We use two methods for studying these equations. They are a Fourier transform approach that applies to the general equation (1.1), and a time-domain approach described further below that applies only to lattice two-scale difference equations. Part I describes Fourier transform results on existence and uniqueness, introduces the time-domain approach, and uses it to establish bounds on the smoothness of L^1-solutions of compact support. Part II studies the time-domain construction in detail and gives sufficient conditions for the existence of nonzero continuous solutions of compact support, and determines their local and global regularity properties.

The Fourier transform provides a method for the study of L^1-solutions f of general two-scale difference equations (1.1). The convolution character of the right side of (1.1) leads to an infinite product expansion for the Fourier transform $\hat{f}(u)$ permitting detailed study. Section 2 uses this approach to obtain existence and uniqueness results for L^1-solutions to (1.1). These depend in a crucial way on the quantity

$$\Delta = \alpha^{-1} \sum_{m=0}^{N} c_n. \tag{1.5}$$

There are no nonzero L^1-solutions if $|\Delta| < 1$ or if $|\Delta| = 1$ and $\Delta \neq 1$. The case of most interest is $\Delta = 1$; it has at most one nonzero L^1-solution, up to a multiplicative scale factor. This solution, if it exists, is of compact support with support $(f) \subset [0, (\alpha-1)^{-1}N]$, and has $\int_{-\infty}^{\infty} f(x)\,dx \neq 0$. For $|\Delta| > 1$ it is possible to have zero, one, or infinitely many L^1-solutions, which need not have compact support, depending on the values $\{\alpha, \beta_n, c_n\}$.

Section 3 studies L^1-functions of compact support solving (1.1), and shows that they are all derived from solutions of the case $\Delta = 1$, in the following sense. If a two-scale difference equation (1.1) has a nonzero L^1-solution f of compact support, then it is unique (up to normalization), and necessarily,

(1) $\Delta = \alpha^m$ for some nonnegative integer m;

(2) The two-scale difference equation with $\Delta = 1$ obtained by replacing the coefficients $\{c_n\}$ with $\{\alpha^{-m}c_n\}$ has a nonzero L^1-solution g of compact support, and for a suitable choice of normalization,

$$\frac{d^m}{dx^m}\, g(x) \equiv f(x) \quad \text{a.e;}$$

The remainder of part I and part II use time-domain methods that apply only to the special case of lattice two-scale difference equations (1.2). This approach exploits the special feature that lattice two-scale difference equations make sense when restricted to the discrete domain $\mathbb{Z}$. Suppose we are given data $\{f(n);\, n \in \mathbb{Z}\}$ which satisfy

$$f(x) = \sum_{n=0}^{N} c_n f(kx-n) \tag{1.6}$$

for all $x \in \mathbb{Z}$. The functional equation then determines $f(x)$ for $x \in \mathbb{Z}/k$, and by iteration for $x \in \bigcup_{n=1}^{\infty} \mathbb{Z}/k^n$. In particular, such data $\{f(n);\, n \in \mathbb{Z}\}$ can be interpolated by at most one continuous solution of (1.6). This approach thus applies most naturally to the problem of finding *continuous* solutions of (1.6). Here we have the two subproblems

of finding solutions to (1.6) on $\mathbb{Z}$, and then determining conditions under which such solutions interpolate to solutions on $\mathbb{R}$.

The time-domain approach applies particularly well in the study of compactly supported continuous solutions, since we then know that $\{f(n);\ n \in \mathbb{Z}\}$ has $f(n) = 0$ off the finite set $0 \leqq n \leqq N/(k-1)$, and the set of solutions on $\mathbb{Z}$ to (1.6) is a finite-dimensional vector space. The iterative process of recursively solving (1.6) on $\{\mathbb{Z}/k^n;\ n = 1, 2, \cdots\}$ can be encoded using products of a finite set of matrices, as is explained in part II, and this provides a vehicle for studying convergence and smoothness of solutions. Such an approach was initiated by Micchelli and Prautzsch (1987a), as we discovered after completing this work.

In the rest of part I we apply the time-domain approach to obtain information about compactly supported solutions in the case where $\Delta = 1$, which by the results of § 3 is essentially the most general case.

Section 4 obtains results on two different iterative methods to find solutions of the lattice two-scale equation (1.6). A solution is a fixed point $f = Vf$ of the linear operator

$$Vf(x) = \sum_{n=0}^{N} c_n f(kx - n), \tag{1.7}$$

and a natural approach is to consider iterative schemes $f_j = Vf_{j-1}$ that converge to a fixed point f starting from suitable f_0. Given data $\{f(n);\ n \in \mathbb{Z}\}$ for an L^1-solution of such an equation with $\Delta = 1$, we can construct a piecewise linear spline f_0 that has $f_0(n) = f(n)$ for all $n \in \mathbb{Z}$. We show that if f is continuous, then the iterates $f_{j+1} = Vf_j$ are piecewise linear splines with successively finer knot sets (Theorem 4.1) and that $f_j \to f$ pointwise, with a rate of convergence depending on the smoothness of f. If f is L times continuously differentiable, then f_0 can be chosen to be a C^L piecewise polynomial spline of degree $2L+1$, with $f_0^{(l)}(n) = f^{(l)}(n)$ for all $n \in \mathbb{Z}$, $l = 0, \cdots, L$. Then the iterates $f_{j+1} = Vf_j$ are again C^L piecewise polynomial splines of degree $2L+1$ with successively finer knot sets, and we prove $f_j^{(l)} \to f^{(l)}$ pointwise, for all $l = 0, \cdots, L$. These results show in particular that convergence to a C^0-solution $f(x)$ occurs when one exists, if we start with correct initial conditions on $\mathbb{Z}$. However, they give no information concerning existence of such solutions.

The second iterative method for finding solutions to (1.6) discussed in § 4 is the "cascade algorithm." The successive approximations f_j in this scheme are again defined by $f_j = Vf_{j-1}$, but the starting point is now $f_0(x) = 1 - |x|$ for $-\frac{1}{2} \leqq x \leqq \frac{1}{2}$ and $f_0(x) = 0$ otherwise. These initial conditions are not usually a solution to (1.6) on $\mathbb{Z}$. The advantage of the cascade algorithm is that f_j can be computed via a "local" method: at every step j, the value of $f_j(x)$ can be determined using *only* the values obtained in the previous step in the region $\{y;\ |y - x| \leqq C2^{-j}\}$ (C independent of j), a neighborhood of x becoming exponentially small as j increases. This lends a "zoom-in" quality to the successive steps of the cascade algorithm (when it converges). It is known that the cascade algorithm does not always converge pointwise to a nonzero C^0-solution when one exists. This scheme has been studied by several authors (cf. Deslauriers and Dubuc (1989), Dyn, Gregory, and Levin (1989), (1990)), and various sufficient conditions for its convergence are known.

Section 5 obtains bounds on the global regularity of any nonzero L^1-solution to (1.6) when $\Delta = 1$. Theorem 5.1 shows that if such a solution is in $C^m(\mathbb{R})$, then $m < N/(k-1) - 1$. This result is best possible in the sense that there exist equations having C^m-solutions, for which $m \geqq N/(k-1) - 2$, for arbitrarily large m.

Finally, § 6 applies these results to three examples.

A number of authors have studied more general solutions to two-scale difference equations and related functional equations. In constructing fractals Barnsley and Demko (1985) study measures μ which are solutions of

$$\mu(S) = \sum_{n=0}^{N} c_n \mu(\alpha S - \beta_n), \qquad S \text{ a Borel set.}$$

The *adjoint operator* (in the L^2-sense) to (1.1) is

$$V^A g(x) = \sum_{n=0}^{N} c_n g(\alpha^{-1}(x+\beta_n)).$$

The stationary measures μ studied by Diaconis and Shashahani (1986) are fixed points of generalizations of such adjoint operators. It is also interesting to note that the mth Bernoulli polynomial $B_m(x)$ satisfies the equation $V^A B_m(x) = B_m(x)$ with

$$V^A g(x) = \sum_{n=0}^{m-1} n^{m-1} g\left(\frac{1}{m}(x+n)\right).$$

2. Existence and uniqueness of L^1-solutions. We are interested in L^1-solutions f to the two-scale difference equation

$$f(x) = \sum_{n=0}^{N} c_n f(\alpha x - \beta_n). \tag{2.1}$$

Since f is in $L^1(\mathbb{R})$, its Fourier transform $\hat{f}$,

$$\hat{f}(u) = \int_{-\infty}^{\infty} e^{ixu} f(x)\, dx,$$

is a bounded continuous function. By viewing (2.1) as a convolution equation, we see that $\hat{f}$ satisfies

$$\hat{f}(u) = P(\alpha^{-1}u)\hat{f}(\alpha^{-1}u) \tag{2.2}$$

where

$$P(u) = \frac{1}{\alpha} \sum_{n=0}^{N} c_n e^{i\beta_n u}. \tag{2.3}$$

The existence and uniqueness of L^1-solutions to (2.1) are governed by the value

$$\Delta = P(0) = \frac{1}{\alpha} \sum_{n=0}^{N} c_n,$$

as shown in the following result.

THEOREM 2.1. *Let Δ be defined as above. Then the following are true.*

(a) *If $|\Delta| \leqq 1$ and $\Delta \neq 1$, then the only L^1-solution of* (2.1) *is the trivial solution $f \equiv 0$.*

(b) *If $\Delta = 1$ then there exists, up to normalization, at most one nontrivial L^1-solution to* (2.1). *If it exists, then its Fourier transform is given by*

$$\hat{f}(u) = A \prod_{j=1}^{\infty} P(\alpha^{-j}u) \tag{2.4}$$

where $A = \hat{f}(0) = \int f(x)\, dx$ and the infinite product converges for all u. Conversely, if the right-hand side of (2.4) *is the inverse Fourier transform of an L^1-function f, then f is a nontrivial L^1-solution to* (2.1).

(c) *If* $|\Delta|>1$, *then the Fourier transform of any* L^1*-solution* f *is necessarily of the form*

$$\hat{f}(u)=\left[\prod_{j=1}^{\infty} p(\alpha^{-j}u)\right]\exp\left(\frac{\ln\Delta}{\ln\alpha}\ln|u|\right)g_{\operatorname{sgn}(u)}\left(\frac{\ln|u|}{\ln\alpha}\right) \tag{2.5}$$

where

$$p(u)=\Delta^{-1}P(u),$$

$g_{\pm}$ *are continuous periodic functions with period* 1, *and*

$$\ln\Delta=\ln|\Delta|+i\theta \quad \text{where } \Delta=|\Delta|\,e^{i\theta} \quad \text{and} \quad -\pi<\theta\leqq\pi.$$

Furthermore, the infinite product converges for all complex u. *Conversely, if* g_+, g_- *are continuous periodic functions of period* 1 *such that the inverse Fourier transform* f *of the right side of* (2.5) *is in* $L^1(\mathbb{R})$, *then* f *satisfies* (2.1).

Proof. (1) We have

$$\begin{aligned}|P(u)-\Delta| &\leqq \alpha^{-1}\sum_{n=0}^{N}|c_n||e^{i\beta_n u}-1| \\ &\leqq K\min(1,|u|)\exp[B|\operatorname{Im}(u)|]\end{aligned} \tag{2.6}$$

where $B=\max|\beta_i|$ and $K=2\alpha^{-1}\sum_{n=0}^{N}|c_n|(1+|\beta_n|)$.

(2) We first treat the case where $|\Delta|<1$. Since $f\in L^1(\mathbb{R})$, $\hat{f}(u)$ is continuous for $u\in\mathbb{R}$. From (2.6) we have (for real u)

$$|\hat{f}(u)|=|P(\alpha^{-1}u)||\hat{f}(\alpha^{-1}u)|\leqq(|\Delta|+K\alpha^{-1}|u|)|\hat{f}(\alpha^{-1}u)|.$$

It follows that, for all $j\in\mathbb{N}$,

$$|\hat{f}(u)|\leqq\|f\|_1\prod_{l=1}^{j}(|\Delta|+K\alpha^{-l}|u|). \tag{2.7}$$

For any real u we can make the product on the right side of (2.7) arbitrarily small by choosing j large enough, since $|\Delta|<1$. Hence $f\equiv 0$. This proves (a), except for $|\Delta|=1$, which we treat below.

(3) For $|\Delta|\geqq 1$ define $p(u)=\Delta^{-1}P(u)$. By (2.6) we have

$$|p(u)-1|\leqq K\,e^{B}\Delta^{-1}|u|:=K'|u|, \tag{2.8}$$

for complex $|u|<1$. Now we define

$$\hat{f}_0(u):=\prod_{j=1}^{\infty}p(\alpha^{-j}u), \tag{2.9}$$

and (2.8) shows that the infinite product converges absolutely and uniformly on compact subsets of $\mathbb{C}$ to an entire function. The bound (2.8) shows that for $|u|\leqq(2K')^{-1}$, $|p(u)|\geqq 1-K'|u|\geqq(1+2K'|u|)^{-1}$ and

$$\begin{aligned}|\hat{f}(\alpha^{-j}u)| &= |\hat{f}(u)|\prod_{l=1}^{j}|P(\alpha^{-l}u)|^{-1} \\ &\leqq |\Delta|^{-j}|\hat{f}(u)|\prod_{l=1}^{j}(1+2K'\alpha^{-l}|u|) \\ &\leqq |\Delta|^{-j}\|f\|_1\exp[2K'(\alpha-1)^{-1}|u|].\end{aligned}$$

This implies that

$$|\hat{f}(u)|\leqq\exp[(\alpha-1)^{-1}]\|f\|_1|\Delta|^{-j} \quad \text{when } |u|\leqq(2K')^{-1}\alpha^{-j}.$$

For any $|u| \leqq (2K')^{-1}$ we can find j so that $(2K')^{-1}\alpha^{-(j+1)} \leqq |u| \leqq (2K')^{-1}\alpha^{-j}$. It follows that

$$\begin{aligned} |\hat{f}(u)| &\leqq \exp[(\alpha-1)^{-1}]\|f\|_1 |\Delta|^{-j} \\ &\leqq \exp[(\alpha-1)^{-1}]\|f\|_1 \alpha^{-j \ln|\Delta|/\ln\alpha} \\ &\leqq C|u|^{\ln|\Delta|/\ln\alpha} \end{aligned} \tag{2.10}$$

for all $|u| \leqq (2K')^{-1}$. Since $|\hat{f}(u)|$ is bounded for real u ($f \in L^1$), (2.10) also extends (with possibly a different constant) to all $u \in \mathbb{R}$. Note that for $|\Delta| > 1$, (2.10) implies that

$$\int_{-\infty}^{\infty} f(x)\,dx = \hat{f}(0) = 0,$$

which can also be obtained directly from (2.1) by integration. Define $F(u)$ by

$$F(u) := \exp\left(-\frac{\ln|\Delta|}{\ln\alpha}\ln|u|\right)\hat{f}(u).$$

Since $\hat{f}$ is continuous, F is continuous as well, except possibly at $u = 0$, and by (2.10), F is bounded near $u = 0$. The function F satisfies the recursion

$$F(u) = e^{i\theta}p(\alpha^{-1}u)F(\alpha^{-1}u), \tag{2.11}$$

where $\Delta = |\Delta|\, e^{i\theta}$ and $-\pi < \theta \leqq \pi$. This yields

$$F(u) = \left[\prod_{j=1}^{J} p(\alpha^{-j}u)\right] e^{iJ\theta}F(\alpha^{-J}u).$$

The first factor has the limit $\hat{f}_0(u)$ as $J \to \infty$. When this limit is not zero, the second factor must also converge as $J \to \infty$, and we denote this limit by $\phi(u)$, so that

$$\phi(u) := [\hat{f}_0(u)]^{-1}F(u).$$

The function ϕ is continuous, except possibly at $u = 0$, where F may be discontinuous, and at the zeros of $\hat{f}_0(u)$. From (2.8) we find for complex $|u| \leqq 1$ that

$$|\hat{f}_0(u) - 1| \leqq K'|u| \exp[B(\alpha-1)^{-1}|u|],$$

which implies that $\hat{f}_0(u)$ is bounded away from zero in a neighborhood of $u = 0$. It follows that ϕ is continuous in a neighborhood of zero, except possibly at $u = 0$. On the other hand, the recursion (2.11) for F gives

$$\phi(u) = e^{i\theta}\phi(\alpha^{-1}u).$$

Define the two functions

$$g_{\pm}(t) := \phi(\pm\alpha^t)\exp(i\theta t), \qquad t \in \mathbb{R}.$$

Then

$$g_{\pm}(t+1) = g_{\pm}(t). \tag{2.12}$$

If the periodic functions $g_{\pm}$ had any singularity (including discontinuities), then ϕ would have infinitely many singularities in a neighborhood of $u = 0$. Since this is impossible, it follows that the $g_{\pm}$ are continuous. To prove the converse statement, it suffices to observe that, under the stated conditions, for $|\Delta| \geqq 1$, the right-hand side of (2.5) satisfies the functional equation $\hat{f}(u) = P(\alpha^{-1}u)\hat{f}(\alpha^{-1}u)$. This establishes (c).

(4) If $|\Delta| = 1$, then the above construction simplifies. We have

$$\hat{f}(u) = \hat{f}_0(u)\phi(u), \tag{2.13}$$

where ϕ satisfies

$$\phi(u) = \Delta\phi(\alpha^{-1}u) = e^{i\theta}\phi(\alpha^{-1}u).$$

Since $\hat{f}_0(u)$ is bounded away from zero for small $|u|$, it follows from (2.13) that ϕ is continuous at zero. In particular,

$$\phi(0) = e^{i\theta}\phi(0),$$

implying either $\Delta = e^{i\theta} = 1$ or $\phi(0) = 0$. However, we also know that

$$\phi(u) = g_{\mathrm{sgn}(u)}\left(\frac{\ln|u|}{\ln\alpha}\right)\exp\left(i\theta\frac{\ln|u|}{\ln\alpha}\right)$$

where $g_{\pm}$ are continuous periodic functions with period 1. If $\Delta \neq 1$ then $\phi(0) = 0$; hence $|g_{\pm}(t)| = |\phi(\pm\alpha^t)| \to 0$ as $t \to -\infty$. Since the functions $g_{\pm}$ are periodic, this forces $g_{\pm} \equiv 0$; hence $\phi \equiv 0$ and $f \equiv 0$ for $\Delta \neq 1$, which proves the rest of (a). If $\Delta = 1$ then $g_{\pm}(t) = \phi(\pm\alpha^t) \to \phi(0)$ as $t \to \infty$. By the periodicity of $g_{\pm}$ this implies that $g_{\pm} \equiv \phi(0)$ are both the same constant function; hence $\hat{f}(u) = \phi(0)\hat{f}_0(u)$. This proves (b). □

Remarks. (1) Theorem 2.1 also holds for "infinite" two-scale difference equations, i.e.,

$$f(x) = \sum_{n=-\infty}^{\infty} c_n f(\alpha x - \beta_n)$$

provided that $\sum_{n=-\infty}^{\infty} |c_n||\beta_n|^{\delta} < \infty$ for some $\delta > 0$. The estimate (2.6) then becomes

$$|P(u) - \Delta| \leqq \alpha^{-1} \sum_{n=-\infty}^{\infty} |c_n| \min\left(2, |\beta_n u|^{\min(1,\delta)}\right) e^{|B||\mathrm{Im}\, u|},$$

and the other estimates can be adjusted similarly.

(2) Note that there may exist distributional solutions even if $|\Delta| < 1$. One example is the equation

$$f(x) = \tfrac{1}{12}f(2x) + \tfrac{1}{6}[f(2x+1) + f(2x-1)] - \tfrac{1}{12}[f(2x+2) + f(2x-2)],$$

which admits $f(x) = x^2$ as a solution. The Fourier transform of this solution is a distribution supported at the origin, so that the continuity argument used in the proof of Theorem 2.1 does not apply.

(3) There are no distributional solutions with Fourier transform continuous at zero if $|\Delta| < 1$. For $|\Delta| \geqq 1$, (2.4) and (2.5) always give distributional solutions to the two-scale equation (2.1), but there may exist other distributional solutions with discontinuous Fourier transforms.

Theorem 2.1 has the following corollary, proved in the lattice case by Deslauriers and Dubuc (1987).

COROLLARY 2.2. *If the two-scale difference equation* (2.1) *with* $\Delta = 1$ *possesses a nontrivial* L^1*-solution* f*, then* $\int_{-\infty}^{\infty} f(x)\,dx \neq 0$ *and* f *has compact support, with*

$$\mathrm{supp}\,(f) \subset [\beta_0(\alpha-1)^{-1}, \beta_N(\alpha-1)^{-1}]. \tag{2.14}$$

Proof. By Theorem 2.1

$$\hat{f}(u) = \hat{f}(0)\prod_{j=1}^{\infty} P(\alpha^{-j}u) = \hat{f}(0)\hat{f}_0(u).$$

Hence $\int_{-\infty}^{\infty} f(x)\,dx = \hat{f}(0) \neq 0$. We can without loss of generality reduce to the case that $\beta_0 = -\beta_N$ by considering

$$f_1(x) = f\left(x - (\alpha-1)^{-1}\frac{\beta_N - \beta_0}{2}\right),$$

which is easily checked to satisfy

$$f_1(x) = \sum_{n=0}^{N} c_n f_1\left(\alpha x - \beta_j + \frac{\beta_0 - \beta_N}{2}\right).$$

Now suppose $\beta_0 = -\beta_N$ and (2.6) becomes

$$|P(u) - 1| \leqq K \min(1, |u|) \exp(B|\operatorname{Im}(u)|)$$

with $B = \beta_N$. On the annulus $\alpha^k \leqq |u| \leqq \alpha^{k+1}$ this gives

$$\begin{aligned} |\hat{f}_0(u)| &\leqq \prod_{j=1}^{k+1} [1 + K\Delta^{-1} \exp(B\alpha^{-j}|\operatorname{Im}(u)|)] \prod_{j=k+2}^{\infty} [1 + K'\alpha^{-j} \exp(B)] \\ &\leqq C(1+|u|)^M \exp[B(\alpha-1)^{-1}|\operatorname{Im}(u)|], \end{aligned} \tag{2.15}$$

where $M = [|\ln((K\Delta^{-1}+1)/\alpha)| + 1]$ and C is a constant. By the Paley–Wiener theorem for distributions (see, e.g., Reed and Simon (1975, Thm. IX.12)) $\hat{f}_0(u)$ is the Fourier transform of a distribution f_0 in $\mathcal{S}'(\mathbb{R})$ having compact support in the interval $|x| \leqq B(\alpha-1)^{-1}$. By hypothesis this distribution is the L^1-function $[\hat{f}(0)]^{-1} f$; hence f has compact support in $|x| \leqq (\beta_n - \beta_0)/(2(\alpha-1))$ and (2.14) follows. □

This proof shows that *all* two-scale difference equations with $\Delta = 1$ possess a distributional solution f in $\mathcal{S}'(\mathbb{R})$ having compact support in $[\beta_0(\alpha-1)^{-1}, \beta_N(\alpha-1)^{-1}]$ which has Fourier transform (2.4). The arguments of § 3 will show that up to a scale factor this is the unique distribution in $\mathcal{S}'(\mathbb{R})$ which satisfies (3.1) and has compact support. The following examples illustrate a few cases, for different values of Δ.

Examples. (1) Consider the lattice two-scale difference equation

$$f(x) = \tfrac{1}{2}\Delta[f(2x) + 2f(2x-1) + f(2x-2)].$$

Depending on the value of Δ, there will be one, infinitely many, or no nontrivial L^1-solutions. If $\Delta = 1$, then any candidate L^1-solution satisfies

$$\begin{aligned} \hat{f}(u) &= \hat{f}(0) \prod_{j=1}^{\infty} \left\{\frac{1}{4}[1 + \exp(i2^{-j}u)]^2\right\} \\ &= \hat{f}(0)\, e^{iu}\left(\frac{\sin(u/2)}{u/2}\right)^2. \end{aligned}$$

It follows that f is a multiple of the function g,

$$g(x) = \begin{cases} x, & 0 \leqq x \leqq 1, \\ 2-x, & 1 \leqq x \leqq 2, \\ 0 & \text{otherwise.} \end{cases}$$

Up to normalization, we therefore have a unique L^1-solution in this case. For $\Delta = 2$, we find

$$\hat{f}(u) = |u|\, e^{iu}\left(\frac{\sin(u/2)}{u/2}\right)^2 g_{\operatorname{sgn}(u)}\left(\frac{\ln|u|}{\ln 2}\right),$$

where $g_{\pm}$ are periodic, continuous functions of period 1. Clearly, $\hat{f} \in L^2(\mathbb{R})$. If $g_{\pm}$ are C^1, then we easily check that also $(\hat{f})' \in L^2$, which implies $f \in L^1$. There is therefore

clearly an infinity of different possible L^1-solutions in this case. Only one of these L^1-solutions is compactly supported (see § 3). For $\Delta = 4$, however, we have

$$\hat{f}(u) = 4\, e^{iu}[\sin(u/2)]^2 g_{\mathrm{sgn}(u)}\left(\frac{\ln|u|}{\ln 2}\right).$$

This tends to zero for $|u| \to \infty$ only if both functions $g_{\pm} \equiv 0$. The only L^1-solution is therefore the trivial solution $f \equiv 0$.

(2) The following example shows that $\Delta = 1$ does not imply the existence of a nontrivial L^1-solution. Take the lattice two-scale difference equation

$$f(x) = 2f(2x-1).$$

Every candidate L^1-solution satisfies

$$\hat{f}(u) = \hat{f}(0) \prod_{j=1}^{\infty} [\exp(i2^{-j}u)] = \hat{f}(0)\, e^{iu}.$$

Since e^{iu} is the Fourier transform of the Dirac δ-measure at $x = 1$, there are no nontrivial L^1-solutions.

(3) Consider the family of two-scale difference equations

$$f_\alpha(x) = \frac{\alpha}{2}\{f_\alpha(\alpha x - 1) + f_\alpha(\alpha x + 1)\},$$

which all have $\Delta = 1$. This equation always has a distributional solution with Fourier transform

$$\hat{f}_\alpha(u) = \prod_{n=1}^{\infty} \cos(\alpha^{-n}u),$$

which has compact support in $[-(\alpha-1)^{-1}, (\alpha-1)^{-1}]$ by the same argument as in the proof of Corollary 2.2. The smoothness of this distribution as a function of $\beta = \alpha^{-1}$ for $0 < \beta < 1$ was studied by Kershner and Wintner (1935), Erdös (1939), (1940), and Garsia (1962). It is known that for $\alpha = 2^{1/k}$, with k sufficiently large, the function f_α is continuous (hence in $L^1(\mathbb{R})$) and arbitrarily smooth. Erdös (1940) showed that for any k there is a constant $c(k)$ such that for almost all $\beta = \alpha^{-1}$ in the interval $[c(k), 1]$ the distribution f_α is a function in $C^{(k)}(\mathbb{R})$.

3. L^1-solutions having compact support. We consider the general two-scale difference equation

$$f(x) = \sum_{n=0}^{N} c_n f(\alpha x - \beta_n), \tag{3.1}$$

and derive necessary conditions for the existence of nonzero L^1-function of compact support.

THEOREM 3.1. *Suppose that the two-scale difference equation* (3.1) *possesses a nonzero L^1-solution f having compact support. Then*:

(a) $\Delta = \alpha^m$ *for a nonnegative integer* m.

(b) f *is unique up to a scale factor and has Fourier transform*

$$\hat{f}(u) = Au^m \prod_{k=1}^{\infty} p(\alpha^{-k}u) \tag{3.2}$$

where $p(u) = \Delta^{-1} \sum_{n=0}^{n} c_n\, e^{i\beta_n u}$.

(c) *The two-scale equation with* $\Delta = 1$ *obtained by replacing* $\{c_n\}$ *by* $\{\alpha^{-m}c_n\}$ *has a nonzero* L^1*-solution* g *unique up to scale, and with a proper choice of scale* $(d^m/dx^m)g(x) \equiv f(x)$.

The main ingredient in the proof is the following result.

LEMMA 3.2. *Suppose that the function* M_0, *defined on* $\mathbb{R} - \{0\}$ *by*

$$M_0(u) := \exp(\gamma_0 \ln |u|) g_{\mathrm{sgn}(u)}(\gamma_1 \ln |u|), \tag{3.3}$$

is such that

(1) $g_{\pm}(t)$ *are periodic functions of period* 1.

(2) γ_1 *is real.*

(3) $M_0(u)$ *possesses an analytic continuation to* $\mathbb{C}$ *which is an entire function of exponential type.*

Then $M_0(u) = Au^m$ *where* m *is a nonnegative integer.*

Proof. (1) The function $h(u) = \exp(\gamma_0 \ln u)$ can be continued analytically to the simply-connected two-sheeted region $\mathbf{R} = \{z = re^{i\theta};\ r > 0 \text{ and } -\frac{3}{2}\pi \leqq \theta \leqq \frac{3}{2}\pi\}$ where $re^{i\theta}$ and $re^{i(\theta+2\pi)}$ are viewed as distinct points and

$$h(re^{i(\theta+2\pi)}) = \exp(2\gamma_0 \pi i) h(re^{i\theta}), \tag{3.4}$$

whenever both sides are in $\mathbf{R}$.

(2) Since $M_0(u)$ is entire and $h(z)$ is nonzero on $\mathbf{R}$, it follows from (3.3) that $g_+(\gamma_1 \ln u)$ has an analytic continuation to $\mathbf{R}$. Therefore, in terms of the variable $t = \gamma_1 \ln u$, $g_+(t)$ has an analytic continuation to the horizontal strip $\mathbf{T} = \{t;\ -\frac{3}{2}\pi\gamma_1 < \mathrm{Im}\,(t) < \frac{3}{2}\pi\gamma_1\}$. The periodicity

$$g_+(t+1) = g_+(t) \tag{3.5}$$

on the real axis extends to this strip by analytic continuation. Now the single-valuedness of $M_0(u)$ on $\mathbb{C}$ means that

$$M_0(re^{i(\theta+2\pi)}) = M_0(re^{i\theta}), \qquad i = 1, 2,$$

on the region $\mathbf{R}$, and combined with (3.3) and (3.4) this implies that

$$g_+(t + 2\gamma_1 \pi i) = \exp(-2\gamma_0 \pi i) g_+(t) \tag{3.6}$$

is valid when both t, $t + 2\gamma_1 \pi i \in \mathbf{T}$, i.e., for $\{t;\ -\frac{3}{2}\pi\gamma_1 < \mathrm{Im}\,(t) < \frac{1}{2}\pi\gamma_1\}$. This relation allows us to continue g_+ analytically to the entire plane, and (3.5), (3.6) then hold for all complex t.

(3) We claim next that $g_+(t)$ is an entire function of exponential type. To see this, note that it is bounded by a constant, say C, on the rectangle $0 \leqq \mathrm{Re}\,(t) \leqq 1$, $0 \leqq \mathrm{Im}\,(t) \leqq 2\pi\gamma_1$, and the periodicity relations (3.5) and (3.6) then give

$$|g_+(t)| \leqq C \exp(2\pi |\gamma_0| |\mathrm{Im}\,(t)|),$$

proving the claim.

Next we show that $g_+(t)$ has no zeros. For if it had a zero at t_0, the periodicity relations (3.5) and (3.6) would give it zeros at $t_0 + m + (2\gamma_1 \pi i)n$ for m, $n \in \mathbb{Z}$, which contradicts the property that an entire function of exponential type has $O(R)$ zeros in the disc $\{t: |t| \leqq R\}$ as $R \to \infty$.

Since $g_+(t)$ is an entire function of exponential type having no zeros, $g_+(t) = A_+ \exp(c_+ z)$ for some constant c_+. The periodicity (3.5) forces $c_+ = 2k\pi i$ for some $k \in \mathbb{Z}$.

(4) A similar argument applied to $g_-(\gamma_1 \ln(-u))$ shows that $g_-(t) = A_- \exp(c_- z)$ where $c_- = 2l\pi i$ for some $l \in \mathbb{Z}$.

(5) Now we have for real u that

$$M_0(u) = \begin{cases} A_+ \exp[(\gamma_0 + 2k\pi i)\ln u], & u > 0, \\ A_- \exp[(\gamma_0 + 2l\pi i)\ln(-u)], & u < 0. \end{cases}$$

The first expression has a singularity at $u = 0$ unless $\gamma_0 + 2k\pi i = m_+$ is an integer. Similarly, we conclude that $\gamma_0 + 2l\pi i = m_-$ is an integer. Analyticity of $M_0(u)$ at $u = 0$ yields $A_+ = A_-$ and $m_+ = m_- = m \geqq 0$, and $M_0(u) = Au^m$ for a nonnegative integer m. □

We now proceed to prove Theorem 3.1.

Proof of Theorem 3.1. (1) By the Paley-Wiener theorem the Fourier-Laplace transform $\hat{f}$ of f is necessarily an entire function of exponential type, satisfying

$$|\hat{f}(u)| \leqq C \exp(B|\operatorname{Im} u|) \tag{3.7}$$

for some constants B, C. Now set

$$\hat{f}_0(u) := \prod_{j=1}^{\infty} p(\alpha^{-j}u),$$

which by the argument in the proof of Corollary 2.2 is also entirely of exponential type. We claim that

$$M(u) := \frac{\hat{f}(u)}{\hat{f}_0(u)} \tag{3.8}$$

is also an entire function of exponential type, i.e., any zero of $\hat{f}(u)$ has at least the multiplicity of $\hat{f}_0(u)$. To see this, note that for any zero u_0 of $\hat{f}_0(u)$ of multiplicity m there is a finite product $\prod_{j=1}^{J} p(\alpha^{-j}u)$ having a zero of the same multiplicity. Iterating the basic recursion (2.2) yields

$$\hat{f}(u) = \Delta^J \left(\prod_{j=1}^{J} p(\alpha^{-j}u) \right) \hat{f}(\alpha^{-J}u).$$

Since all terms on the right side of this expression are analytic at u_0 and the product has a zero of multiplicity m, $\hat{f}(u)$ has a zero there of at least that multiplicity, and the claim follows.

(2) Since $f \in L^1$, it satisfies the formula of Theorem 2.1(c). Thus the hypotheses of Lemma 3.2 are satisfied for $M(u)$ given by (3.8). Consequently, $M = Au^m$ and

$$\hat{f}(u) = Au^m \prod_{k=1}^{\infty} p(\alpha^{-k}u). \tag{3.9}$$

This proves claim (b). On the other hand, the two-scale equation (3.1) implies

$$\hat{f}(u) = \Delta p(\alpha^{-1}u)\hat{f}(\alpha^{-1}u).$$

Substituting (3.9) gives $\Delta = \alpha^m$, which proves (a).

(3) For (c), observe that if $m \geqq 1$ then $\hat{f}(0) = 0$; hence

$$\int_{-\infty}^{\infty} f(x)\,dx = 0. \tag{3.10}$$

Define $f_1(x) = \int_{-\infty}^{x} f(w)\,dw$ and observe that since f has compact support (3.10) shows that $f_1(x)$ is in $L^1(\mathbb{R})$ with compact support. Furthermore, f_1 satisfies the two-scale equation (3.1) with $\{c_n\}$ replaced by $\{\alpha^{-1}c_n\}$, by integrating (3.1). Of course $(d/dx)(f_1(x)) = f(x)$. By integrating m times, (c) follows. □

Remarks. (1) Under the weaker hypothesis that (3.1) possesses a solution which is a tempered distribution of compact support, the conclusions (a) and (b) of the theorem still hold.

(2) L^1-solutions satisfying (a) can exist for arbitrarily large values of m, for suitable values of α and of the c_j, β_j. By (c), this is equivalent to saying that there exist L^1-solutions with arbitrary high regularity for two-scale difference equations with $\Delta = 1$. Examples are given in § 6.

4. Lattice two-scale difference equations: iterative approximations. In the remainder of this paper we study compactly supported continuous solutions of lattice two-scale difference equations,

$$f(x) = \sum_{n=0}^{N} c_n f(kx - n), \tag{4.1}$$

where k is an integer $\geqq 2$. We will suppose that $\Delta = (1/k)\sum_{n=0}^{N} c_n = 1$, which involves essentially no loss of generality by Theorem 3.1.

A continuous solution of such an equation is a fixed point $Vf = f$ of the linear operator

$$Vf(x) = \sum_{n=0}^{N} c_n f(kx - n) \tag{4.2}$$

acting on a function space, e.g., $C^0(\mathbb{R})$. A natural method to construct a solution of (4.1) is as a limit of the iterative approximation scheme $f_{j+1} = Vf_j$, where f_0 is a suitable initial function. In this section we discuss the convergence of two such approximation schemes.

We first suppose that a compactly supported continuous solution $f(x)$ exists, and that the data $\{f(n): n \in \mathbb{Z}\}$ are known. We consider initial functions f_0 which are piecewise linear splines interpolating these data with knots at the integers $\mathbb{Z}$. That is, f_0 is defined by

$$f_0(x) = f(n)(n+1-x) + f(n+1)(x-n) \quad \text{for } n \leqq x \leqq n+1.$$

Since $f(n) = 0$ for $n \notin [0, (k-1)^{-1}N]$, f_0 has compact support in $[0, \lceil (k-1)^{-1}N \rceil]$, so we may regard it as being defined on the finite knot set $\mathbb{Z} \cap [0, \lceil (k-1)^{-1}N \rceil]$. (As usual $\lceil a \rceil$ stands for "smallest integer larger than or equal to a.") It immediately follows that $f_j = V^j f_0$ is a piecewise linear spline with knots at the $k^{-j}n$, $0 \leqq n \leqq \lceil k^j(k-1)^{-1}N \rceil$, which agrees with f at these knots. Consequently we have Theorem 4.1.

THEOREM 4.1. *Suppose that the lattice two-scale equation* (4.1) *with* $\Delta = 1$ *has a nonzero continuous solution* f *of compact support. Let* f_0 *be the spline of degree* 1 *with knot set* $\{n;\ n \in \mathbb{Z} \cap [0, \lceil (k-1)^{-1}N \rceil]$, *and with* $f_0(n) = f(n)$. *Define* $f_j = V^j f_0$, *with* V *as in* (4.2). *Then*

(1) f_j *is an interpolating spline of degree* 1 *with knot set* $k^{-j}(\mathbb{Z} \cap [0, \lceil k^j(k-1)^{-1}N \rceil])$.

(2) f_j *agrees with* f *at its knots,* $f_j(k^{-j}n) = f(k^{-j}n)$.

(3) $\|f - f_j\|_{L^\infty} \to 0$ *as* $j \to \infty$.

(4) *If* $f \in \mathrm{Lip}^\alpha$ *for* $0 < \alpha \leqq 1$, *i.e.,* $|f(x) - f(y)| \leqq C|x-y|^\alpha$, *then* $\|f - f_j\|_{L^\infty} \leqq Ck^{-j\alpha}$.

Proof. (1) and (2) were derived above; (3) and (4) are standard spline convergence results; see, e.g., Schumaker (1981, Thm. 6.15) or Theorem 4.2 below. □

If the compactly supported solution f has more regularity, e.g., if $f \in \mathrm{Lip}^{L,\alpha}$ (which means $f \in C^L$ and $d^L f/dx^L \in \mathrm{Lip}^\alpha$), then the same piecewise linear f_j converge even faster to f (Schumaker (1981, Thm. 6.15)). In order to obtain convergence of the derivatives as well, we need to use an initial function f_0 that is more regular. This can

be achieved by choosing for f_0 a C^L piecewise polynomial spline of degree $2L+1$ that agrees with f and its first L derivatives on the knot set $\mathbb{Z}$. (Similar fast convergence of the f_j and their derivatives can be achieved by other C^L choices for f_0, for which the derivatives on $\mathbb{Z}$ do not necessarily agree with those of f. In our present case, however, we can determine the $f^{(l)}(n)$ easily, and we can therefore afford to pick this particular f_0. The associated f_j will play a role in part II as well.)

THEOREM 4.2. *Suppose that the lattice two-scale equation* (4.1) *with* $\Delta=1$ *has a nonzero solution* f *of compact support which is* L *times continuously differentiable. Let* f_0 *be the* C^L *interpolating spline of degree* $2L+1$ *with knot set* $\{n;\ n\in\mathbb{Z}\cap[0,\ \lceil(k-1)^{-1}N\rceil]\}$ *and such that* $f_0^{(l)}(n)=f^{(l)}(n)$, $l=0,\cdots,L$. *Define* $f_j=V^jf_0$, *with* V *as in* (4.2). *Then*

(1) f_j *is a* C^L *interpolating spline of degree* $2L+1$ *with knot set* $k^{-j}(\mathbb{Z}\cap[0,\ \lceil k^j(k-1)^{-1}N\rceil])$.

(2) $f_j^{(l)}(k^{-j}n)=f^{(l)}(k^{-j}n)$ *for* $n\in\mathbb{Z}$ *and,* $l=0,\cdots,L$.

(3) *For all* l, $0\leqq l\leqq L$, $\|f^{(l)}-f_j^{(l)}\|_{L^\infty}\leqq Ck^{-j(L-l)}$.

(4) *If* $f\in \mathrm{Lip}^{L,\alpha}$, *then* $\|f^{(l)}-f_j^{(l)}\|_{L^\infty}\leqq Ck^{-j(L-l+\alpha)}$ *for* $l=0,\cdots,L$.

Proof. Note first that f_0 exists and is uniquely determined by the constraints imposed: on every interval $[n, n+1]$, the $2L+2$ coefficients of f_0 are linear functions of the $2L+2$ boundary values $f_0^{(l)}(n), f_0^{(l)}(n+1)$, $l=0,\cdots,L$. It is obvious that $f_0\in C^L$. It then immediately follows that f_j is also C^L, that f_j is piecewise polynomial of degree $2L+1$, with knots at $k^{-j}\mathbb{Z}$, and that $f_j^{(l)}(k^{-j}n)=f^{(l)}(k^{-j}n)$, for $l=0,\cdots,L$. Points 3 and 4 are again standard results in spline approximation theory (they can, e.g., easily be proved by methods similar to those used in the proof of Theorem 6.15 in Schumaker (1981)); for the sake of convenience we also give an explicit and simple proof in the Appendix. □

Theorems 4.1 and 4.2 guarantee convergence of spline interpolants, provided we start from the right data $\{f(n);\ n\in\mathbb{Z}\}$ or $\{f^{(l)}(n);\ n\in\mathbb{Z}, l=0,\cdots,L\}$. In the latter case, we obtain very fast convergence of f *and* its derivatives. However, the theorems do not show how to determine these data or how to estimate smoothness of f given the data $\{k, c_1,\cdots,c_n\}$ specifying (4.1).

In the next section we shall see that the $f(n)$, $n=0$ to $\lceil(k-1)^{-1}N\rceil$ can be related to the eigenvector of eigenvalue 1 of a particular matrix constructed from the coefficients c_n. If this eigenvalue is nondegenerate, then this provides a way to determine the $f(n)$. Similarly, nondegenerate eigenvectors of this matrix, corresponding to the eigenvalue k^{-l}, are linked to the $f^{(l)}(n)$. We shall also see how this matrix provides an upper bound for the regularity of f; more subtle matrix techniques in part II will lead to more precise regularity estimates.

There exists another iterative scheme that is often used for the construction of f. The jth approximation function f_j in this scheme is also a spline function with knot set $2^{-j}\mathbb{Z}$, and $f_{j+1}=Vf_j$, but the initial function f_0 is different. It is a continuous, piecewise linear spline, with $f_0(0)=1$, $f_0(n)=0$ for $n\neq 0$. The advantage of this choice for f_0 is that it results in a "local" algorithm called the *cascade algorithm*. We check (see, e.g., Daubechies (1988)) that, for $0\leqq l<k$,

$$f_j(k^{-j}(km+l))=\sum_n c_{l+kn}f_{j-1}(k^{-j+1}(m-n)).$$

This means that the $f_j(k^{-j}n)$ can be computed by using only the values of f_{j-1} in a small neighborhood of $k^{-j}n$; more precisely, $f_j(k^{-j}n)$ is determined by the $f_{j-1}(k^{-j+1}l)$ with $k^{-j}(n-N)\leqq k^{-(j-1)}l\leqq k^{-j}n$. This is quite unlike the previous scheme, where $f_j(k^{-j}n)$ was computed from the $f_{j-1}(k^{-j-1}n-m)$, $0\leqq m\leqq N$. We remark that in general

$f_0(n) = \delta_{n0}$ does not satisfy the two-scale difference equation (4.1) restricted to $\mathbb{Z}$. It does so only if all but one of the coefficients c_{kn} (with index of a multiple of k) vanish, $c_{kn} = \delta_{n0}$. (We suppose here that $c_n = 0$ for $n < N_1$, or $n > N_2$, where N_1 need not be equal to zero. We can shift this to the standard situation $c_n = 0$ for $n < 0$ or $n > N$; in this case we would have $c_{kn+n_0} = \delta_{n0}$ for some n_0, and we would choose $f_0(n) = \delta_{nn_0}$ correspondingly.) In this case the cascade algorithm corresponds to an *interpolating subdivision scheme* (Chaiken (1974), Dyn, Gregory, and Levin (1987), (1989), (1990), Micchelli (1986), Micchelli and Prautzsch (1987a), (1987b), (1989)): at every level j, the function f_j coincides with f_{j-1} at the knots of f_{j-1}, i.e.,

$$f_j(k^{-j+1}n) = f_{j-1}(k^{-j+1}n);$$

the intermediate values $f_j(k^{-j}(kn+l))$, $0 < l < k$, are computed by an appropriate interpolation procedure (determined by the c_n). The "local" aspect of the cascade algorithm makes subdivision schemes of interest for the construction of curves and surfaces. In Daubechies (1988) the same scheme was called the "graphical" construction algorithm.

A drawback of the cascade algorithm is that it does not always converge, even when a continuous solution to the two-scale difference equation exists. An example is

$$f(x) = \tfrac{1}{2}f(2x-3) + f(2x) + \tfrac{1}{2}f(2x+3).$$

This equation corresponds to a subdivision scheme. It has a continuous solution with support $[-3, 3]$, namely,

$$f(x) = \begin{cases} 1 - |x|/3, & |x| \leqq 3, \\ 0 & \text{otherwise.} \end{cases}$$

The cascade algorithm converges to this solution in the sense of distributions, but not in $C^0(\mathbb{R})$: indeed $f_n(1) = 0$ for all n. In the special case of interpolating subdivision schemes ($c_{km} = \delta_{m0}$), Dyn and Levin (1989) give necessary and sufficient conditions to ensure convergence of the cascade algorithm. Daubechies (1988) lists a different set of sufficient conditions for convergence of the cascade algorithm.

5. Lattice two-scale difference equations: global regularity of compactly supported solutions. Assume that the lattice two-scale difference equation

$$f(x) = \sum_{n=0}^{N} c_n f(kx - n), \tag{5.1}$$

with $\Delta = (1/k)\sum_{n=0}^{N} c_n = 1$, has a nontrivial L^1-solution, necessarily of compact support. The regularity of this function can be bounded above purely in terms of its support width.

THEOREM 5.1. *Given a lattice two-scale difference equation, $f(x) = \sum_{n=0}^{N} c_n f(kx-n)$ with $\Delta = 1$. Let N_0 be the largest integer strictly smaller than $N/(k-1)$, and define* M *to be the $N_0 \times N_0$ matrix*

$$\mathsf{M}_{ij} = c_{ki-j}, \qquad i, j = 1, \cdots, N_0. \tag{5.2}$$

If there exists a nontrivial L^1-solution f which is in $C^m(\mathbb{R})$, then $\{1, k^{-1}, \cdots, k^{-m}\} \subset$ spectrum (M). *In particular,*

$$m < \frac{N}{k-1} - 1. \tag{5.3}$$

Proof. (1) Since f is continuous, and support $(f) \subset [0, N/(k-1)]$, it follows that $f(l) = 0$ for $l \leqq 0$ and $l > N_0$. Define $\mathsf{v}^0 \in \mathbb{R}^{N_0}$ by

$$\mathsf{v}_j^0 = f(j), \qquad j = 1, \cdots, N_0.$$

Substituting $x = j$, with $j = 1, \cdots, N_0$, into equation (5.1) leads to

$$\mathsf{v}^0 = \mathsf{M}\mathsf{v}^0,$$

where M is defined by (5.2).

(2) On the other hand, it is clear that $\mathsf{v}^0 \neq 0$. Indeed, if $\mathsf{v}^0 = \mathbf{0}$, i.e. $f(j) = 0$ for all $j \in \mathbb{Z}$, then $f(k^{-l}m) = 0$ would follow, for all $l \in \mathbb{N}$, $m \in \mathbb{Z}$, by applying (5.1). By continuity this would imply $f \equiv 0$. Since $f \neq 0$, we have $\mathsf{v}^0 \neq 0$. Consequently, 1 is an eigenvalue of M.

(3) Similarly we define, for $l \leqq m$, $\mathsf{v}^l \in \mathbb{R}^{N_0}$ by

$$\mathsf{v}_j^l = f^{(l)}(j), \qquad j = 1, \cdots, N_0,$$

where $f^{(l)}$ denotes the lth derivative of f. Differentiating (5.1) l times, and substituting $x = 1, \cdots, N_0$ leads to

$$\mathsf{v}^l = k^l \mathsf{M}\mathsf{v}^l.$$

Again $\mathsf{v}^l = 0$ would imply $f^{(l)} \equiv 0$, hence $f^{(l-1)} \equiv$ constant. Since $f^{(l-1)}$ has compact support, $f^{(l-1)} \equiv 0$ would follow. By induction this would imply that $f \equiv 0$. Since $f \neq 0$, $\mathsf{v}^l \neq 0$, and k^{-l} is an eigenvalue of M for $0 \leqq l \leqq m$.

(4) $f \in C^m(\mathbb{R})$ implies that the $N_0 \times N_0$ matrix M has $m+1$ eigenvalues. Hence $m \leqq N_0 - 1 < N/(k-1) - 1$. □

Remarks. (1) The bound (5.3) of Theorem 5.1 cannot be improved. For $N = (k-1)L$ there exist $\{c_n;\ n = 0, 1, \cdots, N\}$ such that the $(L-1) \times (L-1)$ matrix M has exactly the eigenvalues $1, k^{-1}, \cdots, k^{-L+2}$, and such that the corresponding f is in c^{L-2}. One such example is given by

$$p(\xi) = \sum_{n=0}^{(k-1)L} c_n e^{in\xi} = [(1 + e^{i\xi} + \cdots + e^{i(k-1)\xi})/k]^L,$$

leading to $\hat{f}(\xi) = [(1 + e^{i\xi})/\xi]^L$. The function f is a B-spline of degree $L-1$; it is in C^{L-2}. The fact that any C^{n-1}-spline with knot set $\mathbb{Z}$ must have support width greater than or equal to $n+2$ has long been known (cf. Schoenberg (1973, p. 13)).

(2) The condition $\{1, k^{-1}, \cdots, k^{-m}\} \subset$ spectrum (M) is not sufficient to ensure that $f \in C^m$. For $k = 2$, $N = 3$, e.g., all the choices $c_0 = \frac{1}{4} + \lambda$, $c_1 = \frac{3}{4} + \lambda$, $c_2 = \frac{3}{4} - \lambda$, $c_3 = \frac{1}{4} - \lambda$, all other $c_n = 0$, where $\lambda \in \mathbb{R}$ is arbitrary, lead to 2×2 matrices M with the same spectrum, namely, $\{1, \frac{1}{2}\}$. Nevertheless, the regularity of f depends on λ. Using the techniques of part II, we can check that f is continuous if and only if $|\lambda| < \frac{3}{4}$, and that $f \in C^1$ if and only if $|\lambda| < \frac{1}{4}$. For $\lambda = \frac{1}{4}$, e.g., we find $p(\xi) = (1 + e^{i\xi})^2/4$; hence $f(x) = x$ for $0 \leqq x \leqq 1$, $2 - x$ for $1 \leqq x \leqq 2$, zero otherwise, which is clearly not in C^1.

(3) It follows from the proof that, provided that they are nondegenerate, the eigenvectors of M with eigenvalue k^{-l} determine the $f^{(l)}(n)$, up to normalization. It is not a priori obvious how to choose these $m+1$ different normalizations (one for each l) in a coherent way. In part II we shall see how this can be done, modulo some restrictions on the c_n.

6. Examples.

6.1. The de Rham function. The de Rham function is a classical example of a continuous nowhere-differentiable function. Like many such examples, it is defined as the limit of successive approximations.

Define

$$f_0(x)=\begin{cases}1+x, & -1\leqq x\leqq 0,\\ 1-x, & 0\leqq x\leqq 1,\\ 0, & |x|\geqq 1.\end{cases}$$

Clearly f_0 is piecewise linear; its restriction to the intervals $[m, m+1]$, $m\in\mathbb{Z}$, is linear. The next function f_1 in the approximation scheme is constructed as follows: f_1 is again piecewise linear, with its restriction to the intervals $[m/3, (m+1)/3]$ linear, for all $m\in\mathbb{Z}$. The nodes of f_1 are given by $f_1(m)=f_0(m)$, $f_1(m+\frac{1}{3})=f_0(m+\frac{2}{3})$, $f_1(m+\frac{2}{3})=f_0(m+\frac{1}{3})$, for all $m\in\mathbb{Z}$. Graphically, this corresponds to splitting every interval on which f_0 is linear into three equal parts, exchanging the values at f_0 at the two interior points, and linearly interpolating between the nodes obtained in this way (see Fig. 1). Exactly the same procedure is then repeated to obtain f_{j+1} from f_j, for all $j\in\mathbb{N}$. The resulting f_j are piecewise linear, with linear restrictions to the intervals $[m3^{-j}, (m+1)3^{-j}]$, for all $m\in\mathbb{Z}$. Geometrically it is clear that this process converges pointwise to a continuous limit function f.

It can be checked fairly easily that $f_{n+1}=Vf_n$ where

$$Vf(x)=f(3x)+\tfrac{1}{3}[f(3x+1)+f(3x-1)]+\tfrac{2}{3}[f(3x+2)+f(3x-2)].$$

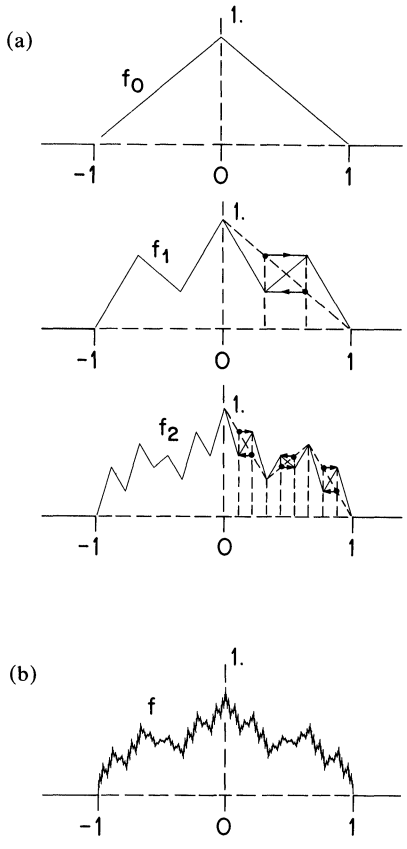

FIG. 1. (a) *The first three approximations f_0, f_1, f_2 to the de Rham function.* (b) *The de Rham function.* (*Note. We have plotted f_8 rather than f. At the scale of the figure, they are indistinguishable.*)

As the pointwise limit of the f_j, the de Rham function f satisfies the two-scale difference equation

$$f(x)=f(3x)+\tfrac{1}{3}[f(3x+1)+f(3x-1)]+\tfrac{2}{3}[f(3x+2)+f(3x-2)]. \tag{6.1}$$

The corresponding trigonometric polynomial is given by

$$p(\xi)=e^{-2i\xi}[(1+e^{i\xi}+e^{2i\xi})/3][(2-e^{i\xi}+2e^{2i\xi})/3];$$

it is not clear how to deduce the continuity of f from this expression for p! In part II we shall use a time-domain method to prove that f is Hölder continuous, with exponent $\gamma=1-\ln 2/\ln 3=.36907\cdots$ but is nowhere differentiable. The method of part II also allows us to analyze local properties of f, to show that there exist fractal sets with nonzero Hausdorff dimension, but zero Lebesgue measure, on which f is "almost" differentiable, in the sense that the local Hölder exponent can be chosen arbitrarily close to 1. (The choice of the fractal set depends on the desired Hölder exponent.)

A variant on the de Rham function is obtained by choosing $k=3$, $c_0=1$, $c_1=c_{-1}=\frac{1}{2}-\alpha$, $c_2=c_{-2}=\frac{1}{2}+\alpha$, all other $c_n\equiv 0$. The corresponding f_j^α and f^α are plotted in Fig. 2; for $\alpha=\frac{1}{6}$ we obviously revert to the de Rham case. The analysis of part II will show

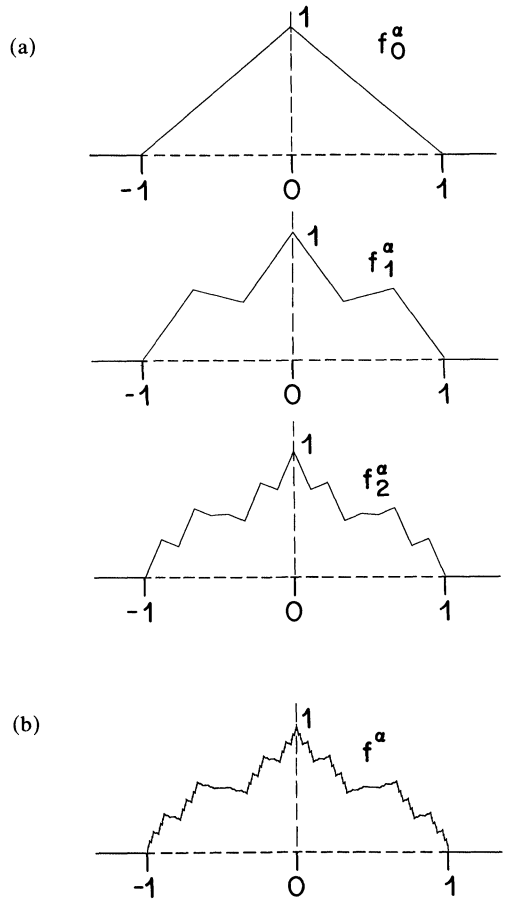

FIG. 2. (a) *The first three approximations* f_j^α, $j=0,1,2$ *for the generalized de Rham function corresponding to* $\alpha=\frac{1}{12}$. (b) *The generalized de Rham function* f^α *itself.*

that for sufficiently small α, $\alpha(1+2\alpha)^2<\frac{2}{27}$, or $\alpha<.0492\cdots$, the resulting function f^α is Lipschitz almost everywhere.

Note that for any α we have $N=4$, hence $N_0=1$, so that the matrix M reduces to the scalar 1. It therefore follows immediately from Theorem 5.1 that f and f^α cannot possibly be C^1, since then M would have at least the two eigenvalues 1 and $\frac{1}{2}$.

6.2. The Lagrange interpolation functions of Deslauriers and Dubuc. These functions are obtained by choosing an integer, $k>1$, called the "base" of the interpolation scheme, and an even integer M, $M\geqq 2$, called the "number of nodes," in the language of Deslauriers and Dubuc (1989). The interpolation function is then defined by the recursive process

$$f[k^{-j}(km+n)]=\sum_{m'=-M/2+1}^{M/2}\beta_{m',n}f[k^{-(j-1)}(m+m')],$$

where

$$\sum_{m'=-M/2+1}^{M/2}\beta_{m',n}=1 \quad \text{for all } n=1,\cdots,k-1. \tag{6.2}$$

This corresponds to a two-scale equation of the type

$$f(x)=f(kx)+\sum_{m=-M/2}^{M/2-1}\sum_{m=1}^{k-1}\alpha_{m,n}f(kx-km-n)$$

where $\alpha_{mn}=\beta_{-m,n}$. The $\beta_{m,n}$, or α_{mn}, are determined by (6.2), by the requirement that $p(\xi)$ be divisible by as many factors $[1+e^{i\xi}+\cdots+e^{i(k-1)\xi}]$ as possible, and by the symmetry condition $\beta_{-l,n}=\beta_{l+1,k-n}$, $0\leqq l\leqq M/2$, $n=1,\cdots,k-1$. For base 2, with four nodes ($k=2$, $M=4$), this leads to the two-scale difference equation

$$f(x)=f(2x)+\tfrac{9}{16}[f(2x+1)+f(2x-1)]-\tfrac{1}{16}[f(2x+3)+f(2x-3)], \tag{6.3}$$

corresponding to

$$\begin{aligned}p(\xi)&=e^{-3i\xi}[(1+e^{i\xi})/2]^4[-\tfrac{1}{2}+2e^{i\xi}-\tfrac{1}{2}e^{2i\xi}]\\&=(\cos\xi/2)^4(2-\cos\xi).\end{aligned}$$

Using $\sup_\xi|2-\cos\xi|=3$, we obtain $|\hat{f}(\xi)|\leqq C|\xi|^{-4+\log_2 3}$ (see, e.g., Lemma 3.2 in Daubechies (1988)), from which it follows that $f\in C^1$. We can bound the regularity of $f(x)$ by Theorem 5.1. We have $N=6$, $k=2$, so that $N_0=5$. The spectrum of the 5×5 matrix M is in this case $\{1,\frac{1}{2},\frac{1}{4},\frac{1}{8}\}$ where the eigenvalue $\frac{1}{4}$ has multiplicity 2. By Theorem 5.1 we know therefore that f can be at most C^3. In fact, however, f is not even C^2, as is shown in Deslauriers and Dubuc (1989), using the infinite product formula for $\hat{f}$ together with the special property that $p(\xi)\geqq 0$. They show that f is "almost" C^2, in the sense that f' is Hölder continuous with exponent $1-\varepsilon$ (ε arbitrarily small), but not C^1. In Dubuc (1986) the sharper estimate $|f(x)-f(x+t)|\leqq C|t|\log(1/|t|)$ is proved, for small enough t. This same example was also studied by Dyn, Gregory, and Levin (1987), with more general weights in (6.3) ($\frac{1}{2}+w$, w instead of $\frac{9}{16}$, $\frac{1}{16}$). For the parameters fixed as in (6.3), their results are slightly weaker than Dubuc's. For a thorough and detailed analysis of this example we refer to Dubuc (1986), Dyn, Gregory, and Levin (1987), or to part II.

6.3. Orthonormal bases of compactly supported wavelets. A family of wavelets is generated by translating and dilating one single function,

$$\psi_{jk}(x)=2^{-j/2}\psi(2^{-j}x-k), \qquad j,k\in\mathbb{Z}.$$

For some choices of ψ, the family ψ_{jk} constitutes an orthonormal basis of $L^2(\mathbb{R})$. One such choice is

$$\psi(x) = \begin{cases} 1, & 0 \leqq x < \frac{1}{2}, \\ -1, & \frac{1}{2} \leqq x < 1, \\ 0 & \text{otherwise.} \end{cases}$$

The corresponding orthonormal basis is well known; it is called the Haar basis, and provides an unconditional basis for all L^p-spaces, $1 < p < \infty$. Recently some other, more interesting choices for ψ have been found. The first one was constructed by Stromberg (1982); later Meyer (1985/86) constructed independently another wavelet basis, which was extended to higher dimensions by Lemarié and Meyer (1986). In the Meyer construction $\hat{\psi}$ is C^∞ and compactly supported; the basis $\{\psi_{jk}\}$ is not only an orthonormal basis for $L^2(\mathbb{R})$, but also an unconditional basis for all the L^p-spaces $(1 < p < \infty)$, the Sobolev spaces, the Besov spaces, etc. Later Battle (1987) and Lemarié (1987) constructed other orthonormal bases of wavelets, based on ψ which have faster (exponential) decay; their examples are K times continuously differentiable (K arbitrarily large, but finite). Mallat (1989) and Meyer (1986), (1990) devised a scheme into which all these constructions fit naturally, which they call *multiresolution analysis.* Finally, Daubechies (1988) constructed orthonormal bases of wavelets generated by *compactly supported* ψ which are K times differentiable.

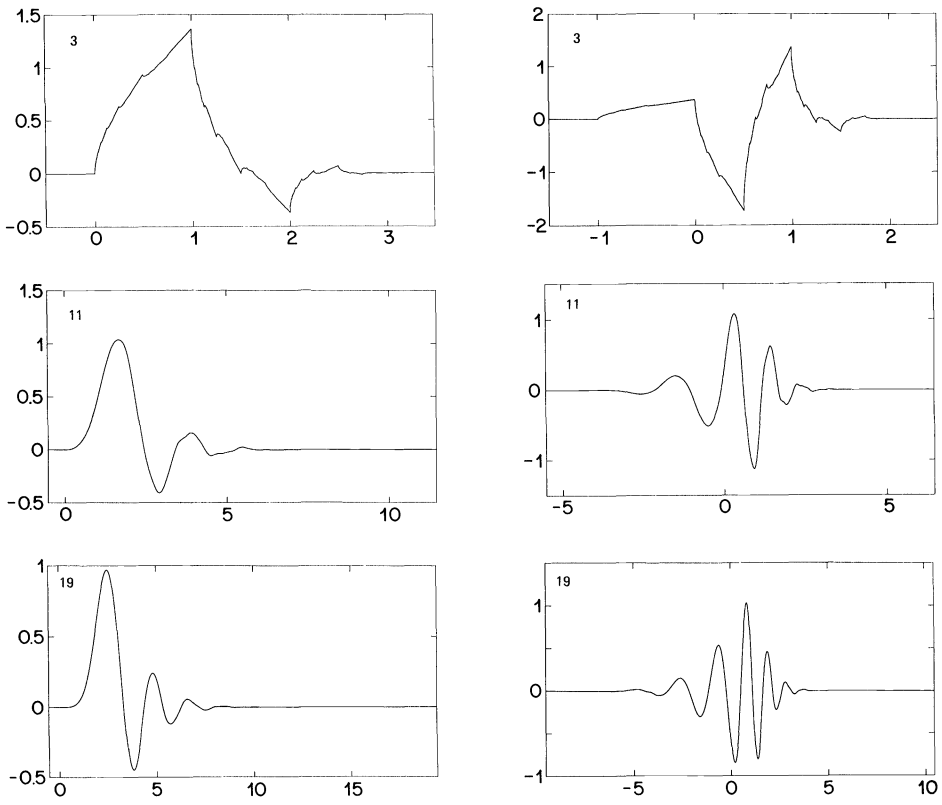

FIG. 3. *Some examples of orthonormal wavelet bases with compact support constructed in Daubechies* (1988). *In every case both* ϕ *and* ψ *are plotted. The number of nonvanishing* c_n *is, respectively,* 4, 12, *and* 20, *corresponding to support widths of, respectively,* 3, 11, *and* 19.

A typical construction of an orthonormal basis of wavelets uses an auxiliary function ϕ such that

$$\phi(x)=\sum c_n\phi(2x-n). \tag{6.4}$$

Provided the $\phi(x-n)$ are an orthonormal set, the function ψ is then given by

$$\psi(x)=\sum_n (-1)^n c_{n+1}\phi(2x+n).$$

(If the functions $\phi(x-n)$ are not orthonormal, we first construct $\tilde{\phi}$ by $\hat{\tilde{\phi}}(\xi)=\hat{\phi}(\xi)\times(\sum_{m\in\mathbb{Z}}|\hat{\phi}(\xi+2\pi m)|^2)^{-1/2}$; the $\tilde{\phi}(x-n)$ are orthonormal, and satisfy an equation of type (6.4), with different $\tilde{c}_n$; for more details see Daubechies (1988) or Mallat (1989)).

A construction of ϕ using only finitely many c_n results in a compactly supported ϕ (see § 2), and therefore a compactly supported ψ. As a finite linear combination of translated and dilated versions of ϕ, ψ has the same regularity as ϕ. It follows that a good understanding of the regularity of solutions of finite two-scale difference equations is important in the construction of orthonormal bases of compactly supported wavelets. The examples constructed in Daubechies (1988) have the property that their support width increases linearly with their regularity. This is illustrated by Fig. 3, which shows the pairs ϕ, ψ for support widths 3, 11, and 19, respectively. It is clear that ϕ, ψ become more regular as their width increases; Daubechies (1988) showed that there exists $\mu>0$ such that

$$\phi_N,\ \psi_N\in C^{\mu N} \quad \text{where } |\operatorname{supp}\phi_N|=|\operatorname{supp}\psi_N|=N.$$

The question then arose whether this linear increase of the support width was necessary. This question is now answered affirmatively by Theorem 5.1: if $\phi\in C^K$, then $|\operatorname{supp}\phi|\geqq K+2$. This also provides a simple proof for the (known) fact that it is impossible to construct wavelet bases generated by a compactly supported C^∞-function ϕ.

Appendix.

PROPOSITION. *Suppose f is a compactly supported function in $\operatorname{Lip}^{L,\alpha}$. Define functions f_j by:*

(1) *On every interval $[n2^{-j},(n+1)2^{-j}]$, f_j is a polynomial of degree $2L+1$.*

(2) *f_j is in C^L and*

$$f_j^{(l)}(n2^{-j})=f^{(l)}(n2^{-j}) \quad \text{for } l=0,\cdots,L, \quad n\in\mathbb{Z}.$$

Then $\|f^{(l)}-f_j^{(l)}\|_{L^\infty}\leqq C2^{-j(L-l+\alpha)}$ for $l=0,\cdots,L$, and for some C independent of j and l.

Proof. (1) Choose $x\in\operatorname{support}(f)$, $j\in\mathbb{N}$ arbitrary. Find n so that $2^{-j}n\leqq x\leqq 2^{-j}(n+1)$. Then

$$\begin{aligned}|f^{(l)}(x)-f_j^{(l)}(x)|\leqq{}&\left|f^{(l)}(x)-\sum_{k=l}^{L}\frac{1}{(k-l)!}f^{(k)}(2^{-j}n)(x-2^{-j}n)^{(k-l)}\right|\\&+\left|f_j^{(l)}(x)-\sum_{k=l}^{L}\frac{1}{(k-l)!}f^{(k)}(2^{-j}n)(x-2^{-j}n)^{(k-l)}\right|.\end{aligned} \tag{A.1}$$

Since $f\in\operatorname{Lip}^{L,\alpha}$ and $\operatorname{support}(f)$ is finite, the first term is bounded by $C|x-2^{-j}n|^{\alpha+(L-l)}\leqq C2^{-j(\alpha+L-l)}$ with C independent of x or j. It therefore suffices to bound the second term.

(2) On $[2^{-j}n,2^{-j}(n+1)]$ we have

$$f_j(y)=\sum_{l=0}^{L}\frac{1}{l!}f^{(l)}(2^{-j}n)(y-2^{-j}n)^l+\sum_{l=0}^{L}\frac{1}{(L+1+l)!}a_{n,l}^j(y-2^{-j}n)^{L+1+l}$$

with the $a^j_{n,l}$ determined by the $L+1$ equations, $0 \leqq m \leqq L$,

$$\sum_{l=0}^{L} \frac{1}{(L+1+l-m)!} a^j_{n,l} 2^{-j(L+1+l-m)} = f^{(m)}(2^{-j}(n+1)) - \sum_{l=m}^{L} \frac{1}{(l-m)!} f^{(l)}(2^{-j}n) 2^{-j(l-m)},$$

or

$$\sum_{l=0}^{L} \frac{1}{(L+1+l-m)!} a^j_{n,l} 2^{-j(l+1)} = b^j_{n,m} \tag{A.2}$$

where

$$b^j_{n,m} = 2^{-j(L-m)} \left[f^{(m)}(2^{-j}(n+1)) - \sum_{l=m}^{L} \frac{1}{(l-m)!} f^{(l)}(2^{-j}n) 2^{-j(l-m)} \right]$$

is bounded, uniformly in n, by $C2^{-j\alpha}$ because $f \in \mathrm{Lip}^{L,\alpha}$ and f is compactly supported. It follows, by inverting the system (A.2), that

$$|a^j_{n,l} 2^{-j(l+1)}| \leqq C 2^{-j\alpha}.$$

(3) Consequently,

$$\begin{aligned} &\left| f_j^{(l)}(x) - \sum_{k=1}^{L} \frac{1}{(k-l)!} f^{(k)}(2^{-n}j)(x-2^{-j}n)^{(k-l)} \right| \\ &\quad = \left| \sum_{k=0}^{L} \frac{1}{(L+1+k-l)!} a^j_{n,k} (x-2^{-j}n)^{L+1+k-l} \right| \\ &\quad \leqq \sum_{k=0}^{L} \frac{1}{(L+1+k-l)!} C 2^{j(k+1)} 2^{-j\alpha} 2^{-j(L+1+k-l)} \\ &\quad \leqq C 2^{-j(L-l+\alpha)}. \end{aligned}$$

Hence $(A.1) \leqq C2^{-j(L-l+\alpha)}$ for all x, with C independent of j, l, or x, and the proposition is proved. □

Acknowledgments. The authors are indebted to C. A. Micchelli and to anonymous referees for supplying many references, and for suggesting the discussion on approximation by splines given in § 4. A helpful conversation with A. M. Odlyzko led to the proof of Lemma 3.2. After completing this work, we learned that some results have also been derived by P. Auscher (1989).

SPECIAL FUNCTIONS AND SINGULAR QUASILINEAR PARTIAL DIFFERENTIAL EQUATIONS*

VICTOR L. SHAPIRO†

Abstract. For Qu a second-order singular quasilinear elliptic operator, the notion of a first eigenvalue is introduced. The terminology singular arises from the fact that the coefficients of Q may be zero on part or all of the boundary or the region of definition may be unbounded. A one-sided nonlinear result for Q is established below the first eigenvalue, and a theorem and corollary (called results at resonance) are established at the first eigenvalue. The corollary presents a condition which is both necessary and sufficient. Examples are given involving Hermite polynomials, Bessel functions, and other special functions.

Key words. quasilinear partial differential equations, special functions, resonance, first eigenvalue

AMS(MOS) subject classifications. 35J60, 33A65

1. Introduction. Let $\Omega \subset \mathbb{R}^N$, $N \geqq 1$, be an open (possibly unbounded) connected set and let p and ρ be two positive functions in Ω with $p \in C^1(\bar{\Omega})$ and $\rho \in C^0(\Omega)$. We set

$$Qu(x) = -D_i[p(x)A_i(x, u, Du)] + \rho(x)B_0(x, u, Du)u \tag{1.0}$$

where $D_i = \partial/\partial x_i$ and $D = (D_1, \cdots, D_N)$. We shall study the singular quasi-linear equation

$$Qu(x) = \rho(x)f(x, u) + G. \tag{1.1}$$

The term singular arises from the fact that Ω may be unbounded or that p may equal zero on part or all of the boundary of Ω. A similar situation occurs for the singular Sturm-Liouville system studied in elementary differential equations (see [1, p. 57], [2, p. 554], or [3, p. 560]).

In (1.0) and for the rest of the paper the summation convention is used for $i = 1, \cdots, N$. Throughout we shall suppose

$$p \in C^0(\bar{\Omega}), \quad p > 0 \quad \text{in } \Omega, \quad \int_\Omega p < \infty, \quad \text{and } p = 0 \quad \text{on } \Gamma_1 \subset \partial\Omega \tag{1.2}$$

where Γ_1 may be the empty set, i.e., $\Gamma_1 = \{x \in \partial\Omega: p(x) = 0\}$.

$$\rho \in C^0(\Omega), \quad \rho > 0 \quad \text{in } \Omega, \quad \text{and} \int_\Omega \rho < \infty. \tag{1.3}$$

In order to explain the type of problem we intend to study for (1.1), we have to introduce some Hilbert spaces. In particular, we let $C^0_\rho(\Omega)$ and $C^1_{p,\rho}(\Omega)$ be the following two pre-Hilbert spaces:

$$C^0_\rho(\Omega) = \left\{ u \in C^0(\Omega): \int_\Omega u^2\rho < \infty \right\} \tag{1.4}$$

* Received by the editors December 27, 1989; accepted for publication (in revised form) September 27, 1990.

† Department of Mathematics, University of California, Riverside, California 92521.

with $\langle u, v\rangle_\rho = \int_\Omega uv\rho$;

$$(1.5)\quad C^1_{p,\rho}(\Omega) = \left\{ u \in C^0(\bar{\Omega}) \cap C^1(\Omega) \colon u = 0 \text{ on } \partial\Omega \backslash \Gamma_1 \text{ and } \int_\Omega |Du|^2 p + u^2 \rho < \infty \right\}$$

with $\langle u, v\rangle_{p,\rho} = \int_\Omega [Du \cdot Dvp + uv\rho]$.

$L^2_\rho(\Omega)$ will designate the Hilbert space that we obtain by completing $C^0_\rho(\Omega)$ using the method of Cauchy sequences with respect to the norm $\|u\|_\rho = \langle u, u\rangle^{1/2}_\rho$, and $H^1_{p,\rho}(\Omega)$ will designate the Hilbert space that we obtain by completing $C^1_{p,\rho}(\Omega)$ with respect to the norm $\|u\|_{p,\rho} = \langle u, u\rangle^{1/2}_{p,\rho}$.

We define $L^q_\rho(\Omega)$ in a similar manner for $1 \leqq q < \infty$ and we also observe that $L^2_p(\Omega)$ is a well-defined space.

Continuing, we make the following assumptions for the functions $A_i(x, t, \xi)$, $i = 1, \cdots, N$, and $B_0(x, t, \xi)$ where $x \in \Omega$, $t \in \mathbb{R}$, and $\xi \in \mathbb{R}^N$.

(Q1) $A_i(x, t, \xi) : \Omega \times \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}$ and $B_0(x, t, \xi) : \Omega \times \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}$, and both satisfy the Caratheodory conditions (i.e., $A_i(x, t, \xi)$ is measurable for x in Ω for every fixed $(t, \xi) \in \mathbb{R} \times \mathbb{R}^N$ and is continuous in (t, ξ) for almost every fixed $x \in \Omega$, and similarly, for $B_0(x, t, \xi)$).

(Q2) There exist $h \geqq 0$ and $c_1 \geqq 0$ with $h \in L^2_p(\Omega)$ and c_1 a constant such that, respectively,

$$|A_i(x, t, \xi)| \leqq h(x) + c_1|\xi| \quad \text{for a.e. } x \in \Omega \quad \text{or}$$

$$|A_i(x, t, \xi)| \leqq h(x) + c_1(t^2 + |\xi|^2)^{1/2} \quad \text{for a.e. } x \in \Omega$$

accordingly as $L^2_\rho(\Omega)$ is not or is continuously imbedded in $L^2_p(\Omega)$ (i.e., the latter means $L^2_\rho(\Omega) \subset L^2_p$ and $\|u\|_p \leqq K\|u\|_\rho$ for all $u \in L_\rho$).

(Q3) There exists a positive constant c_2 such that $|B_0(x, t, \xi)| \leqq c_2$ for almost every $x \in \Omega$ and for all $(t, \xi) \in \mathbb{R} \times \mathbb{R}^N$.

(Q4) There exists a positive constant c_3 and a nonnegative function $Z \in L^1_p(\Omega)$ subject to $A_i(x, t, \xi)\xi_i \geqq c_3|\xi|^2 - Z(x)$ for almost every $x \in \Omega$ and for all $(t, \xi) \in \mathbb{R} \times \mathbb{R}^N$.

(Q5) $[A_i(x, t, \xi) - A_i(x, t, \xi')](\xi_i - \xi'_i) > 0$ for almost every $x \in \Omega$, for all $t \in \mathbb{R}^N$, and for all $\xi, \xi' \in \mathbb{R}^N$ with $\xi \neq \xi'$.

Next, we introduce the semilinear form

$$(1.6)\quad \mathcal{Q}(u, v) = \int_\Omega pA_i(x, u, Du)D_i v + \rho B_0(x, u, Du)uv$$

and we see from (Q1)-(Q3) that $\mathcal{Q}(u, v)$ is well defined for $u, v \in H^1_{p,\rho}$. Also, we define

$$(1.7)\quad \lambda_1^* = \liminf_{\|u\|_\rho \to \infty} \mathcal{Q}(u, u)/\|u\|^2_\rho, \qquad u \in H^1_{p,\rho}.$$

It is clear that if $\mathcal{Q}$ were a linear elliptic operator and p and ρ were equal to one, λ_1^* would be the first eigenvalue associated with the Dirichlet problem (see [7, p. 213]). An easy computation using (Q2)-(Q4) shows that λ_1^* is a finite-valued real number.

The first theorem that we shall present here will involve the interplay between the left-hand side and the right-hand side of (1.1), i.e., between Q and f, at values strictly below λ_1^*. In particular, we shall assume the following:

(f1) $f(x, t)$ meets the usual Caratheodory condition.

(f2) There exist $\tilde{h}_1 \geqq 0$ and $\varepsilon_0 > 0$ with $\tilde{h}_1 \in L^2_\rho(\Omega)$ subject to

$$tf(x, t) \leqq (\lambda_1^* - \varepsilon_0)t^2 + \tilde{h}_1(x)|t| \quad \forall t \in \mathbb{R} \text{ and a.e. } x \in \Omega.$$

(f3) There exist $K > 0$ and $\tilde{h}_2 \geqq 0$ with $\tilde{h}_2 \in L^2_\rho(\Omega)$ subject to

$$|f(x, t)| \leqq \tilde{h}_2(x) + K|t| \quad \forall t \in \mathbb{R} \text{ and a.e. } x \in \Omega.$$

We shall also assume that $G \in [H^1_{p,\rho}(\Omega)]^*$, i.e., $G: H^1_{p,\rho}(\Omega) \to \mathbb{R}$, G is linear, and there exist K_1 subject to

$$|G(u)| \leqq K_1 \|u\|_{p,\rho} \quad \forall u \in H^1_{p,\rho}. \tag{1.8}$$

Next, we state the first theorem we shall prove in this paper. This statement will involve an assumption labeled $O_{p,\rho}(\Omega)$ which will be explained and illustrated using special functions in the paragraphs following the theorem.

THEOREM 1. *Let $\Omega \subset \mathbb{R}^N$, $N \geqq 1$, be an open connected set and let p and ρ satisfy* (1.2) *and* (1.3). *Assume* (Q1)-(Q5), (f1)-(f3), $O_{p,\rho}(\Omega)$, *and that $G \in [H^1_{p,\rho}(\Omega)]^*$. Then there exist $u^* \in H^1_{p,\rho}(\Omega)$ such that*

$$\mathcal{Q}(u^*, v) = \langle f(\cdot, u^*), v\rangle_\rho + G(v) \quad \forall v \in H^1_{p,\rho}(\Omega) \tag{1.9}$$

where $\mathcal{Q}(u^*, v)$ is defined by (1.6).

It is easy to give examples to show that the above theorem is a best possible result, i.e., (1.9) is false if we allow ε_0 to be zero in (f2). We shall do this in the concluding paragraphs of this section.

By assumption $O_{p,\rho}(\Omega)$ we shall mean that the following three conditions (O1)-(O3) hold

(O1) There exists a complete orthonormal sequence of functions $\{\psi_n\}_{n=1}^\infty$ in $L^2_\rho(\Omega)$. Also $\psi_n \in H^1_{p,\rho}(\Omega)$ for all n.

(O2) There exist $\{\lambda_n\}_{n=1}^\infty$ with $1 \leqq \lambda_1 < \lambda_2 \leqq \lambda_3 \leqq \cdots \leqq \lambda_n \leqq \cdots \to \infty$ subject to

$$\langle \psi_n, v\rangle_{p,\rho} = \lambda_n \langle \psi_n, v\rangle_\rho \quad \forall v \in H^1_{p,\rho}(\Omega).$$

(O3) $\psi_1 > 0$ almost everywhere in Ω.

Now there are many unbounded (as well as bounded) open connected sets Ω that satisfy assumption $O_{p,\rho}(\Omega)$. We illustrate this fact using the theory of special functions.

First and first foremost, we take $\Omega = \mathbb{R}^2$ (with a similar situation prevailing in $\mathbb{R}^N$, $N \geqq 1$), set $\rho(x) = p(x) = e^{-(x_1^2 + x_2^2)}$, and take

$$\phi_{mn}(x_1, x_2) = H_m(x_1)H_n(x_2)/(2^{-m}2^{-n}m!\,n!\,\pi)^{1/2} \tag{1.10}$$

where $H_n(t) = (-1)^n e^{t^2} d^n e^{-t^2}/dt^n$ is the familiar Hermite polynomial for $n = 0, 1, 2, \cdots$. As is well known, $\{H_n(t)/(2^n n!\,\pi^{1/2})^{1/2}\}_{n=0}^\infty$ forms a complete orthonormal system over $\mathbb{R}^1$ with respect to the weight e^{-t^2}. Hence it follows from (1.10) that $\{\phi_{mn}\}_{m=0,n=0}^{\infty,\infty}$ forms a CONS for $L^2_\rho(\mathbb{R}^2)$ where $\rho = e^{-(x_1^2+x_2^2)}$ and therefore (O1) holds. Also, $[e^{-t^2}H_n'(t)]' = -2n\,e^{-t^2}H_n(t)$. An easy computation, using this last fact, shows that if $v \in C^1_{p,\rho}(\Omega)$ as defined by (1.5), then with $D_1 = \partial/\partial x_1$,

$$\int_{\mathbb{R}^2} e^{-(x_1^2+x_2^2)} H_n(x_2) D_1 H_m(x_1) D_1 v(x_1, x_2) = 2m \int_{\mathbb{R}^2} e^{-(x_1^2+x_2^2)} H_n(x_2) H_m(x_1) v(x_1, x_2).$$

From this fact, it follows that

$$\langle \phi_{mn}, v\rangle_{p,\rho} = [2(m+n)+1]\langle \phi_{mn}, v\rangle_\rho \quad \forall v \in H^1_{p,\rho}.$$

Consequently, we see that (O2) holds with $\lambda_1 = 1$, $\lambda_2 = 3$, $\lambda_3 = 3$, $\lambda_4 = 5$, etc. Also, we see from (1.10) that $\psi_1 = \pi^{-1/2}$; hence (O3) holds and $O_{p,\rho}(\Omega)$ is established for this case.

For the second example, we work in $\mathbb{R}^3$, take $\tilde{\Omega} \subset \mathbb{R}^2$ to be a bounded open connected set, and $\Omega = \tilde{\Omega} \times \mathbb{R}^1$. So Ω is an infinite cylinder whose axis is parallel to the x_3-axis. We take $p(x) = \rho(x) = e^{-x_3^2}$ and

$$\Phi_{mn}(x) = \phi_m(x_1, x_2) H_n(x_3)/(2^n n! \pi^{1/2})^{1/2}, \qquad m = 1, 2, \cdots, n = 0, 1, \cdots, \tag{1.11}$$

where $\{\phi_m(x_1, x_2)\}_{m=1}^{\infty}$ and $\{\eta_m\}_{m=1}^{\infty}$ are the familiar eigenfunctions and eigenvalues of the Laplace operator in $W_0^{1,2}(\tilde{\Omega})$. Since $\{\phi_m(x_1, x_2)\}_{m=1}^{\infty}$ is a CONS for $L^2(\tilde{\Omega})$ and $\{H_n(x_3)/(2^n n! \pi^{1/2})^{1/2}\}_{n=0}^{\infty}$ is a CONS over $\mathbb{R}^1$ with respect to the weight $e^{-x_3^2}$, it follows that $\{\Phi_{mn}\}_{m=1,n=0}^{\infty,\infty}$ is a CONS for $L_\rho^2(\Omega)$. Therefore (O1) holds.

Using the properties alluded to in the first example, an easy computation shows that

$$\begin{aligned} &\int_\Omega e^{-x_3^2} \phi_m(x_1, x_2) D_3 H_n(x_3) D_3 v(x) \\ &\qquad = 2n \int_\Omega e^{-x_3^2} \phi_m(x_1, x_2) H_n(x_3) v(x) \quad \forall v \in C_{p,\rho}^1(\Omega). \end{aligned} \tag{1.12}$$

Hence, it follows from (1.11) that

$$\langle \Phi_{mn}, v \rangle_{p,\rho} = (\eta_m + 2n + 1) \langle \Phi_{mn}, v \rangle_\rho$$

for all $v \in H_{p,\rho}^1$. Consequently, we see (O2) holds with $\lambda_1 = \eta_1 + 1$ and $\lambda_2 = \eta_2 + 1$ or $\eta_1 + 3$, depending on which is smaller. As is well known [7, p. 214], $\phi_1(x_1, x_2) > 0$ almost everywhere in $\tilde{\Omega}$. Hence $\psi_1(x_1, x_2, x_3) = \phi_1(x_1, x_2) \pi^{-1/2}$ and we see that (O3) holds. Consequently, $O_{p,\rho}(\Omega)$ is established.

For our third example, we work in $\mathbb{R}^2$ and take $\Omega = (0, 1) \times \mathbb{R}^1$ with $p(x_1, x_2) = x_1 e^{-x_2^2} = \rho(x_1, x_2)$. Also we set

$$\phi_{mn}(x_1, x_2) = J_0(\eta_m x_1) H_n(x_2)/[2^{-1} J_1(\eta_m) 2^n n! \pi^{1/2}]^{1/2} \tag{1.13}$$

for $m = 1, 2, \cdots, n = 0, 1, 2, \cdots$, where $J_0(t)$ and $J_1(t)$ are the familier Bessel functions of the first kind and η_m is the mth positive zero of $J_0(t)$. As is well known [8, p. 264], $\{J_0(\eta_m t)/[2^{-1} J_1(\eta_m)]^{1/2}\}_{m=1}^{\infty}$ is CONS with respect to weight t on $[0, 1]$. Hence, it follows that $\{\phi_{mn}\}_{m=1,n=0}^{\infty,\infty}$ is a CONS for $L_\rho^2(\Omega)$. Observing that

$$\int_\Omega e^{-x_2^2} H_n(x_2) x_1 D_1 J_0(\eta_m x_1) D_1 v(x) = \eta_m^2 \int_\Omega e^{-x_2^2} x_1 H_n(x_2) J_0(\eta_m x_1) v(x)$$

for all $v \in C_{p,\rho}^1(\Omega)$ and using the analogue of (1.12) for the current situation, we see from (1.13) that

$$\langle \phi_{mn}, v \rangle_{p,\rho} = (\eta_m^2 + 2n + 1) \langle \phi_{mn}, v \rangle_\rho$$

for all $v \in H_{p,\rho}^1$. Consequently, we see that (O2) holds with $\lambda_1 = \eta_1^2 + 1$, $\lambda_2 = \eta_1^2 + 3$, $\lambda_3 = \eta_1^2 + 5$, etc. Since $J_0(\eta_1 t) > 0$ in $[0, 1)$, we see that $\psi_1(x_1, x_2) = J_0(\eta_1 x_1) \pi^{-1/2} > 0$ in Ω and (O3) holds. Therefore, $O_{p,\rho}(\Omega)$ is established.

For our fourth example, we continue to work in $\mathbb{R}^2$ and take $\Omega = (0, 1) \times (0, 1)$ with $p(x) = \rho(x) = x_1 x_2$. We set

$$\phi_{mn}(x_1, x_2) = J_0(\eta_m x_1) J_0(\eta_n x_2)/[2^{-2} J_1(\eta_m) J_1(\eta_n)]^{1/2}, \tag{1.14}$$

$m, n = 1, 2, \cdots$, where we use the notation of the previous example. Observing that

$$\int_\Omega x_1 x_2 J_0(\eta_n x_2) D_1 J_0(\eta_m x_1) D_1 v(x) = \eta_m^2 \int_\Omega x_1 x_2 J_0(\eta_m x_1) J_0(\eta_n x_2) v(x)$$

for all $v \in C^1_{p,\rho}(\Omega)$, we see, as in the previous example, that (01)-(03) hold here also with

$$\lambda_1 = 2\eta_1^2 + 1, \quad \lambda_2 = \eta_1^2 + \eta_2^2 + 1, \quad \lambda_3 = \eta_1^2 + \eta_2^2 + 1,$$

etc., and

$$\psi_1(x_1, x_2) = J_0(\eta_1 x_1) J_0(\eta_1 x_2) / 2^{-1} J_1(\eta_1).$$

Hence, $O_{p,\rho}(\Omega)$ is established for this case.

In $\mathbb{R}^1$ we see that $O_{p,\rho}(\Omega)$ holds for the following situations:

$$\Omega = (0, \infty), \quad p(x) = x^{\alpha+1} e^{-x}, \quad \rho(x) = x^{\alpha} e^{-x}, \quad \alpha > -1, \tag{1.15}$$

$$\Omega = (-1, 1), \quad p(x) = (1-x)^{\alpha+1}(1+x)^{\beta+1}, \quad \rho = (1-x)^{\alpha}(1+x)^{\beta}, \quad \alpha, \beta > -1. \tag{1.16}$$

For (1.15) we use the Laguerre polynomials and for (1.16) we use the Jacobi polynomials. For the details to be used to show that (O1)-(O3) hold in these cases, we refer the reader to [14].

The terminology special functions usually refers to the Jacobi polynomials, Laguerre polynomials, Hermite polynomials, and Bessel functions. The above examples illustrate why we have used this terminology in the title of the paper.

In closing this section, we shall use the first example above to show that ε_0 cannot be taken equal to zero in (f2); i.e., the theorem as stated is in general false if $\varepsilon_0 = 0$ in (f2).

To see this fact, we take $\Omega = \mathbb{R}^2$ and use the first example from above with $p(x) = \rho(x) = e^{-(x_1^2 + x_2^2)}$. Then as we pointed out, $\lambda_1 = 1$ and $\psi_1 = \pi^{-1/2}$. We take $A_1(x, t, \xi) = \xi_1$, $A_2(x, t, \xi) = \xi_2$, and $B_0(x, t, \xi) = 1$. Therefore,

$$Qu = -[D_1 p D_1 u + D_2 p D_2 u] + pu$$

and we see that (Q1)-(Q5) holds. Also we see that

$$\mathcal{Q}(u, v) = \int_{\mathbb{R}^2} p(x)[D_1 u D_1 v + D_2 u D_2 v + uv] \tag{1.17}$$

for all $u, v \in H^1_{p,\rho}$. Since $p = \rho$ we obtain from (1.17) that $\mathcal{Q}(u, u)/\|u\|^2_\rho \geqq 1$ for $u \neq 0$. Hence it follows from (1.7) that $\lambda_1^* \geqq 1$. But $\psi_1 \in H^1_{p,\rho}$ and $\mathcal{Q}(\psi_1, \psi_1)/\|\psi_1\|^2_\rho = 1$. Therefore, $\lambda_1^* = 1 = \lambda_1$.

Next, we take $f(x, t) = t$ and observe that $f(x, t)$ meets (f1), (f3), and (f2) with $\varepsilon_0 = 0$. Also, we take $G(v) = \langle \psi_1, v \rangle_\rho$ for all $v \in H^1_{p,\rho}$. Suppose the theorem held under such circumstances. Then from (1.9) we see that there exist $u^* \in H^1_{p,\rho}(\mathbb{R}^2)$ such that

$$\mathcal{Q}(u^*, v) = \langle u^*, v \rangle_\rho + \langle \psi_1, v \rangle_\rho \quad \forall v \in H^1_{p,\rho}. \tag{1.18}$$

We take $v = \psi_1$ in (1.18) and observe from (1.17) and the fact $p = \rho$ that

$$\langle u^*, \psi_1 \rangle_\rho = \langle u^*, \psi_1 \rangle_\rho + \langle \psi_1, \psi_1 \rangle_\rho.$$

Therefore, $\langle \psi_1, \psi_1 \rangle_\rho = 0$. But $\langle \psi_1, \psi_1 \rangle_\rho = 1$. We have arrived at a contradiction. No such u^* as in (1.18) exists. Hence our theorem is in a certain sense best possible, as asserted.

The monotonicity assumption (Q5) above enables us to deal with the nonlinear aspect of Du in $A_i(x, u, Du)$ and this part of the paper was motivated by the classical 1970 article of Browder [5] and the 1965 result of Leray and Lions [11].

Theorem 2 of this paper is stated and proved in § 4.

2. Fundamental lemmas. The first lemma we prove is the following.

LEMMA 1. *Assume* (O1)-(O3) *and that* $g \in L^2_\rho(\Omega)$. *Set*

$$\hat{g}(n) = \langle \psi_n, g \rangle_\rho. \tag{2.1}$$

Then $g \in H^1_{p,\rho}$ *if and only if* $\sum_{n=1}^{\infty} \lambda_n |\hat{g}(n)|^2 < \infty$. *Furthermore, if* $g \in H^1_{p,\rho}$, $\|g\|^2_{p,\rho} = \sum_{n=1}^{\infty} \lambda_n |\hat{g}(n)|^2$.

To prove Lemma 1, we observe from (O1) and (O2) that $\langle \psi_n, \psi_n \rangle_{p,\rho} = \lambda_n > 0$. Also, we see that if $v \in H^1_{p,\rho}$ is such that $\langle \psi_n, v \rangle_{p,\rho} = 0$ for all n, then $\langle \psi_n, v \rangle_{\rho} = 0$ for all n. Since $\{\psi_n\}_{n=1}^{\infty}$ is CONS in L^2_ρ, it follows that $v = 0$ almost everywhere in Ω. Hence we conclude that

$$\{\psi_n / \lambda_n^{1/2}\}_{n=1}^{\infty} \quad \text{is CONS in } H^1_{p,\rho}. \tag{2.2}$$

It follows from (2.2) that if $g \in H^1_{p,\rho}$, then

$$\|g\|^2_{p,\rho} = \sum_{n=1}^{\infty} \langle g, \psi_n \rangle^2_{p,\rho} \lambda_n^{-1} < \infty. \tag{2.3}$$

But from (O2) and (2.1), we have $\langle g, \psi_n \rangle_{p,\rho} = \lambda_n \hat{g}(n)$. Consequently, we conclude from (2.3) that

$$\|g\|^2_{p,\rho} = \sum_{n=1}^{\infty} \lambda_n |\hat{g}(n)|^2 < \infty \tag{2.4}$$

and the only if part of the above lemma is established. Also the last line in the conclusion of the lemma is established.

To establish the if part, we assume

$$\sum_{n=1}^{\infty} \lambda_n |\hat{g}(n)|^2 < \infty, \tag{2.5}$$

and set $h_n = \sum_{k=1}^{n} \hat{g}(k)\psi_k = \sum_{k=1}^{n} \sqrt{\lambda_k}\, \hat{g}(k)\psi_k / \sqrt{\lambda_k}$. Then for $m > n$, $\|h_m - h_n\|^2_{p,\rho} = \sum_{n+1}^{m} \lambda_k |\hat{g}(k)|^2$. Hence it follows from (2.5) that $\{h_n\}_{n=1}^{\infty}$ is a Cauchy sequence in the Hilbert space $H^1_{p,\rho}$. Therefore there exist $h \in H^1_{p,\rho}$ such that $\|h_n - h\|_{p,\rho} \to 0$. But this implies that $\|h_n - h\|_{\rho} \to 0$. Since it follows from the definition of h_n and the fact that $g \in L^2_\rho$ that $\|h_n - g\|_{\rho} \to 0$. We conclude that $g = h$ and the lemma is established.

LEMMA 2. *Assume* (O1)-(O3). *The* $H^1_{p,\rho}(\Omega)$ *is compactly imbedded in* $L^2_\rho(\Omega)$.

To establish this lemma, assume that there exists a sequence $\{v_n\}_{n=1}^{\infty}$ in $H^1_{p,\rho}$ and a constant K such that $\|v_n\|^2_{p,\rho} \leqq K$ for all n. Then it follows from Lemma 1 and (2.4) that

$$\sum_{k=1}^{\infty} \lambda_k |\hat{v}_n(k)|^2 \leqq K. \tag{2.6}$$

To complete the proof of the lemma, we have to show that there exist $v \in H^1_{p,\rho}$ and a subsequence $\{v_{n_m}\}_{m=1}^{\infty}$ such that

$$\|v_{n_m} - v\|^2_{\rho} \to 0. \tag{2.7}$$

To establish (2.7), using (2.6), we choose a subsequence $\hat{v}_{(n,1)}(1)$ such that $\hat{v}_{(n,1)}(1) \to a_1$ as $n \to \infty$. Next we choose a subsequence $(n, 2)$ of $(n, 1)$ such that $\hat{v}_{(n,2)}(2) \to a_2$. Continuing in this manner, we obtain subsequences (n, k) and finite number a_k such that

$$\lim_{n \to \infty} \hat{v}_{(n,k)}(k) = a_k \quad \forall k, \tag{2.8}$$

where $(n, k+1)$ is a subsequence of (n, k). Now let j be a fixed positive integer. Then it follows from (2.6) that $\sum_{k=1}^{j} \lambda_k |\hat{v}_{(n,j)}(k)|^2 \leqq K$. Consequently, it follows from (2.8) that $\sum_{k=1}^{j} \lambda_k |a_k|^2 \leqq K$. But then letting $j \to \infty$, we see that

$$\sum_{k=1}^{\infty} \lambda_k |a_k|^2 \leqq K. \tag{2.9}$$

It therefore follows from Lemma 1 that

$$\exists v \in H^1_{p,\rho} \quad \text{subject to } \hat{v}(k) = a_k. \tag{2.10}$$

Next we define $v_{n_m} = v_{(m,m)}$, and we observe from (2.4) and (2.10) that

$$\|v_{n_m} - v\|_\rho^2 = \sum_{k=1}^{\infty} |\hat{v}_{(m,m)}(k) - \hat{v}(k)|^2. \tag{2.11}$$

Once again we let j be a fixed positive integer. Then we see from (2.10) and (2.11) that

$$\|v_{n_m} - v\|_\rho^2 \leqq \sum_{k=1}^{j} |\hat{v}_{(m,m)}(k) - a_k|^2 + \lambda_j^{-1} \sum_{k=1}^{\infty} \lambda_k |\hat{v}_{(m,m)}(k) - a_k|^2.$$

Consequently, it follows from (2.6), (2.8), and (2.9) that

$$\limsup_{m\to\infty} \|v_{n_m} - v\|_\rho^2 \leqq 4K/\lambda_j.$$

But by (O2), $\lambda_j \to \infty$. Hence $\limsup_{m\to\infty} \|v_{n_m} - v\|_\rho^2 = 0$. Therefore (2.7) is established, and the proof of the lemma is complete.

Next, we establish the following lemma.

LEMMA 3. *Assume that the conditions in the hypothesis of the theorem hold. Let n be a fixed positive integer, and let S_n be the subspace of $H^1_{p,\rho}$ spanned by $\psi_1, \cdots, \psi_n$. Then there exist $u_n \in S_n$ such that*

$$\mathcal{Q}(u_n, v) = \langle f(\cdot, u_n), v\rangle_\rho + G(v) \quad \forall v \in S_n. \tag{2.12}$$

To prove this lemma, we let $\alpha = (\alpha_1, \cdots, \alpha_n) \in \mathbb{R}^n$ and set

$$F_k(\alpha) = \mathcal{Q}(\alpha_j\psi_j, \psi_k) - \langle f(\cdot, \alpha_j\psi_j), \psi_k\rangle_\rho - G(\psi_k) \tag{2.13}$$

for $k = 1, \cdots, n$ where we have used the summation convention for $j = 1, \cdots, n$. Then with $F(\alpha) = (F_1(\alpha), \cdots, F_n(\alpha))$, we obtain that

$$F(\alpha)\cdot\alpha = \mathcal{Q}(\alpha_j\psi_j, \alpha_k\psi_k) - \langle f(\cdot, \alpha_j\psi_j), \alpha_k\psi_k\rangle_\rho - G(\alpha_k\psi_k).$$

Consequently, we obtain from (f2) and (O1) that

$$F(\alpha)\cdot\alpha \geqq \mathcal{Q}(\alpha_j\psi_j, \alpha_k\psi_k) - (\lambda_1^* - \varepsilon_0)|\alpha|^2 - \|\tilde{h}\|_\rho|\alpha| - G(\alpha_k\psi_k) \quad \forall \alpha \in \mathbb{R}^n. \tag{2.14}$$

Since $G \in [H^1_{p,\rho}]^*$, there exist K_2 such that

$$|G(v)| \leqq K_2\|v\|_{p,\rho}. \tag{2.15}$$

Also, it follows from Lemma 1 that there exist $K_{3,n}$ such that $\|v\|_{p,\rho} \leqq K_{3,n}\|v\|_\rho$ for all $v \in S_n$. Consequently, we conclude from (2.14) and (2.15) that

$$F(\alpha)\cdot\alpha \geqq \mathcal{Q}(\alpha_j\psi_j, \alpha_k\psi_k) - (\lambda_1^* - \varepsilon_0)|\alpha|^2 - [\|\tilde{h}\|_\rho + K_2K_{3,n}]|\alpha| \quad \forall \alpha \in \mathbb{R}^n. \tag{2.16}$$

From (1.7) we see that there exist $R_0 > 0$ such that $\mathcal{Q}(\alpha_j\psi_j, \alpha_k\psi_k) \geqq |\alpha|^2(\lambda_1^* - \varepsilon_0/2)$ for $|\alpha| \geqq R_0$. Hence we obtain from (2.16) that $|\alpha| \geqq R_0$,

$$F(\alpha)\cdot\alpha \geqq 2^{-1}\varepsilon_0|\alpha|^2 - [\|\tilde{h}\|_\rho + K_2K_{3,n}]|\alpha|. \tag{2.17}$$

From this last inequality, it follows that there exists $R_1 > 0$ such that

$$F(\alpha)\cdot\alpha > 0 \quad \forall |\alpha| \geqq R_1.$$

From (Q1)-(Q3) in conjunction with (1.6) and from (f1) and (f3), it is an easy matter to see from (2.13) that $F_k(\alpha) \in C^0(\mathbb{R}^n)$ for $k = 1, \cdots, n$. Hence it follows from [12, p. 18] that there exist $\alpha^* \in \mathbb{R}^n$ with $|\alpha| < R_1$ such that $F_k(\alpha^*) = 0$ for $k = 1, \cdots, n$. Setting $u_n = \alpha_1^*\psi_1 + \cdots + \alpha_n^*\psi_n$, we consequently see from (2.13) that

$$\mathcal{Q}(u_n, \psi_k) = \langle f(\cdot, u_n), \psi_k\rangle_\rho - G(\psi_k) \quad \text{for } k = 1, \cdots, n. \tag{2.18}$$

But if $v \in S_n$, $v = \hat{v}(1)\psi_1 + \cdots + \hat{v}(n)\psi_n$ and the conclusion of the lemma follows immediately from (2.18).

3. Proof of Theorem 1. To prove Theorem 1 we invoke Lemma 3 and obtain a sequence $\{u_n\}_{n=1}^{\infty}$ where

$$u_n = \alpha_1^n \psi_1 + \cdots + \alpha_n^n \psi_n \tag{3.1}$$

with the property that (2.12) holds.We claim there exists a constant K_4 such that

$$\|u_n\|_{p,\rho} \leqq K_4 \quad \forall n. \tag{3.2}$$

Suppose to the contrary that (3.2) does not hold. For ease of notation and without loss in generality we assume

$$\lim_{n\to\infty} \|u_n\|_{p,\rho} = \infty. \tag{3.3}$$

We will show this assumption gives a contradiction.

Now one of the following two cases present themselves:

$$\exists K_5 \quad \text{subject to } \|u_n\|_\rho \leqq K_5 \quad \forall n, \tag{3.4}$$

$$\exists \{u_{n_j}\}_{j=1}^{\infty} \quad \text{subject to } \lim_{j\to\infty} \|u_{n_j}\|_\rho = \infty. \tag{3.5}$$

Suppose (3.4) holds. Then taking $v = u_n$ in (2.12) and using (f2) and (1.8), we obtain

$$\mathcal{Q}(u_n, u_n) \leqq (\lambda_1^* - \varepsilon_0)\|u_n\|_\rho^2 + \|\tilde{h}\|_\rho \|u_n\|_\rho + K_1 \|u_n\|_{p,\rho}. \tag{3.6}$$

From (Q3), (Q4), and (3.4), we infer from this last inequality that

$$c_3\|u_n\|_{p,\rho}^2 - K_1\|u_n\|_{p,\rho} \leqq (\lambda_1^* - \varepsilon_0)K_5^2 + \|\tilde{h}\|_\rho K_5 + c_3 K_5^2 + \int_\Omega Zp + c_2 K_5^2 \quad \forall n.$$

Since $Z \in L_p^1(\Omega)$, this last inequality is incompatible with (3.3). Hence (3.2) holds for the first case (3.4).

We now suppose that (3.3) and the second case (3.5) hold. Then it follows from (3.6), (1.7), and (1.8) that there exist j_0 such that for $j \geqq j_0$,

$$(\lambda_1^* - \varepsilon_0 2^{-1})\|u_{n_j}\|_\rho^2 \leqq (\lambda_1^* - \varepsilon_0)\|u_{n_j}\|_\rho^2 + \|\tilde{h}\|_\rho \|u_{n_j}\|_\rho + K_1\|u_{n_j}\|_{p,\rho}.$$

Hence we have, for $j \geqq j_0$,

$$2^{-1}\varepsilon_0\|u_{n_j}\|_\rho^2 - \|\tilde{h}\|_\rho \|u_{n_j}\|_\rho \leqq K_1\|u_{n_j}\|_{p,\rho}.$$

We conclude from this inequality and (3.5) that there exist K_6 and j_1 such that

$$\|u_{n_j}\|_\rho^2 \leqq K_6\|u_{n_j}\|_{p,\rho} \quad \text{for } j \geqq j_1. \tag{3.7}$$

From this last inequality, we obtain from (3.6) that there exist K_7 and $j_2 \geqq j_1$ such that

$$\mathcal{Q}(u_{n_j}, u_{n_j}) \leqq K_7\|u_{n_j}\|_{p,\rho} \quad \text{for } j \geqq j_2. \tag{3.8}$$

From (Q3), (Q4), (3.7), and (3.8), we in turn obtain that

$$c_3\|u_{n_j}\|_{p,\rho}^2 \leqq (K_7 + c_2 K_6)\|u_{n_j}\|_{p,\rho} + \int_\Omega Zp$$

for $j \geqq j_2$. Since $Z \in L_p^1(\Omega)$ and c_2 and c_3 are positive constants, this last inequality is incompatible with (3.3), and we have arrived at a contradiction for the second case (3.5) also. Hence (3.2) is fully established.

Since $H^1_{p,\rho}(\Omega)$ is a separable Hilbert space, we see from Lemma 2 that there exists a subsequence (which for ease of notation we take to be the full sequence) and a function $u^* \in H^1_{p,\rho}$ with the following properties:

$$\lim_{n\to\infty} \|u_n - u^*\|_\rho = 0, \tag{3.9}$$

$$\lim_{n\to\infty} u_n(x) = u^*(x) \quad \text{for a.e. } x \text{ in } \Omega, \tag{3.10}$$

$$\lim_{n\to\infty} \langle D_i u_n, v\rangle_p = \langle D_i u^*, v\rangle_p, \quad \forall v \in L^2_p \text{ and } i = 1, \cdots, N, \tag{3.11}$$

$$\lim_{n\to\infty} G(u_n) = G(u^*). \tag{3.12}$$

Next, we propose to show there exists a subsequence $\{u_{n_j}\}_{j=1}^\infty$ subject to

$$\lim_{j\to\infty} Du_{n_j}(x) = Du^*(x) \quad \text{for a.e. } x \text{ in } \Omega. \tag{3.13}$$

Once (3.13) is established it will be an easy matter to complete the proof of the theorem.

To establish (3.13) it is sufficient to establish the following two facts. (1) There exists a subsequence $\{u_{n_j}\}_{j=1}^\infty$ subject to

$$\lim_{j\to\infty} [A_i(x, u_{n_j}, Du_{n_j}) - A_i(x, u_{n_j}, Du^*)][D_i u_{n_j}(x) - D_i u^*(x)] = 0 \tag{3.14}$$

for a.e. x in Ω.

(2) With $\{u_{n_j}\}_{j=1}^\infty$ designating the same subsequence as in (3.14),

$$\{|Du_{n_j}(x)|\}_{j=1}^\infty \text{ is pointwise bounded for almost every } x \text{ in } \Omega. \tag{3.15}$$

To see that (3.14) and (3.15) together imply (3.13), let Ω_1 be the subset of Ω for which (Q5), (3.10), (3.14), and (3.15) hold simultaneously. Consequently,

$$\text{meas}\,(\Omega - \Omega_1) = 0. \tag{3.16}$$

Suppose there exist $x_0 \in \Omega_1$ for which (3.13) does not hold. Hence by (3.15) there exist a further sequence $\{Du_{n_{j_k}}(x_0)\}_{k=1}^\infty$ and a $\xi^* \in \mathbb{R}^N$ with

$$Du^*(x_0) \neq \xi^* \tag{3.17}$$

such that $\lim_{k\to\infty} Du_{n_{j_k}}(x_0) = \xi^*$. Therefore from (3.10)

$$\begin{aligned}\lim_{k\to\infty} &[A_i(x_0, u_{n_{j_k}}, Du_{n_{j_k}}) - A_i(x_0, u_{n_{j_k}}, Du^*)][D_i u_{n_{j_k}}(x_0) - D_i u^*(x_0)] \\ &= [A_i(x_0, u^*(x_0), \xi^*) - A_i(x_0, u^*(x_0), Du^*(x_0)][\xi_i^* - D_i u^*(x_0)].\end{aligned} \tag{3.18}$$

From (Q5) and (3.17) we see that the right-hand side of (3.18) is strictly positive. Hence the limit on the left-hand side of (3.18) is strictly positive. But $x_0 \in \Omega_1$ and by the definition of Ω_1 and (3.14), this limit equals zero. We have arrived at a contradiction. Hence the equality in (3.13) holds for every point in Ω_1 and therefore by (3.16), for almost every x in Ω, and statement (3.13) is fully established.

It remains to show that (3.14) and (3.15) hold. To establish (3.14) we observe from (Q2), (3.9), (3.10), and Egoroff's theorem [13, p. 75] that

$$\lim_{n\to\infty} \int_\Omega |A_i(x, u_n, Du^*) - A_i(x, u^*, Du^*)|^2 p(x) = 0 \tag{3.19}$$

for $i = 1, \cdots, N$. Also, we have from (3.11) that

$$\lim_{n\to\infty} \int_\Omega A_i(x, u^*, Du^*)[D_i u_n - D_i u^*] p(x) = 0. \tag{3.20}$$

From (3.19) and (3.20) in conjunction with (3.2) and Schwarz's inequality, it is not difficult to see that

$$\lim_{n\to\infty}\int_\Omega [A_i(x, u_n, Du_n) - A_i(x, u_n, Du^*)][D_iu_n - D_iu^*]p(x) = 0, \tag{3.21}$$

provided we show

$$\lim_{n\to\infty}\int_\Omega A_i(x, u_n, Du_n)(D_iu_n - D_iu^*)p(x) = 0. \tag{3.22}$$

By (Q5), the integrand in (3.21) is nonnegative for almost every $x\in\Omega$. Hence the integrand converges in L_p^1-norm to zero and (3.14) follows from [13, p. 70]. Therefore, to complete the proof of (3.14), it remains to establish (3.22). From (Q3) and (3.9) we see that (3.22) will follow once we show

$$\lim_{n\to\infty} \mathcal{Q}(u_n, u_n - u^*) = 0. \tag{3.23}$$

Now $u^*\in H_{p,\rho}^1$ and

$$P_nu^* \equiv \sum_{j=1}^{n} \hat{u}^*(j)\psi_j \quad \text{is in } S_n \tag{3.24}$$

where S_n is defined in Lemma 3. Hence it follows from Lemma 1 that

$$\lim_{n\to\infty} \|P_nu^* - u^*\|_{p,\rho} = 0. \tag{3.25}$$

From (Q2), (Q3), (1.6), (3.2), and (3.25), it also follows that $\lim_{n\to\infty} \mathcal{Q}(u_n, P_nu^* - u^*) = 0$. Consequently, we see that (3.23) will follow once we show that

$$\lim_{n\to\infty} \mathcal{Q}(u_n, u_n - P_nu^*) = 0. \tag{3.26}$$

To establish (3.26), we observe from (3.24) that (2.12) holds for u_n with v replaced by $u_n - P_nu^*$. It is easy to see from (1.8), (3.12), and (3.25) that $\lim_{n\to\infty} G(u_n - P_nu^*) = 0$. Consequently, we obtain from (2.12) that (3.26) will follow once we show

$$\lim_{n\to\infty}\int_\Omega f(x, u_n)[u_n - P_nu^*]\rho = 0. \tag{3.27}$$

But from (3.9) and (f3), we see that $\{\|f(\cdot, u_n)\|_\rho^2\}_{n=1}^\infty$ is a uniformly bounded sequence. Also, we see from (3.9) and (3.25) that $\lim_{n\to\infty} \|u_n - P_nu^*\|_\rho = 0$. We conclude from these last two facts and Schwarz's inequality that (3.25) does indeed hold. Hence (3.21) holds and the proof of (3.14) is complete.

To establish (3.15), we let Ω_2 be the set where simultaneously $u^*(x)$, $|Du^*(x)|$, $Z(x)$, $h(x)$, $u_{n_j}(x)$, $A_i(x, u_{n_j}(x), Du_{n_j}(x))$, and $A_i(x, u_{n_j}(x), u^*(x))$ are finite-valued for $i = 1, \cdots, N$ and $j = 1, 2, \cdots$, where (Q2) and (Q4) hold and also where the limits in (3.10) and (3.14) exist. Then

$$\text{meas}\,(\Omega - \Omega_2) = 0. \tag{3.28}$$

Suppose there exist $x_0\in\Omega_2$ such that

$$\lim_{k\to\infty} |Du_{n_{j_k}}(x_0)| = \infty. \tag{3.29}$$

Now,

$$c_3|Du_{n_{j_k}}(x_0)|^2 \leqq A_i(x_0, u_{n_{j_k}}, Du_{n_{j_k}})D_iu_{n_{j_k}}(x_0) + Z(x_0), \tag{3.30}$$

and also

$$
\begin{aligned}
&A_i(x_0, u_{n_{j_k}}, Du_{n_{j_k}})D_iu_{n_{j_k}}(x_0)\\
&\quad = A_i(x_0, u_{n_{j_k}}, Du_{n_{j_k}})D_iu^*(x_0)\\
&\quad\quad + A_i(x_0, u_{n_{j_k}}, Du^*)[D_iu_{n_{j_k}}(x_0) - D_iu^*(x_0)]\\
&\quad\quad + [A_i(x_0, u_{n_{j_k}}, Du_{n_{j_k}}) - A_i(x_0, u_{n_{j_k}}, Du^*)][D_iu_{n_{j_k}}(x_0) - D_iu^*(x_0)].
\end{aligned}
\tag{3.31}
$$

We divide both sides of (3.30) by $|Du_{n_{j_k}}(x_0)|^{3/2}$ and conclude from (Q2), (3.31), (3.14), and the definition of Ω_2 that $\lim_{k\to\infty} |Du_{n_{j_k}}(x_0)|^{1/2} = 0$. This is a contradiction to (3.29). Hence $\{|Du_{n_j}(x)|\}_{j=1}^{\infty}$ is a pointwise bounded sequence for every x in Ω_2. But then (3.15) follows immediately from this fact and (3.28). As we have already shown, (3.14) and (3.15) imply (3.13). Hence (3.13) is completely established.

Next, we let $v_J \in S_J$ where J is a fixed, but arbitrary positive integer. Then it follows from (Q3), (3.9), (3.10), and (3.13) that

$$
\lim_{j\to\infty} \langle B_0(\cdot, u_{n_j}, Du_{n_j})u_{n_j}, v_J\rangle_\rho = \langle B_0(\cdot, u^*, Du^*)u^*, v_J\rangle_\rho. \tag{3.32}
$$

We see next from (f3) and (3.9) that $\{\|f(\cdot, u_{n_j}) - f(\cdot, u^*)\|_\rho\}_{j=1}^{\infty}$ is a uniformly bounded sequence and from (3.10), Egoroff's theorem, and the fact $v_J \in L^2_\rho$ that

$$
\lim_{j\to\infty} \langle f(\cdot, u_{n_j}), v_J\rangle_\rho = \langle f(\cdot, u^*), v_J\rangle_\rho. \tag{3.33}
$$

Likewise, we see from (Q2) and (3.2) that $\{\|A_i(\cdot, u_{n_j}, Du_{n_j}) - A_i(\cdot, u^*, Du^*)\|_p\}_{j=1}^{\infty}$ is a uniformly bounded sequence for $i = 1, \cdots, N$. Hence, it follows from (3.10), (3.13), Egoroff's theorem, and the fact that $|Dv_J| \in L^2_p$ that

$$
\lim_{j\to\infty} \langle A_i(\cdot, u_{n_j}, Du_{n_j}), D_iv_J\rangle_p = \langle A_i(\cdot, u^*, Du^*), D_iv_J\rangle_p. \tag{3.34}
$$

Since (2.12) holds for u_{n_j} and $v_J \in S_J$ when $n_j \geqq J$, we conclude from (1.6), (3.32), (3.33), and (3.34) that

$$
\mathcal{Q}(u^*, v_J) = \langle f(\cdot, u^*), v_J\rangle_\rho + G(v_J). \tag{3.35}
$$

Next given $v \in H^1_{p,\rho}$, we define $P_Jv \in S_J$ as in (3.24) and observe that $\lim_{J\to\infty} \|P_Jv - v\|_{p,\rho} = 0$ as in (3.25). Hence it follows from (Q2) and (Q3) that $\mathcal{Q}(u^*, P_Jv) \to \mathcal{Q}(u^*, v)$, $\langle f(\cdot, u^*), P_Jv\rangle_\rho \to \langle f(\cdot, u^*), v\rangle_\rho$, and $G(P_Jv) \to G(v)$ as $J \to \infty$. We conclude from (3.35) that

$$
\mathcal{Q}(u^*, v) = \langle f(\cdot, u^*), v\rangle_\rho + G(v),
$$

and the proof of Theorem 1 is complete.

4. Resonance and singular quasilinearity. Let

(L1) $a_{ij}(x)$ and $b_0(x)$ be in $L^\infty(\Omega)$, $i, j = 1, \cdots, N$ with $a_{ij}(x) = a_{ji}(x)$ almost everywhere in Ω; and

(L2) $a_{ij}(x)\xi_i\xi_j \geqq c_4|\xi|^2$ for almost every $x \in \Omega$ where $c_4 > 0$

and where the summation convention is used. Set

$$
Lu = -D_i[p(x)a_{ij}(x)D_ju] + b_0(x)\rho(x)u \tag{4.0}
$$

and

$$
\mathcal{L}(u, v) = \int_\Omega pa_{ij}D_iuD_jv + b_0uv\rho \tag{4.1}
$$

for all $u, v \in H^1_{p,\rho}$ where once again we have used the summation convention for $i, j = 1, \cdots, N$.

From Lemma 2 we know that $H^1_{p,\rho}$ is compactly imbedded in L^2_ρ. Hence, using the reasoning on [7, p. 213], it follows that there exists

$$\sigma_1 \leqq \sigma_2 \leqq \cdots \leqq \sigma_n \leqq \cdots \to +\infty \tag{4.2}$$

and a sequence $\{\phi_n\}_{n=1}^\infty$ with $\phi_n \in H^1_{p,\rho}$ enjoying the following two properties:

$$\mathscr{L}(\phi_n, v) = \sigma_n \langle \phi_n, v \rangle_\rho \quad \forall n, \tag{4.3}$$

$$\{\phi_n\}_{n=1}^\infty \text{ is a CONS in } L^2_\rho. \tag{4.4}$$

Furthermore, applying the reasoning of [7, p. 214] to compact subsets of Ω, we see that $\sigma_1 < \sigma_2$ and we can take $\phi_1 > 0$ almost everywhere in Ω. We record this observation as

$$\sigma_1 < \sigma_2 \quad \text{and} \quad \phi_1(x) > 0 \quad \text{for a.e. } x \in \Omega. \tag{4.5}$$

Next with Q as in § 1, we shall say Q is $*$-related to L if the following two facts hold:

$$\lambda_1^* = \sigma_1, \tag{4.6}$$

$$\liminf_{\|u\|_{p,\rho} \to \infty} [\mathscr{Q}(u, u) - \mathscr{L}(u, u)] / \|u\|_{p,\rho} \geqq 0. \tag{4.7}$$

In particular, we see that L is $*$-related to itself. Also, it is easy to see that $Qu = -D_i p\{1 + [1 + |Du|^2]^{-1/2}\} D_i u + \rho u$ meets (Q1)-(Q5) and is $*$-related to $Lu = -D_i p D_i u + \rho u$. (See [9, p. 96]. In the next section the details will be supplied and other examples with be given.) We intend to establish a result similar to Theorem 1, except that in (f2) we shall take $\varepsilon_0 = 0$. As we have shown at the end of § 1, a result of this nature is in general false and therefore to obtain such a result, another condition, usually referred to as a Landesman-Lazer condition, is required. (See [4, p. 284] and [10].) To this end, we define the following:

(f4) There exist $\tilde{h}_1 \geqq 0$ with $\tilde{h}_1 \in L^2_\rho$ subject to $tf(x, t) \leqq \lambda_1^* t^2 + \tilde{h}_1(x)|t|$ for all $t \in \mathbb{R}$ and almost every $x \in \Omega$.

The theorem we intend to prove is the following.

THEOREM 2. *Let the hypotheses of Theorem* 1 *hold with* (f4) *replacing* (f2). *Suppose also that Q is $*$-related to L where L satisfies* (L1) *and* (L2). *Set* $g_+(x) = \limsup_{t \to \infty} [f(x, t) - \lambda_1^* t]$ *and* $g_-(x) = \liminf_{t \to -\infty} [f(x, t) - \lambda_1^* t]$ *and suppose furthermore that*

$$\int_\Omega g_+ \phi_1 \rho < -G(\phi_1) < \int_\Omega g_- \phi_1 \rho. \tag{4.8}$$

Then there exist $u^* \in H^1_{p,\rho}$ *such that*

$$\mathscr{Q}(u^*, u) = \langle f(\cdot, u^*), u \rangle_\rho + G(u) \quad \forall u \in H^1_{p,\rho}. \tag{4.9}$$

From the start, by adding a constant positive multiple of $\rho(x)u$ to Qu in (1.0) and Lu in (4.0), and this same constant multiple to u to $f(x, u)$, we see from (1.7), (4.6), and (4.9) that, with no loss in generality, to prove the theorem we can assume that

$$\lambda_1^* = \sigma_1 > 0 \quad \text{and} \quad b_0(x) > 0 \quad \text{a.e. in } \Omega. \tag{4.10}$$

Also, we set

$$g(x, t) = f(x, t) - \lambda_1^* t \quad \text{for } (x, t) \in \Omega \times \mathbb{R} \tag{4.11}$$

and observe from (f4) and Theorem 1 that there exist $\{u_n\}_{n=1}^{\infty}$ with $u_n \in H^1_{p,\rho}$ such that

$$\mathscr{Q}(u_n, u) = [\lambda_1^* - n^{-1}]\langle u_n, u\rangle_\rho + \langle g(\cdot, u_n), u\rangle_\rho + G(u) \quad \forall u \in H^1_{p,\rho}. \tag{4.12}$$

Next we set

$$\check{w}(n) = \langle \phi_n, w\rangle_\rho \quad \text{for } w \in L^2_\rho \tag{4.13}$$

and also observe from (4.2)-(4.4) and (4.10) that

$$u \in H^1_{p,\rho} \quad \text{and} \quad \mathscr{L}(u, \phi_n) = 0 \quad \forall n \Rightarrow u = 0. \tag{4.14}$$

Furthermore, from (L2), (4.1), and (4.10), we see that if $u \in H^1_{p,\rho}$ and $u \neq 0$, then $\mathscr{L}(u, u) > 0$. Consequently, $\mathscr{L}(\cdot, \cdot)$ can be viewed as an inner product on $H^1_{p,\rho}$ and it follows from (4.3), (4.4), (4.13), and (4.14) that

$$\begin{aligned} &\text{(a)} \ \langle w, w\rangle_\rho = \sum_{n=1}^{\infty} |\check{w}(n)|^2 \qquad \text{for } w \in L^2_\rho, \\ &\text{(b)} \ \mathscr{L}(u, u) = \sum_{n=1}^{\infty} \sigma_n |\check{u}(n)|^2 \text{ for } u \in H^1_{p,\rho}. \end{aligned} \tag{4.15}$$

Continuing with the proof, the first fact we claim is that with $\{u_n\}_{n=1}^{\infty}$ the sequence given in (4.12),

$$\text{There exist } K_8 \text{ such that } \|u_n\|_{p,\rho} \leqq K_8 \text{ for all } n. \tag{4.16}$$

Suppose that (4.16) does not hold. Then there exists a subsequence (which for ease of notation we take to be the full sequence) such that

$$\lim_{n\to\infty} \|u_n\|_{p,\rho} = \infty. \tag{4.17}$$

We shall arrive at a contradiction by showing that this fact implies that one of the inequalities in (4.8) does not hold.

To accomplish this we replace u by u_n in (4.12) and obtain from (f4) and (1.8) that

$$\mathscr{Q}(u_n, u_n) \leqq (\lambda_1^* - n^{-1})\|u_n\|_\rho^2 + \|\tilde{h}_1\|_\rho \|u_n\|_\rho + K_1 \|u_n\|_{p,\rho}. \tag{4.18}$$

Consequently, we obtain from (L1), (L2), (4.7), (4.10), (4.17), and this last inequality that there is a positive constant K_9 such that

$$2^{-1} c_4 \|u_n\|_{p,\rho}^2 - K_1 \|u_n\|_{p,\rho} \leqq K_9 \|u_n\|_\rho^2 + \|\tilde{h}_1\|_\rho \|u_n\|_\rho$$

for n sufficiently large. Since c_4 is a positive constant, it follows from (4.17) that there is a positive constant K_{10} and a positive integer n_1 such that

$$\|u_n\|_{p,\rho} \leqq K_{10} \|u_n\|_\rho \quad \text{for } n \geqq n_1. \tag{4.19}$$

In particular, from (4.17) and (4.19) we see that $\lim_{n\to\infty} \|u_n\|_\rho = \infty$. Next we set

$$v_n = u_n / \|u_n\|_\rho \tag{4.20}$$

and

$$v_{1n} = \check{v}_n(1)\phi_1 \quad \text{and} \quad v_{2n} = v_n - v_{1n}. \tag{4.21}$$

From (4.7), (4.10), (4.15), (4.18), and (4.19), we see that there exist n_2 such that

$$\sum_{k=2}^{\infty} (\sigma_k - \sigma_1)|\check{v}_n(k)|^2 \leqq -n^{-1}\|v_n\|_\rho^2 + [\|\tilde{h}_1\|_\rho + (K_1 + 1)K_{10}]\|v_n\|_\rho \|u_n\|_\rho^{-1}$$

for $n \geqq \max(n_1, n_2)$. From (4.20), we see that $\|v_n\|_\rho = 1$, and from (4.5) and (4.15)(a) that the left-hand side of this last inequality majorizes $(\sigma_2 - \sigma_1)\|v_{n2}\|_\rho^2$. We, consequently, conclude from (4.17) and (4.19) that

$$\lim_{n\to\infty} \|v_{n2}\|_\rho^2 = 0. \tag{4.22}$$

But then it follows from (4.5) and (4.21) that $\lim_{n\to\infty} \|v_{n1}\|_\rho = 1$, and hence

$$\lim_{n\to\infty} |\check{v}_n(1)|^2 = 1. \tag{4.23}$$

From (4.19) and (4.20) we see that $\|v_n\|_{p,\rho} \leqq K_{10}$ for $n \geqq n_1$. Therefore we have from Lemma 2 that there exist $v \in H^1_{p,\rho}$ and a subsequence (which for ease of notation we take to be the full sequence) such that

$$\begin{aligned}
&\text{(a)} \quad \lim_{n\to\infty} \|v_n - v\|_\rho = 0, \\
&\text{(b)} \quad \lim_{n\to\infty} v_n(x) = v(x) \quad \text{for a.e. } x \text{ in } \Omega, \\
&\text{(c)} \quad \lim_{n\to\infty} \int_\Omega D_i v_n w p = \int_\Omega D_i v w p \quad \forall w \in L^2_p, \\
&\text{(d)} \quad \lim_{n\to\infty} G(v_n) = G(v).
\end{aligned} \tag{4.24}$$

From (4.13), (4.21), (4.22), and (4.24)(a), we see that $\check{v}(k) = 0$ for $k \geqq 2$. Consequently, $v = \check{v}(1)\phi_1$ and since $\lim_{n\to\infty} \check{v}_n(1) = \check{v}(1)$, we conclude from (4.23) that $\check{v}(1) = 1$ or -1. We shall assume

$$\check{v}(1) = 1 \quad \text{and} \quad v = \phi_1 \tag{4.25}$$

and arrive at a contradiction. Similar reasoning will lead to a contradiction for the assumption $\check{v}(1) = -1$.

To arrive at this contradiction, we replace u by u_n in (4.12) and use (4.6), (4.7), and (4.15) to obtain the following. Given $\varepsilon > 0$, there exist n_3 such that for $n \geqq n_3$

$$\sum_{k=2}^{\infty} (\sigma_k - \sigma_1)|\check{u}_n(k)|^2 \leqq \langle g(\cdot, u_n), u_n\rangle_\rho + G(u_n) + \varepsilon\|u_n\|_{p,\rho}.$$

Consequently, from (4.19) and (4.20) we see that

$$\int_\Omega [\tilde{h}_1(x)|v_n| - g(x, u_n)v_n|\rho - \int_\Omega \tilde{h}_1(x)|v_n|\rho \leqq G(v_n) + \varepsilon K_{10} \tag{4.26}$$

for $n \geqq n_3$. (f4) in conjunction with (4.11) tells us that the integrand in the first integral on the left in this last inequality is nonnegative. Since $\tilde{h}_1 \in L^2_\rho$, we see from (4.24)(a) that the limit of the second integral on the left is $\langle \tilde{h}_1, |v|\rangle_\rho$. We consequently conclude from (4.24)(d), (4.26), and Fatou's lemma [13, p. 24] that

$$-\int_\Omega \limsup_{n\to\infty} [g(x, u_n)v_n]\rho \leqq G(v) + \varepsilon K_{10}.$$

But $\varepsilon > 0$ is arbitrary. Consequently, we conclude from this last inequality that

$$-\int_\Omega \limsup_{n\to\infty} [g(x, u_n)v_n]\rho \leqq G(v). \tag{4.27}$$

From (4.24)(b) and (4.25), we see that $\lim_{n\to\infty} v_n(x) = \phi_1(x)$ almost everywhere in Ω. Since $u_n = \|u_n\|_\rho v_n$, we conclude from (4.5), (4.17), and (4.19) that $\lim_{n\to\infty} u_n(x) = \infty$ for almost every $x \in \Omega$. Hence we see from (4.11), (4.27), and the definition of $g_+(x)$ that

$$\int_\Omega g_+(x)\phi_1\rho \geqq -G(\phi_1).$$

But this is a direct contradiction of the first inequality in (4.8). Hence, (4.16) does indeed hold.

From (4.16), we immediately obtain from Lemma 2 that there exist $u^* \in H^1_{p,\rho}$ with properties (3.9)-(3.12). We would like to show that (3.13) holds. Equation (3.13) follows from (3.14) and (3.15) exactly in the same manner as before. Hence, it remains to establish (3.14) and (3.15). To establish (3.14), we see that (3.19)-(3.21) follow once we show that (3.22) holds. Since (3.21) implies (3.14) via [13, p. 70], to establish (3.14) it suffices to establish (3.22). We now do this. In particular, we have to show

$$\lim_{n\to\infty} \int_\Omega A_i(x, u_n, Du_n)(D_i u_n - D_i u^*)p(x) = 0 \tag{4.28}$$

under the assumptions that (4.12) and (4.16) hold and also that (3.9)-(3.12) hold. From (3.9) and (Q3), we see that (4.28) will follow once we show

$$\lim_{n\to\infty} \mathcal{Q}(u_n, u_n - u^*) = 0. \tag{4.29}$$

Replacing u by $u_n - u^*$ in (4.12), we see from (3.9) and (3.12) that (4.29) will follow once we show

$$\lim_{n\to\infty} \langle g(\cdot, u_n), u_n - u^*\rangle_\rho = 0. \tag{4.30}$$

Now it follows from (4.11) and (f3) that

$$|g(x, u_n)| \leqq \tilde{h}_2(x) + (K + \lambda_1^*)|u_n|. \tag{4.31}$$

Hence it follows from (3.9) that there exist K_{11} such that $\int_\Omega |g(x, u_n)|^2\rho \leqq K_{11}$ for all n. Using (3.9) once again, in conjunction with this last fact and Schwarz's inequality, gives (4.30). Hence (3.14) is established. Equation (3.15) follows exactly as before using (3.30). Since (3.14) and (3.15) hold, as we have already shown, (3.13) holds.

To complete the proof of the theorem, it remains to show that (3.9)-(3.13) along with (4.12) and (4.16) imply (4.9). Let u be given in $H^1_{p,\rho}$. Then it follows (Q3), (3.9), (3.10), and (3.13) that

$$\lim_{j\to\infty} \langle B_0(\cdot, u_{n_j}, Du_{n_j})u_{n_j}, u\rangle_\rho = \langle B_0(\cdot, u^*, Du^*)u^*, u\rangle_\rho. \tag{4.32}$$

Next, we see from (4.31) and (3.9) that

$$\{\|g(\cdot, u_{n_j}) - g(\cdot, u^*)\|_\rho\}_{n=1}^\infty$$

is a uniformly bounded sequence. Hence, it follows from (3.10) and Egoroff's theorem that

$$\lim_{j\to\infty} \langle g(\cdot, u_{n_j}), u\rangle_\rho = \langle g(\cdot, u^*), u\rangle_\rho. \tag{4.33}$$

Likewise, we see from [Q2] and (4.16) that

$$\{\|A_i(\cdot, u_{n_j}, Du_{n_j}) - A_i(\cdot, u^*, Du^*)\|_p\}_{j=1}^\infty$$

is a uniformly bounded sequence for $i = 1, \cdots, N$. Hence, it follows from (3.10), (3.13), Egoroff's theorem, and the fact $D_i u \in L_p^2$ that

$$\lim_{j\to\infty} \langle A_i(\cdot, u_{n_j}, Du_{n_j}), D_i u\rangle_p = \langle A_i(\cdot, u^*, Du^*), D_i u\rangle_p. \tag{4.34}$$

From (4.12) and (3.9) in conjunction with (4.32)-(4.34), we conclude that

$$\langle \mathcal{Q}(u^*, u)\rangle = \lambda_1^* \langle u^*, u\rangle_p + \langle g(\cdot, u^*), u\rangle_\rho + G(u).$$

From (4.11) we see this is the same as (4.9). The proof of Theorem 2 is therefore complete.

5. A corollary with some examples. Using the techniques presented in this paper, we can also obtain the singular quasilinear analogue of Theorem 3 of [6]. The details are left to the interested reader.

We close with the following corollary and some examples illustrating said corollary. We shall need the following asumption in the sequel. $g(t)$ is a bounded continuous function with

$$g_+ = \limsup_{t\to\infty} g(t), \quad g_- = \liminf_{t\to-\infty} g(t), \quad \text{and } g_+ < g(t) < g_- \quad \text{for } -\infty < t < t\infty. \tag{5.1}$$

COROLLARY. *Let $\Omega \subset \mathbb{R}^N$, $N \geqq 1$, be an open connected set and let p and ρ satisfy* (1.2) *and* (1.3). *Assume that Q given by* (1.0) *satisfies* (Q1)-(Q5), *that $O_{p,\rho}(\Omega)$ holds, and that $G \in [H_{p,\rho}^1(\Omega)]^*$. Assume also that L given by* (4.0) *satisfies* (L1) *and* (L2), *that Q is $*$-related to L, and that*

$$\mathcal{Q}(u, \phi_1) = \lambda_1^* \langle u, \phi_1\rangle_\rho \quad \forall u \in H_{p,\rho}^1(\Omega) \tag{5.2}$$

where ϕ_1 is given in (4.5). *Assume furthermore that g is a bounded continuous function satisfying* (5.1). *Then a necessary and sufficient condition that there exist $u^* \in H_{p,\rho}^1(\Omega)$ with the property that*

$$\mathcal{Q}(u^*, u) = \lambda_1^* \langle u^*, u\rangle_\rho + \langle g(u^*), u\rangle_\rho + G(u) \tag{5.3}$$

for all $u \in H_{p,\rho}^1(\Omega)$ is that

$$g_+ \int_\Omega \phi_1 \rho < -G(\phi_1) < g_- \int_\Omega \phi_1 \rho. \tag{5.4}$$

It is clear that $f(x, t) = g(t) + \lambda_1^* t$ satisfies (f1), (f3), and (f4). Hence the sufficiency condition of the above corollary follows immediately from Theorem 2. To prove the necessary condition, suppose there exist $u^* \in H_{p,\rho}^1$ such that (5.3) holds. Take $u = \phi_1$ in (5.3). Then it follows from (5.2) that

$$-G(\phi_1) = \int_\Omega g(u^*)\phi_1 \rho. \tag{5.5}$$

But (5.1) implies that

$$g_+ < g(u^*(x)) < g_- \quad \text{for a.e. } x \text{ in } \Omega,$$

and (5.4) follows from (1.2), (4.5), and (5.5). Hence the necessary condition of the above corollary is established.

We now give some examples for which the corollary holds. In particular, in the following examples we shall have to show that Q satisfies (Q1)-(Q5), that Q is $*$-related to L, and that (5.2) holds.

For our first example, we consider the case where $\Gamma_1 = \partial\Omega$ in (1.2) and take

$$\begin{aligned} Lu &= -D_i[pD_iu] + \rho u, \\ Qu &= -D_i p\{1+[1+|Du|^2]^{-1/2}\}D_i u + \rho u. \end{aligned} \tag{5.6}$$

We see that $A_i(x, t, \xi) = \{1+[1+|\xi|^2]^{-1/2}\}\xi_i$ and $B_0 = 1$. It is clear from [9, p. 96] that Q meets (Q1)-(Q5) and that

$$\mathcal{Q}(u, v) - \mathcal{L}(u, v) = \int_\Omega p[1+|Du|^2]^{-1/2} D_i u D_i v. \tag{5.6'}$$

Since $\Gamma_1 = \partial\Omega$, constants are in $C^1_{p,\rho}(\Omega)$. It therefore follows from (4.1) and (4.3) that $\phi_1 = \psi_1 = c_5$ where c_5 is a positive constant and $\lambda_1 = \sigma_1 = 1$. Also, we have from (5.6') that $\mathcal{Q}(u, u) - \mathcal{L}(u, u) \geqq 0$. Consequently, (4.7) follows immediately, and also we see from (1.7), (4.15), and this last inequality that $\lambda_1^* \geqq \sigma_1$. But from (5.6'), we have that $\mathcal{Q}(n\phi_1, n\phi_1) = n^2\mathcal{L}(\phi_1, \phi_1) = n^2\sigma_1$. Therefore, $\lim_{n\to\infty} \mathcal{Q}(n\phi_1, n\phi_1)/n^2\langle\phi_1, \phi_1\rangle_\rho = \sigma_1$; hence $\lambda_1^* \leqq \sigma_1$. Thus $\lambda_1^* = \sigma_1$, and (4.6) is established. Since we have already established (4.7), we have that Q is $*$-related to L. From (5.6') we also see that $\mathcal{Q}(u, \phi_1) = \mathcal{L}(u, \phi_1) = \sigma_1\langle u, \phi_1\rangle_\rho$. Consequently, (5.2) holds and our example is fully established.

We observe that $\Gamma_1 = \partial\Omega$ in the cases (1.10), (1.15), and (1.16) discussed in § 1. Hence the above example covers these cases.

For a more sophisticated example, we consider the case where $F(t)$ is a continuous nondecreasing function on $[0, \infty)$ with

$$F(0) \geqq 0 \quad \text{and} \quad \lim_{t\to\infty} t[1-F(t)] = 0, \tag{5.7}$$

e.g., $F(t) = t/\sqrt{1+t^2}$, $t^2/(1+t^2)$, $[(1+t^2)/(2+t^2)]^{3/2}$, etc. For such an F, the first example we consider is where L has the eigenfunctions that are given in (1.11). For this case $\Omega = \tilde{\Omega} \times \mathbb{R}^1$ where $\tilde{\Omega} \subset \mathbb{R}^2$ and $p(x) = \rho(x) = e^{-x_3^2}$. We then have that

$$Lu = -e^{-x_3^2}D_1^2 u - e^{-x_3^2}D_2^2 u - D_3[e^{-x_3^2}D_3 u] + e^{-x_3^2}u \tag{5.8}$$

and we take

$$Qu = -e^{-x_3^2}[D_1^2 u + D_2^2 u] - 2^{-1}D_3\, e^{-x_3^2}[1+F(|D_3 u|)]D_3 u + e^{-x_3^2}u. \tag{5.9}$$

Now it follows from the discussion in § 1 that $\sigma_1 = \lambda_1 = \eta_1 + 1$ and $\phi_1 = \psi_1 = \tilde{\phi}_1(x_1, x_2)H_0(x_3)/\pi^{1/4}$.

From the fact that $H_0(x_3) = 1$, it follows from (1.6) that

$$\begin{aligned} \mathcal{Q}(u, \phi_1) &= \pi^{-1/4}\int_\Omega e^{-x_3^2}\{D_1 u D_1\tilde{\phi}_1 + D_2 u D_2\tilde{\phi}_1 + 2^{-1}[1+F(|D_3 u|)]D_3 u D_3\tilde{\phi}_1\} + \langle u, \phi_1\rangle_\rho \\ &= (\eta_1+1)\langle u, \phi_1\rangle_\rho \quad \forall u \in C^1_{p,\rho}(\Omega). \end{aligned}$$

Hence, it follows that

$$\mathcal{Q}(u, \phi_1) = \sigma_1\langle u, \phi_1\rangle_\rho \quad \forall u \in H^1_{p,\rho} \tag{5.10}$$

and (5.2) is established provided we can show $\sigma_1 = \lambda_1^*$, i.e., that Q satisfies (4.6). We also have to show that Q satisfies (4.7) and (Q1)-(Q5).

To establish these facts, we observe from (5.9) that $B_0=1$, $A_1(x,t,\xi)=\xi_1$, $A_2(x,t,\xi)=\xi_2$, and $A_3(x,t,\xi)=2^{-1}[1+F(|\xi_3|)]\xi_3$. It is clear from (5.7) and the fact that $F(t)$ is nondecreasing on $[0,\infty)$ that Q meets (Q1)-(Q5). Also it follows from (5.8) and (5.9) that

$$\mathcal{Q}(u,u)-\mathcal{L}(u,u)=-2^{-1}\int_\Omega e^{-x_3^2}[1-F(|D_3u|)]|D_3u|^2. \tag{5.11}$$

Consequently, $\mathcal{Q}(u,u)\leqq\mathcal{L}(u,u)$ for all $u\in H^1_{p,\rho}$ and we conclude from (1.7) that

$$\lambda_1^*\leqq\liminf_{\|u\|_\rho^2\to\infty}\mathcal{L}(u,u)/\|u\|_\rho^2,\qquad u\in H^1_{p,\rho}. \tag{5.12}$$

But for $u\neq 0$, $\mathcal{L}(u,u)/\|u\|_\rho^2=\mathcal{L}(u/\|u\|_\rho, u/\|u\|_\rho)$ and from (4.15)(a), (b) we see that

$$\inf_{\|u\|_\rho^2=1}\mathcal{L}(u,u)=\sigma_1,\qquad u\in H^1_{p,\rho}.$$

Hence, it follows from (5.12) that

$$\lambda_1^*\leqq\sigma_1. \tag{5.13}$$

On the other hand, from (Q3) and (Q4) if $\lim_{n\to\infty}\langle u_n,u_n\rangle_\rho=\infty$ and

$$\lim_{n\to\infty}\mathcal{Q}(u_n,u_n)/\langle u_n,u_n\rangle_\rho=\lambda_1^*, \tag{5.13}'$$

we see from (4.7) that $\lambda_1^*\geqq\sigma_1$. This fact coupled with (5.13) gives (4.6).

It remains to establish (4.7). It is clear from (5.11) that (4.7) will follow if we can show the following. Given $\{u_n\}_{n=1}^\infty$ an arbitrary sequence in $C^1_{p,\rho}$ such that

$$\lim_{n\to\infty}\|u_n\|_{p,\rho}=\infty, \tag{5.14}$$

then

$$\lim_{n\to\infty}\int_\Omega e^{-x_3^2}[1-F(|D_3u_n|)]|D_3u_n|^2/\|u_n\|_{p,\rho}=0. \tag{5.15}$$

Now we recall once again that $\Omega=\tilde{\Omega}\times\mathbb{R}^1$ where $\tilde{\Omega}\subset\mathbb{R}^2$ is a bounded open connected set. Let $\varepsilon>0$ be given. Using (5.7), choose $T>0$ such that $t|1-F(t)|<\varepsilon$ for $t\geqq T$. Let $\Omega_{1n}=\{x\in\Omega\colon|D_3u_n(x)|>T\}$ and $\Omega_{2n}=\Omega\backslash\Omega_{1n}$. Since $\Omega=\Omega_{1n}\cup\Omega_{2n}$, it follows that

$$\int_\Omega e^{-x_3^2}|1-F(|D_3u_2|)||D_3u_n|^2\leqq T^2(\text{meas }\tilde{\Omega})\pi^{1/2}+\varepsilon\|u_n\|_{p,\rho}(\text{meas }\tilde{\Omega})^{1/2}\pi^{1/4}.$$

Dividing both sides of this last inequality by $\|u_n\|_{p,\rho}$, we see that

$$\limsup_{n\to\infty}\int_\Omega e^{-x_3^2}|1-F(|D_3u_n|)||D_3u_n|^2/\|u_n\|_{p,\rho}\leqq\varepsilon(\text{meas }\tilde{\Omega})^{1/2}\pi^{1/4}.$$

Since ε is arbitrary, (5.15) is true. Hence (4.7) holds, and our example is completely established.

For our final illustration we choose $\Omega=(0,1)\times\mathbb{R}^1$ and $p(x_1,x_2)=\rho(x_1,x_2)=x_1e^{-x_2^2}$. We take

$$Lu=-D_1[x_1\,e^{-x_2^2}D_1u]-D_2[x_1\,e^{-x_2^2}D_2u]+x_1\,e^{-x_2^2}u \tag{5.16}$$

and

$$Qu=-D_1[x_1\,e^{-x_2^2}D_1u]-D_2\{x_1\,e^{-x_2^2}2^{-1}[1+F(|D_2u|)]D_2u\}+x_1\,e^{-x_2^2}u. \tag{5.17}$$

Then it follows from (1.6) and (4.1) that

$$\mathcal{Q}(u, v) - \mathcal{L}(u, v) = -\int_\Omega x_1 e^{-x_2^2} 2^{-1}[1 - F(|D_2 u|)] D_2 u D_2 v. \tag{5.18}$$

Since $\phi_1(x_1, x_2) =$ constant multiple of $J_0(\eta_1 x_1)$ where η_1 is the first positive zero of J_0, it also follows that the integral on the right-hand side of (5.18) is zero when $v = \phi_1$. Hence, we see from (5.18) and (4.3) that

$$\mathcal{Q}(u, \phi_1) = \mathcal{L}(u, \phi_1) = \sigma_1 \langle u, \phi_1 \rangle_\rho \quad \forall u \in H^1_{p,\rho}. \tag{5.19}$$

Therefore, (5.2) will follow once we show that (4.6) holds. We also have to show that (4.7) holds and that Q satisfies (Q1)-(Q5).

We see from (1.0) and (5.17) that $B_0 = 1$, $A_1(x, t, \xi) = \xi_1$, and $A_2(x, t, \xi) = 2^{-1}[1 + F(|\xi_2|)]\xi_2$. It is an easy matter to see from (5.7) and the fact that $F(t)$ is nondecreasing on $[0, \infty)$ that (Q1)-(Q5) hold. Also it follows from (5.18) that $\mathcal{Q}(u, u) \leqq \mathcal{L}(u, u)$ and hence as we did in (5.12) and (5.13), we obtain that $\lambda_1^* \leqq \sigma_1$. But from (5.13'), we obtain as before using (Q3)-(Q4) and (4.7) that $\lambda_1^* \geqq \sigma_1$. Consequently, (4.6) holds. To establish (4.7) we assume (5.14) holds and show with the identical proof used before for (5.15) that

$$\lim_{n \to \infty} \int_\Omega x_1 e^{-x_2^2}[1 - F(|D_2 u_n|)] D_2 u_n / \|u_n\|_{p,\rho} = 0.$$

Consequently, it follows from (5.18) that (4.7) is true. Therefore, Lu and Qu given, respectively, by (5.16) and (5.17) satisfy the conditions in the hypothesis of the corollary and our last example is completely established.

BIORTHOGONALITY OF A SYSTEM OF RATIONAL FUNCTIONS WITH RESPECT TO A POSITIVE MEASURE ON [−1,1]*

MIZAN RAHMAN†

Abstract. By using the summation and transformation formulas for balanced very well poised basic hypergeometric series an extension of Askey and Wilson's q-beta integral involving five parameters is evaluated, where one of the parameters has modulus greater than 1. The result is then applied to obtain the biorthogonality relation for a system of real-valued rational functions on $[-1,1]$ representable as terminating balanced very well poised ${}_{10}\phi_9$ series.

Key words. balanced and very well poised basic hypergeometric series, q-beta integrals, biorthogonality of rational functions

AMS(MOS) subject classification. 33A65

1. Introduction.

Euler's beta integral

$$\int_{-1}^{1}(1-x)^{\alpha}(1+x)^{\beta}\,dx = 2^{\alpha+\beta+1}\frac{\Gamma(\alpha+1)\Gamma(\beta+1)}{\Gamma(\alpha+\beta+2)}, \tag{1.1}$$

$\mathrm{Re}(\alpha,\beta) > -1$, has been extended in many different ways (see [1]–[10], [17]), but the extension that has received particular attention in recent years is Askey and Wilson's [10] q-beta integral given by

$$\frac{1}{2\pi}\int_{-1}^{1} w(x;a,b,c,d)\,dx = \frac{(abcd;q)_\infty}{(q,ab,ac,ad,bc,bd,cd;q)_\infty}, \tag{1.2}$$

where

$$w(x;a,b,c,d) = \frac{h(x;1,-1,q^{1/2},-q^{1/2})}{h(x;a,b,c,d)}(1-x^2)^{-1/2}, \tag{1.3}$$

with

$$h(x;a_1,a_2,\cdots,a_k) = \prod_{j=1}^{k} h(x;a_j), \tag{1.4}$$

$$\begin{aligned} h(x;a) &= \prod_{n=0}^{\infty}(1-2axq^n+a^2q^{2n}) \\ &= (ae^{i\theta},ae^{-i\theta};q)_\infty \qquad \text{when } x=\cos\theta, \end{aligned} \tag{1.5}$$

and the q-shifted factorials are defined by

$$(a;q)_n = \begin{cases} 1 & \text{if } n=0, \\ (1-a)(1-aq)\cdots(1-aq^n) & \text{if } n=1,2,\cdots, \end{cases} \tag{1.6}$$

*Received by the editors September 8, 1989; accepted for publication September 10, 1990.

†Department of Mathematics and Statistics, Carleton University, Ottawa, Ontario, K1S 5B6, Canada. This research was supported by the Natural Sciences and Engineering Research Council of Canada under grant A6197.

$$(a,q)_\infty = \lim_{n\to\infty}(a;q)_n \quad \text{when } |q|<1, \tag{1.7}$$

$$(a_1,a_2,\cdots,a_k;q)_n = \prod_{j=1}^{k}(a_j;q)_n. \tag{1.8}$$

It will be assumed throughout the paper that $|q|<1$. Formula (1.2) is valid provided $\max(|a|,|b|,|c|,|d|)<1$. If one of the parameters, say a, is greater than 1 in modulus but is such that $|aq^{m+1}|<1<|aq^m|$ for some nonnegative integer m then, as Askey and Wilson [10] showed by a contour integration argument, and as Gasper and Rahman [13] proved by real integration, (1.2) must be modified by the formula

$$\frac{1}{2\pi}\int_{-1}^{1} w(x;a,b,c,d)\,dx + \sum_{k=0}^{m} w_k = \frac{(abcd;q)_\infty}{(q,ab,ac,ad,bc,cd;q)_\infty}, \tag{1.9}$$

where

(1.10)

$$w_k = \frac{(a^{-2};q)_\infty}{(q,ab,ac,ad,a/b,a/c,a/d;q)_\infty}\cdot\frac{(1-a^2q^{2k})(a^2,ab,ac,ad;q)_k}{(1-a^2)(q,aq/b,aq/c,aq/d;q)_k}\left(\frac{q}{abcd}\right)^k.$$

Nasrallah and Rahman [15] considered an extension of the integral in (1.2) by introducing a fifth parameter and in [16] Rahman gave the following extension:

$$\frac{1}{2\pi}\int_{-1}^{1} v(x;a,b,c,d,f)\,dx = \kappa(a,b,c,d,f), \tag{1.11}$$

where

$$v(x;a,b,c,d,f) = \frac{h(x;1,-1,q^{1/2},-q^{1/2},abcdf)}{h(x;a,b,c,d,f)}(1-x^2)^{-1/2}, \tag{1.12}$$

and

$$\kappa(a,b,c,d,f) = \frac{(abcd,abcf,abdf,acdf,bcdf;q)_\infty}{(q,ab,ac,ad,af,bc,bd,bf,cd,cf,df;q)_\infty}, \tag{1.13}$$

provided

$$\max(|a|,|b|,|c|,|d|,|f|)<1. \tag{1.14}$$

Askey [5] gave a direct proof of (1.11) by a functional equation method. Our first objective in this paper is to give an evaluation of the integral in (1.11) when the modulus of one of the parameters exceeds 1 while the moduli of the other four parameters remain less than 1. Suppose m is a nonnegative integer such that

$$|fq^{m+1}|<1<|fq^m|. \tag{1.15}$$

We will prove in §3 that

$$\begin{aligned}\frac{1}{2\pi}\int_{-1}^{1} v(x;a,b,c,d,f)\,dx + \sum_{k=0}^{m} v_k(a,b,c,d,f)\\ = \kappa(a,b,c,d,f),\end{aligned} \tag{1.16}$$

where

$$v_k(a,b,c,d,f) = \frac{(abcd, abcdf^2, f^{-2}; q)_\infty}{(q, af, bf, cf, df, a/f, b/f, c/f, d/f; q)_\infty} \cdot \frac{(1-f^2q^{2k})(f^2, af, bf, cf, df, q/abcd; q)_k}{(1-f^2)(q, fq/a, fq/b, fq/c, fq/d, abcdf^2; q)_k} q^k. \tag{1.17}$$

It is clear that (1.16) reduces to (1.9) when any one of the parameters a, b, c, d approaches zero.

The main objective of this paper, however, is to prove the following theorems.

THEOREM 1. *Let* $\max(|a|,|b|,|c|,|d|) < 1$, $|f| \le \min(|a|,|b|,|c|,|d|)$ *and let* N *be a nonnegative integer such that*

$$|fq^{-N}| < 1 < |fq^{-N-1}|. \tag{1.18}$$

Let

$$\begin{aligned} R_m(x) &= R_m(x; a, b, c, d, f) \\ &= \frac{(a^2bcdf, bcdf, de^{i\theta}, de^{-i\theta}; q)_m}{(ad, d/a, abcdfe^{i\theta}, abcdfe^{-i\theta}; q)_m} \\ &\quad \cdot M_m(x; a, b, c, d, f), \end{aligned} \tag{1.19}$$

$$\begin{aligned} S_n(x) &= S_n(x; a, b, c, d, f) \\ &= \frac{(aq/f, q/af, de^{i\theta}, de^{-i\theta}; q)_n}{(ad, d/a, qe^{i\theta}/f, qe^{-i\theta}/f; q)_n} \\ &\quad \cdot M_n(x; a, b, c, d, fq^{-1}), \end{aligned} \tag{1.20}$$

where $x = \cos\theta$, $0 \le \theta \le \pi$, *and*

$$\begin{aligned} &M_k(x; a, b, c, d, f) \\ &\quad = {}_{10}W_9(aq^{-k}/d; q^{1-k}/bd, q^{1-k}/cd, 1/df, abcf, ae^{i\theta}, ae^{-i\theta}, q^{-k}; q, q), \end{aligned} \tag{1.21}$$

where the symbol ${}_{10}W_9$ *represents a very well poised* ${}_{10}\phi_9$ *series defined in* §2. *Let*

$$L_{m,n} := \int_{-1}^{1} v(x; a, b, c, d, f) R_m(x) S_n(x)\, dx. \tag{1.22}$$

If $m = 0, 1, \cdots$, *and* $n = 0, 1, \cdots, N$, *then*

$$L_{m,n} = \kappa(a, b, c, d, f)\delta_{m,n}/h_n, \tag{1.23}$$

where

$$h_n = \frac{(1-abcdq^{2n-1})(abcdq^{-1}, ab, ac, ad, 1/af, bcdf/q; q)_n}{(1-abcdq^{-1})(q, cd, bd, bc, a^2bcdf, aq/f; q)_n} q^n. \tag{1.24}$$

THEOREM 2. *Let* a, b, c, d, f *satisfy the same conditions as in Theorem* 1. *If* $n \ge N+1$, *then*

$$\begin{aligned} &L_{m,n} + \sum_{k=0}^{n-N-1} v_k(a, b, c, dq^n, fq^{-n}) R_m(x_{n-k}; a, b, c, d, f) \\ &\quad \cdot M_n(x_{n-k}; a, b, c, d, fq^{-1}) \frac{(afq^{-n}, fq^{-n}/a; q)_n}{(ad, d/a; q)_n} \\ &\quad = \kappa(a, b, c, d, g)\delta_{m,n}/h_n, \end{aligned} \tag{1.25}$$

where

$$x_{n-k} = \tfrac{1}{2}(fq^{k-n} + f^{-1}f^{n-k}). \tag{1.26}$$

In §4 we will give the proofs of Theorems 1 and 2. In §2 we will give the definition and some properties of the very well poised basic hypergeometric series that will be needed to complete the proofs in §3 and §4.

In [16] Rahman found a biorthogonality relation for essentially the same rational functions, but with respect to a complex measure on the unit circle. This paper deals with the problems that arise when we try to convert that integral to a real one on the interval $[-1, 1]$.

2. Very well poised basic hypergeometric series. A basic hypergeometric series ${}_{r+1}\phi_r$ in base q and with $r+1$ numerator parameters and r denominator parameters is defined by

$${}_{r+1}\phi_r\left[\begin{matrix}a_1, a_2, \cdots, a_{r+1} \\ b_1, \cdots, b_r\end{matrix}; q, z\right] = \sum_{n=0}^{\infty} \frac{(a_1, a_2, \cdots, a_{r+1}; q)_n}{(q, b_1, \cdots, b_r; q)_n} z^n, \tag{2.1}$$

which terminates and hence becomes a polynomial of degree k in z when one of the numerator parameters is of the form $q^{-k}, k = 0, 1, \cdots$. If the series does not terminate, then we will naturally assume that the series converges, which is guaranteed by the inequality $|z| < 1$. Whether or not the series terminates it will always be assumed that the denominator parameters are such that no zero factors appear in any term of the series in (2.1). When $z = q$ and $qa_1a_2 \cdots a_{r+1} = b_1 \cdots b_r$, we call the series balanced. If $qa_1 = a_2b_1 = a_3b_2 = \cdots = a_{r+1}b_r$, the series is said to be well poised. If, in addition, $a_2 = qa_1^{1/2}$, $a_3 = -qa_1^{1/2}$, the series is said to be very well poised. Because of the frequent use of very well poised series in this paper we shall use the following abbreviated notation:

$$\begin{aligned} &{}_{r+1}W_r(a_1; a_4, a_5, \cdots, a_{r+1}; q, z) \\ &\quad := {}_{r+1}\phi_r\left[\begin{matrix}a_1, qa_1^{1/2}, -qa_1^{1/2}, a_4, \cdots, a_{r+1} \\ a_1^{1/2}, -a_1^{1/2}, a_1q/a_4, \cdots, a_1q/a_{r+1}\end{matrix}; q, z\right]. \end{aligned} \tag{2.2}$$

One of the most useful summation formulas in the theory of basic hypergeometric series is Jackson's [14] formula:

$${}_8W_7(a; b, c, d, e, q^{-n}; q, q) = \frac{(aq, aq/bc, aq/bd, aq/cd; q)_n}{(aq/b, aq/c, aq/d, aq/bcd, ; q)_n}, \tag{2.3}$$

where $n = 0, 1, \cdots$, and

$$a^2q^{n+1} = bcde, \tag{2.4}$$

which expresses that the terminating ${}_8W_7$ series in (2.3) is balanced. Almost as important as (2.3) is Bailey's [11] nonterminating extension of it:

$$\begin{aligned} &{}_8W_7(a; b, c, d, e, f; q, q) \\ &\quad + \frac{(aq, b/a, c, d, e, f, bq/c, bq/d, bq/e, bq/f; q)_\infty}{(qb^2/a, a/b, bc/a, bd/a, be/a, bf/a, aq/c, aq/e, aq/f; q)_\infty} \\ &\quad \cdot {}_8W_7(b^2/a; b, bc/a, bd/a, be/a, bf/a; q, q) \\ &\quad = \frac{(aq, b/a, aq/cd, aq/ce, aq/cf, aq/de, aq/ef; q)_\infty}{(aq/c, aq/d, aq/e, aq/f, bc/a, bd/a, be/a, bf/a; q)_\infty} \end{aligned} \tag{2.5}$$

where the balance condition (2.4) is replaced by

$$qa^2 = bcdef. \tag{2.6}$$

We shall also need Bailey's [12] ${}_{10}\phi_9$ transformation formula see [13, eqn. (2.12.9)], which can be written in a somewhat compact form as follows:

$$\begin{aligned} &V(a;b,c,d,e,f,g,h;q,q) \\ &\quad = \frac{(aq,b/a,\lambda q/f,\lambda q/g,\lambda q/h,bf/\lambda,bg/\lambda,bh/\lambda;q)_\infty}{(\lambda q,b/\lambda,aq/f,aq/g,aq/h,bf/a,bg/a,bh/a;q)_\infty} \\ &\qquad \cdot V(\lambda;b,\lambda c/a,\lambda d/a,\lambda e/a,fg,h;q,q), \end{aligned} \tag{2.7}$$

where

$$q^2a^3 = bcdefgh, \qquad \lambda = qa^2/cde, \tag{2.8}$$

and

(2.9)

$$\begin{aligned} &V(a;b,c,d,e,f,g,h;q,q) \\ &= {}_{10}W_9(a;b,c,d,e,f,g,h;q,q) \\ &\quad + \frac{(aq,b/a,c,d,e,f,g,h,bq/c,bq/d,bq/f,bq/g,bq/h;q)_\infty}{(qb^2/a,a/b,bc/a,bd/a,be/a,bf/a,bg/a,bh/a,aq/c,aq/d,aq/e,aq/f,aq/g,aq/h;q)_\infty} \\ &\quad \cdot {}_{10}W_9(b^2/a;b,bc/a,bd/a,be/a,bf/a,bg/a,bh/a;q,q). \end{aligned}$$

If $h = q^{-n}, n = 0, 1, \cdots$, then the coefficients of the second ${}_{10}W_9$ series in both V-functions in (2.7) vanish and we get the terminating form of (2.7), namely,

(2.10)

$$\begin{aligned} &{}_{10}W_9(a;b,c,d,e,f,g,q^{-n},q,q) \\ &\quad = \frac{(aq,aq/bf,aq/bg,aq/fg;q)_n}{(aq/b,aq/f,aq/b,aq/bfg;q)_n} {}_{10}W_9(\lambda;b,c\lambda/a,d\lambda/a,e\lambda/a,f,g,q^{-n};q,q). \end{aligned}$$

In [16] the author found a representation of a V-function in terms of an integral of the type (1.2) and (1.11). By an iteration of the transformation formula (2.7) that representation can be expressed in the following form:

$$\begin{aligned} &\frac{1}{2\pi}\int_{-1}^{1} \frac{h(x;1,-1.q^{1/2},-q^{1/2},c,d)(1-x^2)^{-1/2}}{h(x;a_1,a_2,a_3,a_4,a_5,a_6)}\,dx \\ &\quad = \frac{\prod_{j=1}^{6}(ca_j,d/a_j;q)_\infty}{(q,c^2,d/c;q)_\infty \prod_{1\le j<k\le 6}(a_ja_k;q)_\infty} \\ &\qquad \cdot V(c^2/q;cd/q,c/a_1,c/a_2,c/a_3,c/a_4,c/a_5,c/a_6;q,q), \end{aligned} \tag{2.11}$$

where the balance condition of the V-function as well as the integrand in (2.11) is expressed by the relation

$$cd = a_1a_2a_3a_4a_5a_6. \tag{2.12}$$

The modulus of each of the denominator parameters $a_j, j = 1, \cdots, 6$, is, of course, less than 1. Situations where this restriction may not hold are no interest to us in this paper. The form of the expression on the right side of (2.11) may not be the most useful one but it is the easiest one to remember because of its symmetry.

3. Proof of (1.16). If $f = \pm 1$ in (1.12) then the functions $h(x; \pm 1)$ and $h(x; f)$ cancel, and hence it follows by continuity that

$$\frac{1}{2\pi}\int_{-1}^{1} v(x; a, b, c, d, \pm 1)\, dx = \kappa(a, b, c, d, \pm 1), \tag{3.1}$$

provided, of course, that

$$\max(|a|, |b|, |c|, |d|) < 1. \tag{3.2}$$

If $f \neq \pm 1$ but $|f| = 1$, then $h(x; f) = 0$ for some x in the interval $(-1, 1)$, and so the integral in (1.11) does not converge. Similary, this integral does not converge if $|fq^n| = 1$ and $fq^n \neq \pm 1$, for some positive integer n. If there is a nonnegative integer m such that

$$|fq^{m+1}| < 1 < |fq^m| \tag{3.3}$$

and if $fa^{\pm 1}, fb^{\pm 1}, fc^{\pm 1}, fd^{\pm 1}$ are not of the form q^{-n} for any nonnegative integer n, then the integral in (1.11) converges and it can be evaluated in the following way. Since

$$\begin{aligned} h(x; f) &= (fe^{i\theta}, fe^{-i\theta}; q)_{m+1} h(x; fq^{m+1}) \\ &= f^{2m+2} q^{m+m^2} \frac{h(x; fq^{m+1}, f^{-m}/f)}{h(x; q/f)}, \end{aligned} \tag{3.4}$$

we get by denoting the integral on the left side of (1.11) by $J(a, b, c, d, f)$,

$$\begin{aligned} &J(a, b, c, d, f) \\ &\quad = f^{-2m-2} q^{-m-m^2} \int_{-1}^{1} \frac{h(x; 1, -1, q^{1/2}, -q^{1/2}, abcdf, q/f)(1 - x^2)^{-1/2}}{h(x; a, b, c, d, fq^{m+1}, q^{-m}/f)}\, dx, \end{aligned} \tag{3.5}$$

where it is assumed that the inequality (3.2) is also satisfied. Since the parameters in the integrand of (3.5) satisfy (2.12), we may apply (2.11) to obtain the following relation:

$$\begin{aligned} J(a, b, c, d, f) =& K_m(a, b, c, d, f) \\ &\cdot V((abcdf)^2/q; abcd, abcf, abdf, acdf, bcdf, abcdq^{-m-1}, abcdf^2 q^m; q, q), \end{aligned} \tag{3.6}$$

where

$$\begin{aligned} K_m(a, b, c, d, f) = &- \frac{(a^2bcdf, ab^2cdf, abc^2df, abcd^2f, abcdf^2; q)_\infty}{(q, ab, ac, ad, bc, bd, cd, af, bf, cf, df; q)_\infty} \\ &\cdot \frac{(abcd, f^{-2}; q)_\infty}{(a/f, b/f, c/f, d/f, (abcdf)^2, 1/abcdf^2; q)_\infty} \\ &\cdot \frac{(qf^2, q/abcd, afq, bfq, cfq, dfq; q)_m}{(q, qabcdf^2, fq/a, fq/b, fq/c, fq/d; q)_m}. \end{aligned} \tag{3.7}$$

We now apply (2.7) on the V-function on the right side of (3.6) to get

$$
\begin{aligned}
&V((abcdf)^2/q; abcd, abcf, abdf, acdf, bcdf, abcdq^{-m-1}, abcdf^2q^m; q, q)\\
&\quad = \frac{((abcdf)^2, q/abcdf^2, abcfq, abc/f, dfq, d/f; q)_\infty}{(a^2b^2c^2df, q/abcf, abcd^2f, q/df, qabcdf^2, f^{-2}; q)_\infty}\\
&\qquad \cdot (qabcdf^2, q, fq/d, fq/abc; q)_m/(abcfq, dfq, qf^2, q/abcd; q)_m\\
&\qquad \cdot V(a^2b^2c^2df/q; abcd, ab, ac, bc, abcf, abcdq^{-m-1}, abcdf^2q^m; q, q).
\end{aligned}
\tag{3.8}
$$

Using the definition (2.9) of the V-functions, we have

$$
\begin{aligned}
&V(a^2b^2c^2df/q; qbcd, 2b, 2c, bc, abcf, abcdq^{-m-1}, abcdf^2q^m; q, q)\\
&\quad = {}_{10}W_9(a^2b^2c^2df/q; abcd, ab, ac, bc, abcf, abcdq^{-m-1}, abcdf^2q^m; q, q)\\
&\qquad + \frac{(a^2b^2c^2df, q/abcf, ab, ac, bc, abcf, abcdq^{-m-1}, abcdf^2q^m; q)_\infty}{(dq^2/f, abcf/q, q/cf, q/bf, q/af, q, dq^{-m}/fdfq^{m+1}; q)_\infty}\\
&\qquad \cdot \frac{(q/cd, q/bd, q/ad, dq/f, q^{m+2}, q^{1-m}/f^2; q)_\infty}{(abc^2df, ab^2cdf, a^2bcdf, abcd, abcfq^{m+1}, abcq^{-m}/f; q)_\infty}\\
&\qquad \cdot {}_{10}W_9(dq/f; abcd, q/af, q/bf, q/cf, q, dq^{-m}/f, dfq^{m+1}; q, q).
\end{aligned}
\tag{3.9}
$$

Because of the cancellation of a numerator and a denominator parameter in the first ${}_{10}W_9$ series on the right side of (3.9), it reduces to

$$
{}_8W_7(a^2b^2c^2df/q; ab, ac, bc, abcdq^{-m-1}, abcdf^2q^m; q, q),
$$

which is very well poised and balanced and so Bailey's summation formula (2.5) is applicable. Thus

$$
\begin{aligned}
&{}_{10}W_9(a^2b^2c^2df/q; abcd, ab, ac, bc, abcf, abcdq^{-m-1}, abcdf^2q^m; q, q)\\
&\quad = \frac{(a^2b^2c^2df, abdf, acdf, bcdf, aq^{-m}/f, bq^{-m}/f, cq^{-m}/f, q^{-m}/abcf; q)_\infty}{(a^2bcdf, ab^2cdf, abc^2df, df, q^{-m}/af, q^{-m}/bf, q^{-m}/cf, abcq^{-m}/f; q)_\infty}\\
&\qquad - \frac{(a^2b^2c^2df, ab, ac, bc, abcdf^2q^m, adq^{-m}, bdq^{-m}, cdq^{-m}; q)_\infty}{(a^2bcdf, ab^2cdf, abc^2df, df, abcfq^m, q^{-m}/af, q^{-m}/bf, q^{-m}/cf; q)_\infty}\\
&\qquad \cdot \frac{(q^{-m}/abcf, q^{-2m}/f^2; q)_\infty}{(abcq^{-m}/f, dq^{-2m}/f; q)_\infty}\\
&\qquad \cdot {}_8W_7(dq^{-2m-1}/f; abcdq^{-m-1}, q^{-m}/af, q^{-m}/bf, q^{-m}/cf, df; q, q).
\end{aligned}
\tag{3.10}
$$

By using cancellation this last ${}_8W_7$ series can be written as a very well poised nonterminating balanced ${}_{10}W_9$ series in many ways, but the one of particular interest to us is the following form:

$$
\begin{aligned}
&{}_8W_7(dq^{-2m-1}/f; abcdq^{-m-1}, q^{-m}/af, q^{-m}/bf, q^{-m}/cf, df; q, q)\\
&\quad = {}_{10}W_9(dq^{-2m-1}/f; dq^{-m}/f, q^{-m}/af, q^{-m}/bf,\\
&\qquad q^{-m}/cf, abcdq^{-m-1}, df, q^{-m}; q, q).
\end{aligned}
\tag{3.11}
$$

The appearance of q^{-m} in the numerator may indicate that it is a terminating series, but in fact it is not because of the cancellation with the q^{-m} term that occurs in the

denominator below dq^{-m}/f when we write out the ${}_{10}W_9$ series in (3.11) as a very well poised ${}_{10}W_9$ series. The whole purpose of this particular choice is that the ${}_{10}W_9$ in (3.11) can now be matched with the second ${}_{10}W_9$ series on the right side of (3.9) and their coefficients are such that they combine into a single V-function.

Using (3.7)–(3.10) in (3.6) and simplifying the coefficients we obtain

(3.12)
$$\begin{aligned} &J(a,b,c,d,f)\\ &\quad=\kappa(a,b,c,d,f)-\frac{(abcd,abcfq^{m+1},abcdf^2q^m,f^{-2};q)_\infty(1-abcf)}{(q,df,abcfq^m,afq,bfq,cfq,a/f,b/f,c/f,d/f;q)_\infty}\\ &\qquad\cdot\frac{(q/ad,q/bd,q/cd,abcfq;q)_m(qf^2;q)_{2m}(df)^m}{(fq/a,fq/b,fq/c;q)_m(fq/d;q)_{2m}}\\ &\qquad\cdot V(dq^{-2m-1}/f;dq^{-m}/f,q^{-m}/af,q^{-m}/bf,q^{-m}/cf,df,abcdq^{-m-1},q^{-m};q,q). \end{aligned}$$

We now apply (2.7) on the V-function on the right side of (3.12) and find that because $(q^{-m};q)_\infty=0$ for $m=0,1,\cdots$, it transforms to a multiple of a single terminating balanced ${}_{10}W_9$ series. Thus we find that

(3.13)
$$\begin{aligned} &J(a,b,c,d,f)\\ &\quad=\kappa(a,b,c,d,f)-\frac{(abcd,abcdf^2,f^{-2};q)_\infty}{(q,af,bf,cf,df,a/f,b/f,c/f,d/f;q)_\infty}\\ &\qquad\cdot\frac{(q/ad,q/bd,q/cd,q/abcd,qf^2,dfq;q)_m}{(q,fq/a,fq/b,fq/c,fq/d,q/abcd^2f;q)_m}\\ &\qquad\cdot{}_{10}W_9(abcd^2fq^{-m-1};dq^{-m}/f,abdf,acdf,bcdf,df,abcdq^{-m-1},q^{-m};q,q). \end{aligned}$$

Using an iteration of (2.10) (see also [13, Ex. (2.19)]), we may now transform this ${}_{10}W_9$ series as follows:

(3.14)
$$\begin{aligned} &{}_{10}W_9(abcd^2fq^{-m-1};dq^{-m}/f,abdf,acdf,bcdf,df,abcdq^{-m-1},q^{-m};q,q)\\ &\quad=\frac{(q/abcd^2f,fq/a,fq/b,fq/c,fq/d,q;q)_m}{(q/ad,q/bd,q/cd,q/abcd,qf^2,dfq;q)_m}\\ &\qquad\cdot{}_{10}W_9(f^2;af,bf,cf,df,q/abcd,f^2q^{m+1},q^{-m};q,q)\\ &\quad=\frac{(q/abcd^2f,fq/a,fq/b,fq/c,fq/d,q;q)_m}{(q/ad,q/bd,q/cd,q/abcd,qf^2,dfq;q)_m}\\ &\qquad\cdot\sum_{k=0}^{m}\frac{(1-f^2q^{2k})(f^2,af,bf,cf,df,q/abcd;q)_k}{(1-f^2)(q,fq/a,fq/b,fq/c,fq/d,abcdf^2;q)_k}q^k. \end{aligned}$$

Substitution of (3.14) into (3.13) then yields (1.16).

It may be remarked that the same method can be applied to evaluate the integral in (1.11) when two or more parameters satisfy inequalities of the form (1.15) and other restrictions so that no zero factors appear in the denominators.

4. Proofs of Theorems 1 and 2. By successive application of (2.10) it can be shown that

$$
\begin{aligned}
R_m(x) &= {}_{10}W_9(a^2bcdfq^{-1}; ae^{i\theta}, ae^{-i\theta}, abcf, abdf, acdf, abcdq^{m-1}, q^{-m}; q, q) \\
&= \frac{(bc, bd, 1/bf, a^2bcdf; q)_m}{(ac, ad, 1/af, ab^2cdf; q)_m} \\
&\quad \cdot {}_{10}W_9(ab^2cdfq^{-1}; be^{i\theta}, be^{-i\theta}, bcdf, bdaf, bcaf, abcdq^{-m-1}, q^{-m}; q, q) \\
&= \frac{(bc, bd, 1/bf, a^2bcdf; q)_m}{(ac, ad, 1/af, ab^2cdf; q)_m} \sum_{j=0}^{m} \frac{(1 - ab^2cdfq^{2j-1})(ab^2cdfq^{-1}, abcf; q)_j}{(1 - ab^2cdfq^{-1})(q, bd; q)_j} \\
&\quad \cdot \frac{(abdf, bcdf, abcdq^{m-1}, q^{-m}; q)_j}{(bc, ab, bfq^{1-m}, ab^2cdfq^m; q)_j} q^j \frac{h(x; b, abcdfq^j)}{h(x; bq^j, abcdf)}.
\end{aligned} \tag{4.1}
$$

Also, (1.20) can be written in the form

$$
\begin{aligned}
&S_n(x) \\
&= \frac{(fq^{-n}/a, afq^{-n}; q)_n}{(ad, d/a; q)_n} \sum_{k=0}^{n} \frac{(1 - aq^{2k-n}/d)(aq^{-n}/d, q^{1-n}/bd, q^{1-n}/cd; q)_k}{(1 - aq^{-n}/d)(q, ab, ac; q)_k} \\
&\quad \cdot \frac{(q/df, abcf/q, q^{-n}; q)_k}{(afq^{-n}, q^{2-n}/bcdf, aq/d; q)_k} d^{2k} q^{2nk-k^2} \frac{h(x; a, d, f)}{h(x; aq^k, dq^{n-k}, fq^{-n})}.
\end{aligned} \tag{4.2}
$$

In (4.1) and (4.2) $x = \cos\theta$, and the h functions are as defined in (1.4) and (1.5). Substituting (4.1) and (4.2) into (1.22) we find that

$$
\begin{aligned}
L_{m,n} &= \frac{(bc, bd, 1/bf, a^2bcdf; q)_m (fq^{-n}/a, afq^{-n}; q)_n}{(ac, ad, 1/af, ab^2cdf; q)_m (ad, d/a; q)_n} \\
&\quad \cdot \sum_{j=0}^{m} \frac{(1 - ab^2cdfq^{2j-1})(ab^2cdfq^{-1}, abcf, abdf, bcdf; q)_j}{(1 - ab^2cdfq^{-1})(q, bd, bc, ab; q)_j} \\
&\quad \cdot \frac{(abcdq^{m-1}, q^{-m}; q)_j}{(bfq^{1-m}, ab^2cdfq^m; q)_j} q^j \sum_{k=0}^{n} \frac{(1 - aq^{2k-n}/d)(aq^{-n}/d, q^{1-n}/bd; q)_k}{(1 - aq^{-n}/d)(q, ab; q)_k} \\
&\quad \cdot \frac{(q^{1-n}/cd, q/df, abcf/q, q^{-n}; q)_k}{(ac, afq^{-n}, q^{2-n}/bcdf, aq/d; q)_k} d^{2k} q^{2nk-k^2} I_{m,n,j,k},
\end{aligned} \tag{4.3}
$$

where

$$
I_{m,n,j,k} = \frac{1}{2\pi} \int_{-1}^{1} v(x; aq^k, bq^j, c, dq^{n-k}, fq^{-n}) dx. \tag{4.4}
$$

For $j \geq 0$, $n \geq k \geq 0$, where $n = 0, 1, \cdots, N$ with $|fq^{-N}| < 1$, the parameters in the integrand of (4.4) are all less than 1 in the modulus and so, by (1.11),

$$
\begin{aligned}
I_{m,n,j,k} &= \kappa(aq^k, bq^j, c, dq^{n-k}, fq^{-n}) \\
&= \kappa(a, b, c, d, f) \frac{(ad, bd, cd, abcfq^{-n}; q)_n}{(afq^{-n}, bfq^{-n}, cfq^{-n}, abcd; q)_n} \\
&\quad \cdot \frac{(ab, bc, bfq^{-n}, bdq^n; q)_j}{(abcdq^n, abcfq^{-n}, abdf, bcdf; q)_j} \\
&\quad \cdot \frac{(afq^{-n}, abq^j, ac, q^{1-j}/bcdf; q)_k}{(q/df, q^{1-n-j}/bd, q^{1-n}/cd, abcfq^{j-n}; q)_k} d^{-2k} q^{k+k^2-2nk}.
\end{aligned} \tag{4.5}
$$

When we substitute this into (4.3) the series over k reduces to

$$ {}_8W_7(aq^{-n}/d; q^{1-n}/bd, abq^j, q^{1-j}/bcdf, abcf/q, q^{-n}; q, q), $$

which is balanced and terminating and hence can be summed by (2.3). The sum is

$$ \frac{(aq^{1-n}/d, cfq^{-n}, ab^2cdfq^{j-1}, q^{-j}; q)_n}{(ab, q^{1-j-n}/bd, abcfq^{j-n}, bcdf/q; q)_n}, $$

which vanishes unless $j \geq n$. Thus, $L_{m,n} = 0$ if $m < n$. Hence, for $m \geq n$ we find after some simplifications that

(4.6)

$$ \begin{aligned} L_{m,n} &= \kappa(a, b, c, d, f) \\ &\quad \cdot \frac{(bc, bd, 1/bf, a^2bcdf; q)_m (aq/f, cd; q)_n (ab^2cdf; q)_{2n}}{(ac, ad, 1/af, ab^2cdf; q)_m (ab, bcdf/q; q)_n (abcd; q)_{2n}} (bf)^n \\ &\quad \cdot \frac{(abcdq^{m-1}, q^{-m}; q)_n}{(bfq^{1-m}, ab^2cdfq^m; q)_n} {}_6W_5(ab^2cdfq^{2n-1}; bf, abcdq^{m+n-1}, q^{n-m}; q, q). \end{aligned} $$

The ${}_6W_5$ series in (4.6) is a special case of the ${}_8W_7$ series in (2.3) and it has the sum

$$ \frac{(ab^2cdfq^{2n}, q^{1+n-m}; q)_{m-n}}{(abcdq^{2n}, bfq^{1-m+n}; q)_{m-n}}, $$

which vanishes unless $m = n$. Hence

$$ \begin{aligned} L_{m,n} &= \kappa(a, b, c, d, f) \\ &\quad \cdot \frac{(bc, bd, cd, 1/bf, aq/f, a^2bcdf; q)_n (abcdq^{n-1}, q^{-n}; q)_n}{(ad, ac, ab, bcdf/q, 1/af; q)_n (bfq^{1-n}; q)_n (abcd; q)_{2n}} \\ &\quad \cdot (bf)^n \delta_{m,n} \qquad (4.7) \\ &= \kappa(a, b, c, d, f) \\ &\quad \cdot \frac{(1 - abcdq^{-1})(q, bc, bd, cd, aq/f, a^2bcdf; q)_n}{(1 - abcdq^{2n-1})(abcdq^{-1}, ad, ac, ab, bcdf/q, 1/af; q)_n} q^{-n} \delta_{m,n}. \end{aligned} $$

This completes the proof of Theorem 1.

Thus, the system of rational functions $S_n(x)$, $n = 0, 1, \cdots, N$, is biorthogonal to $R_m(x)$, $m = 0, 1, \cdots$, when $|fq^{-N}| < 1 < |fq^{-N-1}|$ with respect to the positive measure $v(x; a, b, c, d, f)dx$ on $(-1, 1)$. Orthogonality of finitely many polynomials with respect to positive measures has been a topic of current interest; see Askey [7], [8].

To prove Theorem 2 we observe that when $n = N + 1, N + 2, \cdots, L_{m,n}$ is again given by (4.3) and (4.4), but because of the fact that $|fq^{-n}| > 1$ with $|fq^{-N}| < 1 < |fq^{-N-1}|$, $I_{m,n,j,k}$ has an additional contribution which, via (1.16), is

$$ \begin{aligned} &- \frac{(abcdq^{n+j}, abcdf^2q^{j-n}, f^{-2}q^{2n}; q)_\infty}{(q, afq^{k-n}, bfq^{j-n}, cfq^{-n}, dfq^{-k}, aq^{k+n}/f, bq^n/f, cq^n/f, dq^{2n-k}/f; q)_\infty} \\ &\quad \cdot \sum_{l=0}^{n-N-1} \frac{(1 - f^2q^{2l-2n})(f^2q^{-2n}, afq^{k-n}, bfq^{j-n}, cfq^{-n}; q)_l}{(1 - f^2q^{-2n})(q, fq^{1-k-n}/a, fq^{1-j-n}/b, fq^{1-n}/c; q)_l} \qquad (4.8) \\ &\quad \cdot \frac{(dfq^{-k}, q^{1-n-j}/abcd; q)_l q^l}{(fq^{1-2n+k}/d, abcdf^2q^{j-n}; q)_l}. \end{aligned} $$

As a consequence $L_{m,n}$ has an additional term given by

(4.9)
$$
\begin{aligned}
&- \sum_{l=0}^{n-N-1} v_l(a,b,c,dq^n,fq^{-n}) \\
&\quad \cdot \frac{(bc,bd,1/bf,a^2bcdf;q)_m (fq^{-n}/a,afq^{-n};q)_n}{(ac,ad,1/af,ab^2cdf;q)_m (ad,d/a;q)_n} \\
&\quad \cdot {}_{10}W_9(ab^2cdfq^{-1};abcf,abdf,bcdf,bfq^{l-n},bq^{n-l}/f,abcdq^{m-1},q^{-m};q,q) \\
&\quad \cdot {}_{10}W_9(aq^{-n}/d;q^{1-n}/bd,q^{1-n}/cd,q/df,abcf/q,afq^{l-n},aq^{n-l}/f,q^{-n};q,q).
\end{aligned}
$$

By (1.21),

$$
\begin{aligned}
&{}_{10}W_9(aq^{-n}/d;q^{1-n}/bd,q^{1-n}/cd,q/df,abcf/q,afq^{l-n},aq^{n-l}/f,q^{-n};q,q) \\
&\qquad = M_n(x_{n-l};a,b,c,d,fq^{-1}),
\end{aligned} \tag{4.10}
$$

where x_{n-l} is defined in (1.26).

Also, by (4.1),

$$
\begin{aligned}
&{}_{10}W_9(ab^2cdfq^{-1};abcf,abdf,bcdf,bfq^{l-n},bq^{n-l}/f,abcdq^{m-1},q^{-m};q,q) \\
&\qquad = \frac{(ac,ad,1/af,ab^2cdf;q)_m}{(bc,bd,1/bf,a^2bcdf;q)_m} R_m(x_{n-l};a,b,c,d,f).
\end{aligned} \tag{4.11}
$$

Substitution of (4.10) and (4.11) in (4.9) completes the proof of Theorem 2.

ON ASYMPTOTICS OF JACOBI POLYNOMIALS*

LI-CHEN CHEN†‡ AND MOURAD E. H. ISMAIL†

This paper is dedicated to Frank Olver on the occasion of his 65th birthday.

Abstract. The asymptotic behavior of Jacobi polynomials $P_n^{\alpha+an,\beta+bn}(x)$ and Laguerre polynomials $L_n^{\alpha+an}(b+nx)$ is found when $n\to\infty$ and a, b, α, β are real constants, $a>-1$, $b>-1$, and x is a real variable.

Key words. Jacobi polynomials, Darboux's method, strong asymptotics

AMS(MOS) subject classifications. 33A65, 30E15

1. Introduction. The Jacobi polynomials $\{P_n^{\alpha,\beta}(x)\}$ are orthogonal on $[-1, 1]$ with respect to $(1-x)^\alpha(1+x)^\beta$ when $\alpha>-1$, $\beta>-1$. We shall refer to α and β as the parameters of the Jacobi polynomial. The asymptotics of the Jacobi polynomials, as $n\to\infty$ for fixed x, α, β follow from Darboux's asymptotic method and generating functions (Fields [7], Olver [12], Rainville [14], Szegö [17]). The polynomials oscillate when $x\in(-1, 1)$ and grow exponentially in the complex plane cut along $[-1, 1]$.

In this work we study the asymptotics of $P_n^{\alpha+an,\beta+bn}(x)$ and $L_n^{\alpha+an}(b+nx)$ as $n\to\infty$, and a, b, α, β, x remain fixed. The asymptotics of Jacobi polynomials lay the groundwork for a proposed study of the asymptotics of the Racah coefficients [1], [2], [4], [5], [13]. The connection between the two problems is that the Racah coefficients are integrals of products of Jacobi polynomials.

Askey and Wilson [3] introduced a q-analogue of the 6-j symbols and the Racah coefficients. Ismail and Wilson [9] derived the main term in the asymptotic expansion of these q analogues. Later Ismail [8] derived the complete asymptotic expansions of the q analogue of the 6-j symbols and the Racah coefficients.

The approach we used in this work is to apply the method of Darboux to the generating function

$$\sum_{n=0}^{\infty} P_n^{\alpha+an,\beta+bn}(x)t^n=(1+\xi)^{\alpha+1}(1+\eta)^{\beta+1}[1-a\xi-b\eta-(1+a+b)\xi\eta]^{-1}, \tag{1.1}$$

where ξ and η depend on x and t in the following fashion:

$$\xi=\tfrac{1}{2}(x+1)t(1+\xi)^{1+a}(1+\eta)^{1+b} \quad\text{and}\quad \eta=\tfrac{1}{2}(x-1)t(1+\xi)^{1+a}(1+\eta)^{1+b}. \tag{1.2}$$

The generating function (1.1)-(1.2) is due to Srivastava and Singhal [16].

The singularities of the right-hand side of (1.1) are at $\xi=-1$, $\eta=-1$, or when

$$1-a\xi-b\eta-(1+a+b)\xi\eta=0.$$

It is easy to see that, if $a>-1$ and $b>-1$, then the t-singularities of smallest absolute value make

$$1-a\xi-b\eta-(1+a+b)\xi\eta=0.$$

This occurs if and only if

$$(x+1)-[a(x+1)+b(x-1)]\xi+(1+a+b)(1-x)\xi^2=0, \tag{1.3}$$

since

$$\eta = (x-1)\xi/(x+1). \tag{1.4}$$

The roots of (1.3) are

$$\xi_{\pm} = \frac{b(x-1)+a(1+x)\pm\sqrt{\Delta}}{-2(1+a+b)(x-1)}, \tag{1.5}$$

where

$$\Delta = [a(x+1)+b(x-1)]^2 - 4(1+a+b)(1-x^2). \tag{1.6}$$

The corresponding η's will be denoted by $\eta_{\pm}$.

Section 2 contains some preliminary calculations that will be used to determine the strong asymptotics of the Jacobi polynomials under consideration. Our main results on the strong asymptotics of Jacobi polynomials are stated and proved in § 3. In § 4 we derive the corresponding asymptotic results involving Laguerre polynomials. This work concludes with § 5 where we describe the connection between our results and the results of Mhaskar and Saff [10], Moak, Saff, and Varga [11], and Saff and Varga [15] on nth root asymptotics of Jacobi and Laguerre polynomials. The work on nth root asymptotics was motivated by a theorem of Lorentz on approximation by incomplete polynomials.

2. Preliminaries. Throughout this section we will assume that a, b, and x are real. It follows from (1.2) and (1.5) that the t-roots of (1.3) are

$$t_{\pm} = \frac{b(x-1)+a(1+x)\pm\sqrt{\Delta}}{(a+b+1)(1-x^2)}[1+\xi_{\pm}]^{-a-1}[1+\eta_{\pm}]^{-b-1}. \tag{2.1}$$

We need to know how to expand ξ as a function of t near the singularities $t_{\pm}$. Differentiating the first relation in (1.2) and using (1.4), we find

$$\xi(1+\xi)(1+\eta)\frac{dt}{d\xi} = t[1-a\xi-b\eta-(a+b+1)\xi\eta], \tag{2.2}$$

which shows that $dt/d\xi$ vanishes at $\xi=\xi_{\pm}$. We then proceed to compute $d^2t/d\xi^2$. A calculation gives

$$\left.\frac{d^2t}{d\xi^2}\right|_{\xi_{\pm}} = \pm t_{\pm}\sqrt{\Delta}\,\{\xi_{\pm}(1+x)(1+\xi_{\pm})(1+\eta_{\pm})\}^{-1}.$$

We set

$$A_{\pm} = \pm\tfrac{1}{2}t_{\pm}\sqrt{\Delta}\,\{\xi_{\pm}(1+x)(1+\xi_{\pm})(1+\eta_{\pm})\}^{-1}. \tag{2.3}$$

Therefore as $t\to t_{\pm}$ and $\xi\to\xi_{\pm}$ we must have

$$t_{\pm}-t \approx -A_{\pm}(\xi_{\pm}-\xi)^2. \tag{2.4}$$

This shows that $\xi_{\pm}-\xi \approx \{(t_{\pm}-t)/(-A_{\pm})\}^{1/2}$ as $t\to t_{\pm}$, respectively. We then choose the comparison function

$$g(t) = B_+(t_+-t)^{-1/2} + B_-(t_--t)^{-1/2} \tag{2.5}$$

with constants B_+ and B_- to be determined later. Here $(t_+-t)^{1/2}$ is the branch of the square root which is continuous in the t plane cut along the outward ray through $t_+ = |t_+|\exp(i\tau_+)$ and which satisfies $(t_+-t)^{-1/2}\to|t_+|^{-1/2}\exp(-i\tau_+/2)$ as $t\to 0$. The branch of $(t_--t)^{-1/2}$ is similarly defined.

At this stage we have to consider three separate cases:

$$\text{Case 1: } \Delta<0, \quad \text{Case 2: } \Delta>0, \quad \text{Case 3: } \Delta=0. \tag{2.6}$$

Case 1 is the oscillatory case, while in Cases 2 and 3 the polynomials under consideration grow exponentially.

We first treat Case 1. It follows from (1.6) and $\Delta<0$ that

$$(1+a+b)(1-x^2)>0. \tag{2.7}$$

In this case both t_+ and t_- have the same absolute value. If $f(t)$ denotes the right-hand side of (1.1) then the limit of $(t_\pm - t)^{1/2} f(t)$ as $t \to t_\pm$ from the left is $B_\pm$. In order to compute the comparison function in (2.5) explicitly and derive the desired asymptotic formula we will need the following identities. In this case simple calculations give

$$|3a+b+2-(a+b+2)x \pm \sqrt{\Delta}|^2 = 8(1-x)(a+1)(a+b+1), \tag{2.8}$$

and

$$|-(a+b+2)x-(a+3b+2) \pm \sqrt{\Delta}|^2 = 8(1+x)(b+1)(a+b+1). \tag{2.9}$$

Therefore in Case 1

$$(1-x)(a+1)(a+b+1)>0 \quad \text{and} \quad (1+x)(b+1)(a+b+1)>0 \tag{2.10}$$

hold. We set

$$\frac{a(x+1)+b(x-1)+\sqrt{\Delta}}{(1+a+b)(1-x^2)} = 2\{(1+a+b)(1-x^2)\}^{-1/2} e^{i\rho}, \qquad -\pi<\rho\leqq\pi, \tag{2.11}$$

$$\frac{(a+b+2)x-(3a+b+2)-\sqrt{\Delta}}{2(x-1)(a+b+1)} = \left[\frac{2(a+1)}{(1-x)(a+b+1)}\right]^{1/2} e^{i\theta}, \qquad -\pi<\theta\leqq\pi, \tag{2.12}$$

$$\frac{(a+b+2)x+a+3b+2-\sqrt{\Delta}}{2(x+1)(a+b+1)} = \left[\frac{2(b+1)}{(x+1)(a+b+1)}\right]^{1/2} e^{i\gamma}, \qquad -\pi<\gamma\leqq\pi. \tag{2.13}$$

We then use (1.1), (1.2), (2.1), and (2.3)-(2.5) to establish

$$\begin{aligned} B_+ &= \lim_{t\to t_+} (1+\xi)^{\alpha+1}(1+\eta)^{\beta+1}[1-a\xi-b\eta-(a+b+1)\xi\eta]^{-1}(t_+-t)^{1/2} \\ &= -i(\Delta)^{-1/4}\left[\frac{(a+b+2)x-(3a+b+2)-\sqrt{\Delta}}{2(a+b+1)(x-1)}\right]^{\alpha-a/2} \\ &\quad \cdot\left[\frac{(a+b+2)x+a+3b+2-\sqrt{\Delta}}{2(a+b+1)(x+1)}\right]^{\beta-b/2}. \end{aligned} \tag{2.14}$$

Similarly,

$$\begin{aligned} B_- &= i(-\sqrt{\Delta})^{-1/2}\left[\frac{(a+b+2)x-(3a+b+2)+\sqrt{\Delta}}{2(a+b+1)(x-1)}\right]^{\alpha-a/2} \\ &\quad \cdot\left[\frac{(a+b+2)x+a+3b+2+\sqrt{\Delta}}{2(a+b+1)(x+1)}\right]^{\beta-b/2}. \end{aligned} \tag{2.15}$$

The coefficient of t^n in the comparison function $g(t)$ of (2.5) is

$$(-1)^n \binom{-1/2}{n} [B_+(t_+)^{-n-1/2} + B_-(t_-)^{-n-1/2}],$$

which can be simplified using (2.11)-(2.13), and

$$(-1)^n\binom{-1/2}{n}=\frac{\Gamma(n+\frac{1}{2})}{\Gamma(\frac{1}{2})\Gamma(n+1)}\approx\frac{n^{-1/2}}{\sqrt{\pi}},$$

to establish

$$\begin{aligned}P_n^{\alpha+an,\beta+bn}(x)\approx&\left(\frac{4\sqrt{(-\Delta)}}{\pi n}\right)^{1/2}\left[\frac{(1-x)(a+b+1)}{2(a+1)}\right]^{n(-a-1)/2-\alpha/2-1/4}\\&\cdot\left[\frac{(1+x)(a+b+1)}{2(b+1)}\right]^{n(-b-1)/2-\beta/2-1/4}\left[\frac{(1-x^2)(a+b+1)}{4}\right]^{n/2+1/4}\\&\cdot\cos\left[\left\{(1+a)n+\alpha+\frac{1}{2}\right\}\frac{\theta}{2}+\left\{-(b+1)n+\beta+\frac{1}{2}\right\}\frac{\gamma}{2}-(2n+1)\frac{\rho}{4}-\frac{\pi}{4}\right].\end{aligned}\tag{2.16}$$

We now treat Case 2. It is obvious that $\xi_+\neq\xi_-$ when $\Delta>0$. From (2.2) we see that $dt/d\xi$ does not vanish between ξ_+ and ξ_-, hence t takes different values at ξ_+, ξ_-. Set

$$\begin{aligned}&t_0=t_+\quad\text{if } |t_-|>|t_+|,\quad t_0=t_-\quad\text{if } |t_+|>|t_-|,\\&t_1=t_+\quad\text{if } |t_-|<|t_+|,\quad t_0=t_-\quad\text{if } |t_+|<|t_-|.\end{aligned}\tag{2.17}$$

We also denote the B's that correspond to t_0 and t_1 by B_0 and B_1, respectively. The function $g(t)$ of (2.5) remains a comparison function, but the term that contributes to the dominant term in the asymptotic development of the polynomials under consideration is $B_0(t_0-t)^{-1/2}$.

In Case 3, $\Delta=0$, hence $\xi_+=\xi_-=\xi_0$ and $t_+=t_-$. Set $t_0=t_+=t_-$ and $\xi_0=\xi_+=\xi_-$. In this case both $dt/d\xi$ and $d^2t/d\xi^2$ vanish but $d^3t/d\xi^3$ does not vanish. Indeed upon differentiating (2.2) twice with respect to ξ we get

$$\left.\frac{d^3t}{d\xi^3}\right|_{\xi_0}=\frac{2t_0(a+b+1)}{\xi_0(1+\eta_0)(1+\xi_0)}\cdot\frac{1-x}{x+1}=:c.\tag{2.18}$$

Therefore $\xi_0-\xi\approx\sqrt[3]{6/c}\,(t_0-t)^{1/3}$ as $t\to t_0$. If, as before, we denote the right-hand side of (1.1) by $f(t)$, then we replace the comparison function (2.5) by

$$g(t)=D(t_0-t)^{-2/3},\tag{2.19}$$

where

$$D=\lim_{t\to t_0}\frac{(1+\xi)^{1+\alpha}(1+\eta)^{1+\beta}(t_0-t)^{2/3}}{1-a\xi-b\eta-(a+b+1)\xi\eta}.\tag{2.20}$$

We will evaluate D, using (2.19) and (2.20), and find the asymptotic behavior of the corresponding P_n's in § 3.

3. Asymptotics of Jacobi polynomials. Recall that x is assumed to be real and a and b belong to $(-1,\infty)$. We first state and prove a lemma that characterizes the case $\Delta<0$.

LEMMA 3.1. *In order for* $\Delta<0$ *to hold it is necessary and sufficient that*

(i) *Formulas* (2.7) *and* (2.10) *hold, and so* $a+b+1>0$.

(ii) $(a+b+2)^2x\in(b^2-a^2-4[(a+1)(1+b)(a+b+1)]^{1/2},$
$b^2-a^2+4[(a+1)(1+b)(a+b+1)]^{1/2})$, *when* $a+b\neq-2$.

Proof. Observe that

$$\Delta=(a+b+2)^2x^2-2(b^2-a^2)x+[(b-a)^2-4(a+b+1)]\tag{3.1}$$

follows from (1.6). In § 2 we already demonstrated the necessity of (2.7) and (2.10). It is easy to see that (2.7) and (2.10) imply

$$a+b+1>0. \tag{3.2}$$

Then $\Delta<0$ implies the restrictions on x stated in (ii). This proves the necessity of the conditions in this lemma. We can prove the sufficiency of the assumptions by first establishing (3.2), and then analyze Δ as a quadratic function of x. We will omit the details.

Observe that if $a+b=-1$ the x-interval in (ii) becomes empty.

LEMMA 3.2. *The roots $\xi_{\pm}$ of* (1.3) *are distinct and have equal absolute values if and only if $a+b\neq -1$ and $\Delta<0$.*

Proof. This follows from the well-known fact that in the complex z plane the quantities $z\pm(z^2-1)^{1/2}$ have equal absolute values if and only if z is real and $-1\leqq z\leqq 1$.

THEOREM 3.3. *Assume $a>-1$, $b>-1$, and x satisfies condition* (ii) *of Lemma* 3.1; *then the asymptotic relationship* (2.16) *holds, as $n\to\infty$, where ρ, γ and θ are as in* (2.11)-(2.13).

THEOREM 3.4. *Assume that $a>-1$, $b>-1$, and $\Delta>0$. Then*

$$P_n^{\alpha+an,\beta+bn}(x)\approx\frac{B_0}{\sqrt{n\pi}}\,t_0^{-n-1/2}. \tag{3.3}$$

Proof. The coefficient of t^n in the power series expansion of $(t_0-t)^{-1/2}$ is

$$\frac{\Gamma(n+\frac{1}{2})}{\Gamma(\frac{1}{2})\Gamma(n+1)}\,t_0^{-n-1/2},$$

which is asymptotic to $(n\pi)^{-1/2}t_0^{-n-1/2}$. This proves (3.3).

Finally, we discuss the case $\Delta=0$. This case can be thought of as a transition between Case 1 and Case 2. In Case 3 both $dt/d\xi$ and $d^2t/d\xi^2$ vanish but $d^3t/d\xi^3$ does not vanish. This case occurs if and only if

$$x^2(a+b+2)^2+2x(a^2-b^2)+(a-b)^2-4(a+b+1)=0 \tag{3.4}$$

holds (see (3.1)). There is no choice for a and b that will make the left-hand side of (3.4) identically zero. Thus $\Delta=0$ has at most two solutions. They are

$$x=\frac{b^2-a^2\pm 4\sqrt{(1+a)(1+b)(1+a+b)}}{(2+a+b)^2}\quad\text{if } a+b>-1, \tag{3.5}$$

and at $x=2a+1$ if $a+b=-1$. A calculation shows that the constant D of (2.19) and (2.20) is given by

$$D=9^{-1/3}(1+\xi)^{\alpha+1/3}(1+\eta)^{\beta+1/3}, \tag{3.6}$$

where

$$1+\xi=-a^{-1}\left[-a-1\pm\sqrt{\frac{(1+a)(1+b)}{1+a+b}}\right], \tag{3.7}$$

$$1+\eta=-b^{-1}\left[-b-1\pm\sqrt{\frac{(1+a)(1+b)}{1+a+b}}\right]. \tag{3.8}$$

The calculation above is particularly simplified by the observation

$$b^2\frac{x-1}{x+1}=-2(a+b+1)-ab\pm 2\sqrt{(1+a)(1+b)(1+a+b)}.$$

Note that the difference between $1+\xi$ and $1+\eta$ is that a and b are interchanged and the sign of the square root is reversed. The coefficient of t^n in $g(t)$ is $(t_0)^{-n-2/3}D(2/3)_n/n!$. Therefore the P_n's behave asymptotically like the aforementioned coefficient of t^n. Thus we established the following asymptotic result:

$$P_n^{\alpha+an,\beta+bn}(x) \approx \frac{[(1+x)/(2\xi)]^{n+2/3}}{\sqrt[3]{9n}\,\Gamma(\frac{2}{3})}(1+\xi)^{n(-a-1)+\alpha+1+2a/3}(1+\eta)^{n(-b-1)+\beta+1+2b/3}. \tag{3.9}$$

4. Laguerre polynomials. In this section we briefly analyze the strong asymptotics of the Laguerre polynomials $L_n^{\alpha+an}(b+nx)$ as $n\to\infty$ for real b, α, β, x, and positive a. We will consider only the oscillatory range.

The generating function

$$\sum_{n=0}^{\infty} L_n^{\alpha+an}(b+nx)t^n = (1-\xi)^{1-\alpha}[(1-\xi)^2 - a\xi(1-\xi)+x\xi]^{-1}\exp[-b\xi/(1-\xi)], \tag{4.1}$$

where

$$t = \xi(1-\xi)^a \exp[x\xi/(1-\xi)] \tag{4.2}$$

was proved by Carlitz [6] using Lagrange inversion. It is a limiting case of the Srivastava-Singhal generating function (1.1)-(1.2), which was also proved by Lagrange inversion.

The ξ-singularities of (4.1) are at $\xi=1$, $\xi=\xi_\pm$, where $\xi_\pm$ are the roots of

$$(1-\xi)^2 - a\xi(1-\xi)+x\xi = 0. \tag{4.3}$$

Therefore

$$\xi_\pm = \frac{2+a-x\pm\sqrt{(a-x)^2-4x}}{2(1+a)}. \tag{4.4}$$

In the oscillatory case we must have

$$x-2\sqrt{x} < a < x+2\sqrt{x}. \tag{4.5}$$

It follows that $|\xi_\pm| = 1/(1+a) < 1$, since $a>0$. Thus $\xi=\xi_\pm$ are the singularities of the generating function that are closest to the origin. Let

$$t_\pm = \xi_\pm(1-\xi_\pm)^a \exp[x\xi_\pm/(1-\xi_\pm)]. \tag{4.6}$$

A calculation shows that

$$\frac{dt}{d\xi} = 0, \qquad \frac{d^2t}{d^2\xi} = (1-\xi)^a(1-\xi)^{-3}[-a(1-\xi)+x(1+\xi)]\exp\{x[1-(1-\xi)^{-1}]\} \quad \text{at } \xi=\xi_\pm. \tag{4.7}$$

We can prove

$$L_n^{\alpha+an}(b+nx) \approx \sqrt{\frac{-2}{n\pi\Delta}}\left(\frac{-x\Delta}{1+a}\right)^{1/4}\left(\frac{\sqrt{1+a}}{x}\right)^{an+a+1/2}(1+a)^{n/2+1/4} \cdot \exp\left\{\left(\frac{2b-x}{2\sqrt{x}}\right)\cos\phi\right\}\cos\left\{\left[-\left(\alpha+\frac{1}{2}\right)+\frac{a}{2}\right]\theta-\left(n+\frac{1}{2}\right)(\omega+a\theta)+\frac{\gamma}{2} + \exp\left\{\left[\frac{2b-x}{2\sqrt{x}}\right]\sin\phi\right\}\right\}, \tag{4.8}$$

where

$$\Delta=(a-x)^2-4x, \qquad 1-(1-\xi_{\pm})^{-1}=(x)^{-1/2}\,e^{\pm i\phi},$$
$$-a(1-\xi_{\pm})+x(1+\xi_{\pm})=(-x\Delta/(1+a))^{1/4}\,e^{\pm i\gamma}, \qquad \omega=\arg(\xi_+). \tag{4.9}$$

5. Remarks. In their interesting work on the sharpness of the Lorentz theorem on incomplete polynomials, Saff and Varga [15] were led to two problems involving asymptotics and distribution of zeros of the Jacobi polynomials $\{P_n^{\alpha_n,\beta_n}(x)\}$ as $n\to\infty$. Let $\alpha_n>-1$ and $\beta_n>-1$. The second problem was solved in [11], where Moak, Saff, and Varga proved the following result.

THEOREM 5.1. *Let s_n and l_n be, respectively, the smallest and largest zeros of the Jacobi polynomial $P_n^{\alpha_n,\beta_n}(x)$ and assume that the limits*

$$\lim_{n\to\infty}\frac{\alpha_n}{2n+\alpha_n+\beta_n}=A \quad \textit{and} \quad \lim_{n\to\infty}\frac{\beta_n}{2n+\alpha_n+\beta_n}=B$$

exist. Then as $n\to\infty$, $s_n\to S$, and $l_n\to L$, where

$$S=B^2-A^2-[(A^2+B^2-1)^2-4A^2B^2]^{1/2}$$

and

$$L=B^2-A^2+[(A^2+B^2-1)^2-4A^2B^2]^{1/2}.$$

Furthermore, the zeros of the sequence $\{P_n^{\alpha_n,\beta_n}(x)\}$ are dense in $[S, L]$.

The special case $\alpha_n=\alpha+an$, $\beta_n=\beta+bn$, $a>-1$, $b>-1$, of Theorem 5.1 follows from (2.16). Indeed for $\alpha>-1$ and $\beta>-1$ the zeros of $P_n^{\alpha,\beta}(x)$ belong to $(-1, 1)$. The zeros increase with β and decrease with α. Thus $\{s_n\}$ and $\{l_n\}$ are monotone sequences. The oscillatory nature of the asymptotic formula (2.16) shows that the zeros of the Jacobi polynomials $\{P_n^{\alpha+an,\beta+bn}(x)\}$ are dense in the interval characterized by $\Delta<0$. The interval $\Delta<0$ is precisely the interval (S, L).

The first problem of Saff and Varga [15] involving Jacobi polynomials was to determine the asymptotic behavior of $P_n^{\alpha,\beta+2\theta n/(1-\theta)}(x)$, as $n\to\infty$, for real x, $x\neq-1$. Saff and Varga used the method of steepest descent to prove their results. The asymptotic estimates (2.16) and (3.3) generalize the Saff-Varga estimates. Saff and Varga used their results to prove that a theorem of Lorentz on incomplete polynomials is sharp.

Mhaskar and Saff [10] developed nth root asymptotics for $\{L_n^{\alpha+an}(b+nx)\}$ as a concrete example to illustrate their general results and demonstrate their sharpness. Formula (4.8) gives the main term in the strong (pointwise) asymptotics of the aforementioned Laguerre polynomials and implies the nth root asymptotics. Furthermore, (4.8) shows that the zeros of the Laguerre polynomials under consideration are dense in the interval $(2+a-2\sqrt{1+a},\ 2+a+2\sqrt{1+a})$.

If a sequence of polynomials $\{p_n(x)\}$ is orthogonal with respect to a positive measure $d\mu$ and μ' is supported on a set E, then the zeros of the p_n's are dense in E. The zeros of the polynomial sequences $\{P_n^{\alpha+an,\beta+bn}(x)\}$ and $\{L_n^{\alpha+an}(b+nx)\}$ are dense in certain intervals but neither set is orthogonal unless $a=b=0$, and $a=x=0$, respectively.

Acknowledgment. We thank Ed Saff for the information about [10] and for suggesting that we do the strong asymptotics of § 4.

HYPERGEOMETRIC EXPANSIONS OF HEUN POLYNOMIALS*

E.G. KALNINS† AND W. MILLER, JR.‡

Abstract. The product of two Heun polynomials is expanded in terms of products of two Jacobi polynomials. This is done by making crucial use of group theory and the knowledge of separable coordinate systems on the n-sphere. The expansion presented includes as a special case hypergeometric function expansions of single Heun polynomials that have been derived previously by other methods.

Key words. multivariable orthogonal polynomials, the n-sphere, Heun functions

AMS(MOS) subject classifications. 22E70, 33A65, 33A75

1. Introduction.

Any Fuchsian equation of second order with four singularities can be reduced to the form

$$\frac{d^2w}{dx^2}+\left[\frac{\gamma}{x-e_1}+\frac{\delta}{x-e_2}+\frac{\epsilon}{x-e_3}\right]\frac{dw}{dx}+\frac{\alpha\beta x-q}{(x-e_1)(x-e_2)(x-e_3)}w=0, \tag{1.1}$$

where $\alpha+\beta-\gamma-\delta-\epsilon+1=0$.

The singularities are located at $x=e_1,e_2,e_3$, and ∞ and have indices depending upon $\alpha,\cdots,\epsilon$. The constant q is known as the accessory parameter. This is Heun's equation [1] and solutions may be characterised by the P symbol [2].

$$P\left\{\begin{array}{cccccc} e_1 & e_2 & e_3 & \infty & \\ 0 & 0 & 0 & \alpha & x \\ 1-\gamma & 1-\delta & 1-\epsilon & \beta & \end{array}\right\}. \tag{1.2}$$

Power series expansions for the solutions of Heun's equation have been studied by Heun for various arguments [1], [3]. There turn out to be 96 distinct types of power series. Alternatively, solutions of Heun's equations can be expanded in series of hypergeometric functions. Such expansions were studied by Svartholm [4] and Erdélyi [5]. Typically such expansions have the form

$$P\left\{\begin{array}{cccccc} e_1 & e_2 & e_3 & \infty & \\ 0 & 0 & 0 & \alpha & x \\ 1-\gamma & 1-\delta & 1-\epsilon & \beta & \end{array}\right\}=\sum_{m=0}^{\infty}A_mP\left\{\begin{array}{ccccc} 0 & 1 & \alpha & \\ 0 & 0 & \lambda+m & x \\ 1-\gamma & 1-\delta & \mu-m & \end{array}\right\}, \tag{1.3}$$

where $\lambda+\mu=\gamma+\delta-1=\alpha+\beta-\epsilon$. Two types of expansion were given:

(i) Series of type I for which $\lambda=\alpha,\mu=\beta-\epsilon$. These series converge outside an ellipse with foci at e_1,e_2 and which passes through e_3. There are three distinct expansions of this type.

(ii) Series of type II for which $\mu=0$, $\gamma-1$, $\delta-1$, or $\gamma+\delta-2$.

In all these expansions the coefficients A_m satisfy three-term recurrence relations

$$b_0A_0+c_1A_1=0, \tag{1.4}$$

$$a_rA_{r-1}+b_rA_r+c_{r+1}A_{r+1}=0, \qquad r=1,2,\cdots,$$

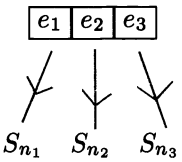
where a_r, b_r, c_r are known expressions in r and $c_r \neq 0$. If q is chosen from a number of characteristic values then expansions of this type converge. In this article we derive some of these expansions for the case of Heun polynomials from considerations based on group theory and its connection with separation of variables solutions of the Laplace–Beltrami eigenvalue equation on the n-sphere. The method used makes a judicious choice of coordinates on the n-sphere. The expansions that are first derived are for products of Heun polynomials as sums of products of Jacobi polynomials. The coefficients in the expansions obey three-term recurrence relations. The corresponding single variable expansions are then obtained by allowing one of the variables to take a fixed value. This paper is an extension of [8], in which its motivation and background can be found.

2. Derivation of the expansion formula. The graphical calculus of separable coordinates for the Laplace–Beltrami eigenvalue equation on the n-sphere has been completely worked out by Kalnins and Miller [6], [7]. To derive an expansion for Heun polynomials we consider coordinate systems corresponding to graphs of the type



on the n sphere, $n = n_1 + n_2 + n_3 + 2$. A suitable choice of coordinates is

$$
\begin{aligned}
s_i &= u_1 w_i, && i = 1, \cdots, n_1 + 1, \\
s_{j+n_1+1} &= u_2 t_j, && j = 1, \cdots, n_2 + 1, \\
s_{k+n_1+n_2+2} &= u_3 z_k, && k = 1, \cdots, n_3 + 1,
\end{aligned} \tag{2.1}
$$

where

$$
\sum_{i=1}^{n_1+1} w_i^2 = 1, \quad \sum_{j=1}^{n_2+1} t_j^2 = 1, \quad \sum_{k=1}^{n_3+1} z_k^2 = 1,
$$

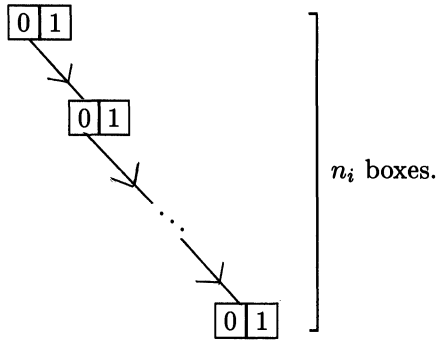
and

$$
u_i^2 = \frac{(x-e_i)(y-e_i)}{(e_j-e_i)(e_k-e_i)}, \qquad i = 1,2,3, \quad i,j,k \text{ pairwise distinct.} \tag{2.2}
$$

The metric on the n sphere is

$$
\begin{aligned}
ds^2 = &-\frac{(x-y)}{4}\left[\frac{dx^2}{(x-e_1)(x-e_2)(x-e_3)} - \frac{dy^2}{(y-e_1)(y-e_2)(y-e_3)}\right] \\
&+ \frac{(x-e_1)(y-e_1)}{(e_2-e_1)(e_3-e_1)} \sum_{i=1}^{n_1+1} dw_i^2 + \frac{(x-e_2)(y-e_2)}{(e_3-e_2)(e_1-e_2)} \sum_{j=1}^{n_2+1} dt_j^2 \\
&+ \frac{(x-e_3)(y-e_3)}{(e_2-e_3)(e_1-e_3)} \sum_{k=1}^{n_3+1} dz_k^2.
\end{aligned} \tag{2.3}
$$

The coordinate systems chosen for w_i, t_j, z_k can be taken to be, say, spherical coordinates in each case, corresponding to the graph [6].



We then seek eigenfunctions ψ of the Laplacian satisfying

$$\Delta\psi = -J(J+n_1+n_2+n_3+1)\psi, \tag{2.4}$$

where J is a nonnegative integer. In the coordinates we have chosen, this equation has the form

(2.5)

$$\begin{aligned}\Delta\psi = -\frac{4}{(x-y)}\Bigg[&(x-e_1)(x-e_2)(x-e_3)\\ &\cdot\left[\frac{\partial^2}{\partial x^2}+\frac{1}{2}\left[\frac{n_1+1}{x-e_1}+\frac{n_2+1}{x-e_2}+\frac{n_3+1}{x-e_3}\right]\frac{\partial}{\partial x}\right]\psi\\ &-(y-e_1)(y-e_2)(y-e_3)\left[\frac{\partial^2}{\partial y^2}+\frac{1}{2}\left[\frac{n_1+1}{y-e_1}+\frac{n_2+1}{y-e_2}+\frac{n_3+1}{y-e_3}\right]\frac{\partial}{\partial y}\right]\psi\Bigg]\\ &+\left[\frac{(e_1-e_2)(e_1-e_3)}{(x-e_1)(y-e_1)}\Delta_1+\frac{(e_2-e_1)(e_2-e_3)}{(x-e_2)(y-e_2)}\Delta_2+\frac{(e_3-e_1)(e_3-e_2)}{(x-e_3)(y-e_3)}\Delta_3\right]\psi\\ &=-J(J+n_1+n_2+n_3+1)\psi,\end{aligned}$$

where Δ_k is the Laplacian on the sphere S_{n_k}.

If we seek eigenfunctions such that

$$\Delta_i\psi = -\ell_i(\ell_i+n_i-1)\psi, \qquad i=1,2,3, \tag{2.6}$$

where the ℓ_i are nonnegative integers, then writing

$$\psi = \prod_{i=1}^{3}[(x-e_i)(y-e_i)]^{\ell_i/2}\phi, \tag{2.7}$$

we find (2.5) has the form

(2.8)

$$\begin{aligned}-\frac{4}{(x-y)}\Bigg\{&(x-e_1)(x-e_2)(x-e_3)\left(\frac{\partial^2}{\partial x^2}+\left[\frac{\ell_1+\frac{1}{2}(n_1+1)}{x-e_1}+\frac{\ell_2+\frac{1}{2}(n_2+1)}{x-e_2}\right.\right.\\ &\left.\left.+\frac{\ell_3+\frac{1}{2}(n_3+1)}{x-e_3}\right]\frac{\partial}{\partial x}\right)\phi+Ax\phi\\ &-(y-e_1)(y-e_2)(y-e_3)\left(\frac{\partial^2}{\partial y^2}+\left[\frac{\ell_1+\frac{1}{2}(n_1+1)}{y-e_1}+\frac{\ell_2+\frac{1}{2}(n_2+1)}{y-e_2}\right.\right.\\ &\left.\left.+\frac{\ell_3+\frac{1}{2}(n_3+1)}{y-e_3}\right]\frac{\partial}{\partial y}\right)\phi-Ay\phi\Bigg\}=-J(J+N+1)\phi,\end{aligned} \tag{2.8}$$

where

$$A = \tfrac{1}{4}(L+N+1)L, \quad L = \ell_1+\ell_2+\ell_3, \quad N = n_1+n_2+n_3.$$

The corresponding separable solutions have the form

$$\psi = u_1^{\ell_1}u_2^{\ell_2}u_3^{\ell_3}\Phi^1_{J\ell_1\ell_2\ell_3 q}(x)\Phi^2_{J\ell_1\ell_2\ell_3 q}(y)\Theta_{\ell_1\ell_2\ell_3}(\mathbf{w},\mathbf{t},\mathbf{z}), \tag{2.9}$$

where a complete set of functions $\Theta_{\ell_1\ell_2\ell_3}(\mathbf{w},\mathbf{t},\mathbf{z})$ can be taken as

$$\Theta_{\ell_1\ell_2\ell_3}(\mathbf{w},\mathbf{t},\mathbf{z}) = \Theta_{\ell_1}(\mathbf{w})\Theta_{\ell_2}(\mathbf{t})\Theta_{\ell_3}(\mathbf{z}) \tag{2.10}$$

and typically,

$$\Theta_{\ell_1}(\mathbf{w}) = \prod_{j=0}^{n_1-2} C^{\frac{1}{2}(n_1-j-1)+K_{j+1}}_{K_j-K_{j+1}}(\cos(\theta_{n_1-j}))(\sin\theta_{n_1-j})^{K_j+1}e^{\pm iK_{n_1-1}\theta_1} \tag{2.11}$$

for $\ell_1 = K_0 \geq K_1 \geq \cdots \geq K_{n_1-1} \geq 0$, and

$$\Delta_{(k)}\Theta_{\ell_1}(\mathbf{w}) = -K_k(K_k+n_1-k-1)\Theta_{\ell_1}(\mathbf{w}), \tag{2.12}$$

where $C^{\nu}_{\mu}(z)$ is a Gegenbauer polynomial. The coordinates on S_{n_1} are

$$\begin{aligned} w_1 &= \sin\theta_{n_1}\cdots\sin\theta_2\sin\theta_1 \\ w_2 &= \sin\theta_{n_1}\cdots\sin\theta_2\cos\theta_1 \\ &\vdots \\ w_{n_1} &= \sin\theta_{n_1}\cos\theta_{n_1-1} \\ w_{n_1+1} &= \cos\theta_{n_1} \end{aligned} \tag{2.13}$$

and the operator $\Delta_{(k)}$ is given by

$$\Delta_{(k)} = \sum_{r<\ell\leq n_1+1-k} I^2_{r\ell}, \quad I_{r\ell} = w_r\frac{\partial}{\partial w_\ell} - w_\ell\frac{\partial}{\partial w_r}, \quad k = 0,\cdots,n_1-1. \tag{2.14}$$

(The $\Delta_{(k)}$ are the second-order symmetry operators for Δ_1 whose eigenvalue equations (2.12) characterize the separable coordinates (2.13); see [6], [7].) The corresponding separation equations are

$$\begin{aligned} &\Big[-4(\lambda-e_1)(\lambda-e_2)(\lambda-e_3) \\ &\cdot\Big[\frac{d^2}{d\lambda^2}+\Big(\frac{\ell_1+\frac{1}{2}(n_1+1)}{\lambda-e_1}+\frac{\ell_2+\frac{1}{2}(n_2+1)}{\lambda-e_2}+\frac{\ell_3+\frac{1}{2}(n_3+1)}{\lambda-e_3}\Big)\frac{d}{d\lambda}\Big] \\ &\quad+(J-L)(J+L+N+1)\lambda+4q\Big]\Phi^{\epsilon}_{J\ell_1\ell_2\ell_3 q}(\lambda) = 0, \end{aligned} \tag{2.15}$$

where $\lambda = x, y$ according as $\epsilon = 1, 2$, respectively. This is Heun's equation of the form (1.1) with $\gamma = \ell_1+\frac{1}{2}(n_1+1)$, $\delta = \ell_2+\frac{1}{2}(n_2+1)$, $\epsilon = \ell_3+\frac{1}{2}(n_3+1)$, $\alpha = \frac{1}{2}(L-J)$, $\beta = \frac{1}{2}(L+J+N+1)$. The solutions for the functions $\Phi^{\epsilon}_{J\ell_1\ell_2\ell_3 q}(\lambda)$ are Heun polynomials which for fixed J will form a complete set of basis functions once the eigenvalues q have been calculated. To calculate the eigenvalues it is convenient to observe that in the coordinate system (2.1) the operator $\mathscr{M}$ whose eigenvalue χ is

$$\begin{aligned} \chi &= (e_1+e_2+e_3)[\ell_1^2+\ell_2^2+\ell_3^2+\ell_1n_1+\ell_2n_2+\ell_3n_3-J(J+N+1)] \\ &\quad+2\ell_1\ell_2e_3+2\ell_1\ell_3e_2+2\ell_2\ell_3e_1-\ell_1e_1-\ell_2e_2-\ell_3e_3 \\ &\quad+\ell_1n_2e_3+\ell_1n_3e_2+\ell_2n_1e_3+\ell_2n_3e_1+\ell_3n_1e_2+\ell_3n_2e_1-4q \end{aligned} \tag{2.16}$$

is given by [6], [7]

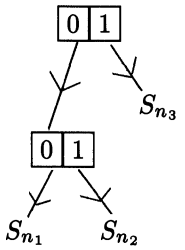
$$\mathscr{M} = (e_1+e_2)\sum_{p\in P}\sum_{q\in Q} I_{pq}^2 + (e_2+e_3)\sum_{q\in Q}\sum_{r\in R} I_{rq}^2 + (e_1+e_3)\sum_{p\in P}\sum_{r\in R} I_{pr}^2, \tag{2.17}$$

$$P = \{1,\cdots,n_1+1\}, Q = \{n_1+2,\cdots,n_1+n_2+2\},$$

$$R = \{n_1+n_2+3,\cdots,n_1+n_2+n_3+3\}.$$

That is, $\mathscr{M}$ is the second-order symmetry operator for the Laplacian ($[\mathscr{M},\Delta]=0$), which corresponds to the separable coordinates x, y. (The separable solutions (2.9) are eigenfunctions of $\mathscr{M}$ with eigenvalues χ.) Expression (2.16) gives the relationship between the eigenvalues χ and q. (The terms involving the ℓ_j result from consideration of the factor $u_1^{\ell_1}u_2^{\ell_2}u_3^{\ell_3}$.)

The basis functions on the sphere S_n corresponding to coordinates of the graph can also be expanded in terms of the basis functions of the coordinate system corresponding to the graph [6],



i.e., the coordinates (2.1) with

$$u_1 = \sin\theta\cos\phi, \quad u_2 = \sin\theta\sin\phi, \quad u_3 = \cos\theta \tag{2.18}$$

and the infinitesimal distance

$$ds^2 = d\theta^2 + \sin^2\theta d\phi^2 + \sin^2\theta\cos^2\phi\sum_{i=1}^{n_1+1} dw_i^2 + \sin^2\theta\sin^2\phi\sum_{j=1}^{n_2+1} dt_j^2 + \cos^2\theta\sum_{k=1}^{n_3+1} dz_k^2. \tag{2.19}$$

Eigenfunction solutions of (2.4) in these coordinates are

$$\begin{aligned}\psi &= (\sin\theta)^M(\cos\theta)^{\ell_3}(\sin\phi)^{\ell_2}(\cos\phi)^{\ell_1} \\ &\quad\times P_{(J-M-\ell_3)/2}^{M+\frac{1}{2}(n_1+n_2),\ell_3+\frac{1}{2}(n_3-1)}(\cos 2\theta) \\ &\quad\times P_{(M-\ell_1-\ell_2)/2}^{\ell_2+\frac{1}{2}(n_2-1),\ \ell_1+\frac{1}{2}(n_1-1)}(\cos 2\phi)\ \Theta_{\ell_1\ell_2\ell_3}(\mathbf{w},\mathbf{t},\mathbf{z}) \\ &= \psi_{JM}\Theta_{\ell_1\ell_2\ell_3},\end{aligned} \tag{2.20}$$

where $P_n^{\alpha,\beta}(z)$ are Jacobi polynomials. Here $J = L+2j$ and $M = L+2m$, where $j = 0,1,\cdots$, $m = 0,1,\cdots j-1, j$. The eigenfunctions satisfy

$$\Delta'\psi = -M(M+n_1+n_2)\psi, \tag{2.21}$$

where

$$\Delta' = \sum_{i>j} I_{ij}^2 \tag{2.22}$$

and i, j range from 1 to $n_1 + n_2 + 2$.

Note that in terms of the Cartesian coordinates u_1, u_2, u_3 on the 2-sphere ($u_1^2 + u_2^2 + u_3^2 = 1$) these eigenfunctions take the form

$$\begin{aligned}\psi_{JM} &= u_1^{\ell_1} u_2^{\ell_2} u_3^{\ell_3} (u_1^2 + u_2^2)^{(M-\ell_1-\ell_2)/2} \\ &\quad \times P_{(J-M-\ell_3)/2}^{M+\frac{1}{2}(n_1+n_2),\ \ell_3+\frac{1}{2}(n_3-1)}(1 - 2u_1^2 - 2u_2^2) \\ &\quad \times P_{(M-\ell_1-\ell_2)/2}^{\ell_2+\frac{1}{2}(n_2-1),\ \ell_1+\frac{1}{2}(n_1-1)}\left(\frac{2u_1^2}{u_1^2+u_2^2} - 1\right) \\ &= u_1^{\ell_1} u_2^{\ell_2} u_3^{\ell_3} \Phi_{jm},\end{aligned} \tag{2.23}$$

i.e., the form $u_1^{\ell} u_2^{\ell_2} u_3^{\ell_3} \Phi(u_1^2, u_2^2)$, where Φ is a polynomial.

This remark leads to another way of viewing the Heun and Jacobi bases. In the equation $\Delta\psi = -J(J + N + 1)\psi$ with $\Delta\psi$ given by (2.5) and Δ_k replaced by the values $-\ell_k(\ell_k + n_k - 1)$, $k = 1, 2, 3$, we set $\psi = u_1^{\ell} u_2^{\ell_2} u_3^{\ell_3} \Phi(x_1, x_2)$ and introduce the new coordinates $x_1 = u_1^2, x_2 = u_2^2$. The eigenvalue equation for Φ reads

$$H\Phi = -j(j + G - 1)\Phi, \tag{2.24}$$

where

$$H = \sum_{i,j=1}^{2} (x_i\delta_{ij} - x_i x_j)\frac{\partial^2}{\partial x_i \partial x_j} + \sum_{i=1}^{2} (\gamma_i - G x_i)\frac{\partial}{\partial x_i}. \tag{2.25}$$

Here $G = \gamma_1 + \gamma_2 + \gamma_3$ and in this particular case

$$\begin{aligned}\gamma_i &= \ell_i + \tfrac{1}{2}(n_i + 1), \qquad i = 1, 2, 3, \\ j &= \tfrac{1}{2}(J - L) = 0, 1, 2, \cdots.\end{aligned} \tag{2.26}$$

This coincides with equation (1.4) in [8]. In particular H maps polynomials of maximum degree m_i in x_i to polynomials of the same type. Furthermore, it is easy to see that the polynomial eigenfunctions of H form a basis for the space of all polynomials $f(x_1, x_2)$ and that the spectrum of H acting on this space is exactly $\{-j(j + G - 1) : j = 0, 1, \cdots\}$. It is also shown in [8] that $H = \Delta_2 + \Lambda_2$ where Δ_2 is the Laplace–Beltrami operator on S_2 and

$$\Lambda_2 = \sum_{i=1}^{2} \left[\gamma_i - \frac{1}{2} + \left(\frac{3}{2} - G\right) x_i\right] \frac{\partial}{\partial x_i}. \tag{2.27}$$

Moreover, H is self-adjoint with respect to the inner product

$$(f_1, f_2) = \iint_{x_1, x_2 > 0, 1 - x_1 - x_2 > 0} f_1(\mathbf{x})\overline{f_2(\mathbf{x})}\, d\omega, \tag{2.28}$$

where

$$\begin{aligned}dw &= x_1^{\gamma_1 - 1} x_2^{\gamma_2 - 1}(1 - x_1 - x_2)^{\gamma_3 - 1} dx_1 dx_2 : \\ &(Hf_1, f_2) = (f_1, Hf_2).\end{aligned} \tag{2.29}$$

Here f_1, f_2 are polynomials in $\mathbf{x} = (x_1, x_2)$. For fixed j the polynomials

(2.30)
$$\Phi_{jm}(x_1, x_2) = (x_1 + x_2)^m P_{j-m}^{\gamma_1+\gamma_2+2m-1,\gamma_3-1}(2x_1 + 2x_2 - 1) \times P_m^{\gamma_2-1,\ \gamma_1-1}\left(\frac{2x_1}{x_1 + x_2} - 1\right), \qquad m = 0, 1, \cdots, j$$

form an orthogonal basis for the eigenspace corresponding to eigenvalue $-j(j + G - 1)$. (This is the orthogonal basis of Proriol [9] and of Karlin and McGregor [10].) Similarly the Heun polynomials $\Phi^1_{J\ell_1\ell_2\ell_3 q}(x)\Phi^2_{J\ell_1\ell_2\ell_3 q}(y)$ where q runs over the possible eigenvalues, form an alternate orthogonal basis for this same space. Moreover as pointed out in [11] these bases correspond to spherical and ellipsoidal coordinates on the 2-sphere and are the only coordinates in which Δ_2 separates.

With this point of view we are operating on the sphere S_2 rather than S_n and our two distinguished orthogonal bases are the only ones possible rather than two out of a multiplicity of separable systems on S_n for large n. The principal advantage of this new point of view is that the eigenfunctions are obviously polynomials in x_1, x_2 and that the only requirement on the constants $\gamma_1, \gamma_2, \gamma_3$ to ensure orthogonality is that they be strictly positive. Thus the ℓ_i and n_i need not be integers; it is only required that $2\ell_i + n_i + 1 > 0$.

In the following our expansion formulas are valid for all real $\gamma_i > 0$. In the special case $\gamma_1 = \gamma_2 = \gamma_3 = \frac{1}{2}$ we have $H = \Delta_2$, the Laplace–Beltrami operator on S_2. In this case the eigenvalue equation $\Delta_2\Phi = -j(j + \frac{1}{2})\Phi$ admits the Lie algebra $so(3)$ as a symmetry algebra. A basis for $so(3)$ is $\{u_1\partial_{u_2} - u_2\partial_{u_1}, u_3\partial_{u_1}, u_3\partial_{u_2}\}$ where $u_3 = \pm(1 - u_1^2 - u_2^2)^{1/2}$. This extra symmetry is associated with the fact that there are additional polynomial solutions of the eigenvalue equation (see §3 of reference [8]). In particular the equation admits polynomial solutions of the form $f(u_1, u_2)$ and the spectrum of Δ_2 acting on the space of all such polynomials is $-j(j + \frac{1}{2})$ where now $2j = 0, 1, 2\cdots$. Furthermore, there exist solutions of the form $u_3 g(u_1, u_2)$ with g a polynomial and with the same eigenvalues. The dimension of each eigenspace is $2j + 1$ rather than $j + 1$ for the general case. In this special case the eigenfunctions corresponding to spherical coordinates are just the spherical harmonics whereas those corresponding to ellipsoidal coordinates are products of Lamé polynomials. For the solution of the problem of expanding the Lamé basis in terms of a spherical harmonic basis, see [11]–[13].

Returning to the case of general ℓ_i, n_i we consider the problem of expanding the Heun basis (2.9) in terms of the Jacobi polynomial basis (2.20), (2.23), (2.30):

(2.31)
$$\psi = u_1^{\ell_1} u_2^{\ell_2} u_3^{\ell_3} \Phi^1_{J\ell_1\ell_2\ell_3 q}(x)\Phi^2_{J\ell_1\ell_2\ell_3 q}(y) = \sum_{m=0}^{j} \xi_m \psi_{J\ell_1\ell_2\ell_3 M}(\theta, \phi).$$

Three-term recurrence relations for the expansion coefficients ξ_m (where $M = \ell_1 + \ell_2 + 2m$) can be deduced by requiring that

(2.32)
$$\mathscr{M}\psi = \chi\psi.$$

To obtain the recurrence relations we need the action of the various pieces of $\mathscr{M}$ on the Jacobi bases $\psi_{J\ell_1\ell_2\ell_3 M}(\theta, \phi)$. Since $\mathscr{M}$ commutes with H there must exist an

expansion of the form $\mathscr{M}\psi_{jm} = \sum_r X_r \psi_{j,m+r}$. Indeed, we have

$$\mathscr{M}\psi_{J\ell_1\ell_2\ell_3 M}(\theta,\phi) = \sum_{r=-1}^{+1} X_r \psi_{J\ell_1\ell_2\ell_3,M+2r}(\theta,\phi), \tag{2.33}$$

where

(2.34)

$$X_1(m,j) = \frac{4(e_1-e_2)(\gamma_1+\gamma_2+\gamma_3+m+j-1)(\gamma_3-m+j-1)(m+1)(\gamma_1+\gamma_2+m-1)}{(\gamma_1+\gamma_2+2m-1)(\gamma_1+\gamma_2+2m)},$$

$$X_{-1}(m,j) = \frac{4(e_1-e_2)(\gamma_1+\gamma_2+m+j-1)(-m+j+1)(\gamma_2-1)(\gamma_1-1)}{(\gamma_1+\gamma_2+2m-1)(\gamma_1+\gamma_2+2m-2)},$$

$$\begin{aligned} X_0(m,j)-\chi &= \frac{2(e_1-e_2)[m^2+m(\gamma_1+\gamma_2-1)-j^2-j(\gamma_1+\gamma_2+\gamma_3--1)](\gamma_1+\gamma_2-2)(\gamma_1-\gamma_2)}{(\gamma_1+\gamma_2+2m-2)(\gamma_1+\gamma_2+2m)} \\ &\quad + 4\frac{(e_1-e_2)m\gamma_3(\gamma_1-\gamma_2)(m+\gamma_2)}{(\gamma_1+\gamma_2+2m-2)(\gamma_1+\gamma_2+2m)} \\ &\quad + 2(e_1+e_2)[-m^2-m(\gamma_1+\gamma_2-1)+j^2+j(\gamma_1+\gamma_2+\gamma_3-1)] \\ &\quad + 4e_3[m^2+m(\gamma_1+\gamma_2-1)]+4q. \end{aligned}$$

Keys to deriving this result are the following recurrence formulas for Jacobi polynomials $P_n^{\alpha,\beta}(x)$:

$$xP_n^{\alpha,\beta} = \mathscr{A}P_{n-1}^{\alpha,\beta} + \mathscr{B}P_n^{\alpha,\beta} + \mathscr{C}P_{n+1}^{\alpha,\beta}, \tag{2.35}$$

$$\mathscr{A} = \frac{2(n+\alpha)(n+\beta)}{(2n+\alpha+\beta+1)(2n+\alpha+\beta)}, \qquad \mathscr{B} = \frac{(\beta-\alpha)(\beta+\alpha)}{(2n+\alpha+\beta+2)(2n+\alpha+\beta)},$$

$$\mathscr{C} = \frac{2(n+1)(n+\alpha+\beta+1)}{(2n+\alpha+\beta+2)(2n+\alpha+\beta+1)},$$

$$(1-x^2)\frac{d}{dx}P_n^{\alpha,\beta} = AP_{n-1}^{\alpha,\beta} + BP_n^{\alpha,\beta} + CP_{n+1}^{\alpha,\beta},$$

$$A = \frac{2(n+\alpha)(n+\beta)(n+\alpha+\beta+1)}{(2n+\alpha+\beta+1)(2n+\alpha+\beta)}, \qquad B = \frac{2n(\alpha-\beta)(n+\alpha+1)}{(2n+\alpha+\beta+2)(2n+\alpha+\beta)},$$

$$C = -\frac{2n(n+1)(n+\alpha+\beta+1)}{(2n+\alpha+\beta+2)(2n+\alpha+\beta+1)}.$$

(To prove (2.33) it is enough to use relations (2.35) to evaluate both sides of (2.33) for a fixed choice of the variable θ. Thus a one-variable expansion in ϕ leads to a two-variable expansion in θ and ϕ.) Now substituting the expansion (2.31) into the eigenvalue equation $\mathscr{M}\psi = \chi\psi$ and using (2.33) we find the three-term recurrence relation

$$X_1(m-1,j)\xi_{m-1} + (X_0(m,j)-\chi)\xi_m + X_{-1}(m+1,j)\xi_{m+1} = 0, \tag{2.36}$$

where $m = 0, 1, \cdots, j$. Consequently, the $j+1$ independent eigenvalues q are calculated from the determinant

(2.37)
$$\begin{vmatrix} X_0(j,j)-\chi & X_1(j-1,j) & & & \\ X_{-1}(j,j) & X_0(j-1,j)-\chi & X_1(j-2,j) & & \\ \ddots & \ddots & \ddots & & \\ & & & & \\ & & & X_{-1}(1,j) & X_0(0,j)-\chi \end{vmatrix} = 0.$$

To obtain the expansions in terms of one variable from (2.31) we proceed as follows. For the two choices of u_i, $i = 1, 2, 3$ given by (2.2) and (2.18), take $y = e_3$, $\theta = \pi/2$. Then the expression has the form

$$\Phi^1_{jq}(x) \equiv \Phi^1_{J\ell_1\ell_2\ell_3 q}(x) = \sum_{m=0}^{j} \hat{\gamma}_m P_m^{\gamma_2-1,\gamma_1-1}(\cos 2\phi), \tag{2.38}$$

where

$$\cos 2\phi = 2\frac{(x-e_1)}{(e_2-e_1)} - 1.$$

This is an expansion of type 2 with $\mu = 0$. A different type of expansion can be obtained by taking $\phi = \pi/2$ and $y = e_1$. The resulting expression has the form

$$\Phi^1_{jq}(x) = \sum_{m=0}^{j} \tilde{\gamma}_m (\sin\theta)^{2m} P_{j-m}^{2m+\gamma_1+\gamma_2-1,\ \gamma_3-1}(\cos 2\theta), \tag{2.39}$$

where

$$\cos 2\theta = -2\frac{(x-e_2)}{(e_2-e_3)} - 1.$$

In both these examples the dependence of the $\hat{\gamma}_m$ and $\tilde{\gamma}_m$ coefficients on the indices $\ell_1, \ell_2, \ell_3, q$ has been suppressed.

This second type of expansion of a Heun polynomial appears to be new. Nothing that was done in the derivation of expansions (except the limits of summation on r) could not be extended to the representation of Heun functions when $J, \ell_1, \ell_2, \ell_3$ are complex. Consequently, representations of such functions in terms of expansions whose coefficients obey three-term recurrence relations can be derived. The convergence of series of this type will be discussed elsewhere.

UNIFORM, EXPONENTIALLY IMPROVED, ASYMPTOTIC EXPANSIONS FOR THE GENERALIZED EXPONENTIAL INTEGRAL*

F. W. J. OLVER†

Abstract. By allowing the number of terms in an asymptotic expansion to depend on the asymptotic variable, it is possible to obtain an error term that is exponentially small as the asymptotic variable tends to its limit. This procedure is called "exponential improvement." It is shown how to improve exponentially the well-known Poincaré expansions for the generalized exponential integral (or incomplete Gamma function) of large argument. New uniform expansions are derived in terms of elementary functions, and also in terms of the error function.

Inter alia, the results supply a rigorous foundation for some of the recent work of M. V. Berry on a smooth interpretation of the Stokes phenomenon.

Key words. coalescing critical points, converging factors, Dingle's terminants, error function, incomplete Gamma function, Stokes' phenomenon

1. Introduction.

Suppose that a function $f(z)$ has an asymptotic expansion of the form

$$f(z)\sim f_0+\frac{f_1}{z}+\frac{f_2}{z^2}+\cdots,$$

as $z\to\infty$ in a certain region $\mathbf{R}$, say, of the complex plane. By definition, if the series is truncated at the term f_{n-1}/z^{n-1}, where n is an arbitrary fixed integer, then the error in representing $f(z)$ by the truncated series is $O(z^{-n})$ as $z\to\infty$ in $\mathbf{R}$. For some time, however, it has been known that if we permit the number of terms in the truncated series to depend on $|z|$, then it is possible to make the truncation error *exponentially* small as $z\to\infty$ in $\mathbf{R}$.

Consider, for example, the exponential integral defined by

$$E_1(z)=e^{-z}\int_0^\infty\frac{e^{-zt}}{1+t}\,dt$$

when $|\text{ph } z|<\pi/2$, and by analytic continuation elsewhere. This has the well-known expansion.

$$e^zE_1(z)\sim\sum_{s=0}^{\infty}(-)^s\frac{s!}{z^{s+1}},\qquad z\to\infty\quad\text{in }|\text{ph } z|\leqq\frac{3}{2}\pi-\delta, \tag{1.1}$$

where δ is an arbitrary positive constant. Let $R_n(z)$ denote the nth remainder term in this expansion, given by

$$e^zE_1(z)=\sum_{s=0}^{n-1}(-)^s\frac{s!}{z^{s+1}}+R_n(z). \tag{1.2}$$

In [9, Chap. 14, § 3.1] it was shown that if ζ is a real or complex variable and θ is real, then

$$R_n\{(n+\zeta)\,e^{i\theta}\}=O(n^{-1/2}\,e^{-n-\zeta}), \tag{1.3}$$

as $n \to \infty$, uniformly with respect to $\theta \in [-\pi+\delta, \pi-\delta]$ and bounded values of $|\zeta|$. Let us now restrict ζ to be real, set $z=(n+\zeta)\,e^{i\theta}$, and regard z as the asymptotic variable instead of n. Then we have

$$R_n(z) = O(z^{-1/2}\,e^{-|z|}), \qquad |z| \to \infty, \tag{1.4}$$

uniformly with respect to ph $z \in [-\pi+\delta, \pi-\delta]$ and bounded values of $\|z|-n|$. For example, (1.4) would apply if $n = \text{int}\,[|z|]$, the integer part of $|z|$. When the approximation given by (1.2) is modified in this way, that is, by taking

$$n = |z| - \zeta \tag{1.5}$$

with $|\zeta|$ bounded, we shall say that the resulting partial sum is *uniformly exponentially accurate* in the sector $|\text{ph}\, z| \leqq \pi - \delta$.

The results in [9, Chap. 14, § 3] actually go much further. The object in this reference was to provide a rigorous basis for the theory of "converging factors." In the case of the asymptotic expansion (1.1) of $E_1(z)$ it was shown that

$$R_n(z) = (-)^n \frac{n!}{z^{n+1}}\, C_n(z), \tag{1.6}$$

where the converging factor $C_n(z)$ possesses an asymptotic expansion of the form

$$C_n\{(n+\zeta)\,e^{i\theta}\} \sim \sum_{s=0}^{\infty} \frac{P_s(\alpha, \zeta)}{n^s}, \qquad n \to \infty, \tag{1.7}$$

in which the $P_s(\alpha, \zeta)$ are polynomials in $\alpha \equiv (1+e^{i\theta})^{-1}$ and ζ. Again, (1.7) is uniformly valid for $\theta \in [-\pi+\delta, \pi-\delta]$ and bounded $|\zeta|$. As before, we restrict ζ to be real and set $z=(n+\zeta)\,e^{i\theta}$. Then (1.5) applies and the combination of (1.6) and (1.7) yields

$$R_n(z) \sim (-)^n \frac{\Gamma(|z|-\zeta+1)}{z^{|z|-\zeta+1}} \sum_{s=0}^{\infty} \frac{P_s(\alpha, \zeta)}{(|z|-\zeta)^s}, \qquad |z| \to \infty.$$

On replacing the Gamma function by Stirling's series and setting $|z| = z\,e^{-i\theta}$, we see that this expansion can be rearranged as an asymptotic expansion in descending powers of z; thus

$$R_n(z) \sim (-)^n\, e^{-|z|} z^{-1/2}\, e^{(\zeta-|z|-1/2)i\theta} \sum_{s=0}^{\infty} \frac{Q_s(\theta, \zeta)}{z^s}, \qquad |z| \to \infty, \tag{1.8}$$

where the coefficients $Q_s(\theta, \zeta)$ are rational functions of $e^{i\theta}$ and polynomials in ζ. Again, this expansion is uniformly valid for ph $z \in [-\pi+\delta, \pi-\delta]$ and bounded $|\zeta|$. We call the combination of (1.2) and (1.8) a *uniform, exponentially improved* ("UEI"), or more precisely, a *uniform, $e^{-|z|}$-improved, asymptotic expansion.*

Recently, Ursell [11] has considered functions $f(z)$ representable as Laplace transforms

$$f(z) = \int_0^{\infty} e^{-zt}\, \psi(t)\, dt,$$

in which $\psi(t)$ is analytic in a neighborhood of the origin. He has shown that the asymptotic expansion of $f(z)$ obtained by straightforward application of Watson's lemma can always be rendered exponentially accurate, in the sense described above. Ursell's analysis applies only to positive real values of z, but it could be extended easily to the complex plane.

The purpose of the present investigation is to show how to construct UEI expansions for a wide class of functions. The new theory goes beyond that presented in [9, Chap. 14] in three ways: (i) the number of functions that can be treated successfully is greatly increased; (ii) nonelementary functions may be used in constructing the expansions; (iii) as a consequence of (ii), regions of validity are extended considerably.

One of the theoretical and practical consequences of this investigation is to provide a rigorous basis for a recent powerful interpretation of the Stokes phenomenon that has been developed by Berry [1]. Indeed, it was this aspect that motivated this work. This is explained fully in [10], and inter alia we shall supply proofs, and significant extensions, of all results that were stated in [10].

In the present paper we confine our attention to the construction of UEI expansions for the generalized exponential integral $E_p(z)$, when p is fixed and $|z|$ is large, both p and z being real or complex. This is because the generalized exponential integral plays a fundamental role in other cases—an observation first made by Dingle [4].

Another investigation of the generalized exponential integral (or incomplete Gamma function) has been provided by Jones. Jones' paper [6] was presented independently of and at the same time as [10]. There is substantial overlap of [6] with the present investigation, but there are significant differences in the method of proof and results achieved.

2. UEI expansions in terms of elementary functions.

2.1. General properties of the generalized exponential integral. For real or complex values of p and z, other than $z=0$, the generalized exponential integral $E_p(z)$ is defined by

$$E_p(z)=z^{p-1}\Gamma(1-p,z)=z^{p-1}\int_z^\infty \frac{e^{-t}}{t^p}\,dt. \tag{2.1}$$

The only restriction on the integration path is that it must not intersect the origin. Accordingly, unless p is a nonpositive integer, $E_p(z)$ is a multiple-valued function of z. On the other hand, $E_p(z)$ is a single-valued function of p; indeed from (2.1) it is clear that for fixed nonzero values of z each branch of $E_p(z)$ is an entire function of p.[1]

On replacing t by $z(1+t)$ we find that $E_p(z)$ is also given by

$$E_p(z)=e^{-z}\int_0^\infty \frac{e^{-zt}}{(1+t)^p}\,dt, \qquad |\mathrm{ph}\, z|<\frac{1}{2}\pi, \tag{2.2}$$

where the integration path now runs along the real axis, and $(1+t)^p$ has its principal value.

An integral representation that we shall find particularly useful is given by

$$E_p(z)=\frac{z^{p-1}e^{-z}}{\Gamma(p)}\int_0^\infty \frac{e^{-zt}t^{p-1}}{1+t}\,dt, \qquad \mathrm{Re}\, p>0, \quad |\mathrm{ph}\, z|<\frac{1}{2}\pi. \tag{2.3}$$

Again the integration path is along the real axis, and t^{p-1} and z^{p-1} assume their principal values. This result may be derived from (2.2) with the aid of the convolution formula for the Laplace transform. The integral on the right-hand side can be regarded as either a Laplace transform or a Stieltjes transform.

Other branches of $E_p(z)$ can be related to the principal branch (for which $-\pi<\mathrm{ph}\, z\leqq\pi$) by rotation of the integration path in (2.3), and analytic continuation with

[1] For the case in which p is a positive integer, various properties and some numerical tables of $E_p(z)$ will be found in [7] and [8].

respect to z. Each time the path crosses the simple pole at $t=-1$ a contribution is made by the residue. Thus we find that

$$E_p(z)=\frac{2\pi i\, e^{-kp\pi i}}{\Gamma(p)}\,\frac{\sin(kp\pi)}{\sin(p\pi)}\,z^{p-1}+E_p(z\,e^{-2k\pi i}), \tag{2.4}$$

where k is any integer. Analytic continuation removes all restrictions on p and z, other than $z=0$, from this result.

2.2. Poincaré expansions for large $|z|$. Let p be fixed and $z\to\infty$. Then by applying the extended form of Watson's lemma, as given by Theorem 3.3 of [9, Chap. 4], to the integral representation (2.2), we find that

$$E_p(z)\sim\frac{e^{-z}}{z}\sum_{s=0}^{\infty}(-)^s\frac{(p)_s}{z^s},\qquad |\mathrm{ph}\,z|\leqq\frac{3}{2}\pi-\delta, \tag{2.5}$$

where $(p)_s$ is Pochhammer's symbol for the ascending factorial $p(p+1)\cdots(p+s-1)$, and δ continues to denote an arbitrary positive constant. Corresponding expansions in other phase ranges are obtainable by combination of (2.4) and (2.5). For example, by taking $k=1$ in (2.4) we derive

$$E_p(z)\sim\frac{2\pi i\, e^{-p\pi i}}{\Gamma(p)}\,z^{p-1}+\frac{e^{-z}}{z}\sum_{s=0}^{\infty}(-)^s\frac{(p)_s}{z^s},\qquad \frac{1}{2}\pi+\delta\leqq\mathrm{ph}\,z\leqq\frac{7}{2}\pi-\delta. \tag{2.6}$$

In the common sector $\pi/2+\delta\leqq\mathrm{ph}\,z\leqq\frac{3}{2}\pi-\delta$, both (2.5) and (2.6) apply. Their apparent discrepancy is a term that is exponentially small compared with the main contribution; hence there is no anomaly. This is, of course, simply a manifestation of Stokes' phenomenon. On the ray $\mathrm{ph}\,z=\pi$, the dominance of one contribution in (2.6) over the other is maximal, and for this reason we call $\mathrm{ph}\,z=\pi$ a *Stokes line.*[2] The other Stokes lines for $E_p(z)$ for large $|z|$ occur at $\mathrm{ph}\,z=k\pi$, where k is any integer.

2.3. UEI expansions for the sector $|\mathrm{ph}\,z|\leqq\pi-\delta$. If n is an arbitrary nonnegative integer, then we have identically

$$\frac{1}{1+t}=1-t+t^2-\cdots+(-)^{n-1}t^{n-1}+(-)^n\frac{t^n}{1+t},\qquad t\neq-1. \tag{2.7}$$

On substituting this expansion in (2.3) and integrating term by term, we obtain the following explicit representation of the remainder term in (2.5):

$$E_p(z)=\frac{e^{-z}}{z}\sum_{s=0}^{n-1}(-)^s\frac{(p)_s}{z^s}+(-)^n\frac{2\pi}{\Gamma(p)}\,z^{p-1}F_{n+p}(z), \tag{2.8}$$

where

$$F_{n+p}(z)=\frac{e^{-z}}{2\pi}\int_0^{\infty}\frac{e^{-zt}t^{n+p-1}}{1+t}\,dt=\frac{\Gamma(n+p)}{2\pi}\,\frac{E_{n+p}(z)}{z^{n+p-1}}. \tag{2.9}$$

In deriving this result we have assumed that $\mathrm{Re}\,p>0$ and $|\mathrm{ph}\,z|<\pi/2$. However, by analytic continuation with respect to p the first condition is replaceable by $\mathrm{Re}\,p>-n$. To ease the second restriction, we rotate the path of integration through an angle $-\gamma$,

[2] Sometimes the name anti-Stokes line is used instead; see the discussion on p. 518 of [9].

where $-\pi<\gamma<\pi$, and set $t=\tau e^{-i\gamma}$. Then by analytic continuation with respect to z we have

$$F_{n+p}(z)=\frac{e^{-i(n+p)\gamma}\,e^{-z}}{2\pi}\int_0^\infty \frac{\exp(-z\tau e^{-i\gamma})\tau^{n+p-1}}{1+\tau e^{-i\gamma}}\,d\tau, \tag{2.10}$$

valid when $\operatorname{Re} p>-n$ and $|\operatorname{ph}(z e^{-i\gamma})|<\pi/2$.

For future reference we also record here the continuation formula for $F_{n+p}(z)$ corresponding to (2.4). This is given by

$$F_{n+p}(z)=(-)^n i\,e^{-kp\pi i}\frac{\sin(kp\pi)}{\sin(p\pi)}+e^{-2kp\pi i}F_{n+p}(z e^{-2k\pi i}), \tag{2.11}$$

$k=0,\pm1,+2,\cdots$.

The ratio of the $(s+1)$st term to the sth term in (2.5) is $(1-p-s)/z$. In consequence, when $|z|$ is large compared with $|p|$, the optimum number of terms (that is, the number of terms preceding the numerically smallest term) is $\operatorname{int}[\hat{n}]+1$, where $\hat{n}$ is the positive number satisfying $|p+\hat{n}|=|z|$. Accordingly, we set

$$z=\rho e^{i\theta},\qquad n=\rho-p+\alpha, \tag{2.12}$$

where ρ is a large positive parameter, θ is real and $|\alpha|$ is bounded.[3] With $\gamma=\theta$ in (2.10), we have

$$F_{n+p}(z)=\frac{e^{-i(\rho+\alpha)\theta}\,e^{-z}}{2\pi}\int_0^\infty \frac{e^{-\rho\tau}\tau^{\rho+\alpha-1}}{1+\tau e^{-i\theta}}\,d\tau, \tag{2.13}$$

valid when $-\pi<\theta<\pi$ and $\operatorname{Re}(\rho+\alpha)>0$.

For large ρ the integrand has a saddlepoint at $\tau=1$. By application of Theorem 7.1 of [9, Chap. 4] (Laplace's method) and use of the second of (2.12) we find that

$$F_{n+p}(z)\sim\frac{e^{-i(\rho+\alpha)\theta}}{1+e^{-i\theta}}\frac{e^{-\rho-z}}{(2\pi\rho)^{1/2}}\sum_{s=0}^{\infty}\frac{a_{2s}(\theta,\alpha)}{\rho^s},\qquad \rho\to\infty, \tag{2.14}$$

where the coefficients $a_{2s}(\theta,\alpha)$ are continuous functions of θ and α. Moreover, by means of a straightforward extension of the proof of the cited theorem, we can prove that the expansion (2.14) holds uniformly with respect to θ and α, when $\theta\in[-\pi+\delta,\pi-\delta]$ and $|\alpha|$ is bounded.

The combination of (2.8), (2.12), and (2.14) is the required expansion. It is a UEI expansion throughout its sector of validity $|\operatorname{ph} z|\leqq\pi-\delta$, because if the series in (2.14) is truncated at its mth term, where m is arbitrary, but fixed, then the relative error in the resulting approximation to $E_p(z)$ is uniformly $O(z^{p-m-1/2}e^{-|z|})$.

The coefficients $a_{2s}(\theta,\alpha)$ are calculable in the usual manner (see, for example, [9, Chap. 3, § 8.1]). One way to express them is found to be

$$a_{2s}(\theta,\alpha)=1\cdot3\cdot5\cdots(2s-1)\sum_{j=0}^{2s}\lambda_{2s-1,j-1}A_j(\theta,\alpha), \tag{2.15}$$

where

$$A_s(\theta,\alpha)=\sum_{j=0}^{s}(-)^j\binom{\alpha}{s-j}\frac{1}{(1+e^{i\theta})^j}, \tag{2.16}$$

[3] This α is unrelated to the α of § 1.

and $\lambda_{s,j}$ is the coefficient of x^s in the expansion of t^j, t being related to x via

$$\tfrac{1}{2}x^2 = t - \ln(1+t) = \tfrac{1}{2}t^2 - \tfrac{1}{3}t^3 + \tfrac{1}{4}t^4 - \cdots,$$

with $x \sim t$ as $t \to 0$. Reversion of the last expansion yields

$$t = x + \tfrac{1}{3}x^2 + \tfrac{1}{36}x^3 - \tfrac{1}{270}x^4 + \tfrac{1}{4320}x^5 + \cdots, \tag{2.17}$$

and with the aid of this result we arrive at the following explicit expressions for the first three coefficients:

$$\begin{aligned} &a_0(\theta, \alpha) = 1, \qquad a_2(\theta, \alpha) = \tfrac{1}{12} + A_2(\theta, \alpha), \\ &a_4(\theta, \alpha) = \tfrac{1}{288} + \tfrac{1}{12}A_2(\theta, \alpha) + 2A_3(\theta, \alpha) + 3A_4(\theta, \alpha). \end{aligned} \tag{2.18}$$

2.4. Remarks. (i) From (2.15), (2.16), and (2.18) we observe that the coefficients $a_{2s}(\theta, \alpha)$ become unbounded as $\theta \to \pm\pi$; in consequence, the interval of validity $|\theta| \leqq \pi - \delta$ of (2.14) is maximal.

(ii) The expansion (2.14) can be rearranged as an expansion for the converging factor in descending powers of n, as indicated in § 1. The writer has verified that in the case where $p = 1$ the first three coefficients in the resulting expansion agree with those found in [9, Chap. 14, § 3.2] by quite different methods. (They are also simpler in form than their counterparts in (2.14).)

(iii) In [10] the function

$$T_{n+p}(z) = e^{(n+p)\pi i}\frac{\Gamma(n+p)}{2\pi i}\frac{E_{n+p}(z)}{z^{n+p-1}}$$

played the role of $F_{n+p}(z)$. An advantage of using $F_{n+p}(z)$ in the present paper is that it leads to a symmetric form for the main result; compare (5.10) and (5.11) below.

3. Nonelementary UEI expansions: formal derivation.

3.1. Approach. The region of validity of the UEI expansion of § 2 falls short of the Stokes lines at ph $z = \pm\pi$. We now seek UEI expansions that hold uniformly in sectors containing these lines. To begin with, we concentrate on the sector $0 < \text{ph } z < 2\pi$.

The essential difficulty is that the integrand in (2.13) has a saddlepoint at $\tau = 1$ and a simple pole at $\tau = -e^{i\theta}$, and these points coincide as $\theta \to \pi$. To overcome this difficulty we use a modification of Laplace's method introduced by van der Waerden [12] and developed subsequently by Jones [5] and Bleistein [2]. This yields an expansion involving a nonelementary function, namely, the complementary error function.

3.2. Transformation of integration variable. We employ a quadratic change of integration variable, given by

$$\tfrac{1}{2}w^2 = \tau - \ln\tau - 1. \tag{3.1}$$

The saddlepoint at $\tau = 1$ then corresponds to $w = 0$. We resolve the ambiguity in the choice of branch of $(2\tau - 2\ln\tau - 2)^{1/2}$ by requiring

$$w \sim \tau - 1 \quad \text{as } \tau \to 1. \tag{3.2}$$

Let $\mathbf{\Delta}$ denote the sector $|\text{ph } \tau| < \pi$ and $\mathbf{W}$ be its map in the w-plane. The mapping is easily determined by passage through the intermediate variable v, given by

$$v = \tau - \ln\tau - 1, \qquad w = \sqrt{2v}.$$

Corresponding points in the τ and w planes are indicated in Figs. 1 and 2. $\mathbf{W}$ is the unshaded region shown in Fig. 2; its boundaries are the curves C_1D_1 and C_2D_2 defined parametrically by

$$\tfrac{1}{2}w^2 = -\sigma - \ln\sigma \mp i\pi - 1, \qquad 0 \leqq \sigma < \infty.$$

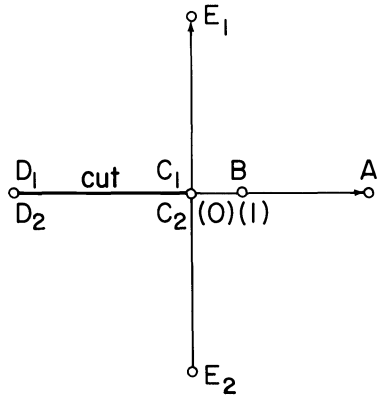

FIG. 1. *τ-plane*: *domain* **Δ**.

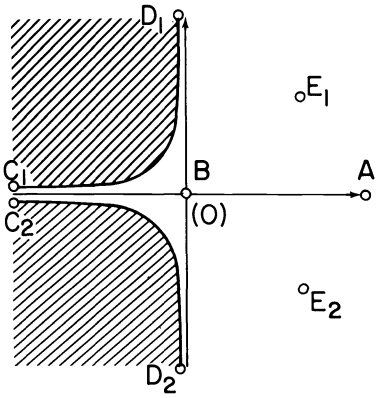

FIG. 2. *w-plane*: *domain* **W**.

From these diagrams and the corresponding map in the v-plane (not illustrated), it is clear that the mapping between the domains **Δ** and **W** is one-to-one, and that τ and w are analytic functions of each other when $\tau \in \mathbf{\Delta}$ and $w \in \mathbf{W}$.

In the w-plane, the pole at $\tau = e^{i(\theta-\pi)}$ corresponds to $w = -ic(\theta)$, say, where

$$\tfrac{1}{2}\{c(\theta)\}^2 = -e^{i(\theta-\pi)} + i(\theta-\pi) + 1. \tag{3.3}$$

In consequence of (3.2) we have

$$c(\theta) \sim -(\theta-\pi) \quad \text{as } \theta \to \pi; \tag{3.4}$$

in fact, the Taylor series expansion of $c(\theta)$ at $\theta = \pi$ begins

$$c(\theta) = -(\theta-\pi) - \frac{i}{6}(\theta-\pi)^2 + \frac{1}{36}(\theta-\pi)^3 + \cdots. \tag{3.5}$$

Graphs of $\frac{1}{2}\{c(\theta)\}^2$ and $c(\theta)$ are indicated in Figs. 3 and 4.[4]

Now consider formula (2.13). This was obtained by rotation of the path of integration in (2.9) and analytic continuation with respect to z, and is valid when

[4] Although in this section we consider only values of θ in the interval $(0, 2\pi)$, the graphs of $\frac{1}{2}\{c(\theta)\}^2$ and $c(\theta)$ are shown for the more extensive range $[-\pi, 3\pi]$ for subsequent reference. The reader should also note that the scales of Figs. 2, 3, and 4 are not the same.

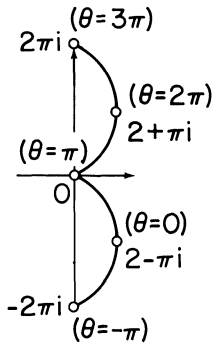

FIG. 3. $\frac{1}{2}\{c(\theta)\}^2$-*plane.*

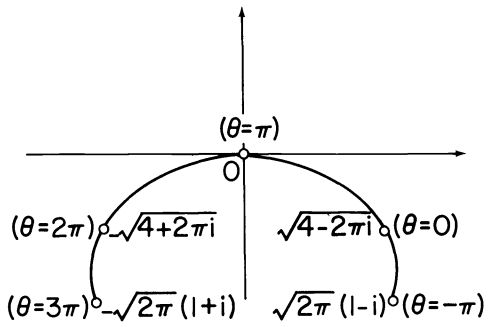

FIG. 4. $c(\theta)$-*plane.*

$-\pi < \theta < \pi$. However, an extension of this process shows that (2.13) continues to be valid when $\pi \leqq \theta < 2\pi$, as long as the integration path in (2.13) is deformed to pass above the pole at $\tau = e^{i(\theta-\pi)}$. In the w-plane this pole is mapped onto the point $w = -ic(\theta)$. In consequence, on transforming variables from τ to w in (2.13), we obtain

$$F_{n+p}(z) = \frac{e^{-i(\rho+\alpha)\theta}\, e^{-\rho-z}}{2\pi} \int_{-\infty}^{\infty} \exp\left(-\frac{1}{2}\rho w^2\right) \frac{f(\theta, \alpha, w)}{w + ic(\theta)}\, dw, \qquad 0 < \theta < 2\pi, \tag{3.6}$$

where[5]

$$f(\theta, \alpha, w) = \frac{w + ic(\theta)}{1 + \tau e^{-i\theta}}\, \tau^{\alpha-1} \frac{d\tau}{dw}, \tag{3.7}$$

and the path is indented to pass above the point $w = -ic(\theta)$ when $\theta \geqq \pi$.

3.3. Formal expansion of the transformed integral. The function $f(\theta, \alpha, w)$ is analytic at $w = -ic(\theta)$, and we may therefore set

$$f(\theta, \alpha, w) = f\{\theta, \alpha, -ic(\theta)\}[1 - \{w + ic(\theta)\}g(\theta, \alpha, w)], \tag{3.8}$$

where $g(\theta, \alpha, w)$ is analytic throughout **W**, including $w = -ic(\theta)$. On substituting this

[5] The reader is cautioned that several notational changes have been made from the earlier paper [10]. For example, c has become $-c(\theta)$, and to obtain the new $f(\theta, \alpha, w)$ from that of [10] it is necessary to replace θ and w by $\theta - \pi$ and $w + ic(\theta)$, respectively, and then multiply the result by $e^{i\alpha(\theta-\pi)}$.

expression for $f(\theta, \alpha, w)$ into (3.6), we obtain

$$F_{n+p}(z) = \frac{e^{-i(\rho+\alpha)\theta}\, e^{-\rho-z}}{2\pi} f\{\theta, \alpha, -ic(\theta)\} \cdot \left\{ \int_{-\infty}^{\infty} \frac{\exp\left(-\frac{1}{2}\rho w^2\right)}{w + ic(\theta)}\, dw - \int_{-\infty}^{\infty} \exp\left(-\frac{1}{2}\rho w^2\right) g(\theta, \alpha, w)\, dw \right\}. \tag{3.9}$$

The first integral in the right-hand side of the last equation is evaluable in terms of the complementary error function:

$$\int_{-\infty}^{\infty} \frac{\exp\left(-\frac{1}{2}\rho w^2\right)}{w + ic(\theta)}\, dw = -\pi i \exp\left(\frac{1}{2}\rho\{c(\theta)\}^2\right) \operatorname{erfc}\left\{ c(\theta) \sqrt{\frac{1}{2}\rho} \right\}. \tag{3.10}$$

In the second integral the path may be taken to be a straight line, since the integrand is analytic in $\mathbf{W}$. We may expand $g(\theta, \alpha, w)$ in a Taylor series centered on the transformed saddlepoint at the origin, in the form

$$g(\theta, \alpha, w) = \sum_{s=0}^{\infty} g_s(\theta, \alpha) w^s, \tag{3.11}$$

and on multiplying by $\exp\left(-\frac{1}{2}\rho w^2\right)$ and integrating formally term by term, we arrive at

$$\int_{-\infty}^{\infty} \exp\left(-\frac{1}{2}\rho w^2\right) g(\theta, \alpha, w)\, dw \sim \sum_{s=0}^{\infty} \Gamma\left(s + \frac{1}{2}\right) g_{2s}(\theta, \alpha) \left(\frac{2}{\rho}\right)^{s+1/2}. \tag{3.12}$$

Lastly, the value of $f\{\theta, \alpha, -ic(\theta)\}$ is found by letting $\tau \to e^{i(\theta-\pi)}$ in (3.7); thus

$$f\{\theta, \alpha, -ic(\theta)\} = -e^{i\alpha(\theta-\pi)}. \tag{3.13}$$

Combination of (3.9), (3.10), (3.12), and (3.13), followed by use of (3.3) and (2.12) yields the desired expansion in the form

$$F_{n+p}(z) \sim (-)^n i\, e^{-p\pi i} \left[\frac{1}{2} \operatorname{erfc}\left\{ c(\theta) \sqrt{\frac{1}{2}\rho} \right\} - i \frac{\exp\left(-\frac{1}{2}\rho\{c(\theta)\}^2\right)}{(2\pi\rho)^{1/2}} \sum_{s=0}^{\infty} \left(\frac{1}{2}\right)_s g_{2s}(\theta, \alpha) \left(\frac{2}{\rho}\right)^s \right]. \tag{3.14}$$

To evaluate the coefficients $g_{2s}(\theta, \alpha)$, we find by reversion of (3.1)

$$\tau = 1 + w + \frac{1}{3} w^2 + \frac{1}{36} w^3 - \frac{1}{270} w^4 + \frac{1}{4320} w^5 + \cdots;$$

compare (2.17). We now substitute this Maclaurin expansion into the formula

$$g(\theta, \alpha, w) = e^{i\alpha(\pi-\theta)} \frac{\tau^{\alpha-1}}{1 + \tau e^{-i\theta}} \frac{d\tau}{dw} + \frac{1}{w + ic(\theta)} \tag{3.15}$$

obtained from (3.7), (3.8), and (3.13), and identify the coefficient of w^{2s} on the right-hand side of (3.11). For example, the first one is found to be

$$g_0(\theta, \alpha) = \frac{e^{i\alpha(\pi-\theta)}}{1 + e^{-i\theta}} - \frac{i}{c(\theta)}, \tag{3.16}$$

the right-hand side being replaced by its limiting value

$$g_0(\pi, \alpha) = \tfrac{2}{3} - \alpha, \tag{3.17}$$

when $\theta = \pi$.

In the next two sections we shall establish the asymptotic nature of the formal series (3.14), and determine its maximum region of validity in the z-plane. At the same time, we shall supply another way of calculating the coefficients $g_{2s}(\theta, \alpha)$.

4. Proof of the validity of the expansion (3.14) when $\delta \leqq \text{ph } z \leqq 2\pi - \delta$.

4.1. Objective. In this section we shall show that if the infinite series in the expansion (3.14) is truncated at the term $s = m-1$, say, where m is any fixed integer, then the difference between the resulting approximation and $F_{n+p}(z)$ is $\exp[-\frac{1}{2}\rho\{c(\theta)\}^2]O(\rho^{-m-1/2})$ as $\rho \to \infty$, uniformly with respect to θ and α. The method of proof is similar to that used in [9, Chap. 9, §§ 9-13].

4.2. Bounds for the coefficients $g_s(\theta, \alpha)$. A preliminary step is to prove that as s increases, the rate of growth of the coefficients $g_s(\theta, \alpha)$ is uniformly algebraic.

Referring to (3.11) and applying Cauchy's integral formula for the derivatives of an analytic function, we have

$$g_s(\theta, \alpha) = \frac{1}{s!}\left[\frac{d^s g(\theta, \alpha, w)}{dw^s}\right]_{w=0} = \frac{1}{2\pi i}\int_{\mathcal{W}} \frac{g(\theta, \alpha, w)}{w^{s+1}}\, dw,$$

where $\mathcal{W}$ is any simple closed contour that encloses the origin and lies within $\mathbf{W}$ (Fig. 2). Let us also require $\mathcal{W}$ to enclose the point $-ic(\theta)$. Then we may substitute in the last integral by means of (3.15) to obtain

$$g_s(\theta, \alpha) = \frac{e^{i\alpha(\pi-\theta)}}{2\pi i}\int_{\mathcal{T}} \frac{1}{w^{s+1}} \frac{\tau^{\alpha-1}}{1+\tau e^{-i\theta}}\, d\tau + \frac{1}{2\pi i}\int_{\mathcal{W}} \frac{dw}{w^{s+1}\{w+ic(\theta)\}}, \tag{4.1}$$

where $\mathcal{T}$ is the map of $\mathcal{W}$ in the τ-plane.

By hypothesis, $\theta \in [\delta, 2\pi - \delta]$. In consequence, we can construct a simple closed contour that (i) lies in the domain $\mathbf{\Delta}$ (Fig. 1); (ii) is independent of θ; (iii) has the arc $\tau = e^{i(\theta-\pi)}$, $\delta \leqq \theta \leqq 2\pi - \delta$, in its interior. We take $\mathcal{T}$ to be this contour and $\mathcal{W}$ its w-map. Let (i) $2\pi l_1$ and $2\pi l_2$ denote the lengths of $\mathcal{T}$ and $\mathcal{W}$, respectively; (ii) M be the maximum value of $|\tau^{\alpha-1}/(1+\tau e^{-i\theta})|$ when $\tau \in \mathcal{T}$, $\theta \in [\delta, 2\pi - \delta]$ and α ranges over its (bounded) set of values; (iii) d be the minimum value of $|w+ic(\theta)|$ when $w \in \mathcal{W}$ and $\theta \in [\delta, 2\pi - \delta]$. Clearly, l_1, l_2, M are finite, and $d > 0$. Since $c(\pi) = 0$, it is also clear that $|w| \geqq d$ when $w \in \mathcal{W}$. Majorizing the two integrals on the right-hand side of (4.1) by use of these bounds, we find that

$$|g_s(\theta, \alpha)| \leqq \frac{l_1 M e^{(\pi-\delta)|\operatorname{Im}\alpha|}}{d^{s+1}} + \frac{l_2}{d^{s+2}} \leqq \frac{A}{d^s}, \tag{4.2}$$

where A is assignable independently of θ and α.

4.3. Bounding the error term. Let m be an arbitrary nonnegative integer, and define $\phi_{2m}(\theta, \alpha, w)$ by the equation

$$g(\theta, \alpha, w) = \sum_{s=0}^{2m-1} g_s(\theta, \alpha) w^s + w^{2m}\phi_{2m}(\theta, \alpha, w); \tag{4.3}$$

compare (3.11). Correspondingly, in (3.14) we have

$$F_{n+p}(z) = (-)^n i\, e^{-p\pi i}\left[\frac{1}{2}\operatorname{erfc}\left\{c(\theta)\sqrt{\frac{1}{2}\rho}\right\} - i\frac{\exp(-\frac{1}{2}\rho\{c(\theta)\}^2)}{(2\pi\rho)^{1/2}} \cdot \left\{\sum_{s=0}^{m-1}\left(\frac{1}{2}\right)_s g_{2s}(\theta, \alpha)\left(\frac{2}{\rho}\right)^s + \Phi_m(\theta, \alpha, \rho)\right\}\right], \tag{4.4}$$

where

$$\Phi_m(\theta, \alpha, \rho) = \sqrt{\frac{\rho}{2\pi}} \int_{-\infty}^{\infty} \exp\left(-\frac{1}{2}\rho w^2\right) w^{2m} \phi_{2m}(\theta, \alpha, w)\, dw. \tag{4.5}$$

Suppose first that $-d/2 \leqq w \leqq d/2$, where d is defined in § 4.2. Then using (4.2) we see that

$$|\phi_{2m}(\theta, \alpha, w)| = \left| \sum_{s=2m}^{\infty} g_s(\theta, \alpha) w^{s-2m} \right| \leqq \frac{2A}{d^{2m}}.$$

Hence

$$\begin{aligned} &\left| \int_{-d/2}^{d/2} \exp\left(-\frac{1}{2}\rho w^2\right) w^{2m} \phi_{2m}(\theta, \alpha, w)\, dw \right| \\ &\quad < \frac{2A}{d^{2m}} \int_{-\infty}^{\infty} \exp\left(-\frac{1}{2}\rho w^2\right) w^{2m}\, dw = O\left(\frac{1}{\rho^{m+1/2}}\right). \end{aligned} \tag{4.6}$$

Second, suppose that $d/2 \leqq w < \infty$. From (3.1) we see that as $w \to +\infty$ we have $\tau \sim w^2/2$ and $d\tau/dw \sim w$. Hence

$$\frac{\tau^{\alpha-1}}{1+\tau e^{-i\theta}} \frac{d\tau}{dw} \sim 2^{2-\alpha} e^{i\theta} w^{2\alpha-3} \quad \text{uniformly as } w \to +\infty.$$

We now refer to (3.15) and bear in mind that $|1+\tau e^{-i\theta}|$ and $|w+ic(\theta)|$ each have positive lower bounds when $w \in [d/2, \infty)$ and $\theta \in [\delta, 2\pi-\delta]$; compare Figs. 1, 2, and 4. In this way we may verify that

$$|g(\theta, \alpha, w)| \leqq A w^a, \qquad \tfrac{1}{2}d \leqq w < \infty,$$

where

$$a = \max_{\forall \alpha} (2 \operatorname{Re} \alpha - 3, -1), \tag{4.7}$$

and we are now using the symbol A generically to denote a finite constant that is independent of θ and α. Substituting into (4.3) by means of this result and (4.2), we conclude that when $m \geqq a/2$ we have

$$|\phi_{2m}(\theta, \alpha, w)| \leqq A, \qquad \tfrac{1}{2}d \leqq w < \infty.$$

Hence

$$\begin{aligned} &\left| \int_{d/2}^{\infty} \exp\left(-\frac{1}{2}\rho w^2\right) w^{2m} \phi_{2m}(\theta, \alpha, w)\, dw \right| \\ &\quad \leqq A \int_{0}^{\infty} \exp\left(-\frac{1}{2}\rho w^2\right) w^{2m}\, dw = O\left(\frac{1}{\rho^{m+1/2}}\right). \end{aligned} \tag{4.8}$$

Lastly, suppose that $-\infty < w \leqq -d/2$. From (3.1) we see that if $w \to -\infty$, then $\tau \sim \exp(-w^2/2 - 1)$ and $d\tau/dw \sim -w\tau$. Hence

$$\frac{\tau^{\alpha-1}}{1+\tau e^{-i\theta}} \frac{d\tau}{dw} \sim -w\tau^{\alpha} \sim -w \exp\left\{-\alpha\left(\frac{1}{2}w^2 + 1\right)\right\},$$

uniformly, and therefore from (3.15) we have

$$|g(\theta, \alpha, w)| \leqq A|w|\, e^{bw^2}, \qquad -\infty < w \leqq -\tfrac{1}{2}d,$$

where

$$b = \max_{\forall \alpha} (-\tfrac{1}{2} \operatorname{Re} \alpha, 0); \tag{4.9}$$

compare (4.7). Substituting in (4.3) by means of this result and (4.2), we conclude that when $m \geqq 1$ we have

$$|\phi_{2m}(\theta, \alpha, w)| \leqq A\, e^{bw^2}, \qquad -\infty < w \leqq -\tfrac{1}{2} d.$$

Hence if, also, $\rho > 2b$ we have

$$\left| \int_{-\infty}^{-d/2} \exp\left(-\frac{1}{2}\rho w^2\right) w^{2m} \phi_{2m}(\theta, \alpha, w)\, dw \right| \leqq A \int_{-\infty}^{0} \exp\left\{-\left(\frac{1}{2}\rho - b\right) w^2\right\} w^{2m}\, dw = O\left(\frac{1}{\rho^{m+1/2}}\right). \tag{4.10}$$

On combining (4.5), (4.6), (4.8), and (4.10), we conclude that the error term in the expansion (4.4) satisfies

$$\Phi_m(\theta, \alpha, \rho) = O(\rho^{-m}), \qquad \rho \to \infty, \tag{4.11}$$

uniformly with respect to $\theta \in [\delta, 2\pi - \delta]$ and bounded values of $|\alpha|$. This is the desired result.

4.4. Remark. The significance of the results established in this section apropos the Stokes phenomenon is as follows. From Fig. 4 it is seen that $\xi \equiv c(\theta)\sqrt{\rho/2}$ lies in the sector $-\pi/4 \leqq \text{ph}\, \xi \leqq 0$ when $-\pi \leqq \theta \leqq \pi$, and in the sector $0 \leqq \text{ph}\,(-\xi) \leqq \pi/4$ when $\pi \leqq \theta \leqq 3\pi$. It is well known that $\text{erfc}\,(\xi) = O(e^{-\xi^2})$ uniformly throughout the first sector, and $\text{erfc}\,(\xi) = 2 + O(e^{-\xi^2})$ uniformly throughout the second sector (see, for example, [9, Chaps. 2-4]). In consequence, if ρ is large and fixed and θ increases continuously from values just below π to values just above π, then $\frac{1}{2}\,\text{erfc}\,\{c(\theta)\sqrt{\rho/2}\}$ changes rapidly, but smoothly, from being exponentially small to being exponentially close to 1. From (4.2) and (4.11) it is easily seen that the same conclusion also applies to the whole content of the square brackets in (4.4). On substituting into (2.8) by means of this result we perceive that if $|z|$ is large and the asymptotic expansion (2.5) is truncated at its optimum number of terms, then there is a rapid, *but smooth*, transition to the form (2.6) in the neighborhood of $\text{ph}\, z = \pi$. Berry described the Stokes phenomenon in this illuminating manner in [1], but his analysis was purely formal. The present investigation serves to place Berry's conclusions on a rigorous basis—in the case of the generalized exponential integral. For further details concerning this aspect see [10].

5. Main results and conclusions.

5.1. Comparison of the expansions of §§ 2 and 4; formulae for the coefficients $g_{2s}(\theta, \alpha)$. Let us summarize the results obtained so far. Setting $z = \rho\, e^{i\theta}$, $n = \rho - p + \alpha$ and defining $F_{n+p}(z)$ by (2.8), we proved in § 2 that

$$F_{n+p}(z) \sim \frac{e^{-i(\rho+\alpha)\theta}}{1 + e^{-i\theta}} \frac{e^{-\rho - z}}{(2\pi\rho)^{1/2}} \sum_{s=0}^{\infty} \frac{a_{2s}(\theta, \alpha)}{\rho^s}, \qquad \rho \to \infty, \tag{5.1}$$

uniformly with respect to bounded $|\alpha|$ and $\theta \in [-\pi + \delta, \pi - \delta]$, δ being an arbitrary positive constant. In §§ 3 and 4, we proved that

$$F_{n+p}(z) \sim (-)^n i\, e^{-p\pi i}\left[\frac{1}{2}\,\text{erfc}\left\{c(\theta)\sqrt{\frac{1}{2}\rho}\right\} - i\frac{\exp\left(-\frac{1}{2}\rho\{c(\theta)\}^2\right)}{(2\pi\rho)^{1/2}} \sum_{s=0}^{\infty} \left(\frac{1}{2}\right)_s g_{2s}(\theta, \alpha)\left(\frac{2}{\rho}\right)^s\right] \tag{5.2}$$

as $\rho \to \infty$, uniformly with respect to bounded $|\alpha|$ and $\theta \in [\delta, 2\pi - \delta]$; here $c(\theta)$ is defined as in § 3.2.

Now consider the common sector of validity, given by $\delta \leqq \theta \leqq \pi - \delta$. From Fig. 4 we see that $c(\theta)$ lies in the fourth quadrant of $\mathbb{C}$ and is bounded away from the origin. We may therefore replace $\frac{1}{2}\operatorname{erfc}\{c(\theta)\sqrt{\rho/2}\}$ by an asymptotic expansion in descending powers of $c(\theta)\sqrt{\rho/2}$ that is appropriate for this region. This is given by[6]

$$\frac{1}{2}\operatorname{erfc}\left\{c(\theta)\sqrt{\frac{1}{2}\rho}\right\} \sim \frac{\exp\left(-\frac{1}{2}\rho\{c(\theta)\}^2\right)}{c(\theta)(2\pi\rho)^{1/2}} \sum_{s=0}^{\infty} (-)^s \frac{(\frac{1}{2})_s}{\{c(\theta)\}^{2s}} \left(\frac{2}{\rho}\right)^s, \tag{5.3}$$

this result being uniformly valid with respect to θ in an interval that includes $[\delta, \pi - \delta]$. Substitution into (5.2) yields

$$\begin{aligned} F_{n+p}(z) \sim (-)^n i\, e^{-p\pi i} & \frac{\exp\left(-\frac{1}{2}\rho\{c(\theta)\}^2\right)}{(2\pi\rho)^{1/2}} \\ & \cdot \left\{ \sum_{s=0}^{\infty} (-)^s \frac{(\frac{1}{2})_s}{\{c(\theta)\}^{2s+1}} \left(\frac{2}{\rho}\right)^s - i \sum_{s=0}^{\infty} \left(\frac{1}{2}\right)_s g_{2s}(\theta, \alpha) \left(\frac{2}{\rho}\right)^s \right\}. \end{aligned} \tag{5.4}$$

We also observe from (2.12) and (3.3) that (5.1) may be recast in the form

$$F_{n+p}(z) \sim (-)^n\, e^{-p\pi i} \frac{e^{i\alpha(\pi-\theta)}}{1+e^{-i\theta}} \frac{\exp\left(-\frac{1}{2}\rho\{c(\theta)\}^2\right)}{(2\pi\rho)^{1/2}} \sum_{s=0}^{\infty} \frac{a_{2s}(\theta, \alpha)}{\rho^s}. \tag{5.5}$$

We now have two uniform asymptotic expansions of the same function in descending powers of ρ. They must therefore be identical. Equating coefficients, we conclude that

$$g_{2s}(\theta, \alpha) = \frac{e^{i\alpha(\pi-\theta)}}{1+e^{-i\theta}} \frac{a_{2s}(\theta, \alpha)}{1 \cdot 3 \cdots (2s-1)} + \frac{(-)^{s-1} i}{\{c(\theta)\}^{2s+1}}, \qquad s = 0, 1, 2, \cdots. \tag{5.6}$$

Analytic continuation extends this formula to all values of θ, other than odd multiples of π; furthermore, at $\theta = \pi$ we may replace the right-hand side by its limiting value.

With the aid of the formula $a_0(\theta, \alpha) = 1$ given at the end of § 2.3, we immediately perceive that (5.6) agrees with (3.16) in the case $s = 0$. For other values of s, formula (5.6) provides a convenient way of evaluating $g_{2s}(\theta, \alpha)$.

5.2. Extending the sector of validity. In expanding the error function that appears in (5.2) in the form (5.3), we considered only values of θ in the interval $[\delta, \pi - \delta]$. However, from Figs. 3 and 4 it is clear that (5.3) continues to be uniformly valid in an interval that includes $[-\pi + \delta, \pi - \delta]$. Since this again leads to an expansion, namely (5.5), that is known to be valid in this larger interval, it follows that (5.2) itself must be uniformly valid in this interval.

By symmetry, we also expect (5.2) to be valid in the interval $[\pi + \delta, 3\pi - \delta]$. And this can be verified by expanding the complementary error function in (5.2) in a form appropriate for this sector, and comparing the result with the expansion

$$F_{n+p}(z) \sim (-)^n i\, e^{-p\pi i} + \frac{e^{-i(\rho+\alpha)\theta}}{1+e^{-i\theta}} \frac{e^{-\rho-z}}{(2\pi\rho)^{1/2}} \sum_{s=0}^{\infty} \frac{a_{2s}(\theta, \alpha)}{\rho^s}, \qquad \pi + \delta \leqq \theta \leqq 3\pi - \delta, \tag{5.7}$$

obtained from (2.11), with $k = 1$, and (5.1).[7]

5.3. Main theorem. Another expansion for $F_{n+p}(z)$ can be obtained from (5.2) by replacing p and z by their complex conjugates, and then taking the conjugate of the whole result. On combining all the expansions obtained so far we arrive at the following theorem.

---

[6] See, for example, [9, pp. 67, 112].

[7] In deriving (5.7), we also need to use (2.12) and the fact that $a_{2s}(\theta, \alpha)$ is periodic in θ, with period 2π.

THEOREM 1. *Let*

$$z=\rho e^{i\theta}, \qquad n=\rho-p+\alpha, \tag{5.8}$$

and define $c(\theta)$ *by* (3.3), (3.4), *and* $g_{2s}(\theta,\alpha)$ *by* (5.6), (2.15), (2.16). *Then*

$$E_p(z)=\frac{e^{-z}}{z}\sum_{s=0}^{n-1}(-)^s\frac{(p)_s}{z^s}+(-)^n\frac{2\pi}{\Gamma(p)}z^{p-1}F_{n+p}(z), \tag{5.9}$$

where for fixed p *and large* $|z|$

$$F_{n+p}(z)\sim(-)^n i\,e^{-p\pi i}\left[\frac{1}{2}\operatorname{erfc}\left\{c(\theta)\sqrt{\frac{1}{2}\rho}\right\}-i\frac{\exp\left(-\frac{1}{2}\rho\{c(\theta)\}^2\right)}{(2\pi\rho)^{1/2}}\sum_{s=0}^{\infty}\left(\frac{1}{2}\right)_s g_{2s}(\theta,\alpha)\left(\frac{2}{\rho}\right)^s\right], \tag{5.10}$$

valid when $-\pi+\delta\leqq\theta\leqq3\pi-\delta$, *and*

$$F_{n+p}(z)\sim(-)^{n-1}i\,e^{p\pi i}\left[\frac{1}{2}\operatorname{erfc}\left\{\overline{c(-\theta)}\sqrt{\frac{1}{2}\rho}\right\}+i\frac{\exp\left(-\frac{1}{2}\rho\{\overline{c(-\theta)}\}^2\right)}{(2\pi\rho)^{1/2}}\sum_{s=0}^{\infty}\left(\frac{1}{2}\right)_s \overline{g_{2s}(-\theta,\bar{\alpha})}\left(\frac{2}{\rho}\right)^s\right], \tag{5.11}$$

valid when $-3\pi+\delta\leqq\theta\leqq\pi-\delta$. *These expansions are uniform with respect to* θ *and bounded values of* $|\alpha|$; *furthermore, the* θ*-intervals of validity are maximal.*

The only part of this theorem we have not established already is the maximality of the θ-intervals of validity. However, this is an immediate consequence of the fact that the coefficients $g_{2s}(\theta,\alpha)$ become infinite as $\theta\to-\pi$ or $\theta\to3\pi$; compare (5.6) and (2.15).

5.4. Remarks. (i) If we truncate the infinite series in (5.10) at the term $s=m-1$, where m is an arbitrary fixed nonnegative integer, then the error in the resulting approximation to $F_{n+p}(z)$ is $\exp\left[-\frac{1}{2}\rho\{c(\theta)\}^2\right]z^{-m-1/2}O(1)$, that is, $e^{-z-|z|}z^{-m-1/2}O(1)$; compare (3.3) (again). On referring to the expansions (2.5) and (2.6) we see that the combination of (5.9) and (5.10) is a uniform, $e^{-|z|}$-improved, expansion (in the sense of § 1) throughout the region of validity of (5.10). Similarly, the combination of (5.9) and (5.11) is a uniform, $e^{-|z|}$-improved, expansion throughout the region of validity of (5.11).

(ii) In applications, the use of (5.10) and (5.11) can be confined to the sectors $0\leqq\operatorname{ph}z\leqq\pi$ and $-\pi\leqq\operatorname{ph}z\leqq0$, respectively, and the continuation formula (2.11) (or equivalently (2.4)) used elsewhere. Indeed, this procedure is consistent with maximum accuracy; compare the observations made in [9, Chap. 14, § 1]. However, there are two reasons we sought the maximal regions of validity of these expansions. First, these extensions show that, for example, the combination of (5.9) and (5.10) includes both (2.5) and (2.6) within most of their regions of validity. Second, the extensions complete the proof of results stated in [10, § 3] in connection with Berry's interpretation of the Stokes phenomenon.

(iii) The expansions (5.10) and (5.11) have the common interval of validity $|\operatorname{ph}z|\leqq\pi-\delta$. The two expansions are not the same here, but their discrepancy is absorbable in the implied error terms. Thus there is also a Stokes phenomenon associated with these expansions in the neighborhood of $\operatorname{ph}z=0$, and it would appear to be possible to extend the whole process to construct UEI expansions of the UEI expansions.[8]

[8] For further comments on this possibility see [3, § 4].

(iv) The most serious deficiency in the present results is a set of realistic error bounds for the expansions (5.10) and (5.11). Unfortunately, at this time this remains a general drawback to asymptotic expansions obtained from integral representations with coalescing critical points.

UNIFORM, EXPONENTIALLY IMPROVED, ASYMPTOTIC EXPANSIONS FOR THE CONFLUENT HYPERGEOMETRIC FUNCTION AND OTHER INTEGRAL TRANSFORMS*

F. W. J. OLVER†

Abstract. A new generalized asymptotic expansion is constructed for the confluent hypergeometric function $U(a, a-b+1, z)$ in which the parameters a and b are real or complex constants, and z is a large complex variable. The expansion is expressed in terms of generalized exponential integrals (or, equivalently, incomplete Gamma functions). It has a larger region of validity and greater accuracy than the conventional expansions of Poincaré type; moreover, it provides insight into the manner in which the Poincaré expansions change smoothly, albeit rapidly, from one to the other in the vicinity of the so-called Stokes lines. The expansion is accompanied by strict error bounds in the most important part of its region of validity.

The method used is quite general and can be applied to other functions that are representable as transforms of Laplace or Stieltjes type.

Key words. coalescing critical points, error bounds, generalized exponential integral, incomplete Gamma function, Laplace transform, Stieltjes transform, Stokes' phenomenon

1. Introduction and summary.

In the preceding paper [10] we investigated the generalized exponential integral $E_p(z)$, in which p and z are unrestricted real or complex variables. We began with the identity

$$E_p(z)=\frac{e^{-z}}{z}\sum_{s=0}^{n-1}(-)^s\frac{(p)_s}{z^s}+(-)^n\frac{2\pi}{\Gamma(p)}z^{p-1}F_{n+p}(z), \tag{1.1}$$

in which n is an arbitrary nonnegative integer, $(p)_s$ denotes the ascending factorial $p(p+1)\cdots(p+s-1)$, and

$$F_p(z)=\frac{\Gamma(p)}{2\pi}\frac{E_p(z)}{z^{p-1}}. \tag{1.2}$$

Writing z in polar form $z=\rho e^{i\theta}$, we were able to prove that if $\rho\to\infty$, with p fixed, then

$$\begin{aligned}F_{n+p}(z)\sim(-)^n i e^{-p\pi i}\Bigg[&\frac{1}{2}\operatorname{erfc}\left\{c(\theta)\sqrt{\frac{1}{2}\rho}\right\}\\&-i\frac{\exp(-\frac{1}{2}\rho\{c(\theta)\}^2)}{(2\pi\rho)^{1/2}}\sum_{s=0}^{\infty}\left(\frac{1}{2}\right)_s g_{2s}(\theta,\alpha)\left(\frac{2}{\rho}\right)^s\Bigg],\end{aligned} \tag{1.3}$$

uniformly with respect to $\theta\in[-\pi+\delta, 3\pi-\delta]$ and bounded values of $|\alpha|$, where $\alpha=n-\rho+p$. Here (and elsewhere) δ denotes an arbitrarily small positive constant; furthermore,

$$c(\theta)=\sqrt{2\{e^{i\theta}+i(\theta-\pi)+1\}},$$

with an appropriate choice of branch of the square root, and the coefficients $g_{2s}(\theta,\alpha)$ are continuous functions of θ and α. We also supplied a similar expansion for $F_{n+p}(z)$ when $\theta\in[-3\pi+\delta, \pi-\delta]$.

The importance of the expansion (1.3) is threefold.

First, the combination of (1.1) and (1.3) unifies the Poincaré-type expansion

$$E_p(z)\sim\frac{e^{-z}}{z}\sum_{s=0}^{\infty}(-)^s\frac{(p)_s}{z^s},\qquad \theta\in\left[-\frac{3}{2}\pi+\delta,\frac{3}{2}\pi-\delta\right], \tag{1.4}$$

and the compound expansion

$$E_p(z)\sim\frac{2\pi i\,e^{-p\pi i}}{\Gamma(p)}z^{p-1}+\frac{e^{-z}}{z}\sum_{s=0}^{\infty}(-)^s\frac{(p)_s}{z^s},\qquad \theta\in\left[\frac{1}{2}\pi+\delta,\frac{7}{2}\pi-\delta\right], \tag{1.5}$$

since these expansions can be derived from (1.1) and (1.3) by appropriate re-expansion in the common regions of validity.

Second, as a consequence of this unification, the combination of (1.1) and (1.3) accurately quantifies the Stokes phenomenon, that is, the rapid but smooth change in form from (1.4) to (1.5) as θ passes through the common interval of validity $[\pi/2+\delta, \frac{3}{2}\pi-\delta]$.

Third, in much of its region of validity the combination of (1.1) and (1.3) is more accurate than either (1.4) or (1.5), owing to the fact that it contains an extra factor $e^{-|z|}$ in its uniform error estimates. For this reason, we called the combination of (1.1) and (1.3) a *uniform, exponentially improved* (UEI), *asymptotic expansion.*

The purpose of the present paper is to furnish a general method for constructing generalized asymptotic expansions that enjoy similar properties, especially uniform exponential improvement. The functions we shall consider are representable as Laplace or Stieltjes transforms. We illustrate the method by detailed treatment of the confluent hypergeometric function defined by

$$U(a,a-b+1,z)=\frac{1}{\Gamma(a)}\int_0^{\infty}e^{-zt}t^{a-1}(1+t)^{-b}\,dt, \tag{1.6}$$

when $\operatorname{Re} a>0$ and $|\operatorname{ph} z|<\pi/2$, and by analytic continuation elsewhere. Special cases of this function include Bessel and modified Bessel functions, parabolic cylinder functions, and Airy functions. However, our method applies to a broader class of functions than those of confluent hypergeometric type.

Instead of expressing the generalized asymptotic expansions in terms of the complementary error function, as was done for the function $E_p(z)$, we find it more convenient, and elegant, to express these expansions in terms of the F_p functions. Our main result is as follows:

THEOREM 1. *Define* $R_n(a,b,z)$ *by*

$$U(a,a-b+1,z)=z^{-a}\sum_{s=0}^{n-1}(-)^s\frac{(a)_s(b)_s}{s!\,z^s}+R_n(a,b,z), \tag{1.7}$$

where

$$n=|z|-a-b+1+\alpha, \tag{1.8}$$

$|z|$ *being large,* a *and* b *being fixed real or complex parameters, and* $|\alpha|$ *being bounded. Then*

$$R_n(a,b,z)=(-)^n2\pi\frac{z^{b-1}\,e^z}{\Gamma(a)\Gamma(b)}\left\{\sum_{s=0}^{m-1}(-)^s\frac{(1-a)_s(1-b)_s}{s!}\frac{F_{n-s+a+b-1}(z)}{z^s}\right.$$
$$\left.+(1-a)_m(1-b)_mR_{m,n}(a,b,z)\right\}, \tag{1.9}$$

where m *is an arbitrary fixed integer, and*

$$R_{m,n}(a,b,z)=O(e^{-z-|z|}z^{-m}),\qquad |\operatorname{ph} z|\leqq\pi, \tag{1.10}$$

$$R_{m,n}(a,b,z)=O(z^{-m}),\qquad \pi\leqq|\operatorname{ph} z|\leqq\tfrac{5}{2}\pi-\delta. \tag{1.11}$$

Furthermore, these sectors of validity are maximal.

Theorem 1 is proved in the next four sections. In § 6 we derive a strict and realistic bound for $R_{m,n}(a, b, z)$ in the sector $|\text{ph } z| \leqq \pi$. Some general conclusions are drawn in § 7.

To conclude this Introduction we make the following observations:

(i) From (1.10) and (1.11) it is seen that the combination of (1.7) and (1.9) furnishes a uniform exponentially improved expansion in a sector that includes $|\text{ph } z| \leqq \pi$. For other phase ranges improved expansions can be constructed immediately by combining (1.7) and (1.9) with the connection formulae [4, p. 27]

$$\begin{aligned} & e^{k(a-b)\pi i} U(a, a-b+1, z e^{2k\pi i}) \\ & = \pm \frac{e^{\mp(a+b)\pi i} \sin k(a-b)\pi - \sin (k \mp 1)(a-b)\pi}{\sin (a-b)\pi} U(a, a-b+1, z) \\ & \quad + \frac{2\pi i \sin k(a-b)\pi}{\sin (a-b)\pi} \frac{e^{\mp b\pi i}}{\Gamma(a)\Gamma(b)} e^z U(1-b, a-b+1, z e^{\pm \pi i}), \end{aligned} \tag{1.12}$$

in which k is an arbitrary integer and either upper signs, or lower signs, are taken throughout.

(ii) The well-known Poincaré-type expansion

$$U(a, a-b+1, z) \sim z^{-a} \sum_{s=0}^{\infty} (-)^s \frac{(a)_s (b)_s}{s! z^s}, \qquad |\text{ph } z| \leqq \tfrac{3}{2}\pi - \delta, \tag{1.13}$$

and the two compound expansions

$$\begin{aligned} U(a, a-b+1, z) & \sim z^{-a} \sum_{s=0}^{\infty} (-)^s \frac{(a)_s (b)_s}{s! z^s} \\ & \quad \mp 2\pi i \frac{e^{\mp(a+b)\pi i}}{\Gamma(a)\Gamma(b)} z^{b-1} e^z \sum_{s=0}^{\infty} \frac{(1-a)_s (1-b)_s}{s! z^s}, \\ & |\text{ph } \{z \exp (\mp \tfrac{3}{2}\pi i)\}| \leqq \pi - \delta, \end{aligned} \tag{1.14}$$

obtained by substitution of (1.13) into (1.12), with $k = \pm 1$, can be recovered from (1.7) and (1.9) by appropriate re-expansion.

(iii) Owing to the presence of the factors $(1-a)_m$ and $(1-b)_m$ in (1.9), $R_n(a, b, z)$ can be expressed exactly as a finite combination of F_p functions when a or b is a positive integer, by taking m to be sufficiently large. Furthermore, the estimates (1.10) and (1.11) enjoy certain uniformity properties with respect to the parameters a and b. In the case of the sector $|\text{ph } z| \leqq \pi$ the last statement is verifiable by inspection of the error bound for $R_{m,n}(a, b, z)$ that is supplied in § 6 below.

(iv) The original purpose of the present paper was to supply proofs of results that were stated in [9, § 4]. In turn, the main purpose of [9] was to provide a rigorous basis for the formal researches of Berry on Stokes' phenomenon [2]. These objectives are achieved, but we go well beyond them, especially with respect to regions of validity and exponential improvement.

(v) A formal expansion of $R_n(a, b, z)$ in terms of the function $z^{n+b} e^z F_{n+b}(z)$ and its derivatives was found by Dingle [5]. This expansion is not equivalent to (1.9) and Dingle was concerned only with the sector $|\text{ph } z| < \pi$. Whether his expansion is valid in a larger sector has not been investigated, but perhaps this question is moot since our new expansion is of a simpler and more revealing form.

(vi) For work on the modified Bessel function $K_\nu(z)$ that is closely related to [9, § 4] and the present paper, see [3] and [6].

2. Representation of the remainder term as a Stieltjes transform. If, in (1.6), we rotate the path of integration through an angle $-\gamma$, γ being an arbitrary number in the interval $(-\pi, \pi)$, then we obtain the analytic continuation of $U(a, a-b+1, z)$ in the sector $|\mathrm{ph}\,(z\,e^{-i\gamma})| < \pi/2$, given by

$$U(a, a-b+1, z) = \frac{1}{\Gamma(a)} \int_0^{\infty e^{-i\gamma}} e^{-zt} t^{a-1} (1+t)^{-b}\, dt. \tag{2.1}$$

We now expand the factor $(1+t)^{-b}$ by Taylor's theorem, in the form

$$(1+t)^{-b} = \sum_{s=0}^{n-1} (-)^s \frac{(b)_s}{s!} t^s + \chi_n(b, t), \tag{2.2}$$

where n is an arbitrary nonnegative integer,

$$\chi_n(b, t) = \frac{t^n}{2\pi i} \int_{\mathscr{L}} \frac{(1+w)^{-b}}{w^n (w-t)}\, dw, \tag{2.3}$$

and $\mathscr{L}$ is a simple closed contour that encloses $w=0$ and $w=t$, but not $w=-1$ (see, for example, [1, Chap. 4, § 3.1]). On substituting into (2.1) by means of (2.2) we obtain (1.7) with the following representation of the remainder term:

$$R_n(a, b, z) = \frac{1}{\Gamma(a)} \int_0^{\infty e^{-i\gamma}} e^{-zt} t^{a-1} \chi_n(b, t)\, dt. \tag{2.4}$$

Now suppose that $\mathrm{Re}\, b + n > 0$. Then the integral of $(1+w)^{-b} w^{-n} (w-t)^{-1}$ around any large circle in the w-plane vanishes as the radius of the circle tends to infinity. Accordingly, the contour $\mathscr{L}$ in (2.3) may be deformed into the loop contour depicted in Fig. 1, giving

$$\chi_n(b, t) = \frac{t^n}{2\pi i} \int_{-\infty}^{(-1-)} \frac{(1+w)^{-b}}{w^n (w-t)}\, dw.$$

If, also, $\mathrm{Re}\, b < 1$, then the loop may be collapsed on to the interval $(-\infty, -1]$ in the usual way. Subsequent replacement of w by $-w$ yields

$$\chi_n(b, t) = (-)^n \frac{\sin(\pi b)}{\pi} t^n \int_1^{\infty} \frac{(w-1)^{-b}}{w^n (w+t)}\, dw, \tag{2.5}$$

where $(w-1)^{-b}$ has its principal value.

We now substitute in (2.4) by means of (2.5), to obtain

$$R_n(a, b, z) = (-)^n \frac{\sin(\pi b)}{\pi \Gamma(a)} \int_0^{\infty e^{-i\gamma}} e^{-zt} t^{n+a-1}\, dt \int_1^{\infty} \frac{(w-1)^{-b}}{w^n (w+t)}\, dw, \tag{2.6}$$

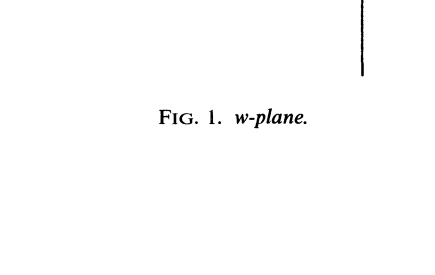

FIG. 1. *w-plane.*

where the fractional powers continue to assume their principal values. The assumptions made so far are given by $0<\operatorname{Re} a$, $-n<\operatorname{Re} b<1$, $|\operatorname{ph}(z\,e^{-i\gamma})|<\pi/2$. However, by analytic continuation with respect to a, we see that (2.4) and (2.6) remain valid when the first condition is relaxed to $-n<\operatorname{Re} a$. By absolute convergence of the repeated integrals we may interchange the order of integration (see, for example, [7, Thm. 1]). Then by replacing t by $w\tau$, we arrive at

$$R_n(a,b,z)=\frac{(-)^n\sin(\pi b)}{\pi\Gamma(a)}\int_1^\infty (w-1)^{-b}w^{a-1}\,dw\int_0^{\infty e^{-i\gamma}}\frac{e^{-zw\tau}\tau^{n+a-1}}{1+\tau}\,d\tau.$$

Provided that $\operatorname{Re} a<\operatorname{Re} b$ the order of integration may again be reversed, and on replacing w by $1+v$, we obtain the desired integral representation for the remainder term, given by

$$R_n(a,b,z)=(-)^n\frac{\sin(\pi b)}{\pi\Gamma(a)}\int_0^{\infty e^{-i\gamma}}\frac{e^{-z\tau}\tau^{n+a-1}}{1+\tau}\,d\tau\int_0^\infty e^{-z\tau v}v^{-b}(1+v)^{a-1}\,dv, \tag{2.7}$$

valid with the conditions

$$-n<\operatorname{Re} a<\operatorname{Re} b<1,\qquad |\operatorname{ph}(z\,e^{-i\gamma})|<\tfrac{1}{2}\pi. \tag{2.8}$$

Remark. A key step in the foregoing analysis is the use of Cauchy's integral formula for the remainder term in a Taylor-series expansion. Since the objective is to represent the remainder term $R_n(a,b,z)$ in the expansion (1.7) as a Stieltjes transform, applicable methods based on properties of Laplace or Stieltjes transforms, given, for example, in [11] and [12], can be used instead. This approach was used by Boyd [3] and Jones [6].

3. Proof of Theorem 1 when $|\operatorname{ph} z|\leqq\pi-\delta$. Throughout this section we continue to assume that all fractional powers take their principal values and that γ is an arbitrary constant in the interval $(-\pi,\pi)$.

Let m be an arbitrary nonnegative integer and $v\in[0,\infty)$. By Taylor's theorem we have

$$(1+v)^{a-1}=\sum_{s=0}^{m-1}(-)^s\frac{(1-a)_s}{s!}v^s+(1-a)_m v^m\phi_m(a,v), \tag{3.1}$$

where $\phi_0(a,v)=(1+v)^{a-1}$ and

$$\phi_m(a,v)=\frac{(-)^m}{(m-1)!}\int_0^1(1-t)^{m-1}(1+vt)^{a-m-1}\,dt,\qquad m\geqq 1. \tag{3.2}$$

Next, if we refer to the definition of $F_p(z)$, given by [10, (2.9)] and then apply analytic continuation with respect to z, we see that

$$F_p(z)=\frac{e^{-z}}{2\pi}\int_0^{\infty e^{-i\gamma}}\frac{e^{-zt}t^{p-1}}{1+t}\,dt,\quad \operatorname{Re} p>0,\quad |\operatorname{ph}(z\,e^{-i\gamma})|<\tfrac{1}{2}\pi. \tag{3.3}$$

Provided that $m<n+\operatorname{Re} a+\operatorname{Re} b$ we may substitute for $(1+v)^{a-1}$ by means of (3.1) in the inner integral in (2.7) and integrate term by term. On referring to (3.3) and using the reflection and recurrence formulae for the Gamma function, we arrive at (1.9) with

$$R_{m,n}(a,b,z)=\frac{z^{1-b}e^{-z}}{2\pi\Gamma(m+1-b)}\int_0^{\infty e^{-i\gamma}}\frac{e^{-z\tau}\tau^{n+a-1}}{1+\tau}\,d\tau\int_0^\infty e^{-z\tau v}v^{m-b}\phi_m(a,v)\,dv. \tag{3.4}$$

The last result has been established with the conditions $\operatorname{Re} a+\operatorname{Re} b>m-n$ and (2.8). From its definition we see that $\phi_m(a,v)$ is a continuous function of a and v and

an entire function of a. Also, if $m > \operatorname{Re} a - 1$, then $|(1+vt)^{a-m-1}| \leqq 1$, and in consequence

$$|\phi_m(a, v)| \leqq 1/m!, \qquad v \in [0, \infty), \quad m > \operatorname{Re} a - 1. \tag{3.5}$$

Hence by analytic continuation with respect to a and b we see that if $|\operatorname{ph}(z e^{-i\gamma})| < \pi/2$ and $n > m$, then (1.9) and (3.4) hold in the region defined by

$$\operatorname{Re} a < m+1, \quad \operatorname{Re} b < m+1, \quad \operatorname{Re} a + \operatorname{Re} b > m+1-n. \tag{3.6}$$

We now seek to majorize $|R_{m,n}(a, b, z)|$ for fixed values of a, b, and m, bounded values of $|\alpha|$, and large values of $\rho \equiv |z|$. Here α is defined (1.8) and m exceeds both $\operatorname{Re} a - 1$ and $\operatorname{Re} b - 1$. (The other two conditions, $n > m$ and $\operatorname{Re} a + \operatorname{Re} b > m+1-n$, are satisfied automatically when $\rho \to \infty$ with $|\alpha|$ bounded.) Also, since we are assuming throughout this section that $\operatorname{ph} z \in [-\pi+\delta, \pi-\delta]$, we may set $\gamma = \operatorname{ph} z = \theta$ without violating the condition $|\operatorname{ph}(z e^{-i\gamma})| < \pi/2$.

With $\gamma = \theta$ we have $\tau = t e^{-i\theta}$, where $0 \leqq t < \infty$. Hence (3.4) may be recast as

$$R_{m,n}(a, b, z) = \frac{e^{-(n+a)i\theta} z^{1-b} e^{-z}}{2\pi\Gamma(m+1-b)} \int_0^\infty \frac{e^{-\rho t} t^{n+a-1}}{1+t e^{-i\theta}}\, dt \int_0^\infty e^{-\rho t v} v^{m-b} \phi_m(a, v)\, dv. \tag{3.7}$$

By use of (3.5) we see that the inner integral satisfies

$$\left| \int_0^\infty e^{-\rho t v} v^{m-b} \phi_m(a, v)\, dv \right| \leqq \frac{\Gamma(m+1-\operatorname{Re} b)}{m!(\rho t)^{m+1-\operatorname{Re} b}}. \tag{3.8}$$

For the outer integral we have

$$|1+t e^{-i\theta}|^{-1} \leqq \operatorname{cosec} \delta. \tag{3.9}$$

Hence

$$|R_{m,n}(a, b, z)| \leqq \frac{e^{\pi(|\operatorname{Im} a| + |\operatorname{Im} b|)} \Gamma(m+1-\operatorname{Re} b)}{2\pi \sin\delta\, m!\, |\Gamma(m+1-b)|} \frac{\Gamma(n-m+\operatorname{Re} a+\operatorname{Re} b-1)|e^{-z}|}{\rho^{n+\operatorname{Re} a+\operatorname{Re} b-1}}. \tag{3.10}$$

Substituting for n by means of (the real part of) (1.8) and using Stirling's formula, we conclude that as $\rho \to \infty$ the right member of this inequality is $O\{e^{-z-|z|}/z^{m+1/2}\}$ uniformly for bounded $|\alpha|$; compare (1.10).

Lastly, the conditions $m > \operatorname{Re} a - 1$ and $m > \operatorname{Re} b - 1$ may be removed in the usual way by replacing m in (1.9) by a sufficiently large integer and referring to [10, (2.14)].[1] This completes the proof of Theorem 1 in the case where $|\operatorname{ph} z| \leqq \pi - \delta$; indeed, we have a slightly stronger asymptotic estimate for $R_{m,n}(a, b, z)$—by a factor $|z|^{-1/2}$—for this sector.

4. Proof of Theorem 1 when $\delta \leqq \operatorname{ph} z \leqq 2\pi - \delta$. We return to the representation of $R_n(a, b, z)$ furnished by (1.9) and (3.4), and valid with the conditions $|\gamma| < \pi$, $|\operatorname{ph}(z e^{-i\gamma})| < \pi/2$, $n > m$, and (3.6). The natural way to try to extend the proof of § 3 to larger values of $\operatorname{ph} z$ would be to rotate further the path of the outer integral in (3.4), that is, to take values of γ equaling or exceeding π. The difficulty is that as $\gamma \to \pi$, the integration path approaches the singularity of the integrand at $\tau = -1$. To overcome this difficulty we adopt, temporarily, the extra conditions $0 < \gamma < \pi$, $\pi/2 < \operatorname{ph} z < \frac{3}{2}\pi$, and decompose $R_{m,n}(a, b, z)$ as follows:

$$R_{m,n}(a, b, z) = R^{(1)}_{m,n}(a, b, z) + R^{(2)}_{m,n}(a, b, z), \tag{4.1}$$

[1] Compare also (4.5) below.

where

$$R^{(1)}_{m,n}(a,b,z)=\frac{z^{1-b}e^{-z}}{2\pi\Gamma(m+1-b)}\int_0^{\infty e^{-i\gamma}}\frac{e^{-z\tau}\tau^{n+a-1}}{1+\tau}\,d\tau \times\int_0^{\infty}e^{zv}v^{m-b}\phi_m(a,v)\,dv, \tag{4.2}$$

$$R^{(2)}_{m,n}(a,b,z)=\frac{z^{1-b}e^{-z}}{2\pi\Gamma(m+1-b)}\int_0^{\infty e^{-i\gamma}}e^{-z\tau}\tau^{n+a-1}\,d\tau \times\int_0^{\infty}\frac{e^{-z\tau v}-e^{zv}}{1+\tau}v^{m-b}\phi_m(a,v)\,dv. \tag{4.3}$$

The right member of (4.2) may be regarded as the product of two single integrals, instead of as a double integral. The first of these is identifiable as an F_p function; the second may be continued analytically by rotating the path of integration through an arbitrary angle $-\hat{\gamma}$, say, where $\hat{\gamma}\in(-\pi,\pi)$. With the aid of (3.3) we obtain

$$R^{(1)}_{m,n}(a,b,z)=\frac{z^{1-b}}{\Gamma(m+1-b)}F_{n+a}(z)\int_0^{\infty e^{-i\hat{\gamma}}}e^{zv}v^{m-b}\phi_m(a,v)\,dv, \tag{4.4}$$

valid with the conditions $\pi/2<|\mathrm{ph}\,(z\,e^{-i\hat{\gamma}})|<\frac{3}{2}\pi$ and (3.6). (The conditions $|\mathrm{ph}\,(z\,e^{-i\gamma})|<\pi/2$ and $\pi/2<\mathrm{ph}\,z<\frac{3}{2}\pi$ disappear.) From Theorem 1 of [10], we obtain[2]

$$F_{n+a}(z)=O(e^{-z-|z|}),\qquad |\mathrm{ph}\,z|\leqq\pi, \tag{4.5}$$

$$F_{n+a}(z)=O(1),\qquad \pi\leqq|\mathrm{ph}\,z|\leqq3\pi-\delta. \tag{4.6}$$

Next, in this section we consider only the sector $\delta\leqq\mathrm{ph}\,z\leqq2\pi-\delta$; hence we may set $\hat{\gamma}=\theta-\pi$. On replacing v by $v\,e^{i(\pi-\theta)}$ we derive

$$\int_0^{\infty e^{-i\hat{\gamma}}}e^{zv}v^{m-b}\phi_m(a,v)\,dv=e^{i(\pi-\theta)(m-b+1)}\int_0^{\infty}e^{-|z|v}v^{m-b}\phi_m(a,v\,e^{i(\pi-\theta)})\,dv. \tag{4.7}$$

One of our assumptions is that $\mathrm{Re}\,a<m+1$; accordingly, from (3.2) we perceive that

$$|\phi_m(a,v\,e^{i(\pi-\theta)})|\leqq A_m, \tag{4.8}$$

where A_m is assignable independently of $\theta\in[\delta,2\pi-\delta]$ and $v\in[0,\infty)$. In consequence, also, of the second condition of (3.6) it follows that

$$\int_0^{\infty e^{-i\hat{\gamma}}}e^{zv}v^{m-b}\phi_m(a,v)\,dv=O(z^{b-m-1}).$$

Then combining this result with (4.4)-(4.6), we arrive at

$$R^{(1)}_{m,n}(a,b,z)=\begin{cases}O(e^{-z-|z|}z^{-m}), & \delta\leqq\mathrm{ph}\,z\leqq\pi,\\ O(z^{-m}), & \pi\leqq\mathrm{ph}\,z\leqq2\pi-\delta.\end{cases} \tag{4.9}$$

For the contribution of $R^{(2)}_{m,n}(a,b,z)$, we first rotate the path for the inner integral in (4.3) through an angle $(\pi-\gamma)/2$. This yields

$$R^{(2)}_{m,n}(a,b,z)=\frac{z^{1-b}e^{-z}}{2\pi\Gamma(m+1-b)}\int_0^{\infty e^{-i\gamma}}e^{-z\tau}\tau^{n+a-1}\,d\tau \times\int_0^{\infty e^{i(\pi-\gamma)/2}}\frac{e^{-z\tau v}-e^{zv}}{1+\tau}v^{m-b}\phi_m(a,v)\,dv, \tag{4.10}$$

[2] In deriving (4.5) and (4.6) from the cited theorem, we have used the following facts: $\mathrm{erfc}\,(\xi)=O(e^{-\xi^2})$ throughout the sector $|\mathrm{ph}\,\xi|\leqq\pi/4$; $\mathrm{erfc}\,(\xi)=O(1)$ throughout the sector $|\mathrm{ph}\,(-\xi)|\leqq\pi/4$ (compare [10, § 4.4]).

valid when $0<\gamma<\pi$, $|\mathrm{ph}\,(z\,e^{-i\gamma})|<\pi/2$, $|\mathrm{ph}\,(z\,e^{i(\pi-3\gamma)/2})|<\pi/2$, and $|\mathrm{ph}\,(z\,e^{-i(\pi+\gamma)/2})|<\pi/2$, that is, when

$$0<\gamma<\pi \quad \text{and} \quad \tfrac{1}{2}\gamma<\mathrm{ph}\,z<\tfrac{3}{2}\gamma. \tag{4.11}$$

Furthermore, because the integrand is now free from singularity at $\tau=-1$ we may extend the rotation of each integration path by increasing γ. Thus (4.10) is also valid with the conditions

$$\pi\leqq\gamma<2\pi \quad \text{and} \quad \tfrac{3}{2}\gamma-\pi<\mathrm{ph}\,z<\pi+\tfrac{1}{2}\gamma. \tag{4.12}$$

In accordance with (4.11) we may set $\gamma=\theta$ $(=\mathrm{ph}\,z)$ in (4.10) when $\delta\leqq\mathrm{ph}\,z<\pi$. Alternatively, if $\pi\leqq\mathrm{ph}\,z\leqq2\pi-\delta$, then we may set $\gamma=\theta$ in (4.10) in accordance with (4.12). In either event we find that

$$\begin{aligned} R^{(2)}_{m,n}(a,b,z)=&\frac{z^{1-b}\,e^{-z}}{2\pi\Gamma(m+1-b)}\int_0^{\infty e^{-i\theta}} e^{-z\tau}\tau^{n+a-1}\,d\tau \\ &\times\int_0^{\infty e^{i(\pi-\theta)/2}}\frac{e^{-z\tau v}-e^{zv}}{1+\tau}\,v^{m-b}\phi_m(a,v)\,dv, \end{aligned} \tag{4.13}$$

valid when $\delta\leqq\mathrm{ph}\,z\leqq2\pi-\delta$.

Once again, subject to (3.6) we seek to estimate $R^{(2)}_{m,n}(a,b,z)$ for fixed values of a, b, and m, bounded values of $|\alpha|$, and large values of $\rho\equiv|z|$.

We first observe that the integration variable of the inner integral in (4.13) lies within the sector $|\mathrm{ph}\,v|<\pi/2$. Hence

$$|\phi_m(a,v)|\leqq e^{\pi|\mathrm{Im}\,a|/2}/m!; \tag{4.14}$$

compare (3.5) and (4.8).

Next, we have identically

$$\frac{e^{-z\tau v}-e^{zv}}{1+\tau}=zv\,e^{-z\tau v}\frac{1-e^{zv(1+\tau)}}{zv(1+\tau)}=zv\,e^{zv}\frac{e^{-zv(1+\tau)}-1}{zv(1+\tau)}.$$

Furthermore, by application of the maximum-modulus theorem it is easily verified that

$$\left|\frac{1-e^{-\zeta}}{\zeta}\right|\leqq1, \qquad \mathrm{Re}\,\zeta\geqq0. \tag{4.15}$$

Combination of the last two results yields

$$\left|\frac{e^{-z\tau v}-e^{zv}}{1+\tau}\right|\leqq\begin{cases}|zv\,e^{-z\tau v}|, & \mathrm{Re}\,\{zv(1+\tau)\}\leqq0,\\ |zv\,e^{zv}|, & \mathrm{Re}\,\{zv(1+\tau)\}\geqq0.\end{cases}$$

With $\mathrm{ph}\,\tau=-\theta$ and $\mathrm{ph}\,v=\pi/2-\theta/2$, we have

$$\mathrm{Re}\,\{zv(1+\tau)\}=\rho|v|(|\tau|-1)\sin\tfrac{1}{2}\theta.$$

Accordingly,

$$\mathrm{Re}\,\{zv(1+\tau)\}\gtrless0 \quad \text{according as} \quad |\tau|\gtrless1.$$

Therefore when $0<|\tau|\leqq1$ we have

$$\begin{aligned} &\left|\int_0^{\infty e^{i(\pi-\theta)/2}}\frac{e^{-z\tau v}-e^{zv}}{1+\tau}\,v^{m-b}\phi_m(a,v)\,dv\right| \\ &\leqq\frac{e^{\pi|\mathrm{Im}\,a|/2}\,e^{(\pi-\theta)\mathrm{Im}\,b/2}\rho}{m!}\int_0^{\infty}e^{-\rho|\tau v|\sin\theta/2}|v|^{m-\mathrm{Re}\,b+1}\,d|v| \\ &\leqq\frac{e^{\pi(|\mathrm{Im}\,a|+|\mathrm{Im}\,b|)/2}\rho}{m!}\,\frac{\Gamma(m+2-\mathrm{Re}\,b)}{(\rho|\tau|\sin\frac{1}{2}\delta)^{m+2-\mathrm{Re}\,b}}. \end{aligned} \tag{4.16}$$

Similarly, when $|\tau| \geqq 1$ we find that

$$\left| \int_0^{\infty e^{i(\pi-\theta)/2}} \frac{e^{-z\tau v} - e^{zv}}{1+\tau} v^{m-b} \phi_m(a, v)\, dv \right| \leqq \frac{e^{\pi(|\operatorname{Im} a|+|\operatorname{Im} b|)/2} \rho}{m!} \frac{\Gamma(m+2-\operatorname{Re} b)}{(\rho \sin \frac{1}{2}\delta)^{m+2-\operatorname{Re} b}}. \tag{4.17}$$

We now prepare to substitute in (4.13) by means of the inequalities just obtained. At this stage it is convenient to use the symbol A_m generically to denote a quantity that may depend on m, a, and b, but is independent of n, z and (bounded values of) α; compare, also, (4.8). In (4.13) we have

$$|\tau^{n+a-1}| \leqq A_m |\tau|^{\rho+\operatorname{Re}\alpha-\operatorname{Re} b};$$

compare (1.8). Hence

$$|R^{(2)}_{m,n}(a, b, z)| \leqq A_m \frac{|e^{-z}|}{\rho^m} \left\{ \int_0^1 e^{-\rho|\tau|} |\tau|^{\rho+\operatorname{Re}\alpha-m-2}\, d|\tau| + \int_1^{\infty} e^{-\rho|\tau|} |\tau|^{\rho+\operatorname{Re}\alpha-\operatorname{Re} b}\, d|\tau| \right\}.$$

Replacing both integration ranges by $(0, \infty)$ and subsequently using Stirling's formula, we derive

$$|R^{(2)}_{m,n}(a, b, z)| \leqq A_m \frac{|e^{-z}|}{\rho^m} \left\{ \frac{\Gamma(\rho+\operatorname{Re}\alpha-m-1)}{\rho^{\rho+\operatorname{Re}\alpha-m-1}} + \frac{\Gamma(\rho+\operatorname{Re}\alpha+1-\operatorname{Re} b)}{\rho^{\rho+\operatorname{Re}\alpha+1-\operatorname{Re} b}} \right\} = O\left(\frac{e^{-z-|z|}}{z^{m+1/2}} \right). \tag{4.18}$$

This result is valid when $\delta \leqq \operatorname{ph} z \leqq 2\pi - \delta$, and on combining it with (4.1) and (4.9) we arrive at

$$R_{m,n}(a, b, z) = \begin{cases} O(e^{-z-|z|} z^{-m}), & \delta \leqq \operatorname{ph} z \leqq \pi, \\ O(z^{-m}), & \pi \leqq \operatorname{ph} z \leqq 2\pi - \delta. \end{cases}$$

After removing the restrictions (3.6) on m in the same manner as that used at the end of § 3 (compare (4.5) and (4.6)), we see that the proof of Theorem 1 is complete for the sector $\delta \leqq \operatorname{ph} z \leqq 2\pi - \delta$.

5. Completion of the proof of Theorem 1. The next extension is to the sector $\frac{3}{2}\pi + \delta \leqq \operatorname{ph} z \leqq \frac{5}{2}\pi - \delta$. Rather than attempting to extend the method of proof introduced in § 4, we appeal to the connection formulae (1.12). An advantage of this approach is that it also determines the maximum regions of validity.

From (1.12) with $k = 1$, z replaced by $z e^{-2\pi i}$ and upper signs taken, we have

$$U(a, a-b+1, z) = e^{-2a\pi i} U(a, a-b+1, z e^{-2\pi i}) + 2\pi i \frac{e^{-a\pi i}}{\Gamma(a)\Gamma(b)} e^{z} U(1-b, a-b+1, z e^{-\pi i}). \tag{5.1}$$

Substituting in each side of this equation by means of (1.7) and (1.9), then using the identity

$$F_{n-s+a+b-1}(z e^{-2\pi i}) = (-)^{n+s} i\, e^{(a+b)\pi i} + e^{2(a+b)\pi i} F_{n-s+a+b-1}(z) \tag{5.2}$$

obtained from [10], (2.11), and carrying out some reduction, we eventually arrive at

$$R_{m,n}(a,b,z)=e^{-2(a+b)\pi i}R_{m,n}(a,b,z\,e^{-2\pi i})+R^{(3)}_{m,n}(a,b,z)+R^{(4)}_{m,n}(a,b,z), \tag{5.3}$$

where

$$R^{(3)}_{m,n}(a,b,z)=(-)^{n-1}i\,e^{-(a+b)\pi i}\sum_{s=m}^{n-1}\frac{(m+1-a)_{s-m}(m+1-b)_{s-m}}{s!\,z^s}, \tag{5.4}$$

and

$$\begin{aligned}R^{(4)}_{m,n}(a,b,z)=2\pi i&\frac{z^{1-a-b}\,e^{-z}}{\Gamma(m+1-a)\Gamma(m+1-b)}\\ &\cdot\left\{\sum_{s=0}^{m-1}\frac{(a)_s(b)_s}{s!}\frac{F_{n-s-a-b+1}(z\,e^{-\pi i})}{z^s}\right.\\ &\left.+(a)_m(b)_m R_{m,n}(1-b,1-a,z\,e^{-\pi i})\right\}.\end{aligned} \tag{5.5}$$

Since $\frac{3}{2}\pi+\delta\leqq\operatorname{ph}z\leqq\frac{5}{2}\pi-\delta$, we have $|\operatorname{ph}(z\,e^{-2\pi i})|\leqq\pi/2-\delta$; hence from the results of § 3 it follows that

$$R_{m,n}(a,b,z\,e^{-2\pi i})=O(e^{-z-|z|}z^{-m-1/2}). \tag{5.6}$$

Next, although the number of terms in the sum in (5.4) increases with $|z|$, it is routine to verify that

$$R^{(3)}_{m,n}(a,b,z)=(-)^{n-1}\frac{i\,e^{-(a+b)\pi i}}{m!\,z^m}+O\left(\frac{1}{z^{m+1}}\right). \tag{5.7}$$

For $R^{(4)}_{m,n}(a,b,z)$ we have $\frac{1}{2}\pi+\delta\leqq\operatorname{ph}(z\,e^{-\pi i})\leqq\frac{3}{2}\pi-\delta$; accordingly, from the results of § 4 it follows that

$$R_{m,n}(1-b,1-a,z\,e^{-\pi i})=O(z^{-m}),$$

and

$$F_{n-s-a-b+1}(z\,e^{-\pi i})=O(1),$$

for each s. Hence

$$R^{(4)}_{m,n}(a,b,z)=O(z^{1-a-b}\,e^{-z}). \tag{5.8}$$

On substituting in (5.3) by means of (5.6), (5.7), and (5.8) we conclude that

$$R_{m,n}(a,b,z)=O(z^{-m}), \tag{5.9}$$

as required. Then combining this estimate with the results of §§ 3 and 4 we establish (1.10) in the sector $-\pi+\delta\leqq\operatorname{ph}z\leqq\pi$, and (1.11) in the sector $\pi\leqq\operatorname{ph}z\leqq\frac{5}{2}\pi-\delta$. A similar proof holds for the conjugate sector, or we can appeal to symmetry.

To complete the proof of Theorem 1, we have only to demonstrate that the estimate (1.10) breaks down after we cross the rays $\operatorname{ph}z=\pm\pi$, and the estimate (1.11) breaks down after we cross $\operatorname{ph}z=\pm\frac{5}{2}\pi$.

In the case where $\operatorname{ph}z=\pi$, we observe from (4.4) and (4.7) that as $z\to\infty$ in the sector $\delta\leqq\operatorname{ph}z\leqq2\pi-\sigma$, we have

$$R^{(1)}_{m,n}(a,b,z)\sim(-)^{m-1}\,e^{-b\pi i}\phi_m(a,0)\frac{F_{n+a}(z)}{z^m}=-\frac{e^{-b\pi i}F_{n+a}(z)}{m!\,z^m};$$

compare also (3.2). And when $\pi+\delta\leqq\operatorname{ph}z\leqq2\pi-\delta$, $(-)^nF_{n+a}(z)$ tends to the constant $i\,e^{-a\pi i}$ (compare Theorem 1 of [10]), giving $R^{(1)}_{m,n}(a,b,z)\sim(\text{constant})z^{-m}$. Obviously from (4.18) this algebraic behavior cannot be cancelled in (4.1) by the contribution of $R^{(2)}_{m,n}(a,b,z)$. A similar argument applies to the ray $\operatorname{ph}z=-\pi$.

Lastly, after we cross $\operatorname{ph}z=\frac{5}{2}\pi$, the contribution of $R^{(4)}_{m,n}(a,b,z)$ in (5.3) is no longer absorbable in the estimate $O(z^{-m})$ because it becomes exponentially large. On

the other hand, the term $e^{-2(a+b)\pi i}R_{m,n}(a, b, z\,e^{-2\pi i})$ remains exponentially small and $R^{(3)}_{m,n}(a, b, z)$ remains $O(z^{-m})$. Similarly for the ray ph $z = -\frac{5}{2}\pi$.

6. Error bounds. For computational purposes the use of (1.7) and (1.9) should be confined to the sector $|\text{ph } z| \leqq \pi$ in which the error term has undergone maximum exponential improvement; elsewhere continuation formulae are to be applied. As always, it is highly desirable to supply a rigorous and realistic bound for the error term in any asymptotic approximation. The analyses supplied in §§ 3-5 lend themselves only in part to achieving this objective.

In § 3, for example, the bound (3.10) breaks down as $\delta \to 0$. However, a slight modification of the analysis leading to this result yields a satisfactory bound when $|\text{ph } z| \leqq \pi/2$: in this sector the right-hand side of (3.9) is replaceable by unity, thus eliminating the factor $(\sin \delta)^{-1}$ from (3.10). Similarly, if we restrict ph $z \in [\pi/2, \pi]$, then the bounds derived in § 4 can be tightened; however, the factor $(\text{cosec } \delta/2)^{m+2-\text{Re}\,b}$ that appears in (4.16) and (4.17) can be replaced only by $(\sqrt{2})^{m+2-\text{Re}\,b}$, which is a drawback.

In this section, we modify the analysis of § 4 in a more substantial manner in order to arrive at a sharper bound for $R_{m,n}(a, b, z)$ in the sector $|\text{ph } z| \leqq \pi$. This modification is based partly on the analysis of Boyd [3] for constructing error bounds for a similar expansion for the modified Bessel function $K_\nu(z)$. The bounds we shall derive are similar to, but not the same as, those of Boyd when the parameters a and b (and ipso facto ν) are real, and they are more readily computable when a, b (and ν) are complex.

As before, we set $z = \rho\, e^{i\theta}$. Throughout the following analysis we restrict $|\theta| < \pi$, relaxing this condition to $|\theta| \leqq \pi$ at the close by appeal to continuity.

In (3.4) we take $\gamma = \theta$, and decompose $R_{m,n}(a, b, z)$ in a manner slightly different from that given by (4.1)-(4.3). We write

$$R_{m,n}(a, b, z) = S^{(1)}_{m,n}(a, b, z) + S^{(2)}_{m,n}(a, b, z), \tag{6.1}$$

where

$$S^{(1)}_{m,n}(a, b, z) = \frac{z^{1-b}\, e^{-z}}{2\pi\Gamma(m+1-b)} \int_0^{\infty e^{-i\theta}} \frac{e^{-z\tau}\tau^{n+a-1}}{1+\tau}\, d\tau \int_0^\infty e^{-\rho v} v^{m-b} \phi_m(a, v)\, dv, \tag{6.2}$$

$$\begin{aligned} S^{(2)}_{m,n}(a, b, z) = {} & \frac{z^{1-b}\, e^{-z}}{2\pi\Gamma(m+1-b)} \int_0^{\infty e^{-i\theta}} e^{-z\tau}\tau^{n+a-1}\, d\tau \\ & \cdot \int_0^\infty \frac{e^{-z\tau v} - e^{-\rho v}}{1+\tau} v^{m-b} \phi_m(a, v)\, dv, \end{aligned} \tag{6.3}$$

these equations being valid with the conditions $|\theta| < \pi$ and (3.6).

As in § 4, the first integral in (6.2) may be identified in terms of $F_{n+a}(z)$. For the second integral, we utilize the bound (3.5) for $\phi_m(a, v)$. Thus we derive

$$|S^{(1)}_{m,n}(a, b, z)| \leqq \frac{e^{\theta\,\text{Im}\,b}\Gamma(m+1-\text{Re}\,b)}{m!|\Gamma(m+1-b)|} \frac{|F_{n+a}(z)|}{\rho^m}. \tag{6.4}$$

In (6.3) we set $\tau = t\, e^{-i\theta}$; thus

$$\begin{aligned} S^{(2)}_{m,n}(a, b, z) = {} & \frac{e^{-(n+a)i\theta}}{2\pi\Gamma(m+1-b)} z^{1-b}\, e^{-z} \int_0^\infty e^{-\rho t} t^{n+a-1}\, dt \\ & \cdot \int_0^\infty \frac{e^{-\rho t v} - e^{-\rho v}}{1+t\, e^{-i\theta}} v^{m-b} \phi_m(a, v)\, dv. \end{aligned} \tag{6.5}$$

To bound the inner integral, the inequalities

$$0 \leqq \frac{e^{-\rho t v} - e^{-\rho v}}{1-t} \leqq \begin{cases} \rho v\, e^{-\rho t v}, & 0 \leqq t \leqq 1, \\ \rho v\, e^{-\rho v}, & t \geqq 1, \end{cases} \tag{6.6}$$

and

$$\left| \frac{1-t}{1+t\,e^{-i\theta}} \right| \leqq 1 \tag{6.7}$$

are applied: (6.6) is easily verified with the aid of (4.15), and (6.7) is verifiable by considering the bilinear transformation $T = (1-t)/(1+t\,e^{-i\theta})$; compare [3, § 4]. Referring again to (3.5), we conclude that

$$\left| \int_0^\infty \frac{e^{-\rho t v} - e^{-\rho v}}{1+t\,e^{-i\theta}}\, v^{m-b} \phi_m(a, v)\, dv \right| \leqq \frac{\rho}{m!} \frac{\Gamma(m+2-\operatorname{Re} b)}{(\rho t_1)^{m+2-\operatorname{Re} b}},$$

where $t_1 = \min(t, 1)$. If we further restrict $\operatorname{Re} a + \operatorname{Re} b > m+2-n$ (compare (3.6)), then we may substitute this bound in (6.5). Referring once again to (1.8), we find that

$$\begin{aligned} |S^{(2)}_{m,n}(a, b, z)| \leqq{}& \frac{e^{\theta(\operatorname{Im} a + \operatorname{Im} b)} \Gamma(m+2-\operatorname{Re} b)}{2\pi\, m!\, |\Gamma(m+1-b)|} \frac{|e^{-z}|}{\rho^m} \\ & \cdot \left\{ \int_0^1 e^{-\rho t} t^{\rho - m + \operatorname{Re}\alpha - 2}\, dt + \int_1^\infty e^{-\rho t} t^{\rho - \operatorname{Re} b + \operatorname{Re}\alpha}\, dt \right\}. \end{aligned} \tag{6.8}$$

Inequalities (6.4) and (6.8) furnish the desired upper bound on $|R_{m,n}(a, b, z)|$ via (6.1). The condition $|\theta| < \pi$ may now be eased by continuity considerations. Thus the aggregate conditions on (6.4) and (6.8) are given by $|\theta| \leqq \pi$ and

$$\operatorname{Re} a < m+1, \quad \operatorname{Re} b < m+1, \quad \operatorname{Re} a + \operatorname{Re} b > m+2-n. \tag{6.9}$$

It remains to bound the integrals that appear in (6.8). A simple approach is to extend each integration range to $[0, \infty)$. This immediately yields

$$\int_0^1 e^{-\rho t} t^{\rho - m + \operatorname{Re}\alpha - 2}\, dt < \frac{\Gamma(\rho - m + \operatorname{Re}\alpha - 1)}{\rho^{\rho - m + \operatorname{Re}\alpha - 1}},$$

$$\int_1^\infty e^{-\rho t} t^{\rho - \operatorname{Re} b + \operatorname{Re}\alpha}\, dt < \frac{\Gamma(\rho - \operatorname{Re} b + \operatorname{Re}\alpha + 1)}{\rho^{\rho - \operatorname{Re} b + \operatorname{Re}\alpha + 1}}.$$

However, each of these bounds overestimates the actual value of the corresponding left-hand side by a factor that approaches two as $\rho \to \infty$. More sophisticated bounds that are free from this defect are supplied in the Appendix.

7. Conclusions. We have constructed a uniform generalized asymptotic expansion for the confluent hypergeometric function $U(a, a-b+1, z)$, valid when the parameters a and b are fixed and z tends to infinity in the sector $|\operatorname{ph} z| \leqq \frac{5}{2}\pi - \delta$, where δ is an arbitrarily small positive constant. This expansion is in terms of generalized exponential integrals (or equivalently incomplete Gamma functions) and it includes as special cases three well-known expansions of Poincaré type valid in the ph z intervals $[-\frac{5}{2}\pi + \delta, -\frac{1}{2}\pi - \delta]$, $[-\frac{3}{2}\pi + \delta, \frac{3}{2}\pi - \delta]$, $[\frac{1}{2}\pi + \delta, \frac{5}{2}\pi - \delta]$. It also quantifies accurately the rapid, but smooth, transitions between these expansions in the neighborhoods of the Stokes lines ph $z = \pm\pi$. These smooth transitions were first described by M. V. Berry using formal analysis and error functions as approximants. The present results serve to place

Berry's conclusions on a rigorous foundation in the case of the confluent hypergeometric function. However, it should be noted that Berry's analysis applied only in the neighborhoods of the Stokes lines, whereas our result is uniformly valid in a sector of total angle $5\pi - 2\delta$.

Our new expansion enjoys the important property that it is a uniform, exponentially improved expansion throughout the sector $|\text{ph } z| \leqq \pi$, in the sense described in [10, § 1]. Furthermore, we have derived strict and realistic bounds for the error term in this sector. Uniform, exponentially improved expansions in other sectors can be easily constructed with the aid of standard connection formulae, and normally we need not compute the new expansion outside the sector $|\text{ph } z| \leqq \pi$.

Although we have treated only the confluent hypergeometric function in the present paper, our method is applicable to a large class of functions that can be represented by Laplace transforms.[3] The basic steps are as follows: (i) The remainder term of the Maclaurin expansion of the kernel of the transform is represented as a contour integral by means of Cauchy's integral formula. (ii) The integral obtained in step (i) is used to construct a Stieltjes transform in the form of a double integral for the remainder term associated with the desired asymptotic expansion. (iii) The double integral is expanded in a series of generalized exponential integrals. (iv) The region of validity is extended by suitable rotations of integration paths and use of continuation formulae. The only step in which we made use of special properties of the confluent hypergeometric function was (iv), where we relied on continuation formulae. However, this was largely a matter of convenience, and in any case this step is the least important.

In Berry's theory the conditions adopted ensure that the function whose asymptotic expansions are under investigation is representable as a Laplace transform of the type admitted above. The scope of the present method therefore appears to be essentially the same as that of Berry.

Appendix. Bounds for some incomplete Gamma functions. In this appendix we construct bounds for the incomplete Gamma functions

$$I_\lambda^{(1)}(\rho) = \int_1^\infty e^{-\rho t} t^{\rho+\lambda-1}\, dt, \qquad I_\lambda^{(2)}(\rho) = \int_0^1 e^{-\rho t} t^{\rho+\lambda-1}\, dt, \tag{A1}$$

that have the same asymptotic forms as the functions themselves when $\rho \to \infty$ with λ positive and fixed. These results were referred to at the end of § 6.

LEMMA. *When λ and ρ are positive*

$$I_\lambda^{(1)}(\rho) \leqq \sqrt{\frac{\pi}{2\rho}}\, e^{-\rho} \exp\left(\frac{\kappa_1^2}{2\rho}\right)\left\{1 + \operatorname{erf}\left(\frac{\kappa_1}{\sqrt{2\rho}}\right)\right\}, \tag{A2}$$

$$I_\lambda^{(2)}(\rho) \leqq \sqrt{\frac{\pi}{2\rho}}\, e^{-\rho} \exp\left(\frac{\kappa_2^2}{2\rho}\right)\left\{1 + \operatorname{erf}\left(\frac{\kappa_2}{\sqrt{2\rho}}\right)\right\}, \tag{A3}$$

where

$$\kappa_1 = \sup_{\tau \in (0,\infty)} \omega(\tau), \qquad \kappa_2 = \sup_{\tau \in (-1,0)} \omega(\tau), \tag{A4}$$

[3] This includes, for example, the integral $\int_0^\infty e^{-zt} t^{d-1} F(a, b; c; -t)\, dt$, in which a, b, c, d are parameters. This is a generalized hypergeometric function of ${}_2F_2$ type.

and[4]

$$\omega(\tau)=\frac{1}{\sqrt{2\tau-2\ln(1+\tau)}}\ln\left\{\frac{(1+\tau)^{\lambda}}{|\tau|}\sqrt{2\tau-2\ln(1+\tau)}\right\}. \tag{A5}$$

To establish this result, we first observe that

$$\omega(\tau)\to 0,\quad \tau\to+\infty;\qquad \omega(\tau)\to\lambda-\tfrac{1}{3},\quad \tau\to 0+;$$
$$\omega(\tau)\to-\infty,\quad \tau\to-1+;\qquad \omega(\tau)\to\tfrac{1}{3}-\lambda,\quad \tau\to 0-.$$

Hence κ_1 and κ_2 are both finite; furthermore, $\kappa_1\geqq\max(\lambda-\frac{1}{3},0)$ and $\kappa_2\geqq\frac{1}{3}-\lambda$.

In the definition (A1) of $I_{\lambda}^{(1)}(\rho)$ let us replace t by $1+\tau$, and then set

$$\tfrac{1}{2}v^2=\tau-\ln(1+\tau), \tag{A6}$$

with $v\sim\tau$ when $\tau\to 0+$. We find that

$$I_{\lambda}^{(1)}(\rho)=e^{-\rho}\int_0^{\infty}\exp\left(-\frac{1}{2}\rho v^2\right)f(v)\,dv, \tag{A7}$$

where

$$f(v)=(1+\tau)^{\lambda-1}\frac{d\tau}{dv}=(1+\tau)^{\lambda}\frac{v}{\tau}.$$

Clearly, $f(v)$ is positive when $v\in(0,\infty)$, and tends to unity when $v\to 0+$. Furthermore, from (A4), (A5), and (A6) we see that

$$f(v)\leqq e^{\kappa_1 v},\qquad 0<v<\infty. \tag{A8}$$

Substitution of this bound into (A7) leads to (A2).

The proof of (A3) is similar.

We note that by applying Laplace's method [8, Chap. 3], to the integrals in the definitions (A1) we derive

$$I_{\lambda}^{(1)}(\rho),\ I_{\lambda}^{(2)}(\rho)\sim\sqrt{\frac{\pi}{2\rho}}\,e^{-\rho},\quad \rho\to\infty.$$

Obviously, the right-hand sides of (A2) and (A3) also have this asymptotic form.

We also observe that for computational purposes the bounds (A2) and (A3) are simplifiable, with an insignificant loss of sharpness when ρ is large. This is achieved via the inequality $\operatorname{erf}(t)\leqq 2t/\sqrt{\pi}$, which is valid for all nonnegative values of t. In this way we derive

$$\begin{aligned} I_{\lambda}^{(1)}(\rho)&\leqq\sqrt{\frac{\pi}{2\rho}}\,e^{-\rho}\exp\left(\frac{\kappa_1^2}{2\rho}\right)\left(1+\sqrt{\frac{2}{\pi\rho}}\,\kappa_1\right)\\ &<\sqrt{\frac{\pi}{2\rho}}\,e^{-\rho}\exp\left(\frac{2\kappa_1^2}{\pi\rho}\right)\left(1+\sqrt{\frac{2}{\pi\rho}}\,\kappa_1\right)<\frac{\pi\,e^{-\rho}}{\sqrt{2\pi\rho}-2\kappa_1}, \end{aligned} \tag{A9}$$

provided that $\rho>2\kappa_1^2/\pi$. (The last step is a consequence of the inequality $(1+t)\,e^{t^2}<(1-t)^{-1}$, $0<t<1$.) The corresponding simplification for $I_{\lambda}^{(2)}(\rho)$ is found to be

$$I_{\lambda}^{(2)}(\rho)<\frac{\pi\,e^{-\rho}}{\sqrt{2\pi\rho}-2\kappa_2},\qquad \rho>\frac{2\kappa_2^2}{\pi}, \tag{A10}$$

[4] In (A5) the positive square root must be taken in both instances. Thus $\sqrt{2\tau-2\ln(1+\tau)}\sim|\tau|$ as $\tau\to 0$ from above or below.

provided that $\kappa_2 > 0$. If $\kappa_2 \leqq 0$, then we have

$$I_\lambda^{(2)}(\rho) \leqq \sqrt{\frac{\pi}{2\rho}}\, e^{-\rho}; \tag{A11}$$

compare (A7) and (A8).

Remark. The method that we have used in this Appendix may also be applied to the general problem of bounding error terms that arise with Watson's lemma and the method of steepest descents. It enjoys some advantages over that described in [8, Chap. 3, § 9; Chap. 4, § 10].

$C^{\alpha}(\bar{\Omega})$ SOLUTIONS OF A CLASS OF NONLINEAR DEGENERATE ELLIPTIC SYSTEMS ARISING IN THE THERMISTOR PROBLEM*

HONG XIE† AND W. ALLEGRETTO†

Abstract. Under realistic assumptions on the electrical and thermal conductivities, the existence is proven, for some $0<\alpha<1$, of positive $C^{\alpha}(\bar{\Omega})$ solutions for a system of degenerate elliptic equations which model a thermistor. A priori bounds are established for the solutions, and then the conductivities are truncated, so that a uniformly elliptic system is obtained. Next, $L^{2,\mu}(\Omega)$ estimates are used to obtain $C^{\alpha}(\bar{\Omega})$ estimates. Finally, the desired results follow from fixed-point argument.

1. Introduction. In this paper, we study the Boundary Value Problem for a class of nonlinear elliptic systems which models a temperature dependent electrical resistor. The electrical potential and the temperature distributions are denoted by φ and u, respectively. These are functions defined on a smooth domain (open, bounded set) Ω in R^N. The cases of practical interest are for $N\leqq 3$ but our proofs also hold for $N>3$. The relevant equations are as follows:

$$\nabla(\sigma(u)\nabla\varphi)=0 \quad \text{in } \Omega \quad \text{and} \quad \varphi=\varphi_0 \quad \text{on } \partial\Omega; \tag{1.1}$$

$$\nabla(k(u)\nabla u)=-\sigma(u)|\nabla\varphi|^2 \quad \text{in } \Omega \quad \text{and} \quad u=u_0 \quad \text{on } \partial\Omega. \tag{1.2}$$

Equations (1.1) and (1.2) express, respectively, the conservation of current and the energy balance including the electrical heating due to the Joule effect. The functions u_0, φ_0 are the distributions on the boundary, while σ, k denote the electrical and thermal conductivity. In many cases of practical interest, σ and k have the following forms:

$$\sigma(u)=Au^{\gamma}\exp(-C/Bu), \tag{1.3}$$

$$k(u)=(D+Eu+Fu^2)^{-1}, \tag{1.4}$$

where u is the temperature, A, B, C, D, E, and F are physical positive constants, and γ is a small positive number or a nonpositive number. Further details on the physical background of this system can be found in [1], [2], and [5].

We observe that system (1.1), (1.2) is degenerate, highly coupled, and that the right-hand side has quadratic growth in the gradient of one of the unknowns. These are features not often found in the nonlinear systems commonly considered in the literature. In particular, it does not appear that arguments based on variational theory and/or Sobolev's Embedding Theorems can be easily applied to system (1.1), (1.2).

Throughout this paper, we make the following assumptions:

(H1) *$\Omega\subset R^N$ is a bounded domain with $\partial\Omega\in C^1$.*

(H2) *$\varphi_0(x)$ and $u_0(x)$ are in $C^{1,\beta}(\bar{\Omega})(\beta>0)$, i.e., there exist positive constants φ_M, u_m and u_M such that*

$$0\leqq\varphi_0(x)\leqq\varphi_M \quad \text{and} \quad u_m\leqq u_0(x)\leqq u_M \quad \text{on } \bar{\Omega}. \tag{1.5}$$

† Department of Mathematics, University of Alberta, Edmonton, Alberta, Canada T6G 2G1.

(H3) *$\sigma(t)$ and $k(t)$ are continuous for $t \geqq 0$, positive and smooth for $t > 0$, and there exists a smooth function f such that*

$$\frac{k(t)}{\sigma(t)} \geqq f(t) > 0 \quad \text{for } t \geqq u_M, \tag{1.6}$$

and: (a) *Either $\int_{u_M}^{\infty} f(t)\,dt = \infty$ or, if $\int_{u_M}^{\infty} f(t)\,dt < \infty$, then*

$$\int_{u_M}^{\infty} f(t)\,dt > \frac{\varphi_M^2}{2}; \tag{1.7}$$

(b) *There exists a sequence $\{t_n\}_1^{\infty}$, tending to infinity, such that $f(t_n) \geqq f(t)$ for $t \in [t_n, \infty)$.*

Remark 1.1. The functions (1.3), (1.4) satisfy (H3) if $F > 0$ and $\gamma \leqq -1$ in (1.3), (1.4). We need only take

$$f(t) = \frac{a_M}{t} \quad \text{with } a_M = \min_{t \geqq u_M} [t\, e^{C/Bt}/(D + Et + Ft^2)t^{\gamma}] > 0.$$

For another example, let $F > 0$ and $\gamma \leqq 0$, and we now choose $f(t) = a_M/t^2$ with $a_M = \min_{t \geqq u_M} [t^2\, e^{C/Bt}/(D + Et + Ft^2)t^{\gamma}] > 0$. Equation (1.7) now implies the restriction $u_M \cdot \varphi_M^2 < 2a_M$.

Remark 1.2. We observe that, unlike the temperature, the potential need not be positive. We can deal with this more general case as follows: Let the arbitrary constants C_m and C_M be such that

$$C_m \leqq \varphi_0(x) \leqq C_M.$$

Note that (1.1), (1.2) are invariant under shifts of φ by an arbitrary constant. Thus by shifting by C_m and letting $\varphi_M = C_M - C_m$ we have

$$0 \leqq \varphi_0(x) - C_m \leqq \varphi_M.$$

Everything remains unchanged except that (1.7) now becomes

$$\int_{u_M}^{\infty} f(t)\,dt > \frac{(C_M - C_m)^2}{2}. \tag{1.7}'$$

This restriction is essential in our method of proof, but we conjecture that the results may be true without it.

We will prove that there exists at least one positive $C^{\alpha}(\bar{\Omega})$ (some $0 < \alpha < 1$) solution of (1.1), (1.2) under (H1)-(H3). The same problem (1.1), (1.2) has been studied in [3] by Cimatti and Prodi. They obtained existence results in $H^1(\Omega)$ when $k(t)$ is constant, but no boundedness of the solution. Both physical and numerical results indicate that the solution should be bounded. Later in [2], Cimatti proved that all solutions of (1.1), (1.2) are bounded under the following assumption:

(H3)′ *There exist three positive constants σ_m, σ_M and k_m such that $\sigma_m \leqq \sigma(t) \leqq \sigma_M$ and $k(t) \geqq k_m$ for all $t \geqq u_m$.*

The assumption (H3)′ is very restrictive and it excludes important practical cases as in (1.3), (1.4).

We would like to indicate that the results in [2] and [3] furnished the motivation for this work.

2. Estimates. We define the weak solutions of the system (1.1), (1.2) as couples $(u(x), \varphi(x)) \in H^1(\Omega)$, which satisfy

$$\varphi - \varphi_0 \in H_0^1(\Omega), \quad \int_\Omega \sigma(u)\nabla\varphi\nabla\chi = 0 \quad \forall \chi \in H_0^1(\Omega); \tag{2.1}$$

$$u - u_0 \in H_0^1(\Omega), \quad \int_\Omega k(u)\nabla u\nabla v = \int_\Omega \sigma(u)|\nabla\varphi|^2 v \quad \forall v \in H_0^1(\Omega). \tag{2.2}$$

A solution (u, φ) is a $C^\alpha(\bar{\Omega})(0 \leqq \alpha \leqq 1)$ solution of (1.1), (1.2), or equivalently, of (2.1), (2.2) if and only if u and φ are in $C^\alpha(\bar{\Omega})$ and satisfy (2.1), (2.2).

In what follows, C denotes a generic constant which may differ from proof to proof or even within the same proof.

THEOREM 2.1 (Boundedness estimate). *Let (u, φ) be a positive $C^\alpha(\bar{\Omega})$ solution of* (2.1), (2.2), *then*

$$0 \leqq \varphi(x) \leqq \varphi_M \quad \text{on } \bar{\Omega}, \tag{2.3}$$

$$u_m \leqq u(x) \leqq M \quad \text{on } \bar{\Omega}, \tag{2.4}$$

where M is a positive constant independent of u.

Proof. Since $u \in C^\alpha(\bar{\Omega})(0 < \alpha < 1)$ and is positive, $0 \leqq \min_\Omega u \leqq u(x) \leqq \max_\Omega u < \infty$. So $0 < \min_\Omega \sigma(u) \leqq \max_\Omega \sigma(u) < \infty$ and $0 < \min_\Omega k(u) \leqq \max_\Omega k(u) < \infty$ by (H3). This implies that the system

$$\varphi - \varphi_0 \in H_0^1(\Omega), \quad \int_\Omega \sigma(u)\nabla\varphi\nabla\chi = 0 \quad \forall \chi \in H_0^1(\Omega), \tag{2.5}$$

$$u - u_0 \in H_0^1(\Omega), \quad \int_\Omega k(u)\nabla u\nabla v = \int_\Omega \sigma(u)|\nabla\varphi|^2 v \quad \forall v \in H_0^1(\Omega) \tag{2.6}$$

is uniformly elliptic. Furthermore, $\varphi \in C^1(\bar{\Omega})$ by (2.5) and (H2), (H3) and standard elliptic estimates [4]. We apply the weak maximum principle [4] to both equations. We have that $0 \leqq \min_{\partial\Omega} \varphi_0 \leqq \varphi(x) \leqq \max_{\partial\Omega} \varphi_0 \leqq \varphi_M$ and $u(x) \geqq \min_{\partial\Omega}(u_0) \geqq u_m$ on $\bar{\Omega}$. In order to get the upper bound on u, we employ the same transformation that was used in [2].

Let $\chi = \varphi v \in H_0^1(\Omega)$ for $v \in H_0^1(\Omega)$, and substitute it into (2.1). We have

$$\int_\Omega \sigma(u)|\nabla\varphi|^2 v = -\int_\Omega \sigma(u)\varphi\nabla\varphi\nabla v \quad \forall v \in H_0^1(\Omega). \tag{2.7}$$

Replace the right-hand side of the equation in (2.2) by (2.7). We see that u satisfies

$$u - u_0 \in H_0^1(\Omega), \quad \int_\Omega k(u)\nabla u\nabla v = -\int_\Omega \sigma(u)\varphi\nabla\varphi\nabla v \quad \forall v \in H_0^1(\Omega). \tag{2.8}$$

Furthermore, we let $\xi(x) = \frac{1}{2}\varphi^2(x) + \int_{u_m}^{u(x)} (k(t)/\sigma(t))\,dt$ and $\xi_0(x) = \frac{1}{2}\varphi_0^2(x) + \int_{u_m}^{u_0(x)} (k(t)/\sigma(t))\,dt$. It is easy to see that $\xi(x)$ and $\xi_0(x)$ are in $H^1(\Omega)$. From (2.8), we have that $\xi(x)$ satisfies

$$\xi - \xi_0 \in H_0^1(\Omega), \quad \int_\Omega \sigma(u)\nabla\xi\nabla v = 0 \quad \forall v \in H_0^1(\Omega).$$

By the weak maximum principle, $\min_{\partial\Omega} \xi_0 \leqq \xi(x) \leqq \max_{\partial\Omega} \xi_0$ on $\bar{\Omega}$, i.e., we have

$$\int_{u_m}^{u(x)} \frac{k(t)}{\sigma(t)}\,dt \leqq \frac{1}{2}\varphi^2 + \int_{u_m}^{u(x)} \frac{k(t)}{\sigma(t)}\,dt \leqq \frac{1}{2}\varphi_M^2 + \int_{u_m}^{u_M} \frac{k(t)}{\sigma(t)}\,dt.$$

It follows that

$$\int_{u_M}^{u(x)} \frac{k(t)}{\sigma(t)}\, dt \leqq \frac{1}{2}\varphi_M^2.$$

Now if $u(x) \leqq u_M$ for $x \in \bar{\Omega}$, we take $M = u_M$. Otherwise, if $u(x) \geqq u_M$ for some $x \in \bar{\Omega}$, then by (H3),

$$\frac{k(t)}{\sigma(t)} \geqq f(t) > 0 \quad \text{for } t \geqq u_M$$

implies

$$\int_{u_M}^{u(x)} f(t)\, dt \leqq \frac{1}{2}\varphi_M^2.$$

Assume first that $\int_{u_M}^{\infty} f(t)\, dt = +\infty$. The inequality above implies that there exists a bound $\tau > 0$ (which is independent of $u(x)$) such that $u(x) \leqq \tau$. Now select t_n such that $t_n \geqq \max\{\tau, u_M\}$ and note that $u(x) \leqq t_n$ for $x \in \bar{\Omega}$. We define $M = t_n$. Next, if $\int_{u_M}^{\infty} f(t)\, dt < \infty$ and $\int_{u_M}^{\infty} f(t)\, dt > \frac{1}{2}\varphi_M^2$, then there exists a small positive constant $\varepsilon > 0$ such that

$$\int_{u_M}^{\infty} f(t)\, dt \geqq \frac{1}{2}\varphi_M^2 + \varepsilon.$$

Thus

$$\int_{u_M}^{\infty} f(t)\, dt - \varepsilon \geqq \frac{1}{2}\varphi_M^2 \geqq \int_{u_M}^{u(x)} f(t)\, dt,$$

and so

$$\int_{u(x)}^{\infty} f(t)\, dt \geqq \varepsilon > 0.$$

This implies that there exists a $\tau > 0$ such that $u(x) \leqq \tau$. As before, we let $t_n \geqq \max\{u_M, \tau\}$ and let $M = t_n$. Estimate (2.4) is proved.

Now truncate $\sigma(t)$ and $k(t)$ as follows:

$$\sigma^*(t) = \begin{cases} \sigma(u_m), & 0 \leqq t \leqq u_m, \\ \sigma(t), & u_m \leqq t \leqq M, \\ \sigma(M), & M \leqq t < \infty \end{cases} \tag{2.9}$$

and

$$k^*(t) = \begin{cases} k(u_m), & 0 \leqq t \leqq u_m, \\ k(t), & u_m \leqq t \leqq M, \\ k(M), & M \leqq t < \infty. \end{cases} \tag{2.10}$$

Consider the following truncated system:

$$\varphi - \varphi_0 \in H_0^1(\Omega), \quad \int_\Omega \sigma^*(u)\nabla\varphi\nabla\chi = 0 \quad \forall \chi \in H_0^1(\Omega); \tag{2.11}$$

$$u - u_0 \in H_0^1(\Omega), \quad \int_\Omega k^*(u)\nabla u\nabla v = \int_\Omega \sigma^*(u)|\nabla\varphi|^2 v \quad \forall v \in H_0^1(\Omega). \tag{2.12}$$

We see that the truncated problem (2.11), (2.12) is a uniformly elliptic system. In fact, there exist two positive constants $\lambda_m \geqq \lambda_M$, such that

$$\lambda_m \leqq \sigma^*(t), \quad k^*(t) \leqq \lambda_M \quad \text{for all } t \geqq 0. \tag{2.13}$$

Moreover, $\sigma^*(t)$, $k^*(t)$ are still Lipschitz for $t \geqq 0$ and satisfy (1.6). Let us check in detail that $\sigma^*(t)$, $k^*(t)$ satisfy (1.6). By definition of $\sigma^*(t)$ and $k^*(t)$, we have

$$\frac{k^*(t)}{\sigma^*(t)} = \begin{cases} k(u_m)/\sigma(u_m), & 0 \leqq t \leqq u_m, \\ k(t)/\sigma(t), & u_m \leqq t \leqq M, \\ k(M)/\sigma(M), & M \leqq t < \infty. \end{cases}$$

Thus

$$\frac{k^*(t)}{\sigma^*(t)} = \frac{k(t)}{\sigma(t)} \geqq f(t) > 0 \quad \text{for } u_m \leqq u_M \leqq t \leqq M$$

$$\frac{k^*(t)}{\sigma^*(t)} = \frac{k(M)}{\sigma(M)} \geqq f(M) = f(t_n) \geqq f(t) \quad \text{for } t \in [t_n, \infty),$$

by (b) of H(3), i.e., (1.6) holds for $\sigma^*(t)$ and $k^*(t)$ with the same f.

LEMMA 2.1. *Any solution* (u, φ) *of* (2.11), (2.12) *satisfies the bound* (2.3), (2.4).

Proof. Since (2.11), (2.12) is uniformly elliptic, by the weak maximum principle [4], it follows that $0 \leqq \varphi(x) \leqq \varphi_M$ and $u(x) \geqq u_m$ on $\bar{\Omega}$. Let $\xi^*(x) = \frac{1}{2}\varphi^2(x) + \int_{u_m}^{u(x)} (k^*(t)/\sigma^*(t))\, dt$ and $\xi_0(x) = \frac{1}{2}\varphi_0^2(x) + \int_{u_m}^{u_0(x)} (k^*(t)/\sigma^*(t))\, dt = \frac{1}{2}\varphi_0^2(x) + \int_{u_m}^{u_0(x)} (k(t)/\sigma(t))\, dt$ since $u_0(x) \leqq M$. The result then follows by the same argument as in the proof of Theorem 2.1, if we can verify that ξ^* and ξ_0^* are in $H^1(\Omega)$. In fact, φ_0 and φ are bounded and in $H^1(\Omega)$, and so are $\frac{1}{2}\varphi^2$ and $\frac{1}{2}\varphi_0^2$. Also, since u and u_0 are in $H^1(\Omega)$ and $\lambda_m/\lambda_M \leqq k^*(t)/\sigma^*(t) \leqq \lambda_M/\lambda_m$ by (2.13), then $\int_{u_m}^{u(x)} (k^*(t)/\sigma^*(t))\, dt$ and $\int_{u_m}^{u_0(x)} (k^*(t)/\sigma^*(t))\, dt = \int_{u_m}^{u_0(x)} (k(t)/\sigma(t))\, dt$ are in $H^1(\Omega)$. The lemma is proved.

COROLLARY 2.1. *Any positive* $C^\alpha(\bar{\Omega})$ *solution of* (2.1), (2.2) *is a* $C^\alpha(\bar{\Omega})$ *solution of* (2.11), (2.12) *and any* $C^\alpha(\bar{\Omega})$ *solution of* (2.11), (2.12) *is a positive* $C^\alpha(\bar{\Omega})$ *solution of* (2.1), (2.2).

Hence, the existence of a positive $C^\alpha(\bar{\Omega})$ solution of (2.1), (2.2) is equivalent to the existence of a $C^\alpha(\bar{\Omega})$ solution of the uniformly elliptic system (2.11), (2.12). The rest of this paper is devoted to the proof of existence of a $C^\alpha(\bar{\Omega})$ solution of (2.11), (2.12).

THEOREM 2.2 ($H^1(\Omega)$ estimate). *Let* (u, φ) *be a* $C^\alpha(\bar{\Omega})$ *solution of* (2.11), (2.12). *We have the following estimates*:

$$\|\varphi\|_{H^1(\Omega)} \leqq C\|\varphi_0\|_{H^1(\Omega)}; \tag{2.14}$$

$$\|u\|_{H^1(\Omega)} \leqq C(\|\varphi_0\|_{H^1(\Omega)} + \|u_0\|_{H^1(\Omega)}), \tag{2.15}$$

where C *only depends on* u_m, M, λ_m, *and* λ_M.

Proof. Estimate (2.14) is obtained by letting $\chi = \varphi - \varphi_0$ in (2.11), i.e.,

$$\varphi - \varphi_0 \in H_0^1(\Omega), \qquad \int_\Omega \sigma^*(u)\nabla\varphi \cdot \nabla(\varphi - \varphi_0)\, dx = 0.$$

Thus

$$\int_\Omega \sigma^*(u)|\nabla(\varphi - \varphi_0)|^2\, dx = -\int_\Omega \sigma^*(u)\nabla\varphi_0 \cdot \nabla(\varphi - \varphi_0)\, dx.$$

Using (2.13) and the Schwarz inequality, we obtain

$$\|\nabla(\varphi - \varphi_0)\|_{L^2(\Omega)} \leqq C\|\nabla\varphi_0\|_{L^2(\Omega)} \leqq C\|\varphi_0\|_{H^1(\Omega)}.$$

Note that $\|\varphi-\varphi_0\|_{H^1(\Omega)} \leqq C\|\nabla(\varphi-\varphi_0)\|_{L^2(\Omega)}$ since $\varphi-\varphi_0 \in H_0^1(\Omega)$, and hence

$$\|\varphi\|_{H^1(\Omega)} \leqq \|\varphi-\varphi_0\|_{H^1(\Omega)} + \|\varphi_0\|_{H^1(\Omega)} \leqq C\|\varphi_0\|_{H^1(\Omega)}$$

by (2.7). We rewrite (2.12) as

$$u-u_0 \in H_0^1(\Omega), \qquad \int_\Omega k^*(u)\nabla u \nabla v\, dx = -\int_\Omega \sigma^*(u)\varphi\nabla\varphi\nabla v\, dx.$$

Since $\varphi \in L^\infty(\Omega)$ and $\nabla\varphi$ can be estimated by (2.14), the same argument as above can be used to obtain (2.15).

Next, we want to establish $C^\alpha(\bar{\Omega})(0<\alpha<1)$ estimates for the solutions of (2.11), (2.12). This is done by employing $L^{2,\mu}(\Omega)$ estimates for equations in divergence form. For convenience to the readers, we first state the definition and some related results about $L^{2,\mu}(\Omega)$ spaces.

DEFINITION 2.1. We say that an $L^2(\Omega)$-function $u \in L^{2,\mu}(\Omega)$ if u satisfies

$$[u]_{2,\mu,\Omega} = \left(\sup_{\substack{x_0\in\bar{\Omega} \\ 0<\rho<\infty}} \rho^{-\mu} \int_{\Omega\cap B(x_0,\rho)} |u-u_{x_0,\rho}|^2\, dx \right)^{1/2} < \infty, \tag{2.16}$$

where $u_{x_0,\rho} = (1/\text{mes}\,(B(x_0,\rho)\cap\Omega)) \int_{B(x_0,\rho)\cap\Omega} u\, dx$, $x_0 \in \bar{\Omega}$.

We recall that $\partial\Omega \in C^1$ by (H1).

LEMMA 2.2. *For $0 \leqq \mu \leqq N+2$, $L^{2,\mu}(\Omega)$ is a Banach space under the norm $\|u\|_{L^{2,\mu}(\Omega)} = \|u\|_{L^2(\Omega)} + [u]_{2,\mu,\Omega}$.*

LEMMA 2.3. (i) *If $0 \leqq \mu \leqq N$, $L^\infty(\Omega) \subset L^{2,\mu}(\Omega)$ and $L^\infty(\Omega)$ is a space of multipliers for $L^{2,\mu}(\Omega)$.*

(ii) *If $N < \mu \leqq N+2$, $L^{2,\mu}(\Omega)$ is isomorphic to $C^\alpha(\bar{\Omega})$ with $\alpha = (\mu-N)/2$.*

LEMMA 2.4. *Let $u \in H^1(\Omega)$ and $\nabla u \in L^{2,\mu}(\Omega)$ with $0 \leqq \mu < N$; then $u \in L^{2,\mu+2}(\Omega)$ with*

$$\|u\|_{L^{2,\mu+2}(\Omega)} \leqq C(\|u\|_{L^2(\Omega)} + \|\nabla u\|_{L^{2,\mu}(\Omega)}),$$

where C is independent of u.

The proofs of the above three lemmas can be found in [7, pp. 28–63]. Our $L^{2,\mu}(\Omega)$ estimate is based on the next lemma, which is a special case of Theorem 2.19 in [7, p. 124]. We note here that Theorem 2.19 in [7] is established explicitly only for $N \geqq 3$, but our $L^{2,\mu}(\Omega)$ estimates (Lemma 2.5) are true not only for $N \geqq 3$ but also for $N = 2$ (see [6, § 5]). For the case where $N = 1$, we can get $C^\alpha(\bar{\Omega})$ estimates directly by Sobolev's Embedding Theorem.

LEMMA 2.5. *Let $u \in H_0^1(\Omega)$ satisfy*

$$\int_\Omega a^{ij} u_{x_i} v_{x_j} = \int_\Omega f^i v_{x_i} \quad \forall v \in H_0^1(\Omega), \tag{2.17}$$

with $\lambda\|\xi\|^2 \leqq a^{ij}\xi_i\xi_j \leqq \Lambda\|\xi\|^2$, $\Lambda \geqq \lambda > 0$, $\xi \in R^N \setminus 0$, and $f^i \in L^{2,\mu}(\Omega)$. Then $\nabla u \in L^{2,\mu}(\Omega)$ and, moreover, we have

$$\|\nabla u\|_{L^{2,\mu}(\Omega)} \leqq C\,(\textstyle\sum \|f^i\|_{L^{2,\mu}(\Omega)} + \|u\|_{H^1(\Omega)}),$$

where $0 < \mu < \mu_0 = N-2+2\delta_0$, $0 < \delta_0 < 1$, and δ_0, C only depend on λ, Λ, and Ω.

THEOREM 2.3 ($L^{2,\mu}(\Omega)$ estimates). *Let $(u,\varphi) \in H^1(\Omega)$ be a $C^\alpha(\bar{\Omega})$ solution of* (2.11), (2.12). *Then we have that*

$$\|\nabla\varphi\|_{L^{2,\mu}(\Omega)} \leqq C(\|\varphi_0\|_{H^1(\Omega)} + \|\nabla\varphi_0\|_{L^{2,\mu}(\Omega)}), \tag{2.18}$$

$$\|\nabla u\|_{L^{2,\mu}(\Omega)} \leqq C(\|\varphi_0\|_{H^1(\Omega)} + \|u_0\|_{H^1(\Omega)} + \|\nabla\varphi_0\|_{L^{2,\mu}(\Omega)} + \|\nabla u_0\|_{L^{2,\mu}(\Omega)}), \tag{2.19}$$

where C only depends on λ_m, M, Λ_M, u_m, φ_M, and Ω, and $0<\mu<\mu_0=N-2+2\delta_0$, $0<\delta_0<1$ depends on λ_m and λ_M only.

Proof. Rewrite (2.11), (2.12) in the following forms:

$$\psi\in H_0^1(\Omega),\quad \int_\Omega \sigma^*(u)\nabla\psi\nabla\chi=-\int_\Omega \sigma^*(u)\nabla\varphi_0\nabla\chi \quad \forall\chi\in H_0^1(\Omega), \tag{2.20}$$

$$\begin{aligned} &W\in H_0^1(\Omega),\quad \int_\eta k^*(u)\nabla W\nabla v \\ &\qquad =\int_\Omega \sigma^*(u)|\nabla\varphi|^2 v-\int_\Omega k^*(u)\nabla u_0\nabla v \quad \forall v\in H_0^1(\Omega); \end{aligned} \tag{2.21}$$

and

$$\varphi(x)=\psi(x)+\varphi_0(x) \quad\text{and}\quad u(x)=W(x)+u_0(x) \qquad \text{on } \bar\Omega. \tag{2.22}$$

Since (u,φ) solves (2.11), (2.12), (W,ψ) solves (2.20), (2.21). By assumption (H2) and Lemmas 2.3 and 2.5, we have that

$$\|\nabla\psi\|_{L^{2,\mu}(\Omega)}\leqq C(\|\sigma^*(U)\nabla\varphi_0\|_{L^{2,\mu}(\Omega)}+\|\psi\|_{H^1(\Omega)}), \tag{2.23}$$

where $0<\mu<\mu_0=N-2+2\delta_0$, $0<\delta_0<1$ only depend on λ_m and λ_M. Since $\int_\Omega \sigma^*(u)|\nabla\varphi|^2 v\,dx=-\int_\Omega \sigma^*(u)\varphi\nabla\varphi\nabla v\,dx$ for all $v\in H_0^1(\Omega)$, we replace $\int_\Omega \sigma^*(u)|\nabla\varphi|^2 v\,dx$ by $-\int_\Omega \sigma^*(u)\varphi\nabla\varphi\nabla v\,dx$ on the right-hand side of the equation in (2.21). We apply Lemma 2.5 again to obtain

$$\|\nabla W\|_{L^{2,\mu}(\Omega)}\leqq C(\|\sigma^*(u)\varphi\nabla\varphi\|_{L^{2,\mu}(\Omega)}+\|k^*(u)\nabla u_0\|_{L^{2,\mu}(\Omega)}+\|W\|_{H^1(\Omega)}). \tag{2.24}$$

Now, by Lemma 2.3, since $\mu<\mu_0=N-2+2\delta_0<N$, it follows that

$$\|\sigma^*(u)\nabla\varphi_0\|_{L^{2,\mu}(\Omega)}\leqq\|\sigma^*(u)\|_{L^\infty(\Omega)}\|\nabla\varphi_0\|_{L^{2,\mu}(\Omega)}\leqq\lambda_M\|\nabla\varphi_0\|_{L^{2,\mu}(\Omega)}, \tag{2.25}$$

$$\|\sigma^*(u)\varphi\nabla\varphi\|_{L^{2,\mu}(\Omega)}\leqq\|\sigma^*(u)\|_{L^\infty(\Omega)}\|\varphi\|_{L^\infty(\Omega)}\|\nabla\varphi\|_{L^{2,\mu}(\Omega)}\leqq\lambda_M\varphi_M\|\nabla\varphi\|_{L^{2,\mu}(\Omega)} \tag{2.26}$$

$$\|k^*(u)\nabla u_0\|_{L^{2,\mu}(\Omega)}\leqq\|k^*(u)\|_{L^\infty(\Omega)}\|\nabla u_0\|_{L^{2,\mu}(\eta)}\leqq\lambda_M\|\nabla u_0\|_{L^{2,\mu}(\Omega)}. \tag{2.27}$$

By Theorem 2.2 and (2.22), we conclude

$$\|\psi\|_{H^1(\Omega)}\leqq\|\varphi\|_{H^1(\Omega)}+\|\varphi_0\|_{H^1(\Omega)}\leqq C\|\varphi_0\|_{H^1(\Omega)}, \tag{2.28}$$

$$\|W\|_{H^1(\Omega)}\leqq\|u\|_{H^1(\Omega)}+\|u_0\|_{H^1(\Omega)}\leqq C(\|u_0\|_{H^1(\Omega)}+\|\varphi_0\|_{H^1(\Omega)}). \tag{2.29}$$

By combining (2.23), (2.25), and (2.28), we get

$$\|\nabla\varphi\|_{L^{2,\mu}(\Omega)}\leqq\|\nabla\varphi\|_{L^{2,\mu}(\Omega)}+\|\nabla\varphi_0\|_{L^{2,\mu}(\Omega)}\leqq C(\|\nabla\varphi_0\|_{L^{2,\mu}(\Omega)}+\|\varphi_0\|_{H^1(\Omega)}). \tag{2.30}$$

And, by (2.24), (2.26), (2.27), (2.29), and (2.30), it follows that

$$\begin{aligned} \|\nabla u\|_{L^{2,\mu}(\Omega)}&\leqq\|\nabla W\|_{L^{2,\mu}(\Omega)}+\|\nabla u_0\|_{L^{2,\mu}(\Omega)} \\ &\leqq C(\|\nabla\varphi_0\|_{L^{2,\mu}(\Omega)}+\|\nabla u_0\|_{L^{2,\mu}(\Omega)}+\|\varphi_0\|_{H^1(\Omega)}+\|u_0\|_{H^1(\Omega)}). \end{aligned} \tag{2.31}$$

Since (2.30), (2.31) hold for all μ with $0<\mu<\mu_0=N-2+2\delta_0$, $0<\delta_0<1$, the theorem follows.

COROLLARY 2.2. *There exist positive constants K, δ_0 such that for any $C^\alpha(\bar\Omega)$ solution (u,φ) of* (2.11), (2.12), *we have*

$$\|u\|_{C^\gamma(\bar\Omega)}\leqq K \quad\text{and}\quad \|\varphi\|_{C^\gamma(\bar\Omega)}\leqq K \tag{2.32}$$

for all γ with $0<\gamma<\delta_0$.

Proof. We need only employ Lemmas 2.3 and 2.4 and Theorem 2.3.

In conclusion we remark that the $H^1(\Omega)$, $L^{2,\mu}(\Omega)$, and C^γ bounds are a consequence of the uniform coefficient bounds and not of the specific nonlinear structure of the equations.

3. Main theorem. We fix α_0 in $(0, \delta_0)$ and consider the existence of a $C^{\alpha_0}(\bar{\Omega})$ solution of (2.11), (2.12)).

THEOREM 3.1 (Existence Theorem). *There exists at least one $C^{\alpha_0}(\bar{\Omega})$ solution of* (2.11), (2.12).

Proof. Let $S = \{u \in C^{\alpha_0}(\bar{\Omega}) \mid \|u\|_{C^{\alpha_0}(\bar{\Omega})} \leqq K \text{ and } u(x) \geqq u_m \text{ on } \bar{\Omega}\}$, where K is determined in Corollary 2.2. Obviously, S is a closed convex set in $C^{\alpha_0}(\bar{\Omega})$. We prove the result by constructing a completely continuous map T from S into S and then applying Schauder's Fixed-Point Theorem. For $u \in S$, we define $W = Tu$ by the following:

$$\varphi - \varphi_0 \in H_0^1(\Omega), \quad \int_\Omega \sigma^*(u)\nabla\varphi\nabla\chi = 0 \quad \forall \chi \in H_0^1(\Omega); \tag{3.1}$$

$$W - u_0 \in H_0^1(\Omega), \quad \int_\Omega k^*(u)\nabla W\nabla v = \int_\Omega \sigma^*(u)|\nabla\varphi|^2 v \quad \forall v \in H_0^1(\Omega). \tag{3.2}$$

We first note that T is well defined from S into S. In fact, since (3.1) is a linear uniformly elliptic Dirichlet problem, we conclude by standard linear theory [4] that there exists a unique solution φ in $C^1(\bar{\Omega})$. By Lemma 2.5, $\nabla\varphi \in L^{2,\mu}(\Omega)$ with $0 < \mu < \mu_0 = N - 2 + 2\delta_0$. If we substitute the solution φ of (3.1) into (3.2), we get another linear uniformly elliptic Dirichlet problem. Since $\int_\Omega \sigma^*(u)|\nabla\varphi|^2 v\,dx = -\int_\Omega \sigma^*(u)\varphi\nabla\varphi\nabla v\,dx$, the right-hand side of the equation in (3.2) defines a bounded linear functional on $H_0^1(\Omega)$. By the Lax–Milgram theorem [4], there exists a unique solution $W \in H^1(\Omega)$ and also by Lemma 2.5, $\nabla W \in L^{2,\mu}(\Omega)$. Now (φ, W) solves (3.1), (3.2). By the same arguments as in the proof of Theorem 2.3 and the corollary, we have $\|W\|_{C^\alpha(\bar{\Omega})} \leqq K$, with α in $(0, \delta_0)$. In particular, let $\alpha = \alpha_0$. and note that we get $\|W\|_{C^{\alpha_0}(\bar{\Omega})} \leqq K$ and $W \geqq u_m$ by the maximum principle, i.e., there exists a unique $W = Tu$ in S. It follows that T is well defined.

Next we prove that (i) T is continuous and (ii) T is compact. Let $\{u_n\}_{n=1}^\infty$ and u in S be such that $u_n \to u$ in $C^{\alpha_0}(\bar{\Omega})$ as $n \to \infty$. Let (φ_n, W_n) and (φ, W) be the solutions of (3.1), (3.2) corresponding to u_n and u, $n = 1, 2, \cdots$; we show that $W_n \to W$ in $C^{\alpha_0}(\bar{\Omega})$. Since φ_n, φ solve (3.1) with respect to u_n and u, we have

$$\varphi_n - \varphi \in H_0^1(\Omega), \quad \int_\Omega \sigma^*(u_n)\nabla(\varphi_n - \varphi)\nabla\chi = \int_\Omega (\sigma^*(u) - \sigma^*(u_n))\nabla\varphi\nabla\chi \tag{3.3}$$

for any $\chi \in H_0^1(\Omega)$, i.e., $\psi = \varphi_n - \varphi$ solves the following problem:

$$\psi \in H_0^1(\Omega), \quad \int_\Omega \sigma^*(u_n)\nabla\psi\nabla\chi = \int_\Omega (\sigma^*(u) - \sigma^*(u_n))\nabla\varphi\nabla\chi \quad \forall \chi \in H_0^1(\Omega). \tag{3.4}$$

By the estimate of Lemma 2.5 we have

$$\|\nabla(\varphi_n - \varphi)\|_{L^{2,\mu}(\Omega)} \leqq C(\|(\sigma^*(u) - \sigma^*(u_n))\nabla\varphi\|_{L^{2,\mu}(\Omega)} + \|\varphi_n - \varphi\|_{H^1(\Omega)}). \tag{3.5}$$

From Lemma 2.3, $\|(\sigma^*(u) - \sigma^*(u_n))\nabla\varphi\|_{L^{2,\mu}(\Omega)} \leqq \max_\Omega \|\sigma^*(u) - \sigma^*(u_n)\| \cdot \|\nabla\varphi\|_{L^{2,\mu}(\Omega)} \leqq CK \max \|\sigma^*(u) - \sigma^*(u_n)\|$ and by letting $\chi = \varphi_n - \varphi$ in (3.3), we get $\|\varphi_n - \varphi\|_{H^1(\Omega)} \leqq C \max_\Omega \|\sigma^*(u) - \sigma^*(u_n)\| \|\varphi\|_{H^1(\Omega)} \leqq KC \max \|\sigma^*(u) - \sigma^*(u_n)\|$. Note

that $u_n \to u$ in $C^{\alpha_0}(\bar{\Omega})$ implies $u_n \to u$ uniformly on $\bar{\Omega}$. By the continuity of $\sigma^*(t)$. It follows that

$$\max_{\Omega} \|\sigma^*(u) - \sigma^*(u_n)\| \to 0 \quad \text{as } n \to \infty,$$

i.e.,

$$\|\nabla(\varphi_n - \varphi)\|_{L^{2,\mu}(\Omega)} \to 0 \quad \text{as } n \to \infty, \quad \text{for } 0 < \mu < \mu_0. \tag{3.6}$$

By Lemmas 2.3 and 2.4, $\varphi_n \to \varphi$ in $C^{\alpha_0}(\bar{\Omega})$. Moreover, for $0 < \mu < \mu_0$, we have

$$\|\varphi_n \nabla \varphi_n - \varphi \nabla \varphi\|_{L^{2,\mu}(\Omega)} \leqq \|\varphi_n - \varphi\|_{C(\bar{\Omega})} \|\nabla \varphi_n\|_{L^{2,\mu}(\Omega)} + \|\varphi\|_{C(\Omega)} \|\varphi_n - \nabla \varphi\|_{L^{2,\mu}(\Omega)},$$

i.e.

$$\|\varphi_n \nabla \varphi_n - \varphi \nabla \varphi\|_{L^{2,\mu}(\Omega)} \to 0 \quad \text{as } n \to \infty.$$

Next note that W_n and W satisfy the following:

$$\int_{\Omega} k^*(u_n) \nabla W_n \nabla v = \int_{\Omega} \sigma^*(u_n) |\nabla \varphi_n|^2 v \quad \forall v \in H_0^1(\Omega),$$

$$\int_{\Omega} k^*(u) \nabla W \nabla v = \int_{\Omega} \sigma^*(u) |\nabla \varphi|^2 v \quad \forall v \in H_0^1(\Omega).$$

Applying (2.7) to both the equations and subtracting yields

$$\int_{\Omega} k^*(u_n) \nabla (W_n - W) \nabla v = \int_{\Omega} [(\sigma^*(u) - \sigma^*(u_n)) \varphi_n \nabla \varphi_n + \sigma^*(u)(\varphi \nabla \varphi - \varphi_n \nabla \varphi_n)$$
$$+ (k^*(u) - k^*(u_n)) \nabla W] \nabla v \quad \forall v \in H_0^1(\Omega).$$

Now, since the same argument applies to the above equation, we have $W_n \to W$ in $C^{\alpha_0}(\bar{\Omega})$, i.e., T is continuous. Finally, that T is compact follows by noting that actually $W = Tu$ is in $C^{\alpha}(\bar{\Omega})$ for $\alpha_0 < \alpha < \delta_0$ and $C^{\alpha}(\bar{\Omega}) \hookrightarrow C^{\alpha_0}(\bar{\Omega})$ is a compact embedding for $\alpha > \alpha_0$. By the Schauder Fixed-Point Theorem T has at least one fixed point in S, which we denote by u^*. Let φ^* be the solution by (3.1) for $u = u^*$. We see that (u^*, φ^*) is a $C^{\alpha_0}(\bar{\Omega})$ solution of (2.11), (2.12), and the proof is complete.

EXISTENCE AND MULTIPLICITY OF POSITIVE RADIAL SOLUTIONS FOR SEMILINEAR ELLIPTIC EQUATIONS IN ANNULAR DOMAINS*

SONG-SUN LIN†‡ AND FENG-MING PAI†

Abstract. The existence and multiplicity of positive radial solutions of equation $\Delta u + f(u) = 0$ is studied in annular domains in $\mathbb{R}^n$, $n \geqq 2$. It is proven that if $f(0) \geqq 0$, f is somewhere negative in $(0, \infty)$ and superlinear at ∞, then there is a large positive radial solutions on all annuli. If $f(0) < 0$ and satisfies certain conditions, then the equation has no solution if the annuli are too wide. Multiplicity results are also obtained when f has many humps with positive areas.

Key words. elliptic, semilinear, positive radial solution, annular domain

AMS(MOS) subject classifications. 35B32, 35JB65, 35P30

1. Introduction. In this paper we consider the existence and multiplicity of positive radial solutions of the semilinear elliptic equation

$$\Delta u(x) + f(u(x)) = 0 \quad \text{in } a < |x| < b, \tag{1.1}$$

$$u(x) = 0 \quad \text{on } |x| = a \quad \text{and} \quad |x| = b, \tag{1.2}$$

$x \in \mathbb{R}^n$, $n \geqq 2$ and $f \in C^1((0, \infty)) \cap C^0([0, \infty))$ satisfying the following hypotheses:

(H1) f is negative somewhere in $(0, \infty)$;

(H2) f is superlinear at $u = \infty$, i.e., $\lim_{u \to \infty} f(u)/u = \infty$.

One of the problems for semilinear elliptic equations in annular domains which have been studied quite extensively in recent years is:

(P) Does (1.1), (1.2) possess a positive radial solution in every annulus?

The answer to (P) was proved affirmative by Nehari [20], assuming that f is positive in $(0, \infty)$ and satisfies the condition: $\exists \delta > 0$ such that $f(u)/u^{1+\delta}$ is monotone increasing in $(0, \infty)$.

Later, (P) was studied by Kazdan and Warner [15], Ni and Nussbaum [21], Bandle, Coffman, and Marcus [2], Garaizar [13], and Lin [17].

In [2], Bandle, Coffman, and Marcus showed that the answer to (P) is affirmative, provided that f is positive in $(0, \infty)$ and satisfies the following conditions:

(A1) f is nondecreasing in $(0, \infty)$;

(A2) $\lim_{u \to 0} f(u)/u = 0$;

(A3) $\lim_{u \to \infty} f(u)/u = \infty$.

In [2], it is remarked that (A1) is not a necessary condition for existence. This have been confirmed by Coffman and Marcus [8] and Lin [17] independently.

With a suitable change of independent variable, (1.1), (1.2) become equations of the form

$$u''(t) + G(t, u) = 0, \qquad t_0 < t < t_1, \tag{1.3}$$

$$u(t_0) = 0 = u(t_1). \tag{1.4}$$

In [3], Bandle and Kwong showed that the answer to (P) is affirmative if G satisfies the following conditions:

(G1) G is C^0 in its first variable and C^1 in its second;

(G2) $\lim_{u\to\infty} G(t, u)/u = \infty$ uniformly on every $[t_0, t_1]$;

(G3) $\lim_{u\to 0} G(t, u)/u = 0$ uniformly on every $[t_0, t_1]$.

$G(t, u)$ is now allowed to be negative for small positive value and $G(t, 0) = 0$ is assumed implicitly with the limit involved exists and finite in (G3).

In this paper, we first generalize the results of Bandle and Kwong [3], showing that (P) is affirmative if (H1), (H2), and (H3) are satisfied.

(H3) $$f(0) \geqq 0.$$

Moreover, solutions obtained are "large" in the following sense: By (H1), there exists $(u_*, u^*) \subset (0, \infty)$ such that

(1.5) $$f(u) \geqq 0 \quad \text{in } (u^*, \infty), \qquad f(u) < 0 \quad \text{in } (u_*, u^*), \qquad f(u_*) = f(u^*) = 0.$$

Let $\gamma > u^*$ be the smallest number such that

(1.6) $$\int_{u_*}^{\gamma} f(u)\, du = 0.$$

The solution u of (1.1), (1.2) is called large if

(1.7) $$\|u\| \equiv \max\{u(x): a \leqq |x| \leqq b\} \geqq \gamma.$$

On the contrary, Garaizar [13] showed that (P) is negative, i.e., (1.1), (1.2) has no positive radial solution if $b - a$ is too large, if f satisfies the following conditions:

(i) $f(0) < 0$;

(ii) There exists $\bar{u} > 0$ such that $F(u) \leqq 0$ in $(0, \bar{u})$ and $f(u) > 0$ in $(\bar{u}, \infty)$;

(iii) There exists $k > 1$ and $d_2 \geqq d_1 > 0$ such that $d_1 u^k \leqq f(u) \leqq d_2 u^k$ for u large, where

$$F(u) = \int_0^u f(t)\, dt.$$

We can also obtain a similar nonexistence result without assuming condition (iii), i.e., if (H2) and the following hold true:

(H3)′(i) $f(0) < 0$;

(ii) There exists $\bar{u} > 0$ such that $F(u) < 0$ in $(0, \bar{u}]$ and $f(u) > 0$ in $(\bar{u}, \infty)$.

On the other hand, when f changes signs, the existence of multiple positive solutions of the equation

(1.8) $$\Delta u + \lambda f(u) = 0 \quad \text{in } \Omega,$$

(1.9) $$u = 0 \quad \text{on } \partial\Omega,$$

$\lambda \geqq 0$ and Ω is a bounded smooth domain in $\mathbb{R}^n$, $n \geqq 2$, has been studied by many authors (see, e.g., Brown and Budin [5], Hess [14], de Figueiredo [12], Clement and Sweers [6], and Wang and Kazarinoff [24]).

In [14], Hess showed that if f satisfies the following conditions:

(f_1) $f(0) > 0$;

(f_2) There exist m numbers $\bar{u}_m > \bar{u}_{m-1} > \cdots > \bar{u}_1 > 0$ such that $f(\bar{u}_k) = 0$ for $k = 1, \cdots, m$;

(f_3) $0 < \max\{F(s): 0 \leqq s \leqq \bar{u}_{k-1}\} < F(\bar{u}_k)$, $k = 2, \cdots, m$,

then there exists a number $\bar{\lambda} > 0$ such that for all $\lambda > \bar{\lambda}$, (1.7), (1.8) have at least $2m - 1$ positive solutions $\hat{u}_1, u_2, \hat{u}_2, \cdots, u_m, \hat{u}_m$ such that $\|\hat{u}_1\| < \bar{u}_1$ and $\bar{u}_{k-1} < \|u_k\|$, $\|\hat{u}_k\| < \bar{u}_k$ for $k = 2, \cdots, m$, and $\hat{u}_{k-1} < \hat{u}_k$ and $u_k < \hat{u}_k$ for $k = 2, \cdots, m$.

Later, de Figueiredo [12] obtained the existence of $2m-1$ ordered positive solutions under slightly different assumptions.

In this paper, we show that if f satisfies (f_2) and (f_3), then there exists $b_m > a$ such that for any $b > b_m$, (1.1), (1.2) has at least m ordered positive radial solutions u_k with $\|u_k\| \in (\bar{u}_{k-1}, \bar{u}_k)$ for $k = 2, \cdots, m$. Moreover, if $f(0) \geqq 0$, then (1.1), (1.2) has at least $2m-1$ positive radial solutions for $b > b_m$.

For the other related problems, note the following:

(i) Uniqueness of positive radial solution, when $f(u) > 0$ for $u \in (0, \infty)$, has been studied by Ni and Nussbaum [21], Bandle, Coffman, and Marcus [2], Bandle and Kwong [3], and Coffman and Marcus [8].

(ii) Symmetry breaking for positive radial solutions has been studied by Brezis and Nirenberg [4], Coffman [7], Suzuki and Nagasaki [22], [23], and Lin [16], [18], [19].

The methods used in this paper are shooting techniques, the phase-plane method, and variational methods. All results obtained in this paper can also be generalized to $f(r, u)$ which satisfies certain uniformity assumptions in r as in (G2) and (G3).

The paper is organized as follows. In § 2, we obtain some preliminary results which are useful. In § 3, we prove that (P) is affirmative when (H1) ~ (H3) are satisfied. In § 4, we prove (P) is negative when (H1) ~ (H3)′ are satisfied. In § 5, we obtain the multiplicity results for wide annuli.

2. Preliminaries. Since we are interested in positive radial solutions of (1.1), we write (1.1), (1.2) in the form

$$u''(r) + \frac{n-1}{r} u'(r) + f(u(r)) = 0 \quad \text{in } (a, b), \tag{2.1}$$

$$u(a) = 0 = u(b). \tag{2.2}$$

For fixed $a > 0$, we consider the family of solutions $u(\cdot) \equiv u(\cdot, \alpha)$ of the initial value problem

$$u''(r) + \frac{n-1}{r} u'(r) + f(u(r)) = 0 \quad \text{for } r > a, \tag{2.3}$$

$$u(a) = 0 \quad \text{and} \quad u'(a) = \alpha, \tag{2.4}$$

where $\alpha \geqq 0$ is the shooting parameter. Furthermore, (2.3), (2.4) can also be written as a dynamical system

$$u' = v, \tag{2.5}$$

$$v' = -\frac{n-1}{r} v - f(u), \tag{2.6}$$

with initial data

$$u(a) = 0 \quad \text{and} \quad v(a) = \alpha. \tag{2.7}$$

We define an energy function $H(\cdot) \equiv H(u(\cdot, \alpha))$ by

$$H(r) = \tfrac{1}{2} v^2(r) + F(u(r)). \tag{2.8}$$

Then, along each trajectory of solution of (2.5), (2.6), H is decreasing; in fact,

$$H'(r) = -\frac{n-1}{r} u'^2(r) \leqq 0. \tag{2.9}$$

Furthermore, $H(r)$ is strictly decreasing in r if $\alpha > 0$.

We first classify the solutions $u(\cdot, \alpha)$.

DEFINITION 2.1. For any $\alpha \geqq 0$, α belongs to one of the following three disjoint sets:

(i) $\alpha \in P$ (or $u(\cdot, \alpha)$ is a P-solution) if $u(r, \alpha) > 0$ for all $r > a$,

(ii) $\alpha \in N$ (or $u(\cdot, \alpha)$ is an N-solution) if there exists $b(\alpha) > 0$ such that $u(r, \alpha) > 0$ in $(a, b(\alpha))$, $u(b(\alpha), \alpha) = 0$ and $u'(b(\alpha), \alpha) < 0$,

(iii) $\alpha \in T$ (or $u(\cdot, \alpha)$ is a T-solution) if there exists $b(\alpha) > 0$ such that $u(r, \alpha) > 0$ in $(a, b(\alpha))$, $u(b(\alpha), \alpha) = 0$ and $u'(b(\alpha), \alpha) = 0$.

We then state some simple but basic properties of solutions $u(\cdot, \alpha)$.

LEMMA 2.2. (i) *If $\alpha \in N$, then $u(\cdot, \alpha)$ has only one local maximum.*

(ii) *If $\alpha \in N \cup T$, then $H(u(r, \alpha)) > 0$ for $r \in (a, b(\alpha))$.*

(iii) *If* (H2) *is satisfied and $u(r, \alpha) > 0$ for all $r > r_0 \geqq a$, then $u(r, \alpha)$ is bounded.*

(iv) *N is an open set.*

Proof. (i) The proof of (i), in the general case, was given by Garaizar [13]. The main idea is using energy $H(r)$, which decreases along the trajectory, and then obtain the following two facts:

(a) the trajectory cannot cross (intersect) itself;

(b) the trajectory cannot be tangent to the u-axis.

Therefore, (i) can be proved. For the details, see [13, Lemma 1].

(ii) Since $H(u(b(\alpha), \alpha)) \geqq 0$, (ii) follows.

(iii) Since

$$H(u(r, \alpha)) = \tfrac{1}{2}u'^2(r) + F(u(r, \alpha)) \leqq H(u(a, \alpha)) = \alpha^2/2,$$

we have $F(u(r, \alpha)) \leqq \alpha^2/2$ for all $r \geqq r_0$. Therefore, (H2) implies $u(r, \alpha)$ is bounded.

(iv) By the Implicit Function Theorem, $b(\alpha)$ is continuously differentiable in N and N is an open set. □

The following lemma indicates there is a great difference between cases $f(0) \geqq 0$ and $f(0) < 0$.

LEMMA 2.3. *If $f(0) \geqq 0$, then $T = \phi$. Furthermore, if $\alpha \in T$ then $u(r, \alpha) > 0$ for all $r > b(\alpha)$.*

Proof. If $f(0) = 0$, then $(u, v) = (0, 0)$ is an equilibrium. Hence, $T = \phi$. If $f(0) > 0$ and there were $\alpha \in T$, then $u''(b(\alpha), \alpha) = -f(0) < 0$. Therefore, $u(r, \alpha) < 0$ for $r < b(\alpha)$ and sufficiently close to it, a contradiction. This proves $T = \phi$.

If $\alpha \in T$, then it is necessary that $f(0) < 0$. Since $H(u(b(\alpha), \alpha)) = 0$ implies that $H(u(r, \alpha)) < 0$ for all $r > b(\alpha)$, then $u''(b(\alpha), \alpha) = -f(0) > 0$ implies that $u(r, \alpha) > 0$ for all $r > b(\alpha)$. □

The following lemma plays a crucial role in the study of problem (P).

LEMMA 2.4. *If there is a sequence $\{\alpha_k\} \subset N \cup T$ such that*

$$\alpha_k \to \bar{\alpha} > 0 \quad \textit{and} \quad b(\alpha_k) \to \infty$$

as $k \to \infty$, then $\bar{\alpha} \in P$ and $u(\cdot, \bar{\alpha})$ satisfies the following monotonicity property:

(M) (i) *$u(r, \bar{\alpha})$ is either strictly increasing in (a, ∞) or there exists $a_1 > a$ such that $u(r, \bar{\alpha})$ is strictly increasing in (a, a_1) and strictly decreasing in (a_1, ∞).*

(ii) *$u(r, \bar{\alpha}) \to \tilde{u}$ as $r \to \infty$ where $f(\tilde{u}) = 0$.*

Proof. First, we observe that $u(\cdot, \bar{\alpha})$ cannot have a local maximum followed by a local minimum. Otherwise, by continuous dependence of ordinary differential equations (o.d.e.), for k sufficiently large, $u(r, \alpha_k)$ will have at least two local maxima in $(a, b(\alpha_k))$, a contradiction to Lemma 2.2(i). It is also clear that $u(r, \bar{\alpha})$ cannot be constant on any finite interval of (a, ∞). Hence, $u(\cdot, \bar{\alpha})$ satisfies (M)(i). Condition (M)(ii) follows by Lemma 2.6 which will be proved later.

As in [2], [3], and [17], it is sometimes convenient to study the existence problem in the form of (1.3), (1.4).

For $n \geqq 3$, in terms of variables

$$s = r^{2-n} \quad \text{and} \quad w(s) = u(r), \tag{2.10}$$

equations (2.1), (2.2) can be rewritten as

$$w''(s) + \rho(s) f(w(s)) = 0 \quad \text{in } (s_0, s_1), \tag{2.11}$$

$$w(s_0) = 0 = w(s_1), \tag{2.12}$$

where $\rho(s) = (n-2)^{-2} s^{-k}$, $k = (2n-2)/(n-2)$, $s_0 = b^{2-n}$, and $s_1 = a^{2-n}$. For $n = 2$, in terms of variables

$$s = \tfrac{1}{2} - \log a + \log r \quad \text{and} \quad w(s) = u(r),$$

equation (2.1) can also be written as (2.11) with $\rho(s) = a^2 e^{2s-1}$, $s_0 = \frac{1}{2}$ and $s_1 = -\frac{1}{2} - \log a + \log b$. In the remaining part of the section, we only treat the case $n \geqq 3$; the case $n = 2$ can also be treated analogously.

The associated initial value problem, now backward shooting in an s-variable, is

$$w''(s) + \rho(s) f(w(s)) = 0 \quad \text{for } s < s_1, \tag{2.13}$$

$$w(s_1) = 0 \quad \text{and} \quad w'(s_1) = -\beta, \tag{2.14}$$

where $\beta \geqq 0$ is the shooting parameter and $s_1 = a^{2-n}$ is a fixed number.

It is easy to check that (2.13), (2.14) is equivalent to

$$w(s) = \beta(s_1 - s) - \int_s^{s_1} (t-s)\rho(t) f(w(t))\, dt \quad \text{for } s < s_1, \tag{2.15}$$

and the solution $w(\cdot, \beta)$ also satisfies the following equation:

$$w(s) = w(\bar{s}) + w'(\bar{s})(s - \bar{s}) + \int_{\bar{s}}^{s} (t-s)\rho(t) f(w(t))\, dt \quad \text{for } 0 < s, \bar{s} < s_1. \tag{2.16}$$

The associated energy function V is defined by

$$V(s) \equiv V(w(s, \beta)) = \tfrac{1}{2} w'^2(s) + \rho(s) F(w(s)). \tag{2.17}$$

It is clear that

$$V'(s) = \rho'(s) F(w(s)),$$

and so

$$V(s) = V(\bar{s}) + \int_{\bar{s}}^{s} \rho'(t) F(w(t))\, dt \tag{2.18}$$

for $0 < s, \bar{s} < s_1$.

If w has a zero in $(0, s_1)$, denote

$$s_0(\beta) = \inf \{ s_0 : w(s, \beta) > 0 \text{ in } (s_0, s_1) \},$$

and $\nu(\beta) \in (s_0(\beta), s_1)$ satisfies

$$w(\nu(\beta), \beta) = \max \{ w(s, \beta) : s \in (s_0(\beta), s_1) \}.$$

With a modification of the argument used in Lin [17], we can prove that $s_0(\beta)$ and $\nu(\beta)$ are well defined for sufficiently large β and tend to s_1 as $\beta \to \infty$. For completeness, we also give a full proof here.

LEMMA 2.5. *If condition* (H2) *is satisfied, then* $s_0(\beta)$ *and* $\nu(\beta)$ *are well defined for sufficiently large* β. *Moreover,*

$$\lim_{\beta\to\infty} \nu(\beta) = s_1, \tag{2.19}$$

$$\lim_{\beta\to\infty} s_0(\beta) = s_1, \tag{2.20}$$

and

$$\lim_{\beta\to\infty} w(\nu(\beta), \beta) = \infty. \tag{2.21}$$

Proof. We first prove (2.19). If (2.19) were false, then there would be a point $\nu_0 \in (0, s_1)$ and a sequence $\beta_k \to \infty$ with

$$w_k(s) > 0 \quad \text{and} \quad w_k'(s) \leqq 0 \quad \text{in } (\nu_0, s_1), \tag{2.22}$$

where $w_k(s) = w(s, \beta_k)$.

Letting $\bar{s} = (\nu_0 + s_1)/2$, we claim that

$$\limsup_{k\to\infty} w_k(\bar{s}) = \infty. \tag{2.23}$$

Suppose this is not the case; then there exists a constant $M > 0$ such that

$$w_k(\bar{s}) \leqq M \quad \text{for all } k. \tag{2.24}$$

Now, by (2.16) and (2.24), we have

$$w_k(\bar{s}) = \frac{1}{2}\beta_k(s_1 - \nu_0) - \int_{\bar{s}}^{s} (t - \bar{s})\rho(t) f(w_k(t))\, dt \geqq \frac{1}{2}\beta_k(s_1 - \nu_0) - C,$$

for some constant $C \geqq 0$. But, by (2.24), this is impossible. Therefore, (2.23) holds.

By choosing a subsequence of β_k if necessary, we may assume that

$$\lim_{k\to\infty} w_k(\bar{s}) = \infty. \tag{2.25}$$

Denote

$$h_k(s) = f(w_k(s))/w_k(s)$$

in $(\nu_0, \bar{s})$ and

$$m_k = \inf\{h_k(s): s \in [\nu_0, \bar{s}]\}.$$

By (2.25) and (H2),

$$\lim_{k\to\infty} m_k = \infty. \tag{2.26}$$

Now $w_k''(s) + \rho(s)h_k(s)w_k(s) = 0$ in $(\nu_0, \bar{s})$ with $\rho(s)h_k(s) \geqq \rho(\bar{s})m_k$ in $(\nu_0, \bar{s})$. By (2.26) and the Sturm Comparison Theorem, w_k has zeros in $(\nu_0, \bar{s})$ for sufficiently large k. But by (2.22) this is impossible. This proves (2.19).

Next, we prove (2.21). By (2.18), we have

$$\frac{1}{2}\beta_k^2 = \rho(\nu_k)F(u(\nu_k)) + \int_{\nu_k}^{s_1} \rho'(t)F(w_k(t))\, dt,$$

where $\nu_k = \nu(\beta_k)$, which implies that $F(w_k(\nu_k)) \to \infty$ as $k \to \infty$. By (H2), (2.21) follows.

Finally, we prove (2.20). If (2.20) were false, then there would be a point $s_0 \in (0, s_1)$ and a sequence $\beta_k \to \infty$ with

$$w_k(s) > 0 \quad \text{in } (s_0, \nu_k). \tag{2.27}$$

Denote $\bar{s} = \frac{1}{2}(s_0 + s_1)$. By (2.19), we may assume that $\bar{s} < \nu_k$ for all k. We first claim that

$$\limsup_{k\to\infty} w_k(\bar{s}) < \infty. \tag{2.28}$$

Let

$$L_k = \min\{w_k(s): s \in [\bar{s}, \nu_k]\}.$$

Then, there exists $L > 0$ such that

$$L_k \leqq L \quad \text{for all } k. \tag{2.29}$$

Otherwise, by the Sturm Comparison Theorem again, w_k has a zero in $(\bar{s}, \nu_k)$, a contradiction to (2.27).

If $w_k(\bar{s}) = L_k$, then (2.28) holds.

If $w_k(\bar{s}) > L_k$, let $s_k \in (\bar{s}, \nu_k)$ such that $w_k(s_k) = L_k$. Denote $r_k = s_k^{1/(2-n)}$, $\bar{r} = \bar{s}^{1/(2-n)}$, and $u_k = w_k$. Then $u_k'(r_k) = 0$, and we have

$$H(u_k(r_k)) = F(L_k) \geqq H(u_k(\bar{r})) \geqq F(u_k(\bar{r})).$$

By (H2) and (2.29),

$$u_k(\bar{r}) \leqq M$$

for some constant $M > 0$. This proves (2.28).

By (H2), there exists $u^* > 0$ such that $f(u) > 0$ for all $u > u^*$. Denote

$$A_k = \{s \in (0, \tau_k): w_k(s) \leqq u^*\}.$$

Then by (2.16), we have

$$\begin{aligned} w_k(\nu_k) &= w_k(\bar{s}) + w_k'(\bar{s})(\nu_k - \bar{s}) + \int_{\bar{s}}^{\nu_k} (t - \nu_k)\rho(t) f(w_k(t))\, dt \\ &\leqq w_k(\bar{s}) + w_k'(\bar{s})(\nu_k - \bar{s}) + \int_{A_k} (t - \nu_k)\rho(t) f(w_k(t))\, dt \\ &\leqq w_k(\bar{s}) + w_k'(\bar{s})(\nu_k - \bar{s}) + C \end{aligned}$$

for some constant $C \geqq 0$. Hence, by (2.20), we have

$$\lim_{k\to\infty} w_k'(\bar{s}) = \infty. \tag{2.30}$$

On the other hand, by (2.16) again, we have

$$\begin{aligned} w_k(s_0) &= w_k(\bar{s}) + w_k'(\bar{s})(s_0 - \bar{s}) + \int_{\bar{s}}^{s_0} (t - s_0)\rho(t) f(w_k(t))\, dt \\ &\leqq w_k(\bar{s}) - \frac{1}{2} w_k'(\bar{s})(s_1 - s_0) - \int_{A_k} (t - s_0)\rho(t) f(w_k(t))\, dt \\ &\leqq w_k(\bar{s}) - \frac{1}{2}(s_1 - s_0) w_k'(\bar{s}) + C_1 \end{aligned}$$

for some constant $C_1 \geqq 0$. By (2.28) and (2.30), $w_k(s_0) \to -\infty$ as $k \to \infty$, a contradiction to (2.27). This proves (2.20). □

LEMMA 2.6. *If $u(r, \alpha) > 0$ for $r > r_0 \geqq a$, then*

$$\liminf_{r \to \infty} |u(r, \alpha) - Z| = 0, \tag{2.31}$$

where $Z = \{\tilde{u} \geqq 0 : f(\tilde{u}) = 0\}$ and $|u - Z| = \inf\{|u - \tilde{u}| : \tilde{u} \in Z\}$. In particular, if $\lim_{r \to \infty} u(r, \alpha) = \tilde{u} \geqq 0$, then $f(\tilde{u}) = 0$.

Proof. If (2.31) were false, then there would be an $\varepsilon > 0$ such that

$$|f(u(r, \alpha))| \geqq \varepsilon.$$

Denote $w(s, \beta) = u(r, \alpha)$. Then by (2.15)

$$|w(s, \beta)| \to \infty \quad \text{as } s \to 0^+.$$

This is impossible in viewing $w(s, \beta) > 0$ and Lemma 2.2(iii). □

3. Existence of large solutions when $f(0) \geqq 0$. *In this section we shall prove that if $(H1) \sim (H3)$ are satisfied, the answer to (P) is affirmative. We first prove the following lemma.*

LEMMA 3.1. *If $\alpha \in N$ and $\|u\| \geqq \gamma$ then*

$$\|u\| > \gamma, \tag{3.1}$$

where γ is in (1.6). *A similar result holds for $\alpha \in T$ with*

$$\max\{u(r, \alpha) : r \in [a, b(\alpha)]\} \geqq \gamma. \tag{3.2}$$

Proof. If $\alpha \in N$, by Lemma 2.2(i), there exists a unique $\tau(\alpha) \in (a, b(\alpha))$, such that

$$u(\tau(\alpha), \alpha) = \|u\|. \tag{3.3}$$

Let $r_1(\alpha) \in (\tau(\alpha), b(\alpha))$ such that

$$u(r_1(\alpha), \alpha) = u_*,$$

where u_* is in (1.5). Then

$$H(u(\tau(\alpha))) = F(u(\tau(\alpha))) > H(u(r_1(\alpha))) > F(u_*),$$

which implies

$$\int_{u_*}^{u(\tau(\alpha))} f(u)\, du > 0.$$

Hence $u(\tau(\alpha)) > \gamma$. This proves (3.1). By the same argument, we can obtain (3.1) if $\alpha \in T$ and (3.2) holds. □

LEMMA 3.2. *Assume conditions* (H1) ~ (H3) *are satisfied. Then*

$$N_1 = \{\alpha \in N : \|u(\cdot, \alpha)\| > \gamma\} \tag{3.4}$$

is a nonempty open set.

Proof. By Lemmas 2.3 and 2.5, N_1 is nonempty. By Lemma 3.1 and continuous dependence of o.d.e., N_1 is an open set. □

We can now prove the main result of this section.

THEOREM 3.3. *Assume conditions* (H1) ~ (H3) *are satisfied. Then for any $b > a > 0$, there exists a positive radial solution $u(r)$ of* (2.1), (2.2) *with $\|u\| > \gamma$.*

Proof. By Lemma 3.2, there exists $\alpha^* \geqq 0$ such that $N_1 \supset (\alpha^*, \infty)$ with $\alpha^* \notin N_1$.

By Lemma 2.5, it suffices to show that

$$\lim_{\alpha \to (\alpha^*)^+} b(\alpha) = \infty. \tag{3.5}$$

We shall prove the theorem according to $f(0) > 0$ and $f(0) = 0$.

If $f(0) > 0$, we claim that $\alpha^* > 0$. In fact, $u''(a, 0) = -f(0) < 0$. Hence, there is an $\varepsilon > 0$ such that $u(r, 0) < 0$ for $r \in (a, a+\varepsilon)$. This implies $\alpha^* > 0$. We claim that $\alpha^* \in P$. If $\alpha^* \notin P$, then $(0, \infty) = N \cup P$ implies $\alpha^* \in N$. Since $\alpha^* \in N_1$, we have $u(\tau(\alpha^*), \alpha^*) \geqq \gamma$. By Lemma 3.1, $\alpha^* \in N_1$, a contradiction. Therefore, $\alpha^* \in P$ and (3.5) follows.

If $f(0) = 0$, then either $\alpha^* > 0$ or $\alpha^* = 0$. If $\alpha^* > 0$, then the previous argument also works and then (3.5) holds. If $\alpha^* = 0$ and (3.5) are false, then there are $b_0 > a$ and $\delta > 0$ such that $b(\alpha) \leqq b_0$ for all $\alpha \in (0, \delta)$. Since $\tau(\alpha) \in (0, b_0)$ for all $\alpha \in (0, \delta)$, there exists a sequence $\alpha_k \to 0$ such that $\tau(\alpha_k) \to \tau_0 \in [0, b_0]$. Since $u(\tau(\alpha_k), \alpha_k) > \gamma$, we have $u(\tau_0, 0) \geqq \gamma$, a contradiction to $u(r, 0) \equiv 0$. Hence, (3.5) holds. □

COROLLARY 3.4. *Assume conditions* (H1)~(H3) *are satisfied and* $f(0) > 0$. *Then for any* $a > 0$, *the equation*

$$u''(r) + \frac{n-1}{r} u'(r) + f(u(r)) = 0 \quad \text{in } (a, \infty), \tag{3.6}$$

$$u(a) = 0 \quad \text{and} \quad u(r) > 0 \quad \text{for } r > a, \tag{3.7}$$

has a solution u *which satisfies* (M).

Proof. In the proof of the previous theorem, we have $N_1 \supset (\alpha^*, \infty)$ with $\alpha^* > 0$ and $\alpha^* \in P$. By (3.5) and Lemma 2.4, $u(\cdot, \alpha^*)$ satisfies (M). □

4. Nonexistence on wide annuli when f(0)<0. In this section we shall prove that if (H2) and (H3)′ are satisfied, then (2.1), (2.2) has no positive solution when $b - a$ is too large.

We first show that $P \neq \phi$ when $f(0) < 0$.

LEMMA 4.1. *If* $f(0) < 0$, *then there exists* $\alpha_* > 0$ *such that* $[0, \alpha_*) \subset P$.

Proof. We first prove $0 \in P$. In fact, $u''(a, 0) = -f(0) > 0$ and $H(u(a, 0)) = 0 > H(u(r, 0))$ for $r > a$ implies $u(r, 0) > 0$ for $r > a$. Hence $0 \in P$.

Next, let $u_0 > 0$ such that $f(u) < 0$ in $[-u_0, u_0]$. Then there exist $\varepsilon > 0$ and $\alpha_0 > 0$ such that for all $\alpha \in [0, \alpha_0]$, we have $|u(r, \alpha)| \leqq u_0$ in $[a, a+\varepsilon]$. Therefore, for all $\alpha \in [0, \alpha_0]$,

$$u''(r) + \frac{n-1}{r} u'(r) > 0 \quad \text{in } [a, a+\varepsilon],$$

which implies $u(r, \alpha) > 0$ in $(a, a+\varepsilon]$.

On the other hand, if $H(u(a+\varepsilon, 0)) < 0$, by continuous dependence of o.d.e., there exists $\alpha_* \in (0, \alpha_0)$ such that $H(u(a+\varepsilon, \alpha)) < 0$ for all $\alpha \in (0, \alpha_*)$. Therefore, for any $\alpha \in (0, \alpha_*)$, $H(u(r, \alpha)) < 0$ for $r > a+\varepsilon$, which implies $u(r, \alpha) > 0$ for $r > a+\varepsilon$. This proves $(0, \alpha_*) \subset P$. □

We now prove the main result of this section.

THEOREM 4.2. *Assume conditions* (H2) *and* (H3)′ *are satisfied. Then there exists* $b^* > a$ *such that for any* $b > b^*$, (2.1), (2.2) *has no positive solution.*

Proof. By Lemma 2.5, there exist $\alpha^* > 0$ and $b_0 > a$ such that $(\alpha^*, \infty) \subset N \cup T$ and $b(\alpha) \leqq b_0$ for all $\alpha \in (\alpha^*, \infty)$. On the other hand, by Lemma 4.1, there exists $\alpha_* > 0$ such that $[0, \alpha_*) \subset P$. Therefore, it suffices to show that there exists $\tilde{b}_0 > a$ such that

$$b(\alpha) \leqq \tilde{b}_0 \quad \text{for any } \alpha \in [\alpha_*, \alpha^*] \cap (N \cup T). \tag{4.1}$$

If (4.1) were false, then there would be a sequence $\alpha_k \in [\alpha_*, \alpha^*] \cap (N \cup T)$ and $\bar{\alpha} \in [\alpha_*, \alpha^*]$ such that $\alpha_k \to \bar{\alpha}$ and $b(\alpha_k) \to \infty$ as $k \to \infty$. By Lemma 2.4, $\bar{\alpha} \in P$ and $u(\cdot, \bar{\alpha})$ satisfies (M). Now, (H3)'(ii) and $u(r, \bar{\alpha}) \to \tilde{u}$ as $r \to \infty$ with $f(\tilde{u}) = 0$ implies $H(u(r, \bar{\alpha})) \to F(\tilde{u}) < 0$ as $r \to \infty$. Therefore, there exists $r_0 > a$ such that $H(u(r_0, \bar{\alpha})) < 0$. By continuous dependence of o.d.e., we have $H(u(r_0, \alpha_k)) < 0$ for k sufficiently large, a contradiction to Lemma 2.2(ii). This proves (4.1). □

5. Multiplicity results on wide annuli. In the previous sections we studied the existence of large (and nonexistence of) positive solutions for (2.1), (2.2) under the various assumptions of f. In this section we shall study the existence of "intermediate size" solutions of (2.1), (2.2) when f may change signs several times and satisfies condition (f_3) in § 1, i.e., f satisfies the following hypothesis:

(H4) there exist m successive numbers $\bar{u}_m > \bar{u}_{m-1} > \cdots > \bar{u}_1 > 0$, which satisfy

(i) $f(\bar{u}_k) = 0$ for $k = 1, \cdots, m$; and

(ii) $0 < \max\{F(s) : 0 \leqq s \leqq \bar{u}_{k-1}\} < F(\bar{u}_k)$ for $k = 2, \cdots, m$.

Let γ_k be the least number in $(\bar{u}_{k-1}, \bar{u}_k)$ such that

$$\int_{\bar{u}_{k-1}}^{\gamma_k} f(u)\, du = 0, \tag{5.1}$$

for $k = 1, \cdots, m$, where $\bar{u}_0 \equiv 0$. We first prove the following lemma.

LEMMA 5.1. *Assume there exists an $\bar{u} > 0$ such that*

$$f(u) = 0 \quad \text{for } u \geqq \bar{u}. \tag{5.2}$$

Then we have the following conditions:

(i) *if $u(r_1, \alpha) = \bar{u}$ and $u'(r_1, \alpha) \geqq 0$ for some $r_1 > a$, then for $r > r_1$,*

$$u(r, \alpha) = \bar{u} + \frac{1}{n-2} r_1 u'(r_1, \alpha) - \frac{1}{n-2} r_1^{n-1} u'(r_1, \alpha) r^{2-n}; \tag{5.3}$$

(ii) *let $U = \{\alpha \in (0, \infty) : u(r_1, \alpha) = \bar{u}$ for some $r_1 > a\}$; then there exists $\alpha^* > 0$ such that $U \supseteq (\alpha^*, \infty)$.*

Proof. (i) By (5.2), we have

$$u''(r) + \frac{n-1}{r} u'(r) = 0 \tag{5.4}$$

as long as $u(r, \alpha) \geqq \bar{u}$. Therefore, by solving (5.4) with initial condition $u(r_1, \alpha) = \bar{u}$ and $u'(r_1, \alpha) \geqq 0$, (5.3) follows.

(ii) We shall prove (ii) by using the method of backward shooting. If (ii) were false, there would be a sequence $\beta_k \to \infty$ such that

$$w_k(s) < \bar{u} \quad \text{as long as } w_k \text{ remain positive}, \tag{5.5}$$

where $w_k(s) \equiv w(s, \beta_k)$. Let

$$\nu_k = \inf\{\tilde{s} \in (0, s_1) : w_k(s) > 0 \text{ and } w_k'(s) \leqq 0 \text{ in } (\tilde{s}, s_1)\}.$$

We claim that

$$\lim_{k \to \infty} \nu_k = s_1. \tag{5.6}$$

If (5.6) were false, there would be $\nu_0 < s_1$ and a subsequence of ν_k (for simplicity,

rename it ν_k), such that $\nu_k \leqq \nu_0$ for all k. Therefore, by (2.15) and (5.5), we have

$$w_k(\nu_0) = \beta_k(s_1 - \nu_0) - \int_{\nu_0}^{s_1} (t - \nu_0)\rho(t)f(w_k(t))$$
$$\geqq \beta_k(s_1 - \nu_0) - C,$$

for some constant $C \geqq 0$, a contradiction to (5.5). Hence (5.6) holds.

On the other hand, by (5.5) again, we have

$$w'(\tau_k) = -\beta_k + \int_{\tau_k}^{s_1} \rho(t)f(w_k(t))\, dt$$
$$\leqq -\beta_k + C$$

for some $C \geqq 0$. Therefore, $w'(\tau_k) < 0$ if k is large enough, a contradiction to the definition of ν_k. This proves (ii). □

The (energy) functional we want to minimize is

$$J(u) = \int_a^b r^{n-1}\left\{\frac{1}{2}u'^2(r) - F(u(r))\right\} dr$$

in $H_0^1((a, b))$, where $H_0^1((a, b)) = \{u : u$ is absolutely continuous in $[a, b]$ with $u(a) = 0 = u(b)$ and $u, u' \in L^2(a, b)\}$.

Since f may change signs, the minimizer u_b of J is not necessarily positive. However, for fixed a, if b is sufficiently large and (H4) is satisfied, then we can prove u_b is positive. To make the proof more transparent, we begin with the study of two simple cases.

LEMMA 5.2. *If f satisfies the following*:

(H5)(i) $f(0) \geqq 0$;

(ii) *There exists $\bar{u} > 0$ such that $f(\bar{u}) = 0$ and $f(u) > 0$ in $(0, \bar{u})$, then, we have the following results*:

(i) *There exists $b^* > a$ such that for any $b > b^*$, (2.1), (2.2) has a positive solution u_b that is also a local minimizer of $J(u)$ over $H_0^1((a, b))$. Moreover,*

$$0 < u_b < \bar{u} \quad \text{in } (a, b), \tag{5.7}$$

and

$$-\frac{b^n}{n}F(\bar{u}) \leqq J(u_b) \leqq -\frac{b^n}{n}F(\bar{u}) + C(b^{n-1} + 1) \tag{5.8}$$

for some positive constant C which is independent of b.

(ii) *If $f(0) > 0$, then there exists a positive solution $\tilde{u}$ of* (3.6), (3.7) *and $\tilde{u}$ is strictly increasing in (a, ∞) and $\tilde{u}(r) \to \bar{u}$ as $r \to \infty$.*

Proof. We first modify the function outside $[0, \bar{u}]$ as Clément and Sweers did in [6]. Denote

$$f_1(u) = \begin{cases} 0 & u \geqq \bar{u}, \\ f(u) & u \in [0, \bar{u}], \\ 2f(0) - f(-u) & \text{if } u < 0, \end{cases} \tag{5.9}$$

$$F_1(u) = \int_0^u f_1(t)\, dt \quad \text{and} \quad J_1(u) = \int_a^b r^{n-1}\left\{\frac{1}{2}u'^2(r) - F_1(u(r))\right\} dr.$$

It is easy to verify that

$$F_1(|u|) = F_1(u) + 2f(0)|u| \quad \text{for } u < 0. \tag{5.10}$$

Hence, for any $u \in H_0^1((a, b))$,

$$J_1(|u|) \leqq J_1(u). \tag{5.11}$$

Since $f(u)$ is bounded, the minimizer of $J_1(u)$ over $H_0^1((a, b))$ is achieved, say u_b, which is a solution of (2.1), (2.2). By (5.11), u_b can be chosen to be nonnegative. If $u_b \not\equiv 0$ in (a, b), then by Lemma 2.3, $u_b > 0$ in (a, b).

If $f(0) > 0$, then $u_b > 0$ in (a, b). If $f(0) = 0$, we want to prove that $u_b > 0$ in (a, b) if b is large enough. This can be done by choosing appropriate test functions $u_b^* \in H_0^1((a, b))$ as follows:

$$u_b^*(r) = \begin{cases} (r-a)\bar{u} & \text{for } r \in [a, a+1], \\ \bar{u} & \text{for } r \in [a+1, b-1], \\ (b-r)\bar{u} & \text{for } r \in [b-1, b]. \end{cases} \tag{5.12}$$

Then

$$J_1(u_b^*) \leqq -\frac{b^n}{n} F(\bar{u}) + C(b^{n-1}+1) \tag{5.13}$$

for some constant C which is independent of b. Therefore, if b is large enough, then $u_b > 0$ in (a, b), and by Lemma 5.1(i), $u_b < \bar{u}$ in (a, b). By (5.13), (5.8) follows. This proves (i).

To prove (ii), we first note that $f(0) > 0$ implies there exists $\alpha_* > 0$ such that $(0, \alpha_*) \subset N$ and

$$\lim_{\alpha \to 0^+} b(\alpha) = a \tag{5.14}$$

(see Lin [18]). On the other hand, by Lemma 5.1(ii), there exists $\alpha^* > \alpha_*$ such that $U \supset (\alpha^*, \infty)$. Therefore, for any $b > b^*$, there exists $\alpha(b) \in (0, \alpha^*]$ such that $u(\cdot, \alpha(b))$ is a minimizer of $J_1(u)$. Therefore, by (5.14) there exists $\bar{\alpha} > 0$ and a sequence $b_k \to \infty$ such that $\alpha(b_k) \to \bar{\alpha}$ as $k \to \infty$. By Lemma 2.4, $\bar{\alpha} \in P$ and $u(\cdot, \bar{\alpha})$ satisfies (M). By Lemma 5.1(i) and (H5)(ii), $u(\cdot, \bar{\alpha})$ is strictly increasing in (a, ∞). This proves (ii). □

Next, we treat the case $f(0) < 0$.

LEMMA 5.3. *If f satisfies the following conditions*:

(H5)′(i) $f(0) \leqq 0$;

(ii) *There exist* $\bar{u} > \underline{u} > 0$ *such that* $f(\underline{u}) = f(\bar{u}) = 0$ *and* $f(u) < 0$ *in* $(0, \underline{u})$ *and* $f(u) > 0$ *in* $(\underline{u}, \bar{u})$;

(iii) $\int_0^{\bar{u}} f(u)\, du > 0$,

then there exists $b^* > a$ *such that for any* $b > b^*$ *there exists a positive solution* u_b *of* (2.1), (2.2) *with* $\|u_b\| \in (\gamma, \bar{u})$, *where*

$$\int_0^{\gamma} f(u)\, du = 0. \tag{5.15}$$

Proof. If $f(0) = 0$, then the arguments in Lemma 5.2 also work and give the result as in Lemma 5.2(i). Note that (H5)′(iii) implies $J_1(u_b^*) < 0$ in (5.13) when b is large enough.

If $f(0) < 0$, then (5.10) implies the extension f_1 in (5.9) is no longer suitable to the minimization problem. Therefore, we want to modify f in a different way and use super- and subsolution methods to obtain solutions for (2.1), (2.2).

Since $f(0) < 0$, we can extend f into $(u_0, 0)$ such that

$$f(u_0) = 0, f(u) < 0 \quad \text{in } (u_0, 0) \tag{5.16}$$

and

$$\int_{u_0}^{\bar{u}} f(u)\,du > 0. \tag{5.17}$$

Let $v = u - u_0$ and denote $v_1 = \underline{u} - u_0$ and $v_2 = \bar{u} - u_0$. Let

$$g(v) = f(u) \quad \text{in } [0, v_2].$$

Then $g(0) = g(v_1) = g(v_2) = 0$,

$$g(v) < 0 \quad \text{in } (0, v_1) \quad \text{and} \quad g(v) > 0 \quad \text{in } (v_1, v_2).$$

We then extend g outside $[0, v_2]$ by making

$$g(v) = 0 \quad \text{for } v > v_2$$

and

$$g(v) = -g(-v) \quad \text{for } v < 0.$$

Denote

$$G(v) = \int_0^v g(t)\,dt.$$

Then, as in (5.10),

$$G(|v|) = G(v) \quad \text{for all } v < 0$$

and (5.17) can be rewritten as

$$G(v_2) = \int_0^{v_2} g(t)\,dt = \int_{u_0}^{\bar{u}} f(u)\,du > 0. \tag{5.18}$$

Define

$$\tilde{J}(v) = \int_a^b r^{n-1}\left\{\frac{1}{2}v'^2(r) - G(v(r))\right\} dr \tag{5.19}$$

in $H_0^1((a, b))$.

Let v_b^* be defined as u_b^* in (5.12), but replace $\bar{u}$ by v_2. Then

$$\tilde{J}(v_b^*) \leqq -\frac{b^n}{n} G(v_2) + C(b^{n-1} + 1) \tag{5.20}$$

for some positive constant C which is independent of b. Therefore, there exists $b^* > a$ such that for any $b > b^*$, the equations

$$v''(r) + \frac{n-1}{r} v'(r) + g(v(r)) = 0 \quad \text{in } (a, b), \tag{5.21}$$

$$v(a) = 0 = v(b) \tag{5.22}$$

have a positive solution v_b which is also a minimizer of $\tilde{J}$ with

$$\tilde{J}(v_b) \leqq -\frac{b^n}{n} G(v_2) + C(b^{n-1} + 1)$$

and

$$\|v_b\| \in (\gamma - u_0, v_2). \tag{5.23}$$

Let $\tilde{u}_b = u_0 + v_b$; then

$$\Delta\tilde{u}_b + f(\tilde{u}_b) = \Delta v_b + g(v_b) = 0 \quad \text{in } a < |x| < b,$$

and

$$\tilde{u}_b = u_0 < 0 \quad \text{on } |x| = a \quad \text{and} \quad |x| = b.$$

Hence, $\tilde{u}_b$ is a subsolution of (2.1), (2.2). Since $\bar{u}$ is a supersolution and $\bar{u} > \tilde{u}_b$, by monotone iteration scheme (see, e.g., [11], [18]), there is a positive solution u_b of (2.1), (2.2) and u_b satisfies $\tilde{u}_b < u_b < \bar{u}$, which also implies $\|u_b\| \in (\gamma, \bar{u})$. □

Now, we can prove the following multiplicity result for general case.

THEOREM 5.4. *Assume condition* (H4) *is satisfied. Then, we have the following results*:

(i) *If* $f(0) \geqq 0$, *then there exists* $b^* < a$ *such that for any* $b > b^*$, (2.1), (2.2) *has at least* $2m-1$ *positive solutions* $\tilde{u}_1, \underset{\sim}{u}_2, \tilde{u}_2, \cdots, \underset{\sim}{u}_m, \tilde{u}_m$ *with* $\tilde{u}_{k-1} < \tilde{u}_k$ *and* $\underset{\sim}{u}_k < \tilde{u}_k$ *in* (a, b), *and* $\|\underset{\sim}{u}_k\|, \|\tilde{u}_k\| \in (\gamma_k, \bar{u}_k)$ *for* $k = 2, \cdots, m$.

(ii) *If* $f(0) < 0$, *then there exists* $b^* > a$ *such that for any* $b > b^*$, (2.1), (2.2) *has at least* m *positive solutions* $\tilde{u}_1 < \cdots < \tilde{u}_m$ *with* $\|\tilde{u}_k\| \in (\gamma_k, \bar{u}_k)$ *for* $k = 1, \cdots, m$.

Proof. We shall prove the theorem by induction on m.

For $m = 1$, the results were proved in Lemmas 5.2 and 5.3 under the conditions (H5) and (H5)′, respectively. The arguments used in the last two lemmas are also valid for general cases; thus the details are omitted.

We first study the case $f(0) \geqq 0$. For $j = 2, \cdots, m$, denote

$$f_j(u) = \begin{cases} f(u) & \text{for } u \in [0, \bar{u}_j], \\ 0 & \text{for } u \in [\bar{u}_j, \infty), \\ 2f(0) - f(-u) & \text{for } u < 0, \end{cases}$$

$$F_j(u) = \int_0^u f_j(t)\, dt,$$

and

$$J_j(u) = \int_a^b r^{n-1} \left\{ \frac{1}{2} u'^2(r) - F_j(u(r)) \right\} dr.$$

It is clear that f_{j+1} is an extension of f_j and

$$\text{if } \|u\| < \bar{u}_j, \quad \text{then } \bar{J}_{j+1}(u) = J_j(u) \tag{5.24}$$

for $j = 1, \cdots, m-1$.

Assume $m = j (\geqq 1)$ is true. Then there exists a $b_j^* > a$ such that for any $b > b_j^*$, $J_j(u)$ has a minimizer $\tilde{u}_{j,b}$ which is a positive solution of (2.1), (2.2) and satisfies

$$\|\tilde{u}_{j,b}\| \in (\gamma_j, \bar{u}_j) \tag{5.25}$$

and

$$-\frac{b^n}{n} F_j(\bar{u}_j) \leqq J_j(\tilde{u}_{j,b}) \leqq -\frac{b^n}{n} F_j(\bar{u}_j) + C_j(b^{n-1} + 1) \tag{5.26}$$

for some positive constant C_j that is independent of b.

Let $u_{j+1,b}^*$ be as in (5.12) with $\bar{u}$ replaced by $\bar{u}_{j+1}$. Then

$$J_{j+1}(u_{j+1,b}^*) \leqq -\frac{b^n}{n} F_{j+1}(\bar{u}_{j+1}) + C_{j+1}(b^{n-1} + 1) \tag{5.27}$$

for some positive constant C_{j+1} independent of b. Therefore, by (5.24) ~ (5.27), there exists $\bar{b}^*_{j+1} \geqq b^*_j$, such that for any $b > \bar{b}^*_{j+1}$, minimizer $\tilde{u}_{j+1,b}$ of J_{j+1} satisfies

$$J_{j+1}(\tilde{u}_{j+1,b}) < J_j(\tilde{u}_{j,b}).$$

Hence, $\tilde{u}_{j+1,b} \neq \tilde{u}_{j,b}$ and $\|\tilde{u}_{j+1,b}\| \in (\gamma_{j+1}, \bar{u}_{j+1})$.

Let

$$N_{j+1} = \{\alpha \in N: \gamma_{j+1} < \|u\| < \bar{u}_{j+1}\}.$$

Then N_{j+1} is an open set and nonempty according to the last paragraph. Therefore, by Lemma 5.1, there exist two positive numbers $\bar{\alpha}_{j+1} > \underline{\alpha}_{j+1}$, such that $(\underline{\alpha}_{j+1}, \bar{\alpha}_{j+1}) \subset N_{j+1}$, $\underline{\alpha}_{j+1} \notin N_{j+1}$ and $\bar{\alpha}_{j+1} \notin N_{j+1}$. By Lemma 2.4, $\underline{\alpha}_{j+1}$ and $\bar{\alpha}_{j+1}$ belong to P. Hence,

$$\lim_{\alpha \to (\underline{\alpha}_{j+1})^+} b(\alpha) = \infty = \lim_{\alpha \to (\bar{\alpha}_{j+1})^-} b(\alpha),$$

and then both $u(\cdot, \underline{\alpha}_{j+1})$ and $u(\cdot, \bar{\alpha}_{j+1})$ satisfy (M). Therefore, there exists $b^*_{j+1} \geqq \bar{b}^*_{j+1}$, such that for any $b > b^*_{j+1}$, (2.1), (2.2) has at least two positive solutions having maximum value in $(\gamma_{j+1}, \bar{u}_{j+1})$. Since $\bar{u}_{j+1}$ is a supersolution, there exists the maximum positive solution $\tilde{u}_{j+1}$ of (2.1), (2.2) having maximum value in $(\gamma_{j+1}, \bar{u}_{j+1})$. This proves (i).

Condition (ii) can be proved by using the arguments used in (i) and Lemma 5.3; thus details are omitted. □

In the proof of last theorem, we obtain the following results for (3.6), (3.7).

COROLLARY 5.5. *Assume condition* (H4) *is satisfied. Then, we have the following results*:

(i) *If* $f(0) > 0$, *then there exist at least* $2m-1$ *positive solutions* $\tilde{u}_1, \underline{u}_2, \tilde{u}_2, \cdots, \tilde{u}_m$ *of* (3.6), (3.7) *and* $\tilde{u}_j(r) \to \bar{u}_j$ *as* $r \to \infty$ *for* $j = 1, \cdots, m$.

(ii) *If* $f(0) \leqq 0$, *then there exist at least* $2m-2$ *positive solutions* $\underline{u}_2, \tilde{u}_2, \cdots, \tilde{u}_m$ *of* (3.6), (3.7) *and* $\tilde{u}_j(r) \to \bar{u}_j$ *as* $r \to \infty$ *for* $j = 2, \cdots, m$.

PARTIAL REGULARITY IN PROBLEMS MOTIVATED BY NONLINEAR ELASTICITY*

NICOLA FUSCO† AND J. HUTCHINSON‡

Abstract. Regularity is proven almost everywhere for minimisers of problems motivated by nonlinear elasticity. Model problems treated include

$$\int_\Omega |Du|^2 + |\det Du|^2,$$

where $u : \Omega (\subset \mathbb{R}^2) \to \mathbb{R}^2$, and

$$\int_\Omega |Du|^2 + |Du|^s + |AdDu|^s + |\det Du|^s,$$

where $u : \Omega (\subset \mathbb{R}^3) \to \mathbb{R}^3$ with $s > 2$.

In particular, continuity of minimisers is not assumed a priori. "Degenerate" convexity of the integrand in the higher minors M of Du is also allowed, in the sense that second derivatives in M may approach zero as $M \to 0$.

Key words. nonlinear elasticity, partial regularity, elliptic systems

AMS(MOS) subject classifications. 35J50, 35J60, 73C50

1. Introduction.

Partial regularity for minimisers of functionals of the form

$$I[u] = \int_\Omega F(u) \quad \left(\text{or} \int_\Omega F(x, u, Du) \right), \tag{1.1}$$

where $\Omega \subset \mathbb{R}^n$ and $u : \Omega \to \mathbb{R}^N$, and F is convex in Du, has been extensively studied. See [G] and the references therein.

Many natural problems, however, only require that F be *quasi-convex* (see [B], [E], and [G]). Existence theory in such cases is now well understood; see [G] for references and [AF] for a nearly optimal result. Partial regularity results were recently obtained by Evans [E] and extended in [FH] and [GM].

All known natural examples of quasi-convex functionals (such as in nonlinear elasticity theory; see [B]) are, in fact, *polyconvex.* Recall that a polyconvex functional in Du is a convex function of the various minors of the matrix [Du]. Polyconvexity implies quasiconvexity [M]. While the converse is not true, the known counter examples are quite pathological. It is natural, then, to investigate the regularity theory for polyconvex functionals.

In this paper we prove new partial regularity results for various polyconvex functionals, rather than for general quasi-convex functionals. Some model problems that are treated include

$$I[u] = \int_\Omega |Du|^2 + |\text{deT } Du|^2 \tag{1.2}$$

in the case where $n = N = 2$, and

$$I[u] = \int_\Omega |Du|^2 + |Du|^s + |\text{Ad } Du|^s + |\det Du|^s \tag{1.3}$$

for $s > 2$, in the case where $n = N = 3$.

Since $|\text{Ad } Du|$ is the Euclidean norm of the map $|Du \wedge Du|$ which sends two-forms to two-forms, and $|\det Du|$ is the corresponding norm in (1.3) for maps on three-forms and in (1.2) for maps on two-forms, the preceding functionals are natural geometric generalisations of the Dirichlet energy. More generally, the linear map $\Lambda_k Du(x)$ sends k-vectors in $\mathbb{R}^n$ to k-vectors in $\mathbb{R}^N$, and the partial regularity result we prove includes the case of the functional

$$I[u] = \int_\Omega |Du|^2 + |Du|^s + \sum_{i=2}^{k} |\Lambda_i Du|^s, \tag{1.4}$$

where $s \geqq 2$ if $n = 2$, and $s > n - 1$ if $n \geqq 3$.

In order to simplify the exposition, which is already quite long, we restrict ourselves to problems of the form

$$I[u] = \int_\Omega F^1(Du) + \sum_{i=2}^{k} F^i(\Lambda_i Du), \tag{1.5}$$

where each $F^i(q)$ has the same growth rate for large q. It is clear, however, that the methods apply to other problems with differing growth rates.

The main result (Theorem 4.1) is that minimisers of $I[u]$ are $C^{1,\alpha}$ except on a closed set of measure zero, for each $0 < \alpha < 1$. Higher regularity follows from the Euler–Lagrange equations by standard bootstrapping arguments.

We now comment on some aspects of the functionals that we consider, as well as on the proof of the theorem.

The set of those competing functions for which the integrand is finite is not a linear space, even for (1.2). This corresponds to the fact that, for 2×2 matrices A and B, we have

$$\det (A + B) = \det A + \det B + A_{11}B_{22} + A_{22}B_{11} - A_{12}B_{21} - A_{21}B_{12},$$

and so we cannot improve on the powers in the estimate

$$\int_\Omega (\det (Du + Dv))^2 \leqq c \int_\Omega ((\det Du)^2 + (\det Dv)^2 + |Du|^4 + |Dv|^4).$$

It follows that if ϕ is a function obtained by smoothly interpolating between u and v, then we cannot normally estimate $I[\phi]$ in terms of $I[u]$ and $I[v]$. In (5.42) we use a new comparison function construction that does enable us to obtain estimates of this form.

In order to include the model problem (1.2) in the theory developed by Evans [E], it would be necessary to include a term of the form $\varepsilon |Du|^4$, for some $\varepsilon > 0$, in the integrand in order to control the determinant term. Similar remarks apply to the more general class of integrands covered in Theorem 4.1.

Note that minimisers are not a priori continuous. Also, the structure conditions allow (in fact require, but that is not necessary, as noted in § 7.2) degenerate ellipticity in the higher-order minors.

The proof of the main theorem involves a blowup argument. As usual, we obtain a sequence of "bad" balls $B(x_m, r_m)$ and a corresponding sequence of normalised

functions v_m defined on the unit ball. We then show that each v_m minimises a certain normalised functional obtained not, as would normally be the case, by linearising about $(Du)_{x_m,r_m}$, but (in the case of (1.3), for example) by linearising the three terms in the integrand about $(Du)_{x_m,r_m}$, $(\mathrm{Ad}\, Du)_{x_m,r_m}$, and $(\det Du)_{x_m,r_m}$, respectively. The proof of this makes essential use of the fact that each minor can be written in divergence form.

The blowup argument is used to prove a decay estimate on the quantity

$$U(x,r)=\fint_{B(x,r)}\Big(|Du-(Du)_{x,r}|^2+|Du-(Du)_{x,r}|^s + \sum_{i=2}^{k}|\Lambda_i(Du)_{x,r}|^{s-2}|\Lambda_i(Du-(Du)_{x,r})|^2+\sum_{i=2}^{k}|\Lambda_i(Du-(Du)_{x,r})|^s\Big), \tag{1.6}$$

where s is the common growth rate of the $F^i(q)$ in (1.5). The first two terms in (1.6) are as in [E], the fourth term is accounted for by the growth rate of the F^i, and the third term is necessary to handle the degenerate ellipticity corresponding to the F^i term. This particular choice of third term was motivated by the quantity $U(x, r)$ shown to decay in [FH2], where an analogous degeneracy problem occurred.

To prove the decay lemma, we first establish that the normalised functions v_m converge to a limit function v in various weak ways (cf. (5.11)), and that v satisfies the linear equation (5.29). In order to obtain the required decay estimate on $U(x, r)$ we establish various strong convergences of the v_m in §§ 5C and 5D. The key point is the construction of suitable comparison functions in (5.42), using the method mentioned previously. Detailed estimates using the minimising properties of the v_m then establish the required forms of strong convergence in (5.64)–(5.67).

We remark that the proof avoids any use of Caccioppoli inequalities, and strongly uses the fact that u is a minimiser of $I[\cdot]$ rather than merely a stationary point. The guiding principle behind the proof is that weak convergence of minimisers should imply strong convergence.

For completeness, we also prove some results of Ball. Although he only considers the cases where $n = N = 2, 3$, the extensions are straightforward. In § 2.4 we show how the elementary symmetric functions of the singular values of Du give rise to polyconvex functions (cf. [B, Thm. 5.1]). The question of regularity of minimisers of such functionals has been raised recently by De Giorgi. In § 3 we establish the existence of minimisers for the class of problems considered in this paper (cf. [B, Thm. 7.7]). Finally, in § 7 we indicate various extensions that can be made to our results.

Under the assumptions with which we work, the weak and pointwise determinants agree (see Lemma 2.2.1), and so our spaces include the ones introduced in [GMS]. On the other hand, we do not know if the two spaces coincide (see also Remarks 2.3.2). However, if we restrict to the closure in $\Lambda_k W^{1,s}$ of C^1 functions, by modifying the proofs somewhat, we are still able to establish the main result, Theorem 4.1. The essential point is to show that the comparison functions stay in the same class. The arguments are somewhat involved.

1.1. Notation. We use the following standard notation:

$$B_t=\{y\in R^n:|y|<t\},$$

$$B(x,r)=\{y\in R^n:|x-y|<r\},$$

$$\fint_E f=|E|^{-1}\int_E f,$$

$$(f)_t = \fint_{B_t} f,$$

$$(f)_{x,r} = \fint_{B(x,r)} f,$$

"$f_m \rightharpoonup f$ in L^k" denotes weak convergence,

"$f_m \to f$ in L^k" denotes strong convergence.

2. Preliminary notions.

2.1. Algebraic preliminaries. Suppose that

$$L: \mathbb{R}^n \to \mathbb{R}^N \tag{2.1}$$

is a linear map. The *standard bases* for $\mathbb{R}^n$ and $\mathbb{R}^N$ will be denoted by $e_1, \cdots, e_n$ and $\varepsilon_1 \cdots, \varepsilon_N$, respectively. *Inner products* are denoted by $(\cdot, \cdot)$ and the associated *inner product norm* is denoted by $|\cdot|$. The *coordinates* of L are given by

$$L_{\alpha i} = (Le_i, \varepsilon_\alpha). \tag{2.2}$$

The *inner product norm* of L is given by

$$|L|^2 = \sum_{i,\alpha} L_{\alpha i}^2. \tag{2.3}$$

For each $k > 1$ the space of k-vectors from $\mathbb{R}^n$ is denoted by $\Lambda_k \mathbb{R}^n$. The standard basis elements for $\Lambda_k \mathbb{R}^n$ are denoted by

$$e_\lambda = e_{\lambda_1} \wedge \cdots \wedge e_{\lambda_k}, \qquad 1 \leqq \lambda_1 < \cdots < \lambda_k \leqq n. \tag{2.4}$$

We define $\Lambda_0 \mathbb{R}^n = \mathbb{R}$, $\Lambda_1 \mathbb{R}^n = \mathbb{R}^n$. If $p > n$, then $\Lambda_p \mathbb{R}^n$ is trivial.

The standard inner product on $\mathbb{R}^n$ induces an inner product on $\Lambda_k \mathbb{R}^n$ where the e_λ defined above form an orthonormal basis.

Similarly, the elements

$$\varepsilon_\mu = \varepsilon_{\mu_1} \wedge \cdots \wedge \varepsilon_{\mu_k}, \qquad 1 \leqq \mu_1 < \cdots < \mu_k \leqq N \tag{2.5}$$

form an orthonormal basis for $\Lambda_k \mathbb{R}^N$.

Recall the identity

$$(u_1 \wedge \cdots \wedge u_k, v_1 \wedge \cdots \wedge v_k) = \det [(u_i, v_j)], \tag{2.6}$$

where u_i and v_j are elements of $\mathbb{R}^n$ (or $\mathbb{R}^N$). In particular,

$$|u_1 \wedge \cdots \wedge u_k|^2 = \det [(u_i, u_j)]. \tag{2.7}$$

For each $k > 1$ there is an induced map $\Lambda_k L$ on k-vectors,

$$\Lambda_k L: \Lambda_k \mathbb{R}^n \to \Lambda_k \mathbb{R}^N, \tag{2.8}$$

where

$$\Lambda_k L(v_1 \wedge \cdots \wedge v_k) = Lv_1 \wedge \cdots \wedge Lv_k. \tag{2.9}$$

We often write

$$\langle \Lambda_k L, v_1 \wedge \cdots \wedge v_k \rangle \tag{2.10}$$

for $\Lambda_k L(v_1 \wedge \cdots \wedge v_k)$.

Analogously to (2.2), $\Lambda_k L$ has coordinates

$$\begin{aligned}(\Lambda_k L)_{\mu\lambda} &= (\Lambda_k L(e_\lambda), \varepsilon_\mu) \\ &= (Le_{\lambda_1} \wedge \cdots \wedge Le_{\lambda_k}, \varepsilon_{\mu_1} \wedge \cdots \wedge \varepsilon_{\mu_k}) \\ &= \det [L_{\mu_j \lambda_i}]_{i,j=1}^k,\end{aligned} \tag{2.11}$$

where we have used (2.6) and (2.2).

For example,

$$\begin{aligned}(\Lambda_2 L)_{(\mu_1,\mu_2)(\lambda_1,\lambda_2)} &= \begin{vmatrix} L_{\mu_1\lambda_1} & L_{\mu_1\lambda_2} \\ L_{\mu_2\lambda_1} & L_{\mu_2\lambda_2} \end{vmatrix} \\ &= L_{\mu_1\lambda_1} L_{\mu_2\lambda_2} - L_{\mu_1\lambda_2} L_{\mu_2\lambda_1}.\end{aligned} \tag{2.12}$$

Thus the coordinates of $\Lambda_k L$ are precisely the $k \times k$ minors of the matrix $[L_{\alpha i}]$.

The inner product norm of $\Lambda_k L$ is given by

$$|\Lambda_k L|^2 = \sum_{\lambda,\mu} (\Lambda_k L)_{\mu\lambda}^2. \tag{2.13}$$

If $A = [a_{\alpha i}]$ and $B = [b_{\alpha i}]$ are $k \times k$ matrices, then

$$\det (A+B) = \det A + \sum_{i=1}^{k-1} \sum A^{(k-i)} B^{(i)} + \det B. \tag{2.14}$$

Here $A^{(k-i)}$ ranges over all $(k-i)\times(k-i)$ minors from A, and $B^{(i)}$ is always the complementary $i \times i$ minor from B.

Suppose that both L, $M : \mathbb{R}^n \to \mathbb{R}^N$ are linear maps. Following (2.14) we write

$$\Lambda_k(L+M) = \Lambda_k L + \sum_{i=1}^{k-1} \Lambda_{k-i} L \odot \Lambda_i M + \Lambda_k M. \tag{2.15}$$

In other words, each component of $\Lambda_k(L+M)$ is a sum of terms of which the first is the corresponding component of $\Lambda_k L$ and the last is the corresponding component of $\Lambda_k M$. The expression $\Lambda_{k-i} L \odot \Lambda_i M$ denotes a sum of terms of the form lm, where l and m are coordinates of $\Lambda_{k-i} L$ and $\Lambda_i M$, respectively.

For example, as we see from (2.12)

$$\begin{aligned}(\Lambda_2(L+M))_{(\mu_1,\mu_2)(\lambda_1,\lambda_2)} &= \begin{vmatrix} L_{\mu_1\lambda_1} + M_{\mu_1\lambda_1} & L_{\mu_1\lambda_2} + M_{\mu_1\lambda_2} \\ L_{\mu_2\lambda_1} + M_{\mu_2\lambda_1} & L_{\mu_2\lambda_2} + M_{\mu_2\lambda_2} \end{vmatrix} \\ &= L_{\mu_1\lambda_1} L_{\mu_2\lambda_2} - L_{\mu_1\lambda_2} L_{\mu_2\lambda_1} \\ &\quad + (L_{\mu_1\lambda_1} M_{\mu_2\lambda_2} + L_{\mu_2\lambda_2} M_{\mu_1\lambda_1} - L_{\mu_1\lambda_1} M_{\mu_2\lambda_1} \\ &\quad - L_{\mu_2\lambda_1} M_{\mu_1\lambda_2}) \\ &\quad + (M_{\mu_1\lambda_1} M_{\mu_2\lambda_2} - M_{\mu_1\lambda_2} M_{\mu_2\lambda_1}).\end{aligned} \tag{2.16}$$

We sometimes write

$$\Lambda_k(L+M) = \sum_{i=0}^{k} \Lambda_{k-i} L \odot \Lambda_i M, \tag{2.17}$$

with the understanding that $\Lambda_0 L = 1$, $\Lambda_0 M = 1$.

2.2. Properties of $\Lambda_k Du$. First suppose

$$u : \Omega (\subset \mathbb{R}^k) \to \mathbb{R}^k, \tag{2.18}$$

where Ω is a smooth bounded domain and u is a smooth map. We will denote by

$$[Du / D_i u^\alpha] \tag{2.19}$$

the matrix obtained from the matrix $[Du]$ by deleting the αth row and ith column (i.e., the row and column containing $D_i u^\alpha$).

Then

$$\sum_{i=1}^{k} (-1)^i D_i \det [Du/D_i u^\alpha] = 0, \qquad \alpha = 1, \cdots, k. \tag{2.20}$$

This follows from the rule for differentiating a determinant together with the alternating character of a determinant (see [M, Lemma 4.4.6, p. 122]).

It follows that

$$\det Du = \sum_{i=1}^{k} (-1)^{i+\alpha} D_i (u^\alpha \det [Du/D_i u^\alpha]), \qquad \alpha = 1, \cdots, k \tag{2.21}$$

$$0 = \sum_{i=1}^{k} (-1)^i D_i (u^\alpha \det [Du/D_i u^\beta]), \qquad \alpha \neq \beta. \tag{2.22}$$

We next consider more general u.

First assume that $k = 2$ and $u \in W^{1,2}(\Omega)$. It is trivial that $\det Du \in L^1(\Omega)$. Moreover, (2.20)-(2.22) hold in the distributional sense. This is easily seen by first writing each of (2.20)-(2.22) in weak, i.e., integral form, and noting that the corresponding integrals are continuous in $W^{1,2}$. Since $C^\infty(\Omega)$ is dense in $W^{1,2}(\Omega)$, this establishes the claim.

Now assume $k > 2$ and $u \in W^{1,k-1}(\Omega)$. Then the determinant of any $j \times j$ minor of Du belongs to $L^{(k-1)/j}(\Omega)$ for $1 \leqq j \leqq k-1$, and in particular $\det [Du/D_i u^\alpha] \in L^1(\Omega)$ for each i and α. Moreover, (2.20) holds for such u by a similar approximation argument as before.

Now assume moreover that $\det [Du/D_i u^\alpha] \in L^{(k-1)/(k-2)}(\Omega)$ for each i and α. It follows immediately by the rule for expanding a determinant that $\det Du \in L^1(\Omega)$. We also claim that (2.21) and (2.22) are now true in the distributional sense.

To see this, let $\{u_m\} \subset C^\infty(\Omega)$ and $u_m \to u$ in $W^{1,k-1}(\Omega)$. Also (as in [B, Lemma 6.1]), let $(\det [Du/D_i u^\alpha])_m$ be obtained by mollifying $\det [Du/D_i u^\alpha]$ with ρ_{ε_m}, where $\rho_{\varepsilon_m}(x) = \varepsilon_m^{-k} \rho(\varepsilon_m^{-1} x)$, $\rho \in C_c^\infty(\Omega)$, $\rho \geqq 0$, $\int \rho = 1$, and $\varepsilon_m \to 0$. Then $(\det [Du/D_i u^\alpha])_m \to \det [Du/D_i u^\alpha]$ in $L^{(k-1)/(k-2)}_{\text{loc}}$. Moreover, for $d(x, \partial\Omega) > \varepsilon_m$, it follows from (2.20) that

$$\sum_{i=1}^{k} (-1)^i D_i (\det [Du/D_i u^\alpha])_m(x) = \sum_{i=1}^{k} (-1)^i \int_\Omega D_i \rho_{\varepsilon_m}(x-y) \det [Du/D_i u^\alpha](y)\, dy$$
$$= 0.$$

It follows for any $\varphi \in C_c^\infty(\Omega)$ and all sufficiently large m, that

$$\int \sum_{i=1}^{k} (-1)^{i+\alpha} D_i u_m^\alpha (\det [Du/D_i u^\alpha])_m \varphi = \int \sum_{i=1}^{k} (-1)^{i+\alpha} D_i (u_m^\alpha \det [Du/D_i u^\alpha])_m \varphi$$
$$= -\int \sum_{i=1}^{k} (-1)^{i+\alpha} u_m^\alpha (\det [Du/D_i u^\alpha])_m D_i \varphi.$$

Letting $m \to \infty$ we obtain (2.21).

(We remark that the key point in the preceding argument was to mollify $\det [Du/D_i u^\alpha]$, rather than to consider $\det [Du_m/D_i u_m^\alpha]$.)

Similarly, if $\alpha \neq \beta$,

$$\int \sum_{i=1}^{k} (-1)^i D_i u_m^\alpha (\det [Du/D_i u^\beta])_m \varphi = -\int \sum_{i=1}^{k} (-1)^{i+\alpha} u_m^\alpha (\det [Du/D_i u^\beta])_m D_i \varphi.$$

Letting $m \to \infty$ and using the fact that $0 = \sum_{i=1}^{k} (-1)^i A_i^\alpha \det [A/A_i^\beta]$ for any $k \times k$ determinant $[A]$ and for $\alpha \neq \beta$, we see (2.22) is also true in the distributional sense.

Equation (2.21) is often used to give a definition of $\det Du$ in the weak, or distributional, sense. Thus we have, in particular, established the following lemma.

LEMMA 2.2.1. *Suppose* $u:\Omega(\subset\mathbb{R}^k)\to\mathbb{R}^k$. *Assume that either* $k=2$ *and* $u\in W^{1,2}(\Omega)$ *or that* $k>2$, $u\in W^{1,k-1}(\Omega)$, *and* $\det[Du/D_iu^\alpha]\in L^{(k-1)/(k-2)}(\Omega)$ *for each* i *and* α. *Then the determinant of any* $j\times j$ *minor of* Du *exists both pointwise and in the weak sense, and both notions agree.*

Next assume

$$u:\Omega(\subset\mathbb{R}^n)\to\mathbb{R}^N, \tag{2.23}$$

where Ω is a smooth bounded domain and u is a smooth map. Then it follows from (2.11) and (2.21) that

$$\begin{aligned}(\Lambda_kDu)_{\mu\lambda}&=\det[D_{\lambda_i}u^{\mu_j}]_{i,j=1}^k\\&=\sum_{i=1}^k(-1)^{i+j}D_{\lambda_i}(u^{\mu_j}(\Lambda_{k-1}Du)_{(\mu_1\cdots\hat{\mu}_j\cdots\mu_k)(\lambda_1\cdots\hat{\lambda}_i\cdots\lambda_k)})\end{aligned} \tag{2.24}$$

for each $j=1,\cdots,k$.

In particular,

$$\begin{aligned}(\Lambda_2Du)_{(\mu_1,\mu_2)(\lambda_1,\lambda_2)}&=\begin{vmatrix}D_{\lambda_1}u^{\mu_1}&D_{\lambda_2}u^{\mu_1}\\D_{\lambda_1}u^{\mu_2}&D_{\lambda_2}u^{\mu_2}\end{vmatrix}\\&=D_{\lambda_1}(u^{\mu_1}D_{\lambda_2}u^{\mu_2})-D_{\lambda_2}(u^{\mu_1}D_{\lambda_1}u^{\mu_2}).\end{aligned} \tag{2.25}$$

A similar expression is obtained on expanding across the second row.

Similarly,

$$\begin{aligned}(\Lambda_3Du)_{(\mu_1,\mu_2,\mu_3)(\lambda_1,\lambda_2,\lambda_3)}&=\begin{vmatrix}D_{\lambda_1}u^{\mu_1}&D_{\lambda2}u^{\mu_1}&D_{\lambda_3}u^{\mu_1}\\D_{\lambda_1}u^{\mu_2}&D_{\lambda_2}u^{\mu_2}&D_{\lambda_3}u^{\mu_2}\\D_{\lambda_1}u^{\mu_3}&D_{\lambda_2}u^{\mu_3}&D_{\lambda_3}u^{\mu_3}\end{vmatrix}\\&=D_{\lambda_1}(u^{\mu_1}(\Lambda_2Du)_{(\mu_2,\mu_3)(\lambda_2,\lambda_3)})\\&\quad-D_{\lambda_2}(u^{\mu_1}(\Lambda_2Du)_{(\mu_2,\mu_3)(\lambda_1,\lambda_3)})\\&\quad+D_{\lambda_3}(u^{\mu_1}(\Lambda_2Du)_{(\mu_2,\mu_3)(\lambda_1,\lambda_2)}).\end{aligned} \tag{2.26}$$

A similar expression is again obtained by expanding across the second or third row.

We usually abbreviate (2.24) to

$$\Lambda_kDu=\sum D(u\odot\Lambda_{k-1}Du), \tag{2.27}$$

or even

$$\Lambda_kDu=D(u\Lambda_{k-1}Du). \tag{2.28}$$

The essential point to observe is that each component function of Λ_kDu is a linear combination of partial derivatives of terms of the form fg, where f is a component function of u and g is a component of $\Lambda_{k-1}Du$. The more precise form in (2.24) will not usually be relevant.

2.3. The class $\Lambda_kW^{1,s}(\Omega)$.

DEFINITION 2.3.1. Assume $\Omega(\subset\mathbb{R}^n)$ is a smooth bounded domain and

$$u:\Omega\to\mathbb{R}^N.$$

Assume $2\leqq k\leqq\min\{n,N\}$ and assume

$$s\geqq 2 \quad\text{if } n=2, \qquad s\geqq n-1 \quad\text{if } n>2.$$

Then

$$\Lambda_k W^{1,s}(\Omega)$$

is the class of functions $u \in W^{1,s}(\Omega)$ such that $\Lambda_i Du \in L^s$ for $i = 1, \cdots, k$.

Remarks 2.3.2. (i) It follows from Lemma 2.2.1 that (each component of) $\Lambda_i Du$ exists also in the weak sense and that the weak and pointwise notions agree. In other words, (2.24) is valid in the distributional sense.

(ii) We can define $\Lambda_k W^{1,s}(\Omega)$ in the weak sense for more general s and develop a corresponding theory, but the weak and pointwise notions will not necessarily agree. Although this is an appropriate setting for variational problems, the regularity theory in § 5 only applies if $s \geqq 2$ (for $n = 2$) or $s > n - 1$ (for $n > 2$).

For this reason we will in future maintain the restrictions on s given in the definition above.

(iii) More general classes of functions could be clearly defined by requiring $\Lambda_i Du \in L^{s_i}$ for different s_i. It is also possible to generalise the regularity results of § 5 in an analogous way.

(iv) It is clear that $\Lambda_k W^{1,s}(\Omega)$ is *not* generally a linear space. This is a basic reason for some of the difficulties we encounter in § 5.

Since $\Lambda_k Du$ is in particular a vector-valued function, we take the usual L^s norm

$$\|\Lambda_k Du\|_{L^s} = \left(\int_\Omega \sum_{\lambda,\mu} |(\Lambda_k Du)_{\mu\lambda}|^s \right)^{1/s}. \tag{2.29}$$

DEFINITION 2.3.3. A sequence $\{u_j\} \subset \Lambda_k W^{1,s}(\Omega)$ converges in the weak $\Lambda_k W^{1,s}$ sense to $u \in W^{1,s}(\Omega)$ if

(a) $u_j \rightharpoonup u$ in $W^{1,s}(\Omega)$,

(b) $\|\Lambda_i Du_j\|_{L^s} \leqq M$ for $1 = 2, \cdots, k$ and some $M < \infty$, independent of j.

We write

$$u_j \rightharpoonup u \quad \text{in} \quad \Lambda_k W^{1,s}(\Omega) \text{ (or } \Lambda_k W^{1,s}).$$

PROPOSITION 2.3.4. *If $u_j \rightharpoonup u$ in $\Lambda_k W^{1,s}(\Omega)$, then, moreover,*

(i) $u \in \Lambda_k W^{1,s}(\Omega)$,

(ii) $\Lambda_i Du_j \rightharpoonup \Lambda_i Du$ *in* $L^s(\Omega)$, $i = 2, \cdots, k$,

(iii) $\|\Lambda_i Du\|_{L^s} \leqq \liminf_{j\to\infty} \|\Lambda_i Du\|$, $i = 2, \cdots, k$.

Proof. We show by induction on i that $u \in \Lambda_i W^{1,s}$ for $i = 2, \cdots, k$ and that (ii) and (iii) are true.

In case $i = 2$ we observe that $u_j Du_j \rightharpoonup uDu$ in L^1, since $u_j \to u$ in L^s and $Du_j \rightharpoonup Du$ in L^s (and $s \geqq 2$). To see that (iii) is true we observe from (2.25) that

$$\|\Lambda_2 Du\|_{L^s} = \sup \left\{ \int_\Omega uDuD\varphi : \int_\Omega |\varphi|^{s/s-1} \leqq 1 \right\},$$

where we are using the same abuse of notation as in (2.28). Standard arguments now imply (iii).

It follows that (i) and (ii) are also true, since weak L^s convergence is equivalent to distributional convergence in the presence of uniform L^s bounds.

Similar arguments apply for $i > 2$ after writing $\Lambda_i Du = D(u\Lambda_{i-1} Du)$ in integral form. □

Although $\Lambda_k W^{1,s}(\Omega)$ is not usually a linear space, we do have from (2.15) that if $u \in \Lambda_k W^{1,s}(\Omega)$ and $\chi \in C^\infty(\Omega)$ then $u + \chi \in \Lambda_k W^{1,s}(\Omega)$ and

$$\Lambda_k D(u+\chi) = \Lambda_k Du + \sum_{i=1}^{k-1} \Lambda_{k-i} Du \odot \Lambda_i D\chi + \Lambda_k D\chi. \tag{2.30}$$

In particular,

$$|\Lambda_k D(u+\chi)| \leqq c(\chi)\left(1+\sum_{i=1}^{k}|\Lambda_i Du|\right).$$

Also, if $\psi:\Omega(\subset\mathbb{R}^n)\to\mathbb{R}^n$ is bi-Lipschitz and $u\in\Lambda_k W^{1,s}(\psi(\Omega))$, then $u\circ\psi\in\Lambda_k W^{1,s}(\Omega)$, and we calculate almost everywhere that

$$\begin{aligned}
&(\Lambda_k D(u\circ\psi))_{(\mu_1,\cdots,\mu_k)(\lambda_1,\cdots,\lambda_k)}\\
&\quad=((\Lambda_k D(u\circ\psi))(e_{\lambda_1}\wedge\cdots\wedge e_{\lambda_k}),\ \varepsilon_{\mu_1}\wedge\cdots\wedge\varepsilon_{\mu_k})\\
&\quad=(D(u\circ\psi)(e_{\lambda_1})\wedge\cdots\wedge D(u\circ\psi)(e_{\lambda_k}),\ \varepsilon_{\mu_1}\wedge\cdots\wedge\varepsilon_{\mu_k})\\
&\quad=(Du(D\psi(e_{\lambda_1}))\wedge\cdots\wedge Du(D\psi(e_{\lambda_k})),\ \varepsilon_{\mu_1}\wedge\cdots\wedge\varepsilon_{\mu_k})\\
&\quad=\sum_{\alpha_1,\cdots,\alpha_k=1}^{n}\frac{\partial\psi^{\alpha_1}}{\partial x_{\lambda_1}}\cdot\cdots\cdot\frac{\partial\psi^{\alpha_k}}{\partial x_{\lambda_k}}(Du(e_{\alpha_1})\wedge\cdots\wedge Du(e_{\alpha_k}),\ \varepsilon_{\mu_1}\wedge\cdots\wedge\varepsilon_{\mu_k})\\
&\quad=\sum_{1\leqq\alpha_1<\cdots<\alpha_k\leqq n}\frac{\partial(\psi^{\alpha_1},\cdots,\psi^{\alpha_k})}{\partial(x_{\lambda_1},\cdots,x_{\lambda_k})}(\Lambda_k Du)_{(\mu_1,\cdots,\mu_k)(\alpha_1,\cdots,\alpha_k)}.
\end{aligned}\tag{2.31}$$

2.4. Singular values and polyconvex functions. Recall that the singular values of a linear map $L:\mathbb{R}^n\to\mathbb{R}^N$ are the eigenvalues $\sigma_1,\cdots,\sigma_N$ of the positive semidefinite $N\times N$ symmetric matrix $\sqrt{L\circ L^*}$, where L^* is the transpose map.

Moreover, we have the following lemma.

LEMMA 2.4.1. *If $\sigma_1,\cdots,\sigma_N$ are the singular values of $L:\mathbb{R}^n\to\mathbb{R}^N$, then $\sigma_{i_1}\cdot\cdots\cdot\sigma_{i_k}$ for $1\leqq i_1<\cdots<i_k\leqq N$ are the singular values of $\Lambda_k L$.*

Proof. First note that if $T:\mathbb{R}^N\to\mathbb{R}^p$ is a linear map, then

$$\Lambda_k(T\circ L)=\Lambda_k T\circ\Lambda_k L.\tag{2.32}$$

This follows immediately by applying each side to an arbitrary basis element $e_{i_1}\wedge\cdots\wedge e_{i_k}$ and using (2.9).

Next note that

$$(\Lambda_k L)^*=\Lambda_k L^*,\tag{2.33}$$

where $(\Lambda_k L)^*$ is the transpose map of $\Lambda_k L$. This follows by considering basis elements $e_\lambda=e_{\lambda_1}\wedge\cdots\wedge e_{\lambda_k}$ in $\Lambda_k\mathbb{R}^n$ and $\varepsilon_\mu=\varepsilon_{\mu_1}\wedge\cdots\wedge\varepsilon_{\mu_k}$ in $\Lambda_k\mathbb{R}^N$. We have

$$\begin{aligned}
((\Lambda_k L^*)\varepsilon_\mu,\ e_\lambda)&=(L^*\varepsilon_{\mu_1}\wedge\cdots\wedge L^*\varepsilon_{\mu_k},\ e_{\lambda_1}\wedge\cdots\wedge e_{\lambda_k})\\
&=\det[(L^*\varepsilon_{\mu_i},\ e_{\lambda_j})]_{i,j=1}^{k}\quad\text{(from (2.6))}\\
&=\det[(\varepsilon_{\mu_i},\ Le_{\lambda_j})]_{i,j=1}^{k}\\
&=(\varepsilon_{\mu_1}\wedge\cdots\wedge\varepsilon_{\mu_k},\ Le_{\lambda_1}\wedge\cdots\wedge Le_{\lambda_k})\quad\text{(from (2.6))}\\
&=(\varepsilon_\mu,\ (\Lambda_k L)e_\lambda)\\
&=((\Lambda_k L)^*\varepsilon_\mu,\ e_\lambda).
\end{aligned}$$

This implies (2.33).

Let $v_1,\cdots,v_N$ be eigenvectors of $L\circ L^*$ with eigenvalues $\sigma_1^2,\cdots,\sigma_N^2$, respectively. We may assume the v_i form an orthonormal basis of $\mathbb{R}^N$.

It follows that

$$\begin{aligned}
\langle\Lambda_k L\circ(\Lambda_k L)^*,\ v_{i_1}\wedge\cdots\wedge v_{i_k}\rangle&=\langle\Lambda_k(L\circ L^*),\ v_{i_1}\wedge\cdots\wedge v_{i_k}\rangle\\
&=(L\circ L^*)v_{i_1}\wedge\cdots\wedge(L\circ L^*)v_{i_k}\\
&=\sigma_{i_1}^2\cdot\cdots\cdot\sigma_{i_k}^2 v_{i_1}\wedge\cdots\wedge v_{i_k}.
\end{aligned}$$

Thus the $v_{i_1} \wedge \cdots \wedge v_{i_k}$ form a basis of eigenvectors for $\Lambda_k L \circ (\Lambda_k L)^*$, with eigenvalues $\sigma_{i_1}^2 \cdot \cdots \cdot \sigma_{i_k}^2$. In particular, the lemma follows.

LEMMA 2.4.2. *Let*

$$F_j(\Lambda_j L) = g_j(\sigma_1 \cdot \cdots \cdot \sigma_j, \cdots, \sigma_{i_1} \cdot \cdots \cdot \sigma_{i_j}, \cdots),$$

where g is convex and increasing in each variable. Then F is polyconvex.

Proof. This follows immediately from the case where $j = 1$ and Lemma 2.4.1. The case where $j = 1$ is established in [B, Thm. 5.1(ii)]. □

Remark. The previous lemma gives a large class of polyconvex functionals, as shown in [B, § 5] in the case where $n = N = 2, 3$. Namely, if

$$F(Du, \Lambda_2 Du, \cdots, \Lambda_k Du) = \sum_{j=1}^{k} g_j(\sigma_1 \cdot \cdots \cdot \sigma_j, \cdots, \sigma_{i_1} \cdot \cdots \cdot \sigma_{i_j}, \cdots),$$

where g_j are as in the previous lemma, then F is polyconvex.

In particular,

$$\begin{aligned} |\Lambda_j Du|^2 &= \text{Trace } (\Lambda_j Du \circ (\Lambda_j Du)^*) \\ &= \text{Trace } (\Lambda_j (Du \circ Du^*)) \\ &= \sum_{i_1 < \cdots < i_j} \sigma_{i_1}^2 \cdot \cdots \cdot \sigma_{i_j}^2, \end{aligned}$$

where $\sigma_1, \cdots, \sigma_N$ are the singular values of Du.

3. Existence of minimisers. We prove the following existence theorem due to Ball [B, Thm. 7.7]. In fact, the theorem is true (with essentially the same proof) provided $s \geqq 2n/(n+1)$, but under this more general condition the weak and pointwise notions of $\Lambda_i Du$ will no longer necessarily agree. Existence results under even more general conditions have recently been established in [GMS, § 6.A] using techniques from geometric measure theory (they also consider the problem of invertibility), and by Müller [Mu].

Suppose $n = 2$ and $s \geqq 2$, or $n > 2$ and $s \geqq n - 1$.

Let

$$I[u] = \int_\Omega F(x, u, Du, \Lambda_2 Du, \cdots, \Lambda_k Du), \tag{3.1}$$

where

$$u : \Omega (\subset \mathbb{R}^n) \to \mathbb{R}^N. \tag{3.2}$$

We assume

$$F = F(x, z, a_1, \cdots, a_k) : \Omega \times \mathbb{R}^N \times \mathbb{R}^{q_1} \times \cdots \times \mathbb{R}^{q_k} \to \mathbb{R} \tag{3.3}$$

for the appropriate q_i. We write $a = (a_1, \cdots, a_k)$. The structure conditions we assume on F are as follows:

(3.4)
- (a) $F \geqq 0$,
- (b) F is measurable in x for all (z, a),
- (c) F is continuous in z for all (y, a),
- (d) F is convex in a for all (x, z),
- (e) $F(x, z, a_1, \cdots, a_k) \geqq \gamma \sum_{i=1}^{k} |a_i|^s$ for some $\gamma > 0$.

THEOREM 3.1 (Ball). *Suppose I and F are as in* (3.1) *and* (3.4), *and* $v \in W^{1,s}(\Omega)$. *Let*

$$\mathscr{C} = \{u \in \Lambda_k W^{1,s}(\Omega) : u - v \in W_0^{1,s}(\Omega)\}.$$

Then if $I[u] < \infty$ *for some* $u \in \mathscr{C}$, *there will exist* $u \in \mathscr{C}$ *which minimises* $I[u]$ *amongst all members of* $\mathscr{C}$.

Proof. Let $\{u_j\} \subset \mathscr{C}$ be a minimising sequence.

On passing to a subsequence we can assume by Poincaré's inequality that $u_j \rightharpoonup u$ in $W^{1,s}(\Omega)$ for some u. Moreover, from (3.4e) we have uniform bounds on $\|\Lambda_i Du_j\|_{L^s(\Omega)}$ for $i = 2, \cdots, k$. It follows from Definition 2.3.3 and Proposition 2.3.4 that $u_j \rightharpoonup u$ in $\Lambda_k W^{1,s}$ for some u, and moreover that $u \in \mathscr{C}$.

Since $\Lambda_i Du_j \rightharpoonup \Lambda_i Du$ in $L^s(\Omega)$ for each i, by Proposition 2.3.4 (ii), and $u_j \to u$ in L^s, a standard lower semicontinuity result [G, Thm. 2.3, p. 18] implies $I[u] \leqq \lim_{j\to\infty} I[u_j]$.

It follows that u is the required minimiser. □

4. Partial regularity theorem. Suppose

$$u : \Omega (\subset \mathbb{R}^n) \to \mathbb{R}^N \tag{4.1}$$

and $u \in \Lambda_k W^{1,s}$. Consider functionals of the form

$$I[u] = \int_\Omega F^1(Du) + \sum_{i=2}^{k} F^i(\Lambda_i Du). \tag{4.2}$$

Assume the following hypotheses:

(H1) F^i is C^2 for $i = 1, \cdots, k$;

(H2) $s \geqq 2$ if $n = 2$, $s > n - 1$ if $n > 2$;

(H3) (a) $|D^2 F^1(p)| \leqq c(1 + |p|^{s-2})$,

(b) $D_{p_i^\alpha p_j^\beta} F^1(p) \xi_i^\alpha \xi_j^\beta \geqq \gamma(1 + |p|^{s-2})|\xi|^2$

for all $\xi \in \mathrm{Hom}\,(\mathbb{R}^n; \mathbb{R}^N)$, some $\gamma > 0$; For $i = 2, \cdots, k$,

(H4) (a) $|D^2 F^i(q)| \leqq c|q|^{s-2}$,

(b) $D_{q_\alpha q_\beta} F^i(q) \xi_\alpha \xi_\beta \geqq \gamma |q|^{s-2} |\xi|^2$

for all $\xi \in \mathbb{R}^{qi}$, some $\gamma > 0$.

Model problems included under these hypotheses are

$$I[u] = \int_\Omega |Du|^2 + |Du|^s + \sum_{i=2}^{k} |\Lambda_i Du|^s, \tag{4.3}$$

where $s \geqq 2$ if $n = 2$, and $s > n - 1$ if $n > 2$.

The main theorem established in this paper is the following.

MAIN THEOREM 4.1. *Suppose* $u \in \Lambda_k W^{1,s}(\Omega)$ *is a minimiser of* $I[\cdot]$, *where* I *satisfies the hypotheses* (H1)-(H4). *Then there exists an open set* $\Omega_0 \subset \Omega$ *such that*

$$\mathscr{L}^n(\Omega \sim \Omega_0) = 0, \qquad u \in C^{1,\alpha}(\Omega_0)$$

for all $0 < \alpha < 1$.

Remark. In § 7 we indicate various extensions and generalisations.

5. Proof of decay estimate. In this section we continue to use the notation of § 4. In particular, $u \in \Lambda_k W^{1,s}(\Omega)$ is a minimiser of $I[\cdot]$, where $I[\cdot]$ satisfies the hypotheses (H1)-(H4).

Consider the following quantity:

$$U(x, r) := \fint_{B_r(x)} \Big[|Du - (Du)_{x,r}|^2 + |Du - (Du)_{x,r}|^s + \sum_{i=2}^{k} \big(|\Lambda_i (Du)_{x,r}|^{s-2} |\Lambda_i (Du - (Du)_{x,r})|^2 + |\Lambda_i (Du - (Du)_{x,r})|^s \big) \Big] \tag{5.1}$$

(if $s = 2$ we drop the second and third terms on the right side).

We will prove the following decay estimate.

THEOREM 5.1. *Suppose $M > 0$. Then for each $0 < \tau < \frac{1}{2}$ there exists $\varepsilon_0 = \varepsilon_0(\tau, M)$ such that for every $B_r(x) \subset \Omega$, if*

$$|(Du)_{x,r}| \leqq M,$$

$$U(x, r) \leqq \varepsilon_0,$$

then

$$U(x, \tau r) \leqq c_1 \tau^2 U(x, r)$$

for some $c_1 = c_1(M)$.

Proof. We specify $c_1(M)$ later (see (5.86) and (5.38)). Assume the theorem is not true for some M and τ, which we fix.

In the following we will allow c to be a constant which may depend on M, but *not* on τ or m, and which may change from line to line.

By assumption there exist balls $B(x_m, r_m) \subset \Omega$ such that $|(Du)_{x_m, r_m}| \leqq M$, $U(x_m, r_m) \to 0$ as $m \to \infty$, and

$$U(x_m, \tau r_m) > c_1 \tau^2 U(x_m, r_m). \tag{5.2}$$

We will establish a contradiction to (5.2) for some sufficiently large $c_1 = c_1(M)$. Let

$$\lambda_m^2 = U(x_m, r_m). \tag{5.3}$$

Then $\lambda_m \neq 0$ (as otherwise Du is constant on $B_{r_m}(x_m)$ and so both sides of (5.2) equal zero, contradicting (5.2)). Thus we take

$$0 < \lambda_m \to 0 \quad \text{as } m \to \infty. \tag{5.4}$$

Define

$$a_m = (u)_{x_m, r_m}, \tag{5.5}$$

$$A_m = (Du)_{x_m, r_m}. \tag{5.6}$$

Then by assumption,

$$|A_m| \leqq M. \tag{5.7}$$

Define the normalised function

$$v_m(z) = \frac{u(x_m + r_m z) - a_m - r_m A_m z}{\lambda_m r_m} \tag{5.8}$$

for $z \in B_1$.

Note that $v_m \in \Lambda_k W^{1,s}(B_1)$ as in (2.30). We also have

$$
\begin{aligned}
&D_{v_m}(z) = \lambda_m^{-1}(Du(x_m + r_m z) - A_m),\\
&(Dv_m)_\tau = \lambda_m^{-1}((Du)_{x_m,\tau r_m} - A_m),\\
&Dv_m(z) - (Dv_m)_\tau = \lambda_m^{-1}(Du(x_m + r_m z) - (Du)_{x_m,\tau r_m}),\\
&(v_m)_1 = 0,\\
&(Dv_m)_1 = 0.
\end{aligned} \tag{5.9}
$$

It follows from (5.3) that

$$
1 = \fint_{B_1} |Dv_m|^2 + \lambda_m^{s-2}|Dv_m|^s + \sum_{i=2}^{k} (|\Lambda_i A_m|^{s-2}\lambda_m^{2i-2}|\Lambda_i Dv_m|^2 + \lambda_m^{si-2}|\Lambda_i Dv_m|^s). \tag{5.10}
$$

On passing to a subsequence we claim that for some $A \in \mathrm{Hom}(\mathbb{R}^n; \mathbb{R}^N)$ and some $v \in L^2(B_1)$ that

$$
\begin{aligned}
&\text{(i)} && A_m \to A \quad \text{pointwise},\\
&\text{(ii)} && v_m \rightharpoonup v \quad \text{in } W^{1,2},\\
&\text{(iii)} && \lambda_m^{1-2/s} v_m \rightharpoonup 0 \quad \text{in } W^{1,s} \quad (\text{if } s > 2),\\
&\text{(iv)} && |\Lambda_i A_m|^{(s/2)-1}\lambda_m^{i-1}\Lambda_i Dv_m \rightharpoonup 0 \quad \text{in } L^2 \cdots 2 \leqq i \leqq k,\\
&\text{(v)} && \lambda_m^{i-(2/s)}\Lambda_i Dv_m \rightharpoonup 0 \quad \text{in } L^s \cdots 2 \leqq i \leqq k,\\
&\text{(vi)} && \lambda_m^{\delta} Dv_m \to 0 \quad \text{a.e. for any } \delta > 0.
\end{aligned} \tag{5.11}
$$

The first two claims are standard from the facts $|A_m| \leqq M$ and $f_{B_1}|Dv_m|^2 \leqq 1$.

To see (iii) we note that $v_m \rightharpoonup v$ in the distributional sense, and hence $\lambda_m^{1-2/s} v_m \rightharpoonup 0$ in the distributional sense. Since $f_{B_1} \lambda_m^{s-2}|Dv_m|^s$ is bounded uniformly in m and since $(v_m)_1 = 0$, it follows from Poincaré's inequality that $\lambda_m^{1-2/s} v_m$ is uniformly bounded in the $W^{1,s}(B_1)$ norm, and so (iii) follows.

To see (iv) in the case where $i = 2$ we note that $v_m \to v$ in L^2, $Dv_m \rightharpoonup Dv$ in L^2, and hence $v_m \odot Dv_m \rightharpoonup v \odot Dv$ in the distributional sense. But then $\Lambda_2 Dv_m \rightharpoonup \Lambda_2 Dv$ in the distributional sense, and hence $\lambda_m|\Lambda_2 A_m|^{s/2-1}\Lambda_2 Dv_m \rightharpoonup 0$ in the distributional sense. Since $\lambda_m|\Lambda_2 A_m|^{s/2-1}\Lambda_2 Dv_m$ is uniformly bounded in $L^2(B_1)$ by (5.10), result (iv) follows.

The proof of (v) in the case where $i = 2$ is similar.

Assume (iv) and (v) are true with i replaced by $i-1$ and $3 \leqq i \leqq k$. Since $v_m \to v$ in L^2 and $\lambda_m^{i-1-2/s}\Lambda_{i-1} Dv_m \rightharpoonup 0$ in L^s (by (v), recall $s \geqq 2$), it follows that $\lambda_m^{i-1-2/s} v_m \odot \Lambda_{i-1} Dv_m \rightharpoonup 0$ in the distributional sense. But then $\lambda_m^{i-1-2/s}\Lambda_i Dv_m \rightharpoonup 0$ in the distributional sense, and hence $\lambda_m^{i-2/s}\Lambda_i Dv_m \rightharpoonup 0$ in the distributional sense. Since $\lambda_m^{i-2/s}\Lambda_i Dv_m$ is uniformly bounded in L^s by (5.10), it follows that $\lambda_m^{i-2/s}\Lambda_i Dv_m \rightharpoonup 0$ in L^s. This establishes (v) for $i = 1, \cdots, k$, by induction.

We also have from the fact $\lambda_m^{i-1-2/s}\Lambda_i Dv_m \rightharpoonup 0$ that $|\Lambda_i A_m|^{s/2-1}\lambda_m^{i-1}\Lambda_i Dv_m \rightharpoonup 0$ in the distributional sense (recall that $|\Lambda_i A_m|$ is uniformly bounded from (5.7)). Since $|\Lambda_i A_m|^{s/2-1}\lambda_m^{i-1}\Lambda_i Dv_m$ is uniformly bounded in L^2 from (5.10), it follows that $|\Lambda_i A_m|^{s/2-1}\lambda_m^{i-1}\Lambda_i Dv_m \rightharpoonup 0$ in the L^2 sense. This establishes (iv) for $i = 1, \cdots, k$, by induction.

Finally (vi) follows immediately from the fact Dv_m is uniformly bounded in L^2 and so $\lambda_m^{\delta} Dv_m \to 0$ in L^2.

The proof of the theorem is rather long, and so we break it into a number of parts.

A. v_m minimises a normalised functional. Define the normalised functions

$$F^1_m(P) = \lambda_m^{-2}[F^1(A_m + \lambda_m P) - F^1(A_m) - DF^1(A_m)\lambda_m P], \tag{5.12}$$

$$\begin{aligned} F^i_m(P) = \lambda_m^{-2}[&F^i(\Lambda_i(A_m + \lambda_m P)) - F^i(\Lambda_i A_m) \\ &- DF^i(\Lambda_i A_m)(\Lambda_i(A_m + \lambda_m P) - \Lambda_i A_m)] \end{aligned} \tag{5.13}$$

for $i = 2, \cdots, k$.

The corresponding normalised functional is defined to be

$$I_m[w] = \fint_{B_1} F^1_m(Dw) + \sum_{i=2}^{k} F^i_m(Dw). \tag{5.14}$$

For $0 < t < 1$ we similarly define

$$I^t_m[w] = \fint_{B_t} \sum_{i=1}^{k} F^i_m(Dw). \tag{5.15}$$

Example 5.2. If $n = N = 2$ and $i = 2$, then

$$\begin{aligned} F^2_m(P) = \lambda_m^{-2}[&F^2(\det(A_m + \lambda_m P) - F^2(\det A_m) \\ &- DF^2(\det A_m)(\det(A_m + \lambda_m P) - \det A_m)]. \end{aligned} \tag{5.16}$$

If, moreover, $F^2(\det P) = (\det P)^2$, then

$$\begin{aligned} F^2_m(P) &= \lambda_m^{-2}[(\det(A_m + \lambda_m P))^2 - (\det A_m)^2 \\ &\qquad - 2\det A_m(\det(A_m + \lambda_m P) - \det A_m)] \\ &= \lambda_m^{-2}(\det(A_m + \lambda_m P) - \det A_m)^2 \\ &= (A_m \tilde{\odot} P + \lambda_m \det P)^2, \end{aligned} \tag{5.17}$$

where we use $\tilde{\odot}$ for the particular linear combination of terms above.

Thus

$$F^2_m(Dw) = (A_m \tilde{\odot} Dw + \lambda_m \det Dw)^2. \tag{5.18}$$

Remark 5.3. In [EG] the authors define a normalised functional which in the present framework would be obtained by setting for $i = 1, \cdots, k$,

$$\tilde{F}^i(P) = F^i(\Lambda_i P), \tag{5.19}$$

$$\tilde{F}^i_m(P) = \lambda_m^{-2}[\tilde{F}^i(A_m + \lambda_m P) - \tilde{F}^i(A_m) - D\tilde{F}^i(A_m)\lambda_m P], \tag{5.20}$$

$$I_m[w] = \fint_{B_1} \sum_{i=1}^{k} \tilde{F}^i_m(Dw). \tag{5.21}$$

Thus in [EG] the function $P \mapsto F^i(\Lambda_i P)$ is normalised about $P = A_m$, whereas here we normalise the function $\Lambda_i P \mapsto F^i(\Lambda_i P)$ about $\Lambda_i P = \Lambda_i A_m$.

If $i = 1$, then $\tilde{F}^i_m(P) = F^i_m(P)$. But if $i > 1$ this is, of course, not true.

In Example 5.2, where $F^2(\det P) = (\det P)^2$, we obtain from the rule for differentiating a determinant,

$$\begin{aligned} \tilde{F}^2_m(P) &= \lambda_m^{-2}[(\det(A_m + \lambda_m P))^2 - (\det A_m)^2 - 2\det A_m(A_m \tilde{\odot} \lambda_m P)] \\ &= \lambda_m^{-2}[\det(A_m + \lambda_m P))^2 - (\det A_m)^2 \\ &\qquad - 2\det A_m(\det(A_m + \lambda_m P) - \det A_m) + 2\lambda_m^2 \det A_m \det P] \\ &= F^2_m(\det P) + 2\det A_m \det P. \end{aligned} \tag{5.22}$$

Returning to the general case, it is easy to check, as noted in [EG], that v_m is a minimiser of $\tilde{I}_m$.

We show here that v_m is a minimiser of I_m, amongst functions in $\Lambda_k W^{1,s}(B_1)$ which agree with v_m outside some compact subset B_1. The essential point is that the extra term introduced as in (5.22) gives rise to an integrand which can be written in divergence form.

LEMMA 5.4. *Suppose* $w \in \Lambda_k W^{1,s}(B_1)$ *and* $w = v_m$ *outside some compact* $K \subset B_1$. *Then*

$$I_m[v_m] \leqq I_m[w].$$

Proof. First note that

$$\begin{aligned} \fint_{B_1} F^i(\Lambda_i(A_m + \lambda_m Dw)) &= \fint_{B_1} F^i(\Lambda_i D(A_m z + \lambda_m w)) \\ &= \fint_{B_{(x_m, r_m)}} F^i(\Lambda_i Dw^*), \end{aligned} \tag{5.23}$$

where

$$w^*(x_m + r_m z) = a_m + r_m A_m z + \lambda_m r_m w(z).$$

In particular, from (5.23) and the definition of v_m,

$$\fint_{B_1} F^i(\Lambda_i(A_m + \lambda_m Dv_m)) = \fint_{B_{(x_m, r_m)}} F^i(\Lambda_i Du).$$

Since u is a minimiser of $I[\cdot]$, it follows that

$$\fint_{B_1} \sum_{i=1}^{k} F^i(\Lambda_i(A_m + \lambda_m Dv_m)) \leqq \fint_{B_1} \sum_{i=1}^{k} F^i(\Lambda_i(A_m + \lambda_m Dw)). \tag{5.24}$$

But we also have that

$$\fint_{B_1} \Lambda_i(A_m + \lambda_m Dv_m) = \fint_{B_1} \Lambda_i(A_m + \lambda_m Dw). \tag{5.25}$$

To see this it is sufficient to show, in view of (2.24), that if $X \in L^1(B_1)$ is a vector-valued function, $X = 0$ outside some compact $K \subset B_1$, and $\operatorname{div} X \in L^1$ (where $\operatorname{div} X$ is defined in the distributional sense), that $\int_{B_1} \operatorname{div} X = 0$.

But if X_ε is obtained by mollifying X in the usual way, then for all sufficiently small ε, $\int \operatorname{div} X_\varepsilon = 0$. Since $\operatorname{div} X_\varepsilon = (\operatorname{div} X)_\varepsilon$ converges to $\operatorname{div} X$ in L^1, the result follows. □

B. v satisfies a linear equation. We need to calculate the Euler–Lagrange equation for v_m by calculating

$$\left.\frac{d}{dt}\right|_{t=0} \Lambda_i(A_m + \lambda_m(Dv_m + tD\varphi)).$$

Let us write

$$\Lambda_i(A+B) = \Lambda_i A + \Lambda_{i-1} A \tilde{\odot} B + \sum_{j=2}^{i-1} \Lambda_{i-j} A \odot \Lambda_j B + \Lambda_i B, \tag{5.26}$$

so that

$$\Lambda_{i-1} A \tilde{\odot} B$$

will always denote this *particular* linear combinations of terms $a_\lambda b_\lambda$, where a_λ and b_λ are components of $\Lambda_{i-1}A$ and B, respectively.

Then for $\varphi \in C_c^\infty(B_1)$,

$$\frac{d}{dt}\bigg|_{t=0} \Lambda_i(A_m + \lambda_m(Dv_m + tD\varphi)) = \Lambda_{i-1}(A_m + \lambda_m Dv_m) \tilde{\odot} \lambda_m D\varphi. \tag{5.27}$$

It follows from (5.12), (5.13), and Lemma 5.4 that v_m satisfies the Euler-Lagrange equation given by

$$\begin{aligned}
0 &= \lambda_m^{-1} \fint_{B_1} [DF^1(A_m + \lambda_m Dv_m) - DF^1(A_m)]\, D\varphi \\
&\quad + \lambda_m^{-1} \fint_{B_1} \sum_{i=2}^{k} [DF^i(\Lambda_i(A_m + \lambda_m Dv_m)) - DF^i(\Lambda_i A_m)] \\
&\qquad \cdot [\Lambda_{i-1}(A_m + \lambda_m Dv_m) \tilde{\odot} D\varphi] \\
&= \fint_{B_1} \left[\int_0^1 D^2F^1(A_m + t\lambda_m Dv_m)\, dt \right] Dv_m\, D\varphi \\
&\quad + \lambda_m^{-1} \fint_{B_1} \sum_{i=2}^{k} \left[\int_0^1 D^2F^i(\Lambda_i A_m + t(\Lambda_i(A_m + \lambda_m Dv_m) - \Lambda_i A_m))\, dt \right] \\
&\qquad \cdot [\Lambda_i(A_m + \lambda_m Dv_m) - \Lambda_i A_m][\Lambda_{i-1}(A_m + \lambda_m Dv_m) \tilde{\odot} D\varphi] \\
&= \fint_{B_1} \left[\int_0^1 D^2F^1(A_m + t\lambda_m Dv_m)\, dt \right] Dv_m\, D\varphi \\
&\quad + \fint_{B_1} \sum_{i=2}^{k} \left[\int_0^1 D^2F^i(\Lambda_i A_m + t(\Lambda_i(A_m + \lambda_m Dv_m) - \Lambda_i A_m))\, dt \right] \\
&\qquad \cdot \left[\Lambda_{i-1} A_m \tilde{\odot} Dv_m + \sum_{j=2}^{i} \lambda_m^{j-1} \Lambda_{i-j} A_m \odot \Lambda_j Dv_m \right] \\
&\qquad \cdot \left[\Lambda_{i-1} A_m \tilde{\odot} D\varphi + \sum_{j=1}^{i-1} \lambda_m^j \Lambda_{i-1-j} A_m \odot \Lambda_j Dv_m \tilde{\odot} D\varphi \right].
\end{aligned} \tag{5.28}$$

We aim to show that v satisfies the linear equation

$$0 = \fint_{B_1} \left[D^2F^1(A)\, Dv\, D\varphi + \sum_{i=2}^{k} D^2F^i(\Lambda_i A)(\Lambda_{i-1} A \tilde{\odot} Dv)(\Lambda_{i-1} A \tilde{\odot} D\varphi) \right] \tag{5.29}$$

for all $\varphi \in C_c^\infty(B_1)$.

This is an elliptic system with ellipticity bounds given by

$$\gamma|\xi|^2 \leqq D^2F^1(A)\xi\xi + \sum_{i=2}^{k} D^2F^i(\Lambda_i A)(\Lambda_{i-1} A \tilde{\odot} \xi)(\Lambda_{i-1} A \tilde{\odot} \xi) \leqq c|\xi|^2 \tag{5.30}$$

for all $\xi \in \mathrm{Hom}\,(\mathbb{R}^n; \mathbb{R}^N)$.

The necessary calculations are simplified by the following lemmas.

LEMMA 5.5. *Suppose* $\{f_m\} \subset L^1(B_1)$, $\{g_m\} \subset L^{1+\eta}(B_1)$ (*some* $\eta > 0$), *and* α *is constant. Suppose*

$$f_m \to \alpha \quad \text{a.e.},$$

$$g_m \rightharpoonup g \quad \text{in } L^{1+\eta},$$

$$\int_\Omega |f_m g_m|^{1+\delta} \leqq A \text{ for some } \delta > 0, \quad \text{some } A < \infty, \quad \text{and all } m.$$

Then

$$f_m g_m \rightharpoonup \alpha g \quad \text{in } L^{1+\delta}.$$

Proof. For any $\varphi \in C^\infty(B_1)$ we have

$$\int_{B_1} (f_m g_m - \alpha g)\varphi = \int_{B_1} (f_m - \alpha) g_m \varphi + \alpha \int_{B_1} (g_m - g)\varphi. \tag{5.31}$$

The second integral on the right side converges to zero as $m \to \infty$.

To see that the same is true of the first integral we note that for each $\varepsilon > 0$ there exists $E \subset B_1$ with $|E| < \varepsilon$ such that $f_m \to \alpha$ uniformly on $B_1 \sim E$. Then

$$\int_{B_1 \sim E} |f_m - \alpha||g_m||\varphi| \leqq c \sup_{B_1 \sim E} |f_m - \alpha| \left(\int_{B_1} |g_m|^{1+\eta} \right)^{1/(1+\eta)}$$

$$\to 0 \quad \text{as } m \to \infty.$$

Moreover,

$$\int_E |f_m - \alpha||g_m||\varphi| \leqq c \left(\int_E |f_m g_m|^{1+\delta} \right)^{1/(1+\delta)} |E|^{\delta/(1+\delta)}$$

$$+ c \left(\int_E |g_m|^{1+\eta} \right)^{1/(1+\eta)} |E|^{\eta/(1+\eta)}$$

$$\leqq c(\varepsilon),$$

where $c(\varepsilon) \to 0$ as $\varepsilon \to 0$. Since $\varepsilon > 0$ is arbitrary, it follows that the first integral on the right side of (5.31) also converges to zero as $m \to \infty$.

This establishes the lemma. □

Remark. The case $g_m \equiv 1$ is also of interest.

LEMMA 5.6. *Suppose* $p, q \geqq 0$ *and all* $a_i \geqq 0$. *Then*

$$(\Sigma a_i^p)(\Sigma a_i^q) \leqq c \Sigma a_i^{p+q}.$$

Proof. Multiply out the left side and use Young's inequality. □

LEMMA 5.7. $|\Lambda_i A_m| \leqq c|\Lambda_j A_m|$ *if* $1 \leqq j \leqq i$, *for some* c *independent of* m.

Proof. If $j = i - 1$ this follows by expanding the determinant corresponding to each component of $\Lambda_i A_m$ along an arbitrary row (or column) and recalling $|A_m|$ is uniformly bounded in m. The result follows for general j by repeating the argument. □

LEMMA 5.8.

$$\Lambda_i(A_m + \lambda_m D v_m) \to \Lambda_i A \quad \text{a.e. as } m \to \infty.$$

Proof. This follows from (5.11)(vi) and the fact $A \mapsto \Lambda_i A$ is clearly a continuous function. □

We now proceed with the proof of (5.29).

Apply Lemma 5.5 to the first integral on the right side of (5.28), with

$$f_m = \int_0^1 D^2 F^1(A_m + t\lambda_m D v_m)\, dt,$$

$$g_m = D v_m, \qquad g = Dv.$$

Then $f_m \to D^2F^1(A)$ almost everywhere from (5.11)(vi), and $g_m \rightharpoonup g$ in L^2 from (5.11)(ii). Also,

$$\begin{aligned}|f_m g_m| &\leqq c(1+\lambda_m^{s-2}|Dv_m|^{s-2})|Dv_m| \\ &\leqq c(|Dv_m|+\lambda_m^{1-2/s}(\lambda_m^{s-2}|Dv_m|^s)^{(s-1)/s}),\end{aligned}$$

and so $f_m g_m \in L^{s/(s-1)}$ uniformly in m. Lemma 5.5 now implies

$$\fint_{B_1}\left[\int_0^1 D^2F^1(A_m+t\lambda_m Dv_m)\,dt\right]Dv_m\,D\varphi \to \fint_{B_1} D^2F^1(A)\,Dv\,D\varphi. \tag{5.32}$$

We next consider the second integral on the right side of (5.28). It is convenient to write this integral in the following form:

$$\begin{aligned}&\sum_{i=2}^{k}\left\{\fint_{B_1}\left[\int_0^1 D^2F^i(\Lambda_i A_m + t(\Lambda_i(A_m+\lambda_m Dv_m)-\Lambda_i A_m))\,dt\right]\right. \\ &\qquad\cdot\Bigg[(\Lambda_{i-1}A_m \tilde{\odot} Dv_m)(\Lambda_{i-1}A_m \tilde{\odot} D\varphi) \\ &\qquad\quad+\left(\sum_{j=2}^{i}\lambda_m^{j-1}\Lambda_{i-j}A_m \odot \Lambda_j Dv_m\right)(\Lambda_{i-1}A_m \tilde{\odot} D\varphi) \\ &\qquad\quad+\left(\sum_{j=1}^{i}\lambda_m^{j-1}\Lambda_{i-j}A_m \odot \Lambda_j Dv_m\right) \\ &\qquad\quad\left.\cdot\left(\sum_{j=1}^{i-1}\lambda_m^{j}\Lambda_{i-1-j}A_m \odot \Lambda_j Dv_m \tilde{\odot} D\varphi\right)\Bigg]\right\} \\ &\quad=\sum_{i=2}^{k}(A_m^i+B_m^i+C_m^i).\end{aligned} \tag{5.33}$$

We first claim

$$A_m^i \to \fint_{B_1} D^2F^i(\Lambda_i A)(\Lambda_{i-1}A \tilde{\odot} Dv)(\Lambda_{i-1}A \tilde{\odot} D\varphi). \tag{5.34}$$

To see this, apply Lemma 5.5 with

$$\begin{aligned}f_m &= \int_0^1 D^2F^i(\Lambda_i A_m + t(\Lambda_i(A_m+\lambda_m Dv_m)-\Lambda_i A_m))\,dt, \\ g_m &= (\Lambda_{i-1}A_m \tilde{\odot} Dv_m)\Lambda_{i-1}A_m.\end{aligned}$$

Then

$$\begin{aligned}&f_m \to D^2F^i(\Lambda_i A) \quad \text{a.e.}, \\ &g_m \rightharpoonup (\Lambda_{i-1}A \tilde{\odot} Dv)\Lambda_{i-1}A \quad \text{in } L^2.\end{aligned}$$

Moreover,

$$\begin{aligned}|f_m g_m| &\leqq c(1+|\Lambda_i(A_m+\lambda_m Dv_m)|^{s-2})|Dv_m| \\ &\leqq c\left(1+\sum_{j=1}^{i}\lambda_m^{j(s-2)}|\Lambda_j Dv_m|^{s-2}\right)|Dv_m| \\ &\leqq c\left(|Dv_m|+\lambda_m^{1-2/s}\sum_{j=1}^{i}(\lambda_m^{j-2/s}|\Lambda_j Dv_m|)^{s-2}(\lambda_m^{1-2/s}|Dv_m|)\right) \\ &\leqq c\Bigg(|Dv_m|+\lambda_m^{1-2/s}\sum_{j=1}^{i}(\lambda_m^{j-2/s}|\Lambda_j Dv_m|)^{s-1} \\ &\qquad\qquad+\lambda_m^{1-2/s}\sum_{j=1}^{i}(\lambda_m^{1-2/s}|Dv_m|)^{s-1}\Bigg).\end{aligned}$$

It follows from (5.11) that $f_m g_m \in L^{s/(s-1)}$, uniformly in m. Hence (5.34) is valid by Lemma 5.5.

We next claim

$$B^i_m \to 0 \quad \text{as } m \to \infty. \tag{5.35}$$

To establish this, apply Lemma 5.5 with

$$f_m = \left[\int_0^1 D^2 F^i(\Lambda_i A_m + t(\Lambda_i(A_m + \lambda_m Dv_m) - \Lambda_i A_m))\, dt \right] \cdot \left(\sum_{j=2}^{i} \lambda_m^{j-1} \Lambda_{i-j} A_m \odot \Lambda_j Dv_m \right) \Lambda_{i-1} A_m,$$

$$g_m = 1.$$

Then $f_m \to 0$ almost everywhere (using (5.11)(vi)). Also,

$$|f_m| \leqq c \left(|\Lambda_i A_m| + \sum_{j=1}^{i} \lambda_m^j |\Lambda_j Dv_m| \right)^{s-2} \left(\sum_{j=2}^{i} \lambda_m^{j-1} |\Lambda_j Dv_m| \right)$$

(using (H4) and (5.7))

$$\leqq c \sum_{j=2}^{i} |\Lambda_i A_m|^{s-2} \lambda_m^{j-1} |\Lambda_j Dv_m| + c\lambda_m^{1-2/s} \left(\sum_{j=1}^{i} \lambda_m^{j-2/s} |\Lambda_j Dv_m| \right)^{s-2} \left(\sum_{j=2}^{i} \lambda_m^{j-2/s} |\Lambda_j Dv_m| \right)$$

$$\leqq c \sum_{j=2}^{i} |\Lambda_j A_m|^{s-2} \lambda_m^{j-1} |\Lambda_j Dv_m| + c\lambda_m^{1-2/s} \left(\sum_{j=1}^{i} \lambda_m^{j-2/s} |\Lambda_j Dv_m| \right)^{s-1},$$

using Lemma 5.7.

It follows from (5.11) that $f_m \in L^{s/(s-1)}$ uniformly in m. Thus (5.35) is established from Lemma 5.5.

Finally, we claim that

$$C^i_m \to 0 \quad \text{as } m \to \infty. \tag{5.36}$$

To see this we calculate

$$|C^i_m| \leqq c \fint_{B_1} \left(|\Lambda_i A_m| + \sum_{j=1}^{i} \lambda_m^j |\Lambda_j Dv_m| \right)^{s-2} \cdot \left(\sum_{j=1}^{i} \lambda_m^{j-1} |\Lambda_j Dv_m| \right) \left(\sum_{j=1}^{i-1} \lambda_m^j |\Lambda_j Dv_m| \right)$$

$$\leqq c \fint_{B_1} |\Lambda_i A_m|^{s-2} \sum_{j=1}^{i} \lambda_m^{2j-1} |\Lambda_j Dv_m|^2 + c \sum_{j=1}^{i} \lambda_m^{js-1} |\Lambda_j Dv_m|^s$$

$$\to 0 \quad \text{as } m \to \infty$$

from (5.11). This proves (5.36).

Thus (5.29) is established, using (5.28), and (5.32)-(5.36).

From standard regularity theory it now follows that

$$v \in C^\infty(B_1), \tag{5.37}$$

and, moreover, that for any $K \subset\subset B_1$ and any $i \geqq 1$, we have from (5.29), (5.30), and (5.10) that

$$\sup_K |D^i v| \leqq c \fint_{B_1} |Dv|^2 \tag{5.38}$$

where $c = c(K, M, i)$.

C. An estimate of $I^t_m(v_m) - I^t_m(v)$ from above. We will show that for almost everywhere $t \in (\frac{1}{2}, 1)$ there exists a subsequence (depending on t) for which

$$\lim_{m\to\infty} (I^t_m(v_m) - I^t_m(v)) \leqq 0. \tag{5.39}$$

This, together with the estimate from below in Part D, are the main estimates.

In order to establish (5.39) we need to define comparison functions w_m that "connect" v to v_m.

More precisely, for each $t \in (\frac{1}{2}, 1)$ and each $\delta \in (0, \frac{1}{4})$ we define

$$w_m = w^{t,\delta}_m \in \Lambda_k W^{1,s}(B_1) \tag{5.40}$$

as follows.

For $x \in B_1$ write

$$x = r\omega, \quad \text{where } r = |x| \quad \text{and} \quad \omega = x/|x|. \tag{5.41}$$

Let

$$w_m(r\omega) = \begin{cases} v(r\omega) & \cdots\ r \leqq t-\delta, \\ v([t-\delta+2(r-(t-\delta))]\omega] & \cdots\ t-\delta \leqq r \leqq t-\delta/2, \\ \dfrac{t-r}{\delta/2}\, v(t\omega) + \dfrac{r-(t-\delta/2)}{\delta/2}\, v_m(t\omega) & \cdots\ t-\dfrac{\delta}{2} \leqq r \leqq t, \\ v_m(r\omega) & \cdots\ t \leqq r \leqq 1. \end{cases} \tag{5.42}$$

Thus w_m equals v on $B_{t-\delta}$. On the annulus $B_{t-\delta/2} \sim B_{t-\delta}$ we obtain w_m by taking v restricted to $B_t \sim B_{t-\delta}$ and then composing with a diffeomorphism from $B_{t-\delta/2} \sim B_{t-\delta}$ to $B_t \sim B_{t-\delta}$. On $B_t \sim B_{t-\delta/2}$ we obtain $w_m(r\omega)$ for $t - \delta/2 \leqq r \leqq t$ by linearly interpolating between $v(t\omega)$ and $v_m(t\omega)$. Finally, w_m agrees with v_m on $B_1 \sim B_t$.

We claim

$$w_m \in \Lambda_k W^{1,s}(B_1) \quad \text{for a.e. } t \in (\tfrac{1}{2}, 1), \tag{5.43}$$

and establish some estimates.

First note that

$$\sup_{B_{t-\delta/2}} |Dw_m| \leqq c \sup_{B_t} |Dv| \leqq c \tag{5.44}$$

from (5.38). It follows that

$$\sup_{B_{t-\delta/2}} |\Lambda_i Dw_m| \leqq c \tag{5.45}$$

for $i = 1, \cdots, k$.

Next consider the annulus $B_t \sim B_{t-\delta/2}$. Let $\tau_1, \cdots, \tau_{n-1}, \nu$ be an orthonormal basis for $\mathbb{R}^n$, where ν is a radial vector (and so $\tau_1, \cdots, \tau_{n-1}$ are orthogonal to ν). Then on $B_t \sim B_{t-\delta/2}$,

$$D_{\tau_i} w_m(r\omega) = \frac{t-r}{\delta/2} \cdot \frac{t}{r} D_{\tau_i} v(t\omega) + \frac{r-(t-\delta/2)}{\delta/2} \cdot \frac{t}{r} D_{\tau_i} v_m(t\omega), \tag{5.46}$$

and so

$$|D_{\tau_i} w_m(r\omega)| \leqq c(1+|Dv_m(t\omega)|), \tag{5.47}$$

since $t/r \leqq 2$, $(t-r)/(\delta/2) \leqq 1$, $(r-(t-\delta/2)/(\delta/2) \leqq 1$, $|Dv| \leqq c$.

Similarly,

$$D_\nu w_m(r\omega) = \frac{2}{\delta}(v_m(t\omega) - v(t\omega)), \tag{5.48}$$

and so

$$|D_\nu w_m(r\omega)| \leqq c\delta^{-1}|v_m(t\omega) - v(t\omega)|. \tag{5.49}$$

It follows that

$$\begin{aligned} &\langle \Lambda_i D w_m(r\omega), \tau_1 \wedge \cdots \wedge \tau_i \rangle \\ &\quad = D_{\tau_1} w_m(r\omega) \wedge \cdots \wedge D_{\tau_i} w_m(r\omega) \\ &\quad = \bigwedge_{j=1}^{i} \left(\frac{t-r}{\delta/2} \cdot \frac{t}{r} D_{\tau_j} v(t\omega) + \frac{r-(t-\delta/2)}{\delta/2} \cdot \frac{t}{r} \cdot D_{\tau_j} v_m(t\omega) \right). \end{aligned}$$

On expanding we obtain terms of the form

$$f(D_{\tau_1} v(t\omega) \text{ or } D_{\tau_1} v_m(t\omega)) \wedge \cdots \wedge (D_{\tau_i} v(t\omega) \text{ or } D_{\tau_i} v_m(t\omega)),$$

where $|f| \leqq c$. Such terms are norm bounded by

$$c\left(1 + \sum_{j=1}^{i} |\Lambda_j D v_m(t\omega)|\right),$$

since $|D_{\tau_j} v(t\omega)| \leqq c$.

Similarly,

$$\begin{aligned} &\langle \Lambda_i D w_m(r\omega), \nu \wedge \tau_1 \wedge \cdots \wedge \tau_{i-1} \rangle \\ &\quad = D_\nu w_m(r\omega) \wedge D_{\tau_1} w_m(r\omega) \wedge \cdots \wedge D_{\tau_{i-1}} w_m(rw) \\ &\quad = \frac{2}{\delta}(v_m(t\omega) - v(t\omega)) \wedge \\ &\qquad \cdot \wedge \bigwedge_{j=1}^{i-1} \left(\frac{t-r}{\delta/2} \cdot \frac{t}{r} D_{\tau_j} v(t\omega) + \frac{r-(t-\delta/2)}{\delta/2} \cdot \frac{t}{r} D_{\tau_j} v_m(t\omega) \right). \end{aligned}$$

As before, such terms are norm bounded by

$$c\delta^{-1}|v_m(t\omega) - v(t\omega)|\left(1 + \sum_{j=1}^{i-1} |\Lambda_j D v_m(t\omega)|\right).$$

It follows from the above that on $B_t \sim B_{t-\delta/2}$

$$|\Lambda_i D w_m| \leqq c(1+\delta^{-1}|v-v_m|)\left(1 + \sum_{j=1}^{i-1} |\Lambda_j D v_m|\right) + c|\Lambda_i D v_m|, \tag{5.50}$$

where the left side is evaluated at $r\omega$ for $t-\delta/2 \leqq r \leqq t$, the right side is evaluated at $t\omega$, and $1 \leqq i \leqq k$.

Since $v_m = w_m$ on $B_1 \sim B_t$,

$$I^t_m(v_m) - I^t_m(w_m) \leqq 0.$$

Hence

$$\begin{aligned} I^t_m(v_m) - I^t_m(v) &= (I^t_m(v_m) - I^t_m(w_m)) + (I^t_m(w_m) - I^t_m(v)) \\ &\leqq I^t_m(w_m) - I^t_m(v) \\ &= \int_{B_t \sim B_{t-\delta}} \sum_{i=1}^{k} (F^i_m(Dw_m) - F^i_m(Dv)). \end{aligned} \tag{5.51}$$

From (5.12) we estimate for any $w \in \Lambda_k W^{1,s}(B_1)$,

$$\begin{aligned} |F^1_m(Dw)| &= \left| \left(\int_0^1 (1-\tau) D^2 F^1(A_m + \tau \lambda_m Dw)\, d\tau \right) Dw\, Dw \right| \\ &\leqq c(1 + \lambda_m^{s-2} |Dw|^{s-2}) |Dw|^2. \end{aligned} \tag{5.52}$$

For $2 \leqq i \leqq k$ we similarly have from (5.13) that

$$\begin{aligned} |F^i_m(Dw)| &= \lambda_m^{-2} \left| \left(\int_0^1 (1-\tau) D^2 F^i [\Lambda_i A_m + \tau(\Lambda_i(A_m + \lambda_m Dw) - \Lambda_i A_m)]\, d\tau \right) \right. \\ &\qquad \left. \cdot (\Lambda_i(A_m + \lambda_m Dw) - \Lambda_i A_m)(\Lambda_i(A_m + \lambda_m Dw) - \Lambda_i A_m) \right| \\ &\leqq c\lambda_m^{-2} (|\Lambda_i A_m|^{s-2} + |\Lambda_i(A_m + \lambda_m Dw) - \Lambda_i A_m|^{s-2}) \\ &\qquad \cdot |\Lambda_i(A_m + \lambda_m Dw) - \Lambda_i A_m|^2 \\ &\leqq c\lambda_m^{-2} \left(|\Lambda_i A_m|^{s-2} + \sum_{j=1}^{i} \lambda_m^{j(s-2)} |\Lambda_j Dw|^{s-2} \right) \left(\sum_{j=1}^{i} \lambda_m^{2j} |\Lambda_j Dw|^2 \right) \\ &\leqq c \sum_{j=1}^{i} |\Lambda_j A_m|^{s-2} \lambda_m^{2j-2} |\Lambda_j Dw|^2 + c \sum_{j=1}^{i} \lambda_m^{js-2} |\Lambda_j Dw|^s. \end{aligned} \tag{5.53}$$

From (5.47), (5.48), and (5.52), we calculate (with the left side evaluated at $r\omega$ and the right side at $t\omega$, where $t - \delta/2 \leqq r \leqq t$)

$$\begin{aligned} |F^1_m(Dw_m)| &\leqq c(1 + \delta^{-1}|v - v_m| + |Dv_m|)^2 \\ &\qquad + c\lambda_m^{s-2}(1 + \delta^{-1}|v - v_m| + |Dv_m|)^s \\ &\leqq c(1 + \delta^{-2}|v - v_m|^2 + |Dv_m|^2) \\ &\qquad + c\lambda_m^{s-2}(\delta^{-s}|v - v_m|^s + |Dv_m|^s). \end{aligned} \tag{5.54}$$

Similarly, for $2 \leqq i \leqq k$, we have from (5.50) and (5.53), with the same evaluation convention, that

$$\begin{aligned} |F^i_m(Dw_m)| &\leqq c \sum_{j=1}^{i} |\Lambda_j A_m|^{s-2} \lambda_m^{2j-2} \left[(1 + \delta^{-2}|v - v_m|^2) \right. \\ &\qquad \left. \cdot \left(1 + \sum_{l=0}^{j-1} |\Lambda_l Dv_m|^2 \right) + |\Lambda_j Dv_m|^2 \right] \\ &\quad + c \sum_{j=1}^{i} \lambda_m^{js-2} \left[(1 + \delta^{-s}|v - v_m|^s) \right. \\ &\qquad \left. \cdot \left(1 + \sum_{l=0}^{j-1} |\Lambda_l Dv_m|^s \right) + |\Lambda_j Dv_m|^s \right]. \end{aligned} \tag{5.55}$$

The first term on the right side is bounded by

$$c\sum_{j=1}^{i}|\Lambda_j A_m|^{s-2}\lambda_m^{2j-2}(1+\delta^{-2}|v-v_m|^2)$$

$$+c\sum_{l=0}^{i-1}|\Lambda_l A_m|^{s-2}\lambda_m^{2l}(1+\delta^{-2}|v-v_m|^2)|\Lambda_l Dv_m|^2$$

$$+c\sum_{j=1}^{i}|\Lambda_j A_m|^{s-2}\lambda_m^{2j-2}|\Lambda_j Dv_m|^2$$

(where we have used $|\Lambda_j A_m|\leqq c|\Lambda_l A_m|$ and $\lambda_m^{2j-2}\leqq c\lambda_m^{2l}$ for $1\leqq l\leqq j-1$)

$$\leqq c(1+\delta^{-2}|v-v_m|^2)$$

$$+c\lambda_m^2\delta^{-2}|v-v_m|^2\sum_{j=1}^{i-1}|\Lambda_j A_m|^{s-2}\lambda_m^{2j-2}|\Lambda_j Dv_m|^2$$

$$+c\sum_{j=1}^{i}|\Lambda_j A_m|^{s-2}\lambda_m^{2j-2}|\Lambda_j Dv_m|^2.$$

Similarly, the second term on the right side of (5.55) is bounded by

$$c\sum_{j=1}^{i}\lambda_m^{js-2}(1+\delta^{-5}|v-v_m|^s)+c\sum_{l=0}^{i-1}\lambda_m^{ls-2+s}(1+\delta^{-5}|v-v_m|^s)|\Lambda_l Dv_m|^s$$

$$+c\sum_{j=1}^{i}\lambda_m^{js-2}|\Lambda_j Dv_m|^s$$

$$\leqq c\lambda_m^{s-2}(1+\delta^{-s}|v-v_m|^s)+c\lambda_m^s\delta^{-s}|v-v_m|^s\sum_{j=1}^{i-1}\lambda_m^{js-2}|\Lambda_j Dv_m|^s$$

$$+c\sum_{j=1}^{i}\lambda_m^{js-2}|\Lambda_j Dv_m|^s.$$

It follows that for $2\leqq i\leqq k$

$$|F_m^i(Dw_m)|\leqq c\left(1+\delta^{-2}|v-v_m|^2+\sum_{j=1}^{i}|\Lambda_j A_m|^{s-2}\lambda_m^{2j-2}|\Lambda_j Dv_m|^2\right)$$

$$+c\lambda_m^2\delta^{-2}|v-v_m|^2\sum_{j=1}^{i-1}|\Lambda_j A_m|^{s-2}\lambda_m^{2j-2}|\Lambda_j Dv_m|^2$$

$$+c\left(\lambda_m^{s-2}\delta^{-s}|v-v_m|^s+\sum_{j=1}^{i}\lambda_m^{js-2}|\Lambda_j Dv_m|^s\right)$$

$$+c\lambda_m^s\delta^{-s}|v-v_m|^s\sum_{j=1}^{i-1}\lambda_m^{js-2}|\Lambda_j Dv_m|^s. \tag{5.56}$$

Remember that the left side is evaluated at $r\omega$ and the right side at $t\omega$, where $t-\delta/2\leqq r\leqq t$.

Applying Fubini's theorem to (5.54) and (5.56) it follows that

$$\begin{aligned}
&\int_{B_t\sim B_{t-\delta/2}} \sum_{i=1}^{k} F_m^i(Dw_m) \\
&\qquad \leqq c\delta \int_{\partial B_t} 1+\delta^{-2}|v-v_m|^2+|Dv_m|^2+\sum_{j=2}^{k}|\Lambda_j A_m|^{s-2}\lambda_m^{2j-2}|\Lambda_j Dv_m|^2 \\
&\qquad +c\delta^{-1}\lambda_m^2 \sup_{\partial B_t}|v-v_m|^2 \int_{\partial B_t}\sum_{j=1}^{k-1}|\Lambda_j A_m|^{s-2}\lambda_m^{2j-2}|\Lambda_j Dv_m|^2 \qquad (5.57)\\
&\qquad +c\delta \int_{\partial B_t}\lambda_m^{s-2}\delta^{-s}|v-v_m|^s+\lambda_m^{s-2}|Dv_m|^s+\sum_{j=2}^{k}\lambda_m^{js-2}|\Lambda_j Dv_m|^s \\
&\qquad +c\delta^{1-s}\lambda_m^s \sup_{\partial B_t}|v-v_m|^s \int_{\partial B_t}\sum_{j=1}^{k-1}\lambda_m^{js-2}|\Lambda_j Dv_m|^s.
\end{aligned}$$

It follows from (5.11) and Lemma 5.10 that for almost everywhere $t\in(\frac{1}{2},1)$ there exists $M_t<\infty$ and a subsequence depending on t for which

$$\begin{aligned}
&\int_{\partial B_t}|Dv_m|^2+\lambda_m^{s-2}|Dv_m|^s+\sum_{j=2}^{k}\lambda_m^{2j-2}|\Lambda_j A_m|^{s-2}|\Lambda_j Dv_m|^2 \\
&\qquad +\sum_{j=2}^{k}\lambda_m^{js-2}|\Lambda_j Dv_m|^s \leqq M_t. \qquad (5.58)
\end{aligned}$$

We may also assume from (5.11) that

$$\int_{\partial B_t}|v-v_m|^2+\lambda_m^{s-2}|v-v_m|^s\to 0. \qquad (5.59)$$

Finally, notice that $\lambda_m^{1-2/s}(v_m-v)\rightharpoonup 0$ in $W^{1,s}(B_1)$ (from (5.11)(ii), (iii)). It follows from (5.58), by using a countable dense set of test functions, that $\lambda_m^{1-2/s}(v_m-v)\rightharpoonup 0$ in $W^{1,s}(\partial B_t)$ for almost everywhere $t\in(\frac{1}{2},1)$. It then follows by the Sobolev compactness theorem, together with the fact that $s>n-1=\text{dimension}(\partial B_t)$, that

$$\lim_{m\to\infty}\lambda_m^{1-2/s}\sup_{\partial B_t}|v-v_m|=0 \qquad (5.60)$$

for almost everywhere $t\in(\frac{1}{2},1)$.

Remark 5.9. This is the main point in the proof where we require $s>n-1$.

It follows from (5.57)-(5.60) that

$$\limsup_{m\to\infty}\int_{B_t\sim B_{t-\delta/2}}\sum_{i=1}^{k}F_m^i(Dw_m)\leqq c\delta(1+M_t) \qquad (5.61)$$

for almost everywhere $t\in(\frac{1}{2},1)$ and some subsequence depending on t.

On the other hand, we easily see from (5.52), (5.53), and (5.45) that

$$\int_{B_{t-\delta/2}\sim B_{t-\delta}}\sum_{i=1}^{k}F_m^i(Dw_m)\leqq c\delta. \qquad (5.62)$$

Finally, from (5.52), (5.53), and (5.38) we see that

$$\left|\int_{B_t\sim B_{t-\delta}}\sum_{i=1}^{k}F_m^i(Dv)\right|\leqq c\delta. \qquad (5.63)$$

From (5.51) and the fact that $\delta\in(0,\frac{1}{4})$ is otherwise arbitrary, it now follows, for almost everywhere $t\in(\frac{1}{2},1)$ and for some subsequence depending on t, that (5.39) is true.

LEMMA 5.10. *Suppose* $\{u_m\}$ *is a sequence of* $L^1(B_1)$ *functions such that* $\int_{B_1}|u_m| \leqq M$, *where* M *is independent of* m. *Then for almost everywhere* $t \in (0,1)$ *there exists a constant* $M_t < \infty$ *and a subsequence depending in* t *such that*

$$I_m(t) := \int_{\partial B_t} |u_m| \leqq M_t.$$

Proof. If the claim were not true, there would exist $S \subset (0,1)$ with $\mathscr{L}^1(S) = \alpha > 0$ such that $t \in S$ implies $\lim_{m\to\infty} I_m(t) = \infty$.

Let

$$S_i = \left\{ t \in S : I_m(t) \geqq \frac{2M}{\alpha} \quad \text{if} \quad m \geqq i \right\}.$$

Since $S_i \uparrow S$ as $i \to \infty$, it follows $\mathscr{L}^1(S_j) > \alpha/2$ for some j. But then

$$\int_{B_1} |u_j| = \int_0^1 \int_{\partial B_t} |u_j| > \frac{\alpha}{2} \cdot \frac{2M}{\alpha} = M,$$

which contradicts the hypotheses.

This proves the lemma. □

D. An estimate of $I^t_m(v_m) - I^t_m(v)$ from below. By estimating $I^t_m(v_m) - I^t_m(v)$ from below, and using (5.39), we will establish that, for almost everywhere $t \in (\frac{1}{2}, 1)$ and for some subsequence depending on t (which can be taken to be the same subsequence as for (5.39)), the following hold:

$$\lim_{m\to\infty} \fint_{B_t} |Dv_m - Dv|^2 = 0, \tag{5.64}$$

$$\lim_{m\to\infty} \fint_{B_t} \lambda_m^{s-2} |Dv_m|^s = 0 \quad \text{if } s > 2, \tag{5.65}$$

$$\lim_{m\to\infty} \fint_{B_t} |\Lambda_i A_m|^{s-2} \lambda_m^{2i-2} |\Lambda_i Dv_m|^2 = 0 \quad \text{if } i = 2, \cdots, k \quad \text{and } s > 2, \tag{5.66}$$

$$\lim_{m\to\infty} \fint_{B_t} \lambda_m^{is-2} |\Lambda_i Dv_m|^s = 0 \quad \text{if } i = 2, \cdots, k. \tag{5.67}$$

Thus, weak convergence in (5.11) is converted into strong convergence.

To show these limits recall

$$I^t_m(v_m) - I^t_m(v) = \fint_{B_t} \sum_{i=1}^{k} F^i_m(Dv_m) - F^i_m(Dv). \tag{5.68}$$

Write

$$\begin{aligned} \fint_{B_t} F^1_m(Dv_m) - F^1_m(Dv) &= \fint_{B_t} F^1_m(Dv_m - Dv) \\ &\quad + \fint_{B_t} F^1_m(Dv_m) - F^1_m(Dv) - F^1_m(Dv_m - Dv) \\ &= A^1_m + B^1_m. \end{aligned} \tag{5.69}$$

From (5.12)

$$A_m^1 = \fint_{B_t} \left(\int_0^1 (1-\tau) D^2 F^1[A_m + \tau\lambda_m(Dv_m - Dv)]\, d\tau \right)(Dv_m - Dv)(Dv_m - Dv)$$

$$\geqq \gamma \fint \left(\int_0^1 (1-\tau)(1+|A_m + \tau\lambda_m(Dv_m - Dv)|^{s-2})\, d\tau \right)|Dv_m - Dv|^2$$

(using (H3)(b)).

But from [E, Lemma 8.1] there exists $\sigma > 0$ such that, for any two $n \times N$ matrices A and B,

$$\sigma(|A|^{s-2} + |B|^{s-2}) \leqq \int_0^1 (1-\tau)|A + \tau B|^{s-2}\, d\tau. \tag{5.70}$$

Thus, for some $\sigma > 0$,

$$\begin{aligned} A_m^1 &\geqq \sigma \fint_{B_t} (1 + |A_m|^{s-2} + \lambda_m^{s-2}|Dv_m - Dv|^{s-2})|Dv_m - Dv|^2 \\ &\geqq \sigma \fint_{B_t} |Dv_m - Dv|^2 + \lambda_m^{s-2}|Dv_m - Dv|^s. \end{aligned} \tag{5.71}$$

On the other hand, we can estimate B_m^1 in a similar way to that in [EG, eqn. (2.16)]. Namely,

$$B_m^1 = \fint_{B_t} \left(\int_0^1 DF_m^1(Dv + \tau(Dv_m - Dv))\, d\tau \right)(Dv_m - Dv)$$

$$- \fint_{B_t} \left(\int_0^1 DF_m^1(\tau(Dv_m - Dv))\, d\tau \right)(Dv_m - Dv)$$

(using the fact that $F_m^1(0) = 0$)

$$= \fint_{B_t} \left(\int_0^1 \int_0^1 D^2 F_m^1(\nu Dv + \tau(Dv_m - Dv))\, d\tau\, d\nu \right)(Dv_m - Dv)Dv$$

$$= \fint_{B_t} \left(\int_0^1 \int_0^1 D^2 F^1[A_m + \lambda_m(\nu Dv + \tau(Dv_m - Dv))]\, d\tau\, d\nu \right)$$

$$\cdot (Dv_m - Dv)Dv$$

(using (5.12)).

We now apply Lemma 5.5 with

$$f_m = \int_0^1 \int_0^1 D^2 F^1[A_m + \lambda_m(\nu Dv + \tau(Dv_m - Dv))]\, d\tau\, d\nu,$$

$$g_m = Dv_m - Dv.$$

Then $f_m \to D^2 F^1(A)$ almost everywhere and $g_m \rightharpoonup 0$ in L^2.

Also,

$$\begin{aligned} |f_m g_m| &\leqq c(1 + \lambda_m^{s-2}|Dv_m|^{s-2})(1 + |Dv_m|) \\ &\leqq c(1 + |Dv_m| + \lambda_m^{s-2}|Dv_m|^{s-1}) \\ &= c(1 + |Dv_m| + \lambda_m^{1-2/s}(\lambda_m^{s-2}|Dv_m|^s)^{(s-1)/s}). \end{aligned}$$

It follows that $f_m g_m \in L^{s/(s-1)}$ uniformly in m.

From Lemma 5.5 it now follows that

$$B_m^1 \to 0 \quad \text{as } m \to \infty. \tag{5.72}$$

We next consider $F_m^i(Dv_m) - F_m^i(Dv)$ for $2 \leqq i \leqq k$. These cases are treated a little differently from $i = 1$. We have

$$\begin{aligned}
&\fint_{B_t} F_m^i(Dv_m) - F_m^i(Dv) \\
&\quad = \lambda_m^{-2} \fint_{B_t} \left(\int_0^1 (1-\tau) D^2 F^i[\Lambda_i A_m + \tau(\Lambda_i(A_m + \lambda_m Dv_m) - \Lambda_i A_m)]\, d\tau \right) \\
&\qquad \cdot (\Lambda_i(A_m + \lambda_m Dv_m) - \Lambda_i A_m)(\Lambda_i(A_m + \lambda_m Dv_m) - \Lambda_i A_m) \\
&\qquad - \lambda_m^{-2} \fint_{B_t} \left(\int_0^1 (1-\tau) D^2 F^i[\Lambda_i A_m + \tau(\Lambda_i A_m + \lambda_m Dv) - \Lambda_i A_m)]\, d\tau \right) \\
&\qquad \cdot (\Lambda_i(A_m + \lambda_m Dv) - \Lambda_i A_m)(\Lambda_i(A_m + \lambda_m Dv) - \Lambda_i A_m)
\end{aligned}$$

(from (5.13))

$$\begin{aligned}
&= \lambda_m^{-2} \fint_{B_t} \left(\int_0^1 (1-\tau) D^2 F^i[\Lambda_i A_m + \tau(\Lambda_i(A_m + \lambda_m Dv_m) - \Lambda_i A_m)]\, d\tau \right) \\
&\qquad \cdot [(\Lambda_i(A_m + \lambda_m Dv_m) - \Lambda_i A_m)(\Lambda_i(A_m + \lambda_m Dv_m) - \Lambda_i A_m) \\
&\qquad\quad - (\Lambda_i(A_m + \lambda_m Dv) - \Lambda_i A_m)(\Lambda_i(A_m + \lambda_m Dv) - \Lambda_i A_m)] \\
&\qquad + \lambda_m^{-2} \fint_{B_t} \left(\int_0^1 (1-\tau) D^2 F^i[\Lambda_i A_m + \tau(\Lambda_i(A_m + \lambda_m Dv_m) - \Lambda_i A_m)] \right. \\
&\qquad\quad \left. - (1-\tau) D^2 F^i[\Lambda_i A_m + \tau(\Lambda_i(A_m + \lambda_m Dv) - \Lambda_i A_m)]\, d\tau \right) \\
&\qquad \cdot (\Lambda_i(A_m + \lambda_m Dv) - \Lambda_i A_m)(\Lambda_i(A_m + \lambda_m Dv) - \Lambda_i A_m) \\
&\quad = C_m^i + D_m^i.
\end{aligned} \tag{5.73}$$

Moreover,

$$\begin{aligned}
C_m^i &= \lambda_m^{-2} \fint_{B_t} \left(\int_0^1 (1-\tau) D^2 F^i[\Lambda_i A_m + \tau(\Lambda_i(A_m + \lambda_m Dv_m) - \Lambda_i A_m)]\, d\tau \right) \\
&\qquad \cdot ([\Lambda_i(A_m + \lambda_m Dv_m) - \Lambda_i(A_m + \lambda_m Dv)] \\
&\qquad\quad \cdot [\Lambda_i(A_m + \lambda_m Dv_m) - \Lambda_i(A_m + \lambda_m Dv)] \\
&\qquad\quad + 2[\Lambda_i(A_m + \lambda_m Dv_m) - \Lambda_i(A_m + \lambda_m Dv)] \\
&\qquad\quad \cdot [\Lambda_i(A_m + \lambda_m Dv) - \Lambda_i A_m]) \\
&\quad = E_m^i + F_m^i,
\end{aligned} \tag{5.74}$$

where we have used the identity

$$D_{q_\alpha q_\beta} F^i(\xi_\alpha \xi_\beta - \eta_\alpha \eta_\beta) = D_{q_\alpha q_\beta} F^i[(\xi_\alpha - \eta_\alpha)(\xi_\beta - \eta_\beta) + 2(\xi_\alpha - \eta_\alpha)\eta_\beta].$$

We have for some $\sigma > 0$,

$$E^i_m \geqq \gamma\lambda_m^{-2} \fint_{B_t} \left(\int_0^1 (1-\tau)|\Lambda_i A_m + \tau(\Lambda_i(A_m+\lambda_m Dv_m) - \Lambda_i A_m)|^{s-2}\, d\tau \right.$$
$$\left. \cdot |\Lambda_i(A_m+\lambda_m Dv_m) - \Lambda_i(A_m+\lambda_m Dv)|^2 \right)$$

(using (H4)(b))

$$\geqq \sigma\lambda_m^{-2} \fint_{B_t} (|\Lambda_i A_m|^{s-2} + |\Lambda_i(A_m+\lambda_m Dv_m) - \Lambda_i A_m|^{s-2})$$
$$\cdot |\Lambda_i(A_m+\lambda_m Dv_m) - \Lambda_i(A_m+\lambda_m Dv)|^2$$

(using (5.70))

$$\geqq \sigma \fint_{B_t} \left(|\Lambda_i A_m|^{s-2} + \lambda_m^{s-2} \left| \sum_{j=1}^{i} \lambda_m^{j-1} \Lambda_{i-j} A_m \odot \Lambda_j Dv_m \right|^{s-2} \right)$$
$$\cdot \left| \sum_{j=1}^{i} \lambda_m^{j-1} \Lambda_{i-j} A_m \odot (\Lambda_j Dv_m - \Lambda_j Dv) \right|^2. \tag{5.75}$$

Also,

$$F^i_m = 2 \fint_{B_t} \left(\int_0^1 (1-\tau) D^2 F^i [\Lambda_i A_m + \tau(\Lambda_i(A_m+\lambda_m Dv) - \Lambda_i A_m)]\, d\tau \right)$$
$$\cdot \left(\Lambda_{i-1} A_m \tilde{\odot} (Dv_m - Dv) + \sum_{j=2}^{i} \lambda_m^{j-1} \Lambda_{i-j} A_m \odot (\Lambda_j Dv_m - \Lambda_j Dv) \right)$$
$$\cdot \left(\sum_{j=1}^{i} \lambda_m^{j-1} \Lambda_{i-j} A_m \odot \Lambda_j Dv \right) \tag{5.76}$$
$$= G^i_m + H^i_m.$$

We now have from (5.68), (5.69), (5.71), (5.73), (5.74), and (5.75)-(5.76) that

$$I^t_m(v_m) - I^t_m(v) \geqq \sigma \fint_{B_t} (|Dv_m - Dv|^2 + \lambda_m^{s-2} |Dv_m - Dv|^s) + B^1_m$$
$$+ \sigma \sum_{i=2}^{k} \fint_{B_t} \left(|\Lambda_i A_m|^{s-2} + \lambda_m^{s-2} \left| \sum_{j=1}^{i} \lambda_m^j \Lambda_{i-j} A_m \odot \Lambda_j Dv_m \right|^{s-2} \right)$$
$$\cdot \left| \sum_{j=1}^{i} \lambda_m^{j-1} \Lambda_{i-j} A_m \odot (\Lambda_j Dv_m - \Lambda_j Dv) \right|^2 \tag{5.77}$$
$$+ \sum_{i=2}^{k} (G^i_m + H^i_m + D^i_m).$$

We first apply Lemma 5.5 to G^i_m, with

$$f_m = 2 \int_0^1 (1-\tau) D^2 F^i [\Lambda_i(A_m + \tau(\Lambda_i(A_m+\lambda_m Dv_m) - \Lambda_i A_m)]\, d\tau),$$

$$g_m = \Lambda_{i-1} A_m \tilde{\odot} (Dv_m - Dv) \lambda_m^{j-1} \Lambda_{i-j} A_m, \quad \text{for each } j = 1, \cdots, i.$$

Then $f_m \to D^2F^i(\Lambda_i A)$ almost everywhere, and $g_m \rightharpoonup 0$ in L^2. Moreover,

$$\begin{aligned}
|f_m g_m| &\leqq c\left(|\Lambda_i A_m|^{s-2} + \sum_{j=1}^{i} \lambda_m^{j(s-2)} |\Lambda_{i-j} A_m|^{s-2} |\Lambda_j Dv_m|^{s-2}\right)(1+|Dv_m|) \\
&\leqq c\left(1+|Dv_m| + \sum_{j=1}^{i} \lambda_m^{j(s-2)} |\Lambda_j Dv_m|^{s-2} + \sum_{j=1}^{i} \lambda_m^{j(s-2)} |\Lambda_j Dv_m|^{s-2} |Dv_m|\right) \\
&\leqq c\Bigg(1+|Dv_m| + \lambda_m^{2-4/s} \sum_{j=1}^{i} (\lambda_m^{j-2/s} |\Lambda_j Dv_m|)^{s-2} \\
&\qquad + \lambda_m^{1-2/s} \sum_{j=1}^{i} (\lambda_m^{j-2/s} |\Lambda_j Dv_m|)^{s-2} (\lambda_m^{1-2/s} |Dv_m|)\Bigg) \\
&\leqq c\Bigg(1+|Dv_m| + \lambda_m^{2-4/s} \sum_{j=1}^{i} (\lambda_m^{js-2} |\Lambda_j Dv_m|^s)^{(s-2)/s} \\
&\qquad + \lambda_m^{1-2/s} \sum_{j=1}^{i} (\lambda_m^{j-2/s} |\Lambda_j Dv_m|)^{s-1} + \lambda_m^{1-2/s} (\lambda_m^{1-2/s} |Dv_m|)^{s-1}\Bigg).
\end{aligned}$$

It follows that $f_m g_m \in L^{s/(s-1)}$, uniformly in m. From Lemma 5.5 it follows that

$$G_m^i \to 0 \quad \text{as } m \to \infty. \tag{5.78}$$

We next claim

$$H_m^i \to 0 \quad \text{as } m \to \infty. \tag{5.79}$$

To see this, apply Lemma 5.5 with

$$\begin{aligned}
f_m &= 2\left(\int_0^1 (1-\tau) D^2F^i[\Lambda_i A_m + \tau(\Lambda_i(A_m + \lambda_m Dv_m) - \Lambda_i A_m)]\, d\tau\right) \\
&\quad \cdot \left(\sum_{j=2}^{i} \lambda_m^{j-1} \Lambda_{i-j} A_m \odot (\Lambda_j Dv_m - \Lambda_j Dv)\right) \lambda_m^{j-1} \Lambda_{i-j} A_m, \\
g_m &= 1,
\end{aligned}$$

where we fix $j \in \{1, \cdots, i\}$.

Then $f_m \to 0$ almost everywhere (using (5.11)). Moreover,

$$\begin{aligned}
|f_m| &\leqq c\left(|\Lambda_i A_m|^{s-2} + \sum_{j=1}^{i} \lambda_m^{j(s-2)} |\Lambda_j Dv_m|^{s-2}\right)\left(1 + \sum_{j=2}^{i} \lambda_m^{j-1} |\Lambda_j Dv_m|\right) \\
&\leqq c\Bigg[|\Lambda_i A_m|^{s-2}\left(1 + \sum_{j=2}^{i} \lambda_m^{j-1} |\Lambda_j Dv_m|\right) + \sum_{j=1}^{i} \lambda_m^{j(s-2)} |\Lambda_j Dv_m|^{s-2} \\
&\qquad + \sum_{j=1}^{i} \lambda_m^{-1} \lambda_m^{j(s-1)} |\Lambda_j Dv_m|^{s-1}\Bigg] \\
&\leqq c\Bigg[1 + \sum_{j=2}^{i} |\Lambda_j A_m|^{s/2-1} \lambda_m^{j-1} |\Lambda_j Dv_m| + \lambda_m^{2-4/s} \sum_{j=1}^{i} (\lambda_m^{js-2} |\Lambda_j Dv_m|^s)^{(s-2)/s} \\
&\qquad + \lambda_m^{1-2/s} \sum_{j=1}^{i} (\lambda_m^{js-2} |\Lambda_j Dv_m|^s)^{(s-1)/s}\Bigg].
\end{aligned}$$

It follows from (5.11) that $f_m \in L^{s/(s-1)}$, uniformly in m. From Lemma 5.5 we see that (5.79) holds.

Finally, we claim that

$$D^i_m \to 0 \quad \text{as } m \to \infty. \tag{5.80}$$

To show this, let

$$\begin{aligned} f_m = \Bigg[\int_0^1 & (1-\tau) D^2 F^i(\Lambda_i A_m + \tau(\Lambda_i(A_m + \lambda_m Dv_m) - \Lambda_i A_m)) \\ & -(1-\tau) D^2 F^i(\Lambda_i A_m + \tau(\Lambda_i(A_m + \lambda_m Dv) - \Lambda_i A_m))\, d\tau \Bigg] \\ & \cdot \left(\sum_{j=1}^{i} \lambda_m^{j-1} \Lambda_{i-j} A_m \odot \Lambda_j Dv \right) \left(\sum_{j=1}^{i} \lambda_m^{j-1} \Lambda_{i-j} A_m \odot \Lambda_j Dv \right). \end{aligned}$$

Then $f_m \to 0$ almost everywhere. Moreover,

$$\begin{aligned} |f_m| &\leqq c \left(|\Lambda_i A_m|^{s-2} + \sum_{j=1}^{i} \lambda_m^{j(s-2)} |\Lambda_j Dv_m|^{s-2} + \sum_{j=1}^{i} \lambda_m^{j(s-2)} |\Lambda_j Dv|^{s-2} \right) \\ &\leqq c \left(1 + \sum_{j=1}^{i} \lambda_m^{j(s-2)} |\Lambda_j Dv_m|^{s-2} \right) \\ &\leqq c \left(1 + \lambda_m^{2-4/s} \left(\sum_{j=1}^{i} \lambda_m^{js-2} |\Lambda_j Dv_m|^s \right)^{(s-2)/s} \right). \end{aligned}$$

Thus $f_m \in L^{s/(s-2)} (\in L^\infty$ if $s=2)$ uniformly in m.

If we apply Lemma 5.5 with $g_m \equiv 1$ we can now establish (5.80).

Combining (5.39) with (5.72) and (5.77)-(5.80), we have that for almost everywhere $t \in (\frac{1}{2}, 1)$ there exists a subsequence depending on t for which

$$\begin{aligned} 0 &\geqq \lim_{m\to\infty} (I^t_m(v_m) - I^t_m(v)) \\ &\geqq \lim_{m\to\infty} \Bigg(\fint_{B_t} |Dv_m - Dv|^2 + \lambda_m^{s-2} |Dv_m - Dv|^s \\ &\qquad + \sum_{i=2}^{k} \fint_{B_t} |\Lambda_i A_m|^{s-2} \left| \sum_{j=1}^{i} \lambda_m^{j-1} \Lambda_{i-j} A_m \odot (\Lambda_j Dv_m - \Lambda_j Dv) \right|^2 \\ &\qquad + \sum_{i=2}^{k} \fint_{B_t} \lambda_m^{s-2} \left| \sum_{j=1}^{i} \lambda_m^{j-1} \Lambda_{i-j} A_m \odot \Lambda_j Dv_m \right|^{s-2} \\ &\qquad \cdot \left| \sum_{j=1}^{i} \lambda_m^{j-1} \Lambda_{i-j} A_m \odot (\Lambda_j Dv_m - \Lambda_j Dv) \right|^2 \Bigg). \end{aligned} \tag{5.81}$$

This now establishes (5.64) and (5.65). Moreover, from the triangle inequality,

$$\begin{aligned} \lim_{m\to\infty} \fint_{B_t} |\Lambda_i A_m|^{s-2} & \left| \Lambda_{i-1} A_m \tilde{\odot} (Dv_m - Dv) \right. \\ & \left. + \sum_{j=2}^{i-1} \lambda_m^{j-1} \Lambda_{i-j} A_m \odot \Lambda_j Dv_m + \lambda_m^{i-1} \Lambda_i Dv_m \right|^2 = 0, \end{aligned} \tag{5.82}$$

$$\begin{aligned} \lim_{m\to\infty} \fint_{B_t} & \lambda_m^{s-2} \left| \sum_{j=1}^{i-1} \lambda_m^{j-1} \Lambda_{i-j} A_m \odot \Lambda_j Dv_m + \lambda_m^{i-1} \Lambda_i Dv_m \right|^{s-2} \\ & \cdot \left| \sum_{j=1}^{i-1} \lambda_m^{j-1} \Lambda_{i-j} A_m \odot \Lambda_j Dv_m + \lambda_m^{i-1} \Lambda_i Dv_m + \varphi^i_m \right|^2 = 0, \end{aligned} \tag{5.83}$$

where φ^i_m is a smooth function, uniformly bounded in m, and $i = 2, \cdots, k$.

From (5.82) with $i=2$, and (5.64), it follows (5.66) is true with $i=2$. Suppose (5.66) is true for $i = 2, \cdots, l (l < k)$. Then it follows from (5.82) with $i = l+1$, the fact

that $|\Lambda_{l+1}A_m| \leqq c|\Lambda_i A_m|$ if $i \leqq l$, and from (5.64), that (5.66) is true with $i = l+1$. It now follows that (5.66) holds for $i = 2, \cdots, k$.

We now claim that (5.67) is true for $i = 2, \cdots, k$.

First note that for $j = 1, \cdots, k$ we have

$$\fint_{B_t} \lambda_m^{s-2} |\lambda_m^{j-1} \Lambda_{i-j} A_m \odot \Lambda_j Dv_m|^{s-2} |\varphi_m^i|^2 \leqq c \fint_{B_t} \lambda_m^{2-4/s} (\lambda_m^{j-2/s} |\Lambda_j Dv_m|)^{s-2} \to 0 \quad \text{as } m \to \infty,$$

since $s > 2$.

From this and (5.83) it follows that

$$\lim_{m\to\infty} \fint_{B_t} \lambda_m^{s-2} \left| \sum_{j=1}^{i-1} \lambda_m^{j-1} \Lambda_{i-j} A_m \odot \Lambda_j Dv_m + \lambda_m^{i-1} \Lambda_i Dv_m \right|^s = 0 \tag{5.84}$$

for $i = 2, \cdots, k$.

From (5.65) and (5.84) with $i = 2$, it follows that (5.67) is true with $i = 2$. Suppose (5.67) holds for $i = 2, \cdots, l (l < k)$. Then it follows from (5.84) with $i = l+1$ that (5.67) is true with $i = l+1$. This establishes (5.67) for $i = 2, \cdots, k$ in the case where $s > 2$.

Consider now the case where $s = 2$. Then directly from (5.81) we have in the case where $i = 2$ that

$$0 \geqq \lim_{m\to\infty} \left(\fint_{B_t} |Dv_m - Dv|^2 + |A_m \odot (Dv_m - Dv) + \lambda_m (\Lambda_2 Dv_m - \Lambda_2 Dv)|^2 \right).$$

Using (5.64) it follows that

$$0 = \lim_{m\to\infty} \fint_{B_t} \lambda_m^2 |\Lambda_2 Dv_m|^2.$$

Since $s = 2$ implies $n = 2$, and hence $\Lambda_i Dv_m$ is trivial if $i > 2$, it follows that (5.67) is now established in the case where $s = 2$.

This completes the proof of (5.64)-(5.67).

E. Completion of proof. Choose $t \in (\frac{1}{2}, 1)$ such that (5.64)-(5.67) are true for some subsequence.

In order to obtain a contradiction to (5.2) we first use (5.1) and (5.59) to compute

$$\begin{aligned} \lambda_m^{-2} U(x_m, \tau r_m) = & \fint_{B_\tau} |Dv_m - (Dv_m)_\tau|^2 + \fint_{B_\tau} \lambda_m^{s-2} |Dv_m - (Dv_m)_\tau|^s \\ & + \fint_{B_\tau} \sum_{i=2}^{k} |\Lambda_i (A_m + \lambda_m (Dv_m)_\tau)|^{s-2} \lambda_m^{2i-2} |\Lambda_i (Dv_m - (Dv_m)_\tau)|^2 \\ & + \fint_{B_\tau} \sum_{i=2}^{k} \lambda_m^{si-2} |\Lambda_i (Dv_m - (Dv_m)_\tau)|^s. \end{aligned} \tag{5.85}$$

Since $\tau \leqq \frac{1}{2} < t$, it follows from (5.64) that $Dv_m \to Dv$ in $L^2(B_\tau)$, and hence $(Dv_m) \to (Dv)_\tau$. Thus the integral on the right side of (5.85) converges to $f_{B_\tau} |Dv - (Dv)_\tau|^2$.

If $s > 2$ then $\lambda_m^{1-2/s} Dv_m \to 0$ in $L^s(B_\tau)$ from (5.65), and hence $\lambda_m^{1-2/s} Dv_m \to 0$. Thus the second integral on the right side converges to zero.

Next note that since $(Dv_m)_\tau \to (Dv)_\tau$, it follows that $\Lambda_i (Dv_m)_\tau$ is bounded uniformly in m for $i = 2, \cdots, k$ (with the bound possibly depending on τ).

Hence, for $i=2,\cdots,k$,

$$\fint_{B_\tau}|\Lambda_i(A_m+\lambda_m(Dv_m)_\tau|^{s-2}\lambda_m^{2i-2}|\Lambda_i(Dv_m-(Dv_m)_\tau)|^s$$

$$\leqq c\fint_{B_\tau}(|\Lambda_iA_m|^{s-2}+\lambda_m^{s-2})\lambda_m^{2i-2}\left(1+\sum_{j=1}^{i}|\Lambda_jDv_m|^2\right)$$

$$\leqq c\fint_{B_\tau}|\Lambda_iA_m|^{s-2}\lambda_m^{2i-2}+\sum_{j=1}^{i}|\Lambda_jA_m|^{s-2}\lambda_m^{2j-2}|\Lambda_jDv_m|^2$$

$$+\lambda_m^{s+2i-4}+\sum_{j=1}^{i}\lambda_m^{s+2j-4}|\Lambda_jDv_m|^2$$

(using $|\Lambda_iA_m|\leqq c|\Lambda_jA_m|$ if $1\leqq j\leqq i$)

$$\leqq c\fint_{B_\tau}|\Lambda_iA_m|^{s-2}\lambda_m^{2i-2}+\sum_{j=1}^{i}|\Lambda_jA_m|^{s-2}\lambda_m^{2j-2}|\Lambda_jDv_m|^2$$

$$+\lambda_m^{s+2i-4}+\lambda_m^{s(1-2/s)^2}\left(\sum_{j=1}^{i}\lambda_m^{j-2/s}|\Lambda_jDv_m|\right)^2$$

$$\to 0 \quad \text{as } m\to\infty$$

(using (5.66), (5.67), and the fact we may here assume that $s>2$).

Finally, for $i=2,\cdots,k$,

$$\fint_{B_\tau}\lambda_m^{is-2}|\Lambda_i(Dv_m-(Dv_m)_\tau)|^s\leqq c\fint_{B_\tau}\lambda_m^{is-2}\left(1+\sum_{j=1}^{i}|\Lambda_jDv_m|^s\right)$$

$$\to 0 \quad \text{as } m\to\infty,$$

from (5.67).

It follows that

$$\lambda_m^{-2}U(x_m,\tau r_m)\to\fint_{B_\tau}|Dv-(Dv)_\tau|^2$$

as $m\to\infty$. But

$$\fint_{B_\tau}|Dv-(Dv)_\tau|^2\leqq c\tau^2\sup_{B_\tau}|D^2v|^2$$

$$\leqq c_2\tau^2 \tag{5.86}$$

from (5.38), where $c_2=c_2(M)$. Hence

$$\lambda_m^{-2}U(x_m,\tau r_m)\leqq 2c_2\tau^2$$

for all sufficiently large m, contradicting (5.2) if we set $c_1=2c_2(M)$.

This contradiction completes the proof of Theorem 5.1. □

6. Proof of the main theorem. We first show how Theorem 5.1 is iterated in the standard manner. We continue to assume $u\in\Lambda_kW^{1,s}(\Omega)$ is a minimiser of $I[\cdot]$ and $I[\cdot]$ satisfies the hypotheses (H1)-(H4).

LEMMA 6.1. *Suppose* $0<\alpha<1$ *and* $M>0$. *Then there exists* $0<\tau<\frac{1}{2}$ *and* $\varepsilon>0$ *such that, for any* $B_r(x)\subset\Omega$, *if*

$$|(Du)_{x,r}|<M,$$
$$U(x,r)<\varepsilon,$$

then

$$U(x,\tau^l r)\leqq(\tau^l)^{2\alpha}U(x,r)$$

for each $l=1,2,\cdots$.

Proof. Using the notation of Theorem 5.1, first choose τ such that

$$0<\tau<\tfrac{1}{2},\quad c_1(2M)\tau^2\leqq\tau^{2\alpha},\quad \tau^\alpha<\tfrac{1}{2}. \tag{6.1}$$

Next, choose ε so that

$$0<\varepsilon\leqq\varepsilon_0(\tau,2M),\qquad \tau^{-n}\varepsilon^{1/2}\leqq\frac{M}{2}. \tag{6.2}$$

Suppose

$$B_r(x)\subset\Omega,\quad |(Du)_{x,r}|<M,\quad U(x,r)<\varepsilon. \tag{6.3}$$

We will prove by induction on $l\geqq0$ that

$$\begin{aligned}&|(Du)_{x,\tau^l r}|\leqq M\left(1+\frac{1}{2}+\cdots+\frac{1}{2^l}\right),\\ &U(x,\tau^l r)\leqq(\tau^l)^{2\alpha}U(x,r).\end{aligned} \tag{6.4}$$

First note that

$$\begin{aligned}|(Du)_{x,\tau^{l+1}r}-(Du)_{x,\tau^l r}|&\leqq\fint_{B(x,\tau^{l+1}r)}|Du-(Du)_{x,\tau^l r}|\\ &\leqq\tau^{-n}\fint_{B(x,\tau^l r)}|Du-(Du)_{x,\tau^l r}|\\ &\leqq\tau^{-n}[U(x,\tau^l r)]^{1/2}.\end{aligned} \tag{6.5}$$

Note that (6.4) is trivially true of $l=0$. Assume that it is true for some l. Then

$$\begin{aligned}|(Du)_{x,\tau^{l+1}r}|&\leqq|(Du)_{x,\tau^l r}|+|(Du)_{x,\tau^{l+1}r}-(Du)_{x,\tau^l r}|\\ &\leqq M\left(1+\frac{1}{2}+\cdots+\frac{1}{2^l}\right)+\tau^{-n}(U(x,\tau^l r))^{1/2}\\ &\leqq M\left(1+\frac{1}{2}+\cdots+\frac{1}{2^l}\right)+\tau^{-n}(\tau^l)^\alpha(U(x,r))^{1/2}\end{aligned}$$

(using (6.4))

$$\leqq M\left(1+\frac{1}{2^l}+\cdots+\frac{1}{2^l}+(\tau^l)^\alpha\frac{M}{2}\right)$$

(using (6.2), (6.3))

$$\leqq M\left(1+\frac{1}{2}+\cdots+\frac{1}{2^l}+\frac{1}{2^{l+1}}\right)$$

(using (6.1)).

Also, from (6.4), (6.2), (6.3) we can apply Theorem 5.1 with M and r there replaced by $2M$ and $\tau^l r$, to deduce

$$U(x, \tau^{l+1}r) \leqq c_1(2M)\tau^2 U(x, \tau^l r)$$
$$\leqq \tau^{2\alpha}(\tau^l)^{2\alpha} U(x, r)$$

(using (6.1) and (6.4))

$$= (\tau^{l+1})^{2\alpha} U(x, r).$$

The proof is now completed by using induction of l. □

LEMMA 6.2. *Suppose* $u \in \Lambda_k W^{1,s}(\Omega)$. *Then*

$$\lim_{r\to 0} \fint_{B(x,r)} |\Lambda_i(Du - (Du)_{x,r})|^s = 0$$

for almost everywhere $x \in \Omega$ *and for* $i = 1, \cdots, k$.

Proof. Let $\{A_\alpha\}_{\alpha\in S}$ be a countable dense subset of Hom $(\mathbb{R}^n; \mathbb{R}^N)$.

By considering the set of Lebesgue points of Du and of the functions $|\Lambda_i(Du - A_\alpha)|^s$ for $i = 1, \cdots, k$ and $\alpha \in S$, there exists $E \subset \Omega$ with $\mathscr{L}^n(\Omega \sim E) = 0$ such that

$$(Du)_{x,r} \to Du(x),$$

$$\fint_{B_{x,r}} |\Lambda_i(Du - A_\alpha)|^s \to |\Lambda_i(Du(x) - A_\alpha)|^s,$$

as $r \to 0$, for all $x \in E$, $\alpha \in S$, and $i = 1, \cdots, k$.

We have for all such x, α, and i,

$$\limsup_{r\to 0} \fint_{B(x,r)} |\Lambda_i(Du - (Du)_{x,r}|^s$$

$$= \limsup_{r\to 0} \fint_{B(x,r)} |\Lambda_i(Du - A_\alpha + A_\alpha - (Du)_{x,r}|^s$$

$$\leqq c \limsup_{r\to 0} \sum_{j=0}^{i} |\Lambda_j(A_\alpha - (Du)_{x,r})|^s \fint_{B(x,r)} |\Lambda_{i-j}(Du - A_\alpha)|^s$$

(using (2.17))

$$= c \sum_{j=0}^{i} |\Lambda_j(A_\alpha - Du(x))|^s |\Lambda_{i-j}(Du(x) - A_\alpha)|^s.$$

Since A_α is dense in Hom $(\mathbb{R}^n; \mathbb{R}^N)$, we can make the right side arbitrarily small. This establishes the lemma. □

6.1. Completion of proof of Main Theorem 4.1. Let

$$\Omega_0 = \Big\{ x \in \Omega: \lim_{r\to 0} (Du)_{x,r} = Du(x), \quad \text{and}$$

$$\lim_{r\to 0} \fint_{B(x,r)} |\Lambda_i(Du - (Du)_{x,r})|^s = 0 \quad \text{for } i = 1, \cdots, k \Big\}.$$

Then $\mathscr{L}^n(\Omega \sim \Omega_0) = 0$ by Lemma 6.2. Moreover, by standard arguments (e.g., [E] or [G]) it follows from Lemma 6.1 that Ω_0 is open and $u \in C^{1,\alpha}(\Omega_0)$. □

7. Concluding remarks. It is clear that the methods of the paper can be applied to other problems.

7.1. We could include quasi-convex, nonpolyconvex terms in (4.2) by allowing F^1 to be quasi convex. More precisely, the hypotheses (H1)-(H4) would remain unchanged, except that (H3)(b) would be replaced by the strict quasi-convexity condition

$$\int F^1(p+D\varphi) \geqq \int F^1(p)+\gamma(|D\varphi|^2+|D\varphi|^s))$$

for all $\varphi \in C_c^\infty(\mathbb{R}^n;\mathbb{R}^N)$ and all $p \in \mathbb{R}^{n\times N}$.

The F^1 term is then treated essentially as in [EG] to obtain (5.71). Note that (5.30) needs to be replaced by the appropriate Legendre-Hadamard condition.

7.2. Model problems of the form

$$I[u]=\int_\Omega \left(1+|Du|^2+\sum_{i=2}^k |\Lambda_i Du|^2\right)^{s/2},$$

or more generally of the form

$$I[u]=\int_\Omega |Du|^s+\left(1+|Du|^2+\sum_{i=2}^k |\Lambda_i Du|^2\right)^{s'/2},$$

where $s \geqq 2$ if $n=2$, $s>n-1$ if $n>2$, and $s' \geqq 2$, are easily treated by our methods. Such model problems were discussed (from an existence point of view) in [GMS, § 6.A].

In order to prove partial regularity, we take the quantity $U(x, r)$ to be

$$U(x,r)=\fint_{B(x,r)} |Du-(Du)_{x,r}|^2+|Du-(Du)_{x,r}|^{\max\{s,s'\}} + \sum_{i=2}^k [|\Lambda_i(Du-(Du)_{x,r})|^2+|\Lambda_i(Du-(Du)_{x,r}|^{s'}].$$

The arguments involved in this case, as opposed to the arguments involved in treating the model problem (1.3), are somewhat easier, as no degeneracy in ellipticity in the $\Lambda_i Du$ terms is allowed.

Partial regularity theory for such problems, but in the case $s>n$, has also been recently treated in [GMS2].

7.3. Many model problems of the form

$$\int |Du|^2+|Du|^{s_1}+\sum_{i=2}^k |\Lambda_i Du|^{s_i},$$

where $s_1 \geqq 2$ if $n=2$, $s_1>n-1$ if $n-2$, and $s_1 \geqq s_2 \geqq \cdots \geqq s_k \geqq 2$, are covered by the present arguments. More generally, we could include more than one term involving $\Lambda_i Du$. We have not checked, however, the appropriate most general conditions on the exponents.

Similarly, we could formulate more general structure conditions. It is not necessary that the integrand in (4.2) split as a sum of terms involving the $\Lambda_i Du$ separately. In this more general case, we define the normalised functional

$$I_m[w]=\int_\Omega F_m(Dw),$$

where F_m is obtained by linearisation about $(A_m, \Lambda_2 A_m, \cdots, \Lambda_k A_m)$.

PERIOD DOUBLING WITH HIGHER-ORDER DEGENERACIES*

BRUCE B. PECKHAM† AND IOANNIS G. KEVREKIDIS‡

Abstract. A family of local diffeomorphisms of $\mathbf{R}^n$ can undergo a period doubling (flip) bifurcation as an eigenvalue of a fixed point passes through -1. This bifurcation is either supercritical or subcritical, depending on the sign of a coefficient determined by higher-order terms. If this coefficient is zero, the resulting bifurcation is "degenerate." The period doubling bifurcation with a single higher-order degeneracy is treated, as well as the more general degenerate period doubling bifurcation where a fixed point has -1 eigenvalue and any number of higher-order degeneracies. The main procedure is a Lyapunov-Schmidt reduction: period-2 orbits are shown to be in one-to-one correspondence with roots of the reduced "bifurcation function," which has $\mathbf{Z}_2$ symmetry. Illustrative examples of the occurrence of the singly degenerate period doubling in the context of periodically forced planar oscillators are also presented.

1. Introduction. This paper describes the local bifurcations that take place when we perturb a diffeomorphism $\mathbf{G}_0$ of $\mathbf{R}^n$ which has a fixed point with a single eigenvalue equal to -1. Since $\mathbf{G}_0$ has a nonhyperbolic fixed point, it is necessary to consider higher-order (nonlinear) terms in order to describe the phase portraits near the fixed point of the map $\mathbf{G}_0$, both by itself and also under perturbation in a family $\mathbf{G}_\mu$, $\mu \in \mathbf{R}^k$.

When G_0 is a map of $\mathbf{R}$, any even-order term in its Taylor series expansion can be eliminated by a change of variables. This is a direct result of the normal forms theorem. After eliminating the constant and second-order terms, the linear coefficient will be -1 and the sign of the resulting coefficient of the third-order term will determine whether G_0 will undergo a supercritical or subcritical period doubling (flip) bifurcation [Ar], [GH]. If the third-order coefficient should happen to be zero (a higher-order degeneracy), then the sign of the fifth-order term becomes important. Perturbations of the resulting map $(G_0(x) = -x + cx^5 + o(x^5),\ c \neq 0)$ produce a greater number of topologically distinct phase portraits than do perturbations of the nondegenerate $(G_0(x) = -x + cx^3 + o(x^3),\ c \neq 0)$ map. Two parameters are needed to fully capture all possible phase portraits near the (singly) degenerate map. By the same token, a degenerate bifurcation will generically occur only in families with at least two parrameters.

This discussion naturally extends to multiply degenerate period doubling maps: $G_0(x) = -x + cx^{2k+1} + o(x^{2k+1}),\ c \neq 0$ ($k-1$ times degenerate). These codimension-k bifurcations will generically occur only in families with at least k parameters.

In § 2, we consider the model $k-1$ times degenerate period doublings $f_0(x) = -x + \delta x^{2k+1}$ where $\delta = \pm 1$, and the corresponding model k-parameter unfoldings $f_\varepsilon(x) = -(\varepsilon_1 + 1)x - \varepsilon_2 x^3 - \cdots - \varepsilon_k x^{2k-1} + \delta x^{2k+1}$. We present the mathematical theory in § 3. We show that the period-2 orbits of the individual maps we study are in one-to-one correspondence with the zeros of a "reduced" bifurcation function. This bifurcation function is obtained by using a standard Lyapunov-Schmidt reduction. Because the

topological equivalence of the maps we study is determined by the period-2 orbits and their stability, knowledge of the corresponding bifurcation functions is sufficient to provide us with the topological classification of the original maps. When we consider a *family* of maps, the possible behaviors of the bifurcation functions are given by standard singularity theory. We need only interpret the singularity theory results in the bifurcation context of the original family of maps. In particular, we show that each family in the class of period doubling bifurcations that we treat is "equivalent" to one of the model families we describe in § 2.

The singly degenerate period doubling has a special significance in two-parameter families of maps such as those generated by periodically forced oscillators, which possess period-q "resonance horns" whose boundaries typically consist of saddlenode bifurcations for the qth iterate of the map. We and other researchers [KAS], [MSA], [P1], [P2], [P3], [SDCM], [VR] have repeatedly observed such a degenerate period doubling bifurcation on the boundaries of period-2 resonance horns. In § 4 we describe two models of periodically operated chemical reactors (a chemostat with simple predator-prey kinetics, and a continuous stirred tank reactor (CSTR) with a single irreversible exothermic reaction) where this bifurcation occurs.

The bifurcation diagrams we obtained for our degenerate period doublings turned out to be virtually the same as those for a Hopf bifurcation with higher-order degeneracies for a *flow* [GS], [Ta]. Consequently, work on the Hopf bifurcation suggested approaches to the period doubling problem. Our analysis in its final form parallels that of Golubitsky and Schaeffer [GS, Chap. VIII]. In particular, the use of the Lyapunov–Schmidt reduction to obtain a bifurcation function, as well as the unreduced function with which to start, was suggested by their exposition. Using the reduction on a "finite sequence space," however, appears to be a new idea in this paper. (We have since found out that Vanderbauwhede [Va] and Brown and Roberts [BR] have independently started using the Lyapunov–Schmidt reduction on finite sequence spaces in current research as well.) See also the bibliography in [GS] for the original references using the Lyapunov–Schmidt reduction and singularity theory to study the Hopf bifurcation for flows.

The Hopf problem for flows and our problem are analogous because both can be reduced to finding roots of the same $\mathbf{Z}_2$-symmetric bifurcation function. The period doubling problem, interestingly, turns out to be significantly easier to handle than the Hopf bifurcation. Many of the issues that [GS] had to treat simply did not appear in the period doubling analysis. Consequently, we are able to obtain slightly stronger stability information from the bifurcation than was obtained for the Hopf bifurcation in [GS]. We discuss the comparison with the Hopf bifurcation further in § 5.

To place our work in context, we provide Table 1, showing model unfoldings for bifurcations with higher-order degeneracies. The unfoldings in the table are not always exactly as in the corresponding reference, and the references are not intended to be complete. In all cases, $\boldsymbol{\varepsilon} \in \mathbf{R}^k$ is the unfolding parameter of the codimension-k bifurcation; $\delta = \pm 1$.

The most widely known higher-order degeneracy in Table 1 is the saddle-node (for either the flow or map) with a single higher-order degeneracy, commonly called the *cusp* bifurcation. The map and flow cases are exactly analogous. We will encounter saddlenode bifurcations with higher-order degeneracies in this paper for period-2 orbits, because they appear in the unfoldings of period doubling points with more than one higher-order degeneracy. Higher-order degeneracies in the Hopf bifurcation for maps, however, are much more complicated to treat than degeneracies in the Hopf bifurcation for flows. The map case includes not only all the subtleties of the flow

case, but also some monumental additional problems caused by resonant interaction of periodic orbits, and the existence of invariant sets other than equilibria and closed orbits. Chenciner [Ch] has performed much work on this problem. Note that the higher-order terms must appear, even in the model unfoldings.

We point out that [HW] provides a short description of the period doubling with a single higher-order degeneracy ($k = 2$ in Table 1). That model, but not the theorems in this paper, is relatively well known to bifurcation researchers.

2. The model period doubling families. This section is devoted to describing the bifurcations that take place in the specific families we use as our models. The new results, including the justification for choosing these particular families as models, are given in § 3. The interested reader may skip directly to that section, if desired. We do, however, make some effort in this section to prepare the groundwork for the techniques of § 3. In particular, we use the zeros of several "bifurcation functions" to help us describe the topological classification of our model families. These bifurcation functions will turn out to be special cases of the more general bifurcation functions obtained from the more general maps treated in § 3. (See Corollary 3.13.)

Recall that for maps of $\mathbf{R}$ having a fixed point with a -1 eigenvalue, the normal forms theorem [Ar], [GH] allows us to eliminate any even-order term by a change of variable. Thus the absence of even-order terms from our models should seem reasonable. Keep in mind that, because we are describing local bifurcations, we are only interested in the germs of our functions in phase × parameter space. The base point of all our model germs is the origin of $\mathbf{R} \times \mathbf{R}^k$.

DEFINITION 2.1. The local (near $(x, \boldsymbol{\varepsilon}) = (0, \mathbf{0})$) family

$$f_{\boldsymbol{\varepsilon};k,\delta}(x) := -(\varepsilon_1 + 1)x - \varepsilon_2 x^3 - \cdots - \varepsilon_k x^{2k-1} + \delta x^{2k+1}, \qquad \delta = \pm 1 \tag{2.2}$$

is called the *model local period doubling bifurcation family with $k-1$ higher-order degeneracies.* The map $f_{\mathbf{0};k,\delta}(x) = -x + \delta x^{2k+1}$ (for x near zero) is called the *model period doubling bifurcation map with $k-1$ higher-order degeneracies.*

Note that the parameter $\boldsymbol{\varepsilon} = (\varepsilon_1, \varepsilon_2, \cdots, \varepsilon_k)$ is in $\mathbf{R}^k$, $k \geqq 1$. We will often drop the subscripts k and δ since their values are assumed to be fixed for a given family.

2.1. Individual maps: Stability of periodic orbits. We first describe the behavior of the map $f_{\boldsymbol{\varepsilon}} = f_{\boldsymbol{\varepsilon};k,\delta}$ for fixed values of the parameters. Zero is the unique fixed point near $x = 0$ of $f_{\boldsymbol{\varepsilon}}$ for any $\boldsymbol{\varepsilon}$ near $\mathbf{0}$. The fixed point is attracting for $\varepsilon_1 < 0$ and repelling for $\varepsilon_1 > 0$. Since $f_{\boldsymbol{\varepsilon}}^2$ is an orientation preserving diffeomorphism of $\mathbf{R}$, fixed points are

the only form of recurrence it can have. Once these fixed points of f_ε^2 have been located, the topological equivalence class of f_ε^2, and therefore that of the orientation reversing f_ε, is determined by the directions in which iterates of f_ε^2 progress in the intervals of $\mathbf{R}\backslash\{\text{fixed points of } f_\varepsilon^2\}$. (This can be proven by fundamental interval arguments.) For nonzero x, it is apparent that if $f_\varepsilon^2(x)-x=0$, then x is on a period-2 orbit for f_ε; if $f_\varepsilon^2(x)-x>0$, the orbit of x increases under iteration of f_ε^2; if $f_\varepsilon^2(x)-x<0$, the orbit of x decreases under iteration of f_ε^2. Since the behavior of f_ε is completely determined by the roots and sign of the function $f_\varepsilon^2(x)-x$, we call it a "bifurcation function" associated with the family $f_\varepsilon=f_{\varepsilon;k,\delta}$ in (2.2).

Even in the nondegenerate case ($k=1$ in $f_{\varepsilon;k,\delta}$), the second iterate f_ε^2 is somewhat cumbersome to handle. The algebra is greatly reduced by noticing that f_ε is an odd, or $\mathbf{Z}_2$-symmetric, function of x: $f_\varepsilon(-x)=-f_\varepsilon(x)$. The consequence is that x is a period-2 orbit if and only if $f_\varepsilon(x)=-x$. Thus $f_\varepsilon^2(x)-x=0$ is equivalent to $-f_\varepsilon(x)-x=0$. We have chosen to use $-f_\varepsilon(x)-x$ instead of $f_\varepsilon(x)+x$ because when they do not equal zero, $\operatorname{sgn}(f_\varepsilon^2(x)-x)=\operatorname{sgn}(-f_\varepsilon(x)-x)$. Thus the function $-x-f_\varepsilon(x)$ is also a bifurcation function for (2.2).

Furthermore, $-x-f_\varepsilon(x)=xP_\varepsilon(x^2)$, where

$$P_{\varepsilon;k,\delta}(u):=P_\varepsilon(u):=\varepsilon_1+\varepsilon_2 u+\cdots+\varepsilon_k u^{k-1}-\delta u^k. \tag{2.3}$$

Since $x=0$ is always a fixed point, the roots of $P_\varepsilon(x^2)$ with $x\neq 0$ are precisely the period-2 points. That is, each positive root r^2 of $P_\varepsilon(u)$ corresponds to the period-2 orbit $r\leftrightarrow -r$. For $x\neq 0$ the sign of $-f_\varepsilon(x)-x$ and therefore the sign of $f_\varepsilon^2(x)-x$ is determined by the sign of $P_\varepsilon(x^2)$. So the stability of the fixed point and any period-2 orbit is also determined by the sign of P_ε. Thus, $P_\varepsilon(u)$ becomes our third and simplest bifurcation function.

It may help to keep in mind Fig. 1a, where we graph the three bifurcation functions $f_\varepsilon^2(x)-x$, $-f_\varepsilon(x)-x$, and $P_\varepsilon(x^2)$ for a specific example: $(\varepsilon;k,\delta)=((.000016,.0024,.09),3,+1)$. Figure 1b shows the phase portrait for f_ε^2 that Fig. 1a determines.

2.2. Bifurcations. We are now ready to analyze the bifurcation sets in phase × parameter space ($\mathbf{R}\times\mathbf{R}^k$) that exist in the model families $f_{\varepsilon;k,\delta}$ for fixed values of k and δ. These consist of the nonhyperbolic fixed and period-2 points, possibly with higher-order degeneracies.

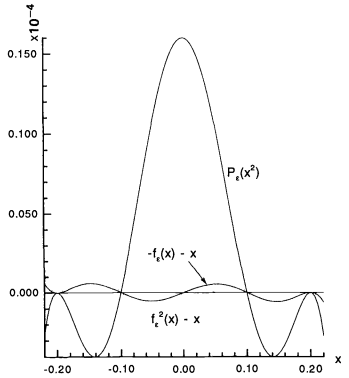

FIG. 1a. *Three bifurcation functions.*

FIG. 1b. *The "flow" of* f_ε^2.

We will treat the fixed-point bifurcations first. Since f_ε is an orientation reversing diffeomorphism of $\mathbf{R}$, the only potential bifurcations for the unique fixed point zero are period doublings. From (2.2), the set in $\mathbf{R}\times\mathbf{R}^k$ of fixed points, which we call D^0, is $\{x=0\}$; the set of period doubling bifurcations is $D^1 := \{x=\varepsilon_1=0\}$; more generally, the set of period doubling bifurcations with at least $i-1$ higher-order degeneracies is apparently (look ahead to Definition 3.1—the model families in (2.2) are already in normal form on the center manifold) the codimension $i+1$ (dimension $k-i$) hyperplane given by

$$D^i := D^i_k = \{(x,\varepsilon)\in\mathbf{R}\times\mathbf{R}^k : x=\varepsilon_1=\cdots=\varepsilon_i=0\}, \qquad i=0,\cdots,k. \tag{2.4}$$

The superscripts have been chosen to indicate the codimension of the corresponding set when projected to the k-dimensional parameter space. The set of simple (nondegenerate) period doubling bifurcation parameters is thus, as usual, a codimension-1 set in the parameter space.

The nonhyperbolic period-2 points are treated by considering f^2_ε. Since f^2_ε is an orientation preserving diffeomorphism of $\mathbf{R}$, the only potential bifurcations for the period-2 orbits are saddlenodes, possibly with higher-order degeneracies. By definition [Ar], [GH], a map $g:\mathbf{R}\to\mathbf{R}$ has a saddlenode with $i-1$ higher-order degeneracies at y_0 if $g(y)-y$ has a zero of multiplicity $i+1$ at $y=y_0$. So the period-2 points in our models have saddlenode bifurcations with $i-1$ higher-order degeneracies at x_0 if, for a fixed value of ε, $f^2_\varepsilon(x)-x$ has a zero of multiplicity $i+1$ at $x=x_0\neq 0$. But $f^2_\varepsilon(x)-x$ having a zero of multiplicity $i+1$ at $x=x_0\neq 0$ is equivalent to $P_\varepsilon(x^2)$ having a zero of multiplicity $i+1$ at $x=x_0\neq 0$. If we define $S^0_{k,\delta}$ as the set of period-2 points and $S^j_{k,\delta}$ as the set of period-2 saddlenode points with at least $j-1$ higher-order degeneracies for $1\leqq j\leqq k-1$, then these sets are

$$S^j := S^j_{k,\delta} = \{(x,\varepsilon)\in\mathbf{R}\times\mathbf{R}^k : P^{(i)}_\varepsilon(x^2)=0 \text{ for } 0\leqq i\leqq j,\ x\neq 0\}. \tag{2.5}$$

2.3. The low codimension period doublings. We can now use (2.4), (2.5), and the sign of P_ε to determine the bifurcation diagrams and phase portraits for the codimension-k bifurcations with $k=1,2,3$.

***k* = 1.** When $k=1$ then $\varepsilon=\varepsilon_1$ and (2.2) becomes the *simple* (nondegenerate) *period doubling bifurcation*: $f_{\varepsilon;1,\delta}(x)=-(\varepsilon_1+1)x+\delta x^3$. $P_\varepsilon(u)=\varepsilon_1-\delta u$ and $P'_\varepsilon(u)=-\delta\neq 0$. From (2.5) we see that period-2 points exist whenever $\delta\varepsilon>0$ and are located on the parabola $x=\pm\sqrt{\delta\varepsilon}$. The period-2 orbits are stable for $\delta=+1$ and unstable for $\delta=-1$. Since $P'_\varepsilon(u)\neq 0$ all period-2 points are hyperbolic. A bifurcation diagram with three representative phase portraits for $\delta=+1$ is shown in Fig. 2. This is the *supercritical* case. The arrows on these phase portraits indicate the direction of travel of second iterates of f_ε. The same figure can be used for $\delta=-1$, the *subcritical* case, by reversing the direction of the ε-axis and the direction of the arrows on the phase portraits. Changing the arrow directions means that the stability of the fixed point and any period-2 orbits for $\delta=-1$ will be the reverse of the stability for $\delta=+1$.

***k* = 2.** In this case, which really motivated the whole paper, (2.2) represents the *singly degenerate period doubling bifurcation* $f_{\varepsilon;2,\delta}(x)=-(\varepsilon_1+1)x-\varepsilon_2x^3+\delta x^5$. Since the coefficient ε_2 of the x^3 term, which determines the criticality of the simple period doubling bifurcation, is allowed to change from positive to negative, we will have both supercritical and subcritical period doublings. All the fixed-point bifurcations have already been identified in (2.4). For the period-2 bifurcations, we use the bifurcation function $P_{\varepsilon;2,\delta}(u)=P_\varepsilon(u)=\varepsilon_1+\varepsilon_2u-\delta u^2$, so $P'_\varepsilon(u)=\varepsilon_2-2\delta u$ and $P''_\varepsilon(u)=-2\delta\neq 0$.

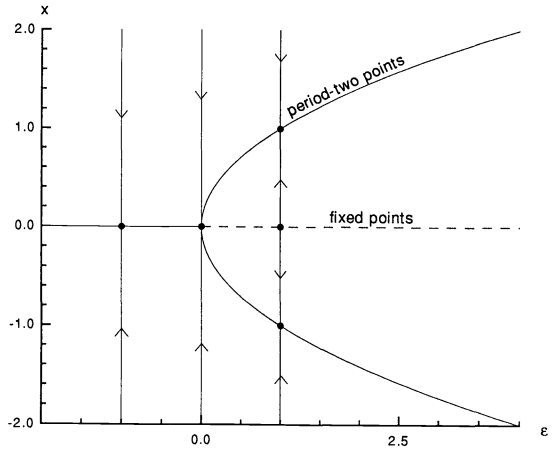

FIG. 2. *Supercritical simple period doubling.*

By (2.5), the period-2 points in $\mathbf{R}\times\mathbf{R}^k$ are $S^0=\{\varepsilon_1=-\varepsilon_2x^2+\delta x^4,\ \varepsilon_2\neq 2\delta x^2\}$ and they project to $\pi_\varepsilon(S^0)=\{\delta\varepsilon_1>0\}\cup\{\delta\varepsilon_2>0$ and $\varepsilon_2^2\geqq -4\delta\varepsilon_1\}$ in the ε-parameter plane $\mathbf{R}^2$. The nonhyperbolic period-2 points are all (nondegenerate) saddlenode bifurcations. They are given by $S^1=\{\varepsilon_1=-\delta x^4,\ \varepsilon_2=2\delta x^2,\ x\neq 0\}$ and project to $\pi_\varepsilon(S^1)=\{\varepsilon_1=(-\delta/4)\varepsilon_2^2,\ \delta\varepsilon_2>0\}$. The formulas for the projections to the ε parameter plane are obtained by eliminating x from the expressions for S^0 and S^1.

Figure 3 shows sketches of the above sets for $\delta=+1$ in phase $\times$ parameter space. The projections to parameter space are drawn on the fixed-point plane $\{x=0\}$. The surface $S^0_{2,+1}$ of period-2 points, the plane D_2^0 of fixed points, the period doubling line D_2^1, the saddlenode curve $S^1_{2,+1}$, and its projection $\pi_\varepsilon(S^1_{2,+1})$ to the ε parameter plane, drawn in the $\{x=0\}$ plane, are all indicated in the figure. Note that all the bifurcation points occur on the "folds" of the period-2 surface $S^0_{2,+1}$.

Various two-dimensional bifurcation diagrams (pieces of Fig. 3) are shown in Fig. 4: 4a gives the projection of the bifurcation sets S^1 (saddlenodes) and D^1 (period doublings) to the parameter space; the other three are representative one-parameter cuts of Fig. 3: 4b and 4c each have a fixed value for ε_2, while a small circular path

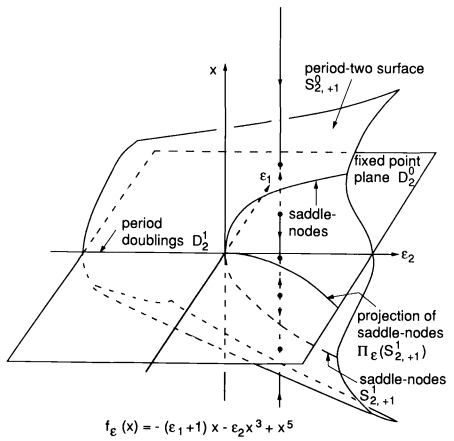

FIG. 3. *Singly degenerate period doubling.*

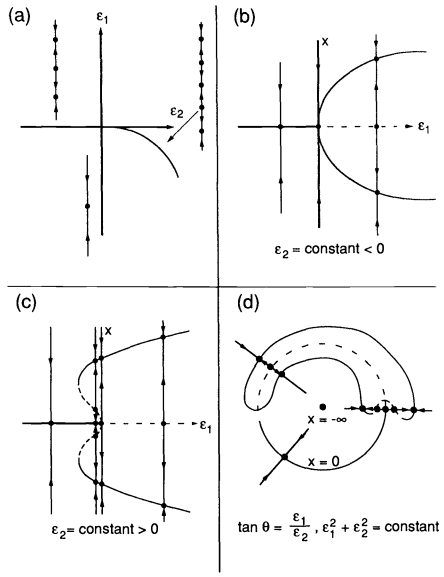

FIG. 4. *Aspects of singly degenerate period doubling.*

around the origin in the ε-plane yields 4d. Arrows all indicate the "flow" of the second iterate of $f_{\varepsilon;2,+1}$. (Compare Figs. 4b and 4c with Fig. 3.1 in [GS, p. 260]; compare Fig. 4d with Fig. 136 in [Ar, p. 283].)

As in the simple period doubling case, Fig. 3 and all Fig. 4 diagrams could be converted from the $\delta = +1$ case to the $\delta = -1$ case by reversing the directions of the ε_1 axis, the ε_2 axis, and the "flow" lines. The stability of the fixed point and all period-2 orbits is opposite for the two cases.

$k \geqq 3$. The program for computing the bifurcation submanifolds can obviously be continued for the model period doublings of any codimension. Because the computations are more lengthy but not much more enlightening, we merely list the results, with special attention to the $(k, \delta) = (3, +1)$ case.

The fixed-point bifurcation sets satisfy $D_k^0 \supset D_k^1 \supset \cdots \supset D_k^{k-1} \supset D_k^k$ where $D_k^{j-1} \backslash D_k^j$ is the codimension-j manifold in $\mathbf{R} \times \mathbf{R}^k$ of period doubling points with exactly $j-2$ higher-order degeneracies. Similarly, the period-2 bifurcation sets satisfy $S_{k,\delta}^0 \supset S_{k,\delta}^1 \supset \cdots \supset S_{k,\delta}^{k-2} \supset S_{k,\delta}^{k-1}$ where $S_{k,\delta}^{j-1} \backslash S_{k,\delta}^j$ is the codimension-j manifold in $\mathbf{R} \times \mathbf{R}^k$ of period-2 saddlenodes with exactly $j-2$ higher-order degeneracies. The set $S_{k,\delta}^{k-1}$ and its projection to parameter space have the explicit parametric representations

$$S_{k,\delta}^{k-1} = \left\{ (x, [\varepsilon_1, \cdots, \varepsilon_k]) = \left(x, -\delta \left[(-1)^k \binom{k}{k} x^{2k}, \cdots, -\binom{k}{3} x^6, \binom{k}{2} x^4, -\binom{k}{1} x^2 \right] \right), x \neq 0 \right\}, \tag{2.6}$$

$$\pi_\varepsilon(S_{k,\delta}^{k-1}) = \left\{ (\varepsilon_1, \cdots, \varepsilon_k) = \left((-1)^{k+1} \frac{\delta \binom{k}{k}}{k^k} \varepsilon_k^{2k-2}, \cdots, \frac{\delta \binom{k}{3}}{k^3} \varepsilon_k^4, \frac{-\delta \binom{k}{2}}{k^2} \varepsilon_k^2, \varepsilon_k \right), \delta \varepsilon_k > 0 \right\}. \tag{2.7}$$

When $k=3$ we obtain

$$S^0_{3,\delta}=\{(x,\varepsilon_1,\varepsilon_2,\varepsilon_3)=(x,-\varepsilon_2x^2-\varepsilon_3x^4+\delta x^6,\varepsilon_2,\varepsilon_3),\ x\neq 0\},$$
$$S^1_{3,\delta}=\{(x,\varepsilon_1,\varepsilon_2,\varepsilon_3)=(x,\varepsilon_3x^4-2\delta x^6,-2\varepsilon_3x^2+3\delta x^4,\varepsilon_3),\ x\neq 0\},$$
$$S^2_{3,\delta}=\{(x,\varepsilon_1,\varepsilon_2,\varepsilon_3)=(x,\delta x^6,-3\delta x^4,3\delta x^2),\ x\neq 0\}$$

(cf. (2.6)). $\pi_\varepsilon(S^0_{3,+1})$, the set of all parameter values with period-2 orbits, is described below.

$$\pi_\varepsilon(S^1_{3,+1})=\left\{(\varepsilon_1,\varepsilon_2,\varepsilon_3)=(\varepsilon_3[W_-(\varepsilon_2,\varepsilon_3)]^2+2[W_-(\varepsilon_2,\varepsilon_3)]^3,\varepsilon_2,\varepsilon_3),\ \varepsilon_3<0,\ 0<\varepsilon_2\leqq\frac{\varepsilon_3^2}{3}\right\}$$
$$\cup\left\{(\varepsilon_1,\varepsilon_2,\varepsilon_3)=(\varepsilon_3[W_+(\varepsilon_2,\varepsilon_3)]^2+2[W_+(\varepsilon_2,\varepsilon_3)]^3,\varepsilon_2,\varepsilon_3),\ \varepsilon_3\geqq 0,\ \varepsilon_2<0 \text{ or } \varepsilon_3<0,\ \varepsilon_2\leqq\frac{\varepsilon_3^2}{3}\right\},$$

where

$$W_\pm(\varepsilon_2,\varepsilon_3):=\frac{-\varepsilon_3\pm\sqrt{\varepsilon_3^3-3\varepsilon_2}}{3};$$
$$\pi_\varepsilon(S^2_{3,+1})=\left\{(\varepsilon_1,\varepsilon_2,\varepsilon_3)=\left(\frac{\varepsilon_3^4}{27},\frac{-\varepsilon_3^2}{3},\varepsilon_3\right),\ \varepsilon_3>0\right\}$$

(cf. (2.7)).

Because the full phase × parameter space is now four-dimensional, the best pictures we can draw are either "slices" or projections of the four-dimensional space. Figure 5 shows the slice corresponding to $\varepsilon_3\equiv$ constant <0. Note the appearance of the cusp point on the curve of saddlenodes, so named for its location on the projection of the saddlenode curve to the parameter plane. Such a point appears only for $k\geqq 3$. The slice corresponding to $\varepsilon_3\equiv$ constant >0 we do not show, because it is qualitatively the same as Fig. 3.

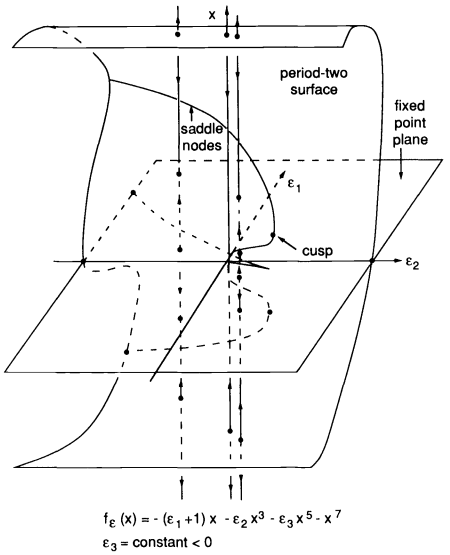

FIG. 5. *Doubly degenerate period doubling.*

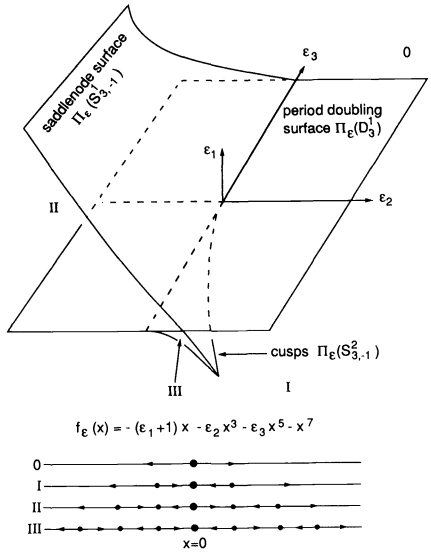

FIG. 6. *Doubly degenerate period doubling: parameter space.*

Figure 6 shows the saddlenode surfaces $\pi_\varepsilon(S^1_{3,+1})$, the cusp curve $\pi_\varepsilon(S^2_{3,+1})$ (where the two saddlenode surfaces, one defined with W_+ and the other with W_-, meet), and the period doubling plane $\pi_\varepsilon(D^1_3)$ in the three-dimensional parameter space. The set $\pi_\varepsilon(S^0_{3,+1})$ is bounded "above" in Fig. 6 by the higher of the saddlenode surfaces (inclusive) and the period doubling plane (not inclusive). Compare our Fig. 6 with Fig. 6 in [Ta]. Note that the plane $\{x=0, \varepsilon_3 = \text{const} < 0\}$ appears in both Fig. 5, as the fixed-point plane, and in Fig. 6, as the leading edge of the graph.

3. General period doubling families. In § 2 we analyzed the local topological behavior of the special families of diffeomorphisms of $\mathbf{R}: f_{\varepsilon;k,\delta}(x) = -(\varepsilon_1+1)x - \varepsilon_2 x^3 - \cdots - \varepsilon_k x^{2k-1} + \delta x^{2k+1}$. We now treat the more general case of a local family of diffeomorphisms of $\mathbf{R}^n$.

DEFINITION 3.1. Fix $k \geqq 1$. Let $\mathbf{G}(\mathbf{x}, \boldsymbol{\mu}) = \mathbf{G}_{\boldsymbol{\mu}}(\mathbf{x})$ be a representative of the germ of a C^{2k+1} function satisfying

(1) $\mathbf{G}: U \to \mathbf{R}^n$, U is a neighborhood of $(\mathbf{x}_0, \boldsymbol{\mu}_0)$ in $\mathbf{R}^n \times \mathbf{R}^m$.

(2) $\mathbf{G}(\mathbf{x}_0, \boldsymbol{\mu}_0) = \mathbf{x}_0$.

(3) $D_{\mathbf{x}}\mathbf{G}(\mathbf{x}_0, \boldsymbol{\mu}_0)$ has a single eigenvalue of -1 and no other eigenvalues on the unit circle.

(4) On its one-dimensional center manifold, the map $\mathbf{G}_{\boldsymbol{\mu}_0}$ can be transformed by a C^{2k+1} change of coordinates to a C^{2k+1} map of the form $y \to -y + cy^{2k+1} + o(y^{2k+1})$, $c \neq 0$.

Then $\mathbf{G}(\mathbf{x}, \boldsymbol{\mu})$ is a *local period doubling bifurcation family with* $k-1$ *higher-order degeneracies*, and $\mathbf{G}_{\boldsymbol{\mu}_0}$ is *a local period doubling bifurcation map with* $k-1$ *higher-order degeneracies.*

The main goal of this section is to establish Theorem 3.15, where we show that on its center manifold, every k-parameter period doubling bifurcation family with $k-1$ higher-order degeneracies is, at least generically, the "same" as one of the model families $f_{\varepsilon;k,\delta}$, where $\delta = \text{sign}(c)$. The main technical tools for Theorem 3.15 are the existence of a "$\mathbf{Z}_2$-symmetric bifurcation function" related to the original period doubling family (Theorem 3.3) and the universal unfolding theorem from $\mathbf{Z}_2$-singularity theory (Lemma 3.21). We are then able to compare $\mathbf{G}_{\boldsymbol{\mu}}$ to the appropriate model family via their respective bifurcation functions.

The Lyapunov-Schmidt reduction. Let $\mathbf{G}(\mathbf{x}, \boldsymbol{\mu})$ be a period doubling family with any number of higher-order degeneracies. For simplicity, we will assume $(\mathbf{x}_0, \boldsymbol{\mu}_0) = (\mathbf{0}, \mathbf{0})$. As with our special functions $f_{\epsilon;k,\delta}$ in (2.2), the implicit function theorem guarantees that $\mathbf{G}(\mathbf{x}, \boldsymbol{\mu})$ has a unique fixed point near $\mathbf{x} = \mathbf{0}$ for each $\boldsymbol{\mu}$ near zero. Having only one phase variable (along with the m parameters) on the center manifold implies that the only other local recurrence can be in the form of period-2 points [CMY].

The period-2 points (including the fixed point) of $\mathbf{G}$ are characterized by the roots of the function $\boldsymbol{\Phi}: \mathbf{R}^n \times \mathbf{R}^n \times \mathbf{R}^m \to \mathbf{R}^n \times \mathbf{R}^n$ defined by

$$\boldsymbol{\Phi}(\mathbf{x}, \mathbf{y}, \boldsymbol{\mu}) := \boldsymbol{\Phi}_{\boldsymbol{\mu}}(\mathbf{x}, \mathbf{y}) := (\mathbf{y} - \mathbf{G}(\mathbf{x}, \boldsymbol{\mu}), \mathbf{x} - \mathbf{G}(\mathbf{y}, \boldsymbol{\mu})). \tag{3.2}$$

The reason this function turns out to be more useful than $\mathbf{G}_{\boldsymbol{\mu}}^2(\mathbf{x}) - \mathbf{x}$ is twofold: $\boldsymbol{\Phi}$ deals only with first iterates of $\mathbf{G}_{\boldsymbol{\mu}}$, and it has an obvious symmetry that will be quite useful. Specifically, $\boldsymbol{\Phi}_{\boldsymbol{\mu}} \mathfrak{R} = \mathfrak{R} \boldsymbol{\Phi}_{\boldsymbol{\mu}}$, where $\mathfrak{R}$ is the reflection that interchanges the variables $\mathbf{x}$ and $\mathbf{y}$ in both the domain and range of $\boldsymbol{\Phi}$. That is, $\boldsymbol{\Phi}_{\boldsymbol{\mu}} \mathfrak{R}(\mathbf{x}, \mathbf{y}) = \boldsymbol{\Phi}_{\boldsymbol{\mu}}(\mathbf{y}, \mathbf{x}) = (\mathbf{x} - \mathbf{G}(\mathbf{y}, \boldsymbol{\mu}), \mathbf{y} - \mathbf{G}(\mathbf{x}, \boldsymbol{\mu})) = \mathfrak{R}(\mathbf{y} - \mathbf{G}(\mathbf{x}, \boldsymbol{\mu}), \mathbf{x} - \mathbf{G}(\mathbf{y}, \boldsymbol{\mu})) = \mathfrak{R} \boldsymbol{\Phi}_{\boldsymbol{\mu}}(\mathbf{x}, \mathbf{y})$.

We now perform the Lyapunov-Schmidt reduction [GS, § I.3] on $\boldsymbol{\Phi}$ to get the following theorem. Although the theorem is stated for C^ρ functions, we will be interested mainly in the case $\rho = \infty$.

THEOREM 3.3. *Let $\mathbf{G}(\mathbf{x}, \boldsymbol{\mu})$ be a C^ρ, $2k+1 \leqq \rho \leqq \infty$, local period doubling bifurcation family with $k-1$ higher-order degeneracies as in Definition* 3.1, *with $(\mathbf{x}_0, \boldsymbol{\mu}_0) = (\mathbf{0}, \mathbf{0})$. Define $\boldsymbol{\Phi}(\mathbf{x}, \mathbf{y}, \boldsymbol{\mu})$ by* (3.2). *Then there exists a C^ρ* bifurcation function *$b: \mathbf{R} \times \mathbf{R}^m \to \mathbf{R}$ of the form $b(s, \boldsymbol{\mu}) = sB(u, \boldsymbol{\mu})$, $u := s^2$, such that solutions of $\boldsymbol{\Phi}(\mathbf{x}, \mathbf{y}, \boldsymbol{\mu}) = \mathbf{0}$ for $(\mathbf{x}, \mathbf{y}, \boldsymbol{\mu})$ near $(\mathbf{0}, \mathbf{0}, \mathbf{0})$ are in one to one correspondence with solutions of $b(s, \boldsymbol{\mu}) = 0$ for $(s, \boldsymbol{\mu})$ near $(0, \mathbf{0})$.*

Proof. The Lyapunov-Schmidt reduction to prove Theorem 3.3 is standard [GS, § 1.3], but we include most of the computations since we will be interested in the specific bifurcation function we get via the reduction, as well as some of the intermediate functions defined in the proof.

Case 1: $x \in \mathbf{R}$. In standard coordinates, the linearization of $\boldsymbol{\Phi}_{\mathbf{0}}$ at $(0, 0)$ is $L := D_{x,y} \boldsymbol{\Phi}_0(0, 0) = \left(\begin{smallmatrix} 1 & 1 \\ 1 & 1 \end{smallmatrix}\right)$. Thus the kernel of L, $\ker L = \langle (1, -1) \rangle$, and range $L = \langle (1, 1) \rangle$. Note that $\mathbf{R}^2 = \ker L \oplus \text{range } L$ so that $E(x, y) := ((x+y)/\sqrt{2}, (x+y)/\sqrt{2})$ is the projection onto range L, and $(I - E)(x, y) := ((x-y)/\sqrt{2}, -(x-y)/\sqrt{2})$ is the projection onto $\ker L$. The equation $\boldsymbol{\Phi}(\mathbf{x}, \mathbf{y}, \boldsymbol{\mu}) = \mathbf{0}$, which we wish to solve, is equivalent to the two equations (with the $\sqrt{2}$ factor introduced for convenience):

$$\sqrt{2}\, E \boldsymbol{\Phi}(x, y, \boldsymbol{\mu}) = (0, 0), \tag{3.4a}$$

$$\sqrt{2}(I - E) \boldsymbol{\Phi}(x, y, \boldsymbol{\mu}) = (0, 0). \tag{3.4b}$$

These two equations are more conveniently expressed in coordinates with respect to the splitting $\mathbf{R}^2 = \ker L \oplus \text{range } L$. Formally, this can be defined by the change of coordinates from (x, y) with respect to the standard basis on $\mathbf{R}^2$ to (s, r) with respect to the new basis which we choose as $\{(1, -1), (1, 1)\}$. The coordinates are related by $x(1, 0) + y(0, 1) = s(1, -1) + r(1, 1)$, or $x = s + r$ and $y = r - s$. Since the s component of the new coordinate version of (3.4a) is automatically satisfied by definition of E, as is the r component of the new coordinate version of (3.4b), the two vector equations in (3.4) are equivalent to the two scalar equations

$$Q(s, r, \boldsymbol{\mu}) := \tfrac{1}{2}\{2r - G(s + r, \boldsymbol{\mu}) - G(-s + r, \boldsymbol{\mu})\} = 0, \tag{3.5a}$$

$$\tfrac{1}{2}\{-2s - G(s + r, \boldsymbol{\mu}) + G(-s + r, \boldsymbol{\mu})\} = 0. \tag{3.5b}$$

Equation (3.5a) is the r component of (3.4a); equation (3.5b) is the s component of (3.4b).

Since $Q(0,0,\mathbf{0})=0$ and $(\partial Q/\partial r)(0,0,\mathbf{0})=2\neq 0$, then the implicit function theorem implies that there exists a unique C^ρ function $R(s,\boldsymbol{\mu})$ satisfying $R(0,\mathbf{0})=0$ and $Q(s,R(s,\boldsymbol{\mu}),\boldsymbol{\mu})=0$ for $(s,\boldsymbol{\mu})$ near $(0,\mathbf{0})$. Plugging this new function $R(s,\boldsymbol{\mu})$ into the left-hand side of (3.5b), we get our reduced bifurcation function $b(s,\boldsymbol{\mu})$:

$$\begin{aligned} b(s,\boldsymbol{\mu}) &:= \tfrac{1}{2}\{-2s-G(s+R(s,\boldsymbol{\mu}),\boldsymbol{\mu})+G(-s+R(s,\boldsymbol{\mu}),\boldsymbol{\mu})\} \\ &= -G(s+R(s,\boldsymbol{\mu}),\boldsymbol{\mu})+(-s+R(s,\boldsymbol{\mu})). \end{aligned} \tag{3.6}$$

The latter form is obtained by substituting $Q(s,R(s,\boldsymbol{\mu}),\boldsymbol{\mu})=0$ from (3.5a) into the first line of (3.6).

It can be verified directly that $R(-s,\boldsymbol{\mu})=R(s,\boldsymbol{\mu})$, and therefore that $b(-s,\boldsymbol{\mu})=-b(s,\boldsymbol{\mu})$, but this is really a consequence of the equivariance of the original function $\boldsymbol{\Phi}$ with respect to the reflection $\mathfrak{R}$. This is because $b(s,\boldsymbol{\mu})$ is really the coordinate representation of a map from $\ker\boldsymbol{\Phi}\times\mathbf{R}^k$ to $\ker\boldsymbol{\Phi}$, and $\mathfrak{R}$ acts on $\ker\boldsymbol{\Phi}$ by $\mathfrak{R}(s(1,-1))=\mathfrak{R}(s,-s)=(-s,s)=-s(1,-1)$.

That $b(s,\boldsymbol{\mu})$ has the form $sB(s^2,\boldsymbol{\mu})$ is immediate from the odd symmetry of $b(s,\boldsymbol{\mu})$. The one-to-one correspondence between solutions of $b(s,\boldsymbol{\mu})=0$ and $\boldsymbol{\Phi}(x,y,\boldsymbol{\mu})=0$ is

$$(s,\boldsymbol{\mu})\leftrightarrow(s+R(s,\boldsymbol{\mu}),-s+R(s,\boldsymbol{\mu}),\boldsymbol{\mu}). \tag{3.7}$$

Note that if $s\neq 0$, solutions s and $-s$ correspond to the same period-2 orbit, but these are distinct solutions for $\boldsymbol{\Phi}:\boldsymbol{\Phi}(x,y,\boldsymbol{\mu})=0$ and $\boldsymbol{\Phi}(y,x,\boldsymbol{\mu})=0$. This completes the proof for $x\in\mathbf{R}$.

Case 2: $\mathbf{x}\in\mathbf{R}^n$, $n>1$, and the coordinates $\mathbf{x}=(x_1,\cdots,x_n)$ have been chosen with respect to the basis $\{\mathbf{e}_i\}_{i=1}^n$ so that matrix of $D_{\mathbf{x}}\mathbf{G}(\mathbf{0},\mathbf{0})$ has the block form $\hat{B}=\left(\begin{smallmatrix}-1 & 0\\ 0 & B\end{smallmatrix}\right)$, where B is an $(n-1)\times(n-1)$ matrix. The $2n\times 2n$ matrix of the linearization of $L=D_{\mathbf{x},\mathbf{y}}\boldsymbol{\Phi}_{\mathbf{0}}(\mathbf{0},\mathbf{0})$ with respect to the induced basis $\{\mathbf{f}_1,\cdots,\mathbf{f}_{2n}\}=\{(\mathbf{e}_1,\mathbf{0}),\cdots,(\mathbf{e}_n,\mathbf{0}),(\mathbf{0},\mathbf{e}_1),\cdots,(\mathbf{0},\mathbf{e}_n)\}$ becomes $L=\left(\begin{smallmatrix}-\hat{B} & I\\ I & -B\end{smallmatrix}\right)$. The first and $(n+1)$st rows of L are identical, but using the fact that no other eigenvalues are on the unit circle, it can be shown that the remaining rows are independent. (This would be easier to see if $\{\mathbf{e}_i\}$ were a basis putting $\hat{B}$ into Jordan canonical form.) So we still have the dimension of $\ker L=1$. In fact, $\ker L=\langle\mathbf{f}_1-\mathbf{f}_{n+1}\rangle$ and range $L=\langle\mathbf{f}_1+\mathbf{f}_{n+1},\mathbf{f}_2,\cdots,\mathbf{f}_n,\mathbf{f}_{n+2},\cdots,\mathbf{f}_{2n}\rangle$. We also still have $\mathbf{R}^{2n}=\ker L\oplus\text{range } L$. The coordinates with respect to this splitting are s on $\ker L$, and $(r,x_2,\cdots,x_n,y_2,\cdots,y_n)$ on range L, where $x_1=s+r$ and $y_1=r-s$, and $\mathbf{x}=(x_1,\cdots,x_n)$ and $\mathbf{y}=(y_1,\cdots,y_n)$ are in coordinates with respect to $\{e_i\}_{i=1}^n$. Solving $\sqrt{2}\mathbf{E}\boldsymbol{\Phi}(\mathbf{x},\mathbf{y},\boldsymbol{\mu})=0$ in the new coordinates is equivalent to $\mathbf{Q}=\mathbf{0}$, where

$$\begin{aligned} &\mathbf{Q}(s,r,x_2,\cdots,x_n,y_2,\cdots,y_n,\boldsymbol{\mu}) \\ &\quad := (\tfrac{1}{2}(2r-G_1(s+r,x_2,\cdots,x_n,\boldsymbol{\mu})-G_1(-s+r,y_2,\cdots,y_n,\boldsymbol{\mu})), \\ &\qquad y_2-G_2(s+r,x_2,\cdots,x_n,\boldsymbol{\mu}),\cdots,y_n-G_n(s+r,x_2,\cdots,x_n,\boldsymbol{\mu}), \\ &\qquad x_2-G_2(-s+r,y_2,\cdots,y_n,\boldsymbol{\mu}),\cdots,x_n-G_n(-s+r,y_2,\cdots,y_n,\boldsymbol{\mu}))=\mathbf{0}. \end{aligned} \tag{3.8}$$

This equation can be solved uniquely by the implicit function theorem for C^ρ functions $r,x_2,\cdots,x_n,y_2,\cdots,y_n$, all in terms of s and $\boldsymbol{\mu}$ in a neighborhood of $(s,\boldsymbol{\mu})=(0,\mathbf{0})$. We shall call these solutions $R(s,\boldsymbol{\mu})$, $X_j(s,\boldsymbol{\mu})$, and $Y_j(s,\boldsymbol{\mu})$. That is,

$$\mathbf{Q}(s,\mathbf{W}(s,\boldsymbol{\mu}),\boldsymbol{\mu})=\mathbf{0}, \tag{3.9}$$

where $\mathbf{W}(s,\boldsymbol{\mu}):=(R(s,\boldsymbol{\mu}),X_2(s,\boldsymbol{\mu}),\cdots,X_n(s,\boldsymbol{\mu}),Y_2(s,\boldsymbol{\mu}),\cdots,Y_n(s,\boldsymbol{\mu}))$. Differentiation of (3.9) with respect to s and using the block form of $D_{\mathbf{x}}\mathbf{G}(\mathbf{0},\mathbf{0})$ yields

$$\frac{\partial\mathbf{W}}{\partial s}=\mathbf{0}. \tag{3.10}$$

As for any Lyapunov-Schmidt reduction involving a symmetry, the symmetry $\mathfrak{R}$ is inherited as $\mathbf{W}\mathfrak{R}(s,\boldsymbol{\mu}) = \mathfrak{R}\mathbf{W}(s,\boldsymbol{\mu})$, interpreted as

$$(R(-s,\boldsymbol{\mu}), X_2(-s,\boldsymbol{\mu}), \cdots, X_n(-s,\boldsymbol{\mu}), Y_2(-s,\boldsymbol{\mu}), \cdots, Y_n(-s,\boldsymbol{\mu}))$$
$$= (R(s,\boldsymbol{\mu}), Y_2(s,\boldsymbol{\mu}), \cdots, Y_n(s,\boldsymbol{\mu}), X_2(s,\boldsymbol{\mu}), \cdots, X_n(s,\boldsymbol{\mu})).$$

Thus $Y_j(s,\boldsymbol{\mu}) = X_j(-s,\boldsymbol{\mu}), j = 2, \cdots, n$, and $R(s,\boldsymbol{\mu}) = R(-s,\boldsymbol{\mu})$. The bifurcation function, analogous to (3.6), is

$$\begin{aligned} b(s,\boldsymbol{\mu}) = \tfrac{1}{2}\{&-2s - G_1(s + R(s,\boldsymbol{\mu}), X_2(s,\boldsymbol{\mu}), \cdots, X_n(s,\boldsymbol{\mu}), \boldsymbol{\mu}) \\ &+ G_1(-s + R(s,\boldsymbol{\mu}), X_2(-s,\boldsymbol{\mu}), \cdots, X_n(-s,\boldsymbol{\mu}), \boldsymbol{\mu})\}, \end{aligned} \tag{3.11}$$

where $\mathbf{G} = (G_1, \cdots, G_n)$. It is clear from the first line, since $R(s,\boldsymbol{\mu}) = R(-s,\boldsymbol{\mu})$, that we still have our $\mathbf{Z}_2$-symmetric bifurcation function: $b(-s,\boldsymbol{\mu}) = -b(s,\boldsymbol{\mu})$. So $b(s,\boldsymbol{\mu})$ is still of the form $sB(s^2,\boldsymbol{\mu})$. The one-to-one correspondence between roots of $b(s,\boldsymbol{\mu})$ and $\boldsymbol{\Phi}(\mathbf{x},\mathbf{y},\boldsymbol{\mu})$, analogous to (3.7), is given by $(s,\boldsymbol{\mu}) \leftrightarrow (\mathbf{X}(s,\boldsymbol{\mu}), \mathbf{Y}(s,\boldsymbol{\mu}), \boldsymbol{\mu})$, where

$$\begin{aligned} &\mathbf{X}(s,\boldsymbol{\mu}) := (s + R(s,\boldsymbol{\mu}), X_2(s,\boldsymbol{\mu}), \cdots, X_n(s,\boldsymbol{\mu})), \\ &\mathbf{Y}(s,\boldsymbol{\mu}) := \mathbf{X}(-s,\boldsymbol{\mu}) = (-s + R(s,\boldsymbol{\mu}), X_2(-s,\boldsymbol{\mu}), \cdots, X_n(-s,\boldsymbol{\mu})). \end{aligned} \tag{3.12}$$

Thus the theorem is true for $\mathbf{x} \in \mathbf{R}^n$, with the assumed coordinate system.

Case 3: $\mathbf{x} \in \mathbf{R}^n$, $n > 1$. Change this general case into the special coordinate form of Case 2 by a linear change of variable. Then follow the procedure outlined in that case. □

We now prove two corollaries that give some insight into the mechanics of the Lyapunov-Schmidt reduction of Theorem 3.3.

COROLLARY 3.13. *For our model families* $f_{\boldsymbol{\varepsilon};k,\delta}(x) = -(\varepsilon_1 + 1)x - \varepsilon_2 x^3 - \cdots - \varepsilon_k x^{2k-1} + \delta x^{2k+1}$, *the bifurcation function* $b_f(s,\boldsymbol{\varepsilon}) = sB_f(s^2,\boldsymbol{\varepsilon}) = -f_\varepsilon(s) - s$. *Also,* $B_f(u,\boldsymbol{\varepsilon}) = P_{\boldsymbol{\varepsilon};k,\delta}(u)$, *where* $P_{\boldsymbol{\varepsilon};k,\delta}(u)$ *is as defined in* (2.3).

Proof. Because our model families $f_{\boldsymbol{\varepsilon};k,\delta}$ are odd, it is apparent from (3.5a) by letting $G(x,\boldsymbol{\varepsilon}) = f_{\boldsymbol{\varepsilon};k,\delta}(x)$ for any fixed values of k and δ that $Q(s,0,\boldsymbol{\varepsilon}) = 0$, so $R(s,\boldsymbol{\varepsilon}) = 0$ must be the unique solution to $Q(s,R(s,\boldsymbol{\varepsilon}),\boldsymbol{\varepsilon}) = 0$. Thus, from (3.6), $b(s,\boldsymbol{\varepsilon}) = sB_f(s^2,\boldsymbol{\varepsilon})$ becomes $-s - f_\varepsilon(s)$. But $= -s - f_\varepsilon(s) = \varepsilon_1 s + \varepsilon_2 s^3 + \cdots + \varepsilon_k s^{2k-1} - \delta s^{2k+1} = sP_{\boldsymbol{\varepsilon};k,\delta}(s^2)$. So $B_f(u,\boldsymbol{\varepsilon}) = P_{\boldsymbol{\varepsilon};k,\delta}(u)$. □

So the seemingly ad hoc method we used in § 2 to analyze our model families turns out to be merely a special case of the more general Lyapunov-Schmidt reduction.

COROLLARY 3.14. *Let* $\mathbf{G}(\mathbf{x},\boldsymbol{\mu})$ *be a local period doubling family with* $k-1$ *higher-order degeneracies at* $(\mathbf{x},\boldsymbol{\mu}) = (\mathbf{0},\mathbf{0}) \in \mathbf{R}^n \times \mathbf{R}^m$. *If* $\{(\mathbf{x},\boldsymbol{\mu}): x_2 = \cdots = x_n = 0\}$ *is the center manifold (instead of just the center eigenspace) of* $\mathbf{G}(\mathbf{x},\boldsymbol{\mu})$, *then*

(A) *the functions* $X_j(s,\boldsymbol{\mu})$ *and* $Y_j(s,\boldsymbol{\mu})$, *defined in* (3.12), *are zero for* $j = 2, 3, \cdots, n$,

(B) *the bifurcation function of* $[\mathbf{G}]$ = *the bifurcation function of* [$\mathbf{G}$ *restricted to its* $1+m$ *dimensional center manifold*].

Proof. (A). We can show there exists a solution to (3.8) with $x_j = y_j = 0$, $j = 2, \cdots, n$. By uniqueness of solutions, the functions $X_j(s,\boldsymbol{\mu})$ and $Y_j(s,\boldsymbol{\mu})$ *must* be zero for $j \geqq 2$.

(B) This follows from (A) by directly computing the two bifurcation functions using (3.8) and (3.11). □

Corollaries 3.13 and 3.14 suggest that using the Lyapunov-Schmidt reduction to obtain the bifurcation function $b_{\mathbf{G}}(s,\boldsymbol{\mu})$ should be compared to the more topological alternative of obtaining a bifurcation function $-\tilde{f}_{\boldsymbol{\mu}}(s) - s$ from $\mathbf{G}(\mathbf{x},\boldsymbol{\mu})$ by the following steps:

(1) Restrict $\mathbf{G}(\mathbf{x}, \boldsymbol{\mu})$ to its $1+m$ dimensional center mainfold: $f(x_1, \boldsymbol{\mu}) := f_{\boldsymbol{\mu}}(x_1) := G_1((x_1, \mathbf{H}(x_1, \boldsymbol{\mu})), \boldsymbol{\mu})$, where the center manifold is the graph of $\mathbf{H}: \mathbf{R} \times \mathbf{R}^m \to \mathbf{R}^{n-1}$.

(2) Put the resulting function into its normal form $\tilde{f}(s, \boldsymbol{\mu}) := \tilde{f}_{\boldsymbol{\mu}}(s) := h_{\boldsymbol{\mu}} \circ f_{\boldsymbol{\mu}} \circ h_{\boldsymbol{\mu}}^{-1}(s)$, where $h(x_1, \boldsymbol{\mu}) := h_{\boldsymbol{\mu}}(x_1)$ are the coordinate changes to put $f_{\boldsymbol{\mu}}$ into its normal form $\tilde{f}_{\boldsymbol{\mu}}$.

(3) Use the resulting odd symmetry to replace the bifurcation function $\tilde{f}_{\boldsymbol{\mu}}^2(s) - s$ with the simpler function $-\tilde{f}_{\boldsymbol{\mu}}(s) - s$.

Besides being a single step, the Lyapunov-Schmidt reduction has another major advantage over the center manifold/normal forms technique. Although the normal forms theorem guarantees a polynomial change of coordinates to put $f_{\boldsymbol{\mu}}(x_1)$ into its normal form up to any finite order, the existence of a coordinate change to eliminate *all* even-order terms in x_1 is not guaranteed. Thus step (2) above may not even be possible. On the other hand, if we put the function $f_{\boldsymbol{\mu}}(x_1)$ into its normal form only up to some finite order, step (3) would not be possible because the resulting function would be odd only up to that finite order. Note also that the original function $\mathbf{G}(\mathbf{x}, \boldsymbol{\mu})$ being C^∞ does not imply that its center manifold realization is C^∞. The Lyapunov-Schmidt bifurcation function $b_{\mathbf{G}}(s, \boldsymbol{\mu})$, however, is C^∞.

Universality of the model families. We now use Theorem 3.3 and some standard results from singularity theory to show that the model unfoldings we considered in Chapter 2 are "universal unfoldings." More specifically, we prove that, when restricted to a center manifold, any map in a local period doubling family is topologically equivalent to one of the model family maps. If certain nondegeneracy conditions are satisfied, the whole family of center manifold maps will be "equivalent" to one of the model families. Our notion of equivalence is embodied in the statement of the theorem.

We use the following notation. Let $\mathbf{G}(\mathbf{x}, \boldsymbol{\mu})$ be any C^∞ period doubling family with $k-1$ higher-order degeneracies at $(\mathbf{0}, \mathbf{0})$. Let $b_{\mathbf{G}}(s, \boldsymbol{\mu}) = sB_{\mathbf{G}}(s^2, \boldsymbol{\mu})$ be a bifurcation function obtained from $\mathbf{G}$ as in Theorem 3.3. Assume x_1 is a coordinate along the eigenspace corresponding to the -1 eigenvalue for the fixed point $\mathbf{x} = \mathbf{0}$ for $\boldsymbol{\mu} = \mathbf{0}$. Let $g_{\boldsymbol{\mu}}(x_1) := g(x_1, \boldsymbol{\mu})$ be the realization of $\mathbf{G}(\mathbf{x}, \boldsymbol{\mu})$ on its $1+m$ dimensional center manifold. By Definition 3.1, the center manifold map in normal form up to order $2k+1$ for $\boldsymbol{\mu} = \mathbf{0}$ is $y \to -y + cy^{2k+1} + o(y^{2k+1})$. Let $f_{\boldsymbol{\varepsilon}}(z) := f_{\boldsymbol{\varepsilon};k,\delta}(z)$ be the model family $-(\varepsilon_1 + 1)z - \varepsilon_2 z^3 - \cdots - \varepsilon_k z^{2k-1} + \delta z^{2k+1}$, where $\delta = -\operatorname{sgn}(c)$. Recall the definitions of the bifurcation sets D_k^i and $S_{k,\delta}^i$ in (2.4) and (2.5) for the model families $f_{\boldsymbol{\varepsilon};k,\delta}$. We now analogously define the bifurcation sets for $\mathbf{G}$.

$D_g^0 = \{(x_1, \boldsymbol{\mu}) \in \mathbf{R} \times \mathbf{R}^m : x_1$ is a fixed point for $g_{\boldsymbol{\mu}}\}$,

$D_g^i = \{(x_1, \boldsymbol{\mu}) \in \mathbf{R} \times \mathbf{R}^m : x_1$ is a fixed point for $g_{\boldsymbol{\mu}}$ with eigenvalue -1 and at least $i-1$ higher-order degeneracies$\}$ for $i \geqq 1$,

$S_g^0 = \{(x_1, \boldsymbol{\mu}) \in \mathbf{R} \times \mathbf{R}^m : x_1$ is a period-2 point for $g_{\boldsymbol{\mu}}\}$,

$S_g^i = \{(x_1, \boldsymbol{\mu}) \in \mathbf{R} \times \mathbf{R}^m : x_1$ is a period-2 point for $g_{\boldsymbol{\mu}}$ with eigenvalue 1 and at least $i-1$ higher-order degeneracies$\}$ for $i \geqq 1$.

THEOREM 3.15. *Let $\mathbf{G}(\mathbf{x}, \boldsymbol{\mu})$ be a C^∞ period doubling family with $k-1$ higher-order degeneracies. Define its center manifold representation $g_{\boldsymbol{\mu}}(x_1)$ and the model family $f_{\boldsymbol{\varepsilon}}(z)$ as in the above paragraph. Assume the "eigenvalue crossing condition:" $\nabla_{\boldsymbol{\mu}} \lambda(\boldsymbol{\mu}) \neq \mathbf{0}$, where $\lambda(\boldsymbol{\mu})$ is the eigenvalue of the unique fixed point of $g_{\boldsymbol{\mu}}$. Then*

(a) *There exists a neighborhood N of $(0, \mathbf{0})$ in $\mathbf{R} \times \mathbf{R}^m$ and a C^∞ function $\boldsymbol{\Psi}: N \to \{\mathbf{R} \times \mathbf{R}^k\} : (x_1, \boldsymbol{\mu}) \to (z, \boldsymbol{\varepsilon})$ of the form $\boldsymbol{\Psi}(x_1, \boldsymbol{\mu}) = (Z_{\boldsymbol{\mu}}(x_1), \psi(\boldsymbol{\mu}))$ with the following properties:*

(1) $\boldsymbol{\Psi}: (0, \mathbf{0}) \to (0, \mathbf{0})$.

(2) *For each fixed parameter value $\boldsymbol{\mu}$, $g_{\boldsymbol{\mu}}(x_1)$ restricted to the neighborhood N and $f_{\psi(\boldsymbol{\mu})}(z)$ restricted to $\boldsymbol{\Psi}(N)$ are topologically conjugate to each other.*

(3) Ψ *maps fixed points, period-2 points, and bifurcation manifolds of g to fixed points, period-2 points, and corresponding bifurcation manifolds of f, respectively.* (*That is,* $\Psi: D_g^i \to D_k^i$ *for* $i=0,\cdots,k$, *and* $S_g^i \to S_{k,\delta}^i$ *for* $i=0,\cdots,k-1$.)

(b) *Let k and* δ *be fixed. Any family that can replace* $f_{\varepsilon:k,\delta}$ *in Theorem* 3.15(a) *must have at least k parameters.* (*This justifies calling the period doubling bifurcation with* $k-1$ *higher-order degeneracies a codimension-k bifurcation.*)

(c) *If* $\mu \in \mathbf{R}^k$ *and*

$$\left\{ \nabla_\mu \left(\frac{\partial^i B_G(u,\mu)}{\partial u^i} \right) \Big|_{(0,0)}, \qquad i=0,\cdots,k-1 \right\}$$

is independent, then ψ *and* Ψ *are* C^∞ *diffeomorphisms.*

Before beginning the proof of this theorem, we make the following comments:

(1) Recall that in the proof of Theorem 3.3, $b_G(s,\mu)$ and therefore $B_G(s,\mu)$ were defined using the implicit function theorem. Although this means the bifurcation functions and their derivatives are not usually computable, their values at $(s,\mu)=(0,\mathbf{0})$ are computable. (See, for example, Lemma 3.16.) Consequently, the nondegeneracy conditions in part (c) of the theorem *are* computable.

(2) The nondegeneracy conditions in part (c) will generically be true. Thus, for a generic k-parameter family of maps, Ψ will be a diffeomorphism. Since the C^∞ diffeomorphism Ψ preserves the bifurcation sets, and the bifurcation sets for the models are analytic, this is what guarantees that the bifurcation manifolds will all be C^∞ and that the pictures obtained from applications (see § 4) all "look like" the bifurcation pictures obtained from the model families in § 2. In particular, the orders of tangency of corresponding bifurcation manifolds will be the same as in the model families. In the codimension-2 case, with only one higher-order degeneracy, the projection to the parameter space of the bifurcation manifolds will always (generically) show a curve of saddlenodes for the second iterate of the map being tangent to a period doubling curve where it terminates. (Look ahead to Figs. 7–9 in comparison to the model family bifurcation diagrams in Figs. 3 and 4.)

(3) Note that the center eigenspace coordinate x_1 can be replaced by any phase space coordinate not perpendicular to x_1 by a one-dimensional linear change of coordinates independent of the parameter. Consequently, any generic phase variable coordinate can be used in place of a center eigenspace coordinate x_1 in drawing the bifurcation sets. This is exactly what was done to obtain Figs. 7–9.

(4) This is a technical comment comparing our notion of "equivalence" implied by the existence in the theorem of the function Ψ to the oft-used notion of "topological conjugacy." Recall that $g(x_1,\mu)$ and $f(z,\varepsilon)$ are (locally) topologically conjugate families if there exists a local homeomorphism $\Phi(x_1,\mu)=(h_\mu(x_1),\phi(\mu))$ such that $g_\mu = h_\mu^{-1} \circ f_{\psi(\mu)} \circ h_\mu$. If the individual topological conjugacies $h_\mu(x_1)$ do not necessarily vary continuously with respect to the parameter μ, then the families are said to be "mildly topologically conjugate" [NPT]. Because Theorem 3.15 guarantees that $g_\mu(x_1)$ and $f_{\psi(\mu)}(z)$ will be topologically conjugate to each other for each fixed value of μ, our equivalence implies the two families $g(x_1,\mu)$ and $f(z,\varepsilon)$ are at least mildly topologically conjugate (by letting $\phi=\psi$) as long as the parameter space map $\psi(\mu)$ is a homeomorphism.

We point out that although the conjugacies $h_\mu(x_1)$ and the functions $Z_\mu(x_1)$ of the theorem are not the same, they are related. Specifically, they will agree on all the bifurcation sets D_g^i and S_g^i. This includes the fixed and period-2 sets. Thus, when restricted to the bifurcation sets, $h_\mu(x_1)$ will not only vary continuously with respect to the parameter μ, but will also be C^∞.

Consequently, when the parameter space map $\psi(\mu)$ is a diffeomorphism, the existence of the function Ψ of Theorem 3.15 is a stronger property than mild topological conjugacy but not comparable to topological conjugacy. Topological conjugacies have the stronger property that the individual conjugacies $h_\mu(x_1)$ should vary continuously with the parameter; our equivalence has the stronger property that the function Ψ is a (C^∞) diffeomorphism, and consequently that the individual conjugacies $h_\mu(x_1)$ *restricted to the bifurcation surfaces* are also diffeomorphisms.

The rest of this section is devoted to the proof of Theorem 3.15. We begin with the following lemmas.

LEMMA 3.16. *If* $x \in \mathbf{R}$ *and* $c \neq 0$, *then* $G(x, \mathbf{0}) = -x + cx^{2k+1} + o(x^{2k+1})$ *implies* $b_G(s, \mathbf{0}) = -cs^{2k+1} + o(x^{2k+1})$.

Proof. We differentiate the definition of $b_G(s, \mu)$ in (3.6), using the derivatives of $R(s, \mu)$ at $(0, \mathbf{0})$, which we obtain from (3.5a) by repeated implicit differentiation. Since R is even in s, we immediately know that $(\partial^j R/\partial s^j)(0, \mathbf{0}) = 0$ for odd j. We also know from the proof of Theorem 3.3 that $R(0, \mathbf{0}) = 0$. It is relatively straightforward to show that the implicit differentiation yields

$$\frac{\partial^2 \mathrm{R}}{\partial \mathrm{s}^2}(0, \mathbf{0}) = \frac{1}{2}\frac{\partial^2 G}{\partial x^2}(0, \mathbf{0}),$$

$$\frac{\partial^4 R}{\partial s^4}(0, \mathbf{0}) = \frac{1}{2}\frac{\partial^4 G}{\partial x^4}(0, \mathbf{0}) + \frac{3}{4}\frac{\partial^2 G}{\partial x^2}(0, \mathbf{0})\left\{2\frac{\partial^3 G}{\partial x^3}(0, \mathbf{0}) + \frac{1}{2}\left[\frac{\partial^2 G}{\partial x^2}(0, \mathbf{0})\right]^2\right\}.$$

In general,

$$\frac{\partial^k R}{\partial s^k}(0, \mathbf{0}) = \frac{1}{2}\frac{\partial^k G}{\partial x^k}(0, \mathbf{0}) + \cdots,$$

where the omitted terms all have factors of $(\partial^j G/\partial x^j)(0, \mathbf{0})$ with $2 \leqq j \leqq k-1$.

Using these derivatives, and the fact that $b_G(s, \mu)$ is odd in r (so that all even derivatives of b_G with respect to r vanish), we obtain

$$\frac{\partial b_G}{\partial r}(0, \mathbf{0}) = 0,$$

$$\frac{\partial^3 b_G}{\partial r^3}(0, \mathbf{0}) = -\frac{\partial^3 G}{\partial x^3}(0, \mathbf{0}) - \frac{3}{2}\left\{\frac{\partial^2 G}{\partial x^2}(0, \mathbf{0})\right\}^2, \tag{3.17}$$

$$\begin{aligned}\frac{\partial^5 b_G}{\partial r^5}(0, \mathbf{0}) = &-\frac{\partial^5 G}{\partial x^5}(0, \mathbf{0}) - 5\frac{\partial^4 G}{\partial x^4}(0, \mathbf{0})\frac{\partial^2 G}{\partial x^2}(0, \mathbf{0}) - \frac{15}{4}\frac{\partial^3 G}{\partial x^3}(0, \mathbf{0})\left(\frac{\partial^2 G}{\partial x^2}(0, \mathbf{0})\right)^2 \\ &-5\left[\frac{1}{2}\frac{\partial^4 G}{\partial x^4}(0, \mathbf{0}) + \frac{3}{4}\frac{\partial^2 G}{\partial x^2}(0, \mathbf{0})\left\{2\frac{\partial^3 G}{\partial x^3}(0, \mathbf{0}) + \frac{1}{2}\left(\frac{\partial^2 G}{\partial x^2}(0, \mathbf{0})\right)^2\right\}\right].\end{aligned} \tag{3.18}$$

The expressions for the seventh-order derivative are not pretty. In general, however, we have the relation

$$\frac{\partial^k b_G}{\partial r^k}(0, \mathbf{0}) = -\frac{\partial^k G}{\partial x^k}(0, \mathbf{0}) + \cdots,$$

where the omitted terms all have factors of $(\partial^j G/\partial x^j)(0, \mathbf{0})$ with $2 \leqq j \leqq k-1$.

The lemma follows immediately. □

Note. The sign of (3.17) determines the criticality of the nondegenerate period doubling bifurcation. If it is negative, the bifurcation is supercritical; if it is positive, the bifurcation is subcritical; if it equals zero, there is at least one higher-order

degeneracy. If both (3.17) and (3.18) are zero, there are at least two higher-order degeneracies.

LEMMA 3.19. *Let the C^∞ period doubling family $\mathbf{G}(\mathbf{x}, \boldsymbol{\mu})$, its center manifold realization $g_{\boldsymbol{\mu}}(x_1)$, and the bifurcation function $b_{\mathbf{G}}(s, \boldsymbol{\mu})$ be as in the paragraph preceding Theorem 3.15. Then there exists a neighborhood N of $(0, \mathbf{0})$ in $\mathbf{R}\times\mathbf{R}^m$ such that for $(s, \boldsymbol{\mu}) \in N$, $g^2_{\boldsymbol{\mu}}(x_1) - x_1$ has the same sign as $b_{\mathbf{G}}(s, \boldsymbol{\mu})$, where $(s, \boldsymbol{\mu})$ and $(x_1, \boldsymbol{\mu})$ are related by the C^∞ diffeomorphism $(x_1, \boldsymbol{\mu}) = (s + R(s, \boldsymbol{\mu}), \boldsymbol{\mu})$ (as in (3.12)).*

Furthermore, for each fixed $\boldsymbol{\mu}$, the multiplicity of the corresponding zeros of $g^2_{\boldsymbol{\mu}}(x_1) - x_1$ and $b_{\mathbf{G}}(s, \boldsymbol{\mu})$ is the same.

Proof. Theorem 3.3 guarantees that roots of $G^2_{\boldsymbol{\mu}}(\mathbf{x}) - \mathbf{x}$ are in one-to-one correspondence with roots of $b_{\mathbf{G}}(s, \boldsymbol{\mu})$. Since roots of $G^2_{\boldsymbol{\mu}}(\mathbf{x}) - \mathbf{x}$ must be on the center manifold of $\mathbf{G}(\mathbf{x}, \boldsymbol{\mu})$, the roots of $g^2_{\boldsymbol{\mu}}(x_1) - x_1$ must also be in one-to-one correspondence with roots of $\mathbf{G}^2_{\boldsymbol{\mu}}(\mathbf{x}) - \mathbf{x}$, and therefore with roots of $b_{\mathbf{G}}(s, \boldsymbol{\mu})$. The correspondence is indicated by (3.12) in the proof of Theorem 3.3:

$$(3.20)\quad s \leftrightarrow \mathbf{x} = \mathbf{X}(s, \boldsymbol{\mu}) = (s + R(s, \boldsymbol{\mu}), X_2(s, \boldsymbol{\mu}), \cdots, X_n(s, \boldsymbol{\mu})) \leftrightarrow x_1 = s + R(s, \boldsymbol{\mu}).$$

For each fixed $\boldsymbol{\mu}$, the multiplicities of corresponding roots of $g^2_{\boldsymbol{\mu}}(x_1) - x_1$ and $b_{\mathbf{G}}(s, \boldsymbol{\mu})$ must be the same, because if they are not, then a perturbation of $\mathbf{G}$ could be made so that their roots would not correspond. (It can be shown that an arbitrarily C^∞ small perturbation of $\mathbf{G}(\mathbf{x}, \boldsymbol{\mu})$ can be chosen to perturb $g^2_{\boldsymbol{\mu}}(x_1) - x_1$ or $b_{\mathbf{G}}(s, \boldsymbol{\mu})$ from a zero of multiplicity ρ to a function with ρ distinct real roots.)

We have left only to show that the signs of the two functions are equal. Since for fixed $\boldsymbol{\mu}$ we already have the zeros and their multiplicities corresponding for $g^2_{\boldsymbol{\mu}}(x_1) - x_1$ and $b_{\mathbf{G}}(s, \boldsymbol{\mu})$, and since these two functions are perturbations of $g^2_{\mathbf{0}}(x_1) - x_1$ and $b_{\mathbf{G}}(s, \mathbf{0})$, respectively, the signs will be the same for $g^2_{\boldsymbol{\mu}}(x_1) - x_1$ and $b_{\mathbf{G}}(s, \boldsymbol{\mu})$ if and only if the signs of the leading coefficients of $g^2_{\mathbf{0}}(x_1) - x_1$ and $b_{\mathbf{G}}(s, \mathbf{0})$ are the same.

According to Definition 3.1, if $x \in \mathbf{R}$ then in normal form up to order $2k+1$, $G(x, \mathbf{0}) = -x + cx^{2k+1} + o(x^{2k+1})$, $c \neq 0$. This makes $G^2_{\mathbf{0}}(x) - x = g^2_{\mathbf{0}}(x) - x = -2cx^{2k+1} + o(x^{2k+1})$. Lemma 3.16 implies $b_G(s, \mathbf{0}) = -cs^{2k+1} + o(s^{2k+1})$. If $\boldsymbol{\mu} = \mathbf{0}$, then $s = 0$ corresponds to $x = x_1 = 0 + R(0, \mathbf{0}) = 0$, so the signs of the leading coefficients of $g^2_{\mathbf{0}}(x) - x$ and $b_G(s, \mathbf{0})$ correspond. If $x \in \mathbf{R}$ but $G(x, \mathbf{0}) = g(x, \mathbf{0})$ is not in normal form up to order $2k+1$, a near identity polynomial change of coordinates $x = h(y)$ can put $g_{\boldsymbol{\mu}}(x)$ into this normal form. That is, $\tilde{g}_{\mathbf{0}}(y) := h^{-1}(g_{\mathbf{0}}(h(y)))$ is in normal form up to order $2k+1$. By perturbation arguments as in the second paragraph of this proof, the multiplicity of the zeros of $\tilde{g}^2_{\mathbf{0}}(y) - y$, $g^2_{\mathbf{0}}(x) - x$, $b_g(s, \mathbf{0})$, and $b_{\tilde{g}}(\tilde{s}, \mathbf{0})$ must all be the same. The same logic works along a whole path of coordinate changes from h_t, $t \in [0, 1]$, from the $h_0 :=$ identity to $h_1 := h$. Therefore, by continuity, the sign of the leading coefficient of $\tilde{g}^2_{\mathbf{0}}(y) - y$ and $g^2_{\mathbf{0}}(x) - x$ must be the same, as must be the sign of the leading coefficient of $b_g(s, \mathbf{0})$ and $b_{\tilde{g}}(\tilde{s}, \mathbf{0})$. Since the sign of the leading coefficients of $\tilde{g}^2_{\mathbf{0}}(y) - y$ and $b_{\tilde{g}}(\tilde{s}, \mathbf{0})$ are equal by the previous paragraph, this forces the sign of the leading coefficients of $g^2_{\mathbf{0}}(x) - x$ and $b_g(s, \mathbf{0})$ to be the same.

If $x \in \mathbf{R}^n$ with $n > 1$, then the realization of $\mathbf{G}$ on its center manifold can also be obtained by a near identity change of coordinates. So by a continuity argument similar to that in the paragraph above, the leading coefficient of $g^2_{\mathbf{0}}(x_1) - x_1$ will have the same sign as the leading coefficient of $b_{\mathbf{G}}(s, \mathbf{0})$. □

One consequence of Lemma 3.19 is that the period doubling map with $k-1$ higher-order degeneracies can be alternatively characterized by

$$\left.\frac{\partial^i B_{\mathbf{G}}(u, \boldsymbol{\mu})}{\partial u^i}\right|_{(0,\mathbf{0})} = 0 \quad \text{for } i = 0, \cdots, k-1,$$

but

$$\left.\frac{\partial^k B_{\mathbf{G}}(u,\boldsymbol{\mu})}{\partial u^k}\right|_{(0,\mathbf{0})} \neq 0.$$

Another consequence is that the sign of $b_{\mathbf{G}}$ or $B_{\mathbf{G}}$ can be used to determine stability of the fixed and period-2 orbits of $\mathbf{G}(\mathbf{x},\boldsymbol{\mu})$ and $g(x_1,\boldsymbol{\mu})$. It is usually more practical, however, to do this by eigenvalue computations, especially because, as mentioned after the statement of Lemma 3.19, the bifurcation functions are defined via the implicit function theorem.

Technical note. Lemma 3.19 and Theorem 3.15 are both stated under the assumption that the coordinate x_1 is already a coordinate on the center eigenspace for $\boldsymbol{\mu}=\mathbf{0}$. When $\mathbf{G}(\mathbf{x},\boldsymbol{\mu})$ does not originally come in this form, there is some leeway in choosing x_1. Its choice, however, involves a change of coordinates from the given form of $\mathbf{G}(\mathbf{x},\boldsymbol{\mu})$. If the change of coordinates is orientation preserving, a path to the identity argument as in the last two paragraphs of the proof of Lemma 3.19 can be used to show that the leading coefficient of $g_{\mathbf{0}}^2(x_1)-x_1$ will have the same sign as the leading coefficient of $b_{\mathbf{G}}(s,\mathbf{0})$. The case of an orientation reversing change of coordinates is converted to the orientation preserving case by noting that the change of variables $x_1\to -x_1$ leaves $b_g(s,\boldsymbol{\mu})$ the same and leaves the leading coefficient of $g_{\mathbf{0}}^2(x_1)-x_1$ the same.

This note shows that even though the bifurcation function constructed in the proof of Theorem 3.3 is not necessarily unique (there is a choice of coordinates made in reducing Case 3 to Case 2), the zeros, including multiplicities, and signs at corresponding nonzero points of any two bifurcation functions arising from the same original function must all be equal.

We now recall the universal unfolding theorem for $\mathbf{Z}_2$-symmetric bifurcation functions.

LEMMA 3.21. *Define the k-parameter family of $\mathbf{Z}_2$-symmetric bifurcation functions* $U(S,\boldsymbol{\varepsilon}):=\varepsilon_0 S+\varepsilon_1 S^3+\cdots+\varepsilon_k S^{2k-1}+\delta S^{2k+1}$, $\delta=\pm 1$. *Let $V(s,\boldsymbol{\mu})$ be any family of $\mathbf{Z}_2$-symmetric bifurcation functions satisfying* $V(s,\mathbf{0})=cs^{2k+1}+\cdots$, *with* $\operatorname{sgn}(c)=\delta$, *and*

$$\nabla_{\boldsymbol{\mu}}\left(\frac{\partial^i V(s,\boldsymbol{\mu})}{\partial s^i}\right)\Bigg|_{(0,\mathbf{0})} \neq \mathbf{0}.$$

Then in a neighborhood of $(0,\mathbf{0})$, *there exist C^∞ functions M, Σ, and $\boldsymbol{\phi}$ such that*

$$V(s,\boldsymbol{\mu})=M(s,\boldsymbol{\mu})U(\Sigma(s,\boldsymbol{\mu}),\boldsymbol{\phi}(\boldsymbol{\mu})) \tag{3.22}$$

with

$$M(s,\boldsymbol{\mu})>0,\ (\partial\Sigma/\partial s)(s,\mathbf{0})>0,\ \Sigma(s,\mathbf{0})=0,$$

$$\boldsymbol{\phi}(\mathbf{0})=\mathbf{0},\ M(-s,\boldsymbol{\mu})=M(s,\boldsymbol{\mu}),\ \Sigma(-s,\boldsymbol{\mu})=-\Sigma(s,\boldsymbol{\mu}).$$

Furthermore, there is no family having the properties of $U(S,\boldsymbol{\varepsilon})$ with fewer than k parameters.

Proof. Combine Proposition 2.14 [GS, p. 256] and Proposition 3.4 [GS, p. 259]. □

Proof of Theorem 3.15. (a) Recall from the paragraph preceding the statement of Theorem 3.15 that $g(x_1,\boldsymbol{\mu})$ is the center manifold realization of $\mathbf{G}(\mathbf{x},\boldsymbol{\mu})$ and $f(z,\boldsymbol{\varepsilon})$ is the appropriate model family. We will define the function $\boldsymbol{\Psi}$ so that the sign of $g_{\boldsymbol{\mu}}^2(x_1)-x_1$ will be the same as the sign of $f_{\boldsymbol{\varepsilon}}^2(z)-z$ for $(z,\boldsymbol{\varepsilon})=\boldsymbol{\Psi}(x_1,\boldsymbol{\mu})$. As previously

noted in § 2.1, this will guarantee that g_μ and f_ε will be topologically conjugate to each other for fixed values of the parameters (and appropriately restricted neighborhoods).

Let $b_G(s, \mu)$ and $b_f(S, \varepsilon)$ be the bifurcation functions determined from $\mathbf{G}(\mathbf{x}, \mu)$ and $f(z, \varepsilon)$, respectively, as in the proof of Theorem 3.3. Let $R^G(s, \mu)$ and $R^f(S, \varepsilon)$ be the respective functions defined following (3.9), with the superscripts added to distinguish the R's arising from the different functions $\mathbf{G}$ and f.

By Lemma 3.19, $g_\mu^2(x_1) - x_1$ has the same sign as $b_G(s, \mu)$, where (s, μ) and (x_1, μ) are related by the diffeomorphism $(x_1, \mu) = (s + R^G(s, \mu), \mu)$. Also by Lemma 3.19, $f_\varepsilon^2(z) - z$ has the same sign as $b_f(S, \varepsilon)$, where (S, ε) and (z, ε) are related by the diffeomorphism $(z, \varepsilon) = (S + R^f(S, \varepsilon), \varepsilon) = (S, \varepsilon)$. This last equality follows from the proof of Corollary 3.13, where we showed that $R^f(S, \varepsilon) = 0$.

Also, by Corollary 3.13, $b_f(S, \varepsilon) = \varepsilon_0 S + \varepsilon_1 S^3 + \cdots + \varepsilon_k S^{2k-1} + \delta S^{2k+1}$, which equals $U(S, \varepsilon)$ as defined in Lemma 3.21. Lemma 3.21 can therefore be used to show that there exist functions Σ and ϕ such that $b_G(s, \mu)$ and $b_f(S, \varepsilon)$ have the same sign for $(S, \varepsilon) = (\Sigma(s, \mu), \phi(\mu))$. Note that this C^∞ map will be a diffeomorphism if $\phi(\mu)$ is a diffeomorphism.

Combining the results of the two paragraphs above, we see that the signs of $g_\mu^2(x_1) - x_1$, $b_G(s, \mu)$, $b_f(S, \varepsilon)$ and $f_\varepsilon^2(z) - z$ are all the same for $x_1 = s + R^G(s, \mu)$, $(S, \varepsilon) = (\Sigma(s, \mu), \phi(\mu))$, and $S = z$. These relationships define the map $\Psi(x_1, \mu)$ by the composition

$$(x_1, \mu) \to (s, \mu) \to (S, \varepsilon) \to (z, \varepsilon). \tag{3.23}$$

Each map in the composition is C^∞ in a neighborhood of $(0, \mathbf{0})$ and each fixes $(0, \mathbf{0})$. Therefore the same is true of Ψ. This establishes (a)(1) and (a)(2) of Theorem 3.15. Part (a)(3) is true because each map in (3.23) preserves not only the zeros but also their multiplicities. (This is true for the first and third maps by Lemma 3.19, and for the middle map by (3.22).)

(b) If there existed a family that could replace f_ε in Theorem 3.15(a), then its bifurcation function would be a "universal unfolding" in the space of $\mathbf{Z}_2$ bifurcation functions with fewer than k parameters. This would contradict the last sentence of the universal unfolding theorem for $\mathbf{Z}_2$-symmetric bifurcation functions, Lemma 3.21.

(c) The condition that

$$\left\{ \nabla_\mu \left(\frac{\partial^i B_G(u, \mu)}{\partial u^i} \right) \Big|_{(0,\mathbf{0})}, \qquad i = 0, \cdots, k-1 \right\}$$

be independent is equivalent to the Jacobian determinant $|\partial \varepsilon_i / \partial \mu_j|_{\mu=\mathbf{0}} \neq 0$ *and therefore is equivalent to the map* $\varepsilon = \psi(\mu)$ *being a local diffeomorphism. In this case* Ψ *is also a local diffeomorphism.* □

4. Applications. Theorem 3.15 states that any period doubling diffeomorphism with $k-1$ higher-order degeneracies is equivalent, both in terms of its topological behavior under iteration (restricted to its center manifold) and in terms of its bifurcation sets, to one of our model families of § 2. In order to support these theoretical results, we used a version of the continuation routine AUTO [DK] that we adapted for use with maps to investigate two examples where we knew a period doubling with a higher-order degeneracy to exist. Both are two-parameter families of maps generated by flows of periodically forced planar oscillators. The stroboscopic map and its derivatives were calculated using ODESSA [LK]. Because our applications involved only two parameters, we would not expect to see a period doubling with more than the single higher-order degeneracy. The bifurcation diagrams we produced from these

applications should be compared to Figs. 3 and 4 for our model period doubling map with a single higher-order degeneracy.

4.1. Resonance horns in forced oscillators. Consider a system of two autonomous coupled nonlinear ODE's

$$d\mathbf{x}/dt = \mathbf{f}(\mathbf{x}, p), \qquad \mathbf{f}: \mathbf{R}^2 \times \mathbf{R} \to \mathbf{R}^2,$$

where $p \in \mathbf{R}$ is a parameter. Assume that for $p = p_0$ the system above has an asymptotically attracting closed orbit with frequency ω_0. Consider the two-parameter family of forced oscillators

$$d\mathbf{x}/dt = \mathbf{f}(\mathbf{x}, p_0 + \alpha g(\omega t)),$$

where α and ω are the parameters (α is the amplitude of the forcing and g has period $T = 1/\omega$). A more convenient second parameter is the ratio ω/ω_0 of the forcing to the natural frequency. Taking the time T return map of this flow (sometimes referred to as the stroboscopic map) gives us a two-parameter family of invertible, orientation preserving maps of the plane. The asymptotic attractivity of the limit cycle of the unforced oscillator guarantees the existence of a normally hyperbolic attracting invariant circle for small forcing amplitude α. According to standard circle map theory [Ar], [Ha], we expect resonance horns (also called entrainment regions of Arnol'd tongues) entering the first quadrant of the ω/ω_0-α parameter plane for every rational value of ω/ω_0. The boundaries of the "q/p resonance horn" emanating from $\omega/\omega_0 = q/p$ are saddlenode bifurcation points for the qth iterate of the map. Inside this q/p resonance horn, the corresponding map has at least one (typically two: a stable and unstable pair) period-q orbit. In particular, we are interested in the situation where $q = 2$, when the boundaries of the $2/p$ horns are saddlenode bifurcations for the second iterate of the map. In continuing these saddlenode curves towards higher values of α, we have repeatedly found them to terminate at a degenerate period doubling where they collide with a period doubling curve. (This was a much easier and less expensive ways of locating the degenerate period doubling points than the method suggested by Definition 3.1 or comment 1 following the statement of Theorem 3.15. To compute the normal form of a map on its center manifold and/or $(\partial^i B_G(u, \boldsymbol{\mu})/\partial u^i)|_{(0,\mathbf{0})}$, we would need higher derivatives of the stroboscopic map generated by numerically integrating the forced oscillator flows.)

Figures 7 and 8 show various features of the period doubling with a single higher-order degeneracy in the context of a 2/3 resonance horn for our first system of periodically forced ODEs:

$$\frac{dx_1}{d\tau} = -(p_0 + \alpha \cos(\omega\tau))x_1 + \frac{ax_2}{b + x_2} x_1,$$

$$\frac{dx_2}{d\tau} = -(p_0 + \alpha \cos(\omega\tau))x_2 + \frac{z_f - x_1 - x_2}{1 + z_f - x_1 - x_2} x_2 - \frac{ax_2}{b + x_2} x_1.$$

These ODEs model a predator-prey system (protozoa preying on bacteria in a chemostat). Here x_1 is the dimensionless concentration of protozoa, x_2 is the dimensionless concentration of bacteria, and z_f is the dimensionless feed concentration of a substrate on which the bacteria grow with Monod-type kinetics [PK]. The parameter we vary periodically is the flow rate of the chemostat. The autonomous system for $a = 0.4$, $b = 2.8125$, $z_f = 12.4$, and $p_0 = 0.2$ has a single attracting limit cycle of period $T = 18.999$ units of dimensionless time τ.

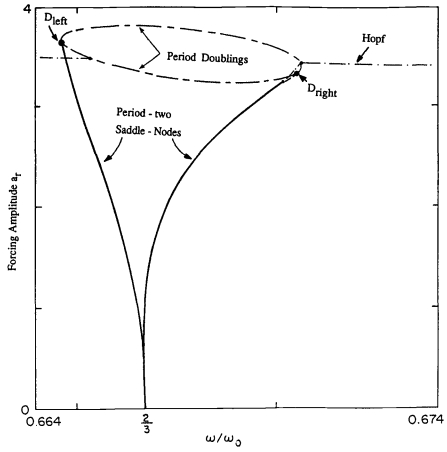

FIG. 7. *Predator-prey parameter plane.*

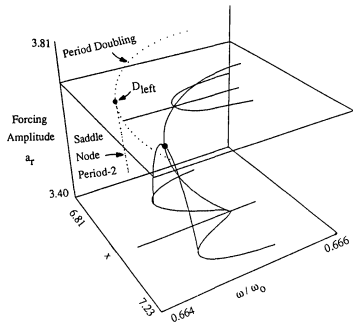

FIG. 8. *Predator-prey: singly degenerate period doubling.*

Figure 7 shows the boundaries of the 2/3 resonance horn for this model ($a_r = \alpha/0.00265$). As we follow both sides of the horn boundary towards higher values of α we encounter degenerate period doubling points D_{left} and D_{right}. Figure 8 is a three-dimensional representation of the full four-dimensional phase × parameter space of the solution surface and the codimension-1 bifurcation curves in the neighborhood of D_{left}. Compare this diagram to Fig. 3.

Another example where we also observed this phenomenon is the Continuous Stirred Tank Reactor (CSTR) in which a simple exothermic reaction $A \rightarrow B$ takes place. This classical chemical reaction engineering system can be modeled by the following set of dimensionless ODEs:

$$\frac{dx_1}{d\tau} = -x_1 + Da(1-x_1)\exp(x_2),$$

$$\frac{dx_2}{d\tau} = -x_2 + B\,\mathrm{Da}\,(1-x_2)\exp(x_2) + \beta(T_c - x_2),$$

where x_1 is a dimensionless concentration of reactant A, x_2 is a dimensionless temperature, and Da (the Damkoehler number), B (the dimensionless heat of reaction),

$T_c = T_{c,0} + \alpha \cos(\omega\tau)$ (the coolant temperature), and β (the dimensionless heat transfer coefficient between the reactor and the coolant fluid) are parameters. For $B = 22$, $\mathrm{Da} = 0.085$, $\beta = 3$, and $T_{c,0} = 0$ the autonomous system ($\alpha = 0$) has an attracting limit cycle of period $T_0 = 1.094996$ surrounding an unstable steady state. In a previous publication [KAS] degenerate period doublings were observed on both $2/p$ horns studied (the 2/1 and the 2/3 horns). Figure 9 is a three-dimensional representation of the full four-dimensional phase × parameter space of the solution surface and the codimension-1 bifurcation curves in the neighborhood of the equivalent of the D_{right} point of Fig. 7 for the 2/1 resonance horn of the periodically forced CSTR ($a_r = 0.063036$). Compare Fig. 9 also to Fig. 3.

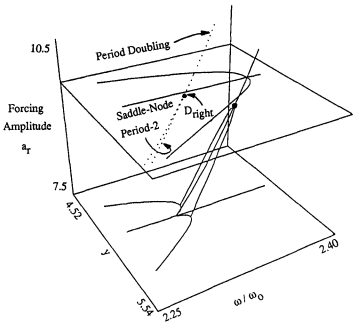

FIG. 9. *Forced* CSTR: *singly degenerate period doubling.*

Recent studies by McKarnin, Schmidt, and Aris [MSA] (a periodically forced surface reaction model), Schreiber et al. [SDCM] (a periodically forced Brusselator), as well as by Vance and Ross [VR] (a periodically forced CSTR) have also repeatedly revealed degenerate period doublings on the boundaries of $2/p$ resonance horns. This bifurcation appears therefore to be ubiquitous in models of periodically forced oscillators arising in various disciplines.

4.2. High-amplitude closing of the resonance horns. In our example (Fig. 7), as well as in the numerous studies of periodically forced oscillators we referred to above, the phenomenon of high-amplitude "closing" of the $2/p$, and generally of the q/p resonance horns was observed. It has been shown that this "closing" phenomenon implies the existence of certain codimension-2 bifurcations for the maps [AMKA], [P1], [P2], [P3]. In most horns, the boundary consists of codimension-1 saddlenode bifurcation curves for the qth iterate of the map along with certain codimension-2 points on these curves. For a $2/p$-horn, however, this boundary typically changes from a saddlenode curve for the 2nd iterate of the map to a period doubling curve in order for the horn to close. The point at which they change is the codimension-2 degenerate period doubling point.

See the references above for details and [Ga] for a related analytical study.

5. Discussion.

5.1. The Hopf bifurcation with higher-order degeneracies. As we mentioned in the introduction, certain higher-order degeneracies in the Hopf bifurcation for flows generate bifurcation diagrams almost identical to those for the period doubling bifurcation with higher-order degeneracies. This is not surprising if we look at the model

flows of Table 1:

$$r' = \varepsilon_1 r + \varepsilon_2 r^3 + \cdots + \varepsilon_{2k-1} r^{2k-1} + \delta r^{2k+1},$$

$$\theta' = \omega + r^2.$$

Circular limit cycles exist whenever r satisfies $r(\varepsilon_1 + \varepsilon_2 r^2 + \cdots + \varepsilon_{2k-1} r^{2k-2} + \delta r^{2k}) = 0$. That is, the roots of this function determine the topological phase portraits of the corresponding flows. But this function is precisely $rP_{\varepsilon;k,\delta}(r^2)$, the bifurcation function we defined in (2.3) and used for our model period doublings in § 2. In both cases, the root at $r = 0$ corresponds to a "center" fixed point; other roots correspond to limit cycles for the Hopf flow and period-2 orbits for the period doubling map. Roots of higher multiplicity determine higher codimension bifurcation manifolds in both cases.

To prove that the general Hopf bifurcations are all like the above models, Golubitsky and Schaeffer ([GS] and references therein) define a function, analogous to Φ in § 3, whose roots determine the limit cycles for a given flow. Among several factors complicating the Hopf analysis are the facts that Φ is defined on an infinite-dimensional function space and that its kernel is two-dimensional. After performing a Lyapunov-Schmidt reduction on this function, however, they obtain the same "reduced" bifurcation function as we obtained in Theorem 3.3. That is, both problems can be reduced to finding roots of the *same* bifurcation function.

We illustrate a more geometric connection between the Hopf bifurcation for flows and the period doubling bifurcation for some fixed parameter value in Fig. 10. The flow in $\mathbf{R}^2$ induces a map in $\mathbf{R}^1$ by taking a return map of the flow along a line (not a ray) through the origin. (Let the origin be a fixed point of the map.) Limit cycles of the flow correspond to period-2 orbits of the induced map.

5.2. Other "finite sequence spaces." We characterized period-2 points of $\mathbf{G}(\mathbf{x})$ in this paper as roots of the function $\Phi(\mathbf{x}, \mathbf{y}) = (\mathbf{y} - \mathbf{G}(\mathbf{x}), \mathbf{x} - \mathbf{G}(\mathbf{y}))$ and then used the Lyapunov-Schmidt procedure to reduce $\Phi = \mathbf{0}$ to a simpler system. Brown and Roberts [BR] and Vanderbauwhede [Va] have recently used Lyapunov-Schmidt reduction for functions on similar "finite sequence spaces" whose roots characterize periodic points of periods other than 2. In general, a period-k orbit $\{\mathbf{x}^1, \cdots, \mathbf{x}^k\}$ of $\mathbf{G}: \mathbf{R}^n \to \mathbf{R}^n$ is characterized as a root of the function $\Phi: (\mathbf{R}^n)^k \to (\mathbf{R}^n)^k$ defined by $\Phi(\mathbf{x}^1, \cdots, \mathbf{x}^k) = (\mathbf{x}^2 - \mathbf{G}(\mathbf{x}^1), \mathbf{x}^3 - \mathbf{G}(\mathbf{x}^2), \cdots, \mathbf{x}^1 - G(\mathbf{x}^k))$. The Lyapunov-Schmidt reduction starts from this function.

Acknowledgments. The authors acknowledge useful discussions and suggestions by Professors D. Aronson, M. Golubitsky, M. Krupa, R. McGehee, and A. Vanderbauwhede, and the referee. The hospitality of the Center of Nonlinear Studies at the Los Alamos National Laboratory is also gratefully acknowledged.

VARIATIONAL PRINCIPLES WITHOUT DEFINITENESS CONDITIONS*

PAUL BINDING†‡ AND QIANG YE†§

Abstract. Variational characterizations of eigentuples are discussed for a self-adjoint problem $Ax = \lambda Bx$ in a Hilbert space H. If the pair (A, B) is simultaneously real diagonable in a certain sense, and if B is 1-1, then all eigenvalues obey certain minimum and maximum principles for a generalised Rayleigh quotient. Sup-inf and inf-sup principles are established for eigenvalues which obey certain interlacing inequalities. Applications are made to both finite- and infinite-dimensional cases.

Key words. minimax principles, indefinite eigenvalue problems

AMS(MOS) subject classification. 49G05

1. Introduction. The study of pairs of self-adjoint operators has a long history. For example, Weierstrass [25] produced a canonical form for a pair of quadratic forms in finite dimensions, and this subject has been revived in recent years, often in the setting of self-adjoint operators on (perhaps indefinite) inner product spaces (cf. [17], [11]). The latter topic was given a firm foundation in infinite dimensions by Pontryagin, Krein, and subsequent workers (cf. [7], [15]). Differential eigenvalue equations involving indefinite operators have been the subject of much recent interest, as evidenced by [18].

This considerable activity has been largely devoted to extending classical results from definite to nondefinite pairs. The pair (A, B) of operators in a Hilbert space H is *self-adjoint* (respectively, *definite*) if A and B are self-adjoint (respectively, admit a definite linear combination). Here we shall discuss variational principles for eigenvalues of a class of pairs with no definiteness assumptions. In definite cases (say with B definite), such principles usually involve the generalised Rayleigh quotient

$$r(x) = a(x)/b(x)$$

where

$$a(x) = (x, Ax), \qquad b(x) = (x, Bx), \tag{1.1}$$

and $r(x)$ is defined for all nonzero $x \in D(A) \cap D(B)$. On the other hand, if B is indefinite, then $b(x)$ necessarily vanishes for certain nonzero x, and then the very definition of $r(x)$ needs modification. It is perhaps for this reason that few variational principles exist for nondefinite pairs. There is recent finite-dimensional work [2] but it seems unrelated to ours. An approach to definite pairs via indefinite inner product spaces was given by Phillips [22] and generalised by Textorius [23] to possibly singular pencils. This approach involves triple extrema, and we hope to return to this elsewhere, but here we shall concentrate on single and double extrema.

Eigenvalue equations

$$Ax = \lambda Bx \tag{1.2}$$

involving nondefinite pairs (A, B) arise in various applications. One of the earliest comes from separation of variables in boundary value problems for waves that are

electromagnetic, acoustic, etc. This leads to two (or more) parameter problems like $Ax=(\lambda B+\mu C)x$ (cf. [24]). Depending on μ/λ and the boundary conditions for A, this problem is generally nondefinite. Another application concerns quantum theory of crystal lattices, involving operators A of the form $-\Delta+q$, where q is a periodic potential [16]. Recently Deift, Hempel, and others have made several investigations of this topic, B representing the potential of an impurity (cf. [8]). Another seminal nondefinite application of (1.2) lies in the stability analysis of population genetics models, where A is a Neumann Laplacian and B is a linearized natural selection term (cf. [10]). Much subsequent work has been carried out on abstract versions, e.g., [14]. We also note that quadratic eigenvalue problems can frequently be put into a nondefinite form (1.2) satisfying our hypotheses. We cite Greenlee's work [12] which applies to certain problems in fluid dynamics, and we shall analyse a problem from mechanics in §4.

For such problems, it turns out that all but finitely many of the real eigenvalues are of either positive or negative "type," depending on the sign of one of the quadratic forms in (1.1) (usually $b(x)$) at eigenvectors, and those of positive (respectively, negative) "type" accumulate only at $+\infty$ (respectively, $-\infty$). For example, the real eigenvalues λ_j of the regular Sturm–Liouville problem

$$(-py')'+qy=\lambda wy \qquad (p>0) \tag{1.3}$$

(with indefinite weight w) may be indexed so that $\lambda_j\to\pm\infty$ as $j\to\pm\infty$ and λ_j corresponds, for $|j|\geq j_1$, to an eigenfunction y with $j-1$ internal zeros. For $j\geq j_1$ (respectively, $j\leq -j_1$), λ_j is of positive (respectively, negative) "type." For a history of such results, see Mingarelli [20], who calls j_1 (which we take to be minimal) the Haupt index after his 1915 paper [13]. For recent work on abstract generalisations of (1.3), including various matrix and partial different equation problems, we refer to [5]. Similar considerations apply to other aspects of (1.3): for large $|j|$, the λ_j (and the corresponding eigenfunctions) behave much as for the (left) definite case. As an example, the eigenfunctions for $|j|\geq j_1$ span a subspace K of finite codimension, and K is a Hilbert space in the inner product generated by a of (1.1) (cf. [9] and [6] for an abstract version).

The importance of the regularity index j_1 for variational principles was pointed out in [19] for matrix problems, and in [1] for the problem

$$(-\Delta+q)y=\lambda wy, \tag{1.4}$$

where Δ is the n-dimensional Laplacian with Dirichlet boundary conditions. Specifically, if a certain diagonability condition holds, then for $j\geq j_1$ the eigenvalues λ_j are of positive "type" and can be characterized by

$$\lambda_j=\sup\{\inf\{r(x):x\in C^+\cap S\}:\operatorname{codim} S=k\}, \tag{1.5}$$

with a similar formula for $j\leq -j_1$ where the eigenvalues are of negative "type." Here

$$C^{\pm}=\{x\in D(A)\cap D(B):\pm b(x)>0\}, \tag{1.6}$$

S is a subspace of H, and k depends on j. On the other hand, it has been conjectured (in private communication) that no such characterization is possible for eigenvalues λ_j with $|j|<j_1$. We shall refer to the latter as "overlap" eigenvalues, since those of positive and negative "type" are no longer separated, and indeed $a(x)=b(x)=0$ is possible, so some eigenvalues may not have a defined "type."

We shall see that (1.5) is valid under quite general circumstances, and does indeed characterize some (although not all) "overlap" eigenvalues. Various related "dual" formulae will also be given. Section 2 contains preliminary results, including a general

minimum principle, valid for all eigenvalues. This gives a complete recursive characterization of eigenvalues for certain pairs. Section 3 is devoted to double extremum principles like (1.5), with simple (mostly finite-dimensional) illustrations. Section 4 contains applications to various matrix, differential, and integral equation problems, including (1.3) and (1.4).

2. Preliminaries. Let us start with our basic assumption, which is the existence of a linear homeomorphism T which "simultaneously diagonalises" A and B. More precisely, we assume the following:

(A1) There exist

(i) an integer index set J, not containing zero,

(ii) a bounded linear operator T on H with bounded inverse,

(iii) a complete orthonormal basis $e_j (j \in J)$ of H,

(iv) real α_j and real β_j taking the sign of j, such that $T^*ATe_j = \alpha_j e_j$, $T^*BTe_j = \beta_j e_j$, $j \in J$.

Remarks. Assumptions (ii) and (iii) mean that the elements Te_j form a Riesz basis of H. We stress that explicit knowledge of T is unnecessary; only its existence is required, and sufficient conditions on A and B will be given in §4. Also (iv) is a "real diagonability" condition; it is straightforward to relax this to all but finitely many $j \in J$, using constructions given in [21] for the span of the remaining Te_j. For notational simplicity, however, we shall adopt (iv) as stated.

We also need some definitions before stating the minimum principle. A complex number λ is an *eigenvalue* of (A, B) if the *eigenspace* $E_\lambda := N(A - \lambda B)$ is nontrivial, and x is a $b\pm$ *eigenvector* if $x \in E_\lambda \cap C^\pm$; see (1.6). We write $\lambda_j = \alpha_j/\beta_j$, and for any real λ we define index sets

$$I_\lambda^\pm = \{j: \pm(\alpha_j - \lambda\beta_j) \geq 0\}, \qquad I_\lambda^0 = I_\lambda^+ \cap I_\lambda^- = \{j: \lambda = \lambda_j\}$$

and subspaces

$$S_\lambda^\pm = \text{Span}\,\{Te_j: j \in I_\lambda^\pm\}, \qquad S_\lambda^0 = \text{Span}\,\{Te_j: j \in I_\lambda^0\},$$

where Span means closed linear span. This notation allows considerable freedom in the ordering of the λ_j, e.g., in the case of several accumulation points. In our examples, $\lambda_j \leq \lambda_{j+1}$ will hold separately for positive and negative j (although $\lambda_1 < \lambda_{-1}$ in the case of "overlap" eigenvalues). As an illustration, suppose that b is definite on each separate eigenspace. If λ is an eigenvalue of (A, B), then S_λ^+ turns out to be the Span of those E_μ on which b is positive definite and $\mu \geq \lambda$, together with those on which b is negative definite and $\mu \leq \lambda$. Also $E_\lambda = S_\lambda^+ \cap S_\lambda^- = S_\lambda^0$.

THEOREM 2.1.

(i) $I_\lambda^0 \neq \emptyset \Leftrightarrow \lambda$ *is an eigenvalue of* (A, B).

(ii) *If* λ *admits a* $b\pm$ *eigenvector* x, *then*

$$\lambda = \min\{r(x): x \in S_\lambda^\pm \cap C^\pm\} \tag{2.1}$$

and x *is a corresponding minimiser.*

(iii) E_λ *is spanned by the set of minimisers* (*using both possible signs*) *in* (2.1).

Proof.

(i) If $I_\lambda^0 \neq \emptyset$, then $\alpha_j = \lambda\beta_j$ for some j. Thus

$$(A - \lambda B)Te_j = T^{-*}(\alpha_j - \lambda\beta_j)e_j = 0.$$

Conversely, if $0 \neq x \in E_\lambda$ and

$$T^{-1}x = y = \sum_{j \in J} y_j e_j, \tag{2.2}$$

then

$$0 = T^*(A-\lambda B)Ty = \sum_{j\in J} (\alpha_j - \lambda\beta_j) y_j e_j. \tag{2.3}$$

If $I_\lambda^0 = \emptyset$, then the inner product of (2.3) with e_k gives $y_k = 0$. Thus $y = 0$, so we obtain the contradiction $x = 0$.

(ii) If $x \in S_\lambda^+ \cap C^+$, then (2.2) gives

$$r(x) = \sum_{j\in I_\lambda^+} \alpha_j |y_j|^2 / \sum_{j\in I_\lambda^+} \beta_j |y_j|^2 \geq \lambda. \tag{2.4}$$

If, moreover, $x \in E_\lambda \cap C^+$, then (2.3) implies $y_j = 0$ unless $j \in I_\lambda^0$, so

$$x \in S_\lambda^0 \cap C^+ \subseteq S_\lambda^+ \cap C^+.$$

It follows that $\geq$ may be replaced by $=$ in (2.4), and the proof is complete for the + sign case. For the − sign case, we replace (A, B) by $(-A, -B)$ and apply the + sign case.

(iii) I_λ^0 partitions into two subsets, one positive and one negative. These subsets generate $b\pm$ eigenvectors Te_j, which by (ii) are minimisers for the two sign cases. Moreover these minimisers span S_λ^0, which as we saw above equals E_λ. □

COROLLARY 2.2. *Equation* (2.1) *may be replaced by*

$$\lambda = \max\{r(x): x \in S_\lambda^\pm \cap C^\pm\}.$$

Proof. Replace A by $-A$ and apply Theorem 2.1(ii). □

Let us briefly examine the consequences for definite pencils in finite dimensions. If B is (say positive) definite (the "right" definite case), then the S_λ^- are trivial, and the S_λ^+ nest. In fact all eigenvalues for (A, B) may be calculated recursively via (2.1), beginning with the least eigenvalue λ, for which $S_\lambda^+ = H$. This is the standard "generalised Rayleigh quotient" recursive characterization, since $C^+ = H\backslash\{0\}$. If instead $A - \lambda_0 B$ is (say positive) definite then b takes the sign of $\lambda - \lambda_0$ on E_λ. Thus again (2.1) characterizes the eigenvalues for (A, B) recursively, beginning with the least $> \lambda_0$ (for which $S_\lambda^+ = H$) and the greatest $< \lambda_0$ (for which $S_\lambda^- = H$). Similar considerations apply in infinite dimensions provided the extreme eigenvalues above exist, but the recursions stop at accumulation points of eigenvalues. See §4 for applications.

We shall need two specific results for perhaps nondiagonable pencils in two dimensions, and we shall first examine the role Theorem 2.1 plays in the indefinite, but real diagonable, case. Recall the notation $\lambda_j = \alpha_j/\beta_j$.

LEMMA 2.3 *Let* $\dim H = 2$ *and* $J = \{-1, 1\}$.

(i) *If* $\lambda_{-1} \leq \lambda_1$ *then* $\min\{r(x): x \in C^+\} = \lambda_1$.

If $\lambda_{-1} > \lambda_1$ *then*

(ii) $\inf\{r(x): x \in C^+\} = -\infty$ *and*

(iii) $\max\{r(x): x \in C^+\} = \lambda_1$.

Proof. Lemma 2.3 (i) follows from Theorem 2.1 since $S_{\lambda_1}^+ = H$. For (ii) we follow (2.2) to give

$$r(x) = \beta_{-1}^{-1}\alpha_{-1} + \beta_1(\lambda_1 - \lambda_{-1})|y_1|^2 / (\beta_{-1}|y_{-1}|^2 + \beta_1|y_1|^2). \tag{2.5}$$

Now let $y_{-1} = 1$, $y_1 \in \mathbb{R}$ and $\beta_1 y_1^2 \downarrow -\beta_{-1}$ to give the result.

Lemma 2.3(iii) follows from Corollary 2.2 since $S_{\lambda_1}^- = H$. □

The other characterizations degenerate for this problem, e.g., $\lambda_1 = \min\{r(x): x \in E_\mu\}$ in (ii).

We can now derive the two special results that we need later. Real diagonability of the corresponding pencils is not assumed.

COROLLARY 2.4. *Let* α_j, β_j *be as in Lemma* 2.3, *and* $\alpha_0 \in \mathbb{R}$. *If* $\lambda_{-1} > \lambda_1$ *and*

$$\alpha(y) := \alpha_{-1} y_{-1}^2 + \alpha_1 y_1^2 + \alpha_0 y_{-1} y_1, \tag{2.6}$$

then

$$\inf\{\alpha(y)/(\beta_{-1} y_{-1}^2 + \beta_1 y_1^2) : \beta_{-1} y_{-1}^2 + \beta_1 y_1^2 > 0, (y_{-1}, y_1) \in \mathbb{R}^2\} = -\infty.$$

Proof. This follows from Lemma 2.3 (ii) provided we choose the sign of y_1 in (2.5) so that $\alpha_0 y_1 \le 0$. □

For the second result, we retain the index set $J = \{-1, 1\}$ for convenience, even though we assume $\beta_{-1} = 0$.

LEMMA 2.5. *Let* $\alpha_{-1} < 0 < \beta_1$; $\alpha_1, \alpha_0, \beta_0 \in \mathbb{R}$ *and* $\alpha(y)$ *be as in* (2.6). *Then*

$$\inf\{\alpha(y)/(\beta_1 y_1^2 + \beta_0 y_{-1} y_1) : \beta_1 y_1^2 + \beta_0 y_{-1} y_1 > 0, (y_{-1}, y_1) \in \mathbb{R}^2\} = -\infty.$$

Proof. We set $y_1 = \beta_0$ if $\beta_0 \neq 0$ and $y_1 = 1$ if $\beta_0 = 0$. It follows that

$$\beta_1 y_1^2 + \beta_0 y_{-1} y_1 > 0$$

for all $y_{-1} > 0$, and as $y_{-1} \to \infty$, $\alpha(y)/y_{-1}^2 \to \alpha_{-1}$. This suffices for the conclusion. □

3. Double extremum principles. We need one more finite-dimensional result in preparation for the variational principle.

LEMMA 3.1. *Let* dim $H = n < \infty$, $b(u_0) < 0$ *and let* J *have* p *positive elements. Then there exists a* p*-dimensional subspace* U, *orthogonal to* Bu_0, *with* b *positive definite on* U.

Proof. Let u_{-j}, $0 \le j \le n - p + 1$, be a basis for a maximal b-negative subspace S. The elements Bu_{-j} are linearly independent, so their span BS has dimension $n - p$. By the law of inertia, b is positive definite on $U = (BS)^{\perp}$. □

In order to state the variational principle efficiently, we shall split the index sets $I_\lambda^\pm$ into two. Specifically, we define

$$J_{\ge\lambda}^{\pm} = \{\pm j > 0 : \lambda_j \ge \lambda\}, \qquad T_{\ge\lambda}^{\pm} = \text{Span}\{Te_j : j \in J_{\ge\lambda}^{\pm}\}$$

with similar definitions for $T_{\le\lambda}^{\pm}$, $T_{<\lambda}^{\pm}$, and $T_{>\lambda}^{\pm}$. Note $S_\lambda^\pm = T_{\ge\lambda}^{\pm} + T_{\le\lambda}^{\mp}$ (cf. the illustration before Theorem 2.1).

THEOREM 3.2. *Let* λ *admit a* $b\pm$ *eigenvector, and suppose* $\mu > \lambda$, *where*

$$\dim T_{<\lambda}^{\pm} = k < \infty, \qquad \dim T_{\ge\mu}^{\mp} = l < \infty,$$

$T_{>\lambda}^{\mp} \cap T_{<\mu}^{\mp} = \{0\}$ *and* $\dim(T_{\ge\lambda}^{\pm} \cap T_{<\mu}^{\pm}) > l$. *Then* $\lambda = \sigma_{k+l}^{\pm}$, *where*

$$\sigma_m^{\pm} = \sup\{\inf\{r(x) : x \in S \cap C^{\pm}\}; \text{codim } S = m\}. \tag{3.1}$$

The dual result involves replacing A by $-A$, and is as follows.

COROLLARY 3.3. *This is the same as for Theorem* 3.2, *with the following changes: all inequalities* (*except* "$m \ge l$") *are reversed, and* "sup" *is interchanged with* "inf."

Remark. Since T is 1-1, it need not be known explicitly to determine dim $T_{<\lambda}^{\pm}$, etc. Roughly, the dimension conditions state (in the case of a $b+$ eigenvector at λ) that there must be enough $\lambda_j^+ \in [\lambda, \mu[$ to "cancel" any $\lambda_j^- \ge \mu$.

Before proving Theorem 3.2, we shall discuss some simple illustrations. Suppose first that dim $H = 4$, and $J = \{\pm 1, \pm 2\}$. We shall concentrate on the positive sign case of (3.1).

Example 3.4. If $\lambda_{-2} < \lambda_{-1} < \lambda_1 < \lambda_2$, then the pencil is definite (there is no "overlap"), $\sigma_0^+ = \lambda_1$ (with $k = l = 0$), in agreement with (2.1), and $\sigma_1^+ = \lambda_2$ (with $k = 1$, $l = 0$), in agreement with [19].

Example 3.5. If $\lambda_{-2} < \lambda_1 < \lambda_2 < \lambda_{-1}$ then the pencil is indefinite, and $\sigma_1^+ = \lambda_1$, with $k = 0$, $l = 1$. We know of no other results that characterize "overlap" eigenvalues like λ_1.

More generally, we have the following result.

THEOREM 3.6. *If* $\dim H = 4$, *then all quantities* σ_j^+ *are either infinite or else characterize eigenvalues via Theorem* 3.2 *or Corollary* 3.3.

We shall not prove this here, since there are many cases. We may note, however, that $\sigma_2^+ = \sigma_3^+ = \infty$ in Examples 3.4 and 3.5, while $\sigma_0^+ = -\infty$ in Example 3.5. Also (3.1) gives $\sigma_1^- = \lambda_{-1}$ with $k = 1$, $l = 0$, in Example 3.5, and the remaining eigenvalues λ_j can be characterized via Corollary 3.3 in the above exaples.

The simplest infinite-dimensional situations with $l = 0$ and $l = 1$ are obtained by expanding the sequences λ_j in Examples 3.4 and 3.5, using negative j to the left and positive j to the right.

Another infinite-dimensional case may be of interest. We assume that B has only finitely many (counting multiciplicity) negative eigenvalues, i.e., there are only finitely many negative β_j. If $J = J_1 \cup J_2 \cup N$ where J_1, J_2 consist of (possibly infinitely many) positive integers, N consists of finitely many negative integers, and

$$\lambda_i < \lambda_j \quad \text{for any } i \in J_1 \quad \text{and} \quad j \in J_2 \cup N,$$

then the eigenvalues $\{\lambda_i : i \in J_1\}$ are characterized by Theorem 3.2. Note that if $N = \varnothing$, i.e., B is positive definite, then the classical minimax theorem characterizes λ_i for $i \in J_1$. So this result says that the minimax theorem remains valid even in the presence of negative index eigenvalues provided that they do not destroy the extreme structure of $\{\lambda_i : i \in J_1\}$. There is, however, an index shift in the characterization.

Proof of Theorem 3.2. The negative sign case in (3.1) may be reduced to the positive sign case by the transformation $(A, B) \to (-A, -B)$, so we shall discuss only the positive sign case. Then Theorem 2.1 gives

$$\lambda = \min \{r(x) : x \in C^+ \cap S_\lambda^+\},$$

and since $T(T^{-1}S_\lambda^+)^\perp = T_{<\lambda}^+ + T_{>\lambda}^-$ has dimension $k + l$, it will suffice to prove that for any S with codimension $k + l$,

$$\text{there exists } x \in S \cap C^+ \text{ such that } r(x) \le \lambda. \tag{3.2}$$

Now let

$$\Sigma \subseteq T_{\le\lambda}^+ + T_{\ge\mu}^- \tag{3.3}$$

be a subspace of (finite) dimension $> k + l$, so there is a nonzero $u_0 = v + w \in \Sigma \cap S$, where $v \in T_{\le\lambda}^+$ and $w \in T_{\ge\mu}^-$. Since $r(v) \le \lambda$, $r(w) \ge \mu$, and $b(v) > 0 > b(w)$, it follows that

$$a(v) \le \lambda b(v) \quad a(w) \le \mu b(w) \quad \text{and} \quad (v, Aw) = (v, Bw) = 0. \tag{3.4}$$

We must consider three possible cases.

Case 1. $b(u_0) > 0$. Then (3.3) gives

$$r(u_0) \le [\lambda b(v) + \mu b(w)]/[b(v) + b(w)]$$

and the right side $\le \lambda$ by Lemma 2.3 (iii), since $\lambda < \mu$. Thus $x = u_0$ suffices for (3.2).

Case 2. $b(u_0) = 0$. By assumption, $\dim T_{<\mu}^+ > k + l$, so there is nonzero $x \in S \cap T_{<\mu}^+$. Choose $x = y_{-1}u_0 + y_1 z$, where $(y_{-1}, y_1) \in \mathbb{R}^2$. Now $b(z) > 0$ and by (3.4)

$$a(u_0) = a(v) + a(w) < \mu b(v) + \mu b(w) = \mu b(u_0), \tag{3.5}$$

so $a(u_0)<0$. Thus

$$r(x)=[a(u_0)y_{-1}^2+a(z)y_1^2+2Re(u_0, Az)y_{-1}y_1]/[b(z)y_1^2+2Re(u_0, Bz)y_{-1}y_1]$$

can be made $\leq\lambda$ by virtue of Lemma 2.5, and (3.2) is satisfied.

Case 3. $b(u_0)<0$. Lemma 3.1, with H replaced by Σ (3.3) gives a b-positive subspace $U\subseteq\Sigma$ of dimension $>k$, orthogonal t Bu_0. Now choose a subspace $V\subset T^+_{\geq\lambda}\cap T^+_{<\mu}$ of finite dimension so that $Q=U+V$ has dimension $>k+l$. Evidently Q is b-positive and orthogonal to Bu_0, and so there is $q\in Q\cap S$ such that

$$b(q)>0 \quad \text{and} \quad (q, Bu_0)=0. \tag{3.6}$$

Moreover dim $Q<\infty$, so $q\in T^+_{\leq\nu}+T^-_{\geq\mu}$ for some $\nu<\mu$, and arguing as for Case 1 we conclude $r(q)\leq\nu$, i.e.,

$$a(q)\leq\nu b(q). \tag{3.7}$$

Now choose $x=y_{-1}u_0+y_1q$, where $(y_{-1}, y_1)\in\mathbb{R}^2$. We may then use (3.5), (3.6), (3.7), and $\nu<\mu$ to show that

$$r(x)=[a(u_0)y_{-1}^2+a(q)y_1^2+2Re(u_0, Aq)y_{-1}y_1]/[b(u_0)y_{-1}^2+b(q)y_1^2]$$

can be made $\leq\lambda$ by virtue of Corollary 2.4, and again (3.2) is satisfied. □

4. Applications. Our starting point is a special case of a canonical form in [4].

THEOREM 4.1. *Suppose $A=I+C$ and B is* 1-1 *with B, C compact symmetric on H. Then there exists a linear homeomorphism T of H, and subspaces F, G such that* dim $F<\infty$, G_A (i.e., *G with the inner product generated by A*) *is a Hilbert space and, relative to the* (*A-orthogonal*) *direct sum $H=F\oplus G$, $T^*AT=A_F\oplus I_G$, $T^*BT=B_F\oplus Q$, where Q is* 1-1, *compact and symmetric on G.*

Explicit constructions are given in [4], A_F and B_F being the Gram operators (in the usual inner product) for A and B on F. Thus assumption (A1) in § 2 reduces to real diagonability of the finite-dimensional operator $B_F^{-1}A_F$, but as we mentioned in the remark after (A1) this diagonability is unnecessary if we use the constructions of [21]. Essentially, therefore, our results hold for (1.2) with A, B as in Theorem 4.1. For more general situations, e.g., with B merely bounded and symmetric, see [4].

In finite dimensions, the results of [19, Thms. 2.1, 2.2] correspond to the case $l=0$ of Theorem 3.2 and Corollary 3.3, and the classical situation of definite pencils is a special case of this. The bounded operator setting given above applies directly to integral equations with symmetric kernels. We remark that there are frequently several problem formulations, which affect (β_j) signs, λ_j accumulation points, etc. For example, the eigenvalues λ of a compact symmetric operator Γ can be obtained via the pair (Γ, I), which is not covered by Theorem 4.1, although (A1) is satisfied. The reciprocals λ^{-1} can be obtained via the pair (I, Γ), which does fit Theorem 4.1 and (A1). All (nonzero) eigenvalues are characterized via Theorem 3.2 and Corollary 3.3: for (Γ, I), $C^{\pm}=H$, while for (I, Γ), $C^{\pm}$ are defined by Γ.

It may also be noted that Theorem 4.1 can also be used to treat (1.2) in the case $A=P+C$, where P is positive definite with a compact inverse and B, C are bounded. Then

$$P^{-1/2}AP^{-1/2}=I+C_1 \quad \text{and} \quad P^{-1/2}BP^{-1/2}=B_1 \tag{4.1}$$

with C_1 and B_1 satisfying the hypothesis of Theorem 4.1, and $P^{-1/2}$ can be combined with T. We stress that T (and $P^{1/2}$), which are difficult to calculate in general, which, need not be determined explicitly: for example codim S equals j if and only if codim (TS) equals j. This applies to certain types of unbounded operator equations, including

various self-adjoint uniformly elliptic boundary value problems like (1.3) and (1.4). Specifically, B and C are the multiplication operators associated with w and q, respectively, and $Py=(-py')'$ for (1.3) and $Py=-\Delta y$ for (1.4). Then the above conditions follow if all coefficients are L_∞ on a compact domain for the equation, and $1/p$ is L_1. We then obtain, for example, [1, Cor. 2.9] in the case $l=0$ of Theorem 3.2.

Finally, let us examine a gyroscopic stabilization problem from mechanics [3], which leads to a quadratic eigenvalue problem

$$(\lambda^2 I+\lambda iG+C)y=0 \tag{4.2}$$

where $G=-G^*$ and $C=C^*>0$. Using a standard linearization, we may rewrite this in the (nondefinite) form (1.2) where

$$A=\begin{bmatrix} iG & I \\ I & 0 \end{bmatrix} \quad \text{and} \quad N=\begin{bmatrix} C & 0 \\ 0 & -I \end{bmatrix}.$$

Under the (gyroscopic stabilizability) condition $G^2+(kI+k^{-1}C)^2<0$ for some $k>0$, it is shown in [3] that each eigenvalue of (4.2), and hence of (1.2), is real and of definite type. Thus the real diagonability condition is satisfied, i.e., assumption (A1) holds as stated.

It is also shown in [3] that if iG is $n\times n$ and has p positive eigenvalues, then the eigenvalues for (4.2), i.e., for (1.2), satisfy

$$\lambda_{-n}\le\cdots\le\lambda_{p-n-1}<\lambda_1\le\cdots\le\lambda_p<0<\lambda_{p-n}\le\cdots\le\lambda_{-1}<\lambda_{p+1}\le\cdots\le\lambda_n.$$

Thus our results characterize λ_j for $j<p-n$, $j>p$, and $1\le j\le 2p-n$ if $2p>n$ (respectively, $-1\ge j\ge n-2p$ if $n>2p$).

PERSISTENCE OF INVARIANT TORI IN SYSTEMS OF COUPLED OSCILLATORS. II. DEGENERATE PROBLEMS*

MASAJI WATANABE†‡ AND HANS G. OTHMER†

Abstract. This paper continues the study of persistence of invariant tori in a class of differential equations that describe indirectly- or capacitatively-coupled systems of nonlinear oscillators. In a previous paper the authors proved that when the unperturbed torus is hyperbolic it persists under weak coupling, and the flow on the perturbed tori was analyzed. In this paper the persistence of invariant tori is proved in certain degenerate cases in which the invariant manifold in the unperturbed problem is not normally hyperbolic. This is done by proving the existence of fixed points in appropriate Banach spaces.

Key words. coupled oscillators, invariant tori

1. Introduction.

A number of applications in physics and biology lead to a system of the form

$$\begin{aligned} \frac{dx_i}{dt} &= f_i(x_i) + \delta P(x_0 - x_i), \qquad i = 1, \cdots, N, \\ \frac{dx_0}{dt} &= \epsilon\delta P\left(\frac{1}{N}\sum_{i=1}^{N} x_i - x_0\right) \end{aligned} \tag{1.1}$$

(cf. [16], hereafter referred to as Part I, for references to the applications). In (1.1) P is an $n \times n$ constant matrix of permeability coefficients or conductances, and the parameters ϵ^{-1} and δ measure the relative capacity of the subunits and the coupling strength, respectively. In the absence of coupling the evolution in the ith subunit is governed by the n-dimensional system

$$\frac{dx_i}{dt} = f_i(x_i), \tag{1.2}$$

and it is assumed that there is a nonconstant periodic solution

$$x_i = \eta_i(t) \tag{1.3}$$

with least period $T_i > 0$ of (1.2) for $i = 1, \cdots, N$. The variable x_0 represents the state of the coupling medium, through which the subunits are coupled [13], [12].

In this paper we study the following generalization of (1.1):

$$\begin{aligned} \frac{dx_i}{dt} &= f_i(x_i) + \delta g_i(x_0, x_1, \cdots, x_N, \delta), \qquad i = 1, \cdots, N, \\ \frac{dx_0}{dt} &= \epsilon\delta\left(Bx_0 + \sum_{i=1}^{N} C_i x_i\right). \end{aligned} \tag{1.4}$$

Here $x_i \in \mathbb{R}^{n_i}$, $i = 1, \cdots, N$, $x_0 \in \mathbb{R}^{N_2}$, B is an $N_2 \times N_2$ matrix, and C_i is an $N_2 \times n_i$ matrix, and thus (1.4) is a system in $\mathbb{R}^{N_2+M}$, where $M = \sum_{i=1}^{N} n_i$. We assume that each n_i-dimensional system (1.2) has a nonconstant periodic solution (1.3) with least period $T_i > 0$, and we make the following assumptions about (1.4).

ASSUMPTION 1.1. (a) $\epsilon = \epsilon_0 \delta^{-p}$ *for* $\epsilon_0 > 0, \delta \geq 0$, *and* $p \in (0,1)$.

(b) *For* $i = 1, \cdots, N$,

$$f_i : \mathbb{R}^{n_i} \longrightarrow \mathbb{R}^{n_i}, \qquad g_i : \mathbb{R}^{N_2+M+1} \longrightarrow \mathbb{R}^{n_i}$$

are $(k+1)$*-times continuously differentiable with* $k \geq 2$.

(c) *For each* $i = 1, \cdots, N$, 1 *is a simple multiplier of*

$$\frac{dx_i}{dt} = Df_i(\eta_i(t))x_i,$$

and the remaining $n_i - 1$ *multipliers have modulus less than* 1.

(d) *The eigenvalues of* B *have negative real parts.*

In Part I we studied the persistence of invariant tori for the singular ($p > 1$) and regular ($p = 1$) cases, where standard results could be used to prove the existence of invariant tori for small coupling that lie near certain invariant tori that exist in the uncoupled system. In this paper we study the degenerate case $p \in (0,1)$, and as we shall see shortly, this case is far more difficult due to the fact that the coupling vanishes faster than the capacitance.

The M-dimensional system, which consists of (1.2) for $i = 1, \cdots, N$, has the N-dimensional invariant torus T_0^N in $\mathbb{R}^M$ defined by

$$x_i = \eta_i(\theta_i), \qquad i = 1, \cdots, N. \tag{1.5}$$

Therefore, when $0 < p < 1$, $T_0^N \times \mathbb{R}^{N_2}$ is an invariant manifold of the unperturbed system ($\delta = 0$) of (1.4) that consists of the N_2-parameter family of N-dimensional invariant tori $\mathcal{T}_{0,c}^N$,

$$\begin{aligned} x_0 &= c, \qquad c \in \mathbb{R}^{N_2}, \\ x_i &= \eta_i(\theta_i), \qquad i = 1, \cdots, N. \end{aligned} \tag{1.6}$$

The simplest example arises for $N = N_2 = 1, n_1 = 2$, in which case the invariant manifold at $\delta = 0$ is the cylinder $\eta \times \mathbb{R} \subset \mathbb{R}^3$.

The problem we address in this paper is that of determining which, if any, of the invariant tori in (1.6) persist for $\delta > 0$. The standard results [4], [9] on persistence of invariant manifolds for flows are not applicable to the degenerate problem that arises from (1.4) at $\delta = 0$, because the compactness of the unperturbed invariant manifold is essential for the proofs. In fact, the invariant manifold (1.6) that exists for the unperturbed problem does not persist, and the question is which of the invariant tori persists. Thus the problem is in essence a bifurcation problem. We address this problem in §3, where we show that the invariant torus given by

$$\begin{aligned} x_0 &= -B^{-1} \sum_{i=1}^{N} C_i \frac{1}{T_i} \int_0^{T_i} \eta_i(s)\, ds, \\ x_i &= \eta_i(\theta_i), \qquad i = 1, \cdots, N \end{aligned} \tag{1.7}$$

persists for all small $\delta > 0$. That is, a one-parameter family of invariant tori bifurcates from (1.6) under Assumption 1.1.

In the following section we show that, depending on the value of p, (1.4) can be transformed into one of the following systems of generalized phase-amplitude equations.

(a) $1 - 1/k \leq p < 1$,

$$\begin{aligned} \frac{d\sigma}{dt} &= \omega + \mathcal{S}(\sigma, w, z, \mu, \rho), \\ \frac{dw}{dt} &= A(\Omega^{-1}\sigma)w + \mathcal{W}(\sigma, w, z, \mu, \rho), \\ \frac{dz}{dt} &= \rho\mu\left[Qz + \mathcal{Z}(\sigma, w, z, \mu, \rho)\right]. \end{aligned} \tag{1.8}$$

(b) $0 < p < 1$,

$$\begin{aligned} \frac{d\sigma}{dt} &= \omega + \mathcal{S}(\sigma, w, z, \mu), \\ \frac{dw}{dt} &= A(\Omega^{-1}\sigma)w + \mathcal{W}(\sigma, w, z, \mu), \\ \frac{dz}{dt} &= \mu\left[Qz + \mathcal{Z}(\sigma, w, z, \mu)\right]. \end{aligned} \tag{1.9}$$

Here σ and w are scaled variables in the phase-amplitude coordinates and z is the deviation of x_0 from the average over T_0^N; thus $\sigma \in \mathbb{R}^N$, $w \in \mathbb{R}^{N_1}$ with $N_1 = M - N$, $z \in \mathbb{R}^{N_2}$. The parameters μ and ρ arise from a scaling of δ (cf. (2.9) and (2.10)), and $\mu \longrightarrow 0$ as $\delta \longrightarrow 0$. In both cases the invariant tori correspond to invariant manifolds of (1.8) and (1.9), and in both cases they are smooth in the natural parameterization for δ fixed. Furthermore, in the first case the tori are also smooth in a fractional power of δ.

The existence and the smoothness of invariant tori are established in §3 where we construct invariant manifolds of (1.8) and (1.9) that correspond to invariant tori of (1.4). This is done as follows. Let I be an open interval. For (1.8) we look for a pair of smooth mappings $q_\rho : \mathbb{R}^N \times I \longrightarrow \mathbb{R}^{N_1}$, $r_\rho : \mathbb{R}^N \times I \longrightarrow \mathbb{R}^{N_2}$, for some ρ such that for each $\mu \in I$, q_ρ and r_ρ are 2π-periodic in each component of $\sigma \in \mathbb{R}^N$, and the manifold defined by $w = q_\rho(\sigma, \mu)$, $z = r_\rho(\sigma, \mu)$ is an invariant manifold of (1.8). Similarly, for (1.9) we look for smooth mappings $q_\mu : \mathbb{R}^N \longrightarrow \mathbb{R}^{N_1}$, $r_\mu : \mathbb{R}^N \longrightarrow \mathbb{R}^{N_2}$, for all small $\mu > 0$ such that q_μ and r_μ are 2π-periodic in each component of $\sigma \in \mathbb{R}^N$, and the manifold defined by $w = q_\mu(\sigma)$, $z = r_\mu(\sigma)$ is an invariant manifold of (1.9). Such pairs are called integral manifolds in [5] and [6], and as we show in §3, these give rise to invariant tori of (1.4). Furthermore, the smoothness of the invariant tori is determined by the smoothness of the integral manifolds. In particular, integral manifolds that are smooth in the natural parameterization give rise to smooth invariant manifolds, and those that are also smooth in μ give rise to smooth invariant manifolds that vary smoothly with δ.

In §4 we study the asymptotic behavior of solutions of (1.8) in a neighborhood of the invariant manifold $w = q_\rho(\sigma, \mu)$, $z = r_\rho(\sigma, \mu)$. It is shown that for sufficiently

small $\mu > 0$ and $\rho > 0$, there is a neighborhood of the manifold in which solutions of (1.8) are attracted to the manifold at an exponential rate in time. We state and prove a similar result for (1.9). These results completely describe the behavior of solutions of (1.4) in a neighborhood of the perturbed torus. That is, for each small $\delta > 0$, there is a neighborhood of the perturbed torus in which solutions of (1.4) are attracted to it at an exponential rate in time. These neighborhoods shrink to (1.7) as $\delta \longrightarrow 0$ and the rates at which solutions are attracted to the perturbed tori tend to zero as $\delta \longrightarrow 0$.

The smoothness of integral manifolds in related systems was first studied carefully by Kelly in [11], where systems of the following type are analyzed.

$$\begin{aligned} \frac{d\theta}{dt} &= a + \epsilon\Theta(\theta, x, z, \epsilon), \\ \frac{dx}{dt} &= Ax + X(\theta, x, z, \epsilon), \\ \frac{dz}{dt} &= Cz + Z(\theta, x, z, \epsilon). \end{aligned} \tag{1.10}$$

The basic assumption made there is the following.

ASSUMPTION 1.2. (a) *A and C are constant square matrices in real canonical form, A has eigenvalues with negative real parts, C has eigenvalues with positive real parts, a is a constant vector.*

(b) *Θ, X, and Z are defined and k-times continuously differentiable in*

$$N_\delta = \{(\theta, x, z, \epsilon) : \theta \text{ arbitrary}, \|x\| + \|z\| + |\epsilon| < \delta\},$$

and ω_i-periodic in θ_i.

(c) *θ, X, and Z, and the Jacobian of X and Z vanish when $(x, z, \epsilon) = 0$.*

Under this assumption it is shown that (1.10) has an integral manifold $x = u(\theta, \epsilon)$, $z = w(\theta, \epsilon)$ which is k-times continuously differentiable. Note that the matrix A in (1.10) is a constant matrix, whereas we have studied in [15] and in this paper the existence and smoothness of integral manifolds of similar systems in which the counterpart is a function of one of the dependent variables. Furthermore, (1.10) does not degenerate at $\epsilon = 0$.

Systems related to (1.8), (1.9), or (2.7) are studied in [3], [5]–[7], [11], and [14]. For example, in [3] Diliberto considers the following systems:

$$\begin{aligned} \frac{d\theta}{dt} &= l + \Theta_1(\theta, y, \epsilon) + \Theta_2(\theta, \epsilon), \\ \frac{dy}{dt} &= B(\theta, \epsilon)y + a(\theta, \epsilon) + Y(\theta, y, \epsilon)y, \end{aligned} \tag{1.11}$$

$$\begin{aligned} \frac{d\theta}{dt} &= l + \epsilon\left[\Theta_1(\theta, y, \epsilon) + \Theta_2(\theta, \epsilon)\right], \\ \frac{dy}{dt} &= \epsilon\left[B(\theta, \epsilon)y + a(\theta, \epsilon) + Y(\theta, y, \epsilon)y\right], \end{aligned} \tag{1.12}$$

under the following assumption.

ASSUMPTION 1.3. (a) $\theta \in \mathbb{R}^N$, $y \in \mathbb{R}^M$, *and* l *is a constant vector.* $\Theta_1(\theta, y, \epsilon)$, $\Theta_2(\theta, \epsilon)$, $B(\theta, \epsilon)$, $a(\theta, \epsilon)$, *and* $Y(\theta, y, \epsilon)$ *are* ω_i*-periodic in* θ_i, *continuously differentiable in* (θ, y), *and continuous in* (θ, y, ϵ).

(b) $Y(\theta, 0, \epsilon) \equiv 0$ *and* $a(\theta, \epsilon) \longrightarrow 0$ *as* $\epsilon \longrightarrow 0$.

(c) *There is* $b > 0$ *such that* $(B(\theta, 0)y, y) \geq b\|y\|_2^2$ *for all* $y \in \mathbb{R}^M$, *and* $\lambda(\theta) < b$ *for all* θ, *where* $\lambda(\theta)$ *is an eigenvalue of*

$$\tfrac{1}{2}[\Omega(\theta) + \Omega^T(\theta)]$$

with

$$\Omega(\theta) = \frac{\partial \Theta_2}{\partial \theta}(\theta, 0).$$

It is shown that under this assumption (1.11) or (1.12) has an integral manifold $y = S(\theta, \epsilon)$, where S is continuous and $S(\theta, \epsilon) \longrightarrow 0$ as $\epsilon \longrightarrow 0$. The system at (1.12) degenerates at $\epsilon = 0$, as do the systems studied here, but the former lacks the normal component that appears in our equations. Furthermore, hypotheses like those in Assumption 1.3 are difficult to check in the original form (1.4) of the equations we study.

Systems similar to (1.8) or (1.9) have also been studied by Hale. The existence of Lipschitz continuous integral manifolds is established in [5] for the system

$$\begin{aligned} \frac{d\theta}{dt} &= d(\epsilon) + \Theta(t, \theta, y, x, \epsilon), \\ \frac{dy}{dt} &= Ay + Y(t, \theta, y, x, \epsilon), \\ \frac{dz}{dt} &= \epsilon C z + \epsilon Z(t, \theta, y, z, \epsilon). \end{aligned} \tag{1.13}$$

Similar results are obtained in [6] and [7]. However, the matrix A in (1.13) is a constant matrix, whereas the counterparts which appear in (1.8) and (1.9) are functions of one of the dependent variables. Moreover, some of the technical assumptions made for (1.13) are not met by the systems related to our degenerate problem, and therefore we cannot apply the existence result in [5] directly. Finally, the smoothness of the manifolds with respect to parameters is not studied in detail there, but smoothness with respect to parameters is important when investigating the flow on the manifolds.

2. Reduction of the equations. In this section we introduce transformations that convert (1.4) to suitable forms for the degenerate case. We first review the transformations introduced in [16]. For each $i = 1, \cdots, N$, there is an $n_i \times (n_i - 1)$-matrix $\Phi_i(\theta_i)$ each entry of which is a $(k+1)$-times continuously differentiable function of θ_i, with the following properties:

$$\begin{aligned} \Phi_i(\theta_i + T_i) &= \Phi_i(\theta_i), \\ \Phi_i(\theta_i)^T \Phi_i(\theta_i) &= I_{(n_i-1)\times(n_i-1)}, \\ f_i(\eta_i(\theta_i))^T \Phi_i(\theta_i) &= O_{1\times(n_i-1)} \end{aligned}$$

for all $\theta_i \in \mathbb{R}$. Then, for each x_i in a neighborhood of the orbit of (1.3), there are $\theta_i \in \mathbb{R}$ and $y_i \in \mathbb{R}^{n_i-1}$ such that

$$\eta_i(\theta_i) + \Phi_i(\theta_i)y_i - x_i = 0. \tag{2.1}$$

Equation (2.1) defines a transformation between a neighborhood of the torus T_0^N and $\mathbb{R} \times \mathcal{G}$ where $\mathcal{G}$ is a neighborhood of the origin in $\mathbb{R}^{N_1}$. Thus we can convert (1.4) to the system for θ, y, and x_0, where

$$\theta = \begin{pmatrix} \theta_1 \\ \vdots \\ \theta_N \end{pmatrix} \quad \text{and} \quad y = \begin{pmatrix} y_1 \\ \vdots \\ y_N \end{pmatrix}, \quad y_i \in \mathbb{R}^{n_i-1}, \quad i = 1, \cdots, N. \tag{2.2}$$

We can write x_0 as the average plus a deviation by defining $a : \mathbb{R}^N \times \mathbb{R} \longrightarrow \mathbb{R}^{N_2}$,

$$a(\theta, \mu) = \begin{cases} \mu \sum_{i=1}^{N} \left[I - e^{\mu B T_i}\right]^{-1} \int_0^{T_i} e^{-\mu B(s-T_i)} C_i \eta_i(\theta_i + s)\, ds, & \mu \neq 0, \\ -B^{-1} \sum_{i=1}^{N} C_i \dfrac{1}{T_i} \int_0^{T_i} \eta_i(s)\, ds, & \mu = 0, \end{cases} \tag{2.3}$$

and setting

$$x_0 = a(\theta, \epsilon\delta) + z. \tag{2.4}$$

Finally, define an N-dimensional vector ω and an $N \times N$-diagonal matrix Ω by

$$\omega = \begin{pmatrix} \omega_1 \\ \vdots \\ \omega_N \end{pmatrix} \text{ and } \Omega = \begin{bmatrix} \omega_1 & & \\ & \ddots & \\ & & \omega_N \end{bmatrix}, \text{ where } \omega_i = \frac{2\pi}{T_i},\ i = 1, \cdots, N, \tag{2.5}$$

and let

$$\sigma = \Omega\theta. \tag{2.6}$$

Using (2.1), (2.4), and (2.6), we obtain from (1.4) the following system of ordinary differential equations for σ, y, and z.

$$\begin{aligned} \frac{d\sigma}{dt} &= \omega + S(\sigma, y, z, \delta, \epsilon\delta), \\ \frac{dy}{dt} &= A(\Omega^{-1}\sigma)y + Y(\sigma, y, z, \delta, \epsilon\delta), \\ \frac{dz}{dt} &= \epsilon\delta \left[Bz + Z(\sigma, y, z, \delta, \epsilon\delta)\right]. \end{aligned} \tag{2.7}$$

Here $A(\theta)$ is the $N_1 \times N_1$ matrix defined by

$$A(\theta) = \bigoplus_{i=1}^{N} A_i(\theta_i),$$

where $A_i(\theta_i)$, $i = 1, \cdots, N$, is the $(n_i - 1) \times (n_i - 1)$ matrix defined by

$$A_i(\theta_i) = \Phi_i(\theta_i)^T [Df_i(\eta_i(\theta_i))\Phi_i(\theta_i) - \Phi_i'(\theta_i)].$$

S, Y, and Z are defined by

$$\begin{aligned}
S(\sigma, y, z, \delta, \mu) &= \Omega\Theta(\Omega^{-1}\sigma, y, z + a(\Omega^{-1}\sigma, \mu), \delta), \\
Y(\sigma, y, z, \delta, \mu) &= \mathcal{Y}(\Omega^{-1}\sigma, y, z + a(\Omega^{-1}\sigma, \mu), \delta), \\
Z(\sigma, y, z, \delta, \mu) &= C(\Omega^{-1}\sigma)y - b(\Omega^{-1}\sigma, \mu)\Theta(\Omega^{-1}\sigma, y, z + a(\Omega^{-1}\sigma, \mu), \delta),
\end{aligned}$$

where

$$\begin{aligned}
\Theta_i(\theta, y, x_0, \delta) = {} & \frac{f_i(\eta_i(\theta_i))^T f_i(\eta_i(\theta_i) + \Phi_i(\theta_i)y_i)}{f_i(\eta_i(\theta_i))^T [f_i(\eta_i(\theta_i)) + \Phi_i'(\theta_i)y_i]} - 1 \\
& + \delta \frac{f_i(\eta_i(\theta_i))^T g_i(x_0, \eta_1(\theta_1) + \Phi_1(\theta_1)y_1, \cdots, \eta_N(\theta_N) + \Phi_N(\theta_N)y_N, \delta)}{f_i(\eta_i(\theta_i))^T [f_i(\eta_i(\theta_i)) + \Phi_i'(\theta_i)y_i]}, \\
\mathcal{Y}_i(\theta, y, x_0, \delta) = {} & \Phi_i(\theta_i)^T [f_i(\eta_i(\theta_i) + \Phi_i(\theta_i)y_i) \\
& \qquad - Df_i(\eta_i(\theta_i))\Phi_i(\theta_i)y_i - \Theta_i(\theta, y, x_0, \delta)\Phi_i'(\theta_i)y_i] \\
& + \delta \Phi_i(\theta_i)^T g_i(x_0, \eta_1(\theta_1) + \Phi_1(\theta_1)y_1, \cdots, \eta_N(\theta_N) + \Phi_N(\theta_N)y_N, \delta),
\end{aligned}$$

and $\Theta(\theta, y, x_0, \delta) = (\Theta_1(\theta, y, x_0, \delta), \cdots, \Theta_N(\theta, y, x_0, \delta))^T$ and $\mathcal{Y}(\theta, y, x_0, \delta) = (\mathcal{Y}_1(\theta, y, x_0, \delta), \cdots, \mathcal{Y}_N(\theta, y, x_0, \delta))^T$. Finally, $C(\theta)$ is the $N_2 \times N_1$-matrix defined by

$$C(\theta) = [C_1\Phi_1(\theta_1) \cdots C_N\Phi_N(\theta_N)],$$

and $b(\theta, \mu)$ is the $N_2 \times N$-matrix defined by

$$\mu b(\theta, \mu) = \frac{\partial a}{\partial \theta}(\theta, \mu).$$

Under Assumption 1.1(b), each entry of $A(\theta)$ is a k-times continuously differentiable function of θ and a T_i-periodic function of θ_i for each $i = 1, \cdots, N$. It follows that each entry of $A(\Omega^{-1}\sigma)$ is a k-times continuously differentiable function of σ and 2π-periodic in each component of σ. Under Assumption 1.1(c), if $\Psi_i(\theta)$ is a fundamental matrix solution of

$$\frac{dy_i}{d\theta} = A_i(\theta)y_i,$$

then there are positive constants α_i and H_i such that

$$\|\Psi_i(\theta)\Psi_i^{-1}(\theta_0)\| \leq H_i e^{-\alpha_i(\theta - \theta_0)} \quad \text{for } \theta \geq \theta_0.$$

Here and hereafter we define the norm $\|x\|$ of $x \in \mathbb{R}^n$ by

$$\|x\| = \sum_{i=1}^{n} |x_i|,$$

where x_i is the ith component of x. The functions $S : \mathbb{R}^N \times \mathcal{G} \times \mathbb{R}^{N_2} \times \mathbb{R}^2 \longrightarrow \mathbb{R}^N$, $Y : \mathbb{R}^N \times \mathcal{G} \times \mathbb{R}^{N_2} \times \mathbb{R}^2 \longrightarrow \mathbb{R}^{N_1}$, and $Z : \mathbb{R}^N \times \mathcal{G} \times \mathbb{R}^{N_2} \times \mathbb{R}^2 \longrightarrow \mathbb{R}^{N_2}$ are k-times continuously differentiable. Moreover, they are 2π-periodic in each component of σ, and

$$\begin{aligned} S(\sigma, y, z, \delta, \mu) &\sim \mathcal{O}(\|y\| + |\delta|), \\ Y(\sigma, y, z, \delta, \mu) &\sim \mathcal{O}(\|y\|^2 + |\delta|), \\ Z(\sigma, y, z, \delta, \mu) &\sim \mathcal{O}(\|y\| + |\delta|). \end{aligned} \tag{2.8}$$

Remark 1. The Floquet reduction could be used to transform (2.7) further to a system in which the second equation becomes a perturbation of a linear system with constant coefficients. However, the periodicity in some of the components of σ might have to be doubled in the vector field obtained by the reduction, if the reduced system is to have real variables. In particular, the period in σ_i is doubled when the linear system

$$\frac{dy_i}{d\theta_i} = A_i(\theta_i) y_i$$

has a real negative multiplier. This reduction leads to no simplification in the analysis and is not used here.

Next we introduce scalings for y and δ that depend on p.

$$1 - \frac{1}{k} \leq p < 1 \quad : \quad y = \rho^{\kappa} \mu^{\nu} w, \quad \delta = \rho^{\nu} \mu^{\nu}, \quad 1 < \kappa < \nu, \tag{2.9}$$

$$0 < p < 1 \quad : \quad y = \mu^{\zeta} w, \quad \delta = \mu^{\nu}, \quad 1 < \zeta < \nu, \tag{2.10}$$

where

$$\nu = \frac{1}{1-p}. \tag{2.11}$$

Using (2.9) and (2.10), we obtain from (2.7) the following systems of equations (2.12) and (2.13), respectively.

$$\begin{aligned} \frac{d\sigma}{dt} &= \omega + S\left(\sigma, \rho^{\kappa} \mu^{\nu} w, z, \rho^{\nu} \mu^{\nu}, \epsilon_0 \rho \mu\right), \\ \frac{dw}{dt} &= A(\Omega^{-1}\sigma) w + \rho^{-\kappa} \mu^{-\nu} Y\left(\sigma, \rho^{\kappa} \mu^{\nu} w, z, \rho^{\nu} \mu^{\nu}, \epsilon_0 \rho \mu\right), \\ \frac{dz}{dt} &= \rho \mu \left[\epsilon_0 B z + \epsilon_0 Z\left(\sigma, \rho^{\kappa} \mu^{\nu} w, z, \rho^{\nu} \mu^{\nu}, \epsilon_0 \rho \mu\right)\right]. \end{aligned} \tag{2.12}$$

$$
\begin{aligned}
\frac{d\sigma}{dt} &= \omega + S\left(\sigma, \mu^{\zeta} w, z, \mu^{\nu}, \epsilon_0 \mu\right), \\
\frac{dw}{dt} &= A(\Omega^{-1}\sigma)w + \mu^{-\zeta} Y\left(\sigma, \mu^{\zeta} w, z, \mu^{\nu}, \epsilon_0 \mu\right), \\
\frac{dz}{dt} &= \mu\left[\epsilon_0 B z + \epsilon_0 Z\left(\sigma, \mu^{\zeta} w, z, \mu^{\nu}, \epsilon_0 \mu\right)\right].
\end{aligned} \tag{2.13}
$$

We have chosen the scalings (2.9) and (2.10) in order for the vector fields in (2.12) and (2.13) to satisfy the following conditions. In view of (2.8), the right-hand side of the first equation in (2.12) consists of ω and the term whose derivatives with respect to σ, w, z, and μ of order less than or equal to k are of the order $o(\rho)$ as $\rho \longrightarrow 0$. The right-hand side of the second equation and the terms inside the brackets of the third equation consist of the linear terms and the terms whose derivatives tend to zero as $\rho \longrightarrow 0$. The derivatives of the nonlinear terms in (2.13) with respect to σ, w, and z satisfy similar order estimates with respect to μ.

Equations (2.12) and (2.13) are special cases of the equations given at (1.8) and (1.9), respectively, and as was indicated above, they satisfy the conditions stated in Assumption 2.1 below. Hereafter we analyze (1.8) and (1.9) under Assumption 2.1, but we note that (2.12) satisfies Assumption 2.1 (a)–(e), while (2.13) satisfies Assumption 2.1 (a)–(c) and (f).

ASSUMPTION 2.1. (a) *$A(\theta)$ is an $N_1 \times N_1$-matrix that has the form*

$$A(\theta) = \bigoplus_{i=1}^{N} A_i(\theta_i),$$

where for each i, $A_i(\theta_i)$ is an $(n_i - 1) \times (n_i - 1)$-matrix each entry of which is a k-times continuously differentiable T_i-periodic function of θ_i and there are $\alpha_i, H_i > 0$ such that if $\Psi_i(\theta)$ is a fundamental matrix solution of

$$\frac{dy_i}{d\theta} = A_i(\theta) y_i,$$

there are positive constants α_i and H_i such that

$$\|\Psi_i(\theta)\Psi_i^{-1}(\theta_0)\| \leq H_i e^{-\alpha_i(\theta-\theta_0)} \quad \text{for } \theta \geq \theta_0.$$

(b) *The spectrum of Q lies in the left-half complex plane. Thus there are positive constants β_2 and K_2 such that for $t \geq s$,*

$$\left\| e^{Q(t-s)} \right\| \leq K_2 e^{-\beta_2(t-s)}.$$

(c) *The N-dimensional vector ω and the $N \times N$-matrix Ω are defined by* (2.5).

(d) *There are neighborhoods F_1 and F_2 of the origin in $\mathbb{R}^{N_1}$ and $\mathbb{R}^{N_2}$, respectively, and open intervals I and I_1 such that if $E = \mathbb{R}^N \times F_1 \times F_2 \times I$,*

$$
\begin{aligned}
\mathcal{S} &: E \times I_1 \longrightarrow \mathbb{R}^N, \\
\mathcal{W} &: E \times I_1 \longrightarrow \mathbb{R}^{N_1}, \\
\mathcal{Z} &: E \times I_1 \longrightarrow \mathbb{R}^{N_2}.
\end{aligned}
$$

For each $\rho \in I_1$, $\mathcal{S}$, $\mathcal{W}$, *and* $\mathcal{Z}$ *are* 2π*-periodic in each component of* σ *and* k*-times continuously differentiable in* E. *There are* $\lambda(\rho)$ *and* $\lambda_i(\rho)$, $i = 1, 2$, *such that if* $0 \leq m_1 + m_2 + m_3 + m_4 \leq k$

$$\left\| \frac{\partial^{m_1+m_2+m_3+m_4}\mathcal{S}}{\partial\sigma^{m_1}\partial w^{m_2}\partial z^{m_3}\partial\mu^{m_4}}(\sigma, w, z, \mu, \rho) \right\| \leq \lambda(\rho)\mu^{k-m_4},$$

$$\left\| \frac{\partial^{m_1+m_2+m_3+m_4}\mathcal{W}}{\partial\sigma^{m_1}\partial w^{m_2}\partial z^{m_3}\partial\mu^{m_4}}(\sigma, w, z, \mu, \rho) \right\| \leq \lambda_1(\rho),$$

$$\left\| \frac{\partial^{m_1+m_2+m_3+m_4}\mathcal{Z}}{\partial\sigma^{m_1}\partial w^{m_2}\partial z^{m_3}\partial\mu^{m_4}}(\sigma, w, z, \mu, \rho) \right\| \leq \lambda_2(\rho)\mu^{k-m_4}$$

for all $(\sigma, w, z, \mu) \in E$, *and*

$$\frac{\lambda(\rho)}{\rho} \longrightarrow 0,$$
$$\lambda_i(\rho) \longrightarrow 0, \qquad i = 1, 2$$

as $\rho \longrightarrow 0$.

(e)

$$\mathcal{W}(\sigma, 0, 0, \mu, \rho) \longrightarrow 0, \quad \mathcal{Z}(\sigma, 0, 0, \mu, \rho) \longrightarrow 0,$$

as $\mu \longrightarrow 0$ *for all* $\sigma \in \mathbb{R}^N$ *and* $\rho \in I_1$.

(f) *There are neighborhoods* F_1 *and* F_2 *of the origin in* $\mathbb{R}^{N_1}$ *and* $\mathbb{R}^{N_2}$, *respectively, and an open interval* $I = (0, \mu_0)$ *such that if* $E = \mathbb{R}^N \times F_1 \times F_2$,

$$\mathcal{S} : E \times I \longrightarrow \mathbb{R}^N, \quad \mathcal{W} : E \times I \longrightarrow \mathbb{R}^{N_1}, \quad \mathcal{Z} : E \times I \longrightarrow \mathbb{R}^{N_2}.$$

For each $\mu \in I$, $\mathcal{S}$, $\mathcal{W}$, *and* $\mathcal{Z}$ *are* 2π*-periodic each component of* σ *and* k*-times continuously differentiable in* E, *and there are* $\lambda(\mu)$ *and* $\lambda_i(\mu)$, $i = 1, 2$, *such that if* $0 \leq m_1 + m_2 + m_3 \leq k$,

$$\left\| \frac{\partial^{m_1+m_2+m_3}\mathcal{S}}{\partial\sigma^{m_1}\partial w^{m_2}\partial z^{m_3}}(\sigma, w, z, \mu) \right\| \leq \lambda(\mu),$$

$$\left\| \frac{\partial^{m_1+m_2+m_3}\mathcal{W}}{\partial\sigma^{m_1}\partial w^{m_2}\partial z^{m_3}}(\sigma, w, z, \mu) \right\| \leq \lambda_1(\mu),$$

$$\left\| \frac{\partial^{m_1+m_2+m_3}\mathcal{Z}}{\partial\sigma^{m_1}\partial w^{m_2}\partial z^{m_3}}(\sigma, w, z, \mu) \right\| \leq \lambda_2(\mu)$$

for all $(\sigma, w, x) \in E$, *and*

$$\frac{\lambda(\mu)}{\mu}, \lambda_1(\mu), \frac{\lambda_2(\mu)}{\mu} \longrightarrow 0$$

as $\mu \longrightarrow 0$.

Remark 2. In what follows we assume without loss of generality that $I \subseteq (-1, 1)$. We also assume that $0 \in I$ whenever the statement $\mu \longrightarrow 0$ appears.

We summarize the results concerning the transformations for the degenerate problem in the following proposition.

PROPOSITION 2.2. *Suppose that the conditions stated in Assumption* 1.1(a), (b), *and* (d) *are satisfied with* $0 < p < 1$. *Using the transformations defined by* (2.1), (2.4), *and* (2.6), *we obtain from* (1.4) *the system of ordinary differential equations* (2.7) *for* σ, y, *and* z. *Further, when* $1 - 1/k \leq p < 1$, *we obtain* (2.12) *from* (2.7) *using* (2.9). *Equation* (2.12) *has the form* (1.8) *and satisfies the conditions stated in Assumption* 2.1(a)–(e). *When* $0 < p < 1$, *we obtain* (2.13) *from* (2.7) *using* (2.10). *Equation* (2.13) *has the form* (1.9) *and satisfies the conditions stated in Assumption* 2.1(a)–(c) *and* (f).

We recover the solutions of (1.4) from the solutions of (2.12) and (2.13) by the transformations (2.1), (2.4), (2.6), (2.9), and (2.10). Therefore integral manifolds of (2.12) and (2.13) generate invariant tori via these transformations. We summarize the relation between the integral manifolds of (2.13) and invariant tori of (1.4) in the following proposition.

PROPOSITION 2.3. (a) *If the pair* $w = q_\rho(\sigma, \mu)$, $z = r_\rho(\sigma, \mu)$ *is an integral manifold of* (2.12), *then*

$$
\begin{aligned}
x_i &= \eta_i(\omega_i^{-1}\sigma_i) + \rho^\kappa \mu^\nu \Phi_i(\omega_i^{-1}\sigma_i) q_{\rho,i}(\sigma, \mu), \qquad i = 1, \cdots, N, \\
x_0 &= r_\rho(\sigma, \mu) + a(\Omega^{-1}\sigma, \epsilon_0 \rho \mu), \\
\mu &= \frac{\delta^{1-p}}{\rho}
\end{aligned}
\tag{2.14}
$$

is an invariant torus of (1.4) *for* $1 - 1/k \leq p < 1$.

(b) *If the pair* $w = q_\mu(\sigma)$, $z = r_\mu(\sigma)$ *is an integral manifold of* (2.13), *then*

$$
\begin{aligned}
x_i &= \eta_i(\omega_i^{-1}\sigma_i) + \mu^\zeta \Phi_i(\omega_i^{-1}\sigma_i) q_{\mu,i}(\sigma), \qquad i = 1, \cdots, N, \\
x_0 &= r_\mu(\sigma) + a(\Omega^{-1}\sigma, \epsilon_0 \mu), \\
\mu &= \delta^{1-p}
\end{aligned}
\tag{2.15}
$$

is an invariant torus of (1.4) *for* $0 < p < 1$.

$q_{\rho,i}(\sigma, \mu)$ *and* $q_{\mu,i}(\sigma)$ *are the components of* $q_\rho(\sigma, \mu)$ *and* $q_\mu(\sigma)$, *respectively, which correspond to components* y_i *of* y *in* (2.2).

Remark 3. In view of (2.3), the one-parameter families of invariant tori given in Proposition 2.3 bifurcate from (1.7) when the integral manifolds tend to zero as $\mu \longrightarrow 0$.

The existence of integral manifolds for (1.8) and (1.9) under Assumption 2.1 will be established in §3.

3. Existence of invariant tori in the perturbed system. In this section we prove the existence and smoothness of integral manifolds for (1.8) under Assumption 2.1(a)–(e). We also prove their existence and smoothness for (1.9) under Assumption 2.1(a)–(c) and (f). The technique which we use to construct the integral manifolds is an extension of those used in [5], [3], and [11]. The construction is done as follows. We define a map on a closed subset of a suitable Banach space of functions, and show that the map has a fixed point. This fixed point is an integral manifold of (1.8) or (1.9), as the case may be.

Let $\mathcal{PC}^k(\mathbb{R}^m \times I, \mathbb{R}^n)$ be the set of all k-times continuously differentiable mappings $s : \mathbb{R}^m \times I \longrightarrow \mathbb{R}^n$ endowed with the norm

$$\|s\|_k = \max_{0 \le i+j \le k} \sup \left\{ \left\| \frac{\partial^{i+j} s}{\partial \sigma^i \partial \mu^j}(\sigma, \mu) \right\| : \sigma \in \mathbb{R}^m, \mu \in I \right\} < \infty$$

and such that

$$s(\sigma + 2\pi e^i, \mu) = s(\sigma, \mu) \quad \text{for all } \sigma \in \mathbb{R}^m \text{ and } i = 1, \cdots, m,$$

where e^i is the ith unit coordinate vector in $\mathbb{R}^m$. Then $\mathcal{PC}^k(\mathbb{R}^m \times I, \mathbb{R}^n)$ is a Banach space (cf. [2], [11]). Let $\mathcal{B}^k_\Delta(I, m, n)$ be the closed ball in $\mathcal{PC}^k(\mathbb{R}^m \times I, \mathbb{R}^n)$ with radius Δ and center at the origin. For (1.8), let $\phi(t, \sigma^0, \mu, q, r, \rho)$ be the solution of

$$\frac{d\sigma}{dt} = \omega + \mathcal{S}(\sigma, q(\sigma, \mu), r(\sigma, \mu), \mu, \rho), \qquad \phi(0, \sigma^0, \mu, q, r, \rho) = \sigma^0, \tag{3.1}$$

where $(q, r) \in \mathcal{B}^k_\Delta(I, N, N_1) \times \mathcal{B}^k_\Delta(I, m, n)$. We will choose I, Δ, and ρ in such a way that this definition makes sense. Then let $\Lambda(t, t_0, \sigma^0, \mu, q, r, \rho)$ be the fundamental matrix solution of

$$\frac{dw}{dt} = A(\Omega^{-1}\phi(t, \sigma^0, \mu, q, r, \rho))w, \qquad \Lambda(t_0, t_0, \sigma^0, \mu, q, r, \rho) = I_{N_1 \times N_1}. \tag{3.2}$$

The properties of $\phi(t, \sigma^0, \mu, q, r, \rho)$ and $\Lambda(t, t_0, \sigma^0, \mu, q, r, \rho)$ are studied in the Appendix. By Lemmas 5.1–5.11, which we prove in the Appendix, $\phi(t, \sigma^0, \mu, q, r, \rho)$ and $\Lambda(t, t_0, \sigma^0, \mu, q, r, \rho)$ are k-times continuously differentiable with respect to t, t_0, σ^0, and μ, and have the following properties.

PROPERTY 3.1. There are positive constants ρ_1, $K_{l,m}$, $\widehat{K}_{l,m}$, $C_{l,m}$, $\widehat{C}_{l,m}$, H, and β_1 such that for $0 < \rho \le \rho_1$ and $s \le 0$ the following holds.

(a)

$$\left\| \frac{\partial \phi}{\partial \sigma^0}(s, \sigma^0, \mu, q, r, \rho) \right\| \le e^{-\lambda(\rho)\mu^k(1+2\Delta)s}.$$

(b) For $2 \le l + 2m$ and $l + m \le k$,

$$\left\| \frac{\partial^{l+m}\phi}{\partial \sigma^0_{i_1} \cdots \partial \sigma^0_{i_l} \partial \mu^m}(s, \sigma^0, \mu, q, r, \rho) \right\|$$

$$\le K_{l,m}\mu^{-m} \left\{ \sum_{i=1}^{l+2m-1} \left[\lambda(\rho)\mu^k(-s)\right]^i \right\} e^{-(l+m)\lambda(\rho)\mu^k(1+2\Delta)s}.$$

(c) For $0 \le l + m \le k - 1$,

$$\left\| \frac{\partial^{l+m}\phi}{\partial \sigma^0_{i_1} \cdots \partial \sigma^0_{i_l} \partial \mu^m}(s, \sigma^0, \mu, q_1, r_1, \rho) - \frac{\partial^{l+m}\phi}{\partial \sigma^0_{i_1} \cdots \partial \sigma^0_{i_l} \partial \mu^m}(s, \sigma^0, \mu, q_2, r_2, \rho) \right\|$$

$$\le \widehat{K}_{l,m} \left(\|q_1 - q_2\|_{l+m} + \|r_1 - r_2\|_{l+m} \right)$$

$$\times \mu^{-m} \left\{ \sum_{i=1}^{l+2m+1} \left[\lambda(\rho)\mu^k(-s)\right]^i \right\} e^{-(l+m+1)\lambda(\rho)\mu^k(1+2\Delta)s}.$$

(d)

$$\|\Lambda(0,s,\sigma^0,\mu,q,r,\rho)\| \le K_1 e^{[\beta_1 - H\lambda(\rho)\mu^k]s}.$$

(e) For $1 \le l+m \le k$,

$$\left\|\frac{\partial^{l+m}\Lambda}{\partial\sigma^0_{i_1}\cdots\partial\sigma^0_{i_l}\partial\mu^m}(0,s,\sigma^0,\mu,q,r,\rho)\right\| \le C_{l,m}\left[\sum_{i=1}^{l+2m}(-s)^i\right]e^{\{\beta_1-[H+(l+m)(1+2\Delta)]\lambda(\rho)\mu^k\}s}.$$

(f) For $0 \le l+m \le k-1$,

$$\left\|\frac{\partial^{l+m}\Lambda}{\partial\sigma^0_{i_1}\cdots\partial\sigma^0_{i_l}\partial\mu^m}(0,s,\sigma^0,\mu,q_1,r_1,\rho) - \frac{\partial^{l+m}\Lambda}{\partial\sigma^0_{i_1}\cdots\partial\sigma^0_{i_l}\partial\mu^m}(0,s,\sigma^0,\mu,q_2,r_2,\rho)\right\|$$
$$\le \widehat{C}_{l,m}\left(\|q_1-q_2\|_{l+m} + \|r_1-r_2\|_{l+m}\right)$$
$$\times\left[\sum_{i=2}^{l+2m+2}(-s)^i\right]e^{\{\beta_1-[H+(l+m+1)(1+2\Delta)]\lambda(\rho)\mu^k\}s}.$$

Estimates in Property 3.1(a)–(c) will be crucial in the contraction mapping argument used later.

To establish the existence of integral manifolds we define a mapping $S_\rho = (S_{\rho,1}, S_{\rho,2})$ on $\mathcal{B}^k_\Delta(I,N,N_1)\times\mathcal{B}^k_\Delta(I,N,N_2)$ by

$$\begin{aligned} S_{\rho,1}(q,r)(\sigma,\mu) &= \int_{-\infty}^0 G_1(s,\sigma,\mu,q,r,\rho)\,ds, \\ S_{\rho,2}(q,r)(\sigma,\mu) &= \int_{-\infty}^0 G_2(s,\sigma,\mu,q,r,\rho)\,ds, \end{aligned} \tag{3.3}$$

where

$$\begin{aligned} G_1(s,\sigma,\mu,q,r,\rho) &= \Lambda(0,s,\sigma,\mu,q,r,\rho)\mathcal{W}(\phi(s),q(\phi(s),\mu),r(\phi(s),\mu),\mu,\rho), \\ G_2(s,\sigma,\mu,q,r,\rho) &= \rho\mu e^{-\rho\mu Q s}\mathcal{Z}(\phi(s),q(\phi(s),\mu),r(\phi(s),\mu),\mu,\rho) \\ \phi(s) &= \phi(s,\sigma,\mu,q,r,\rho). \end{aligned} \tag{3.4}$$

We will show that for sufficiently small $|\rho|$, S_ρ has a fixed point in $\mathcal{PC}^{k-1}(\mathbb{R}^N\times I,\mathbb{R}^{N_1})\times\mathcal{PC}^{k-1}(\mathbb{R}^N\times I,\mathbb{R}^{N_2})$, and that this fixed point is an integral manifold of (1.8).

In the remainder of this section we assume that $0<\rho\le\rho_1$ is fixed and ρ_1 is sufficiently small. By Assumption 2.1(d), we may also assume without loss of generality that

$$\lambda(\rho) \le \rho \quad \text{for } 0<\rho\le\rho_1. \tag{3.5}$$

We summarize the results, which concern some estimates associated with $G_1(s,\sigma,\mu,q,r,\rho)$ and $G_2(s,\sigma,\mu,q,r,\rho)$, in the following lemmas. The proofs are given in the Appendix.

LEMMA 3.2. *For $0 \le l+m \le k$ there is a positive constant K such that for $s \le 0$,*

$$\left\| \frac{\partial^{l+m} G_1}{\partial\sigma_{i_1}\cdots\partial\sigma_{i_l}\partial\mu^m}(s,\sigma,\mu,q,r,\rho) \right\| \le K\lambda_1(\rho)\left[\sum_{i=0}^{l+2m}(-s)^i\right] e^{\{\beta_1-[H+(l+m)(1+2\Delta)]\lambda(\rho)\mu^k\}s}, \tag{3.6}$$

$$\left\| \frac{\partial^{l+m} G_2}{\partial\sigma_{i_1}\cdots\partial\sigma_{i_l}\partial\mu^m}(s,\sigma,\mu,q,r,\rho) \right\| \le K\lambda_2(\rho)\mu^{k-m}\left[\sum_{i=0}^{l+2m}(\rho\mu)^{i+1}(-s)^i\right] e^{[\rho\mu\beta_2-(l+m)\lambda(\rho)\mu^k(1+2\Delta)]s}. \tag{3.7}$$

LEMMA 3.3. *For $0 \le l+m \le k-1$ there is a positive constant C such that for $s \le 0$,*

$$\left\| \frac{\partial^{l+m} G_1}{\partial\sigma_{i_1}\cdots\partial\sigma_{i_l}\partial\mu^m}(s,\sigma,\mu,q_1,r_1,\rho) - \frac{\partial^{l+m} G_1}{\partial\sigma_{i_1}\cdots\partial\sigma_{i_l}\partial\mu^m}(s,\sigma,\mu,q_2,r_2,\rho) \right\|$$

$$\le C\lambda_1(\rho)\left(\|q_1-q_2\|_{l+m}+\|r_1-r_2\|_{l+m}\right) \times\left[\sum_{i=0}^{l+2m+2}(-s)^i\right] e^{\{\beta_1-[H+(l+m+1)(1+2\Delta)]\lambda(\rho)\mu^k\}s}, \tag{3.8}$$

$$\left\| \frac{\partial^{l+m} G_2}{\partial\sigma_{i_1}\cdots\partial\sigma_{i_l}\partial\mu^m}(s,\sigma,\mu,q_1,r_1,\rho) - \frac{\partial^{l+m} G_2}{\partial\sigma_{i_1}\cdots\partial\sigma_{i_l}\partial\mu^m}(s,\sigma,\mu,q_2,r_2,\rho) \right\|$$

$$\le C\lambda_2(\rho)\mu^{k-m}\left(\|q_1-q_2\|_{l+m}+\|r_1-r_2\|_{l+m}\right) \times\left[\sum_{i=0}^{l+2m+2}(\rho\mu)^{i+1}(-s)^i\right] e^{[\rho\mu\beta_2-(l+m+1)\lambda(\rho)\mu^k(1+2\Delta)]s}. \tag{3.9}$$

Now we are ready to state and prove one of the main results.

THEOREM 3.4. *Under Assumptions* 2.1(a)–(d), *there is $\rho_0 > 0$ such that for $0 < \rho \le \rho_0$ S_ρ, defined by* (3.3) *and* (3.4) *maps $\mathcal{B}^k_\Delta(I,N,N_1)\times\mathcal{B}^k_\Delta(I,N,N_2)$ into itself and has a unique fixed point (q_ρ,r_ρ) in the closure of $\mathcal{B}^k_\Delta(I,N,N_1)\times\mathcal{B}^k_\Delta(I,N,N_2)$ in $\mathcal{PC}^{k-1}(\mathbb{R}^N\times I,\mathbb{R}^{N_1})\times\mathcal{PC}^{k-1}(\mathbb{R}^N\times I,\mathbb{R}^{N_2})$. (q_ρ,r_ρ) is an integral manifold of* (1.8) *such that, if $0 \le l+m \le k-1$,*

$$\frac{\partial^{l+m} r_\rho}{\partial\sigma^l\partial\mu^m}(\sigma,\mu) \longrightarrow 0 \tag{3.10}$$

as $\mu \longrightarrow 0$. *Moreover,* q_ρ *and* r_ρ *satisfy the system of first-order quasilinear partial differential equations*

$$\begin{aligned} &\frac{\partial q_\rho}{\partial \sigma}\,[\omega + \mathcal{S}(\sigma^\star, q_\rho, r_\rho, \mu, \rho)] = A(\Omega^{-1}\sigma^\star)q_\rho + \mathcal{W}(\sigma^\star, q_\rho, r_\rho, \mu, \rho), \\ &\frac{\partial r_\rho}{\partial \sigma}\,[\omega + \mathcal{S}(\sigma^\star, q_\rho, r_\rho, \mu, \rho)] = \rho\mu\,[Qr_\rho + \mathcal{Z}(\sigma^\star, q_\rho, r_\rho, \mu, \rho)] \end{aligned} \tag{3.11}$$

$(at\ \sigma = \sigma^\star)$. *In addition, under Assumption* 2.1(e),

$$q_\rho(\sigma, \mu) \longrightarrow 0 \quad as\ \mu \longrightarrow 0 \quad for\ all\ \sigma \in \mathbb{R}^N. \tag{3.12}$$

Proof. Choose ρ_0 such that $0 < \rho_0 \leq \rho_1$ and for $0 < \rho \leq \rho_0$,

$$\beta_1 \geq 2[H + k(1 + 2\Delta)]\lambda(\rho), \tag{3.13}$$

$$\beta_2 \geq 2k(1 + 2\Delta)\frac{\lambda(\rho)}{\rho}, \tag{3.14}$$

$$K\lambda_j(\rho)\left[\sum_{i=0}^{2k} \frac{2^{i+1}i!}{\beta_j^{i+1}}\right] \leq \Delta, \qquad j = 1, 2, \tag{3.15}$$

$$C\lambda_j(\rho)\left[\sum_{i=0}^{2k} \frac{2^{i+1}i!}{\beta_j^{i+1}}\right] \leq \frac{1}{4}, \qquad j = 1, 2. \tag{3.16}$$

By Lemma 5.1, (3.13), and (3.14), $S_\rho(q, r) \in \mathcal{PC}^k(\mathbb{R}^N \times I, \mathbb{R}^{N_1}) \times \mathcal{PC}^k(\mathbb{R}^N \times I, \mathbb{R}^{N_2})$ (cf. [11]). By Lemma 3.2 and (3.15), $S_\rho(q, r) \in \mathcal{B}_\Delta^k(I, N, N_1) \times \mathcal{B}_\Delta^k(I, N, N_2)$. By Lemma 3.3 and (3.16), S_ρ is a contraction in $\mathcal{PC}^{k-1}(\mathbb{R}^N \times I, \mathbb{R}^{N_1}) \times \mathcal{PC}^{k-1}(\mathbb{R}^N \times I, \mathbb{R}^{N_2})$. The existence of a pair (q_ρ, r_ρ) now follows from these facts.

It is shown in [3] that such a pair (q_ρ, r_ρ) defines an integral manifold. However the proof is easy and we include it for completeness. It is easily shown that

$$\phi(s, \phi(t, \sigma^0, \mu, q, r, \rho), \mu, q, r, \rho) = \phi(s + t, \sigma^0, \mu, q, r, \rho),$$

$$\Lambda(0, s, \phi(t, \sigma^0, \mu, q, r, \rho), \mu, q, r, \rho) = \Lambda(t, s + t, \sigma^0, \mu, q, r, \rho).$$

It follows that

$$\begin{aligned} q(\phi(t), \mu) &= \int_{-\infty}^{0} \Lambda(t, s + t)\mathcal{W}(\phi(s + t), q(\phi(s + t), \mu), r(\phi(s + t), \mu), \mu, \rho)\, ds \\ &= \int_{-\infty}^{t} \Lambda(t, s)\mathcal{W}(\phi(s), q(\phi(s), \mu), r(\phi(s), \mu), \mu, \rho)\, ds, \end{aligned}$$

$$\begin{aligned} r(\phi(t), \mu) &= \int_{-\infty}^{0} e^{-Qs}\mathcal{Z}(\phi(s + t), q(\phi(s + t), \mu), r(\phi(s + t), \mu), \mu, \rho)\, ds \\ &= \int_{-\infty}^{t} e^{Q(t-s)}\mathcal{Z}(\phi(s), q(\phi(s), \mu), r(\phi(s), \mu), \mu, \rho)\, ds. \end{aligned}$$

This shows that

$$\sigma = \phi(t, \sigma^0, \mu, q, r, \rho), \quad w = q(\phi(t, \sigma^0, \mu, q, r, \rho), \mu), \quad z = r(\phi(t, \sigma^0, \mu, q, r, \rho), \mu)$$

is a solution of (1.8) (cf. [1]). Thus (q_ρ, r_ρ) is an integral manifold. Moreover, by Lemma 3.2,

$$\left\| \frac{\partial^{l+m} r_\rho}{\partial \sigma^l \partial \mu^m}(\sigma, \mu) \right\| \leq \Delta \mu^{k-m} \tag{3.17}$$

for $0 \leq l + m \leq k - 1$. Now (3.10) follows from (3.17). Equation (3.11) follows from the fact that the manifold defined by $w = q_\rho(\sigma, \mu)$, $z = r_\rho(\sigma, \mu)$ is an invariant manifold of (1.8) (cf. Part I). When $\mathcal{W}$ and $\mathcal{Z}$ satisfy Assumption 2.1(e), we consider the restriction of S_ρ to the closed subspace of $\mathcal{PC}^k(\mathbb{R}^N \times I, \mathbb{R}^{N_1}) \times \mathcal{PC}^k(\mathbb{R}^N \times I, \mathbb{R}^{N_2})$ consisting of all (q, r) such that

$$q(\sigma, \mu) \longrightarrow 0, \qquad r(\sigma, \mu) \longrightarrow 0,$$

as $\mu \longrightarrow 0$ and obtain (3.12). □

COROLLARY 3.5. *Under Assumption* 1.1, *for* $1 - 1/k \leq p < 1$, *there is a* $\delta_1 > 0$ *such that for fixed* $\delta \in (0, \delta_1)$, (1.4) *has a* C^{k-1} *invariant torus given by Proposition* 2.3(a) *and Theorem* 3.4. *The invariant tori are* $(k-1)$*-times continuously differentiable in* δ^{1-p}, *and they bifurcate from the invariant torus of the unperturbed system defined by* (1.7).

The construction of an integral manifold of (1.9) is similar. Let $\mathcal{PC}^k(\mathbb{R}^m, \mathbb{R}^n)$ be the Banach space of all k-times continuously differentiable mappings $s : \mathbb{R}^m \longrightarrow \mathbb{R}^n$ such that

$$\|s\|_k = \max_{0 \leq i \leq k} \sup \left\{ \left\| \frac{\partial^i s}{\partial \sigma^i}(\sigma) \right\| : \sigma \in \mathbb{R}^m \right\} < \infty,$$

and for each $i = 1, \cdots, m$,

$$s(\sigma + 2\pi e^i) = s(\sigma) \quad \text{for all } \sigma \in \mathbb{R}^m.$$

Let $\mathcal{B}^k_\Delta(m, n)$ be the closed ball in $\mathcal{PC}^k(\mathbb{R}^m, \mathbb{R}^n)$ with radius Δ and center at the origin. Let $\phi(t, \sigma^0, q, r, \mu)$ be the solution of

$$\frac{d\sigma}{dt} = \omega + \mathcal{S}(\sigma, q(\sigma), r(\sigma), \mu), \qquad \phi(0, \sigma^0, q, r, \mu) = \sigma^0, \tag{3.18}$$

where $(q, r) \in \mathcal{B}^k_\Delta(N, N_1) \times \mathcal{B}^k_\Delta(N, N_2)$. Then let $\Lambda(t, t_0, \sigma^0, q, r, \mu)$ be the fundamental matrix solution of

$$\frac{dw}{dt} = A(\Omega^{-1}\phi(t, \sigma^0, q, r, \mu))w, \qquad \Lambda(t_0, t_0, \sigma^0, q, r, \mu) = I_{N_1 \times N_1}. \tag{3.19}$$

We define a mapping $S_\mu = (S_{\mu,1}, S_{\mu,2})$ on $\mathcal{B}^k_\Delta(N, N_1) \times \mathcal{B}^k_\Delta(N, N_2)$ by

$$
\begin{aligned}
S_{\mu,1}(q,r)(\sigma) &= \int_{-\infty}^{0} G_1(s,\sigma,q,r,\mu)\,ds, \\
S_{\mu,2}(q,r)(\sigma) &= \int_{-\infty}^{0} G_2(s,\sigma,q,r,\mu)\,ds,
\end{aligned} \tag{3.20}
$$

where

$$
\begin{aligned}
G_1(s,\sigma,q,r,\mu) &= \Lambda(0,s,\sigma,q,r,\mu)\mathcal{W}(\phi(s),q(\phi(s)),r(\phi(s)),\mu), \\
G_2(s,\sigma,q,r,\mu) &= \mu e^{-\mu Q s}\mathcal{Z}(\phi(s),q(\phi(s)),r(\phi(s)),\mu), \\
\phi(s) &= \phi(s,\sigma,q,r,\mu).
\end{aligned} \tag{3.21}
$$

We will show that for all sufficiently small $\mu > 0$, S_μ has a fixed point in $\mathcal{PC}^{k-1}(\mathbb{R}^N, \mathbb{R}^{N_1}) \times \mathcal{PC}^{k-1}(\mathbb{R}^N, \mathbb{R}^{N_2})$ and that this fixed point is an integral manifold of (1.9).

THEOREM 3.6. *Under Assumptions* 2.1(a)–(c) *and* (f), *there is* $\mu_0 > 0$ *such that for* $0 < \mu \le \mu_0$ S_μ, *defined by* (3.20) *and* (3.21), *maps* $\mathcal{B}_\Delta^k(N,N_1) \times \mathcal{B}_\Delta^k(N,N_2)$ *into itself and has a unique fixed point* (q_μ, r_μ) *in the closure of* $\mathcal{B}_\Delta^k(N,N_1) \times \mathcal{B}_\Delta^k(N,N_2)$ *in* $\mathcal{PC}^{k-1}(\mathbb{R}^N, \mathbb{R}^{N_1}) \times \mathcal{PC}^{k-1}(\mathbb{R}^N, \mathbb{R}^{N_2})$. (q_μ, r_μ) *is an integral manifold of* (1.9) *such that if* $0 \le l \le k-1$

$$
\frac{\partial^l q_\mu}{\partial \sigma^l}(\sigma) \longrightarrow 0, \qquad \frac{\partial^l r_\mu}{\partial \sigma^l}(\sigma) \longrightarrow 0,
$$

as $\mu \longrightarrow 0$. *Moreover,* q_μ *and* r_μ *satisfy the system of first-order quasilinear partial differential equations*

$$
\frac{\partial q_\mu}{\partial \sigma}\left[\omega + \mathcal{S}(\sigma^\star, q_\mu, r_\mu, \mu)\right] = A(\Omega^{-1}\sigma^\star)q_\mu + \mathcal{W}(\sigma^\star, q_\mu, r_\mu, \mu),
$$

$$
\frac{\partial r_\mu}{\partial \sigma}\left[\omega + \mathcal{S}(\sigma^\star, q_\mu, r_\mu, \mu)\right] = \mu\left[Q r_\mu + \mathcal{Z}(\sigma^\star, q_\mu, r_\mu, \mu)\right]
$$

$(at\ \sigma = \sigma^\star)$.

Proof. One derives estimates similar to those given in Lemmas 3.2 and 3.3 using Property 5.13 given in Appendix and then repeats the argument in the proof of Theorem 3.4. □

COROLLARY 3.7. *Under Assumption* 1.1, *for* $0 < p < 1$, *there is a* $\delta_1 > 0$ *such that for* $0 < \delta < \delta_1$, (1.4) *has a* C^{k-1} *invariant torus given by Proposition* 2.3(b) *and Theorem* 3.6. *These invariant tori bifurcate from the invariant torus of the unperturbed system defined by* (1.7).

Remark 4. If $\epsilon = \epsilon_0\delta^{-p}$ and $1 - 1/k \le p < 1$, and $w = q_\rho(\sigma,\mu)$, $x = r_\rho(\sigma,\mu)$ is an integral manifold of (2.12) whose existence is proven in Theorem 3.4, then by (2.9),

$$
y = \rho^\kappa \mu^\nu q_\rho(\sigma,\mu), \quad z = r_\rho(\sigma,\mu), \quad \delta = \rho^\nu \mu^\nu \tag{3.22}
$$

is an integral manifold of (2.7). Also, if $\epsilon = \epsilon_0\delta^{-p}$ and $0 < p < 1$, and $w = q_\mu(\sigma)$, $x = r_\mu(\sigma)$ is an integral manifold of (2.13) whose existence is proven in Theorem 3.6, then by (2.10),

$$y = \mu^{\zeta} q_{\mu}(\sigma), \quad z = r_{\mu}(\sigma), \quad \delta = \mu^{\nu} \tag{3.23}$$

is an integral manifold of (2.7). The integral manifolds for the systems of degenerate type (1.12) and (1.13) are at most Lipschitz continuous in θ and continuous with respect to parameters, whereas (3.22) is $(k-1)$-times continuously differentiable in θ and δ, and (3.23) is $(k-1)$-times continuously differentiable in θ.

4. Asymptotic behavior of solutions near integral manifolds. In this section we study the behavior of solutions of (1.8) in a neighborhood of the integral manifold $w = q_{\rho}(\sigma, \mu)$, $z = r_{\rho}(\sigma, \mu)$. We assume that $I \subset \mathbb{R}^{+}$ and show that the integral manifold is asymptotically stable for small $\rho > 0$ in the sense that there is a $\rho_d > 0$ such that for each $\rho \in (0, \rho_d)$ and $\mu \in I$, there is a neighborhood of the integral manifold such that any solution of (1.8) through a point in the neighborhood approaches the manifold at a exponential rate in time (cf. Proposition 4.4). This leads to the following conclusion. For all small $\delta > 0$, there is a neighborhood of the unperturbed torus (1.7) such that the distance between any solution of (1.4) through a point in the neighborhood and its projection onto the torus defined by (2.14) decays at a exponential rate in time (cf. (4.33)). This result is stated in Theorem 4.5. We present similar results concerning the behavior of solutions of (1.9) near the integral manifold $w = q_{\mu}(\sigma)$, $z = r_{\mu}(\sigma)$ and the behavior of solutions of (1.4) near the corresponding invariant tori in Proposition 4.7 and Theorem 4.5.

Let

$$w = u + q_{\rho}(\sigma, \mu), \qquad z = v + r_{\rho}(\sigma, \mu).$$

Then (1.8) becomes

$$\begin{aligned}
\frac{d\sigma}{dt} &= \omega + \mathcal{S}_0(\sigma, u, v, \mu, \rho), \\
\frac{du}{dt} &= A(\Omega^{-1}\sigma)u + U_1(\sigma, u, v, \mu, \rho)u + U_2(\sigma, u, v, \mu, \rho)v, \\
\frac{dv}{dt} &= \rho\mu Q v + V_1(\sigma, u, v, \mu, \rho)u + V_2(\sigma, u, v, \mu, \rho)v,
\end{aligned} \tag{4.1}$$

where

$$\begin{aligned}
\mathcal{S}_0(\sigma, u, v, \mu, \rho) &= \mathcal{S}\left(\sigma, u + q_{\rho}(\sigma, \mu), v + r_{\rho}(\sigma, \mu), \mu, \rho\right) \\
&= \mu\Sigma(\sigma, \mu, \rho) + S_1(\sigma, u, v, \mu, \rho)u + S_2(\sigma, u, v, \mu, \rho)v,
\end{aligned}$$

$$\begin{aligned}
\Sigma(\sigma, \mu, \rho) = \int_0^1 \Bigg[&\frac{\partial \mathcal{S}}{\partial w}(\sigma, q_{\rho}(\sigma, s\mu), r_{\rho}(\sigma, s\mu), s\mu, \rho) \frac{\partial q_{\rho}}{\partial \mu}(\sigma, s\mu) \\
&+ \frac{\partial \mathcal{S}}{\partial z}(\sigma, q_{\rho}(\sigma, s\mu), r_{\rho}(\sigma, s\mu), s\mu, \rho) \frac{\partial r_{\rho}}{\partial \mu}(\sigma, s\mu) \\
&+ \frac{\partial \mathcal{S}}{\partial \mu}(\sigma, q_{\rho}(\sigma, s\mu), r_{\rho}(\sigma, s\mu), s\mu, \rho) \Bigg] \, ds,
\end{aligned}$$

$$S_1(\sigma,u,v,\mu,\rho)=\int_0^1 \frac{\partial \mathcal{S}}{\partial w}(\sigma,su+q_\rho(\sigma,\mu),sv+r_\rho(\sigma,\mu),\mu,\rho)\,ds,$$

$$S_2(\sigma,u,v,\mu,\rho)=\int_0^1 \frac{\partial \mathcal{S}}{\partial z}(\sigma,su+q_\rho(\sigma,\mu),sv+r_\rho(\sigma,\mu),\mu,\rho)\,ds,$$

and

$$U_1(\sigma,u,v,\mu,\rho)=\int_0^1 \frac{\partial \mathcal{W}}{\partial w}(\sigma,su+q_\rho(\sigma,\mu),sv+r_\rho(\sigma,\mu),\mu,\rho)\,ds$$
$$-\frac{\partial q_\rho}{\partial \sigma}(\sigma,\mu)S_1(\sigma,u,v,\mu,\rho),$$

$$U_2(\sigma,u,v,\mu,\rho)=\int_0^1 \frac{\partial \mathcal{W}}{\partial z}(\sigma,su+q_\rho(\sigma,\mu),sv+r_\rho(\sigma,\mu),\mu,\rho)\,ds$$
$$-\frac{\partial q_\rho}{\partial \sigma}(\sigma,\mu)S_2(\sigma,u,v,\mu,\rho),$$

$$V_1(\sigma,u,v,\mu,\rho)=\rho\mu\int_0^1 \frac{\partial \mathcal{Z}}{\partial w}(\sigma,su+q_\rho(\sigma,\mu),sv+r_\rho(\sigma,\mu),\mu,\rho)\,ds$$
$$-\frac{\partial r_\rho}{\partial \sigma}(\sigma,\mu)S_1(\sigma,u,v,\mu,\rho),$$

$$V_2(\sigma,u,v,\mu,\rho)=\rho\mu\int_0^1 \frac{\partial \mathcal{Z}}{\partial z}(\sigma,su+q_\rho(\sigma,\mu),sv+r_\rho(\sigma,\mu),\mu,\rho)\,ds$$
$$-\frac{\partial r_\rho}{\partial \sigma}(\sigma,\mu)S_2(\sigma,u,v,\mu,\rho).$$

Denote by $S_n(x,\varepsilon)$ the open ball of radius ε in $\mathbb{R}^n$ centered at x. Choose a neighborhood of the origin in $\mathbb{R}^{N_1+N_2}$, which we call $\mathcal{D}$, such that

$$\overline{S_{N_1}(0,\Delta)}\times\overline{S_{N_2}(0,\Delta)}+\overline{\mathcal{D}}\subset F_1\times F_2. \tag{4.2}$$

Then for $\rho\in(0,\rho_0)$, $\mathcal{S}_0$, U_1, U_2, V_1, and V_2 are defined and continuously differentiable in $\mathbb{R}^N\times\mathcal{D}\times I$. Choose a positive number ε_0 such that

$$\overline{S_{N_1+N_2}(0,\varepsilon_0)}\subset\mathcal{D}. \tag{4.3}$$

For $\mu\in I$, $\rho\in(0,\rho_0)$, and $(u,v)\in\overline{S_{N_1+N_2}(0,\varepsilon_0)}$,

$$\|\mathcal{S}_0(\sigma,u,v,\mu,\rho)\|\le\lambda(\rho)\mu^k, \tag{4.4}$$

$$\begin{aligned}&\|U_i(\sigma,u,v,\mu,\rho)\|\le\lambda_1(\rho)+\lambda(\rho)\mu^k\Delta, \qquad i=1,2,\\ &\|V_i(\sigma,u,v,\mu,\rho)\|\le\lambda_2(\rho)\rho\mu+\lambda(\rho)\mu^k\Delta, \qquad i=1,2.\end{aligned} \tag{4.5}$$

Let

$$\begin{aligned} \sigma &= \sigma(t) = \sigma(t, \sigma^\star, u^\star, v^\star, \mu, \rho), \\ u &= u(t) = u(t, \sigma^\star, u^\star, v^\star, \mu, \rho), \\ v &= v(t) = v(t, \sigma^\star, u^\star, v^\star, \mu, \rho) \end{aligned} \tag{4.6}$$

be the solution of (4.1) with initial value

$$\sigma(0, \sigma^\star, u^\star, v^\star, \mu, \rho) = \sigma^\star, \qquad u(0, \sigma^\star, u^\star, v^\star, \mu, \rho) = u^\star,$$
$$v(0, \sigma^\star, u^\star, v^\star, \mu, \rho) = v^\star.$$

If $(u^\star, v^\star) \in S_{N_1+N_2}(0, \varepsilon_0)$, there is $t_1 > 0$ such that (4.6) exists and $(u(t), v(t)) \in S_{N_1+N_2}(0, \varepsilon_0)$ for $t \in [0, t_1)$. Let $u = \Xi(t, t_0) = \Xi(t, t_0, \sigma^\star, u^\star, v^\star, \mu, \rho)$ be the fundamental matrix solution of

$$\frac{du}{dt} = A(\Omega^{-1}\sigma(t, \sigma^\star, u^\star, v^\star, \mu, \rho))u, \qquad \Xi(t_0, t_0, \sigma^\star, u^\star, v^\star, \mu, \rho) = I_{N_1 \times N_1}.$$

We assert that $\Xi(t, t_0)$ decays exponentially as t increases in Lemma 4.1. The proof of this lemma is similar to the one for Lemma 5.8 in the Appendix and is left to the reader.

LEMMA 4.1.

$$\|\Xi(t, t_0, \sigma^\star, u^\star, v^\star, \mu, \rho)\| \le K_1 e^{-\left[\beta_1 - H\lambda(\rho)\mu^k\right](t-t_0)} \quad \textit{for } t_0 \le t.$$

We can write $u(t)$ and $v(t)$ in the form

$$\begin{aligned} u(t) = \Xi(t, 0)u^\star + \int_0^t \Xi(t, s) \, &[U_1(\sigma(s), u(s), v(s), \mu, \rho)u(s) \\ &+ U_2(\sigma(s), u(s), v(s), \mu, \rho)v(s)] \, ds, \\ v(t) = e^{\rho\mu Q t}v^\star + \int_0^t e^{\rho\mu Q(t-s)} \, &[V_1(\sigma(s), u(s), v(s), \mu, \rho)u(s) \\ &+ V_2(\sigma(s), u(s), v(s), \mu, \rho)v(s)] \, ds, \end{aligned}$$

and now (4.4), (4.5), and Lemma 4.1 lead to the estimate

$$\begin{aligned} \|u(t)\| &\le K_1\|u^\star\|e^{-\left[\beta_1 - H\lambda(\rho)\mu^k\right]t} \\ &\quad + \int_0^t K_1 \left[\lambda_1(\rho) + \lambda(\rho)\mu^k\Delta\right] e^{-\left[\beta_1 - H\lambda(\rho)\mu^k\right](t-s)} \left(\|u(s)\| + \|v(s)\|\right) ds, \\ \|v(t)\| &\le K_2\|v^\star\|e^{-\rho\mu\beta_2 t} + \int_0^t K_2 \left[\lambda_2(\rho)\rho\mu + \lambda(\rho)\mu^k\Delta\right] \\ &\quad \times e^{-\rho\mu\beta_2(t-s)} \left(\|u(s)\| + \|v(s)\|\right) ds. \end{aligned} \tag{4.7}$$

We prove the following two lemmas in order to show that the functions $u(t)$ and $v(t)$, which satisfy (4.7), decay exponentially as t increases when μ and ρ are sufficiently small.

LEMMA 4.2. *Suppose that h is a continuous nonnegative function on the closed interval $[t_0, t_1]$ such that*

$$h(t) \le e^{A_1(t-t_0)} \left\{ B_1 + C_1 \int_{t_0}^{t} e^{(A_2-A_1)(s-t_0)} \left[B_2 + C_2 \int_{t_0}^{s} e^{-A_2(\tau-t_0)} h(\tau)\, d\tau \right] ds \right\}$$

for all $t \in [t_0, t_1]$, where A_i, B_i, and C_i are real numbers and $C_i \ge 0$ for $i = 1$ and 2. Then

$$h(t) \le e^{\mathcal{R}_0(t-t_0)} \left[B_1 + (B_2C_1 - B_1 r) \frac{1 - e^{-\mathcal{R}(t-t_0)}}{\mathcal{R}} \right] \quad \text{for all } t \in [t_0, t_1], \tag{4.8}$$

where

$$\mathcal{R} = \sqrt{(A_2 - A_1)^2 + 4C_1C_2} = |A_2 - A_1| + 2\mathcal{I},$$

$$\mathcal{R}_0 = \frac{A_1 + A_2 + R}{2} = \max\{A_1, A_2\} + \mathcal{I},$$

$$r = \frac{A_2 - A_1 + R}{2} = \frac{A_2 - A_1 + |A_2 - A_1|}{2} + \mathcal{I},$$

$$\mathcal{I} = \int_0^1 \frac{C_1C_2\, ds}{\sqrt{(A_2 - A_1)^2 + 4C_1C_2 s}}.$$

Proof. Let

$$G(t) = B_1 + C_1 \int_{t_0}^{t} e^{(A_2-A_1)(s-t_0)} \left[B_2 + C_2 \int_{t_0}^{s} e^{-A_2(\tau-t_0)} h(\tau)\, d\tau \right] ds. \tag{4.9}$$

Then

$$h(t) \le e^{A_1(t-t_0)} G(t). \tag{4.10}$$

On the other hand, $G(t)$ is twice continuously differentiable on (t_0, t_1). Moreover,

$$G'(t) = C_1 e^{(A_2-A_1)(t-t_0)} \left[B_2 + C_2 \int_{t_0}^{t} e^{-A_2(\tau-t_0)} h(\tau)\, d\tau \right]. \tag{4.11}$$

Differentiating (4.11) again and using (4.10), we find that

$$\begin{aligned} G''(t) &= (A_2 - A_1)G'(t) + C_1C_2 e^{-A_1(t-t_0)} h(t) \\ &\le (A_2 - A_1)G'(t) + C_1C_2 G(t). \end{aligned} \tag{4.12}$$

Let

$$G(t) = e^{r(t-t_0)}H(t). \tag{4.13}$$

Then using (4.12), we obtain

$$H''(t) + \mathcal{R}H'(t) \leq 0.$$

It follows that

$$H'(t) \leq H'(t_0)e^{-\mathcal{R}(t-t_0)}$$

and

$$H(t) \leq H(t_0) + H'(t_0)\frac{1 - e^{-\mathcal{R}(t-t_0)}}{\mathcal{R}}. \tag{4.14}$$

From (4.9) and (4.13), we find that

$$H(t_0) = G(t_0) = B_1. \tag{4.15}$$

From (4.11), (4.13), and (4.15), we obtain

$$H'(t_0) = G'(t_0) - rH(t_0) = B_2C_1 - B_1r. \tag{4.16}$$

On the other hand, according to (4.10) and (4.13),

$$h(t) \leq e^{A_1(t-t_0)}G(t) \leq e^{(A_1+r)(t-t_0)}H(t). \tag{4.17}$$

Now (4.8) follows from (4.14), (4.15), (4.16), and (4.17). □

LEMMA 4.3. *Suppose that h_1 and h_2 are continuous nonnegative functions on the closed interval $[t_0, t_1]$ such that for $t \in [t_0, t_1]$,*

$$h_1(t) \leq e^{-a_1(t-t_0)}\left\{b_1 + c_1\int_{t_0}^{t} e^{a_1(s-t_0)}\left[h_1(s) + h_2(s)\right]\,ds\right\},$$

$$h_2(t) \leq e^{-a_2(t-t_0)}\left\{b_2 + c_2\int_{t_0}^{t} e^{a_2(s-t_0)}\left[h_1(s) + h_2(s)\right]\,ds\right\},$$

where a_i, b_i, and c_i are real numbers and $c_i \geq 0$. Then for $t \in [t_0, t_1]$,

$$h_1(t) \leq e^{-R_0(t-t_0)}\left[b_1 + (b_2c_1 - b_1r_1)\frac{1 - e^{-R(t-t_0)}}{R}\right], \tag{4.18}$$

$$h_2(t) \leq e^{-R_0(t-t_0)}\left[b_2 + (b_1c_2 - b_2r_2)\frac{1 - e^{-R(t-t_0)}}{R}\right], \tag{4.19}$$

where

$$R = \sqrt{[a_1 - c_1 - (a_2 - c_2)]^2 + 4c_1c_2} = |a_1 - c_1 - (a_2 - c_2)| + 2\mathcal{I}_0,$$

$$r_1 = \frac{a_1 - c_1 - (a_2 - c_2) + R}{2} = \frac{a_1 - c_1 - (a_2 - c_2) + |a_1 - c_1 - (a_2 - c_2)|}{2} + \mathcal{I}_0,$$

$$r_2 = \frac{a_2 - c_2 - (a_1 - c_1) + R}{2} = \frac{a_2 - c_2 - (a_1 - c_1) + |a_1 - c_1 - (a_2 - c_2)|}{2} + \mathcal{I}_0,$$

$$R_0 = a_1 - c_1 - r_1 = a_2 - c_2 - r_2 = \min\{a_1 - c_1, a_2 - c_2\} - \mathcal{I}_0,$$

$$\mathcal{I}_0 = \int_0^1 \frac{c_1c_2\,ds}{\sqrt{[a_1 - c_1 - (a_2 - c_2)]^2 + 4c_1c_2s}}.$$

Proof. It can easily be shown that h_1 and h_2 satisfy

$$h_1(t) \leq e^{-(a_1-c_1)(t-t_0)}\left[b_1 + c_1\int_{t_0}^{t} e^{(a_1-c_1)(s-t_0)}h_2(s)\,ds\right], \tag{4.20}$$

$$h_2(t) \leq e^{-(a_2-c_2)(t-t_0)}\left[b_2 + c_2\int_{t_0}^{t} e^{(a_2-c_2)(s-t_0)}h_1(s)\,ds\right]. \tag{4.21}$$

Substituting (4.21) in (4.20), we obtain

$$h_1(t) \leq e^{-(a_1-c_1)(t-t_0)}\left\{b_1 + c_1\int_{t_0}^{t} e^{[a_1-c_1-(a_2-c_2)](s-t_0)} \times \left[b_2 + c_2\int_{t_0}^{s} e^{(a_2-c_2)(\tau-t_0)}h_1(\tau)\,d\tau\right] ds\right\}.$$

Set

$$A_i = -(a_i - c_i), \qquad B_i = b_i, \qquad C_i = c_i, \qquad i = 1, 2.$$

Now (4.18) follows from Lemma 4.2. A similar argument leads to (4.19). □

We set

$$\begin{aligned} a_1 &= \beta_1 - \lambda(\rho)\mu^k(2\mu\Delta + 1 + \varepsilon_0)H, \qquad b_1 = K_1\|u^\star\|, \\ c_1 &= K_1\left[\lambda_1(\rho) + \lambda(\rho)\mu^k\Delta\right], \\ a_2 &= \rho\mu\beta_2, \qquad b_2 = K_2\|v^\star\|, \\ c_2 &= K_2\left[\lambda_2(\rho)\rho\mu + \lambda(\rho)\mu^k\Delta\right]. \end{aligned} \tag{4.22}$$

Then for all sufficiently small $\rho > 0$, $a_1 - c_1 - (a_2 - c_2)$ is positive and bounded away from zero for all $\mu \in I$ uniformly. R_0 now becomes

$$R_0 = a_2 - c_2 - c_1 c_2 \int_0^1 \frac{ds}{\sqrt{[a_1 - c_1 - (a_2 - c_2)]^2 + 4c_1 c_2 s}}. \tag{4.23}$$

Since

$$a_2 - c_2 = \rho\mu \left\{ \beta_2 - K_2 \left[\lambda_2(\rho) + \frac{\lambda(\rho)}{\rho} \mu^{k-1} \Delta \right] \right\},$$

$$c_1 c_2 = \rho\mu K_1 K_2 \left[\lambda_1(\rho) + \lambda(\rho)\mu^k \Delta \right] \left[\lambda_2(\rho) + \frac{\lambda(\rho)}{\rho} \mu^{k-1} \Delta \right],$$

and the integral in (4.23) is bounded, there is a $\alpha_d > 0$ such that for all small $\rho > 0$, R_0 defined by (4.22) and (4.23) satisfies

$$R_0 > \rho\mu\alpha_d \tag{4.24}$$

for all $\mu \in I$. On the other hand,

$$\begin{aligned} & b_1 + b_2 + (b_2 c_1 - b_1 r_1 + b_1 c_2 - b_2 r_2) \frac{1 - e^{-Rt}}{R} \\ &= b_1 \left[1 + (c_2 - r_1) \frac{1 - e^{-Rt}}{R} \right] + b_2 \left[1 + (c_1 - r_2) \frac{1 - e^{-Rt}}{R} \right] \\ &= \|u^\star\| K_1 \left[1 + (c_2 - r_1) \frac{1 - e^{-Rt}}{R} \right] + \|v^\star\| K_2 \left[1 + (c_1 - r_2) \frac{1 - e^{-Rt}}{R} \right]. \end{aligned}$$

It is easily seen that there is $L_1 > 0$ such that for all small $\rho > 0$,

$$\max \left\{ K_1 \left[1 + (c_2 - r_1) \frac{1 - e^{-Rt}}{R} \right], K_2 \left[1 + (c_1 - r_2) \frac{1 - e^{-Rt}}{R} \right] \right\} \le L_1 \tag{4.25}$$

for all $\mu \in I$ and $t \ge 0$. It follows from Lemma 4.3 that

$$\begin{aligned} \|u(t)\| + \|v(t)\| &\le e^{-R_0 t} \left[b_1 + b_2 + (b_2 c_1 - b_1 r_1 + b_1 c_2 - b_2 r_2) \frac{1 - e^{-Rt}}{R} \right] \\ &\le L_1 \left(\|u^\star\| + \|v^\star\| \right) e^{-\rho\mu\alpha_d t}. \end{aligned} \tag{4.26}$$

For all sufficiently small $\rho > 0$, if

$$(u^\star, v^\star) \in S_{N_1+N_2} \left(0, \frac{\varepsilon_0}{L_1} \right),$$

$$(u(t), v(t)) \in S_{N_1+N_2}(0, \varepsilon_0) \quad \text{for all } t \in [0, t_1).$$

For such $u^\star$ and $v^\star$, $\sigma(t)$, $u(t)$, and $v(t)$ exist and (4.26) is valid for all $t \in [0, \infty)$ (cf. [10]). In particular $u(t)$ and $v(t)$ decay exponentially. We summarize this result in terms of solutions of (1.8) in Proposition 4.4.

PROPOSITION 4.4. *Suppose that*

$$\begin{aligned} \sigma &= \sigma(t) = \sigma(t, \sigma^\star, w^\star, z^\star, \mu, \rho), \\ w &= w(t) = w(t, \sigma^\star, w^\star, z^\star, \mu, \rho), \\ z &= z(t) = z(t, \sigma^\star, w^\star, z^\star, \mu, \rho) \end{aligned} \tag{4.27}$$

is the solution of (1.8) *with the initial value*

$$\begin{aligned} &\sigma(0, \sigma^\star, w^\star, z^\star, \mu, \rho) = \sigma^\star, \quad w(0, \sigma^\star, w^\star, z^\star, \mu, \rho) = w^\star, \\ &z(0, \sigma^\star, w^\star, z^\star, \mu, \rho) = z^\star. \end{aligned} \tag{4.28}$$

Then there are positive constants ρ_d, α_d, ε_d, *and* L_1 *such that for all* $0 < \rho < \rho_d$, *if*

$$\|w^\star - q_\rho(\sigma^\star, \mu)\| + \|z^\star - r_\rho(\sigma^\star, \mu)\| < \varepsilon_d,$$

then (4.27) *exists for all* $t \geq 0$ *and*

$$\begin{aligned} &\|w(t) - q_\rho(\sigma(t), \mu)\| + \|z(t) - r_\rho(\sigma(t), \mu)\| \\ &\qquad \leq L_1 \left(\|w^\star - q_\rho(\sigma^\star, \mu)\| + \|z^\star - r_\rho(\sigma^\star, \mu)\|\right) e^{-\rho\mu\alpha_d t}. \end{aligned} \tag{4.29}$$

Proposition 4.4 now enables us to determine the asymptotic behavior of solutions of (1.4) near the invariant torus defined by (2.14). Let $\mathcal{F}_\delta$ denote the set of all points $(x_0, x_1, \cdots, x_N)$ in $\mathbb{R}^{M+N_2}$ given by

$$\begin{aligned} &x_i^\star = \eta_i(\omega_i^{-1}\sigma_i^\star) + \rho^\kappa \mu^\nu \Phi_i(\omega_i^{-1}\sigma_i^\star) w_i^\star, \qquad i = 1, \cdots, N, \\ &x_0^\star = z^\star + a(\Omega^{-1}\sigma^\star, \epsilon_0 \rho\mu) \quad \text{for } 0 \leq \sigma_i^\star < 2\pi \text{ and } \|y^\star\| + \|z^\star\| < \frac{\varepsilon_d}{2}, \end{aligned} \tag{4.30}$$

where the relationship between δ, ρ, μ, κ, and ν is given by (2.9) and (2.11). Then $\mathcal{F}_\delta$ is a neighborhood of the unperturbed torus defined by (1.6). In view of (3.10) and (3.12), we may assume that for $\rho \in (0, \rho_d)$ and $\mu \in I$,

$$\|q_\rho(\sigma, \mu)\| + \|r_\rho(\sigma, \mu)\| < \frac{\varepsilon_d}{2} \quad \text{for all } \sigma \in \mathbb{R}^N.$$

We will show that when $\delta > 0$ is sufficiently small, the solution of (1.4) through any point in $\mathcal{F}_\delta$ is attracted to the invariant torus defined by (2.14). Let

$$x_i = \phi_i(t) = \phi_i\left(t, x_0^\star, x_1^\star, \cdots, x_N^\star, \delta\right), \qquad i = 0, \cdots, N \tag{4.31}$$

be the solution of (1.4) with the initial value

$$\phi_i\left(0, x_0^\star, x_1^\star, \cdots, x_N^\star, \delta\right) = x_i^\star, \qquad i = 0, \cdots, N. \tag{4.32}$$

Let

$$L_2 = \max_{1\le i\le N} \sup_{0\le\theta_i\le T_i} \{\|\Phi_i(\theta_i)\|\}.$$

If $x_i^\star$, $i = 0, \cdots, N$, are given by (4.30), then

$$\phi_i(t) = \eta_i(\omega_i^{-1}\sigma_i(t)) + \rho^\kappa\mu^\nu\Phi_i(\omega_i^{-1}\sigma_i(t))w_i(t), \qquad i = 1, \cdots, N,$$
$$\phi_0(t) = z(t) + a(\Omega^{-1}\sigma(t), \epsilon_0\rho\mu),$$

where $\sigma = \sigma(t)$, $w = w(t)$, $z = z(t)$, defined in (4.27) and (4.28), is the solution of (2.12) with $\mu = \delta^{1-p}/\rho$. It follows that

$$\begin{aligned}
&\sum_{i=1}^N \left\|\phi_i(t) - \left[\eta_i(\omega_i^{-1}\sigma_i(t)) + \rho^\kappa\mu^\nu\Phi_i(\omega_i^{-1}\sigma_i(t))q_{\rho,i}(\sigma(t),\mu)\right]\right\| \\
&\quad + \left\|\phi_0(t) - \left[r_\rho(\sigma(t),\mu) + a(\Omega^{-1}\sigma(t),\epsilon_0\rho\mu)\right]\right\| \\
&\qquad \le \rho^\kappa\mu^\nu L_2 \sum_{i=1}^N \|w_i(t) - q_{\rho,i}(\sigma(t),\mu)\| + \|z(t) - r_\rho(\sigma(t),\mu)\| \\
&\qquad \le (\rho^\kappa\mu^\nu L_2 + 1)\left(\|w(t) - q_\rho(\sigma(t),\mu)\| + \|z(t) - r_\rho(\sigma(t),\mu)\|\right) \\
&\qquad \le (\rho^\kappa\mu^\nu L_2 + 1)\, L_1 \left(\|w^\star - q_\rho(\sigma^\star,\mu)\| + \|z^\star - r_\rho(\sigma^\star,\mu)\|\right) e^{-\rho\mu\alpha_d t}.
\end{aligned}$$

We summarize this result in Theorem 4.5.

THEOREM 4.5. *Under Assumption* 1.1 *with* $1 - 1/k \le p < 1$, *there are positive numbers* δ_d, ε_d, α_d, *and* L_d *with the following properties. We define a region* $\mathcal{F}_\delta$ *by* (4.30). *Then* $\mathcal{F}_\delta$ *is a neighborhood of the unperturbed torus defined by* (1.7). *For* $0 < \delta \le \delta_d$ *the solution of* (1.4) *through a point in* $\mathcal{F}_\delta$ *is attracted to the invariant torus defined by* (2.14) *in the following sense.*

$$\begin{aligned}
&\sum_{i=1}^N \left\|\phi_i(t) - \left[\eta_i(\omega_i^{-1}\sigma_i(t)) + \rho^\kappa\mu^\nu\Phi_i(\omega_i^{-1}\sigma_i(t))q_{\rho,i}(\sigma(t),\mu)\right]\right\| \\
&\quad + \left\|\phi_0(t) - \left[r_\rho(\sigma(t),\mu) + a(\Omega^{-1}\sigma(t),\epsilon_0\rho\mu)\right]\right\| \\
&\qquad \le L_d \left(\|w^\star - q_\rho(\sigma^\star,\mu)\| + \|z^\star - r_\rho(\sigma^\star,\mu)\|\right) e^{-\rho\mu\alpha_d t}.
\end{aligned} \tag{4.33}$$

In (4.33), $\phi_i(t)$, $i = 0, \cdots, N$, *are the solutions of* (1.4) *defined in* (4.31) *and* (4.32). $\sigma(t)$, $w(t)$, *and* $z(t)$ *are the solutions of* (2.12) *defined in* (4.27) *and* (4.28). *Here the relationship between* $x_i^\star$, $i = 0, \cdots, N$, *and* $(\sigma^\star, y^\star, z^\star)$ *is given in* (4.30). (q_ρ, r_ρ) *is an integral manifold of* (2.12) *that defines an invariant torus of* (1.4) *via* (2.14).

Next we study the behavior of solutions of (1.9) near the integral manifold $w = q_\mu(\sigma)$, $z = r_\mu(\sigma)$. Let

$$w = u + q_\mu(\sigma),$$
$$z = v + r_\mu(\sigma).$$

Then (1.9) becomes

$$\begin{aligned}
\frac{d\sigma}{dt} &= \omega + \mathcal{S}_0(\sigma, u, v, \mu), \\
\frac{du}{dt} &= A(\Omega^{-1}\sigma)u + U_1(\sigma, u, v, \mu)u + U_2(\sigma, u, v, \mu)v, \\
\frac{dv}{dt} &= \mu Q v + V_1(\sigma, u, v, \mu)u + V_2(\sigma, u, v, \mu)v,
\end{aligned} \tag{4.34}$$

where

$$\begin{aligned}
\mathcal{S}_0(\sigma, u, v, \mu) &= \mathcal{S}(\sigma, u + q_\mu(\sigma), v + r_\mu(\sigma), \mu) \\
&= \Sigma(\sigma, \mu) + S_1(\sigma, u, v, \mu)u + S_2(\sigma, u, v, \mu)v, \\
\Sigma(\sigma, \mu) &= \mathcal{S}(\sigma, q_\mu(\sigma), r_\mu(\sigma), \mu), \\
S_1(\sigma, u, v, \mu) &= \int_0^1 \frac{\partial S}{\partial w}(\sigma, su + q_\mu(\sigma), sv + r_\mu(\sigma), \mu)\, ds, \\
S_2(\sigma, u, v, \mu) &= \int_0^1 \frac{\partial S}{\partial z}(\sigma, su + q_\mu(\sigma), sv + r_\mu(\sigma), \mu)\, ds,
\end{aligned}$$

and

$$\begin{aligned}
U_1(\sigma, u, v, \mu) &= \int_0^1 \frac{\partial \mathcal{W}}{\partial w}(\sigma, su + q_\mu(\sigma), sv + r_\mu(\sigma), \mu)\, ds - \frac{\partial q_\mu}{\partial \sigma}(\sigma) S_1(\sigma, u, v, \mu), \\
U_2(\sigma, u, v, \mu) &= \int_0^1 \frac{\partial \mathcal{W}}{\partial z}(\sigma, su + q_\mu(\sigma), sv + r_\mu(\sigma), \mu)\, ds - \frac{\partial q_\mu}{\partial \sigma}(\sigma) S_2(\sigma, u, v, \mu), \\
V_1(\sigma, u, v, \mu) &= \mu \int_0^1 \frac{\partial \mathcal{Z}}{\partial w}(\sigma, su + q_\mu(\sigma), sv + r_\mu(\sigma), \mu)\, ds - \frac{\partial r_\mu}{\partial \sigma}(\sigma) S_1(\sigma, u, v, \mu), \\
V_2(\sigma, u, v, \mu) &= \mu \int_0^1 \frac{\partial \mathcal{Z}}{\partial z}(\sigma, su + q_\mu(\sigma), sv + r_\mu(\sigma), \mu)\, ds - \frac{\partial r_\mu}{\partial \sigma}(\sigma) S_2(\sigma, u, v, \mu).
\end{aligned}$$

Choose a neighborhood of the origin $\mathcal{D}$ in $\mathbb{R}^{N_1+N_2}$ that satisfies (4.2). Then for $\mu \in I$, $\mathcal{S}_0$, U_1, U_2, V_1, and V_2 are defined and continuously differentiable in $\mathbb{R}^N \times \mathcal{D}$. Choose a positive number ε_0 that satisfies (4.3). For $\mu \in I$ and $(u, v) \in \overline{S_{N_1+N_2}(0, \varepsilon_0)}$,

$$\|\mathcal{S}_0(\sigma, u, v, \mu)\| \leq \lambda(\mu), \tag{4.35}$$

$$\begin{aligned}
\|U_i(\sigma, u, v, \mu)\| &\leq \lambda_1(\mu) + \lambda(\mu)\Delta, \qquad i = 1, 2, \\
\|V_i(\sigma, u, v, \mu)\| &\leq \lambda_2(\mu)\mu + \lambda(\mu)\Delta, \qquad i = 1, 2.
\end{aligned} \tag{4.36}$$

Let

$$\begin{aligned} \sigma &= \sigma(t) = \sigma(t, \sigma^\star, u^\star, v^\star, \mu), \\ u &= u(t) = u(t, \sigma^\star, u^\star, v^\star, \mu), \\ v &= v(t) = v(t, \sigma^\star, u^\star, v^\star, \mu) \end{aligned} \tag{4.37}$$

be the solution of (4.34) with initial value

$$\sigma(0, \sigma^\star, u^\star, v^\star, \mu) = \sigma^\star, \quad u(0, \sigma^\star, u^\star, v^\star, \mu) = u^\star, \quad v(0, \sigma^\star, u^\star, v^\star, \mu) = v^\star.$$

If $(u^\star, v^\star) \in S_{N_1+N_2}(0, \varepsilon_0)$, there is $t_1 > 0$ such that (4.37) exists and $(u(t), v(t)) \in S_{N_1+N_2}(0, \varepsilon_0)$ for $t \in [0, t_1)$. Let $u = \Xi(t, t_0) = \Xi(t, t_0, \sigma^\star, u^\star, v^\star, \mu)$ be the fundamental matrix solution of

$$\frac{du}{dt} = A(\Omega^{-1}\sigma(t, \sigma^\star, u^\star, v^\star, \mu))u,$$

$$\Xi(t_0, t_0, \sigma^\star, u^\star, v^\star, \mu) = I_{N_1 \times N_1}.$$

We may assume without loss of generality that for $\mu \in I$,

$$\lambda(\mu) < \omega_i, \qquad i = 1, \cdots, N.$$

It is shown in Lemma 4.6 that $\Xi(t, t_0)$ decays exponentially as t increases. Again its proof is similar to the one in Lemma 5.8 and is left to the reader.

LEMMA 4.6.

$$\|\Xi(t, t_0, \sigma^\star, u^\star, v^\star, \mu)\| \le K_1 e^{-[\beta_1 - \lambda(\mu)H](t-t_0)} \quad \textit{for } t_0 \le t.$$

Write $u(t)$ and $v(t)$ in the form

$$\begin{aligned} u(t) = \Xi(t, 0)u^\star + \int_0^t \Xi(t, s) \, [&U_1(\sigma(s), u(s), v(s), \mu)u(s) \\ &+ U_2(\sigma(s), u(s), v(s), \mu)v(s)] \, ds, \end{aligned}$$

$$\begin{aligned} v(t) = e^{\mu Q t}v^\star + \int_0^t e^{\mu Q(t-s)} \, [&V_1(\sigma(s), u(s), v(s), \mu)u(s) \\ &+ V_2(\sigma(s), u(s), v(s), \mu)v(s)] \, ds. \end{aligned}$$

Equations (4.36), (4.37), and Lemma 4.6 lead to

$$\begin{aligned} \|u(t)\| &\le K_1\|u^\star\|e^{-[\beta_1 - \lambda(\mu)H]t} \\ &+ \int_0^t K_1 \, [\lambda_1(\mu) + \lambda(\mu)\Delta] \, e^{-[\beta_1 - \lambda(\mu)H](t-s)} \, (\|u(s)\| + \|v(s)\|) \, ds, \\ \|v(t)\| &\le K_2\|v^\star\|e^{-\mu\beta_2 t} + \int_0^t K_2 \, [\lambda_2(\mu)\mu + \lambda(\mu)\Delta] \, e^{-\mu\beta_2(t-s)} \, (\|u(s)\| + \|v(s)\|) \, ds. \end{aligned}$$

Now let

$$
\begin{aligned}
a_1 &= \beta_1 - \lambda(\mu)H, \qquad b_1 = K_1\|u^\star\|, \\
c_1 &= K_1\left[\lambda_1(\mu) + \lambda(\mu)\Delta\right], \\
a_2 &= \mu\beta_2, \qquad b_2 = K_2\|v^\star\|, \\
c_2 &= K_2\left[\lambda_2(\mu)\mu + \lambda(\mu)\Delta\right].
\end{aligned} \tag{4.38}
$$

Then using an argument similar to the one leading to (4.24) and (4.25), we conclude that there is a $\tilde{\alpha}_d > 0$ such that for all small $\mu > 0$, R_0 defined by (4.23) and (4.38) satisfies

$$R_0 > \mu\tilde{\alpha}_d$$

for all $\mu \in I$, and that there is $\widetilde{L}_1 > 0$ such that for all small $\mu > 0$,

$$\max\left\{K_1\left[1 + (c_2 - r_1)\frac{1 - e^{-Rt}}{R}\right], K_2\left[1 + (c_1 - r_2)\frac{1 - e^{-Rt}}{R}\right]\right\} \leq \widetilde{L}_1$$

for all $t \geq 0$. It follows from Lemma 4.3 that

$$
\begin{aligned}
\|u(t)\| + \|v(t)\| &\leq e^{-R_0 t}\left[b_1 + b_2 + (b_2c_1 - b_1r_1 + b_1c_2 - b_2r_2)\frac{1 - e^{-Rt}}{R}\right], \\
&\leq \widetilde{L}_1\left(\|u^\star\| + \|v^\star\|\right)e^{-\mu\tilde{\alpha}_d t}.
\end{aligned} \tag{4.39}
$$

For all sufficiently small $\rho > 0$, if

$$
\begin{aligned}
(u^\star, v^\star) &\in S_{N_1+N_2}\left(0, \frac{\varepsilon_0}{\widetilde{L}_1}\right), \\
(u(t), v(t)) &\in S_{N_1+N_2}(0, \varepsilon_0) \quad \text{for all } t \in [0, t_1).
\end{aligned}
$$

For such $u^\star$ and $v^\star$, $\sigma(t)$, $u(t)$, and $v(t)$ exist and (4.39) is valid for all $t \in [0, \infty)$ (cf. [10]). In particular $u(t)$ and $v(t)$ decay exponentially. We summarize this result in Proposition 4.7.

PROPOSITION 4.7. *Suppose that*

$$
\begin{aligned}
\sigma &= \sigma(t) = \sigma(t, \sigma^\star, w^\star, z^\star, \mu), \\
w &= w(t) = w(t, \sigma^\star, w^\star, z^\star, \mu), \\
z &= z(t) = z(t, \sigma^\star, w^\star, z^\star, \mu)
\end{aligned} \tag{4.40}
$$

is the solution of (1.9) *with the initial value*

$$
\begin{aligned}
\sigma(0, \sigma^\star, w^\star, z^\star, \mu) &= \sigma^\star, \\
w(0, \sigma^\star, w^\star, z^\star, \mu) &= w^\star, \\
z(0, \sigma^\star, w^\star, z^\star, \mu) &= z^\star.
\end{aligned} \tag{4.41}
$$

Then there are positive constants μ_d, $\tilde{\alpha}_d$, $\tilde{\varepsilon}_d$, *and* $\widetilde{L}_1$ *such that for all* $\mu \in \mu_d$, *if*

$$\|w^\star - q_\mu(\sigma^\star)\| + \|z^\star - r_\mu(\sigma^\star)\| < \tilde{\varepsilon}_d,$$

then (4.40) *exists for all* $t \geq 0$ *and*

$$\begin{aligned}\|w(t) - q_\mu(\sigma(t))\| + \|z(t) - r_\mu(\sigma(t))\| \\ \leq \widetilde{L}_1 \left(\|w^\star - q_\mu(\sigma^\star)\| + \|z^\star - r_\mu(\sigma^\star)\|\right) e^{-\mu\tilde{\alpha}_d t}.\end{aligned}$$

Next we study the behavior of solutions of (1.4) near the invariant torus defined by (2.15). Let $\widetilde{\mathcal{F}}_\delta$ denote the set of all points $(x_0, x_1, \cdots, x_N)$ in $\mathbb{R}^{M+N_2}$ given by

$$\begin{aligned} x_i^\star &= \eta_i(\omega_i^{-1}\sigma_i^\star) + \mu^\zeta \Phi_i(\omega_i^{-1}\sigma_i^\star) w_i^\star, \qquad i = 1, \cdots, N, \\ x_0^\star &= z^\star + a(\Omega^{-1}\sigma^\star, \epsilon_0\mu) \quad \text{for } 0 \leq \sigma_i^\star < 2\pi \text{ and } \|y^\star\| + \|z^\star\| < \frac{\tilde{\varepsilon}_d}{2}, \end{aligned} \tag{4.42}$$

where the relationship between δ, μ, ζ, and ν is given by (2.10) and (2.11). Then $\widetilde{\mathcal{F}}_\delta$ is a neighborhood of the unperturbed torus defined by (1.6). In view of (3.10) and (3.12), we may assume that for a sufficiently small $\delta > 0$,

$$\|q_\mu(\sigma)\| + \|r_\mu(\sigma)\| < \frac{\tilde{\varepsilon}_d}{2} \quad \text{for all } \sigma \in \mathbb{R}^N.$$

We will show that the solution of (1.4) through any point in $\widetilde{\mathcal{F}}_\delta$ is attracted to the invariant torus. Consider the solution of (1.4) defined in (4.31) and (4.32). If $x_i^\star$, $i = 0, \cdots, N$, are given by (4.42), then

$$\begin{aligned} \phi_i(t) &= \eta_i(\omega_i^{-1}\sigma_i(t)) + \mu^\zeta \Phi_i(\omega_i^{-1}\sigma_i(t)) w_i(t), \qquad i = 1, \cdots, N, \\ \phi_0(t) &= z(t) + a(\Omega^{-1}\sigma(t), \epsilon_0\mu), \end{aligned}$$

and it follows that

$$\begin{aligned} &\sum_{i=1}^N \left\|\phi_i(t) - \left[\eta_i(\omega_i^{-1}\sigma_i(t)) + \mu^\zeta \Phi_i(\omega_i^{-1}\sigma_i(t)) q_{\mu,i}(\sigma(t))\right]\right\| \\ &\qquad + \left\|\phi_0(t) - \left[r_\mu(\sigma(t)) + a(\Omega^{-1}\sigma(t), \epsilon_0\mu)\right]\right\| \\ &\leq \mu^\zeta L_2 \sum_{i=1}^N \|w_i(t) - q_{\mu,i}(\sigma(t))\| + \|z(t) - r_\mu(\sigma(t))\| \\ &\leq \left(\mu^\zeta L_2 + 1\right) \left(\|w(t) - q_\mu(\sigma(t))\| + \|z(t) - r_\mu(\sigma(t))\|\right) \\ &\leq \left(\mu^\zeta L_2 + 1\right) \widetilde{L}_1 \left(\|w^\star - q_\mu(\sigma^\star)\| + \|z^\star - r_\mu(\sigma^\star)\|\right) e^{-\mu\tilde{\alpha}_d t}. \end{aligned}$$

We summarize this result in Theorem 4.8.

THEOREM 4.8. *Under Assumption* 1.1 *with* $0 < p < 1$, *there are positive numbers* $\tilde{\delta}_d$, $\tilde{\varepsilon}_d$, $\tilde{\alpha}_d$, *and* $\widetilde{L}_d$ *with the following properties. We define a region* $\widetilde{\mathcal{F}}_\delta$ *by* (4.42). *Then* $\widetilde{\mathcal{F}}_\delta$ *is a neighborhood of the unperturbed torus defined by* (1.7). *For* $0 < \delta \leq \tilde{\delta}_d$ *the solution of* (1.4) *through a point in* $\widetilde{\mathcal{F}}_\delta$ *is attracted to the invariant torus defined by* (2.15) *in the following sense.*

$$
\begin{aligned}
&\sum_{i=1}^{N} \left\| \phi_i(t) - \left[\eta_i(\omega_i^{-1}\sigma_i(t)) + \mu^{\zeta}\Phi_i(\omega_i^{-1}\sigma_i(t)) q_{\mu,i}(\sigma(t)) \right] \right\| \\
&\qquad + \left\| \phi_0(t) - \left[r_\mu(\sigma(t)) + a(\Omega^{-1}\sigma(t), \epsilon_0\mu) \right] \right\| \\
&\qquad\qquad \leq \widetilde{L}_d \left(\|w^\star - q_\mu(\sigma^\star)\| + \|z^\star - r_\mu(\sigma^\star)\| \right) e^{-\mu\tilde{\alpha}_d t}.
\end{aligned} \tag{4.43}
$$

In (4.43), $\phi_i(t)$, $i = 0, \cdots, N$, *are the solutions of* (1.4) *defined in* (4.31) *and* (4.32). $\sigma(t)$, $w(t)$, *and* $z(t)$ *are the solutions of* (1.9) *defined in* (4.40) *and* (4.41). *Here the relationship between* $x_i^\star$, $i = 0, \cdots, N$, *and* $(\sigma^\star, y^\star, z^\star)$ *is given in* (4.42). (q_μ, r_μ) *is an integral manifold of* (2.13) *that defines an invariant torus of* (1.4) *via* (2.15).

5. Appendix.

5.1. Properties of flows along periodic surfaces. In this Appendix we will prove a number of technical lemmas that are used to prove the existence of integral manifolds in §3. Specifically, in Lemmas 5.1–5.11, we will develop several properties of $\phi(t, \sigma^0, \mu, q, r, \rho)$ and $\Lambda(t, t_0, \sigma^0, \mu, q, r, \rho)$, which are defined as solutions of (3.1) and (3.2), respectively, under Assumption 2.1(a)–(e). These properties are used in the existence proofs for (1.8). Similar results for $\phi(t, \sigma^0, q, r, \mu)$ and $\Lambda(t, t_0, \sigma^0, q, r, \mu)$, defined as solutions of (3.18) and (3.19), respectively, under Assumption 2.1(a–c) and (f) are stated in Property 5.13 and they will be applied to (1.9).

Choose Δ such that

$$
\overline{S_{N_i}(0, \Delta)} \subset F_i, \qquad i = 1, 2.
$$

Recall that $\phi(t, \sigma^0, \mu, q, r, \rho)$ is a solution of (3.1) where $\mathcal{S}$ satisfies Assumption 2.1(e) and $(q, r) \in B_\Delta^k(\mathbb{R}^N \times I, \mathbb{R}^{N_1}) \times B_\Delta^k(\mathbb{R}^N \times I, \mathbb{R}^{N_2})$. For the following Lemmas 5.1–5.11 assume that $(q, r), (q_1, r_1), (q_2, r_2) \in B_\Delta^k(\mathbb{R}^N \times I, \mathbb{R}^{N_1}) \times B_\Delta^k(\mathbb{R}^N \times I, \mathbb{R}^{N_2})$. The proof of Lemma 5.1 is left to the reader.

LEMMA 5.1. *For each* $\rho \in I_1$, $\phi(t, \sigma^0, \mu, q, r, \rho)$ *exists for all* $t \in \mathbb{R}$, $\sigma^0 \in \mathbb{R}^N$, *and* $\mu \in I$, *and it is* k*-times continuously differentiable with respect to* t, σ^0, *and* μ. *Moreover, for* $i = 1, \cdots, N$,

$$
\phi(t, \sigma^0 + 2\pi e^i, \mu, q, r, \rho) = \phi(t, \sigma^0, \mu, q, r, \rho) + 2\pi e^i.
$$

Define

$$
\Upsilon(t, s, \sigma^0, \mu, q, r, \rho) = \frac{\partial \phi}{\partial \sigma^0}(t, \sigma^0, \mu, q, r, \rho) \frac{\partial \phi^{-1}}{\partial \sigma^0}(s, \sigma^0, \mu, q, r, \rho).
$$

LEMMA 5.2. *For all* $t, s \in \mathbb{R}$,

$$
\|\Upsilon(t, s, \sigma^0, \mu, q, r, \rho)\| \leq e^{\lambda(\rho)\mu^k(1+2\Delta)|t-s|}. \tag{5.1}
$$

In particular, for $t \leq 0$,

$$
\left\| \frac{\partial \phi}{\partial \sigma^0}(t, \sigma^0, \mu, q, r, \rho) \right\| \leq e^{-\lambda(\rho)\mu^k(1+2\Delta)t}. \tag{5.2}
$$

Proof. $x = \Upsilon(t, s, \sigma^0, \mu, q, r, \rho)$ satisfies the following linear system.

$$\frac{dx}{dt} = R(t)x, \qquad \Upsilon(s, s, \sigma^0, \mu, q, r, \rho) = I,$$

where

$$\begin{aligned} R(t) = {} & \frac{\partial \mathcal{S}}{\partial \sigma}(\phi(t), q(\phi(t), \mu), r(\phi(t), \mu), \mu, \rho) \\ & + \frac{\partial \mathcal{S}}{\partial w}(\phi(t), q(\phi(t), \mu), r(\phi(t), \mu), \mu, \rho) \frac{\partial q}{\partial \sigma}(\phi(t), \mu) \\ & + \frac{\partial \mathcal{S}}{\partial z}(\phi(t), q(\phi(t), \mu), r(\phi(t), \mu), \mu, \rho) \frac{\partial r}{\partial \sigma}(\phi(t), \mu), \end{aligned} \tag{5.3}$$

$$\phi(t) = \phi(t, \sigma^0, \mu, q, r, \rho).$$

Therefore

$$\Upsilon(t, s, \sigma^0, \mu, q, r, \rho) = I + \int_s^t R(u)\Upsilon(u, s, \sigma^0, \mu, q, r, \rho)\, du$$

and it follows from Assumption 2.1(d) that

$$\left\|\Upsilon(t, s, \sigma^0, \mu, q, r, \rho)\right\| \le 1 + \left| \int_s^t \lambda(\rho)\mu^k(1 + 2\Delta) \left\|\Upsilon(u, s, \sigma^0, \mu, q, r, \rho)\right\| du \right|.$$

Now (5.1) follows from Gronwall's inequality (cf. [1]) and (5.2) follows from (5.1) by setting $s = 0$. □

LEMMA 5.3. *For $2 \le l + 2m$ and $l + m \le k$ there is a positive constant $K_{l,m}$ such that for $t \le 0$,*

$$\begin{aligned} & \left\| \frac{\partial^{l+m}\phi}{\partial \sigma_{i_1}^0 \cdots \partial \sigma_{i_l}^0 \partial \mu^m}(t, \sigma^0, \mu, q, r, \rho) \right\| \\ & \le K_{l,m}\mu^{-m} \left\{ \sum_{i=1}^{l+2m-1} \left[\lambda(\rho)\mu^k(-t)\right]^i \right\} e^{-(l+m)\lambda(\rho)\mu^k(1+2\Delta)t}. \end{aligned} \tag{5.4}$$

Proof. It is easily shown inductively that for $2 \le l + 2m$ and $l + m \le k$

$$x = \frac{\partial^{l+m}\phi}{\partial \sigma_{i_1}^0 \cdots \partial \sigma_{i_l}^0 \partial \mu^m}(t, \sigma^0, \mu, q, r, \rho)$$

satisfies the following nonhomogeneous linear system:

$$\begin{aligned} & \frac{dx}{dt} = R(t)x + f_{(i_1, \cdots, i_l, m)}(t), \\ & \frac{\partial^{l+m}\phi}{\partial \sigma_{i_1}^0 \cdots \partial \sigma_{i_l}^0 \partial \mu^m}(0, \sigma^0, \mu, q, r, \rho) = 0. \end{aligned} \tag{5.5}$$

System (5.5) has the following properties.

PROPERTY 5.4. Matrix $R(t)$ is given by (5.3). $f_{(i_1,\cdots,i_l,m)}(t)$ is a (finite) sum of terms of the form

$$\frac{\partial^{m_1+m_2+m_3+m_4}\mathcal{S}}{\partial\sigma^{m_1}\partial w^{m_2}\partial z^{m_3}\partial\mu^{m_4}}a_1\cdots a_{m_1}B_1\cdots B_{m_2}C_1\cdots C_{m_3},$$

where

$$\frac{\partial^{m_1+m_2+m_3+m_4}\mathcal{S}}{\partial\sigma^{m_1}\partial w^{m_2}\partial z^{m_3}\partial\mu^{m_4}} = \frac{\partial^{m_1+m_2+m_3+m_4}\mathcal{S}}{\partial\sigma^{m_1}\partial w^{m_2}\partial z^{m_3}\partial\mu^{m_4}}(\phi(t),q(\phi(t),\mu),r(\phi(t),\mu),\mu,\rho),$$

$$a_v = \frac{\partial^{l_{1,v}+m_{1,v}}\phi}{\partial\sigma^0_{j_{v,1}}\cdots\partial\sigma^0_{j_{v,l_{1,v}}}\partial\mu^{m_{1,v}}}(t), \qquad v=1,\cdots,m_1,$$

$$B_u = \frac{\partial^{\nu_{2,u}+\chi_{2,u}}q}{\partial\sigma^{\nu_{2,u}}\mu^{\chi_{2,u}}}(\phi(t),\mu)b_{u,1}\cdots b_{u,\nu_{2,u}}, \qquad u=1,\cdots,m_2,$$

$$b_{u,v} = \frac{\partial^{l_{2,u,v}+m_{2,u,v}}\phi}{\partial\sigma^0_{j_{2,u,v,1}}\cdots\partial\sigma^0_{j_{2,u,v,l_{2,u,v}}}\partial\mu^{m_{2,u,v}}}(t), \qquad v=1,\cdots,\nu_{2,u},$$

$$C_u = \frac{\partial^{\nu_{3,u}+\chi_{3,u}}q}{\partial\sigma^{\nu_{3,u}}\mu^{\chi_{3,u}}}(\phi(t),\mu)c_{u,1}\cdots c_{u,\nu_{3,u}}, \qquad u=1,\cdots,m_3,$$

$$c_{u,v} = \frac{\partial^{l_{3,u,v}+m_{3,u,v}}\phi}{\partial\sigma^0_{j_{3,u,v,1}}\cdots\partial\sigma^0_{j_{3,u,v,l_{3,u,v}}}\partial\mu^{m_{3,u,v}}}(t), \qquad v=1,\cdots,\nu_{3,u},$$

$$0\le m_i\le l+m,\ i=1,\cdots,4, \qquad 1\le m_1+m_2+m_3+m_4\le l+m,$$

$$1\le l_{1,v}+m_{1,v},\ l_{2,u,v}+m_{2,u,v},\ l_{3,u,v}+m_{3,u,v}\le l+m-1,$$

$$\sum_{v=1}^{m_1}l_{1,v}+\sum_{u=1}^{m_2}\sum_{v=1}^{\nu_{2,u}}l_{2,u,v}+\sum_{u=1}^{m_3}\sum_{v=1}^{\nu_{3,u}}l_{3,u,v}=l,$$

$$m_4+\sum_{v=1}^{m_1}m_{1,v}+\sum_{u=1}^{m_2}\left(\sum_{v=1}^{\nu_{2,u}}m_{2,u,v}+\chi_{2,u}\right)+\sum_{u=1}^{m_3}\left(\sum_{v=1}^{\nu_{3,u}}m_{3,u,v}+\chi_{3,u}\right)=m.$$

Note that

$$\text{(5.6)}\qquad \text{if } m_4+\sum_{u=1}^{m_2}\chi_{2,u}+\sum_{u=1}^{m_3}\chi_{3,u}=0 \quad \text{then } m_1+\sum_{u=1}^{m_2}\nu_{2,u}+\sum_{u=1}^{m_3}\nu_{3,u}\ge 2.$$

By the variation of constants formula (cf. [7], [8]),

$$\text{(5.7)}\qquad \frac{\partial^{l+m}\phi}{\partial\sigma^0_{i_1}\cdots\partial\sigma^0_{i_l}\partial\mu^m}(t,\sigma^0,\mu,q,r,\rho)=\int_0^t\Upsilon(t,s,\sigma^0,\mu,q,r,\rho)f_{(i_1,\cdots,i_l,m)}(s)\,ds.$$

Now we prove (5.4) inductively. By Lemma 5.2, Property 5.4, and (5.6), there is $K_{2,0}>0$ such that for $t\le 0$,

$$\left\|f_{(i_1,i_2,0)}(t)\right\| \le K_{2,0}\lambda(\rho)\mu^k e^{-2\lambda(\rho)\mu^k(1+2\Delta)t}.$$

By Lemma 5.2 and (5.7)

$$\begin{aligned}\left\|\frac{\partial^2\phi}{\partial\sigma^0_{i_1}\partial\sigma^0_{i_2}}(t,\sigma^0,\mu,q,r,\rho)\right\| &\le \int_t^0 \|\Upsilon(t,s,\sigma^0,\mu,q,r,\rho)\|\|f_{(i_1,i_l,0)}(s)\|\,ds\\ &\le K_{2,0}\lambda(\rho)\mu^k(-t)e^{-2\lambda(\rho)\mu^k(1+2\Delta)t}.\end{aligned}$$

Again by Property 5.4, there is $K_{0,1} > 0$ such that

$$\left\|f_{(1)}(t)\right\| \le K_{0,1}\lambda(\rho)\mu^{k-1},$$

and by Lemma 5.2 and (5.7),

$$\begin{aligned}\left\|\frac{\partial\phi}{\partial\mu}(t,\sigma^0,\mu,q,r,\rho)\right\| &\le \int_t^0 \|\Upsilon(t,s,\sigma^0,\mu,q,r,\rho)\|\|f_{(1)}(s)\|\,ds\\ &\le \frac{K_{0,1}\lambda(\rho)\mu^{k-1}}{\lambda(\rho)\mu^k(1+2\Delta)}\left(e^{-\lambda(\rho)\mu^k(1+2\Delta)t}-1\right)\\ &\le K_{0,1}\lambda(\rho)\mu^{k-1}(-t)e^{-\lambda(\rho)\mu^k(1+2\Delta)t}.\end{aligned}$$

Thus (5.4) holds for $l + 2m = 2$.

Assume that (5.4) holds for all $\hat{l}$ and $\hat{m}$ such that $2 \le \hat{l}+2\hat{m}$ and $\hat{l}+\hat{m} \le l+m-1$. By Lemma 5.2, Property 5.4, and (5.6) there is $K_{l,m} > 0$ such that for $t \le 0$,

$$\left\|f_{(i_1,\cdots,i_l,m)}(t)\right\| \le K_{l,m}\lambda(\rho)\mu^{k-m}\left\{\sum_{i=0}^{l+2m-2}\left[\lambda(\rho)\mu^k(-t)\right]^i\right\}e^{-(l+m)\lambda(\rho)\mu^k(1+2\Delta)t}.$$

Now (5.4) follows from (5.7). □

LEMMA 5.5. *For $0 \le l + m \le k - 1$ there is a positive constant $\widehat{K}_{l,m}$ such that for $t \le 0$,*

$$\begin{aligned}&\left\|\frac{\partial^{l+m}\phi}{\partial\sigma^0_{i_1}\cdots\partial\sigma^0_{i_l}\partial\mu^m}(t,\sigma^0,\mu,q_1,r_1,\rho) - \frac{\partial^{l+m}\phi}{\partial\sigma^0_{i_1}\cdots\partial\sigma^0_{i_l}\partial\mu^m}(t,\sigma^0,\mu,q_2,r_2,\rho)\right\|\\ &\le \widehat{K}_{l,m}\left(\|q_1-q_2\|_{l+m} + \|r_1-r_2\|_{l+m}\right)\\ &\quad\times\mu^{-m}\left\{\sum_{i=1}^{l+2m+1}\left[\lambda(\rho)\mu^k(-t)\right]^i\right\}e^{-(l+m+1)\lambda(\rho)\mu^k(1+2\Delta)t}.\end{aligned} \tag{5.8}$$

Proof. The proof is by induction. Let

$$\phi_1(t) = \phi(t,\sigma^0,\mu,q_1,r_1,\rho), \qquad \phi_2(t) = \phi(t,\sigma^0,\mu,q_2,r_2,\rho).$$

Since

$$\phi_1(t) - \phi_2(t) = \int_0^t [\mathcal{S}_1 - \mathcal{S}_2]\, ds,$$

where

$$\mathcal{S}_1 = \mathcal{S}(\phi_1(s), q_1(\phi_1(s), \mu), r_1(\phi_1(s), \mu), \mu, \rho),$$

$$\mathcal{S}_2 = \mathcal{S}(\phi_2(s), q_2(\phi_2(s), \mu), r_2(\phi_2(s), \mu), \mu, \rho),$$

and

$$\|\mathcal{S}_1 - \mathcal{S}_2\| \leq \lambda(\rho)\mu^k \left[\|q_1 - q_2\|_0 + \|r_1 - r_2\|_0 + (1 + 2\Delta) \|\phi_1(s) - \phi_2(s)\|\right],$$

it follows that

$$\|\phi_1(t) - \phi_2(t)\| \leq \lambda(\rho)\mu^k \left(\|q_1 - q_2\|_0 + \|r_1 - r_2\|_0\right)(-t)$$

$$+ \int_t^0 \lambda(\rho)\mu^k(1 + 2\Delta) \|\phi_1(s) - \phi_2(s)\|\, ds.$$

By Gronwall's inequality

$$\|\phi_1(t) - \phi_2(t)\|$$

$$\leq \frac{\lambda(\rho)\mu^k \left(\|q_1 - q_2\|_0 + \|r_1 - r_2\|_0\right)}{\lambda(\rho)\mu^k(1 + 2\Delta)} \left(e^{-\lambda(\rho)\mu^k(1+2\Delta)t} - 1\right)$$

$$\leq \left(\|q_1 - q_2\|_0 + \|r_1 - r_2\|_0\right) \lambda(\rho)\mu^k(-t)e^{-\lambda(\rho)\mu^k(1+2\Delta)t}.$$

Therefore (5.8) holds for $l + m = 0$.

It is easily shown that for $1 \leq l + m \leq k - 1$,

$$x = \frac{\partial^{l+m}\phi_1}{\partial\sigma_{i_1}^0 \cdots \partial\sigma_{i_l}^0 \partial\mu^m}(t) - \frac{\partial^{l+m}\phi_2}{\partial\sigma_{i_1}^0 \cdots \partial\sigma_{i_l}^0 \partial\mu^m}(t)$$

satisfies the following nonhomogeneous linear system:

$$\begin{aligned} &\frac{dx}{dt} = R_1(t)x + \widehat{f}_{(i_1,\cdots,i_l,m)}(t), \\ &\frac{\partial^{l+m}\phi_1}{\partial\sigma_{i_1}^0 \cdots \partial\sigma_{i_l}^0 \partial\mu^m}(0) - \frac{\partial^{l+m}\phi_2}{\partial\sigma_{i_1}^0 \cdots \partial\sigma_{i_l}^0 \partial\mu^m}(0) = 0. \end{aligned} \tag{5.9}$$

System (5.9) has the following properties.

PROPERTY 5.6.

$$R_1(t) = \frac{\partial\mathcal{S}}{\partial\sigma}(\phi_1(t), q_1(\phi_1(t), \mu), r_1(\phi_1(t), \mu), \mu, \rho)$$

$$+ \frac{\partial\mathcal{S}}{\partial w}(\phi_1(t), q_1(\phi_1(t), \mu), r_1(\phi_1(t), \mu), \mu, \rho) \frac{\partial q_1}{\partial\sigma}(\phi_1(t), \mu)$$

$$+ \frac{\partial\mathcal{S}}{\partial z}(\phi_1(t), q_1(\phi_1(t), \mu), r_1(\phi_1(t), \mu), \mu, \rho) \frac{\partial r_1}{\partial\sigma}(\phi_1(t), \mu)$$

and $\widehat{f}_{(i_1,\cdots,i_l,m)}(t)$ is a (finite) sum of terms of the forms

$$(5.10)\quad \frac{\partial^{m_1+m_2+m_3+m_4}\mathcal{S}_1}{\partial\sigma^{m_1}\partial w^{m_2}\partial z^{m_3}\partial\mu^{m_4}}a_1^1\cdots a_{m_1}^1B_1^1\cdots B_{m_2}^1C_1^2\cdots C_{u-1}^2\left(C_u^1-C_u^2\right)C_{u+1}^1\cdots C_{m_3}^1,$$

$$(5.11)\quad \frac{\partial^{m_1+m_2+m_3+m_4}\mathcal{S}_1}{\partial\sigma^{m_1}\partial w^{m_2}\partial z^{m_3}\partial\mu^{m_4}}a_1^1\cdots a_{m_1}^1B_1^2\cdots B_{u-1}^2\left(B_u^1-B_u^2\right)B_{u+1}^1\cdots B_{m_2}^1C_1^2\cdots C_{m_3}^2,$$

$$(5.12)\quad \frac{\partial^{m_1+m_2+m_3+m_4}\mathcal{S}_1}{\partial\sigma^{m_1}\partial w^{m_2}\partial z^{m_3}\partial\mu^{m_4}}a_1^2\cdots a_{v-1}^2\left(a_v^1-a_v^2\right)a_{v+1}^1\cdots a_{m_1}^1B_1^2\cdots B_{m_2}^2C_1^2\cdots C_{m_3}^2,$$

$$(5.13)\quad \left(\frac{\partial^{m_1+m_2+m_3+m_4}\mathcal{S}_1}{\partial\sigma^{m_1}\partial w^{m_2}\partial z^{m_3}\partial\mu^{m_4}}-\frac{\partial^{m_1+m_2+m_3+m_4}\mathcal{S}_2}{\partial\sigma^{m_1}\partial w^{m_2}\partial z^{m_3}\partial\mu^{m_4}}\right)a_1^2\cdots a_{m_1}^2B_1^2\cdots B_{m_2}^2C_1^2\cdots C_{m_3}^2,$$

where for $i=1,2$,

$$a_v^i=\frac{\partial^{l_{1,v}+m_{1,v}}\phi_i}{\partial\sigma_{j_{v,1}}^0\cdots\partial\sigma_{j_{v,l_{1,v}}}^0\partial\mu^{m_{1,v}}}(t),\qquad v=1,\cdots,m_1,$$

$$B_u^i=\frac{\partial^{\nu_{2,u}+\chi_{2,u}}q_i}{\partial\sigma^{\nu_{2,u}}\mu^{\chi_{2,u}}}(\phi_i(t),\mu)b_{u,1}^i\cdots b_{u,\nu_{2,u}}^i,\qquad u=1,\cdots,m_2,$$

$$b_{u,v}^i=\frac{\partial^{l_{2,u,v}+m_{2,u,v}}\phi_i}{\partial\sigma_{j_{2,u,v,1}}^0\cdots\partial\sigma_{j_{2,u,v,l_{2,u,v}}}^0\partial\mu^{m_{2,u,v}}}(t),\qquad v=1,\cdots,\nu_{2,u},$$

$$C_u^i=\frac{\partial^{\nu_{3,u}+\chi_{3,u}}q}{\partial\sigma^{\nu_{3,u}}\mu^{\chi_{3,u}}}(\phi_i(t),\mu)c_{u,1}^i\cdots c_{u,\nu_{3,u}}^i,\qquad u=1,\cdots,m_3,$$

$$c_{u,v}^i=\frac{\partial^{l_{3,u,v}+m_{3,u,v}}\phi_i}{\partial\sigma_{j_{3,u,v,1}}^0\cdots\partial\sigma_{j_{3,u,v,l_{3,u,v}}}^0\partial\mu^{m_{3,u,v}}}(t),\qquad v=1,\cdots,\nu_{3,u},$$

$$0\le m_i\le l+m,\quad i=1,\cdots,4,\quad 1\le m_1+m_2+m_3+m_4\le l+m,$$

$$\sum_{v=1}^{m_1}l_{1,v}+\sum_{u=1}^{m_2}\sum_{v=1}^{\nu_{2,u}}l_{2,u,v}+\sum_{u=1}^{m_3}\sum_{v=1}^{\nu_{3,u}}l_{3,u,v}=l,$$

$$m_4+\sum_{v=1}^{m_1}m_{1,v}+\sum_{u=1}^{m_2}\left(\sum_{v=1}^{\nu_{2,u}}m_{2,u,v}+\chi_{2,u}\right)+\sum_{u=1}^{m_3}\left(\sum_{v=1}^{\nu_{3,u}}m_{3,u,v}+\chi_{3,u}\right)=m.$$

In (5.10), (5.11), and (5.12)

$$1\le l_{1,v}+m_{1,v}\le l+m-1,\qquad v=1,\cdots,m_1,$$

$$1\le l_{2,u,v}+m_{2,u,v}\le l+m-1,\quad u=1,\cdots,m_2,\quad v=1,\cdots,\nu_{2,u},$$

$$1\le l_{3,u,v}+m_{3,u,v}\le l+m-1,\quad u=1,\cdots,m_3,\quad v=1,\cdots,\nu_{3,u}.$$

In (5.13)

$$1 \le l_{1,v} + m_{1,v} \le l + m, \ v = 1, \cdots, m_1,$$
$$1 \le l_{2,u,v} + m_{2,u,v} \le l + m, \ u = 1, \cdots, m_2, \ v = 1, \cdots, \nu_{2,u},$$
$$1 \le l_{3,u,v} + m_{3,u,v} \le l + m, \ u = 1, \cdots, m_3, \ v = 1, \cdots, \nu_{3,u}.$$

On the other hand, by the variation of constants formula,

$$\begin{aligned} &\frac{\partial^{l+m}\phi}{\partial\sigma^0_{i_1}\cdots\partial\sigma^0_{i_l}\partial\mu^m}(t,\sigma^0,\mu,q_1,r_1,\rho) - \frac{\partial^{l+m}\phi}{\partial\sigma^0_{i_1}\cdots\partial\sigma^0_{i_l}\partial\mu^m}(t,\sigma^0,\mu,q_2,r_2,\rho) \\ &= \int_0^t \Upsilon(t,s,\sigma^0,\mu,q_1,r_1,\rho)\widehat{f}_{(i_1,\cdots,i_l,m)}(s)\,ds. \end{aligned} \tag{5.14}$$

Now assume that (5.8) holds for all $\widehat{l}$ and $\widehat{m}$ such that $\widehat{l} + \widehat{m} \le l + m - 1$. By Lemmas 5.2 and 5.3, and Property 5.6 there is $\widehat{K}_{l,m} > 0$ such that for $t \le 0$,

$$\begin{aligned} \left\|\widehat{f}_{(i_1,\cdots,i_l,m)}(t)\right\| \ &\le \ \widehat{K}_{l,m}\left(\|q_1 - q_2\|_{l+m} + \|r_1 - r_2\|_{l+m}\right)\lambda(\rho)\mu^{k-m} \\ &\quad \times \left\{\sum_{i=0}^{l+2m}\left[\lambda(\rho)\mu^k(-t)\right]^i\right\} e^{-(l+m+1)\lambda(\rho)\mu^k(1+2\Delta)t}. \end{aligned} \tag{5.15}$$

Now (5.8) follows from (5.14) and (5.15). □

Next we will state and prove some properties of $\Lambda(t, t_0, \sigma^0, \mu, q, r, \rho)$, which is defined as the fundamental matrix solution of (3.2), where $A(\theta)$ satisfies Assumption 2.1(a). The proof of Lemma 5.7 is left to the reader.

LEMMA 5.7. *For each $\rho \in I_1$, $\Lambda(t, t_0, \sigma^0, \mu, q, r, \rho)$ exists for all $t, t_0 \in \mathbb{R}$, $\sigma^0 \in \mathbb{R}^N$, and $\mu \in I$, and it is k-times continuously differentiable with respect to t, t_0, σ^0, and μ, and T_i-periodic in σ^0_i for $i = 1, \cdots, N$.*

Let

$$K_1 = \max_{1\le i\le N}\{H_i\}, \quad \beta_1 = \min_{1\le i\le N}\{\alpha_i\}, \quad H = \max_{1\le i\le N}\left\{\frac{\alpha_i + H_i\|A_i\|}{\omega_i}\right\}.$$

By Assumption 2.1(d), there is $\rho_1 > 0$ such that for $|\rho| \le \rho_1$,

$$\lambda(\rho)\mu^k \le \frac{\beta_1}{H} \quad \text{for all } \mu \in I, \tag{5.16}$$

and

$$\lambda(\rho) < \omega_i, \qquad i = 1, \cdots, N. \tag{5.17}$$

In the remainder of this section we assume that $|\rho| \le \rho_1$.

LEMMA 5.8. *For $t_0 \le t$,*

$$\|\Lambda(t,t_0,\sigma^0,\mu,q,r,\rho)\| \le K_1 e^{-[\beta_1 - H\lambda(\rho)\mu^k](t-t_0)}. \tag{5.18}$$

Proof. Let $\Lambda_i(t,t_0,\sigma^0,\mu,q,r,\rho)$ be the fundamental matrix solution of

$$\begin{aligned} &\frac{dw_i}{dt} = A_i(\omega_i^{-1}\phi_i(t,\sigma^0,\mu,q,r,\rho))w_i, \\ &\Lambda_i(t_0,t_0,\sigma^0,\mu,q,r,\rho) = I. \end{aligned} \tag{5.19}$$

By (5.17)

$$\frac{d\phi_i}{dt}(t,\sigma^0,\mu,q,r,\rho) > 0.$$

Therefore we can take $\theta_i = \omega_i^{-1}\phi_i(t,\sigma^0,\mu,r,s,\rho)$ as an independent variable in (5.19) and obtain

$$\begin{aligned} \frac{dw_i}{d\theta_i} &= \frac{dt}{d\theta_i}\frac{dw_i}{dt} \\ &= \frac{\omega_i}{\omega_i + \mathcal{S}_i(\phi(t),q(\phi(t),\mu),r(\phi(t),\mu),\mu,\rho)} A_i(\theta_i)w_i \\ &= A_i(\theta_i)w_i - \frac{\mathcal{S}_i(\phi(t),q(\phi(t),\mu),r(\phi(t),\mu),\mu,\rho)}{\omega_i + \mathcal{S}_i(\phi(t),q(\phi(t),\mu),r(\phi(t),\mu),\mu,\rho)} A_i(\theta_i)w_i. \end{aligned}$$

By the variation of constants formula, Λ_i, as a function of θ_i, is given by

$$\begin{aligned} \Lambda_i(\theta_i) &= \Psi_i(\theta_i)\Psi_i^{-1}(\theta_i^0)\Lambda_i(\theta_i^0) \\ &\quad - \int_{\theta_i^0}^{\theta_i} \Psi_i(\theta_i)\Psi_i^{-1}(s)\frac{\mathcal{S}_i(\phi(t),q(\phi(t),\mu),r(\phi(t),\mu),\mu,\rho)}{\omega_i + \mathcal{S}_i(\phi(t),q(\phi(t),\mu),r(\phi(t),\mu),\mu,\rho)} A_i(s)\Lambda_i(s)\,ds. \end{aligned}$$

Suppose $\theta_i^0 = \omega_i^{-1}\phi_i(t_0,\sigma^0,q,r,\mu,\rho)$. Then $\Lambda_i(\theta_i^0) = I$. Moreover for $t_0 \le t$, $\theta_i^0 \le \theta_i$. Therefore

$$\begin{aligned} \|\Lambda_i(\theta_i)\| &\le H_i e^{-\alpha_i(\theta_i - \theta_i^0)} \\ &\quad + \frac{H_i\,\|A_i\|\,\lambda(\rho)\mu^k}{\omega_i - \lambda(\rho)\mu^k} \int_{\theta_i^0}^{\theta_i} e^{-\alpha_i(\theta_i - s)}\,\|\Lambda_i(s)\|\,ds. \end{aligned}$$

By Gronwall's inequality we obtain

$$\begin{aligned} \|\Lambda_i(\theta_i)\| &\le H_i e^{-\left[\alpha_i - H_i\|A_i\|\lambda(\rho)\mu^k/(\omega_i - \lambda(\rho)\mu^k)\right](\theta_i - \theta_i^0)} \\ &= H_i e^{-\left[\alpha_i\omega_i - (\alpha_i + H_i\|A_i\|)\lambda(\rho)\mu^k\right](\theta_i - \theta_i^0)/(\omega_i - \lambda(\rho)\mu^k)}. \end{aligned}$$

Since

$$\begin{aligned}
&\phi_i(t,\sigma^0,\mu,q,r,\rho) - \phi_i(t_0,\sigma^0,\mu,q,r,\rho)\\
&\quad = \omega_i(t-t_0) + \int_{t_0}^{t} \mathcal{S}_i(\phi(s),q(\phi(s),\mu),r(\phi(s),\mu),\mu,\rho)\,ds\\
&\quad \geq (\omega_i - \lambda(\rho)\mu^k)(t-t_0),
\end{aligned}$$

it follows from (5.16) that for $t_0 \leq t$,

$$\begin{aligned}
\left\|\Lambda_i(t,t_0,\sigma^0,\mu,q,r,\rho)\right\| &\leq H_i e^{-\left[\alpha_i - (\alpha_i + H_i\|A_i\|)/\omega_i\lambda(\rho)\mu^k\right](t-t_0)}\\
&\leq K_1 e^{-[\beta_1 - H\lambda(\rho)\mu^k](t-t_0)}.
\end{aligned}$$

Now (5.18) follows from the fact that

$$\Lambda(t,t_0,\sigma^0,\mu,q,r,\rho) = \bigoplus_{i=1}^{N} \Lambda_i(t,t_0,\sigma^0,\mu,q,r,\rho). \qquad \square$$

LEMMA 5.9. *For $1 \leq l+m \leq k$ there is a positive constant $C_{l,m}$ such that for $t_0 \leq t \leq 0$,*

$$\begin{aligned}
&\left\|\frac{\partial^{l+m}\Lambda}{\partial\sigma_{i_1}^0 \cdots \partial\sigma_{i_l}^0 \partial\mu^m}(t,t_0,\sigma^0,\mu,q,r,\rho)\right\|\\
&\quad \leq C_{l,m}\left[\sum_{i=1}^{l+2m}(-t_0)^i\right] e^{-[\beta_1 - H\lambda(\rho)\mu^k](t-t_0) - (l+m)\lambda(\rho)\mu^k(1+2\Delta)t_0}.
\end{aligned} \tag{5.20}$$

Proof. It is easily shown inductively that for $1 \leq l+m \leq k$

$$x = \frac{\partial^{l+m}\Lambda}{\partial\sigma_{i_1}^0 \cdots \partial\sigma_{i_l}^0 \partial\mu^m}(t,t_0,\sigma^0,\mu,q,r,\rho)$$

satisfies the following nonhomogeneous linear system:

$$\begin{aligned}
&\frac{dx}{dt} = A(\Omega^{-1}\phi(t,\sigma^0,\mu,q,r,\rho))x + g_{(i_1,\cdots,i_l,m)}(t),\\
&\frac{\partial^{l+m}\Lambda}{\partial\sigma_{i_1}^0 \cdots \partial\sigma_{i_l}^0 \partial\mu^m}(t_0,t_0,\sigma^0,\mu,q,r,\rho) = 0.
\end{aligned} \tag{5.21}$$

System (5.21) has the following properties.

PROPERTY 5.10. $g_{(i_1,\cdots,i_l,m)}(t)$ is a (finite) sum of terms of the form

$$\frac{\partial^n A}{\partial\theta^n}(\Omega^{-1}\phi(t))a_1 \cdots a_n b_{n+1},$$

where

$$a_v = \Omega^{-1} \frac{\partial^{l_v+m_v}\phi}{\partial\sigma^0_{j_{v,1}} \cdots \partial\sigma^0_{j_{v,l_{1,v}}} \partial\mu^{m_v}}(t), \qquad v = 1, \cdots, n,$$

$$b_{n+1} = \frac{\partial^{l_{n+1}+m_{n+1}}\Lambda}{\partial\sigma^0_{j_{n+1,1}} \cdots \partial\sigma^0_{j_{n+1,l_{n+1}}} \partial\mu^{m_{n+1}}}(t, t_0, \sigma^0, \mu, q, r, \rho),$$

$$1 \le n \le l + m,$$

$$1 \le l_v + m_v \le l + m, \qquad v = 1, \cdots, n,$$

$$0 \le l_{n+1} + m_{n+1} \le l + m - 1,$$

$$\sum_{v=1}^{n+1} l_v = l, \qquad \sum_{v=1}^{n+1} m_v = m.$$

By the variation of constants formula,

$$\frac{\partial^{l+m}\Lambda}{\partial\sigma^0_{i_1} \cdots \partial\sigma^0_{i_l} \partial\mu^m}(t, t_0, \sigma^0, \mu, q, r, \rho) = \int_0^t \Lambda(t, s, \sigma^0, \mu, q, r, \rho) g_{(i_1,\cdots,i_l,m)}(s)\, ds. \tag{5.22}$$

Now we prove (5.20) inductively using Lemmas 5.2, 5.3, and 5.8, Property 5.10, and (5.16) and (5.22). □

LEMMA 5.11. *For $0 \le l + m \le k - 1$ there is a positive constant $\widehat{C}_{l,m}$ such that for $t_0 \le t \le 0$,*

$$\left\| \frac{\partial^{l+m}\Lambda}{\partial\sigma^0_{i_1} \cdots \partial\sigma^0_{i_l} \partial\mu^m}(t, t_0, \sigma^0, \mu, q_1, r_1, \rho) - \frac{\partial^{l+m}\Lambda}{\partial\sigma^0_{i_1} \cdots \partial\sigma^0_{i_l} \partial\mu^m}(t, t_0, \sigma^0, \mu, q_2, r_2, \rho) \right\|$$

$$\le \widehat{C}_{l,m} \left(\|q_1 - q_2\|_{l+m} + \|r_1 - r_2\|_{l+m} \right) \tag{5.23}$$

$$\times \left[\sum_{i=2}^{l+2m+2} (-t_0)^i \right] e^{-[\beta_1 - H\lambda(\rho)\mu^k](t-t_0) - (l+m+1)\lambda(\rho)\mu^k(1+2\Delta)t_0}.$$

Proof. Let

$$\Lambda_1(t, t_0) = \Lambda(t, t_0, \sigma^0, \mu, q_1, r_1, \rho), \qquad \Lambda_2(t, t_0) = \Lambda(t, t_0, \sigma^0, \mu, q_2, r_2, \rho).$$

We easily show that, for $0 \le l + m \le k - 1$,

$$x = \frac{\partial^{l+m}\Lambda_1}{\partial\sigma^0_{i_1} \cdots \partial\sigma^0_{i_l} \partial\mu^m}(t, t_0) - \frac{\partial^{l+m}\Lambda_2}{\partial\sigma^0_{i_1} \cdots \partial\sigma^0_{i_l} \partial\mu^m}(t, t_0)$$

satisfies the following nonhomogeneous linear system:

$$\begin{aligned}&\frac{dx}{dt} = A(\Omega^{-1}\phi_1(t))x + \widehat{g}_{(i_1,\cdots,i_l,m)}(t),\\ &\frac{\partial^{l+m}\Lambda_1}{\partial\sigma^0_{i_1}\cdots\partial\sigma^0_{i_l}\partial\mu^m}(t_0,t_0) - \frac{\partial^{l+m}\Lambda_2}{\partial\sigma^0_{i_1}\cdots\partial\sigma^0_{i_l}\partial\mu^m}(t_0,t_0) = 0.\end{aligned} \tag{5.24}$$

System (5.24) has the following properties.

PROPERTY 5.12. $\widehat{g}_{(i_1,\cdots,i_l,m)}(t)$ is a (finite) sum of terms of the forms

$$\frac{\partial^n A}{\partial\sigma^n}(\Omega^{-1}\phi_1(t))a^1_1\cdots a^1_n\left(b^1_{n+1} - b^2_{n+1}\right), \tag{5.25}$$

$$\frac{\partial^n A}{\partial\sigma^n}(\Omega^{-1}\phi_1(t))a^2_1\cdots a^2_{v-1}\left(a^1_v - a^2_v\right)a^1_{v+1}\cdots a^1_n b^2_{n+1}, \tag{5.26}$$

$$\left[\frac{\partial^n A}{\partial\sigma^n}(\Omega^{-1}\phi_1(t)) - \frac{\partial^n A}{\partial\sigma^n}(\Omega^{-1}\phi_2(t))\right]a^2_1\cdots a^2_n b^2_{n+1}, \tag{5.27}$$

where for $i = 1, 2$,

$$\begin{aligned}&a^i_v = \Omega^{-1}\frac{\partial^{l_v+m_v}\phi_i}{\partial\sigma^0_{j_{v,1}}\cdots\partial\sigma^0_{j_{v,l_v}}\partial\mu^{m_v}}(t), \qquad v = 1,\cdots,n,\\ &b^i_{n+1} = \frac{\partial^{l_{n+1}+m_{n+1}}\Lambda_i}{\partial\sigma^0_{j_{n+1,1}}\cdots\partial\sigma^0_{j_{n+1,l_{n+1}}}\partial\mu^{m_{n+1}}}(t,t_0),\\ &\sum_{v=1}^{n+1} l_v = l, \qquad \sum_{v=1}^{n+1} m_v = m.\end{aligned}$$

In (5.25) and (5.26)

$$\begin{aligned}&1 \le n \le l+m,\\ &1 \le l_v + m_v \le l+m, \qquad v = 1,\cdots,n,\\ &0 \le l_{n+1} + m_{n+1} \le l+m-1.\end{aligned}$$

In (5.27)

$$\begin{aligned}&0 \le n \le l+m,\\ &1 \le l_v + m_v \le l+m, \qquad v = 1,\cdots,n,\\ &n = 0 \quad \text{if and only if } l_{n+1} = l \text{ and } m_{n+1} = m.\end{aligned}$$

By the variation of constants formula,

$$\begin{aligned}&\frac{\partial^{l+m}\Lambda_1}{\partial\sigma^0_{i_1}\cdots\partial\sigma^0_{i_l}\partial\mu^m}(t,t_0) - \frac{\partial^{l+m}\Lambda_2}{\partial\sigma^0_{i_1}\cdots\partial\sigma^0_{i_l}\partial\mu^m}(t,t_0)\\ &\quad = \int_0^t \Lambda(t,s,\sigma^0,\mu,q_1,r_1,\rho)\widehat{g}_{(i_1,\cdots,i_l,m)}(s)\,ds.\end{aligned} \tag{5.28}$$

Now we prove (5.23) inductively using Lemmas 5.2, 5.3, 5.5, 5.8, and 5.9, Property 5.12, and (5.16) and (5.28). □

Recall that $\phi(t,\sigma^0,q,r,\mu)$ is a solution of (3.18) where $\mathcal{S}$ satisfies Assumption 2.1(f) and $(q,r)\in B^k_\Delta(\mathbb{R}^N,\mathbb{R}^{N_1})\times B^k_\Delta(\mathbb{R}^N,\mathbb{R}^{N_2})$, and $\Lambda(t,t_0,\sigma^0,q,r,\mu)$ is the fundamental matrix solution of (3.19) where $A(\theta)$ satisfies Assumption 2.1(a). Suppose that $(q,r),(q_1,r_1),(q_2,r_2)\in B^k_\Delta(\mathbb{R}^N,\mathbb{R}^{N_1})\times B^k_\Delta(\mathbb{R}^N,\mathbb{R}^{N_2})$. We only state the following properties of $\phi(t,\sigma^0,q,r,\mu)$ and $\Lambda(t,t_0,\sigma^0,q,r,\mu)$ because the proofs are similar to those of Lemmas 5.1–5.11 and even simpler.

PROPERTY 5.13. (a) For each $\mu\in I$, $\phi(t,\sigma^0,q,r,\mu)$ exists for all $t\in\mathbb{R}$, $\sigma^0\in\mathbb{R}^N$, and it is k-times continuously differentiable with respect to t and σ^0. Moreover, for $i=1,\cdots,N$

$$\phi(t,\sigma^0+2\pi e^i,q,r,\mu)=\phi(t,\sigma^0,q,r,\mu)+2\pi e^i.$$

(b) If

$$\Upsilon(t,s,\sigma^0,q,r,\mu)=\frac{\partial\phi}{\partial\sigma^0}(t,\sigma^0,q,r,\mu)\frac{\partial\phi^{-1}}{\partial\sigma^0}(s,\sigma^0,q,r,\mu),$$

then for all $t,s\in\mathbb{R}$,

$$\|\Upsilon(t,s,\sigma^0,q,r,\mu)\|\le e^{\lambda(\mu)(1+2\Delta)|t-s|}.$$

In particular, for $t\le 0$,

$$\left\|\frac{\partial\phi}{\partial\sigma^0}(t,\sigma^0,q,r,\mu)\right\|\le e^{-\lambda(\mu)(1+2\Delta)t}.$$

(c) For $2\le l\le k$ there is a positive constant K_l such that for $t\le 0$,

$$\left\|\frac{\partial^l\phi}{\partial\sigma^0_{i_1}\cdots\partial\sigma^0_{i_l}}(t,\sigma^0,q,r,\mu)\right\|\le K_l\left\{\sum_{i=1}^{l-1}[\lambda(\mu)(-t)]^i\right\}e^{-l\lambda(\mu)(1+2\Delta)t}.$$

(d) For $0\le l\le k-1$ there is a positive constant $\widehat{K}_l$ such that for $t\le 0$,

$$\left\|\frac{\partial^l\phi}{\partial\sigma^0_{i_1}\cdots\partial\sigma^0_{i_l}}(t,\sigma^0,q_1,r_1,\mu)-\frac{\partial^l\phi}{\partial\sigma^0_{i_1}\cdots\partial\sigma^0_{i_l}}(t,\sigma^0,q_2,r_2,\mu)\right\|$$

$$\le\widehat{K}_l\left(\|q_1-q_2\|_l+\|r_1-r_2\|_l\right)\left\{\sum_{i=1}^{l+1}[\lambda(\mu)(-t)]^i\right\}e^{-(l+1)\lambda(\mu)(1+2\Delta)t}.$$

(e) For each $\mu\in I$, $\Lambda(t,t_0,\sigma^0,q,r,\mu)$ exists for all t and $t_0\in\mathbb{R}$, and $\sigma^0\in\mathbb{R}^N$. It is k-times continuously differentiable with respect to t, t_0, and σ^0, and T_i-periodic in σ^0_i for $i=1,\cdots,N$.

(f) If

$$\lambda(\mu)\le\frac{\beta_1}{H},$$

then for $t_0\le t$

$$\left\|\Lambda(t,t_0,\sigma^0,q,r,\mu)\right\| \le He^{-[\beta_1 - H\lambda(\mu)](t-t_0)}.$$

(g) For $1 \le l \le k$ there is a positive constant C_l such that for $t_0 \le t \le 0$,

$$\left\|\frac{\partial^l \Lambda}{\partial\sigma_{i_1}^0 \cdots \partial\sigma_{i_l}^0}(t,t_0,\sigma^0,q,r,\mu)\right\| \le C_l \left[\sum_{i=1}^{l}(-t_0)^i\right] e^{-[\beta_1 - H\lambda(\mu)](t-t_0) - l\lambda(\mu)(1+2\Delta)t_0}$$

(h) For $0 \le l \le k-1$ there is a positive constant $\widehat{C}_l$ such that for $t_0 \le t \le 0$,

$$\left\|\frac{\partial^l \Lambda}{\partial\sigma_{i_1}^0 \cdots \partial\sigma_{i_l}^0}(t,t_0,\sigma^0,q_1,r_1,\mu) - \frac{\partial^l \Lambda}{\partial\sigma_{i_1}^0 \cdots \partial\sigma_{i_l}^0}(t,t_0,\sigma^0,q_2,r_2,\mu)\right\| \le \widehat{C}_l\left(\|q_1-q_2\|_l + \|r_1-r_2\|_l\right)\left[\sum_{i=2}^{l+2}(-t_0)^i\right] e^{-[\beta_1 - H\lambda(\mu)](t-t_0) - (l+1)\lambda(\mu)(1+2\Delta)t_0}.$$

5.2. The proofs of Lemmas 3.1 and 3.2. In this section we prove the lemmas in §3 that lead to Theorem 3.4. Recall that $G_1(s,\sigma,\mu,q,r,\rho)$ and $G_2(s,\sigma,\mu,q,r,\rho)$ are defined by (3.4) where $\phi(t,\sigma^0,\mu,q,r,\rho)$ and $\Lambda(t,t_0,\sigma^0,\mu,q,r,\rho)$ are the solutions of (3.1) and (3.2), respectively.

Proof of Lemma 3.1.

$$\frac{\partial^{l+m} G_1}{\partial\sigma_{i_1}\cdots\partial\sigma_{i_l}\partial\mu^m}(s,\sigma,\mu,q,r,\rho)$$

is a (finite) sum of terms of the form

$$\frac{\partial^{l_1+j_1}\Lambda}{\partial\sigma_{i_{1,1}}\cdots\partial\sigma_{i_{1,l_1}}\partial\mu^{j_1}}\,\frac{\partial^{l_2+j_2}\mathcal{W}}{\partial\sigma_{i_{2,1}}\cdots\partial\sigma_{i_{2,l_2}}\partial\mu^{j_2}},$$

$$l_1 + l_2 = l, \qquad j_1 + j_2 = m, \tag{5.29}$$

$$0 \le l_1, \quad l_2 \le l, \quad 0 \le j_1, \quad j_2 \le m,$$

where Λ and $\mathcal{W}$ are as in (3.4). The second factor of (5.29) is in turn a (finite) sum of terms of the form

$$\frac{\partial^{m_1+m_2+m_3+m_4}\mathcal{W}}{\partial\sigma^{m_1}\partial w^{m_2}\partial z^{m_3}\partial\mu^{m_4}} a_1\cdots a_{m_1} B_1\cdots B_{m_2} C_1\cdots C_{m_3}, \tag{5.30}$$

where

$$a_v = \frac{\partial^{l_{1,v}+m_{1,v}}\phi}{\partial\sigma_{j_{v,1}}\cdots\partial\sigma_{j_{v,l_{1,v}}}\partial\mu^{m_{1,v}}}(s), \qquad v = 1,\cdots,m_1,$$

$$B_u = \frac{\partial^{\nu_{2,u}+\chi_{2,u}}q}{\partial\sigma^{\nu_{2,u}}\mu^{\chi_{2,u}}}(\phi(s),\mu)b_{u,1}\cdots b_{u,\nu_{2,u}}, \qquad u = 1,\cdots,m_2,$$

$$b_{u,v} = \frac{\partial^{l_{2,u,v}+m_{2,u,v}}\phi}{\partial\sigma_{j_{2,u,v,1}}\cdots\partial\sigma_{j_{2,u,v,l_{2,u,v}}}\partial\mu^{m_{2,u,v}}}(s), \qquad v = 1,\cdots,\nu_{2,u},$$

$$C_u = \frac{\partial^{\nu_{3,u}+\chi_{3,u}}q}{\partial\sigma^{\nu_{3,u}}\mu^{\chi_{3,u}}}(\phi(s),\mu)c_{u,1}\cdots c_{u,\nu_{3,u}}, \qquad u = 1,\cdots,m_3,$$

$$c_{u,v} = \frac{\partial^{l_{3,u,v}+m_{3,u,v}}\phi}{\partial\sigma_{j_{3,u,v,1}}\cdots\partial\sigma_{j_{3,u,v,l_{3,u,v}}}\partial\mu^{m_{3,u,v}}}(s), \qquad v = 1,\cdots,\nu_{3,u},$$

$$0 \le m_i \le l_2 + j_2, \quad i = 1,\cdots,4, \quad 1 \le m_1+m_2+m_3+m_4 \le l_2 + j_2,$$

$$\sum_{v=1}^{m_1} l_{1,v} + \sum_{u=1}^{m_2}\sum_{v=1}^{\nu_{2,u}} l_{2,u,v} + \sum_{u=1}^{m_3}\sum_{v=1}^{\nu_{3,u}} l_{3,u,v} = l_2,$$

$$m_4 + \sum_{v=1}^{m_1} m_{1,v} + \sum_{u=1}^{m_2}\left(\sum_{v=1}^{\nu_{2,u}} m_{2,u,v} + \chi_{2,u}\right) + \sum_{u=1}^{m_3}\left(\sum_{v=1}^{\nu_{3,u}} m_{3,u,v} + \chi_{3,u}\right) = j_2.$$

Now (3.6) follows from (5.29), (5.30), and Property 3.1(a)–(e).

Note that

$$\frac{\partial^{l+m}G_2}{\partial\sigma_{i_1}\cdots\partial\sigma_{i_l}\partial\mu^m}(s,\sigma,\mu,q,r,\rho)$$

is a (finite) sum of terms of the form

$$\frac{\partial^{m_1}}{\partial\mu^{m_1}}\left(\rho\mu e^{-\rho\mu Qs}\right)\frac{\partial^{l+m_2}\mathcal{Z}}{\partial\sigma_{i_1}\cdots\partial\sigma_{i_l}\partial\mu^{m_2}},$$

$$m_1 + m_2 = m, \quad 0 \le m_1, \quad m_2 \le m,$$

where $\mathcal{Z}$ is as given in (3.4). Now we show inductively that, for $0 \le m$,

$$\frac{\partial^m}{\partial\mu^m}\left(\rho\mu e^{-\rho\mu Qs}\right) = (-1)^{m-1}\left[m\rho^m(Qs)^{m-1} - \rho^{m+1}\mu(Qs)^m\right]e^{-\rho\mu Qs},$$

and it follows that there is $\widehat{H}_m > 0$ such that for $s \le 0$,

$$\text{(5.31)} \quad \left\|\frac{\partial^m}{\partial\mu^m}\left(\rho\mu e^{-\rho\mu Qs}\right)\right\| \le \begin{cases} K_2\rho\mu e^{\rho\mu\beta_2 s}, & m = 0, \\ \widehat{H}_m\left[\rho^m(-s)^{m-1} + \rho^{m+1}\mu(-s)^m\right]e^{\rho\mu\beta_2 s}, & m > 0. \end{cases}$$

On the other hand, using Property 3.1(a) and (b) and an analysis similar to the one in the first part of the proof, we obtain the estimate

(5.32)

$$\left\| \frac{\partial^{l+m_2} \mathcal{Z}}{\partial \sigma_{i_1} \cdots \partial \sigma_{i_l} \partial \mu^{m_2}} \right\| \leq \widehat{K} \lambda_2(\rho) \mu^{k-m_2} \left\{ \sum_{i=0}^{l+2m_2} \left[\lambda(\rho) \mu^k (-s) \right]^i \right\} e^{-(l+m_2)\lambda(\rho)\mu^k (1+2\Delta)s}.$$

Now (3.7) follows from (3.5), (5.31), and (5.32). □

Proof of Lemma 3.3.

$$\frac{\partial^{l+m} G_1}{\partial \sigma_{i_1} \cdots \partial \sigma_{i_l} \partial \mu^m}(s, \sigma, \mu, q_1, r_1, \rho) - \frac{\partial^{l+m} G_1}{\partial \sigma_{i_1} \cdots \partial \sigma_{i_l} \partial \mu^m}(s, \sigma, \mu, q_2, r_2, \rho)$$

is a (finite) sum of terms of the form

$$\frac{\partial^{l_1+j_1} \Lambda_1}{\partial \sigma_{i_{1,1}} \cdots \partial \sigma_{i_{1,l_1}} \partial \mu^{j_1}} \frac{\partial^{l_2+j_2} \mathcal{W}_1}{\partial \sigma_{i_{2,1}} \cdots \partial \sigma_{i_{2,l_2}} \partial \mu^{j_2}}$$

$$- \frac{\partial^{l_1+j_1} \Lambda_2}{\partial \sigma_{i_{1,1}} \cdots \partial \sigma_{i_{1,l_1}} \partial \mu^{j_1}} \frac{\partial^{l_2+j_2} \mathcal{W}_2}{\partial \sigma_{i_{2,1}} \cdots \partial \sigma_{i_{2,l_2}} \partial \mu^{j_2}}$$

$$= \frac{\partial^{l_1+j_1} \Lambda_1}{\partial \sigma_{i_{1,1}} \cdots \partial \sigma_{i_{1,l_1}} \partial \mu^{j_1}} \left(\frac{\partial^{l_2+j_2} \mathcal{W}_1}{\partial \sigma_{i_{2,1}} \cdots \partial \sigma_{i_{2,l_2}} \partial \mu^{j_2}} - \frac{\partial^{l_2+j_2} \mathcal{W}_2}{\partial \sigma_{i_{2,1}} \cdots \partial \sigma_{i_{2,l_2}} \partial \mu^{j_2}} \right)$$

$$+ \left(\frac{\partial^{l_1+j_1} \Lambda_1}{\partial \sigma_{i_{1,1}} \cdots \partial \sigma_{i_{1,l_1}} \partial \mu^{j_1}} - \frac{\partial^{l_1+j_1} \Lambda_2}{\partial \sigma_{i_{1,1}} \cdots \partial \sigma_{i_{1,l_1}} \partial \mu^{j_1}} \right) \frac{\partial^{l_2+j_2} \mathcal{W}_2}{\partial \sigma_{i_{2,1}} \cdots \partial \sigma_{i_{2,l_2}} \partial \mu^{j_2}},$$

$$l_1 + l_2 = l, \qquad j_1 + j_2 = m,$$

$$0 \leq l_1, \quad l_2 \leq l, \quad 0 \leq j_1, j_2 \leq m,$$

where for $i = 1, 2$,

$$\Lambda_i = \Lambda(0, s, \sigma, \mu, q_i, r_i, \rho), \qquad \mathcal{W}_i = \mathcal{W}(\tau_i(s), q_i(\tau_i(s), \mu), r_i(\tau_i(s), \mu), \mu, \rho).$$

On the other hand,

$$\frac{\partial^{l_2+j_2} \mathcal{W}_1}{\partial \sigma_{i_{2,1}} \cdots \partial \sigma_{i_{2,l_2}} \partial \mu^{j_2}} - \frac{\partial^{l_2+j_2} \mathcal{W}_2}{\partial \sigma_{i_{2,1}} \cdots \partial \sigma_{i_{2,l_2}} \partial \mu^{j_2}}$$

is in turn a (finite) sum of terms of the forms

$$\frac{\partial^{m_1+m_2+m_3+m_4} \mathcal{W}_1}{\partial \sigma^{m_1} \partial w^{m_2} \partial z^{m_3} \partial \mu^{m_4}} a_1^1 \cdots a_{m_1}^1 B_1^1 \cdots B_{m_2}^1 C_1^2 \cdots C_{u-1}^2 \left(C_u^1 - C_u^2 \right) C_{u+1}^1 \cdots C_{m_3}^1,$$

$$\frac{\partial^{m_1+m_2+m_3+m_4} \mathcal{W}_1}{\partial \sigma^{m_1} \partial w^{m_2} \partial z^{m_3} \partial \mu^{m_4}} a_1^1 \cdots a_{m_1}^1 B_1^2 \cdots B_{u-1}^2 \left(B_u^1 - B_u^2 \right) B_{u+1}^1 \cdots B_{m_2}^1 C_1^2 \cdots C_{m_3}^2,$$

$$\frac{\partial^{m_1+m_2+m_3+m_4} \mathcal{W}_1}{\partial \sigma^{m_1} \partial w^{m_2} \partial z^{m_3} \partial \mu^{m_4}} a_1^2 \cdots a_{v-1}^2 \left(a_v^1 - a_v^2 \right) a_{v+1}^1 \cdots a_{m_1}^1 B_1^2 \cdots B_{m_2}^2 C_1^2 \cdots C_{m_3}^2,$$

$$\left(\frac{\partial^{m_1+m_2+m_3+m_4} \mathcal{W}_1}{\partial \sigma^{m_1} \partial w^{m_2} \partial z^{m_3} \partial \mu^{m_4}} - \frac{\partial^{m_1+m_2+m_3+m_4} \mathcal{W}_2}{\partial \sigma^{m_1} \partial w^{m_2} \partial z^{m_3} \partial \mu^{m_4}} \right) a_1^2 \cdots a_{m_1}^2 B_1^2 \cdots B_{m_2}^2 C_1^2 \cdots C_{m_3}^2,$$

where

$$a_v^i = \frac{\partial^{l_{1,v}+m_{1,v}}\tau_i}{\partial\sigma_{j_{v,1}}\cdots\partial\sigma_{j_{v,l_{1,v}}}\partial\mu^{m_{1,v}}}(s), \qquad v=1,\cdots,m_1,$$

$$B_u^i = \frac{\partial^{\nu_{2,u}+\chi_{2,u}}q_i}{\partial\sigma^{\nu_{2,u}}\mu^{\chi_{2,u}}}(\tau_i(s),\mu)b_{u,1}^i\cdots b_{u,\nu_{2,u}}^i, \qquad u=1,\cdots,m_2,$$

$$b_{u,v}^i = \frac{\partial^{l_{2,u,v}+m_{2,u,v}}\tau_i}{\partial\sigma_{j_{2,u,v,1}}\cdots\partial\sigma_{j_{2,u,v,l_{2,u,v}}}\partial\mu^{m_{2,u,v}}}(s), \qquad v=1,\cdots,\nu_{2,u},$$

$$C_u^i = \frac{\partial^{\nu_{3,u}+\chi_{3,u}}q}{\partial\sigma^{\nu_{3,u}}\mu^{\chi_{3,u}}}(\tau_i(s),\mu)c_{u,1}^i\cdots c_{u,\nu_{3,u}}^i, \qquad u=1,\cdots,m_3,$$

$$c_{u,v}^i = \frac{\partial^{l_{3,u,v}+m_{3,u,v}}\tau_i}{\partial\sigma_{j_{3,u,v,1}}\cdots\partial\sigma_{j_{3,u,v,l_{3,u,v}}}\partial\mu^{m_{3,u,v}}}(s), \qquad v=1,\cdots,\nu_{3,u},$$

$$0\le m_i\le l_2+j_2, \quad i=1,\cdots,4, \quad 1\le m_1+m_2+m_3+m_4\le l_2+j_2,$$

$$\sum_{v=1}^{m_1} l_{1,v}+\sum_{u=1}^{m_2}\sum_{v=1}^{\nu_{2,u}} l_{2,u,v}+\sum_{u=1}^{m_3}\sum_{v=1}^{\nu_{3,u}} l_{3,u,v}=l_2,$$

$$m_4+\sum_{v=1}^{m_1} m_{1,v}+\sum_{u=1}^{m_2}\left(\sum_{v=1}^{\nu_{2,u}} m_{2,u,v}+\chi_{2,u}\right)+\sum_{u=1}^{m_3}\left(\sum_{v=1}^{\nu_{3,u}} m_{3,u,v}+\chi_{3,u}\right)=j_2.$$

Now (3.8) follows from this fact and Property 3.1.

Observe that

$$\frac{\partial^{l+m}G_2}{\partial\sigma_{i_1}\cdots\partial\sigma_{i_l}\partial\mu^m}(s,\sigma,\mu,q_1,r_1,\rho)-\frac{\partial^{l+m}G_2}{\partial\sigma_{i_1}\cdots\partial\sigma_{i_l}\partial\mu^m}(s,\sigma,\mu,q_2,r_2,\rho)$$

is a (finite) sum of terms of the form

$$\frac{\partial^{m_1}}{\partial\mu^{m_1}}\left(\rho\mu e^{-\rho\mu Qs}\right)\left(\frac{\partial^{l+m_2}\mathcal{Z}_1}{\partial\sigma_{i_1}\cdots\partial\sigma_{i_l}\partial\mu^{m_2}}-\frac{\partial^{l+m_2}\mathcal{Z}_2}{\partial\sigma_{i_1}\cdots\partial\sigma_{i_l}\partial\mu^{m_2}}\right),$$

$$m_1+m_2=m, \quad 0\le m_1,m_2\le m.$$

An analysis similar to the one in the first part of the proof leads to the estimate

$$\begin{aligned}\left\|\frac{\partial^{l+m_2}\mathcal{Z}_1}{\partial\sigma_{i_1}\cdots\partial\sigma_{i_l}\partial\mu^{m_2}}-\frac{\partial^{l+m_2}\mathcal{Z}_2}{\partial\sigma_{i_1}\cdots\partial\sigma_{i_l}\partial\mu^{m_2}}\right\| &\le \widehat{K}\lambda_2(\rho)\mu^{k-m_2}\left(\|q_1-q_2\|_{l+m_2}+\|r_1-r_2\|_{l+m_2}\right)\\ &\times\left\{\sum_{i=0}^{l+2m_2+2}\left[\lambda(\rho)\mu^k(-s)\right]^i\right\}e^{-(l+m_2+1)\lambda(\rho)\mu^k(1+2\Delta)s}.\end{aligned} \tag{5.33}$$

Now (3.9) follows from (3.5), (5.31), and (5.33). □

THE EXISTENCE OF INFINITELY MANY TRAVELING FRONT AND BACK WAVES IN THE FITZHUGH–NAGUMO EQUATIONS*

BO DENG†

Abstract. Consideration is given to the FitzHugh-Nagumo equations of bistable type. The existence of traveling front and back waves with any finite number of pulses is proved. The speed of such a multiple pulse wave is characterized by its number of pulses: the more pulses it has, the slower it travels. Traveling impulse and traveling train solutions are also found. These traveling waves arise from the bifurcation of a doubly twisted front-back wave loop. The method is based on the theory of heteroclinic loop bifurcation, the geometric theory of singular perturbation and the Melnikov method.

Key words. traveling wave, twisted heteroclinic loop, singular perturbation, Melnikov integral

AMS(MOS) subject classifications. primary 35K57; secondary 34B99, 34C28, 34C45, 34D15

1. Introduction.

Consider the FitzHugh-Nagumo equations

$$v_t = v_{xx} + f(v) - w, \qquad w_t = \varepsilon(v - \gamma w), \tag{1.1}$$

where $f(v) = v(v-a)(1-v)$ is a cubic polynomial and $0 < a < \frac{1}{2}$, $\varepsilon > 0$, and $\gamma > 0$ are parameters. A solution $(v, w)(x, t)$ that is bounded over $x \in \mathbb{R}$ and $t \in \mathbb{R}$ is called a traveling wave if it is a function of one variable and there is a constant c so that $(v, w)(x, t) = (v, w)(x + ct)$.

The simplest traveling waves might be constant, or steady-state solutions. Depending on the value of γ, there are one, two, or three steady states (cf. Fig. 1.1), which are the intersections of the nullclines $w = f(v)$ and $v = \gamma w$. In this paper, however, we are interested in the case when γ is greater than the critical value $\gamma_1 := v_{\max}/f_{\max}$ and there are three steady states. We restrict our attention further to the leftmost and rightmost stable states, which we denote by $\mathbf{a}_1$ and $\mathbf{a}_2$ in Fig. 1.1, respectively, and

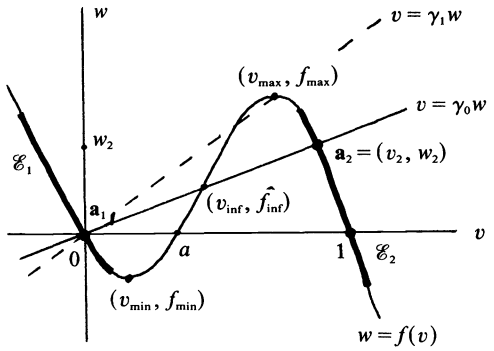

FIG. 1.1. *γ_0 is chosen so that $\mathbf{a}_1$ and $\mathbf{a}_2$ are symmetric with respect to the inflection point $(v_{\inf}, f_{\inf})$ of the cubic curve $w = f(v)$. The thickly drawn segments $\mathscr{E}_1$ and $\mathscr{E}_2$ on $w = f(v)$ do not contain the extreme points but they are long enough so that $\mathscr{E}_1$ contains $\mathbf{a}_1 = 0$ and the intersect point $\{w = w_2\} \cap \{w = f(v)\}$ and $\mathscr{E}_2$ contains $\mathbf{a}_2$ and $(1, 0)$ as interior points, respectively.*

study nonconstant traveling waves connecting $\mathbf{a}_1$ and $\mathbf{a}_2$. The various types of connecting waves considered here are as follows. A traveling wave $(v, w)(x+ct)$ is said to be a *traveling front* if

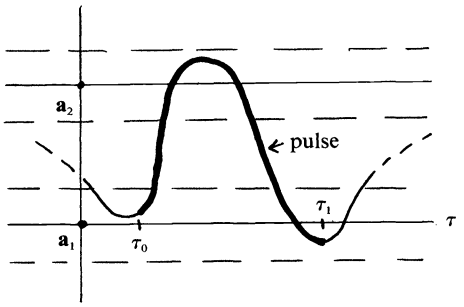
$$\lim_{t\to-\infty}(v, w)(x+ct)=\mathbf{a}_1 \quad \text{and} \quad \lim_{t\to+\infty}(v, w)(x+ct)=\mathbf{a}_2,$$

exist for all x. Likewise, by a *traveling back* wave we mean the same limits exist except that the first limit is $\mathbf{a}_2$ while the second limit is $\mathbf{a}_1$. A traveling wave solution is said to be an *impulse of* $\mathbf{a}_1$ if

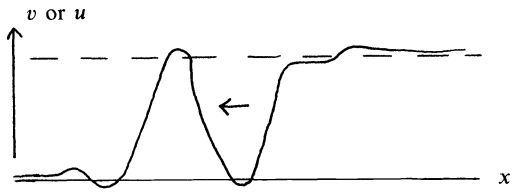
$$\lim_{\tau\to\pm\infty}(v, w)(\tau)=\mathbf{a}_1.$$

An *impulse of* $\mathbf{a}_2$ is analogously defined. Last, a traveling wave solution is said to be a *traveling train* if $(v, w)(\tau)$ is periodic in τ.

We further characterize the waves of the same type according to their numbers of pulses contained. To be precise, choose and fix a neighborhood of each $\mathbf{a}_1$ and $\mathbf{a}_2$ for the equations. A traveling wave has a *pulse* from $\mathbf{a}_1$ if there is a closed interval $\tau_0 \leqq \tau \leqq \tau_1$ such that $(v, w)(\tau)$ arises from the chosen vicinity of $\mathbf{a}_1$, enters into the vicinity of $\mathbf{a}_2$, and only afterwards falls back to the vicinity of $\mathbf{a}_1$ as τ increases from τ_0 to τ_1 (cf. Fig. 1.2). A pulse from $\mathbf{a}_2$ is defined similarly. A front (back, respectively) wave is called *k-front* (k-back, respectively) wave if it has k pulses from $\mathbf{a}_1$. A front (back, respectively) without a pulse is referred to as a simple front (back, respectively). An impulse of $\mathbf{a}_i$ is called a *k-impulse* if it has k pulses from $\mathbf{a}_i$. A traveling train is



(a)



(b)

FIG. 1.2. (a) *One pulse (thickly drawn curve) forms when the traveling wave jumps from a given neighborhood of* $\mathbf{a}_1$ *into a given neighborhood of* $\mathbf{a}_2$ *and only afterwards drops into the neighborhood of* $\mathbf{a}_1$ *again over an interval* $\tau\in[\tau_0, \tau_1]$.

(b) *When the traveling speed* $c>0$, *a 1-front here moves to the left with time.*

called a *k-train* if within the minimum period of the periodic traveling wave there are k pulses. An impulse or a traveling train is simple if there is only one pulse. We emphasize that the comparison among fronts or other types of waves in terms of the number of pulses makes sense only if the neighborhoods of $\mathbf{a}_1$ and $\mathbf{a}_2$ are fixed, but they are allowed to vary with parameters.

The profiles of a given traveling wave are simply the graphs of v and w over the real line (cf. Fig. 1.2). Thus, a traveling wave moves to the left with time if the traveling velocity c is positive. Likewise, it travels to the right if $c<0$. Also, it is trivial to verify that if $(v, w)(x+ct)$ is a traveling wave then $(\bar{v}, \bar{w})(x+(-c)t) := (v, w)(-x+ct)$ is another traveling wave solution, traveling in the opposite direction. For this reason, we only consider the existence of leftward traveling waves (i.e., with $c>0$) from now on.

By smoothness in this paper we mean differentiability of as many times as needed. Our main result is the following theorem.

THEOREM 1.1. *Let $0<a<\frac{1}{2}$ be fixed in the FitzHugh–Nagumo equations* (1.1). *There exists a small ε_0 and two smooth functions $\gamma(\varepsilon)$ and $\delta(\varepsilon)$, $0 \leqq \varepsilon \leqq \varepsilon_0$, such that the following is satisfied for all $0<\varepsilon<\varepsilon_0$.*

(a) *On the relevant (γ, c)-parameter space there are two smooth curves $c = c_{i,0}(\gamma)$ defined on the interval $|\gamma-\gamma(\varepsilon)|<\delta(\varepsilon)$ and $i=1, 2$ ($c_{i,0}$ here and all other curves below are smoothly parametrized by ε also, but ε is usually suppressed for simplicity) such that* (1.1) *has a simple front wave of speed $c_{1,0}(\gamma)$ and a simple back wave of speed $c_{2,0}(\gamma)$.*

(b) *There is a sequence $\{c_{1,k}(\gamma)\}_{k=1}^{\infty}$ of smooth curves of the left half interval $0<\gamma(\varepsilon)-\gamma<\delta(\varepsilon)$ such that* (1.1) *has a k-front wave of speed $c_{1,k}(\gamma)$ for every $k=1, 2, \cdots$ and $0<\gamma(\varepsilon)-\gamma<\delta(\varepsilon)$. Similarly, there is a sequence $\{c_{2,k}(\gamma)\}_{k=1}^{\infty}$ of smooth curves of the right half interval $0<\gamma-\gamma(\varepsilon)<\delta(\varepsilon)$ such that* (1.1) *has a k-back wave of speed $c_{2,k}(\gamma)$ for every $k=1, 2, \cdots$ and $0<\gamma-\gamma(\varepsilon)<\delta(\varepsilon)$.*

(c) *There is a smooth curve $c_{1,\infty}(\gamma)$ of the left half interval $0<\gamma(\varepsilon)-\gamma<\delta(\varepsilon)$ such that* (1.1) *has a simple impulse wave of $\mathbf{a}_1$ with speed $c_{1,\infty}(\gamma)$ for every $0<\gamma(\varepsilon)-\gamma<\delta(\varepsilon)$. Similarly, there is a smooth curve $c_{2,\infty}(\gamma)$ of the right half interval $0<\gamma-\gamma(\varepsilon)<\delta(\varepsilon)$ such that* (1.1) *has a simple impulse wave of $\mathbf{a}_2$ with speed $c_{2,\infty}(\gamma)$ for every $0<\gamma-\gamma(\varepsilon)<\delta(\varepsilon)$.*

(d) *The simple front and back wave curves $c_{i,0}(\gamma)$ intersect transversely at $\gamma(\varepsilon)$. The intersection point, $(\gamma(\varepsilon), c(\varepsilon))$, is smooth in ε. At $\varepsilon=0$, $(\gamma(0), c(0)) = (9/(2-a)(1-2a), (1-2a)/\sqrt{2}) := (\gamma_0, c_0)$. The slopes of $c_{i,0}(\gamma)$ satisfy $c'_{1,0}(\gamma_0)=0$ and $c'_{2,0}(\gamma_0)<0$, respectively, at $\varepsilon=0$. Moreover, for fixed $\varepsilon>0$, γ and $i=1, 2$, the sequence $\{c_{i,k}(\gamma)\}$ is monotone decreasing in $k=0, 1, 2, \cdots$ and converges to the corresponding impulse curve $c_{i,\infty}(\gamma)$ as $k\to\infty$. Furthermore, every $c_{1,k}$ curve is asymptotically tangent to the $c_{1,0}$ curve from the left of $\gamma(\varepsilon)$ as $\gamma\to\gamma(\varepsilon)^-$ and, similarly, every $c_{2,k}$ curve is asymptotically tangent to the $c_{2,0}$ curve from the right of $\gamma(\varepsilon)$ as $\gamma\to\gamma(\varepsilon)^+$.*

(e) *There is a neighborhood of $(\gamma(\varepsilon), c(\varepsilon))$ in the (γ, c)-parameter space for each $0<\varepsilon<\varepsilon_0$ such that* (1.1) *has a simple traveling train solution for some speed c if and only if (γ, c) is in this neighborhood and lies below the curve $c_{1,\infty} \cup c_{2,\infty} \cup (\gamma(\varepsilon), c(\varepsilon))$. See Fig.* 1.3.

It would be of mathematical interest to assume that the recovering variable w also diffuses slightly along the spatial line. This leads to the consideration of the following system of reaction diffusion equations:

$$v_t = v_{xx} + f(v) - w, \qquad w_t = \kappa w_{xx} + \varepsilon(v - \gamma w). \tag{1.2}$$

This is the same as the FitzHugh–Nagumo equations (1.1) except for a small diffusion term κw_{xx} with $|\kappa| \ll 1$ in the w-equation. It is easy to see that the steady states of (1.2),

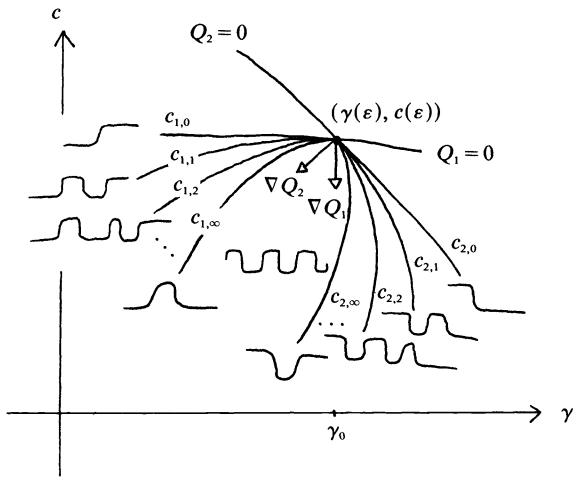


FIG. 1.3. *The bifurcation diagram of Theorem* 1.1. Q_1 *and* Q_2 *here are the Melnikov functions associated with the simple front wave and the simple back wave, respectively. The simple front (back, respectively) wave curve* $c_{1,0}$ ($c_{2,0}$, *respectively) is the level set of* $Q_1=0$ ($Q_2=0$, *respectively*).

in particular, the steady states $\mathbf{a}_1$ and $\mathbf{a}_2$, are the same as those of (1.1) and all the definitions for traveling waves of different types considered above can be directly extended for (1.2). As we will see later, the following theorem is a direct consequence of Theorem 1.1 in the context of singular perturbation.

THEOREM 1.2. *Let* $0<a<\frac{1}{2}$ *be fixed in* (1.2). *There are small constants* ε_0 *and* κ_0 *and smooth functions* $\gamma(\varepsilon,\kappa)$, $c(\varepsilon,\kappa)$, *and* $\delta(\varepsilon,\kappa)$ *of* $0\leqq\varepsilon\leqq\varepsilon_0$ *and* $|\kappa|\leqq\kappa_0$ *such that for* $0<\varepsilon<\varepsilon_0$ *and* $|\kappa|\leqq\kappa_0$ *all the conclusions of Theorem* 1.1 *are satisfied when* $\gamma(\varepsilon,\kappa)$, $c(\varepsilon,\kappa)$, *and* $\delta(\varepsilon,\kappa)$ *are substituted for* $\gamma(\varepsilon)$, $c(\varepsilon)$, *and* $\delta(\varepsilon)$, *respectively. Moreover,* $\gamma(0,\kappa)=\gamma_0$ *and* $c(0,\kappa)=c_0$, *the same constants as in Theorem* 1.1. *In this case, of course, all the curves* $c_{i,k}$ *depend smoothly on* κ *as well.*

The FitzHugh–Nagumo equations have been studied extensively for the last two decades. This system of reaction-diffusion equations is a qualitative model for several applications including nerve conduction (Hodgkin and Huxley (1952), FitzHugh (1961), and Nagumo, Arimoto, and Yoshizawa (1963)), neuronal interactions at the population level (Wilson and Cowan (1972)), chemical and biochemical reaction (Ortoleva and Ross (1975)), as well as electronic transmission lines (Nagumo, Arimoto, and Yoshizawa (1963)). The references quoted here only reflect the author's limited understanding on this subject. For the case when $\gamma=0$, Hastings (1974), (1976) and Casten, Cohen, and Lagerstrom (1975) have studied the existence of impulse and traveling train solutions. Rinzel and Keller (1973) have studied the same problem except that the function f is replaced by a piecewise continuous function $f=H(v-a)-v$ with H to be the Heaviside step function. For the case when ε, a, γ are all small, Hastings (1982) and Evans, Fenichel, and Feroe (1982) have studied the existence of impulse solutions of double pulses and traveling trains of multiple pulses. Their results are closely related to the saddle-focus homoclinic bifurcation theorem by Sil'nikov (1970). Feroe (1982) and, more recently, Wang (1988I) have also studied this type of phenomenon with the piecewise linear function f. For large γ, Carpenter (1977) has studied the existence of traveling front and back waves as well as impulse and traveling train solutions through a constructive singular perturbation approach. Rinzel and Terman (1982) have also considered the same problem for the piecewise

linear case. Indeed, as pointed out by one of the referees of this paper, the existence of traveling waves for (1.1) has been the subject of many other researchers including Aronson and Weinberger (1975), Conley (1975), Greenberg (1973), Keener (1980), Langer (1980), McKean (1970), Pauwelussen (1980), Rauch and Smoller (1978), and probably many more. With only a few exceptions, all the traveling wave solutions investigated so far can be characterized as simple wave solutions in our terminology. The multiple pulse front and back waves obtained here have not previously been proved to exist, nor investigated numerically.

The proof of the theorem is based on three important theories in dynamical systems, namely, the bifurcation theory of a doubly twisted heteroclinic loop by Deng (1991), the geometric singular perturbation theory by Fenichel (1979), and the Melnikov method. Although the idea of using the Melnikov integral together with singular perturbation theory can be found in Kokubu, Nishiura, and Oka (1988) and Lin (1989), our singular perturbation approach is quite different. Whereas other researchers emphasize the "singular" aspects of the problems which inevitably lead to techniques like asymptotic expansion, matching principle, etc., we only need to address the "regular" aspects of the singular perturbation problems. This point of view is taken from Fenichel (1979) which asserts that a singular perturbation problem is essentially a regular perturbation problem in terms of invariant manifold theory, in particular, the center manifold theory. Extending his idea via invariant manifold theory to connecting orbits, we naturally see some connections between the singular perturbation theory and the Melnikov method.

This paper is organized as follows. In § 2, we will state the heteroclinic loop bifurcation theory from Deng (1991) from which the proof of our main result Theorem 1.1 will be derived. The remaining sections are devoted to verifying all the conditions of that theorem. Specifically, we will introduce the Melnikov function (which was called the separation function by Kokubu, Nishiura, and Oka (1988)) in § 3. In §§ 4–8, all the nondegenerate conditions of Theorem 2.1 will be verified. At first sight, these conditions may appear next to impossible to check. However, since they are all generic with respect to the existence of a heteroclinic loop, it is not too surprising to see that the existence of the twisted loop, which only requires our extended Melnikov method, indeed contains enough information for its genericity. In § 9, Theorem 1.2 will be proved based on the singular perturbation method and the proof of Theorem 1.1.

In Theorem 1.1(e) it appears that the neighborhood around $(\gamma(\varepsilon), c(\varepsilon))$ where the traveling train solutions may occur, as well as the lengths of those curves for traveling front, back and impulse waves, depend on the parameter ε. In fact, they can be made uniform for all small $\varepsilon > 0$. Unfortunately, we cannot show this fact in this paper. It requires some nontrivial modification and generalization of our Theorem 2.1 to singularly perturbed systems. The same comment also applies to Theorem 1.2 with respect to $\varepsilon > 0$ and $|\kappa| \ll 1$.

This paper was originally inspired by the work of Rinzel and Terman (1982). David Terman helped me understand their work correctly. This made it possible for me to find the twist structure of the front-back wave loop at the bifurcation point (γ_0, c_0) through their numerical bifurcation diagram for the simple front, simple back, and simple impulse waves (cf. Fig. 1.3). Finally, let us mention the other equally important motivation that lies beyond the scope of this paper. We would like to eventually prove that all the multiple pulse front and back waves found here are stable with respect to the PDEs (1.1) and (1.2). The fact that the steady states $\mathbf{a}_1$, $\mathbf{a}_2$, the simple front, simple back, simple impulse, and simple train solutions near the bifurcation point (γ_0, c_0) are all stable is well known. (See, e.g., Rinzel and Terman (1982)

and the references therein. See also Wang (1988II) for the stability problem of multiple pulse impulses for the piecewise linear case.)

2. The bifurcation of a twisted heteroclinic loop. Recall that a traveling wave (v, w) is a function of one variable τ. Thus, if we let $u := v'$, where the prime denotes the derivative in τ, then (v, u, w) satisfies the following system of first-order ordinary differential equations:

$$v' = u, \quad u' = cu - f(v) + w, \quad w' = \frac{\varepsilon}{c}(v - \gamma w). \tag{2.1}$$

For $\varepsilon > 0$, it is trivial to check that this system has three equilibrium points when $\gamma > \gamma_1$ (cf. Fig. 1.1). They are those points (v, u, w) satisfying that $u = 0$ and (v, w) equals to the steady states of (1.1) discussed in the Introduction. For this reason and for simplicity, we will denote throughout the equilibria with $u = 0$, $(v, w) = \mathbf{a}_i$ just by $\mathbf{a}_i$ alone. Also, as the counterpart of traveling front of (1.1), a solution of (2.1) is call a *heteroclinic* orbit from $\mathbf{a}_1$ to $\mathbf{a}_2$ if

$$\lim_{\tau \to -\infty} (v, u, w)(\tau) = \mathbf{a}_1 \quad \text{and} \quad \lim_{\tau \to +\infty} (v, u, w)(\tau) = \mathbf{a}_2.$$

A heteroclinic orbit from $\mathbf{a}_2$ to $\mathbf{a}_1$ is defined analogously. On the other hand, a solution of (2.1) is called a *homoclinic* orbit to $\mathbf{a}_1$ if

$$\lim_{|\tau| \to \infty} (v, u, w)(\tau) = \mathbf{a}_1.$$

A similar definition applies to a homoclinic orbit to $\mathbf{a}_2$. Note that a heteroclinic orbit of (2.1) from $\mathbf{a}_1$ to $\mathbf{a}_2$ (respectively, from $\mathbf{a}_2$ to $\mathbf{a}_1$) gives rise to a traveling front (respectively, back) wave of (1.1) while a homoclinic orbit of (2.1) gives rise to an impulse wave of (1.1). In a similar way as in the previous section, we can define *k-heteroclinic*, *k-homoclinic*, and *k-periodic* orbits with respect to some neighborhoods of $\mathbf{a}_1$ and $\mathbf{a}_2$ for (2.1). We leave this to the reader. Therefore, our strategy to prove Theorem 1.1 is to prove the same theorem except that (1.1) is replaced by (2.1) and the traveling fronts, etc., are replaced by heteroclinic orbits, etc., respectively. To do this, we will apply a theorem on the bifurcations of a twisted heteroclinic loop from Deng (1991) (cf. Theorem B of Deng (1991)). Although that theorem as well as the result on singular perturbation by Fenichel and the method of Melnikov integral are available for any finite-dimensional system, we will treat them only in $\mathbb{R}^3$ here for simplicity. Also, we need to warn the reader in advance that the theorem we are about to state is the time-reversed version of Theorem B of Deng (1991). Note that upon time reversal, the stable manifold becomes the unstable manifold and vice versa. Also, a heteroclinic orbit from $\mathbf{a}_1$ to $\mathbf{a}_2$ becomes a heteroclinic orbit from $\mathbf{a}_2$ to $\mathbf{a}_1$, and so on. But a homoclinic orbit of $\mathbf{a}_1$ remains the same.

To state the theorem we begin with its hypotheses (2.2a)-(2.2e). Since the bifurcation problem to be discussed is of codimension two, we will only include the so-called relevant parameter α ($\alpha = (\gamma, c)$ in our case) in a vector field $X^\alpha := X^\alpha(x)$, where $x \in \mathbb{R}^3$ and $\alpha \in \mathbb{R}^2$. We certainly allow other parameters (say ε in our case) to be included in the vector field but we will usually suppress them unless otherwise indicated.

(2.2a) *The relative expansion of* $\mathbf{a}_i$. Let X^α denote a family of vector fields in $\mathbb{R}^3$ parametrized by a relevant parameter α in $\mathbb{R}^2$. Suppose $\mathbf{a}_i = \mathbf{a}_i(\alpha)$, $i = 1, 2$ are hyperbolic equilibrium points of X^α for all α and are relatively expansive in the sense that the eigenvalues λ_j of the linearization $DX^\alpha(\mathbf{a}_i)$ satisfy

$$\lambda_1 < \lambda_2 < 0 < \lambda_3 \quad \text{and} \quad \lambda_3 + \lambda_2 > 0.$$

Of course, λ_j here also depends on $\mathbf{a}_i$ for $i=1, 2$. The eigenvalues λ_2 and λ_3 are called the principal stable and the principal unstable eigenvalues, respectively. Their eigenvectors are thus referred to as the principal stable and the principal unstable eigenvectors, respectively (see (1.2) of Deng (1991)).

(2.2b) *The nondegeneracy of a heteroclinic loop.* There is a parameter value α_0 so that the equation $x' = X^{\alpha}(x)$ has a nondegenerate heteroclinic loop. Specifically, there exists a simple heteroclinic orbit $\mathbf{z}_1^*$ from $\mathbf{a}_1$ to $\mathbf{a}_2$ and a simple heteroclinic orbit $\mathbf{z}_2^*$ from $\mathbf{a}_2$ to $\mathbf{a}_1$ at the same parameter α_0. Moreover, by nondegeneracy we mean that the following two conditions are satisfied. First, $\mathbf{z}_i^*(\tau)$ is asymptotically tangent to the principal stable eigenvector of $\mathbf{a}_j$, $j \neq i$ as $\tau \to +\infty$ and the principal unstable eigenvector of $\mathbf{a}_i$ as $\tau \to -\infty$, respectively. Second, the following strong inclination conditions hold:

(2.2b′) $$\lim_{\tau \to -\infty} T_{\mathbf{z}_i^*(\tau)} W_j^s = T_{\mathbf{a}_i} W_i^u + T_{\mathbf{a}_i} W_i^{ss},$$

where $i, j = 1, 2$ and $i \neq j$, $T_{\mathbf{p}} W$ means the tangent space of a given manifold W at a base point $\mathbf{p} \in W$. Also, W_i^s, W_i^u, W_i^{ss} is the standard notation for the stable, unstable, and strong stable manifolds of $\mathbf{a}_i$, respectively. They are two-dimensional, one-dimensional, and one-dimensional, respectively, in this case (see (1.5) and (1.7) of Deng (1991)).

(2.2c) *The double twist of a nondegenerate heteroclinic loop.* Let $\mathbf{z}_1^*$ and $\mathbf{z}_2^*$ form a nondegenerate heteroclinic loop. Let

$$\mathbf{e}_i^- = \lim_{\tau \to -\infty} \frac{\mathbf{z}_i^*(\tau) - \mathbf{a}_i}{\|\mathbf{z}_i^*(\tau) - \mathbf{a}_i\|}, \qquad \mathbf{e}_j^+ = \lim_{\tau \to +\infty} \frac{\mathbf{z}_i^*(\tau) - \mathbf{a}_j}{\|\mathbf{z}_i^*(\tau) - \mathbf{a}_j\|}$$

be the unit principal unstable and stable eigenvectors along which the heteroclinic orbit $\mathbf{z}_i^*$ comes from $\mathbf{a}_i$ and goes towards $\mathbf{a}_j$, respectively, then $\mathbf{e}_i^+$ and $\mathbf{e}_j^-$ point to opposite sides of $T_{\mathbf{z}_i^*(\tau)} W_j^s$ at $\tau \to -\infty$ and $\tau \to +\infty$, respectively. Here, $i, j = 1, 2$, $i \neq j$ (cf. Fig. 2.1 and see (1.9) and Definition 1.1 of Deng (1991)).

Remark. The definition of twisted heteroclinic orbit has much in common with that of twisted homoclinic orbit. The geometric notion of twisted homoclinic orbit was given by Deng (1989) and Chow, Deng, and Fiedler (1990), based on the author's strong λ-lemma. It was inspired by a work of Yanagida (1987).

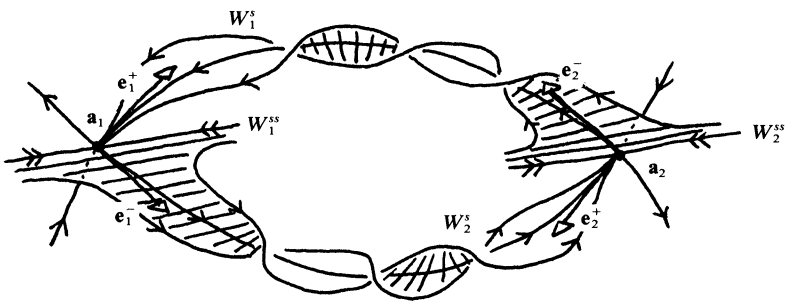

FIG. 2.1. *A nondegenerate and doubly twisted heteroclinic loop in* $\mathbb{R}^3$. $\mathbf{e}_i^-$ *and* $\mathbf{e}_j^+$ *point to the opposite sides of* W_i^s.

(2.2d) *The continuation of* $\mathbf{z}_i^*$. There exist two curves 0-het$_1$ and 0-het$_2$ in the parameter space $\alpha \in \mathbb{R}^2$ which intersect at α_0 transversely so that when $\alpha \in$ 0-het$_i$ there is a simple heteroclinic orbit $\mathbf{z}_{i,\alpha}$ from $\mathbf{a}_i$ to $\mathbf{a}_j$ and $\mathbf{z}_{i,\alpha}$ is the continuation of $\mathbf{z}_i^*$ in the sense that $\mathbf{z}_{i,\alpha_0} = \mathbf{z}_i^*$ and $\mathbf{z}_{i,\alpha}(\tau)$ are continuous in τ and α (see (1.1a) of Deng (1991)).

(2.2e) *The transverse crossing of the stable and unstable manifolds along* $\mathbf{z}_i^*$. Let $Q_i(\alpha)$ be the Melnikov function defined in the next section; then the gradient vectors $\nabla Q_1(\alpha_0)$ and $\nabla Q_2(\alpha_0)$ are linearly independent (see (1.10b) of Deng (1991)). We remark that since the discussions of Melnikov functions in § 3 is independent of what follows, we may certainly find out the precise definition before continuing.

THEOREM 2.1. *Suppose conditions* (2.2a)-(2.2e) *are satisfied. Then the following holds.*

(a) *There is a sequence* $\{k\text{-het}_1\}_{k=1}^{\infty}$ *of smooth curves in* $\mathbb{R}^2$ *such that for every* $k = 1, 2, \cdots$ *the equation* $x' = X^{\alpha}(x)$ *has a k-heteroclinic orbit from* $\mathbf{a}_1$ *to* $\mathbf{a}_2$ *if and only if* $\alpha \in k\text{-het}_1$. *Similarly, there is a sequence* $\{k\text{-het}_2\}_{k=1}^{\infty}$ *of smooth curves in* $\mathbb{R}^2$ *such that for every* $k = 1, 2, \cdots$ *there is a k-heteroclinic orbit from* $\mathbf{a}_2$ *to* $\mathbf{a}_1$ *if and only if* $\alpha \in k\text{-het}_2$.

(b) *There is a smooth curve* hom$_i$ *for each* $i = 1, 2$ *such that there is a simple homoclinic orbit of* $\mathbf{a}_i$ *if and only if* $\alpha \in$ hom$_i$.

(c) *The curve* 0-het$_i$ *is simply the level set of* $Q_i = 0$, *and it is divided by the other* 0-het$_j$ *curve into two parts. Let* 0-het$_i^+$ *be the half of the* 0-het$_i$ *curve that points to the gradient direction of* ∇Q_j (*cf. Fig.* 2.2). *Then all the curves* $\{k\text{-het}_1\}_{k=1}^{\infty}$ *together with*

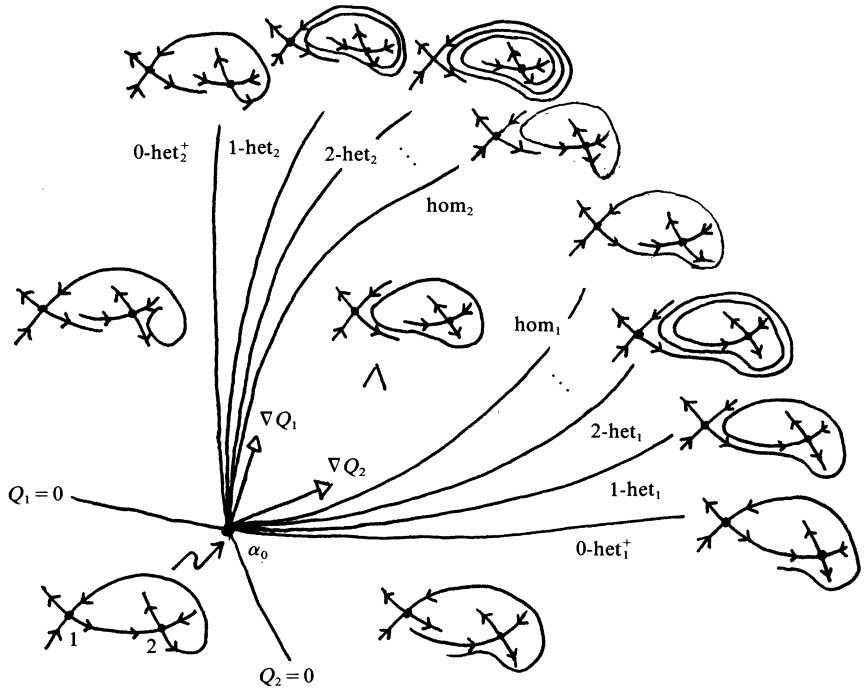

FIG. 2.2. *The bifurcation diagram of Theorem* 2.1. *The doubly twisted heteroclinic loop is drawn in* $\mathbb{R}^2$. ∇Q_i *and* 0-het$_j^+$ *point to the same side of the* 0-het$_i$ *curve which is the level set* $Q_i = 0$ *and* Q_i *is the Melnikov function for the primary connection from* $\mathbf{a}_i$ *to* $\mathbf{a}_j$ *when* $\alpha = \alpha_0$.

hom_1 *are in the sector bounded by* 0-het_1^+ *and* 0-het_2^+ *and converge to* α_0 *asymptotically tangent to* 0-het_1^+. *Moreover,* $\{k\text{-ket}_1\}_{k=1}^{\infty}$ *lies between the* 0-het_1^+ *and* hom_1 *curves and converges to the* hom_1 *curve monotonely in* $k=1, 2, \cdots$ (*cf. Fig.* 2.2). *Analogous result holds for the sequence* $\{h\text{-het}_2\}_{k=1}^{\infty}$ *and the* hom_2 *curve.*

(d) *Let* Λ *be the sector bounded by the homoclinic curves* hom_1 *and* hom_2. *Then there is a simple periodic solution of the vector field* X^α *if and only if* $\alpha \in \Lambda$.

Proof. The theorem is the same as Theorem B of Deng (1991) provided that the vector field X^α is replaced by its time-reversed vector field $-X^\alpha$. Thus the proof is complete. What follows is meant to help the reader pin down the parallel comparisons between the Melnikov functions from condition (2.2e) and from that theorem, respectively. First, the Melnikov function Q_j here is essentially a positive constant multiple of $Q_{i\alpha}^{(1)}$ there. Second, the condition (1.10b) of Theorem B is replaced by $\partial Q_{j\alpha}^{(1)}/\partial\alpha_j > 0$ which was really what we used in the proof of Theorem B of Deng (1991). Note that the 0-het_i curve here is the α_i-axis there, which is the level set $Q_{j\alpha}^{(1)}=0$, and that the positive direction of α_i in Theorem B, which is the same as 0-het_i^+ here, was chosen in correspondence with $\partial Q_{i\alpha}^{(1)}/\partial\alpha_i > 0$. This positive derivative in turn is equivalent to that $\nabla Q_{i\alpha}^{(1)}$ and 0-het_i^+ point to the same side of the level set $Q_{i\alpha}^{(1)}=0$. Also, the linear independence of $\nabla Q_{1\alpha}^{(1)}$ and $\nabla Q_{2\alpha}^{(1)}$ is equivalent to the transverse intersection of 0-het_1 and 0-het_2 at α_0. □

3. The Melnikov method. Let $X^\alpha(x)$ be a sufficiently smooth vector field in $\mathbb{R}^3$ with parameter α. Let $\mathbf{a}_1$ and $\mathbf{a}_2$ be two equilibrium points having a two-dimensional stable manifold $W^s(\mathbf{a}_i, \alpha)$ and a one-dimensional unstable manifold $W^u(\mathbf{a}_i, \alpha)$, respectively. In what follows we will write W^s, or $W^s(\mathbf{a}_i)$ interchangeably for the stable manifold and so on for simplicity, provided that there is no confusion involved. Suppose at some α_0 there is a heteroclinic orbit $\mathbf{z}^*$ from $\mathbf{a}_1$ to $\mathbf{a}_2$ (an identical consideration can also be given to $\mathbf{a}_2$ to $\mathbf{a}_1$ connections). Then it must be $\mathbf{z}^* \subset W^u(\mathbf{a}_1) \cap W^s(\mathbf{a}_2)$ at α_0. We would like to know how the heteroclinic connection $\mathbf{z}^*$ changes with the parameter. In many applications, the Melnikov method presented below is very useful for attacking this problem.

Naturally, we would like to examine how the "signed distance" between the stable and unstable manifolds changes with the parameter. To implement this intuitive idea, we choose and fix a point $\mathbf{z}_0^* \in \mathbf{z}^*$ from the orbit and a two-dimensional plane Σ which is perpendicular to $\mathbf{z}^{*\prime}$ and through $\mathbf{z}_0^*$. The intersection $\Sigma \cap W^s$ is necessarily a curve, whereas $\Sigma \cap W^u$ is just a point for every α near α_0. Choose and fix a vector $\mathbf{e}$ on Σ that is perpendicular to the curve $\Sigma \cap W^s$ at $\mathbf{z}_0^*$ and α_0. Let l be a straight line that goes through the point $\mathbf{p}^u(\alpha) := \Sigma \cap W^u(\mathbf{a}_1, \alpha)$ and that is of the direction of $\mathbf{e}$. Then l must intersect the stable manifold $\Sigma \cap W^s(\mathbf{a}_2, \alpha)$ at a unique point $\mathbf{p}^s(\alpha)$ for α sufficiently close to α_0. $\mathbf{p}^u(\alpha)$ and $\mathbf{p}^s(\alpha)$ can be chosen differentiable and satisfying $\mathbf{p}^s(\alpha_0) = \mathbf{p}^u(\alpha_0) = \mathbf{z}_0^*$. Now, there must be a smooth function $Q(\alpha)$ such that

$$\mathbf{p}^s(\alpha) - \mathbf{p}^u(\alpha) = Q(\alpha)\mathbf{e} \quad \text{or} \quad Q(\alpha) = (\mathbf{p}^s(\alpha) - \mathbf{p}^u(\alpha)) \cdot \mathbf{e}/\|\mathbf{e}\|^2. \tag{3.1}$$

See Fig. 3.1. The function $Q(\alpha)$ serves what we called the "signed distance" between $W^s(\mathbf{a}_2)$ and $W^u(\mathbf{a}_1)$ above. We will call it the Melnikov function (or the separation function by Kokubu, Nishiura, and Oka (1988)). We are interested in the solutions of $Q(\alpha)=0$ since that precisely gives rise to those parameters at which there is a heteroclinic orbit from $\mathbf{a}_1$ to $\mathbf{a}_2$.

Several modifications can be made in the construction of $Q(\alpha)$ above. The requirements that Σ be perpendicular to $\mathbf{z}^*$ and that $\mathbf{e}$ be perpendicular to $\Sigma \cap W^s$ are not necessary. For instance, take the case where Σ is the same as above but $\mathbf{e}$ is replaced

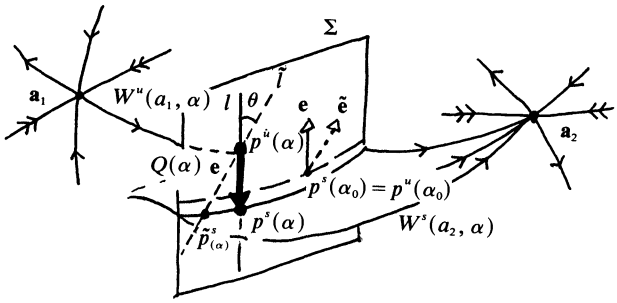

FIG. 3.1. *The long dashed curve represents the intersection curve of the stable manifold of* $\mathbf{a}_2$ *at the bifurcation point* $\alpha = \alpha_0$ *and the plane* Σ. *The Melnikov function* $Q(\alpha)$ *is defined as* $Q(\alpha) = (\mathbf{p}^s(\alpha) - \mathbf{p}^u(\alpha))\mathbf{e}/\|\mathbf{e}\|^2$.

by another vector $\tilde{\mathbf{e}}$ that is just transverse to the stable manifold curve $\Sigma \cap W^s(\mathbf{a}_2, \alpha_0)$ at $\mathbf{z}_0^*$. Similarly, let $\tilde{l}$ be the line through $\mathbf{p}^u(\alpha)$ that is parallel to $\tilde{\mathbf{e}}$, let $\tilde{\mathbf{p}}^s(\alpha)$ be the corresponding intersection point $\tilde{l} \cap \Sigma \cap W^s(\mathbf{a}_2, \alpha)$, and let $\tilde{Q}(\alpha) = (\tilde{\mathbf{p}}^s(\alpha) - \mathbf{p}^u(\alpha)) \cdot \tilde{\mathbf{e}}/\|\tilde{\mathbf{e}}\|^2$ be the Melnikov function. Then it is easy to see from Fig. 3.1 that there is a nonzero constant β independent of α so that

$$\tilde{Q}(\alpha) = \beta Q(\alpha) + o(|\tilde{\mathbf{p}}^s(\alpha) - \mathbf{p}^s(\alpha)|).$$

In fact, $\beta = \|\mathbf{e}\| \cos\theta/\|\tilde{\mathbf{e}}\|$ and β is positive (respectively, negative) if $\mathbf{e}$ and $\tilde{\mathbf{e}}$ point to the same (respectively, opposite) side of $W^s(\mathbf{a}_2) \cap \Sigma$, where θ is the angle between $\mathbf{e}$ and $\tilde{\mathbf{e}}$ (cf. Fig. 3.1). It is clear that if we want to solve the equation $Q(\alpha) = 0$ by the implicit function theorem it is important to know the behavior of the partial derivatives of Q at the bifurcation point $\alpha = \alpha_0$. But, this alternative definition $\tilde{Q}$ simply says that both functions are essentially the same in the sense that

$$\frac{\partial \tilde{Q}(\alpha_0)}{\partial \alpha} = \beta \frac{\partial Q(\alpha_0)}{\partial \alpha}. \tag{3.2}$$

The same conclusion also holds true if we relax the choice of Σ to be a plane transverse, instead of perpendicular, to the heteroclinic orbit $\mathbf{z}^*$. We also remark that the definition of the Melnikov function above is not necessarily just restricted to vector fields in $\mathbb{R}^3$. It can be easily extended to stable and unstable manifolds of any finite dimensions under the condition that they are in general position along $\mathbf{z}_0^*$. Moreover, in the case of nonhyperbolic equilibrium points, we can analogously define the Melnikov function between $W^u(\mathbf{a}_1, \alpha)$ and $W^{cs}(\mathbf{a}_2, \alpha)$. Another extension we will need later is the "signed distance" between points of a center unstable manifold $W^{cu}(\mathbf{a}_1, \alpha)$ and a center stable manifold $W^{cs}(\mathbf{a}_2, \alpha)$ whose dimensions satisfy, for our consideration only, dim W^{cs} = dim $W^{cu} = 2$ and dim $W^c = 1$. Let Σ and $\mathbf{e}$ be the same as above. Then $\Sigma \cap W^{cu}(\mathbf{a}_1, \alpha)$ is a curve too. Suppose this curve is parametrized by $w \in [-1, 1]$ so that $w = 0$ always corresponds to the intersection point $\Sigma \cap W^u(\mathbf{a}_1, \alpha)$. Let $\mathbf{p}^{cu}(\alpha, w)$ be a given point from $\Sigma \cap W^{cu}$ and $\mathbf{p}^{cs}(\alpha, w)$ be the corresponding point of $l \cap \Sigma \cap W^{cs}$, where l is the line through $\mathbf{p}^{cu}(\alpha, w)$ with direction $\mathbf{e}$. Define

$$q(\alpha, w) = (\mathbf{p}^{cs}(\alpha, w) - \mathbf{p}^{cu}(\alpha, w)) \cdot \mathbf{e}/\|\mathbf{e}\|^2, \tag{3.3}$$

which represents a differential along the $\mathbf{e}$ direction from W^{cu} to W^{cs}. Of course, we have $q(\alpha, 0) = Q(\alpha)$, where $Q(\alpha)$ is the Melnikov function between $W^u(\mathbf{a}_1)$ and $W^{cs}(\mathbf{a}_2)$. The purpose to introduce this function $q(\alpha, s)$ is to relate the condition

$$\frac{\partial q(\alpha_0, 0)}{\partial w} \neq 0$$

to the transverse intersection of $W^{cu}(\mathbf{a}_1, \alpha_0)$ and $W^{cs}(\mathbf{a}_2, \alpha_0)$ along the connection $\mathbf{z}^*$ at α_0. The other useful property is

$$\frac{\partial Q(\alpha_0)}{\partial \alpha} = \frac{\partial q(\alpha_0, 0)}{\partial \alpha}, \tag{3.4}$$

which will be used later in computing the derivative of $q(\cdot, 0)$.

Now, let us return to Theorem 2.1, in particular, the choice of the Melnikov functions $Q_1(\alpha)$ and $Q_2(\alpha)$ from the hypothesis (2.2e). Note that we explicitly talked about the directions $\nabla Q_i(\alpha)$ which determine the bifurcation directions of those multiple pulse heteroclinic orbits in our main theorem. But, on the other hand, we have the freedom of choosing either $\mathbf{e}$ or $-\mathbf{e}$, which is also transverse to $W^s(\mathbf{a}_2, \alpha_0) \cap \Sigma$, in the definition of the Melnikov function $Q(\alpha)$. Thus, from now on we will specify the direction $\mathbf{e}$. To this end, recall the strong inclination limit (2.2b′). From that condition, we can easily conclude that the principal stable unit eigenvector $\mathbf{e}_1^+$ is transverse to the stable manifold $W^s(\mathbf{a}_2, \alpha_0)$ near $\mathbf{a}_1$. Thus, $\mathbf{e}_1^+$ defines an orientation for $W^s(\mathbf{a}_2, \alpha_0)$. Now, in the definition of $Q_1(\alpha)$, choose a vector $\mathbf{e}$ which points to the same side of $W^s(\mathbf{a}_2)$ at $\mathbf{z}_0^*$ as $\mathbf{e}_1^+$ does up to the flow homotopy. Indeed, when $\mathbf{z}_0^*$ is sufficiently close to $\mathbf{a}_1$, we can simply let $\mathbf{e} = \mathbf{e}_1^+$. And, as mentioned earlier, $Q_1(\alpha)$ can be chosen to be (or essentially to be) a positive constant multiple of $Q_{2\alpha}^{(1)}$ in the proof of Theorem B of Deng (1991), or (5.41), (5.43) of Chow, Deng, and Terman (1990).

So much for the theoretical aspect of the Melnikov function $Q(\alpha)$. When an application comes, what really matters is the so-called Melnikov integral which provides us with a computable formula for the derivative $\partial Q(\alpha_0)/\partial \alpha$. We introduce this integral below.

Without loss of generality, let Σ and $\mathbf{e}$ be perpendicular to $\mathbf{z}^*$ and $\Sigma \cap W^s$, respectively. Let the orbit $\mathbf{z}^*(\tau)$ be parametrized so that $\mathbf{z}^*(0) = \mathbf{z}_0^*$ and $\mathbf{z}^*(\tau)$ satisfies the equation $x' = X^{\alpha_0}(x)$. Consider the variational equation $y' = DX^{\alpha_0}(\mathbf{z}^*(\tau))y$ along $\mathbf{z}^*$ and its adjoint equation $y' = -(DX^{\alpha_0}(\mathbf{z}^*(\tau))^T y$. Then there is a unique bounded solution $\varphi(\tau)$, $\tau \in \mathbb{R}$, of the adjoint equation with the initial condition $\varphi(0) = \mathbf{e}$ (see, e.g., Palmer (1984)). It is well known that

$$\frac{\partial Q}{\partial \alpha}(\alpha_0) = -\int_{-\infty}^{\infty} \varphi(\tau) \cdot \frac{\partial X^{\alpha_0}(\mathbf{z}^*(\tau))}{\partial \alpha}\, d\tau,$$

where $Q(\alpha) = (\mathbf{p}^s(\alpha) - \mathbf{p}^u(\alpha)) \cdot \mathbf{e}/\|\mathbf{e}\|^2$ (see Holmes (1980), Palmer (1984), or Guckenheimer and Holmes (1983)). In particular, when the vector field is two-dimensional and $\mathbf{e}$ is chosen to be of the orthogonal vector $(-z_2^{*\prime}(0), z_1^{*\prime}(0))$ of $\mathbf{z}^{*\prime}(0)$ where $\mathbf{z}^{*\prime}(0) := (z_1^{*\prime}(0), z_2^{*\prime}(0))$ is the component form, it can be directly checked that

$$\varphi(\tau) = \exp\left[-\int_0^{\tau} \operatorname{tr} DX^{\alpha_0}(\mathbf{z}^*(s))\, ds\right](-z_2^{*\prime}(\tau), z_1^{*\prime}(\tau)),$$

where $\operatorname{tr} A$ means the trace of a given square matrix A. See, e.g., Melnikov (1964), Holmes (1980), and Palmer (1984). Note that $\mathbf{e}$ here is uniquely determined (cf. Fig. 3.2). In summary, we have

$$\frac{\partial Q(\alpha_0)}{\partial \alpha} = -\int_{-\infty}^{\infty} \exp\left[-\int_0^{\tau} \operatorname{tr} DX^{\alpha_0}(\mathbf{z}^*(s))\, ds\right](-z_2^{*\prime}(\tau), z_1^{*\prime}(\tau)) \cdot \frac{\partial X^{\alpha_0}(\mathbf{z}^*(\tau))}{\partial \alpha}\, d\tau, \tag{3.5}$$

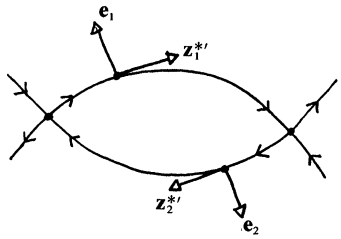

FIG. 3.2. *The unique choice of the vector* **e**.

which is referred to as the Melnikov integral. Last, let us remark that in light of (3.2) we will sometimes slightly abuse the notation by writing $\partial\tilde{Q}(\alpha_0)/\partial\alpha$ as the same Melnikov integral as above provided that the directions **e** and $\tilde{\mathbf{e}}$ point to the same side of the stable manifold. A justification for this is based on the statement of Theorem 2.1 that only the signs of the derivatives of a Melnikov function really count.

4. Proof of conditions (2.2a, d). Beginning with this section, we will show that the hypotheses (2.2a–e) of Theorem 2.1 are satisfied for the reduced FitzHugh–Nagumo equation (2.1). It is straightforward to see that the condition (2.2d) for the continuation of the simple heteroclinic orbits is superfluous. Indeed, it is implied by the existence of the simple heteroclinic orbits $\mathbf{z}_i^*$ at α_0 from condition (2.2b) and the linear independence of $\nabla Q_1(\alpha_0)$ and $\nabla Q_2(\alpha_0)$. The reason to include it in the statement of Theorem 2.1 is simply for a convenient parallel comparison between that theorem and Theorem B of Deng (1991). Thus, the condition (2.2d) may now be removed from our checklist.

To show condition (2.2a), recall the equilibria $\mathbf{a}_i = (v_i, 0, w_i)$ from § 1 and consider the linearization of (2.1) at $\mathbf{a}_i$

$$V' = U, \quad U' = cU - f'(v_i)V + W, \quad W' = \frac{\varepsilon}{c}(V - \gamma W).$$

The corresponding characteristic equation is

$$\Delta(\lambda, \varepsilon) = \lambda(c-\lambda)\left(\frac{\varepsilon\gamma}{c}+\lambda\right) - f'(v_i)\left(\frac{\varepsilon\gamma}{c}+\lambda\right) + \frac{\varepsilon}{c} = 0.$$

When $\varepsilon = 0$, it is straightforward to check that since $f'(v_i) < 0$ for $i = 1, 2$ (cf. Fig. 1.1), $\Delta(\lambda, 0) = 0$ has roots

$$\lambda_1 = \frac{c - \sqrt{c^2 - 4f'(v_i)}}{2} < \lambda_2 = 0 < \lambda_3 = \frac{c + \sqrt{c^2 - 4f'(v_i)}}{2}. \tag{4.1}$$

Since $\Delta(0, \varepsilon) = -f'(v_i)\varepsilon\gamma/c + \varepsilon/c > 0$ for $\varepsilon > 0$ and $\partial\Delta(0, 0)/\partial\lambda = -f'(v_i) > 0$, the second root λ_2 must move to the left of the origin while λ_1 and λ_3 stay uniformly away from the origin for small $\varepsilon > 0$. Hence $\lambda_1(\varepsilon) < \lambda_2(\varepsilon) < 0 < \lambda_3(\varepsilon)$ and $\lambda_3(\varepsilon) + \lambda_2(\varepsilon) > 0$ for small $\varepsilon > 0$ by continuity. This proves condition (2.2a) that the equilibrium points are relatively expansive by definition.

5. Proof of condition (2.2b). The methods used in this section include the geometric theory of singular perturbations by Fenichel (1979) and the Melnikov method discussed above. It is a rather long section but it contains all the information we will need for verifying the remaining conditions (2.2c–e).

Let us begin with the singular perturbation. The singular parameter for (2.1) is ε. When $\varepsilon = 0$, it becomes

$$v' = u, \quad u' = cu - f(v) + w, \quad w' = 0. \tag{5.1a}$$

Note that the variable w can be regarded as a parameter and the entire cubic curve $w = f(v)$ on the plane $u = 0$ consists of equilibrium points of (5.1a). Let $\mathscr{E}_i$ be a bounded, connected and closed segment on the cubic curve $w = f(v)$ which contains $\mathbf{a}_i$ and the intersection point $\{w = w_j\} \cap \{w = f(v)\}$ but does not contain any of the extreme points of the cubic curve (cf. Fig. 1.1). It is easy to check that the linearization at $\mathscr{E}_i$ is

$$V' = U, \quad U' = cU - f'(v)V + W, \quad W' = 0,$$

where v are those points that $\{w = f(v)\} \subset \mathscr{E}_i$, and thus $f'(v) < 0$ since $\mathscr{E}_i$ does not contain any extreme point. Similar to (4.1), the roots for the characteristic equation are the same as λ_j in (4.1) except that $f'(v_i)$ there is now replaced by $f'(v)$. It is also straightforward to check that the corresponding eigenvectors are

$$\mathbf{v}_1 = \begin{pmatrix} 1 \\ \lambda_1 \\ 0 \end{pmatrix}, \quad \mathbf{v}_2 = \begin{pmatrix} -1 \\ 0 \\ -f'(v) \end{pmatrix}, \quad \mathbf{v}_3 = \begin{pmatrix} 1 \\ \lambda_3 \\ 0 \end{pmatrix}. \tag{5.1b}$$

See Fig. 5.1. Since λ_1 and λ_3 are strictly nonzero, the eigendirections $\mathbf{v}_1$ and $\mathbf{v}_3$ are normal to $\mathscr{E}_i$. Therefore, $\mathscr{E}_i$ is normally hyperbolic according to Fenichel (1979). Thus, by Theorem 9.1 of Fenichel (1979), there exists a global center-stable manifold $W^{cs}_\varepsilon(\mathscr{E}_i)$ and a global center-unstable manifold $W^{cu}_\varepsilon(\mathscr{E}_i)$. These manifolds are smooth in ε for $|\varepsilon| \ll 1$. Moreover, when $\varepsilon > 0$, W^{cs}_ε is precisely the stable manifold $W^s(\mathbf{a}_i, \varepsilon)$ of $\mathbf{a}_i$ while the unstable manifold $W^u(\mathbf{a}_i, \varepsilon)$ of $\mathbf{a}_i$ is the unstable fiber, called $\mathscr{F}^u_\varepsilon$ by Fenichel (1979), through $\mathbf{a}_i$. $W^u(\mathbf{a}_i, \varepsilon)$ is also smooth in ε for $|\varepsilon| \ll 1$. Furthermore, all the invariant manifolds above depend smoothly on all other parameters. Thus, our strategy now becomes to show the existence of a connection, i.e., $W^u(\mathbf{a}_i, \varepsilon) \cap W^{cs}_\varepsilon(\mathscr{E}_j) \neq \emptyset$, when $\varepsilon = 0$ and to show the continuation of that connection for $\varepsilon > 0$ by the Melnikov method.

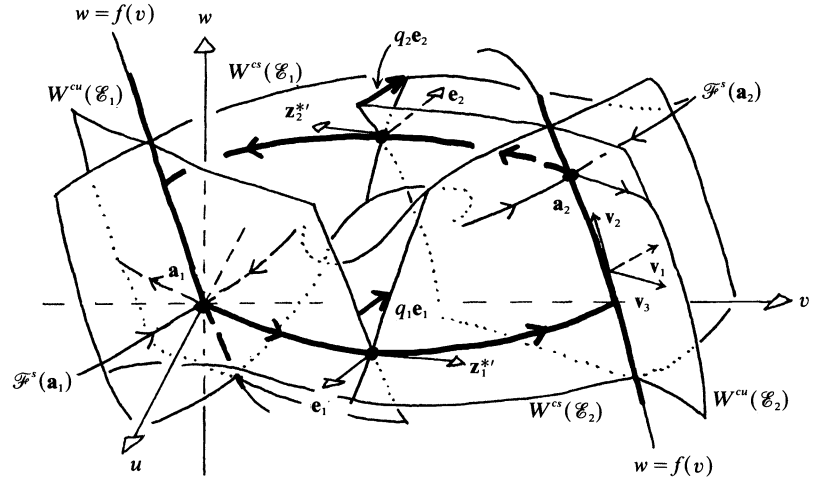

FIG. 5.1. *The strange loop at $\varepsilon = 0$. The two vertical heavy curves are $\mathscr{E}_1$ and $\mathscr{E}_2$, respectively. At the critical parameter $(\gamma, c) = (\gamma_0, c_0)$, $\mathbf{z}_1^*$ lies on the plane $\{w = 0\}$ while $\mathbf{z}_2^*$ lies on the plane $\{w = w_2\}$, connecting $\mathscr{E}_1$ and $\mathscr{E}_2$. At the appropriately perturbed point $(\gamma, c) = (\gamma(\varepsilon), c(\varepsilon))$ with $\varepsilon > 0$, $\mathbf{z}_1^*$ becomes a connection from $\mathbf{a}_1$ to $\mathbf{a}_2$, and it connects opposite sides of $W^{cs}(\mathscr{E}_1)$, which is the stable manifold of $\mathbf{a}_1$ after the perturbation $\varepsilon > 0$. Similarly, $\mathbf{z}_2^*$ connects opposite sides of $W^{cs}(\mathscr{E}_2)$ when $(\gamma, c) = (\gamma(\varepsilon), c(\varepsilon))$ and $\varepsilon > 0$.*

The existence of the desired connections when $\varepsilon = 0$ is given in the Appendix. The useful properties are summarized as follows. There is a connection $\mathbf{z}_1^* = (v_1^*, u_1^*, 0)$ from $\mathbf{a}_1 = 0$ to the intersection point $\{w = 0\} \cap \mathscr{E}_2 = (1, 0, 0)$ for (5.1a) when $c = c_0 = (1-2a)/\sqrt{2}$ for all γ and $v_1^* > 0$, $u_1^* > 0$. For the same c_0, when $\gamma = \gamma_0 = 9/(2-1)(1-2a)$ there is a connection $\mathbf{z}_2^* = (v_2^*, u_2^*, w_2)$ from $\mathbf{a}_2 = (v_2, 0, w_2)$ back to the intersection point $\{w = w_2\} \cap \mathscr{E}_1$ for (5.1a) with $u_2^* < 0$, where $v_2 = \gamma_0 w_2$, $w_2 = f(v_2)$ and (γ_0, c_0) is the same as in Theorem 1.1(d).

Next, let us show that these two connections can be continued for parameters near $(\varepsilon, \gamma, c) = (0, \gamma_0, c_0)$ via the Melnikov method. We consider this question for the $\mathbf{z}_1^*$ connection first. Let $\mathbf{z}_0^*$ be an arbitrarily chosen point from $\mathbf{z}_1^*$, and let Σ be the corresponding plane perpendicular to $\mathbf{z}_1^*$ at $\mathbf{z}_0^*$. Without loss of generality, let $\mathbf{z}_1^*(0) = \mathbf{z}_0^*$ and $\mathbf{z}_1^*(\tau) = (v_1^*, u_1^*, 0)(\tau)$ up to time translation along the solution. Since w in (5.1a) can be regarded as a parameter, the center-stable manifold $W_0^{cs}(\mathscr{E}_2) \cap \Sigma$ of $\mathscr{E}_2$ on Σ can be parametrized by w. Let $\mathbf{e}$ be the vector $(-u_1^{*\prime}(0), v_1^{*\prime}(0), 0)$ (which is labeled as $\mathbf{e}_1$ in Fig. 5.1) on $\{w = 0\}$ as discussed in the last section for vector field in $\mathbb{R}^2$; then $\mathbf{e}$ must be transverse to $W_0^{cs}(\mathscr{E}_2)$ near $\mathbf{z}_0^*$ since it points forwards (cf. Fig. 5.1). Let $Q_1(\varepsilon, \gamma, c)$ be the corresponding Melnikov function for $W^u(\mathbf{a}_1, \varepsilon)$ and $W_\varepsilon^{cs}(\mathscr{E}_2)$ (we will see later in § 7 that the direction $\mathbf{e}$ is indeed consistent with the requirement of § 3 that it points to the same side of $W^s(\mathbf{a}_2)$ as $\mathbf{e}_1^+$ does). On the other hand, as mentioned earlier, since w can be viewed as a parameter for the two-dimensional system

$$v' = u, \quad u' = cu - f(v) + w, \tag{5.2}$$

we can define a Melnikov function $Q(c, w)$ for the connection (v_1^*, u_1^*) at the parameters $w = 0$ and $c = c_0$ with respect to the corresponding straight line $\Sigma \cap \{w = 0\}$ and the same direction $\mathbf{e}$ on $\{w = 0\}$. It is easy to see that $(\partial/\partial c) Q_1(0, \gamma_0, c_0) = (\partial/\partial c) Q(c_0, 0)$. Thus, by (3.2) and the Melnikov integral (3.5) we have, up to a positive constant multiple,

$$\begin{aligned} \frac{\partial Q_1}{\partial c}(0, \gamma_0, c_0) &= -\int_{-\infty}^{\infty} \exp(-c\tau)(-u_1^{*\prime}(\tau), v_1^{*\prime}(\tau)) \cdot (0, u_1^*(\tau))\, d\tau \\ &= -\int_{-\infty}^{\infty} \exp(-c\tau) u_1^*(\tau)^2\, d\tau < 0. \end{aligned} \tag{5.3a}$$

Therefore, by the implicit function theorem, the solutions of $Q_1 = 0$ can be expressed as a function of $c = c_{1,0}(\gamma, \varepsilon)$, or $c = c_{1,0}(\gamma)$ for short, near $(0, \gamma_0, c_0)$. Moreover, an identical argument yields

$$\frac{\partial Q_1}{\partial \gamma}(0, \gamma_0, c_0) = 0. \tag{5.3b}$$

Therefore,

$$\frac{\partial c_{1,0}(\gamma_0, 0)}{\partial \gamma} = 0 \quad \text{or} \quad c_{1,0}'(\gamma_0) = 0 \tag{5.3c}$$

by the implicit function theorem. Similarly, define the other Melnikov function $Q_2(\varepsilon, \gamma, c)$ for $W^u(\mathbf{a}_2, \varepsilon)$ and $W_\varepsilon^{cs}(\mathscr{E}_1)$ with the same kind of choices of Σ and $\mathbf{e}$ except that $(v_1^*, u_1^*, 0)$ above is replaced by (v_2^*, u_2^*, w_2), where w_2 is a constant satisfying $v_2 = \gamma_0 w_2$, $w_2 = f(v_2)$. By the same argument,

$$\frac{\partial Q_2}{\partial c}(0, \gamma_0, c_0) = -\int_{-\infty}^{\infty} \exp(-c\tau) u_2^*(\tau)^2\, d\tau < 0. \tag{5.4a}$$

The only difference is that $\partial Q_2/\partial\gamma\ (0, \gamma_0, c_0) = \partial Q/\partial w\ (c_0, w_2) \cdot \partial w_2/\partial\gamma < 0$. Indeed, since w_2 is strictly decreasing in γ (cf. Fig. 1.1) and, by the Melnikov integral (3.5),

$$\frac{\partial Q}{\partial w}(c_0, w_2) = -\int_{-\infty}^{\infty} \exp(-c\tau)(-u_2^{*\prime}(\tau), v_2^{*\prime}(\tau)) \cdot (0, 1)\, d\tau$$

$$= -\int_{-\infty}^{\infty} \exp(-c\tau) u_2^*(\tau)\, d\tau > 0$$

for $u_2^* < 0$, we have

$$\frac{\partial Q_2}{\partial\gamma}(0, \gamma_0, c_0) < 0. \tag{5.4b}$$

Thus, by the implicit function theorem the solution function $c = c_{2,0}(\gamma, \varepsilon)$, or $c_{2,0}(\gamma)$, of $Q_2 = 0$ satisfies

$$\frac{\partial c_{2,0}(\gamma_0, 0)}{\partial\gamma} < 0 \quad \text{or} \quad c'_{2,0}(\gamma_0) < 0. \tag{5.4c}$$

This and (5.3c) show that $c_{1,0}$ and $c_{2,0}$ intersect transversely near (γ_0, c_0) for small ε. More precisely, the $c_{2,0}$ curve crosses the $c_{1,0}$ curve transversely from above into below as γ increases through γ_0. Let the intersection be $(\gamma(\varepsilon), c(\varepsilon))$. Then at $(\gamma(\varepsilon), c(\varepsilon))$ with $\varepsilon > 0$ there exists a heteroclinic loop connecting $\mathbf{a}_1$ and $\mathbf{a}_2$.

Next, to show the heteroclinic orbit $\mathbf{z}_1^*$ of (5.1a) converges to $\mathbf{a}_2$ along the principal stable eigenvector of $\mathbf{a}_2$ we only need to show that $\mathbf{z}_1^*$ is not contained in the strong stable manifold $W^{ss}(\mathbf{a}_2, \varepsilon)$ of $\mathbf{a}_2$ which is the stable fiber, $\mathscr{F}_\varepsilon^s$, through $\mathbf{a}_2$ on the center-stable manifold of $\mathscr{E}_2$. Since in limit $\varepsilon = 0$ $\mathscr{F}_\varepsilon^s$ lies on $\{w = w_2\}$ while $\mathbf{z}_1^*$ lies on $\{w = 0\}$ and $w_2 > 0$ because $\gamma_0 = 9/(2-a)(1-2a) \neq 0$ for $0 < a < \frac{1}{2}$ and $w_2 = f(v_2)$, $v_2 = \gamma_0 w_2 \neq 0$, $\mathscr{F}_\varepsilon^s$ still stays away from $\mathbf{z}_1^*$ uniformly for small $\varepsilon > 0$ by continuity. Similar arguments apply to the $\mathbf{z}_2^*$ connection.

Last, to show the strong inclination property (2.2b′) along $\mathbf{z}_1^*$ we show first that the center-stable and the center-unstable manifolds of (5.1a) intersect transversely along $\mathbf{z}_1^*$ at the limit $\varepsilon = 0$ and then we will relate this transverse intersection to the strong inclination property for $\varepsilon > 0$. Recall that $\mathscr{E}_1$ and $\mathscr{E}_2$ lie on $\{u = 0\}$ and can be parametrized by w so that when $w = 0$, $c = c_0$ there is the connection $\mathbf{z}_1^*$ from $\mathbf{a}_1$ to $\mathscr{E}_2 \cap \{w = 0\}$. Recall the definition of the differential function $q(\varepsilon, \gamma, c, w)$ along the forward pointing direction $\mathbf{e}$ from § 3, where $\mathbf{e}$ is the same as in the definition of the Melnikov function Q_1 above in this section (cf. Fig. 5.1). As mentioned earlier in § 3, we need to show

$$\frac{\partial q(0, \gamma, c_0, 0)}{\partial w} \neq 0$$

in order to prove the transverse intersection of $W^{cs}(\mathscr{E}_2)$ and $W^{cu}(\mathscr{E}_1)$ along $\mathbf{z}_1^*$. However, by treating (5.1a) as a two-dimensional system (5.2) again, it is easy to see that the differential q between W^{cs} and W^{cu} for the three-dimensional system (5.1a) at $\varepsilon = 0$ is precisely the Melnikov function $Q(c, w)$ of (5.2). Thus, $\partial q(0, \gamma, c_0, 0)/\partial w = \partial Q(c_0, 0)/\partial w$. Hence, by (3.2) and the Melnikov integral (3.5) we have

$$\frac{\partial q(0, \gamma, c_0, 0)}{\partial w} = -\int_{-\infty}^{\infty} \exp(-c\tau)(-u_1^{*\prime}(\tau), v_1^{*\prime}(\tau)) \cdot (0, 1)\, d\tau$$

$$= -\int_{-\infty}^{\infty} \exp(-c\tau) u_1^*(\tau)\, d\tau < 0 \tag{5.5a}$$

since $u_1^*(\tau) > 0$. Similarly, for the other connection $\mathbf{z}_2^*$ from $\mathbf{a}_2$ back to $\mathscr{E}_1$, we can show

$$\frac{\partial q(0, \gamma, c_0, w_2)}{\partial w} = -\int_{-\infty}^{\infty} \exp(-c\tau) u_2^*(\tau)\, d\tau > 0 \tag{5.5b}$$

since $u_2^*(\tau) < 0$. This shows that by definition $W^{cu}(\mathscr{E}_i)$ and $W^{cs}(\mathscr{E}_j)$ intersect transversely and the corresponding strong inclination property is satisfied by the strong λ-lemma of Deng (1989), (1990). By "strong inclination property" for nonhyperbolic system we mean that the same limit as (2.2b′) exists except that W_j^s, W_i^u, and W_i^{ss} in the formula are understood as $W^{cs}(\mathbf{a}_j)$, $\mathscr{F}_0^u(\mathbf{a}_i)$, and $\mathscr{F}_0^s(\mathbf{a}_i)$, respectively. Because the strong inclination property is generic, that is, it persists for those small perturbations of the vector field along which there exists the continuation of the connection $\mathbf{z}_i^*$, the strong inclination property (2.2b′) also holds true for sufficiently small $\varepsilon > 0$. This completes the proof for condition (2.2b).

Remark. The nonzeroness of the Melnikov integrals in (5.3a), (5.4a), (5.5a), and (5.5b) have also been derived by Lin (1989).

6. Proof of condition (2.2c). Recall that the connection $\mathbf{z}_1^*$ is twisted if the principal eigenvectors $\mathbf{e}_2^-$ and $\mathbf{e}_1^+$ along which the other connection $\mathbf{z}_2^*$ comes from $\mathbf{a}_2$ and goes to $\mathbf{a}_1$, respectively, point to opposite sides of the stable manifold $W^s(\mathbf{a}_2)$ of $\mathbf{a}_2$ along $\mathbf{z}_1^*$. Using the same strategy as above, let us examine the limiting case $\varepsilon = 0$ first. Note that in limit $\varepsilon = 0$, $\mathbf{e}_1^+$ is of the direction of the center eigenvector $\mathbf{v}_2$ of $\mathbf{a}_1$ and $\mathbf{e}_2^-$ is of the direction of the unstable tangent fiber $-\mathbf{v}_3$ of $\mathbf{a}_2$ (cf. Fig. 5.1). Thus, it suffices to show $\mathbf{v}_2$ of $\mathbf{a}_1$ and $-\mathbf{v}_3$ of $\mathbf{a}_2$ point to opposite sides of the center stable manifold $W^{cs}(\mathscr{E}_2)$ of $\mathscr{E}_2$. To show this, recall the differential function q from the previous section and the property (5.5a). $\partial q/\partial w < 0$ implies that $W^{cu}(\mathscr{E}_1)$ and $W^{cs}(\mathscr{E}_2)$ must split in such a way that when $w > 0$, $W^{cs}(\mathscr{E}_2)$ lies behind $W^{cu}(\mathscr{E}_1)$ near $\mathbf{z}_1^*$ (cf. Fig. 5.1). Thus, $\mathbf{v}_2$ of $\mathbf{a}_1$ and $\mathbf{v}_3$ of the intersection point $\mathscr{E}_2 \cap \{w = 0\}$ point to the same side of $W^{cs}(\mathscr{E}_2)$. Since $\mathbf{v}_3$ of $\mathscr{E}_2 \cap \{w = 0\}$ and $-\mathbf{v}_3$ of $\mathbf{a}_2$ point to opposite sides of $W^{cs}(\mathscr{E}_2)$, the desired result is proved. Similar arguments show that $\mathbf{z}_2^*$ is twisted. This proves condition (2.2c).

7. Proof of condition (2.2e). Recall from (5.3a, b) that when $(\varepsilon, \gamma, c) = (0, \gamma_0, c_0)$, $\partial Q_1/\partial c < 0$, $\partial Q_1/\partial \gamma = 0$. Also recall from (5.4a, b) that $\partial Q_2/\partial c < 0$, $\partial Q_2/\partial \gamma < 0$. It obviously follows that ∇Q_1 and ∇Q_2 are linearly independent for small $\varepsilon > 0$, where the gradient operator ∇ is taken with respect to the relevant parameters γ and c. Last, from the proof of the twist of $\mathbf{z}_i^*$ above, it is easy to see that the vectors $\mathbf{e}_i$ and $\mathbf{e}_i^+$ do point to the same side of $W^s(\mathbf{a}_j)$ (cf. Fig. 5.1). Hence, the Melnikov function Q_i, $i = 1$, 2, satisfies the specific requirement with respect to the direction $\mathbf{e}_i$ in § 3. This proves condition (2.2e).

Remark. Back in 1980, Langer proved that the stable and unstable manifolds cross transversely with the velocity parameter c for small $\varepsilon > 0$. This is also implied by the nonzeroness of $\partial Q_i/\partial c$, which also indicates the direction in which the transversal crossing takes place.

8. Proof of Theorem 1.1. As discussed in § 2, to prove Theorem 1.1 we only need to show that Theorem 2.1 is applicable to the reduced FitzHugh–Nagumo equation (2.1). We have shown in §§ 4–7 above that the hypotheses of Theorem 2.1 are all satisfied. Thus, it is only left to determine the bifurcation directions for the curves of the multiple pulse front and back waves by Theorem 2.1(c). Again, recall from (5.3a, b) and (5.4a, b), or from the previous section, that $\partial Q_1/\partial c < 0$, $\partial Q_1/\partial \gamma = 0$, and $\partial Q_2/\partial c < 0$,

$\partial Q_2/\partial\gamma < 0$ at $(\varepsilon, \gamma, c) = (0, \gamma_0, c_0)$. That is, ∇Q_1 and ∇Q_2 point downward at $(\gamma, c) = (\gamma(\varepsilon), c(\varepsilon))$ on the (γ, c)-plane for small $\varepsilon \geqq 0$. Therefore, all the interesting bifurcations take place in the southwest sector bounded by $Q_1 = 0$ and $Q_2 = 0$ in the (γ, c)-plane. This completes the proof. □

9. Proof of Theorem 1.2. To prove this theorem it suffices to show that the reduced traveling wave equations when restricted to the center manifold with respect to the singular parameter κ are "almost" the same as the FitzHugh-Nagumo equations (1.1). To begin with, recast (1.2) into the traveling wave equations with $\tau = x + ct$:

$$v' = u, \quad u' = cu - f(v) + w, \quad w' = x, \quad \kappa x' = cx - \varepsilon(v - \gamma w). \tag{9.1}$$

Treating κ as a singular parameter and writing this equation in terms of the fast time $t := \tau/\kappa$ variable, we have

$$\dot{v} = \kappa u, \quad \dot{u} = \kappa(cu - f(v) + w), \quad \dot{w} = \kappa x, \quad \dot{x} = cx - \varepsilon(v - \gamma w), \tag{9.2}$$

where the dot means the derivative in t. Note that when $\kappa = 0$ the equilibrium points of (9.2) consist of the entire three-dimensional manifold:

$$\mathscr{E}_0 := \left\{ x = \frac{\varepsilon}{c}(v - \gamma w) \right\}.$$

The linearization of (9.2) at $\mathscr{E}_0$ when $\kappa = 0$ is $\dot{V} = \dot{U} = \dot{W} = 0$ and $\dot{X} = cX$. It has only one nonzero eigenvalue $c > 0$ and the corresponding eigenvector $(0, 0, 0, 1)$ is normal to the manifold $\mathscr{E}_0$. For simplicity, let $\mathscr{E}_0$ also denote a sufficiently large, connected, and compact set in what follows. Therefore, in the context of Fenichel (1979) the invariant manifold $\mathscr{E}_0$ is normally hyperbolic. Also by Theorem 9.1 of Fenichel (1979) again there is a center manifold

$$\mathscr{E}_\kappa := \{x = h(v, u, w, \kappa)\}$$

in a neighborhood of $\mathscr{E}_0$ for all $|\kappa| \ll 1$, and it is a smooth continuation of $\mathscr{E}_0$, namely,

$$h(v, u, w, 0) = \frac{\varepsilon}{c}(v - \gamma w).$$

Here, the other parameters are suppressed from the expression of h for simplicity. It is very important to note from (9.2) that when $\varepsilon = 0$, $\{x = 0\}$ is always an invariant manifold regardless of the parameter κ. This implies that the function h can be chosen so that

$$h(v, u, w, \kappa) = \frac{\varepsilon}{c}(v - \gamma w) + O(\varepsilon\kappa). \tag{9.3}$$

According to the singular perturbation theory of Fenichel (1979) this manifold $\mathscr{E}_\kappa$ is invariant for both the slow and fast equations (9.1) and (9.2) for all $|\kappa| \ll 1$. Now, recasting (9.1) on the center manifold $\mathscr{E}_\kappa$ yields

$$v' = u, \quad u' = cu - f(v) + w, \quad w' = \frac{\varepsilon}{c}(v - \gamma w) + O(\varepsilon\kappa), \tag{9.4}$$

because of $w' = w = h(v, u, w, \kappa)$ and the estimate (9.3). Note that this is exactly the same FitzHugh-Nagumo equation (1.1) except for a perturbation term $O(\varepsilon\kappa)$ to the w equation. Now, it is easy to see that all the analysis for (2.1) in the previous sections applies to (9.4) as well. More specifically, ε is the singular parameter, γ and c are the relevant parameters. The additional parameter κ represents a trivial direction of

perturbation. That is to say, it will not change any qualitative structure of the system with respect to the heteroclinic loop bifurcation of Theorem 2.1, neither the singular perturbation structure in terms of ε nor the Melnikov method. This completes the proof. □

Appendix. The result presented below is taken from McKean (1970) and Casten, Cohen, and Lagerstrom (1975). Consider (5.1a). Since $w' = 0$, we can treat w as a parameter. For $f_{\min} < w_0 < f_{\max}$, there are three roots for $-f(v) + w_0 = 0$. Denote them by $\beta_1 < \beta_2 < \beta_3$ which implicitly depend on w_0 (cf. Fig. A). Then (5.1a) is equivalent to

$$u\frac{du}{dv} = cu + (v-\beta_1)(v-\beta_2)(v-\beta_3),$$

since $d\tau = dv/u$. Now, it is straightforward to check that $u = \lambda(v-\beta_1)(\beta_3 - v)$ with $\lambda = \pm 1/\sqrt{2}$, $c = \lambda(\beta_1 + \beta_3 - 2\beta_2)$ is a polynomial solution going through β_1 and β_3. In particular, when $w_0 = 0$, $\beta_1 = 0$, $\beta_2 = a$, $\beta_3 = 1$, and $\lambda = 1/\sqrt{2}$ we obtain a connection with a positive speed $c_{1,0} = (1-2a)/\sqrt{2}$. Denote the corresponding solution by (v_1^*, u_1^*); then $1 > v_1^* > 0$, $u_1^* > 0$. This implies that the connection is from $\mathbf{a}_1$ to $\mathscr{C}_2 \cap \{w = 0\}$ since $v_1^{*\prime} = u_1^* > 0$. On the other hand, choosing $\lambda = -1/\sqrt{2}$, we obtain another connecting orbit (v_2^*, u_2^*) for $c_{2,0} = \lambda(\beta_1 + \beta_3 - 2\beta_2)$. But, in this case $u_2^* < 0$ since $\beta_1 < v_2^* < \beta_3$; thus $v_2^{*\prime} < 0$. This implies that the connection is from $\mathscr{C}_2 \cap \{w = w_0\}$ back to $\mathscr{C}_1 \cap \{w = w_0\}$. Thus, it is only left to determine whether the corresponding speed c is positive and equal to $c_{1,0}$ at some γ in order to obtain a "loop." Because the cubic curve $w = f(v)$ is symmetric with respect to the inflection point $(v_{\inf}, f_{\inf}) := ((1+a)/3, (1+a)(1-2a)(2-1)/27)$ of $w = f(v)$, we can choose (v_2, w_2) from the curve $w = f(v)$ to be the point that is symmetric to the origin (0, 0) with respect to the inflection point. Because of this symmetry $c_{2,0} = -(\beta_1 + \beta_3 - 2\beta_2)/\sqrt{2} = (1-2a)/\sqrt{2} = c_{1,0}$ at $w_0 = w_2$. A direct computation yields $\gamma_0 := v_2/w_2 = 9/(2-a)(1-2a)$, which is the same as in Theorem 1.1(d). Certainly, for this parameter γ_0, the connection (v_2^*, u_2^*) is from $\mathbf{a}_2$ back to $\mathscr{C}_1 \cap \{w = w_2\}$.

STABILITY ANALYSIS OF STATIONARY SOLUTIONS OF BISTABLE REACTION-VARIABLE DIFFUSION SYSTEMS*

HIDEO IKEDA† AND MASAYASU MIMURA‡

Abstract. From a wave-blocking viewpoint, a bistable reaction-variable diffusion system is considered:

$$u_t = (D(z)u_z)_z + \frac{1}{\sigma} f(u, v),$$

$$z \in \mathbf{R}, \quad t > 0.$$

$$v_t = (D(z)v_z)_z + \sigma g(u, v),$$

Depending on σ and $D(z)$, there exist stationary solutions that connect two stable states at $z = \pm\infty$. By using the linearized stability criterion, the role of these solutions in wave-blocking phenomena is discussed.

Key words. stability, variable diffusion, singular perturbation, wave-blocking

AMS(MOS) subject classifications. 35B25, 35B40, 35K57

1. Introduction.

In this paper, we consider the following reaction-diffusion system:

$$u_t = (D(z)u_z)_z + \frac{1}{\sigma} f(u, v),$$

$$z \in \mathbf{R}, \quad t > 0, \tag{1.1}$$

$$v_t = (D(z)v_z)_z + \sigma g(u, v),$$

where $D(z)$ is the *variable* diffusion rates of u and v. For the nonlinearities f and g, we assume that there exist three constant steady states as in Fig. 1: Two of them $(u_\pm, v_\pm)$ are stable, while the other (u_0, v_0) is unstable. $1/\sigma^2$ is the ratio of the reaction rates of u and v. If σ is small, u reacts faster than does v. Conversely, if σ is large, the situation is vice versa. In chemical terms, (1.1) describes the situation where two ion components u and v diffuse in one-dimensional heterogeneous medium and react with each other in bistable dynamics.

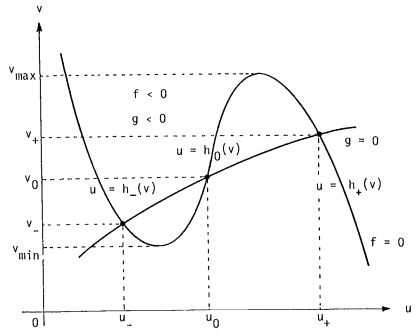

FIG. 1 *Functional forms of* $f = 0$ *and* $g = 0$.

In studying the influence of variable diffusion on qualitative properties of solutions, there are many works on scalar equations. The main concerns are with the existence, stability, and bifurcation properties of *nonconstant* stationary solutions. Along these lines, [M], [Y], [CH], [FH], and [FP] treat these problems in a finite interval or on the whole line. From an application viewpoint, in [P] and [K] wave-blocking phenomena due to the effect of a change in geometry of a nerve axon on the propagation of potential waves are studied.

Here we are interested in these problems for a system of equations (1.1), when the variable diffusion rate $D(z)=d(z/\varepsilon)$, where $d(\xi)$ is a strictly monotone $C^1(\mathbf{R})$ function satisfying

$$d(\xi)=\begin{cases} d & \text{as } \xi\to-\infty, \\ 1 & \text{as } \xi\to+\infty \end{cases} \tag{1.2}$$

and ε is a small positive constant. That is, this situation indicates that the diffusion rate $D(z)$ has an abrupt change at $z=0$. Let

$$x=\tau(z)\equiv\int_0^z ds/d\left(\frac{s}{\varepsilon}\right).$$

Clearly, τ maps $\mathbf{R}$ into $\mathbf{R}$ and its inverse τ^{-1} is well defined. Introducing x as the independent variable into (1.1), we have

$$\begin{aligned} u_t &= \delta_\varepsilon(x)u_{xx}+\frac{1}{\sigma}f(u,v), \\ & \qquad\qquad x\in\mathbf{R}, \quad t>0, \\ v_t &= \delta_\varepsilon(x)v_{xx}+\sigma g(u,v), \end{aligned} \tag{1.3}$$

where $\delta_\varepsilon(x)=1/d(\tau^{-1}(x)/\varepsilon)$. Set $\varepsilon=0$. Then (1.3) reduces to the following limiting system:

$$\begin{aligned} u_t &= \delta_0(x)u_{xx}+\frac{1}{\sigma}f(u,v), \\ & \qquad\qquad x\in\mathbf{R}, \quad t>0, \\ v_t &= \delta_0(x)v_{xx}+\sigma g(u,v), \end{aligned} \tag{1.4}$$

where

$$\delta_0(x)=\begin{cases} 1/d, & x<0, \\ 1, & x>0. \end{cases}$$

When $\varepsilon>0$ is sufficiently small, perturbation techniques suggest that (1.4) becomes a nice approximation to (1.3) in some sense. So we study the above limiting system (1.4).

When $d=1$ or $\delta_0(x)=1$ (homogeneous medium), (1.4) reduces to a usual reaction-diffusion system

$$\begin{aligned} u_t &= u_{xx}+\frac{1}{\sigma}f(u,v), \\ & \qquad\qquad x\in\mathbf{R}, \quad t>0. \\ v_t &= v_{xx}+\sigma g(u,v), \end{aligned} \tag{1.5}$$

For (1.5), we could expect that there are traveling wave solutions connecting one stable state (u_-, v_-) at $x=-\infty$ and the other (u_+, v_+) at $x=+\infty$. In fact, when f and g are specified as

$$\begin{aligned} f(u, v) &= u(1-u)(u-a)-v, \\ g(u, v) &= u-\gamma v, \end{aligned} \tag{1.6}$$

there are three constant steady states $(0, 0)$, $(\bar{u}_+, \bar{u}_+/\gamma)$, and $(\bar{u}_-, \bar{u}_-/\gamma)$ for some values of a and γ, where $\bar{u}_-$ and $\bar{u}_+$ $(\bar{u}_- < \bar{u}_+)$ are two solutions of $(1-u)(u-a)=1/\gamma$. Numerical simulations show that two different types of traveling wave solutions connecting $(0, 0)$ at $x=-\infty$ and $(\bar{u}_+, \bar{u}_+/\gamma)$ at $x=+\infty$ coexist: one is a *front* wave that propagates to the left direction, and the other is a *back* wave that goes in the opposite direction (see Fig. 2). We state briefly the results obtained in [IM2]. Suppose that f and g take the form (1.6) for simplicity and γ_0, γ_1, and γ_2 are the critical values as shown in Fig. 4. The qualitative property of traveling waves depends on the value of σ. When σ is sufficiently large, there is a unique stable traveling wave solution for fixed $\gamma > \gamma_0$ as in Fig. 5(i). On the other hand, when σ is sufficiently small, there are three solutions for fixed $\gamma \in (\gamma_0, \gamma_2)$ as in Fig. 5(ii); two of them are stable, whereas the other is unstable.

What happens in the case when $d \neq 1$ (heterogeneous medium)? As in Fig. 3, numerical simulations show three typical behaviours when σ is sufficiently small, where a, σ, and γ are the same values as in Fig. 2: (i) When d is close to 1, we could expect that the front and back waves pass through the point of discontinuity $x=0$ and propagate to the left and right directions, respectively (see Fig. 3(i)). (ii) When d is

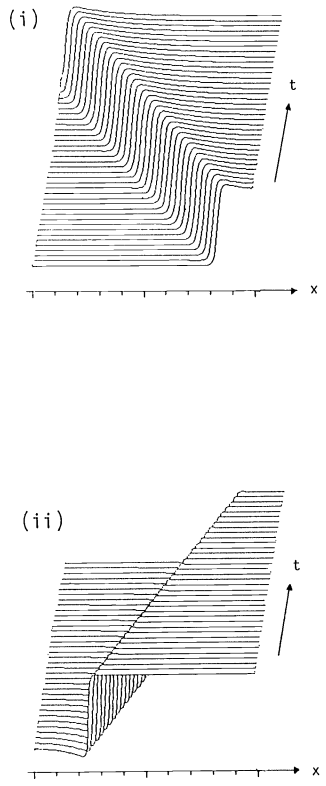

FIG. 2. (i) *Traveling front wave.* (ii) *Traveling back wave* ($a=0.25$, $\sigma=0.1$ *and* $\gamma=10.5$).

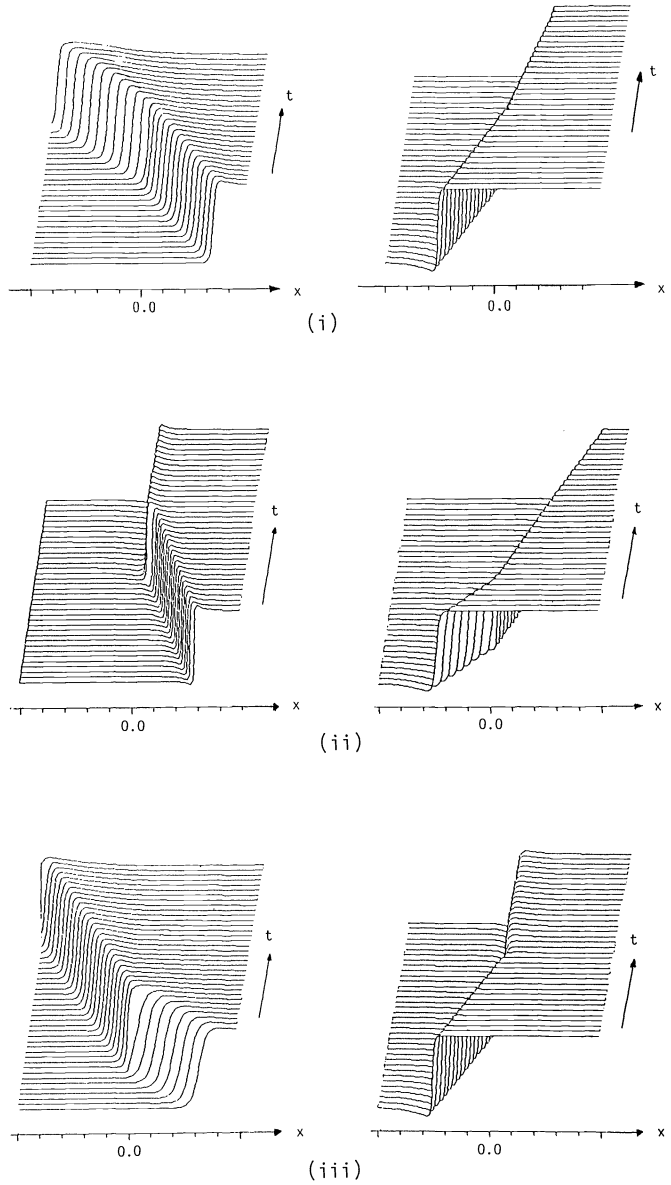

FIG. 3. *Numerical computations for wave-blocking phenomena*: (i) *When d is close to* 1, *the front and back waves pass through*; (ii) *When d is large, the front wave is blocked, whereas the back wave passes through*; (iii) *When d is small, the front wave passes through, whereas the back wave is blocked.*

large, the back wave passes through the point $x = 0$ and propagates to the right direction, while the front wave is blocked at $x = 0$ (see Fig. 3 (ii)). (iii) When d is small, the situation is opposite to that in (ii) (see Fig. 3(iii)). The last two cases (ii) and (iii) indicate that the traveling waves are blocked and there appear *new* stationary solutions. These evidences clearly show that such wave-blocking phenomena are caused by the heterogeneity of $\delta_0(x)$.

For the problem of wave-blocking phenomena in a heterogeneous medium, the dependency on d of stationary solutions is considered in [IM1] when σ is sufficiently

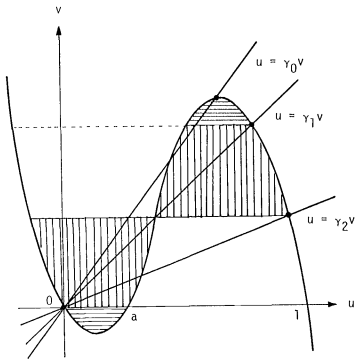

FIG. 4. *Critical values of* γ.

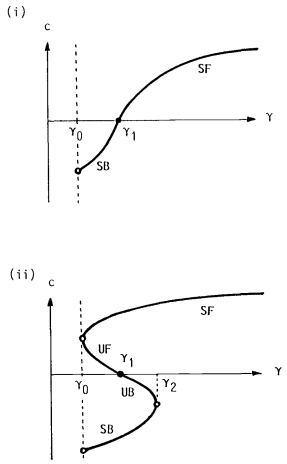

FIG. 5. *The global diagrams of traveling waves with respect to* γ. *The symbols SF, SB, UF, and UB stand for a stable front branch, a stable back branch, an unstable front branch, and an unstable back branch, respectively*: (i) σ *is sufficiently large*; (ii) σ *is sufficiently small.*

large or small. Suppose that σ is sufficiently large. If γ is fixed to satisfy $\gamma \in (\gamma_1, \infty)$, there exist two stationary solutions for large d (see Fig. 6(i)) and if γ is fixed to satisfy $\gamma \in (\gamma_0, \gamma_1)$, there exist two solutions for small d (see Fig. 6(ii)). On the other hand, if σ is sufficiently small, then the situation is different from the above. If γ is fixed to satisfy $\gamma \in (\gamma_2, \infty)$, then there exist two stationary solutions for large d (see Fig. 7(i)). However, if γ is fixed to satisfy $\gamma \in (\gamma_0, \gamma_2)$, there exist two solutions for large as well as small d (see Figs. 7(ii) and 7(iii)). This evidence shows that the qualitative property of stationary solutions depends on the value of σ as well as d.

Integrating these and using complementary numerical results, we arrive at the following conjecture. For simplicity, we consider the case when σ is sufficiently small and γ satisfies $\gamma \in (\gamma_1, \gamma_2)$. Under this situation, there are one front wave and one back wave, which are stable, in a homogeneous medium. For large fixed d, the front wave is blocked at $x = 0$ and one of the stationary solutions $(\underline{U}^*, \underline{V}^*)$ acts as its *barrier*, while the other $(\bar{U}^*, \bar{V}^*)$ acts as a *separator* between the barrier and the traveling like front wave (in a heterogeneous medium) as in Fig. 3(ii), whereas the back wave passes through. On the other hand, for small fixed d, the back wave is blocked and one of the stationary solutions $(\bar{U}_*, \bar{V}_*)$ acts as its barrier, while the other $(\underline{U}_*, \underline{V}_*)$ acts as

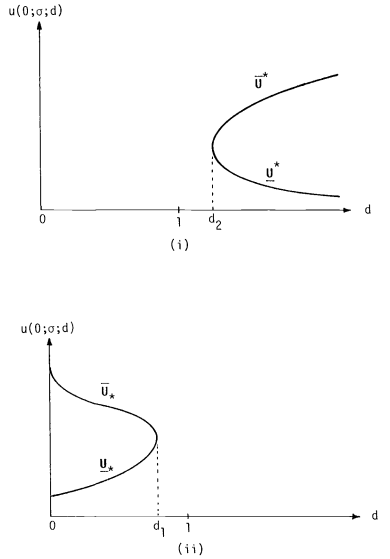

FIG. 6. *The schematic global diagrams of stationary solutions of* (1.1) *with* (1.4) *when* σ *is sufficiently large*: (i) $\gamma > \gamma_1$; (ii) $\gamma_0 < \gamma < \gamma_1$.

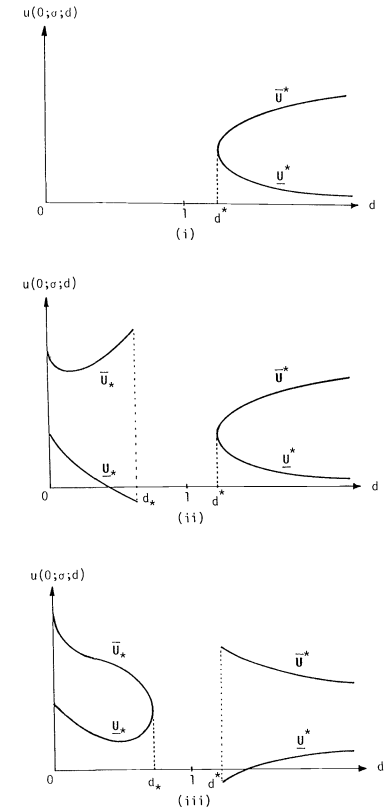

FIG. 7. *The schematic global diagrams of stationary solutions of* (1.1) *with* (1.4) *when* σ *is sufficiently small*: (i) $\gamma > \gamma_2$; (ii) $\gamma_1 < \gamma < \gamma_2$; (iii) $\gamma_0 < \gamma < \gamma_1$.

a separator between the barrier and the traveling like back wave as in Fig. 3(iii), whereas the front wave passes through. For intermediate fixed d, there are no stationary solutions and two waves pass through the discontinuous point $x=0$ as in Fig. 3(i).

Motivated by this evidence, we study the stability of the stationary solutions constructed in [IM1]. When σ is sufficiently small and γ satisfies $\gamma\in(\gamma_1, \gamma_2)$, for instance, the result is stated as follows. For large d, the $(\underline{U}^*, \underline{V}^*)$-branch is stable and the $(\bar{U}^*, \bar{V}^*)$-branch is unstable, while for small d, the $(\bar{U}_*, \bar{V}_*)$-branch is stable and the $(\underline{U}_*, \underline{V}_*)$-branch is unstable (see Fig. 7(ii)). The details will be discussed in § 3.

Since $\delta_0(x)$ is discontinuous at $x=0$, let us define weak solutions $(u, v)(t, x)$ of (1.4) by (u, v), which satisfies the following equations:

$$\begin{aligned} &u_t=\delta_0(x)u_{xx}+\frac{1}{\sigma}f(u, v),\\ &\qquad\qquad x\in\mathbf{R}\backslash\{0\},\quad t>0 \qquad (1.7)_a\\ &v_t=\delta_0(x)v_{xx}+\sigma g(u, v), \end{aligned}$$

with boundary conditions

$$(u, v)(t, \pm\infty)=(u_\pm, v_\pm) \qquad (1.7)_b$$

and compatibility conditions

$$\begin{aligned} &(u, v)(t, -0)=(u, v)(t, +0),\\ &\qquad\qquad t>0. \qquad (1.7)_c\\ &(u_x, v_x)(t, -0)=(u_x, v_x)(t, +0), \end{aligned}$$

We now study the spectral analysis for the linearized equations of $(1.7)_a$ around the specified stationary solution obtained in [IM1]. The spectrum of the linearized operator consists of essential spectrum and isolated eigenvalues. Since the essential spectrum is strictly bounded away from the imaginary axis to the left (see the Appendix), it is sufficient for the stability argument to study the distribution of isolated eigenvalues only. Our assertion is that there is only one eigenvalue that essentially determines the stability and its sign corresponds, in a one-to-one manner, to that of the Jacobian of the matching condition which is defined in constructing solutions by use of singular perturbation methods (see (2.14)). Here we discuss only the case where σ is sufficiently small. The case where σ is sufficiently large is briefly stated in the final section.

We first state the following assumptions on the nonlinearities f and g (see Fig. 1):

(A1) $f=0$ is S-shaped and consists of three branches $u=h_-(v)$, $h_0(v)$, and $h_+(v)$ $(h_-(v)\leqq h_0(v)\leqq h_+(v))$, and $g=0$ intersects each branch once. That is, there is only one intersection point on each branch $u=h_-(v)$ (respectively, $u=h_0(v)$ or $u=h_+(v)$), which is denoted by (u_-, v_-) (respectively, (u_0, v_0) or $(u_+, v_+))(v_-<v_0<v_+)$. The signs of f and g are both negative in the region above the curves $f=0$ and $g=0$.

(A2) $\mathcal{I}(v)=\int_{h_-(v)}^{h_+(v)}f(u, v)\,du$ has a unique isolated zero at $v^*\in(v_{\min}, v_{\max})$.

(A3) $f_u(h_\pm(v), v)<0$ for $v\in[v_-, v_+]$, $g(h_-(v), v)<0<g(h_+(v), v)$ for $v\in(v_-, v_+)$, and $g_u(h_\pm(v), v)h'_\pm(v)+g_v(h_\pm(v), v)<0$ at $v=v_\pm$.

(A4) $f_v(u, v)<0$ for $(u, v)\in\{(u, v)\,|\,h_-(v)\leqq u\leqq h_+(v),\ v_-\leqq v\leqq v_+\}$, $g_u(u, v)>0$ and $g_v(u, v)<0$ at $(u, v)=(u_\pm, v_\pm)$.

(A5) $g_v(u, v)<0$ for $(u, v)\in\{(u, v)\,|\,g(u, v)=0,\ v_-\leqq v\leqq v_+\}$.

Throughout this paper, we shall use the following function spaces. For $I=\mathbf{R}_-$, $\mathbf{R}_+$, or $\mathbf{R}$, positive numbers σ and μ, and an integer n, let

$$X^n_{\mu,\sigma}(I)=\left\{u\in C^n(I)\,\middle|\,\|u\|_{X^n_{\mu,\sigma}(I)}\equiv\sum_{i=0}^{n}\sup_{x\in I}\left|e^{\mu|x|}\left(\sigma\frac{d}{dx}\right)^i u(x)\right|<+\infty\right\},$$

$$\mathring{X}^n_{\mu,\sigma}(I)=\{u\in X^n_{\mu,\sigma}(I)\,|\,u(0)=0\},$$

$$BC^n(I)=\{\text{the set of functions all of whose derivatives of order}\leqq n\text{ are bounded and uniformly continuous on }I\}.$$

2. Construction of stationary solutions. We assume that σ is sufficiently small. First, we shall summarize the existence result for stationary solutions of (1.7) which is stated in [IM1]. Putting $y=\sqrt{\sigma}\,x$, we rewrite the stationary problem of (1.7) as

$$\begin{aligned}&(u,v)\in\mathcal{D}\times\mathcal{D},\\&\sigma^2\delta_0(y)u_{yy}+f(u,v)=0,\\&\qquad\qquad\qquad\qquad y\in\mathbf{R}/\{0\},\\&\delta_0(y)v_{yy}+g(u,v)=0,\\&u(\pm\infty)=u_\pm,\qquad v(\pm\infty)=v_\pm,\end{aligned}\tag{2.1}$$

where $\mathcal{D}\equiv\{u\in BC^1(\mathbf{R})\cap BC^2((-\infty,0])\cap BC^2([0,\infty))\,|\,\delta_0(y)u_{yy}\in BC(\mathbf{R})\}$. Let us seek a solution of (2.1) $(u,v)(y;\sigma;d)\in\mathcal{D}\times\mathcal{D}$ under (A1)-(A4). Since $\delta_0(y)(d\neq 1)$ has a discontinuity at $y=0$, we separate the problem (2.1) into the following two parts:

$$\begin{aligned}&\sigma^2\delta_0(y)u^\pm_{yy}+f(u^\pm,v^\pm)=0,\\&\qquad\qquad\qquad\qquad y\in\mathbf{R}_\pm,\\&\delta_0(y)v^\pm_{yy}+g(u^\pm,v^\pm)=0,\\&u^\pm(\pm\infty)=u_\pm,\qquad u^\pm(0)=\alpha,\\&v^\pm(\pm\infty)=v_\pm,\qquad v^\pm(0)=\beta,\end{aligned}\tag{2.2}_\pm$$

where α and β are constants that will be specified later. Using classical singular perturbation techniques, we construct solutions of $(2.2)_\pm$ in each subinterval $\mathbf{R}_\pm$, and then determine α and β so as to match these solutions in the C^1-sense at $y=0$. In § 2.1, we construct *outer solutions* that are approximate solutions to $(2.2)_\pm$ outside a layer region, and in §2.2, we construct *inner solutions* that are approximations to $(2.2)_\pm$ in a boundary layer region. In § 2.3, using these approximate solutions, we construct *singular limit solutions* as $\sigma\downarrow 0$, which become nice approximations to (2.1) uniformly on $\mathbf{R}$. Finally, in § 2.4, by using the singular limit solutions we prove the existence of solutions of (2.1) for a sufficiently small (but not zero) σ and draw the global picture of solution structures with respect to d. We emphasize that it is inherited from that of the singular limit solutions as $\sigma\downarrow 0$.

2.1. Outer solutions. We consider the reduced problems, by putting $\sigma=0$ in $(2.2)_\pm$. These are described by

$$\begin{aligned}&f(u^\pm,v^\pm)=0,\\&\qquad\qquad\qquad y\in\mathbf{R}_\pm,\\&\delta_0(y)v^\pm_{yy}+g(u^\pm,v^\pm)=0,\\&v^\pm(\pm\infty)=v_\pm,\qquad v^\pm(0)=\beta.\end{aligned}\tag{2.3}_\pm$$

Since $f(u^{\pm}, v^{\pm}) = 0$ are reduced to $u^{\pm} = h_{\pm}(v^{\pm})$ by the conditions $v^{\pm}(\pm\infty) = v_{\pm}$, $(2.3)_{\pm}$ can be rewritten as

$$(2.4)_{\pm} \qquad \begin{aligned} &\delta_0(y)v^{\pm}_{yy} + g(h_{\pm}(v^{\pm}), v^{\pm}) = 0, \qquad y \in \mathbf{R}_{\pm}, \\ &v^{\pm}(\pm\infty) = v_{\pm}, \qquad v^{\pm}(0) = \beta. \end{aligned}$$

Here β is arbitrarily fixed to satisfy $\beta \in (v_-, v_+)$.

LEMMA 2.1. *Equations* $(2.4)_{\pm}$ *have unique strictly monotone increasing solutions* $V_0^+(y; \beta)(y \in \mathbf{R}_+)$ *and* $V_0^-(y; \beta; d)(y \in \mathbf{R}_-)$ *satisfying*

$$|V_0^+(y; \beta) - v_+| \in X^2_{\mu_+,1}(\mathbf{R}_+), |V_0^-(y; \beta; d) - v_-| \in X^2_{\mu_-(d),1}(\mathbf{R}_-),$$

where $\mu_+ = \sqrt{-D_+(v_+)}$ *and* $\mu_-(d) = \sqrt{-dD_-(v_-)}$ *with* $D_{\pm}(v) = g_u(h_{\pm}(v), v)h'_{\pm}(v) + g_v(h_{\pm}(v), v)$. *Moreover,* $V_0^+(y; \beta)$ *(respectively,* $V_0^-(y; \beta; d)$*) is continuous with respect to* β *in the* $X^2_{\mu_+,1}(\mathbf{R}_+)$ *(respectively,* $X^2_{\mu_-(d),1}(\mathbf{R}_-)$*)-topology and satisfies*

$$\frac{d}{dy} V_0^+(0; \beta) = \sqrt{2 \int_{\beta}^{v_+} g(h_+(v), v)\, dv}$$

$$\left(\textit{resp.}, \frac{d}{dy} V_0^-(0; \beta; d) = \sqrt{2d \int_{\beta}^{v_-} g(h_-(v), v)\, dv} \right).$$

Using $V_0^+(y; \beta)$ and $V_0^-(y; \beta; d)$, we define $U_0^+(y; \beta)$ and $U_0^-(y; \beta; d)$ by

$$U_0^+(y; \beta) \equiv h_+(V_0^+(y; \beta)), \qquad y \in \mathbf{R}_+$$

and

$$U_0^-(y; \beta; d) \equiv h_-(V_0^-(y; \beta; d)), \qquad y \in \mathbf{R}_-,$$

respectively. Although $U_0^+(y; \beta)$ and $U_0^-(y; \beta; d)$ do not satisfy the boundary conditions at $y = 0$, we expect that when σ is small, $(U_0^{\pm}, V_0^{\pm})$ become nice approximations to solutions of $(2.2)_{\pm}$ outside a neighborhood of $y = 0$, which are called the *outer solutions* of $(2.2)_{\pm}$.

2.2. Inner solutions. We introduce $W_0^{\pm}(\xi)$ with the stretched variable $\xi = y/\sigma$ such that $(U_0^{\pm} + W_0^{\pm}, V_0^{\pm})$ become approximations to $(2.2)_{\pm}$ in a neighborhood of $y = 0$. Substituting $(U_0^{\pm} + W_0^{\pm}, V_0^{\pm})$ into $(2.2)_{\pm}$ and then setting $\sigma = 0$, we have the following problems with respect to $W_0^{\pm}$:

$$(2.5)_{\pm} \qquad \begin{aligned} &\delta_0(\xi)(W_0^{\pm})_{\xi\xi} + f(h_{\pm}(\beta) + W_0^{\pm}, \beta) = 0, \qquad \xi \in \mathbf{R}_{\pm}, \\ &W_0^{\pm}(\pm\infty) = 0, \qquad W_0^{\pm}(0) = \alpha - h_{\pm}(\beta). \end{aligned}$$

When $v^* < v_+$, $\omega_0(\beta)$ is uniquely determined for any $\beta \in [v^*, v_+]$ by $\int_{\omega_0(\beta)}^{h_+(\beta)} f(u, \beta)\, du = 0$. When $v_- < v^*$, $\omega_1(\beta)$ is uniquely determined for any $\beta \in [v_-, v^*]$ by $\int_{h_-(\beta)}^{\omega_1(\beta)} f(u, \beta)\, du = 0$. Using $\omega_0(\beta)$ and $\omega_1(\beta)$, we define Σ_1, Σ_2, and Σ_3 in (α, β)-space in $\mathbf{R}^2$ as follows. For $v_- < v^* < v_+$,

$$\Sigma_1 \equiv \{(\alpha, \beta) \in \mathbf{R}^2 \mid v^* \leqq \beta \leqq v_+, \omega_0(\beta) < \alpha < h_+(\beta) \text{ or } v_- \leqq \beta \leqq v^*, h_-(\beta) < \alpha < \omega_1(\beta)\};$$

for $v^* \leqq v_-$,

$$\Sigma_2 \equiv \{(\alpha, \beta) \in \mathbf{R}^2 \mid v_- \leqq \beta \leqq v_+, \omega_0(\beta) < \alpha < h_+(\beta)\};$$

for $v_+ \leqq v^*$,

$$\Sigma_3 \equiv \{(\alpha, \beta) \in \mathbf{R}^2 \mid v_- \leqq \beta \leqq v_+, h_-(\beta) < \alpha < \omega_1(\beta)\}.$$

LEMMA 2.2. *For any* $(\alpha, \beta) \in \Sigma_i$ $(i = 1, 2, 3)$, the $(2.5)_{\pm}$ *have unique strictly monotone increasing solutions* $W_0^+(\xi; \alpha, \beta)(\xi \in \mathbf{R}_+)$ *and* $W_0^-(\xi; \alpha, \beta; d)(\xi \in \mathbf{R}_-)$ *satisfying*

$$|W_0^+(\xi; \alpha, \beta)| \in X^2_{\tau_+(\beta),1}(\mathbf{R}_+), \qquad |W_0^-(\xi; \alpha, \beta; d)| \in X^2_{\tau_-(\beta; d),1}(\mathbf{R}_-),$$

where $\tau_+(\beta) = \sqrt{-f_u(h_+(\beta), \beta)}$ *and* $\tau_-(\beta; d) = \sqrt{-df_u(h_-(\beta), \beta)}$. *Moreover,* $W_0^+(\xi; \alpha, \beta)$ *(respectively,* $W_0^{\nabla}(\xi; \alpha, \beta; d)$*) is continuous with respect to* (α, β) *in the* $X^2_{\tau_+(\beta),1}(\mathbf{R}_+)$ *(respectively,* $X^2_{\tau_-(\beta; d),1}(\mathbf{R}_-)$*)-topology and satisfies*

$$\frac{d}{d\xi} W_0^+(0; \alpha, \beta) = \sqrt{2 \int_{\alpha}^{h_+(\beta)} f(u, \beta)\, du}$$

$$\left(\textit{resp.}, \frac{d}{d\xi} W_0^-(0; \alpha, \beta; d) = \sqrt{2d \int_{\alpha}^{h_-(\beta)} f(u, \beta)\, du} \right).$$

2.3. Singular limit solutions. In the previous sections, we constructed the lowest-order approximations $(U_0^+(y;\beta) + W_0^+(y/\sigma; \alpha, \beta), V_0^+(y; \beta))$ and $(U_0^-(y; \beta; d) + W_0^-(y/\sigma; \alpha, \beta; d), V_0^-(y; \beta; d))$ to the problems $(2.2)_{\pm}$, respectively. In order to construct an approximate solution to (2.1), which belongs to $\mathscr{D} \times \mathscr{D}$, we choose α and β such that $(U_0^+(y; \beta) + W_0^+(y/\sigma; \alpha, \beta), V_0^+(y; \beta))$ and $(U_0^-(y; \beta; d) + W_0^-(y/\sigma; \alpha, \beta; d), V_0^-(y; \beta; d))$ are matched to give C^1-continuity at $y = 0$. That is, we determine α and β as functions of d such that

$$\begin{aligned} &\Phi_0(\alpha, \beta; d) \equiv \frac{d}{d\xi} W_0^+(0; \alpha, \beta) - \frac{d}{d\xi} W_0^-(0; \alpha, \beta; d) = 0, \\ &\Psi_0(\beta; d) \equiv \frac{d}{dy} V_0^+(0; \beta) - \frac{d}{dy} V_0^-(0; \beta; d) = 0. \end{aligned} \tag{2.6}$$

We call the relations $\Phi_0(\alpha, \beta; d) = 0$ and $\Psi_0(\beta; d) = 0$ the *inner* and *outer matching conditions*, respectively. By Lemma 2.1, we find that

$$\Psi_0(\beta; d) = \sqrt{2 \int_{\beta}^{v_+} g(h_+(v), v)\, dv} - \sqrt{2d \int_{\beta}^{v_-} g(h_-(v), v)\, dv}.$$

Then we directly obtain the following result.

LEMMA 2.3. $\Psi_0(\beta; d) = 0$ *has a unique root* $\beta = \beta_0(d)$ *for all* $d > 0$, *which is strictly monotone decreasing and satisfies*

$$\lim_{d \downarrow 0} \beta_0(d) = v_+ \quad \textit{and} \quad \lim_{d \uparrow \infty} \beta_0(d) = v_-.$$

On the other hand, by Lemma 2.2, $\Phi_0(\alpha, \beta; d) = 0$ is rewritten as

$$d \int_{\alpha}^{h_-(\beta)} f(u, \beta)\, du - \int_{\alpha}^{h_+(\beta)} f(u, \beta)\, du = 0,$$

that is,

$$d = d_0(\alpha, \beta) = \frac{\displaystyle\int_{\alpha}^{h_+(\beta)} f(u, \beta)\, du}{\displaystyle\int_{\alpha}^{h_-(\beta)} f(u, \beta)\, du}. \tag{2.7}$$

LEMMA 2.4. *$d_0(\alpha, \beta)$ is a function defined in each Σ_i $(i=1,2,3)$ and satisfies $(\partial/\partial\beta)d_0(\alpha,\beta)<0$. Moreover:*

(i) *For any fixed β satisfying $v^*<\beta<v_+$, $d_0(\alpha,\beta)$ is less than 1 and monotone increasing in $(\omega_0(\beta), h_0(\beta))$ and monotone decreasing in $(h_0(\beta), h_+(\beta))$ and satisfies $\lim_{\alpha\downarrow\omega_0(\beta)} d_0(\alpha,\beta)=0=\lim_{\alpha\uparrow h_+(\beta)} d_0(\alpha,\beta)$ and $\lim_{\alpha\uparrow h_+(\beta)}(\partial/\partial\alpha)d_0(\alpha,\beta)=0=(\partial/\partial\alpha)d_0(h_0(\beta),\beta)$;*

(ii) *For any fixed β satisfying $v_-<\beta<v^*$, $d_0(\alpha,\beta)$ is greater than 1 and monotone decreasing in $(h_-(\beta), h_0(\beta))$ and monotone increasing in $(h_0(\beta), \omega_1(\beta))$ and satisfies $\lim_{\alpha\downarrow h_-(\beta)} d_0(\alpha,\beta)=+\infty=\lim_{\alpha\uparrow\omega_1(\beta)} d_0(\alpha,\beta)$, and $(\partial/\partial\alpha)d_0(h_0(\beta),\beta)=0$;*

(iii) *For $\beta=v^*$, $d_0(\alpha,\beta)=1$ in $(h_-(\beta), h_+(\beta))$.*

Consequently, by Lemma 2.3, it is sufficient to determine $\alpha=\alpha(d)$ such that

$$\Phi_0(\alpha, \beta_0(d); d)=0 \tag{2.8}$$

holds, which is obtained by Lemma 2.4. Combining the above results, we obtain Lemma 2.5.

LEMMA 2.5. (i) *When $v_-<v^*<v_+$, the following three cases occur:*

(a) *If $\beta_0(1)>v^*$, there are two points d_1 and d_2 $(d_1<1<d_2)$ such that (2.8) has two roots $\alpha=\bar\alpha_1(d)$ and $\alpha=\underline\alpha_1(d)$ with $\bar\alpha_1(d)>\underline\alpha_1(d)$ and $\bar\alpha_1(d_1)=\underline\alpha_1(d_1)$ defined for $d\in(0,d_1]$ and has two roots $\alpha=\bar\alpha_2(d)$ and $\alpha=\underline\alpha_2(d)$ with $\bar\alpha_2(d)>\underline\alpha_2(d)$ defined for $d\in[d_2,\infty)$;*

(b) *If $\beta_0(1)<v^*$, there are two points d_1 and d_2 $(d_1<1<d_2)$ such that (2.8) has two roots $\alpha=\bar\alpha_1(d)$ and $\alpha=\underline\alpha_1(d)$ with $\bar\alpha_1(d)>\underline\alpha_1(d)$ defined for $d\in(0,d_1]$ and has two roots $\alpha=\bar\alpha_2(d)$ and $\alpha=\underline\alpha_2(d)$ with $\bar\alpha_2(d)>\underline\alpha_2(d)$ and $\bar\alpha_2(d_2)=\underline\alpha_2(d_2)$ defined for $d\in[d_2,\infty)$;*

(c) *If $\beta_0(1)=v^*$, (2.8) has two roots $\alpha=\bar\alpha_1(d)$ and $\alpha=\underline\alpha_1(d)$ with $\bar\alpha_1(d)>\underline\alpha_1(d)$ defined for $d\in(0,1]$ and has two roots $\alpha=\bar\alpha_2(d)$ and $\alpha=\underline\alpha_2(d)$ with $\bar\alpha_2(d)>\underline\alpha_2(d)$ defined for $d\in[1,\infty)$. Especially when $d=1$, $\bar\alpha_1(1)=\bar\alpha_2(1)$, $\underline\alpha_1(1)=\underline\alpha_2(1)$, and (2.8) also holds for any $\alpha\in(\bar\alpha_1(1), \underline\alpha_1(1))$.*

(ii) *When $v^*\leqq v_-$, there is $d_1(<1)$ such that (2.8) has two roots $\alpha=\bar\alpha_1(d)$ and $\alpha=\underline\alpha_1(d)$ with $\bar\alpha_1(d)>\underline\alpha_1(d)$ and $\bar\alpha_1(d_1)=\underline\alpha_1(d_1)$ defined for $d\in(0,d_1]$.*

(iii) *When $v_+\leqq v^*$, there is d_2 (>1) such that (2.8) has two roots $\alpha=\bar\alpha_2(d)$ and $\alpha=\underline\alpha_2(d)$ with $\bar\alpha_2(d)>\underline\alpha_2(d)$ and $\bar\alpha_2(d_2)=\underline\alpha_2(d_2)$ defined for $d\in[d_2,\infty)$.*

For any $(\alpha^*(d), \beta^*(d))$ satisfying the inner and outer matching conditions (2.6), we define

$$U_0(y;\sigma;d)\equiv\begin{cases} U_0^+(y;\beta^*(d))+W_0^+\left(\dfrac{y}{\sigma};\alpha^*(d),\beta^*(d)\right), & y\in\mathbf{R}_+,\\ U_0^-(y;\beta^*(d);d)+W_0^-\left(\dfrac{y}{\sigma};\alpha^*(d),\beta^*(d);d\right), & y\in\mathbf{R}_-\end{cases}$$

and

$$V_0(y;\sigma;d)\equiv\begin{cases} V_0^+(y;\beta^*(d)), & y\in\mathbf{R}_+,\\ V_0^-(y;\beta^*(d);d), & y\in\mathbf{R}_-,\end{cases}$$

which becomes the lowest-order approximate solution uniformly on $\mathbf{R}$. We call $(U_0, V_0)(y;\sigma;d)$ a *singular limit solution of* (2.1). By Lemma 2.5, we obtain Theorem 2.1.

THEOREM 2.1. *Suppose that* (A1)-(A4) *hold and d_1 and d_2 are the same constants as in Lemma* 2.5.

(i) *When* $v_- < v^* < v_+$, *the following three cases occur*:

(a) *If* $\beta_0(1) > v^*$, (2.1) *has two singular limit solutions*

$$(\bar{U}_{0,*}, \bar{V}_{0,*})(y;\sigma;d), \quad (\underline{U}_{0,*}, \underline{V}_{0,*})(y;\sigma;d) \quad \textit{for } d \in (0, d_1],$$
$$(\bar{U}_0^*, \bar{V}_0^*)(y;\sigma;d), \quad (\underline{U}_0^*, \underline{V}_0^*)(y;\sigma;d) \quad \textit{for } d \in [d_2, \infty);$$

(b) *If* $\beta_0(1) < v^*$, (2.1) *has two singular limit solutions*

$$(\bar{U}_{0,*}, \bar{V}_{0,*})(y;\sigma;d), \quad (\underline{U}_{0,*}, \underline{V}_{0,*})(y;\sigma;d) \quad \textit{for } d \in (0, d_1],$$
$$(\bar{U}_0^*, \bar{V}_0^*)(y;\sigma;d), \quad (\underline{U}_0^*, \underline{V}_0^*)(y;\sigma;d) \quad \textit{for } d \in [d_2, \infty);$$

(c) *If* $\beta_0(1) = v^*$, (2.1) *has two singular limit solutions*

$$(\bar{U}_{0,*}, \bar{V}_{0,*})(y;\sigma;d), \quad (\underline{U}_{0,*}, \underline{V}_{0,*})(y;\sigma;d) \quad \textit{for } d \in (0, 1],$$
$$(\bar{U}_0^*, \bar{V}_0^*)(y;\sigma;d), \quad (\underline{U}_0^*, \underline{V}_0^*)(y;\sigma;d) \quad \textit{for } d \in [1, \infty);$$

(ii) *When* $v^* \leqq v_-$, (2.1) *has two singular limit solutions* $(\bar{U}_{0,*}, \bar{V}_{0,*})(y;\sigma;d)$ *and* $(\underline{U}_{0,*}, \underline{V}_{0,*})(y;\sigma;d)$ *for* $d \in (0, d_1]$.

(iii) *When* $v_+ \leqq v^*$, (2.1) *has two singular limit solutions* $(\bar{U}_0^*, \bar{V}_0^*)(y;\sigma;d)$ *and* $(\underline{U}_0^*, \underline{V}_0^*)(y;\sigma;d)$ *for* $d \in [d_2, \infty)$.

2.4. Existence theorem. We construct solutions of (2.1) for small σ, which tend to the above singular limit solutions as $\sigma \downarrow 0$ in a suitable topology. We assume that $(\alpha^*(d), \beta^*(d))$ satisfies the inner and outer matching conditions

$$\Phi_0(\alpha^*(d), \beta^*(d); d) = 0 = \Psi_0(\beta^*(d); d) \tag{2.9}$$

and moreover

$$\frac{\partial}{\partial \alpha} \Phi_0(\alpha^*(d), \beta^*(d); d) \neq 0. \tag{2.10}$$

In order to prove the existence of solutions of (2.1) for small but not zero σ, we need to assume (2.10). For any fixed $(\alpha, \beta) \in \Lambda_\nu \equiv \{(\alpha, \beta) \,|\, |\alpha - \alpha^*(d)| + |\beta - \beta^*(d)| \leqq \nu\}$, we first look for solutions of the problems $(2.2)_\pm$, which take the forms

$$\begin{aligned} u^+(y;\sigma;\alpha,\beta) &= U_0^+(y;\beta) + W_0^+\left(\frac{y}{\sigma};\alpha,\beta\right) + r^+(y;\sigma;\alpha,\beta) \\ &\quad + h_+(V_0^+(y;\beta))s^+(y;\sigma;\alpha,\beta), \\ v^+(y;\sigma;\alpha,\beta) &= V_0^+(y;\beta) + \sigma^2 Y^+\left(\frac{y}{\sigma};\alpha,\beta\right) + s^+(y;\sigma;\alpha,\beta), \end{aligned} \tag{2.11}_+$$

and

$$\begin{aligned} u^-(y;\sigma;\alpha,\beta;d) &= U_0^-(y;\beta;d) + W_0^-\left(\frac{y}{\sigma};\alpha,\beta;d\right) + r^-(y;\sigma;\alpha,\beta;d) \\ &\quad + h_-(V_0^-(y;\beta;d))s^-(y;\sigma;\alpha,\beta;d), \\ v^-(y;\sigma;\alpha,\beta;d) &= V_0^-(y;\beta;d) + \sigma^2 Y^-\left(\frac{y}{\sigma};\alpha,\beta;d\right) + s^-(y;\sigma;\alpha,\beta;d), \end{aligned} \tag{2.11}_-$$

where

$$Y^+\left(\frac{y}{\sigma};\alpha,\beta\right) = Y_0^+\left(\frac{y}{\sigma};\alpha,\beta\right) - e^{-\mu y} Y_0^+(0;\alpha,\beta)$$

with

$$Y_0^+(\xi;\alpha,\beta)=-\int_{\xi}^{+\infty}\int_{\eta}^{+\infty}\{g(h_+(\beta)+W_0^+(\zeta;\alpha,\beta),\beta)-g(h_+(\beta),\beta)\}\,d\zeta\,d\eta$$

and

$$Y^-\left(\frac{y}{\sigma};\alpha,\beta;d\right)=Y_0^-\left(\frac{y}{\sigma};\alpha,\beta;d\right)-e^{\mu y}Y_0^-(0;\alpha,\beta;d)$$

with

$$Y_0^-(\xi;\alpha,\beta;d)=-d\int_{-\infty}^{\xi}\int_{-\infty}^{\eta}\{g(h_-(\beta)+W_0^-(\zeta;\alpha,\beta;d),\beta)-g(h_-(\beta),\beta)\}\,d\zeta\,d\eta$$

and μ is an arbitrarily fixed number satisfying $\mu>\max(\mu_+,\mu_-(d))$. Let us define a function space $\mathring{X}_\sigma(\mathbf{R}_\pm)$ by

$$\mathring{X}_\sigma(\mathbf{R}_\pm)\equiv\mathring{X}^2_{\rho,\sigma}(\mathbf{R}_\pm)\times\mathring{X}^2_{\rho,1}(\mathbf{R}_\pm)$$

for any fixed constant ρ $(0<\rho<\min(\mu_+,\mu_-(d)))$. Then we obtain the following result for the remainders $t^\pm=(r^\pm,s^\pm)$.

LEMMA 2.6. *There are $\sigma_1>0$ and $\nu_1>0$ such that for any $\sigma\in(0,\sigma_1)$ and $(\alpha,\beta)\in\Lambda_{\nu_1}$, there exist $t^\pm(\sigma;\alpha,\beta)\in\mathring{X}_\sigma(\mathbf{R}_\pm)$ for which $(2.11)_\pm$ satisfy $(2.2)_\pm$. Moreover, $t^\pm(\sigma;\alpha,\beta)$, $(\partial t^\pm/\partial\alpha)(\sigma;\alpha,\beta)$ and $(\partial t^\pm/\partial\beta)(\sigma;\alpha,\beta)$ are uniformly continuous with respect to $(\sigma,\alpha,\beta)\in(0,\sigma_1)\times\Lambda_{\nu_1}$ in the $\mathring{X}_\sigma(\mathbf{R}_\pm)$-topology and satisfy*

$$\|t^\pm(\sigma;\alpha,\beta)\|_{\mathring{X}_\sigma(\mathbf{R}_\pm)}=o(1),$$

$$\left\|\frac{\partial t^\pm}{\partial\alpha}(\sigma;\alpha,\beta)\right\|_{\mathring{X}_\sigma(\mathbf{R}_\pm)}=o(1),$$

$$\left\|\frac{\partial t^\pm}{\partial\beta}(\sigma;\alpha,\beta)\right\|_{\mathring{X}_\sigma(\mathbf{R}_\pm)}=o(1)$$

as $\sigma\downarrow 0$ uniformly in $(\alpha,\beta)\in\Lambda_{\nu_1}$.

Finally, we construct a solution of (2.1) on the whole interval $\mathbf{R}$ by matching $(u^+,v^+)(y;\sigma;\alpha,\beta)$ and $(u^-,v^-)(y;\sigma;\alpha,\beta;d)$ at $y=0$ in the C^1-sense. For this purpose, we define

$$\begin{aligned}\Phi(\sigma;\alpha,\beta;d)&\equiv\sigma\frac{d}{dy}u^+(0;\sigma;\alpha,\beta)-\sigma\frac{d}{dy}u^-(0;\sigma;\alpha,\beta;d),\\ \Psi(\sigma;\alpha,\beta;d)&\equiv\frac{d}{dy}v^+(0;\sigma;\alpha,\beta)-\frac{d}{dy}v^-(0;\sigma;\alpha,\beta;d),\end{aligned}\tag{2.12}$$

and determine α and β as functions of σ and d such that the relations

$$\Phi(\sigma;\alpha,\beta;d)=0=\Psi(\sigma;\alpha,\beta;d)\tag{2.13}$$

hold. We call (2.13) the *matching condition*. We extend Φ and Ψ continuously so as to be defined for $\sigma=0$. Putting $\sigma=0$ in (2.12), we obtain by Lemma 2.6 that

$$\Phi(0;\alpha,\beta;d)=\Phi_0(\alpha,\beta;d),$$

$$\Psi(0;\alpha,\beta;d)=\Psi_0(\beta;d).$$

Here we define $\mathbf{I}(d)$ by using the *Jacobian of the matching condition* (2.13) at $\sigma=0$ as follows:

$$\mathbf{I}(d)=\operatorname{sign}\{\mathbf{J}(d)\} \tag{2.14}$$

with

$$\mathbf{J}(d)\equiv \det\begin{bmatrix} \dfrac{\partial}{\partial\alpha}\Phi_0(\alpha^*(d),\beta^*(d);d) & \dfrac{\partial}{\partial\beta}\Phi_0(\alpha^*(d),\beta^*(d);d) \\ \dfrac{\partial}{\partial\alpha}\Psi_0(\beta^*(d);d) & \dfrac{\partial}{\partial\beta}\Psi_0(\beta^*(d);d) \end{bmatrix},$$

where

$$\operatorname{sign}\{x\}=\begin{cases} +1 & \text{for } x>0, \\ 0 & \text{for } x=0, \\ -1 & \text{for } x<0. \end{cases}$$

Since $\alpha^*(d)$ and $\beta^*(d)$ satisfy (2.9) and (2.10), we find by Lemmas 2.1 and 2.2 that

$$\frac{\partial}{\partial\beta}\Psi_0(\beta^*(d);d)=\frac{dg(h_-(\beta^*(d)),\beta^*(d))-g(h_+(\beta^*(d)),\beta^*(d))}{\sqrt{2\int_{\beta^*(d)}^{v_+} g(h_+(s),s)\,ds}}<0$$

and

$$\frac{\partial}{\partial\alpha}\Phi_0(\alpha^*(d),\beta^*(d);d)=\frac{(d-1)f(\alpha^*(d),\beta^*(d))}{\sqrt{2\int_{\alpha^*(d)}^{h_+(\beta^*(d))} f(u,\beta^*(d))\,du}}. \tag{2.15}$$

We note that $\mathbf{I}(d)$ is essentially determined by the inner matching condition. Since $\mathbf{I}(d)\neq 0$ follows from assumption (2.10), the implicit function theorem can be applied to (2.13). That is, there is $\sigma_2>0$ such that there uniquely exist continuous functions $\alpha(\sigma;d)$ and $\beta(\sigma;d)$ satisfying (2.13) for $\sigma\in[0,\sigma_2)$ and $\lim_{\sigma\downarrow 0}\alpha(\sigma;d)=\alpha^*(d)$ and $\lim_{\sigma\downarrow 0}\beta(\sigma;d)=\beta^*(d)$. Thus, we obtain the desired theorem.

THEOREM 2.2. *Suppose that* (A1)-(A4) *hold and d is fixed arbitrarily such that* $(\alpha^*(d),\beta^*(d))$ *satisfies* (2.9) *and* (2.10), *that is,* $\mathbf{I}(d)\neq 0$. *Then for any* $\sigma\in(0,\sigma_2)$ *there exists a solution* $(u,v)(y;\sigma;d)$ *of* (2.1) *corresponding to the singular limit solution* (U_0,V_0) *such that*

$$\|u(y;\sigma;d)-U_0(y;\sigma;d)\|_{X^1_{\rho,\sigma}(\mathbf{R})}+\|v(y;\sigma;d)-V_0(y;\sigma;d)\|_{X^1_{\rho,1}(\mathbf{R})}\to 0$$

holds as $\sigma\downarrow 0$.

COROLLARY 2.1. *Suppose that* (A1)-(A4) *hold and* d_1 *and* d_2 *are the same constants as in Lemma* 2.5.

(i) *When* $v_-<v^*<v_+$, *the following three cases occur*:

(a) If $\beta_0(1)>v^*$, (2.1) *has two solutions*

$(\bar U_*,\bar V_*)(y;\sigma;d)(\mathbf{I}(d)=1)$, $(\underline U_*,\underline V_*)(y;\sigma;d)(\mathbf{I}(d)=-1)$ *for* $d\in(0,d_1)$,

$(\bar U^*,\bar V^*)(y;\sigma;d)(\mathbf{I}(d)=-1)$, $(\underline U^*,\underline V^*)(y;\sigma;d)(\mathbf{I}(d)=1)$ *for* $d\in[d_2,\infty)$;

(b) *If* $\beta_0(1)<v^*$, (2.1) *has two solutions*

$(\bar U_*,\bar V_*)(y;\sigma;d)(\mathbf{I}(d)=1)$, $(\underline U_*,\underline V_*)(y;\sigma;d)(\mathbf{I}(d)=-1)$ *for* $d\in(0,d_1]$,

$(\bar U^*,\bar V^*)(y;\sigma;d)(\mathbf{I}(d)=-1)$, $(\underline U^*,\underline V^*)(y;\sigma;d)(\mathbf{I}(d)=1)$ *for* $d\in(d_2,\infty)$;

(c) *If* $\beta_0(1)=v^*$, (2.1) *has two solutions*

$(\bar U_*,\bar V_*)(y;\sigma;d)(\mathbf{I}(d)=1)$, $(\underline U_*,\underline V_*)(y;\sigma;d)(\mathbf{I}(d)=-1)$ *for* $d\in(0,1)$,

$(\bar U^*,\bar V^*)(y;\sigma;d)(\mathbf{I}(d)=-1)$, $(\underline U^*,\underline V^*)(y;\sigma;d)(\mathbf{I}(d)=1)$ *for* $d\in(1,\infty)$;

(ii) *When* $v^* \leqq v_-$, (2.1) *has two solutions* $(\bar{U}_*, \bar{V}_*)(y; \sigma; d)(\mathbf{I}(d) = 1)$ *and* $(\underline{U}_*, \underline{V}_*)(y; \sigma; d)(\mathbf{I}(d) = -1)$ *for* $d \in (0, d_1)$.

(iii) *When* $v_+ \leqq v^*$, (2.1) *has two solutions* $(\bar{U}^*, \bar{V}^*)(y; \sigma; d)(\mathbf{I}(d) = -1)$ *and* $(\underline{U}^*, \underline{V}^*)(y; \sigma; d)(\mathbf{I}(d) = 1)$ *for* $d \in (d_2, \infty)$ (*see Fig.* 8).

Remark 2.1. If f and g are given by (1.6), the cases where $\gamma > \gamma_2$, $\gamma \in (\gamma_1, \gamma_2)$, and $\gamma \in (\gamma_0, \gamma_1)$ correspond to (iii) $(v_+ \leqq v^*)$, (i)(b) $(v_- < v^* < v_+, \beta_0(1) < v^*)$, and (i)(a) $(v_- < v^* < V_+, \beta_0(1) > v^*)$, respectively.

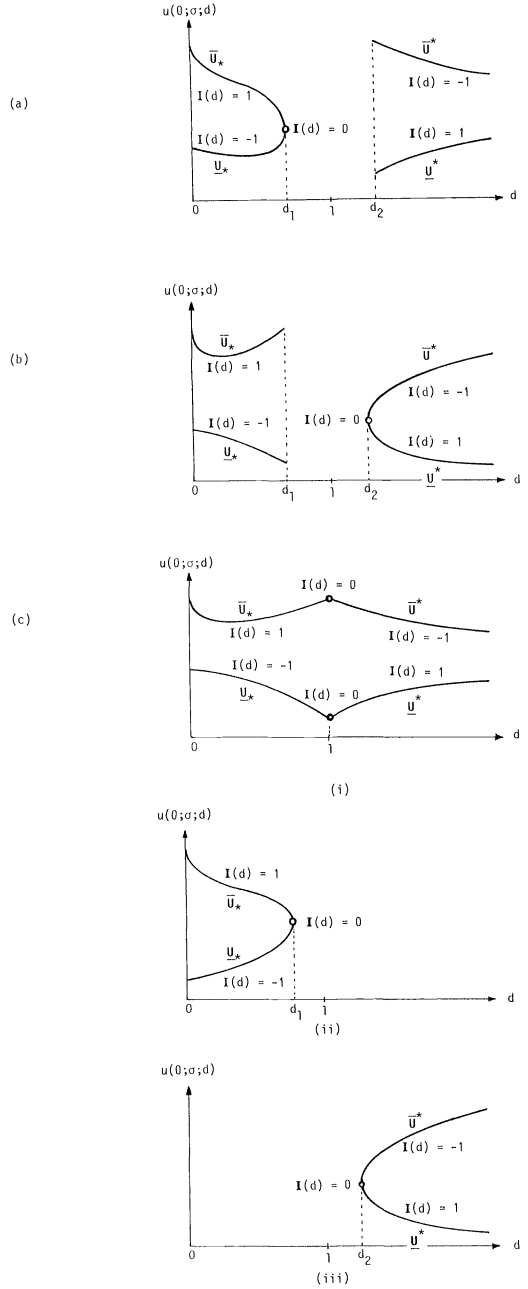

FIG. 8. *Global pictures of stationary solutions of* (1.1) *and these* $\mathbf{I}(d)$: (i) $v_- < v^* < v_+$: (a) $\beta_0(1) > v^*$, (b) $\beta_0(1) < v^*$, (c) $\beta_0(1) = v^*$; (ii) $v^* \leqq v_-$; (iii) $v_+ \leqq v^*$.

3. Stability of stationary solutions. Our aim in this section is to show that under (A1)-(A4), $\mathbf{I}(d)$ corresponds in a one-to-one manner to the stability of stationary solutions of (1.7) constructed in § 2, that is, the stationary solution is *stable* (respectively, *unstable*) if and only if $\mathbf{I}(d)$ is $+1$ (respectively, -1). We remark that this result is closely related to the index argument on stability properties of nerve equations [Ev1], [Ev2], [AGJ], [GJ], [I].

3.1. Preliminaries for stability analysis. Let $(U, V)(x; \sigma; d)$ be a stationary solution of (1.7). We will determine its stability by the linearized stability criterion. The linearized eigenvalue problem of (1.7) at $(U, V)(x; \sigma; d)$ is given by

$$\mathscr{L}^{\sigma,d}\begin{bmatrix}\varphi\\ \psi\end{bmatrix} = \lambda\begin{bmatrix}\varphi\\ \psi\end{bmatrix}, \qquad x \in \mathbf{R}\backslash\{0\}, \tag{3.1}$$

where

$$\mathscr{L}^{\sigma,d} \equiv \begin{bmatrix} \delta_0(x)\dfrac{d^2}{dx^2} + \dfrac{1}{\sigma} f_u^{\sigma,d} & \dfrac{1}{\sigma} f_v^{\sigma,d} \\ \sigma g_u^{\sigma,d} & \delta_0(x)\dfrac{d^2}{dx^2} + \sigma g_v^{\sigma,d} \end{bmatrix}.$$

Here $f_u^{\sigma,d}$, $f_v^{\sigma,d}$, $g_u^{\sigma,d}$, and $g_v^{\sigma,d}$ denote the partial derivatives of f and g evaluated at $(U, V)(x; \sigma; d)$. The underlying space for (3.1) is taken as $BC(\mathbf{R}) \times BC(\mathbf{R})$ with

$$\mathscr{D}(\mathscr{L}^{\sigma,d}) = \mathscr{D} \times \mathscr{D}.$$

Since $\mathscr{L}^{\sigma,d}$ is a sectorial operator, its spectral analysis assures the nonlinear stability or instability of the stationary solution (for instance, see [H]). Therefore it suffices to consider the following two problems:

(i) Distribution of the *essential spectrum*;

(ii) Distribution of *isolated eigenvalues.*

Noting that $(u_\pm, v_\pm)$ are both stable constant solutions, we first show the following proposition.

PROPOSITION 3.1. *Assume* (A1)-(A4). *Then there exists a positive constant* l_1 *independently of* d *and* σ *such that*

$$\mathrm{Re}\,\{\textit{essential spectrum of } (3.1)\} \leqq -\sigma l_1$$

holds for any $d > 0$ *and small* $\sigma > 0$.

The proof is given in the Appendix.

Since the essential spectrum of (3.1) is strictly bounded away from the imaginary axis, the stability property of the stationary solution is studied by the distribution of the isolated eigenvalues. The complex number λ is called an eigenvalue of (3.1) if and only if (3.1) has a nontrivial solution $(\varphi, \psi)(x; \sigma; d; \lambda)$ belonging to $BC(\mathbf{R}) \times BC(\mathbf{R})$. Therefore the eigenfunction $(\varphi, \psi)(x; \sigma; d; \lambda)$ must belong to $\mathscr{D}(\mathscr{L}^{\sigma,d})$. By the definition of $\mathscr{D}$, the eigenvalue problem (3.1) can be rewritten equivalently as

$$\begin{aligned} &\delta_0(x)\varphi_{xx}^{\pm} + \frac{1}{\sigma} f_u^{\sigma,d}\varphi^{\pm} + \frac{1}{\sigma} f_v^{\sigma,d}\psi^{\pm} = \lambda\varphi^{\pm}, \qquad x \in \mathbf{R}_\pm \\ &\delta_0(x)\psi_{xx}^{\pm} + \sigma g_u^{\sigma,d}\varphi^{\pm} + \sigma g_v^{\sigma,d}\psi^{\pm} = \lambda\psi^{\pm}, \end{aligned} \tag{3.2}_\pm$$

with compatibility conditions

$$\begin{aligned} &\varphi^+(0; \sigma; d; \lambda) = \varphi^-(0; \sigma; d; \lambda), \qquad \psi^+(0; \sigma; d; \lambda) = \psi^-(0; \sigma; d; \lambda), \\ &\varphi_x^+(0; \sigma; d; \lambda) = \varphi_x^-(0; \sigma; d; \lambda), \qquad \psi_x^+(0; \sigma; d; \lambda) = \psi_x^-(0; \sigma; d; \lambda), \end{aligned} \tag{3.3}$$

where $\varphi^+(x;\sigma;d;\lambda)$, $\psi^+(x;\sigma;d;\lambda)\in BC^2([0,\infty))$, and $\varphi^-(x;\sigma;d;\lambda)$, $\psi^-(x;\sigma;d;\lambda)\in BC^2((-\infty,0])$. Then, the eigenfunctions φ and ψ of (3.1) are, respectively, represented as

$$\varphi(x;\sigma;d;\lambda)=\begin{cases}\varphi^+(x;\sigma;d;\lambda), & x\geqq 0,\\ \varphi^-(x;\sigma;d;\lambda), & x\leqq 0,\end{cases}$$

and

$$\psi(x;\sigma;d;\lambda)=\begin{cases}\psi^+(x;\sigma;d;\lambda), & x\geqq 0,\\ \psi^-(x;\sigma;d;\lambda), & x\leqq 0.\end{cases}$$

Let us rewrite the problems $(3.2)_\pm$, (3.3) as the four-dimensional systems

$$(3.4)_\pm\qquad \begin{aligned}&\frac{dv_1^\pm}{dx}=v_2^\pm,\\ &\frac{dv_2^\pm}{dx}=\left(\lambda-\frac{1}{\sigma}f_u^{\sigma,d}\right)v_1^\pm/\delta_0(x)-\frac{1}{\sigma}f_v^{\sigma,d}v_3^\pm/\delta_0(x),\\ &\frac{dv_3^\pm}{dx}=v_4^\pm,\\ &\frac{dv_4^\pm}{dx}=-\sigma g_u^{\sigma,d}v_1^\pm/\delta_0(x)+(\lambda-\sigma g_v^{\sigma,d})v_3^\pm/\delta_0(x),\end{aligned}\qquad x\in\mathbf{R}_\pm,$$

$$(3.5)\qquad \begin{aligned}&v_1^+(0;\sigma;d;\lambda)=v_1^-(0;\sigma;d;\lambda),\qquad v_3^+(0;\sigma;d;\lambda)=v_3^-(0;\sigma;d;\lambda),\\ &v_2^+(0;\sigma;d;\lambda)=v_2^-(0;\sigma;d;\lambda),\qquad v_4^+(0;\sigma;d;\lambda)=v_4^-(0;\sigma;d;\lambda),\end{aligned}$$

where $v_1^\pm=\varphi^\pm$, $v_2^\pm=\varphi_x^\pm$, $v_3^\pm=\psi^\pm$, and $v_4^\pm=\psi_x^\pm$. Using $\mathbf{V}^\pm=(v_1^\pm,v_2^\pm,v_3^\pm,v_4^\pm)^t$, we simply write $(3.4)_\pm$ as

$$(3.6)_\pm\qquad \frac{d}{dx}\mathbf{V}^\pm=A(x;\sigma;d;\lambda)\mathbf{V}^\pm,\qquad x\in\mathbf{R}_\pm.$$

Since the stationary solution $(U,V)(x;\sigma;d)$ approaches the equilibrium states $(u_\pm,v_\pm)$ with exponential order as $x\to\pm\infty$, the asymptotic behaviour of eigenfunctions for large $|x|$ can be studied by using the limiting systems of $(3.6)_\pm$ with constant coefficients

$$(3.7)_\pm\qquad \frac{d}{dx}\mathbf{V}^\pm=A(\pm\infty;\sigma;d;\lambda)\mathbf{V}^\pm,\qquad x\in\mathbf{R}_\pm,$$

where

$$A(\pm\infty;\sigma;d;\lambda)=\begin{bmatrix}0 & 1 & 0 & 0\\ (\lambda-(1/\sigma)f_u(u_\pm,v_\pm))/\delta_0(\pm\infty) & 0 & -(1/\sigma)f_v(u_\pm,v_\pm)/\delta_0(\pm\infty) & 0\\ 0 & 0 & 0 & 1\\ -\sigma g_u(u_\pm,v_\pm)/\delta_0(\pm\infty) & 0 & (\lambda-\sigma g_v(u_\pm,v_\pm))/\delta_0(\pm\infty) & 0\end{bmatrix}$$

with $\delta_0(+\infty)=1$ and $\delta_0(-\infty)=1/d$. Let $\mu_i^\pm(\sigma;d;\lambda)$ $(i=1,2,3,4)$ satisfying $\mathrm{Re}\,\{\mu_1^\pm\}\leqq\mathrm{Re}\,\{\mu_2^\pm\}\leqq\mathrm{Re}\,\{\mu_3^\pm\}\leqq\mathrm{Re}\,\{\mu_4^\pm\}$ denote the eigenvalues of $A(\pm\infty;\sigma;d;\lambda)$.

LEMMA 3.1. *There exists a positive constant l_2 independently of σ and d such that*

$$\begin{aligned}\mathrm{Re}\,\{\mu_1^{\pm}(\sigma; d; \lambda)\} \leqq \mathrm{Re}\,\{\mu_2^{\pm}(\sigma; d; \lambda)\} &< 0 \\ &< \mathrm{Re}\,\{\mu_3^{\pm}(\sigma; d; \lambda)\} \leqq \mathrm{Re}\,\{\mu_4^{\pm}(\sigma; d; \lambda)\}\end{aligned}$$

hold for all $\lambda \in \mathbf{C}_{l_2} \equiv \{\lambda \in \mathbf{C} \,|\, \mathrm{Re}\,\{\lambda\} \geqq -l_2\}$.

This lemma can be proved in a way similarly to Lemma 4.1 in [I], so we omit the proof.

By virtue of Lemma 3.1 and $(3.7)_{\pm}$, $(3.6)_{+}$ has just two linearly independent solutions $\mathbf{V}_i^{+}(x; \sigma; d; \lambda)$ $(i = 1, 2)$ for any $\lambda \in \mathbf{C}_{l_2}$, which satisfy

$$\mathbf{V}_i^{+}(x; \sigma; d; \lambda) \to \mathbf{0} \quad \text{as } x \to \infty \qquad (i = 1, 2)$$

and $(3.6)_{-}$ has just two linearly independent solutions $\mathbf{V}_i^{-}(x; \sigma; d; \lambda)$ $(i = 1, 2)$ for any $\lambda \in \mathbf{C}_{l_2}$, which satisfy

$$\mathbf{V}_i^{-}(x; \sigma; d; \lambda) \to \mathbf{0} \quad \text{as } x \to -\infty \qquad (i = 1, 2).$$

By a short calculation, we can find that $\mu_i^{\pm}(\sigma; d; \lambda)$ $(i = 1, 2, 3, 4)$ and $\mathbf{V}_i^{\pm}(x; \sigma; d; \lambda)$ $(i = 1, 2)$ depend analytically on $\lambda \in \mathbf{C}_{l_2}$.

A nontrivial solution of $(3.4)_{\pm}$

$$\mathbf{V}(x; \sigma; d; \lambda) \equiv \begin{cases} \mathbf{V}^{+}(x; \sigma; d; \lambda), & x \geqq 0, \\ \mathbf{V}^{-}(x; \sigma; d; \lambda), & x \leqq 0, \end{cases}$$

which corresponds to an eigenvalue $\lambda \in \mathbf{C}_{l_2}$, must satisfy

$$\mathbf{V}^{\pm}(x; \sigma; d; \lambda) \to \mathbf{0} \quad \text{as } x \to \pm\infty.$$

Hence $\mathbf{V}^{\pm}(x; \sigma; d; \lambda)$ can be written as

$$\mathbf{V}^{\pm}(x; \sigma; d; \lambda) = \sum_{i=1}^{2} \alpha_i^{\pm} \mathbf{V}_i^{\pm}(x; \sigma; d; \lambda), \qquad x \in \mathbf{R}_{\pm}$$

for some constants $\alpha_i^{\pm}$ $(i = 1, 2)$. Conditions (3.5) lead to

$$\sum_{i=1}^{2} \alpha_i^{+} \mathbf{V}_i^{+}(0; \sigma; d; \lambda) = \sum_{i=1}^{2} \alpha_i^{-} \mathbf{V}_i^{-}(0; \sigma; d; \lambda).$$

That is, $\lambda = \lambda_0$ is an eigenvalue of (3.1) if and only if the vectors $\mathbf{V}_i^{\pm}(0; \sigma; d; \lambda)$ $(i = 1, 2)$ are not linearly independent when $\lambda = \lambda_0$. Let

$$(3.8) \quad g(\sigma; d; \lambda) \equiv \det[\mathbf{V}_1^{+}(0; \sigma; d; \lambda), \mathbf{V}_2^{+}(0; \sigma; d; \lambda), \mathbf{V}_1^{-}(0; \sigma; d; \lambda), \mathbf{V}_2^{-}(0; \sigma; d; \lambda)].$$

We find that $g(\sigma; d; \lambda)$ is an analytic function of $\lambda \in \mathbf{C}_{l_2}$ and we have the following lemma.

LEMMA 3.2. *For any $\lambda \in \mathbf{C}_{l_2}$, λ is an eigenvalue of* (3.1) *if and only if $g(\sigma; d; \lambda) = 0$ holds.*

3.2. Relation between I(d) and stability of stationary solutions. In order to examine the distribution of eigenvalues, that is, to find solutions λ of $g(\sigma; d; \lambda) = 0$, we construct linearly independent solutions $\mathbf{V}_i^{\pm}(x; \sigma; d; \lambda)$ $(i = 1, 2)$ satisfying

$$(3.9)_{\pm} \qquad \frac{d}{dx}\mathbf{V}_i^{\pm} = A(x; \sigma; d; \lambda)\mathbf{V}_i^{\pm}, \qquad x \in \mathbf{R}_{\pm},$$

$$(3.10)_{\pm} \qquad \mathbf{V}_i^{\pm}(x; \sigma; d; \lambda) \to \mathbf{0} \quad \text{as } x \to \pm\infty.$$

First, we solve the following problems for $(\varphi^{\pm}, \psi^{\pm})$ in $\mathbf{R}_{\pm}$:

$$
(3.11)_{\pm}\qquad
\begin{aligned}
&\delta_0(x)\varphi^{\pm}_{xx}+\frac{1}{\sigma}f^{\sigma,d}_u\varphi^{\pm}+\frac{1}{\sigma}f^{\sigma,d}_v\psi^{\pm}=\lambda\varphi^{\pm}, && x\in\mathbf{R}_{\pm},\\
&\delta_0(x)\psi^{\pm}_{xx}+\sigma g^{\sigma,d}_u\varphi^{\pm}+\sigma g^{\sigma,d}_v\psi^{\pm}=\lambda\psi^{\pm},\\
&\varphi^{\pm}(\pm\infty)=0, \qquad \varphi^{\pm}(0)=a,\\
&\psi^{\pm}(\pm\infty)=0, \qquad \psi^{\pm}(0)=b,
\end{aligned}
$$

where a and b are arbitrarily fixed constants, and denote their solutions by $(\varphi^{\pm}, \psi^{\pm})$-$(x; \sigma; d; \lambda; a, b)$. Letting

$$
(3.12)\qquad
\begin{aligned}
\mathbf{V}^{\pm}_1(x;\sigma;d;\lambda)&=\begin{bmatrix}\varphi^{\pm}(x;\sigma;d;\lambda;1,0)\\ \varphi^{\pm}_x(x;\sigma;d;\lambda;1,0)\\ \psi^{\pm}(x;\sigma;d;\lambda;1,0)\\ \psi^{\pm}_x(x;\sigma;d;\lambda;1,0)\end{bmatrix} && (x\in\mathbf{R}_{\pm}),\\
\mathbf{V}^{\pm}_2(x;\sigma;d;\lambda)&=\begin{bmatrix}\varphi^{\pm}(x;\sigma;d;\lambda;0,1)\\ \varphi^{\pm}_x(x;\sigma;d;\lambda;0,1)\\ \psi^{\pm}(x;\sigma;d;\lambda;0,1)\\ \psi^{\pm}_x(x;\sigma;d;\lambda;0,1)\end{bmatrix} && (x\in\mathbf{R}_{\pm}),
\end{aligned}
$$

we find that $\mathbf{V}^{+}_i(x;\sigma;d;\lambda)$ $(i=1,2)$ are linearly independent solutions of $(3.9)_+$, $(3.10)_+$, and that $\mathbf{V}^{-}_i(x;\sigma;d;\lambda)$ $(i=1,2)$ are linearly independent solutions of $(3.9)_-$, $(3.10)_-$. Making use of $\mathbf{V}^{\pm}_i(x;\sigma;d;\lambda)$ $(i=1,2)$, we are able to seek λ satisfying $g(\sigma;d;\lambda)=0$ and arrive at the following stability theorem.

THEOREM 3.1. *Assume* (A1)-(A4) *and let* $(U_0, V_0)(x;\sigma;d)$ *and* $(U, V)(x;\sigma;d)$ *be an arbitrary singular limit solution and the corresponding stationary solution constructed in* § 2 *and define* $\mathbf{I}(d)$ *by* (2.14). *Then there exists a positive constant* l_3 *such that for any* $\lambda\in\mathbf{C}_{\sigma l_3}$ *the following hold: If* $\mathbf{I}(d)=1$, *the equation* $g(\sigma;d;\lambda)=0$ *has no roots, that is,* $(U, V)(x;\sigma;d)$ *is stable. Conversely, if* $\mathbf{I}(d)=-1$, $g(\sigma;d;\lambda)=0$ *has a unique simple positive root* $\lambda(\sigma;d)$, *that is,* $(U, V)(x;\sigma;d)$ *is unstable* (*see Fig.* 8).

The proof will be given in the next section.

4. Proof of Theorem 3.1. In this section, we shall represent the explicit form of the function $g(\sigma;d;\lambda)$ and then find solutions λ of $g(\sigma;d;\lambda)=0$.

First, setting $y=\sqrt{\sigma}\,x$, $(3.11)_{\pm}$ can be rewritten as

$$
(4.1)_{\pm}\qquad
\begin{aligned}
&\sigma^2\delta_0(y)\Phi^{\pm}_{yy}+\hat{f}^{\sigma,d}_u\Phi^{\pm}+\hat{f}^{\sigma,d}_v\Psi^{\pm}=\sigma^2\mu\Phi^{\pm}, && y\in\mathbf{R}_{\pm},\\
&\delta_0(y)\Psi^{\pm}_{yy}+\hat{g}^{\sigma,d}_u\Phi^{\pm}+\hat{g}^{\sigma,d}_v\Psi^{\pm}=\mu\Psi^{\pm},\\
&\Phi^{\pm}(\pm\infty)=0, \qquad \Phi^{\pm}(0)=1,\\
&\Psi^{\pm}(\pm\infty)=0, \qquad \Psi^{\pm}(0)=b,
\end{aligned}
$$

where $\mu=\lambda/\sigma$, $\hat{f}^{\sigma,d}_u=f_u(U(y/\sqrt{\sigma};\sigma;d), V(y/\sqrt{\sigma};\sigma;d))$, and $\hat{f}^{\sigma,d}_v$, $\hat{g}^{\sigma,d}_u$, and $\hat{g}^{\sigma,d}_v$ are similarly defined. Here we may set $a=1$. For solutions $(\Phi^{\pm}, \Psi^{\pm})(y;\sigma;d;\mu;b)$ and $(\varphi^{\pm}, \psi^{\pm})(x;\sigma;d;\lambda;a,b)$ of $(4.1)_{\pm}$ and $(3.11)_{\pm}$, respectively, we have the following obvious relations:

$$
(4.2)_{\pm}\qquad
\begin{aligned}
(\varphi^{\pm}, \psi^{\pm})(x;\sigma;d;\lambda;1,0)&=(\Phi^{\pm}, \Psi^{\pm})(\sqrt{\sigma}\,x;\sigma;d;\lambda/\sigma;0),\\
(\varphi^{\pm}, \psi^{\pm})(x;\sigma;d;\lambda;0,1)&=(\Phi^{\pm}, \Psi^{\pm})(\sqrt{\sigma}\,x;\sigma;d;\lambda/\sigma;1)\\
&\quad-(\Phi^{\pm}, \Psi^{\pm})(\sqrt{\sigma}x;\sigma;d;\lambda/\sigma;0).
\end{aligned}
$$

By using singular perturbation techniques, we solve $(4.1)_{\pm}$ for any $\mu \in \mathbf{C}_{l_3}$, where l_3 is a positive constant specified later. To do so, the discussion will be divided into four cases according to the dependency of μ on σ:

I. $\mu = \mu(\sigma) = O(1)$ (that is, $\lambda(\sigma) = O(\sigma)$) as $\sigma \downarrow 0$.

For the other three cases, we have $|\mu(\sigma)| \uparrow \infty$ as $\sigma \downarrow 0$, and we know by Lemma 1.1.1 of [Ec] that there exists a real positive and continuous function $\omega(\sigma)$ satisfying $\omega(\sigma) \uparrow \infty$ as $\sigma \downarrow 0$ such that $\mu(\sigma)$ is represented as

$$\mu(\sigma) = \omega(\sigma)\hat{\mu}(\sigma), \tag{4.3}$$

where $\hat{\mu}(\sigma)$ satisfies $|\hat{\mu}(0)| \neq 0$ (that is, under the assumption $\mu \in \mathbf{C}_{l_3}$, it holds that either $\operatorname{Re}\{\hat{\mu}(0)\} > 0$ or if $\operatorname{Re}\{\hat{\mu}(0)\} = 0$, $\operatorname{Im}\{\hat{\mu}(0)\} \neq 0$). Then, with $z = \sqrt{\omega(\sigma)}\, y$, $(4.1)_{\pm}$ are rewritten as

$$\begin{aligned}
&\sigma^2\omega(\sigma)\delta_0(z)\Phi^{\pm}_{zz} + \tilde{f}^{\sigma,d}_u\Phi^{\pm} + \tilde{f}^{\sigma,d}_v\Psi^{\pm} = \sigma^2\omega(\sigma)\hat{\mu}(\sigma)\Phi^{\pm}, \\
&\delta_0(z)\Psi^{\pm}_{zz} + \frac{\tilde{g}^{\sigma,d}_u}{\omega(\sigma)}\Phi^{\pm} + \frac{\tilde{g}^{\sigma,d}_v}{\omega(\sigma)}\Psi^{\pm} = \hat{\mu}(\sigma)\Psi^{\pm}, \qquad z \in \mathbf{R}_{\pm}, \\
&\Phi^{\pm}(\pm\infty) = 0, \qquad \Phi^{\pm}(0) = 1, \\
&\Psi^{\pm}(\pm\infty) = 0, \qquad \Psi^{\pm}(0) = b,
\end{aligned} \tag{4.4}_{\pm}$$

where $\tilde{f}^{\sigma,d}_u = f_u(U(z/\sqrt{\sigma\omega(\sigma)}; \sigma; d), V(z/\sqrt{\sigma\omega(\sigma)}; \sigma; d))$ and $\tilde{f}^{\sigma,d}_v$, $\tilde{g}^{\sigma,d}_u$, and $\tilde{g}^{\sigma,d}_v$ are similarly defined. We discuss $(4.4)_{\pm}$ by dividing the coefficient of $\Phi^{\pm}_{zz}$, say $\sigma^2\omega(\sigma)$, into the following three cases:

II. $\sigma^2\omega(\sigma) \downarrow 0$ and $\omega(\sigma) \uparrow \infty$ (that is, $\sigma\lambda(\sigma) \downarrow 0$ and $\lambda(\sigma)/\sigma \uparrow \infty$) as $\sigma \downarrow 0$;

III. $\sigma^2\omega(\sigma) \to \kappa$ for some positive constant κ (that is, $\sigma\lambda(\sigma)$ is bounded but does not converge to zero) as $\sigma \downarrow 0$;

IV. $\sigma^2\omega(\sigma) \uparrow \infty$ (that is, $\sigma\lambda(\sigma) \uparrow \infty$) as $\sigma \downarrow 0$.

Case I. $\mu(\sigma) = O(1)$ as $\sigma \downarrow 0$. In order to construct approximate solutions to $(4.1)_{\pm}$, we formally put $\sigma = 0$ in $(4.1)_{\pm}$. The resulting equations are

$$\begin{aligned}
&\hat{f}^{0,\pm}_u\Phi^{\pm}_0 + \hat{f}^{0,\pm}_v\Psi^{\pm}_0 = 0, \\
&\delta_0(y)(\Psi^{\pm}_0)_{yy} + \hat{g}^{0,\pm}_u\Phi^{\pm}_0 + \hat{g}^{0,\pm}_v\Psi^{\pm}_0 = \mu(0)\Psi^{\pm}_0, \qquad y \in \mathbf{R}_{\pm}, \\
&\Psi^{\pm}_0(\pm\infty) = 0, \qquad \Psi^{\pm}_0(0) = b,
\end{aligned} \tag{4.5}_{\pm}$$

where $\hat{f}^{0,\pm}_u = f_u(U^{\pm}_0(y; \beta^*(d)), V^{\pm}_0(y; \beta^*(d)))$ with the outer solutions $(U^{\pm}_0, V^{\pm}_0)(y; \beta^*(d))$ obtained in § 2.1. $\hat{f}^{0,\pm}_v$, $\hat{g}^{0,\pm}_u$, and $\hat{g}^{0,\pm}_v$ are similarly defined. By (A3), the first equations in $(4.5)_{\pm}$ are written as

$$\Phi^{\pm}_0 = -\hat{f}^{0,\pm}_v\Psi^{\pm}_0/\hat{f}^{0,\pm}_u.$$

Then $(4.5)_{\pm}$ are reduced to the following equations:

$$\begin{aligned}
&\delta_0(y)(\Psi^{\pm}_0)_{yy} + \{H^{\pm}(y; d) - \mu(0)\}\Psi^{\pm}_0 = 0, \qquad y \in \mathbf{R}_{\pm}, \\
&\Psi^{\pm}_0(\pm\infty) = 0, \qquad \Psi^{\pm}_0(0) = b,
\end{aligned} \tag{4.6}_{\pm}$$

where $H^{\pm}(y; d) = (\hat{f}^{0,\pm}_u\hat{g}^{0,\pm}_v - \hat{f}^{0,\pm}_v\hat{g}^{0,\pm}_u)/\hat{f}^{0,\pm}_u$. The following lemma is very useful for our purposes.

LEMMA 4.1. *Consider the problems for* $\Pi^{\pm}$:

$$\begin{aligned}
&\delta_0(y)\Pi^{\pm}_{yy} + \{H^{\pm}(y; d) - \mu\}\Pi^{\pm} = 0, \qquad y \in \mathbf{R}_{\pm}, \\
&\Pi^{\pm}(\pm\infty) = 0, \qquad \Pi^{\pm}(0) = 1.
\end{aligned} \tag{4.7}_{\pm}$$

Then there exists a positive constant l_3 such that for any $\mu \in \mathbf{C}_{l_3} = \{\mu \in \mathbf{C} \mid \mathrm{Re}\,\{\mu\} \geqq -l_3\}$, the $(4.7)_\pm$ have unique solutions $\Pi^\pm(y; d; \mu)$.

The proof is given in the Appendix.

We thus find that, for any $\mu(0) \in \mathbf{C}_{l_3}$, the $(4.5)_\pm$ have unique solutions

$$\Psi_0^\pm(y; d; \mu(0); b) = b\Pi^\pm(y; d; \mu(0))$$

and

$$\Phi_0^\pm(y; d; \mu(0); b) = -\hat{f}_v^{0,\pm}\Psi_0^\pm(y; d; \mu(0); b)/\hat{f}_u^{0,\pm}.$$

By using these functions $(\Phi_0^\pm, \Psi_0^\pm)$, we now construct solutions $(\Phi^\pm, \Psi^\pm)$ of $(4.1)_\pm$. However, $\Phi_0^\pm(y; d; \mu(0); b)$ do not satisfy the boundary conditions at $y = 0$, so that we must modify these by adding other approximate solutions in a neighborhood of $y = 0$. That is, we introduce correction terms $\Gamma_0^\pm(y/\sigma)$ such that $(\Phi_0^\pm + \Gamma_0^\pm, \Psi_0^\pm)$ become approximate solutions to $(4.1)_\pm$ uniformly on $\mathbf{R}_\pm$. Substituting $(\Phi_0^\pm + \Gamma_0^\pm, \Psi_0^\pm)$ into $(4.1)_\pm$ and setting $\sigma = 0$, we have the following problems:

$$(4.8)_\pm \quad \begin{aligned} &\delta_0(\xi)(\Gamma_0^\pm)_{\xi\xi} + f_u(h_\pm(\beta^*(d)) + W_0^\pm, \beta^*(d))\Gamma_0^\pm = bP^\pm(\xi; d), \qquad \xi \in \mathbf{R}, \\ &\Gamma_0^\pm(\pm\infty) = 0, \qquad \Gamma_0^\pm(0) = 1 - bh'_\pm(\beta^*(d)), \end{aligned}$$

where $\xi = y/\sigma$, $W_0^\pm$ are the inner solutions obtained in § 2.2. With the representation

$$\begin{aligned} P^\pm(\xi; d) = h'_\pm(\beta^*(d))\{&f_u(h_\pm(\beta^*(d)), \beta^*(d)) - f_u(h_\pm(\beta^*(d)) + W_0^\pm, \beta^*(d))\} \\ &+ \{f_v(h_\pm(\beta^*(d)), \beta^*(d)) - f_v(h_\pm(\beta^*(d)) + W_0^\pm, \beta^*(d))\}, \end{aligned}$$

solutions of $(4.8)_\pm$ are represented as

$$\begin{aligned} \Gamma_0^\pm(\xi; d; b) = &\{1 - bh'_\pm(\beta^*(d))\}\frac{(W_0^\pm)_\xi(\xi)}{(W_0^\pm)_\xi(0)} \\ &- b(W_0^\pm)_\xi(\xi)\int_0^\xi ((W_0^\pm)_\eta(\eta))^{-2}\int_\eta^{\pm\infty}(W_0^\pm)_\zeta(\zeta)P^\pm(\zeta; d)\,d\zeta\,d\eta. \end{aligned}$$

Using the functions $(\hat{\Phi}_0^\pm, \hat{\Psi}_0^\pm)$ defined by

$$\hat{\Phi}_0^\pm(y; \sigma; d; \mu(0); b) = \Phi_0^\pm(y; d; \mu(0); b) + \Gamma_0^\pm\left(\frac{y}{\sigma}; d; b\right),$$

$$\hat{\Psi}_0^\pm(y; \sigma; d; \mu(0); b) = \Psi_0^\pm(y; d; \mu(0); b),$$

we can obtain solutions $(\Phi^\pm, \Psi^\pm)(y; \sigma; d; \mu(\sigma); b)$ of $(4.1)_\pm$ for any $\mu(\sigma)$ satisfying $\mu(0) \in \mathbf{C}_{l_3}$, which satisfy

$$\|\Phi^\pm - \hat{\Phi}_0^\pm\|_{\hat{X}^2_{\rho,\sigma}(\mathbf{R}_\pm)} + \|\Psi^\pm - \hat{\Psi}_0^\pm\|_{\hat{X}^2_{\rho,1}(\mathbf{R}_\pm)} \to 0 \quad \text{as } \sigma \downarrow 0.$$

The proof can be done by using standard singular perturbation techniques (see § 2 or [IM1]). By (3.12) and $(4.2)_\pm$, (3.8) is represented as

$$\begin{aligned} g(\sigma; d; \lambda(\sigma)) &= g(\sigma; d; \sigma\mu(\sigma)) \\ &= -\{(\Gamma_0^+)_\xi(0; d; 0) - (\Gamma_0^-)_\xi(0; d; 0)\} \\ &\quad \times \{(\Psi_0^+)_y(0; d; \mu(0); 1) - (\Psi_0^-)_y(0; d; \mu(0); 1)\} + o(1) \end{aligned}$$

as $\sigma \downarrow 0$. From the condition (2.10), it follows that

$$\begin{aligned} (\Gamma_0^+)_\xi(0; d; 0) - (\Gamma_0^-)_\xi(0; d; 0) &= \{(W_0^+)_{\xi\xi}(0) - (W_0^-)_{\xi\xi}(0)\}/(W_0^-)_\xi(0) \\ &= (d-1)f(\alpha^*(d), \beta^*(d))/(W_0^-)_\xi(0) \\ &\neq 0. \end{aligned} \tag{4.9}$$

Here, with

$$\mu = \mu^R + i\mu^I \quad \text{and} \quad \Psi_0^{\pm} = P^{\pm} + iQ^{\pm}$$

we define $G(d; \mu)$ by

$$G(d; \mu) = (\Psi_0^+)_y(0; d; \mu; 1) - (\Psi_0^-)_y(0; d; \mu; 1)$$

and show $G(d; \mu) \neq 0$ for any $\mu \in \mathbf{C}_{l_3}$. We rewrite $(4.6)_{\pm}$ with $b = 1$ as the following problems for $(P^{\pm}, Q^{\pm})(y; d; \mu; 1)$:

$$(4.10)_{\pm} \qquad \begin{aligned} &\delta_0(y)P^{\pm}_{yy} + \{H^{\pm}(y; d) - \mu^R\}P^{\pm} + \mu^I Q^{\pm} = 0, \qquad y \in \mathbf{R}_{\pm}, \\ &P^{\pm}(\pm\infty) = 0, \qquad P^{\pm}(0) = 1 \end{aligned}$$

and

$$(4.11)_{\pm} \qquad \begin{aligned} &\delta_0(y)Q^{\pm}_{yy} + \{H^{\pm}(y; d) - \mu^R\}Q^{\pm} - \mu^I P^{\pm} = 0, \qquad y \in \mathbf{R}_{\pm}, \\ &Q^{\pm}(\pm\infty) = 0, \qquad Q^{\pm}(0) = 0. \end{aligned}$$

Multiplying $(4.10)_{\pm}$ by $Q^{\pm}$ and integrating these over the intervals $\mathbf{R}_{\pm}$, we have

$$(4.12)_{\pm} \qquad \begin{aligned} &-\int_0^{\pm\infty} \delta_0(y)(P^{\pm})_y(Q^{\pm})_y \, dy + \int_0^{\pm\infty} \{H^{\pm}(y; d) - \mu^R\}P^{\pm}Q^{\pm} \, dy \\ &\quad + \mu^I \int_0^{\pm\infty} (Q^{\pm})^2 \, dy = 0. \end{aligned}$$

Similarly, multiplying $(4.11)_{\pm}$ by $P^{\pm}$ and integrating these over the intervals $\mathbf{R}_{\pm}$, we obtain

$$(4.13)_{\pm} \qquad \begin{aligned} &-\delta_0(\pm 0)(Q^{\pm})_y(0; d; \mu; 1) - \int_0^{\pm\infty} \delta_0(y)(P^{\pm})_y(Q^{\pm})_y \, dy \\ &\quad + \int_0^{\pm\infty} \{H^{\pm}(y; d) - \mu^R\}P^{\pm}Q^{\pm} \, dy - \mu^I \int_0^{\pm\infty} (P^{\pm})^2 \, dy = 0. \end{aligned}$$

Combining $(4.12)_{\pm}$ with $(4.13)_{\pm}$, we know that

$$\mu^I \int_0^{\pm\infty} \{(P^{\pm})^2 + (Q^{\pm})^2\} \, dy = -\delta_0(\pm 0)(Q^{\pm})_y(0; d; \mu; 1).$$

We thus find

$$\begin{aligned} \operatorname{Im}\{G(d; \mu)\} &= (Q^+)_y(0; d; \mu; 1) - (Q^-)_y(0; d; \mu; 1) \\ &= -\mu^I \left[\frac{1}{\delta_0(-0)} \int_{-\infty}^{0} \{(P^-)^2 + (Q^-)^2\} \, dy \right. \\ &\qquad \left. + \frac{1}{\delta_0(+0)} \int_0^{+\infty} \{(P^+)^2 + (Q^+)^2\} \, dy \right], \end{aligned}$$

which implies that $G(d; \mu) \neq 0$ if $\mu^I \neq 0$.

Next we consider the case $\mu^I = 0$; that is, μ is a real number. Letting $R^{\pm}(y; d; \mu) = (\partial/\partial\mu)\Psi_0^{\pm}(y; d; \mu; 1)$, we obtain the following equations:

$$(4.14)_{\pm} \qquad \begin{aligned} &\delta_0(y)R^{\pm}_{yy} + \{H^{\pm}(y; d) - \mu\}R^{\pm} = \Psi_0^{\pm}, \qquad y \in \mathbf{R}_{\pm}, \\ &R^{\pm}(\pm\infty) = 0, \qquad R^{\pm}(0) = 0. \end{aligned}$$

Multiplying $(4.14)_{\pm}$ by $\Psi_0^{\pm}$ and integrating these over $\mathbf{R}_{\pm}$, we have

$$-\delta_0(\pm 0)(R^{\pm})_y(0; d; \mu) = \int_0^{\pm\infty} (\Psi_0^{\pm})^2 \, dy.$$

Thus, we know that

$$\begin{aligned}\frac{d}{d\mu} G(d; \mu) &= \frac{\partial}{\partial \mu}(\Psi_0^+)_y(0; d; \mu; 1) - \frac{\partial}{\partial \mu}(\Psi_0^-)_y(0; d; \mu; 1) \\ &= -\left[\frac{1}{\delta_0(-0)} \int_{-\infty}^{0} (\Psi_0^-)^2 \, dy + \frac{1}{\delta_0(+0)} \int_0^{+\infty} (\Psi_0^+)^2 \, dy\right] \\ &< 0\end{aligned}$$

holds for any $\mu > -l_3$. On the other hand, we obtain

$$\begin{aligned}G(d; 0) &= (\Psi_0^+)_y(0; d; 0; 1) - (\Psi_0^-)_y(0; d; 0; 1) \\ &= \{(V_0^+)_{yy}(0; \beta^*(d)) - (V_0^-)_{yy}(0; \beta^*(d))\}/(V_0^-)_y(0; \beta^*(d)) \\ &= \{-g(h_+(\beta^*(d)), \beta^*(d))/\delta_0(+0) \\ &\quad + g(h_-(\beta^*(d)), \beta^*(d))/\delta_0(-0)\}/(V_0^-)_y(0; \beta^*(d)) \\ &< 0\end{aligned}$$

(see § 2.1). Combining these inequalities, we find that

$$G(d; \mu) \neq 0 \quad \text{for any } \mu > -l_3$$

(if necessary, we choose the positive constant l_3 to be smaller). Therefore we find that

$$G(d; \mu) \neq 0 \quad \text{for any } \mu(\sigma) \text{ satisfying } \mu(0) \in \mathbf{C}_{l_3} \tag{4.15}$$

so that from (4.9)

$$g(\sigma; d; \lambda(\sigma)) \neq 0$$

holds for any $\lambda(\sigma) = \sigma\mu(\sigma)$ satisfying $\mu(0) \in \mathbf{C}_{l_3}$, when σ is sufficiently small.

Case II. $\sigma^2\omega(\sigma) \downarrow 0$ and $\omega(\sigma) \uparrow \infty$ as $\sigma \downarrow 0$. Since $(4.1)_{\pm}$ and $(4.4)_{\pm}$ are quite similar forms, applying the same method as that in Case I to $(4.4)_{\pm}$, we can conclude that

$$g(\sigma; d; \lambda(\sigma)) \neq 0$$

for any $\lambda(\sigma)$ satisfying $\sigma\lambda(\sigma) \downarrow 0$ and $\lambda(\sigma)/\sigma \uparrow \infty$ as $\sigma \downarrow 0$.

Case III. $\sigma^2\omega(\sigma) \to \kappa$ as $\sigma \downarrow 0$. For this case, $(4.4)_{\pm}$ fall into regularly perturbed problems, because the coefficients of $\Phi_{zz}^{\pm}$ do not degenerate as $\sigma \downarrow 0$. First we construct approximate solutions to $(4.4)_{\pm}$. Using the transformation $\xi = z/\sqrt{\kappa}$ and putting $\sigma = 0$ in $(4.4)_{\pm}$, we obtain the following systems:

$$\begin{aligned}&\delta_0(\xi)(\Phi_0^{\pm})_{\xi\xi} + f_u(h_{\pm}(\beta^*(d)) + W_0^{\pm}, \beta^*(d))\Phi_0^{\pm} \\ &\qquad + f_v(h_{\pm}(\beta^*(d)) + W_0^{\pm}, \beta^*(d))\Psi_0^{\pm} = \kappa\hat{\mu}(0)\Phi_0^{\pm}, \qquad \xi \in \mathbf{R}_{\pm}, \\ &\delta_0(\xi)(\Psi_0^{\pm})_{\xi\xi} = \kappa\hat{\mu}(0)\Psi_0^{\pm}, \\ &\Phi_0^{\pm}(\pm\infty) = 0, \qquad \Phi_0^{\pm}(0) = 1, \\ &\Psi_0^{\pm}(\pm\infty) = 0, \qquad \Psi_0^{\pm}(0) = b.\end{aligned} \tag{4.16}_{\pm}$$

Noting that $\hat{\mu}(0)$ satisfies

$$\operatorname{Re}\{\hat{\mu}(0)\} \geqq 0 \quad \text{and} \quad |\hat{\mu}(0)| \neq 0, \tag{4.17}$$

we find that

$$\Psi_0^{\pm}(\xi; d; \hat{\mu}(0); b) = b \exp\{\mp \sqrt{\kappa\hat{\mu}(0)/\delta_0(\pm 0)}\, \xi\}.$$

Therefore, $(4.16)_{\pm}$ are reduced to

$$(4.18)_{\pm} \qquad \begin{aligned} &\delta_0(\xi)(\Phi_0^{\pm})_{\xi\xi} + \{f_u(h_{\pm}(\beta^*(d)) + W_0^{\pm}, \beta^*(d)) - \kappa\hat{\mu}(0)\}\Phi_0^{\pm} \\ &\quad = -f_v(h_{\pm}(\beta^*(d)) + W_0^{\pm}, \beta^*(d))\Psi_0^{\pm}, \qquad \xi \in \mathbf{R}_{\pm}, \\ &\Phi_0^{\pm}(\pm\infty) = 0, \qquad \Phi_0^{\pm}(0) = 1. \end{aligned}$$

Applying results similar to Lemma 4.1 to the systems

$$\begin{aligned} &\delta_0(\xi)\Pi_{\xi\xi}^{\pm} + \{f_u(h_{\pm}(\beta^*(d)) + W_0^{\pm}, \beta^*(d)) - \kappa\mu\}\Pi^{\pm} = 0, \qquad \xi \in \mathbf{R}_{\pm}, \\ &\Pi^{\pm}(\pm\infty) = 0, \qquad \Pi^{\pm}(0) = 1, \end{aligned}$$

we find that $(4.18)_{\pm}$ have unique solutions $\Phi_0^{\pm}(\xi; d; \hat{\mu}(0); b)$ for any $\hat{\mu}(0) \in \mathbf{C}$ satisfying (4.17). According to a standard perturbation process, for any $\hat{\mu}(0)$ satisfying (4.17), we can find exact solutions $(\Phi^{\pm}, \Psi^{\pm})(z; \sigma; d; \hat{\mu}(\sigma); b)$ of $(4.4)_{\pm}$ which satisfy

$$\|\Phi^{\pm}(z) - \Phi_0^{\pm}(z/\sqrt{\kappa})\|_{\hat{X}^2_{\rho,1}(\mathbf{R}_{\pm})} + \|\Psi^{\pm}(z) - \Psi_0^{\pm}(z/\sqrt{\kappa})\|_{\hat{X}^2_{\rho,1}(\mathbf{R}_{\pm})} \to 0 \quad \text{as } \sigma \downarrow 0.$$

In a way similar to that in Case I, we obtain

$$\begin{aligned} g(\sigma; d; \lambda(\sigma)) &= g(\sigma; d; \sigma\omega(\sigma)\hat{\mu}(\sigma)) \\ &= -\frac{\sigma\omega(\sigma)}{\kappa}[\{(\Phi_0^+)_{\xi}(0; d; \hat{\mu}(0); 0) - (\Phi_0^-)_{\xi}(0; d; \hat{\mu}(0); 0)\} \\ &\qquad \times \{(\Psi_0^+)_{\xi}(0; d; \hat{\mu}(0); 1) - (\Psi_0^-)_{\xi}(0; d; \hat{\mu}(0); 1)\} + o(1)] \\ &= \frac{\sigma\omega(\sigma)}{\kappa}\left[\{(\Phi_0^+)_{\xi}(0; d; \hat{\mu}(0); 0) - (\Phi_0^-)_{\xi}(0; d; \hat{\mu}(0); 0)\} \right. \\ &\qquad \left. \times \left\{\sqrt{\frac{\kappa\hat{\mu}(0)}{\delta_0(+0)}} + \sqrt{\frac{\kappa\hat{\mu}(0)}{\delta_0(-0)}}\right\} + o(1)\right] \end{aligned}$$

as $\sigma \downarrow 0$. Put

$$\begin{aligned} \hat{g}(\sigma; d; \mu) &= \{(\Phi_0^+)_{\xi}(0; d; \mu; 0) - (\Phi_0^-)_{\xi}(0; d; \mu; 0)\} \\ &\qquad \times \{\sqrt{\kappa\mu/\delta_0(+0)} + \sqrt{\kappa\mu/\delta_0(-0)}\} + o(1). \end{aligned}$$

Since $\hat{g}(\sigma; d; \mu)$ can be extended continuously so as to be defined for $\sigma = 0$, we obtain

$$\begin{aligned} \hat{g}(0; d; \mu) &= \{(\Phi_0^+)_{\xi}(0; d; \mu; 0) - (\Phi_0^-)_{\xi}(0; d; \mu; 0)\} \\ &\qquad \times \{\sqrt{\kappa\mu/\delta_0(+0)} + \sqrt{\kappa\mu/\delta_0(-0)}\}. \end{aligned}$$

In a way similar to that in Case I, we know that

$$\hat{g}(\sigma; d; \mu) \neq 0 \quad \text{for } \operatorname{Im}\{\mu\} \neq 0.$$

That is, $\hat{g}(\sigma; d; \mu) = 0$ has no roots μ satisfying $\operatorname{Im}\{\mu\} \neq 0$. Then it suffices to consider the case when μ is a real number; that is, for any $\mu > 0$, we find roots μ of $\hat{g}(0; d; \mu) = 0$. For any $\mu > 0$, $\hat{g}(0; d; \mu) = 0$ is equivalent to the equation

$$G(d; \mu) \equiv (\Phi_0^+)_{\xi}(0; d; \mu; 0) - (\Phi_0^-)_{\xi}(0; d; \mu; 0) = 0.$$

Therefore, we consider $G(d;\mu)=0$ instead of $\hat{g}(0;d;\mu)=0$. By the same method as that in Case I, we can show that

$$\frac{d}{d\mu}G(d;\mu)<0 \quad \text{for any } \mu>0,$$

and

$$G(d;\mu)=-\sqrt{\kappa\mu/\delta_0(+0)}-\sqrt{\kappa\mu/\delta_0(-0)}+O(1)\to-\infty \quad \text{as } \mu\uparrow\infty.$$

Moreover it holds that

$$\begin{aligned}G(d;0)&=(\Phi_0^+)_\xi(0;d;0;0)-(\Phi_0^-)_\xi(0;d;0;0)\\&=\{(W_0^+)_{\xi\xi}(0;\alpha^*(d),\beta^*(d))\\&\qquad-(W_0^-)_{\xi\xi}(0;\alpha^*(d),\beta^*(d))\}/(W_0^-)_\xi(0;\alpha^*(d),\beta^*(d))\\&=(d-1)f(\alpha^*(d),\beta^*(d))/(W_0^-)_\xi(0;\alpha^*(d),\beta^*(d)).\end{aligned}$$

Using the relations (2.14) and (2.15), we conclude that

$$\operatorname{sign}\{G(d;0)\}=-\mathbf{I}(d).$$

Then we directly have the following.

LEMMA 4.2. *If* $\mathbf{I}(d)=1$, $\hat{g}(0;d;\mu)\neq 0$ *for any* $\mu>0$. *Conversely, if* $\mathbf{I}(d)=-1$, *there exists a unique simple positive number* $\mu^*(d)$ *satisfying* $\hat{g}(0;d;\mu^*(d))=0$.

Applying the implicit function theorem to $\hat{g}(\sigma;d;\mu)=0$, it follows from Lemma 4.2 that

(i) When $\mathbf{I}(d)=1$, $\hat{g}(\sigma;d;\hat{\mu}(\sigma))\neq 0$ for any $\hat{\mu}(\sigma)\in\mathbf{C}$ satisfying (4.17);

(ii) When $\mathbf{I}(d)=-1$, $\hat{g}(\sigma;d;\hat{\mu}(\sigma))=0$ has a unique simple positive root $\hat{\mu}(d;\sigma)$ satisfying (4.17) such that $\lim_{\sigma\to 0}\hat{\mu}(d;\sigma)=\mu^*(d)$.

Therefore, if $\mathbf{I}(d)=1$, $g(\sigma;d;\lambda(\sigma))\neq 0$ holds for any $\lambda(\sigma)=\sigma\omega(\sigma)\hat{\mu}(\sigma)$ satisfying (4.17), while, if $\mathbf{I}(d)=-1$, $g(\sigma;d;\lambda(\sigma))=0$ has a unique simple positive root $\lambda=\lambda(\sigma)=\sigma\omega(\sigma)\hat{\mu}(d;\sigma)$.

Case IV. $\sigma^2\omega(\sigma)\uparrow\infty$ as $\sigma\downarrow 0$. In the same spirit of the proof of Lemma 4.3 in Case I, we can prove that

$$g(\sigma;d;\lambda(\sigma))\neq 0$$

for any $\lambda(\sigma)$ satisfying $\sigma\lambda(\sigma)\uparrow\infty$ as $\sigma\downarrow 0$. So we leave the proof to the reader.

Combining the above four cases, we are able to complete the proof of Theorem 3.1.

5. Concluding remarks. In the previous sections, we have not mentioned the case where σ is sufficiently large. Here under the assumptions (A1) and (A5), we briefly state the results on the stability as well as the existence of stationary solutions for this case. Let $v=h(u)$ be the function uniquely defined by the relation $g(u,h(u))=0$ (see (A5)) and let $S=\int_{u_-}^{u_+}f(u,h(u))\,du$. In [IM1], under the assumptions (A1) and (A5), we have shown the following existence result:

(i) When $S<0$, there exists d_1 (<1) such that (1.7) has two stationary solutions $(\bar{U}_*,\bar{V}_*)$ and $(\underline{U}_*,\underline{V}_*)(\bar{U}_*>\underline{U}_*)$ for any $d\in(0,d_1)$;

(ii) When $S>0$, there exists d_2 (>1) such that (1.7) has two stationary solutions $(\bar{U}^*,\bar{V}^*)$ and $(\underline{U}^*,\underline{V}^*)(\bar{U}^*>\underline{U}^*)$ for any $d\in(d_2,\infty)$ (see Fig. 9).

Using the same method as that in §§3 and 4, we can show that when $S<0$, the upper branch corresponding to $(\bar{U}_*,\bar{V}_*)$ is stable, while the lower one corresponding to $(\underline{U}_*,\underline{V}_*)$ is unstable. Conversely, when $S>0$, the lower one corresponding to $(\underline{U}^*,\underline{V}^*)$ is stable, whereas the upper one corresponding to $(\bar{U}^*,\bar{V}^*)$ is unstable.

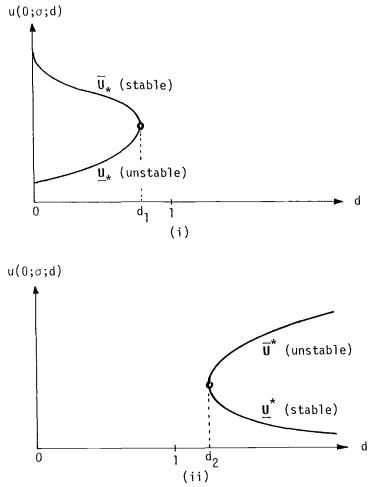

FIG. 9. *Global pictures of stationary solutions of* (1.1) *and their stability*; (i) $S<0$; (ii) $S>0$.

In this paper, motivated by the wave-blocking phenomena, we have discussed the stability property of stationary solutions for the special case when the reaction rates of u and v are totally different; in other words, σ is very large or small. Unfortunately, we are not able to discuss here the case when the reaction rates are almost equal. This is a future problem.

Appendix.

Proof of Proposition 3.1. The location of the essential spectrum for the operator $\mathscr{L}^{\varepsilon,d}$ is contained in the union of the following two sets:

$$S^{\pm}=\{\lambda\in\mathbf{C}\,|\,\det(-\nu^2D^{\pm}+N^{\pm}-\lambda I)=0,\ \nu\in\mathbf{R}\},$$

where

$$D^{\pm}=\begin{bmatrix}\delta_0(\pm\infty) & 0\\ 0 & \delta_0(\pm\infty)\end{bmatrix},\qquad N^{\pm}=\begin{bmatrix}f_u^{\pm}/\sigma & f_v^{\pm}/\sigma\\ \sigma g_u^{\pm} & \sigma g_v^{\pm}\end{bmatrix},$$

$f_u^{\pm}=f_u(u_{\pm},v_{\pm})$ and $f_v^{\pm}$, $g_u^{\pm}$, and $g_v^{\pm}$ are similarly defined. From the relations

$$\det(-\nu^2D^{\pm}+N^{\pm}-\lambda I)=0,$$

it follows that

$$\lambda^2+\left(2\nu^2\delta_0(\pm\infty)-\frac{1}{\sigma}f_u^{\pm}-\sigma g_v^{\pm}\right)\lambda+\left(\nu^2\delta_0(\pm\infty)-\frac{1}{\sigma}f_u^{\pm}\right)(\nu^2\delta_0(\pm\infty)-\sigma g_v^{\pm})-f_v^{\pm}g_u^{\pm}=0.$$

The roots of these equations are given by

$$\lambda=\frac{1}{2}\left[-2\nu^2\delta_0(\pm\infty)+\frac{1}{\sigma}f_u^{\pm}+\sigma g_v^{\pm}+\sqrt{\left(\frac{1}{\sigma}f_u^{\pm}-\sigma g_v^{\pm}\right)^2+4f_v^{\pm}g_u^{\pm}}\right]$$

or

$$\lambda=\frac{1}{2}\left[-2\nu^2\delta_0(\pm\infty)+\frac{1}{\sigma}f_u^{\pm}+\sigma g_v^{\pm}-\sqrt{\left(\frac{1}{\sigma}f_u^{\pm}-\sigma g_v^{\pm}\right)^2+4f_v^{\pm}g_u^{\pm}}\right].$$

Using the assumptions (A3) and (A4), we find that for small $\sigma>0$,

$$\begin{aligned}\operatorname{Re}\lambda&\leqq\frac{1}{2}\left[-2\nu^2\delta_0(\pm\infty)+\frac{1}{\sigma}f_u^{\pm}+\sigma g_v^{\pm}+\left|\frac{1}{\sigma}f_u^{\pm}-\sigma g_v^{\pm}\right|\right]\\&=-\nu^2\delta_0(\pm\infty)+\sigma g_v^{\pm}.\end{aligned}$$

That is, for any $\nu \in \mathbf{R}$ and small $\sigma > 0$

$$\operatorname{Re} \lambda \leqq \sigma g_{\nu}^{\pm}$$

hold. Then we can conclude Proposition 3.1 with $l_1 = -\max\{g_{\nu}^{+}, g_{\nu}^{-}\}(>0)$. □

Proof of Lemma 4.1. Proving Lemma 4.1 is equivalent to showing the following.

LEMMA A1. *Consider the homogeneous problems*

$$(A1)_{\pm} \qquad \begin{aligned} &\delta_0(y)(\Pi_0^{\pm})_{yy} + \{H^{\pm}(y; d) - \mu\}\Pi_0^{\pm} = 0, \qquad y \in \mathbf{R}_{\pm}, \\ &\Pi_0^{\pm}(\pm\infty) = 0, \qquad \Pi_0^{\pm}(0) = 0. \end{aligned}$$

Then there exists a positive constant l such that for any $\mu \in \mathbf{C}_l$, *the* $(A1)_{\pm}$ *have only trivial solutions.*

Proof. Let $L^{\pm}$ be linear operators defined by

$$L^{\pm}u^{\pm} \equiv \delta_0(y)u_{yy}^{\pm} + H^{\pm}(y; d)u^{\pm}.$$

According to the Sturm-Liouville theory, all the eigenvalues of $(A1)_{\pm}$ are real and simple. Furthermore, it is known that the eigenfunctions $u_0^{\pm}$ corresponding to the largest eigenvalues $\mu_0^{\pm}$ have no zeros in $\mathbf{R}_{\pm}$, respectively. Without loss of generality, we assume $u_0^{\pm} \geqq 0$ in $\mathbf{R}_{\pm}$. That is,

$$(A2)_{\pm} \qquad \begin{aligned} &\delta_0(y)(u_0^{\pm})_{yy} + \{H^{\pm}(y; d) - \mu_0^{\pm}\}u_0^{\pm} = 0, \qquad y \in \mathbf{R}_{\pm}, \\ &u_0^{\pm}(\pm\infty) = 0, \qquad u_0^{\pm}(0) = 0 \end{aligned}$$

hold. On the other hand, the derivatives of the outer solutions $V_0^{\pm}$, say $P^{\pm} \equiv (V_0^{\pm})_y > 0$, satisfy the following equations:

$$(A3)_{\pm} \qquad \begin{aligned} &\delta_0(y)P_{yy}^{\pm} + H^{\pm}(y; d)P^{\pm} = 0, \qquad y \in \mathbf{R}_{\pm}, \\ &P^{\pm}(\pm\infty) = 0, \qquad P^{\pm}(0) = (V_0^{\pm})_y(0; \beta^*(d)). \end{aligned}$$

Using the above relations $(A2)_{\pm}$ and $(A3)_{\pm}$, we obtain

$$\begin{aligned} \mu_0^{\pm} \int_0^{\pm\infty} u_0^{\pm} P^{\pm}\, dy &= \int_0^{\pm\infty} \{\delta_0(y)(u_0^{\pm})_{yy} + H^{\pm}(y; d)u_0^{\pm}\}P^{\pm}\, dy \\ &= -\delta_0(\pm 0)(u_0^{\pm})_y(0)P^{\pm}(0) + \int_0^{\pm\infty} \{\delta_0(y)P_{yy}^{\pm} + H^{\pm}(y; d)P^{\pm}\}u_0^{\pm}\, dy \\ &= -\delta_0(\pm 0)(u_0^{\pm})_y(0)P^{\pm}(0). \end{aligned}$$

Then

$$\mu_0^{\pm} = -\delta_0(\pm 0)(u_0^{\pm})_y(0)P^{\pm}(0) \Big/ \int_0^{\pm\infty} u_0^{\pm} P^{\pm}\, dy$$

hold. Noting that $(u_0^{+})_y(0) > 0$, $(u_0^{-})_y(0) < 0$, $P^{\pm}(0) > 0$ and $u_0^{\pm}(y)P^{\pm}(y) \geqq 0$ in $\mathbf{R}_{\pm}$, we find that

$$\mu_0^{\pm} < 0.$$

Thus if we put $l = \max\{\mu_0^{-}, \mu_0^{+}\}$, Lemma A1 is proved. □

INTEGRAL EQUATION METHODS IN A QUASI-PERIODIC DIFFRACTION PROBLEM FOR THE TIME-HARMONIC MAXWELL'S EQUATIONS*

J. C. NEDELEC† AND F. STARLING†

Abstract. The problem of the time-harmonic Maxwell's equations is considered in the exterior in R^3 of a domain which has a doubly periodic structure in a plane of R^3. It is proved that except for a discrete set of value of the frequency, this problem has a unique solution.

Key words. Maxwell equations, doubly periodic domain, integral equation

AMS(MOS) subject classifications. 45B05, 45P05, 78A95, 78A25

Introduction. There is an increasing interest in the study of radiation patterns created by the new periodic structures of phased arrays antennas. These antennas consist in the superposition of a great number of identical electromagnetic horns. The calculus of the radiation pattern of such a horn, when it is considered separately from the others, can be handled by integral equations techniques (see [1]). However, the complete calculus by this method, taking account of all mutual influences, leads to a great number of unknowns and consequently to very heavy computations. Here, we present a mathematical model of such a problem that shall lead us, later on, to its numerical resolution. It is based on a reduction to a "quasi-periodic" formulation (see [4]), which enables us to focus the analysis of one "elementary scatterer." On that starting point, we modify the methods in [1] to get existence and uniqueness results, which shall justify a rough numerical method. New mathematical difficulties, which differ from those found in [1], appear in our analysis and are to be be related to the kind of model discussed.

The paper is organized as follows. In § 1, we introduce the mathematical model and framework to be considered. Section 2 is devoted to the analysis of uniqueness properties for this model. Finally, § 3 gives the integral equation formulation of the problem, which provides existence results and will lead to numerical computations.

1. The mathematical model. This section will lead us to a precise mathematical framework for our electromagnetic diffraction problem. We begin with a general description of the geometrical setting of the problem.

1.1. Geometrical structure and notation. If Y and Y' are elements of $\mathbb{C}^\nu$, $Y = (y_1, \cdots, y_\nu)$, $Y' = (y'_1, \cdots, y'_\nu)$, we will use the following general notation:

$\bar{Y} := (\bar{y}_1, \cdots, \bar{y}_\nu)$ is the complex conjugate of Y,
$Y.\ Y' := y_1 y'_1 + \cdots + y_\nu y'_\nu$ is the scalar product of Y, Y',
$Y.\ \overline{Y'} := y_1 \bar{y}'_1 + \cdots + y_\nu \bar{y}'_\nu$ is the Hermitian scalar product of Y, Y',
$|Y| := (Y.\ \bar{Y})^{1/2} = (y_1 \bar{y}_1 + \cdots + y_\nu \bar{y}_\nu)^{1/2}$ is the modulus of Y.

Let $(\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3)$ be an orthonormal basis of $\mathbb{R}^3$, related to a system of coordinates (x_1, x_2, x_3).

Let ω be a bounded open regular set of $\mathbb{R}^3$, with connected complement in $\mathbb{R}^3$; ω will be our basic scatterer, repeated periodically in a plane of $\mathbb{R}^3$.

Indeed, we will consider a "doubly periodic" scatterer, consisting in the union of identical scatterers, translated from ω in the following way.

* Received by the editors May 2, 1988; accepted for publication (in revised form) July 4, 1990.
† Centre de Mathématiques Appliquées, Ecole Polytechnique, 91128 Palaiseau Cedex, France.

We assume that (d_1, d_2) are two positive reals such that

$$\forall I = (i_1, i_2) \in \mathbb{Z}^2 \quad \text{if } \omega_I := \omega + i_1 d_1 \mathbf{e}_1 + i_2 d_2 \mathbf{e}_2;$$

then

$$\omega_1 \cap \omega_j = \varnothing \quad \text{if } I \neq J, \quad J \in \mathbb{Z}^2. \tag{1.1}$$

Our doubly periodic scatterer is defined by the disjoint union

$$S := \bigcup_{J \in \mathbb{Z}^2} \omega_J$$

(d_1, d_2) hence represents the double periodicity of the structure. (See Fig. 1.) This geometrical structure leads us to the following splitting in the system of coordinates, which will widely simplify the notation: we will write

$$(x_1, x_2, x_3) = (X, Z)$$

where X stands for the $\mathbb{R}^2$ element (x_1, x_2) and Z stands for the $\mathbb{R}$ element x_3.

Property (1.1) implies that we can choose an origin O in $\mathbb{R}^3$ such that ω is completely embedded in the "cylindrical" set of $\mathbb{R}^3$:

$$\Omega :=]-d_1/2, d_1/2[\times]-d_2/2, d_2/2[\times \mathbb{R}.$$

We will call this set the "elementary cell."

We will see in § 1.4 that the diffraction problem, which is set on $\mathbb{R}^3 \backslash \bar{S}$, can be reduced to a boundary value problem which is set only in the complement of ω with respect to the "elementary cell" Ω. To this end, we define such an exterior domain by

$$\Omega^{\text{ext}} := \Omega \backslash \bar{\omega},$$

and we will also need to truncate this domain Ω^{ext} to obtain some compactness properties in § 2; thus, we set, for every real ρ,

$$\Omega_\rho := \Omega \cap \{(X, Z) \in \mathbb{R}^d / |Z| < \rho\},$$

$$\Omega_\rho^{\text{ext}} := \Omega^{\text{ext}} \cap \{(X, Z) \in \mathbb{R}^d / |Z| < \rho\}.$$

As $\bar{\omega}$ is bounded, we can assume that it is embedded in a set

$$\{(X, Z) \in \mathbb{R}^3 / |Z| < \rho_0\}$$

for a positive real ρ_0. It follows that Ω_ρ contains $\bar{\omega}$ if $\rho \geqq \rho_0$.

We also define sections Σ^ρ of the "elementary cell" Ω by setting

$$\Sigma^\rho :=]-d_1/2, d_1/2[\times]-d_2/2, d_2/2[\times \{Z \in \mathbb{R}^3 / |Z| = \rho\}$$

for every real $\rho \geqq \rho_0$.

Finally, we set $Q :=]-d_1/2, d_1/2[\times]-d_2/2, d_2/2[$.

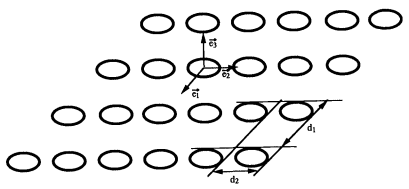

FIG. 1

1.2. Maxwell's equations. Generally speaking, the determination of the time-harmonic diffracted field by a perfectly conducting body gives rise to the following kind of boundary value problem, where the time dependence, in $\exp(-i\omega_0 t)$ (with $i=\sqrt{-1}$), is dropped by linearity:

(Max. 0) Find $(\mathbf{e}, \mathbf{h})$ such that

$$\begin{aligned} &\operatorname{curl}\mathbf{e} - i\omega_0\mu\mathbf{h} = \mathbf{0} && \text{in the exterior domain,}\\ &\operatorname{curl}\mathbf{h} + i\omega_0\varepsilon\mathbf{e} = \mathbf{0} && \text{in the exterior domain,}\\ &\mathbf{n}\times\mathbf{e} = -\mathbf{n}\times\mathbf{e}^{\mathrm{inc}} && \text{on the conducting body.}\end{aligned}$$

$(\mathbf{e}, \mathbf{h})$ satisfies an outgoing wave condition at infinity.

Here $\mathbf{e}^{\mathrm{inc}}$ is the electric part of the incident electromagnetic field; k, the wave number of the phenomenon, is related to the pulsation of the incident wave ω_0 by the formula $k=\omega_0\sqrt{\varepsilon\mu}$ with ε and μ the electromagnetic characteristics of the exterior domain; $\mathbf{n}$ is the outwardly directed normal on the body.

Following [1], we can eliminate $\mathbf{h}$ from these equations to obtain the equivalent problem:

(Max. 1) Find $\mathbf{e}$ such that

$$\begin{aligned} &\Delta\mathbf{e} + k^2\mathbf{e} = \mathbf{0} && \text{in the exterior domain,}\\ &\operatorname{div}\mathbf{e} = 0 && \text{in the exterior domain,}\\ &\mathbf{n}\times\mathbf{e} = -\mathbf{n}\times\mathbf{e}^{\mathrm{inc}} && \text{on the conducting body.}\end{aligned}$$

$\mathbf{e}$ satisfies an outgoing wave condition at infinity.

In this form, the diffraction problem has been widely analysed and its mathematical properties are well known (see [1], [2]; part of our study will be based on this knowledge). However, our doubly periodic scattering problem has not, strictly speaking, a physical meaning because we assume that the scatterer is of infinite extent. Hence, to give a precise meaning to problems (Max. 0) and (Max 1), we must add some specific conditions on the behaviour of the diffracted fields, and also specify an appropriate outgoing wave condition, generalizing the usual ones.

First of all, we restrict our study to the case where the incident field has a plane wave structure. Other kinds of excitations of such a system are possible. Thus, we write, in a fixed system of coordinates (X, Z),

$$\mathbf{e}^{\mathrm{inc}}(X, Z) = \mathbf{e}_0^{\mathrm{inc}} \exp(i\mathbf{K}\cdot X)\exp(i\mathbf{K}_z\cdot Z) \tag{1.2}$$

where the wave vector of $\mathbf{e}^{\mathrm{inc}}$ is $\mathbf{k}=\mathbf{K}+\mathbf{K}_z$, $|\mathbf{k}|=k$, and $\mathbf{K}\in\operatorname{Vect}(\mathbf{e}_1, \mathbf{e}_2)$, $\mathbf{K}_z\in\operatorname{Vect}(\mathbf{e}_3)$.

Consequently, the tangential component of our diffracted field, which is matched with the incident field on conductors, will satisfy the following "quasi-periodicity" condition:

For all $J=(j_1, j_2)\in\mathbb{Z}^2$, if $X_J := (j_1 d_1, j_2 d_2)$,
$(\mathbf{n}\times\mathbf{e})(X+X_J, Z) = (\mathbf{n}\times\mathbf{e})(X, Z)\exp(i\mathbf{K}\cdot X_J)$.

This suggests searching for a diffracted field $\mathbf{e}$ satisfying such a "quasi-periodicity" condition not only on the conductors, and for the tangential component of the field, but everywhere in $\mathbb{R}^3\backslash\bar{S}$ and for the whole field $\mathbf{e}$. In fact, we can guess that this requirement is necessary, for, assuming that the solution of our problem is in some sense unique, an X_J translation of the scatterer gives rise to the two following kinds of solutions:

$$\mathbf{e}^J(X, Z) = \mathbf{e}(X+X_J, Z) \quad \text{(translation of the scatter),}$$

$$\mathbf{e}^*(X, Z) = \mathbf{e}(X, Z)\exp(i\mathbf{K}\cdot X_J) \quad \text{(modification of the incident wave),}$$

so that writing $\mathbf{e}^J(X, Z) = \mathbf{e}^*(X, Z)$, we find again our "quasi-periodicity" condition:

$$\text{For all } J \text{ in } \mathbb{Z}^2, \quad \mathbf{e}(X + X_J, Z) = \mathbf{e}(X, Z) \exp(i\mathbf{K} \cdot X_J). \tag{1.3}$$

We can now state our "quasi-periodic" boundary value problem, in a more specific form:

(1.4) Find $\mathbf{e}$ defined on $\mathbb{R}^3 \backslash \bar{S}$ such that

$$\begin{aligned} &\Delta \mathbf{e} + k^2 \mathbf{e} = \mathbf{0} && \text{in } \mathbb{R}^3 \backslash \bar{S}, \\ &\operatorname{div} \mathbf{e} = 0 && \text{in } \mathbb{R}^3 \backslash \bar{S}, \\ &\mathbf{n} \times \mathbf{e} = -\mathbf{n} \times \mathbf{e}^{\text{inc}} && \text{on each conductor.} \end{aligned}$$

$\mathbf{e}$ satisfies (1.3) and a suitable outgoing wave condition at infinity.

Here $\mathbf{e}^{\text{inc}}$ has the form (1.2).

At this point, a precise meaning for the outgoing wave condition can be derived. It is easily seen that a function $\mathbf{e}$ satisfying conditions (1.4) can be expanded in a "quasi-periodic" Fourier series for sufficiently large $|Z|$:

$$\mathbf{e}(X, Z) = \sum_{J \in \mathbb{Z}^2} \exp(i(\mathbf{K} + \mathbf{K}_J) \cdot X) \mathbf{e}_J(Z), \qquad |Z| > \rho_0 \tag{1.5}$$

where

$$\mathbf{K}_J := (2\pi j_1 / d_1, 2\pi j_2 / d_2), \qquad J = (j_1, j_2)$$

and

$$\mathbf{e}_J(Z) := \frac{1}{d_1 d_2} \int_Q \mathbf{e}(X, Z) \exp(-i(\mathbf{K} + \mathbf{K}_J) \cdot X) \, d\sigma_X.$$

This series (1.5) is absolutely convergent and termwise infinitely differentiable, for $\mathbf{e}$, solving problem (1.4), is necessarily very regular.

Furthermore, each component $\mathbf{e}_J(\cdot)$ must satisfy

$$\frac{\partial^2}{\partial Z^2} \mathbf{e}_J(Z) + (k^2 - |\mathbf{K} + \mathbf{K}_J|^2) \mathbf{e}_J(Z) = \mathbf{0} \quad \text{for } |Z| > \rho_0. \tag{1.6}$$

The general solution of (1.6) can, of course, be given explicitly; however, having in mind that (1.6) is a Helmholtz equation set in a classical framework, we will select the different kinds of solutions by the usual Sommerfeld's radiation conditions:

$$\begin{aligned} &\mathbf{e}_J(Z) = O(1) \quad \text{for large } |Z| \text{ and all } J \text{ in } \mathbb{Z}^2, \\ &\frac{\partial}{\partial |Z|} \mathbf{e}_J(Z) - i\mu_J(k) \mathbf{e}_J(Z) = o(1) \quad \text{for large } |Z| \text{ and all } J \text{ in } \mathbb{Z}^2 \end{aligned} \tag{1.7}$$

where

$$\begin{aligned} &\mu_J(k) := (k^2 - |\mathbf{K} + \mathbf{K}_J|^2)^{1/2} && \text{if } k \geqq |\mathbf{K} + \mathbf{K}_J|, \\ &\mu_J(k) := i(|\mathbf{K} + \mathbf{K}_J|^2 - k^2)^{1/2} && \text{if } k < |\mathbf{K} + \mathbf{K}_J|. \end{aligned} \tag{1.8}$$

1.3. Functional spaces. In this section, we describe the functional setting needed to state our boundary value problem in a suitable mathematical form.

We shall use standard notation for the usual functional spaces: $L^2(G)$ is the space of complex square integrable functions defined on G, where G stands either for an open regular set of $\mathbb{R}^3$, or for the regular boundary of such a domain. The norm and scalar product on $L^2(G)$ will be denoted, as usual, by $|\cdot|_{0,G}$ and $(\cdot|\cdot)_{0,G}$.

$C_0^\infty(G)$ (respectively, $C_0^\infty(\bar{G})$) is the space of regular functions defined on G (respectively, $\bar{G}$), with compact support in G (respectively, $\bar{G}$).

$H^s(G)$ is the usual Sobolev space of order s, $s \in \mathbb{R}$.

$H_\Delta^1(G)$ is the set of functions u in $H^1(G)$, with Δu in $L^2(G)$.

$L^{2,\mathrm{loc}}(G)$ (respectively, $H^{s,\mathrm{loc}}(G)$, $H_\Delta^{1,\mathrm{loc}}(G)$) is the set of functions which are in $L^2(G_R)$ (respectively, $H^s(G_R)$, $H_\Delta^1(G_R)$), where $G_R := G \cap \{(X, Z) \in \mathbb{R}^3 / |(X, Z)| < R\}$ for every positive R.

We need to define Sobolev spaces of "quasi-periodic" functions. To this end, let $C_K^\infty(\mathbb{R}^3)$ be the space of those scalar functions $u \in C^\infty(\mathbb{R}^3)$ satisfying:

(i) u has compact support in Z, i.e., Supp $u \subset \{|Z| < \rho\}$ for some real positive ρ.

(ii) $u(X + X_J, Z) = u(X, Z) \exp(i\mathbf{K} \cdot X_J)$ for all $J = (j_1, j_2) \in \mathbb{Z}^3$, with $X_J = (j_1 d_1, j_2 d_2)$.

For an open set $\vartheta \subset \mathbb{R}^3$, $C_K^\infty(\vartheta)$ will be the space of restrictions to ϑ of functions of $C_K^\infty(\mathbb{R}^3)$, and $C_{0K}^\infty(\vartheta)$ the subset of $C_K^\infty(\vartheta)$ of those functions with compact support in ϑ.

This enables us to consider the following "quasi-periodic" Sobolev space, closure of $C_K^\infty(\vartheta)$ in $H^1(\vartheta)$, i.e.,

$$H_K^1(\vartheta) := \overline{C_K^\infty(\vartheta)}^{H^1(\vartheta)}.$$

It is not difficult to see that, equipped with the usual $H^1(\vartheta)$ norm and Hilbertian scalar product denoted by $|\cdot|_{1,\vartheta}$ and $(\cdot|\cdot)_{1,\vartheta}$, $H_K^1(\vartheta)$ becomes a Hilbert space.

To reduce our boundary value problem to one set only in the "elementary cell" Ω, we need a space of functions, defined on Ω^{ext}, which can be extended to $\mathbb{R}^3 \backslash \bar{S}$ as "quasi-periodic" functions, in a sufficiently smooth way, with respect to conditions dictated by the partial differential equations. To this end we define:

-The "quasi-periodic" extension of $u \in L^{2,\mathrm{loc}}(\Omega^{\mathrm{ext}})$, say $u^{(K)} \in L^{2,\mathrm{loc}}(\mathbb{R}^3 \backslash \bar{S})$, defined by

$u^{(K)}$ is given in $\Omega^{\mathrm{ext}} + X_J$, for each J in $\mathbb{Z}^2$, by
$u^{(K)}(X + X_J, Z) := u(X, Z) \exp(i\mathbf{K} \cdot X_J)$, for almost every (X, Z) in Ω^{ext}.

-The space $H_{\Delta,K}^1(\Omega^{\mathrm{ext}})$, of functions which are in $H_K^1(\Omega^{\mathrm{ext}}) \cap H_\Delta^1(\Omega^{\mathrm{ext}})$, and for which the "quasi-periodic" extension $u^{(K)}$ belongs to $H_\Delta^{1,\mathrm{loc}}(\mathbb{R}^3 \backslash S)$. This space, equipped with the natural norm $\|.\|_{\Delta,\Omega^{\mathrm{ext}}}$ given by

$$\|u\|_{\Delta,\Omega^{\mathrm{ext}}}^2 = |\Delta u|_{0,\Omega^{\mathrm{ext}}}^2 + \|u\|_{1,\Omega^{\mathrm{ext}}}^2,$$

is a Hilbert space. Two facts which will be useful in the sequel can be shown: first, $H_{\Delta,K}^1(\Omega^{\mathrm{ext}})$ can be given a weak characterization by means of a Green formula (see proof of Proposition 1.1); second, $C_K^\infty(\Omega^{\mathrm{ext}})$ is a dense subset of the Hilbert space $H_{\Delta,K}^1(\Omega^{\mathrm{ext}})$.

We will also use the Fréchet spaces of functions that are locally in $H_K^1(\Omega^{\mathrm{ext}})$ or in $H_{\Delta,K}^1(\Omega^{\mathrm{ext}})$, in the same sense as above. They will be, as above, designated by $H_K^{1,\mathrm{loc}}(\Omega^{\mathrm{ext}})$ or $H_{\Delta,K}^{1,\mathrm{loc}}(\Omega^{\mathrm{ext}})$.

For vector-valued functions, defined on an open set ϑ of $\mathbb{R}^3$, we will use the following notation. $F(\vartheta, \mathbb{C}^3)$ will always stand for the space of complex fields $\mathbf{e} := (e^1, e^2, e^3)$, with $e^i \in F(\vartheta)$, where F is any of the functional spaces described above. Note that with our choice of a basis $(\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3)$, we can identify $F(\vartheta, \mathbb{C}^3)$ with $\{F(\vartheta)\}^3$.

For vector fields defined on $\partial\omega$, we will write $\mathbf{H}^s(\partial\omega) := \{H^2(\partial\omega)\}^3$, and following [1], we will split $\mathbf{H}^s(\partial\omega)$ in two subspaces of tangential fields and normal fields to $\partial\omega$: if $\mathbf{n}$ is the unit normal vector of $\partial\omega$, we have

$$\mathbf{e} := \Pi\mathbf{e} + (\mathbf{e} \cdot \mathbf{n})\mathbf{n}$$

where Π is the normal projection on the tangent plane to $\partial\omega$. Thus we can set

$$TH^s(\partial\omega) := \{\mathbf{e} \in \mathbf{H}^s(\partial\omega)/(\mathbf{e}\cdot\mathbf{n}) = 0\},$$
$$NH^s(\partial\omega) := \{\mathbf{e} \in \mathbf{H}^s(\partial\omega)/\mathbf{e} = \mathbf{e}\mathbf{n},\ e \in H^s(\partial\omega)\},$$

and so

$$\mathbf{H}^s(\partial\omega) = TH^s(\partial\omega) \oplus NH^s(\partial\omega).$$

For the norms, we will use the standard Sobolev spaces notation, noting that all the new "quasi-periodic" spaces that we have defined are Hilbert spaces when equipped with the norms issued from the usual Sobolev spaces.

Finally, we recall some facts about Green formulae and traces. For sufficiently smooth $\mathbf{e}$ and $\mathbf{e}^*$, defined on a regular open set ϑ of $\mathbb{R}^3$, the following formulae hold:

$$\begin{aligned}\int_{\vartheta} [\Delta\mathbf{e}\cdot\overline{\mathbf{e}^*} + \operatorname{curl}\mathbf{e}\cdot\overline{\operatorname{curl}\mathbf{e}^*} + \operatorname{div}\mathbf{e}\,\overline{\operatorname{div}\mathbf{e}^*}]\,dv \\ = \int_{\partial\vartheta} [(\operatorname{curl}\mathbf{e}\times\mathbf{n})\cdot\overline{\mathbf{e}^*} + \gamma_0 \operatorname{div}\mathbf{e}(\mathbf{n}\cdot\overline{\mathbf{e}^*})]\,d\sigma,\end{aligned} \tag{1.9}$$

$$\int_{\vartheta} \Delta\mathbf{e}\cdot\overline{\mathbf{e}^*}\,dv = -\sum_{\alpha=1}^{3}\int_{\vartheta} \nabla e^{\alpha}\cdot\overline{\nabla e^{*\alpha}}\,dv + \int_{\partial\vartheta} \gamma_1\mathbf{e}\cdot\overline{\gamma_0\mathbf{e}}\,d\sigma. \tag{1.10}$$

We now give a precise formulation of these properties in our "q.p." framework.

PROPOSITION 1.1. *Let* $\mathbf{e}$ *and* $\mathbf{e}^*$ *belong to* $C_K^{\infty}(\mathbb{R}^3, \mathbb{C}^3)$. *Then* (1.9) *and* (1.10) *can be written*

$$\begin{aligned}\int_{\Omega^{\mathrm{ext}}} [\Delta\mathbf{e}\cdot\overline{\mathbf{e}^*} + \operatorname{curl}\mathbf{e}\cdot\overline{\operatorname{curl}\mathbf{e}^*} + \operatorname{div}\mathbf{e}\cdot\overline{\operatorname{div}\mathbf{e}^*}]\,dv \\ = \int_{\partial\omega} [(\operatorname{curl}\mathbf{e}\times\mathbf{n})\cdot\overline{\mathbf{e}^*} + \gamma_0 \operatorname{div}\mathbf{e}(\mathbf{n}\cdot\overline{\mathbf{e}^*})]\,d\sigma,\end{aligned} \tag{1.11}$$

$$\int_{\Omega^{\mathrm{ext}}} \Delta\mathbf{e}\cdot\overline{\mathbf{e}^*}\,dv = -\sum_{\alpha=1}^{3}\int_{\Omega^{\mathrm{ext}}} \nabla e^{\alpha}\cdot\overline{\nabla e^{*\alpha}}\,dv + \int_{\partial\omega} \gamma_1\mathbf{e}\cdot\overline{\gamma_0\mathbf{e}^*}\,d\sigma. \tag{1.12}$$

Moreover, these formulae can be extended to $\mathbf{e}$ *in* $H^1_{\Delta,K}(\Omega^{\mathrm{ext}}, \mathbb{C}^3)$ *and* $\mathbf{e}^*$ *in* $H^1_K(\Omega^{\mathrm{ext}}, \mathbb{C}^3)$. (*The integrals over* $\partial\omega$ *are then to be considered in a duality sense.*)

Remark. As mentioned earlier, we will show in fact that (1.12) leads to the following characterization of $H^1_{\Delta,K}(\Omega^{\mathrm{ext}}, \mathbb{C}^3)$:

$$\begin{aligned}H^1_{\Delta,K}(\Omega^{\mathrm{ext}}, \mathbb{C}^3) = \{\mathbf{e} \in H^1_K(\Omega^{\mathrm{ext}}, \mathbb{C}^3) \cap H^1_{\Delta}(\Omega^{\mathrm{ext}}, \mathbb{C}^3)/ \\ (1.12) \text{ holds for every } \mathbf{e}^* \in H^1_K(\Omega^{\mathrm{ext}}, \mathbb{C}^3)\}.\end{aligned}$$

Proof. $\partial\Omega^{\mathrm{ext}}$ can be written in the following form:

$$\partial\Omega^{\mathrm{ext}} = \partial\omega \cup \partial\Omega \quad \text{where } \partial\Omega \text{ is a lateral boundary, i.e.,}$$

$$\partial\Omega = \{-d_1/2, d_1/2\}\times[-d_2/2, d_2/2]\times\mathbb{R} \cup \{-d_2/2, d_2/2\}\times[-d_1/2, d_1/2]\times\mathbb{R}.$$

It is easy to see that "q.p." conditions for regular functions imply that the sum over $\partial\Omega$ vanishes. To extend these results to $H^1_{\Delta,K}(\Omega^{\mathrm{ext}}, \mathbb{C}^3)$ and $H^1_K(\Omega^{\mathrm{ext}}, \mathbb{C}^3)$ functions, we have first to give a precise meaning for the traces on $\partial\omega$ and $\partial\Omega$:

Using a compactly supported smooth extension of the normal field $\mathbf{n}$, defined on $\partial\omega$, to a neighbourhood of $\partial\omega$, with the property that $|\mathbf{n}| \equiv 1$ near $\partial\omega$, for $\mathbf{e}$ in $H^1_K(\Omega^{\mathrm{ext}}, \mathbb{C}^3) \cap H^1_{\Delta}(\Omega^{\mathrm{ext}}, \mathbb{C}^3)$, we can define the traces

$$\gamma_0 \operatorname{curl}\mathbf{e}\times\mathbf{n} \quad \text{in } TH^{-1/2}(\partial\omega), \qquad \gamma_1(\boldsymbol{n}\cdot E) \quad \text{in } H^{-1/2}(\partial\omega).$$

Here $\gamma_1(\cdot)$ stands for the second trace or normal derivative of a function defined in a neighbourhood of $\partial\omega$. As usual, for $\mathbf{e}$ in $H^1_K(\Omega^{\text{ext}}, \mathbb{C}^3) \cap H^1_\Delta(\Omega^{\text{ext}}, \mathbb{C}^3)$, we can define the traces

$$\gamma_0 \operatorname{div} \mathbf{e} \quad \text{in } H^{-1/2}(\partial\omega), \qquad \gamma_1 \mathbf{e} \quad \text{in } H^{-1/2}(\partial\omega).$$

Note that only the local regularity near $\partial\omega$ is needed to define the traces above.

In an equivalent way, we can define the same kind of traces on $\partial\Omega$:

$$\gamma_0 \operatorname{curl} \mathbf{e} \times \mathbf{n} \quad \text{in } TH^{-1/2}(\partial\Omega), \qquad \gamma_1(\mathbf{n} \cdot E) \quad \text{in } H^{-1/2}(\partial\Omega),$$

$$\gamma_0 \operatorname{div} \mathbf{e} \quad \text{in } H^{-1/2}(\partial\Omega), \qquad \gamma_1 \mathbf{e} \quad \text{in } H^{-1/2}(\partial\Omega).$$

The presence of "corners" and the infinite extent of this boundary is handled by a suitable localization of trace definitions.

Formulae (1.9) and (1.10) are used in the setting of the above definitions, and are naturally extended for functions in $H^1_K(\Omega^{\text{ext}}, \mathbb{C}^3) \cap H^1_\Delta(\Omega^{\text{ext}}, \mathbb{C}^3)$. We have to prove that if $\mathbf{e}$ is, moreover, in $H^1_{\Delta,K}(\Omega^{\text{ext}}, \mathbb{C}^3)$ then there is no contribution from $\partial\Omega$. In fact, (1.11) (respectively, (1.12)) gives the following characterization of $H^1_{\Delta,K}(\Omega^{\text{ext}}, \mathbb{C}^3)$:

$$H^1_{\Delta,K}(\Omega^{\text{ext}}, \mathbb{C}^3) = \{\mathbf{e} \in H^1_K(\Omega^{\text{ext}}, \mathbb{C}^3) \cap H^1_\Delta(\Omega^{\text{ext}}, \mathbb{C}^3)/(1.11) \text{ (respectively, (1.12)) holds for every } \mathbf{e}^* \text{ in } H^1_K(\Omega^{\text{ext}}, \mathbb{C}^3)\}.$$

To see this, we write

$$\int_{\partial\Omega} \gamma_1 \mathbf{e} \cdot \overline{\mathbf{e}^*}\, d\sigma = \int_{\Gamma_1} [\gamma_1 \mathbf{e}^{(K)}]_1 \cdot \overline{\mathbf{e}^*}\, d\sigma + \int_{\Gamma_2} [\gamma_1 \mathbf{e}^{(K)}]_2 \cdot \overline{\mathbf{e}^*}\, d\sigma$$

where

$\Gamma_1 := \{-d_1/2\} \times]-d_2/2, d_2/2[\times \mathbb{R}$,

$\Gamma_2 :=]-d_1/2, d_1/2[\times \{-d_2/2\} \times \mathbb{R}$,

$[\cdot]_i$ is the jump across Γ_i of functions with traces on these boundaries:

$$[\mathbf{u}]_1 := \mathbf{u}((-d_1/2)^+, x_2, x_3) - \mathbf{u}((-d/2)^-, x_2, x_3),$$

$$[\mathbf{u}]_2 := \mathbf{u}(x_1, (-d_2/2)^+, x_3) - \mathbf{u}(x_1, (-d_1/2)^-, x_3).$$

The + or − signs represent the two sides of each boundary $\partial\Omega$, oriented by the axes $(0, \mathbf{e}_1)$ and $(0, \mathbf{e}_2)$ (see Fig. 2).

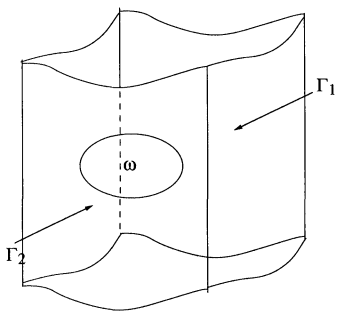

FIG. 2

It is not difficult to see that $\mathbf{e}^{(K)}$ is in $H^1_\Delta(\mathbb{R}^3\backslash\bar{S}, \mathbb{C}^3)$ if and only if the jumps $[\gamma_1\mathbf{e}^{(K)}]$ vanish, yielding the required result. □

These formulae are also valid if we take Ω^{ext}_ρ instead of Ω^{ext} but we then must consider contributions from Σ^ρ.

We now come to some facts involving traces and differential geometry tools. The following formulae can be used for smooth $\mathbf{e}$, $\mathbf{e}^*$:

$$\gamma_0 \operatorname{div} \mathbf{e} = \operatorname{div}_{\partial\omega}(\Pi\mathbf{e}) + 2H\mathbf{e}\cdot\mathbf{n} + \gamma_1(\mathbf{e}\cdot\mathbf{n}), \tag{1.13}$$

$$\mathbf{n}\cdot\mathbf{e}^*\gamma_0 \operatorname{div}\mathbf{e} = 2H\mathbf{e}\cdot\mathbf{e}^* + \gamma_1\mathbf{e}\cdot\overline{\gamma_0\mathbf{e}^*} \tag{1.14}$$

when $\mathbf{e}$ and $\mathbf{e}^*$ satisfy $\Pi\mathbf{e} = \Pi\mathbf{e}^* = \mathbf{0}$. Here, $\operatorname{div}_{\partial\omega}(\ )$ is the superficial divergence of a tangential field to $\partial\omega$, Π is the normal projection operator on the tangential plane of $\partial\omega$, and H is the mean value of the curvature at each point of the smooth surface $\partial\omega$. These formulae can be extended, by density, to fields $\mathbf{e}$ in $H^1_K(\Omega^{\text{ext}}, \mathbb{C}^3) \cap H^1_\Delta(\Omega^{\text{ext}}, \mathbb{C}^3)$ and $\mathbf{e}^*$ in $H^1_K(\Omega^{\text{ext}}, \mathbb{C}^3)$.

For a detailed analysis of all these properties, we refer the reader to [1].

1.4. The boundary value problem. We now have all the elements needed to set a mathematical boundary value problem, describing the physical situation, and which can be handled by standard functional analysis tools, related to Sobolev spaces formulations.

Our "whole space" problem will be:

(1.5) Find $\mathbf{e}$ in $H^{1,\text{loc}}_K(\mathbb{R}^3\backslash\bar{S}, \mathbb{C}^3) \cap H^{1,\text{loc}}_\Delta(\mathbb{R}^3\backslash\bar{S}, \mathbb{C}^3)$ such that

$$\begin{aligned} &\Delta\mathbf{e} + k^2\mathbf{e} = 0 && \text{in } \mathbb{R}^3\backslash\bar{S},\\ &\operatorname{div}\mathbf{e} = 0 && \text{in } \mathbb{R}^3\backslash\bar{S},\\ &\mathbf{n}\times\mathbf{e} = -\mathbf{n}\times\mathbf{e}^{\text{inc}} && \text{on } \partial S. \end{aligned}$$

$\mathbf{e}$ satisfies outgoing wave conditions (1.7).

We show that this problem is equivalent to the following one, which is set only in the "elementary cell":

(1.16) Find $\mathbf{e}$ in $H^{1,\text{loc}}_{\Delta,K}(\Omega^{\text{ext}}, \mathbb{C}^3)$ such that

$$\begin{aligned} &\Delta\mathbf{e} + k^2\mathbf{e} = 0 && \text{in } \Omega^{\text{ext}},\\ &\operatorname{div}\mathbf{e} = 0 && \text{in } \Omega^{\text{ext}},\\ &\mathbf{n}\times\mathbf{e} = -\mathbf{n}\times\mathbf{e}^{\text{inc}} && \text{on } \partial\omega. \end{aligned}$$

$\mathbf{e}$ satisfies outgoing wave conditions (1.7).

Indeed, $\mathbf{e}$ satisfying (1.15) can be extended by "quasi-periodicity" and its "quasi-periodic" extension $\mathbf{e}^{(K)}$ is easily found to solve (1.16). Conversely, the restriction to Ω^{ext} of any solution of (1.16) is clearly in $H^{1,\text{loc}}_{\Delta,K}(\Omega^{\text{ext}}, \mathbb{C}^3)$, and so solves (1.15).

Our study will now be focused on the analysis of problem (1.19) or on a slight extension of it:

(1.17) Find $\mathbf{e}$ in $H^{1,\text{loc}}_{\Delta,K}(\Omega^{\text{ext}}, \mathbb{C}^3)$ such that

$$\begin{aligned} &\Delta\mathbf{e} + k^2\mathbf{e} = 0 && \text{in } \Omega^{\text{ext}},\\ &\operatorname{div}\mathbf{e} = 0 && \text{in } \Omega^{\text{ext}},\\ &\mathbf{n}\times\mathbf{e} = \mathbf{c} \in TH^{1/2}(\partial\omega). \end{aligned}$$

$\mathbf{e}$ satisfies outgoing wave conditions (1.7).

2. Uniqueness properties. Our purpose is to establish the following uniqueness theorem.

THEOREM 2.1. *The problem*:

(P_k) *Find* $\mathbf{e}$ *in* $H^{1,\mathrm{loc}}_{\Delta,K}(\Omega^{\mathrm{ext}})$ *such that*

$$\Delta\mathbf{e}+k^2\mathbf{e}=\mathbf{0} \quad \text{in } \Omega^{\mathrm{ext}},$$
$$\operatorname{div}\mathbf{e}=0 \quad \text{in } \Omega^{\mathrm{ext}},$$
$$\mathbf{n}\times\mathbf{e}=\mathbf{0} \quad \text{on } \partial\omega.$$

$\mathbf{e}$ *satisfies the outgoing wave conditions* (1.13)

can have nontrivial solutions only if k *belongs to a set* K_{sing} *of exceptional values.* K_{sing} *is a countable set of positive reals that can be ordered in a nondecreasing sequence* $(k_n)_{n\geq 0}$, *tending to* $+\infty$.

Theorem 2.1 will be proved after some preliminary work: we will show that we can identify the restriction to $\Omega^{\mathrm{ext}}_\rho$ of a solution of (P_k) with an eigenvector of an operator acting on $L^2(\Omega^{\mathrm{ext}}_\rho)$, for which a complete spectral decomposition can be done.

To see how the truncated problem must be set, we begin by an analysis of some properties of a solution of (P_k).

2.1. Properties of solutions of (P_k). We begin with the following proposition.

PROPOSITION 2.2. *Let* $\mathbf{e}$ *be a solution of* (P_k). *Then* $\mathbf{e}$ *belongs to* $C^\infty(\overline{\Omega^{\mathrm{ext}}})$, *and the following expansion holds for* $|Z|>\rho_0$:

$$\mathbf{e}(X,Z)=\sum_{J\in\mathbb{Z}^2}\exp\left(i(\mathbf{K}+\mathbf{K}_J)\cdot X\right)\mathbf{e}_J(Z)$$

where the $\mathbf{e}_J$*'s are given by*

$$\mathbf{e}_J(Z)=\mathbf{e}_J^{0+}\exp\left(i\mu_J Z\right), \qquad Z>\rho_0,$$
$$\mathbf{e}_J(Z)=\mathbf{e}_J^{0-}\exp\left(-i\mu_J Z\right), \qquad Z<-\rho_0.$$

This series is absolutely convergent and termwise infinitely differentiable.

Proof. Regularity properties are local properties; thus, it can be easily deduced from the usual regularity properties (cf. [1], [2], for example), that

$$\mathbf{e}\in C^\infty(\Omega\backslash\omega,\mathbb{C}^3) \quad (\text{regularity up to } \partial\omega).$$

Having in mind then that the "q.p." extension of $\mathbf{e}$, $\mathbf{e}^{(k)}$ satisfies the Helmholtz equation in $\mathbb{R}^3\backslash S$, and using elliptic regularity properties for this equation again, but in $\mathbb{R}^3\backslash S$, we see that regularity goes up to the lateral part of the boundary, that is to say, $\partial\Omega$, and so we have

$$\mathbf{e}\in C^\infty(\overline{\Omega^{\mathrm{ext}}},\mathbb{C}^3).$$

The expansion can then be established as in § 1, having in mind that the regularity properties of $\mathbf{e}$ ensure that the series has the requested convergence. □

LEMMA 2.3. *Let* $\mathbf{e}$ *solve* (P_k) *and set*

$$J_k^+ := \{J\in\mathbb{Z}^2/|\mathbf{K}+\mathbf{K}_J|\geq k\},$$
$$J_k^- := \{J\in\mathbb{Z}^2/|\mathbf{K}+\mathbf{K}_J|<k\}.$$

Then $\mathbf{e}_J(Z)=0$ *for* $J\in J_k^-$ *and* $|Z|>\rho_0$; *hence, we have* $\mathbf{e}\in H^1_{\Delta,K}(\Omega^{\mathrm{ext}},\mathbb{C}^3)$, *except the case where there is a* J *in* J_k^+ *such that* $|\mathbf{K}+\mathbf{K}_J|=k$.

Proof. We apply Green formula in its usual form (see § 1.3) to the functions $\mathbf{e}$ and $\mathbf{e}$ in the set $\Omega^{\mathrm{ext}}_\rho$, for an arbitrarily chosen $\rho>\rho_0$:

$$0=\int_{\Omega^{\mathrm{ext}}_\rho}(\Delta\mathbf{e}\cdot\bar{\mathbf{e}}-\Delta\mathbf{e}\cdot\mathbf{e})\,dv=\int_{\partial\omega\cup\Sigma^\rho}(\gamma_1\mathbf{e}\cdot\overline{\gamma_0\mathbf{e}}-\overline{\gamma_1\mathbf{e}}\cdot\gamma_0\mathbf{e})\,d\sigma. \tag{2.1}$$

We treat separately the contributions from $\partial\omega$ and Σ^ρ to the boundary integral in (2.1).

On $\partial\omega$, the first trace of div $\mathbf{e}$, γ_0 div $\mathbf{e}$ vanishes. The use of (1.17) then yields

$$0 = 2H|\mathbf{e}|^2 + \gamma_1\mathbf{e} \cdot \overline{\gamma_0\mathbf{e}}. \tag{2.2}$$

Hence $\gamma_1\mathbf{e} \cdot \overline{\gamma_0\mathbf{e}}$ is real and the contribution of $\partial\omega$ to (2.1) cancels.

We now consider the contribution from Σ^ρ to the boundary integral in (2.1); thanks to the expansion of Proposition 2.2, we have

$$\int_{\Sigma^\rho} \gamma_1\mathbf{e} \cdot \overline{\gamma_0\mathbf{e}}\, d\sigma = d_1 d_2 \sum_{J\in\mathbb{Z}^2} i\mu_J(|\mathbf{e}_J^{0+}|^2 + |\mathbf{e}_J^{0-}|^2) \exp(i(\mu_J - \overline{\mu_J})\rho).$$

Now, we see that

$$J \in J_k^+ \Rightarrow i\mu_J \exp(i(\mu_J - \overline{\mu_J})\rho) \in \mathbb{R}.$$

This, with (2.1), implies that

$$2d_1 d_2 \sum_{J\in J_k^-} i\mu_J(|\mathbf{e}_J^{0+}|^2 + |\mathbf{e}_J^{0-}|^2) = 0.$$

Thus we find that

$$|\mathbf{e}_J^{0+}| = |\mathbf{e}_J^{0-}| = 0 \quad \text{for all } J \text{ in } J_k^-.$$

Hence $\mathbf{e}_J(Z) = 0$ for all J in J_k^- and $|Z| > \rho_0$.

If there is no index $J \in \mathbb{Z}^2$ such that $|\mathbf{K} + \mathbf{K}_J| = k$, the fact that $\mathbf{e}$ is in $H^1_{\Delta,K}(\Omega^{\text{ext}})$ follows easily from the exponential decrease of $\mathbf{e}_J(Z)$ for J in J_k^+. □

Lemma 2.3 shows, in this last case, that a solution of (P_k) appears as an eigenfunction of the unbounded operator of $\mathbf{L}^2(\Omega^{\text{ext}}, \mathbb{C}^3)$, A, defined by

$$D(A) := \{\mathbf{e} \in H^1_{\Delta,K}(\Omega^{\text{ext}})/\mathbf{n}\times\mathbf{e} = \mathbf{0} \text{ on } \partial\omega;\ \gamma_0 \text{ div } \mathbf{e} = 0 \text{ on } \partial\omega\},$$

$$A\mathbf{e} := -\Delta\mathbf{e} \quad \text{for } \mathbf{e} \quad \text{in } D(A).$$

We will not study directly the spectrum of A. However, the main properties of A are summarized in the following proposition which will be given without its proof.

PROPOSITION 2.4. *A is a self-adjoint operator on $\mathbf{L}^2(\Omega^{\text{ext}}; C^3)$, with dense domain. Its spectrum $\Sigma(A)$ is such that*

$$\Sigma(A) \subset [0; +\infty[,$$

$$\Sigma_{\text{ess}}(A) = [m; +\infty[$$

where

$$m = \min_{J\in Z^2} \{|K + K_J|\}.$$

Theorem 2.1 states that A has at most a sequence tending to $+\infty$ of eigenvalues in its spectrum.

2.2. The truncated problem. We now turn to the study of a problem set in a truncated domain Ω_ρ^{ext} for $\rho \geqq \rho_0$. To this end, we introduce Hilbert spaces of "q.p." functions defined on Ω_ρ^{ext}, which are given by

$$C_K^\infty(\Omega_\rho^{\text{ext}}, \mathbb{C}^3) = \{\mathbf{e}_{|\Omega_\rho^{\text{ext}}} : \mathbf{e} \in C_K^\infty(\Omega^{\text{ext}}, \mathbb{C}^3)\},$$

$$H_K^1(\Omega_\rho^{\text{ext}}, \mathbb{C}^3) = \{\mathbf{e}_{|\Omega_\rho^{\text{ext}}} : \mathbf{e} \in H_K^1(\Omega_\rho^{\text{ext}}, \mathbb{C}^3)\},$$

$$H^1_{\Delta,K}(\Omega_\rho^{\text{ext}}, \mathbb{C}^3) = \{\mathbf{e}_{|\Omega_\rho^{\text{ext}}} : \mathbf{e} \in H^1_{\Delta,K}(\Omega^{\text{ext}}, \mathbb{C}^3)\}.$$

These spaces are endowed with their natural norms. We begin by giving some trace properties on Σ^ρ for functions in $H^1_K(\Omega^{\text{ext}}_\rho, \mathbb{C}^3)$ and $H^1_{\Delta,K}(\Omega^{\text{ext}}_\rho, \mathbb{C}^3)$, which will enable us to set the appropriate truncation relations on Σ^ρ. The usual trace properties are slightly complicated by the decomposition of $\partial\Omega^{\text{ext}}_\rho$ in three parts of different "nature": $\partial\Omega^{\text{ext}}_\rho = \partial\omega \cup \Sigma^\rho \cup \Gamma_1$, where Γ_1 is the lateral part of the boundary i.e., $\Gamma_1 := \partial\Omega^{\text{ext}}_\rho \cap \partial\Omega$. (See Fig. 3.)

We show that we can extend a "q.p." version of the first trace γ_0, well defined for functions in $C^\infty_K(\Omega^{\text{ext}}_\rho, \mathbb{C}^3)$, to $H^1_K(\Omega^{\text{ext}}_\rho \mathbb{C}^3)$, with values in a fractionary order Sobolev space of "q.p." functions over Σ^ρ. We then get similar results for second traces of functions in $H^1_{\Delta,K}(\Omega^{\text{ext}}_\rho, \mathbb{C}^3)$, which will be defined in a fractionary order Sobolev space of "q.p." distributions on Σ^ρ.

Let $\mathbf{e}$ be in $C^\infty_K(\Omega^{\text{ext}}_\rho, \mathbb{C}^3)$ and φ be a $C^\infty(\mathbb{R})$ function, with $\varphi \equiv 1$ near $Z = \pm\rho$ vanishing for $|Z| < \rho_0$. Consider the "q.p." expansion of $\mathbf{e}$; we have

$$|\mathbf{e}_J(\rho)|^2 = 2\,\text{Re}\left(\int_{\rho_0}^{+\rho} \frac{\partial}{\partial z}\mathbf{e}_J(z)\cdot\overline{\mathbf{e}_J(z)}\varphi(z)\,dz\right) + \int_{\rho_0}^{+\rho}\frac{\partial}{\partial z}\varphi(z)|\mathbf{e}_J(z)|^2\,dz.$$

Hence there exist two constants C and C' such that

$$|\mathbf{e}_J(\rho)|^2 \leqq 2C|\mathbf{e}_J|_{L^2(\rho_0,\rho)} \times \left|\frac{\partial}{\partial z}\mathbf{e}_J\right|_{L^2(\rho_0,\rho)} + C'|\mathbf{e}_J|^2_{L^2(\rho_0,\rho)}.$$

So, multiplying this inequality by $|\mathbf{K}+\mathbf{K}_J|$ and adding the corresponding terms, we have

$$\sum_{J\in\mathbb{Z}^2}|\mathbf{K}+\mathbf{K}_J||\mathbf{e}_J(\rho)|^2 \leqq C\left(\sum_{J\in\mathbb{Z}^2}|\mathbf{K}+\mathbf{K}_J|^2|\mathbf{e}_J|^2_{L^2(\rho_0,\rho)} + \sum_{J\in\mathbb{Z}^2}\left|\frac{\partial}{\partial z}\mathbf{e}_J\right|^2_{L^2(\rho_0,\rho)}\right) + C'\sum_{J\in\mathbb{Z}^2}|\mathbf{K}+\mathbf{K}_J||\mathbf{e}_J|^2_{L^2(\rho_0,\rho)}.$$

Thus we conclude that

$$\sum_{J\in\mathbb{Z}^2}|\mathbf{K}+\mathbf{K}_J||\mathbf{e}_J(\rho)|^2 \leqq C''|\mathbf{e}|^2_{1,\Omega^{\text{ext}}_\rho}$$

and the same estimate holds for $Z = -\rho$.

For $\mathbf{e}$ in $L^2(\Sigma^\rho, \mathbb{C}^3)$ we set

$$|\mathbf{e}|^2_{1/2,\Sigma^\rho} := \sum_{J\in\mathbb{Z}^2}(1+|\mathbf{K}+\mathbf{K}_J|^2)^{1/2}(|\mathbf{e}^+_J|^2+|\mathbf{e}^-_J|^2) \tag{2.3}$$

where

$$\mathbf{e}^+_J \text{ (respectively, } \mathbf{e}^-_J) := \int_{\Sigma^\rho\cap\{z=+\rho\,(\text{respectively, } z=-\rho)\}} \mathbf{e}(X)\exp\left(-i(\mathbf{K}+\mathbf{K}_J)\cdot X\right)d\sigma_X$$

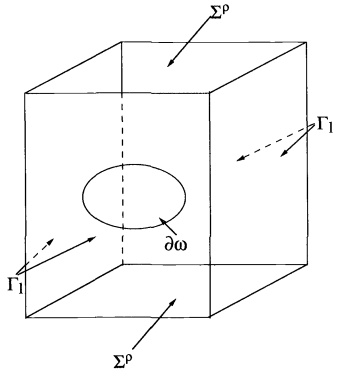

FIG. 3

and we define $H_K^{1/2}(\Sigma^\rho, \mathbb{C}^3)$ as the space of functions $\mathbf{e}$ in $L^2(\Sigma^\rho, \mathbb{C}^3)$ for which $|\mathbf{e}|_{1/2,\Sigma^\rho} < +\infty$.

$H_K^{1/2}(\Sigma^\rho, \mathbb{C}^3)$ can be given a Hilbert space structure, by means of formula (2.3). It is then clear that we can define a continuous trace γ_0 on Σ^ρ for functions of $H_K^1(\Omega_\rho^{\text{ext}}, \mathbb{C}^3)$, in the space $H_K^{1/2}(\Sigma^\rho, \mathbb{C}^3)$, extending by density formula (2.3).

Now, for functions in $H_{\Delta,K}^1(\Omega_\rho^{\text{ext}}, \mathbb{C}^3)$ we carry out the same program and show that we can define a second trace in the space $H_K^{-1/2}(\Sigma^\rho, \mathbb{C}^3)$, defined similarly to $H_K^{1/2}(\Sigma^\rho, \mathbb{C}^3)$ by

$$H_K^{-1/2}(\Sigma^\rho, \mathbb{C}^3) = \left\{ \mathbf{v} = \sum_{J \in Z^2} \mathbf{v}_J \exp\left(i(K + K_J) \cdot X\right) : \sum_{J \in Z^2} |\mathbf{v}_J|^2 (1 + |K + K_J|^2)^{-1/2} < +\infty \right\}$$

where the summation over Z^2 of the oscillating exponentials is to be understood in a distributional sense ("q.p." distributions on the "torus" Σ^ρ). $H_K^{-1/2}(\Sigma^\rho, \mathbb{C}^3)$ can be identified with $(H_K^{1/2}(\Sigma^\rho, \mathbb{C}^3))'$, the dual space of $H_K^{1/2}(\Sigma^\rho, \mathbb{C}^3)$, when $L^2(\Sigma^\rho, \mathbb{C}^3)$ is identified with its own dual. The (anti-)duality pairing between these spaces is obviously given by

$$\langle \mathbf{v}', \mathbf{v} \rangle_{-1/2,1/2} = \sum_{J \in Z^2} \mathbf{v}_J' \mathbf{v}_J.$$

Let $\mathbf{e}$ be in $C_K^\infty(\Omega_\rho^{\text{ext}}, \mathbb{C}^3)$ and take φ as above; we have

$$\left| \frac{\partial}{\partial z} \mathbf{e}_J(\rho) \right|^2 = 2 \operatorname{Re} \left(\int_{\rho_0}^{+\rho} \frac{\partial^2}{\partial z^2} \mathbf{e}_J(z) \cdot \frac{\partial}{\partial z} \overline{\mathbf{e}_J(z)} \varphi(z)\, dz \right) + \int_{\rho_0}^{+\rho} \frac{\partial}{\partial z} \varphi(z) \left| \frac{\partial}{\partial z} \mathbf{e}_J(z) \right|^2 dz.$$

Hence

$$\left| \frac{\partial}{\partial z} \mathbf{e}_J(\rho) \right|^2 \leqq 2C \left| \frac{\partial^2}{\partial z^2} \mathbf{e}_J \right|_{L^2(\rho_0,\rho)} \times \left| \frac{\partial}{\partial z} \mathbf{e}_J \right|_{L^2(\rho_0,\rho)} + C' \left| \frac{\partial}{\partial z} \mathbf{e}_J \right|^2_{L^2(\rho_0,\rho)}.$$

So, dividing this inequality by $p_J := (1 + |\mathbf{K} + \mathbf{K}_J|^2)^{1/2}$ and adding the corresponding terms, we have

$$\begin{aligned} \sum_{J \in \mathbb{Z}^2} \frac{1}{p_J} \left| \frac{\partial}{\partial z} \mathbf{e}_J(\rho) \right|^2 &\leqq C \left(\sum_{J \in \mathbb{Z}^2} \frac{1}{p_J^2} \left| \frac{\partial^2}{\partial z^2} \mathbf{e}_J \right|^2_{L^2(\rho_0,\rho)} + \sum_{J \in \mathbb{Z}^2} \left| \frac{\partial}{\partial z} \mathbf{e}_J \right|^2_{L^2(\rho_0,\rho)} \right) \\ &\quad + C' \sum_{J \in \mathbb{Z}^2} \frac{1}{p_J} |\mathbf{e}_J|^2_{L^2(\rho_0,\rho)}. \end{aligned} \tag{2.4}$$

As $\mathbf{e}$ is very regular, each one of the sums in the right member of (2.4) makes sense; we now try to get estimates in $H_{\Delta,K}^1(\Omega_\rho^{\text{ext}}, \mathbb{C}^3)$ as follows. We have

$$\begin{aligned} &\frac{1}{p_J^2} \left| \frac{\partial^2}{\partial z^2} \mathbf{e}_J \right|^2_{L^2(\rho_0,\rho)} \\ &\quad \leqq \frac{3}{2} \left(\frac{1}{p_J^2} \left| \frac{\partial^2}{\partial z^2} \mathbf{e}_J - |\mathbf{K} + \mathbf{K}_J|^2 \mathbf{e}_J \right|^2_{L^2(\rho_0,\rho)} + \frac{|\mathbf{K} + \mathbf{K}_J|^4}{p_J^2} |\mathbf{e}_J|^2_{L^2(\rho_0,\rho)} \right) \end{aligned}$$

and

$$\Delta \mathbf{e}(X, Z) = \sum_{J \in \mathbb{Z}^2} \left(\frac{\partial^2}{\partial z^2} \mathbf{e}_J - |\mathbf{K} + \mathbf{K}_J|^2 \mathbf{e}_J \right) \exp\left(i(\mathbf{K} + \mathbf{K}_J) \cdot X\right) \quad \text{for } \rho \geqq |Z| \leqq \rho_0,$$

is in $L^2(\Omega_\rho^{\text{ext}}, \mathbb{C}^3)$. Thus, we conclude that

$$\sum_{J \in \mathbb{Z}^2} (1 + |\mathbf{K} + \mathbf{K}_J|^2)^{-1/2} \left| \frac{\partial}{\partial z} \mathbf{e}_J(\rho) \right|^2 \leqq C''(|\mathbf{e}|^2_{1,\Omega_\rho^{\text{ext}}} + |\Delta \mathbf{e}|^2_{0,\Omega_\rho^{\text{ext}}})$$

and the same estimate holds for $Z = -\rho$.

This shows that the mapping $\mathbf{e} \to (\partial \mathbf{e}/\partial \mathbf{n}) = \gamma_1 \mathbf{e}$ can be continuously extended to $H^1_{\Delta,K}(\Omega_\rho^{\text{ext}}, \mathbb{C}^3)$ with values in $H_K^{-1/2}(\Sigma^\rho, \mathbb{C}^3)$. Here we have used the fact, pointed out in § 1.3, that $H^1_K(\Omega_\rho^{\text{ext}}, \mathbb{C}^3)$ is the closure of $C^\infty_K(\Omega_\rho^{\text{ext}}, \mathbb{C}^3)$ for the $\|.\|_{\Delta,\Omega_\rho^{\text{ext}}}$ norm.

We now come to the definition of an operator, acting on the space $H_K^{1/2}(\Sigma^\rho, \mathbb{C}^3)$ with values in $(H_K^{1/2}(\Sigma^\rho, \mathbb{C}^3))'$ given by the following proposition ($(\cdot)^+$ (respectively, $(\cdot)^-$), is the value on $Z = +\rho$ (respectively, $Z = -\rho$), of a function defined on Σ^ρ).

PROPOSITION 2.5. *Let $C^\infty_K(\Sigma^\rho, \mathbb{C}^3)$ be the set of regular* "q.p." *functions of Σ^ρ. Then T_k defined for $\mathbf{e}$ in $C^\infty_K(\Sigma^\rho, \mathbb{C}^3)$ by*

$$(T_k \mathbf{e})^+ = i \sum_{J \in J_k^+} \mu_J(k) \mathbf{e}_J^+ \exp\left(i(\mathbf{K}+\mathbf{K}_J)\cdot X\right),$$

$$(T_k \mathbf{e})^- = i \sum_{J \in J_k^+} \mu_J(k) \mathbf{e}_J^- \exp\left(i(\mathbf{K}+\mathbf{K}_J)\cdot X\right)$$

can be extended to a continuous linear operator from $H_K^{1/2}(\Sigma^\rho, \mathbb{C}^3)$ to the set $(H_K^{1/2}(\Sigma^\rho, \mathbb{C}^3))'$.

Moreover, T_k satisfies the following relations. For all

$$\mathbf{e}, \mathbf{e}^* \in \{H_K^{1/2}(\Sigma^\rho, \mathbb{C}^3)\}^2:$$

(i) $$\langle T_k \mathbf{e}, \mathbf{e}^* \rangle = \langle T_k \mathbf{e}^*, \mathbf{e} \rangle,$$

(ii) $$\langle T_k \mathbf{e}, \mathbf{e} \rangle \leqq 0.$$

$\langle \cdot, \cdot \rangle$ stands for the duality brackets between $(H_K^{1/2}(\Sigma^\rho, \mathbb{C}^3))'$ and $H_K^{1/2}(\Sigma^\rho, \mathbb{C}^3)$.

Proof. Take smooth $\mathbf{e}$ and $\mathbf{e}^*$ and consider

$$\int_{\Sigma^\rho} T_k \mathbf{e} \cdot \overline{\mathbf{e}^*}\, d\sigma_X = -d_1 d_2 \sum_{J \in J_k^+} |\mu_J(k)| (\mathbf{e}_J^+ \cdot \overline{\mathbf{e}_J^{+*}} + \mathbf{e}_J^- \cdot \overline{\mathbf{e}_J^{-*}}).$$

We clearly have

$$\left| \sum_{J \in J_k^+} \left| \mu_J(k) |\mathbf{e}_J^+ \cdot \overline{\mathbf{e}_J^{+*}}|^2 \leqq \left(\sum_{J \in J_k^+} |\mu_J(k)| |\mathbf{e}_J^+|^2 \right) \left(\sum_{J \in J_k^+} |\mu_J(k)| |\mathbf{e}_J^{+*}|^2 \right) \right.$$

and the same estimate holds for the terms with a minus sign. But

$$|\mu_J(k)| \leqq |\mathbf{K} + \mathbf{K}_J|$$

and so,

$$|\langle T_k \mathbf{e}, \mathbf{e}^* \rangle| \leqq c |\mathbf{e}|_{1/2,\Sigma^\rho} |\mathbf{e}^*|_{1/2,\Sigma^\rho}.$$

This estimate ends the proof of the first part of Proposition 2.5. Properties (i) and (ii) are immediate for regular functions and can be extended by density for functions in $H_K^{1/2}(\Sigma^\rho, \mathbb{C}^3)$. □

The following proposition justifies the introduction of T.

PROPOSITION 2.6. *Let $\mathbf{e}$ solve (P_k); then the traces on Σ^ρ of the restriction to Ω_ρ^{ext} of $\mathbf{e}$ satisfy*

$$\gamma_1 \mathbf{e} = T(\gamma_0 \mathbf{e}). \tag{2.5}$$

Proof. We just have to consider the expansion of $\mathbf{e}$ given by Proposition 2.2 and take its normal derivative on Σ^ρ. Using then Proposition 2.2, we see that there is no component $\mathbf{e}_J(z)$, with $J \in J_k^-$. This enables us to write (2.5). □

We are now led to the study of an operator A_k, defined as a realization of $-\Delta$ on Ω_ρ^{ext}, satisfying (2.5) on Σ^ρ, the electric boundary value condition on $\partial\omega$, and "q.p." conditions on the lateral boundary.

$$D(A_k) := \{\mathbf{e} \in H^1_{\Delta,K}(\Omega_\rho^{\text{ext}}, \mathbb{C}^3)/\mathbf{n}\times\mathbf{e} = \mathbf{0} \text{ on } \partial\omega;$$
$$\gamma_0 \operatorname{div} \mathbf{e} = 0 \text{ on } \partial\omega\colon \gamma_1\mathbf{e} = T(\gamma_0\mathbf{e}) \text{ on } \Sigma^\rho\},$$
$$A_k\mathbf{e} := -\Delta\mathbf{e} \quad \text{for } \mathbf{e} \text{ in } D(A_k).$$

Thanks to Proposition 1.1 and the above trace properties, we can state the following characterization of the space $H^1_{\Delta,K}(\Omega_\rho^{\text{ext}}, \mathbb{C}^3)$, which will make easier the analysis of A_k.

$$H^1_{\Delta,K}(\Omega_\rho^{\text{ext}}, \mathbb{C}^3) := \Big\{ \mathbf{e} \in H^1_K(\Omega_\rho^{\text{ext}}, \mathbb{C}^3) \cap H^1_\Delta(\Omega_\rho^{\text{ext}}, \mathbb{C}^3) \Big/$$
$$\forall\, \mathbf{e}^* \in H^1_K(\Omega_\rho^{\text{ext}}, \mathbb{C}^3) \int_{\Omega_\rho^{\text{ext}}} \Delta\mathbf{e} \cdot \overline{\mathbf{e}^*}\, dv$$
$$= -\sum_{\alpha=1}^{3} \int_{\Omega_\rho^{\text{ext}}} \nabla e^\alpha \cdot \overline{\nabla e^\alpha}\, dv + \int_{\partial\omega \cup \Sigma^\rho} \gamma_1\mathbf{e} \cdot \overline{\gamma_0\mathbf{e}^*}\, d\sigma \Big\}.$$

Here, the sum over $\partial\omega \cup \Sigma^\rho$ is to be understood in a duality sense.

We will prove the following theorem.

THEOREM 2.7. *A_k is a self-adjoint, densely defined operator, with compact resolvent.*

Proof. The set of smooth functions vanishing in a neighbourhood of $\partial\Omega_\rho^{\text{ext}}$ is dense in $L^2(\Omega_\rho^{\text{ext}}, \mathbb{C}^3)$ and is embedded in $D(A_k)$.

Take $\mathbf{e}$ and $\mathbf{e}^*$ in $D(A_k)$; using Green formula we get

$$\int_{\Omega_\rho^{\text{ext}}} (\Delta\mathbf{e} \cdot \overline{\mathbf{e}^*} - \overline{\Delta\mathbf{e}^*} \cdot \mathbf{e})\, dv = \int_{\partial\omega \cup \Sigma^\rho} (\gamma_1\mathbf{e} \cdot \overline{\gamma_0\mathbf{e}^*} - \overline{\gamma_1\mathbf{e}^*} \cdot \gamma_0\mathbf{e})\, d\sigma. \tag{2.6}$$

Using formulae (1.16), (1.17) on $\partial\omega$, we see that

$$\gamma_1\mathbf{e} \cdot \overline{\gamma_0\mathbf{e}^*} - \overline{\gamma_1\mathbf{e}^*} \cdot \gamma_0\mathbf{e} = -2H\gamma_0\mathbf{e} \cdot \overline{\gamma_0\mathbf{e}^*} + 2H\overline{\gamma_0\mathbf{e}^*} \cdot \gamma_0\mathbf{e} = 0 \quad \text{on } \partial\omega.$$

On Σ^ρ, boundary relations enable us to write

$$\int_{\Sigma^\rho} (\gamma_1\mathbf{e} \cdot \overline{\gamma_0\mathbf{e}^*} - \overline{\gamma_1\mathbf{e}^*} \cdot \gamma_0\mathbf{e})\, d\sigma = \langle T_k\mathbf{e}, \mathbf{e}^*\rangle - \overline{\langle T_k\mathbf{e}^*, \mathbf{e}\rangle} = 0.$$

Thus the left-hand side of (2.6) vanishes and A_k is symmetric.

We show that, for δ sufficiently large, $A_k + \delta I$ is maximal positive, so that self-adjointness will follow standard arguments. For this purpose, let us analyse the following problem:

(2.7) For $\mathbf{f}$ in $L^2(\Omega_\rho^{\text{ext}}, \mathbb{C}^3)$, find $\mathbf{e}$ in $D(A_k)$ such that

$$A_k\mathbf{e} + \gamma\mathbf{e} = \mathbf{f}.$$

Problem (2.7) has one and only one solution, for γ large enough, which is given by the solution of a variational problem set as follows.

We define

$$\mathbf{V}(\Omega_\rho^{\text{ext}}) := \{\mathbf{e} \in H^1_K(\Omega_\rho^{\text{ext}}, \mathbb{C}^3)/\mathbf{n}\times\mathbf{e} = \mathbf{0} \text{ on } \partial\omega\}$$

and

$$a_k(\mathbf{e}, \mathbf{e}^*) := \sum_{\alpha=1}^{3} (\nabla e^\alpha \,|\, \nabla e^{*\alpha})_{0,\Omega_\rho^{\text{ext}}} - \langle T_k\mathbf{e}, \mathbf{e}^*\rangle - 2\int_{\partial\omega} H(\mathbf{e} \cdot \overline{\mathbf{e}^*})\, d\sigma.$$

Then, a variational formulation of (2.7) is:

(2.8) Find $\mathbf{e}$ in $\mathbf{V}(\Omega_\rho^{\text{ext}})$ such that, for all $\mathbf{e}^*$ in $\mathbf{V}(\Omega_\rho^{\text{ext}})$,

$$a_k(\mathbf{e}, \mathbf{e}^*) + \gamma(\mathbf{e}|\mathbf{e}^*)_{0,\Omega_\rho^{\text{ext}}} = (\mathbf{f}|\mathbf{e}^*)_{0,\Omega_\rho^{\text{ext}}}.$$

Lemma 2.8, which will be proved later, gives the properties of (2.8).

LEMMA 2.8. *There is a positive real γ^* such that, for all $\gamma \geqq \gamma^*$, we have that $a_k(\cdot,\cdot)+\gamma(\cdot|\cdot)_{0,\Omega_\rho^{\text{ext}}}$ is a continuous coercive sesquilinear form on the Hilbert space $(\mathbf{V}(\Omega_\rho^{\text{ext}}), \|\cdot\|_{1,\Omega_\rho^{\text{ext}}})$.*

Lemma 2.8 and the Lax-Milgram theorem enable us to state that problem (2.8) has one and only one solution, for a given $\mathbf{f}$ in $L^2(\Omega_\rho^{\text{ext}})$ and $\gamma \geqq \gamma^*$.

It remains to show that the solution of (2.6) belongs to $D(A_k)$, and leads to (2.7). This is a matter of classical tools in the analysis of variational problems, and we omit the proof.

$D(A_k)$ is compactly embedded in $L^2(\Omega_\rho^{\text{ext}}, \mathbb{C}^3)$; thus, A_k has compact resolvent. This ends the proof of Theorem 2.7. □

Proof of Lemma 2.8. In view of Proposition 2.5 and trace results of § 1, it is clear that $a_k(\cdot,\cdot)$ is well defined and continuous on $(\mathbf{V}_k(\Omega_\rho^{\text{ext}}), \|\cdot\|_{1,\Omega_\rho^{\text{ext}}})$. We now prove that $a_k(\cdot,\cdot)+\gamma(\cdot|\cdot)_{0,\Omega_\rho^{\text{ext}}}$ is coercive, with respect to the norm $\|\cdot\|_{1,\Omega_\rho^{\text{ext}}}$. Thanks to Proposition 2.5(ii), we have

$$a_k(\mathbf{e}, \mathbf{e}) + \gamma(\mathbf{e}|\mathbf{e})_{0,\Omega_\rho^{\text{ext}}} \geqq |\mathbf{e}|^2_{1,\Omega_\rho^{\text{ext}}} + \gamma|\mathbf{e}|^2_{0,\Omega_\rho^{\text{ext}}} \int_{\partial\omega} 2H|\mathbf{e}|^2 \, d\sigma.$$

But for every $\varepsilon > 0$, we have the estimate (see [7])

$$|\mathbf{e}|^2_{0,\partial\omega} \leqq \varepsilon|\mathbf{e}|^2_{1,\Omega_\rho^{\text{ext}}} + c(\varepsilon)|\mathbf{e}|^2_{0,\Omega_\rho^{\text{ext}}}.$$

Thus for γ large enough, $a_k(\mathbf{e}, \mathbf{e})+\gamma(\mathbf{e}|\mathbf{e})_{0,\Omega_\rho^{\text{ext}}} \geqq \alpha\|\mathbf{e}\|^2_{1,\Omega_\rho^{\text{ext}}}$ for a positive real α. □

A_k is the m-sectorial operator related to the sesquilinear form $a_k(\cdot,\cdot)$ in the sense of Kato's first representation theorem (see [6]).

Our next step is to get the spectral structure of A_k. We can apply to A_k standard results on self-adjoint operators, bounded from below and with compact resolvent. Thus we can state the following theorem (see [5]).

THEOREM 2.9. *There is a complete orthonormal basis of $L^2(\Omega_\rho^{\text{ext}}, \mathbb{C}^3)$, $\{\bar{\Phi}_n\}$, in $D(A_k)$ such that*

$$A_k\bar{\Phi}_n = \lambda_n\bar{\Phi}_n \quad \text{with } \lambda_1 \leqq \lambda_2 \leqq \cdots \leqq \lambda_n \uparrow +\infty$$

and $\lambda_n = \lambda_n(A_k)$ is given by the Min-Max *principle, which can be written in the following form*:

$$\lambda_n(A_k) = \operatorname*{Max}_{\mathbf{e}_1,\cdots,\mathbf{e}_n} \left\{ \operatorname*{Min}_{\substack{\mathbf{e}\in[\mathbf{e}_1,\cdots,\mathbf{e}_n]^\perp \\ |\mathbf{e}|_{0,\Omega_\rho^{\text{ext}}}=1;\ \mathbf{e}\in\mathbf{V}(\Omega_\rho^{\text{ext}})}} a_k(\mathbf{e}, \mathbf{e}) \right\} \tag{2.9}$$

Proof (see [5, Thm. XIII.64]). Here, we write the Min-Max principle in its "form" version [5, Thm. XIII.2], having in mind that the form domain of $a_k(\cdot,\cdot)$ is just $\mathbf{V}(\Omega_\rho^{\text{ext}})$. □

The Min-Max principle allows us to study the behaviour of $\lambda_n(A_k)$ as a function of k as follows.

PROPOSITION 2.10. *For each n, $\lambda_n(A_k)$ is a decreasing continuous function of k.*

Proof. Let $\mathbf{e}$ belong to $\mathbf{V}(\Omega_\rho^{\text{ext}})$; the dependence on k of $a_k(\mathbf{e}, \mathbf{e})$ is given by the sum

$$i \sum_{J\in J_k^+} \mu_J(k)(|\mathbf{e}_J^+|^2 + |\mathbf{e}_J^-|^2) \qquad (\in \mathbb{R}). \tag{2.10}$$

But clearly each term in (2.10) is a decreasing function of k; moreover, the sets $(J_k^+)_k$ decrease when k increases so that the sum (2.10) has the same property. This behaviour is conserved when we consider the Min-Max (2.9).

Take $\mathbf{e}$ in $\mathbf{V}(\Omega_\rho^{\text{ext}})$, with $|\mathbf{e}|_{0,\Omega_\rho^{\text{ext}}} = 1$. Then

$$a_k(\mathbf{e},\mathbf{e}) - a_{k'}(\mathbf{e},\mathbf{e}) = i \sum_{J \in J_k^+} (\mu_J(k) - \mu_J(k'))(|\mathbf{e}_J^+|^2 + |\mathbf{e}_J^-|^2).$$

We next consider the family $\hat{\mu}_J(k)$ of the extensions of $\mu_J(k)$ by 0, when $k \geqq |\mathbf{K} + \mathbf{K}_J|$. It is easily seen that the resulting family $\hat{\mu}_J(k)$ is equicontinuous. Hence for every $\varepsilon > 0$ there is an $\eta(\varepsilon)$ such that

$$|k - k'| \leqq \eta(\varepsilon) \Rightarrow \forall J \in \mathbb{Z}^2, \qquad |\mu_J(k) - \mu_J(k')| \leqq \varepsilon.$$

Hence, if $|k - k'| \leqq \eta(\varepsilon)$,

$$a_k(\mathbf{e},\mathbf{e}) - a_{k'}(\mathbf{e},\mathbf{e}) \leqq \varepsilon \sum_{J \in \mathbb{Z}^2} (|\mathbf{e}_J^+|^2 + |\mathbf{e}_J^-|^2).$$

Now choosing γ as in Lemma 2.8, we get

$$a_k(\mathbf{e},\mathbf{e}) \leqq a_{k'}(\mathbf{e},\mathbf{e}) + \varepsilon c(a_{k'}(\mathbf{e},\mathbf{e}) + \gamma)$$

where c is a constant independent of $\mathbf{e}$. For ε small enough, taking the Max-Min of this inequality, we obtain

$$\lambda_n(A_k) \leqq \lambda_n(A_{k'})(1 + c\varepsilon) + \varepsilon c\gamma.$$

We can also write

$$\lambda_n(A_{k'})(1 - c\varepsilon) \leqq \lambda_n(A_k) + \varepsilon c\gamma.$$

Hence

$$|\lambda_n(A_{k'}) - \lambda_n(A_k)| \leqq \varepsilon c |\lambda_n(A_{k'})| + \varepsilon\gamma c,$$

which yields the continuity of $\lambda_n(A_k)$ as a function of k.

In fact, it can be shown that $\lambda_n(A_k)$ is a piecewise analytical function of k, by using results of [6] on holomorphic families of operators for a suitable extension of A_k for complex values of k.

LEMMA 2.11. *The set K_{sing} of real numbers k for which there is an $n \in \mathbb{N}$ such that*

$$\lambda_n(A_k) = k^2 \tag{2.12}$$

is, at most, an increasing sequence $(k_n)_n$ tending to $+\infty$.

Proof. The situation is now understood after the analysis of Fig. 4. We just look after the crossings of the graphs of $k \to k^2$ and $k \to \lambda_n(A_k)$, for the different values of

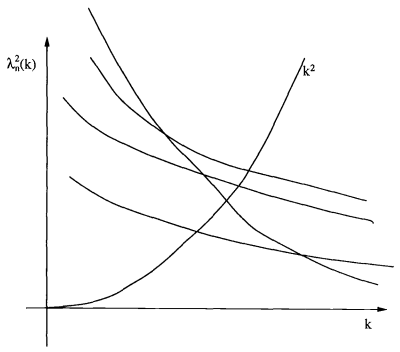

FIG. 4. *Different curves $k \to \lambda_n(k)$ and $k \to k^2$.*

n. The properties of $k \to \lambda_n(A_k)$ imply that, for each n, there exists a unique value of k satisfying $\lambda_n(A_k) = k^2$. We denote this value by k_n. Suppose now that the sequence $(k_n)_{n\in N}$ has an accumulation point at k_0^2. We can then extract a subsequence $(k_{n_p})_{n_p\in N}$ such that

$$\lim_{p\to\infty} \lambda_{n_p}(A_{k_{n_p}}) = \lim_{p\to\infty} k_{n_p}^2 = k_0^2.$$

Then

$$|\lambda_{n_p}(A_{k_0}) - k_0^2| \leqq |\lambda_{n_p}(A_{k_{n_p}}) - \lambda_{n_p}(A_{k_0})| + |\lambda_{n_p}(A_{k_{n_p}}) - k_0^2|.$$

Due to the uniformity in n of continuity estimates for $\lambda_n(A_k)$, we obtain that if $k_{n_p} - k_0$ is sufficiently small, i.e., $\partial\omega$ for p great enough, the value of $|\lambda_{n_p}(A_{k_0}) - k_0^2|$ can be made arbitrarily small. This contradicts the results of Theorem 2.9. □

The proof of Theorem 2.1 now becomes natural.

Proof of Theorem 2.1. Let $\mathbf{e}$ solve (P_k); we have already seen that $\mathbf{e}_{|\Omega_\rho^{ext}}$ is in $D(A_k)$. But the relation $\Delta\mathbf{e} + k^2\mathbf{e} = 0$ holds on Ω_ρ^{ext}, so that $\mathbf{e}$ is an eigenvector of A_k. Consequently, k is one of the values satisfying (2.12), and Lemma 2.11 gives the required result. □

2.3. Concluding remarks. We now want to underline some facts about our method. The construction of § 2.2 enables us to identify a solution of (1.16) with an eigenvector of A_k. The question now is, does an eigenvector of A_k give rise to a solution of (P_k)? If this were the case, we could state that there are really values of k for which problem (1.16) is not uniquely solvable. But eigenvectors of A_k cannot always be extended to the whole Ω^{ext}, satisfying the conditions dictated by the partial differential equations.

The first critical point is that we do not know if $\mathbf{e}_J(\overset{+}{-}\rho) = 0$ for J in J_k^-, so that we can extend each $\mathbf{e}_J(\cdot)$, J in J_k^- by zero, as is required by Lemma 2.2. Even if these conditions are satisfied, we then have to prove that the divergence of the extended eigenvector is zero, and this problem is related to that of the eigenvalues for the scalar case, with Dirichlet boundary conditions. Uniqueness properties for an arbitrarily smooth scatterer ω in this case have already been analysed, and have led to the same conclusions as Theorem 2.1: there is at most an increasing sequence of values k for which uniqueness is not satisfied, for the scalar Dirichlet problem; moreover, an eigenvector of this case gives, by considering its gradient field, an eigenvector for the Maxwell's equations problem (1.16). Besides, if ω satisfies a geometrical condition related to convexity properties we know that the scalar Dirichlet problem has no eigenvalue (no such criterion is known for the Neumann case). Granted these results, we can state that, if we are in the situation decribed above and if k^2 is not an eigenvalue of the scalar Dirichlet problem, then the extended eigenvector is actually a solution of (P_k).

3. Green kernel and integral equation formulation. It is known [1], [2], [8] that the determination of the diffracted field by a perfectly conducting body ω can be reduced to that of the surface currents $\mathbf{p}$ and charges λ on $\partial\omega$, which satisfy an integral equation, involving a suitable kernel, dictated by conditions at infinity. In this section we show that the same program can be carried out for the "quasi-periodic" diffraction problem, deriving by the way the expression of the requested Green kernel.

3.1. The Green kernel. We look for a function $\mathbf{G}^{qp}(X, Z)$ defined on Ω, which is "quasi periodic" and satisfies radiation conditions in the sense of § 1, and which is also an elementary solution of the Helmholtz equation in Ω. To this end we consider

the family

$$(\chi_J)_{J\in\mathbb{Z}^2};\ \chi_J := \frac{1}{i\mu_J(k)} \exp(i\mu_J(k)|Z|) \tag{3.1}$$

where we assume that $\mu_J(k) \neq 0$ ($|\mathbf{K}+\mathbf{K}_J| \neq k$) for all J in $\mathbb{Z}^2$.

χ_J is an elementary solution of the Helmholtz equation (1.6) with the radiation conditions (1.7).

We then consider formally the sum

$$\mathbf{G}^{qp}(X, Z) := \frac{1}{2d_1d_2} \sum_{J\in\mathbb{Z}^2} \chi_J(Z) \exp(-i(\mathbf{K}+\mathbf{K}_J)\cdot X). \tag{3.2}$$

PROPOSITION 3.1. *Assume that for every $J \in \mathbb{Z}^2 |\mathbf{K}+\mathbf{K}_J| \neq k$. Then* (3.2) *defines an $L^{2,\mathrm{loc}}(\mathbb{R}^3)$ function, which satisfies*:

(i) $\Delta\mathbf{G}^{qp} + k^2\mathbf{G}^{qp} = \sum_{J\in\mathbb{Z}^2} \delta(X_J, 0) \exp(i\mathbf{K}\cdot X_J)$ *in* $(C_0^\infty(\mathbb{R}^3))'$,

(ii) $\Delta\mathbf{G}^{qp} + k^2\mathbf{G}^{qp} = \delta_K$ *in* $(C_K^\infty(\Omega))'$,

(iii) $\mathbf{G}^{qp}$ *is a C^∞ function in $\bar{\Omega}\backslash\{(0,0,0)\}$, which satisfies "quasi-periodicity" conditions and radiation conditions.*

Here, δ_K is the Dirac distribution of the dual space of $C_K^\infty(\Omega)$, defined by $\langle\delta_K, \varphi\rangle := \varphi(0,0,0)$ for all $\varphi \in C_K^\infty(\Omega)$ where $\langle\cdot,\cdot\rangle$ stands for the duality bracket between $(C_K^\infty(\Omega))'$ and $C_K^\infty(\Omega)$.

Remark. We have to eliminate the case $|\mathbf{K}+\mathbf{K}_J| = k$, because a Green function satisfying radiation conditions cannot be constructed in this way.

Proof. Let J be in J_k^+, and consider

$$\xi_J(\rho) := \int_{-\rho}^{+\rho} |\chi_J|^2\, dZ \quad \text{for } \rho > 0.$$

Elementary calculus shows that

$$\xi_J(\rho) = 2/|\mu_J(k)|^3(1-\exp(-2\rho|\mu_J(k)|)).$$

Hence the family $(\xi_J(\rho))_{J\in J_k^+}$ is summable even if we take $\rho = +\infty$. For J in J_k^-, we also define

$$\xi_J(\rho) := \int_{-\rho}^{+\rho} |\chi_J|^2\, dZ \quad \text{for } \rho > 0$$

$$= 2\frac{\rho}{|\mu_J(k)|^2}.$$

But there is only a finite number of such terms, so that $(\xi_J(\rho))_{J\in\mathbb{Z}^2}$ is a summable family.

Now it is clear that for every finite part $F \subset \mathbb{Z}^2$

$$\left|\sum_{J\in F} \chi_J(Z) \exp(-i(\mathbf{K}+\mathbf{K}_J)\cdot X)\right|_{0,\Omega_\rho}^2 = d_1d_2 \sum_{J\in F} \xi_J(\rho) \leqq d_1d_2 \sum_{J\in\mathbb{Z}^2} \xi_J(\rho).$$

We conclude that $\mathbf{G}^{qp}$ is in $L^{2,\mathrm{loc}}(\Omega)$, and so (3.1) is almost everywhere summable in Ω. Now (3.2) defines a "q.p." function almost everywhere on $\mathbb{R}^3$, which is clearly in $L^{2,\mathrm{loc}}(\mathbb{R}^3)$.

We now come to point (i); indeed we have in a distributional sense the following expansion:

$$\Delta\mathbf{G}^{qp} + k^2\mathbf{G}^{qp} = 1/d_1d_2 \sum_{j\in\mathbb{Z}^2} \exp(-i(\mathbf{K}+\mathbf{K}_J)\cdot X) \otimes \delta_{Z=0} \quad \text{in } (C_0^\infty(\mathbb{R}^3))'.$$

Hence for φ in $C_0^\infty(\mathbb{R}^3)$, we get

$$\langle \Delta \mathbf{G}^{qp} + k^2 \mathbf{G}^{qp}, \varphi \rangle = 1/d_1 d_2 \sum_{J \in \mathbb{Z}^2} \int_{\mathbb{R}^2} \exp(-i(\mathbf{K}+\mathbf{K}_J)\cdot X)\varphi(X,0)\, dX$$

$$= 1/d_1 d_2 \sum_{J \in \mathbb{Z}^2} F_X(\varphi)(\mathbf{K}+\mathbf{K}_J, 0)$$

$$= \sum_{J \in \mathbb{Z}^2} \varphi(X_J, 0) \exp(-i\mathbf{K}\cdot X_J)$$

by using Poisson's formula for the Fourier transform in the X variable. Thus, we obtain (i).

In (ii), we consider $\mathbf{G}^{qp}$ as a distribution that is "q.p." in the X variable and acts as a usual distribution on the Z variable. "q.p." distributions are defined similarly to periodic distributions (see [10]), noting that, if $F(X)$ is a "q.p." function, $F(X)\exp(-iK\cdot X)$ is a periodic function. To prove (ii), we just note that δ_K has the following expansion in $(C_K^\infty(\Omega))'$:

$$\delta_K = 1/d_1 d_2 \sum_{J \in \mathbb{Z}^2} \exp(-i(\mathbf{K}+\mathbf{K}_J)\cdot X) \otimes \delta_{Z=0}$$

and that is exactly what we get, applying $(\Delta + k^2)$ to $\mathbf{G}^{qp}$. □

PROPOSITION 3.2. *Let $\mathbf{G}^0$ be a usual elementary solution of the Helmholtz equation*:

$$\mathbf{G}^0((X,Z)) := \frac{\exp(ik|(X,Z)|)}{4\pi|(X,Z)|}.$$

Then $\mathbf{G}^r := \mathbf{G}^0 - \mathbf{G}^{qp}$ is a C^∞ function in every open set which does not contain a point $(X_J, 0)$, $J \in \mathbb{Z}^2$, $j \neq (0,0)$. Hence $\mathbf{G}^{qp}$ is a C^∞ function in $\bar{\Omega}\backslash\{(0,0,0)\}$ and satisfies radiation conditions (1.7).

Proof. In an open set ϑ which does not contain a point $(X_J, 0)$, $\mathbf{G}^r$ satisfies

$$\Delta \mathbf{G}^r + k^2 \mathbf{G}^r = 0 \quad \text{in } (C^\infty(\vartheta))'.$$

But $\mathbf{G}^r$ is in $L^{2,\mathrm{loc}}(\mathbb{R}^3)$ so that, applying classical results on elliptic regularity for Laplace operator, we obtain that $\mathbf{G}^r$ is a $C^\infty(\vartheta)$ function. The rest of Proposition 3.2 is easy, because we know explicitly the behaviour of $\mathbf{G}^0$, and radiation conditions follow from the definition of $\mathbf{G}^{qp}$. □

3.2. Integral formulations and existence results. Let $\mathbf{e}$ be defined almost everywhere in Ω by the following: $\mathbf{e}$ is a solution of (1.16) in Ω^{ext}, and $\mathbf{e}$ is a solution of the interior problem related to (1.16) in ω.

Find $\mathbf{e}$ in $H^1_\Delta(\omega, \mathbb{C}^3)$ such that

$$\begin{aligned} &\Delta \mathbf{e} + k^2 \mathbf{e} = \mathbf{0} && \text{in } \omega, \\ &\operatorname{div} \mathbf{e} = 0 && \text{in } \omega, \\ &\mathbf{n} \times \mathbf{e} = \mathbf{c} && \text{on } \partial\omega. \end{aligned}$$

Regularity results yield $\mathbf{e} \in C^\infty(\bar{\omega}, \mathbb{C}^3) \cup C_K^\infty(\overline{\Omega^{\mathrm{ext}}}, \mathbb{C}^3)$.

We can then state the following proposition, giving a representation formula for $\mathbf{e}$.

PROPOSITION 3.3. $\mathbf{e}$ *admits the representation*

$$\mathbf{e}(X,Z) = -\operatorname{grad} v(\lambda)(X,Z) + \mathbf{A}(\mathbf{p})(X,Z) \quad \textit{for all } (X,Z) \quad \textit{in } \Omega^{\mathrm{ext}} \cup \omega, \tag{3.3}$$

$$v(\lambda)(X,Z) := \int_{\partial\omega} \mathbf{G}^{qp}(X'-X, Z'-Z)\lambda(X',Z')\, d\sigma', \tag{3.4}$$

$$\mathbf{A}(\mathbf{p})(X, Z) := \int_{\partial\omega} \mathbf{G}^{qp}(X'-X, Z'-Z)\mathbf{p}(X', Z')\, d\sigma', \quad \textit{and} \tag{3.5}$$

$$\lambda := -[\mathbf{e}\cdot n], \tag{3.6}$$

$$\mathbf{p} := [\operatorname{curl}\mathbf{e}\times n]. \tag{3.7}$$

Here $[\cdot]$ *stands for the jump across* $\partial\omega$ *of a function with exterior and interior traces at* $\partial\omega$.

Proof. We apply Green formula to the vector fields $\mathbf{G}^{qp}\mathbf{e}^*$ and $\mathbf{e}$, where $\mathbf{e}^*$ is an arbitrary constant vector of $\mathbb{R}^3$ in the sets ω and Ω_ρ^{ext}, respectively. This yields (after some tedious but classical computations) the following. If $|Z| < \rho$, then

$$\begin{aligned}\mathbf{e}(X, Z)\cdot\mathbf{e}^* = {} & (-\operatorname{grad} v(\lambda)(X, Z) + \mathbf{A}(\mathbf{p})(X, Z))\cdot\mathbf{e}^* \\ & + \int_{\Sigma^\rho} ((\nabla_X\cdot\mathbf{G}^{qp}(X'-X, Z'-Z)\times\mathbf{e}^*)\times\mathbf{e}_3)\cdot\mathbf{e}(X', Z')\, d\sigma' \\ & + \int_{\Sigma^\rho} (\nabla_X\cdot\mathbf{G}^{qp}(X'-X, Z'-Z)\cdot\mathbf{e}^*)(\mathbf{e}_3\cdot\mathbf{e}^*(X', Z'))\, d\sigma' \\ & - \int_{\Sigma^\rho} (\mathbf{G}^{qp}(X'-X, Z'-Z)\mathbf{e}^*)\cdot(\operatorname{curl}\mathbf{e}(X', Z')\times\mathbf{e}_3)\, d\sigma'.\end{aligned}$$

Thus, we only have to show that our radiation conditions imply that the contribution from Σ^ρ vanishes: again this is only a matter of computation and we omit the proof. □

We now give a more precise framework for the integral equation analysis, which is to be related to the study done in [2]. We begin by recalling some results that can be found in [2].

To this end, we set

$$\begin{aligned}\mathbf{H} &:= TH^{-1/2}(\partial\omega), \\ \mathbf{X} &:= \{\mathbf{p}\in H;\ \operatorname{div}_{\partial\omega}\mathbf{p}\in H^{-1/2}(\partial\omega)\}, \\ \mathbf{M} &:= \{\lambda\in H^{-1/2}(\partial\omega);\ \langle\lambda, 1\rangle = 0\}, \\ \mathbf{L} &:= \{\lambda\in M;\ \lambda\in H^{1/2}(\partial\omega)\}\end{aligned}$$

(these spaces are endowed with their natural norms), and we define the following operators, for smooth $\mathbf{p}$ and λ:

$$\mathbf{A}^0(\mathbf{p})(X, Z) := \int_{\partial\omega} \mathbf{G}^0(X'-X, Z'-Z)\mathbf{p}(X', Z')\, d\sigma,$$

$$v^0(\lambda)(X, Z) := \int_{\partial\omega} \mathbf{G}^0(X'-X, Z'-Z)\lambda(X', Z')\, d\sigma',$$

$$\mathbf{C}(\rho)(X, Z) := \int_{\partial\omega} \frac{1}{4\pi|(X'-X, Z'-Z)|}\rho(X', Z')\, d\sigma'.$$

From [9], we can state that $\mathbf{C}(\cdot)$ defines an isomorphism from $H^s(\partial\omega)$ onto $H^{s+1}(\partial\omega)$, for every positive real s.

From [2], we can state the following theorem.

THEOREM (Bendali). *The operator defined for smooth* $(\mathbf{p}, \lambda)$ *in* $\mathbf{X}\times\mathbf{L}$ *by*

$$\Lambda(\mathbf{p}, \lambda) := (\mathbf{A}^0(\mathbf{p}) - \operatorname{grad}_{\partial\omega}(v^0(\lambda)), \mathbf{C}(\operatorname{div}_{\partial\omega}\mathbf{p} + k^2\lambda))$$

can be extended to a continuous linear operator from $\mathbf{X}\times\mathbf{L}$ *onto* $TH^{1/2}(\partial\omega)\times\mathbf{M}'$. *Moreover,* Λ *is an isomorphism from* $\mathbf{X}\times\mathbf{L}$ *onto* $TH^{1/2}(\partial\omega)\times\mathbf{M}'$.

As a corollary of this result we state the following corollary.

COROLLARY. *The operator defined for smooth* $\mathbf{p}$ *in* $\mathbf{X}$ *by*

$$\tilde{\Lambda}(\mathbf{p}) := \mathbf{A}^0(\mathbf{p}) + 1/k^2 \operatorname{grad}_{\partial\omega}(v^0(\operatorname{div}_{\partial\omega}\mathbf{p}))$$

can be extended to an isomorphism from $\mathbf{X}_+ := \{\mathbf{p}\in\mathbf{X};\ \operatorname{div}_{\partial\omega}\mathbf{p}\in H^{1/2}(\partial\omega)\}$ *onto* $TH^{1/2}(\partial\omega)$. *The norm on* $\mathbf{X}^+$ is $\|\mathbf{p}\|_{\mathbf{X}_+} = \|\mathbf{p}\|_{-1/2,\partial\omega} + \|\operatorname{div}_{\partial\omega}\mathbf{p}\|_{1/2,\partial\omega}$.

Proof. We want to solve

$$\tilde{\Lambda}(\mathbf{p}) = \mathbf{c} \quad \text{for } \mathbf{c} \quad \text{in } TH^{1/2}(\partial\omega).$$

Let $(\mathbf{p}, \lambda)$ be the solution of

$$\Lambda(\mathbf{p}, \lambda) = (\mathbf{c}, 0);$$

then

$$\operatorname{div}_{\partial\omega}\mathbf{p} = -k^2\lambda \in H^{1/2}(\partial\omega)$$

and hence

$$\mathbf{p}\in\mathbf{X}_+ \quad \text{and} \quad \tilde{\Lambda}(\mathbf{p}) = \mathbf{c}$$

Now, $\tilde{\Lambda}$ is clearly continuous and injective; this follows from the properties of Λ. □

PROPOSITION 3.4. *The operator* Λ^{qp}, *defined for smooth* $\mathbf{p}$ *in* $\mathbf{X}_+$ *by*

$$\Lambda^{qp}(\mathbf{p}) = 1/k^2 \operatorname{grad}_{\partial\omega}(v^{qp}(\operatorname{div}_{\partial\omega}\mathbf{p})) + \mathbf{A}^{qp}(\mathbf{p}), \tag{3.8}$$

where

$$v^{qp}(\lambda)(X, Z) := \int_{\partial\omega} \mathbf{G}^{qp}(X'-X, Z'-Z)\lambda(X', Z')\, d\sigma', \tag{3.9}$$

$$\mathbf{A}^{qp}(\mathbf{p})(X, Z) := \int_{\partial\omega} \mathbf{G}^{qp}(X'-X, Z'-Z)\mathbf{p}(X', Z')\, d\sigma' \tag{3.10}$$

can be extended to a bounded linear operator from $\mathbf{X}_+$ *to* $TH^{1/2}(\partial\omega)$.

Let $\mathbf{c}$ *be in* $TH^{1/2}(\partial\omega)$, *and let* $\mathbf{p}$ *in* $\mathbf{X}_+$ *satisfy the integral equation*

$$\Lambda^{qp}(\mathbf{p}) = \mathbf{c}. \tag{3.11}$$

Then $\mathbf{e}$ *defined by*

$$\mathbf{e}(X, Z) = -\operatorname{grad}(v^{qp}(\operatorname{div}_{\partial\omega}\mathbf{p}))(X, Z) + \mathbf{A}^{qp}(\mathbf{p})(X, Z) \tag{3.12}$$

for all (X, Z) *in* $\Omega^{\text{ext}}\cup\omega$, *is a solution of* (1.16), *and of the related interior problem, and we have*

$$\mathbf{p} = [\operatorname{curl}\mathbf{e}\times\mathbf{n}]. \tag{3.13}$$

Proof. We use the splitting of $\mathbf{G}^{qp}$:

$$\mathbf{G}^{qp} = \mathbf{G}^0 + \mathbf{G}^r.$$

This decomposition leads us to define analogously to (3.9) and (3.10) for the kernel $\mathbf{G}^r$:

$$v^r(\lambda)(X, Z) := \int_{\partial\omega} \mathbf{G}^r(X'-X, Z'-Z)\lambda(X', Z')\, d\sigma',$$

$$\mathbf{A}^r(\mathbf{p})(X, Z) := \int_{\partial\omega} \mathbf{G}^r(X'-X, Z'-Z)\mathbf{p}(X', Z')\, d\sigma'.$$

From the Bendali theorem and its corollary we know that the mapping defined for smooth $\mathbf{p}$ in $\mathbf{X}$, by

$$\tilde{\Lambda}^0(\mathbf{p}) := 1/k^2 \operatorname{grad}_{\partial\omega} v^0(\operatorname{div}_{\partial\omega} \mathbf{p}) + \mathbf{A}^0(\mathbf{p})$$

can be extended to a bounded linear operator from $\mathbf{X}_+$ to $TH^{1/2}(\partial\omega)$.

Now it is easily seen that the regular kernel $\mathbf{G}^r$ defines a regularizing operator, which maps $\mathbf{X}_+$ on $TC^\infty(\partial\omega)$ (smooth tangential fields on $\partial\omega$), by

$$\Lambda^r(\mathbf{p}) := 1/k^2 \operatorname{grad}_{\partial\omega} v^r(\operatorname{div}_{\partial\omega} \mathbf{p}) + \mathbf{A}^r(\mathbf{p}).$$

Thus $\Lambda^{qp} = \Lambda^0 + \Lambda^r$ can be extended to a bounded linear operator from $\mathbf{X}_+$ to $TH^{1/2}(\partial\omega)$.

Thanks to the splitting $\mathbf{G}^{qp} = \mathbf{G}^0 + \mathbf{G}^r$, it is already seen that $\mathbf{e}(X, Z)$, defined by (3.12), satisfies

$$\mathbf{e} \text{ is in } H^{1,\mathrm{loc}}_{\Delta,K}(\Omega^{\mathrm{ext}}, \mathbb{C}^3),$$

$$\Delta\mathbf{e} + k^2\mathbf{e} = 0 \quad \text{in } \Omega^{\mathrm{ext}} \cup \omega.$$

Classical potential relations can be applied to the kernel $\mathbf{G}^0$, giving the continuity of the tangential component of (3.12) across $\partial\omega$, having in mind that the regular kernel $\mathbf{G}^r$ introduces no discontinuity across $\partial\omega$:

$$\begin{aligned}\Pi\mathbf{e} &= \Pi(1/k^2 \operatorname{grad} v^{qp}(\operatorname{div}_{\partial\omega} \mathbf{p}) + \mathbf{A}^{qp}(\mathbf{p})) \\ &= 1/k^2 \operatorname{grad}_{\partial\omega} v^{qp}(\operatorname{div}_{\partial\omega} \mathbf{p}) + \mathbf{A}^{qp}(\mathbf{p}) = \mathbf{c}.\end{aligned}$$

Moreover, radiation conditions are satisfied: indeed, for $z \geqq \rho_0$, for example, the following expansion holds:

$$\mathbf{e}(X, Z) = \sum_{j \in \mathbb{Z}^2} \mathbf{e}_J^{0+} \exp(i(\mathbf{K} + \mathbf{K}_J) \cdot X) \exp(iZ\mu_J(k))$$

where $\mathbf{e}_J^{0+}$ is the constant vector of $\mathbb{C}^3$ given by

$$\begin{aligned}\mathbf{e}_J^{0+} := \Bigg(-\frac{1}{k^2} \Bigg[\int_{\partial\omega} & \frac{\exp(-i(\mathbf{K} + \mathbf{K}_J) \cdot X')}{i\mu_J(k)} \\ & \cdot \exp(iZ'\mu_J(k)) \operatorname{div}_{\partial\omega} \mathbf{p}(X', z')\, d\sigma' \Bigg] (i(\mathbf{K} + \mathbf{K}_J) + i\mu_J(k)\mathbf{e}_3) \\ + \int_{\partial\omega} & \frac{\exp(-i(\mathbf{K} + \mathbf{K}_J) \cdot X')}{i\mu_J(k)} \exp(iZ'\mu_J(k)) \mathbf{p}(X', z')\, d\sigma \Bigg)\end{aligned}$$

and the series is absolutely convergent and termwise infinitely differentiable.

We just have now to check div $\mathbf{e}$:

$$\begin{aligned}\operatorname{div} \mathbf{e} &= 1/k^2 \Delta v^{qp}(\operatorname{div}_{\partial\omega} \mathbf{p}) + \operatorname{div}(\mathbf{A}^{qp}(\mathbf{p})) \\ &= -v^{qp}(\operatorname{div}_{\partial\omega} \mathbf{p}) + \operatorname{div}(\mathbf{A}^{qp}(\mathbf{p}))\end{aligned} \tag{3.14}$$

and $\operatorname{div}(\mathbf{A}^{qp}(\mathbf{p}))$ is given by

$$\begin{aligned}\operatorname{div}(\mathbf{A}^{qp}(\mathbf{p}))(X, Z) &:= \int_{\partial\omega} \nabla_X \mathbf{G}^{qp}(X' - X, Z' - Z)\mathbf{p}(X', Z')\, d\sigma' \\ &= -\int_{\partial\omega} \nabla_{\partial\omega, X} \cdot \mathbf{G}^{qp}(X' - X, Z' - Z)\mathbf{p}(X', Z')\, d\sigma'\end{aligned}$$

and using the Stokes formula:

$$\int_{\partial\omega} \nabla_{\partial\omega X} \cdot \mathbf{G}^{qp}(X'-X, Z'-Z)\mathbf{p}(X', Z')\, d\sigma'$$

$$= -\int_{\partial\omega} \mathbf{G}^{qp}(X'-X, Z'-Z)\, \mathrm{div}_{\partial\omega}\, \mathbf{p}(X', Z')\, d\sigma',$$

and so (3.14) vanishes.

To prove (3.13), we just recall that the regular kernel $\mathbf{G}^r$ induces no jump across $\partial\omega$, and then we apply results of [2]. □

Equation (3.11) defines an integral equation for the unknown $\mathbf{p}$; it gives rise to solutions of (1.16) and of its related interior problem in ω, so that we can use the uniqueness results of § 2 in our analysis.

THEOREM 3.5. *Let* $\mathbf{N}$ *be defined by*

$$\mathbf{N} := \{r \in \mathbb{R}_+;\ (r \in K_{\text{sing}})\}$$
$$\cup \{-r^2 \text{ is an eigenvalue of } \Delta \text{ in } \omega \text{ with Dirichlet homogenous condition}\}$$
$$\cup \{\exists J \in \mathbb{Z}^2 / r = |\mathbf{K} + \mathbf{K}_J|)\}.$$

Suppose that $k \notin \mathbf{N}$; *then the integral equation* (3.11) *is uniquely solvable, and so gives rise to a unique solution to problem* (1.16).

Proof. Our purpose is to show that (3.11) can be handled by a Fredholm alternative technique. As $TC^\infty(\partial\omega)$ is compactly embedded in $TH^{1/2}(\partial\omega)$, Λ^r is found to be a compact perturbation of Λ^0. Hence we can now state the conclusions of the Fredholm alternative if we show that first part of Fredholm alternative holds when k is not in $\mathbf{N}$.

Let us suppose that

$$\Lambda^{qp}(\mathbf{p}) = \mathbf{0}.$$

By uniqueness results of § 2, applied to the vector field $\mathbf{e}$ given in Ω_ρ^{ext} by (3.12), we have $\mathbf{e} = \mathbf{0}$ in Ω_ρ^{ext}. In ω, the hypothesis that $-k^2$ is not an eigenvalue of the Laplace operator with homogenous Dirichlet boundary condition ensures that $\mathbf{e} = \mathbf{0}$ in ω (see [2], [9]). Thus $\mathbf{p} = [\text{curl } \mathbf{e} \times \mathbf{n}] = \mathbf{0}$. Fredholm's alternative then implies that (3.11) has one and only one solution. □

DIFFUSION OF FLUID IN A FISSURED MEDIUM WITH MICROSTRUCTURE*

R. E. SHOWALTER† AND N. J. WALKINGTON‡

Abstract. A system of quasilinear degenerate parabolic equations arising in the modeling of diffusion in a fissured medium is studied. There is one such equation in the local cell coordinates at each point of the medium, and these are coupled through a similar equation in the global coordinates. It is shown that the initial boundary value problems are well posed in the appropriate spaces.

Key words. porous medium, double porosity, degenerate parabolic system

AMS(MOS) subject classifications. 35K55, 35K65

1. Introduction.

We shall study the Cauchy–Dirichlet problem for degenerate parabolic systems of the form

$$\frac{\partial}{\partial t}a(u) - \vec{\nabla}\cdot\widetilde{A}(x,\vec{\nabla}u) + \int_{\Gamma_x}\widetilde{B}(x,s,\vec{\nabla}_y U)\cdot\vec{\nu}\,ds \ni f, \qquad x\in\Omega, \tag{1.1a}$$

$$\frac{\partial}{\partial t}b(U) - \vec{\nabla}_y\cdot\widetilde{B}(x,y,\vec{\nabla}_y U) \ni F, \qquad y\in\Omega_x, \tag{1.1b}$$

$$\widetilde{B}(x,y,\vec{\nabla}_y U)\cdot\vec{\nu} + \mu\big(U(x,y,t) - u(x,t)\big) \ni 0, \qquad y\in\Gamma_x. \tag{1.1c}$$

Here Ω is a domain in $\mathbb{R}^n$ and for each value of the macrovariable $x\in\Omega$ is specified a domain Ω_x with boundary Γ_x for the microvariable $y\in\Omega_x$. Each of a, b, μ is a maximal monotone graph. These graphs are not necessarily strictly increasing; they may be piecewise constant or multivalued. The elliptic operators in (1.1a) and (1.1b) are of p-Laplacian type, i.e., they are nonlinear in the gradient of degree $p-1>0$ and $q-1>0$, respectively, with $\frac{1}{q}+\frac{1}{n}\geq\frac{1}{p}$, so some specific degeneracy is also permitted here. Certain first-order spatial derivatives can be added to (1.1a) and (1.1b) with no difficulty, and corresponding problems with constraints, i.e., variational inequalities, can be treated similarly. A particular example important for applications is the linear constraint

$$U(x,y,t) = u(x,t), \qquad y\in\Gamma_x, \quad x\in\Omega \tag{1.1c$'$}$$

which then replaces (1.1c). The system (1.1) with $\mu(s)=\frac{1}{\varepsilon}|s|^{q-2}s$ is called a *regularized microstructure model*, and (1.1a), (1.1b), (1.1c$'$) is the corresponding *matched microstructure model* in which (formally) $\varepsilon\to 0$. An example of such a system as a model for the flow of a fluid (liquid or gas) through a fractured medium will be given below. In such a context, (1.1a) prescribes the flow on the global scale of the fissure system and (1.1b) gives the flow on the microscale of the individual cell at a specific

point x in the fissure system. The transfer of fluid between the cells and surrounding medium is prescribed by (1.1c) or (1.1c′). A major objective is to accurately model this fluid exchange between the cells and fissures.

Systems of the form (1.1) were developed in [21], [22], [10] in physical chemistry as models for diffusion through a medium with a prescribed microstructure. Similar systems arose in soil science [5], [14] and in reservoir models for fractured media [11], [16]. An existence-uniqueness theory for linear problems which exploits the strong parabolic structure of the system was given in [24]. Alternatively it is possible to eliminate U and obtain a single functional differential equation for u in the simpler space $L^2(\Omega)$, but the structure of the equation then obstructs the optimal parabolic type results [18]. Also see [13] for a nonlinear system with reaction–diffusion local effects.

These systems also arise from methods of homogenization. There an exact model is assumed periodic and described by a parabolic equation with periodic coefficients corresponding to the properties of the two components, the cells and fissures. The limit of this highly singular problem as the period tends to zero is the system (1.1), which is thereby justified as an approximation for the exact model. Homogenization theory provides not only a justification of the linear case of (1.1) as a model but also a means of calculating the coefficients in (1.1) in terms of those of the exact model, and a deeper analysis may describe the convergence itself [25], [17], [2], [3]. Here we study the nonlinear system directly. The task of determining the coefficients in (1.1) directly from, e.g., boundary observations, is an intriguing open problem.

The plan of this paper is as follows. In § 2 we shall give the precise description and resolution of the stationary problem in a variational formulation by monotone operators from Banach spaces to their duals. In order to achieve this we describe first the relevant Sobolev spaces, the continuous direct sums of these spaces, and the distributed trace and constant functionals which occur in the system. The operators are monotone functions or multivalued subgradients and serve as models for nonlinear elliptic equations in divergence form. We develop an abstract Green's theorem to describe the resolution of the variational form as the sum of a partial differential equation and a complementary boundary operator. Then sufficient conditions of coercivity type are given to assert the existence of generalized solutions of the variational equations. In § 3 we describe the restriction of our system to appropriate products of L^r spaces. The Hilbert space case, $r = 2$, serves not only as a convenient starting point but also leads to the generalized accretive estimates we shall need for the singular case of (1.1) in which a or b is not only nonlinear but multivalued. The stationary operator for (1.1) is shown to be m-accretive in the L^1 space, so we obtain a *generalized solution* in the sense of the nonlinear semigroup theory for general Banach spaces. As an intermediate step we shall show the special case of $a = b =$ identity is resolved as a *strong solution* in every L^r space, $1 < r < \infty$, and also in appropriate dual Sobolev spaces.

In order to motivate the system (1.1), let us consider the flow of a fluid through a fissured medium. This is assumed to be a structure of porous and permeable blocks or cells which are separated from each other by a highly developed system of fissures. The majority of fluid transport will occur along flow paths through the fissure system, and the relative volume of the cell structure is much larger than that of the fissure system. There is assumed to be no direct flow between adjacent cells, since they are individually isolated by the fissures, but the dynamics of the flux exchanged between each cell and its surrounding fissures is a major aspect of the model. The distributed microstructure models that we develop here contain explicitly the local geometry of

the cell matrix at each point of the fissure system, and they thereby reflect more accurately the flux exchange on the microscale of the individual cells across their intricate interface.

Let the flow region Ω be a bounded domain in $\mathbb{R}^n$ with boundary $\Gamma = \partial\Omega$. Let $\rho(x,t)$ and $p(x,t)$ be the *density* and *pressure*, respectively, at $x \in \Omega$ and $t > 0$, each being obtained by averaging over an appropriately small neighborhood of x. At each such x let there be given a cell Ω_x, a bounded domain in $\mathbb{R}^n$ with smooth boundary $\Gamma_x = \partial\Omega_x$. The collection of these Ω_x, $x \in \Omega$, is the distribution of blocks or cells in the structure. Within each Ω_x there is fluid of density $\tilde{\rho}(x,y,t)$ and pressure $\tilde{p}(x,y,t)$, respectively, for $y \in \Omega_x$, $t > 0$. The conservation of fluid mass in the fissure system yields the global diffusion equation

$$\frac{\partial}{\partial t}\big(\rho + a_0(p)\big) - \sum_{j=1}^{n} \frac{\partial}{\partial x_j}\left(\rho k_j\left(\rho\frac{\partial p}{\partial x_j}\right)\frac{\partial p}{\partial x_j}\right) + q(x,t) = f(x,t), \qquad x \in \Omega, \tag{1.2a}$$

in which the total concentration $\rho + a_0(p)$ includes adsorption or capillary effects, the function k_j gives the permeability of the fissure system in the jth coordinate direction, $q(x,t)$ is the density of mass flow of fluid into the cell Ω_x at x, and f is the density of fluid sources. Similarly, we have within each cell

$$\frac{\partial}{\partial t}\big(\tilde{\rho} + b_0(\tilde{p})\big) = \sum_{j=1}^{n} \frac{\partial}{\partial y_j}\left(\tilde{\rho}\tilde{k}_j\left(\tilde{\rho}\frac{\partial \tilde{p}}{\partial y_j}\right)\frac{\partial \tilde{p}}{\partial y_j}\right), \qquad y \in \Omega_x, \tag{1.2b}$$

where b_0 denotes adsorption or capillary effects and the function $\tilde{k}_j$ gives the local cell permeability. Assume the flux across the cell boundary is driven by the pressure difference and is also proportional to the *average density* $\bar{\rho}$ on that pressure interval. Thus, we have the interface condition

$$\sum_{j=1}^{n} \tilde{\rho}\tilde{k}_j\left(\tilde{\rho}\frac{\partial \tilde{p}}{\partial y_j}\right)\frac{\partial \tilde{p}}{\partial y_j}\nu_j + \mu\big(\bar{\rho}(\tilde{p} - p)\big) \ni 0, \qquad y \in \Gamma_x, \tag{1.2c}$$

where $\vec{\nu}$ is the unit outward normal on Γ_x and μ is the relation between the flux across the interface and the density-weighted pressure difference as indicated. The total mass flow into the cell is given by

$$q(x,t) = \int_{\Gamma_x} \tilde{\rho} \sum_{j=1}^{n} \tilde{k}_j\left(\tilde{\rho}\frac{\partial \tilde{p}}{\partial y_j}\right)\frac{\partial \tilde{p}}{\partial y_j}\nu_j \, ds. \tag{1.2d}$$

In order to complete the dynamical system we need only to add a boundary condition on Γ to (1.2a) and to postulate the *state equation*

$$\rho = s(p) \tag{1.2e}$$

for the fluid in the fissure and cell systems. Here $s(\cdot)$ is a given monotone function (or graph) determined by the fluid.

In order to place (1.2) in a more convenient form, we introduce the monotone function

$$S(w) \equiv \int_0^w s(r)\,dr$$

and the corresponding flow potentials for the fluid in the fissures and cells

$$u = S(p), \qquad U = S(\tilde{p})\ .$$

In these variables with a change of notation the system (1.2) can be written in the form (1.1) together with boundary conditions on Γ for u or $\widetilde{A}(\nabla u)\cdot\nu$ and initial conditions at $t = 0$ on $a(u)$, $b(U)$. Note that the average density on the pressure interval $p, \tilde{p}$ is given by

$$\bar{\rho} = \frac{1}{p-\tilde{p}}\int_{\tilde{p}}^{p} s(r)\,dr = \frac{u-U}{p-\tilde{p}}.$$

As an alternative to (1.2c), we could require that $\tilde{p} = p$ on Γ_x and this leads to (1.1c′) in place of (1.1c). Finally, we note that the classical Forchheimer-type corrections to the Darcy law for fluids lead to the case $p = q = \frac{3}{2}$.

2. The variational formulation. We begin by stating and resolving the stationary forms of our systems. Let Ω be a bounded domain in $\mathbb{R}^n$ with smooth boundary, $\Gamma = \partial\Omega$. Let $1 \le p < \infty$ and denote by $L^p(\Omega)$ the space of pth power-integrable functions on Ω, by $L^\infty(\Omega)$ the essentially bounded measurable functions, and the duality pairing by

$$(u, f)_{L(\Omega)} = \int_\Omega u(x)f(x)\,dx, \qquad u \in L^p(\Omega), \quad f \in L^{p'}(\Omega),$$

for any pair of conjugate powers, $\frac{1}{p} + \frac{1}{p'} = 1$. Let $C_0^\infty(\Omega)$ denote the space of infinitely differentiable functions with compact support in Ω. $W^{m,p}(\Omega)$ is the Banach space of functions in $L^p(\Omega)$ for which each partial derivative up to order m belongs to $L^p(\Omega)$, and $W_0^{m,p}(\Omega)$ is the closure of $C_0^\infty(\Omega)$ in $W^{m,p}(\Omega)$. See [1] for information on these Sobolev spaces. In addition, we shall be given for each $x \in \Omega$ a bounded domain Ω_x which lies locally on one side of its smooth boundary Γ_x. Let $1 < q < \infty$ and denote by $\gamma_x : W^{1,q}(\Omega_x) \to L^q(\Gamma_x)$ the *trace* map which assigns boundary values. Let T_x be the range of γ_x; this is a Banach space with the norm induced by γ_x from $W^{1,q}(\Omega_x)$. Since Γ_x is smooth, there is a unit outward normal $\nu_x(s)$ at each $s \in \Gamma_x$. Finally, we define $W_x^{1,q}(\Omega_x)$ to be that closed subspace consisting of those $\varphi \in W^{1,q}(\Omega_x)$ with $\gamma_x\varphi \in \mathbb{R}$, i.e., each $\gamma_x(\varphi)$ is *constant* almost everywhere on Γ_x. We shall denote by $\vec{\nabla}_y$ the gradient on $W^{1,q}(\Omega_x)$ and by $\vec{\nabla}$ the gradient on $W^{1,p}(\Omega)$.

The essential construction to be used below is an example of a *continuous direct sum* of Banach spaces. The special case that is adequate for our purposes can be described as follows. Let S be a measure space and consider the product (measure) space $Q = \Omega \times S$, where Ω has Lebesgue measure. If $U \in L^q(Q)$ then from the Fubini theorem it follows that $U(x)(z) \equiv U(x, z)$, $x \in \Omega$, $z \in S$ defines $U(x) \in L^q(S)$ at almost everywhere $x \in \Omega$, and for each $\Phi \in L^{q'}(Q)$

$$\int_\Omega \big(U(x), \Phi(x)\big)_{L(S)}\,dx \equiv \int_\Omega \left\{\int_S U(x,z)\Phi(x,z)\,dz\right\}dx = \iint_Q U\Phi.$$

Thus $L^q(Q)$ is naturally identified with $L^q(\Omega, L^q(S))$, the Bochner qth integrable (equivalence classes of) functions from Ω to $L^q(S)$.

In order to prescribe a measurable family of cells $\{\Omega_x, x \in \Omega\}$, set $S = \mathbb{R}^n$, let $Q \subset \Omega \times \mathbb{R}^n$ be a given measurable set for which each section $\Omega_x = \{y \in \mathbb{R}^n : (x,y) \in Q\}$ is a bounded domain in $\mathbb{R}^n$. By zero-extension we identify $L^q(Q) \hookrightarrow L^q(\Omega \times \mathbb{R}^n)$ and each $L^q(\Omega_x) \hookrightarrow L^q(\mathbb{R}^n)$. Thus we obtain from above

$$L^q(Q) \cong \Big\{U \in L^q\big(\Omega, L^q(\mathbb{R}^n)\big) : U(x) \in L^q(\Omega_x) \text{ a.e. } x \in \Omega\Big\}.$$

We shall denote the duality on this Banach space by

$$(U, \Phi)_{L(Q)} = \int_\Omega \left\{ \int_{\Omega_x} U(x,y)\Phi(x,y)\, dy \right\} dx \ ,$$
$$U \in L^q(Q), \ \Phi \in L^{q'}(Q).$$

The *state space* for our problems will be the product $L^1(\Omega) \times L^1(Q)$.

Note that $W^{1,q}(\Omega_x)$ is continuously imbedded in $L^q(\Omega_x)$, uniformly for $x \in \Omega$. It follows that the direct sum

$$\mathcal{W}_q \equiv L^q\big(\Omega, W^{1,q}(\Omega_x)\big) \equiv \Big\{U \in L^q(Q) : U(x) \in W^{1,q}(\Omega_x) \text{ a.e. } x \in \Omega \ ,$$
$$\text{and} \quad \int_\Omega \|U(x)\|^q_{W^{1,q}}\, dx < \infty\Big\}$$

is a Banach space. We shall use a variety of such spaces which can be constructed in this manner. Moreover, we shall assume that each Ω_x lies locally on one side of its boundary Γ_x, and Γ_x is a C^2-manifold of dimension $n-1$. We assume the trace maps $\gamma_x : W^{1,q}(\Omega_x) \to L^q(\Gamma_x)$ are *uniformly* bounded. Thus for each $U \in \mathcal{W}_q$ it follows that the *distributed trace* $\gamma(U)$ defined by $\gamma(U)(x,s) \equiv \gamma_x(U(x))(s)$, $s \in \Gamma_x$, $x \in \Omega$, belongs to $L^q(\Omega, L^q(\Gamma_x))$. The distributed trace γ maps $\mathcal{W}_q$ onto $\mathcal{T}_q \equiv L^q(\Omega, T_x) \hookrightarrow L^q(\Omega, L^q(\Gamma_x))$.

Next consider the collection $\{W^{1,q}_x(\Omega_x) : x \in \Omega\}$ of Sobolev spaces given above and denote by $\mathcal{W}_1 \equiv L^q(\Omega, W^{1,q}_x(\Omega_x))$ the corresponding direct sum. Thus for each $U \in \mathcal{W}_1$ it follows that the distributed trace $\gamma(U)$ belongs to $L^q(\Omega)$. We define $\mathcal{W}^{1,p}_0$ to be the subspace of those $U \in \mathcal{W}_1$ for which $\gamma(U) \in W^{1,p}_0(\Omega)$. Since $\gamma : \mathcal{W}_1 \to L^q(\Omega)$ is continuous, $\mathcal{W}^{1,p}_0$ is complete with the norm

$$\|U\|_{\mathcal{W}^{1,p}_0} \equiv \|U\|_{\mathcal{W}_q} + \|\gamma U\|_{W^{1,p}_0}.$$

This Banach space $W^{1,p}_0(\Omega) \times \mathcal{W}_q$ will be the *energy space* for the regularized problem (1.1) and $\mathcal{W}^{1,p}_0$ will be the energy space for the constrained problem in which (1.1c) is replaced by the Dirichlet condition (1.1c′). Note that $\mathcal{W}^{1,p}_0$ is identified with the closed subspace $\{[\gamma U, U] : U \in \mathcal{W}^{1,p}_0\}$ of $W^{1,p}_0(\Omega) \times \mathcal{W}_q$. Finally, we shall let $\mathcal{W}_0$ denote the kernel of γ, $\mathcal{W}_0 = \{U \in \mathcal{W}_q : \gamma U = 0 \text{ in } \mathcal{T}_q\}$.

We have defined $W^{1,q}_x(\Omega_x)$ to be the set of $w \in W^{1,q}(\Omega_x)$ for which $\gamma_x w$ is a constant multiple of $\mathbf{1}_x$, the constant function equal to one on Γ_x. Thus $W^{1,q}_x(\Omega_x)$ is the pre-image by γ_x of the subspace $\mathbb{R} \cdot \mathbf{1}_x$ of T_x. We specified the subspace $\mathcal{W}_1$ similarly as the subspace of $\mathcal{W}_q$ obtained as the pre-image by γ of the subspace $L^q(\Omega)$ of $\mathcal{T}_q$. To be precise, we denote by λ the map of $L^q(\Omega)$ into $\mathcal{T}_q$ given by $\lambda v(x) = v(x) \cdot \mathbf{1}_x$,

almost everywhere $x \in \Omega$, $v \in L^q(\Omega)$; λ is an isomorphism of $L^q(\Omega)$ onto a closed subspace of $\mathcal{T}_q$. The dual map λ' taking $\mathcal{T}_q'$ into $L^{q'}(\Omega)$ is given by

$$\lambda' g(v) = g(\lambda v) = \int_\Omega g_x(\mathbf{1}_x) \cdot v(x)\, dx, \qquad g \in \mathcal{T}_q', \quad v \in L^q(\Omega),$$

so we have $\lambda' g(x) = g_x(\mathbf{1}_x)$, almost everywhere $x \in \Omega$.

Moreover, when $g_x \in L^{q'}(\Gamma_x)$ it follows that

$$g_x(\mathbf{1}_x) = \int_{\Gamma_x} g_x(y)\, dy,$$

the integral of the indicated boundary functional. Thus, for $g \in L^{q'}(\Omega, L^{q'}(\Gamma_x)) \subset \mathcal{T}_q'$, $\lambda' g \in L^{q'}(\Omega)$ is given by

$$\lambda' g(x) = \int_{\Gamma_x} g_x(y)\, dy \qquad \text{a.e. } x \in \Omega. \tag{2.1}$$

The imbedding λ of $L^q(\Omega)$ into $\mathcal{T}_q$ and its dual map λ' will play an essential role in our system below.

We consider elliptic differential operators in divergence form as realizations of monotone operators from Banach spaces to their duals. Assume we are given $\widetilde{A} : \Omega \times \mathbb{R}^n \to \mathbb{R}^n$ such that for some $1 < p < \infty$, $g_1 \in L^{p'}(\Omega)$, $g_0 \in L^1(\Omega)$, c and $c_0 > 0$

(2.2a) $\widetilde{A}(x, \vec{\xi})$ is continuous in $\vec{\xi} \in \mathbb{R}^n$ and measurable in x, and
$$|\widetilde{A}(x, \vec{\xi})| \le c|\xi|^{p-1} + g_1(x),$$

(2.2b) $$\langle \widetilde{A}(x, \vec{\xi}) - \widetilde{A}(x, \vec{\eta}),\, \vec{\xi} - \vec{\eta} \rangle \ge 0,$$

(2.2c) $$\widetilde{A}(x, \vec{\xi}) \cdot \vec{\xi} \ge c_0 |\vec{\xi}|^p - g_0(x)$$
for a.e. $x \in \Omega$ and all $\vec{\xi}, \vec{\eta} \in \mathbb{R}^n$.

Then the global diffusion operator $\mathcal{A} : W_0^{1,p}(\Omega) \to W^{-1,p'}(\Omega)$ is given by

$$\mathcal{A}u(v) = \int_\Omega \widetilde{A}\big(x, \vec{\nabla} u(x)\big) \vec{\nabla} v(x)\, dx, \qquad u, v \in W_0^{1,p}(\Omega).$$

Thus, each $\mathcal{A}u$ is equivalent to its restriction to $C_0^\infty(\Omega)$, the distribution

$$Au \equiv \mathcal{A}u\big|_{C_0^\infty(\Omega)} = -\vec{\nabla} \cdot \widetilde{A}(\cdot, \vec{\nabla} u),$$

which specifies the value of this nonlinear elliptic divergence operator.

In order to specify a collection of local diffusion operators, $\mathcal{B}_x : W^{1,q}(\Omega_x) \to W^{1,q}(\Omega_x)'$, assume we are given $\widetilde{B} : Q \times \mathbb{R}^n \to \mathbb{R}^n$ such that for some $1 < q < \infty$, $h_1 \in L^{q'}(Q)$, $h_0 \in L^1(Q)$, c and $c_0 > 0$

(2.3a) $\widetilde{B}(x, y, \vec{\xi})$ is continuous in $\vec{\xi} \in \mathbb{R}^n$ and measurable in $(x, y) \in Q$, and
$$|\widetilde{B}(x, y, \vec{\xi})| \le c|\vec{\xi}|^{q-1} + h_1(x, y),$$

(2.3b) $$\langle \widetilde{B}(x, y, \vec{\xi}) - \widetilde{B}(x, y, \vec{\eta}),\, \vec{\xi} - \vec{\eta} \rangle \ge 0,$$

(2.3c) $$\widetilde{B}(x, y, \vec{\xi}) \cdot \vec{\xi} \ge c_0 |\vec{\xi}|^q - h_0(x, y)$$
for a.e. $(x, y) \in Q$ and all $\vec{\xi}, \vec{\eta} \in \mathbb{R}^n$.

Then define for each $x \in \Omega$

$$\mathcal{B}_x w(v) = \int_{\Omega_x} \widetilde{B}\big(x, y, \vec{\nabla}_y w(y)\big)\vec{\nabla}_y v(y)\, dy\,, \qquad w, v \in W^{1,q}(\Omega_x).$$

The elliptic differential operator on Ω_x is given by the *formal part* of $\mathcal{B}_x$, the distribution

$$B_x w \equiv \mathcal{B}_x w\big|_{C_0^\infty(\Omega_x)} = -\vec{\nabla}_y \cdot \widetilde{B}(x, \cdot, \vec{\nabla}_y w)$$

in $W_0^{1,q}(\Omega_x)'$. Also, we shall denote by $\mathcal{B} : \mathcal{W}_q \to \mathcal{W}_q'$ the *distributed* operator constructed from the collection $\{\mathcal{B}_x : x \in \Omega\}$ by

$$\mathcal{B}U(x) = \mathcal{B}_x\big(U(x)\big) \qquad \text{a.e. } x \in \Omega,\ U \in \mathcal{W}_q,$$

and we note that this is equivalent to

$$\mathcal{B}U(V) \equiv \int_\Omega \mathcal{B}_x\big(U(x)\big)V(x)\, dx, \qquad U, V \in \mathcal{W}_q.$$

The coupling term in our system will be given as a monotone graph which is a subgradient operator. Thus, assume $m : \mathbb{R} \to \mathbb{R}^+$ is convex and bounded by

$$m(s) \le C(|s|^q + 1), \qquad s \in \mathbb{R}, \tag{2.4}$$

hence, continuous. Then by

$$\tilde{m}(g) \equiv \int_\Omega \int_{\Gamma_x} m\big(g(x,s)\big)\, ds\, dx, \qquad g \in L^q\big(\Omega, L^q(\Gamma_x)\big),$$

we obtain the convex, continuous $\tilde{m} : L^q(\Omega, L^q(\Gamma_x)) \to \mathbb{R}^+$. Assume $\frac{1}{q} + \frac{1}{n} \ge \frac{1}{p}$ so that $W_0^{1,p}(\Omega) \hookrightarrow L^q(\Omega)$, and consider the linear continuous maps

$$\lambda : W_0^{1,p}(\Omega) \to L^q\big(\Omega, L^q(\Gamma_x)\big), \qquad \gamma : \mathcal{W}_q \to L^q\big(\Omega, L^q(\Gamma_x)\big).$$

Then the composite function

$$M[u, U] \equiv \tilde{m}(\gamma U - \lambda u), \qquad u \in W_0^{1,p}(\Omega)\,,\ U \in \mathcal{W}_q,$$

is convex and continuous on $W_0^{1,p}(\Omega) \times \mathcal{W}_q$. The subgradients are directly computed by standard results [12]. Specifically, we have $\hat{g} \in \partial\tilde{m}(g)$ if and only if

$$\hat{g}(x,s) \in \partial m\big(g(x,s)\big) \quad \text{a.e. } s \in \Gamma_x, \quad \text{a.e. } x \in \Omega,$$

and we have $[f, F] \in \partial M[u, U]$ if and only if $f = -\lambda'(\mu)$ in $W^{-1,p'}(\Omega)$ and $F = \gamma'(\mu)$ in $\mathcal{W}_q'$ for some $\mu \in \partial\tilde{m}(\gamma U - \lambda u)$.

The following result gives sufficient conditions for the *stationary regularized problem* to be well posed.

PROPOSITION 1. *Assume* $1 < p, q$, $\frac{1}{q} + \frac{1}{n} \ge \frac{1}{p}$, *and define the spaces and operators* λ, γ *as above. Specifically, the sets* $\{\Omega_x : x \in \Omega\}$ *are uniformly bounded with smooth*

boundaries, and the trace maps $\{\gamma_x\}$ *are uniformly bounded. Let the functions* $\widetilde{A}, \widetilde{B}$, *and* m *satisfy* (2.2)–(2.4), *and assume in addition that*

$$m(s) \geq c_0|s|^q, \qquad s \in \mathbb{R}. \tag{2.5}$$

Then for each pair $f \in W^{-1,p'}(\Omega)$, $F \in \mathcal{W}_q'$ *there exists a solution of*

$$u \in W_0^{1,p}(\Omega) : A(u) - \lambda'(\mu) = f \quad \text{in } W^{-1,p'}(\Omega), \tag{2.6a}$$

$$U \in \mathcal{W}_q : \mathcal{B}(U) + \gamma'(\mu) = F \quad \text{in } \mathcal{W}_q', \tag{2.6b}$$

$$\mu \in L^{q'}\big(\Omega, L^{q'}(\Gamma_x)\big) : \mu \in \partial\tilde{m}(\gamma U - \lambda u). \tag{2.6c}$$

For any such solution we have

$$\int_{\Gamma_x} \mu(x,s)\,ds = \big\langle F(x), \mathbf{1}_x \big\rangle \qquad \text{a.e. } x \in \Omega, \tag{2.7}$$

where $\mathbf{1}_x$ *denotes the constant unit function in* $W^{1,q}(\Omega_x)$.

Proof. The system (2.6) is a "pseudo-monotone plus subgradient" operator equation of the form

$$\begin{aligned} &[u,U] \in W_0^{1,p}(\Omega) \times \mathcal{W}_q : \quad \text{for all } [v,V] \in W_0^{1,p}(\Omega) \times \mathcal{W}_q, \\ &\mathcal{A}u(v) + \mathcal{B}U(V) + \partial M[u,U]\big([v,V]\big) \ni f(v) + F(V). \end{aligned} \tag{2.6$'$}$$

It remains only to verify a coercivity condition, namely,

$$\frac{\mathcal{A}u(u) + \mathcal{B}U(U) + \tilde{m}(\gamma U - \lambda u)}{\|u\|_{W_0^{1,p}(\Omega)} + \|U\|_{\mathcal{W}_q}} \to +\infty \tag{2.8}$$

$$\text{as } \|u\|_{W_0^{1,p}(\Omega)} + \|U\|_{\mathcal{W}_q} \to +\infty.$$

Choose $k = \max\{|y_n| : y \in \Omega_x,\ x \in \Omega\}$ and let $\nu_x = (\nu_x^1, \cdots, \nu_x^n)$ be the unit normal on Γ_x. For $v \in W^{1,q}(\Omega_x)$ we have by Gauss' theorem

$$\begin{aligned} \int_{\Omega_x} \big(|v|^q + y_n q|v|^{q-1}\partial_n v\big) &= \int_{\Omega_x} \partial_n\big(y_n|v(y)|^q\big)\,dy \\ &= \int_{\Gamma_x} \nu_x^n(s) s_n |\gamma_x v(s)|^q\,ds. \end{aligned}$$

Hölder's inequality then shows

$$\|v\|_{L^q(\Omega_x)}^q \leq k\|\gamma_x v\|_{L^q(\Gamma_x)}^q + qk\|v\|_{L^q(\Omega_x)}^{q-1}\|\partial_n v\|_{L^q(\Omega_x)},$$

and from this follows

$$\|v\|_{L^q(\Omega_x)}^q \leq 2k\|\gamma_x v\|_{L^q(\Gamma_x)}^q + (2k)^q(q-1)^{q-1}\|\partial_n v\|_{L^q(\Omega_x)}^q$$

by Young's inequality. From here we obtain

$$c_0\|V\|_{L^q(Q)}^q \leq \|\gamma V\|_{L^q(\Omega, L^q(\Gamma_x))}^q + \|\nabla_y V\|_{L^q(Q)}^q, \qquad V \in \mathcal{W}_q. \tag{2.9}$$

Thus from the a priori estimate

$$\begin{aligned} &\mathcal{A}u(u) + \mathcal{B}U(U) + M(\gamma U - \lambda u) \\ &\geq c_0\|\vec{\nabla}u\|^p_{L^p(\Omega)} - \|g_0\|_{L^1(\Omega)} + c_0\|\vec{\nabla}_y U\|^q_{L^q(Q)} - \|h_0\|_{L^1(Q)} \\ &\quad + c_0\|\gamma U - \lambda u\|^q_{L^q(\Omega, L^q(\Gamma_x))}, \qquad u \in W_0^{1,p}(\Omega),\ U \in \mathcal{W}_q, \end{aligned} \tag{2.10}$$

the Poincaré-type inequality (2.9) and the equivalence of $\|\nabla u\|_{L^p(\Omega)}$ with the norm on $W_0^{1,p}(\Omega)$, we can obtain the coercivity condition (2.8). Specifically, if (2.8) is bounded by K, then (2.10) is bounded above by

$$\begin{aligned} &K\big(\|u\|_{W_0^{1,p}(\Omega)} + \|\nabla_y U\|_{L^q(Q)} + \|\gamma U\|_{L^q(\Omega, L^q(\Gamma_x))}\big) \\ &\leq K\big(\|u\|_{W_0^{1,p}(\Omega)} + \|\nabla_y U\|_{L^q(Q)} + \|\gamma U \\ &\quad - \lambda\varphi\|_{L^q(\Omega, L^q(\Gamma_x))} + \|\lambda u\|_{L^q(\Omega)}\big), \end{aligned}$$

and the last term is dominated by the first. This gives an explicit bound on each of these terms and, hence, on $\|u\|_{W_0^{1,p}(\Omega)} + \|U\|_{\mathcal{W}_q}$.

Finally, we apply (2.6b) to the function $V \in \mathcal{W}_q$ given by $V(x,y) = v(x)$ for some $v \in L^q(\Omega)$, and this shows

$$\mu(\gamma v) = \langle F, v\rangle$$

since $\mathcal{B}U(V) = 0$, and thus

$$\int_\Omega \lambda'\mu(x)v(x)\,dx = \mu(\lambda v) = \mu(\gamma v) = \int_\Omega \langle F(x), 1\rangle v(x)\,dx.$$

The identity (2.7) now follows from (2.1).

For the more general case of the *degenerate stationary problem* corresponding to (1.1), we obtain the following result.

COROLLARY 1. *Let $\varphi : \mathbb{R} \to \mathbb{R}^+$ and $\Phi : \mathbb{R} \to \mathbb{R}^+$ be convex and continuous, with $\varphi(0) = \Phi(0) = 0$, and assume*

$$\varphi(s) \leq C\big(|s|^q + 1\big), \qquad \Phi(s) \leq C\big(|s|^q + 1\big), \qquad s \in \mathbb{R}. \tag{2.11}$$

For each pair $f \in W^{-1,p'}(\Omega)$, $F \in \mathcal{W}_q'$, there exists a solution of

$$u \in W_0^{1,p}(\Omega) : a + A(u) - \lambda'(\mu) = f \quad \text{in } W^{-1,p'}(\Omega), \tag{2.12a}$$

$$U \in \mathcal{W}_q : b + \mathcal{B}(U) + \gamma'(\mu) = F \quad \text{in } \mathcal{W}_q', \tag{2.12b}$$

$$\mu \in \partial\tilde{m}(\gamma U - \lambda u) \quad \text{in } L^{q'}\big(\Omega, L^{q'}(\Gamma_x)\big), \tag{2.12c}$$

$$a \in \partial\varphi(u) \quad \text{in } L^{q'}(\Omega), \qquad b \in \partial\Phi(U) \quad \text{in } L^{q'}(Q). \tag{2.12d}$$

For any such solution we have

$$\int_{\Omega_x} b(x,y)\,dy + \int_{\Gamma_x} \mu(x,s)\,ds = \langle F(x), \mathbf{1}_x\rangle \quad \text{a.e. } x \in \Omega. \tag{2.13}$$

Proof. This follows as above but with the continuous convex function

$$\Psi[u,U] = \int_\Omega \varphi\big(u(x)\big)\,dx + \int_\Omega \int_{\Omega_x} \Phi\big(U(x,y)\big)\,dy\,dx + \tilde{m}(\gamma U - \lambda u), \qquad [u,U] \in W_0^{1,p}(\Omega) \times \mathcal{W}_q.$$

The subgradient can be computed termwise because the three terms are continuous on $L^q(\Omega)$, $L^q(Q)$, and $L^q(\Omega, L^q(\Gamma_x))$, respectively.

Remark. The lower bound (2.5) on $m(\cdot)$ may be deleted in Corollary 1 if such a lower estimate is known to hold for Φ. It is also unnecessary in the matched microstructure model; see below.

In order to prescribe the boundary condition (1.1c) explicitly, we develop an appropriate Green's formula for the operators $\mathcal{B}_x$.

Note that we can identify $L^{q'}(\Omega_x) \subset W^{-1,q'}(\Omega_x)$ since $W_0^{1,q}(\Omega_x)$ is dense in $L^q(\Omega_x)$, so it is meaningful to define

$$D_x \equiv \big\{w \in W^{1,q}(\Omega_x) : B_x w \in L^{q'}(\Omega_x)\big\}.$$

This is the domain for the *abstract Green's theorem.*

LEMMA 1. *There is a unique operator $\partial_x : D_x \to T_x'$ for which $\mathcal{B}_x w = B_x w + \gamma_x' \partial_x w$ for all $w \in D_x$. That is, we have*

$$\mathcal{B}_x w(v) = (B_x w, v)_{L(\Omega_x)} + \langle \partial_x w, \gamma_x v\rangle, \qquad v \in W^{1,q}(\Omega_x), \tag{2.14}$$

for every $w \in D_x$.

Proof. The strict morphism γ_x of $W^{1,q}(\Omega_x)$ onto T_x has a dual γ_x' which is an isomorphism of T_x' onto $W_0^{1,q}(\Omega_x)^\perp$, the annihilator in $W^{1,q}(\Omega_x)'$ of the kernel of γ_x. For each $w \in D_x$, the difference $\mathcal{B}_x w - B_x w$ is in $W_0^{1,q}(\Omega_x)^\perp$, so it is equal to $\gamma_x'(\partial_x w)$ for a unique element $\partial_x w \in T_x'$.

Remark. The identity (2.14) is a generalized decomposition of $\mathcal{B}_x$ into a partial differential operator on Ω_x and a boundary condition on Γ_x. If Γ_x is smooth, ν_x denotes the unit outward normal on Γ_x, and if $\tilde{B}(x,\cdot,\vec{\nabla}_y w) \in [W^{1,q'}(\Omega_x)]^n$, then $w \in D_x$ and from the classical Green's theorem we obtain

$$\mathcal{B}_x w(v) - (B_x w, v)_{L(\Omega_x)} = \int_{\Gamma_x} \widetilde{B}(x,s,\vec{\nabla}_y w)\vec{\nu}_x(s)\gamma v(s)\,ds, \qquad v \in W^{1,q}(\Omega_x).$$

Thus, $\partial_x w = \widetilde{B}(x,\cdot,\vec{\nabla}_y w)\cdot \vec{\nu}_x$ is the indicated normal derivative in $L^{q'}(\Gamma_x)$ when $\widetilde{B}(x,\cdot,\vec{\nabla}_y w)$ is as smooth as above, and so we can regard $\partial_x w$ in general as an extension of this nonlinear differential operator on the boundary.

The *formal part* of $\mathcal{B} : \mathcal{W}_q \to \mathcal{W}_q'$ is the operator $B : \mathcal{W}_q \to \mathcal{W}_0'$ given by the restriction $B(U) \equiv \mathcal{B}U|_{\mathcal{W}_0}$. Since $\mathcal{W}_0$ is dense in $L^q(Q)$ we can specify the domain

$$D \equiv \big\{U \in \mathcal{W}_q : B(U) \in L^{q'}(Q)\big\}$$

on which we obtain as before a distributed form of Green's theorem.

LEMMA 2. *There is a unique operator $\partial : D \to \mathcal{T}_q'$ such that*

$$\mathcal{B}(U)(V) = \big(B(U), V\big)_{L(Q)} + \langle \partial U, \gamma V\rangle, \qquad U \in D,\ V \in \mathcal{W}_q.$$

PROPOSITION 2. *Let the Sobolev spaces and trace operators be given as above. We summarize them in the following diagrams*:

$$\begin{array}{ccccc}
L^q(\Omega_x) & & L^q(\Gamma_x) & L^q(Q) & L^q(\Omega, L^q(\Gamma_x)) \\
\cup & & \cup & \cup & \cup \\
W^{1,q}(\Omega_x) & \xrightarrow{\gamma_x} & T_x & \mathcal{W}_q & \xrightarrow{\gamma} \quad \mathcal{T}_q \\
\cup & & \lambda_x \uparrow\downarrow & \cup & \lambda \uparrow\downarrow \\
W_x^{1,q}(\Omega_x) & \longrightarrow & \mathbb{R}\cdot\mathbf{1}_x & \mathcal{W}_1 & \xrightarrow{\gamma_1} \quad L^q(\Omega) \\
\cup & & \cup & \cup & \uparrow \\
W_0^{1,q}(\Omega_x) & \longrightarrow & \{0\} & \mathcal{W}_0 & \longrightarrow \quad \{0\}
\end{array}$$

in which γ_1 is the restriction of γ to $\mathcal{W}_1$. $W_0^{1,q}(\Omega_x)$, $\mathcal{W}_0$ are dense in $L^q(\Omega_x)$, $L^q(Q)$, respectively. Let operators $\mathcal{B}_x$, $x \in \Omega$, and $\mathcal{B}$ be given and define their formal parts B_x, B as above. Then construct the domains D_x, D and boundary operators ∂_x, ∂ as in Lemmas 1 *and* 2, *respectively. It follows that for any $U \in \mathcal{W}_q$,*

(a) *$BU(x) = B_x(U(x))$ in $W_0^{1,q}(\Omega_x)'$ for a.e. $x \in \Omega$, and $U \in D$ if and only if $U(x) \in D_x$ for a.e. $x \in \Omega$ and $x \mapsto B_xU(x)$ belongs to $L^{q'}(Q)$;*

(b) *for each $U \in D$,*

$$\partial U(x) = \partial_x\big(U(x)\big) \quad \text{in } T_x' \text{ for a.e. } x \in \Omega$$

and

$$\mathcal{B}U = BU + \gamma_1'(\lambda'\partial U) \quad \text{in } \mathcal{W}_1',$$

and for each $V \in \mathcal{W}_1$ we have

$$\int_\Omega \mathcal{B}_xU(x)\big(V(x)\big)\,dx = \int_Q B_xU(x)V(x)\,dy\,dx + \int_\Omega \big\langle \partial_xU(x), \mathbf{1}_x\big\rangle(\gamma_1V)(x)\,dx.$$

Proof. (a) For $V \in \mathcal{W}_0$ we obtain from the definitions of B, $\mathcal{B}$, and B_x, respectively,

$$\int_\Omega BU(x)V(x)\,dx = \int_\Omega \mathcal{B}U(V)\,dx = \int_\Omega \mathcal{B}_xU(x)\big(V(x)\big)\,dx = \int_\Omega B_xU(x)V(x)\,dx,$$

and so the first equality holds since $\mathcal{W}_0' = L^{q'}(\Omega, W_0^{1,q}(\Omega_x)')$. The characterization of D is immediate now.

(b) For $V \in \mathcal{W}_q$ we obtain from the definitions of $\gamma, \partial, \partial_x$, respectively, and (a)

$$\int_\Omega \partial U\big(\gamma_xV(x)\big)\,dx = \int_\Omega \partial U(\gamma V)\,dx = \int_\Omega (\mathcal{B}U - BU)(x)V(x)\,dx = \int_\Omega \partial_x\big(U(x)\big)\gamma_xV(x)\,dx.$$

Since the range of γ is $\mathcal{T}_q' = L^{q'}(\Omega, T_x')$, the first equality follows. The second is immediate from Lemma 2 since on $\mathcal{W}_1$, $\gamma = \lambda \circ \gamma_1$ and $\gamma' = \gamma_1' \lambda'$, and the third follows from the preceding remarks.

COROLLARY 2. *In the situation of Corollary* 1, $f \in L^{q'}(\Omega)$ *and* $F \in L^{q'}(Q)$ *if and only if* $Au \in L^{q'}(\Omega)$ *and* $B(U) \in L^{q'}(Q)$, *and in that case the solution satisfies almost everywhere*

$$
\begin{aligned}
&a(x) \in \partial\varphi\big(u(x)\big),\\
&a(x) + Au(x) + \int_{\Omega_x} b(x,y)\,dy = f(x) + \int_{\Omega_x} F(x,y)\,dy, \qquad x \in \Omega,\\
&u(s) = 0, \qquad s \in \Gamma,\\
&b(x,y) \in \partial\Phi\big(U(x,y)\big), \quad b(x,y) + BU(x,y) = F(x,y), \qquad y \in \Omega_x,\\
&\mu(x,s) \in \partial m\big(\gamma U(x,s) - u(x)\big), \qquad \partial_x\big(U(x)\big)(s) + \mu(x,s) = 0, \quad s \in \Gamma_x.
\end{aligned}
$$

Finally, we note that corresponding results for the *stationary matched microstructure model* are obtained directly by specializing the system (2.6′) to the space $\mathcal{W}_0^{1,p}$. This is identified with $\{[\gamma U, U] : U \in \mathcal{W}_0^{1,p}\}$ as a subspace of $W_0^{1,p}(\Omega) \times \mathcal{W}_q$, and we need only to restrict the solution $[u, U]$ and the test functions $[v, V]$, $v = \gamma V$, to this subspace to resolve the matched model. Then the coupling term M does not occur in the system; see the proof of Proposition 1, especially for the coercivity. These observations yield the following analogous results for the matched microstructure model.

PROPOSITION 1′. *Assume* $1 < p, q, \frac{1}{q} + \frac{1}{n} \geq \frac{1}{p}$, *and define the spaces and operators* λ, γ *as before. Let the functions* $\widetilde{A}, \widetilde{B}$, *and* m *satisfy* (2.2)–(2.4). *Then for each pair* $f \in W^{-1,p'}(\Omega)$, $F \in \mathcal{W}_1'$ *there exists a unique solution of*

$$
\begin{aligned}
&u \in W_0^{1,p}(\Omega) : A(u) = f + \langle F, \mathbf{1}\rangle \quad \text{in } W^{-1,p'}(\Omega), && (2.15a)\\
&U \in \mathcal{W}_1 : B(U) = F \quad \text{in } \mathcal{W}_0', && (2.15b)\\
&\gamma U = \lambda u \quad \text{in } L^q(\Omega) \subset \mathcal{T}_q. && (2.15c)
\end{aligned}
$$

COROLLARY 1′. *Suppose* φ, Φ *are given as before and assume* (2.11). *For* f, F *as above there exists a unique solution of*

$$
\begin{aligned}
&u \in W_0^{1,p}(\Omega) : a + \langle b, \mathbf{1}\rangle + A(u) = f + \langle F, \mathbf{1}\rangle \quad \text{in } W^{-1,p'}(\Omega), && (2.16a)\\
&U \in \mathcal{W}_1 : b + B(U) = F \quad \text{in } \mathcal{W}_0', && (2.16b)\\
&\gamma U = \lambda u \quad \text{in } L^q(\Omega) \subset \mathcal{T}_q, && (2.16c)\\
&a \in \partial\varphi(u) \ \text{ in } L^{q'}(\Omega), \qquad b \in \partial\Phi(U) \quad \text{in } L^{q'}(Q). && (2.16d)
\end{aligned}
$$

In addition, $f \in L^{q'}(\Omega)$ and $F \in L^{q'}(Q)$ if and only if $Au \in L^{q'}(\Omega)$ and $B(U) \in L^{q'}(Q)$, and in that case the solution satisfies almost everywhere

$$a(x) \in \partial\varphi\big(u(x)\big),$$

$$a(x) + Au(x) + \int_{\Omega_x} b(x,y)\,dy = f(x) + \int_{\Omega_x} F(x,y)\,dy\,, \qquad x \in \Omega,$$

$$u(s) = 0, \qquad s \in \Gamma\,,$$

$$b(x,y) \in \partial\Phi\big(U(x,y)\big), \quad b(x,y) + BU(x,y) = F(x,y), \qquad y \in \Omega_x,$$

$$U(x,s) = u(x), \qquad s \in \Gamma_x\,.$$

Remark. For the very special case of $p = q \geq 2$ and $a(u) = u$, $b(U) = U$ in the situation of Proposition 1 it follows from [7] or [20] that the Cauchy–Dirichlet problem for (1.1) is well posed in the space $L^p(0,T; W_0^{1,p}(\Omega) \times \mathcal{W}_p)$ with appropriate initial data $u(x,0)$, $U(x,y,0)$ and source functions $f(x,t)$, $F(x,y,t)$. A similar remark holds in the case of Proposition 1′ for the matched model with (1.1c′). These restrictive assumptions will be substantially relaxed in the next section.

Furthermore, variational inequalities may be resolved for problems corresponding to either the regularized or the matched microstructure model by adding the indicator function of a convex constraint set to the convex function Ψ. Thus such problems can be handled with constraints on the global variable u, the local variables U, or their difference $\lambda u - \gamma U$ on the interface.

3. The L^r-operators. Assume we are in the situation of Proposition 1. We define a relation or multi-valued operator $\mathbb{C}_2$ on the Hilbert space $L^2(\Omega) \times L^2(Q)$ as follows: $\mathbb{C}_2[u,U] \ni [f,F]$ if and only if

$$u \in L^2(\Omega) \cap W_0^{1,p}(\Omega) : \mathcal{A}(u) - \lambda'\mu = f \in L^2(\Omega), \tag{3.1a}$$

$$U \in L^2(Q) \cap \mathcal{W}_q : \mathcal{B}(U) + \gamma'\mu = F \in L^2(Q) \tag{3.1b}$$

$$\text{for some } \mu \in \partial\tilde{m}(\gamma U - \lambda u) \quad \text{in } L^{q'}(\Omega, L^{q'}(\Gamma_x)).$$

Thus, $\mathbb{C}_2$ is the restriction of (2.6) to $L^2(\Omega) \times L^2(Q)$. Note that $\lambda'\mu \in L^2(\Omega)$ by (2.7).

LEMMA 3. *If $\sigma : \mathbb{R} \to \mathbb{R}$ is monotone, Lipschitz, and $\sigma(0) = 0$, then for each pair*

$$\mathbb{C}_2[u_j, U_j] \ni [f_j, F_j]\,, \qquad j = 1,2,$$

there follows

$$\big(f_1 - f_2,\, \sigma(u_1 - u_2)\big)_{L^2(\Omega)} + \big(F_1 - F_2,\, \sigma(U_1 - U_2)\big)_{L^2(Q)} \geq 0.$$

Proof. Since σ is Lipschitz and $\sigma(0) = 0$, we have $\sigma(u_1 - u_2) \in W_0^{1,p}(\Omega)$ and $\sigma(U_1 - U_2) \in \mathcal{W}_q$. Also the chain rule applies to these functions, so we compute

$$\big\langle \mathcal{A}u_1 - \mathcal{A}u_2,\, \sigma(u_1, u_2)\big\rangle$$

$$= \int_\Omega \big(\widetilde{A}(x, \vec{\nabla} u_1) - \widetilde{A}(x, \nabla u_2)\big)\vec{\nabla}(u_1 - u_2)\sigma'(u_1 - u_2)\,dx,$$

$$\big\langle \mathcal{B}U_1 - \mathcal{B}U_2,\, \sigma(U_1 - U_2)\big\rangle$$

$$= \int_\Omega \int_{\Omega_x} \big(\widetilde{B}(x,y,\vec{\nabla}_y U_1) - \widetilde{B}(x,y,\vec{\nabla}_y U_2)\big)$$

$$\vec{\nabla}_y(U_1 - U_2)\sigma'(U_1 - U_2)\,dy\,dx\,.$$

Both of these are nonnegative because of (2.1b), (2.2b), and $\sigma' \geq 0$. The remaining term to check is

$$\big(-\lambda'(\mu_1-\mu_2),\, \sigma(u_1-u_2)\big)_{L^2(\Omega)} + \big\langle \gamma'(\mu_1-\mu_2),\, \sigma(U_1-U_2)\big\rangle$$

$$= \int_\Omega \int_{\Gamma_x} \big(\mu_1(x,s)-\mu_2(x,s)\big)\big(\sigma(\gamma U_1-\gamma U_2)-\sigma(\lambda u_1-\lambda u_2)\big)\, ds\, dx.$$

Since σ is a monotone function and ∂m is a monotone graph, this integrand is nonnegative and the result follows.

As a consequence of Lemma 3 with $\sigma(s)=s$, the operator $\mathbb{C}_2$ is monotone on the Hilbert space $L^2(\Omega)\times L^2(Q)$. Moreover, we obtain the following.

PROPOSITION 3. *The operator $\mathbb{C}_2$ is maximal monotone on $L^2(\Omega)\times L^2(Q)$. Let $j:\mathbb{R}\to\mathbb{R}^+$ be convex, lower-semicontinuous, and $j(0)=0$. If ∂m is a function, then $\mathbb{C}_2$ is also single valued and*

$$\big(\mathbb{C}_2[u_1,U_1]-\mathbb{C}_2[u_2,U_2],[\sigma_1,\sigma_2]\big)_{L^2(\Omega)\times L^2(Q)} \geq 0 \tag{3.2}$$

for any selections $\sigma_1\in\partial j(u_1-u_2)$ in $L^2(\Omega)$ and $\sigma_2\in\partial j(U_1-U_2)$ in $L^2(Q)$.

Proof. To show $\mathbb{C}_2$ is maximal monotone it suffices to show that for any pair $[f,F]\in L^2(\Omega)\times L^2(Q)$ there is a solution of

$$u\in L^2(\Omega)\cap W_0^{1,p}(\Omega): u+\mathcal{A}(u)-\lambda'(\mu)=f \ \text{ in } W^{-1,p'}(\Omega), \tag{3.3a}$$

$$U\in L^2(Q)\cap \mathcal{W}_q: U+\mathcal{B}(U)+\gamma'(\mu)=F \ \text{ in } \mathcal{W}_q' \tag{3.3b}$$

$$\mu\in L^{q'}\big(\Omega, L^{q'}(\Gamma_x)\big): \mu\in\partial\tilde{m}(\gamma U-\lambda u). \tag{3.3c}$$

The existence of a (unique) solution of (3.3) follows as in Proposition 1, but by considering the pseudomonotone operator $[\mathcal{A},\mathcal{B}]$ on the product space $L^2(\Omega)\cap W_0^{1,p}(\Omega)\times L^2(Q)\cap\mathcal{W}_q$ and the convex function, $\frac{1}{2}\|u\|^2_{L^2(\Omega)}+\frac{1}{2}\|U\|^2_{L^2(Q)}+\tilde{m}(\gamma U-\lambda u)$, on that space.

To establish the estimate (3.2), we consider the lower-semicontinuous convex function

$$\tilde{j}[u,U]=\int_\Omega\Big(j\big(u(x)\big)+\int_{\Omega_x} j\big(U(x,y)\big)\,dy\Big)\,dx, \tag{3.4}$$
$$[u,U]\in L^2(\Omega)\times L^2(Q).$$

The subgradient of $\tilde{j}$ is given on this product space by

$$\tilde{\sigma}=[\sigma_1,\sigma_2]\in\partial\tilde{j}[u,U] \ \text{ if and only if}$$

$$\tilde{\sigma}[v,V]=\int_\Omega\Big(\sigma_1(x)v(x)+\int_{\Omega_x}\sigma_2(x,y)V(x,y)\,dy\Big)\,dx,$$
$$[v,V]\in L^2(\Omega)\times L^2(Q),$$

where

$$\sigma_1(x)\in\partial j\big(u(x)\big), \quad \text{a.e. } x\in\Omega,$$
$$\sigma_2(x,y)\in\partial j\big(U(x,y)\big), \quad \text{a.e. } (x,y)\in Q.$$

The Yoshida approximation $\tilde{j}_\varepsilon$ of $\tilde{j}$ is given as in (3.4) but with j replaced by j_ε. Since the derivative of j_ε is Lipschitz, monotone, and contains the origin, it follows by

Lemma 3 that the special case of (3.2) with j_ε is true. Thus, $\mathbb{C}_2$ is $\partial\tilde{j}$-monotone [8] and the desired result follows, since the single-valued $\mathbb{C}_2$ equals its minimal section.

We define the realization of (2.6) in $L^r(\Omega) \times L^r(Q)$, $1 \le r < \infty$, as follows. For $r \ge 2$, $\mathbb{C}_r$ is the restriction of $\mathbb{C}_2$ to $L^r(\Omega) \times L^r(Q)$, and for $1 \le r < 2$, $\mathbb{C}_r$ is the closure in $L^r(\Omega) \times L^r(Q)$ of $\mathbb{C}_2$.

COROLLARY 3. *The operator $\mathbb{C}_r$ is m-accretive in $L^r(\Omega) \times L^r(Q)$ for $1 \le r < \infty$.*

Proof. Let $(I + \varepsilon\mathbb{C}_2)([u_j, U_j]) \ni [f_j, F_j]$, $j = 1, 2$, and assume $[f_j, F_j] \in L^r(\Omega) \times L^r(Q)$ if $r \ge 2$. Set $j(s) = |s|^r$, $s \in \mathbb{R}$. From Proposition 4.7 of [8] it follows that

$$\|[u_1 - u_2, U_1 - U_2]\|_{L^r(\Omega)\times L^r(Q)} \le \|[f_1 - f_2, F_1 - F_2]\|_{L^r(\Omega)\times L^r(Q)}.$$

Taking $[f_2, F_2] = [0, 0]$, we see that $L^r(\Omega) \times L^r(Q)$ is invariant under $(I + \varepsilon\mathbb{C}_2)^{-1}$, and then the estimate shows this operator is a contraction on that space. We have $Rg(I + \varepsilon\mathbb{C}_r) = L^r(\Omega) \times L^r(Q)$ directly from the definition for $r \ge 2$, and for $1 \le r < 2$, $Rg(I + \varepsilon\mathbb{C}_r) \supset L^2(\Omega) \times L^2(Q)$, which is dense, so the result follows easily.

Remarks. The Cauchy–Dirichlet problem for the regularized model (1.1) is well posed in $L^r(\Omega) \times L^r(Q)$ when $a(u) = u$, $b(U) = U$, and $r > 1$. This follows from Corollary 3 and the theory of evolution equations generated by m-accretive operators in a uniformly convex Banach space. For example, from [19] we recall the following:

If $\mathfrak{f} \in W^{1,1}(0, T; X)$ and $w_0 \in D(\mathbb{C}_r)$, where $\mathbb{C}_r$ is m-accretive on the uniformly convex Banach space X, then there exists a unique Lipschitz function $w : [0, T] \to X$ for which

$$w'(t) + \mathbb{C}_r\big(w(t)\big) \ni \mathfrak{f}(t), \quad \text{a.e. } t \in (0, T),$$

$$w(t) \in D(\mathbb{C}_r) \quad \text{for all } t \in [0, T], \quad \text{and}$$

$$w(0) = w_0.$$

See [4] for details (Theorem III.2.3) and references. By applying this result to the operator $\mathbb{C}_r$ given in $X \equiv L^r(\Omega) \times L^r(Q)$, $1 < r < \infty$, we obtain a generalized strong solution $w(t) = [u(t), U(t)]$ of the system

$$\frac{\partial u(x,t)}{\partial t} + Au(x,t) + \int_{\Omega_x} \frac{\partial U(x,y,t)}{\partial t}\, dy = f(x,t) + \int_{\Omega_x} F(x,y,t)\, dy, \qquad x \in \Omega,\ t \in (0,T),$$

$$u(s,t) = 0, \qquad s \in \Gamma,$$

$$\frac{\partial U(x,y,t)}{\partial t} + BU(x,y,t) = F(x,y,t), \qquad y \in \Omega_x,$$

$$\mu(x,s,t) \in \partial m\big(U(x,s,t) - u(x,t)\big), \qquad \partial_x U(x,s,t) + \mu(x,s,t) = 0, \quad s \in \Gamma_x,$$

$$u(x,0) = u_0(x), \quad U(x,y,0) = U_0(x,y).$$

The restrictions on the data $\mathfrak{f}(t) = [f(t), F(t)]$ and $w_0 = [u_0, U_0]$ can be considerably relaxed in the Hilbert space case $r = 2$ [8].

By applying Proposition 1′ similarly, it follows that corresponding results for the matched model are obtained. Thus we obtain a generalized strong solution in $L^r(\Omega) \times L^r(Q)$, $1 < r < \infty$, of the system

$$\frac{\partial u(x,t)}{\partial t} + Au(x,t) + \int_{\Omega_x} \frac{\partial U(x,y,t)}{\partial t}\, dy = f(x,t) + \int_{\Omega_x} F(x,y,t)\, dt, \qquad x \in \Omega, \quad t \in (0,T),$$

$$u(s,t) = 0, \qquad s \in \Gamma,$$

$$\frac{\partial U(x,y,t)}{\partial t} + BU(x,y,t) = F(x,y,t), \qquad y \in \Omega_x,$$

$$U(x,s,t) = u(x,t), \qquad s \in \Gamma_x,$$

$$u(x,0) = u_0(x), \qquad U(x,y,0) = U_0(x,y).$$

This follows as above from the analogue of Proposition 3 and Corollary 3.

We return to consider the fully nonlinear model (1.1). The generator of this evolution system will be obtained by closing up the composition of $\mathbb{C}_2$ with the inverse of $[\partial\varphi, \partial\Phi]$ in $L^1(\Omega) \times L^1(Q)$. Thus, we begin with the following.

DEFINITION. $\mathbb{C}[a,b] \ni [f,F]$ if $\mathbb{C}_2[u,U] \ni [f,F]$ and $a \in \partial\varphi(u)$ in $L^2(\Omega)$, $b \in \partial\Phi(U)$ in $L^2(Q)$ for some pair $[u,U]$ as in (3.1).

LEMMA 4. *The operator $\mathbb{C}$ is accretive on $L^1(\Omega)\times L^1(Q)$ if either ∂m is a function or if both $\partial\varphi$ and $\partial\Phi$ are functions.*

Proof. Let $\varepsilon > 0$ and suppose that $(I + \varepsilon\mathbb{C})[a_j, b_j] \ni [f_j, F_j]$ for $j = 1, 2$. Thus we have $\varepsilon\mathbb{C}_2[u_j, U_j] \ni [f_j - a_j, F_j - b_j]$, $a_j \in \partial\varphi(u_j)$, $b_j \in \partial\Phi(U_j)$ as above. First we choose $\sigma(s) = \operatorname{sgn}_\delta^+(s)$, the Yoshida approximation of the maximal monotone sgn^+, apply Lemma 3 and obtain

$$\big(a_1 - a_2, \operatorname{sgn}_\delta^+(u_1 - u_2)\big)_{L^2(\Omega)} + \big(b_1 - b_2, \operatorname{sgn}_\delta^+(U_1 - U_2)\big)_{L^2(Q)} \le \|(f_1 - f_2)^+\|_{L^1(\Omega)} + \|(F_1 - F_2)^+\|_{L^1(Q)}.$$

If $\partial\varphi$ and $\partial\Phi$ are functions, then

$$(a_1 - a_2)\operatorname{sgn}_0^+(u_1 - u_2) = (a_1 - a_2)^+,$$
$$(b_1 - b_2)\operatorname{sgn}_0^+(U_1 - U_2) = (b_1 - b_2)^+,$$

so letting $\delta \to 0$ gives

$$\|(a_1 - a_2)^+\|_{L^1(\Omega)} + \|(b_1 - b_2)^+\|_{L^1(Q)} \le \|(f_1 - f_2)^+\|_{L^1(\Omega)} + \|(F_1 - F_2)^+\|_{L^1(Q)}. \tag{3.5}$$

The same holds for negative parts, so it follows that $(I + \varepsilon\mathbb{C})^{-1}$ is an order-preserving contraction with respect to $L^1(\Omega) \times L^1(Q)$ for each $\varepsilon > 0$.

Next we suppose ∂m is a function. Choose $j(s) = s^+$, so that $\partial j = \operatorname{sgn}^+$, and then set

$$\sigma_1(x) = \operatorname{sgn}_0^+(u_1 - u_2 + a_1 - a_2) \in \operatorname{sgn}^+(u_1 - u_2) \cap \operatorname{sgn}^+(a_1 - a_2),$$
$$\sigma_2(x,y) = \operatorname{sgn}_0^+(U_1 - U_2 + b_1 - b_2) \in \operatorname{sgn}^+(U_1 - U_2) \cap \operatorname{sgn}^+(b_1 - b_2).$$

Proposition 3 applies here to give (3.5). A similar estimate for negative parts yields the result.

Although $\mathbb{C}$ is not accretive on L^r for $1 < r$, we can obtain L^∞ estimates when the graphs $\partial\varphi$, $\partial\Phi$ are not too dissimilar.

COROLLARY 4. *If* $(I + \varepsilon\mathbb{C})[a, b] \ni [f, F]$ *with* $\varepsilon > 0$, *then*

$$\begin{aligned} \|a^+\|_{L^\infty(\Omega)} &\le \max\big(a_0(k), \|f^+\|_{L^\infty(\Omega)}\big), \\ \|b^+\|_{L^\infty(Q)} &\le \max\big(b_0(k), \|F^+\|_{L^\infty(Q)}\big), \end{aligned} \tag{3.6}$$

where $k \equiv \max(a_0^{-1}(\|f^+\|_{L^\infty}), b_0^{-1}(\|F^+\|))$.

Remarks. Here a_0 is the *minimal section* $(\partial\varphi)_0$, a_0^{-1} is the minimal section of $(\partial\varphi)^{-1}$, and b_0, b_0^{-1} are defined similarly from $\partial\Phi$. Specifically, we obtain an explicit a priori bound on $\|a^+\|_{L^\infty(\Omega)}$ and $\|b^+\|_{L^\infty(Q)}$ when $\|f^+\|_{L^\infty(\Omega)} in Rg(\partial\varphi)$ and $\|F^+\|_{L^\infty(Q)} \in Rg(\partial\Phi)$. By similar estimates for negative parts, we obtain explicit estimates on $\|a\|_{L^\infty(\Omega)}$ and $\|b\|_{L^\infty(Q)}$ for *any* pair $f \in L^\infty(\Omega)$, $F \in L^\infty(\Omega)$ if $Rg(\partial\varphi) = \mathbb{R}$ and $Rg(\partial\Phi) = \mathbb{R}$ or (trivially) if both $Rg(\partial\varphi)$ and $Rg(\partial\Phi)$ are bounded in $\mathbb{R}$. Finally, we note that in the special case $\varphi = \Phi$, we obtain

$$\max\big(\|a^+\|_{L^\infty(\Omega)}, \|b^+\|_{L^\infty(Q)}\big) \le \max\big(\|f^+\|_{L^\infty(\Omega)}, \|F^+\|_{L^\infty(Q)}\big).$$

Proof. By the choice of $k \ge 0$ we have

$$\partial\varphi(k) \ni \ell_1 \ge \|f^+\|_{L^\infty}, \qquad \partial\Phi(k) \ni \ell_2 \ge \|F^+\|_{L^\infty}$$

for some pair ℓ_1, ℓ_2. Subtract these from the operator equation, multiply by either

$$\operatorname{sgn}_\delta^+(u - k), \qquad \operatorname{sgn}_\delta^+(U - k)$$

or by

$$\operatorname{sgn}_0^+(a - \ell_1 + u - k), \qquad \operatorname{sgn}_0^+(b - \ell_2 + U - k)\ ,$$

depending on whether $\partial\varphi$ and $\partial\Phi$ are functions or ∂m is a function, respectively. Apply Lemma 3 and let $\delta \to 0$ or apply Proposition 3, respectively, to obtain

$$\begin{aligned} &\|(a - \ell_1)^+\|_{L^1(\Omega)} + \|(b - \ell_2)^+\|_{L^1(Q)} \\ &\quad \le \|(f^+ - \ell_1)^+\|_{L^1(\Omega)} + \|(F^+ - \ell_2)^+\|_{L^1(Q)}. \end{aligned}$$

The right side is zero, so the result follows.

PROPOSITION 4 (Moser). *Let* $(u, U) \in W_0^{1,p}(\Omega) \times \mathcal{W}_q$ *be a solution to*

$$\begin{aligned} &\mathcal{A}(u) - \lambda'\mu \ni f \quad \text{in } W^{-1,p'}(\Omega), \\ &\mathcal{B}(U) + \gamma'\mu \ni F \quad \text{in } \mathcal{W}_q', \\ &\qquad \mu \in \partial m(\gamma U - \lambda u). \end{aligned}$$

(a) *If* $(f, F) \in L^{\tau'}(\Omega) \times L^{\tau'}(Q)$ *with* $\tau' > \frac{n}{p}$, *and*

$$\widetilde{A}(x, \vec{\xi}) \cdot \vec{\xi} \ge c_0|\xi|^p - g_0(x) \tag{2.2c$'$}$$

where $g_0 \in L^{\tau'}(\Omega)$, *then* $u \in L^\infty(\Omega)$.

(b) *If, additionally,* $F \in L^\infty[\Omega; L^{t'}(\Omega_x)]$ *with* $t' > \frac{n}{q}$,

$$\widetilde{B}(x, y, \vec{\xi}) \cdot \vec{\xi} \geq c_0|\xi|^q - h_0(x, y), \tag{2.3c'}$$

where $h_0 \in L^\infty[\Omega; L^{t'}(\Omega_x)]$, *and* m *satisfies the growth condition* (2.5) *and* $m(0) = 0$, *then* $U \in L^\infty(Q)$.

Proof. (a) Estimate (2.7) of Proposition 1 shows that $\lambda'\mu \in L^{\tau'}(\Omega)$, so that

$$\mathcal{A}(u) = f - \lambda'\mu = \tilde{f} \in L^{\tau'}(\Omega).$$

Lemma 3 of [23] can now be used to conclude $u \in L^\infty(\Omega)$.

(2) Define $\widetilde{U} = U - u\mathbf{1}$. Since $\mathcal{B}(\widetilde{U}) = B(U)$, it follows that

$$\mathcal{B}(\widetilde{U}) + \gamma'\mu = F \text{ in } \mathcal{W}_q', \qquad \mu \in \partial m(\gamma\widetilde{U}),$$

and for almost every $x \in \Omega$, and every $V \in \mathcal{W}_q$

$$(*) \qquad \int_{\Omega_x} \widetilde{B}\big(x, \cdot, \nabla_y \widetilde{U}(x)\big) \cdot \nabla_y V(x) + \int_{\Gamma_x} \mu(x)\gamma V(x) = \int_{\Omega_x} F(x, \cdot)V(x),$$

with $\mu(x) \in \partial m(\gamma\widetilde{U}(x))$. We will now use Moser iteration with $(*)$ to conclude $\|\widetilde{U}(x)\|_{L^\infty(\Omega_x)} \leq C$, where C is to be chosen independently of $x \in \Omega$.

If $\widetilde{U}(x) \in L^r(\Omega_x)$ ($r = q$ suffices for the first iterate), define $s = 1 + (r - t/tq)$ ($\frac{1}{t} + \frac{1}{t'} = 1$). Let $H \in C^1(\mathbb{R})$ satisfy $H(s) = |s|^s$ if $|s| \leq s_0$, H affine for $|s| > s_0$, and define $G(s) = \int_0^s |H'(\xi)|^q \, d\xi$. Since H has linear growth, it follows that $G(\widetilde{U}) \in \mathcal{W}_q$. Substituting $G(\widetilde{U})$ for V in $(*)$ gives

$$\int_{\Omega_x} \widetilde{B}\big(x, \cdot, \nabla_y \widetilde{U}(x)\big) \cdot \nabla_y \widetilde{U}(x) G'\big(\widetilde{U}(x)\big) + \int_{\Gamma_x} \mu(x)\gamma G\big(\widetilde{U}(x)\big) = \int_{\Omega_x} F(x, \cdot) G\big(\widetilde{U}(x)\big).$$

The first term of the formula above is bounded below using (2.3c'). To estimate the second term, use

(i) $\mu\widetilde{U} \geq m(\widetilde{U})$ (as $m(0) = 0$), and

(ii) $\operatorname{sgn}(\widetilde{U}) = \operatorname{sgn}\big(G(\widetilde{U})\big)$ (so that $G(\widetilde{U})/\widetilde{U} \geq 0$ when $\widetilde{U} \neq 0$)

to get

$$\begin{aligned} \mu G(\widetilde{U}) = \mu\widetilde{U}\, G(\widetilde{U})/\widetilde{U} &\geq m(\widetilde{U})\, G(\widetilde{U})/\widetilde{U} \\ &\geq c_0|\widetilde{U}|^q\, G(\widetilde{U})/\widetilde{U} = c_0|\widetilde{U}|^{q-1}|G(\widetilde{U})|, \end{aligned}$$

$$c_0 \int_{\Omega_x} |\nabla_y \widetilde{U}|^q G'(\widetilde{U}) + c_0 \int_{\Gamma_x} |\widetilde{U}|^{q-1}|G(\widetilde{U})| \leq \int_{\Omega_x} FG(\widetilde{U}) + h_0 G'(\widetilde{U}).$$

The first term may be written as $|\nabla_y H(\widetilde{U})|^q$ which, using the Sobolev embedding theorem, is bounded below by

$$c(\varepsilon)\|H(\widetilde{U})\|^q_{L^{\frac{nq}{n-q}}(\Omega_x)} - \varepsilon \int_{\Gamma_x} |H(\widetilde{U})|^q,$$

where $\varepsilon > 0$ can be chosen arbitrarily small (see (2.9)). The right-hand side is bounded using Hölder's inequality.

$$c(\varepsilon)\|H(\widetilde{U})\|^q_{L^{nq/(n-q)}(\Omega_x)} + \int_{\Gamma_x} |\widetilde{U}|^{q-1}|G(\widetilde{U})| - \varepsilon|H(\widetilde{U})|^q$$

$$\leq \frac{1}{c_0}\left(\|F\|_{L^{t'}(\Omega_x)}\|G(\widetilde{U})\|_{L^t(\Omega_x)} + \|h_0\|_{L^{t'}(\Omega_x)}\|G'(\widetilde{U})\|_{L^t(\Omega_x)}\right)$$

when $s_0 \to \infty$, $H(\widetilde{U}) \to |\widetilde{U}|^s$, and $|\widetilde{U}|^{q-1}|G(\widetilde{U})| \to \eta(r)|\widetilde{U}|^{sq}$, where $\eta(r) = \frac{t}{r}s^q = \frac{t}{r}(1 + (r - t/qt))^q$. If ε is chosen as $\varepsilon = \min_{q \leq r < \infty} \eta(r)$, it follows that

$$\|\widetilde{U}\|_{L^{sq(n/n-q)}(\Omega_x)} \leq (cs)^{1/s} \max\left[1, \|\widetilde{U}\|_{L^r(\Omega_x)}\right].$$

The result now follows by iteration of the above estimate.

THEOREM 1. *Assume the hypotheses of Proposition* 1, *Corollary* 1, *Lemma* 4, *and Proposition* 4. *Also, assume that* $Rg(\partial\varphi)$ *and* $Rg(\partial\Phi)$ *are both bounded or that both are equal to* $\mathbb{R}$. *Then* $\overline{\mathbb{C}}$, *the closure of* $\mathbb{C}$ *in* $L^1(\Omega) \times L^1(Q)$, *is m-accretive.*

Proof. Let $f \in L^\infty(\Omega)$ and $F \in L^\infty(Q)$. Corollary 1 asserts there is a solution of (2.12). If the graphs $\partial\varphi$ and $\partial\Phi$ have bounded range, then $a \in L^\infty(\Omega)$, $b \in L^\infty(Q)$, and it follows from Proposition 4 that $u \in L^2(\Omega)$ and $U \in L^2(Q)$. This shows $\mathbb{C}_2[u, U] \ni [a - f, b - F]$, so $(I + \mathbb{C})([a, b]) \ni [f, F]$. Thus, $Rg(I + \overline{\mathbb{C}})$ is dense in and, hence, equal to $L^1(\Omega) \times L^1(Q)$.

If the ranges of $\partial\varphi$ and $\partial\Phi$ equal $\mathbb{R}$, then by Corollary 4 any solution satisfies

$$\|a\|_{L^\infty(\Omega)} \leq K, \qquad \|b\|_{L^\infty(Q)} \leq K,$$

where K depends on f and F. Replace $\partial\varphi, \partial\Phi$ by the appropriately truncated $\partial\varphi_K, \partial\Phi_K$.

The solution with these truncated graphs, then, is a solution of the equation with the original graphs, so we are done.

COROLLARY 5. *Under the hypotheses of Theorem* 1, *problem* (1.1) *has a unique generalized solution* $(a, b) \in C[0, T; L^1(\Omega) \times \overline{L^1(Q)}]$, *provided the data satisfy* $(f, F) \in L^1[0, T; L^1(\Omega) \times L^1(Q)]$, *and* $(a(0), b(0)) \in \overline{D(\mathbb{C})}$.

This follows from the Crandall–Liggett theorem [9], which is proved by showing that the step functions (a^N, b^N), constructed from solutions to the differencing scheme

$$(a^n, b^n) - (a^{n-1}, b^{n-1}) + \tau\mathbb{C}(a^n, b^n) \ni \tau(f^n, F^n) \tag{3.7}$$

($\tau = \frac{T}{N}$), converge uniformly when the operator $\mathbb{C}$ is m-accretive. Benilan [6] proves that these generalized solutions are unique.

All of our results hold for the matched microstructure model problem. Specifically, Lemma 4 and Corollary 4 are obtained from Proposition 3, and Proposition 4 is actually simpler for the matched problem. The analogues of Theorem 1 and Corollary 5 show that the matched problem (1.1a), (1.1b), (1.1c′) has a unique generalized solution $(a, b) \in C[0, T; L^1(\Omega) \times L^1(Q)]$.

The next theorem shows that if the data is further restricted, the generalized solutions will satisfy the partial differential equation (1.1). The following notation is used:

$$L^r(T) = L^r\left[0, T; L^r(\Omega) \times L^r(Q)\right], \qquad 1 \leq r \leq \infty,$$
$$V = W_0^{1,p}(\Omega) \times \mathcal{W}_q,$$
$$\mathcal{V}(T) = L^p\left[0, T; W_0^{1,p}(\Omega)\right] \times L^q[0, T; \mathcal{W}_q],$$
$$\widehat{\mathcal{V}}(T) = W^{1,p'}\left[0, T; W^{-1,p'}(\Omega)\right] \times W^{1,q'}[0, T; \mathcal{W}_q'].$$

THEOREM 2. *Assume the hypotheses of Theorem* 1 *hold and in addition that* $(f,F) \in L^1(T) \cap \mathcal{V}(T)'$ *and* $(a(0),b(0)) \in \overline{D(\mathbb{C})} \cap V'$. *Then the generalized solutions of Corollary* 5 *satisfy*

$$(a,b) \in \widehat{\mathcal{V}}(T), \qquad (u,U) \in \mathcal{V}(T), \tag{3.8a}$$

$$\frac{\partial}{\partial t}(a,b) + \big(\mathcal{A}(u) - \lambda'\mu,\ \mathcal{B}(U) + \gamma'\mu\big) = (f,F) \text{ in } \mathcal{V}(T)', \tag{3.8b}$$

$$(a,b) \in \big(\partial\phi(u), \partial\Phi(U)\big), \qquad \mu \in \partial\tilde{m}(\lambda u - \gamma U). \tag{3.8c}$$

Proof. The results of Grange and Mignot [15] show that the step functions (a^N, b^N) and (u^N, U^N) generated from the differencing scheme (3.7) converge weakly in $\widehat{\mathcal{V}}(T)$ and $\mathcal{V}(T)$, respectively. Moreover, equation (3.8) will be satisfied in the limit, provided the weak limits (a,b) and (u,U) satisfy $(a,b) \in (\partial\phi(u), \partial\Phi(U))$. To establish this inclusion, let $(v,V) \in \mathcal{V}(T)$ and $(\tilde{a},\tilde{b}) \in (\partial\phi(v), \partial\Phi(V))$. The growth conditions on ϕ and Φ guarantee that (a^N, b^N) and $(\tilde{a},\tilde{b}) \in \mathcal{V}(T)'$ are functions, so it is possible to define $(a^N - \tilde{a},\ b^N - \tilde{b})_s$ to be the pair of functions truncated above and below by $\pm s$ $(s > 0)$. This pair of functions is bounded in $L^\infty(T)$ and converges in $L^1(T)$ to $(a - \tilde{a},\ b - \tilde{b})_s$, and so converges in $L^r(T)$ for $1 \le r < \infty$. If $r \ge \max(p', q')$, it follows that $L^r(T) \subset \mathcal{V}(T)'$, so the sequence $(a^N - \tilde{a},\ b^N - \tilde{b})_s$ converges strongly in $\mathcal{V}(T)'$. The monotonicity of $\partial\phi$ and $\partial\Phi$ imply

$$0 \le \Big\langle (a^N - \tilde{a},\ b^N - \tilde{b})_s,\ (u^N - v,\ U^n - V) \Big\rangle.$$

Passing to the limit as $N \to \infty$ and then letting $s \to \infty$ yields

$$0 \le \Big\langle (a - \tilde{a},\ b - \tilde{b})\ ,\ (u - v,\ U - V) \Big\rangle, \qquad (\tilde{a},\tilde{b}) \in \big(\partial\phi(v), \partial\Phi(V)\big).$$

Since $(\partial\phi(\cdot), \partial\Phi(\cdot))$ is maximally monotone, it follows that $(a,b) \in (\partial\phi(u), \partial\Phi(U))$.

Finally, we note that the corresponding solution of the matched problem satisfies

$$(a,b) \in \widetilde{\mathcal{V}}(T), \qquad (\gamma U, U) \in \mathcal{V}(T), \tag{3.8a$'$}$$

$$\frac{\partial}{\partial t}(a,b) + \big(\mathcal{A}(\gamma U), \mathcal{B}(U)\big) = (f,F) \text{ in } \mathcal{V}_0(T)', \tag{3.8b$'$}$$

$$(a,b) \in \big(\partial\varphi(\gamma U), \partial\Phi(U)\big), \qquad U \in \mathcal{W}_0, \tag{3.8c$'$}$$

where the space $\mathcal{V}_0(T)$ is given by

$$\mathcal{V}_0(T) \equiv \Big\{ U \in L^q[0,T;\mathcal{W}_1] : \gamma(U) \in L^p\big[0,T;W_0^{1,p}(\Omega)\big] \Big\}$$

with the appropriate norm for which $(\gamma(U), U) \in \mathcal{V}(T)$ for each $U \in \mathcal{V}_0(T)$.

ON PARABOLIC VOLTERRA EQUATIONS IN SEVERAL SPACE DIMENSIONS*

HONG-MING YIN†

Abstract. In this paper some parabolic integrodifferential equations in n-space dimensions are studied. For the solution of such a linear equation, the classical Schauder and $L_p(Q_T)$ estimates are derived. As a direct corollary, the continuous dependence and the uniqueness of the solution for the full nonlinear integrodifferential equation are obtained. Then the global solvability for a class of quasilinear integrodifferential equations is considered. Using the method of energy estimates and the integral iteration technique along with the results of linear equations, an a priori estimate in the classical space $C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)$ is deduced and the global solution of our problem is established by the continuation argument similar to the case of a parabolic equation.

Key words. nonlinearity, a priori estimates, global existence

AMS(MOS) subject classifications. 35Q25, 45K05

1. Introduction.

Let $T > 0$ and $Q_T = \Omega \times (0, T]$, $T > 0$, where Ω is an open bounded region in R^n with a smooth boundary $\partial\Omega$. In this paper we first study the linear equation:

$$u_t - L_1 u = \int_0^t L_2 u d\tau + f(x,t), \qquad \text{in } Q_T \tag{1.1}$$

where L_1 is a linear elliptic operator:

$$L_1 u = a_{ij}(x,t)u_{x_i x_j} + b_i(x,t)u_{x_i} + c(x,t)u$$

and L_2 is an arbitrary differential operator of the second order:

$$L_2 u = c_{ij}(x,t,\tau)u_{x_i x_j} + d_i(x,t,\tau)u_{x_i} + e(x,t,\tau)u.$$

For the solution of this linear equation, we shall derive a priori Schauder and $W_p^{2,1}(Q_T)$ estimates which are well known for solutions of parabolic partial differential equations. Using these results, we then consider a class of nonlinear equations:

$$\begin{aligned} u_t = {} & \frac{\partial}{\partial x_i}\left[a_{ij}\left(x,t,u,\int_0^t u d\tau\right)\frac{\partial u}{\partial x_j}\right] \\ & + \int_0^t \left[\frac{\partial}{\partial x_i} b_i(x,t,\tau,u) + c(x,t,\tau,u)\right] d\tau \quad \text{in } Q_T \end{aligned} \tag{1.2}$$

and establish the global solvability. Here and throughout the paper we shall use the standard notation: $u_x = (u_{x_1}, \cdots, u_{x_n}) \in R^n, u_{xx} = (u_{x_i x_j}) \in R^{n^2}$ and the repeated subscript implies summation from 1 to n.

The equation (1.1) or its more general form

$$u_t = A(x,t,u,u_x,u_{xx}) + \int_0^t B(x,t,\tau,u,u_x,u_{xx})d\tau \quad \text{in } Q_T, \tag{1.3}$$

where the ellipticity condition

$$\frac{\partial A(x,t,u,p,r)}{\partial r_{ij}}\xi_i\xi_j \geq A_0|\xi|^2 \qquad (A_0 > 0) \tag{1.4}$$

holds, is often called a Volterra integrodifferential equation of parabolic type. This kind of equation represents many mathematical models in physical and engineering fields such as heat transfer in a material with memory, the propagation of disturbances in viscous media, and so on (cf. [19]). The nonlinear equation (1.2) can be regarded as the generalization of some practical models in physics and biology. As an example, we consider the nonlinear version of the nuclear reactor model (cf. [21, p. 172]

$$u_t - \frac{\partial}{\partial x_i}[a_{ij}(x,t,u,v)u_{x_j}] = u(\lambda - bv), \tag{1.5}$$

$$v_t = -cv + au, \tag{1.6}$$

where u represents the fast neutron density and v the fuel temperature. It is easy to see by (1.6) that

$$v(x,t) = v_0(x) + a\int_0^t e^{-c(t-\tau)}u(x,\tau)d\tau.$$

Hence, the system (1.5)–(1.6) can be written as the form which is similar to the equation (1.2). Similar models can be found in [21] such as the Fitzhugh–Nagumo system and the degenerate Volterra–Lotka model in which only one species diffuses is included. Recently, much attention has been received in the study of the well-posedness of the problem as well as its numerical solution. A large group of people write the equation (1.3) as a Volterra type integrodifferential equation in an abstract Banach space:

$$\frac{du(t)}{dt} = A(t,u(t)) + \int_0^t B(s,u(s))ds.$$

They employ the analytic semigroup theory to study the solvability of the problem and other properties (cf., e.g., [4], [7], [9], [12], [13], [16], [18]). There are also a number of authors who take the derivative with respect to t in the equation (1.3) and obtain a third-order partial differential equation which is of mixed type (cf. [3], [5], [6], [8], [20], [22], etc.). For such an equation, they use the Galerkin approach and some special treatments to investigate the local and global solvability of the problem when the principal part $A(x,t,u,u_x,u_{xx})$ is a linear elliptic operator. These methods are powerful and many good results have been carried out previously under certain conditions. For a nonlinear elliptic operator A, the global solvability of the problem becomes much more difficult. Some effort has been devoted to this investigation (cf., e.g., [4], [16], [18], etc.). More recently, Yin [24] and [25] considers the problem from a rather different viewpoint. He regards the equation (1.1) as a parabolic one with a perturbation (the integral term). Hence, the theory of parabolic equations can be applied to the study of the problem. Indeed, as will be seen in §2 of this paper, the solution of the linear equation possesses many features such as Schauder and $W_p^{2,1}(Q_T)$ estimates which play important roles when studying nonlinear equations. In [24] and [25], the author establishes the global existence of the solutions for two classes of nonlinear integrodifferential equations in one space dimension. In the present

paper we will show global solvability for the nonlinear equation (1.2). We first derive a uniform bound by applying the integral iteration technique. Then we employ an analogous approach as in [2] to derive the $W_p^{2,1}$-estimate. Finally, the results for the solutions of linear problems are used to deduce an a priori estimate in $C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)$ and then the global solution is obtained by the method of continuity.

Remark. The argument presented in this paper can be used to deal with a more general equation than (1.2). However, these generalizations are left to the reader.

In §2 the Schauder and $L_p(Q_T)$ estimates are proved, and then as a direct corollary the continuous dependence and uniqueness of the solution for the full nonlinear equation (1.3) are obtained. In §3 we establish the global existence of the solution for the equation (1.3) associated with the suitable initial and boundary conditions.

For the reader's convenience, we list the following notation: Let $Q_t = \Omega \times (0,t]$ for $t \in (0,T]$, $S = \partial\Omega$, $S_T = S \times [0,T]$, $P_T = Q_T \times [0,T]$.

$$
\begin{aligned}
&||u||_{C(\bar{Q}_T)} = \max_{\bar{Q}_T} |u(x,t)|,\\
&[u]_{C^{\alpha,\alpha/2}(Q_t)} = \sup_{(x,s)\neq(x',s'),0\leq s,s'\leq t} \frac{|u(x,s)-u(x',s')|}{|x-x'|^\alpha + |s-s'|^{\alpha/2}},\\
&||u||_{C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_T)} = ||u||_{C(\bar{Q}_T)} + [u]_{C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_T)},\\
&||u||_{C^{1+\alpha,\frac{1+\alpha}{2}}(\bar{Q}_T)} = ||u||_{C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_T)} + ||u_x||_{C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_T)},\\
&||u||_{C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)} = ||u||_{C^{1+\alpha,\frac{1+\alpha}{2}}(\bar{Q}_T)} + ||u_{xx}||_{C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_T)} + ||u_t||_{C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_T)},\\
&||u||^p_{W^1_p(\Omega)} = \int_\Omega (u^p + u_x^p)dx,\\
&||w||^p_{W_p^{2,1}(Q_T)} = \int\int_{Q_T} [|u|^p + |u_x|^p + |u_{xx}|^p + |u_t|^p]dxdt
\end{aligned}
$$

for $p > 1$ arbitrary. Moreover, on $P_T = Q_T \times (0,T]$,

(1.7)
$$
[u]^*_{C^{\alpha,\alpha/2,\alpha/2}(P_T)} = \sup_{(x,t,s)\neq(x',t',s'),0\leq t,t',s,s'\leq T} \frac{|u(x,t,s)-u(x',t',s')|}{|x-x'|^\alpha + |t-t'|^{\alpha/2} + |s-s'|^{\alpha/2}}.
$$

The norms $||\cdot||^*_{C^{\alpha,\alpha/2,\alpha/2}(P_T)}, \cdots, ||\cdot||^*_{C^{2+\alpha,1+\alpha/2,1+\alpha/2}(P_T)}$ can be defined similarly.

2. Schauder and $L_P(Q_T)$ estimates. It is well known that the theory of Schauder and $L_p(Q_T)$ estimates are important in the study of parabolic equations. In this section we shall derive such a priori estimates for the solutions of linear integrodifferential equations. We begin with the following Gronwall's inequality without its proof (cf. [14, Lemma 7.1.1].

LEMMA 2.1. *Assume that the function $g(t)$ is a nonnegative, nondecreasing, and integrable function on $[0,T]$. The function $f(t)$ satisfies*

$$
0 \leq f(t) \leq g(t) + \int_0^t \frac{f(\tau)}{(t-\tau)^\alpha} d\tau, \qquad 0 \leq t \leq T, \tag{2.1}
$$

where $0 \leq \alpha < 1$. Then

$$
f(t) \leq C(\alpha,T)g(t), \qquad t \in [0,T],
$$

where $C(\alpha, T)$ depends only on α and the upper bound of T.

The following lemma is elementary.

LEMMA 2.2. *Let $g(x,t)$ be a function in $C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_T)(0 \le \alpha < 1)$ and $G(x,t)$ be a function defined as $\int_0^t h(x,t,\tau)g(x,\tau)d\tau$, where $h(x,t,s)$ is defined on $Q_T \times [0,T]$ and Hölder continuous with respect to x,t and s with the exponent α, $\frac{\alpha}{2}$ and $\frac{\alpha}{2}$, respectively. Then*

$$||G||_{C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_t)} \le C\int_0^t \left[2 + \frac{1}{(t-\tau)^\alpha}\right] ||g(x,s)||_{C^{\alpha,\alpha/2}(\bar{Q}_\tau)}d\tau, \tag{2.2}$$

where C depends on the Hölder norm of $h(x,t,s)$ and T.

Proof. By the definition, we have

$$||G(x,\tau)||_{C(\bar{Q}_t)} \le C\int_0^t ||g(x,s)||_{C(\bar{Q}_\tau)}d\tau.$$

For any two points (x,s) and (x',s') in Q_t, we assume $s' > s$ without loss of generality.

$$\begin{aligned}
&\frac{|G(x,s) - G(x',s')|}{|x-x'|^\alpha + |s-s'|^{\frac{\alpha}{2}}} \\
&= \frac{|\int_0^s h(x,s,z)g(x,z)dz - \int_0^{s'} h(x',s',z)g(x',z)dz|}{|x-x'|^\alpha + |s-s'|^{\frac{\alpha}{2}}} \\
&\le \frac{\int_0^s [h(x,s,z) - h(x',s',z)]g(x,z)dz + \int_0^s |h||g(x,z) - g(x',z)|dz + \int_s^{s'} |h||g(x',z)|dz}{|x-x'|^\alpha + |s-s'|^{\frac{\alpha}{2}}}.
\end{aligned}$$

We split the above fraction into three terms denoted by K_1, K_2, and K_3. It is clear by the Hölder continuity of $h(x,t,s)$ that

$$K_1 \le C\int_0^s ||g(x,s)||_{C(\bar{Q}_\tau)}d\tau$$

and

$$\begin{aligned}
K_2 &\le C\int_0^s \frac{|g(x,z) - g(x',z)|}{|x-x'|^\alpha}dz \\
&\le C\int_0^{s'} ||g(x,\tau)||_{C^{\alpha,\alpha/2}(\bar{Q}_z)}dz.
\end{aligned}$$

To estimate K_3, noting that $s \le z \le s'$, we have

$$\frac{1}{|s'-s|} \le \frac{1}{|s'-z|}.$$

Therefore,

$$\begin{aligned}
K_3 &\le C\int_s^{s'} \frac{|g(x',z)|}{|s'-z|^{\frac{\alpha}{2}}}dz \\
&\le C\int_0^{s'} \frac{|g(x',z)|}{|s'-z|^{\frac{\alpha}{2}}}dz \\
&\le C\int_0^{s'} \frac{1}{|s'-z|^{\frac{\alpha}{2}}}||g||_{C(Q_z)}dz.
\end{aligned}$$

By combining the estimates for K_1, K_2, and K_3 and then taking the supremum over $\bar{Q}_t$ on both sides of the above inequality in conjunction with the maximum norm of $G(x,t)$, we obtain

$$||G||_{C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_t)} \leq C \sup_{0\leq s'\leq t} \int_0^{s'} \left[2 + \frac{1}{(s'-\tau)^\alpha}\right] ||g(x,s)||_{C^{\alpha,\alpha/2}(\bar{Q}_\tau)} d\tau.$$

Since $||g(x,s)||_{C^{\alpha,\alpha/2}(\bar{Q}_\tau)}$ is a monotone increasing function of τ, by the integration by parts, we see that the function

$$\int_0^{s'} \left[2 + \frac{1}{(s'-\tau)^\alpha}\right] ||g(x,s)||_{C^{\alpha,\alpha/2}(\bar{Q}_\tau)} d\tau$$

is monotone increasing. Thus, we end our proof.

Now we consider the following linear initial boundary value problem:

$$u_t - L_1 u = \int_0^t L_2 u dx + f(x,t), \qquad Q_T, \tag{2.3}$$

$$u(x,t) = g(x,t), \qquad (x,t) \in S_T, \tag{2.4}$$

$$u(x,0) = u_0(x), \qquad x \in \bar{\Omega}, \tag{2.5}$$

where the operators L_1 and L_2 are the same as in (1.1).

To obtain a Schauder type estimate, we assume the following conditions hold.

H(2.1). The coefficients of the operators L_1 and L_2 are in the Banach spaces $C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_T)$ and $C^{\alpha,\frac{\alpha}{2},\frac{\alpha}{2}}(\bar{P}_T)$, respectively. Moreover, there exists a constant A_0 which may depend on Q_T such that

$$\sum_{i,j=1}^n [||a_{ij}||_{C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_T)} + ||c_{ij}||^*_{C^{\alpha,\alpha/2,\alpha/2}(P_T)}] + \sum_{i=1}^n [||b_i||_{C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_T)} + ||d_i||^*_{C^{\alpha,\alpha/2,\alpha/2}(P_T)}]$$
$$+ ||c||_{C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_T)} + ||e||^*_{C^{\alpha,\alpha/2,\alpha/2}(P_T)} \leq A_0.$$

The function $f(x,t) \in C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_T)$. Moreover, the ellipticity condition

$$a_{ij}(x,t)\xi_i\xi_j \geq a_0|\xi|^2 \qquad (a_0 > 0),$$

for $\xi \in R^n$ holds.

H(2.2). There exists a function $\Phi(x,t) \in C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)$ such that $\Phi(x,t) = g(x,t)$ on S_T and $\Phi(x,0) = u_0(x)$ on $\bar{\Omega}$.

Now we state the Schauder estimate.

THEOREM 2.1. *Under the conditions* H(2.1), (2.2), *the solution* $u(x,t)$ *of the problem* (2.3)–(2.5) *satisfies*

$$||u||_{C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)} \leq C[||\Phi||_{C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)} + ||f||_{C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_T)}]. \tag{2.6}$$

Proof. Let $u(x,t)$ be an arbitrary classical solution of the problem (2.3)–(2.5). Regarding the right side of the equation (2.3) as an inhomogeneous term $F(x,t)$, we apply the Schauder estimate (cf. [10], Thm. 6, Chap. 3) for a parabolic equation to obtain

$$||u||_{C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_t)} \leq C[||F||_{C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_t)} + ||\Phi||_{C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_t)}],$$

where the constant C depends only on a_0, A_0, and Q_T.

Since the coefficients of L_2 are Hölder continuous over P_T, by a direct calculation and using Lemma 2.2, we find that

$$||F||_{C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_t)} \le C\int_0^t \left[2+\frac{1}{(t-\tau)^{\frac{\alpha}{2}}}\right]||u||_{C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_\tau)}d\tau + ||f||_{C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_t)},$$

where the constant C depends only on the Hölder norms of the coefficients of L_2. Thus, the desired result follows from Gronwall's inequality (Lemma 2.1).

From the above result, we immediately have the following corollaries.

COROLLARY 2.1. *Under conditions* H(2.1), (2.2), *the problem* (2.3)–(2.5) *has a unique classical solution.*

COROLLARY 2.2. *Assume that the functions A and B in* (1.3) *are smooth with respect to all of their arguments and the ellipticity condition* (1.4) *is satisfied. Let $u_1(x,t)$ and $u_2(x,t)$ be two classical solutions of the* (1.3) *corresponding to the initial-boundary data $(u_{01}(x), g_1(x,t))$ and $(u_{02}(x), g_2(x,t))$, respectively. Then*

$$||u_1-u_2||_{C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)} \le C||\Phi||_{C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)},$$

where $\Phi(x,t) \in C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)$ coincides with $g_1(x,t)-g_2(x,t)$ on S_T and $u_{01}(x)-u_{02}(x)$ on $\{(x,t): x\in\bar{\Omega}, t=0\}$.

In fact, the existence of the solution for (2.3)–(2.5) can be obtained by the method of continuity or the bootstrap argument (see the proof of Theorem 3.1). To prove the result of Corollary 2.2, let $w(x,t) = u_1(x,t) - u_2(x,t)$. Then $w(x,t)$ satisfies the linear equation (2.3) with the Hölder coefficients of L_1 and L_2. Hence, the Schauder estimate (2.6) implies the desired result.

To study nonlinear parabolic integrodifferential equations, we often need the following $W_p^{2,1}$-estimate.

THEOREM 2.2. *Assume that $a_{ij}(x,t)$ is continuous on $\bar{Q}_T$ and*

$$a_{ij}(x,t)\xi_i\xi_j \ge a_0|\xi|^2 \qquad (a_0>0).$$

Moreover, the coefficients of L_1 and L_2 are in $L^\infty(Q_T)$ and $L^\infty(P_T)$ $f(x,t)\in L^p(Q_T)$. There exists a function $\Phi(x,t)\in W_p^{2,1}(Q_T)$ with $\Phi(x,0)=u_0(x)$ on $\bar{\Omega}$ and $\Phi(x,t)=g(x,t)$ on S_T. Then

$$||u||_{W_p^{2,1}(Q_T)} \le C[||\Phi(x,t)||_{W_p^{2,1}(Q_T)} + ||f(x,t)||_{L^p(Q_T)}], \tag{2.7}$$

where C depends only on the continuity modulus of $a_{ij}(x,t)$ and the bounds of the coefficients of L_1 and L_2.

Proof. We regard the right side of (2.3) as $F(x,t)$ again and apply $W_p^{2,1}(Q_T)$-estimate for parabolic equations (cf. [17, Thm. 9.1, p. 341]) to obtain

$$\begin{aligned}||u||_{W_p^{2,1}(Q_T)} &\le C[||\Phi||_{W_p^{2,1}(Q_T)} + ||F||_{L_p(Q_T)}]\\ &\le C[||\Phi||_{W_p^{2,1}(Q_T)} + \int_0^T ||u||_{W_p^{2,1}(Q_t)}dt].\end{aligned}$$

Since T can be arbitrary, an application of Gronwall's inequality implies our result.

3. Global solvability. In this section we are concerned with the global existence of the solution for the equation

$$u_t = \frac{\partial}{\partial x_i}\left[a_{ij}\left(x,t,u,\int_0^t u d\tau\right)\frac{\partial u}{\partial x_j}\right] + \int_0^t \left[\frac{\partial}{\partial x_i} b_i(x,t,\tau,u) + c(x,t,\tau,u)\right] d\tau \quad \text{in } Q_T \tag{3.1}$$

subject to the initial and boundary conditions

$$u(x,t) = 0, \qquad (x,t) \in S_T, \tag{3.2}$$

$$u(x,0) = u_0(x), \qquad x \in \bar{\Omega}, . \tag{3.3}$$

Throughout this section, the following conditions are assumed.

H(3.1). The function $a_{ij}(x,t,u,s) \in C^{2,2,2,3}(\bar{Q}_T \times R^2)$ and $a_{ij}(x,t,u,s)\xi_i\xi_j \geq a_0|\xi|^2$ $(a_0 > 0)$ for any $\xi \in R^n$. The functions $b_i(x,t,s,u)$ and $c(x,t,s,u)$ are in $C^{2,1,1,2}(\bar{Q}_T \times [0,T] \times R)$. Moreover, there exists a constant A_0 such that

$$\sum_{i=1}^{n} |b_i(x,t,s,u)| + |c(x,t,s,u)| \leq A_0[1+|u|],$$

where a_0 and A_0 may depend on Q_T.

The initial data $u_0(x) \in C^{2+\alpha}(\bar{\Omega})$ and the consistency conditions

$$u_0(x) = 0, \qquad \frac{\partial}{\partial x_i}[a_{ij}(x,0,u_0(x),0)u_{x_j}] = 0 \quad \text{on } \partial\Omega$$

hold. To obtain the global existence, we shall derive an a priori estimate in the Banach space $C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)$. Since the classical maximum principle is no longer valid, we will employ energy estimates to deduce such a bound step-by-step.

LEMMA 3.1. *The solution $u(x,t)$ of (3.1)–(3.3) satisfies*

$$\int_\Omega u^2 dx + \int_0^t \int_\Omega u_x^2 dx \leq C_1, \tag{3.4}$$

where C_1 depends only on the known data and the upper bound of T.

Proof. If the equation (3.1) is multiplied by $u(x,t)$ and integrated over Q_t, we have

$$\frac{1}{2}\int_\Omega u(x,t)^2 dx + a_0 \int_0^t \int_\Omega u_x^2 dx dt \leq \frac{1}{2}\int_\Omega u_0^2 dx + \left| \int_0^t \int_\Omega u \left\{ \int_0^\tau \left[\frac{\partial}{\partial x_i} b_i(\cdots) + c(\cdots)\right] d\xi \right\} dx d\tau \right|.$$

We perform the integration by parts to the second term of the right side of the above inequality and apply condition H(3.1). It follows by Cauchy's inequality that

$$\begin{aligned} &\left| \int_0^t \int_\Omega u \left\{ \int_0^\tau \left[\frac{\partial}{\partial x_i} b_i(\cdots) + c(\cdots)\right] d\xi \right\} dx d\tau \right| \\ &= \left| \int_0^t \int_\Omega \left\{ -u_{x_i} \left[\int_0^\tau b_i(\cdots) d\xi\right] + \left[\int_0^\tau c(\cdots)\right] d\xi \right\} dx d\tau \right| \\ &\leq C(T) + \varepsilon \int\int_{Q_t} u_x^2 dx + C(\varepsilon) \int\int_{Q_t} u^2 dx dt. \end{aligned}$$

By taking $\varepsilon = a_0/2$ and applying Gronwall's inequality, we have the desired result.

LEMMA 3.2. *There exists a constant C_2 which depends only on the known data and the upper bound of T such that*

$$\sup_{0\le t\le T} ||u(\cdot,t)||_{L^\infty(\Omega)} \le C_2. \tag{3.5}$$

Proof. The proof is based on the integral iteration technique similar to Alikakos [1]. We do the following calculation for any $p = 2^k$ with $k \ge 1$:

$$\begin{aligned}
&\int_0^t \frac{d}{d\tau}\left[\int_\Omega u^p dx\right] d\tau \\
&\quad = \int_0^t \int_\Omega p u^{p-1} u_\tau dx d\tau \\
&\quad = \int_0^t \int_\Omega p u^{p-1}\left[\frac{\partial}{\partial x_i} a_{ij}(\cdots)\frac{\partial u}{\partial x_j}\right] dx d\tau \\
&\qquad + \int_0^t \int_\Omega p u^{p-1}\left\{\int_0^\tau \left[\frac{\partial}{\partial x_i} b_i(\cdots) + c(\cdots)\right] d\xi\right\} dx d\tau \\
&\quad = -\int_0^t \int_\Omega p(p-1)u^{p-2} u_{x_i} u_{x_j} a_{ij}(\cdots) dx d\tau \\
&\qquad - \int_0^t \int_\Omega p(p-1)u^{p-2} u_{x_i}\left[\int_0^\tau b_i(\cdots) d\xi\right] dx d\tau + \int_0^t \int_\Omega p u^{p-1}\left[\int_0^\tau c(\cdots) d\xi\right] dx d\tau \\
&\quad = I_1 + I_2 + I_3.
\end{aligned}$$

It is clear that the elliptic condition implies

$$I_1 \le -a_0 \int_0^t \int_\Omega p(p-1)u^{p-2} u_x^2 dx dt.$$

By Cauchy's inequality and condition H(3.1), we have

$$\begin{aligned}
|I_2| &\le \frac{a_0}{2} p(p-1)\int\int_{Q_t} u^{p-2} u_x^2 dx dt + Cp(p-1)\int\int_{Q_t} u^{p-2}\left[\int_0^\tau (1+u^2) d\xi\right] dx d\tau \\
&\le \frac{a_0}{2} p(p-1)\int\int_{Q_t} u^{p-2} u_x^2 dx dt + C(T)p(p-1)\int\int_{Q_t} [u^{p-2} + u^p] dx dt.
\end{aligned}$$

Here at the final step we have used Young's inequality:

$$ab \le \eta \frac{a^r}{r} + \eta^{-\frac{s}{r}} \frac{b^s}{s}$$

for $\frac{1}{r} + \frac{1}{s} = 1$ $(a, b \ge 0,\ r, s > 1)$.

Similarly,

$$|I_3| \le C(T)p \int\int_{Q_t} [|u|^{p-1} + u^p] dx d\tau.$$

We may assume that

$$\sup_{0\le t\le T} ||u(\cdot,t)||_{L^\infty(\Omega)} \ge 1.$$

Otherwise, we have the result. We also assume that there exists an integer p_0 such that

$$\int_\Omega u_0^p dx \le \frac{1}{2} \sup_{0\le t\le T} \int_\Omega u^p dx \tag{3.6}$$

holds for $p > p_0$. Otherwise, there exists a sequence p_i which approaches ∞ as $i \to \infty$ such that

$$\int_\Omega u_0^{p_i} dx \ge \frac{1}{2} \sup_{0\le t\le T} \int_\Omega u^{p_i} dx.$$

If p_ith root is taken on both sides of the above inequality, the desired result is obtained. Let p_0 be the smallest integer such that the inequality (3.6) holds for $p > p_0$. Hence we combine the above estimates to obtain for $p > p_0$

$$\begin{aligned} &\int_\Omega u(x,t)^p dx + p(p-1)\int_0^t \int_\Omega u^{p-2} u_x^2 dx dt \\ &\qquad \le Cp(p-1) \sup_{0\le t\le T} \int_\Omega u^p dx, \end{aligned} \tag{3.7}$$

where C depends only on the known data and the upper bound of T. Note that Gagliardo–Nirenberg's inequality (cf. [17, p. 62]) for $v(x) \in W_2^1(\Omega)$ with $v(x) = 0$ on $\partial\Omega$ implies:

$$||v(x)||_{L_2(\Omega)} \le \varepsilon ||v_x(x)||_{L_2(\Omega)} + \varepsilon^{-\frac{n}{2}} C ||v(x)||_{L_1(\Omega)}.$$

Observe that

$$\int_\Omega p(p-1) u^{p-2} u_x^2 dx \ge 2 \int_\Omega [(u^{\frac{p}{2}})_x]^2 dx.$$

We apply the above interpolation inequality for $v(x) = u(x,t)^{\frac{p}{2}}$ and take $\varepsilon^2 = [(p(p-1))/2]^{-1}$ in (3.7) to obtain

$$\int_\Omega u^p dx \le Cp^{n+2} \sup_{0\le t\le T} \int_\Omega u^{\frac{p}{2}} dx.$$

If we define

$$A_k = \sup_{0\le t\le T} [\int_\Omega u^p dx]^{\frac{1}{p}}$$

for $p = 2^k, k \ge 1$, we have

$$A_k \le [C2]^{\frac{(n+2)k}{2^k}} A_{k-1}.$$

Letting $k \to \infty$, we have

$$\sup_{0\le t\le T} ||u(\cdot,t)||_{L^\infty(\Omega)} \le C A_{p_0}$$

since

$$\sum_{k=1}^{\infty} \frac{(n+2)k}{2^k}$$

is convergent.

If $p_0 = 2$, then the estimate (3.4) indicates that A_0 is bounded, and so is A_∞. If $p_0 > 2$, since p_0 is the smallest integer such that the inequality (3.6) holds, then

$$A_{p_0} \leq \left[2 \int_\Omega u_0^{p_0} dx\right]^{\frac{1}{p_0}}$$

which is bounded. Therefore, we conclude the result.

By Lemma 3.2, we can obtain the Hölder estimate for the solution of the problem (3.1)–(3.3).

COROLLARY 3.1. *For the solution $u(x,t)$ of* (3.1)–(3.3), *there exist two constants $\alpha (0 < \alpha < 1)$ and C_3 which depends only on the known data and T such that*

$$||u||_{C^{\alpha, \frac{\alpha}{2}}(\bar{Q}_T)} \leq C_3. \tag{3.8}$$

Proof. To show the estimate, we rewrite (3.1) in the following form:

$$u_t = \frac{\partial}{\partial x_i}\left[a_{ij}\left(x,t,u,\int_0^t u d\tau\right)\frac{\partial u}{\partial x_j}\right] + \frac{\partial}{\partial x_i}\left[\int_0^t b_i(x,t,\tau,u)\right] + \int_0^t c(x,t,\tau,u)d\tau \quad \text{in } Q_T.$$

Since $u(x,t)$ is uniformly bounded by the estimate (3.5), it follows that the functions $\int_0^t b_i(x,t,\tau,u)d\tau$ and $\int_0^t c(x,t,\tau,u)d\tau$ are uniformly bounded. We apply the results of [17, Thm. 10.1, Chap. 3, p. 204] to conclude the result.

Next we shall modify the idea in [2] to derive a $W_p^{2,1}(Q_T)$-estimate for $p > 1$. For $\sigma \in [0,1]$, consider the following problem (P_σ) with the equation

$$u_t - \frac{\partial}{\partial x_i}\left[a_{ij}\left(x,t,\sigma u,\int_0^t u d\tau\right)\frac{\partial u}{\partial x_j}\right] = \int_0^t \left\{\frac{\partial}{\partial x_i}[b_i(x,t,\tau,u)] + c(x,t,\tau,u)\right\} d\tau \tag{3.9}$$

subject to the initial-boundary conditions (3.2), (3.3).

It is easy to see by Lemmas 3.1 and 3.2 that any solution $u_\sigma(x,t)$ of the problem (P_σ) satisfies the estimates (3.4), (3.5), and (3.8), which we will use frequently in the sequel without explanation.

We first need a $W_p^{2,1}(Q_T)$-estimate for the case of $\sigma = 0$.

LEMMA 3.3. *Assume that $u(x,t)$ is a classical solution of (P_0). Then*

$$||u||_{W_p^{2,1}(Q_T)} \leq C, \tag{3.10}$$

where C depends only on the known data and the upper bound of T.

Proof. To apply the $W_p^{2,1}(Q_T)$-estimate, we need to rewrite (3.9) in the form:

$$u_t - a_{ij}\left(x,t,0,\int_0^t u d\tau\right)u_{x_i x_j} = a_{ijx_i}u_{x_j} + a_{ijs}\int_0^t u_{x_i}d\tau u_{x_j} + \int_0^t \left\{\frac{\partial}{\partial x_i}[b_i(x,t,\tau,u)] + c(x,t,\tau,u)\right\} d\tau.$$

We denote the right-hand side of the above equation by $G(x,t,u) = J_1 + J_2 + J_3$. Since we have obtained an a priori bound of the Hölder norm for $u(x,t)$ by Corollary 3.1, the continuity moduli of the coefficients $a_{ij}(x,t,0,\int_0^t u d\tau)$ are known. Therefore, for any solution $u(x,t)$ of (P_0), the $W_p^{2,1}(Q_T)$ estimate for parabolic equations (cf. [17 p. 341]) can be applied to obtain

$$||u||_{W_p^{2,1}(Q_T)} \leq C||G||_{L^p(Q_T)}, \qquad p > 1,$$

where C depends only on C_2 and C_3.

It is easy to see that

$$||J_1||_{L^p(Q_T)} + ||J_3||_{L^p(Q_T)} \leq C[1 + ||u_x||_{L^p(Q_T)}]$$

which can be dominated by means of the interpolation inequality (cf. [11, Thm. 1.10.1]) by

$$\varepsilon||u||_{W_p^{2,1}(Q_T)} + C(\varepsilon).$$

To estimate J_2, we use Cauchy's inequality to get

$$\begin{aligned} ||J_2||^p_{L^p(Q_T)} &\leq \int_0^T \int_\Omega \left[\int_0^t |u_x| d\tau \cdot |u_x|\right]^p dx \\ &\leq \varepsilon \int_0^T \int_\Omega u_x^{2p} dx + C(\varepsilon) T \int_0^T \int_\Omega \int_0^t u_x^{2p} dx \\ &\equiv J_{21} + J_{22}. \end{aligned}$$

Now for any fixed $t \in [0,T]$ we use Gagliardo–Nirenberg's inequality (cf. [11, Thm. 1.10.1]):

$$||u(\cdot,t)_x^2||_{L^p(\Omega)} \leq C||u(\cdot,t)||_{L^\infty(\Omega)}||u(\cdot,t)||_{W_p^2(\Omega)}.$$

It follows that

$$\int_\Omega u_x^{2p} dx \leq C + C\int_\Omega u_{xx}^p dx.$$

Consequently,

$$\int_0^T \int_\Omega u_x^{2p} dx dt \leq C + C\int_0^T \int_\Omega u_{xx}^p dx dt$$

and

$$\int_0^T \int_0^t \int_0^\Omega u_x^{2p} dx d\tau dt \leq C + C\int_0^T \int_0^t \int_\Omega u_{xx}^p dx d\tau dt.$$

Finally, we first take ε to be small enough such that $C\varepsilon < \frac{1}{2}$ and then employ Gronwall's inequality to conclude the desired estimate.

We now intend to estimate $u_\sigma(x,t)$ in the norm of $W_p^{2,1}(Q_T)$. Let u_1 and u_2 be two classical solutions of (P_σ) corresponding to the parameters σ_1 and σ_2.

Define $w(x,t) = u_1(x,t) - u_2(x,t)$, $(x,t) \in \bar{Q}_T$. It is easy to see that $w(x,t)$ satisfies the following equations:

$$
\begin{aligned}
&w_t - \frac{\partial}{\partial x_i}\left[a_{ij}\left(x,t,\sigma_1 u_1, \int_0^t u_1 d\tau\right)\frac{\partial w}{\partial x_j}\right] \\
&\quad = \frac{\partial}{\partial x_i}\left\{\left[A_{1ij}(x,t)\sigma_1 w + A_{2ij}(x,t)\int_0^t w d\tau + A_{3ij}(x,t)(\sigma_1 - \sigma_2)\right]\frac{\partial u_2}{\partial x_j}\right\} \\
&\quad + \int_0^t \left\{\frac{\partial}{\partial x_i}[B_i(x,t,\tau)w(x,\tau)] + C(x,t,\tau)w(x,\tau)\right\} d\tau, \qquad (3.11)
\end{aligned}
$$

$$
w(x,t) = 0, \qquad (x,t) \in S_T, \qquad (3.12)
$$

$$
w(x,0) = 0, \qquad x \in \bar{\Omega}, \qquad (3.13)
$$

where

$$
\begin{aligned}
A_{1ij}(x,t) &= \int_0^1 a_{iju}\left(x,t,z(\sigma_1 u_1) + (1-z)(\sigma_1 u_2), \int_0^t u_1 d\tau\right) dz, \\
A_{2ij}(x,t) &= \int_0^1 a_{ijs}\left(x,t,\sigma_2 u_2, z\int_0^t u_1 d\tau + (1-z)\int_0^t u_2 d\tau\right) dz, \\
A_{3ij}(x,t) &= \int_0^1 a_{iju}\left(x,t,z(\sigma_1 u_2) + (1-z)(\sigma_2 u_2), \int_0^t u_1 d\tau\right) dz, \\
B_i(x,t,\tau) &= \int_0^1 b_{iu}(x,t,\tau, zu_1 + (1-z)u_2) dz, \\
C(x,t,\tau) &= \int_0^1 c_u(x,t,\tau, zu_1 + (1-z)u_2) dz,
\end{aligned}
$$

which are uniformly bounded $(i,j = 1,\cdots,n)$.

We claim that

$$
\sup_{0\le t\le T} ||w(\cdot,t)||_{L^\infty(\Omega)} \le C(\sigma_1 - \sigma_2), \qquad (3.14)
$$

where the constant C depends only on the known data and the upper bound of T.

Indeed, if we multiply the equation (3.11) by $w(x,t)$ and integrate it over Q_T, by a similar calculation to that of Lemma 3.1 we find

$$
\sup_{0\le t\le T}\int_\Omega w^2 dx + \int_0^T\int_\Omega w_x^2 dx dt \le C[\sigma_1 - \sigma_2]^2.
$$

By an analogous computation to that in the proof of Lemma 3.2 and noting the uniform boundedness of $w(x,t)$, we can deduce our assertion (3.14).

With the above auxiliary estimates in hand we are ready to show the following result.

LEMMA 3.4. *Let $u(x,t)$ be a solution of the problem* (3.1)–(3.3). *There exists a constant C_4 which depends only on the known data and the upper bound of T such that*

$$
||u||_{W_p^{2,1}(Q_T)} \le C_4. \qquad (3.15)
$$

Proof. We assert that the following estimate holds:

$$||w||^p_{w_p^{2,1}(Q_T)} \leq C + C\int_0^T \int_\Omega w_x^{2p} dxdt.$$

In fact, we write (3.11) into a nondivergence form and note that

$$\left\| \frac{\partial A_{kij}}{\partial x_i} \right\|_{L^p(Q_T)} \leq C[||u_{1x}||_{L^p(Q_T)} + ||u_{2x}||_{L^p(Q_T)}].$$

Then we perform the same calculation for the solution $w(x,t)$ of the problem (3.11)–(3.13) as for $u(x,t)$ of (P_0) in Lemma 3.2 and then employ $W_p^{2,1}$-estimate as well as Cauchy's inequality to get

$$||w||^p_{W_p^{2,1}(Q_T)} \leq C[1 + ||u_{1x}^2||^p_{L^p(Q_T)} + ||u_{2x}^2||^p_{L^p(Q_T)} + ||w_x^2||^p_{L^p(Q_T)}].$$

Hence, the relationship $u_2 = w - u_1$ yields

$$||w||^p_{w_p^{2,1}(Q_T)} \leq C\left[1 + \int_0^T \int_\Omega u_{1x}^{2p} dxdt + \int_0^T \int_\Omega w_x^{2p}\right] dxdt.$$

Again, we apply Gagliardo–Nirenberg's inequality

$$||w_x^2||_{L^p(Q_T)} \leq C||w||_{L^\infty(\Omega)}||w||_{W_p^2(\Omega)}$$

and the estimate (3.14) to arrive at

$$||w||^p_{W_p^{2,1}(Q_T)} \leq C\left[1 + \int_0^T \int_\Omega u_{1x}^{2p} dxdt + |\sigma_1 - \sigma_2|||w||^p_{W_p^{2,1}(Q_T)}\right].$$

Now we take $\sigma_1 = 0$ and $u_1(x,t)$ is the corresponding solution of (P_0). Moreover, we restrict that $\sigma_2 \in [0, \frac{1}{N}]$, where N is large enough such that $\frac{C}{N} \leq \frac{1}{2}$. Thus, we obtain the estimate (3.15) for u_{σ_2} with $\sigma_2 \in [0, \frac{1}{N}]$ since u_1 satisfies (3.10). We can repeat the above procedure and derive the estimate (3.15) for the solution u_σ with $\sigma \in [\frac{1}{N}, \frac{2}{N}]$. After N steps, we finally reach the estimate (3.15) for $\sigma = 1$.

By Lemma 3.3, we immediately have the following corollary.

COROLLARY 3.2. *For any solution $u(x,t)$ of* (3.1)–(3.3), *we have*

$$||u||_{C^{1+\alpha,\frac{1+\alpha}{2}}(\bar{Q}_T)} \leq C_6. \tag{3.16}$$

Proof. This follows from Lemma 3.4 and the interpolation inequality (cf. [17, Cor., p. 342]) if $p > \frac{n+2}{2}$.

LEMMA 3.5. *There exists a constant C_7 which depends only on the known data and T such that*

$$||u||_{C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)} \leq C_7. \tag{3.17}$$

Proof. We rewrite (3.1) in the following form:

$$u_t - a_{ij}\left(x,t,u,\int_0^t u d\tau\right)u_{x_ix_j} = a_{iju}u_{x_i}u_{x_j} + \left[a_{ijx_i} + a_{ijs}\cdot\int_0^t u_{x_i}d\tau\right]u_{x_j} + \int_0^t\left[\frac{\partial}{\partial x_i}b_i(x,t,\tau,u) + c(x,t,\tau,u)\right]d\tau.$$

From Corollary 3.2, the right side of the above equality is uniformly bounded in the norm of $C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_T)$. Moreover, the coefficient $a_{ij}(\cdots)$ is Hölder continuous on $\bar{Q}_T$. By the Schauder estimate (2.6), we conclude the result.

THEOREM 3.1. *The problem* (3.1)–(3.3) *has a unique global solution.*

Proof. The result can be demonstrated by the continuation argument which is similar to that of parabolic equations (cf. [10, Chap. 3]). For $\lambda \in [0,1]$, we consider the system (P_λ)

$$u_t - \frac{\partial}{\partial x_i}\left[a_{ij}(x,t,u,\lambda\int_0^t u d\tau)\frac{\partial u}{\partial x_j}\right] = \lambda\int_0^t\left[\frac{\partial}{\partial x_i}b_i(x,t,\tau,u) + c(x,t,\tau,u)\right]d\tau \quad \text{in } Q_T$$

subject to the initial-boundary conditions (3.2), (3.3), where the initial data $u_0(x)$ is replaced by $\lambda u_0(x)$. Clearly, the estimate in Lemma 3.5 is also true for any solution u_λ of (P_λ). Let $\Sigma = \{\lambda :$ the problem (P_λ) is solvable on $[0,T]\}$. It is easy to see (cf., e.g., [17, Thm. 6, p. 452]) that $0 \in \Sigma$. By applying the a priori estimate (3.17) we can show that the set Σ is open as well as closed. It follows that $\Sigma = [0,1]$. When $\lambda = 1$, it follows that the problem (3.1)–(3.3) is solvable on $[0,T]$ for any $T > 0$.

Remark. With the a priori estimate (3.17), Theorem 3.1 can alternatively be shown by the bootstrap argument (cf. [21]).

Acknowledgments. The author thanks the referees for their many valuable comments.

ANALYTICITY OF SOLUTIONS OF THE KORTEWEG–DE VRIES EQUATION*

NAKAO HAYASHI†

Abstract. It is proven that if the initial function of the Korteweg-de Vries equation is analytic and has an analytic continuation to a strip containing the real axis, then the local in time solution has the same property, although the width of the strip might decrease with time. The result contains the case of the complex-valued initial function.

Key words. analyticity of solutions, Korteweg-de Vries equation

AMS(MOS) subject classification. 35Q20

1. Introduction.

We consider the following equation:

$$\text{(KdV)}\qquad \begin{aligned} &\partial_t u+\partial_x^3 u+a(u)\partial_x u=0 \qquad (t,x)\in \mathbb{R}^+\times\mathbb{R},\\ &u(0,x)=\phi(x), \qquad x\in\mathbb{R}, \end{aligned}$$

where $a(\lambda)$ is a polynomial. We show that if ϕ is analytic and has an analytic continuation to a strip containing the real axis, then the local in time solution of (KdV) has the same property for space variable, although the width of the strip might decrease with time.

We shall establish existence and analyticity simultaneously. This is in contrast to the work of Kato and Masuda [5]. They proved analyticity of the solution whose existence is guaranteed by $W^{s,2}$-theory (see [2]-[6]). Existence theorems in $W^{s,2}$-theory are based essentially on the following estimate: If u is real valued, then

$$|(a(u)\partial_x u, u)_{W^{s',2}}|\leqq \tilde{a}(\|u\|_{W^{s,2}})\|u\|^2_{W^{s',2}},$$

where $\frac{3}{2}<s\leqq s'\leqq s+1$ and $\tilde{a}(\lambda)$ is a certain polynomial depending only on a and s (see [4]). Therefore the arguments in [5] seem to work only for the case where ϕ is real valued. Our method in this paper is different from [5] and is a modification of the methods in [1]. Of course, our arguments work for complex valued ϕ. It should be noted that in [5] the function $a(\lambda)$ is only assumed to be real analytic, while we assume that $a(\lambda)$ is a polynomial.

We state notation and introduce function spaces. We let $L^p=\{f(x)$ is measurable on $\mathbb{R}$, $\|f\|_p<\infty\}$, where $\|f\|_p=(\int|f(x)|^p\,dx)^{1/p}$ if $1\leqq p<\infty$ and $\|f\|_\infty=\sup\{|f(x)|;\ x\in\mathbb{R}\}$. We denote by $(\cdot,\cdot)$ the inner product in L^2. We let $W^{m,p}(\mathbb{R})=\{f\in L^p;\ \|f\|_{m,p}<\infty\}$, where $\|f\|^p_{m,p}=\sum_{j=0}^m\|\partial_x^j f\|_p^p$ if $1\leqq p<\infty$ and $\|f\|_{m,\infty}=\sum_{j=0}^m\|\partial_x^j f\|_\infty$. We denote by $[\mathcal{F}f](\xi)$ (or $\hat{f}(\xi)$) the Fourier transform $\int e^{-ix\xi}f(x)\,dx$ and by $[\mathcal{F}^{-1}g](x)$ the inverse Fourier transform of $g(\xi)$. For $r>0$ we define

$$L_r=\{f\in L^2:\ \|f\|^2_{L_r}=(f,f)_{L_r}=(\cosh(2r\xi)\hat{f},\hat{f})<\infty\},$$

$$X_r=\left\{f\in L^2;\ \|f\|^2_{X_r}=(f,f)_{X_r}=\sum_{j=0}^1(\xi^{2j}(\cosh(2r\xi)+\xi\sinh(2r\xi))\hat{f},\hat{f})<\infty\right\},$$

$$Y_r=\left\{f,\partial_x f\in L^2;\ \|f\|^2_{Y_r}=(f,f)_{Y_r}=\sum_{j=0}^1(\xi^{2j+2}\cosh(2r\xi)\hat{f},\hat{f})<\infty\right\}.$$

* Received by the editors January 17, 1990; accepted for publication (in revised form) December 14, 1990.
† Department of Mathematics, Faculty of Engineering, Gunma University, Kiryu 376, Japan.

Obviously, $X_r \subset L_r$; if $\partial_x f \in X_r$, then $f \in Y_r$. We let $z = x + iy$ $(x, y \in \mathbb{R})$ and let $S(r)$ be the strip $\{z = x + iy; |y| < r\}$. Note that the above function spaces are closely related to the analytic Hardy space $H^p(r) = \{F: F$ is analytic on $S(r)$, $\|F\|_{H^p(r)} = \sup_{|y|<r} \|F(\cdot + iy)\|_p < \infty\}$ on the strip $S(r)$ in the sense of Stein-Weiss [7]. For a nonnegative integer m we let

$$H^{m,p}(r) = \left\{ F \in H^p(r): \|F\|^p_{H^{m,p}(r)} = \sum_{j=0}^{m} \|\partial_z^j F\|^p_{H^p(r)} < \infty \right\}.$$

Obviously, $H^{0,p}(r) = H^p(r)$; $\|F\|_{H^{m,p}(r)} = \sup_{|y|<r} \|F(\cdot + iy)\|_{m,p}$. We have observed the following [1].

THEOREM 1 [1]. *We assume that $F \in H^2(r)$ and let f be the trace of F on the real axis. Then $f \in L_r$ and*

$$\|f\|_{L_r} \leqq \sqrt{2} \|F\|_{H^2(r)}.$$

Conversely, we assume that $f \in L_r$. Then f has an analytic extension $F \in H^2(r)$ and

$$\|F\|_{H^2(r)} \leqq \sqrt{2} \|f\|_{L_r}.$$

For the convenience of the reader we shall give a proof of Theorem 1 in § 2. For an interval I or $\mathbb{R}$ and a Banach space B with norm $\|\cdot\|_B$, we let $C(I; B) = \{f(t): f(t)$ is continuous from I to B, $\sup\{\|f(t)\|_B; t \in I\} < \infty\}$.

Our main result is the following theorem.

THEOREM 2. *If $\phi \in X_{\sigma_0}$ for $\sigma_0 > 0$, then there exist a positive constant $T = T(\|\phi\|_{X_{\sigma_0}}, a)$ and a positive monotone decreasing function $\sigma(t)$ satisfying $\sigma(0) = \sigma_0$ such that* (KdV) *has a unique solution $u(t, x) \in C([0, T]; X_{\sigma(T)}) \cap X_{\sigma(t)}$ for $0 \leqq t \leqq T$.*

From Theorems 1 and 2, we have Corollary 1.

COROLLARY 1. *Let $u(t, x)$ be the solution constructed in Theorem 2. Then $u(t, x)$ has an analytic continuation to $S(\sigma(t))$ for $0 \leqq t \leqq T$.*

2. Preliminary estimates. In this section we collect some preliminary estimates. We first prove Theorem 1.

Proof of Theorem 1. For $F \in H^2(r)$ and $|y| < r$ we let $f_y(x) = F(x + iy)$. We note that the trace f of F on the real axis is equal to f_0. It is well known that

$$\hat{f}_y(\xi) = e^{-y\xi} \hat{f}(\xi) \qquad \text{(see [7, p. 99])}. \tag{2.1}$$

The Plancherel theorem says

$$\|f_y\|_2^2 = \int e^{-2y\xi} |\hat{f}(\xi)|^2 \, d\xi \leqq 2 \int \cosh(2r\xi) |\hat{f}(\xi)|^2 \, d\xi$$

for $|y| < r$. This yields the second inequality of the theorem. Conversely, observe from the monotone convergence theorem that

$$\|f_y\|_2^2 \geqq \int_0^\infty e^{-2y\xi} |\hat{f}(\xi)|^2 \, d\xi \to \int_0^\infty e^{2r\xi} |\hat{f}(\xi)|^2 \, d\xi$$

as $y \to -r$. Hence

$$\|F\|^2_{H^2(r)} \geqq \int_0^\infty \cosh(2r\xi) |\hat{f}(\xi)|^2 \, d\xi,$$

and similarly

$$\|F\|^2_{H^2(r)} \geqq \int_{-\infty}^0 \cosh(2r\xi) |\hat{f}(\xi)|^2 \, d\xi.$$

Thus we have the first inequality of the theorem.

As a result we have the following lemma.

LEMMA 2.1. *Let $r>0$.*

(a) *If $f\in X_r$, then f has an analytic continuation F on $S(r)$ and*

$$\|F\|_{H^{1,2}(r)}\leqq\sqrt{2}\|f\|_{X_r}.$$

(b) *If $f\in Y_r$, then f has an analytic continuation F on $S(r)$ and*

$$\|\partial_z F\|_{H^{1,2}(r)}\leqq\sqrt{2}\|f\|_{Y_r}.$$

Proof. Let $f\in X_r$. By Theorem 1 f has an analytic continuation $F\in H^2(r)$. Let $f_y=F(\cdot+iy)$ for $|y|<r$. Then by (2.1) $f_y=\mathscr{F}^{-1}(\cosh(y\xi)\hat{f})+\mathscr{F}^{-1}(\sinh(-y\xi)\hat{f})$. Hence the Schwarz inequality yields

$$\|f_y\|_2^2+\|\partial_x f_y\|_2^2\leqq 2\sum_{j=0}^{1}(\|\partial_x^j\mathscr{F}^{-1}\cosh(y\xi)\hat{f}\|_2^2+\|\partial_x^j\mathscr{F}^{-1}\sinh(-y\xi)\hat{f}\|_2^2).$$

By a direct calculation we see that the right-hand side of the above inequality is equal to

$$2\sum_{j=0}^{1}((\xi^{2j}\cosh(y\xi)\hat{f},\cosh(y\xi)\hat{f})+(\xi^{2j}\sinh(y\xi)\hat{f},\sinh(y\xi)\hat{f}))$$

$$=2\sum_{j=0}^{1}(\xi^{2j}\cosh(2y\xi)\hat{f},\hat{f})\leqq 2\sum_{j=0}^{1}(\xi^{2j}\cosh(2r\xi)\hat{f},\hat{f}).$$

This is less than or equal to $2\|f\|_{X_r}^2$. Thus we obtain (a). The assertion (b) is proved in the same way as in the proof of (a) and so we omit it.

Conversely, the inner product $(\cdot,\cdot)_{X_r}$ is controlled by the Hardy norm in the following way.

LEMMA 2.2. *Let $r>0$. Suppose $F\in H^{1,2}(r)$ and $V\in H^{2,2}(r)$. If f and v are the traces of F and V on the real axis, then*

$$|(f,v)_{X_r}|\leqq C_1\|F\|_{H^{1,2}(r)}\|V\|_{H^{2,2}(r)}.$$

Proof. Let $0<\rho<r$. By a simple calculation

$$2(f,v)_{X_\rho}=2\sum_{j=0}^{1}(\xi^j(\cosh(2\rho\xi)+\xi\sinh(2\rho\xi))\hat{f},\xi^j\hat{v})$$

$$=\sum_{j=0}^{1}\{(\xi^j e^{\rho\xi}\hat{f},\xi^j(1+\xi)e^{\rho\xi}\hat{v})+(\xi^j e^{-\rho\xi}\hat{f},\xi^j(1-\xi)e^{-\rho\xi}\hat{v})\}$$

$$=\sum_{j=0}^{1}\{(\partial_x^j f_{-\rho},\partial_x^j(1-i\partial_x)v_{-\rho})+(\partial_x^j f_\rho,\partial_x^j(1+i\partial_x)v_\rho)\},$$

where $f_{\pm\rho}=F(\cdot\pm i\rho)$ and $v_{\pm\rho}=V(\cdot\pm i\rho)$. Therefore we have from the Schwarz inequality

$$|(f,v)_{X_\rho}\|\leqq C_2\cdot(\|f_\rho\|_{1,2}\|v_\rho\|_{2,2}+\|f_{-\rho}\|_{1,2}\|v_{-\rho}\|_{2,2})$$

$$\leqq 2C_2\|F\|_{H^{1,2}(r)}\|V\|_{H^{2,2}(r)}.$$

The monotone convergence theorem completes the proof.

Using Sobolev's inequality for $F(\cdot+iy)$, we obtain a multiplicative property of $\|F\|_{H^{1,2}(r)}$.

LEMMA 2.3. *Let $r>0$. Suppose $F, G\in H^{1,2}(r)$. Then $FG\in H^{1,2}(r)$ and*

$$\|FG\|_{H^{1,2}(r)}\leqq C_3\|F\|_{H^{1,2}(r)}\|G\|_{H^{1,2}(r)}.$$

Proof. Sobolev's inequality shows

$$\|F\|_{H^\infty(r)} \leqq C_4 \|F\|_{H^{1,2}(r)}.$$

Hence

$$\|FG\|_{H^2(r)} \leqq \|F\|_{H^\infty(r)} \|G\|_{H^2(r)} \leqq C_4 \|F\|_{H^{1,2}(r)} \|G\|_{H^{1,2}(r)},$$

$$\begin{aligned}\|\partial_z(FG)\|_{H^2(r)} &\leqq \|\partial_z F\|_{H^2(r)} \|G\|_{H^\infty(r)} + \|F\|_{H^\infty(r)} \|\partial_z G\|_{H^2(r)} \\ &\leqq 2C_4 \|F\|_{H^{1,2}(r)} \|G\|_{H^{1,2}(r)}.\end{aligned}$$

The lemma follows.

We are now in a position to prove the main estimate.

LEMMA 2.4. *There exists a polynomial $\tilde{a}$ of which coefficients are all nonnegative with the following property: If $r>0$ and $f, g, v \in X_r \cap Y_r$, then*

$$\begin{aligned}&|(a(f)\partial_x f - a(g)\partial_x g, v)_{X_r}| \\ &\quad \leqq \tilde{a}(\|f\|_{X_r}, \|g\|_{X_r})\{\|f\|_{Y_r}\|f-g\|_{X_r} + \|f-g\|_{Y_r}\}(\|v\|_{X_r} + \|v\|_{Y_r}).\end{aligned}$$

COROLLARY. *There exists a polynomial $\tilde{a}_1$ with nonnegative coefficient such that if $f, v \in X_r \cap Y_r$, then*

$$|(a(f)\partial_x f, v)_{X_r}| \leqq \tilde{a}_1(\|f\|_{X_r})\|f\|_{Y_r}(\|v\|_{X_r} + \|v\|_{Y_r}).$$

Proof of Lemma 2.4. We have

$$a(f)\partial_x f - a(g)\partial_x g = b(f, g)(f-g)\partial_x f + a(g)\partial_x(f-g),$$

where $b(f, g)$ is a polynomial. Let us estimate $(b(f, g)(f-g)\partial_x f, v)_{X_r}$ and $(a(g)\partial_x(f-g), v)_{X_r}$ separately. By Lemma 2.1 we see that f, g, and v gave analytic continuations F, G, and V on $S(r)$. Obviously, $b(F, G)$ is the analytic continuation of $b(f, g)$. It follows from Lemmas 2.2 and 2.3 that

$$\begin{aligned}|(b(f, g)(f-g)\partial_x f, v)_{X_r}| &\leqq C_1 \|b(F, G)(F-G)\partial_x F\|_{H^{1,2}(r)} \|V\|_{H^{2,2}(r)} \\ &\leqq C_5 \|b(F, G)\|_{H^{1,2}(r)} \|F-G\|_{H^{1,2}(r)} \|\partial_x F\|_{H^{1,2}(r)} \|V\|_{H^{2,2}(r)} \\ &\leqq a_1(\|F\|_{H^{1,2}(r)}, \|G\|_{H^{1,2}(r)}) \|F-G\|_{H^{1,2}(r)} \|\partial_x F\|_{H^{1,2}(r)} \|V\|_{H^{2,2}(r)},\end{aligned}$$

where a_1 is a polynomial with nonnegative coefficients. Hence Lemma 2.1 yields

$$|(b(f, g)(f-g)\partial_x f, v)_{X_r}| \leqq C_6 a_1(\|f\|_{X_r}, \|g\|_{X_r}) \|f-g\|_{X_r} \|f\|_{Y_r}(\|v\|_{X_r} + \|v\|_{Y_r}).$$

In the same way,

$$|(a(g)\partial_x(f-g), v)_{X_r}| \leqq a_2(\|g\|_{X_r}) \|f-g\|_{Y_r}(\|v\|_{X_r} + \|v\|_{Y_r}),$$

where a_2 is a polynomial with nonnegative coefficients. The lemma follows.

3. Proof of Theorem 2. For any fixed $\sigma_0 > 0$, we let $\sigma(t) = \sigma_0 e^{-At/\sigma_0}$ with a positive constant A to be determined later. For $T>0$ we define

$$B(T) = \left\{ v(t, x);\ \|v\|^2_{B(T)} = \sup_{0 \leqq t \leqq T} \|v(t)\|^2_{X_{\sigma(t)}} + A \int_0^T \|v(t)\|^2_{Y_{\sigma(t)}}\, dt < \infty \right\}$$

and

$$B_\rho(T) = \{v \in B(T);\ \|v\|_{B(T)} \leqq \rho\}.$$

We shall show that there exist $t>0$ and $A>0$ depending only on $\|\phi\|_{X_{\sigma_0}}$ such that (KdV) has a unique solution $u(t,x)\in B(T)$. Let $\rho=2\|\phi\|_{X_{\sigma_0}}$. For $v\in B_\rho(T)$ we define the mapping M by $u=Mv$, where u is the solution of the following linearized equation:

$$\partial_t u+\partial_x^3 u=-a(v)\partial_x v, \qquad (t,x)\in\mathbb{R}^+\times\mathbb{R},$$
$$u(0,x)=\phi(x), \qquad x\in\mathbb{R}.$$

It is sufficient to show that M is a contraction mapping from $B_\rho(T)$ to itself for suitable chosen T and A. Hereafter we let

$$e^{-AT/\sigma_0}>\tfrac{1}{2}. \tag{3.1}$$

Take $v\in B_\rho(T)$. By the Fourier transform

$$\partial_t\hat{u}-i\xi^3\hat{u}=-\mathcal{F}[a(v)\partial_x v]. \tag{3.2}$$

We multiply both sides of (3.2) by $\xi^{2j}(\cosh(2\sigma(t)\xi)+\xi\sinh(2\sigma(t)\xi)\hat{u}$, integrate in ξ and take the real part to obtain

$$\begin{aligned}&\frac{d}{dt}(\|u(t)\|^2_{X_{\sigma(t)}})-2\sigma'(t)(\xi^{2j}(\xi\sinh(2\sigma(t)\xi)+\xi^2\cosh(2\sigma(t)\xi))\hat{u}(t),\hat{u}(t))\\ &\quad=-2\,\mathrm{Re}\,(a(v)\partial_x v,u)_{X_{\sigma(t)}}.\end{aligned} \tag{3.3}$$

For the sake of brevity we suppress the subscript $\sigma(t)$ of $X_{\sigma(t)}$ and $Y_{\sigma(t)}$. From (3.3) and the corollary to Lemma 2.4 it follows that

$$\begin{aligned}&\frac{d}{dt}(\|u(t)\|_X^2)+2Ae^{-At/\sigma_0}\|u(t)\|_Y^2\\ &\quad\le 2\tilde{a}_1(\|v(t)\|_X)\|v(t)\|_Y(\|u(t)\|_X+\|u(t)\|_Y)\\ &\quad\le 2\tilde{a}_1(\rho)\|v(t)\|_Y(\|u(t)\|_X+\|u(t)\|_Y).\end{aligned}$$

Integrating in t and using the Schwarz inequality, we obtain from (3.1)

$$\begin{aligned}&\sup_{0\le t\le T}\|u(t)\|_X^2+A\int_0^T\|u(t)\|_Y^2\,dt\\ &\quad\le\|\phi\|^2_{X_{\sigma_0}}+2\tilde{a}_1(\rho)\left(\int_0^T\|v(t)\|_Y^2\,dt\right)^{1/2}\left\{\left(\int_0^T\|u(t)\|_X^2\,dt\right)^{1/2}\right.\\ &\qquad\left.+\left(\int_0^T\|u(t)\|_Y^2\,dt\right)^{1/2}\right\}.\end{aligned}$$

Hence we have

$$\begin{aligned}\|u\|^2_{B(T)}&\le\frac{\rho^2}{4}+\frac{\tilde{a}_1(\rho)}{\sqrt{A}}4\rho\left(\sqrt{T}+\frac{1}{\sqrt{A}}\right)\|u\|_{B(T)}\\ &\le\frac{\rho^2}{4}+\frac{1}{2}\left\{\frac{\tilde{a}_1(\rho)}{\sqrt{A}}4\rho\left(\sqrt{T}+\frac{1}{\sqrt{A}}\right)\right\}^2+\frac{1}{2}\|u\|^2_{B(T)}.\end{aligned}$$

This implies

$$\|u\|^2_{B(T)}\le 2\left\{\frac{1}{4}+\frac{8\tilde{a}_1(\rho)^2}{A}\left(\sqrt{T}+\frac{1}{\sqrt{A}}\right)^2\right\}\rho^2.$$

Therefore, if

$$\frac{\tilde{a}_1(\rho)}{\sqrt{A}}\left(\sqrt{T}+\frac{1}{\sqrt{A}}\right)<\frac{1}{4\sqrt{2}}, \tag{3.4}$$

then M is a mapping from $B_\rho(T)$ into itself.

Take $v_1, v_2 \in B_\rho(T)$. Let $w = Mv_1 - Mv_2$. In the same way as in the proof of (3.3) we have

$$\frac{d}{dt}\|w(t)\|_X^2 + 2Ae^{-At/\sigma_0}\|w(t)\|_Y^2 \leqq -2\,\mathrm{Re}\,(a(v_1)\partial_x v_1(t) - a(v_2)\partial_x v_2(t), w(t))_X.$$

From Lemma 2.4 the right-hand side is estimated by

$$\begin{aligned}&2\tilde{a}(\rho,\rho)\{\|v_1(t)\|_Y\|v_1(t)-v_2(t)\|_X + \|v_1(t)-v_2(t)\|_Y\}(\|w(t)\|_X + \|w(t)\|_Y)\\ &\quad\leqq 2\tilde{a}(\rho,\rho)\{\|v_1(t)\|_Y\|v_1-v_2\|_{B(T)} + \|v_1(t)-v_2(t)\|_Y\}(\|w(t)\|_X + \|w(t)\|_Y).\end{aligned}$$

Integrating in t and using the Schwarz inequality, we obtain from (3.1)

$$\begin{aligned}\|w\|_{B(T)}^2 &\leqq 2\tilde{a}(\rho,\rho)\left\{\|v_1-v_2\|_{B(T)}\left(\int_0^T \|v_1(t)\|_Y^2\,dt\right)^{1/2} + \left(\int_0^T \|v_1(t)-v_2(t)\|_Y^2\,dt\right)^{1/2}\right\}\\ &\quad\times\left\{\left(\int_0^T \|w(t)\|_X^2\,dt\right)^{1/2} + \left(\int_0^T \|w(t)\|_Y^2\,dt\right)^{1/2}\right\}\\ &\leqq 2\tilde{a}(\rho,\rho)\frac{1}{\sqrt{A}}(\|v_1\|_{B(T)}+1)\|v_1-v_2\|_{B(T)}\left(\sqrt{T}+\frac{1}{\sqrt{A}}\right)\|w\|_{B(T)}.\end{aligned}$$

Hence

$$\|w\|_{B(T)} \leqq \tilde{a}(\rho,\rho)\frac{2}{\sqrt{A}}(\rho+1)\left(\sqrt{T}+\frac{1}{\sqrt{A}}\right)\|v_1-v_2\|_{B(T)}.$$

Therefore, if

$$\tilde{a}(\rho,\rho)\frac{2}{\sqrt{A}}(\rho+1)\left(\sqrt{T}+\frac{1}{\sqrt{A}}\right) < 1, \tag{3.5}$$

then M is a contraction mapping. We can, in fact, choose $T>0$, $A>0$ satisfying (3.1), (3.4), and (3.5) altogether. For these T and A, M is a contraction mapping from $B_\rho(T)$ to itself and has a unique fixed point. This fixed point is the solution of (KdV). The property that $u(t,x) \in C([0,T]; X_{\sigma(T)})$ follows from $\sup_{0\leqq t\leqq T}\|u(t)\|_{X_{\sigma(T)}}^2 \leqq \|u\|_{B(T)}^2$ immediately.

Acknowledgments. The author is grateful to Professor H. Aikawa for his careful reading of the first manuscript and many valuable comments. The author also thanks the referee for important remarks.

GEOMETRY OF RATIONAL FUNCTIONS AND NONLINEAR INTEGRABLE SYSTEMS*

YOSHIMASA NAKAMURA†

Abstract. A complete parametrization of the space $\mathrm{Rat}_p(n)$ of rational functions of degree n and fixed denominator $p(z)$ in terms of a nonlinear integrable system is established. The space $\mathrm{Rat}_p(n)$ can be viewed as the moduli space of certain controllable and observable linear dynamical systems. It is proved that $\mathrm{Rat}_p(n)$ is diffeomorphic to the moduli (or parameter) space of solutions of a natural generalization of the celebrated finite Toda equation called the cyclic-Toda hierarchy. The original Toda flow is identified with one of the connected components of $\mathrm{Rat}_p(n)$, where $p(z)$ is the characteristic polynomial of a Jacobi matrix. To prove the correspondence we use an exponential of cyclic matrix polynomials and its QR factorization which induces isospectral deformations.

Key words. space of rational functions, nonlinear integrable systems, scaling theory for linear systems, cyclic-Toda equation hierarchy

AMS(MOS) subject classifications. 93B27, 58F07, 34A05

1. Introduction. There have been some systematic efforts toward a theory of dynamical systems with parameters. Brockett and Krishnaprasad [3] presented an analysis of the action of certain one-parameter groups on the space rat (n) of strictly proper rational functions of (McMillan) degree n with real coefficients and discussed its application to the identification problem for linear dynamical systems. We denote each function of rat (n) by the form

$$f(z)=\frac{q_{n-1}z^{n-1}+\cdots+q_0}{z^n+p_{n-1}z^{n-1}+\cdots+p_0}=\frac{q(z)}{p(z)}\in \mathrm{rat}\,(n), \tag{1a}$$

where $p(z)$ and $q(z)$ do not have any common factor. They considered five types of one-parameter groups due to (1) frequency scaling, (2) shift of imaginary axis, (3) amplitude scaling, (4) output feedback, and (5) shift of time axis, and showed that these group actions leave invariant connected components rat $(n-m, m)$, $0\leqq m\leqq n$, of rat (n). Here the connected components rat $(n-m, m)$ are distinguished by the Cauchy index $2m-n$ viewed as a continuous map from rat (n) into the set $\{-n, -n+2, \cdots, n-2, n\}$ [2]. In the geometry of rational functions it is natural to introduce the equivalence relation $f(z)\sim e^{\theta}f(z)$, $\theta\in\mathbb{R}$, under the third one-parameter group action. We set

$$\mathrm{Rat}\,(n)=\mathrm{rat}\,(n)/\sim. \tag{1b}$$

Let us restrict ourselves to the fifth one-parameter group taking the form

$$f(z)=C^T(zI-A)^{-1}B\to C^T(zI-A)^{-1}\,e^{\sigma A}B, \tag{2}$$

for $\sigma\in\mathbb{R}$, where I is the $n\times n$ unit matrix and C^T denotes the transpose of C. The function $f(z)\in\mathrm{rat}\,(n)$ is regarded as the transfer function of the controllable and observable linear dynamical system

$$\frac{d}{dt}x(t)=Ax(t)+Bu(t),\qquad y(t)=C^Tx(t), \tag{3}$$

* Received by the editors August 16, 1989; accepted for publication (in revised form) November 14, 1990.

where $A \in \mathbb{R}^{n\times n}$, $B \in \mathbb{R}^{n\times 1}$, $C \in \mathbb{R}^{n\times 1}$, and $x(t) \in \mathbb{R}^{n\times 1}$, $u(t) \in \mathbb{R}$, $y(t) \in \mathbb{R}$, and $t \in \mathbb{R}$. The flow (2) on the space rat (n) is given as the Laplace transform of time shift $C^T e^{tA} B \to C^T e^{(t+\sigma)A} B$ for the weight function of (3). Byrnes [4] discussed the action of time shift on the space of symmetric matrix-valued rational functions and its relationship to a network synthesis problem for RC and RLC networks with parameters. Fuhrmann and Krishnaprasad [6] pointed out that only the fifth action (2) does not leave invariant the continued fraction cell decomposition of the space rat (n). It is to be noted that the differential equation $(d/ds) \log F(s) = f(s)$ defines a generalization of Pearson's family of probability distributions [18], where $F(s)$ denotes the density function and $s \in \mathbb{R}$. It seems that in these results we see increasing significance of group actions, especially of the time shift, in the geometry of rational functions and its applications.

The importance of nonlinear integrable systems (or equations) in control theory lies in the fact that they have rich information about the moduli (or parameter) space of a special class of solutions and they describe isospectral deformations of some linear operator or matrix. Because of this importance, various applications of nonlinear integrable systems have been proposed. We recall the early work by Hermann [9]. Helmke [8] and Sontag [22] studied moduli spaces of multimode and bilinear systems, respectively, in terms of the moduli space of instanton solutions of the self-dual Yang-Mills equations of gauge theory. Nakamura [14] introduced a fractional transformation group acting on the space of linear predictors (solutions of linear prediction problems for stochastic processes). It was shown in [14] and [15] that a special member of such a transformation group gives solutions of certain nonlinear integrable systems and describes a discrete isospectral deformation of a given matrix. Recently, Nakamura and Duncan [17] observed an equivalence between the moduli space of n-monopole solutions of the SU(2) Yang-Mills-Higgs equations and the space rat$^{\mathbb{C}}$ (n) of rational functions of degree n over $\mathbb{C}$.

Krishnaprasad, in his remarkable paper [11], considered the action of time shift (2) on the connected component rat $(n, 0)$ of rat (n) and showed that the action is equivalent to the flow of nonlinear integrable equation of Lax type called the finite nonperiodic Toda lattice [13]

$$\frac{d}{d\sigma} A = [A_L^T - A_L, A], \qquad A = \begin{pmatrix} b_1 & a_1 & \cdots & 0 \\ a_1 & & \ddots & \vdots \\ \vdots & \ddots & \ddots & a_{n-1} \\ 0 & \cdots & a_{n-1} & b_n \end{pmatrix}, \tag{4}$$

where A_L denotes the strictly lower triangular part of A, $A_L^T = (A_L)^T$, $[M, N] = MN - NM$ and $a_j \neq 0$. Note that $A = A(\sigma)$ is a Jacobi (or real tridiagonal) matrix having n real distinct eigenvalues. In Moser's coordinates $\{\alpha_j, \zeta_j\}_{1\leqq j\leqq n}$ [13] defined by

$$e_n^T (zI - A)^{-1} e_n = \frac{1}{\sum_{j=1}^n \exp(\alpha_j)} \sum_{j=1}^n \frac{1}{z - \zeta_j} \exp(\alpha_j) \in \text{rat}(n, 0), \tag{5}$$

where $\alpha_j \in \mathbb{R}$, $\zeta_j \in \mathbb{R}$, $\zeta_k \neq \zeta_l$ for $k \neq l$ and $e_n = (0 \cdots 0\ 1)^T$, the Toda equation (4) becomes the system $(1 \leqq j \leqq n)$ of linear equations

$$\frac{d}{d\sigma} \alpha_j = \zeta_j, \qquad \frac{d}{d\sigma} \zeta_j = 0. \tag{6}$$

Hence α_j and ζ_j are regarded as generalized coordinates and momentums, respectively, for the dynamical system with Hamiltonian $H = \frac{1}{2} \text{Tr}(A^2) = \frac{1}{2} \sum_{j=0}^n \zeta_j^2$. Krishnaprasad

[11] proved that for $f(z)=e_n^T(zI-A)^{-1}e_n$ the action (2) takes the form

$$(7)\qquad f(z)\to e_n^T(zI-A)^{-1}e^{\sigma A}e_n=\frac{1}{\sum_{j=1}^n \exp(\alpha_j+\sigma\zeta_j)}\sum_{j=1}^n \frac{1}{z-\zeta_j}\exp(\alpha_j+\sigma\zeta_j)$$

by using the Laurent expansion $f(z)=\sum_{k=0}^{\infty} h_k z^{-k-1}$ and observed that the expression (7) is precisely the linearlized Toda flow (6). Thus it is concluded that the Toda equation (4) can be reduced to a linear flow on the connected component rat $(n, 0)$ induced by the time shift. We remark here that the Toda flow leaves invariant the poles of $f(z)$ and rat $(n, 0)$ is diffeomorphic to the phase space $\mathbb{R}^n\times\mathbb{R}^n$ of (4) via Moser's coordinates $\{\alpha_j, \zeta_j\}_{1\leq j\leq n}$. Inspired by this pioneer work, Byrnes [4] considered a periodic Toda flow on a space of matrix-valued rational functions. Let us note that the Toda flow also arises in closely related problems, for example, the topology of the space of symmetric matrices with fixed eigenvalues [24] and the existence of Morse-Smale diffeomorphism on some quotient space induced by linear maps with fixed eigenvalues [21].

It will be well worth stating how the invariant tori/cylinder theorem in classical mechanics [1, p. 395] can be used in the geometry of rational functions. Krishnaprasad and Martin [12] made clear the importance of the concept of families of linear systems and their parameter variations. They considered the family of controllable and observable linear systems and the corresponding space of rational functions

$$(8a)\qquad \mathrm{rat}_p(n)=\left\{f(z)\,\middle|\, f(z)=\frac{q(z)}{p(z)}\in \mathrm{rat}(n),\ p(z):\text{fixed}\right\},$$

where $p=\{p_0,\cdots,p_{n-1}\}\in\mathbb{R}^n$. It was known (cf. [12. Thm. 2]) that the upper bound of the number of connected components of $\mathrm{rat}_p(n)$ is 2^r, where r is the number of real distinct roots of $p(z)$. Krishnaprasad [11] also observed that each connected component of $\mathrm{rat}_p(n)$ is diffeomorphic to $T^l\times\mathbb{R}^{n-l}$, where T^l denotes the l-torus and $l\in\{0,\cdots,n-1\}$. The integer l is constant on an open subset of rat $(n-m, m)$. This implies that rat $(n-m, m)$ has an n-dimensional foliation whose leaves are diffeomorphic to $T^l\times\mathbb{R}^{n-l}$. For example, on the connected component rat $(n, 0)$, l is equal to zero. Let us fix denominators as some $p(z)$. Then the connected component $\mathrm{rat}_p(n, 0)$ of $\mathrm{rat}_p(n)$ is diffeomorphic to $\mathbb{R}^n$ and the foliation is a trivial fibration $\mathbb{R}^n\times\mathbb{R}^n$. Recall that $\mathbb{R}^n\times\mathbb{R}^n$ is the phase space of the Toda equation (4) via $\{\alpha_j, \zeta_j\}_{1\leq j\leq n}$, where ζ_j are real distinct roots of $p(z)=\det(zI-A)$ and A is Jacobi. Since ζ_j are conserved, we see that the Toda flow gives a parametrization (of an open dense subset) of $\mathrm{rat}_p(n, 0)$ (Moser and Krishnaprasad's theorem [11], [13]). However, it is not known what nonlinear integrable system completely parametrizes the whole space of rational functions with any fixed denominator.

What we shall do in this paper is to solve this open problem and to show that the same sort of analysis used in various problems [3], [4], [6], [11]-[13] can be performed in more general situations. We consider the space of equivalence classes

$$(8b)\qquad \mathrm{Rat}_p(n)=\mathrm{rat}_p(n)/\sim,$$

where $f(z)\sim e^{\theta}f(z)$ for $\theta\in\mathbb{R}$. The space $\mathrm{Rat}_p(n)$ is characterized by n real parameters and the first one can be limited to ± 1. The number of connected components of $\mathrm{Rat}_p(n)$ is equal to that of $\mathrm{rat}_p(n)$. It will be proved that the moduli space of solutions of a nonlinear integrable system is *diffeomorphic* to the space $\mathrm{Rat}_p(n)$ of rational functions. The nonlinear system we use is regarded as a natural generalization of the original Toda equation (4) and will be called the *cyclic-Toda hierarchy.*

2. The cyclic-Toda hierarchy. Let $f(z)$ be an element of $\mathrm{rat}_p(n)$ with fixed denominator $p(z)$. According to the state space realization theory, $f(z)$ admits the unique factorization

$$f(z) = C_0^T (zI - A_0)^{-1} B_0,$$

$$A_0 = \begin{pmatrix} 0 & \cdots & 0 & -p_0 \\ 1 & & \vdots & \vdots \\ 0 & \ddots & & \\ \vdots & & 0 & -p_{n-2} \\ 0 & \cdots & 1 & -p_{n-1} \end{pmatrix}, \tag{9}$$

$$B_0 = \begin{pmatrix} q_0 \\ \vdots \\ q_{n-2} \\ q_{n-1} \end{pmatrix}, \qquad C_0 = \begin{pmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{pmatrix},$$

where the characteristic polynomial of A_0 is equal to the given $p(z)$,

$$p(z) = \det(zI - A_0). \tag{10}$$

The expression (9) of $f(z)$ is the observable canonical form, namely,

$$\operatorname{rank}(C_0 \; A_0^T C_0 \; \cdots \; (A_0^T)^{n-1} C_0) = n. \tag{11a}$$

Since the numerator $q(z)$ and the denominator $p(z)$ of $f(z)$ have no common factor, it follows that

$$\operatorname{rank}(B_0 \; A_0 B_0 \; \cdots \; A_0^{n-1} B_0) = n. \tag{11b}$$

The proof can be found in [10, p. 127]. The vectors B_0 and C_0 are called cyclic vectors of A_0. In this paper, we call $\{A_0, B_0, C_0\}$ a *cyclic triplet* if it satisfies (11a) and (11b). In linear systems theory $\{A_0, B_0, C_0\}$ is called a minimal realization of $f(z)$. We can associate each $f(z) = C_0^T (zI - A_0)^{-1} B_0 \in \mathrm{rat}_p(n)$ with the controllable and observable linear dynamical system

$$\frac{d}{dt} x(t) = A_0 x(t) + B_0 u(t), \qquad y(t) = C_0^T x(t). \tag{12}$$

A nonlinear (completely) integrable system is always related to some kind of group factorization. For example, the Toda equation (4) can be solved by the Bruhat decomposition [5], and the self-dual Yang-Mills equations are solved by the Riemann-Hilbert factorization [25]. The hierarchy point of view has also played quite an important role in the study of nonlinear integrable systems (see [19], [20] on soliton equations and [16] on gauge field equations). Here the terminology "hierarchy" indicates a system of differential equations that describes infinite (or finite) sets of commutative flows on the solution space of original equation. Let us show that if we go further in this direction toward a characterization of the space $\mathrm{Rat}_p(n)$ in terms of a nonlinear intgrable system, then we shall encounter a finite hierarchy of cyclic-Toda equations in a very natural way.

Every real nonsingular matrix M has a unique QR factorization $M = Q^{-1}R$, where Q is orthogonal and R is upper triangular with positive diagonal entries. Proof is given by the Gramm-Schmid orthogonalization (see [26, pp. 233-244]). Let τ be a set of n real parameters,

$$\tau = \{\tau_0, \cdots, \tau_{n-1}\} \in \mathbb{R}^n. \tag{13}$$

Let us consider the QR factorization with parameters

$$\exp\left(\sum_{k=0}^{n-1}\tau_k A_0^k\right)=Q^{-1}(\tau)R(\tau),\quad Q(\mathbf{0})=I,\quad R(\mathbf{0})=I, \tag{14}$$

where $\mathbf{0}=\{0,\cdots,0\}\in\mathbb{R}^n$. The parameter τ_0 appears only in $R(\tau)$ as a diagonal factor $\exp(\tau_0 I)$. Taking derivatives on both sides, we have

$$QA_0^kQ^{-1}=-\frac{\partial}{\partial\tau_k}Q\cdot Q^{-1}+\frac{\partial}{\partial\tau_k}R\cdot R^{-1} \tag{15}$$

for $0\leqq k\leqq n-1$. Since the first and the second terms of the right-hand side are skew-symmetric and upper triangular, it follows that

$$\begin{aligned}\frac{\partial}{\partial\tau_k}Q\cdot Q^{-1}&=(QA_0^kQ^{-1})_L^T-(QA_0^kQ^{-1})_L,\\ \frac{\partial}{\partial\tau_k}R\cdot R^{-1}&=(QA_0^kQ^{-1})_U+(QA_0^kQ^{-1})_L^T,\end{aligned} \tag{16}$$

where $M_U=M-M_L$. We have proved Lemma 2.1.

LEMMA 2.1. *If the nonsingular matrix* $\exp(\sum_{k=0}^{n-1}\tau_k A_0^k)$ *has the* QR *factorization* (14), *then the resulting* C^∞*-factors* $Q(\tau)$ *and* $R(\tau)$ *solve the initial value problem* (16) *with* $Q(\mathbf{0})=I$ *and* $R(\mathbf{0})=I$.

It is to be noted that $QA_0^kQ^{-1}$ in the right-hand side of (16) is the kth power of the similarity transform QA_0Q^{-1} of A_0 by the factor Q. The next lemma shows that $Q(\tau)$ induces a flow on $\mathbb{R}^{n\times n}$ characterized by a system of nonlinear equations.

LEMMA 2.2. *Let* $A(\tau)$ *be a* C^∞*-matrix defined by*

$$A(\tau)=Q(\tau)A_0Q^{-1}(\tau); \tag{17}$$

then $A(\tau)$ *solves the initial value problem for the system* $(0\leqq k\leqq n-1)$

$$\begin{aligned}\frac{\partial}{\partial\tau_k}A(\tau)&=[A^k(\tau)_L^T-A^k(\tau)_L,A(\tau)]\\&=[A^k(\tau)_U+A^k(\tau)_L^T,A(\tau)],\qquad A(\mathbf{0})=A_0,\end{aligned} \tag{18}$$

where $A_L^{kT}=(A^k)_L^T$.

Taking derivatives of (17), we have $(\partial/\partial\tau_k)A=[(\partial/\partial\tau_k)Q\cdot Q^{-1},A]$. By (16) with (15) and (17), the assertion of Lemma 2.2 is proved. The solution $A(\tau)$ clearly does not depend on the parameter τ_0; however, τ_0 is useful in our parametrization of $\mathrm{Rat}_p(n)$. Lemmata 2.1 and 2.2 imply that the maximal interval of existence for initial value problem (18) is $(-\infty,\infty)$ for each τ_k. Furthermore, since $A(\tau)$ is always orthogonally similar to A_0 for $\tau\in\mathbb{R}^n$, the flow $A(\tau)$ is *isospectral*, namely, $\mathrm{Spec}\,A(\tau)=\mathrm{Spec}\,A_0$. Indeed, the trace of $A^k(\tau)$ is an integral of motion of (18) expressed by the eigenvalues of A_0. Since A_0 commutes with $Q^{-1}(\tau)R(\tau)$, we obtain $A(\tau)=R(\tau)A_0R^{-1}(\tau)$. This implies that $A(\tau)$ is upper-Hessenberg. Set $\mathbb{1}=\{1,\cdots,1\}\in\mathbb{R}^n$. From (14), $\exp(\sum_{k=0}^{n-1}A_0^k)=Q^{-1}(\mathbb{1})R(\mathbb{1})$. On the other hand, since

$$\begin{aligned}\exp\left(\sum_{k=0}^{n-1}\tau_k A^k(\tau)\right)&=Q(\tau)\exp\left(\sum_{k=0}^{n-1}\tau_k A_0^k\right)Q^{-1}(\tau)\\&=R(\tau)Q^{-1}(\tau),\end{aligned}$$

we derive $\exp(\sum_{k=0}^{n-1}A^k(\mathbb{1}))=R(\mathbb{1})Q^{-1}(\mathbb{1})$. Thus the time evolution (17) from $\tau=\mathbf{0}$ to $\tau=\mathbb{1}$ performs the QR iteration [26, pp. 515–521] for the exponential of matrix

$\exp(\sum_{k=0}^{n-1} A_0^k)$. If the eigenvalues of A_0 satisfy $|\lambda_1|<|\lambda_2|<\cdots<|\lambda_n|$ and A_0 can be diagonalized, $MA_0M^{-1}=\operatorname{diag}(\lambda_1,\lambda_2,\cdots,\lambda_n)$, by a nonsingular matrix M which admits an LU factorization, then $A(\tau)$ approaches an upper triangular matrix as $|\tau|\to\infty$.

Next, we introduce a time evolution of the vectors B_0 and C_0.

LEMMA 2.3. *Let $B(\tau)$ and $C(\tau)$ be vectors defined by*

$$B(\tau)=R(\tau)B_0,\qquad C(\tau)=Q(\tau)C_0; \tag{19}$$

then they satisfy the system of linear equations $(0\leqq k\leqq n-1)$

$$\begin{aligned}\frac{\partial}{\partial\tau_k}B(\tau)&=(A^k(\tau)+A^k(\tau)_L^T-A^k(\tau)_L)B(\tau),\qquad B(\mathbf{0})=B_0,\\ \frac{\partial}{\partial\tau_k}C(\tau)&=(A^k(\tau)_L^T-A^k(\tau)_L)C(\tau),\qquad C(\mathbf{0})=C_0.\end{aligned} \tag{20}$$

The proof is given by (16) with (15) and (17). Thus we obtain the nontrivial flow $\{A_0,B_0,C_0\}\to\{A(\tau),B(\tau),C(\tau)\}$ on $\mathbb{R}^{n\times n+2n}$. The following proposition is the key connection between the system (18) with (20) and the space $\operatorname{rat}_p(n)$ of rational functions.

PROPOSITION 2.4. *If $\{A_0,B_0,C_0\}$ is a cyclic triplet, then $\{A(\tau),B(\tau),C(\tau)\}$ is also a cyclic triplet for every $\tau\in\mathbb{R}^n$.*

Proof. It is known from (14), (17), and (19) that

$$\begin{aligned}(B\,AB\cdots A^{n-1}B)&=(RB_0\;QA_0Q^{-1}RB_0\cdots QA_0^{n-1}Q^{-1}RB_0)\\&=Q(\exp(H_\tau)B_0\;A_0\exp(H_\tau)B_0\cdots A_0^{n-1}\exp(H_\tau)B_0)\\&=Q\exp(H_\tau)(B_0\;A_0B_0\cdots A_0^{n-1}B_0),\\(C\,A^TC\cdots(A^T)^{n-1}C)&=Q(C_0\;A_0^TC_0\cdots(A_0^T)^{n-1}C_0),\end{aligned}$$

where $H_\tau=\sum_{k=0}^{n-1}\tau_kA_0^k$. This implies that $\operatorname{rank}(B\,AB\cdots A^{n-1}B)=n$ and $\operatorname{rank}(C\,A^TC\cdots(A^T)^{n-1}C)=n$. □

Since $\operatorname{Spec}A(\tau)=\operatorname{Spec}A_0$, it is easy to prove Proposition 2.5.

PROPOSITION 2.5. *If the controllable and observable linear system* (12) *is stable* (*respectively, unstable*), *then the parametric linear systems*

$$\begin{aligned}\frac{d}{dt}x(t;\tau)&=A(\tau)x(t;\tau)+B(\tau)u(t;\tau),\\y(t;\tau)&=C(\tau)^Tx(t;\tau)\end{aligned} \tag{21}$$

are stable (*respectively, unstable*) *as well as controllable and observable.*

The hierarchy (18) for $0\leqq k\leqq n-1$ is a generalization of the system of nonlinear equations discussed by Moser [13], $(d/dt)L=[B_p,L]$ for $1\leqq p\leqq n-1$ in his notation, where L is *Jacobi* and $(d/dt)L=[B_1,L]$ is the original Toda equation (4). Indeed, when $f(z)$ is in rat $(n,0)$, we can always transform $A(\tau)$ into a Jacobi matrix via Cauer's canonical form (5). Moreover, the hierarchy is clearly different from the known hierarchy of finite Toda equations [23] which is a finite truncated form of the infinite Toda hierarchy. The system (20) describing the time evolution of cyclic vectors is essentially new.

Finally in this section, we discuss the compatibility of (18) and (20) in the sense in which $A(\tau)$, $B(\tau)$, and $C(\tau)$ satisfy the integrability condition with respect to τ. Set

$$F_k(A)=A^k(\tau)_L^T-A^k(\tau)_L, \tag{22}$$

for simplicity. By a standard theory of Toda equation, we see that each equation of (18) is equivalent to the Lax pair $AY=\zeta Y$ and $(\partial/\partial\tau_k)Y=F_k(A)Y$, where $Y=Y(\tau;\zeta)\in\mathbb{C}^{n\times 1}$. The integrability for Y leads to the system of zero curvature equations

$$\frac{\partial}{\partial\tau_l}F_k(A)-\frac{\partial}{\partial\tau_k}F_l(A)+[F_k(A),F_l(A)]=0 \tag{23}$$

for $0\leqq k,\ l\leqq n-1$. Thus if $F_k(A)$ solve (23), then the system (18) is clearly integrable. It is to be noted that the skew symmetric matrices $F_k(A)$ given by $F_k(A)=(\partial/\partial\tau_k)Q\cdot Q^{-1}$ obviously satisfy (23). See (16), (17), and (22). Conversely, let $A(\tau)$ solve (18). We have

$$\begin{aligned}0&=\frac{\partial}{\partial\tau_l}A^k-[F_l,A^k]\\&=\left(\frac{\partial}{\partial\tau_l}G_k-\frac{\partial}{\partial\tau_k}F_l-[F_l,G_k]\right)+\left(\frac{\partial}{\partial\tau_k}F_l-\frac{\partial}{\partial\tau_l}F_k+[F_l,F_k]\right),\end{aligned}$$

where $G_k=A^k+F_k$. Noting that $A(\tau)$ is upper-Hessenberg and G_k is upper triangular, we can prove that $F_k=F_k(A)$ solves (23). Thus (18) is equivalent to (23). Equations (20) are expressed as $(\partial/\partial\tau_k)B=(A^k+F_k(A))B$ and $(\partial/\partial\tau_k)C=F_k(A)C$. Since

$$\left(\frac{\partial}{\partial\tau_l}\frac{\partial}{\partial\tau_k}-\frac{\partial}{\partial\tau_k}\frac{\partial}{\partial\tau_l}\right)H=\left(\frac{\partial}{\partial\tau_l}F_k(A)-\frac{\partial}{\partial\tau_k}F_l(A)+[F_k(A),F_l(A)]\right)H$$

for $H=B$ and C, the system (23) guarantees the integrability of linear system (20). We conclude that the hierarchy (18) with (20) is compatible. Since (18) satisfies the Cauchy-Kovalevskaya condition, the solution given by (17) is unique. In the next section, we shall show that the triplet $\{A(\tau),B(\tau),C(\tau)\}$ is quite important in the parametrization of $\mathrm{Rat}_p(n)$.

DEFINITION 2.6. The hierarchy of nonlinear integrable equations (18) with the supplementary system (20), where $0\leqq k\leqq n-1$, is called the *cyclic-Toda hierarchy*. The space of C^∞-solutions $A(\tau)$ of (18) for *any* equivalence class $[\{A_0,B_0,C_0\}]$ of initial cyclic triplets satisfying (9)-(11b) under the relation $f(z)\sim e^\theta f(z)$, $\theta\in\mathbb{R}$, is called the *moduli* (or *parameter*) *space* of the cyclic-Toda hierarchy. We denote the moduli space as $\mathcal{M}_p$.

3. Parametrization of the space of rational functions: main result. First we show that the cyclic-Toda hierarchy induces a set of n flows parametrized by $\tau\in\mathbb{R}^n$ on the space $\mathrm{rat}_p(n)$ of rational functions of degree n and the fixed denominator $p(z)$. In the previous section, we obtained the nontrivial flow $\{A_0,B_0,C_0\}\to\{A(\tau),B(\tau),C(\tau)\}$ on $\mathbb{R}^{n\times n+2n}$. This flow can be projected onto the space $\mathrm{rat}_p(n)$. For any $f(z)=C_0^T(zI-A_0)^{-1}B_0\in\mathrm{rat}_p(n)$, let us define

$$f(z;\tau)=C(\tau)^T(zI-A(\tau))^{-1}B(\tau). \tag{24}$$

From Proposition 2.4 and $\det(zI-A(\tau))=p(z)$, it is not hard to see $f(z;\tau)\in\mathrm{rat}_p(n)$ for every $\tau\in\mathbb{R}^n$. Furthermore, we prove Proposition 3.1.

PROPOSITION 3.1. *The parameter τ_0 and τ_1 of τ describe the amplitude scaling and the shift on time axis, respectively, for the controllable and observable linear system* (12).

Proof. From the definition of the flow and $Q^TQ=I$, we have

$$\begin{aligned}f(z;\tau)&=(QC_0)^T(zI-QA_0Q^{-1})^{-1}RB_0\\&=C_0^T(zI-A_0)^{-1}Q^{-1}RB_0\\&=C_0^T(zI-A_0)^{-1}\exp(H_\tau)B_0,\end{aligned}$$

where $H_\tau = \sum_{k=0}^{n-1} \tau_k A_0^k$. Thus $f(z;\tau)$ is the Laplace transform of the weight function $W(t;\tau) = C_0^T \exp(tA_0 + H_\tau)B_0$. The parameter τ_0 clearly describes the amplitude scaling $f(z) \to \exp(\tau_0) f(z)$. Setting $\tau = \{0, \tau_1, 0, \cdots, 0\}$, we obtain the expression

$$f(z) \to f(z;\tau) = C_0^T (zI - A_0)^{-1} \exp(\tau_1 A_0) B_0$$

of the action of time shift for the linear system (12). □

This proposition is a straightforward generalization of the result in [3] and [11] (see (2)-(6)). But the proof has been carried out without using the Laurent expansion of $f(z)$ and without supposing that A_0 is Jacobi and $B_0 = C_0 = e_n$. The remaining parameters $\{\tau_2, \cdots, \tau_{n-1}\}$ give actions of one-parameter groups being outside the known ones.

Now we shall discuss the correspondence between $\mathrm{Rat}_p(n)$ and the moduli space $\mathcal{M}_p$ of the cyclic-Toda hierarchy. First we shall construct a one-to-one mapping from $\mathrm{Rat}_p(n)$ to $\mathcal{M}_p$. Let $A(\tau)$ be an arbitrary C^∞-solution of the cyclic-Toda hierarchy for an initial value $\{A_0, B_0, C_0\}$ satisfying (9)-(11b). Recall that $A(\tau)$ is an isospectral deformation of A_0. By a theorem [7, p. 219] there are nonsingular upper triangular matrices $R(\tau)$ such that

$$A(\tau)R(\tau) = R(\tau)A_0, \qquad R(\mathbf{0}) = I. \tag{25}$$

We note that each $R(\tau)$ with B_0 gives a cyclic vector $B(\tau)$ via (19) which solves the supplementary system (20). Thus $(\partial/\partial\tau_k)R \cdot R^{-1} = A^k + F_k(A)$. Let us consider

$$\frac{\partial}{\partial \tau_k} Q(\tau) = F_k(A)Q(\tau), \qquad Q(\mathbf{0}) = I. \tag{26}$$

There is a unique C^∞-solution of (26). This follows from the compatibility proved in § 2. The resulting $Q(\tau)$ and C_0 give $C(\tau)$, which solves (20). Since $F_k(A)$ is skew-symmetric, $Q(\tau)$ is an orthogonal matrix. Multiplying $A(\tau)$ to (26) from the left and using $(\partial/\partial\tau_k)A = [F_k(A), A]$ derived from (18) and (22), we obtain $(\partial/\partial\tau_k)(AQ) = F_k(A)AQ$, where $A(\mathbf{0})Q(\mathbf{0}) = A_0$. On the other hand, $(\partial/\partial\tau_k)QA_0 = F_k(A)QA_0$ and $Q(\mathbf{0})A_0 = A_0$. Because of the uniqueness of solution, $A(\tau)Q(\tau) = Q(\tau)A_0$. Thus we obtain $Q(\tau)A_0Q^{-1}(\tau) = A(\tau)$. Set $U(\tau) = Q^{-1}(\tau)R(\tau)$. By differentiating this, we have

$$\begin{aligned} Q(\tau)\frac{\partial}{\partial \tau_k} U(\tau) \cdot R^{-1}(\tau) &= -\frac{\partial}{\partial \tau_k} Q(\tau) \cdot Q^{-1}(\tau) + \frac{\partial}{\partial \tau_k} R(\tau) \cdot R^{-1}(\tau) \\ &= A^k(\tau) \\ &= Q(\tau) A_0^k Q^{-1}(\tau) \end{aligned}$$

and consequently, we see that $U(\tau)$ satisfies $(\partial/\partial\tau_k)U = A_0^k U$, $U(\mathbf{0}) = I$. Thus

$$U(\tau) = \exp\left(\sum_{k=0}^{n-1} \tau_k A_0^k\right). \tag{27}$$

Let $f(z;\tau)$ be a rational function defined by $f(z;\tau) = C(\tau)^T (zI - A(\tau))^{-1} B(\tau)$. Since $f(z;\tau) = C_0^T (zI - A_0)^{-1} U(\tau) B_0$, we conclude from (27) and Proposition 2.4 that $f(z;\tau) \in \mathrm{rat}_p(n)$ for any $\tau \in \mathbb{R}^n$. Note that the solution of (25) is not unique even if we suppose that the diagonal entries of $R(\tau)$ are positive. Indeed, if $R(\tau)$ satisfies (25), then $R(\tau')$ does also, where $\tau' = \{\tau_0 + \theta, \tau_1, \cdots, \tau_{n-1}\}$ for $\theta \in \mathbb{R}$. By identifying $R(\tau)$ with $R(\tau')$, we can obtain a unique rational function of $\mathrm{Rat}_p(n)$. Note that this identification amounts to the equivalence class $[\{A_0, B_0, C_0\}]$ of initial values. Namely, each point on the cyclic-Toda flow $A(\tau)$ for $[\{A_0, B_0, C_0\}]$ corresponds to a unqiue rational function of $\mathrm{Rat}_p(n)$. Thus we have obtained a one-to-one mapping $\alpha: \mathrm{Rat}_p(n) \to \mathcal{M}_p$.

Conversely, let $f(z)$ be an arbitrary rational function of $\mathrm{rat}_p(n)$. Recall that $f(z)$ admits a unique factorization (9). As was shown in the previous section, there always exists a flow of the cyclic-Toda hierarchy $\{A(\tau), B(\tau), C(\tau)\}$ for $\tau \in \mathbb{R}^n$. We see from (24) that this flow induces a flow $f(z;\tau)$ on $\mathrm{rat}_p(n)$ which passes $f(z)$ at $\tau = \mathbf{0}$. Furthermore, by introducing the equivalence relation $f(z) \sim e^{\theta} f(z)$, $\theta \in \mathbb{R}$, we obtain a unique cyclic-Toda flow for the equivalence class $[\{A_0, B_0, C_0\}]$ of initial triplets. Thus α is an onto mapping from $\mathrm{Rat}_p(n)$ to $\mathcal{M}_p$. We have established the following theorem.

THEOREM 3.2. *There is a one-to-one correspondence between* (a) *the space* $\mathrm{Rat}_p(n)$ *of rational functions of degree n and fixed denominator* $p(z)$ *and* (b) *the moduli space* $\mathcal{M}_p$ *of the cyclic-Toda hierarchy for any equivalence class* $[\{A_0, B_0, C_0\}]$ *of initial cyclic triplets.*

Furthermore, the mapping $\alpha: \mathrm{Rat}_p(n) \to \mathcal{M}_p$ clearly depends differentiably on each parameter of $\tau \in \mathbb{R}^n$. Recall that solutions $Q(\tau)$ and $R(\tau)$ of (25) and (26) are of class C^{∞}. This guarantees the differentiability of α^{-1}. Combining this with Theorem 3.2, we have proved a stronger result.

THEOREM 3.3. *The bijection* $\alpha: \mathrm{Rat}_p(n) \to \mathcal{M}_p$ *is a diffeomorphism with the natural topologies on* $\mathrm{Rat}_p(n)$ *and* $\mathcal{M}_p$ *induced by* $\mathbb{R}^n$.

To compute the number of connected components of $\mathrm{Rat}_p(n)$, it is important to recall that only real zeros of $f(z)$ create obstructions to deformations on $\mathrm{rat}_p(n)$ [12]. This fact was first noted by Brockett [2]. The position of zeros of (9) depends on A_0 and B_0. The cyclic-Toda hierarchy for the initial value $\{A_0, B_0, C_0\}$ induces a set of flows parametrized by $\tau \in \mathbb{R}^n$ on one of the connected components of $\mathrm{rat}_p(n)$. Since C_0 is fixed, the choice of the connected components is determined by that of A_0 and B_0. Let $f(z) = q(z)/p(z) \in \mathrm{rat}_p(n)$ and ζ_j be roots of $p(z) = \det(zI - A_0)$. By the spectral mapping theorem we see a cyclic matrix polynomial $\sum_{k=0}^{n-1} q_k A_0^k$ is nonsingular if and only if $q(\zeta_j) \neq 0$ for any ζ_j. Thus any rational function of $\mathrm{Rat}_p(n)$ uniquely determines a nonsingular matrix H_q of the space $\mathcal{H}_{A_0}$ defined by

$$\mathcal{H}_{A_0} = \mathcal{h}_{A_0}/\sim, \qquad \mathcal{h}_{A_0} = \{H_q \mid H_q = \textstyle\sum_{k=0}^{n-1} q_k A_0^k : \text{nonsingular}, q \in \mathbb{R}^n\}, \tag{28}$$

where $H_q \sim e^{\theta} H_q$ for $\theta \in \mathbb{R}$ and vice versa. The mapping $\beta: \mathrm{Rat}_p(n) \to \mathcal{H}_{A_0}$ and its inverse are clearly differentiable with respect to $q = \{q_0, \cdots, q_{n-1}\} \in \mathbb{R}^n$. Thus $\mathcal{H}_{A_0}$ is diffeomorphic to $\mathrm{Rat}_p(n)$. Define the spaces of cyclic vectors

$$\mathcal{W}_{A_0} = \omega_{A_0}/\sim, \qquad \omega_{A_0} = \{W \mid W \in \mathbb{R}^{n\times 1}, \operatorname{rank}(W A_0 W \cdots A_0^{n-1} W) = n\}, \tag{29}$$

where $W \sim e^{\theta} W$ for $\theta \in \mathbb{R}$. We see that $\mathcal{H}_{A_0}$ acts freely on $\mathcal{W}_{A_0}$, $\mathcal{H}_{A_0} \times \mathcal{W}_{A_0} \to \mathcal{W}_{A_0}$ by $(H_q, W) \to H_q W$. Thus $\mathcal{W}_{A_0}$ is diffeomorphic to $\mathcal{H}_{A_0}$ and the number of connected components of $\mathcal{W}_{A_0}$ is equal to that of $\mathrm{Rat}_p(n)$.

Suppose that $p(z)$ admits r real distinct zeros ζ_j, where $r \geqq 1$ and $1 \leqq j \leqq r$. We write ζ_j in order, $\zeta_1 < \zeta_2 < \cdots < \zeta_r$. Set $s = \{s_0, s_1, \cdots, s_{r-1}\}$, where $s_j = 0$ or 1. If an odd number of zeros of $f(z)$ are on the interval (ζ_j, ζ_{j+1}), then we assign 1 to s_j for $1 \leqq j \leqq r-1$. Otherwise, we assign zero to s_j. Set $s_0 = 1$ (respectively, zero) if the coefficient of the highest power of z in $q(z)$ is positive (respectively, negative). Thus the multi-index s labels the connected components of $\mathrm{rat}_p(n)$. The maximum number of such components is 2^r. We express each component as $\mathrm{rat}_p^s(n)$. If there is no real root of $p(z)$, $\mathrm{rat}_p(n)$ itself is connected and denoted by $\mathrm{rat}_p^{\phi}(n)$. Note that $\mathrm{Rat}_p^s(n) = \mathrm{rat}_p^s(n)/\sim$ is exactly one of the connected components of $\mathrm{Rat}_p(n)$. From this result and Theorem 3.3, we prove Corollary 3.4.

COROLLARY 3.4. *Let* $\{A_0, B_0, C_0\}$ *be a cyclic triplet such that* $C_0^T (zI - A_0)^{-1} B_0 \in \mathrm{rat}_p^s(n)$. *Then the cyclic-Toda flow* $A(\tau)$, $\tau \in \mathbb{R}^n$, *for the initial value* $\{A_0, B_0, C_0\}$ *is identified with the connected component* $\mathrm{Rat}_p^s(n)$.

This corollary hints that the space $\mathrm{Rat}_p(n)$ is the primary object, rather than $\mathrm{rat}_p(n)$ that was used to prove Theorem 3.2.

Finally, we shall give simple but conspicuous examples. Let

$$\left\{A_0=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}, B_0=\begin{pmatrix}\alpha\\ \beta\end{pmatrix}, C_0=\begin{pmatrix}0\\ 1\end{pmatrix}\right\}$$

be a cyclic triplet. We obtain $f(z)=(\alpha+\beta)/2(z-1)+(\beta-\alpha)/2(z+1)$ and

$$\exp\left(\sum_{k=0}^{1}\tau_k A_0^k\right)=\exp(\tau_0)\cdot\begin{pmatrix}\cosh(\tau_1) & \sinh(\tau_1)\\ \sinh(\tau_1) & \cosh(\tau_1)\end{pmatrix}.$$

If $|\beta|>|\alpha|$, then the zero of $f(z)$ is on the interval $(-1, 1)$, and then the flow is identified with $\mathrm{Rat}_p^s(n)$, where $p=\{0,-1\}$ and $s=\{1,1\}$ for $\beta>0$ or $s=\{0,1\}$ for $\beta<0$. Let us note that the Cauchy index of $f(z;\tau)$ is equal to ± 2, namely, $f(z;\tau)\in \mathrm{rat}_p(2,0)\approx\mathbb{R}^2$ or $\mathrm{rat}_p(0,2)\approx\mathbb{R}^2$. Setting $\alpha=0$, we derive a hierarchy of the usual 2×2 Toda equation. If $|\alpha|>|\beta|\neq 0$, then $f(z)$ admits a zero on $(-\infty,-1)$ or $(1,\infty)$. Therefore, the resulting flow is identified with $\mathrm{Rat}_p^{s'}(n)$, where $s'=\{1,0\}$ for $\beta>0$ or $s'=\{0,0\}$ for $\beta<0$. Here the Cauchy index of $f(z;\tau)$ is always zero, namely, $f(z;\tau)\in\mathrm{rat}_p(1,1)\approx\mathbb{R}^1\times S^1$. If $\beta=0$, then $f(z)$ has no zero. The flow is identified with $\mathrm{Rat}_p^{s''}(n)$, where $s''=\{1,0\}$ for $\alpha>0$ or $s''=\{0,0\}$ for $\alpha<0$, and then $f(z;\tau)\in\mathrm{rat}_p(1,1)$.

Let $\tilde{p}(z)=z^n+\tilde{p}_{n-1}z^{n-1}+\cdots+\tilde{p}_0$ have n real distinct roots. Any $f(z)$ of $\mathrm{rat}_{\tilde{p}}(n)$ can be factored into $f(z)=C_0^T(zI-A_0)^{-1}B_0$, where $B_0=C_0$, A_0 is Jacobi, and B_0 is cyclic. In this case, we obtain a subhierarchy of (18) called the *Jacobi-Toda hierarchy* whose moduli space is homeomorphic to $\mathrm{Rat}_{\tilde{p}}(n)$. By setting $B_0=(0\cdots 01)^T$, we obtain the Jacobi-Toda flow being identified with $\mathrm{Rat}_{\tilde{p}}^s(n)$, where $s=\{s_0,1,\cdots,1\}$. This is exactly the case analyzed by Moser [13]. The original Toda equation (4) is a special member of this flow parametrized by τ_1. Thus we can conclude that the extension to general cyclic triplet $\{A_0, B_0, C_0\}$ is not a trivial formal generalization. As we have observed, the cyclic-Toda hierarchy gives a *complete* parametrization of the space $\mathrm{Rat}_p(n)$ of controllable and observable linear systems for the fixed polynomial $p(z)=\det(zI-A_0)$. Let us recall that by taking the union with respect to $p=\{p_0,\cdots,p_{n-1}\}$, we recover the whole space $\mathrm{Rat}(n)$ of rational functions of degree n,

$$\mathrm{Rat}(n)=\bigcup_{p\in\mathbb{R}^n}\mathrm{Rat}_p(n).$$

It would be interesting to study the topology of the flows of nonlinear integrable systems on $\mathrm{Rat}(n)$ and its applications, for example, to various cellular decompositions of $\mathrm{Rat}(n)$ and to the problem of limiting linear systems.

Acknowledgments. It is a pleasure to thank T. E. Duncan, H. Fukawa, and P. S. Krishnaprasad for their helpful advice, and especially D. Hinrichsen for various fruitful discussions during my stay as a guest professor of the Forschungsschwerpunkt Dynamische Systeme, Universität Bremen.

THE INTERIOR TRANSMISSION PROBLEM AND INVERSE SCATTERING FROM INHOMOGENEOUS MEDIA*

B. P. RYNNE† AND B. D. SLEEMAN‡

Abstract. This paper is concerned with the class of far field patterns corresponding to the scattering of time harmonic acoustic plane waves by an inhomogeneous medium in a bounded domain B, with refractive index $n(x)$. It has previously been shown that the class of far field patterns is complete in $L_2(S^2)$ except at wavenumbers k, which are so-called transmission eigenvalues of the homogeneous interior transmission problem. In this paper the interior transmission problem is studied and, under milder conditions on n than previously used, the set of transmission eigenvalues is shown to be discrete. Also, at points other than transmission eigenvalues, it is shown that the inhomogeneous interior transmission problem is uniquely solvable. This result is of importance in certain methods for solving the inverse scattering problem of determining the function n from the scattered far fields.

Key words. far field patterns, acoustic waves, inverse scattering

AMS(MOS) subject classifications. 35P25, 76Q05

1. Introduction. This paper is concerned with the class of far field patterns corresponding to the scattering of time harmonic acoustic plane waves by an inhomogeneous medium in a bounded domain B, with refractive index $n(x)$. In [4] it was shown that the class of far field patterns is complete in the Hilbert space $L_2(S^2)$ (where S^2 is the unit sphere in $\mathbb{R}^3$) for all positive wavenumbers k, except possibly on a discrete set of points, provided that the medium is nonabsorbing and the function $m(x) = 1 - n(x)$ is smooth, is strictly positive (or strictly negative) in B, and satisfies a certain integral bound (which restricts the behavior of m near the boundary of B). Here we allow m to be nonsmooth and to change sign. In addition, the medium may be absorbent in B. However, we assume that m is bounded away from zero in B; thus if m changes sign it must do so discontinuously. Also, m must be discontinuous at the boundary ∂B of B (since by definition, $m \equiv 0$ outside B). This is in contrast with the condition imposed in [4], which requires that m be smooth and approach zero near ∂B at a certain rate. In our analysis we will employ, essentially, ideas drawn from the theory of partial differential operators, in contrast to the integral operator methods of [4]; thus this paper complements the results of [4].

Of particular interest is the study of the so-called interior transmission problem, which plays a fundamental role in solving the inverse scattering problem in [3]. This is treated in §§ 3 and 4 and offers an alternative to the treatment in [4]. Also in § 4, we consider the question of approximating the solutions of the interior transmission problem by Herglotz wave functions. This is required in the discussion of inverse scattering in [3]. In §§ 2–4 we consider the case of a nonabsorbing medium. The modifications required to deal with the case of an absorbing medium are described in § 5.

2. Wave propagation and far field patterns. Consider acoustic scattering of a plane harmonic incident wave

$$u^i(x, t) = \exp(ikx \cdot \hat{\alpha} - i\omega t), \tag{2.1}$$

where $\omega > 0$ is the frequency, $k = \omega/c_0$ is the wavenumber, $c_0 > 0$ is the speed of sound outside the medium, and the unit vector $\hat{\alpha}$ is the direction of propagation of the wave. Let $c(x)$ be the local sound speed at any point $x \in \mathbb{R}^3$, and let $n(x) = (c_0/c(x))^2$, $m(x) = 1 - n(x)$. Letting

$$B = \{x \in \mathbb{R}^3 : n(x) \neq 1\},$$

we assume that the set B is an open, bounded, simply connected set with C^4 boundary ∂B and suppose that the function n is measurable and satisfies

$$\text{ess} \cdot \sup \{n(x) : x \in B\} < \infty, \qquad \text{ess} \cdot \inf \{|m(x)| : x \in B\} > 0 \tag{2.2}$$

(note that we are allowing m to change sign in B, but (2.2) implies that it must do so discontinuously). Without loss of generality, we will assume that the origin $x = 0$ belongs to B. If we factor out the time dependence $\exp(-i\omega t)$, then the velocity potential u of the total field belongs to $H_2(B)$ (the Sobolev space of order 2 on B; see [1]) and is a solution of the problem

$$\Delta u + k^2 n u = 0 \quad \text{in } \mathbb{R}^3, \tag{2.3}$$

$$u(x) \equiv \exp(ikx \cdot \hat{\alpha}) + u^s(x), \tag{2.4}$$

$$\lim_{r \to \infty} \left(\frac{\partial u^s}{\partial r} - iku^s \right) = 0, \tag{2.5}$$

where $u^s(x)$ denotes the scattered field, $|x| = r$, and the Sommerfeld radiation condition (2.5) is assumed to hold uniformly in $\hat{x} = x/|x| \in S^2$.

As in [4] it is easy to show that as $r \to \infty$ the scattered field $u^s(x)$ has the asymptotic behavior

$$u^s(x) = \frac{\exp(ikr)}{r} F(\hat{x}; k, \hat{\alpha}) + O(r^{-2}),$$

where the function $F(\hat{x}; k, \hat{\alpha})$ is the *far field pattern* corresponding to the incident plane wave (2.1). The following result is similar to Lemma 2 of [4].

Let $\{\hat{\alpha}_n : n = 1, \cdots, \infty\}$ be a countable dense set of vectors on the unit sphere S^2, and for each fixed k define the class $\mathbf{F}$ of far field patterns by

$$\mathbf{F} = \text{span} \{F(\hat{x}; k, \hat{\alpha}) : n = 1, 2, \cdots\}.$$

LEMMA 2.1 [4]. *The orthogonal complement of* $\mathbf{F}$ *in* $L_2(S^2)$ *consists of those functions* $g \in L_2(S^2)$ *for which there exists* $w \in H_2(B)$ *and* v *defined by*

$$v(x) = \int_{S^2} g(\hat{y}) \exp(ikx \cdot \hat{y}) \, ds(y) \tag{2.6}$$

such that the pair $\{v, w\}$ *is a solution to*

$$\Delta v + k^2 v = 0, \tag{2.7}$$

$$\Delta w + k^2 n w = 0, \tag{2.8}$$

$$v - w|_{\partial B} = \frac{\partial}{\partial \nu}(v - w)|_{\partial B} = 0, \tag{2.9}$$

where (2.7) *and* (2.8) *are to be regarded as holding in* $L_2(B)$; $\partial/\partial \nu$ *denotes differentiation along the exterior normal to* ∂B; *the notation* $\phi|_{\partial B}$ *denotes the trace of a function* ϕ *on the boundary* ∂B *in the* L_2 *sense* (*see* [1]); *equation* (2.9) *holds on* ∂B *in the* L_2 *sense. Similar interpretations apply to the equations below except where stated otherwise.*

The functions v defined by (2.6) are called *Herglotz wave functions* with *Herglotz kernel g*. The boundary value problem (2.7)-(2.9) is the *homogeneous interior transmission problem*, studied in [3], [4], and others, which, together with the inhomogeneous interior transmission problem considered later, plays a fundamental role in solving the inverse scattering problem of determining the speed of sound in an inhomogeneous medium (see [3]). For this purpose it is important to prove that the set **F** is complete in $L_2(S^2)$. It follows from Lemma 2.1 and the theory of Herglotz wave functions (see [5]) that this is so, except for those values of k for which (2.7)-(2.9) possesses a nontrivial solution $\{v, w\}$. In the next section we will show that such values form a discrete set in $\mathbb{C}$, and hence, for almost all k, **F** is complete.

3. The homogeneous interior transmission problem. The space $H_2^{\text{loc}}(B)$ is defined to be the set of measurable functions ϕ on B that have the property that $\phi \in H_2(D)$ for all open subsets D such that $\bar{D} \subset B$. We will say that the pair of functions $\{v, w\}$ is a strong solution of the homogeneous interior transmission problem if $v, w \in H_2^{\text{loc}}(B) \cap L_2(B)$, $v - w \in H_2(B)$, and equations (2.7)-(2.9) are satisfied for some $k \in \mathbb{C}$. If a nontrivial strong solution of the homogeneous interior transmission problem exists for some $k \in \mathbb{C}$, then k is said to be a transmission eigenvalue.

Suppose that k is a transmission eigenvalue and let

$$z = w - v \in H_2(B). \tag{3.1}$$

It follows from (2.9) that $z \in H_2^0(B)$, where $H_2^0(B) \subset H_2(B)$ is the set of functions $\phi \in H_2(B)$ whose derivatives up to order 1 vanish on ∂B. Also, from (2.7) and (2.8) we have

$$(\Delta + k^2)z = k^2 m w, \tag{3.2}$$

where $m(x) = 1 - n(x)$, $x \in B$. It follows from (2.2) that the function $x \to 1/m(x)$, which we denote by m^{-1}, is essentially bounded on B, so from (3.2) we have

$$m^{-1}(\Delta + k^2)z = k^2 w.$$

Now, by definition $w \in H_2^{\text{loc}}(B)$, and so we may apply $(\Delta + k^2 n)$ to both side of this equation to yield, by (2.8),

$$(\Delta + k^2 n)m^{-1}(\Delta + k^2)z = 0. \tag{3.3}$$

Thus, in order for k to be a transmission eigenvalue there must be a nontrivial function $z \in H_2^0(B)$ that satisfies (3.3).

Since we have only required that $z \in H_2^0(B)$ and (3.3) is a fourth-order equation, we will introduce a weak formulation of this equation. For any complex number k we define the sesquilinear form F_k on $H_2^0(B)$ by

$$\begin{aligned} F_k(\phi, \psi) &= \int_B m^{-1}(\Delta + k^2)\phi(\Delta + \bar{k}^2 n)\bar{\psi}\, dx \\ &= (m^{-1}(\Delta + k^2)\phi, (\Delta + \bar{k}^2 n)\psi), \qquad \phi, \psi \in H_2^0(B) \end{aligned} \tag{3.4}$$

(we let $(\cdot, \cdot)$ and $\|\cdot\|$ denote the standard $L_2(B)$ inner product and norm). Clearly, the form F_k is bounded on the space $H_2^0(B)$.

LEMMA 3.1. *A nonzero point $k \in \mathbb{C}$ is a transmission eigenvalue if and only if there exists a nonzero function $z \in H_2^0(B)$ such that*

$$F_k(z, \psi) = 0, \quad \text{all } \psi \in H_2^0(B). \tag{3.5}$$

Proof. It follows immediately from (3.3), using integration by parts, that if k is a transmission eigenvalue then the function z defined in (3.1) satisfies (3.5).

Now suppose that $z \in H_2^0(B)$ is nonzero and satisfies (3.5). Since $z \in H_2^0(B)$, we can define the functions v, $w \in L_2(B)$ by

$$w = k^{-2} m^{-1} (\Delta + k^2) z \tag{3.6}$$

and

$$v = w - z. \tag{3.7}$$

By definition we have

$$(w, (\Delta + \bar{k}^2 n)\psi) = k^{-2}(m^{-1}(\Delta + k^2)z, (\Delta + \bar{k}^2 n)\psi) = k^{-2} F_k(z, \psi) = 0, \quad \text{all } \psi \in H_2^0(B),$$

and by standard interior regularity results for elliptic operators (see [1, Thm. 6.3]) this shows that $w \in H_2^{\text{loc}}(B)$ and satisfies (2.8). Since $z \in H_2^0(B)$, we also have $v \in H_2^{\text{loc}}(B)$. Now,

$$(\Delta + k^2)v = (\Delta + k^2)w - (\Delta + k^2)z = k^2 mw - k^2 mw = 0,$$

using (3.6) and (2.8). Thus v satisfies (2.7). These results show that the nontrivial pair of functions $\{v, w\}$ is a strong solution of the homogeneous interior transmission problem, and hence k is a transmission eigenvalue. This completes the proof of the lemma.

We now define another form $\langle \cdot, \cdot \rangle$ on $H_2^0(B)$ by

$$\langle \phi, \psi \rangle = (\Delta\phi, \Delta\psi), \qquad \phi, \psi \in H_2^0(B).$$

Also, we let $(\cdot, \cdot)_j$ and $\|\cdot\|_j$ denote the inner product and norm in $H_j(B)$ for any integer $j \geqq 0$.

LEMMA 3.2. *There exists $c_1 > 0$ such that for any $\phi \in H_2^0(B)$,*

$$\langle \phi, \phi \rangle \geqq c_1 \|\phi\|_2^2. \tag{3.8}$$

Proof. The inequality follows immediately from Lemma 7.7 in [1].

For any $k \in \mathbb{C}$, we can decompose the form F_k into a sum of forms $F^0 + F_k^1 + F_k^2$, where

$$F^0(\phi, \psi) = (m^{-1}\Delta\phi, \Delta\psi), \quad F_k^1(\phi, \psi) = (m^{-1}(\Delta + k^2)\phi, \bar{k}^2 n\psi),$$
$$F_k^2(\phi, \psi) = (k^2 m^{-1}\phi, \Delta\psi),$$

where $\phi, \psi \in H_2^0(B)$. Lemma 3.2 and the Lax-Milgram theorem (see [7, p. 344]) allow us to define bounded linear operators S_k, S^0, S_k^1, S_k^2, on $H_2^0(B)$ by means of the following identities, which are supposed to hold for all $\phi, \psi \in H_2^0(B)$:

$$F_k(\phi, \psi) = \langle S_k\phi, \psi \rangle, \quad F^0(\phi, \psi) = \langle S^0\phi, \psi \rangle, \quad F_k^1(\phi, \psi) = \langle S_k^1\phi, \psi \rangle,$$
$$F_k^2(\phi, \psi) = \langle S_k^2\phi, \psi \rangle.$$

Clearly,

$$S_k = S^0 + S_k^1 + S_k^2. \tag{3.9}$$

LEMMA 3.3. *For any $k \in \mathbb{C}$, the operators S_k^1, S_k^2 are compact.*

Proof. Let $\phi \in H_2^0(B)$. Then by the definition of $\langle \cdot, \cdot \rangle$, F_k^1 and S_k^1,

$$(\Delta S_k^1\phi, \Delta\psi) = \bar{k}^2(nm^{-1}(\Delta + k^2)\phi, \psi) = \bar{k}^2(\theta, \psi), \quad \text{all } \psi \in H_2^0(B),$$

where $\theta = nm^{-1}(\Delta + k^2)\phi \in L_2(B)$. By a standard regularity result for elliptic operators (see [1, Thm. 9.8]), this implies that $S_k^1\phi \in H_4(B) \cap H_2^0(B)$ and

$$\|S_k^1\phi\|_4 \leqq c_2(\|\phi\|_0 + \|S_k^1\phi\|_0) \leqq c_3\|\phi\|_2.$$

Since this holds for all $\phi \in H_2^0(B)$ and the injection operator from $H_4(B)$ to $H_2(B)$ is compact, this shows that the operator S_k^1 is compact. To show that S_k^2 is compact we first choose a sequence of functions m_j^*, $j=1,2,\cdots$, such that $m_j^* \in C^\infty(B)$, and $m_j^* \to m^{-1}$ in $L_2(B)$ (this is possible by Theorem 1.7 of [1]), and we define the sequence of operators $S_{k,j}^2 : H_2^0(B) \to H_2^0(B)$ by the relations

$$\langle S_{k,j}^2 \phi, \psi \rangle = (k^2 m_j^* \phi, \Delta\psi), \qquad \phi, \psi \in H_2^0(B).$$

As before, for any $\phi \in H_2^0(B)$, we have

$$(\Delta S_{k,j}^2 \phi, \Delta\psi) = (k^2 m_j^* \phi, \Delta\psi), \quad \text{all } \psi \in H_2^0(B),$$

and so

$$\Delta S_{k,j}^2 \phi = k^2 m_j^* \phi \tag{3.10}$$

in $L_2(B)$. Now, the right-hand side of (3.10) belongs to $H_2^0(B)$, so by the regularity properties of the Dirichlet problem for the Laplace operator $S_{k,j}^2 \phi \in H_4(B) \cap H_2^0(B)$ and

$$\|S_{k,j}^2 \phi\|_4 \leqq c_4 \|m_j^* \phi\|_2 \leqq c_{4,j} \|\phi\|_2,$$

since $m_j^* \in C^\infty(\bar{B})$. Hence the operators $S_{k,j}^2$ are compact. Also, since $m^{-1}\phi \in L_2(B)$, we have, by a similar argument,

$$\|(S_k^2 - S_{k,j}^2)\phi\|_2 \leqq c_5 \|(m^{-1} - m_j^*)\phi\| \leqq c_5 \|m^{-1} - m_j^*\| \, |\phi| \leqq c_6 \|m^{-1} - m_j^*\| \, \|\phi\|_2,$$

by Sobolev's inequality (where $|\phi|$ is the sup norm of ϕ on B). Hence

$$\|S_k^2 - S_{k,j}^2\|_2 \leqq c_6 \|m^{-1} - m_j^*\|$$

(where the norm on the left of this inequality is the uniform operator norm on $H_2^0(B)$), and so S_k^2 is the uniform limit of a sequence of compact operators and so is compact. This completes the proof of the lemma.

We will now impose the following assumption which is, essentially, a condition on the function m.

Assumption. The operator S^0 is nonsingular.

This assumption does not seem to be unduly restrictive. We conjecture that it holds for "generic" functions m on B. If $m(x) \geqq c_7 > 0$ (or $m(x) \leqq c_7 < 0$), then the assumption is certainly true (this follows from (3.8) and [7, p. 344]).

LEMMA 3.4. *A nonzero point $k \in \mathbb{C}$ is a transmission eigenvalue if and only if the operator S_k is singular.*

Proof. It follows from Lemma 3.1 that any nonzero $k \in \mathbb{C}$ is a transmission eigenvalue if and only if

$$N(S_k) \neq 0. \tag{3.11}$$

However, by Lemma 3.3 and the Fredholm alternative for compact operators it can easily be shown that this holds if and only if S_k is singular.

We can now prove the main result of this section.

THEOREM 3.5. *The set of transmission eigenvalues is discrete.*

Proof. It is clear from the definitions of the forms F_k^1, F_k^2, $k \in \mathbb{C}$ that these are bounded-holomorphic families of forms (see [6, § VII-4.1, p. 395]). Consequently, the families of operators S_k^1, S_k^2, are bounded holomorphic (with respect to the uniform operator norm on $H_2^0(B)$). Hence it follows easily from [6, Thm. VII-1.9, p. 370] that (3.11) holds for either a discrete set of points $k \in \mathbb{C}$, or for all $k \in \mathbb{C}$. However, S^0 is nonsingular, so the latter alternative cannnot hold, which proves the theorem.

4. The inverse scattering problem and Herglotz wave functions. The inverse scattering problem is to determine the index of refraction $n(x)$ from the far field patterns $F(\hat{x}; k, \hat{\alpha})$ for a range of k, $\hat{\alpha} \in S^2$. This problem has been discussed by Colton and Monk [3] using the following approach. First of all, for a fixed k, we seek a function $g \in L_2(S^2)$ such that

$$\int_{S^2} F(\hat{x}; k, \hat{\alpha}) g(\hat{x})\, ds(\hat{x}) = 1 \tag{4.1}$$

for all $\hat{\alpha} \in S^2$. If we define the Herglotz wave function v by (2.6) then it can be shown that (4.1) holds if and only if there is a function w such that the pair $\{v, w\}$ is a solution of the following inhomogeneous interior transmission problem (the proof is similar to the proof of Lemma 2 in [4]; see also [3, § 3]). The pair of functions $\{v, w\}$ is said to be a strong solution of the inhomogeneous interior transmission problem if $v, w \in H_2^{\text{loc}}(B) \cap L_2(B)$, $v - w \in H_2(B)$, and

$$\Delta v + k^2 v = 0, \tag{4.2}$$

$$\Delta w + k^2 n w = 0, \tag{4.3}$$

$$v - w|_{\partial B} = \frac{1}{r} e^{-ikr}, \tag{4.4}$$

$$\frac{\partial}{\partial \nu}(v - w)|_{\partial B} = \frac{\partial}{\partial \nu}\left(\frac{1}{r} e^{-ikr}\right) \tag{4.5}$$

for some $k \in \mathbb{C}$. The method of Colton and Monk is to determine n from (4.1) and the interior transmission problem (see [3]). To apply their methods it is necessary to show that the homogeneous interior transmission problem has a unique solution and, in addition, it is necessary to show that the function v thus found can be approximated by Herglotz wave functions. The proofs of these results as given in [3] are not valid here, so we now proceed to prove them for the present situation.

THEOREM 4.1. *If $k \neq 0$ is not a transmission eigenvalue, then there exists a unique strong solution to the inhomogeneous interior transmission problem.*

Proof. First, note that if there were two distinct solutions to the inhomogeneous problem then their difference would satisfy the homogeneous problem, and hence k would be a transmission eigenvalue. Thus we have uniqueness whenever k is not a transmission eigenvalue. It remains to prove existence.

Choose a function $g \in C^\infty(\mathbb{R}^3)$ such that

$$g(x) = \frac{1}{r} e^{-ikr}$$

in some open neighbourhood of ∂B, which does not contain the origin, and $g(x) = 0$ elsewhere. We now define a function $f_g : H_2^0(B) \to \mathbb{C}$ by

$$f_g(\psi) = (m^{-1}(\Delta + k^2)g, (\Delta + k^2)\psi), \qquad \psi \in H_2^0(B). \tag{4.6}$$

Clearly, f_g is bounded and antilinear, so that by the Lax–Milgram theorem there exists an element $\theta_g \in H_2^0(B)$ such that

$$f_g(\psi) = \langle \theta_g, \psi \rangle, \qquad \psi \in H_2^0(B).$$

Now, by Lemma 3.4, S_k^{-1} exists and is bounded since k is not a transmission eigenvalue. Therefore, we may define $\xi_g = S_k^{-1}\theta_g \in H_2^0(B)$ and we have, by the above definitions,

$$F_k(\xi_g, \psi) = \langle \theta_g, \psi \rangle = F_k(g, \psi), \qquad \psi \in H_2^0(B)$$

(where $F_k(g, \psi)$ is defined by (4.6), even though $g \notin H_2^0(B)$). Thus, if we put $z = g - \xi_g$ we can obtain a strong solution of the inhomogeneous interior transmission problem from z in the same way that we obtained a strong solution of the homogeneous problem in the proof of Lemma 3.1.

Now let $H \subset L_2(B)$ be the linear span in $L_2(B)$ of the set of functions

$$x \to j_l(k|x|)\, Y_l(x/|x|), \quad x \in B, \quad l = 0, 1, \cdots, \quad -l \leqq m \leqq l,$$

where j_l is a spherical Bessel function and Y_l is a spherical harmonic. Let $\bar{H}$ be the closure of H in $L_2(B)$ and let $\bar{H}^{\perp}$ denote the orthogonal complement of $\bar{H}$ in $L_2(B)$.

THEOREM 4.2. *Suppose that* $v \in H_2^{\mathrm{loc}}(B) \cap L_2(B)$ *satisfies equation* (2.7). *Then* $v \in \bar{H}$.

Proof. If $h \in H$ then

$$(h, (\Delta + k^2)\phi) = 0, \quad \text{all } \phi \in C_0^{\infty}(B), \tag{4.7}$$

and, by continuity, (4.7) holds for all $h \in \bar{H}$. Putting

$$v = v_1 + v_2, \quad v_1 \in \bar{H}, \quad v_2 \in \bar{H}^{\perp},$$

then v_1 must satisfy (4.7) and, from our hypothesis that v satisfies (2.7), v also satisfies (4.7), and so v_2 must satisfy (4.7). Thus, by continuity, we have

$$(v_2, (\Delta + k^2)\phi) = 0, \quad \text{all } \phi \in H_2^0(B). \tag{4.8}$$

Now, let

$$\Phi(x, y) = \frac{\exp(ik|x-y|)}{4\pi|x-y|}, \qquad x, y \in \mathbb{R}^3,$$

and define

$$z(x) = \int_B v_2(y)\Phi(x, y)\, dy, \qquad x \in \mathbb{R}^3.$$

Then $z \in H_2(\mathbb{R}^3)$ and, since $v_2 \in \bar{H}^{\perp}$, it follows from the addition formula for Bessel functions (see, [2, eqn. (3.60), p. 94]) that $z(x) = 0$ when $x \notin B$. Thus the restriction of z to B, which we denote by z_B, belongs to $H_2^0(B)$ and

$$(\Delta + k^2) z_B = v_2. \tag{4.9}$$

Now, by (4.8),

$$\|(\Delta + k^2) z_B\|^2 = ((\Delta + k^2) z_B, (\Delta + k^2) z_B) = (v_2, (\Delta + k^2) z_B) = 0,$$

and hence z satisfies the Helmholtz equation

$$(\Delta + k^2) z = 0 \quad \text{in } \mathbb{R}^3. \tag{4.10}$$

It now follows from [1] that $z \in C^2(\mathbb{R}^3)$ and by [2] z is analytic. Hence, since z is identically zero outside B, it must be zero everywhere, and so by (4.9), $v_2 = 0$. This proves the theorem.

5. Absorbent media. In this section we will briefly describe the modifications required in the preceding analysis to deal with the case where the medium in B is absorbing. Let $a(x) \geqq 0$ denote the absorption coefficient at the point $x \in \mathbb{R}^3$ ($a(x) = 0$ for x outside B), and let $\kappa^2(x) = k^2 + ika(x)/c_0$. Then in the fundamental equation (2.3) describing the wave propagation, the term k^2 should be replaced by κ^2. Similarly, in the interior transmission problem the term k^2 in (2.8) should be replaced by κ^2. Now, we again define the function z on B by (3.1), but (3.2) now becomes

$$(\Delta + k^2) z = k^2 m w + ikanw. \tag{5.1}$$

Putting $M(x) = km(x) + ia(x)n(x)$, we obtain the following analogue of the basic equation (3.3):

$$(\Delta + \kappa^2 n)M^{-1}(\Delta + k^2)z = 0. \tag{5.2}$$

From this point onwards the analysis follows the above lines, with κ^2 replacing k^2 at appropriate points and M replacing m. One slight difference is that S^0 now depends on k (via the function M) and it is necessary to assume that S^0 is nonsingular for all k. A sufficient condition for this to be true is that $a(x) \geqq c_8 > 0$ for all $x \in B$ (to see this we observe that if this condition holds then, for each k, the numerical range of S^0 is bounded away from zero, and so the result follows from Theorem VI.3.1 of [7]).

ON THE INVERSE OF THE DISCRETE TWO-DIMENSIONAL WAVE OPERATOR AT CFL*

ROBERT GLASSEY†, ERNST HORST‡, ANDREW LENARD†, AND JACK SCHAEFFER§

Abstract. The initial value problem for the linear nonhomogeneous wave equation in two space dimensions is discretized in the usual way via centered second-order differences, with the timestep size chosen on the CFL "boundary:" $\Delta x = \Delta y = h$, $\Delta t = h/\sqrt{2}$. The solution of this discrete problem is explicitly given as a functional of the data.

Key words. finite differences, fundamental solution, CFL, Courant-Friedrichs-Levy

AMS(MOS) subject classifications. 35L05, 65M99

1. Introduction. In the analysis of convergence of difference schemes for hyperbolic partial differential equations, energy estimates naturally arise. For nonlinear problems in more than one space dimension, these often do not suffice and must be supplemented with additional inequalities. Even in the continuous case, higher-order estimates usually cannot be obtained directly; a uniform (L^∞) estimate is needed first. The problem studied in this paper arose from an attempt to prove convergence of a particle-finite difference method for the two-dimensional Vlasov-Maxwell equations from plasma physics. There we desire an L^∞ estimate on a solution to a discetized inhomogeneous wave equation, as is suggested by the continuous theory [3]. Of course, the standard energy estimate for the wave equation does not provide an L^∞ bound in two dimensions. Thus a *representation* for the discrete solution as an explicit functional of the data is an important first step.

Our results concern discretization of the initial value problem for the wave equation

$$\begin{aligned} &\frac{\partial^2 u}{\partial t^2} - \frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} = f(t, x, y) \qquad (0 < t < \infty,\ x, y \in \mathbb{R}), \\ &u(0, x, y) = \phi(x, y), \qquad u_t(0, x, y) = \psi(x, y), \end{aligned} \tag{1}$$

where we will assume that the data ϕ, ψ, and f are smooth and have compact support in x, y. We choose a stepsize

$$\Delta x = \Delta y = h > 0$$

and then choose the maximum timestep Δt allowed by the classical Courant-Friedrichs-Levy (CFL) condition

$$\Delta t = \frac{h}{\sqrt{2}}. \tag{2}$$

Approximating (1) by standard second-order differences and writing

$$\begin{aligned} &x_k = kh, \quad y_j = jh, \quad t^n = n\Delta t \quad (k, j \in \mathbb{Z},\ n \in \mathbb{N}), \\ &u^n_{kj} \cong u(t^n, x_k, y_j) \end{aligned}$$

we get

$$\frac{u_{kj}^{n+1}-2u_{kj}^{n}+u_{kj}^{n-1}}{\Delta t^2}-\left[\frac{u_{k+1,j}^{n}-2u_{kj}^{n}+u_{k-1,j}^{n}}{h^2}\right]-\left[\frac{u_{k,j+1}^{n}-2u_{kj}^{n}+u_{k,j-1}^{n}}{h^2}\right]=f_{kj}^{n} \tag{3}$$

or, in view of (2),

$$u_{kj}^{n+1}=-u_{kj}^{n-1}+\tfrac{1}{2}[u_{k+1,j}^{n}+u_{k-1,j}^{n}+u_{k,j+1}^{n}+u_{k,j-1}^{n}]+\Delta t^2 f_{kj}^{n}. \tag{4}$$

As is standard for this second-order scheme, we specify as initial conditions

$$\begin{aligned} u_{kj}^{0}&=\phi_{kj}\equiv\phi(x_k, y_j),\\ u_{kj}^{1}&=\phi_{kj}+\Delta t\psi_{kj}. \end{aligned} \tag{5}$$

For the purpose of this introduction, we will describe our result for the case $\phi\equiv 0$, $\psi\equiv 0$.

THEOREM 1. *Let $\phi=\psi=0$. Then the solution of* (4) *is given by*

$$u_{kj}^{n+1}=\Delta t^2\sum_{l=0}^{n-1}2^{-l}\sum_{p=0}^{[l/2]}\sum_{\substack{\alpha,\beta\\ |\alpha-k|+|\beta-j|=l-2p}} S_{p,k-\alpha}^{l} f_{\alpha\beta}^{n-l}, \tag{6}$$

where the kernel S arises in the form

$$S_{p,k}^{l}=\sum_{m=0}^{p}(-4)^m\binom{l-m}{m}\binom{l-2m}{p-m}\binom{l-2m}{|k|+p-m}. \tag{7}$$

We know that the fundamental solution of the wave equation is positive inside the light cone $t=|x|$, yet (7) does not "look" positive. Moreover, the discretization need not a priori preserve positivity. However, *the kernel $S_{p,k}^{l}$ is nonnegative*, as we see in Theorem 2.

THEOREM 2. *Denote by $P_n^{(\alpha,\beta)}(x)$ the* Jacobi polynomial *of degree n in x, with parameters α, β (cf.* [5]). *Then for $k\geqq 0$,*

$$S_{p,k}^{l}=\frac{\binom{l-p}{k}}{\binom{k+p}{k}}\cdot 4^p\cdot[P_p^{(k,l-2p-k)}(0)]^2. \tag{8}$$

The relations (6) and (8) then resolve the Cauchy problem for (4) with zero data.

In order to "recognize" the representation (6), we use the classical Duhamel formula to write the solution to (1) with $\phi=\psi=0$ ($x\in\mathbb{R}^2$):

$$\begin{aligned} 2\pi u(t,x)&=\int_0^t d\tau\int_{|y-x|<t-\tau}\frac{f(\tau,y)\,dy}{\sqrt{(t-\tau)^2-|y-x|^2}}\\ &=\int_0^t d\tau\int_0^{t-\tau}\frac{dr}{\sqrt{(t-\tau)^2-r^2}}\int_{|y-x|=r} f(\tau,y)\,ds_y. \end{aligned} \tag{9}$$

Replacing r by ξ through $r=t-\tau-2\xi$, we obtain

$$\begin{aligned} 2\pi u(t,x)&=\int_0^t d\tau\int_0^{(1/2)(t-\tau)}\frac{d\xi}{\sqrt{\xi}\sqrt{t-\tau-\xi}}\int_{|y-x|=t-2\xi-\tau} f(\tau,y)\,ds_y\\ &=\int_0^t d\tau\int_0^{(1/2)\tau}\frac{d\xi}{\sqrt{\xi}\sqrt{\tau-\xi}}\int_{|y-x|=\tau-2\xi} f(t-\tau,y)\,ds_y, \end{aligned} \tag{10}$$

which is the continuous analogue of (6).

2. Construction of the representation. The representation (6) will follow from the discrete Fourier transformation applied to (4). Since (4) is an explicit scheme, uniqueness of a solution follows immediately.

Consider (4) with zero initial values and $\lambda \equiv \Delta t/h = 1/\sqrt{2}$.

Given a sequence $\{u_{kj}\}_{k,j=-\infty}^{\infty}$ that is summable, we define its *Fourier transform* by

$$\hat{u}(\theta_1, \theta_2) = \sum_{k,j} e^{-i(k\theta_1 + j\theta_2)} u_{kj} = \mathcal{F}u(\theta) \qquad (\theta = (\theta_1, \theta_2)). \tag{11}$$

Given a *translation* τ_j $(j = (j_1, j_2))$ defined by

$$(\tau_j u)_k = u_{k+j} \qquad (k = (k_1, k_2)), \tag{12}$$

it is well known that

$$(\tau_j u)\hat{}\,(\theta) = e^{i(j\cdot\theta)}\hat{u}(\theta). \tag{13}$$

The scheme (4) can be written as

$$u^{n+1} = -u^{n-1} + \tfrac{1}{2}[\tau_{1,0} + \tau_{-1,0} + \tau_{0,1} + \tau_{0,-1}]u^n + \Delta t^2 \cdot f^n \tag{14}$$

and, after Fourier transformation, it becomes

$$\hat{u}^{n+1} = -\hat{u}^{n-1} + \tfrac{1}{2}[2\cos\theta_1 + 2\cos\theta_2]\hat{u}^n + \Delta t^2 \cdot \hat{f}^n \tag{15}$$

or

$$\hat{u}^{n+1} = -\hat{u}^{n-1} + \beta\hat{u}^n + \Delta t^2 \cdot \hat{f}^n, \tag{16}$$

where

$$\beta = \cos\theta_1 + \cos\theta_2. \tag{17}$$

Since $|\beta| \leqq 2$, we can define an angle ψ by

$$\cos\psi = \frac{\beta}{2}. \tag{18}$$

When $\hat{f}^n \equiv 0$, (16) is the Chebyshev difference equation that possesses the linearly independent solutions

$$T_n(\cos\psi) = \cos n\psi, \qquad U_n(\cos\psi) = \frac{\sin(n+1)\psi}{\sin\psi}. \tag{19}$$

Here $T_n(x)$ denotes the standard Chebyshev polynomial, and, with $x = \cos\psi = \beta/2$,

$$U_n(x) = \sum_{m=0}^{[n/2]} (-1)^m \binom{n-m}{m} (2x)^{n-2m} \tag{20}$$

(cf. [5, p. 257]). To represent the solution of (16), we use the classical Duhamel formula ([4, p. 409])

$$\hat{u}^{n+1}(\theta) = \sum_{l=0}^{n-1} \Delta t^2 \cdot \hat{f}^{l+1} \cdot \frac{\sin(n-l)\psi}{\sin\psi}. \tag{21}$$

In view of (21) and the convolution theorem, it will suffice to find the Fourier inverse of $\sin n\psi/\sin\psi$. For this purpose we recall that

$$2x = \beta = \cos\theta_1 + \cos\theta_2,$$

so that (20) is

$$\frac{\sin(n+1)\psi}{\sin\psi} = \sum_{m=0}^{[n/2]} (-1)^m \binom{n-m}{m} (\cos\theta_1 + \cos\theta_2)^{n-2m}.$$

Now consider the sequence

$$\chi_{kj} = \delta_{|k|+|j|,1} = \begin{cases} 1 & \text{if } |k|+|j|=1, \\ 0 & \text{otherwise,} \end{cases} \tag{22}$$

defined for $k, j \in \mathbb{Z}$. Then by an elementary computation,

$$\begin{aligned} \hat{\chi}(\theta) &= \sum_{\substack{k,j \\ (k,j)=(\pm 1,0) \\ (k,j)=(0,\pm 1)}} e^{-i(k\theta_1+j\theta_2)}\chi_{kj} \\ &= e^{-i\theta_1} + e^{i\theta_1} + e^{-i\theta_2} + e^{i\theta_2} = 2(\cos\theta_1 + \cos\theta_2). \end{aligned} \tag{23}$$

It follows that

$$\frac{\sin(n+1)\psi}{\sin\psi} = \sum_{m=0}^{[n/2]} (-1)^m \binom{n-m}{m} 2^{2m-n} (\hat{\chi}(\theta))^{n-2m}. \tag{24}$$

Now define

$$\chi^{*(N)} \equiv \underbrace{\chi * \chi * \cdots * \chi}_{N \text{ times}} \qquad (\chi^{*(1)} \equiv \chi), \tag{25}$$

so that

$$\mathcal{F}(\chi^{*(N)})(\theta) = (\hat{\chi}(\theta))^N. \tag{26}$$

Applying $\mathcal{F}^{-1}$ to (24) we then have

$$\mathcal{F}^{-1}\left(\frac{\sin(n+1)\psi}{\sin\psi}\right)_{kj} = \sum_{m=0}^{[n/2]} (-1)^m \binom{n-m}{m} 2^{2m-n} (\chi^{*(n-2m)})_{kj}. \tag{27}$$

Thus our representation will follow once we have computed the N-fold convolution $\chi^{*(N)}$.

LEMMA 1. *For $k, j \in \mathbb{Z}$ and $n \geq 2$,*

$$(\chi^{*(n)})_{kj} = \sum_{p=0}^{[n/2]} \binom{n}{p} \binom{n}{|k|+p} \delta_{|k|+|j|,n-2p}.$$

Proof. By definition,

$$\begin{aligned} (\chi^{*(n)})_{kj} = (\chi * \chi^{*(n-1)})_{kj} &= \sum_{\substack{m,l \\ (m,l)=(\pm 1,0) \\ (m,l)=(0,\pm 1)}} \chi_{ml}\chi^{*(n-1)}_{k-m,j-l} \\ &= \chi^{*(n-1)}_{k-1,j} + \chi^{*(n-1)}_{k+1,j} + \chi^{*(n-1)}_{k,j-1} + \chi^{*(n-1)}_{k,j+1}. \end{aligned}$$

(From this it follows that $\chi^{*(n)}$ is symmetric in each quadrant.) Thus for $n = 2$,

$$(\chi^{*(2)})_{kj} = \delta_{|k-1|+|j|,1} + \delta_{|k+1|+|j|,1} + \delta_{|k|+|j-1|,1} + \delta_{|k|+|j+1|,1}. \tag{28}$$

Now consider, for $N \in \mathbb{N}$, the expression

$$\begin{aligned} \delta_{|k-1|+|j|,N} + \delta_{|k+1|+|j|,N} &= \begin{cases} \delta_{|k|+|j|,N+1} + \delta_{|k|+|j|,N-1} & \text{if } |k| \geq 1, \\ 2\delta_{|k|+|j|,N-1} & \text{if } k = 0, \end{cases} \\ &= 2\delta_{k0}\delta_{|k|+|j|,N-1} + (1-\delta_{k0})(\delta_{|k|+|j|,N-1} + \delta_{|k|+|j|,N+1}) \\ &= (1+\delta_{k0})\delta_{|k|+|j|,N-1} + (1-\delta_{k0})\delta_{|k|+|j|,N+1} \end{aligned} \tag{29}$$

for $N \geq 1$.

Using (29) with $N=1$ in (28) twice, we obtain

$$\begin{aligned}(\chi^{*(2)})_{kj} &= (1+\delta_{k0})\delta_{|k|+|j|,0}+(1-\delta_{k0})\delta_{|k|+|j|,2}\\ &\quad +(1+\delta_{j0})\delta_{|k|+|j|,0}+(1-\delta_{j0})\delta_{|k|+|j|,2}\\ &= 4\delta_{|k|+|j|,0}+(2-\delta_{k0}-\delta_{|k|,2})\delta_{|k|+|j|,2}.\end{aligned}$$

The claim of Lemma 1 is that, when $n=2$,

$$\begin{aligned}(\chi^{*(2)})_{kj} &= \sum_{p=0}^{1}\binom{2}{p}\binom{2}{|k|+p}\delta_{|k|+|j|,2-2p}\\ &= \binom{2}{|k|}\delta_{|k|+|j|,2}+\binom{2}{1}\binom{2}{|k|+1}\delta_{|k|+|j|,0}\\ &= \binom{2}{|k|}\delta_{|k|+|j|,2}+4\delta_{|k|+|j|,0}.\end{aligned}$$

Thus the initial stage $n=2$ is verified if

$$\binom{2}{|k|} = 2-\delta_{k0}-\delta_{|k|,2}$$

holds for $k=0, \pm1, \pm2$, and this is obvious.

Proceeding by induction, we assume that the lemma is valid at some index $n\geqq 2$. Then by the first lines of the proof,

$$\begin{aligned}(\chi^{*(n+1)})_{kj} &= \chi^{*(n)}_{k-1,j}+\chi^{*(n)}_{k+1,j}+\chi^{*(n)}_{k,j-1}+\chi^{*(n)}_{k,j+1}\\ &= \sum_{p=0}^{[n/2]}\binom{n}{p}\left[\binom{n}{|k-1|+p}\delta_{|k-1|+|j|,n-2p}+\binom{n}{|k+1|+p}\delta_{|k+1|+|j|,n-2p}\right]\\ &\quad +\sum_{p=0}^{[n/2]}\binom{n}{p}\binom{n}{|k|+p}[\delta_{|k|+|j-1|,n-2p}+\delta_{|k|+|j+1|,n-2p}].\end{aligned}$$

Using the symmetry cited above, we first assume that $k\geqq 1$, $j\geqq 1$. Then

$$\begin{aligned}(\chi^{*(n+1)})_{kj} &= \sum_{p=0}^{[n/2]}\binom{n}{p}\left[\binom{n}{|k|+p-1}\delta_{|k|+|j|,n-2p+1}+\binom{n}{|k|+p+1}\delta_{|k|+|j|,n-2p-1}\right]\\ &\quad +\sum_{p=0}^{[n/2]}\binom{n}{p}\binom{n}{|k|+p}[\delta_{|k|+|j|,n-2p+1}+\delta_{|k|+|j|,n-2p-1}]\\ &= \sum_{p=0}^{[n/2]}\binom{n}{p}\left[\binom{n}{|k|+p-1}+\binom{n}{|k|+p}\right]\delta_{|k|+|j|,n-2p+1}\\ &\quad +\sum_{p=0}^{[n/2]}\binom{n}{p}\left[\binom{n}{|k|+p+1}+\binom{n}{|k|+p}\right]\delta_{|k|+|j|,n-2p-1}.\end{aligned}$$

Using the identity $\binom{x}{r-1}+\binom{x}{r}=\binom{x+1}{r}$, we get

$$\begin{aligned}(\chi^{*(n+1)})_{kj} &= \sum_{p=0}^{[n/2]}\binom{n}{p}\binom{n+1}{|k|+p}\delta_{|k|+|j|,n+1-2p}+\sum_{p=0}^{[n/2]}\binom{n}{p}\binom{n+1}{|k|+p+1}\delta_{|k|+|j|,n-2p-1}\\ &= \sum_{p=0}^{[n/2]}\binom{n}{p}\binom{n+1}{|k|+p}\delta_{|k|+|j|,n+1-2p}+\sum_{p=1}^{[n/2]+1}\binom{n}{p-1}\binom{n+1}{|k|+p}\delta_{|k|+|j|,n+1-2p}.\end{aligned}$$

Now we can extend the first sum to $p=[n/2]+1$ since the Kronecker delta factor then vanishes at this $p: n+1-2p \leqq 0$, while $|k|+|j|>0$ by assumption. Similarly, we can extend the second sum to $p=0$ since the factor $\binom{n}{p-1}$ then vanishes by convention. Therefore,

$$(\chi^{*(n+1)})_{kj} = \sum_{p=0}^{[n/2]+1} \binom{n+1}{|k|+p} \left[\binom{n}{p} + \binom{n}{p-1} \right] \delta_{|k|+|j|,n+1-2p}$$

and this proves the result. (The remaining cases, $(k,j)=(0,0)$, $(\pm 1,0)$, $(0,\pm 1)$, are easily treated as above.)

Now, using Lemma 1, we have from (27)

$$\mathscr{F}^{-1}\left(\frac{\sin(n+1)\psi}{\sin\psi}\right) = \sum_{m=0}^{[n/2]} (-1)^m \binom{n-m}{m} 2^{2m-n} \sum_{p=0}^{[(n-2m)/2]} \binom{n-2m}{p} \cdot \binom{n-2m}{|k|+p} \delta_{|k|+|j|,n-2m-2p}$$

and, according to (21), we have

$$u_{kj}^{n+1} = \sum_{l=0}^{n-1} \Delta t^2 \left\{ f^{l+1} * \mathscr{F}^{-1}\left(\frac{\sin(n-l)\psi}{\sin\psi}\right) \right\}_{kj}. \tag{30}$$

The indicated convolution equals

$$\begin{aligned} &\sum_{\alpha,\beta} f_{\alpha\beta}^{l+1} \sum_{m=0}^{[(n-l-1)/2]} (-1)^m \binom{n-l-1-m}{m} 2^{2m-n+l+1} \\ &\quad \cdot \sum_{p=0}^{[(n-l-1-2m)/2]} \binom{n-l-1-2m}{p} \binom{n-l-1-2m}{|k-\alpha|+p} \delta_{|k-\alpha|+|j-\beta|,n-l-1-2m-2p} \\ &= \sum_{m=0}^{[(n-l-1)/2]} (-1)^m \binom{n-l-1-m}{m} 2^{2m-n+l+1} \\ &\quad \cdot \sum_{p=0}^{[(n-l-2m-1)/2]} \binom{n-l-1-2m}{p} \sum_{\substack{\alpha,\beta \\ |\alpha-k|+|\beta-j|=n-l-1-2m-2p}} f_{\alpha\beta}^{l+1} \binom{n-l-1-2m}{|k-\alpha|+p} \end{aligned}$$

Summing this over l, $0 \leqq l \leqq n-1$ and multiplying the result by Δt^2, as (30) dictates, we find a representation for u_{kj}^{n+1}. When we replace l by $n-l-1$ there, we get

$$\begin{aligned} u_{kj}^{n+1} = \Delta t^2 \sum_{l=0}^{n-1} \sum_{m=0}^{[l/2]} (-1)^m \binom{l-m}{m} 2^{2m-l} \\ \cdot \sum_{p=0}^{[(l/2)-m]} \binom{l-2m}{p} \sum_{\substack{\alpha,\beta \\ |\alpha-k|+|\beta-j|=l-2m-2p}} f_{\alpha\beta}^{n-l} \binom{l-2m}{|k-\alpha|+p}, \end{aligned}$$

and then by replacing p by $p+m$ we have

$$\begin{aligned} u_{kj}^{n+1} = \Delta t^2 \sum_{l=0}^{n-1} \sum_{m=0}^{[l/2]} (-1)^m \binom{l-m}{m} 2^{2m-l} \\ \cdot \sum_{p=m}^{[l/2]} \binom{l-2m}{p-m} \sum_{\substack{\alpha,\beta \\ |\alpha-k|+|\beta-j|=l-2p}} f_{\alpha\beta}^{n-l} \binom{l-2m}{|k-\alpha|+p-m}. \end{aligned}$$

This sum is taken over those grid points as shown in Fig. 1.

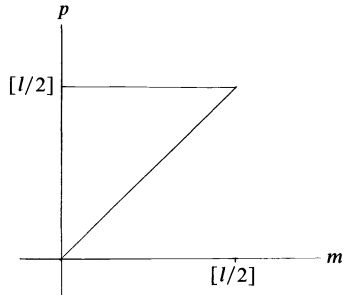

FIG. 1.

Inverting the order of the p, m summations, we can write the result above as

$$u_{kj}^{n+1} = \sum_{l=0}^{n-1} \Delta t^2 \cdot 2^{-l} \sum_{p=0}^{[l/2]} \sum_{\substack{\alpha,\beta \\ |\alpha-k|+|\beta-j|=l-2p}} f_{\alpha\beta}^{n-l} \sum_{m=0}^{p} (-4)^m \binom{l-m}{m} \binom{l-2m}{p-m} \cdot \binom{l-2m}{|k-\alpha|+p-m}. \tag{31}$$

From (7) we recognize the sum over m to be $S_{p,k-\alpha}^{l}$. Thus (31) is the same as (6), and this proves Theorem 1.

Remark. As is seen in (31), the parameters n and p, k, l in $S_{p,k}^{l}$ satisfy $n = 1, 2, \cdots$; $l = 0, 1, \cdots, n-1$; $p = 0, 1, \cdots, [l/2]$; $|k| = 0, 1, \cdots$. Under certain additional conditions on the parameters, it is known that

$$S_{p,k}^{l} = \frac{(-4)^p (l-p)!}{p!\,k!\,(l-2p-k)!}\, {}_4F_3\left(\begin{matrix} -p,\ l+1-p,\ \frac{l+1}{2}-p,\ \frac{l+2}{2}-p \\ l+1-2p,\ k+1,\ l+1-2p-k \end{matrix}; 1\right).$$

We thank R. Asley for this observation. We refer to [1], [5] for the definition of the generalized hypergeometric function ${}_4F_3$.

COROLLARY. *Consider the homogeneous wave equation*

$$u_{tt} - \Delta u = 0$$

and its discretization as in (3):

$$(Lu)_{kj}^{n} \equiv \frac{u_{kj}^{n+1} - 2u_{kj}^{n} + u_{kj}^{n-1}}{\Delta t^2} - \frac{1}{h^2}[u_{k+1,j}^{n} - 2u_{kj}^{n} + u_{k-1,j}^{n}] - \frac{1}{h^2}[u_{k,j+1}^{n} - 2u_{kj}^{n} + u_{k,j-1}^{n}] = 0, \tag{32}$$

where $\Delta x = \Delta y \equiv h$, $\Delta t/h = 1/\sqrt{2}$.

(a) *The solution of*

$$(Lv)_{kj}^{n} = 0, \quad v_{kj}^{0} = \phi_{kj}, \quad v_{kj}^{1} = 0$$

is represented by

$$v_{kj}^{2} = -\phi_{kj}, \quad v_{kj}^{n} = -2^{2-n} \sum_{p=0}^{[(n-2)/2]} \sum_{\substack{\alpha,\beta \\ |\alpha-k|+|\beta-j|=n-2-2p}} S_{p,k-\alpha}^{n-2} \phi_{\alpha\beta} \quad \textit{for } n \geqq 3.$$

(b) *The solution of*

$$(Lw)^n_{kj} = 0, \quad w^0_{kj} = 0, \quad w^1_{kj} = g_{kj}$$

is represented by

$$w^n_{kj} = 2^{1-n} \sum_{p=0}^{[(n-1)/2]} \sum_{\substack{\alpha,\beta \\ |\alpha-k|+|\beta-j|=n-1-2p}} S^{n-1}_{p,k-\alpha} g_{\alpha\beta}.$$

Proof. To prove (a) we make the special choice

$$f^n_{kj} = -(\Delta t)^{-2} \cdot \delta_{n,1} \phi_{kj}$$

in (31). Then (a) follows: the expression (a) is clearly a solution of (32), and it is easily checked that it generates the correct initial values for $n = 2, 3$.

(b) is established by taking the result of (a) and making the identifications

$$w^n_{kj} = -v^{n+1}_{kj}; \qquad \phi_{kj} = g_{kj}.$$

Again, a direct check of the initial values concludes the proof.

3. Positivity of the kernel $S^l_{p,k}$. We will sketch several proofs of Theorem 2 (which sums $S^l_{p,k}$ and establishes its positivity). The first argument cites early work of Watson [6]. Using it has two drawbacks:

(i) It renders the present work non-self-contained;

(ii) The required identification of $S^l_{p,k}$ with a multiple of a particular hypergeometric function of seven parameters holds only under additional restrictions on p, k, l.

For these reasons we also sketch two other proofs. One of these is based on the derivation of a linear recursion for S and on an unusual factorization. The proof of this factorization can be based on generating functions, and this is the content of the second proof.

3.1. Watson's proof. As is standard we denote by ${}_2F_1(a, b, c; z)$ the hypergeometric function of three parameters, and ${}_4F_3\left[\begin{smallmatrix} a,b,c,d \\ e,f,g \end{smallmatrix}; z\right]$ that of seven (cf. [1], [2], [5]). Furthermore, $F_4(\cdots)$ denotes the Appell hypergeometric function ([1, Chap. 9]). Then Watson's result [6] can be written as

$$\begin{aligned} &{}_2F_1(-n, n+a, b; x) \cdot {}_2F_1(-n, n+a, b; 1-x) \\ &= (-1)^n \frac{(a+1-b)_n}{(b)_n} F_4(-n, n+a, b, a+1-b; x(1-x), x(1-x)) \\ &= \frac{(-1)^n (a+1-b)_n}{(b)_n} {}_4F_3\left[\begin{matrix} -n, n+a, \frac{a}{2}, \frac{a+1}{2} \\ a+1-b, b, a, \end{matrix}; 4x(1-x)\right], \end{aligned} \tag{33}$$

where $(a)_n \equiv a(a+1)(a+2)\cdots(a+n-1)$.

We make the following choices:

$$b = k+1, \quad a = l-2p+1, \quad n = p, \quad x = \tfrac{1}{2}.$$

Then the ${}_4F_3(\cdots)$ appearing here is proportional to $S^l_{p,k}$, as is seen from the remark following (31). On the left side of (33) we then have the square of

$${}_2F_1\left(-p, l-p+1, k+1; \frac{1}{2}\right) = \binom{p}{p+k} P_p^{(k,l-2p-k)}(0)$$

using [5, p. 212]. Theorem 2 now follows. We thank G. Gasper for bringing Watson's result to our attention.

3.2. A recursion and factorization for S. First we symmetrize S by defining

$$\tilde{S}^l_{p,q} = \sum_{m=0}^{\infty} (-4)^m \binom{l-m}{m}\binom{l-2m}{p-m}\binom{l-2m}{q-m} \tag{34}$$

for $l = 0, 1, 2, \cdots$; $p, q, = 0, 1, \cdots, l$. Furthermore, we define $\tilde{S}^l_{p,q} = 0$ for integers $p, q, l \geqq 0$ not in the above range. Thus in our previous notation, $S^l_{p,k} = \tilde{S}^l_{p,k+p}$ for $k \geqq 0$, and $m \leqq \max\{p, q\}$ in the above sum.

LEMMA 2. *For $l = 0, 1$ set*

$$\tilde{S}^0_{p,q} = \binom{0}{p}\binom{0}{q}, \qquad \tilde{S}^1_{p,q} = \binom{1}{p}\binom{1}{q}.$$

Then for all integers $p, q, l \geqq 0$, the following recursion holds:

$$\tilde{S}^l_{p,q} = \tilde{S}^{l-1}_{p,q} + \tilde{S}^{l-1}_{p-1,q} + \tilde{S}^{l-1}_{p,q-1} + \tilde{S}^{l-1}_{p-1,q-1} - 4\tilde{S}^{l-2}_{p-1,q-1}.$$

We omit the straightforward but lengthy proof, which uses the recursion for the binomial coefficients. This recursion can be used as follows for integers $p, l = 0, 1, 2, \cdots$ and $q = 0, 1, \cdots, l$. Define

$$R^l_{p,q} = \sum_{\nu=0}^{\infty} (-2)^\nu \binom{p}{\nu}\binom{l-\nu}{q-\nu}, \tag{35}$$

and define $R^l_{p,q} = 0$ for integers $p, q, l \geqq 0$ not in the range above. Then we have the following identity.

LEMMA 3. $\tilde{S}^l_{p,q}$ *admits the factorization*

$$\tilde{S}^l_{p,q} = R^l_{p,q} \cdot R^l_{q,p}.$$

The proof is carried out by showing that both sides satisfy the recursion of Lemma 2. In order to use this result, we recall that $p \leqq q = k + p$, $k \geqq 0$. Since

$$R^l_{p,q} = \binom{l}{q} \sum_\nu (-2)^\nu \frac{\binom{p}{\nu}\binom{q}{\nu}}{\binom{l}{\nu}},$$

$$\tilde{S}^l_{p,q} = \binom{l}{p}\binom{l}{q}\left[\sum_\nu (-2)^\nu \frac{\binom{p}{\nu}\binom{q}{\nu}}{\binom{l}{\nu}}\right]^2 \geqq 0,$$

and we obtain Theorem 2 as follows: by Lemma 3,

$$\tilde{S}^l_{p,q} = R^l_{p,q} R^l_{q,p} = (-2)^{p+q} P_p^{(q-p,l-p-q)}(0) \cdot P_q^{(p-q,l-p-q)}(0),$$

where we have used the definition of the Jacobi polynomial (cf. [5]). For the second factor, we have from [5, p. 210]

$$P_q^{(p-q,l-p-q)}(0) = \frac{\binom{l-p}{q-p}}{\binom{q}{q-p}}\left(-\frac{1}{2}\right)^{q-p} P_p^{(q-p,l-p-q)}(0).$$

When we evaluate the product $\tilde{S}^l_{p,q}$ with $q = k + p$, Theorem 2 results.

Having recognized the existence of the factorization in Lemma 3, we can give a different proof of its validity using generating functions.

The first step is to determine explicitly the generating functions

$$\tilde{S}(x, y, z) = \sum_{p,q,l} \tilde{S}^l_{p,q} x^p y^q z^l,$$

$$R(x, y, z) = \sum_{p,q,l} R^l_{p,q} x^p y^q z^l.$$

Here x, y, z are independent complex variables, restricted to a suitably small neighborhood of the origin in $\mathbb{C}^3$ to make the series absolutely convergent. We find

$$\tilde{S}(x, y, z) = \frac{1}{1 - z(1+x)(1+y) + 4z^2xy},$$

$$R(x, y, z) = \frac{1}{(1 - z(1+y))(1 - zx(1-y))}.$$

To verify the first of these formulae, for instance, we may expand first the geometrical series in powers of $z(1+x)(1+y) - 4z^2xy$, then use the binomial theorem several times, and finally collect terms with equal powers of x, y, z. It is similar for the second formula. The absolute convergence condition for the series $\tilde{S}(x, y, z)$ is

$$|z(1+x)(1+y) - 4z^2xy| < 1;$$

for $R(x, y, z)$ the two conditions

$$|z(1+y)| < 1, \qquad |zx(1-y)| < 1.$$

Before proceeding further, it is useful to make a general remark. Suppose a_n and b_n are two sequences with respective generating functions $f(x) = \sum_n a_n x^n$, $g(x) = \sum_n b_n x^n$, converging absolutely and uniformly in the closed complex disk $|x| \leqq r$. Suppose that x is some complex value for which the strict inequality $|x| < r^2$ holds and we look at the product $f(\xi x) g(1/\xi)$ as a function of ξ. Formally, it is given by the double series $\sum_n \sum_m a_n b_m x^n \xi^{n-m}$, which is a Laurent series in ξ. But by our assumption about f and g it converges uniformly and absolutely in the closed circular annulus

$$\frac{1}{r} \leqq |\xi| \leqq \frac{r}{|x|}.$$

If C is a positively oriented circle around the origin lying inside this annulus we may integrate term by term and obtain

$$\frac{1}{2\pi i} \int_C \frac{d\xi}{\xi} f(x\xi) g\left(\frac{1}{\xi}\right) = \sum_n a_n b_n x^n.$$

This is the basic formula for the generating function of a product sequence $a_n b_n$ in terms of the generating functions of the component sequences a_n and b_n. We propose to apply the three-variable version of this formula to find the generating function of the triple sequence $R^l_{p,q} R^l_{q,p}$.

Accordingly, this generating function will be

$$\frac{1}{(2\pi i)^3} \int_{C_1} \frac{d\xi}{\xi} \int_{C_2} \frac{d\eta}{\eta} \int_{C_3} \frac{d\zeta}{\zeta} R(x\xi, y\eta, z\zeta) R\left(\frac{1}{\eta}, \frac{1}{\xi}, \frac{1}{\zeta}\right)$$

provided x, y, z are small enough and the radii of the circles C_1, C_2, C_3 are suitably fixed. It proves convenient to take a small positive ε (whose actual size is regulated by some detail of the calculations below) and require

$$|x|, |y|, |z| \leqq \varepsilon;$$

furthermore, we take a positive ρ such that

$$2<\rho<\frac{1}{2\varepsilon}.$$

It is then seen that all three integration circles may be taken with radius ρ, and the conditions of validity for the above integral formula are met. We may now do the repeated integrals in any order most convenient for abbreviating the calculations. It turns out that we should first integrate over η, then over ζ, and last over ξ. The integrand is a rational function of η whose polynomial denominator has three factors depending on η; but, fortunately, *only one* vanishes, and that one at a simple zero, inside the contour $|\eta|=\rho$. Thus the η-integral is easily calculated by the Residue theorem, yielding a rational function of ζ and ξ with three factors in the denominator. The story repeats itself, and only one of the three vanishes inside the next integration contour $|\zeta|=\rho$. In the last step we are left with two factors in the denominator depending on ξ, but again only one vanishes inside $|\xi|=\rho$. After the last residue calculation we are left with

$$\frac{1}{(1-zx-zxy)(1-z-zy)+(z-zy)(-zx+zxy)},$$

and a little algebra shows that this is $\tilde{S}(x, y, z)$ as required.

COROLLARY 1. *The kernel $S^{l}_{p,k}$ vanishes when the parameters satisfy any of the following conditions*:

(i) $l=2(k+p)$, *p odd*;

(ii) $l=2p$, $k=p-1, p-3, \cdots, p+1-2[p/2]$;

(iii) $l=8j+1 (j\geqq 1)$, $p=2j$, $k=p+2$, *i.e.*, $l=4p+1$, *p even*, $k=p+2$;

(iv) $l=j^2$, $j=2, 4, 6, \cdots$; $p=2$, $k=\frac{1}{2}(j^2+j-4)$.

Proof. (i) In this case the parameters in $P_p^{(\alpha,\beta)}(0)$ satisfy $\alpha=k$, $\beta\equiv l-2p-k=k=\alpha$. By the Rodrigues formula [5],

$$\begin{aligned}P_p^{(k,k)}(0)&=\frac{(-1)^p}{p!2^p}\frac{d^p}{dx^p}[(1-x^2)^{k+p}]|_{x=0}\\&=c_p\frac{d^p}{dx^p}\sum_{j=0}^{k+p}\binom{k+p}{j}(-1)^j x^{2j}|_{x=0}.\end{aligned}$$

This is an odd-order derivative of an even polynomial, evaluated at $x=0$, and hence vanishes, as claimed.

(ii) Here we have $\alpha=k$, $\beta=l-2p-k=-k=-\alpha$.
By [5, p. 210],

$$P_p^{(k,-k)}(0)=(-1)^p P_p^{(-k,k)}(0)=\frac{(-1)^p\binom{p+k}{k}}{\binom{p}{k}}\left(-\frac{1}{2}\right)^k P_{p-k}^{(k,k)}(0).$$

Applying the Rodrigues formula again, we get

$$\begin{aligned}P_{p-k}^{(k,k)}(0)&=\frac{(-1)^{p-k}}{(p-k)!2^{p-k}}\frac{d^{p-k}}{dx^{p-k}}[(1-x^2)^p]\Big|_{x=0}\\&=\frac{(-1)^{p-k}}{(p-k)!2^{p-k}}\frac{d^{p-k}}{dx^{p-k}}\sum_{\nu=0}^{p}(-1)^\nu\binom{p}{\nu}x^{2\nu}\Big|_{x=0}.\end{aligned}$$

Since $p-k$ is odd, this vanishes as in case (i), and (ii) is proved.

(iii) Here the parameters α, β satisfy

$$\alpha = k, \qquad \beta = l - 2p - k = 8j + 1 - 4j - (2j+2),$$

so $\beta = 2j - 1 = p - 1$ and $\alpha = k = p + 2 = 2j + 2$.
Thus we will show that

$$P_p^{(p+2,p-1)}(0) = 0 \qquad (p \geqq 2).$$

Using Rodrigues again, we see that this vanishes if and only if

$$R_p \equiv \frac{d^p}{dx^p}[(1-x)^{2p+2}(1+x)^{2p-1}]|_{x=0} = 0.$$

Now

$$R_p = \frac{d^p}{dx^p}[(1-x^2)^{2p-1}(1-x)^3]|_{x=0}$$
$$= \sum_{k=0}^{3} \binom{p}{k} \frac{d^k}{dx^k}(1-x)^3|_{x=0} \frac{d^{p-k}}{dx^{p-k}}(1-x^2)^{2p-1}|_{x=0}.$$

Defining $I^l = (d^l/dx^l)(1-x^2)^{2p-1}|_{x=0}$, we obtain

$$R_p = I^p - 3pI^{p-1} + 6\binom{p}{2} I^{p-2} - 6\binom{p}{3} I^{p-3}.$$

Since p is even in case (iii), the terms I^{p-1} and I^{p-3} vanish as in the arguments above. Next we expand $(1-x^2)^{2p-1}$ and differentiate; after a brief calculation we obtain

$$I^p = (-1)^{p/2}\binom{2p-1}{p/2} p!$$

and

$$I^{p-2} = (-1)^{(p-2)/2}\binom{2p-1}{\frac{p-2}{2}}(p-2)!,$$

from which it follows that $R_p = 0$.

(iv) Since $p = 2$, we have by [5]

$$P_p^{(\alpha,\beta)}(0) = P_2^{(\alpha,\beta)}(0)$$
$$= (\alpha+1)(\alpha+2) + (\beta+1)(\beta+2) - 2(\alpha+2)(\beta+2).$$

Substituting $\alpha = k$, $\beta = l - 2p - k = l - 4 - k$, and setting $P_2^{(\alpha,\beta)}(0) = 0$, we obtain the quadratic

$$4k^2 + 4(4-l)k + l^2 - 9l + 16 = 0.$$

The zeros are then written as a function of $l = j^2$, and (iv) follows.

COROLLARY 2. *Define* $\sigma^l = \sum_{p,q \geqq 0} \tilde{S}_{p,q}^l$ *for* $l = 0, 1, \cdots$ *and let* $\tilde{S}_{p,q}^l$ *have the initial values given in Lemma* 2. *Then* $\sigma^l = (1+l) \cdot 2^l$. *Thus, since* $\tilde{S} \geqq 0$ *by Theorem* 2, *the* L^1-*norm of* $S_{p,k}^l$ *is known.*

Proof. Summing the recursion of Lemma 2 over p, q, we obtain $\sigma^l = 4\sigma^{l-1} - 4\sigma^{l-2}$ whence $\sigma^l = (A + Bl)2^l$. Use of the initial values

$$\sigma^0 = 1, \qquad \sigma^1 = 4$$

then gives the result immediately.

Acknowledgment. We are grateful to Professors R. Askey and G. Gasper for sharing their special functions expertise with us.

APPROXIMATION BY PIECEWISE EXPONENTIALS*

JUNJIANG LEI AND RONG-QING JIA†

Abstract. A function is called an exponential if it is a linear combination of products of polynomials with pure exponentials. In this paper lower and upper bounds for families of spaces of piecewise exponentials are established. In particular, the exact L_p-approximation order ($1 \leq p \leq \infty$) is found for a family $\{S_h\}_{h>0}$ of function spaces when each S_h is generated by an exponential box spline and its multi-integer translates.

Key words. multivariate approximation, order of approximation, exponentials, exponential box splines

1. Introduction.

Spaces spanned by multi-integer translates of compactly supported functions have recently attracted much attention. The general setup can be described as follows: Let $\{S_h\}_h$ be a family of function spaces each of which is spanned by the $h\mathbb{Z}^n$-translates of one or several compactly supported functions on $\mathbb{R}^n$. We want to investigate the approximation order of $\{S_h\}_h$ and the ways to realize this approximation order. Here the approximation order of $\{S_h\}_h$ is defined to be the largest real number k for which

$$\operatorname{dist}(f, S_h) = O(h^k)$$

for all sufficiently smooth complex-valued functions on a domain $G \subseteq \mathbb{R}^n$, where dist is measured by some norm (usually an L_p-norm).

A case of particular interest is the scaling case that occurs when the refined spaces S_h are dilations of S_1, i.e.,

$$S_h = \sigma_h S_1$$

with σ_h being the scaling operator

$$\sigma_h : f \mapsto f(\cdot/h).$$

As early as 1946, Schoenberg [19] considered the scaling case where S_1 is spanned by the integer translates of a single compactly supported function ϕ on $\mathbb{R}$. In the late sixties and early seventies Schoenberg's work was extended to the case where S_1 is spanned by several compactly supported functions on $\mathbb{R}^n$. In particular, in the setting of the finite element method, Strang and Fix [20] successfully characterized the so-called controlled approximation order of $\{\sigma_h S_1\}_h$ when S_1 is spanned by a single compactly supported function. However, when S_1 is spanned by several compactly supported functions, their attempt at characterizing the controlled approximation order of $\{\sigma_h S_1\}_h$ failed, as was demonstrated by Jia's counterexample [13]. Nevertheless, the conditions formulated by them to ensure a certain approximation power of $\{\sigma_h S_1\}_h$ have been widely used, and these conditions are now called the Strang–Fix

* Received by the editors July 16, 1990; accepted for publication (in revised form) December 3, 1990.

conditions. In [4] de Boor and Jia gave a characterization of the local approximation order of $\{\sigma_h S_1\}_h$ in terms of the Strang–Fix conditions.

Both the work of Strang and Fix [20] and that of de Boor and Jia [4] put some restriction on the approximation from $\{\sigma_h S_1\}_h$ (either "controlled" or "local"), and hence do not give a characterization for the (unconditional) approximation order. However, when S_1 is spanned by the multi-integer translates of a box spline, the approximation order of $\{\sigma_h S_1\}_h$ was already established by de Boor and Höllig in [3]. Their work was extended by Ron [18] to the case where S_1 is spanned by the multi-integer translates of a compactly supported function on $\mathbb{R}^n$ under an additional condition. Earlier, Jia [14] characterized the approximation order of $\{\sigma_h S_1\}_h$ when S_1 is spanned by the integer translates of several compactly supported functions on $\mathbb{R}$.

Examples of the nonscaling case were given by Dyn and Ron in [12]. In particular, they emphasized that the Strang–Fix conditions are not applicable to approximation by translates of exponential box splines, which were first introduced by Ron [17]. Using quasi-interpolant schemes based on the Neumann series approach (see [7]), Dyn and Ron [12] established a lower bound for the L_∞-approximation order, but they did *not* show that this lower bound is, in fact, the exact approximation order. This is in sharp contrast to the case where $S_h = \sigma_h S_1$ and S_1 is spanned by the multi-integer translates of a box spline. In such a case, the approximation order is relatively easy to determine (see [3]). Even though a characterization of the approximation order was given by Ron [18], it is not clear how his characterization can be applied to actually find the exact order of approximation from $\{S_h\}_h$, where S_h are spaces spanned by the translates of exponential box splines.

The primary goal of this paper is to fill this gap. For this purpose we need to introduce some terminology and notation first. We shall use the standard multi-index notation. Let $\mathbb{N}$ be the set of nonnegative integers. An element $\alpha = (\alpha_1, \cdots, \alpha_n) \in \mathbb{N}^n$ is called a multi-index, and the length of α is defined to be $|\alpha| := \sum_{j=1}^n \alpha_j$. The factorial of α is $\alpha! := \alpha_1! \cdots \alpha_n!$. Let $\mathbb{Z}$ be the set of integers. An element of $\mathbb{Z}^n$ is called a multi-integer. A mapping from $\mathbb{Z}^n$ to $\mathbb{C}$ is called a sequence on $\mathbb{Z}^n$.

Let $\mathbb{R}^n$ be the n-dimensional real space equipped with the uniform norm, i.e.,

$$\|x\| := \max_{1 \le j \le n} |x_j|, \qquad x = (x_1, \cdots, x_n) \in \mathbb{R}^n.$$

If $\Omega \subseteq \mathbb{R}^n$ and $r \ge 0$, we denote by $B_r(\Omega)$ the *closed* ball of radius r around Ω, that is,

$$B_r(\Omega) := \{\, x \in \mathbb{R}^n : \ \operatorname{dist}(x, \Omega) \le r \,\}$$

with

$$\operatorname{dist}(x, \Omega) := \inf_{y \in \Omega} \|x - y\|.$$

When $\Omega = \{x\}$, we write $B_r(x)$ for $B_r(\Omega)$, and simply write B_r for $B_r(0)$. Evidently, if Ω is a closed set, then

$$B_r(\Omega) = \Omega + B_r := \{\, x + y : \ x \in \Omega,\, y \in B_r \,\}.$$

If f is a measurable function on a measurable subset Ω of $\mathbb{R}^n$, we denote by $\|f\|_p(\Omega)$ the quantity $(\int_\Omega |f|^p\,dx)^{1/p}$. Similarly,

$$|f|_{k,p}(\Omega) := \sum_{|\alpha|=k} \|D^\alpha f\|_p(\Omega) \quad \text{and} \quad \|f\|_{k,p}(\Omega) := \sum_{|\alpha|\le k} \|D^\alpha f\|_p(\Omega).$$

When Ω is omitted, the norm is understood to be taken over $\mathbb{R}^n$. For a subspace H of $L_p(\Omega)$ and an element $f \in L_p(\Omega)$, let

$$\operatorname{dist}_p(f, H)(\Omega) := \inf_{g\in H} \|f - g\|_p(\Omega).$$

Let $W_p^k = W_p^k(\mathbb{R}^n)$ be the usual Sobolev space equipped with the norm $\|\cdot\|_{k,p}$.

We denote by $\Pi = \Pi(\mathbb{R}^n)$ the linear space of all polynomials on $\mathbb{R}^n$. For a nonnegative integer k, we denote by Π_k (respectively, $\Pi_{<k}$) its subspace of all polynomials of (total) degree at most k (respectively, less than k). In particular, the monomials given by

$$(\ )^\alpha : x \mapsto x^\alpha = x_1^{\alpha_1} \cdots x_n^{\alpha_n}, \qquad x \in \mathbb{R}^n,$$

are elements of Π. If $p(x) = \sum a_\alpha x^\alpha$ is a polynomial, then $p(D)$ denotes the differential operator induced by p, i.e., $p(D) = \sum a_\alpha D^\alpha$. In particular, $D^\alpha = D_1^{\alpha_1} \cdots D_n^{\alpha_n}$ with D_j being the jth partial derivative operator, $j = 1, \cdots, n$.

Following de Boor and Ron [6], we call a function on $\mathbb{R}^n$ an exponential if it is a linear combination of products of polynomials with the pure exponentials

$$e_\theta : x \mapsto e^{\theta\cdot x}, \qquad \theta \in \mathbb{C}^n,$$

where $\theta \cdot x$ denotes the inner product of θ and x. Note that any finite-dimensional D-invariant (i.e., invariant under differentiation) space of distributions is a space of exponentials (see [1]).

Let A_0 be the linear space of all functions analytic at the origin. An element $f \in A_0$ can be expanded into a power series in a neighborhood of the origin:

$$f(x) = \sum_{\alpha\in\mathbb{N}^n} D^\alpha f(0) x^\alpha/\alpha!.$$

For $j \in \mathbb{N}$, let f_j be the jth homogeneous part of f, i.e.,

$$f_j = \sum_{|\alpha|=j} D^\alpha f(0)(\ )^\alpha/\alpha!.$$

The least term of f, denoted by $f_\downarrow$, is defined as f_j with j being the smallest integer for which $f_j \neq 0$ (see [5]). For a subspace H of A_0 we denote by $H_\downarrow$ the space spanned by all $f_\downarrow$ for $f \in H$.

Now let H be a finite-dimensional space of exponentials. In §3, we will prove our main result, which states that if each S_h consists of piecewise H-functions only, then

the approximation order of $\{S_h\}_h$ does not exceed any integer k for which $\Pi_k \not\subseteq H_\downarrow$. This result was already obtained by de Boor and Höllig [3] for the case where H itself is a space of polynomials.

Lower bounds for the approximation order of $\{S_h\}_h$ are usually established by a concrete approximation scheme using quasi-interpolant methods. In the scaling case, the Strang–Fix conditions and their various equivalent forms are the core of such a quasi-interpolant scheme. As pointed out by Dyn and Ron in [12], the original form of the Strang–Fix conditions is not applicable to the nonscaling case. However, a modified version of the Strang–Fix conditions is still available if we are content with spaces of exponentials, as demonstrated by Jia in [15]. In §2, based on de Boor's survey paper [2], and on our recent work [16], we shall give a construction of L_p-approximation ($1 \le p \le \infty$) from $\{S_h\}_h$ when each S_h is spanned by $h\mathbb{Z}^n$-translates of a compactly supported function on $\mathbb{R}^n$.

In [6], [12], and [18], only L_∞-approximation was considered. In this paper we deal not only with L_∞-approximation, but also L_p-approximation ($1 \le p < \infty$). We contend that L_p-approximation is important. Indeed, Strang and Fix concentrated on L_2-approximation, since their main concern was the finite element method. In the work of DeVore and Popov [11] on approximation by multivariate splines with free knots, L_p-approximation ($0 < p < \infty$) played an essential role. Furthermore, L_p-approximation ($1 \le p < \infty$) has a nature different from that of L_∞-approximation. We can say that L_∞-approximation is essentially local, while L_p-approximation ($1 \le p < \infty$) is global. This point will be made clear in the following sections.

2. Lower bounds for the approximation order. In this section, using a quasi-interpolation scheme, we provide lower bounds for the L_p-approximation order ($1 \le p < \infty$) of a family $\{S_h\}_h$ of approximating spaces, each of which is spanned by the $h\mathbb{Z}^n$-translates of a single compactly supported function.

Let ϕ be a complex-valued Lebesgue-measurable function on $\mathbb{R}^n$. We say that ϕ is a normal function (see [15]), if for any $x \in \mathbb{R}^n$

$$\phi(x) = \lim_{\varepsilon \to 0} \frac{1}{m(B_\varepsilon(x))} \int_{B_\varepsilon(x)} \phi(y)\, dy,$$

where m denotes the Lebesgue measure.

Let ϕ be a compactly supported normal function. For a sequence b on $\mathbb{Z}^n$, the semidiscrete convolution product $\phi *' b$ is the function given by

$$\phi *' b := \sum_{\nu \in \mathbb{Z}^n} \phi(\cdot - \nu) b(\nu).$$

More generally, for a sequence b on $h\mathbb{Z}^n$, the h-scaled semidiscrete convolution product $\phi *'_h b$ is given by

$$\phi *'_h b := \sum_{\nu \in \mathbb{Z}^n} \phi(\cdot - h\nu) b(h\nu).$$

In this section, we assume that $\{\phi_h\}_h$ is a collection of normal functions on $\mathbb{R}^n$ satisfying the following three conditions:

(i) $\operatorname{supp} \phi_h \subseteq hB_r$,

(ii) $\|\phi_h\|_\infty \le c$, and

(iii) $h^{-n}|\hat{\phi}_h(0)| \ge b$,

where r, b and c are positive constants independent of h. In the third condition above, $\hat{\phi}$ denotes the Fourier transform of ϕ:

$$\hat{\phi}(\xi) := \int_{\mathbb{R}^n} \phi(x) e^{-i\xi\cdot x}\, dx.$$

These conditions were first formulated in [6].

Let H be a finite-dimensional D-invariant space of exponentials. From [1] we know that H has the form $\sum_{\theta\in T} e_\theta P_\theta$, where T is a finite subset of $\mathbf{C}^n$ and each P_θ is a D-invariant polynomial space.

THEOREM 2.1. *Let $H = \sum_{\theta\in T} e_\theta P_\theta$ be a finite-dimensional D-invariant exponential space such that $H_\downarrow \supseteq \Pi_{<k}$ for some positive integer k. Assume that $\{\phi_h\}_{h>0}$ is a collection of normal functions on $\mathbb{R}^n$ satisfying the above conditions* (i), (ii), *and* (iii). *If, in addition, each ϕ_h satisfies the Strang–Fix conditions for H, i.e., for each $\theta \in T$,*

$$q(-iD)\hat{\phi}_h(2\pi\nu/h - i\theta) = 0 \quad \text{for all } q \in P_\theta \text{ and } \nu \in \mathbb{Z}^n\backslash\{0\}, \tag{2.1}$$

then with $S_h := \operatorname{range}(\phi_h *'_h)$, $\{S_h\}_{h>0}$ provides L_p-approximation of order at least k $(1 \le p \le \infty)$.

Proof. This theorem is a consequence of Lemma 2.2 and Theorem 2.4, which will be proved later. □

Remark. The Strang–Fix conditions as given in (2.1) are equivalent to the statement that $\phi_h *'_h$ maps $e_\theta P_\theta$ to itself for each $\theta \in T$ (see [15]). Obviously, the latter implies that $\phi_h *'_h$ maps H to itself, while the converse is true if $h(T-T)\cap 2\pi i\mathbb{Z}^n = \{0\}$ (see [6]). Since T is fixed (independent of h), this condition is satisfied for sufficiently small h. Also see [8] for some related results.

LEMMA 2.2. *Let $\{\phi_h\}_{h>0}$ be a collection of compactly supported normal functions on $\mathbb{R}^n$ satisfying the Strang–Fix conditions for $H = \sum_{\theta\in T} e_\theta P_\theta$ as given in* (2.1). *Then for each $\theta \in T$,*

$$\phi_h *'_h (e_\theta p) = h^{-n} e_\theta \big(p(\cdot - iD)\hat{\phi}_h\big)(-i\theta) \quad \text{for all } p \in P_\theta. \tag{2.2}$$

If, in addition, $\{\phi_h\}_{h>0}$ satisfies the condition (i), (ii), *and* (iii), *then for each $h > 0$ there exists a linear combination ψ_h of ϕ_h and its $h\mathbb{Z}^n$-translates such that $\psi_h *'_h$ is an identity on H, and the family $\{\psi_h\}_{h>0}$ satisfies the same conditions* (i) *and* (ii) *with possibly different constants r and c.*

Proof. The proof of Theorem 3.2 in [15] can be carried over verbatim to prove the first statement of this lemma. The second statement was proved by de Boor and Ron in [6]. Here we sketch a proof, taking the Neumann series approach as introduced by Chui and Diamond in [7], and developed by Dyn and Ron in [12]. In the following we denote by 1 the identity mapping.

Conditions (i) and (ii) imply that for $\xi \in \mathbf{C}^n$,

$$\begin{aligned} h^{-n}|\hat{\phi}_h(\xi) - \hat{\phi}_h(0)| &= h^{-n}\left|\int_{B_{rh}} \phi_h(x)(e^{-i\xi\cdot x} - 1)\,dx\right| \\ &\le h^{-n}c\int_{B_{rh}} |e^{-i\xi\cdot x} - 1|\,dx \le h^{-n}c(2rh)^n \max_{\|x\|\le rh} |e^{-i\xi\cdot x} - 1|; \end{aligned}$$

hence $h^{-n}|\hat{\phi}_h(\xi) - \hat{\phi}_h(0)| \to 0$ as $h \to 0$. Thus, if we set $b_{\theta,h} := h^{-n}\hat{\phi}_h(-i\theta)$ for $\theta \in T$ and $h > 0$, then by condition (iii), $|b_{\theta,h}| \ge b/2$ for all $\theta \in T$ and sufficiently small $h > 0$. It follows from (2.2) that for any $\theta \in T$, $p \in P_\theta$, and sufficiently small $h > 0$,

$$(1 - \phi_h *_h' / b_{\theta,h})(e_\theta p) = e_\theta q$$

for some polynomial $q \in P_\theta$ of degree less than $\deg p$. Let $d_\theta := \max\{\deg p : p \in P_\theta\}$ for each $\theta \in T$. We see that the operator $(1 - \phi_h *_h' / b_{\theta,h})^{d_\theta+1}$ annihilates $e_\theta P_\theta$. For each $h > 0$ let V_h be the polynomial in one variable given by

$$V_h(t) := \left\{1 - \prod_{\theta\in T}(1 - t/b_{\theta,h})^{d_\theta+1}\right\}/t, \qquad t \in \mathbb{R},$$

and set

$$\psi_h := V_h(\phi_h *_h')\phi_h.$$

Then $\psi_h *_h'$ is an identity on H, since $1 - \psi_h *_h' = \prod_{\theta\in T}(1 - \phi_h *_h' / b_{\theta,h})^{d_\theta+1}$ annihilates H. Furthermore, we see from the construction of ψ_h that the family $\{\psi_h\}_{h>0}$ satisfies conditions (i) and (ii) with possibly different constants r and c. □

Now let $\{\phi_h\}_{h>0}$ be a collection of normal functions satisfying the conditions (i) and (ii). Suppose that H is a finite-dimensional D-invariant space of exponentials such that $H_\downarrow \supseteq \Pi_{<k}$ and $\phi_h *_h'$ is the identity on H for every $h > 0$. Let $S_h := \text{range}(\phi_h *_h')$. Given $f \in W_p^k(\mathbb{R}^n)$ $(1 \le p \le \infty)$, we want to construct an L_p-approximation scheme from $\{S_h\}_{h>0}$. In the case $p = \infty$, this was done by de Boor and Ron in [6]. For $f \in W_\infty^k$ and $h > 0$, let

$$s_h(x) := \sum_{\nu\in\mathbb{Z}^n} \phi_h(x - \nu h) f(\nu h), \qquad x \in \mathbb{R}^n. \tag{2.3}$$

Then there exists a positive constant C_1 independent of f and h such that

$$|f(x) - s_h(x)| \le C_1 \text{dist}_\infty(f, H)(B_{rh}(x)) \quad \text{for all } x \in \mathbb{R}^n,$$

where r is the constant appearing in the condition (i). Since $H_\downarrow \supseteq \Pi_{<k}$, for given $f \in W_\infty^k$ there exists a constant C_2 independent of h and f such that

$$\text{dist}_\infty(f, H)(B_{rh}(x)) \le C_2 h^k \|f\|_{k,\infty}(B_{rh}(x))$$

(see [12, Thm. 3.1]). Thus with $C = C_1C_2$ we have

$$|f(x) - s_h(x)| \le Ch^k \|f\|_{k,\infty}(B_{rh}(x)) \quad \text{for } x \in \mathbb{R}^n. \tag{2.4}$$

To deal with L_p-approximation ($1 \le p < \infty$) we shall apply a smoothing technique as employed in [16]. Choose a function $\chi \in C_c^\infty(\mathbb{R}^n)$ such that $\operatorname{supp} \chi \subseteq B_1(0)$, $\chi \ge 0$ and $\int \chi = 1$. Set

$$\chi_h := \chi(\cdot/h)/h^n, \qquad h > 0.$$

For a given function $f \in W_p^k$ and $h > 0$, consider the following function:

$$f_h(x) := \int_{\mathbb{R}^n} (f - \nabla_u^k f)(x)\chi_h(u)\, du, \qquad x \in \mathbb{R}^n, \tag{2.5}$$

where ∇_u denotes the difference operator given by

$$\nabla_u f := f - f(\cdot - u).$$

In the univariate case, such a smoothing technique was first introduced by DeVore [10].

The following lemma was proved in [16].

LEMMA 2.3. *The functions f_h are C^∞-smooth. Moreover, there exists a constant C depending only on k such that for any measurable set $\Omega \subseteq \mathbb{R}^n$*

(a) $\|f_h\|_p(\Omega) \le C\|f\|_p(B_{kh}(\Omega))$;

(b) $\|f_h\|_\infty(\Omega) \le Ch^{-n/p}\|f\|_p(B_{kh}(\Omega))$;

(c) $\|f - f_h\|_p(\Omega) \le Ch^k|f|_{k,p}(B_{kh}(\Omega))$.

We are now in a position to construct an L_p-approximation scheme for $1 \le p < \infty$.

THEOREM 2.4. *Let $\{\phi_h\}_{h>0}$ be a collection of normal functions satisfying the conditions* (i) *and* (ii). *Suppose that H is a finite-dimensional D-invariant space of exponentials such that $H_\downarrow \supseteq \Pi_{<k}$ and $\phi_h *_h' $ is the identity on H for every $h > 0$. For a given function $f \in W_p^k$ $(1 \le p \le \infty)$ and any $h > 0$, set*

$$s_h(x) := \sum_{\nu \in \mathbb{Z}^n} \phi_h(x - h\nu) f_h(h\nu), \qquad x \in \mathbb{R}^n,$$

where f_h are given by (2.5). *Then for sufficiently small $h > 0$,*

$$\|f - s_h\|_p \le C\|f\|_{k,p} h^k,$$

where C is a constant independent of f, h, and p.

Proof. By Lemma 2.3(c),

$$\|f - f_h\|_p \le Ch^k|f|_{k,p}.$$

Hence it remains to show that

$$\|f_h - s_h\|_p \le Ch^k \|f\|_{k,p}.$$

When $p = \infty$, this follows from (2.4), if we replace f by f_h in (2.3). In what follows we assume that $1 \le p < \infty$. Our argument is motivated by the work of Dahmen and Micchelli [9]. For $\alpha \in \mathbb{Z}^n$ and $h > 0$, let

$$G_{\alpha,h} := (\alpha + [0,1]^n)h.$$

By (2.4), there exists a constant C_1 such that

$$|f_h(x) - s_h(x)| \le C_1 \|f_h\|_{k,\infty}(B_{rh}(x)) \qquad \text{for all } x \in \mathbb{R}^n.$$

Since the volume of each $G_{\alpha,h}$ is h^n, it follows that

$$\begin{aligned} \int_{G_{\alpha,h}} |f_h(x) - s_h(x)|^p \, dx &\le h^n \sup_{x \in G_{\alpha,h}} |f_h(x) - s_h(x)|^p \\ &\le C_1^p h^n \|f_h\|_{k,\infty}^p (G_{\alpha,h} + B_{rh}). \end{aligned} \tag{2.6}$$

By Lemma 2.3(b), there exists a constant C_2 such that

$$\|f_h\|_{k,\infty}(G_{\alpha,h} + B_{rh}) \le C_2 h^{-n/p} \|f\|_{k,p}(G_{\alpha,h} + B_{(r+k)h}). \tag{2.7}$$

Now, (2.6) and (2.7) together imply

$$\begin{aligned} \|f_h - s_h\|_p^p &= \sum_{\alpha \in \mathbb{Z}^n} \int_{G_{\alpha,h}} |f_h(x) - s_h(x)|^p \, dx \\ &\le (C_1 C_2)^p \sum_{\alpha \in \mathbb{Z}^n} \|f\|_{k,p}^p (G_{\alpha,h} + B_{(r+k)h}). \end{aligned} \tag{2.8}$$

Let $\beta \in \mathbb{N}^n$, $|\beta| \le k$. Then

$$\sum_{\alpha \in \mathbb{Z}^n} \|D^\beta f\|_p^p (G_{\alpha,h} + B_{(r+k)h}) = \int_{\mathbb{R}^n} |D^\beta f(x)|^p \sum_{\alpha \in \mathbb{Z}^n} \rho_\alpha(x) \, dx, \tag{2.9}$$

where ρ_α is the characteristic function of the set $G_{\alpha,h} + B_{(r+k)h}$. For any fixed $x \in \mathbb{R}^n$, the number of $\alpha \in \mathbb{Z}^n$ such that $\rho_\alpha(x) \ne 0$ does not exceed $(2r + 2k + 2)^n$; hence

$$\int_{\mathbb{R}^n} |D^\beta f(x)|^p \sum_{\alpha \in \mathbb{Z}^n} \rho_\alpha(x) \, dx \le (2r + 2k + 2)^n \|D^\beta f\|_p^p. \tag{2.10}$$

Since

$$\|f\|_{k,p}^p = \sum_{|\beta| \le k} \|D^\beta f\|_p^p,$$

it follows from (2.8)–(2.10) that there is a constant C independent of f, h, and p such that

$$\|f_h - s_h\|_p^p \le C^p \|f\|_{k,p}^p,$$

as desired. □

3. Upper bounds for the approximation order. In this section we provide upper bounds for the L_p-approximation order ($1 \le p \le \infty$) of a family $\{S_h\}_{h>0}$ of approximating spaces, each of which is $h\mathbb{Z}^n$-translation invariant and consists of piecewise exponentials.

THEOREM 3.1. *Let H be a finite-dimensional D-invariant space of exponentials, and let Ω be a nonempty open subset of the open unit cube $(0,1)^n \subset \mathbb{R}^n$. Assume that $\{S_h\}_{h>0}$ is a family of linear spaces of functions such that*

$$S_h|_{h\Omega+h\nu} \subseteq H|_{h\Omega+h\nu} \quad \text{for all } \nu \in \mathbb{Z}^n. \tag{3.1}$$

Then for $1 \le p \le \infty$ the L_p-approximation order of $\{S_h\}_{h>0}$ on any domain $G \subseteq \mathbb{R}^n$ does not exceed k, where k is the largest integer such that $\Pi_{<k} \subseteq H_\downarrow$.

Proof. Let $\{q_1, \cdots, q_N\}$ be a basis of homogeneous polynomials for $H_\downarrow$. There exists a basis $\{f_1, \cdots, f_N\}$ for H such that $q_j = f_{j\downarrow}$, $j = 1, \cdots, N$ (see [5]). Moreover, since $\Pi_{<k} \subseteq H_\downarrow$, we can choose f_j $(j = 1, \cdots, N)$ so that

$$f_j(x) - q_j(x) = O(x^k) \quad \text{as } x \to 0.$$

Let

$$d_j := \max\{k-1, \deg q_j\}.$$

Since $f_1, \cdots, f_N$ are exponentials, there exists a positive constant M such that for all $\|x\| \le 1$,

$$|f_j(x) - q_j(x)| \le M\|x\|^{d_j+1}, \qquad j = 1, \cdots, N. \tag{3.2}$$

Since $\Pi_k \not\subseteq H_\downarrow$, there exists $\beta \in \mathbb{N}^n$, $|\beta| = k$, such that $q := (\ )^\beta \notin H_\downarrow$. Let G be a bounded domain in $\mathbb{R}^n$. Our goal is to estimate $\operatorname{dist}_p(q, S_h)(G)$ from below, i.e., to prove that for some positive constant C independent of h,

$$\operatorname{dist}_p(q, S_h)(G) \ge Ch^k. \tag{3.3}$$

Without loss of generality, we may assume that G has Lebesgue measure less than 1. Then by Hölder's inequality,

$$\operatorname{dist}_p(q, S_h)(G) \ge \operatorname{dist}_1(q, S_h)(G) \quad \text{for all } p \ge 1.$$

Hence it suffices to prove (3.3) for $p = 1$.

Note that $q, q_1, \cdots, q_N$ are linearly independent, hence the function given by

$$(a_0, a_1, \cdots, a_N) \mapsto \left\| a_0 q + \sum_{j=1}^{N} a_j q_j \right\|_1 (\Omega) \quad \text{for } (a_0, a_1, \cdots, a_N) \in \mathbf{C}^{N+1}$$

induces a norm on $\mathbf{C}^{N+1}$. Since any two norms on $\mathbf{C}^{N+1}$ are equivalent, there exists a positive constant C_1 such that

$$\left\| a_0 q + \sum_{j=1}^{N} a_j q_j \right\|_1 (\Omega) \geq C_1 \sum_{j=0}^{N} |a_j| \quad \text{for all } a_0, a_1, \cdots, a_N \in \mathbf{C}. \tag{3.4}$$

For any $w \in \mathbb{R}^n$, $q(\cdot + w) - q \in \Pi_{<k} \subseteq H_\downarrow$; hence it is a linear combination of $q_1, \cdots, q_N$:

$$q(\cdot + w) - q = \sum_{j=1}^{N} b_j(w) q_j,$$

where b_j are continuous functions on $\mathbb{R}^n$ with $b_j(0) = 0$ $(j = 1, \cdots, N)$.

In what follows we assume that $0 < h < 1$. For any $a_1, \cdots, a_N \in \mathbf{C}$, we have

$$\begin{aligned} \left\| q(\cdot + h\nu) - \sum_{j=1}^{N} a_j f_j \right\|_1 (h\Omega) &= \left\| q + \sum_{j=1}^{N} b_j(h\nu) q_j - \sum_{j=1}^{N} a_j f_j \right\|_1 (h\Omega) \\ &\geq \left\| q + \sum_{j=1}^{N} (b_j(h\nu) - a_j) q_j \right\|_1 (h\Omega) \\ &\quad - \left\| \sum_{j=1}^{N} a_j (f_j - q_j) \right\|_1 (h\Omega). \end{aligned} \tag{3.5}$$

To estimate the first term of the far right side of (3.5) we note that

$$\|g\|_1(h\Omega) = h^n \|g(h\cdot)\|_1(\Omega).$$

This together with (3.4) implies that

$$\begin{aligned} J_1 := \left\| q + \sum_{j=1}^{N} (b_j(h\nu) - a_j) q_j \right\|_1 (h\Omega) \\ = h^n \left\| h^k q + \sum_{j=1}^{N} (b_j(h\nu) - a_j) h^{\deg q_j} q_j \right\|_1 (\Omega) \\ \geq C_1 h^n \left(h^k + \sum_{j=1}^{N} |b_j(h\nu) - a_j| h^{d_j} \right). \end{aligned} \tag{3.6}$$

To estimate the second term of the far right side of (3.5) we note that for any $g \in L_1(h\Omega)$

$$\|g\|_1(h\Omega) \le h^n \sup_{x\in h\Omega} |g(x)|, \tag{3.7}$$

since $h\Omega \subset h(0,1)^n$. It follows from (3.2) and (3.7) that

$$J_2 := \left\| \sum_{j=1}^N a_j(f_j - q_j) \right\|_1 (h\Omega) \le \sum_{j=1}^N |a_j| \|f_j - q_j\|_1(h\Omega) \le Mh^n \sum_{j=1}^N |a_j| h^{d_j+1}. \tag{3.8}$$

For sufficiently small h, say $h \le C_1/M$, we have

$$C_1|b_j(h\nu) - a_j| \ge Mh\left(|a_j| - |b_j(h\nu)|\right).$$

This together with (3.6) and (3.8) yields

$$J_1 - J_2 \ge h^n \left(C_1 h^k - M \sum_{j=1}^N |b_j(h\nu)| h^{d_j+1} \right).$$

Since $d_j + 1 \ge k$, while $b_j(h\nu)$ can be made small if $h\nu$ is small, we conclude that there exists $\delta > 0$ such that

$$\left\| q(\cdot + h\nu) - \sum_{j=1}^N a_j f_j \right\|_1 (h\Omega) \ge J_1 - J_2 \ge (C_1/2)h^{k+n} \quad \text{for } \|\nu\| \le \delta/h.$$

The above estimate holds for any $a_1, \cdots, a_N \in \mathbf{C}$; hence

$$\operatorname{dist}_1\left(q(\cdot + h\nu), H\right)(h\Omega) \ge (C_1/2)h^{k+n} \quad \text{for } \|\nu\| \le \delta/h.$$

Since H is translation invariant, it follows that

$$\begin{aligned} \operatorname{dist}_1(q, H)(h\Omega + h\nu) &= \operatorname{dist}_1(q(\cdot + h\nu), H)(h\Omega) \\ &\ge (C_1/2)h^{k+n} \quad \text{for } \|\nu\| \le \delta/h. \end{aligned} \tag{3.9}$$

We are now ready to estimate $\operatorname{dist}_1(q, S_h)(B_\delta) =: \varepsilon(h)$. Observe that

$$B_\delta \supseteq \bigcup_{\|\nu\| \le \delta/h - 1} (h\Omega + h\nu).$$

It follows that

$$\varepsilon(h) \ge \sum_{\|\nu\| \le \delta/h - 1} \operatorname{dist}_1(q, S_h)(h\Omega + h\nu). \tag{3.10}$$

But by (3.1), $S_h|_{h\Omega+h\nu} \subseteq H|_{h\Omega+h\nu}$; hence by (3.9) we have

$$\begin{aligned} \operatorname{dist}_1(q, S_h)(h\Omega + h\nu) &\geq \operatorname{dist}_1(q, H)(h\Omega + h\nu) \\ &\geq (C_1/2)h^{k+n} \quad \text{for } \|\nu\| \leq \delta/h. \end{aligned} \tag{3.11}$$

For sufficiently small $h > 0$, the set $\{\nu \in \mathbb{Z}^n : \|\nu\| \leq \delta/h - 1\}$ has cardinality $\geq (\delta/h)^n$; therefore (3.10) and (3.11) yield

$$\varepsilon(h) \geq (\delta/h)^n (C_1/2)h^{n+k} = (C_1/2)\delta^n h^k.$$

This shows that for sufficiently small $h > 0$,

$$\operatorname{dist}_1(q, S_h)(B_\delta) \geq Ch^k,$$

where $C = (C_1/2)\delta^n$. This proves (3.3) for $p = 1$, as desired. □

Finally, we apply the previous results to the problem of approximation by exponential box splines. Following Dyn and Ron [12], we introduce the h-scaled EB-splines as follows. Let Γ be a finite set of pairs (not necessarily distinct) of the form

$$\gamma = (x_\gamma, \lambda_\gamma), \qquad x_\gamma \in \mathbb{R}^n \backslash \{0\}, \quad \lambda_\gamma \in \mathbb{C}.$$

Hereafter we always assume that $X := \{x_\gamma : \gamma \in \Gamma\} \subseteq \mathbb{Z}^n$ and that X spans $\mathbb{R}^n$. The h-scaled EB-spline $B_h(\Gamma \mid \cdot)$ is defined by the equation

$$\int_{\mathbb{R}^n} B_h(\Gamma \mid x)\psi(x)\,dx = h^{n-\#\Gamma} \int_{[0,h]^\Gamma} \left(\prod_{\gamma\in\Gamma} e^{\lambda_\gamma t_\gamma} \right) \psi\left(\sum_{\gamma\in\Gamma} t_\gamma x_\gamma \right) dt,$$

where ψ is taken from a suitable space of test functions. It is known from [12] that the collection $\{B_h(\Gamma \mid \cdot)\}_{h>0}$ satisfies conditions (i), (ii), and (iii).

Let $\mathcal{D}'(\mathbb{R}^n)$ denote the space of all n-dimensional complex-valued distributions. For $K \subseteq \Gamma$, let $p_K(D)$ be the differential operator induced by the polynomial

$$p_K(x) := \prod_{\gamma\in K} (x \cdot x_\gamma - \lambda_\gamma).$$

Let

$$K(\Gamma) := \{K \subseteq \Gamma : \ \operatorname{span}\{x_\gamma\}_{\gamma\in\Gamma\backslash K} \neq \mathbb{R}^n\},$$

and

$$k(X) := \min\{\#K : \ K \in K(\Gamma)\}.$$

Define

$$H := \{f \in \mathcal{D}'(\mathbb{R}^n) : \ p_K(D)f = 0 \text{ for all } K \in K(\Gamma)\}.$$

Then H is a finite-dimensional D-invariant space of exponentials (see, e.g., [1]). Let S_h be the range of $B_h(\Gamma \mid \cdot)*'_h$. Then S_h is $h\mathbb{Z}^n$-translation invariant, $S_h \supset H$, and $S_h|_{(0,h)^n}$ consists of piecewise H-functions. It is also known from [12] that with $k = k(X)$, $H_\downarrow \supseteq \Pi_{<k}$ but $H_\downarrow \not\supseteq \Pi_k$. Dyn and Ron [12] proved that k is a lower bound for the L_∞-approximation order of $\{S_h\}_{h>0}$. Now that $\{S_h\}_{h>0}$ and H satisfy the conditions of Theorems 2.1 and 3.1, we have the following concluding result.

THEOREM 3.2. *Let S_h be the range of $B_h(\Gamma \mid \cdot)*'_h$. Then the exact L_p-approximation order of $\{S_h\}_{h>0}$ is $k(X)$ $(1 \le p \le \infty)$.*

Acknowledgment. The authors thank Professor Carl de Boor for his valuable suggestions and comments on this paper.

ON THE DETERMINATION OF ZIGLIN MONODROMY GROUPS*

RICHARD C. CHURCHILL† AND DAVID L. ROD‡

Abstract. The monodromy group of a second-order linear differential equation with rational coefficients is called Ziglin if it preserves a nonconstant rational function. The determination of which monodromy groups are Ziglin is essential in integrability questions for complex analytic Hamiltonian systems. In this paper the problem is solved completely for the Fuchsian case by using the Kovacic algorithm to determine the differential Galois group of that second-order equation and then relating this to the monodromy group. Applications are given to Hamiltonian systems.

Key words. Ziglin group, Hamiltonian system, nonintegrable, monodromy group, differential Galois group, linear differential equation GL(2, $\mathbb{C}$), SL(2, $\mathbb{C}$), Kovacic algorithm, Fuchsian equation

AMS(MOS) subject classifications. 58F05, 34A20, 34A30, 20G20, 13N05, 13B10

Introduction. Consider a linear differential equation $y''+p(x)y'+q(x)y=0$, $'=(d/dx)$, with rational coefficients on the Riemann sphere $\mathbb{P}^1$ or, more generally, a holomorphic (flat) connection on a rank 2 complex vector bundle over a Riemann surface (see [1]). The monodromy group can be viewed as an automorphism group of some distinguished fiber, and is called Ziglin if it preserves a nonconstant rational function on this vector space (see [20]). The determination of which monodromy groups are Ziglin is crucial in integrability questions for complex analytic Hamiltonian systems. Here we solve the problem completely for the Fuchsian case on $\mathbb{P}^1$, and in more general bundle contexts where symmetries allow reduction to this first case. The key elements are a classification of Ziglin subgroups of GL(2, $\mathbb{C}$) and an algorithm of Kovacic [10] that determines the nature of the differential Galois group of a second-order equation (as above) on $\mathbb{P}^1$.

The necessary background in differential Galois theory appears in § 2, and its application to determining the Ziglin subgroups of GL(2, $\mathbb{C}$) in § 3. The Kovacic algorithm is outlined for the Fuchsian case in § 4, with applications to Hamiltonian systems in § 5. We note that, although the Kovacic algorithm works for any second-order linear differential equation, we consider the Fuchsian case because it is only in that case the Zariski closure of the monodromy group is equal to the differential Galois group. (In the irregular case it is necessary to add the Stokes multipliers.) For background in these group theoretical properties of differential equations we refer to [7], [9], and [11], and especially the surveys [16] and [17]. After this paper was completed the authors became aware of the recent thesis of Morales [21], which also considers Ziglin analysis in terms of differential Galois theory, but with a different emphasis and without Kovacic's algorithm. We refer the reader to this work and [22] for their many nice examples and as complementary reading.

1. Motivation. Let X be a Riemann surface and ∇ a connection on a rank 2 complex vector bundle $\pi_E: E \to X$. To each loop γ in X based at $x_0 \in X$ assign the

* Received by the editors April 16, 1990; accepted for publication (in revised form) November 6, 1990. This work was supported in part by the Institute for Mathematics and Its Applications with funds provided by the National Science Foundation.

automorphism of the fiber $E_0 = \pi_E^{-1}(\{x_0\})$ which results on sending $v \in E_0$ to the endpoint of the horizontal lift of γ^{-1} issuing from v. Since ∇ is flat, this lift depends only on the homotopy class of γ in $\pi_1(X, x_0)$, and defines the *monodromy representation* $\rho : \pi_1(X, x_0) \to \mathrm{Aut}(E_0)$. The image $G_0 = \rho(\pi_1(X, x_0))$ is the *monodromy group* of ∇ at x_0. Different choices of basepoint give isomorphic monodromy groups, and given a basis of E_0 we can identify G_0 with a subgroup of $\mathrm{GL}(2, \mathbb{C})$. In the classical case $X = \mathbb{C}\backslash\{\text{finite set}\}$ and ∇ can be viewed as a linear ordinary differential equation on the complex plane with possible singularities on this finite set as well as at ∞ (see [4, p. 93]). Then E_0 is identified with the initial values (and hence germs at x_0) of solutions, and ρ, and hence G_0, are defined by analytic continuation of these solutions along γ^{-1}.

Throughout this paper any function said to be an "integral" will be assumed nonconstant. Thus G_0 has an *integral* f, or is a *Ziglin group*, if there is a nonconstant rational function f on E_0 that is preserved by the action; that is, $g^* f = f$ for all $g \in G_0$. An equivalent condition is the existence of an *integral* F for ∇, that is, a meromorphic function F on E that is rational on fibers and constant along horizontal lifts of curves in X. Indeed, $f = F \mid E_0$ will be preserved by G_0, hence G_0 will be Ziglin, and any such f can be uniquely extended to a corresponding integral F of ∇ through "parallel transport."

Example 1.1 (Ziglin theory for two degree-of-freedom Hamiltonian systems). Let M be a complex symplectic 4-manifold and Γ a nonequilibrium phase curve, within an energy surface Σ, of a holomorphic Hamiltonian vector field X_H on M. Linearization along Γ induces a holomorphic (hence flat) connection ∇ on the normal bundle $N = (T\Sigma \mid \Gamma)/T\Gamma$ of Γ in Σ, called the *normal variational equation* (NVE). By a result of Ziglin [20] any meromorphic integral of X_H independent on a neighborhood (in M) of Γ (but not necessarily on Γ itself) will induce an integral for ∇; hence G_0 will be a Ziglin group. Therefore, if G_0 is not a Ziglin group, X_H cannot be integrable by such meromorphic functions on a neighborhood of the phase curve (although X_H could still be integrable, say, by differentiable functions).

When reasonable symmetries are present a connection can be reduced. Specifically, suppose a finite group G acts π_E-equivariantly on $E \to X$, freely and properly discontinuously on X, and linearly on fibers. Then X/G is again a Riemann surface and the connection $\tilde{\nabla} = (1/|G|) \sum_{g \in G} g^* \nabla$ is preserved by G, thus inducing a connection ∇_G on $E/G \to X/G$. We say ∇ is *symmetric* (with respect to G) if $\nabla = \tilde{\nabla}$.

THEOREM 1.2. *Let ∇ be symmetric with respect to the finite group G which acts on $E \to X$ as above. Then ∇ admits an integral if and only if this is the case for ∇_G. In particular, the monodromy group of ∇ is Ziglin if and only if the monodromy group of ∇_G is Ziglin.*

Proof. (a) Assume that ∇ admits an integral. It suffices to show that the existence of an integral F for ∇ implies the existence of a G-invariant integral. We do this by adapting an argument from [20, p. 186], which deals with a related situation.

Let $G = \{g_j\}_{j=1}^m$ with $g_1 = \mathrm{id}$, and set $f_j = g_j^* F$. Assume $\{f_1, \cdots, f_k\}$ are the distinct f_j, and let m_j be the number of occurrences of f_j in $\{f_1, \cdots, f_m\}$. Now consider the G-invariant integrals $\psi_i = \sum_{j=1}^m (f_j)^i$ of ∇. Since

$$\det \frac{\partial(\psi_1, \cdots, \psi_k)}{\partial(f_1, \cdots, f_k)} = (k!)\left(\prod_{j=1}^k m_j\right) \prod_{1 \le i < j \le k} (f_j - f_i) \neq 0$$

(the last term is a standard Vandermonde determinant), we can solve locally for the f_i as analytic functions of the $\{\psi_j\}$. In particular, we can write $F = f_1$ locally as an analytic function of the $\{\psi_j\}$, and when restricted to a fiber we then have $0 \neq dF = \sum a_j \, d\psi_j$

for appropriate a_j. We conclude that some ψ_j must be nonconstant and hence a symmetric integral for ∇.

(b) The converse of (a) follows from the fact that the monodromy group of ∇ can be identified with a subgroup of the monodromy group of ∇_G (see [4, Prop. 1.1, p. 94]) and the comments preceding Example 1.1 on the relation between integrals of the monodromy group and integrals of the connection. □

COROLLARY 1.3. *Assume the connection ∇ on $N \to \Gamma$ of Example* 1.1 *is symmetric with respect to a finite group G acting as in Theorem* 1.2. *If the monodromy group of the reduced connection ∇_G is not Ziglin, then X_H has no meromorphic integral independent of H.*

We will see an example of Corollary 1.3 in § 5. We refer to [3] and [4] for examples of symmetric connections. In particular, [3, § 4] presents a general theory concerning the case when a given connection is symmetric. In examples the group G is often given as an action on the base space X; [4, Prop. 2.3] shows when this can be lifted to a π_E-equivariant action on $E \to X$ under which ∇ is symmetric (see also [3, § 4]).

In the next few sections we will assume that reduction has transformed ∇ to a connection ∇_G that can be viewed as a linear ordinary differential equation on $\mathbb{P}^1$. When ∇_G is Fuchsian we show that the monodromy group of ∇_G is Ziglin if and only if the differential Galois group of ∇_G is Ziglin. We then adapt an algorithm of Kovacic [10] (see also [5]) in § 4 to determine whether the differential Galois group has this property.

2. Preliminaries on differential Galois theory. In this section we collect some standard results on differential Galois theory and algebraic subgroups of $\mathrm{SL}(2,\mathbb{C})$ needed in later sections. Let $\mathbb{C}(x)$ denote the field of rational functions in x with coefficients in $\mathbb{C}$ and consider the (normalized) linear ordinary differential equation

$$y'' = r(x)y, \qquad ' = (d/dx) \tag{2.1}$$

on the Riemann sphere $\mathbb{P}^1$, where $r(x) \in \mathbb{C}(x)$. Let Λ denote the set of poles of $r(x)$, set $X = \mathbb{P}^1 \setminus (\Lambda \cup \{\infty\})$, and fix $x_0 \in X$.

$\mathcal{M}$ will denote the field of germs of meromorphic functions at x_0, which we view as an extension of $\mathbb{C}(x)$ by identifying the latter with the germs of such functions at x_0. $V \subset \mathcal{M}$ will denote the linear space of germs of solutions of (2.1) at x_0, $V' \subset \mathcal{M}$ the associated derivatives, and $E \subset \mathcal{M}$ the extension of $\mathbb{C}(x)$ generated by $V \cup V'$. E is the *Picard-Vessiot extension* of $\mathbb{C}(x)$ associated to (2.1), and the *differential Galois group* $G_D = G(E/\mathbb{C}(x))$ of that equation is the group of automorphisms of E that fix $\mathbb{C}(x)$ and commute with differentiation. Elements of G_D are determined by their action on V; hence G_D may be viewed as a subgroup of $\mathrm{Aut}(V)$.

A subgroup of $\mathrm{Aut}(V) \cong \mathrm{GL}(2,\mathbb{C})$ is (1) *reducible* (or *triangulizable*) if it is conjugate to a (lower) triangular subgroup of $\mathrm{GL}(2,\mathbb{C})$ and (2) a DP-*group* if it is conjugate to a subgroup of $\{\left(\begin{smallmatrix}\alpha & 0\\ 0 & \beta\end{smallmatrix}\right)\} \cup \{\left(\begin{smallmatrix}0 & \gamma\\ \delta & 0\end{smallmatrix}\right)\} \subset \mathrm{GL}(2,\mathbb{C})$. (This terminology for "diagonal permutation" (DP) is from [2].) Note that a diagonalizable group is both reducible and a DP-group.

PROPOSITION 2.2. *Let G_N be the monodromy group of* (2.1) *and G_D its differential Galois group. Then*

(a) *G_D is an algebraic unimodular subgroup of* $\mathrm{Aut}(V)$. *In particular, it is Zariski closed in this space.*

(b) *Any element of E fixed by all elements of G_D must be in $\mathbb{C}(x)$.*

(c) *$G_N \subset G_D$.*

Moreover, if (2.1) *is Fuchsian we have*

(d) *$\bar{G}_N = G_D$, i.e., G_N is Zariski dense in G_D;*

(e) *G_N is reducible, diagonalizable, or a* DP*-group if and only if G_D is such*; *and*

(f) *G_N is finite if and only if G_D is such, in which case $G_N = G_D$.*

Proof. (a) and (b) are standard (e.g., see [9, pp. 36, 38, and 41]). (c) is adapted from [18]: analytic continuation along the inverse of any loop in X based at x_0 defines an element of G_N and one of G_D, and these are identical when viewed in Aut (V). (d) is Proposition III of [18]. (e) and (f) are immediate from (c) and (d). □

PROPOSITION 2.3. *An algebraic subgroup of* SL $(2, \mathbb{C})$ *is either*

Case I: *reducible*;

Case II: *a DP-group*;

Case III: *a finite group which, if not of Case* I *or* II, *must be projectively* (*i.e.*, mod ±id) *the tetrahedral, octahedral, or icosahedral group*; *or*

Case IV: SL $(2, \mathbb{C})$.

In particular, the differential Galois group G_D of (2.1) must have one of these forms.

Proof. See [9, pp. 31, 32] or [10, pp. 7, 27]. □

PROPOSITION 2.4. *If every element of an algebraic subgroup of* GL $(n, \mathbb{C})$ *has finite order, then that group must be finite.*

Proof. This is a lemma in [18, p. 1328]. □

3. Ziglin subgroups of GL (2, C). Application of Corollary 1.3 when the action of the group G is not symplectic may yield a reduced connection ∇_G that is Fuchsian on $\mathbb{P}^1$ but not of the form (2.1). The monodromy of ∇_G will then be a subgroup of GL $(2, \mathbb{C})$ rather than SL $(2, \mathbb{C})$. The purpose of this section is to develop relationships (see Theorem 3.5 and Corollary 3.6 below) that allow us to exploit the classification of algebraic subgroups of SL $(2, \mathbb{C})$ given in Proposition 2.3 (which should be compared with Corollary 3.4 below).

Recall from § 1 that a subgroup $Z \subset$ GL $(2, \mathbb{C})$ is *Ziglin*, or a *Ziglin group*, if there is a nonconstant rational function $f: \mathbb{C}^2 \to \mathbb{C}$ preserved by Z; i.e., such that $g^* f = f$ for all $g \in Z$.

PROPOSITION 3.1. (a) *Any conjugate of a Ziglin group Z is again Ziglin.*

(b) *Any subgroup of a Ziglin groupis again Ziglin.*

(c) *The Zariski closure $\bar{Z}$ of any Ziglin subgroup Z preserves any rational function f preserved by Z. In particular, $\bar{Z}$ must be Ziglin.*

(d) *A subgroup $Z \subset$ GL $(2, \mathbb{C})$ is Ziglin if and only if the Zariski closure $\bar{Z}$ is Ziglin.*

Proof. For (a), $g^* f = f$ implies $(h^{-1}gh)^* h^* f = h^* f$ for any $h \in$ GL $(2, \mathbb{C})$. (b) is obvious. For (c), write $f = (p/q)$ where p and q are polynomials and fix $w \in \mathbb{C}^2$. Then $P_w(g) = (g^* p)(w) \cdot q(w) - p(w) \cdot (g^* q)(w)$ is a polynomial vanishing on Z; hence $\bar{Z}$ is contained in the zero set of P_w. Since w was arbitrary the result follows. We obtain (d) by (b) and (c). □

Now let $Z \subset$ GL $(2, \mathbb{C})$ be Ziglin and let $f = (p/q)$ be a nonconstant rational function preserved by Z. Since $g^* f = f$ for $g \in Z$ if and only if $(g^* p) \cdot q = p \cdot (g^* q)$, by comparing lowest- (or highest-) order terms in this last expression, we see that p and q may be assumed homogeneous. Then by factoring and, if necessary, conjugating by some suitable rotation h, we can assume

$$f(x, y) = \prod_{j=1}^{r} (x - \lambda_j y)^{m_j}, \tag{3.2}$$

where the $\{\lambda_j\}$ are distinct and $m_j \in \mathbb{Z} \setminus \{0\}$. Note that such a factorization does not generally hold for homogeneous polynomials in three or more variables (e.g., see [6, pp. 50, 51]).

THEOREM 3.3. *The Ziglin subgroups of* $\mathrm{GL}(2,\mathbb{C})$ *are precisely those that can be conjugated to a subgroup of one of the following groups*:

(1) $T(n)=\left\{\begin{pmatrix}\alpha & 0\\ \delta & \beta\end{pmatrix}\mid \alpha^n=1\right\}$,

(2) $T(m,n)=\left\{\begin{pmatrix}\alpha & 0\\ 0 & \beta\end{pmatrix}\mid \alpha^m\beta^n=1\right\}$,

(3) $D(n)=\left\{\begin{pmatrix}\alpha & 0\\ 0 & \beta\end{pmatrix}\mid (\alpha\beta)^n=1\right\}\cup\left\{\begin{pmatrix}0 & \gamma\\ \delta & 0\end{pmatrix}\mid (\delta\gamma)^n=1\right\}$,

(4) *The projectively finite groups.*

Proof. Let Z be a Ziglin subgroup of $\mathrm{GL}(2,\mathbb{C})$ that fixes the rational function (3.2). We have three cases.

Case I ($r=1$). Z then fixes the line $x=\lambda_1 y$, and hence there is a conjugacy h so that $(h^*f)(x,y)=x^n$ (on setting $m_1=n$) and $(h^{-1}Zh)\subset T(n)$. Conversely, $(h^{-1}Z_0h)\subset T(n)$ implies that the subgroup Z_0 preserves $(h^{-1})^*(x^n)$.

Case II ($r=2$). Each $g\in Z$ will preserve or permute the two lines $x=\lambda_j y$, $j=1,2$. There is then a conjugacy h so that $(h^*f)(x,y)=x^m y^n$ (on setting $m_1=m$, $m_2=n$) and $(h^{-1}Zh)\subset\{\left(\begin{smallmatrix}\alpha & 0\\ 0 & \beta\end{smallmatrix}\right)\}\cup\{\left(\begin{smallmatrix}0 & \gamma\\ \delta & 0\end{smallmatrix}\right)\}$. If there are no elements of the form $g=\left(\begin{smallmatrix}0 & \gamma\\ \delta & 0\end{smallmatrix}\right)$ in $(h^{-1}Zh)$, then $\alpha^m\beta^n=1$ implies $(h^{-1}Zh)\subset T(m,n)$. If there is such an element g then $(g^*f)(x,y)=\gamma^m\delta^n x^n y^m=x^m y^n$ implies $m=n$ and $(h^{-1}Zh)\subset D(n)$. Conversely, if $(h^{-1}Z_0h)$ is a subgroup of (2) or (3) above, then Z_0 preserves $(h^{-1})^*(x^m y^n)$, with $m=n$ for case (3).

Case III ($r\geqq 3$). Let $K=\{c\cdot \mathrm{id}\mid c\in\mathbb{C}\backslash\{0\}\}$. We must show that the projectivization $PZ=Z/(Z\cap K)$ is finite. There is a positive integer n so that for all $g\in Z$ the element g^n fixes each of the lines $x=\lambda_j y$ ($j=1,\cdots,r$). Since $r\geqq 3$, this forces $g^n=c(g)\cdot\mathrm{id}$, where $c(g)$ is a constant dependent on g.

(a) If in (3.2) we have $\sum_{j=1}^r m_j\neq 0$, then $(g^n)^*f=f$ implies each $c(g)$ is a root of unity. By Proposition 3.1(c) we may replace Z by the algebraic group $\bar{Z}$; hence Z itself must be finite by Proposition 2.4.

(b) Now assume $\sum_{j=1}^r m_j=0$ in (3.2). Then PZ preserves (3.2), and applying the last part of the argument in (a) above to the Zariski closure of $[PZ\cup(-1)PZ]$ (which we can think of as a subgroup of $\mathrm{SL}(2,\mathbb{C})$ and which also preserves f), we see that PZ is finite.

Conversely, any subgroup $Z_0\subset\mathrm{GL}(2,\mathbb{C})$, for which the projectivization PZ_0 is finite, preserves the rational function $f_\lambda(x,y)$ where $f_\lambda=(\prod g^*x)/(\prod g^*(x-\lambda y))$ and the products are taken over $g\in PZ_0$. We then choose the parameter $\lambda\in\mathbb{C}\backslash\{0\}$ so that f_λ is nontrivial (we must be careful on this point since, for example, $(\prod g^*x)/(\prod g^*y)=1$ for g in the two-element group $\{\left(\begin{smallmatrix}1 & 0\\ 0 & 1\end{smallmatrix}\right),\left(\begin{smallmatrix}0 & 1\\ 1 & 0\end{smallmatrix}\right)\}$). □

COROLLARY 3.4 (Baider). *The Ziglin subgroups of* $\mathrm{SL}(2,\mathbb{C})$ *are precisely those that can be conjugated to a subgroup of one of the following groups*:

(1) $T(n)\cap\mathrm{SL}(2,\mathbb{C})$,

(2) $D(n)\cap\mathrm{SL}(2,\mathbb{C})$,

(3) *The finite groups.*

Proof. $T(m, n) \cap \mathrm{SL}(2, \mathbb{C}) \subset T(m-n) \cap \mathrm{SL}(2, \mathbb{C})$ since $\alpha\beta = 1$. □

The format of the next theorem follows that in the algorithm due to Kovacic [10] that we explain in § 4. Moreover, the groups G_M and G_N will be the respective monodromy groups of the differential equations (4.1) and (4.2) in that section.

THEOREM 3.5. *For $\theta_j \in \mathbb{C}\backslash\{0\}$ let $N = \{N_j\}_{j=1}^k \subset \mathrm{GL}(2, \mathbb{C})$ and $M = \{M_j = \theta_j N_j\}_{j=1}^k$ generate the respective groups G_N and G_M. Then G_N and G_M are simultaneously reducible, diagonalizable, or* DP*-groups. Moreover, they are simultaneously finite if and only if all θ_j are roots of unity. Now assume that $G_N \subset \mathrm{SL}(2, \mathbb{C})$. Then*

(a) *If G_N is reducible but not diagonalizable, under a conjugacy h for which $h^{-1}N_j h = \left(\begin{smallmatrix} \lambda_j & 0 \\ * & \lambda_j^{-1} \end{smallmatrix}\right)$, then G_M is Ziglin if and only if all $\theta_j\lambda_j$ are roots of unity.*

(b) *If G_N is diagonalizable with $h^{-1}N_j h = \left(\begin{smallmatrix} \lambda_j & 0 \\ 0 & \lambda_j^{-1} \end{smallmatrix}\right)$, then G_M is Ziglin if and only if all $\theta_j\lambda_j$ are roots of unity or there are integers m and n such that $(\theta_j)^{m+n} \cdot (\lambda_j)^{m-n} = 1$ for all j.*

(c) *If G_N is a* DP*-group but is not reducible, with $h^{-1}N_j h = \left(\begin{smallmatrix} \lambda_j & 0 \\ 0 & \lambda_j^{-1} \end{smallmatrix}\right)$ or $\left(\begin{smallmatrix} 0 & \rho_j \\ -\rho_j^{-1} & 0 \end{smallmatrix}\right)$, then G_M is Ziglin if and only if all θ_j are roots of unity.*

(d) *If G_N is finite then G_M is Ziglin.*

(e) *If none of the cases above hold for G_N, then G_M is not Ziglin.*

Proof. The initial statements concerning reducibility, diagonalizability, the DP-structure, and finiteness are clear. Statements (a)-(d) follow from the statement and proof of Theorem 3.3 (in (c) we must use the presence of an element $\left(\begin{smallmatrix} 0 & \rho_j \\ -\rho_j^{-1} & 0 \end{smallmatrix}\right)$).

For (e) assume that G_M is Ziglin. Then the assumptions on G_N imply by Proposition 2.3 that the Zariski closure $\bar{G}_N = \mathrm{SL}(2, \mathbb{C})$ and by Theorem 3.3 that the projectivization PG_M is finite. We can then readily construct a homogeneous polynomial that vanishes on PG_M and hence on G_M and G_N but not on $\mathrm{SL}(2, \mathbb{C})$, contradicting the fact that $\bar{G}_N = \mathrm{SL}(2, \mathbb{C})$. □

PROPOSITION 3.6. *If all $\{\theta_j\}_{j=1}^k$ are roots of unity, then G_N is Ziglin if and only if G_M is Ziglin.*

Proof. There is an integer d so that $(\theta_j)^d = 1$ for all j. Now raise the respective polynomials in the proof of Theorem 3.3 to the d-th power. □

For many applications the assumption on the $\{\theta_j\}$ in Proposition 3.6 is natural.

4. The algorithm. Here we show how to determine whether the monodromy group $G_M \subset \mathrm{GL}(2, \mathbb{C})$ of a second-order Fuchsian equation

$$z'' + p(x)z' + q(x)z = 0, \qquad ' = \frac{d}{dx}, \tag{4.1}$$

on $\mathbb{P}^1$ is a Ziglin group. This is done with the aid of an algorithm due to Kovacic [10] that decides which of the cases (a)-(e) of Theorem 3.5 holds for (4.1) in its normal form,

$$y'' = r(x)y, \quad r(x) = -[q(x) - (\tfrac{1}{4})p^2(x) - (\tfrac{1}{2})p'(x)], \quad ' = (d/dx), \tag{4.2}$$

which, we note, is also Fuchsian. We need to establish some notation.

In (4.1) we have

$$p(x) = \sum_{j=1}^k \frac{A_j}{(x-a_j)}, \quad q(x) = \sum_{j=1}^k \frac{B_j}{(x-a_j)^2} + \sum_{j=1}^k \frac{C_j}{(x-a_j)}, \quad \sum_{j=1}^k C_j = 0. \tag{4.3}$$

This implies that in (4.2) we have

$$r(x) = \sum_{j=1}^k \frac{\beta_j}{(x-a_j)^2} + \sum_{j=1}^k \frac{\delta_j}{(x-a_j)}, \qquad \sum_{j=1}^k \delta_j = 0, \tag{4.4}$$

where, on setting $A_\infty = \sum_{j=1}^k A_j$, $B_\infty = \sum_{j=1}^k (B_j + C_j a_j)$, and $\beta_\infty = \sum_{j=1}^k (\beta_j + \delta_j a_j)$,

$$\begin{aligned} \beta_j &= (\tfrac{1}{4})[(1-A_j)^2 - 4B_j - 1], \\ \delta_j &= -C_j + (\tfrac{1}{2})A_j\left[\sum_{i\neq j}^{k} \frac{A_i}{(a_j - a_i)}\right], \\ \beta_\infty &= (\tfrac{1}{4})[(1-A_\infty)^2 - 4B_\infty - 1]. \end{aligned} \tag{4.5}$$

Note that the characteristic exponents of (4.2) are

$$\begin{aligned} &\tau_j^{\pm} = \tfrac{1}{2}[1 \pm \{1 + 4\beta_j\}^{1/2}] = \tfrac{1}{2}[1 \pm \{(1-A_j)^2 - 4B_j\}^{1/2}] \quad \text{at } a_j, \\ &\tau_\infty^{\pm} = \tfrac{1}{2}[-1 \pm \{1 + 4\beta_\infty\}^{1/2}] = \tfrac{1}{2}[1 \pm \{(1-A_\infty)^2 - 4B_\infty\}^{1/2}] \quad \text{at } \infty. \end{aligned} \tag{4.6}$$

Let $\Lambda = \{a_1, \cdots, a_k\}$ be the finite poles of $p(x)$ and $q(x)$ as in (4.3), set $X = \mathbb{P}^1 \backslash (\Lambda \cup \{\infty\})$, and fix $x_0 \in X$. For each point $a_j \in \Lambda$ let γ_j be a positively oriented loop in X based at x_0 that encircles only a_j; then $\pi_1(X, x_0)$ is freely generated by $\{\gamma_j\}_{j=1}^k$. Also, let γ_∞ be a corresponding loop around ∞ satisfying $(\prod_{j=1}^k \gamma_j)\gamma_\infty = I$. Then the monodromy representation $\rho_M: \pi_1(X, x_0) \to \mathrm{GL}(2, \mathbb{C})$ of (4.1) with $M_j = \rho_M(\gamma_j)$, $M_\infty = \rho_M(\gamma_\infty)$, satisfies $(\prod_{j=1}^k M_j)M_\infty = I$, and $\{M_j\}_{j=1}^k$ generates the monodromy group G_M of (4.1).

The poles of $r(x)$ in (4.4) are a subset of $\Lambda \cup \{\infty\}$. The monodromy representation ρ_N of (4.2) has range $G_N \subset \mathrm{SL}(2,\mathbb{C})$ and is generated by $\{N_j = \rho_N(\gamma_j)\}_{j=1}^k$. Moreover (see [3, § 6]),

$$M_j = \theta_j N_j, \quad \text{where } \theta_j = \exp\left[-\frac{1}{2}\int_{\gamma_j^{-1}} p\right] = \exp(\pi i A_j). \tag{4.7}$$

The algorithm below consists of three successive cases. Each case is examined in turn, and lack of success in determining a solution in all three cases will correspond to (e) in Theorem 3.5 (with the first case covering both (a) and (b) of that theorem). Throughout we let G_D denote the differential Galois group of (4.2).

Case I (The reducible-diagonalizable case). The algorithm is phrased in terms of the "modified" characteristic exponents

$$\begin{aligned} &\alpha_j^{\pm} = \tau_j^{\pm} \quad \text{if } \beta_j \neq 0; \quad \alpha_j^{\pm} = 1 \quad \text{if } \beta_j = 0,\ \delta_j \neq 0; \quad \alpha_j^{\pm} = 0 \quad \text{if } \beta_j = 0 = \delta_j, \\ &\alpha_\infty^{\pm} = \tau_\infty^{\pm} + 1 \quad \text{if } \beta_\infty \neq 0; \quad \alpha_\infty^{+} = 0 \quad \text{and} \quad \alpha_\infty^{-} = 1 \quad \text{if } \beta_\infty = 0. \end{aligned} \tag{4.8}$$

THEOREM 4.9. *The following two statements are equivalent*:

(a) G_M, G_N, *and* G_D *are simultaneously reducible.*

(b) *There is a solution of* (4.2) *of the form* $y = \exp(\int \theta)$, *with* $\theta \in \mathbb{C}(x)$, *which is necessarily a common eigenvector for* G_N.

Moreover, there is a solution as in (b) *if and only if*

(1) *There is a choice* $s(j)$ *and* $s(\infty)$ *of a plus or minus sign so that*

$$d = \left[\alpha_\infty^{s(\infty)} - \sum_{j=1}^{k} \alpha_j^{s(j)}\right] \text{ is a nonnegative integer;}$$

(2) *There is a unique monic, degree* d *polynomial* P (*which can be found by the method of undetermined coefficients*) *satisfying*

$$P'' + 2\omega P' + (\omega' + \omega^2 - r)P = 0, \quad \text{where } \omega = \omega(x) = \sum_{j=1}^{k} \frac{\alpha_j^{s(j)}}{(x - a_j)},$$

and

(3) $\theta = \omega + (P'/P)$.

The algorithm above will generate two distinct θ's if and only if the three groups in (a) above are simultaneously diagonalizable. If there are no such solutions these groups are irreducible.

Proof. The statement in (a) is just a combination of Proposition 2.2(e) and the first part of Theorem 3.5, and similarly for simultaneous diagonalizability of these groups. For the equivalence of (a) and (b) see [10, pp. 7, 8]. The algorithm given in steps (1)-(3) for finding solutions of the form $y = \exp(\int \theta)$ with $\theta \in \mathbb{C}(x)$ is a restatement of [10, pp. 11, 12] for the Fuchsian case. The remainder of the theorem can be found in the proof in Kovacic [10, pp. 15-17], with the uniqueness of P in (2) being shown by calculating the Wronskian of the two solutions. □

Such reducibility criteria have a long history; for example, see [15, pp. 176-178], which was published in 1895. For the Fuchsian case with three regular singular points (e.g., the hypergeometric equation), simpler formulations are available (see [2, Thm. 2.24]). It should be noted that Kovacic's algorithm is not restricted to the Fuchsian case of (4.2).

COROLLARY 4.10. *Assume the reducibility algorithm implicit in steps* (1)-(3) *of Theorem* 4.9 *has yielded* (1) *only one solution, or* (2) *two independent solutions of* (4.2) *with the form* $y = \exp(\int \theta)$, *where*

$$\theta = \sum_{j=1}^{k} \frac{\alpha_j^{s(j)}}{(x - a_j)} + (P'/P).$$

Then:

(1) *In case* (1) *the monodromy group* G_M *of* (4.1) *is a Ziglin group if and only if each of the numbers* $[A_j + 2\alpha_j^{s(j)}]$, $j = 1, 2, \cdots, k$, *is rational.*

(b) *In case* (2) G_M *is a Ziglin group if and only if there are integers* m *and* n *so that* $[(m+n)A_j + 2(m-n)\alpha_j^{s(j)}]$ *is an even integer for* $j = 1, 2, \cdots, k$. *In particular,* G_M *is Ziglin if each of the numbers* $[A_j \pm 2\alpha_j^{s(j)}]$, $j = 1, 2, \cdots, k$, *is rational.*

Proof. In terms of a basis $\{*, y\}$ of germs of solutions of (4.2) at x_0 we have

$$N_j = \begin{bmatrix} \exp(2\pi i \alpha_j^{s(j)}) & 0 \\ * & \exp(-2\pi i \alpha_j^{s(j)}) \end{bmatrix}.$$

The result then follows from (4.7) and Theorem 3.5(a) and (b), respectively. □

Case II (The DP-case). The algorithm is stated in terms of the following sets:

$$\begin{aligned} &E_j = \{2 + e(1 + 4\beta_j)^{1/2} \mid e = 0, \pm 2\} \cap \mathbb{Z} \quad \text{if } \beta_j \neq 0, \\ &E_j = \{4\} \quad \text{if } \beta_j = 0, \quad \delta_j \neq 0, \\ &E_j = \{0\} \quad \text{if } \beta_j = 0 = \delta_j, \end{aligned} \tag{4.11}$$

and

$$\begin{aligned} &E_\infty = \{2 + e(1 + 4\beta_\infty)^{1/2} \mid e = 0, \pm 2\} \cap \mathbb{Z} \quad \text{if } \beta_\infty \neq 0, \\ &E_\infty = \{0, 2, 4\} \quad \text{if } \beta_\infty = 0. \end{aligned} \tag{4.12}$$

THEOREM 4.13. *The following two statements are equivalent*:

(a) G_M, G_N, *and* G_D *are irreducible* (*i.e., Case* I *does not hold*) *but are simultaneously* DP-*groups.*

(b) *There is a solution of* (4.2) *of the form* $y = \exp(\int \omega)$, *where* ω *is algebraic over* $\mathbb{C}(x)$ *of degree* 2, *and Case* I *does not hold.*

Moreover, there is a solution as in (b) *if and only if*

(1) *There is a choice of* $e_j \in E_j$ *and* $e_\infty \in E_\infty$ *which are* not *all even integers so that* $d = \frac{1}{2}[e_\infty - \sum_{j=1}^{k} e_j]$ *is a nonnegative integer*; *and*

(2) *There is a monic, degree d polynomial P (which can be found by the method of undetermined coefficients) satisfying*

$$P'''+3\theta P''+(3\theta^2+3\theta'-4r)P'+(\theta''+3\theta\theta'+\theta^3-4r\theta-2r')P=0,$$

where $\theta=\frac{1}{2}\sum_{j=1}^{k}(e_j/(x-a_j))$.

Specifically, for P as in (2) let $\phi=\theta+(P'/P)$ and choose a solution ω of $\omega^2+\phi\omega+[\frac{1}{2}\phi'+\frac{1}{2}\phi^2-r]=0$; then $y=\exp(\int\omega)$ will be a solution of (4.2) as in (b) above.

Proof. For the equivalence of (a) and (b) see [10, pp. 7, 8]. The remainder is a restatement of [10, p. 18] for the Fuchsian case. □

COROLLARY 4.14. *Assume that* G_D *is irreducible but that the* DP*-algorithm implicit in* (1) *and* (2) *and the final statement of Theorem* 4.13 *results in a solution of the required form. Then the monodromy group* G_M *of* (4.1) *is Ziglin if and only if all* A_j *are rational.*

Proof. This follows from (4.7) and Theorem 3.5(c). □

Remark 4.15. A necessary condition for the algorithm of Theorem 4.13 to give a solution of the required form is that in (4.4) some $\beta_j\neq 0$ (see [10, p. 8]). Thus, if all $\beta_j=0$ we need to examine only Cases I and III.

Case III (The finite case). The algorithm is stated in terms of the following sets, where $n=4$, 6, or 12:

$$F_j(n)=\left\{6+\frac{12e}{n}(1+4\beta_j)^{1/2}\,\middle|\,e=0,\pm1,\cdots,\pm\frac{n}{2}\right\}\cap\mathbb{Z}\quad\text{if }\beta_j\neq 0,$$

$$F_j(n)=\{12\}\quad\text{if }\beta_j=0,\ \delta_j\neq 0, \tag{4.16}$$

$$F_j(n)=\{0\}\quad\text{if }\beta_j=0=\delta_j,$$

and

$$F_\infty(n)=\left\{6+\frac{12e}{n}(1+4\beta_\infty)^{1/2}\,\middle|\,e=0,\pm1,\cdots,\pm\frac{n}{2}\right\}\cap\mathbb{Z}, \tag{4.17}$$

regardless of whether or not $\beta_\infty=0$.

THEOREM 4.18. *Assume that* G_D *is not reducible and not a* DP*-group (i.e., Cases* I *and* II *do not hold). Then the following procedure will determine if* G_D *is finite with all solutions of* (4.2) *being algebraic over* $\mathbb{C}(x)$.

(1) *Let* $n=4$ *and write down all choices of* $f_j\in F_j(n)$ *and* $f_\infty\in F_\infty(n)$ *for which* $d=(n/12)[f_\infty-\sum_{j=1}^{k}f_j]$ *is a nonnegative integer;*

(2) *For each such choice set* $\theta=(n/12)\sum_{j=1}^{k}(f_j/(x-a_j))$, *and with* $S=\Pi(x-a_j)$ (*where the product is taken over only those* a_j *which are poles of* $r(x)$) *determine* (*e.g., by the method of undetermined coefficients*) *if there is a monic, degree d polynomial P such that if we set* $P_n=-P$ *and recursively define*

$$P_{i-1}=-SP_i'+[(n-i)S'-S\theta]P_i-(n-i)(i+1)S^2rP_{i+1}$$

for $i=n,\ n-1,\cdots,0$, *then* $P_{-1}\equiv 0$;

(3) *Repeat, if necessary, steps* (1) *and* (2) *with* $n=6$ *and then with* $n=12$; *and*

(4) *If such a P is found in* (2) *for* $n=4$, 6, *or* 12, *then* G_D *is finite. Moreover, a solution* ω *to the equation* $\sum_{i=0}^{n}((S^iP_i)/(n-i)!)\omega^i=0$ *will give a solution* $y=\exp(\int\omega)$ *to* (4.2).

Proof. See [10, pp. 7, 8 and pp. 22, 23] and recall that (4.2) is Fuchsian. □

COROLLARY 4.19. *Assume* G_D *is irreducible and not a* DP*-group, but is finite. Then* G_M *is Ziglin.*

Proof. The proof is obtained by Theorem 3.5(d). □

Remarks 4.20. A success in the algorithm (1)-(4) of Theorem 4.19 implies G_D is finite and projectively the tetrahedral ($n=4$), octahedral ($n=6$), or iscosahedral

($n=12$) group (see [10, p. 27]). A failure implies that $G_D = \mathrm{SL}(2,\mathbb{C})$ (see [10, p. 7]). Necessary conditions for a success in the algorithm of Theorem 4.19 are that all the characteristic exponents $\tau_j^{\pm}$ and $\tau_\infty^{\pm}$ of (4.6) be rational; that is, all $(1+4\beta_j)^{1/2}$ and $(1+4\beta_\infty)^{1/2}$ are rational (see [10, p. 8]). If this does not hold, only Cases I and II need to be examined.

5. Applications.

Example (a). Let $a(x)$, $b(x)$, and $c(x,y)$ be arbitrary meromorphic functions on $\mathbb{C}^2=\{(x,y)\}$, let $h\in\mathbb{C}$, and consider the analytic set

$$\gamma=\{(x,y)\in\mathbb{C}^2 \,|\, b(x)c(x,y)=h\}. \tag{5.1}$$

As an example, if $b(x)$ is a separable polynomial of positive degree $(2g+1)$ or $(2g+2)$, $h=1$, and $c(x,y)=y^{-2}$, then γ is a punctured algebraic curve of genus g. Returning to generalities, suppose $\Gamma\subset\gamma$ is a Riemann surface on which $a(x)/b(x)$ is finite, and having the property that the projection $\pi(x,y)=x$ of Γ into $\mathbb{C}$ is unbounded. Via the embedding $(x,y)\to(x,0,y,0)$ we may view $E=\{(x,\xi_2,y,\eta_2)\,|\,(x,y)\in\Gamma\}\subset\mathbb{C}^4$ with projection $(x,\xi_2,y,\eta_2)\to(x,y)$ as a rank 2 complex vector bundle over Γ. A holomorphic connection ∇ can then be defined on E through the local coordinate representation

$$d\begin{pmatrix}\xi_2\\ \eta_2\end{pmatrix}=\begin{pmatrix}0 & 1\\ \dfrac{-a(x)}{b(x)} & 0\end{pmatrix}\begin{pmatrix}\xi_2\\ \eta_2\end{pmatrix}dx. \tag{5.2}$$

∇ is designed so as to be the pullback of

$$\xi''+\frac{a(x)}{b(x)}\xi=0,\quad \xi=\xi_2,\quad '=\frac{d}{dx}, \tag{5.3}$$

under the projection $\pi:\Gamma\to\mathbb{C}$ (see [2, § 4]). As a consequence, the monodromy group G_0 of ∇ embeds into the monodromy group G_N of (5.3) (see [4, Prop. 1.1]). If G_N is Ziglin, then Proposition 3.1(b) implies that G_0 is Ziglin.

There are simple instances in which we can view the projection $\pi:\Gamma\to\mathbb{C}$ as a reduction with respect to a finite symmetry group G. For example, if Γ is invariant under each mapping

$$(\exp(2\pi ij/n),(x,y))\to(x,\exp(2\pi ij/n)\cdot y),\qquad j=1,2,\cdots,n,$$

as would be the case if $c(x,y)=y^{\pm n}$, then Theorem 1.2 can be applied (the group action on the fibers of $E\to\Gamma$ being the identity map in the (ξ_2,η_2)-coordinates of (5.2)).

The algorithm of § 4 applies directly to (5.3) when $r(x)=-[a(x)/b(x)]$ is of the form given in (4.4). For example, suppose

$$r(x)=\left[\frac{1}{x^2}+\frac{1}{(x-1)^2}+\frac{1}{(x-2)^2}-\frac{1}{x}+\frac{1}{(x-1)}\right]. \tag{5.4}$$

Then (I) there is no choice of the $\alpha_j^{\pm}=\frac{1}{2}[1\pm\sqrt{5}]$ and $\alpha_\infty^{\pm}=\frac{1}{2}[1\pm\sqrt{17}]$ that makes the d of Theorem 4.9(1) a nonnegative integer; (II) all $E_j=\{2\}=E_\infty$ so that there are no choices of the e_j and e_∞, not all even, with which to construct a nonnegative d as in Theorem 4.13(1); and (III) $\beta_1=1$ implies $(1+4\beta_1)^{1/2}=\sqrt{5}$ is not rational so that Case III does not apply (see the necessary conditions in Remark 4.20). The differential Galois group G_D of (5.3)-(5.4) is then $\mathrm{SL}(2,\mathbb{C})$. Recalling Proposition 2.2(d), we see that by Proposition 3.1(d) and Corollary 3.4 the monodromy group $G_M=G_N$ of (5.3)-(5.4) cannot be Ziglin. If (5.3)-(5.4) is achieved from the ∇ of (5.2) by reduction using a finite group (see the previous paragraph for an example), then by Theorem 1.2 the monodromy group G_0 of ∇ is also not Ziglin.

To fit this into a Hamiltonian context, give $\mathbb{C}^4=\{(x, x_2, y, y_2)\}$ the standard symplectic structure $\omega=dx\wedge dy+dx_2\wedge dy_2$, let $p(x, y)=a(x)(\partial c/\partial y)(x, y)$ and $q(x, y)=b(x)c(x, y)$, and consider the Hamiltonian

$$H(x, x_2, y, y_2)=q(x, y)+\tfrac{1}{2}p(x, y)x_2^2+\tfrac{1}{2}(\partial q/\partial y)(x, y)y_2^2+\mathcal{O}_3(x_2, y_2). \tag{5.5}$$

The associated vector field X_H is tangent to the (x, y)-plane, a phase curve Γ in that plane of energy h is contained in the set γ of (5.1), and the normal variational equation (NVE) along Γ may be identified with (5.2) where (ξ_2, η_2) are the (global) linearized variables associated to (x_2, y_2) (see [2, § 4]). In the context of the previous paragraphs, conclusions about the nonintegrability of X_H can be drawn from Corollary 1.3.

Example (b). For our second example we illustrate how reduction can be combined with Kovacic's algorithm to explicitly compute the monodromy of a holomorphic connection that arises in a Hamiltonian system.

First consider the Fuchsian equation

$$y''+p(x)y'+q(x)y=0, \qquad '=\frac{d}{dx}, \tag{5.6}$$

on $\mathbb{C}$ with

$$\begin{aligned} p(x)&=\left[\frac{1}{x}+\frac{(1/2)}{(x-1)}\right], \\ q(x)&=\left[-\frac{1}{x^2}+\frac{(1/2)}{x}-\frac{(1/2)}{(x-1)}\right], \end{aligned} \tag{5.7}$$

and the associated normal form

$$y''=r(x)y, \quad r(x)=\left[\frac{(3/4)}{x^2}-\frac{(3/16)}{(x-1)^2}+\frac{(3/4)}{x(x-1)}\right]. \tag{5.8}$$

Applying Case I of § 4, we find only two choices of the $\alpha^{\pm}$ for which the d in Theorem 4.9(1) is a nonnegative integer:

$$\begin{aligned} \{\alpha_\infty^+, \alpha_1^+, \alpha_2^+\}&=\{\tfrac{7}{4}, \tfrac{3}{2}, \tfrac{1}{4}\} \quad \text{with } d=0, \\ \{\alpha_\infty^+, \alpha_1^-, \alpha_2^-\}&=\{\tfrac{7}{4}, -\tfrac{1}{2}, \tfrac{1}{4}\} \quad \text{with } d=2. \end{aligned}$$

Both cases lead to the single solution

$$y(x)=x^{3/2}(x-1)^{1/4} \tag{5.9}$$

of (5.8).

From the proof of Corollary 4.10 we see that the monodromy group G_N of (5.8) is generated by $N_1=\left(\begin{smallmatrix}-1 & 0\\ -a & -1\end{smallmatrix}\right)$ and $N_2=\left(\begin{smallmatrix}i & 0\\ b & -i\end{smallmatrix}\right)$. Note that $a\neq 0$ in N_1, since otherwise the distinct eigenvalues of N_2 would imply that G_N was diagonalizable, contrary to the algorithm giving us only the one solution (5.9) in Case I. Now recall from (4.7) that the monodromy group G_M of (5.6) is generated by $M_j=\theta_j N_j$, where $\theta_j=\exp(\pi i A_j)$, $j=1, 2$, with the A_j defined as in (4.3). From $p(x)$ in (5.7) we see that $A_1=1$ and $A_2=\frac{1}{2}$, and so $M_1=-N_1=\left(\begin{smallmatrix}1 & 0\\ a & 1\end{smallmatrix}\right)$ and $M_2=iN_2=\left(\begin{smallmatrix}-1 & 0\\ ib & 1\end{smallmatrix}\right)$.

Equation (5.6) with (5.7) occurs in a Hamiltonian context somewhat as in Example (a). Using the standard symplectic structure on $\mathbb{C}^4$ and

$$H(x_1, x_2, y_1, y_2)=\tfrac{1}{2}(y_1^2+y_2^2)+\tfrac{1}{2}(x_1^2+x_2^2)+\tfrac{2}{3}x_1^3+x_1x_2^2, \tag{5.10}$$

the associated vector field X_H is tangent to the (x_1, y_1)-plane, and there is a phase curve Γ within this plane at energy $h=0$ contained in the algebraic curve defined by

$$y_1^2=x_1^2[-\tfrac{4}{3}x_1-1]. \tag{5.11}$$

The $\mathbb{Z}_2$-action $(x_1, y_1) \to (x_1, -y_1)$ preserves (5.11) and lifts to a symmetry of the NVE ∇ along Γ, where ∇ is the pullback of (5.6)-(5.7) under the reduction mapping $(x_1, y_1) \to -(4/3)x_1 = x$. (Analogous computations are done in [4, Ex. C, pp. 110-112].) This mapping is unbranched over $x = 0$ and branched with order 2 over $x = 1$. Since $a \neq 0$ and $M_2^2 = id$, we see that the monodromy group of ∇ is isomorphic to the infinite cyclic group generated by M_1.

The Hamiltonian (5.10) is but one member of a family that has been extensively studied using Ziglin analysis (see [8, Thm. 4, p. 472] and [13, Cor. 1, p. 266]), which in this case fails to detect the nonexistence of a second independent integral. We might have anticipated some degeneracy in the monodromy of ∇ from the fact that the above Hamiltonian (5.10) and one which is known to be completely integrable have the same linearized equations about solutions in the (x_1, y_1)-plane (see [12, § 5]). However, the integrability status of (5.10) is unknown. For another example of a Hamiltonian system that is completely integrable with infinite cyclic monodromy group for its NVE, see [3, § 5]. For other examples in Ziglin analysis we refer to [3] and [4] and the surveys [14] and [19].

Acknowledgments. The authors thank Michael Singer for lengthy discussions on differential Galois theory, for suggesting that such methods would prove useful in Ziglin analysis, and for communicating a preliminary result which is now subsumed by Theorem 3.5(e). We also thank Alberto Baider for extensive discussions on the Ziglin group classification problem, and for communicating Corollary 3.4, which led directly to Theorem 3.3. Comments on the second example of § 5 by Haruo Yoshida are also gratefully acknowledged. Finally, we thank the Director and staff of the Institute for Mathematics and Its Applications at the University of Minnesota, Minneapolis, for their hospitality while this work was carried out, and also the anonymous referee of this paper for many helpful comments.

ADDENDUM: HYPERGEOMETRIC EXPANSIONS OF HEUN POLYNOMIALS*

E. G. KALNINS† AND W. MILLER, JR.‡

We should have pointed out the earlier papers on Heun functions by Sleeman [3] and Schmidt and Wolf [2]. These authors take a somewhat similar point of view to ours and use the simultaneous separability of a generalized Schrödinger equation in several cooordinate systems to derive integral relations for Heun functions. In [4] and in the present paper we are making clear the geometrical setting of their results and ours: polynomial orthogonal bases on the n-sphere characterized as eigenfunctions of commuting sets of self-adjoint symmetry operators.
