psi'(t) + \psi''(t) - (\psi''(t))^2 s, -(\psi''(t))^2, -\psi''(t))\end{aligned}$$

gives a two-section of M_Δ if the Jacobian $\partial(t - s, \psi(t) + 2\psi''(t)s)/\partial(t, s)$ is nonsingular, which is a two-graph extension of v. Proposition 1.2 applies; the map $x: \mathbb{R}^2 \to \mathbb{R}^2$ is explicitly given by $x(t, s) = (t - s, \psi(t) + 2\psi''(t)s)$, and we are assured the existence of $w: \mathbb{R}^2 \to \mathbb{R}^1$ such that $\bar{v}(t, s) = (x(t, s), \mathrm{pr}^{(1)} w(x(t, s)))$ with $\Delta(x(t, s), \mathrm{pr}^{(1)} w(x(t, s))) = 0$. Recovering w normally requires use of the Implicit Function Theorem.

The classical characteristic equations (e.g., see [4]) associated with $\Delta = u_{x_1} + u_{x_2}^2$ are (using $p_i = u_{x_i}$) $\dot{x}_i = \partial\Delta/\partial p_i$, $\dot{u} = \sum p_i\, \partial\Delta/\partial p_i$, $\dot{p}_i = -\partial\Delta/\partial x_i - (\partial\Delta/\partial u)p_i$, $i = 1, 2$ which, for Δ as above, gives rise to the vector field $-V$, with V as in (2.14). Thus, for a first-order equation, the extension of an initial strip manifold via Theorem 1 and Cauchy characteristics is the same.

Remark 2.3. The vector field V, given in (2.14), is not a banal contact vector field, i.e., the prolongation of a vector field on $\mathbb{R}^2 \times \mathbb{R}^1$. Indeed, any such prolongation would have coefficients of $\partial/\partial x_1$, $\partial/\partial x_2$, and $\partial/\partial u$, which are functions only of x_1, x_2, u. Thus even in the case of a first-order equation, banal contact vector fields do not suffice.

3. Extensions in the jet bundle of the induced equation. As illustrated, and as was classically known, Theorem 1 applies to first-order pde's. It was also known at the turn of the century that Cauchy characteristics (i.e., extensions via vector fields) did not work for higher than first-order equations. This does not imply, however, that it is impossible to extend an initial data "strip" (i.e., in the case $\Delta: J^2(\mathbb{R}^2, \mathbb{R}^1) \to \mathbb{R}^1$ a two-graph $\tau \to v(\tau) \in M_\Delta$) into a two graph giving a two-dimensional section of M_Δ to which Proposition 1.2 can be applied via the flow of a (nonautonomous) differential equation. We could attempt this in the jet bundle of the original equation. For the

sake of exposition, and simplicity of geometry, we choose to do this in the jet bundle of the induced equation and for the specific case of the contact map $F: J^2(\mathbb{R}^2, \mathbb{R}^1) \to J^6(\mathbb{R}^1, \mathbb{R}^1)$ as given in Example 2.1. Our setting for this section is, therefore, as follows:

(i) $F: J^2(\mathbb{R}^2, \mathbb{R}^1) \to J^6(\mathbb{R}^1, \mathbb{R}^1)$ as in Example 2.1.

(ii) $\Delta: J^2(\mathbb{R}^2, \mathbb{R}^1) \to \mathbb{R}^1$ is a second-order pde with Jacobian of maximal rank so $M_\Delta \subset J^2(\mathbb{R}^2, \mathbb{R}^1)$ is well defined (locally).

(iii) $\tilde{\Delta}: J^6(\mathbb{R}^1, \mathbb{R}^1) \to \mathbb{R}^2$ is the induced equation, assumed to have the form

$$\sigma^{(6)} - f(\sigma, \sigma^{(1)}, \cdots, \sigma^{(5)}) = 0. \tag{3.1}$$

(iv) $F(M_\Delta) = \{(t, \sigma, \cdots, \sigma^{(6)}) \in J^6(\mathbb{R}^1, \mathbb{R}^1): \tilde{\Delta} = 0\}$.

(v) $$\Omega_3^6 = F^{-1*}\Omega^2 \quad \text{so} \quad F^*\Omega_3^6 = \Omega^2(\mathbb{R}^2, \mathbb{R}^1). \tag{3.2}$$

Explicitly, Ω_3^6 is generated by

$$\mu^1 = (\sigma^{(2)} + \sigma^{(1)}\sigma^{(4)}, -\sigma^{(4)}, -1, 0, 0, 0, 0, 0),$$

$$\mu^2 = (\sigma^{(3)} + \sigma^{(4)}\sigma^{(2)} + 2\sigma^{(1)}\sigma^{(5)} - (\sigma^{(1)})^2\sigma^{(6)}, -\sigma^{(5)} - \sigma^{(1)}\sigma^{(6)}, -\sigma^{(4)}, -1, 0, -\sigma^{(1)}, 0, 0),$$

$$\mu^3 = (\sigma^{(5)} + \sigma^{(1)}\sigma^{(6)}, -\sigma^{(6)}, 0, 0, -1, 0, 0).$$

(vi) $\pi: J^2(\mathbb{R}^2, \mathbb{R}^1) \to \mathbb{R}^2$ is projection.

Vector fields whose flows extend arbitrary two-graphs $\tau \to v(\tau) \in M_\Delta$, and therefore vector fields whose flows extend arbitrary six-graphs $\tau \to \gamma(\tau) \in F(M_\Delta)$, cannot be expected. Should such an extending vector field exist, the properties it must satisfy are given in the next proposition (basically Theorem 1 restated in the jet bundle of the induced equation), which serves to motivate the properties required for an extension via a (nonautonomous) differential equation.

PROPOSITION 3.1 (Motivational). *Let V be a vector field on $J^6(\mathbb{R}^1, \mathbb{R}^1)$ and $\gamma: \mathbb{R}^1 \to F(M_\Delta) \subset J^6(\mathbb{R}^1, \mathbb{R}^1)$ be such that*:

(a) *V is tangent to $F(M_\Delta)$, i.e., $V\tilde{\Delta} = 0$ on $F(M_\Delta)$.*

(b) *$\langle \Omega_3^6, V \rangle = 0$ on $F(M_\Delta)$.*

(c) *$L_V\Omega_3^6 \subset \Omega_3^6$.*

(d) *$\gamma^*\Omega_3^6 = \{0\}$.*

Define

$$\bar{v}(\tau, s) = F^{-1} \circ (\exp sV) \circ \gamma(\tau). \tag{3.3}$$

Then $\bar{v}^*\Omega^2(\mathbb{R}^2, \mathbb{R}^1) = \{0\}$ and if $\pi \circ \bar{v}: \mathbb{R}^2 \to \mathbb{R}^2$ is an immersion, $(\tau, s) \to \bar{v}(\tau, s)$ is a two-graph in M_Δ to which Proposition 1.2 applies, i.e., $\bar{v}$ gives a parametric solution of $\Delta = 0$.

The proof of Proposition 3.1 is essentially the same as that for Theorem 1 and hence will be omitted.

Let D_t denote "total derivative," i.e., $D_t f(\sigma, \cdots, \sigma^{(5)}) = (\partial f/\partial\sigma)\sigma^{(1)} + \cdots + (\partial f/\partial\sigma^{(5)})\sigma^{(6)}$. We may readily show that through each point $q \in F(M_\Delta)$ there is a *unique* six-graph $s \to (\exp sW)(q) \in F(M_\Delta)$ where

$$W = \frac{\partial}{\partial t} + \sigma^{(1)}\frac{\partial}{\partial\sigma} + \cdots + \sigma^{(6)}\frac{\partial}{\partial\sigma^{(5)}} + (D_t f)\frac{\partial}{\partial\sigma^{(6)}}. \tag{3.4}$$

With this uniqueness in mind, the hope for Proposition 3.1 stems from the fact that although the maps $\tau \to \gamma(\tau) \in F(M_\Delta)$, $s \to (\exp sV)(\gamma(\tau)) \in F(M_\Delta)$ must be transverse (in order that $\pi \circ \bar{v}$ be an immersion) they need not be six-graphs. On the other hand, their images in M_Δ under F^{-1} are two-graphs, and we may verify that if V exists satisfying Proposition 3.1, then $F_*^{-1}V$ is an extending vector field on M_Δ for $\tau \to v(\tau) = F^{-1} \circ \gamma(\tau)$, which is not to be expected.

The method of extension is, therefore, via the flow of a (usually nonautonomous) ode on $J^6(\mathbb{R}^1, \mathbb{R}^1)$, and this ode will not extend arbitrary maps $\gamma: \mathbb{R}^1 \to F(M_\Delta)$ with $\gamma^* \Omega_3^6 = \{0\}$ but instead it will be constructed relative to a specific such γ.

3.1. Extensions via solutions of nonautonomous equations. It is convenient, in view of hypothesis (b) of Proposition 3.1, to have a basis for the vector fields V that satisfy $\langle \Omega_3^6, V\rangle = \{0\}$. We can, by inspection, find vector fields $W^1, \cdots, W^5$ on $J^2(\mathbb{R}^2, \mathbb{R}^1)$ that form a basis for the vector fields W such that $\langle \Omega^2, W\rangle = \{0\}$. Then since $F^{-1*}\Omega^2 = \Omega_3^6$, we have $\{0\} = \langle F^* F^{-1*} \Omega^2, W^i\rangle = \langle \Omega_3^6, F_* W^i\rangle$. Computing $F_* W^i$, $i = 1, \cdots, 5$ and simplifying via linear combinations yields a basis for the vector fields V that satisfy $\langle \Omega_3^6, V\rangle = \{0\}$ consisting of

$$V^1 = \frac{\partial}{\partial t} + \sigma^{(1)} \frac{\partial}{\partial \sigma} + \sigma^{(2)} \frac{\partial}{\partial \sigma^{(1)}} + \sigma^{(3)} \frac{\partial}{\partial \sigma^{(2)}} + \sigma^{(5)} \frac{\partial}{\partial \sigma^{(4)}},$$

$$V^2 = \frac{\partial}{\partial \sigma^{(3)}}, \quad V^3 = \frac{\partial}{\partial \sigma^{(5)}}, \quad V^4 = \frac{\partial}{\partial \sigma^{(6)}},$$

$$V^5 = -\frac{\partial}{\partial \sigma} + \sigma^{(4)} \frac{\partial}{\partial \sigma^{(1)}} + (\sigma^{(5)} - (\sigma^{(4)})^2) \frac{\partial}{\partial \sigma^{(2)}} + \sigma^{(6)} \frac{\partial}{\partial \sigma^{(4)}}.$$

Let $V = \sum_{i=1}^5 a_i V^i$. With $\tilde{\Delta}$ of the form given in (3.1), the requirement $V\tilde{\Delta} = 0$ implies that

$$\begin{aligned} a_4 = {} & (a_1 \sigma^{(1)} - a_5) \frac{\partial f}{\partial \sigma} + (a_1 \sigma^{(2)} + a_5 \sigma^{(4)}) \frac{\partial f}{\partial \sigma^{(1)}} + (a_1 \sigma^{(3)} + a_5 \sigma^{(5)} - a_5 (\sigma^{(4)})^2) \frac{\partial f}{\partial \sigma^{(2)}} \\ & + a_2 \frac{\partial f}{\partial \sigma^{(3)}} + (a_1 \sigma^{(5)} + a_5 \sigma^{(6)}) \frac{\partial f}{\partial \sigma^{(4)}} + a_3 \frac{\partial f}{\partial \sigma^{(5)}}. \end{aligned} \tag{3.5}$$

In summary, the most general V that satisfies both $\langle \Omega_3^6, V\rangle = \{0\}$ and $V\tilde{\Delta} = 0$ is given by

$$\begin{aligned} V = {} & a_1 \frac{\partial}{\partial t} + (a_1 \sigma^{(1)} - a_5) \frac{\partial}{\partial \sigma} + (a_1 \sigma^{(2)} + a_5 \sigma^{(4)}) \frac{\partial}{\partial \sigma^{(1)}} + (a_1 \sigma^{(3)} + a_5 \sigma^{(5)} - a_5 (\sigma^{(4)})^2) \frac{\partial}{\partial \sigma^{(2)}} \\ & + a_2 \frac{\partial}{\partial \sigma^{(3)}} + (a_1 \sigma^{(5)} + a_5 \sigma^{(6)}) \frac{\partial}{\partial \sigma^{(4)}} + a_3 \frac{\partial}{\partial \sigma^{(5)}} + a_4 \frac{\partial}{\partial \sigma^{(6)}} \end{aligned} \tag{3.6}$$

with a_4 given by (3.5), a_1, a_2, a_3, a_5 arbitrary. In particular, if these depend on the local coordinates $(t, \sigma, \cdots, \sigma^{(6)})$, then V is a vector field. We also allow, however, that $a_i = a_i(s, t, \sigma, \cdots, \sigma^{(6)})$, $i = 1, 2, 3, 5$ where s is a real variable in which case we may view these a_i as "control functions" and the differential equations associated with (3.6) will no longer be autonomous. If $a_1 \neq 0$, it can be considered a common factor and hence with a change of independent variable, here s, this factor could be made one. Thus we assume $a_1 = 1$ and (with little loss of generality) that $a_i = a_i(s, \sigma, \cdots, \sigma^{(6)})$, $i = 2, 3, 5$ are smooth in $\sigma, \cdots, \sigma^{(6)}$ for fixed s and measurable in s for fixed $\sigma, \cdots, \sigma^{(6)}$.

Let $\tau \to \gamma(\tau) \in F(M_\Delta)$ satisfy $\gamma^* \Omega_3^6 = \{0\}$. Then explicitly, from (3.6), the differential equations that will be used to extend this initial data are (with a_4 given by (3.5))

$$\begin{aligned} & t'(s) = 1, \quad t(0) = \gamma_1(\tau), \qquad \sigma'(s) = \sigma^{(1)} - a_5, \quad \sigma(0) = \gamma_2(\tau), \\ & \sigma^{(1)\prime}(s) = \sigma^{(2)} + a_5 \sigma^{(4)}, \quad \sigma^{(1)}(0) = \gamma_3(\tau), \\ & \sigma^{(2)\prime}(s) = \sigma^{(3)} + a_5 \sigma^{(4)} - a_5 (\sigma^{(4)})^2, \quad \sigma^{(2)}(0) = \gamma_4(\tau), \\ & \sigma^{(3)\prime}(s) = a_2, \quad \sigma^{(3)}(0) = \gamma_5(\tau), \qquad \sigma^{(4)\prime}(s) = \sigma^{(5)} + a_5 \sigma^{(6)}, \quad \sigma^{(4)}(0) = \gamma_6(\tau), \\ & \sigma^{(5)\prime}(s) = a_3, \quad \sigma^{(5)}(0) = \gamma_7(\tau), \qquad \sigma^{(6)\prime}(s) = a_4, \quad \sigma^{(6)}(0) = \gamma_8(\tau). \end{aligned} \tag{3.7}$$

Let $s \to \phi(s, \gamma(\tau), a)$ denote the solution of this initial value problem for (3.7) for some choice $a = (a_2, a_3, a_5)$ and $\phi^*(s, q, a)$ denote the cotangent space map induced by $q \to \phi(s, q, a)$. Then

$$\phi(s, \gamma(\tau), a) \in F(M_\Delta), \qquad \langle \phi'(s, \gamma(\tau), a), \Omega_3^6 \rangle = \{0\}. \tag{3.8}$$

This means that if we now define

$$\bar{v}(\tau, s) = F^{-1} \circ \phi(s, \gamma(\tau), a), \tag{3.9}$$

then $\bar{v}(\tau, s) \in M_\Delta$, and if v_1 is the map $\bar{v}$ with τ fixed, i.e., $s \to \bar{v}(\tau, s) = v_1(s)$, then $v_1^* \Omega^2 = \{0\}$. What remains is that if v_2 is the map $\bar{v}$ with s fixed, i.e., $\tau \to \bar{v}(\tau, s) = v_2(\tau)$, then we would need $v_2^* \Omega^2 = \{0\}$. Computing gives $v_2^* \Omega^2 = v_2^* F^* \Omega_3^6 = \gamma^* \phi^* \Omega_3^6$, which yields the desired condition $\phi^* \Omega_3^6 \subset \ker \gamma^*$. We summarize these calculations as Theorem 2.

THEOREM 2. *Let $\tau \to v(\tau) \in M_\Delta$ be a given two-graph and $\gamma(\tau) = F \circ v(\tau)$. (Note that this implies $\gamma^* \Omega_3^6 = \{0\}$.) Suppose, in system* (3.7), *that $a(s, \sigma, \cdots, \sigma^{(6)}) = (a_2, a_3, a_5)$ can be chosen so that the corresponding solution $\phi(s, \gamma(\tau), a) = (\phi_1(s, \gamma(\tau), a), \cdots, \phi_8(s, \gamma(\tau), a))$ satisfies the following*:

(i) *$\phi^*(s, \gamma(\tau), a) \Omega_3^6 \subset \ker \gamma^*$ along $\tau \to \gamma(\tau)$.*

(ii) *The Jacobian $\partial(\phi_1(s, \gamma(\tau), a), \phi_2(s, \gamma(\tau), a))/\partial(s, \tau)$ is nonsingular.*

Then $\bar{v}(\tau, s) = F^{-1} \circ \phi(s, \gamma(\tau), a)$ is a two-graph in M_Δ such that $\pi \circ \bar{v}: \mathbb{R}^2 \to \mathbb{R}^2$ is an immersion, and hence (by Proposition 1.2) *$\bar{v}$ gives a parametric solution to the problem $\Delta = 0$ with initial data given by v.*

Proof. The conclusion $\bar{v}^* \Omega^2 = \{0\}$ follows from the discussion preceding the statement of Theorem 2. The condition $\pi \circ \bar{v}$, an immersion, follows immediately from (ii) and the first two components of F. □

Remark 3.1. We may define the Lie derivative of a one-form ω with respect to a "time varying" vector field V as follows. Let $V = \sum_{i=1}^n a_i(s, x) \partial/\partial x_i$ (s denotes time) and $\omega = \sum_{i=1}^n b_i(x)\, dx_i$. Then

$$L_V \omega = \sum_{j=1}^n \left(Vb_j + \sum_{i=1}^n b_i \left(\frac{\partial a_i}{\partial s} + \frac{\partial a_i}{\partial x_j} \right) \right) dx_j.$$

Now in Theorem 2, the requirement that v be a two-graph implies (as noted) that $\Omega_3^6 \subset \ker \gamma^*$. We can therefore replace the (weak but difficult to verify) condition (i) by the "infinitesimal" condition

$$L_V(\ker \gamma^*) \subset \ker \gamma^*, \tag{i'}$$

which implies $\phi^*(s, \gamma(\tau), a) \ker \gamma^* \subset \ker \gamma^*$.

Computing ϕ^* means computing the fundamental solution matrix of the variational equation associated with system (3.7). We next give an example.

Example 3.1 (Burgers' equation). Here the induced equation is $\sigma^{(6)} = f(\sigma, \cdots, \sigma^{(5)}) = \sigma^{(2)}$. Consider the special choice of control

$$\begin{aligned} a_2(s, \sigma, \cdots, \sigma^{(6)}) &= \alpha_2(s)\sigma + \cdots + \alpha_8(s)\sigma^{(6)}, \\ a_3(s, \sigma, \cdots, \sigma^{(6)}) &= \beta_2(s)\sigma + \cdots + \beta_8(s)\sigma^{(6)}, \\ a_5 &= 0. \end{aligned} \tag{3.10}$$

The first equation in system (3.7) can always be explicitly solved, i.e., $\phi_1(s, \gamma(\tau), a) = s + \gamma_1(\tau)$. With the above choice of a_2, a_3, a_5, the remaining seven equations satisfy a linear system, hence the associated variational equation is again the same linear system. In this case, $\phi^*(s, \gamma(\tau), a)$ is independent of γ.

Subcase (trivial). Let $\tau \to v(\tau) = (0, -\tau, 1, 0, 0, 0, 0, 0)$. Then $\gamma(\tau) = F \circ v(\tau) = (0, \tau, 1, 0, 0, 0, 0, 0)$. Note that γ is not a six-graph. Choose $\alpha_2 = \cdots = \alpha_8 = \beta_2 = \cdots = \beta_8 = 0$ in (3.10). Then

$$\phi^*(s, \gamma(\tau), a) = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & s & s^2 & s^3 & 0 & 0 & 0 \\ 0 & 0 & 1 & s & s^2 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & s & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & s & 0 \\ 0 & 0 & 0 & 0 & s & 0 & 0 & 1 \end{bmatrix}.$$

In components

$$\phi^*\mu^1 = (\sigma^{(2)} + \sigma^{(1)}\sigma^{(4)}, -\sigma^{(4)}, -s\sigma^{(4)} - 1, -s^2\sigma^{(4)} - s, -s^3\sigma^{(4)} - s^2, 0, 0),$$

$$\phi^*\mu^2 = (\sigma^{(3)} + \sigma^{(4)}\sigma^{(2)} + 2\sigma^{(1)}\sigma^{(5)} - (\sigma^{(1)})^2\sigma^{(6)}, -\sigma^{(5)} - \sigma^{(1)}\sigma^{(6)}, -s\sigma^{(5)} - s\sigma^{(1)}\sigma^{(6)} - \sigma^{(4)},$$
$$-s^2\sigma^{(5)} - s^2\sigma^{(1)}\sigma^{(6)} - s\sigma^{(4)} - 1, -s^3\sigma^{(5)} - s^3\sigma^{(1)}\sigma^{(6)} - s^2\sigma^{(4)} - s, -\sigma^{(1)}, -s\sigma^{(1)}, 0),$$

$$\phi^*\mu^3 = (\sigma^{(5)} + \sigma^{(1)}\sigma^{(6)}, -\sigma^{(6)}, -s\sigma^{(6)}, -s^2\sigma^{(6)}, -s^3\sigma^{(6)}, -1, -s, 0).$$

Here $\ker \gamma^*$ is spanned by dt, $d\sigma^{(1)}$, $d\sigma^{(2)}$, $d\sigma^{(3)}$, $d\sigma^{(4)}$, $d\sigma^{(5)}$, $s\sigma^{(6)}$ and along $\gamma(\tau)$, $\phi^*\mu^i \in \ker \gamma^*$, $i = 1, 2, 3$. Next, $\phi(s, \gamma(\tau), a) = (s, \tau + s, 1, 0, 0, 0, 0, 0)$ so the Jacobian condition (ii) of Theorem 2 is satisfied. Finally, $\bar{v}(\tau, s) = F^{-1} \circ \phi(s, \gamma(\tau), a) = (s, -\tau - s, 1, 0, 0, 0, 0, 0)$, which merely extends the constant data $u(x_1(\tau, 0), x_2(\tau, 0)) = u(0, -\tau) = 1$ to $u(s, -\tau - s) = 1$, which is a solution of Burgers' equation. The point here was to provide as simple as possible an example to illustrate the computations involved.

QUASI CONVERGENCE AND STABILITY FOR STRONGLY ORDER-PRESERVING SEMIFLOWS*

HAL L. SMITH† AND HORST R. THIEME†

Abstract. Hirsch's results concerning quasi convergence of almost all trajectories of strongly monotone semiflows are derived under weaker assumptions adopted from Matano. The proofs are based on a sequential limit set trichotomy, which follows from the nonordering principle and the limit set dichotomy. The assumption excluding totally ordered arcs of equilibria, which is required for the set of asymptotically stable points to be dense, is verified for dynamical systems that are analytic on the state space.

Key words. quasi convergence, monotone dynamical system, strongly order-preserving semiflow, open dense set of quasiconvergent points, limit set dichotomy, nonordering principle, sequential limit set trichotomy, totally ordered continua of equilibria, global asymptotic stability

AMS(MOS) subject classifications. 34C35, 34G20, 47H20

1. Introduction. In a recent paper [8], Hirsch establishes that most orbits of a strongly monotone semiflow on a strongly ordered space X tend to the set E of the equilibria. Somewhat more precisely, Hirsch shows that the set of all $x \in X$ for which $\omega(x)$, the omega (positive) limit set of x, satisfies $\omega(x) \subset E$, is a "large" (open dense, residual, set of full measure) subset of X. Points x for which $\omega(x) \subset E$ are called *quasiconvergent* points; they are called *convergent* points if $\omega(x)$ consists of a single point of E. The theory of monotone semiflows, as developed by Hirsch, is both powerful and deep. Unfortunately, it can also be awkward to apply in some situations. One reason is that the state space for the dynamical system must be a *strongly* ordered Banach space, that is, one for which the nonnegative cone has nonempty interior. It is quite often the case that the "natural" state space for the dynamical system does not have this property. We can usually rectify this problem by finding a Banach subspace, imbedded in the natural space, which is strongly ordered. We can then apply the results of the theory to this smaller strongly ordered space. In the case where the semiflow maps points in the natural state space continuously into the smaller space, perhaps for suitably large times, we can bootstrap the results obtained for the dynamical system on the smaller space up to the natural state space. Even when all this can be done, it is so inconvenient that it is desirable to have an approach available that avoids these difficulties from the beginning. Second, Hirsch's results concerning stable and asymptotically stable points [8, §§ 8-10] require the semiflow to be restricted to an invariant, strongly ordered subset X_0 of the space X. This condition essentially forces X_0 to be an open subset of X and precludes immediate application of the results to such important examples as the case $X_0 = X_+$, the nonnegative cone in a Banach space X, or when X_0 is an order interval.

Matano [11], [12] has outlined a competing theory of monotone dynamical systems, parallel to Hirsch's, which does not require that the space be strongly ordered. The main results of Matano have appeared in conference proceedings [11], [12] without proofs. One of the main results of Matano's theory, as does that of Hirsch, provides sufficient conditions for "most" points to be quasiconvergent.

In this paper, we combine the ideas of Hirsch and Matano to obtain a theory that improves several of the results of both authors, while at the same time being conceptually

simpler. We adopt (a slight generalization of) Matano's idea of a *strongly order-preserving* semiflow that does not require the space to be strongly ordered. On the other hand, all our results are based on modified versions of two fundamental results due to Hirsch, namely, the *nonordering principle* for limit sets [8] and the *limit set dichotomy* [8]. These two principles also hold under Matano's weaker assumptions (see [12]) and can actually be shown by modifying Hirsch's proofs accordingly. They alone lead to a simple proof of our Proposition 3.1 (*sequential limit set trichotomy*), a result from which most of our theory follows. In this sense, we feel that the theory develops more naturally and more simply.

In the remainder of this section we describe some basic ideas and notation and preview several of the main results.

Let X be an ordered metric space with metric d and order relation $\leqq$. We write $x < y$ if $x \leqq y$ and $x \neq y$. Points x and y in X are *ordered* if either $x < y$ or $y < x$. Given two subsets A and B of X we write $A \leqq B$ ($A < B$) whenever $x \leqq y$ ($x < y$) for each choice of $x \in A$ and $y \in B$. If $x < y$ then $[x, y] = \{z \in X : x \leqq z \leqq y\}$. A subset Y of X is *order convex* if $[y_1, y_2] \subset Y$ whenever $y_1, y_2 \in Y$ and $y_1 < y_2$.

We assume that the order and the topology on X are compatible in the sense that $x \leqq y$ whenever $x_n \to x$, $y_n \to y$, and $x_n \leqq y_n$ for all n. If $x \in X$ we say that x can be approximated from below (above) in X if there exists a sequence $\{x_n\}$ in X satisfying $x_n < x_{n+1} < x$ ($x < x_{n+1} < x_n$) for $n \geqq 1$ and $x_n \to x$.

Let $\Phi : X \times \Re^+ \to X$ be a semiflow on X, that is, Φ is continuous and $\Phi_t(x) \equiv \Phi(x, t)$ satisfies $\Phi_0(x) = x$ for every x and $\Phi_t \Phi_s = \Phi_{t+s}$ for every $t, s \geqq 0$. For $x \in X$, let

$$\mathcal{O}^+(x) = \{\Phi_t(x) : t \geqq 0\}, \qquad \omega(x) = \bigcap_{t \geqq 0} \overline{\mathcal{O}^+(\Phi_t(x))}$$

be the orbit initiating at x and the omega (positive) limit set of $\mathcal{O}^+(x)$, respectively. Of course the latter may be empty. Hence we require some compactness properties to hold for the semiflow Φ. Namely,

(C) For each $x \in X$, $\mathcal{O}^+(x)$ has compact closure in X. In addition, for each compact subset K of X, $\bigcup_{x \in K} \omega(x)$ has compact closure in X.

We will assume that (C) holds throughout the remainder of this section. It is a relatively mild compactness assumption, weaker than required by Matano [11], [12].

If $\mathcal{O}^+(x)$ has compact closure in X then $\omega(x)$ is nonempty, compact, connected, and invariant, i.e., $\Phi_t(\omega(x)) = \omega(x)$, $t \geqq 0$, and $\Phi_t(x) \to \omega(x)$ as $t \to \infty$. We let $E = \{x \in X : \Phi_t(x) = x, t \geqq 0\}$ be the set of equilibria. The set of quasiconvergent points is denoted by $Q = \{x \in X : \omega(x) \subset E\}$ and the set of convergent points by $C = \{X \in Q : \omega(x)$ is a singleton set$\}$.

The semiflow Φ is said to be *monotone* provided

$$\Phi_t(x) \leqq \Phi_t(y) \quad \text{whenever } x \leqq y.$$

Following Matano [11], [12], Φ is said to be *strongly order-preserving* if Φ is monotone, and whenever $x, y \in X$ with $x < y$, there exist open sets U and V, $x \in U$, $y \in V$, and $t_0 \geqq 0$ such that $\Phi_{t_0}(U) \leqq \Phi_{t_0}(V)$. By monotonicity, it follows that

$$\Phi_t(U) \leqq \Phi_t(V) \quad \text{for } t \geqq t_0.$$

One of our main results is the following theorem (cf. [12, Thm. 5] and [8, Thm. 7.5]).

THEOREM 1. *Let X be an ordered metric space and let Φ_t be a strongly order-preserving semiflow on X. Suppose that each point of X can be approximated from above or from below in X. Then* Int Q *is dense in X.*

Some remarks on the theorem are appropriate here. First, note that we require minimal assumptions on the space X. Since subsets of ordered metrizable spaces are themselves ordered metrizable spaces under the inherited order and metric, we may view X as a subset of some larger space. The requirement that every point may be approximated from above or from below in the space X is not a particularly strong one. For example, if X is the nonnegative cone or a nontrivial order interval in an ordered Banach space then X has the required property.

Theorem 1 is a generalized and simplified version of a result by Matano [12, Thm. 5]. In particular we do not require the existence of a bounded set that every orbit must eventually enter and remain in, and our compactness requirement (C) is milder than Matano's (H.2). Hirsch proves [8, Thm. 7.5 and Cor. 7.6] that Q (not Int Q) is dense without compactness hypotheses but with much stronger assumptions on the space. For smooth strongly monotone flows defined by semilinear parabolic equations, Poláčik [14] has shown that Int C is dense in X.

With an additional compatibility relation between the metric and the order, a significantly stronger conclusion can be drawn. The space X is said to be normally ordered if there exists a constant $k>0$ such that

$$d(u, v) \leqq k d(x, y)$$

for all x, y, u, v with $u, v \in [x, y]$. A subset X of an ordered Banach space possessing a normal positive cone (e.g., $C(\Omega)$, $L^p(\Omega)$) is normally ordered.

THEOREM 2. *Let X be a normally ordered metric space, and let Φ_t be a strongly order-preserving semiflow on X. Suppose that each point x in X can be approximated from above or from below in X, and there exists an open and dense subset X_0 in X with the property that each point of X_0 can be approximated both from above and from below in X. Then $A \cup \operatorname{Int}(S \cap C)$ is dense in X.*

The set A in Theorem 2 is the set of *asymptotically stable* points, as defined by Hirsch [8]. A point x belongs to A if there is a neighborhood V of x with the property that for every $\varepsilon>0$ there exists $t_\varepsilon>0$ such that $d(\Phi_t(x), \Phi_t(y))<\varepsilon$ if $t \geqq t_\varepsilon$ and $y \in V$. The set S is the set of stable points. A point x belongs to S if for every $\varepsilon>0$ there exists $\delta>0$ such that $d(\Phi_t(x), \Phi_t(y))<\varepsilon$ for $t \geqq 0$ whenever $y \in X$ and $d(x, y)<\delta$. Hirsch observes [8] (see also Proposition 3.4 in § 3) that A is open and $A \subset S \subset Q$. Note that the map $x \mapsto \omega(x)$ is locally constant near an asymptotically stable point and continuous at a stable point. Theorem 2 asserts that an open and dense set of points of X consists of either asymptotically stable quasiconvergent points or stable convergent points having the property that sufficiently nearby points are also convergent.

Theorem 2 may be compared with Proposition 9.5 of Hirsch [8], which draws essentially the same conclusion assuming the "astrictive" condition [8, Def. 8.9] and, of course, that X is strongly ordered and Φ is strongly monotone. The astrictive condition of Hirsch is difficult to verify directly. Hirsch provides several sufficient conditions [8, Thms. 8.11–8.14] for the astrictive condition to hold. Those sufficient conditions that are most likely to be useful in infinite-dimensional settings require a stronger compactness condition than (C).

Our next result improves the global stability result of Hirsch [8, Thm. 10.3] at the expense of an additional compactness condition (the second part of (C)).

THEOREM 3. *Let X be a connected, ordered metric space with the property that each point of X can be approximated from above and from below in X. If X does not contain two ordered equilibria, then X contains a unique equilibrium point to which every orbit converges.*

The assumption that X does not contain two equilibria $p, q \in E$, with $p < q$ certainly holds if X is known to contain at most one equilibrium point. Hirsch assumes the existence of a unique equilibrium point.

The following convergence result seems to be new.

THEOREM 4. *Suppose that X is an order convex subset of a normally ordered Banach space Y. Let Φ_t be a strongly order-preserving semiflow on X such that Φ_t is condensing on every order interval in X for $t > 0$. Assume that any point in $X \setminus E$ can be approximated both from above and below. If X contains at most two order-related equilibria, then $X = Q$. If X contains no more than two equilibria, then every trajectory in X converges towards one of them.*

This result is optimal insofar as five-dimensional single-loop positive-feedback systems (which induce strongly order-preserving semiflows) can have three order-related equilibria with the middle one undergoing an unstable Hopf bifurcation. See Selgrade [17].

Our next result provides sufficient conditions (similar to those in Hirsch [8, Thm. 9.6]) for the set A of asymptotically stable points to be dense in X. We need to assume that each point $x \in X$ belongs to some totally ordered arc in X. A subset J of X is a totally ordered arc provided $J = \psi(I)$ where I is a nontrivial interval of real numbers and ψ is a continuous function from I onto J such that $\psi(s) < \psi(t)$ whenever $s, t \in I$ and $s < t$.

THEOREM 5. *Suppose that X is a normally ordered metric space and that each $x \in X$ belongs to some totally ordered arc in X. Let Φ_t be a strongly order-preserving semiflow on X. If there does not exist a totally ordered arc of equilibria in X then A is open and dense in X.*

Section 4 is devoted to providing a verifiable sufficient condition for excluding the existence of totally ordered arcs of equilibria contained in bounded open subsets of a Banach lattice. By exploiting an analyticity hypothesis on the semiflow Φ, we are able to show that a bounded open set U contains no totally ordered arc of equilibria provided the boundary of U does not contain equilibria for which the infinitesimal generator of the variational semigroup has vanishing spectral bound (see Theorem 4.1). This result provides a testable condition in order that the main hypothesis of Theorem 4 holds.

For applications of the results of monotone dynamical systems theory, we refer the reader to [5]–[7], [18] for applications to systems of ordinary differential equations, to [8], [11], [12], [14], [15] for applications to parabolic initial boundary value problems, to [19], [20] for applications to functional differential equations, and to [9], [10] for applications to systems of parabolic equations with time delays. We conclude this section by giving a concrete example of a semiflow generated by a semilinear parabolic equation to which our results apply. We do not aim for utmost generality. Articles [8], [11], [12] contain applications to parabolic initial boundary value problems of much greater generality. Our example can even be treated by energy methods as it generates a gradient flow [4]. Our results, however, apply directly to a state space that is not strongly ordered. As it parallels a similar example treated in [8], we closely follow the treatment given there.

Let Ω be a bounded open set in $\mathbf{R}^n$ with boundary, $\partial\Omega$, of class $C^{2+\alpha}$, $\alpha > 0$. Let $f: \bar{\Omega} \times \mathbf{R} \to \mathbf{R}$ satisfy the following:

(F) (a) $f(x, 0) = 0$ for $x \in \partial\Omega$.

(b) There exist $a, b \in \mathbf{R}$, $a < b$, $a \leqq 0 \leqq b$, such that

$$f(x, b) \leqq 0 \leqq f(x, a), \qquad x \in \bar{\Omega}.$$

(c) f is a Lipschitz on $\bar{\Omega}\times[a, b]$ (in both arguments jointly).

Consider the initial boundary value problem

$$\text{(P)}\qquad \begin{aligned} &\frac{\partial u}{\partial t}=\Delta u+f(x, u), && x\in\Omega, \quad t>0,\\ &u=0, && x\in\partial\Omega, \quad t>0,\\ &u(x, 0)=u_0(x), && x\in\Omega. \end{aligned}$$

The Laplace operator Δ appearing in (P) could be replaced by any second-order uniformly strongly elliptic differential operator. The nonlinear term f could depend on the gradient of u with appropriate hypotheses [8], [11], [12]. Other boundary conditions could be considered, however, the Dirichlet boundary conditions will allow us to generate a strongly order-preserving semiflow on a natural state space, which is not a strongly monotone semiflow.

Let $C^r(\bar{\Omega})$, $r=0$, 1, be the Banach spaces of continuous ($r=0$) and continuously differentiable ($r=1$) functions on $\bar{\Omega}$ with the usual norms. Denote by ${}_0C^r(\bar{\Omega})$ the Banach subspace of functions vanishing on the boundary of Ω and by ${}_0C^r_+(\bar{\Omega})$ the cone of nonnegative functions in ${}_0C^r(\bar{\Omega})$. As noted in [8], $\operatorname{Int}{}_0C^0_+(\bar{\Omega})$ is empty while

$$\operatorname{Int}{}_0C^1_+(\bar{\Omega})=\left\{u\in{}_0C^1_+(\bar{\Omega}): \frac{\partial u}{\partial \nu}<0 \text{ on } \partial\Omega\right\}\neq\varnothing,$$

where ν is the outer normal unit vector field on $\partial\Omega$ and $\partial u/\partial\nu$ is the directional derivative in the direction ν. In particular, ${}_0C^0(\bar{\Omega})$ is not a strongly ordered space.

As in Hirsch, we observe the following facts. Mild solutions of (P) generate a local semiflow Φ on ${}_0C^0(\bar{\Omega})$ [8, Thm. 4.4], which satisfies the following:

(S) $\Phi_t: {}_0C^0(\bar{\Omega})\to{}_0C^1(\bar{\Omega})$ is continuous for $t>0$, and

(M) $u_0<u_1$ in ${}_0C^0(\bar{\Omega})$ implies $\Phi_t(u_0)<\Phi_t(u_1)$.

Fact (M) follows from the maximum principle and the fact that mild solutions are classical solutions for $t>0$ (see Remark 4.2 of [8]).

Let

$$X=\{u\in{}_0C^0(\bar{\Omega}): a\leqq u(x)\leqq b, x\in\bar{\Omega}\}.$$

X is a normally ordered metric space with the order and metric it inherits from ${}_0C^0(\bar{\Omega})$. Indeed, it is an order convex subset of the normally ordered Banach space ${}_0C^0(\bar{\Omega})$. It is easy to see that every point of X can be approximated from above or from below in X. Arguments similar to those yielding (M) give the following:

(I) Φ restricts to a monotone (global) semiflow on X.

Moreover, we have [8, Thm. 4.4] the following:

(K) Φ_t is completely continuous on X.

Our compactness hypothesis (C) follows immediately from (K).

Although X is not a strongly ordered space, since $\operatorname{Int}{}_0C^0(\bar{\Omega})=\varnothing$, and thus $\Phi_t: X\to X$ cannot be strongly monotone, we nonetheless have the following proposition.

PROPOSITION 6. *Φ is strongly order preserving on X.*

Proof. Let u_0, $v_0\in X$ with $u_0<v_0$. By (M), $\Phi_t(u_0)<\Phi_t(v_0)$ for $t>0$. Let $t_0>0$. Now $u(x, t)\equiv[\Phi_t(u_0)](x)$ is a classical solution ($t>0$) so maximum principle arguments apply. If there exists $x_0\in\Omega$ such that $v(x_0, t_0)=u(x_0, t_0)$ then $v(x, t)\equiv u(x, t)$

for $x \in \Omega$, $t \leqq t_0$ by the maximum principle. It follows that $v(x, t) > u(x, t)$ for all $x \in \Omega$, $t > 0$. But then the boundary point principle implies $\partial/\partial\nu(u - v) > 0$ on $\partial\Omega$. Thus

$$\Phi_{t_0}(v_0) - \Phi_{t_0}(u_0) \in \operatorname{Int}{}_0C^1_+(\bar{\Omega}).$$

Hence we may find neighborhoods U_0 and V_0 of $\Phi_{t_0}(u_0)$, $\Phi_{t_0}(v_0)$ in ${}_0C^1(\bar{\Omega})$ such that

$$U_0 \leqq V_0 \quad \text{in } {}_0C^1(\bar{\Omega}).$$

Since $\Phi_{t_0}: X \to {}_0C^1(\bar{\Omega})$ is continuous there are neighborhoods U and V of u_0 and v_0 in X such that

$$\Phi_{t_0}(U) \subset U_0, \qquad \Phi_{t_0}(V) \subset V_0.$$

Thus $\Phi_{t_0}(U) \leqq \Phi_{t_0}(V)$. This completes the proof.

The equilibria of Φ are given by the solutions $u \in X$ of the boundary value problem

$$\text{(E)} \qquad \begin{aligned} \Delta u + f(x, u) &= 0, \qquad x \in \Omega, \\ u &= 0, \qquad x \in \partial\Omega. \end{aligned}$$

Theorem 2 applies to the above example, implying that an open and dense set of initial conditions in X consists of asymptotically stable quasiconvergent points or stable convergent points. For these initial data, corresponding solutions converge to the set of solutions of (E) above.

In the following section we state some preliminary results. Section 3 contains the statements and proofs of our main results.

2. Nonordering principle and limit set dichotomy. Throughout this section we assume that X is an ordered metric space with metric d and that Φ is a semiflow on X, which is strongly order preserving. In addition, we assume that every orbit has compact closure in X. The following result is used extensively in this section.

LEMMA 2.1. *Let K_1 and K_2 be two compact subsets of X satisfying $K_1 < K_2$. Then there exist open sets U and V, $K_1 \subset U$, $K_2 \subset V$, and $t_1 \geqq 0$, $\varepsilon > 0$ such that*

$$\Phi_{t+s}(U) \leqq \Phi_t(V) \quad \textit{for } t \geqq t_1, \quad 0 \leqq s \leqq \varepsilon.$$

Proof. Let $x \in K_1$. For each $y \in K_2$ there exists $t_y \geqq 0$ and a neighborhood U_y of x and a neighborhood V_y of y such that $\Phi_t(U_y) \leqq \Phi_t(V_y)$ for $t \geqq t_y$ since Φ is strongly order preserving. Then $\{V_y\}_{y \in K_2}$ is an open cover of K_2, so we may choose a finite subcover: $K_2 \subset \bigcup_{i=1}^n V_{y_i} \equiv \tilde{V}$ where $y_i \in K_2$, $1 \leqq i \leqq n$. Let $\tilde{U} = \bigcap_{i=1}^n U_{y_i}$, so $\tilde{U}$ is a neighborhood of x and let $\tilde{t} = \max_{1 \leqq i \leqq n} t_{y_i}$. Then, for each i, $\Phi_{\tilde{t}}(\tilde{U}) \subset \Phi_{\tilde{t}}(U_{y_i}) \leqq \Phi_{\tilde{t}}(V_{y_i})$, so $\Phi_t(\tilde{U}) \leqq \Phi_t(V_{y_i})$ for each i, $1 \leqq i \leqq n$, and $t \geqq \tilde{t}$. It follows that $\Phi_t(\tilde{U}) \leqq \Phi_t(\tilde{V})$ for $t \geqq \tilde{t}$. For the remainder of the proof we write $\tilde{U}_x = \tilde{U}$ and $\tilde{V}_x = \tilde{V}$ to emphasize the dependence of these open sets on the point $x \in K_1$. Similarly $\tilde{t} = \tilde{t}_x$. Since $x \in K_1$ was arbitrary, we find for each $x \in K_1$ an open neighborhood $\tilde{U}_x$ of x, an open neighborhood $\tilde{V}_x$ of K_2, and $\tilde{t}_x \geqq 0$ such that $\Phi_t(\tilde{U}_x) \leqq \Phi_t(\tilde{V}_x)$ for $t \geqq t_x$. Again, $\{\tilde{U}_x\}_{x \in K_1}$ is an open cover of K_1, so we extract a finite subcover $\tilde{U}_{x_i}$, $1 \leqq i \leqq m$, and set $U = \bigcup_{i=1}^m \tilde{U}_{x_i} \supset K_1$, $V = \bigcap_{i=1}^m \tilde{V}_{x_i} \supset K_2$ and $t_1 = \max_{1 \leqq i \leqq m} \tilde{t}_{x_i}$. Since $V \subset \tilde{V}_{x_i}$, $\Phi_t(\tilde{U}_{x_i}) \leqq \Phi_t(V)$ for $t \geqq t_1$, for each i, so $\Phi_t(U) \leqq \Phi_t(V)$ for $t \geqq t_1$.

To obtain the stronger conclusion of the lemma, note that for each $x \in K_1$ there exists $\varepsilon_x > 0$ and a neighborhood W_x of x such that $\Phi([0, \varepsilon_x) \times W_x) \subset U$. As $\{W_x\}_{x \in K_1}$ is an open cover of K_1, there exists $x_1, x_2, \cdots, x_m \in K_1$ such that $K_1 \subset \bigcup_{i=1}^m W_{x_i}$. Let $U' = \bigcup_{i=1}^m W_{x_i}$ and $\varepsilon = \min_{1 \leqq i \leqq m} \varepsilon_{x_i}$. If $x \in U'$ and $0 \leqq s < \varepsilon$ then $x \in W_{x_i}$ for some i so $\Phi_s(x) \in U$. Thus $\Phi([0, \varepsilon) \times U') \subset U$ so $\Phi_s(U') \subset U$, $0 \leqq s < \varepsilon$. It follows that $\Phi_{t+s}(U') \subset \Phi_t(U) \leqq \Phi_t(V)$ for $t \geqq t_1$, $0 \leqq s < \varepsilon$.

Our main result is based on the following two results, which were first stated and proved by Hirsch [7], [8] for strongly monotone semiflows.

PROPOSITION 2.2 (Nonordering of limit sets). *An omega limit set cannot contain two ordered points.*

The following result is stated by Matano in [12] without proof.

PROPOSITION 2.3 (Limit set dichotomy). *If $x < y$ then either*

(a) $\omega(x) < \omega(y)$, *or*

(b) $\omega(x) = \omega(y) \subset E$.

We do not give detailed proofs of either Proposition 2.2 or Proposition 2.3 since this would involve repeating arguments very similar to those given by Hirsch in his proofs of corresponding results in [8, Thms. 6.2, 6.8]. A proof of Proposition 2.3 is obtained by proving analogues of the various results in Hirsch [8, § 6] and then arguing precisely as in Hirsch's proof of his limit set dichotomy. We state below those results, parallel to ones in [8], which are required for the proofs of Propositions 2.2 and 2.3. We will prove two of them to illustrate how our assumptions replace those by Hirsch [8].

Proposition 2.2 follows quite simply from the next result.

PROPOSITION 2.4 (Convergence criterion for strongly order-preserving flows). *If $\Phi_T(x) > x$ for some $T > 0$, then $\Phi_t(x) \to p \in E$ as $t \to \infty$.*

Proof. As in Lemma 6.3 of [8], $\omega(x)$ is an orbit of period T. Since Φ is strongly order preserving, there exist neighborhoods U of x and V of $\Phi_t(x)$ and $t_0 \geqq 0$ such that $\Phi_{t_0}(U) \leqq \Phi_{t_0}(V)$. For sufficiently small $\varepsilon > 0$, $\Phi_{T+s}(x) \in V$ for $0 \leqq s \leqq \varepsilon$ and hence $\Phi_{t_0}(x) < \Phi_{T+t_0+s}(x)$ for such s. This implies again that $\omega(\Phi_{t_0}(x)) = \omega(x)$ is an orbit of period $T+s$, $0 \leqq s \leqq \varepsilon$. Let $p \in \omega(x)$. Then $\Phi_{T+s}(p) = p$ for $0 \leqq s \leqq \varepsilon$. Hence $p = \Phi_s \Phi_T p = \Phi_s p$ for $0 \leqq s \leqq \varepsilon$. Let $t = n\varepsilon + s$ with $n \in N$ and $0 \leqq s < \varepsilon$. Then $\Phi_t p = \Phi_s \Phi_\varepsilon^n p = \Phi_s p = p$. Since any $t \geqq 0$ can be represented in this way, p is an equilibrium. As $\omega(x)$ is a periodic orbit, $\omega(x) = \{p\}$.

Simple modifications of Joel Friedman's argument in Proposition 6.6 of [8] yield Proposition 2.5.

PROPOSITION 2.5 (Colimiting principle). *If $x < y$ and for some sequence $t_k \to \infty$,*

$$\Phi_{t_k}(x) \to p, \quad \Phi_{t_k}(y) \to p, \quad \text{then } p \in E.$$

The next result follows immediately from Propositions 2.2 and 2.5 exactly as in Hirsch [8, Lemma 6.7].

PROPOSITION 2.6 (Intersection principle). *If $x < y$, then $\omega(x) \cap \omega(y) \subset E$.*

In addition to Proposition 2.6, two additional results are required for the proof of the limit set dichotomy. One of these is the following.

PROPOSITION 2.7 (Absorption principle). *Suppose that $x, y \in X$ and that neither are convergent points. If $\omega(x)$ contains a point $u < \omega(y)$, then $\omega(x) < \omega(y)$. If $\omega(x)$ contains a point $u > \omega(y)$, then $\omega(x) > \omega(y)$.*

The proof of the Absorption principle is similar to Hirsch's although we require an application of Lemma 2.1.

The next result is also used to prove the limit set dichotomy.

PROPOSITION 2.8 (Limit set separation principle). *Let x and y be as in Proposition 2.7 and $x < y$. If there exists $t_k \to \infty$ such that $\Phi_{t_k}(x) \to a$, $\Phi_{t_k}(y) \to b$, and $a < b$ then $\omega(x) < \omega(y)$.*

The proof of Proposition 2.8 is identical to that given by Hirsch [8, Lemma 6.10]. In particular, the proof requires the following result.

LEMMA 2.9. *Given the hypotheses of Proposition 2.8 then $\mathcal{O}^+(a) < b$.*

We give the proof of this lemma because it requires some modifications of Hirsch's corresponding proof [8, Lemma 6.10]. It also serves as another illustration of how, technically, our assumptions replace those of Hirsch.

Proof. For $u \in \overline{\mathcal{O}^+(x)}$, $v \in \overline{\mathcal{O}^+(y)}$, $u \leqq v$ define

$$\mathcal{J}(u, v) = \sup\{r \geqq 0: \Phi_t(u) \leqq v, 0 \leqq t \leqq r\}.$$

We verify two important properties of $\mathcal{J}$.

(P_1) $\mathcal{J}(\Phi_t(u), \Phi_t(v))$ is monotone nondecreasing in t.

It suffices to establish $\mathcal{J}(\Phi_t(u), \Phi_t(v)) \geqq \mathcal{J}(u, v)$. For $s \leqq \mathcal{J}(u, v)$, $\Phi_s(u) \leqq v$, so $\Phi_s\Phi_t(u) \leqq \Phi_t\Phi_s(u) \leqq \Phi_t(v)$. Hence

$$\mathcal{J}(\Phi_t(u), \Phi_t(v)) \geqq s \quad \text{for all } s \leqq \mathcal{J}(u, v).$$

(P_2) If $u_k \leqq v_k$, $u_k \in \overline{\mathcal{O}^+(x)}$, $v_k \in \overline{\mathcal{O}^+(y)}$ and $u_k \to u$, $v_k \to v$ then $\limsup_{k\to\infty} \mathcal{J}(u_k, v_k) \leqq \mathcal{J}(u, v)$.

Suppose that $\mathcal{J}(u, v) < \infty$ and $\limsup_{k\to\infty} \mathcal{J}(u_k, v_k) - \varepsilon > \mathcal{J}(u, v)$ for some $\varepsilon > 0$. Then $\mathcal{J}(u, v) + \delta < \mathcal{J}(u_{k_i}, v_{k_i})$ for all large i, for each δ, $0 \leqq \delta < \varepsilon$, where $\lim_{i\to\infty} \mathcal{J}(u_{k_i}, v_{k_i}) = \limsup_{k\to\infty} \mathcal{J}(u_k, v_k)$. It follows that $\Phi_{\mathcal{J}(u,v)+\delta}(u_{k_i}) \leqq v_{k_i}$ for all large i, $0 \leqq \delta < \varepsilon$. Letting $i \to \infty$, we obtain $\Phi_{\mathcal{J}(u,v)+\delta}(u) \leqq v$ for $0 \leqq \delta < \varepsilon$, a contradiction to the definition of $\mathcal{J}(u, v)$. Thus (P_2) holds.

It follows from (P_1) that $\alpha = \lim_{t\to\infty} \mathcal{J}(\Phi_t(x), \Phi_t(y))$ exists in $[0, \infty]$. By (P_2), $\mathcal{J}(a, b) \geqq \alpha$. Suppose the conclusion of the lemma does not hold, i.e., suppose $\mathcal{J}(a, b) < \infty$. For $0 \leqq r \leqq \mathcal{J}(a, b)$, $\Phi_r(a) \leqq b$. Actually, $\Phi_r(a) < b$, $0 \leqq r \leqq \mathcal{J}(a, b)$ since otherwise $a, b \in \omega(x)$ by invariance of $\omega(x)$ and $a < b$ gives a contradiction to Proposition 2.2. Let $K = \{\Phi_r(a): 0 \leqq r \leqq \mathcal{J}(a, b)\}$ so K is compact and $K < b$. By Lemma 2.1, there exist t_1, $\varepsilon > 0$ and open sets U and V with $K \subset U$ and $b \in V$ such that $\Phi_{t_1+\delta}(U) \leqq \Phi_{t_1}(V)$, $0 \leqq \delta \leqq \varepsilon$. It follows that $\Phi_{t_k}(y) \in V$ for $k \geqq k_0$ for some integer k_0. We claim that $\Phi_r\Phi_{t_k}(x) \in U$ for $0 \leqq r \leqq \mathcal{J}(a, b)$ and all large k. If not, we find a subsequence t_k' of t_k and a sequence $r_k \in [0, \mathcal{J}(a, b)]$ such that $\Phi_{r_k}\Phi_{t_k'}(x) \notin U$, $k = 1, 2, \cdots$. We may assume $r_k \to r \in [0, \mathcal{J}(a, b)]$ by passing to a subsequence if necessary. Letting $k \to \infty$, we obtain that $\Phi_r a \notin U$. But this is a contradiction to our choice of U and K and our claim is established.

Hence there exists k_2 such that

$$\Phi_{t_1+\delta}\Phi_r\Phi_{t_k}(x) \leqq \Phi_{t_1}\Phi_{t_k}(y),$$

for $k \geqq k_2$, $0 \leqq r \leqq \mathcal{J}(a, b)$, $0 \leqq \delta \leqq \varepsilon$. Thus,

$$\Phi_{r+\delta}\Phi_{t+t_k}(x) \leqq \Phi_{t+t_k}(y),$$

for $t \geqq t_1$, $k \geqq k_2$, $0 \leqq r \leqq \mathcal{J}(a, b)$, $0 \leqq \delta \leqq \varepsilon$. It follows that $\mathcal{J}(\Phi_{t+t_k}(x), \Phi_{t+t_k}(y)) \geqq \mathcal{J}(a, b) + \varepsilon$, $k \geqq k_2$. Letting $k \to \infty$, we obtain $\alpha \geqq \mathcal{J}(a, b) + \varepsilon$. But $\mathcal{J}(a, b) \geqq \alpha$ and this provides a contradiction. Hence $\mathcal{J}(a, b) = \infty$ and the conclusion of the lemma follows.

The proof of the limit set dichotomy (Proposition 2.3) can now be constructed exactly like Hirsch's original proof.

3. Convergence, quasi convergence, and stability. In this section we state and prove our main results. Several of these results (Theorems 3.3 and 3.10, and Corollary 3.12) overlap similar results of Hirsch [8] and Matano [11], [12]. In these cases, our results are more general and the proofs, we believe, are simpler. Essentially all the results of this section are based on Proposition 3.1 and Corollary 3.2, which, in turn, follow from the nonordering of limit sets (Proposition 2.2) and the limit set dichotomy (Proposition 2.3).

The following definitions will be used throughout this section. We say that $x \in X$ can be approximated from below (above) in X provided there exists a sequence x_n in X satisfying $x_n < x_{n+1} < x$ ($x < x_{n+1} < x_n$) and $x_n \to x$. If $x, y \in X$ then $[x, y] = \{z \in X: x \leqq z \leqq y\}$ is an order interval in X. A subset Y of X is order convex if $[y_1, y_2] \subset Y$ whenever $y_1, y_2 \in Y$ and $y_1 < y_2$.

We require the following compactness hypothesis for our semiflow Φ on X for all our results:

(C) For each $x \in X$, $\mathcal{O}^+(x)$ has compact closure in X. In addition, for each compact subset K of X, $\bigcup_{x\in K} \omega(x)$ has compact closure in X.

We assume that (C) holds throughout this section without further mention. This assumption is a relatively weak compactness requirement. It is certainly satisfied if, for example, every bounded (or even just compact) set $B \subset X$ has a bounded orbit $\mathcal{O}^+(B) = \bigcup_{x\in B} \mathcal{O}^+(x)$ and Φ_t is asymptotically smooth (see [4]). In particular, if bounded sets have bounded orbits and Φ_t is conditionally completely continuous for $t \geqq t_0$, $t_0 > 0$, then (C) holds. Recall that Φ_t is (conditionally) completely continuous if $\Phi_t(B)$ has compact closure in X whenever B is a bounded subset of X (and $\Phi_t(B)$ is a bounded set).

PROPOSITION 3.1 (Sequential limit set trichotomy). *Let X be an ordered metric space, and let Φ_t be a strongly order-preserving semiflow on X. Let $x_0 \in X$ have the property that it can be approximated from below in X by a sequence $\tilde{x}_n$. Then there exists a subsequence x_n of $\tilde{x}_n$ such that $x_n < x_{n+1} < x_0$, $n \geqq 1$, with $x_n \to x_0$ satisfying one of the following.*

(a) *There exists $u_0 \in E$ such that*

$$\omega(x_n) < \omega(x_{n+1}) < u_0 = \omega(x_0), \qquad n \geqq 1,$$

and

$$\lim_{n\to\infty} \operatorname{dist}(\omega(x_n), u_0) = 0.$$

(b) *There exists $u_0 \in E$ such that*

$$\omega(x_n) = u_0 < \omega(x_0), \qquad n \geqq 1.$$

If $u \in E$ and $u < \omega(x_0)$ then $u \leqq u_0$.

(c) *$\omega(x_n) = \omega(x_0) \subset E$ for $n \geqq 1$.*

Recall that $\operatorname{dist}(D, x) = \inf_{y\in D} d(y, x)$ gives the distance of a point $x \in X$ from a subset D of X.

Proof of Proposition 3.1. Let $\tilde{x}_n$ be any sequence satisfying $\tilde{x}_n < \tilde{x}_{n+1} < x_0$, $n \geqq 1$ and $\tilde{x}_n \to x_0$. By the limit set dichotomy (Prop. 2.3) either there exists a positive integer N such that $\omega(\tilde{x}_n) = \omega(\tilde{x}_m)$ for all m, n larger than N or there is a subsequence $\tilde{x}_{n_i}$ such that $\omega(\tilde{x}_{n_i}) < \omega(\tilde{x}_{n_{i+1}})$ for all i. By passing to this subsequence or renumbering the sequence, we may assume that either $\omega(x_n) = \omega(x_m)$ for all n, m or $\omega(x_n) < \omega(x_{n+1})$ for $n \geqq 1$, where x_n is the appropriate subsequence of $\tilde{x}_n$.

Suppose that the latter is the case. Then $\omega(x_n) < \omega(x_0)$ for all n. For if $\omega(x_n) = \omega(x_0)$ for some $n = n_0$ then $\omega(x_n) = \omega(x_0)$ for $n \geqq n_0$, a contradiction to $\omega(x_n) < \omega(x_{n+1})$. Let $\Omega = \{y\colon y = \lim y_n, y_n \in \omega(x_n)\} \subset \overline{\bigcup_{x\in K} \omega(x)}$ where $K = \{x_n\}_n \cup \{x_0\}$. By hypothesis, $\bigcup_{x\in K} \omega(x)$ has compact closure in X so Ω is nonempty and compact. Suppose y and u belong to Ω so that $y_n \to y$, $u_n \to u$ where $y_n, u_n \in \omega(x_n)$. Since $y_n < u_{n+1}$ and $u_n < y_{n+1}$ holds for all n, we obtain $y \leqq u$ and $u \leqq y$ so $u = y$. Thus Ω is a singleton, $\Omega = \{u_0\}$. Furthermore, Ω is invariant since each $\omega(x_n)$ is invariant. Thus $u_0 \in E$. It follows immediately from the definition of Ω and the fact that $\bigcup_{n\geqq 1} \omega(x_n)$ has compact closure in X that $\lim_{n\to\infty} \operatorname{dist}(\omega(x_n), u_0) = 0$. Finally, $\omega(x_n) < \omega(x_0)$ for all n implies that $u_0 \leqq \omega(x_0)$. If $u_0 \in \omega(x_0)$ then $\omega(x_0) = u_0$ by the nonordering principle for limit sets (Proposition 2.2). This is just (a) of the proposition. If $u_0 < \omega(x_0)$ then choose a neighborhood W of $\omega(x_0)$ and $t_0 \geqq 0$ such that $u_0 \leqq \Phi_t(W)$ for $t \geqq t_0$ (Lemma 2.1).

Now there exists $t_1 > 0$ such that $\Phi_{t_1}(x_0) \in W$ and by continuity of Φ_{t_1}, there is an integer n such that $\Phi_{t_1}(x_n) \in W$. It follows that $u_0 \leqq \Phi_t(x_n)$ for $t \geqq t_0 + t_1$. But $u_0 \in E$, so necessarily, $\omega(x_n) \geqq u_0$. On the other hand, $\omega(x_n) < \omega(x_{n+1}) \leqq u_0$ holds for every n so $\omega(x_n) < u_0$ holds for every n. This contradiction shows that $\omega(x_0) = u_0$. Thus (a) holds if $\omega(x_n) < \omega(x_{n+1})$, $n \geqq 1$.

Suppose now that $\omega(x_n) = \omega(x_1)$, $n \geqq 1$. Since $x_n < x_0$, the limit set dichotomy implies that either $\omega(x_n) = \omega(x_1) < \omega(x_0)$ or $\omega(x_n) = \omega(x_0)$ for $n \geqq 1$. The latter is precisely case (c) of the proposition. Suppose $\omega(x_1) < \omega(x_0)$. Let $u_0 \in \omega(x_1) = \omega(x_n) \subset E$ so $u_0 < \omega(x_0)$. By Lemma 2.1 there exists an open set W containing $\omega(x_0)$ and $t_0 \geqq 0$ such that $u_0 \leqq \Phi_t(W)$ for $t \geqq t_0$. Now, arguing exactly as in the previous paragraph, we obtain $u_0 \leqq \Phi_t(x_n)$ for some n and all large t. This yields $\omega(x_n) \geqq u_0$ and since $u_0 \in \omega(x_n)$ it follows that $\omega(x_n) = u_0$ by the nonordering principle for limit sets. Thus $\omega(x_1) = \omega(x_n) = u_0$ as asserted in case (b). Finally, if $u \in E$ and $u < \omega(x_0)$, we may argue exactly as above with u_0, that $u_0 = \omega(x_n) \geqq u$ for all large n, establishing that $u_0 \geqq u$.

Clearly, an analogous result holds if x_0 can be approximated from above in X.

In our next result we summarize some stability information which follows from the proof of Proposition 3.1.

COROLLARY 3.2. *Assume the hypotheses of Proposition* 3.1 *hold. In cases* (a), (b), *and* (c) *of Proposition* 3.1 *we have, in addition, the following*:

(a) *For any n there exists a neighborhood U_n of x_0 and $t_n \geqq 0$ such that*

$$\Phi_t(x_n) \leqq \Phi_t(U_n) \quad \text{for } t \geqq t_n.$$

(b) (i) *There exists a neighborhood O of u_0, t_0, $t_1 \geqq 0$, and n such that*

$$\Phi_t(O) \leqq \Phi_{t+t_1}(x_n) \quad \text{for } t \geqq t_0.$$

(ii) *There is a neighborhood U of x_0 with the following property: for each $x \in U$, $x < x_0$, there exists a neighborhood $V = V_x$ of x in U, an integer $N = N_x$ and $T = T_x > 0$ such that*

$$u_0 \leqq \Phi_t(V) \leqq \Phi_t(x_N), \quad \text{for } t \geqq T.$$

(c) *There is a neighborhood U of x_0 with the following property: for each $x \in U$, $x < x_0$, there exists a neighborhood $V = V_x$ of x in U and $T = T_x > 0$ such that*

$$\Phi_t(x_1) \leqq \Phi_t(V) \leqq \Phi_t(x_0) \quad \text{for } t \geqq T.$$

Moreover,

$$d(\Phi_t(x_0), \Phi_t(x_1)) \to 0 \quad \text{as } t \to \infty.$$

Proof. For (a), fix n. Since $\omega(x_n) < \omega(x_0)$, Lemma 2.1 implies the existence of neighborhoods $W_1 \supset \omega(x_n)$ and $W_2 \supset \omega(x_0)$ and $t_0 \geqq 0$ such that $\Phi_t(W_1) \leqq \Phi_t(W_2)$ for $t \geqq t_0$. There exists $t_1 > 0$ such that $\Phi_{t_1}(x_n) \in W_1$ and $\Phi_{t_1}(x_0) \in W_2$. By continuity of Φ_{t_1}, there is a neighborhood U_n of x_0 such that $\Phi_{t_1}(U_n) \subset W_2$. Hence $\Phi_{t+t_1}(x_n) \leqq \Phi_{t+t_1}(U_n)$ for $t \geqq t_0$, so (a) holds with $t_n = t_0 + t_1$.

Now consider (b). Since $u_0 < \omega(x_0)$, by Lemma 2.1, there exists a neighborhood W of $\omega(x_0)$, a neighborhood O of u_0, and $t_0 \geqq 0$ such that $\Phi_t(O) \leqq \Phi_t(W)$ for $t \geqq t_0$. There exists $t_1 > 0$ such that $\Phi_t(x_0) \in W$ for $t \geqq t_1$. By continuity of Φ_{t_1}, there exists n such that $\Phi_{t_1}(x_n) \in W$. It follows that

$$\Phi_t(O) \leqq \Phi_{t+t_1}(x_n), \qquad t \geqq t_0.$$

Choose a neighborhood U of x_0 such that $\Phi_{t_1}(U) \subset W$ and let $x \in U$ satisfy $x < x_0$. Then there exist neighborhoods V of x, $V \subset U$, $\mathcal{N}$ of x_0, and $t_2 \geqq 0$ such that $\Phi_t(V) \leqq \Phi_t(\mathcal{N})$ for $t \geqq t_2$. Choosing N such that $x_N \in \mathcal{N}$, we have $\Phi_t(V) \leqq \Phi_t(x_N)$ for $t \geqq t_2$. As $\Phi_{t_1}(V) \subset \Phi_{t_1}(U) \subset W$ we have from the paragraph above that

$$u_0 = \Phi(t)u_0 \in \Phi_t(O) \leqq \Phi_t(W) \leqq \Phi_t(\Phi_{t_1}(V)) = \Phi_{t+t_1}(V), \qquad t \geqq t_0,$$

hence

$$u_0 \leqq \Phi_t(V) \leqq \Phi_t(x_N), \qquad t \geqq t_0 + t_1 + t_2.$$

This establishes (b) with $T = t_0 + t_1 + t_2$.

Now consider (c). Since $x_1 < x_0$, there exists a neighborhood U of x_0 and $t_3 \geqq 0$ such that $\Phi_t(x_1) \leqq \Phi_t(U)$ for $t \geqq t_3$. Hence, if $x \in U$ and $x < x_0$ then there is a neighborhood V of x, $V \subset U$, and $t_4 \geqq 0$ such that $\Phi_t(V) \leqq \Phi_t(x_0)$ for $t \geqq t_4$. Since $V \subset U$, it follows that

$$\Phi_t(x_1) \leqq \Phi_t(V) \leqq \Phi_t(x_0) \quad \text{for } t \geqq t_3 + t_4.$$

If $d(\Phi_t(x_0), \Phi_t(x_1)) \to 0$ as $t \to \infty$ does not hold, then there exists $\varepsilon > 0$, $t_n \to \infty$ such that $d(\Phi_{t_n}(x_0), \Phi_{t_n}(x_1)) \geqq \varepsilon$ for $n \geqq 1$. Without loss of generality, we can assume $\Phi_{t_n}(x_0) \to u$, $\Phi_{t_n}(x_1) \to v$ where $u, v \in \omega(x_0)$. But $u \geqq v$ and nonordering of limit sets, Proposition 2.2, implies that $u = v$. This contradiction completes the proof of the corollary.

Remark 3.1. Corollary 3.2 contains stability information that will be exploited more fully later under the additional hypothesis that X is normally ordered (see Remark 3.2). A few remarks here will give the general idea.

(b) (i): Observe that if $x \in O$ and $x > u_0$ then $u_0 < \Phi_t(x) \leqq \Phi_{t+t_1}(x_n)$ for $t \geqq t_0$. Since $\Phi_t(x_n) \to u_0$ as $t \to \infty$, $\omega(x) = u_0$. Thus u_0 is "upper asymptotically stable" in the sense that $\omega(x) = u_0$ for all $x \in O$ with $x \geqq u_0$.

(b) (ii): Similarly, $\Phi_t(x_N) \to u_0$ as $t \to \infty$, so $\omega(v) = u_0$ for all $v \in V$. In particular, $\omega(x) = u_0$ for all $x \in U$ with $x < x_0$.

(c) Similar arguments imply that $\omega(x) = \omega(x_0)$ for all $x \in U$ with $x < x_0$.

THEOREM 3.3. *Let X be an ordered metric space, and let Φ_t be a strongly order-preserving semiflow on X. Suppose each point of X can be approximated from above or from below in X. Then $X = \operatorname{Int} Q \cup \overline{\operatorname{Int} C}$. In particular,* Int Q *is dense in X.*

Proof. Suppose $x_0 \in X \setminus \operatorname{Int} Q$. Then there exists a sequence $y_n \in X \setminus Q$ such that $y_n \to x_0$. By passing to a subsequence if necessary, we can assume that either y_n can be approximated from below in X for each n or y_n can be approximated from above in X for each n. We consider only the former case as the latter case is similar. Each y_n is the limit of a sequence $x_m^n \to y_n$, $x_m^n < x_{m+1}^n < y_n$. For each y_n, case (b) of Proposition 3.1 must hold since $y_n \notin Q$. By Corollary 3.2 and Remark 3.1, it follows that $y_n \in \overline{\operatorname{Int} C}$ for each n because $x_m^n \in \operatorname{Int} C$ for all large m. Hence $x_0 \in \overline{\operatorname{Int} C}$.

DEFINITION. If $x \in X$, then x is a stable point if for every $\varepsilon > 0$ there exists $\delta > 0$ such that $d(\Phi_t(x), \Phi_t(y)) < \varepsilon$ for $t \geqq 0$ whenever $y \in X$ and $d(x, y) < \delta$. We let S be the subset of stable points of X. A point x is an asymptotically stable point if there is a neighborhood V of x with the property that for every $\varepsilon > 0$ there exists $t_\varepsilon > 0$ such that $d(\Phi_t(x), \Phi_t(y)) < \varepsilon$ if $t \geqq t_\varepsilon$ and $y \in V$. We let A denote the set of all asymptotically stable points.

Note that A is an open subset of X and that $A \subset S$. In fact, $A \subset S \subset Q$ under the hypotheses of Theorem 3.3. See also [8, Thm. 8.3 and § 9].

PROPOSITION 3.4. *If the hypotheses of Theorem* 3.3 *hold, then $S \subset Q$.*

Proof. If $x \in S$, then nearby points have nearby limit sets. It follows that only alternatives (a) and (c) of Proposition 3.1 are possible. Thus $x \in Q$.

DEFINITION. An ordered metric space X is called normally ordered if there exists a constant $k>0$ such that

$$d(u, v) \leqq k d(x, y)$$

for all x, y, u, v with $u, v \in [x, y]$.

Remark 3.2. If X is normally ordered, then in (b) and (c) of Corollary 3.2, each $x \in U$ with $x < x_0$ belongs to A. Indeed, the neighborhood V of x, in (b)(ii) of the corollary, can be taken for the neighborhood V in the definition of an asymptotically stable point. For if $y \in V$ then

$$d(\Phi_t(x), \Phi_t(y)) \leqq d(\Phi_t(x), u_0) + d(\Phi_t(y), u_0) \leqq 2kd(\Phi_t(x_N), u_0), \qquad t \geqq T.$$

Similarly, in case (c), if $y \in V$ then

$$\begin{aligned} d(\Phi_t(x), \Phi_t(y)) &\leqq d(\Phi_t(x), \Phi_t(x_0)) + d(\Phi_t(x_0), \Phi_t(y)) \\ &\leqq 2kd(\Phi_t(x_0), \Phi_t(x_1)), \qquad t \geqq T. \end{aligned}$$

Since the term on the right-hand side of each inequality tends to zero, it follows that $x \in A$. Similarly, the equilibrium u_0 in (b)(i) is upper asymptotically stable (see Hirsch [8]) in the sense that for every $\varepsilon > 0$ there exists $t_\varepsilon > 0$ such that if $x \in O$ and $x > u_0$ then $d(\Phi_t(x), u_0) < \varepsilon$ for $t > t_\varepsilon$.

THEOREM 3.5. *Let X be a normally ordered metric space, and let Φ_t be a strongly order-preserving semiflow on X. Assume that each $x \in X$ can be approximated from above or from below in X. Then $A \cup \operatorname{Int} C$ is dense in X.*

Proof. If $A \cup \operatorname{Int} C$ is not dense in X there exists an open set U in X such that $U \cap A = \varnothing = U \cap \operatorname{Int} C$. Let $x \in U$ and assume that x can be approximated from below. Then there is a sequence x_n such that $x_n < x_{n+1} < x$, $x_n \to x$ and one of the alternatives (a), (b), or (c) of Proposition 3.1 and Corollary 3.2 holds. We can assume $x_n \in U$ for all n. As $U \cap A = \varnothing$, only case (a) can hold (see Remark 3.2). Hence x is convergent. Since $x \in U$ was arbitrary, $U \subset C$. So $U \subset \operatorname{Int} C$ in contradiction to our assumption.

PROPOSITION 3.6. *Let X be an ordered metric space, and let Φ_t be a strongly order-preserving semiflow on X. Let $x_0 \in X$ be such that it can be approximated from above in X and from below in X. Then there exist sequences x_n and z_n in X satisfying $x_n \to x_0$, $z_n \to x_0$, $x_n < x_{n+1} < x_0 < z_{n+1} < z_n$, $n \geqq 1$, and one of the following holds*:

(a) *There exists $u_0 \in E$ such that, for $n \geqq 1$,*

$$\omega(x_n) < \omega(x_{n+1}) < \omega(x_0) = u_0 < \omega(z_{n+1}) < \omega(z_n)$$

and

$$\lim_{n\to\infty} \operatorname{dist}(\omega(x_n), u_0) = \lim_{n\to\infty} \operatorname{dist}(\omega(z_n), u_0) = 0.$$

(b) *There exists $u_0, v_0 \in E$ such that, for $n \geqq 1$, either*

(i) $\omega(x_n) < \omega(x_{n+1}) < \omega(x_0) = u_0 < v_0 = \omega(z_n)$,

$$\lim_{n\to\infty} \operatorname{dist}(\omega(x_n), u_0) = 0$$

and whenever $v \in E$, $v > u_0$ then $v \geqq v_0$, or

(ii) $\omega(x_n) = u_0 < v_0 = \omega(x_0) < \omega(z_{n+1}) < \omega(z_n)$

$$\lim_{n\to\infty} \operatorname{dist}(\omega(z_n), v_0) = 0$$

and whenever $u \in E$ and $u < v_0$ then $u \leqq u_0$.

(c) *There exists* $u_0 \in E$ *such that, for* $n \geqq 1$, *either*

(i) $\omega(x_n) < \omega(x_{n+1}) < \omega(x_0) = u_0 = \omega(z_n)$,

$$\lim_{n\to\infty} \operatorname{dist}(\omega(x_n), u_0) = 0$$

or

(ii) $\omega(x_n) = u_0 = \omega(x_0) < \omega(z_{n+1}) < \omega(z_n)$ *and*

$$\lim_{n\to\infty} \operatorname{dist}(\omega(z_n), u_0) = 0.$$

(d) *There exist equilibria* u_0 *and* v_0 *such that, for* $n \geqq 1$,

$$\omega(x_n) = u_0 < \omega(x_0) < v_0 = \omega(z_n).$$

If $u \in E$ *and* $u < \omega(x_0)$ *then* $u \leqq u_0$. *If* $v \in E$ *and* $\omega(x_0) < v$ *then* $v \geqq v_0$.

(e) *There exists* $u_0 \in E$ *such that, for* $n \geqq 1$, *either*

(i) $\omega(x_n) = u_0 < \omega(x_0) = \omega(z_n)$ *and, whenever* $u \in E$ *satisfies* $u < \omega(x_0)$, *then* $u \leqq u_0$, *or*

(ii) $\omega(x_n) = \omega(x_0) < u_0 = \omega(z_n)$ *and, whenever* $u \in E$ *satisfies* $u > \omega(x_0)$, *then* $u \geqq u_0$.

(f) *For* $n \geqq 1$, $\omega(x_n) = \omega(x_0) = \omega(z_n) \subseteq E$.

Proof. The proof is immediate from Proposition 3.1.

As in Proposition 3.1, the sequence $x_n(z_n)$ can be chosen to be a subsequence of any sequence $\tilde{x}_n(\tilde{z}_n)$ approximating x_0 from below (above) in X.

PROPOSITION 3.7. *Let the hypotheses of Proposition* 3.6 *hold. If* $x_0 \notin Q$, *then* (d) *of Proposition* 3.6 *holds. Moreover,* u_0 *and* v_0 *are upper and lower asymptotically stable equilibria, respectively. There is a neighborhood* U *of* x_0 *with the property that for each* $x \in U$ *with* $x < x_0$ $(x > x_0)$ *there exists a neighborhood* V *of* x *in* U *such that* $\omega(y) = u_0$ $(\omega(y) = v_0)$ *for every* $y \in V$. *If* $x \in U$, *then* $\omega(x) \subset [u_0, v_0]$. *If* X *is normally ordered, then* $x \in A$ *for each* $x \in U$ *satisfying* $x < x_0$ *or* $x > x_0$. *Finally, in addition to the above, assume that there exists an ordered Banach space* Y *with normal positive cone* Y_+ *such that* $X \subseteq Y$ *and the metric* d *and order* $\leqq$ *on* X *are inherited from the norm and partial order on* Y. *Assume that the order interval* $[u_0, v_0]$ *in* Y *is contained in* X *and that* Φ_t *is condensing on* $[u_0, v_0]$ *with respect to some measure of noncompactness for each* $t > 0$. *Then there exists* $w_0 \in E$ *satisfying* $u_0 < w_0 < v_0$.

Recall that Φ_t is condensing on $[u_0, v_0]$ if, for a suitable measure of noncompactness β, $\beta(\Phi_t(K)) < \beta(K)$ for any subset K of $[u_0, v_0]$, which is not relatively compact. See [21, § 11.3], for example.

Proof. It follows immediately that if $x_0 \notin Q$ then (d) of Proposition 3.6 holds since all other cases lead to $x_0 \in Q$. That $u_0(v_0)$ is upper (lower) asymptotically stable follows from Corollary 3.2 and Remark 3.2. Similarly, the existence of a neighborhood U of x_0 with the stated properties, follows from Corollary 3.2. If X is normally ordered, then the assertion that $x \in A$ if $x \in U$ and $x < x_0$ or $x > x_0$ follows from Remark 3.2.

It remains only to establish the final assertion. Suppose that the additional hypotheses contained in the last sentence of the proposition hold. Fix $t_0 > 0$ small and consider the map Φ_{t_0} restricted to $[u_0, v_0]$. We modify the proof of a result of Amann [1, Thm. 14.2, see also remarks on p. 667] using the fixed-point index on a suitable compact convex subset K of $[u_0, v_0]$ to establish the existence of a fixed point for Φ_{t_0} in $[u_0, v_0]$ different from u_0 and v_0.

First we show that there exists a compact convex subset K of $[u_0, v_0]$ containing both u_0 and v_0 and $\Phi_{t_0}(K) \subseteq K$. Following the proof of Sadovskii's Fixed-Point Theorem

in [21, § 11.5], we let $\mathscr{X}$ be the family of all closed convex subsets K of $[u_0, v_0]$ such that $u_0, v_0 \in K$ and $\Phi_{t_0}(K) \subseteq K$. Set

$$K = \cap\, \mathscr{X}, \qquad K_1 = \overline{\text{co}}\, \Phi_{t_0}(K).$$

Apparently, $K \in \mathscr{X}$ and $K_1 \subseteq K$. This implies $\Phi_{t_0}(K_1) \subseteq K_1$ so that $K_1 \in \mathscr{X}$. Hence $K = K_1 = \overline{\text{co}}\, \Phi_{t_0}(K)$. As Φ_{t_0} is condensing, the measure of noncompactness of K is zero.

On the convex compact set K the fixed-point index $i(g, U) = i_K(g, U)$ with the usual properties can be defined for continuous mappings $g: K \to K$ and for open (in the relative topology) subsets U of K. See [1].

By Corollary 3.2(b)(i) there exists $r > 0$ such that each point x of the closure of $B(u_0) = \{x \in K;\ d(u_0, x) < r\}$, respectively, $B(v_0) = \{x \in K;\ d(v_0, x) < r\}$, relative to K, satisfies $\omega(x) = u_0$, respectively, $\omega(x) = v_0$. Hereafter, all topological notions are to be understood relative to K. We will establish

$$i(\Phi_{t_0}, B(u_0)) = i(\Phi_{t_0}, B(v_0)) = i(\Phi_{t_0}, K) = +1,$$

which implies, by the additivity property of the fixed-point index, that Φ_{t_0} has a fixed point w_0 in $K \setminus (B(u_0) \cup B(v_0))$. Define the homotopy $F: [0, 1] \times \overline{B(u_0)} \to K$ by $F(\lambda, x) = \lambda u_0 + (1-\lambda)\Phi_{t_0}(x)$. If $F(\lambda, x) = x$ then $x - \Phi_{t_0}(x) = \lambda(u_0 - \Phi_{t_0}(x)) \leqq 0$ because $[u_0, v_0]$ is invariant under Φ. Equality can only hold if $x = u_0$ because u_0 is the only fixed point of Φ_{t_0} in $\overline{B(u_0)}$. Inequality implies $\Phi_{t_0}(x) > x$ that, by Proposition 2.4, gives that $\Phi_t(x)$ converges to an equilibrium larger than x. But this is impossible for any $x \in \overline{B(u_0)}$ because $\omega(x) = \{u_0\}$. We have shown that the fixed-point set of $F(\lambda, \cdot)$ in $\overline{B(u_0)}$ is precisely $\{u_0\}$. The homotopy property of the fixed-point index implies that

$$i(\Phi_{t_0}, B(u_0)) = i(F(1, \cdot), B(u_0)) = +1.$$

For the latter see [1]. Similar arguments yield the other equalities above. Thus there exists $w_0 \in K \setminus (B(u_0) \cup B(v_0))$ such that $\Phi_{t_0}(w_0) = w_0$. As $t_0 > 0$ was arbitrary, we obtain fixed points $w_n \in [u_0, v_0] \setminus (B(u_0) \cap B(v_0))$ of $\Phi_{2^{-n}}$ for all large n. The set $\{w_n\}$ is precompact in $[u_0, v_0]$ since each w_n is a fixed point of $\Phi_{2^{-j}}$ for all $n \geqq j$ and $\Phi_{2^{-j}}$ is condensing. A standard argument gives that a limit point of $\{w_n\}$ is an equilibrium of Φ in $[u_0, v_0] \setminus (B(u_0) \cup B(v_0))$: Let $w_{n_l} \to w$ for $l \to \infty$ and $t_l = 2^{-n_l}$, $\bar{w}_l = w_{n_l} \to w$. If $t > 0$, represent $t = m_l t_l + r_l$, $0 \leqq r_l < t_l$, with a nonnegative integer m_l, $l = 1, 2, \cdots$. Then

$$\Phi_t(w) = \lim_l \Phi_t(\bar{w}_l) = \lim_l \Phi_{r_l} \Phi_{m_l t_l}(\bar{w}_l) = \lim_l \Phi_{r_l}(\bar{w}_l) = w.$$

PROPOSITION 3.8. *Assume that the hypotheses of Proposition* 3.6 *hold and that X is normally ordered. If* (a) *of Proposition* 3.6 *holds then $x_0 \in S$. If* (*f*) *of Proposition* 3.6 *holds then $x_0 \in A$ and there exists a neighborhood U of x_0 such that $\omega(x) = \omega(x_0)$ for all $x \in U$.*

Proof. Suppose (a) of Proposition 3.6 holds. Since $\omega(x_n) < \omega(x_0) < \omega(z_n)$, Lemma 2.1 implies the existence of neighborhoods $W_1 \supset \omega(x_n)$ and $W_0' \supset \omega(x_0)$ and $t_n \geqq 0$ such that $\Phi_t(W_1) \leqq \Phi_t(W_0')$ for $t \geqq t_n$ and neighborhoods $W_0^2 \supset \omega(x_0)$ and $W_2 \supset \omega(z_n)$ and $s_n \geqq 0$ such that $\Phi_t(W_0^2) \leqq \Phi_t(W_2)$ for $t \geqq s_n$. If we let $U_n = W_0' \cap W_0^2$ and $T_n = \max\{t_n, s_n\}$ then $\Phi_t(W_1) \leqq \Phi_t(U_n) \leqq \Phi_t(W_2)$ for $t \geqq T_n$. Now we can argue exactly as in the proof of Corollary 3.2(a) that there exists $r_n \geqq T_n$ such that

$$\Phi_t(x_n) \leqq \Phi_t(U_n) \leqq \Phi_t(z_n) \quad \text{for } t \geqq r_n.$$

Since X is normally ordered it follows that

$$d(\Phi_t(x), \Phi_t(x_0)) \leqq k d(\Phi_t(x_n), \Phi_t(z_n)),$$

for $t \geqq r_n$, $x \in U_n$. Let $\varepsilon > 0$ be given and choose n such that $\operatorname{dist}(\omega(x_n), \omega(z_n)) < \varepsilon$. As $\Phi_t(x_n) \to \omega(x_n)$ and $\Phi_t(z_n) \to \omega(z_n)$ as $t \to \infty$, we can find $p_n > 0$ such that $d(\Phi_t(x_n), \Phi_t(z_n)) < 2\varepsilon$ if $t \geqq p_n$. Hence

$$d(\Phi_t(x), \Phi_t(x_0)) \leqq 2k\varepsilon,$$

for $t \geqq \max\{r_n, p_n\}$ if $x \in U_n$. By continuity of the semiflow, we may choose a neighborhood V_n of x_0, $V_n \subset U_n$, such that

$$d(\Phi_t(x), \Phi_t(x_0)) \leqq 2k\varepsilon, \qquad x \in V_n$$

for all $t \geqq 0$. It follows that $x_0 \in S$.

Suppose now that (f) of Proposition 3.6 holds. Arguing as in the proof of Corollary 3.2(c) we find a neighborhood U of x_0 and $T > 0$ such that

$$\Phi_t(x_1) \leqq \Phi_t(U) \leqq \Phi_t(z_1) \quad \text{for } t \geqq T.$$

Since X is normally ordered, we may conclude that

$$d(\Phi_t(x), \Phi_t(x_0)) \leqq k[d(\Phi_t(x_0), \Phi_t(x_1)) + d(\Phi_t(z_1), \Phi_t(x_0))],$$

for $x \in U$ and $t \geqq T$. Both $d(\Phi_t(x_0), \Phi_t(x_1)) \to 0$ and $d(\Phi_t(z_1), \Phi_t(x_0)) \to 0$ as $t \to \infty$ implying that $x \in A$.

THEOREM 3.9. *Let X be a normally ordered metric space and Φ_t be a strongly order-preserving semiflow on X. Suppose that each point x in X can be approximated from above or from below in X, and X contains an open and dense subset X_0 of points that can be approximated both from above and from below in X. Then $A \cup \operatorname{Int}(S \cap C)$ is dense in X.*

Proof. Recall the proof of Theorem 3.5. If U is open in X such that $A \cap U = \varnothing$, then $U \subset C$. But $\varnothing \neq U_0 := U \cap X_0 \subseteq S$. Actually, if $x \in U_0$, then $x \notin A$, so only alternative (a) of Proposition 3.6 can hold for x. Thus, by Proposition 3.8, $x \in S$. Hence $U_0 \subseteq \operatorname{Int}(S \cap C)$. These considerations imply that $U \cap [A \cup \operatorname{Int}(S \cap C)] \neq \varnothing$ for every open set U in X.

THEOREM 3.10 (Global Asymptotic Stability). *Let the hypotheses of Proposition 3.6 hold and suppose that every point of X can be approximated from above and from below in X. If X is connected and does not contain two ordered equilibria then X contains a unique equilibrium point which is the positive limit set of every orbit.*

Proof. Since no two points of E can be ordered, then for each $x_0 \in X$, only alternatives (a), (c), and (f) of Proposition 3.6 may hold. In particular, $x_0 \in Q$ for every $x_0 \in X$. But then no two limit sets $\omega(x_0)$, $\omega(x_1)$ can be ordered, $\omega(x_0) < \omega(x_1)$ or $\omega(x_1) < \omega(x_0)$ since each consists of equilibria. It follows that alternatives (a) and (c) of Proposition 3.6 cannot occur; only alternative (f) may occur. Fix $x_0 \in X$ and let $M = \{x \in X : \omega(x) = \omega(x_0)\}$. By Proposition 3.8, M is open in X. Similarly, the complement of M is open in X. Since X is connected and M is nonempty, it follows that $M = X$. Thus $\omega(x) = \omega(x_0) \subset E$ for all $x \in X$. If $u \in \omega(x_0)$ then $u = \omega(u) = \omega(x_0)$, so $\omega(x_0)$ is a single equilibrium. The proof is complete.

The hypothesis that no two equilibria are ordered is, of course, weaker than assuming that X contains exactly one equilibria, as assumed by Hirsch in a corresponding result [7], [8].

THEOREM 3.11. *Suppose that X is an order convex subset of a normally ordered Banach space Y. Let Φ_t be a strongly order-preserving semiflow on X such that Φ_t is condensing on every order interval in X for $t > 0$. Assume that any point in $X \setminus E$ can be approximated both from above and below and that X contains at most two order-related equilibria. Then $X = Q$.*

Proof. The proof is immediate from Proposition 3.7.

Remark 3.3. If X contains at most two equilibria, then we obtain from Theorem 3.11 that all points in X are convergent points. A typical application is $X = Y_+$ with zero being an equilibrium and X containing only one equilibrium different from zero. Then Theorem 3.11 implies that all trajectories converge to zero or to the other equilibrium. Actually a stronger alternative holds for trajectories starting in between the two equilibria.

COROLLARY 3.12. *Let $u < v$ be two elements in a normally ordered Banach space X, and let Φ_t be a strongly order-preserving condensing semiflow on the order interval $[u, v]$. Let u, v be the only equilibria of Φ_t on $[u, v]$. Then the following alternative holds. Either the trajectories starting in $[u, v]\backslash\{u, v\}$ all converge to u or they all converge to v.*

A similar result has been proved by Hirsch [8, Thm. 10.5]. Hirsch allows for topological vector spaces, but his compactness and order assumptions are stronger than ours and exclude examples like functional differential equations.

Proof of Corollary 3.12. Assume that there are elements $x, y \in [u, v]\backslash\{u, v\}$ with $\Phi_t(x) \to u$, $\Phi_t(y) \to v$, $t \to \infty$. As Φ is strongly order preserving, we find neighborhoods U, V of u, v and $t_0 > 0$ such that $\Phi_t(U) \leqq \Phi_t(x)$, $\Phi_t(V) \geqq \Phi_t(y)$ for $t \geqq t_0$. As X is normally ordered, we have that

$$\Phi_t(U \cap [u, v]) \to u, \quad \Phi_t(V \cap [u, v]) \to v, \quad t \to \infty.$$

The same proof as in Proposition 3.7 now implies that there is a third equilibrium between u and v in contradiction to our assumption.

Our next result provides sufficient conditions for the set of asymptotically stable points A to be dense in X. For this result, we need to assume that each point $x \in X$ belongs to some totally ordered arc in X. A subset J of X is a totally ordered arc provided $J = \psi(I)$ where I is a nontrivial interval in $\mathfrak{R}$, ψ is a continuous function from I into X, and $\psi(s) < \psi(t)$ whenever $s, t \in I$ and $s < t$.

THEOREM 3.13. *Suppose that X is a normally ordered metric space and that each $x \in X$ belongs to some totally ordered arc in X. Let Φ_t be a strongly order-preserving semiflow on X. If there does not exist a totally ordered arc of equilibria in X then A is dense in X.*

Proof. Assume that $x \in X\backslash\bar{A}$ and $x = \psi(0)$ with $\psi([0, 1])$ being a nontrivial totally ordered arc. In particular, $\psi([0, \varepsilon]) \subseteq X\backslash\bar{A}$ for some $\varepsilon > 0$. As in the proof of Theorem 3.9 ($U = X\backslash\bar{A}$), $\psi((0, \varepsilon))$ is a totally ordered arc of stable convergent points and $\omega(\psi(s)) \neq \omega(\psi(\tilde{s}))$ for $s \neq \tilde{s}$. Hence $\tilde{\psi}(s) = \omega(\psi(s)) = \{\tilde{\psi}(s)\}$ defines a continuous mapping from $(0, \varepsilon)$ into E forming a nontrivial totally ordered arc of equilibria in contradiction to our assumptions.

4. Ruling out nontrivial totally ordered connected sets of equilibria. To have the asymptotically stable points be dense we had to assume that there are no totally ordered arcs of equilibria. This assumption may be hard to verify for large systems of differential equations. A quite general condition is available, however, provided that the semiflow is analytic.

Let us make precise our scenario.

Scenario. We consider an open bounded set U in a Banach lattice X, with the cone X_+ having nonempty interior, and a monotone semiflow Φ on $\bar{U}$.

Let $X + iX$ be the complexification of X. We assume that, for any equilibrium $x_0 \in U$ there exist a neighborhood V of 0 in X and numbers $0 < \varepsilon < t_0$ such that Φ can be extended to a continuous mapping from $(t_0 - \varepsilon, t_0 + \varepsilon) \times (x_0 + V + iV)$ to $X + iX$.

We further assume that, for any $t \in (t_0-\varepsilon, t_0+\varepsilon)$, Φ_t is complex differentiable (i.e., analytic) as a mapping from x_0+V+iV to $X+iX$ and that

$$D\Phi_t(x) \in L(X+iX)$$

depends continuously on X uniformly in $t \in (t_0-\varepsilon, t_0+\varepsilon)$. Here $L(X+iX)$ denotes the complex Banach space of bounded linear operators on $L(X+iX)$ endowed with the uniform operator norm.

Finally, we assume that, for any $t>0$, Φ_t is continuously differentiable as a mapping from U to U and that $D\Phi_t: U \to L(X)$ can be continuously extended to $\bar{U}$. Furthermore, we assume that, for any equilibrium $x_0 \in \bar{U}$, $D\Phi_t(x_0)$, $t \geqq 0$, forms an irreducible strongly continuous semigroup on X such that the essential type $\omega_{\text{ess}}(x_0)$ (or essential growth bound) is strictly negative.

We recall that

$$\omega_{\text{ess}}(x_0) = \inf_{t>0} \frac{1}{t} \ln |D\Phi_t(x_0)|_\beta = \lim_{t\to\infty} \frac{1}{t} \ln |D\Phi_t(x_0)|_\beta,$$

with $|\cdot|_\beta$ denoting the measure of noncompactness. See § 8 of [3]. Furthermore,

$$r_{\text{ess}}(D\Phi_t(x_0)) = e^{w_{\text{ess}}(x_0)t}, \qquad t \geqq 0,$$

with r_{ess} denoting the essential spectral radius. $\omega_{\text{ess}}(x_0) = -\infty$, e.g., if $D\Phi_t(x_0)$ is compact for some $t>0$. Before we formulate the main result of this section let us recall some facts about irreducible strongly continuous semigroups.

Let $A(x_0)$ be the infinitesimal generator of $D\Phi_t(x_0)$, with x_0 being an equilibrium. Then the *spectral bound* $s(x_0)$ of $A(x_0)$ is defined by

$$s(x_0) = \sup \{\text{Re } \lambda; \lambda \text{ spectral value of } A(x_0)\}.$$

It is well known that $s(x_0)$ is a spectral value itself if $s(x_0) > -\infty$. See, e.g., Theorem 8.7 of [3].

We are now able to formulate our main result.

THEOREM 4.1. *Consider the scenario outlined above. Assume further that any closed set of equilibria in $\bar{U}$ is compact and that*

$$s(x_0) \neq 0,$$

for any equilibrium $x_0 \in \partial U$ (if there are any). Then every totally ordered connected set of equilibria in $\bar{U}$ is a singleton (i.e., consists of one element only).

It is convenient to prove the following result first.

LEMMA 4.2. *Consider the scenario outlined at the beginning of this section. Let D be a totally ordered connected set of equilibria in $\bar{U}$ which consists of more than one element. Then $s(x_0) = 0$ for any $x_0 \in D$.*

Proof. Let $x_0 \in D$. Then x_0 can be approximated by other elements in D from above or from below. We assume that there are elements $x_n > x_0$ such that $x_n \to x_0$. Recall that x_0, x_n are equilibria. Thus, defining

$$u_n = \frac{1}{\|x_n - x_0\|}(x_n - x_0),$$

we obtain that

$$u_n - D\Phi_t(x_0)u_n \to 0 \quad \text{for } n \to \infty, \quad t \geqq 0.$$

Let β be the measure of noncompactness. See § A.3.1 of [3]. Then

$$\beta(\{u_n; n \in N\}) \leqq |D\Phi_t(x_0)|_\beta \beta(\{u_n\}_n) \leqq (M e^{(w_{\text{ess}}(x_0)+\varepsilon)t})\beta(\{u_n; n \in N\}),$$

with $\varepsilon > 0$ such that $w_{ess}(x_0) + \varepsilon < 0$ and M depending on ε. Hence we realize from choosing t large enough that

$$\beta(\{u_n;\, n \in \mathbf{N}\}) = 0.$$

This implies that the closure of $\{u_n;\, n \in \mathbf{N}\}$ is compact, and we find $v \geqq 0$, $\|v\| = 1$ such that

$$D\Phi_t(x_0)v = v \quad \text{for all } t \geqq 0.$$

Clearly, v is an eigenvector of $A(x_0)$ belonging to the eigenvalue zero. As $D\Phi_t(x_0)$, $t \geqq 0$, is irreducible, $v \in \operatorname{Int} X_+$. This implies that the spectral radius of $D\Phi_t(x_0) \leqq 1$, hence $s(A) \leqq 0$. See Proposition 8.6 and the preceding remarks of [3]. As zero is an eigenvalue of A, $s(A) = 0$.

Remark 4.1. It follows from our assumptions that $s(x_0) = 0$ is a pole of the resolvent of $A(x_0)$. The irreducibility of $D\Phi_t(x_0)$ implies that $s(x_0)$ is a simple eigenvalue of $A(x_0)$ with an eigenvector $v \in \operatorname{Int} X_+$ and a strictly positive eigenfunctional $v^* \in X^*$ of $A^*(x_0)$. If we normalize v^* and v such that $\|v\| = 1$, $v^*(v) = 1$, then

$$Px = v^*(x)v$$

is the projection onto the eigenspace of zero. In particular, there exists $\varepsilon > 0$, $M > 0$ such that

$$\|(I - P)D\Phi_t(x_0)x\| = \|D\Phi_t(x_0)x - v^*(x)v\| \leqq M e^{-\varepsilon t}\|x\|,$$

$t \geqq 0$. See Theorem 9.11 of [3]. Moreover, v is the only eigenvector of $A(x_0)$ in X_+.

We are now able to give the proof of Theorem 4.1.
