AN APPROACH FOR CONSTRUCTING FAMILIES OF HOMOGENIZED EQUATIONS FOR PERIODIC MEDIA. I: AN INTEGRAL REPRESENTATION AND ITS CONSEQUENCES*

R. C. MORGAN† AND I. BABUŠKA†

Abstract. The paper, which is the first in a series of two, presents an approach by which it is possible to derive a family of homogenization approaches and assess the accuracy of any homogenization in the relation of given input data.

Key words. homogenization, composite materials

AMS(MOS) subject classifications. 35J05, 35J99, 73K20

1. Introduction. The study of periodic media is one application of partial differential equations that have highly oscillatory, periodic coefficients. Essentially, the problem is to solve the elliptic differential equation

$$-\sum_{p,q=1}^{n} \frac{\partial}{\partial x_p}\left(a_{pq}\left(\frac{x}{h}\right)\frac{\partial u^h}{\partial x_q}(x)\right)+a_0\left(\frac{x}{h}\right)u^h(x)=f(x) \tag{1}$$

on $\Omega \subset \mathbb{R}^n$ with prescribed boundary conditions or $\Omega=\mathbb{R}^n$, in which a_{pq} and a_0 are real-valued 2π-periodic functions and h is a positive number that is small in comparison to the diameter of the domain Ω.

The problem is to get the solution of (1) for relatively (to what?) small h. There is a large available mathematical literature that addresses the behavior of the solution of (1) as $h \to 0$. We mention here, for example, [3], [9], [10], and the survey [21].

One of the main applications for differential equations of type (1) is in the field of composite materials. Here the aim is to replace the composite by homogeneous materials with the bulk material properties. For various aspects we refer to [1], [2], [12], [13], [19]. A brief history is given in [2]. The accuracy of such replacement depends, of course, on the goals of the analysis. *Hence many approaches are used in applications.* The most obvious approach, namely, to use asymptotic analysis for $h \to 0$, is not always applicable because *h is given* and cannot be changed and because of particular aims of the analysis. When numerically solving problem (1) directly, we face essential difficulties of how to represent the microstructure of the composite materials. This difficulty falls into the class of solution of elliptic equations with rough coefficients. For various aspects of this problem, we refer to [6]-[8].

As was said above, various approaches can be and are used for solving (1). These approaches often give very different results (see, e.g., [10]). In addition, some of them are formulated in an abstract or in more or less analytic form. These approaches give theoretical insight, but are not well suited to a numerical treatment of the problem.

This paper presents and thoroughly analyzes an approach directed to overcoming the various major difficulties mentioned above:

(a) It allows the design of an entire class of "homogenization" formulations and judges the accuracy and reliability of any homogenization approach. It also allows the

† Institute for Physical Science and Technology and Mathematics Department, University of Maryland, College Park, Maryland 20742.

specification of the class of problems (e.g., loads) for which a homogenization approach is applicable. In addition, it leads to a hierarchal construction of the homogenization formulations.

(b) The implementation is completely numerical, and allows adaptive modeling (selection of the equations).

We will address here only the problem with $\Omega = \mathbb{R}^n$, although very important features of the solution occur near the boundary when Ω is a bounded domain. These problems have a special character and will not be addressed here. Some brief comments will be made in § 5.

We will assume that

(i) $\Omega = \mathbb{R}^n$,

(ii) $a_0(x) \geqq \gamma_0 > 0$,

(iii) $f \in L_2(\mathbb{R}^n)$,

and that the problem is elliptic and self-adjoint.

The restriction of our analysis to a single differential equation is of a technical character only, as the ideas are also applicable to a system of equations, which would arise in elasticity problems, for example. The main idea of the approach, under the assumptions stated above, is based on the result that the solution u^h of (1) can be written in the form

$$u^h(x) = \frac{1}{(2\pi)^{n/2}} \int_{\mathbb{R}^n} \hat{f}(t) \phi\left(\frac{x}{h}, h, t\right) e^{it \cdot x} \, dt, \tag{2}$$

in which $\hat{f}$ is the Fourier transform of f and $\phi(y, h, t)$ is a function that is 2π-periodic in y and analytic in h and t, and that solves the differential equation

$$-e^{iht \cdot y} \sum_{p,q=1}^{n} \frac{\partial}{\partial y_p} \left(a_{pq}(y) \frac{\partial}{\partial y_p} (\phi(y) \, e^{iht \cdot y}) \right) + h^2 a_0(y) \phi(y) = h^2 \tag{3}$$

on $\{y \in \mathbb{R}^n : |y_p| < \pi\}$. There are some other representations of u^h that are related to (2), but are developed in a different context. For example, in [9] (§§ 3.1 and 3.2 of Chapter 4) and [17], a spectral decomposition of the operator (3) defined on the cell (respectively, shifted cell) is used and $u^h(x)$ is expressed through Bloch expansion.

By taking various approximations of Φ, we can express approximately the solution u^h in terms of solutions of auxiliary partial differential equations with constant coefficients, or even pseudodifferential equations. We can also use Φ for the construction of the basis functions of the finite-element method. Considering the error analysis associated with the approximations of ϕ, we can design an adaptive method of selecting a "model" that would yield an approximate solution, whose accuracy meets a prescribed tolerance. These ideas are more fully discussed in [5], where we have introduced a method to systematically derive numerical, computer-oriented methods for an approximation of u^h. In § 5 we will elaborate on these ideas.

In this paper, we concentrate our attention on representation (2), whereas in [16], we make a thorough analysis of $\phi(y, h, t)$. Consequently, the properties of ϕ that are used in this paper will be stated without proof. The integral in (2) is defined as a Bochner integral of an $H^1_{-\nu}(\mathbb{R}^n)$-valued function ($H^1_{-\nu}(\mathbb{R}^n)$ is defined in the next section). As a simple application of (2), in § 5 we will give an alternate proof of the classical homogenization result (the limit of u^h as $h \to 0$).

This paper and [16] are based on the first author's Ph.D. thesis [15], in which additional details and references can be found.

2. Notation and statement of the problem. For $j=0,1$, and for any $\nu\in\mathbb{R}$, define the weighted Sobolev space $H^j_\nu(\mathbb{R}^n)$ to be the completion of $C_0^\infty(\mathbb{R}^n)$ (the complex-valued C^∞-functions that have compact support on $\mathbb{R}^n$), with respect to $\|\cdot\|_{j,\nu}$, where

$$\|u\|^2_{j,\nu}=\int_{\mathbb{R}^n}\sum_{|\alpha|\leqq j}|D^\alpha u(x)|^2\exp(2\nu|x|)\,dx.$$

(For $x\in\mathbb{R}^n$, $|x|\equiv|x_1|+\cdots+|x_n|$.) We will use $H^j(\mathbb{R}^n)$ and $\|\cdot\|_j$ to denote the standard Sobolev space and norm on $\mathbb{R}^n$ (i.e., when $\nu=0$). Next, we introduce the Sobolev spaces of periodic functions for which

$$S\equiv\{y\equiv(y_1,\cdots,y_n)\in\mathbb{R}^n\colon |y_k|<\pi \text{ for } k=1,\cdots,n\}$$

is the fundamental period. For $j=0,1$, we denote the standard Sobolev norm on S by $\|\cdot\|_{j,S}$, and we define $H^j_{\text{per}}(S)$ to be the completion, with respect to the norm $\|\cdot\|_{j,S}$, of the complex-valued C^∞-functions on $\mathbb{R}^n$ that are 2π-periodic in each coordinate variable.

Let a_{pq} $(p,q=1,\cdots,n)$ and a_0 be real-valued, 2π-periodic, L_∞-functions defined on $\mathbb{R}^n$. Furthermore, assume $a_{qp}=a_{pq}$ and assume that there exist positive constants γ_0 and γ_1 such that

$$\text{(4)}\qquad \begin{cases} a_0(x)\geqq\gamma_0 & \text{for all } \zeta_p\in\mathbb{C},\\ \displaystyle\sum_{p,q=1}^n a_{pq}(x)\zeta_q\bar\zeta_p\geqq\gamma_1\sum_{p=1}^n|\zeta_p|^2 & \end{cases}$$

almost everywhere on $\mathbb{R}^n$. For each $h>0$, define

$$\Psi(h)[u,v]=\int_{\mathbb{R}^n}\left\{\sum_{p,q=1}^n a_{pq}\left(\frac{x}{h}\right)\frac{\partial u}{\partial x_q}(x)\overline{\frac{\partial v}{\partial x_p}(x)}+a_0\left(\frac{x}{h}\right)u(x)\overline{v(x)}\right\}dx.$$

An immediate consequence of the conditions imposed on the coefficients a_0 and a_{pq} is that there exists a constant C, independent of $h>0$, such that

$$\text{(5)}\qquad \begin{aligned} &|\Psi(h)[u,v]|\leqq C\|u\|_1\|v\|_1,\\ &|\Psi(h)[v,v]|\geqq\min\{\gamma_0,\gamma_1\}\|v\|_1^2 \end{aligned}$$

for all u and v in $H^1(\mathbb{R}^n)$. Then, according to the Lax-Milgram theorem, for each $h>0$ and each $f\in L_2$, there exists a unique function $u^h\in H^1(\mathbb{R}^n)$ that satisfies

$$\text{(6)}\qquad \Psi(h)[u^h,v]=\int_{\mathbb{R}^n}f(x)\overline{v(x)}\,dx\quad\text{for all } v\in H^1(\mathbb{R}^n),$$

because

$$\text{(7)}\qquad v\mapsto\int_{\mathbb{R}^n}f(x)\overline{v(x)}\,dx$$

is a bounded linear functional on $H^1(\mathbb{R}^n)$.

Next, for each $h\in\mathbb{C}$ and $t\in\mathbb{C}^n$, define the sesquilinear form $\Phi(h,t)\colon H^1_{\text{per}}(s)\times H^1_{\text{per}}(s)\to\mathbb{C}$ by

$$\Phi(h,t)[\phi,v]\equiv\int_S\left\{\sum_{p,q=1}^n a_{pq}(y)\frac{\partial}{\partial y_p}(\phi(y)\,e^{iht\cdot y})\cdot\frac{\partial}{\partial y_p}(\overline{v(y)}\,e^{-iht\cdot y})+h^2a_0(y)\phi(y)\overline{v(y)}\right\}dy.$$

LEMMA 1. *A neighborhood $\hat{G} \subset \mathbb{C}^{n+1}$ of $\mathbb{R}^{n+1}$ can be found such that for each $(h, t) \in \hat{G}$, there exists a unique function $\phi(\cdot, h, t) \in H^1_{\text{per}}(S)$ that satisfies*

$$\Phi(h, t)[\phi(\cdot, h, t), v] = h^2 \int_S \overline{v(y)}\, dy \quad \text{for all } v \in H^1_{\text{per}}(S).$$

Furthermore, the mapping $(h, t) \in \hat{G} \mapsto \phi(\cdot, h, t) \in H^1_{\text{per}}(S)$ is holomorphic, by which we mean that about each point in $\hat{G}$, the function $(h, t) \mapsto \phi(\cdot, h, t)$ can be expanded in a power series, convergent in $H^1_{\text{per}}(S)$ and in which each coefficient is an element in $H^1_{\text{per}}(S)$.

For the most part, the proofs of statements concerning $\phi(\cdot, h, t)$ are omitted in this paper since we give a fairly comprehensive analysis of $\phi(\cdot, h, t)$ in [16].

In § 4, we show that u^h admits the representation

$$u^h(x) = \frac{1}{(2\pi)^{n/2}} \int_{\mathbb{R}^n} \hat{f}(t) \phi\left(\frac{x}{h}, h, t\right) e^{it \cdot x}\, dt, \tag{8}$$

in which $\hat{f}(t) = (1/(2\pi)^{n/2}) \int_{\mathbb{R}^n} f(x)\, e^{-it \cdot x}\, dx$ and in which the integral is a Bochner integral of $H^1_{-\nu}(\mathbb{R}^n)$-valued functions. Our proof of (8) has as its first step the claim that for each $h > 0$ and $t \in \mathbb{R}^n$,

$$x \mapsto \phi\left(\frac{x}{h}, h, t\right) e^{it \cdot x} \tag{9}$$

solves (6) when $f(x) = e^{it \cdot x}$. However, (9) is not an element of $H^1(\mathbb{R}^n)$, and for this choice of f, (7) is not a bounded linear functional on $H^1(\mathbb{R}^n)$. Consequently, we consider $\Psi(h)$ as a sesquilinear form on $H^1_{-\nu}(\mathbb{R}^n) \times H^1_{\nu}(\mathbb{R}^n)$ for (sufficiently small) positive numbers ν.

The main tool for analyzing $\Psi(h)$ is Theorem 2 below.

THEOREM 2. *Let H_1 and H_2 be two complex Hilbert spaces with respective norms $\|\cdot\|_k$ and associated inner products $(\cdot, \cdot)_k$ for $k = 1, 2$. Let $B[\cdot, \cdot]$ be a sesquilinear form defined on $H_1 \times H_2$ for which there exist positive constants M and γ such that*

(a) $|B[u, v]| \leqq M \|u\|_1 \|v\|_2$ *for all* $u \in H_1$ *and* $v \in H_2$,

(b) $\inf_{\substack{u \in H_1 \\ \|u\|_1 = 1}} \sup_{\substack{v \in H_2 \\ \|u\|_2 \leqq 1}} |B[u, v]| \geqq \gamma > 0$,

(c) $\sup_{u \in H_1} |B[u, v]| > 0$ *for each* $v \in H_2$, $v \neq 0$.

If $f \in H_2^*$, the space of bounded conjugate-linear functionals on H_2, then there exists a unique $u_0 \in H_1$ such that

(d) $B[u_0, v] = f(v)$ *for all* $v \in H_2$,

(e) $\|u_0\|_1 \leqq \frac{1}{\gamma} \|f\|_{H_2^*}$.

A proof of Theorem 2 in the case of real Hilbert spaces can be found in [4] (as Theorem 5.2.1). The method of proof in the complex case is essentially unchanged and thus will be omitted.

We now prove the following lemma.

LEMMA 3. *There exist positive constants ν_0, C, and γ such that for all $\nu \in (0, \nu_0)$ and all $h > 0$,*

(i) $|\Psi(h)[u, v]| \leqq C \|u\|_{1,-\nu} \|v\|_{1,\nu}$,

(ii) $\inf_{\|u\|_{1,-\nu}=1} \sup_{\|v\|_{1,\nu}=1} |\Psi(h)[u, v]| \geqq \gamma > 0$,

(iii) $\sup_{u \in H^1_{-\nu}(\mathbb{R}^n)} |\Psi(h)[u, v]| > 0$ *for all* $v \in H^1_{\nu}(\mathbb{R}^n)$ *and* $v \neq 0$.

The constants ν_0, C, and γ are independent of $h > 0$; however, γ depends on ν_0.

Proof. Statement (i) follows because $\Psi(h)$ has L_∞-coefficients. To prove statement (ii), define $(Tu)(x) \equiv u(x)e^{-2\nu|x|}$ for $u \in H^1_{-\nu}(\mathbb{R}^n)$. Then for $\nu > 0$,

$$\|Tu\|^2_{1,\nu} = \int_{\mathbb{R}^n} \left(\sum_{j=1}^n \left| \frac{\partial u}{\partial x_j}(x) - 2\nu \operatorname{sgn}(x_j) u(x) \right|^2 + |u(x)|^2 \right) e^{-2\nu|x|}\, dx \tag{10}$$
$$\leqq 2(1+4n\nu^2)\|u\|^2_{1,-\nu}.$$

Now,

$$\begin{aligned}
\Psi(h)[u, Tu] &= \int_{\mathbb{R}^n} \left\{ \sum_{p,q=1}^n a_{pq}\left(\frac{x}{h}\right) \frac{\partial u}{\partial x_q}(x) \overline{\frac{\partial (Tu)}{\partial x_p}(x)} + a_0\left(\frac{x}{h}\right) u(x) \overline{T(u)} \right\} dx \\
&= \int_{\mathbb{R}^n} \left\{ \sum_{p,q=1}^n a_{pq}\left(\frac{x}{h}\right) \frac{\partial u}{\partial x_q}(x) \overline{\frac{\partial u}{\partial x_p}(x)} + a_0\left(\frac{x}{h}\right) u(x)\overline{u(x)} \right\} \exp(-2\nu|x|)\, dx \\
&\quad -2\nu \int_{\mathbb{R}^n} \left\{ \sum_{p,q=1}^n a_{pq}\left(\frac{x}{h}\right) \frac{\partial u}{\partial x_q}(x) \operatorname{sgn}(x_p) \overline{u(x)} \right\} \exp(-2\nu|x|)\, dx \\
&\equiv \Psi_1(h)[u] - 2\nu\Psi_2(h)[u].
\end{aligned} \tag{11}$$

A simple consequence of (4) is $\Psi_1(h)[u] \geqq \min\{\gamma_0, \gamma_1\}\|u\|^2_{1,-\nu}$. We also have $|\Psi_2(h)[u]| \leqq c\|u\|^2_{1,-\nu}$ for some constant c, independent of h. Combining these two inequalities with (10) and (11) yields

$$\begin{aligned}
|\Psi(h)[u, Tu]| &\geqq (\min\{\gamma_0, \gamma_1\} - 2c\nu)\|u\|^2_{1,-\nu} \\
&\geqq \frac{\min\{\gamma_0, \gamma_1\} - 2c\nu}{\sqrt{2(1+4n\nu^2)}} \|u\|_{1,-\nu}\|Tu\|_{1,\nu}.
\end{aligned}$$

Consequently, there exist positive constants ν_0 and γ, which are independent of $h > 0$, for which $\Psi(h)[u, Tu] \geqq \gamma\|u\|_{1,-\nu}\|Tu\|_{1,\nu}$ for all $\nu \in (0, \nu_0)$. This proves (ii).

Statement (iii) is proven in a similar manner. □

Throughout the remainder of this paper, we implicitly assume $\nu \in (0, \nu_0)$. Let $f \in L_2(\mathbb{R}^n)$; then

$$\left| \int_{\mathbb{R}^n} f(x)\overline{v(x)}\, dx \right| \leqq \|f\|_0\|v\|_{1,\nu} \quad \text{for all } v \in H^1_\nu(\mathbb{R}^n).$$

Lemma 3, in conjunction with Theorem 2, now yields the next theorem.

THEOREM 4. *For each $h > 0$ and $f \in L_2(\mathbb{R}^n)$ there exists a unique function $u^h \in H^1_{-\nu}(\mathbb{R}^n)$ for which*

$$\Psi(h)[u^h, v] = \int_{\mathbb{R}^n} f(x)\overline{v(x)}\, dx \quad \textit{for all } v \in H^1_\nu(\mathbb{R}^n). \tag{12}$$

Furthermore, $\|u^h\|_{1,-\nu} \leqq (1/\gamma)\|f\|_0$.

There is no ambiguity in denoting the unique solutions of (6) and (12) by u^h because $H^1_\nu(\mathbb{R}^n) \subset H^1(\mathbb{R}^n) \subset H^1_{-\nu}(\mathbb{R}^n)$ implies they are the same function. However, (12) can be solved when f belongs to a broader class of functions than the class of L_2-functions, namely, when f belongs to the dual space of $H^1_\nu(\mathbb{R}^n)$. One such function is defined by $f(x) = e^{it\cdot x}$.

3. Preliminaries.

THEOREM 5. *There exists a constant C_0 independent of t, such that*

$$\|\chi\, e^{it\cdot x}\|_{1,S} \leqq C_0(1+\|t\|)\|\chi\|_{1,S}$$

for all $\chi \in H^1(S)$ and for all $t \in \mathbb{R}^n$, where $\|t\|^2 \equiv t_1^2 + \cdots + t_n^2$.

For each $h>0$ and each $\omega \in \mathbb{Z}^n$, define

$$S(h, \omega) \equiv \{x \in \mathbb{R}^n : (\omega_j - 1)\pi h < x_j < (\omega_j + 1)\pi h, j = 1, \cdots, n\}.$$

Note that $S(1, (0, \cdots, 0)) = S$ is the fundamental domain for the periodic spaces.

LEMMA 6. *For each $h>0$ and $\nu>0$, there exists a constant $C_1(h, \nu)$ that remains bounded as $h \to 0$, such that for all $t \in \mathbb{R}^n$, and for any $\chi \in H^0_{\text{per}}(S)$,*

$$\text{(i)} \qquad \left\| \chi\left(\frac{x}{h}\right) e^{it\cdot x} \right\|_{0,-\nu} \leqq C_1(h, \nu) \|\chi\|_{0,S}$$

and for any $\chi \in H^1_{\text{per}}(S)$,

$$\text{(ii)} \qquad \left\| \chi\left(\frac{x}{h}\right) e^{it\cdot x} \right\|_{1,-\nu} \leqq (1+h^{-1}) C_1(h, \nu) \|\chi \exp(iht \cdot y)\|_{1,S}.$$

Proof.

$$\left\| \chi\left(\frac{x}{h}\right) \exp(it \cdot x) \right\|^2_{1,-\nu}$$

$$\leqq \sum_{\omega \in \mathbb{Z}^n} \int_{S(h,2\omega)} \left(\sum_{p=1}^{n} \left| \frac{\partial}{\partial x_p} \left(\chi\left(\frac{x}{h}\right) \exp(it \cdot x) \right) \right|^2 + \left| \chi\left(\frac{x}{h}\right) \right|^2 \right) \exp(-2\nu|x|)\, dx,$$

where $2\omega \equiv (2\omega_1, \cdots, 2\omega_n)$. Making the substitution $(x/h) - y + 2\pi\omega$ in the integral over $S(h, 2\omega)$ and using the periodicity of χ yields a constant $\tilde{c}$, independent of h, such that

$$\left\| \chi\left(\frac{x}{h}\right) \exp(it \cdot x) \right\|^2_{1,-\nu}$$

$$= \sum_{\omega \in \mathbb{Z}^n} \left\{ \int_S \left(h^{-1} \sum_{p=1}^{n} \left| \frac{\partial}{\partial y_p} (\chi(y) \exp(iht \cdot y)) \exp(i2\pi h\omega \cdot t) \right|^2 + |\chi(y)|^2 \right) \right.$$

$$\left. \cdot \exp(-2\nu h|y + 2\pi\omega|) h^n\, dy \right\}$$

$$\leqq \tilde{c}(1+h^{-2}) \left(\sum_{\omega \in \mathbb{Z}^n} \exp(-4\pi\nu h|\omega|) \right) h^n \|\chi \exp(iht \cdot y)\|^2_{1,S}.$$

It is not difficult to prove that there is a constant c that is independent of h such that

$$h^n \sum_{\omega \in \mathbb{Z}^n} \exp(-4\pi\nu h|\omega|) \leqq c h^n \left(1 + \int_{\mathbb{R}^n} \exp(-r\pi\nu h|x|)\, dx \right).$$

Upon setting $C_1(h, \nu) \equiv \sqrt{\tilde{c}c(h^n + (2\pi\nu)^{-n})}$, (ii) follows.

A similar argument, in which the contribution from the first-order derivatives is ignored, produces (i). □

LEMMA 7. *For all $h>0$ and $t \in \mathbb{R}^n$, we have*

$$\|\phi(\cdot, h, t)\|_{0,S} \leqq \frac{(2\pi)^{n/2}}{\gamma_0},$$

$$\|\phi(\cdot, h, t) \exp(iht \cdot y)\|_{1,S} \leqq C_2(h)$$

for some positive number $C_2(h)$.

Proof. It follows from (4) and Lemma 1 that

$$\gamma_1 \int_S \sum_{p=1}^{n} \left| \frac{\partial}{\partial y_p} (\phi(y, h, t) \exp(iht \cdot y)) \right|^2 dy + \gamma_0 h^2 \|\phi(\cdot, h, t)\|_{0,S}^2$$
$$\leqq \Phi(h, t)[\phi(\cdot, h, t), \phi(\cdot, h, t)]$$
$$\leqq (2\pi)^{n/2} h^2 \|\phi(\cdot, h, t)\|_{0,S}.$$

The lemma now follows with

$$C_2(h) \equiv \frac{(2\pi)^{n/2}}{\min\{\gamma_0, \gamma_1 h^{-2}\}}. \qquad \square$$

4. The representation of u^h. We begin with Theorem 8 below.

THEOREM 8. *For each $h > 0$ and $t \in \mathbb{R}^n$,*

(i) *$x \mapsto \phi((x/h), h, t)\, e^{it\cdot x}$ is in $H^1_{-\nu}(\mathbb{R}^n)$;*

(ii) *$\Psi(h)[\phi((x/h), h, t)\, e^{it\cdot x}, v] = \int_{\mathbb{R}^n} \exp(it\cdot x)\overline{v(x)}\, dx$ for all $v \in H^1_\nu(\mathbb{R}^n)$.*

Furthermore,

(iii) $$\left\| \phi\left(\frac{x}{h}, h, t\right) e^{it\cdot x} \right\|_{1,-\nu} \leqq \frac{1}{\gamma \nu^{n/2}}.$$

Proof. Statement (i) follows from Lemmas 6 and 7, which imply $\|\phi((x/h), h, t)\, e^{it\cdot x}\|_{1,-\nu} \leqq (1 + h^{-1}) C_1(h, \nu) C_2(h)$. Assuming that (ii) is true, (iii) is a consequence of Theorem 2, Lemma 3, and the fact $|\int_{\mathbb{R}^n} e^{it\cdot x}\overline{v(x)}\, dx| \leqq (1/\nu^{n/2})\|v\|_{1,\nu}$. The proof of (ii) is based upon determining the relationship between $\Psi(h)$ and $\Phi(h, t)$, and then using Lemma 1.

For each $h > 0$, there exists a locally finite, C^∞-partition of unity $\{\sigma_\omega(\cdot, h) : \omega \in \mathbb{Z}^n\}$ subordinated to $\{S(h, \omega) : \omega \in \mathbb{Z}^n\}$ such that $\sum_{\omega\in\mathbb{Z}^n} \sigma_\omega(\cdot, h)v$ converges to v in $H^1_\nu(\mathbb{R}^n)$ whenever $v \in H^1_\nu(\mathbb{R}^n)$. The basic requirement of the partition of unity is that $|\sigma_\omega(x, h)|$ and $|(\partial\sigma_\omega/\partial x_p)(x, h)|$ for $p = 1, \cdots, n$ are uniformly bounded for $x \in \mathbb{R}^n$ and $\omega \in \mathbb{Z}^n$. Then $v_\omega(\cdot, h) \equiv \sigma_\omega(\cdot, h)v$ has compact support in $S(h, \omega)$, and for any $\chi \in H^1_{\text{per}}(S)$,

$$\Psi(h)\left[\chi\left(\frac{x}{h}\right) e^{it\cdot x}, v\right] = \sum_{\omega\in\mathbb{Z}^n} \Psi(h)\left[\chi\left(\frac{x}{h}\right) \exp(it\cdot x), v_\omega(x, h)\right]$$

$$\leqq \sum_{\omega\in\mathbb{Z}^n} \int_{S(h,\omega)} \left(\sum_{p,q=1}^{n} a_{pq}\left(\frac{x}{h}\right) \frac{\partial}{\partial x_q}\left(\chi\left(\frac{x}{h}\right) \exp(it\cdot x)\right) \overline{\frac{\partial v_\omega}{\partial x_p}(x, h)} \right. \tag{13}$$
$$\left. + a_0\left(\frac{x}{h}\right)\chi\left(\frac{x}{h}\right)\left(\exp(it\cdot x)\overline{v_\omega(x, h)}\right) \right) dx$$

because $\Psi(h)$ is a continuous sesquilinear form on $H^1_{-\nu}(\mathbb{R}^n) \times H^1_\nu(\mathbb{R}^n)$, according to Lemma 3 (i). In an effort to transform the region of integration $S(h, \omega)$ into $S = S(1, (0, \cdots, 0))$ in each integral, make the substitution $x/h = y + \pi\tilde{\omega}$ for $x \in S(h, \omega)$, in which $\tilde{\omega}$ is the n-tuple of even integers, that is, derived from ω according to

$$\tilde{\omega}_p = \begin{cases} \omega_p, & \omega_p \text{ even}, \\ \omega_p - 1, & \omega_p \text{ odd}. \end{cases}$$

Using the periodicity of a_0, $\{a_{pq} : p, q = 1, \cdots, n\}$, and χ, each integral in (13) becomes

$$\int_{S(1,\omega-\tilde{\omega})} \left\{ h^{-2} \sum_{p,q=1}^{n} a_{pq}(y) \frac{\partial}{\partial y_q}(\chi(y) \exp(iht\cdot(y + \pi\tilde{\omega}))) \overline{\frac{\partial v_\omega}{\partial x_p}(h(y + \pi\tilde{\omega}), h)} \right. \tag{14}$$
$$\left. + a_0(y)\chi(y) \exp(iht\cdot(y + \pi\tilde{\omega}))\overline{v_\omega(h(y + \pi\tilde{\omega}), h)} \right\} h^n\, dy.$$

Next, for each $\omega \in \mathbb{Z}^n$, define

$$v^0_\omega(y, h, t) \equiv v_\omega(h(y + \pi\tilde{\omega}), h) \exp(-iht\cdot(y + \pi\tilde{\omega})) \tag{15}$$

for $y \in S(1, \omega - \tilde{\omega})$ and extend $v_\omega^0(\cdot, h, t)$ to all of $\mathbb{R}^n$ by 2π-periodicity. Since the support of $y \mapsto v_\omega(h(y + \pi\tilde{\omega}), h)$ is contained in $S(1, \omega - \tilde{\omega})$, it follows that $v_\omega^0(\cdot, h, t) \in H^1_{\text{per}}(S)$. Using (15) to substitute for $v_\omega(h(y + \pi\tilde{\omega}), h)$ in (14) yields

$$\int_{S(1,\omega-\tilde{\omega})} \left\{ h^{-2} \sum_{p,q=1}^{n} a_{pq}(y) \frac{\partial}{\partial y_q}(\chi(y) \exp(iht \cdot y)) \frac{\partial}{\partial y_q} \overline{(v_\omega^0(y, h, t) \exp(-iht \cdot y))} \right.$$
$$\left. + \sigma a_0(y) \chi(y) \overline{v_\omega^0(y, h, t)} \right\} h^n \, dy.$$

Now, the domain of integration $S(1, \omega - \tilde{\omega})$ can be replaced with $S(1, (0, \cdots, 0)) = S$, and consequently

$$\Psi(h)\left[\chi\left(\frac{x}{h}\right) \exp(it \cdot x), v\right] = \sum_{\omega \in \mathbb{Z}^n} h^{n-2} \Phi(h, t)[\chi, v_\omega^0(\cdot, h, t)] \tag{16}$$

for all $v \in H^1_\nu(\mathbb{R}^n)$.

Noting Lemma 1, it is now a simple matter to prove (ii):

$$\Psi(h)\left[\phi\left(\frac{x}{h}, h, t\right) \exp(it \cdot x), v\right] = \sum_{\omega \in \mathbb{Z}^n} h^{n-2} \Phi(h, t)[\phi(\cdot, h, t), v_\omega^0(\cdot, h, t)]$$
$$= \sum_{\omega \in \mathbb{Z}^n} h^n \int_S \overline{v_\omega^0(y, h, t)} \, dy$$
$$= \int_{\mathbb{R}^n} \exp(it \cdot x) v(x) \, dx)$$

for all $v \in H^1_\nu(\mathbb{R}^n)$, since $v_\omega^0(\cdot, h, t) \in H^1_{\text{per}}(S)$. □

LEMMA 9. *For each $h > 0$, $t \in \mathbb{R}^n \mapsto \phi((x/h), h, t) \exp(it \cdot x) \in H^1_{-\nu}(\mathbb{R}^n)$ is a continuous mapping.*

Proof. The continuity of $t \mapsto e^{itx} \in H^1_{-\nu}(\mathbb{R}^n)$ follows in a straightforward manner. Upon setting $t = 0$ and $\chi = \phi(\cdot, h, t) - \phi(\cdot, h, \tau)$ in Lemma 6,

$$\lim_{t \to \tau} \left\| \phi\left(\frac{x}{h}, h, t\right) - \phi\left(\frac{x}{h}, h, \tau\right) \right\|_{1,-\nu}$$
$$\leqq (1 + h^{-1}) C_1(h, \nu) \lim_{t \to \tau} \|\phi(\cdot, h, t) - \phi(\cdot, h, \tau)\|_{1,S}$$
$$= 0$$

follows from Lemma 1. □

For each $f \in L_2(\mathbb{R}^n)$, the Fourier transform of f is defined by

$$\hat{f}(t) = \frac{1}{(2\pi)^{n/2}} \int_{\mathbb{R}^n} f(x) \exp(-it \cdot x) \, dx.$$

The following notation will be used with the function f only (as it appears in (12)). For any $f \in L_2(\mathbb{R}^n)$ and $N > 0$, define $f_N \in L_2(\mathbb{R}^n)$ as the inverse Fourier transform of $\hat{f}|_{\{t: \|t\| \leqq N\}}$, i.e.,

$$f_N(x) = \frac{1}{(2\pi)^{n/2}} \int_{\|t\| \leqq N} \hat{f}(t) \exp(it \cdot x) \, dt, \qquad \hat{f}_N(t) = \begin{cases} \hat{f}(t), & \|t\| \leqq N, \\ 0, & \|t\| > N. \end{cases}$$

Parseval's inequality implies

$$\lim_{N \to \infty} \|f - f_N\|_0 = \lim_{N \to \infty} \|\hat{f} - \hat{f}_N\|_0 = 0.$$

Next, for each $N>0$, define $u^h(\cdot; N)\in H^1_{-\nu}(\mathbb{R}^n)$ by

$$u^h(x; N)=\frac{1}{(2\pi)^{n/2}}\int_{\|t\|\leqq N}\hat{f}(t)\phi\left(\frac{x}{h}, h, t\right)\exp(it\cdot x)\,dt$$

$$\left(=\frac{1}{(2\pi)^{n/2}}\int_{\mathbb{R}^n}\hat{f}_N(t)\phi\left(\frac{x}{h}, h, t\right)\exp(it\cdot x)\,dt\right),$$

in which the integral is to be interpreted as a Bochner integral of $H^1_{-\nu}(\mathbb{R}^n)$-valued function (cf. [18]). In order to show that the integral has such a meaning, we need to show that the integrand is strongly measurable and that $t\mapsto\|\hat{f}(t)\phi(x/h, h, t)\,e^{it\cdot x}\|_{1,-\nu}$ is Lebesgue integrable over $\{t:\|t\|\leqq N\}$. This integrability condition is satisfied as a result of Theorem 8 (iii) and because $\hat{f}$ is an L_1-function on $\{t:\|t\|\leqq N\}$. By strong measurability of the integrand, we mean that there exists a sequence of simple functions $t\mapsto w_k(\cdot, t)\in H^1_{-\nu}(\mathbb{R}^n)$ such that

$$\lim_{k\to\infty}\left\|\hat{f}(t)\phi\left(\frac{x}{h}, h, t\right)\exp(it\cdot x)-w_k(x, t)\right\|_{1,-\nu}=0. \tag{17}$$

It is easy to construct such a sequence (and we do so in the proof of Theorem 10 below) using Lemma 9 and the measurability of f. Furthermore, if the sequence of simple functions satisfies

$$\lim_{K\to\infty}\int_{\|t\|\leqq N}\left\|\hat{f}(t)\phi\left(\frac{x}{h}, h, t\right)\exp(it\cdot x)-w_k(x, t)\right\|_{1,-\nu}=0 \tag{18}$$

then

$$\int_{\|t\|\leqq n}\hat{f}(t)\phi\left(\frac{x}{h}, h, t\right)e^{it\cdot x}\,dt=\lim_{k\to\infty}\int_{\|t\|\leqq N}w_k(\cdot, t)\,dt\quad\text{in } H^1_{-\nu}(\mathbb{R}^n),$$

in which the integral of a simple function is defined in the standard manner.

THEOREM 10. *For each $N>0$,*

$$\psi(h)[u^h(\cdot; N), v]=\int_{\mathbb{R}^n}f_N(x)\overline{v(x)}\,dx\quad\textit{for all } v\in H^1_\nu(\mathbb{R}^n).$$

Proof. The essence of this proof is that a sequence of simple functions satisfying (17) and (18) can be chosen so that each value of each simple function is of the form $c\phi((x/h), h, \tau)\,e^{i\tau\cdot x}$ for some $\tau\in\{t:\|t\|\leqq N\}$ and for some complex number c. With this being the case, Theorem 8 (ii) can be used to evaluate $\Psi(h)[u, v]$ whenever u is the integral of one of these simple functions.

To begin, note that $H^1_\nu(\mathbb{R}^n)\subset L_1(\mathbb{R}^n)$. Consequently, $\hat{v}$ is continuous (cf. [15]) when $v\in H^1_\nu(\mathbb{R}^n)$, and it follows from Theorem 8 that

$$\Psi(h)\left[\phi\left(\frac{x}{h}, h, \tau\right)e^{i\tau\cdot x}, v\right]=(2\pi)^{n/2}\widehat{\bar{v}(\tau)}$$

is well defined for each $\tau\in\mathbb{R}^n$.

Set $\Omega\equiv\{t\in\mathbb{R}^n:\|t\|\leqq N\}$. Now select a sequence of simple functions $s_k:\Omega\to\mathbb{C}$ and a sequence of collections $\{\Omega_{k,j}:j=0,\cdots, M_k\}$ of measurable subsets of Ω for $k=1, 2,\cdots$ and for which the following is true. For each k:

(a) $\Omega=\cup_{j=0}^{M_k}\Omega_{k,j}$, $\Omega_{k,j}\cap\Omega_{k,l}=\phi$ for $j\neq l$;

(b) for $j=1,\cdots,M_k$, if t and τ are in $\Omega_{k,j}$, then

$$\left\| \phi\left(\frac{x}{h}, h, t\right) \exp(it\cdot x) - \phi\left(\frac{x}{h}, h, t\right) \exp(it\cdot x) \right\|_{1,-\nu} < 2^{-k},$$

and $|\hat{v}(t)-\hat{v}(\tau)|<2^{-k}$;

(c) s_k is constant on $\Omega_{k,j}$ for $j=0,\cdots,M_k$, with $s_k(t)=0$ for $t\in\Omega_{k,0}$, $s_k\to\hat{f}_N$ pointwise almost everywhere on Ω, and $|s_k(t)|\leqq|\hat{f}_N(t)|$ almost everywhere on Ω. Next, for each k, pick a $\tau^{k,j}\in\Omega_{k,j}$ for each $j=1,\cdots,M_k$, and define

$$w_k(x,t)=\begin{cases}0, & t\in\Omega_{k,0},\\ \phi(x/h,h,\tau^{k,j})\exp(i\tau^{k,j}\cdot x), & t\in\Omega_{k,j},\end{cases}$$

$$r_k(t)=\begin{cases}0, & t\in\Omega_{k,0},\\ \hat{v}(\tau^{k,j}), & t\in\Omega_{k,j}.\end{cases}$$

A consequence of the preceding construction and of Theorem 8 (iii) is

$$\left\| \hat{f}_N(t)\phi\left(\frac{x}{h}, h, t\right) e^{it\cdot x} - s_k(t)w_k(x,t) \right\|_{1,-\nu} \leqq |\hat{f}_N(t)-s_k(t)|\frac{1}{\gamma\nu^{n/2}} + |\hat{f}_N(t)|2^{-k}$$

$$\leqq \left(\frac{1}{\gamma\nu^{n/2}}+2^{-k}\right)|\hat{f}_N(t)|.$$

It follows from the first inequality that

$$\lim_{k\to\infty} \left\| \hat{f}_N(t)\phi\left(\frac{x}{h}, h, t\right) \exp(it\cdot x) - s_k(t)w_k(\cdot,t) \right\|_{1,-\nu} = 0 \quad \text{a.e.}$$

Furthermore, the Lebesgue dominated convergence theorem and the second inequality imply

$$\lim_{k\to\infty} \int_\Omega \left\| \hat{f}_N(t)\phi\left(\frac{x}{h}, h, t\right) \exp(it\cdot x) - s_k(t)w_k(\cdot,t) \right\|_{1,-\nu} dt = 0.$$

Consequently,

$$u^h(\cdot,N) = \lim_{k\to\infty} (2\pi)^{-n/2} \int_{\|t\|\leqq N} s_k(t)w_k(\cdot,t)\,dt \quad \text{in } H^1_{-\nu}(\mathbb{R}^n).$$

Finally, the continuity of $u\mapsto\Psi(h)[u,v]$ (Lemma 3); the definitions of s_k, w_k, and r_k; and Parseval's equality imply

$$\Psi(h)[u^h(\cdot;N),v] = \lim_{k\to\infty} (2\pi)^{-n/2}\left[\int_{\|t\|\leqq N} s_k(t)w_k(\cdot,t)\,dt, v\right]$$

$$= \lim_{k\to\infty} \int_{\|t\|\leqq N} s_k(t)r_k(t)\,dt$$

$$= \int_{\|t\|\leqq N} \hat{f}_N(t)\overline{\hat{v}(t)}\,dt$$

$$= \int_{\mathbb{R}^n} f_N(x)\overline{v(x)}\,dx$$

for all $v\in H^1_\nu(\mathbb{R}^n)$, because $\hat{f}_N(t)=0$ for $\|t\|>N$. □

It is now a simple matter to prove the main result of this paper.

THEOREM 11. *Suppose $h>0$ and $f\in L_2(\mathbb{R}^n)$. Let $u^h\in H^1_{-\nu}(\mathbb{R}^n)$ be the solution of* (12). *Then*

$$u^h(x)=\lim_{N\to\infty}(2\pi)^{-n/2}\int_{\|t\|\leqq N}\hat{f}(t)\phi\left(\frac{x}{h},h,t\right)\exp(it\cdot x)\,dt \quad \text{in } H^1_{-\nu}(\mathbb{R}^n), \tag{19}$$

where, for each N, the integral is defined as a Bochner integral of $H^1_{-\nu}(\mathbb{R}^n)$-valued functions.

Proof. A consequence of Theorem 10 is that

$$\Psi(h)[u^h-u^h(\cdot;N),v]=\int_{\mathbb{R}^n}(f(x)-f_N(x))\overline{v(x)}\,dx \tag{20}$$

for all $v\in H^1_{\nu}(\mathbb{R})$, from which the inequality

$$\|u^h-u^h(\cdot;N)\|_{1,-\nu}\leqq\frac{1}{\gamma}\|f-f_N\|_0 \tag{21}$$

is easily derived (cf. Theorem 2 and Lemma 3). Then (19) follows. □

Actually, (19) converges in $H^1(\mathbb{R}^n)$ even though each integral is defined only as a function in $H^1_{-\nu}(\mathbb{R}^n)$. The reasoning that allows us to identify the unique solutions of (6) and (12) also yields $u^h(\cdot;N)\in H^1(\mathbb{R}^n)$ and the fact that (20) is valid for all $v\in H^1(\mathbb{R}^n)$. Now, the Lax-Milgram theorem and (5) imply

$$\|u^h-u^h(\cdot;N)\|_1\leqq\frac{1}{\min\{\gamma_0,\gamma_1\}}\|f-f_N\|_0.$$

5. Homogenization. In this section we derive first the classical result of homogenization, which states that u^h converges, as h tends to zero, to a function that is the solution of a constant coefficient partial differential equation. This is an example of analyzing u^h through (19) and an analysis of $\phi(\cdot,h,t)$.

According to Lemma 1, it is possible to expand $\phi(\cdot,h,t)$ in powers of h, for each $t\in\mathbb{R}^n$. Consequently, we can write

$$\phi(\cdot,h,t)=\phi_0(\cdot,t)+\phi_1(\cdot,t)h+\cdots. \tag{22}$$

The functions $\{\phi_j(\cdot,t):j=0,1,\cdots\}$ can be determined by expanding (3) in powers of h and substituting (22). Here we are interested in only the constant term, and solving for it yields

$$\phi_0(\cdot,t)=g_0(t)=\frac{1}{\sum_{p,q=t}^{n}A_{pq}t_qt_p+A_0},$$

where A_0 and $\{A_{pq}: p,q=1,\cdots,n\}$ are derived from the periodic coefficients a_0 and $\{a_{pq}: p,q=1,\cdots,n\}$ and certain auxiliary functions. Complete details are given in [16], where proofs of the properties of $\phi(\cdot,h,t)$ that are stated in the following lemma can also be found.

LEMMA 12. *There exist positive constants θ and G_0, and continuous functions $g_0:\mathbb{R}^n\to(0,\infty)$ and $G_1:\{(h,t)\in\mathbb{R}^{n+1}: 0\leqq\theta h(1+\|t\|)<1\}\to(0,\infty)$ such that*

(i) $g_0(t)\leqq G_0/1+\|t\|^2$,

(ii) $\|\phi(\cdot,h,t)-g_0(t)\|_{1,S}\leqq G_1(h,t)h$ *for each $h\geqq 0$ and $t\in\mathbb{R}^n$ that satisfy $\theta h(1+\|t\|)<1$.*

A consequence of (i) is that we can define functions u_0 and $u_0(\cdot\,; N)$, for $N>0$, in $H^2(\mathbb{R}^n)$ by

$$u_0(x) = (2\pi)^{-n/2} \int_{\mathbb{R}^n} \hat{f}(t) g_0(t) \exp(it \cdot x)\, dt,$$
$$u_0(x; N) = (2\pi)^{-n/2} \int_{\|t\|<N} \hat{f}(t) g_0(t) \exp(it \cdot x)\, dt \tag{23}$$

whenever $\hat{f} \in L_2(\mathbb{R}^n)$ (cf. [18]). Note that $u_0(\cdot\,; N) = u_0$ with $f = f_N$. We have $\hat{u}_0 = \hat{f} g_0$ and $(u_0(\cdot\,; N)) = \hat{f}_N g_0$, and then Parseval's equality implies

$$\|u_0 - u_0(\cdot\,; N)\|_0 \leqq G_0 \|f - f_N\|_0. \tag{24}$$

The integrals that define u_0 and $u_0(\cdot\,; N)$ are to be interpreted as Lebesgue integrals of numerical-valued functions. However, we want to interpret $u_0(\cdot\,; N)$ as an integral of $H^1_{-\nu}(\mathbb{R}^n)$-valued functions. In the Appendix we show that the integral in (23) can be interpreted in both ways, in an unambiguous and consistent manner. Furthermore, note that u_0 is the solution of the constant coefficient differential equation

$$-\sum_{p,q=1}^{n} A_{pq} \frac{\partial^2 u_0}{\partial x_p \partial x_q}(x) + A_0 u_0(x) = f(x). \tag{25}$$

We can now prove the classical result in homogenization.

THEOREM 13. *Let $f \in L_2(\mathbb{R}^n)$. Let $u^h \in H^1_{-\nu}(\mathbb{R}^n$ be the solution of* (12) *for $h>0$, and let $u_0 \in H^1(\mathbb{R}^n) \subset H^1_{-\nu}(\mathbb{R}^n)$ be the solution of* (25). *Then* $\lim_{h\to 0} \|u^h - u_0\|_{0,-\nu} = 0$.

Proof. For each $N>0$, we have

$$\begin{aligned} \|u^h - u_0\|_{0,-\nu} &\leqq \|u^h - u^h(\cdot\,; N)\|_{0,-\nu} \\ &\quad + \|u^h(\cdot\,; N) - u_0(\cdot\,; N)\|_{0,-\nu} + \|u_0(\cdot\,; N) - u_0\|_{0,-\nu}. \end{aligned} \tag{26}$$

Let $\varepsilon>0$ be given. It follows from (21) and (24) that we can choose an $N>0$ that makes each of the first and third terms on the right-hand side of (26) smaller than ε, uniformly in h. Next, a consequence of Lemmas 6 and 12 is that there exists $h_0 \in (0, 1/\theta(1+N))$ such that for all $h \in (0, h_0)$,

$$\begin{aligned} &\|u^h(\cdot\,; N) - u_0(\cdot\,; N)\|_{0,-\nu} \\ &\quad \leqq (2\pi)^{-n/2} \int_{\|t\|\leqq N} |\hat{f}(t)| \left\| \left(\phi\left(\frac{x}{h}, h, t\right) - g_0(t) \right) \exp(it \cdot x) \right\|_{0,-\nu} dt \\ &\quad \leqq (2\pi)^{-n/2} C_1(h, \nu) h \int_{\|t\|\leqq N} |\hat{f}(t)| G_1(h, t)\, dt \\ &\quad < \varepsilon. \end{aligned}$$

□

We have shown that an expansion of the function $\Phi(\cdot, h, t)$ leads directly to the classical homogenization. A truncated series (22) is a special approximation of Φ. Comparing it with Φ, we get precise information whether the results are for given h and f in the range of admissible accuracy.

We, of course, have many other possibilities to employ function Φ for a derivation of homogenized equation and numerical treatment of the (original) problem, so that the admissible accuracy is achieved. We mention some of them here.

(a) For given h (which in engineering applications cannot be made "sufficiently" small), we can approximate the function $\Phi(\cdot, h, t)$ in the form

$$\Phi(\cdot, h, t) \cong \sum_{k=1}^{n} \varphi_k(\cdot)\psi_k(t), \tag{27}$$

where $\psi_k(t)$ are rational functions. The approximation (27) is such that the error

$$\varepsilon = \Phi(\cdot, h, t) - \sum_{k=1} \varphi_k(\cdot)\psi_k(t)$$

is small for $t_0 \leqq t \leqq t_1$, $0 \leqq x/h \leqq 2\pi$, where $\hat{f}(t)$ is not negligible. We can also (by a smoothing technique) decompose f,

$$f = \sum_{j=1}^{n} f_j$$

so that $\hat{f}_j$ is small outside of $t_j < t < t_{j+1}$, and solve m homogenization problems separately. By this approach any prescribed accuracy can be achieved. Every $\psi_k(t) = \bar{\psi}_k(t)/\rho_k(t)$ is the symbol of the homogenized problem

$$L_1 u^h = L_2 f.$$

Here L_1, respectively, L_2, are operators associated to ψ_k, respectively, ρ_k.

(b) We can approximate the function Φ separately for every fixed value x and derive homogenized equations associated with this point. This is important in application because usually we are interested in the solutions in some specific (dangerous) places only.

(c) Often we are interested not in the solution but in the fluxes (stresses), stress intensity factors, etc., in some specific points. Writing expressions analogous to (2) for these points we can construct other adequate homogenizations.

(d) Given a concrete homogenization we can compare its symbol with Φ and get the information about the admissible range of f and accuracy of such an approach. For example, we can judge whether h is "sufficiently" small. By this we can characterize the approximation of various approaches in much more effective ways than have been used in [11].

The function $\Phi(\cdot, h, t)$ is the solution of the elliptic problem (3) with parameters h and t. The function $\Phi(\cdot, h, t)$ can be found numerically without any difficulties by the finite-element method (in the range of a priori given tolerance). The computation for various values t and h can be done in parallel. The approximation we mentioned above is then simply post-processing of the computed data.

(e) The function Φ can be directly employed for the construction of a special element for solving the original problem analogously as has been discussed in [8]. Here we will use the finite-element basis function of the form

$$\varphi_{i,j} = \rho_j(x)\Phi\left(\frac{x}{h}, h, t_i\right), \qquad i = 1, \cdots, s, \tag{28}$$

where t_i are properly chosen points and ρ_j is the classical "hat" function associated to the nodal point x_j in the finite element method. Here, of course, denoting by H the meshsize of the elements, we have $H \gg h$.

There are many other opportunities to employ the function Φ for computational purposes and to create a hierarchical family of homogenizations. The selection of the adequate homogenized equation then could be made adaptively. Nevertheless, it is out of the scope of this paper to elaborate more and we refer to [5] for additional aspects and numerical examples.

So far we assumed that $\Omega = \mathbb{R}^n$. If Ω has a bounded boundary (e.g., crack problem) the solution is much more complicated. Here always a boundary layer or singular behavior is present. A practical way to deal with this problem is to use refined meshes and basis functions of the form (24) with sufficiently large s (which also could be determined in an adaptive way).

6. Appendix. Define $w(x, t) = (w\pi)^{n/2}\hat{f}(t)g_0(t)\, e^{it\cdot x}$, where $f \in L_2(\mathbb{R}^n)$ and g_0 is defined as in Lemma 13. According to (22), $u_0(\cdot\,; N) \in H^2(\mathbb{R}^n)$ is defined by

$$u_0(x; N) = \int_{\|t\| \leqq N} w(x, t)\, dt$$

as an integral of numerical-valued functions. Since

$$t \mapsto w(\cdot, t) \text{ is strongly measurable in } H^1_{-\nu}(\mathbb{R}^n),$$

$$\int_{\|t\| \leqq N} \|w(\cdot, t)\|_{1,-\nu}\, dt \leqq (2\pi)^{n/2} G_0 \nu^{-n/2} \int_{\|t\| \leqq N} |\hat{f}(t)|\, dt < \infty,$$

it follows that

$$W = \int_{\|t\| \leqq N} w(\cdot, t)\, dt$$

can be defined as an integral of $H^1_{-\nu}(\mathbb{R}^n)$-valued functions. We want to prove the following lemma.

LEMMA 14. *$u_0(\cdot\,; N) = W$ as a function in $H^1_{-\nu}(\mathbb{R}^n)$.*

Proof. It suffices to show that $x \mapsto u_0(x; N) \exp(-\nu|x|)$ and $x \mapsto W(x) \exp(-\nu|x|)$ generate the same generalized function. It follows from (27) that a sequence $t \mapsto w_k(\cdot, t) \in H^1_{-\nu}(\mathbb{R}^n)$ of simple functions can be chosen so that

$$\lim_{k\to\infty} \|w_k(\cdot, t) - w(\cdot, t)\|_{1,-\nu} = 0 \quad \text{a.e.},$$

$$\lim_{k\to\infty} \int_{\|t\| \leqq N} \|w_k(\cdot, t) - w(\cdot, t)\|_{1,-\nu}\, dt = 0,$$

$$\|w_k(\cdot, t)\|_{1,-\nu} \leqq \frac{3}{2} \|w(\cdot, t)\|_{1,-\nu} \quad \text{a.e.}$$

Then by definition, $W = \lim_{k\to\infty} \int_{\|t\| \leqq N} w_k(\cdot, t)\, dt$ in $H^1_{-\nu}(\mathbb{R}^n)$.

Let $\psi \in C_0^\infty(\mathbb{R}^n)$. Then Fubini's theorem, the Lebesgue dominated convergence theorem, and the definitions of w_k and W imply

$$\begin{aligned}
\int_{\mathbb{R}^n} u_0(x; N) \exp(-\nu|x|)\overline{\psi(x)}\, dx &= \int_{\|t\| \leqq N} \int_{\mathbb{R}^n} w(x, t) \exp(-\nu|x|)\overline{\psi(x)}\, dx\, dt \\
&= \lim_{k\to\infty} \int_{\|t\| \leqq N} \int_{\mathbb{R}^n} w_k(x, t) \exp(-\nu|x|)\overline{\psi(x)}\, dx \\
&= \int_{\mathbb{R}^n} W(x) \exp(-\nu|x|)\overline{\psi(x)}\, dx. \qquad \square
\end{aligned}$$

AN APPROACH FOR CONSTRUCTING FAMILIES OF HOMOGENIZED EQUATIONS FOR PERIODIC MEDIA. II: PROPERTIES OF THE KERNEL*

R. C. MORGAN† AND I. BABUŠKA†

Abstract. This paper is the second in the series devoted to the study of constructions of families of homogenizations. The first paper [*SIAM J. Math. Anal.*, 22 (1991), pp. 1-15] used the properties of the kernel $\Phi(\cdot, h, t)$. In this paper these properties are established.

Key words. homogenization, composite materials

AMS(MOS) subject classifications. 35J05, 35JPP, 73K20

1. Introduction. In [8] we developed an integral representation of the solution to a differential equation that models the equations that arise in the study of periodic media (e.g., composite materials). The elliptic differential equation studied in [8] is

$$-\sum_{p,q=1}^{n} \frac{\partial}{\partial x_p}\left(a_{pq}\left(\frac{x}{h}\right)\frac{\partial u^h}{\partial x_q}(x)\right)+a_0\left(\frac{x}{h}\right)u^h(x)=f(x)$$

on $\mathbb{R}^n$, in which a_{pq} and a_0 are real-valued 2π-periodic functions and h is a given positive number. An alternate proof of the classical homogenization result (the limit of u^h as $h\to 0$) is given in [8], based on the integral formula for u^h that was developed there.

The integral representation of u^h depends on the 2π-periodic function $\phi(\cdot, h, t)$ that satisfies

$$-e^{-iht\cdot y}\sum_{p,q=1}^{n}\frac{\partial}{\partial y_p}\left(a_{pq}(y)\frac{\partial}{\partial y_q}(\phi(y,h,t)\,e^{iht\cdot y})\right)+h^2a_0(y)\phi(y,h,t)=h^2$$

on $\{y\in\mathbb{R}^n: |y_p|<\pi\}$, in which $t\in\mathbb{R}^n$. The main emphasis of [8] is placed on the function u^h; the properties of ϕ that are needed there are stated without proof. This paper presents an analysis of ϕ in order to prove these claims, namely, Lemmas 1 and 12 in [8]. Theorem 1 in this paper is equivalent to Lemma 1 in [8], whereas the content of Lemma 12 and the discussion preceding it in [8] are contained in Theorems 9 and 11 here.

In § 2, the notation used here and the equation that $\phi(\cdot, h, t)$ satisfies are given along with the statement of Theorem 1. The proof of Theorem 1 is presented in § 3. The expansion of $\phi(\cdot, h, t)$ in powers of h and properties of this expansion are developed in § 4. Section 5 is devoted to developing several analyticity results associated with families of sesquilinear forms. The results of § 5 are used extensively in § 3. Additional details and references can be found in [7].

A method for systematically developing classes of differential equations, or even pseudodifferential operators, that describe the behavior of composite materials with a periodic structure has been introduced in [3] and is based on the results of [8] and this paper.

2. Notation and statement of the problem. Let $S \equiv \{y \equiv (y_1, \cdots, y_n) \in \mathbb{R}^n : |y_k| < \pi$ for $k = 1, \cdots, n\}$, and for $j = 0, 1$, denote the standard Sobolev norm on S by $\|\cdot\|_j$. In addition, define $|\cdot|_1$ by

$$|v_1| \equiv \left(\int_S \sum_{p=1}^{n} \left| \frac{\partial v}{\partial y_p}(y) \right|^2 dy \right)^{1/2}.$$

The Sobolev spaces of periodic functions for which S is the fundamental period, is denoted by $H^j_{\text{per}}(S)$, and is defined to be the completion with respect to $\|\cdot\|_j$, of the complex-valued, C^∞-functions on $\mathbb{R}^n$ that are 2π-periodic in each coordinate variable.

Let a_{pq}, for $p, q = 1, \cdots, n$, and a_0 be real valued, 2π-periodic, with L_∞-functions defined on $\mathbb{R}^n$. Furthermore, assume $a_{qp} = a_{pq}$ and that there exist positive constants γ_0 and γ_1 such that

$$\begin{aligned} &a_0(x) \geqq \gamma_0, \\ &\sum_{p,q=1}^{n} a_{qp}(x)\zeta_q\bar{\zeta}_p \geqq \gamma_1 \sum_{p=1}^{n} |\zeta_p|^2 \quad \text{for all } \zeta_p \in \mathbb{C}, \end{aligned} \tag{1}$$

almost everywhere on $\mathbb{R}^n$. For each $h \in \mathbb{C}$ and $t \in \mathbb{C}^n$, define the sesquilinear form $\Phi(h, t) : H^1_{\text{per}}(S) \times H^1_{\text{per}}(S) \to \mathbb{C}$ by

$$\begin{aligned} &\Phi(h, t)[\phi, v] \\ &= \int_S \left\{ \sum_{p,q=1}^{n} a_{pq}(y) \frac{\partial}{\partial y_q}(\phi(y)\, e^{iht\cdot y}) \frac{\partial}{\partial y_q}(\overline{v(y)}\, e^{-iht\cdot y}) + h^2 a_0(y)\phi(y)\overline{v(y)} \right\} dy. \end{aligned} \tag{2}$$

In § 3 we will prove Theorem 1 below.

THEOREM 1. *There exists a neighborhood $\hat{G}$ of $\mathbb{R}^{n+1}$ (contained in $\mathbb{C}^{n+1}$), such that a unique function $\phi(\cdot, h, t) \in H^1_{\text{per}}(S)$ exists for each $(h, t) \in \hat{G}$ and satisfies*

$$\Phi(h, t)[\phi(\cdot, h, t), v] = h^2 \int_S \overline{v(y)}\, dy \quad \text{for all } v \in H^1_{\text{per}}(S). \tag{3}$$

Furthermore, the mapping

$$(h, t) \mapsto \phi(\cdot, h, t) \in H^1_{\text{per}}(S) \tag{4}$$

is holomorphic on $\hat{G}$ (see Definition 12 in § 5).

In the proof of Theorem 1, the following eigenvalue problem will be considered: Seek $\lambda(h, t) \in \mathbb{C}$ and a nonzero function $\psi(\cdot, h, t) \in H^1_{\text{per}}(S)$ such that

$$\Phi(h, t)[\psi(\cdot, h, t), v] = \lambda(h, t) \int_S \psi(y, h, t)\overline{v(y)}\, dy \quad \text{for all } v \in H^1_{\text{per}}(S). \tag{5}$$

Before proceeding to the proof of Theorem 1, we give two lemmas that we will use repeatedly.

LEMMA 2. *A constant C_0 exists such that*

$$\frac{1}{C_0(1 + \|t\|)} \|v\|_1 \leqq \|v\, e^{it\cdot y}\|_1 \leqq C_0(1 + \|t\|)\|v\|_1$$

for all $v \in H^1(S)$, the standard Sobolev space, and for all $t \in \mathbb{R}^n$, where $\|t\|^2 \equiv t_1^2 + \cdots + t_n^2$.

Proof. The proof of the right-hand inequality is straightforward. The inequality on the left is proved by applying the right-hand inequality to the function $w = v\, e^{it\cdot y}$:

$$\|v\|_1 = \|w\, e^{-it\cdot y}\|_1 \leqq C_0(1 + \|t\|)\|w\|_1. \qquad \square$$

LEMMA 3. *Let H be a complex Hilbert space with norm $\|\cdot\|_H$ and inner product $(\cdot,\cdot)_H$, and let $\Phi: H\times H\to\mathbb{C}$ be a sesquilinear form (i.e., $\Phi[\phi, v]$ is linear in ϕ and conjugate-linear in v). If there exist constants M and γ such that*

$$|\Phi[\phi, v]|\leqq M\|\phi\|_H\|v\|_H,$$

$$\gamma\|v\|_H^2\leqq|\phi[v, v]|$$

for all ϕ and v in H, then for each $f\in H^*$, the space of bounded conjugate-linear functionals on H, there is a unique $\phi\in H$ such that

$$\Phi[\phi, v]=f(v)\quad \text{for all } v\in H.$$

Moreover, $\|\phi\|_H\leqq(1/\gamma)\|f\|_{H^*}$.

Lemma 3 is known as the Lax–Milgram theorem (see [2]). The essence of the proof of Lemma 3 is the existence of a bounded operator A that maps H isomorphically onto H such that $\Phi[\phi, v]=(A\phi, v)_H$ for all ϕ and v in H. This fact will be used in the proof of Theorem 15 in § 5.

3. Proof of Theorem 1. The ideas and results of § 5 will be used extensively in this section. Note that $H^0_{\text{per}}(S)$ and $H^1_{\text{per}}(S)$ satisfy the conditions imposed on H and V, respectively, in § 5, i.e., $H^1_{\text{per}}(S)$ is a continuously, densely, and compactly embedded subspace of $H^0_{\text{per}}(S)$. (A discussion of spaces of periodic functions is contained in [1].) Clearly, $(h, t)\in\mathbb{C}^{n+1}\mapsto\Phi(h, t)[\phi, v]\in\mathbb{C}$ is an analytic function for each ϕ and v in $H^1_{\text{per}}(S)$.

We start here by determining an open set $G\subset\mathbb{C}^{n+1}$ such that $\mathbb{R}^{n+1}\subset G$ and such that $\Phi(h, t)$ satisfies inequalities similar to (34) and (35) for each $(h, t)\in G$. Then we will show that, in the sense of (5), zero is not an eigenvalue of $\Phi(h, t)$ when $h\neq 0$ and $(h, t)\in\mathbb{R}^{n+1}$, but that zero is a simple eigenvalue of $\Phi(0, t)$. The conclusions of Theorems 19 and 20 in § 5 get us part of the way through the proof of Theorem 1; we must investigate further the eigenvalue problem associated to $\Phi(0, t)$.

LEMMA 4. *There exist an open set $G\subset\mathbb{C}^{n+1}$ and real-valued functions M, γ, and μ such that μ is continuous on G and for each $(h, t)\in G$, $M(h, t)>0$, $\gamma(h, t)>0$*

(i) $|\Phi(h, t)[\phi, v]|\leqq M(h, t)\|\phi\|_1\|v\|_1$ *for all ϕ and v in $H^1_{\text{per}}(S)$,*

(ii) $\gamma(h, t)\|v\|_1^2\leqq\text{Re}\,(\Phi(h, t)[v, v])+\mu(h, t)\|v\|_0^2$ *for all $v\in H^1_{\text{per}}(S)$.*

Moreover, G can be chosen so that $\mathbb{R}^{n+1}\subset G$ and so that $(\bar h, \bar t)\in G$ whenever $(h, t)\in G$.

Proof. For each $z\in\mathbb{C}^n$ and ϕ and v in $H^1_{\text{per}}(S)$, define the sesquilinear form

$$B(z)[\phi, v]=\int_S\sum_{p,q=1}^n a_{pq}(y)\frac{\partial}{\partial y_q}(\phi(y)\,e^{iz\cdot y})\frac{\partial}{\partial y_q}(\overline{v(y)}\,e^{-iz\cdot y})\,dy;$$

thus, $\Phi(h, t)[\phi, v]=B(ht)[\phi, v]+h^2\int_S a_0(y)\phi(y)\overline{v(y)}\,dy$. Whenever it is convenient in this proof, we will use $ht=\rho+i\sigma$, where ρ and σ are real n-vectors. Defining

$$\begin{aligned}F(\rho, \sigma)[\phi, v]&=B(\rho+i\sigma)[\phi, v]-B(\rho)[\phi, v]\\&=\int_S\sum_{p,q=1}^n a_{pq}(y)\Big\{\sigma_p\frac{\partial}{\partial y_q}(\phi(y)\,e^{i\rho\cdot y})\overline{v(y)}\,e^{-i\rho\cdot y}\\&\qquad-\sigma_q\phi(y)\,e^{i\rho\cdot y}\frac{\partial}{\partial y_q}(\overline{v(y)}\,e^{-i\rho\cdot y})-\sigma_q\sigma_p\phi(y)\overline{v(y)}\Big\}\,dy\end{aligned}$$

it follows, since each a_{pq} is an L_∞-function, that there exists a constant K such that

$$|F(\rho, \sigma)[\phi, v]|\leqq K\|\sigma\|(1+\|\sigma\|)\|\phi\,e^{i\rho\cdot y}\|_1\|v\,e^{i\rho\cdot y}\|_1.\tag{6}$$

In addition, there is a constant K' such that

$$|B(\rho)[\phi, v]| \leqq K'|\phi\, e^{i\rho\cdot y}|_1 |v\, e^{i\rho\cdot y}|_1.$$

Using Lemma 2 and the fact that a_0 is bounded, it follows that there exists a positive number $M(h, t)$ for each (h, t) $\mathbb{C}^{n+1}$ such that (i) is true.

Next, a consequence of (1) is that

$$B(\rho)[v, v] \geqq \gamma_1 |v\, e^{i\rho\cdot y}|_1^2$$

and therefore

$$\text{(7)} \qquad \begin{aligned} \operatorname{Re}(B(\rho+i\sigma)[v, v]) + \gamma_1\|v\|_0^2 &= B(\rho)[v, v] + \operatorname{Re}(F(\rho, \sigma)[v, v]) + \gamma_1\|v\|_0^2 \\ &\geqq (\gamma_1 - K\|\sigma\|(1+\|\sigma\|))\|v\, e^{i\rho\cdot y}\|_1^2. \end{aligned}$$

We now define G by

$$G \equiv \left\{(h, t) \in \mathbb{C}^{n+1}\colon K\|\operatorname{Im}(ht)\|(1+\|\operatorname{Im}(ht)\|) < \frac{\gamma_1}{2}\right\}$$

and set

$$\gamma(h, t) = \frac{\gamma_1}{2C_0^2(1+\|\operatorname{Re}(ht)\|)^2}$$

in which C_0 is defined in Lemma 2. Finally, setting $K'' = \|a_0\|_{L_\infty(S)}$ and using (7) and Lemma 2, we conclude that

$$\begin{aligned} \operatorname{Re}(\Phi(h, t)[v, v]) + \gamma_1\|v\|_0^2 &= \operatorname{Re}(B(ht)[v, v]) + \operatorname{Re}\left(h^2\int_S a_0(y)|v(y)|^2\, dy\right) + \gamma_1\|v\|_0^2 \\ &\leqq \gamma(h, t)\|v\|_1^2 - K''|h|^2\|v\|_0^2 \end{aligned}$$

for $(h, t) \in G$, which yields (ii) with $\mu(h, t) = K''|h|^2 + \gamma_1$. □

For each $(h, t) \in G$, we can associate to $\Phi(h, t)$ a closed operator $T(h, t)$ as in Theorem 15:

$$\Phi(h, t)[\phi, v] = (T(h, t)\phi, v)_{H^0_{\text{per}}(S)} \quad \text{for all } v \in H^1_{\text{per}}(S)$$

and for all ϕ in the domain of $T(h, t)$, which is a dense subspace of $H^1_{\text{per}}(S)$. Reference is made to $T(h, t)$ in the next few paragraphs in order to draw upon the results of § 5.

For each $(h, t) \in \mathbb{R}^{n+1}$, a direct consequence of (1) and Lemma 2 is

$$\text{(8)} \qquad \Phi(h, t)[v] \geqq \gamma_1 |v\, e^{iht\cdot y}|_1^2 + \gamma_0 h^2\|v\|_0^2 \geqq \frac{\min\{\gamma_0 h^2, \gamma_1\}}{2C_0^2(1+\|(ht\|)^2}\|v\|_1^2$$

for all $v \in H^1_{\text{per}}(S)$. If $(h, t) \in \mathbb{R}^{n+1}$ and $h \neq 0$, then the hypotheses of Lemma 3 are satisfied; hence $\Phi(h, t)[\phi, v] = \int_S w(y)\overline{v(y)}\, dy$ for all $v \in H^1_{\text{per}}(S)$, is uniquely solvable for each $w \in H^0_{\text{per}}(S)$. Consequently, zero is in the resolvent set of $T(h, t)$, and by Theorem 20, $\{(h, t) \in \mathbb{R}^{n+1}\colon h \neq 0\}$ is contained in an open set in $\mathbb{C}^{n+1}$ on which (4) is holomorphic.

Now let $h = 0$. For any $\tau \in \mathbb{R}^n$ (or $\mathbb{C}^n$), we have from the first inequality in (8) that

$$\Phi(0, \tau)[v, v] \geqq \gamma_1 |v|_1^2.$$

If zero is an eigenvalue of $\Phi(0, \tau)$ with $\psi_0 \in H^1_{\text{per}}(S)$ being an associated eigenfunction, then

$$0 = \Phi(0, \tau)[\psi_0, \psi_0] \geqq \gamma_1 |\psi_0|_1,$$

and, consequently, ψ_0 is a constant function, which depends on τ. Therefore, zero is an eigenvalue of (the associated closed operator) $T(0, \tau)$, and ψ_0 is the only eigenfunction associated to zero. There are no generalized eigenfunctions when $\tau \in \mathbb{R}^n$ because the identity $\Phi(0, \tau)[v, \phi] = \overline{\Phi(0, \tau)[\varphi, v]}$ implies, by Corollary 18, that $T(0, \tau)$ is self-adjoint.

The following conclusions can now be drawn from Theorem 20. For each $\tau \in \mathbb{R}^n$, there exists a neighborhood $G_\tau \subset G$ of $(0, \tau)$, and there exists a complex-valued function λ, analytic on G_τ, such that $\lambda(0, t) = 0$ for $(0, t) \in G_\lambda$ and such that $\lambda(h, t)$ is a simple eigenvalue of $\Phi(h, t)$ when $(h, t) \in G$. Furthermore, there exist two holomorphic functions $(h, t) \in G_\tau \mapsto P(h, t)$ and $(h, t) \in G_\tau \mapsto R_2(0, h, t)$, with values in the space of bounded linear operators that map $H^0_{\text{per}}(S)$ into $H^{(1)}_{\text{per}}(S)$, such that $P(h, t)$ projects $H^0_{\text{per}}(S)$ onto the one-dimensional eigenspace spanned by the eigenvector associated to $\lambda(h, t)$, and such that

$$\phi(\cdot, h, t) = \frac{h^2}{\lambda(h, t)} P(h, t)\mathbf{1} + h^2 R_2(0, h, t)\mathbf{1} \tag{9}$$

for each $(h, t) \in G_\tau$ for which $\lambda(h, t) \neq 0$. Here $\mathbf{1}$ is the constant function that takes on the value 1 on S. Note that $\lambda(h, t)$ is not identically zero on G_τ since zero is not an eigenvalue of $\Phi(h, \tau)$ when h is a nonzero real number; therefore, this representation of $\phi(\cdot, h, t)$ is meaningful.

Clearly, the holomorphy of $(h, t) \mapsto \phi(\cdot, h, t)$ on G_τ is completely determined by that of $h^2/\lambda(h, t)$. We will show that $h^2/\lambda(h, t)$ has an analytic continuation to $h = 0$, and that there is a suitable restriction G'_τ of G_τ, on which $\lambda(h, t) = 0$ if and only if $h = 0$. This will be done by determining part of the Taylor expansion of $\lambda(h, t)$ in powers of h about $h = 0$, where it will be seen that the coefficient of h^k is zero for $k = 0, 1$.

For the moment, we assume the existence of a function ω, analytic on G_τ, such that

$$\lambda(h, t) = h^2 \omega(h, t) \quad \text{for } (h, t) \in G_\tau. \tag{10}$$

Letting $\psi(\cdot, h, t) \in H^1_{\text{per}}(S)$ be the eigenfunction associated to $\lambda(h, t)$ as in (5), the first inequality in (8) yields

$$\gamma_0 h^2 \|(\cdot, h, t)\|_0^2 \leqq \Phi(h, t)[\psi(\cdot, h, t), \psi(\cdot, h, t)] = \lambda(h, t)\|\psi(\cdot, h, t)\|_0^2$$

for $(h, t) \in G_\tau \cap \mathbb{R}^{n+1}$. Consequently, $\omega(h, t) \geqq \gamma_0$ for $(h, t) \in G_\tau \cap \mathbb{R}^{n+1}$, and by continuity, there is an open set $G'_\tau \subset G_\tau$ such that $(G_\tau \cap \mathbb{R}^{n+1}) \subset G'_\tau$ and $\operatorname{Re}(\omega(h, t)) > 0$ for $(h, t) \in G'_\tau$. Thus $(h, t) \mapsto h^2/\lambda(h, t) = 1/\omega(h, t)$ is analytic on G'_τ, from which it follows that (9) is holomorphic on G'_τ as well. Assuming that (10) is valid, Theorem 1 is proven.

In the process of determining the Taylor expansion of $\lambda(h, t)$ in powers of h about $h = 0$, we develop a similar expansion of the eigenfunction $\psi(\cdot, h, t)$. In § 5 (see (45)), we show that $\psi(\cdot, h, t)$ can be chosen so that it depends holomorphically on $(h, t) \in G_\tau$. The Taylor expansion of $\lambda(h, t)$ and $\psi(\cdot, h, t)$ in powers of h will be obtained next, by expanding the eigenvalue equation (5) in powers of h and equating the coefficients of like powers.

Upon setting

$$\Phi_0[\phi, v] \equiv \int_S \sum_{p,q=1}^{n} a_{pq}(y) \frac{\partial \phi}{\partial y_q}(y) \overline{\frac{\partial \phi}{\partial y_p}(y)}\, dy,$$

$$\Phi_1(t)[\phi, v] \equiv i \int_S \sum_{p,q=1}^{n} a_{pq}(y) \left(\phi(y) \overline{\frac{\partial v}{\partial y_p}(y)} t_q - \frac{\partial \phi}{\partial y_q}(y) v(y) t_p \right) dy, \tag{11}$$

$$\Phi_2(t)[\phi, v] \equiv \int_S \left(\sum_{p,q=1}^{n} a_{pq}(y) t_q t_p + a_0(y) \right) \phi(y) \overline{v(y)}\, dy$$

for all ϕ and v in $H^1_{\text{per}}(S)$ and for all $t \in \mathbb{C}^n$, it follows from the definition of $\Phi(h, t)$ that

$$\Phi(h, t) = \Phi_0 + \Phi_1(t)h + \Phi_2(t)h^2. \tag{12}$$

Substituting the expansions $\lambda(h, t) = \sum_{k=0}^{n} \lambda_k(t) h^k$, $\psi(\cdot, h, t) = \sum_{k=0}^{n} \psi(\cdot, t) h^k$, and (12) into (5), equating like powers of h, and noting that $\lambda_0(t) = \lambda(0, t) = 0$, we derive the following system of equations:

$$\Phi_0[\psi_k(\cdot, t), v] = \begin{cases} 0, & k = 0, \\ \lambda_1(t) \displaystyle\int_S \psi_0(y, t) \overline{v(y)}\, dy - \Phi_1(t)[\psi_0(\cdot, t), v], & k = 1, \\ \displaystyle\sum_{l=1}^{k} \lambda_l(t) \int_S \Psi_{k-l}(y, t) \overline{v(y)}\, dy & \\ \quad - \displaystyle\sum_{l=1}^{z} \Phi_l(t)[\psi_{k-l}(\cdot, t), v], & k \geqq 2, \end{cases} \tag{13}$$

for all $v \in H^1_{\text{per}}(S)$. Successively solving the equations in (13) will yield formulas for the $\lambda_k(t)$ and $\psi_k(\cdot, t)$.

The method of solving (13) will be based on Lemma 6 below. First note that

$$\Phi_0[\phi, 1] = \Phi_0[1, \phi] = \Phi_1(t)[1, 1] = 0 \tag{14}$$

for all $\phi \in H^1_{\text{per}}(S)$ and for each $t \in \mathbb{C}^n$.

DEFINITION 5.

$$W \equiv \left\{ v \in H^1_{\text{per}}(S) : \int_S v(y)\, dy = 0 \right\}.$$

Each function $H^1_{\text{per}}(S)$ can be represented uniquely as the sum of a constant function and a function in W.

LEMMA 6. *$|\cdot|_1$ is a norm on W, and there exists a constant K such that*

$$|\Phi_0[\phi, v]| \leqq K |\phi|_1 |v|_1, \qquad \Phi_0[v, v] \geqq \gamma_1 |v|_1^2$$

for all ϕ and v in W.

Each equation in (13) is of the form

$$\Phi_0[\psi_k, v] = F_k(v) \quad \text{for all } v \in H^1_{\text{per}}(S),$$

in which F_k is a conjugate-linear form on $H^1_{\text{per}}(S)$ which depends on t; $\lambda_1(t), \cdots, \lambda_k(t)$; and $\psi_0(\cdot, t), \cdots, \psi_{k-1}(\cdot, t)$. Furthermore, F_k is bounded on $H^1_{\text{per}}(S)$. It is also bounded on W, as a result of the closed graph theorem (see (31)). A consequence of (14) is that we must ensure that $F_k(1) = 0$, which will determine $\lambda_k(t)$ uniquely. Then Lemmas 3 and 6 imply that $\psi_k(\cdot, t)$ is determined uniquely as an element in W, that is, up to an additive constant. However, the arbitrary constants in $\psi_k(\cdot, t)$ will remain essentially

arbitrary because, being an eigenfunction, $\psi(\cdot, h, t)$ is uniquely determined up to a multiplicative constant only.

THEOREM 7. *For $k \geqq 1$, define functions $\tilde{\chi}_k(\cdot, t) \in W$ according to*

$$\Phi_0[\tilde{\chi}_k(\cdot, t), v] = \begin{cases} -\Phi_1(t)[1, v], & k = 1, \\ -\Phi_1(t)[\tilde{\chi}_1(\cdot, t), v] - \Phi_2(t)[1, v], & k = 2, \\ \sum_{j=2}^{k-1} \lambda_j(t) \int_S \tilde{\chi}_{k-j}(y, t)\overline{v(y)}\, dy & \\ \quad - \sum_{j=1}^{2} \Phi_j(t)[\tilde{\chi}_{k-j}(\cdot, t), v], & k \geqq 3, \end{cases} \tag{15}$$

for all $v \in W$, where

$$\lambda_l(t) = \begin{cases} 0, & l = 1, \\ \dfrac{1}{(2\pi)^n}(\Phi_1(t)[\tilde{\chi}_1(\cdot, t), 1] + \Phi_2(t)[1, 1]), & l = 2, \\ \dfrac{1}{(2\pi)^n}(\Phi_1(t)[\tilde{\chi}_{l-1}(\cdot, t), 1] + \Phi_2(t)[\tilde{\chi}_{l-2}(\cdot, t), 1]), & l \geqq 3. \end{cases} \tag{16}$$

Next, define $\psi_l(\cdot, t) \in H^1_{\text{per}}(S)$ for $l \geqq 0$ by

$$\psi_l(\cdot, t) = \begin{cases} f_0(t), & l = 0, \\ \sum_{j=0}^{l-1} f_j(t)\tilde{\chi}_{l-j}(\cdot, t) + f_l(t), & l \geqq 1, \end{cases} \tag{17}$$

in which each f_l is a holomorphic function (in a neighborhood of $t = \tau$) and $f_0(t) \neq 0$ for all t. Then (16) *and* (17) *solve* (13).

Proof. Upon solving (13) with $k = 0$, we have that $\psi_0(\cdot, t)$ must be a constant function, which we denote by $f_0(t)$ and which we assume is nonzero for each t because $f_0(t) - \psi_0(\cdot, t) = \psi(\cdot, 0, t)$ is an eigenfunction.

In order to simplify notation, we will drop the dependence on t in the remainder of the proof.

For $k = 1$, (13) becomes

$$\Phi_0[\psi_1, v] = \lambda_1 f_0 \int_S v(y)\, dy - f_0\Phi_1[1, v] \quad \text{for all } v \in H^1_{\text{per}}(S).$$

Setting $v = 1$ and using (14) yields $0 = \lambda_1 f_0 (2\pi)^n$, which implies $\lambda_1 = 0$ because $f_0 \neq 0$. Now (13) with $k = 1$ can be reduced to

$$\Phi_0[\psi_1, v] = -f_0\Phi_1[1, v] \quad \text{for all } v \in W,$$

the solution of which is given by (17) with $l = 1$.

Substituting (16) and (17) into (13) with $k = 2$ yields

$$\Phi_0[\psi_2, v] = \lambda_2 f_0 \int_S \overline{v(y)}\, dy - (f_0\Phi_1[\tilde{\chi}_1, 1] + f_1\Phi_1[1, v]) - f_0\Phi_2[1, v]$$

for all $v \in H^1_{\text{per}}(S)$. Again, set $v = 1$ and use (14) to obtain $0 = \lambda_2 f_0 (2\pi)^n - f_0(\Phi_1[\tilde{\chi}_1, 1] + \Phi_1[1, 1])$. Since $f_0 \neq 0$, the solution to this equation is given by (16). Now (13) with $k = 2$ can be reduced to

$$\Phi_0[\psi_2, v] = -f_0(\Phi_1[\tilde{\chi}_1, v] + \Phi_1[1, v]) - f_1\Phi_1[1, v] \quad \text{for all } v \in W,$$

and the solution to this equation is given in (17).

An induction argument, similar to the one we will use in the proof of Theorem 8, establishes the remaining formulas in (16) and (17). □

As we noted earlier, the arbitrary nature of the constants $f_l(t)$ can be traced to the fact that the eigenfunction $\psi(\cdot, h, t)$ is determined uniquely, up to a multiplicative constant, only. To see this, let $c(h, t) = \sum_{k=0}^{\infty} c_k(t)h^k$ be analytic in h and t, with $c_0(t) \neq 0$, and define

$$f_k^*(t) = \sum_{l=0}^{k} p^{-l} c_l(t) f_{k-l}(t), \qquad k \geq 0,$$

$$\psi_k^*(\cdot, t) = \begin{cases} f_0^*(t), & k = 0, \\ \sum_{j=0}^{k-1} f_j^*(t)\tilde{\chi}_{k-j}(\cdot, t) + f_k^*(t), & k \geq 1. \end{cases}$$

Then $\sum_{k=0}^{\infty} \psi_k^*(\cdot, t)h^k$ is the power series expansion of $c(h, t)\psi(\cdot, h, t)$; clearly the form of ψ_k^* is the same as that of ψ_k.

We have shown that (10) is correct, and consequently, the proof of Theorem 1 is complete.

4. Expansion in powers of h. The expansion of $\phi(\cdot, h, t)$ in powers of h can be determined formally by expanding (3) in powers of h and equating like powers. This formal process is valid because $h \mapsto \phi(\cdot, h, t) \in H^1_{\text{per}}(S)$ is holomorphic at $h = 0$ for each $t \in \mathbb{C}^n$ such that $(0, t) \in \hat{G}$ (see Theorem 1), and because $\Phi(h, t)[\phi, v]$ is a polynomial in h and t for fixed ϕ and v in $H^1_{\text{per}}(S)$. By substituting

$$\phi(\cdot, h, t) = \sum_{k=0}^{\infty} \phi_k(\cdot, t)h^k \tag{18}$$

and (12) into (3), we obtain the following system of equations for the coefficients $\phi_k(\cdot, t)$.

$$\Phi_0[\phi_k(\cdot, t), v] = \begin{cases} 0, & k = 0, \\ \Phi_1(t)[\phi_0(\cdot, t), v], & k = 1, \\ \int_S v(y)\, dy - \Phi_1(t)[\phi_{k-1}(\cdot, t), v] - \Phi_2(t)[\phi_{k-2}(\cdot, t), v], & k = 2, \\ -\Phi_1(t)[\phi_{k-1}(\cdot, t), v] - \Phi_2(t)[\phi_{k-2}(\cdot, t), v], & k \geq 3, \end{cases} \tag{19}$$

for all $v \in H^1_{\text{per}}(S)$. The radius of convergence of (18) depends on t, and each coefficient $\phi_k(\cdot, t)$ is in $H^1_{\text{per}}(S)$ and depends holomorphically on t.

The method of determining each ϕ_k is similar to that used in the proof of Theorem 7 to determine the Taylor expansions of $h \mapsto \lambda(h, t)$ and $h \mapsto \psi(\cdot, h, t)$. Recall that W is the subspace of $H^1_{\text{per}}(S)$ of functions that have an average value of zero. A consequence of (14) is that the right-hand side of (19) must be equal to zero when $v = 1$. On the other hand, restricting v to be in W, Lemmas 3 and 6, applied to (19), uniquely determine $\phi_k(\cdot, t)$ as an element in W (i.e., up to an additive constant), in terms of $\phi_{k-1}(\cdot, t)$ and $\phi_{k-2}(\cdot, t)$. Then $\phi_k(\cdot, t)$ becomes uniquely defined as an element in $H^1_{\text{per}}(S)$ by requiring the right-hand side of the equation for $\phi_{k+2}(\cdot, t)$ in (19) to be zero when $v = 1$.

THEOREM 8. *For each $k \geq 1$ define $\chi_k(\cdot, t) \in W$ to be the solution of*

$$\Phi_0[\chi_k(\cdot, t), v] = \begin{cases} -\Phi_1(t)[1, v], & k = 1, \\ -\Phi_1(t)[\chi_1(\cdot, t), v] - \Phi_2(t)[1, v], & k = 2, \\ -\Phi_1(t)[\chi_{k-1}(\cdot, t), v] - \Phi_2(t)[\chi_{k-2}(\cdot, t), v], & k \geq 3 \end{cases} \tag{20}$$

for all $v \in W$, and for each $k \geqq 0$ define $g_k(t) \in \mathbb{C}$ by

(21)
$$g_k(t) = \begin{cases} \dfrac{(2\pi)^n}{\Phi_1(t)[\chi_1(\cdot, t), 1] + \Phi_2(t)[1, 1]}, & k = 0, \\ -\dfrac{g_0(t)}{(2\pi)^n} \sum_{j=0}^{k-1} g_j(t)(\Phi_1(t)[\chi_{k+1-j}(\cdot, t), 1] + \Phi_2(t)[\chi_{k-j}(\cdot, t), 1]), & k \geqq 1. \end{cases}$$

Then the coefficient of h^k in (18) *is given by*

(22)
$$\phi_k(\cdot, t) = \begin{cases} g_0(t), & k = 0, \\ \sum_{j=0}^{k-1} g_j(t)\chi_{k-j}(\cdot, t) + g_k(t), & k \geqq 1. \end{cases}$$

Proof. Throughout this proof we will suppress all dependence upon t. First, each χ_k is well defined in W by (20) because of Lemmas 3 and 6 and because each right-hand side in (20) is a bounded conjugate-linear form on W (see (30) and (31)).

It follows immediately from (19) with $k = 0$ that ϕ_0 is a constant function, which we denote by g_0. For $k = 1$ in (19), we now have

$$\Phi_0[\phi_1, v] = -g_0\phi_1[1, v] \quad \text{for all } v \in H^1_{\text{per}}(S).$$

Since $\Phi_1[1, 1] = 0$ (see (14)), the solution ϕ_1 has the form of (22); χ_1 is defined by (20), but g_0 and g_1 are arbitrary constants.

We next consider $k = 2$ in (19), and substituting (22), we obtain

(23)
$$\Phi_0[\phi_2, v] = \int_S \overline{v(y)}\, dy - (g_0\Phi_1[\chi_1, v] + g_1\Phi_1[1, v]) - g_0\Phi_2[1, v] \quad \text{for all } v \in H^1_{\text{per}}(S).$$

Setting $v = 1$ and using (14) yields

$$0 = \Phi_0[\Phi_2, 1] = (2\pi)^n - g_0(\Phi_1[\chi_1, 1] + \Phi_2[1, 1]).$$

Solving for g_0 yields (21) with $k = 0$. On the other hand, requiring v to be in W, and using (20), gives

$$\begin{aligned} \Phi_0[\phi_2, v] &= -g_0(\Phi_1[\chi_1, v] + \Phi_2[1, v]) - g_1\Phi_1[1, v] \\ &= g_0\Phi_0[\chi_2, v] + g_1\Phi_0[\chi_1, v], \end{aligned}$$

which can be solved easily for ϕ_2 as a function in W. Thus, ϕ_0 is completely determined as in (22), whereas ϕ_1 and ϕ_2 have the form of (22); we have yet to show that g_1 and g_2 have been correctly defined.

Now let $k \geqq 3$, and assume that $\phi_0, \cdots, \phi_{k-3}$ are given by (22), and that ϕ_{k-2} and ϕ_{k-1} have the form of (22). That is, we are certain that $g_0, \cdots, g_{k-3}$ are correctly defined in (21), but are not sure about g_{k-2} and g_{k-1}. We wish to show that g_{k-2} is correctly defined in (21) and that ϕ_k has the form of (22). By our assumptions, (19) becomes

$$\begin{aligned} \Phi_0[\phi_k, v] = -\sum_{j=0}^{k-3} g_j(\Phi_1[\chi_{k-1-j}, v] + \Phi_2[\chi_{k-2-j}, v]) \\ - g_{k-2}(\Phi_1[\chi_1, v] + \Phi_2[1, v]) - g_{k-1}\Phi_1[1, v]. \end{aligned}$$

Setting $v = 1$ yields

$$0 = \Phi_0[\phi_k, 1] = -\sum_{j=0}^{k-3} g_j(\Phi_1[\chi_{(k-2)+1-j}, v] + \Phi_2[\chi_{(k-2)-j}, 1]) - \frac{(2\pi)^n}{g_0} g_{k-2},$$

which can be solved for g_{k-2}, and thus obtaining (21). Finally, upon requiring v to be in W, it follows from (20) that ϕ_k has the form given in (22). □

Next, we sufficiently investigate the properties of the expansion of $\phi(\cdot, h, t)$ in powers of h to be able to prove Lemma 12 in [8]. The results are stated here in Theorems 9 and 11.

We begin by determining the dependence on t of $\chi_1(\cdot, t)$. Expanding the right-hand side of (20) with $k=1$, according to (11) yields

$$\Phi_0[\chi_1(\cdot, t), v] = -i \sum_{q=1}^{n} \left(\int_S \sum_{p=1}^{n} a_{pq}(y) \overline{\frac{\partial v}{\partial y_q}(y)}\, dy \right) t_q$$

for all $v \in W$. Now define $\chi_{1;q} \in W$, for each $q = 1, \cdots, n$, to be the unique solution (cf. Lemmas 3 and 6) of

$$\Phi_0[\chi_{1;q}, v] = \int_S \sum_{p=1}^{n} a_{pq}(y) \overline{\frac{\partial v}{\partial y_q}(y)}\, dy \quad \text{for all } v \in W. \tag{24}$$

Consequently,

$$-\chi_1(\cdot, t) = i \sum_{q=1}^{n} \chi_{1;q} t_q. \tag{25}$$

Note that $\chi_{1;q}$ is a real-valued function because the same is true for each a_{pq}. Furthermore, it follows from (24) and the definition of Φ_0 that

$$\Phi_0[\chi_{1;q} + y_q, v] = 0 \quad \text{for all } v \in W. \tag{26}$$

The following formula for $g_0(t)$ can be easily obtained by substituting (11) and (25) into (21):

$$g_0(t) = \frac{1}{\sum_{p,q=1}^{n} A_{pq} t_q t_p + A_0}, \tag{27}$$

where

$$\begin{aligned} A_0 &\equiv \frac{1}{(2\pi)^n} \int_S a_0(y)\, dy, \\ A_{pq} &\equiv \frac{1}{(2\pi)^n} \int_S \left(a_{pq}(y) + \sum_{r=1}^{n} a_{pr}(y) \frac{\partial \chi_{1;q}}{\partial y_r}(y) \right) dy. \end{aligned} \tag{28}$$

THEOREM 9. *$A_0 \in \mathbb{R}$, $A_{pq} \in \mathbb{R}$, $A_{pq} = A_{qp}$, and $0 < g_0(t) \leqq 1/(\gamma_1 \|t\|^2 + \gamma_0)$ for $t \in \mathbb{R}^n$.*

Proof. A_0 and $\{A_{pq} : p, q = 1, \cdots, n\}$ are real numbers because each integrand in (28) is a real-valued function. It follows from the definition of Φ_0 and from the formula for A_{pq} that

$$A_{pq} = \frac{1}{(2\pi)^n} \Phi_0[\chi_{1;q} + y_q, y_p];$$

and upon using (26) with $v = \chi_{1;p}$ we obtain

$$A_{pq} = \frac{1}{(2\pi)^n} \Phi_0[\chi_{1;q} + y_q, \chi_{1;p} + y_p] \quad \text{for all } p, q = 1, \cdots, n. \tag{29}$$

The symmetry of A_{pq} follows from (29) (and (11)), since symmetry conditions are imposed on the coefficients a_{pq}, and since each function involved in (29) is real valued.

An immediate consequence of (1) and (28) is $A_0 \geqq \gamma_0$. Next, define $\xi(y, t) = \sum_{q=1}^{n} t_q y_q$. Then (25), (26), Lemma 6, and the fact that $\chi_1(\cdot, t)$ is a periodic function imply

$$\begin{aligned}
\sum_{p,q=1}^{n} A_{pq} t_q t_p &= \frac{1}{(2\pi)^n} \Phi_0[-i\chi_1(\cdot, t) + \xi(\cdot, t), -i\chi_1(\cdot, t) + \xi(\cdot, t)] \\
&\geqq \frac{\gamma_1}{(2\pi)^n} |-i\chi_1(\cdot, t) + \xi(\cdot, t)|_1^2 \\
&= \frac{\gamma_1}{(2\pi)^n} \int_S \sum_{p=1}^{n} \left| -i \frac{\partial \chi_1}{\partial y_p}(y, t) + t_p \right|^2 dy \\
&= \frac{\gamma_1}{(2\pi)^n} \left\{ |\chi_1(\cdot, t)|_1^2 + 2 \sum_{p=1}^{n} t_p \int_S \operatorname{Im}\left(\frac{\partial \chi_1}{\partial y_p}(y, t) \right) dy + (2\pi)^n \|t\|^2 \right\} \\
&\geqq \gamma_1 \|t\|^2.
\end{aligned}$$

Then $1/(g_0(t)) \geqq \gamma_1 \|t\|^2 + \gamma_0$ follows from (27). □

Next we prove Lemma 10 below.

LEMMA 10. *There are positive constants η and θ, which are independent of $t \in \mathbb{R}^n$ such that*

$$\|\phi_k(\cdot, t)\|_1 \leqq \eta g_0(t) \theta^k (1 + \|t\|)^k \quad \textit{for each } k \geqq 0.$$

Proof. After stating a few preliminary results, the proof is presented in three steps. First, an upper bound for $|\chi_k(\cdot, t)|_1$ is derived from (20). This result is then used with (21) in order to obtain an upper bound on $|g_k(t)|$. Finally these two bounds and (22) will give an upper bound on $\|\phi_k(\cdot, t)\|_1$.

It follows from (11) that there is a constant c_1 such that

$$|\Phi_k(t)[\phi, v]| \leqq c_1 (1 + \|t\|)^k \|\phi\|_1 \|v\|_1 \quad \text{for } k = 1, 2, \tag{30}$$

because the coefficients a_0 and a_{pq} are L_∞-functions. The closed graph theorem implies that there is a constant c_2, which we take to be larger than $(2\pi)^{n/2}$, such that

$$\|v\|_1 \leqq c_2 |v|_1 \quad \text{for all } v \in W. \tag{31}$$

We now have from (20) that

$$|\Phi_0[\chi_k(\cdot, t), v]| \leqq \begin{cases} c_1 c_2^2 (1 + \|t\|) |v|_1, & k = 1, \\ c_1 c_2^2 \{(1 + \|t\|) |\chi_1(\cdot, t)|_1 + (1 + \|t\|)^2\} |v|_1, & k = 2, \\ c_1 c_2^2 \sum_{j=1}^{2} (1 + \|t\|)^j |\xi_{k-j}(\cdot, t)|_1 |v|_2, & k \geqq 3. \end{cases}$$

Lemmas 3 and 6 imply

$$|\chi_k(\cdot, t)|_1 \leqq \begin{cases} c_e (1 + \|t\|), & k = 1, \\ c_3 (|\chi_1(\cdot, t)|_1 + (1 + \|t\|))(1 + \|t\|), & k = 2, \\ c_3 (|\chi_{k-1}(\cdot, t)|_1 + (1 + \|t\|) |\chi_{k-2}(\cdot, t)|_1)(1 + \|t\|), & k \geqq 3, \end{cases}$$

in which $c_3 \equiv c_1 c_2^2 / \gamma_1$. An induction argument proves

$$|\chi_k(\cdot, t)|_1 \leqq (c_3 + 1)^k (1 + \|t\|)^k \quad \text{for } k = 1, 2, \cdots. \tag{32}$$

Next, using (30)–(32) in (21) yields

$$|g_k(t)| \leqq \frac{g_0(t)}{(2\pi)^n} \sum_{j=0}^{k-1} |g_j(t)| c_1 c_2^2 (1+\|t\|) \cdot (|\chi_{k+1-j}(\cdot, t)|_1 + (1+\|t\|)|\chi_{k-j}(\cdot, t)|_1)$$

$$\leqq \frac{c_1 c_2^2 (c_3+2)}{(2\pi)^n} g_0(t)(1+\|t\|)^2 \sum_{j=0}^{k-1} |g_j(t)|(c_3+1)^{k-j}(1+\|t\|)^{k-j}$$

for $k \geqq 1$. A consequence of Theorem 9 is that this last inequality can be rewritten as

$$|g_k(t)| \leqq c_4 \sum_{j=0}^{k-1} |g_j(t)|(c_3+1)^{k-j}(1+\|t\|)^{k-j} \quad \text{for } k \geqq 1,$$

where

$$c_4 = \frac{2c_1 c_2^2 (c_3+2)}{(2\pi)^n \min\{\gamma_0, \gamma_1\}}.$$

Another induction argument then proves

$$|g_k(t)| \leqq g_0(t)(c_3+1)^k (c_4+1)^k (1+\|t\|)^k \quad \text{for } k \geqq 0. \tag{33}$$

Finally, substitute (32) and (33) into (22) to obtain

$$\|\phi_k(\cdot, t)\|_1 \leqq \sum_{j=0}^{k-1} g_0(t) c_2 (c_3+1)^k (c_4+1)^j (1+\|t\|)^k + g_0(t) c_2 (c_3+1)^k (c_4+1)^j (1+\|t\|)^k$$

$$\leqq c_2 g_0(t)(c_3+1)^k (c_4+2)^k (1+\|t\|)^k,$$

which finishes the proof. □

By computing a majorizing series for (18), the next theorem is a consequence of Lemma 10.

THEOREM 11. *Let η and θ be given as in Lemma* 17, *and suppose $h>0$ and $t \in \mathbb{R}^n$ satisfy $\theta(1+\|t\|)h < 1$. Then*

$$\|\phi(\cdot, h, t)\|_1 \leqq \frac{\eta g_0(t)}{1-\theta(1+\|t\|)h},$$

$$\left\| \phi(\cdot, h, t) - \sum_{j=0}^{k} \phi_j(\cdot, t) h^j \right\|_1 \leqq \frac{\eta \theta^{k+1} g_0(t)}{1-\theta(1+\|t\|)h} (1+\|t\|)^{k+1} h^{k+1}$$

for $k \geqq 0$.

5. Appendix. In this section we develop some of the theory that was used in § 3 when making some of our analyticity claims. The main goals here are Theorems 19 and 20. Throughout this section we make the following assumptions. Let V and H be separable, complex Hilbert spaces in which V is a compactly and continuously embedded dense subspace of H. We denote the associated inner products by $(\cdot, \cdot)_V$ and $(\cdot, \cdot)_H$, and the associated norms by $\|\cdot\|_V$ and $\|\cdot\|_H$. Let G be an open set in $\mathbb{C}^n$, and consider a family of sesquilinear forms $\Phi(z): V \times V \to \mathbb{C}$, defined for each $z \in G$. Suppose that there are real-valued functions M, γ, and μ defined on G such that $M(z) > 0$ and $\gamma(z) > 0$ for $z \in G$, μ is continuous on G, and for each $z \in G$

$$|\Phi(z)[\phi, v]| \leqq M(z)\|\phi\|_V \|v\|_V \quad \text{for all } \phi \text{ and } v \text{ in } V, \tag{34}$$

$$\gamma(z)\|v\|_V^2 \leqq \operatorname{Re}(\Phi(z)[v, v]) + \mu(z)\|v\|_H^2 \quad \text{for all } v \in V. \tag{35}$$

Furthermore, suppose that $z \mapsto \Phi(z)[\phi, v]$ is analytic on G, for each ϕ and v in V.

For a given $w \in H$, we want to determine the dependence on z, in particular situations, of $\phi(z) \in V$, which satisfies

$$\Phi(z)[\phi(z), v] = (w, v)_H \quad \text{for all } v \in V.$$

In so doing, we will consider the eigenvalue problem: Seek $\lambda(z) \in \mathbb{C}$ and $\psi(z) \in V$ such that

$$\Phi(z)[\psi(z), v] = \lambda(z)(\psi(z), v)_H \quad \text{for all } v \in V.$$

Let $a \in G$. If zero is not an eigenvalue of $\Phi(a)$, then we will show that $\Phi(z)$ exists for, and depends analytically on, z in a neighborhood of a. If zero is a "simple" eigenvalue of $\Phi(a)$, then we will show that λ, with $\lambda(a) = 0$, is analytic in a neighborhood of a, and we will derive an expression for $\phi(z)$, exhibiting its dependence on $\lambda(z)$.

When z is one complex variable, many of the results of this section can be found in [5]. An important difference is that we have imposed alternate conditions ((34) and (35)) on $\Phi(z)$. This allows us to conclude that ϕ is analytic with values in V, rather than in H, which is the conclusion in [5].

At this point we want to give a definition of analyticity, or holomorphy, for Banach space-valued functions of several complex variables. Several definitions are possible. In a setting more general than Banach spaces, three definitions are stated and proven to be equivalent, in Chapter III of [4]. First an open polydisc $\Delta(a, \rho)$ in $\mathbb{C}^n$ with center a and multiradius $\rho \equiv (\rho_1, \cdots, \rho_n)$, where $0 < \rho_j < \infty$, is defined by

$$\Delta(a, \rho) \equiv \{z \in \mathbb{C}^n : |z_j - a_j| < \rho_j \text{ for } j = 1, \cdots, n\}.$$

DEFINITION 12. Let W be a Banach space, and recall that G is an open set in $\mathbb{C}^n$. A function $w : G \to W$ is analytic, or holomorphic, if for each $a \in G$ there is a polydisc $\Delta(a, \rho) \subset G$ and a set of coefficients $\{w_\alpha(a) : \alpha \text{ is a multi-index}\} \subset W$ such that $\sum_{0 \leq |\alpha|} w_\alpha(a)(z-a)^\alpha$ converges in W to $w(z)$ for each $z \in \Delta(a, \rho)$.

We will have several occasions in which the next two lemmas will be used. When $n = 1$, proofs can be found in [5], and for the general case they are proved in [7]. Let H_1 and H_2 be two separable, complex Hilbert spaces and denote the inner product on H_2 by $(\cdot, \cdot)_2$. Denote the space of bounded linear operators mapping H_1 into H_2 by $B(H_1, H_2)$.

LEMMA 13. *Let $T(z) \in B(H_1, H_2)$ for each $z \in G$. The following statements are equivalent:*

(i) *$T : G \to B(H_1, H_2)$ is holomorphic;*

(ii) *$T(\cdot)\phi : G \to H_2$ is holomorphic for each $\phi \in H_1$;*

(iii) *$(T(\cdot)\phi, v)_2 : G \to \mathbb{C}$ is holomorphic for each $\phi \in H_1$ and $v \in H_2$.*

LEMMA 14. *Suppose $T : G \to B(H_1, H_2)$ is holomorphic, and let $a \in G$. If $T(a)^{-1} \in B(H_2, H_1)$, then there exists a neighborhood $G_a \subset G$ of a such that $T(z)^{-1}$ exists for $z \in G_1$ and $T(\cdot)^{-1} : G_1 \to B(H_2, H_1)$ is holomorphic.*

We are now ready to state and prove the results on which the main theorems of this section are based. We begin by showing that there exists a closed operator $T(z) : D(T(z)) \subset V \to H$ such that $\Phi(z)[\phi, v] = (T(z)\phi, v)_H$ for all $\phi \in D(T(z))$ and $v \in V$. The next theorem gives one way of constructing such an operator, which will be convenient for us in what follows. Other forms of this representation theorem can be found in [5] and [6]. (See also [1] and [9].)

Throughout this section, we will denote the domain and range of an operator T by $D(T)$ and $R(T)$. Also, in the next theorem only, the dependence on z, as we have stated so far, is inconsequential, and so we drop it.

THEOREM 15. *Let $\Phi: V \times V \to \mathbb{C}$ be a sesquilinear form for which there exist real constants $M > 0$, $\gamma > 0$, and μ such that*

$$|\Phi[\phi, v]| \leqq M \|\phi\|_V |v\|_V \quad \text{for all } \phi \text{ and } v \text{ in } V, \tag{34'}$$

$$\phi \|v\|_V^2 \leqq R(\Phi[v, v]) + \mu \|v\|_H^2 \quad \text{for all } v \in V. \tag{35'}$$

Then there is a unique closed operator $T: V \to H$ such that

(i) *$D(T)$ is dense in V;*

(ii) *$\Phi[\phi, v] = (T\phi, v)_H$ for all $\phi \in D(T)$ and $v \in V$;*

(iii) *given $\phi \in V$ and $w \in H$, if $\Phi[\phi, v] = (w, v)_H$ for all v in a dense subspace of V, then $\phi \in D(T)$ and $T\phi = w$.*

Proof. Uniqueness follows from (iii); let there be another closed operator S such that $\Phi[\phi, v] = (S\phi, v)_H$ for all $\phi \in D(S)$ and $v \in V$. Then $\phi \in D(T)$ and $T\phi = S\phi$.

Since the embedding of V in H is continuous, it follows from the Riesz representation theorem that there is a linear operator $F \in B(H, V)$ such that

$$(w, v)_H = (Fw, v)_V \quad \text{for all } w \in H \text{ and } v \in V.$$

Furthermore, F is a 1-1 map, and $R(F)$ is dense in V.

Next, it follows from (34') and (35') that $\Phi[\cdot, \cdot] + \mu(\cdot, \cdot)_H$, as a sesquilinear form on $V \times V$, satisfies the hypotheses of Lemma 3. From the discussion that follows Lemma 3, it follows that there exists an operator $A_\mu \in B(V, V)$ such that $A_\mu^{-1} \in B(V, V)$ and $\Phi[\phi, v] + \mu(\Phi, v)_H = (A_\mu \phi, v)_V$ for all ϕ and v in V. Now define

$$D(T) \equiv \{\phi \in V: A_\mu \phi \in R(F)\}$$

and set

$$T = (F^{-1} A_\mu - \mu I)_{D(T)},$$

in which I is the identity operator on H.

Clearly the choice of μ in (35') is not unique. That the definitions of $D(T)$ and T are independent of μ can be seen, as follows. Let $\mu' \neq \mu$ be a real number for which (35') remains valid when μ is replaced by μ'. (The value of $\gamma > 0$ makes no difference.) The definitions of A_μ and $A_{\mu'}$ imply

$$(A_{\mu'} \phi, v)_V - \mu'(F\phi, v)_V = (A_\mu \phi, v)_V - \mu(F\phi, v)_V$$

for all ϕ and v in V. Thus

$$(A_{\mu'} - \mu' F)\phi = (A_\mu - \mu F)\phi \quad \text{for all } \phi \in V,$$

from which it follows that $A_{\mu'} \phi \in R(F)$ if and only if $A_\mu \phi \in R(F)$, and that

$$T = (F^{-1} A_\mu - \mu I)|_{D(T)} = (F^{-1} A_{\mu'} - \mu' I)|_{D(T)}.$$

Since A_μ is an isomorphism on V and $R(F)$ is dense in V, it follows that $D(T)$ is dense in V, which proves (i).

Statement (ii) follows from the definitions of A_μ and T.

To prove (iii), let $\phi \in V$ and $w \in H$ such that $\Phi[\phi, v] = (w, v)_H$ for all v in a dense subset of V. Then

$$(A_\mu \phi - \mu F\phi, v)_V = \Phi[\phi, v] = (W, v)_H = (Fw, v)_V$$

for all v in a dense subset of V, which implies $A_\mu \phi - \mu F\phi = Fw$ so that $\phi \in D(T)$ and $T\phi = w$.

Finally, $T: D(T) \subset V \to H$ is a closed operator because $A_\mu^{-1} F \in B(H, V)$. □

Noting (34) and (35), Theorem 15 implies the existence of a unique closed operator $T(z): V \to H$ for each $z \in G$, such that $D(T(z))$ is dense in v; $\Phi(z)[\phi, v] = (T(z)\phi, v)_H$ for all $\phi \in D(T(z))$ and $v \in V$; and for any $w \in H$,

$$T(z)\phi = w \quad \text{if and only if } \phi(z)[\phi, v] = (w, v)_H \text{ for all } v \text{ in a dense subset of } V. \tag{36}$$

Since $T(z): D(T(z)) \subset V \to H$ is closed, the resolvent operator $R(\zeta, z) \equiv (T(z) - \zeta)^{-1}$ belongs to $B(H, V)$ for each $\zeta \in \rho(T(z))$, the resolvent set of $T(z)$. A consequence of (34)-(36) and Lemma 3 is that $\rho(T(z))$ contains $\{\zeta \in \mathbb{C}: -\mathrm{Re}\, \zeta \geqq \mu(z)\}$. A standard result in the spectral theory of operators is that $\rho(T(z))$ is an open set in $\mathbb{C}$. In Theorem 17 below, we will prove that

$$\mathcal{G} \equiv \{(\zeta, z) \in \mathbb{C}^{n+1}: \zeta \in \rho(T(z)) \text{ and } z \in G\} \tag{37}$$

is an open set also, and that $R: \mathcal{G} \to B(H, V)$ is holomorphic.

First we prove a preliminary result.

LEMMA 16. *For each $a \in G$, if $\zeta \in \rho(T(a))$ then there exists a neighborhood $G_{a\zeta} \subset G$, of a such that*

(i) *$\zeta \in \rho(T(z))$ and $R(\zeta, z) \in B(H, V)$ for all $z \in G_{a\zeta}$;*

(ii) *$z \mapsto R(\zeta, z) \in B(H, V)$ is holomorphic on $G_{a\zeta}$.*

Proof. The continuity of μ allows us to choose a neighborhood $G_a \subset G$ of a, and a number $\mu_a \geqq \mu(z)$ for $z \in G_a$; that is,

$$\gamma(z)\|v\|_V^2 \leqq \mathrm{Re}\,(\Phi(z)[v, v]) + \mu_a \|v\|_H^2$$

for all $v \in V$ and $z \in G_a$. We will first prove the lemma for $\zeta = -\mu_a$ and then use the identity

$$(T(z) - \zeta) r(-\mu_a, z) = I_H - (\zeta + \mu_a) R(-\mu_a, z) \quad \text{for } z \in G_a, \tag{38}$$

to prove the lemma for arbitrary $\zeta \in \rho(T(a))$.

As in the proof of Theorem 15, associate an operator $A_a(z) \in B(V, V)$ to $\Phi(z)$ such that

$$\Phi(z)[\phi, v] + \mu_a(\phi, v)_H = (A_a(z)\phi, v)_V \tag{39}$$

for all ϕ and v in V. It was shown there that while $A_a(z)$ depends on the choice of μ_a, $A_a(z) - \mu_a F$ does not depend on μ_a, where $F \in B(H, V)$ is defined by $(Fw, v)_V = (w, v)_H$ for all $w \in H$ and $v \in V$. Furthermore, $D(T(z)) = \{\phi \in V: A_a(z)\phi \in R(F)\}$ and $T(z) = (F^{-1}A_a(z) - \mu_a)|_{D(T(z))}$ for $z \in G_a$. Consequently, $T(z) + \mu_a = F^{-1}A_a(z)|_{D(T(z))}$ is a one-to-one map of $D(T(z))$ onto H, and it follows that $-\mu_a \in \rho(T(z))$ whenever $z \in G_1$. According to Lemma 13 and the hypothesis that $z \mapsto \Phi(z)[\phi, v]$ is analytic, it follows from (39) that $A_a: G_a \to B(V, V)$ is holomorphic. Since $A_a(z)^{-1} \in B(V, V)$ for each z in G_a, Lemma 14 implies that $A_a(\cdot)^{-1}: G_1 \to B(V, V)$ is holomorphic. Therefore $z \mapsto R(-\mu_a, z) = A_a(z)^{-1}F \in B(H, V)$ is holomorphic on G_a.

Now, $\zeta \in \rho(T(a))$. When $z = a$, the left-hand side of (38) is a one-to-one map of H onto H; hence its inverse exists and belongs to $B(H, H)$. As a function of z with values in $B(H, H)$, $R(-\mu_a, z)$ is holomorphic on G_a because it is holomorphic as a function with values in $B(H, V)$ and because the embedding of V into H is bounded. Thus the right-hand side of (38), as a function of z with values in $B(H, H)$, is

holomorphic on G_a, and its inverse belongs to $B(H, H)$ when $z = a$. According to Lemma 21, there is a neighborhood $G_{a\zeta} \subset G_a$ of a on which

$$z \mapsto (I - (\zeta + \mu_a)R(-\mu_a, z))^{-1} \in B(H, H)$$

is holomorphic. Therefore, $\zeta \in \rho(T(z))$ for $z \in G_{a\zeta}$, and the holomorphy of

$$z \in G_{a\zeta} \mapsto R(\zeta, z) = R(-\mu_a, z)(I - (\zeta + \mu_a)R(-\mu_a, z))^{-1} \in B(H, V)$$

follows.

THEOREM 17. *The set $\mathcal{G}$, defined by* (37), *is open in $\mathbb{C}^{n+1}$, and $(\zeta, z) \mapsto R(\zeta, z) \in B(H, V)$ is holomorphic on $\mathcal{G}$.*

Proof. Let $(\eta, a) \in \mathcal{G}$. This proof is essentially a careful repetition of the second part of Lemma 16, with η replacing $-\mu_a$. Lemma 16 implies that a neighborhood $G_{a\eta} \subset G$ of a can be found such that $\eta \in \rho(T(z))$ for $z \in G_{a\eta}$, and $z \mapsto R(\eta, z) \in B(H, V)$ is holomorphic on $G_{a\eta}$. Analogous to (38), we have

$$(T(z) - \zeta)R(\eta, z) = I - (\zeta - \eta)R(\eta, z) \quad \text{for } z \in G_{a\eta}. \tag{40}$$

Now the right-hand side of (40), as a function of (ζ, z), with values in $B(H, H)$, is holomorphic on $\mathbb{C} \times G_{a\eta}$ and takes on the value I when $(\zeta, z) = (\eta, a)$. A consequence of Lemma 14 is that there is a neighborhood $\mathcal{G}_{\eta a} \subset \mathbb{C} \times G_{a\eta}$ of $(h\ a)$ on which $(\zeta, z) \mapsto (I - (\zeta - \eta)R(\eta, z))^{-1} \in B(H, H)$ is holomorphic. Hence, $\zeta \in \rho(T(z))$ for $(\zeta, z) \in \mathcal{G}_{\eta a}$, which implies that $\mathcal{G}$ is open. It follows that

$$(\zeta, z) \mapsto R(\zeta, z) = R(\eta, z)(I - (\zeta - \eta)R(\eta, z))^{-1} \in B(H, V)$$

is holomorphic on $\mathcal{G}_{\eta a}$. □

The next corollary states a condition on the family $\{\Phi(z): z \in G\}$ which guarantees that the operator $T(z)$ is self-adjoint if $z \in G \cap \mathbb{R}^n$.

COROLLARY 18. *Suppose that $\bar{z} = (z_1, \cdots, \bar{z}_n) \in G$ whenever $z \in G$. If $\Phi(z)[v, \phi] = \Phi(\bar{z})[\phi, v]$ for all ϕ and v in V and for $z \in G$, then $T(z)^* = T(z)$ for all $z \in G$, in which $T(z)^*$ is the adjoint of $T(z)$ as an operator on H.*

Note that $R(\zeta, z)$ is compact as an operator on H, when $\zeta \in \rho(T(z))$, because $R(\zeta, z) \in B(H, V)$ and V is compactly embedded in H by hypothesis. Consequently, the spectrum of $T(a)$ consists entirely of eigenvalues that have finite multiplicity and no finite accumulation point.

Recall that given $w \in H$, we want to determine the existence and the dependence upon z of the solution $\phi(z) \in V$ of

$$\Phi(z)[\phi(z), v] = (w, v)_H \quad \text{for all } v \in V.$$

It follows from (36) that this is equivalent to solving $T(z)\phi(z) = w$. When zero is not an eigenvalue $\phi(z) = R(0, z)w$. Lemma 16 yields the following theorem.

THEOREM 19. *$\phi: \{z \in G: 0 \in \rho(T(z))\} \to V$ is holomorphic.*

When zero is a simple eigenvalue, we have the following result.

THEOREM 20. *Let $a \in G$ and suppose zero is a simple eigenvalue of $T(a)$. Then there exists a neighborhood $G_a \subset G$ of a and two functions λ and $z \mapsto P(z) \in B(H, V)$, which are holomorphic on G_a, such that $\lambda(a) = 0$, $\lambda(z)$ is a simple eigenvalue of $T(z)$, and $P(z)$ projects H onto the one-dimensional eigenspace that corresponds to $\lambda(z)$. Furthermore, there exists another holomorphic function $z \in G_a \mapsto R_2(0, z) \in B(H, V)$ such that*

$$\phi(z) = \frac{1}{\lambda(z)} P(z)w + R_2(0, z)w \tag{41}$$

for all $z \in G_a$ for which $\lambda(z) \neq 0$.

The remainder of this section will be devoted to the proof of Theorem 20. The theory concerning the eigenvalue problem associated to $T(z)$ is well developed (cf. [5]). In fact, the form of $\phi(z)$ in (41) is a direct consequence of that theory. Here we repeat many of these ideas in the process of proving the conclusions about analyticity.

Since the spectrum of $T(a)$ is a discrete set of eigenvalues having no finite accumulation point, a Jordan curve $\mathscr{C}$ can be drawn in $\rho(T(a))$ so as to enclose an open set in $\mathbb{C}$ containing zero in its interior and the other eigenvalues in the exterior of its closure. Then $\mathscr{C}\times\{a\}\subset\mathscr{G}$, where $\mathscr{G}$ is the open set defined by (37). Hence for each $\zeta\in\mathscr{C}$ there is a disc $D(\zeta, r(\zeta))\subset\mathbb{C}$ ($r(\zeta)>0$, is the radius), and a polydisc $\Delta(a, \rho(\zeta))\subset\mathbb{C}^n$ such that

$$(\zeta, a)\in D(\zeta, r(\zeta))\times\Delta(a, \rho(\zeta))\subset\mathscr{G}.$$

However, $\mathscr{C}$ is compact, so a finite set $\{\zeta_j\in\mathscr{C}: j=1, \cdots, k\}$ can be chosen such that $\{D(\zeta_j, r(\zeta_j)): j=1, \cdots, k\}$ covers $\mathscr{C}$. Consequently, $\mathscr{C}\subset\rho(T(z))$ for $z\in G_a'\equiv\bigcap_{j=1}^{k}\Delta(a, \rho(\zeta_j))$.

Next the operator $P(z)$ is defined for $z\in G_a'$ as a Riemann integral of $B(H, V)$-valued functions by

$$P(z)\equiv-\frac{1}{2\pi i}\int_{\mathscr{C}} R(\zeta, z)\,d\zeta. \tag{42}$$

It is shown in Theorems III-6.17 and VII-1.7 of [5] that $P(z)$ is a projection operator and that $P(a)$ maps H onto $M_1(a)$, the one-dimensional eigenspace associated with the eigenvalue 0 of $T(a)$. Moreover, H can be decomposed as $H=M_1(z)+M_2(z)$ for $z\in G_a'$, in which

$$M_1(z)\equiv P(z)H \quad\text{and}\quad M_2(z)\equiv(I-P(z))H. \tag{43}$$

It is also true that $P: G_a'\to B(H, V)$ is holomorphic because, by Theorem 17, the same is true of $R: \mathscr{G}\to B(H, V)$. Since $\dim(M_1(a))=1$, and since $P: G_a'\to B(H, H)$ is continuous (recall that V is continuously embedded in H), it follows from [5, ¶¶I-§ 4.6, IV-§ 3.4] that

$$\dim(M_1(z))=1 \quad\text{for } z\in G_a'. \tag{44}$$

Now let $\psi_a\in M_1(a)$ and nonzero, and define G_a to be an open connected subset of G_a' such that $a\in G_a$ and $(P(z)\psi_a, \psi_a)\neq 0$ for $z\in G_a$. Next, define

$$\psi(z)\equiv P(z)\psi_a \quad\text{for } z\in G_a; \tag{45}$$

it follows that $\psi: G_a\to V$ is holomorphic with $\psi(a)=\psi_a$.

It follows from [5, ¶¶ III-§ 5.6, III-§ 6.1] of [5] that for $z\in G_a$,

$$P(z)v\in D(T(z)) \quad\text{for all } v\in D(T(z)),$$

$$T(z)v\in M_k(z) \quad\text{for } v\in M_k(z)\cap D(T(z)) \text{ and } k=1.$$

Thus $T_k(z): M_k(z)\to M_k(z)$ for $k=1, 2$, and for $z\in G_a$ can be defined by $T_k(z)\equiv T(z)|_{M_k(z)\cap D(T(z))}$. The eigenvalue problem has now been decomposed into two eigenvalue problems, one for each $T_k(z)$ in $M_k(z)$. Of particular interest here is the eigenvalue problem for $T_1(z)$, because 0 and ψ_a form an eigenvalue-eigenfunction pair for $T_1(a)$.

According to (44), $T_1(z)$ is a one-dimensional operator. Therefore, $\lambda(z)\equiv$ trace $(T_1(z))$ is the eigenvalue of $T_1(z)$, i.e., for each $z\in G_a$,

$$T(z)\psi_a=T_1(z)\psi_z=\lambda(z)\psi_z \quad\text{for all } \psi_z\in M_1(z)\cap D(T(z)). \tag{46}$$

In (46), setting $\psi_z = P(z)\psi_a$ and taking inner products in H with ψ_a yields

$$\lambda(z) = \frac{(T(z)P(z)\psi_a, \psi_a)_H}{(P(z)\psi_a, \psi_a)_H} \quad \text{for } z \in G_a. \tag{47}$$

Since $T(z)$ is a closed operator, it follows from (42) and the identity $T(z)R(\zeta, z) = I + \zeta R(\zeta, z)$ that $T(z)P(z) = -(1/2\pi i)\int_{\mathscr{C}} \zeta R(\zeta, z)\, d\zeta$. Consequently, $z \mapsto T(z)P(z) \in B(H, V)$ is holomorphic on G_a ($\subset G_a'$). Therefore, the analyticity of λ on G_a follows from (47) because G_a was chosen so that $(P(z)\psi_a, \psi_a) \neq 0$ when $z \in G_a$. Since $\mathscr{C} \subset \rho(T(z))$ for all $z \in G_a$, $\lambda(z)$ lies in the interior of the open set enclosed by $\mathscr{C}$, whereas the remainder of the spectrum of $T(z)$ must lie in the open set that is exterior to $\mathscr{C}$.

Let $z \in G_a$ such that $\lambda(z) \neq 0$. Then $R(0, z)$ exists and commutes with $P(z)$. Consequently, we can define $R_k(0, z) \in B(H, V)$ for $k = 1, 2$, by

$$R_1(0, z) \equiv R(0, z)P(z) = P(z)R(0, z),$$

$$R_2(0, z) \equiv R(0, z)(I - P(z)) = (I - P(z))R(0, z).$$

By passing $R(0, z)$ under the integral sign in (42), then using the resolvent equation to obtain $R(0, z) - R(\zeta, z) = -\zeta R(0, z)R(\zeta, z)$ when zero and ζ are in $\rho(T(z))$, and noting that zero lies inside the open set enclosed by $\mathscr{C}$,

$$R(0, z)P(z) = R(0, z) - \frac{1}{2\pi i}\int_{\mathscr{C}} \frac{R(\zeta, z)}{\zeta}\, d\zeta \tag{48}$$

is obtained for each $z \in G_a$ such that $\lambda(z) \neq 0$. However, $\mathscr{C} \subset \rho(T(z))$ for all $z \in G_a$, so that the second term on the right-hand side of (48) is holomorphic as a function of z on G_a with values in $B(H, V)$. Consequently, $z \mapsto R_2(0, z) \in B(H, V)$ can be continued analytically to all of G_a.

Finally, it is clear from (43) and the definition of $R_1(0, z)$ that $R_1(0, z)w \in M_1(z) \cap D(T(z))$ for all $w \in H$ and for each $z \in G$ such that $\lambda(z) \neq 0$. Then (46) implies

$$\lambda(z)R_1(0, z)w = T(z)R_1(0, z)w = T(z)R(0, z)P(z)w = P(z)w,$$

from which $R_1(0, z)w = (1/\lambda(z))P(z)w$ is obtained from all $w \in H$ and for each $z \in G$ such that $\lambda(z) \neq 0$. This finishes the proof of Theorem 20 because $\phi(z) = R(0, z)w = R_1(0, z)w + R_2(0, z)w$ when $\lambda(z) \neq 0$.

ASYMPTOTIC BEHAVIOUR OF SOLUTIONS OF THE POROUS MEDIUM EQUATION WITH CHANGING SIGN*

SHOSHANA KAMIN† AND JUAN LUIS VAZQUEZ‡

Abstract. It is proved that solutions of the porous medium equation $u_t = \Delta(|u|^{m-1}u)$, $m>1$, defined in $Q=\mathbb{R}^N\times(0,\infty)$ with initial data $u(x,0)$ integrable, compactly supported, and with changing sign, become nonnegative in finite time if $\int u_0(x)\,dx>0$. Precise asymptotic convergence rates then follow. The positivity result is related to finite propagation and is false for the heat equation, $m=1$. Nevertheless, we obtain asymptotic convergence rates for $1\geqq m>(N-2)_+/N$ as $t\to\infty$.

The same analysis works for the equation $u_t=\operatorname{div}(|\nabla u|^{p-1}\nabla u)$ with $p>1$. The case of zero mass, $\int u_0(x)\,dx=0$, is also studied for the porous medium equation (in $N=1$) and the solution is shown to converge to an antisymmetric profile in that case.

Key words. nonlinear parabolic equations, flows in porous media, asymptotic behavior

AMS(MOS) subject classifications. 35K65, 35B40

1. Introduction.

In this paper we study the large-time behaviour of the solutions of the porous medium equation

$$u_t=\Delta(|u|^{m-1}u) \quad \text{for } x\in\mathbb{R}^N,\quad t>0, \tag{1.1}$$

with $m>0$, $N\geqq 1$, and initial data

$$u(x,0)=u_0(x) \quad \text{for } x\in\mathbb{R}^N. \tag{1.2}$$

We begin the paper with the assumption that $m>1$. We make the assumptions

$$u_0\in L^1(\mathbb{R}^N), \tag{1.3}$$

$$u_0 \text{ has compact support,} \tag{1.4}$$

but we make *no* assumption on the sign of u_0. Our main result is the following theorem.

THEOREM 1. *Let u be the solution of* (1.1)-(1.4) *with*

$$M\equiv\int u_0(x)\,dx>0. \tag{1.5}$$

Then u becomes nonnegative in a finite time $T=T(u_0)$. Similarly u becomes nonpositive if $M<0$.

The result is false for $m=1$, i.e., the classical heat equation $u_t=\Delta u$, as the following simple example shows. Let

$$u_0(x)=-\delta(x)+M\delta(x+ae_1),$$

where δ stands for Dirac's mass, $a>0$ and $M>1$ are constants, $x=(x_1,x_2,\cdots,x_N)\in\mathbb{R}^N$, and $e_1=(1,0,\cdots,0)$. Then the solution is given by

$$u(x,t)=-E(x,t)+ME(x+ae_1,t), \tag{1.6}$$

where E is the fundamental solution

$$E(x, t) = (4\pi t)^{-N/2} \exp\left(-\frac{|x|^2}{4t}\right). \tag{1.7}$$

This expression is negative precisely in the region

$$x_1 > \frac{2t}{a} \lg M - \frac{a}{2}. \tag{1.8}$$

An example with $u_0 \in L^1(\mathbb{R}^N)$ is obtained by displacing the origin of time to $t = \tau > 0$. Observe that some solutions initially having changing sign eventually become positive. Take for instance

$$u_0(x) = -\delta(x) + M\delta(x + ae_1) + M\delta(x - ae_1)$$

with $M > \frac{1}{2}$.

The main property of the porous medium ($m > 1$) which is not shared by the heat equation (nor by the fast diffusion equation $u_t = \Delta(|u|^{m-1}u)$, $0 < m < 1$) is *finite propagation*, which in particular means that a solution u such that u_0 has compact support has the same property for all fixed times $t > 0$; cf. [OKC] or the survey papers [P], [Ar]. The equivalent of the fundamental solution E of the heat equation is the self-similar solution (Barenblatt's solution [B], [ZK])

$$w(x, t) = t^{-k}\left(C - \frac{(m-1)k}{2mN}|\xi|^2\right)_+^{1/(m-1)}, \tag{1.9}$$

where $k = (m - 1 + (2/N))^{-1}$, $\xi = xt^{-k/N}$, $(s)_+$ means $\max(s, 0)$ and C is an arbitrary constant which can be determined by fixing the mass

$$M = \int w(x, t)\, dx,$$

so that $C = a(m, N)M^l$ with $l = 2(m-1)k/N$. (We will often write w_M instead of w to stress dependence on M.) Observe that w_M takes the initial data $M\delta(x)$ and that w vanishes in the region

$$|x| \geqq \rho_M(t) \equiv b(m, N)(M^{m-1}t)^{k/N}. \tag{1.10}$$

Solutions for $u_0(x) = -M\delta(x)$ are obtained by just changing the signs.

We can now see an intuitive explanation for the different behaviour regarding Theorem 1 in the cases where $m > 1$ and $m = 1$. While a fundamental solution $ME(x + ae_1, t)$ will never dominate $-E(x, t)$ over the whole space $\mathbb{R}^n$ even if t is large, this will happen with $w_M(x + ae_1, t)$ and $w_{-1}(x, t) = -w_1(x, t)$. Of course, since (1.1) with $m > 1$ is nonlinear, this is no proof of our result.

The asymptotic behaviour of nonnegative solutions to problem (1.1), (1.2) has been investigated by various authors for different assumptions on u_0; cf. [AR], [K], [FK], [Ve], $\cdots$. In particular, when $u_0 \in L^1(\mathbb{R}^N)$, convergence to the self-similar solution w with the same mass M as u_0 has been established by Kamin [K] in 1973 for $N = 1$, and by Friedman and Kamin [FK] in 1980 for any space dimensions. The theorem follows.

THEOREM 2 [FK]. *Let u be the solution to* (1.1)-(1.4) *with $u \geqq 0$, $m > 1$. Then as $t \to \infty$*

$$t^k|u(x, t) - w_M(x, t)| \to 0 \tag{1.11}$$

uniformly in $x \in \mathbb{R}^N$, with $M = \int u_0(x)\, dx$ and $k = (m - 1 + (2/N))^{-1}$.

When u_0 has compact support and one space dimension, $N=1$, very detailed information on the convergence of solutions and interfaces to the self-similar profile is known (cf. [V1], [AV], [An]). Less is known in several space variables. In particular, the evolution of the support is studied by Caffarelli, Vazquez, and Wolanski [CVW] who prove that it expands at the same rate as w_M. More precisely, if supp $(u_0) \subset B_{R_0}(0)$, $M = \int u_0(x)\,dx$ $(u_0 \geqq 0)$, and we define

$$r(t) = \min\{|x|: u(x,t) > 0\}, \qquad R(t) = \max\{|x|: u(x,t) > 0\},$$

we have

$$\begin{aligned} &R(t) \geqq \rho_M(t), \\ &R(t) - r(t) \leqq 2R_0, \\ &R(t) \leqq \lambda \rho_M(t) + R_0 \quad \text{for some } \lambda = \lambda(m) > 0. \end{aligned} \tag{1.12}$$

In fact, we can do better for large times.

THEOREM 3. *As* $t \to \infty$

$$\lim_{t\to\infty} \frac{r(t)}{\rho_M(t)} = \lim_{t\to\infty} \frac{R(t)}{\rho_M(t)} = 1. \tag{1.13}$$

The proof of the theorem is just a variant of the method used to prove Theorem 2 in [FK]. Since by Theorem 1 our solutions become nonnegative, Theorems 2 and 3 apply to *all* solutions with positive mass, even if u_0 has changing sign.

Solutions with no sign restriction have been less studied. Existence and uniqueness of weak solutions are discussed in [BC], [BCP]. Continuity with a uniform modulus is established in [dB] and [S], while Hölder continuity is obtained in [dBF]. An application to model the evolution of the interface separating fresh and salt water has been proposed by de Josselin de Jong and van Duijn [JvD]. (See also [BH].)

Theorem 1 will be proved in § 2, where we also show how to obtain Theorem 3 and establish a convergence rate when $M = 0$.

We devote § 3 to the case $1 \geqq m > (N-2)_+/N$, where we have infinite speed of propagation. In that range of exponents, Theorem 2 is also valid for nonnegative solutions with finite mass. Although we do not have $u \geqq 0$ in finite time, we have convergence to a positive Barenblatt solution as $t \to \infty$ if $\int u_0(x)\,dx = M > 0$ with the rate (1.11) for all $u_0 \in L^1(\mathbb{R}^N)$.

We recall that in the range $0 < m < (N-2)/N$ $(N > 2)$ we have extinction in finite time for initial data in $L^p(\mathbb{R}^N) \cap L^1(\mathbb{R}^N)$ with $p = N(1-m)/2$. This settles the large-time behaviour.

In § 4 we extend Theorems 1 and 2 to the p-Laplacian equation

$$u_t = \operatorname{div}(|\nabla u|^{p-2}\nabla u) \tag{1.14}$$

with $p > 2$ under assumptions (1.2)-(1.5) on the initial data. This will be a key ingredient in our study of the case $M = 0$ for (1.1), which we will perform in § 5 restricted to one space dimension. If the moment $\int x u_0(x)\,dx \neq 0$, we find convergence to an antisymmetric profile obtained as the derivative of the Barenblatt profile for (1.14). Explicit computations for $m = 1$ show that similar phenomena should occur for $N > 1$.

2. Case $m > 1$. According to [BC] and [BCP], for every $u_0(x) \in L^1(\mathbb{R}^N)$ there is a unique function, $u \in C([0,\infty): L^1(\mathbb{R}^N))$, which solves (1.1) in the sense of distributions and takes on the initial data u_0. This solution is bounded for $t \geqq \tau > 0$. In fact, since the Maximum Principle holds, a bound for u is derived from the well-known estimates

for nonnegative solutions. Thus, if u_1 is the solution with initial data $u_{01} = u_0^+$ and u_2 has $u_{20} = u_0^-$ ($\equiv \max(-u_0, 0)$), then

$$-u_2(x,t) \leqq u(x,t) \leqq u_1(x,t). \tag{2.1}$$

Using the well-known estimate ("smoothing effect"; cf. [Ve], [V2]) we get

$$-c(M_{20}^{2/N}/t)^k \leqq u(x,t) \leqq c(M_{10}^{2/N}/t)^k, \tag{2.2}$$

where $M_{10} = \int u_0^+ \, dx$, $M_{20} = \int u_0^- \, dx$, $M = M_{10} - M_{20}$, and c is the exact constant appearing in the estimate for the self-similar solutions w. Throughout §§ 2–4, k will keep the value $(m-1+(2/N))^{-1}$.

The solutions have some further regularity: by [BCP, Prop. 1.6], $\nabla(|u|^{m-1}u) \in H^1_{\mathrm{loc}}(Q)$, $Q = \mathbb{R}^N \times (0,\infty)$. We may now apply the results of [dB], [dBF], and [S] and conclude that u is Hölder continuous in Q with constants and modulus depending only on M_{10} and M_{20}. This gives equicontinuity needed later in passing to the limit as $t \to \infty$.

We also have bounds for the support derived from what is known for u_1 and u_2. Thus, by (1.12) we know that u_1 and u_2, hence also u, vanish for

$$|x| \geqq Ct^{k/N}, \qquad C = c(m,N)(\max(M_{10}, M_{20}))^{(m-1)k/N} \tag{2.3}$$

if t is large. This estimate can be strengthened replacing $\max(M_{10}, M_{20})$ by M after we prove Theorem 1, but we do not need it for the moment.

Let us now define

$$M_1(t) = \int u^+(x,t)\, dx, \qquad M_2(t) = \int u^-(x,t)\, dx. \tag{2.4}$$

It is clear that $M_1(0) = M_{10}$, $M_2(0) = M_{20}$, and $M = M_1(t) - M_2(t)$ since there is conservation of mass. We also have Lemma 1 below.

LEMMA 1. *$M_1(t)$ and $M_2(t)$ are nonincreasing in t.*

Proof. Consider the solution v_τ to (1.1) with initial data at time $t = \tau$, $v_\tau(x,\tau) = u^+(x,\tau)$. By the Maximum Principle $u(x,t) \leqq v_\tau(x,t)$ for $t \geqq \tau$, $x \in \mathbb{R}^N$. Conservation of mass proves that

$$M_1(\tau) = \int v_\tau(x,\tau)\, dx = \int v_\tau(x,t)\, dx \geqq \int u^+(x,t)\, dx$$

whenever $t \geqq \tau$, and hence $M_1(\tau) \geqq M_1(t)$. The proof is similar for M_2. □

More generally it is known that for every convex function $\phi : \mathbb{R}^+ \to \mathbb{R}^+$ with $\phi(0) = 0$, the integral $\int \phi(u)\, dx$ is nonincreasing in time. Our lemma comes from the particular case $\phi(s) = s^+$ applied to u and $-u$. (We thank the referee for this observation.)

As a consequence of the monotonicity we may define the asymptotic masses

$$M_1 = \lim_{t\to\infty} M_1(t), \qquad M_2 = \lim_{t\to\infty} M_2(t). \tag{2.5}$$

Clearly M_1, $M_2 \geqq 0$ and $M_1 - M_2 = M > 0$.

We now recall the rescaling operation, which is very useful for formulating and proving asymptotic results. Given $\lambda > 0$, we associate to any solution u the function $T_\lambda u \equiv u_\lambda$ given by

$$(T_\lambda u)(x,t) = \lambda^k u(\lambda^{k/N}x, \lambda t) \tag{2.6}$$

with $k = (m-1+(2/N))^{-1}$ as above. It is easy to check that $T_\lambda u$ is again a solution of (1.1) with initial data $T_\lambda u_0(x) = \lambda^k u_0(\lambda^{k/N}x)$, which has exactly the same mass as u_0. Moreover, w_M is invariant under T_λ, i.e., $T_\lambda w_M \equiv w_M$.

In terms of T_λ the convergence result of [FK] simply says that

$$\lim_{\lambda\to\infty} T_\lambda u(x,1) = w_M(x,1) \tag{2.7}$$

uniformly in x. This holds for $u \geqq 0$. In the case of changing sign we have the next lemma.

LEMMA 2. *As* $\lambda \to \infty$

$$(T_\lambda u^+)(x,1) \to w_{M_1}(x,1), \tag{2.8}$$

$$(T_\lambda u^-)(x,1) \to w_{M_2}(x,1) \tag{2.9}$$

uniformly in $\mathbb{R}^N$.

Proof. Consider again the solution v_τ with initial data $u^+(x,\tau)$ for $\tau > 0$ (and large). By (2.7) we have

$$T_\lambda v_\tau(x,1) \to w_{M_1(\tau)}(x,1)$$

as $\lambda \to \infty$. Therefore for τ and λ large enough we obtain

$$|T_\lambda v_\tau(x,1) - w_{M_1}(x,1)| < \varepsilon$$

since $M_1(\tau) \to M_1$. We now recall that $u \leqq v_\tau$ for $t \geqq \tau$, so that

$$(T_\lambda u^+)(x,1) \leqq w_{M_1}(x,1) + \varepsilon \tag{2.10}$$

if λ is large enough. On the other hand, we know by (2.2) that the family $T_\lambda u^+(x,1)$ is uniformly bounded and that by (2.3) its supports are also contained in a fixed ball. Moreover, the family $\{T_\lambda u\}$ is uniformly equicontinuous on compact subsets of Q as explained above. Since $T_\lambda(u^+) = (T_\lambda u)^+$ the family $T_\lambda(u^+)$ is also equicontinuous. All this implies that along a sequence $\lambda_n \to \infty$, $T_\lambda(u^+)(x,1)$ converges to a function f such that

$$0 \leqq f(x) \leqq w_{M_1}(x,1),$$

$$\int f(x)\,dx = \lim \int T_{\lambda_n} u^+(x,1)\,dx = \lim M_1(\lambda_n) = M_1.$$

Together these two facts imply that $f \equiv w_{M_1}(\cdot, 1)$. The uniqueness of the limit implies that $T_\lambda u^+$ converges to f along any sequence, thus establishing (2.8). The proof of (2.9) is similar. □

COROLLARY 3. $M_2 = 0$.

Proof. The above convergences imply that

$$t^k u^+(0,t) \to c_1(m) M_1^{2k/N}, \tag{2.11}$$

$$t^k u^-(0,t) \to c_1(m) M_2^{2k/N}. \tag{2.12}$$

Since necessarily $M_1 > 0$, (2.12) *can only hold if* $M_2 = 0$. □

End of proof of Theorem 1. Take $\varepsilon \ll M$ and t_0 such that

$$\int u^-(x,t)\,dx \leqq \varepsilon$$

for $t \geqq t_0$. According to (1.12), the support of the solution v with initial data $v(x,0) = u^-(x,t_0)$ grows as $t \to \infty$ like

$$O(\varepsilon^\alpha t^\beta), \qquad \alpha = (m-1)k/N, \quad \beta = k/N.$$

By the Maximum Principle, the same happens for $u^-(x,t)$. In terms of the rescaled solution, this means that

$$T_\lambda u(x,1) \geqq 0 \quad \text{for } |x| \geqq C\varepsilon^\alpha$$

for $\lambda \geqq \lambda_1(\varepsilon)$. Now for $|x| \leqq C\varepsilon^\alpha \ll bM^{(m-1)k/N}$ we already know that $T_\lambda u(x,1) > 0$ if λ is large enough, $\lambda \geqq \lambda_2(\varepsilon)$, because of the uniform convergence (2.8). Therefore $T_\lambda u(x,1) \geqq 0$ for $\lambda \geqq \max(\lambda_1(\varepsilon), \lambda_2(\varepsilon)) = \lambda_3$ which means that $u(x,t) \geqq 0$ for every $x \in \mathbb{R}^N$ if $t \geqq \lambda_3$. □

Though we cannot obtain the same conclusion when the mass $M = 0$, as we will see in § 5, the above applies as far as Corollary 3, thus showing that $M_1 = M_2 = 0$. Thus we obtain the following result.

THEOREM 4. *Let u be a solution of* (1.1)-(1.4) *with* $\int u_0(x)\,dx = 0$. *Then*

$$\lim_{t\to\infty} t^k u(x,t) = 0 \quad \textit{uniformly in } \mathbb{R}^N.$$

Let us end this section by mentioning the modification needed in the paper [FK] to obtain the asymptotic behaviour of the support, Theorem 3. The method of finding a family of Barenblatt solutions w_τ, with growing masses that lie below the solution for $t \geqq \tau$ and letting $\tau \to \infty$, should be changed into a family from above with decreasing masses that tend to M as $\tau \to \infty$. That this can be done is already observed in Remarks 1 and 2 at the end of that paper for the case of exponents $1 \geqq m > (N-2)/N$.

3. Case $m \leqq 1$. The considerations of the previous section apply to the solutions of problem (1.1)-(1.5) when $1 \geqq m > (N-2)_+/N$ to establish the following result.

THEOREM 5. *If u is a solution with mass $M \in \mathbb{R}$, then*

$$\lim_{t\to\infty} t^k |u(x,t) - w_M(x,t)| = 0 \quad \textit{uniformly in } \mathbb{R}^N. \tag{3.1}$$

Here $w_M(x,t)$ is given by the same formula (1.9) if $m < 1$ and by the limit as $m \to 1$, which is precisely $ME(x,t)$ if $m = 1$. Observe that these solutions are positive everywhere in $Q = \mathbb{R}^N \times \mathbb{R}^+$.

The result is known for nonnegative solutions and proved in the same paper [FK, Remark 2, p. 562]. For $m = 1$ we may of course prove (3.1) directly using the representation formula.

To prove (3.1) for $m < 1$ and general u_0 we repeat the plan of § 2. We recall that existence and uniqueness of solutions can be found in [HP], while a uniform modulus of continuity is found at the end of [dB] and in [S]. We have estimates (2.1) and (2.2) (which make sense since $k > 0$ precisely for $m > (N-2)/N$) and the same rescaling operators. Lemma 1 is true without modifications.

In order to prove Lemma 2 we face the problem of infinite propagation, i.e., the supports are just $\mathbb{R}^N$. We replace control of supports with control over decay as $|x| \to \infty$. In fact we have the following lemma.

LEMMA 4. *The family $\{T_\lambda u(x,1)\}_{\lambda>1}$ decays uniformly as $|x| \to \infty$ like $O(|x|^{-\gamma})$, $\gamma = 2/(1-m)$.*

Proof. We use the following estimate from [HP]:

$$|u(x,t)| \leqq C\left[t^{-k}\left(\int_{B_{4R}(x)} |u_0| \right)^{2k/N} + (t/R^2)^{1/(1-m)} \right]. \tag{3.2}$$

We choose $4R + R_0 = |x|$, assuming that u_0 is supported in the ball $B_{R_0}(0)$ (as will be $T_r u_0$ for $r > 1$), so that the integral in the second member vanishes. Put $t = 1$ and $T_\lambda u$ instead of u to obtain the decay. □

Since $\gamma > N$ precisely for $m > (N-2)/N$ we have uniform integrability as $|x| \to \infty$. Therefore the family converges in $L^1(\mathbb{R}^N)$ weakly. In this way we may continue through the proofs of Lemma 2 and Corollary 3 and obtain (3.1). □

We remark that in the case $M > 0$, Theorem 5 implies that u will be positive for large t in at least a *core* of the form

$$|x| \leqq C(t)t^{k/N} \tag{3.3}$$

with $C(t) \to \infty$ as $t \to \infty$. But, as shown in (1.6), u may very well continue to be negative for some x, i.e., solutions may need an infinite time to become positive everywhere, so to speak. (In the example (1.6)-(1.8) for $m = 1$ the positive region extends to a distance of order of t, so $C(t) \cong t^{1-k/N} = t^{1/2}$.)

4. The *p*-Laplacian equation. The ingredients in our treatment of (1.1) can be summarized in the following list:

(i) An existence and uniqueness theory for the Cauchy problem with integrable data having compact support;
(ii) The maximum principle;
(iii) Conservation of mass;
(iv) Boundedness for positive solutions;
(v) Equicontinuity;
(vi) Invariance of the equation under mass-preserving rescaling;
(vii) Convergence of nonnegative solutions to a selfsimilar solution, invariant under rescaling;
(viii) Finite propagation (essential for Theorem 1).

All of these properties are true in the case of the equation

$$u_t = \operatorname{div}(|\nabla u|^{p-2}\nabla u) \equiv \Delta_p(u) \tag{4.1}$$

when $p > 2$. For existence and uniqueness under general initial conditions we refer to [dBH], (ii) and (iii) are well known, and (v) is proved by [dBF]. The equation is invariant under the rescaling

$$(T_\lambda u)(x, t) = \lambda^k u(\lambda^{k/N}x, \lambda t), \tag{4.2}$$

which formally equals (2.6), but now the value of k is $(p-2+(p/N))^{-1}$, a value which will be kept throughout this section and also in § 5 for $p = m+1$. The fundamental solutions are now of the form

$$\hat{w}_M(x, t) = t^{-k}(C - q|\xi|^{p/(p-1)})_+^{(p-1)/(p-2)}, \qquad \xi = xt^{-k/N}, \tag{4.3}$$

where C is again related to the mass $M = \int \hat{w}(x, t)\,dx$; $C = c(p, N)M^\alpha$ with $\alpha = p(p-2)k/N(p-1)$, and $q = ((p-2)/p)(k/N)^{1/(p-1)}$. The support of w is given by

$$|x| \leqq \hat{\rho}_M(t) = \hat{b}(p, N)(M^{p-2}t)^{k/N}. \tag{4.4}$$

A smoothing effect of the form

$$u(x, t) \leqq \hat{w}_M(0, t) \equiv \hat{c}(p, N)(M^{(p/N)}/t)^k \tag{4.5}$$

is proved in [V3] (cf. also [Ve]). Finite propagation holds exactly for $p > 2$ (cf. [DH], [HV]). Finally, the convergence of u to $\hat{w}_M$, as in (1.11), has been proved for $N = 1$ in [EV] and is extended to $N > 1$ in our paper [KV].

In this way the proofs of § 2 hold and Theorems 1-4 hold for problem (4.1), (1.2), (1.3) (with our present values of $\hat{\omega}_M$ and k).

Remarks. The explicit solutions $\hat{w}_M$ appear in [B] for $N=1, 2, 3$, and have been used by several authors. We have taken some care in writing them down with the different coefficients and exponents attached to them because they are sometimes misprinted in the literature. Observe also that many authors write $p+1$ instead of p (so that $\Delta_p(u) \equiv \operatorname{div}(|Du|^{p-1}Du)$ and then the range is $p>1$).

5. The porous medium equation with zero mass ($N=1$). Now we consider the problem

$$u_t = (|u|^{m-1}u)_{xx} \quad \text{for } (x, t) \in Q = \mathbb{R} \times (0, \infty), \tag{5.1}$$

$$u(x, 0) = u_0(x) \quad \text{for } x \in \mathbb{R}, \tag{5.2}$$

where $m>1$ and the initial data u_0 are integrable and have compact support and zero mass

$$\int u_0(x)\, dx = 0. \tag{5.3}$$

We also assume that the first moment is nonzero:

$$\int x u_0(x)\, dx \neq 0. \tag{5.4}$$

To be specific we take $P = -\int x u_0(x)\, dx > 0$. By (formally for the moment) integrating in x from $-\infty$ we obtain for the variable

$$v(x, t) = \int_{-\infty}^{x} u(y, t)\, dy \tag{5.5}$$

the problem

$$v_t = (|v_x|^{m-1}v_x)_x \quad \text{in } Q, \tag{5.6}$$

$$v(x, 0) = v_0(x) \quad \text{in } \mathbb{R}, \tag{5.7}$$

where $v_0(x) = \int_{-\infty}^{x} u_0(y)\, dy$ is bounded, and has compact support (because of (5.3)) and mass P; if $\operatorname{supp}(u_0) \subset [a, b]$ we have

$$\int_{\mathbb{R}} v_0(x)\, dx = \int_a^b dx \int_a^x u_0(y)\, dy = b \int u_0(y)\, dy - \int y u_0(y)\, dy = P.$$

Since the solution v is continuous with v_x continuous [dBF] and satisfies (5.6) in a strong sense (cf. [EV]), it is easy to show that v_x is a weak solution of (5.1), (5.2). By uniqueness $u = v_x$.

By the version of Theorem 1 for the p-Laplacian equation (with $p = m+1 > 2$), the solution of problem (5.6), (5.7) becomes nonnegative in finite time. We can now apply the results of [EV] to conclude that v converges to $\hat{w} = \hat{w}_P$ as $t \to \infty$ at a certain rate. Therefore in some sense v_x converges to $\hat{w}_x$ too. We show next that the convergence is uniform. In fact, in our case $N=1$, $p = m+1$ we have

$$\hat{w} = t^{-k}(C - q|\xi|^{(m+1)/m})_+^{m/(m-1)} \tag{5.8}$$

with $k = 1/2m$, $\xi = xt^{-k}$, and $C = C(m, P)$. Therefore,

$$z(x, t) \equiv \hat{w}_x(x, t) = -dt^{-1/m}\xi^{1/m}(C - q|\xi|^{(m+1)/m})_+^{1/(m-1)}, \tag{5.9}$$

where $d = q(m+1)/(m-1)$. It is antisymmetric in x, positive for $-\hat{\rho}(t) < x < 0$, and negative for $0 < x < \hat{\rho}(t)$, with $\hat{\rho}(t) = \hat{b}(P^{m-1}t)^k$. It decays like $t^{-1/m}$ and expands like $t^{1/2m}$, both rates different from the positive case ($t^{-1/(m-1)}$ and $t^{1/(m+1)}$, respectively).

We have for a general solution Theorem 6 below.

THEOREM 6. *As* $t \to \infty$

$$t^{1/m}|u(x,t) - z(x,t)| \to 0 \tag{5.10}$$

uniformly in $x \in \mathbb{R}$. *Moreover, u vanishes outside a region*

$$s_1(t) < x < s_2(t), \tag{5.11}$$

where

$$s_2(t) = \hat{\rho}_P(t) + o(1), \qquad s_2(t) \geqq \hat{\rho}_P(t), \tag{5.12}$$

$$s_1(t) = -\hat{\rho}_P(t) + o(1), \qquad s_1(t) \leqq -\hat{\rho}_P(t). \tag{5.13}$$

Proof. The result is a consequence of the asymptotic formulas obtained in [EV, § 5]. In fact s_1 and s_2 are the left- and right-hand interfaces of v, and for large t, $v(x,t) > 0$ precisely if $s_1(t) < x < s_2(t)$. Established are not only (5.12) and (5.13), but also estimates for the derivatives

$$s_2'(t) = \hat{\rho}_P'(t) + o(1/t), \tag{5.14}$$

$$s_1'(t) = -\hat{\rho}_P'(t) + o(1/t). \tag{5.15}$$

To go further we need to introduce the so-called "pressure variable"

$$\sigma(x,t) = \frac{m}{m-1} v^{(m-1)/m} \tag{5.16}$$

for which [EV] proves the fundamental estimate

$$(|\sigma_x|^{m-1}\sigma_x)_x \geqq -\frac{1}{2mt}, \tag{5.17}$$

which is exact for the (pressure of the) solutions $\hat{w}$. Moreover, we have the interface equation

$$(|\sigma_x|^{m-1}\sigma_x)(s_i(t), t) = -s_i'(t). \tag{5.18}$$

Combining (5.12)-(5.18) we obtain the estimate

$$|\sigma_x|^{m-1}\sigma_x + \frac{x}{2mt} = o\left(\frac{1}{t}\right) \tag{5.19}$$

in $s_1(t) < x < s_2(t)$. Integration gives

$$\sigma - \hat{\sigma} = o(t^{-1/2m}), \tag{5.20}$$

where $\hat{\sigma}$ is the pressure corresponding to $\hat{w}_P$. Now we observe that $\sigma_x = v_x v^{-1/m}$. Hence

$$u = c(m)\sigma^{1/(m-1)}\sigma_x \tag{5.21}$$

to obtain uniform convergence of u to $z = \hat{w}_x$ with an error that decays faster than $t^{-1/m}$ (we mention the exponent $1/m$ because it is the decay rate for z and u). □

As the consequence of (5.10), u will be positive in the region $-\hat{\rho}(t)(1-\varepsilon) < x < -\varepsilon\hat{\rho}(t)$ and negative in $\varepsilon\hat{\rho}(t) < x < (1-\varepsilon)\hat{\rho}(t)$ if $0 < \varepsilon < 1$ and $t \geqq t_\varepsilon$. On the other hand, it is easy to prove that v is nondecreasing in x for $x \leqq a$ and nonincreasing for $x \geqq b$ where $[a, b] \supset \operatorname{supp}(u_0)$. Therefore the only region where u changes sign for large t is $a \leqq x \leqq b$.

Similar results hold for $P>0$, i.e., $\int xu_0(x)\,dx>0$ (just change x in $-x$). On the contrary, we cannot handle the case where $M=0$, $P=0$.

Let us mention that solution (5.9) was published by Barenblatt and Zeldovich [BZ] in 1957, with the observation that it takes a dipole as initial data, $u_0(x)=\delta'(x)$. Application of (5.6) to study the propagation of (5.1) with $M=0$ appears, e.g., in [HV].

Finally, in order to have some insight about the situation in several dimensions, we discuss briefly the linear heat equation

$$u_t=\Delta u, \qquad (x,t)\in Q \tag{5.22}$$

with $u(x,0)=u_0(x)\in L^1(\mathbb{R}^N)$, $\int u_0(x)\,dx=0$, and moments

$$P_i=\int x_i u_0(x)\,dx \tag{5.23}$$

not all zero. Let $\vec{P}=(P_1,\cdots,P_N)$. Then the asymptotic development of $u(x,t)$ has as first term

$$u(x,t)\cong \sum_{i=1}^{N} P_i\cdot\frac{\partial E}{\partial x_i}=\frac{\vec{P}\cdot\vec{x}}{4t}E(x,t), \tag{5.24}$$

which is positive on the half-space $\vec{P}\cdot x>0$ and negative on $\vec{P}\cdot x<0$. Therefore there is a unique pattern (as in $N=1$) which has as parameters the amplitude and orientation of the moment vector $\vec{P}$. It is very likely that this situation holds for $m\neq 1$. □

Appendix.

A.1. At the suggestion of one of the referees we prove the necessity of the condition of compact support for the initial data u_0 (condition (1.4)) in Theorem 1. We do this by constructing an example of a solution that does not become nonnegative in finite time even though its initial data satisfy conditions (1.3) and (1.5).

We consider the solution $u(x,t)$ to (1.1) with $m>1$ and with an initial function $u_0(x)\in C(\mathbb{R}^N)$ that is positive in the ball $\{x:|x|<1\}$, negative for $|x|>1$, and satisfies (1.3) and (1.5). Let $v(x,t)$ be the solution with $v(x,0)$ equal to the positive part of $u_0(x)$. Then $v\geqq 0$ and $v\geqq u$ in $\mathbb{R}^n\times(0,\infty)$. Moreover, by Theorem 3 there is an increasing function of t, $R(t)$ (which behaves like t^k as $t\to\infty$ according to (1.13)), such that $v(\cdot,t)$ vanishes outside a ball of radius $R(t)$. This means that $u(x,t)\leqq 0$ for every $t>0$ and $|x|>R(t)$.

We now claim that in fact $u(x,t)<0$ whenever $|x|>R(t)$. To prove this, we fix a time $T>0$ and consider the solution $u(x,t)$ in a cylinder of the form $Q=B\times(0,T)$, where $B=B_\rho(a)$ is the ball of center a, radius $\rho>0$ in $\mathbb{R}^N$, and a and ρ satisfy

$$R(T)+\rho\leqq|a|. \tag{A.1}$$

Then we compare our solution u restricted to the cylinder Q with the solution $w(x,t)$ of the mixed problem

$$\begin{aligned} &w_t=\Delta(|w|^{m-1}w) && \text{in } Q,\\ &w(x,t)=0 && \text{for } |x-a|=\rho,\quad 0<t<T,\\ &w(x,0)=w_0(x) && \text{for } |x-a|<\rho \end{aligned} \tag{A.2}$$

for some suitable w_0 with $0\geqq w_0(x)\geqq u_0(x)$ in B. Now it is known [AP] that this problem admits solutions of the separated-variables form

$$w(x,t)=f(x)/(t+\tau)^\alpha \quad \text{with } \alpha=1/(m-1),$$

where $\tau>0$ is arbitrary and f is a smooth function that is negative in B. By taking τ large enough we may get $w(x,0)\geqq u(x,0)$ in B, and since also $w\geqq u$ on the lateral

boundary of Q, by the Maximum Principle we conclude that $w(x, t) \geq u(x, t)$. Hence $u(x, t) < 0$ in Q, which proves our claim. On the other hand, different variations of this example are easy to construct using the same basic idea.

A.2. Since we are commenting on the necessity of the hypotheses of Theorem 1, let us mention that the integrability assumption on u_0, condition (1.3) together with (1.4), can be weakened into the assumptions

$$u_0^- \in L^1(\mathbb{R}^N), \tag{A.3}$$

$$u_0^- \text{ has compact support,} \tag{A.4}$$

i.e., only the negative part of the initial data, $u_0^-(x) = \max(0, -u_0(x))$, needs to be integrable and have compact support. Of course, if this happens and $u_0^+ \notin L^1(\mathbb{R}^N)$ then $M = \infty$. The proof of this version of Theorem 1 follows from the standard case thanks to the Maximum Principle (consider the solutions $\bar{u}_n$ with initial data $\min(u(x), n)$, which satisfy Theorem 1 for large n and are smaller than u).

Acknowledgments. Several improvements in the text are due to a referee's observations, for which the authors are very grateful.

UNIFORM ENERGY DECAY RATES FOR EULER-BERNOULLI EQUATIONS WITH FEEDBACK OPERATORS IN THE DIRICHLET/NEUMANN BOUNDARY CONDITIONS*

J. BARTOLOMEO† AND R. TRIGGIANI‡

Abstract. The uniform stabilization problem is studied for the Euler-Bernoulli equation (though the methods apply also to the corresponding nonconstant coefficient case) defined in a smooth, bounded domain Ω of R^n, with suitable dissipative boundary feedback operators. These either are active in both the Dirichlet and Neumann boundary conditions, or are active in only the Dirichlet and inactive in the Neumann boundary condition. The uniform stabilization results presented are fully consistent with recently established exact controllability and optimal regularity theories for the solutions, which in fact motivate the choices of functional spaces in the first place. In particular, these uniform stabilization results require no geometrical conditions on Ω in the case of active Dirichlet/Neumann feedback operators, and require some geometrical conditions on Ω in the case of an active feedback operator only in the Dirichlet boundary condition, as is the case of recent exact controllability theories [I. Lasiecka and R. Triggiani, *SIAM J. Control Optim.*, 27 (1989), pp. 330-373]. Moreover, the forms of the dissipative feedback controls are natural consequences of (i) the type of boundary conditions selected; (ii) the choice that the control in the lowest boundary condition be L_2 in time and space.

Key words. Euler-Bernoulli equations, uniform stabilization

1. Introduction, preliminaries, and statement of main results.

1.1. Introduction and literature. Let Ω be an open bounded domain in R^n, n typically $\geqq 2$, with sufficiently smooth boundary Γ. In Ω we consider the Euler-Bernoulli mixed problem in $w(t, x)$ on an arbitrary time interval $(0, T]$ with Dirichlet and Neumann boundary conditions:

$$w_{tt} + \Delta^2 w = 0 \qquad \text{in } (0, T] \times \Omega, \tag{1.1a}$$

$$w(0, x) = w_0(x), \quad w_t(0, x) = w_1(x) \qquad \text{in } \Omega, \tag{1.1b}$$

$$w(t, \sigma) = g_1(t, \sigma) \qquad \text{in } (0, T] \times \Gamma, \tag{1.1c}$$

$$\frac{\partial w}{\partial \nu}(t, \sigma) = g_2(t, \sigma) \qquad \text{in } (0, T] \times \Gamma \tag{1.1d}$$

with nonhomogeneous forcing terms (control functions) g_1 and g_2 in the Dirichlet and Neumann boundary conditions. There has recently been a keen resurgence of interest (e.g., [34], [10], [16], and references cited therein) in plate equation theory, of which the Euler-Bernoulli equation (1.1a) is a canonical model, presumably stimulated by two main sources: (i) renewed studies in the dynamics, feasibility, and implementation of so-called large-scale flexible structures envisioned to be employed in space; (ii) recent mathematical advances in regularity theory of second-order mixed hyperbolic

problems (canonically, the wave equation) of both Dirichlet type [12], [21], [22], [35]) and Neumann type [21]–[24], [36] with L_2-boundary data. In either case, a prime thrust of motivation has come from dynamical control studies, at either the engineering or the theoretical level.

With reference to the specific problem (1.1), we cite [15], [18], [19], [31] for optimal regularity theory and exact controllability theory with respect to classes of interest for the initial data $\{w_0, w_1\}$ and of boundary data $\{g_1, g_2\}$, which markedly improved upon regularity of prior literature [17].

In the present paper, we focus on the problem of *boundary feedback uniform stabilization* for the dynamics (1.1) by *explicit feedback operators*, to be more properly defined below. Our results are fully consistent with the corresponding exact controllability results [18], [19] with respect not only to the function spaces for $\{g_1, g_2\}$ and $\{w, w_t\}$ as mentioned above, but also to the lack of geometrical conditions on Ω when both g_1 and g_2 are active, or to the presence of similar geometrical conditions on Ω—to be expected—when only g_1 is active while g_2 is taken $g_2 \equiv 0$. We note, in passing, that uniform stabilization of (1.1) by means of a feedback operator acting on $\{w, w_t\}$, (defined in terms of the algebraic Riccati operator that arises in the study of the optimal quadratic cost problem on an infinite horizon $0 \leqq t \leqq T = \infty$) has already been achieved in the abstract treatment of [5] (see in particular Appendix 2 of [5]) as a consequence—among others—of the optimal regularity and exact controllability results mentioned before. (Indeed, because of these results, the abstract treatment of the wave equation in [28, § 5] also covers, mutatis mutandis, the plate problem (1.1), as noted in [5]. See also [30].)

Mathematically, the present work is guided by, and partially rests upon, techniques developed in two main sources: (i) the studies of exact controllability [18], [19] for problem (1.1); (ii) the study of uniform stabilization of the wave equation with boundary feedback in the Dirichlet boundary conditions [20] and in the Neumann boundary conditions (B.C.) [39]. Of course, these studies must be seen, in turn, in the context of recent investigations including (a) uniform stabilization of the wave equation with feedback in the Neumann boundary conditions [2], [8], [9], [20, § 4]; (b) regularity theory for hyperbolic equations in [12], [21], [22], [35] as well as corresponding exact controllability theory [13], [14], [25], [7], [38]; (c) exact controllability results for Euler–Bernoulli equations with different boundary conditions [13], [14], [26], [27]; and (d) corresponding optimal quadratic cost problems [4], [28], and [5]. We stress the following point of view: we choose g_1, say, in "open loop" form to be in $L^2(0, T; L^2(\Gamma))$, $T < \infty$. This determines the corresponding solution of (1.1) with $w_0 = w_1 = g_2 = 0$ to be: $\{w, w_t\} \in C([0, T]; Z)$, where Z is the space identified in (1.6) below. This is an optimal regularity result [15], [19]. Next, we choose g_2 (respectively, $\{w_0, w_1\}$) such that the corresponding solution of (1.1) with $g_1 = w_0 = w_1 = 0$ (respectively, $g_1 = g_2 = 0$) also produces $\{w, w_t\} \in C([0, T]; Z)$, again as an optimal regularity result. This leads to $\{w_0, w_1\} \in Z$ and $g_2 \in L^2(0, T; H^{-1}(\Gamma))$ [15], [19]. In other words, only one choice is made, that $g_1 \in L^2(0, T; L^2(\Gamma))$; then, we work with other data and resulting solutions in corresponding optimal spaces. Our solution of the uniform stabilization problem below is fully consistent with these "open-loop" considerations: uniform stabilization will be achieved in the space Z with controls in feedback form $g_1 \in L^2(0, \infty; L^2(\Gamma))$ and $g_2 \in L^2(0, \infty; H^{-1}(\Gamma))$; see Theorem 1.2 below. For other uniform stabilization results for plates, we refer to the monograph [10], as well as to [11], where, however, higher-order boundary conditions are treated. It should be emphasized that all these problems are very sensitive to the particular choice of boundary conditions, which in turn determine the appropriate spaces of solutions. The lower boundary

conditions considered in the present paper, which yield low-regularity spaces for the solutions, make it necessary—unlike the case of higher-order boundary conditions—to transform the original problem (1.1) in w to a new problem ((3.16) in p below), through a suitable change of variable ((3.12) below from w to p), before applying the correct multipliers (which are different from the multiplers used for higher-order boundary conditions). The case of feedback in $L^2(0, \infty; L^2(\Gamma))$ only in the Neumann B.C. requires a different state space of optimal regularity, $L^2(\Omega) \times H^{-2}(\Omega)$, and different multipliers, and will be reported elsewhere [33]. Sharp results on the lack of uniform stabilization are in [40].

1.2. Formulation of the uniform stabilization problem and main statements. Throughout the paper, we let $A: L^2(\Omega) \supset \mathcal{D}(A) \to L^2(\Omega)$ be the positive self-adjoint operator defined by

$$Af = \Delta^2 f, \qquad \mathcal{D}(A) = H^4(\Omega) \cap H_0^2(\Omega). \tag{1.2}$$

We have [6], [19, App. C]

$$\mathcal{D}(A^{1/4}) = H_0^1(\Omega), \quad \mathcal{D}(A^{3/4}) = V, \quad V = \left\{ f \in H^3(\Omega): f|_\Gamma = \left.\frac{\partial f}{\partial \nu}\right|_\Gamma = 0 \right\} \tag{1.3}$$

with equivalent norms. Thus, for $f \in \mathcal{D}(A^{1/4}) = H_0^1(\Omega)$,

$$\begin{aligned} &\|f\|_{\mathcal{D}(A^{1/4})} = \|A^{1/4} f\|_{L^2(\Omega)}, \\ &\text{equivalent to } \|f\|_{H^1(\Omega)}, \\ &\text{in turn equivalent to } \left\{ \int_\Omega |\nabla f|^2 \, d\Omega \right\}^{1/2} \end{aligned} \tag{1.4}$$

by Poincaré inequality. Similarly, for $f \in \mathcal{D}(A^{3/4}) = V$,

$$\|f\|_{\mathcal{D}(A^{3/4})} = \|A^{3/4} f\|_{L^2(\Omega)} \qquad \text{equivalent to } \left\{ \int_\Omega |\nabla(\Delta f)|^2 \, d\Omega \right\}^{1/2} \tag{1.5}$$

Our optimal space will be

$$Z = H^{-1}(\Omega) \times V' = [\mathcal{D}(A^{1/4})]' \times [\mathcal{D}(A^{3/4})]' \tag{1.6}$$

where $'$ denotes duality with respect to the $L^2(\Omega)$-topology.

Next, let $g_1 = g_2 = 0$ in (1.1). Then, the corresponding evolution of (1.1) is governed by the operator

$$\mathcal{A}_0 = \begin{vmatrix} 0 & I \\ -A & 0 \end{vmatrix},$$

which generates a strongly continuous *unitary* group on the space $\mathcal{D}(A^{1/2}) \times L^2(\Omega)$ with domain $\mathcal{D}(\mathcal{A}_0) = \mathcal{D}(A) \times \mathcal{D}(A^{1/2})$ and hence on the space Z of our interest with domain $\mathcal{D}(\mathcal{A}_0) = \mathcal{D}(A^{1/4}) \times [\mathcal{D}(A^{1/4})]' = H_0^1(\Omega) \times H^{-1}(\Omega)$, denoted by $e^{\mathcal{A}_0 t}$. Thus the free solutions of (1.1) with $g_1 = g_2 = 0$ are norm preserving on Z:

$$\|[w(t), w_t(t)]\|_Z \equiv \|e^{\mathcal{A}_0 t}[w_0, w_1]\|_Z \equiv \|[w_0, w_1]\|_Z, \qquad t \in R.$$

With this well-known result at hand, we can state the aim of the paper. Motivated by, and consistent with, the function spaces in the optimal regularity and exact controllability theories [15], [18], [19] of (1.1), we will study the question of existence and construction of explicit boundary feedback operators $\mathcal{F}_1$ and $\mathcal{F}_2$ based on the velocity w_t

$$w_t \in [\mathcal{D}(A^{3/4})]' = V' \to \mathcal{F}_1(w_t) \in L^2(0, \infty; L^2(\Gamma)), \tag{1.7}$$

$$w_t \in [\mathcal{D}(A^{3/4})]' = V' \to \mathcal{F}_2(w_t) \in L^2(0, \infty; H^{-1}(\Gamma)), \tag{1.8}$$

such that the boundary feedback functions

$$g_1 = \mathcal{F}_1(w_t), \qquad g_2 = \mathcal{F}_2(w_t) \tag{1.9}$$

inserted in (1.1c, d) produce a *strongly continuous* (*s.c.*) (*feedback*) *semigroup on Z that is exponentially stable in the uniform operator norm $\mathcal{L}(Z)$ of the space Z in* (1.6). (The feedback $B^*P[w, w_t]$ based on the Riccati operator P, referred to in § 1.1, acts instead on the full pair $\{w, w_t\}$ [5].)

Choice of operators $\mathcal{F}_1$ and $\mathcal{F}_2$. It is justified in § 2 (see (2.2)), that the following choices of $\mathcal{F}_1$ and $\mathcal{F}_2$:

$$g_1 = \mathcal{F}_1(w_t) = -k_1^2(x) G_1^* A^{-1/2} w_t = -k_1^2(x) G_1^* A A^{-3/2} w_t = -k_1^2(x) \left.\frac{\partial \Delta(A^{-3/2} w_t)}{\partial \nu}\right|_\Sigma, \tag{1.10}$$

$$\begin{aligned} g_2 = \mathcal{F}_2(w_t) &= -k_2(x)\Lambda^2 k_2(x)[G_2^* A^{-1/2} w_t] \\ &= -k_2(x)\Lambda^2 k^2(x)[G_2^* A A^{-3/2} w_t] \\ &= k_2(x)\Lambda^2 k_2(x)[\Delta(A^{-3/2} w_t)]_\Sigma \end{aligned} \tag{1.11}$$

provide reasonable *candidates* for the uniform stabilization problem of (1.1), in the sense that the closed-loop feedback dynamics with (1.10) and (1.11) inserted in (1.1c, d), respectively, is well posed in the semigroup sense in Z, and all of its solutions originating in Z decrease as $t \to +\infty$ in the Z-norm. (This, however, does not say that such Z-norms decrease to zero as $t \to +\infty$, let alone in the uniform norm of $\mathcal{L}(Z)$. To show this conclusion will be our major task.) In (1.10), (1.11) we have that:

(a) (1.12) $k_i(x)$ = smooth functions on Γ, $k_i(x) \geqq k_0 \geqq 0$;

(b) (1.13) Λ: isomorphism $H^s(\Gamma)$ onto $H^{s-1}(\Gamma)$, self-adjoint on $L^2(\Gamma)$ so that for $s = 1$, if ∇_σ denotes the tangential gradient on Γ,

$$\|\Lambda g\|_{L^2(\Gamma)} = \|g\|_{H^1(\Gamma)} = \left\{ \int_\Gamma |\nabla_\sigma g|^2 + g^2 \, d\Gamma \right\}^{1/2}; \tag{1.14}$$

(c) The operators G_i^* are the adjoints, in the sense that

$$(G_i g, v)_{L^2(\Omega)} = (g, G_i^* v)_{L^2(\Gamma)}, \qquad g \in L^2(\Gamma), \, v \in L^2(\Omega) \tag{1.15}$$

of the operators G_i defined by $G_1 g_1 = v$, respectively, $G_2 g_2 = y$, where

$$\Delta^2 v = 0 \quad \text{in } \Omega, \qquad \Delta^2 y = 0 \quad \text{in } \Omega, \tag{1.16a}$$

$$v|_\Gamma = g_1 \quad \text{on } \Gamma, \qquad y|_\Gamma = 0 \quad \text{on } \Gamma, \tag{1.16b}$$

$$\left.\frac{\partial v}{\partial \nu}\right|_\Gamma = 0 \quad \text{on } \Gamma, \qquad \left.\frac{\partial y}{\partial \nu}\right|_\Gamma = g_2 \quad \text{on } \Gamma. \tag{1.16c}$$

Elliptic theory [17], [32] gives for any $s \in R$

$$G_1: \text{continuous } H^s(\Gamma) \to H^{s+1/2}(\Omega), \tag{1.17}$$

$$G_2: \text{continuous } H^s(\Gamma) \to H^{s+3/2}(\Omega). \tag{1.18}$$

Moreover, it is proved by Green's theorem that [19, Lemma 2.0 and Lemma 4.0, respectively]

$$G_1^* A f = \left.\frac{\partial(\Delta f)}{\partial \nu}\right|_\Gamma, \qquad f \in \mathcal{D}(A), \tag{1.19}$$

$$G_2^* A f = -(\Delta f)|_\Gamma, \qquad f \in \mathcal{D}(A). \tag{1.20}$$

Identities (1.19), (1.20) are used in the last steps of (1.10) and (1.11), respectively.

Thus the resulting candidate feedback system, whose stability properties in Z we will investigate, is

$$w_{tt}+\Delta^2 w=0 \qquad \text{in } (0,\infty)\times\Omega=Q, \tag{1.21a}$$

$$w(0,x)=w_0(x)\colon\ w_t(0,x)=w_1(x) \qquad \text{in } \Omega, \tag{1.21b}$$

$$w|_\Sigma=-k_1(x)\left.\frac{\partial\Delta(A^{-3/2}w_t)}{\partial\nu}\right|_\Sigma \qquad \text{in } (0,\infty)\times\Gamma=\Sigma, \tag{1.21c}$$

$$\left.\frac{\partial w}{\partial\nu}\right|_\Sigma=k_2(x)\Lambda^2k_2(x)[\Delta(A^{-3/2}w_t)]_\Sigma \qquad \text{in } \Sigma. \tag{1.21d}$$

Using the techniques of [21], [37], problem (1.21) can be rewritten more conveniently in abstract form as

$$\frac{d}{dt}\begin{vmatrix} w\\ w_t\end{vmatrix}=\mathscr{A}\begin{vmatrix} w\\ w_t\end{vmatrix} \quad \text{on } Z, \tag{1.22}$$

$$\begin{aligned}&\mathscr{A}=\begin{vmatrix} 0 & I\\ -A & -A[G_1k_1^2G_1^*A^{-1/2}+G_2k_2\Lambda^2k_2G_2^*A^{-1/2}]\end{vmatrix},\\ &\mathscr{D}(\mathscr{A})=\{y\in Z\colon \mathscr{A}y\in Z\}.\end{aligned} \tag{1.23}$$

A more explicit description of $\mathscr{D}(\mathscr{A})$ will be given below. Our main results are as follows.

THEOREM 1.1. (i) (Well-posedness on Z). *The operator $\mathscr{A}$ in* (1.23) *is dissipative on $Z=[\mathscr{D}(A^{1/4})]'\times[\mathscr{D}(A^{3/4})]'$, see* (1.6), *and satisfies here*: range $(\lambda I-\mathscr{A})=Z$ *for* $\lambda>0$. *Thus, by the Lumer–Phillips theorem, $\mathscr{A}$ generates a strongly continuous contraction semigroup $e^{\mathscr{A}t}$ on Z. The resolvent operator $R(\lambda,\mathscr{A})$ is given by*

$$R(\lambda,\mathscr{A})=\begin{vmatrix}(I-V^{-1}(\lambda))/\lambda & V^{-1}(\lambda)A^{-1}\\ -V^{-1}(\lambda) & \lambda V^{-1}(\lambda)A^{-1}\end{vmatrix}, \tag{1.24}$$

$$V(\lambda)=(I+\lambda G_1k_1^2G_1^*A^{-1/2}+\lambda G_2k_2\Lambda^2k_2G_2^*A^{-1/2}+\lambda^2A^{-1}) \tag{1.25}$$

and is compact on Z for $\operatorname{Re}\lambda>0$. *Moreover, $0\in\rho(\mathscr{A})$, the resolvent set of $\mathscr{A}$.*

(ii) (L_2-boundedness in time of feedback operators.) *For $\{w_0,w_1\}\in Z$, we have for problem* (1.21)

$$-w|_\Sigma=k_1^2G_1^*A^{-1/2}w_t=k_1^2\frac{\partial\Delta(A^{-3/2}w_t)}{\partial\nu}\in L^2(0,\infty;L^2(\Gamma)), \tag{1.26}$$

$$-\left.\frac{\partial w}{\partial\nu}\right|_\Sigma=k_2\Lambda^2k_2G_2^*A^{-1/2}w_t=k_2\Lambda^2k_2[\Delta(A^{-3/2}w_t)]_\Sigma\in L^2(0,\infty;H^{-1}(\Gamma)). \tag{1.27}$$

More precisely

$$\int_0^\infty\|w\|^2_{L^2(\Gamma)}\,dt=\int_0^\infty\|k_1^2G_1^*A^{-1/2}w_t\|^2_{L^2(\Gamma)}\,dt\leqq\|\{w_0,w_1\}\|^2_Z, \tag{1.28}$$

$$\int_0^\infty\left\|\frac{\partial w}{\partial\nu}\right\|^2_{L^2(\Gamma)}dt=\int_0^\infty\int_\Gamma\|\Lambda k_2G_2^*A^{-1/2}w_t\|^2_{L^2(\Gamma)}\,dt\leqq\|\{w_0,w_1\}\|^2_Z. \tag{1.29}$$

(iii) *Now let $k_2\equiv0$, i.e., $(\partial w/\partial\nu)=0$ on Σ in* (1.21d). *Then the resolvent $R(\lambda,\mathscr{A})$ is well defined and compact on Z also on the imaginary axis, and hence for all* $\operatorname{Re}\lambda\geqq0$, *provided that the following elliptic uniqueness property holds true: with $\lambda>0$, if ϕ solves*

$$\Delta^2\phi=\lambda\phi \qquad \text{in } \Omega \tag{1.30}$$

$$\phi|_\Gamma=\left.\frac{\partial\phi}{\partial\nu}\right|_\Gamma=\left.\frac{\partial(\Delta\phi)}{\partial\nu}\right|_\Gamma=0 \tag{1.31}$$

(*elliptic problem with three homogeneous boundary conditions*) *then $\phi\equiv0$.*

THEOREM 1.2. (Uniform stabilization on Z with both feedback operators in the absence of geometrical conditions on Ω.) *The following property holds for the feedback problem* (1.21), *or* (1.22), (1.23): *there are constants* $M, \delta > 0$ *such that, if* $k_0 > 0$ *in* (1.12),

$$\left\| \begin{vmatrix} w(t) \\ w_t(t) \end{vmatrix} \right\|_Z = \left\| e^{\mathcal{A}t} \begin{vmatrix} w_0 \\ w_1 \end{vmatrix} \right\|_Z \leqq M e^{-\delta t} \left\| \begin{vmatrix} w_0 \\ w_1 \end{vmatrix} \right\|_Z, \quad t \geqq 0. \tag{1.32}$$

THEOREM 1.3. (Uniform stabilization on Z with only the first feedback operator g_1 and $g_2 \equiv 0$, in the presence of geometrical conditions on Ω.) *Consider the feedback problem* (1.1) *with* g_1 *given by* (1.10) *with* $k_1(x) \geqq k_0 > 0$ *while* $g_2 \equiv 0$, *i.e.*, (1.21) *with* $(\partial w/\partial \nu) = 0$ *on* Σ. *Then there are constants* $M, \delta > 0$ *such that the uniform decay* (1.32) *holds true, provided that* Ω *satisfies the following geometrical conditions: there exists a smooth vector field* $h(x) \in [C^2(\bar{\Omega})]^n$ *such that*

(i) (1.33) $h \cdot \nu \geqq \gamma > 0$ *on* Γ, ν = *unit outward normal*, γ = *constant*;

(ii) *There exists a positive constant* $\rho > 0$ *such that*

$$\int_\Omega H(x) v(x) \cdot v(x)\, d\Omega \geqq \rho \int_\Omega |v(x)|^2_{R^n}\, d\Omega \quad \forall v(x) \in [L^2(\Omega)]^n, \tag{1.34}$$

$$H(x) = \begin{vmatrix} \dfrac{\partial h_1}{\partial x_1} & \cdots & \dfrac{\partial h_1}{\partial x_n} \\ \vdots & & \vdots \\ \dfrac{\partial h_n}{\partial x_1} & \cdots & \dfrac{\partial h_n}{\partial x_n} \end{vmatrix}. \tag{1.35}$$

(*A checkable condition for* (ii) *to hold true is that the symmetric matrix* $H(x) + H^*(x)$ *be uniformly positive definite on* $\bar{\Omega}$).

Both conditions (i), (ii) *are satisfied automatically with* $h(x) = x - x_0$ *if*

$$(x - x_0) \cdot \nu \geqq \gamma > 0 \quad \text{on } \Gamma. \tag{1.36}$$

Remark 1.1. In the proof of Theorem 1.2, it will suffice to take a radial vector field $h(x) = x - x_0$. Then, in this case, the "const" in (3.2) below can be *explicitly* estimated (as in Theorem 1.3A below). As a consequence, the proof in [41, Thm. 4.1] provides an *explicit* estimate of the constant δ of decay rate in (1.32). The same conclusion that δ in (1.32) can be *explicitly* estimated also holds true for Theorem 1.3 in the case where the vector field $h(x)$ postulated there is radial (or linear), in which case Theorem 1.3B is not needed as $K_2 = 0$ in (1.37). The loss of explicit control of the "const" in (3.2) occurs in the proof of Theorem 1.3B, which is needed for a general vector field $h(x)$ (nonlinear) to absorb a "lower-order term." These considerations on the explicit estimate, or lack thereof, of the constant δ in (1.32) are *irrespective* of whether we use criterion (3.2) or the equivalent (*) in Remark 3.2: a radial vector field yields an explicit δ, while a more general vector field requires "absorption" of "lower-order terms," and this step loses control of the constant (in the case of criterion (*) in Remark 3.2, by virtue of the proof by contradiction in the compactness/unique argument in, say [19]. □

(By a local variation of the proof at the level of (3.54), (3.55) below, we may take $\gamma = 0$; see [14], [19, footnote 2].) The proof of Theorem 1.3 will be broken up in § 3 into two main results, Theorem 1.3A, B below.

THEOREM 1.3A. *Consider the feedback problem* (1.21) *with* $\partial w/\partial \nu = 0$ *on* Σ *in* (1.21d), *i.e., with* $k_2 \equiv 0$. *Then, under assumptions* (i)/(1.33) and (ii)/(1.34) *in Theorem*

1.3, *we have for* $\beta > 0$

$$\int_0^\infty e^{-2\beta t} E(t)\, dt \leqq K_1 E(0) + K_2 \int_0^\infty e^{-2\beta t} [\|A^{-1/2} w(t)\|^2_{L^2(\Omega)} + \|A^{-1} w_t(t)\|^2_{L^2(\Omega)}]\, dt + K_3 \int_0^\infty e^{-2\beta t} \|w(t)|_\Gamma\|^2_{L^2(\Gamma)}\, dt \tag{1.37}$$

where $E(t) \equiv \|A^{-1/4} w(t)\|^2_{L^2(\Omega)} + \|A^{-3/4} w_t(t)\|^2_{L^2(\Omega)}$, *and where the constants* K_1, K_2, K_3—*which can be explicitly estimated from the proof below—are independent of* β, $0 < \beta \leqq \beta_0 < \infty$. *Also, in particular,* $K_2 = 0$ *if the assumed vector field* $h(x)$ *is radial (or linear)* (K_2 *is proportional to* $\max |\nabla(\operatorname{div} h)|$ *over* $\bar{\Omega}$).

THEOREM 1.3B. *Consider the feedback problem* (1.21) *with* $\partial w/\partial \nu = 0$ *on* Σ *in* (1.21d). *Then, under uniqueness property assumption* (iii) *of Theorem* 1.3, *we have: for every* $\varepsilon > 0$ *there exists* C_ε *such that for every* $0 < \beta$

$$\int_0^\infty e^{-2\beta t} [\|A^{-1/2} w(t)\|^2_{L^2(\Omega)} + \|A^{-1} w_t(t)\|^2_{L^2(\Omega)}]\, dt \leqq \varepsilon \int_0^\infty e^{-2\beta t} [\|A^{-1/4} w(t)\|^2_{L^2(\Omega)} + \|A^{-3/4} w_t(t)\|^2_{L^2(\Omega)}] + C_\varepsilon E(0). \tag{1.38}$$

2. Preliminaries and proof of Theorem 1.1 (sketch).

Step 1. (Abstract model for the closed-loop problem.) We follow the conceptual approach of [21], [37], [39] for the wave equation, and of [19], [26], and [27] for the Euler–Bernoulli problem. The abstract differential version of (1.1)—which corresponds to the integral version of [19, eq. (2.3)] defining the explicit input $\{g_1, g_2\} \to$ solution $\{w, w_t\}$ map—is given in additive form by

$$w_{tt} = -Aw + AG_1 g_1 + AG_2 g_2 \tag{2.1a}$$

where the operators G_i are defined by (1.16), and where the operator A on the right of (2.1a) is the extension, with the same symbol $L^2(\Omega) \to [\mathscr{D}(A)]'$ of the original operator in (1.2). The corresponding first-order equation is

$$\frac{d}{dt} \begin{vmatrix} w \\ w_t \end{vmatrix} = \begin{vmatrix} 0 & I \\ -A & 0 \end{vmatrix} \begin{vmatrix} w \\ w_t \end{vmatrix} + \begin{vmatrix} 0 \\ AG_1 g_1 + AG_2 g_2 \end{vmatrix}. \tag{2.1b}$$

Since $\left|\begin{smallmatrix} 0 & I \\ -A & 0 \end{smallmatrix}\right|$ is skew-adjoint on Z (see (1.6)), then (2.1b) and (1.6) plainly suggest that we take $g_1 = -k_1^2 G_1^* A^{-1/2} w_t$ and $g_2 = -k_2 \Lambda^2 k_2 G_2^* A^{-1/2} w_t$ (as explicitly noted in (1.10), (1.11)) as natural candidates for feedback stabilization, as this choice then makes the corresponding feedback operator $\mathscr{A}$ defined by (1.23) dissipative on Z. Indeed, for $y = [y_1, y_2] \in \mathscr{D}(\mathscr{A})$,

$$\begin{aligned} \operatorname{Re} (\mathscr{A} y, y)_Z &= -(AG_1 k_1^2 G_1^* A^{-1/2} y_2, y_2)_{[\mathscr{D}(A^{3/4})]'} - (AG_2 k_2 \Lambda^2 k_2 G_2^* A^{-1/2} y_2, y_2)_{[\mathscr{D}(A^{3/4})]'} \\ &= -(A^{-1/2} G_1 k_1^2 G_1^* A^{-1/2} y_2, y_2)_{L^2(\Omega)} - (A^{-1/2} G_2 k_2 \Lambda^2 k_2 G_2^* A^{-1/2} y_2, y_2)_{L^2(\Omega)} \\ &= -\|k_1 G_1^* A^{-1/2} y_2\|^2_{L^2(\Gamma)} - \|\Lambda k_2 G_2^* A^{-1/2} y_2\|^2_{L^2(\Gamma)} \leqq 0 \end{aligned} \tag{2.2}$$

by (1.12), (1.13). Thus the resulting closed-loop problem, where (1.10) and (1.11) are inserted in (1.1c, d), respectively, takes the form

$$w_{tt} = -Aw - A[G_1 k_1^2 G_1^* A^{-1/2} w_t + G_2 k_2 \Lambda^2 k_2 G_2^* A^{-1/2} w_t] \tag{2.3}$$

on, say, $[\mathscr{D}(A)]'$, i.e., takes the explicit p.d.e. form (1.21). Henceforth, unless otherwise noted, we will take $k_1(x) = k_2(x) = 1$ for simplicity of notation when dealing with two feedbacks; and $k_1(x) \equiv 1$, $k_2 \equiv 0$ when dealing only with the feedback g_1, while $g_2 \equiv 0$.

Step 2. (Well-posedness.) Generation by $\mathscr{A}$ of an s.c. semigroup on Z follows via the Lumer–Phillips theorem, since $\mathscr{A}$ is actually maximal dissipative; and indeed direct computations show the explicit expression (1.24), (1.25) of the resolvent operator. To solve $(\lambda I - \mathscr{A})y = z \in Z$ with $\lambda > 0$ fixed, i.e., by (1.23)

$$\lambda y_1 - y_2 = z_1 \in [\mathscr{D}(A^{1/4})]', \tag{2.4}$$

$$A[y_1 + G_1 G_1^* A^{-1/2} y_2 + G_2 \Lambda^2 G_2^* A^{-1/2} y_2] + \lambda y_2 = z_2 \in [\mathscr{D}(A^{3/4})]' \tag{2.5}$$

for $y \in \mathscr{D}(\mathscr{A})$, we apply λA^{-1} to the second equation, subtract off the first, and obtain $V(\lambda) y_2 = \lambda A^{-1} z_2 - z_1 \in [\mathscr{D}(A^{1/4})]'$ via (1.25). But $V(\lambda)$ is boundedly invertible on $[\mathscr{D}(A^{1/4})]'$, since equivalently $A^{-1/4} V(\lambda) A^{1/4} = I + \lambda A^{-1/4} G_1 G_1^* A^{-1/4} + \lambda A^{-1/4} G_2 \Lambda^2 G_2^* A^{-1/4} + \lambda^2 A^{-1}$ is boundedly invertible on $L^2(\Omega)$ for $\lambda > 0$. This way (1.24) is obtained. Finally, from (1.24), compactness of $R(\lambda, \mathscr{A})$ on Z is readily seen to be a consequence of compactness on $L^2(\Omega)$ of the following operators:

$$\begin{aligned} &A^{-1/4} V^{-1}(\lambda) A^{1/4} A^{-1/2}, \qquad A^{-3/4} V^{-1}(\lambda) A^{1/4} A^{-1/2}, \\ &A^{-1/4}(I - V^{-1}(\lambda)) A^{1/4}, \qquad A^{-1/2} A^{-1/4} V^{-1}(\lambda) A^{1/4}. \end{aligned} \tag{2.6}$$

But the first and the fourth are compact here since, as shown above, $(A^{-1/4} V(\lambda) A^{1/4})^{-1} \in \mathscr{L}(L^2(\Omega))$ and of course A^{-1} is compact. The same is then seen to hold true for the third operator in (2.6), by

$$I - V^{-1}(\lambda) = \lambda V^{-1}(\lambda) G_1 G_1^* A^{-1/2} + \lambda V^{-1}(\lambda) G_2 \Lambda^2 G_2^* A^{-1/2} + \lambda^2 V^{-1}(\lambda) A^{-1},$$

which is obtained from (1.25) by applying $V^{-1}(\lambda)$ and using the preceding results. Finally, $\mathscr{A} y = 0$ yields $y = 0$ by (1.23) and $0 \in \rho(\mathscr{A})$.

Step 3. The L_2-boundedness in time (1.28), (1.29) follows at once from (2.2) with $y = [w(t), w_t(t)]$, since then the left of (2.2) is $\frac{1}{2}(d/dt)\|\exp(\mathscr{A}t)[w_0, w_1]\|_Z^2$: integrating in t and using contraction yields the conclusion.

Step 4. By contradiction, let $\lambda = \mathrm{ir}$, r real $\neq 0$, and let $V(\mathrm{ir})x = 0$. Taking the $[\mathscr{D}(A^{1/4})]'$-inner product, we obtain from the definition of $V(\cdot)$ in (1.25) (with $k_2 \equiv 0$ and $k_1 \equiv 1$)

$$G_1^* A^{-1/2} x = G_1^* A A^{-3/2} x = \frac{\partial \Delta}{\partial \nu} A^{-3/2} x|_\Gamma = 0 \tag{2.7}$$

using (1.19). Moreover, we obtain using (2.7) in $V(\lambda)$ that $Ax = r^2 x$. Thus, either $x = 0$ as desired, or else x is an eigenvector of A, say $x = e_n$, with eigenvalue r^2. Thus, $e_n|_\Gamma = (\partial e_n / \partial \nu)|_\Gamma = 0$. Moreover, $A^{-3/2} e_n = (1/r^2)^{3/2} e_n$ and (2.7) implies $(\partial \Delta e_n / \partial \nu)|_\Gamma = 0$. Then the uniqueness property to be proved in Steo 5 implies $x = e_n = 0$. Thus, the (point) spectrum of $\mathscr{A}$ is in $\mathrm{Re}\,\lambda < 0$.

Step 5. We prove the uniqueness property for problems (1.30), (1.31). Define the nonnegative self-adjoint operator

$$Af = \Delta^2 f; \qquad \mathscr{D}(A) = \left\{ f \in H^4(\Omega) : \frac{\partial f}{\partial \nu}\bigg|_\Gamma = \frac{\partial(\Delta f)}{\partial \nu}\bigg|_\Gamma = 0 \right\}. \tag{2.8}$$

Then plainly

$$A^{1/2} f = -\Delta f; \qquad \mathscr{D}(A^{1/2}) = \left\{ f \in H^2(\Omega) : \frac{\partial f}{\partial \nu}\bigg|_\Gamma = 0 \right\}. \tag{2.9}$$

Problems (1.30), (1.31) can be rewritten taking $\lambda = r^2$, with $r > 0$

$$A\phi = r^2 \phi \quad \text{plus } \phi|_\Gamma = 0. \tag{2.10}$$

Thus either $\phi \equiv 0$ and we are done, or else ϕ is an eigenvector of A with eigenvalue r^2. Applying $A^{-1/2}$ to (2.10) yields $A^{1/2}\phi = r\phi$ plus $\phi|_\Gamma = 0$; i.e., by (2.9)

$$\begin{cases} -\Delta\phi = r\phi, \\ \phi|_\Gamma = \dfrac{\partial\phi}{\partial\nu}\Big|_\Gamma = 0 \end{cases} \tag{2.11}$$

and (2.11) plainly implies $\phi \equiv 0$ in Ω (with sufficiently smooth Γ), as desired. □

3. Proof of Theorems 1.2 and 1.3.

3.1. Preliminaries and a change of variable. For the feedback problem (1.21) in the case of Theorem 1.2 (respectively, (1.21a-c)) and $(\partial w/\partial\nu)_\Sigma = 0$ in the case of Theorem 1.3) we define (the "energy functional") $E(t) \equiv E(w, t)$ by the squared norm of the semigroup in Theorem 1.1(i) on $Z = [\mathscr{D}(A^{1/4})]' \times [\mathscr{D}(A^{3/4})]'$:

$$\begin{aligned} E(t) &= \left\| e^{\mathscr{A}t} \begin{vmatrix} w_0 \\ w_1 \end{vmatrix} \right\|_Z^2 = \left\| \begin{vmatrix} w(t) \\ w_t(t) \end{vmatrix} \right\|_Z^2 \\ &= \|A^{-1/4} w(t)\|_{L^2(\Omega)}^2 + \|A^{-3/4} w_t(t)\|_{L^2(\Omega)}^2 \leqq E(0) \end{aligned} \tag{3.1}$$

by the contraction property of Theorem 1.1(i). Our main goal will be, as usual [8], [39], to show that

$$\int_0^\infty E(t)\, dt \leqq \text{const } E(0) \quad \forall [w_0, w_1] \in \mathscr{D}(\mathscr{A}) \tag{3.2}$$

where the constant is independent of the initial data $[w_0, w_1]$ whereby (3.2) can be extended by continuity to all $\{w_0, w_1\} \in Z$. After this, Datko's theorem [3] will yield the desired uniform bound (1.32). Thus, unless otherwise stated, we assume henceforth that $[w_0, w_1] \in \mathscr{D}(\mathscr{A})$.

Remark 3.1. Instead of (3.2), we may of course use the other well-known and equivalent criterion for uniform decay of a semigroup: that there is some $0 < T < \infty$ such that

$$(*) \qquad E(T) \leqq rE(0), \quad r < 1 \quad \text{or} \quad \|e^{\mathscr{A}T}\|_{\mathscr{L}(Z)} < 1.$$

Generally speaking, each of the two criteria, while requiring very closely related approaches and computations, offers some advantages and some disadvantages over the other. In the case of constant coefficients (canonically, with Δ^2) and with a radial vector field $h(x) = x - x_0$, as in the proof of our Theorem 1.2, the use of (*) offers some streamlining in the computations over use of (3.2): we may take $\beta = 0$ below and integrate in time over a finite interval, without needing to show that terms arising from integration by parts in time go to zero as $t \to \infty$. On the other hand, in the non-constant coefficient case (in space variable) and in working with a general vector field $h(x)$ as in the proof of Theorem 1.3 below, the need arises to absorb "lower-order terms." In using (*), we resort to some arguments of compactness type already used in the corresponding exact controllability results. These, however, ultimately rely on a Holmgren-type uniqueness property, and hence require smooth (analytic) coefficients. In contrast, in using criterion (3.2), absorption of lower-order terms requires a new result, such as our Theorem 1.3B in the case of the present paper. Such a result needs only minimal smoothness of the coefficients (in space); besides, it is of interest in itself. See, for instance, [8, § 5] for a more general wave equation with Neumann feedback, where the counterpart of (3.2) is used. As noted in Remark 1.1, achievement of an *explicit* estimate of the constant δ in (1.32) is *irrespective* of whether we use criterion

(3.2) or the equivalent condition (*) above. Indeed, it depends on whether $h(x)$ is radial (linear) or not.

Returning to (1.23), we see a more explicit description of $y=[y_1, y_2]\in\mathscr{D}(\mathscr{A})$:

(i) (3.3) $y_2\in[\mathscr{D}(A^{1/4})]'$; i.e., $A^{-1/4}y_2\in L^2(\Omega)$, i.e., $y_2\in H^{-1}(\Omega)$,

(ii) (3.4) $A[y_1+G_1G_1^*A^{-1/2}y_2+G_2\Lambda^2G_2^*A^{-1/2}y_2]\in[\mathscr{D}(A^{3/4})]'$,

$$y_1+G_1G_1^*A^{-1/2}y_2+G_2\Lambda^2G_2^*A^{-1/2}y_2\in\mathscr{D}(A^{1/4})=H_0^1(\Omega),$$

which implies a fortiori

$$y_1\in H^1(\Omega). \tag{3.5}$$

Conclusion (3.5) is a consequence of $A^{-1/2}y_2\in H_0^1(\Omega)$ by (3.3) and (1.3a), and of the following maps:

$$G_1G_1^*\text{: continuous } \mathscr{D}(A^{1/4})=H_0^1(\Omega)\to H^2(\Omega), \tag{3.6}$$

$$G_2\Lambda^2G_2^*\text{: continuous } \mathscr{D}(A^{1/4})=H_0^1(\Omega)\to H^2(\Omega). \tag{3.7}$$

Indeed, returning to (1.17) and (1.18), we see that these imply, respectively,

$$G_1^*\text{: continuous } H_0^1(\Omega)\to H^{3/2}(\Gamma) \tag{3.8}$$

by duality on (1.17) with $s=-\frac{3}{2}$, and

$$G_2^*\text{: continuous } H_0^1(\Omega)\to H^{5/2}(\Gamma) \tag{3.9}$$

by duality on (1.18) with $s=-\frac{5}{2}$. Then (3.8), followed by (1.17) with $s=\frac{3}{2}$, yields (3.6). Also, (3.9) and the definition (1.13) of Λ gives first

$$\Lambda^2G_2^*\text{: continuous } H_0^1(\Omega)\to H^{1/2}(\Gamma); \tag{3.10}$$

this followed by (1.18) with $s=\frac{1}{2}$ yields (3.7). Finally, (3.6), (3.7) used in (3.4) yield (3.5) via (3.3) as desired. Next, by Theorem 1.1(i),

$$\text{If } \{w_0, w_1\}\in\mathscr{D}(\mathscr{A}) \quad \text{then } \{w(t), w_t(t)\}\in C([0, T]; \mathscr{D}(\mathscr{A})) \tag{3.11a}$$

and thus by (3.3) and (3.5)

$$A^{-1/4}w_t\in C([0, T]; L^2(\Omega)), \quad w\in C([0, T]; H^1(\Omega)), \quad \{w_0, w_1\}\in\mathscr{D}(\mathscr{A}). \tag{3.11b}$$

Motivated by the multiplier techniques of [18] and [19], and by [20], we introduce a new variable p by setting $A^{3/4}p=A^{-3/4}w_t$; i.e.,

$$p=A^{-3/2}w_t\in\begin{cases}C([0, T]; \mathscr{D}(A^{3/4})) & \text{if } \{w_0, w_1\}\in Z,\\ C([0, T]; \mathscr{D}(A^{5/4})) & \text{if } \{w_0, w_1\}\in\mathscr{D}(\mathscr{A});\end{cases} \tag{3.12a, b}$$

see (1.6), Theorem 1.1(i) and (3.11b) respectively. Thus, by (2.3),

$$\begin{aligned}p_t=A^{-3/2}w_{tt}&=-A^{-1/2}[w+G_1G_1^*A^{-1/2}w_t+G_2\Lambda^2G_2^*A^{-1/2}w_t]\\ &\in\begin{cases}L^2(0, T; \mathscr{D}(A^{1/4})) & \text{if } \{w_0, w_1\}\in Z,\\ C([0, T]; \mathscr{D}(A^{3/4}) & \text{if } \{w_0, w_1\}\in\mathscr{D}(\mathscr{A})\end{cases}\end{aligned} \tag{3.13a, b}$$

where the regularity follows from Theorem 1.1(i), (1.28), (1.29), or (3.11a), (3.4), respectively; hence

$$p_{tt}=-A^{-1/2}[w_t+G_1G_1^*A^{-1/2}w_{tt}+G_2\Lambda^2G_2^*A^{-1/2}w_{tt}], \tag{3.14a}$$

$$p_{tt}=-Ap+F_1+F_2, \tag{3.14b}$$

$$F_1=-A^{-1/2}G_1G_1^*A^{-1/2}w_{tt}, \quad F_2=-A^{-1/2}G_2\Lambda^2G_2^*A^{-1/2}w_{tt}. \tag{3.15}$$

In terms of the scalar function $p(t,x)$, $x\in\Omega$, corresponding to the vector-valued function $p(t)=p(t,\cdot)$, the abstract equation (3.14b) can be rewritten explicitly as the following Euler-Bernoulli homogeneous problem with initial condition (I.C.) well defined at $t_0>0$ by (3.13b) and (2.3) for $w_{tt}(t_0)$

$$p_{tt}+\Delta^2 p=F_1+F_2 \qquad \text{in } (t_0,\infty)\times\Omega=Q, \tag{3.16a}$$

$$p(t_0,x)=p_0=A^{-3/2}w_t(t_0);\ p_t(t_0,x)=p_1=A^{-3/2}w_{tt}(t_0) \qquad \text{in } \Omega, \tag{3.16b}$$

$$p|_\Sigma=0 \qquad \text{in } (t_0,\infty)\times\Gamma=\Sigma, \tag{3.16c}$$

$$\left.\frac{\partial p}{\partial \nu}\right|_\Sigma=0 \qquad \text{in } \Sigma \tag{3.16d}$$

where the homogeneous boundary conditions are a consequence of $p\in\mathscr{D}(A^{3/4})$ from (3.12), and of (1.3). In our argument in the sequel, we will have to consider pointwise values $p_t(t)$. Note from (3.13b) that these make sense for initial data $\{w_0,w_1\}\in\mathscr{D}(\mathscr{A})$ *as assumed*, while from (3.13a) the pointwise meaning of p_t in $H_0^1(\Omega)=\mathscr{D}(A^{1/4})$ is lost for general initial data in Z. In the analysis below of the p-system (3.16), we will use the crucial results, from (1.3)-(1.5) via (3.12) and (3.13), that

$$\|A^{-3/4}w_t\|_{L^2(\Omega)}=\|A^{3/4}p\|_{L^2(\Omega)} \quad \text{equivalent to} \quad \left\{\int_\Omega |\nabla(\Delta p)|^2\,d\Omega\right\}^{1/2}, \tag{3.17}$$

$$\|A^{3/4}p(t)\|^2_{L^2(\Omega)}\leqq E(0) \quad \forall t\geqq 0, \tag{3.18}$$

$$A^{1/4}p_t=-A^{-1/4}w+O(\|G_1^*A^{-1/2}w_t\|_{L^2(\Gamma)}+\|\Lambda G_2^*A^{-1/2}w_t\|_{L^2(\Gamma)}), \tag{3.19}$$

the $L^2(\Gamma)$-terms being the feedback in (1.28), (1.29), since G_1 and $G_2\Lambda$ are bounded on $L^2(\Gamma)$ and

$$\|A^{1/4}p_t\|_{L^2(\Omega)} \quad \text{equivalent to} \quad \left\{\int_\Omega |\nabla p_t|^2\,d\Omega\right\}^{1/2}. \tag{3.20}$$

In (3.19) the symbol O means, as usual, bounded above by a constant. The norms on the right of (3.17) and (3.20) will arise in the multiplier approach used below (following [18], [19]); this justifies the need to introduce the variable p. Before applying the multiplier approach, we need to note what follows. Since $\lambda=0\in\rho(\mathscr{A})$, the resolvent set of $\mathscr{A}$, by Theorem 1.1(i), we have for $\{w_0,w_1\}\in\mathscr{D}(\mathscr{A})$

$$\left\|\begin{vmatrix} w(t)\\ w_t(t)\end{vmatrix}\right\|_{\mathscr{D}(\mathscr{A})}=\left\|e^{\mathscr{A}t}\begin{vmatrix} w_0\\ w_1\end{vmatrix}\right\|_{\mathscr{D}(\mathscr{A})}=\left\|e^{\mathscr{A}t}\mathscr{A}\begin{vmatrix} w_0\\ w_1\end{vmatrix}\right\|_Z\leqq\left\|\mathscr{A}\begin{vmatrix} w_0\\ w_1\end{vmatrix}\right\|_Z, \qquad t\geqq 0 \tag{3.21}$$

by the contraction property. A fortiori, (3.21) implies via (3.11b) for $\{w_0,w_1\}\in\mathscr{D}(\mathscr{A})$

$$\|w(t)\|^2_{H^1(\Omega)}+\|A^{-1/4}w_t(t)\|^2_{L^2(\Omega)}\leqq\left\|\mathscr{A}\begin{vmatrix} w_0\\ w_1\end{vmatrix}\right\|^2_Z \quad \forall t\geqq t_0. \tag{3.22}$$

By (3.12), $A^{5/4}p(t)=A^{-1/4}w_t(t)$, and by (3.13)

$$\begin{aligned} A^{1/4}p_t(t)=&-A^{-1/4}w(t)-A^{-1/4}G_1G_1^*A^{-1/4}A^{-1/4}w_t(t)\\ &-A^{-1/4}G_2\Lambda^2G_2^*A^{-1/4}A^{-1/4}w_t(t), \end{aligned} \tag{3.23}$$

so that from (3.22) we obtain

$$\|A^{5/4}p(t)\|^2_{L^2(\Omega)}+\|A^{1/4}p_t(t)\|^2_{L^2(\Omega)}\leqq\text{const}\left\{E(t_0)+\left\|\mathscr{A}\begin{vmatrix} w_0\\ w_1\end{vmatrix}\right\|^2_Z\right\}, \quad t\geqq t_0 \tag{3.24}$$

since $A^{-1/4}w(t) \in C([0, T]; L^2(\Omega))$ for all $\{w_0, w_1\} \in Z$ and $G_1 G_1^* A^{-1/4}$ are bounded on $L^2(\Omega)$ (see (3.6) and (3.7)).

3.2. An identity for the *p*-system.

PROPOSITION 3.1. *The following identity holds true for problem* (3.16), *where* $\{w_0, w_1\} \in \mathscr{D}(\mathscr{A})$; *hence* $\{p_0, p_1\} \in \mathscr{D}(A^{5/4}) \times \mathscr{D}(A^{3/4})$ *by* (3.12b), (3.13b), *where* $\beta > 0$ *is an arbitrary constant, and* $Q = (t_0, \infty) \times \Omega$, $\Sigma = (t_0, \infty) \times \Gamma$, *and* $h(x)$ *is a smooth vector field*:

$$
\begin{aligned}
&\int_\Sigma e^{-2\beta t} \frac{\partial(\Delta p)}{\partial \nu} h \cdot \nabla(\Delta p)\, d\Sigma - \frac{1}{2} \int_\Sigma e^{-2\beta t} |\nabla(\Delta p)|^2 h \cdot \nu\, d\Sigma \\
&\quad = \int_Q e^{-2\beta t} H \nabla(\Delta p) \cdot \nabla(\Delta p)\, dQ + \int_Q e^{-2\beta t} H \nabla p_t \cdot \nabla p_t\, dQ \\
&\qquad + \int_Q e^{-2\beta t} p_t \nabla p_t \cdot \nabla(\operatorname{div} h)\, dQ \\
&\qquad + \frac{1}{2} \int_Q e^{-2\beta t} \{|\nabla p_t|^2 - |\nabla(\Delta p)|^2\} \operatorname{div} h\, dQ \\
&\qquad + \int_Q e^{-2\beta t} (F_1 + F_2) h \cdot \nabla(\Delta p)\, dQ \\
&\qquad - 2\beta \int_Q e^{-2\beta t} p_t h \cdot \nabla(\Delta p)\, dQ + e^{-2\beta t_0} (p_1, h \cdot \nabla(\Delta p_0))_\Omega .
\end{aligned} \tag{3.25}
$$

Proof. Most of the proof is carried out in Appendix A and Leads to identities (A.8) and (A.10). It only remains to show that for the assumed initial data

$$
\lim_{T \to x} e^{-2\beta T} (p_t(T), h \cdot \nabla(\Delta p(T)))_\Omega = 0. \tag{3.26}
$$

Indeed, we have by using (3.17), (3.18) with $T \geqq t_0$, and (3.24)

$$
\begin{aligned}
|(p_t(T), h \cdot \nabla(\Delta p(T)))_\Omega| &\leqq c_h \{\| p_t(T) \|^2_{L^2(\Omega)} + \| A^{3/4} p(T) \|^2_{L^2(\Omega)}\} \\
&\leqq \text{const} \left\{ E(t_0) + \left\| \mathscr{A} \begin{vmatrix} w_0 \\ w_1 \end{vmatrix} \right\|^2_Z \right\}.
\end{aligned} \tag{3.27}
$$

□

It will be shown below that all the terms in (3.25) are well defined. But before doing so, we will rewrite the fourth integral over Q on the right of (3.25) in a more convenient form.

PROPOSITION 3.2. *The following identity holds true for problem* (3.16), *where* $\{w_0, w_1\} \in \mathscr{D}(\mathscr{A})$ *and* $\beta > 0$

$$
\begin{aligned}
&\int_Q e^{-2\beta t} \{|\nabla p_t|^2 - |\nabla(\Delta p)|^2\} \operatorname{div} h\, dQ \\
&\quad = -\int_\Sigma e^{-2\beta t} \frac{\partial(\Delta p)}{\partial \nu} \Delta p \operatorname{div} h\, d\Sigma + \int_Q e^{-2\beta t} (F_1 + F_2) \Delta p \operatorname{div} h\, dQ \\
&\qquad + \int_Q e^{-2\beta t} \Delta p \nabla(\Delta p) \cdot \nabla(\operatorname{div} h)\, dQ - 2\beta \int_Q e^{-2\beta t} p_t \Delta p \operatorname{div} h\, dQ \\
&\qquad - \int_Q e^{-2\beta t} p_t \nabla p_t \cdot (\operatorname{div} h)\, dQ + e^{-2\beta t_0} (p_1, \Delta p_0 \operatorname{div} h)_\Omega .
\end{aligned} \tag{3.28}
$$

Proof. Most of the proof is carried out in Appendix B and leads to identity (B.4). We must show only that

$$\lim_{T\to\infty} e^{-2\beta T}\int_\Omega \nabla p(T)\cdot\nabla(p_t(T)\operatorname{div} h)\,d\Omega = 0 \tag{3.29}$$

for the assumed initial data. Indeed, as in (3.27) we have by (3.20) and (3.24) for $T \geqq t_0$,

$$\begin{aligned}\left|\int_\Omega \nabla p(T)\cdot\nabla(p_t(T)\operatorname{div} h)\,d\Omega\right| &\leqq C_h\{\|A^{1/4}p(T)\|^2_{L^2(\Omega)}+\|A^{1/4}p_t(T)\|^2_{L^2(\Omega)}\}\\ &\leqq \text{const}\left\{E(t_0)+\left\|\mathscr{A}\begin{vmatrix}w_0\\ w_1\end{vmatrix}\right\|^2_Z\right\}.\end{aligned} \tag{3.30}$$

□

By combining Proposition 3.1 with Proposition 3.2 we readily obtain the following final identity.

PROPOSITION 3.3. *The following identity holds true for problem* (3.16), *where* $\{w_0, w_1\}\in\mathscr{D}(\mathscr{A})$, $\beta>0$ *is an arbitrary constant, and* $Q=(t_0,\infty)\times\Omega$; $\Sigma=(t_0,\infty)\times\Gamma$; *and* $h(x)$ *is a smooth vector field*

$$\begin{aligned}&\int_\Sigma e^{-2\beta t}\frac{\partial(\Delta p)}{\partial\nu}h\cdot\nabla(\Delta p)\,d\Sigma-\frac{1}{2}\int_\Sigma e^{-2\beta t}|\nabla(\Delta p)|^2 h\cdot\nu\,d\Sigma\\ &\quad+\frac{1}{2}\int_\Sigma e^{-2\beta t}\frac{\partial(\Delta p)}{\partial\nu}\Delta p\operatorname{div} h\,d\Sigma\\ &=\int_Q e^{-2\beta t}H\nabla(\Delta p)\cdot\nabla(\Delta p)\,dQ+\int_Q e^{-2\beta t}H\nabla p_t\cdot\nabla p_t\,dQ\\ &\quad+\int_Q e^{-2\beta t}(F_1+F_2)h\cdot\nabla(\Delta p)\,dQ+\frac{1}{2}\int_Q e^{-2\beta t}(F_1+F_2)\Delta p\operatorname{div} h\,dQ\\ &\quad+\frac{1}{2}\int_Q e^{-2\beta t}p_t\nabla p_t\cdot\nabla(\operatorname{div} h)\,dQ+\frac{1}{2}\int_Q e^{-2\beta t}\Delta p\nabla(\Delta p)\cdot\nabla(\operatorname{div} h)\,dQ\\ &\quad-2\beta\int_Q e^{-2\beta t}p_t h\cdot\nabla(\Delta p)\,dQ-\beta\int_Q e^{-2\beta t}p_t\Delta p\operatorname{div} h\,dQ\\ &\quad+e^{-2\beta t_0}(p_1, h\cdot\nabla(\Delta p_0))_\Omega+\frac{1}{2}e^{-2\beta t_0}(p_1,\Delta p_0\operatorname{div} h)_\Omega.\end{aligned} \tag{3.31}$$

The analysis below will show a fortiori that the terms in identity (3.31) are well defined by establishing appropriate estimates thereof.

3.3. Analysis of the terms involving F_i and the initial data. Crucial terms are those involving F_1, F_2 multiplied by $h\cdot\nabla(\Delta p)$.

PROPOSITION 3.4. *For* $\{w_0, w_1\}\in\mathscr{D}(\mathscr{A})$, *we have the following identity with* $\beta>0$:

(a)

$$\begin{aligned}&\int_Q e^{-2\beta t}(F_1+F_2)h\cdot\nabla(\Delta p)\,dQ+e^{-2\beta t_0}(p_1, h\cdot\nabla(\Delta p_0))_\Omega\\ &\quad-e^{-2\beta t_0}(A^{-1/2}w(t_0), h\cdot\nabla(\Delta p_0))_\Omega\\ &=\int_{t_0}^\infty e^{-2\beta t}(A^{-1/2}G_1G_1^*A^{-1/2}w_t+A^{-1/2}G_2\Lambda^2G_2^*A^{-1/2}w_t, h\cdot\nabla(\Delta p_t))_\Omega\,dt\\ &\quad+2\beta\int_{t_0}^\infty e^{-2\beta t}(A^{-1/2}G_1G_1^*A^{-1/2}w_t\\ &\quad+A^{-1/2}G_2\Lambda^2G_2^*A^{-1/2}w_t, h\cdot\nabla(\Delta p))_\Omega\,dt.\end{aligned} \tag{3.32}$$

(b) *For* $\{w_0, w_1\} \in \mathscr{D}(\mathscr{A})$ *and for any* $\varepsilon > 0$, *the following estimate holds for the first term of* (3.32):

$$\begin{aligned}
&\int_{t_0}^{\infty} e^{-2\beta t}(A^{-1/2}G_1G_1^*A^{-1/2}w_t + A^{-1/2}G_2\Lambda^2G_2^*A^{-1/2}w_t,\ h\cdot\nabla(\Delta p_t))_\Omega\, dt \\
&= \frac{1}{\varepsilon}\, O\left\{\int_{t_0}^{\infty} e^{-2\beta t}[\|G_1^*A^{-1/2}w_t\|^2_{L^2(\Gamma)} + \|\Lambda G_2^*A^{-1/2}w_t\|^2_{L^2(\Gamma)}]\, dt\right\} \qquad (3.33)\\
&\quad + \varepsilon\left\{\int_{t_0}^{\infty} e^{-2\beta t}E(t)\, dt\right\}
\end{aligned}$$

where O denotes upper bound with a multiplicative constant *independent* of β, and t_0 and the right-hand side of (3.33) are finite by Theorem 1.1(ii), (1.28), (1.29), and the contraction property (3.1) of $E(t)$.

(c)

$$\begin{aligned}
&\int_Q e^{-2\beta t}(F_1+F_2)h\cdot\nabla(\Delta p)\, dQ + e^{-2\beta t_0}(p_1,\ h\cdot\nabla(\Delta p_0))_\Omega \\
&= O\{E(t_0)\} + \frac{1}{\varepsilon}\, O\left\{\int_{t_0}^{\infty} e^{-2\beta t}[\|G_1^*A^{-1/2}w_t\|^2_{L^2(\Gamma)} + \|\Lambda G_2^*A^{-1/2}w_t\|^2_{L^2(\Gamma)}]\, dt\right\} \qquad (3.34)\\
&\quad + \varepsilon\left\{\int_{t_0}^{\infty} e^{-2\beta t}E(t)\, dt\right\}.
\end{aligned}$$

Proof. (a) Recalling F_1 from (3.15) and integrating by parts in t we obtain

$$\begin{aligned}
-\int_Q e^{-2\beta t}F_1h\cdot\nabla(\Delta p)\, dQ &= \int_{t_0}^{\infty}(A^{-1/2}G_1G_1^*A^{-1/2}w_{tt},\ e^{-2\beta t}h\cdot\nabla(\Delta p))_\Omega\, dt \\
&= -e^{-2\beta t_0}(A^{-1/2}G_1G_1^*A^{-1/2}w_t(t_0),\ h\cdot\nabla(\Delta p_0))_\Omega \\
&\quad + 2\beta\int_{t_0}^{\infty} e^{-2\beta t}(A^{-1/2}G_1G_1^*A^{-1/2}w_t,\ h\cdot\nabla(\Delta p))_\Omega\, dt \qquad (3.35)\\
&\quad - \int_{t_0}^{\infty} e^{-2\beta t}(A^{-1/2}G_1G_1^*A^{-1/2}w_t,\ h\cdot\nabla(\Delta p_t))_\Omega\, dt
\end{aligned}$$

since for $\{w_0, w_1\} \in \mathscr{D}(\mathscr{A})$ as assumed we have

$$\lim_{T\to\infty} e^{-2\beta T}(A^{-1/2}G_1G_1^*A^{-1/2}w_t(T),\ h\cdot\nabla(\Delta p(T))_\Omega = 0. \qquad (3.36)$$

Since $A^{-1/2}G_1G_1^*$ is a bounded operator on $L^2(\Omega)$, we arrive at (3.36) readily by applying the Schwarz inequality to the inner product in Ω, using $\|A^{-1/2}w_t(T)\| = \|Ap(T)\|$ by (3.12) and $\||\nabla(\Delta p(T))|\| \sim \|A^{3/4}p(T)\|$ by (3.17), and recalling (3.24). Similarly, recalling F_2 from (3.15) we obtain, integrating by parts in t,

$$\begin{aligned}
-\int_Q e^{-2\beta t}F_2h\cdot\nabla(\Delta p)\, dQ &= \int_{t_0}^{\infty}(A^{-1/2}G_2\Lambda^2G_2^*A^{-1/2}w_{tt},\ e^{-2\beta t}h\cdot\nabla(\Delta p))_\Omega\, dt \\
&= -e^{-2\beta t_0}(A^{-1/2}G_2\Lambda^2G_2^*A^{-1/2}w_t(t_0),\ h\cdot\nabla(\Delta p_0))_\Omega \qquad (3.37)\\
&\quad + 2\beta\int_{t_0}^{\infty} e^{-2\beta t}(A^{-1/2}G_2\Lambda^2G_2^*A^{-1/2}w_t,\ h\cdot\nabla(\Delta p))_\Omega\, dt \\
&\quad - \int_{t_0}^{\infty} e^{-2\beta t}(A^{-1/2}G_2\Lambda^2G_2^*A^{-1/2}w_t,\ h\cdot\nabla(\Delta p_t))_\Omega\, dt \qquad (3.38)
\end{aligned}$$

since for $\{w_0, w_1\} \in \mathscr{D}(\mathscr{A})$ as assumed we have

$$\lim_{T\to\infty} e^{-2\beta T}(A^{-1/2}G_2\Lambda^2 G_2^* A^{-1/2} w_t(T), h\cdot\nabla(\Delta p(T)))_\Omega = 0. \tag{3.39}$$

An argument similar to the one below (3.36) establishes (3.39), this time with $A^{-1/2}G_2\Lambda^2 G_2^* A^{-1/4}$ a bounded operator on $L^2(\Omega)$ by (3.7), and with $\|A^{-1/4}w_t(T)\| = \|A^{5/4}p(T)\|$ by (3.12), so that we can once again invoke (3.24). Finally, to obtain (3.32), we sum up (3.35) with (3.37) and use (3.13) in combining the two $(\ ,\ )_\Omega$-terms for $t = t_0$. Part (a) is proved.

(b) We treat each term on the left of (3.33) separately. We will use the following lemma.

LEMMA 3.5. *For $h = [h_1(x), \cdots, h_n(x)] \in [C^2(\bar\Omega)]^n$, we have*

$$\|A^{-1/2}(h\cdot\nabla(\Delta p_t))\|_{L^2(\Omega)} \leqq C_h \|A^{1/4}p_t\|_{L^2(\Omega)}. \tag{3.40}$$

Proof of Lemma 3.5. We have that $\mathscr{D}(A^{1/2}) = H_0^2(\Omega)$ (see [19, App. C]) so that $[\mathscr{D}(A^{1/2})]' = H^{-2}(\Omega)$ (with equivalent norms). Then, since $p_t|_\Gamma = 0$ so that (3.20) applies,

$$\|A^{-1/2}(h\cdot\nabla(\Delta p_t))\|_{L^2(\Omega)} = \|h\cdot\nabla(\Delta p_t)\|_{[\mathscr{D}(A^{1/2})]'} \leqq c_1\|h\cdot\nabla(\Delta p_t)\|_{H^{-2}(\Omega)} \tag{3.41}$$

$$\leqq C_h \||\nabla(\Delta p_t)|\|_{H^{-2}(\Omega)} \leqq C_h\|p_t\|_{H^1(\Omega)} = C_h\|A^{1/4}p_t\|_{L^2(\Omega)}. \tag{3.42}$$

In going from (3.41) to (3.42) we have used (see also [17, p. 31]) the fact that if z is a scalar function in $H^{-2}(\Omega)$, and $h_i \in C^2(\bar\Omega)$, then we have $h_i z \in H^{-2}(\Omega)$ continuously, as it follows directly by duality. If $y \in H_0^2(\Omega)$ and $h_i \in C^2(\bar\Omega)$, then $h_i y \in H_0^2(\Omega)$, since $(h_i y)|_\Gamma = 0$ and $\partial(h_i y)/\partial\nu|_\Gamma = 0$ by using the same properties for y. □

Then (3.33) follows at once from (3.40) (after moving the self-adjoint $A^{-1/2}$ across the $(\ ,\ )_\Omega$-inner product) and from (3.19) and (3.1).

(c) We use (1.28), (1.29) and (3.17), (3.18) to obtain readily

$$\begin{aligned} &2\beta\int_{t_0}^\infty e^{-2\beta t}(A^{-1/2}G_1G_1^*A^{-1/2}w_t + A^{-1/2}G_2\Lambda^2G_2^*A^{-1/2}w_t, h\cdot\nabla(\Delta p))_\Omega\, dt \\ &\leqq 2\beta[E(t_0) + \int_{t_0}^\infty e^{-2\beta t}E(t)\, dt] = (2\beta+1)O(E(t_0)) \end{aligned} \tag{3.43}$$

by the contraction property of $E(t)$. Then (3.33) and (3.43) used in (3.32) readily yield (3.34). □

The integral terms in (3.31) involving the lower-order terms $F_i\Delta p$ div h are a fortiori handled by the analysis in Proposition 3.4 that deals with the integral terms involving the higher-order terms $F_i h\cdot\nabla(\Delta p)$. Thus, we have the following easy counterpart of (3.34) of Proposition 3.4c.

PROPOSITION 3.6. *For $\{w_0, w_1\} \in \mathscr{D}(\mathscr{A})$ we have the following estimate with $\beta > 0$:*

$$\begin{aligned} &\int_Q e^{-2\beta t}(F_1+F_2)\Delta p \text{ div } h\, dQ + e^{-2\beta t_0}(p_1, \Delta p_0 \text{ div } h)_\Omega \\ &= \frac{1}{\varepsilon} O\left\{\int_{t_0}^\infty e^{-2\beta t}[\|G_1^*A^{-1/2}w_t\|^2_{L^2(\Gamma)} + \|\Lambda G_2^*A^{-1/2}w_t\|^2_{L^2(\Gamma)}]\, dt\right\} \\ &\quad + \varepsilon\left(\int_{t_0}^\infty e^{-2\beta t}E(t)\, dt\right) + O\{E(t_0)\}. \end{aligned} \tag{3.44}$$

3.4. Completion of the proof of Theorem 1.2: two feedback controls g_1 and g_2, in the absence of geometrical conditions on Ω.

Right-hand side of (3.31). We will specialize the vector field $h(x)$ to a radial field $h(x)=x-x_0\in R^n$. Thus, $H(x)\equiv$ Identity, div $h\equiv \dim\Omega=n$, and the two integral terms in identity (3.31) involving ∇ (div h) vanish. As to the integral terms in (3.31) premultiplied by β, we readily see by (3.17), (3.19), (3.1), and (1.28), (1.29) that

$$2\beta\int_Q e^{-2\beta t}p_t h\cdot\nabla(\Delta p)\,dQ-\beta\int_Q e^{-2\beta t}p_t\Delta p\ \text{div}\ h\,dQ=(\beta+1)O(E(t_0)) \tag{3.45}$$

Hence, using (3.34), (3.44), and (3.45) on the right-hand side (R.H.S.) of identity (3.31), we obtain

$$\begin{aligned}\text{R.H.S. of (3.31)}=&\int_Q e^{-2\beta t}[|\nabla(\Delta p)|^2+|\nabla p_t|^2\,dQ+\varepsilon\int_{t_0}^{\infty}e^{-2\beta t}E(t)\,dt\\ &+\frac{1}{\varepsilon}O\left\{\int_{t_0}^{\infty}e^{-2\beta t}[\|G_1^*A^{-1/2}w_t\|^2_{L^2(\Gamma)}+\|\Lambda G_2^*A^{-1/2}w_t\|^2_{L^2(\Gamma)}]\,dt\right\}\\ &+O(E(t_0)).\end{aligned} \tag{3.46}$$

Thus, recalling again (3.17), (3.19), (3.20), and (3.1), we finally obtain from (3.46) with $c_{i\varepsilon}$ positive constants:

$$\text{R.H.S. of (3.31)}\geqq c_{1\varepsilon}\int_{t_0}^{\infty}e^{-2\beta t}E(t)\,dt-c_{2\varepsilon}E(t_0), \tag{3.47}$$

which is the desired estimate.

Left-hand side of (3.31). We collect the three pieces of information that are needed. First, by (1.10), (1.19), (3.12), and (1.28), we obtain

$$-w|_\Sigma=G_1^*A^{-1/2}w_t=G_1^*AA^{-3/2}w_t=\frac{\partial(\Delta p)}{\partial\nu}\in L^2(0,\infty;L^2(\Gamma)) \tag{3.48}$$

continuously in $E(0)$. Next, in a similar way, by (1.20) and (1.29) we find

$$\Lambda G_2^*A^{-1/2}w_t=\Lambda G_2^*AA^{-3/2}w_t=-\Lambda(\Delta p)\in L^2(0,\infty;L^2(\Gamma)) \tag{3.49}$$

continuously in $E(0)$, i.e., via the definition of Λ in (1.13):

$$\int_{t_0}^{\infty}\|\Lambda(\Delta p)\|^2_{L^2(\Gamma)}\,dt=\int_{t_0}^{\infty}\int_\Gamma(\Delta p)^2+|\nabla_\sigma(\Delta p)|^2\,d\Gamma\,dt\leqq E(t_0). \tag{3.50}$$

We now return to the left-hand side (L.H.S.) of identity (3.31) and see that by (3.48)–(3.50), along with $|\nabla(\Delta p)|^2=|\partial(\Delta p)/\partial\nu|^2+|\nabla_\sigma(\Delta p)|^2$, (1.28), (1.29), and (3.17) we obtain for any $\varepsilon>0$

$$\begin{aligned}\text{L.H.S. of (3.31)}&\leqq C_{h,\varepsilon}\int_\Sigma e^{-2\beta t}\left[\left(\frac{\partial(\Delta p)}{\partial\nu}\right)^2+|\nabla_\sigma(\Delta p)|^2+(\Delta p)^2\right]d\Sigma\\ &\leqq C_{h,\varepsilon}E(t_0),\end{aligned} \tag{3.51}$$

which is the desired estimate. Finally, we combine (3.47) and (3.51) and we conclude that if $\{w_0,w_1\}\in\mathcal{D}(\mathcal{A})$ and $\beta>0$ then

$$\int_{t_0}^{\infty}e^{-2\beta t}E(t)\,dt\leqq\text{const}\,E(t_0) \tag{3.52}$$

with const independent of β_0, $0<\beta\leqq\beta_0$, and of $\{w_0,w_1\}$. Letting $\beta\downarrow 0$ in (3.52) we easily obtain (3.2). The proof of Theorem 1.2 is complete. □

3.5. Completion of the proof of Theorem 1.3A: feedback control for g_1 while $g_2 \equiv 0$, under geometrical conditions for Ω. Now let $h(x)$ be a general smooth vector field as assumed in (1.33), (1.34) of Theorem 1.3. Then we estimate the two integral terms involving ∇ (div h) by

$$\int_Q e^{-2\beta t} p_t \nabla p_t \cdot \nabla(\operatorname{div} h)\, dQ + \int_Q e^{-2\beta t} \Delta p \nabla(\Delta p) \cdot \nabla(\operatorname{div} h)\, dQ$$
$$= \varepsilon O\left(\int_Q e^{-2\beta t} [|\nabla p_t|^2 + |\nabla(\Delta p)|^2]\, dQ \right)$$
$$+ \frac{1}{\varepsilon} O\left(\int_Q e^{-2\beta t} [p_t^2 + (\Delta p)^2]\, dQ \right).$$

Thus, the new contribution in the R.H.S. of (3.31) is given by the above terms when $h(x)$ is not linear, where $\|\Delta p\| = \|A^{1/2} p\| = \|A^{-1} w_t\|$ in the $L^2(\Omega)$-norm by (3.12); moreover, $\|p_t\|$ is estimated by (3.13) (with $k_2 = 0$ as we are taking $g_2 \equiv 0$ now), subject to the feedback bound (1.28). Thus the counterpart of (3.51) is

$$\text{R.H.S. of (3.31)} \geqq C_{1\varepsilon} \int_{t_0}^{\infty} e^{-2\beta t} E(t)\, dt - C_{2\varepsilon} E(t_0)$$
$$- C_{3h\varepsilon} \int_{t_0}^{\infty} e^{-2\beta t} [\|A^{-1/2} w\|^2_{L^2(\Omega)} + \|A^{-1} w_t\|^2_{L^2(\Omega)}]\, dt \tag{3.53}$$

after we use (1.34) on the matrix $H(x)$, with positive constants independent of β and t_0, where $C_{3h\varepsilon} = 0$ if $h(x)$ is linear in x ($C_{3h\varepsilon}$ is proportional to $\max |\nabla(\operatorname{div} h)|$ over $\bar{\Omega}$). In the absence of a feedback control on g_2, i.e., with $g_2 \equiv 0$, we estimate the L.H.S. of (3.31) differently. We use the assumption (1.33) on h and obtain, since $\|\Delta p\|_{L^2(\Gamma)} \leqq C\|\Delta p\|_{H^1(\Omega)} \leqq C\|p\|_{H^3(\Omega)} \leqq C\|A^{3/4} p\|_{L^2(\Omega)}$ because $p|_\Gamma = (\partial p/\partial \nu)|_\Gamma = 0$,

$$\text{L.H.S. of (3.31)} \leqq \frac{c_h}{\varepsilon} \int_\Sigma e^{-2\beta t} \left(\frac{\partial(\Delta p)}{\partial \nu} \right)^2 d\Sigma + \left(\varepsilon - \frac{\gamma}{2} \right) \int_\Sigma e^{-2\beta t} |\nabla(\Delta p)|^2\, dQ$$
$$- \varepsilon \int_{t_0}^{\infty} e^{-2\beta t} \|A^{3/4} p\|^2_{L^2(\Omega)}\, dt \tag{3.54}$$

$$\leqq O(E(t_0)) - \varepsilon \int_{t_0}^{\infty} e^{-2\beta t} E(t)\, dt \tag{3.55}$$

after selecting $\varepsilon < \gamma/2$, dropping the $|\nabla(\Delta p)|^2$-term, and recalling (3.48) and (3.17). Combining (3.53) with (3.55) yields (1.37) in Theorem 1.3A. (A local variation of the argument in (3.54), (3.55) also allows us to take $\gamma = 0$; see [14], [19, footnote 2].) □

3.6. Proof of Theorem 1.3B.

Step 1.[1] From $\|A^{-1/2} w\|^2 = (A^{-1/4} w, A^{-3/4} w)$ and $\|A^{-1} w_t\|^2 = (A^{-3/4} w_t, A^{-5/4} w_t)$ we obtain for any $\varepsilon > 0$

$$2 \int_0^{\infty} e^{-2\beta t} \|A^{-1/2} w(t)\|^2\, dt \leqq \varepsilon \int_0^{\infty} e^{-2\beta t} \|A^{-1/4} w(t)\|^2\, dt$$
$$+ \frac{1}{\varepsilon} \int_0^{\infty} e^{-2\beta t} \|A^{-3/4} w(t)\|^2\, dt, \tag{3.56}$$

[1] All norms and inner products in this subsection are in $L^2(\Omega)$, unless otherwise noted explicitly. Note that the absorption within ε of Theorem 1.3B is in the space variable, not in the time variable as in [8], [39].

$$2\int_0^\infty e^{-2\beta t}\|A^{-1}w_t(t)\|^2\,dt \leqq \varepsilon\int_0^\infty e^{-2\beta t}\|A^{-3/4}w_t(t)\|^2\,dt + \frac{1}{\varepsilon}\int_0^\infty e^{-2\beta t}\|A^{-5/4}w_t(t)\|^2\,dt. \tag{3.57}$$

Thus, in view of (3.56), (3.57), to prove (1.38) in Theorem 1.3B, all we need is the following result.

PROPOSITION 3.7. *With reference to the closed-loop problem* (1.21) *with* $k_2 \equiv 0$, *i.e.*, $\partial w/\partial \nu \equiv 0$ *on* Σ, *for every* ε_1 *there is a* $C_{\varepsilon_1} > 0$ *such that for every* $\beta > 0$

(a)

$$\int_0^\infty e^{-2\beta t}\|A^{-3/4}w(t)\|^2\,dt \leqq \varepsilon_1\int_0^\infty e^{-2\beta t}\|A^{-3/4}w_t(t)\|^2\,dt + C_{\varepsilon_1}E(0), \tag{3.58}$$

(b)

$$\int_0^\infty e^{-2\beta t}\|A^{-5/4}w_t(t)\|^2\,dt \leqq \varepsilon_1\int_0^\infty e^{-2\beta t}\|A^{-5/4}w_{tt}(t)\|^2\,dt + C_{\varepsilon_1}E(0) \tag{3.59}$$

where by (2.3)

$$\|A^{-5/4}w_{tt}\|^2 \leqq 2\|A^{-1/4}w\|^2 + \text{const}\,\|G_1^*A^{-1/2}w_t\|^2_{L^2(\Gamma)} \quad \textit{a.e. in } t, \tag{3.60}$$

so that (3.59) *implies by* (3.60) *and by the feedback bound* (1.28)

$$\int_0^\infty e^{-2\beta t}\|A^{-5/4}w_t(t)\|^2\,dt \leqq 2\varepsilon_1\int_0^\infty e^{-2\beta t}\|A^{-1/4}w(t)\|^2\,dt + C'_{\varepsilon_1}E(0). \tag{3.61}$$

Step 3. Using (3.58) and (3.61) in (3.56) and (3.57), respectively, with $\varepsilon_1 < \varepsilon^2$ we obtain (1.35) in Theorem 1.3B.

Step 4. *Proof of Proposition* 3.7. Patterned after the proof in [39, § 3.2] of Theorem 2 in [8] for the case of wave equation problem considered there. We introduce a new variable

$$u(t,x) = \phi(t)w(t,x), \quad \phi \in C^\infty(R), \quad \phi(0) = \phi'(0) = \phi''(0) = 0, \quad \phi(t) \equiv 1, \quad \text{for } t \geqq 1. \tag{3.62}$$

Then, in the new variable u, (1.21) with $\partial w/\partial \nu \equiv 0$ on Σ becomes

$$u_{tt} + \Delta^2 u = b \qquad \text{in } (0,\infty)\times\Omega, \tag{3.63a}$$

$$u|_{t=0} = 0;\ u_t|_{t=0} = 0 \qquad \text{in } \Omega, \tag{3.63b}$$

$$u|_\Sigma = -G_1^*A^{1/2}u_t + G_1^*A^{-1/2}\phi' w \qquad \text{in } (0,\infty)\times\Gamma, \tag{3.63c}$$

$$\left.\frac{\partial u}{\nabla \nu}\right|_\Sigma \equiv 0 \qquad \text{in } (0,\infty)\times\Gamma, \tag{3.63d}$$

$$b = \phi'' w + 2\phi' w_t, \tag{3.64}$$

whose explicit solution, according to the operator model in e.g., [18], [19] is

$$u(t) = A\int_0^t S(t-\tau)G_t[-G_1^*A^{-1/2}u_t(\tau) + G_1^*A^{-1/2}\phi'(\tau)w(\tau)]\,d\tau + \int_0^t S(t-\tau)b(\tau)\,d\tau \tag{3.65}$$

where $S(t)=\int_0^t C(\tau)\,d\tau$, $C(\cdot)$ being the cosine operator on $L^2(\Omega)$ generated by the negative self-adjoint operator $-A$. Taking the Laplace transform of (3.65) with $\hat{u}_t(\lambda)=\lambda\hat{u}(\lambda)$ by (3.63b) and $\widehat{S(t)}=R(\lambda^2,-A)$, $\lambda=\beta+i\alpha$, we obtain

$$\begin{aligned}[I+\lambda AR(\lambda^2,-A)G_1G_1^*A^{-1/2}]\hat{u}(\lambda)\\ =AR(\lambda^2,-A)G_1G_1^*A^{-1/2}[\widehat{\phi' w}](\lambda)+R(\lambda^2,-A)\hat{b}(\lambda).\end{aligned}\tag{3.66}$$

But, if we recall the definition of $V(\lambda)$ in (1.25) (with $k_1\equiv 1$, $k_2\equiv 0$), we see that

$$\begin{aligned}I+\lambda AR(\lambda^2,-A)G_1G_1^*A^{-1/2}&=R(\lambda^2,-A)A[I+\lambda G_1G_1^*A^{-1/2}+\lambda^2A^{-1}]\\ &=AR(\lambda^2,-A)V(\lambda)\end{aligned}\tag{3.67}$$

inserted in (3.66) yields

$$\begin{aligned}AR(\lambda^2,-A)V(\lambda)\hat{u}(\lambda)&=AR(\lambda^2,-A)G_1G_1^*A^{-1/2}[\widehat{\phi' w}](\lambda)\\ &\quad+AR(\lambda^2,-A)A^{-1}\hat{b}(\lambda),\end{aligned}\tag{3.68}$$

valid at least for all $\lambda=\beta+i\alpha$, $\beta\geqq 0$, with $\lambda^2=\beta^2-\alpha^2+2i\alpha\beta\neq\{-\mu_n,\ n=1,2\cdots\}$, $\mu_n>0$, the eigenvalues of A; i.e., except $\beta=0$ and $\alpha^2=\mu_n$, or $\lambda=\lambda_n=\pm i\sqrt{\mu_n}$, where $R(\lambda^2,-A)$ is *not* defined. Then (3.68) yields after a crucial cancellation

$$\hat{u}(\lambda)=V^{-1}(\lambda)[G_1G_1^*A^{-1/2}(\widehat{\phi' w})+A^{-1}\hat{b}](\lambda).\tag{3.69}$$

Moreover, since $\phi' w$ and b both vanish at $t=0$ by (3.64) and (3.62), we have

$$\begin{aligned}\lambda[\widehat{\phi' w}](\lambda)&=[(\widehat{\phi' w})_t](\lambda)=[\widehat{\phi'' w}+\widehat{\phi' w_t}](\lambda),\\ \lambda\hat{b}(\lambda)&=[\hat{b}_t](\lambda)=[\widehat{\phi''' w}+3\widehat{\phi'' w_1}+2\widehat{\phi' w_{tt}}](\lambda)\end{aligned}\tag{3.70}$$

and thus by (3.69), (3.70)

$$[\hat{u}_t](\lambda)=\lambda\hat{u}(\lambda)=V^{-1}(\lambda)[G_1G_1^*A^{-1/2}[(\widehat{\phi' w})_t]+A^{-1}\hat{b}_t](\lambda).\tag{3.71}$$

Then, by Theorem 1.1(iii), the resolvent $R(\lambda,\mathcal{A})$ is well defined also on the imaginary axis. Hence, we have that $V^{-1}(\lambda)\in\mathcal{L}(L^2(\Omega))$ in the closed right half plane $\operatorname{Re}\lambda\geqq 0$, including the imaginary axis $\beta=0$, and is holomorphic in $\operatorname{Re}\lambda>0$. Moreover, for any λ in the *closed* rectangle $\mathcal{R}_{\alpha_0}$: $0\leqq\operatorname{Re}\lambda\leqq 1$, $|\operatorname{Im}\lambda|\leqq\alpha_0$, with $\alpha_0>0$ arbitrary, we have

$$\|V^{-1}(\lambda)\|_{\mathcal{L}(L^2(\Omega))}\leqq C_{\alpha_0},\qquad \lambda\in\mathcal{R}_{\alpha_0}.\tag{3.72}$$

Proof of part (a), (3.58). With $\lambda=\beta+i\alpha$, β fixed, $0<\beta\leqq 1$, we obtain from (3.69) and (3.72) by use of Parseval equality and obvious majorizations on bounded operators since $\phi'=\phi''\equiv 0$ for $t\geqq 1$

$$\begin{aligned}&\int_{|\alpha|\leqq\alpha_0}\|A^{-3/4}\hat{u}(\lambda)\|^2\,d\alpha\\ &\leqq C_{\alpha_0}\left\{\int_{|\alpha|\leqq\alpha_0}\|[A^{-1/4}\widehat{\phi' w}](\lambda)\|^2\,d\alpha+\int_{|\alpha|\leqq\alpha_0}\|[A^{-3/4}\hat{b}](\lambda)\|^2\,d\alpha\right\}\end{aligned}$$

$$\leqq C_{\alpha_0}\left\{\int_0^\infty e^{-2\beta t}\|A^{-1/4}\phi' w\|^2\,dt+\int_0^\infty e^{-2\beta t}\|A^{-3/4}(\phi'' w+2\phi' w_t)\|^2\,dt\right\} \tag{3.73}$$

(by (3.64b))

$$\leqq C_\phi C_{\alpha_0}\left\{\int_0^1 \|A^{-1/4}w\|^2+\|A^{-3/4}w_t\|^2\,dt\right\}\leqq C_\phi C_{\alpha_0}E(0)$$

by the contraction property of $E(t)$. Next, for $|\alpha|>\alpha_0>0$, where $1/|\lambda|^2\leqq(\alpha^2/\alpha_0^2)(1/|\lambda|^2)\leqq 1/\alpha_0^2$, the Parseval equality gives

$$\begin{aligned}\int_{|\alpha|>\alpha_0}|A^{-3/4}\hat{u}(\lambda)\|^2\,d\alpha &= \int_{|\alpha|>\alpha_0}\frac{1}{|\lambda|^2}\|A^{-3/4}\lambda\hat{u}(\lambda)\|^2\,d\alpha\\ &\leqq\frac{1}{\alpha_0^2}\int_{|\alpha|>\alpha_0}\|A^{-3/4}\hat{u}_t(\lambda)\|^2\,d\alpha\\ &\leqq\frac{2\pi}{\alpha_0^2}\int_0^\infty e^{-2\beta t}\|A^{-3/4}u_t\|^2\,dt.\end{aligned} \tag{3.74}$$

Choosing $1/\alpha_0^2=\varepsilon_1$, we obtain from (3.73), (3.74) and the Parseval equality

$$2\pi\int_0^\infty e^{-2\beta t}\|A^{-3/4}u(t)\|^2\,dt\leqq\varepsilon_1\int_0^\infty e^{-2\beta t}\|A^{-3/4}u_t(t)\|^2\,dt+C_{\varepsilon_1}E(0), \tag{3.75}$$

which is an inequality of the type desired, but for u, not w. We return from u to w: since $u\equiv w$ for $t\geqq 1$ by (3.62), and $u_t=\phi' w+\phi w_t$, so that

$$\|A^{-3/4}u_t\|^2=O(\|A^{-1/4}w\|^2+\|A^{-3/4}w_t\|^2), \tag{3.76}$$

$$\begin{aligned}\int_0^\infty e^{-2\beta t}\|A^{-3/4}w(t)\|^2\,dt &= \int_0^1 e^{-2\beta t}\|A^{-3/4}w(t)\|^2\,dt+\int_1^\infty e^{-2\beta t}\|A^{-3/4}u(t)\|^2\,dt\\ &\leqq CE(0)+\varepsilon_1\int_0^1 e^{-2\beta t}\|A^{-3/4}u_t(t)\|^2\,dt\\ &\quad+\varepsilon_1\int_1^\infty e^{-2\beta t}\|A^{-3/4}w_t(t)\|^2\,dt+C_{\varepsilon_1}E(0)\\ &\leqq C_{\varepsilon_1}E(0)+\varepsilon_1\int_0^1 e^{-2\beta t}\|A^{-3/4}w_t(t)\|^2\,dt\\ &\quad+\varepsilon_1\int_1^\infty e^{-2\beta t}\|A^{-3/4}w_t(t)\|^2\,dt\end{aligned} \tag{3.77}$$

(by (3.76) in $0\leqq t\leqq 1$)

and part (a), (3.58) is proved.

Proof of part (b), (3.59). The proof is conceptually similar. We start from (3.71). We have that the resolvent $R(\lambda,\mathscr{A})$ is well defined in all of $\operatorname{Re}\lambda\geqq 0$ and hence (see the proof of Theorem 1.1 following (2.5))

$$\|A^{-1/4}V^{-1}(\lambda)A^{1/4}\|_{\mathscr{L}(L^2(\Omega))}\leqq C_{\alpha_0},\qquad \lambda\in\mathscr{R}_{\alpha_0}. \tag{3.78}$$

Then, from (3.71), writing $A^{-5/4}V^{-1}(\lambda)A^{1/4}A^{-5/4}\hat{b}$ and using (3.78) and (3.70), since $\phi' = \phi'' = \phi''' = 0$ for $t \geqq 1$ we obtain

$$\begin{aligned}
&\int_{|\alpha|\leqq\alpha_0} \|A^{-5/4}\hat{u}_t(\lambda)\|^2\, d\alpha \\
&\quad \leqq C_{\alpha_0}\left\{\int_{|\alpha|\leqq\alpha_0} \|G_1^* A^{-1/2}[(\phi' w)_t](\lambda)\|^2\, d\alpha + \int_{|\alpha|\leqq\alpha_0} \|A^{-5/4}[\hat{b}_t](\lambda)\|^2\, d\alpha\right\} \\
&\quad \leqq C_{\alpha_0}\left\{\int_0^\infty e^{-2\beta t}\|G_1^* A^{-1/2}(\phi'' w + \phi' w_t)\|^2\, dt\right. \\
&\qquad \left. + \int_0^\infty e^{-2\beta t}\|A^{-5/4}(\phi''' w + 3\phi'' w_t + 2\phi' w_{tt}))\|^2\, dt\right\} \quad \text{(by (3.70))} \qquad (3.79) \\
&\quad \leqq C_\phi C_{\alpha_0}\left\{\int_0^1 [\|A^{-1/4}w\|^2 + \|G_1^* A^{-1/2} w_t\|^2_{L^2(\Gamma)}]\, dt\right. \\
&\qquad \left. + \int_0^1 [\|A^{-1/4}w\|^2 + \|A^{-3/4}w_t\|^2 + \|A^{-5/4}w_{tt}\|^2]\, dt\right\} \\
&\quad \leqq C_{\alpha_0} E(0),
\end{aligned}$$

since from (2.3) $A^{-5/4}w_{tt} = -A^{-1/4}w - A^{-1/4}G_1 G_1^* A^{-1/2} w_t$, and then (3.1), the contraction of $E(t)$, and (1.28) apply. The rest of the proof proceeds as before. We obtain as in (3.74)

$$\int_{|\alpha|>\alpha_0} \|A^{-5/4}\hat{u}_t(\lambda)\|^2\, d\alpha \leqq \frac{2\pi}{\alpha_0^2}\int_0^\infty e^{-2\beta t}\|A^{-5/4}u_{tt}\|^2\, dt \qquad (3.80)$$

and have as in (3.75) with $\varepsilon_1 = 1/\alpha_0^2$

$$2\pi\int_0^\infty e^{-2\beta t}\|A^{-5/4}u_t(t)\|^2\, dt \leqq \varepsilon_1\int_0^\infty e^{-2\beta t}\|A^{-5/4}u_{tt}(t)\|^2\, dt + C_{\varepsilon_1}E(0), \qquad (3.81)$$

from which the passage from u satisfying (3.81) to w satisfying (3.59) takes place as before. The proof of Theorem 1.3B is complete. □

Appendix A. Proof of Proposition 3.1. Adapting the multiplier technique of [18], [19] to present circumstances, where $t_0 \leqq t \leqq \infty$, we multiply (3.16a) by $e^{-2\beta t}h \cdot \nabla(\Delta p)$, where $\beta > 0$ is an arbitrary constant and $h(x) \in C^2(\bar{\Omega})$ is a vector field on $\bar{\Omega}$. For future reference to uniform stabilization problems for (1.1a) with boundary conditions of possibly different type from (1.1c, d), we will first derive a general identity for p which solves only (3.16a) with no use of boundary conditions (3.16c, d) (see (A.8) below). Only subsequently will we specialize such identity (A.8) to p which also satisfies the boundary conditions (3.16c, d).

Identity for p which satisfies (3.16a). With $Q = (t_0, \infty)\times\Omega$, $\Sigma = (t_0, \infty)\times\Gamma$, we multiply (3.16a) by $e^{-2\beta t}h \cdot \nabla(\Delta p)$ and integrate by parts. We will use the identity, obtained via the divergence theorem

$$\int_\Omega fh \cdot \nabla\psi\, d\Omega = \int_\Gamma f\psi h \cdot \nu\, d\Gamma - \int_\Omega \psi h \cdot \nabla f\, d\Omega - \int_\Omega f\psi \operatorname{div} h\, d\Omega \qquad (A.1)$$

with f, ψ two $H^1(\Omega)$-functions. In addition we will use the identity

$$\int_Q e^{-2\beta t}\Delta\phi h\cdot\nabla\phi\,dQ=\int_\Sigma e^{-2\beta t}\frac{\partial\phi}{\partial\nu}h\cdot\nabla\phi\,d\Sigma-\frac{1}{2}\int_\Sigma e^{-2\beta t}|\nabla\phi|^2h\cdot\nu\,d\Sigma$$
$$-\int_Q e^{-2\beta t}H\nabla\phi\cdot\nabla\phi\,dQ+\frac{1}{2}\int_Q e^{-2\beta t}|\nabla\phi|^2\operatorname{div}h\,dQ \tag{A.2}$$

already proved in, e.g., [39, eq. (A.3), App. A] (with similar multiplier $e^{-2\beta t}h\cdot\nabla\phi$), where $H(x)$ is the matrix defined in (1.33) (transpose of the Jacobian of $h(x)$).

Term $p_{tt}\,e^{-2\beta t}h\cdot\nabla(\Delta p)$. Integrating by parts in t

$$\int_Q e^{-2\beta t}p_{tt}h\cdot\nabla(\Delta p)\,dQ=\lim_{T\to\infty}e^{-2\beta T}(p_t(T),h\cdot\nabla(\Delta p(T)))_\Omega$$
$$-e^{-2\beta t_0}(p_1,h\cdot\nabla(\Delta p_0))_\Omega \tag{A.3}$$
$$+2\beta\int_Q e^{-2\beta t}p_th\cdot\nabla(\Delta p)\,dQ-\int_Q e^{-2\beta t}p_th\cdot\nabla(\Delta p_t)\,dQ$$

(using (A.1) in the last integral above with $f=p_t$ and $\psi=\Delta p_t$)

$$=\lim_{T\to\infty}e^{-2\beta T}(p_t(T),h\cdot\nabla(\Delta p(T))_\Omega-e^{-2\beta t_0}(p_1,h\cdot\nabla(\Delta p_0))_\Omega$$
$$+2\beta\int_Q e^{-2\beta t}p_th\cdot\nabla(\Delta p)\,dQ-\int_\Sigma e^{-2\beta t}p_t\Delta p_th\cdot\nu\,d\Sigma \tag{A.4}$$
$$+\int_Q e^{-2\beta t}p_t\Delta p_t\operatorname{div}h\,dQ+\int_Q e^{-2\beta t}\Delta p_th\cdot\nabla p_t\,dQ.$$

Invoking (A.2) with $\phi=p_t$ for the last integral in (A.5) we obtain

$$\int_Q e^{-2\beta t}p_{tt}h\cdot\nabla(\Delta p)\,dQ=\lim_{T\to\infty}e^{-2\beta T}(p_t(T),h\cdot\nabla(\Delta p)(T)))_\Omega-e^{-2\beta t_0}(p_1,h\cdot\nabla(\Delta p_0))_\Omega$$
$$-\int_\Sigma e^{-2\beta t}p_t\Delta p_th\cdot\nu\,d\Sigma+\int_\Sigma e^{-2\beta t}\frac{\partial p_t}{\partial\nu}h\nabla p_t\,d\Sigma$$
$$-\frac{1}{2}\int_\Sigma e^{-2\beta t}|\nabla p_t|^2h\cdot\nu\,d\Sigma \tag{A.5}$$
$$-\int_Q e^{-2\beta t}H\nabla p_t\cdot\nabla p_t\,dQ+\frac{1}{2}\int_Q e^{-2\beta t}|\nabla p_t|^2\operatorname{div}h\,dQ$$
$$+2\beta\int_Q e^{-2\beta t}p_th\cdot\nabla(\Delta p)\,dQ+\int_Q e^{-2\beta t}\Delta p_tp_t\operatorname{div}h\,dQ.$$

Now, using Green's first theorem on the last integral at the right of (A.5) along with the identity

$$\nabla p_t\cdot\nabla(p_t\operatorname{div}h)=p_t\nabla(\operatorname{div}h)\cdot\nabla p_t+|\nabla p_t|^2\operatorname{div}h$$

we finally obtain from (A.5)

$$\int_Q e^{-2\beta t}p_{tt}h\cdot\nabla(\Delta p)\,dQ=\lim_{T\to\infty}[e^{-2\beta t}(p_t,h\cdot\nabla(\Delta p))_\Omega]_{t_0}^T-\int_\Sigma e^{-2\beta t}p_t\Delta p_th\cdot\nu\,d\Sigma$$
$$-\frac{1}{2}\int_\Sigma e^{-2\beta t}|\nabla p_t|^2h\cdot\nu\,d\Sigma+\int_\Sigma e^{-2\beta t}\frac{\partial p_t}{\partial\nu}h\cdot\nabla p_t\,d\Sigma$$

$$
\begin{aligned}
&+\int_\Sigma e^{-2\beta t}\frac{\partial p_t}{\partial \nu}p_t \operatorname{div} h\, dQ-\int_Q e^{-2\beta t}H\nabla p_t\cdot\nabla p_t\, dQ\\
&-\frac{1}{2}\int_Q e^{-2\beta t}|\nabla p_t|^2 \operatorname{div} h\, dQ\\
&-\int_Q e^{-2\beta t}p_t\nabla(\operatorname{div} h)\cdot\nabla p_t\, dQ\\
&+2\beta\int_Q e^{-2\beta t}p_t h\cdot\nabla(\Delta p)\, dQ.
\end{aligned}
\tag{A.6}
$$

Term $e^{-2\beta t}\Delta^2 ph\cdot\nabla(\Delta p)$. Using identity (A.2), this time with $\phi=\Delta p$, we obtain

$$
\begin{aligned}
&\int_Q e^{-2\beta t}\Delta^2 ph\cdot\nabla(\Delta p)\, dQ\\
&\quad=\int_\Sigma e^{-2\beta t}\frac{\partial(\Delta p)}{\partial\nu}h\cdot\nabla(\Delta p)\, d\Sigma-\frac{1}{2}\int_\Sigma e^{-2\beta t}|\nabla(\Delta p)|^2 h\cdot\nu\, d\Sigma\\
&\quad\quad-\int_Q e^{-2\beta t}H\nabla(\Delta p)\cdot\nabla(\Delta p)\, dQ+\frac{1}{2}\int_Q e^{-2\beta t}|\nabla(\Delta p)|^2\operatorname{div} h\, dQ.
\end{aligned}
\tag{A.7}
$$

Summing up (A.6) and (A.7) and recalling (3.16a) we obtain

$$
\begin{aligned}
&\int_\Sigma e^{-2\beta t}\frac{\partial p_t}{\partial\nu}h\cdot\nabla p_t\, d\Sigma+\int_\Sigma e^{-2\beta t}\frac{\partial p_t}{\partial\nu}p_t\operatorname{div} h\, d\Sigma-\int_\Sigma e^{-2\beta t}p_t\Delta p_t h\cdot\nu\, d\Sigma\\
&\quad-\frac{1}{2}\int_\Sigma e^{-2\beta t}|\nabla p_t|^2 h\cdot\nu\, d\Sigma+\int_\Sigma e^{-2\beta t}\frac{\partial(\Delta p)}{\partial\nu}h\cdot\nabla(\Delta p)\, d\Sigma\\
&\quad-\frac{1}{2}\int_\Sigma e^{-2\beta t}|\nabla(\Delta p)|^2 h\cdot\nu\, d\Sigma\\
&=\int_Q e^{-2\beta t}[H\nabla(\Delta p)\cdot\nabla(\Delta p)+H\nabla p_t\cdot\nabla p_t]\, dQ\\
&\quad+\frac{1}{2}\int_Q e^{-2\beta t}\{|\nabla p_t|^2-|\nabla(\Delta p)|^2\}\operatorname{div} h\, dQ+\int_Q e^{-2\beta t}p_t\nabla p_t\cdot\nabla(\operatorname{div} h)\, dQ\\
&\quad-2\beta\int_Q e^{-2\beta t}p_t h\cdot\nabla(\Delta p)\, dQ+\int_Q e^{-2\beta t}(F_1+F_2)h\cdot\nabla(\Delta p)\, dQ\\
&\quad-\lim_{T\to\infty}[e^{-2\beta t}(p_t, h\cdot\nabla(\Delta p))_\Omega]_{t_0}^T
\end{aligned}
\tag{A.8}
$$

which is the desired identity for p which satisfies (3.16a).

Specialization of the left-hand side of (A.8) *to p which satisfies also the boundary conditions* (3.16c, d). Recalling (3.16c, d) we have

$$
p_t|_\Sigma\equiv 0,\quad \nabla p\perp\Gamma\quad\text{and}\quad|\nabla p|=\left|\frac{\partial p}{\partial\nu}\right|\equiv 0\quad\text{on }\Sigma\quad\text{(by (3.16d))}
\tag{A.9a}
$$

$$
\left.\frac{\partial p_t}{\partial\nu}\right|_\Sigma\equiv 0,\quad \nabla p_t\perp\Gamma\quad\text{and}\quad|\nabla p_t|=\left|\frac{\partial p_t}{\partial\nu}\right|\equiv 0\quad\text{on }\Sigma.
\tag{A.9b}
$$

Thus, using (3.16c, d) and (A.9a, b) on the L.H.S. of (A.8), we find that this simplifies to

$$\text{(A.10)}\quad \text{L.H.S. of (A.8)} = \int_\Sigma e^{-2\beta t}\frac{\partial(\Delta p)}{\partial \nu} h\cdot\nabla(\Delta p)\,d\Sigma - \frac{1}{2}\int_\Sigma e^{-2\beta t}|\nabla(\Delta p)|^2 h\cdot \nu\,d\Sigma.$$

Appendix B. Proof of Proposition 3.2. Again, we will first obtain an identity, (B.3) below, for p which solves only (3.16a) and for an arbitrary smooth vector field $h\in C^2(\bar\Omega)$. Next, we shall specialize this identity (B.3) to the case where p also satisfies the boundary conditions (3.16c, d). We multiply (3.16a) by $e^{-2\beta t}\Delta p$ div h and integrate over Q by parts in t and by Green's first theorem:

$$\begin{aligned}\int_Q e^{-2\beta t}p_{tt}\Delta p \text{ div } h\,dQ &= \lim_{T\to\infty}\left[e^{-2\beta t}\int_\Omega \Delta p p_t \text{ div } h\,d\Omega\right]_{t_0}^{T} + 2\beta\int_Q e^{-2\beta t}p_t\Delta p \text{ div } h\,dQ\\ &\quad -\int_Q e^{-2\beta t}p_t\Delta p_t \text{ div } h\,dQ\\ &= \lim_{T\to\infty}\left[e^{-2\beta t}\int_\Omega \Delta p p_t \text{ div } h\,d\Omega\right]_{t_0}^{T} \qquad \text{(B.1)}\\ &\quad +2\beta\int_Q e^{-2\beta t}p_t\Delta p \text{ div } h\,dQ - \int_\Sigma e^{-2\beta t}\frac{\partial p_t}{\partial \nu}p_t \text{ div } h\,d\Sigma\\ &\quad +\int_Q e^{-2\beta t}|\nabla p_t|^2 \text{ div } h\,dQ + \int_Q e^{-2\beta t}p_t\nabla p_t\cdot\nabla(\text{div } h)\,dQ.\end{aligned}$$

Also, again by Green's first theorem

$$\begin{aligned}\int_Q e^{-2\beta t}\Delta^2 p\Delta p \text{ div } h\,dQ &= \int_\Sigma e^{-2\beta t}\frac{\partial(\Delta p)}{\partial\nu}\Delta p \text{ div } h\,d\Sigma\\ &\quad -\int_Q e^{-2\beta t}|\nabla(\Delta p)|^2 \text{ div } h\,dQ \qquad \text{(B.2)}\\ &\quad -\int_Q e^{-2\beta t}\Delta p\nabla(\Delta p)\cdot\nabla(\text{div } h)\,dQ.\end{aligned}$$

Summing up (B.1) and (B.2) and recalling (3.16a) we find the identity

$$\begin{aligned}&\int_Q e^{-2\beta t}\{|\nabla p_t|^2 - |\nabla(\Delta p)|^2\}\text{ div } h\,dQ\\ &\quad = \int_\Sigma e^{-2\beta t}\frac{\partial p_t}{\partial\nu}p_t \text{ div } h\,d\Sigma - \int_\Sigma e^{-2\beta t}\frac{\partial(\Delta p)}{\partial\nu}\Delta p \text{ div } h\,d\Sigma\\ &\quad\quad +\int_Q e^{-2\beta t}\Delta p\nabla(\Delta p)\cdot\nabla(\text{div } h)\,dQ \qquad \text{(B.3)}\\ &\quad\quad -2\beta\int_Q e^{-2\beta t}p_t\Delta p \text{ div } h\,dQ - \int_Q e^{-2\beta t}p_t\nabla p_t\cdot\nabla(\text{div } h)\,dQ\\ &\quad\quad -\lim_{T\to\infty}\left[e^{-2\beta t}\int_\Omega \Delta p p_t \text{ div } h\,d\Omega\right]_{t_0}^{T} + \int_Q e^{-2\beta t}(F_1+F_2)\Delta p \text{ div } h\,dQ\end{aligned}$$

for p satisfying (3.16a). If p now satisfies also the boundary conditions (3.16c, d), then (B.3) specializes to

$$\begin{aligned}
&\int_Q e^{-2\beta t}\left\{|\nabla p_t|^2-|\nabla(\Delta p)|^2\right\}\operatorname{div} h\,dQ\\
&\quad=-\int_\Sigma e^{-2\beta t}\frac{\partial(\Delta p)}{\partial\nu}\Delta p\operatorname{div} h\,d\Sigma+\int_Q e^{-2\beta t}\Delta p\nabla(\Delta p)\cdot\nabla(\operatorname{div} h)\,dQ\\
&\quad-2\beta\int_Q e^{-2\beta t}p_t\Delta p\operatorname{div} h\,dQ-\int_Q e^{-2\beta t}p_t\nabla p_t\cdot\nabla(\operatorname{div} h)\,dQ\\
&\quad+\int_Q e^{-2\beta t}(F_1+F_2)\Delta p\operatorname{div} h\,dQ\\
&\quad+\lim_{T\to\infty}e^{-2\beta T}\int_\Omega\nabla p(T)\cdot\nabla(p_t(T)\operatorname{div} h)\,d\Omega\\
&\quad-e^{-2\beta t_0}\int_\Omega\nabla p_0\cdot\nabla(p_1\operatorname{div} h)\,d\Omega.
\end{aligned}\tag{B.4}$$

GLOBAL EXISTENCE AND ASYMPTOTIC STABILITY FOR A NONLINEAR INTEGRODIFFERENTIAL EQUATION MODELING HEAT FLOW*

DEBORAH BRANDON†

Abstract. This paper studies initial value problems that arise from models for one-dimensional heat flow (with finite wave speeds) in materials with memory. Under assumptions that ensure compatibility of the constitutive relations with the second law of thermodynamics, the resulting integrodifferential equation is hyperbolic near equilibrium. The existence of unique, globally (in time) defined, classical solutions to the problems under consideration is established, provided the data are smooth and sufficiently close to equilibrium. Both Dirichlet and Neumann boundary conditions are treated, as well as the problem on the entire real line.

Local existence is proved using a contraction-mapping argument which involves estimates for linear hyperbolic partial differential equations with variable coefficients. Global existence is obtained by deriving a priori energy estimates. These estimates are based on inequalities for strongly positive Volterra kernels (including a new inequality that is needed due to the form of the constitutive relations). Furthermore, compatibility with the second law plays an essential role in the proof in order to obtain an existence result under less restrictive assumptions on the data.

Key words. integrodifferential equation, second sound, heat flow, hyperbolic equation

AMS(MOS) subject classifications. 45K05, 35L60, 80A20

Introduction. In this paper we establish global existence and asymptotic stability of solutions to initial value problems arising from integral models for heat flow that were introduced in [2]. These models are based on Gurtin and Pipkin's theory of heat conduction [6]. The situations we are concerned with are such that the heat flux depends on the temporal history of the temperature gradient (and possibly on the present value and the history of the temperature), but is independent of the present value of the temperature gradient.

As in [2], we restrict our attention to one-dimensional rigid heat conductors in which the only nonzero component of the heat flux is its x-component, q. Here q and the absolute temperature $\theta > 0$ are functions of x and time t. Moreover, we assume that the material under consideration is homogeneous and has unit density. The first two laws of thermodynamics then take the form

$$e_t + q_x = r, \tag{0.1}$$

$$\eta_t \geqq -\left(\frac{q}{\theta}\right)_x + \frac{r}{\theta}, \tag{0.2}$$

where $e = e(x, t)$ is the (specific) internal energy, $r = r(x, t)$ is the external heat supply, and $\eta = \eta(x, t)$ is the (specific) entropy. Subscripts t and x indicate partial derivatives. If we define the (specific) free energy $\psi = \psi(x, t)$ through

$$\psi := e - \theta\eta, \tag{0.3}$$

The work was concluded at the Institute for Mathematics and Its Applications, University of Minnesota, Minneapolis, Minnesota.

† Department of Mathematics, Virginia Polytechnic Institute and State University, Blacksburg, Virginia 24061.

then the law of balance of energy (0.1) and the entropy inequality (0.2) can be combined to give the Clausius-Duhem inequality

$$\psi_t + \eta\theta_t + \frac{q\theta_x}{\theta} \leqq 0. \tag{0.4}$$

Gurtin and Pipkin consider materials characterized by constitutive equations that express $\psi(x, t)$, $\eta(x, t)$, and $q(x, t)$ as functionals of $(\theta(x, t), \bar{\theta}^t(x, \cdot), \bar{\theta}^t_x(x, \cdot))$. Here $\bar{\theta}^t$ and $\bar{\theta}^t_x$ denote the summed histories up to time t of the temperature and the temperature gradient. The summed history up to time t of θ is defined by

$$\bar{\theta}^t(x, s) := \int_{t-s}^{t} \theta(x, z)\, dz, \qquad x \in B, \quad s \geqq 0, \tag{0.5}$$

where $B \subset \mathbb{R}$ denotes the interval occupied by the body. Gurtin and Pipkin require that their constitutive relations be compatible with thermodynamics in the sense that the Clausius-Duhem inequality (0.4) is satisfied for all smooth processes consistent with the constitutive relations. They derive conditions that are both necessary and sufficient for compatibility with thermodynamics. These conditions can be summarized roughly as follows:

(i) The entropy is minus the derivative of the free energy with respect to the present value of the temperature;

(ii) The heat flux is determined from the free energy through a differential equation called the heat flux relation;

(iii) A functional differential inequality called the dissipation inequality, holds for all smooth processes.

We note that by virtue of (0.3), condition (ii) implies a relation between q and e and hence, e will generally depend on $\bar{\theta}^t_x$.

MacCamy considered a model motivated by Gurtin and Pipkin's linearized constitutive equations [10]. He replaced the linear equation for the heat flux with

$$q(x, t) = -\int_0^\infty a(s) f(\theta_x(x, t-s))\, ds, \tag{0.6}$$

but retained the linear equation for the internal energy

$$\begin{aligned} e(x, t) &= b + c\theta(x, t) - \int_0^\infty \beta'(s)\bar{\theta}^t(x, s)\, ds \\ &= b + c\theta(x, t) + \int_0^\infty \beta(s)\theta(x, t-s)\, ds. \end{aligned} \tag{0.7}$$

Here b and c are constants, a and β are smooth kernels that decay sufficiently rapidly at infinity, and f is a smooth function. MacCamy proved global existence and asymptotic stability for a corresponding initial boundary value problem. Similar existence theorems for MacCamy's model were established by Dafermos and Nohel [5] and Staffans [13].

MacCamy does not address the issue of compatibility with thermodynamics. However, we can show that there are smooth processes consistent with (0.6), (0.7) but for which an inequality implied by (0.4) is violated; within the context of [5], [10], and [13] this probably is not a serious difficulty since the solutions discussed there remain close to equilibrium (i.e., close to a state where θ is a constant and $\theta_x \equiv 0$), and under reasonable assumptions on a, β, and f, the aforementioned inequality is

satisfied by a suitable class of processes that are close to equilibrium. (See [2, § 1] for further details.)

Here we consider the constitutive relations[1]

$$\psi(x,t)=\hat{\psi}(\theta(x,t))+\int_0^\infty \hat{\Psi}(s,\theta(x,t),\bar{\theta}^t(x,s),\bar{\theta}_x^t(x,s))\,ds,$$

$$\eta(x,t)=-\hat{\psi}'(\theta(x,t))-\int_0^\infty \hat{\Psi}_{,2}(s,\theta(x,t),\bar{\theta}^t(x,s),\bar{\theta}_x^t(x,s))\,ds, \tag{0.8}$$

$$q(x,t)=-\theta(x,t)\int_0^\infty \hat{\Psi}_{,4}(s,\theta(x,t),\bar{\theta}^t(x,s),\bar{\theta}_x^t(x,s))\,ds,$$

and hence by (0.3) we have

$$e(x,t)=\hat{e}(\theta(x,t))+\int_0^\infty \hat{E}(s,\theta(x,t),\bar{\theta}^t(x,s),\bar{\theta}_x^t(x,s))\,ds \tag{0.9}$$

with

$$\hat{e}(\nu):=\hat{\psi}(\nu)-\nu\hat{\psi}'(\nu),\qquad \hat{E}(s,\nu,\alpha,\gamma):=\hat{\Psi}(s,\nu,\alpha,\gamma)-\nu\hat{\Psi}_{,2}(s,\nu,\alpha,\gamma), \tag{0.10}$$
$$s,\nu>0,\quad \alpha\geqq 0,\quad \gamma\in\mathbb{R}.$$

Here $\hat{\Psi}$ is normalized so that

$$\hat{\Psi}(s,\nu,\nu s,0)=0\quad \forall s,\nu>0 \tag{0.11}$$

and $\hat{\Psi}$ satisfies hypotheses which ensure that the integrals in (0.8) will be well behaved for a reasonable class of functions θ.

We assume that $\hat{\Psi}$ satisfies

$$\hat{\Psi}_{,1}(s,\nu,\alpha,\gamma)+\nu\hat{\Psi}_{,3}(s,\nu,\alpha,\gamma)\leqq 0\qquad \forall s,\nu>0,\quad \alpha\geqq 0,\quad \gamma\in\mathbb{R} \tag{0.12}$$

and thus by the main result obtained in [2] the constitutive relations (0.8) are compatible with thermodynamics and

$$\hat{\Psi}_{,j}(s,\nu,\nu s,0)=0,\qquad j=1,2,3,4\quad \forall s,\nu>0. \tag{0.13}$$

Substitution of $(0.8)_3$ and (0.9) into the law of balance of energy (0.1) yields

$$\begin{aligned}&\hat{c}_I(\theta(x,t),\bar{\theta}^t(x,\cdot),\bar{\theta}_x^t(x,\cdot))\theta_t(x,t)\\&\quad+\frac{\partial}{\partial x}\left\{\int_0^\infty \hat{Q}(s,\theta(x,t),\bar{\theta}^t(x,s),\bar{\theta}_x^t(x,s))\,ds\right\}\\&\quad+\int_0^\infty \hat{E}_{,3}(s,\theta(x,t),\bar{\theta}^t(x,s),\bar{\theta}_x^t(x,s))[\theta(x,t)-\theta(x,t-s)]\,ds\\&\quad+\int_0^\infty \hat{E}_{,4}(s,\theta(x,t),\bar{\theta}^t(x,s),\bar{\theta}_x^t(x,s))[\theta_x(x,t)-\theta_x(x,t-s)]\,ds=r(x,t),\end{aligned} \tag{0.14}$$
$$x\in B,\quad t\geqq 0.$$

Here $\hat{Q}$ is given by

$$\hat{Q}(s,\nu,\alpha,\gamma):=-\nu\hat{\Psi}_{,4}(s,\nu,\alpha,\gamma),\qquad s,\nu>0,\quad \alpha\geqq 0,\quad \gamma\in\mathbb{R}, \tag{0.15}$$

[1] We use $F_{,j}$ to denote the partial derivative of a function F with respect to its jth argument.

and

$$\hat{c}_I(\theta(s,t), \bar{\theta}^t(x,\cdot), \bar{\theta}^t_x(x,\cdot)) \tag{0.16}$$
$$:= \hat{e}'(\theta(x,t)) + \int_0^\infty \hat{E}_{,2}(s, \theta(x,t), \bar{\theta}^t(x,s), \bar{\theta}^t_x(x,s))\, ds$$

is the instantaneous heat capacity at $(\theta(x,t), \bar{\theta}^t(x,\cdot), \bar{\theta}^t_x(x,\cdot))$; the equilibrium heat capacity $\hat{c}_E(\nu)$ at the temperature ν is given by

$$\hat{c}_E(\nu) := \hat{e}'(\nu). \tag{0.17}$$

It is generally assumed in practice that the heat capacities are positive.

We seek a smooth solution to (0.14) subject to the initial conditions

$$\begin{aligned} &\theta(x,t) = \varphi(x,t), && x \in B, \quad t < 0, \\ &\theta(x,0) = \theta_0(x), && x \in B, \end{aligned} \tag{0.18}$$

and appropriate boundary conditions if $B \neq \mathbb{R}$. Here $\varphi > 0$ and $\theta_0 > 0$ are prescribed smooth functions. Observe that (0.18) permits a temporal jump discontinuity in θ at $t = 0$. Even if such a discontinuity is present in the data, we can obtain a solution that is smooth for $t \geqq 0$ provided that θ_0 and $r(\cdot, 0)$ satisfy certain compatibility conditions at the endpoints of B.

It follows from the arguments of Gurtin and Pipkin [6] that compatibility with thermodynamics, strict positivity of the equilibrium heat capacity, and some assumptions of nondegeneracy imply that (0.14) is of hyperbolic type near equilibrium. (See [12, Chap. II] for determination of type for equations with memory terms.) The characteristic speeds for (0.14) are not constant, and it is therefore possible that weak waves will be amplified and shocks will develop. On the other hand, (0.14) includes a natural damping mechanism induced by memory. It is not clear which effect is dominant. A great deal of insight into this question is given by Chen [3], who assumed the existence of solutions containing singularities called temperature rate waves and obtained a formula for the amplitude of these waves. He found that an amplitude of small initial value decays as $t \to \infty$, and if the initial amplitude is large then blowup may occur in finite time. This suggests that when the data are close to equilibrium, (0.14) has a global solution, whereas if the data are sufficiently far away from equilibrium the solution may develop singularities in finite time.

To keep the analysis relatively clean, while retaining the important features (from the point of view of the analysis) of (0.14) we treat the following special case in detail:

$$\begin{aligned} \psi(x,t) &= \hat{\psi}(\theta(x,t)) - \frac{1}{\theta(x,t)} \int_0^\infty a'(s) F(\bar{\theta}^t_x(x,s))\, ds, \\ \eta(x,t) &= -\hat{\psi}'(\theta(x,t)) - \frac{1}{\theta(x,t)^2} \int_0^\infty a'(s) F(\bar{\theta}^t_x(x,s))\, ds, \\ q(x,t) &= \int_0^\infty a'(s) F'(\bar{\theta}^t_x(x,s))\, ds. \end{aligned} \tag{0.19}$$

Here $\hat{\psi}: (0,\infty) \to \mathbb{R}$, $a: [0,\infty) \to \mathbb{R}$, and $F: \mathbb{R} \to \mathbb{R}$ are smooth functions with $a \in W^{3,1}(0,\infty)$ and $F(0) = 0$. Observe that unlike (0.8), in (0.19) there is no dependence on the summed history of the temperature; moreover, here the kernel (a') factors out. We assume that

$$a \text{ is convex}, \qquad F \geqq 0; \tag{0.20}$$

the arguments used in [2] can be applied in the present setting to show that (0.20) implies that the constitutive equations (0.19) are compatible with thermodynamics. We note that by (0.20) we have

$$a' \leqq 0, \quad a \geqq 0, \quad F'(0) = 0, \quad F''(0) \geqq 0. \tag{0.21}$$

The corresponding equation for e is

$$e(x, t) = \hat{e}(\theta(x, t)) - \frac{2}{\theta(x, t)} \int_0^\infty a'(s) F(\bar{\theta}_x^t(x, s))\, ds, \tag{0.22}$$

where $\hat{e}$ is as in $(0.10)_1$. Thus (0.1) yields

$$\begin{aligned} &\left(\hat{e}'(\theta(x, t)) + \frac{2}{\theta(x, t)^2} \int_0^\infty a'(s) F(\bar{\theta}_x^t(x, s))\, ds\right) \theta_t(x, t) \\ &\quad + \int_0^\infty a'(s) F''(\bar{\theta}_x^t(x, s)) \bar{\theta}_{xx}^t(x, s)\, ds \\ &\quad - \frac{2}{\theta(x, t)} \int_0^\infty a'(s) F'(\bar{\theta}_x^t(x, s))[\theta_x(x, t) - \theta_x(x, t-s)]\, ds = r(x, t), \\ &\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad x \in B, \quad t \geqq 0. \end{aligned} \tag{0.23}$$

We establish global existence and asymptotic stability of smooth solutions to the initial value problem (0.23), (0.18) for smooth data (r, φ, θ_0) that are close to equilibrium. We treat Dirichlet and Neumann boundary conditions as well as the problem with $B = \mathbb{R}$. We also make some remarks concerning the extension of our work to the initial value problem (0.14), (0.18).

To indicate the nature of our results let us consider the case where $B = [0, 1]$, $\varphi \equiv \theta_0 \equiv \theta^*$, with Dirichlet boundary conditions

$$\theta(0, t) = \theta(1, t) = \theta^*, \qquad t \geqq 0, \tag{0.24}$$

where $\theta^* > 0$ is a given constant.

In order to prove global existence of solutions to (0.23), (0.24), (0.18) we need to make additional assumptions on the constitutive relations and on the data. Concerning the constitutive equations we require that

$$a \not\equiv 0, \tag{0.25}$$

and we strengthen the inequality $(0.21)_4$ to the strict inequality

$$F''(0) > 0. \tag{0.26}$$

These two conditions imply that the linearized relation for the heat flux is nontrivial. We also assume that the equilibrium heat capacity is strictly positive, i.e.,[2]

$$\hat{e}' > 0. \tag{0.27}$$

Assumptions (0.25)–(0.27) imply that (0.23) is hyperbolic near equilibrium. Since we have dependence on the summed history of the temperature gradient (for which we do not obtain a pointwise bound), we need to make a growth restriction on F that is related to the decay rate of a. In addition, we assume that the heat supply r is smooth, decays with time, and is small in a sense that will be stated more precisely later.

[2] For our purposes it suffices to assume that $\hat{e}'(\theta^*) > 0$; however, assumption (0.27) is in accord with experience and leads to certain simplifications in the proofs of Theorems 1.2 and 1.3.

Moreover, to ensure the existence of smooth classical solutions the heat supply r must satisfy the condition

$$r(0,0)=r(1,0)=r_t(0,0)=r_t(1,0)=0, \tag{0.28}$$

which guarantees compatibility of the data with the boundary conditions at $t=0$. We note that our assumptions imply that a is a strongly positive-definite kernel in the sense of [11]. Inequalities for such kernels play an essential role in the proof of global existence.

Observe that if $r\equiv 0$, then $\theta\equiv\theta^*$ is a solution. We look for classical solutions to (0.23), (0.24), (0.18) near the prescribed equilibrium temperature θ^* for $t\geqq 0$. We show that (0.23), (0.24), (0.18) has a unique solution $\theta>0$ with θ, θ_x, θ_t, θ_{xx}, θ_{xt}, θ_{tt}, θ_{xxx}, θ_{xxt}, θ_{xtt}, $\theta_{ttt}\in C([0,\infty);L^2(0,1))$ and θ, θ_x, θ_t, θ_{xx}, θ_{xt}, $\theta_{tt}\in L^2((0,\infty);L^2(0,1))\cap L^\infty((0,\infty);L^2(0,1))$. Moreover, as $t\to\infty$, $\theta(\cdot,t)\to\theta^*$ and $\theta_x(\cdot,t)$, $\theta_t(\cdot,t)\to 0$ uniformly on $[0,1]$. An analogous result can be obtained for Neumann boundary conditions as well as for the problem with $B=\mathbb{R}$.

The arguments used to prove global existence in [5], [10], and [13] for MacCamy's model are similar in spirit to the arguments used here. The primary differences between our existence proof and those for MacCamy's model arise from the dependence of e on the summed history of θ_x. This dependence complicates the analysis and necessitates the use of a new inequality for strongly positive-definite kernels. Global existence is obtained by deriving a priori estimates; in these derivations we exploit the compatibility of our constitutive relations with thermodynamics, i.e., we make use of the entropy inequality (0.2). It is interesting to note that we can obtain an existence result for (0.23), (0.24), (0.18) without utilizing the thermodynamical restrictions, provided the linearized equation has the appropriate features. However, the compatibility conditions imposed on our constitutive relations by the thermodynamical restrictions allow us to establish a global existence result under less restrictive assumptions on the data.

The paper is organized as follows. Precise statements of global existence results are given in § 1. Section 2 is concerned with appropriate local existence results and with properties of strongly positive-definite kernels relevant to our needs. Section 3 is devoted to the proof of the theorems stated in § 1; the proof for the problem with Dirichlet boundary conditions is discussed in detail and remarks are made concerning other boundary conditions.

1. Statement of results. We first consider the problem

$$\begin{aligned}&\left(\hat{e}'(\theta(x,t))+\frac{2}{\theta(x,t)^2}\int_0^\infty a'(s)F(\bar{\theta}_x^t(x,s))\,ds\right)\theta_t(x,t)\\&\quad+\int_0^\infty a'(s)F''(\bar{\theta}_x^t(x,s))\bar{\theta}_{xx}^t(x,s)\,ds\\&\quad-\frac{2}{\theta(x,t)}\int_0^\infty a'(s)F'(\bar{\theta}_x^t(x,s))[\theta_x(x,t)-\theta_x(x,t-s)]\,ds=r(x,t),\\&\qquad\qquad x\in[0,1],\quad t\geqq 0,\end{aligned} \tag{1.1}$$

$$\theta(x,t)=\theta^*,\qquad x\in[0,1],\quad t<0, \tag{1.2}$$

$$\theta(x,0)=\theta_0(x),\qquad x\in[0,1], \tag{1.3}$$

$$\theta(0,t)=\theta(1,t)=\theta^*,\qquad t\geqq 0. \tag{1.4}$$

Here, $\theta^*>0$ is a given constant and $\theta_0:[0,1]\to(0,\infty)$ is a prescribed smooth function.

Concerning $\hat{e}$, F, and a we require that

$$\hat{e} \in C^4(0, \infty), \tag{1.5}$$

$$\hat{e}' > 0; \tag{1.6}$$

$$F \in C^5(\mathbb{R}), \tag{1.7}$$

$$F(0) = 0, \quad F''(0) > 0, \quad F(\gamma) \geqq 0 \quad \forall \gamma \in \mathbb{R}, \tag{1.8}$$

and there are constants $K > 0$, $k > 1$ such that

$$|F^{(j)}(\xi) - F^{(j)}(0)| \leqq K(|\xi| + |\xi|^k), \qquad j = 0, 1, 2, 3, 4, 5, \quad \xi \in \mathbb{R}; \tag{1.9}$$

$$a \in W^{3,1}(0, \infty), \quad a \text{ is strongly positive definite}, \quad a'' \geqq 0, \tag{1.10}$$

and

$$\int_0^\infty |a'(z)| z^{k+1}\, dz, \int_0^\infty |a''(z)| z^{k+1}\, dz, \int_0^\infty |a'''(z)| z^k\, dz < \infty. \tag{1.11}$$

We note that there is some redundancy in (1.11) due to assumption (1.10); however, we feel that the present form (which is not as compact as possible) is clearer from an expository point of view. The definition of a strongly positive-definite kernel is given in the next section. For now, it suffices to know that

(i) $(1.10)_{1,2}$ implies $a(0) > 0$;

(ii) If $a \in W^{3,1}(0, \infty)$, $a \not\equiv 0$, and $a'' \geqq 0$, then a is strongly positive definite.

The data are assumed to have the following regularity:

$$\theta_0 \in H^3(0, 1), \tag{1.12}$$

$$r, r_x, r_t, r_{xt}, r_{tt} \in C([0, \infty); L^2(0, 1)) \cap L^2((0, \infty); L^2(0, 1)) \cap L^\infty((0, \infty); L^2(0, 1)), \tag{1.13}$$

$$r(\cdot, 0) \in H^2(0, 1), \qquad r_{ttt} \in L^2((0, \infty); L^2(0, 1)). \tag{1.14}$$

We also assume that the following compatibility conditions hold on the boundary:

$$\theta_0(0) = \theta_0(1) = \theta^*, \tag{1.15}$$

$$r(0, 0) = r(1, 0) = 0, \tag{1.16}$$

$$r_t(0, 0) = a(0)F''(0)\left(-\theta_0''(0) + \frac{2}{\theta^*}\theta_0'(0)^2\right), \tag{1.17}$$

$$r_t(1, 0) = a(0)F''(0)\left(-\theta_0''(1) + \frac{2}{\theta^*}\theta_0'(1)^2\right). \tag{1.18}$$

The interpretation of (1.15) is clear; conditions (1.16)–(1.18) ensure that $\theta_t(\cdot, 0)$ and $\theta_{tt}(\cdot, 0)$ vanish on the boundary. To state our results, it is convenient to define

$$\Theta_0 := \int_0^1 ([\theta_0(x) - \theta^*]^2 + \theta_0'(x)^2 + \theta_0''(x)^2)\, dx \tag{1.19}$$

and

$$\mathbf{R}_0 := \sup_{t \geqq 0} \int_0^1 (r^2 + r_t^2)(x, t)\, dx + \int_0^1 r_x^2(x, 0)\, dx + \left(\sup_{\substack{x \in [0,1] \\ t \geqq 0}} |r(x, t)|\right) + \int_0^\infty \int_0^1 (r^2 + r_t^2 + r_{tt}^2)(x, t)\, dx\, dt. \tag{1.20}$$

We establish the following result.

THEOREM 1.1. *Assume that* (1.5)-(1.11) *hold. Then there is a constant* $\delta > 0$ *such that for all* θ_0 *and* r *satisfying* (1.12)-(1.18) *and*

$$\Theta_0 + R_0 \leqq \delta^2, \tag{1.21}$$

the initial value problem (1.1)-(1.4) *has a unique solution* $\theta > 0$ *with*

$$\theta, \theta_x, \theta_t, \theta_{xx}, \theta_{xt}, \theta_{tt}, \theta_{xxx}, \theta_{xxt}, \theta_{xtt}, \theta_{ttt} \in C([0, \infty); L^2(0, 1)) \tag{1.22}$$

and

$$\theta - \theta^*, \theta_x, \theta_t, \theta_{xx}, \theta_{xt}, \theta_{tt} \in L^\infty((0, \infty); L^2(0, 1)) \cap L^2((0, \infty); L^2(0, 1)). \tag{1.23}$$

Moreover, as $t \to \infty$

$$\theta(\cdot, t) \to \theta^* \tag{1.24}$$

and

$$\theta_x(\cdot, t), \theta_t(\cdot, t) \to 0 \quad \textit{uniformly on } [0, 1]. \tag{1.25}$$

Remark 1.1. The constant δ in Theorem 1.1 depends on θ^* and on properties of the functions appearing in the constitutive relations.

Remark 1.2. By the Sobolev embedding theorem, (1.22) implies that $\theta \in C^2([0, 1] \times [0, \infty))$.

A result analogous to Theorem 1.1 can be established if we replace the Dirichlet boundary conditions (1.4) with Neumann boundary conditions

$$\theta_x(0, t) = \theta_x(1, t) = 0, \qquad t \geqq 0. \tag{1.26}$$

Remark 1.3. Under the assumptions of Theorem 1.2 below (1.26) holds if and only if

$$q(0, t) = q(1, t) = 0, \qquad t \geqq 0. \tag{1.27}$$

(Recall that the heat flux q is given by $(0.19)_3$.) It is obvious that (1.26) implies (1.27). In order to show that (1.27) implies (1.26) we first differentiate the relation for the heat flux $(0.19)_3$ with respect to t on the boundary, making use of (1.2). We then add and subtract terms to obtain the identity

$$\begin{aligned} a(0)\theta_x(\xi, t) + \int_0^t a'(t-s)\theta_x(\xi, s)\, ds \\ = \frac{1}{F''(0)} \frac{\partial}{\partial t} \left\{ \int_0^t \theta_x(\xi, s) \int_{t-s}^\infty a'(y) \right. \\ \left. \cdot \int_0^1 [F''(z\bar{\theta}_x^t(\xi, y)) - F''(0)]\, dz\, dy\, ds \right\}, \\ \xi = 0, 1, \quad t \geqq 0. \end{aligned} \tag{1.28}$$

We can now solve (1.28) for θ_x and make use of Lemma 2.3 below to show that (1.26) is the only continuous solution of (1.28) that vanishes at $t = 0$.

We now require that r satisfy (1.13), (1.14), and

$$r \in L^1((0, \infty); L^2(0, 1)); \tag{1.29}$$

in addition, we assume that the following compatibility conditions hold:

$$\theta_0'(0) = \theta_0'(1) = 0, \tag{1.30}$$

$$r(0,0) = r(1,0) = 0, \tag{1.31}$$

$$r_t(0,0) = -a(0)F''(0)\theta_0''(0), \tag{1.32}$$

$$r_t(1,0) = -a(0)F''(0)\theta_0''(1). \tag{1.33}$$

THEOREM 1.2. *Assume that* (1.5)-(1.11) *hold. Then there is a constant* $\delta > 0$ *such that for every* θ_0 *and* r *that satisfy* (1.12)-(1.14), (1.29)-(1.33) *and*

$$\Theta_0 + R_0 + \left(\int_0^\infty \left(\int_0^1 r(x,t)^2 \, dx \right)^{1/2} dt \right)^2 \leqq \delta^2 \tag{1.34}$$

the initial value problem (1.1)-(1.3), (1.26) *has a unique solution* $\theta > 0$ *with*

$$\theta, \theta_x, \theta_t, \theta_{xx}, \theta_{xt}, \theta_{tt}, \theta_{xxx}, \theta_{xxt}, \theta_{xtt}, \theta_{ttt} \in C([0,\infty); L^2(0,1)), \tag{1.35}$$

$$\theta_x, \theta_t, \theta_{xx}, \theta_{xt}, \theta_{tt} \in L^\infty((0,\infty); L^2(0,1)) \cap L^2((0,\infty); L^2(0,1)), \tag{1.36}$$

and

$$\theta \in L^\infty((0,\infty); L^2(0,1)). \tag{1.37}$$

Furthermore, as $t \to \infty$, $\theta(\cdot, t)$ *converges to a constant* $\theta^{**} > 0$ *uniformly on* $[0,1]$ *and*

$$\theta_x(\cdot, t), \theta_t(\cdot, t) \to 0 \quad \textit{uniformly on } [0,1]. \tag{1.38}$$

Remark 1.4. The value of θ^{**} can be determined from (1.1) as follows. If the assumptions of Theorem 1.2 hold and θ satisfies (1.1)-(1.3), (1.26) then integrating (1.1) over $[0,1]\times[0,t]$, $t > 0$, and passing to the limit as $t \to \infty$ yields

$$\hat{e}(\theta^{**}) = \int_0^1 \hat{e}(\theta_0(x)) \, dx + \int_0^\infty \int_0^1 r(x,t) \, dx \, dt. \tag{1.39}$$

By (1.6) $\hat{e}$ is strictly monotone and hence there is a unique solution θ^{**} of (1.39).

Let us now consider the problem stated below in which the heat conductor occupies the entire real line:

$$\begin{aligned} &\left(\hat{e}'(\theta(x,t)) + \frac{2}{\theta(x,t)^2} \int_0^\infty a'(s) F(\bar{\theta}_x^t(x,s)) \, ds \right) \theta_t(x,t) \\ &\quad + \int_0^\infty a'(s) F''(\bar{\theta}_x^t(x,s)) \bar{\theta}_{xx}^t(x,s) \, ds \\ &\quad - \frac{2}{\theta(x,t)} \int_0^\infty a'(s) F'(\bar{\theta}_x^t(x,s)) [\theta_x(x,t) - \theta_x(x,t-s)] \, ds = r(x,t), \\ &\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad x \in \mathbb{R}, \quad t \geqq 0, \end{aligned} \tag{1.40}$$

$$\theta(x,t) = \theta^*, \qquad x \in \mathbb{R}, \quad t < 0, \tag{1.41}$$

$$\theta(x,0) = \theta_0(x), \qquad x \in \mathbb{R}. \tag{1.42}$$

We assume that

$$\theta_0 - \theta^* \in H^3(\mathbb{R}), \tag{1.43}$$

$$\begin{aligned} r_x, r_t, r_{xt}, r_{tt} \in C([0,\infty); L^2(\mathbb{R})) \cap L^2((0,\infty); L^2(\mathbb{R})) \\ \cap L^\infty((0,\infty); L^2(\mathbb{R})), \end{aligned} \tag{1.44}$$

$$r \in C([0,\infty); L^2(\mathbb{R})) \cap L^1((0,\infty); L^2(\mathbb{R})) \cap L^\infty((0,\infty); L^2(\mathbb{R})), \tag{1.45}$$

$$r(\cdot,0) \in H^2(\mathbb{R}), \qquad r_{ttt} \in L^2((0,\infty); L^2(\mathbb{R})). \tag{1.46}$$

Note that (1.45) implies $r \in L^2((0,\infty); L^2(\mathbb{R}))$. We define

$$\Theta_1 := \int_{-\infty}^{\infty} ([\theta_0(x) - \theta^*]^2 + \theta_0'(x)^2 + \theta_0''(x)^2)\, dx \tag{1.47}$$

and

$$\begin{aligned} R_1 := \sup_{t \geqq 0} \int_{-\infty}^{\infty} (r^2 + r_t^2)(x,t)\, dx + \int_{-\infty}^{\infty} r_x^2(x,0)\, dx + \left(\sup_{\substack{x \in \mathbb{R} \\ t \geqq 0}} |r(x,t)| \right)^2 \\ + \int_0^{\infty} \int_{-\infty}^{\infty} (r^2 + r_t^2 + r_{tt}^2)(x,t)\, dx\, dt \\ + \left(\int_0^{\infty} \left(\int_{-\infty}^{\infty} r(x,t)^2\, dx \right)^{1/2} dt \right)^2. \end{aligned} \tag{1.48}$$

THEOREM 1.3. *If* (1.5)-(1.11) *hold, then there is a constant* $\delta > 0$ *such that when* θ_0 *and* r *satisfy* (1.43)-(1.46) *and*

$$\Theta_1 + R_1 \leqq \delta^2, \tag{1.49}$$

the initial value problem (1.40)-(1.42) *has a unique solution* $\theta > 0$ *with*

$$\theta - \theta^*,\ \theta_x,\ \theta_t,\ \theta_{xx},\ \theta_{xt},\ \theta_{tt},\ \theta_{xxx},\ \theta_{xxt},\ \theta_{xtt},\ \theta_{ttt} \in C([0,\infty); L^2(\mathbb{R})), \tag{1.50}$$

$$\theta_x,\ \theta_t,\ \theta_{xx},\ \theta_{xt},\ \theta_{tt} \in L^\infty((0,\infty); L^2(\mathbb{R})) \cap L^2((0,\infty); L^2(\mathbb{R})), \tag{1.51}$$

and

$$\theta - \theta^* \in L^\infty((0,\infty); L^2(\mathbb{R})). \tag{1.52}$$

In addition, as $t \to \infty$,

$$\theta(\cdot,t) \to \theta^* \quad \textit{uniformly on } \mathbb{R} \tag{1.53}$$

and

$$\theta_x(\cdot,t),\ \theta_t(\cdot,t) \to 0 \quad \textit{uniformly on } \mathbb{R} \textit{ and in } L^2(\mathbb{R}). \tag{1.54}$$

Remark 1.5. A detailed proof of Theorem 1.1 is given in § 3. With some minor modifications the argument used to establish Theorem 1.1 can be applied to prove Theorems 1.2 and 1.3; these modifications are discussed in § 3.

Remark 1.6. Assumption (1.11) is not the weakest possible to obtain the global estimates of § 3. However, in order to establish Lemma 2.2 below, the replacement of (1.11) with a weaker assumption would necessitate a more complicated argument than the one used in this paper.

The results established here can be modified and extended, as is illustrated below.

(i) *Solutions with less regularity.* Using a density argument we can show that under weaker assumptions on the data, our initial value problems have a unique, globally defined solution with less regularity than the solutions discussed above. More precisely, for instance in Theorem 1.1, if we replace (1.12)-(1.18) with

$$\theta_0 \in H^2(0,1), \tag{1.55}$$

$$\begin{aligned} r,\ r_t \in C([0,\infty); L^2(0,1)) \cap L^2((0,\infty); L^2(0,1)) \\ \cap L^\infty((0,\infty); L^2(0,1)), \end{aligned} \tag{1.56}$$

$$r \in L^\infty((0,1)\times(0,\infty)), \quad r(\cdot,0) \in H^1(0,1), \quad r_{tt} \in L^2((0,\infty); L^2(0,1)), \tag{1.57}$$

and

$$\theta_0(0) = \theta_0(1) = \theta^*, \qquad r(0,0) = r(1,0) = 0, \tag{1.58}$$

then the result of Theorem 1.1 is true with (1.22) replaced with

$$\theta, \theta_x, \theta_t, \theta_{xx}, \theta_{xt}, \theta_{tt} \in C([0,\infty); L^2(0,1)). \tag{1.59}$$

(ii) *Nonequilibrium history.* Results analogous to Theorems 1.1–1.3 can be obtained if a more general history is prescribed. For example, a result similar to Theorem 1.1 can be established if (1.2) is replaced by

$$\theta(x,t) = \varphi(x,t), \qquad x \in [0,1], \quad t < 0, \tag{1.60}$$

where $\varphi : [0,1] \times (-\infty, 0] \to (0,\infty)$ satisfies

$$\begin{aligned} &\varphi_x, \varphi_{xx}, \varphi_{xt}, \varphi_{xxx}, \varphi_{xxt}, \varphi_{xtt} \in C((-\infty,0]; L^2(0,1)) \\ &\quad \cap L^2((-\infty,0); L^2(0,1)) \cap L^\infty((-\infty,0); L^2(0,1)), \end{aligned} \tag{1.61}$$

$$\int_0^\infty a'(s) F'(\bar{\varphi}_x^0(\cdot, s))\, ds \in H^3(0,1), \tag{1.62}$$

and the compatibility conditions (1.16)–(1.18) are modified accordingly. In addition, the quantity

$$\begin{aligned} \Phi := &\sup_{t \in (-\infty,0)} \int_0^1 (\varphi_x^2 + \varphi_{xx}^2 + \varphi_{xt}^2)(x,t)\, dx \\ &+ \int_{-\infty}^0 \int_0^1 (\varphi_x^2 + \varphi_{xx}^2 + \varphi_{xt}^2)(x,t)\, dx\, dt \\ &+ \int_0^1 \left(\int_0^\infty a'(s) \frac{\partial^2}{\partial x^2} \{F'(\bar{\varphi}_x^0(x,s))\}\, ds \right)^2 dx \end{aligned} \tag{1.63}$$

must be sufficiently small, i.e., condition (1.21) is to be replaced with

$$\Theta_0 + \Phi + R_0 \leqq \delta^2. \tag{1.64}$$

In § 3 we discuss modifications needed in order to adapt the proof of Theorem 1.1 to this case. We note that for the analogue of Theorem 1.2, if we assume that

$$\varphi_x(0,t) = \varphi_x(1,t) = 0, \qquad t \leqq 0 \tag{1.65}$$

then, following the procedure discussed in Remark 1.3, we can show that (1.26) is equivalent to (1.27).

(iii) *General integral models.* These results can be extended to the case where the constitutive equations (0.8) are considered. In these equations the dependence on the summed history of θ is nontrivial; hence a term involving $\theta(x,t)$ appears in the analogue of (1.1). In the corresponding linearized equation the coefficient of $\theta(x,t)$ is

$$E^* := \int_0^\infty \hat{E}_{,3}(s, \theta^*, \theta^* s, 0)\, ds; \tag{1.66}$$

we can show that compatibility with thermodynamics implies that E^* is nonnegative and hence the methods we use here can be adopted to produce analogous results to those stated in Theorems 1.1–1.3. The precise statement of the technical assumptions required would be very complicated and not very illuminating, e.g., the mapping

$$s \mapsto Q_{,4}(s, \theta^*, \theta^* s, 0) \tag{1.67}$$

would have to be such that our assumptions on

$$s \mapsto a'(s)F''(0) \tag{1.68}$$

would hold. We will not discuss this case in further detail.

2. Preliminaries. We begin by stating a local existence result for (1.1)-(1.4). We first note that (1.1) is hyperbolic near equilibrium, but may lose its evolutionary character at states sufficiently far from equilibrium. To ensure that (1.1)-(1.4) is well posed we assume that θ_0 is close to equilibrium in the sense described below. We choose $\varepsilon \in (0, \theta^*)$ sufficiently small so that there are constants e^*, $q^* > 0$ with the following property:

$$\hat{e}'(w(x,t)) + \frac{2}{w(x,t)^2}\int_0^\infty a'(s)F(\bar{w}_x^t(x,s))\,ds \geqq e^* \qquad \forall x \in [0,1], \quad t \in [0,T], \tag{2.1}$$

and

$$-\int_0^\infty a'(s)F''(\bar{w}_x^t(x,s))\,ds \geqq q^* \quad \forall x \in [0,1], \quad t \in [0,T], \tag{2.2}$$

for every $T > 0$ and every $w \in L^\infty((-\infty, T); H^1(0,1))$ satisfying

$$|w(x,t) - \theta^*|, |w_x(x,t)| \leqq \varepsilon \quad \forall x \in [0,1], \quad t \in (-\infty, T]. \tag{2.3}$$

Such a choice is possible by virtue of our assumptions on a and F. (Indeed, the left-hand sides of (2.1) and (2.2) are strictly positive when $w(x,t) \equiv \theta^*$. A simple perturbation about $w = \theta^*$ guarantees the existence of a suitable ε. In fact, we may take $e^* = \frac{1}{2}\hat{e}'(\theta^*)$ and $q^* = \frac{1}{2}a(0)F''(0)$.) We assume that θ_0 satisfies

$$|\theta_0(x) - \theta^*|, |\theta_0'(x)| \leqq \eta \quad \forall x \in [0,1], \tag{2.4}$$

for some $\eta \in (0, \varepsilon)$.

We can now state the following lemma.

LEMMA 2.1. *Assume that* (1.5)-(1.18) *and* (2.4) *are satisfied. Then the initial value problem* (1.1)-(1.4) *has a unique solution* $\theta > 0$, *defined on a maximal time interval* $[0, T_0)$, $T_0 > 0$, *with*

$$\theta, \theta_x, \theta_t, \theta_{xx}, \theta_{xt}, \theta_{tt}, \theta_{xxx}, \theta_{xxt}, \theta_{xtt}, \theta_{ttt} \in C([0, T_0); L^2(0,1)) \tag{2.5}$$

and

$$|\theta(x,t) - \theta^*|, |\theta_x(x,t)| < \varepsilon \quad \forall x \in [0,1], \quad t \in [0, T_0). \tag{2.6}$$

Moreover, if

$$\sup_{\substack{x \in [0,1] \\ t \in [0,T_0)}} |\theta(x,t) - \theta^*|, \sup_{\substack{x \in [0,1] \\ t \in [0,T_0)}} |\theta_x(x,t)| < \varepsilon \tag{2.7}$$

and

$$\sup_{t \in [0,T_0)} \int_0^1 (\theta^2 + \theta_x^2 + \theta_t^2 + \theta_{xx}^2 + \theta_{xt}^2 + \theta_{tt}^2 + \theta_{xxx}^2 + \theta_{xxt}^2 + \theta_{xtt}^2 + \theta_{ttt}^2)(x,t)\,dx < \infty, \tag{2.8}$$

then $T_0 = \infty$.

A result analogous to Lemma 2.1 can be established if we replace (1.4) by (1.26) (i.e., if instead of Dirichlet boundary conditions we consider Neumann boundary

conditions) and (1.15)-(1.18) with (1.29)-(1.33). Similarly to (1.1)-(1.4), the initial value problem (1.1)-(1.3), (1.26) has a unique solution θ defined on a maximal time interval $[0, T_0)$, $T_0 > 0$ satisfying (2.5) and (2.6). We can also obtain a corresponding result for the case when the heat conductor occupies the entire real line; the assumptions required in this case would be the analogues on $\mathbb{R}$ of the assumptions stated above.

The proof of Lemma 2.1 is given in Chapter III of [1][3]; this proof is very technical but standard. Proofs similar in spirit have been used by several authors to obtain local existence results (cf., e.g., [12, Chap. III]) and hence we omit the proof of the lemma. It is interesting to note that although compatibility of the constitutive relations (0.19), (0.22) with thermodynamics determines the form of (1.1) it plays no further role in the proof of Lemma 2.1. However, a bootstrapping argument, in which the thermodynamical restrictions play an essential part, can be applied to strengthen the result described in Lemma 2.1. More precisely, we can show that under the assumptions of Lemma 2.1, if θ satisfies (1.1)-(1.4) on a maximal time interval $[0, T_0)$, $T_0 > 0$ (and hence θ satisfies the entropy inequality (0.2)), then a bound on the $L^\infty([0, T_0); L^2(0, 1))$ norms of θ and its derivatives through order 2 implies that there is a bound on the aforementioned norms of third-order derivatives of θ. Hence, we can establish the following lemma.

LEMMA 2.2. *Suppose that the assumptions of Lemma* 2.1 *hold and that* θ *is a solution of* (1.1)-(1.4) *on a maximal time interval* $[0, T_0)$, $T_0 > 0$. *If* θ *satisfies* (2.7) *and*

$$\sup_{t \in [0, T_0)} \int_0^1 (\theta^2 + \theta_x^2 + \theta_t^2 + \theta_{xx}^2 + \theta_{xt}^2 + \theta_{tt}^2)(x, t)\, dx < \infty, \tag{2.9}$$

then $T_0 = \infty$.

Remark 2.1. If θ is a solution of (1.1)-(1.4), then θ satisfies the entropy inequality (0.2), where the entropy and the heat flux are given by $(0.19)_2$ and $(0.19)_3$, i.e.,

$$\begin{aligned} &-\frac{\partial}{\partial x}\left\{\frac{1}{\theta(x, t)} \int_0^\infty a'(s) F'(\bar{\theta}_x^t(x, s))\, ds\right\} \\ &\leqq \frac{\partial}{\partial t}\left\{-\hat{\psi}'(\theta(x, t)) - \frac{1}{\theta(x, t)^2} \int_0^\infty a'(s) F(\bar{\theta}_x^t(x, s))\, ds\right\} - \frac{r(x, t)}{\theta(x, t)}. \end{aligned} \tag{2.10}$$

Recall that

$$\hat{e}(\nu) := \hat{\psi}(\nu) - \nu \hat{\psi}'(\nu), \qquad \nu > 0, \tag{2.11}$$

hence (1.5) implies

$$\hat{\psi}'' \in C(0, \infty). \tag{2.12}$$

Before proving Lemma 2.2 we introduce the following definition. For $T > 0$ and $0 < h < T$, we define the forward difference operator Δ_h (with respect to the time

[3] Assumption $(1.15)_2$ of Chapter III of [1] does not suffice to ensure that $\theta_t(\cdot, 0+) \in H^2(0, 1)$. We need to make the additional assumption that

$$\int_0^\infty a'(s) F'(\bar{\varphi}_x^0(\cdot, s))\, ds \in H^3(0, 1),$$

where $\varphi : [0, 1] \times [-\infty, 0] \to (0, \infty)$ is a prescribed general history, i.e.,

$$\theta(x, t) = \varphi(x, t), \qquad x \in [0, 1], \quad t < 0.$$

However, the arguments used to prove Theorem 1.1 of [1, Chap. III] remain valid.

variable) by

$$(\Delta_h w)(x,t) := w(x,t+h) - w(x,t), \qquad x \in [0,1], \quad t \in [0, T-h] \tag{2.13}$$

for every $w \in C([0,T]; L^2(0,1))$.

Proof of Lemma 2.2. Let θ be a solution of (1.1)–(1.4) on a maximal time interval $[0, T_0)$, $T_0 > 0$, such that (2.7) holds. Our aim is to show that if $T_0 < \infty$, then

$$\sup_{t \in [0,T_0)} \int_0^1 (\theta^2 + \theta_x^2 + \theta_t^2 + \theta_{xx}^2 + \theta_{xt}^2 + \theta_{tt}^2)(x,t)\, dx = \infty. \tag{2.14}$$

For this purpose it is convenient to introduce the quantities

$$\gamma_2(t) := \sup_{s \in [0,t]} \int_0^1 (\theta^2 + \theta_x^2 + \theta_t^2 + \theta_{xx}^2 + \theta_{xt}^2 + \theta_{tt}^2)(x,s)\, dx, \qquad t \in [0, T_0), \tag{2.15}$$

$$\gamma_3(t) := \sup_{s \in [0,t]} \int_0^1 (\theta^2 + \theta_x^2 + \theta_t^2 + \theta_{xx}^2 + \theta_{xt}^2 + \theta_{tt}^2 + \theta_{xxx}^2 + \theta_{xxt}^2 + \theta_{xtt}^2 + \theta_{ttt}^2)(x,s)\, dx, \qquad t \in [0, T_0), \tag{2.16}$$

$$\Theta := \int_0^1 (\theta_0(x)^2 + \theta_0'(x)^2 + \theta_0''(x)^2 + \theta_0'''(x)^2)\, dx, \tag{2.17}$$

and

$$\begin{aligned} R := {} & \sup_{t \in (0,\infty)} \int_0^1 (r^2 + r_x^2 + r_t^2 + r_{xt}^2 + r_{tt}^2)(x,t)\, dx + \int_0^1 r_{xx}^2(x,0)\, dx \\ & + \int_0^\infty \int_0^1 (r^2 + r_x^2 + r_t^2 + r_{xt}^2 + r_{tt}^2 + r_{ttt}^2)(x,t)\, dx\, dt. \end{aligned} \tag{2.18}$$

In the following calculations we make use of the inequalities

$$\left(\sum_{i=1}^N A_i \right)^2 \leqq N \sum_{i=1}^N A_i^2, \qquad A_1, \cdots, A_N \in \mathbb{R}, \tag{2.19}$$

$$|AB| \leqq \frac{A^2}{4\lambda} + \lambda B^2, \qquad A, B \in \mathbb{R}, \quad \lambda > 0, \tag{2.20}$$

and

$$\| A * B \|_{L^p((0,T);L^2(0,1))} \leqq \| A \|_{L^1(0,\infty)} \| B \|_{L^p((0,T);L^2(0,1))} \tag{2.21}$$

for every $T > 0$, $A \in L^1(0,\infty)$, and $B \in L^p((0,T); L^2(0,1))$, where $1 \leqq p \leqq \infty$ and $A * B$ denotes the convolution of A with B. We use Γ to denote a (possible large) positive generic constant which is independent of θ_0, r, and T_0.

We first differentiate (1.1) twice with respect to t and then apply the forward difference operator Δ_h to the resulting expression. We multiply the new equation by $\Delta_h \theta_{tt}$ and integrate over $[0,1] \times [0,t]$, $t \in (0, T_0)$. After several integrations by parts, we divide both sides by h^2 and let $h \downarrow 0$ to obtain the identity

(2.22)

$$\begin{aligned} & \frac{1}{2} \int_0^1 \left(\hat{e}'(\theta(x,t)) + \frac{2}{\theta(x,t)^2} \int_0^\infty a'(s) F(\bar{\theta}_x^t(x,s))\, ds \right) \theta_{ttt}^2(x,t)\, dx \\ & \quad - \frac{1}{2} \int_0^1 \int_0^\infty a'(s) F''(\bar{\theta}_x^t(x,s))\, ds\, \theta_{xtt}^2(x,t)\, dx \end{aligned}$$

$$
\begin{aligned}
&= -\int_0^t \int_0^1 \frac{\partial}{\partial x}\left\{\frac{1}{\theta(x,s)}\int_0^\infty a'(z)F'(\bar\theta_x^s(x,z))\,dz\right\}\theta_{ttt}^2(x,s)\,dx\,ds\\
&\quad+\frac{1}{2}\int_0^1 \hat e'(\theta_0(x))\theta_{ttt}^2(x,0)\,dx+\frac{1}{2}a(0)F''(0)\int_0^1\theta_{xtt}^2(x,0)\,dx\\
&\quad+\frac{1}{2}\int_0^t\int_0^1\frac{\partial}{\partial s}\left\{\hat e'(\theta(x,s))+\frac{2}{\theta(x,s)^2}\int_0^\infty a'(z)F(\bar\theta_x^s(x,z))\,dz\right\}\theta_{ttt}^2(x,s)\,dx\,ds\\
&\quad-\frac{1}{2}\int_0^t\int_0^1\frac{\partial}{\partial s}\left\{\int_0^\infty a'(z)F''(\bar\theta_x^s(x,z))\,dz\right\}\theta_{xtt}^2(x,s)\,dx\,ds\\
&\quad+\int_0^t\int_0^1\frac{\partial^3}{\partial s^3}\left\{r(x,s)-\frac{2}{\theta(x,s)}\int_0^s a'(z)F'(\bar\theta_x^s(x,z))\theta_x(x,s-z)\,dz\right\}\theta_{ttt}(x,s)\,dx\,ds\\
&\quad-\int_0^t\int_0^1\theta_t(x,s)\frac{\partial^3}{\partial s^3}\left\{\hat e'(\theta(x,s))+\frac{2}{\theta(x,s)^2}\right.\\
&\qquad\qquad\left.\cdot\int_0^\infty a'(z)F(\bar\theta_x^s(x,z))\,dz\right\}\theta_{ttt}(x,s)\,dx\,ds\\
&\quad-3\int_0^t\int_0^1\frac{\partial}{\partial s}\left\{\theta_{tt}(x,s)\frac{\partial}{\partial s}\left\{\hat e'(\theta(x,s))+\frac{2}{\theta(x,s)^2}\right.\right.\\
&\qquad\qquad\left.\left.\cdot\int_0^\infty a'(z)F(\bar\theta_x^s(x,z))\,dz\right\}\right\}\theta_{ttt}(x,s)\,dx\,ds\\
&\quad+\int_0^t\int_0^1\frac{\partial^2}{\partial s^2}\left\{\int_0^s a'(z)F''(\bar\theta_x^s(x,z))\theta_{xx}(x,s-z)\,dz\right\}\theta_{ttt}(x,s)\,dx\,ds\\
&\quad+\int_0^t\int_0^1\frac{\partial^2}{\partial s^2}\left\{\int_0^s a'(z)F'''(\bar\theta_x^s(x,z))\bar\theta_{xx}^s(x,z)\theta_x(x,s-z)\,dz\right\}\theta_{ttt}(x,s)\,dx\,ds\\
&\quad-\int_0^t\int_0^1\theta_x(x,s)\frac{\partial^2}{\partial s^2}\left\{\int_0^s a'(z)F'''(\bar\theta_x^s(x,z))\bar\theta_{xx}^s(x,z)\,dz\right\}\theta_{ttt}(x,s)\,dx\,ds\\
&\quad-2\int_0^t\int_0^1\theta_{xt}(x,s)\frac{\partial}{\partial s}\left\{\int_0^s a'(z)F'''(\bar\theta_x^s(x,z))\bar\theta_{xx}^s(x,z)\,dz\right\}\theta_{ttt}(x,s)\,dx\,ds\\
&\quad+\int_0^t\int_0^1\theta_x(x,s)\frac{\partial^3}{\partial s^3}\left\{\frac{2}{\theta(x,s)}\int_0^\infty a'(z)F'(\bar\theta_x^s(x,z))\,dz\right\}\theta_{ttt}(x,s)\,dx\,ds\\
&\quad+3\int_0^t\int_0^1\frac{\partial}{\partial s}\left\{\theta_{xt}(x,s)\frac{\partial}{\partial s}\left\{\frac{2}{\theta(x,s)}\int_0^\infty a'(z)F'(\bar\theta_x^s(x,z))\,dz\right\}\right\}\theta_{ttt}(x,s)\,dx\,ds\\
&\quad-\int_0^t\int_0^1\frac{\partial^2}{\partial s^2}\left\{\int_0^\infty a'(z)F''(\bar\theta_x^s(x,z))\,dz\right\}\theta_{xx}(x,s)\theta_{ttt}(x,s)\,dx\,ds\\
&\quad-2\int_0^t\int_0^1\frac{\partial}{\partial s}\left\{\int_0^\infty a'(z)F''(\bar\theta_x^s(x,z))\,dz\right\}\theta_{xxt}(x,s)\theta_{ttt}(x,s)\,dx\,ds,\qquad t\in[0,T_0).
\end{aligned}
$$

Here $\theta_{ttt}(\cdot,0)$ and $\theta_{xtt}(\cdot,0)$ are determined from (1.1). Only a partial description of the estimates involved in obtaining (2.23), (2.25), and (2.29) (from (2.22)) will be given since the calculations are similar in spirit to those described in § 3 below. Making use of (2.1), (2.2), (2.10) (to estimate the first term on the right-hand side of (2.22)),

(2.19)-(2.21), and the Sobolev embedding theorem we can show that

$$\begin{aligned}&\int_0^1 (\theta_{xtt}^2+\theta_{ttt}^2)(x,t)\,dx\\ &\leqq \Gamma\Big\{\Theta+R+\gamma_2^2(t)+\gamma_2^3(t)+[1+R^{1/2}+(1+t)(\gamma_2^{1/2}(t)+\gamma_2^{(k+1)/2}(t))]\\ &\qquad\cdot\int_0^t\int_0^1 (\theta_{xxx}^2+\theta_{xxt}^2+\theta_{xtt}^2+\theta_{ttt}^2)(x,s)\,dx\,ds\Big\}\quad \forall t\in[0,T_0).\end{aligned}\tag{2.23}$$

We differentiate (1.1) twice with respect to t, square the resulting expression, and then integrate over $[0,1]$ to obtain the inequality

$$\begin{aligned}&\int_0^1\left(\int_0^\infty a'(s)F''(\bar\theta_x^t(x,s))\,ds\right)^2\theta_{xxt}^2(x,t)\,dx\\ &\leqq 5\int_0^1\left(\frac{\partial^3}{\partial t^3}\left\{\hat e(\theta(x,t))-\frac{2}{\theta(x,t)}\int_0^\infty a'(s)F(\bar\theta_x^t(x,s))\,ds\right\}\right)^2dx\\ &\quad+5\int_0^1\left(\theta_{xx}(x,t)\frac{\partial}{\partial t}\left\{\int_0^\infty a'(s)F''(\bar\theta_x^t(x,s))\,ds\right\}\right)^2dx\\ &\quad+5\int_0^1\left(\frac{\partial}{\partial t}\left\{\int_0^t a'(s)F''(\bar\theta_x^t(x,s))\theta_{xx}(x,t-s)\,ds\right\}\right)^2dx\\ &\quad+5\int_0^1\left(\frac{\partial}{\partial t}\left\{\int_0^t a'(s)\frac{\partial}{\partial t}(F''(\bar\theta_x^t(x,s)))\bar\theta_{xx}^t(x,s)\,ds\right\}\right)^2dx\\ &\quad+5\int_0^1 r_{tt}^2(x,t)\,dx\quad\forall t\in[0,T_0).\end{aligned}\tag{2.24}$$

Using (2.2) to get a lower bound on the left-hand side of (2.24), and estimating the right-hand side of (2.24) we can show that

$$\begin{aligned}&\int_0^1\theta_{xxt}^2(x,t)\,dx\leqq\Gamma\Big\{R+\gamma_2(t)+\gamma_2^{k+3}(t)\\ &\qquad+(1+\gamma_2(t)+\gamma_2^k(t))\\ &\qquad\cdot\int_0^1(\theta_{xtt}^2+\theta_{ttt}^2)(x,t)\,dx\Big\}\quad\forall t\in[0,T_0).\end{aligned}\tag{2.25}$$

We now differentiate (1.1) once with respect to t and then once with respect to x. We square the result and integrate over $[0,1]$ to get

$$\begin{aligned}&\int_0^1\left(\int_0^\infty a'(s)F''(\bar\theta_x^t(x,s))\,ds\right)^2\theta_{xxx}^2(x,t)\,dx\\ &\leqq 5\int_0^1\left(\frac{\partial^3}{\partial x\,\partial t^2}\left\{\hat e(\theta(x,t))-\frac{2}{\theta(x,t)}\int_0^\infty a'(s)F(\bar\theta_x^t(x,s))\,ds\right\}\right)^2dx\\ &\quad+5\int_0^1\left(\theta_{xx}(x,t)\frac{\partial}{\partial x}\left\{\int_0^\infty a'(s)F''(\bar\theta_x^t(x,s))\,ds\right\}\right)^2dx\\ &\quad+5\int_0^1\left(\frac{\partial}{\partial x}\left\{\int_0^t a'(s)F''(\bar\theta_x^t(x,s))\theta_{xx}(x,t-s)\,ds\right\}\right)^2dx\\ &\quad+5\int_0^1\left(\frac{\partial}{\partial x}\left\{\int_0^t a'(s)\frac{\partial}{\partial t}\{F''(\bar\theta_x^t(x,s))\}\bar\theta_{xx}^t(x,s)\,ds\right\}\right)^2dx\\ &\quad+5\int_0^1 r_{xt}^2(x,t)\,dx\quad\forall t\in[0,T_0).\end{aligned}\tag{2.26}$$

To obtain bounds on the third and fourth terms on the right-hand side of (2.26) we make use of the following observation. We have

$$g(x,t)=g(x,0)+\int_0^t g_t(x,s)\,ds, \qquad x\in[0,1], \quad t\in[0,T] \tag{2.27}$$

and hence

$$\int_0^1 g^2(x,t)\,dx \leqq 2\int_0^1 g^2(x,0)\,dx+2t\int_0^t\int_0^1 g_t^2(x,s)\,dx\,ds \quad \forall t\in[0,T] \tag{2.28}$$

for every $T>0$ and every smooth function $g:[0,1]\times[0,T]\to\mathbb{R}$. Thus we arrive at the inequality

$$\begin{aligned}\int_0^1 \theta_{xxx}^2(x,t)\,dx \leqq \Gamma\Big\{ & R+\gamma_2(t)+\gamma_2^{k+3}(t)\\ & +(1+\gamma_2(t)+\gamma_2^k(t))\int_0^1(\theta_{xxt}^2+\theta_{xtt}^2)(x,t)\,dx\\ & +t(1+\gamma_2(t)+\gamma_2^{k+2}(t))\int_0^t\int_0^1\theta_{xxx}^2(x,s)\,dx\,ds\Big\} \quad \forall t\in[0,T_0).\end{aligned} \tag{2.29}$$

As remarked earlier, we will not give further details of the calculations involved to obtain the above estimates.

Combining (2.23), (2.25), and (2.29) it is easy to show that there is a constant $N=N(k)>2$ such that

$$\begin{aligned}&\int_0^1(\theta_{xxx}^2+\theta_{xxt}^2+\theta_{xtt}^2+\theta_{ttt}^2)(x,t)\,dx\\ &\quad\leqq\bar\Gamma\Big\{\Theta+\Theta^2+R+R^2+\gamma_2(T_0)+\gamma_2^N(T_0)\\ &\qquad+[1+R^{1/2}+R+(1+T_0)(\gamma_2^{1/2}(T_0)+\gamma_2^N(T_0))]\\ &\qquad\cdot\int_0^t\int_0^1(\theta_{xxx}^2+\theta_{xxt}^2+\theta_{xtt}^2+\theta_{ttt}^2)(x,s)\,dx\,ds\Big\} \quad \forall t\in[0,T_0),\end{aligned} \tag{2.30}$$

where $\bar\Gamma$ is a fixed positive constant independent of r, θ_0, and T_0. Thus Gronwall's inequality implies

$$\begin{aligned}\gamma_3(T_0)\leqq\bar\Gamma[&\Theta+\Theta^2+R+R^2+\gamma_2(T_0)+\gamma_2^N(T_0)]\\ &\cdot\exp\{\bar\Gamma T_0[1+R^{1/2}+R+(1+T_0)(\gamma_2^{1/2}(T_0)+\gamma_2^N(T_0))]\}.\end{aligned} \tag{2.31}$$

According to Lemma 2.1, if $T_0<\infty$ then $\gamma_3(T_0)=\infty$ and hence (2.31) leads to the desired conclusion. □

In the analysis of (1.1)–(1.4) we make essential use of several properties of strongly positive-definite kernels. A function $b\in L^1_{\mathrm{loc}}[0,\infty)$ is said to be *positive definite* if

$$\int_0^t w(s)\int_0^s b(s-z)w(z)\,dz\,ds\geqq 0 \quad \forall t\geqq 0, \tag{2.32}$$

for every $w\in C[0,\infty)$. The kernel b is said to be *strongly positive definite* if there is a constant $c>0$ such that the mapping $t\mapsto b(t)-c\,e^{-t}$ is positive definite.

This definition is generally not easy to check directly. We can show that if $b \in L^1(0, \infty)$, then b is strongly positive definite if and only if there is a constant $c > 0$ such that

$$\text{Re } \mathscr{L}[b](i\omega) \geqq \frac{c}{\omega^2 + 1} \quad \forall \omega \in \mathbb{R}, \tag{2.33}$$

where $\mathscr{L}[\cdot]$ denotes the Laplace transform. It is useful to know that if $b \in C^2[0, \infty)$ and

$$(-1)^j b^{(j)}(t) \geqq 0 \quad \forall t \geqq 0, \quad j = 0, 1, 2, \quad b' \not\equiv 0, \tag{2.34}$$

then b is strongly positive definite. With sufficient regularity, we can obtain information concerning the pointwise behaviour near zero of strongly positive-definite functions. In particular, $(1.10)_{1,2}$ imply that

$$a(0) > 0, \qquad a'(0) < 0. \tag{2.35}$$

This follows easily by expressing $a(0)$ and $a'(0)$ in terms of the Laplace transform of a (cf., e.g., [7, § 2]). Condition (2.35) plays an important role in the analysis. See, for example, [11] for more information on strongly positive-definite kernels.

To obtain certain estimates, we need to solve (1.1) for θ_{xx}. For this purpose we recall that for each $y \in L^1_{\text{loc}}[0, \infty)$, the equation

$$a(0)w(t) + \int_0^t a'(t-s)w(s)\, ds = y(t), \qquad t \geqq 0, \tag{2.36}$$

has a unique solution $w \in L^1_{\text{loc}}[0, \infty)$; this solution is given by

$$w(t) = \frac{1}{a(0)}\left(y(t) + \int_0^t m(t-s)y(s)\, ds\right), \qquad t \geqq 0, \tag{2.37}$$

where m, the *resolvent kernel of* a', is defined to be the unique solution of the resolvent equation

$$a(0)m(t) + \int_0^t m(t-s)a'(s)\, ds = -a'(t), \qquad t \geqq 0. \tag{2.38}$$

Using a Paley-Wiener type argument, $(1.10)_{1,2}$, and properties of strongly positive kernels, we establish the following lemma.

LEMMA 2.3. *Assume that* $(1.10)_{1,2}$ *is satisfied. Then the solution* m *to* (2.38) *satisfies* $m' \in L^1(0, \infty)$.

Remark 2.2. Under assumptions $(1.10)_{1,2}$ and $(1.11)_1$ we can also show that

$$m(t) = \frac{a(0)}{\mathscr{L}[a](0)} + M(t), \qquad t \geqq 0, \tag{2.39}$$

where $M \in L^1(0, \infty)$.

Proof of Lemma 2.3. Define $\Pi := \{\xi \in \mathbb{C}: \text{Re } \xi \geqq 0\}$. Formally taking Laplace transforms in (2.38) we find that

$$\mathscr{L}[m](\xi) = \frac{-\mathscr{L}[a'](\xi)}{a(0) + \mathscr{L}[a'](\xi)}, \qquad \xi \in \Pi. \tag{2.40}$$

Recall that $(1.10)_{1,2}$ imply (2.35). Thus, by (2.38) we have

$$\mathscr{L}[m'](\xi) = \frac{a'(0)}{a(0)} - \frac{\xi \mathscr{L}[a'](\xi)}{a(0) + \mathscr{L}[a'](\xi)}, \qquad \xi \in \Pi. \tag{2.41}$$

After a simple computation we obtain

$$\mathscr{L}[m'](\xi)=\frac{a'(0)}{a(0)}+\frac{a(0)}{\mathscr{L}[a](\xi)}-\xi, \qquad \xi\in\Pi. \tag{2.42}$$

By (2.33) and the maximum principle for analytic functions $\mathscr{L}[a]$ does not vanish on Π. Hence, by $(2.35)_1$ and (2.33), $\mathscr{L}[m']$ is locally analytic on Π in the sense of Definition 2.1 of [9]. Observe that for ξ near infinity we have

$$\begin{aligned}\mathscr{L}[m'](\xi)&=\frac{-a(0)(\xi\mathscr{L}[a'](\xi)-a'(0))+a'(0)\mathscr{L}[a'](\xi)}{a(0)(a(0)+\mathscr{L}[a'](\xi))}\\&=\frac{-a(0)\mathscr{L}[a''](\xi)+a'(0)\mathscr{L}[a'](\xi)}{a(0)(a(0)+\mathscr{L}[a'](\xi))}.\end{aligned} \tag{2.43}$$

Thus $\mathscr{L}[m']$ is locally analytic at infinity and $\mathscr{L}[m'](\infty)=0$. Therefore, by Proposition 2.3 of [9] $m'\in L^1(0,\infty)$, and the proof is complete. □

Before describing our next result we introduce the following notation (which is also used in the next section). For $b\in L^1_{\mathrm{loc}}[0,\infty)$ we define

$$Q(w,t,b):=\int_0^t\int_0^1 w(x,s)\int_0^s b(s-z)w(x,z)\,dz\,dx\,ds, \qquad t\in[0,T], \tag{2.44}$$

for every $T>0$ and every $w\in C([0,T];L^2(0,1))$. The result below was motivated by Lemma 2 of [8].

LEMMA 2.4. *Assume that* $(1.10)_{1,2}$ *hold. Then there exists a constant* $L>0$ *such that*

$$\begin{aligned}\int_0^1 w^2(x,t)\,dx\leqq L\int_0^1 w^2(x,0)\,dx+L\int_0^t\int_0^1 w^2(x,s)\,dx\,ds\\+L\liminf_{h\downarrow 0}\frac{1}{h^2}Q(\Delta_h w,t,a)\quad\forall t\in[0,T],\end{aligned} \tag{2.45}$$

for every $T>0$ *and every* $w\in C([0,T];L^2(0,1))$ *and consequently, by Lemma* 2.5 *of* [7], *there is a constant* $L^*>0$ *such that*

$$\begin{aligned}\int_0^1 w^2(x,t)\,dx+\int_0^t\int_0^1 w^2(x,s)\,dx\,ds\leqq L^*\int_0^1 w^2(x,0)\,dx+L^*Q(w,t,a)\\+L^*\liminf_{h\downarrow 0}\frac{1}{h^2}Q(\Delta_h w,t,a)\quad\forall t\in[0,T],\end{aligned} \tag{2.46}$$

for every $T>0$ *and every* $w\in C([0,T];L^2(0,1))$.

For the proof of Lemma 2.4 it is convenient to introduce the following notation:

$$e(t):=e^{-t}, \qquad t\in[0,\infty). \tag{2.47}$$

In addition, for $T>0$ and $0<h<T$, we define the quantity

$$(D_h w)(x,t):=\int_0^t \Delta_h w(x,s)\,ds, \qquad t\in[0,T-h], \tag{2.48}$$

for every $w\in C([0,T];L^2(0,1))$. We note that

$$(D_h w)(x,t)=\int_t^{t+h} w(x,s)\,ds-\int_0^h w(x,s)\,ds, \qquad t\in[0,T-h]. \tag{2.49}$$

Proof of Lemma 2.4. We first observe that by $(1.10)_{1,2}$ there exists a constant $c>0$ such that

$$0 \leqq Q(v, t, e) \leqq cQ(v, t, a) \quad \forall t \in [0, T], \tag{2.50}$$

for every $T>0$ and every $v \in C([0, T]; L^2(0, 1))$. Let $T>0$, $h \in (0, T)$, and $w \in C([0, T]; L^2(0, 1))$ be given. Integration by parts (twice) leads to the following identity:

$$\begin{aligned} Q(\Delta_h w, t, e) = &\frac{1}{2}\int_0^1 (D_h w)(x, t)^2\, dx + \int_0^t \int_0^1 (D_h w)(x, s)^2\, dx\, ds \\ &- \int_0^1 (D_h w)(x, t) \int_0^t e^{-(t-s)} (D_h w)(x, s)\, ds\, dx \\ &- \int_0^t \int_0^1 (D_h w)(x, s) \int_0^s e^{-(s-z)} (D_h w)(x, z)\, dz\, dx\, ds. \end{aligned} \tag{2.51}$$

Dividing both sides of (2.51) by h^2 and letting $h \downarrow 0$ we can show that $\lim_{h \downarrow 0} (1/h^2) Q(\Delta_h w, t, e)$ exists and is given by

$$\begin{aligned} \lim_{h \downarrow 0} \frac{1}{h^2} Q(\Delta_h w, t, e) = &\frac{1}{2}\int_0^1 [w(x, t) - w(x, 0)]^2\, dx + \int_0^t \int_0^1 [w(x, s) - w(x, 0)]^2\, dx\, ds \\ &- \int_0^1 [w(x, t) - w(x, 0)] \int_0^t e^{-(t-s)} [w(x, s) - w(x, 0)]\, ds\, dx \\ &- \int_0^t \int_0^1 [w(x, s) - w(x, 0)] \int_0^s e^{-(s-z)} [w(x, z) - w(x, 0)]\, dz\, dx\, ds. \end{aligned} \tag{2.52}$$

After some simple computations we obtain the following expression for the last two terms on the right-hand side of (2.52):

$$\begin{aligned} &- \int_0^1 [w(x, t) - w(x, 0)] \int_0^t e^{-(t-s)} [w(x, s) - w(x, 0)]\, ds\, dx \\ &\quad = -\int_0^1 w(x, t) \int_0^t e^{-(t-s)} w(x, s)\, ds\, dx \\ &\qquad + \int_0^1 w(x, 0) \int_0^t e^{-(t-s)} w(x, s)\, ds\, dx \\ &\qquad - \int_0^1 w^2(x, 0)[1 - e^{-t}]\, dx + \int_0^1 w(x, t) w(x, 0)[1 - e^{-t}]\, dx, \end{aligned} \tag{2.53}$$

$$\begin{aligned} &- \int_0^t \int_0^1 [w(x, s) - w(x, 0)] \int_0^s e^{-(s-z)} [w(x, z) - w(x, 0)]\, dz\, dx\, ds \\ &\quad = -Q(w, t, e) - \int_0^t \int_0^1 w^2(x, 0)\, dx\, ds + \int_0^1 w^2(x, 0)[1 - e^{-t}]\, dx \\ &\qquad + 2\int_0^t \int_0^1 w(x, s) w(x, 0)\, dx\, ds - \int_0^t \int_0^1 w(x, s) w(x, 0)\, e^{-s}\, dx\, ds \\ &\qquad - \int_0^t \int_0^1 w(x, s) w(x, 0)\, e^{-(t-s)}\, dx\, ds. \end{aligned} \tag{2.54}$$

Hence, (2.52) implies

$$\begin{aligned}\frac{1}{2}\int_0^1 w^2(x,t)\,dx &= \lim_{h\downarrow 0}\frac{1}{h^2}Q(\Delta_h w,t,e)+Q(w,t,e)-\int_0^t\int_0^1 w^2(x,s)\,dx\,ds\\ &\quad -\frac{1}{2}\int_0^1 w^2(x,0)\,dx+\int_0^1 w(x,t)\int_0^t e^{-(t-s)}w(x,s)\,ds\,dx\\ &\quad +\int_0^1 w(x,t)w(x,0)\,e^{-t}\,dx\\ &\quad +\int_0^t\int_0^1 w(x,s)w(x,0)\,e^{-s}\,dx\,ds.\end{aligned}\tag{2.55}$$

To complete the proof we use the inequality (2.20); for $\lambda>0$

$$\begin{aligned}&\left|\int_0^1 w(x,t)\int_0^t e^{-(t-s)}w(x,s)\,ds\,dx\right|\\ &\leqq \lambda\int_0^1 w^2(x,t)\,dx+\frac{1}{4\lambda}\int_0^1\left(\int_0^t e^{-(t-s)}w(x,s)\,ds\right)^2 dx\\ &\leqq \lambda\int_0^1 w^2(x,t)\,dx+\frac{1}{8\lambda}\int_0^t\int_0^1 w^2(x,s)\,dx\,ds,\end{aligned}\tag{2.56}$$

$$\left|\int_0^1 w(x,t)w(x,0)\,e^{-t}\,dx\right|\leqq\lambda\int_0^1 w^2(x,t)\,dx+\frac{1}{4\lambda}\int_0^1 w^2(x,0)\,dx,\tag{2.57}$$

and similarly

$$\begin{aligned}&\left|\int_0^t\int_0^1 w(x,s)w(x,0)\,e^{-s}\,dx\,ds\right|\\ &\leqq\int_0^t\int_0^1 w^2(x,s)\,dx\,ds+\frac{1}{4}\int_0^t e^{-2s}\,ds\int_0^1 w^2(x,0)\,dx\\ &\leqq\int_0^t\int_0^1 w^2(x,s)\,dx\,ds+\frac{1}{8}\int_0^1 w^2(x,0)\,dx.\end{aligned}\tag{2.58}$$

Hence, if $\lambda>0$ is chosen to be sufficiently small the desired conclusion follows from (2.50). □

3. Proof of Theorem 1.1. We choose $\varepsilon\in(0,\theta^*)$ as in the first paragraph of § 2. If (1.21) holds with $\delta<\eta/2$, for some $\eta\in(0,\varepsilon)$, then the Sobolev embedding theorem implies

$$|\theta_0(x)-\theta^*|,\ |\theta_0'(x)|\leqq\sqrt{2\Theta_0}<\eta\quad\forall x\in[0,1].\tag{3.1}$$

Therefore, by Lemmas 2.1 and 2.2, the initial value problem (1.1)-(1.4) has a unique solution $\theta>0$ that satisfies

$$\theta,\ \theta_x,\ \theta_t,\ \theta_{xx},\ \theta_{xt},\ \theta_{tt},\ \theta_{xxx},\ \theta_{xxt},\ \theta_{xtt},\ \theta_{ttt}\in C([0,T_0);L^2(0,1))\tag{3.2}$$

and

$$|\theta(x,t)-\theta^*|,\ |\theta_x(x,t)|<\varepsilon\quad\forall x\in[0,1],\quad t\in[0,T_0)\tag{3.3}$$

on a maximal time interval $[0, T_0)$, $T_0 > 0$. Our aim is to show that if (1.21) holds for $\delta > 0$ sufficiently small, then

$$\sup_{t\in[0,T_0)} \int_0^1 ([\theta(x,t)-\theta^*]^2+\theta_x^2(x,t)+\theta_t^2(x,t)+\theta_{xx}^2(x,t) + \theta_{xt}^2(x,t)+\theta_{tt}^2(x,t))\,dx < \infty \tag{3.4}$$

and

$$\sup_{\substack{x\in[0,1]\\ t\in[0,T_0)}} |\theta(x,t)-\theta^*|, \qquad \sup_{\substack{x\in[0,1]\\ t\in[0,T_0)}} |\theta_x(x,t)| < \varepsilon \tag{3.5}$$

and hence $T_0 = \infty$ (by Lemma 2.2). For this purpose it is convenient to introduce the quantities

$$\begin{aligned}\mathscr{E}(t) := \sup_{s\in[0,t]} \int_0^1 &([\theta(x,s)-\theta^*]^2+\theta_x^2(x,s)+\theta_t^2(x,s)+\theta_{xx}^2(x,s) \\ &+\theta_{xt}^2(x,s)+\theta_{tt}^2(x,s))\,dx \\ +\int_0^t \int_0^1 &([\theta(x,s)-\theta^*]^2+\theta_x^2(x,s)+\theta_t^2(x,s)+\theta_{xx}^2(x,s) \\ &+\theta_{xt}^2(x,s)+\theta_{tt}^2(x,s))\,dx\,ds, \qquad t\in[0,T_0)\end{aligned} \tag{3.6}$$

and

$$\begin{aligned}\nu(t) := \sup_{\substack{x\in[0,1]\\ s\in[0,t]}} &([\theta(x,s)-\theta^*]^2+\theta_x^2(x,s)+\theta_t^2(x,s))^{1/2} \\ &+\left(\int_0^t \left(\sup_{x\in[0,1]} |\theta_x(x,s)|\right)^2 ds\right)^{1/2}, \qquad t\in[0,T_0).\end{aligned} \tag{3.7}$$

Equation (1.1) can be rewritten as follows:

$$\begin{aligned}&\hat{e}'(\theta^*)\theta_t(x,t) - F''(0)\int_0^t a(t-s)\theta_{xx}(x,s)\,ds \\ &= -[\hat{e}'(\theta(x,t))-\hat{e}'(\theta^*)]\theta_t(x,t) - \int_0^t \theta_{xx}(x,s) \\ &\quad \cdot \int_{t-s}^\infty a'(z)[F''(\bar{\theta}_x^t(x,z))-F''(0)]\,dz\,ds \\ &\quad -\frac{2}{\theta(x,t)^2}\theta_t(x,t)\int_0^\infty a'(s)F(\bar{\theta}_x^t(x,s))\,ds \\ &\quad +\frac{2}{\theta(x,t)}\theta_x(x,t)\int_0^\infty a'(s)F'(\bar{\theta}_x^t(x,s))\,ds \\ &\quad -\frac{2}{\theta(x,t)}\int_0^t a'(s)F'(\bar{\theta}_x^t(x,s))\theta_x(x,t-s)\,ds + r(x,t), \\ &\qquad\qquad x\in[0,1], \quad t\in[0,T_0).\end{aligned} \tag{3.8}$$

In the derivation of this equation from (1.1) we make use of (1.2) and (1.8). The second terms on both sides of (3.8) are obtained through the following computation:

$$\int_0^\infty a'(s)F''(\bar\theta_x^t(x,s))\bar\theta_{xx}^t(x,s)\,ds = \int_0^\infty \int_{t-s}^t a'(s)F''(\bar\theta_x^t(x,s))\theta_{xx}(x,z)\,dz\,ds$$

$$= \int_0^t \theta_{xx}(x,z)\int_{t-z}^\infty a'(s)F''(\bar\theta_x^t(x,s))\,ds\,dz. \tag{3.9}$$

The aim of the computations that follow is to establish the inequality (3.40) below; to do so we employ energy methods. We use two main types of estimates in this argument:

(i) Estimates derived directly from energy integrals;

(ii) Additional estimates obtained from equation (3.8) through the use of inverse Volterra operators.

In our energy integrals, the left-hand side of (3.8) will lead to positive-definite contributions and the right-hand side will lead to terms that are small provided the solution is near equilibrium. We make essential use of Lemma 2.4 in the estimates of type (i); in addition, in order to estimate the energy integral of highest order we must exploit compatibility of our constitutive relations (0.19), (0.22) with thermodynamics; i.e., we make use of the fact that a solution of (1.1)–(1.4) satisfies the entropy inequality (0.2). (See Remark 2.1 for further details.) Lemma 2.3 plays an important role in the estimates of type (ii). A reader who is unfamiliar with energy methods and seeks further motivation for our computations may wish to look at the argument following (3.40) before reading the derivation of (3.40).

In the numerous estimations that follow we make frequent use of the inequalities (2.19)–(2.21). We use Γ to denote a (possibly large) positive generic constant which is independent of θ_0, r, and T_0.

To obtain our first energy integral we multiply equation (3.8) by $(\theta-\theta^*)$ and integrate over $[0,1]\times[0,t]$, $t\in[0,T_0)$. After integration by parts we find that

$$\frac{1}{2}\hat e'(\theta^*)\int_0^1[\theta(x,t)-\theta^*]^2\,dx + F''(0)Q(\theta_x,t,a)$$

$$= \frac{1}{2}\hat e'(\theta^*)\int_0^1[\theta_0(x)-\theta^*]^2\,dx + \int_0^t\int_0^1[\theta(x,s)-\theta^*]$$

$$\cdot\Bigg(-[\hat e'(\theta(x,s))-\hat e'(\theta^*)]\theta_t(x,s)$$

$$-\int_0^s \theta_{xx}(x,y)\int_{s-y}^\infty a'(z)[F''(\bar\theta_x^s(x,z))-F''(0)]\,dz\,dy$$

$$-\frac{2}{\theta(x,s)^2}\theta_t(x,s)\int_0^\infty a'(z)F(\bar\theta_x^s(x,z))\,dz$$

$$+\frac{2}{\theta(x,s)}\theta_x(x,s)\int_0^\infty a'(z)F'(\bar\theta_x^s(x,z))\,dz - \frac{2}{\theta(x,s)}$$

$$\cdot\int_0^s a'(z)F'(\bar\theta_x^s(x,z))\theta_x(x,s-z)\,dz + r(x,s)\Bigg)\,dx\,ds, \qquad t\in[0,T_0). \tag{3.10}$$

We next differentiate (3.8) with respect to t:

$$\begin{aligned}
&\hat{e}'(\theta^*)\theta_{tt}(x,t) - F''(0)a(0)\theta_{xx}(x,t) - F''(0)\int_0^t a'(t-s)\theta_{xx}(x,s)\,ds \\
&\quad = \frac{\partial}{\partial t}\Big\{ -[\hat{e}'(\theta(x,t)) - \hat{e}'(\theta^*)]\theta_t(x,t) \\
&\qquad - \int_0^t \theta_{xx}(x,s)\int_{t-s}^{\infty} a'(z)[F''(\bar{\theta}_x^t(x,z)) - F''(0)]\,dz\,ds \\
&\qquad - \frac{2}{\theta(x,t)^2}\theta_t(x,t)\int_0^{\infty} a'(s)F(\bar{\theta}_x^t(x,s))\,ds \\
&\qquad + \frac{2}{\theta(x,t)}\theta_x(x,t)\int_0^{\infty} a'(s)F'(\bar{\theta}_x^t(x,s))\,ds \\
&\qquad - \frac{2}{\theta(x,t)}\int_0^t a'(s)F'(\bar{\theta}_x^t(x,s))\theta_x(x,t-s)\,ds + r(x,t)\Big\}, \\
&\qquad\qquad x\in[0,1], \quad t\in[0,T_0).
\end{aligned} \tag{3.11}$$

Multiplying this equation by θ_t and integrating over $[0,1]\times[0,t]$, $t\in[0,T_0)$ we obtain the following expression:

$$\begin{aligned}
&\frac{1}{2}\hat{e}'(\theta^*)\int_0^1 \theta_t^2(x,t)\,dx + F''(0)Q(\theta_{xt},t,a) \\
&\quad = F''(0)\int_0^t\int_0^1 a(s)\theta_0''(x)\theta_t(x,s)\,dx\,ds + \frac{1}{2}\hat{e}'(\theta^*)\int_0^1 \theta_t^2(x,0)\,dx + \int_0^t\int_0^1 \theta_t(x,s)\frac{\partial}{\partial s} \\
&\qquad \cdot\Big\{ -[\hat{e}'(\theta(x,s)) - \hat{e}'(\theta^*)]\theta_t(x,s) \\
&\qquad - \int_0^s \theta_{xx}(x,y)\int_{s-y}^{\infty} a'(z)[F''(\bar{\theta}_x^s(x,z)) - F''(0)]\,dz\,dy \\
&\qquad - \frac{2}{\theta(x,s)^2}\theta_t(x,s)\int_0^{\infty} a'(z)F(\bar{\theta}_x^s(x,z))\,dz \\
&\qquad + \frac{2}{\theta(x,s)}\theta_x(x,s)\int_0^{\infty} a'(z)F'(\bar{\theta}_x^s(x,z))\,dz \\
&\qquad - \frac{2}{\theta(x,s)}\int_0^s a'(z)F'(\bar{\theta}_x^s(x,z))\theta_x(x,s-z)\,dz + r(x,s)\Big\}\,dx\,ds, \qquad t\in[0,T_0).
\end{aligned} \tag{3.12}$$

We note that according to (3.8) we have

$$\theta_t(x,0) = \frac{1}{\hat{e}'(\theta_0(x))}r(x,0), \qquad x\in[0,1]. \tag{3.13}$$

Differentiation of (3.11) with respect to t yields (after integrating several terms by parts)

(3.14)

$$\begin{aligned}
&\hat{e}'(\theta^*)\theta_{ttt}(x,t) - F''(0)a(0)\theta_{xxt}(x,t) - F''(0)\int_0^t a'(t-s)\theta_{xxt}(x,s)\,ds \\
&\quad = F''(0)a'(t)\theta_0''(x)
\end{aligned}$$

$$+\frac{\partial^2}{\partial t^2}\left\{-[\hat{e}'(\theta(x,t))-\hat{e}'(\theta^*)]\theta_t(x,t)-\frac{2}{\theta(x,t)}\right.$$
$$\left.\cdot\int_0^t a'(s)F'(\bar{\theta}_x^t(x,s))\theta_x(x,t-s)\,ds+r(x,t)\right\}$$
$$+\frac{\partial}{\partial t}\left\{\int_0^t \theta_{xx}(x,t-s)a'(s)[F''(\bar{\theta}_x^t(x,s))-F''(0)]\,ds\right.$$
$$\left.+\int_0^t \theta_{xx}(x,s)\int_{t-s}^t a'(z)F'''(\bar{\theta}_x^t(x,z))\theta_x(x,t-z)\,dz\,ds\right\}$$
$$-\theta_{xx}(x,t)\frac{\partial}{\partial t}\left\{\int_0^\infty a'(s)[F''(\bar{\theta}_x^t(x,s))-F''(0)]\,ds\right\}$$
$$-\theta_x(x,t)\frac{\partial}{\partial t}\left\{\int_0^t \theta_{xx}(x,s)\int_{t-s}^\infty a'(z)F'''(\bar{\theta}_x^t(x,z))\,dz\,ds\right\}$$
$$-\frac{\partial}{\partial x}\left\{\theta_{xt}(x,t)\int_0^\infty a'(s)[F''(\bar{\theta}_x^t(x,s))-F''(0)]\,ds\right\}$$
$$-\theta_t(x,t)\frac{\partial^2}{\partial t^2}\left\{\frac{2}{\theta(x,t)^2}\int_0^\infty a'(s)F(\bar{\theta}_x^t(x,s))\,ds\right\}$$
$$-\theta_{tt}(x,t)\frac{\partial}{\partial t}\left\{\frac{4}{\theta(x,t)^2}\int_0^\infty a'(s)F(\bar{\theta}_x^t(x,s))\,ds\right\}$$
$$-\theta_{ttt}(x,s)\frac{2}{\theta(x,t)^2}\int_0^\infty a'(s)F(\bar{\theta}_x^t(x,s))\,ds$$
$$+\theta_x(x,t)\frac{\partial^2}{\partial t^2}\left\{\frac{2}{\theta(x,t)}\int_0^\infty a'(s)F'(\bar{\theta}_x^t(x,s))\,ds\right\}$$
$$+\theta_{xt}(x,t)\frac{\partial}{\partial t}\left\{\frac{4}{\theta(x,t)}\int_0^\infty a'(s)F'(\bar{\theta}_x^t(x,s))\,ds\right\}$$
$$+\theta_{xtt}(x,t)\frac{2}{\theta(x,t)}\int_0^\infty a'(s)F'(\bar{\theta}_x^t(x,s))\,ds,\qquad x\in[0,1],\quad t\in[0,T_0).$$

In analogy with the previous calculation, we multiply (3.14) by θ_{tt} and integrate over $[0,1]\times[0,t]$, $t\in[0,T_0)$. The resulting relation is

(3.15)

$$\frac{1}{2}\hat{e}'(\theta^*)\int_0^1 \theta_{tt}^2(x,t)\,dx+F''(0)Q(\theta_{xtt},t,a)$$
$$=F''(0)\int_0^t\int_0^1 a'(s)\theta_0''(x)\theta_{tt}(x,s)\,dx\,ds-F''(0)\int_0^1 a(t)\theta_{xt}(x,0)\theta_{xt}(x,t)\,dx$$
$$+F''(0)a(0)\int_0^1 \theta_{xt}^2(x,0)\,dx+F''(0)\int_0^t\int_0^1 a'(s)\theta_{xt}(x,0)\theta_{xt}(x,s)\,dx\,ds$$
$$+\frac{1}{2}\hat{e}'(\theta^*)\int_0^1 \theta_{tt}^2(x,0)\,dx+\int_0^t\int_0^1 \theta_{tt}(x,s)\frac{\partial^2}{\partial s^2}$$
$$\cdot\left\{-[\hat{e}'(\theta(x,s))-\hat{e}'(\theta^*)]\theta_t(x,s)\right.$$
$$\left.-\frac{2}{\theta(x,s)}\int_0^s a'(z)F'(\bar{\theta}_x^s(x,z))\theta_x(x,s-z)\,dz+r(x,s)\right\}dx\,ds$$

$$+\int_0^t\int_0^1 \theta_{tt}(x,s)\frac{\partial}{\partial s}\Big\{\int_0^s \theta_{xx}(x,s-z)a'(z)[F''(\bar\theta_x^s(x,z))-F''(0)]\,dz + \int_0^s \theta_{xx}(x,y) \cdot \int_{s-y}^s a'(z)F'''(\bar\theta_x^s(x,z))\theta_x(x,s-z)\,dz\,dy\Big\}\,dx\,ds$$

$$-\int_0^t\int_0^1 \theta_{tt}(x,s)\theta_{xx}(x,s)\frac{\partial}{\partial s}\Big\{\int_0^\infty a'(z)[F''(\bar\theta_x^s(x,z))-F''(0)]\,dz\Big\}\,dx\,ds$$

$$-\int_0^t\int_0^1 \theta_{tt}(x,s)\theta_x(x,s)\frac{\partial}{\partial s}\Big\{\int_0^s \theta_{xx}(x,y)\int_{s-y}^\infty a'(z)F'''(\bar\theta_x^s(x,z))\,dz\,dy\Big\}\,dx\,ds$$

$$+\frac{1}{2}\int_0^1 \theta_{xt}^2(x,t)\int_0^\infty a'(s)[F''(\bar\theta_x^t(x,s))-F''(0)]\,ds\,dx$$

$$-\frac{1}{2}\int_0^t\int_0^1 \theta_{xt}^2(x,s)\frac{\partial}{\partial s}\Big\{\int_0^\infty a'(z)[F''(\bar\theta_x^s(x,z))-F''(0)]\,dz\Big\}\,dx\,ds$$

$$-\int_0^t\int_0^1 \theta_{tt}(x,s)\theta_t(x,s)\frac{\partial^2}{\partial s^2}\Big\{\frac{2}{\theta(x,s)^2}\int_0^\infty a'(z)F(\bar\theta_x^s(x,z))\,dz\Big\}\,dx\,ds$$

$$-\int_0^t\int_0^1 \theta_{tt}^2(x,s)\frac{\partial}{\partial s}\Big\{\frac{4}{\theta(x,s)^2}\int_0^\infty a'(z)F(\bar\theta_x^s(x,z))\,dz\Big\}\,dx\,ds$$

$$-\int_0^1 \frac{1}{\theta(x,t)^2}\theta_{tt}^2(x,t)\int_0^\infty a'(s)F(\bar\theta_x^t(x,s))\,ds\,dx$$

$$+\int_0^t\int_0^1 \theta_{tt}^2(x,s)\frac{\partial}{\partial s}\Big\{\frac{1}{\theta(x,s)^2}\int_0^\infty a'(z)F(\bar\theta_x^s(x,z))\,dz\Big\}\,dx\,ds$$

$$+\int_0^t\int_0^1 \theta_{tt}(x,s)\theta_x(x,s)\frac{\partial^2}{\partial s^2}\Big\{\frac{2}{\theta(x,s)}\int_0^\infty a'(z)F'(\bar\theta_x^s(x,z))\,dz\Big\}\,dx\,ds$$

$$+\int_0^t\int_0^1 \theta_{tt}(x,s)\theta_{xt}(x,s)\frac{\partial}{\partial s}\Big\{\frac{4}{\theta(x,s)}\int_0^\infty a'(z)F'(\bar\theta_x^s(x,z))\,dz\Big\}\,dx\,ds$$

$$-\int_0^t\int_0^1 \theta_{tt}^2(x,s)\frac{\partial}{\partial x}\Big\{\frac{1}{\theta(x,s)}\int_0^\infty a'(z)F'(\bar\theta_x^s(x,z))\,dz\Big\}\,dx\,ds, \qquad t\in[0,T_0).$$

We note that (3.13) implies

$$\theta_{xt}(x,0)=-\frac{\hat e''(\theta_0(x))}{\hat e'(\theta_0(x))}\theta_0'(x)\theta_t(x,0)+\frac{1}{\hat e'(\theta_0(x))}r_x(x,0), \qquad x\in[0,1] \tag{3.16}$$

and from (3.11) we have

$$\theta_{tt}(x,0)=\frac{F''(0)a(0)}{\hat e'(\theta_0(x))}\theta_0''(x)-\frac{\hat e''(\theta_0(x))}{\hat e'(\theta_0(x))}\theta_t^2(x,0) -\frac{2F''(0)a(0)}{\theta_0(x)\hat e'(\theta_0(x))}\theta_0'(x)^2+\frac{1}{\hat e'(\theta_0(x))}r_t(x,0), \qquad x\in[0,1]. \tag{3.17}$$

We add (3.10), (3.12), and (3.15) and make use of Lemma 2.4 to obtain a lower bound on the left-hand side of the resulting identity. We then make some routine estimations to derive the inequality

$$\begin{aligned}&\int_0^1 ([\theta(x,t)-\theta^*]^2+\theta_x^2(x,t)+\theta_t^2(x,t)+\theta_{xt}^2(x,t)+\theta_{tt}^2(x,t))\,dx\\&\quad+\int_0^t\int_0^1 (\theta_x^2(x,s)+\theta_{xt}^2(x,s))\,dx\,ds\\&\leqq\Gamma\{\Theta_0+R_0\}+\Gamma\{\sqrt{\Theta_0}+\sqrt{R_0}\}\sqrt{\mathscr{E}(t)}\\&\quad+\Gamma\sqrt{R_0}\,\mathscr{E}(t)+\Gamma\{\nu(t)+\nu^{k+2}(t)\}\mathscr{E}(t)\quad\forall t\in[0,T_0).\end{aligned}\tag{3.18}$$

To indicate how (3.18) was derived we show detailed estimations of certain typical terms of (3.10), (3.12), and (3.15), as follows. Many of the terms can be estimated in a simple way, for instance,

$$\begin{aligned}&\left|\int_0^t\int_0^1 \hat{e}'''(\theta(x,s))\theta_t^2(x,s)\theta_{tt}(x,s)\,dx\,ds\right|\\&\leqq\sup_{\substack{x\in[0,1]\\s\in[0,t]}}|\hat{e}'''(\theta(x,s))\theta_t(x,s)|\int_0^t\int_0^1|\theta_t(x,s)\theta_{tt}(x,s)|\,dx\,ds\\&\leqq\sup_{|\theta-\theta^*|<\varepsilon}|\hat{e}'''(\theta)|\sup_{\substack{x\in[0,1]\\s\in[0,t]}}|\theta_t(x,s)|\int_0^t\int_0^1|\theta_{tt}(x,s)\theta_t(x,s)|\,dx\,ds\\&\leqq\Gamma\nu(t)\int_0^t\int_0^1(\theta_{tt}^2(x,s)+\theta_t^2(x,s))\,dx\,ds\\&\leqq\Gamma\nu(t)\mathscr{E}(t)\quad\forall t\in[0,T_0)\end{aligned}\tag{3.19}$$

or

$$\begin{aligned}&\left|F''(0)\int_0^t\int_0^1 a'(s)\theta_0''(x)\theta_{tt}(x,s)\,dx\,ds\right|\\&\leqq F''(0)\left(\int_0^t\int_0^1 a'(s)^2\theta_0''(x)^2\,dx\,ds\right)^{1/2}\left(\int_0^t\int_0^1\theta_{tt}^2(x,s)\,dx\,ds\right)^{1/2}\\&\leqq F''(0)\left(\int_0^\infty a'(s)^2\,ds\right)^{1/2}\left(\int_0^1\theta_0''(x)^2\,dx\right)^{1/2}\sqrt{\mathscr{E}(t)}\\&\leqq\Gamma\sqrt{\Theta_0}\sqrt{\mathscr{E}(t)}\quad\forall t\in[0,T_0).\end{aligned}\tag{3.20}$$

Some of the terms must be rewritten carefully before they are estimated: e.g., the term estimated in (3.25) below arises from

$$\int_0^t\int_0^1\theta_{tt}(x,s)\frac{\partial^2}{\partial s^2}\left\{\frac{2}{\theta(x,s)}\int_0^s a'(z)F'(\bar{\theta}_x^s(x,z))\theta_x(x,s-z)\,dz\right\}dx\,ds,\tag{3.21}$$

which appears on the right-hand side of (3.15). We first differentiate the integral appearing in the integrand of (3.21) once with respect to s and then make the following change of variable:

$$\begin{aligned}&\int_0^s a'(z)F'(\bar{\theta}_x^s(x,z))\theta_{xt}(x,s-z)\,dz\\&\quad=\int_0^s a'(s-\zeta)F'(\bar{\theta}_x^s(x,s-\zeta))\theta_{xt}(x,\zeta)\,d\zeta.\end{aligned}\tag{3.22}$$

We next differentiate the right-hand side of (3.22) with respect to s and then repeat the same change of variable to obtain the integral estimated in (3.25). We note that a similar procedure is used when differentiating terms of the form

$$\int_{s-y}^{\infty} a'(z)F'''(\bar{\theta}_x^s(x,z))\,dz \tag{3.23}$$

with respect to s; the change of variable in this case takes the form

$$\int_{s-y}^{\infty} a'(z)F'''(\bar{\theta}_x^s(x,z))\,dz = \int_{-\infty}^{y} a'(s-\zeta)F'''(\bar{\theta}_x^s(x,s-\zeta))\,d\zeta. \tag{3.24}$$

We now continue to show some typical calculations. The computations below are more involved than those used in (3.19) and (3.20): we obtain a bound on a term appearing on the right-hand side of (3.15):

(3.25)

$$\begin{aligned}
&\left|\int_0^t\int_0^1 \theta_{tt}(x,s)\frac{2}{\theta(x,s)}\int_0^s a'(z)F''(\bar{\theta}_x^s(x,z))\theta_x(x,s-z)\theta_{xt}(x,s-z)\,dz\,dx\,ds\right| \\
&\quad\leqq \Gamma \sup_{\substack{x\in[0,1]\\ s\in[0,t]}}|\theta_x(x,s)|\int_0^t\int_0^1|\theta_{tt}(x,s)|\int_0^s|a'(z)|(F''(0) \\
&\qquad +|F''(\bar{\theta}_x^s(x,z))-F''(0)|)|\theta_{xt}(x,s-z)|\,dz\,dx\,ds \\
&\quad\leqq \Gamma\nu(t)\int_0^t\int_0^1|\theta_{tt}(x,s)| \\
&\qquad\cdot\int_0^s|a'(z)|(F''(0)+K(|\bar{\theta}_x^s(x,z)|+|\bar{\theta}_x^s(x,z)|^k))|\theta_{xt}(x,s-z)|\,dz\,dx\,ds \\
&\quad\leqq \Gamma\nu(t)\int_0^t\int_0^1|\theta_{tt}(x,s)|\int_0^s|a'(z)| \\
&\qquad\cdot\left(F''(0)+K\left[\sqrt{z}\left(\int_{s-z}^s\theta_x^2(x,\xi)\,d\xi\right)^{1/2}\right.\right. \\
&\qquad\quad\left.\left.+(\sqrt{z})^k\left(\int_{s-z}^s\theta_x^2(x,\xi)\,d\xi\right)^{k/2}\right]\right)|\theta_{xt}(x,s-z)|\,dz\,dx\,ds \\
&\quad\leqq \Gamma\nu(t)\left(\int_0^t\int_0^1\theta_{tt}^2(x,s)\,dx\,ds\right)^{1/2} \\
&\qquad\cdot\left(\int_0^t\int_0^1\left(\int_0^s|a'(z)|[1+\nu(t)\sqrt{z}\right.\right. \\
&\qquad\quad\left.\left.+\nu^k(t)(\sqrt{z})^k]|\theta_{xt}(x,s-z)|\,dz\right)^2 dx\,ds\right)^{1/2} \\
&\quad\leqq \Gamma\nu(t)\sqrt{\mathscr{E}(t)}\left(\int_0^t\int_0^1\theta_{xt}^2(x,s)\,dx\,ds\right)^{1/2}
\end{aligned}$$

$$\cdot\left(\int_0^\infty |a'(z)|\,dz+\nu(t)\int_0^\infty |a'(z)|\sqrt{z}\,dz\right.$$

$$\left.+\nu^k(t)\int_0^\infty |a'(z)|(\sqrt{z})^k\,dz\right)$$

$$\leqq\Gamma\{\nu(t)+\nu^2(t)+\nu^{k+1}(t)\}\mathscr{E}(t)\leqq\Gamma\{\nu(t)+\nu^{k+1}(t)\}\mathscr{E}(t)\quad\forall t\in[0,T_0)$$

and from (3.10) we estimate the following term:

(3.26)

$$\left|\int_0^t\int_0^1[\theta(x,s)-\theta^*]\int_0^s\theta_{xx}(x,y)\int_{s-y}^\infty a'(z)[F''(\bar\theta_x^s(x,z))-F''(0)]\,dz\,dy\,dx\,ds\right|$$

$$\leqq K(\nu(t)+\nu^k(t))\int_0^t\int_0^1|\theta(x,s)-\theta^*|\int_0^s|\theta_{xx}(x,y)|$$

$$\cdot\int_{s-y}^\infty|a'(z)|(\sqrt{z}+(\sqrt{z})^k)\,dz\,dy\,dx\,ds$$

$$\leqq K(\nu(t)+\nu^k(t))\sqrt{\mathscr{E}(t)}\left(\int_0^t\int_0^1\left(\int_0^s|\theta_{xx}(x,y)|\int_{s-y}^\infty|a'(z)|(\sqrt{z}\right.\right.$$

$$\left.\left.+(\sqrt{z})^k)\,dz\,dy\right)^2dx\,ds\right)^{1/2}$$

$$\leqq K(\nu(t)+\nu^k(t))\mathscr{E}(t)\int_0^\infty\int_s^\infty|a'(z)|(\sqrt{z}+(\sqrt{z})^k)\,dz\,ds$$

$$\leqq\Gamma\{\nu(t)+\nu^k(t)\}\mathscr{E}(t)\quad\forall t\in[0,T_0).$$

The rest of the terms on the right-hand side of (3.10), (3.12), and (3.15), except for the last term in (3.15), are handled in a similar fashion to (3.19), (3.20), (3.25), and (3.26). (Recall that (1.8) implies $F(0)=F'(0)=0$.) The last term on the right-hand side of (3.15) is first estimated from above, making use of compatibility with thermodynamics, i.e., we utilize the entropy inequality (0.2) in the estimation below: by (2.10) we have

$$-\int_0^t\int_0^1\theta_{tt}^2(x,s)\frac{\partial}{\partial x}\left\{\frac{1}{\theta(x,s)}\int_0^\infty a'(z)F'(\bar\theta_x^s(x,z))\,dz\right\}dx\,ds$$

$$\leqq\int_0^t\int_0^1\theta_{tt}^2(x,s)\left(\frac{\partial}{\partial s}\left\{-\hat\psi'(\theta(x,s))-\frac{1}{\theta(x,s)^2}\right.\right.$$

(3.27)

$$\left.\left.\cdot\int_0^\infty a'(z)F(\bar\theta_x^s(x,z))\,dz\right\}-\frac{r(x,s)}{\theta(x,s)}\right)dx\,ds$$

$$\forall t\in[0,T_0),$$

where $\hat\psi''\in C(0,\infty)$ (see Remark 2.1). Thus, it can be shown that

(3.28)

$$-\int_0^t\int_0^1\theta_{tt}^2(x,s)\frac{\partial}{\partial x}\left\{\frac{1}{\theta(x,s)}\int_0^\infty a'(z)F'(\bar\theta_x^s(x,z))\,dz\right\}dx\,ds$$

$$\leqq\Gamma\{\nu(t)+\nu^{k+1}(t)\}\mathscr{E}(t)+\Gamma\sqrt{R_0}\,\mathscr{E}(t)\quad\forall t\in[0,T_0).$$

Additional estimates are derived directly from equation (3.8) in the following manner. In order to obtain a temporal-L^2 estimate for θ_t we first multiply (3.8) by θ_{xx} and integrate the resulting identity over $[0, 1]\times[0, t]$, $t\in[0, T_0)$. We arrive at the relation

$$\begin{aligned}
&\frac{1}{2}\hat{e}'(\theta^*)\int_0^1 \theta_x^2(x, t)\,dx + F''(0)Q(\theta_{xx}, t, a)\\
&\quad=\frac{1}{2}\hat{e}'(\theta^*)\int_0^1 \theta_0'(x)^2\,dx\\
&\qquad+\int_0^t\int_0^1 \theta_{xx}(x, s)\Big([\hat{e}'(\theta(x, s))-\hat{e}'(\theta^*)]\theta_t(x, s)\\
&\qquad\qquad+\int_0^s \theta_{xx}(x, y)\int_{s-y}^{\infty} a'(z)[F''(\bar{\theta}_x^s(x, z))-F''(0)]\,dz\,dy\\
&\qquad\qquad+\frac{2}{\theta(x, s)^2}\theta_t(x, s)\int_0^{\infty} a'(z)F(\bar{\theta}_x^s(x, z))\,dz\\
&\qquad\qquad-\frac{2}{\theta(x, s)}\theta_x(x, s)\int_0^{\infty} a'(z)F'(\bar{\theta}_x^s(x, z))\,dz\\
&\qquad\qquad+\frac{2}{\theta(x, s)}\int_0^s a'(z)F'(\bar{\theta}_x^s(x, z))\theta_x(x, s-z)\,dz - r(x, s)\Big)\,dx\,ds,
\end{aligned}\tag{3.29}$$

$$t\in[0, T_0).$$

This relation leads to the inequality

$$Q(\theta_{xx}, t, a)\leqq\Gamma\Theta_0+\Gamma\sqrt{R_0}\sqrt{\mathscr{E}(t)}+\Gamma\{\nu(t)+\nu^k(t)\}\mathscr{E}(t)\quad\forall t\in[0, T_0).\tag{3.30}$$

We now square (3.8) and integrate over $[0, 1]\times[0, t]$, $t\in[0, T_0)$. The squares of the terms on the right-hand side of (3.8) are under control, and the square of the convolution term on the left-hand side of (3.8) can be estimated using (1.10), Lemma 4.2 of [13], and (3.30). Hence, we arrive at the estimate

$$\begin{aligned}
\int_0^t\int_0^1 \theta_t^2(x, s)\,dx\,ds &\leqq\Gamma\{\Theta_0+R_0\}+\Gamma\sqrt{R_0}\sqrt{\mathscr{E}(t)}\\
&\quad+\Gamma\{\nu(t)+\nu^{2k}(t)\}\mathscr{E}(t)\quad\forall t\in[0, T_0).
\end{aligned}\tag{3.31}$$

Equation (3.11) can be written as

$$\hat{e}'(\theta^*)\theta_{tt}(x, t)-F''(0)a(0)\theta_{xx}(x, t)-F''(0)\int_0^t a'(t-s)\theta_{xx}(x, s)\,ds = G_t(x, t),\tag{3.32}$$

$$x\in[0, 1],\quad t\in[0, T_0),$$

where $G(x, t)$ denotes the right-hand side of (3.8).

Solving for θ_{xx} in terms of θ_{tt} and G_t (see (2.36) and (2.37)) we get

$$\begin{aligned}
-F''(0)a(0)\theta_{xx}(x, t) &= G_t(x, t)-\hat{e}'(\theta^*)\theta_{tt}(x, t)\\
&\quad+\int_0^t m(t-s)[G_t(x, s)-\hat{e}'(\theta^*)\theta_{tt}(x, s)]\,ds
\end{aligned}\tag{3.33}$$

$$x\in[0, 1],\quad t\in[0, T_0)$$

where m is the resolvent of a' (see (2.38)). We note that by (3.8) $G(x,0)-\hat{e}'(\theta^*)\theta_t(x,0)=0$ for all $x\in[0,1]$, and by (2.38) $m(0)=-a'(0)/a(0)$. Thus, after integrating the last term on the right-hand side of (3.33) by parts we arrive at the expression

$$\begin{aligned}-F''(0)a(0)\theta_{xx}(x,t)&\\ =G_t(x,t)-\hat{e}'(\theta^*)\theta_{tt}(x,t)-\frac{a'(0)}{a(0)}[G(x,t)-\hat{e}'(\theta^*)\theta_t(x,t)]&\\ +\int_0^t m'(t-s)[G(x,s)-\hat{e}'(\theta^*)\theta_t(x,s)]\,ds, \qquad x\in[0,1],\quad t\in[0,T_0).&\end{aligned}\tag{3.34}$$

We now square (3.34) and integrate over $[0,1]$. By (3.18) and Lemma 2.3 we have

$$\begin{aligned}\int_0^1\theta_{xx}^2(x,t)\,dx\leqq\Gamma\{\Theta_0+R_0\}+\Gamma\{\sqrt{\Theta_0}+\sqrt{R_0}\}\sqrt{\mathscr{E}(t)}&\\ +\Gamma\sqrt{R_0}\,\mathscr{E}(t)+\Gamma\{\nu(t)+\nu^{2k+2}(t)\}\mathscr{E}(t)\quad\forall t\in[0,T_0).&\end{aligned}\tag{3.35}$$

To obtain a temporal-L^2 bound on θ_{tt} we multiply (3.34) by θ_{tt} and integrate over $[0,1]\times[0,t]$, $t\in[0,T_0)$. We note that

$$\begin{aligned}\int_0^t\int_0^1\theta_{tt}(x,s)\theta_{xx}(x,s)\,dx\,ds&=-\int_0^t\int_0^1\theta_x(x,s)\theta_{xtt}(x,s)\,dx\,ds\\ &=-\int_0^1\theta_x(x,t)\theta_{xt}(x,t)\,dx+\int_0^1\theta_0'(x)\theta_{xt}(x,0)\,dx\\ &\quad+\int_0^t\int_0^1\theta_{xt}^2(x,s)\,dx\,ds,\qquad t\in[0,T_0).\end{aligned}\tag{3.36}$$

Thus we have

$$\begin{aligned}\int_0^t\int_0^1\theta_{tt}^2(x,s)\,dx\,ds\leqq\Gamma\{\Theta_0+R_0\}+\Gamma\{\sqrt{\Theta_0}+\sqrt{R_0}\}\sqrt{\mathscr{E}(t)}&\\ +\Gamma\sqrt{R_0}\,\mathscr{E}(t)+\Gamma\{\nu(t)+\nu^{k+2}(t)\}\mathscr{E}(t)\quad\forall t\in[0,T_0).&\end{aligned}\tag{3.37}$$

(Here, we make crucial use of (2.20).) We now square (3.34) and integrate over $[0,1]\times[0,t]$, $t\in[0,T_0)$ using (3.18), (3.31), (3.37), and Lemma 2.3 to obtain the following estimate:

$$\begin{aligned}\int_0^t\int_0^1\theta_{xx}^2(x,s)\,dx\,ds\leqq\Gamma\{\Theta_0+R_0\}+\Gamma\{\sqrt{\Theta_0}+\sqrt{R_0}\}\sqrt{\mathscr{E}(t)}&\\ +\Gamma\sqrt{R_0}\,\mathscr{E}(t)+\Gamma\{\nu(t)+\nu^{2k+2}(t)\}\mathscr{E}(t)\quad\forall t\in[0,T_0).&\end{aligned}\tag{3.38}$$

Observe that by Poincaré's inequality there is a constant $c>0$ such that

$$\int_0^t\int_0^1[\theta(x,s)-\theta^*]^2\,dx\,ds\leqq c\int_0^t\int_0^1\theta_x^2(x,s)\,dx\,ds\quad\forall t\in[0,T_0).\tag{3.39}$$

It follows from (3.18), (3.31), (3.35), and (3.37)–(3.39) that

$$\begin{aligned}\mathscr{E}(t)\leqq\Gamma\{\Theta_0+R_0\}+\Gamma\{\sqrt{\Theta_0}+\sqrt{R_0}\}\sqrt{\mathscr{E}(t)}+\Gamma\sqrt{R_0}\,\mathscr{E}(t)&\\ +\Gamma\{\nu(t)+\nu^{2k+2}(t)\}\mathscr{E}(t)\quad\forall t\in[0,T_0).&\end{aligned}\tag{3.40}$$

Using (2.20), (3.40) yields

$$\mathscr{E}(t)\leqq\bar{\Gamma}\{\Theta_0+R_0\}+\bar{\Gamma}\sqrt{R_0}\,\mathscr{E}(t)+\bar{\Gamma}\{\nu(t)+\nu^{2k+2}(t)\}\mathscr{E}(t)\quad\forall t\in[0,T_0),\tag{3.41}$$

where $\bar{\Gamma}$ denotes a fixed positive constant which is independent of θ_0, r, and T_0. We choose $\bar{\mathscr{E}}$, $\delta > 0$ such that

$$\bar{\mathscr{E}} < \varepsilon^2/2, \quad \bar{\Gamma}\{\sqrt{2\bar{\mathscr{E}}} + (\sqrt{2\bar{\mathscr{E}}})^{2k+2}\} \leqq \tfrac{1}{6}, \quad \bar{\Gamma}\delta^2 \leqq \tfrac{1}{6}\bar{\mathscr{E}}, \quad \bar{\Gamma}\delta \leqq \tfrac{1}{6}, \tag{3.42}$$

and

$$\delta < \tfrac{1}{2}\eta \tag{3.43}$$

for some $\eta \in (0, \varepsilon)$.

Suppose now that (1.21) holds for the above choice of δ. By the Sobolev embedding theorem

$$\nu(t) \leqq \sqrt{2\mathscr{E}(t)} \quad \forall t \in [0, T_0). \tag{3.44}$$

Thus, it follows from (3.41) that for any $t \in [0, T_0)$ with $\mathscr{E}(t) \leqq \bar{\mathscr{E}}$, we actually have $\mathscr{E}(t) \leqq \frac{1}{2}\bar{\mathscr{E}}$. Hence by continuity, if $\mathscr{E}(0) \leqq \frac{1}{2}\bar{\mathscr{E}}$ then

$$\mathscr{E}(t) \leqq \tfrac{1}{2}\bar{\mathscr{E}} \quad \forall t \in [0, T_0). \tag{3.45}$$

It is possible to choose a smaller $\delta > 0$ (if necessary) so that (1.21) implies $\mathscr{E}(0) \leqq \frac{1}{2}\bar{\mathscr{E}}$. Consequently, for $\delta > 0$ small enough, (3.45) holds; moreover, by the Sobolev embedding theorem

$$\sup_{\substack{x\in[0,1]\\ t\in[0,T_0)}} |\theta(x,t) - \theta^*|, \quad \sup_{\substack{x\in[0,1]\\ t\in[0,T_0)}} |\theta_x(x,t)| \leqq \sqrt{2\bar{\mathscr{E}}} < \varepsilon. \tag{3.46}$$

Therefore, by Lemma 2.2 we have $T_0 = \infty$. In addition, (1.23) is an immediate consequence of (3.45). Moreover, (1.24) and (1.25) follow from (1.23) by standard embedding inequalities, e.g., from (1.23) we have

$$\theta - \theta^* \in L^\infty((0,\infty); L^2(0,1)) \tag{3.47}$$

and

$$\theta_x, \theta_{xt} \in L^2((0,\infty); L^2(0,1)). \tag{3.48}$$

We note that (3.48) implies

$$\theta_x(\cdot, t) \to 0 \quad \text{in } L^2(0,1) \quad \text{as } t \to \infty. \tag{3.49}$$

Observe that

$$\begin{aligned} [\theta(x,t) - \theta^*]^2 &= 2\int_0^x [\theta(\xi,t) - \theta^*]\theta_x(\xi,t)\, d\xi \\ &\leqq 2\int_0^1 |\theta(\xi,t) - \theta^*||\theta_x(\xi,t)|\, d\xi \\ &\leqq 2\left(\int_0^1 [\theta(\xi,t) - \theta^*]^2\, d\xi\right)^{1/2}\left(\int_0^1 \theta_x^2(\xi,t)\, d\xi\right)^{1/2} \quad \forall x \in [0,1], \quad t \geqq 0. \end{aligned} \tag{3.50}$$

Hence, by (3.47) and (3.49)

$$\theta(\cdot, t) \to \theta^* \quad \text{uniformly on } [0,1] \quad \text{as } t \to \infty. \tag{3.51}$$

This completes the proof of Theorem 1.1. □

The proofs of Theorems 1.2 and 1.3 are very similar to the proof above. In both cases, however, since we cannot use Poincaré's inequality, we do not obtain a temporal-L^2 estimate for $\theta-\theta^*$, and hence before we proceed with the calculations we divide equations (1.1) and (1.40) by $\hat{e}'(\theta(x,t))$. For the same reason, in Theorem 1.2, for example, we require that (1.29) hold in order to obtain the following estimate:

$$
\begin{aligned}
&\left|\int_0^t\int_0^1 \frac{1}{\hat{e}'(\theta(x,s))}[\theta(x,s)-\theta^*]r(x,s)\,dx\,ds\right| \\
&\quad\leqq \Gamma\int_0^t\left(\int_0^1[\theta(x,s)-\theta^*]^2\,dx\right)^{1/2}\left(\int_0^1 r^2(x,s)\,dx\right)^{1/2}ds \\
&\quad\leqq \Gamma\sup_{s\in[0,t]}\left(\int_0^1[\theta(x,s)-\theta^*]^2\,dx\right)^{1/2}\int_0^t\left(\int_0^1 r^2(x,s)\,dx\right)^{1/2}ds \\
&\quad\leqq \Gamma\sqrt{\mathscr{E}(t)}\int_0^\infty\left(\int_0^1 r^2(x,t)\,dx\right)^{1/2}dt \quad \forall t\in[0,T_0);
\end{aligned}
\tag{3.52}
$$

the other terms with which we must be careful can be handled by integration by parts, e.g.,

$$
\begin{aligned}
&\left|\int_0^t\int_0^1 \frac{1}{\hat{e}'(\theta(x,s))}[\theta(x,s)-\theta^*]\int_0^\infty a'(z)[F''(\bar{\theta}_x^s(x,z))-F''(0)]\bar{\theta}_{xx}^s(x,z)\,dz\,dx\,ds\right| \\
&\quad=\left|-\int_0^t\int_0^1 \frac{1}{\hat{e}'(\theta(x,s))}[\theta(x,s)-\theta^*]\frac{\partial}{\partial x}\right. \\
&\qquad\left.\cdot\left\{\int_0^\infty a(z)[F''(\bar{\theta}_x^s(x,z))-F''(0)]\theta_x(x,s-z)\,dz\right\}dx\,ds\right| \\
&\quad=\left|\int_0^t\int_0^1\left(-\frac{\hat{e}''(\theta(x,s))}{\hat{e}'(\theta(x,s))^2}[\theta(x,s)-\theta^*]+\frac{1}{\hat{e}'(\theta(x,s))}\right)\theta_x(x,s)\right. \\
&\qquad\left.\cdot\int_0^s a(z)[F''(\bar{\theta}_x^s(x,z))-F''(0)]\theta_x(x,s-z)\,dz\,dx\,ds\right| \\
&\quad\leqq\Gamma(\nu(t)+\nu^{k+1}(t))\mathscr{E}(t) \quad \forall t\in[0,T_0).
\end{aligned}
\tag{3.53}
$$

The argument to show that $\theta(\cdot,t)\to\theta^{**}$ uniformly on $[0,1]$ as $t\to\infty$ for Theorem 1.2 is essentially the same as the argument used to establish an analogous result in § 3 of [4]: We first observe that standard embedding inequalities yield (1.38) as well as boundedness of θ on $[0,1]\times[0,\infty)$. Hence, every sequence of times tending to infinity has a subsequence on which θ converges uniformly to a constant, namely, θ^{**}.

Theorems 1.2 and 1.3 can be proved using an argument in the same spirit as in [13], i.e., instead of taking temporal derivatives of the equation and multiplying by corresponding time derivatives of θ, we can take spatial derivatives of the equation and multiply by appropriate x derivatives of θ. This cannot be done for Theorem 1.1 since we have a term involving $\theta_x(x,t)$ on the right-hand side of (1.1) which would lead to uncontrollable boundary terms.

In the case of nonequilibrium history the argument is essentially the same. The main modification needed arises when we want to make use of an inequality of the form (2.21); we then extend a to $\mathbb{R}$ by zero. To give an indication of where such a

modification is needed we consider the analogue of the term treated in (3.26):

$$\left|\int_0^t\int_0^1 [\theta(x,s)-\theta^*]\int_{-\infty}^s \theta_{xx}(x,y)\int_{s-y}^{\infty} a'(z)[F''(\bar\theta_x^s(x,z))-F''(0)]\,dz\,dy\,dx\,ds\right|$$

$$\leqq \left|\int_0^t\int_0^1 [\theta(x,s)-\theta^*]\int_{-\infty}^0 \theta_{xx}(x,y)\right.$$

$$\left.\cdot\int_{s-y}^{\infty} a'(z)[F''(\bar\theta_x^s(x,z))-F''(0)]\,dz\,dy\,dx\,ds\right| \tag{3.54}$$

$$+\left|\int_0^t\int_0^1 [\theta(x,s)-\theta^*]\int_0^s \theta_{xx}(x,y)\right.$$

$$\left.\cdot\int_{s-y}^{\infty} a'(z)[F''(\bar\theta_x^s(x,z))-F''(0)]\,dz\,dy\,dx\,ds\right|.$$

The second term on the right-hand side of (3.54) can clearly be handled in the same manner as in (3.26) and once a is extended by zero, the first term on the right-hand side of (3.54) can also be treated in the same way.

Remark 3.1. We note that in order to obtain a priori bounds in the above proof it suffices to assume that the data satisfy (1.55)-(1.58). It is in the proof of local existence that we need the original assumptions on the data (1.12)-(1.18).

Remark 3.2. If, for example, in the case of Theorem 1.1 assumption (1.21) is replaced with

$$\Theta_0+\int_0^1 \theta_0'''(x)^2\,dx+R_0+\sup_{t\geqq 0}\int_0^1 (r_x^2+r_{xt}^2+r_{tt}^2)(x,t)\,dx$$

$$+\int_0^1 r_{xx}^2(x,0)\,dx+\int_0^{\infty}\int_0^1 (r_x^2+r_{xt}^2+r_{ttt}^2)(x,t)\,dx\leqq\delta^2, \tag{3.55}$$

then we can establish the existence of a unique solution $\theta>0$ satisfying (1.22)-(1.25); moreover,

$$\theta_{xxx},\ \theta_{xxt},\ \theta_{xtt},\ \theta_{ttt}\in L^{\infty}((0,\infty);\ L^2(0,1))\cap L^2((0,\infty);\ L^2(0,1)), \tag{3.56}$$

and

$$\theta_{xx}(\cdot,t),\ \theta_{xt}(\cdot,t),\ \theta_{tt}(\cdot,t)\to 0 \quad \text{uniformly on } [0,1] \tag{3.57}$$

as $t\to\infty$. The arguments used to establish such a result are similar in spirit to the arguments used to prove Theorem 1.1 except that here there is no need to make use of the entropy inequality (0.2) or any other consequence of the thermodynamical restrictions.

Acknowledgments. I thank my thesis advisor W. J. Hrusa for numerous valuable discussions. Many of the results described in this paper are due to his suggestions.

RAPIDLY STRETCHING PLASTIC JETS: THE LINEARIZED PROBLEM*

FERNANDO REITICH†

Abstract. A linearized version of the Levy-von Mises equations modeling the evolution of rapidly stretching plastic jets is studied. Under the assumptions of axial symmetry and stress-free surface, existence and uniqueness of a solution is shown for the resulting (nonstandard) linear initial-boundary value problem. Some growth and periodicity properties of the solution are also established.

Key words. jets, Levy-von Mises equations, linearization

AMS(MOS) subject classifications. 35Q20, 76D25

Introduction. A typical example of a rapidly stretching jet is furnished by the jet produced by a shaped-charge [1], [2], [9], [12]. A shaped-charge consists of an explosive with a conical cavity lined with a thin metal sheet; the explosion will cause the metal to collapse toward the axis where an extremely high velocity jet will instantly be formed. The velocity of the particles in these jets increases linearly with the distance from the rear end, so that the jet experiences a very significant stretching.

In a recent paper, Romero [14] analyzes the stability of these jets using the Levy-von Mises equations for an incompressible perfectly plastic material (see § 1 below). He finds that a rapidly stretching plastic jet can be initially stable due to inertial effects, a result that had been anticipated by Frankel and Weihs [4] based on their study of the stability of a capillary jet of an ideal fluid (see also, e.g., Rayleigh [13], Weber [15], Levich [11], Goldin et al. [8], Bogy [3]).

Assuming that the jet is axially symmetric and that its surface is stress-free, Romero finds a particular solution ("the undisturbed flow"), for which the axial velocity is linearly increasing. He then linearizes the equations about it, introducing scaled space variables (r, z) $(0<r<1, -\infty<z<\infty)$ and a scaled time variable t $(0\leqq t\leqq T)$, to reduce this linear system to a system of three equations, essentially of the form

$$\frac{\partial\phi}{\partial t}=\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial\phi}{\partial r}\right)-\frac{\partial^2\phi}{\partial z^2}-\frac{\partial p}{\partial z}, \tag{0.1}$$

$$\frac{\partial\psi}{\partial t}=\frac{\partial^2\psi}{\partial z^2}-\frac{\partial p}{\partial r}, \tag{0.2}$$

$$\operatorname{div}(\phi,\psi)=0, \tag{0.3}$$

where ϕ, ψ, p correspond to scaled versions of the perturbations in the axial velocity, radial velocity, and pressure, respectively.

Here r represents the radial variable scaled according to the radius of the free boundary (i.e., the moving boundary of the jet) and z is an appropriately scaled axial variable. The stress-free and compatibility conditions on the surface of the jet yield nonstandard boundary conditions for (0.1)-(0.3) of the form

$$p=B_1(\phi,\psi,\Omega) \quad \text{at } r=1, \tag{0.4}$$

* Received by the editors May 22, 1989; accepted for publication (in revised form) February 8, 1990.
† School of Mathematics, University of Minnesota, Minneapolis, Minnesota 55455.

$$\frac{\partial \phi}{\partial r} = B_2(\psi, \Omega) \quad \text{at } r = 1, \tag{0.5}$$

$$\frac{\partial \Omega}{\partial t} = \psi \quad \text{at } r = 1, \tag{0.6}$$

where B_1 and B_2 are certain first-order differential operators and $\Omega = \Omega(t, z)$ denotes the perturbation in the radius of the jet scaled according to the actual radius.

To complete the setting of the problem we need to impose initial conditions, namely,

$$\phi(0, r, z) = \phi_0(r, z), \tag{0.7}$$

$$\Omega(0, 0) = \Omega_0. \tag{0.8}$$

The system (0.1)–(0.8) is a nonstandard linear problem, due both to the "mixed type" differential equations and the boundary conditions.

While the main purpose of [14] is to study the stability of (0.1)–(0.8), the main result of the present paper is an existence and uniqueness theorem for this system. Romero's analysis of the stability of short wavelength solutions

$$\begin{aligned} &\phi(t, r, z) = \phi^*(t, r, \mu)\, e^{i\mu z}, \qquad \psi(t, r, z) = \psi^*(t, r, \mu)\, e^{i\mu z}, \\ &p(t, r, z) = p^*(t, r, \mu)\, e^{i\mu z}, \qquad \Omega(t, z) = \Omega^*(t, \mu)\, e^{i\mu z}, \end{aligned} \tag{0.9}$$

with $|\mu| \gg 1$

leads him to the conclusion that such disturbances do not undergo significant growth. However, his argument is based on the assumption that, in (0.9),

$$\begin{aligned} &\phi^*(t, r, \mu) = \tilde{\phi}(r, \mu)\, e^{\gamma_1 t}, \qquad \psi^*(t, r, \mu) = \tilde{\psi}(r, \mu)\, e^{\gamma_2 t}, \\ &p^*(t, r, \mu) = \tilde{p}(r, \mu)\, e^{\gamma_3 t}, \qquad \Omega^*(t, \mu) = \tilde{\Omega}(\mu)\, e^{\gamma_4 t}, \end{aligned} \tag{0.10}$$

which translates into quite restrictive conditions for ϕ_0. In this paper we consider general initial conditions $\phi_0(r, z)$. Since the jet is expected to eventually become unstable (cf. [14]), the system may develop ill-posedness (as in the backward heat equation): for this reason we assume that ϕ_0 is entire analytic in the variable z. More precisely, we show that if $\phi_0(x, y, z) = \phi_0((x^2+y^2)^{1/2}, z)$ is $C^{2+\alpha}$ in (x, y) (for some $\alpha \in (0, 1)$) and if $\phi_0(x, y, \cdot)$ extends to an entire function in z of order 1 and sufficiently small type, then there exists a unique solution of (0.1)–(0.8).

In § 1 we briefly describe the linearization procedure which leads to (0.1)–(0.6). In § 2 we reduce the system into another system which is much more convenient to work with; in particular, ψ and Ω do not appear in the new system. In § 3 we state the main existence and uniqueness results (Theorem 3.1) and in § 4 we prove a preliminary lemma (Lemma 4.1), which immediately implies Theorem 3.1 in the special case of initial conditions of the form $\phi_0(x, y, z) = u_0(x, y)z^n (n \geqq 0)$. Section 5 is devoted to the proof of Theorem 3.1 and, finally, in § 6 we establish periodicity and growth properties of the solution.

1. The linearized system. We shall assume that the flow obeys the laws for an incompressible perfectly plastic material satisfying the Levy–von Mises equations and that the surface of the jet is stress-free. The Levy–von Mises equations are

$$\rho\left(\frac{\partial \bar{u}}{\partial t} + \bar{u} \cdot \nabla \bar{u}\right) = -\nabla p + \operatorname{div} \bar{\bar{T}}, \tag{1.1}$$

$$\nabla \cdot \bar{u} = 0, \tag{1.2}$$

where ρ is the constant material density, p is the pressure, and $\bar{\bar{T}}$ is the deviatoric stress. In Cartesian coordinates $\bar{\bar{T}}$ is given by

$$T_{ij} = 2\mu\dot{\varepsilon}_{ij}, \tag{1.3}$$

where $\dot{\varepsilon}_{ij}$ is the rate of strain tensor

$$\dot{\varepsilon}_{ij} = \frac{1}{2}\left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i}\right), \tag{1.4}$$

μ is the effective viscosity

$$\mu = Y(2\dot{\varepsilon}_{kl}\dot{\varepsilon}_{kl})^{-1/2}, \tag{1.5}$$

and Y is the yield stress of the material.

Assuming axial symmetry, let (z, r) be the cylindrical coordinates and let (u, v) be their corresponding velocities. Then, a special solution, satisfying stress-free boundary conditions and the compatibility relation of the time rate of change of the free surface to the velocity field at the boundary, is given by (see [14])

$$u_0(t, r, z) = \frac{\beta(0)z}{q(t)}, \tag{1.6}$$

$$v_0(t, r, z) = \frac{-\beta(0)r}{2q(t)}, \tag{1.7}$$

$$p_0(t, r, z) = \frac{3}{8}\rho\beta(t)^2(r^2 - R_0(t)^2) - \frac{Y}{3^{1/2}}, \tag{1.8}$$

$$R_0(t, z) = \frac{a_0(0)}{q(t)^{1/2}}, \tag{1.9}$$

where $a_0(0)$ is the initial radius of the jet, $\beta(0)$ is the initial strain rate, $\beta(t) = \beta(0)/q(t)$, and $q(t) = \beta(0)t + 1$.

Linearizing about this solution and introducing scaled variables

$$\hat{t} = \ln(q(t)), \tag{1.10}$$

$$\hat{r} = \frac{r}{R_0(t)}, \tag{1.11}$$

$$\hat{z} = \frac{z}{L(t)}, \tag{1.12}$$

where $L(t) = q(t)L(0)$ and the parameter $L(0)$ is the initial length scale, the linearized system takes the form (after dropping the ^'s)

$$\frac{\partial\phi}{\partial t} = \Gamma^{-2}\left(\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial\phi}{\partial r}\right) - \alpha^2\frac{\partial^2\phi}{\partial z^2}\right) - \phi - \alpha^2\frac{\partial p}{\partial z}, \tag{1.13}$$

$$\frac{\partial\psi}{\partial t} - 2\psi = \alpha^2\Gamma^{-2}\frac{\partial^2\psi}{\partial z^2} - \frac{\partial p}{\partial r}, \tag{1.14}$$

$$\frac{\partial\phi}{\partial z} + \frac{1}{r}\frac{\partial}{\partial r}(r\psi) = 0 \tag{1.15}$$

for $(t, r, z) \in [0, T] \times (0, 1] \times \mathbb{R}$ $(T > 0)$, and

$$\Gamma^2 p = 2\left(\frac{\partial \psi}{\partial r} + \frac{1}{2}\frac{\partial \phi}{\partial z}\right) + \frac{3}{4}\Omega\Gamma^2 \equiv \Gamma^2 B_1(\phi, \psi, \Omega) \quad \text{at } r = 1, \tag{1.16}$$

$$\frac{\partial \phi}{\partial r} = 3\alpha^2 \frac{\partial \Omega}{\partial z} - \alpha^2 \frac{\partial \psi}{\partial z} \equiv B_2(\psi, \Omega) \quad \text{at } r = 1, \tag{1.17}$$

$$\frac{\partial \Omega}{\partial t} = \psi \quad \text{at } r = 1, \tag{1.18}$$

(1.19) ψ is finite as r approaches zero,

where ϕ, ψ, p, and Ω are scaled versions of the perturbations in the axial velocity, radial velocity, pressure, and jet radius, respectively. Also, the functions α and Γ depend only on t and are given by

$$\alpha(t)^2 = \alpha(0)^2 e^{-3t}, \qquad \Gamma(t)^2 = \Gamma(0)^2 e^{-3t},$$

where

$$\alpha(0)^2 = (a_0(0)/L(0))^2, \qquad \Gamma(0)^2 = 3^{1/2}\rho a_0(0)^2 \beta(0)^2 / Y.$$

We supplement the system by adding the initial conditions

$$\phi(0, r, z) = \phi_0(r, z), \tag{1.20}$$

$$\Omega(0, 0) = \Omega_0. \tag{1.21}$$

2. An equivalent linear system. The purpose of this section is to reduce the nonstandard system (1.13)-(1.21) into a form which will be more recognizable and easier to work with. The new system will not involve Ω and ψ and it will be amenable to the theory of elliptic and parabolic differential equations.

The first step is to note that if (ϕ, ψ, p, Ω) is a solution of (1.13)-(1.20) with $\Omega(0, 0) = \Omega_0$, then

$$(\phi, \psi, p + \tfrac{3}{4}(\omega_0 - \Omega_0), \Omega + \omega_0 - \Omega_0)$$

is a solution of (1.13)-(1.20) satisfying $\Omega(0, 0) = \omega_0$. Thus, we may assume that

$$\Omega(0, 0) = -\frac{1}{3}\int_0^1 r \frac{\partial \phi_0}{\partial z}(r, 0)\, dr. \tag{2.1}$$

LEMMA 2.1. *Assume that*

$$\frac{\partial \phi_0}{\partial r}(1, z) = 0, \qquad z \in \mathbb{R}. \tag{2.2}$$

Then, (ϕ, ψ, p, Ω) *is a solution of* (1.13)-(1.20) *satisfying* (2.1) *if and only if*

(i) (ϕ, p) *satisfy*

$$\frac{\partial \phi}{\partial t} + \phi = -\alpha^2 \frac{\partial p}{\partial z} + \Gamma^{-2}\left(\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial \phi}{\partial r}\right) - \alpha^2 \frac{\partial^2 \phi}{\partial z^2}\right), \tag{2.3a}$$

$$\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial p}{\partial r}\right) = \frac{\partial}{\partial t}\left(\frac{\partial \phi}{\partial z}\right) - 2\frac{\partial \phi}{\partial z} - \alpha^2 \Gamma^{-2}\frac{\partial^3 \phi}{\partial z^3} \tag{2.3b}$$

for $(t, r, z) \in [0, T] \times (0, 1] \times \mathbb{R}$, *with initial-boundary conditions given by*

$$\frac{\partial \phi}{\partial r} = -3\alpha^2 \int_0^t \int_0^1 \rho \frac{\partial^2 \phi}{\partial z^2}(s, \rho, z)\, d\rho\, ds - \alpha^2 \int_0^1 \rho \frac{\partial^2 \phi_0}{\partial z^2}(\rho, z)\, d\rho + \alpha^2 \int_0^1 \rho \frac{\partial^2 \phi}{\partial z^2}(t, \rho, z)\, d\rho \quad \text{at } r = 1, \tag{2.4}$$

$$p = -\frac{3}{4} \int_0^t \int_0^1 \rho \frac{\partial \phi}{\partial z}(s, \rho, z)\, d\rho\, ds - \Gamma^{-2} \frac{\partial \phi}{\partial z} - \frac{1}{4} \int_0^1 \rho \frac{\partial \phi_0}{\partial z}(\rho, z)\, d\rho + 2\Gamma^{-2} \int_0^1 \rho \frac{\partial \phi}{\partial z}(t, \rho, z)\, d\rho \quad \text{at } r = 1, \tag{2.5}$$

$$\phi(0, r, z) = \phi_0(r, z); \tag{2.6}$$

and

(ii) ψ *and* Ω *are given by*

$$\psi(t, r, z) = -\frac{1}{r} \int_0^r \rho \frac{\partial \phi}{\partial z}(t, \rho, z)\, d\rho, \tag{2.7}$$

$$\Omega(t, z) = -\int_0^t \int_0^1 \rho \frac{\partial \phi}{\partial z}(s, \rho, z)\, d\rho\, ds - \frac{1}{3} \int_0^1 \rho \frac{\partial \phi_0}{\partial z}(\rho, z)\, d\rho. \tag{2.8}$$

Proof. Suppose that (ϕ, ψ, p, Ω) is a solution of (1.13)-(1.20) satisfying (2.1). We want to show that (2.3)-(2.8) hold.

First note that (2.3a), (2.6) are exactly (1.13), (1.20). To prove (2.3b) multiply (1.14) by r and differentiate with respect to r to obtain (using (1.15))

$$-r \frac{\partial}{\partial t}\left(\frac{\partial \phi}{\partial z}\right) + 2r \frac{\partial \phi}{\partial z} = -\frac{\partial}{\partial r}\left(r \frac{\partial p}{\partial r}\right) - cr \frac{\partial^3 \phi}{\partial z^3},$$

where $c = \alpha(t)^2 \Gamma(t)^{-2} = a_0(0)^2 (L(0)\Gamma(0))^{-2} \geqq 0$. Dividing by r, we get

$$-\frac{\partial}{\partial t}\left(\frac{\partial \phi}{\partial z}\right) + 2 \frac{\partial \phi}{\partial z} = -\frac{1}{r} \frac{\partial}{\partial r}\left(r \frac{\partial p}{\partial r}\right) - c \frac{\partial^3 \phi}{\partial z^3},$$

which gives (2.3b).

In order to prove (2.4), (2.5) we must first establish (2.7), (2.8). Multiplying (1.15) by r and integrating with respect to r we get

$$\psi(t, 1, z) - r\psi(t, r, z) = -\int_r^1 \rho \frac{\partial \phi}{\partial z}(t, \rho, z)\, d\rho.$$

Using (1.19) we conclude that

$$\psi(t, 1, z) = -\int_0^1 \rho \frac{\partial \phi}{\partial z}(t, \rho, z)\, d\rho,$$

so that

$$-r\psi(t, r, z) = -\int_r^1 \rho \frac{\partial \phi}{\partial z}(t, \rho, z)\, d\rho + \int_0^1 \rho \frac{\partial \phi}{\partial z}(t, \rho, z)\, d\rho = \int_0^r \rho \frac{\partial \phi}{\partial z}(t, \rho, z)\, d\rho,$$

and (2.7) follows. Now we can use (1.18) and (2.7) to obtain

$$\begin{aligned}\Omega(t,z) &= \int_0^t \psi(s,1,z)\,ds + \Omega(0,z) \\ &= -\int_0^t \int_0^1 \rho \frac{\partial \phi}{\partial z}(s,\rho,z)\,d\rho\,ds + \Omega(0,z).\end{aligned} \tag{2.9}$$

On the other hand, specializing (1.17) at $t=0$ and using (2.7) once again

$$\frac{\partial \phi_0}{\partial r}(1,z) - \alpha(0)^2\left(\int_0^1 \rho \frac{\partial^2 \phi_0}{\partial z^2}(\rho,z)\,d\rho\right) = 3\alpha(0)^2 \frac{\partial \Omega}{\partial z}(0,z),$$

which, due to assumption (2.2), is

$$\frac{\partial \Omega}{\partial z}(0,z) = -\frac{1}{3}\int_0^1 \rho \frac{\partial^2 \phi_0}{\partial z^2}(\rho,z)\,d\rho. \tag{2.10}$$

But (2.1) and (2.10) imply

$$\Omega(0,z) = -\frac{1}{3}\int_0^1 \rho \frac{\partial \phi_0}{\partial z}(\rho,z)\,d\rho, \tag{2.11}$$

which, together with (2.9), gives (2.8).

Thus, we may now use (2.7), (2.8) to rewrite the boundary condition (1.17) as

$$\begin{aligned}\frac{\partial \phi}{\partial r} - \alpha^2 \int_0^1 \rho \frac{\partial^2 \phi}{\partial z^2}(t,\rho,z)\,d\rho = -3\alpha^2 \int_0^t \int_0^1 \rho \frac{\partial^2 \phi}{\partial z^2}(s,\rho,z)\,d\rho\,ds \\ -\alpha^2 \int_0^1 \rho \frac{\partial^2 \phi_0}{\partial z^2}(\rho,z)\,d\rho \quad \text{at } r=1,\end{aligned}$$

which is (2.4).

Finally, using (1.15) we can rewrite (1.16) as

$$2\left(-\psi - \frac{\partial \phi}{\partial z} + \frac{1}{2}\frac{\partial \phi}{\partial z}\right) - \Gamma^2 p + \frac{3}{4}\Omega\Gamma^2 = 0 \quad \text{at } r=1,$$

or

$$-2\psi - \frac{\partial \phi}{\partial z} - \Gamma^2 p + \frac{3}{4}\Omega\Gamma^2 = 0 \quad \text{at } r=1, \tag{2.12}$$

and (2.5) follows from (2.7), (2.8), and (2.12).

From the above computations it is clear how to proceed in proving the converse statement, that is, if ϕ, p satisfy (2.3)-(2.6) and ψ, Ω are given by (2.7) and (2.8), then (ϕ, ψ, p, Ω) is a solution of (1.13)-(1.20) satisfying (2.1).

This completes the proof of Lemma 2.1. □

It will be convenient to rewrite the system (2.3)-(2.6) in Cartesian coordinates. Taking r to be the radial variable, $r=(x^2+y^2)^{1/2}$, and setting $\Delta = \partial^2/\partial x^2 + \partial^2/\partial y^2$, B_1 = unit disc in $\mathbb{R}^2$, $G = [0,T] \times B_1 \times \mathbb{R}$, $\Gamma_0 = [0,T] \times \partial B_1 \times \mathbb{R}$, we can write

$$\frac{\partial \phi}{\partial t} - \Gamma(t)^{-2}\Delta\phi + c\frac{\partial^2 \phi}{\partial z^2} + \phi = -\alpha(t)^2 \frac{\partial p}{\partial z} \quad \text{in } G, \tag{2.13a}$$

$$\Delta p = \frac{\partial}{\partial t}\left(\frac{\partial \phi}{\partial z}\right) - 2\frac{\partial \phi}{\partial z} - c\frac{\partial^3 \phi}{\partial z^3} \quad \text{in } G, \tag{2.13b}$$

$$\frac{\partial\phi}{\partial\nu} = -3\frac{\alpha(t)^2}{2\pi}\int_0^t\int_{B_1}\frac{\partial^2\phi}{\partial z^2}(s,x,y,z)\,dx\,dy\,ds$$

$$+\frac{\alpha(t)^2}{2\pi}\int_{B_1}\frac{\partial^2\phi}{\partial z^2}(t,x,y,z)\,dx\,dy \tag{2.13c}$$

$$-\frac{\alpha(t)^2}{2\pi}\int_{B_1}\frac{\partial^2\phi_0}{\partial z^2}(x,y,z)\,dx\,dy \quad \text{on } \Gamma_0,$$

$$p = -\frac{3}{8\pi}\int_0^t\int_{B_1}\frac{\partial\phi}{\partial z}(s,x,y,z)\,dx\,dy\,ds - \Gamma(t)^{-2}\frac{\partial\phi}{\partial z}$$

$$-\frac{1}{8\pi}\int_{B_1}\frac{\partial\phi_0}{\partial z}(x,y,z)\,dx\,dy \tag{2.13d}$$

$$+\frac{\Gamma(t)^{-2}}{\pi}\int_{B_1}\frac{\partial\phi}{\partial z}(t,x,y,z)\,dx\,dy \quad \text{on } \Gamma_0,$$

$$\phi(0,x,y,z) = \phi_0(x,y,z), \tag{2.13e}$$

where ν = exterior unit normal to ∂B_1 and $c = \alpha(t)^2\Gamma(t)^{-2} = (a_0(0)/L(0)\Gamma(0))^2$ $(c \geqq 0)$.

3. Statement of the existence and uniqueness results. Before stating our main result, which will be proved in § 5, we need to define the class of "admissible" initial data.

Let $C^{2+\alpha}(\overline{B_1})$ denote the classical space of functions defined on $\overline{B_1}$ whose second derivatives are Hölder continuous with exponent α $(\alpha \in (0,1))$, and let $\bar{C}_\alpha$, $\bar{C}_{2+\alpha}$ denote the parabolic Hölder spaces on $[0,T]\times\overline{B_1}$ (see, e.g., Friedman [6, pp. 61–63]). For $f \in C^{2+\alpha}(\overline{B_1})$, $g \in \bar{C}_\alpha$, $h \in \bar{C}_{2+\alpha}$ we introduce the notation

$$\|f\|_{2+\alpha}^0 = \|f\|_{2+\alpha,\overline{B_1}},$$

$$\|g\|_\alpha = \|g\|_{\alpha,[0,T]\times\overline{B_1}},$$

$$\|h\|_{2+\alpha} = \|h\|_{2+\alpha,[0,T]\times\overline{B_1}}.$$

Finally, if k is a function satisfying $k \in \bar{C}_\alpha$, $k(t,\cdot) \in C^{2+\alpha}(\overline{B_1})$ $(t \in [0,T])$, we shall write

$$|||k||| = \|k\|_{\alpha,[0,T]\times\overline{B_1}} + \sup_{t\in[0,T]}\|k(t,\cdot)\|_{2+\alpha,\overline{B_1}}.$$

DEFINITION. A function $f: \overline{B_1}\times\mathbb{R}\to\mathbb{R}$ is said to belong to the class A_η^α $(0<\alpha<1, 0<\eta)$ if f satisfies the following conditions:

(i) For each $(x,y) \in \overline{B_1}$, $f(x,y,\cdot)$ extends to an entire function in $\mathbb{C}$.

(ii) For each $\zeta \in \mathbb{C}$, $f(\cdot,\zeta) \in C^{2+\alpha}(\overline{B_1})$.

(iii) For each $\varepsilon > 0$, there exists a constant $c_\varepsilon \geqq 0$ such that

$$\|f(\cdot,\zeta)\|_{2+\alpha,\overline{B_1}} \leqq c_\varepsilon\, e^{(\eta+\varepsilon)|\zeta|} \quad \forall\zeta\in\mathbb{C}. \tag{3.1}$$

(iv) $\partial_\nu f(x,y,\zeta) = 0$ for $(x,y) \in \partial B_1$, $\zeta \in \mathbb{C}$.

(Note that condition (iv) coincides with (2.2).) Examples of functions in A_η^α can be constructed as follows:

(1) Let $h \in C^{2+\alpha}(\overline{B_1})$ with $\partial_\nu h = 0$ on ∂B_1, and let $g(\zeta)$ be an entire function of order 1 and type η. Then $f(x,y,\zeta) = h(x,y)g(\zeta) \in A_\eta^\alpha$.

(2) Let $\varphi: \overline{B_1}\times\mathbb{R}\to\mathbb{R}$ satisfy:

(a) $\partial_\nu\varphi = 0$, $(x,y) \in \partial B_1$.

(b) $\|\varphi(\cdot,\mu)\|_{2+\alpha} \leqq M$ for $|\mu| \leqq \eta/(2\pi)$, for some constant $M \geqq 0$.

(c) $\varphi(x, y, \mu) = 0$ for $|\mu| > \eta/(2\pi)$.

Then, the function

$$f(x, y, \zeta) = \varphi(x, y, \cdot)\hat{}(\zeta) = \int_{\mathbb{R}} \varphi(x, y, \mu)\, e^{-2\pi i \mu \zeta}\, d\mu$$

belongs to A_η^α.

THEOREM 3.1. *Let $T > 0$, $0 < \alpha < 1$. Then, there exists a number $\eta_0 < 1$ such that, for every $\phi_0 \in A_{\eta_0}^\alpha$, there exists a unique solution (ϕ, p) of (2.13) satisfying:*

(i) $\phi \equiv \phi_0$ *at* $t = 0$.

(ii) *For each* $(x, y) \in \overline{B_1}$, $t \in [0, T]$, $\phi(t, x, y, \cdot)$, *and* $p(t, x, y, \cdot)$ *extend to entire functions in* $\mathbb{C}$.

(iii)

$$\phi(\cdot, \zeta) \in \bar{C}_{2+\alpha}([0, T] \times \overline{B_1}), \qquad \zeta \in \mathbb{C},$$

$$p(\cdot, \zeta) \in \bar{C}_\alpha([0, T] \times \overline{B_1}), \qquad \zeta \in \mathbb{C},$$

$$p(t, \cdot, \zeta) \in C^{2+\alpha}(\overline{B_1}), \qquad \zeta \in \mathbb{C}, \quad t \in [0, T].$$

(iv) *For every $\varepsilon > 0$, there exists $c_\varepsilon > 0$ such that*

$$\|\phi(\cdot, \zeta)\|_{2+\alpha} + |||p(\cdot, \zeta)||| \leqq c_\varepsilon\, e^{(\eta_0 + \varepsilon)|\zeta|} \quad \forall \zeta \in \mathbb{C}. \tag{3.2}$$

Remark. It will be evident from the proof of Theorem 3.1 that, for each α fixed, $\eta_0 \to 0$ as $T \to \infty$.

Note that $\phi_0(x, y, \cdot)$ is not necessarily a tempered distribution for $\phi_0 \in A_\eta^\alpha$. This prevents us from using the Paley-Wiener theorem (see § 6) in the proof of Theorem 3.1. The underlying approach for proving this theorem is by superposition: we expand the initial data into a power series in z, $\phi_0(x, y, z) = \sum_{n=0}^\infty a_n(x, y) z^n$, solve the problem with initial data $\phi_0^n(x, y, z) = a_n(x, y) z^n$, and then sum over n. In order to solve for ϕ_0^n we take the Fourier transform in the z variable, solve the resulting problem (using a fixed-point argument) and then take the inverse transform. Finally, using the growth condition for ϕ_0, we shall show that the resulting series actually converges to a solution of (2.13).

By Fourier transforming (2.13) in z and setting $\phi(t, x, y, \cdot)\hat{}(\mu) = u(t, x, y, \mu)$, $p(t, x, y, \cdot)\hat{}(\mu) = v(t, x, y, \mu)$, $\phi_0(x, y, \cdot)\hat{}(\mu) = u_0(x, y, \mu)$, we are led to the following system:

$$\frac{\partial u}{\partial t} - \Gamma^{-2} \Delta u + c(2\pi i \mu)^2 u + u = -\alpha^2 2\pi i \mu v \quad \text{in } G, \tag{3.3a}$$

$$\Delta v = 2\pi i \mu \frac{\partial u}{\partial t} - 2(2\pi i \mu) u - c(2\pi i \mu)^3 u \quad \text{in } G, \tag{3.3b}$$

$$\begin{aligned} \frac{\partial u}{\partial \nu} = &-\frac{3\alpha^2}{2\pi} (2\pi i \mu)^2 \int_0^t \int_{B_1} u(s, x, y, \mu)\, dx\, dy\, ds \\ &+ \frac{\alpha^2}{2\pi} (2\pi i \mu)^2 \int_{B_1} u(t, x, y, \mu)\, dx\, dy \\ &- \frac{\alpha^2}{2\pi} (2\pi i \mu)^2 \int_{B_1} u_0(x, y, \mu)\, dx\, dy \quad \text{on } \Gamma_0, \end{aligned} \tag{3.3c}$$

$$v=-\frac{3}{8\pi}(2\pi i\mu)\int_0^t\int_{B_1}u(s,x,y,\mu)\,dx\,dy\,ds-\Gamma^{-2}(2\pi i\mu)u$$

$$-\frac{(2\pi i\mu)}{8\pi}\int_{B_1}u_0(x,y,\mu)\,dx\,dy \tag{3.3d}$$

$$+\frac{\Gamma^{-2}}{\pi}(2\pi i\mu)\int_{B_1}u(t,x,y,\mu)\,dx\,dy\quad\text{on }\Gamma_0,$$

$$u(0,x,y,\mu)=u_0(x,y,\mu). \tag{3.3e}$$

Replacing $-iv$ by v we may rewrite (3.3) as

$$\frac{\partial u}{\partial t}-\Gamma^{-2}\Delta u+(1-4\pi^2c\mu^2)u=\alpha^2 2\pi\mu v\quad\text{in } G, \tag{3.4a}$$

$$\Delta v=2\pi\mu\frac{\partial u}{\partial t}+(8\pi^3c\mu^3-4\pi\mu)u\quad\text{in } G, \tag{3.4b}$$

$$\frac{\partial u}{\partial\nu}=6\pi\alpha^2\mu^2\int_0^t\int_{B_1}u-2\pi\alpha^2\mu^2\int_{B_1}u+2\pi\alpha^2\mu^2\int_{B_1}u_0\quad\text{on }\Gamma_0, \tag{3.4c}$$

$$v=-\frac{3}{4}\mu\int_0^t\int_{B_1}u-\Gamma^{-2}2\pi\mu u-\frac{\mu}{4}\int_{B_1}u_0+2\Gamma^{-2}\mu\int_{B_1}u\quad\text{on }\Gamma_0, \tag{3.4d}$$

$$u(0,x,y,\mu)=u_0(x,y,\mu). \tag{3.4e}$$

Note that, for fixed μ, (3.4) is an "elliptic-parabolic" system. In the next section we prove existence and uniqueness of a solution for the special case where u_0 is independent of μ (which constitutes the main step towards proving Theorem 3.1).

4. Proof of Theorem 3.1 in a special case.

LEMMA 4.1. *Let* $u_0:\overline{B_1}\to\mathbb{R}$ *satisfy*

$$u_0\in C^{2+\alpha}(\overline{B_1}), \tag{4.1}$$

$$\frac{\partial u_0}{\partial\nu}=0\quad\text{on }\partial B_1. \tag{4.2}$$

Then, there exists a unique solution of (3.4) *satisfying*: $u(t,x,y,\cdot)$, $v(t,x,y,\cdot)\in C^\infty(\mathbb{R})$, $\partial_\mu^l u(\cdot,\mu)\in\bar{C}_{2+\alpha}([0,T]\times\overline{B_1})$, $\partial_\mu^l v(\cdot,\mu)\in\bar{C}_\alpha([0,T]\times\overline{B_1})$, $\partial_\mu^l v(t,\cdot,\mu)\in C^{2+\alpha}(\overline{B_1})$, *and* $\partial_t\partial_\mu^l v(t,\cdot,\mu)\in C^{2+\alpha}(B_1)\cap C^0(\overline{B_1})$ $(l\geqq 0)$.

Furthermore, for each $l\geqq 0$, *we have*

$$\left\|\frac{\partial^l u}{\partial\mu^l}(\cdot,0)\right\|_{2+\alpha}\leqq c_1c_2^l l!\,\|u_0\|^0_{2+\alpha}, \tag{4.3}$$

$$\left|\!\left|\!\left|\frac{\partial^l v}{\partial\mu^l}(\cdot,0)\right|\!\right|\!\right|\leqq c_1c_2^l l!\,\|u_0\|^0_{2+\alpha} \tag{4.4}$$

for some constants c_1, $c_2>0$.

Assume for a moment that the conclusions of the lemma hold, and let (u,v) be the solution of (3.4) for u_0 independent of μ. Then, if we set

$$\phi(t,x,y,z)=\langle(-2\pi i)^{-n}\partial_\mu^n\delta,\,u(t,x,y,\mu)\,e^{2\pi i\mu z}\rangle$$

$$=\frac{1}{(2\pi i)^n}\sum_{k=0}^n\binom{n}{k}(2\pi iz)^k\partial_\mu^{n-k}u(t,x,y,0)$$

and

$$p(t,x,y,z)=\langle(-2\pi i)^{-n}\partial_\mu^n\delta,\ iv(t,x,y,\mu)\,e^{2\pi i\mu z}\rangle$$
$$=\frac{i}{(2\pi i)^n}\sum_{k=0}^{n}\binom{n}{k}(2\pi iz)^k\partial_\mu^{n-k}v(t,x,y,0),$$

where δ is the Dirac delta acting on the variable μ, it is easy to check that (ϕ, p) is a solution of (2.13) satisfying (i)-(iv) of Theorem 3.1 with $\phi_0(x,y,z)=u_0(x,y)z^n$.

Proof of Lemma 4.1. We shall use c_μ to denote a generic constant (not always the same), depending only on μ. We divide the proof into five steps.

Step I (Transformation of the system). First we transform (3.4) into a more convenient form. Using (3.4a), we may replace (3.4b) by

$$\Delta v-4\pi^2\mu^2\alpha^2v=2\pi\mu\Gamma^{-2}\Delta u+2\pi\mu(8\pi^2c\mu^2-3)u$$

and setting $w=v-2\pi\mu\Gamma^{-2}u$, we are led to

$$\frac{\partial u}{\partial t}-\Gamma^{-2}\Delta u+(1-8\pi^2c\mu^2)u=\alpha^2 2\pi\mu w \quad \text{in } G, \tag{4.5a}$$

$$\Delta w-4\pi^2\alpha^2\mu^2w=(24\pi^3c\mu^3-6\pi\mu)u \quad \text{in } G, \tag{4.5b}$$

with initial-boundary conditions given by

$$\frac{\partial u}{\partial\nu}=6\pi\alpha^2\mu^2\int_0^t\int_{B_1}u-2\pi\alpha^2\mu^2\int_{B_1}u+2\pi\alpha^2\mu^2\int_{B_1}u_0 \quad \text{on } [0,T]\times\partial B_1\times\mathbb{R}, \tag{4.5c}$$

$$w=-\frac{3}{4}\mu\int_0^t\int_{B_1}u-\Gamma^{-2}4\pi\mu u-\frac{\mu}{4}\int_{B_1}u_0+2\Gamma^{-2}\mu\int_{B_1}u \quad \text{on } [0,T]\times\partial B_1\times\mathbb{R}, \tag{4.5d}$$

$$u(0,x,y,\mu)=u_0(x,y) \quad \text{on } B_1. \tag{4.5e}$$

Finally, we want to write the right-hand side of (4.5c) in terms of u_0 and w.

Integrating (4.5a) over B_1 we get

$$f'(t)+(1-8\pi^2c\mu^2)f(t)-\Gamma^{-2}2\pi\frac{\partial u}{\partial\nu}=g(t), \tag{4.6}$$

where

$$f(t)=\int_{B_1}u\,dx\,dy, \qquad g(t)=2\pi\alpha^2\mu\int_{B_1}w\,dx\,dy,$$

and using (4.5c) we can replace $\partial_\nu u$ in (4.6), to get

$$f'(t)+(1-4\pi^2c\mu^2)f(t)-12\pi^2c\mu^2\int_0^t f(s)\,ds-4\pi^2c\mu^2\int_{B_1}u_0=g(t). \tag{4.7}$$

Since $f(0)=\int_{B_1}u_0(x,y)\,dx\,dy$, we may solve (4.7) for f in terms of u_0 and w. Replacing in (4.5c), we see that, on ∂B_1,

$$\frac{\partial u}{\partial\nu}=E_2(u_0,w),$$

where $E_2(u_0,w)$ is an expression in (u_0,w) (which can be explicitly written) depending only on t and with the property that, if $w\in\bar{C}_\alpha([0,T]\times\overline{B_1})$ and $u_0\in C^{2+\alpha}(\overline{B_1})$, we have $\partial_tE_2(u_0,w)\in\bar{C}_\alpha([0,T]\times\overline{B_1})$.

Thus, if we set

$$E_1(u_0, u) = -\frac{3}{4}\mu \int_0^t \int_{B_1} u - \Gamma^{-2} 4\pi\mu u - \frac{\mu}{4} \int_{B_1} u_0 + 2\Gamma^{-2}\mu \int_{B_1} u,$$

then we need to study system (4.5a), (4.5b) subject to the initial-boundary conditions

$$\frac{\partial u}{\partial \nu} = E_2(u_0, w) \quad \text{on } \partial B_1, \tag{4.8a}$$

$$w = E_1(u_0, u) \quad \text{on } \partial B_1, \tag{4.8b}$$

$$u(0, x, y, \mu) = u_0(x, y) \quad \text{on } B_1. \tag{4.8c}$$

Step II (Local existence). We now show that there exists a solution of (4.5a), (4.5b), (4.8) if T is small enough.

Fix $\mu \in \mathbb{R}$. Given $F \in \bar{C}_{2+\alpha}$ such that $F(0, x, y) = u_0(x, y)$, let $\mathcal{R}F = L$ be the unique solution of

$$\Delta L - 4\pi^2\alpha^2\mu^2 L = (24\pi^3 c\mu^3 - 6\pi\mu)F \quad \text{on } [0, T] \times B_1, \tag{4.9a}$$

$$L = E_1(u_0, F) \quad \text{on } [0, T] \times \partial B_1. \tag{4.9b}$$

It is then clear that $L = \mathcal{R}F$ satisfies:

$$L(t, \cdot) \in C^{2+\alpha}(\overline{B_1}), \quad \partial_t L \in C^{2+\alpha}(B_1), \quad \text{and} \quad L \in \bar{C}_\alpha.$$

Furthermore, if $F_1, F_2 \in \bar{C}_{2+\alpha}$, $F_1(0, x, y) = F_2(0, x, y) = u_0(x, y)$, and $L_i = \mathcal{R}F_i$ $(i = 1, 2)$, then, for some constant c_μ we have

$$\|L_1 - L_2\|_\alpha \leqq c_\mu \|F_1 - F_2\|_E, \tag{4.10}$$

where

$$\|h\|_E = \|h\|_{\infty, D} + \left\|\frac{\partial h}{\partial x}\right\|_{\infty, D} + \left\|\frac{\partial h}{\partial y}\right\|_{\infty, D} + \left\|\frac{\partial^2 h}{\partial x^2}\right\|_{\infty, D} + \left\|\frac{\partial^2 h}{\partial y^2}\right\|_{\infty, D} + \left\|\frac{\partial^2 h}{\partial x\, \partial y}\right\|_{\infty, D} + \left\|\frac{\partial h}{\partial t}\right\|_{\infty, D}$$

and $D = [0, T] \times \overline{B_1}$.

Indeed, this is a straightforward consequence of the maximum principle and the following result.

LEMMA 4.2. *Let* $U, W \in C^{2+\alpha}(\overline{B_1})$, $V \in C^{1+\alpha}(\overline{B_1})$ *satisfy*

$$\Delta U - \lambda^2 U = V \quad \text{on } B_1 \quad (B_1 \subset \mathbb{R}^2),$$

$$U = W \quad \text{on } \partial B_1.$$

Then

$$\|\nabla U\|_0 \leqq 6[\|V\|_1 + \lambda^2 \|W\|_0 + \|W\|_2],$$

where $\|h\|_k = \sum_{|\alpha| \leqq k} \|\partial^\alpha h / \partial x^{\alpha_1}\, \partial y^{\alpha_2}\|_{\infty, B_1}$.

(See, e.g., Gilbarg and Trudinger [7, p. 48]).

Now, given $L \in \bar{C}_\alpha$ let $\mathcal{S}L = F$ be the unique solution of

$$\frac{\partial F}{\partial t} - \Gamma^{-2}\Delta F + (1 - 8\pi^2 c\mu^2)F = \alpha^2 2\pi\mu L \quad \text{on } [0, T] \times B_1, \tag{4.11a}$$

$$\frac{\partial F}{\partial \nu} = E_2(u_0, L) \quad \text{on } [0, T] \times \partial B_1, \tag{4.11b}$$

$$F(0, x, y) = u_0(x, y) \quad \text{on } B_1. \tag{4.11c}$$

Note that, from the hypotheses on u_0 ((4.1) and (4.2)), the compatibility condition

$$\frac{\partial u_0}{\partial \nu} = E_2(u_0, L) \quad \text{on } \partial B_1 \quad \text{at } t = 0 \tag{4.12}$$

is satisfied. Thus, $F = \mathcal{S}L \in \bar{C}_{2+\alpha}$ and the parabolic Schauder estimates (see, e.g., Ladyženskaja, Solonnikov, and Ural'ceva [10, pp. 320-321]) imply that:

If L_1, $L_2 \in \bar{C}_\alpha$, $F_i = \mathcal{S}L_i$ $(i = 1, 2)$, then

$$\|F_1 - F_2\|_{2+\alpha} \leqq c_\mu \|L_1 - L_2\|_\alpha. \tag{4.13}$$

Let $\mathcal{Q} = \mathcal{S}\mathcal{R}$; then, combining the above results, we obtain

$$\|\mathcal{Q}(F_1) - \mathcal{Q}(F_2)\|_{2+\alpha} \leqq c_\mu T^{\alpha/2} \|F_1 - F_2\|_{2+\alpha} \tag{4.14}$$

for every F_1, $F_2 \in \bar{C}_{2+\alpha}$ such that $F_i(0, x, y) = u_0(x, y)$ $(i = 1, 2)$. (Note that $(\mathcal{R}F_1 - \mathcal{R}F_2)(0, x, y) \equiv 0$.)

Let $X = \{F \in \bar{C}_{2+\alpha} \mid F(0, x, y) = u_0(x, y)\} \subset \bar{C}_{2+\alpha}$. Then, choosing $T = T_0 = T_0(\mu)$ small enough, we may apply the Contraction Mapping Theorem to conclude that there exists a unique $F_1 \in X$ such that $\mathcal{Q}(F_1) = F_1$. Hence, if we set $L_1 = \mathcal{R}F_1$, then (F_1, L_1) satisfy:

$$\frac{\partial F_1}{\partial t} - \Gamma^{-2}\Delta F_1 + (1 - 8\pi^2 c\mu^2)F_1 = \alpha^2 2\pi\mu L_1 \quad \text{on } [0, T_0] \times B_1, \tag{4.15a}$$

$$\Delta L_1 - 4\pi^2\alpha^2\mu^2 L_1 = (24\pi^3 c\mu^3 - 6\pi\mu)F_1 \quad \text{on } [0, T_0] \times B_1 \tag{4.15b}$$

and

$$\frac{\partial F_1}{\partial \nu} = E_2(u_0, L_1) \quad \text{on } [0, T_0] \times \partial B_1, \tag{4.15c}$$

$$L_1 = E_1(u_0, F_1) \quad \text{on } [0, T_0] \times \partial B_1, \tag{4.15d}$$

$$F_1(0, x, y) = u_0(x, y) \quad \text{on } B_1, \tag{4.15e}$$

with $F_1 \in \bar{C}_{2+\alpha}$, $L_1 \in \bar{C}_\alpha$, $L_1(t, \cdot) \in C^{2+\alpha}(\overline{B_1})$, and $\partial_t L_1(t, \cdot) \in C^{2+\alpha}(B_1) \cap C^0(\overline{B_1})$.

We now want to show that

$$\|F_1\|_{2+\alpha} \leqq c_\mu \|u_0\|^0_{2+\alpha}, \tag{4.16}$$

$$\sup_{t \in [0, T_0]} \|L_1(t, \cdot)\|^0_{2+\alpha} \leqq c_\mu \|u_0\|^0_{2+\alpha}, \tag{4.17}$$

and

$$\left\| \frac{\partial L_1}{\partial t} \right\|_0 = \left\| \frac{\partial L_1}{\partial t} \right\|_{\infty, [0, T_0] \times B_1} \leqq c_\mu \|u_0\|^0_{2+\alpha}. \tag{4.18}$$

Using the elliptic Schauder estimates and the maximum principle (in (4.9)), (4.17) and (4.18) easily follow from (4.16). Finally, (4.16) (for $T_0(\mu)$ small enough) follows from (4.15), Lemma 4.2, and the parabolic Schauder estimates.

Step III (Global existence and uniqueness). In order to prove global existence of a solution on $[0, T] \times B_1$ we just need to write

$$u_1(x, y) = u_0(x, y) + 3 \int_0^{T_0} F_1(s, x, y)\, ds$$

and repeat the above argument for the system

$$\frac{\partial F}{\partial t} - \Gamma^{-2}\Delta F + (1 - 8\pi^2 c\mu^2)F = \alpha^2 2\pi\mu L \quad \text{on } [T_0, 2T_0] \times B_1, \tag{4.19a}$$

$$\Delta L - 4\pi^2\alpha^2\mu^2 L = (24\pi^3 c\mu^3 - 6\pi\mu)F \quad \text{on } [T_0, 2T_0] \times B_1 \tag{4.19b}$$

with initial boundary conditions

$$(4.19c)\quad \frac{\partial F}{\partial \nu}=6\pi\alpha^2\mu^2\int_{T_0}^{t}\int_{B_1}F-2\pi\alpha^2\mu^2\int_{B_1}F+2\pi\alpha^2\mu^2\int_{B_1}u_1 \quad \text{for } (x,y)\in\partial B_1,$$

$$(4.19d)\quad L=-\frac{3}{4}\mu\int_{T_0}^{t}\int_{B_1}F-\Gamma^{-2}4\pi\mu F-\frac{\mu}{4}\int_{B_1}u_1+2\Gamma^{-2}\mu\int_{B_1}F \quad \text{for } (x,y)\in\partial B_1,$$

$$(4.19e)\quad F(T_0,x,y)=F_1(T_0,x,y) \quad \text{on } B_1.$$

(Here we use the fact that the size of the time interval for local existence depends only on μ, not on the initial data.)

Thus, we have proved that there exists a solution (u, v) of (3.4) satisfying:

$$u(\cdot,\mu)\in\bar{C}_{2+\alpha}([0,T]\times\overline{B_1}),\qquad v(\cdot,\mu)\in\bar{C}_{\alpha}([0,T]\times\overline{B_1}),$$
$$v(t,\cdot,\mu)\in C^{2+\alpha}(\overline{B_1}),\qquad \partial_t v(t,\cdot,\mu)\in C^{2+\alpha}(B_1)\cap C^0(\overline{B_1}).$$

Also,

$$(4.20)\quad \|u(\cdot,\mu)\|_{2+\alpha}+|||v(\cdot,\mu)|||\leqq c_\mu\|u_0\|^0_{2+\alpha}.$$

The uniqueness of the solution (u, v) easily follows from (4.5), (4.8) and the uniqueness statement in the Contraction Mapping Theorem.

Step IV (Regularity of the solution). We want to show:

(a) $u(t,x,y,\cdot)$, $v(t,x,y,\cdot)\in C^\infty(\mathbb{R})$.

(b) $\partial^l_\mu u(\cdot,\mu)\in\bar{C}_{2+\alpha}([0,T]\times\overline{B_1})$, $\partial^l_\mu v(\cdot,\mu)\in\bar{C}_\alpha([0,T]\times\overline{B_1})$, $\partial^l_\mu v(t,\cdot,\mu)\in C^{2+\alpha}(\overline{B_1})$, $\partial_t\partial^l_\mu v(t,\cdot,\mu)\in C^{2+\alpha}(B_1)\cap C^0(\overline{B_1})$ for each $l\geqq 0$.

Fix $\mu_0\in\mathbb{R}$ and let, for $h\in\mathbb{R}$,

$$U_0(x,y,t)=u(t,x,y,\mu_0),\qquad U_h(x,y,t)=u(t,x,y,\mu_0+h),$$
$$V_0(x,y,t)=v(t,x,y,\mu_0),\qquad V_h(x,y,t)=v(t,x,y,\mu_0+h).$$

Then, using (3.4) we can write a system of equations for

$$\left(\frac{U_h-U_0}{h}\right)\quad\text{and}\quad\left(\frac{V_h-V_0}{h}\right),$$

and, proceeding as before, we can prove, with the aid of (4.20), that

$$\left\|\left(\frac{U_h-U_0}{h}\right)\right\|_{2+\alpha}+\left|\left|\left|\left(\frac{V_h-V_0}{h}\right)\right|\right|\right|\leqq c_{\mu_0}(\|U_h\|_{2+\alpha}+|||V_h|||+\|u_0\|^0_{2+\alpha})$$
$$\leqq c_{\mu_0}\|u_0\|^0_{2+\alpha}$$

for small h. Thus we may conclude that $u(t,x,y,\cdot)$ and $v(t,x,y,\cdot)$ are differentiable at μ_0 and that $\partial^l_\mu u(\cdot,\mu_0)$, $\partial^l_\mu v(\cdot,\mu_0)$ satisfy (b) for $l=1$.

Furthermore, we have

$$(4.21a)\quad \frac{\partial}{\partial t}\frac{\partial u}{\partial\mu}-\Gamma^{-2}\Delta\frac{\partial u}{\partial\mu}+(1-4\pi^2c\mu^2)\frac{\partial u}{\partial\mu}$$
$$=\alpha^2 2\pi\mu\frac{\partial v}{\partial\mu}+(8\pi^2c\mu u+2\pi\alpha^2 v)\quad\text{on } [0,T]\times B_1\times\mathbb{R},$$

$$(4.21b)\quad \Delta\frac{\partial v}{\partial\mu}=2\pi\mu\frac{\partial}{\partial t}\frac{\partial u}{\partial\mu}+(8\pi^3c\mu^3-4\pi\mu)\frac{\partial u}{\partial\mu}$$
$$+\left[(24\pi^3c\mu^2-4\pi)u+2\pi\frac{\partial u}{\partial t}\right]\quad\text{on } [0,T]\times B_1\times\mathbb{R},$$

$$\frac{\partial}{\partial\nu}\frac{\partial u}{\partial\mu}=6\pi\alpha^2\mu^2\int_0^t\int_{B_1}\frac{\partial u}{\partial\mu}-2\pi\alpha^2\mu^2\int_{B_1}\frac{\partial u}{\partial\mu}$$

$$+\left\{12\pi\alpha^2\mu\int_0^t\int_{B_1}u-4\pi\alpha^2\mu\int_{B_1}u+4\pi\alpha^2\mu\int_{B_1}u_0\right\} \tag{4.21c}$$

on $[0, T]\times\partial B_1\times\mathbb{R}$,

$$\frac{\partial v}{\partial\mu}=-\frac{3}{4}\mu\int_0^t\int_{B_1}\frac{\partial u}{\partial\mu}-\Gamma^{-2}2\pi\mu\frac{\partial u}{\partial\mu}+2\Gamma^{-2}\mu\int_{B_1}\frac{\partial u}{\partial\mu}$$

$$+\left\{-\frac{1}{4}\int_{B_1}u_0-\frac{3}{4}\int_0^t\int_{B_1}u-2\pi\Gamma^{-2}u+2\Gamma^{-2}\int_{B_1}u\right\} \tag{4.21d}$$

on $[0, T]\times\partial B_1\times\mathbb{R}$,

$$\frac{\partial u}{\partial\mu}(0, x, y, \mu)=0. \tag{4.21e}$$

By repeating this procedure we may conclude that (a) and (b) hold.

Step V (Bounds on the μ-derivatives at $\mu=0$). Consider the system (4.5) and let (for $l\geqq 0$)

$$F_l(t, x, y)=\frac{1}{l!}\frac{\partial^l u}{\partial\mu^l}(t, x, y, 0),$$

$$L_l(t, x, y)=\frac{1}{l!}\frac{\partial^l w}{\partial\mu^l}(t, x, y, 0),$$

and $F_l\equiv L_l\equiv 0$ if $l<0$. It is then clear that, for $l\geqq 0$,

$$\frac{\partial F_l}{\partial t}-\Gamma^{-2}\Delta F_l+F_l=\alpha^2 2\pi L_{l-1}+8\pi^2 cF_{l-2} \quad \text{on } [0, T]\times B_1, \tag{4.22a}$$

$$\Delta L_l=4\pi^2\alpha^2 L_{l-2}+24\pi^3 cF_{l-3}-6\pi F_{l-1} \quad \text{on } [0, T]\times B_1, \tag{4.22b}$$

$$\frac{\partial F_l}{\partial\nu}=6\pi\alpha^2\int_0^t\int_{B_1}F_{l-2}-2\pi\alpha^2\int_{B_1}F_{l-2}+2\pi\alpha^2\int_{B_1}F_{l-2}^0 \quad \text{on } [0, T]\times\partial B_1, \tag{4.22c}$$

$$L_l=-\frac{3}{4}\int_0^t\int_{B_1}F_{l-1}-\Gamma^{-2}4\pi F_{l-1}-\frac{1}{4}\int_{B_1}F_{l-1}^0+2\Gamma^{-2}\int_{B_1}F_{l-1} \quad \text{on } [0, T]\times\partial B_1, \tag{4.22d}$$

$$F_l(0, x, y)=F_l^0(x, y) \quad \text{on } B_1, \tag{4.22e}$$

where

$$F_l^0(x, y)=\begin{cases}u_0(x, y) & \text{if } l=0,\\ 0 & \text{if } l\neq 0.\end{cases} \tag{4.23}$$

First we note that (4.22) implies that

$$F_{2k+1}\equiv L_{2k}\equiv 0 \qquad (k\geqq 0).$$

On the other hand, for $l\geqq 0$,

$$\|F_l\|_{2+\alpha}\leqq\gamma_1(\|L_{l-1}\|_\alpha+\|F_{l-2}\|_{2+\alpha}+\|F_l^0\|_{2+\alpha}^0+\|F_{l-2}^0\|_{2+\alpha}^0), \tag{4.24a}$$

$$|||L_{l+1}|||\leqq\gamma_2(|||L_{l-1}|||+\|F_{l-2}\|_{2+\alpha}+\|F_l\|_{2+\alpha}+\|F_l^0\|_{2+\alpha}^0) \tag{4.24b}$$

for some constants γ_1, γ_2.

But then, from (4.24) we may conclude that

$$|||L_{l+1}||| \leqq \gamma_2(|||L_{l-1}||| + \|F_{l-2}\|_{2+\alpha} + \|F_l^0\|_{2+\alpha}^0) + \gamma_1\gamma_2(|||L_{l-1}||| + \|F_{l-2}\|_{2+\alpha} + \|F_l^0\|_{2+\alpha}^0 + \|F_{l-2}\|_{2+\alpha}^0)$$

so that

$$|||L_{l+1}||| \leqq \gamma_3(|||L_{l-1}||| + \|F_{l-2}\|_{2+\alpha} + \|F_l^0\|_{2+\alpha}^0 + \|F_{l-2}\|_{2+\alpha}^0) \tag{4.25}$$

for some constant γ_3.

Let $a_l = \|F_l\|_{2+\alpha} + |||L_{l+1}|||$; then, from (4.24a) and (4.25) we get

$$a_l \leqq \gamma(a_{l-2} + \|F_l^0\|_{2+\alpha}^0 + \|F_{l-2}^0\|_{2+\alpha}^0)$$

for some constant γ.

In particular, for $k \geqq 2$

$$a_{2k} \leqq \gamma a_{2(k-1)}$$

so that

$$a_{2k} \leqq \gamma^{k-1} a_2. \tag{4.26}$$

But,

$$\begin{aligned} a_2 &\leqq \gamma(a_0 + \|F_0^0\|_{2+\alpha}^0) \\ &\leqq \gamma(\gamma\|F_0^0\|_{2+\alpha}^0 + \|F_0^0\|_{2+\alpha}^0) \\ &\leqq (\gamma+\gamma^2)\|u_0\|_{2+\alpha}^0. \end{aligned}$$

Hence, there exists a constant γ_0 such that

$$a_l \leqq \gamma_0^l \|u_0\|_{2+\alpha}^0. \tag{4.27}$$

Finally, since $v = w + \Gamma^{-2} 2\pi\mu u$, we conclude from (4.27) that (4.3) and (4.4) hold.

Thus, the proof of Lemma 4.1 is complete. □

5. Proof of Theorem 3.1.

5.1. Existence. Write $\phi_0(x, y, \zeta) = \sum_{n=0}^{\infty} a_n(x, y)\zeta^n$. Then, using the fact that $\phi_0 \in A_{\eta_0}^{\alpha}$ and Cauchy's formula, we get that $a_n \in \bar{C}_{2+\alpha}(\overline{B_1})$ and, for every $\varepsilon > 0$

$$\|a_n\|_{2+\alpha}^0 \leqq c_\varepsilon \frac{(\eta_0+\varepsilon)^n e^n}{n^n} \quad \text{for } n \geqq 1. \tag{5.1}$$

Now let $(A_n(t, x, y, \mu), B_n(t, x, y, \mu))$ be the solution of (3.4) given by Lemma 4.1 when u_0 is replaced by a_n.

Finally, set

$$\phi(t, x, y, \zeta) = \sum_{n=0}^{\infty} \frac{1}{(2\pi i)^n} \sum_{k=0}^{n} \binom{n}{k} (2\pi i\zeta)^k \frac{\partial^{n-k} A_n}{\partial \mu^{n-k}}(t, x, y, 0), \tag{5.2a}$$

$$p(t, x, y, \zeta) = \sum_{n=0}^{\infty} \frac{i}{(2\pi i)^n} \sum_{k=0}^{n} \binom{n}{k} (2\pi i\zeta)^k \frac{\partial^{n-k} B_n}{\partial \mu^{n-k}}(t, x, y, 0). \tag{5.2b}$$

We claim:

If η_0 is small enough, then (ϕ, p) defined by (5.2) is a solution of (2.13) satisfying (i)-(iv) of Theorem 3.1.

Proof. We have

$$\|\phi(\cdot, \zeta)\|_{2+\alpha} \leqq \sum_{n=0}^{\infty} \frac{1}{(2\pi)^n} \sum_{k=0}^{n} \binom{n}{k} (2\pi|\zeta|)^k \left\| \frac{\partial^{n-k} A_n}{\partial \mu^{n-k}}(\cdot, 0) \right\|_{2+\alpha}.$$

But from (4.3) we know that

$$\left\| \frac{\partial^{n-k} A_n}{\partial \mu^{n-k}}(\cdot, 0) \right\|_{2+\alpha} \leqq c_1 c_2^{n-k} (n-k)! \|a_n\|^0_{2+\alpha}$$

so that

$$\|\phi(\cdot, \zeta)\|_{2+\alpha} \leqq c_1 \sum_{n=0}^{\infty} n! \sum_{k=0}^{n} \frac{|\zeta|^k}{k!} c_2^{n-k} \|a_n\|^0_{2+\alpha}. \tag{5.3}$$

Thus, using (5.1),

$$\|\phi(\cdot, \zeta)\|_{2+\alpha} \leqq c_1 c_\varepsilon \left(\sum_{n=1}^{\infty} n! \sum_{k=1}^{n} \frac{|\zeta|^k}{k!} c_2^{n-k} \frac{(\eta_0+\varepsilon)^n e^n}{n^n} + \sum_{n=1}^{\infty} n! c_2^n \frac{(\eta_0+\varepsilon)^n e^n}{n^n} + 1 \right),$$

and changing the order of summation,

$$\|\phi(\cdot, \zeta)\|_{2+\alpha} \leqq c_1 c_\varepsilon \left(\sum_{k=1}^{\infty} \frac{[(\eta_0+\varepsilon)|\zeta|]^k}{k!} \sum_{n \geqq k} (c_2(\eta_0+\varepsilon))^{n-k} \frac{n!\, e^n}{n^n} + \sum_{n=1}^{\infty} (c_2(\eta_0+\varepsilon))^n \frac{n!\, e^n}{n^n} + 1 \right). \tag{5.4}$$

By using the estimate

$$\frac{n!\, e^n}{n^n} \leqq c_3 n^{1/2}, \tag{5.5}$$

we get

$$\|\phi(\cdot, \zeta)\|_{2+\alpha} \leqq c_1 c_3 c_\varepsilon \left(\sum_{k=1}^{\infty} \frac{[(\eta_0+\varepsilon)|\zeta|]^k}{k!} \sum_{n \geqq k} (c_2(\eta_0+\varepsilon))^{n-k} n^{1/2} + \sum_{n=1}^{\infty} (c_2(\eta_0+\varepsilon))^n n^{1/2} + 1 \right),$$

that is,

$$\|\phi(\cdot, \zeta)\|_{2+\alpha} \leqq \tilde{c}_\varepsilon \left(\sum_{k=1}^{\infty} \frac{[(\eta_0+\varepsilon)|\zeta|]^k}{k!} \sum_{n \geqq 0} (c_2(\eta_0+\varepsilon))^n (n+k)^{1/2} + \sum_{n=1}^{\infty} (c_2(\eta_0+\varepsilon))^n n^{1/2} + 1 \right) \qquad (\tilde{c}_\varepsilon = c_1 c_3 c_\varepsilon). \tag{5.6}$$

Therefore, if $\eta_0 < 1/c_2$ and $0 < \varepsilon < 1/c_2 - \eta_0$, then (5.6) implies

$$\|\phi(\cdot, \zeta)\|_{2+\alpha} \leqq \hat{c}_\varepsilon (1+|\zeta|)\, e^{(\eta_0+\varepsilon)|\zeta|}, \tag{5.7a}$$

for some constant $\hat{c}_\varepsilon$.

In a similar way, but using (4.4) instead of (4.3), we can prove that

$$|||p(\cdot, \zeta)||| \leqq \tilde{\tilde{c}}_\varepsilon (1+|\zeta|)\, e^{(\eta_0+\varepsilon)|\zeta|}. \tag{5.7b}$$

Since (5.7) clearly implies (3.2) we see that (ϕ, p) satisfies (ii)-(iv) of Theorem 3.1, and it only remains to show that (ϕ, p) is a solution of (2.13).

First we check (2.13e); we have

$$\phi(0,x,y,z)=\sum_{n=0}^{\infty}\frac{1}{(2\pi i)^n}\sum_{k=0}^{n}\binom{n}{k}(2\pi iz)^k\frac{\partial^{n-k}a_n}{\mu^{n-k}}(x,y)$$

$$=\sum_{n=0}^{\infty}\frac{1}{(2\pi i)^n}(2\pi iz)^n a_n(x,y)=\phi_0(x,y,z).$$

Now set

$$A_{n,k}=\partial_\mu^{n-k}A_n(\cdot,0),\qquad B_{n,k}=\partial_\mu^{n-k}B_n(\cdot,0).$$

Then from (3.4) we have

$$\frac{\partial A_{n,k}}{\partial t}-\Gamma^{-2}\Delta A_{n,k}+A_{n,k}=4\pi^2c(n-k)(n-k-1)A_{n,k+2}$$
$$+2\pi\alpha^2(n-k)B_{n,k+1}\quad\text{on }[0,T]\times B_1, \tag{5.8a}$$

$$\Delta B_{n,k}=2\pi(n-k)\frac{\partial A_{n,k+1}}{\partial t}+8\pi^3c(n-k)(n-k-1)(n-k-2)A_{n,k+3}$$
$$-4\pi(n-k)A_{n,k+1}\quad\text{on }[0,T]\times B_1 \tag{5.8b}$$

and, on $[0,T]\times\partial B_1$,

$$\frac{\partial A_{n,k}}{\partial\nu}=6\pi\alpha^2(n-k)(n-k-1)\int_0^t\int_{B_1}A_{n,k+2}$$
$$-2\pi\alpha^2(n-k)(n-k-1)\int_{B_1}A_{n,k+2}+2\pi\alpha^2(n-k)(n-k-1)\delta_{k,n-2}\int_{B_1}a_n, \tag{5.8c}$$

$$B_{n,k}=-\frac{3}{4}(n-k)\int_0^t\int_{B_1}A_{n,k+1}-\frac{1}{4}\delta_{k,n-1}\int_{B_1}a_n$$
$$-\Gamma^{-2}2\pi(n-k)A_{n,k+1}+2\Gamma^{-2}(n-k)\int_{B_1}A_{n,k+1}. \tag{5.8d}$$

Using (5.8a),

$$\frac{\partial\phi}{\partial t}-\Gamma^{-2}\Delta\phi+\phi$$

$$=\sum_{n=0}^{\infty}\frac{1}{(2\pi i)^n}\sum_{k=0}^{n}\binom{n}{k}(2\pi iz)^k\left[\frac{\partial A_{n,k}}{\partial t}-\Gamma^{-2}\Delta A_{n,k}+A_{n,k}\right]$$

$$=\sum_{n=0}^{\infty}\frac{1}{(2\pi i)^n}\sum_{k=0}^{n}\binom{n}{k}(2\pi iz)^k[4\pi^2c(n-k)(n-k-1)A_{n,k+2}+2\pi\alpha^2(n-k)B_{n,k+1}]$$

$$=-c\sum_{n=0}^{\infty}\frac{1}{(2\pi i)^n}\sum_{k=0}^{n-2}\binom{n}{k}(2\pi i)^{k+2}(n-k)(n-k-1)A_{n,k+2}z^k$$
$$-\sum_{n=0}^{\infty}\frac{i}{(2\pi i)^n}\sum_{k=0}^{n-1}\binom{n}{k}(2\pi i)^{k+1}\alpha^2(n-k)B_{n,k+1}z^k$$

$$=-c\sum_{n=0}^{\infty}\frac{1}{(2\pi i)^n}\sum_{j=2}^{n}\binom{n}{j-2}(2\pi i)^j(n-j+2)(n-j+1)A_{n,j}z^{j-2}$$
$$-\alpha^2\sum_{n=0}^{\infty}\frac{i}{(2\pi i)^n}\sum_{j=1}^{n}\binom{n}{j-1}(2\pi i)^j(n-j+1)B_{n,j}z^{j-1}$$

so that

$$\frac{\partial\phi}{\partial t}-\Gamma^{-2}\Delta\phi+\phi=-c\sum_{n=0}^{\infty}\frac{1}{(2\pi i)^n}\sum_{j=2}^{n}\binom{n}{j}(2\pi i)^j j(j-1)z^{j-2}A_{n,j}$$
$$-\alpha^2\sum_{n=0}^{\infty}\frac{i}{(2\pi i)^n}\sum_{j=1}^{n}\binom{n}{j}(2\pi i)^j jz^{j-1}B_{n,j}$$
$$=-c\frac{\partial^2\phi}{\partial z^2}-\alpha^2\frac{\partial p}{\partial z}$$

and therefore (2.13a) is satisfied.

Similarly, using (5.8d) we see that, on Γ_0,

$$p=\sum_{n=0}^{\infty}\frac{i}{(2\pi i)^n}\sum_{k=0}^{n}\binom{n}{k}(2\pi iz)^k B_{n,k}$$
$$=\sum_{n=0}^{\infty}\frac{i}{(2\pi i)^n}\sum_{k=0}^{n}\binom{n}{k}(2\pi iz)^k\left[-\frac{3}{4}(n-k)\int_0^t\int_{B_1}A_{n,k+1}-\frac{1}{4}\delta_{k,n-1}\right.$$
$$\left.\cdot\int_{B_1}a_n-\Gamma^{-2}2\pi(n-k)A_{n,k+1}+2\Gamma^{-2}(n-k)\int_{B_1}A_{n,k+1}\right].$$

Hence,

$$p=-\frac{3}{8\pi}\int_0^t\int_{B_1}\left(\sum_{n=0}^{\infty}\frac{1}{(2\pi i)^n}\sum_{k=0}^{n-1}\binom{n}{k}(2\pi i)^{k+1}z^k(n-k)A_{n,k+1}\right)$$
$$-\frac{1}{8\pi}\int_{B_1}\left(\sum_{n=0}^{\infty}\frac{1}{(2\pi i)^n}\sum_{k=0}^{n}\binom{n}{k}(2\pi i)^{k+1}z^k\delta_{k,n-1}a_n\right)$$
$$-\Gamma^{-2}\left(\sum_{n=0}^{\infty}\frac{1}{(2\pi i)^n}\sum_{k=0}^{n-1}\binom{n}{k}(2\pi i)^{k+1}z^k(n-k)A_{n,k+1}\right)$$
$$+\frac{\Gamma^{-2}}{\pi}\int_{B_1}\left(\sum_{n=0}^{\infty}\frac{1}{(2\pi i)^n}\sum_{k=0}^{n-1}\binom{n}{k}(2\pi i)^{k+1}z^k(n-k)A_{n,k+1}\right)$$
$$=-\frac{3}{8\pi}\int_0^t\int_{B_1}\frac{\partial\phi}{\partial z}-\frac{1}{8\pi}\int_{B_1}\frac{\partial\phi_0}{\partial z}-\Gamma^{-2}\frac{\partial\phi}{\partial z}+\frac{\Gamma^{-2}}{\pi}\int_{B_1}\frac{\partial\phi}{\partial z},$$

so that (2.13d) also holds.

In a similar way we can show that (2.13b) and (2.13c) are satisfied, thus completing the existence proof for Theorem 3.1. □

5.2. Uniqueness. Let (ϕ, p) be a solution of (2.13) satisfying (i)-(iv) of Theorem 3.1 for $\phi_0\equiv 0$. We wish to show that $\phi\equiv p\equiv 0$. Write

$$\phi(t,x,y,z)=\sum_{n=0}^{\infty}\phi^n(t,x,y)z^n/n!,\qquad p(t,x,y,z)=\sum_{n=0}^{\infty}p^n(t,x,y)z^n/n!.$$

Then, for each $n\geqq 0$,

$$\frac{\partial\phi^n}{\partial t}-\Gamma^{-2}\Delta\phi^n+\phi^n=-\alpha^2p^{n+1}-c\phi^{n+2}\quad\text{on } [0,T]\times B_1, \tag{5.9a}$$

$$\Delta p^n=\frac{\partial\phi^{n+1}}{\partial t}-2\phi^{n+1}-c\phi^{n+3}\quad\text{on } [0,T]\times B_1, \tag{5.9b}$$

(5.9c) $$\frac{\partial \phi^n}{\partial \nu} = -\frac{3\alpha^2}{2\pi}\int_0^t \int_{B_1} \phi^{n+2} + \frac{\alpha^2}{2\pi}\int_{B_1} \phi^{n+2} \quad \text{on } [0, T]\times \partial B_1,$$

(5.9d) $$p^n = -\frac{3}{8\pi}\int_0^t \int_{B_1} \phi^{n+1} - \Gamma^{-2}\phi^{n+1} + \frac{\Gamma^{-2}}{\pi}\int_{B_1} \phi^{n+1} \quad \text{on } [0, T]\times \partial B_1,$$

(5.9e) $$\phi^n(0, x, y) = 0.$$

Using (5.9a), (5.9c), (5.9e) together with the parabolic Schauder estimates we get

(5.10) $$\|\phi^n\|_{2+\alpha} \leqq k_1(|||p^{n+1}||| + \|\phi^{n+2}\|_{2+\alpha})$$

for some constant k_1.

Also, using (5.9b), (5.9d) and the maximum principle

$$|||p^{n-1}||| \leqq k_2(\|\phi^n\|_{2+\alpha} + \|\phi^{n+2}\|_{2+\alpha})$$

and using (5.10)

(5.11) $$|||p^{n-1}||| \leqq k_3(|||p^{n+1}||| + \|\phi^{n+2}\|_{2+\alpha})$$

for some constant k_3.

For $n \geqq 0$ set

$$\gamma_n = \|\phi^n\|_{2+\alpha} + |||p^{n-1}|||,$$

where, by definition, $p^{-1} \equiv 0$. Then, (5.10) and (5.11) give

(5.12) $$\gamma_n \leqq k_0\gamma_{n+2}, \qquad n \geqq 0$$

for some constant k_0.

On the other hand, using Cauchy's formula and part (iv) of Theorem 3.1 we see that, for $m \geqq 2$,

$$\gamma_m \leqq c_\varepsilon\left[m!\frac{(\eta_0+\varepsilon)^m e^m}{m^m} + (m-1)!\frac{(\eta_0+\varepsilon)^{m-1} e^{m-1}}{(m-1)^{m-1}}\right]$$

and from (5.5)

(5.13) $$\gamma_m \leqq \tilde{c}_\varepsilon(\eta_0+\varepsilon)^m m^{1/2} \quad \text{for } \varepsilon > 0, \quad m \geqq 2.$$

Fix $n \geqq 0$; then from (5.12)

(5.14) $$\gamma_n \leqq k_0^l\gamma_{n+2l} \quad \forall l \geqq 0$$

so that from (5.13), (5.14) we obtain

(5.15) $$\gamma_n \leqq \tilde{c}_\varepsilon k_0^l(\eta_0+\varepsilon)^{n+2l}(n+2l)^{1/2}, \qquad l \geqq 1.$$

Thus, for every $l \geqq 1$

(5.16) $$\gamma_n \leqq \tilde{c}_\varepsilon(\eta_0+\varepsilon)^n[((\eta_0+\varepsilon)^2 k_0)^l(n+2l)^{1/2}].$$

Hence, letting $l \to \infty$ we get

$$\gamma_n = 0 \quad \forall n \geqq 0,$$

provided $\eta_0 < (1/k_0)^{1/2}$ and $0 < \varepsilon < (1/k_0)^{1/2} - \eta_0$ and, consequently,

$$\phi \equiv p \equiv 0.$$

This completes the proof of Theorem 3.1 provided we choose $\eta_0 < \min(1/c_2, (1/k_0)^{1/2})$. (Recall that c_2 is the constant in (4.3), (4.4).) □

6. Properties of the solution.

THEOREM 6.1. *Let $\phi_0 \in A^{\alpha}_{\eta_0}$ where $0<\alpha<1$ and η_0 is as in Theorem* 3.1. *Let (ϕ, p) be the solution of* (2.13) *given in Theorem* 3.1. *Then*:

(a) *If ϕ_0 is periodic in z (i.e., $\phi_0(\cdot, z+Z)=\phi_0(\cdot, z)$ for some $Z\in\mathbb{R}$ and all $z\in\mathbb{R}$) then also ϕ and p are periodic in z, with the same period Z.*

(b) *Let $m\geqq 2$ and assume that*

$$\|\phi_0(\cdot, z)\|^0_{2+\alpha} \leqq \frac{c_0}{(1+|z|)^m} \tag{6.1}$$

for some constant $c_0>0$ $(z\in\mathbb{R})$. Then

$$\|\phi(\cdot, z)\|_{2+\alpha} + |||p(\cdot, z)||| = o((1+|z|)^{2-m}) \quad \text{as } z\to\infty. \tag{6.2}$$

THEOREM 6.2. *Let ϕ_0, ϕ and p be as in Theorem* 6.1. *If we assume that $\phi_0(x, y, z) = \phi_0(x, y, -z)$ and*

$$\int_{\mathbb{R}} \left\| \frac{\partial \phi_0}{\partial z} \right\|^0_{2+\alpha} dz < \infty, \tag{6.3}$$

then

$$\phi(t, x, y, z) = \phi(t, x, y, -z), \qquad p(t, x, y, z) = -p(t, x, y, -z) \tag{6.4}$$

and

$$\left\| \frac{\partial \phi}{\partial z}(\cdot, z) \right\|_{2+\alpha} + \left|\left| \frac{\partial p}{\partial z}(\cdot, z) \right|\right| = o(1) \quad \text{as } z\to\infty. \tag{6.5}$$

In order to prove Theorems 6.1 and 6.2 we shall use the following theorem.

THEOREM (Paley-Wiener). *Let K be a compact, convex, and balanced subset of $\mathbb{R}^n$, and let $I_K(\eta) = \sup_{\mu\in K} |\langle \eta, \mu\rangle|$ (where $\langle \eta, \mu\rangle = \eta\cdot\mu = \sum_{i=1}^n \eta_i\mu_i$).*

Let $T\in\mathcal{S}'$ (i.e., T is a tempered distribution). Then the following are equivalent:

(i) supp $T\subset K$.

(ii) *$\hat{T}$ has an entire holomorphic extension to $\mathbb{C}^n$ so that, for some $m\geqq 0$,*

$$|\hat{T}(\zeta)| \leqq c(1+|\zeta|)^m \exp I_K(\operatorname{Im}(\zeta)).$$

(*Actually m can be taken to be the order of T.*)

(For a proof see, e.g., [5, pp. 145-146].)

Proof of Theorem 6.1. Note that (a) follows immediately from the uniqueness of solutions: in fact, if we set $\tilde{\phi}(t, x, y, z) = \phi(t, x, y, z+Z)$, $\tilde{p}(t, x, y, z) = p(t, x, y, z+Z)$ it is clear that $(\tilde{\phi}, \tilde{p})$ is a solution of (2.13) satisfying (i)-(iv) of Theorem 3.1, so that, by uniqueness, we must have $\tilde{\phi}\equiv\phi$, $\tilde{p}\equiv p$.

We now turn to the proof of (b). Clearly, $u_0(x, y, \mu) = \phi_0(x, y, \cdot)\hat{}(\mu)$ satisfies

$$u_0(\cdot, \mu) \in \bar{C}_{2+\alpha}(\overline{B_1}), \tag{6.6a}$$

$$u_0(x, y, \cdot) \in C^{m-2}(\mathbb{R}). \tag{6.6b}$$

Also, an application of the Paley-Wiener theorem shows that $u_0(x, y, \cdot)$ is compactly supported and that, for each $(x, y)\in\overline{B_1}$

$$\text{supp } u_0(x, y, \cdot) \subset I_0 = \{\mu \,|\, |\mu| \leqq \eta_0\}. \tag{6.6c}$$

We may then consider the Fourier transformed system (3.3) with initial data $u_0(x, y, \mu)$. Following the proof of Lemma 4.1 we see that there exists a solution (u, v) of (3.3) satisfying:

$$u(t, x, y, \cdot), v(t, x, y, \cdot) \in C_0^{m-2}(\mathbb{R}),$$

$$\frac{\partial^l u}{\partial \mu^l}(\cdot, \mu) \in \bar{C}_{2+\alpha}([0, T] \times \overline{B_1}) \qquad (0 \leqq l \leqq m-2),$$

$$\frac{\partial^l v}{\partial \mu^l}(\cdot, \mu) \in \bar{C}_{\alpha}([0, T] \times \overline{B_1}) \qquad (0 \leqq l \leqq m-2),$$

$$\frac{\partial^l v}{\partial \mu^l}(t, \cdot, \mu) \in C^{2+\alpha}(\overline{B_1}) \qquad (0 \leqq l \leqq m-2),$$

$$\frac{\partial}{\partial t}\frac{\partial^l v}{\partial \mu^l}(t, \cdot, \mu) \in C^{2+\alpha}(B_1) \cap C^0(\overline{B_1}) \qquad (0 \leqq l \leqq m-2).$$

Furthermore, for each $(x, y) \in \overline{B_1}$, $t \in [0, T]$

$$\text{supp } u(t, x, y, \cdot) \subset I_0 \quad \text{and} \quad \text{supp } v(t, x, y, \cdot) \subset I_0. \tag{6.7}$$

Then, if we set

$$\tilde{\phi}(t, x, y, z) = u(t, x, y, \cdot)^{\vee}(z) \quad \text{and} \quad \tilde{p}(t, x, y, z) = v(t, x, y, \cdot)^{\vee}(z)$$

we see that $(\tilde{\phi}, \tilde{p})$ is a solution of (2.13) satisfying (6.2). But yet another application of the Paley-Wiener theorem (using (6.7)) implies that $(\tilde{\phi}, \tilde{p})$ satisfy (i)-(iv) of Theorem 3.1. Thus, by uniqueness, $(\tilde{\phi}, \tilde{p}) = (\phi, p)$, and this completes the proof of (b). □

Proof of Theorem 6.2. If $\phi_0(x, y, z) = \phi_0(x, y, -z)$, set $\tilde{\phi}(t, x, y, z) = \phi(t, x, y, -z)$ and $\tilde{p}(t, x, y, z) = -p(t, x, y, -z)$. It is easily checked then that $(\tilde{\phi}, \tilde{p})$ is a solution of (2.13) satisfying (i)-(iv) of Theorem 3.1 and hence, by uniqueness, we obtain $\tilde{\phi} \equiv \phi$ and $\tilde{p} \equiv p$. This proves (6.4).

Finally, (6.5) may be proved using an argument similar to that used for proving (6.2). □

Acknowledgments. The author thanks L. A. Romero for presenting the problem that is the subject of this paper and Professor A. Friedman for his help and encouragement. He also thanks Professor E. Fabes for several enlightening discussions.

NONLINEAR AGE-DEPENDENT POPULATION DYNAMICS WITH CONSTANT SIZE*

TANYA KOSTOVA† AND FABIO MILNER‡

Abstract. The existence of populations of constant size is studied for the Gurtin-MacCamy model. Necessary and sufficient conditions are given and some examples of their implications are considered.

Key words. population dynamics, age-structured, constant size population

AMS(MOS) subject classification. 92A15

1. Introduction. In their classic paper Gurtin and MacCamy [2] considered the following equations describing nonlinear age-dependent population dynamics with an age distribution $u = u(a, t)$ satisfying

$$\begin{aligned} &u_a + u_t = -d(a, P(t))u, \qquad a, t > 0, \\ &u(0, t) = \int_0^\infty b(a, P(t))u(a, t)\, da, \qquad t \geqq 0, \\ &u(a, 0) = \phi(a), \qquad a \geqq 0, \end{aligned} \tag{1.1}$$

where a is the age, t is the time, d is the deathrate, b is the birthrate, and $P(t) = \int_0^\infty u(a, t)\, da$ is the total population size.

In [2] a necessary and sufficient condition for the existence of an equilibrium age distribution $u(a)$ of (1.1) with a prescribed population size $P_0 = \int_0^\infty u(a)\, da$ was derived. More precisely, given a constant $P_0 > 0$ and assuming that $b(\cdot, P_0) \exp(-\int_0^\cdot d(s, P_0)\, ds) \in L^1(\mathbb{R}^+)$, a necessary and sufficient condition for the equations

$$\begin{aligned} &u_a = -d(a, P_0)u, \qquad a > 0, \\ &u(0) = \int_0^\infty b(a, P_0)u(a)\, da, \\ &P_0 = \int_0^\infty u(a)\, da \end{aligned}$$

to have a solution is that

$$\int_0^\infty b(a, P_0) \exp\left(-\int_0^a d(\tau, P_0)\, d\tau\right) da = 1. \tag{1.2}$$

In this case $u(a)$ is determined explicitly as

$$u(a) = \frac{P_0 \exp(-\int_0^a d(\tau, P_0)\, d\tau)}{\int_0^\infty \exp(-\int_0^a d(\tau, P_0)\, d\tau)\, da}. \tag{1.3}$$

Equilibrium solutions are of major importance, as they may be asymptotically stable provided some conditions on the birthrate $b(a, P)$, death rate $d(a, P)$, and the initial age distribution $\phi(a)$ are fulfilled; thus they may determine the asymptotic behavior of the solutions of (1.1) having suitable initial age distributions. That is why much attention has been paid to the investigation of the properties of the steady state (we refer to [1]-[5], just to mention some of this work). Still, in real situations the available data on population dynamics is more often given in terms of the total population size than in terms of the age distribution. There are contemporary examples of human populations whose size does not change in time, though they may have a time-dependent age distribution. An interesting question for which we find the answer here is what the relation between the birth and death rates is in such occasions.

This paper is organized as follows. In § 2 we derive some necessary and sufficient conditions for the existence of a population of constant size in terms of its initial distribution and its fertility and mortality. In § 3 we give some examples of consequences of these results and discuss their implications.

2. Populations of constant size. Let P_0 be a prescribed number. We shall assume that b, d, and ϕ in (1.1) are piecewise continuous functions, $d \not\equiv 0$, and ϕ is integrable. We shall say $u(a, t)$ is a *distribution of constant size* P_0 if $P(t) \equiv P_0$. Consider equations (1.1) and also assume the following compatibility conditions on initial and boundary data:

$$\int_0^\infty \phi(a)\, da = P_0, \qquad \phi(0) = \int_0^\infty b(a, P_0)\phi(a)\, da. \tag{2.1}$$

Suppose that (1.1) has a solution $u(a, t)$ such that $\int_0^\infty u(a, t)\, da = P_0$ for all t. Integrating the first equation of (1.1) in the age variable, we obtain the following equation for $P(t)$:

$$P'(t) = \int_0^\infty [b(a, P_0) - d(a, P_0)]u(a, t)\, da, \qquad t > 0,$$

and, therefore, in our case, $P(t) \equiv P_0$ is equivalent to the condition:

$$\int_0^\infty b(a, P_0)u(a, t)\, da = \int_0^\infty d(a, P_0)u(a, t)\, da, \qquad t \geqq 0. \tag{2.2}$$

This last equality is a necessary and sufficient condition for $u(a, t)$ to be of constant size but it still does not determine an explicit relation between $b(a, P_0)$ and $d(a, P_0)$. It obviously leads to the conclusion that $u(a, t)$ is the solution of the system

$$\begin{aligned} &u_a + u_t = -d(a, P_0)u, && a, t > 0, \\ &u(0, t) = \int_0^\infty d(a, P_0)u(a, t)\, da, && t \geqq 0, \\ &u(a, 0) = \phi(a), && a \geqq 0. \end{aligned} \tag{2.3}$$

Remark 2.1. The condition $b(a, P_0) = d(a, P_0)$ in (1.1) is sufficient for the validity of (2.2) and, therefore, any solution of (2.3) is of constant size. This system is one which also admits equilibrium age distributions in the case where $\int_0^\infty d(a, P_0)\, da = \infty$, since then, $\int_0^\infty d(a, P_0) \exp\left(-\int_0^a d(s, P_0)\, ds\right) da = 1$ (see (1.2)). Equilibrium distributions exist only when $\phi(a)$ is given by (1.3). Hence, for any other function ϕ, the solution of (2.3) is of constant size but not an equilibrium one.

Several questions arise, which we shall answer here.

(a) When is there a nonequilibrium solution $u(a, t)$ of (1.1) with $P(t) \equiv P_0$?

(b) Given an initial age distribution $\phi(a)$ with $\int_0^\infty \phi(a)\, da = P_0$, does a solution with constant size exist?

(c) If the answer to (b) is yes, what condition must $b(a, P_0)$ and $d(a, P_0)$ satisfy?

It is well known (see [2]) that the solution of (1.1) can be represented in the following implicit way:

$$u(a, t) = \begin{cases} B(t-a, P_0) \exp\left(-\int_0^a d(\tau, P_0)\, d\tau\right), & t \geqq a, \\ \phi(a-t) \exp\left(-\int_0^t d(a-t+\tau, P_0)\, d\tau\right), & t < a, \end{cases} \tag{2.4}$$

where

$$B(s, P_0) = \int_0^\infty b(a, P_0) u(a, s)\, da \tag{2.5}$$

is the birth function.

Combining (2.4) and (2.5) we obtain the following formula:

$$\begin{aligned} B(t, P_0) = &\int_0^t b(a, P_0) B(t-a, P_0) \exp\left(-\int_0^a d(\tau, P_0)\, d\tau\right) da \\ &+ \int_t^\infty b(a, P_0) \phi(a-t) \exp\left(-\int_0^t d(a-t+\tau, P_0)\, d\tau\right) da. \end{aligned} \tag{2.6}$$

Recall now that we have assumed that $P(t) \equiv P_0$ and, therefore, (2.2) is valid. This means that $B(t, P_0) = \int_0^\infty d(a, P_0) u(a, t)\, da$, and thus we shall also have

$$\begin{aligned} B(t, P_0) = &\int_0^t d(a, P_0) B(t-a, P_0) \exp\left(-\int_0^a d(\tau, P_0)\, d\tau\right) da \\ &+ \int_t^\infty d(a, P_0) \phi(a-t) \exp\left(-\int_0^t d(a-t+\tau, P_0)\, d\tau\right) da. \end{aligned} \tag{2.7}$$

Conversely, if (2.7) is valid, then (2.2) will hold (because (2.6) holds) and $u(a, t)$ will be of constant size. Equation (2.7) is another necessary and sufficient condition for the existence of a population of constant size P_0; but it is still implicit, as we do not know $B(t, P_0)$. We can use Laplace transforms to obtain an equation involving only b, d, and ϕ. For this purpose, assume that $d(a, P_0)$ and $b(a, P_0)$ are bounded. As $u(\cdot, t) \in L^1(\mathbb{R}^+)$ for each t (since $\int_0^\infty u(a, t)\, da \equiv P_0$), then $B(t, P_0) = \int_0^\infty b(a, P_0) u(a, t)\, da \leqq \|b\|_{L^\infty} P_0$, that is, $B(t, P_0)$ is a bounded function of t. On the other hand, $\int_t^\infty b(a, P_0) \phi(a-t) \exp\left(-\int_0^t d(a-t+\tau, P_0)\, d\tau\right) da \leqq \|b\|_{L^\infty} \int_0^\infty \phi(s)\, ds = \|b\|_{L^\infty} P_0$ and, similarly, $\int_t^\infty d(a, P_0) \phi(a-t) \exp\left(-\int_0^t d(a-t+\tau, P_0)\, d\tau\right) da$ is bounded. Therefore, for $s \geqq 0$, we can take the Laplace transform $\mathscr{L}$ of both sides of (2.6) and (2.7) and, making use of the special convolution form of the first integrals in the right-hand sides, we arrive at

$$\mathscr{L}(B)(s) = \mathscr{L}(B)(s) \mathscr{L}(\Pi)(s) + \mathscr{L}(B_0)(s), \tag{2.8}$$

$$\mathscr{L}(B)(s) = \mathscr{L}(B)(s) \mathscr{L}(\theta)(s) + \mathscr{L}(D_0)(s), \tag{2.9}$$

where

$$\mathcal{L}(f)(s) = \int_0^\infty e^{-st} f(t)\, dt,$$

$$\Pi(t) = b(t, P_0) \exp\left(-\int_0^t d(\tau, P_0)\, d\tau\right),$$

$$\theta(t) = d(t, P_0) \exp\left(-\int_0^t d(\tau, P_0)\, d\tau\right), \tag{2.10}$$

$$B_0(t) = \int_0^\infty \phi(a) b(a+t, P_0) \exp\left(-\int_0^t d(a+\tau, P_0)\, d\tau\right) da,$$

$$D_0(t) = \int_0^\infty \phi(a) d(a+t, P_0) \exp\left(-\int_0^t d(a+\tau, P_0)\, d\tau\right) da.$$

Therefore, if $u(a, t)$ is a solution of (1.1) of constant size P_0, then (2.9) holds for all $s > 0$ and, of course, (2.8) does too.

Conversely, if (2.9) is valid then, as (2.8) holds, (2.6) and (2.7) will also hold and the solution of (1.1) will be of constant size.

Now consider the quantity

$$1 - \mathcal{L}(\theta)(s) = 1 - \int_0^\infty e^{-st}\, d(t, P_0) \exp\left(-\int_0^t d(\tau, P_0)\, d\tau\right) dt.$$

For $s = 0$,

$$0 \leqq \mathcal{L}(\theta)(0) = 1 - \exp\left(-\int_0^\infty d(\tau, P_0)\, d\tau\right) \leqq 1.$$

If we note that for $s > 0$, we have $0 \leqq \mathcal{L}(\theta)(s) < \mathcal{L}(\theta)(0)$, then we see that

$$1 - \mathcal{L}(\theta)(s) > 0 \quad \text{for } s > 0.$$

Therefore, we can express $\mathcal{L}(B)$ from (2.9) as

$$\mathcal{L}(B)(s) = \mathcal{L}(D_0)(s)/(1 - \mathcal{L}(\theta)(s)),$$

which, substituted in (2.8), yields the relation

$$\frac{1 - \mathcal{L}(\Pi)(s)}{1 - \mathcal{L}(\theta)(s)} \mathcal{L}(D_0)(s) = \mathcal{L}(B_0)(s);$$

that is,

$$[1 - \mathcal{L}(\Pi)(s)]\mathcal{L}(D_0)(s) = \mathcal{L}(B_0)(s)[1 - \mathcal{L}(\theta)(s)], \qquad s > 0. \tag{2.11}$$

This last equality can also be rewritten in another way, as we show below. Having in mind that for $s > 0$ and for $X(\cdot, t) \in L^1(\mathbb{R}^+)$, $t > 0$, the following relation holds:

$$\mathcal{L}\left(\int_0^\infty X(a, t)\, da\right) = \frac{1}{s}\int_0^\infty X(a, 0)\, da + \frac{1}{s}\mathcal{L}\left(\int_0^\infty \frac{\partial X}{\partial t}(a, t)\, da\right),$$

we obtain, after some sample computations, the relations

$$\mathcal{L}(B_0)(s) = \frac{1}{s}\phi(0)(1 - \mathcal{L}(\Pi)(s))$$

$$-\frac{1}{s}\mathcal{L}\left(\int_0^\infty (\phi'(a) + d(a, P_0)\phi(a)) b(a+t, P_0)\right.$$

$$\left. \cdot \exp\left(-\int_0^t d(a+\tau, P_0)\, d\tau\right) da\right)(s),$$

and

$$\mathscr{L}(D_0)(s)=\frac{1}{s}\int_0^\infty d(a)\phi(a)\,da(1-\mathscr{L}(\theta)(s))$$
$$-\frac{1}{s}\mathscr{L}\Big(\int_0^\infty[\phi'(a)+d(a,P_0)\phi(a)]d(a+t,P_0)$$
$$\cdot\exp\Big(-\int_0^t d(a+\tau,P_0)\,d\tau\Big)\,da\Big)(s).$$

It follows that (2.11) is equivalent to the following two relations:

$$\phi(0)=\int_0^\infty d(a,P_0)\phi(a)\,da,$$
$$[1-\mathscr{L}(\Pi)]\mathscr{L}\Big(\int_0^\infty[\phi'(s)+d(s,P_0)\phi(s)]d(s+t,P_0)$$
$$\cdot\exp\Big(-\int_0^t d(s+\tau,P_0)\,d\tau\Big)\,ds\Big) \tag{2.12}$$
$$=[1-\mathscr{L}(\theta)]\mathscr{L}\Big(\int_0^\infty[\phi'(s)+d(s,P_0)\phi(s)]b(s+t,P_0)$$
$$\cdot\exp\Big(-\int_0^t d(s+\tau,P_0)\,d\tau\Big)\,ds\Big),$$

as seen by substituting $\phi(0)$, D_0, and B_0 in (2.11). We have shown that (2.11) and (2.12) are other necessary and sufficient conditions for the solution (1.1) to be of constant size.

Let $Q(t)$ and $R(t)$ be defined as

$$Q(t)=\int_0^\infty[\phi'(s)+d(s,P_0)\phi(s)]d(s+t,P_0)\exp\Big(-\int_0^t d(s+\tau,P_0)\,d\tau\Big)\,ds,$$
$$R(t)=\int_0^\infty[\phi'(s)+d(s,P_0)\phi(s)]b(s+t,P_0)\exp\Big(-\int_0^t d(s+\tau,P_0)\,d\tau\Big)\,ds.$$

Taking inverse Laplace transforms, we obtain the following result.

THEOREM 2.1. *Suppose that ϕ, b, d are bounded, nonnegative, piecewise continuous functions, satisfying the compatibility conditions* (2.1). *The necessary and sufficient condition for the solution of* (1.1) *to be of constant size P_0 is that either of the following relations holds*:

(i) $$D_0(t)-\int_0^t D_0(s)\Pi(t-s)\,ds=B_0(t)-\int_0^t B_0(s)\theta(t-s)\,ds,$$

where D_0, B_0, Π, and θ are defined by (2.10),

(ii) $$Q(t)-\int_0^t Q(s)\Pi(t-s)\,ds=R(t)-\int_0^t R(s)\theta(t-s)\,ds,$$
$$\phi(0)=\int_0^\infty d(a,P_0)\phi(a)\,da.$$

Next we shall derive another necessary and sufficient condition for the solution of (1.1) to be of constant size, which proves useful for some special cases and does not impose boundedness restrictions on b, d, and ϕ. Let us assume again that (1.1) has a solution of constant size P_0. As $P_0 \equiv \int_0^\infty u(a, t)\, da$, then integrating (2.4) in age and differentiating in time, we get

$$0 = \int_0^t B_t(t-a, P_0) \exp\left(-\int_0^a d(\tau, P_0)\, d\tau\right) da + \int_t^\infty \frac{d}{dt}\left[\phi(a-t) \exp\left(-\int_0^t d(a-t+\tau, P_0)\, dt\right)\right] da. \tag{2.13}$$

The second term in the right-hand side of (2.13) depends only on the functions ϕ and d and (2.13) may then be considered as a Volterra equation for $B_t(t-a, P_0)$. Let us denote

$$F(t) = -\int_t^\infty \frac{d}{dt}\left[\phi(a-t) \exp\left(-\int_0^t d(a-t+\tau, P_0)\, d\tau\right)\right] da$$
$$= \int_t^\infty [\phi'(a-t) + \phi(a-t) d(a-t, P_0)] \exp\left(-\int_0^t d(a-t+\tau, P_0)\, d\tau\right) da.$$

Consequently,

$$F(t) = \int_0^\infty [\phi'(s) + \phi(s) d(s, P_0)] \exp\left(-\int_0^t d(s+\tau, P_0)\, d\tau\right) ds. \tag{2.14}$$

Let $H(s) = B_t(s, P_0)$. Then, $H(t)$ satisfies the following Volterra equation of the first kind

$$\int_0^t H(s) \exp\left(-\int_0^{t-s} d(\tau, P_0)\, d\tau\right) ds = F(t). \tag{2.15}$$

On the other hand, since (2.2) is valid for all t, including $t = 0$, it follows from (2.2) and (2.5) that

$$\phi(0) = B(0, P_0) = \int_0^\infty b(a, P_0)\phi(a)\, da = \int_0^\infty d(a, P_0)\phi(a)\, da.$$

Then, (2.14) implies that

$$F(0) = -\phi(0) + \int_0^\infty \phi(s) d(s, P_0)\, ds = 0.$$

Therefore, we can use the following well-known result. Let $I = [0, T]$ and let $S = \{(t, s): 0 \leqq s \leqq t \leqq T\}$. Let $F \in C^1(I)$ with $F(0) = 0$ and let $K(t, s)$, $\partial K/\partial t \in C^0(S)$. Assume that $K(t, t) \neq 0$ for all $t \in I$. Under these conditions $\int_0^t K(t, s) y(s)\, ds = F(t)$ has a unique solution $y \in C^0(I)$.

Applying this theorem, we see that, if $d \in C^0(I)$ and

$$[\phi'(\cdot) + \phi(\cdot) d(\cdot, P_0)] \exp\left(-\int_0^t d(\cdot + \tau, P_0)\, d\tau\right) \in L^1(\mathbb{R}^+),$$

then (2.15) has a unique solution H:

$$H = \mathscr{L}^{-1}\left(\mathscr{L}(F)/\mathscr{L}\left(\exp\left(-\int d(\cdot, P_0)\right)\right)\right),$$

where $\mathscr{L}^{-1}(f)$ is the inverse Laplace transform of f. Therefore, $B(t, P_0)$ can be determined explicitly in terms of H by integrating

$$B(t, P_0) = \phi(0) + \int_0^t H(s)\, ds. \tag{2.16}$$

If B is then inserted in the renewal equation (2.6), we arrive at a necessary condition which $b(a, P_0)$ and $d(a, P_0)$ must satisfy.

On the other hand, if u is a solution of (1.1), then it satisfies (2.6) with $B(t, P_0) = \int_0^\infty b(a, P_0)u(a, t)\, da$. Assume that (2.14)-(2.16) are fulfilled. It follows that $P'(t) = 0$ and therefore $P(t) \equiv P_0$. Thus, we have proved the following result.

THEOREM 2.2. *Let $d \in C^0(I)$ and let $\phi \in L^1(\mathbb{R}^+)$ and b satisfy the compatibility conditions* (2.1) *and* $[\phi'(\cdot) + \phi(\cdot)d(\cdot, P_0)] \exp(-\int_0^t d(\cdot + \tau, P_0)\, d\tau) \in L^1(\mathbb{R}^+)$ *for each $t \in I$. Then,* (1.1) *has a solution with constant size P_0 in the time interval $I = [0, T]$ if and only if $b(a, P_0)$, $d(a, P_0)$, $\phi(a)$, and $B(t)$ satisfy* (2.6) *and* (2.14)-(2.16). *In such case, the solution $u(a, t)$ is given explicitly by* (2.4), *where $B(t)$ is determined from* (2.15), *and* (2.16).

Remark 2.2. Note that in this theorem we do not impose boundedness conditions on b and ϕ as we did in Theorem 2.1.

Remark 2.3. Let $P_0 > 0$ and let the assumptions of Theorem 2.2 hold. Let $d(a, P_0)$ and $\phi(a)$ be such that $F(t) \not\equiv 0$ (which is always possible, in view of (2.14)). Then, $B(t)$ can be determined uniquely and $u(a, t)$ subsequently from it. We should note that such populations of constant size are not equilibrium distributions. Indeed, suppose that $u(a, t) \equiv u(a)$. Then, $B(t) = B(0) = \phi(0)$ and, therefore, $H(u) = 0$ and $F(t) = 0$. This is a contradiction. Therefore $u(a, t)$ is not an equilibrium distribution of (1.1).

The only case when there does not exist a nonequilibrium solution with constant size is when $\phi(s) = \phi(0) \exp(-\int_0^s d(\tau, P_0)\, d\tau)$. In this case $F \equiv 0$ (since $\phi' + d\phi \equiv 0$) and so, $H \equiv 0$, which gives $B(t) \equiv B(0) = \phi(0)$. Therefore, the relation following (2.15) transforms into $1 = \int_0^\infty b(a, P_0) \exp(-\int_0^a d(\tau, P_0)\, d\tau)\, da$ and $u(a, t) = \phi(0) \exp(-\int_0^a d(\tau, P_0)\, d\tau) = u(a)$. In other words, from an initial equilibrium distribution the only possible solution of (1.1) with constant size is that equilibrium distribution (1.3). We have proved the following result.

THEOREM 2.3. *Let $P_0 > 0$ be given and let b and ϕ satisfy the compatibility conditions* (2.1). *Then, for any continuous function $d(a, P_0)$ such that $F(t) \not\equiv 0$ and such that* $(\phi'(s) + \phi(s)d(s, P_0)) \exp(-\int_0^t d(s + \tau, P_0)\, d\tau) \in L^1$, *there exists a nonequilibrium solution $u(a, t)$ of* (1.1) *such that $\int_0^\infty u(a, t)\, da \equiv P_0$. Furthermore, if $\phi(a) = \phi(0) \exp(-\int_0^a d(\tau, P_0)\, d\tau)$, then, the solution is the equilibrium one, $u(a, t) \equiv \phi(a)$.*

Theorem 2.3 answers the questions (a), (b), and (c) at the beginning of this section.

3. Some examples. We shall treat some special cases of (1.1) and discuss its solutions of constant size applying the above theory.

(I) Let $d(a, P) \equiv d$. Then $u(a, t)$ is a solution of constant size P_0 if and only if (2.12) holds. Since $1 - \mathscr{L}(\theta)$ can vanish at one point, at most, and all the functions of which we take transforms are piecewise continuous, it follows that (2.12), for the case of a constant death rate, is equivalent to the following relations:

$$\int_0^\infty [\phi'(a) + d\phi(a)]\, da = 0, \tag{3.1}$$

$$\int_0^\infty [\phi'(a) + d\phi(a)]b(a + t, P_0)\, da = 0, \qquad t \geqq 0. \tag{3.2}$$

The last relation follows by observing that, if (3.1) holds and d is constant, then, the left-hand side of the second equation of (2.12) vanishes. Conversely, (3.1) and (3.2) imply that u has constant size invoking Theorem 2.1. In summary, if the death rate is constant and b and ϕ are piecewise continuous bounded functions such that the compatibility conditions (2.1) hold, then u is of constant size if and only if (3.1) and (3.2) hold. In such case, the solution of (1.1) of size P_0 is

$$u(a,t)=\begin{cases} dP_0\, e^{-ad}, & t \geqq a, \\ \phi(a-t)\, e^{-td}, & t < a. \end{cases}$$

(II) Let

$$\phi(s)=\begin{cases} K>0, & 0 \leqq s \leqq c, \\ 0 \quad \text{otherwise}, \end{cases}$$

be a uniform distribution on the interval $(0, c)$ so that $P_0 = Kc$. Assume that all individuals die before reaching age c. Then, $\int_0^c d(a, P_0)\, da = +\infty$. Now note that (1.1) and (2.2) give in this case

$$\phi(0) = B(0) = \int_0^\infty b(a, P_0)u(a, 0)\, da = \int_0^c b(a, P_0)\phi(0)\, da$$
$$= \int_0^c d(a, P_0)\phi(0)\, da,$$

which implies

$$\int_0^c d(a, P_0)\, da = \int_0^c b(a, P_0)\, da = 1,$$

a contradiction. Therefore, given a uniform initial age-distribution on the finite age interval $(0, c)$, if the initial and boundary date are compatible, then, for any death rate $d(a)$ such that the life span of any individual is at most c, the population cannot have constant size, independently of the birthrate b.

(III) Let $b(a, P) \equiv b$. Then, u is of constant size P_0 if, and only if,

$$B(t) = \int_0^\infty b(a, P_0)u(a, t)\, da = b \int_0^\infty u(a, t)\, da = bP(t) \equiv bP_0,$$

which is equivalent to the following relations:

$$B_t(t) = 0, \qquad B(0) = bP_0.$$

Using Theorem 2.2 we see that these relations are equivalent to the following necessary and sufficient conditions for a population with constant birthrate b to have constant size P_0:

$$\int_0^\infty [\phi'(a) + d(a, P_0)\phi(a)] \exp\left(-\int_0^t d(a+\tau, P_0)\, d\tau\right) da = 0, \qquad t \geqq 0,$$

$$\phi(0) = bP_0.$$

In such a case, u is explicitly given by

$$u(a,t)=\begin{cases} bP_0 \exp\left(-\int_0^a d(\tau, P_0)\, d\tau\right), & t \geqq a, \\ \phi(a-t) \exp\left(-\int_0^t d(a-t+\tau, P_0)\, d\tau\right), & t < a. \end{cases}$$

L^{∞}_{loc}-ESTIMATES FOR LOCAL SOLUTIONS OF DEGENERATE PARABOLIC EQUATIONS*

DANIELE ANDREUCCI†

Abstract. A local sup-estimate for local (sub)solutions of degenerate parabolic equations is proved. Such *local* estimates do not involve any dependence on the initial and boundary data, but rather, provide a bound for the solution in a given domain, only in terms of some integral norm of the solution in a larger domain. Estimates of this kind for solutions of linear *nondegenerate* parabolic equations are due to Moser (*Comm. Pure Appl. Math.*, 17 (1964), pp. 101-134). Sharp estimates of this kind have not been available in the literature in the degenerate case. The new input here is an interpolation process that permits one to deal with the degeneracy of the equation. The estimates shown here are sharp and reduce to the classical ones of Moser in the linear nondegenerate case.

Key words. degenerate parabolic equations, local solutions, local sup-estimates

AMS(MOS) subject classifications. 35K65, 35B45

1. Introduction. Local sup-estimates for solutions of the porous media equation (or its quasilinear variations) are employed in several papers to study the behavior (local or at infinity) of such solutions (e.g., [1], [3], [4]).

We are interested here in local sup-estimates that are completely independent of initial or boundary data. Such a dependence typically appears in estimates relying on the maximum principle. To our knowledge, quantitative estimates of this kind are not present in the literature, in a form that is sharp or comparable with analogous results for nondegenerate equations. In this paper we prove a sharp estimate (see (1.6) below), coinciding with known results in the linear case [6]. The estimate will take the form of an interpolation inequality with a free parameter.

We remark that sup-estimates for solutions defined in the whole space $\mathbb{R}^N$ have been obtained in [2], where, in particular, a connection is traced between regularizing effect and sup-estimates.

We will consider nonnegative local subsolutions of the equation

$$u_t - \operatorname{div} \vec{a}(x, t, u, \nabla\phi(u)) = 0, \tag{1.1}$$

where $\phi : [0, \infty) \to [0, \infty)$ is a locally AC (absolutely continuous) function satisfying, for some $\Lambda > 1$,

$$1 < \frac{\phi'(s)s}{\phi(s)} \leqq \Lambda \quad \text{a.e. } s > 0. \tag{1.2}$$

The first inequality in (1.2) can be allowed to be nonstrict; see Remarks 3.1 and 3.3 below. For the sake of brevity we carry out the proofs only in case (1.2).

We define $\Phi(s) = \phi(s)s^{-1}$, $s > 0$, and assume in the following that the function $(x, t) \to \vec{a}(x, t, u(x, t), \nabla\phi(u(x, t))$ is measurable and satisfies

$$\vec{a}(x, t, u, \nabla\phi(u)) \cdot \nabla u \geqq \Lambda^{-1}\Phi(u)|\nabla u|^2, \tag{1.3}$$

$$|\vec{a}(x, t, u, \nabla\phi(u))| \leqq \Lambda\Phi(u)|\nabla u| \tag{1.4}$$

(of course the constants in (1.3), (1.4) are named Λ just for notational simplicity).

In order to state our main result we introduce the following notation:

$$B_\rho = \{x \in \mathbb{R}^N \,|\, |x - x_0| < \rho\},$$

$$Q_\infty = B_\rho \times \left(\frac{t}{2}, t\right),$$

$$Q_0 = B_{(1+\sigma)\rho} \times \left(\frac{t}{2} - \frac{\sigma}{2} t, t\right),$$

where ρ, $t > 0$, $\sigma \in (0, 1)$, $x_0 \in \mathbb{R}^N$ are given. We also use the notation

$$\fint\!\!\int_{Q_0} f\,dx\,dt = (\text{meas}\,(Q_0))^{-1} \int\!\!\int_{Q_0} f\,dx\,dt.$$

Let us define a local subsolution u to (1.1) in Q_0 as a function

$$u \in C(t_0, t; L^1(B_{(1+\sigma)\rho})), \qquad t_0 \equiv \frac{t}{2} - \frac{\sigma}{2} t,$$

$$\nabla \phi(u) \in L^2(Q_0),$$

satisfying

$$u_t - \operatorname{div} \vec{a}(x, t, u, \nabla \phi(u)) \leqq 0, \tag{1.5}$$

in the usual weak sense in Q_0 (see, for example, [5]). Then we have the following theorem.

THEOREM. *Let u be a bounded nonnegative local subsolution of* (1.1) *in Q_0. Then for all η, $\varepsilon > 0$*

$$\begin{aligned} \phi(\|u\|_{\infty, Q_\infty}) &\leqq \eta \frac{\rho^2}{t} \Phi^{-1}\left(\eta \frac{\rho^2}{t}\right) \\ &+ \gamma\left(1 + \frac{1}{\eta}\right)^{(N+2)/2\varepsilon} \left(\frac{t}{\rho^2}\right)^{1/\varepsilon} \left(\fint\!\!\int_{Q_0} \Phi(u) \phi(u)^\varepsilon \,dx\,d\tau\right)^{1/\varepsilon}, \end{aligned} \tag{1.6}$$

where $\gamma = \gamma(\varepsilon, \sigma, \Lambda, N)$: γ becomes unbounded as ε (or σ, or Λ^{-1}) tends to zero.

We note that (1.6) is also valid for any nonnegative subsolution which can be approximated locally by bounded subsolutions.

In § 2 we prove the theorem, and in § 3 we collect some comments and generalizations.

2. Proof of (1.6). We will need the following elementary inequalities:

$$h^\Lambda \phi(s) \leqq \phi(sh) \leqq h \phi(s), \qquad s > 0, \quad h \in (0, 1), \tag{2.1}$$

$$h^{\Lambda - 1} \Phi(s) \leqq \Phi(sh) \leqq \Phi(s), \qquad s > 0, \quad h \in (0, 1), \tag{2.2}$$

(2.1) is proved integrating on (hs, s):

$$\frac{1}{s} \leqq \frac{\phi'(s)}{\phi(s)} \leqq \frac{\Lambda}{s},$$

and (2.2) follows from (2.1).

We notice that (2.1), (2.2) imply that $\phi(s)$ and $\phi(s)^\alpha s^{-2}$ $(\alpha > 2)$ are increasing functions of s, and that Φ is nondecreasing.

LEMMA. *Let us define for* $z,\ z_0 \geqq 0$, *and* $\alpha > 2$

$$F(z, z_0) = \left(\int_{z_0}^{z} \left(\int_{z_0}^{r} \frac{\phi(s)^\alpha}{s^2}\, ds \right)_+ dr \right)^{1/2}.$$

Then we have for all $z > 0$, $z \neq z_0$,

$$\frac{\phi(z)^\alpha}{z^2} \geqq c \left| \frac{\partial F}{\partial z}(z, z_0) \right|^2, \tag{2.3}$$

where $c = c(\alpha, \Lambda)$.

Proof. If $z \in (0, z_0)$, $F(z, z_0) \equiv 0$ and there is nothing to prove.

If $z > z_0$,

$$\left| \frac{\partial F}{\partial z}(z, z_0) \right|^2 = \frac{\left(\int_{z_0}^{z} \frac{\phi(s)^\alpha}{s^2}\, ds \right)^2}{4 \left(\int_{z_0}^{z} dr \int_{z_0}^{r} \frac{\phi(s)^\alpha}{s^2}\, ds \right)}. \tag{2.4}$$

Hence

$$4 \left| \frac{\partial F}{\partial z} \right|^2 \leqq \frac{\phi(z)^{2\alpha}}{z^4} (z - z_0)^2 \left(z^{-2} \int_{z_0}^{z} dr \int_{z_0}^{r} \phi(s)^\alpha\, ds \right)^{-1}.$$

Now we consider two cases: (i) $z_0 \geqq z/2$ and (ii) $z_0 < z/2$. In case (i)

$$\int_{z_0}^{z} dr \int_{z_0}^{r} \phi(s)^\alpha\, ds \geqq \int_{z_0}^{z} dr \int_{z_0}^{r} \phi\left(\frac{z}{2}\right)^\alpha ds \geqq 2^{-\Lambda\alpha - 1} \phi(z)^\alpha (z - z_0)^2.$$

In case (ii)

$$\int_{z_0}^{z} dr \int_{z_0}^{r} \phi(s)^\alpha\, ds \geqq \int_{z/2}^{z} dr \int_{z/2}^{r} \phi\left(\frac{z}{2}\right)^\alpha ds \geqq 2^{-\Lambda\alpha - 3} \phi(z)^\alpha z^2.$$

Therefore (2.3) is proved with $c = 2^{-\Lambda\alpha - 1}$.

Remark 1.1. Notice that (2.3) implies $F(\cdot, z_0) \in \mathrm{Lip}_{\mathrm{loc}}(\mathbb{R}^+)$ and that $F(z, \cdot)$ is nonincreasing on $\mathbb{R}^+$.

Proof of the theorem. We use the approach of [1] and define for all $n \geqq 0$

$$t_n = \frac{t}{2} - \frac{\sigma t}{2^{n+1}}, \quad \rho_n = \rho + \frac{\sigma}{2^n}\rho, \quad k_n = k - \frac{k}{2^{n+1}},$$

$$B_n = B_{\rho_n}, \quad Q_n = B_{\rho_n} \times (t_n, t), \quad B_n(\tau) = B_n \times \{\tau\};$$

here $k > 0$ is to be chosen later.

We consider also a cutoff function ζ_n such that

$$\zeta_n(x, \tau) \equiv 0, \quad (x, \tau) \notin Q_n, \qquad \zeta_n(x, \tau) \equiv 1, \quad (x, \tau) \in Q_{n+1},$$

$$|\nabla \zeta_n| \leqq \frac{2^{n+1}}{\sigma\rho}, \qquad 0 \leqq \zeta_{n\tau} \leqq \frac{2^{n+2}}{\sigma t},$$

and we use as testing functions in the weak formulation of (1.5)

$$f_n(x, \tau) = \left(\int_{k_{n+1}}^{u(x,\tau)} \frac{\phi(s)^\alpha}{s^2}\, ds \right)_+ \zeta_n(x, \tau)^2,$$

with $\alpha > 2$.

The time part of (1.5) yields for all $\bar{t} \in (t_n, t)$ (the calculations below can be made rigorous by means of a Steklov averaging process)

$$\begin{aligned}
&\iint_{Q_n \cap \{\tau < \bar{t}\}} u_\tau \left(\int_{k_{n+1}}^{u} \frac{\phi(s)^\alpha}{s^2}\, ds \right)_+ \zeta_n^2 \, dx\, d\tau \\
&\quad = \iint_{Q_n \cap \{\tau < \bar{t}\}} \zeta_n^2 \frac{\partial}{\partial \tau} F(u, k_{n+1})^2 \, dx\, d\tau \\
&\quad \geqq -\frac{2^{n+3}}{\sigma t} \iint_{Q_n} F(u, k_n)^2 \, dx\, d\tau + \int_{B_n(\bar{t})} F(u, k_{n+1})^2 \zeta_n^2 \, dx.
\end{aligned} \tag{2.5}$$

We use the lemma in treating the space part:

$$\begin{aligned}
-\iint_{Q_n} (\operatorname{div} \vec{a}) f_n \, dx\, d\tau &= \iint_{Q_n} \vec{a} \cdot \nabla \left(\left(\int_{k_{n+1}}^{u} \frac{\phi(s)^\alpha}{s^2}\, ds \right)_+ \zeta_n^2 \right) dx\, d\tau \\
&\geqq \frac{1}{\Lambda} \iint_{Q_n \cap \{u > k_{n+1}\}} \Phi(u) \frac{\phi(u)^\alpha}{u^2} |\nabla u|^2 \zeta_n^2 \, dx\, d\tau \\
&\quad - 2\Lambda \iint_{Q_n} \Phi(u) \left(\int_{k_{n+1}}^{u} \frac{\phi(s)^\alpha}{s^2}\, ds \right)_+ \zeta_n |\nabla \zeta_n| |\nabla u| \, dx\, d\tau \\
&\geqq 2^{-3\alpha\Lambda} \iint_{Q_n} \Phi(u) |\nabla F(u, k_{n+1})|^2 \zeta_n^2 \, dx\, d\tau \\
&\quad - \frac{2\Lambda^2}{\theta} \iint_{Q_n} \Phi(u) |\nabla \zeta_n|^2 F(u, k_{n+1})^2 \, dx\, d\tau \\
&\quad - \frac{\theta}{2} \iint_{Q_n} \Phi(u) \zeta_n^2 |\nabla u|^2 F(u, k_{n+1})^{-2} \left(\int_{k_{n+1}}^{u} \frac{\phi(s)^\alpha}{s^2}\, ds \right)_+^2 dx\, d\tau.
\end{aligned}$$

But

$$F(z, z_0)^{-2} \left(\int_{z_0}^{z} \frac{\phi(s)^\alpha}{s^2}\, ds \right)^2 = 4 \left| \frac{\partial F}{\partial z}(z, z_0) \right|^2;$$

therefore, for a $\theta > 0$ suitably chosen, we arrive at the following inequality:

$$\begin{aligned}
-\iint_{Q_n} (\operatorname{div} \vec{a}) f_n \, dx\, d\tau &\geqq 2^{-4\alpha\Lambda} \Phi(k) \iint_{Q_n} |\nabla F(u, k_{n+1}) \zeta_n|^2 \, dx\, d\tau \\
&\quad - 2^{8\alpha\Lambda} \frac{2^{2n}}{\sigma^2 \rho^2} \iint_{Q_n} \Phi(u) F(u, k_n)^2 \, dx\, d\tau,
\end{aligned} \tag{2.6}$$

where we have also used $u \geqq k_{n+1} > k_0 = (k/2)$, and (2.2).

Adding (2.5) to (2.6) we get

$$\begin{aligned}
&\sup_{t_n \leqq \tau \leqq t} \int_{B_n(\tau)} F(u, k_{n+1})^2 \zeta_n^2 \, dx + \Phi(k) \iint_{Q_n} |\nabla F(u, k_{n+1}) \zeta_n|^2 \, dx\, d\tau \\
&\qquad \leqq \gamma_1 \frac{2^{2n}}{\sigma^2 t} \left(1 + \frac{t}{\rho^2} \Phi(\|u\|_{\infty, Q_0}) \right) \iint_{Q_n} F(u, k_n)^2 \, dx\, d\tau, \qquad \gamma_1 = 2^{20\alpha\Lambda}.
\end{aligned} \tag{2.7}$$

Now fix $\eta > 0$. First we consider the case

$$\mu \equiv \frac{t}{\rho^2} \Phi(\|u\|_{\infty, Q_0}) \geqq \eta. \tag{2.8}$$

Then the right-hand side (r.h.s.) of (2.7) is majorized by

$$\gamma_1 \frac{2^{2n}}{\sigma^2 t}\left(1+\frac{1}{\eta}\right)\mu \int\int_{Q_n} F(u, k_n)^2 \, dx \, d\tau.$$

We also need the following estimate for

$$|A_{n+1}| \equiv \text{meas}\,\{(x, \tau) \in Q_n | u(x, \tau) > k_{n+1}\}.$$

Using (2.1) again we have

$$\begin{aligned} \int\int_{Q_n} F(u, k_n)^2 \, dx \, d\tau &\geqq |A_{n+1}| \int_{k_n}^{k_{n+1}} dr \int_{k_n}^{r} \frac{\phi(s)^\alpha}{s^2} \, ds \\ &\geqq |A_{n+1}| \frac{\phi(k_n)^\alpha}{k_n^2} \frac{(k_{n+1}-k_n)^2}{2} \\ &\geqq 2^{-\alpha\Lambda(n+2)} |A_{n+1}| \phi(k)^\alpha. \end{aligned} \tag{2.9}$$

From (2.7)-(2.9) and the embedding of [5, pp. 74-75], there follows

$$\begin{aligned} &\int\int_{Q_{n+1}} F(u, k_{n+1})^2 \, dx \, d\tau \\ &\quad \leqq \int\int_{Q_n} F(u, k_{n+1})^2 \zeta_n^2 \, dx \, d\tau \\ &\quad \leqq |A_{n+1}|^{2/(N+2)} \left(\int\int_{Q_n} [F(u, k_{n+1})^2 \zeta_n^2]^{(N+2)/N} \, dx \, d\tau \right)^{N/(N+2)} \\ &\quad \leqq C(N) |A_{n+1}|^{2/(N+2)} \left(\int\int_{Q_n} |\nabla F(u, k_{n+1}) \zeta_n|^2 \, dx \, d\tau \right)^{N/(N+2)} \\ &\qquad \cdot \left(\sup_{t_n \leqq \tau \leqq t} \int_{B_n(\tau)} F(u, k_{n+1})^2 \zeta_n^2 \, dx \right)^{2/(N+2)} \\ &\quad \leqq DB^n \left(1+\frac{1}{\eta}\right) \mu (\sigma^2 t)^{-1} \phi(k)^{-\alpha(2/(N+2))} \Phi(k)^{-N/(N+2)} \\ &\qquad \cdot \left(\int\int_{Q_0} F(u, k_n)^2 \, dx \, d\tau \right)^{1+(2/N+2)}, \end{aligned} \tag{2.10}$$

with $D = C(N) 2^{25\alpha\Lambda}$, $B = 2^{2\alpha\Lambda}$; here and below $C(N)$ is a constant depending only on N.

If k is such that

$$\begin{aligned} \int\int_{Q_0} F(u, k_0)^2 \, dx \, d\tau &\leqq \int\int_{Q_0} F(u, 0)^2 \, dx \, d\tau \\ &= D^{-(N+2)/2} B^{-((N+2)/2)^2} \left[(\sigma^2 t)^{-1} \left(1+\frac{1}{\eta}\right) \mu \right]^{-(N+2)/2} \cdot \phi(k)^\alpha \Phi(k)^{N/2}, \end{aligned}$$

Lemma 5.6 on page 95 of [5] implies that $\iint_{Q_n} F(u, k_n)^2 \, dx \, d\tau \to 0$ as $n \to \infty$, i.e., $\|u\|_{\infty, Q_\infty} \leqq k$.

Thus, taking into account $F(u,0)^2 \leqq \phi(u)^\alpha$ and recalling the definitions of Φ and μ,

$$\phi(\|u\|_{\infty,Q_\infty})^{\alpha+(N/2)}\|u\|_{\infty,Q_\infty}^{-(N/2)} \leqq \gamma_2(\sigma\rho)^{-(2+N)}\left(1+\frac{1}{\eta}\right)^{(N+2)/2}\phi(\|u\|_{\infty,Q_0})^{\alpha+(N/2)-\varepsilon}\|u\|_{\infty,Q_0}^{-1-(N/2)}\iint_{Q_0}\phi(u)^{1+\varepsilon}\,dx\,d\tau \tag{2.11}$$

($\gamma_2 = C(N)2^{60\alpha\Lambda N^2}$) if we assume also $\alpha > 1+\varepsilon$, e.g.,

$$\alpha = 2+\varepsilon. \tag{2.12}$$

Since obviously

$$\|u\|_{\infty,Q_\infty} \leqq \|u\|_{\infty,Q_0}, \qquad \phi(u)\|u\|_{\infty,Q_0}^{-1} \leqq \phi(u)u^{-1} \quad \text{in } Q_0,$$

we get from (2.11)

$$\phi(\|u\|_{\infty,Q_\infty})^{\alpha+(N/2)} \leqq \gamma_2(\sigma\rho)^{-(2+N)}\left(1+\frac{1}{\eta}\right)^{(N+2)/2}\phi(\|u\|_{\infty,Q_0})^{\alpha+(N/2)-\varepsilon} \cdot \iint_{Q_0}\Phi(u)\phi(u)^\varepsilon\,dx\,d\tau. \tag{2.13}$$

Let us define

$$\beta = 1-\frac{\varepsilon}{\alpha+(N/2)},$$

$$Q(s,\tau) = \{(x,\theta)\,|\,|x-x_0|<s,\ \tau<\theta<t\},$$

$$U(s,\tau) = \phi(\|u\|_{\infty,Q(s,\tau)})^{\alpha+(N/2)}.$$

With this notation, on applying Young's inequality to (2.13) we have

$$U\left(\rho,\frac{t}{2}\right) \leqq \delta U(\rho_0,t_0) + \gamma_3(\rho_0-\rho)^{-(2+N)/(1-\beta)}M_0, \tag{2.14}$$

for any $\delta \in (0,1)$; here

$$M_0 = \delta^{-\beta/(1-\beta)}\left(1+\frac{1}{\eta}\right)^{(N+2)/(2(1-\beta))}\left(\iint_{Q_0}\Phi(u)\phi(u)^\varepsilon\,dx\,d\tau\right)^{1/(1-\beta)}$$

and $\gamma_3 = \gamma_2^{1/(1-\beta)}$.

Define

$$s_0 = \rho, \qquad s_{i+1}-s_i = (1-\sigma)\sigma^i(\sigma\rho),$$

$$\tau_0 = \frac{t}{2}, \qquad \tau_i - \tau_{i+1} = (1-\sigma)\sigma^i\left(\sigma\frac{t}{2}\right),$$

for $i = 0, 1, 2, \cdots$ and note that (2.14) holds in the form

$$U(s_i,\tau_i) \leqq \delta U(s_{i+1},\tau_{i+1}) + \gamma_3((1-\sigma)\sigma\rho)^{-(N+2)/(1-\beta)}\sigma^{-(N+2)/(1-\beta)i}M_0.$$

By iteration

$$U(s_0,\tau_0) \leqq \delta^n U(s_n,\tau_n) + \gamma_3((1-\sigma)\sigma\rho)^{-(N+2)/(1-\beta)}M_0\sum_{i=0}^{n}[\delta\sigma^{-(N+2)/(1-\beta)}]^i.$$

Now we choose $\delta = \frac{1}{2}\sigma^{(N+2)/(1-\beta)}$ and let $n \to \infty$. Then, taking the $(\alpha + (N/2))$th root of both sides of the inequality so obtained, we arrive at

$$\phi(\|u\|_{\infty,Q_\infty}) \leqq \gamma_4 \left(\frac{t}{\rho^2}\right)^{1/\varepsilon} (1-\sigma)^{-(N+2)/\varepsilon} \sigma^{-(N+\alpha)^2/\varepsilon^2} \left(1+\frac{1}{\eta}\right)^{(N+2)/2\varepsilon} \cdot \left(\fint\!\!\!\int_{Q_0} \Phi(u)\phi(u)^\varepsilon \, dx\, d\tau\right)^{1/\varepsilon}, \tag{2.15}$$

$\gamma_4 = (2\gamma_2)^{1/\varepsilon}$.

Finally, if (2.8) is not true, we have

$$\|u\|_{\infty,Q_\infty} \leqq \Phi^{-1}\left(\eta \frac{\rho^2}{t}\right). \tag{2.16}$$

Estimate (1.6) follows when we combine (2.15) with (2.16) and $\phi(\Phi^{-1}(x)) = x\Phi^{-1}(x)$ (note that Φ^{-1} exists because of the strict inequality in (1.2)).

3. Comments and generalizations.

Remark 3.1. If $\phi(u) = u^m$, $m > 1$, (1.6) reads (take $\varepsilon = \lambda/m$, $\lambda > 0$)

$$\|u\|_{\infty,Q_\infty} \leqq \left(\eta \frac{\rho^2}{t}\right)^{1/(m-1)} + \gamma \left(\frac{t}{\rho^2}\right)^{1/\lambda} \left(1+\frac{1}{\eta}\right)^{(N+2)/2\lambda} \left(\fint\!\!\!\int_{Q_0} u^{m-1+\lambda} \, dx\, d\tau\right)^{1/\lambda},$$

for all $\eta, \lambda > 0$.

In the linear case $\phi(u) = u$, $\Phi \equiv 1$, we can take $\eta = t/\rho^2$ in (2.8), so that our estimate takes the form (2.15), which in turn reduces to Moser's sup-estimate [6].

Remark 3.2. A solution of $u_t - \Delta u^m = 0$, $m > 1$, is given by

$$V(x,t) = \alpha |x|^{2/(m-1)} \left(1 - \frac{t}{T^*}\right)^{-1/(m-1)}, \qquad t \in (0, T^*), \quad x \in \mathbb{R}^N,$$

$$T^* = (m-1)(2m(N(m-1)+2)\alpha^{m-1})^{-1}, \quad \alpha \text{ fixed.}$$

Applying to V the estimate of Remark 3.1, we can see that the functional dependence on u of the second term on the r.h.s. of (1.6) is sharp.

We also note that, in (1.6), a corrective term balancing the second term on the r.h.s. is needed (just consider solutions $u \equiv \text{const}$, and let $\rho \to \infty$). Moreover, in our estimate, the behavior as $\rho \to \infty$ of the corrective term $(\eta\rho^2/t)\Phi^{-1}(\eta\rho^2/t)$, is the one predicted by sup-estimates at infinity for solutions of (1.1) ([1], [3], [4]).

The interpolation form assumed by (1.6) allows us to give our estimate for the subsolution u itself, rather than for $w = \max(u, c)$ ($c > 0$ fixed arbitrarily: see Remark 3.3 for an estimate of w).

Remark 3.3. Assume ϕ satisfies (1.2) (where we now allow the first inequality to be nonstrict) only for $s > \Lambda \geqq 1$, and u satisfies in Q_0

$$u_t - \operatorname{div} \vec{a}(x,t,u,\nabla\phi(u)) \leqq b(x,t,u,\nabla\phi(u)),$$

where

$$\vec{a}(x,t,u,\nabla\phi(u)) \cdot \nabla u \geqq \Lambda^{-1}\Phi(u)|\nabla u|^2 - \Lambda(1+u\phi(u)),$$
$$|\vec{a}(x,t,u,\nabla\phi(u))| \leqq \Lambda(\Phi(u)|\nabla u| + \phi(u) + 1),$$
$$|b(x,t,u,\nabla\phi(u))| \leqq \Lambda(\Phi(u)|\nabla u| + \phi(u) + 1).$$

Then, using the techniques of the lemma and theorem above, we can prove for $w = \max(u, 2\Lambda)$

$$\phi(\|w\|_{\infty,Q_\infty}) \leqq \gamma \left\{(1+t)\left(\frac{t}{\rho^2} + \frac{\rho^2}{t}\right)^2 (1 + \Phi(\Lambda)^{-1})\right\}^{(N+2)/2\varepsilon} \left(\fint\!\!\!\int_{Q_0} \Phi(w)\phi(w)^\varepsilon \, dx\, d\tau\right)^{1/\varepsilon}. \tag{3.1}$$

Indeed, in the proof we can take $k \geqq 2\Lambda$, so that (2.1), (2.2) still hold in $[k/2, \infty)$. Moreover, (2.8) certainly holds if we take

$$\eta = \Phi(\Lambda)\frac{t}{\rho^2};$$

this choice accounts for the appearance of $\Phi(\Lambda)$ in (3.1).

Remark 3.4. Solutions of variable sign. Assume $\phi : \mathbb{R} \to \mathbb{R}$ is an increasing AC function satisfying (1.2) almost everywhere $s \in \mathbb{R}$, and u is a bounded local solution of (1.1) in Q_0 (in the class defined above); u is not required to have constant sign. Then the previous arguments, with minor changes, prove estimates similar to (1.6) for the positive and negative parts of u. Analogous extensions hold if ϕ merely satisfies the assumptions of Remark 3.3 for large values of $|s|$.

AN INVERSE PROBLEM FOR A CLASS OF QUASILINEAR PARABOLIC EQUATIONS*

YANPING LIN†

Abstract. The identification of the source control $q = q(t)$ of one-dimensional quasilinear parabolic equations is considered via additional information on the solution of integral type. Existence, uniqueness, and continuous dependence of the solution upon the data are demonstrated by employing some a priori estimates, compactness arguments, and the strong maximum principle.

Key words. inverse problem, parabolic, a priori estimates, maximum principle

AMS(MOS) subject classifications. 35R25, 35R30

1. Introduction. We study the identification of the unknown source control $q = q(t)$ in the following quasilinear parabolic equation:

$$\begin{aligned} &u_t = a(x, t, u, u_x)_x + q(t)u + F(x, t, u, u_x, q(t)) \quad \text{in } Q_T, \\ &u(x, 0) = \phi(x), \qquad 0 < x < 1, \\ &u(0, t) = f(t), \quad u(1, t) = g(t), \quad 0 < t < T, \end{aligned} \tag{1.1}$$

subject to the integral identity

$$\int_0^{s(t)} \Phi(x, t)u(x, t)\, dx = E(t), \qquad 0 < t < T, \quad 0 < s(t) \leqq 1, \tag{1.2}$$

where $Q_T = \{(x, t) | 0 < x < 1, 0 < t < T\}$ with $T > 0$, the functions $a = a(x, t, u, p)$, $F = F(x, t, u, p, q)$, ϕ, f, g, s, E, and Φ are known and

$$a_p = \frac{\partial a}{\partial p}(x, t, u, p) \geqq a_0 > 0. \tag{1.3}$$

Problem (1.1)-(1.2) and other similar inverse problems, or parameters identification problems, have recently been studied by several authors both in one- and n-dimensional spaces [3], [4], [5], [15], [16]. In [3]-[5] Cannon and Lin solve these problems classically, while abstract semigroup methods were employed in [15] and [16]. When $a = p$ and (1.1) is subject to the second boundary conditions $u_x(0, t) = f(t)$ and $u_x(1, t) = g(t)$, problem (1.1)-(1.2) has been treated by Cannon and Lin [5] with $s(t) \equiv 1$. There existence, uniqueness, and stability of the solution are derived via potential theoretic representation techniques. It is obvious that the method used in [5] will no longer be good for problem (1.1)-(1.2) due to the nonlinearity of the leading term, which suggests the need for another alternative.

To interpret the integral condition (1.2), we consider the following. First, if u is a temperature, then (1.1)-(1.2) can be regarded as a control problem with source control. Here we investigate the identification of the source control $q(t)$ necessary to produce the specified or desired energy $E(t)$ on a portion of the domain. Second, let us consider the example of certain chemicals absorbing light at various frequencies given by Cannon, Esteva, and van der Hoek in [2]. The intensity of such light on a

† Department of Mathematics and Statistics, McGill University, Montreal, Québec, Canada, H3A 2K6. Present address, Department of Applied Mathematics, University of Waterloo, Waterloo, Ontario, Canada N2L 3G1.

photoelectric cell gives an electric signal which is proportional to the total amount of chemical present in the volume through which the light passes. If u denotes the concentration of such a chemical which is diffusing in a straight glass tube with x measured in the direction of the axis of the tube, then the electric signal produced by a light beam passing through the tube at the right angles to the tube between $x=0$ and $x=s(t)$ is proportional to the integral in (1.2) (with $\Phi=1$) which is the total mass of the chemical in $0\leqq x\leqq s(t)$ at the time t. For such diffusion processes, the integral condition (1.2) arises naturally and can be used as supplementary information in the determination of the unknown concentration u and the source $q(t)$. We can also find other examples in which the integral condition (1.2) arises, for instance, heat transmission in a thin rod in particle diffusion in turbulent plasma [1], [7], [11], [12].

Following [5] we want to eliminate the term $q(t)u$ in (1.1) by introducing the following transformations:

$$v(x,t)=u(x,t)\exp\left\{\int_0^t -q(\xi)\,d\xi\right\},\qquad r(t)=\exp\left\{-\int_0^t q(\xi)\,d\xi\right\}, \tag{1.4}$$

$$u(x,t)=v(x,t)\exp\left\{\int_0^t q(\xi)\,d\xi\right\},\quad q(t)=\frac{-\dot r(t)}{r(t)},\quad \dot r=\frac{dr}{dt}. \tag{1.5}$$

Thus, (1.1)-(1.2) can be written equivalently, by $(u,q)\to(v,r)$, as

$$\begin{aligned} &v_t=r(t)a\left(x,t,\frac{v}{r},\frac{v_x}{r}\right)_x+r(t)F\left(x,t,\frac{v}{r},\frac{v_x}{r},\frac{-\dot r}{r}\right)\quad \text{in } Q_T,\\ &v(x,0)=\phi(x),\qquad 0<x<1,\\ &v(0,t)=r(t)f(t),\quad v(1,t)=r(t)g(t),\quad 0<t<T, \end{aligned} \tag{1.6}$$

and

$$r(t)=\frac{1}{E(t)}\int_0^{s(t)}\Phi(x,t)v(x,t)\,dx,\qquad 0<t<T,\quad 0<s(t)\leqq 1. \tag{1.7}$$

Problem (1.6)-(1.7) now can be viewed as a quasilinear parabolic equation with nonlocal boundary condition and nonlinear functional of the solution if we substitute (1.7) into (1.6). Although (1.6)-(1.7) looks more complicated than does problem (1.1)-(1.2), it is easier to handle as we shall see below. We now define the solution pair (u,q) and (v,r).

DEFINITION 1.1. A pair (u,q) is called a solution for problem (1.1)-(1.2) if there exists an α, $0<\alpha<1$, such that

$$u\in C^{1+\alpha}(\bar Q_T)\cap C^{2+\alpha}(Q_T)\quad\text{and}\quad q\in C^{\alpha/2}([0,T]),$$

and that the pair (u,q) satisfy equations (1.1)-(1.2).

DEFINITION 1.2. A pair (v,r) is called a solution for problem (1.6)-(1.7) if $r(t)\neq 0$ and there exists an α, $0<\alpha<1$, such that

$$v\in C^{1+\alpha}(\bar Q_T)\cap C^{2+\alpha}(Q_T)\quad\text{and}\quad r\in C^{1+\alpha/2}([0,T]),$$

and that the pair (v,r) satisfy equations (1.6)-(1.7).

Here and throughout this paper we shall use the standard notation for Hölder spaces, C^{α}, $C^{1+\alpha}$, etc. defined in [9]. We shall also use the following notation:

$$\|v(\cdot,t)\|_{L^p(0,1)}=\left(\int_0^1|v(x,t)|^p\,dx\right)^{1/p},\qquad 1\leqq p<\infty,$$

$$\|v(\cdot,t)\|_{L^\infty(0,1)}=\operatorname{ess}\sup_{x\in(0,1)}|v(x,t)|,$$

for the functions $v = v(x, t)$ defined on Q_T, and $\|f\|_{L^p(0,T)}$, $1 \leqq p \leqq \infty$, for the functions defined on $(0, T)$.

Under these definitions we have the following lemma.

LEMMA 1.1. *If (u, q) is a unique solution pair for* (1.1)-(1.2), *then the pair (v, r) defined by* (1.4)-(1.5) *is a unique solution pair for* (1.6)-(1.7) *and vice versa provided that $r(t) > 0$ for $t \in [0, T)$.*

Proof. It is an elementary argument which we omit. □

Our approach as in [5] is that we shall show problem (1.6)-(1.7) has a unique solution pair (v, r) with $r(t) > 0$, and then by Lemma 1.1 we will conclude that the inverse problem (1.1)-(1.2) possesses a unique solution pair (u, q) via the transformations (1.4)-(1.5).

In order to have a direct relation between $\dot{r}$ and r, v, v_x, we differentiate (1.7) and use (1.6) to obtain

$$\begin{aligned}\dot{r} = &-\frac{\dot{E}}{E^2}\int_0^{s(t)} \Phi v\,dx + \frac{1}{E}\left\{\Phi(s(t), t)v(s(t), t)\dot{s}(t) + \int_0^{s(t)} \Phi_t v\,dx\right\} \\ &+\frac{1}{E}r(t)\left\{\Phi(s(t), t)a\left(s(t), t, \frac{v(s(t), t)}{r(t)}, \frac{v_x(s(t), t)}{r(t)}\right)\right. \\ &\left.-\Phi(0, t)a\left(0, t, \frac{v(0, t)}{r(t)}, \frac{v_x(0, t)}{r(t)}\right)\right\} \qquad (1.8) \\ &-\frac{1}{E}\int_0^{s(t)} \Phi_x(x, t)r(t)a\left(x, t, \frac{v}{r}, \frac{v_x}{r}\right)dx \\ &+\frac{1}{E}\int_0^{s(t)} \Phi(x, t)r(t)F\left(x, t, \frac{v}{r}, \frac{v_x}{r}, \frac{-\dot{r}}{r}\right)dx.\end{aligned}$$

We now state our assumptions on the data.

Assumption (H1). Assume that $a = a(x, t, u, p)$ is a smooth function with respect to all of its variables and satisfies the following growth conditions:

$$|a(x, t, u, p)| \leqq C(1 + |u| + |p|), \qquad |a_u(x, t, u, p)| + |a_x(x, t, u, p)| \leqq C. \qquad (1.9)$$

Here and in what follows, we denote by C a generic constant which depends only upon known quantities.

Assumption (H2). $f \geqq 0$, $g \geqq 0$, $\phi \geqq 0$ (ϕ is not identically zero), $0 < s(t) \leqq 1$, $\Phi(x, t) > 0$, $E(t) > 0$, and there exists α, $0 < \alpha < 1$, such that

$$\phi \in C^{2+\alpha}([0, 1]), \quad \Phi \in C^{2+\alpha}(\bar{Q}_T), \quad E, s, f, g \in C^{1+\alpha/2}([0, T]).$$

Assumption (H3). $F = F(x, t, u, p, q)$ is a smooth function with respect to all of its variables, $F \geqq 0$ and

$$|F(x, t, u, p, q)| \leqq \delta|q| + C(|u| + |p| + 1), \qquad (1.10)$$

where $\delta > 0$ is such that

$$0 \leqq \delta^* = \delta \max_{0 \leqq t \leqq T}\left\{E(t)^{-1}\int_0^{s(t)} \Phi(x, t)\,dx\right\} < 1. \qquad (1.11)$$

Remark 1.1. A consequence of (H3) is that equation (1.8) is uniquely solvable for $\dot{r}$, given r, v, v_x.

Assumption (H4). The data satisfies the following compatibility conditions:

$$\phi(0)=f(0), \quad \phi(1)=g(0), \quad E(0)=\int_0^{s(0)} \Phi(x,0)\phi(x)\,dx,$$

$$\dot{f}(0)=a(x,0,\phi(x),\phi_x(x))_x|_{x=0}+F(0,0,\phi(0),\phi_x(0),q(0)),$$

$$\dot{g}(0)=a(x,0,\phi(x),\phi_x(x))_x|_{x=1}+F(q,0,\phi(1),\phi_x(1),q(0)),$$

where $q(0)$ is uniquely determined from known data and satisfies

$$\dot{E}(0)=\Phi(s(0),0)\phi(s(0))\dot{s}(0)+\int_0^{s(0)} \Phi_t(x,0)\phi(x)\,dx+q(0)E(0)+a(x,0,\phi,\phi_x)|_0^{s(0)}$$

$$+\int_0^{s(0)} \Phi(x,0)F(x,0,\phi,\phi_x,q(0))\,dx-\int_0^{s(0)} \Phi_x(x,0)a(x,0,\phi,\phi_x)\,dx.$$

This paper is organized in the following way. In § 2, we derive by using integral inequalities, Young's inequality, and interpolation inequalities [6], [8], some a priori bounds on the solution pair (v, r). In § 3, we approximate our solution pair (v, r) by a sequence of smooth functions $\{v^\theta, r^\theta\}$, and we employ the a priori estimates obtained in § 2, the strong maximum principle and compactness arguments to conclude that there is a subsequence of $\{v^\theta, r^\theta\}$ which will converge to the real solution of problem (1.6)-(1.7). Also, we demonstrate the uniqueness and continuous dependence of the solution upon the data, and finally, we state our main results for problem (1.1)-(1.2).

2. A priori bounds on (v, r). We shall in this section derive various a priori bounds for the solution pair (v, r) for problem (1.6)-(1.7) under the assumption that the solution pair (v, r) exists and is such that $r=r(t)\neq 0$ for $t\in[0, T)$.

First, we shall show the following result.

LEMMA 2.1. *There exists a $C>0$ such that*

$$\iint_{Q_t} v_{xx}^2\,dx\,d\tau+\int_0^1 v_x^2\,dx+\int_0^t (r^2+\dot{r}^2)\,d\tau\leqq C, \qquad t\in(0, T), \tag{2.1}$$

and

$$\|v\|_{C(\bar{Q}_T)}+\|r\|_{C([0,T])}\leqq C. \tag{2.2}$$

Proof. We multiply equation (1.6) by v_{xx} and integrate over Q_t to obtain

$$\begin{aligned}\iint_{Q_t} v_t v_{xx}\,dx\,d\tau &= \iint_{Q_t} r(t)a\left(x,t,\frac{v}{r},\frac{v_x}{r}\right)_x v_{xx}\,dx\,d\tau \\ &\quad+\iint_{Q_t} r(t)F\left(x,t,\frac{v}{r},\frac{v_x}{r},\frac{-\dot{r}}{r}\right)v_{xx}\,dx\,d\tau \\ &= I_1+I_2.\end{aligned} \tag{2.3}$$

We know from integration by parts that

$$\begin{aligned}\iint_{Q_t} v_t v_{xx}\,dx\,d\tau &= \int_0^t v_t v_x|_0^1\,d\tau-\iint_{Q_t} v_x v_{xt}\,dx\,d\tau \\ &= \int_0^t v_t v_x|_0^1\,d\tau-\frac{1}{2}\int_0^1 v_x^2\,dx+\frac{1}{2}\int_0^1 \phi_x^2\,dx.\end{aligned}$$

Since

$$r(t)a\left(x, t, \frac{v}{r}, \frac{v_x}{r}\right)_x = a_p v_{xx} + a_u v_x + r(t)a_x,$$

we have from assumption (H1),

$$\begin{aligned} I_1 &\geqq a_0 \iint_{Q_t} v_{xx}^2 \, dx\, d\tau - C \iint_{Q_t} |v_{xx}|(|r|+|v|+|v_x|) \, dx\, d\tau \\ &\geqq (a_0-\varepsilon) \iint_{Q_t} v_{xx}^2 \, dx\, d\tau - C(\varepsilon) \iint_{Q_t} (|r|^2+|v|^2+|v_x|^2) \, dx\, d\tau. \end{aligned} \tag{2.4}$$

Similarly, we see from assumption (H3) that

$$|I_2| \leqq \varepsilon \iint_{Q_t} v_{xx}^2 \, dx\, d\tau + C(\varepsilon)\left\{\iint_{Q_t} (|v|^2+|v_x|^2) \, dx\, d\tau + \int_0^t (|r|^2+|\dot{r}|^2) \, d\tau\right\}. \tag{2.5}$$

It is easy to see from (1.8) and assumptions (H1)-(H3) that

$$|\dot{r}| \leqq C\{\|v(\cdot, t)\|_{L^\infty(0,1)} + \|v_x(\cdot, t)\|_{L^\infty(0,1)}\} + \delta^*|\dot{r}|$$

from which it follows that

$$|\dot{r}| \leqq \frac{C}{1-\delta^*}\{\|v(\cdot, t)\|_{L^\infty(0,1)} + \|v_x(\cdot, t)\|_{L^\infty(0,1)}\}. \tag{2.6}$$

But, from $v(0, t) = r(t)f(t)$ and $v(1, t) = r(t)g(t)$, it follows that

$$|v_t(0, t)| \leqq C|\dot{r}f + r\dot{f}| \leqq C(|r|+|\dot{r}|), \qquad |v_t(1, t)| \leqq C|\dot{r}g + r\dot{g}| \leqq C(|r|+|\dot{r}|). \tag{2.7}$$

Since

$$\int_0^t v_t v_x|_0^1 \, d\tau = \int_0^t (v_t(1, \tau)v_x(1, \tau) - v_t(0, \tau)v_x(0, \tau)) \, d\tau, \tag{2.8}$$

we obtain from (2.6)-(2.8) and the trace inequalities [14] that

$$\begin{aligned} \left|\int_0^t v_t v_x|_0^1 \, d\tau\right| &\leqq C \int_0^t \|v_x(\cdot, \tau)\|_{L^\infty(0,1)}(|r|+|\dot{r}|) \, d\tau \\ &\leqq C \int_0^t (\|v_x(\cdot, \tau)\|_{L^\infty(0,1)} + \|v(\cdot, \tau)\|_{L^\infty(0,1)}) \, d\tau \\ &\leqq \varepsilon C \iint_{Q_t} v_{xx}^2 \, dx\, d\tau + C(\varepsilon) \iint_{Q_t} (|v_x|^2+|v|^2) \, dx\, d\tau. \end{aligned} \tag{2.9}$$

Hence, by taking ε small and fixed, we have from (2.3)-(2.9) that

$$\iint_{Q_t} v_{xx}^2 \, dx\, d\tau + \int_0^1 v_x^2 \, dx \leqq C\left\{1 + \iint_{Q_t} (|v|^2+|v_x|^2) \, dx\, d\tau + \int_0^t (|r|^2+|\dot{r}|^2) \, d\tau\right\}. \tag{2.10}$$

Since

$$\iint_{Q_t} v^2 \, dx\, d\tau \leqq C \int_0^t |f|^2 \, d\tau + C \iint_{Q_t} v_x^2 \, dx\, d\tau \tag{2.11}$$

we see via (2.6) and the trace inequalities that

$$\begin{aligned} \int_0^t (|r|^2+|\dot{r}|^2) \, d\tau &\leqq C \int_0^t (\|v(\cdot, \tau)\|_{L^\infty(0,1)} + \|v_x(\cdot, \tau)\|_{L^\infty(0,1)}) \, d\tau \\ &\leqq \varepsilon C \iint_{Q_t} v_{xx}^2 \, dx\, d\tau + C(\varepsilon) \iint_{Q_t} (|v|^2+|v_x|^2) \, dx\, d\tau, \end{aligned} \tag{2.12}$$

after substituting (2.11)-(2.12) with ε sufficiently small (fixed) into (2.10) and using Gronwall's lemma, we have

$$\int\int_{Q_t} v_{xx}^2\,dx\,d\tau+\int_0^1 v_x^2\,dx\leqq C$$

and then by (2.12)

$$\int_0^t (|r|^2+|\dot r|^2)\,d\tau\leqq C.$$

Finally, (2.2) is a direct application of (2.1). □

LEMMA 2.2. *There exists $C>0$ such that*

$$\|v_x\|_{L^\infty(\bar Q_T)}+\|\dot r\|_{L^\infty(0,T)}\leqq C. \tag{2.13}$$

We need the following two well-known inequalities to prove our Lemma 2.2. The interpolation inequality:

$$\|u\|_{L^\infty(0,1)}\leqq C\|u\|_{H^1(0,1)}^{2/3}\|u\|_{L^1(0,1)}^{1/3},\qquad u\in H^1(0,1), \tag{2.14}$$

and Young's inequality:

$$AB\leqq \eta\frac{A^\sigma}{\sigma}+\eta^{-h/\sigma}\frac{B^h}{h},\quad A,B\geqq 0,\quad \eta>0,\quad \frac{1}{\sigma}+\frac{1}{h}=1,\quad \sigma,h>1. \tag{2.15}$$

Proof of Lemma 2.2. Let $P>2$; then we have

$$\begin{aligned}\int_0^1 v_x^P\,dx-\int_0^1 \phi_x^P\,dx&=\int_0^t\frac{d}{dt}\int_0^1 v_x^P\,dx\,d\tau\\&=\int_0^t Pv_x^{P-1}v_t|_0^1\,d\tau-\int\int_{Q_t}P(P-1)v_x^{P-2}v_{xx}v_t\,dx\,d\tau\\&=J_1+J_2.\end{aligned}$$

From assumptions (H1)-(H3) and (1.6), we see that there holds for a small $\varepsilon>0$

$$\begin{aligned}J_2&=-\int\int_{Q_t}P(P-1)v_x^{P-2}v_{xx}\left\{a_pv_{xx}+a_uv_x+r(t)a_x+r(t)F\left(x,t,\frac{v}{r},\frac{v_x}{r},\frac{-\dot r}{r}\right)\right\}dx\,d\tau\\&\leqq -a_0\int\int_{Q_t}P(P-1)v_x^{P-2}v_{xx}^2\,dx\,d\tau\\&\quad+\int\int_{Q_t}P(P-1)|v_x|^{p-2}|v_{xx}|(|v_x|+|v|+|r|+|\dot r|)\,dx\,d\tau\\&\leqq(\varepsilon-a_0)\int\int_{Q_t}P(P-1)v_x^{P-2}v_{xx}^2\,dx\,d\tau\\&\quad+C(\varepsilon)\int\int_{Q_t}P(P-1)|v_x|^{P-2}(|v_x|^2+|v|^2+|r|^2+|\dot r|^2)\,dx\,d\tau\end{aligned}$$

and by (2.12) and Lemma 2.1,

$$\begin{aligned}J_2&\leqq(\varepsilon-a_0)\int\int_{Q_t}P(P-1)v_x^{P-2}v_{xx}^2\,dx\,d\tau\\&\quad+C(\varepsilon)\int\int_{Q_t}P(P-1)(\|v_x(\cdot,\tau)\|_{L^\infty(0,1)}^{P}+\|v_x(\cdot,\tau)\|_{L^\infty(0,1)}^{P-2})\,dx\,d\tau.\end{aligned}$$

We know from (2.6) and (2.8) that

$$|J_1| \leqq C \int_0^t P(\|v(\cdot, \tau)\|_{L^\infty(0,1)}^P + \|v_x(\cdot, \tau)\|_{L^\infty(0,1)}^P)\, d\tau,$$

and then, we obtain from the estimates for $J_i's$ that

$$\begin{aligned} &\int_0^1 v_x^P\, dx + \iint_{Q_t} P(P-1) v_x^{P-2} v_{xx}^2\, dx\, d\tau \\ &\leqq CP^2 + C\int_0^1 \phi_x^P\, dx + C\int_0^T P^2 \|v_x(\cdot, \tau)\|_{L^\infty(0,1)}^P\, d\tau. \end{aligned} \tag{2.16}$$

Here we have used (2.2) to bound $\|v\|_{L^\infty(Q_T)}$ and $\|r\|_{L^\infty(0,T)}$.

If $\|v_x(\cdot, t)\|_{L^\infty(0,1)} \leqq \max\{1, \|\phi_x\|_{L^\infty(0,1)}\}$ for all $t \in (0, T)$, then we are done. Otherwise, it follows from the continuity of v_x that the interval $(0, T)$ can be decomposed into two parts: $(0, T) = G_T \cup L_T$, where

$$G_T = \{t \mid \|v_x(\cdot, t)\|_{L^\infty(0,1)} \geqq \max\{1, \|\phi_x\|_{L^\infty(0,1)}\},\ t \in (0, T)\},$$

$$L_T = \{t \mid \|v_x(\cdot, t)\|_{L^\infty(0,1)} < \max\{1, \|\phi_x\|_{L^\infty(0,1)}\},\ t \in (0, T)\},$$

and $\text{Meas}(G_T) > 0$. Thus,

$$1 + \int_0^1 \phi_x^P\, dx \leqq \frac{2}{\text{Meas}\,(G_T)} \int_{G_T} \|v_x(\cdot, \tau)\|_{L^\infty(0,1)}^P\, d\tau \leqq C\int_0^T \|v_x(\cdot, \tau)\|_{L^\infty(0,1)}^P\, d\tau,$$

and hence, (2.16) will become

$$\int_0^1 v_x^P\, dx + \iint_{Q_T} P(P-1) v_x^{P-2} v_{xx}^2\, dx\, d\tau \leqq C\int_0^T P^2 \|v_x(\cdot, \tau)\|_{L^\infty(0,1)}^P\, d\tau. \tag{2.17}$$

Here the constant C is dependent upon Meas (G_T).

Now we see from the interpolation inequality (2.14) that

$$\|v_x^{P/2}\|_{L^\infty(0,1)} \leqq C\|v_x^{P/2}\|_{H^1(0,1)}^{2/3} \|v_x^{P/2}\|_{L^1(0,1)}^{1/3},$$

and then, by Young's inequality (2.15) with $\sigma = \frac{3}{2}$ and $h = 3$,

$$\begin{aligned} \|v_x\|_{L^\infty(0,1)}^P &\leqq C\|v_x^{P/2}\|_{H^1(0,1)}^{4/3} \|v_x^{P/2}\|_{L^1(0,1)}^{2/3}, \\ &\leqq C\eta \|v_x^{P/2}\|_{H^1(0,1)}^2 + C\eta^{-2} \|v_v^{P/2}\|_{L^1(0,1)}^2. \end{aligned}$$

Since,

$$\|v_x^{P/2}\|_{H^1(0,1)}^2 = \frac{P^2}{4} \int_0^1 v_x^{P-2} v_{xx}^2\, dx + \int_0^1 v_x^P\, dx$$

and

$$\|v_x^{P/2}\|_{L^1(0,1)}^2 = \|v_x\|_{L^{P/2}(0,1)}^P,$$

we see that for $t \in [0, T]$,

$$\begin{aligned} &\int_0^1 v_x^P\, dx + P(P-1) \int_0^T \int_0^1 v_x^{P-2} v_{xx}^2\, dx\, dt \\ &\leqq CP(P-1)\left\{ P^2\eta \int_0^T \int_0^1 v_x^{P-2} v_{xx}^2\, dx\, dt + \eta \int_0^T \int_0^1 v_x^P\, dx\, dt \right\} \\ &\quad + CP^2\eta^{-2} \int_0^T \|v_x(\cdot, t)\|_{L^{P/2}(0,1)}^P\, dt. \end{aligned}$$

If we let $\eta = \min\{1/2CP^2, 1/2Tp(p-1)\}$, we obtain from the above inequality

$$\sup_{0<t<T} \int_0^1 v_x^P \, dx \leqq CP^4 \int_0^T \|v_x(\cdot, t)\|^P_{L^{P/2}(0,1)} \, dt \leqq CP^4 \sup_{0<t<T} \|v_x(\cdot, t)\|^P_{L^{P/2}(0,1)}. \tag{2.18}$$

Let $P = P_k = 2^k$ and $A_k = \sup_{0<t<T} (\int_0^1 v_x^{P_k} \, dx)^{1/P_k}$. We take the P_kth root of (2.18) and, by induction, obtain

$$A_k \leqq d_k A_{k-1} \leqq \cdots \leqq \left\{ \prod_{m=1}^{k} d_m \right\} A_1,$$

where $d_m = (CP_m^4)^{1/P_m}$. But, we know that

$$\prod_{m=1}^{k} d_m \leqq \exp\left\{ (\ln C + \ln 2) \sum_{m=1}^{\infty} \frac{4m+1}{2^m} \right\} < \infty,$$

so that $\prod_{m=1}^{\infty} d_m \leqq C$. Consequently, we can conclude from $\|v_x\|_{L^\infty(\bar{Q}_T)} = \lim_{k\to\infty} A_k$ and $A_1 \leqq C$ (by Lemma 2.1) that

$$\|v_x\|_{L^\infty(\bar{Q}_T)} \leqq C. \tag{2.19}$$

Then, by (2.6) it follows that $\|\dot{r}\|_{L^\infty(0,1)} \leqq C$. □

LEMMA 2.3. *There exist $C > 0$ and $\beta \in (0, \alpha)$ such that*

$$\|v\|_{C^{1+\beta}(\bar{Q}_T)} + \|r\|_{C^{1+\beta/2}([0,T])} \leqq C. \tag{2.20}$$

Proof. If we write equation (1.6) as the linear equation

$$v_t = a_p v_{xx} + B,$$

where

$$B(x, t) = a_u v_x + r(t) a_x + r(t) F\left(x, t, \frac{v}{r}, \frac{v_x}{r}, \frac{-\dot{r}}{r}\right)$$

and a_p are bounded functions by Lemma 2.2 and assumptions (H1)-(H3). Thus, we see from Theorem 6 of [13, p. 363] that there exist $\beta \in (0, \alpha)$ such that (2.20) holds. □

As a corollary of this lemma we have from Schauder's estimates [9], [14] that

$$\|v\|_{C^{2+\beta}(Q_T)} \leqq C(r_*), \tag{2.21}$$

where $r_* = \inf\{|r(t)| | t \in (0, T)\}$.

3. Existence and uniqueness of the solutions. In this section we shall use standard approximation techniques to prove the existence of our solution pair (v, r).

Let $\theta > 0$ be a small parameter. We define a sequence $\{v^\theta, r^\theta, \rho^\theta\}$ by

$$v_t^\theta = r^\theta(t) a\left(x, t, \frac{v^\theta}{r^\theta}, \frac{v_x^\theta}{r^\theta}\right)_x + r^\theta(t) F\left(x, t, \frac{v^\theta}{r^\theta}, \frac{v_x^\theta}{r^\theta}, \frac{-\rho^\theta}{r^\theta}\right) \quad \text{in } Q_T,$$

$$v^\theta(x, 0) = \phi(x), \qquad 0 < x < 1, \tag{3.1}$$

$$v^\theta(0, t) = r^\theta(t) f(t), \quad v^\theta(1, t) = r^\theta(t) g(t), \quad 0 < t < T,$$

and

$$r^\theta(t)=\frac{1}{E(t)}\int_0^{s(t)}\Phi(x,t)\bar v^\theta(x,t)\,dx,\qquad 0<t<T,\quad 0<s(t)\leqq 1, \tag{3.2}$$

$$\begin{aligned}\rho^\theta(t)=&-\frac{\dot E}{E^2}\int_0^{s(t)}\Phi\bar v^\theta\,dx+\frac{1}{E}\left\{\Phi(s(t),t)\bar v^\theta(s(t),t)\dot s(t)+\int_0^{s(t)}\Phi_t\bar v^\theta\,dx\right\}\\&+\frac{1}{E}r^\theta(t)\left\{\Phi(s(t),t)a\left(s(t),t,\frac{\bar v^\theta(s(t),t)}{r^\theta(t)},\frac{\bar v_x^\theta(s(t),t)}{r^\theta(t)}\right)\right.\\&\left.-\Phi(0,t)a\left(0,t,\frac{\bar v^\theta(0,t)}{r^\theta(t)},\frac{\bar v_x^\theta(0,t)}{r^\theta(t)}\right)\right\}\\&-\frac{1}{E}\int_0^{s(t)}\Phi_x(x,t)r^\theta(t)a\left(x,t,\frac{\bar v^\theta}{r^\theta},\frac{\bar v_x^\theta}{r^\theta}\right)dx\\&+\frac{1}{E}\int_0^{s(t)}\Phi(x,t)r^\theta(t)F\left(x,t,\frac{\bar v^\theta}{r^\theta},\frac{\bar v_x^\theta}{r^\theta},\frac{-\rho^\theta}{r^\theta}\right)dx,\end{aligned} \tag{3.3}$$

where

$$\bar v^\theta(x,t)=\begin{cases}\phi(x), & 0\leqq t\leqq\theta,\\ v^\theta(x,t-\theta), & \theta\leqq t<T.\end{cases} \tag{3.4}$$

In fact, ρ^θ is an approximation of the derivative $\dot r$ of r. We know from (3.4) that $\bar v^\theta$ is determined by initial data ϕ in $0\leqq t\leqq\theta$ and $r^\theta(0)=1$ by the compatibility assumption (H4). We see from (3.2)-(3.3) and assumption (H3) that $\{r^\theta,\rho^\theta\}$ is uniquely determined in $0\leqq t\leqq\theta$ by Lemma 1.2 of [5]. Then, we can solve (3.1) uniquely in the usual classical sense [9], [14] in $0\leqq t\leqq\theta$ and $v^\theta>0$ by the strong maximum principle [10, pp. 74-75]. This will determine $\bar v^\theta$ in $\theta\leqq t\leqq 2\theta$ by (3.4), and then the pair $\{r^\theta,\rho^\theta\}$ is determined in $\theta\leqq t\leqq 2\theta$ with $r^\theta>0,\cdots$. By induction, we have that problem (3.1)-(3.4) possesses a unique triple $\{v^\theta,r^\theta,\rho^\theta\}$ with $r^\theta>0$.

We now apply the arguments for Lemmas 2.1 and 2.2 to (3.1)-(3.3) and see that there exist $\beta\in(0,\alpha]$ and $C>0$ independent of θ,

$$\|v^\theta\|_{C^{1+\beta}(\bar Q_T)}+\|r^\theta\|_{C^{\beta/2}([0,T])}+\|\rho^\theta\|_{C^{\beta/2}([0,T])}\leqq C \tag{3.5}$$

and $\|v^\theta\|_{C^{2+\beta}(Q_T)}\leqq C(r_*^\theta)$, where $r_*^\theta=\inf\{r^\theta(t)|t\in(0,T)\}$. Thus, we see from compactness arguments that there exist $v\in C^{1+\beta}(\bar Q_T)$, $r\in C^{\beta/2}([0,T])$, and $\rho\in C^{\beta/2}([0,T])$, and a subsequence of $\{v^\theta,r^\theta,\rho^\theta\}$, also denoted by itself, such that

$$v^\theta\to v,\quad r^\theta\to r,\quad \rho^\theta\to\rho\quad\text{as }\theta\to 0, \tag{3.6}$$

and the convergence is uniform in $C^{1+\lambda}(\bar Q_T)\times C^{\lambda/2}([0,T])\times C^{\lambda/2}([0,T])$ if $\lambda<\beta$.

Unfortunately, we cannot take the limit in (3.1)-(3.3) as $\theta\to 0$ since $r^\theta>0$ will not guarantee that the limit function $r(t)>0$ for all $t\in[0,T)$. We must first show that $r(t)>0$ on $[0,T)$. Since $r^\theta(0)=1$, we see that $r(0)=1$. By continuity there exists at least a small time interval such that $r(t)>0$. Let $T^*\in(0,T)$ be defined by

$$T^*=\inf\{t|r(t)=0,\ t\in(0,T)\}>0. \tag{3.7}$$

Thus, by letting $\theta\to 0$ in (3.1)-(3.4) in $\Omega\times(0,T^*)$, we see that (v,r,ρ) will be a solution of (3.1)-(3.3) in Q_{T^*} with θ and the bar on v removed. From the strong maximum principle [10, pp. 74-75] and continuity of v, we see that $v(x,T^*)>0$ in $(0,1)$. Since

$$r(T^*)=\frac{1}{E(T^*)}\int_0^{s(T^*)}\Phi(x,T^*)v(x,T^*)\,dx>0$$

and $r(T^*)=0$ by (3.7), this contradiction implies that $r(t)>0$ in $[0,T]$.

Hence, the limit in (3.1)-(3.3) as $\theta\to 0$ can be taken and the triple (v,r,ρ) is actually a global solution for problem (3.1)-(3.3) without θ and the bar on v. This is

because $\|v^\theta\|_{C^{2+\beta}(Q_T)} \leqq C$, where $C>0$ is independent of θ, but depends on $r_* = \inf\{r(t) | t \in (0, t)\} > 0$ which depends upon the data. The identity $\dot{r} \equiv \rho$ in $[0, T]$ follows from differentiating (3.2) (with θ and the bar on u removed) and comparing $\dot{r}$ and ρ together with Lemma 2.1 of [4, p. 598].

We shall now summarize the above as the following theorem.

THEOREM 3.1. *Under assumptions* (H1)-(H4), *there exists a unique solution pair* (v, r) *with* $r>0$ *for problem* (1.6)-(1.7), *which is continuously dependent upon the data.*

Proof. The existence follows from the above argument. If we let (v^k, r^k) be the two solutions corresponding to the data $\{\phi^k, f^k, g^k, s^k, E^k, \Phi^k, F^k\}$ $(k=1, 2)$, then there exists an $M>0$ such that

$$\|v^k\|_{C^{2,1}(\bar{Q}_T)} + \|r^k\|_{C^{1+\lambda}([0,T])} \leqq M, \qquad k=1, 2,$$

where M depends only upon the data. Hence, it follows from an argument similar to that of [4] and [5] that there exists a $C>0$ dependent upon the data such that the following stability estimate holds:

$$\begin{aligned} &\|v^1 - v^2\|_{C^{1+\lambda}(\bar{Q}_T)} + \|r^1 - r^2\|_{C^{1+\lambda/2}([0,T])} \\ &\quad \leqq C\{\|f^1 - f^2\|_{C^{1+\lambda/2}([0,T])} + \|g^1 - g^2\|_{C^{1+\lambda/2}([0,T])} + \|s^1 - s^2\|_{C^{1+\lambda/2}([0,T])} \\ &\qquad + \|E^1 - E^2\|_{C^{1+\lambda/2}([0,T])} + \|\phi^1 - \phi^2\|_{C^{1+\lambda/2}([0,1])} \\ &\qquad + \|F^1 - F^2\|_{L^\infty(\bar{Q}_T \times [-N,N]^3)}\}, \end{aligned} \tag{3.8}$$

for some $0<\lambda \leqq \alpha<1$, where n is such that $|v/r|, |v_x/r|, |\dot{r}/r| \leqq N$ for all x and t. □

THEOREM 3.2. *Under assumptions* (H1)-(H4), *there exists a unique solution pair* (u, p) *for problem* (1.6)-(1.7), *which is continuously dependent upon the data.*

Proof. The proof follows from the transformation (1.4)-(1.5), Lemma 1.1, and Theorem 3.1. □

Remark 3.1. We see from the method developed in this paper that if we replace (1.1) by the more general form

$$u_t = a(x, t, u, u_x, q(t))_x + q(t)u + F(x, t, u, u_x, q(t)),$$

our results still hold if the following additional growth conditions are satisfied:

$$|a(x, t, u, p, q)| \leqq \delta_1 |q| + C(1 + |u| + |p|),$$

where $\delta_1 > 0$ is such that

$$0 \leqq \delta_1^* = \delta_1 \max_{0 \leqq t \leqq T} \left\{ E(t)^{-1} \left(2\|\Phi(\cdot, t)\|_{L^\infty(0,1)} + \int_0^{s(t)} |\Phi_x(x, t)|\, dx \right) \right\} < 1$$

and

$$0 \leqq \delta^* + \delta_1^* < 1.$$

Actually, these conditions are required to guarantee the unique solvability for $\dot{r}$ in the following equation:

$$\begin{aligned} \dot{r} = &-\frac{\dot{E}}{E^2} \int_0^{s(t)} \Phi v\, dx + \frac{1}{E} \left\{ \Phi(s(t), t) v(s(t), t) \dot{s}(t) + \int_0^{s(t)} \Phi_t v\, dx \right\} \\ &+ \frac{1}{E} r(t) \left\{ \Phi(s(t), t) a\left(s(t), t, \frac{v(s(t), t)}{r(t)}, \frac{v_x(s(t), t)}{r(t)}, \frac{-\dot{r}(t)}{r(t)} \right) \right. \\ &\left. - \Phi(0, t) a\left(0, t, \frac{v(0, t)}{r(t)}, \frac{v_x(0, t)}{r(t)}, \frac{-\dot{r}(t)}{r(t)} \right) \right\} \end{aligned}$$

$$-\frac{1}{E}\int_0^{s(t)} \Phi_x(x,t)r(t)a\left(x,t,\frac{v}{r},\frac{v_x}{r},\frac{-\dot{r}}{r}\right)dx$$

$$+\frac{1}{E}\int_0^{s(t)} \Phi(x,t)r(t)F\left(x,t,\frac{v}{r},\frac{v_x}{r},\frac{-\dot{r}}{r}\right)dx,$$

if r, v, and v_x are given.

Acknowledgment. The author thanks Professor J. R. Cannon for many comments, suggestions, and criticisms during the preparation of this paper.

ENTIRE SOLUTIONS OF REAL AND COMPLEX MONGE-AMPÈRE EQUATIONS*

TAKAŜI KUSANO† AND CHARLES A. SWANSON‡

Abstract. Real and complex Monge-Ampère equations

$$\det\left(\frac{\partial^2 u}{\partial x_i \partial x_j}\right) = f(|x|, u, |\nabla u|), \qquad x \in \mathbb{R}^N, \quad N \geqq 2, \tag{A}$$

$$\det\left(\frac{\partial^2 u}{\partial z_i \partial \bar{z}_j}\right) = f(|z|, u, |\nabla u|), \qquad z \in \mathbb{C}^N, \quad N \geqq 2 \tag{B}$$

are considered in the entire spaces $\mathbb{R}^N$ and $\mathbb{C}^N$, respectively, $N \geqq 2$. A unified fixed-point approach is used to generate various conditions for (A) to have radial, strictly convex solutions $u(x)$ in $\mathbb{R}^N$ that are asymptotic to positive constant multiples of $|x|$ as $|x| \to \infty$, and for (B) to have radial, strictly plurisubharmonic solutions $u(z)$ in $\mathbb{C}^N$ that are asymptotic to positive constant multiples of $\log|z|$ as $|z| \to \infty$.

Key words. Monge-Ampère equation, entire solution, convex, plurisubharmonic, Gaussian curvature

AMS(MOS) subject classifications. 35J60, 35Q99

1. Introduction.

Our primary objective is to present a unified approach for establishing the existence and structure of radial entire solutions of real and complex Monge-Ampère equations

$$\det\left(\frac{\partial^2 u}{\partial x_i \partial x_j}\right) = f(|x|, u, |\nabla u|), \qquad x \in \mathbb{R}^N, \quad N \geqq 2, \tag{A}$$

$$\det\left(\frac{\partial^2 u}{\partial z_i \partial \bar{z}_j}\right) = f(|z|, u, |\nabla u|), \qquad z \in \mathbb{C}^N, \quad N \geqq 2, \tag{B}$$

respectively, $i, j = 1, \cdots, N$, under various hypotheses in §2 on the function $f \in C(\bar{\mathbb{R}}_+ \times \mathbb{R}_+ \times \bar{\mathbb{R}}_+, \mathbb{R}_+)$ or $f \in C(\bar{\mathbb{R}}_+ \times \mathbb{R} \times \bar{\mathbb{R}}_+, \mathbb{R}_+)$, where $\mathbb{R}_+ = (0, \infty)$, $\bar{\mathbb{R}}_+ = [0, \infty)$. As usual, $|x|$ and $|z|$ denote the Euclidean and Hermitian norms of points $x = (x_1, \cdots, x_N)$ and $z = (z_1, \cdots, z_N)$ in real and complex N-space $\mathbb{R}^N$ and $\mathbb{C}^N$, respectively, and ∇ denotes the gradient with respect to the coordinates in either space. An *entire solution* of (A) is defined to be a real-valued function $u \in C^2(\mathbb{R}^N)$ satisfying (A) at every point of $\mathbb{R}^N$. An entire solution of (B) is a real-valued function $u \in C^2(\mathbb{C}^N)$ satisfying (B) at every point of $\mathbb{C}^N$. Our attention will be directed toward *radial solutions* of (A) or (B), i.e., solutions that are functions of $t = |x|$ or $t = |z|$, respectively.

The main theorems in §2 contain various sufficient conditions for (A) to have infinitely many radial entire solutions $u(x)$, which are strictly convex and asymptotic to positive constant multiples of $|x|$ as $|x| \to \infty$, and for (B) to have infinitely many radial entire solutions $u(z)$, which are strictly plurisubharmonic and asymptotic to positive constant multiples of $\log|z|$ as $|z| \to \infty$. Such solutions are positive throughout $\mathbb{R}^N$ [or $\mathbb{C}^N$] under the hypotheses of Theorems 2.1A and 2.3A (or Theorems 2.1B and 2.3B, respectively). The proofs are given in §3 on the basis of the Schauder-Tychonov fixed-point theorem. Some variants of these results are included in §4.

Since their origin in geometry two centuries ago, Monge-Ampère equations have retained their central theoretical role in various geometric problems, including the problem of constructing manifolds with prescribed Gaussian curvature; see, for example, Bakel'man [3], Kazdan [9], and Pogorelov [17]-[19]. Among the numerous investigations of Monge-Ampère equations, we mention only the recent studies [1]-[10], [12]-[23]. Most of the literature, however, has been concerned primarily with solvability and regularity questions for boundary value problems in *bounded* domains, whereas information on Monge-Ampère equations in unbounded domains seems to be limited to results of Popivanov and Kutev [20] concerning the Neumann problem for (A) in exterior domains, and the present authors [11] for (A) in $\mathbb{R}^2$.

Standard calculations [7], [8], [16] show that the existence of a positive radial entire solution $u(x)=y(t)(t=|x|)$ of (A) is equivalent to the existence of a positive solution $y\in C^2(\bar{\mathbb{R}}_+)$ of the ordinary differential equation

$$([y'(t)]^N)'=Nt^{N-1}f(t,y(t),|y'(t)|),\qquad t>0 \tag{$1.1)_A$}$$

satisfying initial conditions $y(0)=c>0$ and $y'(0)=0$. A parallel statement for a positive radial entire solution $u(z)=y(t)(t=|z|)$ of (B) holds if $(1.1)_A$ is replaced by

$$([ty'(t)]^N)'=N2^{N+1}t^{2N-1}f(t,y(t),\tfrac{1}{2}|y'(t)|),\qquad t>0. \tag{$1.1)_B$}$$

In §3 we consider the more general problem of existence of solutions $y\in C^2(\bar{\mathbb{R}}_+)$ of the equation

$$([t^\alpha y'(t)]^N)'=t^{N(\alpha+1)-1}g(t,y(t),y'(t)),\qquad t>0 \tag{1.2}$$

satisfying $y(0)=c$, $y'(0)=0$, and $y'(t)>0$ for $t>0$, where $\alpha\in[0,1]$ is a constant. Evidently (1.2) is of type $(1.1)_A$ or $(1.1)_B$ when $\alpha=0$ or $\alpha=1$, respectively. Such a problem for (1.2) will be solved by obtaining an appropriate solution of the associated integrodifferential equation

$$y(t)=c+\int_0^t s^{-\alpha}\left[\int_0^s r^{N(\alpha+1)-1}g(r,y(r),y'(r))\,dr\right]^{1/N}ds,\qquad t\geqq 0 \tag{1.3}$$

by a fixed-point analysis.

2. Statement of theorems and examples. The existence of radial entire solutions of (A) and (B) will be proved under conditions on the function f selected from the list below. For convenience the domain of f is taken to be $\mathbb{D}=\bar{\mathbb{R}}_+\times\mathbb{R}\times\bar{\mathbb{R}}_+$; a restriction to $\bar{\mathbb{R}}_+\times\mathbb{R}_+\times\bar{\mathbb{R}}_+$ is understood if only positive solutions of (A) or (B) are being considered.

(f_1) $f(t,y,z)$ is positive and continuous in $\mathbb{D}$, and nondecreasing with respect to y and z.

(f_2) $k^{-N}f(t,ky,kz)$ is a nondecreasing function of k in some interval $(0,k_0]$ and $\lim_{k\to 0+}k^{-N}f(t,ky,kz)=0$ for each $(t,y,z)\in\mathbb{D}$.

(f_2') $k^{-N}f(t,ky,kz)$ is a nonincreasing function of k in some interval $[k_0,\infty)$ and $\lim_{k\to\infty}k^{-N}f(t,ky,kz)=0$ for each $(t,y,z)\in\mathbb{D}$.

(f_3) $\lim_{y\to-\infty}f(t,y,z)=0$ for each fixed (t,z).

(f_4) $\displaystyle\int_0^\infty t^{N-1}f(t,at,a)\,dt<\infty$ for some constant $a>0$.

(f_5) $\displaystyle\int_1^\infty t^{2N-1}f\left(t,a\log t,\frac{a}{t}\right)dt<\infty$ for some constant $a>0$.

THEOREM 2.1A. *If* (f_1), (f_4), *and one of* (f_2), (f_2') *hold, then* (A) *has an infinitude of positive radial strictly convex entire solutions* $u(x)$ *in* $\mathbb{R}^N$ *such that* $|x|^{-1}u(x)$ *has a positive finite limit as* $|x|\to\infty$.

THEOREM 2.1B. *If* (f_1), (f_5), *and one of* (f_2), (f_2') *hold, then* (B) *has an infinitude of positive radial strictly plurisubharmonic entire solutions* $u(z)$ *in* $\mathbb{C}^N$ *such that* $(\log|z|)^{-1}u(z)$ *has a positive finite limit as* $|z|\to\infty$.

It can be verified easily that the conclusion of Theorem 2.1A holds for the example

$$\det(\partial^2 u/\partial x_i\,\partial x_j) = p(|x|)u^\gamma + q(|x|)|\nabla u|^\delta, \qquad x\in\mathbb{R}^N, \tag{2.1}$$

where either $\gamma>1$ and $\delta>1$ or $\gamma<1$ and $\delta<1$, and p, q are positive continuous functions in $\bar{\mathbb{R}}_+$ such that

$$\int_0^\infty t^{N+\gamma-1}p(t)\,dt<\infty, \qquad \int_0^\infty t^{N-1}q(t)\,dt<\infty. \tag{2.2}$$

Likewise Theorem 2.1B applies to the complex Monge-Ampère equation

$$\det(\partial^2 u/\partial z_i\,\partial\bar z_j) = p(|z|)u^\gamma + q(|z|)|\nabla u|^\delta, \qquad z\in\mathbb{C}^N,$$

where γ, δ are as in (2.1), but (2.2) is replaced by

$$\int_1^\infty t^{2N-1}(\log t)^\gamma p(t)\,dt<\infty, \qquad \int_1^\infty t^{2N-\delta-1}q(t)\,dt<\infty. \tag{2.3}$$

THEOREM 2.2A. *Conditions* (f_1), (f_3), *and* (f_4) *imply that* (A) *has an infinitude of radial strictly convex entire solutions* $u(x)$ *in* $\mathbb{R}^N$ *such that* $|x|^{-1}u(x)$ *has a positive finite limit as* $|x|\to\infty$.

THEOREM 2.2B. *Conditions* (f_1), (f_3), *and* (f_5) *imply that* (B) *has an infinitude of radial strictly plurisubharmonic entire solutions* $u(z)$ *in* $\mathbb{C}^N$ *such that* $(\log|z|)^{-1}u(z)$ *has a positive finite limit as* $|z|\to\infty$.

Theorem 2.2A is applicable to the example

$$\det(\partial^2 u/\partial x_i\,\partial x_j) = p(|x|)\,e^u, \qquad x\in\mathbb{R}^N$$

for any positive continuous function p in $\bar{\mathbb{R}}_+$ satisfying

$$\int^\infty t^{N-1}e^{at}p(t)\,dt<\infty \quad \text{for some } a>0.$$

Similarly, Theorem 2.2B applies to the equation

$$\det(\partial^2 u/\partial z_i\,\partial\bar z_j) = p(|z|)e^u, \qquad z\in\mathbb{C}^N,$$

where p is a positive continuous function in $\bar{\mathbb{R}}_+$ satisfying

$$\int^\infty t^{2N-1+a}p(t)\,dt<\infty \quad \text{for some } a>0.$$

The final theorems in this section assert, in effect, that hypotheses (f_2), (f_2') can be deleted from Theorems 2.1A and 2.1B provided the integrals in (f_4) or (f_5) are sufficiently small. It is convenient to prove these results for the equations:

$$\det(\partial^2 u/\partial x_i\,\partial x_j) = \lambda f(|x|, u, |\nabla u|), \qquad x\in\mathbb{R}^N, \tag{A_λ}$$

$$\det(\partial^2 u/\partial z_i\,\partial\bar z_j) = \lambda f(|z|, u, |\nabla u|), \qquad z\in\mathbb{C}^N, \tag{B_λ}$$

where λ denotes a small positive parameter.

THEOREM 2.3A. *For every* λ *in some interval* $(0, \lambda_0]$, *conditions* (f_1) *and* (f_4) *are sufficient for* (A_λ) *to have an infinitude of positive radial entire solutions with the properties stated in Theorem* 2.1A.

THEOREM 2.3B. *For every* λ *in some interval* $(0, \lambda_0]$, *conditions* (f_1) *and* (f_5) *are sufficient for* (B_λ) *to have an infinitude of positive radial entire solutions with the properties stated in Theorem* 2.1B.

As an illustration, consider an equation of prescribed Gaussian curvature:

$$\det(\partial^2 u/\partial x_i\,\partial x_j) = \lambda p(|x|)(1+|\nabla u|^2)^{(N+2)/2}, \qquad x \in \mathbb{R}^N, \tag{2.4}$$

where p is a positive continuous function in $\bar{\mathbb{R}}_+$ satisfying

$$\int_0^\infty t^{N-1} p(t)\,dt < \infty. \tag{2.5}$$

If λ is sufficiently small, Theorem 2.3A implies that (2.4) has positive radial entire solutions $u(x)$ in $\mathbb{R}^N$ that are asymptotic to constant multiples of $|x|$ as $|x| \to \infty$. If $u(x)$ is any such solution of (2.4), it is obvious that $u(x)+K$ also is an entire solution of (2.4) for any constant K.

We note that if the exponent $(N+2)/2$ is replaced by $\nu \in (0, N/2)$, then (f_2') is satisfied, and hence Theorem 2.1A implies that (2.4) has, if (2.5) holds, positive radial entire solutions $u(x) \sim (\text{constant})|x|$ at ∞ for arbitrary $\lambda > 0$.

3. Proofs of the theorems. The proofs of parts A and B of the theorems in §2 will be given essentially together by considering the generalized equation (1.2). We employ the following notation throughout this section without further comment:

$$\phi_\alpha(t) = \begin{cases} 1/(1-\alpha)\max\{1, t^{1-\alpha}\} & \text{if } 0 \leqq \alpha < 1, \\ \max\{1, \log(et)\} & \text{if } \alpha = 1, \end{cases}$$

$$\psi_\alpha(t) = \min\{1, t^{-\alpha}\}, \qquad 0 \leqq \alpha \leqq 1.$$

Hypotheses on the function g in (1.2) will be selected from (g_1), (g_2), (g_2'), (g_3), defined to be identical to (f_1), (f_2), (f_2'), (f_3), respectively, with g replacing f; and we also adjoin the condition

$$\int_0^\infty t^{N(\alpha+1)-1} g(t, a\phi_\alpha(t), a\psi_\alpha(t))\,dt < \infty \tag{$g_{4+\alpha}$}$$

for some constant $a > 0$.

THEOREM 3.1. *If* (g_1), $(g_{4+\alpha})$ *and one of* (g_2), (g_2') *hold, then* (1.2) *has infinitely many positive solutions* $y \in C^2(\bar{\mathbb{R}}_+)$ *such that* $y'(0) = 0$ *and* $\lim_{t\to\infty} y(t)/\phi_\alpha(t)$ *is positive and finite.*

THEOREM 3.2. *If* (g_1), (g_3), *and* $(g_{4+\alpha})$ *hold, then* (1.2) *has infinitely many solutions* $y \in C^2(\bar{\mathbb{R}}_+)$ *such that* $y'(0) = 0$ *and* $\lim_{t\to\infty} y(t)/\phi_\alpha(t)$ *is positive and finite.*

Proof of Theorem 3.1. In view of $(g_{4+\alpha})$ and (g_2) or (g_2'), the dominated convergence theorem implies that

$$\lim_{c\to 0+} c^{-N} \int_0^\infty t^{N(\alpha+1)-1} g(t, c\phi_\alpha(t), c\psi_\alpha(t))\,dt = 0,$$

or

$$\lim_{c\to\infty} c^{-N} \int_0^\infty t^{N(\alpha+1)-1} g(t, c\phi_\alpha(t), c\psi_\alpha(t))\,dt = 0,$$

respectively. Thus, under either hypothesis (g_2) or (g_2'), there exists a positive constant c such that

$$\int_0^\infty t^{N(\alpha+1)-1} g(t, 2c\phi_\alpha(t), 2c\psi_\alpha(t))\, dt \leqq c^N. \tag{3.1}$$

Since $(g_{4+\alpha})$ implies a fortiori

$$\int_0^\infty t^{N-1} g(t, a\phi_\alpha(t), a\psi_\alpha(t))\, dt < \infty$$

for the same $a > 0$, virtually the same argument as for (3.1) ensures the existence of a constant $c > 0$ such that

$$\int_0^\infty t^{N-1} g(t, 2c\phi_\alpha(t), 2c\psi_\alpha(t))\, dt \leqq c^N. \tag{3.2}$$

Obviously c can be chosen such that both (3.1) and (3.2) are satisfied; in fact, there exists a continuum of such positive constants c.

Let $\mathscr{C}^1(\bar{\mathbb{R}}_+)$ denote the Fréchet space of all $\mathscr{C}^1$-functions in $\bar{\mathbb{R}}_+$ with the topology of uniform convergence of functions and their first derivatives on compact intervals of $\bar{\mathbb{R}}_+$. For a fixed constant c satisfying (3.1) and (3.2), we define a closed convex subset $\mathscr{Y}_\alpha$ of $\mathscr{C}^1(\bar{\mathbb{R}}_+)$ and a mapping $\mathscr{F}_\alpha : \mathscr{Y}_\alpha \to \mathscr{C}^1(\bar{\mathbb{R}}_+)$ by

$$\mathscr{Y}_\alpha = \{y \in \mathscr{C}^1(\bar{\mathbb{R}}_+) : c \leqq y(t) \leqq 2c\phi_\alpha(t),\ 0 \leqq y'(t) \leqq 2c\psi_\alpha(t),\ t \geqq 0\}, \tag{3.3}$$

$$\mathscr{F}_\alpha y(t) = c + \int_0^t s^{-\alpha} \left[\int_0^s r^{N(\alpha+1)-1} g(r, y(r), y'(r))\, dr \right]^{1/N} ds, \qquad t \geqq 0. \tag{3.4}$$

In order to conclude from the Schauder–Tychonov fixed-point theorem that there exists $y \in \mathscr{Y}_\alpha$ such that $\mathscr{F}_\alpha y = y$, we will now verify that $\mathscr{F}_\alpha$ maps $\mathscr{Y}_\alpha$ continuously into a relatively compact subset of $\mathscr{Y}_\alpha$.

If $y \in \mathscr{Y}_\alpha$ and $0 \leqq \alpha < 1$, then (3.1) and (g_1) imply that

$$c \leqq \mathscr{F}_\alpha y(t) \leqq c + \int_0^t s^{-\alpha} \left[\int_0^\infty r^{N(\alpha+1)-1} g(r, 2c\phi_\alpha(r), 2c\psi_\alpha(r))\, dr \right]^{1/N} ds$$

$$\leqq c + \frac{c}{1-\alpha} t^{1-\alpha} \leqq 2c\phi_\alpha(t), \qquad t \geqq 0.$$

If $y \in \mathscr{Y}_\alpha$ and $\alpha = 1$, we use (3.1), (3.2), and (g_1) to obtain

$$c \leqq \mathscr{F}_1 y(t) \leqq c + \int_0^t s^{-1} \left[\int_0^s r^{2N-1} g(r, 2c\phi_1(r), 2c\psi_1(r))\, dr \right]^{1/N} ds$$

$$\leqq c + \int_0^1 \left[\int_0^s r^{N-1} g(r, 2c\phi_1(r), 2c\psi_1(r))\, dr \right]^{1/N} ds$$

$$\leqq c + c = 2c\phi_1(t), \qquad 0 \leqq t \leqq 1,$$

$$c \leqq \mathscr{F}_1 y(t) \leqq c + \int_0^1 s^{-1} \left[\int_0^s r^{2N-1} g(r, 2c\phi_1(r), 2c\psi_1(r))\, dr \right]^{1/N} ds$$

$$+ \int_1^t s^{-1} \left[\int_0^s r^{2N-1} g(r, 2c\phi_1(r), 2c\psi_1(r))\, dr \right]^{1/N} ds$$

$$\leqq 2c + c \log t = c + c \log et \leqq 2c\phi_1(t), \qquad t \geqq 1.$$

Thus $c \leqq \mathscr{F}_\alpha y(t) \leqq 2c\phi_\alpha(t)$ for all $t \geqq 0$, $\alpha \in [0, 1]$. Moreover, if $y \in \mathscr{Y}_\alpha$, $0 \leqq \alpha \leqq 1$, also

$$\begin{aligned} 0 \leqq (\mathscr{F}_\alpha y)'(t) &= t^{-\alpha}\left[\int_0^t r^{N(\alpha+1)-1} g(r, y(r), y'(r))\, dr\right]^{1/N} \\ &\leqq \left[\int_0^t r^{N-1} g(r, 2c\phi_\alpha(r), 2c\psi_\alpha(r))\, dr\right]^{1/N} \\ &\leqq c \quad \text{for } 0 \leqq t \leqq 1, \\ 0 \leqq (\mathscr{F}_\alpha y)'(t) &\leqq t^{-\alpha}\left[\int_0^\infty r^{N(\alpha+1)-1} g(r, 2c\phi_\alpha(r), 2c\psi_\alpha(r))\, dr\right]^{1/N} \\ &\leqq ct^{-\alpha} \quad \text{for } t \geqq 1, \end{aligned}$$

implying that $0 \leqq (\mathscr{F}_\alpha y)'(t) \leqq 2c\psi_\alpha(t)$ for all $t \geqq 0$. Hence $\mathscr{F}_\alpha y \in \mathscr{Y}_\alpha$, and accordingly $\mathscr{F}_\alpha$ maps $\mathscr{Y}_\alpha$ into itself.

To prove the continuity of $\mathscr{F}_\alpha$, let $\{y_n\}$ be a sequence in $\mathscr{Y}_\alpha$ with $\lim_{n\to\infty} y_n = y \in \mathscr{C}^1(\bar{\mathbb{R}}_+)$ in the $\mathscr{C}^1(\bar{\mathbb{R}}_+)$-topology. We use the abbreviations $\nu = N(\alpha+1)-1$ and

$$G_n(t) = g(t, y_n(t), y_n'(t)), \qquad G(t) = g(t, y(t), y'(t)).$$

Then, for $0 \leqq \alpha \leqq 1$,

$$\begin{aligned} |(\mathscr{F}_\alpha y_n)(t) - (\mathscr{F}_\alpha y)(t)| &\leqq \int_0^t s^{-\alpha}\left|\left[\int_0^s r^\nu G_n(r)\, dr\right]^{1/N} - \left[\int_0^s r^\nu G(r)\, dr\right]^{1/N}\right| ds \\ &\leqq \int_0^t s^{-\alpha}\left[\int_0^s r^\nu |G_n(r) - G(r)|\, dr\right]^{1/N} ds \end{aligned}$$

for all $t \geqq 0$, and

$$\begin{aligned} |(\mathscr{F}_\alpha y_n)'(t) - (\mathscr{F}_\alpha y)'(t)| &\leqq t^{-\alpha}\left|\left[\int_0^t r^\nu G_n(r)\, dr\right]^{1/N} - \left[\int_0^t r^\nu G(r)\, dr\right]^{1/N}\right| \\ &\leqq t^{-\alpha}\left[\int_0^t r^\nu |G_n(r) - G(r)|\, dr\right]^{1/N} \\ &\leqq \left[\int_0^t r^{N-1} |G_n(r) - G(r)|\, dr\right]^{1/N}, \qquad t \geqq 0. \end{aligned}$$

In view of (g_1) and (3.1)-(3.3), the dominated convergence theorem implies that $(\mathscr{F}_\alpha y_n)(t) \to (\mathscr{F}_\alpha y)(t)$ and $(\mathscr{F}_\alpha y_n)'(t) \to (\mathscr{F}_\alpha y)'(t)$ as $n \to \infty$ uniformly on compact subintervals of $\bar{\mathbb{R}}_+$, establishing the continuity of $\mathscr{F}_\alpha$.

Local equicontinuity of the set $(\mathscr{F}_0\mathscr{Y}_0)' = \{(\mathscr{F}_0 y)' : y \in \mathscr{Y}_0\}$ is a consequence of the following inequality, holding for all $y \in \mathscr{Y}_0$, $0 \leqq t_1 < t_2 \leqq T < \infty$:

$$\begin{aligned} |(\mathscr{F}_0 y)'(t_2) - (\mathscr{F}_0 y)'(t_1)| &= \left|\left[\int_0^{t_2} r^\nu G(r)\, dr\right]^{1/N} - \left[\int_0^{t_1} r^\nu G(r)\, dr\right]^{1/N}\right| \\ &\leqq \left[\int_{t_1}^{t_2} r^\nu g(r, 2c\phi_0(r), 2c\psi_0(r))\, dr\right]^{1/N}. \end{aligned}$$

Then, for any compact interval $I = [0, T]$ and arbitrary $\varepsilon > 0$, there is a corresponding $\delta > 0$, independent of t_1, $t_2 \in I$ and $y \in \mathscr{Y}_0$, such that $|(\mathscr{F}_0 y)'(t_2) - (\mathscr{F}_0 y)'(t_1)| < \varepsilon$ for all t_1, $t_2 \in I$ with $|t_2 - t_1| < \delta$.

The proof of local equicontinuity of $(\mathscr{F}_\alpha \mathscr{Y}_\alpha)'$ for $\alpha \in (0, 1]$ requires the modification indicated below:

$$
\begin{aligned}
&|(\mathscr{F}_\alpha y)'(t_2) - (\mathscr{F}_\alpha y)'(t_1)| \\
&\quad = \left| t_2^{-\alpha} \left[\int_0^{t_2} r^\nu G(r)\, dr \right]^{1/N} - t_1^{-\alpha} \left[\int_0^{t_1} r^\nu G(r)\, dr \right]^{1/N} \right| \\
&\quad \leqq t_2^{-\alpha} \left| \left[\int_0^{t_2} r^\nu G(r)\, dr \right]^{1/N} - \left[\int_0^{t_1} r^\nu G(r)\, dr \right]^{1/N} \right| \\
&\qquad + |t_2^{-\alpha} - t_1^{-\alpha}| \left[\int_0^{t_1} r^\nu G(r)\, dr \right]^{1/N} \\
&\quad \leqq t_2^{-\alpha} \left[\int_{t_1}^{t_2} r^\nu G_\alpha(r)\, dr \right]^{1/N} + |t_2^{-\alpha} - t_1^{-\alpha}| \left[\int_0^{t_1} r^\nu G_\alpha(r)\, dr \right]^{1/N},
\end{aligned} \tag{3.5}
$$

where $G_\alpha(r) = g(r, 2c\phi_\alpha(r), 2c\psi_\alpha(r))$. Define

$$
K_\alpha = \left[\frac{1}{\nu+1} \max_{0 \leqq r \leqq T} G_\alpha(r) \right]^{1/N},
$$

and note that $\nu+1 = N(\alpha+1)$ and

$$
t_2^{\nu+1} - t_1^{\nu+1} \leqq (\nu+1) t_2^\nu (t_2 - t_1).
$$

Then (3.5) yields

$$
\begin{aligned}
|(\mathscr{F}_\alpha y)'(t_2) - (\mathscr{F}_\alpha y)'(t_1)| &\leqq K_\alpha \left[t_2^{-\alpha} (t_2^{\nu+1} - t_1^{\nu+1})^{1/N} + \frac{t_1^{\alpha+1}(t_2^\alpha - t_1^\alpha)}{t_1^{2\alpha}} \right] \\
&\leqq K_\alpha [(\nu+1)^{1/N} t_2^{1-1/N} (t_2 - t_1)^{1/N} + t_1^{1-\alpha} (t_2 - t_1)^\alpha],
\end{aligned}
$$

implying the equicontinuity of $(\mathscr{F}_\alpha \mathscr{Y}_\alpha)'$ on any compact interval I.

The local equicontinuity of $\mathscr{F}_\alpha \mathscr{Y}_\alpha$ can be verified more easily, and the local uniform boundedness of $\mathscr{F}_\alpha \mathscr{Y}_\alpha$ and $(\mathscr{F}_\alpha \mathscr{Y}_\alpha)'$ is clear. It then follows from Ascoli's theorem that $\mathscr{F}_\alpha \mathscr{Y}_\alpha$ has compact closure in $\mathscr{Y}_\alpha$.

Therefore we can apply the Schauder-Tychonov theorem to conclude that $\mathscr{F}_\alpha$ has a fixed point $y \in \mathscr{Y}_\alpha$. Clearly $y(t)$ satisfies (1.3), and hence also $y(t)$ is a solution of the original differential equation (1.2) such that $y(0) = c$, $y(t) > 0$ for $t \geqq 0$, $y'(0) = 0$, and

$$
y'(t) = t^{-\alpha} \left[\int_0^t s^{N(\alpha+1)-1} g(s, y(s), y'(s))\, ds \right]^{1/N} > 0 \quad \text{for } t > 0.
$$

It follows from this formula for $y'(t)$ and L'Hôpital's rule that $y \in C^2(\bar{\mathbb{R}}_+)$; in particular

$$
y''(0) = \lim_{t \to 0+} \frac{y'(t)}{t} = \left[\frac{g(0, c, 0)}{(\alpha+1)N} \right]^{1/N}. \tag{3.6}
$$

The proof can be given readily from the equations

$$
\frac{y'(t)}{t} = \left[t^{-N(\alpha+1)} \int_0^t s^{N(\alpha+1)-1} g(s, y(s), y'(s))\, ds \right]^{1/N}, \qquad t > 0,
$$

$$
\begin{aligned}
y''(t) = &-\alpha \left[t^{-N(\alpha+1)} \int_0^t s^{N(\alpha+1)-1} g(s, y(s), y'(s))\, ds \right]^{1/N} \\
&+ \frac{1}{N} g(t, y(t), y'(t)) \left[t^{-N(\alpha+1)} \int_0^t s^{N(\alpha+1)-1} g(s, y(s), y'(s))\, ds \right]^{(1-N)/N},
\end{aligned}
$$

$$
t > 0,
$$

in the limit $t \to 0+$. For these conclusions it is important that $g(0, c, 0) > 0$, as guaranteed by hypothesis (g_1) (see also (f_1)). We remark that (f_2) or (f_2') is easily possible under the positivity condition in (f_1); see example (2.1) as an illustration.

Using the above formula for $y'(t)$ (or (1.3)), we conclude that $t^\alpha y'(t)$ is nondecreasing for $t \geqq 1$ and bounded above on account of (3.1), (3.3), and the nondecreasing hypothesis in (f_1). Therefore the limit

$$\lim_{t\to\infty} \frac{y(t)}{\phi_\alpha(t)} = \lim_{t\to\infty} t^\alpha y'(t) = \left[\int_0^\infty s^{N(\alpha+1)-1} g(s, y(s), y'(s))\, ds\right]^{1/N}$$

is positive and finite. (For the left equality we used the now well-known general form of L'Hôpital's rule, not requiring that $\lim_{t\to\infty} |y(t)| = \infty$). This proves the asymptotic property in Theorem 3.1. An infinitude of such solutions of (1.2) exists corresponding to a continuum of allowable initial values c satisfying (3.1) and (3.2).

Proof of Theorem 3.2. On account of $(g_{4+\alpha})$ and the alternative hypothesis (g_3), the dominated convergence theorem yields

$$\lim_{b\to-\infty} \int_0^\infty t^{N(\alpha+1)-1} g(t, b + a\phi_\alpha(t), a\psi_\alpha(t))\, dt = 0,$$

and hence, as in (3.1) and (3.2), there exists a constant b_0 such that both

$$\int_0^\infty t^{N(\alpha+1)-1} g(t, b + a\phi_\alpha(t), a\psi_\alpha(t))\, dt \leqq a^N, \tag{3.7}$$

$$\int_0^\infty t^{N-1} g(t, b + a\phi_\alpha(t), a\psi_\alpha(t))\, dt \leqq a^N \tag{3.8}$$

for all $b \leqq b_0$. With (3.7) and (3.8) replacing (3.1) and (3.2), respectively, almost identical procedure to that used for Theorem 3.1 shows that the mapping (3.4) has a fixed point in the modified set

$$\mathcal{Y}_\alpha = \{y \in \mathcal{C}^1(\bar{\mathbb{R}}_+) : b \leqq y(t) \leqq b + a\phi_\alpha(t),\ 0 \leqq y'(t) \leqq a\psi_\alpha(t),\ t \geqq 0\}$$

for any $b \leqq b_0$. The proof is then completed as in Theorem 3.1.

Proof of Theorems 2.1(A, B) *and* 2.2(A, B). Equation (1.2) specializes to $(1.1)_A$ and $(1.1)_B$ in the respective cases

$$\alpha = 0, \qquad g(t, y, z) = Nf(t, y, z),$$

$$\alpha = 1, \qquad g(t, y, z) = N2^{N+1} f\left(t, y, \frac{z}{2}\right).$$

It is easy to see that the hypotheses $(f_1) - (f_5)$ in Theorems 2.1A, B and 2.2A, B imply the corresponding hypotheses in Theorems 3.1 and 3.2. In particular, (f_5) implies that

$$\int_e^\infty t^{2N-1} f\left(t, a \log t, \frac{a}{t}\right) dt < \infty$$

for some constant $a > 0$. Let $\tilde{a} = a/2$. Then for $t \geqq e$, since $g(t, y, z)$ is nondecreasing in y and z,

$$\begin{aligned} g(t, \tilde{a}\phi_1(t), \tilde{a}\psi_1(t)) &= g\left(t, \frac{a}{2}(1 + \log t), \frac{a}{2t}\right) \\ &\leqq g\left(t, a \log t, \frac{2a}{t}\right) \\ &= N2^{N+1} f\left(t, a \log t, \frac{a}{t}\right), \end{aligned}$$

and hence (g_5) holds. It follows that the conclusions of Theorems 3.1 and 3.2 apply to $(1.1)_A$ and $(1.1)_B$, implying the existence of radial entire solutions $u(x)=y(|x|)$ and $u(z)=y(|z|)$ of (A) and (B), respectively, with the asymptotic behavior described in Theorems 2.1A, B and 2.2A, B. The strict convexity of $u(x)=y(|x|)$ in part (A) of these theorems is a consequence of

$$\det(\partial^2 u/\partial x_i\,\partial x_j)=\left[\frac{y'(t)}{t}\right]^{N-1}y''(t)>0$$

for $t=|x|\geqq 0$. (For $t=0$, this is obtained from a limit as $t\to 0+$, as in (3.6)). The proof given by Delanoë [7, p. 339] shows that the solutions $u(z)$ in Theorems 2.1B and 2.2B are strictly plurisubharmonic in $\mathbb{C}^N$.

In order to prove Theorems 2.3A, B, we obtain positive radial entire solutions $u(x)=y(t)(t=|x|)$ of (A_λ) and $u(z)=y(t)(t=|z|)$ of (B_λ) as positive solutions $y\in C^2(\bar{\mathbb{R}}_+)$ of the ordinary differential equations

$$([y'(t)]^N)'=\lambda N t^{N-1}f(t,y(t),|y'(t)|),\qquad t>0,$$
$$([ty'(t)]^N)'=\lambda N 2^{N+1}t^{2N-1}f(t,y(t),\tfrac{1}{2}|y'(t)|),\qquad t>0,$$

respectively, containing a positive parameter λ. These equations are both of the type

$$([t^\alpha y'(t)]^N)'=\lambda t^{N(\alpha+1)-1}g(t,y(t),y'(t)),\qquad t>0 \tag{3.9}$$

for $\alpha=0$ or $\alpha=1$, respectively. Accordingly, the following result implies the truth of both Theorems 2.3A, B.

THEOREM 3.3. *If* (g_1) *and* $(g_{4+\alpha})$ *hold,* $0\leqq\alpha\leqq 1$, *then* (3.9), *for every* λ *in some interval* $(0,\lambda_0]$, *has an infinitude of positive solutions* $y\in C^2(\bar{\mathbb{R}}_+)$ *such that* $y'(0)=0$ *and* $\lim_{t\to\infty}y(t)/\phi_\alpha(t)$ *is positive and finite.*

Proof. In Theorem 3.1, condition (g_2) or (g_2') was needed only to obtain (3.1) and (3.2). However, since (3.9) contains a parameter λ, conditions (g_1) and $(g_{4+\alpha})$ are sufficient for the existence of a number $\lambda_0>0$ such that

$$\lambda_0\int_0^\infty t^{N(\alpha+1)-1}g(t,2c\phi_\alpha(t),2c\psi_\alpha(t))\,dt\leqq c^N,$$
$$\lambda_0\int_0^\infty t^{N-1}g(t,2c\phi_\alpha(t),2c\psi_\alpha(t))\,dt\leqq c^N$$

for all c in some compact subinterval of $(0,a)$, where a is the number in $(g_{4+\alpha})$ (preceding Theorem 3.1). The proof then proceeds as in Theorem 3.1 with λg replacing g.

4. Variations and extensions. The following variant of Theorem 3.1 applies to the equation

$$([t^\alpha y'(t)]^N)'=t^{N(\alpha+1)-1}g(t,y(t)),\qquad t>0 \tag{4.1}$$

for $0\leqq\alpha\leqq 1$, where now $g(t,y)$ is *nonincreasing* in y and satisfies

$$\int_0^\infty t^{N(\alpha+1)-1}g(t,a)\,dt<\infty \tag{4.2}$$

for some positive constant a.

THEOREM 4.1. *Suppose that* $g(t,y)$ *is positive and continuous in* $\bar{\mathbb{R}}_+\times\mathbb{R}_+$ *and nonincreasing with respect to* y *for fixed* t. *If* (4.2) *holds, then* (4.1) *has an infinitude of positive solutions* $y\in C^2(\bar{\mathbb{R}}_+)$ *such that* $y'(0)=0$ *and* $\lim_{t\to\infty}y(t)/\phi_\alpha(t)$ *is positive and finite.*

Proof. By the nonincreasing assumption for $g(t, y)$ and by (4.2), a constant $c > a$ can be selected large enough that both

$$\int_0^\infty t^{N(\alpha+1)-1} g(t, c)\, dt \leqq c^N \quad \text{and} \quad \int_0^\infty t^{N-1} g(t, c)\, dt \leqq c^N.$$

For such a number c, consider the mapping $\mathscr{F}_\alpha$ defined by

$$(\mathscr{F}_\alpha y)(t) = c + \int_0^t s^{-\alpha} \left[\int_0^s r^{N(\alpha+1)-1} g(r, y(r))\, dr \right]^{1/N} ds, \qquad t \geqq 0.$$

The procedure in Theorem 3.1 can then be used to verify that $\mathscr{F}_\alpha$ has a fixed point $y \in \mathscr{Y}_\alpha$, where $\mathscr{Y}_\alpha$ is given by (3.3), generating the stated solution in Theorem 4.1.

This theorem implies the following results for the real Monge–Ampère equation

$$\det (\partial^2 u / \partial x_i\, \partial x_j) = f(|x|, u), \qquad x \in \mathbb{R}^N \tag{4.3}$$

and the complex Monge–Ampère equation

$$\det (\partial^2 u / \partial z_i\, \partial \bar{z}_j) = f(|z|, u), \qquad z \in \mathbb{C}^N, \tag{4.4}$$

where f in (4.3) or (4.4) satisfies the respective conditions

$$\int_0^\infty t^{N-1} f(t, a)\, dt < \infty, \tag{4.5}$$

$$\int_0^\infty t^{2N-1} f(t, a)\, dt < \infty \tag{4.6}$$

for some positive constant a.

THEOREM 4.2A. *Suppose $f(t, u)$ is positive and continuous in $\bar{\mathbb{R}}_+ \times \mathbb{R}_+$ and nonincreasing with respect to u for fixed t. If* (4.5) *holds, then* (4.3) *has an infinitude of positive radial strictly convex entire solutions $u(x)$ in $\mathbb{R}^N$ such that $|x|^{-1} u(x)$ has a positive finite limit as $|x| \to \infty$.*

THEOREM 4.2B. *If $f(t, u)$ is as in Theorem* 4.2A *and* (4.6) *holds, then* (4.4) *has an infinitude of positive radial entire solutions $u(z)$ in $\mathbb{C}^N$ such that $(\log |z|)^{-1} u(z)$ has a positive finite limit as $|z| \to \infty$.*

Our results in §3 also can be applied to another class of complex Monge–Ampère equations

$$\det (\partial^2 u / \partial z_i\, \partial \bar{z}_j) = f(|z|, u, \Phi u), \qquad z \in \mathbb{C}^N, \tag{4.7}$$

where Φ denotes the operator defined by

$$\Phi = \sum_{j=1}^N \left(x_j \frac{\partial}{\partial x_j} + y_j \frac{\partial}{\partial y_j} \right), \qquad x_j = \operatorname{Re} z_j, \quad y_j = \operatorname{Im} z_j.$$

This type of equation has been studied by Derridj [8] and Popivanov and Kutev [21]. The ordinary differential equation for radial solutions $u(z) = y(t)$ $(t = |z|)$ of (4.7) is, instead of $(1.1)_B$,

$$([t y'(t)]^N)' = N 2^{N+1} t^{2N-1} f(t, y(t), t y'(t)), \qquad t > 0. \tag{4.8}$$

Application of Theorems 3.1 and 3.2 to (4.8) yields the following results under the hypothesis

$$\int_1^\infty t^{2N-1} f(t, a \log t, a)\, dt < \infty \quad \text{for some constant } a > 0. \tag{4.9}$$

THEOREM 4.3. *If* (4.9), (f_1), *and one of* (f_2), (f_2') *hold, then* (4.8) *has an infinitude of positive radial entire solutions* $u(z)$ *in* $\mathbb{C}^N$ *such that* $(\log|z|)^{-1}u(z)$ *has a positive finite limit as* $|z|\to\infty$.

THEOREM 4.4. *If* (4.9), (f_1), *and* (f_3) *hold, then* (4.8) *has an infinitude of radial entire solutions* $u(z)$ *in* $\mathbb{C}^N$ *such that* $(\log|z|)^{-1}u(z)$ *has a positive finite limit as* $|z|\to\infty$.

Our methods for (A) and (B) can be extended without essential change to establish the existence of radial entire solutions for *systems* of Monge-Ampère equations of any of the three types

(i) $$\det(\partial^2 u_k/\partial x_i\,\partial x_j)=f_k(|x|,u_1,\cdots,u_M,|\nabla u_1|,\cdots,|\nabla u_M|),$$
$$k=1,\cdots,M,\quad x\in\mathbb{R}^N,\quad N\geqq 2,$$

(ii) $$\det(\partial^2 u_k/\partial z_i\,\partial\bar z_j)=f_k(|z|,u_1,\cdots,u_M,|\nabla u_1|,\cdots,|\nabla u_M|),$$
$$k=1,\cdots,M,\quad z\in\mathbb{C}^N,\quad N\geqq 2,$$

(iii) $$\det(\partial^2 u_k/\partial z_i\,\partial\bar z_j)=f_k(|z|,u_1,\cdots,u_M,\Phi u_1,\cdots,\Phi u_M),$$
$$k=1,\cdots,M,\quad z\in\mathbb{C}^N,\quad N\geqq 2.$$

An example of the real Monge-Ampère equation (A) is

$$\det(\partial^2 u/\partial x_i\,\partial x_j)=2^N(2|x|^2+1)\exp[(N-\gamma)|x|^2]u^\gamma,\qquad x\in\mathbb{R}^N, \tag{4.10}$$

where γ is a positive constant. It is easily checked that $u(x)=\exp(|x|^2)$ is a positive radial entire solution of (4.10). If $\gamma>N$, then (f_1), (f_2), and (f_4) hold, and hence Theorem 2.1(A) shows that (4.10) has positive radial entire solutions $u(x)$ with the asymptotic behavior $u(x)\sim\omega|x|$ as $|x|\to\infty$ for some positive constant ω. Equation (4.10) then has positive entire solutions having different types of asymptotic behavior at infinity. A similar example is easy to construct for (B).

SYMMETRY AND BIFURCATION TO 2π-PERIODIC SOLUTIONS OF NONLINEAR SECOND-ORDER EQUATIONS WITH $2\pi/m$-PERIODIC FORCINGS*

M. FÜRKOTTER† AND H. M. RODRIGUES‡

Abstract. Consider the equation $\ddot{u}+u=g(u,p)+\mu f(t)$ where p, μ are small parameters, f is an even continuous $2\pi/m$-periodic function, $m\geqq 2$ is an integer, and g is an odd smooth nonlinear function of u. The main result is that, under certain conditions, the small 2π-periodic solutions maintain some symmetry properties of the forcing function $f(t)$, when $\mu\neq 0$. Other interesting results describe the changes of the number of such solutions as p and μ vary in a small neighborhood of the origin. The main tool used in this work is the Lyapunov-Schmidt method.

Key words. periodic solutions, symmetry, bifurcation, nonlinear equations, small solutions

1. Introduction.

We consider the equation

$$\ddot{u}+u=g(u,p)+\mu f(t) \tag{1.1}$$

where p, μ are small parameters, f is an even continuous $2\pi/m$-periodic function, g is an odd function of u, sufficiently smooth, and $m\geqq 2$ is an integer.

Our main results are, under certain conditions on g and f, that the small 2π-periodic solutions of (1.1) maintain some symmetry properties of the forcing term $f(t)$, when $\mu\neq 0$. We also find the bifurcation curves and describe the changes of the number of such solutions, as (p,μ) varies in a small neighborhood of the origin. A conjecture which was stated in Fürkotter and Rodrigues [2] is proved.

Hale and Rodrigues [1], [5] by studying Duffing's equation $\ddot{u}+u=pu-u^3+\mu\cos t$, showed that the only small 2π-periodic solutions are even functions of t, if $\mu\neq 0$. They also stated the same result for a general even forcing function with minimal period 2π under the condition $\int_0^{2\pi} f(s)\cos s\,ds\neq 0$.

Rodrigues and Vanderbauwhede [6] generalized this result for equations such as (1.1) where f satisfies the former hypothesis and $g(u,p)=O(|pu|+u^2)$ as $(u,p)\to(0,0)$. They also presented an abstract version for equations in Banach spaces. Vanderbauwhede [7] also considers problems related to those above in an abstract form.

Fürkotter and Rodrigues [2] considered the case in which f is π-periodic, that is, $m=2$.

In this work we emphasize the case where f is $2\pi/m$-periodic for $m\geqq 3$, but we also make some comments about the case $m=2$ because, in some respects, the techniques presented here are different from the ones of the work above. The main features of these papers are to find a set of small 2π-periodic solutions of (1.1) and to prove that these are the only feasible solutions.

In § 2, using the Lyapunov-Schmidt method, we show that symmetries in (1.1) imply symmetries in the solutions of the auxiliary equation. We call special attention to Theorem 2.1 which plays a central role in this work.

In § 3, under certain conditions on $g(u, p)$ and on f, we prove that if $u(t)$ is a small 2π-periodic solution of (1.1) then there exists k, $-m/2 < k \leqq m/2$, such that $u(t + k\pi/m)$ is even in t, for (p, μ) small and $\mu \neq 0$. This is stated in Theorem 3.3, where it is required that a certain coefficient, $\rho = \rho(g, f)$, is nonzero.

Our results indicate that the bifurcation equation are more degenerate when more symmetries are present in (1.1).

At the end of § 3 we give some examples.

In § 4 we prove that the condition $\rho \neq 0$ is generic. It is also proved that ρ only depends on the coefficients of the Taylor expansion of $g(u, 0)$, around $u = 0$, up to the order $m+1$ if m is even and up to the order m if m is odd.

An application which can be reduced to (1.1) is the equation $\ddot{v} + \omega_0^2 v + G(v) = \sigma f(\omega t)$ where $G(v)$ is $O(v^2)$ as v tends to zero, f is an even $2\pi/m$-periodic function and we look for $2\pi/\omega$-periodic solutions for ω close to ω_0. This includes the pendulum equation and many other mechanical and electrical oscillators. If we let $u(t) \overset{\text{def}}{=} v(t/\omega)$ and $\omega_0^2/\omega^2 = 1 - p$, we get an equation like (1.1).

We thank a referee for pointing out that this problem could also be treated by using a complexification technique and representation of group $\boldsymbol{Z}_m$, such as appears in Golubitsky, Stewart, and Schaeffer [3].

A similar approach is used by Vanderbauwhede [8], where he considers a related problem.

We point out that, if we suppose that $f(t + \pi/m) = -f(t)$ for m even, the conditions of this work no longer hold and the bifurcation equations become more degenerate. This is a harder problem which will be presented in a future work. The case $m = 2$ is treated by Fürkotter and Rodrigues in [2].

2. The auxiliary equation. Consider equation (1.1)

$$\ddot{u} + u = g(u, p) + \mu f(t),$$

where (p, μ) varies in a small neighborhood of the origin, and the following hypothesis:

(A) f is a real $2\pi/m$-periodic, even function, continuous on R, and $m \geqq 2$ is an integer.

(B) g is a C^∞ real function defined in a neighborhood of $(u, p) = (0, 0)$, odd in u, and $g(u, p) = pu + \alpha u^3 + \beta u^5 + O(|pu^3| + |u|^7)$, as (u, p) goes to $(0, 0)$.

Let $\mathcal{P}$ be the space of all 2π-periodic real functions, continuous on R, with the norm $\|w\| = \sup_{0 \leqq t \leqq 2\pi} |w(t)|$, and let $\mathcal{P}^{(2)}$ be the space of all 2π-periodic real functions, with second derivative continuous on R, with the norm $\|w\| = \sup \{|w^{(j)}(t)|,\ 0 \leqq t \leqq 2\pi,\ j = 0, 1, 2\}$.

On these spaces we consider the projection

$$(Pw)(t) \overset{\text{def}}{=} \frac{\cos t}{\pi} \int_0^{2\pi} w(s) \cos s \, ds + \frac{\sin t}{\pi} \int_0^{2\pi} w(s) \sin s \, ds. \tag{2.1}$$

The Fredholm alternative implies that the equation $\ddot{u} + u = h(t)$, with h in $\mathcal{P}$, has a solution in $\mathcal{P}^{(2)}$ if and only if $Ph = 0$. Moreover, if $Ph = 0$ then there exists a unique solution $u(t)$ in $\mathcal{P}^{(2)}$ such that $Pu = 0$. We indicate this solution by $\mathcal{K}h$. From the variation of constants formula, we obtain

$$\mathcal{K}h = (I - P)\left[-\cos(\cdot) \int_0^{(\cdot)} h(s) \sin s \, ds + \sin(\cdot) \int_0^{(\cdot)} h(s) \cos s \, ds \right]. \tag{2.2}$$

Following the usual procedure of the Lyapunov-Schmidt method, the problem of finding a 2π-periodic solution $u(t)$ of (1.1) is reduced to that of finding a solution w in $\mathcal{P}^{(2)}$ of the following equations:

$$w = \mathcal{K}(I-P)[g(r\cos(\cdot-\phi)+w, p)+\mu f(\cdot)], \tag{2.3a}$$

$$P[g(r\cos(\cdot-\phi)+w, p)+\mu f(\cdot)] = 0 \tag{2.3b}$$

where $u(t) = r\cos(t-\phi)+w(t)$, $r\in R$ and $\phi\in(-\pi/2, \pi/2]$.

Equations (2.3a) and (2.3b) are called the auxiliary and the bifurcation equation, respectively. It follows from the implicit function theorem that (2.3a) has a unique small solution, for (p, μ) in a small neighborhood of the origin. We denote this solution by $w^*(r, \phi, p, \mu)(t)$. If we substitute in (2.3b) we obtain the following equivalent system of equations:

$$F(r, \phi, p, \mu) \overset{\text{def}}{=} \frac{1}{\pi}\int_0^{2\pi} g(r\cos s + w^*(r, \phi, p, \mu)(s+\phi), p)\cos s\, ds = 0, \tag{2.4a}$$

$$G(r, \phi, p, \mu) \overset{\text{def}}{=} \frac{1}{\pi}\int_0^{2\pi} g(r\cos s + w^*(r, \phi, p, \mu)(s+\phi), p)\sin s\, ds = 0. \tag{2.4b}$$

The following lemma gives information about some symmetries and estimates of w^*.

LEMMA 2.1. *If hypotheses* (A) *and* (B) *are satisfied, then the solution* w^* *of* (2.3a) *has the following properties*:

(2.5) $w^*(0, \phi, p, \mu)(t)$ *is an even* $2\pi/m$*-periodic function of* t *and is independent of* ϕ;

(2.6) $w^*(r, k\pi/m, p, \mu)(t+k\pi/m)$ *is even in* t *for* $-m/2 < k \leqq m/2$;

(2.7) $w^*(r, \phi, p, 0)(t+\phi)$ *is even in* t;

(2.8) $w^*(0, \phi, p, \mu) = \mu\mathcal{K}f + O(|p\mu|+|\mu^3|)$ *as* $(p, \mu)\to(0, 0)$;

(2.9) $w^*(r, \phi, p, \mu) = w^*(0, \phi, p, \mu) + rS(r, \phi, p, \mu)$
where $S(r, \phi, p, \mu) = O(r^2+|\mu|)$, *as* $(r, p, \mu)\to(0, 0, 0)$.

If m *is even then the following properties hold*:

$$w^*(r, \phi, p, \mu)(t) = w^*(-r, \phi, p, \mu)(t-\pi), \tag{2.10}$$

$$w^*(r, \phi, p, \mu)(t) = -w^*(r, \phi, p, -\mu)(t-\pi). \tag{2.11}$$

If $m = 3$, *the following hold*:

$$w^*(r, -\pi/3, p, \mu)(t-\pi/3) = w^*(r, \pi/3, p, \mu)(t+\pi/3), \tag{2.12}$$

$$w^*(-r, \pi/3, p, \mu)(t-2\pi/3) = w^*(r, 0, p, \mu)(t). \tag{2.13}$$

Proof. Properties (2.5)-(2.7), and (2.10)-(2.13) follow essentially from the fact that the auxiliary equation is invariant under certain transformations. Properties (2.8) and (2.9) can be proved in a natural way. □

Let $\mathcal{P}_{2\pi\times 2\pi} = \{f: R\times R\to R: f(t+2\pi, \phi) = f(t, \phi) = f(t, \phi+2\pi)$ for every $(t, \phi)\in R\times R$, f continuous$\}$ with the sup norm.

Let m and n be positive integers, with $m\geqq 2$ and $n\leqq m-1$. If n is even we define $\mathcal{F}_n$ as the space of the functions $y\in\mathcal{P}_{2\pi\times 2\pi}$, such that $y(t, \phi)$ can be written in the form:

$$\sum_{j=0}^{n/2}[a_{n,2j}(t)\cos 2j(t-\phi) + b_{n,2j}(t)\sin 2j(t-\phi)] \tag{2.14}$$

where $a_{n,2j}$ is an even $2\pi/m$-periodic function and $b_{n,2j}$ is an odd $2\pi/m$-periodic function, for $j = 0, \cdots, n/2$.

If n is an odd integer, we define $\mathcal{F}_n$ as the space of the functions $y \in \mathcal{P}_{2\pi\times 2\pi}$, such that $y(t, \phi)$ can be written in the form:

$$\sum_{j=0}^{(n-1)/2} [a_{n,2j+1}(t) \cos (2j+1)(t-\phi) + b_{n,2j+1}(t) \sin (2j+1)(t-\phi)] \tag{2.15}$$

where $a_{n,2j+1}$ is an even $2\pi/m$-periodic function and $b_{n,2j+1}$ is an odd $2\pi/m$-periodic function for $j = 0, 1, \cdots, (n-1)/2$.

Remark 2.1. In Lemmas 2.2–2.4 and Theorem 2.1 we allow ϕ to vary in R. To avoid picking up the same solution twice, in § 3 we restrict ϕ to $(-\pi/2, \pi/2]$.

LEMMA 2.2. *$\mathcal{F}_n$ is closed in $\mathcal{P}_{2\pi\times 2\pi}$.*

Proof. Let us assume first that n is even and that y is in $\mathcal{F}_n$. Then it has the form (2.14).

It is possible to prove that

$$a_{n,2j}(t) = \frac{1}{\pi} \int_0^{2\pi} y(t, \phi) \cos 2j(t-\phi)\, d\phi$$

and

$$b_{n,2j}(t) = \frac{1}{\pi} \int_0^{2\pi} y(t, \phi) \sin 2j(t-\phi)\, d\phi.$$

From this fact it follows that if a sequence $y_k \in \mathcal{F}_n$ converges in $\mathcal{P}_{2\pi\times 2\pi}$, then its limit is in $\mathcal{F}_n$.

If n is odd the proof is similar. □

LEMMA 2.3. *If q_i, n_i, β are positive integers, $y_i \in \mathcal{F}_{n_i}$, $i = 1, \cdots, \beta$ and $\alpha = \sum_{i=1}^{\beta} q_i n_i \leqq m-1$, then $\prod_{i=1}^{\beta} y_i^{q_i} \in \mathcal{F}_\alpha$.*

The next lemma plays an important role in this work.

LEMMA 2.4. *If m and n are positive integers, with $m \geqq 2$, $n \leqq m-1$, and $f \in (I-P)\mathcal{F}_n$ then $\mathcal{K}f$, that is, the function $(t, \phi) \mapsto \mathcal{K}f(\cdot, \phi)(t)$, belongs to $(I-P)\mathcal{F}_n$.*

Proof. Let us suppose first that n is even.

Our purpose is to prove that there exist coefficients $a_{n,2j}$, $b_{n,2j}$ in such a way that a function $x(t)$ given by (2.14) is a solution of $\ddot{x} + x = f(t, \phi)$ and $x \in (I-P)\mathcal{F}_n$. Since $\mathcal{K}f(\cdot, \phi)$ is the unique 2π-periodic solution which belongs to the range of $I-P$, it will follow that $x = \mathcal{K}f(\cdot, \phi)$.

If we substitute (2.14) into $\ddot{x} + x = f(t, \phi)$, where $f(t, \phi) \overset{\text{def}}{=} \sum_{j=0}^{n/2} [A_{n,2j}(t) \cos 2j(t-\phi) + B_{n,2j}(t) \sin 2j(t-\phi)]$ and equate coefficients, we obtain the equivalent system:

$$\ddot{a}_{n,2j} - (4j^2-1)a_{n,2j} + 4j\dot{b}_{n,2j} = A_{n,2j},$$
$$\ddot{b}_{n,2j} - (4j^2-1)b_{n,2j} + 4j\dot{a}_{n,2j} = B_{n,2j}$$

for $j = 0, \cdots, n/2$.

Now, if we let $y_1 = a_{n,2j}$, $\dot{y}_1 = y_2$, $y_3 = 3b_{n,2j}$, $\dot{y}_3 = y_4$, $y = \text{col}\,(y_1, y_2, y_3, y_4)$, we obtain the equivalent equation:

$$\dot{y} = C_j y + F_j$$

where $F_j = \text{col}\,(0, A_{n,2j}, 0, B_{n,2j})$ and

$$C_j = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 4j^2-1 & 0 & 0 & -4j \\ 0 & 0 & 0 & 1 \\ 0 & 4j & 4j^2-1 & 0 \end{bmatrix}$$

for $j = 0, \cdots, n/2$.

The eigenvalues of C_j are $\pm(2j+1)i$ and $\pm(2j-1)i$.

If m is even then the system $\dot{y} = C_j y$ is noncritical with respect to $\mathcal{P}_{2\pi/m}$, the space of $2\pi/m$-periodic continuous functions. The same holds if m is odd, $0 \leqq j \leqq n/2 \leqq (m-1)/2$, or $0 \leqq j \leqq n/2 < (m-1)/2$. If $j = n/2 = (m-1)/2$, then the system $\dot{y} = C_j y$ is critical with respect to $\mathcal{P}_{2\pi/m}$.

For the noncritical cases the equation $\dot{y} = C_j y + F_j$ has a unique $2\pi/m$-periodic solution $y(t) = \operatorname{col}(y_1(t), y_2(t), y_3(t), y_4(t))$. Since $z(t) \overset{\text{def}}{=} \operatorname{col}(y_1(-t), -y_2(-t), -y_3(-t), y_4(-t))$ is also a $2\pi/m$-periodic solution, it follows that $y_1(t)$ must be even and $y_3(t)$ must be odd functions of t.

For $j = n/2 = (m-1)/2$ we have a critical case. Following Hale [4, p. 275] we have that

$$\phi(t) \overset{\text{def}}{=} \begin{bmatrix} \cos mt & \sin mt \\ -m \sin mt & m \cos mt \\ \sin mt & -\cos mt \\ m \cos mt & m \sin mt \end{bmatrix}$$

is a matrix whose columns form a basis of the space of $2\pi/m$-periodic solutions of $\dot{y} = C_j(y)$, and

$$\Psi(t) = \begin{bmatrix} -(m-2)\sin mt & \cos mt & (m-2)\cos mt & \sin mt \\ (m-2)\cos mt & \sin mt & (m-2)\sin mt & -\cos mt \end{bmatrix}$$

is a matrix whose rows form a basis of the space of $2\pi/m$-periodic solutions of the adjoint equation, $\dot{z} = -zC_j$.

If we define projections $\bar{P}$, $\bar{Q}$ as in Hale [4, (2.5), p. 276], we obtain

$$\bar{P}f = \Phi(\cdot)\left[\int_0^{2\pi/m} \Phi'(t)\Phi(t)\,dt\right]^{-1} \int_0^{2\pi/m} \Phi'(t)f(t)\,dt,$$

$$\bar{Q}f = \psi'(\cdot)\left[\int_0^{2\pi/m} \Psi(t)\Psi'(t)\,dt\right]^{-1} \int_0^{2\pi/m} \Psi(t)f(t)\,dt.$$

$Pf(\cdot, \phi) = 0$ implies that $\bar{Q}F_j = 0$, for $j = (m-1)/2$.

Then $\dot{y} = C_j y + F_j$ has a unique $2\pi/m$-periodic solution $y(t)$ such that $(\bar{P}y)(t) \equiv 0$.

If $z(t) \overset{\text{def}}{=} \operatorname{col}(y_1(-t), -y_2(-t), -y_3(-t), y_4(-t))$, then $z(t)$ is also a solution of the same equation with $(\bar{P}z)(t) \equiv 0$. This implies that y_1 is even and $y_3(t)$ is odd.

The above information will provide a solution $x(t)$ of $\ddot{x} + x = f(t, \phi)$, and the condition $\bar{P}y = 0$ implies that $Px = 0$. This shows that $x \in (I-P)\mathcal{F}_n$ and that $x(t) = \mathcal{K}f(\cdot, \phi)(t)$.

The case n odd is similar.

LEMMA 2.5. *Let X be a Banach space, and let $I \subset R$ be an interval. Let $\xi: I \to X$ and $g: X \to X$ be functions with continuous derivatives up to the order n. Let $H = g \circ \xi$. Then for $n \geqq 1$, $\partial^n H/\partial r^n(r)$ can be written as a sum of terms of the form*

$$\gamma_i \frac{\partial^i g}{\partial u^i}(\xi(r))\left(\frac{d^{\alpha_1^i}\xi}{dr^{\alpha_1^i}}\right)^{\beta_1^i} \cdots \left(\frac{d^{\alpha_{k_i}^i}\xi}{dr^{\alpha_{k_i}^i}}\right)^{\beta_{k_i}^i}$$

where $\alpha_1^i\beta_1^i + \cdots + \alpha_{k_i}^i\beta_{k_i}^i = n$, $\beta_1^i + \cdots + \beta_{k_i}^i = i$ and γ_i are constants, for $i = 1, \cdots, n$. Moreover, if $i > 1$, then $\alpha_j^i < n$ and $\partial g/\partial u(\xi(r))d^n\xi/dr^n$ is the only term containing $d^n\xi/dr^n$.

The next theorem will be very important in the proof of our main results.

THEOREM 2.1. *Suppose hypotheses* (A) *and* (B) *are satisfied. If $1 \leqq n \leqq m-1$, then $\partial^n w^*/\partial r^n(0, \cdot, p, \mu)(\cdot)$ belongs to $(I-P)\mathcal{F}_n$. Moreover, it has the form* (2.14) *or* (2.15),

for m even or odd, respectively, with the coefficients $a_{ij}(t)=a_{ij}(p,\mu)(t)$ *and* $b_{ij}(t)=b_{ij}(p,\mu)(t)$.

Proof. We will do the proof by induction. If $n=1$ then $\partial w^*/\partial r(0,\cdot,p,\mu)(\cdot)$ is the unique solution of $\mathcal{H}y=y$, where $(\mathcal{H}y)(t,\phi)\overset{\text{def}}{=}\mathcal{K}(I-P)\times[\partial g/\partial u(w^*(0,\phi,p,\mu)(\cdot),p)(y+\cos(\cdot-\phi))](t)$ is a uniform contraction with respect to p, μ for (p,μ) in a small neighborhood of $(0,0)$.

From Lemmas 2.1 and 2.4, after some calculations we prove that $(I-P)\mathcal{F}_1$ is invariant under $\mathcal{H}$. Since, by Lemma 2.2, $(I-P)\mathcal{F}_1$ is closed in $\mathcal{P}_{2\pi\times 2\pi}$ it follows that the fixed point of $\mathcal{H}$ is in $(I-P)\mathcal{F}_1$.

Now let us assume that the result is true up to order $n-1$. We will prove that it is true for n.

$y=\partial^n w^*/\partial r^n(0,\cdot,p,\mu)$ is the unique solution of $y=\mathcal{H}y$ where

$$(\mathcal{H}y)(t,\phi)\overset{\text{def}}{=}\mathcal{K}(I-P)\left[\frac{\partial g}{\partial u}(w^*(0,\phi,p,\mu),p)y+T(\phi,p,\mu)\right](t),$$

and $T(\phi,p,\mu)$, by Lemma 2.5, can be written as a sum of terms of the form

$$\gamma_i\frac{\partial^i g}{\partial u^i}(w^*,p)\left(\cos(\cdot-\phi)+\frac{\partial w^*}{\partial r}\right)^{\beta_1^i}\left(\frac{\partial^{\alpha_2^i}w^*}{\partial r^{\alpha_2^i}}\right)^{\beta_2^i}\cdots\left(\frac{\partial^{\alpha_{k_i}^i}w^*}{\partial r^{\alpha_{k_i}^i}}\right)^{\beta_{k_i}^i}$$

where $i>1$ and $\partial^l w^*/\partial r^l$, above, means $\partial^l w^*/\partial r^l(0,\phi,p,\mu)$ for $l=0,1,\cdots,\alpha_{k_i}^i$. Moreover, $\alpha_j^i<n$, $\alpha_1^i\beta_1^i+\cdots+\alpha_{k_i}^i\beta_{k_i}^i=n$ and $\beta_1^i+\cdots+\beta_{k_i}^i=i$, for $j=1,\cdots,k_i$, $i=1,\cdots,n$.

As before $\mathcal{H}$ is a uniform contraction in $\mathcal{P}_{2\pi\times 2\pi}$ for (p,μ) in a small neighborhood of $(0,0)$.

From Lemmas 2.1, 2.3, and 2.4, after some calculations it follows that $(I-P)\mathcal{F}_n$ is closed in $\mathcal{P}_{2\pi\times 2\pi}$. Then the fixed point of $\mathcal{H}$ belongs to $(I-P)\mathcal{F}_n$. □

3. The bifurcation equations. Since in § 2 we obtained much information about the solution of the auxiliary equation, we now are able to analyze the bifurcation equations given in (2.4).

LEMMA 3.1. *Under hypotheses* (A) *and* (B) *the following hold*:

(i) $G(r,\phi,p,0)\equiv 0$.

(ii) *If m is even, then F and G are odd functions of r and even functions of* μ.

Proof. The first part follows from Lemma 2.1, (2.7) and the second part follows from Lemma 2.1, (2.10) and (2.11). □

THEOREM 3.1. *Suppose hypotheses* (A) *and* (B) *are satisfied. Then for* (r,p,μ) *in a small neighborhood of the origin,* $G(r,\phi,p,\mu)=r^{m-1}\mu\sin m\phi(\rho+\cdots)$, *if m is odd and* $G(r,\phi,p,\mu)=r^{m-1}\mu^2\sin m\phi(\rho+\cdots)$, *if m is even, where* ρ *is independent of* ϕ, p, μ *and* $(\cdots)$ *indicates terms of order* $O(|p|+|\mu|+|r|)$ *uniformly on* ϕ, *as* $(r,p,\mu)\to(0,0,0)$.

Proof. We will first prove that

$$\frac{\partial^l G}{\partial r^l}(0,\phi,p,\mu)=0,\qquad l=1,2,\cdots,m-2.$$

If we let $H(r,s)\overset{\text{def}}{=}g(r\cos(s-\phi)+w^*(r,\phi,p,\mu)(s),p)$, then

$$\frac{\partial^l G}{\partial r^l}(0,\phi,p,\mu)=\frac{1}{\pi}\int_0^{2\pi}\frac{\partial^l H}{\partial r^l}(0,s)\sin(s-\phi)\,ds.$$

From Lemma 2.5 it follows that $\partial^l H/\partial r^l(0,s)$ is a sum of terms of the form

$$\gamma_i\frac{\partial^i g}{\partial u^i}(w^*,p)\left(\cos(\cdot-\phi)+\frac{\partial w^*}{\partial r}\right)^{\beta_1^i}\left(\frac{\partial^{\alpha_2^i}w^*}{\partial r^{\alpha_2^i}}\right)^{\beta_2^i}\cdots\left(\frac{\partial^{\alpha_{\beta_{k_i}}^i}w^*}{\partial r}\right)^{\alpha_{\beta_{k_i}}^i}$$

where $\partial^q w^*/\partial r^q = \partial^q w^*/\partial r^q(0, \phi, p, \mu)(s)$, $q = 0$, $\alpha_1^i, \cdots, \alpha_{k_i}^i$, $\alpha_1^i\beta_1^i + \cdots + \alpha_{k_i}^i\beta_{k_i}^i = l$ and $\beta_1^i + \cdots + \beta_{k_i}^i = i$.

Let us assume first that l is even. From Theorem 2.1 and Corollary 2.1 it follows that $\partial^l G/\partial r^l(0, \phi, p, \mu)$ is a sum of integrals of the form

$$\int_0^{2\pi} [a(s)\cos 2j(s-\phi) + b(s)\sin 2j(s-\phi)]\sin(s-\phi)\,ds$$

where $0 \leqq j \leqq l/2 < (m-1)/2$ and $a(s)$, $b(s)$ are $2\pi/m$-periodic functions.

That integral can be written as

$$\frac{1}{2}\left\{-\sin(2j+1)\phi \int_0^{2\pi} [a(s)\cos(2j+1)s + b(s)\sin(2j+1)s]\,ds \right.$$
$$\left. + \sin(2j-1)\phi \int_0^{2\pi} [a(s)\cos(2j-1)s + b(s)\sin(2j-1)s]\,ds\right\}.$$

Since $j < (m-1)/2$ implies that $(2j+1) < m$ and since $a(s)$, $b(s)$ are $2\pi/m$-periodic it follows that the above integrals vanish.

The case l odd, $l < m-1$ is similar.

The same idea shows that $(\partial^{m-1}/\partial r^{m-1})G(0, \phi, p, \mu)$ is a sum of integrals of the form

$$-\frac{\sin m\phi}{2}\int_0^{2\pi} [a(s)\cos ms + b(s)\sin ms]\,ds$$

where $a(s) = a(p, \mu)(s)$, $b(s) = b(p, \mu)(s)$ are $2\pi/m$-periodic functions of s.

From Lemma 2.1, (2.6) it follows that $G(r, k\pi/m, p, \mu) \equiv 0$.

The proof can be completed by using Lemma 3.1 and the above results. □

Remark 3.1. To evaluate ρ it is sufficient to compute

$$\left(\frac{\partial^{m+1}G}{\partial r^{m-1}\partial\mu^2}(0, \phi, 0, 0)\right)\Big/\sin m\phi \quad \text{or} \quad \left(\frac{\partial^m G}{\partial r^{m-1}\partial\mu}(0, \phi, 0, 0)\right)\Big/\sin m\phi,$$

for m even or odd, respectively.

The case $m = 2$ is considered by Fürkotter and Rodrigues in [2]. The cases where $m = 3, 4, 5$ are considered with details in § 3 in the section of examples.

THEOREM 3.2. *Suppose* (A) *and* (B) *are satisfied and* $\rho \neq 0$. *Then the only small* 2π*-periodic solutions of* (1.1) *are such that* $u(t + k\pi/m)$ *is even in* t, *for some* k, $-m/2 < k \leqq m/2$, *for* (p, μ) *small and* $\mu \neq 0$.

Proof. Since $G(r, \phi, p, \mu) = r^{m-1}\mu \sin m\phi(\rho + \cdots)$ if m is odd, $G = 0$, $\mu \neq 0$ implies $r = 0$ or $\sin m\phi = 0$. Since $u(t) = r\cos(t-\phi) + w^*(r, \phi, p, \mu)(t)$, from Lemma 2.1 it follows that $u(t)$ is even if $r = 0$. If $\sin m\phi = 0$ then $\phi = k\pi/m$, $-m/2 < k \leqq m/2$. Still from Lemma 2.1 it follows that $u(t + k\pi/m) = r\cos t + w^*(r, k\pi/m, p, \mu)(t + k\pi/m)$ is even in t. □

In what follows we will assume that $\rho \neq 0$.

Now let us analyze the first bifurcation equation (2.4a),

$$F(r, \phi, p, \mu) = \frac{1}{\pi}\int_0^{2\pi} g(r\cos s + w^*(r, \phi, p, \mu)(s + \phi), p)\cos s\,ds = 0.$$

If we let $g(u, p) = pu + \alpha u^3 + O(|pu^3| + |u^5|)$ and since $F(0, \phi, p, \mu) \equiv 0$, after some calculations we obtain for $m > 3$,

$$F(r, \phi, p, \mu) = r(p + \tfrac{3}{4}\alpha r^2 + 3\alpha\eta r\mu + 3\alpha\lambda\mu^2 + \cdots) = 0$$

where

$$\lambda \overset{\text{def}}{=} \frac{1}{2\pi}\int_0^{2\pi}[(\mathcal{K}f)(t)]^2\,dt, \qquad \eta \overset{\text{def}}{=} \frac{\cos 3\phi}{4\pi}\int_0^{2\pi}(\mathcal{K}f)(t)\cos 3t\,dt$$

and $\cdots$ indicates higher-order terms.

We know that $r=0$ solves $F=0$ and $u(t)=w^*(0,\phi,p,\mu)(t)$ is $2\pi/m$-periodic in t.

In order to find other solutions, we consider $J \overset{\text{def}}{=} F/r$. To find multiple roots of $J=0$ we consider the system:

$$J(r,\phi,p,\mu)=p+\tfrac{3}{4}\alpha r^2+3\alpha\eta r\mu+3\alpha\lambda\mu^2+\cdots=0,$$

$$J_r(r,\phi,p,\mu)=\tfrac{3}{2}\alpha r+3\alpha\eta\mu+\cdots=0.$$

Since $\det(\partial(J,J_r)/\partial(p,r))=\frac{3}{2}\alpha$, for $r=p=\mu=0$, if $\alpha\neq 0$, from the implicit function theorem it follows that p and r can be found as functions of μ in a small neighborhood of the origin, for each fixed ϕ.

In what follows, the case $m=3$ requires a different treatment from the case $m>3$.

If $m=3$ the admissible values of ϕ are $\phi=0$ and $\phi=\pm\pi/3$. From Lemma 2.1, (2.12) it follows that $F(r,-\pi/3,p,\mu)=F(r,\pi/3,p,\mu)$, which implies that the bifurcation equations are the same for $\phi=-\pi/3$ and $\phi=\pi/3$.

Also from Lemma 2.1, (2.13) it follows that $F(-r,\pi/3,p,\mu)=-F(r,0,p,\mu)$, which implies $J(-r,\pi/3,p,\mu)=J(r,0,p,\mu)$. Therefore the bifurcation curve $p=p(\mu)$ for $\phi=0$ is the same as for $\phi=\pi/3$, while $r=r(\mu)$ changes sign.

The bifurcation curve for $\phi=0$ is given by $p=3\alpha(\eta^2-\lambda)\mu^2+O(|\mu|^3)$. The value of r where the bifurcation occurs is given by $r=-2\eta\mu+O(\mu^2)$.

If $m>3$ we assure that $J_r(0,\phi,p,\mu)\equiv 0$. This follows from Theorem 2.1 and Lemma 2.1.

It also follows from Theorem 2.1 that $J(0,\phi,p,\mu)$ is independent of ϕ.

Since $J(0,\phi,p,\mu)$ does not depend on ϕ and $J_r(0,\phi,p,\mu)\equiv 0$, it follows that the solution $p=p(\mu)$ which we obtain by solving $J(0,\phi,p,\mu)=0$ and $r=0$ is the unique solution of $J(0,\phi,p,\mu)=0$, $J_r(0,\phi,p,\mu)=0$ of r and p as functions of μ. Therefore for $m>3$ we have a unique bifurcation curve, which is given by

$$p=-3\alpha\lambda\mu^2+O(|\mu|^3).$$

The next theorem is very interesting and it describes the changes of the number of the small $2\pi/m$-periodic solutions of (1.1) as (p,μ) crosses the bifurcation curve.

THEOREM 3.3. *Suppose* (A) *and* (B) *are satisfied,* $m\geqq 3$, $\alpha\neq 0$ *and* ρ, *given in Remark* 3.1, *is nonzero. Then there exists a unique bifurcation curve* Γ, *which is given by* $p=-3\alpha\lambda\mu^2+O(\mu^3)$ *where* $\lambda=(1/2\pi)\int_0^{2\pi}[(\mathcal{K}f)(s)]^2\,ds$ *and* $\mathcal{K}f$ *is the* $2\pi/m$*-periodic solution of* $\ddot{u}+u=f(t)$, *if* $m>3$ *and by* $p=3\alpha(\eta^2-\lambda)\mu^2+O(\mu^3)$ *if* $m=3$, *where* $\eta^2=(\cos 3\phi/4\pi)\int_0^{2\pi}(\mathcal{K}f)(t)\cos 3t\,dt$.

The curve Γ *divides a neighborhood of the origin into regions as is shown in Figs.* 3.1 *and* 3.2 *for* $m>3$ *and* $m=3$, *respectively, for* α, $\lambda>0$, $\mu\neq 0$. *The number of* 2π*-periodic solutions of* (1.1) *is indicated in the figures.*

Examples. In what follows we will analyze the cases $m=3$, 4, 5. We recall that the case $m=2$ was studied in Fürkotter and Rodrigues [2] where we considered the example $f(t)=1+\cos 2t$. From the calculation that will be presented below, if $g(u,0)=\alpha u^3+\beta u^5+O(|u^7|)$, to compute the value of ρ for $m=3$, we only use α, while for $m=4$, 5 both α and β have contribution on the value of ρ.

For $m=3$, we have $\rho=-(3/4\pi)\alpha\int_0^{2\pi}(\mathcal{K}f)(t)\cos 3t\,dt$.

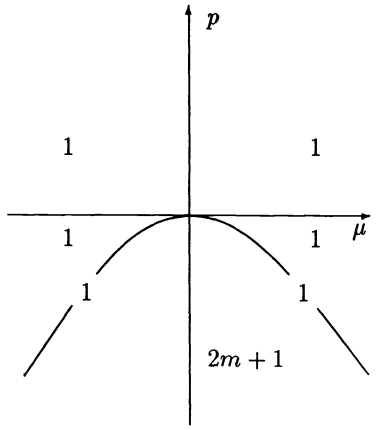

FIG. 3.1

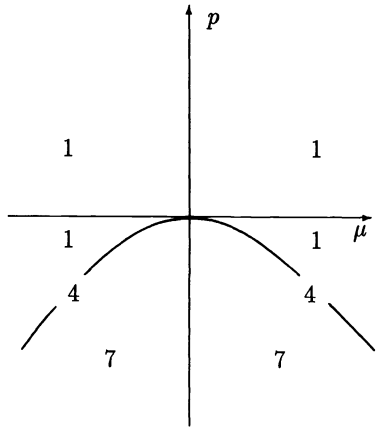

FIG. 3.2

For $m = 4$,

$$\rho = -\frac{9}{4\pi}\alpha^2 \int_0^{2\pi} \mathcal{K}(I-P)[\cos(\cdot)(\mathcal{K}f)^2](s)\cos 3s\, ds$$
$$-\frac{9}{4\pi}\alpha^2\left(\int_0^{2\pi} (\mathcal{K}f)(s)\mathcal{K}[\cos 2(\cdot)\mathcal{K}f](s)\cos 2s\, ds\right.$$
$$\left.-\int_0^{2\pi} (\mathcal{K}f)(s)\mathcal{K}[\sin 2(\cdot)\mathcal{K}f](s)\sin 2s\, ds\right)$$
$$+\frac{3}{64\pi}\alpha^2 \int_0^{2\pi} [(\mathcal{K}f)(s)]^2 \cos 4s\, ds - \frac{5\beta}{4\pi}\int_0^{2\pi} [(\mathcal{K}f)(s)]^2 \cos 4s\, ds.$$

For $m = 5$,

$$\rho = \frac{45}{64\pi}\alpha^2 \int_0^{2\pi} (\mathcal{K}f)(s)\cos 5s\, ds + \frac{3}{64\pi}\alpha^2 \int_0^{2\pi} (\mathcal{K}f)(s)\cos 5s\, ds$$
$$-\frac{5}{16\pi}\beta \int_0^{2\pi} (\mathcal{K}f)(s)\cos 5s\, ds.$$

Let us now consider the equation $\ddot{u}+u=g(u,p)+\mu f(t)$, where $g(u,p)=pu+\alpha u^3+\beta u^5+\cdots$, for some specific examples of $f(t)$:

(1) If $f(t)=\cos 3t$, then $\rho=3\alpha/32$, $\lambda=1/128$, and $\eta=-(1/32)\cos 3\phi$.

(2) If $f(t)=1+\cos 4t$, then $\rho=-\alpha^2/8+\beta/6$, $\lambda=1/450$, and $\eta=0$.

(3) If $f(t)=\cos 5t$, then $\rho=-(5/1024)\alpha^2+(5/384)\beta$, $\lambda=1/1152$, and $\eta=0$.

4. The genericity of the condition $\rho\neq 0$. In this chapter we will suppose that $g\in C^{m+2}$

$$g(u,0)=\sum_{i=1}^{(m-1)/2}\alpha_{2i+1}u^{2i+1}+O(|u|^{m+2}),$$

if m is odd and $g\in C^{m+3}$,

$$g(u,0)=\sum_{i=1}^{m/2}\alpha_{2i+1}u^{2i+1}+O(|u|^{m+3}),$$

if m is even. In both cases we suppose that $g(\cdot,p)$ is odd.

LEMMA 4.1. *Under the above assumptions and* (A), *if* $k\geqq 3$ *is an integer,* $k\leqq(m-1)/2$ *if* m *is odd* $k\leqq m/2$ *if* m *is even, then there exist continuous functions,* $W_1=W_1(\alpha_3,\cdots,\alpha_{2k-1},r,\phi,\mu,f)=O((|r|+|\mu|)^3)$, $W_2=W_2(r,\phi,\mu,f)=O((|r|+|\mu|)^{2k+1})$, *such that*

$$w^*(r,\phi,0,\mu)=\mu(\mathcal{K}f)+W_1+\alpha_{2k+1}W_2+O((|r|+|\mu|)^{2k+3}).$$

The proof of the above lemma can be done by induction on k.

LEMMA 4.2. *Under the assumptions of Lemma* 4.1, *the following hold*:

(1) *If* $m\geqq 4$ *is even, then there exists a continuous function* $K(\alpha_3,\cdots,\alpha_{m-1},f)$, *such that*

$$\rho=-\frac{m(m+1)}{2^m\pi}\alpha_{m+1}\int_0^{2\pi}[(\mathcal{K}f)(s)]^2\cos ms\,ds+K(\alpha_3,\cdots,\alpha_{m-1},f).$$

(2) *If* $m\geqq 5$ *is odd, then there exists a continuous function* $K(\alpha_3,\cdots,\alpha_{m-2},f)$, *such that*

$$\rho=-\frac{m}{2^{m-1}\pi}\alpha_m\int_0^{2\pi}(\mathcal{K}f)(s)\cos ms\,ds+K(\alpha_3,\cdots,\alpha_{m-2},f).$$

Proof. If m is even, from Lemma 4.1 it follows that

$$w^*=\mu\mathcal{K}f+W_1+\alpha_{m+1}W_2+\cdots$$

where $\cdots\overset{\text{def}}{=}O((|r|+|\mu|)^{m+3})$.

Therefore,

$$\begin{aligned}
G(r,\phi,0,\mu)&=\frac{1}{\pi}\int_0^{2\pi}\sum_{l=1}^{m/2}\alpha_{2l+1}(r\cos s+w^*(s+\phi))^{2l+1}\sin s\,ds+\cdots\\
&=\frac{1}{\pi}\int_0^{2\pi}\alpha_{m+1}(r\cos s+w^*(s+\phi))^{m+1}\sin s\,ds\\
&\quad+\frac{1}{\pi}\int_0^{2\pi}\sum_{l=1}^{(m-2)/2}\alpha_{2l+1}(r\cos s+w^*(s+\phi))^{2l+1}\sin s\,ds+\cdots\\
&=\frac{1}{\pi}\int_0^{2\pi}\alpha_{m+1}[r\cos s+\mu(\mathcal{K}f)(s+\phi)]^{m+1}\sin s\,ds\\
&\quad+\frac{1}{\pi}\int_0^{2\pi}\sum_{l=1}^{(m-2)/2}\alpha_{2l+1}[r\cos s+\mu(\mathcal{K}f)(s+\phi)+W_1]^{2l+1}\sin s\,ds+\cdots.
\end{aligned}$$

From Theorem 3.1, it follows that

$$G(r, \phi, p, \mu) = r^{m-1}\mu^2 \sin m\phi[\rho + O(|p|+|\mu|+|r|)].$$

Therefore, to determine ρ it suffices to consider the part of G, which contains terms involving $r^{m-1}\mu^2$, for $p=0$.

Let us first consider the term

$$\frac{\alpha_{m+1}}{\pi}\int_0^{2\pi}[r\cos s + \mu(\mathcal{K}f)(s+\phi)]^{m+1}\sin s\, ds.$$

The part of this term that involves $r^{m-1}\mu^2$ is given by

$$\frac{\alpha_{m+1}}{\pi}\frac{m(m+1)}{2}r^{m-1}\mu^2\int_0^{2\pi}\cos^{m-1}s[(\mathcal{K}f)(s+\phi)]^2\sin s\, ds.$$

By induction we can prove that

$$\cos^{m-1} s \sin s = \frac{1}{2^{m-1}}\Big\{[\sin ms - \sin(m-2)s] + \sum_{j=1}^{(m-2)/2}\beta_j[\sin(m-2j)s - \sin(m-2(j+1))s]\Big\}$$

where β_j are constants.

Since $\mathcal{K}f$ is $2\pi/m$-periodic, we have that

$$\int_0^{2\pi}[(\mathcal{K}f)(s+\phi)]^2\sin ks\, ds = 0 \quad \text{if } 0 \leqq k < m.$$

Therefore,

$$\frac{\alpha_{m+1}}{\pi}\frac{m(m+1)}{2}r^{m-1}\mu^2\int_0^{2\pi}[(\mathcal{K}f)(s+\phi)]^2\cos^{m-1}s\sin s\, ds$$
$$= -\frac{\alpha_{m+1}}{2^m\pi}m(m+1)r^{m-1}\mu^2\sin m\phi\int_0^{2\pi}[(\mathcal{K}f)(s)]^2\cos ms\, ds.$$

If we define $K(\alpha_3, \cdots, \alpha_{m-1}, f)$ as the coefficient of the term $r^{m-1}\mu^2\sin m\phi$ obtained from

$$\frac{1}{\pi}\int_0^{2\pi}\sum_{l=1}^{(m-2)/2}\alpha_{2l+1}[r\cos + \mu(\mathcal{K}f)(s+\phi) + W_1]^{2l+1}\sin s\, ds,$$

then we conclude that ρ has the stated form.

The second part of our lemma is similar. □

THEOREM 4.1. *Under the assumptions on g, in the beginning of this section, the condition $\rho \neq 0$ is generic.*

Proof. Let us consider the case $m \geqq 2$, even. The case $m=2$ is simple. For $m \geqq 4$ we have, from Lemma 4.2 that

$$\rho = \alpha_{m+1}c_m\int_0^{2\pi}[(\mathcal{K}f)(s)]^2\cos ms\, ds + K(\alpha_3, \cdots, \alpha_{m-1}, f)$$

where $c_m \neq 0$.

Without loss of generality, we can assume that

$$\int_0^{2\pi}[(\mathcal{K}f)(s)]^2\cos ms\, ds \neq 0.$$

If $\rho(f, g) = 0$, then we consider $\bar{g}(u) = g(u, 0) + \varepsilon u^{m+1}$. Then $\rho(f, \bar{g}) = \varepsilon c_m \int_0^{2\pi} [(\mathcal{H}f)(s)]^2 \cos ms \, ds \neq 0$ and $\bar{g}$ is close to g in the c^{m+3}-topology, if ε is small.

The remaining part of the proof is easy.

The case m odd is similar. □

ANALYSIS AND COMPUTATION OF SYMMETRY-BREAKING BIFURCATION AND SCALING LAWS USING GROUP THEORETIC METHODS*

P. J. ASTON†

Abstract. Group theoretic methods are used to analyse symmetry-breaking bifurcation for nonlinear equations defined on a real Hilbert space. An important result is the decomposition of the Hilbert space into orthogonal isotypic components, since the Jacobian of the nonlinear operator can be decomposed on the isotypic components. This decomposition is exploited in the detection and computation of bifurcation points. Then scaling laws that arise in many problems are considered, and a natural context is developed for the existence of a scaling law based on the symmetry of the problem. The effect of the scaling law on the bifurcation theory is explored. This theory is applied to the gravity wave problem. Also shown is the way in which the theory can extend to boundary value problems, where the natural group equivariance of the equations is destroyed by the boundary conditions.

Key words. symmetry-breaking bifurcation, symmetry groups, isotypic components, scaling laws, gravity waves

AMS(MOS) subject classifications. 58F14, 22E70

1. Introduction. In this paper, we use group theoretic methods to analyse symmetry-breaking bifurcation for problems defined on a real Hilbert space. Sattinger (1977), (1979) pioneered work in this field, developing much of the theory in a complex Banach space. Fujii, Mimura, and Nishiura (1982) extended this theory by considering the standard, or isotypic, decomposition of a complex Hilbert space. Bossavit (1986) describes in detail how this isotypic decomposition can be employed when solving linear boundary value problems on a complex Hilbert space. However, there are some fundamental differences between group representation theory in real and complex spaces, most notably the corollary to Schur's lemma (Corollary 2.9), and so not all of these results generalise naturally to the real Hilbert space setting. Vanderbauwhede (1982) considered such problems in real Banach spaces but avoided the differences between the theory in real and complex spaces.

Golubitsky, Stewart, and Schaeffer (1988) have considered in detail the analysis of bifurcation in real finite-dimensional spaces on the premise that problems defined on an infinite-dimensional space can often be reduced to finite dimensions using the Lyapunov–Schmidt procedure. However, our aim is to develop efficient numerical methods for the detection and direct computation of symmetry-breaking bifurcation points. Thus we work with a nonlinear, parameter-dependent equation in a real Hilbert space, and investigate properties of the equation and the Jacobian of the nonlinear operator that can be exploited numerically. As bifurcation from a branch of nontrivial solutions cannot be analysed analytically, in general, we develop the theory assuming certain generic conditions.

In § 2, we present systematically the group theoretic results required later on, culminating in the main result of the section, Theorem 2.11, which gives the isotypic decomposition of a real Hilbert space. We turn our attention to bifurcation problems in § 3 and apply the results of the previous section, assuming that the problem is equivariant with respect to a representation of a compact Lie group. We show that the

Jacobian can be decomposed on the isotypic components and exploit this decomposition in the detection and direct computation of bifurcation points. Other authors (Werner (1988), Healey (1988b), Dellnitz and Werner (1989)) have considered the computational advantage of restricting to fixed-point subspaces. However, for the determination of bifurcation points, we will see that the use of isotypic components is a much more powerful tool.

In § 4, we consider scaling laws which arise in many problems. A natural context for the existence of a scaling law is developed based on the symmetry of the problem, and the effect of the scaling law on the bifurcation theory of § 3 is then explored. Often one branch of solutions is related to another by a simple scaling, and so there is no need to compute such a branch. However, we show that bifurcation points can occur on a scaled branch which do not exist on the original branch. We also show how the use of a scaling law can lead to a proof of existence of bifurcating branches at a mode interaction point in some cases.

Finally, in § 5, we apply the preceding theory to the gravity wave problem on a fluid of infinite depth. We also show how the theory can be extended to boundary value problems where the natural group equivariance of the equations is destroyed by the boundary conditions.

2. Group theoretic results. In this section we collect the group theoretic results required in later sections. We develop the theory systematically for the sake of numerical analysts who may not be familiar with it. We consider the group representation theory on a *real* Hilbert space, whereas most textbooks work with complex Hilbert spaces. Many of the results for real spaces are proved in essentially the same way as the corresponding results on complex spaces, and so we do not give these proofs, but refer the reader to Barut and Raczka (1986) or Bröcker and Tom Dieck (1985) (which we will henceforth abbreviate as [BR] and [BtD], respectively). However, there are fundamental differences in the theory of irreducible representations on real and complex spaces (see Corollary 2.9 and the following assertions), and so we then prove the relevant results culminating in our main result of the section, Theorem 2.11, which gives the decomposition of a real Hilbert space into its orthogonal isotypic components.

We will consider only *compact Lie groups.* If Γ is a compact Lie group, we say that Σ is a *subgroup* of Γ if $\sigma\delta^{-1} \in \Sigma$, for all $\sigma, \delta \in \Sigma$, and Σ is closed in Γ so that Σ is also a Lie group [BtD, p. 28]. Also, Σ is a *normal subgroup* of Γ if it is a subgroup and $\gamma\Sigma = \Sigma\gamma$ for all $\gamma \in \Gamma$. If Σ is a normal subgroup of Γ, then the quotient group $\Gamma/\Sigma = \{\gamma\Sigma\colon \gamma \in \Gamma\}$ is also a Lie group [BtD, p. 35]. The *centre* of Γ, defined by

$$Z(\Gamma) = \{\delta \in \Gamma\colon \delta\gamma = \gamma\delta \ \forall \gamma \in \Gamma\},$$

is a normal subgroup of Γ. Further, a *homomorphism* of Lie groups is a smooth (infinitely differentiable) group homomorphism and an *isomorphism* (denoted by $\cong$) is an invertible homomorphism. The kernel of a homomorphism $\beta : \Gamma \to \tilde{\Gamma}$ is the set of elements of Γ that are mapped onto the identity element of $\tilde{\Gamma}$ and is a normal subgroup of Γ. The following result plays an important role in our derivation of scaling laws in § 4.

LEMMA 2.1. *Let Γ and $\tilde{\Gamma}$ be compact Lie groups and let $\beta : \Gamma \to \tilde{\Gamma}$ be a homomorphism with kernel K. Then*

$$\beta(\Gamma) \cong \Gamma/K. \tag{2.1}$$

Proof. There is a group isomorphism between $\beta(\Gamma)$ and Γ/K (Fraleigh (1977, p. 114)) and so it remains to prove that it is smooth. Now K is a (closed) normal subgroup of Γ and so Γ/K is a Lie group. Also $\beta(\Gamma)$ is a closed subgroup of $\tilde{\Gamma}$ since

β is continuous, and is thus a Lie group. Finally, a bijective homomorphism of Lie groups is an isomorphism [BtD, p. 22] which proves the result. □

Every compact Lie group Γ has a unique normalised Haar measure $d\gamma$ [BtD, p. 46] which has the invariance property that for any continuous function $f:\Gamma\to\mathbf{R}$ and any $\delta\in\Gamma$,

$$\int_\Gamma f(\gamma)\,d\gamma=\int_\Gamma f(\delta\gamma)\,d\gamma=\int_\Gamma f(\gamma\delta)\,d\gamma=\int_\Gamma f(\gamma^{-1})\,d\gamma$$

and is normalised such that

$$\int_\Gamma d\gamma=1.$$

If X is a real Hilbert space with inner product $(,)$, then integration can be extended to continuous functions $h:\Gamma\to X$ by defining $\int_\Gamma h(\gamma)\,d\gamma\in X$ to be the unique Riesz representor of the continuous linear functional $x\to\int_\Gamma (h(\gamma),x)\,d\gamma$ [BtD, p. 48]. Thus

$$\left(\int_\Gamma h(\gamma)\,d\gamma,x\right)=\int_\Gamma (h(\gamma),x)\,d\gamma. \tag{2.2}$$

Let X be a real Hilbert space with inner product $(,)$ and let the space of linear homeomorphisms from X to itself be denoted by $GL(X)$. If Γ is a compact Lie group, a *representation* of Γ on X is a group homomorphism $T:\Gamma\to GL(X)$ such that the mapping $(\gamma,x)\to T(\gamma)x$ of $\Gamma\times X$ onto X is continuous. The dimension of a representation is defined to be the dimension of the space X. An *action* of Γ on X is a continuous mapping

$$\rho:\Gamma\times X\to X,\qquad (\gamma,x)\to\rho(\gamma,x)\equiv\gamma x$$

such that

$$\mathbf{1}x=x,\qquad (\gamma_1\gamma_2)x=\gamma_1(\gamma_2 x)$$

for all $x\in X$ and $\gamma_1,\gamma_2\in\Gamma$, where $\mathbf{1}$ is the group identity element. For any action ρ of Γ on X, we can define a representation T of Γ on X by

$$T(\gamma)x\equiv\gamma x.$$

Then T is called the representation of Γ on X induced by the action ρ.

A representation T is called *orthogonal* if $T(\gamma)$ is orthogonal for all $\gamma\in\Gamma$. Important results concerning orthogonal representations of compact groups are given in the following two lemmas (cf. [BR, pp. 166, 140]).

LEMMA 2.2. *Let T be an arbitrary representation of a compact group Γ on X. Then the inner product $\langle,\rangle$ on X defined by*

$$\langle x,y\rangle\equiv\int_\Gamma (T(\gamma)x,T(\gamma)y)\,d\gamma \tag{2.3}$$

for all $x,y\in X$, defines a norm equivalent to the original one, relative to which T is an orthogonal representation of Γ.

The inner product defined by (2.3) is called Γ-*invariant* since

$$\langle x,y\rangle=\langle T(\gamma)x,T(\gamma)y\rangle$$

for all $x,y\in X$, $\gamma\in\Gamma$. *We will henceforth assume that X is a real, separable Hilbert space with a Γ-invariant inner product denoted by $\langle,\rangle$, so that T is an orthogonal representation of Γ on X.*

We say that representations T and $\tilde{T}$ of Γ on real Hilbert spaces X and $\tilde{X}$, respectively, are *equivalent* if there exists a linear homeomorphism $A: X \to \tilde{X}$ such that

$$AT(\gamma) = \tilde{T}(\gamma)A \quad \forall \gamma \in \Gamma.$$

If A is also orthogonal, we say that T and $\tilde{T}$ are *orthogonally equivalent.* We then have the following result.

LEMMA 2.3. *Two equivalent orthogonal representations are orthogonally equivalent.*

Two structures that will be used extensively in later sections are fixed-point subspaces and isotropy subgroups. For any subgroup Σ of Γ, the *fixed-point subspace* X^{Σ} is defined by

$$X^{\Sigma} = \{x \in X: T(\sigma)x = x \ \forall \sigma \in \Sigma\},$$

which is a closed subspace of X since it is the intersection of the null spaces of the bounded linear operators $T(\sigma) - I$ for all $\sigma \in \Sigma$. Also, for any $x \in X$,

$$\Sigma_x = \{\gamma \in \Gamma: T(\gamma)x = x\}$$

is a subgroup of Γ called the *isotropy subgroup* of x. (It is closed in Γ because T is a representation and so it is also a Lie group.) We extend the notion of isotropy subgroups of elements to subspaces, and so we define the isotropy subgroup Σ_Y of a subspace Y of X by

$$\Sigma_Y = \{\gamma \in \Gamma: T(\gamma)y = y \ \forall y \in Y\}.$$

A subspace W of X is Γ-*invariant* if $T(\gamma)w \in W \ \forall w \in W$, $\gamma \in \Gamma$. A nontrivial, closed, Γ-invariant subspace W of X is Γ-*irreducible* if it has no proper, closed, Γ-invariant subspaces. Otherwise it is Γ-*reducible.* (If there is no ambiguity with regard to the group Γ, we will refer to a subspace simply as invariant, irreducible, etc.)

We now aim to show that the Hilbert space X can be decomposed as an orthogonal direct sum of finite-dimensional irreducible subspaces, that is,

$$X = \sum_i \oplus X_i$$

where each X_i is irreducible, X_i and X_j are orthogonal for $i \neq j$, and every $x \in X$ can be decomposed into the convergent series

$$x = \sum_i x_i, \qquad x_i \in X_i.$$

The first result we require is the following (cf. [BR, pp. 141–142]).

LEMMA 2.4. *Let W be a closed, Γ-invariant subspace of X and let $W^{\perp}$ be the orthogonal complement of W such that $X = W \oplus W^{\perp}$. Then*

(i) *$W^{\perp}$ is a closed, Γ-invariant subspace of X.*

(ii) *The restriction of $T(\gamma)$ to W is also a representation of Γ.*

COROLLARY 2.5. *Every finite-dimensional invariant subspace of X can be decomposed as an orthogonal direct sum of irreducible subspaces.*

The next theorem shows that the infinite-dimensional space X can be decomposed in a similar way (cf. [BR, pp. 169–170]).

THEOREM 2.6. *Let Γ be a compact Lie group and let T be an orthogonal representation of Γ on the real Hilbert space X. Then X can be decomposed as an orthogonal direct sum of finite-dimensional irreducible subspaces.*

COROLLARY 2.7. *Every irreducible subspace of X is finite dimensional.*

A representation on an irreducible subspace is itself called irreducible. We now take a closer look at those linear operators that commute with irreducible representations, since this is where the group representation theory on real and complex spaces

starts to differ. Let W be an irreducible subspace of X on which the (irreducible) representation of Γ is τ. The *endomorphism algebra of* τ (over $\mathbf{R}$) is

$$D^{\Gamma}(\tau) = \{A: W \to W: A\tau(\gamma) = \tau(\gamma)A \ \forall \gamma \in \Gamma \text{ and } A \text{ is linear}\}.$$

A fundamental result in the theory of group representations is Schur's lemma and its corollary, which can be found in Kirillov (1976).

THEOREM 2.8 (Schur's lemma). *Let τ_1 and τ_2 be irreducible representations of the compact Lie group Γ on subspaces W_1 and W_2 of X, respectively. Let $A: W_1 \to W_2$ be a linear mapping such that*

$$A\tau_1(\gamma) = \tau_2(\gamma)A$$

for all $\gamma \in \Gamma$. Then A is either zero, or it is invertible, in which case τ_1 and τ_2 are equivalent representations.

COROLLARY 2.9. *Let τ be an irreducible representation of Γ. Then $D^{\Gamma}(\tau)$ is isomorphic to either $\mathbf{R}$, $\mathbf{C}$, or $\mathbf{H}$ (the quaternions) which are one-, two-, or four-dimensional algebras over $\mathbf{R}$, respectively, and τ (and W) are said to be of real, complex, or quaternionic type, respectively.*

If τ is an irreducible representation of real type on the subspace W, then the only linear mappings that commute with τ are real multiples of the identity, and in this case τ (and W) are also called *absolutely irreducible.* (Note that for any irreducible representation on a complex space, the only commuting linear mappings are complex multiples of the identity.)

The following result plays an important role in the proof of Theorem 2.11.

THEOREM 2.10. *Let W be a Γ-irreducible subspace of X with corresponding irreducible representation τ. If $A \in D^{\Gamma}(\tau)$ is self-adjoint, then it is a (real) multiple of the identity on W.*

Proof. As A is self-adjoint, all its eigenvalues are real. Now consider the three classes of irreducible representations:

(i) If τ is of real type then $A = aI$, $a \in \mathbf{R}$ and so the result holds in this case.

(ii) If τ is of complex type, then $D^{\Gamma}(\tau) \cong \mathbf{C}$ and so

$$A = aI + bM, \qquad a, b \in \mathbf{R}$$

where $M^2 = -I$. Thus the only eigenvalues of A are $a \pm ib$, which are real if and only if $b = 0$. Then $A = aI$ as required.

(iii) If τ is of quaternionic type, then $D^{\Gamma}(\tau) \cong \mathbf{H}$ and so

$$A = aI + bM_i + cM_j + dM_k$$

where $M_i^2 = M_j^2 = M_k^2 = -I$, $M_iM_j = -M_jM_i = M_k$, $M_jM_k = -M_kM_j = M_i$, and $M_kM_i = -M_iM_k = M_j$. Using these relations, it is easily shown that the only eigenvalues of A are $a \pm i(b^2 + c^2 + d^2)^{1/2}$, which are real if and only if $b = c = d = 0$, giving $A = aI$. □

The main result of this section is the decomposition of the Hilbert space X into orthogonal isotypic components. This decomposition and the associated projections are well known for complex Hilbert spaces (see Knapp (1986)).

THEOREM 2.11. *Let T be an orthogonal representation of Γ on X and let $X = \sum_i \oplus X_i$, where each X_i is irreducible. Let $\{X_{i_k}\}$ be a maximal set of mutually inequivalent irreducible subspaces. For each k, let V_k^{Γ} be the closure of the sum of all the irreducible subspaces X_i which are equivalent to X_{i_k}. Then*

(i) *$V_k^{\Gamma} \perp V_l^{\Gamma}$, $k \neq l$ and $X = \sum_k \oplus V_k^{\Gamma}$.*

(ii) *The linear operator P_k^{Γ} defined by*

$$P_k^{\Gamma} = \frac{n_k}{d_k} \int_{\Gamma} \chi_k(\gamma) T(\gamma)\, d\gamma \tag{2.4}$$

is an orthogonal projection operator whose range is V_k^Γ, *where* n_k *is the dimension of* X_{i_k}, d_k *is the dimension of the endomorphism algebra associated with* X_{i_k} (*i.e.*, 1, 2, *or* 4), *and* $\chi_k : \Gamma \to \mathbf{R}$ *is the character of the irreducible representation* τ_{i_k} *associated with* X_{i_k}, *defined by*

$$\chi_k(\gamma) = \operatorname{Tr}(\tau_k(\gamma))$$

where Tr *denotes the trace.*

Before giving a proof of this theorem, we make some remarks. The subspaces $V_k^\Gamma = P_k^\Gamma X$ are called the Γ-*isotypic components* of X. If Γ is a finite group, the Haar integral is replaced by a finite sum and so the projections onto the isotypic components become

$$P_k^\Gamma = \frac{n_k}{d_k|\Gamma|} \sum_{\gamma\in\Gamma} \chi_k(\gamma) T(\gamma)$$

where $|\Gamma|$ is the order of the group Γ. Also, if T is a unitary representation on a complex Hilbert space then the projections onto the isotypic components are

$$P_k^\Gamma = n_k \int_\Gamma \overline{\chi_k(\gamma)} T(\gamma)\, d\gamma.$$

On an equivalence class of irreducible representations, the character, dimension, and type are all constant, and so the isotypic decomposition does not depend on the choice of the maximal set of nonequivalent irreducible subspaces. This ensures that the isotypic decomposition is unique, in contrast to the decomposition of X into irreducible subspaces (Theorem 2.6) which is not unique.

Theorem 2.6, Corollary 2.7, and Theorem 2.11 are analogous to part of the Peter–Weyl theorem for unitary representations on a complex Hilbert space (see Knapp (1986)).

Proof of Theorem 2.11. In order to prove the theorem, we need some basic results on group characters of real representations (see [BtD, pp. 80, 101]). If χ_k is the character of the irreducible representation τ_k, then for all $\gamma, \delta \in \Gamma$

(i) $\chi_k(\gamma^{-1}) = \chi_k(\gamma)$,

(ii) $\chi_k(\delta\gamma\delta^{-1}) = \chi_k(\gamma)$,

(iii) $$\int_\Gamma \chi_k(\gamma)\chi_j(\gamma)\, d\gamma = \begin{cases} 0, & \tau_j, \tau_k \text{ not equivalent,} \\ d_k, & \tau_j, \tau_k \text{ equivalent.} \end{cases}$$

For the sake of convenience, we will omit the superscript Γ on the operators P_k^Γ and the isotypic components V_k^Γ throughout the proof. The first step is to show that P_k commutes with the representation T. Let $\delta \in \Gamma$. Then

$$\begin{aligned} T(\delta^{-1})P_k T(\delta) &= \frac{n_k}{d_k} \int_\Gamma \chi_k(\gamma) T(\delta)^{-1} T(\gamma) T(\delta)\, d\gamma \\ &= \frac{n_k}{d_k} \int_\Gamma \chi_k(\gamma) T(\delta^{-1}\gamma\delta)\, d\gamma \\ &= \frac{n_k}{d_k} \int_\Gamma \chi_k(\delta\gamma\delta^{-1}) T(\gamma)\, d\gamma \\ &= \frac{n_k}{d_k} \int_\Gamma \chi_k(\gamma) T(\gamma)\, d\gamma \\ &= P_k \end{aligned}$$

using the homomorphism property of T, the invariance of the Haar measure, and result (ii) on group characters, which proves that

$$P_k T(\delta) = T(\delta) P_k.$$

In order to prove that P_k is an orthogonal projection, it is sufficient to show that it is a bounded, self-adjoint projection on X. Now P_k is bounded since Γ is compact, χ_k and T are continuous, and n_k is finite. We now prove that it is self-adjoint. If $x, y \in X$ then

$$\begin{aligned}
\langle P_k x, y\rangle &= \left\langle \frac{n_k}{d_k} \int_\Gamma \chi_k(\gamma) T(\gamma) x \, d\gamma, y \right\rangle \\
&= \left\langle x, \frac{n_k}{d_k} \int_\Gamma \chi_k(\gamma) T(\gamma)^* y \, d\gamma \right\rangle \\
&= \left\langle x, \frac{n_k}{d_k} \int_\Gamma \chi_k(\gamma) T(\gamma^{-1}) y \, d\gamma \right\rangle \\
&= \left\langle x, \frac{n_k}{d_k} \int_\Gamma \chi_k(\gamma^{-1}) T(\gamma) y \, d\gamma \right\rangle \\
&= \left\langle x, \frac{n_k}{d_k} \int_\Gamma \chi_k(\gamma) T(\gamma) y \, d\gamma \right\rangle \\
&= \langle x, P_k y\rangle
\end{aligned}$$

using (2.2), the fact that T is an orthogonal representation, the homomorphism property of T, the invariance of the Haar measure, and result (i) on group characters. Thus P_k is self-adjoint.

Now consider the restriction of P_k to an irreducible subspace W with corresponding (irreducible) representation τ_j. As $\tau_j(\gamma)$: $W \to W$, then $P_k : W \to W$ also. Since P_k commutes with T, we conclude that $P_k|_W \in D^\Gamma(\tau_j)$. As P_k is also self-adjoint, it follows from Theorem 2.10 that $P_k|_W = cI|_W$, $c \in \mathbf{R}$. Taking the trace (on W) gives

$$cn_j = \frac{n_k}{d_k} \int_\Gamma \chi_k(\gamma) \chi_j(\gamma) \, d\gamma$$

where n_j and χ_j are the dimension and character, respectively, of τ_j. If τ_j is equivalent to τ_k, then $n_j = n_k$ and so $c = 1$ using result (iii) on group characters. Similarly, if τ_j is not equivalent to τ_k, then $c = 0$. Thus P_k acts as the identity on all irreducible subspaces whose representation is equivalent to τ_k, and as zero on every other irreducible subspace so that $P_k^2 = P_k$ and $P_j P_k = 0$, $j \neq k$. Hence P_k is an orthogonal projection and the isotypic components are mutually orthogonal.

Now let $M = \sum_k \oplus V_k$ and suppose that $M \neq X$. Then M is a closed, invariant subspace and so $M^\perp$ is also a closed, invariant subspace by Lemma 2.4(i). Thus by Theorem 2.6 we conclude that $M^\perp$ can be decomposed as an orthogonal sum of irreducible subspaces, which contradicts the definition of the isotypic components V_k. Hence $M^\perp = 0$ and so $M = X$. □

3. Symmetry-breaking bifurcation theory. In this section, we apply the group theoretic results of § 2 to symmetry-breaking bifurcation theory, which we approach from a computational viewpoint. Our analysis will therefore deal with a nonlinear equation in an infinite-dimensional real Hilbert space, without first reducing the problem to finite dimensions using the Lyapunov–Schmidt procedure.

Consider the bifurcation problem

$$g(x, \lambda) = 0 \tag{3.1}$$

where $g: X \times \mathbf{R} \to X$ is a C^2-mapping and X is a real, separable Hilbert space. We suppose that g satisfies the equivariance condition

$$T(\gamma) g(x, \lambda) = g(T(\gamma)x, \lambda), \qquad \gamma \in \Gamma \tag{3.2}$$

where T is a representation of the compact Lie group Γ on X. We assume, without loss of generality (Lemma 2.2), that X has a Γ-invariant inner product so that the representation T is an orthogonal representation of Γ. It follows immediately from (3.2) that if (x, λ) is a solution of (3.1), then $(T(\gamma)x, \lambda)$ is also a solution for all $\gamma \in \Gamma$. These are called *conjugate solutions.*

Throughout this section, we assume the existence of a smooth curve of solutions of (3.1) contained in $X^\Gamma \times \mathbf{R}$, which we call the primary branch. We then consider the possibility of bifurcation from such a branch. Note that Γ can be *any* group that satisfies (3.2), not necessarily the largest such group.

The following important result uses the isotypic decomposition of Theorem 2.11.

THEOREM 3.1. *Let P_k^Γ be the projection onto the Γ-isotypic components of X. If $x \in X^\Gamma$, then $g_x(x, \lambda): V_k^\Gamma \to V_k^\Gamma$ for all k, where $V_k^\Gamma \equiv P_k^\Gamma X$.*

Proof. Taking the Fréchet derivative of (3.2) with respect to x gives

$$T(\gamma) g_x(x, \lambda)\varphi = g_x(T(\gamma)x, \lambda) T(\gamma)\varphi = g_x(x, \lambda) T(\gamma)\varphi \tag{3.3}$$

for all $\gamma \in \Gamma$, $x, \varphi \in X$, and $\lambda \in \mathbf{R}$ since $x \in X^\Gamma$. It follows from this that

$$P_k^\Gamma g_x(x, \lambda) = g_x(x, \lambda) P_k^\Gamma$$

using definition (2.4) of the projection operators P_k^Γ. The result follows. □

As a result of Theorem 3.1, if $x \in X^\Gamma$ then $g_x(x, \lambda)$ can be decomposed into "block diagonal" form as

$$g_x(x, \lambda) = \operatorname{diag}\,(g_x^k(x, \lambda))$$

where $g_x^k(x, \lambda) = g_x(x, \lambda)|_{V_k^\Gamma}$ and $g_x^k(x, \lambda): V_k^\Gamma \to V_k^\Gamma$. Thus $g_x(x, \lambda)$ has a nontrivial nullspace if and only if $g_x^k(x, \lambda)$ has a nontrivial nullspace for at least one k. This means that in general there are many different possible modes of bifurcation, although, as we will see, some of these do not arise generically.

This decomposition can be used in solving any linear equation where the linear operator $A: X \to X$ commutes with a representation of a compact Lie group Γ on the (real or complex) Hilbert space X and is the underlying principle of the paper by Bossavit (1986). In particular the linear equation $Ax = b$ can be decomposed into several subproblems as

$$A^k x_k = P_k^\Gamma b$$

where $A^k = A|_{V_k^\Gamma}$, $A^k: V_k^\Gamma \to V_k^\Gamma$ and $x_k \in V_k^\Gamma$. The solution to the original problem is then $x = \sum_k x_k$. Similarly, the eigenvalue problem $Ax = \lambda x$ can be decomposed as

$$A^k x_k = \lambda x_k.$$

When applied to boundary-value problems, this decomposition can result in a considerable savings computationally, as the subproblems can be solved on domains or "symmetry cells" smaller than the origin domain (see Bossavit (1986)). Since the subproblems are independent, computational efficiency can be increased by solving them in parallel. Saffman (1980) observed this decomposition in his study of bifurcation of gravity waves on deep water but gave no explanation of it.

We are interested in analysing singular points $(x_0, \lambda_0) \in X^\Gamma \times \mathbf{R}$ on the primary branch at which $\mathcal{N}_0 = \text{Null}\,(g_x(x_0, \lambda_0))$ is nontrivial. Now $\mathcal{N}_0$ is a closed subspace of X since $g_x(x, \lambda)$ is a bounded linear operator. Also, it follows from (3.3) that $\mathcal{N}_0$ is Γ-invariant since $x_0 \in X^\Gamma$. We now consider which isotypic components generically give rise to a nontrivial null space of $g_x(x, \lambda)$. For this result, we consider two classes of operators that map $X \times \mathbf{R} \to X$. We define C_1 to be the class of Γ-equivariant C^2-mappings and C_2 to be the class of operators $g \in C_1$ such that $g(x, \lambda) = \nabla G(x, \lambda)$ for some function $G: X \times \mathbf{R} \to \mathbf{R}$. Note that if $g \in C_2$, then $g_x(x, \lambda)$ is self-adjoint for all $(x, \lambda) \in X \times \mathbf{R}$.

THEOREM 3.2. *Suppose that $g_x(x, \lambda)$ is a Fredholm operator of index zero and let $g_x^k(x, \lambda) \equiv g_x(x, \lambda)|_{V_k^\Gamma}$, where V_k^Γ is an isotypic component of X associated with the irreducible representation τ_k of Γ. Also, let $\mathcal{GN}_0^k$ be the generalised nullspace of $g_x^k(x_0, \lambda_0)$ for some $(x_0, \lambda_0) \in X^\Gamma \times \mathbf{R}$ on the primary branch.*

(a) *Suppose that $g \in C_1$. Then*

(i) *If τ_k is absolutely irreducible and $\mathcal{GN}_0^k$ is nontrivial, then generically $\mathcal{GN}_0^k$ is irreducible (and hence absolutely irreducible).*

(ii) *If τ_k is non-absolutely irreducible, then generically $\mathcal{GN}_0^k$ is trivial.*

(b) *Suppose that $g \in C_2$. If $\mathcal{GN}_0^k$ is nontrivial, then generically $\mathcal{GN}_0^k$ is irreducible regardless of the type of τ_k.*

Proof. We base our proof on the ideas contained in the sketch proof of Golubitsky, Stewart, and Schaeffer (1988, p. 84).

(a) We first prove that if $\mathcal{GN}_0^k$ is not irreducible then a small perturbation makes it irreducible. This is done in two steps. The first step consists of introducing a perturbation that makes the generalised nullspace and the nullspace coincide. The second step then reduces the generalised nullspace to an irreducible subspace by an appropriate perturbation.

Let $g \in C_1$. As we are considering the linear operator $g_x^k(x, \lambda)$, we restrict attention to the space V_k^Γ. Since $g_x(x, \lambda)$ is a Fredholm operator of index zero, $\mathcal{GN}_0^k$ is finite dimensional and V_k^Γ can be decomposed as (Dancer (1971))

$$V_k^\Gamma = \mathcal{GN}_0^k \oplus Y.$$

Also, since $x_0 \in X^\Gamma$, $\mathcal{GN}_0^k$ is Γ-invariant and so, by Lemma 2.4, Y is also Γ-invariant.

Define $\mathcal{N}_0^k \equiv \text{Null}\,(g_x^k(x_0, \lambda_0))$ and suppose that $\mathcal{N}_0^k \neq \{0\}$ and $\mathcal{N}_0^k \neq \mathcal{GN}_0^k$. Then $\mathcal{GN}_0^k$ can be decomposed as

$$\mathcal{GN}_0^k = \mathcal{N}_0^k \oplus M. \tag{3.4}$$

For the first step, we define the linear operator $L_1: X \to X$ by

$$L_1|_{(V_k^\Gamma)^\perp} = 0, \quad L_1|_Y = 0, \quad L_1|_{\mathcal{N}_0^k} = 0, \quad L_1|_M = \text{Id}|_M$$

and we define $\tilde{g}(x, \lambda) \equiv g(x, \lambda) + \varepsilon_1 L_1 x \in C_1$. Then

$$\tilde{g}_x^k(x, \lambda) \equiv \tilde{g}_x(x, \lambda)|_{V_k^\Gamma} = g_x^k(x, \lambda) + \varepsilon_1 L_1.$$

It is then easily shown that

$$\text{Null}\,(\tilde{g}_x^k(x_0, \lambda_0)) = \mathcal{N}_0^k$$

and that the generalised nullspace of $\tilde{g}_x^k(x_0, \lambda_0)$ coincides with $\mathcal{N}_0^k$.

For the second step, we decompose $\mathcal{N}_0^k$ as

$$\mathcal{N}_0^k = V \oplus W$$

where V is Γ-irreducible and W is Γ-invariant. We then define another linear operator $L_2: X \to X$ by

$$L_2|_{(V_k^\Gamma)^\perp} = 0, \quad L_2|_Y = 0, \quad L_2|_M = 0,$$
$$L_2|_V = 0, \qquad L_2|_W = \mathrm{Id}|_W$$

and we define $\hat{g}(x, \lambda) \equiv \tilde{g}(x, \lambda) + \varepsilon_2 L_2 x \in C_1$. Then

$$\hat{g}_x^k(x, \lambda) \equiv \hat{g}_x(x, \lambda)|_{V_k^\Gamma} = \tilde{g}_x^k(x, \lambda) + \varepsilon_2 L_2.$$

In this case, the generalised nullspace of $\hat{g}_x^k(x_0, \lambda_0)$ coincides with the nullspace and is equal to V. Thus if the generalised nullspace of $\tilde{g}_x^k(x_0, \lambda_0)$ is not irreducible, then a small perturbation makes it irreducible.

We now consider whether an irreducible generalised nullspace is stable under perturbation. Suppose that $\mathcal{GN}_0^k = \mathcal{N}_0^k$ and is Γ-irreducible. Then a Lyapunov–Schmidt reduction can be used to give an equivalent finite-dimensional problem

$$\tilde{G}(X, \Lambda) = 0, \qquad \tilde{G}: V \times \mathbf{R} \to \tilde{V} \tag{3.5}$$

where $V \equiv \mathcal{N}_0^k$, $\tilde{G}$ is Γ-equivariant, and $\tilde{G}(0, 0) = 0$ (Golubitsky and Schaeffer (1985, Chap. VII)). By restricting attention to the isotypic component V_k^Γ, we conclude that the restrictions of the representation T of Γ to V and $\tilde{V}$ are equivalent and so there exists an invertible linear operator $A: \tilde{V} \to V$ which commutes with T. Thus, the modified equations

$$G(X, \Lambda) \equiv A\tilde{G}(X, \Lambda) = 0, \qquad G: V \times \mathbf{R} \to V \tag{3.6}$$

have the same solutions as (3.5) and G is also Γ-equivariant.

Now the representation of Γ on V is τ_k and $G_X(X, \Lambda)$ commutes with this representation. Thus $G_X(X, \Lambda) \in D^\Gamma(\tau_k)$, the endomorphism algebra of τ_k. By the proof of Theorem 2.10, if τ_k is of real type (i.e., absolutely irreducible), then $G_X(X, \Lambda)$ has only one (repeated) real eigenvalue $a(\Lambda)$ with

$$a(0) = 0. \tag{3.7}$$

If τ_k is of complex type, then $G_X(X, \Lambda)$ has only the complex conjugate eigenvalues $a(\Lambda) \pm ib(\Lambda)$ with

$$a(0) = b(0) = 0. \tag{3.8}$$

Finally, if τ_k is of quaternionic type, then $G_X(X, \Lambda)$ has only the complex conjugate eigenvalues $a(\Lambda) \pm i(b(\Lambda)^2 + c(\Lambda)^2 + d(\Lambda)^2)^{1/2}$ with

$$a(0) = b(0) = c(0) = d(0) = 0. \tag{3.9}$$

Clearly the solution (3.7) of one equation in one variable is stable under perturbation, whereas the solutions (3.8) and (3.9) of more than one equation in only one variable are not stable under perturbation. In these cases, perturbations exist that reduce the nullspace of $G_X(X, \Lambda)$ to being trivial in a neighbourhood of the origin.

Thus if τ_k is of real type, then $\mathcal{GN}_0^k$ is generically irreducible. If τ_k is not of real type, then a small perturbation destroys the generalised nullspace. Also, if $\mathcal{GN}_0^k$ is trivial, then for any sufficiently small perturbation, it will remain trivial and so in this case, generically $\mathcal{GN}_0^k$ is trivial.

(b) If $g \in C_2$, then $\mathcal{GN}_0^k = \mathcal{N}_0^k$ and so, in the decomposition (3.4), $M = \{0\}$. The perturbed problem

$$\tilde{g}(x, \lambda) \equiv g(x, \lambda) + \varepsilon L_2 x \in C_2$$

then has an irreducible nullspace, following the proof of (a).

Performing a Lyapunov-Schmidt reduction in this case leads to the finite-dimensional problem

$$G(X, \Lambda) = 0, \qquad G: V \times \mathbf{R} \to V$$

where $V \equiv \mathcal{N}_0^k$, G is Γ-equivariant, $G(0, 0) = 0$, and $G_X(X, \Lambda)$ is self-adjoint. Since $G_X(X, \Lambda) \in D^\Gamma(\tau_k)$ also, by Theorem 2.10 the eigenvalues of $G_X(X, \Lambda)$ are of the form $a(\Lambda)$ irrespective of the type of τ_k. In this case, the solution

$$a(0) = 0$$

is stable under perturbation and so generically $\mathcal{GN}_0^k$ is irreducible irrespective of the type of τ_k. □

We note that if the generalised nullspace of $g_x(x_0, \lambda_0)$ is irreducible, then it coincides with the nullspace and is then the "smallest" possible invariant subspace. Also, Hopf bifurcation is associated with complex type irreducible representations (see Golubitsky, Stewart, and Schaeffer (1988, Chap. XVI)).

Let $(x_0, \lambda_0) \in X^\Gamma \times \mathbf{R}$ be a point on the primary branch such that $g_x^k(x_0, \lambda_0)$ has a nontrivial nullspace contained in V_k^Γ for some k. If $\psi \in \text{Null}\,(g_x^k(x_0, \lambda_0)^*)$, where $*$ denotes the adjoint operator, then $\psi \in V_k^\Gamma$, since X is a Hilbert space and $g_x^k(x_0, \lambda_0): V_k^\Gamma \to V_k^\Gamma$, and so ψ has the property that $\langle \psi, x \rangle = 0$ for all $x \in \sum_{j \neq k} \oplus V_j^\Gamma$ due to the orthogonality of the isotypic components. Also, $g_\lambda(x_0, \lambda_0) \in X^\Gamma$ since $x_0 \in X^\Gamma$.

The isotypic component V_1^Γ say, corresponding to the trivial (irreducible) representation, is the fixed-point space X^Γ whose irreducible subspaces are one-dimensional and absolutely irreducible. If the nullspace of $g_x^1(x_0, \lambda_0)$ is nontrivial, then, from Theorem 3.2, generically it will be one-dimensional. Also, if $\psi \in \text{Null}\,(g_x^1(x_0, \lambda_0)^*)$, then $\psi \in V_1^\Gamma = X^\Gamma$. Thus, if $g_\lambda(x_0, \lambda_0) \neq 0$, then generically $\langle \psi, g_\lambda(x_0, \lambda_0) \rangle \neq 0$, in which case $g_\lambda(x_0, \lambda_0) \notin \text{Range}\,(g_x(x_0, \lambda_0))$ and so a singularity of $g_x^1(x_0, \lambda_0)$ corresponds generically to a limit point (Moore and Spence (1980)). It is easy to prove from (3.2) that if $x_0 \in X^\Gamma$ then $g_{xx}(x_0, \lambda_0): X^\Gamma \times X^\Gamma \to X^\Gamma$, and so generically $\langle \psi, g_{xx}(x_0, \lambda_0)\varphi\varphi \rangle \neq 0$, where $\varphi \in \text{Null}\,(g_x^1(x_0, \lambda_0))$. Thus generically the limit point is simple.

However, if the nullspace of $g_x^k(x_0, \lambda_0)$ is nontrivial for $k \neq 1$ and $\psi \in \text{Null}\,(g_x(x_0, \lambda_0)^*)$, then $\psi \in V_k^\Gamma$ and so $\langle \psi, g_\lambda(x_0, \lambda_0) \rangle = 0$ since ψ and $g_\lambda(x_0, \lambda_0)$ are in different (orthogonal) isotypic components. Thus $g_\lambda(x_0, \lambda_0) \in \text{Range}\,(g_x(x_0, \lambda_0))$ and so, for $k \neq 1$, we would expect a singularity of $g_x^k(x_0, \lambda_0)$ to give rise to a bifurcation point. Conditions for the existence of a bifurcating branch of solutions at such a singular point are given in Theorem 3.4. Therefore, we conclude that, generically, symmetry must be broken for bifurcation from a nontrivial solution branch to occur.

In some cases the linear operators $g_x^k(x, \lambda)$ can themselves be further decomposed as the following result shows.

THEOREM 3.3. *Let τ_k be an irreducible representation of Γ of dimension $n_k > 1$. If Σ is a subgroup of Γ with the property that $\tau_k|_\Sigma$ is not Σ-irreducible and has at least two nonequivalent Σ-irreducible components, then V_k^Γ can be decomposed as*

$$V_k^\Gamma = \sum_{j=1}^{m} \oplus V_{k,j}^{\Gamma,\Sigma}$$

where $V_{k,j}^{\Gamma,\Sigma} = V_k^\Gamma \cap V_j^\Sigma \neq \{0\}$, V_j^Σ *are the* Σ*-isotypic components of* X *that intersect* V_k^Γ *nontrivially and* m *is the number of nonequivalent* Σ*-irreducible components of* τ_k. *If* $x \in X^\Gamma$, *then* $g_x^k(x, \lambda)$: $V_{k,j}^{\Gamma,\Sigma} \to V_{k,j}^{\Gamma,\Sigma}$ *and so* $g_x^k(x, \lambda)$ *can itself be decomposed as* $g_x^k(x, \lambda) = \operatorname{diag}(g_x^{k,j}(x, \lambda))$, *where* $g_x^{k,j}(x, \lambda)$: $V_{k,j}^{\Gamma,\Sigma} \to V_{k,j}^{\Gamma,\Sigma}$.

Proof. First, note that $\Sigma \neq \Gamma$ or else τ_k would not be Γ-irreducible, and Σ cannot be the trivial group since all the irreducible components of the trivial group are equivalent, so Σ must be a proper subgroup of Γ. The number of Σ-irreducible components of τ_k cannot exceed its dimension, and so $m \leqq n_k$ and is therefore finite as τ_k is finite dimensional by Corollary 2.7.

From the hypotheses of the theorem we conclude that each Γ-irreducible subspace of the isotypic component V_k^Γ can be decomposed into m Σ-irreducible subspaces, which we can assume to be an orthogonal direct sum by Theorem 2.6. Collecting together the equivalent, Σ-irreducible subspaces in V_k^Γ, we obtain a Σ-isotypic decomposition of V_k^Γ resulting in the stated decomposition of V_k^Γ.

Now if $x \in X^\Gamma$, then $x \in X^\Sigma$ also as Σ is a subgroup of Γ and so, by Theorem 3.1, $g_x(x, \lambda)$: $V_j^\Sigma \to V_j^\Sigma$ for all j. Thus $g_x(x, \lambda)$: $V_{k,j}^{\Gamma,\Sigma} \to V_{k,j}^{\Gamma,\Sigma}$ and so $g_x^k(x, \lambda)$ can be decomposed as stated. □

Let $(x_0, \lambda_0) \in X^\Gamma \times \mathbf{R}$ be a point on the primary branch at which $\mathcal{N}_0 \equiv \operatorname{Null}(g_x(x_0, \lambda_0))$ is nontrivial and irreducible with corresponding irreducible representation τ_k. Then $\mathcal{N}_0 \subset V_k^\Gamma$. If Σ is a subgroup of Γ that satisfies the hypotheses of Theorem 3.3, then $\mathcal{N}_0$ can be decomposed into Σ-isotypic components $\mathcal{N}_0^j = \mathcal{N}_0 \cap V_j^\Sigma$, $j = 1, \cdots, m$, which are not Γ-invariant. Clearly $\operatorname{Null}(g_x^{k,j}(x_0, \lambda_0)) = \mathcal{N}_0^j$ and so the subspaces $\mathcal{N}_0^j$, $j = 1, \cdots, m$ are *all* nontrivial. Thus in order to detect a singular point, it is sufficient to consider $g_x^{k,j}(x, \lambda)$ for only one j. In particular, if there is a Σ-isotypic component of $\mathcal{N}_0$ of odd dimension with $j = 1$, say, then the sign of the determinant of $g_x^{k,1}(x, \lambda)$ can be checked numerically while following the primary branch of solutions in order to detect a singular point, and the other $g_x^{k,j}(x, \lambda)$, $j \neq 1$ need not be considered. A special case of this occurs when the Σ-irreducible decomposition of τ_k includes the trivial representation with multiplicity 1, in which case $\dim(\mathcal{N}_0 \cap X^\Sigma) = 1$ since X^Σ is the Σ-isotypic component of X corresponding to the trivial irreducible representation. This important special case is featured in the Equivariant Branching Lemma of Cicogna (1981) and Vanderbauwhede (1982).

THEOREM 3.4 (Equivariant Branching Lemma). *Let* $x_0 \in X^\Gamma$. *Suppose that* $g_x(x_0, \lambda_0)$ *is Fredholm of index zero and that* $\mathcal{N}_0 \equiv \operatorname{Null}(g_x(x_0, \lambda_0))$ *is nontrivial. If*

(i) $\mathcal{N}_0 \cap X^\Gamma = \{0\}$;

(ii) *There exists an isotropy subgroup* Σ *of* Γ *such that*

$$\dim(\mathcal{N}_0 \cap X^\Sigma) = 1;$$

(iii) *The nondegeneracy condition*

$$\langle \psi_0, g_{x\lambda}(x_0, \lambda_0)\varphi_0 + g_{xx}(x_0, \lambda_0)\varphi_0 v \rangle \neq 0 \tag{3.10}$$

is satisfied where $\varphi_0 \in \mathcal{N}_0 \cap X^\Sigma$, $\psi_0 \in \operatorname{Null}(g_x(x_0, \lambda_0)^*) \cap X^\Sigma$, *and* $v \in X^\Gamma$ *is the unique solution of*

$$g_x(x_0, \lambda_0)v + g_\lambda(x_0, \lambda_0) = 0,$$

then there exists a secondary branch of solutions tangent to φ_0 *with isotropy subgroup* Σ.

The Equivariant Branching Lemma gives sufficient conditions for the existence of a bifurcating branch of solutions that apply to many practical situations, but bifurcation can also occur when the secondary branches are contained in X^Σ with $\dim(\mathcal{N}_0 \cap X^\Sigma) > 1$ (see Lauterbach (1986)).

It can be proved in a way similar to the proof of Theorem 3.1 that if $x_0 \in X^\Gamma$, then $g_{x\lambda}(x_0, \lambda_0)$: $V_k^\Gamma \to V_k^\Gamma$ and $g_{xx}(x_0, \lambda_0)$: $V_k^\Gamma \times X^\Gamma \to V_k^\Gamma$. Also, for any subgroup Ω of Γ, $g_{x\lambda}(x_0, \lambda_0)$: $X^\Omega \to X^\Omega$ and $g_{xx}(x_0, \lambda_0)$: $X^\Omega \times X^\Gamma \to X^\Omega$. Thus if $\varphi_0 \in V_k^\Gamma \cap X^\Sigma$, then

$$g_{x\lambda}(x_0, \lambda_0)\varphi_0 + g_{xx}(x_0, \lambda_0)\varphi_0 v \in V_k^\Gamma \cap X^\Sigma$$

also and so the nondegeneracy condition (3.10) is satisfied generically.

Our next consideration is the type of bifurcation, i.e., pitchfork or transcritical, which occurs as a result of the Equivariant Branching Lemma. Since the secondary branches are contained in $X^\Sigma \times \mathbf{R}$, it is sufficient to consider the reduced problem

$$g_\Sigma(x, \lambda) = 0, \qquad g_\Sigma \equiv g|_{X^\Sigma \times \mathbf{R}} : X^\Sigma \times \mathbf{R} \to X^\Sigma. \tag{3.11}$$

Now the closed fixed-point space X^Σ is invariant with respect to the normaliser N_Γ of Σ in Γ, defined by

$$N_\Gamma(\Sigma) = \{\gamma \in \Gamma : \gamma\Sigma = \Sigma\gamma\}.$$

Thus the reduced problem (3.11) is equivariant with respect to the quotient group $N_\Gamma(\Sigma)/\Sigma$. The following result has been proved by Dellnitz and Werner (1989).

THEOREM 3.5. *Let* $\mathcal{N}_0 = \text{Null}\,(g_x(x_0, \lambda_0))$, *where* $x_0 \in X^\Gamma$. *Suppose there exists an isotropy subgroup* Σ *of* Γ *such that* $\dim(\mathcal{N}_0 \cap X^\Sigma) = 1$.

(i) *If* $\dim \mathcal{N}_0 = 1$ *then* Σ *is the isotropy subgroup of* $\mathcal{N}_0$, $N_\Gamma(\Sigma) = \Gamma$, *and* $N_\Gamma(\Sigma)/\Sigma = \Gamma/\Sigma$ *is isomorphic to* Z_2.

(ii) *If* $\dim \mathcal{N}_0 > 1$ *then* $N_\Gamma(\Sigma)/\Sigma$ *is either isomorphic to* Z_2 *or is trivial.*

Now if $N_\Gamma(\Sigma)/\Sigma$ is isomorphic to Z_2, then the bifurcation is a symmetric pitchfork (see Werner and Spence (1984)) with conjugate secondary branches where, if (x, λ) is a solution of (3.11) on a secondary branch, then $(T(\delta)x, \lambda)$ is the corresponding solution on the conjugate branch for all $\delta \in N(\Sigma)\backslash\Sigma$. Alternatively, if $N_\Gamma(\Sigma)/\Sigma$ is trivial, then the bifurcation will be nonsymmetric (either pitchfork or transcritical) and the two secondary branches have distinct (nonconjugate) solutions.

We now consider extended systems of equations for which a bifurcation point is an isolated solution. The following result is a generalisation of Theorem 3.1 of Werner and Spence (1984), which considers the case $\Gamma = Z_2$. It is proved in a similar way and is straightforward.

THEOREM 3.6. *Let* $(x_0, \lambda_0) \in X^\Gamma \times \mathbf{R}$ *and let* $\mathcal{N}_0 = \text{Null}\,(g_x(x_0, \lambda_0))$ *have finite dimension. If* $\mathcal{N}_0 \cap V_k^\Gamma \neq \{0\}$ *for some* $k \neq 1$ *and conditions* (i) *and* (ii) *of the Equivariant Branching Lemma* (*Theorem* 3.4) *hold, then the extended system*

$$\begin{aligned} &G(y) = 0, \qquad G : Y \to Y, \\ &G(y) \equiv \begin{pmatrix} g(x, \lambda) \\ g_x(x, \lambda)\varphi \\ \langle l, \varphi \rangle - 1 \end{pmatrix}, \\ &y = (x, \varphi, \lambda) \in Y \equiv X^\Gamma \times (V_k^\Gamma \cap X^\Sigma) \times \mathbf{R}, \qquad l \in V_k^\Gamma \cap X^\Sigma \end{aligned} \tag{3.12}$$

has an isolated solution $(x_0, \varphi_0, \lambda_0)$, *where* $\varphi_0 \in \mathcal{N}_0 \cap V_k^\Gamma \cap X^\Sigma$ *if and only if the nondegeneracy condition* (3.10) *is satisfied.*

Alternative forms of the extended system (3.12) may also be used, for example

$$\begin{aligned} &\tilde{G}(x, \lambda) \equiv \begin{pmatrix} g(x, \lambda) \\ \langle \psi, g_x(x, \lambda)\varphi \rangle \end{pmatrix} = 0, \\ &\tilde{G} : X^\Gamma \times \mathbf{R} \to X^\Gamma \times \mathbf{R} \end{aligned} \tag{3.13}$$

where $\varphi, \psi \in V_k^\Gamma \cap X^\Sigma$ are the singular vectors associated with the singular value $\sigma = \langle \psi, g_x(x, \lambda)\varphi \rangle$, which are related by the equations

$$\begin{aligned} g_x(x, \lambda)\varphi &= \sigma\psi, \qquad \langle \psi, \psi \rangle = 1, \\ g_x^*(x, \lambda)\psi &= \sigma\varphi, \qquad \langle \varphi, \varphi \rangle = 1. \end{aligned} \tag{3.14}$$

Finally, all the theory of this section extends to the situation when $g: X \times \mathbf{R} \to Y$ and satisfies the equivariance condition

$$\tilde{T}(\gamma) g(x, \lambda) = g(T(\gamma)x, \lambda), \qquad \gamma \in \Gamma \tag{3.15}$$

where T and $\tilde{T}$ are equivalent orthogonal representations of Γ on X and Y, respectively. In particular,

$$\tilde{P}_k^\Gamma g_x(x, \lambda) = g_x(x, \lambda) P_k^\Gamma$$

where $\tilde{P}_k^\Gamma$ is the projection onto the Γ-isotypic component $\tilde{V}_k^\Gamma$ of Y (since the dimension, character, and type of equivalent irreducible representations are constant). Thus $g_x(x, \lambda)\colon V_k^\Gamma \to \tilde{V}_k^\Gamma$. All the other results can be generalised in a similar way.

4. Scaling laws. For many problems, it is possible to take one solution and perform a "change of scale" to give another solution. Thus for bifurcation problems, distinct branches of solutions are often related by a simple scaling. This relation can be expressed as a *scaling law*, which is similar to the equivariance condition (3.2) but also involves the parameter of the problem. (See Scovel, Kevrekidis, and Nicolaenko (1988) for an example of such a scaling law.)

We first consider the problem of finding such scaling laws in a given problem and show that the symmetry of the problem defines a natural context for the existence of scaling laws. We then consider how the scaling law relates to the bifurcation theory of § 3 and show that, in some cases, the existence of bifurcating branches at a mode interaction point can be proved using the scaling.

Consider the bifurcation problem

$$g(x, \lambda) = 0, \qquad g: X \times \mathbf{R} \to Y \tag{4.1}$$

where X and Y are real Hilbert spaces and g is C^2. We suppose that g satisfies the equivariance condition

$$\tilde{T}(\gamma) g(x, \lambda) = g(T(\gamma)x, \lambda) \quad \forall \gamma \in \Gamma \tag{4.2}$$

where T and $\tilde{T}$ are equivalent representations of the compact Lie group Γ on X and Y, respectively. By Lemma 2.2, we can assume without loss of generality that T and $\tilde{T}$ are orthogonal representations. For the sake of simplicity we will take $Y = X$ and $T = \tilde{T}$ but all our results generalise to the case $Y \neq X$, $T \neq \tilde{T}$.

We now show that a natural context for scaling laws can be derived by considering the group Γ. Our aim is to define a subproblem of (4.1), where the group Γ acts on a "different scale," whose solutions are related by a scaling transformation to the solutions of (4.1). The solutions of the subproblem will, however, also be solutions of (4.1). The subproblem will be defined by use of a particular fixed-point space.

Let $\beta: \Gamma \to \Gamma$ be an epimorphism (i.e., β is a homomorphism and $\beta(\Gamma) = \Gamma$) with a nontrivial kernal K. Then the mapping

$$\Gamma/K \to \Gamma, \qquad \gamma K \to \beta(\gamma) \tag{4.3}$$

is an isomorphism by Lemma 2.1. The quotient group Γ/K has a natural representation on the fixed-point space X^K given by

$$T_K: \Gamma/K \to GL(X^K), \qquad T_K(\gamma K) \equiv T(\gamma)|_{X^K} \tag{4.4}$$

since K acts trivially on X^K. This representation is well defined since X^K is closed and Γ-invariant (as K is a normal subgroup of Γ) and so $T(\gamma)\colon X^K \to X^K$ is a homeomorphism by Lemma 2.4 (ii) for all $\gamma \in \Gamma$. It is well known and easily proved that $g\colon X^K \times \mathbf{R} \to X^K$ and so we define our subproblem to be $g_K(x, \lambda) = 0$, where $g_K \equiv g|_{X^K \times \mathbf{R}}$. Clearly g_K is equivariant with respect to the representation T_K of Γ/K.

We have established that the groups Γ/K and Γ are isomorphic. The corresponding representations on X^K and X, respectively, are equivalent if there exists a linear homeomorphism $h\colon X \to X^K$ such that

$$T_K(\gamma K)h \equiv T(\gamma)h = hT(\beta(\gamma)) \quad \forall \gamma \in \Gamma. \tag{4.5}$$

If such an h exists, we can assume without loss of generality that it is orthogonal by Lemma 2.3 since T_K and T are orthogonal representations. We are now in a position to define a scaling law:

If there exists an orthogonal linear homeomorphism $h\colon X \to X^K$ satisfying (4.5), *and constants $b, c, l \in \mathbf{R}\backslash\{0\}$, such that*

$$chg(x, \lambda) = g(bhx, l\lambda) \equiv g_K(bhx, l\lambda) \tag{4.6}$$

then (4.6) *is called a scaling law.*

If such a scaling law exists, then $h' \equiv hT(\gamma)$ is also an orthogonal linear homeomorphism from X to X^K for all $\gamma \in \Gamma$, which satisfies (4.6) and also satisfies (4.5) if $\gamma \in Z(\Gamma)$, the centre of Γ. The following result proves the converse.

THEOREM 4.1. *If h_1 and h_2 are scaling transformations that satisfy* (4.5) *and* (4.6) *for fixed constants $b, c, l \neq 0$, then $h_2 = h_1 T(\gamma)$ for some $\gamma \in Z(\Gamma)$, the centre of Γ (restricting attention to the Γ-equivariance of g).*

Proof. It is straightforward to show that if h_1 and h_2 both satisfy (4.6), then

$$h_1^{-1}h_2 g(x, \lambda) = g(h_1^{-1}h_2 x, \lambda).$$

Now $h_1^{-1}h_2 \in GL(X)$ and is orthogonal. As we have restricted attention to the Γ-equivariance of g, we conclude that $h_1^{-1}h_2 = T(\gamma)$ for some $\gamma \in \Gamma$. As h_1 and h_2 also satisfy (4.5), then $\gamma \in Z(\Gamma)$. □

Since nothing is gained by combining scaling and group transformations, we restrict attention to one scaling transformation h satisfying (4.5) and (4.6).

The existence of a scaling law imposes conditions on Γ and X. Since K is nontrivial, the requirement that Γ/K be isomorphic to Γ cannot be satisfied if Γ is a finite group or if K is not a finite group. Also, the existence of the linear homeomorphism $h\colon X \to X^K$ requires that X and X^K have the same dimension, which cannot hold if X is finite dimensional.

The scaling law defines a relation between the solutions of $g = 0$ and $g_K = 0$. Thus $(x, \lambda) \in X \times \mathbf{R}$ is a solution of $g = 0$ if and only if $(bhx, l\lambda) \in X^K \times \mathbf{R}$ is a solution of $g_K = 0$ (although, of course, solutions of $g_K = 0$ are also solutions of $g = 0$). Also, (4.5) defines a relation between the representations T of Γ on X and T_K of Γ/K on X^K with the property that, for any $x \in X$, $\gamma \in \Gamma$, there exists $y \in X$ such that

$$y = T(\beta(\gamma))x \;\Leftrightarrow\; hy = T_K(\gamma K)hx = T(\gamma)hx.$$

We now consider how a scaling law relates to the bifurcation theory of § 3. An immediate consequence of the scaling law (4.6) is that if bifurcation occurs at $(x_0, \lambda_0) \in X \times \mathbf{R}$ then it must also occur at $(bhx_0, l\lambda_0) \in X^K \times \mathbf{R}$, since both the primary and secondary branches are "rescaled" by h. We now attempt to express this relation more formally.

Let Ω be a subgroup of Γ and define

$$\Omega^\beta = \{\gamma \in \Gamma\colon \beta(\gamma) \in \Omega\}, \tag{4.7}$$

which is also a subgroup of Γ. Clearly $\beta(\Omega^\beta)=\Omega$, K is a (normal) subgroup of Ω^β, and from Lemma 2.1, Ω^β/K is isomorphic to Ω. We then have the following results.

LEMMA 4.2. *Let Ω_x and Ω_{hx} be the isotropy subgroups of $x\in X$ and $hx\in X^K$, respectively, where h satisfies* (4.5). *If Ω is a subgroup of Γ, then $\Omega_x=\Omega$ if and only if $\Omega_{hx}=\Omega^\beta$ (i.e., $(\Omega_x)^\beta=\Omega_{hx}$).*

Proof. First, suppose that $\Omega_x=\Omega$. Then for every $\gamma\in\Omega^\beta$,

$$T(\gamma)hx=hT(\beta(\gamma))x=hx$$

using (4.5) and as $\beta(\gamma)\in\Omega=\Omega_x$. Thus $\gamma\in\Omega_{hx}$ and so Ω^β is a subgroup of Ω_{hx}. Similarly, for every $\gamma\in\Omega_{hx}$,

$$hT(\beta(\gamma))x=T(\gamma)hx=hx$$

again using (4.5). Since h is a linear homeomorphism, we conclude that $T(\beta(\gamma))x=x$ and so $\beta(\gamma)\in\Omega_x=\Omega$. Hence $\gamma\in\Omega^\beta$ and so Ω_{hx} is a subgroup of Ω^β. Combining these results, we conclude that $\Omega_{hx}=\Omega^\beta$.

The converse is proved similarly. □

LEMMA 4.3. *If $h: X\to X^K$ is an orthogonal linear homeomorphism satisfying* (4.5), *then the restriction of h to X^Ω is an orthogonal linear homeomorphism onto X^{Ω^β} for every subgroup Ω of Γ.*

Proof. If $x\in X^\Omega$ and $\gamma\in\Omega^\beta$, then $\beta(\gamma)\in\Omega$ and so, by (4.5),

$$T(\gamma)hx=hT(\beta(\gamma))x=hx.$$

Thus $hx\in X^{\Omega^\beta}$. It remains to prove that the mapping $h: X^\Omega\to X^{\Omega^\beta}$ is a surjection since h is an orthogonal linear homeomorphism on X.

Let $y\in X^{\Omega^\beta}$. Then $y=hx$ for some $x\in X$. If $\tilde\gamma\in\Omega$, then there exists $\gamma\in\Omega^\beta$ such that $\beta(\gamma)=\tilde\gamma$ since β is surjective. Thus

$$hT(\tilde\gamma)x=T(\gamma)hx=T(\gamma)y=y=hx$$

using (4.5) and as $y\in X^{\Omega^\beta}$. Since h is a linear homeomorphism (on X), we conclude that $T(\tilde\gamma)x=x$ for all $\tilde\gamma\in\Omega$ and so $x\in X^\Omega$. Thus h is a surjection as required. □

LEMMA 4.4. *Let Ω be a subgroup of Γ and let h satisfy* (4.5). *Then W is a closed, Ω-invariant subspace of X if and only if $W^h\equiv hW$ is a closed, Ω^β-invariant subspace of X^K.*

Proof. Since h is a homeomorphism, W is closed if and only if W^h is closed. Let $w\in W$. If $\gamma\in\Omega^\beta$, then $\beta(\gamma)\in\Omega$, and by (4.5) we have

$$T(\gamma)hw=hT(\beta(\gamma))w.$$

If W is Ω-invariant, then for all $w\in W$, $T(\beta(\gamma))w\in W$ for all $\beta(\gamma)\in\Omega$ and so $T(\gamma)hw\in W^h$ for all $\gamma\in\Omega^\beta$. Thus W^h is Ω^β-invariant. Conversely, if W^h is Ω^β-invariant, then for all $w\in W$, $T(\gamma)hw\in W^h$ for all $\gamma\in\Omega^\beta$ and so $T(\beta(\gamma))w\in W$ for all $\gamma\in\Omega^\beta$, since h is a homeomorphism. Now $\beta:\Omega^\beta\to\Omega$ is surjective and so $T(\tilde\gamma)w\in W$ for all $\tilde\gamma\in\Omega$, $w\in W$. Thus W is Ω-invariant. □

LEMMA 4.5. *Let Ω be a subgroup of Γ and let h satisfy* (4.5). *Then W is an Ω-irreducible subspace of X if and only if $W^h\equiv hW$ is an Ω^β-irreducible subspace of X^K.*

Proof. The equivalent result that W is an Ω-reducible subspace of X if and only if W^h is an Ω^β-reducible subspace follows immediately from Lemma 4.4. □

LEMMA 4.6. *Let Ω be a subgroup of Γ and let h satisfy* (4.5). *Then W is an Ω-absolutely irreducible subspace of X if and only if $W^h\equiv hW$ is an Ω^β-absolutely irreducible subspace of X^K.*

Proof. First suppose that W is Ω-absolutely irreducible. Let $A: W^h \to W^h$ commute with the representation of Ω^β on W^h. If $x \in W$ and $\gamma \in \Omega^\beta$, then $\beta(\gamma) \in \Omega$ and we have

$$\begin{aligned} h^{-1}AhT(\beta(\gamma))x &= h^{-1}AT(\gamma)hx \\ &= h^{-1}T(\gamma)Ahx \\ &= T(\beta(\gamma))h^{-1}Ahx \end{aligned}$$

using (4.5) and since A commutes with $T(\gamma)$ for all $\gamma \in \Omega^\beta$. Thus $h^{-1}Ah$ commutes with the representation of Ω on W, and as W is Ω-absolutely irreducible, we conclude that $h^{-1}Ah = cI|_W$, $c \in \mathbf{R}$. Thus $A = cI|_{W^h}$ and so W^h is Ω^β-absolutely irreducible.

The converse is proved similarly. □

We now consider how the presence of a scaling law affects bifurcation theory. Henceforth, we will assume the existence of a smooth branch of solutions of (4.1) contained in $X^\Omega \times \mathbf{R}$ for some subgroup Ω of Γ, which we will refer to as the primary branch. As a consequence of the scaling law (4.6), by Lemma 4.3 there must also be another branch of solutions of (4.1), contained in $X^{\Omega^\beta} \times \mathbf{R}$, which we will refer to as the scaled branch. (Indeed there may be many scaled branches obtained by a repeated application of the scaling law (4.6), but for our analysis we consider only one such branch.)

In the results that follow, we use the notation

$$\mathcal{N}_0 = \text{Null}\,(g_x(x_0, \lambda_0)), \qquad \mathcal{N}_0^* = \text{Null}\,(g_x(x_0, \lambda_0)^*),$$

$$\mathcal{N}_h = \text{Null}\,(g_x(bhx_0, l\lambda_0)), \qquad \mathcal{N}_h^* = \text{Null}\,(g_x(bhx_0, l\lambda_0)^*),$$

where $(x_0, \lambda_0) \in X \times \mathbf{R}$ satisfies (4.1). We also make the assumption that $g_x(x, \lambda)$ is a Fredholm operator of index zero.

LEMMA 4.7. *If $x_0 \in X^\Omega$, then $\mathcal{N}_0$ is a closed, Ω-invariant subspace of X, $\mathcal{N}_h$ is a closed, Ω^β-invariant subspace of X, and $h\mathcal{N}_0 = \mathcal{N}_h \cap X^K$. Also, $\mathcal{N}_0$ is Ω-absolutely irreducible if and only if $h\mathcal{N}_0$ is Ω^β-absolutely irreducible.*

Proof. Since $g_x(x, \lambda)$ is bounded, both $\mathcal{N}_0$ and $\mathcal{N}_h$ are closed. It is well known and easily proved that if $x \in X^\Sigma$ for some subgroup Σ of Γ, then Null $(g_x(x, \lambda))$ is Σ-invariant. Thus since $x_0 \in X^\Omega$, $\mathcal{N}_0$ is Ω-invariant. Also, $hx_0 \in X^{\Omega^\beta}$ by Lemma 4.3 and so $\mathcal{N}_h$ is Ω^β-invariant. Taking the Fréchet derivative of (4.6) with respect to x and evaluating it at (x_0, λ_0) gives

$$chg_x(x_0, \lambda_0)\varphi = bg_x(bhx_0, l\lambda_0)h\varphi \tag{4.8}$$

for all $\varphi \in X$. Thus if $\varphi \in \mathcal{N}_0$, then $h\varphi \in \mathcal{N}_h$ and so $h\mathcal{N}_0 \subseteq \mathcal{N}_h \cap X^K$. Also, if $\tilde{\varphi} \in \mathcal{N}_h \cap X^K$, then $\tilde{\varphi} = h\varphi$ for some $\varphi \in X$ and so from (4.6), $\varphi \in \mathcal{N}_0$. Hence $h\mathcal{N}_0 = \mathcal{N}_h \cap X^K$. The final statement of the lemma regarding absolute irreducibility follows directly from Lemma 4.6. □

We now define a *bifurcation point* to be a point (x_0, λ_0) such that the Equivariant Branching Lemma (Theorem 3.4) guarantees the existence of a secondary branch of solutions bifurcating from (x_0, λ_0), and we then have the following result.

THEOREM 4.8. *If $x_0 \in X^\Omega$, then (x_0, λ_0) is a bifurcation point where the secondary branch of solutions has isotropy subgroup Σ if and only if $(bhx_0, l\lambda_0)$ is a bifurcation point where the secondary branch of solutions has isotropy subgroup Σ^β.*

Proof. We must prove that the conditions of the Equivariant Branching Lemma hold at (x_0, λ_0) if and only if they hold at $(bhx_0, l\lambda_0)$. First, if $\dim \mathcal{N}_0 > 0$ then $\dim \mathcal{N}_h > 0$, since $h\mathcal{N}_0 \subseteq \mathcal{N}_h$ by Lemma 4.7 and h is a homeomorphism. Conversely, if $\dim \mathcal{N}_h > 0$

and $\dim(\mathcal{N}_h \cap X^{\Sigma^\beta}) = 1$ then $\dim(\mathcal{N}_h \cap X^K) \geqq 1$ since K is a subgroup of Σ^β. Thus $\dim \mathcal{N}_0 > 0$ since $h\mathcal{N}_0 = \mathcal{N}_h \cap X^K$ by Lemma 4.7 and h is a homeomorphism.

Now consider the three hypotheses of the Equivariant Branching Lemma:

(i) We observe that, since h is injective,

$$\begin{aligned} h(\mathcal{N}_0 \cap X^\Omega) &= h\mathcal{N}_0 \cap X^{\Omega^\beta} \\ &= \mathcal{N}_h \cap X^K \cap X^{\Omega^\beta} \\ &= \mathcal{N}_h \cap X^{\Omega^\beta} \end{aligned}$$

using Lemma 4.3, Lemma 4.7, and the fact that $X^{\Omega^\beta} \subseteq X^K$ since K is a subgroup of Ω^β. Thus $\mathcal{N}_0 \cap X^\Omega = \{0\}$ if and only if $\mathcal{N}_h \cap X^{\Omega^\beta} = \{0\}$ since h is a homeomorphism.

(ii) By an argument similar to (i), we have $h(\mathcal{N}_0 \cap X^\Sigma) = \mathcal{N}_h \cap X^{\Sigma^\beta}$ since K is a subgroup of Σ^β. Thus $\dim(\mathcal{N}_0 \cap X^\Sigma) = 1$ if and only if $\dim(\mathcal{N}_h \cap X^{\Sigma^\beta}) = 1$ since h is a homeomorphism.

(iii) For the sake of brevity, we introduce the notation $g^0 = g(x_0, \lambda_0)$, $g^h = g(bhx_0, l\lambda_0)$, etc. The nondegeneracy condition to be satisfied at (x_0, λ_0) is

$$\langle \psi_0, g^0_{x\lambda}\varphi_0 + g^0_{xx}\varphi_0 v\rangle \neq 0 \tag{4.9}$$

where $\varphi_0 \in \mathcal{N}_0 \cap X^\Sigma$, $\psi_0 \in \mathcal{N}_0^* \cap X^\Sigma$ and $v \in X^\Omega$ is the unique solution of

$$g^0_x v + g^0_\lambda = 0. \tag{4.10}$$

Similarly, the nondegeneracy condition to be satisfied at $(bhx_0, l\lambda_0)$ is

$$\langle \psi_h, g^h_{x\lambda}\varphi_h + g^h_{xx}\varphi_h v_h\rangle \neq 0 \tag{4.11}$$

where $\varphi_h \in \mathcal{N}_h \cap X^{\Sigma^\beta}$, $\psi_h \in \mathcal{N}_h^* \cap X^{\Sigma^\beta}$, and $v_h \in X^{\Omega^\beta}$ is the unique solution of

$$g^h_x v_h + g^h_\lambda = 0. \tag{4.12}$$

By differentiating the scaling law (4.6), it is easily shown that $v \in X^\Omega$ is a solution of (4.10) if and only if $v_h = (b/l)hv \in X^{\Omega^\beta}$ is a solution of (4.12) since $b, c, l \neq 0$. Also, we saw in (ii) that $h(\mathcal{N}_0 \cap X^\Sigma) = \mathcal{N}_h \cap X^{\Sigma^\beta}$ and so we can write $\varphi_h = h\varphi_0$. As h is an orthogonal transformation, we have

$$\begin{aligned} \langle x_1, g^0_x x_2\rangle &= \langle hx_1, hg^0_x x_2\rangle \\ &= \frac{b}{c}\langle hx_1, g^h_x hx_2\rangle \end{aligned}$$

for all $x_1, x_2 \in X$ using (4.8). Thus

$$\langle (g^0_x)^* x_1, x_2\rangle = \frac{b}{c}\langle (g^h_x)^* hx_1, hx_2\rangle,$$

and so $x_1 \in \mathcal{N}_0^*$ if and only if $hx_1 \in \mathcal{N}_h^*$, that is, $h\mathcal{N}_0^* = \mathcal{N}_h^* \cap X^K$. Hence $h(\mathcal{N}_0^* \cap X^\Sigma) = \mathcal{N}_h^* \cap X^{\Sigma^\beta}$ by Lemma 4.3 and the fact that $X^{\Sigma^\beta} \subseteq X^K$, and so we can write $\psi_h = h\psi_0$. It is then a matter of calculation to verify that

$$\begin{aligned} \langle \psi_h, g^h_{x\lambda}\varphi_h + g^h_{xx}\varphi_h v_h\rangle &= \left\langle h\psi_0, g^h_{x\lambda}h\varphi_0 + \frac{b}{l}g^h_{xx}h\varphi_0 hv\right\rangle \\ &= \left\langle h\psi_0, \frac{c}{bl}h(g^0_{x\lambda}\varphi_0 + g^0_{xx}\varphi_0 v)\right\rangle \\ &= \frac{c}{bl}\langle \psi_0, g^0_{x\lambda}\varphi_0 + g^0_{xx}\varphi_0 v\rangle \end{aligned}$$

since h is orthogonal. As $b, c, l \neq 0$, we conclude that (4.9) holds if and only if (4.11) holds. □

As a consequence of Theorem 4.8, it is clear that every bifurcation point on the primary branch can be rescaled to produce a bifurcation point on the scaled branch. However, a bifurcation point on the scaled branch can be scaled back onto the primary branch if and only if the isotropy subgroup $\tilde{\Sigma}$ of the secondary branch has K as a subgroup, since both the scaled branch and the secondary branch that bifurcates from it then have solutions in the range of h. In this case, the branch that bifurcates from the primary branch has isotropy subgroup $\beta(\tilde{\Sigma})$. It is possible that the symmetry of K can be lost at a bifurcation point on the scaled branch so that the bifurcation point cannot be scaled back to a bifurcation point of the primary branch.

The situation may occur where $\Omega^\beta = \Omega$ (e.g., $\Omega = \Gamma$), in which case the primary and scaled branches could coincide. However, Theorem 4.8 still holds in this situation and the two secondary branches then bifurcate from the same branch at different values of λ (provided that $l \neq 1$).

In § 3 (Theorem 3.5 and following) we saw that the type of bifurcation can be determined by considering $N_\Omega(\Sigma)/\Sigma$. It is intuitively obvious that the type of bifurcation from the primary and scaled branches must be the same. This is formalised by the following result.

THEOREM 4.9. *The mapping $\tilde{\beta}$ defined by*

$$\tilde{\beta}: N_{\Omega^\beta}(\Sigma^\beta)/\Sigma^\beta \to N_\Omega(\Sigma)/\Sigma, \qquad \gamma\Sigma^\beta \to \beta(\gamma)\Sigma$$

is an isomorphism.

Proof. We first show that $\beta(N_{\Omega^\beta}(\Sigma^\beta)) = N_\Omega(\Sigma)$. Let $\gamma \in N_{\Omega^\beta}(\Sigma^\beta)$. Then $\gamma\Sigma^\beta = \Sigma^\beta\gamma$ by the definition of $N_{\Omega^\beta}(\Sigma^\beta)$ and so $\beta(\gamma)\Sigma = \Sigma\beta(\gamma)$ since $\beta(\Sigma^\beta) = \Sigma$. Thus $\beta(N_{\Omega^\beta}(\Sigma^\beta))$ is a subgroup of $N_\Omega(\Sigma)$.

Now let $\gamma \in N_\Omega(\Sigma)$. Then $\gamma\sigma\gamma^{-1} \in \Omega$ for all $\sigma \in \Sigma$. Now $\gamma = \beta(\tilde{\gamma})$ for some $\tilde{\gamma} \in \Gamma$ since β is surjective. Thus for any $\tilde{\sigma} \in \Sigma^\beta$, $\beta(\tilde{\gamma}\tilde{\sigma}\tilde{\gamma}^{-1}) = \gamma\sigma\gamma^{-1} \in \Sigma$, where $\sigma = \beta(\tilde{\sigma}) \in \Sigma$, and so $\tilde{\gamma}\tilde{\sigma}\tilde{\gamma}^{-1} \in \Sigma^\beta$ for all $\tilde{\sigma} \in \Sigma^\beta$ giving $\tilde{\gamma} \in N_{\Omega^\beta}(\Sigma^\beta)$. Thus $N_\Omega(\Sigma)$ is a subgroup of $\beta(N_{\Omega^\beta}(\Sigma^\beta))$ and so we conclude that $\beta(N_{\Omega^\beta}(\Sigma^\beta)) = N_\Omega(\Sigma)$.

It is straightforward to prove that $\tilde{\beta}$ is a homomorphism and so we now prove that it is bijective. Let $\gamma \in N_\Omega(\Sigma)$. Then $\gamma\Sigma \in N_\Omega(\Sigma)/\Sigma$. Since β is surjective, there exists $\tilde{\gamma} \in \Gamma$ such that $\beta(\tilde{\gamma}) = \gamma$. By the above result, we conclude that $\tilde{\gamma} \in N_{\Omega_\beta}(\Sigma^\beta)$. Thus $\tilde{\beta}(\tilde{\gamma}\Sigma^\beta) = \gamma\Sigma$ and $\tilde{\gamma}\Sigma^\beta \in N_{\Omega^\beta}(\Sigma^\beta)/\Sigma^\beta$ and so $\tilde{\beta}$ is surjective.

Let $\gamma_1, \gamma_2 \in N_{\Omega^\beta}(\Sigma^\beta)$. Then

$$\begin{aligned}
\tilde{\beta}(\gamma_1\Sigma^\beta) = \tilde{\beta}(\gamma_2\Sigma^\beta) &\Rightarrow \beta(\gamma_1)\Sigma = \beta(\gamma_2)\Sigma \\
&\Rightarrow \beta(\gamma_2^{-1}\gamma_1)\Sigma = \Sigma \\
&\Rightarrow \beta(\gamma_2^{-1}\gamma_1) \in \Sigma \\
&\Rightarrow \gamma_2^{-1}\gamma_1 \in \Sigma^\beta \\
&\Rightarrow \gamma_2^{-1}\gamma_1\Sigma^\beta = \Sigma^\beta \\
&\Rightarrow \gamma_1\Sigma^\beta = \gamma_2\Sigma^\beta
\end{aligned}$$

using the definition of $\tilde{\beta}$ and the homomorphism property of β. Thus $\tilde{\beta}$ is also injective. We therefore conclude that $\tilde{\beta}$ is an isomorphism since it is a bijective homomorphism of Lie groups [BtD, p. 22]. □

Throughout our analysis, we have not been able to say that $\mathcal{N}_h = h\mathcal{N}_0$, only that $h\mathcal{N}_0 \subseteq \mathcal{N}_h$. In the generic situation, both $\mathcal{N}_0$ and $\mathcal{N}_h$ are (absolutely) irreducible (Theorem 3.2), in which case equality holds by Lemma 4.5 (cf. Lemma 4.6 also).

However, in a two-parameter problem, it is possible that mode interaction could occur on the scaled branch so that $\mathcal{N}_h \neq h\mathcal{N}_0$ at a critical value of the second parameter. In this case, Theorem 4.8 still applies, ensuring the existence of a secondary branch bifurcating from the scaled branch, thus providing some information about the bifurcating branches at a point of mode interaction.

We note that it is not possible for a scaled branch to be the continuation of the primary branch, since the branches have different isotropy subgroups, and the isotropy subgroup of a branch of solutions is preserved globally along the branch (Healey (1988a)). However, the primary and scaled branches could intersect at a bifurcation point.

The purpose of this analysis has been to determine when branches of solutions are related by a simple scaling, since the numerical computation of two such branches is clearly unnecessary and wasteful. Thus we conclude that it is sufficient to compute only those branches of solutions whose isotropy subgroup Ω satisfies either $\Omega^\beta = \Omega$ or $\Omega^\beta \neq \Omega$ and K is not a subgroup of Ω. However, it may be necessary to scale the solution up (in the second case) in order to check for the existence of bifurcation points on the scaled branch that do not occur on the primary branch.

5. Application to the gravity wave problem. In this section, we apply the theory of the previous sections to the problem of determining the profile of periodic, two-dimensional, irrotational travelling waves on the surface of an inviscid, incompressible fluid of constant density in a channel of infinite depth in the presence of gravity g, but without surface tension. By taking a frame of reference that moves with the travelling waves, the problem can be posed as a steady-state equation involving c, the speed of the flow at infinite depth, as the bifurcation parameter. Bifurcation from the trivial solution was discussed by Nekrasov (1920), who formulated the problem as an integral equation on the free surface, and by Levi-Civita (1925). More recently, Chen and Saffman (1980) and Saffman (1980) have discovered numerically secondary bifurcations on the primary branches far away from the trivial solution. We extend their results and describe a pattern which occurs in the secondary bifurcations.

The profile of the free surface can be found by solving the following differential equation (Okamoto (1990)):

$$G(\theta, \nu) \equiv \nu e^{-2\tau(s)}\tau'(s) + e^{\tau(s)} \sin \theta(s) = 0 \tag{5.1}$$

where $\nu = c^2/g$, the 2π-periodic function $\theta(s)$ given by

$$\theta(s) \sim \sum_{k=1}^{\infty} (a_k \sin ks + b_k \cos ks) \tag{5.2}$$

is the angle between the horizontal and the free surface at the point $(x(s), y(s))$ defined by

$$(x(s), y(s)) = -\int_0^s (e^{\tau(t)} \cos \theta(t), e^{\tau(t)} \sin \theta(t))\, dt, \tag{5.3}$$

and $-\tau$ is the conjugate of θ, given by

$$\tau(s) \sim \sum_{k=1}^{\infty} (a_k \cos ks - b_k \sin ks). \tag{5.4}$$

By integrating around a contour in the $x-y$ plane, it can be shown (see Okamoto (1990)) that

$$\int_0^{2\pi} e^{\tau(s)} \sin \theta(s)\, ds = 0. \tag{5.5}$$

This condition ensures that the resulting wave profile is periodic since (5.5) is equivalent to $y(2\pi)=0$ and $y(0)=0$ from (5.3). A similar argument can be used to show that

$$\int_0^{2\pi} \theta(s)\, ds = 0, \tag{5.6}$$

which is the justification for omitting the constant term from the Fourier series in (5.2).

We pose this problem in a Hilbert space setting so that the results of the previous sections can be applied. Thus we define

$$X = \left\{ f(s) \sim \sum_{k=1}^{\infty} (a_k \sin ks + b_k \cos ks) : \sum_{k=1}^{\infty} k^2(a_k^2 + b_k^2) < \infty \right\}$$

with inner product

$$\langle f_1, f_2 \rangle_X = \frac{1}{\pi} \int_0^{2\pi} f_1'(s) f_2'(s)\, ds$$

and similarly

$$Y = \left\{ f(s) \sim \sum_{k=1}^{\infty} (a_k \sin ks + b_k \cos ks) : \sum_{k=1}^{\infty} (a_k^2 + b_k^2) < \infty \right\}$$

with inner product

$$\langle f_1, f_2 \rangle_Y = \frac{1}{\pi} \int_0^{2\pi} f_1(s) f_2(s)\, ds.$$

Clearly $X \subset H^1[0, 2\pi]$, $Y \subset L^2[0, 2\pi]$, and $X \subset Y$. Also, if $\theta \in X$, then $\tau \in X$ and so $G: X \times \mathbf{R} \to Y$ (as the constant component of G vanishes due to (5.5)).

Nekrasov's integral equation can be derived from this formulation by solving (5.1) for τ in terms of θ and ν and then substituting the resulting expression for τ into an integral equation expressing the conjugacy relation between θ and τ.

Having set the problem up, we must determine the group that satisfies the equivariance condition (3.2) and look for scaling laws of the form (4.6). We define the following action of the group $O(2)$ on Y:

$$R_\alpha f(s) = f(s+\alpha), \qquad \alpha \in [0, 2\pi), \tag{5.7a}$$

$$Sf(s) = -f(-s), \tag{5.7b}$$

$$SR_\alpha f(s) = -f(-s-\alpha), \qquad \alpha \in [0, 2\pi). \tag{5.7c}$$

Then X is an $O(2)$-invariant subspace of Y. This action defines representations of $O(2)$ on X and Y. It follows from (5.2) and (5.4) that $S\tau(s) = \tau(-s)$, and it is then straightforward to show that G is equivariant with respect to the representations of $O(2)$ on X and Y induced by the action (5.7). Also, the inner products on X and Y are $O(2)$-invariant, and so the representations of $O(2)$ on X and Y induced by the group action (5.7) are orthogonal representations. Further, X and Y are linearly homeomorphic and the representations on X and Y are equivalent as required.

When seeking scaling laws of the form (4.6), we first determine all the discrete normal subgroups of $O(2)$. These consist of the finite cyclic groups Z_n, $n \in \mathbf{Z}^+$, generated by $R_{2\pi/n}$, which are the kernels of the epimorphisms $\beta_n: O(2) \to O(2)$ defined by

$$\beta_n(R_\alpha) = R_{n\alpha}, \qquad \alpha \in [0, 2\pi),$$

$$\beta_n(S) = S.$$

The fixed-point subspaces corresponding to the finite cyclic groups are

$$X^{Z_n} = \{f \in X : f(s) = f(s + 2\pi/n)\}$$

and similarly for Y^{Z_n}, $n \in \mathbf{Z}^+$. We now define the mapping h_n by

$$h_n f(s) = f(ns), \qquad n \in \mathbf{Z}^+.$$

Clearly h_n maps X onto X^{Z_n} and Y onto Y^{Z_n}. It is easily verified that h_n is an orthogonal linear homeomorphism which satisfies

$$R_\alpha h_n = h_n R_{n\alpha},$$

$$S h_n = h_n S.$$

Thus h_n meets all the requirements for a scaling transformation and we observe that G satisfies the scaling law

$$h_n G(\theta, \nu) = G(h_n \theta, \nu/n), \qquad n \in \mathbf{Z}^+. \tag{5.8}$$

We note that by Theorem 4.1 the scaling transformations h_n are uniquely defined since the centre of $O(2)$ is trivial.

5.1. Bifurcation from the trivial solution. The gravity wave problem (5.1) has the trivial solution $\theta = 0$ for all $\nu \geqq 0$ which corresponds to a flat free surface. This is the only solution that has $O(2)$ as its isotropy subgroup. We first consider bifurcation from the trivial solution, which is of course, well known, and so we only review it briefly in the current framework. Linearising (5.1) about the trivial solution gives

$$G_\theta(0, \nu)\tilde{\theta} = \nu\tilde{\tau}' + \tilde{\theta}$$

for all $\tilde{\theta} \in X$, where $-\tilde{\tau}$ is the conjugate of $\tilde{\theta}$.

The nontrivial irreducible representations of $O(2)$ on X (and Y) are

$$R_\alpha = \begin{pmatrix} \cos n\alpha & \sin n\alpha \\ -\sin n\alpha & \cos n\alpha \end{pmatrix}, \quad S = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad n = 1, 2, 3, \cdots.$$

It is easily verified that all these irreducible representations are absolutely irreducible. The corresponding isotypic components of X are

$$V_n = \text{span}\,\{\sin ns, \cos ns\}, \qquad n = 1, 2, 3, \cdots$$

and similarly for Y. It is interesting to observe that in this case, the isotypic components are irreducible. We note that the irreducible representation $R_\alpha = I$, $S = -I$ does not arise since $\theta(s) = c$, $c \in \mathbf{R}$ does not belong to X (or Y).

When $\nu = 1/n$, $n \in \mathbf{Z}^+$, then Null $(G_\theta(0, \nu)) = V_n$ and is thus irreducible. Now the isotropy subgroup of V_n is the cyclic group Z_n generated by $R_{2\pi/n}$. However, dim $(V_n \cap X^{D_n}) = 1$, where D_n is the dihedral group generated by $R_{2\pi/n}$ and S. It is a matter of calculation to verify that the nondegeneracy condition (3.10) is satisfied with $\varphi_0 = \sin ns \in V_n \cap X^{D_n}$. Thus by the Equivariant Branching Lemma, there is a branch of solutions with isotropy subgroup D_n which bifurcates from the trivial solution at $\nu = 1/n$. On such a branch, θ has the form

$$\theta(s) \sim \sum_{k=1}^{\infty} a_k \sin nks.$$

The normaliser of D_n in $O(2)$ is D_{2n} and $D_{2n}/D_n \cong Z_2$. Thus each bifurcation is a symmetric pitchfork by Theorem 3.5 and subsequent assertions. The distinct conjugate solutions of $\theta \in X^{D_n}$ are $R_\alpha \theta(s)$ for $\alpha \in (0, 2\pi/n)$ and so there is a one-parameter

"sheet" of solutions (see Sattinger (1973)). The only conjugate solution that is symmetric (relative to S) is

$$R_{\pi/n}\theta(s) \sim \sum_{k=1}^{\infty} (-1)^k a_k \sin nks,$$

which is the conjugate branch of the pitchfork. We will refer to the branch with $a_1 > 0$ initially as primary branch n and to the branch with $a_1 < 0$ initially as primary conjugate branch n.

When θ is symmetric (relative to S), it is an odd function of s. However, the wave profile is then an even function of x.

Clearly, the scaling transformations h_n do not affect the trivial solution. If we let $\Sigma = \{I, S\}$, then $\Sigma^{\beta_n} = D_n$, $n = 2, 3, 4, \cdots$, where Σ^{β_n} is defined by (4.7). Using the scaling law (5.8), we can see from Theorem 4.8 that all the primary branches which bifurcate from the trivial solution and have isotropy subgroup D_n are a scaled copy of the first branch, and so there is essentially only one distinct primary branch.

5.2. Bifurcation from D_n-symmetric branches. In general, it is not possible to study secondary bifurcation analytically, and so we solve the problem numerically. Thus we now consider the possible modes of secondary bifurcation from D_n-symmetric branches, assuming the generic conditions that the nullspace of $G_\theta(\theta, \nu)$, $\theta \in X^{D_n}$ is D_n-irreducible and that the nondegeneracy condition (3.10) is satisfied. The nontrivial irreducible representations of the group D_n, generated by $R_{2\pi/n}$ and S, on X (and Y) are given by

(i) $R_{2\pi/n} = I, \quad S = -I,$

(ii) $R_{2\pi/n} = -I, \quad S = I \quad (n \text{ even}),$

(iii) $R_{2\pi/n} = -I, \quad S = -I \quad (n \text{ even})$

(iv) $$R_{2\pi/n} = \begin{bmatrix} \cos\dfrac{2\pi m}{n} & \sin\dfrac{2\pi m}{n} \\ -\sin\dfrac{2\pi m}{n} & \cos\dfrac{2\pi m}{n} \end{bmatrix},$$

$$S = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix},$$

$$m = 1, \cdots, \tfrac{1}{2}n - 1 \quad (n \text{ even}),$$

$$= 1, \cdots, \tfrac{1}{2}(n-1) \quad (n \text{ odd}).$$

Again, all of these irreducible representations are absolutely irreducible and the corresponding isotypic components of X are

$$\tilde{V}_1 = \left\{ f(s) \sim \sum_{k=1}^{\infty} a_k \cos nks : f \in X \right\},$$

$$\tilde{V}_2 = \left\{ f(s) \sim \sum_{k=0}^{\infty} a_k \sin\left(nk + \frac{n}{2}\right)s : f \in X \right\} \quad (n \text{ even}),$$

$$\tilde{V}_3 = \left\{ f(s) \sim \sum_{k=0}^{\infty} a_k \cos\left(nk + \frac{n}{2}\right)s : f \in X \right\} \quad (n \text{ even}),$$

$$\tilde{V}_{4,m} = \Big\{ f(s) \sim \sum_{k=0}^{\infty} [a_k \sin(nk+m)s + b_k \sin(n(k+1)-m)s + c_k \cos(nk+m)s + d_k \cos(n(k+1)-m)s] : f \in X \Big\},$$

$$m = 1, \cdots, \tfrac{1}{2}n - 1 \quad (n \text{ even}),$$
$$= 1, \cdots, \tfrac{1}{2}(n-1) \quad (n \text{ odd}),$$

and similarly for Y. Since the linear operator $G_\theta(\theta, \nu)$, $\theta \in X^{D_n}$ maps each isotypic component of X to the corresponding isotypic component of Y (by the generalisation of Theorem 3.2), we can consider the situation when $\mathcal{N} \equiv \text{Null}\,(G_\theta(\theta, \nu))$ is an irreducible subspace of each isotypic component separately. By differentiating the equivariance condition (3.15) with respect to x, it is easily verified that if $\varphi \in \text{Null}\,(G_\theta(\theta, \nu))$, then $R_{\pi/n}\varphi \in \text{Null}\,(G_\theta(R_{\pi/n}\theta, \nu))$, and so for every singular point on the primary branch, there is a corresponding singular point on the primary conjugate branch to consider. We are then interested in any conjugacy relation between the secondary branches that bifurcate from the primary and primary conjugate branches.

(i) At every solution $(\theta, \nu) \in X^{D_n} \times \mathbf{R}$ of (5.1), we have

$$G_\theta(\theta, \nu) A\theta = 0$$

where $A\theta \equiv (d/d\alpha)\theta(s+\alpha)|_{\alpha=0} = \theta'(s)$. This is easily shown by differentiating the R_α-equivariance condition with respect to α and evaluating at $\alpha = 0$. Now if $\theta \in X^{D_n}$, then $\theta'(s) \in \tilde{V}_1$; therefore the component of $G_\theta(\theta, \nu)$ associated with $\tilde{V}_1$ is singular at every (nontrivial) solution point, and so the Equivariant Branching Lemma cannot be applied directly in this case. Zufiria (1987b) has investigated this class of bifurcation for the gravity wave problem and we will not consider it further. A consideration of bifurcation of this type for more general problems is given in Aston, Spence, and Wu (1990).

(ii) If $\mathcal{N} \subset \tilde{V}_2$ is irreducible, then $\dim \mathcal{N} = 1$ and so the bifurcation will be a symmetric pitchfork by Theorem 3.5. The isotropy subgroup of $\tilde{V}_2$ is $D_{n/2}$ generated by $R_{4\pi/n}$ and S and so this case corresponds to a period-doubling bifurcation. The secondary conjugate branch is obtained by applying $R_{2\pi/n}$. Now if $\varphi \in \mathcal{N} \subset \tilde{V}_2$, then $R_{\pi/n}\varphi \in \tilde{V}_3$, and so the corresponding secondary branches which bifurcate from the primary conjugate branch are associated with a different isotypic component and are not symmetric relative to S. We note, however, that all these branches are $O(2)$-conjugate and so there is essentially only one distinct secondary branch of solutions at the bifurcation point. We will refer to this case as bifurcation of mode $(n/2)^+$.

(iii) If $\mathcal{N} \subset \tilde{V}_3$ is irreducible, then $\dim \mathcal{N} = 1$. The isotropy subgroup of $\tilde{V}_3$ is the dihedral group $\tilde{D}_{n/2}$, generated by $R_{4\pi/n}$ and $SR_{2\pi/n}$. Thus we again have a symmetric pitchfork, period-doubling bifurcation. In this case, if $\varphi \in \mathcal{N} \subset \tilde{V}_3$ then $R_{\pi/n}\varphi \in \tilde{V}_2$ and so the secondary branches that bifurcate from the primary conjugate branch are symmetric with respect to S. Again, there is essentially only one distinct secondary branch of solutions. We will refer to this case as bifurcation of mode $(n/2)^-$. The period-doubling scenario is summarised in Fig. 1.

Before moving on, we must emphasise the difference in the isotropy subgroups of the secondary branches emanating from the primary and primary conjugate branches associated with period-doubling bifurcation. In Toland and Jones (1985) and Jones and Toland (1986), bifurcation at a double eigenvalue in the capillary-gravity wave problem (i.e., when the surface tension is nonzero) is considered, together with the effect of a small perturbation in the surface tension from a critical value. The group

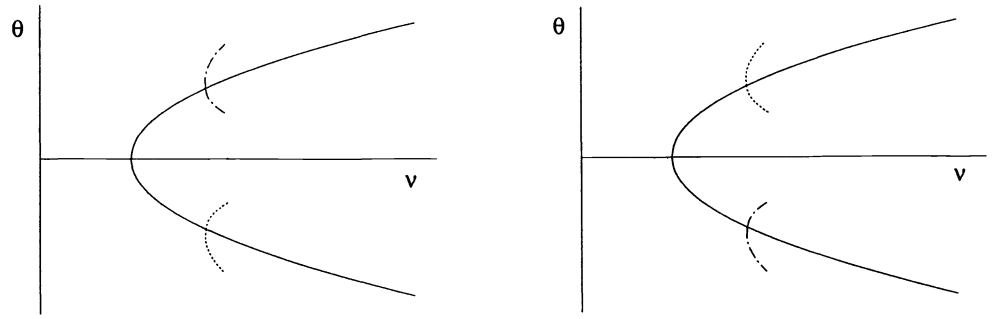

FIG. 1. *Period-doubling bifurcations.* —— D_n*-symmetric solutions,* – · – $D_{n/2}$*-symmetric solutions, and* ····· $\tilde{D}_{n/2}$*-symmetric solutions.*

that satisfies the equivariance condition for the capillary-gravity wave problem is the same group $O(2)$, and so the period-doubling scenario just described applies for this problem. Toland and Jones considered only symmetric waves (that is, solutions which satisfy $S\theta = \theta$) and found that at mode interactions between branch 2 and higher branches, a perturbation in the surface tension resulted in secondary bifurcations on branch 2 on both the primary and primary conjugate branches. They then claimed that these bifurcation points are related by symmetry, which clearly cannot be true since they are associated with the different isotypic components $\tilde{V}_2$ and $\tilde{V}_3$. Thus we must conclude that the two secondary bifurcation points are, in fact, independent of each other.

(iv) We first observe that these D_n-irreducible representations restricted to the subgroup $Z_2 = \{I, S\}$ are not Z_2-irreducible. Thus by Theorem 3.3, the isotypic components $\tilde{V}_{4,m}$ can be decomposed as

$$\tilde{V}_{4,m} = \tilde{V}^s_{4,m} \oplus \tilde{V}^a_{4,m}$$

where

$$\tilde{V}^s_{4,m} = \{f \in \tilde{V}_{4,m} : Sf = f\},$$

$$\tilde{V}^a_{4,m} = \{f \in \tilde{V}_{4,m} : Sf = -f\}.$$

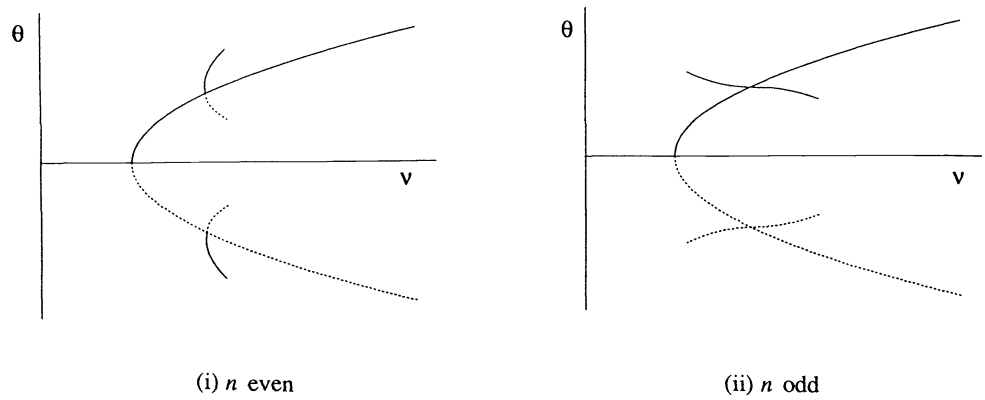
Also, the linear operator $G_\theta(\theta, \nu)$, $\theta \in X^{D_n}$ maps the subspace $\tilde{V}^s_{4,m}$ of X to the corresponding subspace of Y and similarly for $\tilde{V}^a_{4,m}$. Thus if $\mathcal{N} \subset \tilde{V}_{4,m}$ is D_n-irreducible, then $\dim \mathcal{N} = 2$ but $\dim(\mathcal{N} \cap \tilde{V}^s_{4,m}) = 1$ and $\dim(\mathcal{N} \cap \tilde{V}^a_{4,m}) = 1$. Now the isotropy subgroup of $\tilde{V}^a_{4,m}$ is the cyclic group Z_l, where $l = \gcd(m, n)$, whereas the isotropy subgroup of $\tilde{V}^s_{4,m}$ is the dihedral group D_l. Thus $\dim(\mathcal{N} \cap X^{D_l}) = 1$ and so there is a secondary branch of solutions with isotropy subgroup D_l. Clearly such a bifurcation can be detected numerically by a sign change in the determinant of the approximation to $G_\theta(\theta, \nu)|_{\tilde{V}^s_{4,m}}$ and so the linear operator $G_\theta(\theta, \nu)|_{\tilde{V}^a_{4,m}}$ need not be considered.

If n/l is odd, then the normaliser of D_l in D_n is simply D_l, and so the bifurcation is nonsymmetric by Theorem 3.5 and the solutions on the two secondary branches are distinct. However, in this case, a shift by π/l (i.e., an odd multiple of π/n) applied to $\varphi \in \mathcal{N} \cap X^{D_l}$ results in a symmetric function, and so the secondary branches bifurcating from the primary conjugate branch are $O(2)$-conjugate to those bifurcating from the primary branch.

If n/l is even, then the normaliser of D_l in D_n is D_{2l} and $D_{2l}/D_l \cong Z_2$. Thus the bifurcation is a symmetric pitchfork by Theorem 3.5, where the secondary conjugate

branch is obtained by applying the shift operator $R_{\pi/l}$. In this case, no shift by an odd multiple of π/n applied to $\varphi \in \mathcal{N} \cap X^{D_l}$ results in a symmetric function. Since dim $\mathcal{N} = 2$ on the primary conjugate branch, we can again restrict attention to the symmetric part of the isotypic component $\tilde{V}_{4,m}$, resulting in a distinct secondary branch of solutions bifurcating from the primary conjugate branch.

Thus in each case, there are two distinct branches of solutions which bifurcate. Dellnitz and Werner (1989) show that no other subgroups of D_n give rise to distinct branches of solutions via the Equivariant Branching Lemma. We will refer to this case as bifurcation of mode m (for $m < n/2$). These results are summarised in Fig. 2.



(i) n even (ii) n odd

FIG. 2. *Structure of secondary bifurcations from primary branch* $n \geqq 3$. —— *distinct solutions and* ····· *conjugate solutions.*

We note that if $l \neq 1$, then the secondary bifurcation point can be scaled down onto branch n/l and so, on any branch, the only bifurcation points that have not already occurred on lower branches are those for which m and n are coprime.

5.3. Numerical procedures for the gravity-wave problem. A pseudospectral collocation method is used to solve the gravity wave problem (5.1) numerically using the Fourier coefficients of the function θ as the degrees of freedom. This method has the advantage of spectral accuracy as θ is a smooth function. Also, the fixed-point subspaces and isotypic components of the finite-dimensional approximation spaces are easily identified. However, there is the drawback that the Jacobian matrix is full and has no banded structure.

On primary branch n, it is sufficient to solve for θ on the interval $(0, \pi/n)$ using the equally spaced meshpoints $s_i = (i\pi/(N+1)n)$, $i = 1, 2, \cdots, N$, where N is the number of sine functions in the approximation for $\theta \in X^{D_n}$. For a given vector of Fourier coefficients, both the functions θ and τ can be evaluated at the collocation points using only one Fast Fourier Transform (FFT). The FFT will be most efficient if N is chosen such that $N+1$ is a power of 2.

Since secondary bifurcation points must occur on the primary conjugate branch whenever they occur on the primary branch, it is sufficient to check only the primary branch for possible bifurcation points. When seeking bifurcation from branch n, $n \geqq 3$ of mode $m < n/2$, it is sufficient to solve for $\varphi \in \tilde{V}^S_{4,m}$ on the interval (or symmetry cell) $(0, 2\pi/n]$. We observe that in this case φ is always symmetric (relative to S). Now it is computationally convenient to work only with symmetric functions and so, when seeking bifurcation from branch 2, we can find both possible modes of bifurcation

by checking both the primary and primary conjugate branches for bifurcation with $\varphi \in \tilde{V}_2$ (so that φ is symmetric). The isotypic component $\tilde{V}_3$ does not then need to be considered. Also, it is sufficient to solve for $\varphi \in \tilde{V}_2$ on the interval $(0, \pi/2]$. Thus if N collocation points are used to solve for θ on a primary branch, all the possible bifurcation points can be found by considering only matrices of order at most $2N+2$, irrespective of the increase in the period of the solution on the secondary branch. This clearly illustrates the power of this approach.

In order to find a secondary bifurcation point, the path-following package PITCON (Rheinboldt (1986)) is used to follow a primary branch of solutions away from the trivial solution, initially using the first Fourier coefficient associated with the lowest-order sine function in the expression for θ as the continuation parameter. At each step, the determinant of the Jacobian matrix defined on an isotypic component (or the appropriate subspace of an isotypic component) of the finite-dimensional approximation space is evaluated. Clearly, many such matrices can be found and their determinants evaluated at each step and, as the matrices are dependent only on the primary branch solution, this procedure could be performed in parallel, resulting in a considerable saving in computation time. Once a sign change of a determinant has been detected, the bifurcation point can be found directly by solving the extended system (3.13) by Newton's method, using the last computed point on the primary branch as the initial approximation. The singular value σ and the singular vectors φ and ψ are found by performing inverse iteration on the eigenvalue equations

$$J^T J\varphi = \sigma^2 \varphi, \qquad JJ^T \psi = \sigma^2 \psi,$$

which can be derived from (3.14), where J is the Jacobian matrix under consideration. Only one LU-decomposition of the matrix J is required to perform the inverse iteration since forward and backward substitutions can then be used twice for each system. Generally, the vectors φ and ψ change very little at each Newton iteration of the extended system, and so one inverse iteration is usually sufficient to update φ and ψ between Newton iterates. Alternatively, the vectors φ and ψ need not be corrected after every Newton iterate, in which case an updated value of σ is obtained as

$$\sigma = \psi^T J\varphi$$

using the updated matrix J. This procedure saves the costly LU-decomposition of J at some of the Newton iterates.

The full Newton method is used to solve the extended system, as the cost of evaluating the function, which requires computing the singular value σ, is more expensive than the decomposition of the Jacobian of the extended system. Also, the same storage space can then be used for the matrix J and the Jacobian of the extended system so that storage for only one matrix is required.

The advantage of using the extended system (3.13) instead of (3.12) is that the vector of derivatives of the singular value σ with respect to the Fourier coefficients of θ can be evaluated efficiently using FFTs. Otherwise, this operation would be very costly.

Once a secondary bifurcation point has been located, branch switching is easily achieved by adding a small multiple of the singular vector φ onto the symmetric solution and using one of the (nonzero) Fourier coefficients of φ as the continuation parameter.

It is well known that the primary branch solutions develop sharp crests as the amplitude of the wave increases, resulting in a limiting wave profile that has a 120-degree corner at the crest (Amick, Fraenkel, and Toland (1982)). This produces a boundary layer in θ at the origin as the primary branches are followed away from the trivial

solution, and so the number of terms N in the Fourier expansion for θ has to be increased as the computation proceeds. Clearly, a local mesh refinement strategy would be required to follow the primary branches up towards the limiting wave, which is not possible with a spectral method (although see Tanaka (1983)). However, we will not be concerned with the near limiting waves.

5.4. Numerical results for the gravity-wave problem. Primary branches 2–10 were followed in the range $1/n \leqq \nu \leqq 1.19/n$, $n = 2, 3, \cdots, 10$, checking for all possible modes of bifurcation. On branch 2, no bifurcation of mode 1^- was found, but a bifurcation point of mode 1^+ was found. Exactly one of every other possible mode of bifurcation was found on each of the branches 3–10 in the specified range. These bifurcation points, scaled back onto the first primary branch for purposes of comparison, are presented in Table 1. The bifurcation points on branches 2 and 3 agree closely with the results of Chen and Saffman (1980), and those of mode 1 agree with the results of Saffman (1980) but are given to greater accuracy. The results in Table 1 were all computed with $N = 255$. By taking $N = 383$, we can verify that the error in the computed values of ν is of the order of 10^{-11}, whereas the error in the computed values of $\|\theta\|_\infty$ is of the order of 10^{-6}. Also, Zufiria (1987b) checked primary branch 1 for a bifurcation which breaks the reflectional symmetry (associated with the isotypic component $\tilde{V}_1$), and found none.

TABLE 1
Bifurcation points on branches 2–10.

10	3	0.4399996	1.17503053726		

From these results there appears to be an ordering of the bifurcation points. Let $\nu_{m,n}$ be the value of ν at which there is a bifurcation from branch n of mode m, scaled back to the first branch (by multiplying by n). Then these results suggest the following ordering on the bifurcation points:

$$\frac{m_1}{n_1} < \frac{m_2}{n_2} \Rightarrow \nu_{m_1,n_1} < \nu_{m_2,n_2}.$$

This ordering is the same as that found by Zufiria (1987a) for a Hamiltonian approximation to the finite-depth problem. Such an ordering has also been explored

by Scovel, Kevrekidis, and Nicolaenko (1988) in their investigation of the Kuramoto-Sivashinsky equation. It is interesting to observe that both Zufiria and Scovel et al. were solving fourth-order ordinary differential equations that are $O(2)$-equivariant and satisfy scaling laws of the form (4.6).

We seek to determine the value ν_∞ defined by

$$\nu_\infty = \lim_{n\to\infty} \nu_{1,n}.$$

To this end, we computed bifurcation points of mode 1 on higher branches; the results are given in Table 2. We make the assumption that as $n \to \infty$,

$$\nu_{1,n} \simeq \nu_\infty + \alpha \frac{1}{n}$$

for some $\alpha \in \mathbf{R}$. Using the last two values in Table 2 for $n = 500$ and $n = 1000$, we obtain an approximation to ν_∞ given by

$$\nu_\infty = 1.17307544040.$$

In the same way, we obtain an approximation to the norm of θ at $\nu = \nu_\infty$, which is given by

$$\|\theta(\nu_\infty)\|_\infty = 0.4362479.$$

Having established this pattern in the bifurcation structure, we conjecture that *there are no secondary bifurcation points on any primary branch with* $\|\theta\|_\infty < 0.4362479$.

5.5. Extension to nonperiodic problems. The procedure outlined in this section based on $O(2)$-equivariance can be applied to nonperiodic problems in certain cases. As an example, consider a second-order, ordinary differential equation of the form

$$\begin{aligned} &g(x, \lambda) \equiv x'' + f(x, x', \lambda) = 0, \\ &g : H^2[0, \pi] \times \mathbf{R} \to L^2[0, \pi], \end{aligned} \tag{5.9}$$

together with the homogeneous Neumann boundary conditions

$$x'(0) = x'(\pi) = 0. \tag{5.10}$$

We can define a corresponding periodic problem by $g(x, \lambda) = 0$, $g : H^2[-\pi, \pi] \times \mathbf{R} \to L^2[-\pi, \pi]$, together with 2π-periodic boundary conditions. The periodic problem is equivariant with respect to the translations

$$R_\alpha x(s) = x(s + \alpha), \qquad \alpha \in \mathbf{R},$$

and we assume that it is also equivariant with respect to the reflection

$$S_1 x(s) = x(-s).$$

TABLE 2
Bifurcation points of mode 1 *on higher branches.*

Branch	Mode	$\|\theta\|_\infty$	ν
20	1	0.4371592	1.17355440666
50	1	0.4366304	1.17327590512
100	1	0.4364422	1.17317717624
250	1	0.4363263	1.17311646942
500	1	0.4362871	1.17309598530
1000	1	0.4362675	1.17308571285

Thus the periodic problem is $O(2)$-equivariant. However, the only group action that respects the Neumann boundary conditions and leaves the interval $[0, \pi]$ invariant is $S_1 R_\pi$, the reflection about the midpoint of the interval.

Now any solution of the Neumann problem can be extended onto the interval $[-\pi, 0]$ using the reflection operator S_1. This extended function is C^1 at $s=0$ and it is also in $H^2[-\pi, \pi]$. Since g is equivariant with respect to S_1, the extended function satisfies (5.9) on the interval $[-\pi, \pi]$. Similarly, this function can be extended to a 2π-periodic function which satisfies (5.9) on the whole of the real line using the translation operators $R_{2\pi n}$, $n \in \mathbf{Z}$. Thus every solution of the Neumann problem can be extended to a solution of the periodic problem. Now the S_1-symmetric solutions of the periodic problem are precisely those which satisfy the Neumann boundary conditions (since 2π-periodic even functions are also even about $s=\pi$). Thus in order to find solutions of the Neumann problem, we can use the procedure described in this section to find S_1-symmetric solutions of the corresponding periodic problem. This technique has been employed previously by Fujii, Mimura, and Nishiura (1982) and by Armbruster and Dangelmayr (1987).

Similarly, if the boundary conditions associated with (5.9) are the homogeneous Dirichlet conditions

$$x(0) = x(\pi) = 0, \tag{5.11}$$

and g is equivariant with respect to R_α, $\alpha \in \mathbf{R}$ and the odd reflection S_2 defined by

$$S_2 x(s) = -x(-s),$$

then any solution of (5.9) which satisfies the boundary conditions (5.11) can be extended onto the interval $[-\pi, 0]$ using the reflection operator S_2. This extended function is C^1 at $s=0$, is in $H^2[-\pi, \pi]$, and satisfies (5.9) on the interval $[-\pi, \pi]$. As before, this function can be extended periodically over the real line. In this case, the S_2-symmetric solutions of the periodic problem are those which satisfy the boundary conditions (5.11). Thus we can find solutions of the Dirichlet problem by using the procedure described in this section to find S_2-symmetric solutions of the corresponding $O(2)$-equivariant periodic problem.

Many equations of the form (5.9) are equivariant with respect to the group generated by R_α, S_1, and S_2, which we will call $O^2(2)$. In this case, branches that bifurcate from the $O^2(2)$-symmetric solution (which is often the trivial solution) have isotropy subgroup generated either by $R_{2\pi/n}$, S_1, and $S_2 R_{\pi/n}$, in order to satisfy the Neumann boundary conditions (5.10), or by $R_{2\pi/n}$, S_2, and $S_1 R_{\pi/n}$ in order to satisfy the Dirichlet boundary conditions (5.11). These two classes of solution are conjugate solutions of the 2π-periodic problem and are related by the shift operator $R_{\pi/2n}$. In both cases, the group is the dihedral group D_{2n} generated by the "rotation" $S_1 S_2 R_{\pi/n}$ and the reflection either S_1 or S_2 (since $(S_1 S_2 R_{\pi/n})^2 = R_{2\pi/n}$). The analysis of secondary bifurcation is then very similar to that of § 5.2 but is applied to the group D_{2n}.

We now consider the case where (5.9) is defined on the interval $[0, \pi/2]$ and the associated boundary conditions are the mixed conditions

$$x(0) = x'(\pi/2) = 0. \tag{5.12}$$

If g is equivariant with respect to $O^2(2)$ generated by R_α, S_1, and S_2, then any solution of (5.9) that satisfies the boundary conditions (5.12) can be extended onto the interval $[\pi/2, \pi]$ using the reflection operator $S_1 R_\pi$, and this function can then be extended onto the interval $[-\pi, 0]$ using the reflection operator S_2. This extended function is in $H^2[-\pi, \pi]$, satisfies (5.9) on the interval $[-\pi, \pi]$, and can be extended

periodically over the real line as before. The solutions of the $O^2(2)$-equivariant, 2π-periodic problem which satisfy the boundary conditions (5.12) are those which are symmetric relative to S_2 and S_1R_π. Such solutions must have period $2\pi/n$ for some *odd* integer n.

In all of these cases, we have been able to extend the group of symmetries under consideration from the discrete group Z_2 or the trivial group to the continuous group $O(2)$ or $O^2(2)$). Thus it is possible that a scaling law could exist for the problem as described in § 4.

Finally, we consider the situation where the boundary conditions and the group reflection do not "match" as they do in the above examples. For the purposes of illustration, we will consider the case where g is equivariant with respect to R_α and S_1 only and we have the Dirichlet boundary conditions (5.11). If a solution of (5.9) that satisfies the boundary conditions (5.11) is extended onto $[-\pi, 0]$ using the reflection S_1, the resulting function is only C^0 at $s=0$ and so cannot be in $H^2[-\pi, \pi]$. Thus the procedure of selecting solutions of the 2π-periodic problem that have certain symmetries breaks down in this case. Hence we must consider only the group actions that respect the boundary conditions. This leaves the group Z_2 generated by the reflection S_1R_π about the midpoint of the interval. Bifurcation could then occur by breaking the reflectional symmetry, resulting in a symmetric pitchfork bifurcation. However, generically, secondary bifurcation will not occur since all the symmetry in the problem has been broken. Alternatively, if (5.9) has a trivial solution for all λ, then bifurcation from the trivial solution might occur without breaking the reflectional symmetry, and generically this would be a transcritical bifurcation. On such a primary branch, secondary bifurcation might occur by breaking the reflectional symmetry. Clearly, a scaling law of the type described in § 4 cannot hold in this case since the group Z_2 is discrete.

Thus we conclude that if g is just $O(2)$-equivariant, then the choice of boundary conditions makes a fundamental difference to the structure of the solution set of (5.9). All these extensions can also be applied to elliptic partial differential equations in rectangular domains of higher dimension.

Acknowledgments. I would like to acknowledge many helpful discussions with Professor J. F. Toland throughout the course of this work.

UNIFORM SIMPLIFICATION AT A TRANSITION POINT AND THE PROBLEM OF RESONANCE*

SHIGEMI OHKOHCHI†

This article is dedicated to Professor Tosihusa Kimura on the occasion of his 60th birthday.

Abstract. The sufficiency of the Matkowsky condition concerning the differential equation $\varepsilon y''+f(x,\varepsilon)y'+g(x,\varepsilon)y=0$ is considered under the assumption that $f(0,\varepsilon)=f'(0,\varepsilon)=\cdots=f^{(m-1)}(0,\varepsilon)=0$ and $f^{(m)}(0,\varepsilon)\neq 0$. It is proved that the Matkowsky condition implies resonance in the sense of N. Kopell. Y. Sibuya has proved such a problem if $f(0,\varepsilon)=0$ and $f'(0,\varepsilon)\neq 0$ $[m=1]$.

Key words. ordinary differential equation, turning point, singular perturbation

AMS(MOS) subject classification. 34E20

1. Introduction.

In this paper we consider a differential equation

$$\varepsilon\frac{d^2v}{dx^2}+F(x,\varepsilon)\frac{dv}{dx}+G(x,\varepsilon)v=0, \tag{1.1}$$

where F and G are holomorphic in two complex variables x and ε in a domain

$$x\in D_0,\ |\varepsilon|<\rho_0, \tag{1.2}$$

where D_0 is a domain in the x-plane and ρ_0 is a positive number. We assume that D_0 contains a real interval

$$I_0=\{x;\ -a\leqq \operatorname{Re} x\leqq b,\ \operatorname{Im} x=0\}, \tag{1.3}$$

where a and b are positive numbers. We also assume that

$$F(x,0)=-2x^m, \tag{1.4}$$

where m is a positive integer.

We say that the differential equation (1.1) satisfies the *Matkowsky condition on* I_0, if there exists a nontrivial formal power series solution of (1.1),

$$v(x,\varepsilon)=\sum_{n=0}^{\infty}v_n(x)\varepsilon^n, \tag{1.5}$$

such that all the $v_n(x)$ are bounded on the real interval I_0. We also say that the differential equation (1.1) exhibits *resonance in the sense of N. Kopell on* I_0, if there exists a solution $v(x,\varepsilon)$ that converges uniformly on I_0 as $\varepsilon\to+0$ to a nontrivial solution of the reduced equation

$$F(x,0)\frac{dv}{dx}+G(x,0)v=0. \tag{1.6}$$

We will prove the following main theorem.

THEOREM 1.1. *The Matkowsky condition implies resonance in the sense of N. Kopell.*

Y. Sibuya [9] has proved that the Matkowsky condition implies resonance for the case in which

$$F(x,0)=-2x, \tag{1.4}_{m=1}$$

* Received by the editors August 31, 1987; accepted for publication (in revised form) January 12, 1990.
† Faculty of Engineering, Oita University, Oita 870-11, Japan.

and D_0 is a disk with the center at $x=0$, i.e.,

$$D_0=\{x;\,|x|<r_0\} \quad \text{for some } r_0>0, \tag{1.7}$$

by using the properties of Whittaker's parabolic cylinder functions and Hermite polynomials. Furthermore, in that proof, Theorem 1.2 below, and a theorem concerning uniform simplification [8], play an important part.

THEOREM 1.2 (Y. Sibuya [9]). *Let*

$$S_j=\{\varepsilon;\,a_j<\arg\varepsilon<b_j,\,0<|\varepsilon|<\rho\},\qquad j=1,2,\cdots,\nu \tag{1.8}$$

be sectors in the complex ε-plane, where ρ is a positive number and the a's and the b's are real numbers. Let $\delta_1(\varepsilon),\cdots,\delta_\nu(\varepsilon)$ be functions of ε. Assume that

(i) $S_1\cup S_2\cup\cdots\cup S_\nu=\{\varepsilon;\,0<|\varepsilon|<\rho\}$.

(ii) *$\delta_j(\varepsilon)$ is holomorphic in S_j.*

(iii) *$\delta_j(\varepsilon)$ is asymptotically zero as $\varepsilon\to 0$ in S_j, i.e.,*

$$|\delta_j(\varepsilon)|\leqq K_N|\varepsilon|^N,\qquad N=0,1,\cdots \quad \text{in } S_j$$

for some positive numbers K_N.

(iv) *If $S_j\cap S_k\neq\varnothing$, we have*

$$|\delta_j(\varepsilon)-\delta_k(\varepsilon)|\leqq c_0\exp\left[-c_1/|\varepsilon|^\lambda\right] \quad \text{in } S_j\cap S_k \tag{1.9}$$

for some positive numbers c_0, c_1, and λ.

Then there exists a positive number H such that

$$|\delta_j(\varepsilon)|\leqq H\exp\left[-c_1/|\varepsilon|^\lambda\right] \quad \text{in } S_j \quad j=1,2,\cdots,\nu. \tag{1.10}$$

Lin [4] has shown that the condition that D_0 is a disk is not necessary, so that the sufficiency of the Matkowsky condition is proved for the general case for $m=1$, by the use of Lin's cohomological theorem, as follows.

THEOREM 1.3 (C. H. Lin [5]). *Let $S_j=\{\varepsilon;\,\alpha_j<\arg\varepsilon<\beta_j,\,0<|\varepsilon|<\rho\}$, $j=1,\cdots,\nu$, be sectors in the right half complex ε-plane, where $\rho>0$:*

$$-\tfrac{1}{2}\pi<-\omega_0<\alpha_1<\alpha_2<\beta_1<\alpha_3<\beta_2<\alpha_4<\beta_3<\cdots<\alpha_\nu<\beta_{\nu-1}<\beta_\nu=\omega_0<\tfrac{1}{2}\pi.$$

Let $\phi^1(\varepsilon),\phi^2(\varepsilon),\cdots,\phi^\nu(\varepsilon)$ be functions of ε. Assume that

(i) *$\phi^j(\varepsilon)$ is holomorphic in S_j and continuous on*

$$S_j^*=\{\varepsilon;\,\alpha_j\leqq\arg\varepsilon\leqq\beta_j,\,0<|\varepsilon|\leqq\rho\}.$$

(ii) *$\phi^j(\varepsilon)$ is asymptotically zero as ε tends to zero in S_j.*

(iii)
$$|\phi^1(\varepsilon)|\leqq H_1\exp\{-\mu\cdot\mathrm{Re}\,[1/|\varepsilon|]\}$$

on the line segment $\arg\varepsilon=-\omega_0$, $0<|\varepsilon|<\rho$;

$$|\phi^\nu(\varepsilon)|\leqq H_1\exp\{-\mu\cdot\mathrm{Re}\,[1/|\varepsilon|]\}$$

on the line segment $\arg\varepsilon=-\omega_0$, $0<|\varepsilon|<\rho$, *for some positive numbers μ and H_1.*

(iv)
$$|\phi^j(\varepsilon)-\phi^{j+1}(\varepsilon)|\leqq H_1\exp\{-\mu\cdot\mathrm{Re}\,[1/|\varepsilon|]\} \quad \text{in } S_j\cap S_{j+1} \quad (j=1,2,\cdots,\nu).$$

Then there exists a positive number H such that

$$|\phi^j(\varepsilon)|\leqq H\cdot\exp\{-\mu\cdot\mathrm{Re}\,[1/|\varepsilon|]\} \quad \text{in } S_j \quad (j=1,2,\cdots,\nu).$$

Matkowsky [6] has demonstrated that the resonance phenomenon occurs for functions $F(x, \varepsilon)$ more general than those having a single simple zero in the interval by the following example:

$$\varepsilon t'' - x^3(x^2-1)(x-2)^2 y' = 0, \qquad -a \leqq x \leqq b, \quad b > 1, \tag{1.11}$$

$$y(-2) = \alpha, \quad y(b) = \beta, \quad n \neq 2. \tag{1.12}$$

In this paper we will prove the theorem concerning uniform simplification in a full neighborhood of a higher-order transition point and treat the problem of resonance for the case in which $F(x, \varepsilon)(F(x, 0) = -2x''')$ has a higher-order zero in the interval I_0 and D_0 is a domain (*not disk*) in the x-plane containing the real interval $[-a, b]$. In this analysis we will use Theorems 1.2 and 1.3.

2. Reduction to a standard form. Let ρ_0 be a positive number, and let D be a domain in the complex ξ-plane which contains a real interval

$$I = \{\xi: -\alpha \leqq \operatorname{Re} \xi \leqq \beta, \operatorname{Im} \xi = 0\}, \tag{2.1}$$

where α and β are positive numbers.

We will consider a linear differential equation

$$\varepsilon \frac{d^2 v}{d\xi^2} + f(x, \varepsilon) \frac{dv}{d\xi} + g(x, \varepsilon) v = 0, \tag{2.2}$$

where f and g are holomorphic in two variables ξ and ξ in the domain

$$\xi \in D, \qquad |\varepsilon| < \rho_0. \tag{2.3}$$

Set

$$f_0(\xi) = f(\xi, 0). \tag{2.4}$$

We assume that

$$f_0(0) = f_0'(0) = \cdots = f_0^{(m-1)}(0) = 0, \qquad f_0^{(m)}(0) \neq 0, \tag{2.5}$$

$$\xi^m f_0(\xi) < 0 \quad \text{for } \xi \in I \quad \text{if } \xi \neq 0. \tag{2.6}$$

Under this situation, we can write f_0 as

$$f_0(\xi) = \xi^m h(\xi), \tag{2.7}$$

where $h(\xi)$ is holomorphic in the domain D and

$$h(\xi) < 0 \quad \text{for } \xi \in I. \tag{2.8}$$

Let us change the independent variable by

$$x = \phi(\xi) = \left[-\int_0^{\xi} \frac{m+1}{2} f_0(t)\, dt \right]^{1/(m+1)}. \tag{2.9}$$

Then (2.2) becomes

$$\varepsilon \frac{d^2 v}{dx^2} + F(x, \varepsilon) \frac{dv}{dx} + G(x, \varepsilon) v = 0, \tag{2.10}$$

where

$$\begin{aligned} F(\phi, \varepsilon) &= \{\phi'(\xi)\}^{-2}[\phi'(\xi) f(\xi, \varepsilon) + \varepsilon \phi''(\xi)], \\ G(\phi, \varepsilon) &= \{\phi'(\xi)\}^{-2} g(\xi, \varepsilon). \end{aligned} \tag{2.11}$$

Since

$$(m+1)\{\phi(\xi)\}^m\phi'(\xi) = -\frac{m+1}{2}\cdot f_0(\xi),$$

we have

$$F(x,\varepsilon) = -2x^m + \varepsilon k(x,\varepsilon), \tag{2.12}$$

and $k(x,\varepsilon)$ and $G(x,\varepsilon)$ are holomorphic in the domain

$$x \in D_0, \qquad |\varepsilon| < \rho_0, \tag{2.13}$$

where D_0 is a domain in the x-plane which contains the real interval

$$I_0 = \{x: -a \leqq \operatorname{Re} x \leqq b, \operatorname{Im} x = 0\}, \tag{2.14}$$

where

$$a = \left[-\int_0^{-\alpha} f_0(t)\,dt\right]^{1/(m+1)}, \qquad b = \left[-\int_0^{\beta} f_0(t)\,dt\right]^{1/(m+1)}.$$

Let r_2 be a sufficiently small positive number and r_1 be a positive number with $r_1 > b, a$, respectively. Set

$$D_1 = \{x = x_1 + ix_2: -r_2 < x_2 < r_2, -(r_1^2 - x_2^2)^{1/2} < x_1 < (r_1^2 - x_2^2)^{1/2}\}. \tag{2.15}$$

Then D_1 is a simply connected domain in the complex x-plane which contains the real interval I_0. We can choose r_1 and r_2 so that $D_1 \subset D_0$.

Another transformation,

$$v = w\cdot\exp\left[-\frac{1}{2\varepsilon}\int_0^x F(t,\varepsilon)\,dt\right], \tag{2.16}$$

takes (2.10) to

$$\varepsilon^2\frac{d^2w}{dx^2} - \left[\frac{1}{4}F(x,\varepsilon)^2 + \varepsilon\left[\frac{1}{2}\frac{\partial F}{\partial x}(x,\varepsilon) - G(x,\varepsilon)\right]\right]w = 0. \tag{2.17}$$

Note that

$$\frac{1}{4}F^2 + \varepsilon\left[\frac{1}{2}\frac{\partial F}{\partial x} - G\right] = x^{2m} + \varepsilon R(x,\varepsilon), \tag{2.18}$$

where $R(x,\varepsilon)$ is holomorphic in a domain (2.13).

3. Formal simplification and outer expansions. We consider the system

$$\varepsilon\frac{d}{dx}\begin{pmatrix} w \\ \varepsilon\dfrac{dw}{dx}\end{pmatrix} = \begin{pmatrix} 0 & 1 \\ x^{2m}+\varepsilon R(x,\varepsilon) & 0\end{pmatrix}\begin{pmatrix} w \\ \varepsilon\dfrac{dw}{dx}\end{pmatrix}, \tag{3.1}$$

which is equivalent to the single linear differential equation (2.17). It is well known among experts that there exists a two-by-two matrix

$$T(x,\varepsilon) = \sum_{h=0}^{\infty} T_h(x)\varepsilon^h \tag{3.2}$$

whose components are formal power series in ε such that

(i) The components of the two-by-two matrices $T_h(x)$ are holomorphic in the domain D_0.

(ii) $\det T_0(x) \equiv 1$ in the domain D_0.

(iii) The formal transformation

$$\begin{pmatrix} w \\ \varepsilon \dfrac{dw}{dx} \end{pmatrix} = T(x, \varepsilon) \begin{pmatrix} u \\ \varepsilon \dfrac{du}{dx} \end{pmatrix}, \tag{3.3}$$

reduces (3.1) to

$$\varepsilon \frac{d}{dx} \begin{pmatrix} u \\ \varepsilon \dfrac{du}{dx} \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ x^{2m} + \varepsilon \sum_{r=0}^{2m-1} a_r(\varepsilon) x^r & 0 \end{pmatrix} \begin{pmatrix} u \\ \varepsilon \dfrac{du}{dz} \end{pmatrix} \tag{3.4}$$

and each $a_r(\varepsilon)$ is a formal power series in ε with constant coefficients. Furthermore, if we put

$$a_r(x) = \sum_{h=0}^{\infty} a_{r,h} \varepsilon^h, \tag{3.5}$$

we have

$$R(x, 0) - \sum_{r=0}^{2m-2} a_{r,0} x^r = O(x^{2m-1}) \tag{3.6}$$

in the neighborhood of $x = 0$ [1], [2].

Note that (3.4) is equivalent to the single linear differential equation

$$\varepsilon^2 \frac{d^2u}{dx^2} - \left[x^{2m} + \varepsilon \sum_{r=0}^{2m-2} a_r(\varepsilon) x^r \right] u = 0. \tag{3.7}$$

A formal power series in ε:

$$v(x, \varepsilon) = \sum_{n=0}^{\infty} v_n(x) \varepsilon^n \tag{3.8}$$

is called an *outer expansion*, associated with the differential equation (2.10), if (3.8) formally satisfies (2.10). The power series (3.8) is an outer expansion if and only if

$$-2x^m \frac{dv_0(x)}{dx} + G_0(x) v_0(x) = 0, \tag{3.9}$$

$$-2x^m \frac{dv_k(x)}{dx} + G_0(x) v_k(x) = L_k(x) - \frac{d^2 v_{k-1}(x)}{dx^2}, \qquad k = 1, 2, \cdots, \tag{3.10}$$

where $G_0(x) = G(x, 0)$ and $L_k(x)$ is linearly homogeneous in $v_0, v_1, \cdots, v_{k-1}$ and $(dv_0/dx), (dv_1/dx), \cdots, (dv_{k-1}/dx)$ with coefficients holomorphic in D_0.

DEFINITION 3.1. The differential equation (2.10) is said to satisfy the *Matkowsky condition* if there exists a nontrivial outer expansion (3.8) such that all the $v_k(x)$ are bounded on the interval I_0.

LEMMA 3.2. *The differential equation* (2.10) *satisfies the Matkowsky condition. Then the differential equation* (3.7) *satisfies*

(i) $a_{m-1,0} + m$ *is a nonpositive even integer*;

(ii) $a_{r,0} = 0$ $(r = 0, 1, \cdots, m-2)$.

Proof. The transformation

$$u = y \cdot \exp\left[-x^{m+1}/(m+1)\varepsilon\right] \tag{3.11}$$

changes (3.7) into

$$\varepsilon y''-2x^m y'-\left[\sum_{r=0}^{2m-2}\left[\sum_{j=0}^{\infty} a_{r,j}\varepsilon^j\right]x^r+mx^{m-1}\right]y=0. \tag{3.12}$$

If the differential equation (2.10) satisfies the Matkowsky condition, then, by manipulating the transformations (2.16) and (3.3) together with (3.11), we can show that the differential equation (3.12) satisfies the same condition. It follows from (3.12) that

$$2x^m v_0'(x)+\left[\sum_{r=0}^{2m-2} a_{r,0}x^r+mx^{m-1}\right]v_0(x)=0; \tag{3.13}$$

that is,

$$v_0(x)=c\cdot x^{-1/2a_{m-1,0}-m/2}\exp\left[-\sum_{r=0,r\neq m-1}^{2m-2}\frac{1}{2(r+1-m)}a_{r,0}x^{r+1-m}\right], \tag{3.14}$$

where c is a constant.

Hence, if $v_0(x)$ is to be holomorphic at $x=0$, it must hold that

(i) $-\frac{1}{2}(a_{m-1,0}+m)$ is a nonnegative integer;

(ii) $a_{r,0}=0$ $(r=0,1,\cdots,m-2)$.

This completes the proof of Lemma 3.2.

4. Uniform simplification. We will assume that the transformed differential equation (3.7) satisfies conditions (i) and (ii) of Lemma 3.2. Then (3.7) is called fully reducible by stretching and shearing (Wasow [10]). Let us change the independent variable by the stretching transformation

$$x=\mu^{-2}t, \qquad \varepsilon^{-1}=\mu^{2m+2}. \tag{4.1}$$

Then (3.7) becomes

$$\frac{d^2u}{dt^2}-\left[t^{2m}+\sum_{r=0}^{2m-2}\mu^{2m-2r-2}\cdot a_r(\varepsilon)t^r\right]u=0, \tag{4.2}$$

where

$$\mu^{2m-2r-2}\cdot a_r(\varepsilon)=\begin{cases}o(1), & r\neq m-1,\\ a_{m-1,0}+o(1), & r=m-1.\end{cases} \tag{4.3}$$

Let $b_1, b_2, \cdots, b_{2m}$ be complex parameters and b be a *real* constant, and consider the differential equation of the form

$$y''-[z^{2m}+b_1z^{2m-1}+\cdots+[b+b_{m+1}]z^{m-1}+\cdots+b_{2m}]y=0. \tag{4.4}$$

The differential equation (4.4) has a solution

$$y(z, b, b_j)=y(z, b; b_1, \cdots, b_{m+1}, \cdots, b_{2m}),$$

which is an entire function of $z, b, b_1, \cdots, b_{2m}$. Respectively, $y(z, b, b_j)$ and $y'(z, b, b_j)$ admit the asymptotic representations

$$\begin{aligned} y(z, b, b_j)&=z^{-\alpha_{m+1}(b,b_j)-m/2}\exp\left[\sum_{0\leqq k<m+1}\frac{-\alpha_k(b, b_j)}{m+1-k}z^{m+1-k}\right]\\ &\quad\cdot\{1+O(z^{-1/2})\},\\ y'(z, b, b_j)&=z^{-\alpha_{m+1}(b,b_j)+m/2}\exp\left[\sum_{0\leqq k<m+1}\frac{-\alpha_k(b, b_j)}{m+1-k}z^{m+1-k}\right]\\ &\quad\cdot\{-1+O(z^{-1/2})\}\end{aligned} \tag{4.5}$$

uniformly on each compact set in the $(b_1, \cdots, b_{2m})$-space, as z tend to infinity in any closed subsector of the open sector $|\arg z| < 3\pi/(2m+2)$. Here

$$\left[1+\sum_{j=1, j\neq m+1}^{2m} b_j \cdot z^{-j} + (b+b_{m+1})z^{-m-1}\right]^{1/2} = 1+\sum_{h=1}^{\infty} \alpha_h(b, b_j) z^{-h}. \tag{4.6}$$

The solution $y(z, b, b_j)$ is subdominant on $|\arg z| < \pi/(2m+2)$ and therefore it is uniquely determined. Furthermore, if we put

$$y(z, b, b_j) = \eta(z, b) + \sum_{j=1}^{2m} \eta_j(z, b) b_j + O(|b_1|^2 + \cdots + |b_{2m}|^2) \tag{4.7}$$

in the neighborhood of $(b_1, \cdots, b_{m+1}, \cdots, b_{2m}) = (0, \cdots, 0)$, we can obtain the following properties of $\eta(z, b)$.

LEMMA 4.1 (Ohkohchi [7]). *If z is positive real and the constant b is real, then $\eta(z, b)$ is a real-valued function. Furthermore, $\eta(z, b)$ satisfies the following conditions*:

(i) *$\eta(z, b)$ is an entire function of (z, b).*

(ii) *$\eta(z, b)$ and $\eta'(z, b)$ admit, respectively, the asymptotic representations*

$$\eta(z, b) = z^{-b/2-m/2} \exp\left[-\frac{1}{m+1} z^{m+1}\right][1+O(z^{-1/2})], \tag{4.8}$$

$$\eta'(z, b) = z^{-b/2+m/2} \exp\left[-\frac{1}{m+1} z^{m+1}\right][-1+O(z^{-1/2})] \tag{4.9}$$

uniformly on each compact set in the b-space, as z tends to infinity in any closed subsector of the open sector $|\arg z| < 3\pi/(2m+2)$.

(iii)

$$\eta(0, b) = 2^{(m+b)/(2m+2)}(m+1)^{-(m+b)/(2m+2)} \frac{\Gamma(1/(m+1))}{\Gamma((b+m+2)/(2m+2))}, \tag{4.10}$$

$$\eta'(0, b) = 2^{(b+m+2)/(2m+2)}(m+1)^{-1-(b+m)/(2m+2)} \frac{\Gamma(-1/(m+1))}{\Gamma((b+m)/(2m+2))}. \tag{4.11}$$

If we put

$$y_k(z, b, b_j) = y(\omega^{-k} z, (-1)^k b, G^k(b_j)), \tag{4.12}$$

where

$$\omega = \exp\left[\frac{\pi i}{m+1}\right] \quad \text{and} \quad G^k(b_j) = (\omega^{-k} b_1, \cdots, \omega^{-2mk} b_{2m}),$$

then, for each integer k, $y_k(z, b, b_j)$ is a solution of the differential equation (4.4) (see Sibuya [8]). Note that

$$y_k(z, b, b_j) = y_h(z, b, b_j) \quad \text{if } k \equiv h \pmod{2m+2}.$$

It holds from (4.5) that

$$y_k(z, b, b_j) = (\omega^{-k} z)^{(-1)^{k+1}\alpha_{m+1}(b, b_j)-(m/2)} \cdot [1+O(z^{-1/2})] \cdot \exp\left[(-1)^{k+1} \sum_{0 \leqq p < m+1} \frac{\alpha_p(b, b_j)}{m+1-p} z^{m+1-p}\right],$$

$$y_k'(z, b, b_j) = \omega^{-k\{(-1)^{k+1}\alpha_{m+1}(b, b_j)-(m/2)\}} z^{(m/2)+(-1)^{k+1}\alpha_{m+1}(b, b_j)} \cdot \exp\left[(-1)^{k+1} \sum_{0 \leqq p < m+1} \frac{\alpha_p(b, b_j)}{m+1-p} z^{m+1-p}\right]\{(-1)^{k+1} + O(z^{-1/2})\}.$$

Here we used the identities

$$\alpha_h((-1)^k b, G^k(b_j)) = \omega^{-hk} \cdot \alpha_h(b, b_j) \qquad (h = 1, 2, \cdots).$$

The solution $y_k(z, b, b_j) \to 0$ as $x \to \infty$ in the sector

$$\left| \arg x - \frac{k}{m+1} \pi \right| < \frac{\pi}{2m+2}. \tag{4.13}$$

Therefore, the solution $y_k(z, b, b_j)$ is called a subdominant solution in sector (4.13).

The two solutions $y_{k+1}(z, b, b_j)$ and $y_{k+2}(z, b, b_j)$ of the differential equation (4.4) are linearly independent (see Lemma 4.2 below). Therefore, $y_k(z, b, b_j)$ is a linear combination of $y_{k+1}(z, b, b_j)$ and $y_{k+2}(z, b, b_j)$.

Set

$$y_k(z, b, b_j) = C_k(b, b_j) y_{k+1}(z, b, b_j) + \tilde{C}_k(b, b_j) y_{k+2}(z, b, b_j). \tag{4.14}$$

Relation (4.14) is a connection formula for $y_k(z, b, b_j)$. The coefficients $C_k(b, b_j)$ and $\tilde{C}_k(b, b_j)$ are the Stokes multipliers for $y_k(z, b, b_j)$ with respect to $y_{k+1}(z, b, b_j)$ and $y_{k+2}(z, b, b_j)$. We will study the Stokes multipliers $C_k(b, b_j)$ and $\tilde{C}_k(b, b_j)$ as functions of $b_1, \cdots, b_j, \cdots, b_{2m}$.

Let us put

$$C_0(b, b_j) = C(b, b_j), \qquad \tilde{C}_0(b, b_j) = \tilde{C}(b, b_j), \tag{4.15}$$

$$C_1(b, b_j) = C^*(b, b_j), \qquad \tilde{C}_1(b, b_j) = \tilde{C}^*(b, b_j). \tag{4.16}$$

Then we have

$$y_0(z, b, b_j) = C(b, b_j) y_1(z, b, b_j) + \tilde{C}(b, b_j) y_2(z, b, b_j), \tag{4.17}$$

$$y_1(z, b, b_j) = C^*(b, b_j) y_2(z, b, b_j) + \tilde{C}^*(b, b_j) y_3(z, b, b_j). \tag{4.18}$$

From (4.12), (4.17), and (4.18) we easily derive

$$\begin{aligned} y_{2k}(z, b, b_j) &= C((-1)^{2k} b, G^{2k}(b_j)) y_{2k+1}(z, b, b_j) \\ &\quad + \tilde{C}((-1)^{2k} b, G^{2k}(b_j)) y_{2k+2}(z, b, b_j), \end{aligned} \tag{4.19}$$

$$\begin{aligned} y_{2k+1}(z, b, b_j) &= C^*((-1)^{2k} b, G^{2k}(b_j)) y_{2k+2}(z, b, b_j) \\ &\quad + \tilde{C}^*((-1)^{2k} b, G^{2k}(b_j)) y_{2k+3}(z, b, b_j), \end{aligned} \tag{4.20}$$

$$(k = 0, 1, \cdots, m).$$

From (4.12), (4.19), and (4.20) we obtain

$$\begin{aligned} C_{2k}(b, b_j) &= C((-1)^{2k} b, G^{2k}(b_j)), \\ \tilde{C}_{2k}(b, b_j) &= \tilde{C}((-1)^{2k} b, G^{2k}(b_j)), \\ C_{2k+1}(b, b_j) &= C^*((-1)^{2k} b, G^{2k}(b_j)), \\ \tilde{C}_{2k+1}(b, b_j) &= \tilde{C}^*((-1)^{2k} b, G^{2k}(b_j)), \end{aligned} \tag{4.21}$$

$$(k = 0, 1, 2, \cdots, m).$$

Next, let us put

$$W_{k,h}(b, b_j) = \begin{vmatrix} y_k(z, b, b_j) & y_h(z, b, b_j) \\ y_k'(z, b, b_j) & y_h'(z, b, b_j) \end{vmatrix}. \tag{4.22}$$

The determinant is known as the *Wronskian* of the functions y_k and y_h. It follows from (4.4) that the right-hand member of (4.22) is independent of x. Then we have the following lemmas.

LEMMA 4.2 (Hsieh and Sibuya [3]).

$$W_{k,k+1}(b, b_j) = 2 \cdot \omega^{-\alpha_{m+1}((-1)^k b, G^k(b))+m/2-k}. \tag{4.23}$$

LEMMA 4.3.

$$\left.\frac{\partial \alpha_{m+1}(b, b_j)}{\partial b_j}\right|_{b_2=\cdots=b_{2m}=0} = \begin{cases} 0 & (j \neq m+1), \\ 1/2 & (j = m+1). \end{cases} \tag{4.24}$$

Proof. Differentiating (4.6) with respect to b_j and putting $b_1 = \cdots = b_{2m} = 0$, we derive

$$\frac{1}{2}[1 + b \cdot z^{-m-1}]^{-1/2} \cdot z^{-j} = \sum_{h=1}^{\infty} A_j^h \cdot z^{-h}, \tag{4.25}$$

where

$$A_j^h = \left.\frac{\partial \alpha_h(b)}{\partial b_j}\right|_{b_1=\cdots=b_{2m}=0}.$$

It follows from (4.25) that

$$A_j^1 = \cdots = A_j^{j-1} = 0, \quad A_j^j = \tfrac{1}{2}, \quad A_j^{j+1} = \cdots = A_j^{j+m} = 0.$$

Thus we get (4.24).

Using these results, we can obtain the properties of the Stokes multipliers $C(b, b_j)$, $C^*(b, b_j)$, $\tilde{C}(b, b_j)$, and $\tilde{C}^*(b, b_j)$ as follows.

LEMMA 4.4.

$$C(b, 0) = 0 \qquad \text{for } b + m = -(2m+2)k, -(2m+2)k-2, \quad k = 0, 1, 2, \cdots,$$

$$C^*(b, 0) \neq 0 \qquad \text{for } b + m = -2k, \quad k = 0, 1, 2, \cdots. \tag{4.26}$$

LEMMA 4.5.

$$\tilde{C}(b, b_j) = -\omega^{1-2\cdot\alpha_{m+1}(b,b_j)},$$
$$\tilde{C}^*(b, b_j) = -\omega^{1+2\cdot\alpha_{m+1}(b,b_j)}.$$

LEMMA 4.6.

$$\det \begin{vmatrix} \dfrac{\partial C(b, b_j)}{\partial b_p} & \dfrac{\partial C(b, b_j)}{\partial b_{p+m+1}} \\ \dfrac{\partial C^*(b, b_j)}{\partial b_p} & \dfrac{\partial C^*(b, b_j)}{\partial b_{p+m+1}} \end{vmatrix} \neq 0 \tag{4.27}$$

for

$$b = -m - 2k(m+1), -m-2-2k(m+1) \qquad (k = 0, 1, 2, \cdots),$$
$$(b_2, b_3, \cdots, b_{2m}) = (0, 0, \cdots, 0), \tag{4.28}$$
$$p = 1, 2, \cdots, m-1.$$

LEMMA 4.7.

$$\left.\frac{\partial C(b, b_j)}{\partial b_p}\right|_{\substack{b_1=\cdots=b_{2m}=0, \\ b=-m-2k(m+1),-m-2-2k(m+1)}} \neq 0 \qquad (p \neq m).$$

Using Lemmas 4.5–4.7, we can obtain the following lemma. The proof is similar to that of Sibuya [8, Case iv].

LEMMA 4.8. *There exist two positive numbers* ρ_1 *and* ρ_2, *functions* $\delta_1(\varepsilon)$, $\delta_2(\varepsilon), \cdots, \delta_{2m}(\varepsilon)$, *and a two-by-two matrix* $P(x, \varepsilon)$ *such that*

(i) $\delta_j(\varepsilon)$ $(j=1, 2, \cdots, 2m)$ *are holomorphic in the sector*

$$S=\{\varepsilon; |\arg \varepsilon|<\rho_1, 0<|\varepsilon|<\rho_2\}; \tag{4.29}$$

(ii) $\delta_j(\varepsilon)$ *are asymptotically zero as* $\varepsilon \to 0$ *in the sector* S,

$$|\delta_j(\varepsilon)| \leqq K_N|\varepsilon|^N, \qquad N=0, 1, 2, \cdots \quad \text{in } S \tag{4.30}$$

for some positive numbers K_N.

(iii) *Entries of* $P(x, \varepsilon)$ *and* $P^{-1}(x, \varepsilon)$ *are holomorphic in the domain*

$$x \in D_2=\{x; |x|<r\}, \qquad \varepsilon \in S. \tag{4.31}$$

(iv) $P(x, \varepsilon)$ *admits the formal transformation matrix* $T(x, \varepsilon)$ (3.2) *as an asymptotic expansion as* $\varepsilon \to 0$ *in* S *which is valid uniformly in* D_2.

(v) *The transformation*

$$W=P(x, \varepsilon)V \tag{4.32}$$

takes (3.1) *into*

$$\varepsilon \frac{dV}{dx}=\begin{pmatrix} 0 & 1 \\ x^{2m}+\varepsilon \cdot \sum_{p=1}^{2m}\{a_p(\varepsilon)+\delta_p(\varepsilon)\}x^{2m-p} & 0 \end{pmatrix} \cdot V \tag{4.33}$$

in the domain (4.31).

Using this result and manipulating with rotations of the disk D_2, we can prove the following lemma.

LEMMA 4.9. *There exist sectors*

$$S_j=\{\varepsilon: \alpha_j<\arg \varepsilon<\beta_j, 0<|\varepsilon|<\rho_3\}, \qquad j=1, 2, \cdots, k, \tag{4.34-j}$$

where ρ_3 *is a positive number and the* α*'s and* β*'s are real numbers, functions* $\delta_p^j(\varepsilon)$ $(j=1, 2, \cdots, k; p=1, 2, \cdots, 2m)$, *and two-by-two matrices* $P_1(x, \varepsilon)$, $P_2(x, \varepsilon)$, $\cdots, P_k(x, \varepsilon)$ *such that*

(i) $S_1 \cup S_2 \cup \cdots \cup S_k=\{\varepsilon; 0<|\varepsilon|<\rho_3\}$.

(ii) $\delta_p^j(\varepsilon)$ $(p=1, 2, \cdots, 2m; j=1, 2, \cdots, k)$ *is holomorphic in the sector* S_j.

(iii) $\delta_p^j(\varepsilon)$ $(p=1, 2, \cdots, 2m; j=1, 2, \cdots, k)$ *is asymptotically zero as* $\varepsilon \to 0$ *in the sector* S_j.

(iv) *Entries of* $P_j(x, \varepsilon)$ *and* $P_j^{-1}(x, \varepsilon)$ *are holomorphic in the domain*

$$x \in D_2, \qquad \varepsilon \in S_j. \tag{4.35-j}$$

(v) $P_j(x, \varepsilon)$ *admits the formal transformation matrix* $T(x, \varepsilon)$ *as an asymptotic expansion as* $\varepsilon \to 0$ *in the sector* S_j *which is valid uniformly in the domain* D_2.

(vi) *The transformation*

$$W=P_j(x, \varepsilon)V_j \tag{4.36}$$

takes (3.1) *into*

$$\varepsilon \frac{dV_j}{dx}=\begin{pmatrix} 0 & 1 \\ x^{2m}+\varepsilon \cdot \sum_{p=1}^{2m}[a_p(\varepsilon)+\delta_p^j(\varepsilon)]x^{2m-p} & 0 \end{pmatrix} V_j \tag{4.37-j}$$

in the domain (4.35-j).

Remark 4.10. In Lemmas 4.8 and 4.9,

$$\delta_m(\varepsilon), \qquad \delta_m^j(\varepsilon)=0.$$

5. An estimate for $\delta(\varepsilon)$. In the previous section we have obtained that $\delta_p^j(\varepsilon)$ is asymptotically zero as $\varepsilon \to 0$ in the sector S_j. In this section we will derive an estimate

$$|\delta_p^j(\varepsilon)| \leqq H_{j,p} \exp\left[-\frac{r^{m+1}}{|\varepsilon|}\right] \quad \text{for } \varepsilon \in S_j \quad \text{and} \quad p = 1, 2, \cdots, 2m, \tag{5.1}$$

in the domain D_2(disk), where $H_{j,p}$ is a positive number. To do this we need the following theorem, which is easily obtained from Theorem 1.2.

THEOREM 5.1. *Let*

$$S_j = \{\varepsilon : \alpha_j < \arg \varepsilon < \beta_j, 0 < |\varepsilon| < \rho_3\}, \qquad j = 1, 2, \cdots, k, \tag{5.2}$$

be sectors in the complex ε-plane, where ρ_3 is a positive number and the α's and β's are real numbers. Let $\delta_p^j(\varepsilon)$ $(j = 1, 2, \cdots, k;\ p = 1, 2, \cdots, 2m)$ be functions of ε. Assume that

(i) $S_1 \cup S_2 \cup \cdots \cup S_k = \{\varepsilon : 0 < |\varepsilon| < \rho_3\}$;

(ii) *$\delta_p^j(\varepsilon)$ are holomorphic in the sector S_j.*

(iii) *$\delta_p^j(\varepsilon)$ are asymptotically zero as $\varepsilon \to 0$ in the sector S_j;*

$$|\delta_p^j(\varepsilon)| \leqq K_{N,p} |\varepsilon|^N, \quad N = 0, 1, \cdots \quad \text{in } S_j \tag{5.3}$$

for some positive numbers $K_{N,p}$;

(iv) *If $S_j \cap S_h \neq \varnothing$, we have*

$$|\delta_p^j(\varepsilon) - \delta_p^h(\varepsilon)| \leqq c_0 \exp\left[-c_1/|\varepsilon|^\lambda\right] \quad \text{in } S_j \cap S_h \tag{5.4}$$

for some positive numbers c_0, c_1, and λ. Then, there exist positive numbers H_p $(p = 1, 2, \cdots, 2m)$ such that

$$|\delta_p^j(\varepsilon)| \leqq H_p \cdot \exp\left[-c_1/|\varepsilon|^\lambda\right] \quad \text{in } S_j, \qquad j = 1, 2, \cdots, k. \tag{5.5}$$

To derive (5.1), we have only to prove that, if $S_j \cap S_l \neq \varnothing$, we have for each p $(p = 1, 2, \cdots, 2m)$

$$|\delta_p^j(\varepsilon) - \delta_p^l(\varepsilon)| \leqq M_{j,l} \cdot \exp\left[-r^{m+1}/|\varepsilon|\right] \quad \text{for } \varepsilon \in S_j \cap S_l, \tag{5.6}$$

where $M_{j,l}$ is a positive number. To derive an estimate (5.6), we need some preparations.

Roughly speaking, we shall derive in this section that the difference between two Stokes multipliers of the differential equations (4.37-j) and (4.37-l) is exponentially small. Then, using the implicit function theorem, we show that the difference $\delta^j(\varepsilon) - \delta^l(\varepsilon)$ is exponentially small.

Let us consider the differential equation (4.4). This equation admits solutions $y_k(z, b, b_j)$ $(k = 0, 1, \cdots, 2m+1)$. Set

$$\Psi_k(z, b, b_j) = \begin{pmatrix} y_k(z, b, b_j) & y_{k+1}(z, b, b_j) \\ y_k'(z, b, b_j) & y_{k+1}'(z, b, b_j) \end{pmatrix}, \tag{5.7-k}$$

where $'$ denotes $\partial/\partial z$. These matrices (5.7-k) are fundamental matrix solutions of (4.4) and

$$\Psi_k(z, b, b_j) = \Psi_h(z, b, b_j) \quad \text{if } k \equiv h \bmod 2m+2.$$

Set

$$\Gamma_k(b, b_j) = \begin{pmatrix} C_k(b, b_j) & 1 \\ \tilde{C}_k(b, b_j) & 0 \end{pmatrix} \qquad (k = 0, 1, \cdots, 2m+1). \tag{5.8}$$

Then, we have from (4.14) that

$$\Psi_k(z, b, b_j) = \Psi_{k+1}(z, b, b_j)\Gamma_k(b, b_j). \tag{5.9}$$

Fix l and j so that $S_l \cap S_j \neq \emptyset$. Choose a branch of $\varepsilon^{1/(m+1)}$ in the sector $S_l \cap S_j$. Set

$$\Lambda(\varepsilon) = \begin{pmatrix} 1 & 0 \\ 0 & \varepsilon^{1/(m+1)} \end{pmatrix}. \tag{5.10}$$

Now, we consider (4.37-j) and (4.37-l). If we put

$$\begin{aligned} \Phi_{l,h}(x, \varepsilon) &= \Lambda(\varepsilon)\Psi_h(x\varepsilon^{-1/(m+1)}, a, a_1 + \delta_1^l, \cdots, a_{2m} + \delta_{2m}^l) \\ &= \Lambda(\varepsilon)\Psi_h(x\varepsilon^{-1/(m+1)}, a, a_p + \delta_p^l), \qquad \text{(5.11-}h\text{)} \\ \Phi_{j,h}(x, \varepsilon) &= \Lambda(\varepsilon)\Psi_h(x\varepsilon^{-1/(m+1)}, a, a_p + \delta_p^j) \qquad (h = 0, 1, 2, \cdots, 2m+1), \end{aligned}$$

then $\Phi_{l,h}(x, \varepsilon)$ and $\Phi_{j,h}(x, \varepsilon)$ are fundamental matrix solutions of (4.37-l) and (4.37-j), respectively. Furthermore we have

$$\Phi_{l,h}(x, \varepsilon) = \Phi_{l,h+1}(x, \varepsilon)\Gamma_h(a, a_p + \delta_p^l), \tag{5.12}$$

$$\Phi_{j,h}(x, \varepsilon) = \Phi_{j,h+1}(x, \varepsilon)\Gamma_h(a, a_p + \delta_p^j) \qquad (h = 0, 1, 2, \cdots, 2m+1). \tag{5.13}$$

Set

$$J = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \tag{5.14}$$

$$\begin{aligned} Q_{l,h}(x, \varepsilon) &= \Phi_{l,h}(x, \varepsilon) \exp\{(-1)^h E(z, a_p + \delta_p^l)J\} \\ Q_{j,h}(x, \varepsilon) &= \Phi_{j,h}(x, \varepsilon) \exp\{(-1)^h E(z, a_p + \delta_p^j)J\} \qquad \text{(5.15)} \\ &\qquad\qquad (h = 0, 1, \cdots, 2m+1), \end{aligned}$$

where

$$\begin{aligned} z &= x\varepsilon^{-1/(m+1)}, \\ E(z, a_p + \delta_p^j) &= \sum_{0 \leqq k < m+1} \frac{\alpha_k(a, a_p + \delta_p^j)}{m+1-k} z^{m+1-k}. \end{aligned} \tag{5.16}$$

It is known that, if (x, ε) is in a domain

$$\left| \arg x\varepsilon^{-1/(m+1)} - \frac{h}{m+1}\pi \right| \leqq \frac{3\pi}{2m+2} - v, \qquad x \in D_2, \quad \varepsilon \in S_l \cap S_j, \tag{5.17-}h$$

where v is a small positive number, we have

$$\|Q_{j,h}(x, \varepsilon)\| \leqq H \cdot |\varepsilon|^q, \qquad \|Q_{j,h}(x, \varepsilon)^{-1}\| \leqq H \cdot |\varepsilon|^q, \tag{5.18}$$

where H is a positive number depending on v, q is a real number, and $\|\cdot\|$ denotes a usual norm of matrices. Furthermore, the matrix

$$Q_{j,h}(x, \varepsilon) - Q_{l,h}(x, \varepsilon) \tag{5.19}$$

is asymptotically zero as $\varepsilon \to 0$ in the sector $S_l \cap S_j$ uniformly in the domain (5.17-h) (see Sibuya [8]).

Let $P_l(x, \varepsilon)$ and $P_j(x, \varepsilon)$ be the matrices given in Lemma 4.9. Then $P_l(x, \varepsilon)\Phi_{l,h}(x, \varepsilon)$ and $P_j(x, \varepsilon)\Phi_{j,h}(x, \varepsilon)$ are two fundamental matrix solutions of (3.1) in the domain

$$x \in D_2, \qquad \varepsilon \in S_l \cap S_j. \tag{5.20}$$

Therefore, there exists a two-by-two matrix $L_h(\varepsilon)$ such that

$$P_l(x, \varepsilon)\Phi_{l,h}(x, \varepsilon) = P_j(x, \varepsilon)\Phi_{j,h}(x, \varepsilon)L_h(\varepsilon). \tag{5.21}$$

Note that $L_h(\varepsilon)$ does not depend on x. It follows from (5.21) that

$$\begin{aligned}(5.22)\qquad &\exp\{-E(z, a_p+\delta_p^j)\cdot J\}\cdot L_h(\varepsilon)\cdot\exp\{E(z, a_p+\delta_p^l)\cdot J\}\\ &\quad = Q_{j,h}(x,\varepsilon)^{-1}P_j(x,\varepsilon)^{-1}P_l(x,\varepsilon)Q_{l,h}(x,\varepsilon).\end{aligned}$$

Hence, the matrix

$$(5.23)\qquad \exp\{-E(z, a_p+\delta_p^j)J\}\cdot L_h(\varepsilon)\cdot\exp\{E(z, a_p+\delta_p^l)J\}-I_2$$

is asymptotically zero as $\varepsilon\to 0$ in the sector $S_l\cap S_j$ uniformly in the domain (5.17-h), where I_2 is the two-by-two identity matrix.

LEMMA 5.2. *Let*

$$(5.24)\qquad L_h(\varepsilon)=\begin{pmatrix} d_{11}^h(\varepsilon) & d_{12}^h(\varepsilon)\\ d_{21}^h(\varepsilon) & d_{22}^h(\varepsilon)\end{pmatrix}.$$

Then

$$(5.25)\qquad d_{11}^h(\varepsilon)-1,\qquad d_{22}^h(\varepsilon)-1\simeq 0\quad \text{as } \varepsilon\to 0\quad \text{in } S_l\cap S_j$$

$$(5.26)\qquad |d_{12}^h(\varepsilon)|\leqq c\cdot\exp\left\{-\frac{2r^{m+1}}{(m+1)|\varepsilon|}\right\},\qquad |d_{21}^h(\varepsilon)|\leqq c\cdot\exp\left\{-\frac{2r^{m+1}}{(m+1)|\varepsilon|}\right\}$$

for $\varepsilon\in S_l\cap S_j$, where c is a positive constant.

Proof. Using (5.24), we get from (5.23) that

$$\begin{aligned}&\begin{pmatrix}\exp[-E(z, a_p+\delta_p^j)] & 0\\ 0 & \exp[E(z, a_p+\delta_p^j)]\end{pmatrix}\begin{pmatrix} d_{11}^h(\varepsilon) & d_{12}^h(\varepsilon)\\ d_{21}^h(\varepsilon) & d_{22}^h(\varepsilon)\end{pmatrix}\\ &\quad\cdot\begin{pmatrix}\exp[E(z, a_p+\delta_p^l)] & 0\\ 0 & \exp[-E(z, a_p+\delta_p^l)]\end{pmatrix}-\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}\\ &=\begin{pmatrix} d_{11}^h(\varepsilon)\exp\{-E(z, a_p+\delta_p^j)+E(z, a_p+\delta_p^l)\}-1 & d_{12}^h(\varepsilon)\exp\{-E(z, a_p+\delta_p^j)-E(z, a_p+\delta_p^l)\}\\ d_{21}^h(\varepsilon)\exp\{E(z, a_p+\delta_p^j)+E(z, a_p+\delta_p^l)\} & d_{22}^h(\varepsilon)\exp\{E(z, a_p+\delta_p^j)-E(z, a_p+\delta_p^l)\}-1\end{pmatrix}\\ &\simeq 0\end{aligned}$$

as $\varepsilon\to 0$ in $S_l\cap S_j$.

On the other hand,

$$\begin{aligned}E(z, a_p+\delta_p^j)&=E(x\varepsilon^{-1/(m+1)}.\ a_p+\delta_p^j)\\ &=\frac{1}{(m+1)\varepsilon}x^{m+1}+\sum_{k=1}^{m}\frac{1}{m+1-k}\alpha_k(a, a_p+\delta_p^j)\frac{x^{m+1-k}}{\varepsilon^{(m+1-k)/(m+1)}}\end{aligned}$$

and, since $\delta_p^l(\varepsilon)$ and $\delta_p^j(\varepsilon)$ $(p=1, 2, \cdots, 2m)$ are asymptotically zero as $\varepsilon\to 0$, it holds that

$$\alpha_k(a, a_p+\delta_p^l)-\alpha_k(a, a_p+\delta_p^j)\simeq 0\qquad(\varepsilon\to 0).$$

Note that there are values of $x\in D_2$ and of $\varepsilon\in S_l\cap S_j$ for which (5.17-h) is true and $z^{m+1}=\{x\varepsilon^{-1/(m+1)}\}^{m+1}$ is positive, as well as other such values for which z^{m+1} is negative. Choosing such values with $|x|=r$, we can obtain Lemma 5.1.

DEFINITION 5.3. To shorten the expressions for the calculation that follows, the notation

$$a(\varepsilon) \approx b(\varepsilon) \quad \text{in the sector } S$$

will be introduced to indicate that

$$[a(\varepsilon) - b(\varepsilon)] \exp [2r^{m+1}/(m+1)|\varepsilon|]$$

remains bounded, as $\varepsilon \to 0$ in the sector S (see Wasow [10]). Furthermore, the notation

$$a(\varepsilon) :\approx b(\varepsilon) \quad \text{in the sector } S$$

will be interpreted as the sense that, for $0 < r' < r$,

$$\{a(\varepsilon) - b(\varepsilon)\} \exp \{2r'^{m+1}/(m+1)|\varepsilon|\} \to 0,$$

as $\varepsilon \to 0$ in the sector S.

We easily obtain from (5.12), (5.13), and (5.21) that

$$L_{h+1}(\varepsilon)\Gamma_h(a, a_p + \delta_p^l) = \Gamma_h(a, a_p + \delta_p^j) L_h(\varepsilon). \tag{5.27}$$

That is

$$\begin{aligned} &\begin{pmatrix} d_{11}^{h+1}(\varepsilon) & d_{12}^{h+1}(\varepsilon) \\ d_{21}^{h+1}(\varepsilon) & d_{22}^{h+1}(\varepsilon) \end{pmatrix} \begin{pmatrix} C_h(a, a_p + \delta_p^l) & 1 \\ \tilde{C}_h(a, a_p + \delta_p^l) & 0 \end{pmatrix} \\ &\quad = \begin{pmatrix} C_h(a, a_p + \delta_p^j) & 1 \\ \tilde{C}_h(a, a_p + \delta_p^j) & 0 \end{pmatrix} \begin{pmatrix} d_{11}^h(\varepsilon) & d_{12}^h(\varepsilon) \\ d_{21}^h(\varepsilon) & d_{22}^h(\varepsilon) \end{pmatrix}. \end{aligned} \tag{5.28}$$

This relation is important in the following analysis.

LEMMA 5.4.

$$\tilde{C}_h(a, a_p + \delta_p^l) - \tilde{C}_h(a, a_p + \delta_p^j) \approx 0 \quad \textit{in the sector } S_j \cap S_l. \tag{5.29}$$

Proof. The determinants of both sides of (5.28) imply that

$$\begin{aligned} &\{d_{11}^{h+1}(\varepsilon) d_{22}^{h+1}(\varepsilon) - d_{12}^{h+1}(\varepsilon) d_{21}^{h+1}(\varepsilon)\} \tilde{C}_h(a, a_p + \delta_p^l) \\ &\quad = \tilde{C}_h(a, a_p + \delta_p^j) \{d_{11}^h(\varepsilon) d_{22}^h(\varepsilon) - d_{12}^h(\varepsilon) d_{21}^h(\varepsilon)\}. \end{aligned}$$

That is

$$d_{11}^{h+1}(\varepsilon) d_{22}^{h+1}(\varepsilon) \tilde{C}_h(a, a_p + \delta_p^l) \approx \tilde{C}_h(a, a_p + \delta_p^j) d_{11}^h(\varepsilon) d_{22}^h(\varepsilon). \tag{5.30}$$

Here we used (5.26).

On the other hand, we see from the (1, 2)-element of the matrix relation (5.28) that

$$d_{11}^{h+1}(\varepsilon) = C_h(a, a_p + \delta_p^j) d_{12}^h(\varepsilon) + d_{22}^h(\varepsilon).$$

That is

$$d_{11}^{h+1}(\varepsilon) \approx d_{22}^h(\varepsilon). \tag{5.31}$$

It follows from (5.30) and (5.31) that

$$d_{22}^{h+1}(\varepsilon) \tilde{C}_h(a, a_p + \delta_p^l) \approx \tilde{C}_h(a, a_p + \delta_p^j) d_{11}^h(\varepsilon).$$

Furthermore, using (5.31) ($d_{22}^{h+1}(\varepsilon) \approx d_{11}^{h+2}(\varepsilon)$), we get

$$d_{11}^{h+2}(\varepsilon) \tilde{C}_h(a, a_p + \delta_p^l) \approx d_{11}^h(\varepsilon) \tilde{C}_h(a, a_p + \delta_p^j).$$

That is

$$\begin{aligned} &d_{11}^{h+2}(\varepsilon) \{\tilde{C}_h(a, a_p + \delta_p^l) - \tilde{C}_h(a, a_p + \delta_p^j)\} \\ &\quad - \tilde{C}_h(a, a_p + \delta_p^j) \{d_{11}^h(\varepsilon) - d_{11}^{h+2}(\varepsilon)\} \approx 0. \end{aligned}$$

Hence, we can obtain

$$d_{11}^{h}(\varepsilon)-d_{11}^{h+2}(\varepsilon)\approx\frac{d_{11}^{h+2}(\varepsilon)}{\tilde{C}_h(a,a_p+\delta_p^j)}\{\tilde{C}_h(a,a_p+\delta_p^l)-\tilde{C}_h(a,a_p+\delta+\delta_p^j)\}.$$

Similarly, we get

$$\begin{aligned}&d_{11}^{h+2k}(\varepsilon)-d_{11}^{h+2k+2}(\varepsilon)\\&\quad\approx\frac{d_{11}^{h+2k+2}(\varepsilon)}{\tilde{C}_{h+2k}(a,a_p+\delta_p^j)}\cdot\{\tilde{C}_{h+2k}(a,a_p+\delta_p^l)-\tilde{C}_{h+2k}(a,a_p+\delta_p^j)\},\end{aligned}\tag{5.32}$$

$$(k=0,1,\cdots,m).$$

Note that

$$d_{11}^{h}(\varepsilon)=d_{11}^{h+2m+2}(\varepsilon),$$
$$\tilde{C}_{h+2m}(a,a_p+\delta_p^j)=\tilde{C}_{h+2m-2}(a,a_p+\delta_p^j)=\cdots=\tilde{C}_h(a,a_p+\delta_p^j)$$

(cf. Sibuya [9, form. (11.47)]). We can obtain from (5.32) that

$$\{\tilde{C}_h(a,a_p+\delta_p^l)-\tilde{C}_h(a,a_p+\delta_p^j)\}\frac{1}{\tilde{C}_h(a,a_p+\delta_p^j)}\cdot\sum_{s=1}^{m+1}d_{11}^{h+2s}(\varepsilon)\approx 0.$$

Since

$$\tilde{C}_h(a,a_p+\delta_p^j)\neq 0\quad\text{and}\quad d_{11}^{h+2s}(\varepsilon)\simeq 1,$$

we can get (5.29).

LEMMA 5.5.

$$C_1(a,a_p+\delta_p^l)\cdot C_{2h+2}(a,a_p+\delta_p^l):\approx C_1(a,a_p+\delta_p^j)\cdot C_{2h+2}(a,a_p+\delta_p^j)\tag{5.33}$$

$$(h=0,1,\cdots,m-2).$$

Proof. It follows from (5.27) that

$$\begin{aligned}&L_{h+2}(\varepsilon)\Gamma_{h+1}(a,a_p+\delta_p^l)\Gamma_h(a,a_p+\delta_p^l)\\&\quad=\Gamma_{h+1}(a,a_p+\delta_p^j)L_{h+1}(\varepsilon)\Gamma_h(a,a_p+\delta_p^j)\\&\quad=\Gamma_{h+1}(a,a_p+\delta_p^j)\Gamma_h(a,a_p+\delta_p^j)L_h(\varepsilon).\end{aligned}\tag{5.34}$$

That is

$$\begin{aligned}&\begin{pmatrix}d_{11}^{h+2}(\varepsilon)&d_{12}^{h+2}(\varepsilon)\\d_{21}^{h+2}(\varepsilon)&d_{22}^{h+2}(\varepsilon)\end{pmatrix}\begin{pmatrix}C_{h+1}(a,a_p+\delta_p^l)&1\\\tilde{C}_{h+1}(a,a_p+\delta_p^l)&0\end{pmatrix}\begin{pmatrix}C_h(a,a_p+\delta_p^1)&1\\\tilde{C}_h(a,a_p+\delta_p^l)&0\end{pmatrix}\\&\quad=\begin{pmatrix}C_{h+1}(a,a_p+\delta_p^j)&1\\\tilde{C}_{h+1}(a,a_p+\delta_p^j)&0\end{pmatrix}\begin{pmatrix}C_h(a,a_p+\delta_p^j)&1\\\tilde{C}_h(a,a_p+\delta_p^j)&0\end{pmatrix}\begin{pmatrix}d^{h_{11}}(\varepsilon)&d_{12}^{h}(\varepsilon)\\d_{21}^{h}(\varepsilon)&d_{22}^{h}(\varepsilon)\end{pmatrix}.\end{aligned}\tag{5.35}$$

We see from the (1, 1)-element of the matrix relation (5.35) that

$$\begin{aligned}&d_{11}^{h+2}(\varepsilon)\{C_{h+1}(a,a_p+\delta_p^l)C_h(a,a_p+\delta_p^l)+\tilde{C}_h(a,a_p+\delta_p^l)\}\\&\quad+d_{12}^{h+2}(\varepsilon)\tilde{C}_{h+1}(a,a_p+\delta_p^l)C_h(a,a_p+\delta_p^l)\\&=d_{11}^{h}(\varepsilon)\{C_{h+1}(a,a_p+\delta_p^j)C_h(a,a_p+\delta_p^j)+\tilde{C}_h(a,a_p+\delta_p^j)\}\\&\quad+d_{21}^{h}(\varepsilon)C_{h+1}(a,a_p+\delta_p^j).\end{aligned}\tag{5.36}$$

Note that

$$d_{11}^{h+2}(\varepsilon)\approx d_{11}^{h}(\varepsilon)\quad\text{in } S_l\cap S_j,$$

which follows from (5.32). Using (5.29) and (5.26), we can obtain from (5.36) that

$$C_{h+1}(a,a_p+\delta_p^l)C_h(a,a_p+\delta_p^l)\approx C_{h+1}(a,a_p+\delta_p^j)C_h(a,a_p+\delta_p^j)\quad\text{in } S_l\cap S_j.\tag{5.37}$$

So we have proved $(5.33)_{h=0}$.

Putting $h=1, 3$ in (5.37), we can get

$$C_1(a, a_p+\delta_p^l)C_2(a, a_p+\delta_p^l)C_3(a, a_p+\delta_p^l)C_4(a, a_p+\delta_p^l)$$
$$\approx C_1(a, a_p+\delta_p^j)C_2(a, a_p+\delta_p^j)C_3(a, a_p+\delta_p^j)C_4(a, a_p+\delta_p^j) \quad \text{in } S_j \cap S_l.$$

Hence we get

$$\{C_1(a, a_p+\delta_p^l)C_4(a, a_p+\delta_p^l)-C_1(a, a_p+\delta_p^j)C_4(a, a_p+\delta_p^j)\}$$
$$\cdot C_2(a, a_p+\delta_p^l)C_3(a, a_p+\delta_p^l)$$
$$\approx\{C_2(a, a_p+\delta_p^j)C_3(a, a_p+\delta_p^j)-C_2(a, a_p+\delta_p^l)C_3(a, a_p+\delta_p^l)\} \tag{5.38}$$
$$\cdot C_1(a, a_p+\delta_p^j)C_4(a, a_p+\delta_p^j)$$
$$\text{in the sector } S_l \cap S_j.$$

It holds from Lemmas 4.4 and 4.7 that

$$C_{2k}(a, a_p+\delta_p^l)|_{\varepsilon=0}=0 \quad \text{and} \quad \left.\frac{\partial C_{2k}(a, a_p+\delta_p^l)}{\partial(a_p+\delta_p^l)}\right|_{\varepsilon=0} \neq 0.$$

Hence we get

$$C_{2k}(a, a_p+\delta_p^l)=O(a_p+\delta_p^l)=O(a_p)=O(\varepsilon^q) \quad \text{as } \varepsilon \to 0, \tag{5.39}$$

where q is a some real number. Since

$$C_{2k+1}(a, a_p+\delta_p^l)|_{\varepsilon=0} \neq 0, \tag{5.40}$$

we obtain

$$\frac{C_1(a, a_p+\delta_p^j)C_4(a, a_p+\delta_p^j)}{C_2(a, a_p+\delta_p^l)C_3(a, a_p+\delta_p^l)}=O(\varepsilon^{q'}) \quad \text{as } \varepsilon \to 0,$$

where q' is a real number.

Therefore, from (5.38) we get

$$\{C_1(a, a_p+\delta_p^l)C_4(a, a_p+\delta_p^l)-C_1(a, a_p+\delta_p^j)C_4(a, a_p+\delta_p^j)\} \cdot \exp\left[\frac{2r'^{m+1}}{(m+1)|\varepsilon|}\right]$$
$$=O(\varepsilon^{q'}) \cdot \exp[\{2r'^{m+1}-2r^{m+1}\}/(m+1)|\varepsilon|]$$
$$\to 0 \quad \text{as } \varepsilon \to 0,$$

where r' is positive and $r-r'$ is a sufficiently small positive number. Here we used $(5.37)_{h=2}$. Thus we have proved $(5.33)_{h=2}$.

Similarly, we can prove Lemma 5.5.

LEMMA 5.6.

$$\frac{C_{2h+1}(a, a_p+\delta_p^l)}{C_1(a, a_p+\delta_p^l)} :\approx \frac{C_{2h+1}(a, a_p+\delta_p^j)}{C_1(a, a_p+\delta_p^j)} \tag{5.41}$$
$$\text{in } S_l \cap S_j \quad (h=1, 2, \cdots, m-1).$$

Proof. Putting $h=1, 2$ in (5.37), we can get

$$C_1(a, a_p+\delta_p^l)C_2(a, a_p+\delta_p^l)C_2(a, a_p+\delta_p^l)C_1(a, a_p+\delta_p^l)$$
$$\cdot \frac{C_3(a, a_p+\delta_p^l)}{C_1(a, a_p+\delta_p^l)}$$
$$\approx C_1(a, a_p+\delta_p^j)C_2(a, a_p+\delta_p^j)C_2(a, a_p+\delta_p^j)C_1(a, a_p+\delta_p^j) \tag{5.42}$$
$$\cdot \frac{C_3(a, a_p+\delta_p^j)}{C_1(a, a_p+\delta_p^j)} \quad \text{in } S_j \cap S_l.$$

Hence

$$
\begin{aligned}
&\{C_1(a, a_p+\delta_p^l)C_2(a, a_p+\delta_p^l)\}^2 \cdot \left[\frac{C_3(a, a_p+\delta_p^l)}{C_1(a, a_p+\delta_p^l)}-\frac{C_3(a, a_p+\delta_p^j)}{C_1(a, a_p+\delta_p^j)}\right] \\
&\approx \frac{C_3(a, a_p+\delta_p^j)}{C_1(a, a_p+\delta_p^j)} \\
&\quad \cdot \{C_1(a, a_p+\delta_p^j)C_2(a, a_p+\delta_p^j)+C_1(a, a_p+\delta_p^l)C_2(a, a_p+\delta_p^l)\} \\
&\quad \cdot \{C_1(a, a_p+\delta_p^j)C_2(a, a_p+\delta_p^j)-C_1(a, a_p+\delta_p^l)C_2(a, a_p+\delta_p^l)\} \\
&\qquad\qquad \text{in } S_j \cap S_l.
\end{aligned} \tag{5.43}
$$

So, by an argument similar to the proof of Lemma 5.5, we can obtain

$$
\frac{C_3(a, a_p+\delta_p^l)}{C_1(a, a_p+\delta_p^l)}-\frac{C_3(a, a_p+\delta_p^j)}{C_1(a, a_p+\delta_p^j)} :\approx 0 \quad \text{in } S_l \cap S_j.
$$

Here we used (5.39), (5.40), and $(5.37)_{h=1}$. Thus we have proved $(5.41)_{h=1}$. Similarly, we can prove Lemma 5.6.

We put

$$
\begin{aligned}
s &= (s_1, \cdots, s_{m-1}, s_{m+1}, s_{m+2}, \cdots, s_{2m}) \\
&= (\delta_1^l-\delta_1^j, \cdots, \delta_{m-1}^l-\delta_{m-1}^j, \delta_{m+1}^l-\delta_{m+1}^j, \cdots, \delta_{2m}^l-\delta_{2m}^j).
\end{aligned} \tag{5.44}
$$

Note that, if $a(\varepsilon) \approx b(\varepsilon)$ in S, then $a(\varepsilon) :\approx b(\varepsilon)$ in S. We have obtained in Lemmas 5.4–5.6 that

$$
\begin{aligned}
&\tilde{C}_h(a, a_p+\delta_p^j+s_p)-\tilde{C}_h(a, a_p+\delta_p^j) \\
&\quad = -\omega^{1-(-1)^h 2\alpha_{m+1}(a, a_p+\delta_p^j+s_p)}+\omega^{1-(-1)^h 2\alpha_{m+1}(a, a_p+\delta_p^j)} \\
&\quad :\approx 0 \quad \text{in } S_l \cap S_j,
\end{aligned} \tag{5.45}
$$

$$
\begin{aligned}
&C^*(a, a_p+\delta_p^j+s_p)C(a, G^{2h+2}(a_p+\delta_p^j+s_p)) \\
&\qquad -C^*(a, a_p+\delta_p^j)C(a, G^{2h+2}(a_p+\delta_p^j)) \\
&\quad = C^*(a, a_p+\delta_p^j+s_p)C^*(a, G^{2h+1}(a_p+\delta_p^j+s_p)) \\
&\qquad -C^*(a, a_p+\delta_p^j)C^*(a, G^{2h+1}(a_p+\delta_p^j)) \\
&\quad :\approx 0 \quad \text{in } S_j \cap S_l \quad (h=0, 1, \cdots, m-2),
\end{aligned} \tag{5.46}
$$

$$
\begin{aligned}
&\frac{C^*(a, G^{2h}(a_p+\delta_p^j+s_p))}{C^*(a, a_p+\delta_p^j+s_p)}-\frac{C^*(a, G^{2h}(a_p+\delta_p^j))}{C^*(a, a_p+\delta_p^j)} :\approx 0 \\
&\qquad\qquad \text{in } S_l \cap S_j \quad (h=1, 2, \cdots, m-1).
\end{aligned} \tag{5.47}
$$

LEMMA 5.7. *Let*

$$
\begin{aligned}
f_{2h}(a_p, s_p) &= \frac{C^*(a, G^{2h}(a_p+\delta_p^j+s_p))}{C^*(a, a_p+\delta_p^j+s_p)}-\frac{C^*(a, G^{2h}(a_p+\delta_p^j)}{C^*(a, a_p+\delta_p^j)} \qquad (h=1, 2, \cdots, m-1), \\
f_{2h+1}(a_p, s_p) &= C^*(a, a_p+\delta_p^j+s_p)C(a, G^{2h+2}(a_p+\delta_p^j+s_p)) \\
&\quad -C^*(a, a_p+\delta_p^j)C(a, G^{2h+2}(a_p+\delta_p^j)) \qquad (h=0, 1, \cdots, m-2), \\
f_{2m-1}(a_p, s_p) &= -\omega^{1+\alpha_{m+1}(a, a_p+\delta_p^j+s_p)}+\omega^{1-\alpha_{m+1}(a, a_p+\delta_p^j)}.
\end{aligned}
$$

Assume that ε_1 and ε_2 are sufficiently small positive numbers. Then, if

$$
\begin{aligned}
&|a_1|+|a_2|+\cdots+|a_{2m}| \leqq \varepsilon_1, \\
&|a_1'|+|a_2'|+\cdots+|a_{2m-1}'| \leqq \varepsilon_2,
\end{aligned} \tag{5.48}
$$

there exists a unique solution

$$s = g(a_p, a'_p)$$
$$= (g_1(a_p, a'_p), \cdots, g_{m-1}(a_p, a'_p), g_{m+1}(a_p, a'_p), \cdots, g_{2m}(a_p, a'_p))$$

of the system of equations

$$f_k(a_p, s_p) = a'_k \qquad (k = 1, 2, \cdots, 2m-1;\ p = 1, \cdots, m-1, m+1, \cdots, 2m), \tag{5.49}$$

such that $g_1, g_2, \cdots, g_{m-1}, g_{m+1}, \cdots, g_{2m}$ *are holomorphic in the domain* (5.48) *and*

$$g_k(a_p, 0) = 0 \qquad (k = 1, \cdots, m-1, m+1, \cdots, 2m).$$

Proof. It holds that

$$\left.\frac{\partial f_{2h}(a_p, s_p)}{\partial s_k}\right|_{a_p=0, s_p=0} = (\omega^{-2hk} - 1)\frac{1}{C^*(a, 0)}\left.\frac{\partial C^*(a, a_p)}{\partial a_k}\right|_{a_p=0} \tag{5.50}$$
$$(h = 1, 2, \cdots, m-1)$$

$$\left.\frac{\partial f_{2h+1}(a_p, s_p)}{\partial s_k}\right|_{a_p=0, s_p=0} = \omega^{-(2h+2)k} \cdot C^*(a, 0)\left.\frac{\partial C(a, a_p)}{\partial a_k}\right|_{a_p=0} \tag{5.51}$$
$$(h = 0, 1, \cdots, m-2),$$

$$\left.\frac{\partial f_{2m-1}(a_p, s_p)}{\partial s_k}\right|_{a_p=0, s_p=0} = \begin{cases} 0 & (k \neq m+1), \\ -\omega^{1+a} & (k = m+1). \end{cases} \tag{5.52}$$

Here we used (4.25), (4.26), and (4.24).

Now we consider the Jacobian determinant of system (5.49) with respect to $s_1, \cdots, s_{m-1}, s_{m+1}, \cdots, s_{2m}$ at $a_p = 0$, $s_p = 0$.

$$V = \det\left(\frac{\partial f_k}{\partial s_p}\right)_{a_p=0, s_p=0}$$

$$= \begin{vmatrix} & \dfrac{\partial f_{2h+2}}{\partial s_k} & & 0 \\ & & & \vdots \\ & & & 0 \\ 0 & \cdots & 0 \quad \dfrac{\partial f_{2m-1}}{\partial s_{m+1}} \quad 0 & \cdots \quad 0 \\ & \dfrac{\partial f_{2h+1}}{\partial s_k} & & 0 \\ & & & \vdots \\ & & & 0 \end{vmatrix} \qquad \begin{matrix} & \dfrac{\partial f_{2h+2}}{\partial s_{k+m+1}} & \\ & & \\ & & \\ & & \\ & \dfrac{\partial f_{2h+1}}{\partial s_{k+m+1}} & \\ & & \end{matrix}$$

$$(h = 0, 1, \cdots, m-2;\ k = 1, 2, \cdots, m-1),$$

$$= -\omega^{1+a} \cdot \begin{vmatrix} & \vdots & & \vdots & \\ \cdots & (\omega^{-2jk} - 1)\dfrac{1}{C^*}\dfrac{\partial C^*}{\partial a_k} & \cdots & (\omega^{-2jk} - 1)\dfrac{1}{C^*}\dfrac{\partial C^*}{\partial a_{k+m+1}} & \cdots \\ & \vdots & & \vdots & \\ \cdots & \omega^{-2jk} \cdot C^*\dfrac{\partial C}{\partial a_k} & \cdots & \omega^{-2jk} \cdot C^*\dfrac{\partial C}{\partial a_{k+m+1}} & \cdots \\ & \vdots & & \vdots & \end{vmatrix}$$

$$(j, k = 1, 2, \cdots, m-1),$$

$$= -\omega^{1+a} \cdot \begin{vmatrix} V_1 & 0 \\ 0 & V_2 \end{vmatrix}.$$

(5.53)
$$\begin{vmatrix} \ddots & & & \\ \dfrac{\partial C^*}{\partial a_k} & \ddots & \dfrac{\partial C^*}{\partial a_{k+m+1}} & \ddots \\ \ddots & & & \\ \dfrac{\partial C}{\partial a_k} & \ddots & \dfrac{\partial C}{\partial a_{k+m+1}} & \ddots \end{vmatrix} \begin{matrix} \\ m-1 \\ \\ m-1 \end{matrix},$$

where V_1 and V_2 are the $(m-1)$-by-$(m-1)$ matrices whose components are $\omega^{-2jk}-1$ and ω^{-2jk} $(j, k=1, 2, \cdots, m-1)$.

Hence we get

(5.54)
$$V=\frac{1}{2}\cdot|V_1|\cdot|V_2|\cdot\prod_{k=1}^{m-1}\begin{vmatrix} \dfrac{\partial C^*}{\partial a_k} & \dfrac{\partial C^*}{\partial a_{k+m+1}} \\ \dfrac{\partial C}{\partial a_k} & \dfrac{\partial C}{\partial a_{k+m+1}} \end{vmatrix}.$$

Note that

$$|V_1|=\begin{vmatrix} 1 & 1 & \cdots & 1 \\ \omega^{-2} & \omega^{-4} & \cdots & \omega^{-2(m-1)}) \\ \omega^{-4} & \omega^{-8} & \cdots & \omega^{-4(m-1)} \\ \vdots & \vdots & & \vdots \\ \omega^{-2(m-2)} & \omega^{-4(m-2)} & \cdots & \omega^{-2(m-2)(m-1)} \end{vmatrix}$$
$$\cdot\begin{vmatrix} \omega^{-2}-1 & & & \\ & \omega^{-4}-1 & & \\ & & \ddots & \\ & & & \omega^{-2(m-1)}-1 \end{vmatrix}\neq 0.$$

Therefore, by virtue of (4.27), the Jacobian determinant V is different from zero. Thus we have proved this lemma.

Now we apply this lemma to (5.45)-(5.47). If we put

$$a_k'(\varepsilon):\approx 0 \quad \text{in the sector } S_l\cap S_j,$$

we can obtain from Lemma 5.7 that

$$s=g(a_p, a_p')=O(|a_p'|).$$

That is

$$|\delta_k^l(\varepsilon)-\delta_k^j(\varepsilon)|\leqq H\cdot\exp[-2r'^{m+1}/(m+1)|\varepsilon|] \quad \text{in } S_l\cap S_j$$
$$(k=1, \cdots, m-1, m+1, \cdots, 2m)$$

for some positive number H, where $r-r'$ is a sufficiently small positive number.

Therefore, thanks to Theorem 5.1, we can obtain

$$|\delta_k^j(\varepsilon)|\leqq H_{j,k}\cdot\exp[-2r'^{m+1}/(m+1)|\varepsilon|] \quad \text{for } \varepsilon\in S_j,$$

where $H_{j,k}$ are positive numbers.

6. Proof of the main theorem. In this section, as an application of Theorem 1.3, we will prove the main theorem. Let S_j be sectors in Theorem 1.3. Furthermore, for simplicity, we assume that $m+1$ is even.

To prove the main theorem we need the following lemmas which were proved by Lin [3]. We state them here.

LEMMA 6.1. *Let $f_j(\varepsilon)$ be holomorphic in $S_j \cap S_{j+1}$ and asymptotically* 1 *as ε tends to zero in $S_j \cap S_{j+1}$.*

Then there exist functions $g_j(\varepsilon)$ in S_j that are, respectively, holomorphic in S_j and asymptotically 1 *as ε tends to zero in S_j such that*

$$f_j(\varepsilon) = g_{j+1}(\varepsilon)/g_j(\varepsilon) \qquad (j = 1, 2, \cdots, \nu - 1) \quad \text{in } S_j \cap S_{j+1}.$$

We are now in a position to prove the main theorem, Theorem 1.1.

Case I. $x > 0$. The transformation

$$u = y \cdot \exp\left[-x^{m+1}/(m+1)|\varepsilon|\right] \tag{6.1}$$

changes the formally transformed equation (3.7) into

$$\varepsilon y'' - 2x^m y' - \left\{ \sum_{r=0}^{2m-1} a_r(\varepsilon) x^r + m x^{m-1} \right\} y = 0. \tag{6.2}$$

If the differential equation (2.10) satisfies the Matkowsky condition, then, by manipulating the transformations, we can show that the differential equation (6.2) satisfies the Matkowsky condition. So (6.2) has a formal power series solution

$$y(x, \varepsilon) = \sum_{n=0}^{\infty} y_n(x) \varepsilon^n. \tag{6.3}$$

Therefore, (3.7) has a formal solution of the form

$$\exp\left[-x^{m+1}/(m+1)\varepsilon\right] \cdot \sum_{n=0}^{\infty} y_n(x) \varepsilon^n, \tag{6.4}$$

which is subdominant on the positive real axis.

On the other hand, it follows from (4.2) that (3.7) has two independent solutions $y_0(x\varepsilon^{-1/(m+1)}, b, b_p)$ and $y_1(x\varepsilon^{-1/(m+1)}, b, b_p)$. Since y_0 is subdominant and y_1 is dominant on the positive real axis, there exists $c(\varepsilon)$, which does not depend on x, such that

$$\sum_{n=0}^{\infty} y_n(x) \varepsilon^n = c(\varepsilon) \cdot y_0(x\varepsilon^{-1/(m+1)}, b, b_p) \exp\left[\frac{x^{m+1}}{(m+1)\varepsilon}\right]. \tag{6.5}$$

We can choose S_j such that the sector S_j contains $\arg \varepsilon = 0$. Set

$$y^{\#}(x, \varepsilon) = y_0(x\varepsilon^{-1/(m+1)}, b, b_p + \delta_p^j) \exp\left[x^{m+1}/(m+1)\varepsilon\right]. \tag{6.6}$$

Note that (5.16) and

$$\begin{aligned} &\left|\{y_k(z, b, b_p + \delta_p) - y_k(z, b, b_p)\} \exp\{(-1)^k E(z, b_p)\}\right| \\ &\qquad \leqq K|\varepsilon|^q \cdot \sum_{p=1}^{2m} |\delta_p(\varepsilon)| \\ &\qquad\qquad\qquad\qquad (k = 0, 1, \cdots, 2m+1), \end{aligned} \tag{6.7}$$

where K is a positive number and q is some real number (see Sibuya [9, Lemma 3.1]). It follows that

$$\begin{aligned} &\frac{x^{m+1}}{(m+1)\varepsilon} - E(x\varepsilon^{-1/(m+1)}, b_p(\varepsilon)) \\ &\qquad = \sum_{k=1}^{m} \frac{\alpha_k(b, b_p)}{m+1-k} x^{m+1-k} \varepsilon^{-(m+1-k)/(m+1)} \end{aligned} \tag{6.8}$$

remains bounded as $\varepsilon \to 0$. Here we used

$$\alpha_h(b, b_p) = O(b_h(\varepsilon)) = O(\mu^{2h-(2m+2)}) = O(\varepsilon^{1-h/(m+1)}) \qquad (h = 2, \cdots, m), \qquad \alpha_1(b, b_p) = 0.$$

So we get from (6.5) and (6.6) that

$$\begin{aligned} c(\varepsilon)y^{\#}(x, \varepsilon) - \sum_{n=0}^{\infty} y_n(x)\varepsilon^n \\ = c(\varepsilon)\{y_0(z, b, b_p + \delta_p^j) - y_0(z, b, b_p)\} \exp\{E(z, b_p\} \\ \cdot \exp[x^{m+1}/(m+1)\varepsilon - E(z, b_p)] \\ = O(\delta_p^j(\varepsilon)) \simeq 0 \end{aligned}$$

as $\varepsilon \to +0$ uniformly on $x > 0$. We have shown that the actual solution $c(\varepsilon)y^{\#}(x, \varepsilon)$ tends to the formal solution $\sum y_n(x)\varepsilon^n$ as $\varepsilon \to 0$ on the positive real axis $x > 0$.

Case II. $x < 0$. We consider the asymptotic behavior of $c(\varepsilon)y^{\#}(x, \varepsilon)$ on the negative real axis $x < 0$, by using the connection formulas for $y_k(z, b, b_p)$ and $y_k(z, b, b_p + \delta_p)$.

Let us put

$$y^{\#\#}(x, \varepsilon) = y_1(z, b, b_p) \exp[x^{m+1}/(m+1)\varepsilon],$$

$$Y^{\#}(x, \varepsilon) = \begin{pmatrix} y^{\#}(x, \varepsilon) & y^{\#\#}(x, \varepsilon) \\ \dfrac{d}{dx} y^{\#}(x, \varepsilon) + x^m \varepsilon^{-1} y^{\#}(x, \varepsilon) & \dfrac{d}{dx} y^{\#\#}(x, \varepsilon) + x^m \varepsilon^{-1} y^{\#\#}(x, \varepsilon) \end{pmatrix}$$

$$C(\varepsilon) = \begin{pmatrix} c(\varepsilon) \\ 0 \end{pmatrix}.$$

So we have

$$\begin{aligned} Y^{\#}(x, \varepsilon)C(\varepsilon) &= \Phi_{j,0}(x, \varepsilon) \exp[x^{m+1}/(m+1)\varepsilon] \cdot I_2 \cdot C(\varepsilon) \\ &= \Phi_{j,m+1}(x, \varepsilon) \cdot \prod_{h=0}^{m} \Gamma(b, b_p(\varepsilon) + \delta_p^j(\varepsilon)) \\ &\quad \cdot \exp\left[\frac{x^{m+1}}{(m+1)\varepsilon}\right] \cdot I_2 \cdot C(\varepsilon). \end{aligned} \tag{6.9}$$

Similarly, putting

$$\begin{aligned} y^*(x, \varepsilon) &= y_0(z, b, b_p(\varepsilon)) \exp[x^{m+1}/(m+1)\varepsilon] \\ &= c(\varepsilon)^{-1} \cdot \sum_{n=0}^{\infty} y_n(x)\varepsilon^n, \end{aligned}$$

$$y^{**}(x, \varepsilon) = y_1(z, b, b_p(\varepsilon)) \exp[x^{m+1}/(m+1)\varepsilon],$$

$$Y^*(x, \varepsilon) = \begin{pmatrix} y^*(x, \varepsilon) & y^{**}(x, \varepsilon) \\ \dfrac{d}{dx} y^*(x, \varepsilon) + x^m \varepsilon^{-1} y^*(x, \varepsilon) & \dfrac{d}{dx} y^{**}(x, \varepsilon) + x^m \varepsilon^{-1} y^{**}(x, \varepsilon) \end{pmatrix},$$

we get

$$
\begin{aligned}
Y^*(x,\varepsilon)C(\varepsilon) &= \tilde{\Phi}_0(x,\varepsilon)\cdot\exp[x^{m+1}/(m+1)\varepsilon]\cdot I_2\cdot C(\varepsilon)\\
&= \tilde{\Phi}_{m+1}(x,\varepsilon)\cdot\prod_{h=0}^{m}\Gamma(b,b_p(\varepsilon))\cdot\exp\left[\frac{x^{m+1}}{(m+1)\varepsilon}\right]\cdot I_2\cdot C(\varepsilon),
\end{aligned}
\tag{6.10}
$$

where

$$
\tilde{\Phi}_h(x,\varepsilon)=\Lambda(\varepsilon)\Psi(x\varepsilon^{-1/(m+1)\varepsilon},\, b,\, b_p)\qquad (h=0,1,\cdots,2m+1),
$$

which is a fundamental matrix solution of (3.4). Note that $\Phi_{m+1}(x,\varepsilon)$ and $\tilde{\Phi}_{m+1}(x,\varepsilon)$ are asymptotically known on the negative real axis $\arg x=\pi$.

If we put

$$
\prod_{h=0}^{m}\Gamma(b,b_p(\varepsilon))=\begin{pmatrix}A_{11}(b_p) & A_{12}(b_p)\\ A_{21}(b_p) & A_{22}(b_p)\end{pmatrix},
\tag{6.11}
$$

we can obtain from (6.10) that

$$
\begin{aligned}
\sum_{n=0}^{\infty}y_n(x)\varepsilon^n &= c(\varepsilon)y^*(x,\varepsilon)\\
&= c(\varepsilon)\{A_{11}(b_p)y_{m+1}(z,b,b_p)+A_{21}(b_p)y_{m+2}(z,b,b_p)\}\\
&\quad\cdot\exp[x^{m+1}/(m+1)\varepsilon].
\end{aligned}
\tag{6.12}
$$

On the other hand, we have from (6.9) that

$$
\begin{aligned}
c(\varepsilon)y^{\#}(x,\varepsilon) = c(\varepsilon)\{&A_{11}(b_p+\delta_p^j)y_{m+1}(z,b,b_p+\delta_p^j)\\
&+A_{21}(b_p+\delta_p^j)y_{m+2}(z,b,b_p+\delta_p^j)\}\\
&\cdot\exp[x^{m+1}/(m+1)\varepsilon].
\end{aligned}
\tag{6.13}
$$

Since $m+1$ is even, it follows from (6.12) that

$$
A_{21}(b_p)\cdot\exp[2x^{m+1}/(m+1)\varepsilon]
$$

remains bounded as $\varepsilon\to+0$ on $x<0$. So, as an application of Theorem 1.3, we prove that

$$
A_{21}(b_p+\delta_p^j)\cdot\exp[2x^{m+1}/(m+1)\varepsilon]
$$

remains bounded as $\varepsilon\to+0$ on $x<0$. To shorten the expressions for the calculation that follows, the notation $a(\varepsilon)\approx; b(\varepsilon)$ in S will be introduced to indicate that

$$
\{a(\varepsilon)-b(\varepsilon)\}\cdot\exp[2r_0^{m+1}/(m+1)\varepsilon]
$$

remains bounded, as $\varepsilon\to 0$ in the sector S for $\underline{a,\, b<r_0<r_1}$ (cf. Definition 5.3). That is

$$
\{a(\varepsilon)-b(\varepsilon)\}\cdot\exp[2r_0^{m+1}/(m+1)\cdot\mathrm{Re}(1/\varepsilon)]
$$

remains bounded as $\varepsilon\to 0$ in S.

Noting that

$$
\alpha_k(b,b_p+\delta_p^{l+1})-\alpha_k(b,b_p+\delta_p^{l})\simeq 0\qquad(\varepsilon\to 0 \text{ in } S_l\cap S_{l+1}),
$$

by the same argument as Lemma 5.2, we can easily obtain

$$
d_{ii}^h(\varepsilon)\simeq 1\qquad(\varepsilon\to 0 \text{ in } S_l\cap S_{l+1}),\quad(i=1,2;\, h=0,1,\cdots,2m+1),
\tag{6.14}
$$

$$d_{12}^{h}(\varepsilon)\cdot\exp\left[\frac{2x^{m+1}}{(m+1)\varepsilon}\right]\simeq 0,\qquad d_{21}^{h}(\varepsilon)\cdot\exp\left[\frac{2x^{m+1}}{(m+1)\varepsilon}\right]\simeq 0 \tag{6.15}$$

as $\varepsilon\to 0$ in $S_l\cap S_{l+1}$ uniformly in (5.17-h). In (6.15), we consider the cases in which $h=0$ and $h=m+1$. Since $-\pi/2<\arg\varepsilon<\pi/2$, it follows from (5.17-0) that $-\pi/(m+1)<\arg x<\pi/(m+1)$. So we can choose values of $x\in D_1$ such that $\arg x=0$. Hence we have from (6.15) that

$$d_{21}^{0}(\varepsilon)\approx;0\quad\text{in } S_l\cap S_{l+1}. \tag{6.16}$$

Similarly, in (5.17-($m+1$)) we can choose a value $x\in D_1$ such that $\arg x=\pi$. Then we get from (6.15) that

$$d_{21}^{m+1}(\varepsilon)\approx;0\quad\text{in } S_l\cap S_{l+1}. \tag{6.17}$$

Since

$$L_{h+1}(\varepsilon)\Gamma_h(b,b_p+\delta_p^l)=\Gamma_h(b,b_p+\delta_p^{l+1})L_h(\varepsilon), \tag{5.27}$$

we get

$$L_{m+1}(\varepsilon)\cdot\prod_{h=0}^{m}\Gamma_h(b\cdot b_p+\delta_p^l)=\prod_{h=0}^{m}\Gamma_h(b,b_p+\delta_p^{l+1})\cdot L_0(\varepsilon).$$

That is

$$\begin{aligned}&\begin{pmatrix}d_{11}^{m+1}(\varepsilon) & d_{12}^{m+1}(\varepsilon)\\ d_{21}^{m+1}(\varepsilon) & d_{22}^{m+1}(\varepsilon)\end{pmatrix}\begin{pmatrix}A_{11}(b_p+\delta_p^l) & A_{12}(b_p+\delta_p^l)\\ A_{21}(b_p+\delta_p^l) & A_{22}(b_p+\delta_p^l)\end{pmatrix}\\ &\quad=\begin{pmatrix}A_{11}(b_p+\delta_p^{l+1}) & A_{12}(b_p+\delta_p^{l+1})\\ A_{21}(b_p+\delta_p^{l+1}) & A_{22}(b_p+\delta_p^{l+1})\end{pmatrix}\begin{pmatrix}d_{11}^{0}(\varepsilon) & d_{12}^{0}(\varepsilon)\\ d_{21}^{0}(\varepsilon) & d_{22}^{0}(\varepsilon)\end{pmatrix}.\end{aligned} \tag{6.18}$$

We see from the (2, 1)-element of the matrix relation (6.18) that

$$\begin{aligned}&d_{21}^{m+1}(\varepsilon)\cdot A_{11}(b_p+\delta_p^l)+d_{22}^{m+1}(\varepsilon)\cdot A_{21}(b_p+\delta_p^l)\\ &\quad=d_{11}^{0}(\varepsilon)\cdot A_{21}(b_p+\delta_p^{l+1})+d_{21}^{0}(\varepsilon)\cdot A_{22}(b_p+\delta_p^{l+1}).\end{aligned}$$

That is

$$\begin{aligned}&A_{21}(b_p+\delta_p^l)-A_{21}(b_p+\delta_p^{l+1})\cdot\frac{d_{11}^{0}(\varepsilon)}{d_{22}^{m+1}(\varepsilon)}\\ &=\frac{1}{d_{22}^{m+1}(\varepsilon)}[d_{21}^{0}(\varepsilon)\cdot A_{22}(b_p+\delta_p^{l+1})-d_{21}^{m+1}(\varepsilon)\cdot A_{11}(b_p+\delta_p^l)]\\ &\approx;0\quad\text{in } S_l\cap S_{l+1}.\end{aligned} \tag{6.19}$$

Here we used (6.16) and (6.17). Since

$$d_{11}^{0}(\varepsilon)/d_{22}^{m+1}(\varepsilon)\simeq 1\qquad(\varepsilon\to 0\text{ in }S_l),$$

which follows from (6.14), by virtue of Lemma 6.1 there exist functions $g_l(\varepsilon)$ ($l=1,2,\cdots,\nu$) in S_l such that

$$g_l(\varepsilon)\simeq 1\qquad(\varepsilon\to 0\text{ in }S_l), \tag{6.20}$$

$$d_{11}^{0}(\varepsilon)/d_{22}^{m+1}(\varepsilon)=g_{l+1}(\varepsilon)/g_l(\varepsilon)\quad\text{in } S_l\cap S_{l+1}. \tag{6.21}$$

Then (6.19) reduces to

$$g_l(\varepsilon)A_{21}(b_p+\delta_p^l)-g_{l+1}(\varepsilon)A_{21}(b_p+\delta_p^{l+1})\approx;0 \quad \text{in } S_l\cap S_{l+1}. \tag{6.22}$$

In § 5 we considered the case in which the domain D is a disk with center at zero. In this section, the domain of x contains a disk with center at zero, although the radius of the disk is small. So we get

$$|\delta_p^l(\varepsilon)|\leqq H_1\cdot\exp[-2r_2^{m+1}/(m+1)|\varepsilon|] \quad \text{in } S_l$$
$$(l=1,2,\cdots,\nu;\ p=1,2,\cdots,2m),$$

for some positive number H_1.

Let r_0 be a positive number with $a<r_0<r_1$ and choose ω_0 with $0<\omega_0<\pi/2$ such that $r_3^{m+1}\geqq r_0^{m+1}\cdot\cos\omega_0>0$. Then if $\arg\varepsilon=\omega_0$ (or $-\omega_0$), we get

$$r_2^{m+1}/|\varepsilon|\geqq r_0^{m+1}\cdot\mathrm{Re}[1/\varepsilon].$$

Therefore, for some sector that contains the line segment $\arg\varepsilon=\omega_0$ (or $-\omega_0$), say S_ν (or S_1), we have

$$|\delta_p^1(\varepsilon)|,|\delta_p^\nu(\varepsilon)|\leqq H_1\cdot\exp\left[-2r_0^{m+1}/(m+1)\cdot\mathrm{Re}\left(\frac{1}{\varepsilon}\right)\right],\qquad (p=1,2,\cdots,2m).$$

That is

$$\begin{aligned}&\delta_p^1(\varepsilon)\approx;0 \quad \text{in } \arg\varepsilon=-\omega_0,\\ &\delta_p^\nu(\varepsilon)\approx;0 \quad \text{in } \arg\varepsilon=\omega_0 \quad (p=1,2,\cdots,2m).\end{aligned} \tag{6.23}$$

On the other hand, it holds that

$$A_{21}(b_p+\delta_p^l)-A_{21}(b_p)=O(\delta_p^l(\varepsilon)),$$
$$A_{21}(b_p)\approx;0.$$

Putting $l=1$, ν and using (6.23) and (6.20), we obtain

$$\begin{aligned}&g_1(\varepsilon)\cdot A_{21}(b_p+\delta_p^1)\approx;0 \quad \text{in } \arg\varepsilon=-\omega_0,\\ &g_\nu(\varepsilon)\cdot A_{21}(b_p+\delta_p^\nu)\approx;0 \quad \text{in } \arg\varepsilon=\omega_0.\end{aligned} \tag{6.24}$$

If we put $\phi_j(\varepsilon)=g_j(\varepsilon)\cdot A_{21}(b_p(\varepsilon)+\delta_p^j(\varepsilon))$ and apply Theorem 1.3 to (6.23) and (6.24), we can obtain

$$g_j(\varepsilon)\cdot A_{21}(b_p(\varepsilon)+\delta_p^j(\varepsilon))\approx;0 \quad \text{in } S_j.$$

That is

$$A_{21}(b_p(\varepsilon)+\delta_p^j(\varepsilon))\approx;0 \quad \text{in } S_j \quad (j=1,2,\cdots,\nu). \tag{6.25}$$

Here we used (6.20).

Now, by virtue of Cauchy's integral representation theorem, we can prove that

$$\begin{aligned}&|\{A_{21}(b_p(\varepsilon)+\delta_p^j(\varepsilon))-A_{21}(b_p(\varepsilon))\}\exp[2r_{r0}^{m+1}/(m+1)\varepsilon]|\\ &\leqq H\cdot\sum_{p=1}^{2m}|\delta_p^j(\varepsilon)|,\end{aligned} \tag{6.26}$$

where H is a positive number (cf. the proof of Lemma 3.1 in [8]).

We now return to (6.12) and (6.13), and use (6.25) and (6.26). Then we get

$$
\begin{aligned}
& c(\varepsilon)y^{\#}(x,\varepsilon)-\sum_{n=0}^{\infty}y_n(x)\varepsilon^n \\
&= c(\varepsilon)[\{A_{11}(b_p+\delta_p^j)-A_{11}(b_p)\}y_{m+1}(z,b,b_p+\delta_p^j) \\
&\qquad +A_{11}(b_p)\{y_{m+1}(z,b,b_p+\delta_p^j)-y_{m+1}(z,b,b_p)\}] \\
&\quad \cdot \exp\{+E(z,b_p)\}\cdot\exp[-E(z,b_p)+x^{m+1}/(m+1)\varepsilon] \\
&\quad +c(\varepsilon)[\{A_{21}(b_p+\delta_p^j)-A_{21}(b_p)\}y_{m+2}(z,b,b_p+\delta_p^j) \\
&\qquad +A_{21}(b_p)\{y_{m+2}(z,b,b_p+\delta_p^j)-y_{m+2}(z,b,b_p)\}] \\
&\quad \cdot \exp\{-E(z,b_p)\}\cdot\exp[+E(z,b_p)+x^{m+1}/(m+1)\varepsilon] \\
&= c(\varepsilon)\cdot O(\delta_p^j(\varepsilon))\cdot y_{m+1}(\cdot,\cdot,\cdot)\exp\{E(z,b_p)\}+c(\varepsilon)\cdot A_{11}(b_p)\cdot O(\delta_p^j(\varepsilon)) \\
&\quad +c(\varepsilon)\cdot O(\delta_p^j(\varepsilon))\cdot y_{m+2}(\cdot,\cdot,\cdot)\exp\{-E(z,b,b_p)\} \\
&\qquad +c(\varepsilon)\cdot A_{21}(b_p)\exp[2x^{m+1}/(m+1)\varepsilon]\cdot O(\delta_p^j(\varepsilon)) \\
&\simeq 0
\end{aligned}
$$

as $\varepsilon \to +0$ uniformly on $x<0$.

Thus we have proved that $c(\varepsilon)y^{\#}(x,\varepsilon)$ converges uniformly on a real interval to a nontrivial solution as ε tends to zero on the positive real axis.

Acknowledgment. I thank Professor Y. Sibuya for his suggestions contributing to this research.

REDUCTION TO CANONICAL FORMS AND THE STOKES PHENOMENON IN THE THEORY OF LINEAR DIFFERENCE EQUATIONS*

G. K. IMMINK†

Abstract. Previous results concerning the existence of right inverses of linear difference operators on Banach Spaces of holomorphic functions are extended. The Stokes phenomenon is analyzed for a class of very singular linear difference equations.

Key words. linear difference operator, right inverse, asymptotic expansion, canonical form, Stokes phenomenon, connection matrix

AMS(MOS) subject classification. 39A10

Introduction. This paper is concerned with homogeneous linear difference equations of the type

$$y(s+1)-A(s)y(s)=0, \tag{0.1}$$

where s is a complex variable and A is an $n\times n$ matrix function, meromorphic at ∞. More precisely, we shall assume that $A\in \mathrm{Gl}(n;\mathbb{C}\{s^{-1}\}[s])$, $n\in\mathbb{N}$. We are interested in the global asymptotic properties of solutions of (0.1), i.e., their behaviour as $s\to\infty$ in an arbitrary direction.

It should be noted here that, in general, solutions of (0.1) are not analytic in a (reduced) neighbourhood of ∞. However, it is easily seen from (0.1) that any solution, analytic in a left half plane, can be continued analytically to a region of the form $-U(R)$, where

$$U(R)=\{s\in\mathbb{C}: |s+x|\geqq R\forall x\geqq 0\},\qquad R>0. \tag{0.2}$$

Similarly, the relation

$$y(s)=A(s)^{-1}y(s+1)$$

implied by (0.1), shows that any solution, analytic in a right halfplane, can be continued analytically to a region of the form $U(R)$, $R>0$. Therefore, we shall consider the asymptotic behaviour of solutions of (0.1) in regions of either type.

The usual approach to this kind of problem is the following. First, the existence of fundamental solutions of the equation with a prescribed asymptotic behaviour, in different sectors covering a neighbourhood of ∞ is established. Next, the relations between these solutions are studied.

For example, let Y_1 and Y_2 be holomorphic fundamental solutions of (0.1), admitting the same asymptotic representation in a left and an upper halfplane, respectively. The connection matrix P is defined by

$$Y_1=Y_2P. \tag{0.3}$$

As $Y_1(s+1)Y_1(s)^{-1}=Y_2(s+1)Y_2(s)^{-1}=A(s)$, P is a periodic function of period 1. Obviously, (0.3) defines the analytic continuation of Y_1 to an upper halfplane and knowledge of P implies knowledge of the asymptotic behaviour of Y_1 in this upper half plane.

* Received by the editors March 23, 1988; accepted for publication (in revised form) March 12, 1990.

The asymptotic representations that play a role in the study of (0.1) are the so-called formal solutions of this equation. It is known that (0.1) possesses a formal fundamental solution of the form

$$\hat{Y}(s) = \hat{F}(s) \operatorname{diag}\{s^{G_1} \exp q_1(s), \cdots, s^{G_m} \exp q_m(s)\},$$

where $\hat{F} \in \mathrm{Gl}(n; \mathbb{C}[[s^{-1/p}]][s^{1/p}])$ for some $p \in \mathbb{N}$, $m \in \mathbb{N}(m \leqq n)$, G_j is a constant matrix and

$$q_j(s) = d_j s \log s + \sum_{h=1}^{p} \mu_{j,h} s^{h/p} \tag{0.4}$$

with $d_j \in \mathbb{Q}$ and $\mu_{j,h} \in \mathbb{C}$ for each $j \in \{1, \cdots, m\}$, $h \in \{1, \cdots, p\}$ (cf. [2], [13], [16]). All constants figuring in this representation are uniquely determined by the matrix function A, except for $\mu_{j,p}$, which is determined up to a multiple of $2\pi i$ (this is related to the fact that any matrix solution of (0.1), when multiplied from the right with a periodic matrix function, remains a solution of (0.1)).

If $d_i = d_j$ for all $i, j \in \{1, \cdots, m\}$, the numbers

$$\frac{1}{p} \operatorname{degr}(q_i - q_j)$$

will be called the "levels" of the difference equation. The most difficult case to deal with is when $d_i \neq d_j$ for at least one pair (i, j) with $i \neq j$. In this case we will say that the "level 1^+" is present in (0.1). If $d_i \neq d_j$ for all $i \neq j$, we shall, with a slight abuse of terminology, speak of a difference equation of level 1^+ (cf. [4]).

Existence theorems for solutions of homogeneous linear difference equations with a prescribed asymptotic behaviour have been the subject of various studies since the beginning of this century (cf. [1], [3], [5], [7], [12]). The most general result so far is a theorem by Birkhoff and Trjitzinsky (cf. [1]). It states that, in every quadrant Γ of the form

$$\Gamma = \left\{ s \in \mathbb{C}: k\frac{\pi}{2} \leqq \arg(s - s_0) \leqq (k+1)\frac{\pi}{2}; |s| \geqq R \right\}, \qquad k \in \mathbb{Z}, \quad s_0 \in \mathbb{C}, \quad R > 0,$$

there exists a holomorphic fundamental solution of (0.1), represented asymptotically by a given formal fundamental solution as $s \to \infty$ in Γ, provided R is sufficiently large. However, the proof of this result contains some inaccuracies and its correctness has been questioned.

In [7] we have derived existence theorems for both linear and nonlinear difference equations using a method developed by Hukuhara, Sibuya, Malgrange and others, for analogous problems in the theory of differential equations (cf. [6], [11], [14], [17]). It is based on the existence of right inverses of linear difference operators on Banach spaces of functions that are holomorphic in suitable ("proper") regions of the complex plane. Later we realized that the class of "proper" regions considered in [7], at least in the presence of level 1^+, was too restricted, and that our results could be easily extended. This is explained in § 2 of the present paper. These generalizations permit us to give a straightforward proof of the theorem of Birkhoff and Trjitzinsky, thereby settling the first half of our problem.

Next, we turn to the second part: the connection problem or Stokes phenomenon, i.e., the change in asymptotic behaviour of solutions of the equation, as they are continued analytically beyond certain "maximal regions." This phenomenon has been studied in [8], under "generic" conditions, and in particular the link with the theory of resurgent functions was explained. It is closely related to the problem of analytic

classification of difference equations, which has been solved by Ecalle in [4]. Nevertheless, the precise nature of the Stokes phenomenon in the most general case of (0.1) has remained somewhat mysterious. The results presented in § 2 also contribute to a better understanding of this phenomenon.

The maximal regions in which a solution of (0.1) may be represented asymptotically by a given formal solution are bounded by curves of the form

$$\operatorname{Re}\{q_i(s)-q_j(s)\}=c, \qquad i,j\in\{1,\cdots,m\}, \quad i\neq j.$$

We shall call these curves Stokes curves of level k if $d_i=d_j$ and $1/p \operatorname{degr}(q_i-q_j)=k$, and Stokes curves of level 1^+ if $d_i\neq d_j$. Due to the infinite number of possible determinations of the $\mu_{j,p}$ in (0.4), there is a countably infinite number of Stokes curves of the levels 1 and 1^+ (we do not distinguish between curves that differ only in the value of c). Whereas two Stokes curves of a level less than or equal to 1 generally have distinct limiting directions, those of level 1^+ all have the same limiting directions, viz. those of the positive and negative imaginary axis. This makes the analysis of the Stokes phenomenon more delicate in the presence of the level 1^+ than otherwise. In order to distinguish between different solutions, we must take into consideration their behaviour along curves of the type

$$\operatorname{Re} s(\log s+i\theta)=c, \qquad \theta\in\mathbb{R}.$$

Section 4 deals with the Stokes phenomenon of homogeneous linear difference equations of level 1^+. We study the properties of the periodic matrix functions connecting two fundamental solutions of (0.1) represented asymptotically by the formal fundamental solution in different maximal regions (a method to compute the leading parts of these connection matrices from the asymptotic behaviour of the coefficients of the formal fundamental solution is discussed in [9]).

Throughout this paper, we have restricted ourselves to "classical" asymptotic expansions, just as in [7], however, all statements remain valid (with slight modifications) when these expansions are replaced by asymptotic expansions with suitable Gevrey-type error bounds (cf. also [10]).

1. Definitions and notation.

1.1. Classes of holomorphic functions admitting an asymptotic power series representation. In order to describe the asymptotic properties of solutions of (0.1), we introduce families of closed unbounded regions of $\mathbb{C}$, indexed by a parameter $R\in\mathbb{R}^+$, which measures the distance to the origin. We define classes of holomorphic functions on these regions, admitting an asymptotic expansion with uniform error bounds.

We shall restrict our attention to subregions of $\mathbb{C}\backslash\mathbb{R}^-$. All results obtained for this type of regions can be easily "translated" into analogous statements for corresponding regions in $\mathbb{C}\backslash\mathbb{R}^+$, by means of the following equality:

$$y(s+1)-A(s)y(s)=-A(s)\{\tilde{y}(-s)-\tilde{A}(-s-1)\tilde{y}(-s-1)\},$$

where $\tilde{A}$ and $\tilde{y}$ are defined by

$$\tilde{A}(s)=A(-s-1)^{-1}, \qquad \tilde{y}(s)=y(-s).$$

DEFINITION 1.1.1. An asymptotic set S of closed regions is a decreasing set of closed unbounded regions $S(R)$ of the complex plane, defined for all $R>1$, with the property that $d(S(R),0)\to\infty$ as $R\to\infty$.

DEFINITION 1.1.2. Let I be an index set and let $S_i=\{S_i(R), R>1\}$ be an asymptotic set of closed regions for all $i\in I$. By $\bigcup_{i\in I} S_i$ and $\bigcap_{i\in I} S_i$ we shall denote

the sets

$$\left\{\bigcup_{i\in I} S_i(R),\ R>1\right\},\qquad \left\{\bigcap_{i\in I} S_i(R),\ R>1\right\},$$

respectively. A set of the first type will be called an asymptotic set.

If I is a finite set then $\bigcup_{i\in I} S_i$ is again an asymptotic set of closed regions. If, in addition, $\bigcap_{i\in I} S_i(R)\neq\emptyset$ for all $R>0$, then also $\bigcap_{i\in I} S_i$ is an asymptotic set of closed regions.

DEFINITION 1.1.3. Let S be an asymptotic set of closed regions. By $\mathcal{M}(S)$ we shall denote the set of all functions f on $\mathbb{C}$ with the following properties:

(i) There exists a positive number R such that f is continuous on $S(R)$ and holomorphic in int $S(R)$.

(ii) There exist an integer h_0, a positive integer p and complex numbers a_h, $h\in\mathbb{Z}$, such that, for all $N\in\mathbb{N}$,

$$\sup_{s\in S(R)}\left|s^{N/P}\left\{f(s)-\sum_{h=h_0}^{N-1} a_h s^{-h/p}\right\}\right|<\infty.$$

If these conditions are fulfilled we write

$$\sum_{h=h_0}^{\infty} a_h s^{-h/p}=\hat{f}\quad\text{and}\quad f\sim\tilde{f},\quad s\to\infty,\quad s\in S(R).$$

Remark. Different functions that coincide on $S(R)$ for some $R>0$, will be identified. More precisely, a "function" f is to be thought of as a representative of the equivalence class of all functions g with the property that there exists a positive number R such that $g(s)=f(s)$ for all $s\in S(R)$.

Let I be a finite index set and suppose that, for every $i\in I$, S_i is an asymptotic set of closed regions. Then, obviously, $\mathcal{M}(\bigcup_{i\in I} S_i)$ is contained in $\bigcap_{i\in I}\mathcal{M}(S_i)$. If, in addition, int $\bigcup_{i\in I} S_i(R)=\bigcup_{i\in I}$ int $S_i(R)$ for all $R>1$, then it immediately follows that $\mathcal{M}(\bigcup_{i\in I} S_i)=\bigcap_{i\in I}\mathcal{M}(S_i)$.

DEFINITION 1.1.4. Let I be an index set and, for every $i\in I$, let S_i be an asymptotic set of closed regions such that

$$\text{int}\bigcup_{i\in I} S_i(R)=\bigcup_{i\in I}\text{int}\,S_i(R)\quad\text{for all } R>1.$$

Let $S=\bigcup_{i\in I} S_i$. By $\mathcal{M}(S)$ we shall denote the set

$$\mathcal{M}(S)=\bigcap_{i\in I}\mathcal{M}(S_i),$$

by $\mathcal{A}(S)$ the set of all $f\in\mathcal{M}(S)$ such that

$$\hat{f}\in\bigcup_{p\in\mathbb{N}}\mathbb{C}[\![s^{-1/p}]\!],$$

and by $\mathcal{A}_0(S)$ the set of $f\in\mathcal{M}(S)$ with the property that $\hat{f}=0$.

In the following definition some particular examples of asymptotic sets are given.

DEFINITION 1.1.5. For all α_0, $\beta_0\in[-\pi,\pi]$ such that $\alpha_0<\beta_0$, we define the following asymptotic sets:

(i) The "closed sector" $S[\alpha_0,\beta_0]$ defined by

$$S[\alpha_0,\beta_0](R)=\{s\in\mathbb{C}\backslash\mathbb{R}^-\colon \alpha_0\leqq\arg(s+\mathrm{Re}^{i\alpha})\leqq\beta_0\text{ for all }\alpha\in[-\pi,\pi]\};$$

(ii) The "half-open sectors" $S[\alpha_0,\beta_0)=\bigcup_{\alpha_0<\beta<\beta_0} S[\alpha_0,\beta]$ and $S(\alpha_0,\beta_0]=\bigcup_{\alpha_0<\alpha<\beta_0} S[\alpha,\beta_0]$;

(iii) The "open sector" $S(\alpha_0,\beta_0)=\bigcup_{\alpha_0<\alpha<\beta<\beta_0} S[\alpha,\beta]$.

If S is any of the sectors defined in (ii) and (iii), then $\bar{S}$ will denote the closed sector $S[\alpha_0, \beta_0]$.

1.2. Canonical forms and formal invariants. We use the following notation:

$$K = \bigcup_{p \in N} \mathbb{C}\{s^{-1/p}\}[s^{1/p}], \qquad \hat{K} = \bigcup_{p \in \mathbb{N}} \mathbb{C}[\![s^{-1/p}]\!][s^{1/p}].$$

Let S be an asymptotic set. If $A \in \mathrm{End}(n; \mathcal{M}(S))$ and $F \in \mathrm{Gl}(n; \mathcal{M}(S))$, or $A \in \mathrm{End}(n; \hat{K})$ and $F \in \mathrm{Gl}(n; \hat{K})$ we shall denote by A^F the matrix function

$$A^F(s) = F(s+1)^{-1} A(s) F(s).$$

By Δ_A we shall denote the linear difference operator defined by

$$\Delta_A y(s) = y(s+1) - A(s) y(s),$$

where y belongs to a suitable space of n-dimensional vector functions.

Let $A, B \in \mathrm{Gl}(n; \mathcal{M}(S))$. The difference operators Δ_A and Δ_B are said to be formally equivalent if there exists a matrix function $F \in \mathrm{Gl}(n; \hat{K})$ with the property that

$$\hat{A}^F = \hat{B}.$$

If $A \in \mathrm{Gl}(n; \mathcal{M}(S))$ the difference operator Δ_A is known to be formally equivalent to a difference operator $\Delta_{\overset{c}{A}}$ of the following particular type. The matrix function $\overset{c}{A}$ is block diagonal,

$$\overset{c}{A} = \mathrm{diag}\{\overset{c}{A}_1, \cdots, \overset{c}{A}_m\}, \qquad m \in \mathbb{N}$$

with diagonal blocks of the form

$$\overset{c}{A}_j(s) = \exp\{q_j(s+1) - q_j(s)\}(1 + 1/s)^{G_j},$$

where, for $j \in \{1, \cdots, m\}$,

(1.2.1)
$$q_j(s) = d_j s \log s + \sum_{h=1}^{p} \mu_{j,h} s^{h/p}, \qquad p \in \mathbb{N}, \quad d_j \in \mathbb{Z}/p, \quad \mu_{j,1}, \cdots, \mu_{j,p} \in \mathbb{C},$$

$0 \leqq \mathrm{Im}\, \mu_{j,p} < 2\pi$, and

$G_j = \gamma_j I_{n_j} + N_j$, $\gamma_j \in \mathbb{C}$, $0 \leqq \mathrm{Re}\, \gamma_j < 1/p$, $n_j \in \mathbb{N}$, N_j is a nilpotent $n_j \times n_j$ matrix.

The matrix function $\overset{c}{A}$ is uniquely determined by A up to permutations of the diagonal blocks. We shall assume that the blocks are arranged in such a way that

$$d_i \leqq d_j \quad \text{if } i < j, \quad i, j \in \{1, \cdots, m\}.$$

DEFINITION 1.2.2. A matrix function $\overset{c}{A}$ with the above-mentioned properties will be called a canonical matrix or a canonical form of A.

The numbers d_j, γ_j, and $\mu_{j,h}$ ($j \in \{1, \cdots, m\}$, $h \in \{1, \cdots, p\}$) are formal invariants of the difference equation $\Delta_A y = 0$. They are uniquely determined by the matrix function A.

We shall further use the following notation:

$Q = \mathrm{diag}\{q_1 I_{n_1}, \cdots, q_m I_{n_m}\}$,

$\overset{c}{Y}(s) = e^{Q(s)} s^G$ (note that $\overset{c}{A}(s) = \overset{c}{Y}(s+1)\overset{c}{Y}(s)^{-1}$),

$d(A) = \{d_1, \cdots, d_m\}$,

$k(A) = \{\mathrm{degr}\, q_j : j \in \{1, \cdots, m\}$ such that $d_j = 0\}$ (degr q_j here is understood to be a rational number not exceeding 1).

DEFINITION 1.2.3. Let $k \in k(A)$, $k \neq 0$. By $\Sigma_k(A)$ we shall denote the set of all real numbers α with the property that there is a $j \in \{1, \cdots, m\}$ such that $d_j = 0$, degr $q_j = k$ and

$$\alpha = \frac{1}{k}\left(\frac{\pi}{2} - \arg \mu_{j,pk}\right) \quad \text{if } k \neq 1,$$

$$\alpha = \frac{\pi}{2} - \arg (\mu_{j,p} \bmod 2\pi i) \quad \text{if } k = 1.$$

Furthermore, we define: $\Sigma_0(A) = \varnothing$ and $\Sigma(A) = \bigcup_{k \in k(A)} \Sigma_k(A)$.

The elements of $\Sigma(A)$ are comparable to the Stokes directions in the theory of homogeneous linear differential equations.

DEFINITION 1.2.4. By $\theta(A)$ we shall denote the set of all real numbers θ with the property that there is a $j \in \{1, \cdots, m\}$ such that $d_j \neq 0$ and

$$d_j \theta = \operatorname{Im} \mu_{j,p} \bmod 2\pi.$$

The problem of transforming a given matrix function A into a canonical form $\overset{c}{A}$ is equivalent to that of finding a solution of the equation

$$Y(s+1) = A(s)\, Y(s) \overset{c}{A}(s)^{-1}$$

in some appropriate set of matrix functions Y. By $\sigma(A)$ we shall denote the matrix function corresponding to the linear mapping

$$Y \to A Y \overset{c}{A}^{-1}.$$

It is easily verified that $\sigma(\overset{c}{A})$ is a canonical form of $\sigma(A)$. Hence it follows, for example, that

$$d(\sigma(A)) = \{d - d' \colon d, d' \in d(A)\}.$$

It will often prove convenient to partition other matrices in the same way as a given canonical matrix $\overset{c}{A}$ (cf. (1.2.1)) associated with the particular problem under consideration. If M is an $n \times n$ matrix, the notation M_{ij} $(i, j \in \{1, \cdots, m\})$ will always refer to a block of M in that partition and not to a single matrix element.

2. Existence theorems.

2.1. Preliminaries. The following sections are mainly concerned with the existence of right inverses of linear difference operators Δ_A defined on Banach spaces of holomorphic functions of the type described in the definition below.

DEFINITION 2.1.1. Let $r \in \mathbb{R}$ and let G be a closed region of the complex plane. By $B_r(G)$ we denote the Banach space of all functions f with the following properties:

(i) f is continuous on G and holomorphic in int G;

(ii) $\|f\|_r \equiv \sup_{s \in G} |s^r f(s)| < \infty$.

If S is an asymptotic set of closed regions the following two statements are equivalent:

(i) $f \in \mathscr{A}_0(S)$;

(ii) There exists a positive number R such that $f \in B_r(S(R))$ for all $r \in \mathbb{R}$.

Let S be an asymptotic set of closed regions $S(R)$ with the additional property that $s \in S(R)$ implies $s+1 \in S(R)$ for all $R > 1$ and let $A \in \mathrm{Gl}(n; \mathscr{M}(S))$. It is easily seen that there exists a real number u such that the difference operator Δ_A maps $B_r(S(R))^n$ into $B_{r-u}(S(R))^n$ for all $r \in \mathbb{R}$ and all sufficiently large R.

DEFINITION 2.1.2. An asymptotic set of closed regions S is proper for the difference operator Δ if there exist real numbers r_0 and v, positive numbers R_0 and K, and linear mappings

$$\Lambda_{r,R} : B_r(S(R))^n \to B_{r-v}(S(R))^n$$

defined for all $r \geqq r_0$ and all $R \geqq R_0$ such that

(i) $\Delta\Lambda_{r,R} f = \Lambda_{r-u,R}\Delta f = f$ for all $f \in B_r(S(R))^n$,
(ii) $\|\Lambda_{r,R} f\|_{r-v} \leqq K\|f\|_r$,
(iii) If $r' > r \geqq r_0$, then $\Lambda_{r,R}|_{B_{r'}(S(R))^n} = \Lambda_{r',R}$.

2.2. The asymptotic sets S_θ. Let $C > 0$, $\theta \in \mathbb{R}$. We shall consider regions of the complex plane bounded by curves of the following type:

$$\sigma_C(\theta) = \{s \in \mathbb{C} : \operatorname{Re}(s \log s e^{i\theta}) = C\},$$

where $\log s$ has the principal value.

We begin by deriving some properties of these curves. First of all, note that a change from θ to $-\theta$ is equivalent to a reflection of $\sigma_C(\theta)$ with respect to the real axis. Therefore, we shall restrict the discussion to nonnegative values of θ.

If $|s| < 1$, then $\operatorname{Re} s \log|s| < 1/e$ and, consequently, $\operatorname{Re}(s \log s e^{i\theta}) < 1/e + \pi + \theta$. From now on we shall always assume that C is so large that $d(\sigma_C(\theta), 0) > 1$. We put

$$\operatorname{Im} s = x, \qquad \operatorname{Re} s = \rho.$$

On the set $V = \{(x, \rho) \in \mathbb{R}^2 : x \neq 0 \text{ if } \rho \leqq 0\}$ we define a function F by

$$F(x, \rho) = \rho \log\sqrt{(\rho^2 + x^2)} - x\{\arg(\rho + ix) + \theta\}.$$

By assumption, $F(x, \rho) < C$ for all (x, ρ) with the property that $\rho^2 + x^2 \leqq 1$. Furthermore, we have

$$D_\rho F(x, \rho) = 1 + \log\sqrt{(\rho^2 + x^2)}.$$

Consequently, $D_\rho F(x, \rho) > 1$ whenever $\rho^2 + x^2 \geqq 1$. Hence it follows that, for every $x \in \mathbb{R}$, there is a unique $\rho \in \mathbb{R}$ such that

$$F(x, \rho) = C. \tag{2.2.1}$$

Indicating this number by $\rho(x)$ and differentiating (2.2.1) with respect to x we obtain

$$\rho'(x) = \{\theta + \arg(\rho(x) + ix)\}\{1 + \log\sqrt{(\rho(x)^2 + x^2)}\}^{-1}, \qquad x \in (-\infty, \infty). \tag{2.2.2}$$

Obviously, the function $\rho(x)/x \log\sqrt{(\rho(x)^2 + x^2)}$ is bounded on $|x| > 1$ and hence

$$\rho(x) = O\left(\frac{x}{\log x}\right), \qquad |x| \to \infty. \tag{2.2.3}$$

For a more detailed description of the curve $\sigma_C(\theta)$ it is convenient to distinguish the following three cases.

Case 1. $0 \leqq \theta < \pi/2$. The corresponding class of curves (reflected with respect to the imaginary axis) has been studied in [7]. These curves are completely contained in the right halfplane $\rho > 0$. $\rho(x)$ has an absolute minimum which is attained when $\arg(\rho(x) + ix) = -\theta$. The symmetrical case ($\theta = 0$) is represented in Fig. 1.

Case 2. $\theta = \pi/2$. In this case $\rho'(x)$ is positive for all $x \in \mathbb{R}$, but tends to 0 as $x \to -\infty$. The curve $\sigma_C(\pi/2)$ is contained in the right halfplane $\rho > 0$ and is asymptotic to the negative imaginary axis. It is easily seen that $\rho(x) = O(1/\log x)$ as $x \to -\infty$ (see Fig. 2).

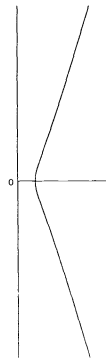

FIG. 1

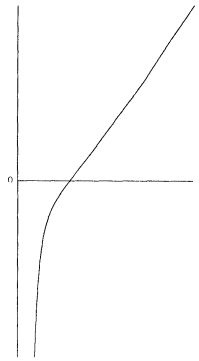

FIG. 2

Case 3. $\theta > \pi/2$. The curves in this class intersect the negative imaginary axis at $x = -C(\theta - \pi/2)^{-1}$. Furthermore, we have

$$\arg(\rho(x) + ix) + \theta > 0 \quad \text{for all } x \in \mathbb{R}$$

in this case, as can be seen from the following argument. Suppose that $\arg(\rho(x) + ix) + \theta < 0$ for some $x < 0$. This would imply that

$$\rho(x) \log \sqrt{(\rho(x)^2 + x^2)} = C + x\{\arg(\rho(x) + ix) + \theta\} > 0,$$

but this is in contradiction with the fact that $\arg(\rho(x) + ix) < -\theta < -\pi/2$ and, consequently, $\rho(x) < 0$. Hence, by (2.2.2), it follows that $\rho'(x) > 0$ for all $x \in \mathbb{R}$ (see Fig. 3).

Now let $\theta \in \mathbb{R}$ and $R > 1$. By $C(\theta, R)$ we shall denote the value of C such that $d(\sigma_C(\theta), 0) = R$.

DEFINITION 2.2.4. Let $\theta \in \mathbb{R}$. S will denote the asymptotic set of closed regions $\{S_\theta(R), R > 1\}$, where

$$S_\theta(R) = \{s \in \mathbb{C}: \operatorname{Re}(s \log s\, e^{i\theta}) \geqq C(\theta, R)\}.$$

Furthermore, we shall put

$$S(-\pi, 0] = S_\infty, \quad S[0, \pi) = S_{-\infty}, \quad S(0, \pi] = \tilde{S}_\infty, \quad S[-\pi, 0) = \tilde{S}_{-\infty}.$$

2.3. Proper asymptotic sets. Let $\theta \in \mathbb{R}$ and $\Delta = \Delta_A$, where $A \in \mathrm{Gl}(n, \mathcal{M}(S_\theta))$. In order to prove the existence of linear mappings $\Lambda_{r,R}$ defined on the Banach spaces $B_r(S_\theta(R))^n$ and possessing the properties mentioned in Definition 2.1.2, we proceed exactly as in [7, § 12]. Thus we obtain the following addition to Proposition 4.12 in [7].

PROPOSITION 2.3.1. *Let $S = \bigcup_{\theta \in [\alpha, \beta]} S_\theta$, where α and β are real numbers such that $\alpha \leqq \beta$. Let $A \in \mathrm{Gl}(n; \mathcal{M}(S))$ and assume that*

(i) $[\pi/2 - \pi/k, -\pi/2] \cap \Sigma_k(A) = \varnothing$ *for all* $k \in k(A)$ *such that* $k \neq 0$;

(ii) $[\alpha, \beta] \cap \theta(A) = \varnothing$.

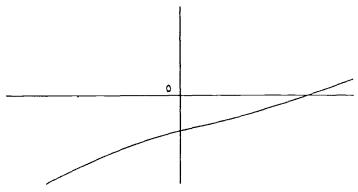

FIG. 3

Then S is proper for the difference operator Δ_A.

The next proposition is concerned with the cases $S=\bar{S}_\infty$ and $S=\bar{S}_{-\infty}$ (note that $\bar{S}_\infty$ is the set of lower halfplanes $\{s\in\mathbb{C}: \operatorname{Im} s\leqq -R\}$, $R>1$, whereas $\bar{S}_{-\infty}$ is a set of upper halfplanes). Although it shows some resemblance to Proposition 4.16 in [7], the assumptions made here are much more restrictive and therefore a stronger statement can be made.

PROPOSITION 2.3.2. *Let $S=\bar{S}_\infty$ or $S=\bar{S}_{-\infty}$ and $A\in \mathrm{Gl}(n;\mathcal{M}(S))$. Assume that there exists a positive number α less than 1 and a positive number R_0 such that, for all $s\in S(R_0)$ either of the following inequalities holds:*

$$|A(s)|\leqq\alpha \quad \text{or} \quad |A(s)^{-1}|\leqq\alpha.$$

Then S is proper for the difference operator Δ_A.

Proof. Without loss of generality we may assume that A is continuous on $S(R_0)$ and holomorphic in int $S(R_0)$. For every $R\geqq R_0$ and $r\geqq 0$ we define a linear mapping $\Lambda_{r,R}$ by either of the following expressions: for all $f\in B_r(S(R))^n$,

(i) $\Lambda_{r,R}f(s)=f(s-1)+\sum_{h=1}^{\infty}A(s-1)\cdots A(s-h)f(s-h-1)$ if the first inequality holds, and

(ii) $\Lambda_{r,R}f(s)=-\sum_{h=0}^{\infty}A(s)^{-1}\cdots A(s+h)^{-1}f(s+h)$ if the second inequality holds.

Consider the first case. For all $s\in S(R)$ we have

$$|s^r\Lambda_{r,R}f(s)|\leqq\sum_{h=0}^{\infty}\alpha^h\left|\frac{s}{s-h-1}\right|^r\sup_{s\in S(R)}|s^rf(s)|$$

hence

$$\|\Lambda_{r,R}f\|_r\leqq\sum_{h=0}^{\infty}\alpha^h\left(1+\frac{h+1}{R_0}\right)^r\|f\|_r.$$

With the aid of these estimates we readily verify that the mappings $\Lambda_{r,R}$ possess the required properties. The second case can be dealt with analogously.

2.4. Analytic simplification of linear difference operators. Propositions 2.3.1 and 2.3.2 can be used to derive existence theorems for solutions of nonlinear difference equations, admitting asymptotic power series expansions in appropriate regions of the complex plane. These, in their turn, can be applied to achieve analytic simplification of homogeneous linear difference systems. Thus, for example, the statements made in Theorems 15.16 (concerning a class of nonlinear equations) and 17.13 (on block diagonalization) of [7] can now be extended immediately to all proper asymptotic sets mentioned in Proposition 2.3.1. We shall not explicitly state the generalized versions of these theorems here, but refer the reader to [7].

One immediate consequence of Proposition 2.3.1 is the following theorem.

THEOREM 2.4.1. *Let $S=\bigcup_{\theta\in[\alpha,\beta]}S_\theta$, where α and β are real numbers such that $\alpha\leqq\beta$. Let $A\in\mathrm{Gl}(n;\mathcal{M}(S))$, let $\overset{c}{A}$ be a canonical form of A, and let $\Phi\in\mathrm{Gl}(n;\hat{K})$ such that $A^{\Phi}=\overset{c}{A}$. Furthermore, assume that*

(i) $[\pi/2-\pi/k,\pi/2]\cap\Sigma_k(\sigma(A))=\varnothing$ *for all $k\in k(\sigma(A))$ such that $k\neq 0$;*

(ii) $[\alpha,\beta]\cap\theta(\sigma(A))=\varnothing$.

Then there exists a unique matrix function $F\in\mathrm{Gl}(n;\mathcal{M}(S))$ such that $\hat{F}=\Phi$ and $A^F=\overset{c}{A}$.

With the aid of the above-mentioned extension of Theorem 17.13 in [7] the following result is obtained.

THEOREM 2.4.2. *Let $A\in\mathrm{Gl}(n;\mathcal{M}(S(-\pi,\pi)))$ and let $\overset{c}{A}$ be a canonical form of A.*

(i) *If* $-\pi/2 \notin \Sigma(\sigma(A))$ *there exists a matrix function* $F \in \mathrm{Gl}\,(n; \mathcal{M}(S[-\pi/2, \pi/2)))$ *such that* $A^F = \overset{c}{A}$.

(ii) *If* $\pi/2 \notin \Sigma(\sigma(A))$ *there exists a matrix function* $F \in \mathrm{Gl}\,(n; \mathcal{M}(S(-\pi/2, \pi/2])))$ *such that* $A^F = \overset{c}{A}$.

Remark. The condition $A \in \mathrm{Gl}\,(n; \mathcal{M}(S(-\pi, \pi)))$ may be replaced by $A \in \mathrm{Gl}\,(n; \mathcal{M}(S_\theta))$ *for some* θ *greater than* $\pi/2$ in case (i) or less than $-\pi/2$ in case (ii).

The proof of Theorem 2.4.2 is roughly analogous to that of Theorem 18.13 in [7]. The difference with the latter theorem consists in the fact that here the asymptotic expansion of the matrix function F is also valid as $s \to \infty$ in the direction of the negative (case (i)) or positive (case (ii)) imaginary axis. The asymptotic behaviour of F in the opposite direction can be deduced from the following lemma (by identifying F with a vector solution of the equation $\Delta_{\sigma(A)} y = 0$).

LEMMA 2.4.3. *Let* $\theta \in \mathbb{R}$ *and* $A \in \mathrm{Gl}\,(n; \mathcal{M}(S_\theta \cup S[-\pi/2, \pi/2]))$. *Assume that* f *is a solution of the equation* $\Delta_A y = 0$ *with the following properties*:

(i) f *is continuous on the set* $S_\theta(R) \cup S[-\pi/2, \pi/2](R)$ *and holomorphic in its interior, for some* $R > 0$.

(ii) f *grows at most exponentially of order* 1 *as* $s \to \infty$ *in* $S_\theta(R)$. *Then* f *grows at most exponentially of order* 1 *as* $s \to \infty$ *in* $S[-\pi/2, \pi/2](R)$ *provided* R *is sufficiently large.*

Proof. Let $s \in S[-\pi/2, \pi/2](R)$ and suppose that $|\mathrm{Im}\, s| > e$ and $s \notin S_\theta(R)$. Let $n(s)$ be the smallest integer such that $s + n(s) \in S_\theta(R)$. Suppose that R is so large that A^{-1} is continuous on the set $S_\theta(R) \cup S[-\pi/2, \pi/2](R)$ and holomorphic in its interior. Then we have

$$y(s) = A(s)^{-1} A(s+1)^{-1} \cdots A(s+n(s)-1)^{-1} y(s+n(s)).$$

By assumption, there exist positive numbers c and C such that, for all $\zeta \in S_\theta(R)$,

$$|y(\zeta)| \leqq C e^{c|\zeta|}.$$

Moreover, there exist positive constants d and D such that, for all $\zeta \in S_\theta(R) \cup S[-\pi/2, \pi/2](R)$,

$$|A(\zeta)^{-1}| \leqq D|\zeta|^d.$$

Hence it follows that

$$|y(s)| \leqq C D^{n(s)} |s + n(s)|^{dn(s)}\, e^{c|s+n(s)|}. \tag{2.4.4}$$

According to (2.2.3) there exists a positive constant K, independent of s, such that

$$\mathrm{Re}\,(s + n(s)) \leqq K \frac{|\mathrm{Im}\, s|}{\log |\mathrm{Im}\, s|}.$$

Since $|\mathrm{Im}\, s| > e$, this implies that

$$|s + n(s)| \leqq (K+1)|\mathrm{Im}\, s|.$$

Hence

$$n(s) \log |s + n(s)| \leqq K |\mathrm{Im}\, s| \{1 + \log (K+1)\}.$$

The proof is completed by inserting the last two estimates into (2.4.4).

The next two theorems are based on Proposition 2.3.2. They can be proved by the familiar method of successive block diagonalizing transformations. The existence (and uniqueness) of these transformations can be deduced from Proposition 2.3.2 in the usual manner.

THEOREM 2.4.5. *Let* $S = \bar{S}_\infty$ *or* $\bar{S}_{-\infty}$, *let* $A \in \mathrm{Gl}\,(n; \mathcal{M}(S))$, *and let* $\overset{c}{A}$ *be a canonical form of* A *of the form* (1.2.1). *Assume that, for all* $i, j \in \{1, \cdots, m\}$ *such that* $i \neq j$ *and* $d_i = d_j$,

$$\mathrm{degr}\, \mathrm{Re}\,(q_i - q_j) = 1.$$

Then there exists a matrix function $F \in \mathrm{Gl}(n; \mathcal{M}(S))$ *such that*

$$A^F(s) = \overset{c}{A}(s)(I_n + s^{-r}B(s))$$

where $r \in \mathbb{Q}$, $r > 1$, $B \in \mathrm{End}(n; \mathcal{A}(S))$, *and* $B = \mathrm{diag}\{B_{11}, \cdots, B_{mm}\}$. *Moreover, this matrix function* F *is determined uniquely by its asymptotic expansion.*

A complete reduction of A to the canonical form in general is possible only if we drop the requirement that the asymptotic expansion of F be valid as $s \to \infty$ in both horizontal directions. The following theorem will be needed in § 4.

THEOREM 2.4.6. *Let* $S \in \{S_\infty, S_{-\infty}, \tilde{S}_\infty, \tilde{S}_{-\infty}\}$. *Let* $A \in \mathrm{Gl}(n; \mathcal{M}(\bar{S}))$ *and let* $\overset{c}{A}$ *be a canonical form of* A. *Assume that the conditions of Theorem* 2.4.5 *are satisfied. For every* $\Phi \in \mathrm{Gl}(n; \hat{K})$ *such that* $A^\Phi = \overset{c}{A}$, *there exists a unique matrix function* $F \in \mathrm{Gl}(n; \mathcal{M}(S))$ *with the following properties*:

(i) $A^F = \overset{c}{A}$ *and* $\hat{F} = \Phi$;

(ii) *There exist positive numbers* k *and* R *such that both* $F(s) = O(s^k)$ *and* $F(s)^{-1} = O(s^k)$, $s \to \infty$, $s \in \bar{S}(R)$.

Remark. If A is upper or lower block triangular in the usual partition, then the same is true of F.

3. A result of Birkhoff and Trjitzinsky. Let $A \in \mathrm{Gl}(n; \mathbb{C}\{s^{-1}\}[s])$, or, more generally, $A \in \mathrm{Gl}(n; K)$, and let $\overset{c}{A}$ be a canonical form of A. As we mentioned in § 1.2, there exists a matrix function $\Phi \in \mathrm{Gl}(n; \hat{K})$ with the property that

$$A^\Phi = \overset{c}{A}.$$

This section deals with the following problem.

If α is any direction in the complex plane, does there exist a matrix function F, analytic in a sector containing a half-line with direction α, such that

$$A^F = \overset{c}{A} \quad \text{and} \quad \hat{F} = \Phi?$$

So far we have been able to answer this question in the affirmative for all directions except those of the positive and negative imaginary axis. In order to include the latter directions we had to impose a rather mild condition, viz. that either $d(\sigma(A)) = \{0\}$, or else that 0 or π or both $-\pi/2$ and $\pi/2$ do not belong to $\Sigma(\sigma(A))$ (cf. Theorem 2.4.2 above and Theorem 18.18 in [7]). It is the purpose of this section to remove this last restrictive condition.

DEFINITION 3.1. A quadrant Γ is an asymptotic set of closed regions $\Gamma(R)$ $(R > 1)$ of the following type:

$$\Gamma(R) = \left\{ s \in \mathbb{C} : \alpha \leqq \arg(s - s_0) \leqq \alpha + \frac{\pi}{2}, |s| \geqq R \right\},$$

where $s_0 \in \mathbb{C}$, $\alpha = l(\pi/2)$, $l \in \mathbb{Z}$.

THEOREM 3.2. *Let* $A \in \mathrm{Gl}(n; K)$ *and let* $\overset{c}{A}$ *be a canonical form of* A. *Let* Γ *be any quadrant. There exists a matrix function* $F \in \mathrm{Gl}(n; \mathcal{M}(\Gamma))$ *such that*

$$A^F = \overset{c}{A}.$$

As a matter of fact this theorem was proved by Birkhoff and Trjitzinsky in [1]. Unfortunately, their methods are not very transparent and the argument is very hard

to follow. Here we have tried to remedy certain inaccuracies contained in this paper and have sketched a considerably simplified version of their proof.

We shall consider the case that $\alpha = -\pi/2$. All other cases can be proved analogously.

The proof consists of two steps. The first step is to carry the matrix function A into a block-triangular form by a suitable transformation. In the paper by Birkhoff and Trjitzinsky this is achieved by a rather particular method which has been exposed in earlier papers by Birkhoff alone. It is quite different from the one we used in [7], but the results are essentially the same. These can be stated as follows (cf. Lemma 9 of [1]).

PROPOSITION 3.3. *Let* $\hat{S}_0 = S(-\pi, \pi)$ *and* $A \in \mathrm{Gl}(n; \mathscr{M}(\hat{S}_0))$. *Let* $\overset{c}{A}$ *be a canonical form of* A. *There exists a matrix function* $F_1 \in \mathrm{Gl}(n; \mathscr{M}(\hat{S}_0))$ *such that*

$$A^{F_1} = \overset{c}{A}(I_n + s^{-r}B(s)),$$

where $r > 1$, $B \in \mathrm{End}(n; \mathscr{A}(\hat{S}_0))$ *and* $B_{ij} \equiv 0$ *if* $i > j$, $i, j \in \{1, \cdots, m\}$.

For the proof of this proposition we refer the reader to Proposition 18.15 of [7].

The second and more delicate step is the final transformation of A^{F_1} into $\overset{c}{A}$. Put $A^{F_1} = A_1$. We now search a matrix function $F \in \mathrm{Gl}(n; \mathscr{A}(\Gamma))$ with the following properties:

(i) $A_1^F = \overset{c}{A}$;

(ii) $F_{ij} \equiv 0$ if $i > j$, $i, j \in \{1, \cdots, m\}$.

If $j \in \{1, \cdots, m\}$ and $i \leqq j$, the block F_{ij} must satisfy the following inhomogeneous difference equation:

$$Z(s+1) = (A_1)_{ii}(s)Z(s)\overset{c}{A}_j(s)^{-1} + \sum_{i<h\leqq j} (A_1)_{ih}(s)F_{hj}(s)\overset{c}{A}_j(s)^{-1}. \tag{3.4}$$

For every $j > 1$ there are j equations that we can solve successively, beginning with F_{jj}, then $F_{j-1\,j}$, etc. First, let us suppose that $d_i = d_j$ for some $i < j$. As $d_l \leqq d_j$ for all $l < j$, it follows that $d_l = d_j$ for all l such that $i \leqq l \leqq j$.

LEMMA 3.5. *Let* $i \leqq j$ *and assume that* $d_i = d_j$. *Then there exists a number* $\varepsilon \in (0, \pi/2)$ *and, for every* l *such that* $i \leqq l \leqq j$, *a matrix function* $F_{lj} \in \mathrm{Hom}(\mathscr{A}(\hat{S}_\varepsilon)^{n_j}, \mathscr{A}(\hat{S}_\varepsilon)^{n_l})$, *where* $\hat{S}_\varepsilon = S(-\pi + \varepsilon, \varepsilon)$, *satisfying* (3.4) *with* i *replaced by* l.

The statement above can easily be deduced from Theorem 15.1 of [7] by means of induction on $j - l$. If $d_i = d_j$ for all $i, j \in \{1, \cdots, m\}$ the assertion of Theorem 3.2 follows immediately. Now suppose that $d_i < d_j$ for some $j \in \{1, \cdots, m\}$ and some $i < j$. Consequently, $d_l < d_j$ for all $l \leqq i$. In that case the proof is completed by repeated application of Lemma 3.7 below.

DEFINITION 3.6. Let $\theta, x_0 \in \mathbb{R}$. By Γ_{θ,x_0} we shall denote the asymptotic set of closed regions $\Gamma_{\theta,x_0}(R)$ $(R > 1)$ defined by

$$\Gamma_{\theta,x_0}(R) = \{s \in S_\theta(R) : \mathrm{Im}\, s \leqq x_0\}.$$

LEMMA 3.7. *Let* $\theta, x_0 \in \mathbb{R}$, $B \in \mathrm{End}(n; \mathscr{A}(\Gamma_{\theta,x_0}))$, *and* $h \in (\mathscr{A}(\Gamma_{\theta,x_0}))^n$. *Let*

$$A(s) = \exp\{q(s+1) - q(s)\}(I_n + s^{-1}B(s)),$$

where $q(s) = ds \log s + \sum_{h=1}^{p} \mu_h s^{h/p}$, $p \in \mathbb{N}$, $d \in \mathbb{Z}/p$, $\mu_h \in \mathbb{C}$ *for all* $h \in \{1, \cdots, p\}$. *Suppose that* $d < 0$ *and* $d\theta \neq \mathrm{Im}\, \mu_p \bmod 2\pi$. *Then the equation*

$$\Delta_A y = h \tag{3.8}$$

possesses a solution $y \in \bigcap_{x<x_0} \mathscr{A}(\Gamma_{\theta,x})^n$.

Proof. The homogeneous equation $\Delta_A y = 0$ possesses a fundamental matrix Y of the form

$$Y(s) = Z(s)s^G e^{q(s)},$$

where G is a constant matrix and $Z \in \mathrm{Gl}(n; \mathscr{A}(\Gamma_{\theta,x_0}))$. Since, by assumption, $\theta \neq 1/d$ ($\mathrm{Im}\ \mu_p \bmod 2\pi$) and as μ_p obviously is determined modulo $2\pi i$ by A, we may assume that

$$d\theta < \mathrm{Im}\ \mu_p < d\theta + 2\pi.$$

Let R be a positive number such that Z is holomorphic in $\mathrm{int}\,\Gamma_{\theta,x_0}(R)$ and represented asymptotically by $\hat{Z}$ as $s \to \infty$ in $\Gamma_{\theta,x_0}(R)$. Let s_0 denote the point on the boundary of $S_\theta(R)$ with the property that $\mathrm{Im}\ s_0 = x_0$. Consider the linear mapping Λ of $B_0(\Gamma_{\theta,x_0}(R))$ (cf. Definition 2.1.1) defined by the following formula:

$$\Lambda f(s) = Y(s) \int_{C(s)} d\zeta \frac{Y(\zeta+1)^{-1} f(\zeta)}{1-\exp\{2\pi i(s-\zeta)\}} + A(s)^{-1} f(s),$$

where $f \in B_0(\Gamma_{\theta,x_0}(R))$, $s \in \Gamma_{\theta,x_0}(R)$ such that $\mathrm{Im}\ s < x_0$ and $C(s)$ is a path going from s_0 to infinity in such a way that it intersects the line $\mathrm{Im}\ \zeta = \mathrm{Im}\ s$ exactly once, in a point between s and $s+1$.

It can easily be verified that the vector function Λh is a solution of the equation (3.8). In order to prove that it has the desired asymptotic properties, we shall show that, for all $r > 0$ and all $x < x_0$, Λ maps the Banach space $B_r(\Gamma_{\theta,x_0}(R))$ into $B_{r+v}(\Gamma_{\theta,x}(R))$, where v is some fixed real number.

For all $s \in \Gamma_{\theta,x_0}(R)$ let s' denote the point on the boundary of Γ_{θ,x_0} with the property that

$$\mathrm{Re}\,(s' \log s' e^{i\theta}) = \mathrm{Re}\,\{(s+\tfrac{1}{2}) \log (s+\tfrac{1}{2})\, e^{i\theta}\}.$$

Let $C_1(s)$ be the path from ∞ to s' such that

$$\mathrm{Re}\,(\zeta \log \zeta e^{i\theta}) = \mathrm{Re}\,(s' \log s'\, e^{i\theta}), \qquad \zeta \in C_1(s)$$

and let $C_2(s)$ denote the directed line segment from s' to s_0 (see Fig. 4). Let $r > 0$, $x < x_0$, and $f \in B_r(\Gamma_{\theta,x}(R))$. Putting

$$Y(s) \int_{C_i(s)} d\zeta \frac{Y(\zeta+1)^{-1} f(\zeta)}{1-\exp\{2\pi i(s-\zeta)\}} = I_i(s), \qquad i = 1, 2$$

we have

$$\Lambda f(s) = I_1(s) + I_2(s) + A(s)^{-1} f(s). \tag{3.9}$$

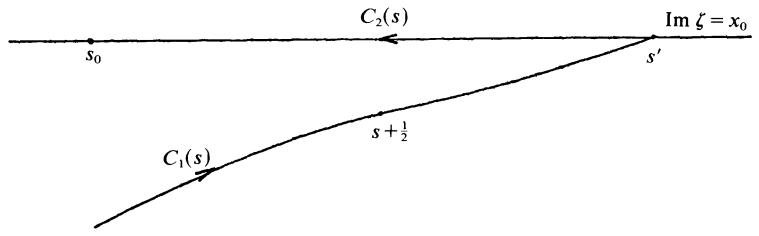

FIG. 4

The second term may be written as follows:

$$I_2(s) = Y(s)\,Y(s')^{-1} \exp\{2\pi i(s'-s)\} \exp\{2\pi i(s-s')\} I_2(s'). \tag{3.10}$$

Noting that, for all $s \in \Gamma_{\theta,x}(R)$ and all $\zeta \in C_2(s)$,

$$\left| \frac{\exp\{2\pi i(s-s')\}}{1-\exp\{2\pi i(s-\zeta)\}} \right| = |\exp\{-2\pi i(s-\zeta)\}-1|^{-1} \leqq [1-\exp\{2\pi(x-x_0)\}]^{-1}$$

and taking into account the rapid decrease of $Y(\zeta+1)^{-1}$ along $C_2(s)$ we readily verify that

$$\sup_{s \in \Gamma_{\theta,x}(R)} |(s')^{r+d} \exp\{2\pi i(s-s')\} I_2(s')| < \infty.$$

The term $I_1(s)$ in (3.9) and the product

$$Y(s)\,Y(s')^{-1} \exp\{2\pi i(s'-s)\}$$

in (3.10) can be dealt with by the methods used in [7, § 12]. Indeed, the integral $I_1(s)$ is similar to the one figuring in (12.2) of [7], where the above product can be estimated in much the same way as the integrand of $I_+(s)$ defined on p. 71 of [7]. Thus we find that $\Lambda f \in B_{r+d}(\Gamma_{\theta,x}(R))$, provided R is sufficiently large. Hence it follows that $\Lambda h \in \mathscr{A}(\Gamma_{\theta,x})^n$ for all $x < x_0$. This concludes the proof of the lemma.

Remark. With the aid of Lemma 3.7 we can prove a slightly stronger statement than the one made in Theorem 3.2, namely, the existence, for all $x \in \mathbb{R}$ and all $\theta \notin \theta(\sigma(A))$, of a matrix function $F \in \mathrm{Gl}\,(n; \mathscr{M}(\Gamma_{\theta,x}))$ with the property that $A^F = \overset{c}{A}$.

4. The Stokes phenomenon.

4.1. A preliminary transformation. In the remaining sections we shall determine the "maximal asymptotic sets" for and study the connection between different fundamental matrix solutions of the linear homogeneous difference equation

$$\Delta_A y = 0 \tag{4.1.1}$$

where $A \in \mathrm{Gl}\,(n; \mathbb{C}\{s^{-1}\}[s])$.

In order to avoid the complications caused by the intermingling of different types of Stokes phenomena (associated with different levels) we shall make the simplifying assumption that the set $d(A)$ defined in § 1.2 has m distinct elements.

Let $\overset{c}{A}$ be a canonical form of A and let U denote the asymptotic set of closed regions $U(R)(R>1)$, defined by (0.2). According to Theorem 18.16 in [7] there exists a matrix function $T \in \mathrm{Gl}\,(n; \mathscr{M}(U))$ such that

$$A^T(s) = \overset{c}{A}(s)(I_n + s^{-r}B(s)),$$

where $r>1$, $B \in \mathrm{End}\,(n; \mathscr{A}(U))$ and $B_{ij} \equiv 0$ if $i>j$, $i, j \in \{1, \cdots, m\}$. (Actually, Theorem 18.16 only states the existence of matrix functions $T_1 \in \mathrm{Gl}\,(n; \mathscr{M}(S[-\pi, \pi))$ and $T_2 \in \mathrm{Gl}\,(n; \mathscr{M}(S(-\pi, \pi]))$ with analogous properties, but these can be seen to coincide in some sector, provided $\hat{T}_1 = \hat{T}_2$.) Let S be an asymptotic set of closed regions with the property that $S(R) \subset U(R)$ for all $R>1$. In the following sections we shall consider fundamental matrix solutions of (4.1.1) of the form

$$Y = TF\overset{c}{Y},$$

where F is a solution of the equation

$$Z(s+1) = A^T(s)Z(s)\overset{c}{A}(s)^{-1} \tag{4.1.2}$$

with the properties that $F \in \mathrm{Gl}(n; \mathscr{A}(S))$, $F(\infty) = I_n$, and $F_{ij} \equiv 0$ if $i > j$, $i, j \in \{1, \cdots, m\}$.

4.2. Connection matrices. Let G_1 and G_2 be open regions in $U(1)$ such that $G_1 \cap G_2 \neq \emptyset$. Let F_1 and F_2 be solutions of (4.1.2), holomorphic in G_1 and G_2, respectively.

DEFINITION 4.2.1. The connection matrix of the pair (F_1, F_2) is the matrix function P defined by the expression

$$P = \overset{c}{Y}^{-1} F_1^{-1} F_2 \overset{c}{Y}.$$

Obviously, P is a periodic matrix function of period 1. If both F_1 and F_2 are upper block-triangular in the usual partition, then so is P.

In what follows we shall always be concerned with the case that one of the two regions G_1 and G_2 is a lower or an upper halfplane. It can easily be verified that (4.1.2) possesses a unique formal solution $\sum_{h=0}^{\infty} F_h s^{-h/p} (p \in \mathbb{N})$, with the property that $F_0 = I_n$. Hence, according to Theorem 2.4.6, there exist four unique matrix functions

$$F^{\infty} \in \mathrm{Gl}(n; \mathscr{A}(S_{\infty})), \qquad F^{-\infty} \in \mathrm{Gl}(n; \mathscr{A}(S_{-\infty})),$$
$$\tilde{F}^{\infty} \in \mathrm{Gl}(n; \mathscr{A}(\tilde{S}_{\infty})), \qquad \tilde{F}^{-\infty} \in \mathrm{Gl}(n; \mathscr{A}(\tilde{S}_{-\infty})),$$

with the properties mentioned in the theorem. Moreover, all four matrix functions are upper block triangular (cf. the remark below Theorem 2.4.6). Let P^{∞} and $P^{-\infty}$ denote the connection matrices of the pairs $(F^{\infty}, \tilde{F}^{-\infty})$ and $(F^{-\infty}, \tilde{F}^{\infty})$, respectively. Obviously, these too are upper block triangular. Let $\overset{c}{A}$ have the form (1.2.1). For all $i, j \in \{1, \cdots, m\}$ we have

$$P_{ij}^{\infty}(s) = \exp(q_j(s) - q_i(s)) s^{-G_i} (F^{\infty}(s)^{-1} \tilde{F}^{-\infty}(s))_{ij} s^{G_j}.$$

If $i < j$, due to the fact that $d_i < d_j$, the first factor on the right-hand side of this identity decreases very rapidly as $\mathrm{Re}\, s \to -\infty$. In view of the growth properties of F^{∞} and $\tilde{F}^{-\infty}$ this implies that P_{ij}^{∞} tends to zero as $\mathrm{Re}\, s \to -\infty$ and hence must vanish identically.

Similarly, it can be seen that $P_{ij}^{-\infty} \equiv 0$ if $i \neq j$. Now consider the diagonal blocks F_{ii}^{∞} and $\tilde{F}_{ii}^{-\infty}$, $i \in \{1, \cdots, m\}$. Both satisfy the equation

$$Z(s+1) = A_{ii}^{T}(s) Z(s) \overset{c}{A}_i(s)^{-1}$$
$$= \left(1 + \frac{1}{s}\right)^{N_i} (I_{n_i} + s^{-r} B_{ii}(s)) Z(s) \left(1 + \frac{1}{s}\right)^{-N_i}.$$

This equation has a solution $F_i \in \mathrm{Gl}(n_i; \mathscr{A}(S(-\pi, \pi)))$ represented by the infinite product

$$F_i(s) = s^{N_i} \prod_{n=0}^{\infty} (I_{n_i} + B_i(s+n))^{-1} s^{-N_i}, \qquad s \in U(R_0) \tag{4.2.2}$$

and a solution $\tilde{F}_i \in \mathrm{Gl}(n_i; \mathscr{A}(\tilde{S}_{\infty}) \cap \mathscr{A}(\tilde{S}_{-\infty}))$ represented by

$$\tilde{F}_i(s) = s^{N_i} \prod_{n=1}^{\infty} (I_{n_i} + B_i(s-n)) s^{-N_i}, \qquad s \in \bar{S}_{\infty}(R_0) \cup \bar{S}_{-\infty}(R_0),$$

where $B_i(s) = s^{-r} s^{-N_i} B_{ii}(s) s^{N_i}$ and R_0 is some sufficiently large positive number. It is easily seen that

$$\lim_{\mathrm{Res} \to \infty} F_i(s) = \lim_{\mathrm{Res} \to -\infty} \tilde{F}_i(s) = I_{n_i}.$$

Furthermore, if R_0 is sufficiently large, F_i and $\tilde{F}_i$ as well as their inverses are bounded on $\bar{S}_\infty(R_0) \cup \bar{S}_{-\infty}(R_0)$. Hence, by Theorem 2.4.6, F_i must coincide with F_{ii}^∞ in a lower halfplane and with $F_{ii}^{-\infty}$ in an upper halfplane, whereas $\tilde{F}_i$ must coincide with $\tilde{F}_{ii}^{-\infty}$ in a lower halfplane and with $\tilde{F}_{ii}^\infty$ in an upper halfplane. Consequently, the connection matrices P_{ii}^∞ and $P_{ii}^{-\infty}$ can both be represented by the infinite product

$$\prod_{n=-\infty}^{\infty} (I_{n_i} + B_i(s-n)), \qquad i \in \{1, \cdots, m\}$$

in a lower and an upper halfplane, respectively. We shall assume that R_0 is so large that F^∞ and $(F^\infty)^{-1}$ are bounded on the (closed) halfplane $\bar{S}_\infty(R_0)$, and, moreover, $F^{-\infty}$ and its inverse have the same properties with respect to $\bar{S}_{-\infty}(R_0)$.

Now let G be an open region in $U(R_0)$ such that

$$G = \bigcup_{x \in \mathbb{R}^+} G + x,$$

and $\sup_{s \in G} \operatorname{Im} s = -\inf_{s \in G} \operatorname{Im} s = \infty$.

Let F be a solution of (4.1.2), holomorphic in G and with diagonal blocks $F_{ii} = F_i$, where F_i is defined by (4.2.2), for all $i \in \{1, \cdots, m\}$. F may be continued analytically to a holomorphic function in

$$\bigcup_{x \in \mathbb{R}} G + x \cap U(R_0).$$

This function will again be denoted by F.

In the following lemma we consider the connection matrices of (F^∞, F) and $(F^{-\infty}, F)$.

LEMMA 4.2.3. *Let* $Y_i = F_i \overset{c}{Y}_i$, $i \in \{1, \cdots, m\}$ *and let* P *denote the matrix function defined by*

$$P(s) = \begin{cases} \overset{c}{Y}(s)^{-1} F^\infty(s)^{-1} F(s) \overset{c}{Y}(s) & \text{if } s \in \bar{S}_\infty(R_0), \\ \overset{c}{Y}(s)^{-1} F^{-\infty}(s)^{-1} F(s) \overset{c}{Y}(s) & \text{if } s \in \bar{S}_{-\infty}(R_0). \end{cases}$$

For all $i, j \in \{1, \cdots, m\}$ *and all* $s \in \bar{S}_\infty(R_0) \cup \bar{S}_{-\infty}(R_0)$ *the following identity holds*:

$$P_{ij}(s) = \lim_{n \to \infty} Y_i(s-n)^{-1} F_{ij}(s-n) \overset{c}{Y}_j(s-n).$$

Proof. We shall prove the statement for all $s \in \bar{S}_\infty(R_0)$, by means of induction on $j - i$. If $j - i = 1$ we have, for all $s \in \bar{S}_\infty(R_0)$ and all $n \in \mathbb{Z}$,

$$P_{ij}(s) = Y_i(s-n)^{-1} F_{ij}(s-n) \overset{c}{Y}_j(s-n) + \overset{c}{Y}_i(s-n)^{-1} (F^\infty)_{ij}^{-1}(s-n) Y_j(s-n).$$

Due to the fact that $d_i < d_j$ while $(F^\infty)^{-1}$ is bounded on $\bar{S}_\infty(R_0)$, the second term on the right-hand side of this identity tends to zero as $n \to \infty$.

Now suppose that $j - i > 1$ and that the statement is true for all pairs of indices (k, l) such that $l - k < j - i$. Then we have

$$\begin{aligned} &P_{ij}(s) - Y_i(s-n)^{-1} F_{ij}(s-n) \overset{c}{Y}_j(s-n) \\ &\quad = \sum_{i < h \leqq j} \overset{c}{Y}_i(s-n)^{-1} (F^\infty)_{ih}^{-1}(s-n) Y_h(s-n) Y_h(s-n)^{-1} F_{hj}(s-n) \overset{c}{Y}_j(s-n). \end{aligned}$$

Again the product $\overset{c}{Y}_i(s-n)^{-1} (F^\infty)_{ih}^{-1}(s-n)^{-1} Y_h(s-n)$ tends to zero as $n \to \infty$ for all $h > i$. By assumption, for all $h < j$ the product $Y_h(s-n)^{-1} F_{hj}(s-n) \overset{c}{Y}_j(s-n)$ tends to a finite limit, namely, $P_{hj}(s)$, as $n \to \infty$. Consequently, the right-hand side of the above

identity tends to zero as $n \to \infty$ and the result follows. For $s \in \bar{S}_{-\infty}(R_0)$ the proof is analogous.

4.3. Maximal asymptotic sets. Let $\theta_0 = \max\{\theta \in \theta(\sigma(A)) : \theta \leqq 0\}$ and let all elements of $\theta(\sigma(A))$ be numbered in such a way that $\theta_N < \theta_{N+1}$, $N \in \mathbb{Z}$. For all $N \in \mathbb{Z}$ and all $i, j \in \{1, \cdots, m\}$, $n_{ij}(N)$ will denote the smallest integer not less than

$$\frac{1}{2\pi}\{(d_i - d_j)\theta_N - \operatorname{Im}(\mu_{i,p} - \mu_{j,p})\}.$$

By the definition of $\theta(\sigma(A))$, there exists an integer M such that

$$n_{ij}(N) = \frac{1}{2\pi}\{(d_i - d_j)\theta_M - \operatorname{Im}(\mu_{i,p} - \mu_{j,p})\}$$

and an integer M' such that

$$n_{ij}(N) + 1 = \frac{1}{2\pi}\{(d_i - d_j)\theta_{M'} - \operatorname{Im}(\mu_{i,p} - \mu_{j,p})\}.$$

Suppose that $i < j$. This implies that $d_i < d_j$. Then, obviously $M' < M \leqq N$. Hence it follows that

$$0 \leqq n_{ij}(N-1) - n_{ij}(N) \leqq 1, \qquad i, j \in \{1, \cdots, m\}, \quad i < j, \quad N \in \mathbb{Z}. \tag{4.3.1}$$

For all $N \in \mathbb{Z}$ we define an upper block-triangular matrix function F_N by means of the following recursive relation for the blocks $(F_N)_{ij}$:

$$(F_N)_{ii} = F_i \quad \text{(defined in (4.2.2))},$$

$$(F_N)_{ij}(s) = Y_i(s) \int_{C(s)} d\zeta \frac{\exp\{2n_{ij}(N)\pi i(s-\zeta)\}}{1 - \exp\{2\pi i(s-\zeta)\}} I_{ij}^N(\zeta) \overset{c}{Y}_j(s)^{-1}, \qquad i < j, \tag{4.3.2}$$

$s \in \operatorname{int} U(R_0)$, where

$$I_{ij}^N(\zeta) = Y_i(\zeta+1)^{-1} \sum_{i < h \leqq j} A_{ih}^T(\zeta)(F_N)_{hj}(\zeta) \overset{c}{Y}_j(\zeta) \tag{4.3.3}$$

and $C(s)$ is a contour in $U(R_0)$, enclosing the negative imaginary axis as well as the points $s - n$, $n \in \mathbb{N}$, but not s (see Fig. 5).

LEMMA 4.3.4. *Let R and R' be positive numbers such that $R' > R > R_0$. Let $U_0 = U(R) \setminus U(R')$. There exist positive constants c and C such that, for all $i, j \in \{1, \cdots, m\}$ and all $N \in \mathbb{Z}$,*

$$\sup_{s \in U_0} |Y_i(s)^{-1}(F_N)_{ij}(s) \overset{c}{Y}_j(s)| \leqq C e^{c|N|}.$$

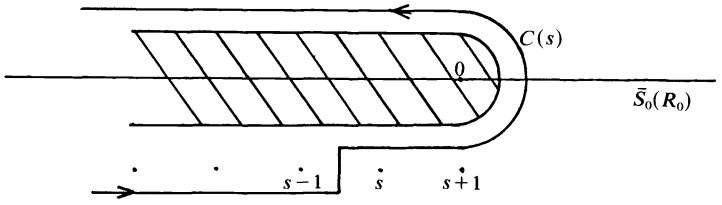

FIG. 5

Proof. For all $k \in \{1, \cdots, m\}$ we define $U_k = U(R - k\varepsilon) \setminus U(R' + k\varepsilon)$, where ε is a sufficiently small positive number such that $U_m \subset U(R_0)$. For all $(s, \zeta) \in U_m \times U_m$ we have

$$|\exp\{2n_{ij}(N)\pi i(s-\zeta)\}| \leqq \exp\{4(R' + m\varepsilon)\pi |n_{ij}(N)|\}.$$

Hence, in view of (4.3.1), we obtain the inequality

$$|\exp\{2n_{ij}(N)\pi i(s-\zeta)\}| \leqq C_0\, e^{c_0|N|}, \tag{4.3.5}$$

where c_0 and C_0 are positive numbers independent of N.

If $s \in U_k$ for some $k \in \{1, \cdots, m-1\}$ the contour $C(s)$ in (4.3.2) may be chosen in such a way that $C(s) \subset U_{k+1}$ and $d(\zeta, s + \mathbb{Z}) \geqq \varepsilon$ for all $\zeta \in C(s)$. Then there exists a positive number K such that

$$|1 - \exp\{2\pi i(s-\zeta)\}|^{-1} \leqq K \quad \text{for all } s \in U_{m-1} \text{ and all } \zeta \in C(s). \tag{4.3.6}$$

We shall prove the lemma by means of induction on $j - i$. If $j - i = 1$ the expression in (4.3.3) is reduced to

$$I_{ij}^N(\zeta) = Y_i(\zeta + 1)^{-1} A_{ij}^T(\zeta)\, Y_j(\zeta).$$

Due to the fact that $d_i < d_j$, this function tends to zero very rapidly as $\operatorname{Re}\zeta \to -\infty$, uniformly on U_m. Consequently, the integrals

$$\int_{C(s)} |I_{ij}^N(\zeta)||d\zeta|, \qquad s \in U_{m-1}$$

exist and are bounded by a constant, independent of N. With (4.3.5) and (4.3.6) it follows that, for all $N \in \mathbb{Z}$,

$$\sup_{s \in U_{m-1}} |Y_i(s)^{-1}(F_N)_{ij}(s)\overset{c}{Y}_j(s)| \leqq C_1\, e^{c_1|N|},$$

where c_1 and C_1 are positive constants independent of N.

Now let $j - i = k > 1$ and suppose that for all $l < k$ there exist positive numbers c_l and C_l such that

$$\sup_{s \in U_{m-l}} |Y_g(s)^{-1}(F_N)_{gh}(s)\overset{c}{Y}_h(s)| \leqq C_l\, e^{c_l|N|} \tag{4.3.7}$$

for all $N \in \mathbb{Z}$ and all $h, g \in \{1, \cdots, m\}$ such that $h - g = l$. Then we have, for all $N \in \mathbb{Z}$, all $h \in \{1, \cdots, m\}$ such that $i < h < j$ and all $s \in U_{m-j+h}$,

$$|Y_i(s+1)^{-1}A_{ih}^T(s)(F_N)_{hj}(s)\overset{c}{Y}_j(s)| \leqq |Y_i(s+1)^{-1}A_{ih}^T(s)\, Y_h(s)|C_{j-h}\, e^{c_{j-h}|N|}.$$

Inserting this into (4.3.3) and using the estimates (4.3.5) and (4.3.6) we conclude that there exist positive numbers c_k and C_k such that (4.3.7) holds for $l = k$ as well. Hence it follows that for all $l \in \{1, \cdots, m-1\}$ there exist positive numbers c_l and C_l such that (4.3.7) holds. Since $U_0 \subset U_l$ for all $l \in \{1, \cdots, m-1\}$ this proves the lemma.

With the aid of residue calculus it is readily verified that, for all $i, j \in \{1, \cdots, m\}$ such that $i < j$ and all $N \in \mathbb{Z}$, the matrix function $(F_N)_{ij}$ satisfies the equation

$$Z(s+1) = A_{ii}^T(s)Z(s)\overset{c}{A}_j(s)^{-1} + \sum_{i < h \leqq j} A_{ih}^T(s)(F_N)_{hj}(s)\overset{c}{A}_j(s)^{-1}.$$

Hence it follows that, for all $N \in \mathbb{Z}$, F_N is a solution of (4.1.2).

THEOREM 4.3.8. *For all $N \in \mathbb{Z}$ let P_N^+ and P_N^- denote the connection matrices of (F^∞, F_N) and $(F^{-\infty}, F_N)$, respectively. Let $R_1 > R_0$. There exist positive numbers d and D such that, for all $j \in \{1, \cdots, m\}$, all $i < j$ and all $N \in \mathbb{Z}$, the following inequalities hold:*

$$\sup_{s \in \bar{S}_\infty(R_1)} |(P_N^+)_{ij}(s) \exp\{-2(n_{ij}(N)-1)\pi i s\}| \leqq D\, e^{d|N|},$$

$$\sup_{s \in \bar{S}_{-\infty}(R_1)} |(P_N^-)_{ij}(s) \exp\{-2n_{ij}(N)\pi i s\}| \leqq D\, e^{d|N|}.$$

COROLLARY 4.3.9. *There exists a positive number R such that*

$$\lim_{N \to \infty} F_N(s) = F^\infty(s) \quad \text{if } \operatorname{Im} s \leqq -R,$$

$$\lim_{N \to -\infty} F_N(s) = F^{-\infty}(s) \quad \text{if } \operatorname{Im} s \geqq R.$$

Proof. For all $N \in \mathbb{Z}$, all $i, j \in \{1, \cdots, m\}$ such that $i < j$ and all $s \in \bar{S}_\infty(R_0)$ we have

$$(F_N)_{ij}(s) = F_{ij}^\infty(s) + \sum_{i \leqq h < j} F_{ih}^\infty(s) \overset{c}{Y}_h(s) (P_N^+)_{hj}(s) \overset{c}{Y}_j(s)^{-1}. \tag{4.3.10}$$

Applying Theorem 4.3.8 and noting that, according to (4.3.1),

$$n_{hj}(0) - n_{hj}(N) \leqq N \quad \text{for all } h < j, \quad N \in \mathbb{Z},$$

we obtain the following inequality for all $s \in \bar{S}_\infty(R_1)$:

$$|(F_N)_{ij}(s) - F_{ij}^\infty(s)| \leqq \sum_{i \leqq h < j} |F_{ih}^\infty(s) \overset{c}{Y}_h(s)|\, |\overset{c}{Y}_j(s)^{-1}| D_{hj}(s) \exp\{N(d - 2\pi \operatorname{Im} s)\},$$

where $D_{hj}(s) = D \exp\{2\pi(n_{hj}(0)+1) \operatorname{Im} s\}$. If we take $R > \max(R_1, d/2\pi)$ the first statement follows immediately. The second statement is proved analogously.

Proof of Theorem 4.3.8. Let C_0 be a U-shaped contour in the interior of $U(R_1) \setminus U(R_0)$ enclosing the negative imaginary axis. By means of residue calculus it is easily shown that

$$Y_i(s)^{-1} (F_N)_{ij} \overset{c}{Y}_j(s)^{-1} = (P_N)_{ij}(s) + \sum_{l=1}^{\infty} I_{ij}^N(s-l),$$

where I_{ij}^N is defined by (4.3.3) and

$$(P_N)_{ij}(s) = \int_{C_0} d\zeta \frac{\exp\{2n_{ij}(N)\pi i(s-\zeta)\}}{1 - \exp\{2\pi i(s-\zeta)\}} I_{ij}^N(\zeta),$$

for all $N \in \mathbb{Z}$, all $i, j \in \{1, \cdots, m\}$ such that $i < j$ and all s with the property that $|\operatorname{Im} s| \geqq R_1$.

Consequently, the following identity holds for all $n \in \mathbb{N}$:

$$Y_i(s-n)^{-1} (F_N)_{ij}(s-n) \overset{c}{Y}_j(s-n) = (P_N)_{ij}(s) + \sum_{l=n}^{\infty} I_{ij}^N(s-l).$$

Making $n \to \infty$ and applying Lemma 4.2.3 we find

$$(P_N)_{ij}(s) = \begin{cases} (P_N^+)_{ij}(s) & \text{if } \operatorname{Im} s \leqq -R_1, \\ (P_N^-)_{ij}(s) & \text{if } \operatorname{Im} s \geqq R_1. \end{cases}$$

Hence it follows that

$$\exp\{-2(n_{ij}(N)-1)\pi i s\}(P_N^+)_{ij}(s) = \int_{C_0} d\zeta \frac{\exp\{-2(n_{ij}(N)-1)\pi i \zeta\}}{\exp\{-2\pi i(s-\zeta)\} - 1} I_{ij}^N(\zeta) \tag{4.3.11}$$

for all $s \in \bar{S}_{\infty}(R_1)$, whereas

$$\exp\{-2n_{ij}(N)\pi i s\}(P_N^-)_{ij}(s) = \int_{C_0} d\zeta \frac{\exp\{-2n_{ij}(N)\pi i\zeta\}}{1-\exp\{2\pi i(s-\zeta)\}} I_{ij}^N(\zeta) \tag{4.3.12}$$

for all $s \in \bar{S}_{-\infty}(R_1)$. Writing

$$I_{ij}^N(\zeta) = \sum_{i<h\leqq j} Y_i(\zeta+1)^{-1} A_{ih}^T(\zeta)\, Y_h(\zeta)\, Y_h(\zeta)^{-1} (F_N)_{hj}(\zeta) \overset{c}{Y}_j(\zeta)$$

and using Lemma 4.3.4 we obtain, for all $\zeta \in C_0$, the estimate

$$I_{ij}^N(\zeta) \leqq C\, e^{c|N|} \sum_{i<h\leqq j} |Y_i(\zeta+1)^{-1} A_{ih}^T(\zeta)\, Y_h(\zeta)|,$$

where c and C are positive constants. As $d_i < d_h$ if $i<h$, the integral

$$\int_{C_0} |d\zeta|\, |Y_i(\zeta+1)^{-1} A_{ih}^T(\zeta)\, Y_h(\zeta)|$$

is convergent for all $i<h$. Furthermore, the functions

$$\varphi(s,\zeta) = [\exp\{-2\pi i(s-\zeta)\}-1]^{-1}$$

and

$$\psi(s,\zeta) = [1-\exp\{2\pi i(s-\zeta)\}]^{-1}$$

are obviously bounded on $\bar{S}_{\infty}(R_1)\times C_0$ and $\bar{S}_{-\infty}(R_1)\times C_0$, respectively. With (4.3.1) it is now easily verified that the expressions in (4.3.11) and (4.3.12) lead to estimates of the required form.

Remark. The matrix elements of P_N^{-1} (i.e., the connection matrix of (F_N, F^{∞}) and $(F_N, F^{-\infty})$) can be computed from F_N by means of the following recursive relation:

$$(P_N^{-1})_{ij} = \delta_{ij} \quad \text{if } i \geqq j,$$

$$= \delta_{ij} - \sum_{i<l\leqq j} \int_{C_0} d\zeta \frac{\exp\{2n_{il}(N)\pi i(s-\zeta)\}}{1-\exp\{2\pi i(s-\zeta)\}} I_{il}^N(\zeta)(P_N^{-1})_{lj} \quad \text{if } i<j$$

where I_{il}^N is defined by (4.3.3).

The next, and final, proposition is concerned with the asymptotic behaviour of the matrix functions F_N.

PROPOSITION 4.3.13. *Let $N \in \mathbb{Z}$ and $S_N^* = \cup_{\theta_N<\theta<\theta_{N+1}} S_\theta$. We have*

$$F_N \in \mathrm{Gl}(n; \mathscr{A}(S_N^*)).$$

Moreover, F_N is the unique solution of (4.1.2) *which is analytic in a right half plane and possesses the properties mentioned in Theorem* 4.3.8.

Proof. Let $\theta \in (\theta_N, \theta_{N+1})$ and let

$$S_\theta^- = S_\theta \cap \bar{S}_{\infty}.$$

Putting

$$d_h - d_j = d_{hj}, \qquad \mu_h - \mu_j + 2(n_{hj}(N)-1)\pi i = \mu_{hj}^N$$

for all $h, j \in \{1, \cdots, m\}$ and all $N \in \mathbb{Z}$, and using Theorem 4.3.8 we find

$$|\overset{c}{Y}_h(s)(P_N^+)_{hj}(s)\overset{c}{Y}_j(s)^{-1}| = \exp\{(d_{hj}s\log s + \mu_{hj}^N s)(1+o(1))\}, \quad s\to\infty, \quad s \in S_\theta^-(R_1),$$

for all $j \in \{1, \cdots, m\}$ and all $h<j$. By Definition 2.2.4,

$$\mathrm{Re}\, s\log s\, e^{i\theta} \geqq C(\theta, R_1)$$

for all $s \in S_\theta(R_1)$, hence

$$\operatorname{Re}(d_{hj} s \log s + \mu_{hj}^N s) \leqq d_{hj} C(\theta, R_1) + \operatorname{Re}\{(\mu_{hj}^N - i d_{hj}\theta) s\}$$

if $h < j$ and $s \in S_\theta(R_1)$. Now, $\theta \in (\theta_N, \theta_{N+1})$ implies that

$$0 < d_{hj}\theta - \operatorname{Im} \mu_{hj}^N < 2\pi.$$

With the aid of the above inequalities we readily verify that

$$\overset{c}{Y}_h(s)(P_N^+)_{hj}(s)\overset{c}{Y}_j(s)^{-1} \sim 0, \qquad s \to \infty, \quad s \in S_\theta^-(R),$$

if $h < j$ and R is a sufficiently large number. With (4.3.10) we conclude that

$$F_N - F^\infty \in \mathrm{Gl}(n; \mathscr{A}_0(S_\theta^-)).$$

In a similar manner we prove that

$$F_N - F^{-\infty} \in \mathrm{Gl}(n; \mathscr{A}_0(S_\theta \cap \bar{S}_{-\infty})).$$

As F^∞ and $F^{-\infty}$ are represented asymptotically by the series $\sum_{h=0}^\infty F_h s^{-h/p}$ as $s \to \infty$ in $\bar{S}_\infty(R_1)$ and $\bar{S}_{-\infty}(R_1)$, respectively, it remains to be shown that F_N admits the same asymptotic expansion as $s \to \infty$ in a "strip" of the form $S_\theta(R) \cap \{s \in \mathbb{C} : |\operatorname{Im} s| \leqq R\}$, where R is a suitable positive number. This follows immediately from a Phragmén-Lindelöf-type of argument (cf. [15, p. 180]). Thus we conclude that $F_N \in \mathrm{Gl}(n; \mathscr{A}(S_\theta))$ for all $\theta \in (\theta_N, \theta_{N+1})$ and, consequently, $F_N \in \mathrm{Gl}(n; \mathscr{A}(S_N^*))$. Since here we have not used any properties of F_N, except for those mentioned in Theorem 4.3.8, the second statement now follows from Theorem 2.4.1.

In conclusion we can say that, unless $P_{N-1} = P_N$ or $P_N = P_{N+1}$, the asymptotic sets S_N^* mentioned in Proposition 4.3.13 are maximal in the following sense: for every $N \in \mathbb{Z}$ there exists a (unique) matrix function $F_N \in \mathrm{Gl}(n; \mathscr{A}(S_N^*))$ with the property that $A^{F_N} = \overset{c}{A}$, whereas $F_N \notin \mathrm{Gl}(n; \mathscr{A}(S_{\theta_N}))$ and $F_N \notin \mathrm{Gl}(n; \mathscr{A}(S_{\theta_{N+1}}))$. Analogously, there exist maximal asymptotic sets $\tilde{S}_N$, defined by

$$\tilde{S}_N = \bigcup_{\theta_N < \theta < \theta_{N+1}} e^{i\pi} S_{\theta+\pi}, \qquad N \in \mathbb{Z}$$

and unique matrix functions $\tilde{F}_N \in \mathrm{Gl}(n; \mathscr{A}(\tilde{S}_N))$ such that $A^{\tilde{F}_N} = \overset{c}{A}$. The Stokes phenomenon in the class of difference equations considered in this section can be completely described by determining the connection matrices of (F_N, F_{N+1}) and $(\tilde{F}_N, \tilde{F}_{N+1})$, $N \in \mathbb{Z}$, and the connection matrices P^∞ and $P^{-\infty}$ defined below Definition 4.2.1.

INEQUALITIES FOR THE ZEROS OF THE AIRY FUNCTIONS*

GIOVANNA PITTALUGA† AND LAURA SACRIPANTE†

Abstract. By using a theorem of Sturm type the authors show that the approximations obtained by truncating the asymptotic series for the real zeros of the Airy functions Ai (x) or Bi (x) are in fact lower and upper bounds. A lower bound for the zeros of the derivatives of these functions is also derived.

Key words. Airy functions, zeros, inequalities, Sturm comparison theorem

AMS(MOS) subject classifications. primary 33A40; secondary 34C10

1. Introduction. It is well known that the Airy functions Ai (x) and Bi (x) play an important rôle in the asymptotic theory of differential equations (see Olver [7, Chap. 11]). They satisfy the so-called Airy differential equation

$$y''-xy=0, \tag{1.1}$$

which arises naturally as an approximation to the general second-order differential equation reduced to the normal form [5, p. B4].

The functions Ai (x) and Bi (x) have infinitely many real zeros on the negative axis:

$$0>a_1>a_2>\cdots \quad \text{and} \quad 0>b_1>b_2>\cdots,$$

respectively.

For these zeros the following asymptotic expansions, due to Miller [5], hold:

$$a_n \cong -f(\lambda_n), \tag{1.2}$$

$$b_n \cong -f(\mu_n), \tag{1.3}$$

where

$$\lambda_n=\frac{3(4n-1)\pi}{8}, \quad \mu_n=\frac{3(4n-3)\pi}{8}, \quad n=1,2,\cdots,$$
$$f(z)=z^{2/3}\left(1+\frac{5}{48z^2}-\frac{5}{36z^4}+\frac{77125}{82944z^6}-\frac{108056875}{6967296z^8}+\frac{162375596875}{334430208z^{10}}+\cdots\right). \tag{1.4}$$

These approximations, even if truncated to the first terms, give good numerical results also for moderate values of n, but do not furnish any information about the error. Moreover,

$$a_1=-2.33810741\cdots, \qquad b_1=-1.17371322\cdots, \tag{1.5}$$

and, as $n\to\infty$,

$$a_n \cong -\left[\frac{3}{8}(4n-1)\pi\right]^{2/3}, \qquad b_n \cong -\left[\frac{3}{8}(4n-3)\pi\right]^{2/3}. \tag{1.6}$$

For the properties of the Airy functions, we refer to Miller [5], Olver [7], and Abramowitz and Stegun [1].

One- and two-term asymptotic representations for the zeros a_n, with bounds for the error term, can be found in a paper of Hethcote [2]. In a more recent paper, Laforgia [4] has found an analogous one-term asymptotic representation for the zeros b_n.

Inequalities for the zeros a_n and b_n can be obtained by means of the following theorem of Sturm type, due to Hethcote [3].

THEOREM 1.1. *Let c_n and d_n, $n=1, 2, \cdots$, be the zeros (in increasing order) of $u(x)$ and $v(x)$, respectively, which are nontrivial solutions of $u''+p(x)u=0$ and $v''+q(x)v=0$ with continuous $p(x)$ and $q(x)$. If $c_n-d_n\to 0$ as $n\to\infty$, $p(x)\geqq q(x)$ and either $p(x)$ or $q(x)$ is nonincreasing, then $c_n\geqq d_n$ for $n=1, 2, \cdots$.*

By applying this theorem, Hethcote [3] has found the following inequalities for the nth zero a_n of the function Ai (x):

$$-\left(\lambda_n+\frac{3}{2}\arctan\frac{5}{48\lambda_n}\right)^{2/3}\leqq a_n\leqq -\lambda_n^{2/3}, \tag{1.7}$$

where $\lambda_n=3(4n-1)\pi/8$ and $n=1, 2, \cdots$.

The Hethcote result shows that a_n is greater than the two-term approximation obtained by truncating asymptotic expansion (1.2). Indeed, it is easily verified that

$$a_n\geqq -\left(\lambda_n+\frac{3}{2}\arctan\frac{5}{48\lambda_n}\right)^{2/3}>-\lambda_n^{2/3}\left(1+\frac{5}{32\lambda_n^2}\right)^{2/3}>-\lambda_n^{2/3}\left(1+\frac{5}{48\lambda_n^2}\right). \tag{1.8}$$

The aim of this paper is to improve (1.7) by means of Theorem 1.1. We also derive, in a similar way, lower and upper bounds for the zeros b_n, $n=1, 2, \cdots$, of the function Bi (x), by truncating the asymptotic series (1.3).

The main results are stated in the following theorem.

THEOREM 1.2. *The error in stopping at any of the first five terms of Miller's expansions* (1.2) *and* (1.3) *is bounded by the next term and has the same sign. Furthermore, the following inequalities hold*:

$$a_n>-F(\lambda_n),\qquad b_n>-F(\mu_n),$$

where

$$\lambda_n=\frac{3(4n-1)\pi}{8},\quad \mu_n=\frac{3(4n-3)\pi}{8},\quad n=1, 2, \cdots,$$

$$F(z)=z^{2/3}\left(1+\frac{5}{48z^2}-\frac{5}{36z^4}+\frac{77125}{82944z^6}-\frac{108056875}{6967296z^8}+\frac{162375596875}{334430208z^{10}}\right).$$

To establish these results, it is necessary to prove, step by step, that the approximations obtained by considering an even or odd number of terms in the asymptotic series (1.2) and (1.3) are in fact lower and upper bounds, respectively. The essence of each successive step is quite similar, but details are progressively more complicated. So, in the following two sections, we will give only the outline of the proof for the first of the required results related to the zeros a_n of Ai (x) that improve the Hethcote inequality (1.8).

We have established the complete proof of Theorem 1.2 by using the symbolic system MAPLE, as we will explain at the end of § 3.

2. The comparison equation. In order to apply Theorem 1.1 we will refer to, instead of (1.1), the differential equation

$$u''+\left(1+\frac{5}{36\xi^2}\right)u=0, \tag{2.1}$$

which is satisfied by the functions

$$A(\xi) = (\tfrac{3}{2}\xi)^{1/6}\,\mathrm{Ai}\,[-(\tfrac{3}{2}\xi)^{2/3}],$$
$$B(\xi) = (\tfrac{3}{2}\xi)^{1/6}\,\mathrm{Bi}\,[-(\tfrac{3}{2}\xi)^{2/3}]. \tag{2.2}$$

If α_n and β_n, $n = 1, 2, \cdots$, denote the positive zeros (in increasing order) of $A(\xi)$ and $B(\xi)$, respectively, then we have

$$\alpha_n = \tfrac{2}{3}(-a_n)^{3/2}, \quad \beta_n = \tfrac{2}{3}(-b_n)^{3/2}, \quad n = 1, 2, \cdots. \tag{2.3}$$

Hence, from the asymptotic expansions (1.2) and (1.3), we get

$$\alpha_n \cong T(\lambda_n), \qquad \beta_n \cong T(\mu_n), \tag{2.4}$$

where λ_n and μ_n have the previous values (1.4), and

$$T(z) = \frac{2}{3}z\left(1 + \frac{5}{32z^2} - \frac{1255}{6144z^4} + \frac{272075}{196608z^6} - \frac{4084035425}{176160768z^8} + \frac{4098107432375}{5637144576z^{10}} + \cdots\right).$$

Furthermore, (1.5) and (1.6) give

$$\alpha_1 = 2.383446612\cdots, \qquad \beta_1 = 0.8477186453\cdots,$$

and, as $n \to \infty$,

$$\alpha_n \cong \frac{\pi}{4}(4n-1), \qquad \beta_n \cong \frac{\pi}{4}(4n-3).$$

The differential equation (2.1) will be compared with the differential equation

$$v'' + G(\xi)v = 0, \tag{2.5}$$

where

$$G(\xi) = \frac{1}{2}\frac{g'''}{g'} - \frac{3}{4}\left(\frac{g''}{g'}\right)^2 + g'^2, \tag{2.6}$$

which is satisfied by

$$v(\xi) = (g')^{-1/2}\cos g(\xi). \tag{2.7}$$

As we will see, (2.1) and (2.5) are "very close" for a proper choice of the function $g(\xi)$. For this choice it will be necessary to take into account that the asymptotic expansions (2.4) yield

$$\lambda_n \cong S(\alpha_n), \qquad \mu_n \cong S(\beta_n), \tag{2.8}$$

where

$$S(z) = \frac{3}{2}z\left(1 - \frac{5}{72z^2} + \frac{1105}{31104z^4} - \frac{82825}{746496z^6} + \frac{1282031525}{1504935936z^8} - \frac{1683480621875}{139314069504z^{10}}\cdots\right).$$

3. The first approximation for the zeros of Ai (x). In this section we will prove the following inequality for the zeros a_n of Ai (x):

$$a_n < -\lambda_n^{2/3}\left(1 + \frac{5}{48\lambda_n^2} - \frac{5}{36\lambda_n^4}\right). \tag{3.1}$$

For this purpose we use in (2.6)

$$g(\xi) = \xi - \frac{5}{72\xi} + \frac{1105}{31104\xi^3} - \frac{\pi}{4}, \tag{3.2}$$

as suggested by (2.8). From (2.6) we obtain

$$G(\xi) - \left(1 + \frac{5}{36\xi^2}\right) = \frac{y^3}{[g'(y)]^2}p(y),$$

where $y = 5/72\xi^2$ and

$$p(y) = \frac{221^4}{10^4} y^5 - \frac{221^3}{250} y^4 - \frac{103 \cdot 221^2}{125} y^3 - \frac{10487 \cdot 221}{250} y^2 + \frac{194801}{100} y - 3313.$$

So, we easily get

$$G(\xi) - \left(1 + \frac{5}{36\xi^2}\right) < 0,$$

for $\xi > \eta$, with $\eta = 0.335 \cdots$.

Now we note that the function (2.7), with $g(\xi)$ given by (3.2), has infinitely many positive zeros ξ_n, $n = 1, 2, \cdots$, belonging to the interval $\eta < \xi < \infty$. Hence, observing that

$$\lim_{n\to\infty} \xi_n = +\infty, \qquad \lim_{n\to\infty} (\xi_n - \alpha_n) = 0,$$

and that the coefficient of u in (2.1) is a continuous decreasing function in $0 < \xi < \infty$, we see that the conditions required in Theorem 1.1 are satisfied. Thus we may conclude that

$$\xi_n \leqq \alpha_n \quad \text{for } n \geqq 1.$$

Now we consider the equation

$$\xi - \frac{5}{72\xi} + \frac{1105}{31104\xi^3} - \frac{\pi}{4} = (2n-1)\frac{\pi}{2}. \tag{3.3}$$

This can be written in the form

$$\xi = \psi_n(\xi),$$

with

$$\psi_n(\xi) = \frac{5}{72\xi} - \frac{1105}{31104\xi^3} + \frac{2}{3}\lambda_n,$$

where λ_n is defined in (1.4).

We observe that the root of (3.3), which we have previously denoted by ξ_n, lies in the interval $\sqrt{221}/12 < \xi < \infty$, where the function $\psi_n(\xi)$ decreases. Since from (1.8) and (2.3)

$$\alpha_n < \delta_n \equiv \frac{2}{3}\lambda_n\left(1 + \frac{5}{32\lambda_n^2}\right),$$

we have $\xi_n \leqq \alpha_n < \delta_n$, and consequently,

$$\alpha_n \geqq \psi_n(\xi_n) > \psi_n(\delta_n).$$

Then, taking into account that

$$\alpha_n > \frac{2}{3}\lambda_n\left(1 + \frac{5}{32\lambda_n^2} - \frac{1255}{6144\lambda_n^4}\right),$$

we obtain

$$a_n < -\lambda_n^{2/3}\left(1 + \frac{5}{32\lambda_n^2} - \frac{1255}{6144\lambda_n^4}\right)^{2/3}.$$

Finally, by observing that

$$0 < \frac{5}{32\lambda_n^2} - \frac{1255}{6144\lambda_n^4} < 1$$

and using a well-known inequality [6, p. 35], i.e.,

$$(1+h)^{\alpha} > 1+\alpha h+\binom{\alpha}{2}h^2, \quad 0<h<1, \quad 0<\alpha<1,$$

we establish (3.1).

Now, to complete the proof of Theorem 1.2 it is necessary to repeat the previous procedure three times. Since the algebraic calculations become progressively harder, we have overcome this difficulty by using a symbolic mathematical system. Therefore, rather than go into full details, we will limit ourselves to some remarks.

First, we add a term to $g(\xi)$. Consequently, using the same notation,

(a) We find the function $G(\xi)$ and, to apply the Hethcote theorem, we prove that the difference $G(\xi)-(1+(5/36\xi^2))$ does not change sign in the interval of the zeros.

(b) We prove that, in the same interval, the function $\psi_n(\xi)$ is always decreasing.

(c) We reach a new inequality by evaluating $\psi_n(\xi)$ in the bound previously established.

The most important functions and the inequalities arising at each step of our proof are:

1. *First step.*

$$g(\xi)=\xi-\frac{5}{72\xi}+\frac{1105}{31104\xi^3}-\frac{82825}{746496\xi^5}-\frac{\pi}{4},$$

$$G(\xi)-\left(1+\frac{5}{36\xi^2}\right)=\frac{y^4}{[g'(y)]^2}p_1(y),$$

$$a_n > -\lambda_n^{2/3}\left(1+\frac{5}{48\lambda_n^2}-\frac{5}{36\lambda_n^4}+\frac{77125}{82944\lambda_n^6}\right).$$

2. *Second step.*

$$g(\xi)=\xi-\frac{5}{72\xi}+\frac{1105}{31104\xi^3}-\frac{82825}{746496\xi^5}+\frac{1282031525}{1504935936\xi^7}-\frac{\pi}{4},$$

$$G(\xi)-\left(1+\frac{5}{36\xi^2}\right)=\frac{y^5}{[g'(y)]^2}p_2(y),$$

$$a_n < -\lambda_n^{2/3}\left(1+\frac{5}{48\lambda_n^2}-\frac{5}{36\lambda_n^4}+\frac{77125}{82944\lambda_n^6}-\frac{108056875}{6967296\lambda_n^8}\right).$$

3. *Third step.*

$$g(\xi)=\xi-\frac{5}{72\xi}+\frac{1105}{31104\xi^3}-\frac{82825}{746496\xi^5}+\frac{1282031525}{1504935936\xi^7}-\frac{1683480621875}{139314069504\xi^9}-\frac{\pi}{4},$$

$$G(\xi)-\left(1+\frac{5}{36\xi^2}\right)=\frac{y^6}{[g'(y)]^2}p_3(y),$$

$$a_n > -\lambda_n^{2/3}\left(1+\frac{5}{48\lambda_n^2}-\frac{5}{36\lambda_n^4}+\frac{77125}{82944\lambda_n^6}-\frac{108056875}{6967296\lambda_n^8}+\frac{162375596875}{334430208\lambda_n^{10}}\right),$$

where $y=5/72\xi^2$ and

$$p_1(y)=\frac{51281261}{100}-\frac{27372926}{125}y+\frac{7794996033}{500}y^2-\frac{50103718291}{250}y^3$$
$$-\frac{7012956328919}{10000}y^4+\frac{8691232890407}{500}y^5+\frac{5244570435487}{200}y^6$$

$$-\frac{8036308150637}{20}y^7+\frac{120471895488961}{16}y^8,$$

$$p_2(y)=-538713799/4+\frac{14820773151}{1000}y-\frac{22493384194527}{5000}y^2$$
$$+\frac{3278666826931429}{8000}y^3-\frac{1046709128741315107}{100000}y^4$$
$$-\frac{1261062200876664583}{50000}y^5+\frac{6390468125205053 4991}{50000}y^6$$
$$-\frac{65735260766514133374699}{1000000}y^7-\frac{201944954419818577655571}{2000000}y^8$$
$$+\frac{514517617846345251536371 51}{20000000}y^9-\frac{44678390902083129973969 0853}{4000000}y^{10}$$
$$+\frac{69156783124351054388530995 14641}{1600000000}y^{11},$$

$$p_3(y)=\frac{53751522223401}{1000}+\frac{20773109330799}{2500}y$$
$$+\frac{11109302866435629}{8000}y^2-\frac{10150465536010571741}{50000}y^3$$
$$+\frac{5891049024457820012593}{200000}y^4-\frac{1248226635247820542 90243}{100000}y^5$$
$$-\frac{19155021338580508161711 99}{1000000}y^6$$
$$+\frac{17640498460982180295968469}{125000}y^7$$
$$-\frac{27553584174318977467203014 8599}{20000000}y^8$$
$$+\frac{24072387103655940191454086 96631}{2000000}y^9$$
$$+\frac{27147944733527654973290247 82474641}{1600000000}y^{10}$$
$$-\frac{87433525211356346353713691 60970219}{16000000}y^{11}$$
$$+\frac{48793719536427679447591219 47186563}{1280000}y^{12}$$
$$-\frac{80173897396755453632596736 92504139}{25600}y^{13}$$
$$+\frac{84223328375724498468133493 019784801}{4096}y^{14}.$$

4. Bounds for the zeros of Bi (x). In this section we will consider again the differential equation (2.1), but we will refer to the second solution, i.e., to the function $B(\xi)$ defined in (2.2). Let us remember that we have denoted by β_n, $n=1, 2, \cdots$, the positive increasing zeros of $B(\xi)$ that are related to the zeros b_n, $n=1, 2, \cdots$, by the second relation in (2.3).

The procedure for deriving inequalities satisfied by the zeros b_n is perfectly analogous to that used for the zeros a_n. We give only a sketch of this procedure.

In the first instance, let us consider the simple case

$$g(\xi)=\xi+\frac{\pi}{4}.$$

Here it is very easy to verify that Theorem 1.1 can be applied. So we obtain

$$\beta_n \geqq \tfrac{2}{3}\mu_n, \qquad n=1, 2, \cdots, \tag{4.1}$$

i.e.,

$$b_n \leqq -\mu_n^{2/3}, \qquad n=1, 2, \cdots.$$

The next step is to choose

$$g(\xi)=\xi-\frac{5}{72\xi}+\frac{\pi}{4}.$$

We observe that

$$G(\xi)-\left(1+\frac{5}{36\xi^2}\right)>0 \quad \text{if } \xi>0,$$

and that, from (4.1), the zeros β_n lie in the interval $((\pi/4), +\infty)$.

Now, as in § 3, it is possible to obtain a lower bound for b_n by applying Theorem 1.1, that is,

$$b_n > -\mu_n^{2/3}\left(1+\frac{5}{48\mu_n^2}\right), \qquad n=1, 2, \cdots.$$

The next steps parallel the ones for the function Ai (x).

5. A bound for the zeros of Ai′ (x) and Bi′ (x). To complete the study of the zeros of the Airy functions, it is natural to ask whether the same analysis can be adapted to establish similar bounds for the zeros a_n' and b_n' of the derivatives Ai′ (x) and Bi′ (x).

In fact, it is well known that the following asymptotic expansions due to Miller hold:

$$a_n' \cong -\bar{f}(\mu_n), \qquad b_n' \cong -\bar{f}(\lambda_n),$$

where

$$\bar{f}(z)=z^{2/3}\left(1-\frac{7}{48z^2}+\frac{35}{288z^4}-\cdots\right),$$

while μ_n and λ_n are given by (1.4).

Unfortunately we can prove only the following theorem.

THEOREM 5.1. *For the zeros a_n' and b_n' of the derivatives of the Airy functions* Ai′ (x) *and* Bi′ (x), *respectively, the following inequalities hold*:

$$a_n' \geqq -[\tfrac{3}{8}(4n-3)\pi]^{2/3}, \quad b_n' \geqq -[\tfrac{3}{8}(4n-1)\pi]^{2/3}, \quad n=1, 2, \cdots. \tag{5.1}$$

Indeed, if we denote by α'_n, $n=1, 2, \cdots$, the positive zeros (in increasing order) of the function

$$\bar{A}(\xi)=(\tfrac{3}{2}\xi)^{-1/6}\,\mathrm{Ai}'\,[-(\tfrac{3}{2}\xi)^{2/3}],$$

which satisfies the differential equation

$$u''+\left(1-\frac{7}{36\xi^2}\right)u=0, \tag{5.2}$$

we have

$$\alpha'_n\cong\frac{2}{3}\,\mu_n\left(1-\frac{7}{32\mu_n^2}+\frac{1169}{6144\mu_n^4}+\cdots\right),$$

and consequently

$$\mu_n\cong\frac{3}{2}\,\alpha'_n\left(1+\frac{7}{72\alpha_n'^2}-\frac{1463}{31104\alpha_n'^4}+\cdots\right).$$

As in the previous section, we first compare (5.2) with the differential equation (2.5), by assuming that in (2.6)

$$g(\xi)=\xi+\frac{\pi}{4}.$$

We find that $G(\xi)=1$, and so we can apply the Hethcote theorem and easily establish the first of the two inequalities (5.1).

Then, if we add a term to $g(\xi)$, i.e.,

$$g(\xi)=\xi+\frac{7}{72\xi}+\frac{\pi}{4},$$

we find

$$G(\xi)=\left(1-\frac{7}{72\xi^2}\right)^2-\frac{1512}{(72\xi^2-7)^2}.$$

Since in this case $G(\xi)$ is an increasing function, the conditions required in Theorem 1.1 are not satisfied.

The same remarks hold for the zeros of $\mathrm{Bi}'(x)$.

Acknowledgment. The authors are grateful to Professor F. W. J. Olver for his careful reading of the manuscript and useful suggestions for improved formulation of the paper.

INDUCTIVELY GENERATING THE SPHERICAL HARMONICS*

ALLAN FRYANT†

Abstract. The spherical harmonics of degree less than or equal to k in R^{n-1} are used to generate the spherical harmonics of degree k in R^n.

Key words. spherical harmonics, generating function

AMS(MOS) subject classifications. 33A45, 31B99

A homogeneous polynomial of degree k in the real variables, $x_1, x_2, \cdots, x_n$, that satisfies Laplace's equation,

$$\frac{\partial^2 H}{\partial x_1^2}+\frac{\partial^2 H}{\partial x_2^2}+\cdots+\frac{\partial^2 H}{\partial x_n^2}=0,$$

is called a spherical harmonic of degree k in R^n.

The set of all spherical harmonics of degree k in R^n forms a vector space over the field of complex numbers. We denote this vector space by H_n^k. Let $d_n^k = \dim H_n^k$. Then

$$d_n^k = (n+2k-2)\frac{(n+k-3)!}{k!(n-2)!}$$

[2, p. 140]. An elementary argument by induction on k shows that

$$d_n^k = \sum_{j=0}^{k} d_{n-1}^j, \qquad n=3,4,5,\cdots.$$

This dimensional equality suggests a deep relationship between the spherical harmonics of degree less than or equal to k in R^{n-1} and the spherical harmonics of degree k in R^n. We investigate this relationship here.

Let $\sum_{n-1}$ denote the unit sphere in R^n, and $\langle f, g\rangle$ be the usual inner product on $\sum_{n-1}$. That is,

$$\langle f, g\rangle = \int_{\sum_{n-1}} f(x)g(x)\,dx, \tag{1}$$

where

$$\sum_{n-1} = \{(x_1, x_2, \cdots, x_n): x_1^2+x_2^2+\cdots+x_n^2=1\} \subset R^n.$$

Spherical harmonics of different degrees are orthogonal with respect to the inner product (1) [2, p. 144]. Thus, letting $\{P_j^1, P_j^2, \cdots, P_j^{d_{n-1}^j}\}$ be orthonormal bases for each of the vector spaces H_{n-1}^j, on taking the union of these bases over $j \leqq k$ we obtain a set of d_n^k orthonormal spherical harmonics that forms a basis for the vector space of harmonic polynomials of degree not exceeding k in R^{n-1}. Re-indexing, we let $\{P_1, P_2, \cdots, P_{d_n^k}\}$ denote such a basis.

The following theorem shows how the spherical harmonics in R^{n-1} can be used to generate the spherical harmonics in R^n, $n=2, 3, 4, \cdots$.

THEOREM. *Let* $P_1, P_2, \cdots, P_{d_n^k}$ *be orthonormal spherical harmonics in* R^{n-1} *of degree less than or equal to* k. *If* $x=(x_1, x_2, \cdots, x_n)\in R^n$, *and* $t=(t_1, t_2, \cdots, t_{n-1})\in \sum_{n-2}$, *then*

$$(x_1+ix_2t_1+ix_3t_2+\cdots+ix_nt_{n-1})^k=\sum_{j=1}^{d_n^k} Y_k^j(x)P_j(t),$$

where Y_k^j, $j=1, 2, \cdots, d_n^k$, *are homogeneous harmonic polynomials of degree* k *in* R^n, *and* $\langle Y_k^j, Y_k^l\rangle=0$ *if* $j\neq l$.

Proof. Consider the multinomial expansion

$$(x_1+ix_2t_1+\cdots+ix_nt_{n-1})^k=\sum_{\nu=1}^{l} c_\nu x^{\alpha_\nu}t^{\beta_\nu}.$$

Here $\alpha_\nu=(\alpha_1^\nu, \alpha_2^\nu, \cdots, \alpha_n^\nu)$, and $x^{\alpha_\nu}=x_1^{\alpha_1^\nu}x_2^{\alpha_2^\nu}\cdots x_n^{\alpha_n^\nu}$, and similarly for t^{β_ν}. When restricted to the unit sphere $\sum_{n-2}$, any polynomial of degree j in $t_1, t_2, \cdots, t_{n-1}$ is a linear combination of spherical harmonics of degree not exceeding j [2, p. 140]. Thus, on restricting t to the unit sphere, each monomial t^{β_ν} can be written as a linear combination of the spherical harmonics $P_1, P_2, \cdots, P_{d_n^k}$. A rearrangement then yields

$$(x_1+ix_2t_1+\cdots+ix_nt_{n-1})^k=\sum_{j=1}^{d_n^k} Y_k^j(x)P_j(t).$$

The Y_k^j are clearly homogeneous polynomials of degree k in $x_1, x_2, \cdots, x_n$. Further, since $t_1^2+t_2^2+\cdots+t_{n-1}^2=1$, they are harmonic. To see that these Y_k^j are orthogonal, consider the function

$$G(u, b)=\int_{\sum_{n-1}}(\xi_1u_1+\xi_2u_2+\cdots+\xi_nu_n)^k(\xi_1b_1+\xi_2b_2+\cdots+\xi_nb_n)^k\,d\xi$$

$$=\int_{\Sigma_{n-1}}(u, \xi)^k(b, \xi)^k\,d\xi.$$

The function G is an orthogonal invariant. That is, $G(Ou, Ob)=G(u, b)$ for any orthogonal transformation O of R^n. Thus, there exists a polynomial $\Phi(\lambda, \mu, \nu)$ such that

$$G(u, b)=\Phi[(u, u), (u, b), (b, b)]$$

[1, pp. 244–245]. Further, since $G(u, b)$ is homogeneous and of degree k in the components of u and b, it follows that

$$\Phi[(u, u), (u, b), (b, b)]=\sum c_{\alpha\beta\gamma}(u, u)^\alpha(u, b)^\beta(b, b)^\gamma,$$

where the sum is over all nonnegative integers α, β, γ such that $2\alpha+\beta=k$ and $2\gamma+\beta=k$. Thus we have the polynomial equation

$$\sum c_{\alpha\beta\gamma}(u, u)^\alpha(u, b)^\beta(b, b)^\gamma=\int_{\sum_{n-1}}(u, \xi)^k(b, \xi)^k\,d\xi. \tag{2}$$

Now let

$$u=(1, it_1, it_2, \cdots, it_{n-1}), \qquad t\in\sum_{n-2},$$

$$b=(1, -is_1, -is_2, \cdots, -is_{n-1}), \qquad s\in\sum_{n-2}.$$

Then $(u, u) = (b, b) = 0$, and (2) becomes

$$c_k(u, b)^k = \int_{\Sigma_{n-1}} (\xi_1 + i\xi_2 t_1 + \cdots + i\xi_n t_{n-1})^k (\xi_1 - i\xi_2 s_1 - \cdots - i\xi_n s_{n-1})^k \, dx$$

$$= \int_{\Sigma_{n-1}} \left[\sum_{j=1}^{d_n^k} Y_k^j(x) P_j(t) \right] \left[\sum_{l=1}^{d_n^k} \overline{Y_k^l(x) P_l(s)} \right] dx$$

$$= \sum_{j=1}^{d_n^k} \sum_{l=1}^{d_n^k} \left[\int_{\Sigma_{n-1}} Y_k^j(x) \overline{Y_k^l(x)} \, dx \right] P_j(t) \overline{P_l(s)}.$$

But

$$(u, b)^k = (1 + s_1 t_1 + s_2 t_2 + \cdots + s_{n-1} t_{n-1})^k.$$

Further, appealing to the fact that any polynomial of degree j when restricted to the unit sphere is a linear combination of spherical harmonics of degree not exceeding j, and using the Funk–Hecke theorem [1, p. 247], it follows that

$$(1 + s_1 t_1 + s_2 t_2 + \cdots + s_{n-1} t_{n-1})^k = \sum_{j=1}^{d_n^k} \lambda_j P_j(t) \overline{P_j(s)},$$

where the λ_j are constants. Thus we have

$$\sum_{j=1}^{d_n^k} \sum_{l=1}^{d_n^k} \left[\int_{\Sigma_{n-1}} Y_k^j(\xi) \overline{Y_k^l(\xi)} \, d\xi \right] P_j(t) \overline{P_l(s)} = c_k \sum_{j=1}^{d_n^k} \lambda_j P_j(t) \overline{P_j(s)},$$

from which it follows that

$$\int_{\Sigma_{n-1}} Y_k^j(\xi) \overline{Y_k^l(\xi)} \, d\xi = 0 \quad \text{for } j \neq l.$$

This completes the proof.

It is perhaps interesting to note that the generating function given in the preceding theorem produces the same spherical harmonics in R^2 as does taking the real and imaginary parts of $(x + iy)^k$. Laplace's equation in R^1 is $\partial^2 H / \partial x^2 = 0$, and thus the only harmonic functions in R^1 are 1 and t. These are the spherical harmonics in R^1. The unit sphere in R^1 has equation $t^2 = 1$, and the result of the theorem in this case is

$$(x + iyt)^k = Y_k^1(x, y) \cdot 1 + Y_k^2(x, y) \cdot t.$$

Thus, $Y_k^1(x, y) = \operatorname{Re}\{(x + iy)^k\}$ and $Y_k^2(x, y) = i \operatorname{Im}\{(x + iy)^k\}$. Our dimension-invariant result therefore suggests that use of the complex $i = \sqrt{-1}$ provides a simple means of generating the spherical harmonics in R^2 only because i behaves as does t when t is restricted to the unit sphere $t^2 = 1$.

The result of our theorem can be used to develop integral operators for harmonic functions in R^n [3]. That is, if $x = (x_1, x_2, \cdots, x_n) \in R^n$ and $H(x)$ satisfies

$$\frac{\partial^2 H}{\partial x_1^2} + \frac{\partial^2 H}{\partial x_2^2} + \cdots + \frac{\partial^2 H}{\partial x_n^2} = 0, \qquad \|x\| < R,$$

then there exists a function $h(z, t)$, analytic in the complex variable z in the disk $|z| < R$, and continuous in $t \in R^{n-1}$ on the unit sphere $\|t\| = 1$, such that

$$H(x) = F_n(h)$$

$$= \int_{t=1} h(x_1 + ix_2 t_1 + ix_3 t_2 + \cdots + ix_n t_{n-1}, t) \, dt.$$

In the case $n = 3$, this integral operator reduces to the Bergman B_3 integral operator [4].

In view of the inductive relation that obtains for the spherical harmonics in increasing dimensions, it appears that the generating function presented here is, in a sense, natural. It is certainly far simpler than classical generating functions for the spherical harmonics [5]. In particular, the simplicity of this generating function makes it easy to construct the spherical harmonics in rectangular coordinates, as polynomials in their variables. This can be done by hand, or using a symbol manipulation computer language such as MACSYMA.

FAMILIES OF ORTHOGONAL AND BIORTHOGONAL POLYNOMIALS ON THE N-SPHERE*

E. G. KALNINS†, WILLARD MILLER, JR.‡, AND M. V. TRATNIK§

Abstract. The Laplace–Beltrami eigenvalue equation $H\Phi = \lambda\Phi$ on the n-sphere is studied, with an added vector potential term motivated by the differential equations for the polynomial Lauricella functions F_A. The operator H is self-adjoint with respect to the natural inner product induced on the sphere and, in certain special coordinates, it admits a spectral decomposition with eigenspaces composed entirely of polynomials. The eigenvalues are degenerate but the degeneracy can be broken through use of the possible separable coordinate systems on the n-sphere. Then a basis for each eigenspace can be selected in terms of the simultaneous eigenfunctions of a family of commuting second-order differential operators that also commute with H. The results provide a multiplicity of n-variable orthogonal and biorthogonal families of polynomials that generalize classical results for one and two variable families of Jacobi polynomials on intervals, disks, and paraboloids.

Key words. multivariable orthogonal and biorthogonal polynomials, the n-sphere

AMS(MOS) subject classifications. 22E70, 33A65, 33A75

1. Introduction.

Orthogonal polynomials in one variable which also satisfy second-order ordinary differential or difference equations have proven extraordinarily useful in the development of special function theory and in the practical approximation of functions (e.g., Askey [2]). Orthogonal and biorthogonal families of polynomials in several variables which satisfy second-order partial differential or difference equations are similarly very useful but there is as yet no general theory and more examples are needed. In this paper we will study such families which are related to the Laplace–Beltrami eigenvalue equation on the n-sphere. Our procedure provides a uniform setting within which to classify several known examples related to the n-sphere and to generate many new examples. Our approach falls within the theory of Dunkl's differential-difference operators (Dunkl, [5], [6]); the main contribution of our paper is to point out the power of separation of variable methods in this theory. (Note: There is also a considerable literature on discrete analogues of the Laplace–Beltrami eigenvalue equation on the sphere in which the symmetry groups are finite, e.g., Stanton [25].)

It was shown by Lam and Tratnik [21] that the Lauricella functions

$$\Phi = F_A\left[\begin{matrix} M+G-1; & -m_1,\cdots,-m_n \\ & \gamma_1,\cdots,\gamma_n \end{matrix}; x_1,\cdots,x_n\right] \tag{1.1}$$

and

$$(1.2)\qquad (1-x)^M F_A\left[\begin{matrix}-M-\gamma_{n+1}+1; & -m_1,\cdots,-m_n \\ & \gamma_1,\cdots,\gamma_n\end{matrix}; -\frac{x_1}{1-x},\cdots,-\frac{x_n}{1-x}\right]$$

form a biorthogonal polynomial family where $m_i = 0,1,2,\cdots$, $M = \sum_{k=1}^n m_i$, $G = \sum_{\ell=1}^{n+1}\gamma_\ell$, $x = \sum_{k=1}^n x_i$, and the γ_ℓ are positive real numbers. (We will derive the inner product later.) Here, the Lauricella function F_A is defined by the series

$$(1.3)\qquad \begin{aligned} &F_A\left[\begin{matrix}a; & b_1,\cdots,b_n \\ & c_1,\cdots,c_n\end{matrix}; z_1,\cdots,z_n\right] \\ &\quad = \sum_{m_1,\cdots,m_n=0}^{\infty} \frac{(a)_{m_1+\cdots+m_n}(b_1)_{m_1}\cdots(b_n)_{m_n} z_1^{m_1}\cdots z_n^{m_n}}{(c_1)_{m_1}\cdots(c_n)_{m_n} m_1!\cdots m_n!}, \end{aligned}$$

where

$$(a)_m = \begin{cases} 1 & \text{if } m = 0 \\ a(a+1)\cdots(a+m-1) & \text{if } m \geq 1. \end{cases}$$

As is easily verified by adding the standard partial differential equations for the F_A (Appell and Kampe de Feriet [1]), these polynomial functions Φ satisfy the eigenvalue equation

$$(1.4)\qquad H\Phi = -M(M+G-1)\Phi,$$

where

$$(1.5)\qquad H = \sum_{i,j=1}^n (x_i\delta_{ij} - x_i x_j)\partial_{x_i x_j} + \sum_{i=1}^n (\gamma_i - G x_i)\partial_{x_i}.$$

Here δ_{ij} is the Kronecker delta. Note that H maps polynomials of maximum order m_i in x_i to polynomials of the same type. It is easy to see that as the m_i range over all nonnegative integers the functions (1.1) form a basis for the space of all polynomials in variables $x_1,\cdots,x_n$, and that the spectrum of H acting on this space is exactly

$$\{-M(M+G-1) : M = 0,1,2,\cdots\}.$$

(For $n = 2$ equation (1.4) appears in the classification by Krall and Sheffer [20] of all second-order partial differential operators such that the Mth order orthogonal polynomials in two variables, with respect to some weight function, are eigenfunctions of the operator.) We will look for other bases of solutions to equation (1.4), both orthogonal and biorthogonal with respect to a natural inner product.

Equation (1.4) is closely related to the Laplace–Beltrami eigenvalue equation on the n-sphere (Eisenhart [7]). To see this, consider the contravariant metric determined by the second derivative terms in H:

$$(1.6)\qquad g^{ij} = \delta_{ij}x_i - x_i x_j, \qquad 1 \leq i,j \leq n.$$

Then $\det(g^{ij}) = g^{-1} = x_1 x_2 \cdots x_n(1-x)$ and

$$g_{ij} = \frac{1}{1-x} + \frac{\delta_{ij}}{x_i}. \tag{1.7}$$

Note that

$$\sum_{j=1}^{n} g^{ij} g_{jk} = \delta_k^i = \begin{cases} 1 & \text{if } i = k, \\ 0 & \text{otherwise.} \end{cases}$$

Thus

$$ds^2 = \sum_{i,j=1}^{n} g_{ij} dx_i dx_j$$

determines a metric on a Riemannian space with associated Laplace–Beltrami operator

$$\Delta_n = \frac{1}{\sqrt{g}} \sum_{i,j=1}^{n} \partial_{x_i}(g^{ij}\sqrt{g}\, \partial_{x_j}). \tag{1.8}$$

A straightforward computation yields

$$H = \Delta_n + \Lambda_n \tag{1.9}$$

where

$$\Lambda_n = \sum_{j=1}^{n} \left[\gamma_j - \frac{1}{2} + \left(\frac{n+1}{2} - G\right) x_j\right] \partial_{x_j}. \tag{1.10}$$

Thus if $\gamma_1 = \cdots = \gamma_{n+1} = \frac{1}{2}$ then $H \equiv \Delta_n$, but in general H differs from Δ_n by the first-order differential operator Λ_n.

To identify the Riemannian space we introduce Cartesian coordinates $z_0, z_1, \cdots, z_n$ in $n+1$ dimensional Euclidean space and restrict these coordinates by the conditions

$$\begin{aligned} z_0^2 &= 1 - \sum_{i=1}^{n} x_i = 1 - x \\ z_1^2 &= x_1 \\ z_2^2 &= x_2 \\ &\vdots \\ z_n^2 &= x_n. \end{aligned} \tag{1.11}$$

Note that $z_0^2 + z_1^2 + \cdots + z_n^2 = 1$. Defining a metric ds^2 by

$$ds^2 = \sum_{m=0}^{n} (dz_m)^2$$

we find

$$ds^2 = \frac{1}{4}\sum_{i,j=1}^{n}\left(\frac{1}{1-x}+\frac{\delta_{ij}}{x_i}\right)dx_i dx_j. \tag{1.12}$$

Thus the space corresponds to a portion of the n-sphere S^n. We can consider the coordinates $\{x_i\}$ for $0 \le x_i$ and $x \le 1$ as covering the portion of the n-sphere given by $0 \le z_i$, $\sum_{k=1}^{n} z_k^2 = 1$.

We can transfer the Schrödinger equation (1.4) with vector potential Λ_n to one with a scalar potential V_n through the use of a multiplier transformation ρ. Setting $\Phi(\mathbf{x}) = \rho(\mathbf{x})\Psi(\mathbf{x})$ for a nonzero scalar function ρ we find

$$\begin{aligned}(\Delta_n + \Lambda_n)\Phi &= -M(M+G-1)\Phi \\ &\iff (\Delta_n + V_n(\mathbf{x}))\Psi = -M(M+G-1)\Psi,\end{aligned}$$

provided

$$\rho^{-1} = x_1^{\gamma_1/2-1/4}\cdots x_n^{\gamma_n/2-1/4}(1-x)^{\gamma_{n+1}/2-1/4}. \tag{1.13}$$

A straightforward but tedious computation gives for the scalar potential:

$$\begin{aligned}V_n = &-\frac{1}{4}\sum_{i=1}^{n}\frac{(\gamma_i-\frac{1}{2})(\gamma_i-\frac{3}{2})}{x_i} - \frac{1}{4}\frac{(\gamma_{n+1}-\frac{1}{2})(\gamma_{n+1}-\frac{3}{2})}{1-x} \\ &+\frac{1}{4}\left[(1-G)^2 - 1 - \frac{(n-3)(n+1)}{4}\right]\end{aligned} \tag{1.14}$$

or, in terms of Cartesian coordinates,

$$\begin{aligned}V_n = &-\frac{1}{4}\sum_{i=1}^{n}\frac{(\gamma_i-\frac{1}{2})(\gamma_i-\frac{3}{2})}{z_i^2} - \frac{1}{4}\frac{(\gamma_{n+1}-\frac{1}{2})(\gamma_{n+1}-\frac{3}{2})}{z_0^2} \\ &+\frac{1}{4}\left[(1-G)^2 - 1 - \frac{(n-3)(n+1)}{4}\right].\end{aligned} \tag{1.15}$$

The equation $H'\Psi \equiv (\Delta_n + V_n)\Psi = \lambda\Psi$ has a natural Riemannian metric

$$d\omega = g^{\frac{1}{2}}dx_1\cdots dx_n = x_1^{-\frac{1}{2}}\cdots x_n^{-\frac{1}{2}}(1-x)^{-\frac{1}{2}}dx_1\cdots dx_n \tag{1.16}$$

(Eisenhart [7]). Furthermore, the operator $H' = \rho^{-1}H\rho = \Delta_n + V_n$ is formally self-adjoint with respect to the inner product

$$\langle\Psi_1,\Psi_2\rangle = \int\cdots\int_{x_i>0,x<1}\Psi_1(\mathbf{x})\overline{\Psi_2}(\mathbf{x})d\omega \tag{1.17}$$

where Ψ_1, Ψ_2 are twice continuously differentiable functions of the x_j which take complex values:

$$\langle H'\Psi_1, \Psi_2\rangle = \langle \Psi_1, H'\Psi_2\rangle.$$

This induces an inner product on the space of polynomial functions $\Phi(\mathbf{x}) = \rho\Psi$, with respect to which H is self-adjoint:

$$\begin{aligned}(\Phi_1, \Phi_2) &\equiv \langle \Psi_1, \Psi_2\rangle \\ &= \int\cdots\int_{x_i>0, x<1} \Phi_1(\mathbf{x})\overline{\Phi_2}(\mathbf{x})\rho^{-2}(\mathbf{x})\, d\omega \\ &= \int\cdots\int_{x_i>0, x<1} \Phi_1\overline{\Phi_2}\, d\tilde{\omega},\end{aligned} \tag{1.18}$$

$$d\tilde{\omega} = x_1^{\gamma_1-1}\dots x_n^{\gamma_n-1}(1-x)^{\gamma_{n+1}-1}dx_1\dots dx_n,$$
$$(H\Phi_1, \Phi_2) = (\Phi_1, H\Phi_2).$$

(Indeed, H is clearly formally self-adjoint and the boundary terms obviously vanish for the γ_i sufficiently large. The result can then be extended to all $\gamma_i > 0$ by analytic continuation.) Thus $(\cdot,\cdot)$ is the natural inner product associated with equation (1.4).

A *first-order symmetry operator* for the equation $H\Phi = \lambda\Phi$ is a differential operator

$$K = \sum_{i=1}^{n} f_i(\mathbf{x})\partial_{x_i} + g(\mathbf{x})$$

such that

$$[H, K] \equiv HK - KH = 0$$

(Miller [22]). The first-order symmetry operators form a real Lie algebra under addition of operators, multiplication of an operator by a real scalar, and the commutator bracket $[A, B] = AB - BA$. If $\gamma_1 = \gamma_2 = \cdots = \gamma_{n+1} = \frac{1}{2}$ then $H = \Delta_n$ and it is well known (Eisenhart [7], [8]) that the Lie algebra of real symmetry operators of Δ_n is $so(n+1)$, with dimension $n(n+1)/2$ and a basis of the form $\{L_{\ell k}\}$ where $0 \le \ell < k \le n$ and $L_{\ell k} = -L_{k\ell}$. Explicitly,

$$L_{\ell k} = z_\ell\partial_{z_k} - z_k\partial_{z_\ell} \tag{1.19}$$

and

$$\begin{aligned}L_{ij} &= 2\sqrt{x_i x_j}(\partial_{x_j} - \partial_{x_i}), \qquad 1 \le i, j \le n, \\ L_{0i} &= 2\sqrt{x_i(1-x)}\partial_{x_i}, \qquad 1 \le i \le n.\end{aligned} \tag{1.20}$$

Furthermore, all real second-order differential operators S that commute with Δ_n can be expressed as linear combinations over $\mathbb{R}$ of real constants, elements $L_{\ell k}$ and elements $L_{\ell k}L_{\ell' k'}$. For $\gamma_1, \cdots, \gamma_{n+1}$ arbitrary, however, we have the following lemma.

LEMMA 1. *If K is a first-order operator such that $[K, H] = 0$ then $K = c$, multiplication by the real constant c. The second-order operators*

$$\begin{aligned} S_{ij} &\equiv 4x_ix_j(\partial_{x_i} - \partial_{x_j})^2 + 4(\gamma_i x_j - \gamma_j x_i)(\partial_{x_i} - \partial_{x_j}) \\ &= L_{ij}^2 + 4[(\gamma_i - \tfrac{1}{2})x_j - (\gamma_j - \tfrac{1}{2})x_i](\partial_{x_i} - \partial_{x_-j}) \\ &= S_{ji}, \qquad 1 \le i < j \le n, \end{aligned} \tag{1.21}$$

$$\begin{aligned} S_{0i} &\equiv 4x_i(1-x)\partial_{x_i}^2 + 4[\gamma_i(1-x) - \gamma_{n+1}x_i]\partial_{x_i} \\ &= L_{0i}^2 + 4[(\gamma_i - \tfrac{1}{2})(1-x) - (\gamma_{n+1} - \tfrac{1}{2})x_i]\partial_{x_i} \\ &= S_{i0}, \qquad 1 \le i \le n, \end{aligned} \tag{1.22}$$

do commute with H: $[S_{ij}, H] = [S_{0i}, H] = 0$. Also

$$8H \equiv \sum_{i,j=1}^{n} S_{ij} + 2\sum_{i=1}^{n} S_{0i}. \tag{1.23}$$

We conjecture, but have not proven, that linear combinations of the S_{ij} and S_{0i} are the only second-order operators commuting with H.

If S is a second-order symmetry operator for H then $S' = \rho^{-1}S\rho$ is a second-order symmetry for $H' = \Delta_n + V_n$ and, necessarily, $S' = \Upsilon + f$ where Υ is a second-order symmetry for Δ_n and f is a real-valued function. Thus S' is a formally self-adjoint operator with respect to the inner product $\langle \cdot, \cdot \rangle$ and S is formally self-adjoint with respect to $(\cdot, \cdot)$.

2. Orthogonal bases of separable solutions. In the paper (Kalnins and Miller [13]) and in the book (Kalnins [11]) all separable coordinates for the equation $\Delta_n\Psi = \lambda\Psi$ are constructed, where Δ_n is the Laplace–Beltrami operator on S^n. It is shown that all separable coordinates are orthogonal and that for each separable coordinate system the corresponding separated solutions are characterized as simultaneous eigenfunctions of a set of n second-order commuting symmetry operators for Δ_n. These operators are real linear combinations of the symmetries L_{ij}^2, $1 \le i < j \le n+1$, where L_{ij} is a rotational generator in so$(n+1)$. For $n = 2$ there are two separable systems (ellipsoidal and spherical coordinates), while for $n = 3$ there are six systems. The number of separable systems grows rapidly with n, but all systems can be constructed through a simple graphical procedure. (In general, the possible separable systems are the various polyspherical coordinates (Vilenkin [26]), the basic ellipsoidal coordinates, and combinations of polyspherical and ellipsoidal coordinates.) Moreover, the equation $(\Delta_n + V_n)\Psi = \lambda\Psi$, where the scalar potential takes the form

$$V_n = \sum_{i=1}^{n} \frac{\alpha_i}{z_i^2} + \frac{\alpha_0}{z_0^2}, \qquad \alpha_0, \alpha_1, \cdots, \alpha_n \text{ const.}, \tag{2.1}$$

is separable in *all* the coordinate systems in which the Laplace–Beltrami eigenvalue equation is separable. (That is, V_n of this form is a *Stäckel multiplier* for all separable coordinate systems on S^n; see Boyer, Kalnins, and Miller [3].) Indeed, the equation

with potential (2.1) is separable in general ellipsoidal coordinates. Since all other coordinates are limiting cases of ellipsoidal coordinates, the conclusion follows. (Note: If each $\alpha_j = -\frac{1}{4}k_j(k_j + m_j - 1)$ where k_j and m_j are nonnegative integers with $m_j \geq 1$, then the equation $(\Delta_n + V_n)\Psi = \lambda\Psi$ can be viewed as a resriction of the Laplace–Beltrami eigenvalue equation $(\Delta_M + V_M)\Psi' = \lambda\Psi'$ on the N-sphere where $N = \sum_{j=0}^{n} m_j + n$, in which the variable dependence on the subspheres S^{m_j} has already been factored out. Moreover, using the canonical equation technique found in Kalnins, Manocha, and Miller [12] we can show that all solutions of the above equation for general γ_i are solutions of the flat-space wave equation in $2n + 2$ dimensions with signature $(n + 1, n + 1)$. Thus the conformal symmetry algebra of the wave equation can be expected to transform solutions of the eigenvalue equations among themselves. Lemma 2 and Corollary 1 below are examples of this action.)

The results of Kalnins and Miller, characterizing separable systems by symmetry operators, can easily be translated to the present case. In those references (for $V_n = 0$) the symmetry operators are given explicitly as linear combinations of the symmetries L_{ij}^2. The results for the potential (1.14) are similar: L_{ij}^2 is replaced by $S'_{ij} = \rho^{-1}S_{ij}\rho$ and takes the same linear combinations. Moreover, since the defining symmetry operators for a separable system are real linear combinations of the L_{ij}^2 plus scalar functions, they are formally self-adjoint with respect to the inner product $\langle \cdot, \cdot \rangle$.

These results can now easily be extended to results for solutions of

$$(\Delta_n + \Lambda_n)\Phi = \lambda\Phi \tag{2.2}$$

through the mappings

$$\begin{aligned} &\Delta_n + \Lambda_n = \rho(\Delta_n + V_n)\rho^{-1} \\ &S_{ij} = \rho S'_{ij}\rho^{-1} \\ &\Phi = \rho\Psi. \end{aligned} \tag{2.3}$$

Thus all separable solutions Ψ map to R-separable solutions Φ of (2.2) (Miller [22]). The R-separable coordinates and solutions are determined by commuting symmetry operators S of $\Delta_n + \Lambda_n$ which are obtained from expressions in Kalnins and Miller [13] or Kalnins [11], where each occurrence of L_{ij}^2 is replaced by S_{ij}. The defining symmetry operators are all formally self-adjoint with respect to the inner product $(\cdot, \cdot)$. Finally, since each S_{ij} maps polynomials of maximum order m_k in x_k to polynomials of the same type, it follows that a basis of separated solutions can be expressed as *polynomials* in the x_i. Since the symmetry operators are self-adjoint, the basis of simultaneous eigenfunctions can be chosen to be *orthogonal*.

We conclude from this argument that every separable coordinate system for the Laplace–Beltrami eigenvalue equation on the n-sphere yields an orthogonal basis of polynomial solutions of equation (1.4), hence an orthogonal basis for all n-variable polynomials with inner product (1.18).

As an example we work out the separation equations for spherical coordinates $\{u_i\}$ on S^n:

$$
\begin{aligned}
z_0^2 &= 1 - x = 1 - u_n \\
z_1^2 &= x_1 = u_1 u_2 \dots u_n \\
z_2^2 &= x_2 = (1 - u_1) u_2 \dots u_n \\
&\vdots \\
z_{n-1}^2 &= x_{n-1} = (1 - u_{n-2}) u_{n-1} u_n \\
z_n^2 &= x_n = (1 - u_{n-1}) u_n .
\end{aligned} \tag{2.4}
$$

(Note that in terms of angles $\{\theta_i\}$ we usually set $u_i = \sin^2 \theta_i$.) It follows that

$$
u_j = \begin{cases} w_j / w_{j+1}, & j = 1, \cdots, n-1 \\ w_n, & j = n \end{cases}, \tag{2.5}
$$

where

$$
w_\ell = \sum_{i=1}^{\ell} x_i .
$$

In terms of the $\{u_i\}$, the operator (1.5) becomes

$$
H = \sum_{i=1}^{n} \frac{1}{u_{i+1} \cdots u_n} \left[u_i (1 - u_i) \partial_{u_i}^2 + \left(\sum_{j=1}^{i} \gamma_j - \left(\sum_{p=1}^{i+1} \gamma_p \right) u_i \right) \partial_{u_i} \right] . \tag{2.6}
$$

Equation (1.4) is separable in these coordinates with separation equations

$$
\begin{aligned}
& u_1 (1 - u_1) \partial_{u_1}^2 \Theta_1 + [\gamma_1 - (\gamma_1 + \gamma_2) u_1] \partial_{u_1} \Theta_1 = c_1 \Theta_1 , \\
& \left[\frac{c_{k-1}}{u_k} + u_k (1 - u_k) \partial_{u_k}^2 \right] \Theta_k + \left[\sum_{j=1}^{k} \gamma_j - \left(\sum_{p=1}^{k+1} \gamma_p \right) u_k \right] \partial_{u_k} \Theta_k = c_k \Theta_k , \\
& \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad k = 2, 3, \cdots, n .
\end{aligned} \tag{2.7}
$$

Here $\Theta = \prod_{k=1}^{n} \Theta_k(u_k)$ and the c_i are the separation constants, with $c_n = -M(M + G - 1)$.

Noting that the hypergeometric equation

$$
u(1 - u) \frac{d^2 g}{du^2} + [c - (a + b + 1) u] \frac{dg}{du} - abg = 0
$$

admits the solution

$$
g = {}_2F_1 \left(\begin{matrix} a, & b \\ & c \end{matrix} ; u \right) = \sum_{m=1}^{\infty} \frac{(a)_m (b)_m}{(c)_m m!} u^m ,
$$

a polynomial for $a = 0, -1, -2, \cdots$, and requiring that Θ be a polynomial in the $\{x_i\}$ we obtain the solutions

(2.8)

$$\Theta_1(u_1) = {}_2F_1\left(\begin{matrix}-\ell_1, & \ell_1+\gamma_1+\gamma_2-1\\ & \gamma_1\end{matrix}; u_1\right)$$

$$c_1 = -\ell_1(\ell_1+\gamma_1+\gamma_2-1),$$

$$\Theta_k(u_k) = u_k^{\ell_1+\ell_2+\cdots+\ell_{k-1}}\,{}_2F_1\left(\begin{matrix}-\ell_k, & 2(\ell_1+\cdots+\ell_{k-1})+\ell_k+\gamma_1+\cdots+\gamma_{k+1}-1\\ & 2(\ell_1+\cdots+\ell_{k-1})+\gamma_1+\cdots+\gamma_k\end{matrix}; u_k\right),$$

$$c_k = -(\ell_1+\cdots+\ell_k)(\ell_1+\cdots+\ell_k+\gamma_1+\cdots+\gamma_{k+1}-1),$$

$$k = 2,3,\cdots,n,$$

where $\sum_{i=1}^n \ell_i = M$ and $\ell_i = 0,1,2\cdots$. This determines Θ to within a normalization factor.

In the special case $n = 2$ we have the result of (Proriol [23]) and of (Karlin and McGregor [14]):

$$\begin{aligned}\Theta_{\ell_1,\ell_2}(x_1,x_2) =& {}_2F_1\left(\begin{matrix}-\ell_1, & \ell_1+\gamma_1+\gamma_2-1\\ & \gamma_1\end{matrix}; \frac{x_1}{x_1+x_2}\right)(x_1+x_2)^{\ell_1}\\ &\times {}_2F_1\left(\begin{matrix}-\ell_2, & 2\ell_1+\ell_2+\gamma_1+\gamma_2+\gamma_3-1\\ & 2\ell_1+\gamma_1+\gamma_2\end{matrix}; x_1+x_2\right)\\ &\sim P_{\ell_2}^{(\gamma_3-1,\gamma_1+\gamma_2+2\ell_1-1)}(2x_1+2x_2-1)\,(x_1+x_2)^{\ell_1}\\ &\times P_{\ell_1}^{(\gamma_2-1,\gamma_1-1)}\left(\frac{2x_1}{x_1+x_2}-1\right),\end{aligned} \tag{2.9}$$

where $P_k^{(\alpha,\beta)}(x)$ is a Jacobi polynomial.

Returning to the general case, we have the eigenvalue equations

$$S_\ell\Theta_\ell = c_\ell\Theta_\ell, \qquad \ell = 1,\cdots,n, \tag{2.10}$$

where

$$\begin{aligned}S_1 &= u_1(1-u_1)\partial_{u_1}^2 + [\gamma_1-(\gamma_1+\gamma_2)u_1]\,\partial_{u_1},\\ S_k &= \frac{1}{u_k}S_{k-1} + u_k(1-u_k)\partial_{u_k}^2 + [\gamma_1+\cdots+\gamma_k-(\gamma_1+\cdots+\gamma_{k+1})u_k]\,\partial_{u_k},\\ &\qquad k = 2,3,\cdots,n,\end{aligned} \tag{2.11}$$

and $S_n = H$. Furthermore, $[S_i, S_j] = 0$ and the S_i are self-adjoint with respect to the inner product $(\cdot,\cdot)$. It follows immediately that

$$(\Theta_\ell, \Theta_{\mathbf{m}}) = 0$$

unless $\ell_1 = m_1$, $\ell_2 = m_2,\cdots$, $\ell_n = m_n$. The measure $d\tilde{\omega}$ becomes in these coordinates

$$d\tilde{\omega} = u_1^{\gamma_1-1}u_2^{\gamma_1+\gamma_2-1}\cdots u_n^{\gamma_1+\cdots+\gamma_n-1}(1-u_1)^{\gamma_2-1}(1-u_2)^{\gamma_3-1}\cdots(1-u_n)^{\gamma_{n+1}-1}du_1\cdots du_n,$$

where $0 < u_i < 1$. In terms of the symmetries S_{ij}, S_{0i}, (1.21)–(1.22), we have

$$S_k = \frac{1}{8}\sum_{i,j=1}^{k+1} S_{ij}, \qquad k = 1, \cdots, n-1 \tag{2.12}$$

$$S_n = H = \frac{1}{8}\left(\sum_{h,p=0}^{n} S_{hp}\right),$$

where we set $S_{hh} = 0$.

3. Orthogonal bases for another space of polynomials. Now we make the change of coordinates $x_i = y_i^2$, $1 \le i \le n$, and look for solutions of (1.4) that are polynomials in the y_i. In general, H does not map polynomials in the y_i to polynomials, but in the special case $\gamma_1 = \gamma_2 = \cdots = \gamma_n = \frac{1}{2}$, $G = \gamma_{n+1} + n/2 = s/2 + (n+1)/2$, we have

$$H = \frac{1}{4}\sum_{i,j=1}^{n}(\delta_{ij} - y_i y_j)\partial_{y_i y_j} + \frac{1}{2}\left(\frac{1}{2} - G\right)\sum_{j=1}^{n} y_j \partial_{y_j}, \tag{3.1}$$

and H does map polynomials to polynomials of at most the same degree. Moreover, the differential operators

$$L_{ij} = -L_{ji} = y_i\partial_{y_j} - y_j\partial_{y_i}, \qquad 1 \le i < j \le n, \tag{3.2}$$

commute with H and form a basis for the symmetry algebra so(n). The special second-order symmetries take the form $S_{ij} = L_{ij}^2$, $1 \le i < j \le n$, and

$$S_{0i} = L_{0i}^2 - 2\left(G - \frac{1}{2}\right) y_i\partial_{y_i} = \left(1 - \sum_{j=1}^{n} y_j^2\right)\partial_{y_i}^2 - 2G y_i \partial_{y_i},$$

and clearly map polynomials to polynomials of at most the same degree. The measure takes the form

$$d\tilde{\omega} = (1 - y_1^2 - \cdots - y_n^2)^{s/2-(1/2)} dy_1 \cdots dy_n, \tag{3.3}$$

where $-1 \le y_i \le 1$ and

$$\rho^{-1} = (1 - y_1^2 - \cdots - y_n^2)^{s/4}. \tag{3.4}$$

Again, H and the $S_{\ell k}$ are formally self-adjoint with respect to the inner product

$$(\Phi_1, \Phi_2) = \int \cdots \int_{\sum y_i^2 < 1} \Phi_1(\mathbf{y})\overline{\Phi_2}(\mathbf{y})\, d\tilde{\omega}, \tag{3.5}$$

where Φ_1, Φ_2 are polynomials in the y_i.

Every separable coordinate system for the equation

$$H\Phi = -M(M+G-1)\Phi, \qquad 2M \text{ a nonnegative integer,} \tag{3.6}$$

where H is given by (3.1) yields an orthogonal basis of multivariable polynomials with respect to the inner product $(\cdot,\cdot)$. (For $n = 2$ this equation is also on the list of Krall and Sheffer [20].) Indeed, for spherical coordinates $u_i = \sin^2\theta_i$ we obtain the orthogonal basis of polynomials in $\mathbf{y}$:

(3.7)

$$e^{\pm 2i\ell_1\theta_1}\prod_{k=2}^{n-1}[\sin\theta_k]^{2(\ell_1+\cdots+\ell_{k-1})}C_{2\ell_k}^{2(\ell_1+\cdots+\ell_{k-1})+(k-1)/2}(\cos\theta_k)$$
$$\times u_n^{\ell_1+\cdots+\ell_{n-1}}{}_2F_1\left(\begin{matrix}-\ell_n, & 2(\ell_1+\cdots+\ell_{n-1})+\ell_n+(n-1)/2+s/2\\ & 2(\ell_1+\cdots+\ell_{n-1})+n/2\end{matrix};u_n\right),$$

where $2\ell_i = 0,1,2,\cdots$ for $1 \le i \le n-1$, $\ell_n = 0,1,2,\cdots$, and the $C_k^\lambda(x)$ are Gegenbauer polynomials

$$C_k^\lambda(x) = \frac{(2\lambda)_k}{k!}{}_2F_1\left(\begin{matrix}-k, & k+2\lambda\\ & \lambda+\frac{1}{2}\end{matrix};\tfrac{1}{2}-x/2\right)$$

(Erdélyi et al. [9]). (The eigenvalues are defined as before.)

Using the results of [11] or [13], many other orthogonal bases can be worked out. Moreover, the symmetry group $\mathrm{SO}(n)$ permits the derivation of addition theorems for the basis elements, related to the addition theorem for Gegenbauer polynomials and Koornwinder's addition theorem [15]–[17].

Next we relate the Cartesian coordinates z_ℓ and the y_a via

$$\begin{aligned} z_0^2 &= y_1^2\\ z_1^2 &= y_2^2\\ &\vdots\\ z_{n-1}^2 &= y_n^2\\ z_n^2 &= 1-y_1^2-\cdots-y_n^2, \end{aligned} \tag{3.8}$$

a simple permutation of the relations (2.4), so that the (separable) spherical coordinates v_i are associated with the y_a through

$$v_1 = \frac{y_2^2}{y_2^2+y_3^2}, \quad v_2 = \frac{y_2^2+y_3^2}{y_2^2+y_3^2+y_4^2}, \quad \cdots, \quad v_{n-2} = \frac{y_2^2+\cdots+y_{n-1}^2}{y_2^2+\cdots+y_n^2},$$

$$v_{n-1} = \frac{y_2^2+\cdots+y_n^2}{1-y_1^2}, \qquad v_n = 1-y_1^2. \tag{3.9}$$

From the point of view of separability for the Laplace–Beltrami eigenvalue equation, these v_i coordinates are equivalent to the u_i coordinates introduced earlier, since one system can be obtained from the other through the action of an element of the $\mathrm{SO}(n+1)$ symmetry group for this equation. However, the term Λ_n breaks this

symmetry so that from the viewpoint of the eigenvalue equation for H, with $\gamma_1 = \gamma_2 = \cdots \gamma_n = \frac{1}{2}$, these are distinct coordinates. The separation equations for the v_i are identical to those for the u_i if we interchange $\gamma_n = \frac{1}{2}$ and $\gamma_{n+1} = s/2 + \frac{1}{2}$. For $n = 2$ the orthogonal basis of polynomials is

$$C_{2\ell_1}^{s/2}(\sin\theta_1) C_{2\ell_2}^{2\ell_1+s/2+\frac{1}{2}}(\cos\theta_2)\sin^{2\ell_1}\theta_2, \tag{3.10}$$

where $\ell_1, \ell_2 = 0, \frac{1}{2}, 1, \frac{3}{2}, \cdots$, $\ell_1 + \ell_2 = N$ and $v_j = \sin^2\theta_j$. This is in agreement with the basis of Koschmieder [18], [19].

For $n > 2$ we have an orthogonal basis of polynomials of the form $\Theta = \prod_{k=1}^{n} \Theta_k$, where

(3.11)

$$\Theta_1 = e^{\pm 2i\ell_1\theta_1}, \quad \ell_1 = 0, 1/2, 1, 3/2, \cdots,$$

$$\Theta_k = [\sin\theta_k]^{2(\ell_1+\cdots+\ell_{k-1})} C_{2\ell_k}^{2(\ell_1+\cdots+\ell_{k-1})+(k-1)/2}(\cos\theta_k)$$

$$\ell_k = 0, \tfrac{1}{2}, 1, \cdots, \qquad 1 < k < n-1,$$

$$\Theta_{n-1} = v_{n-1}^{\ell_1+\cdots+\ell_{n-2}} {}_2F_1\left(\begin{matrix} -\ell_{n-1}, & 2(\ell_1+\cdots+\ell_{n-2}) + \ell_{n-1} + (n-2)/2 + s/2 \\ & 2(\ell_1+\cdots+\ell_{n-2}) + (n-1)/2 \end{matrix}; v_{n-1}\right)$$

$$\ell_{n-1} = 0, 1, 2, \cdots,$$

$$\Theta_n = [\sin\theta_n]^{2(\ell_1+\cdots+\ell_{n-1})} C_{2\ell_n}^{2(\ell_1+\cdots+\ell_{n-1})+(n-1)/2+s/2}(\cos\theta_n)$$

$$\ell_n = 0, \tfrac{1}{2}, 1, \cdots,$$

where $\ell_1 + \cdots + \ell_n = M$ and $v_j = \sin^2\theta_j$.

4. The "mixed" case. Next we consider the more general mixed case with variables $x_1, \cdots, x_{n_1}, y_1, \cdots, y_{n_2}$, $n_1 + n_2 = n$, where

$$\begin{aligned} z_0^2 &= 1 - \sum_{i=1}^{n_1} x_i - \sum_{a=1}^{n_2} y_a^2, \\ z_1^2 &= x_1, \\ &\vdots \\ z_{n_1}^2 &= x_{n_1}, \\ z_{n_1+1}^2 &= y_1^2, \\ &\vdots \\ z_n^2 &= y_{n_2}^2, \end{aligned} \tag{4.1}$$

and look for polynomial solutions in x_i, y_a of the equation

$$H\Phi(\mathbf{x}, \mathbf{y}) = -M(M + G - 1)\Phi(\mathbf{x}, \mathbf{y}), \tag{4.2}$$

where $\gamma_{n_1+1} = \gamma_{n_1+2} = \cdots = \gamma_n = \frac{1}{2}$ and

$$
\begin{aligned}
H &= \frac{1}{4}\sum_{a,b}(\delta_{ab}-y_ay_b)\partial_{y_ay_b}+\sum_{i,j}(\delta_{ij}x_i-x_ix_j)\partial_{x_ix_j}\\
&\quad -\sum_{a,i}y_ax_i\partial_{y_ax_i}+\sum_i(\gamma_i-Gx_i)\partial_{x_i}+\frac{1}{2}\sum_a\left(\frac{1}{2}-G\right)y_a\partial_{y_a},\\
G &= \frac{n_2+1}{2}+\sum_i\gamma_i+\frac{s}{2}, \qquad 2M \text{ a nonnegative integer.}
\end{aligned}
\tag{4.3}
$$

For reference,

$$
\begin{aligned}
\Delta_n &= \frac{1}{4}\sum_{a,b}(\delta_{ab}-y_ay_b)\partial_{y_ay_b}+\sum_{i,j}(\delta_{ij}x_i-x_ix_j)\partial_{x_ix_j}\\
&\quad -\sum_{a,i}y_ax_i\partial_{y_ax_i}+\frac{1}{2}\sum_i(1-(n+1)x_i)\,\partial_{x_i}-\frac{n}{4}\sum_a y_a\partial_{y_a},\\
\Lambda_n &= \sum_i\left[\gamma_i-\frac{1}{2}+\left(\frac{n+1}{2}-G\right)x_i\right]\partial_{x_i}+\frac{1}{2}\sum_a\left(\frac{n+1}{2}-G\right)y_a\partial_{y_a}.
\end{aligned}
\tag{4.4}
$$

Note that H maps polynomials in x_i, y_a to polynomials of at most the same order. The induced measure is

$$
\begin{aligned}
&d\tilde{\omega} = x_2^{\gamma_1-1}\cdots x_{n_2}^{\gamma_{n_1}-1}(1-\sum x_i-\sum y_a^2)^{s/2-\frac{1}{2}}dx_1\cdots dx_{n_1}dy_1\cdots dy_{n_2},\\
&0<x_i, \quad -1<y_a<1, \quad \sum_i x_i+\sum_a y_a^2<1,
\end{aligned}
\tag{4.5}
$$

and

$$
\rho^{-1} = x_1^{\gamma_1/2-1/4}\cdots x_{n_1}^{\gamma_{n_1}/2-1/4}\left(1-\sum_i x_i-\sum_a y_a^2\right)^{s/4}.
$$

Equation (4.2) admits the symmetry algebra $\mathrm{so}(n_2)$ with basis

$$
L_{ab} = -L_{ba} = y_a\partial_{y_b}-y_b\partial_{y_a}, \qquad 1\le a<b\le n_2.
$$

The operators H and S_{mk} are formally self-adjoint on the space of polynomials in x_i, y_a with respect to the inner product

$$
(\Phi_1,\Phi_2) = \int\cdots\int_{0<x_i,\sum_i x_i+\sum_a y_a^2<1}\Phi_1(\mathbf{x},\mathbf{y})\overline{\Phi_2}(\mathbf{x},\mathbf{y})\,d\tilde{\omega}.
$$

However, in general the S_{mk} do not map a polynomial to one of the same or lower order in each variable, e.g.,

$$
S_{ia} = 4x_iy_a^2\partial_{x_i}^2+x_i\partial_{y_a}^2-4x_iy_a\partial_{x_iy_a}+4\gamma_iy_a^2\partial_{x_i}-2x_i\partial_{x_i}-2\gamma_iy_a\partial_{y_a},
$$

although they do map polynomials to polynomials. It is still true that each symmetry operator S maps a polynomial eigenspace of H into itself.

It follows that all separable coordinate systems for the n-sphere yield bases of orthogonal polynomials in the mixed case (indeed multiple sets of such bases, depending on the ordering of the variables x_i, y_a). For example, if we choose spherical coordinates $u_\ell = \sin^2\theta_\ell$ in the form

$$u_\ell = \frac{w_\ell}{w_{\ell+1}},$$

where

$$w_\ell = \begin{cases} \sum_{i=1}^{\ell} x_i, & \ell = 1,\cdots,n_1 \\ \sum_{i=1}^{n_1} x_i + \sum_{a=1}^{\ell-n_1} y_a^2, & \ell = n_1+1,\cdots,n_1+n_2 \\ 1, & \ell = n_1+n_2+1 \end{cases} \tag{4.6}$$

we find the orthogonal basis of polynomials:

$$\Theta = \prod_{k=1}^{n} \Theta_k(u_k),$$

where

(4.7)

$$\Theta_k(u_k) = u_k^{\ell_1+\cdots+\ell_{k-1}}\,{}_2F_1\left(\begin{matrix}-\ell_k, & 2(\ell_1+\cdots+\ell_{k-1})+\ell_k+\gamma_1+\cdots+\gamma_{k+1}-1 \\ & 2(\ell_1+\cdots+\ell_{k-1})+\gamma_1+\cdots+\gamma_k\end{matrix}; u_k\right),$$

$$c_k = -(\ell_1+\cdots+\ell_k)(\ell_1+\cdots+\ell_k+\gamma_1+\cdots+\gamma_{k+1}-1),$$

$$k = 1,\cdots,n_1,$$

$$\Theta_k(u_k) = [\sin\theta_k]^{2(\ell_1+\cdots+\ell_{k-1})} C_{2\ell_k}^{2(\ell_1+\cdots+\ell_{k-1})+\sum_{i=1}^{k}\gamma_i-\frac{1}{2}}(\cos\theta_k),$$

$$c_k = -(\ell_1+\cdots+\ell_k)(\ell_1+\cdots+\ell_k+\gamma_1+\cdots+\gamma_{k+1}-1),$$

$$k = n_1+1,\cdots,n_2+n_1-1,$$

$$\Theta_n(u_n) = u_n^{\ell_1+\cdots+\ell_{n-1}}\,{}_2F_2\left(\begin{matrix}-\ell_n, & 2(\ell_1+\cdots+\ell_{n-1})+\ell_n+G-2 \\ & 2(\ell_1+\cdots+\ell_{n-1})+G-s/1-\frac{1}{2}\end{matrix}; u_n\right).$$

Here $\ell_1,\cdots,\ell_{n_1}$, ℓ_n and $2\ell_{n_1+1},\cdots,2\ell_{n_1+n_2-1}$ are nonnegative integers. (Recall that $\gamma_{n_1+1} = \gamma_{n_1+2} = \cdots = \gamma_{n_1+n_2} = \frac{1}{2}$.)

5. Biorthogonal families of polynomials on S^n. We begin this section with a simplified proof of the biorthogonality of the polynomials (1.1) and (1.2) with respect to the inner product $(\cdot,\cdot)_\gamma$; see (1.18), (1.19). Let $\mathscr{S}_\gamma$ be the space of all polynomials in $x_1,\cdots,x_n$ with respect to this inner product and let $\mathscr{H}_{\gamma,M}$ be the subspace of $\mathscr{S}_\gamma$ consisting of solutions Φ to the eigenvalue equation

$$H\Phi = -M(M+G-1)\Phi, \tag{5.1}$$

where H is given by (1.5). Since the functions

$$D_{\mathbf{m}}^{\gamma}(\mathbf{x}) = F_A\left[\begin{matrix}M+G-1; & -m_1,\cdots,-m_n \\ & \gamma_1,\cdots,\gamma_n\end{matrix}; x_1,\cdots,x_n\right] \tag{5.2}$$

clearly satisfy (5.1) for $M = \sum_{i=1}^{n} m_i$ and since the highest order monomial in these solutions is $x_1^{m_1}\cdots x_n^{m_n}$ it follows that the $D_{\mathbf{m}}^{\gamma}$ for $m_1+\cdots+m_n \equiv m = M$ form

a basis for $\mathscr{H}_{\gamma,M}$ and, as the m_i range over all nonnegative integers, a basis for $\mathscr{S}_\gamma$. (Note: $\dim \mathscr{H}_{\gamma,M} = \binom{M+n-1}{n-1}$.) Since H is self-adjoint we have $\mathscr{H}_{\gamma,M} \perp \mathscr{H}_{\gamma,M'}$ for $M' \neq M$. Thus

$$(D^\gamma_{\mathbf{m}'}, D^\gamma_{\mathbf{m}})_\gamma = 0 \quad \text{for } m' \neq m. \tag{5.3}$$

It is simple to verify the recurrence relation

$$\partial_{x_i} D^\gamma_{\mathbf{m}}(\mathbf{x}) = \frac{(M+G-1)(-m_i)}{\gamma_i} D^{\hat{\gamma}}_{\hat{\mathbf{m}}}(\mathbf{x}), \tag{5.4}$$

where

$$\hat{\gamma}_j = \begin{cases} \gamma_j & \text{for } j \neq i,\ 1 \leq j \leq n \\ \gamma_i + 1 & \text{for } j = i \\ \gamma_{n+1} + 1 & \text{for } j = n+1 \end{cases}$$

$$\hat{m}_j = \begin{cases} m_j & \text{for } j \neq i,\ 1 \leq j \leq n \\ m_i - 1 & \text{for } j = i \end{cases} \tag{5.5}$$

$$\hat{M} = M - 1, \qquad \hat{G} = G + 2.$$

We can consider $P_i = \partial_{x_i}$ as an operator

$$P_i : \mathscr{S}_\gamma \to \mathscr{S}_{\hat{\gamma}}.$$

Indeed we have the following lemma.

LEMMA 2. *P_i, $(1 \leq i \leq n)$, maps $\mathscr{H}_{\gamma,M}$ onto $\mathscr{H}_{\hat{\gamma},\hat{M}}$.*

Proof. The proof is immediate from (5.4). For a basis free proof we can easily verify the operator identity

$$\hat{H}P_i = GP_i + P_iH, \tag{5.6}$$

where $\hat{H}$ is the operator H with the γ_j replaced by $\hat{\gamma}_j$. Then if $H\Phi = -M(M+G-1)\Phi$ we have $\hat{H}(P_i\Phi) = -\hat{M}(\hat{M}+\hat{G}-1)(P_i\Phi)$. The null space of P_i acting on $\mathscr{H}_{\gamma,M}$ is of dimension $\binom{M+n-2}{n-2}$ for $n \geq 2$, hence the dimension of the range of P_i is

$$\binom{M+n-1}{n-1} - \binom{M+n-2}{n-2} = \binom{M+n-2}{n-1} = \dim \mathscr{H}_{\hat{\gamma},\hat{M}}. \qquad \square$$

COROLLARY 1. *The operator $P_i - P_j$ maps $\mathscr{H}_{\gamma,M}$ into $\mathscr{H}_{\tilde{\gamma},\tilde{M}}$, where $1 \leq i < j \leq n$ and*

$$\tilde{\gamma}_k = \begin{cases} \gamma_k & \text{for } 1 \leq k \leq n+2,\ k \neq i,j \\ \gamma_i + 1 & \text{for } k = i \\ \gamma_j + 1 & \text{for } k = j \end{cases}$$

$$\tilde{M} = M - 1, \qquad \tilde{G} = G + 2.$$

Proof.

$$\tilde{H}(P_i - P_j) = G(P_i - P_j) + (P_i - P_j)H.$$

Thus if $H\Phi = -M(M+G-1)\Phi$ we have

$$\tilde{H}([P_i - P_j]\Phi) = -\tilde{M}(\tilde{M}+\tilde{G}-1)[P_i - P_j]\Phi. \qquad \square$$

The operator P_i induces an adjoint operator $P_i^* : \mathscr{S}_{\hat{\gamma}} \to \mathscr{S}_\gamma$, defined by

$$(P_i^*\Phi, \Phi')_\gamma = (\Phi, P_i\Phi')_{\hat{\gamma}}$$

for all $\Phi \in \mathscr{S}_{\hat{\gamma}}$, $\Phi' \in \mathscr{S}_\gamma$. A straightforward computation yields

$$P_i^* = -x_i(1-x)\partial_{x_i} - \gamma_i(1-x) + \gamma_{n+1}x_i. \tag{5.7}$$

THEOREM 1. *P_i^* is a 1-1 map of $\mathscr{H}_{\hat{\gamma},\hat{M}}$ into $\mathscr{H}_{\gamma,M}$.*

Proof. Taking the adjoint of the relation (5.4) we obtain

$$P_i^*\hat{H} = GP_i^* + HP_i^*.$$

Furthermore, P_i^* is 1-1 since P_i is onto. □

Let

$$C_{\mathbf{m}}^\gamma(\mathbf{x}) = (P_1^*)^{m_1} \cdots (P_n^*)^{m_n} 1 \in \mathscr{S}_\gamma$$

be the result of applying m_n operators $P_n^*, \cdots, m_1$ operators P_1^*, one at a time, to the function $1 \in \mathscr{S}_{\gamma'}$, where

$$\gamma_i' = \gamma_i + m_i, \qquad 1 \le i \le n,$$
$$\gamma_{n+1}' = \gamma_{n+1} + m.$$

(Each time an operator P_j^* is applied it lowers γ_j and γ_{n+1} by 1 and leaves the other γ_k's unchanged. The order in which these operators are applied makes no difference in the result.) It follows from the recurrence relation

$$\left(x_i \sum_{j=1}^n x_j\partial_{x_j} - x_i\partial_{x_i} + x_i(-M-\gamma_{n+1}+1) - \gamma_i + 1\right) \tag{5.8}$$
$$\times F_A\left[\begin{matrix} -M-\gamma_{n+1}+1; & -m_1, \cdots, -m_n \\ & \gamma_1, \cdots, \gamma_n \end{matrix}; x_1, \cdots, x_n\right]$$
$$= (1-\gamma_i)F_A\left[\begin{matrix} -(M+1)-(\gamma_{n+1}-1)+1; & -m_1, \cdots, -(m_i+1), \cdots, -m_n \\ & \gamma_1, \cdots, \gamma_i - 1, \cdots, \gamma_n \end{matrix}; x_1, \cdots, x_n\right]$$

and a simple induction argument that

$$C_{\mathbf{m}}^\gamma(\mathbf{x}) = c_{\gamma,m}(1-x)^M F_A\left[\begin{matrix} -M-\gamma_{n+1}+1; & -m_1, \cdots, -m_n \\ & \gamma_1, \cdots, \gamma_n \end{matrix}; -\frac{x_1}{1-x}, \cdots, -\frac{x_n}{1-x}\right], \tag{5.9}$$

where $c_{\gamma,m}$ is a nonzero constant. It follows from Theorem 1 that the $C_{\mathbf{m}}^\gamma$ belong to $\mathscr{H}_{\gamma,M}$ for $M = m_1 + \cdots + m_n$. Since there are $\binom{M+n-1}{n-1}$ of these functions for fixed M and since they are clearly linearly independent, they form a basis for $\mathscr{H}_{\gamma,M}$.

Now consider the inner product

$$(C_{\mathbf{m}}^\gamma, D_{\mathbf{m}'}^\gamma)_\gamma.$$

If $m = M \neq m' = M'$ the inner product vanishes, since $\mathscr{H}_{\gamma,M} \perp \mathscr{H}_{\gamma,M'}$. If $m = m'$ but $\mathbf{m} \not\equiv \mathbf{m}'$ then $m_i > m_i'$ for some i. Thus

$$(C_{\mathbf{m}}^\gamma, D_{\mathbf{m}'}^\gamma)_\gamma = \kappa\,(1, P_1^{m_1} \cdots P_n^{m_n} D_{\mathbf{m}'}^\gamma)_{\gamma'} = 0$$

since $P_i^{m_i} D_{\mathbf{m}'}^\gamma = 0$. (Here, κ is a nonzero constant.) We conclude that the set $\{C_{\mathbf{m}}^\gamma, D_{\mathbf{m}'}^\gamma\}$ is biorthogonal. (This family is a generalization of biorthogonal polynomials in two variables studied by Appell and Kampé de Fériet [1] and extended by Fackerell and Littler [10].)

Note that the norm of the weight function is

(5.10)
$$\int_0^1 dx_1 \int_0^{1-x_1} dx_2 \cdots \int_0^{1-x_1-\cdots-x_{n-1}} dx_n \left[\prod_{k=1}^n x_k^{\gamma_k-1}\right](1-x)^{\gamma_{n+1}-1}$$
$$= (1,1)_\gamma = \frac{\left[\prod_{k=1}^{n+1}\Gamma(\gamma_k)\right]}{\Gamma(G)}.$$

The relation
$$(P_i^* C_{\hat{\mathbf{m}}}^{\hat{\gamma}}, D_{\mathbf{m}'}^{\gamma})_\gamma = (C_{\hat{\mathbf{m}}}^{\hat{\gamma}}, P_i D_{\mathbf{m}'}^{\gamma})_{\hat{\gamma}}$$
yields (for $\mathbf{m} = \mathbf{m}'$) the recurrence relation
$$(C_{\mathbf{m}}^{\gamma}, D_{\mathbf{m}}^{\gamma})_\gamma = -\frac{m_i(M+G-1)}{\gamma_i}(C_{\hat{\mathbf{m}}}^{\hat{\gamma}}, D_{\hat{\mathbf{m}}}^{\hat{\gamma}})_{\hat{\gamma}}.$$
The normalization of the biorthogonal basis can be obtained from this result and (5.10).

Now we extend the biorthogonality relations to the full n-sphere. We make the change of variables
$$x_k = y_k^2, \qquad k = 1, 2, \cdots, n$$
in (5.10) and extend the domain of integration to negative values of y_k, since the integrand is even in all variables, to get
$$\int_{-1}^1 dy_1 \int_{-\sqrt{1-y_1^2}}^{\sqrt{1-y_1^2}} dy_2 \cdots \int_{-\sqrt{1-y_1^2-\cdots-y_{n-1}^2}}^{\sqrt{1-y_1^2-\cdots-y_{n-1}^2}} dy_n$$
$$\cdot \left[\prod_{k=1}^n (y_k^2)^{\gamma_k-1/2}\right](1-y_1^2-\cdots-y_n^2)^{s/2-1/2}$$
$$= (1,1)'_\gamma = \frac{[\prod_{k=1}^n \Gamma(\gamma_k)]\Gamma(\frac{s}{2}+\frac{1}{2})}{\Gamma(\gamma_1+\cdots+\gamma_n+\frac{s}{2}+\frac{1}{2})}. \tag{5.11}$$

Here we have set $\gamma_{n+1} = \frac{s}{2} + \frac{1}{2}$. (This is a generalization of the weight function for the biorthogonal family $\{V_m^{(s)}(\mathbf{x}), U_m^{(s)}(\mathbf{x})\}$ on the n-sphere of [1], which is obtained by setting $\gamma_1 = \cdots = \gamma_n = \frac{1}{2}$.) Under this change of variables the polynomials $\{C_{\mathbf{m}}^{\gamma}, D_{\mathbf{m}'}^{\gamma}\}$ become

(5.12)
$$U_{2m}^{(\gamma,s)}(\mathbf{y}) = (1-y_1^2-\cdots-y_n^2)^M$$
$$\times F_A\left(\begin{matrix}-M-s/2+\frac{1}{2}; & -m_1,\cdots,-m_n \\ \gamma_1,\cdots,\gamma_n & \end{matrix}; \frac{-y_1^2}{1-y_1^2-\cdots-y_n^2},\cdots,\frac{-y_n^2}{1-y_1^2-\cdots-y_n^2}\right),$$
$$V_{2m}^{(\gamma,s)}(\mathbf{y}) = F_A\left(\begin{matrix}M+\gamma_1+\cdots+\gamma_n+s/2-\frac{1}{2}; & -m_1,\cdots,-m_n \\ \gamma_1,\cdots,\gamma_n & \end{matrix}; y_1^2,\cdots,y_n^2\right).$$

In the special case $\gamma_2 = \cdots = \gamma_n = \frac{1}{2}$ these are exactly the $U_m^{(s)}(\mathbf{y})$ and $V_m^{(s)}(\mathbf{y})$ of [1, p. 269]. (To see this transform $m_k \to m'_k/2$, reverse the order of the sums in F_A by transforming the summation indices as $j_k \to m'_k/2 - j_k$, and then use the reflection formula $\Gamma(z)\Gamma(1-z) = \pi/\sin(\pi z)$ to represent these polynomials in terms of F_B, as given on p. 269.) The biorthogonality demonstration given above immediately implies
$$(V_{2m}^{(\gamma,s)}, U_{2m'}^{(\gamma,s)})'_\gamma \sim \prod_{k=1}^n \delta_{m_k m'_k}, \tag{5.13}$$

where

$$(V,U)'_\gamma = \int\cdots\int_{y_1^2+\cdots+y_n^2<1}\left[\prod_{k=1}^{n}(y_k^2)^{\gamma_k-1/2}\right] \cdot(1-y_1^2-\cdots-y_n^2)^{s/2-1/2}V(\mathbf{y})\overline{U}(\mathbf{y})dy_1\cdots dy_n. \tag{5.14}$$

Also, since the operator H is self-adjoint with respect to this inner product and since $U_m^{(s)}$ and $V_m^{(s)}$ are eigenfunctions of H we have

$$(V_{2m}^{(\gamma,s)}, V_{2m'}^{(\gamma,s)})'_\gamma = (U_{2m}^{(\gamma,s)}, U_{2m'}^{(\gamma,s)})'_\gamma = 0 \quad \text{if } M \neq M'. \tag{5.15}$$

Here, $U_{2m}^{(s)}(\mathbf{y})$ and $V_{2m}^{(s)}(\mathbf{y})$ are strictly even degree in all the variables y_k with total degree $2M$. We define odd degree polynomials as follows:

$$V_{2m+1}^{(\gamma,s)}(\mathbf{y}) \equiv \left[\prod_{k\in Q} y_k\right] V_{2m}^{(\gamma',s)}(\mathbf{y}),$$

$$U_{2m+1}^{(\gamma,s)}(\mathbf{y}) \equiv \left[\prod_{k\in Q} y_k\right] U_{2m}^{(\gamma',s)}(\mathbf{y}), \tag{5.16}$$

where Q is any subset of $(1,2,\cdots,n)$, and

$$\begin{aligned} \gamma'_k &= \gamma_k + 1 \quad \text{if } k \in Q, \\ \gamma'_k &= \gamma_k \quad \text{if } k \notin Q. \end{aligned} \tag{5.17}$$

Since the weight function is even in all variables and the odd degree polynomials are odd in the variables y_k, $k \in Q$, we immediately deduce by parity

$$\begin{aligned} \left(V_{2m+1}^{(\gamma,s)}, V_{2m'}^{(\gamma,s)}\right)'_\gamma &= \left(U_{2m+1}^{(\gamma,s)}, U_{2m'}^{(\gamma,s)}\right)'_\gamma = 0, \\ \left(V_{2m+1}^{(\gamma,s)}, U_{2m'}^{(\gamma,s)}\right)'_\gamma &= \left(V_{2m}^{(\gamma,s)}, U_{2m'+1}^{(\gamma,s)}\right)'_\gamma = 0. \end{aligned} \tag{5.18}$$

Also, $(V_{2m+1}^{(\gamma,s)}, U_{2m'+1}^{(\gamma,s)})'_\gamma$ vanishes by parity unless both polynomials are odd in exactly the same variables, in which case it is easy to verify that

$$\left(V_{2m+1}^{(\gamma,s)}, U_{2m'+1}^{(\gamma,s)}\right)'_\gamma = \left(V_{2m+1}^{(\gamma',s)}, U_{2m'+1}^{(\gamma',s)}\right)'_{\gamma'} \sim \prod_{k=1}^{n}\delta_{m_k m'_k}. \tag{5.19}$$

Similarly,

$$\left(V_{2m+1}^{(\gamma,s)}, V_{2m'+1}^{(\gamma,s)}\right)'_\gamma = \left(U_{2m+1}^{(\gamma,s)}, U_{2m'}^{(\gamma,s)}\right)'_\gamma = 0 \quad \text{if } M \neq M'. \tag{5.20}$$

THEOREM 2. *Let*

$$V_m^{(\gamma,s)}(\mathbf{y}) \equiv \begin{cases} V_{2q}^{(\gamma,s)}(\mathbf{y}) \\ V_{2q+1}^{(\gamma,s)}(\mathbf{y}), \end{cases}$$

$$U_m^{(\gamma,s)}(\mathbf{y}) \equiv \begin{cases} U_{2q}^{(\gamma,s)}(\mathbf{y}) \\ U_{2q+1}^{(\gamma,s)}(\mathbf{y}). \end{cases}$$

Then

$$\left(V_m^{(\gamma,s)}, U_{m'}^{(\gamma,s)}\right)'_\gamma \sim \prod_{k=1}^{n} \delta_{m_k m'_k},$$
$$\left(V_m^{(\gamma,s)}, V_{m'}^{(\gamma,s)}\right)'_\gamma = \left(U_m^{(\gamma,s)}, U_{m'}^{(\gamma,s)}\right)'_\gamma = 0 \quad \text{if } M \neq M'.$$

In the case $n = 1$ the biorthogonal polynomials are orthogonal:

$$V_{2m}^{(\gamma,s)}(y) = U_{2m}^{(\gamma,s)}(y) = {}_2F_1\left(\begin{matrix} m+\gamma+s/2-\frac{1}{2}, -m \\ \gamma \end{matrix}; y^2\right), \tag{5.21}$$
$$V_{2m+1}^{(\gamma,s)}(y) = U_{2m+1}^{(\gamma,s)}(y) = y\ {}_2F_1\left(\begin{matrix} m+\gamma+s/2+\frac{1}{2}, -m \\ \gamma+1 \end{matrix}; y^2\right).$$

The measure on the interval $-1 \leq y \leq 1$ is

$$d\omega(y) = (y^2)^{\gamma-1/2}(1-y^2)^{s/2-1/2}\, dy.$$

For $\gamma = \frac{1}{2}$ these are exactly the Gegenbauer polynomials. For general γ they are a generalization of these polynomials [4, p. 256].

The same construction with $U_m = V_m$ can be carried out for *all* the orthogonal systems of polynomials in the variables x_k as found in §2 to obtain orthogonal polynomials in the variables y_k on the full n-sphere. In general, something is lost in this construction, however. The polynomials $U_m = V_m$ are (except for the even case) no longer eigenfunctions of H. Indeed, we have the following lemma.

LEMMA 3. *Let $\Phi(\mathbf{y})$ be a polynomial eigenfunction of H:*

$$H\Phi = -M(M+G-1)\Phi$$

in the coordinates y_k, where $x_k = y_k^2$, $1 \leq k \leq n$, and let Q be a subset of $\{1, 2, \cdots, n\}$ with $|Q| > 0$ elements. Then $\Psi_Q \equiv [\prod_{i\in Q} y_i]\Phi(\mathbf{y})$ is an eigenfunction of the operator H' corresponding to parameters $\gamma'_k, \gamma'_{n+1}, G'$ if and only if

$$\gamma_k = \tfrac{3}{2} \quad \text{for } k \in Q$$

and

$$\gamma'_k = \tfrac{1}{2} \quad \text{for } k \in Q,$$
$$\gamma'_k = \gamma_k \quad \text{for } k \notin Q,$$
$$G' = G - |Q|, \qquad M' = M + \frac{|Q|}{2}.$$

Then

$$H'\Psi_Q = -M'(M'+G'-2)\Psi_Q.$$

It follows from this result that in the case where $\gamma_1 = \cdots = \gamma_n = \frac{1}{2}$, the construction leading to Theorem 2 yields the biorthogonal polynomials $U_m^{(s)}(\mathbf{y})$ and $V_m^{(s)}(\mathbf{y})$ of [1]. These polynomials are all eigenfunctions of H. Similarly, for $\gamma_1 = \cdots = \gamma_n = \frac{1}{2}$ the same construction applied to the families of orthogonal polynomials in x_k, found in §2, leads to the families of orthogonal polynomials in y_k, found in §3, all eigenfunctions of H.

As a referee has kindly pointed out, Lemma 3 can be generalized if we use Dunkl's differential-difference operator [5]. In the coordinates y_i and for general $\gamma_1, \cdots, \gamma_{n+1}$,

Dunkl's operator $\tilde{H}$ is defined as

$$\tilde{H}p(\mathbf{y}) = \frac{1}{4}\Big[\sum_{i,j=1}^{n}(\delta_{ij} - y_i y_j)\partial_{y_i y_j} p + (1-2G)\sum_{j=1}^{n} y_j \partial_{y_j} p + \sum_{j=1}^{n}\left(\gamma_j - \frac{1}{2}\right)\left(\frac{2}{y_j}\partial_{y_j} p - \frac{p(\mathbf{y}) - p(\cdots, -y_j, \cdots)}{y_j^2}\right)\Big].$$

(This differs from the operator (1.5) with $x_j = y_j^2$ only in the last term.) The eigenvalue equation is

$$\tilde{H}p(\mathbf{y}) = -M(M+G-1)p(\mathbf{y}).$$

Note that $\tilde{H}$ always maps polynomials in the y_i to polynomials and that $\tilde{H}p \equiv Hp$ for polynomials p which are even in each of the variables y_j and $\tilde{H} \equiv H$ if $\gamma_j = \frac{1}{2}$ for all j. Furthermore, since the operators I_j, which map $p(\mathbf{y})$ to $p(y_1, \cdots, -y_j, \cdots, y_n)$ for $j = 1, \cdots, n$, commute with $\tilde{H}$, we can assume, without loss of generality, that each eigenfunction is either even or odd in every one of its variables y_j. We have the following generalization of Lemma 3.

LEMMA 3′. *Let $\Phi(\mathbf{y})$ be a polynomial eigenfunction of $\tilde{H}$:*

$$\tilde{H}\Phi = -M(M+G-1)\Phi$$

in the coordinates y_k, where $x_k = y_k^2$, $1 \le k \le n$, and let Q be a subset of $\{1, 2, \cdots, n\}$ with $|Q| > 0$ elements. Then $\Psi_Q \equiv [\prod_{i\in Q} y_i]\Phi(\mathbf{y})$ is an eigenfunction of the operator $\tilde{H}'$ corresponding to parameters $\gamma_k', \gamma_{n+1}', G'$ if and only if

$$\gamma_k' = \gamma_k - 1 \quad \text{for } k \in Q,$$

and

$$\gamma_k' = \gamma_k \quad \text{for } k \notin Q,$$
$$G' = G - |Q|, \qquad M' = M + \frac{|Q|}{2}.$$

Then

$$\tilde{H}'\Psi_Q = -M'(M'+G'-1)\Psi_Q.$$

Similar comments apply to the "mixed" case in §6.

6. The "mixed" biorthogonal case. Using the techniques introduced in §5 we can now easily determine a biorthogonal basis of polynomials in the mixed case with coordinates (4.1). We set

$$n_1 + n_2 = n, \quad x \equiv \sum_{k=1}^{n_1} x_k, \quad y^2 \equiv \sum_{k=1}^{n_2} y_k^2,$$
$$M \equiv \sum_{k=1}^{n_1} m_k, \quad \tilde{M} \equiv \sum_{k=1}^{n_2} \tilde{m}_k.$$

The basic building blocks are the polynomials

(6.1)
$$C_{m,2\tilde{m}}^{(\gamma,s)}(\mathbf{x},\mathbf{y}) = (1-x-y^2)^{M+\tilde{M}} F_A \cdot \left(\begin{matrix} -M-\tilde{M}-s/2+\frac{1}{2}; -m_k, -\tilde{m}_k \\ \gamma_k, \quad s_k \end{matrix}; \frac{-x_k}{1-x-y^2}, \frac{-y_k^2}{1-x-y^2}\right)$$

and

(6.2)

$$D^{(\gamma,s)}_{m,2\tilde{m}}(\mathbf{x},\mathbf{y}) = F_A\left(\begin{matrix} M+\tilde{M}+\gamma_1+\cdots+\gamma_{n_1}+s_1+\cdots+s_{n_2}+s/2-\frac{1}{2}; -m_k, -\tilde{m}_k \\ \gamma_k, \quad s_k \end{matrix}; x_k, y_k^2\right).$$

The weight function is

$$w(\mathbf{x},\mathbf{y}) = \left[\prod_{k=1}^{n_1} x_k^{\gamma_k-1}\right]\left[\prod_{k=1}^{n_2}(y_k^2)^{s_k-1/2}\right](1-x-y^2)^{s/2-1/2} \tag{6.3}$$

with $\gamma_k, s_k > 0$ and $s > -1$. The inner product is

(6.4)

$$\langle \Phi_2, \Phi_2\rangle_{\gamma,s} = \int\cdots\int_{0<x_i,x+y^2<1} \Phi_1(\mathbf{x},\mathbf{y})\overline{\Phi_2}(\mathbf{x},\mathbf{y})\; w(\mathbf{x},\mathbf{y})dx_1\cdots dx_{n_1}dy_1\cdots dy_{n_2}.$$

Furthermore,

$$\langle 1,1\rangle_{\gamma,s} = \frac{[\prod_{k=1}^{n_1}\Gamma(\gamma_k)][\prod_{k=1}^{n_2}\Gamma(s_k)]\Gamma(s/2+1/2)}{\Gamma(\gamma_1+\cdots+\gamma_{n_1}+s_1+\cdots+s_{n_2}+s/2+1/2)}. \tag{6.5}$$

It follows from the results immediately preceding (5.10) that the polynomial sets (6.1) and (6.2) are biorthogonal. However, since they are even functions of the y_k they do not form a basis for all polynomial functions in the variables x_k, y_k. To construct such a basis we define functions

$$\begin{aligned} C^{(\gamma,s)}_{m,2\tilde{m}+1}(\mathbf{x},\mathbf{y}) &= \left[\prod_{k\in Q} y_k\right] C^{(\gamma,s_k+1,s)}_{m,2\tilde{m}}(\mathbf{x},\mathbf{y}), \\ D^{(\gamma,s)}_{m,2\tilde{m}+1}(\mathbf{x},\mathbf{y}) &= \left[\prod_{k\in Q} y_k\right] D^{(\gamma,s_k+1,s)}_{m,2\tilde{m}}(\mathbf{x},\mathbf{y}), \end{aligned} \tag{6.6}$$

where Q is any nonempty subset of $(1,2,\cdots,n_2)$.

By parity we have

$$\begin{aligned} &\langle C^{(\gamma,s)}_{m,2\tilde{m}+1}, D^{(\gamma,s)}_{m',2\tilde{m}'}\rangle_{\gamma,s} = 0, \qquad \langle C^{(\gamma,s)}_{m,2\tilde{m}}, D^{(\gamma,s)}_{m',2\tilde{m}'+1}\rangle_{\gamma,s} = 0, \\ &\langle C^{(\gamma,s)}_{m,2\tilde{m}+1}, D^{(\gamma,s)}_{m',2\tilde{m}'+1}\rangle_{\gamma,s} = 0 \quad \text{if } Q \neq Q'. \end{aligned}$$

If $Q = Q'$ a simple computation yields

$$\langle C^{(\gamma,s)}_{m,2\tilde{m}+1}, D^{(\gamma,s)}_{m',2\tilde{m}'+1}\rangle_{\gamma,s} = \langle C^{(\gamma,s_k+1,s)}_{m,2\tilde{m}}, D^{(\gamma,s_k+1,s)}_{m',2\tilde{m}'}\rangle_{\gamma,s_k+1,s} \sim \prod_{k=1}^{n_1}\delta_{m_k m'_k}\prod_{k=1}^{n_2}\delta_{\tilde{m}_k,\tilde{m}'_k}.$$

Since $C^{(\gamma,s)}_{m,2\tilde{m}}$ and $D^{(\gamma,s)}_{m,2\tilde{m}}$ are eigenfunctions of H there are additional orthogonality relations obeyed by the C's alone and by the D's alone. Collecting all these results, we have the following theorem.

THEOREM 3. *Let*

$$\begin{aligned} C^{(\gamma,s)}_{m,\tilde{m}}(\mathbf{x},\mathbf{y}) &\equiv \begin{cases} C^{(\gamma,s)}_{m,2\tilde{q}}(\mathbf{x},\mathbf{y}) \\ C^{(\gamma,s)}_{m,2\tilde{q}+1}(\mathbf{x},\mathbf{y}), \end{cases} \\ D^{(\gamma,s)}_{m,\tilde{m}}(\mathbf{x},\mathbf{y}) &\equiv \begin{cases} D^{(\gamma,s)}_{m,2\tilde{q}}(\mathbf{x},\mathbf{y}) \\ D^{(\gamma,s)}_{m,2\tilde{q}+1}(\mathbf{x},\mathbf{y}). \end{cases} \end{aligned}$$

Then

$$\langle C^{(\gamma,s)}_{m,\tilde{m}}, D^{(\gamma,s)}_{m',\tilde{m}'}\rangle_{\gamma,s} \sim \prod_{k=1}^{n_1} \delta_{m_k m'_k} \prod_{k=1}^{n_2} \delta_{\tilde{m}_k \tilde{m}'_k},$$

$$\langle C^{(\gamma,s)}_{m,\tilde{m}}, C^{(\gamma,s)}_{m',\tilde{m}'}\rangle_{\gamma,s} = 0 \quad \text{if } M + \tilde{M} \neq M' + \tilde{M}',$$

$$\langle D^{(\gamma,s)}_{m,\tilde{m}}, D^{(\gamma,s)}_{m',\tilde{m}'}\rangle_{\gamma,s} = 0 \quad \text{if } M + \tilde{M} \neq M' + \tilde{M}'.$$

In general, the biorthogonal polynomials listed in Theorem 3 are not eigenfunctions of H. However, in the case $s_1 = \cdots = s_{n_2} = \frac{1}{2}$ it follows from Lemma 3 that each of the polynomials satisfies the eigenvalue equation

$$H\Phi = -(M + \tilde{M})(M + \tilde{M} + G - 1)\Phi,$$

where $G = \sum_{k=1}^{n_1} \gamma_k + (n_2 + 1)/2 + s$.

Similarly, the above procedure when applied to any one of the orthogonal bases discussed in §2 leads to an orthogonal polynomial basis with respect to the inner product $\langle \cdot, \cdot \rangle_{\gamma,s}$. Restriction to the case $s_1 = \cdots = s_{n_2} = \frac{1}{2}$ yields eigenfunctions of H and coincides with the results of §4.

THE ADDITION FORMULA FOR LITTLE q-LEGENDRE POLYNOMIALS AND THE $SU(2)$ QUANTUM GROUP*

TOM H. KOORNWINDER†

Abstract. From the interpretation of little q-Jacobi polynomials as matrix elements of the irreducible unitary representations of the SU(2) quantum group an addition formula is derived for the little q-Legendre polynomials. It involves an expansion in terms of Wall polynomials. A product formula for little q-Legendre polynomials follows by q-integration.

Key words. quantum groups, SU(2), little q-Jacobi polynomials, little q-Legendre polynomials, Wall polynomials, addition formula, product formula

AMS(MOS) subject classifications. 33A65, 33A75, 22E70

1. Introduction. Quantum groups were recently introduced by Drinfeld [5] and Woronowicz [17]. Interesting examples are provided by deformation into a noncommutative Hopf algebra of some suitable commutative Hopf algebra of functions on a specific group. The most elementary nontrivial example comes from deformation of the algebra of polynomials on $SU(2)$ (cf. Woronowicz [18]). We denote the resulting quantum group by $SU_\mu(2)$.

It has been proved by Vaksman and Soibelman [15], Masuda et al. [11], [12], and Koornwinder [10] that the matrix elements of the irreducible unitary representations of the quantum group $SU_\mu(2)$ can be expressed in terms of the little q-Jacobi polynomials. In the present paper we use this interpretation to derive an addition formula for the little q-Legendre polynomials, i.e., for the q-analogues of the Legendre polynomials within the class of little q-Jacobi polynomials. The derivation of this formula is straightforward and analogous to a proof of the addition formula for Legendre polynomials using irreducible representations of $SU(2)$ (cf. Vilenkin [16, Chap. 3]). However, the resulting formula involves noncommuting variables. It is less easy to rewrite it equivalently as a formula involving only commuting variables. We can do this by using an infinite-dimensional irreducible $*$-representation of the Hopf algebra considered as a $*$-algebra. The result (Theorem 4.1) gives an expansion in terms of Wall polynomials (little q-Jacobi polynomials with the second parameter equal to zero).

Our addition formula somewhat resembles an addition formula for (continuous) q-ultraspherical polynomials derived by Rahman and Verma [14], but for that formula a (quantum) group-theoretic interpretation is not yet known. It would have been hard to find our formula without guidance from the quantum group. Indeed, that it is possible to obtain such a formula demonstrates the power and depth of the quantum group-theoretic interpretation of special functions. It turns out to be highly nontrivial to prove this formula analytically or to show that its limit case for $q \uparrow 1$ is the addition formula for Legendre polynomials. The analytic proof has been done by Rahman [13] and the limit result is proved by Van Assche and Koornwinder [2].

The contents of this paper are as follows. In §§ 2 and 3 the preliminaries about q-hypergeometric orthogonal polynomials and quantum groups, respectively, are presented. The derivation of the addition formula is given in § 4. Finally, a product formula for little q-Legendre polynomials is derived from the addition formula in § 5.

2. Some q-hypergeometric orthogonal polynomials. Let $1 \neq q \in \mathbb{C}$. We use the familiar definitions and notation for q-shifted factorials and q-hypergeometric functions (cf. [6, Chap. 1], [10, § 2]). The *little q-Jacobi polynomials*

$$p_n(x; a, b \mid q) := {}_2\phi_1\left(\begin{matrix} q^{-n}, abq^{n+1} \\ aq \end{matrix}; q, qx\right) \tag{2.1}$$

occur as part of a classification by Hahn [7] of orthogonal polynomials satisfying q-difference equations. Their detailed properties as orthogonal polynomials are given by Andrews and Askey [1]. For $a = b = 1$ we will call these polynomials *little q-Legendre polynomials.*

The special little q-Jacobi polynomials obtained by putting $b := 0$ in (2.1) are known as *Wall polynomials*; cf. Chihara [3, § 5, Case I], [4, Chap. 6, § 11]:

$$p_n(x; a, 0 \mid q) = {}_2\phi_1(q^{-n}, 0; aq; q, qx) \tag{2.2}$$

(Chihara uses another notation). We will put $a := q^\alpha$. These polynomials can be viewed as one of the many q-analogues of the Laguerre polynomials in view of the limit formula

$$\lim_{q \uparrow 1} p_n((1-q)x; q^\alpha, 0 \mid q) = L_n^\alpha(x)/L_n^\alpha(0).$$

By specialization of the orthogonality relations for the little q-Jacobi polynomials we obtain the orthogonality relations for the Wall polynomials:

$$\frac{(q^{\alpha+1}; q)_\infty}{(1-q)(q; q)_\infty} \int_0^1 p_n(t; q^\alpha, 0 \mid q) p_m(t; q^\alpha, 0 \mid q) t^\alpha (qt; q)_\infty \, d_q t = \delta_{n,m} \frac{q^{n(\alpha+1)}(q; q)_n}{(q^{\alpha+1}; q)_n}, \tag{2.3}$$

where the q-integral is defined by

$$\int_0^1 f(t) \, d_q t := \sum_{k=0}^{\infty} f(q^k)(q^k - q^{k+1}),$$

and where we suppose that $0 < q < 1$ and $\alpha > -1$. From [3, Forms. (5.1), (5.2)] together with (2.2) we obtain the three-term recurrence relation

$$\begin{aligned} x p_n(x; a, 0 \mid q) = {} & -q^n(1 - aq^{n+1}) p_{n+1}(x; a, 0 \mid q) \\ & + q^n(1 + a - aq^n - aq^{n+1}) p_n(x; a, 0 \mid q) \\ & - q^n(a - aq^n) p_{n-1}(x; a, 0 \mid q), \\ p_{-1}(x; a, 0 \mid q) = 0, \qquad & p_0(x; a, 0 \mid q) = 1. \end{aligned} \tag{2.4}$$

Put

$$\begin{aligned} P_n(q^k; q^\alpha \mid q) := {} & \left(\frac{(q^{\alpha+1}; q)_\infty (q^{k+1}; q)_\infty (q^{\alpha+1}; q)_n}{(q; q)_\infty (q; q)_n} \right)^{1/2} \\ & \cdot (-1)^n q^{(k-n)(\alpha+1)/2} p_n(q^k; q^\alpha, 0 \mid q). \end{aligned} \tag{2.5}$$

Then (2.3) can be rewritten as

$$\sum_{k=0}^{\infty} P_n(q^k; q^\alpha \mid q) P_m(q^k; q^\alpha \mid q) = \delta_{n,m}, \qquad n, m = 0, 1, 2, \cdots. \tag{2.6}$$

Since the orthogonality measure in (2.3) has compact support, the orthonormal system

$$\{P_n(q^k; q^\alpha \mid q)\}_{k=0,1,2,\cdots}, \qquad n = 0, 1, 2, \cdots,$$

is complete in the Hilbert space l^2. Hence, we have also the dual orthogonality relations

$$\sum_{n=0}^{\infty} P_n(q^k; q^\alpha \mid q) P_n(q^l; q^\alpha \mid q) = \delta_{k,l}, \qquad k, l = 0, 1, 2, \cdots. \tag{2.7}$$

We conclude this section with an expression of Wall polynomials in terms of a ${}_3\phi_2$:

$$p_n(x; q^\alpha, 0 \mid q) = \frac{(-1)^n q^{n(n+2\alpha+1)/2} x^n}{(q^{\alpha+1}; q)_n} {}_3\phi_2\left(\begin{matrix} q^{-n}, q^{-n-\alpha}, x^{-1} \\ 0, 0 \end{matrix}; q, q\right). \tag{2.8}$$

This follows by putting $b := 0$ in

$$\begin{aligned} {}_2\phi_1\left(\begin{matrix} q^{-n}, abq^{n+1} \\ aq \end{matrix}; q, qx\right) &= (q^{-n+1}x; q)_n \, {}_2\phi_2\left(\begin{matrix} q^{-n}, q^{-n}b^{-1} \\ qa, q^{-n+1}x \end{matrix}; q, q^{n+2}abx\right) \\ &= \frac{(qb; q)_n q^{n(n-1)/2}(-aqx)^n}{(qa; q)_n} {}_3\phi_2\left(\begin{matrix} q^{-n}, q^{-n}\alpha^{-1}, x^{-1} \\ qb, 0 \end{matrix}; q, q\right). \end{aligned}$$

Here we have used a transformation formula for ${}_2\phi_1$ (cf. [6, Chap. 1]) in the first equality and reversion of summation order in the second equality (see also [8]).

3. The quantum group $SU_\mu(2)$. In the rest of this paper we fix $0 \neq \mu \in (-1, 1)$. Let $\mathscr{A}$ be the unital $*$-algebra generated by the two elements α and γ satisfying the relations

$$\alpha\gamma = \mu\gamma\alpha, \quad \alpha\gamma^* = \mu\gamma^*\alpha, \quad \gamma\gamma^* = \gamma^*\gamma,$$
$$\alpha^*\alpha + \gamma\gamma^* = I, \qquad \alpha\alpha^* + \mu^2\gamma\gamma^* = I.$$

Let $\Phi: \mathscr{A} \to \mathscr{A} \otimes \mathscr{A}$ be the unital $*$-homomorphism such that

$$\Phi(\alpha) = \alpha \otimes \alpha - \mu\gamma^* \otimes \gamma, \qquad \Phi(\gamma) = \gamma \otimes \alpha + \alpha^* \otimes \gamma.$$

Then Φ acts as a comultiplication and $\mathscr{A}$ thus becomes a Hopf algebra with involution which we say to be *associated with the compact matrix quantum group* $SU_\mu(2)$. In the limit for $\mu \uparrow 1$, $\mathscr{A}$ becomes the algebra of polynomials in the matrix elements of the natural representation of $SU(2)$, and the comultiplication is then induced by the group structure of $SU(2)$.

It is possible to embed the $*$-algebra $\mathscr{A}$ as a dense $*$-subalgebra of a C^*-algebra by a universal construction. The C^*-algebra approach is emphasized in particular by Woronowicz [17], [18]. In this paper we could work with the C^*-algebra, but only elements of the dense $*$-subalgebra $\mathscr{A}$ will be needed, so we will use this latter algebra. Other references for $SU_\mu(2)$ besides [17] and [18], are [5], [15], [11], and [12].

The irreducible unitary co-representations of $\mathscr{A}$ (which are called irreducible unitary representations of $SU_\mu(2)$ in [18] and [10]) have been completely classified [18], [9], [15], [11], [12], [10]. Up to equivalence, there is one such co-representation for each finite dimension. We will denote the co-representation of dimension $2l+1$ by $t^{l,\mu}$ ($l = 0, \frac{1}{2}, 1, \cdots$), and its matrix elements with respect to a suitable orthonormal basis corresponding to the quantum subgroup $U(1)$ by $t^{l,\mu}_{n,m}$ ($n, m = -l, -l+1, \cdots, l$). Then the co-representation property of $t^{l,\mu}$ is expressed by

$$\Phi(t^{l,\mu}_{n,m}) = \sum_{k=-l}^{l} t^{l,\mu}_{n,k} \otimes t^{l,\mu}_{k,m}. \tag{3.1}$$

The $t^{l,\mu}_{n,m}$ have been computed explicitly in terms of little q-Jacobi polynomials (cf. [15], [11], [12], [10]). Here we will only need the cases that $l = 0, 1, 2, \cdots$ and m or $n = 0$. Put

$$p^\mu_{l,k}(x) := \begin{bmatrix} l \\ k \end{bmatrix}^{1/2}_{\mu^2} \begin{bmatrix} l+k \\ k \end{bmatrix}^{1/2}_{\mu^2} \mu^{-k(l-k)} p_{l-k}(x; \mu^{2k}, \mu^{2k} \mid \mu^2), \tag{3.2}$$

$$p^\mu_l(x) := p^\mu_{l,0}(x) = p_l(x; 1, 1 \mid \mu^2). \tag{3.3}$$

Here the notation (2.1) for the little q-Jacobi polynomials is used and (3.3) gives a little q-Legendre polynomial. Then (cf. [10, Thm. 5.3]), for $k=0,1,\cdots,l$,

$$
\begin{aligned}
t^{l,\mu}_{k,0} &= (\alpha^*)^k p^{\mu}_{l,k}(\gamma\gamma^*)\gamma^k,\\
t^{l,\mu}_{0,k} &= (\alpha^*)^k p^{\mu}_{l,k}(\gamma\gamma^*)(-\mu\gamma^*)^k,\\
t^{l,\mu}_{-k,0} &= (-\mu\gamma^*)^k p^{\mu}_{l,k}(\gamma\gamma^*)\alpha^k,\\
t^{l,\mu}_{0,-k} &= \gamma^k p^{\mu}_{l,k}(\gamma\gamma^*)\alpha^k.
\end{aligned}
\tag{3.4}
$$

Hence

$$
t^{l,\mu}_{0,0} = p^{\mu}_l(\gamma\gamma^*). \tag{3.5}
$$

The irreducible $*$-representations of the $*$-algebra $\mathscr{A}$ on a Hilbert space are classified in [15, Thm. 3.2]. There is a family of one-dimensional and a family of infinite-dimensional representations, both parametrized by the unit circle. We pick one of these infinite-dimensional representations: Let $\mathscr{H}$ be a Hilbert space with orthonormal basis $e_0, e_1, \cdots$. Put $e_{-1}, e_{-2}, \cdots := 0$. We define a $*$-representation of τ of $\mathscr{A}$ on $\mathscr{H}$ by specifying the action of the generators of $\mathscr{A}$:

$$
\begin{aligned}
\tau(\alpha)e_n &:= (1-\mu^{2n})^{1/2}e_{n-1},\\
\tau(\alpha^*)e_n &:= (1-\mu^{2n+2})^{1/2}e_{n+1},\\
\tau(\gamma)e_n &:= \mu^n e_n,\\
\tau(\gamma^*)e_n &:= \mu^n e_n.
\end{aligned}
\tag{3.6}
$$

4. Proof of the addition formula. Let $l=0,1,2,\cdots$. A special case of (3.1) is

$$
\Phi(t^{l,\mu}_{0,0}) = \sum_{k=-l}^{l} t^{l,\mu}_{0,k}\otimes t^{l,\mu}_{k,0}.
$$

Hence, by (3.4) and (3.5),

$$
\begin{aligned}
p^{\mu}_l(\Phi(\gamma\gamma^*)) &= p^{\mu}_l(\gamma\gamma^*)\otimes p^{\mu}_l(\gamma\gamma^*)\\
&\quad + \sum_{k=1}^{l} (\alpha^*)^k p^{\mu}_{l,k}(\gamma\gamma^*)(-\mu\gamma^*)^k \otimes (\alpha^*)^k p^{\mu}_{l,k}(\gamma\gamma^*)\gamma^k\\
&\quad + \sum_{k=1}^{l} \gamma^k p^{\mu}_{l,k}(\gamma\gamma^*)\alpha^k \otimes (-\mu\gamma^*)^k p^{\mu}_{l,k}(\gamma\gamma^*)\alpha^k.
\end{aligned}
\tag{4.1}
$$

This formula might already be called an addition formula for little q-Legendre polynomials p^{μ}_l. It involves noncommuting variables. In the limit, for $\mu\uparrow 1$, the variables commute and (4.1) becomes the classical addition formula for Legendre polynomials. In three steps we will rewrite (4.1) into a formula involving commuting variables: First, we represent (4.1) as an operator identity on the Hilbert space $\mathscr{H}\otimes\mathscr{H}$ by using the representation $\tau\otimes\tau$ (cf. (3.6)). Second, we let these operators act on the standard basis of $\mathscr{H}\otimes\mathscr{H}$. Thus we obtain a family of vector identities in $\mathscr{H}\otimes\mathscr{H}$. Third, we take inner products with respect to another suitable orthonormal basis of $\mathscr{H}\otimes\mathscr{H}$. This will yield a family of scalar identities.

Apply $\tau\otimes\tau$ to both sides of (4.1) and let both sides of the resulting operator equality act on $e_{x+y}\otimes e_y$. Then

$$
\begin{aligned}
p_l^{\mu}((\tau\otimes\tau)\Phi(\gamma\gamma^*))\, e_{x+y}\otimes e_y &= p_l^{\mu}(\mu^{2x+2y})p_l^{\mu}(\mu^{2y})\, e_{x+y}\otimes e_y \\
&\quad + \sum_{k=1}^{l} (-1)^k \mu^{k(x+2y+1)}(\mu^{2(x+y+1)};\mu^2)_k^{1/2}(\mu^{2(y+1)};\mu^2)_k^{1/2} \\
&\quad \cdot p_{l,k}^{\mu}(\mu^{2x+2y})p_{l,k}^{\mu}(\mu^{2y})\, e_{x+y+k}\otimes e_{y+k} \\
&\quad + \sum_{k=1}^{l} (-1)^k \mu^{k(x+2y-2k+1)}(\mu^{2(x+y)};\mu^{-2})_k^{1/2}(\mu^{2y};\mu^{-2})_k^{1/2} \\
&\quad \cdot p_{l,k}^{\mu}(\mu^{2x+2y-2k})p_{l,k}^{\mu}(\mu^{2y-2k})\, e_{x+y-k}\otimes e_{y-k}.
\end{aligned} \tag{4.2}
$$

(Remember the convention that $e_n = 0$ for $n < 0$.)

In order to say more about the left-hand side of (4.2) we consider the action of

$$\Phi(\gamma\gamma^*) = (\gamma\otimes\alpha + \alpha^*\otimes\gamma)(\gamma^*\otimes\alpha^* + \alpha\otimes\gamma^*)$$

on $e_{x+y}\otimes e_y$. We obtain

$$
\begin{aligned}
&(\tau\otimes\tau)(\Phi(\gamma\gamma^*))\, e_{x+y}\otimes e_y \\
&\quad = \mu^{x+2y+1}(1-\mu^{2x+2y+2})^{1/2}(1-\mu^{2y+2})^{1/2}\, e_{x+y+1}\otimes e_{y+1} \\
&\qquad + (\mu^{2x+2y} + \mu^{2y} - \mu^{2x+4y} - \mu^{2x+4y+2})\, e_{x+y}\otimes e_y \\
&\qquad + \mu^{x+2y-1}(1-\mu^{2x+2y})^{1/2}(1-\mu^{2y})^{1/2}\, e_{x+y-1}\otimes e_{y-1}.
\end{aligned}
$$

Hence, if

$$f := \sum_{y=0}^{\infty} c_y\, e_{x+y}\otimes e_y$$

belongs to $\mathcal{H}\otimes\mathcal{H}$, then

$$
\begin{aligned}
(\tau\otimes\tau)(\Phi(\gamma\gamma^*))f = \sum_{y=0}^{\infty} [\, & c_{y-1}\mu^{x+2y-1}(1-\mu^{2x+2y})^{1/2}(1-\mu^{2y})^{1/2} \\
& + c_y(\mu^{2x+2y} + \mu^{2y} - \mu^{2x+4y} - \mu^{2x+4y+2}) \\
& + c_{y+1}\mu^{x+2y+1}(1-\mu^{2x+2y+2})^{1/2}(1-\mu^{2y+2})^{1/2}]\, e_{x+y}\otimes e_y.
\end{aligned} \tag{4.3}
$$

Now choose

$$c_y := P_y(\mu^{2z};\mu^{2x}|\mu^2),$$

where P_y is defined in terms of Wall polynomials by (2.5). Then $f\in\mathcal{H}\otimes\mathcal{H}$ and, by (2.4), the expression in square brackets on the right-hand side of (4.3) is equal to $\mu^{2z}c_y$. Define

$$f_z^x := \sum_{y=0}^{\infty} P_y(\mu^{2z};\mu^{2x}|\mu^2)\, e_{x+y}\otimes e_y. \tag{4.4}$$

Then, by the orthogonality relations (2.7), the vectors $\{f_z^x\}_{z=0,1,2,\ldots}$ form an orthonormal basis of

$$\bigoplus_{y=0}^{\infty} \mathbb{C}\, e_{x+y}\otimes e_y. \tag{4.5}$$

We also have

$$(\tau\otimes\tau)(\Phi(\gamma\gamma^*))f_z^x = \mu^{2z}f_z^x. \tag{4.6}$$

Now take the inner product of both sides of (4.2) with respect to f_z^x and apply (4.4), (4.6), and the self-adjointness of $\Phi(\gamma\gamma^*)$ acting on $\mathscr{H}\otimes\mathscr{H}$. Assume also the convention that $P_n := 0$ and $p_n := 0$ for $n<0$. Then we obtain

$$
\begin{aligned}
p_l^{\mu}(\mu^{2z})P_y(\mu^{2z};\mu^{2x}|\mu^2) &= p_l^{\mu}(\mu^{2x+2y})p_l^{\mu}(\mu^{2y})P_y(\mu^{2z};\mu^{2x}|\mu^2)\\
&\quad+\sum_{k=1}^{l}(-1)^k\mu^{k(x+2y+1)}(\mu^{2(x+y+1)};\mu^2)_k^{1/2}(\mu^{2(y+1)};\mu^2)_k^{1/2}\\
&\quad\cdot p_{l,k}^{\mu}(\mu^{2x+2y})p_{l,k}^{\mu}(\mu^{2y})P_{y+k}(\mu^{2z};\mu^{2x}|\mu^2)\\
&\quad+\sum_{k=1}^{l}(-1)^k\mu^{k(x+2y-2k+1)}(\mu^{2(x+y)};\mu^{-2})_k^{1/2}(\mu^{2y};\mu^{-2})_k^{1/2}\\
&\quad\cdot p_{l,k}^{\mu}(\mu^{2x+2y-2k})p_{l,k}^{\mu}(\mu^{2y-2k})P_{y-k}(\mu^{2z};\mu^{2x}|\mu^2).
\end{aligned}
\tag{4.7}
$$

Finally substitute (3.2), (3.3), and (2.5) in (4.7) and replace μ^2 by q. Then we obtain the following theorem.

THEOREM 4.1 (addition formula for little q-Legendre polynomials). *For $x, y, z = 0, 1, 2, \cdots$ we have*

$$
\begin{aligned}
&p_l(q^z;1,1|q)p_y(q^z;q^x,0|q)\\
&\quad=p_l(q^{x+y};1,1|q)p_l(q^y;1,1|q)p_y(q^z;q^x,0|q)\\
&\qquad+\sum_{k=1}^{l}\frac{(q;q)_{x+y+k}(q;q)_{l+k}q^{k(y-l+k)}}{(q;q)_{x+y}(q;q)_{l-k}(q;q)_k^2}\\
&\qquad\cdot p_{l-k}(q^{x+y};q^k,q^k|q)p_{l-k}(q^y;q^k,q^k|q)p_{y+k}(q^z;q^x,0|q)\\
&\qquad+\sum_{k=1}^{l}\frac{(q;q)_y(q;q)_{l+k}q^{k(x+y-l+1)}}{(q;q)_{y-k}(q;q)_{l-k}(q;q)_k^2}\\
&\qquad\cdot p_{l-k}(q^{x+y-k};q^k,q^k|q)p_{l-k}(q^{y-k};q^k,q^k|q)p_{y-k}(q^z;q^x,0|q).
\end{aligned}
\tag{4.8}
$$

Remark 4.1. We could have derived the final result (4.8) from (4.1) as well by using one of the other members of the series of infinite-dimensional irreducible $*$-representations of $\mathscr{A}$ as given by [15, Thm. 3.2]. The same result would also have been obtained by use of the faithful $*$-representation of $\mathscr{A}$ given in [18, Thm. 1.2]. Furthermore, it can be shown that formula (4.8) taken for all $x, y, z = 0, 1, 2, \cdots$ and with $q=\mu^2$ is equivalent to (4.1).

Remark 4.2. It is possible to give a more conceptual interpretation of the occurrence of Wall polynomials in the addition formula. Namely, it can be shown that Wall polynomials have an interpretation as Clebsch–Gordan coefficients for the decomposition of the $*$-representation $(\tau\otimes\tau)\circ\Phi$ of $\mathscr{A}$ as a direct integral of irreducible $*$-representations of $\mathscr{A}$.

5. The product formula for little q-Legendre polynomials. If we multiply both sides of (4.7) with $P_y(\mu^{2z};\mu^{2x}|\mu^2)$ and sum over z, then by (2.6) we obtain the product formula

$$
p_l^{\mu}(\mu^{2x+2y})p_l^{\mu}(\mu^{2y})=\sum_{z=0}^{\infty}p_l^{\mu}(\mu^{2x})(P_y(\mu^{2z};\mu^{2x}|\mu^2))^2.
$$

After substituting (3.3), (2.5), and (2.8) and after replacing x by $x-y$ and μ^2 by q, we get the desired product formula.

THEOREM 5.1. *For $x, y = 0, 1, 2, \cdots$ we have*

$$p_l(q^x; 1, 1 \mid q) p_l(q^y; 1, 1 \mid q) = (1-q) \sum_{z=0}^{\infty} p_l(q^z; 1, 1 \mid q) K(q^x, q^y, q^z \mid q) q^z$$

with

$$K(q^x, q^y, q^z \mid q) := \frac{(q^{x+1}; q)_\infty (q^{y+1}; q)_\infty (q^{z+1}; q)_\infty q^{xy+xz+yz}}{(q; q)_\infty^2 (1-q)} \cdot \left\{ {}_3\phi_2 \left(\begin{matrix} q^{-x}, q^{-y}, q^{-z} \\ 0, 0 \end{matrix} ; q, q \right) \right\}^2.$$

ASYMPTOTIC BEHAVIOUR FOR WALL POLYNOMIALS AND THE ADDITION FORMULA FOR LITTLE q-LEGENDRE POLYNOMIALS*

WALTER VAN ASSCHE† AND TOM H. KOORNWINDER‡

Abstract. Wall polynomials $W_n(x; b, q)$ are considered and their asymptotic behaviour is described when $q = c^{1/n}$ and n tends to infinity. The results are then used to derive the addition and product formulas for the Legendre polynomials from the recently obtained addition and product formulas for little q-Legendre polynomials.

Key words. Wall polynomials, addition formula, product formula, basic hypergeometric polynomials, Legendre polynomials

AMS(MOS) subject classifications. 33A65, 42C05

1. Introduction.

The Wall polynomials $W_n(x; b, q)$ are defined by the recurrence formula

$$W_{n+1}(x; b, q) = \{x - [b + q - (1+q)bq^n]q^n\} W_n(x; b, q) - b(1-q^n)(1-bq^{n-1})q^{2n} W_{n-1}(x; b, q), \qquad n = 0, 1, 2, \cdots \tag{1.1}$$

with initial values $W_{-1} = 0$ and $W_0 = 1$. Clearly $W_n(x; b, q)$ is a monic polynomial of degree n in the variable x. Some properties of Wall polynomials are given in Chihara's book [4, p. 198]. These polynomials are closely related to the continued fraction

$$1 + \frac{x}{1+} \frac{(1-b)qx}{1} + \frac{(1-q)bqx}{1} + \frac{(1-bq)q^2x}{1} + \cdots,$$

which was studied by H. S. Wall [16]. The Wall polynomials were also studied by Chihara [5] because they have a Brenke-type generating function, i.e.,

$$\sum_{n=0}^{\infty} W_n(x; b, q) \frac{z^n}{(b; q)_n (q; q)_n} = A(z)B(zx),$$

where

$$A(z) = \sum_{n=0}^{\infty} (-1)^n q^{n(n+1)/2} \frac{z^n}{(q; q)_n} = (zq; q)_\infty,$$

$$B(z) = \sum_{n=0}^{\infty} \frac{z^n}{(b; q)_n (q; q)_n}.$$

We have used the notation

$$(b; q)_n = (1-b)(1-bq) \cdots (1-bq^{n-1}),$$

$$(b; q)_\infty = \lim_{n \to \infty} (b; q)_n;$$

the latter limit exists whenever $|q|<1$. From this generating function we easily find

$$W_n(x;b,q)=(-1)^n(b;q)_n q^{n(n+1)/2}\sum_{k=0}^{n}\frac{(q;q)_n}{(q;q)_{n-k}(q;q)_k}q^{k(k-1)/2}\frac{(-q^{-n}x)^k}{(b;q)_k}$$
$$=(-1)^n(b;q)_n q^{n(n+1)/2}{}_2\phi_1(q^{-n},0;b;q,x), \tag{1.2}$$

where the q-hypergeometric (or basic hypergeometric [6]) function is defined by

$${}_{r+1}\phi_r(a_1,\cdots,a_{r+1};b_1,\cdots,b_r;q,z)=\sum_{k=0}^{\infty}\frac{(a_1;q)_k\cdots(a_{r+1};q)_k}{(b_1;q)_k\cdots(b_r;q)_k}\frac{z^k}{(q;q)_k}.$$

If $0<q<1$ and $0<b<1$ then the Wall polynomials are orthogonal with respect to a positive measure supported on the geometric sequence $\{q^n: n=1,2,3,\cdots\}$ and we have

$$\sum_{k=0}^{\infty}W_n(q^{k+1};b,q)W_m(q^{k+1};b,q)\frac{b^k}{(q;q)_k}=0,\qquad n\neq m.$$

The orthonormal polynomials are given by

$$w_n(x;b,q)=\frac{q^{-n(n+1)/2}}{\sqrt{b^n(q;q)_n(b;q)_n}}W_n(x;b,q), \tag{1.3}$$

and they satisfy

$$(b;q)_\infty\sum_{k=0}^{\infty}w_n(q^{k+1};b,q)w_m(q^{k+1};b,q)\frac{b^k}{(q;q)_k}=\delta_{n,m},\qquad n,m\geqq 0 \tag{1.4}$$

and the three-term recurrence relation (1.1) becomes

$$xw_n(x;b,q)=a_{n+1}w_{n+1}(x;b,q)+b_nw_n(x;b,q)+a_nw_{n-1}(x;b,q) \tag{1.5}$$

with $w_{-1}=0$, $w_0=1$, and

$$a_n=a_n(b,q)=q^n\sqrt{b(1-q^n)(1-bq^{n-1})},\qquad n=1,2,3,\cdots,$$
$$b_n=b_n(b,q)=q^n[b+q-(1+q)bq^n],\qquad n=0,1,2,\cdots. \tag{1.6}$$

Sometimes it is convenient to use the notation

$$(b;q)_\infty\sum_{k=0}^{\infty}f(q^{k+1})\frac{b^k}{(q;q)_k}=\int_0^1 f(z)\,d\mu(z;b,q),\qquad f\in C[0,1] \tag{1.7}$$

so that $\mu(\cdot;b,q)$ is the orthogonality measure for the Wall polynomials $W_n(x;b,q)$.

Recently Koornwinder [8] obtained the addition formula for little q-Legendre polynomials by using the fact that the matrix elements of the irreducible unitary representations of the quantum group $S_\mu U(2)$ (see, e.g., Woronowicz [17], [18]) can be expressed in terms of little q-Jacobi polynomials (Masuda et al. [9], Vaksman and Soibelman [13], Koornwinder [7]). The little q-Jacobi polynomials are defined in terms of q-hypergeometric functions by

$$p_n(x;a,b\,|\,q)={}_2\phi_1(q^{-n},abq^{n+1};aq;q,qx).$$

If $a=q^\alpha$ and $b=q^\beta$ then these little q-Jacobi polynomials approach the Jacobi polynomials $P_n^{(\alpha,\beta)}(1-2x)/P_n^{(\alpha,\beta)}(1)$ as q tends to 1 [1], [3]. If $a=b=1$ then we have

the little q-Legendre polynomials. Notice that for $b=0$ we essentially have the Wall polynomials:

$$p_n\left(\frac{x}{q};\frac{b}{q},0\,|\,q\right)=(-1)^n\frac{q^{-n(n+1)/2}}{(b;q)_n}W_n(x;b,q)$$
$$=(-1)^n\left\{\frac{b^n(q;q)_n}{(b;q)_n}\right\}^{1/2}w_n(x;b,q). \tag{1.8}$$

The addition formula for little q-Legendre polynomials is

$$\begin{aligned}
&p_m(q^z;1,1\,|\,q)p_y(q^z;q^x,0\,|\,q)\\
&\quad=p_m(q^{x+y};1,1\,|\,q)p_m(q^y;1,1\,|\,q)p_y(q^z;q^x,0\,|\,q)\\
&\qquad+\sum_{k=1}^{m}\frac{(q;q)_{x+y+k}(q;q)_{m+k}q^{k(y-m+k)}}{(q;q)_{x+y}(q;q)_{m-k}(q;q)_k^2}p_{m-k}(q^{x+y};q^k,q^k\,|\,q)\\
&\qquad\cdot p_{m-k}(q^y;q^k,q^k\,|\,q)p_{y+k}(q^z;q^x,0\,|\,q)\\
&\qquad+\sum_{k=1}^{m}\frac{(q;q)_y(q;q)_{m+k}q^{k(x+y-m+1)}}{(q;q)_{y-k}(q;q)_{m-k}(q;q)_k^2}p_{m-k}(q^{x+y-k};q^k,q^k\,|\,q)\\
&\qquad\cdot p_{m-k}(q^{y-k};q^k,q^k\,|\,q)p_{y-k}(q^z;q^x,0\,|\,q)
\end{aligned} \tag{1.9}$$

with $x,y,z=0,1,2,\cdots$. Rahman [11] has given an analytic proof of this addition formula while Rahman and Verma [12] have given similar formulas for the continuous q-ultraspherical polynomials. The right-hand side of the above formula can be considered as an expansion of the left-hand side in terms of Wall polynomials. For $q\uparrow 1$ we should get the familiar addition formula for Legendre polynomials (see, e.g., [2, pp. 29-38]), but this limit involves some interesting asymptotic formulas for the Wall polynomials $W_n(x;b,c^{1/n})$ with $0<c<1$ and n tending to infinity. This was the main reason for investigating such asymptotic formulas for Wall polynomials.

In §2 we establish some weak asymptotics for Wall polynomials. In § 3 we show how the addition formula for Legendre polynomials can be obtained from the addition formula for little q-Legendre polynomials by letting $q\to 1$, and in § 4 we obtain the familiar product formulas for Legendre polynomials from the product formulas for little q-Legendre polynomials.

2. Weak asymptotics for Wall polynomials. For little q-Jacobi polynomials $p_n(x;a,b\,|\,q)$ we can put $a=q^\alpha$ and $b=q^\beta$ and let $q\uparrow 1$ to find Jacobi polynomials on $[0,1]$. However, if either a or b is zero, which is exactly what happens for Wall polynomials, then the limit as $q\uparrow 1$ is $(1+(x/(a-1))^n$. Therefore another approach is needed to handle the behaviour of Wall polynomials as $q\uparrow 1$. It turns out that we can find some relevant results if we consider the polynomials $W_n(x;b,c^{1/n})$ for $n\to\infty$. We will prove a more general result for orthonormal polynomials $\{p_k(x;n)\colon k=0,1,2,\cdots;\ n\in\mathbb{N}\}$, where k is the degree of the polynomial and n an extra (discrete) parameter. The recurrence formula for these polynomials is given by

$$xp_k(x;n)=a_{k+1,n}p_{k+1}(x;n)+b_{k,n}p_k(x;n)+a_{k,n}p_{k-1}(x;n), \tag{2.1}$$

where $a_{k,n}>0$, $b_{k,n}\in\mathbb{R}$, $p_0(x;n)=1$, and $p_{-1}(x;n)=0$. Orthogonal polynomials with regularly varying recurrence coefficients [15] are of this type.

THEOREM 1. *Assume that* $[r, s]$ *is a finite interval that, for all* n, *contains the support of the orthogonality measure for* $\{p_k(x; n)\}$. *Assume moreover that*

$$\lim_{n\to\infty} a_{n,n} = A > 0, \qquad \lim_{n\to\infty} b_{n,n} = B \in \mathbb{R} \tag{2.2}$$

and that

$$\lim_{n\to\infty} (a_{k,n}^2 - a_{k-1,n}^2) = 0, \qquad \lim_{n\to\infty} (b_{k,n} - b_{k-1,n}) = 0, \tag{2.3}$$

uniformly in k, *then*

$$\lim_{n\to\infty} \frac{p_{n+1}(x; n)}{p_n(x; n)} = \rho\left(\frac{x-B}{2A}\right), \tag{2.4}$$

uniformly on compact sets of $\mathbb{C}\backslash[r, s]$, *where* $\rho(x) = x + \sqrt{x^2-1}$ (*the square root here is defined to be the one for which* $|\rho(x)| > 1$ *for* $x \in \mathbb{C}\backslash[-1, 1]$).

Proof. Let K be a compact set in $\mathbb{C}\backslash[r, s]$; then the distance between K and $[r, s]$ is strictly positive. Denote this distance by $\delta > 0$. A decomposition into partial fractions gives

$$\frac{p_{k-1}(x; n)}{p_k(x; n)} = a_{k,n} \sum_{j=1}^{k} \frac{d_{j,k}}{x - x_{j,k}},$$

where $\{x_{j,k}: 1 \leqq j \leqq k\}$ are the zeros of $p_k(x; n)$ and $\{d_{j,k}: 1 \leqq j \leqq k\}$ are positive numbers adding up to 1. Since all the zeros of $p_k(x; n)$ are in $[r, s]$ we have $|x - x_{j,k}| > \delta$ for $x \in K$ and therefore

$$\left|\frac{p_{k-1}(x; n)}{p_k(x, n)}\right| < \frac{a_{k,n}}{\delta} \tag{2.5}$$

holds uniformly for $x \in K$. Consider the Turán determinant

$$D_k(x; n) = p_k^2(x; n) - \frac{a_{k+1,n}}{a_{k,n}} p_{k+1}(x; n) p_{k-1}(x; n).$$

By using the recurrence relation (2.1) we find

$$\begin{aligned} D_k(x; n) = D_{k-1}(x; n) &+ \frac{b_{k,n} - b_{k-1,n}}{a_{k,n}} p_k(x; n) p_{k-1}(x; n) \\ &+ \frac{a_{k,n}^2 - a_{k-1,n}^2}{a_{k,n} a_{k-1,n}} p_{k-2}(x; n) p_k(x; n) \end{aligned} \tag{2.6}$$

(see [14, Thm. 4.10, p. 117]). If we define

$$R_{k,n}(x) = \frac{D_k(x; n)}{p_{k+1}(x; n) p_k(x; n)},$$

then by (2.6)

$$\begin{aligned} |R_{k,n}(x)| \leqq |R_{k-1,n}(x)| &\left|\frac{p_{k-1}(x; n)}{p_{k+1}(x; n)}\right| + \frac{|b_{k,n} - b_{k-1,n}|}{a_{k,n}} \left|\frac{p_{k-1}(x; n)}{p_{k+1}(x; n)}\right| \\ &+ \frac{|a_{k,n}^2 - a_{k-1,n}^2|}{a_{k,n} a_{k-1,n}} \left|\frac{p_{k-2}(x; n)}{p_{k+1}(x; n)}\right|, \end{aligned}$$

so that by (2.5) we have for $x \in K$

$$|R_{k,n}(x)| \leqq \frac{a_{k,n} a_{k+1,n}}{\delta^2} |R_{k-1,n}(x)| + |b_{k,n} - b_{k-1,n}| \frac{a_{k+1,n}}{\delta^2} + |a_{k,n}^2 - a_{k-1,n}^2| \frac{a_{k+1,n}}{\delta^3}.$$

By the conditions imposed there exists a constant C such that $a_{k,n} < C$ for every n and k (cf. [4, Chap. IV, Example 2.12]). Therefore, by (2.3),

$$|R_{k,n}(x)| \leqq \left(\frac{C}{\delta}\right)^2 |R_{k-1,n}(x)| + A_n, \qquad x \in K,$$

where $A_n \to 0$ as $n \to \infty$. Iteration gives

$$|R_{n,n}(x)| \leqq A_n \frac{(C/\delta)^{2n}-1}{(C/\delta)^2-1} + |R_{0,n}(x)|(C/\delta)^{2n}, \qquad x \in K.$$

If $\delta > C$ then obviously $R_{n,n}(x) \to 0$ as $n \to \infty$ (use $|R_{0,n}| = |p_0(x; n)/p_1(x; n)| < a_{1,n}/\delta$), which by (2.2), (2.3), and (2.5) leads to

$$\lim_{n\to\infty} \left| \frac{p_n(x; n)}{p_{n+1}(x; n)} - \frac{p_{n-1}(x; n)}{p_n(x; n)} \right| = 0, \tag{2.7}$$

uniformly for $x \in K$ (provided $\delta > C$). By (2.5) the sequence of analytic functions $p_n(x; n)/p_{n+1}(x; n)$ is uniformly bounded on compact sets of $\mathbb{C}\backslash[r, s]$ and thus there exists a subsequence converging to some function $L(x)$, uniformly on K. Use the recurrence formula (2.1) and the properties (2.2), (2.3), and (2.7) to find that this limit satisfies

$$x = \frac{A}{L(x)} + B + AL(x),$$

and since $|p_n(x; n)/p_{n+1}(x; n)| < C/\delta < 1$ for $x \in K$ by (2.5) we have

$$\frac{1}{L(x)} = \rho\left(\frac{x-B}{2A}\right).$$

This gives the result for $\delta > C$. This can be extended to hold for $\delta > 0$ by using the Stieltjes-Vitali theorem (cf. [4, p. 121]) and the uniform bound (2.5). □

Remark. The asymptotic behaviour actually holds uniformly on compact sets of $\mathbb{C}\backslash\Omega$, where Ω is the closure of the set of zeros of $p_n(x; n)$ as n runs through the integers. Clearly, Ω is a subset of $[r, s]$ since the zeros of $p_n(x; n)$ are all inside the interval $[r, s]$. The condition that the joint supports of the orthogonality measures should be contained in the finite interval $[r, s]$ can also be relaxed. Only the zeros of $p_k(x; n)(k \leqq n+1, n = 0, 1, 2, \cdots)$ must lie in $[r, s]$.

COROLLARY 1. *Suppose* $0 < b < 1$ *and* $0 < c < 1$. *Then*

$$\lim_{n\to\infty} \frac{W_{n+k}(x; b, c^{1/n})}{W_n(x; b, c^{1/n})} = \{b(1-c)(1-bc)c^2\}^{k/2} \rho^k\left(\frac{x-[b+1-2bc]c}{2c\sqrt{b(1-c)(1-bc)}}\right) \tag{2.8}$$

uniformly on compact sets of $\mathbb{C}\backslash[0, 1]$.

Proof. The proof follows immediately from

$$\lim_{n\to\infty} \frac{W_{n+k}(x; b, c^{1/n})}{W_{n+k-1}(x; b, c^{1/n})} - \{b(1-c)(1-bc)c^2\}^{1/2} \rho\left(\frac{x-[b+1-2bc]c}{2c\sqrt{b(1-c)(1-bc)}}\right),$$

which in turn can be proved by using Theorem 1 with recurrence coefficients $a_{k,n} = a_k(b, c^{1/n})$ and $b_{k,n} = b_k(b, c^{1/n})$ given by (1.6). □

COROLLARY 2. *Suppose* $0 < b < 1$ *and* $0 < c < 1$. *Then*

$$\lim_{n\to\infty} \frac{p_{n+k}(z; b, 0|c^{1/n})}{p_n(z; b, 0|c^{1/n})} = (-1)^k \left\{\frac{b(1-c)}{1-bc}\right\}^{k/2} \rho^k\left(\frac{z-[b+1-2bc]c}{2c\sqrt{b(1-c)(1-bc)}}\right) \tag{2.9}$$

uniformly for z on compact subsets of $\mathbb{C}\backslash[0,1]$, where $p_n(x; a, b \mid q)$ are the little q-Jacobi polynomials.

Proof. This follows immediately from (1.8) and Corollary 1. □

It is important in the asymptotic formula (2.4) that the variable x stays away from the zeros of $p_n(x; n)$. On the set Ω, the closure of the zeros of $p_n(x; n)$, the orthogonal polynomials will oscillate. The following theorem gives a result about the weak convergence of measures involving the polynomials $p_k(x; n)$ on $[r, s]$ in terms of their orthogonality measures.

THEOREM 2. *Assume that $[r, s]$ is a finite interval that, for all n, contains the support of the orthogonality measure μ_n for the orthonormal polynomials $\{p_k(x; n): k = 0, 1, 2, \cdots\}$. Assume, moreover, that for all $k \in \mathbb{Z}$*

$$\lim_{n\to\infty} a_{n+k,n} = A, \qquad \lim_{n\to\infty} b_{n+k,n} = B; \tag{2.10}$$

then for every continuous function f on $[r, s]$

$$\lim_{n\to\infty} \int_r^s f(z)p_n(z; n)p_{n+k}(z; n)d\mu_n(z) = \frac{1}{\pi}\int_{B-2A}^{B+2A} \frac{f(z)T_k((z-B)/(2A))}{\sqrt{4A^2-(z-B)^2}}\,dz,$$

where $T_n(x)$ are the Chebyshev polynomials of the first kind.

Proof. We follow the ideas of Nevai and Dehesa [10, Lemma 3]. Let m be a positive integer and apply the recurrence formula (2.1) repeatedly to get

$$z^m p_n(z; n) = \sum_{\substack{-1\le k_i\le 1\\ i=1,2,\cdots,m}} \alpha_{n,n+k_1}\alpha_{n+k_1,n+k_1+k_2}\cdots\alpha_{n+k_1+\cdots+k_{m-1},n+k_1+\cdots+k_m}p_{n+k_1+\cdots+k_m}(z; n),$$

where

$$\alpha_{j,k} = \begin{cases} a_{j,n} & \text{if } k = j-1,\\ b_{j,n} & \text{if } k = j,\\ a_{j+1,n} & \text{if } k = j+1. \end{cases}$$

Hence

$$\int_r^s z^m p_n(z; n)p_{n+k}(z; n)d\mu_n(z) = \sum_{\substack{-1\le k_i\le 1\\ i=1,2,\cdots,m\\ k_1+\cdots+k_m=k}} \alpha_{n,n+k_1}\alpha_{n+k_1,n+k_1+k_2}\cdots\alpha_{n+k_1+\cdots+k_{m-1},n+k}.$$

Because of this equation and by (2.10) it follows that the limit as $n\to\infty$ of $\int_r^s z^m p_n(z; n)p_{n+k}(z; n)d\mu_n(z)$ is the same as the limit of

$$\frac{1}{2A^2\pi}\int_{B-2A}^{B+2A} z^m U_n\left(\frac{z-B}{2A}\right)U_{n+k}\left(\frac{z-B}{2A}\right)\sqrt{4A^2-(z-B)^2}\,dz$$

since the Chebyshev polynomials of the second kind $U_n((z-B)/2A)$ are the orthogonal polynomials with constant recurrence coefficients $a_n = A$ and $b_n = B$. Use the identity

$$U_n(x)U_{n+k}(x) = \frac{1}{2}\frac{T_k(x) - T_{2n+k+2}(x)}{1-x^2}$$

to find

$$\frac{1}{2A^2\pi}\int_{B-2A}^{B+2A} z^m U_n\left(\frac{z-B}{2A}\right)U_{n+k}\left(\frac{z-B}{2A}\right)\sqrt{4A^2-(z-B)^2}\,dz$$
$$= \frac{1}{\pi}\int_{B-2A}^{B+2A} \frac{z^m T_k((z-B)/2A)}{\sqrt{4A^2-(z-B)^2}}\,dz - \frac{1}{\pi}\int_{B-2A}^{B+2A} \frac{z^m T_{2n+k+2}((z-B)/2A)}{\sqrt{4A^2-(z-B)^2}}\,dz.$$

If $2n+k+2>m$ then the second term on the right-hand side vanishes because of orthogonality, and thus we have the result when $f(x)=x^m$. The general result follows from the Hahn-Banach theorem: let the operators $L_{k,n}(k, n=0, 1, 2, \cdots)$, defined on the Banach space $C[r, s]$ of continuous functions equipped with the supremum norm, be given by

$$L_{k,n}f=\int_r^s f(z)p_n(z; n)p_{n+k}(z; n)\, d\mu_n(z).$$

These are uniformly bounded operators because, by Schwarz's inequality and the orthonormality,

$$\begin{aligned}\left|\int_r^s f(z)p_n(z; n)p_{n+k}(z; n)\, d\mu_n(z)\right|^2 &\\ \leqq \int_r^s |f(z)|p_n^2(z; n)\, d\mu_n(z) \int_r^s |f(z)|p_{n+k}^2(z; n)\, d\mu_n(z) &\\ \leqq \|f\|_\infty^2.&\end{aligned}$$

Now use Weierstrass's result that the polynomials form a dense subspace of $C[r, s]$. □

COROLLARY 3. *Suppose* $0<b<1$ *and* $0<c<1$. *Then for every continuous function* f *on* $[0, 1]$

$$\begin{aligned}\lim_{n\to\infty}\int_0^1 f(z)w_n(z; b, c^{1/n})w_{n+k}(z; b, c^{1/n})d\mu(z; b, c^{1/n})&\\ =\frac{1}{\pi}\int_{B-2A}^{B+2A}\frac{f(z)T_k((z-B)/(2A)}{\sqrt{4A^2-(z-B)^2}}\, dz,&\end{aligned}$$

where $A=c\sqrt{b(1-c)(1-bc)}$, $B=(b+1-2bc)c$, *and* $T_n(x)$ *are the Chebyshev polynomials of the first kind.*

Proof. The proof follows because the Wall polynomials $w_n(x; b, c^{1/n})$ satisfy the conditions of Theorem 2, with recurrence coefficients $a_{k,n}=a_k(b, c^{1/n})$ and $b_k(b, c^{1/n})$ given by (1.6). □

3. The addition formula. The little q-Legendre polynomials $p_n(z; 1, 1|q)$ and the Wall polynomials $p_n(z; a, 0|q)$ are analytic functions of z and the addition formula (1.9) holds for every $z\in\{q^n: n=0, 1, 2, \cdots\}$ (which is a set with an accumulation point). Therefore it follows that

$$\begin{aligned}&p_m(z; 1, 1|q)p_y(z; q^x, 0|q)\\ &\quad=p_m(q^{x+y}; 1, 1|q)p_m(q^y; 1, 1|q)p_y(z; q^x, 0|q)\\ &\qquad+\sum_{k=1}^m\frac{(q; q)_{x+y+k}(q; q)_{m+k}q^{k(y-m+k)}}{(q; q)_{x+y}(q; q)_{m-k}(q; q)_k^2}p_{m-k}(q^{x+y}; q^k, q^k|q)\\ &\qquad\cdot p_{m-k}(q^y; q^k, q^k|q)p_{y+k}(z; q^x, 0|q)\\ &\qquad+\sum_{k=1}^m\frac{(q; q)_y(q; q)_{m+k}q^{k(x+y-m+1)}}{(q; q)_{y-k}(q; q)_{m-k}(q; q)_k^2}p_{m-k}(q^{x+y-k}; q^k, q^k|q)\\ &\qquad\cdot p_{m-k}(q^{y-k}; q^k, q^k|q)p_{y-k}(z; q^x, 0|q)\end{aligned}\tag{3.1}$$

holds for every $z\in\mathbb{C}$ and $x, y=0, 1, 2, \cdots$. It is well known that

$$\lim_{q\uparrow 1}p_n(z; q^\alpha, q^\beta|q)=R_n^{(\alpha,\beta)}(1-2z),\tag{3.2}$$

where $R_n^{(\alpha,\beta)}(x)$ are Jacobi polynomials with the normalization $R_n^{(\alpha,\beta)}(1)=1$, i.e., $R_n^{(\alpha,\beta)}(x)=P_n^{(\alpha,\beta)}(x)/P_n^{(\alpha,\beta)}(1)$. Fix b, c in $(0,1)$ such that $\log b/\log c=\beta/\gamma$ with β, γ positive integers, substitute in (3.1) $q=b^{1/(n\beta)}=c^{1/(n\gamma)}$, $x=n\beta$, $y=n\gamma$, and let $n\to\infty$ through the integers. Then by (2.9), (3.1), and (3.2)

$$\begin{aligned}R_m^{(0,0)}(1-2z)&=R_m^{(0,0)}(1-2bc)R_m^{(0,0)}(1-2b)\\&\quad+\sum_{k=1}^{m}\frac{(m+k)!}{(m-k)!(k!)^2}(1-bc)^k c^k R_{m-k}^{(k,k)}(1-2bc)R_{m-k}^{(k,k)}(1-2c)\\&\quad\cdot(-1)^k\left\{\frac{b(1-c)}{1-bc}\right\}^{k/2}\rho^k\left(\frac{z-[b+1-2bc]c}{2c\sqrt{b(1-c)(1-bc)}}\right)\\&\quad+\sum_{k=1}^{m}\frac{(m+k)!}{(m-k)!(k!)^2}(1-c)^k(bc)^k R_{m-k}^{(k,k)}(1-2bc)R_{m-k}^{(k,k)}(1-2c)\\&\quad\cdot(-1)^k\left\{\frac{1-bc}{b(1-c)}\right\}^{k/2}\rho^{-k}\left(\frac{z-[b+1-2bc]c}{2c\sqrt{b(1-c)(1-bc)}}\right).\end{aligned}$$

Now use the formula $T_k(x)=[\rho^k(x)+\rho^{-k}(x)]/2$; then

$$\begin{aligned}R_m^{(0,0)}(1-2z)&=R_m^{(0,0)}(1-2bc)R_m^{(0,0)}(1-2b)\\&\quad+2\sum_{k=1}^{m}(-1)^k\frac{(m+k)!}{(m-k)!(k!)^2}c^k[b(1-c)(1-bc)]^{k/2}\\&\quad\cdot R_{m-k}^{(k,k)}(1-2bc)R_{m-k}^{(k,k)}(1-2c)\,T_k\left(\frac{z-[b+1-2bc]c}{2c\sqrt{b(1-c)(1-bc)}}\right).\end{aligned}$$

Finally, choose

$$\begin{aligned}1-2z&=xy-\sqrt{1-x^2}\sqrt{1-y^2}\,t,\\1-2bc&=x,\\1-2c&=y;\end{aligned}$$

then

$$\begin{aligned}R_m^{(0,0)}(xy-\sqrt{1-x^2}\sqrt{1-y^2}\,t)&=R_m^{(0,0)}(x)R_m^{(0,0)}(y)\\&\quad+2\sum_{k=1}^{m}(-1)^k\frac{(m+k)!}{(m-k)!(k!)^2}2^{-2k}\{\sqrt{1-x^2}\sqrt{1-y^2}\}^k\\&\quad\cdot R_{m-k}^{(k,k)}(x)R_{m-k}^{(k,k)}(y)\,T_k(t),\end{aligned}$$

which is the familiar addition formula for Legendre polynomials. By our method of proof this formula only holds for $t\in\mathbb{C}\backslash\mathbb{R}$ (because we use Corollary 2), but since all the functions considered are analytic in t, the result definitely holds for every $t\in\mathbb{C}$.

4. Product formulas. If we multiply both sides of the addition formula (1.9) by $p_{y+k}(q^z;q^x,0|q)q^{(x+1)z}/(q;q)_z$ and sum from $z=0$ to ∞, then by the orthogonality (1.4) and by (1.8)

$$\begin{aligned}&\sum_{z=0}^{\infty}p_m(q^z;1,1|q)p_y(q^z;q^x,0|q)p_{y+k}(q^z;q^x,0|q)\frac{q^{(x+1)z}}{(q;q)_z}\\&\quad=\frac{(q;q)_{x+y+k}(q;q)_{m+k}q^{k(y-m+k)}}{(q;q)_{x+y}(q;q)_{m-k}(q;q)_k^2}p_{m-k}(q^{x+y};q^k,q^k|q)p_{m-k}(q^y;q^k,q^k|q)\\&\quad\cdot\sum_{z=0}^{\infty}p_{y+k}^2(q^z;q^x,0|q)\frac{q^{(x+1)z}}{(q;q)_z},\end{aligned}$$

which holds whenever $k \in \{0, 1, \cdots, m\}$. In terms of orthonormal Wall polynomials we have by (1.8)

$$
\begin{aligned}
& p_{m-k}(q^{x+y}; q^k, q^k \mid q) p_{m-k}(q^y; q^k, q^k \mid q) \\
& \quad = (-1)^k \frac{(q;q)_{m-k}(q;q)_k^2}{(q;q)_{m+k}} q^{-k(y+k-m)} \left\{ q^{-k(x+1)} \frac{(q;q)_y (q;q)_{x+y}}{(q;q)_{y+k}(q;q)_{x+y+k}} \right\}^{1/2} \\
& \quad \cdot (q^{x+1}; q)_\infty \sum_{z=0}^{\infty} p_m(q^z; 1, 1 \mid q) w_y(q^{z+1}; q^{x+1}, q) \\
& \quad \cdot w_{y+k}(q^{z+1}; q^{x+1}, q) \frac{q^{(x+1)z}}{(q;q)_z},
\end{aligned} \tag{4.1}
$$

which can be considered as a product formula for the little q-Legendre polynomials and which (for $k=0$) is equivalent with the product formula given by Koornwinder [8]. If we use the notation (1.7) then

$$
\begin{aligned}
& (q^{x+1}; q)_\infty \sum_{z=0}^{\infty} p_m(q^z; 1, 1 \mid q) w_y(q^{z+1}; q^{x+1}, q) w_{y+k}(q^{z+1}; q^{x+1}, q) \frac{q^{(x+1)z}}{(q;q)_z} \\
& \quad = \int_0^1 p_m\left(\frac{z}{q}; 1, 1 \mid q\right) w_y(z; q^{x+1}, q) w_{y+k}(z; q^{x+1}, q)\, d\mu(z; q^{x+1}, q).
\end{aligned}
$$

Fix b, c in $(0,1)$ such that $\log b / \log c = \beta/\gamma$ with β and γ positive integers and let $q = b^{1/(n\beta)} = c^{1/(n\gamma)}$, $1+x = n\beta$, $y = n\gamma$. Then as $n \to \infty$ we have by Corollary 3 and by the uniform convergence in (3.2) (keep in mind that $p_m((z/q); 1, 1 \mid q)$ is a polynomial of degree m)

$$
\begin{aligned}
R_{m-k}^{(k,k)}(1-2bc) R_{m-k}^{(k,k)}(1-2c) &= (-1)^k \frac{(m-k)!(k!)^2}{(m+k)!} c^{-k} \{b(1-c)(1-bc)\}^{-k/2} \\
&\quad \cdot \frac{1}{\pi} \int_{B-2A}^{B+2A} R_m^{(0,0)}(1-2z) \frac{T_k((z-B)/2A)}{\sqrt{4A^2-(z-B)^2}}\, dz,
\end{aligned}
$$

where $A = c\sqrt{b(1-c)(1-bc)}$ and $B = (b+1-2bc)c$. Setting $bc = x$, $c = y$ gives the familiar product formulas for Legendre polynomials:

$$
\begin{aligned}
R_{m-k}^{(k,k)}(1-2x) R_{m-k}^{(k,k)}(1-2y) &= (-1)^k \frac{(m-k)!(k!)^2}{(m+k)!} \{xy(1-y)(1-x)\}^{-k/2} \\
&\quad \cdot \frac{1}{\pi} \int_{B-2A}^{B+2A} R_m^{(0,0)}(1-2z) \frac{T_k((z-B)/2A)}{\sqrt{4A^2-(z-B)^2}}\, dz,
\end{aligned}
$$

with $A = \sqrt{xy(1-x)(1-y)}$ and $B = x+y-2xy$.

AN EXISTENCE THEOREM FOR MODEL EQUATIONS RESULTING FROM KINETIC THEORIES OF POLYMER SOLUTIONS*

MICHAEL RENARDY†

Abstract. A local existence and uniqueness theorem is proved for a set of partial differential equations modelling the flow of polymer solutions. The constitutive relations considered here are motivated by kinetic theory. The stress tensor is given by an integral which involves the solution of a linear diffusion equation. The coefficients of this diffusion equation depend on the velocity gradient.

Key words. polymer rheology, kinetic theories, local existence

1. Introduction.

General existence theorems for the partial differential equations of continuum mechanics are relatively recent, even for the case of elasticity. The initial value problem for compressible elastic materials occupying all of space was solved in [6], and the Dirichlet initial-boundary value problem is treated in [7], [2], and [3]. Existence results for incompressible materials were obtained in [4] and [12] for the initial value problem on all of space and in [5] for the Dirichlet problem.

Viscoelastic fluids such as polymers are characterized by a constitutive relation which gives the stress as a functional of the deformation history. Most popular models fall into two categories: integral and differential models. Integral models give the stress by an integral expression involving the history of the deformation gradient; differential models give the stress as the solution of a differential equation which involves the stress and velocity gradient. There is, however, a class of models motivated by considerations of kinetic theory, which can in general not be represented in either integral or differential form. Instead, such models require the solution of a diffusion equation in order to determine the stress [1]. Because of the practical impossibility—except in special cases—of solving this diffusion equation, such models have only had limited applications in solving flow problems. For the case of dumbbell models, however, computers may soon have the capacity to obtain solutions, at least in two-dimensional flow problems.

For materials with instantaneous elasticity, the terms of leading differential order in the equations of motion are like those for elasticity. A natural approach to a mathematical existence theory is therefore to regard the problem as essentially "elastic" and to treat the memory as a perturbation. This has been successfully carried out for integral models; see, e.g., Chapter III of [9], and also for differential models [11]. In this paper, we shall discuss the models from kinetic theory in a similar fashion. We shall in part be able to rely on the results of [11], but the solution of the diffusion equation raises new issues.

The equations of motion for an incompressible fluid are

$$\rho\Big(\frac{\partial \mathbf{v}}{\partial t} + (\mathbf{v}\cdot\nabla)\mathbf{v}\Big) = \operatorname{div}\mathbf{T} - \nabla p + \mathbf{f}, \qquad \operatorname{div}\mathbf{v} = 0. \tag{1}$$

Here $\mathbf{v}$ denotes the velocity, p the pressure, $\mathbf{T}$ the extra stress tensor, ρ the density (assumed constant), and $\mathbf{f}$ is a given body force. We investigate molecular models which are based on treating polymer molecules as dumbbells consisting of two beads connected by a spring and floating in a Newtonian solvent. We shall assume that the solvent contribution to the stress is small relative to the polymer contribution and can be neglected; if this is not the case, the equations of motion can be treated as a perturbation of the Stokes equations, and existence results can be obtained along the lines of [10]. Let $\mathbf{R}$ denote the vector between the two ends of the dumbbell, and let $\psi(\mathbf{R},\mathbf{x},t)$ denote the probability density for dumbbells in $\mathbf{R}$-space (this probability density depends on the point $\mathbf{x}$ in space and the time t; since ψ has the interpretation of a probability density, it will always be nonnegative and $\int \psi(\mathbf{R},\mathbf{x},t)\,d\mathbf{R} = 1$). The spring force is given by $\mathbf{F}(\mathbf{R}) = -\gamma(|\mathbf{R}|^2)\mathbf{R}$, and the stress is given by

$$T_{ij}(\mathbf{x},t) = -n\int R_i F_j(\mathbf{R})\psi(\mathbf{R},\mathbf{x},t)\,d\mathbf{R}. \tag{2}$$

Here n is the number density of dumbbells and the integral extends over all possible values of $\mathbf{R}$. We shall consider infinitely extensible as well as finitely extensible dumbbells. For infinitely extensible dumbbells, $\mathbf{R}$ can be any vector in $\mathbb{R}^3$. For finitely extensible dumbbells, the potential associated with $\mathbf{F}(\mathbf{R})$ becomes infinite at a finite value R_0 of $|\mathbf{R}|$, and the integral in (2) extends only over the ball $|\mathbf{R}| \le R_0$. The probability density $\psi(\mathbf{R},\mathbf{x},t)$ obeys the diffusion equation

$$\Big(\frac{\partial}{\partial t} + (\mathbf{v}\cdot\nabla_{\mathbf{x}})\Big)\psi = \alpha\Delta_{\mathbf{R}}\psi + \operatorname{div}_{\mathbf{R}}\Big(-(\nabla_{\mathbf{x}}\mathbf{v})\cdot\mathbf{R}\psi - \beta\mathbf{F}(\mathbf{R})\psi\Big). \tag{3}$$

Here we have used subscripts $\mathbf{R}$ and $\mathbf{x}$ to indicate the variables with respect to which derivatives are being taken. Our convention for the gradient of a vector is that the first index refers to the component of the vector and the second index to the direction of differentiation. The quantities α and β are positive constants. The reader is referred to [1] for the derivation of (2) and (3) and for a discussion of possible generalizations.

We seek solutions of (1)–(3) for $\mathbf{x}\in\Omega$, $t>0$, where Ω is a bounded domain in $\mathbb{R}^3$ with smooth boundary. We impose Dirichlet boundary conditions,

$$\mathbf{v}(\mathbf{x},t) = \mathbf{0}, \quad \mathbf{x}\in\partial\Omega, \quad t\ge 0, \tag{4}$$

and initial conditions,

$$\mathbf{v}(\mathbf{x},0) = \mathbf{v}_0(\mathbf{x}), \qquad \psi(\mathbf{R},\mathbf{x},0) = \psi_0(\mathbf{R},\mathbf{x}). \tag{5}$$

Concerning the spring force, we shall make one of the following two assumptions:

(F) The function γ is C^∞-smooth from $[0,\infty)$ to $(0,\infty)$, $\gamma' \ge 0$, and there exist numbers $\sigma \ge 0$ and $k > 0$ such that $\lim_{|\mathbf{R}|\to\infty}\gamma(|\mathbf{R}|^2)/|\mathbf{R}|^\sigma = k$. Moreover, $\limsup_{|\mathbf{R}|\to\infty}\gamma'(|\mathbf{R}|^2)/|\mathbf{R}|^{\sigma-2}$ is finite and higher derivatives of γ have at most polynomial growth as $|\mathbf{R}|\to\infty$.

(F′) For some $R_0 > 0$, the function γ is C^∞-smooth from $[0, R_0^2)$ to $(0, \infty)$, $\gamma' \geq 0$, and there exist numbers $\sigma > 1$ and $k > 0$ such that $\lim_{|\mathbf{R}| \to R_0} \gamma(|\mathbf{R}|^2)(R_0 - |\mathbf{R}|)^\sigma = k$. Moreover, $\limsup_{|\mathbf{R}| \to R_0} \gamma'(|\mathbf{R}|^2)(R_0 - |\mathbf{R}|)^{\sigma+1}$ is finite and higher derivatives of γ grow at most like powers of $(R_0 - |\mathbf{R}|)^{-1}$ as $|\mathbf{R}| \to R_0$.

In the first case, the dumbbell is infinitely extensible, in the second case it is finitely extensible. The assumption $\gamma' \geq 0$ means that the spring gets stiffer as the dumbbell is extended; this assumption is usually made in molecular models. The analysis that follows can be modified to allow faster growth of γ as $|\mathbf{R}| \to \infty$ or, respectively, $|\mathbf{R}| \to R_0$, but slower growth would pose difficulties. In particular, we have to exclude $\sigma = 1$ in (F′). This case corresponds to the most popular model of finitely extensible dumbbells (see [1]). There is, however, no specific reason to assume $\sigma = 1$ rather than a larger value of σ.

The goal of this paper is an existence and uniqueness theorem for solutions of the problem defined by (1)–(5). The paper is organized as follows. In §2, we define an iteration scheme which is used to construct the solution. The scheme alternates between solving an equation of the same type as encountered in incompressible elasticity and solving a linear diffusion equation such as (3). In §3 we define the function spaces used to carry out the analysis and state a precise theorem. The proof is given in §4.

2. Iterative construction of solution. We apply the operation $\partial/\partial t + (\mathbf{v}\cdot\nabla) + (\nabla\mathbf{v})^T$ to the equation of motion (1). The resulting equation, written in components, reads (here and in the rest of the paper, the summation convention is used)

$$
\begin{aligned}
\rho\left[\frac{\partial}{\partial t} + (\mathbf{v}\cdot\nabla)\right]^2 v_i = &\frac{\partial}{\partial x_j}\left[\left(\frac{\partial}{\partial t} + (\mathbf{v}\cdot\nabla)\right)T_{ij}\right] - \frac{\partial q}{\partial x_i} \\
&- \frac{\partial v_k}{\partial x_j}\frac{\partial T_{ij}}{\partial x_k} + \frac{\partial v_k}{\partial x_i}\frac{\partial T_{kj}}{\partial x_j} - \rho\frac{\partial v_j}{\partial x_i}\left[\frac{\partial}{\partial t} + (\mathbf{v}\cdot\nabla)\right]v_j \\
&+ \left[\frac{\partial}{\partial t} + (\mathbf{v}\cdot\nabla)\right]f_i + \frac{\partial v_j}{\partial x_i}f_j,
\end{aligned} \tag{6}
$$

where $q = \partial p/\partial t + (\mathbf{v}\cdot\nabla)p$. Using (2), we find that

$$
\left[\frac{\partial}{\partial t} + (\mathbf{v}\cdot\nabla)\right]T_{ij} = -n\int R_iF_j(\mathbf{R})\left[\frac{\partial}{\partial t} + (\mathbf{v}\cdot\nabla_{\mathbf{x}})\right]\psi(\mathbf{R},\mathbf{x},t)\,d\mathbf{R}, \tag{7}
$$

and using (3), we find further

$$
\begin{aligned}
&\left[\frac{\partial}{\partial t} + (\mathbf{v}\cdot\nabla)\right]T_{ij} \\
&\quad = -n\int R_iF_j(\mathbf{R})\left[\alpha\Delta_{\mathbf{R}}\psi + \operatorname{div}_{\mathbf{R}}\left(-(\nabla_{\mathbf{x}}\mathbf{v})\cdot\mathbf{R}\psi - \beta\mathbf{F}(\mathbf{R})\psi\right)\right]d\mathbf{R} \\
&\quad = -n\alpha\int \Delta_{\mathbf{R}}(R_iF_j(\mathbf{R}))\psi\,d\mathbf{R} - n\beta\int\frac{\partial}{\partial R_k}(R_iF_j(\mathbf{R}))F_k(\mathbf{R})\psi\,d\mathbf{R} \\
&\qquad - n\int\frac{\partial}{\partial R_k}(R_iF_j(\mathbf{R}))\frac{\partial v_k}{\partial x_l}R_l\psi\,d\mathbf{R}.
\end{aligned} \tag{8}
$$

Next we note that

$$
\begin{aligned}
\frac{\partial}{\partial R_k}(R_iF_j(\mathbf{R})) &= -\frac{\partial}{\partial R_k}(R_iR_j\gamma(|\mathbf{R}|^2)) \\
&= -\gamma(|\mathbf{R}|^2)(R_j\delta_{ik} + R_i\delta_{jk}) - 2R_iR_jR_k\gamma'(|\mathbf{R}|^2).
\end{aligned} \tag{9}
$$

By combining (8) and (9), we find

$$
\begin{aligned}
&\frac{\partial}{\partial x_j}\left[\Big(\frac{\partial}{\partial t}+(\mathbf{v}\cdot\nabla)\Big)T_{ij}\right] \\
&\quad = n\frac{\partial^2 v_k}{\partial x_j \partial x_l}\int(\gamma(|\mathbf{R}|^2)R_jR_l\delta_{ik}+2\gamma'(|\mathbf{R}|^2)R_iR_jR_kR_l)\psi\ d\mathbf{R} \\
&\quad\quad - n\alpha\int\Delta_{\mathbf{R}}(R_iF_j(\mathbf{R}))\frac{\partial\psi}{\partial x_j}\ d\mathbf{R} - n\beta\int\frac{\partial}{\partial R_k}(R_iF_j(\mathbf{R}))F_k(\mathbf{R})\frac{\partial\psi}{\partial x_j}\ d\mathbf{R} \\
&\quad\quad - n\frac{\partial v_k}{\partial x_l}\int\frac{\partial}{\partial R_k}(R_iF_j(\mathbf{R}))R_l\frac{\partial\psi}{\partial x_j}\ d\mathbf{R}.
\end{aligned}
\tag{10}
$$

By inserting (10) into (6), we finally obtain

$$
\begin{aligned}
&\rho\left[\frac{\partial}{\partial t}+(\mathbf{v}\cdot\nabla)\right]^2 v_i \\
&\quad = n\frac{\partial^2 v_k}{\partial x_j \partial x_l}\int(\gamma(|\mathbf{R}|^2)R_jR_l\delta_{ik}+2\gamma'(|\mathbf{R}|^2)R_iR_jR_kR_l)\psi\ d\mathbf{R} - \frac{\partial q}{\partial x_i} \\
&\quad\quad - n\alpha\int\Delta_{\mathbf{R}}(R_iF_j(\mathbf{R}))\frac{\partial\psi}{\partial x_j}\ d\mathbf{R} - n\beta\int\frac{\partial}{\partial R_k}(R_iF_j(\mathbf{R}))F_k(\mathbf{R})\frac{\partial\psi}{\partial x_j}\ d\mathbf{R} \\
&\quad\quad - n\frac{\partial v_k}{\partial x_l}\int\frac{\partial}{\partial R_k}(R_iF_j(\mathbf{R}))R_l\frac{\partial\psi}{\partial x_j}\ d\mathbf{R} \\
&\quad\quad - \frac{\partial v_k}{\partial x_j}\frac{\partial T_{ij}}{\partial x_k}+\frac{\partial v_k}{\partial x_i}\frac{\partial T_{kj}}{\partial x_j} - \rho\frac{\partial v_j}{\partial x_i}\left[\frac{\partial}{\partial t}+(\mathbf{v}\cdot\nabla)\right]v_j \\
&\quad\quad + \left[\frac{\partial}{\partial t}+(\mathbf{v}\cdot\nabla)\right]f_i+\frac{\partial v_j}{\partial x_i}f_j.
\end{aligned}
\tag{11}
$$

The iteration is based on equations (3) and (11). Given an iterate $\mathbf{v}^m$, we determine ψ^m by solving equation (3),

$$
\left(\frac{\partial}{\partial t}+(\mathbf{v}^m\cdot\nabla_{\mathbf{x}})\right)\psi^m = \alpha\Delta_{\mathbf{R}}\psi^m+\operatorname{div}_{\mathbf{R}}\ (-(\nabla_{\mathbf{x}}\mathbf{v}^m)\cdot\mathbf{R}\psi^m-\beta\mathbf{F}(\mathbf{R})\psi^m),
\tag{12a}
$$

$$
\psi^m(\mathbf{R},\mathbf{x},0)=\psi_0(\mathbf{R},\mathbf{x}).
\tag{12b}
$$

We define $\mathbf{T}^m$ in terms of ψ^m by equation (2) and then determine a new velocity field $\mathbf{v}^{m+1}$ by solving the problem

$$
\begin{aligned}
&\rho\left[\frac{\partial}{\partial t}+(\mathbf{v}^m\cdot\nabla)\right]^2 v_i^{m+1} \\
&= n\frac{\partial^2 v_k^{m+1}}{\partial x_j \partial x_l}\int(\gamma(|\mathbf{R}|^2)R_jR_l\delta_{ik}+2\gamma'(|\mathbf{R}|^2)R_iR_jR_kR_l)\psi^m\ d\mathbf{R} - \frac{\partial q^{m+1}}{\partial x_i} \\
&\quad - n\alpha\int\Delta_{\mathbf{R}}(R_iF_j(\mathbf{R}))\frac{\partial\psi^m}{\partial x_j}\ d\mathbf{R} - n\beta\int\frac{\partial}{\partial R_k}(R_iF_j(\mathbf{R}))F_k(\mathbf{R})\frac{\partial\psi^m}{\partial x_j}\ d\mathbf{R} \\
&\quad - n\frac{\partial v_k^m}{\partial x_l}\int\frac{\partial}{\partial R_k}(R_iF_j(\mathbf{R}))R_l\frac{\partial\psi^m}{\partial x_j}\ d\mathbf{R} \\
&\quad - \frac{\partial v_k^m}{\partial x_j}\frac{\partial T_{ij}^m}{\partial x_k}+\frac{\partial v_k^m}{\partial x_i}\frac{\partial T_{kj}^m}{\partial x_j} - \rho\frac{\partial v_j^m}{\partial x_i}\left[\frac{\partial}{\partial t}+(\mathbf{v}^m\cdot\nabla)\right]v_j^m \\
&\quad + \left[\frac{\partial}{\partial t}+(\mathbf{v}^m\cdot\nabla)\right]f_i+\frac{\partial v_j^m}{\partial x_i}f_j,
\end{aligned}
\tag{13a}
$$

$$\text{div } \mathbf{v}^{m+1} = 0, \tag{13b}$$

$$\mathbf{v}^{m+1} = \mathbf{0}, \quad x \in \partial\Omega, \quad t \geq 0. \tag{13c}$$

$$\mathbf{v}^{m+1}(\mathbf{x}, 0) = \mathbf{v}_0(\mathbf{x}), \quad \frac{\partial \mathbf{v}^{m+1}}{\partial t}(\mathbf{x}, 0) = \mathbf{v}_1(\mathbf{x}). \tag{13d}$$

Here $\mathbf{v}_1$ is the initial value of $\partial \mathbf{v}/\partial t$, which can be computed by applying the Hodge projection to (1). Equations (13) also yield a new iterate for q, from which an approximation to the pressure p may be recovered. However, this is not necessary in order to proceed to the next step of the iteration.

3. Definition of function spaces and statement of results. Since ψ has the meaning of a probability density, L^1-spaces are natural for the $\mathbf{R}$-dependence. However, the definition of $\mathbf{T}$ in (2) involves integrals of ψ against increasing functions of $\mathbf{R}$, and we shall therefore use weighted L^1-spaces. We define

$$X_{n,0} = \left\{ \psi : \ \mathbb{R}^3 \to \mathbb{R} \ \middle| \ \int (1 + |\mathbf{R}|^n)|\psi(\mathbf{R})| \ d\mathbf{R} < \infty \right\}, \tag{14a}$$

in the case of infinitely extensible dumbbells, and

$$X_{n,0} = \left\{ \psi : \ B \to \mathbb{R} \ \middle| \ \int (R_0 - |\mathbf{R}|)^{-n}|\psi(\mathbf{R})| \ d\mathbf{R} < \infty \right\}, \tag{14b}$$

in the case of finitely extensible dummbells. Here B denotes the ball of radius R_0. Moreover, we let $X_{n,k}$ be the space of all ψ whose derivatives up to order k lie in $X_{n,0}$. Finally, let

$$X_k = \bigcap_{n=0}^{\infty} X_{n,k}, \tag{15}$$

with the natural topology of a Fréchet space. The space X_k consists of functions which, together with their derivatives, vanish at infinite order as $|\mathbf{R}| \to \infty$ or $|\mathbf{R}| \to R_0$, respectively. Instead of working with this Fréchet space, it would be possible to work with Banach spaces of functions vanishing at sufficiently high order; however, different orders of decay would have to be chosen for higher derivatives of ψ than for ψ itself. This would make the precise statement of a theorem rather laborious. The analysis that follows is not substantially complicated by the fact that X_k is a Fréchet space rather than a Banach space.

We make the following smoothness assumptions:

(S1) The domain $\Omega \subset \mathbb{R}^3$ is bounded and $\partial\Omega$ is of class C^5.

(S2) $\mathbf{v}_0 \in H^4(\Omega)$.

(S3) $\psi_0 \in \bigcap_{k=0}^{4} H^k(\Omega; X_{8-2k})$, where $H^k(\Omega; X_l)$ stands for $\bigcap_{n=0}^{\infty} H^k(\Omega; X_{n,l})$. Moreover, $\psi_0 \geq 0$ and $\int \psi_0(\mathbf{R}, \mathbf{x}) \ d\mathbf{R} = 1$ for every $\mathbf{x} \in \Omega$.

(S4) For some $T > 0$, we have $\mathbf{f} \in \bigcap_{k=0}^{4} W^{k,1}([0, T]; H^{4-k}(\Omega))$.

In addition, we need compatibility conditions between the initial data and the incompressibility and boundary conditions. Note that by applying the Hodge projection

operator to equation (1), we can obtain an initial value for $\partial \mathbf{v}/\partial t$, and, after differentiating (1) with respect to t, we can obtain initial values of higher time derivatives in an analogous fashion. We shall denote the initial value of $\partial^i \mathbf{v}/\partial t^i$ by $\mathbf{v}_i$. These initial values for time derivatives of $\mathbf{v}$ satisfy the incompressibility condition because of their construction, but we still need to require that they satisfy the boundary conditions. We assume the following compatibility conditions:

(C1) div $\mathbf{v}_0 = 0$ and $\mathbf{v}_0 = \mathbf{0}$ on $\partial\Omega$.

(C2) $\mathbf{v}_1$, $\mathbf{v}_2$ and $\mathbf{v}_3$ vanish on $\partial\Omega$.

The goal of the paper is the following result.

THEOREM. *Assume that* (S1)–(S4), (C1), (C2), *and* (F) *or, respectively,* (F′) *hold. Then there is a* $T' \in (0,T]$ *such that the problem* (1)–(5) *has a unique solution with the regularity*

$$\mathbf{v} \in \bigcap_{k=0}^{4} C^k([0,T']; H^{4-k}(\Omega)); \quad \mathbf{T} \in \bigcap_{k=0}^{3} C^k([0,T']; H^{3-k}(\Omega));$$
$$\psi \in \bigcap_{k=0}^{3} \bigcap_{l=0}^{3-k} C^k([0,T']; H^l(\Omega; X_{8-2k-2l})). \tag{16}$$

The proof will be based on showing that the mapping $\Sigma : \mathbf{v}^m \to \mathbf{v}^{m+1}$ defined by (12) and (13) is a contraction in an appropriate complete space of functions. This space of functions, denoted by $Z(M,T')$, is defined as the set of all functions $\mathbf{v} : \Omega \times [0,T'] \to \mathbb{R}^3$ with the following properties:

$$\mathbf{v} \in \bigcap_{k=0}^{4} W^{k,\infty}([0,T']; H^{4-k}(\Omega)), \tag{17a}$$

$$\|\mathbf{v}\|_{0,4} + \|\mathbf{v}\|_{1,3} + \|\mathbf{v}\|_{2,2} + \|\mathbf{v}\|_{3,1} + \|\mathbf{v}\|_{4,0} \le M, \tag{17b}$$

$$\operatorname{div} \mathbf{v} = 0, \tag{17c}$$

$$\mathbf{v}|_{\partial\Omega} = \mathbf{0}, \tag{17d}$$

(17e)
$$\mathbf{v}(\mathbf{x},0) = \mathbf{v}_0(\mathbf{x}), \quad \frac{\partial \mathbf{v}}{\partial t}(\mathbf{x},0) = \mathbf{v}_1(\mathbf{x}), \quad \frac{\partial^2 \mathbf{v}}{\partial t^2}(\mathbf{x},0) = \mathbf{v}_2(\mathbf{x}), \quad \frac{\partial^3 \mathbf{v}}{\partial t^3}(\mathbf{x},0) = \mathbf{v}_3(\mathbf{x}).$$

Here $\|\cdot\|_{k,l}$ denotes the norm in $W^{k,\infty}([0,T']; H^l(\Omega))$; below we shall also use the notation $\|\cdot\|_{k,l,p}$ for the norm in $W^{k,p}([0,T']; H^l(\Omega))$. In $Z(M,T')$, we introduce the metric

$$d(\mathbf{v},\mathbf{w}) = \|\mathbf{v}-\mathbf{w}\|_{0,3} + \|\mathbf{v}-\mathbf{w}\|_{1,2} + \|\mathbf{v}-\mathbf{w}\|_{2,1} + \|\mathbf{v}-\mathbf{w}\|_{3,0}. \tag{18}$$

It is easy to see that $Z(M,T')$ with this metric is complete. We refer to [11] for a proof that it is not empty (provided M is large enough).

We note that (13) is of the same type as problem (16) considered in [11]. The quantity

$$\int (\gamma(|\mathbf{R}|^2) R_j R_l \delta_{ik} + 2\gamma'(|\mathbf{R}|^2) R_i R_j R_k R_l) \psi^m \, d\mathbf{R} \tag{19}$$

assumes the role of C_{ijkl} in [11]. We note that the symmetry condition

$$C_{ijkl} = C_{klij} \tag{20}$$

and the strong ellipticity condition

$$C_{ijkl}\zeta_i\zeta_k\eta_j\eta_l \geq \kappa|\zeta|^2|\eta|^2 \quad \forall\zeta,\eta \in \mathbb{R}^3, \tag{21}$$

with $\kappa > 0$ depending continuously on $\psi \in \{\psi \in L^1 \mid \psi \geq 0, \int \psi\, d\mathbf{R} = 1\}$, are satisfied, because we have assumed γ to be an increasing function of $|\mathbf{R}|^2$. Hence the results of [11] are applicable to (13), and most of the proof in the following section will be concerned with solving the diffusion equation (12).

4. Proof of the theorem. In order to show that Σ is a contraction in $Z(M,T')$, we shall have to choose M sufficiently large and T' sufficiently small. The estimates used in the proof will involve bounds of the form $K(M,T',a_1,a_2,\cdots)$, where the size of a_1, a_2 etc., can be kept within given bounds. It is important that the size of K for large M can be controlled by choosing T' small enough. This leads us to the following definition.

DEFINITION. A continuous function $K(M,T',a_1,a_2,\cdots) : \mathbb{R}^+ \times \mathbb{R}^+ \times \mathbb{R}^+ \cdots \to \mathbb{R}^+$ is called controllable, if there are continuous positively valued functions $\tau(M,a_1,a_2,\cdots)$ and $\omega(a_1,a_2,\cdots)$ such that $K(M,T',a_1,a_2,\cdots) \leq \omega(a_1,a_2,\cdots)$ as long as $T' \leq \tau(M,a_1,a_2,\cdots)$.

We begin by stating the results of [11], which can be applied to problem (13). This problem is of the form

$$\begin{gathered}\rho\left[\frac{\partial}{\partial t} + (\mathbf{v}\cdot\nabla)\right]^2 w_i = -\frac{\partial q}{\partial x_i} + C_{ijkl}(\mathbf{x},t)\frac{\partial^2 w_k}{\partial x_j \partial x_l} + h_i, \\ \operatorname{div}\mathbf{w} = 0, \quad \mathbf{w}|_{\partial\Omega} = \mathbf{0}, \quad \mathbf{w}(\mathbf{x},0) = \mathbf{w}_0(\mathbf{x}), \quad \dot{\mathbf{w}}(\mathbf{x},0) = \mathbf{w}_1(\mathbf{x}).\end{gathered} \tag{22}$$

LEMMA 1. *Let* $\mathbf{v}$, $\mathbf{h}$ *and* $\mathbf{C}$ *be given such that* $\operatorname{div}\mathbf{v} = 0$, $\mathbf{v}|_{\partial\Omega} = 0$ *and* $\mathbf{C}$ *satisfies the symmetry condition* (20) *and the strong ellipticity condition* (21) *with a positive lower bound* γ *for* κ *in* (21). *Moreover, assume that bounds of the following kind hold:*

$$\|\mathbf{v}\|_{0,4} + \|\mathbf{v}\|_{1,3} + \|\mathbf{v}\|_{2,2} + \|\mathbf{v}\|_{3,1} + \|\mathbf{v}\|_{4,0} \leq M, \tag{23a}$$

$$\|\mathbf{v}\|_{0,3} + \|\mathbf{v}\|_{1,2} + \|\mathbf{v}\|_{2,1} + \|\mathbf{v}\|_{3,0} \leq K, \tag{23b}$$

$$\|\mathbf{C}\|_{0,3} + \|\mathbf{C}\|_{1,2} + \|\mathbf{C}\|_{2,1} + \|\mathbf{C}\|_{3,0} \leq M, \tag{23c}$$

$$\|\mathbf{C}\|_{0,2} + \|\mathbf{C}\|_{1,1} + \|\mathbf{C}\|_{2,0} \leq K, \tag{23d}$$

$$\|\mathbf{h}\|_{0,2} + \|\mathbf{h}\|_{1,1} + \|\mathbf{h}\|_{2,0} \leq K, \tag{23e}$$

$$\left\|\frac{\partial\mathbf{h}}{\partial t} + (\mathbf{v}\cdot\nabla)\mathbf{h}\right\|_{0,2,1} + \left\|\frac{\partial\mathbf{h}}{\partial t} + (\mathbf{v}\cdot\nabla)\mathbf{h}\right\|_{1,1,1} + \left\|\frac{\partial\mathbf{h}}{\partial t} + (\mathbf{v}\cdot\nabla)\mathbf{h}\right\|_{2,0,1} \leq K. \tag{23f}$$

Finally, assume that $\mathbf{w}_0 \in H^4(\Omega)$, $\mathbf{w}_1 \in H^3(\Omega)$ *with norms bounded by* K, *that* $\operatorname{div} \mathbf{w}_0 = \operatorname{div} \mathbf{w}_1 = 0$, *and that* $\mathbf{w}_0$, $\mathbf{w}_1$, *and the initial values of* $\partial^2\mathbf{w}/\partial t^2$ *and* $\partial^3\mathbf{w}/\partial t^3$, *as determined by* (22), *are compatible with the boundary condition* $\mathbf{w}|_{\partial\Omega} = \mathbf{0}$. *Then* (22) *has a solution*

$$\mathbf{w} \in \bigcap_{k=0}^{4} C^k([0,T']; H^{4-k}(\Omega)),$$

and we have

$$\|\mathbf{w}\|_{0,4} + \|\mathbf{w}\|_{1,3} + \|\mathbf{w}\|_{2,2} + \|\mathbf{w}\|_{3,1} + \|\mathbf{w}\|_{4,0} \le \phi(M,T',K,\gamma), \tag{24}$$

where ϕ *is controllable.*

LEMMA 2. *Consider* (22) *and a second equation*

$$\begin{aligned} &\rho\left[\frac{\partial}{\partial t} + (\tilde{\mathbf{v}}\cdot\nabla)\right]^2 \tilde{w}_i = -\frac{\partial \tilde{q}}{\partial x_i} + \tilde{C}_{ijkl}(\mathbf{x},t)\frac{\partial^2 \tilde{w}_k}{\partial x_j \partial x_l} + \tilde{h}_i, \\ &\operatorname{div} \tilde{\mathbf{w}} = 0, \quad \tilde{\mathbf{w}}|_{\partial\Omega} = \mathbf{0}, \quad \tilde{\mathbf{w}}(\mathbf{x},0) = \mathbf{w}_0(\mathbf{x}), \quad \dot{\tilde{\mathbf{w}}}(\mathbf{x},0) = \mathbf{w}_1(\mathbf{x}). \end{aligned} \tag{25}$$

Assume that the assumptions of Lemma 1 *also hold for* (25) (*with the same constants* M, K *and* γ). *Moreover, assume that for* $t = 0$ *we have*

$$\mathbf{v} = \tilde{\mathbf{v}}, \quad \dot{\mathbf{v}} = \dot{\tilde{\mathbf{v}}}, \quad \ddot{\mathbf{v}} = \ddot{\tilde{\mathbf{v}}}, \quad \mathbf{C} = \tilde{\mathbf{C}}, \quad \dot{\mathbf{C}} = \dot{\tilde{\mathbf{C}}}, \quad \mathbf{h} = \tilde{\mathbf{h}}, \quad \dot{\mathbf{h}} = \dot{\tilde{\mathbf{h}}}. \tag{26}$$

Then we have an estimate of the form

$$\begin{aligned} &\|\mathbf{w}-\tilde{\mathbf{w}}\|_{0,3} + \|\mathbf{w}-\tilde{\mathbf{w}}\|_{1,2} + \|\mathbf{w}-\tilde{\mathbf{w}}\|_{2,1} + \|\mathbf{w}-\tilde{\mathbf{w}}\|_{3,0} \le \psi(M,T',K,\gamma) \\ &\quad\cdot\Big[\|\mathbf{v}-\tilde{\mathbf{v}}\|_{0,3} + \|\mathbf{v}-\tilde{\mathbf{v}}\|_{1,2} + \|\mathbf{v}-\tilde{\mathbf{v}}\|_{2,1} + \|\mathbf{v}-\tilde{\mathbf{v}}\|_{3,0} \\ &\qquad + \|\mathbf{C}-\tilde{\mathbf{C}}\|_{0,2} + \|\mathbf{C}-\tilde{\mathbf{C}}\|_{1,1} + \|\mathbf{C}-\tilde{\mathbf{C}}\|_{2,0} + \|\mathbf{h}-\tilde{\mathbf{h}}\|_{0,1} + \|\mathbf{h}-\tilde{\mathbf{h}}\|_{1,0} \\ &\qquad + \left\|\frac{\partial \mathbf{h}}{\partial t} + (\mathbf{v}\cdot\nabla)\mathbf{h} - \frac{\partial \tilde{\mathbf{h}}}{\partial t} - (\tilde{\mathbf{v}}\cdot\nabla)\tilde{\mathbf{h}}\right\|_{0,1,1} \\ &\qquad + \left\|\frac{\partial \mathbf{h}}{\partial t} + (\mathbf{v}\cdot\nabla)\mathbf{h} - \frac{\partial \tilde{\mathbf{h}}}{\partial t} - (\tilde{\mathbf{v}}\cdot\nabla)\tilde{\mathbf{h}}\right\|_{1,0,1}\Big]. \end{aligned} \tag{27}$$

The function $\psi(M,T',K,\gamma)$ *tends to zero as* $T' \to 0$.

We need to establish analogous results for (12). For given $\mathbf{v} \in Z(M,T')$, we have to find ψ satisfying

$$\begin{aligned} \left(\frac{\partial}{\partial t} + (\mathbf{v}\cdot\nabla_{\mathbf{x}})\right)\psi &= \alpha\Delta_{\mathbf{R}}\psi + \operatorname{div}_{\mathbf{R}}(-(\nabla_{\mathbf{x}}\mathbf{v})\cdot\mathbf{R}\psi - \beta\mathbf{F}(\mathbf{R})\psi), \\ \psi(\mathbf{R},\mathbf{x},0) &= \psi_0(\mathbf{R},\mathbf{x}). \end{aligned} \tag{28}$$

The following lemma holds.

LEMMA 3. *Given* $\mathbf{v} \in Z(M,T')$, *there exists a unique solution of* (28) *which has the regularity*

$$\psi \in \bigcap_{k=0}^{3}\bigcap_{l=0}^{3-k} C^k([0,T']; H^l(\Omega; X_{8-2k-2l})). \tag{29}$$

Let $\|\cdot\|_{(n)}$ *be the norm in*

$$\bigcap_{k=0}^{3}\bigcap_{l=0}^{3-k} C^k([0,T'];H^l(\Omega;X_{n,8-2k-2l})). \tag{30}$$

For every n, *we have an estimate of the form*

$$\|\psi\|_{(n)} \leq C_n \cdot K(M,T',n), \tag{31}$$

where C_n *depends only on the initial data and* K *is controllable.*

We note that it is in general neither possible nor necessary to obtain a bound for $K(M,T',n)$ which is independent of n. By using (29) and (28), we find, moreover, that

$$\frac{\partial\psi}{\partial t} + (\mathbf{v}\cdot\nabla_{\mathbf{x}})\psi \in \bigcap_{k=0}^{3}\bigcap_{l=0}^{3-k} W^{k,\infty}([0,T'];H^l(\Omega;X_{6-2k-2l})). \tag{32}$$

In addition to (28), let us consider a second equation of the same form:

$$\begin{aligned}\Big(\frac{\partial}{\partial t} + (\tilde{\mathbf{v}}\cdot\nabla_{\mathbf{x}})\Big)\tilde{\psi} &= \alpha\Delta_{\mathbf{R}}\tilde{\psi} + \operatorname{div}_{\mathbf{R}}((-\nabla_{\mathbf{x}}\tilde{\mathbf{v}})\cdot\mathbf{R}\tilde{\psi} - \beta\mathbf{F}(\mathbf{R})\tilde{\psi}),\\ \tilde{\psi}(\mathbf{R},\mathbf{x},0) &= \psi_0(\mathbf{R},\mathbf{x}).\end{aligned} \tag{33}$$

The following result holds.

LEMMA 4. *Let* $\mathbf{v}$, $\tilde{\mathbf{v}} \in Z(M,T')$ *be given. Let* $\|\cdot\|_{[n]}$ *denote the norm in*

$$\bigcap_{k=0}^{2}\bigcap_{l=0}^{2-k} C^k([0,T'];H^l(\Omega;X_{6-2k-2l})). \tag{34}$$

Then for every n, *we have an estimate of the form*

$$\|\psi - \tilde{\psi}\|_{[n]} \leq K(M,T',n)d(\mathbf{v},\tilde{\mathbf{v}}). \tag{35}$$

Here $d(\mathbf{v},\tilde{\mathbf{v}})$ *is as defined in* (18). *The function* $K(M,T',n)$ *tends to zero as* $T' \to 0$.

Using the equations, we find, as a consequence, a similar estimate for

$$\Big(\frac{\partial}{\partial t} + (\mathbf{v}\cdot\nabla_{\mathbf{x}})\Big)\psi - \Big(\frac{\partial}{\partial t} + (\tilde{\mathbf{v}}\cdot\nabla_{\mathbf{x}})\Big)\tilde{\psi} \tag{36}$$

in the space

$$\bigcap_{k=0}^{2}\bigcap_{l=0}^{2-k} C^k([0,T'];H^l(\Omega;X_{4-2k-2l})). \tag{37}$$

By combining Lemmas 1 through 4, it follows easily that Σ is a contraction in $Z(M,T')$ if M is chosen sufficiently large and T' is chosen sufficiently small. The theorem follows immediately. The rest of the paper will therefore be concerned with the proofs of Lemmas 3 and 4.

We introduce Lagrangian coordinates, which we shall denote by $\mathbf{X}$. Let $\mathbf{x}(\mathbf{X},t)$ denote the Eulerian coordinate corresponding to $\mathbf{X}$, i.e., the solution of the problem

$$\frac{\partial}{\partial t}\mathbf{x}(\mathbf{X},t) = \mathbf{v}(\mathbf{x}(\mathbf{X},t),t), \qquad \mathbf{x}(\mathbf{X},0) = \mathbf{X}. \tag{38}$$

Let $\phi(\mathbf{R},\mathbf{X},t) = \psi(\mathbf{R},\mathbf{x}(\mathbf{X},t),t)$. Equation (28) can then be written in the alternative form

$$\begin{aligned} &\frac{\partial}{\partial t}\phi(\mathbf{R},\mathbf{X},t) = \alpha\Delta_{\mathbf{R}}\phi + \operatorname{div}_{\mathbf{R}}(-(\nabla_{\mathbf{x}}\mathbf{v}(\mathbf{x}(\mathbf{X},t),t))\cdot\mathbf{R}\phi - \beta\mathbf{F}(\mathbf{R})\phi), \\ &\phi(\mathbf{R},\mathbf{X},0) = \psi_0(\mathbf{R},\mathbf{X}). \end{aligned} \tag{39}$$

This is a parabolic equation for ϕ, in which the only derivatives are with respect to $\mathbf{R}$ and t, while $\mathbf{X}$ only appears as a parameter in the coefficients and initial conditions. We note that the transformation $(\mathbf{X},t) \to (\mathbf{x}(\mathbf{X},t),t)$ is smooth enough so that if ψ has the regularity claimed by Lemma 3, then so does ϕ and vice versa.

The fact that solutions of (39) with the regularity claimed by Lemma 3 are unique follows from a straightforward application of the maximum principle. It also follows from the maximum principle that positivity is preserved, and by integrating both sides of (39) we find that $\int \phi(\mathbf{R},\mathbf{X},t)\,d\mathbf{R} = \int \psi(\mathbf{R},\mathbf{x},t)\,d\mathbf{R} = 1$ for all t. To show the existence of solutions, we cannot use standard results available in the literature because the coefficients of the equation are unbounded. To get around this difficulty, we use a sequence of approximating problems with bounded coefficients, for which we derive uniform estimates. The cases of infinitely and, respectively, finitely extensible dumbbells have to be treated somewhat differently, and we shall first deal with infinitely extensible dumbbells.

Let $\chi(\mathbf{R})$ be a C^∞-function such that $\chi(\mathbf{0}) = 1$, χ is a monotone decreasing function of $|\mathbf{R}|$, and $\chi(\mathbf{R}) = |\mathbf{R}|^{-\nu}$ for large $|\mathbf{R}|$, where ν is a sufficiently large number. For $N \in \mathbb{N}$, let $\chi_N(\mathbf{R}) = \chi(\mathbf{R}/N)$. We now replace (39) by the approximate problem

$$\begin{aligned} &\frac{\partial\phi_N}{\partial t} = \alpha\Delta_{\mathbf{R}}\phi_N + \operatorname{div}_{\mathbf{R}}\Big[\chi_N(\mathbf{R})\big(-(\nabla_{\mathbf{x}}\mathbf{v}(\mathbf{x}(\mathbf{X},t),t))\cdot\mathbf{R}\phi_N - \beta\mathbf{F}(\mathbf{R})\phi_N\big)\Big], \\ &\phi_N(\mathbf{R},\mathbf{X},0) = \psi_0(\mathbf{R},\mathbf{X}). \end{aligned} \tag{40}$$

We note that equation (40) has bounded coefficients. Hence the existence of solutions and their decay as $|\mathbf{R}| \to \infty$ are easily established. We now multiply (40) by $|\mathbf{R}|^{2n}$ and integrate. This yields after an integration by parts

$$\begin{aligned} &\frac{\partial}{\partial t}\int |\mathbf{R}|^{2n}\phi_N(\mathbf{R},\mathbf{X},t)\,d\mathbf{R} \\ &\quad = \alpha(4n^2+2n)\int |\mathbf{R}|^{2n-2}\phi_N(\mathbf{R},\mathbf{X},t)\,d\mathbf{R} \\ &\qquad + 2n\int |\mathbf{R}|^{2n-2}\chi_N(\mathbf{R})\Big[\mathbf{R}\cdot(\nabla_{\mathbf{x}}\mathbf{v}(\mathbf{x}(\mathbf{X},t),t))\cdot\mathbf{R} \\ &\qquad\qquad + \beta\mathbf{R}\cdot\mathbf{F}(\mathbf{R})\Big]\phi_N(\mathbf{R},\mathbf{X},t)\,d\mathbf{R}. \end{aligned} \tag{41}$$

The term $\mathbf{R}\cdot\mathbf{F}(\mathbf{R})$ is negative, and all other terms on the right-hand side of (41) can be estimated by a constant (depending on n but not on N) times $\int(1+|\mathbf{R}|^{2n})$ $\phi_N(\mathbf{R},\mathbf{X},t)\,d\mathbf{R}$. Hence (41) yields a bound of the form

$$\int |\mathbf{R}|^{2n}\phi_N(\mathbf{R},\mathbf{X},t) \le K(n,Mt)\int(1+|\mathbf{R}|^{2n})\psi_0(\mathbf{R},\mathbf{X})\,d\mathbf{R}. \tag{42}$$

We next derive estimates for derivatives with respect to $\mathbf{R}$. We differentiate (40) with respect to R_i and obtain

$$\begin{aligned}\frac{\partial^2\phi_N}{\partial R_i\partial t} &= \alpha\Delta_{\mathbf{R}}\frac{\partial\phi_N}{\partial R_i} + \operatorname{div}_{\mathbf{R}}\Big[\chi_N(\mathbf{R})\big(-(\nabla_{\mathbf{x}}\mathbf{v}(\mathbf{x}(\mathbf{X},t),t))\cdot\mathbf{R}-\beta\mathbf{F}(\mathbf{R})\big)\frac{\partial\phi_N}{\partial R_i}\Big]\\ &\quad + \operatorname{div}_{\mathbf{R}}\Big[\frac{\partial}{\partial R_i}\Big(\chi_N(\mathbf{R})(-(\nabla_{\mathbf{x}}\mathbf{v}(\mathbf{x}(\mathbf{X},t),t))\cdot\mathbf{R}-\beta\mathbf{F}(\mathbf{R}))\Big)\phi_N\Big],\\ \frac{\partial\phi_N}{\partial R_i}(\mathbf{R},\mathbf{X},0) &= \frac{\partial\psi_0}{\partial R_i}(\mathbf{R},\mathbf{X}).\end{aligned}\tag{43}$$

The last term on the right-hand side of this equation can be further transformed as follows:

$$\begin{aligned}&\operatorname{div}_{\mathbf{R}}\Big[\frac{\partial}{\partial R_i}\Big(\chi_N(\mathbf{R})(-(\nabla_{\mathbf{x}}\mathbf{v}(\mathbf{x}(\mathbf{X},t),t))\cdot\mathbf{R}-\beta\mathbf{F}(\mathbf{R}))\Big)\phi_N\Big]\\ &\quad=\phi_N\operatorname{div}_{\mathbf{R}}\Big[\frac{\partial}{\partial R_i}\Big(\chi_N(\mathbf{R})(-(\nabla_{\mathbf{x}}\mathbf{v})\cdot\mathbf{R}-\beta\mathbf{F}(\mathbf{R}))\Big)\Big]\\ &\qquad+\frac{\partial\phi_N}{\partial R_j}\Big[\frac{\partial\chi_N}{\partial R_i}\Big(-\frac{\partial v_j}{\partial x_k}R_k-\beta F_j(\mathbf{R})\Big)+\chi_N(\mathbf{R})\Big(-\frac{\partial v_j}{\partial x_i}-\beta\frac{\partial F_j}{\partial R_i}\Big)\Big].\end{aligned}\tag{44}$$

Since $\partial\phi_N/\partial R_i$ is not positive, we cannot proceed in exact analogy to (41) above. Instead, we first decompose $\partial\phi_N/\partial R_i=\pi_i^+-\pi_i^-$, where π_i^+ and π_i^- are solutions to the problems,

$$\begin{aligned}\frac{\partial\pi_i^+}{\partial t} &= \alpha\Delta_{\mathbf{R}}\pi_i^+ + \operatorname{div}_{\mathbf{R}}\Big[\chi_N(\mathbf{R})\big(-(\nabla_{\mathbf{x}}\mathbf{v})\cdot\mathbf{R}\pi_i^+-\beta\mathbf{F}(\mathbf{R})\pi_i^+\big)\Big]+s_i^+,\\ \pi_i^+(\mathbf{R},\mathbf{X},0) &= \max\Big(\frac{\partial\psi_0}{\partial R_i}(\mathbf{R},\mathbf{X}),0\Big),\end{aligned}\tag{45}$$

and, respectively,

$$\begin{aligned}\frac{\partial\pi_i^-}{\partial t} &= \alpha\Delta_{\mathbf{R}}\pi_i^- + \operatorname{div}_{\mathbf{R}}\Big[\chi_N(\mathbf{R})\big(-(\nabla_{\mathbf{x}}\mathbf{v})\cdot\mathbf{R}\pi_i^--\beta\mathbf{F}(\mathbf{R})\pi_i^-\big)\Big]-s_i^-,\\ \pi_i^-(\mathbf{R},\mathbf{X},0) &= \max\Big(-\frac{\partial\psi_0}{\partial R_i}(\mathbf{R},\mathbf{X}),0\Big).\end{aligned}\tag{46}$$

Here s_i^+ and s_i^- denote the positive and negative parts of the expression in (44). Since π_i^+ and π_i^- are positive, we can now proceed as above. In place of (41), we obtain

$$\begin{aligned}&\frac{\partial}{\partial t}\int|\mathbf{R}|^{2n}\pi_i^+(\mathbf{R},\mathbf{X},t)\,d\mathbf{R}\\ &=\alpha(4n^2+2n)\int|\mathbf{R}|^{2n-2}\pi_i^+(\mathbf{R},\mathbf{X},t)\,d\mathbf{R}+2n\int|\mathbf{R}|^{2n-2}\chi_N(\mathbf{R})\\ &\quad\cdot\Big[\mathbf{R}\cdot(\nabla_{\mathbf{x}}\mathbf{v}(\mathbf{x}(\mathbf{X},t),t))\cdot\mathbf{R}+\beta\mathbf{R}\cdot\mathbf{F}(\mathbf{R})\Big]\pi_i^+(\mathbf{R},\mathbf{X},t)\,d\mathbf{R}+\int|\mathbf{R}|^{2n}s_i^+\,d\mathbf{R},\end{aligned}\tag{47}$$

and an analogous equation for π_i^-. (A minor problem in deriving (47) arises from the fact that $\Delta\pi_i^+$ does not necessarily exist at $t=0$, but we may justify the argument by

approximating the initial value of π_i^+ by a sequence of smoother functions and then passing to the limit.) Using (44), we find that

$$\begin{aligned}
&\int |\mathbf{R}|^{2n} s_i^+ \, d\mathbf{R} \\
&\qquad \le \int |\mathbf{R}|^{2n} \phi_N \left| \operatorname{div}_{\mathbf{R}} \left[\frac{\partial}{\partial R_i} \Big(\chi_N(\mathbf{R})(-(\nabla_{\mathbf{x}} \mathbf{v}) \cdot \mathbf{R} - \beta \mathbf{F}(\mathbf{R})) \Big) \right] \right| d\mathbf{R} \\
&\qquad + \int |\mathbf{R}|^{2n} (\pi_j^+ + \pi_j^-) \left[\left| \frac{\partial \chi_N}{\partial R_i} \right| \left(\left| \frac{\partial v_j}{\partial x_k} R_k \right| + \beta |F_j(\mathbf{R})| \right) \right. \\
&\qquad \left. + \chi_N(\mathbf{R}) \left(\left| \frac{\partial v_j}{\partial x_i} \right| + \beta \left| \frac{\partial F_j}{\partial R_i} \right| \right) \right] d\mathbf{R}.
\end{aligned} \tag{48}$$

The first integral on the right-hand side of (48) involves only ϕ_N and no derivatives of ϕ_N; it can hence be estimated using (42) above. The integrand in the second integral can be estimated for large $|\mathbf{R}|$ by a constant times $\chi_N(\mathbf{R})(M|\mathbf{R}|^{2n} + |\mathbf{R}|^{2n-1}|\mathbf{F}(\mathbf{R})|) \sum_j (\pi_j^+ + \pi_j^-)$. From (47), we therefore obtain an estimate of the form

$$\begin{aligned}
&\frac{\partial}{\partial t} \int |\mathbf{R}|^{2n} \pi_i^+(\mathbf{R}, \mathbf{X}, t) \, d\mathbf{R} \\
&\qquad \le K_1(n, M) \int (1 + |\mathbf{R}|^{2n}) \pi_i^+(\mathbf{R}, \mathbf{X}, t) \, d\mathbf{R} + K_2(n, M) \\
&\qquad + 2n \int |\mathbf{R}|^{2n-2} \chi_N(\mathbf{R}) \beta \mathbf{R} \cdot \mathbf{F}(\mathbf{R}) \pi_i^+(\mathbf{R}, \mathbf{X}, t) \, d\mathbf{R} \\
&\qquad + K_3 \int (1 + |\mathbf{R}|^{2n-1} \chi_N(\mathbf{R}) |\mathbf{F}(\mathbf{R})| + M \chi_N(\mathbf{R}) |\mathbf{R}|^{2n}) \\
&\qquad \cdot \sum_j (\pi_j^+ + \pi_j^-)(\mathbf{R}, \mathbf{X}, t) \, d\mathbf{R}.
\end{aligned} \tag{49}$$

Note that K_3 does not depend on n, but that the previous term in (49), which is negative, has a factor n in front. By summing the inequalities corresponding to (49) over all values of i and all choices of $+$ or $-$, we can therefore get bounds for $\int |\mathbf{R}|^{2n} \pi_i^+ \, d\mathbf{R}$. As a consequence, we have found estimates for the first derivatives of ϕ_N. Bounds for higher derivatives are obtained in an analogous fashion after differentiating (40) with respect to the components of $\mathbf{R}$. The calculation involves higher derivatives of ϕ_N than are known to exist at $t = 0$, but the argument can be justified by approximating the initial datum by smoother functions and passing to the limit. Proceeding in this fashion, we find that

$$\phi_N \in L^\infty([0, T']; L^2(\Omega; X_8)). \tag{50}$$

Derivatives of ϕ_N with respect to $\mathbf{X}$ can be estimated by taking difference quotients in (40), estimating the difference quotients of ϕ_N, and then taking limits. Problems near the boundary of Ω are avoided by first extending $\mathbf{v}$ and ψ_0 so that they are defined for $\mathbf{X}$ outside Ω. This can be done in such a fashion that the extended functions have the same level of regularity as the original ones; for example, the method of reflection across the boundary can be used to obtain such extensions (cf. [8], p. 38).

Mixed derivatives with respect to $\mathbf{R}$ and $\mathbf{X}$ can be estimated by taking difference quotients with respect to $\mathbf{X}$ after first differentiating with respect to $\mathbf{R}$. The calculations are tedious but straightforward and we omit them. We find in this way that

$$\phi_N \in \bigcap_{l=0}^{3} L^\infty([0,T']; H^l(\Omega; X_{8-2l})). \tag{51}$$

Finally, temporal derivatives of ϕ_N can be estimated by using the equation itself. This yields

$$\phi_N \in \bigcap_{k=0}^{3} \bigcap_{l=0}^{3-k} W^{k,\infty}([0,T']; H^l(\Omega; X_{8-2k-2l})). \tag{52}$$

All these estimates are uniform in N.

Using the uniform bounds on the ϕ_N, we can extract a subsequence which converges, in the sense of distributions, to a solution ϕ of (39). Unfortunately, it is not a priori clear that

$$\phi \in \bigcap_{k=0}^{3} \bigcap_{l=0}^{3-k} W^{k,\infty}([0,T']; H^l(\Omega; X_{8-2k-2l})). \tag{53}$$

The difficulty is that the spaces X_k are based on L^1-type norms, and the limit of a distributionally convergent bounded sequence in L^1 may not be an L^1-function, but a singular measure. To show (53), we need a separate argument. We approximate the initial datum ψ_0 by a sequence ψ_0^M such that ψ_0^M has the additional regularity

$$\psi_0^M \in \bigcap_{k=0}^{4} H^k(\Omega; X_{10-2k}), \tag{54}$$

and $\psi_0^M \to \psi_0$ in the topology of

$$\bigcap_{k=0}^{4} H^k(\Omega; X_{8-2k}). \tag{55}$$

Let ϕ_N^M be the solution of (40) which is obtained when the initial datum is replaced by ψ_0^M. Then the same argument as above yields

$$\phi_N^M \in \bigcap_{k=0}^{3} \bigcap_{l=0}^{3-k} W^{k,\infty}([0,T']; H^l(\Omega; X_{10-2k-2l})); \tag{56}$$

moreover, in the topology of

$$\bigcap_{k=0}^{3} \bigcap_{l=0}^{3-k} W^{k,\infty}([0,T']; H^l(\Omega; X_{8-2k-2l})), \tag{57}$$

we have $\phi_N^M \to \phi_N$ uniformly in N. From (56) and (40), we conclude that

$$\frac{\partial \phi_N^M}{\partial t} \in \bigcap_{k=0}^{3} \bigcap_{l=0}^{3-k} W^{k,\infty}([0,T']; H^l(\Omega; X_{8-2k-2l})). \tag{58}$$

From (56) and (58) it follows that

$$\phi_N^M \in \bigcap_{k=0}^{3} \bigcap_{l=0}^{3-k} C^k([0,T']; H^l(\Omega; X_{8-2k-2l})). \tag{59}$$

For fixed M, the bounds for ϕ_N^M are again uniform in N. Let now Π_n be a reflexive Banach space such that

$$\begin{aligned} &\left[\bigcap_{k=0}^{3} \bigcap_{l=0}^{3-k} W^{k,\infty}([0,T'];H^l(\Omega; X_{n,10-2k-2l}))\right] \\ &\qquad \cap \left[\bigcap_{k=0}^{3} \bigcap_{l=0}^{3-k} W^{k+1,\infty}([0,T']; H^l(\Omega; X_{n,8-2k-2l}))\right] \\ &\qquad \subset \Pi_n \subset \bigcap_{k=0}^{3} \bigcap_{l=0}^{3-k} C^k([0,T']; H^l(\Omega; X_{n-1,8-2k-2l})). \end{aligned} \tag{60}$$

Such a space Π_n can be constructed using appropriate Sobolev norms. Let $\Pi = \bigcap_{n\in\mathbb{N}} \Pi_n$. Then, for every M, we have a uniform bound for ϕ_N^M in the norm of each Π_n, hence we can extract a subsequence which converges weakly in each Π_n to an element ϕ^M of Π. Since, for $M \to \infty$, ϕ_N^M converges to ϕ_N uniformly in N, we find that the sequence ϕ^M also converges in

$$\bigcap_{k=0}^{3} \bigcap_{l=0}^{3-k} C^k([0,T']; H^l(\Omega; X_{8-2k-2l})). \tag{61}$$

By taking $\phi = \lim_{M\to\infty} \phi^M$, we obtain a solution with the desired regularity. This concludes the proof of Lemma 3 for the case of the infinitely extensible dumbbell.

The proof of Lemma 4 is based on the same type of estimates, applied to the function $\psi - \tilde{\psi}$. We omit the details.

For the case of finitely extensible dumbbells, we use approximation by infinitely extensible dumbbells. We extend the initial datum ψ_0 by zero for $|\mathbf{R}| > R_0$, and we define an approximation γ_ϵ to the spring constant γ as follows. Let χ be a C^∞-function $[0,1] \to [0,1]$ such that $\chi(s) = 1$ in a neighborhood of 0 and $\chi(s) = 0$ in a neighborhood of 1. Let $\chi_\epsilon(\mathbf{R}) = \chi(\frac{2}{\epsilon}(|\mathbf{R}| - R_0 + \epsilon))$. Then we define

$$\gamma_\epsilon(|\mathbf{R}|^2) = \begin{cases} \gamma(|\mathbf{R}|^2) & \text{if } |\mathbf{R}| \le R_0 - \epsilon, \\ \gamma((R_0 - \frac{\epsilon}{2})^2) & \text{if } |\mathbf{R}| \ge R_0 - \frac{\epsilon}{2}, \\ \chi_\epsilon(\mathbf{R})\gamma(|\mathbf{R}|^2) + (1 - \chi_\epsilon(\mathbf{R}))\gamma((R_0 - \frac{\epsilon}{2})^2) & \text{if } R_0 - \epsilon < |\mathbf{R}| \\ & \qquad < R_0 - \frac{\epsilon}{2}. \end{cases} \tag{62}$$

We now consider the problem with spring constant γ_ϵ, which is infinitely extensible and satisfies the assumptions which we required for the infinitely extensible case. We now define

$$w_\epsilon(\mathbf{R}) = \begin{cases} \frac{1}{R_0^2 - |\mathbf{R}|^2} & \text{if } |\mathbf{R}| \le R_0 - \epsilon, \\ \frac{1}{\epsilon(2R_0 - \epsilon)} + \frac{2(R_0-\epsilon)}{\epsilon^2(2R_0-\epsilon)^2}(|\mathbf{R}| - R_0 + \epsilon) & \text{if } |\mathbf{R}| > R_0 - \epsilon. \end{cases} \tag{63}$$

The function w_ϵ and its gradient are continuous at $|\mathbf{R}| = R_0$, and w_ϵ has linear growth at infinity. We now repeat the estimates above, but instead of multiplying the equation

by powers of $|\mathbf{R}|$, we multiply by powers of $w_\epsilon(|\mathbf{R}|)$. The resulting estimates turn out to be uniform in ϵ as $\epsilon \to 0$, and Lemma 3 follows by passing to the limit.

THE EFFECT OF TEMPERATURE DEPENDENT VISCOSITY ON SHEAR FLOW OF INCOMPRESSIBLE FLUIDS*

M. BERTSCH†, L. A. PELETIER‡, AND S. M. VERDUYN LUNEL§

Abstract. This paper studies the effect of temperature dependence of the viscosity on the stability of classical Couette flow between two parallel plates. When the viscosity increases with temperature, it is well known that the flow becomes increasingly stable. With decreasing viscosity, however, if the dependence is sufficiently strong, the flow is found to become unstable.

Key words. fluid dynamics, plane Couette flow, temperature dependent viscosity, reaction-diffusion equations, invariant sets

AMS(MOS) subject classifications. 35B30, 35K57, 76E30

1. Introduction. In this paper we consider a rectilinear flow of an incompressible Newtonian viscous fluid, and assume that the viscosity is temperature dependent. In particular, we are interested in situations where the viscosity decreases with increasing temperature.

In general, the dissipation caused by viscosity has a stabilizing effect. However, when the heat generated by this mechanism raises the temperature, thus causing the viscosity to decrease, the flow may nevertheless become unstable. It is the object of this note to investigate if, and when, this possibility might arise. We do this for a simple problem of an adiabatic rectilinear shearing flow between parallel plates, one moving with respect to another, at constant distance from one another.

Choosing Cartesian coordinates, with the x-axis perpendicular to the plates, we choose units such that the plates are situated in the planes $x=0$ and $x=1$. We assume that the plate at $x=0$ is at rest and that the plate at $x=1$ moves with the constant velocity V in the direction of the positive y-axis. Between the plates the flow is parallel to the plates and uniform in the y- and the z-direction. Thus it is completely described by the velocity $v(x, t)$ and the temperature $\theta(x, t)$.

If we normalize units so that the density and the specific heat both become unity, conservation of momentum and energy yield the equations

$$v_t = \sigma_x, \qquad 0<x<1, \quad t>0, \tag{1.1}$$

$$\theta_t = \sigma v_x, \qquad 0<x<1, \quad t>0. \tag{1.2}$$

Here σ denotes the shear stress. We shall assume that it is related to the velocity gradient through the linear expression

$$\sigma = \mu(\theta) v_x, \tag{1.3}$$

where μ denotes the (temperature-dependent) viscosity.

At the plates we have

$$v(0, t) = 0, \qquad v(1, t) = V \tag{1.4}$$

and at $t=0$ we prescribe the velocity and the temperature

$$v(x, 0) = v_0(x), \quad \theta(x, 0) = \theta_0(x), \quad 0<x<1. \tag{1.5}$$

Here v_0 and θ_0 are given functions such that $v_0 > 0$ when $0 < x \leqq 1$ and $\theta_0 > 0$ when $0 \leqq x \leqq 1$, and v_0 is taken compatible with the boundary conditions (1.4), that is, $v_0(0) = 0$ and $v_0(1) = V$.

Note that the boundary conditions (1.4) imply the following *compatibility condition* for σ and θ:

$$\int_0^1 \frac{\sigma(x, t)}{\mu(\theta(x, t))}\, dx = V. \tag{1.6}$$

If $v_0(x) = Vx$ and $\theta_0(x) = a$, where a is a positive number, then the solution of (1.1)-(1.5) can be written down explicitly:

$$v(x, t) = Vx, \qquad \theta(x, t) = h(t), \tag{1.7}$$

where $h(t)$ is determined by

$$\int_a^{h(t)} \frac{ds}{\mu(s)} = V^2 t. \tag{1.8}$$

Since $v_x(x, t) \equiv V$ for this solution, it describes a *uniform* shearing flow.

Problem (1.1)-(1.5) was first studied in some detail by Dafermos and Hsiao [DH] and subsequently by Tzavaras [T1]-[T3]. These authors have shown that if $\mu(\theta)$ tends monotonically to some *finite positive constant* as $\theta \to \infty$, and either μ^2 is concave or μ is convex, then for sufficiently smooth initial data, problem (1.1)-(1.5) has a unique solution, which converges to the uniform shearing flow as $t \to \infty$.

If, however, $\mu(\theta)$ tends to zero as $\theta \to \infty$, the situation becomes much more delicate [DH], [T1]. Thus, if μ is taken to be

$$\mu(\theta) = \theta^{-\alpha}, \qquad \alpha > 0, \tag{1.9}$$

then global existence is still ensured provided $\alpha < 1$, i.e., provided μ does not decrease too rapidly, and the flow converges to the uniform shearing flow as $t \to \infty$ [DH], [T1]. However, when $\alpha \geqq 1$, no such results are known. It is the object of this paper to explore in particular this parameter range.

It is natural to distinguish three cases:

(I) $\alpha \in (0, 1)$,

(II) $\alpha = 1$,

(III) $\alpha > 1$.

Assuming throughout that $v_0 \in W^{2,2}(0, 1)$ and $\theta_0 \in W^{1,2}(0, 1)$ we shall prove the following theorems.

THEOREM A. *Suppose that* $0 < \alpha < 1$. *Then* (1.1)-(1.5) *has a unique global solution* $(v(x, t), \theta(x, t))$ *that converges asymptotically to the uniform shearing flow*:

$$v_x(x, t) = V + O(t^{-(1-\alpha)/(1+\alpha)}) \quad \text{as } t \to \infty,$$

$$\theta(x, t) = \{(1+\alpha) V^2 t\}^{1/(1+\alpha)} [1 + O(t^{-(1-\alpha)/(1+\alpha)})] \quad \text{as } t \to \infty.$$

This theorem is not new. It has been proved in [DH] and [T1] by means of energy methods. Here we use maximum principle arguments to identify appropriate invariant regions, in order to establish existence and asymptotic behaviour. This method has recently also been used for this purpose by Tzavaras [T3].

THEOREM B. *Suppose that* $\alpha = 1$. *Then* (1.1)-(1.5) *has a unique global solution* $(v(x, t), \theta(x, t))$ *which behaves asymptotically as*

$$\lim_{t\to\infty} v_x(x, t) = \frac{V}{\sqrt{2}}\theta^*(x),$$

$$\lim_{t\to\infty} t^{-1/2}\theta(x, t) = \theta^*(x),$$

where θ^* *is a positive function that depends on the initial data. In addition*

$$\sigma(x, t) = \frac{V}{\sqrt{2t}}[1 + O(t^{-1})] \quad \text{as } t\to\infty$$

for every $x \in [0, 1]$.

Remark. In view of the compatibility condition (1.6), we can say about θ^* that

$$\int_0^1 \theta^*(x)\, dx = V\sqrt{2}.$$

For $\alpha > 1$ we will show that the situation becomes completely different. Specifically, we will prove the following result.

THEOREM C. *Suppose* $\alpha > 1$. *Then the uniform shearing flow is unstable.*

The proof is based on the study of the solutions emanating from a particular family of initial functions (v_0, θ_0). For such solutions we prove the following dichotomy: *Either* there exists a point $x_0 \in [0, 1]$ and a finite time T such that

$$\theta(x_0, t)\to\infty \quad \text{as } t\uparrow T,$$

or

$$v(x, t)\to V \quad \text{as } t\to\infty$$

on a set $[0, 1]\setminus\mathscr{E}$, where the exceptional set $\mathscr{E}$ can be made arbitrary small by a suitable choice of initial data.

To prove these results it will be more convenient to use σ instead of v as a dependent variable. By (1.3) we have, when we use (1.9),

$$v_x = \theta^\alpha\sigma, \tag{1.10}$$

and so, when we differentiate (1.1) with respect to x and use (1.2) we obtain after some rearrangement

$$\sigma_t = -\alpha\theta^{\alpha-1}\sigma^3 + \theta^{-\alpha}\sigma_{xx} \quad \text{in } Q, \tag{1.11}$$

$$\theta_t = \theta^\alpha\sigma^2 \quad \text{in } Q, \tag{1.12}$$

where $Q = (0, 1)\times\mathbf{R}^+$. The boundary conditions become in terms of σ, in view of (1.1):

$$\sigma_x(0, t) = 0, \quad \sigma_x(1, t) = 0, \quad t > 0, \tag{1.13}$$

and the initial conditions,

$$\sigma(x, 0) = \sigma_0(x), \quad \theta(x, 0) = \theta_0(x), \quad x \in [0, 1], \tag{1.14}$$

where $\sigma_0 = \theta_0^{-\alpha}v_{0x}$. The remainder of the paper will be devoted to the study of system (1.11)-(1.14) for the three ranges of the parameter α.

We note that by a simple scaling of the variables it is possible to set the velocity of the top plate V equal to unity. Specifically, if $(v(x, t), \theta(x, t))$ is a solution of (1.1)-(1.5) with μ given by (1.9), then $(\hat{v}(x, \hat{t}), \hat{\theta}(x, \hat{t}))$ is a solution of (1.1)-(1.5) with $V=1$ if we set

$$\hat{t} = V^{-2\alpha} t, \quad \hat{v}(x, \hat{t}) = \frac{1}{V} v(x, t), \quad \hat{\theta}(x, \hat{t}) = V^{-2}\theta(x, t) \tag{1.15}$$

and scale the initial data appropriately. Thus setting $V=1$ in §§ 2 and 3 involves no loss of generality. In § 4, where we construct specific initial data, it is more convenient to choose V appropriately.

2. The case $0 < \alpha < 1$. For $\alpha \in (0, 1)$ it is convenient to replace θ by a new variable

$$q = \frac{1}{1-\alpha} \theta^{1-\alpha}. \tag{2.1}$$

Then system (1.11)-(1.14) becomes

$$\sigma_t = -\frac{\alpha}{1-\alpha} \frac{\sigma^3}{q} + \{(1-\alpha)q\}^{-\alpha/(1-\alpha)} \sigma_{xx} \quad \text{in } Q, \tag{2.2}$$

$$q_t = \sigma^2 \quad \text{in } Q, \tag{2.3}$$

$$\sigma_x(0, t) = 0, \quad \sigma_x(1, t) = 0, \quad t > 0, \tag{2.4}$$

$$\sigma(x, 0) = \sigma_0(x), \quad q(x, 0) = q_0(x), \quad x \in [0, 1], \tag{2.5}$$

where $q_0 = \theta_0^{1-\alpha}/(1-\alpha)$.

Seeking solutions of (2.2)-(2.3) which are independent of x, we arrive at the following system of ordinary differential equations:

$$y' = -\frac{1+\alpha}{1-\alpha} y^2, \qquad q' = qy, \tag{2.6}$$

where primes denote differentiation with respect to t and we have set

$$y = \frac{\sigma^2}{q}. \tag{2.7}$$

This system can be solved explicitly. It yields

$$y(t) = \frac{1-\alpha}{1+\alpha} \frac{1}{t+A}, \qquad q(t) = B(t+A)^{(1-\alpha)/(1+\alpha)}, \tag{2.8}$$

where A and B are positive constants. Hence

$$\sigma(t) = \left(\frac{1-\alpha}{1+\alpha} B\right)^{1/2} (t+A)^{-\alpha/(1+\alpha)}. \tag{2.9}$$

Plainly (2.8)-(2.9) is a solution of (2.2)-(2.5) for suitably chosen initial values of σ and q.

The solution (2.8)-(2.9) suggests new dependent variables

$$\tilde{r}(x, t) = (t+1)^{-(1-\alpha)/(1+\alpha)} q(x, t), \tag{2.10}$$

$$\tilde{s}(x, t) = (t+1)^{\alpha/(1+\alpha)} \sigma(x, t). \tag{2.11}$$

If we rewrite (2.2)-(2.5) in these variables, define the new time

$$\tau = \log(t+1) \tag{2.12}$$

and set

$$r(x, \tau) = \tilde{r}(x, t), \qquad s(x, \tau) = \tilde{s}(x, t),$$

we obtain the following system of parabolic equations:

$$\begin{aligned} r_\tau &= -r\left(\frac{1-\alpha}{1+\alpha} - \frac{s^2}{r}\right) \quad \text{in } Q, \\ s_\tau &= +\frac{\alpha}{1-\alpha}\, s\left(\frac{1-\alpha}{1+\alpha} - \frac{s^2}{r}\right) + \{(1-\alpha)r\}^{-\alpha/(1-\alpha)}\, e^{\mu\tau} s_{xx} \quad \text{in } Q, \end{aligned} \tag{2.13a}$$

together with the initial and boundary conditions

$$\begin{aligned} &s_x(0, t) = 0, \qquad s_x(1, t) = 0, \qquad t > 0 \\ &r(x, 0) = r_0(x), \qquad s(x, 0) = s_0(x), \qquad x \in [0, 1], \end{aligned} \tag{2.13b}$$

where $\mu = 1/(1+\alpha)$ and r_0 and s_0 are positive functions on $[0, 1]$. If $r_0, s_0 \in W^{1,2}(0, 1)$, then the local existence and the uniqueness of a classical solution on an interval $0 \leqq t \leqq T_0$, where T_0 depends only on the supremum norm of r_0 and s_0, and of $1/r_0$ and $1/s_0$, follow from a straightforward contraction argument [S]. Thus, if we obtain a priori bounds from above and below for r and s, which are uniform in time, it follows that the problem (2.13) has a solution that exists for all $t \geqq 0$.

To prove the a priori bounds, we use the notion of invariant regions. An application of Theorem 4.1 of [CCS] yields that the rectangles

$$\Sigma_{ab} = \left\{(r, s):\ a < r < b,\ \left(\frac{1-\alpha}{1+\alpha}\, a\right)^{1/2} < s < \left(\frac{1-\alpha}{1+\alpha}\, b\right)^{1/2}\right\}, \qquad 0 < a < b,$$

(see Fig. 1) are invariant regions for (2.13).

Consequently problem (2.13) admits arbitrarily large invariant rectangles. Thus, if $r_0, s_0 \in W^{1,2}(0, 1)$ and there exist positive constants r^0, r^1, s^0, and s^1 such that

$$r^0 \leqq r_0(x) \leqq r^1, \qquad s^0 \leqq s_0(x) \leqq s^1,$$

then (2.13) has a unique global solution $(r(x, t), s(x, \tau))$. If in addition we assume that the constants r^k, s^k $(k = 0, 1)$ are related through the expression

$$(s^k)^2 = (1-\alpha) r^k / (1+\alpha),$$

which involves no loss of generality, then

$$\begin{aligned} &r^0 \leqq r(x, \tau) \leqq r^1, \\ &s^0 \leqq s(x, \tau) \leqq s^1 \end{aligned} \qquad \text{in } Q. \tag{2.14}$$

Thus we have proved the following theorem.

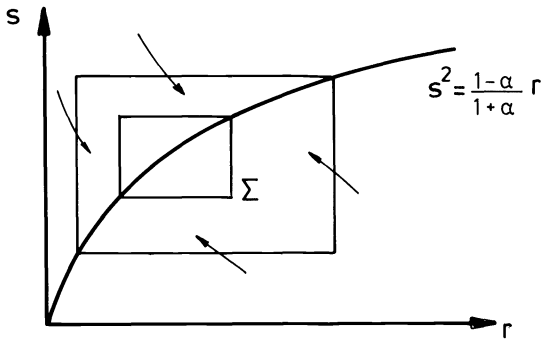

FIG. 1. *Invariant regions.*

THEOREM 2.1. *Problem* (1.11)-(1.14) *with initial data* $\theta_0, \sigma_0 \in W^{1,2}(0,1)$ *such that*

$$0 < \sigma^0 \leqq \sigma_0(x) \leqq \sigma^1, \qquad 0 \leq \theta^0 \leqq \theta_0(x) \leqq \theta^1$$

has a unique classical solution on $\bar{Q}$. *In addition*

$$\sigma^0(t+1)^{-\alpha/(1+\alpha)} \leqq \sigma(x,t) \leqq \sigma^1(t+1)^{-\alpha/(1+\alpha)} \quad \text{in } \bar{Q},$$

$$\theta^0(t+1)^{1/(1+\alpha)} \leqq \theta(x,t) \leqq \theta^1(t+1)^{1/(1+\alpha)} \quad \text{in } \bar{Q},$$

when the constants $\sigma^k, \theta^k (k=0,1)$ *satisfy the relation* $(\sigma^k)^2 = (\theta^k)^{1-\alpha}/(1+\alpha)$.

Having established global bounds for σ and θ in Q, we can now turn to the question of large-time behaviour. We begin with the observation that *both* σ and θ converge to their mean values $\bar{\sigma}$ and $\bar{\theta}$ defined by

$$\bar{\sigma}(t) = \int_0^1 \sigma(x,t)\,dx, \qquad \bar{\theta}(t) = \int_0^1 \theta(x,t)\,dx.$$

Defining $\bar{s}(t)$ and $\bar{r}(t)$ in a similar fashion we obtain the following estimate.

LEMMA 2.2. *We have*

(a) $$\|s(\cdot,\tau) - \bar{s}(\tau)\|_\infty = O(e^{-\mu r}) \quad \text{as } \tau \to \infty,$$

(b) $$\|r(\cdot,\tau) - \bar{r}(\tau)\|_\infty = O(e^{-\gamma\tau}) \quad \text{as } \tau \to \infty,$$

where

$$\mu = \frac{1}{1+\alpha}, \qquad \gamma = \frac{1-\alpha}{1+\alpha}$$

and $\|\cdot\|_\infty$ *denotes the norm in* $L^\infty(0,1)$.

Proof. We multiply the equation for s by $-s_{xx}$ and integrate over $(0,1)$. This yields, when we integrate the left-hand side by parts and use the boundary conditions,

$$\frac{1}{2}\frac{d}{dt}\int_0^1 s_x^2\,dx = -e^{\mu\tau}\int_0^1 \{(1-\alpha)r\}^{-\alpha/(1-\alpha)} s_{xx}^2\,dx - \int_0^1 g(s,r)s_{xx}\,dx,$$

where

$$g(s,r) = \frac{\alpha}{1-\alpha}\, s\left(\frac{1-\alpha}{1+\alpha} - \frac{s^2}{r}\right).$$

Because $r(x,\tau)$ is bounded above by r^1 in Q, we have

$$\{(1-\alpha)r(x,\tau)\}^{-\alpha/(1-\alpha)} \geqq \{(1-\alpha)r^1\}^{-\alpha/(1-\alpha)} \stackrel{\text{def}}{=} a_0$$

and so

$$\frac{1}{2}\frac{d}{dt}\int_0^1 s_x^2\,dx \leqq -a_0\, e^{\mu\tau}\int_0^1 s_{xx}^2\,dx + \frac{\lambda}{2}\int_0^1 s_{xx}^2\,dx + \frac{1}{2\lambda}\int_0^1 g^2\,dx, \tag{2.15}$$

where λ is a positive number, which may depend on τ. If we choose $\lambda = a_0\, e^{\mu\tau}$, (2.15) becomes

$$\frac{1}{2}\frac{d}{dt}\int_0^1 s_x^2\,dx \leqq -\frac{1}{2}\,a_0\, e^{\mu\tau}\int_0^1 s_{xx}^2\,dx + \frac{1}{2a_0}\,e^{-\mu\tau}\int_0^1 g^2\,dx. \tag{2.16}$$

Finally, we observe that in view of the boundary conditions $s_x \in H_0^1(0,1)$, and we can use Poincaré's inequality to estimate the first term on the right of (2.16). This yields in the end

$$\frac{d}{dt}\int_0^1 s_x^2\,dx \leqq -A\, e^{\mu\tau}\int_0^1 s_x^2\,dx + B\, e^{-\mu\tau}, \tag{2.17}$$

where A and B are positive constants, because g is uniformly bounded in Q by (2.14). An elementary computation now reveals that (2.17) implies that

$$\int_0^1 s_x^2(x, \tau)\, dx \leqq C e^{-2\mu\tau}, \qquad \tau \geqq 0, \tag{2.18}$$

where C is some positive constant.

To complete the proof of part (a), we note that for some $\hat{x}(\tau) \in [0, 1]$ we have $s(\hat{x}(\tau), \tau) = \bar{s}(\tau)$. Hence

$$s(x, \tau) - \bar{s}(\tau) = \int_{\hat{x}(\tau)}^{x} s_x(\xi, \tau)\, d\xi$$

and so

$$|s(x, \tau) - \bar{s}(\tau)| \leqq \int_0^1 |s_x(\xi, \tau)|\, d\xi \leqq \left(\int_0^1 s_x^2(\xi, \tau)\, d\xi \right)^{1/2}. \tag{2.19}$$

Substituting (2.18) into (2.19), we arrive at the desired bound.

To prove part (b), we solve the equation for r in terms of s. This is possible since the equation is linear in r:

$$r_\tau = -\gamma r + s^2.$$

We obtain

$$r(x, \tau) = e^{-\gamma\tau} r(x, 0) + e^{-\gamma\tau} \int_0^\tau e^{\gamma p} s^2(x, p)\, dp.$$

However, by part (a) and the uniform lower bound for s,

$$s^2(x, \tau) = \bar{s}^2(\tau) + \varepsilon(x, \tau),$$

where

$$\|\varepsilon(\cdot, \tau)\|_\infty \leqq e^{-\mu\tau}.$$

Hence

$$r(x, \tau) = e^{-\gamma\tau} r(x, 0) + e^{-\gamma\tau} \int_0^\tau e^{\gamma p} \bar{s}^2(p)\, dp + \rho(x, \tau), \tag{2.20}$$

where

$$\|\rho(\cdot, \tau)\|_\infty \leqq C e^{-\mu\tau}.$$

If we integrate (2.20) over $(0, 1)$, we obtain

$$\bar{r}(\tau) = e^{-\gamma\tau} \bar{r}(0) + e^{-\gamma\tau} \int_0^\tau e^{\gamma p} \bar{s}^2(p)\, dp + \int_0^1 \rho(x, \tau)\, dx, \tag{2.21}$$

whence

$$r(x, \tau) - \bar{r}(\tau) = e^{-\gamma\tau} \{ r(x, 0) - \bar{r}(0) \} - \int_0^1 \rho(x, \tau)\, dx,$$

i.e.,

$$\|r(\cdot, \tau) - \bar{r}(\tau)\|_\infty \leqq C e^{-\gamma\tau},$$

because $\gamma < \mu$.

Remark. Equation (2.21) yields a relation between $\bar{r}$ and $\bar{s}$. In view of the estimate for $\rho(\cdot, \tau)$ we can write it as

$$\bar{r}(\tau) = e^{-\gamma\tau} \int_0^\tau e^{\gamma p} \bar{s}^2(p)\, dp + O(e^{-\gamma\tau}). \tag{2.22}$$

Another relation between $\bar{r}$ and $\bar{s}$ is supplied by the compatibility relation (1.6) in which we have set $V = 1$. This yields after transformation

$$\int_0^1 s(x, \tau)\{r(x, \tau)\}^{\alpha/(1-\alpha)}\, dx = (1-\alpha)^{-\alpha/(1-\alpha)}. \tag{2.23}$$

Applying Lemma 2.2, we deduce from (2.23) that

$$\bar{s}(\tau)\{\bar{r}(\tau)\}^{\alpha/(1-\alpha)} = (1-\alpha)^{-\alpha/(1-\alpha)} + O(e^{-\gamma\tau}). \tag{2.24}$$

It now remains to determine the asymptotic behaviour of $\bar{r}(\tau)$ and $\bar{s}(\tau)$ as $\tau \to \infty$. This is done by means of the equation for $r(x, \tau)$. It yields, upon integration over $(0, 1)$,

$$\bar{r}' = -\gamma\bar{r} + \int_0^1 s^2\, dx = -\gamma\bar{r} + \bar{s}^2(\tau) + \omega(\tau),$$

where the prime denotes differentiation with respect to τ and $\omega(\tau) = O(e^{-\mu\tau})$ as $\tau \to \infty$. Eliminating $\bar{s}$ by means of (2.24) we finally obtain the equation

$$\bar{r}' = g(\bar{r}) + \tilde{\omega}(\tau), \tag{2.25}$$

where

$$g(\xi) = -\gamma\xi + \{(1-\alpha)\xi\}^{-2\alpha/(1-\alpha)}, \qquad \xi > 0$$

and $\tilde{\omega}(\tau) = O(e^{-\gamma\tau})$ as $\tau \to \infty$. Plainly, g has a unique zero ξ_0 given by

$$\xi_0 = \frac{1}{1-\alpha}(1+\alpha)^{(1-\alpha)/(1+\alpha)},$$

$$g(\xi) \begin{cases} > 0 & \text{if } 0 < \xi < \xi_0, \\ < 0 & \text{if } \xi_0 < \xi < \infty. \end{cases}$$

Thus

$$\bar{r}(\tau) \to \xi_0 \quad \text{as } \tau \to \infty$$

and, because $g'(\xi_0) < -\gamma$,

$$\bar{r}(\tau) = \xi_0 + O(e^{-\gamma\tau}) \quad \text{as } \tau \to \infty.$$

The limiting behaviour of $\bar{s}(\tau)$ now follows from (2.24):

$$\bar{s}(\tau) = \eta_0 + O(e^{-\gamma\tau}) \quad \text{as } \tau \to \infty,$$

where

$$\eta_0 = \{(1-\alpha)\xi_0\}^{-\alpha/(1-\alpha)} = (1+\alpha)^{-\alpha/(1-\alpha)}.$$

In summary, we have proved the following theorem.

THEOREM 2.3. *Let the initial data σ_0 and θ_0 satisfy the conditions of Theorem* 2.1 *and let $V = 1$. Then the asymptotic behaviour of the solution (σ, θ) of problem* (1.15)–(1.18) *is given by*

$$\sigma(x, t) = \{(1+\alpha)t\}^{-\alpha/(1+\alpha)}[1 + O(t^{-1/(1+\alpha)})] \qquad \text{as } t \to \infty,$$

$$\theta(x, t) = \{(1+\alpha)t\}^{1/(1+\alpha)}[1 + O(t^{-(1-\alpha)/(1+\alpha)})] \qquad \text{as } t \to \infty,$$

and v_x satisfies

$$v_x(x, t) = 1 + O(t^{-(1-\alpha)/(1+\alpha)}) \quad \text{as } t \to \infty.$$

The error terms are all uniform with respect to $x \in [0, 1]$.

Remark. It is readily seen from the solution (y, q) of the system of ordinary differential equations (2.6) that the powers in the error terms in Theorem 2.3 are optimal.

3. The case $\alpha = 1$. When $\alpha = 1$, Problem (1.11)-(1.14) becomes

$$\sigma_t = -\sigma^3 + \theta^{-1}\sigma_{xx} \quad \text{in } Q, \tag{3.1}$$

$$\theta_t = \theta\sigma^2 \quad \text{in } Q \tag{3.2}$$

with

$$\sigma_x(0, t) = 0, \qquad \sigma_x(1, t) = 0, \qquad t > 0, \tag{3.3}$$

$$\sigma(x, 0) = \sigma_0(x), \qquad \theta(x, 0) = \theta_0(x), \qquad x \in [0, 1]. \tag{3.4}$$

As in § 2, we rescale the variables, writing

$$\tilde{r}(x, t) = (t+1)^{-1/2}\theta(x, t), \qquad \tilde{s}(x, t) = (t+1)^{1/2}\sigma(x, t).$$

If in addition we introduce again the new time variable $\tau = \log(t+1)$, we obtain for

$$r(x, \tau) = \tilde{r}(x, t) \quad \text{and} \quad s(x, \tau) = \tilde{s}(x, t)$$

the system of equations

$$s_\tau = -s\left(s^2 - \frac{1}{2}\right) + \frac{1}{r}e^{\tau/2}s_{xx}, \tag{3.5}$$

$$r_\tau = r\left(s^2 - \frac{1}{2}\right) \tag{3.6}$$

with boundary conditions

$$s_x(0, t) = 0, \quad s_x(1, t) = 0, \quad t > 0 \tag{3.7}$$

and initial conditions

$$s(x, 0) = \sigma_0(x), \quad r(x, 0) = \theta_0(x), \quad x \in [0, 1]. \tag{3.8}$$

Observe that because

$$v_x = rs,$$

the boundary conditions (1.4), with $V = 1$, yield the identity

$$\int_0^1 r(x, t)s(x, t)\, dx = 1. \tag{3.9}$$

To prove the a priori bounds on r and s, we no longer can use the method of invariant regions. However, since the lower-order terms in (3.5) for s now do not depend on r, we can still use a maximum principle argument to obtain the desired bounds. As before, we consider the pair of ordinary differential equations obtained from (3.5)-(3.6) by omitting the diffusion term:

$$y' = -y(y^2 - \tfrac{1}{2}), \tag{3.10}$$

$$z' = z(y^2 - \tfrac{1}{2}). \tag{3.11}$$

Here primes denote differentiation with respect to τ. Let $y(\tau; a)$ be the solution of (3.10) with initial value $y(0; a) = a$ and let $z(\tau; a, b)$ be the solution of (3.11) with $y = y(\tau; a)$ and initial value $z(0; a, b) = b$. For any $a \in \mathbf{R}$ the solution $y(\tau; a)$ exists, is unique and bounded for all $\tau \geqq 0$. It can actually be found explicitly and for any $a > 0$ its large-time behaviour is given by

$$y(\tau; a) = \frac{1}{\sqrt{2}} + O(e^{-\tau}) \quad \text{as } \tau \to \infty. \tag{3.12}$$

Because z satisfies a linear equation with bounded coefficients, $z(\tau; a, b)$ also exists for all time.

By uniqueness we have

$$a_1 < a_2 \Rightarrow y(\tau; a_1) < y(\tau; a_2) \quad \text{for } \tau \geqq 0 \tag{3.13}$$

and because the right-hand side of (3.11) is increasing in y when $y > 0$, we also have

$$\begin{aligned} &a_1 < a_2, \qquad b_1 < b_2 \\ &\Rightarrow z(\tau; a_1, b_1) < z(\tau; a_2, b_2) \quad \text{for } \tau \geqq 0. \end{aligned} \tag{3.14}$$

Set $a_1 = \min \sigma_0$ and $a_2 = \max \sigma_0$. Then by the maximum principle

$$y(\tau; a_1) \leqq s(x, \tau) \leqq y(\tau; a_2) \quad \text{in } \bar{Q},$$

and so, by (3.12),

$$s(x, \tau) = \frac{1}{\sqrt{2}} + O(e^{-\tau}) \quad \text{as } \tau \to \infty, \tag{3.15}$$

uniformly in $[0, 1]$.

To estimate r we set $b_1 = \min \theta_0$ and $b_2 = \max \theta_0$, leaving a_1 and a_2 unchanged. Then for any $x \in [0, 1]$ we have $\theta_0 \in [b_1, b_2]$ and hence

$$z(\tau; a_1, b_1) \leqq r(x, \tau) \leqq z(\tau; a_2, b_2) \quad \text{in } \bar{Q}.$$

Note that (3.10) and (3.11) imply that

$$\frac{z'}{z} = -\frac{y'}{y}.$$

Therefore

$$z(\tau; a, b) = \frac{ab}{y(\tau; a)}$$

and hence

$$z(\tau; a, b) = \sqrt{2}\, ab + O(e^{-\tau}) \quad \text{as } \tau \to \infty.$$

Thus we have established the existence of a global solution (r, s) of (3.5)-(3.8) as well as uniform bounds in $\bar{Q}$.

Reformulating this result in terms of the solution (σ, θ) of (3.1)-(3.4) we obtain the following theorem.

THEOREM 3.1. *Problem* (3.1)-(3.4), *with initial data* $\sigma_0, \theta_0 \in W^{1,2}(0, 1)$ *that are positive in* $[0, 1]$, *has a unique solution* $(\sigma(x, t), \theta(x, t))$ *on* $\bar{Q}$. *In addition there exist positive constants* $A^{\pm}$, $B^{\pm}$ *such that*

$$A^-(t+1)^{-1/2} \leqq \sigma(x, t) \leqq A^+(t+1)^{-1/2} \quad \text{in } \bar{Q},$$

$$B^-(t+1)^{1/2} \leqq \theta(x, t) \leqq B^+(t+1)^{1/2} \quad \text{in } \bar{Q}.$$

For the asymptotic behaviour of solutions of (3.1)-(3.4) we have only a partial answer.

THEOREM 3.2. *Let* $(\sigma(x, t), \theta(x, t))$ *be the solution of* (3.1)-(3.4). *Then*

(a) $$\sigma(x, t) = \frac{1}{\sqrt{2t}}[1 + O(t^{-1})] \quad \text{as } t \to \infty,$$

(b) $$\theta(x, t) = \theta^*(x)\sqrt{t}[1 + o(1)] \quad \text{as } t \to \infty,$$

uniformly with respect to $x \in [0, 1]$, *where* θ^* *is a positive function that depends on the initial data.*

Proof. Part (a) is an immediate consequence of (3.12).

To prove part (b), we observe that

$$\frac{d}{d\tau}\{\log r(x, \tau)\} = s^2(x, \tau) - \frac{1}{2} = \nu(x, \tau) \tag{3.16}$$

and recall that $\nu(x, \tau) = O(e^{-\tau})$ as $\tau \to \infty$ uniformly in x. Integration of (3.16) over $(0, \tau)$ yields

$$r(x, \tau) = r(x, 0) \exp\left(\int_0^\tau \nu(x, s)\, ds\right), \tag{3.17}$$

and hence, because $\nu(x, \cdot) \in L^1(0, \infty)$ for every $x \in [0, 1]$,

$$\lim_{\tau \to \infty} r(x, \tau) \text{ exists.}$$

Returning to θ gives the second limit.

Theorem 3.2, (1.3), and (1.8) yield the following corollary.

COROLLARY 3.3. *Let* $(\sigma(x, t), \theta(x, t))$ *be the solution of* (3.1)-(3.4). *Then*

$$\lim_{t \to \infty} v_x(x, t) = \frac{1}{\sqrt{2}}\theta^*(x), \qquad 0 \leqq x \leqq 1.$$

This completes the proof of Theorem B.

Remarks. 1. If s_0 does not depend on x, then neither do $s(x, t)$ nor, by (3.16), do $\nu(x, t)$ depend on x. Hence we deduce from (3.17) that in that case θ^* is a constant if and only if θ_0 is a constant. This example shows that in general we cannot expect convergence to the uniform shearing flow if $\alpha = 1$.

2. Because $\theta^*(x) > 0$ for every $x \in [0, 1]$ it follows from Theorem 3.2 that, as when $0 < \alpha < 1$, $\theta(x, t) \to \infty$ as $t \to \infty$ for every $x \in [0, 1]$. As we will see in the next section, this will cease to be true when α becomes greater than 1.

4. The case $\alpha > 1$. In this section we shall study a particular family of solutions of the problem defined by (1.11)-(1.14).

As in the case $0 < \alpha < 1$, we introduce the function

$$q = \frac{1}{\alpha - 1}\theta^{1-\alpha}$$

and use q to rewrite system (1.11)-(1.14) as

$$\sigma_t = -\frac{\alpha}{\alpha - 1}\frac{\sigma^3}{q} + \{(\alpha - 1)q\}^{\alpha/(\alpha-1)}\sigma_{xx} \quad \text{in } Q, \tag{4.1}$$

$$q_t = -\sigma^2 \quad \text{in } Q \tag{4.2}$$

with boundary and initial conditions

$$\sigma_x(0, t) = 0, \quad \sigma_x(1, t) = 0, \quad t > 0, \tag{4.3}$$

$$\sigma(x, 0) = \sigma_0(x), \quad q(x, 0) = q_0(x), \quad x \in [0, 1], \tag{4.4}$$

where $\sigma_0 = \theta_0^{-\alpha} v_{0x}$. For positive initial values σ_0, $\theta_0 \in W^{1,2}(0, 1)$ the local existence and uniqueness of a solution (σ, θ) of (4.1)-(4.4) are readily established.

Let $0 < c < 1$ be a constant to be determined appropriately and $0 < \gamma < 1$ a parameter. Define

$$\beta = \frac{\alpha}{\alpha - 1} \quad \text{and} \quad \delta = c^{\beta}\gamma.$$

We define the following family of initial functions:

$$\sigma_0(x) = (\alpha - 1)^{\beta/2} \quad \text{for } 0 \leqq x \leqq 1, \tag{4.5}$$

$$q_{0,\gamma}(x) = \begin{cases} c & \text{for } x \in [0, \delta], \\ 1 & \text{for } x \in (\delta, 1]. \end{cases} \tag{4.6}$$

For what follows it will be convenient to introduce the integral

$$I_\gamma \overset{\text{def}}{=} \int_0^1 \sigma_0^2(x)\{(\alpha - 1)q_{0,\gamma}(x)\}^{-\beta}\, dx. \tag{4.7}$$

Note that

$$I_\gamma = (1 - c^{\beta})\gamma + 1 \quad \text{and} \quad V_\gamma = (\alpha - 1)^{-\beta/2} I_\gamma$$

and that

$$I_\gamma \to 1 \quad \text{and} \quad V_\gamma \to V_0 \overset{\text{def}}{=} (\alpha - 1)^{-\beta/2} \quad \text{as } \gamma \to 0.$$

In terms of the original variables v and θ the initial data are now given by

$$v_{0\gamma}(x) = \int_0^x \{(\alpha - 1)q_{0,\gamma}(s)\}^{-\beta}\sigma_0(s)\, ds, \qquad x \in [0, 1],$$

$$\theta_{0,\gamma}(x) = \{(\alpha - 1)q_{0,\gamma}(x)\}^{-1/(\alpha-1)}, \qquad x \in [0, 1].$$

It is readily verified that

$$v_{0,\gamma}(x) \to V_0 x \quad \text{in } L^2(0, 1) \quad \text{as } \gamma \to 0,$$

$$\theta_{0,\gamma}(x) \to (\alpha - 1)^{-1/(\alpha-1)} \quad \text{in } L^2(0, 1) \quad \text{as } \gamma \to 0.$$

The idea underlying this choice of initial functions is based on the observation that if we set q small compared to σ in the neighbourhood of $x = 0$, it will soon reach zero, according to (4.2), unless σ drops sufficiently fast. However, diffusion of σ towards the origin may prevent this from happening and thus cause q to remain positive for all time. Which of these two possibilities will occur is still an open question.

In this section we will use the family of solutions introduced above to show that the uniform shear flow $(\hat{v}, \hat{\theta}(t))$ is unstable. By this we mean that there exists a $\rho > 0$ such that for any $\varepsilon > 0$ there exist initial functions $(v_{0,\gamma}, \theta_{0,\gamma})$ from the family introduced above such that if

$$\|v_{0,\gamma} - \hat{v}\|_{L^2} + \|\theta_{0,\gamma} - \hat{\theta}(0)\|_{L^2} + |V_\gamma - V_0| < \varepsilon,$$

then there exists a finite time T_ε such that *either* the solution ceases to exist at $t = T_\varepsilon$, *or*

$$\|v_\gamma(t) - \hat{v}\|_{L^2} + (1+t)^{-1/(\alpha+1)} \|\theta_\gamma(t) - \hat{\theta}(t)\|_{L^2} + |V_\gamma - V_0| > \rho \quad \text{for } t = T_\varepsilon.$$

More precisely, we will prove the following theorem.

THEOREM 4.1. *Let* $\alpha > 1$ *and let for some* $b \in (0, 1)$,

$$c = \frac{b(1-b)}{8(1+b)}.$$

Let $v_{0,\gamma}$, $\theta_{0,\gamma}$ *and* V_γ *be defined as before and let* $(v_\gamma(x, t), \theta_\gamma(x, t))$ *be the corresponding solution of* (1.1)-(1.4), (1.9) *on a maximal interval* $[0, T_\gamma)$, *where* $0 < T_\gamma \leqq \infty$. *If*

$$0 < \gamma < \frac{4c}{b} \quad \text{and} \quad T_\gamma = \infty,$$

then

(a) $$|v_\gamma(x, t) - V_\gamma| = O(t^{-1/2}) \quad \text{as } t \to \infty$$

uniformly on $(\delta, 1]$;

(b) $\theta(x, t)$ *is uniformly bounded on* $(\delta, 1] \times [0, \infty)$.

Using the definition of $v_{0,\gamma}$, $\theta_{0,\gamma}$ and V_γ, we can readily check that the uniform shear flow $(\hat{v}, \hat{\theta}(t))$ corresponding to the initial and boundary conditions $v_0(x) = V_0 x$ and $\theta_0 = (\alpha - 1)^{-1/(\alpha-1)}$ is unstable in the sense formulated above. In particular, Theorem C follows from Theorem 4.1.

The proof of Theorem 4.1 is based on estimates for the solution pair (σ, q) (from now on we shall omit the subscript γ). We begin with an upper bound for q.

LEMMA 4.2. *Let* (σ, θ) *be the solution of* (4.1)-(4.4). *Then for* $0 \leqq \xi < \eta \leqq 1$ *and* $b > 0$ *we have*

$$q(\xi, t) \leqq q(\xi, 0) - \frac{b}{1+b} \int_0^t \sigma^2(\eta, \tau)\, d\tau + b \int_0^t \int_0^1 \sigma_x^2(x, \tau)\, dx\, d\tau. \tag{4.8}$$

Proof. Integration of σ_x over (ξ, η) yields

$$\sigma(\eta, t) - \sigma(\xi, t) = \int_\xi^\eta \sigma_x(x, t)\, dx \leqq \left(\int_0^1 \sigma_x^2(x, t)\, dx \right)^{1/2}$$

or

$$\sigma(\xi, t) \geqq \sigma(\eta, t) - \left(\int_0^1 \sigma_x^2(x, t)\, dx \right)^{1/2}. \tag{4.9}$$

Hence, for small t, when in view of the initial data the right-hand side of (4.9) is nonnegative,

$$\begin{aligned} \sigma^2(\xi, t) &\geqq \sigma^2(\eta, t) \left\{ 1 - \frac{1}{\sigma(\eta, t)} \left(\int_0^1 \sigma_x^2(x, t)\, dx \right)^{1/2} \right\}^2 \\ &\geqq \frac{b}{1+b} \sigma^2(\eta, t) - b \int_0^1 \sigma_x^2(x, t)\, dx, \end{aligned} \tag{4.10}$$

where we have used the inequality

$$(1-x)^2 \geqq \frac{b}{1+b} - bx^2, \qquad 0 \leqq x \leqq 1, \quad b > 0. \tag{4.11}$$

Note that if the right-hand side of (4.9) is negative, the right-hand side of (4.10) is also negative, and hence (4.10) is still satisfied.

Integration of (4.2) finally yields, together with (4.10),

$$q(\xi, t) = q(\xi, 0) - \int_0^t \sigma^2(\xi, \tau)\, d\tau$$

$$\leqq q(\xi, 0) - \frac{b}{1+b} \int_0^t \sigma^2(\eta, \tau)\, d\tau + b \int_0^t \int_0^1 \sigma_x^2(x, \tau)\, dx\, d\tau,$$

which we set out to prove.

In the next lemma we show that the diffusion term in (4.8) is uniformly bounded with respect to γ for bounded γ.

LEMMA 4.3. *Let* (σ, q) *be the solution of* (4.1), (4.2) *with initial data* (σ_0, q_0) *given by* (4.5) *and* (4.6). *Then*

$$\int_0^t \int_0^1 \sigma_x^2(x, \tau)\, dx\, d\tau < \frac{1}{2} I_\gamma. \tag{4.12}$$

Proof. Because of boundary condition (4.3), we have

$$\begin{aligned} \int_0^1 \sigma_x^2(x, t)\, dx &= -\int_0^1 \sigma(x, t)\sigma_{xx}(x, t)\, dx \\ &= -\int_0^t \sigma\{(\alpha-1)q\}^{-\beta}\left(\sigma_t + \beta\frac{\sigma^3}{q}\right) dx \qquad (4.13) \\ &= -\int_0^1 \sigma\sigma_t\{(\alpha-1)q\}^{-\beta}\, dx - \alpha\int_0^1 \sigma^4\{(\alpha-1)q\}^{-\beta-1}\, dx. \end{aligned}$$

We now integrate (4.13) over $(0, t)$. Because

$$\begin{aligned} \int_0^t \int_0^1 \sigma\sigma_t\{(\alpha-1)q\}^{-\beta}\, dx\, d\tau &= \frac{1}{2}\int_0^1 \sigma^2\{(\alpha-1)q\}^{-\beta}\, dx \\ &\quad -\frac{1}{2}\int_0^1 \sigma_0^2\{(\alpha-1)q_0\}^{-\beta}\, dx \qquad (4.14) \\ &\quad -\frac{1}{2}\alpha\int_0^t \int_0^1 \sigma^4\{(\alpha-1)q\}^{-\beta-1}\, dx\, d\tau, \end{aligned}$$

this yields in the end

$$\int_0^t \int_0^1 \sigma_x^2(x, \tau)\, dx\, d\tau \leqq \frac{1}{2}\int_0^1 \sigma_0^2\{(\alpha-1)q_0\}^{-\beta}\, dx,$$

and the lemma follows from (4.7).

Observe that by (4.2)

$$\int_0^t \sigma^2(x, \tau)\, d\tau = 1 - q(x, t), \qquad \delta < x \leqq 1.$$

Hence, putting the results of Lemmas 4.2 and 4.3 together, and remembering that

$q(\xi, 0) = c$ if $\xi \leqq \delta$, we obtain the upper bound

$$
\begin{aligned}
q(\xi, t) &\leqq c - \frac{b}{1+b}\{1 - q(\eta, t)\} + \frac{b}{2} I_\gamma \\
&\leqq c - \frac{b}{1+b}\{1 - q(\eta, t)\} + \frac{b}{2}(1+\gamma) \qquad (4.15) \\
&= c - \frac{b}{2(1+b)}\{1 - b - \gamma(1+b) - 2q(\eta, t)\}
\end{aligned}
$$

for $0 \leqq \xi < \delta$ and $\xi < \eta \leqq 1$. We now choose

$$
0 < b < 1, \quad c = \frac{b(1-b)}{8(1+b)}, \quad \gamma = \frac{4c}{b}
$$

for $0 \leqq \xi < \delta$ and $\xi < \eta \leqq 1$. Then (4.15) becomes

$$
q(\xi, t) \leqq \frac{b}{1+b}\left\{ q(\eta, t) - \frac{1}{8}(1-b) \right\}.
$$

We distinguish two cases.

Case I. There exists a point $\eta_1 \in (\delta, 1]$ and a time $T_1 > 0$ such that

$$
q(\eta_1, T_1) < \frac{1-b}{8}.
$$

This means that $q(\xi, t)$ must have vanished at some time $t = T_0 < T_1$.

Case II. We have

$$
q(x, t) \geqq \frac{1-b}{8} \quad \text{for all } \delta < x \leqq 1, \quad t \geqq 0.
$$

In the first case, the solution ceases to exist at $t = T_0$, or possibly even before.

To prove Theorem 4.1, we may assume that the solution exists for all time and we are necessarily in the second case. In view of the definition of q this means that

$$
\theta(x, t) \leqq \{\tfrac{1}{8}(1-b)(\alpha-1)\}^{-1/(\alpha-1)} \quad \text{for } \delta < x \leqq 1, \quad t \geqq 0 \qquad (4.16)
$$

and so, according to (1.3) and (1.9),

$$
0 \leqq v_x(x, t) \leqq K\sigma(x, t), \qquad \delta < x \leqq 1, \quad t \geqq 0 \qquad (4.17)
$$

for some positive constant K.

It now remains to show that $\sigma(x, t) \to 0$ as $t \to 0$. From the differential equation (4.2) for q, we see that q is decreasing in t. Therefore $q(x, t) < q(x, 0) \leqq 1$. This means that the function $\bar{\sigma}(x, t) = y(t)$ defined as the solution of the initial value problem

$$
\begin{aligned}
y' &= -\beta y^3, \qquad t > 0, \\
y(0) &= (\alpha - 1)^{\beta/2}
\end{aligned}
$$

is a supersolution of (4.1), (4.3), and (4.4). Hence

$$
0 < \sigma(x, t) \leqq (c_0 + 2\beta t)^{-1/2}, \qquad 0 \leqq x \leqq 1, \quad t \geqq 0,
$$

where $c_0 = (\alpha - 1)^{-\beta}$, and thus by (4.17),

$$
|v_x(x, t)| \leqq K(c_0 + 2\beta t)^{-1/2}, \qquad \delta < x \leqq 1, \quad t \geqq 0.
$$

Therefore

$$
|v(x, t) - V| = O(t^{-1/2}) \quad \text{as } t \to \infty
$$

uniformly on $(\delta, 1]$. Since θ is uniformly bounded on $(\delta, 1]$ by (4.16), the proof of Theorem 4.1 is complete.

Remark. The initial function $q_{0,\gamma}$ defined by (4.6) does not belong to $W^{1,2}(0, 1)$ as has been assumed throughout this paper. This assumption was made for computational reasons. However, if for some $\gamma > 0$, $q_{0,\gamma}$ is an initial value for which the solution blows up in finite time, so is any function $\tilde{q}$ with the properties (i) $\tilde{q} = c$ for $0 \leqq x \leqq \delta$; (ii) $c \leqq \tilde{q}(x) \leqq 1$; and (iii) $\|\tilde{q} - q_{0,\gamma}\|_{L^2}$ sufficiently small.

THE NONCONVEX MULTI-DIMENSIONAL RIEMANN PROBLEM FOR HAMILTON–JACOBI EQUATIONS*

MARTINO BARDI† AND STANLEY OSHER‡

Abstract. Simple inequalities are presented for the viscosity solution of a Hamilton–Jacobi equation in N space dimension when neither the initial data nor the Hamiltonian need be convex (or concave). The initial data are uniformly Lipschitz and can be written as the sum of a convex function in a group of variables and a concave function in the remaining variables, therefore including the nonconvex Riemann problem. The inequalities become equalities wherever a "maxmin" equals a "minmax" and thus a representation formula for this problem is then obtained, generalizing the classical Hopf's formulas.

Key words. Hamilton–Jacobi equations, viscosity solutions, Riemann problem, Godunov's scheme, Hopf's representation formulas

AMS(MOS) subject classifications. 35L99, 35L65, 65M15, 65M10

1. Introduction.

We are concerned with viscosity solutions (see Crandall and Lions [3], Crandall, Evans, and Lions [2], Lions [12]) to the following partial differential equation:

$$\varphi_t + H(D_x\varphi) = 0 \quad \text{in } \mathbb{R}^N \times (0, \infty), \tag{H-J}$$

satisfying the initial data

$$\varphi(x, 0) = \varphi_0(x) \quad \text{in } \mathbb{R}^N, \tag{IC}$$

where $H \in C(\mathbb{R}^N)$, $D_x\varphi = (\varphi_{x_1}, \cdots, \varphi_{x_N})$ is the spatial gradient of φ, and φ_0 is at least uniformly continuous. This Cauchy problem has, for any $T > 0$, a unique viscosity solution $\varphi(x, t)$ in the space $UC_x(\mathbb{R}^N \times [0, T])$ of the continuous functions which are uniformly continuous in $x \in \mathbb{R}^N$ uniformly in $t \in [0, T]$, see Ishii [10] or Crandall and Lions [5].

We are interested in giving explicit pointwise upper and lower bounds for the solution, providing in some cases a representation formula for φ, for some special initial data but without extra assumptions on the Hamiltonian H.

Some general representation formulas for viscosity solutions of Cauchy problems for Hamilton–Jacobi equations are due to Evans [6] and Evans and Souganidis [7]. However, they either involve an infinite number of max-min operations over $\mathbb{R}^N$ [6], or a single max-min operation over infinite-dimensional sets of "controls" and "strategies" [7]. Two simpler formulas solving almost everywhere (H-J)(IC), one dual of the other, were derived by Hopf [9] for two special cases. The first one holds for convex Hamiltonians and general (Lipschitz) initial data, and it is well known in the theory of conservation laws in the case $N = 1$ (it is often called the Lax formula). It was shown to give the viscosity solution to the problem by Lions [12], Evans [6], Bardi and Evans [1], with different proofs and slightly different assumptions. The second

Hopf's formula is valid for general Hamiltonians and convex or concave (Lipschitz) initial data φ_0, and it is

$$\varphi(x,t)=\sup_{v\in\mathbb{R}^N}\{x\cdot v-\varphi_0^*(v)-tH(v)\} \tag{1.1}$$

for φ_0 convex, and

$$\varphi(x,t)=\inf_{v\in\mathbb{R}^N}\{x\cdot v-\varphi_0^*(-v)-tH(v)\} \tag{1.2}$$

for φ_0 concave, where φ_0^* is the Legendre transform (or Fenchel conjugate) of φ_0, that is

$$\varphi_0^*(v):=\sup_{x\in\mathbb{R}^N}\{x\cdot v-\varphi_0(x)\}\leqq+\infty$$

for φ_0 convex, while for φ_0 concave it is

$$\varphi_0^*(v):=-(-\varphi_0)^*(v)=\inf_{x\in\mathbb{R}^N}\{-x\cdot v-\varphi_0(x)\}\geqq-\infty.$$

Osher [14] rederived for the viscosity solution of (H-J) the special case of formula (1.1) occurring when the initial data are of Riemann type (and convex), i.e., they are piecewise affine with one jump in the derivative across a plane. Bardi and Evans [1] showed the connection between Osher's formulas for convex Riemann data and Hopf's formulas, and proved that (1.1) and (1.2) give the viscosity solution of (H-J)(IC) in the general case. Lions and Rochet [13] gave a different proof under slightly more general assumptions.

We are now going to describe our main result. Let j be an integer, $0\leqq j\leqq N$, and for any $v\in\mathbb{R}^N$ set

$$v=(v_A,v_B),\quad v_A:=(v_1,\cdots,v_j)\in\mathbb{R}^j,\quad v_B:=(v_{j+1},\cdots,v_N)\in\mathbb{R}^{N-j}.$$

THEOREM 1. *Assume* $H\in C(\mathbb{R}^N)$, $\varphi_1:\mathbb{R}^j\to\mathbb{R}$ *uniformly Lipschitz and convex,* $\varphi_2:\mathbb{R}^{N-j}\to\mathbb{R}$ *uniformly Lipschitz and concave. Then the unique viscosity solution* $\varphi\in UC_x(\mathbb{R}^N\times[0,T])$ *of* (H-J) *taking on the initial data*

$$\varphi(x,0)=\varphi_1(x_A)+\varphi_2(x_B)$$

satisfies for all $x\in\mathbb{R}^N$ *and* $t\geqq0$

$$\sup_{v_A\in\mathbb{R}^j}\inf_{v_B\in\mathbb{R}^{N-j}}G(v,x,t)\leqq\varphi(x,t)\leqq\inf_{v_B\in\mathbb{R}^{N-j}}\sup_{v_A\in\mathbb{R}^j}G(v,x,t), \tag{1.3}$$

where

$$G(v,x,t):=x\cdot v-\varphi_1^*(v_A)-\varphi_2^*(-v_B)-tH(v).$$

Note that the pointwise estimate (1.3) gives a representation formula for the solution whenever the first and last terms are equal (as they are for $t=0$). A trivial case where this occurs is for $j=N$ or $j=0$, because (1.3) reduces to Hopf's formulas (1.1) or (1.2). A more interesting case occurs when the Hamiltonian separates the variables v_A and v_B, that is,

$$H(v)=H_1(v_A)+H_2(v_B).$$

In this case we get

$$\varphi(x,t)=\sup_{v_A\in\mathbb{R}^j}\{x_A\cdot v_A-\varphi_1^*(v_A)-tH_1(v_A)\}+\inf_{v_B\in\mathbb{R}^{N-j}}\{x_B\cdot v_B-\varphi_2^*(-v_B)-tH_2(v_B)\},$$

which is the superposition of the solutions to the problems

$$\varphi_t + H_i(D_x\varphi) = 0, \qquad \varphi(\cdot, 0) = \varphi_i$$

for $i = 1, 2$.

Next we specialize formula (1.3) to a particular class of (Riemann) initial data. Let A, u_i^+, u_i^- be constants and define

$$u_i(x) := \begin{cases} u_i^+ & \text{if } x_i > 0, \\ u_i^- & \text{if } x_i < 0 \end{cases}$$

for $i = 1, \cdots, N$. Then take

$$\varphi_0(x) = A + \sum_{i=1}^{N} x_i u_i(x) = A + x \cdot u(x). \tag{1.4}$$

These data correspond to a Riemann problem for the system of conservation laws satisfied (formally) by the spatial gradient of φ; see Remark 2.2. Let, for $i = 1, \cdots, N$,

$$\Omega_i := \{s \mid \min(u_i^+, u_i^-) \leqq s \leqq \max(u_i^+, u_i^-)\},$$
$$\chi_i := \operatorname{sign}(u_i^+ - u_i^-),$$

and reorder the indices, without loss of generality, so that

$$\chi_i = 1 \quad \text{for } i = 1, \cdots, j; \qquad \chi_i = -1 \quad \text{for } i = j+1, \cdots, N \tag{1.5}$$

$(0 \leqq j \leqq N)$. Finally set

$$\Omega_A := \Omega_1 \times \cdots \times \Omega_j; \quad \Omega_B := \Omega_{j+1} \times \cdots \times \Omega_N; \quad \Omega := \Omega_A \times \Omega_B.$$

COROLLARY 2. *The viscosity solution to* (H-J)(IC) *with the initial data given by* (1.4) *under the convention* (1.5) *satisfies*

$$A + \max_{v_A \in \Omega_A} \min_{v_B \in \Omega_B} \{x \cdot v - tH(v)\} \leqq \varphi(x, t) \leqq A + \min_{v_B \in \Omega_B} \max_{v_A \in \Omega_A} \{x \cdot v - tH(v)\}. \tag{1.6}$$

The rest of the paper is organized as follows. In § 2, as motivation, we show how formula (1.6) was first (formally) derived in connection with numerical approximation schemes for Hamilton–Jacobi equations and for conservation laws. In § 3 we give the proofs of Theorem 1 and Corollary 2, which are quite different from the previous derivation, and rather simple, in that they make use only of Hopf's formulas (1.1), (1.2) and a comparison argument.

2. A derivation of (1.6) by means of Godunov's Hamiltonians. The purpose of this section is to motivate Corollary 2 and to explain its connection with approximation schemes for (H-J). The rigorous proofs will be given in § 3. We assume that the solutions of (H-J) have the following properties:

(P1) The solution $\varphi(x, t)$ is a nondecreasing function of the initial data.

(P2) The partial derivatives φ_{x_i} satisfy a maximum principle at points of continuity, i.e., for $i = 1, \cdots, N$:

$$\min(u_i^-, u_i^+) \leqq \varphi_{x_i} \leqq \max(u_i^-, u_i^+).$$

(P3) The speed of propagation is finite.

(P4) If $\psi(x_2, \cdots, x_N, t)$ is a viscosity solution of

$$\psi_t + H(v_1, \psi_{x_2}, \cdots, \psi_{x_N}) = 0$$

for a constant v_1 then

$$\varphi(x, t) = v_1 x_1 + \psi(x_2, \cdots, x_N, t)$$

is a viscosity solution to (H-J).

It is easy to see formally that the solution to the Cauchy problem (H-J)(IC), with initial data given by (1.4), satisfies

$$\varphi(x,t) = tg\left(\frac{x}{t}\right) + A = tg(\zeta) + A, \tag{2.1}$$

where g satisfies:

$$g = \zeta \cdot D_\zeta g - H(D_\zeta g) \tag{2.2}$$

whenever $D_\zeta g$ is continuous.

In (H-J), we let $\tau = t$, $y_i = x_i - \zeta_i t$ for ζ fixed. (H-J) becomes

$$\varphi_\tau + H(D_y\varphi) - \zeta D_y\varphi = \varphi_\tau + H^1(D_y\varphi) = 0 \qquad \text{(defining } H^1(D_y\varphi)\text{)} \tag{H-J^1}$$

with the same initial data (1.4).

Thus, by (2.2), to evaluate $g(\zeta)$ we need only evaluate $-H^1(D_y(g(y)))$ at $y=0$ for any $t>0$. From (P2) above we know that $(D_y g)_{y=0}$ lies in Ω for $t>0$. Moreover, if we integrate (H-J)^1 from $\tau=0$ to $\tau=\Delta t$ we have

$$\begin{aligned}\varphi(0,\Delta t) &= A - \Delta t H^1((D_y g)_{y=0}) \\ &= \varphi_0(0) - \Delta t \tilde{H}^1(D_+^{x_1}\varphi_0(0), D_-^{x_1}\varphi_0(0); D_+^{x_2}\varphi_0(0), D_-^{x_2}\varphi_0(0); \cdots \\ &\quad \cdots; D_+^{x_N}\varphi_0(0), D_-^{x_N}\varphi_0(0)).\end{aligned} \tag{2.3}$$

Here

$$D_\pm^{x_i}\varphi_0(0) = \pm\frac{(\varphi_0(\pm h e_i) - \varphi_0(0))}{h} = u_i^\pm \tag{2.4}$$

where $e_i = \{0, 0, \cdots, 1, 0, \cdots\}$, the ith unit vector, and $\tilde{H}^1(u_1^+, u_1^-; u_2^+, u_2^-; \cdots; u_N^+, u_N^-)$ is determined by (2.3).

This formula can be interpreted as a numerical algorithm. Suppose we are given a grid

$$x_{j_i}^i = j_i h, \qquad i = 1, \cdots, N; \qquad j_i = 0, \pm 1, \cdots$$

and values of a discrete function $\psi_j = \psi_{j_1 j_2 \cdots j_N}$. Then for each j, we construct the piecewise affine function which, in each of the 2^N orthants centered at j, interpolates ψ_j and its N nearest neighbors, $\psi_{j\pm e_i}$ for $i = 1, \cdots, N$. From (P3), if

$$\text{(CFL)} \qquad \frac{\Delta t}{h} \max_{\substack{v\in\Omega^{(j)} \\ i=1,\cdots,N}} |H_{u_i}^1| \leqq \frac{1}{N^{1/2}}, \tag{2.5}$$

where $\Omega^{(j)}$ is the same as Ω with each u_i^-, u_i^+ replaced by $D_-^{x_i}\psi_j$, $D_+^{x_i}\psi_j$, then the solution to the initial value problem (H-J^1) with the above affine initial data in the diamond centered at j when evaluated at $x = x_j$ and $t = \Delta t$ is independent of the values of the initial data outside of this diamond.

Thus (2.3) (with $\varphi_0(0)$ replaced by ψ_j^n and $\varphi(0,\Delta t)$ by ψ_j^{n+1}), gives us a monotone finite difference scheme approximating (H-J^1) which is in differenced form with numerical Hamiltonian $\tilde{H}^1$. These concepts were introduced in [4]. The scheme is monotone, which means that the right side of (2.3) is an increasing function of all the $\varphi_{j\pm e_i}$, because of property (P1). The function $\tilde{H}^1$ is called Godunov's Hamiltonian by analogy with the definition of Godunov's scheme for conservation laws in one space dimension [8]. The scheme is consistent, which means

$$\tilde{H}^1(u_1, u_1; u_2, u_2; \cdots; u_N, u_N) = H^1(u_1, u_2, \cdots, u_N).$$

Monotonicity implies that

$$\tilde{H}^1(u_1^+, u_1^-; u_2^+, u_2^-; \cdots; u_N^+, u_N^-)$$

is a nonincreasing function of all the u_i^+ and a nondecreasing function of all the u_i. In particular, for $N=1$, this means for any $v_1 \in \Omega = \Omega_1$:

$$\begin{aligned} \operatorname{sgn}(u_1^+ - u_1^-)[\tilde{H}^1(u_1^+, u_1^-) - H^1(v_1)] &= \operatorname{sgn}(u_1^+ - v_1)[\tilde{H}^1(u_1^+, u_1^-) - \tilde{H}^1(v_1, u_1^-)] \\ &\quad + \operatorname{sgn}(v_1 - u_1^-)[\tilde{H}^1(v_1, u_1^-) - \tilde{H}^1(v_1, v_1)] \\ &\leqq 0. \end{aligned} \tag{2.6}$$

But, by (P2), $\tilde{H}^1(u_1^+, u_1^-) = H^1(\tilde{u}_1)$ for some $\tilde{u}_1$ in Ω. Thus we have

$$\tilde{H}^1(u_1^+, u_1^-) = \chi_1 \min_{v_1 \in \Omega_1} \chi_1 H^1(v_1). \tag{2.7}$$

(This formula was obtained earlier in [14].) Now we proceed inductively. Suppose, for $N \leqq M-1$, we have

$$\begin{aligned} &\max_{v_{j+1} \in \Omega_{j+1}} \cdots \max_{v_N \in \Omega_N} \min_{v_1 \in \Omega_1} \cdots \min_{v_j \in \Omega_j} H^1(v_1, v_2, \cdots, v_N) \\ &\leqq \tilde{H}^1(u_1^+, u_1^-; u_2^+, u_2^-; \cdots; u_N^+, u_N^-) \\ &\leqq \min_{v_1 \in \Omega_1} \cdots \min_{v_j \in \Omega_j} \max_{v_{j+1} \in \Omega_{j+1}} \cdots \max_{v_N \in \Omega_N} H^1(v_1, v_2, \cdots, v_N), \end{aligned} \tag{2.8}$$

where

$$\begin{aligned} \chi_i &= 1, \qquad i = 1, \cdots, j, \\ \chi_i &= -1, \qquad i = j+1, \cdots, N. \end{aligned}$$

Next we have, $N = M$ and for any $v_1 \in \Omega_1$:

$$\chi_1[\tilde{H}^1(u_1^+, u_1^-; u_2^+, u_2^-; \cdots; u_M^+, u_M^-) - \tilde{H}^1(v_1, v_1; u_2^+, u_2^-; \cdots; u_M^+, u_M^-)] \leqq 0, \tag{2.9}$$

using the same argument as in (2.6).

Now, for any fixed v_1, $\tilde{H}^1(v_1, v_1; u_2^+ u_2^-, \cdots; u_M^+, u_M^-)$ is Godunov's Hamiltonian when the initial data for (H-J^1) has a constant x_1 derivative,

$$\frac{\partial \varphi_0}{\partial x_1}(x) \equiv v_1.$$

Then it follows from (P4) that

$$g\left(\frac{x}{t}\right) = \frac{x_1}{t} v_1 + \tilde{g}\left(\frac{x_2}{t}, \frac{x_3}{t}, \cdots, \frac{x_M}{t}\right)$$

(where $\tilde{g}$ also depends on v_1).

By the induction hypothesis, this means we have

$$\begin{aligned} &\chi_1 \tilde{H}^1(u_1^+, u_1^-; u_2^+, u_2^-; \cdots; u_M^+, u_M^-) \\ &\quad \leqq \chi_1 \tilde{H}^1(v_1, v_1; u_2^+, u_2^-; \cdots; u_M^+, u_M^-) \\ &\quad = -\chi_1 \tilde{g}(0, 0, \cdots, 0) \\ &\quad \leqq \chi_1 \chi_2 \min_{v_2 \in \Omega_2} \chi_2 \cdots \chi_M \min_{v_M \in \Omega_M} \chi_M H^1(v_1, v_2 \cdots v_M) \\ &\quad = \chi_1 H^1(v_1, \tilde{v}_2, \cdots, \tilde{v}_M) \end{aligned} \tag{2.10}$$

where the extrema is taken on at $\tilde{v}_2, \cdots, \tilde{v}_M$, which depends on v_1. The vector $(v_1, \tilde{v}_2, \cdots, \tilde{v}_N) \in \Omega_1$, where $v_1 \in \Omega_1$ is arbitrary. We next take $\min_{v_1}$ of the expression in (2.10). If all the $\chi_i \equiv 1$ or all the $\chi_i \equiv -1$ we have equality by (P2). Otherwise, $\chi_i \equiv 1$, $1 \leqq i \leqq j$, $\chi_i \equiv -1$, $j+1 \leqq i \leqq M$, and we have the right-hand inequality in (2.8). Next we have, for any $v_{j+1} \in \Omega_{j+1}$, following the argument above:

$$
\begin{aligned}
&\tilde{H}^1(u_1^+, u_1^-; u_2^+, u_2^-; \cdots; u_M^+, u_M^-) \\
&\quad \geqq \tilde{H}^1(u_1^+, u_1^-; \cdots; v_{j+1}; \cdots; u_M^+, u_M^-) \\
&\quad \geqq \chi_{j+2} \min_{v_{j+2} \in \Omega_{j+2}} \chi_{j+2} \cdots \chi_M \min_{v_M \in \Omega_M} \chi_M \chi_1 \min_{v_1 \in \Omega_1} \chi_1 \cdots \chi_j \\
&\qquad \cdot \min_{v_j \in \Omega_j} \chi_j H^1(v_1, v_2, \cdots, v_M).
\end{aligned} \tag{2.11}
$$

We next take the $\max_{v_{j+1}}$ of the expression in (P4) which gives us the left-hand inequality in (2.8).

We have now obtained formula (2.8) for any N; using (2.1) and (2.2) gives us our intuitive derivation of (1.6).

Remark 2.1. We note that (2.8) validates the conjecture about Godunov's Hamiltonian in [15] when the inequalities in (2.10) and (2.11) become equalities. That paper also discusses the high-order accurate nonoscillatory numerical solution of (H-J) in some detail. See also [16] for a further discussion of these issues.

Remark 2.2. If we take the space gradient of (H-J) and call $u_1 = \varphi_{x_1}$, $u_2 = \varphi_{x_2}$, etc., we arrive at the system of conservation laws

$$
(u_i)_t + \frac{\partial}{\partial_{x_i}} H(u_1, \cdots, u_N) = 0, \qquad i = 1, \cdots, N \tag{2.12}
$$

with initial data:

$$
u_i(x, 0) = \begin{cases} u_i^+ & \text{if } x_i > 0 \\ u_i^- & \text{if } x_i < 0, \end{cases} \qquad i = 1, \cdots, N.
$$

Thus (1.6) gives us information about the solution to this special Riemann problem for a special system of conservation laws.

3. Proofs.

Proof of Theorem 1. Since φ_2 can be written as the Legendre transform of its Legendre transform

$$
\varphi_2(x_B) = \inf_{v_B \in \mathbb{R}^N} \{-x_B \cdot v_B - \varphi_2^*(v_B)\},
$$

we will first solve (H-J) with the initial data

$$
\psi_0(v_B, x) = \varphi_1(x_A) - x_B \cdot v_B - \varphi_2^*(v_B), \tag{3.1}
$$

and then take the infimum as v_B varies in $\mathbb{R}^{N-j}$. Since the initial data ψ_0 are convex in x for each choice of v_B, we can write Hopf's formula for the solution $\psi(v_B, x, t)$ of (H-J) plus

$$
\psi(v_B, x, 0) = \psi_0(v_B, x) \quad \text{for all } x \in \mathbb{R}^N.
$$

To do this we compute the Legendre transform with respect to x of ψ_0:

$$
\begin{aligned}
\psi_0^*(v_B, y) &= \sup_{x \in \mathbb{R}^N} \{x_A \cdot y_A + x_B \cdot (y_B + v_B) - \varphi_1(x_A) + \varphi_2^*(v_B)\} \\
&= \begin{cases} +\infty & \text{if } y_B \neq -v_B, \\ \varphi_1^*(y_A) + \varphi_2^*(v_B) & \text{if } y_B = -v_B, \end{cases}
\end{aligned}
$$

and then apply (1.1) to get

$$\psi(v_B, x, t) = \sup_{y_A \in \mathbb{R}^j} \{x_A \cdot y_A - x_B \cdot v_B - \varphi_1^*(y_A) - \varphi_2^*(v_B) - tH(y_A, -v_B)\}$$
$$= \sup_{v_A \in \mathbb{R}^j} G(-v, x, t).$$

Since $\psi(v_B, \cdot, \cdot) \in UC_x(\mathbb{R}^N \times [0, T])$ for all v_B and $\psi(v_B, x, 0) \geqq \varphi(x, 0)$, a standard comparison theorem for unbounded viscosity solutions [10], [5] gives

$$\psi(v_B, x, t) \geqq \varphi(x, t) \quad \text{for all } (x, t) \in \mathbb{R}^N \times [0, T], \quad v_B \in \mathbb{R}^{N-j}.$$

Then

$$\inf_{v_B \in \mathbb{R}^{N-j}} \sup_{v_A \in \mathbb{R}^j} G(v, x, t) = \inf_{v_B \in \mathbb{R}^{N-j}} \psi(v_B, x, t) \geqq \varphi(x, t),$$

which is the second inequality in (1.3).

The first inequality is proved in a similar way. We apply Hopf's formula (1.2) to compute the solution $\psi(v_A, x, t)$ of (H-J) with the concave initial condition

$$\psi(v_A, x, 0) = \varphi_2(x_B) + x_A \cdot v_A - \varphi_1^*(v_A) \leqq \varphi(x, 0).$$

Since

$$\psi^*(v_A, y, 0) = \begin{cases} -\infty & \text{if } y_A \neq -v_A, \\ \varphi_1^*(v_A) + \varphi_2^*(y_B) & \text{if } y_A = -v_B, \end{cases}$$

we get

$$\psi(v_A, x, t) = \inf_{v_B \in \mathbb{R}^{N-j}} G(v, x, t),$$

and, as before, we conclude by means of a comparison theorem. □

Remark 3.1. The first and the third member of (1.3) coincide with φ at $t = 0$, but in general it is not clear whether they are continuous. However, they are anyway respectively a subsolution and a supersolution of (H-J) in the generalized viscosity sense of Ishii [11]. This follows from Proposition 2.4 in [11], because they are, respectively, a supremum and an infimum of solutions of (H-J).

Proof of Corollary 2. We set

$$\varphi_1(x_A) = A + x_A \cdot u(x_A), \qquad \varphi_2(x_B) = x_B \cdot u(x_B),$$

and compute the Legendre transforms

$$\varphi_1^*(v_A) = -A + \sup_{x_A \in \mathbb{R}^j} x_A \cdot (v_A - u(x_A))$$
$$= \begin{cases} +\infty & \text{if } v_i > u_i^+ \text{ or } v_i < u_i^- \quad \text{for some } 1 \leqq i \leqq j, \\ -A & \text{if } u_i^- \leqq v_i \leqq u_i^+ \quad \text{for all } i = 1, \cdots, j \end{cases}$$
$$= \begin{cases} +\infty & \text{if } v_A \notin \Omega_A, \\ -A & \text{if } v_A \in \Omega_A; \end{cases}$$

$$\varphi_2^*(-v_B) = \begin{cases} -\infty & \text{if } v_B \notin \Omega_B, \\ 0 & \text{if } v_B \in \Omega_B; \end{cases}$$

which substituted in (1.3) give immediately (1.6). □

THE ANALYSIS OF A MODEL FOR WAVE MOTION IN A LIQUID SEMICONDUCTOR: BOUNDARY INTERACTION AND VARIABLE CONDUCTIVITY*

WILLIAM V. SMITH

Abstract. The theory of conducting fluids in relative motion with small conductivity is studied with a model including the Maxwell displacement current. The model is linearized, and the interaction of waves with a plane boundary in three space is studied for two orientations of the external magnetic field. It is found that two *families* of boundary conditions preserve energy in one orientation (external field orthogonal to the boundary), while in the other (external field parallel to the boundary) only one condition exists which preserves energy. It is shown that generalized Fourier transforms exist, generated from the generalized eigenfunction expansions. Further, it is shown that surface waves are not supported by this model, indicating that their presence is unstable when relative motion of the fluid is allowed (surface waves exist in the still fluid case). Finally, the problem of variable conductivity (decaying to zero at infinity) is studied and steady-state and time dependent solutions are shown to exist for certain force terms.

Key words. eigenfunction expansions, energy preserving boundaries, variable conductivity, Maxwell's equations, magnetofluiddynamics, liquid semiconductor

AMS(MOS) subject classifications. 35L50, 76W05

1. Introduction. The theoretical modeling of problems in "magnetofluiddynamics" is a rich source of interesting and unusual systems of partial differential equations and corresponding wave motions [LL]. The problem we consider here involves waves of *finite energy* in a fluid-like conducting medium which we assume to be a relatively dense poor conductor, and we treat the *Maxwell displacement current as significant.* The model (like most in this area) can be said to be "physical" only in a certain range of the parameters. For example, in the model studied here, frequency must be relatively high but not high enough to require a particle treatment. (It may also be assumed that permitivity is high relative to free space.) The problem we study here is also of physical interest in a true gas where the constitutive equations (see (1.2)) are much simpler, but we want to examine the fluid case first as, perhaps, a kind of transition state (the theory of liquid semiconductors is still in a rather primitive state with few settled issues [C]). The conductivity appears in only one of the model equations explicitly (see (1.17)). Our model, at apparent zero conductivity, does not reduce (formally) to the uncoupled Maxwell equatoins and fluid motion equations. This is because the (finite) conductivity is implicitly present in the equations containing E'. Mixed frame equations of this type are useful in studying dissipative nonlinear processes since they remove terms which are second order in time. It is this fact that makes the model useful to consider for the undamped behavior of small amplitude waves in a rather dense poor conductor, as this effect makes it possible to study the essentially dissipative problem (1.17) as the bounded perturbation of a symmetric problem. Hence the solutions of (1.17) will be like those of its associated symmetric problem modulo an exponentially decreasing (with time) factor. Elsewhere [S1], [S2], we have already studied the MHD fluid case (perfect conductor), and we refer the reader there for a more detailed

exposition at various points of our treatment here. We note that while this introductory section is mathematically informal (but rather typical of the theoretical treatments of the subject) the following sections are completely rigorous in nature and are founded securely on functional analysis and in particular the Hilbert space theory of differential equations. However, at the end of this section we shall give a brief summary of the results contained in this paper, a comparison to related problems and some comments about the computational difficulties in discussing the differential equations.

The derivation of the problem considered here is founded on Maxwell's equations. The properties of the medium are assumed to be enough like those of a fluid that the continuum approach is reasonably close to reality. We will assume that all fluid *velocities are nonrelativistic*, and that acceleration is small in magnitude (compared to the velocity of light). In order to illustrate the differences between our model and the classical case of a perfect conductor, we will indicate the contrasting assumptions that lead to these two models in their respective derivations.

The Maxwell equations in RMKS units are

$$\nabla \circ D = \rho_e, \qquad \nabla \circ B = 0,$$

$$\nabla \times E = -\frac{\partial B}{\partial t}, \qquad \nabla \times H = J + \frac{\partial D}{\partial t}, \tag{1.1}$$

which hold in any frame of reference, either the rest frame (with respect to the fluid) or the laboratory frame. The constitutive equations must be used and these are (in the laboratory frame):

$$D = \varepsilon_0 E + \varepsilon_0 V \times B - \frac{1}{c^2} V \times H,$$

$$B = \mu_0 H - \mu_0 V \times D + \frac{1}{c^2} V \times E. \tag{1.2}$$

Here as usual, ε_0 is the electric permitivity (for free space), μ_0 the magnetic permeability, E the electric field, H the magnetic field, B the magnetic flux, and D the electric flux. We assume a linear isotropic medium so that μ_0 and ε_0 are scalar constants (this can be modified somewhat—see §§ 4 and 5). c is the speed of light. V is the fluid velocity. We now assume the electric fields to be of order $V \times B$, that is, of the order of magnitude of the induced effects. In other words, the induced magnetic field is much smaller than the externally applied magnetic field. From this it is easily shown that the magnetic induction is the same in all reference frames. Of course, because B is the same in all frames of reference does not mean the same is true for H, but we will see that this is the case under our assumptions on V and the electric field. Let us write H' for the rest frame field and H the laboratory frame. By our Newtonian assumption and the Lorentz transformation,

$$H' = H - V \times (\varepsilon(E + V \times B) - 1/c^2(V \times H)), \tag{1.3}$$

so that $H = H'$ is valid if the magnitude of $V\varepsilon\mu$ is $\ll 1$ ($\varepsilon\mu = 1/c^2$), or in other words, E is approximated by $V \times B$ (here we have used $B = \mu H$). For E' we have

$$E' = E + V \times B. \tag{1.4}$$

E' must always be considered, since to get $H' = H$ as noted, E and $V \times B$ must have the same order of magnitude. We now assume that the period of variation of the fields is large compared to the mean free time of the conduction electrons and that the

Larmor frequency is small compared with the mean free time of the conduction electrons. (In rarefied gases this may break down). This allows the assumption of a constant conductivity σ [LL] (see § 5 below). (We will also assume it is a scalar quantity to begin with—see the remarks on ρ_e below.)

In the MHD approximation, the displacement current $\partial D/\partial t$ would be neglected compared to J, at least when σ is significant. (In a dielectric J is virtually zero.) Here we assume that the displacement current is *not* trivial (in a true metal, for example, the displacement current is essentially meaningless, except at frequencies where the other hypotheses we use begin to break down). In Ohm's law, ρ_e (the space charge) may usually be neglected in a liquid (it must be retained in some gases—we ignore this); hence we have

$$J = \sigma E' + \rho_e V = \sigma(E + V \times B) + (V \circ J/c^2)V. \tag{1.5}$$

The second term is small compared to the first (the coefficient of V in the second term being ρ_e). Thus we take

$$J = \sigma(E + V \times B).$$

Now the Maxwell equations become (note that ρ_e is not present now)

$$\begin{aligned} &-\nabla \times E' + \nabla \times (V \times B) = \frac{\partial B}{\partial t}, \\ &\nabla \times H = \sigma E' + \frac{\partial D}{\partial t}, \\ &\nabla \circ J = 0, \\ &\nabla \circ B = 0, \end{aligned} \tag{1.6}$$

Ohm's law:

$$J = \sigma(E + V \times B).$$

The fluid equations are

$$\frac{\partial p}{\partial t} + \nabla \circ (\rho V) = 0 \qquad \text{(continuity)}, \tag{1.7}$$

(1.8)

$$\rho\left(\frac{\partial V}{\partial t} + \nabla\left(\frac{V \circ V}{2}\right) - V \times (\nabla \times V)\right) = -\nabla P - \rho \nabla \psi + \nabla \circ \tau' + J \times B + \Sigma \qquad \text{(motion)},$$

with the other terms on the right of the motion equation (Σ) depending on the displacement current if it is considered in a fluid—in a gas Σ is zero (see below). Here ψ is the gravitational potential and τ' is the shear part of the mechanical stress tensor τ. From the Maxwell equations,

$$J \times B = (\sigma E' \times B) = -\sigma B \times E' \tag{1.9}$$

(*in the perfect conductor case, we would use the Maxwell equation to get J here—see below* (1.12)) and so the motion equation becomes

$$\rho\left(\frac{\partial V}{\partial t} + (V \circ \nabla)V\right) = -\nabla P - \rho \nabla \psi + \nabla \circ \tau' - \sigma B \times E', \tag{1.10}$$

$$\rho\left(\frac{\partial V}{\partial t} + (V \circ \nabla)V\right) = -\nabla P - \rho \nabla \psi + \nabla \circ \tau' - \mu H \times (\nabla \times H) \tag{1.11}$$

and replacing τ' by its value in terms of velocity and viscosity,

(1.12)
$$\rho\left(\frac{\partial V}{\partial t}+(V\circ\nabla)V\right)=-\nabla P-\rho\nabla\psi+\rho\nu\nabla^2 H+\left(\zeta+\frac{1}{3}\rho\nu\right)\nabla(\nabla\circ V)+\mu(\nabla\times H)\times H,$$

where the second and third equations are the perfect conductor case ($\partial D/\partial t=0$ and so $J=\nabla\times H$). We write this down because it turns out that (1.10) is correct for the case of a gas only, while (1.12) is correct for a fluid because it includes the complete body force (see (1.16) below). Here we have used P for pressure; ν and ζ are, respectively, the first and second coefficients of viscosity.

In many problems it is useful to make the assumption of infinite conductivity in order to obtain qualitative information about physical situations, since this assumption generally allows a much simpler mathematical formulation. An important application of the concept of infinite conductivity is in high temperature plasma studies, such as those associated with fusion devices. In interstellar matter, the decay of the magnetic fields is so slow that infinite conductivity gives a good approximation. In such cases (where infinite conductivity is assumed) the results differ from physical reality by a damping term. When the displacement current is neglected, we can combine the two curl Maxwell equations using Ohm's law and the divergence equation for B to obtain

(1.13)
$$\frac{\partial B}{\partial t}=\eta\nabla^2 B+\nabla\times(V\times B),$$

the so-called magnetic transport equation. Here $\eta=(1/\sigma\mu)$ and is called the magnetic diffusivity by obvious analogy. *For $\sigma=\infty$ we have, formally, that B becomes "frozen into" the fluid (the transport term vanishes).* The neglect of gravitational force and viscosity together with the appropriate equation of state yields the well-known equations of magnetohydrodynamics:

(1.14)
$$\begin{aligned}
&\frac{\partial B}{\partial t}=\nabla\times(V\times B),\\
&\rho\frac{DV}{Dt}=-a^2\nabla\rho+\mu(\nabla\times H)\times H,\\
&\frac{D\rho}{Dt}=0,\\
&\nabla\circ B=0,
\end{aligned}$$

where we have used the convective derivative notation in the second and third equations. a is the sound speed from the equation of state.

Equations (1.14) are mentioned only for comparison's sake since the case of interest here is when σ is relatively small. So, supposing that the displacement current is significant compared to the conduction current, and if we note the equation for D given above, that is,

$$D=\varepsilon_0 E'-\frac{1}{c^2}V\times H,$$

then we have

(1.15)
$$\varepsilon_0\frac{\partial E'}{\partial t}=\nabla\times H-\sigma E'+\frac{1}{c^2}\frac{\partial V\times H}{\partial t}.$$

The essential assumptions made so far are that V is relatively small, external forces (gravity) may be neglected, and dissipation from viscous effects is small. Now, using (1.15), and the constitutive expression for D (there is some question as to the proper form for the body force here but we take the one implied by the Abraham tensor [LL])

and considering the motion equation with the body force term, assuming no steady D field, and neglecting space charge effects, we have for the body force density (last terms in the motion equation)

$$J\times B+\frac{\partial}{\partial t}(D\times B)-\frac{1}{c^2}\frac{\partial}{\partial t}(E\times H)=J\times B+\Sigma. \tag{1.16}$$

Now if the permitivity ε of the medium is comparable to frequency over conductivity (in sea water for example, at frequencies above about 200 megacycles), (or else $\varepsilon \gg \varepsilon_0$), we may neglect the last term on the left side of (1.16) compared to the others. If the magnitude of acceleration is small compared to c we can neglect the last term in (1.15) and so finally obtain

$$\begin{aligned}
&\varepsilon_0\frac{\partial E'}{\partial t}=\nabla\times H-\sigma E',\\
&\frac{\partial B}{\partial t}=\nabla\times(V\times B)-\nabla\times E',\\
&\rho\frac{DV}{Dt}=-a^2\nabla\rho+(\nabla\times B)\times\mu^{-1}B,\\
&\frac{D\rho}{Dt}=0,\\
&\nabla\circ B=0,\qquad \nabla\circ J=0.
\end{aligned} \tag{1.17}$$

The reader will notice that formally, (1.17) reduces to (1.1) when $V=0$ or to (1.14) when $\sigma=\infty$.

Introducing small disturbances about a steady-state condition and neglecting the second-order terms, we finally arrive at a form to observe in terms of wave motion (see (2.1)). It is well known that in the MHD approximation (1.14) ($\eta=0$, or $\sigma=\infty$) there exist essentially three modes of propagation, namely, Alfven waves, and the slow and fast magnetosonic waves [LL], [A], [K], etc. The Alfven waves do not involve acoustic effects but are simply disturbances in the velocity and magnetic fields. As we will see below, the "Alfven waves" in (1.17) degenerate in the sense that they appear as disturbances which are like sound waves (the external field is not "frozen into" the medium) but move more rapidly in the direction of the external field.

It has often been stated that surface wave phenomena are important in the physics of conducting fluids. But as noted in [A], for example, and shown rigorously in [S2], (1.14) does not support surface waves. The displacement current term is needed to generate surface wave phenomena but as we will see, the *presence of surface waves is unstable*: *Whether conductivity is high* (MHD *case*) *or low* (*the case studied here*) *surface waves do not exist when the fluid is in motion. We may say that such surface disturbances are convected away by the fluid. At zero velocity however, a type* I *boundary for orthogonal external fields or the boundary for horizontal external field both support surface waves.* These matters are fully explained below.

As to boundary conditions that are appropriate for the system (1.17), these may be derived from the boundary conditions for Maxwell fields plus the appropriate conditions on the fluid equations. We remark here that the boundary conditions discovered in [Sc1] are related to those derived here in the case where the external magnetic field is parallel to the boundary. This might be expected since the derivation of (1.17) is based on the Maxwell equations. In fact, the boundary conditions in this case are (taking account of the larger number of variables) the so-called "strange"

boundary conditions of [Sc1]. It is perhaps then of some surprise that no surface waves exist in this configuration. This is the instability just mentioned.

In terms of the confinement of fusion plasmas, a number of simple conditions have been studied. No matter the shape of the confinement device for a conducting fluid the boundary problem may frequently be reduced to the consideration of a half-space [J]. That is, the problem may be studied as though the medium occupies a volume with a plane boundary, at least locally.

The boundary conditions for (1.17) with $\sigma = 0$ in a half-space, which are energy conserving, are particularly useful in the study of the dissipative problem $\sigma > 0$. These are derived in the next section.

We have said that one of the main (negative?) results we prove is the absence of surface waves for this model. Another is the absence of steady-state motion for low frequencies. This is proved even for the anisotropic case (see § 5). The reader may consult [S3] and [S4] for a treatment of general systems of the type considered here.

The results given below require very complex computations involving large symbolic matrices and polynomials in several variables. Nearly all of these were carried out using a combination of certain observations about the structure of the matrices involved and certain computer-based symbolic algebra routines constructed by the author as well as those standard packages available from commercial vendors, most computations being done in MAPLE and MACSYMA and a few in MATHEMATICA. A frontal attack on the problems leads nowhere, however, and considerable pattern recognition/reduction is required on the human side. Such techniques are nearly always very specific to the problem and are of an ad hoc nature. Once required objects were derived, checking was done by essentially the same methods, i.e., a combination of human observation and machine interaction. There are several methods of computing the large eigenprojector matrices used here. But they are based on the following facts.

Suppose $A(p)$ is a real symmetric matrix depending on the parameter(s) $p \neq 0$. The spectrum of $A(p)$ is real for all p. $A(p)$ is assumed to have the property that all its entries are linear combinations of the parameter(s) p. The positive and negative eigenvalues of $A(p)$ are equal in number and as continuous functions of p may be enumerated as an ordered list (counting possible multiplicities) as

$$\lambda_k(p) \geqq \lambda_{k-1}(p) \geqq \cdots \geqq 0 (= \lambda_0(p)) \geqq \lambda_{-1}(p) \geqq \cdots \geqq \lambda_{-k}(p).$$

The $\lambda_j(p)$ have the two properties

(1) $\lambda_j(\alpha p) = \alpha \lambda_j(p)$ for all $\alpha > 0$,

(2) $\lambda_j(-p) = -\lambda_{-j}(p)$.

The $\lambda_j(p)$ are roots of the minimal polynomial for $A(p)$ which has the form

$$S = \lambda^{\pi(r(p))}\{\lambda^{2\alpha(p)} + S_1(p)\lambda^{2\alpha(p)-1} + \cdots + S_{2\alpha(p)}(p)\}.$$

In case $A(p)$ has constant rank, $r(p)$ (=dimension of A minus the rank of A) and $\alpha(p)$ are constant. ($\pi(p) = 0$ or 1 depending on whether A is of full rank or not.) We need only deal with the constant rank case in our problem. $D(p)$, the discriminate of S in λ is a homogeneous polynomial and hence the set $\beta = \{p \mid D = 0\}$ is an algebraic cone (in n space for some n). β is the locus of points p where one or more of the functions $\lambda_j(p)$ coincide (and is a set of Lebesgue measure zero). $\lambda_j(p)$ is an analytic function of p on $R^n - \beta$. The orthogonal projection of C^m (A is $m \times m$ and m is related to k in the obvious way) onto the eigenspace for $\lambda_j(p)$ is given by

$$P_j(p) = -\frac{1}{2}\pi i \int_{\gamma_j(p)} (A(p) - z)^{-1}\, dz, \qquad p \in R^n - \beta,$$

where $\gamma_j(p) = \{z \,||z - \lambda_j(p)| = \rho_j(p)\}$ and the $\rho_j(p)$ are chosen so small that the $\gamma_j(p)$

do not intersect. The $P_j(p)$ have the properties ($p \neq 0$)

(1) $P_j(p)$ is analytic on $R^n - \beta$,

(2) $P_j(p) = P_j(\alpha p)$ for all $\alpha > 0$ and $p \in R^n - \beta$,

(3) $P_j(-p) = P_{-j}(p)$ for $p \in R^n - \beta$,

(4) $\sum_j P_j(p) = I$ (the identity matrix),

(5) $A(p)P_j(p) = \lambda_j(p)P_j(p)$.

Each of these facts plays a role in the actual computation of the matrices $P_j(p)$ the results of which are given in § 3 below for a certain $A(p)$ defined by the system of partial differential equations studied here. The path integral for $P_j(p)$ may be computed in a number of ways in a given example; the Cauchy integral theorem is an obvious method of attack. Many of the wave propagation problems of classical physics present with symbols ($A(p)$) of a particularly simple and useful form (the nonzero entries are contained in two nonintersecting submatrices each being the transpose of the other) [Sc1] but the problem we consider here is one of the interesting exceptions to that rule. Hence the computations are more difficult and resolution of the problem requires more basic methods, particularly since we need to extend one of the real parameters p into the complex plane.

2. Boundary conditions. The energy-preserving boundary conditions for the case of a perfect conductor (1.14), $\sigma = \infty$, were characterized in [S1] (see also [S2] and [S5]). The computations are somewhat more complex for the case of (1.17), and since they are carried out in essentially the same manner as in [S1], we will not give the complete details. We will nevertheless construct a complete set of boundary conditions. The divergence equations in (1.17) are contained in the other equations and so will not be needed here. It may be expected that E is divergence free as well. In fact, by the Lorentz transformation of E, the divergence of E' will be related to the divergence of V (the reader will recall that the space charge was neglected in the derivation of (1.17)). This requires that $\nabla \circ (E' - V \times B) = 0$. We will discuss this further below (see (4.18), (4.19)).

Since there is a boundary to consider, the direction of the external magnetic field may not be trivialized by the choice of a convenient coordinate system. The complications arising by treatment of general magnitude and direction of the external field require a great deal of space; we will treat two special cases, namely, external fields which are either parallel or orthogonal to the boundary plane. Oblique fields may be considered at a later time, provided a way can be discovered to sufficiently compress the expressions in a meaningful way.

The linearized version of (1.17) is

$$
\begin{aligned}
&\frac{\partial B}{\partial t} = \nabla \times (V \times B_0) - \nabla \times E', \\
&\varepsilon_0 \frac{\partial E'}{\partial t} = \nabla \times H - \sigma E', \\
&\rho_0 \frac{\partial V}{\partial t} = -a^2 \nabla \rho + (\nabla \times B) \times \mu^{-1} B_0, \\
&\frac{\partial \rho}{\partial t} = -\rho_0 \nabla \circ V.
\end{aligned}
\tag{2.1}
$$

Here, ρ_0 is the equilibrium density, $B_0 = (h_1, h_2, h_3)$ is the external magnetic field, a is the equilibrium speed of sound, μ is the magnetic permeability, B is the internal magnetic field, V is the velocity field, and ρ is the density. If we choose units in which $\varsigma\mu^2 \approx \sqrt{\varepsilon_0}/a^3$ and $h_i \approx \sqrt{\varepsilon_0}/\sqrt{\mu\rho_0}$ numerically, (these may be nonstandard units for

these quantities) then a change of variables in (2.1) allows us to take ρ_0, ε_0, a, and μ as unity, and h_3 or $h_2 = 1$ depending on which external field we consider. *We will assume this to be the case from now on* except where it is necessary to record the location of the external field components. σ has a somewhat different expression, but this is unimportant for our purposes and we still refer to it with the same notation.

We may then write (2.1) in matrix form (we have rearranged the order of the equations in (2.1) as indicated by the definition of u below) as

$$
\begin{aligned}
&-i\frac{\partial u}{\partial t} = -i\sum_{j=1}^{3} A_j \frac{\partial u}{\partial x_j} + iKu, \\
&K = \operatorname{diag}(0, 0, 0, 0, 0, 0, 0, \sigma, \sigma, \sigma), \\
&u = (V, B, \rho, E)^t.
\end{aligned} \tag{2.2}
$$

The superscipt t in (2.2) means transpose and $i = \sqrt{-1}$ (this is added for later convenience), "diag" means the square diagonal matrix with entries as shown and the A_j are given by

$$
A_1 = \begin{bmatrix}
0 & 0 & 0 & 0 & -h_2 & -h_3 & -1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & h_1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & h_1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
-h_2 & h_1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
-h_3 & 0 & h_1 & 0 & 0 & 0 & 0 & 0 & -1 & 0 \\
-1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}, \tag{2.3}
$$

$$
A_2 = \begin{bmatrix}
0 & 0 & 0 & h_2 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & -h_1 & 0 & -h_3 & -1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & h_2 & 0 & 0 & 0 & 0 \\
h_2 & -h_1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & -h_3 & h_2 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}, \tag{2.4}
$$

$$
A_3 = \begin{bmatrix}
0 & 0 & 0 & h_3 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & h_3 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & -h_1 & -h_2 & 0 & -1 & 0 & 0 & 0 \\
h_3 & 0 & -h_1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\
0 & h_3 & -h_2 & 0 & 0 & 0 & 0 & -1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}. \tag{2.5}
$$

We write D_j for $-i\partial/\partial x_j$ and $D=(D_1, D_2, D_3)$. For the right-hand side of (2.2) (taking $K=0$), we write $A(D)$. As we noted above, we will consider the case of a half-space where the vector B_0 is given by either $(0, 0, h_3)$ or $(0, h_2, 0)$. When it is necessary to distinguish between these two cases, we will do so by using a superscript as $A^3(D)$ and $A^2(D)$. By n, we mean the inward unit normal vector to ∂G (=boundary of G), where G is some domain in $\mathbb{R}^3$. From here on, $G=\mathbb{R}^3_+=\{x \mid x=(x_1, x_2, x_3),\ x_3>0\}$.

DEFINITION 2.1 [LP]. A subspace $\mathcal{S}(n)$ of $\mathbb{R}^{10}$ is a maximal conservative boundary space for $A(D)$ in G if and only if $\zeta \circ A(n)\zeta=0$ for all ζ in $\mathcal{S}(n)$ and $\mathcal{S}(n)$ is maximal with respect to this property.

To proceed further, it is necessary to consider the eigenvalues of the symbol of $A(D)$. These are the solutions to the equation $\det(A(p)-\lambda I)=0$, where $p=(p_1, p_2, p_3)\in\mathbb{R}^3\backslash\{0\}$ (the plane wave speeds). They are given by (for A^3):

$$
\begin{aligned}
&{}_3\lambda_0(p)=0 \qquad \text{(multiplicity 4)},\\
&{}_3\lambda_{\pm1}(p)=\pm(2p_3^2+|n|^2)^{1/2} \qquad \text{(each with multiplicity 1)},\\
&{}_3\lambda_{\pm2}(p)=\frac{\pm(-(p_3^2(p_3^2+6|n|^2)+5|n|^4)^{1/2}+3(p_3^2+|n|^2))^{1/2}}{\sqrt{2}},\\
&{}_3\lambda_{\pm3}(p)=\frac{\pm((p_3^2(p_3^2+6|n|^2)+5|n|^4)^{1/2}+3(p_3^2+|n|^2))^{1/2}}{\sqrt{2}}
\end{aligned}
\tag{2.6}
$$

(each with multiplicity 1 for almost all p). Here we have used the notation $|n|=(p_1^2+p_2^2)^{1/2}$ and in (2.7), $|n_1|=(p_1^2+p_3^2)^{1/2}$. For A^2,

$$
\begin{aligned}
&{}_2\lambda_0(p)=0 \qquad \text{(multiplicity 4)},\\
&{}_2\lambda_{\pm1}(p)=\pm(|n_1|^2+2p_2^2)^{1/2},
\end{aligned}
\tag{2.7}
$$

and similarly for the rest, exchanging p_2 and p_3, n and n_1 in (2.6). For future reference, we record the following: (cf. (3.24) and also (3.33))

$$
\begin{aligned}
&\frac{\partial {}_3\lambda_{\pm1}}{\partial\tau}=\frac{2\tau}{{}_3\lambda_{\pm1}},\\
&\frac{\partial {}_3\lambda_{\pm2}}{\partial\tau}=\frac{-1}{2\,{}_3\lambda_{\pm2}}\left(\frac{2\tau(\tau^2+6|n|^2)+2\tau^3)}{\tau^2(\tau^2+6|n|^2)+5|n|^4)^{1/2}}+3\tau\right),\\
&\frac{\partial {}_3\lambda_{\pm3}}{\partial\tau}=\frac{1}{2\,{}_3\lambda_{\pm3}}\left(\frac{2\tau(\tau^2+6|n|^2)+2\tau^3)}{\tau^2(\tau^2+6|n|^2)+5|n|^4)^{1/2}}+3\tau\right)
\end{aligned}
\tag{2.6a}
$$

with the expressions for ${}_2\lambda_{\pm j}$ obtained in a similar fashion. The multiplicity of the second and third eigenvalues in (2.6) may change for p of certain direction and magnitude ($p=(0, 0, \pm1)$). This is important for the application of Lemma 2.2 below. We will refer to ${}_i\lambda_{\pm1}$ (2.6), (2.7) as the quasi-Alfven wave speeds since the constant speed surfaces of these waves have the same relation to the electromagnetosonic constant speed surfaces as do Alfven waves for the MHD slow and fast magnetosonic waves (i.e., roughly speaking, first the fast wave arrives, then the Alfven wave, and finally the slow wave; in the direction of the external field, the Alfven wave may arrive at the same time as either the slow or fast wave depending upon certain relationships of the parameters (see [CH]).

It is evident from (2.6), (2.7) that $A(D)$ is strongly propagative [Wi]. It is instructive to compare this with the MHD case [S2]. For MHD there are (almost everywhere)

three nonzero plane wave speeds, and they are given (using the notation above) by

$$
\begin{aligned}
&{}_3\lambda_0 \equiv 0,\\
&{}_3\lambda_{\pm 1} \equiv \pm p_3,\\
&{}_3\lambda_{\pm 2} \equiv \pm(|p|^2 - |n||p|)^{1/2},\\
&{}_3\lambda_{\pm 3} \equiv \pm(|p|^2 + |n||p|)^{1/2},
\end{aligned}
\tag{2.8}
$$

and

$$
\begin{aligned}
&{}_2\lambda_0 \equiv 0,\\
&{}_2\lambda_{\pm 1} \equiv \pm p_2,\\
&{}_2\lambda_{\pm 2} \equiv \pm(|p|^2 - |n_1||p|)^{1/2},\\
&{}_2\lambda_{\pm 3} \equiv \pm(|p|^2 + |n_1||p|)^{1/2}.
\end{aligned}
\tag{2.9}
$$

Here, if p is orthogonal to B_0 ($=(0, 0, 1)$ or $(0, 1, 0)$ in (2.8) or (2.9), respectively), then $\lambda_{\pm 1,2}$ vanish. $\lambda_{\pm 1,2}$ are the Alfven and slow magnetosonic wave speeds, respectively [CH]. It is instructive to consider the slow magnetosonic speed profile (see Fig. 1) (the normal surface or "slowness surface" [CH], [Wi]) compared to the electromagnetosonic profiles of (2.1) (see Figs. 2, 3, and 4—the grids in these figures are the same relative size). These are just the unit level surfaces of the functions ${}_i\lambda_j(p)$ in p space—in Figs. 2–4, the plane is the p_1p_2 plane, $i = 3$. From Fig. 1 we see the constant speed (normal) surface for the slow magnetosonic wave. It is unbounded (it tends to the direction of the Alfven wave surface (a plane!) to which it is parallel at ∞), while that for the slow electromagnetosonic wave (Fig. 2) is roughly inverse to that of Fig. 1; it is bounded. The quasi-Alfven surface is caught between the slow and fast surfaces just as for MHD (see the illustrations on page 615 of [CH] for a two-dimensional cross

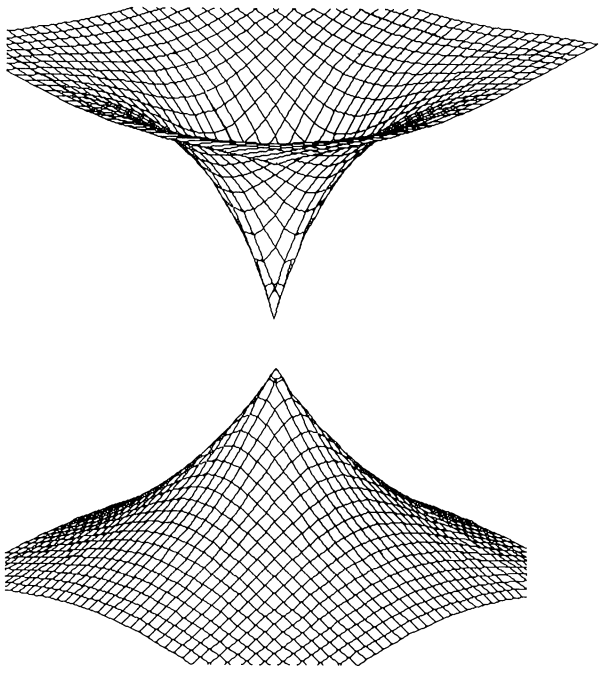

FIG. 1

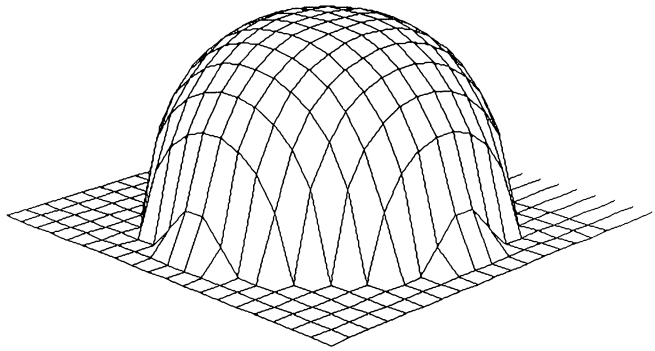

FIG. 2

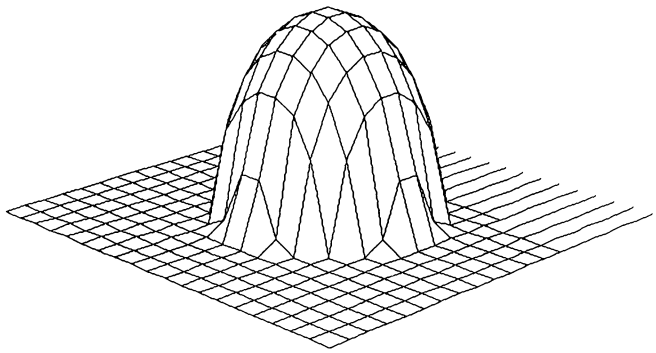

FIG. 3

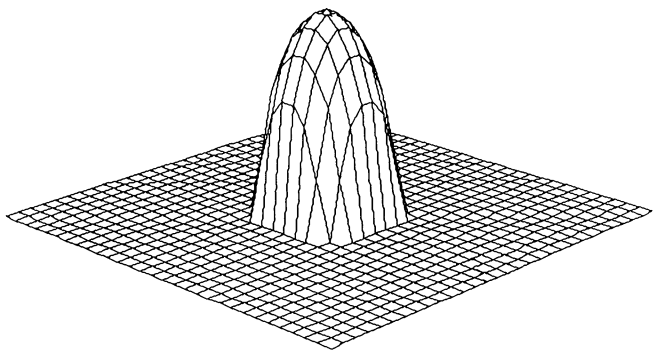

FIG. 4

section for MHD). In our choice of units and external field intensity, the quasi-Alfven surface meets the fast wave surface at the external magnetic axis (vertical in all figures) and is disjoint from the slow wave surface.

By the positive and negative eigenvectors we mean those corresponding to the positive and negative eigenvalues, respectively. Their number depends on B_0.

LEMMA 2.2 [Sc1]. *Let $\mathcal{N}(A(n))$, $\mathcal{X}(n)$, $\mathcal{Y}(n)$ denote, respectively, the null space of $A(n)$, the subspace spanned by the positive eigenvectors of $A(n)$, and the subspace spanned by the negative eigenvectors of $A(n)$. Let ζ_j be any orthonormal base of $\mathcal{N}(A(n))$. Let ξ_j be any base of $\mathcal{X}(n)$ that is orthonormal with respect to $A(n)$, i.e., $\xi_i \circ A(n)\xi_j = \delta_{ij}$, and*

η_j be any base of $\mathcal{Y}(n)$ orthonormal with respect to $-A(n)$ (j as for $\mathcal{X}(n)$). Suppose $\mathcal{S}^{3,2}(n)$ is the subspace of $\mathbb{R}^{10}$ spanned by $\{\zeta_j, \xi_j+\eta_j \text{ (all } j)\}$. Then $\mathcal{S}^{3,2}(n)$ is a maximal conservative boundary space for $A(D)$ and any such boundary space may be constructed in this way.

The lemma is obvious when the eigenvalues of $A(n)$ ($=A_3$, see (2.5)) are computed. (Recall that $n=(0,0,1)$.)

To classify such spaces, we proceed as in [S1] and [S5]. Consider any basis of $\mathcal{X}\oplus\mathcal{Y}$, say for A^3. We have ξ_1, ξ_2, ξ_3 and η_1, η_2, η_3 with $\lambda_1\leftrightarrow\xi_1$, $\lambda_2\leftrightarrow\xi_2$, $\lambda_3\leftrightarrow\xi_3$, etc. Let e_2^1, e_2^2, e_1^3, e_{-2}^1, e_{-2}^2, e_{-1}^3 be any such fixed basis. Then we have

$$
\begin{aligned}
&\eta_i = d_{i1}e_{-2}^1 + d_{i2}e_{-2}^2 \qquad (i=1,2),\\
&\eta_3 = d_3 e_{-1}^3,\\
&\xi_i = c_{i1}e_2^1 + c_{i2}e_2^2 \qquad (i=1,2),\\
&\xi_3 = c_3 e_1^3,
\end{aligned}
\tag{2.10}
$$

In order that the orthonormality conditions be satisfied, it must be that $c_{i1}c_{j1}+c_{i2}c_{j2}=\delta_{ij}$, and thus the matrix $[c_{ij}]$ must be orthogonal and the same is true of $[d_{ij}]$. The constants d_3 and c_3 must have the value 1. Thus by letting $C=[c_{ij}]$ and $D=[d_{ij}]$ run through all possible such matrices, we obtain all possible orientations of the boundary spaces associated with A^3. This allows us to compute operators whose kernels identify the boundary spaces for A^3 (and by a similar process, for A^2). For the details, we refer the reader to [S1] and [Sc1]. In any case, the boundary operators obtained by this process for A^3 consist of two one-parameter families which can be written (here we include the effect of the external field intensity) as

$$
\begin{aligned}
G_{1,\lambda} &= \begin{bmatrix} h_3\lambda & -h_3 & 0 & 0 & 0 & 0 & 0 & 1 & \lambda & 0 \\ 0 & 0 & 0 & 1 & \lambda & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \end{bmatrix},\\
G_{2,\lambda} &= \begin{bmatrix} h_3\lambda & 0 & 0 & 0 & -1 & 0 & 0 & 0 & \lambda & 0 \\ 0 & h_3\lambda & 0 & 1 & 0 & 0 & 0 & -\lambda & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \end{bmatrix}.
\end{aligned}
\tag{2.11}
$$

One thing which is immediately apparent from (2.11) is that for orthogonal external magnetic fields, the fluid density must vanish at the boundary, if the energy is confined to a half space. This has been proposed in the physical literature, see [A] for example. This fact is in contrast to the orthogonal field case in MHD, where the component of velocity orthogonal to the boundary must vanish ([S1] or [S2]) (nothing is required of the density) and the boundary conditions do not depend on the field intensity. $G_{1,\lambda}$ couples the velocity and electric fields at the boundary while $G_{2,\lambda}$ couples all three fields. Neither condition requires anything from the induced field components orthogonal to the boundary.

For the case of the parallel external field, there is but a single boundary condition for which energy is preserved, and it does not depend on the external field intensity. The boundary condition is

$$
G_2 = \begin{bmatrix} 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix}.
\tag{2.12}
$$

Once again we see that the density must vanish at the boundary. The reader should compare (1.7) with the "strange" boundary condition of [Sc2] to see that they are the same, modulo the density term. Again there is no condition on the velocity field, while the magnetic and electric field components in the direction of the external field must vanish at the boundary. The parallel field case in MHD also gives a single energy-preserving boundary condition but there the boundary condition depends on the external field intensity. However (see [S2]), in MHD the density and induced field component in the direction of the external field are coupled at the boundary ($h_2H_2 + r = 0$ at $x_3 = 0$). Thus in the MHD case, if the density does vanish at the boundary, so also must H_2, which is reminiscent of G_2. One other comparison between MHD and the present system should be noted: the modes are uncoupled in the parallel case for MHD (an incident slow wave generates only a slow wave, etc. [S2, Thm. 3.6], and they are here, too.

DEFINITION 2.3. The operators $A^{3,2}$ in $L_2(\mathbb{R}^2 \times \mathbb{R}_+, \mathbb{C}^{10}) = \mathscr{H}$ with their associated boundary spaces $\mathscr{S}^{3,2}$ are defined with domains:

$$D(A^{3,2}) = \{u \mid u, A^{3,2}u \text{ are in } \mathscr{H} \text{ and } G_{i,\lambda}u \text{ or } G_2 u = 0 \text{ if } x_3 = 0 \ (i = 1 \text{ or } 2)\}.$$

The proof of self-adjointness is essentially the same as in Theorem 3.1 of [Sc2] and will not be repeated here. We note the following, which may be proved in a manner similar to that of [Sc1].

THEOREM 2.4. *If u is in $\mathscr{D}(A) \cap \mathscr{N}(A)^{\perp}$, then the D_3 derivative of u lies in $L_2(\mathbb{R}_+, \mathscr{H}^{-1})$ where $\mathscr{H}^{-1}$ is the usual Sobolev space, $u(\cdot, 0)$ is in $\mathscr{S}$ in the $\mathscr{H}^{-1/2}$ sense and there exists a sequence*

$$\{u_k\} \subset \mathscr{H}^1(\mathbb{R}^2 \times \mathbb{R}_+, \mathbb{C}^{10}) \cap C(\mathbb{R}^2 \times (\mathbb{R}_+ \backslash \{0\}), \mathbb{C}^{10}) \cap \mathscr{D}(A) \cap \mathscr{N}(A)^{\perp}$$

such that $u_k(x_1, x_2, 0)$ is in $\mathscr{S}$ (with either orientation), $u_k(\cdot, 0) \to u(\cdot, 0)$ in $\mathscr{H}^{-1/2}$, and $u_k \to u$ in graph norm.

3. Resolvent kernels. The analysis here is based on Stone's theorem for the construction of the spectral family of a self-adjoint operator A in a Hilbert space $\mathscr{H}$ with inner product $(,)$. Let $R(\lambda) = (A - \lambda I)^{-1}$ (the resolvent of A) and let $E(\lambda)$ be the (right continuous) spectral family of A. Then for (a, b) a finite interval and for f, g in $\mathscr{H}$,

$$\begin{aligned} &\left(\frac{(E(b) + E(b-))f}{2} - \frac{(E(a) + E(a-))f}{2}, g \right) \\ &\quad = \lim_{\varepsilon \to 0} \int_a^b ((R(k + i\varepsilon) - R(k - i\varepsilon))f, g) \frac{dk}{2\pi i}. \end{aligned} \tag{3.1}$$

Using the well-known relations (* signifies adjoint operator),

$$\begin{aligned} &R^*(\lambda) = R(\bar{\lambda}), \\ &R(\lambda_1) - R(\lambda_2) = (\lambda_1 - \lambda_2) R(\lambda_1) R(\lambda_2). \end{aligned} \tag{3.2}$$

Using the second equation of (3.2), the integral of the right-hand side of (3.1) may be rewritten as

$$\lim_{\varepsilon \to 0^+} \int_a^b (R(k - i\varepsilon)f, R(k - i\varepsilon)g) \, dk(\varepsilon/\pi). \tag{3.3}$$

Taking $f = g$ and using the first equation of (3.2) we have

$$\left(\frac{(E(b) + E(b-))}{2} f - \frac{(E(a) + E(a-))}{2} f, f \right) = \lim_{\varepsilon \to 0^+} \frac{\varepsilon}{\pi} \int_a^b |R(k - i\varepsilon)f|^2 \, dk \tag{3.4}$$

with $|\cdot|$ representing the norm in $\mathcal{H}$. Equation (3.4) gives (2.1) upon polarization. Therefore, we seek to compute (3.4) for A^3 and A^2. When it is not necessary to distinguish these operators we simply write A.

We will need the Fourier transform. On $\mathcal{S}(\mathbb{R}^n, \mathbb{C}^m)$, the space of smooth, rapidly decreasing $\mathbb{C}^m$-valued functions on $\mathbb{R}^n$, the Fourier transform is defined ($x \circ y = \sum x_i y_i$) as:

$$\Phi_n f(p) = (2\pi)^{-n/2} \int_{\mathbb{R}^n} e^{-ix\circ p} f(x)\, dx \tag{3.5}$$

with $\Phi_n^{-1} = \Phi_n^*$ defined by

$$(\Phi_n^{-1} f)(p) = (\Phi_n f)(-p). \tag{3.6}$$

Φ_n is an isomorphism on $\mathcal{S}$ which extends by duality to $\mathcal{S}'$ the continuous dual of $\mathcal{S}$ and by continuity to $L^2(\mathbb{R}^n, \mathbb{C}^m)$ (see [R], for example). We will employ the notation $\mathcal{H}$ for $L^2(\mathbb{R}^3_+, \mathbb{C}^7)$. Now, using Parseval's formula in the case of Φ_3, (3.4) may be written (here and below, χ_c is the characteristic function of the set c) as

$$\lim_{\varepsilon \to 0^+} \frac{\varepsilon}{\pi} \int_a^b |\Phi_3(\chi_{R^3_+} R(k - i\varepsilon) f)|^2\, dk \tag{3.7}$$

$$= \lim_{\varepsilon \to 0^+} \int_{R^3} \frac{\varepsilon}{\pi} \int_a^b |(\Phi_3 \chi_{R^3_+} R(k - i\varepsilon) f)(p)|^2\, dk\, dp. \tag{3.8}$$

We first wish to obtain

$$\frac{\varepsilon}{\pi} (\Phi_3 \chi_{\mathbb{R}^3} R(k - i\varepsilon) f)(p) \tag{3.9}$$

in a form which can be studied as $\varepsilon \to 0+$. To this end, we need to compute the "resolvent kernel" of $R(\lambda)$. This is a function $R(x, y; z)$ such that for f in $\mathcal{H}$,

$$R(z) f(x) = \int_{\mathbb{R}^3_+} R(x, y; z) f(y)\, dy. \tag{3.10}$$

The idea is to seek $R(x, y; z)$ in the form

$$\mathcal{E}(x - y; z) - F(x, y; z), \tag{3.11}$$

where $\mathcal{E}(x - y; z)$ is a solution in $\mathcal{S}'$ of

$$(A(D) - zI)\mathcal{E}(x; z) = \delta(x) I_{10\times 10}, \tag{3.12}$$

and F satisfies the three conditions:

$$(A(D) - zI) F(x, y; z) = 0, \qquad x, y \in \mathbb{R}^3_+ \text{ (differentiation on } x), \tag{3.13}$$

$$G^i_{\lambda,j} F(x_1, x_2, 0, y; z) = G^i_{\lambda,j} \mathcal{E}(x - y; z)|_{x_3 = 0}, \qquad y \in \mathbb{R}^3_+, \tag{3.14}$$

$$\int_{\mathbb{R}^3_+} F(x, y; z) f(y)\, dy \text{ is in } \mathcal{H} \text{ for } f \text{ in } \mathcal{H}. \tag{3.15}$$

Let us define $A(p)$ to be $\sum A_j p_j$ for all nonzero p in $\mathbb{R}^3$. Then it is clear from our definition of Φ_3 that in $\mathcal{S}'$,

$$\mathcal{E}(\cdot; z) = (2\pi)^{-3/2} \Phi_3^* (A(p) - zI)^{-1} \Phi_3. \tag{3.16}$$

Taking the Fourier transform Φ_2 (on (x_1, x_2)) of (3.13) and (3.14) results in a first-order initial value problem in x_3. To solve this, it is necessary to compute $\Phi_2 G^i_{\lambda,j}\mathscr{E}(x-y; z)|_{x_3=0}$. It is evident that we will need $\Phi_2\mathscr{E}(x-y; z)|_{x_3=0}$ explicitly. In $\mathscr{S}'$ this means the evaluation of the integral (im $(z) \neq 0$) (which may be regarded as a member of $\mathscr{S}'$ or it may be computed in the usual way, by insertion of an appropriate exponential factor $e^{-p_3\varepsilon}\chi_{(0,\infty)}(p_3)$, for example, then letting $\varepsilon \to 0$)

$$(3.17) \qquad (2\pi)^{-2} e^{-iy'\circ n} \int_{-\infty}^{\infty} e^{-iy_3 p_3}[A(n, p_3) - z]^{-1}\, dp_3,$$

where we have used the notation $n = (p_1, p_2)$, $y' = (y_1, y_2)$. This will be done by means of the residue theorem through deforming the integration into the lower half plane. It is therefore necessary to consider the integrand as being extended as a function of p_3 into $\mathbb{C}$; n, z are not zero.

We write $\tau = p_3 + i\alpha$. We must consider the zeros of

$$(3.18) \qquad \det([A(n, \tau) - z])$$

in τ. These occur in the upper and lower half plane at values $\tau_\pm$, respectively. We consider the cases $A = A^3$ and $A = A^2$ separately now. The roots of $\det(A(p) - \lambda I)$ are given by (2.6), (2.7) above.

For $i = 2, 3$ and $j = 0, 1, 2, 3$ let ${}_iP_{\pm j}(p)$ be the associated eigenprojectors on $\mathbb{C}^{10}$ of $A^i(p)$. By the spectral theorem,

$$(3.19) \qquad [A^i(p) - z]^{-1} = \sum_{j=-3}^{3} ({}_i\lambda_j(p) - z)^{-1}\, {}_iP_j(p).$$

We wish to extend (in single-valued fashion) ${}_i\lambda_j(n, p_3)$ to ${}_i\lambda_j(n, \tau)$ and likewise ${}_iP_j(n, p_3)$ to ${}_iP_j(n, \tau)$ so that (3.19) remains valid, with all poles determined by the coefficients $({}_i\lambda_j(n, \tau) - z)^{-1}$. For ${}_i\lambda_{\pm 1}$, ${}_i\lambda_{\pm 2}$ and ${}_i\lambda_{\pm 3}$ we will make branchcuts in the τ plane (see Fig. 5) along the intervals $[(-i\infty, -i\sqrt{(2p_2^2 + p_1^2)}), (i\sqrt{(2p_2^2 + p_1^2)}, i\infty)]$, $[(-i\infty, -i\sqrt{(2p_2^2 + p_1^2)}), (i\sqrt{(2p_2^2 + p_1^2)}, i\infty)]$, $[(-i\infty, -in), (in, i\infty)]$, respectively, for A^2 and $[(-i\infty, -in/\sqrt{2}), (in/\sqrt{2}, i\infty)]$, $[(-i\infty, -in/\sqrt{2}), (in/\sqrt{2}, i\infty)]$, $[(-i\infty, -in), (in, i\infty)]$, respectively, for A^3.

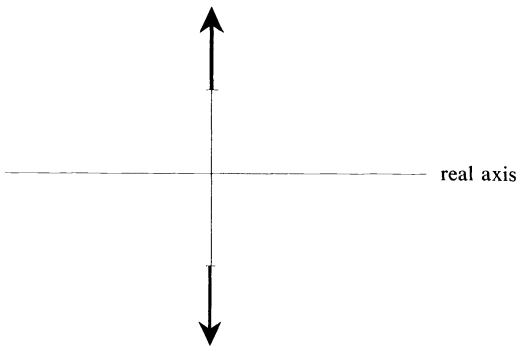

FIG. 5. *τ-plane branchcuts.*

The (τ) zeros of ${}_i\lambda_j(n,\tau)-z$ in the plane are given by

$$
\begin{aligned}
{}_2\tau_{\pm 1} &= \pm(z^2-(2p_2^2+p_1^2))^{1/2},\\
{}_2\tau_{\pm 2} &= \pm\frac{((5z^4-6p_2^2z^2+p_2^4)^{1/2}+3z^2-3p_2^2-2p_1^2)^{1/2}}{\sqrt{2}},\\
{}_2\tau_{\pm 3} &= \pm\frac{(-(5z^4-6p_2^2z^2+p_2^4)^{1/2}+3z^2-3p_2^2-2p_1^2)^{1/2}}{\sqrt{2}},
\end{aligned}
\tag{3.20}
$$

$$
\begin{aligned}
{}_3\tau_{\pm 1} &= \frac{\pm(z^2-n^2)^{1/2}}{\sqrt{2}},\\
{}_3\tau_{\pm 2} &= \frac{((z^4+6n^2z^2+n^4)^{1/2}+3z^2-3n^2)^{1/2}}{2},\\
{}_3\tau_{\pm 3} &= \frac{(-(z^4+6n^2z^2+n^4)^{1/2}+3z^2-3n^2)^{1/2}}{2}.
\end{aligned}
\tag{3.21}
$$

Here branchcuts are made for (3.20) $(A2)$ on the intervals

$$
\begin{aligned}
&[(-\infty,-\sqrt{(2p_2^2+p_1^2)}),(\sqrt{(2p_2^2+p_1^2)},\infty)],\\
&\left[\left(-\infty,\frac{-3n^2-(9n^4-4p_2^2n^2)^{1/2})^{1/2}}{\sqrt{2}}\right),\left(\frac{(3n^2-(9n^4-4p_2^2n^2)^{1/2})^{1/2}}{\sqrt{2}},\infty\right)\right],\\
&\left[\left(-\infty,\frac{(3n^2+(9n^4-4p_2^2n^2)^{1/2})^{1/2}}{\sqrt{2}}\right),\right.\\
&\left(\frac{(3n^2-(9n^4-4p_2^2n^2)^{1/2})^{1/2}}{\sqrt{2}},\frac{(3n^2-(9n^4-4p_2^2n^2)^{1/2})^{1/2}}{\sqrt{2}}\right)\\
&\left.\left(\frac{(3n^2+(9n^4-4p_2^2n^2)^{1/2})^{1/2}}{\sqrt{2}},\infty\right)\right],
\end{aligned}
\tag{3.22}
$$

respectively, and for (3.21) (A^3) we make the branchcuts (see Fig. 6)

$$
\begin{aligned}
&[(-\infty,-n),(n,\infty)]\\
&\left[\left(-\infty,-\left(\frac{3-\sqrt{5}}{2}\right)^{1/2}n\right),\left(\left(\frac{3-\sqrt{5}}{2}\right)^{1/2}n,\infty\right)\right]\\
&\left[\left(-\infty,-\left(\frac{3+\sqrt{5}}{2}\right)^{1/2}n\right),\left(-\left(\frac{3-\sqrt{5}}{2}\right)^{1/2}n,\left(\frac{3-\sqrt{5}}{2}\right)^{1/2}n\right),\left(\left(\frac{3+\sqrt{5}}{2}\right)^{1/2}n,\infty\right)\right].
\end{aligned}
\tag{3.23}
$$

It is easily verified that $\pm\operatorname{im}({}_i\tau_{\pm j})>0$. Using the residue theorem, we obtain for (3.17) the expression (see Fig. 7):

$$
-(2\pi i)^{-1}\,e^{-y'\circ n}\sum_{j=1}^{3}e^{iy_i\tau_j}\,{}_ic_j\,{}_iP_j(n,-{}_i\tau_j,z),
\tag{3.24}
$$

where the expression ${}_ic_j$ is determined by l'Hopital's rule as the reciprocal of

$$
\left.\frac{\partial_i\lambda_j}{\partial\tau}\right|_{\tau={}_i\tau_j}.
$$

The matrices ${}_iP_j(n,-{}_i\tau_j,z)$ are obtained from (3.19) by substitution of ${}_i\tau_j$ for p_3. They are given here (note that in ${}_2P_2$ and ${}_2P_3$, $a_1=s_{12}^2-z^2$, $a_2=s_{12}^2-2z^2$, $a_3=s_{12}^2-3z^2$,

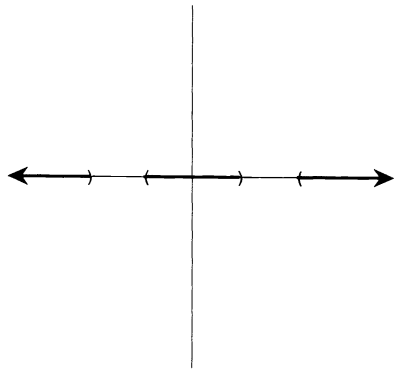

FIG. 6. *z-plane branchcuts (center cut used only for* λ_3*).*

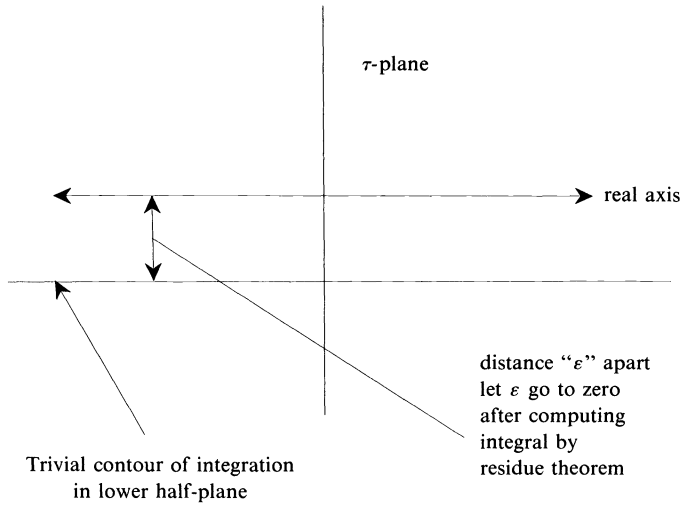

FIG. 7

$b_1 = s_{13}^2 - z^2$, $b_2 = s_{13}^2 - 2z^2$, $b_3 = s_{13}^2 - 3z^2$, $s_{ij} = {}_2\lambda_1({}_i\tau_j)$ and in ${}_3P_2$, ${}_3P_3$, $a_1 = n^2 + {}_3\tau_2^2 - z^2$, $a_2 = 2_3\tau_2^2 + n^2 - 2z^2$, $b_1 = z^2 - {}_3\tau_3^2 - n^2$, $b_2 = 2z^2 - 2_2\tau_3^2 - n^2$, the functions f_{ij} are normalization factors)(see Figs. 8-10).

We are able to write down the resolvent kernel now. First, we note that in the solution of (3.13), (3.14) we have

$$\Phi_{x'}F(n, x_3, y, z) = \frac{-1}{2\pi i} e^{-iy'\circ n} \sum_{j=1}^{3} e^{ix_3 {}_i\tau_j} {}_ic_j \, {}_iP_j \, {}_iM_j,$$

where the matrices ${}_iM_j$ are selected so that (3.14) is satisfied. Generally there are many possible choices for the ${}_iM_j$. The idea is to select the simplest among these for each of the boundary conditions. The ${}_iM_j$ are functions of z, t, n and are bounded except near points z where the so-called Lopatinski determinant vanishes. These (real) points yield the speeds of any surface waves. We discuss this further in the next section. We note that for $h_3 \neq 1$ or $h_2 \neq 1$, the development above is completely parallel except for the explicit formulas of the ${}_ic_j$ and ${}_iP_j$.

DEFINITION. For $k \neq j \neq 0$, let β be the set of points in p space where any ${}_i\lambda_j$ coincides with another ${}_i\lambda_k$. It is easy to see that this is a set of measure zero in p space.

$$

0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}$$

FIG. 10

We may now write down $\Phi_3 \chi_{\mathbb{R}^3_+} R(p, y, z)$ by applying Φ_1 in x_3 to (3.31), using (3.11) to get

$$
\begin{aligned}
&(2\pi)^{-3/2} e^{-iy'\circ n}(e^{-iy_3 p_3}[A^3(p) - zI]^{-1} + \sum_{j=1}^{3} \frac{e^{iy_3 {}_3\tau_j}}{({}_3\tau_j + p_3)} {}_3c_j \, {}_3P_j(n, -{}_3\tau_j, z)) \\
&\quad + 2\pi e^{-iy'\circ n} \sum_{j=1}^{3} \left(\frac{{}_3c_j}{{}_3\tau_j - p_3}\right) {}_3P_j(n, {}_3\tau_j, z) {}_3M_j
\end{aligned} \tag{3.32}
$$

with a completely analogous expression for A^2. Here it is helpful to note that the functions ${}_ic_j$ are not singular. For later reference we also note the facts:

$$
\begin{aligned}
&\text{(i)} \quad \lim_{z \to {}_i\lambda_{kj}(p) \pm i0} {}_i\tau_j(p', z) = \pm k |p_3|, \qquad k = \pm 1, \\
&\text{(ii)} \quad \lim_{z \to {}_i\lambda_{kl}(p) \pm i0} {}_i\tau_j(p', z) \neq \pm k |p_3|, \qquad l \neq j.
\end{aligned} \tag{3.33}
$$

4. Eigenfunction expansions. In the computation of the spectral families of the various operators A^i_λ arising from the different combinations of external fields and boundary conditions, the (first-order) singularities of the resolvent kernel give rise to the terms of the spectral family. These singularities include the eigenvalues ${}_i\lambda_j$ but may also include singularities of the matrices ${}_iM_j$. The singularities of the ${}_iM_j$ are the surface wave speeds and may be computed directly from (3.14). This reduces to the search for real zeros (in z) of the Lopatinski determinant [Wa]. This is defined as follows.

DEFINITION 4.1 (A^3). The Lopatinski determinant is the family of determinants $\det[G_3P_1^j, G_3P_2^k, G_3P_3^l]$. A number $s(n, z)$ is a zero of the Lopatinski determinant if it is a zero for each member of the above family. Here, G is fixed to be one of the A^3 boundary conditions (2.11) and $G_3P_k^j$ is the jth column of G_3P_k. The definition for A^2 is entirely similar.

THEOREM 4.2. *The Lopatinski determinant has no real zeros for either A^3 or A^2, and hence neither of these supports surface waves.*

The proof is rather tedious but is just a matter of finding one of each family of determinants that has no real zeros. We give the computation for A^2 as an example. The matrices G_2P_j, $j = 1, 2, 3$, respectively, are given as in Fig. 11. The Lopatinski determinant is seen to be essentially $a_2 + b_2$. This has no real zeros. In fact, we may give (up to a nice scalar factor determined by (3.14) and (3.31)) the matrices ${}_2M_j$, $j = 1, 2, 3$ (respectively) as

$$
\begin{aligned}
&\text{diag}\,(-1, a, 1, -1, a, 1, a, 1, 1, -1), \\
&\text{diag}\,(1, 1, -1, 1, 1, -1, 1, -1, a, 1), \\
&\text{diag}\,(1, 1, -1, 1, 1, -1, 1, -1, a, 1),
\end{aligned} \tag{4.1}
$$

where "a" means the entry is arbitrary. Combining this with the fact that (1.17) reduces to the Maxwell equations when $V = 0$, and results of [Sc2] together with the remarks above (cf. (2.11)) we have the following corollary.

COROLLARY 4.3. *The presence of surface waves is unstable in a liquid semiconductor modeled by* (1.17) *for either parallel or orthogonal external fields.*

DEFINITION 4.4.

$$
{}_i\psi_j^*(p, y, z^*) = ({}_i\lambda_j(p) - z^*)\chi_{\mathbb{R}^3 \setminus \beta}(p) \Phi_3 \chi_{\mathbb{R}^3_+} R(p, y, z^*), \tag{4.2}
$$

$$
{}_i\hat{f}_j(p, z) = \int_{\mathbb{R}^3_+} {}_i\psi_j^*(p, y, z) f(y)\, dy, \tag{4.3}
$$

$$G_2P_1=\begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ m_1^2p_2\tau_1 & 0 & -n_1^2p_1p_2 & n_1^2\tau_1z & 0 & -n_1^2p_1z & 0 & 0 & -n_1^2\tau_1p_2 & n_1^4 & -n_1^2p_2\tau_1 \end{bmatrix},$$

$$G_2P_2=\begin{bmatrix} a_1a_2^2p_1z & a_1^2a_2p_2z & a_1a_2^2\tau_2z & a_1a_2a_3p_1p_2 & a_1^2a_2^2 & a_1a_2a_3p_2\tau_2 & a_1^2a_2z^2 & -a_1a_2\tau_2z^3 & 0 & a_1a_2p_1z^3 \\ a_1a_2p_1z & a_1^2p_2z^3 & a_1a_2\tau_2z^3 & a_1a_3p_1p_2z^2 & a_1^2a_2z^2 & a_1a_3p_2\tau_2z^2 & a_1^2z^4 & -a_1\tau_2z^5 & 0 & a_1p_1z^5 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix},$$

$$G_2P_3=\begin{bmatrix} b_1b_2^2p_1z & b_1^2b_2p_2z & b_1b_2^2\tau_3z & b_1b_2b_3p_2 & b_1^2b_2^2 & b_1b_2b_3p_2\tau_3 & -b_1^2b_2z^2 & -b_1b_2\tau_3z^3 & 0 & b_1b_2p_1z^3 \\ -b_1b_2p_1z^3 & -b_1^2p_2z^3 & -b_1b_2\tau_3z^3 & -b_1b_3p_1p_2z^2 & -b_1^2b_2z^2 & -b_1b_3p_2\tau_3z^2 & b_1^2z^4 & b_1\tau_3z^5 & 0 & -b_1p_1z^5 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}.$$

FIG. 11

where f is smooth and has bounded support.

Set $k = \pm 1$ and

$$(4.4)\qquad {}_i\psi^*_{kj}(p, y) = \lim_{z \to {}_i\lambda_{kj}(p)+i0} {}_i\psi^*_j(p, y, z)$$

$$(4.5)\qquad \begin{aligned} &= (2\pi)^{-3/2}\chi_{\mathbb{R}^3\setminus\beta}(p)\chi_{\mathbb{R}_{-k}}(p_3)\,{}_iP_j(p) \\ &\quad \times \{e^{iy\circ p}I - {}_iM_j(n, {}_i\lambda_{kj}(p) - i0, y_3)\, e^{-iy'\circ n}\}. \end{aligned}$$

LEMMA 4.5. *If f is smooth and has compact support, then*

$$(4.6)\qquad {}_i\hat{f}_{\pm j}(p) = \lim_{z \to {}_i\lambda_{\pm j}(p)+i0} {}_j\hat{f}_j(p, z) = \int_{\mathbb{R}^3_+} {}_i\psi^*_{\pm j}(p, y) f(y)\, dy$$

defines a function which is smooth and rapidly decreasing almost everywhere.

Proof. Equations (4.2) and (4.5) show that the function on the left-hand side of (4.3) in this case converges by the definition of ${}_iM_j$ and the dominated convergence theorem as indicated. The fact that the Fourier transform of f is smooth and rapidly decreasing together with (4.5) gives the result.

Most of the results in this section are essentially independent of external field direction, at least in their statements. So that the notation does not become unwieldy, we will omit the front subscript from most expressions. The generalized Fourier transforms are defined by (4.6). These will also be denoted by expression Φ. Whether the ordinary or generalized transform is meant should be clear from the context.

LEMMA 4.6.

$$(4.7)\qquad \begin{aligned} &\lim_{\varepsilon\to 0} \int_{\mathbb{R}^3} \frac{\varepsilon}{\pi} \int_a^b |\Phi_3 \chi_{\mathbb{R}^3_+} R(k - i\varepsilon) f(p)|^2\, dk\, dp \\ &\quad = \int_{\mathbb{R}^3_+} \lim_{\varepsilon\to 0^+} \frac{\varepsilon}{\pi} \int_a^b |\Phi_3 \chi_{\mathbb{R}^3_+} R(k - i\varepsilon) f(p)|^2\, dk\, dp. \end{aligned}$$

There is no problem in switching the order of integration for positive e, since the integrand is continuous in k and measurable in p and nonnegative. The proof of this lemma is tedious but straightforward.

THEOREM 4.7.

$$(4.8)\qquad \lim_{\varepsilon\to 0^+} \frac{\varepsilon}{\pi} \int_a^b |\Phi_3 \chi_{\mathbb{R}^3_+} R(k - i\varepsilon) f(p)|^2\, dk = \sum_{j\neq 0} \chi_{\lambda_j(p)\in(a,b)}(p) |\hat{f}_j(p)|^2$$

for all f in the orthogonal complement of the null space of A^i.

THEOREM 4.8. *The modes of propagation are uncoupled for A^2 and for A^3 with type* II *boundary at $\lambda = \infty$. For A^3 with type* II *boundary at $\lambda = 0$, the quasi-Alfven mode is uncoupled.*

Proof of Theorem 4.7. We apply the classical elementary fact:

$$(4.9)\qquad \lim_{\varepsilon\to 0^+} \frac{\varepsilon}{\pi} \int_a^b \frac{f(x)}{(k-x)^2 + \varepsilon^2}\, dk = \chi_{(a,b)}(x) f(x)$$

for any continuous f.

For $p \notin \beta$, and δ small, the sets

$$(4.10)\qquad \Delta_j = (a, b) \cap (\lambda_j(p) - \delta, \lambda_j(p) + \delta)$$

are pairwise disjoint. Making the appropriate substitution for f above, we have $(z^* = k - i\varepsilon)$

$$(4.11)\qquad \sum_j \lim_{\varepsilon\to 0^+} \frac{1}{\pi}\int_{\Delta_j} \frac{\varepsilon}{(\lambda_j(p)-k)^2+\varepsilon^2}|(\lambda_j(p)-z^*)\Phi_3\chi_{\mathbb{R}^3_+}R(k-i\varepsilon)f(p)|^2\,dk$$

from which the result follows.

Proof of Theorem 4.8. Here we must use (3.14) to obtain the equations for M_j as follows:

$$(4.12)\qquad \sum_{j=1}^{3} G(e^{iy_3\tau_j}c_j(-\tau_j)P_j(n,-\tau_j,z)-c_jP_j(n,\tau_j,z)M_j)=0.$$

Now from (4.5) it follows that one mode is uncoupled from the others when M_j can be found for that j so that

$$(4.13)\qquad G(e^{iy_3\tau_j}c_j(-\tau_j)P_j(n,-\tau_j,z)-c_jP_j(n,\tau_j,z)M_j)=0.$$

The result for A^2 now follows from (4.1) and for A^3, $\lambda=\infty$,

$$\begin{aligned}&\text{diag}\,(1,1,a,-1,-1,a,a,1,1,-1),\\ &\text{diag}\,(1,1,-1,-1,-1,1,1,1,1,a),\\ &\text{diag}\,(1,1,-1,-1,-1,1,1,1,1,a),\end{aligned}\qquad(4.14)$$

and for $\lambda=0$ for

$$(4.15)\qquad \text{diag}\,(-1,-1,1,1,a,a,-1,-1,1).$$

To check that coupling occurs for the other boundary conditions is a straightforward computation and is omitted.

In order to continue, we must define the null spaces associated with the operators A^2 and A^3. These null spaces are determined, respectively, by the sums of two collections of orthoprojectors given by the pseudodifferential operator kernels

$$(4.16)\qquad {}_2P_{01}=\frac{1}{p^2}(0,0,0,p_1,p_2,p_3,0,0,0,0)\otimes(0,0,0,p_1,p_2,p_3,0,0,0,0),$$

$$(4.17)\qquad {}_2P_{02}=\frac{1}{p^2}(0,0,0,0,0,0,0,p_1,p_2,p_3)\otimes(0,0,0,0,0,0,0,p_1p_2,p_3),$$

$$(4.18)\qquad {}_2P_{03}={}_2m_3\otimes{}_2m_3,$$

$$(4.19)\qquad {}_2P_{04}={}_2m_4\otimes{}_2m_4,$$

where

$$(4.20)\qquad {}_2m_3=(-p^2p_2p_3,p^2p_1p_3,0,0,0,0,0,p_1p_2p_3^2,p_2^2p_3^2,-n^2p_2p_3)/({}_2\lambda_1 p|p_3|n),$$

$$(4.21)\qquad {}_2m_4=(-p_1^2p_3,-p_1p_2p_3,n^2p_1,0,0,0,0,-p_1p_2^2,p_1^2p_2,0)/({}_2\lambda_1 n|p_1|),$$

and for A^3

$$(4.22)\qquad {}_3P_{01}={}_2P_{01},$$

$$(4.23)\qquad {}_3P_{02}={}_2P_{02},$$

$$(4.24)\qquad {}_3m_3=(-p^2p_2,p^2p_1,0,0,0,0,0,p_1p_3^2,p_2p_3^2,-n^2p_3)/({}_3\lambda_1 np),$$

$$(4.25)\qquad {}_4m_4=(-p_1^2p_3,-p_1p_2p_3,n^2p_1,0,0,0,0,-p_1p_2p_3,p_1^2p_3,0)N({}_3\lambda_1 n|p_1|),$$

From this we see that the usual Maxwell divergence equations continue to hold for B and E' for both A^2 and A^3. The other two auxiliary conditions are more complex, relating E' and V.

Defining ${}_2P_0 = {}_2P_{01} + {}_2P_{02} + {}_2P_{03} + {}_2P_{04}$ and similarly for ${}_3P_0$, we obtain the following result.

THEOREM 4.9. *If $g, h \in (I - P_0)\mathscr{H}$ then*

$$(E(I)g, h) = \sum_{j \neq 0} \int_{\mathbb{R}^3} \chi_{(\lambda_j(p) \in I)}(p) \hat{g}_j(p)^* \hat{h}_j(p)\, dp, \tag{4.26}$$

where E is the spectral family for A and I is any subinterval of $\mathbb{R}$.

Proof. This follows from (4.9) and the polarization identity. (See Lemma 4.5 for the notation $\hat{}$.) We can define the generalized transforms now.

DEFINITION 4.10. For $g \in \mathscr{D}(\mathbb{R}^3_+)$ define

$$\Phi_j g(p) = \hat{g}_j(p) \tag{4.27}$$

and by Theorem 4.9 extend to all of $\mathscr{H}$. The adjoints of the maps Φ_j are given by

$$\Phi_j^* f(x) = \int_{\mathbb{R}^3} \psi_j^{**}(p, x) f(p)\, dp. \tag{4.28}$$

This follows easily for functions in $\mathscr{D}$ by definition and the general case follows by extension. The maps Φ_j yield the reduction of the unitary groups e^{-itA^i}. To check that they are orthogonal in the sense that the range of Φ_j^* is in the null space of Φ_j, $k \neq j$, suppose f is smooth and rapidly decreasing. Then the expression

$$\begin{aligned} \Phi_j f(r) &= \int_{\mathbb{R}^3_+} \psi_j^*(x, r) f(x)\, dx \\ &= (2\pi)^{-3/2} \chi_{\mathbb{R}^3 \setminus \beta} \chi_{\mathbb{R}}(r_3) P_j(r) \int_{\mathbb{R}^3_+} \{e^{-ix \circ r} I - M_j(r)\, e^{-ix' \circ r'}\} f(x)\, dx \end{aligned} \tag{4.29}$$

makes sense pointwise and further (here we have assumed $j, k > 0$),

$$\begin{aligned} \Phi_k^* g(x) &= \int_{\mathbb{R}^3} \psi_k^{**}(x, s) g(s)\, ds \\ &= (2\pi)^{-3/2} \int_{\mathbb{R}^3} \chi_{\mathbb{R}_-}(s_3) \chi_{\mathbb{R}^3 \setminus \beta}(s) \{e^{ixs} I - e^{ix' \circ s'} M_k^*(s) P_k(s) g(s)\, ds \end{aligned} \tag{4.30}$$

is a smooth rapidly decreasing function if g is, and if g vanishes in a neighborhood of β for a fixed p on a neighborhood of the set of s such that $\lambda_k(s) = \lambda_j(p)$. If F satisfies this condition, then $g(s) = F(s)/(\lambda_j(p) - \lambda_k(s))$ also satisfies the same condition.

Let $\mathscr{D}_1 = \{f \in \mathscr{D}(\mathbb{R}^3, \mathbb{C}^7) \mid \beta \cap \operatorname{supp}(f) = \varnothing\}$. Fix $F \in \mathscr{D}_1$ and $p \in \mathbb{R}^3$, and set $g(s)$ as above; $g \in \mathscr{D}_1$. Then $\Phi_k^* g$ is smooth, rapidly decreasing, and satisfies the boundary conditions and so is in the domain of A, and $A\Phi_k^* g = \Phi_k^* \lambda_k(\cdot) g$. Hence $\Phi_j A \Phi_k^* g = \Phi_j \Phi_k^* \lambda_k(\cdot) g$. But also $\Phi_j A \Phi_k^* g = \lambda_j(p) \Phi_j \Phi_k^* g(p)$. Subtracting, we obtain $\Phi_j \Phi_k^* F(p) = 0$. Since p is arbitrary and $\mathscr{D}_1$ is dense, this proves the required relation.

It follows from the preceding that the maps $[{}_i\Phi_j^*\, {}_i\Phi_j]$ are projections on $\mathscr{H}$.

In a similar way, we may show the spectral representation

$$e^{-itA^i} f = \sum_{j \neq 0} {}_i\Phi_j^*\, e^{-i|p|t}\, {}_i\Phi_j f. \tag{4.31}$$

The theory of potential scattering in a half-space may be studied for the operators A^i. We will not do this here. The interested reader may consult Theorems 3.8–3.10 of [S2], where this was done in the perfect conductor case. The method is entirely similar for the present problem. Instead, we take up the problem of when $\sigma = \sigma(x)$, or $\sigma = \sigma(t, x)$ is nonzero but decays at infinity in an appropriate sense. The case of σ that do not decay will be studied elsewhere.

5. Variable conductivity. We now wish to consider the problem of nonvanishing conductivity which may vary in space and/or time. First we consider the spatial variation only. We allow for possible anisotropy of the medium.

Assumption. Let $\sigma(x)$ be any two-tensor of dimension 3 whose components σ_{ij} $(i, j = 1, 2, 3)$ are almost everywhere uniformly bounded and satisfy the condition

$$|\sigma_{ij}(x)| < 0(|x|^{-1-\varepsilon}) \quad \text{as } |x| \to \infty \tag{5.1}$$

for some $\varepsilon > 0$.

We wish to study the operator determined by the right-hand side of (2.2) but where $B = i[\sigma_{ij}]$. We write $\Lambda(D, x)u = A(D)u + B(x)u$, where $A(D)$ is given by the first terms on the right side of (2.2). It is easily established that $\Lambda(D, x)$ is maximal dissipative in $L^2(\mathbb{R}^3, \mathbb{C}^{10})$. We will show that steady-state solutions of

$$-i\frac{\partial u}{\partial t} = \Lambda(D, x)u \tag{5.2}$$

exist in certain weighted spaces when the initial disturbance lies in the dual of the given weighted space. The interesting concept of "spectral barrier" arises here (see the appendix of [S3]).

We define the weighted spaces $L_{2,\alpha}(\mathbb{R}^3, \mathbb{C}^{10})$ as

$$L_{2,\alpha}(\mathbb{R}^3, \mathbb{C}^{10}) = \left\{ f \,\middle|\, \int_{\mathbb{R}^3} (1+|x|^2)^{\alpha} |f(x)|^2 \, dx < \infty, \, f : \mathbb{R}^3 \to \mathbb{C}^{10} \right\}.$$

It is noted here that the λ_j satisfy the "strongly propagative" hypothesis (λ_j is either bounded away from zero or is identically zero—see [Wi]).

The steady-state form of (5.2) at frequency λ is given by

$$A(D)u + B(x)u - \lambda u = f, \tag{5.3}$$

where f is assumed to belong to $L_{2,\alpha}$ with $\alpha > \frac{1}{2}$ and u is sought in a space $L_{2,-\beta}$, $\beta > \frac{1}{2}$. Note that $L_{2,-\beta} \supseteq L^2 \supseteq L_{2,\alpha}$. Note that B, considered as a multiplication operator, maps $L_{2,-\beta}$ to $L_{2,\alpha}$ if α and β are sufficiently close to $\frac{1}{2}$ (we will assume they are from now on). We will use the notation $\mathbb{C}^{\pm} = \{z \in \mathbb{C} \mid \pm\text{imaginary part of } z > 0\}$. Without loss of generality, we may assume $A(D) = A^3(D)$ by choice of coordinates since we are working in all of $\mathbb{R}^3$. Let $P_1 = I - {}_3P_0$, $P_0 = {}_3P_0$ in L^2. Assume $\lambda \in \mathbb{C}^{\pm}$ and operate on both sides of (5.2) with $(A(D) - \lambda I)^{-1}$ in the sense of L^2. This makes sense because $A(D)$ is self-adjoint. From (2.9) of [We] we may conclude that $P_1(A(D) - \lambda I)^{-1}$, thought of as mapping $L_{2,\alpha}$ to $L_{2,-\beta}$ is continuous in $\mathbb{C}^{\pm}$ and has continuous extensions $P_1(A(D) - \lambda I)_{\pm}^{-1}$ to the closure of $\mathbb{C}^+$ or $\mathbb{C}^-$ (i.e., down to or up to the real axis), that assume compact values as operators from $L_{2,\alpha}$ to $L_{2,-\beta}$. P_0 has a bounded extension to $L_{2,-\beta}$. We may "solve" for u now when λ is real as

$$u_{\pm}(x, \lambda) = (I - P_0(B/\lambda) + \lambda P_1(A(D) - \lambda I)_{\pm}^{-1}(B/\lambda))^{-1}(A(D) - \lambda I)_{\pm}^{-1} f.$$

The Fredholm theory (see [S4], for example) now allows us to say $u_{\pm}$ exists (in $L_{2,-\beta}$) when $|\lambda|$ is sufficiently large. (There may be some other exceptional values of λ besides

the "small" values for which a solution fails to exist—these form a countable nowhere dense set of linear measure zero [S4].) The difficulty for small λ is that the operator $(I - P_0(B/\lambda))^{-1}$ may not exist. In fact, using the explicit formula for P_0 given above, it is possible to construct examples exhibiting this difficulty. $u_\pm$ exists provided λ does not belong to the set of exceptional values or to the spectrum of P_0B (the spectrum of P_0B is the "spectral barrier."

For $\sigma = \sigma(t, x)$, a similar technique can be employed. We quote the following result from [S3, Thm. 4.2], adapted to the present situation.

THEOREM 5.1. *Suppose $B(t, x)$ is measurable in (t, x) and $t \to B(t, x)$ is a continuous map from $\mathbb{R}$ to the set of bounded operators on L^2. If $|B(t, x)| \leqq C(1+|t|)^{-1-\varepsilon}$ $(\varepsilon > 0)$ then for any $f(t, x)$ in the space $L_{2,\alpha}(\mathbb{R}, L^2(\mathbb{R}^3, \mathbb{C}^{10}))(\alpha > \frac{1}{2})$ there is a solution $u(t, x)$ of*

$$-i\frac{\partial u}{\partial t} = \Lambda(D, x)u + f(t, x)$$

in the space $L_{2,-\beta}(\mathbb{R}, L^2(\mathbb{R}^3, \mathbb{C}^{10}))$.

In fact, since the medium is a semiconductor, we may assume that C in the statement of Theorem 5.1 is small. In that case, the continuity hypothesis on B may be discarded (see Theorem 4.1 of [S3]).

Acknowledgment. The author would like to thank the referees for many helpful comments and corrections.

QUALITATIVE THEORY OF THE CAUCHY PROBLEM FOR A ONE-STEP REACTION MODEL ON BOUNDED DOMAINS*

JOEL D. AVRIN†

Abstract. A system of reaction-diffusion equations on a bounded domain arising as a model of laminar flames in a premixed reactive gas is considered. The equations couple the temperature T and the concentration Y subject to Arrhenius kinetics. After establishing the existence of unique global strong solutions for arbitrary nonnegative initial data in L^p, the bulk of the paper is devoted to an examination of the qualitative behavior of solutions subject to various boundary conditions, showing in particular that both T and Y remain bounded in most of the cases discussed.

In the no-flux case in which both T and Y satisfy zero Neumann boundary conditions, it is shown that if the average of the initial temperature over the domain is larger than ignition temperature, then eventually T is uniformly above ignition temperature and Y eventually decays exponentially to zero. This situation is called complete asymptotic burning, and an example is given to show that it does not always occur if the averaging condition is not met; if Q is the chemical heat release it is in fact shown in the case of equal diffusion coefficients that there exist parameters Q^* and Q_* with $Q_* \leqq Q^*$ such that complete asymptotic burning or eventual flame quenching occurs if, respectively, $Q > Q^*$ or $Q < Q_*$. In this case convergence to constant steady states is also established if $Q > Q^*$ or $Q < Q_*$.

For T satisfying fixed Dirichlet boundary conditions an example of complete asymptotic burning, and an example of flame quenching in at least portions of the domain are constructed. When Y satisfies fixed Dirichlet boundary condtions, cases are constructed where Y is bounded away from zero in portions of the domain if a certain parameter appearing in the Arrenius rate law is small enough.

Key words. laminar flames, boundary conditions, complete asymptotic burning, flame quenching

AMS(MOS) subject classifications. 35B40, 35K57, 80A25

1. Introduction. For the one-step reaction $A \to B$, let $Y = Y(x, t)$ denote the concentration of A and let $T = T(x, t)$ denote the temperature, where for a spatial domain Ω and time t we have $(x, t) \in \Omega \times \mathbb{R}^+$. The following reaction-diffusion equations model the dynamic interaction of T and Y subject to first-order Arrhenius kinetics:

$$T_t = d_0 \Delta T + QYf(T), \tag{1.1a}$$

$$Y_t = d_1 \Delta Y - Yf(T). \tag{1.1b}$$

Here d_0, d_1, and Q are positive constants, with d_0 and d_1 representing the thermal and mass diffusivities, respectively, while Q is proportional to the chemical heat release. For positive constants B and E, $f(T)$ is given by the usual Arrhenius rate law

$$f(T) = \begin{cases} 0, & T \leqq T_I, \\ B \exp\left(-E/(T - T_I)\right), & T > T_I \end{cases} \tag{1.2}$$

where the nonnegative constant T_I represents the ignition temperature. Here B is the preexponential factor and E is proportional to the activation energy. For a physical background of these equations, see Williams [22].

With f as in (1.2), the system (1.1) has appeared in a variety of contexts. For the case $\Omega = \mathbb{R}$, traveling wave solutions have been studied as models of propagating flame fronts. Existence of traveling wave solutions was established in [5] for $T_I > 0$ (for the case $T_I = 0$, see [13], [14], [20]). It is interesting to note that for Lewis number $L = d_1/d_0$ far from one, these solutions are known to be unstable. This fact was shown by formal

asymptotics in [18] and [6], and a rigorous proof has recently been found [21]. Meanwhile the solutions have been shown to be stable for L close to one [18], [6]. As traveling wave solutions are not stable in all cases, it is worthwhile to consider the Cauchy problem for (1.1) on $\Omega = \mathbb{R}$ with arbitrary initial data. Basic qualitative theory is obtained for the Cauchy problem for wide classes of initial data in [4], [12], and [17] with some overlap of results (see, e.g., §§ 2–5 of [4] and § 2 of [17]).

Additional qualitative theory is developed in §§ 6 and 7 of [4], in which the important case of ignition at one end only is treated. It is shown in § 6 of [4] that if the average of the initial temperature values at $+\infty$ and $-\infty$ is above ignition temperature, then on any ray coming from the ignition end the temperature is eventually uniformly above ignition temperature and the concentration decays uniformly to zero. As this ray can be continually enlarged by making t large enough, a rough sense of flame propagation is thus obtained. If the "averaging condition" on the initial temperature is not met, examples of both flame propagation or flame quenching can be constructed (see § 7 of [4]).

In this paper we consider the system (1.1) when Ω is a bounded domain in $\mathbb{R}^n$, $n \geqq 1$, with the usual smoothness assumptions on the boundary Γ. Various numerical studies exist [19] and for the steady-state problem for a porous pellet with exothermic reaction asymptotic solutions were derived and studied in [10]. We consider here the Cauchy problem for (1.1) with various boundary conditions and arbitrary nonnegative initial data in $L^p(\Omega)$ for any real $p > 1$. After establishing the existence and uniqueness of global strong solutions we will examine their qualitative behavior.

Consider first the case of zero Neumann boundary conditions for both T and Y, i.e., $\partial T/\partial \nu = \partial Y/\partial \nu = 0$ on Γ, where ν is the outward normal. Let T_{AV} denote the average of the initial temperature $T(x, 0) \equiv T_0(x)$ over Ω, i.e.,

$$T_{AV} = \frac{1}{|\Omega|} \int_\Omega T_0(x)\, dx \tag{1.3}$$

where $|\Omega|$ is the volume of Ω. We will show that if $T_{AV} > T_I$ then eventually T is uniformly above ignition temperature and Y eventually decays exponentially to zero. We will refer to this phenomenon as complete asymptotic burning. If $T_{AV} < T_I$, we will show that complete asymptotic burning still occurs if the initial data $Y_0(x)$ for Y is bounded from below by a positive constant and Q is large enough. In the case where $d_0 = d_1$ and with $T_{AV} < T_I$ we will show that eventual uniform flame quenching occurs (i.e., T is eventually uniformly below T_I) if Q is small enough. When $T_{AV} < T_I$, $d_0 = d_1$, and $Y_0(x)$ is bounded below by a positive constant we will show that there exist positive numbers Q_* and Q^* with $Q_* \leqq Q^*$ such that complete asymptotic burning occurs whenever $Q > Q^*$ while eventual flame quenching occurs if $Q < Q_*$.

The assumption $d_0 = d_1$ makes it easy for us to establish steady-state convergence results in these cases of complete asymptotic burning or flame quenching. If $T_{AV} > T_I$ not only does $Y(t)$ converge uniformly to zero, but $T(t)$ converges uniformly to the average of $T_0 + QY_0$ on Ω. If $T_{AV} < T_I$ and we add the assumption that $Y_0(x) \geqq \gamma$ for some $\gamma > 0$, then, as noted above, there exists a constant Q^* such that $Q > Q^*$ implies complete asymptotic burning and a constant Q_* such that $Q < Q_*$ implies eventual flame quenching; thus if $Q > Q_*$ the steady-state convergence is the same as in the case $T_{AV} > T_I$. If $Q < Q_*$ we will show that there exist constants T_1 and Y_1 such that $T(t)$ and $Y(t)$ converge to T_1 and Y_1, respectively; moreover, the averages of $T_1 + QY_1$ and $T_0 + QY_0$ over Ω are equal.

Our results for these boundary conditions closely parallel the results in [4] for the case $\Omega = \mathbb{R}$. In fact, our results here are somewhat better as we are able to show

that T is bounded as well as Y when $T_{AV} > T_I$, and we obtain a uniform exponential decay estimate for Y in that case.

Specializing to the case where $T_I = 0$ we note that unless T_0 is zero throughout Ω we have that $T_{AV} > 0$. Hence, whenever we have nontrivial solutions in the case $T_I = 0$, we have that $T_{AV} > T_I$, so that regardless of all other parameters (e.g., Q) $T(t)$ remains bounded for all $t \geqq 0$ and Y decays exponentially to zero. Our results in this case relate somewhat to those in [15], in which the examples treated include the system (1.1) with $T_I = 0$ in (1.2) and $Yf(T)$ is replaced by the more general case $Y^p f(T)$ where p is a positive integer. Marion shows that there exists a maximal attractor which attracts the bounded sets of $L^2(\Omega)$, and she estimates the fractal Hausdorff dimensions of this attractor (the attractor is compact in L^2 and bounded in the closed subset of H^1 appropriate for the boundary conditions). These results also hold in the case of periodic or zero Dirichlet boundary conditions, so there is also some relationship with our results described below.

Consider next the assumptions that T satisfies a fixed Dirichlet boundary condition and Y satisfies either a zero Neumann boundary condition or a fixed Dirichlet condition on Γ. The boundary condition on T corresponds physically to the case of an exothermic reaction in which the exterior heat source is fixed. Meanwhile the boundary conditions for Y correspond, respectively, to the no-flux case mentioned earlier and physical situations of which the permeable pellet as studied in [10] is a special case.

For these situations we will show that both T and Y remain bounded for all time; moreover, if the values of T on Γ are uniformly above ignition temperature and Y satisfies zero Neumann boundary conditions then complete asymptotic burning occurs. This latter condition imposed on the boundary values of T can occur, for example, in engines equipped with a precombustion chamber [19]. If on some nonempty open portions of Γ we have that T is below T_I we will show that if Q is small enough eventual flame quenching occurs in certain portions of Ω. This last result will be obtained regardless of the initial values of T and Y or the boundary conditions on Y.

In our final example we will allow either arbitrary fixed Dirichlet or Neumann conditions for T, and fixed nonzero Dirichlet conditions for Y. For each choice of initial conditions on T and Y we will show that if B is small enough then in portions of Ω Y is bounded uniformly above zero. Thus the rate at which Y burns is small enough to allow the boundary conditions to maintain a positive level for Y in subsets of Ω.

These latter results will be established in § 5 below. The exothermic case mentioned earlier will be handled in § 4, while the case of zero Neumann conditions for T and Y on Γ will be developed in § 3. We begin in § 2 with some preliminary observations and the construction of unique global strong solutions for (1.1).

2. Preliminaries and global existence. Let B_0, B_1 be a pair of boundary value operators; in particular, for $u \in C^2(\Omega)$, $B_i u = 0$ means that u satisfies either zero Dirichlet or zero Neumann boundary conditions, $i = 0, 1$. The indexing will correspond in what follows to the boundary conditions desired for T and Y, respectively. For $i = 0, 1$ set

$$C^2_{B_i} = \{u \in C^2(\Omega) \mid B_i u = 0\}.$$

We will correspondingly write $L^p(\Omega)$ and the usual Sobolev spaces $W^{m,p}(\Omega)$ in the abbreviated form L^p and $W^{m,p}$.

Each of the operators $d_0\Delta$ and $d_1\Delta$ is a continuous linear map from $C^2_{B_i}$ to $C(\Omega)$. It is well known that $C^2_{B_i}$ is dense in L^p for $1 < p < +\infty$ and that the closure of both

of the above operators is well defined and generates an analytic semigroup on L^p, $1<p<+\infty$. These facts are also true when $p=1$ (see, e.g., [3] where this is shown for a general class of second-order elliptic operators). Let A_0 and A_1 denote the closures of $d_0\Delta$ and $d_1\Delta$ in L^1 with domains $D(A_0)$ and $D(A_1)$. It is also shown in [3] that (for $i=0, 1$) $D(A_i)\cap L^p$ is the domain of the closure of the operator $d_i\Delta$ in L^p, $1<p<+\infty$, and A_i restricted to $D(A_i)\cap L^p$ (which we call $A_{i,p}$) equals this closure. We denote the domains $D(A_i)\cap L^p$ by $D_p(A_i)$; meanwhile we will denote the semigroups generated by $A_{0,p}$ and $A_{1,p}$ by $W_0(t)$ and $W_1(t)$. With $B_0T=B_1Y=0$ on Γ the system (1.1) then has the corresponding integral equations

$$T(t)=W_0(t)T_0+Q\int_0^t W_0(t-s)Y(s)f(T(s))\,ds, \tag{2.1a}$$

$$Y(t)=W_1(t)Y_0-\int_0^t W_1(t-s)Y(s)f(T(s))\,ds \tag{2.1b}$$

where $T_0=T(x,0)$ and $Y_0=Y(x,0)$ are in L^p. We have followed the usual convention of suppressing the dependence on x in writing (2.1).

The following existence result for $B_0T=B_1Y=0$ on Γ follows easily by considering the usual types of contraction maps on appropriate metric spaces defined by the right-hand sides of (2.2), once we note that $Yf(T)$ is a globally Lipschitz continuous map in Y and T by l'Hôpital's rule as follows.

THEOREM 2.1. *Let T_0 and Y_0 be in L^p for any $p\in(1,+\infty)$; then there exists an $S>0$ such that* (2.1a), (2.1b) *have unique solutions T, $Y\in C([0,S];L^p)$.*

COROLLARY 2.1. *The mild solutions found in Theorem* 2.1 *are, in fact, global solutions, i.e., T, $Y\in C([0,+\infty);L^p)$.*

Corollary 2.1, in particular, follows easily by exploiting the globally Lipschitz continuous properties of the nonlinearities and employing the usual contradiction argument on the hypothesis that finite-time blowup occurs. Meanwhile, the case of nonzero boundary conditions will be handled later in this section.

The next result establishes regularity for $t>0$; again the proof is straightforward, using standard semigroup techniques and the fact that every derivative of f is continuous and bounded.

THEOREM 2.2. *For each j, $k\geqq 1$ we have that T, $Y\in C^j([0,+\infty);C^k(\bar{\Omega}))\cap C([0,+\infty);L^p)$.*

The proof of the results above, in fact, follow directly from, or are simple adaptations of, the corresponding existence and regularity results found in [4] and [12].

The results summarized in the next theorem hold also when $\Omega=\mathbb{R}$ (see [4, § 2]) and easily follow from the maximum principle (see, e.g., [16]), (2.1a) and (1.2).

THEOREM 2.3. *Let T and Y be as above. If in addition T_0 and Y_0 are nonnegative, then $T(t)$ and $Y(t)$ remain nonnegative for all $t>0$. Also, if T_0, $Y_0\in C(\bar{\Omega})$, then for all $t>0$*

$$\|Y(t)\|_\infty\leqq\|Y_0\|_\infty, \tag{2.2a}$$

$$\|T(t)\|_\infty\leqq\|T_0\|_\infty+Q\|Y_0\|_\infty Bt. \tag{2.2b}$$

We now indicate how to modify Theorems 2.1–2.3 and Corollary 2.1 to handle cases with nonzero boundary conditions (if $n=1$ we do this only for Dirichlet conditions or with the appropriate matching conditions imposed in the Neumann case). Let g and h be measurable (e.g., continuous) functions on Γ such that the elliptic problem $\Delta w=0$ in Ω with respective boundary conditions $B_0w=g$ and $B_1w=h$ on Γ has a

unique strong solution. Denote these solutions by w_0 and w_1, respectively. The corresponding integral equations such that T and Y satisfy these boundary conditions are

$$T(t) = W_0(t)(T_0 - w_0) + w_0 + Q\int_0^t W_0(t-s)\,Y(s)f(T(s))\,ds, \tag{2.3a}$$

$$Y(t) = W_1(t)(Y_0 - w_1) + w_1 - \int_0^t W_1(t-s)\,Y(s)f(T(s))\,ds. \tag{2.3b}$$

Standard regularity theory (see, e.g., [7]) allows us to select g and h smooth enough so that w_0 and w_1 are in $C^k(\bar{\Omega})$ for any given $k \geqq 0$. Then if $W_0(t)T_0$ and $W_1(t)Y_0$ are replaced by $W_0(t)(T_0 - w_0) + w_0$ and $W_1(t)(Y_0 - w_1) + w_1$, respectively, the above existence and regularity techniques apply to (2.3) instead of (2.1) with only minor modification. In this way we obtain the following result.

THEOREM 2.4. *Given an integer $k \geqq 2$ select g and h as above such that $w_i \in C^k(\bar{\Omega})$, $i = 0, 1$. Then for each choice of T_0 and Y_0 in L^p for any $p \in (1, +\infty)$ there exist unique global strong solutions T and Y of (1.1) with $B_0 T = g$ and $B_1 Y = h$ on Γ such that T, $Y \in C^j((0, +\infty); C^k(\bar{\Omega})) \cap C([0, +\infty); L^p)$ for each $j \geqq 1$.*

From the maximum principle, (1.2), and (2.3) we can modify Theorem 2.3 to handle $B_0 T = g$ and $B_1 Y = h$ in the case where B_0 and B_1 are Dirichlet boundary operators on Γ as follows.

THEOREM 2.5. *Let T and Y be as in Theorem 2.4. Then if T_0, $Y_0 \geqq 0$ then $T(t)$, $Y(t) \geqq 0$ for all $t > 0$. If in addition T_0, $Y_0 \in C(\bar{\Omega})$, then for all $t > 0$ and g and h as in Theorem 2.4 with $g \geqq 0$ and $h \geqq 0$ we have that*

$$\| Y(t) \|_\infty \leqq \| Y_0 \|_\infty + \sup_\Gamma h, \tag{2.4}$$

$$\| T(t) \|_\infty \leqq \| T_0 \|_\infty + \sup_\Gamma g + QBt\left(\| Y_0 \|_\infty + \sup_\Gamma h \right). \tag{2.5}$$

3. Zero Neumann boundary conditions for T and Y. Let ν denote the outward normal on Ω; then we assume throughout this section that $B_0 = B_1 = \partial/(\partial\nu)$, i.e.,

$$\frac{\partial T}{\partial \nu} = \frac{\partial Y}{\partial \nu} = 0 \quad \text{on } \Gamma. \tag{3.1}$$

Let T_{AV} be as in (1.3). We first note a fairly standard fact about the Laplace operator with zero Neumann boundary conditions.

PROPOSITION 3.1. *If $B_0 T = \partial T/(\partial\nu) = 0$ on Γ we have that*

$$\lim_{t \to \infty} W_0(t) T_0 = T_{AV} \tag{3.2}$$

uniformly in x.

Proof. For $T_0 \in C^1(\bar{\Omega})$ the result follows from expanding $W_0(t)T_0$ in terms of the eigenfunctions of $-A_{0,2}$. The first term in the expansion is T_{AV}, corresponding to the first eigenfunction $1/|\Omega|$ with eigenvalue zero. The sum of the next terms decays uniformly to zero as $O(\exp(-\lambda_2 t))$, where λ_2 is the first nonzero eigenvalue of $-A_{0,2}$. For $T_0 \in L^p$ with $1 < p < +\infty$, we note that $W_0(t)$ conserves L^1-norms; this can be seen by integrating the heat equation satisfied by $W_0(t)T_0$ on both sides with respect to x, and then applying the divergence theorem (recall that T_0 is nonnegative and $W_0(t)$ is positivity preserving). Thus we can replace T_0 in (3.2) by any $T(t_1)$ with $t_1 > 0$. But $T(t_1)$ is $C^1(\bar{\Omega})$ by parabolic regularity, and thus the result holds for general $T_0 \in L^p$. □

The next proposition asserts that Y decays uniformly to zero exponentially if the temperature starts out uniformly above ignition temperature throughout Ω.

PROPOSITION 3.2. *Let T and Y be as in Theorem* 2.2 *such that* (3.1) *holds. Suppose that there exists an α such that $T_0(x) \geqq \alpha > T_I$ for all $x \in \Omega$. Then for $\beta = f(\alpha)$*

$$\| Y(t) \|_p \leqq \| Y_0 \|_p e^{-\beta t}, \qquad t \geqq 0. \tag{3.3}$$

If in addition $Y_0 \in C(\bar{\Omega})$, then

$$\| Y(t) \|_\infty \leqq \| Y_0 \|_\infty e^{-\beta t}, \qquad t \geqq 0. \tag{3.3a}$$

Proof. Since the integral part of (2.1a) is nonnegative for all $t \geqq 0$, we have that $T(x, t) \geqq \alpha$ for all $t \geqq 0$ and all $x \in \Omega$. Since $f(T)$ is strictly increasing in T for $T > 0$, we thus have that $f(T(x, t)) \geqq f(\alpha) = \beta$ for all $t \geqq 0$ and all $x \in \Omega$. Let $V(t)$ denote multiplication by $f(T(t))$ and let $U(t, s)$ be the fundamental solution generated by the (time-dependent) operator $A_{1,p} - V(t)$, i.e., $U(t, s)$ is the unique operator-valued function satisfying $\partial U(t, s)/(\partial t) = (A_{1,p} - V(t)) U(t, s)$, $U(s, s) = I$ for every $0 \leqq s \leqq t$; we have that $Y(t) = U(t, 0) Y_0$. If $U_\beta(t, s)$ is the fundamental solution generated by $A_{1,p} - V(t) + \beta I$, then

$$\| U_\beta(t, 0) Y_0 \|_p \leqq \| Y_0 \|_p. \tag{3.4}$$

Inequality (3.3) now follows since

$$U(t, 0) = U_\beta(t, 0) e^{-\beta t}. \tag{3.5}$$

If $Y_0 \in C(\bar{\Omega})$ we obtain (3.3a) by replacing p and ∞ in (3.4) and then using (3.5). □

Our main result of this section follows by combining the above propositions.

THEOREM 3.1. *Let T and Y be as in Theorem* 2.2 *such that* (3.1) *holds. Then if $T_{AV} > T_I$ we have that Y eventually decays to zero exponentially; that is, there exists a $t_1 > 0$ and a $\beta > 0$ such that for all $t \geqq t_1$*

$$\| Y(t) \|_p \leqq \| Y_0 \|_p e^{-\beta(t - t_1)}. \tag{3.6}$$

If in addition $Y_0 \in C(\bar{\Omega})$, then for all $t \geqq t_1$

$$\| Y(t) |_\infty \leqq \| Y_0 \|_\infty e^{-\beta(t - t_1)}. \tag{3.6a}$$

Proof. Let α be a constant such that $T_{AV} > \alpha > T_I$. By Proposition 3.1 there exists a $t_1 > 0$ such that $t \geqq t_1$ implies that $(W_0(t) T_0)(x) \geqq \alpha$ for all $x \in \Omega$. Again, from (1.2) and (2.1a) this implies that $T(x, t) \geqq \alpha$ for all $t \geqq t_1$ and all $x \in \Omega$. If we now consider (1.1) with initial data $T(t_1)$, $Y(t_1)$, the inequality (3.6) now follows from Proposition 3.2, noting that $\| Y(t_1) \|_p \leqq \| Y_0 \|_p$ since $U(t, s)$ (as in the proof of Proposition 3.2) is nonexpansive on L^p. If $Y_0 \in C(\bar{\Omega})$ (3.6a) follows similarly, making use of (2.2a). □

The next result asserts that if T_0, Y_0 are in $C(\bar{\Omega})$ then under the above conditions $T(t)$ (as well as $Y(t)$) is bounded for all t.

THEOREM 3.2. *Under the conditions of Theorem* 3.1 *assume in addition that T_0 and Y_0 are in $C(\bar{\Omega})$. Then there exists a constant K such that $\| T(t) \|_\infty \leqq K$ for all $t \geqq 0$.*

Proof. Let t_1 be as in Theorem 3.1. From (2.1a) and (3.6a) we have for $t \geqq t_1$ that

$$\begin{aligned} 0 \leqq T(t) &= W_0(t) T_0 + Q \int_0^{t_1} W_0(t - s) Y(s) f(T(s))\, ds \\ &\quad + Q \int_{t_1}^{t} W_0(t - s) Y(s) f(T(s))\, ds \\ &\leqq \| T_0 \|_\infty + Q \| Y_0 \|_\infty B t_1 + Q \int_{t_1}^{t} \| Y(s) \|_\infty B\, ds \\ &\leqq \| T_0 \|_\infty + Q \| Y_0 \|_\infty B \left[t_1 + \int_{t_1}^{\infty} e^{-\beta(s - t_1)}\, ds \right] \end{aligned} \tag{3.7}$$

$$= \| T_0 \|_\infty + Q \| Y_0 \|_\infty B[t_1 + (1/\beta)].$$

Thus the result is established with K taken as the right-hand side of (3.7). □

Note that Theorem 3.1 asserts that in the case where $T_I = 0$ we have complete asymptotic burning whenever T_0 is nonnegative in Ω and positive on a subset of positive measure in Ω. However, if $T_I > 0$, different results can occur depending on the value of other parameters. We illustrate below with two examples in which eventual flame extinction occurs in the first case for a small enough value of Q and in the second case complete asymptotic burning occurs if Q is large enough.

PROPOSITION 3.3. *Under the conditions of Theorem* 2.3 *with* T *and* Y *satisfying* (3.1), *suppose in addition that* $d_0 = d_1$ *and* $T_{AV} < T_I$; *then for small enough* Q *we have that* $T(t)$ *eventually stays below ignition temperature.*

Proof. From (2.1b) and the nonnegativity of Y and $f(T)$ we have for all $t \geqq 0$ that

$$0 \leqq \int_0^t W_1(t-s)\, Y(s) f(T(s))\, ds \leqq W_1(t)\, Y_0 \leqq \| Y_0 \|_\infty. \tag{3.8}$$

Since $d_0 = d_1$ we have that $W_0(t) = W_1(t)$, hence from (2.1a) and (3.8) it follows that

$$0 \leqq T(t) \leqq W_0(t)\, T_0 + Q \| Y_0 \|_\infty. \tag{3.9}$$

Given γ such that $T_{AV} < \gamma < T_I$, by Proposition 3.1 there exists a t_2 such that $t \geqq t_2$ implies that $W_0(t) T_0 \leqq \gamma$. Thus if Q is such that $Q \| Y_0 \|_\infty < T_I - \gamma$ we have from (3.9) that $T(t) < T_I$ for all $t \geqq t_2$. Thus the proposition is established. □

We next construct a case in which we can have $T_{AV} < T_I$ but complete asymptotic burning prevails if Q is large enough. To simplify the proof, we place some restrictions on the initial data. In this case no restrictions are placed on the diffusion coefficients.

PROPOSITION 3.4. *Under conditions* (3.1) *assume in addition that there exists a constant* $\gamma > 0$ *such that* $Y_0(x) \geqq \gamma$ *for all* $x \in \Omega$. *Assume also that there exists a constant* $\alpha > T_I$ *and a subset* E_0 *of* Ω *such that* E_0 *has positive measure and* $T_0(x) \geqq \alpha$ *for all* $x \in E_0$. *Then if* Q *is large enough we have complete asymptotic burning.*

Proof. Select t_0 small enough so that $t_0 B \| Y_0 \|_\infty \leqq \gamma/2$; then from (1.2), (2.1b), and (2.2a) we have that

$$Y(t) \geqq W_1(t)\, Y_0 - tB \| Y_0 \|_\infty \geqq W_1(t)\, Y_0 - \gamma/2 \tag{3.10}$$

whenever $0 \leqq t \leqq t_0$. Since $W_1(t)$ is positivity preserving we have that $(W_1(t) Y_0)(x) \geqq \gamma$ for all $x \in \Omega$, hence it follows from (3.10) that $Y(x, t) \geqq \gamma/2$ for all $x \in \Omega$, if t is small enough.

Meanwhile, by the continuity of $W_0(t)$ in t, there exist positive constants t_1 and $\alpha_1 > T_I$, and a subset E_1 of E_0 with positive measure, such that $(W_0(t) T_0)(x) \geqq \alpha_1$ for $x \in E_1$ whenever $0 \leqq t \leqq t_1$. Set $\beta_1 = f(\alpha_1)$; then if $0 \leqq t \leqq \min\{t_0, t_1\}$ we have that

$$W_0(t-s)\, Y(s) f(T(s)) \geqq W_0(t-s)[(\gamma/2)\beta_1 \aleph_{E_1}] \tag{3.11}$$

on Ω for all $s \in [0, t]$, where $\aleph_{E_1}$ is the indicator function for E_1. Similarly to the choice of t_1, α_1, and E_1, we can find positive constants $t_2 \leqq \min\{t_0, t_1\}$ and β_2, and a subset E_2 of E_1 with positive measure, such that

$$(W_0(t-s)[(\gamma/2)\beta_1 \aleph_{E_1}])(x) \geqq \beta_2 \tag{3.12}$$

whenever $0 \leqq s \leqq t \leqq t_2$ and $x \in E_2$. Then for all $t \in [0, t_2]$ and all $x \in E_2$ we have from (2.1a), (3.11), (3.12), and the choice of α_1 that

$$T(x, t) \geqq \alpha_1 + Q\beta_2 t. \tag{3.13}$$

Since $T(x, t)$ is bounded below by zero on Ω, we see from (3.13) that by selecting $t = t_2$ and Q large enough we can arrange that

$$\frac{1}{|\Omega|}\int_{\Omega} T(x, t_2)\, dx > T_I. \tag{3.14}$$

Considering (1.1) with initial data $T(x, t_2)$ and $Y(x, t_2)$, we then obtain complete asymptotic burning by Theorem 3.1, which proves the proposition. □

Theorem 3.1 and Propositions 3.3 and 3.4 show that T_{AV} is a "semithreshold parameter." We use this term to describe the fact that when T_{AV} is above the critical value T_I, complete asymptotic burning occurs regardless of all other parameters; when T_{AV} is less than T_I, complete asymptotic burning or eventual flame quenching occurs depending on the other parameters, in particular, depending on Q. In fact, the next result shows that under the above conditions there exists a closed interval $[Q_*, Q^*]$ such that if $Q > Q^*$ we are guaranteed complete asymptotic burning and if $Q < Q_*$ we are guaranteed eventual flame quenching.

THEOREM 3.3. *Under all conditions of Propositions* 3.3 *and* 3.4, *there exists a positive constant* Q^* *such that for every* $Q > Q^*$ *complete asymptotic burning occurs and there exists a positive constant* Q_* *such that for every* $Q < Q_*$ *eventual flame quenching occurs.*

Proof. Set $X = T + QY$; then as in § 7 of [4] we assume, for simplicity, that $d_0 = d_1 = 1$ and rewrite (1.1a), (1.1b) as

$$T_t = T_{xx} + (X - T)f(T), \tag{3.15a}$$

$$X_t = X_{xx}. \tag{3.15b}$$

Here $X(0) = T_0 + QY_0 \equiv X_0$ so that $X(t) = e^{t\Delta}X_0$. Thus we can rewrite (3.15a), (3.15b) as the single equation

$$T_t = T_{xx} + (e^{t\Delta}X_0 - T)f(T). \tag{3.16}$$

Now suppose T' solves (3.15) with X_0 replaced by X_0', with

$$X_0' \geqq X_0. \tag{3.17}$$

Set $\bar{T} = T' - T$; then $\bar{T}$ satisfies

$$\bar{T}_t = \bar{T}_{xx} + V_1(t)\bar{T} + V_2(t) \tag{3.18}$$

where

$$\begin{aligned} V_1(t) &= (X(t) - T)f'(\varphi) - f(T'), \\ V_2(t) &= e^{t\Delta}(X_0' - X_0)f(T'). \end{aligned} \tag{3.19}$$

Here $\varphi = T + \theta(T' - T)$, where $\theta \in (0, 1)$ is chosen so that

$$f(T') - f(T) = f'(\varphi)(T' - T). \tag{3.20}$$

Let $U(t, s)$ be the fundamental solution for the operator $(\cdot)_{xx} + V_1(t)$, then from (3.18) we see that $\bar{T}$ satisfies

$$\bar{T}(t) = U(t, 0)\bar{T}_0 + \int_0^t U(t, s)V_2(s)\, ds \tag{3.21}$$

where $\bar{T}_0 = T_0' - T_0$.

Since $U(t, s)$ is positivity preserving and (3.17) holds, we see that $\bar{T}(t) \geqq 0$ for all $t \geqq 0$ provided $T_0' \geqq T_0$. In particular, if all other parameters remain fixed, replacing Q by Q' in W_0 with $Q' \geqq Q$ implies that $T'(t) \geqq T(t)$.

With all parameters fixed and $d_0 = d_1$, let S^* be the set of all Q such that eventual flame propagation occurs and let S_* be the set of all Q such that eventual flame

quenching occurs. Our two examples in Propositions 3.3 and 3.4 show that both sets are nonempty. Set $Q^* = \inf S^*$ and set $Q_* = \sup S_*$. Our comparison principle that we have just shown for Q then implies the conclusions of the theorem. □

The above proof is basically reproduced from parts of § 7 of [4]. We have included it here for completeness.

We now continue with the case where $d_0 = d_1$ and show that the above results provide a detailed picture of the large-time behavior of T and Y under this assumption. Our next result follows easily from Theorem 3.1 and the proof of Theorem 3.3.

COROLLARY 3.1. *Under the conditions of Theorem* 3.1 *we have that Y converges to zero uniformly in t and T converges uniformly in t to the average of $T_0 + QY_0$ over Ω.*

Proof. From the proof of Theorem 3.3 we have that $T + QY = \exp(t\Delta)(T_0 + QY_0)$. Hence $T + QY$ converges uniformly to the average of $T_0 + QY_0$ over Ω, i.e., the constant obtained by replacing T_0 by $T_0 + QY_0$ in the right-hand side of (1.3). But by Theorem 3.1, $Y(t)$ converges uniformly to zero in t, hence $T(t)$ converges uniformly to this constant, and the proof of the corollary is completed. □

Our final result of this section shows that, when $d_0 = d_1$ and T_0, Y_0 satisfy the (not too restrictive) assumptions of Theorem 3.3, we have a nearly complete portrait of the asymptotic dynamics of the model given by (1.1) if Q is not in the interval $[Q_*, Q^*]$.

THEOREM 3.4. *Let Q_*, Q^* be as in Theorem* 3.3; *then under the conditions of Theorem* 3.3 *we have that if $Q > Q^*$, Y converges uniformly to zero and T converges uniformly to the average of $T_0 + QY_0$ over Ω. If $Q < Q_*$, then there exists a constant $T_1 \leqq T_I$ and a constant Y_1 such that $T(t)$ converges uniformly to T_1 and $Y(t)$ converges uniformly to Y_1. We have that the averages of $T_1 + QY_1$ and $T_0 + QY_0$ over Ω are equal.*

Proof. If $Q > Q^*$, then the result follows by Proposition 3.4 and Corollary 3.1. If $Q < Q_*$ we have that there exists a positive constant t_0 such that $t \geqq t_0$ implies that $T(t) \leqq T_I$. Hence $Y(t)f(T(t)) = 0$ for $t \geqq t_0$. Considering (1.1) with initial data $T(t_0)$, $Y(t_0)$, we thus see that $T(t) = \exp(t\Delta)(T(t_0))$ and $Y(t) = \exp(t\Delta)(Y(t_0))$ for $t \geqq t_0$, and thus we can take T_1 and Y_1 to be the averages of $T(t_0)$ and $Y(t_0)$ over Ω, respectively. That the average of $T_1 + QY_1$ over Ω equals the average of $T_0 + QY_0$ over Ω follows from the opening remarks of the proof of Corollary 3.1. This concludes the proof of the theorem, as well as our discussion of (1.1) with boundary conditions (3.1). □

4. Dirichlet boundary conditions for T. In this section we assume that B_0 is the Dirichlet operator on Γ. Let g and h be nonnegative continuous functions on Γ which are smooth enough so that the desired regularity of Theorem 2.4 holds. We assume throughout this section that the following boundary conditions hold for T and Y:

$$T(x) = g(x), \qquad x \in \Gamma, \tag{4.1a}$$

$$B_1 Y(x) = h(x), \qquad x \in \Gamma \tag{4.1b}$$

where B_1 is either the Dirichlet or Neumann boundary operator; in the latter case we set $h \equiv 0$. Our first task is to show that $T(t)$ is bounded uniformly in t. Recall from Theorem 2.5 that we already have that Y is bounded. Recall from § 2 that A_0 is the closure in L^1 of $d_0\Delta$ on $C^2_{B_0}$, and $A_{0,p}$ is A_0 restricted to $D(A_0) \cap L^p$. Let λ_1 be the first eigenvalue of $-A_{0,2}$. Then $\lambda_1 > 0$ and it is shown in [3] that there exists a constant M such that for all $u \in C(\bar{\Omega})$ and all $t \geqq 0$

$$\| W_0(t)u \|_\infty \leqq M \| u \|_\infty e^{-\lambda_1 t}. \tag{4.2}$$

The next result then follows easily.

THEOREM 4.1. *Let T and Y satisfy* (4.1) *on* Γ *under the conditions of Theorem* 2.5. *In particular, assume that T_0 and Y_0 are in $C(\bar{\Omega})$; then there exists a constant K such that $\|T(t)\|_\infty \leqq K$ for all $t \geqq 0$.*

Proof. From (1.2), (2.3), (2.4), and (4.2) we have that

$$\begin{aligned}\|T(t)\|_\infty &\leqq \|T_0\|_\infty + \sup_\Gamma g + Q\int_0^t \|W_0(t-s)Y(s)f(T(s))\|_\infty\, ds \\ &\leqq \|T_0\|_\infty + \sup_\Gamma g + Q\int_0^t M\|Y(s)f(T(s))\|_\infty\, e^{-\lambda_1(t-s)}\, ds \\ &\leqq \|T_0\|_\infty + \sup_\Gamma g + QMBK_1\int_0^\infty e^{-\lambda_1(t-s)}\, ds \\ &\leqq \|T_0\|_\infty + \sup_\Gamma g + QMBK_1(1/\lambda_1)\end{aligned} \tag{4.3}$$

where K_1 equals the right-hand side of (2.4). The proof is thus established with K as the right-hand side of (4.3). □

THEOREM 4.2. *Under the conditions of Theorem* 4.1 *assume, in addition, that $g(x) > T_I$ for all $x \in \Gamma$, and that B_1 is the Neumann operator; then complete asymptotic burning occurs at a rate which is eventually exponential.*

Proof. As Γ is compact, there exists an $x_0 \in \Gamma$ such that $g(x) \geqq g(x_0) > T_I$ for all $x \in \Gamma$. Set $\alpha_0 = g(x_0)$; then by the maximum principle (see, e.g., [7] or [16]) $w_0(x) \geqq \alpha_0$ for all $x \in \Omega$. Now while $W_0(t)(T_0 - w_0)$ may not always be nonnegative, it goes to zero uniformly by (4.2), thus for any ε_1 such that $0 < \varepsilon_1 < \alpha_0 - T_I$, there exists a t_1 such that $t \geqq t_1$ implies that $\|W_0(t)(T_0 - w_0)\|_\infty < \varepsilon_1$. Set $\alpha_1 = \alpha_0 - \varepsilon_1$; then since $W_0(t)$ is positivity preserving and both Y and $f(T)$ are nonnegative, it follows from (2.3a) that $T(x, t) \geqq \alpha_1 > T_I$ for all $x \in \Omega$ and all $t \geqq t_1$. Set $\beta_1 = f(\alpha_1)$; then as in the proof of Theorem 3.1 it follows that

$$\|Y(t)\|_\infty \leqq \|Y_0\|_\infty\, e^{-\beta_1(t-t_1)} \tag{4.4}$$

for all $t \geqq t_1$. This completes the proof of the theorem. □

To underscore the advantage gain when T is kept above ignition temperature on the boundary, for the last result of this section we consider cases where T is below T_I on some (not necessarily connected) open subset of Γ. Recall that Q is proportional to the chemical heat release; the next theorem shows that eventually no combustion can occur in subsets of Ω of positive measure if Q is small enough.

THEOREM 4.3. *Under the conditions of Theorem* 4.1 *assume, in addition, that $g(x) < T_I$ for x in an open nonempty subset of Γ. Then there exists a set E of positive measure in Ω and a $t_1 > 0$ such that $T(x, t) \leqq T_I$ for all $x \in E$ and $t \geqq t_1$ if Q is small enough.*

Proof. Let K_1 equal the right-hand side of (2.4); then from the proof of Theorem 4.1 and the fact that $W_0(t)(T_0 - w_0) \leqq W_0(t)T_0$, we have that

$$T(x, t) \leqq (W_0(t)T_0)(x) + w_0(x) + QMBK_1(1/\lambda_1) \tag{4.5}$$

where, as before, λ_1 is the first eigenvalue of $-A_{0,2}$. By the continuity of $w_0(x)$ there exists a set of positive measure E_0 in Ω such that $w_0(x) < T_I$ for $x \in E_0$. In particular, there exists a $\gamma < T_I$ and a subset E of E_0 with positive measure such that $w_0(x) \leqq \gamma$ for $x \in E$. For positive ε such that $\varepsilon < T_I - \gamma$, choose t_1 such that $\|W_0(t)T_0\| < \varepsilon$ for all $t \geqq t_1$; then from (4.5) we have that for all $x \in E$ and all $t \geqq t_1$

$$T(x, t) \leqq \gamma + \varepsilon + QMBK_1(1/\lambda_1). \tag{4.6}$$

As $\gamma + \varepsilon < T_I$, it is now clear that if Q is small enough, $T(x, t) \leqq T_I$ for all $x \in E$ and all $t \geqq t_1$, thus completing the proof. □

We note that Theorem 4.3 holds regardless of whether B_1 represents the Dirichlet or Neumann operator, and regardless of the initial conditions T_0 and Y_0. In particular, even if combustion occurs initially throughout Ω, i.e., $T_0(x) > T_I$ for all $x \in \Omega$, we have eventual flame quenching on portions of Ω with positive measure.

5. Examples of maintained concentration levels in Ω. We allow in this section for B_0 to be either the Dirichlet or Neumann operator, and set B_1 to be the Dirichlet operator. Let g and h be nonnegative continuous functions on Γ with enough smoothness for the desired regularity in Theorem 2.4. Thus the boundary conditions assumed in this section are:

$$B_0 T = g \quad \text{on } \Gamma, \tag{5.1a}$$

$$Y = h \quad \text{on } \Gamma. \tag{5.1b}$$

Let λ_1 be the first eigenvalue of $-A_{1,2}$; then as with $A_{0,2}$ in § 4, $\lambda_1 > 0$ and there exists a constant M such that for all u in $C(\bar{\Omega})$

$$\| W_1(t)u \|_\infty \leqq M \| u \|_\infty e^{-\lambda_1 t} \tag{5.2}$$

for all $t \geqq 0$. We now use techniques similar to those in previous sections in obtaining the next result.

THEOREM 5.1. *Under the conditions of Theorem* 2.5 *assume that T and Y satisfy* (5.1) *on Γ. Then if h is strictly positive on a nonempty open subset of Γ, there exists a subset E of Ω with positive measure and constants $\gamma > 0$ and $t_1 > 0$ such that if the preexponential factor B is small enough we have that $Y(x, t) \geqq \gamma$ for all $x \in E$ and all $t \geqq t_1$.*

Proof. Let w_1 be as in Theorem 2.4; then by continuity there exists a subset E_0 of Ω with positive measure such that w_1 is strictly positive on E_0. Hence there exists a subset of E_0 with positive measure and a constant $\gamma_1 > 0$ such that $w_1(x) \geqq \gamma_1$ for all $x \in E$. Given ε such that $0 < \varepsilon < \gamma_1$, there exists by (5.2) a $t_1 > 0$ such that $\| W_1(t) w_1 \|_\infty < \varepsilon$ if $t \geqq t_1$. Then from (2.3b) and (5.2) we have for all $x \in E$ and $t \geqq t_1$ that

$$\begin{aligned} Y(x, t) &\geqq (W_1(t) Y_0)(x) + (\gamma_1 - \varepsilon) - \int_0^t \| W_1(t-s) Y(s) f(T(s)) \|_\infty \, ds \\ &\geqq (W_1(t) Y_0)(x) + (\gamma_1 - \varepsilon) - \int_0^t M \| Y(s) f(T(s)) \|_\infty e^{-\lambda_1 (t-s)} \, ds \\ &\geqq (W_1(t) Y_0)(x) + (\gamma_1 - \varepsilon) - M \left(\| Y_0 \|_\infty + \sup_\Gamma h \right) B \int_0^\infty e^{-\lambda_1 (t-s)} \, ds \\ &= (W_1(t) Y_0)(x) + (\gamma_1 - \varepsilon) - BM \left(\| Y_0 \|_\infty + \sup_\Gamma h \right) (1/\lambda_1). \end{aligned} \tag{5.3}$$

Note that $(\gamma_1 - \varepsilon) > 0$ and $(W_1(t) Y_0)(x) \geqq 0$, so that if we set

$$\gamma = (\gamma_1 - \varepsilon) - BM \left(\| Y_0 \|_\infty + \sup_\Gamma h \right) (1/\lambda_1), \tag{5.4}$$

then if B is small enough we have that $\gamma > 0$ and $Y(x, t) \geqq \gamma$ for all $x \in E$ and all $t \geqq t_1$, as desired. This completes the proof of the theorem. □

Fixed Dirichlet boundary conditions for Y occur, for example, in the case of a permeable pellet, as studied in [10], and in models of a combustible fluid where the burning occurs in a thin layer at the surface of the fluid. Theorem 5.1 shows that if B is small enough then in portions of Ω the rate of burning does not exceed the rate at which the concentration is diffusing in from the boundary.

6. Remarks. We note that the averaging condition $T_{AV} > T_I$ imposed on the initial temperature T_0 in Theorem 3.1 is a reasonable one since in practice T_I is a small number while the burnt temperature is typically very large. The importance of this condition is underscored by Proposition 3.3, in which an example of eventual flame quenching is produced when the averaging condition is not met. T_{AV} is in some sense the analogue of the quantity $(T_0(-\infty)+T_0(+\infty))/2$ considered in [4] with $\Omega=\mathbb{R}$. Note that in both cases imposing the condition that the respective average involving T_0 is above ignition temperature guarantees that eventually $T(x, t) > T_I$ and $Y(x, t) \to 0$ as $t \to \infty$ regardless of the values of all other parameters.

Meanwhile, we note that global existence and uniqueness results have been established for the more general Cauchy problem in $\mathbb{R}$ which couples T and Y with pressure, velocity, and density terms under certain conditions placed on these additional terms [12], [17].

The system (1.1) is a special case of a general class of equations for which boundedness results are already known for Dirichlet and Neumann conditions imposed on both components (see, e.g., [8], [9], [11] and the references contained therein). These results could have been substituted for Theorem 3.2, and for Theorem 4.1 when both T and Y satisfy fixed Dirichlet boundary conditions. Note that Theorem 4.1 holds with mixed conditions, although the techniques in the aforementioned papers can probably be modified to handle this case as well. Our purpose in developing self-contained boundedness results here has been to obtain bounds depending directly on the special structure of (1.1) and (1.2), and to preserve a common thread of argument.

STABILITY ANALYSIS FOR THE SLOW TRAVELING PULSE OF THE FITZHUGH–NAGUMO SYSTEM*

GILBERTO FLORES†

Abstract. This paper is concerned with the existence and stability of the slow traveling pulse for the FitzHugh–Nagumo system $u_t = u_{xx} + u(1-u)(u-a) - w$, $w_t = \varepsilon(u - \gamma w)$. This traveling wave is obtained as a perturbation of the standing wave of the Nagumo equation $u_t = u_{xx} + u(1-u)(u-a)$. Its existence is established by analyzing how the unstable manifold of the origin exits a suitable block. This geometric proof is an alternative approach to the singular perturbation expansion proposed by Casten, Cohen, and Lagerstrom [*Quart. Appl. Math.*, 32 (1975), pp. 335-367], as well as to the existence proof of Hastings [*SIAM J. Appl. Math.*, 42 (1982), pp. 247-260].

The method also allows use of the techniques developed by Evans [*Indiana Univ. Math. J.*, 24 (1985), pp. 193-226] to analyze the spectrum of the variational equation around the traveling wave. It is shown that there is exactly one unstable mode.

Introduction. The FitzHugh–Nagumo system

$$\text{(A)} \qquad \begin{aligned} u_t &= u_{xx} + u(1-u)(u-a) - w, \qquad -\infty < x < \infty, \\ w_t &= \varepsilon(u - \gamma w), \end{aligned}$$

where $0 < a < \frac{1}{2}$, $\varepsilon \geqq 0$, $\gamma \geqq 0$, is a simplified version of the model proposed by Hodgkin and Huxley [12a, b] to describe the conduction of electrical impulses along a nerve axon. The experimental and numerical evidence shows that the voltage travels along the nerve with little distortion of the shape and amplitude, and at nearly constant speed. The mathematical problem is to classify the waveforms and to determine their stability.

This program has been carried out for the Nagumo equation $u_t = u_{xx} + f(u)$, $f(u) = u(1-u)(u-a)$, which corresponds to $\varepsilon = 0$, $w \equiv 0$ in (A). The equation has a front, that is, a traveling wave $\varphi(\xi)$, $\xi = x + ct$, with $\varphi(-\infty) = 0$, $\varphi(+\infty) = 1$. The speed is $c = \sqrt{2}(\frac{1}{2} - a)$. Fife and McLeod [7] proved that this front is globally stable: If the initial datum $u_0(x)$ satisfies $u_0(-\infty) < a < u_0(+\infty)$, then the corresponding solution approaches a translate of the front. The Nagumo equation also has a solitary wave, that is, a wave solution with a single hump and vanishing at $\pm\infty$. Its speed is $c = 0$, so it is a standing wave. It has been established in [9] that the standing wave is a saddle of codimension 1, and that it is a threshold for the steady state $\bar{u} = 1$. The status of the problem for the FitzHugh–Nagumo system and related models will be discussed at the end of the introduction.

In terms of a moving frame $\xi = x + ct$, (A) becomes

$$\text{(B)} \qquad \begin{aligned} u_t &= u_{\xi\xi} - cu_\xi + f(u) - w, \\ w_t &= -cw_\xi + \varepsilon(u - \gamma w). \end{aligned}$$

Traveling waves of (A) correspond to stationary solutions (B). Carpenter [1], Hastings [10], and Langer [14] have proved the existence of a fast traveling pulse, $((u(\xi), w(\xi)) \to (0, 0)$ as $|\xi| \to \infty)$ with speed $c(\varepsilon) = \sqrt{2}(\frac{1}{2} - a) + o(1)$. The construction in Carpenter [1]

and Langer [14] is explicit: for small $\varepsilon > 0$, the fast pulse is a perturbation of a singular orbit formed by piecing together the front of the Nagumo equation with the graph of $w = f(u)$. Jones [13] has proved that this wave is stable under small perturbations. He has shown that the continuous spectrum of the linearization of (B) around the fast traveling wave is contained in a half-plane $\operatorname{Re}(\lambda) < -b^2$, that $\lambda = 0$ is a simple eigenvalue, and that there are no eigenvalues with positive real part.

Using singular perturbations, Casten, Cohen, and Lagerstrom [2], have constructed a series expansion of a slow traveling pulse with $c(\varepsilon) = O(\sqrt{\varepsilon})$, the first term being the standing wave of the Nagumo equation. Hastings [7] has proved the existence of a pulse with $c(\varepsilon) = O(\sqrt{\varepsilon})$. The numerical evidence for this kind of problems suggests that slow waves are unstable.

In this work, the existence of a slow traveling wave ($c(\varepsilon) = O(\sqrt{\varepsilon})$) is proved by the method of isolating blocks, which yields the slow wave as a perturbation of the standing wave for the scalar equation. It is also shown that for small $\varepsilon > 0$, the continuous spectrum of the linearization of (B) around the slow wave lies in a half-plane $\operatorname{Re}(\lambda) < -b^2$, and that there is exactly one positive eigenvalue. The stability analysis in this case is simplified by the fact that the slow pulse is a perturbation of a homoclinic orbit, and by the convergence of the analytic functions determining the point spectrum of the linearization of (B) at the wave to the corresponding function of the reduced equation.

The limit of the fast pulses is a "singular orbit" consisting of heteroclinic orbits and critical points. The behavior of the analytic functions is more complicated (see Jones [13]).

The analogy with the scalar equation suggests that the stable manifold of the slow pulse is a threshold for the nerve impulse: solutions below this manifold should decay, while solutions above it should propagate and approach the fast pulse. The decay of solutions of initial-boundary problems corresponding to small initial data has been proved by Schoenbeck [18] and Weixi [20].

The existence of multiple pulses and infinite trans of the FitzHugh-Nagumo system has been proved by Hastings [10], [11] and Carpenter [1], but there are no results concerning their stability. The situation for the Hodgkin-Huxley equation is the same.

A little more is known about the piecewise linear model introduced by McKean [15], where the cubic is replaced by the broken line $-u + H(u-a)$, H being the Heaviside step function. Rinzel and Keller [17] have proved the existence of solitary waves and some infinite trains. They have also made numerical studies to establish the instability of the slow waves. The existence of multiple pulses was proved by Evans, Fenichel, and Feroe [4]. Feroe [5] proved that the fast pulse is stable, and he has also made numerical studies on the stability of multiple impulses [6]: the fastest is stable, and the others are unstable. The interesting fact is that some unstable modes correspond to growth in the amplitude, and some correspond to the spacing between the pulses. The only analytic results in this direction are bounds on the number of unstable modes of n pulse solutions, which were obtained by Wang [19a, b]: fast n-pulses have at most n unstable modes, slow n-pulses have at least n and at most $2n-1$ unstable modes.

1. Existence of the slow traveling wave. It will be shown that the system for traveling wave solutions of the FitzHugh-Nagumo equation

$$
\begin{aligned}
u' &= v, \\
v' &= cv - f(u) + w, \qquad ' = d/d\xi, \\
w' &= \varepsilon / c(u - \gamma w),
\end{aligned}
\tag{1}
$$

has a homoclinic orbit for $c = O(\sqrt{\varepsilon})$, which is a perturbation of the standing wave of the Nagumo equation.

Let $M = \max\{f'(u): 0 \leqq u \leqq 1\}$; then $\frac{1}{6} < M < \frac{1}{3}$. Choose $\gamma < 1/M$ (so that the origin is the only critical point of (1)), and $\delta > 0$ such that $M + \delta < 1/\gamma$. We will consider parameter values ε, c in the region $\varepsilon \leqq (M+\delta)c^2$. Since $\varepsilon/c \leqq (M+\delta)c$, the (one-dimensional) unstable manifold of the origin for (1), denoted by $U_{\varepsilon,c}(\xi)$, depends continuously on (ε, c) in the region under consideration.

We use the notion of an isolating block as defined in § 1 of Carpenter [1]: equation (1) is the autonomous system $X' = G(X)$, where $X = (u, v, w)$.

DEFINITION. A set B is *block* for (1) if it is homeomorphic to $[0,1]^3$ and there exist C^1 functions $f_1, \cdots, f_6 : \mathbb{R}^3 \to \mathbb{R}$ such that $B = \bigcap_{i=1}^{6} f_i^{-1}([0,\infty])$ and $\langle \nabla f_i, G\rangle \neq 0$ on $f_i = 0$.

Thus a block is a set homeomorphic to a closed ball, such that the trajectories of the flow are transversal to its boundary.

Take a block $\tilde{B}$ around $(0,0)$ for the reduced system $u' = v, v' = -f(u)$, with sides parallel to the lines $v = \pm u$, in such a way that the standing wave leaves $\tilde{B}$ through b_1^- and comes back through b_2^+ (see Fig. 1).

Similarly, we can construct blocks for $u' = v, v' = -f(u) + w$, for $|w|$ small, around the smallest root $u_1 = u_1(w)$ of the equation $w = f(u)$ (see Fig. 2). The three-dimensional

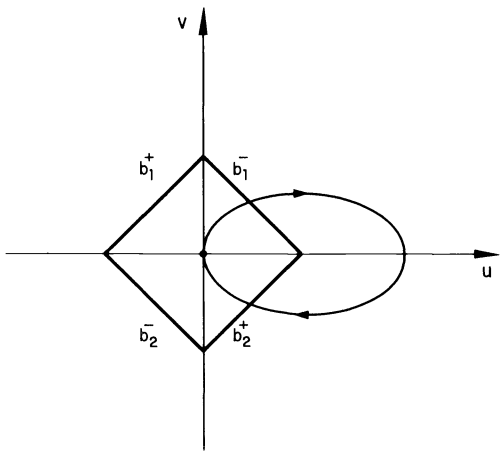

FIG. 1. *Exit set* $\tilde{B}^- = b_1^- \cup b_2^-$. *Entrance set* $\tilde{B}^+ = b_1^+ \cup b_2^+$.

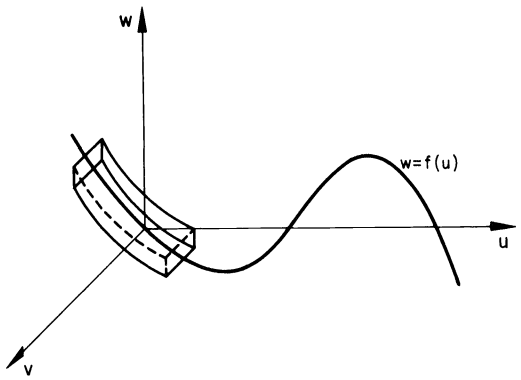

FIG. 2. *Exit set* $B^- = b_1^- \cup b_2^-$ *front and back.*

box constructed in this manner is a block for (1) because the top and bottom, being parallel to the u, v plane, are transversal to the vector field for $\varepsilon > 0$.

We will concentrate on the behavior of the unstable manifold $U_{\varepsilon,c}(\xi)$ after it returns to B through b_2^+. $U_{\varepsilon,c}(\xi)$ is normalized by the condition $U_{\varepsilon,c}(\xi) = a$ for the first time at $\xi = 0$. The asymptotic behavior of $U_{\varepsilon,c}(\xi)$ has been analyzed by Hastings [11]: the sets $E^- = \{(u, v, w)\colon u < 0,\ v < 0,\ v' < 0,\ w' < 0\}$ and $E^+ = \{(u, v, w)\colon u > 1, v > 0, v' > 0, w' > 0\}$ are invariant regions for (1). Moreover, $U_{\varepsilon,c}(\xi)$ enters $E^+(E^-)$ if and only if u and v tend to $+\infty(-\infty)$.

Let $\Omega = \{(c, \varepsilon)\colon c > 0, \varepsilon \geqq 0\}$, $\Omega_1 = \{(c, \varepsilon)\colon U_{\varepsilon,c}(\xi)$ is bounded$\}$, $\Omega_2 = \{(c, \varepsilon)\colon U_{\varepsilon,c}(\xi)$ enters $E^+\}$, $\Omega_3 = \{(c, \varepsilon)\colon U_{\varepsilon,c}(\xi)$ enters $E^-\}$; then Ω_2 and Ω_3 are disjoint open sets, and $\Omega = \Omega_1 \cup \Omega_2 \cup \Omega_3$. The region between the parabolas $\varepsilon = Mc^2$ and $\varepsilon = (1/\gamma)c^2$ is contained in Ω_2. Let C_3 be the component of Ω_3 containing the segment $(0, c_0) \times \{0\}$, where $c_0 = \sqrt{2}(\frac{1}{2} - a)$ (see Fig. 3). It will be shown that C_3 contains a portion of a parabola. For $0 < c < c_0$, $U_{\varepsilon,c}(\xi)$ returns to B through b_2^+. For $0 < c < c_0$ and $\varepsilon = 0$, $U_{0,c}(\xi)$ leaves B for the second time through b_2^-, and $u < 0$, $v' < 0$ at the exit point. By continuity, the same is true for $0 \leqq \varepsilon \leqq \varepsilon_0$, $0 < c \leqq c_0$. The claim is that $U_{\varepsilon,c}(\xi)$ enters E^- if it leaves B through b_2^- for $c \leqq c_0$ and $\varepsilon \leqq (M + \delta)c^2$. This is the content of the following lemma.

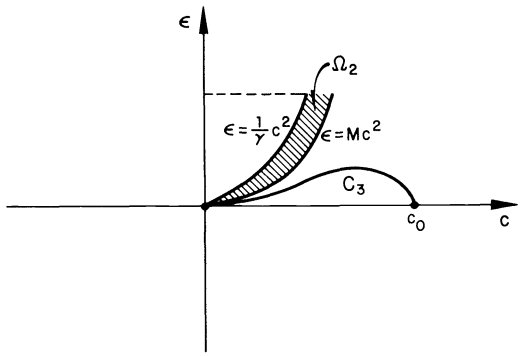

FIG. 3

LEMMA 1. *If $c \leqq c_0$, $\varepsilon \leqq (M + \delta)c^2$ and $U_{\varepsilon,c}(\xi)$ leaves B through b_2^-, then $U_{\varepsilon,c}(\xi_0) \in E^-$ for some $\xi_0 > 0$.*

Proof. Assume that $U_{\varepsilon,c}(\xi)$ leaves B (after returning through b_2^+) for the first time at $\xi = T(\varepsilon, c)$, and that $U_{\varepsilon,c}(T) \in b_2^-$, then $u(T) < 0$, $v(T) < 0$ and $v'(T) < 0$. There are two possibilities:

(i) $w(T) \geqq 0$, in which case $w'(T) = (\varepsilon/c)(u(T) - \gamma w(T)) < 0$, so that $U_{\varepsilon,c}(T) \in E^-$.

(ii) $w(T) < 0$. Only the case $w'(T) \geqq 0$ needs to be considered. There are two subcases:

(a) $U_{\varepsilon,c}(\xi)$ leaves the region $u < 0$, $v < 0$, $v' < 0$ for the first time at $T_1 > T$, and $w'(\xi) \geqq 0$ at $T \leqq \xi \leqq T_1$. In this situation, $v'(T_1) = 0$, which implies $w(T_1) > 0$. For small $\delta > 0$, the inequalities $u(T_1 - \delta) < 0$, $v(T_1 - \delta) < 0$, $v'(T_1 - \delta) < 0$, and $w(T_1 - \delta) > 0$ hold, so that $w'(T_1 - \delta) < 0$, a contradiction.

(b) $U_{\varepsilon,c}(\xi)$ remains in the region $u < 0$, $v < 0$, $v' < 0$ as long as it exists, and $w'(\xi) \geqq 0$ for $T \leqq \xi < T^*(\varepsilon, c)$ (T^* is the largest positive time for which $U_{\varepsilon,c}(\xi)$ is defined). If $T^* < \infty$, then $u(\xi) \to -\infty$, $v(\xi) \to -\infty$ as $\xi \to T^*$, from which it follows that $w'(\xi) = (\varepsilon/c)(u(\xi) - \gamma w(\xi)) \to -\infty$ as $\xi \to T^*$, so that eventually $w'(\xi) < 0$, a contradiction.

If $T^* = \infty$, the claim is that $w(\xi) \to 0$ as $\xi \to \infty$. If this were not true, there would exist $\alpha > 0$ such that $w(\xi) \leqq -\alpha$ for $\xi \geqq T$, then $v'(\xi) \leqq -\alpha$, so that $v(\xi) \to -\infty$ and $u(\xi) \to -\infty$ as $\xi \to \infty$. This implies that $w'(\xi) \to -\infty$, a contradiction. But if $w(\xi) \to 0$, then $w'(\xi) \to -\infty$, again a contradiction.

It follows that $U_{\varepsilon,c}(\xi)$ must enter E^- at some $\xi > T$. The proof is finished.

Now let $\tilde{w} = (1/\sqrt{\varepsilon})w$ and $\sqrt{\varepsilon} = \alpha c$. Then (1) becomes

$$u' = v, \quad v' = cv - f(u) + \alpha c\tilde{w}, \quad \tilde{w}' = \alpha(u - \gamma\alpha c\tilde{w}). \tag{2}$$

When $\alpha = 0$, we get $u' = v$, $v' = cv - f(u)$, $\tilde{w}' = 0$, so that $\tilde{U}_{0,c}(\xi)$ leaves B through b_2^- if $c \leqq c_0$, and by continuity the same is true for $\alpha \leqq \sqrt{m}$. By Lemma 1, $U_{\alpha,c}(\xi)$ enters E^- if $c \leqq c_0$, $\alpha \leqq \sqrt{m}$, so that $(\varepsilon, c) \in \Omega_3$ if $c \leqq c_0$ and $\varepsilon \leqq mc^2$.

Restrict the values of (ε, c) to the region $c \leqq c_0$, $\varepsilon \leqq \min\{(M+\delta)c^2, \varepsilon_0\}$, where $\varepsilon_0 = mc_0^2$. Take $0 < \varepsilon < \varepsilon_0$, and define $c_2 = \sqrt{\varepsilon/(M+\delta)}$, $c_3 = \sqrt{\varepsilon/m}$. Since B is a block, the exit point of $U_{\varepsilon,c}(\xi)$ depends continuously on (ε, c). Therefore, $U_{\varepsilon,c}(\xi)$ leaves B through b_2^- if $c_3 < c < c_0$. Since $(\varepsilon, c_2) \in \Omega_2$, it follows from Lemma 1 that $U_{\varepsilon,c}(\xi)$ leaves B through b_1^-. By continuity, there exists $\bar{c}$, such that $\sqrt{\varepsilon}/\sqrt{M+\delta} < \bar{c} < \sqrt{\varepsilon}/\sqrt{m}$ and $U_{\varepsilon,\bar{c}}(\xi)$ remains in B after returning through b_2^+. By choosing B small enough we can guarantee that $U_{\varepsilon,\bar{c}}(\xi) \to (0,0,0)$ as $\xi \to \infty$, and therefore $U_{\varepsilon,\bar{c}}(\xi)$ is the slow traveling pulse.

2. Stability analysis. To simplify the notation, we make the change $c \to -c$. The system for traveling waves is

$$u' = v, \quad v' = -cv - f(u) + w, \quad w' = -\frac{\varepsilon}{c}(u - \gamma w). \tag{3}$$

If $U_\varepsilon = (u_\varepsilon, v_\varepsilon, w_\varepsilon)$ is the travelling wave found in the previous section, and L_ε is the linearization around U_ε of

$$u_t = u_{\xi\xi} + cu_\xi + f(u) - w, \qquad w_t = cw_\xi + \varepsilon(u - \gamma w), \tag{4}$$

then

$$L_\varepsilon \begin{pmatrix} p \\ r \end{pmatrix} = \begin{pmatrix} \dfrac{d^2p}{d\xi^2} + c\dfrac{dp}{d\xi} + f'(u_\varepsilon)p - r \\ c\dfrac{dr}{c\xi} + \varepsilon(p - \gamma r) \end{pmatrix}.$$

The spectrum of L_ε, denoted by $\sigma(L_\varepsilon)$, consists of the values of $\lambda \in \mathbb{C}$ for which $L_\varepsilon \binom{p}{r} = \lambda \binom{p}{r}$ has a bounded solution. The spectrum can be divided into two parts: the point spectrum $\sigma_p(L_\varepsilon)$, which consists of isolated eigenvalues of finite multiplicity, and the essential spectrum $\sigma_e(L_\varepsilon) = \sigma(L_\varepsilon) \setminus \sigma_p(L_\varepsilon)$.

In the limit case $\varepsilon = 0$ (and $c = 0$), the corresponding linear operator is $L_0(p) = (d^2p)/dx^2 + f'(u_0)p$, where $u_0(x)$ is the standing wave of the Nagumo equation. The spectrum of L_0 can be computed: $\sigma_e(L_0) = (-\infty, -a]$, and there is exactly one positive eigenvalue (see Flores [9] and McKean and Moll [16]). It will be shown that for small $\varepsilon > 0$, $\sigma_e(L\varepsilon)$ lies in the left half-plane, and that the point spectrum has one positive eigenvalue, so that U_ε is a saddle of codimension 1.

The eigenvalue equation $L_\varepsilon \binom{p}{r} = \lambda \binom{p}{r}$ can be written as the system

$$\begin{aligned} p' &= q, \\ q' &= cq + [\lambda - f'(u_\varepsilon)]p + r, \\ r' &= -\frac{\varepsilon}{c}p + \left(\frac{\lambda + \varepsilon\gamma}{c}\right)r. \end{aligned} \tag{5}$$

If $z=(p, q, r)$, then (5) is the linear system in $\mathbb{C}^3$: $z'=Az$, where

$$A=\begin{pmatrix} 0 & 1 & 0 \\ \lambda - f'(u_\varepsilon) & -c & 1 \\ -\varepsilon/c & 0 & (\lambda+\varepsilon\gamma)/c \end{pmatrix}.$$

System (5) is asymptotically autonomous, the asymptotic equation being given by the matrix

$$A_0=\begin{pmatrix} 0 & 1 & 0 \\ \lambda + a & -c & 1 \\ -\varepsilon/c & 0 & (\lambda+\varepsilon\gamma)/c \end{pmatrix}.$$

Let L_1 be the linearization of (4) around $(0, 0, 0)$, that is,

$$L_1\begin{pmatrix} p \\ r \end{pmatrix}=\begin{pmatrix} \dfrac{d^2p}{d\xi^2}+c\dfrac{dp}{d\xi}-ap-r \\ c\dfrac{dr}{c\xi}+\varepsilon(p-\gamma r) \end{pmatrix};$$

then $\sigma_e(L_1)=S=\{\lambda\in\mathbb{C}: A_0(\lambda)$ has a pure imaginary eigenvalue$\}$.

Since

$$L_\varepsilon = L_1+\begin{pmatrix} [f'(u_{\varepsilon_0})+a]p \\ 0 \end{pmatrix},$$

and the second term in the right-hand side is a relatively compact perturbation, it follows that any connected component of $\mathbb{C}\backslash S$ is entirely the essential spectrum, or the only spectrum in it is discrete.

The claim is that S lies in the left half-plane for small $\varepsilon>0$. Let

$$P(\alpha, \varepsilon, \lambda)=\det(A_0(\varepsilon, \lambda)-\alpha I)=[\alpha^2+c\alpha-(\lambda+a)]\left[\frac{\lambda+\varepsilon\gamma}{c}-\alpha\right]-\frac{\varepsilon}{c}.$$

Since $c(\varepsilon)<0$, $S=\{\lambda\in\mathbb{C}: c(\varepsilon)P(\alpha, \varepsilon, \lambda)=0$ for some $\alpha=i\tau, \tau\in\mathbb{R}\}$. When $\varepsilon=0$, the equation is $[\alpha^2-(\lambda+a)]\lambda=0$, and this has solutions $\alpha=i\tau$, $\tau\in\mathbb{R}$ if and only if $\lambda\leqq -a$, so that $S_0=(-\infty, -a]$. By continuity, S lies in the left half-plane for small $\varepsilon>0$.

Let G be the connected component of $\mathbb{C}\backslash S$ which contains a half-plane of the form $\{\lambda: \mathrm{Re}\,(\lambda)>b\}$, $b<0$. From Theorem 1 and Corollary 3 of Evans [3c], $\lambda\in\rho(L_\varepsilon)$ if $|\lambda|$ is large. Therefore, the only part of the spectrum in G is $\sigma_p(L_\varepsilon)$. Moreover, the number of eigenvalues of $A_0(\lambda)$ in $\mathrm{Re}\,(\lambda)>0$ is constant in G. To compute this number, note that $c(\varepsilon)P(\alpha, \varepsilon, \lambda)=[a^2+c\alpha-(\lambda+a)][\lambda+\varepsilon\gamma-c\alpha]-\varepsilon=0$. At $\varepsilon=0$ we get $[\alpha^2-(\lambda+a)]\lambda=0$. For $\lambda\neq 0$ there are two eigenvaues: $\alpha_1(0, \lambda)=\sqrt{\lambda+a}$, and $\alpha_2(0, \lambda)=-\sqrt{\lambda+a}$ with $\mathrm{Re}\,(\alpha_2(0, \lambda))<0<\mathrm{Re}\,(\alpha_1(0, \lambda))$. By continuity there are two eigenvalues $\alpha_1(\varepsilon, \lambda)$, $\alpha_2(\varepsilon, \lambda)$ with $\mathrm{Re}\,(\alpha_2(\varepsilon, \lambda))<0<\mathrm{Re}\,(\alpha_1(\varepsilon, \lambda))$ for small $\varepsilon>0$. Since $\alpha_1+\alpha_2+\alpha_3=(\lambda+\varepsilon\gamma)/c-c$, it follows that $\alpha_3(\varepsilon, \lambda)\sim\lambda/c$. In particular $\mathrm{Re}\,(\alpha_3)\sim\mathrm{Re}\,(\lambda/c)\sim -k^2/\sqrt{\varepsilon}$.

Therefore, the eigenvalues of A_0 satisfy $\mathrm{Re}\,(\alpha_3(\varepsilon, \lambda))<\mathrm{Re}\,(\alpha_2(\varepsilon, \lambda))<0<\mathrm{Re}\,(\alpha_1(\varepsilon, \lambda))$ if ε is small enough. Let X_1, X_2, X_3 be the eigenvalues of A_0 corresponding to $\alpha_1, \alpha_2, \alpha_3$, respectively, then $X_1=(1, \alpha_1, -\varepsilon(c\alpha_1-(\lambda+\varepsilon\gamma))^{-1})$. System (5) has a solution $\varphi(\xi; \varepsilon, \lambda)=X_1e^{\alpha_1(\varepsilon, \lambda)\xi}+o(e^{\alpha_1(\varepsilon, \lambda)\xi})$ as $\xi\to-\infty$. This is a candidate for being an eigenfunction. To see if $\varphi(\xi; \varepsilon, \lambda)$ is bounded as $\xi\to+\infty$, consider the adjoint system $z^{*\prime}=Bz^*$, where $B=-A^*$. This system is asymptotic to $z^{*\prime}=B_0z^*$, where $B_0=-A_0^*$.

The eigenvalues of B_0 are $\{\beta_1, \beta_2, \beta_3\} = \{-\bar{\alpha}_1, -\bar{\alpha}_2, -\bar{\alpha}_3\}$. Let Y_1, Y_2, Y_3 be the corresponding eigenvectors. Y_1 is given by

$$Y_1 = \left(1, (c-\beta_1)^{-1}, \left[(\beta_1 - c)\left(\beta_1 + \frac{\bar{\lambda} + \varepsilon\gamma}{c}\right)\right]^{-1}\right).$$

The adjoint system has a solution $\psi(\xi; \varepsilon, \lambda) = Y_1 e^{\beta_1 \xi} + o(e^{\beta_1 \xi})$ as $\xi \to \infty$. The function $D_\varepsilon(\lambda) = \varphi(\xi; \varepsilon, \lambda) \cdot \psi(\xi; \varepsilon, \lambda)$, originally introduced by Evans [3a-d], containing the information relative to the stability. Indeed, λ is an eigenvalue of L_ε if and only if $D_\varepsilon(\lambda) = 0$. To see this take $\{\varphi_1, \varphi_2, \varphi_3\}$, $\{\psi_1, \psi_2, \psi_3\}$ as fundamental systems of $z' = Az$ and $z^{*\prime} = Bz^*$, respectively, such that $\varphi_i \sim X_i e^{\alpha_i \xi}$ as $\xi \to \infty$, $\psi_i \sim Y_i e^{\beta_i \xi}$ as $\xi \to \infty$. Since $X_2 \cdot Y_1 = 0$, $X_3 \cdot Y_1 = 0$, and $\varphi(\xi; \varepsilon, \lambda) = \sum_{i=1}^{3} c_i(\lambda)\varphi_i(\xi, \varepsilon, \lambda)$ it follows that

$$D_\varepsilon(\lambda) = \varphi(\xi; \varepsilon, \lambda) \cdot \psi(\xi; \varepsilon, \lambda) = \sum_{i=1}^{3} c_i(\lambda)\varphi_i(\xi; \varepsilon, \lambda) \cdot \psi(\xi; \varepsilon, \lambda) \sim c_1(\lambda) X_1 \cdot Y_1$$

as $\xi \to \infty$ so that $D_\varepsilon(\lambda) = 0$ if and only if $c_1(\lambda) = 0$, in which case $\varphi(\xi; \varepsilon, \lambda)$ is bounded as $\xi \to \infty$.

There are solutions $\psi_0(\xi; \lambda)$, $\psi_0(\xi; \lambda)$ corresponding to the reduced system

$$p' = q, \qquad q' = [\lambda - f'(u_0)]p. \tag{6}$$

The function $D_0(\lambda) = \varphi_0(\xi; \lambda) \cdot \psi_0(\xi; \lambda)$ has roots at $\lambda_0 = 0$ and $\lambda_1 > 0$. These are the only roots in the half-plane $\mathrm{Re}\,(\lambda) \geqq 0$. It will be shown that $D_\varepsilon(\lambda) = 0$ has exactly one positive root for small $\varepsilon > 0$. This is due to the fact that $D_\varepsilon(\lambda) \to D_0(\lambda)$ as $\varepsilon \downarrow 0$, uniformly on compact subsets of G.

Let $\varphi(\xi; \varepsilon, \lambda) = (p(\xi; \varepsilon, \lambda), q(\xi; \varepsilon, \lambda), r(\xi; \varepsilon, \lambda))$ be the solution of (5) with $\varphi(\xi; \varepsilon, \lambda) \sim X_1 e^{\alpha_1 \xi}$ as $\xi \to -\infty$; then

$$r(\xi; \varepsilon, \lambda) = e^{(\lambda/c)\xi} r(0; \varepsilon, \lambda) + \frac{\varepsilon}{c} \int_0^\xi e^{(\lambda/c)(\xi - \sigma)} [(p(\sigma) - \gamma r(\sigma)]\, d\sigma.$$

Since $\alpha_1(\varepsilon, \lambda) = \sqrt{\lambda + a} + o(1)$ as $\varepsilon \to 0$, there are bounds of the form $|\varphi(\xi; \varepsilon, \lambda)| \leqq M e^{\alpha \xi}$, $\xi \geqq 0$, ε small, where the constants M and α are uniform for λ in compact subsets of G. Moreover, $\mathrm{Re}\,(\lambda/c) \to -\infty$ as $\varepsilon \downarrow 0$, uniformly for $0 \leqq \xi \leqq \xi_0$ and λ in compact subsets of G. From the construction of the slow wave $U_\varepsilon(\xi)$, it follows that $|u_\varepsilon(\xi) - u_0(\xi)| \to 0$ as $\varepsilon \downarrow 0$, and therefore $D_\varepsilon(\lambda) \to D_0(\lambda)$ as $\varepsilon \downarrow 0$ uniformly on compacts subsets of G. By Rouché's theorem, $D_\varepsilon(\lambda) = 0$ has exactly one root $\lambda_1(\varepsilon)$ near λ_1, the positive root of $D_0(\lambda) = 0$, and since $D_\varepsilon(\lambda)$ is real for λ real, it follows that $\lambda_1(\varepsilon) > 0$.

ON THE BIFURCATION OF RADIALLY SYMMETRIC STEADY-STATE SOLUTIONS ARISING IN POPULATION GENETICS*

K. J. BROWN† AND A. TERTIKAS‡

Abstract. This paper considers a semilinear elliptic equation which arises in a selection-migration model in population genetics, involving two alleles A_1 and A_2 such that A_1 is at an advantage over A_2 in certain subregions and at a disadvantage in others. The system is studied on all of R^n and is assumed to possess radial symmetry. Existence and asymptotic properties of solutions of the corresponding ordinary differential equation are investigated and, by using shooting method type arguments, results are obtained on the bifurcation of solutions from the trivial solutions corresponding to the cases where A_1 or A_2 is extinct. The nature of the results obtained varies according to whether A_1 or A_2 has an overall advantage.

Key words. population genetics, bifurcation theory, indefinite weight functions, radial symmetry

1. Introduction. In this paper we discuss the steady-state solutions of the semilinear parabolic problem

$$u_t(x,t)=\Delta u+\lambda g(|x|)f(u) \quad \text{for } x \text{ in } R^n, \quad t\geqq 0 \tag{1.1}$$

where Δ denotes the Laplacian, g assumes both positive and negative values on R^n, and $f:[0,1]\to R$ is a nonnegative concave function such that $f(0)=0=f(1)$.

Such problems arise in population genetics. Consider a model with two alleles A_1 and A_2 corresponding to three possible genotypes: A_1A_1, A_1A_2, and A_2A_2. Let $u(x,t)$ denote the frequency of the allele A_1 at time t at the point x in R^n. Changes in gene frequency are assumed to be caused only by the flow of genes and by selective advantages for certain genotypes in certain subregions of D. Then u satisfies (1.1); the term $\Delta u/\lambda$ represents the effect of gene flow; the term $g(x)f(u)$ with $f(u)=u(1-u)[h(1-u)+(1-h)u]$ for some constant h, $0<h<1$, represents the effect of natural selection where the fitness coefficients of the genotypes A_1A_2 and A_2A_2 relative to A_1A_1 are, respectively, $1-hg(x)$ and $1-g(x)$. The fact that g changes sign on R^n corresponds to the allele A_1 being at an advantage in some parts of R^n and at a disadvantage in others. A more detailed account of this model can be found in Fleming [3].

Since u represents a population frequency, the physically meaningful steady-state solutions of (1.1) satisfy

$$-\Delta u=\lambda g(|x|)f(u) \quad \text{on } R^n\colon 0\leqq u\leqq 1. \tag{1.2}_\lambda$$

It is clear that $(1.2)_\lambda$ has the trivial constant solutions $u\equiv 0$ and $u\equiv 1$ corresponding to the extinction of one of the alleles. We are interested in the existence of nontrivial solutions.

Nontrivial radially symmetric solutions of $(1.2)_\lambda$ satisfy the ordinary differential equation (ODE)

$$\begin{aligned} &u''(r)+\frac{n-1}{r}u'(r)+\lambda g(r)f(u(r))=0 \quad \text{for } r>0,\\ &u'(0)=0, \qquad 0<u(r)<1 \quad \text{for } r>0. \end{aligned} \tag{1.3}_\lambda$$

We have already studied various aspects of $(1.2)_\lambda$ in [2] and [7]. As in [2] and [7] we shall assume throughout that g satisfies

(G_0) $g:[0,\infty)\to R$ is locally Holder continuous and there exists r_0, $R_0>0$ such that $g(r_0)>0$ and $g(r)<0$ for $r>R_0$.

The uniqueness of radially symmetric solutions of $(1.3)_\lambda$ is discussed by Tertikas in [7] under the additional hypothesis that f is concave (this occurs whenever $\frac{1}{3}<h<\frac{2}{3}$). In [2] equation $(1.2)_\lambda$ was studied without assuming that g is radially symmetric or that f is concave and results on the existence and nonexistence of solutions were obtained. These results correspond closely to what might be expected from the model. It was shown that, if g is negative and bounded away from zero at infinity and λ is sufficiently small, then there exist no solutions of $(1.2)_\lambda$; this corresponds to the fact that if the allele A_1 suffers a significant overall disadvantage and the rate of gene flow is sufficiently large, then A_1 and A_2 cannot coexist. On the other hand, if the alleles both hold some kind of advantage in the sense that $\int_{R^n} g\,dx>0$, although g is negative at infinity, then it was shown that, when $n=1, 2$, solutions of $(1.2)_\lambda$ can exist no matter how great the rate of gene flow. The purpose of this paper is to demonstrate how the results of [2] can be considerably sharpened in the case where g is assumed to be radially symmetric so that the problem may be attacked by using ODE methods. Because of the radial symmetry of g we are able to replace the bare existence results of [2] with precise descriptions of the bifurcation diagrams in the (λ, u) plane for $(1.2)_\lambda$. Properties of bifurcation diagrams for $(1.2)_\lambda$ on bounded regions have been studied by Fleming [3] in the case of Neumann boundary conditions and by Hess and Kato [5] in the case of Dirichlet boundary conditions. In general, it is difficult to obtain bifurcation results for problems on unbounded regions because the linearized problem can no longer be formulated as a problem involving compact operators and so it is no longer obvious that the linearized problem has eigenvalues which might correspond to bifurcation points. However, in this special case, using ODE techniques we are able to describe how bifurcation occurs.

We now describe how the paper is organized. In § 2 we prove the existence of radially symmetric solutions of $(1.2)_\lambda$ for sufficiently large λ by constructing appropriate weak sub- and supersolutions. Similar existence theorems are proved in [2] and [7] but the sub- and supersolutions used here are simpler than those used previously. In order to obtain our main results an understanding of the asymptotic properties of solutions as $r\to\infty$ is necessary; in § 3 we prove the required asymptotic results, obtaining conditions in terms of integrals involving g for all solutions to tend to zero at infinity. In § 4 we study $(1.3)_\lambda$ by using the shooting method; the uniqueness results of [7] make possible a very clear and simple description of what happens to solutions as the initial value changes and this description is the principal tool in the proofs of our main existence results. In addition at the end of § 4 we deduce that all solutions of $(1.2)_\lambda$ are radially symmetric; this result is of interest as the radial symmetry of all solutions is proved without the assumption that g is a decreasing function of r (cf. Gidas, Ni, and Nirenberg [4]). Finally, in §§ 5 and 6 we describe our main existence results. In § 5 we show that bifurcation occurs from the zero solution when g is bounded away from zero at infinity and that the bifurcation diagram is as shown in Fig. 1. In § 6 we consider the case where $\int_{R^n} g\,dx>0$ and show that the bifurcation diagram is as shown in Fig. 2, i.e., a nontrivial branch of solutions bifurcates from the trivial branch $u\equiv 1$ at $\lambda=0$.

2. Existence of solutions for large λ. We shall prove the existence of solutions by constructing appropriate sub- and supersolutions.

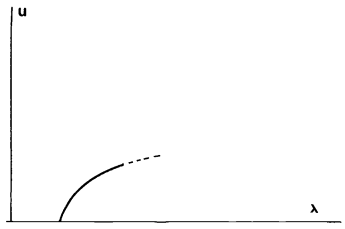

FIG. 1. *Bifurcation diagram when* $\int g < 0$.

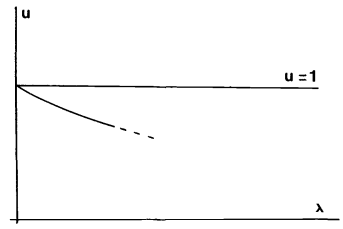

FIG. 2. *Bifurcation diagram when* $\int g > 0$.

Let $D \subset R^n$ be a domain with smooth boundary, and let D_1 be a subregion of D such that ∂D_1 is smooth and $\bar{D}_1 \subset D$. Let $D_2 = D - D_1$, and let $n(x)$ denote the outward normal to D_1 at $x \in \partial D_1$. Suppose that u_1 and u_2 are smooth subsolutions of $-\Delta u = \lambda g(x) f(u)$ on D_1 and D_2, respectively, and that on ∂D_1, $u_1 = u_2$ and $\partial u_1/\partial n \leqq \partial u_2/\partial n$. Then, if we define u by

$$u = u_1 \quad \text{on } D_1, \qquad u = u_2 \quad \text{on } D_2,$$

we say that u is a weak subsolution of $-\Delta u = \lambda g(x) f(u)$ on D. Roughly speaking, u can be regarded as the supremum of the two subsolutions u_1 and u_2. Weak supersolutions are defined similarly. Such weak sub- and supersolutions are discussed by Berestycki and Lions in [1] in the case of bounded regions with Dirichlet boundary conditions and the existence of solutions lying between weak sub- and supersolutions is obtained. Ni in [6] proves the existence of a solution lying between smooth sub- and supersolutions for semilinear elliptic equations on all of R^n; the solution is obtained as the limit of solutions on bounded regions and so the proof in [6] can be adapted to apply to the case of weak sub- and supersolutions.

LEMMA 2.1. *Suppose* $f: [0, 1] \to R$ *satisfies*

(F_0) $\quad f(0) = f(1) = 0, \quad f(u) > 0$ *for* $0 < u < 1, \quad f'(0) > 0, \quad f'(1) < 0.$

There exists $\Lambda_0 > 0$ *such that* $(1.2)_\lambda$ *has arbitrarily small nontrivial radially symmetric weak subsolutions for all* $\lambda > \Lambda_0$.

Proof. By our assumption (G_0) on g there exists an annulus or ball Ω centred at r_0 and a constant $m > 0$ such that $g(|x|) \geqq m$ for all $x \in \Omega$. Let λ_1 denote the principal eigenvalue and φ_1 the corresponding positive radially symmetric eigenfunction such that $\sup_\Omega \varphi_1(x) = 1$ of

$$-\Delta \varphi = \lambda \varphi \quad \text{on } \Omega, \qquad \varphi = 0 \quad \text{on } \partial\Omega.$$

Let $f_1(u) = \lambda m f(u) - \lambda_1 u$. Then $f_1(0) = 0$, and $f_1'(0) = \lambda m f'(0) - \lambda_1$. Hence $f_1'(0) > 0$ provided $\lambda > \lambda_1 / m f'(0) = \Lambda_0$, say. Thus

$$\tau(\lambda) = \sup \{t \in [0, 1];\ \lambda m f(u) > \lambda_1 u \text{ for } 0 \leqq u \leqq t\} > 0 \tag{2.1}$$

for any $\lambda > \Lambda_0$.

Suppose $\lambda > \Lambda_0$ and $0 < \varepsilon < \tau(\lambda)$. Then

$$\Delta(\varepsilon\varphi_1) + \lambda g(|x|) f(\varepsilon\varphi_1) \geqq -\lambda_1 \varepsilon_1 \varphi_1 + \lambda m f(\varepsilon\varphi_1) \geqq 0$$

for all $x \in \Omega$ and so the function

$$\underline{u}_\varepsilon(x) = \begin{cases} \varepsilon\varphi_1(x) & \text{for } x \in \Omega, \\ 0 & \text{for } x \in R^n - \Omega \end{cases}$$

is a weak subsolution of $(1.2)_\lambda$.

LEMMA 2.2. *Let f satisfy the hypotheses of Lemma* 2.1. *Then there exists $\Lambda_1 > 0$ such that $(1.2)_\lambda$ has radially symmetric weak supersolutions arbitrarily close to one for all $\lambda > \Lambda_1$.*

Proof. Let Ω be an annulus or ball such that $g(|x|) \leqq -m$ for $x \in \Omega$ where m is a positive constant. Now u is a solution of

$$-\Delta u = \lambda g(|x|) f(u) \quad \text{in } \Omega, \qquad u = 1 \quad \text{on } \partial\Omega \tag{2.2}$$

if and only if $v = 1 - u$ is a solution of

$$-\Delta v = \lambda \hat{g}(|x|) \hat{f}(v) \quad \text{in } \Omega, \qquad v = 0 \quad \text{on } \partial\Omega \tag{2.3}$$

where $\hat{g}(r) = -g(r)$ and $\hat{f}(v) = f(1 - v)$. By Lemma 2.1 there exist arbitrarily small subsolutions of the form $\varepsilon\varphi_1$ of (2.3) and so there exist supersolutions of (2.2) of the form $1 - \varepsilon\varphi_1$ arbitrarily close to 1. Therefore a radially symmetric weak supersolution of $(1.2)_\lambda$ is given by

$$\bar{u}_\varepsilon(x) = \begin{cases} 1 - \varepsilon\varphi_1(x) & \text{for } x \in \Omega, \\ 1 & \text{for } x \in R^n - \Omega \end{cases}$$

and so the proof is complete.

THEOREM 2.3. *Let f satisfy the hypotheses of Lemma* 2.1. *Then for all $\lambda > \max\{\Lambda_0, \Lambda_1\}$, problem $(1.2)_\lambda$ has a nontrivial radially symmetric solution u_λ such that $\sup_{x \in R^n} u_\lambda(x) \to 1$ and $\inf_{x \in R^n} u_\lambda(x) \to 0$ as $\lambda \to \infty$.*

Proof. By Lemmas 2.1 and 2.2 we have that for each $\lambda > \max\{\Lambda_0, \Lambda_1\}$ there exist weak sub- and supersolutions $\underline{u}_\varepsilon$ and $\bar{u}_\varepsilon$. By choosing ε sufficiently small we can ensure that $\underline{u}_\varepsilon < \bar{u}_\varepsilon$. Hence by Ni's existence theorem in [6] there exists a solution to $(1.2)_\lambda$. Moreover, since g, $\underline{u}_\varepsilon$, and $\bar{u}_\varepsilon$ are radially symmetric, the iteration scheme of [6] will give us a radially symmetric solution.

The proof of the second part of the theorem depends on the construction of the weak sub- and supersolutions. In the notation of Lemma 2.1 we have that $u_\lambda(x) \geqq \tau(\lambda)\varphi_1(x)$ for all $x \in \Omega$. It is clear from (2.1) that $\lim_{\lambda \to \infty} \tau(\lambda) = 1$ and so $\limsup_{\lambda \to \infty} u_\lambda(x) = 1$. Similarly, in the notation of Lemma 2.2 we have that $u_\lambda(x) \leqq 1 - \tau(\lambda)\varphi_1(x)$, and so $\liminf_{\lambda \to \infty} u_\lambda(x) = 0$.

3. Asymptotic behaviour of solutions. The main objective of this section is to obtain conditions which ensure that all solutions of $(1.3)_\lambda$ tend to zero as $r \to \infty$. We also obtain information on rates of decay by investigating the asymptotic behavior of $u'(r)/u(r)$. We shall later require asymptotic results on solutions of the linearization of $(1.3)_\lambda$ about zero. So that we may deal with $(1.3)_\lambda$ where $f(u) = u(1-u)((1-h)u + h(1-u))$ and its linearization simultaneously we assume throughout this section only that f satisfies

$$\text{(F)} \qquad f : [0, 1] \to R^+, \qquad f(0) = 0, \qquad f'(0) > 0, \qquad 0 < f(u) \leqq u \quad \text{for } 0 < u < 1.$$

The assumption that $g(r)<0$ for r sufficiently large is essential for our results of this section. If g is allowed to oscillate arbitrarily at ∞, then $\lim_{r\to\infty} u(r)$ need not exist. For example, $u(x)=(1+e^{\cos x})^{-1}$ satisfies the differential equation

$$u''(x)-[\cos x+(e^{\cos x}-1)(e^{\cos x}+1)^{-1}]u(1-u)=0 \quad \text{for } x\in R, \qquad u'(0)=0.$$

First we discuss the case $n=1, 2$. Our main result is the following.

THEOREM 3.1. *Let f satisfy* (F), *and let u be a solution of* $(1.3)_\lambda$.

(i) *Suppose $n=1$. Then $\lim_{r\to\infty} u(r)=0$ if and only if $\int^\infty rg(r)\,dr=-\infty$.*

(ii) *Suppose $n=2$. Then $\lim_{r\to\infty} u(r)=0$ if and only if $\int^\infty r\ln rg(r)\,dr=-\infty$.*

For $n=2$ the classical transformation

$$s=\ln r, \qquad v(s)=u(r)$$

transforms $(1.3)_\lambda$ into

$$v_{ss}+\lambda\, e^{2s}g(e^s)f(v(s))=0.$$

Thus we can investigate the asymptotics of $(1.3)_\lambda$ for $n=1, 2$ by studying the asymptotics of solutions of

$$w''(x)+G(x)f(w(x))=0 \quad \text{for } x>0, \qquad 0<w<1 \tag{3.1}$$

where $G(x)=\lambda g(x)$ when $n=1$, and $G(x)=\lambda\, e^{2x}g(e^x)$ when $n=2$. Clearly, $G(x)<0$ for $x>R_0$.

Suppose w is a solution of (3.1). Since w is bounded and eventually convex, it is easy to see that w is eventually decreasing, $\lim_{x\to\infty} w'(x)=0$, and $\lim_{x\to\infty} w(x)$ exists.

LEMMA 3.2. *If $\int^\infty xG(x)\,dx=-\infty$, then $\lim_{x\to\infty} w(x)=0$.*

Proof. Multiplying (3.1) by x and integrating gives

$$xw'(x)-R_0w'(R_0)-w(x)+w(R_0)+\int_{R_0}^{x} tG(t)f(w(t))\,dt=0.$$

Suppose that $\lim_{x\to\infty} w(x)=\beta>0$. Then $\lim_{x\to\infty} f(w(x))=f(\beta)>0$ and so $\int^\infty tG(t)f(w(t))\,dt=-\infty$. Hence $xw'(x)\to\infty$ as $x\to\infty$, which is impossible as $w'(x)\leqq 0$ for $x>R_0$. Thus $\lim_{x\to\infty} w(x)=0$.

LEMMA 3.3. *If $\int^\infty xG(x)\,dx>-\infty$, then $\lim_{x\to\infty} w(x)>0$.*

Proof. Suppose the contrary, i.e., $\lim_{x\to\infty} w(x)=0$. Since $f'(0)>0$, there exists $\alpha>R_0$ such that $f(w(\cdot))$ is a decreasing function for $x>\alpha$. Integrating (3.1), we obtain

$$w'(X)-w'(x)+\int_x^X G(t)f(w(t))\,dt=0$$

where $\alpha\leqq x\leqq X$. Since, for $t>x$, $f(w(t))\leqq f(w(x))\leqq w(x)$, it follows that

$$w'(X)-w'(x)+w(x)\int_x^X G(t)\,dt\leqq 0,$$

and so, letting $x\to\infty$,

$$\frac{w'(x)}{w(x)}\geqq\int_x^\infty G(t)\,dt. \tag{3.2}$$

Integrating from $x=\alpha$ to $x=\infty$, we obtain

$$\int_\alpha^\infty\int_x^\infty G(t)\,dt\,dx=\int_\alpha^\infty (t-\alpha)G(t)\,dt>-\infty$$

whereas

$$\int_{\alpha}^{\infty} \frac{w'(x)}{w(x)}\,dx = \lim_{x\to\infty} [\ln w(x) - \ln w(\alpha)] = -\infty,$$

which contradicts (3.2). Hence $\lim_{x\to\infty} w(x) > 0$.

It is clear that Theorem 3.1 follows directly from the two previous lemmas.

We now study the case $n \geqq 3$. Suppose that u is a solution of $(1.3)_\lambda$. Since

$$(r^{n-1}u')' = -\lambda r^{n-1} g(r) f(u),$$

$r^{n-1}u'$ is eventually increasing and so is eventually of one sign. Hence u is eventually monotone, and so $\lim_{r\to\infty} u(r)$ exists.

The following result, which can be proved by an argument similar to that used in the proof of Lemma 3.2, enables us to evaluate this limit.

LEMMA 3.4. *Suppose f satisfies (F) and $\int^{\infty} rg(r)\,dr = -\infty$. Let u be a solution of $(1.3)_\lambda$ such that $\lim_{r\to\infty} u(r) = \beta$. Then $f(\beta) = 0$.*

We can now give our main asymptotic result for the case $n \geqq 3$.

THEOREM 3.5. *Suppose $n \geqq 3$ and u is a solution of $(1.3)_\lambda$. Then $\lim_{r\to\infty} u(r) = 0$ when either*

(i) $\int^{\infty} rg(r)\,dr = -\infty$ *and* $f(u) = u$, *or*

(ii) $\lim_{r\to\infty} r^2 g(r) = -\infty$ *and* $f:[0,1] \to R$ *satisfies* (F_0).

Proof. Part (i) is immediate from Lemma 3.4.

(ii) It follows from Lemma 3.4 that either $\lim_{r\to\infty} u(r) = 0$ or $\lim_{r\to\infty} u(r) = 1$. Suppose that $\lim_{r\to\infty} u(r) = 1$. Let $v(r) = r^{1/2(n-1)}(u(r) - 1)$. Then $v(r) < 0$ for all r and

$$v''(r) + \frac{1}{4} r^{-2} \left\{ 4\lambda r^2 g(r) \frac{f(u(r))}{u(r)-1} - (n-1)(n-3) \right\} v = 0,$$

i.e.,

$$v''(r) + \tfrac{1}{4} q(r) r^{-2} v = 0. \tag{3.3}$$

Since $\lim_{r\to\infty} u(r) = 1$, $\lim_{r\to\infty} f(u(r))/(u(r)-1) = f'(1)$, and so $\underline{\lim}_{r\to\infty} q(r) > 1$. If $k > 1$ every solution of the Euler equation

$$w''(r) + \tfrac{1}{4} k r^{-2} w(r) = 0$$

is oscillatory. Hence it follows from the Sturmian comparison theorem that every solution of (3.3) is oscillatory, i.e., that v is oscillatory. This is impossible and so $\lim_{r\to\infty} u(r) = 0$.

Finally, in this section we investigate the asymptotic behavior of u'/u. In the next two results we deal only with the case where $n \geqq 2$; the same results hold when $n = 1$ and the corresponding proofs are simpler.

LEMMA 3.6. *Suppose f satisfies* (F) *and that g is bounded below. If u is a solution of $(1.3)_\lambda$ such that $\lim_{r\to\infty} u(r) = 0$, then $u'(r)/u(r)$ is uniformly bounded for $r > 0$.*

Proof. Let $z(r) = u'(r)/u(r)$. Then $z' = u''/u - z^2$, and so it follows from $(1.3)_\lambda$ that

$$z' + z^2 + \frac{n-1}{r} z + \lambda g(r) \frac{f(u)}{u} = 0.$$

Hence

$$z' + \frac{1}{2} z^2 = -\lambda g(r) \frac{f(u)}{u} - \frac{n-1}{r} z - \frac{1}{2} z^2.$$

Since $f(u)/u \leqq 1$ and $g(r)$ is bounded, there exists $K>0$ such that $z'+\frac{1}{2}z^2<0$ whenever $z<-K$. Hence, when $z<-K$, $z'/z^2<-\frac{1}{2}$, and so $d/dz(1/z)>\frac{1}{2}$. Thus, if $z(x_0)<-K$, $1/z$ is an increasing function, and so $z(x)<-K$ for all $x>x_0$. Since, however, $d/dz(1/z)>\frac{1}{2}$, $1/z$ must eventually become positive and this is impossible. Hence $z(x)\geqq -K$ for all x and the proof is complete.

THEOREM 3.7. *Suppose f satisfies* (F), *g is bounded below, and g is bounded away from zero at ∞, i.e., there exist $k, R_0>0$ such that $g(r)<-k$ for $r\geqq R_0$. If u is a solution of* $(1.3)_\lambda$, *then* $\lim_{r\to\infty} e^{\beta r}u(r)=0$ *for any* $\beta<\sqrt{\lambda k f'(0)}$.

Proof. It follows from Theorems 3.1 and 3.5 that $\lim_{r\to\infty} u(r)=0$. Since

$$\frac{u''}{u}=-\frac{n-1}{r}\frac{u'}{u}-\lambda g(r)\frac{f(u)}{u}$$

and $\lim_{r\to\infty} f(u)/u=f'(0)$, we have that

$$u''(r)\geqq \alpha u(r) \quad \text{for } r \text{ sufficiently large}$$

for any constant $\alpha<\lambda k f'(0)$.

It is now easy to complete the proof by using standard differential inequality arguments.

The previous theorem shows that solutions decay exponentially when g is bounded away from zero at infinity. The final two results in this section show that exponential decay does not occur when $|g|$ is small at infinity.

THEOREM 3.8. *Suppose $n=1$, f satisfies* (F), *and $\int_0^\infty g(r)\,dr$ converges. If u is a solution of* $(1.3)_\lambda$, *then* $\lim_{r\to\infty} u'(r)/u(r)=0$.

Proof. Dividing $(1.3)_\lambda$ by u and integrating, we obtain

$$\int_0^r \frac{u''}{u}\,ds+\lambda\int_0^r g(s)\frac{f(u(s))}{u(s)}\,ds=0.$$

Since $f(u)/u$ is bounded, the second integral converges and so the first integral must converge. Hence

$$\lim_{r\to\infty}\left\{\frac{u'(r)}{u(r)}+\int_0^r\left[\frac{u'(s)}{u(s)}\right]^2 ds\right\} \text{ exists.}$$

If $\int_0^\infty [u'(s)/u(s)]^2\,ds$ converges the conclusion is obvious. Suppose $\int_0^\infty [u'(s)/u(s)]^2\,ds$ diverges. Then there exists $R>0$ such that

$$-\frac{u'(r)}{u(r)}>\frac{1}{2}\int_0^r\left[\frac{u'(s)}{u(s)}\right]^2 ds \quad \text{for } r\geqq R. \tag{3.4}$$

Let $v(r)=\int_0^r [u'(s)/u(s)]^2\,ds$. Then $\lim_{r\to\infty} v(r)=\infty$. However, (3.4) implies that $v'(r)>\frac{1}{4}[v(r)]^2$, and so $d/dr(1/v)\leqq -\frac{1}{4}$ for $r\geqq R$. Hence $1/v(r)\leqq -\frac{1}{4}r+C$ for some constant C and this is a contradiction.

COROLLARY 3.9. *Suppose $n=2$, f satisfies* (F) *and $\int_0^\infty rg(r)\,dr$ converges. If u is a solution of* $(1.3)_\lambda$, *then* $\lim_{r\to\infty} ru'(r)/u(r)=0$.

Proof. By using the transformation $s=\ln r$ and $v(s)=u(r)$, equation $(1.3)_\lambda$ can be transformed into

$$v_{ss}+\lambda G(s)f(v)=0$$

where $G(s)=e^{2s}g(e^s)$. Then $\int_0^\infty G(s)\,ds=\int^\infty rg(r)\,dr$ and so $\lim_{r\to\infty} v_s(s)/v(s)=0$ by Theorem 3.8. But $v_s=ru_r$ and the proof is complete.

4. The shooting method. Uniqueness of solutions of boundary value problems plays a vital role in the development of the shooting method for the study of $(1.3)_\lambda$. We require the following results which are proved in [7] and [8], respectively.

THEOREM 4.1. *Suppose f satisfies* (F_0) *of Lemma* 2.1 *and f is concave, i.e., $f''(u) \leqq 0$ for $0 \leqq u \leqq 1$.*

(i) *Equation* $(1.2)_\lambda$ *has at most one nontrivial radially symmetric solution u such that* $\lim_{|x|\to\infty} u(x) = 0$.

(ii) *Let $R > 0$, $k \geqq 0$, and let $B_R = \{x \in R^n : |x| \leqq R\}$. Then the boundary value problem*

$$\begin{aligned} &-\Delta u(x) = \lambda g(x) f(u) \quad \text{in } B_R, \\ &0 < u(x) < 1 \quad \text{in } B_R, \qquad u = k \quad \text{on } \partial B_R \end{aligned} \tag{4.1}$$

has at most one radially symmetric solution.

For the remainder of this section we assume that f satisfies (F_0) and is concave. In addition we assume that

$$\begin{aligned} &\int^{\infty} r g(r)\, dr = -\infty && \text{if } n = 1, \\ &\int r \ln r\, g(r)\, dr = -\infty && \text{if } n = 2, \\ &\lim_{r\to\infty} r^2 g(r) = -\infty && \text{if } n \geqq 3. \end{aligned} \tag{G_1}$$

It follows from Theorems 3.1 and 3.5 that all solutions of $(1.3)_\lambda \to 0$ as $|x| \to \infty$ provided f satisfies (F_0) and g satisfies (G_0) and (G_1).

Consider the initial value problem

$$\begin{aligned} &u''(r) + \frac{n-1}{r} u'(r) + \lambda g(r) f(u) = 0 \quad \text{for } r > 0, \\ &u'(0) = 0, \qquad u(0) = p \quad \text{where } 0 < p < 1. \end{aligned} \tag{$4.2)_\lambda$}$$

We denote a solution of $(4.2)_\lambda$ by $u(\cdot, p, \lambda)$. It follows from standard theorems on the continuous dependence of solutions on parameters and on initial data that $(p, \lambda) \to u(\cdot, p, \lambda)$ is a continuous function from $[0, 1] \times [0, \infty)$ to $C[0, R]$ for any $R > 0$.

Let $A(\lambda) = \{p \in (0, 1)$: there exists $R > 0$ such that $0 < u(r, p, \lambda) < 1$ for $0 \leqq r < R$ and $u(R, p, \lambda) = 0\}$ and $B(\lambda) = \{p \in (0, 1)$: there exists $R > 0$ such that $0 < u(r, p, \lambda) < 1$ for $0 \leqq r < R$ and $u(R, p, \lambda) = 1\}$.

It is straightforward to prove from the continuous dependence of solutions on parameters that $A(\lambda)$ and $B(\lambda)$ are open disjoint subsets of $(0, 1)$. Thus the following result is obvious.

LEMMA 4.2. (i) *Let $p \in (0, 1)$. Then $u(\cdot, p, \lambda)$ is a solution of* $(1.3)_\lambda$ *if and only if $p \notin A(\lambda) \cup B(\lambda)$.*

(ii) *If $A(\lambda)$ and $B(\lambda)$ are both nonempty, then there exists a solution of* $(1.3)_\lambda$.

We next use the uniqueness result of Theorem 4.1(ii) to obtain further information about $A(\lambda)$ and $B(\lambda)$.

LEMMA 4.3. (i) *If $A(\lambda) \neq \emptyset$, then there exists $p(\lambda)$, $0 < p(\lambda) \leqq 1$, such that $A(\lambda) = (0, p(\lambda))$.*

(ii) *Suppose* $(1.3)_\lambda$ *has a solution. Then there exists $p(\lambda)$, $0 < p(\lambda) < 1$ such that $A(\lambda) = (0, p(\lambda))$, $B(\lambda) = (p(\lambda), 1)$ and $u(\cdot, p(\lambda), \lambda)$ is the solution of* $(1.3)_\lambda$.

Proof. If $p \in A(\lambda)$, there exists $R > 0$ such that $0 < u(r, p, \lambda) < 1$ for $0 < r < R$ and $u(R, p, \lambda) = 0$. Assume that $q < p$ and $q \notin A(\lambda)$. Then either $u(r_0, q, \lambda) = 1$ for some r_0, $0 < r_0 \leqq R$ or $u(r, q, \lambda) > 0$ for $0 < r \leqq R$. In either case there exists r_1, $0 < r_1 < R$, such that $u(r_1, q, \lambda) = u(r_1, p, \lambda) (= k$, say). Thus $u(\cdot, p, \lambda)$ and $u(\cdot, q, \lambda)$ correspond to

distinct radially symmetric solutions of (4.1), which is impossible. Hence there exists $p(\lambda) \in (0, 1)$ such that $A(\lambda) = (0, p(\lambda))$. Part (ii) follows from the fact that under our hypotheses on f and g, $(1.3)_\lambda$ has at most one solution.

We shall use the preceding result to investigate the bifurcation of solutions. To this end let

$$\Lambda = \{\lambda > 0: \text{there exists a solution of } (1.3)_\lambda\}.$$

It follows from straightforward continuous dependence arguments that Λ is an open set. The results of § 2 show that $\lambda \in \Lambda$ provided that λ is sufficiently large. If $\lambda \in \Lambda$, by Theorem 4.1 equation $(1.3)_\lambda$ has a unique solution, which we denote by u_λ. The next result shows how $p(\lambda)$ and u_λ behave as λ approaches the boundary of Λ.

LEMMA 4.4. *Suppose that $\mu > 0$ is such that $(\mu, \mu + \varepsilon) \subset \Lambda$ for some $\varepsilon > 0$ but $\mu \notin \Lambda$. Then, as $\lambda \to \mu^+$,*

(i) *Either $p(\lambda) \to 1$ and $u_\lambda \to 1$ uniformly on compact subintervals of $[0, \infty)$, or*

(ii) *$p(\lambda) \to 0$ and $u_\lambda \to 0$ uniformly on compact subintervals of $[0, \infty)$.*

Proof. Since $\mu \notin \Lambda$, either $A(\mu) = (0, 1)$ or $B(\mu) = (0, 1)$. Suppose $A(\mu) = (0, 1)$. Let $q \in (0, 1)$. Then $q \in A(\mu)$. Using continuous dependence of solutions it is easy to show that $q \in A(\lambda)$, provided that λ is sufficiently close to μ. But, if $q \in A(\lambda)$, then by Lemma 4.3, $p(\lambda) > q$. Since q can be chosen arbitrarily close to 1, it follows that $p(\lambda) \to 1$ as $\lambda \to \mu^+$. By the continuous dependence of solutions on initial data $u_\lambda(r) = u(r, p(\lambda), \lambda) \to 1$ uniformly on compact subintervals of $[0, \infty)$.

In the case where $B(\mu) = (0, 1)$ a similar argument shows that (ii) holds.

Finally in this section we make use of our previous results on the shooting method to prove that under certain hypotheses all solutions of $(1.2)_\lambda$ are radially symmetric.

LEMMA 4.5. (i) *If $A(\lambda) \neq \emptyset$, then there are arbitrarily small radially symmetric weak subsolutions of $(1.2)_\lambda$.*

(ii) *If $B(\lambda) \neq \emptyset$, then there are radially symmetric weak supersolutions of $(1.2)_\lambda$ which are arbitrarily close to 1 on any compact subinterval of $[0, \infty)$.*

Proof. If $A(\lambda) \neq \emptyset$, then $A(\lambda) = (0, p(\lambda))$. For all $p < p(\lambda)$ let $R(p)$ denote the first positive zero of $u(r, p, \lambda)$. Let

$$v_p(r) = \begin{cases} u(r, p, \lambda) & \text{for } 0 \leqq r \leqq R(p), \\ 0 & \text{for } r > R(p). \end{cases}$$

Clearly, $v_p(r)$ is a radially symmetric weak subsolution of $(1.2)_\lambda$. Let $\varepsilon > 0$. There exists $p_1 \leqq p(\lambda)$ such that $|u(r, p, \lambda)| < \varepsilon$ for all $p \leqq p_1$ and $r \leqq R_0$. If $R(p) \leqq R_0$, clearly $v_p(r) < \varepsilon$ for all $r > 0$. If $R(p) > R_0$, then since

$$u'' + \frac{n-1}{r} u' = -\lambda g(r) f(u) > 0 \quad \text{for } R_0 < r < R(p),$$

u has no local maximum turning points for $R_0 < r < R(p)$, and so $u(r, p, \lambda)$ is a decreasing function on $(R_0, R(p))$; hence $v_p(r) < \varepsilon$ for all $r > 0$. Hence arbitrarily small radially symmetric weak subsolutions v_p can be obtained by making p sufficiently small.

Part (ii) has a similar proof.

LEMMA 4.6. *Suppose that $(1.2)_\lambda$ has a nonradially symmetric solution u. Then $(1.2)_\lambda$ also has a radially symmetric solution.*

Proof. Assume the contrary. Then $A(\lambda) = (0, 1)$ or $B(\lambda) = (0, 1)$. Suppose $A(\lambda) = (0, 1)$. Then by Lemma 4.5 there exist arbitrarily small radially symmetric subsolutions, with compact support. It follows from the maximum principle that $0 < u(x) < 1$ for all x in R^n. Hence there exists a radially symmetric weak subsolution $\underline{u}$ such that

$0 \leqq \underline{u}(|x|) \leqq u(x)$ for all $x \in R^n$. Using Ni's results in [6], we have that the iteration starting from the radially symmetric subsolution $\underline{u}$ converges to a radially symmetric solution lying below the (super) solution u. This is a contradiction, and so the proof is complete. A similar contradiction arises if $B(\lambda) = (0, 1)$.

THEOREM 4.7. *Suppose f satisfies* (F_0) *and is concave and g satisfies* (G_1). *Then every solution of* $(1.2)_\lambda$ *is radially symmetric.*

Proof. Suppose u is a nonradially symmetric solution of $(1.2)_\lambda$. Then there exists a radially symmetric solution of $(1.2)_\lambda$, and so by Lemma 4.3 $A(\lambda)$ and $B(\lambda)$ are nonempty. Hence by Lemma 4.5 there exist radially symmetric weak sub- and supersolutions $\underline{u}$ and $\bar{u}$ such that $\underline{u} \leqq u \leqq \bar{u}$. Ni's results in [6] imply the existence of radially symmetric solutions u_1 and u_2 such that $\underline{u} \leqq u_1 \leqq u \leqq u_2 \leqq \bar{u}$. Since u is nonradially symmetric, $u_1 \neq u$ and $u_2 \neq u$, and so $u_1 \neq u_2$. But this is impossible because of Theorem 4.1, and so every solution of $(1.2)_\lambda$ is radially symmetric.

5. The case $\int_{R^n} g(x)\,dx < 0$. In this section we shall discuss the equation

$$-\Delta u = \lambda g(|x|)u(1-u)(h(1-u)+(1-h)u) \quad \text{on } R^n: 0 < u < 1 \tag{5.1}_\lambda$$

where $\frac{1}{3} < h < \frac{2}{3}$. Then $f(u) = u(1-u)(h(1-u)+(1-h)u)$ satisfies (F_0) and is concave. We shall assume throughout the section that g satisfies (G_1). Thus the results of § 4 apply to equation $(5.1)_\lambda$.

We first show that $(1.3)_\lambda$ has no solutions when λ is sufficiently small.

LEMMA 5.1. *If $-\infty \leqq \int_{R^n} g(x)\,dx < 0$, then there exists $\lambda_0 > 0$ such that*

$$\int_{R^n} |\nabla u|^2\,dx \geqq \lambda_0 \int_{R^n} g(x)f(u)u\,dx$$

for all $u \in H^1(R^n)$ such that $0 \leqq u \leqq 1$ and $\int_{R^n} gu^2\,dx > 0$.

Proof. Choose $R > R_0$ such that $\int_B g\,dx < 0$ where $B = \{x \in R^n: |x| \leqq R\}$. It is proved in [2] that there exists $\lambda_1 > 0$ such that

$$\int_B |\nabla u|^2\,dx \geqq \lambda_1 \int_B u^2\,dx$$

for all $u \in H^1(B)$ such that $\int_B gu^2\,dx > 0$.

Let $K = \sup\{|g(x)|: x \in B\}$ and $M = \sup\{f(u)/u: 0 \leqq u \leqq 1\}$. Let $u \in H^1(R^n)$ such that $0 \leqq u \leqq 1$ and $\int_{R^n} gu^2\,dx > 0$. Then $\int_B gu^2\,dx > 0$ and so

$$\begin{aligned}\int_{R^n} |\nabla u|^2\,dx &\geqq \int_B |\nabla u|^2\,dx \geqq \lambda_1 \int_B u^2\,dx \\ &\geqq (KM)^{-1}\lambda_1 \int_B g(x)f(u)u\,dx \\ &\geqq (KM)^{-1}\lambda_1 \int_{R^n} g(x)f(u)u\,dx.\end{aligned}$$

THEOREM 5.2. *Suppose $-\infty \leqq \int_{R^n} g(x)\,dx < 0$, λ_0 is as in Lemma* 5.1, *and $\lambda < \lambda_0$. Then there does not exist a solution of* $(5.1)_\lambda$.

Proof. Assume the contrary, that $(5.1)_\lambda$ has a solution u. Then by Lemma 4.3, $A(\lambda)$ is nonempty, and so there exists $p \in (0, 1)$ and $R > 0$ such that $0 < u(r, p, \lambda) < 1$ for $r \in (0, R)$ and $u(R, p, \lambda) = 0$. Define v by $v(r) = u(r, p, \lambda)$ for $0 \leqq r \leqq R$ and $v(r) = 0$ for $r > R$. Clearly, $0 \leqq v < 1$ and $v \in H^1(R^n)$. We now show that $\int_{R^n} gv^2\,dx > 0$. Let

$w = v^2/f(v)$. Since v is bounded away from 1, $w \in L^2(R^n)$. Moreover,

$$\nabla w = v/f^2(v)[2f(v) - vf'(v)]\nabla v,$$

and so $w \in H^1(R^n)$. Since v satisfies

$$-\Delta v = \lambda g(r)f(v) \quad \text{on } B = \{x \in R^n : |x| \leqq R\}, \qquad v(x) = 0 \quad \text{on } \partial B \tag{5.2}$$

multiplying by w and integrating, we obtain

$$\lambda \int_B gv^2\,dx = -\int_B \Delta v\, w = \int_B \nabla v \cdot \nabla w\,dx$$

$$= \int_B v/f^2(v)[2f(v) - vf'(v)]|\nabla v|^2\,dx > 0$$

as $f(v) = v(1-v)(h(1-v) + (1-h)v)$. Hence $\int_{R^n} gv^2\,dx > 0$. Therefore by Lemma 5.1

$$\int_{R^n} |\nabla v|^2\,dx \geqq \lambda_0 \int_{R^n} g(x)f(v)v\,dx.$$

However, multiplying (5.2) by v and integrating gives

$$\int_{R^n} |\nabla v|^2\,dx = \lambda \int_{R^n} g(x)f(v)v\,dx,$$

and this is a contradiction.

The previous theorem shows that Λ is bounded away from zero. The following results show that bifurcation from the zero solution occurs at points on the boundary of Λ.

THEOREM 5.3. *Suppose* $-\infty \leqq \int_{R^n} g(x)\,dx < 0$. *Suppose* $\mu \notin \Lambda$ *but* $(\mu, \mu + \varepsilon) \subset \Lambda$ *for some* $\varepsilon > 0$. *Then*

(i) $u_\lambda \to 0$ *as* $\lambda \to \mu^+$,

(ii) μ *is an eigenvalue for the linear problem*

$$-\Delta u = \lambda g(r)f'(0)u \quad \text{for } x \text{ in } R^n, \qquad \lim_{x\to\infty} u(x) = 0 \tag{5.3}$$

and there exists a corresponding nonnegative radially symmetric eigenfunction.

Proof (i). Suppose the contrary. Then by Lemma 4.4 $u_\lambda \to 1$ uniformly on compact subintervals of $[0, \infty)$ as $\lambda \to \mu^+$. Choose $R > R_0$ such that $\int_{|x|\leqq R} g(x)\,dx < 0$. Now $u = u_\lambda$ satisfies

$$\frac{(r^{n-1}u')'}{1-u} + \frac{\lambda r^{n-1}g(r)f(u)}{1-u} = 0 \quad \text{for } r > 0.$$

Integrating from 0 to R, we obtain

$$\frac{R^{n-1}u'(R)}{1-u(R)} - \int_0^R \frac{s^{n-1}[u'(s)]^2}{(1-u(s))^2}\,ds + \lambda \int_0^R \frac{s^{n-1}g(s)f(u(s))}{1-u(s)}\,ds = 0. \tag{5.4}$$

Since $\lim_{r\to\infty} u(r) = 0$ and $u''(r) > 0$ at any critical point of u when $r > R_0$, it follows that $u'(R) \leqq 0$. Hence by (5.4)

$$\int_0^R \frac{s^{n-1}g(s)f(u(s))}{1-u(s)}\,ds > 0.$$

As $\lambda \to \mu^+$, $u_\lambda \to 1$ and so $f(u_\lambda(s))/(1-u_\lambda(s)) \to -f'(1)$ uniformly on $[0, R]$. Hence $f'(1)\int_0^R s^{n-1}g(s)\,ds \leqq 0$, and this is a contradiction.

(ii) Suppose $\lambda_k \to \mu^+$. Let u_k denote u_{λ_k} and let r_k denote the point where u_k attains its maximum value. Since u_k is decreasing on $[R_0, \infty)$, $r_k \leqq R_0$. Let $v_k = u_k/u_k(r_k)$. Then

$$(r^{n-1}v_k')' + \lambda_k r^{n-1} g(r)[f(u_k)/u_k]v_k = 0 \quad \text{for } r > 0, \qquad v_k'(0) = 0.$$

Hence

$$r^{n-1}v_k'(r) = -\lambda_k \int_0^r s^{n-1} g(s) \left[\frac{f(u_k)}{u_k}\right] v_k \, ds. \tag{5.5}$$

Let $R > R_0$. It follows from (5.5) that $\{v_k\}$ is a bounded, equicontinuous sequence of functions on $[0, R]$. By considering the integral equation satisfied by v_k and letting $k \to \infty$, it is straightforward to show that $v'(0) = 0$ and that v must satisfy $-\Delta v = \lambda g(r) f'(0) v$ on $[0, R]$. Using a standard diagonalization procedure we can find a subsequence $\{v_k\}$ converging to v on $[0, \infty)$ such that v satisfies $-\Delta v = \lambda g(r) f'(0) v$ on $[0, \infty)$. Since $v_k \geqq 0$ for all k, $v \geqq 0$. As v_k attains the value one at some point of $[0, R_0)$ for all k, $v \not\equiv 0$. Finally, as g satisfies (G_1), it follows from the results of § 3 that $\lim_{r\to\infty} v(r) = 0$.

By placing further restrictions on g we can ensure that bifurcation occurs from the zero solution at only a single point.

LEMMA 5.4. *Suppose that g is bounded below and that g is bounded away from zero as $r \to \infty$. If μ and ν are eigenvalues of* (5.3) *corresponding to positive eigenfunctions u and v, then $\mu = \nu$.*

Proof. We may suppose without loss of generality that $\mu \leqq \nu$. Multiplying the u-equation by u and integrating, we obtain

$$r^{n-1}u'(r)u(r) - \int_0^r s^{n-1}(u')^2 \, ds + \mu f'(0) \int_0^r s^{n-1} g(s) u^2 \, ds = 0. \tag{5.6}$$

Multiplying the v-equation by u^2/v and integrating we obtain

$$\begin{aligned} &r^{n-1}\frac{v'(r)}{v(r)}[u(r)]^2 - \int_0^r s^{n-1} v' \left[\frac{2uu'}{v} - \frac{u^2 v'}{v^2}\right] ds \\ &\quad + \nu f'(0) \int_0^r s^{n-1} g(s) u^2 \, ds = 0. \end{aligned} \tag{5.7}$$

By Lemma 3.6, u'/u and v'/v are bounded, and by Theorem 3.7, u, v, u', v' decay exponentially. Hence letting $r \to \infty$ and then combining appropriate multiples of (5.6) and (5.7), we obtain

$$\nu \int_0^\infty s^{n-1}(u')^2 \, ds - \mu \int_0^\infty s^{n-1} v' \left[\frac{2uu'}{v} - \frac{u^2 v'}{v^2}\right] ds = 0,$$

i.e.,

$$\int_0^\infty s^{n-1} \left[(\nu - \mu)(u')^2 + \mu \left(\frac{uv'}{v} - u'\right)^2\right] ds = 0.$$

Hence $\nu = \mu$ and the proof is complete.

It follows from the preceding results that the boundary of Λ must coincide with the unique eigenvalue of (5.3) corresponding to a positive eigenfunction. Thus we have Theorem 5.5.

THEOREM 5.5. *Suppose that g is bounded below, and that g is bounded away from zero as $r \to \infty$. Then there exists $\mu_0 > 0$ such that for problem $(5.1)_\lambda$, $\Lambda = (\mu_0, \infty)$ and $u_\lambda \to 0$ as $\lambda \to \mu_0^+$.*

6. Bifurcation from $u \equiv 1$. We again discuss $(5.1)_\lambda$ with the assumption that $\frac{1}{3} < h < \frac{2}{3}$ (so that f is concave). We restrict attention to the cases $n = 1$, 2. We shall assume that g satisfies

$$(G_2) \qquad \begin{aligned} &\lim_{r\to\infty} r^2 g(r) = -\infty \quad \text{when } n = 1, \\ &\lim_{r\to\infty} r^2 (\ln r)^2 g(r) = -\infty \quad \text{when } n = 2. \end{aligned}$$

Clearly, (G_2) implies (G_1), and so, if g satisfies (G_2), equation $(5.1)_\lambda$ has at most one solution u, and u must be radially symmetric and $\lim_{r\to\infty} u(r) = 0$.

We shall also assume that g satisfies

$$(G_3) \qquad \int_{R^n} g(|x|)\, dx > 0.$$

Hypotheses (G_2) and (G_3) are satisfied by functions g which have the following asymptotic behavior as $r \to \infty$:

$$g(r) \sim -r^{-\alpha} \quad \text{where } 1 < \alpha < 2 \quad \text{when } n = 1,$$

$$g(r) \sim -r^{-2}(\ln r)^{-\alpha} \quad \text{where } 1 < \alpha < 2 \quad \text{when } n = 2.$$

We shall prove results only for the case $n = 2$; identical results with somewhat simpler proofs hold when $n = 1$. Our main result (Theorem 6.4) shows that bifurcation occurs from the branch of trivial solutions $u \equiv 1$ when $\lambda = 0$.

It is shown in [2] that, if g satisfies (G_3), then $(5.1)_\lambda$ has subsolution with compact support for all $\lambda > 0$ and that, if g satisfies (G_2), then $(5.1)_\lambda$ has a supersolution which is identically equal to 1 on a big interval of the form $[0, R]$ for all $\lambda > 0$. Thus we have the following result.

LEMMA 6.1. *Suppose g satisfies (G_2) and (G_3). Then equation $(5.1)_\lambda$ has a unique solution u_λ for all $\lambda > 0$.*

We now investigate the behavior of u_λ as $\lambda \to 0$. The following identity enables us to exclude the possiblity that $u_\lambda \to 0$.

LEMMA 6.2. *Suppose g satisfies (G_2) and (G_3). If u is a solution of $(5.1)_\lambda$ then*

$$\int_0^\infty r\left[\frac{u'}{f(u)}\right]^2 f'(u)\, dr + \lambda \int_0^\infty r g(r)\, dr = 0.$$

Proof. Since u is a solution of $(5.1)_\lambda$, we have

$$(ru')'/f(u) + \lambda r g(r) = 0 \quad \text{for } r > 0.$$

Hence

$$(6.1) \qquad \frac{ru'}{f(u)} + \int_0^r s\left(\frac{u'}{f(u)}\right)^2 f'(u)\, ds + \lambda \int_0^r s g(s)\, ds = 0.$$

By Corollary 3.9, $\lim_{r\to\infty} ru'/u = 0$, and so $\lim_{r\to\infty} ru'/f(u) = 0$. Since $\int_0^\infty rg(r)\, dr$ converges, the required identity follows by letting $r \to \infty$ in (6.1).

COROLLARY 6.3. *Suppose g satisfies (G_2) and (G_3). Let u be a solution of $(5.1)_\lambda$. Then $\max\{u(r): r > 0\} \geqq \sigma$ where $\sigma = \inf\{u \in (0, 1): f'(u) = 0\}$.*

Proof. Assume the contrary. Then $u(r) < \sigma$, and so $f'(u(r)) > 0$ for all $r > 0$. This is clearly impossible because of Lemma 6.2.

THEOREM 6.4. *Suppose g satisfies* (G_2) *and* (G_3). *Suppose* $\lambda_k \to 0$ *and* $u_k = u_{\lambda_k}$. *Then* $u_k \to 1$ *uniformly on compact subintervals of* $[0, \infty)$.

Proof. Because of the continuous dependence of $u(\cdot, p, \lambda)$ on p and λ it suffices to prove that $\lim_{k\to\infty} u_k(0) = 1$. Assume the contrary. Then there exist $l \in [0, 1)$ and subsequences which we again denote by λ_k and u_k such that $\lim_{k\to\infty} u_k(0) = l$.

Suppose $l = 0$. It follows from continuous dependence arguments that u_k converges uniformly to zero on $[0, R_0]$, and so, since u_k is decreasing on $[R_0, \infty)$, that u_k converges uniformly to zero on R. This is impossible because of Corollary 6.3.

Suppose $0 < l < 1$. Since

$$(ru_k')' = \lambda_k r g(r) f(u_k) \quad \text{for } r > 0, \qquad u_k'(0) = 0 \tag{6.2}$$

it follows that

$$u_k(r) = u_k(0) + \lambda_k \int_0^r s \ln\left(\frac{r}{s}\right) g(s) f(u_k(s))\, ds \quad \text{for } r > 0. \tag{6.3}$$

Since $\lim_{k\to\infty} \lambda_k \int_0^r s \ln(r/s) g(s) f(u_k(s))\, ds = 0$ for all r, $0 \leqq r \leqq R$, letting $k \to \infty$ in (6.3), we have that u_k converges uniformly to l on $[0, R]$. Hence

$$\lim_{k\to\infty} \int_0^\infty r g(r) f(u_k)\, dr = \int_0^\infty r g(r) f(l)\, dr > 0. \tag{6.4}$$

However, integrating (6.2) from zero to infinity and using Corollary 3.9, shows that $\int_0^\infty r g(r) f(u_k)\, dr = 0$ for all k, and this is a contradiction.

Hence $\lim_{k\to\infty} u_k(0) = 1$ and the proof is complete.

ON THE REPRESENTATION OF STOKES FLOWS*

WERNER KRATZ†

Abstract. In this paper representations of Stokes flows in dimensions 2 and 3, which reduce the Stokes equations to the Laplace equation for an auxiliary function, are given. While it is known that two- and three-dimensional Stokes flows may be reduced to biharmonic problems, the representations here are new. The main result of this paper reads as follows: Given a domain $G \subseteq \mathbb{R}^3$, which is star-shaped with respect to the origin, and functions $\vec{v}: G \to \mathbb{R}^3$, $p: G \to \mathbb{R}$, then $\vec{v}$ and p represent a Stokes flow with velocity field $\vec{v}$ and pressure p in G (i.e., $\Delta \vec{v} = \operatorname{grad} p$ and $\operatorname{div} \vec{v} = 0$ in G) if and only if $\vec{v}$ and p are of the form

$$\vec{v}(\vec{x}) = \tilde{\vec{v}}(\vec{x}) - \tfrac{1}{3}\{\operatorname{div} \tilde{\vec{v}}(\vec{x}) \cdot \vec{x} + \vec{x} \times \operatorname{curl} \tilde{\vec{v}}(\vec{x})\}, \qquad p(\vec{x}) = -\tfrac{4}{3} \operatorname{div} \tilde{\vec{v}}(\vec{x}),$$

where $\tilde{\vec{v}}$ is a harmonic function (i.e., $\Delta \tilde{\vec{v}} = 0$) in G.

Key words. Stokes flows, Stokes equations, harmonic functions

AMS(MOS) subject classifications. 76D07, 35Q10, 31A10

1. Introduction. In this paper we derive formulae for the velocity field $\vec{v}$ and the pressure p of two- and three-dimensional *Stokes flows*, which represent $\vec{v}$ and p via a certain (uniquely determined) auxiliary *harmonic function* $\tilde{\vec{v}}$. For dimension 2 our Theorem 1 extends a result of [3, Thm. 1 and Lemma 2], where $\vec{v}$ and p of a Stokes flow are expressed by two holomorphic functions provided the corresponding domain $G \subseteq \mathbb{R}^2$ is simply connected. Our two-dimensional representation formula here is valid for any domain $G \subseteq \mathbb{R}^2$, and, moreover, we can express the auxiliary function $\tilde{\vec{v}}$ explicitly in terms of $\vec{v}$ and p. Besides the result in [3] there are well-known reductions of the Stokes problem in dimensions 2 and 3 to biharmonic problems (see, e.g., [1], [9], and [6]).

The *main result* of this paper is a representation theorem (Theorem 2 below) for *three-dimensional Stokes flows*. This theorem is quite similar to the two-dimensional Theorem 1, and its essential part reads as follows. Given a domain $G \subseteq \mathbb{R}^3$, which is *star-shaped* with respect to the origin, and given functions $\vec{v}: G \to \mathbb{R}^3$, $p: G \to \mathbb{R}$, then $\vec{v}$ and p represent a Stokes flow in G, i.e.,

$$\Delta \vec{v} = \operatorname{grad} p, \qquad \operatorname{div} \vec{v} = 0 \quad \text{in } G,$$

if and only if there exists a harmonic function $\tilde{\vec{v}}$ (i.e., $\Delta \tilde{\vec{v}} = 0$) in G such that

$$\vec{v}(\vec{x}) = \tilde{\vec{v}}(\vec{x}) - \tfrac{1}{3}\{\operatorname{div} \tilde{\vec{v}}(\vec{x}) \cdot \vec{x} + \vec{x} \times \operatorname{curl} \tilde{\vec{v}}(\vec{x})\},$$
$$p(\vec{x}) = -\tfrac{4}{3} \operatorname{div} \tilde{\vec{v}}(\vec{x}) \quad \text{for } \vec{x} \in G.$$

Moreover, $\tilde{\vec{v}}$ is uniquely determined by $\vec{v}$ and p, and we give an explicit formula expressing $\tilde{\vec{v}}$ in terms of $\vec{v}$ and p (see Theorem 2 below). In the case of so-called *potential flows* (i.e., $\vec{v} = \operatorname{grad} \phi$ with $\Delta \phi = 0$) our representation formula becomes trivial, i.e., $\vec{v} = \tilde{\vec{v}}$ (since $\operatorname{div} \vec{v} = 0$, $\operatorname{curl} \vec{v} = 0$ in that case). Moreover, it may be interesting to ask whether the auxiliary harmonic function $\tilde{\vec{v}}$ has any "concrete" physical interpretation with respect to the Stokes flow.

Let us shortly summarize the setup of this paper. In § 2 we state our results on two- and three-dimensional Stokes equations (Theorems 1 and 2). Some auxiliary

† Abteilung Mathematik, Universität Ulm, Albert-Einstein-Allee 11, D-7900 Ulm, Federal Republic of Germany.

formulae from the vector analysis are given in § 3. Section 4 is devoted to the proof of the two-dimensional result. The main result, i.e., the three-dimensional Theorem 2, is shown in § 5, where we also discuss the assumption on the domain (i.e., *star-shaped* with respect to the origin) in detail. But it remains an open question whether Theorem 2 can be extended to more general domains (e.g., simply connected domains).

Finally, we want to point out that these representation formulae can serve as the basis of numerical algorithms (see [3] for such an algorithm in dimension two via conformal mappings) to solve Stokes boundary value problems. In view of our results these problems reduce to solving Laplace's equation $\Delta\tilde{\vec{v}} = 0$ with "suitably adapted" boundary conditions.

2. Main results. To formulate our results we need some *notation* and *notions*. We will use the usual *inner product* in $\mathbb{R}^2$ or $\mathbb{R}^3$ and *vector product* in $\mathbb{R}^3$. The differential operators grad, div, and Δ denote the *gradient*, *divergence*, and *Laplacian* of scalar functions, respectively, vector fields in $\mathbb{R}^2$ or $\mathbb{R}^3$. While curl is defined as usual for vector fields in $\mathbb{R}^3$, we introduce the following additional notation in $\mathbb{R}^2$:

$$\operatorname{curl}\vec{v} := \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} \quad \text{for a vector field } \vec{v} = \begin{pmatrix} u \\ v \end{pmatrix} \quad \text{in } \mathbb{R}^2;$$

$$\vec{x}^{\perp}\alpha := \begin{pmatrix} \alpha y \\ -\alpha x \end{pmatrix}, \quad \text{and} \quad \vec{x}^{\perp} := \begin{pmatrix} y \\ -x \end{pmatrix} \quad \text{for } \vec{x} = \begin{pmatrix} x \\ y \end{pmatrix} \in \mathbb{R}^2, \quad \alpha \in \mathbb{R}.$$

Moreover, we need the following definition.

DEFINITION 1. Let $G \subseteq \mathbb{R}^n$ be a domain. A function $\vec{v}: G \to \mathbb{R}^n$ is called

(i) *harmonic* in G, if $\vec{v} \in C_2(G)$ and if $\Delta\vec{v}(\vec{x}) = 0$ for $\vec{x} \in G$; and it is called a

(ii) *Stokes function* in G, if $\vec{v} \in C_2(G)$ and if there exists a (pressure-) function $p: G \to \mathbb{R}$ with $p \in C_1(G)$ and

$$\Delta\vec{v}(\vec{x}) = \operatorname{grad} p(\vec{x}), \qquad \operatorname{div}\vec{v}(\vec{x}) = 0 \quad \text{for } \vec{x} \in G. \tag{1}$$

Remark 1. Obviously, for a given Stokes function the corresponding pressure p is unique up to an additive constant. Next, every function that is harmonic in a domain G belongs to $C_\infty(G)$, even every continuous solution q of $\Delta q = h$ if $h \in C_\infty(G)$. Moreover, by a result of Weyl [10], every Stokes function $\vec{v}$ in a domain G is in $C_\infty(G)$, and a corresponding pressure-function p is harmonic in G, since $\Delta p = \operatorname{div}\{\operatorname{grad} p\} = \operatorname{div}\{\Delta\vec{v}\} = 0$ by (1). For this reason, we will not discuss differentiability conditions from now on.

THEOREM 1. *Let $G \subseteq \mathbb{R}^2$ be a domain. A function $\vec{v}: G \to \mathbb{R}^2$ is a Stokes function with corresponding pressure p in G, if and only if there exists a harmonic function $\tilde{\vec{v}}$ in G such that*

$$\begin{aligned} \vec{v}(\vec{x}) &= \tilde{\vec{v}}(\vec{x}) - \tfrac{1}{2}\{\operatorname{div}\tilde{\vec{v}}(\vec{x})\cdot\vec{x} + \vec{x}^{\perp}\operatorname{curl}\tilde{\vec{v}}(\vec{x})\}, \\ p(\vec{x}) &= -2\operatorname{div}\tilde{\vec{v}}(\vec{x}) \quad \textit{for } \vec{x} \in G; \end{aligned} \tag{2}$$

this harmonic function $\tilde{\vec{v}}$ is unique, and we have

$$\tilde{\vec{v}}(\vec{x}) = \vec{v}(\vec{x}) - \tfrac{1}{4}\{p(\vec{x})\cdot\vec{x} - \vec{x}^{\perp}\operatorname{curl}\vec{v}(\vec{x})\} \quad \text{for } \vec{x} \in G. \tag{3}$$

This theorem is a quite statisfactory completion of [3, Thm. 1], where G was assumed to be simply connected. But our main objective here is the following representation theorem in the most interesting dimension 3, where no such result seems to exist. The assumption on the domain G is not as satisfactory as in dimension 2 above. We have to assume that G is *star-shaped with respect to the origin*, i.e., $t\vec{x} \in G$ for all $t \in [0, 1]$ whenever $\vec{x} \in G$.

THEOREM 2. *Assume that $G \subseteq \mathbb{R}^3$ is a star-shaped domain with respect to the origin. Then a function $\vec{v}: G \to \mathbb{R}^3$ is a Stokes function with corresponding pressure p in G, if and only if there exists a harmonic function $\tilde{\vec{v}}$ in G such that*

$$\begin{aligned} \vec{v}(\vec{x}) &= \tilde{\vec{v}}(\vec{x}) - \tfrac{1}{3}\{\operatorname{div} \tilde{\vec{v}}(\vec{x}) \cdot \vec{x} + \vec{x} \times \operatorname{curl} \tilde{\vec{v}}(\vec{x})\}, \\ p(\vec{x}) &= -\tfrac{4}{3} \operatorname{div} \tilde{\vec{v}}(\vec{x}) \quad \text{for } \vec{x} \in G; \end{aligned} \tag{4}$$

this harmonic function $\tilde{\vec{v}}$ is unique, and we have

$$\tilde{\vec{v}}(\vec{x}) = \vec{v}(\vec{x}) - \tfrac{1}{4}\{p(\vec{x}) \cdot \vec{x} - \vec{x} \times \operatorname{curl} \vec{v}(\vec{x})\} + \vec{x} \times \operatorname{grad} \phi(\vec{x}) \quad \text{for } \vec{x} \in G, \tag{5}$$

where the function ϕ is harmonic in G and given by

$$\phi(\vec{x}) = -\frac{1}{4} \int_0^1 t^4 \vec{x} \cdot \operatorname{curl} \vec{v}(t\vec{x})\, dt \quad \text{for } \vec{x} \in G. \tag{6}$$

We will prove this theorem in § 5, in particular the assumption on G (i.e., star-shaped with respect to the origin) will be discussed there in detail.

Remark 2. Of course, two-dimensional Stokes functions $\vec{v} = \binom{u}{v}$ are also Stokes functions in dimension 3 (with $u_z = v_z \equiv 0$) by setting the third component $w \equiv 0$. But in that case the three-dimensional representation formula (4) above does *not* reduce to the corresponding two-dimensional formula (2) (e.g., we have the factor $\frac{1}{3}$ in (4) instead of $\frac{1}{2}$ in (2)). Moreover, it is not clear at all, how the representation (2) can be derived from formula (4) (or vice versa) in the case of two-dimensional flows.

3. Auxiliary formulae from the vector analysis. For the proofs of Theorems 1 and 2 we need several formulae from the vector analysis, which are, at least partly, well known (see, e.g., [8, § 124, p. 384]). These formulae can be verified directly, and we assume, of course, the existence and/or continuity of the partial derivatives involved.

LEMMA 1. *Let $\vec{v}: G \to \mathbb{R}^n$, $\phi: G \to \mathbb{R}$, $G \subseteq \mathbb{R}^n$. Then*

$$\operatorname{curl}\{\phi(\vec{x}) \cdot \vec{x}\} = \operatorname{grad} \phi(\vec{x}) \cdot \vec{x}^{\perp} \quad \text{for } n = 2; \tag{7}$$

$$\operatorname{curl}\{\vec{x}^{\perp} \operatorname{curl} \vec{v}(\vec{x})\} = [\Delta \vec{v}(\vec{x}) - \operatorname{grad}\{\operatorname{div} \vec{v}(\vec{x})\}] \cdot \vec{x}^{\perp} - 2 \operatorname{curl} \vec{v}(\vec{x}) \quad \text{for } n = 2; \tag{8}$$

$$\begin{aligned} \operatorname{div}\{\phi(\vec{x}) \cdot \vec{x}\} &= 2\phi(\vec{x}) + \vec{x} \cdot \operatorname{grad} \phi(\vec{x}) \text{ for } n = 2, \textit{ respectively}, \\ \operatorname{div}\{\phi(\vec{x}) \cdot \vec{x}\} &= 3\phi(\vec{x}) + \vec{x} \cdot \operatorname{grad} \phi(\vec{x}) \text{ for } n = 3; \end{aligned} \tag{9}$$

$$\operatorname{curl}\{\phi(\vec{x}) \cdot \vec{x}\} = -\vec{x} \times \operatorname{grad} \phi(\vec{x}) \quad \text{for } n = 3; \tag{10}$$

$$\Delta\{\phi(\vec{x}) \cdot \vec{x}\} = 2 \operatorname{grad} \phi(\vec{x}) + \Delta\phi(\vec{x}) \cdot \vec{x} \quad \text{for } n = 2 \text{ or } n = 3; \tag{11}$$

$$\begin{aligned} \operatorname{curl}\{\operatorname{grad} \phi(\vec{x})\} &= 0 \quad \text{for } n = 2 \text{ or } n = 3, \\ \operatorname{div}\{\operatorname{curl} \vec{v}(\vec{x})\} &= 0, \qquad \operatorname{div}\{\vec{x} \times \operatorname{grad} \phi(\vec{x})\} = 0 \quad \text{for } n = 3; \end{aligned} \tag{12}$$

$$\begin{aligned} \operatorname{div}\{\vec{x}^{\perp} \operatorname{curl} \vec{v}(\vec{x})\} &= \vec{x} \cdot \Delta \vec{v}(\vec{x}) - \vec{x} \cdot \operatorname{grad}\{\operatorname{div} \vec{v}(\vec{x})\} \quad \text{for } n = 2, \textit{ respectively}, \\ \operatorname{div}\{\vec{x} \times \operatorname{curl} \vec{v}(\vec{x})\} &= \vec{x} \cdot \Delta \vec{v}(\vec{x}) - \vec{x} \cdot \operatorname{grad}\{\operatorname{div} \vec{v}(\vec{x})\} \quad \text{for } n = 3; \end{aligned} \tag{13}$$

$$\begin{aligned} \Delta\{\vec{x}^{\perp} \operatorname{curl} \vec{v}(\vec{x})\} &= \vec{x}^{\perp} \operatorname{curl}\{\Delta \vec{v}(\vec{x})\} - 2\Delta \vec{v}(\vec{x}) \\ &\quad + 2 \operatorname{grad}\{\operatorname{div} \vec{v}(\vec{x})\} \quad \text{for } n = 2, \textit{ respectively}, \\ \Delta\{\vec{x} \times \operatorname{curl} \vec{v}(\vec{x})\} &= \vec{x} \times \operatorname{curl}\{\Delta \vec{v}(\vec{x})\} - 2\Delta \vec{v}(\vec{x}) \\ &\quad + 2 \operatorname{grad}\{\operatorname{div} \vec{v}(\vec{x})\} \quad \text{for } n = 3; \end{aligned} \tag{14}$$

$$\text{curl}\,\{\text{curl}\,\vec{v}(\vec{x})\} = \text{grad}\,\{\text{div}\,\vec{v}(\vec{x})\} - \Delta\vec{v}(\vec{x}) \quad \textit{for } n = 3; \tag{15}$$

$$\Delta\{\vec{x}\cdot\text{curl}\,\vec{v}(\vec{x})\} = \vec{x}\cdot\text{curl}\,\{\Delta\vec{v}(\vec{x})\} \quad \textit{for } n = 3; \tag{16}$$

$$\begin{aligned}\text{curl}\,\{\vec{x}\times\text{curl}\,\vec{v}(\vec{x})\} &= \vec{x}\times\text{grad}\,\{\text{div}\,\vec{v}(\vec{x})\} - \text{grad}\,\{\vec{x}\cdot\text{curl}\,\vec{v}(\vec{x})\}\\ &\quad - \text{curl}\,\vec{v}(\vec{x}) - \vec{x}\times\Delta\vec{v}(\vec{x}) \quad \textit{for } n = 3;\end{aligned} \tag{17}$$

$$\Delta\{\vec{x}\times\text{grad}\,\phi(\vec{x})\} = \vec{x}\times\text{grad}\,\{\Delta\phi(\vec{x})\} \quad \textit{for } n = 3; \tag{18}$$

$$\text{curl}\,\{\vec{x}\times\text{grad}\,\phi(\vec{x})\} = \Delta\phi(\vec{x})\cdot\vec{x} - \text{grad}\,\{\phi(\vec{x}) + \vec{x}\cdot\text{grad}\,\phi(\vec{x})\} \quad \textit{for } n = 3. \tag{19}$$

4. Derivation and proof of the two-dimensional theorem. Using essentially the formulae of Lemma 1 for dimension 2 we can now derive Theorem 1.

Proof of Theorem 1. (i) First, assume that $\tilde{\vec{v}}$ is harmonic in G and that $\vec{v}$ and p are given by (2). Then the representation (2) and the formulae (9), (11), (13), and (14) (with $\tilde{\vec{v}}$ instead of $\vec{v}$ and $\phi = \text{div}\,\tilde{\vec{v}}$) yield:

$$\begin{aligned}&\text{div}\,\vec{v} = \text{div}\,\tilde{\vec{v}} - \tfrac{1}{2}\{2\,\text{div}\,\tilde{\vec{v}} + \vec{x}\cdot\text{grad}\,(\text{div}\,\tilde{\vec{v}}) - \vec{x}\cdot\text{grad}\,(\text{div}\,\tilde{\vec{v}})\} \equiv 0,\\ &\Delta\vec{v} = -\tfrac{1}{2}\{2\,\text{grad}\,(\text{div}\,\tilde{\vec{v}}) + 2\,\text{grad}\,(\text{div}\,\tilde{\vec{v}})\} = \text{grad}\,p \text{ in } G.\end{aligned}$$

Hence, $\vec{v}$ is a Stokes function with corresponding pressure $p = -2\,\text{div}\,\tilde{\vec{v}}$ in G according to Definition 1.

(ii) Now, assume that $\vec{v}$ is a Stokes function with corresponding pressure p and that $\tilde{\vec{v}}$ is given by (3). Then the formulae (1), (7)-(9), and (11)-(14) (use also that $\Delta p \equiv 0$ by Remark 1) show that

$$\begin{aligned}\Delta\tilde{\vec{v}} &= \Delta\vec{v} - \tfrac{1}{4}\{2\,\text{grad}\,p + \Delta p\cdot\vec{x} - \vec{x}^{\perp}\,\text{curl}\,(\Delta\vec{v})\\ &\quad + 2\Delta\vec{v} - 2\,\text{grad}\,(\text{div}\,\vec{v})\} \equiv 0,\\ \text{div}\,\tilde{\vec{v}} &= \text{div}\,\vec{v} - \tfrac{1}{4}\{2p + \vec{x}\cdot\text{grad}\,p - \vec{x}\cdot\Delta\vec{v} + \vec{x}\cdot\text{grad}\,(\text{div}\,\vec{v})\} = -\tfrac{1}{2}p,\\ \vec{x}^{\perp}\,\text{curl}\,\tilde{\vec{v}} &= \vec{x}^{\perp}\{\text{curl}\,\vec{v} - \tfrac{1}{4}[(\text{grad}\,p - \Delta\vec{v} + \text{grad}\,(\text{div}\,\vec{v}))\cdot\vec{x}^{\perp} + 2\,\text{curl}\,\vec{v}]\}\\ &= \tfrac{1}{2}\vec{x}^{\perp}\,\text{curl}\,\vec{v},\\ \vec{v} &= \tilde{\vec{v}} + \tfrac{1}{4}\{-2\,\text{div}\,\tilde{\vec{v}}\cdot\vec{x} - 2\vec{x}^{\perp}\,\text{curl}\,\tilde{\vec{v}}\},\end{aligned}$$

which is (3). This completes the proof of Theorem 1 up to the uniqueness of $\tilde{\vec{v}}$, which is a consequence of the following proposition. □

PROPOSITION 1. *Assume that $\vec{v}_1$ and $\vec{v}_2$ are harmonic in G such that*

$$\begin{aligned}&\vec{v}_1(\vec{x}) - \tfrac{1}{2}\{\text{div}\,\vec{v}_1(\vec{x})\cdot\vec{x} + \vec{x}^{\perp}\,\text{curl}\,\vec{v}_1(\vec{x})\}\\ &\quad = \vec{v}_2(\vec{x}) - \tfrac{1}{2}\{\text{div}\,\vec{v}_2(\vec{x})\cdot\vec{x} + \vec{x}^{\perp}\,\text{curl}\,\vec{v}_2(\vec{x})\} \quad \textit{for } \vec{x}\in G.\end{aligned}$$

Then there exists $\alpha\in\mathbb{R}$ with

$$\vec{v}_1(\vec{x}) - \vec{v}_2(\vec{x}) = \alpha\vec{x} \quad \textit{for } \vec{x}\in G.$$

Proof. Consider $\vec{v} = \vec{v}_1 - \vec{v}_2$, so that $\vec{v} = \tfrac{1}{2}\{\text{div}\,\vec{v}\cdot\vec{x} + \vec{x}^{\perp}\,\text{curl}\,\vec{v}\}$ and $\Delta\vec{v}\equiv 0$. Then the formulae (2) and (13) yield that $\text{curl}\,\vec{v} = -\text{curl}\,\vec{v}$, i.e., $\text{curl}\,\vec{v}\equiv 0$, and $\text{grad}\,(\text{div}\,\vec{v})\equiv 0$ (use $\Delta\vec{v}\equiv 0$ again). Hence, $\text{curl}\,\vec{v}\equiv 0$ and $\text{div}\,\vec{v}\equiv 2\alpha\in\mathbb{R}$ in G, and it follows that $\vec{v} = \tfrac{1}{2}\{\text{div}\,\vec{v}\cdot\vec{x} + \vec{x}^{\perp}\,\text{curl}\,\vec{v}\} = \alpha\vec{x}$ for $\vec{x}\in G$. □

Remark 3. Since $\text{div}\,(\alpha\vec{x}) = 2\alpha$ it follows that $\tilde{\vec{v}}$ is uniquely determined by (2) when $\vec{v}$ and p are given; and this constant α is just the free additive constant in the pressure p (compare Remark 1) for a given Stokes function $\vec{v}$.

5. Derivation and proof of the three-dimensional theorem. The main Theorem 2 of this paper follows from Propositions 2-4, and Lemma 2 below.

PROPOSITION 2. *Let $G \subseteq \mathbb{R}^3$ be a domain, and assume that $\vec{v}$ and p are given by* (4), *where $\tilde{\vec{v}}$ is harmonic in G. Then $\vec{v}$ is a Stokes function with corresponding pressure p in G.*

Proof. The representation (4) and the formulae (9), (11), (13), and (14) (with $\tilde{\vec{v}}$ instead of $\vec{v}$ and $\phi = \operatorname{div} \tilde{\vec{v}}$) yield:

$$\operatorname{div} \vec{v} = \operatorname{div} \tilde{\vec{v}} - \tfrac{1}{3}\{3 \operatorname{div} \tilde{\vec{v}} + \vec{x} \cdot \operatorname{grad} (\operatorname{div} \tilde{\vec{v}}) - \vec{x} \cdot \operatorname{grad} (\operatorname{div} \tilde{\vec{v}})\} \equiv 0,$$

$$\Delta \vec{v} = -\tfrac{1}{3}\{2 \operatorname{grad} (\operatorname{div} \tilde{\vec{v}}) + 2 \operatorname{grad} (\operatorname{div} \tilde{\vec{v}})\} = \operatorname{grad} p. \qquad \square$$

Remark 4. For *fixed* $\vec{x}_0 \in \mathbb{R}^3$ we have obviously that

$$\vec{v}(\vec{x}) := \tilde{\vec{v}}(\vec{x}) - \tfrac{1}{3}\{\operatorname{div} \tilde{\vec{v}}(\vec{x}) \cdot (\vec{x} - \vec{x}_0) + (\vec{x} - \vec{x}_0) \times \operatorname{curl} \tilde{\vec{v}}(\vec{x})\}$$

is also a Stokes function in G with corresponding pressure

$$p(\vec{x}) := -\tfrac{4}{3} \operatorname{div} \tilde{\vec{v}}(\vec{x}), \quad \text{whenever } \tilde{\vec{v}} \text{ is harmonic in } G.$$

The next proposition deals with the question whether a given Stokes function *can be represented by* (4) with a harmonic $\tilde{\vec{v}}$.

PROPOSITION 3. *Assume that $\vec{v}$ is a Stokes function with corresponding pressure p in a domain $G \subseteq \mathbb{R}^3$. Then the representation formula* (4) *holds with a function $\tilde{\vec{v}}$, which is harmonic in G, if and only if this function $\tilde{\vec{v}}$ satisfies* (5), *where ϕ is harmonic in G such that*

$$4\phi(\vec{x}) + \vec{x} \cdot \operatorname{grad} \phi(\vec{x}) + \tfrac{1}{4}\vec{x} \cdot \operatorname{curl} \vec{v}(\vec{x}) = 0 \quad \text{for } \vec{x} \in G. \tag{20}$$

SUPPLEMENT. *Assume that formula* (4) *holds with a function $\tilde{\vec{v}}$, which is harmonic in G. Then, it follows that formula* (5) *holds for the function*

$$\phi(\vec{x}) := -\tfrac{1}{12}\vec{x} \cdot \operatorname{curl} \tilde{\vec{v}}(\vec{x}), \tag{21}$$

and this ϕ is harmonic in G and satisfies (20).

Proof. First, it follows from Definition (1) and (12) that

$$\operatorname{curl} \{\Delta \vec{v}(\vec{x})\} = 0 \quad \text{for } \vec{x} \in G. \tag{22}$$

(i) Assume that (5) holds with a function ϕ, which is harmonic and which satisfies (20). Then the formulae (5), (11), (14), (18), (22) and (1) (observe that $\Delta\phi = 0$ and that $\Delta p = \operatorname{div} (\operatorname{grad} p) = 0$ by (1)) yield

$$\Delta \tilde{\vec{v}} = \Delta \vec{v} - \tfrac{1}{4}\{2 \operatorname{grad} p + 2 \operatorname{grad} p\} = 0.$$

Hence, $\tilde{\vec{v}}$ is harmonic in G. Moreover, by (1), (9), (13), (12), and (10), (17), (19), (20) we obtain that

$$\begin{aligned}
\operatorname{div} \tilde{\vec{v}} &= -\tfrac{3}{4} p, \\
\operatorname{curl} \tilde{\vec{v}} &= \operatorname{curl} \vec{v} - \tfrac{1}{4}\{-\vec{x} \times \operatorname{grad} p + \operatorname{grad} \{\vec{x} \cdot \operatorname{curl} \vec{v}\} \\
&\qquad + \operatorname{curl} \vec{v} + \vec{x} \times \operatorname{grad} p\} - \operatorname{grad} \{\phi + \vec{x} \cdot \operatorname{grad} \phi\} \\
&= \tfrac{3}{4} \operatorname{curl} \vec{v} + 3 \operatorname{grad} \phi.
\end{aligned}$$

By putting these identities into (5), it follows that

$$\begin{aligned}
&\tilde{\vec{v}} - \tfrac{1}{3}\{\operatorname{div} \tilde{\vec{v}} \cdot \vec{x} + \vec{x} \times \operatorname{curl} \tilde{\vec{v}}\} \\
&\quad = \vec{v} - \tfrac{1}{4}\{p\vec{x} - \vec{x} \times \operatorname{curl} \vec{v}\} + \vec{x} \times \operatorname{grad} \phi \\
&\qquad - \tfrac{1}{3}\{-\tfrac{3}{4} p\vec{x} + \tfrac{3}{4}\vec{x} \times \operatorname{curl} \vec{v} + 3\vec{x} \times \operatorname{grad} \phi\} \\
&\quad = \vec{v},
\end{aligned}$$

and

$$p = -\tfrac{4}{3} \operatorname{div} \tilde{\vec{v}};\ \text{i.e., (4) holds.}$$

(ii) Now, assume that (4) holds with a harmonic function $\tilde{\vec{v}}$, and define $\phi(\vec{x}) := -\frac{1}{12}\vec{x} \cdot \operatorname{curl} \tilde{\vec{v}}(\vec{x})$ for $\vec{x} \in G$ according to (21). Then ϕ is harmonic in G by (16). By (4), (10), (17), and (21) (observe that $\Delta\tilde{\vec{v}} = 0$) we get $\operatorname{div} \tilde{\vec{v}} = -\frac{3}{4}p$, and

$$\begin{aligned}\operatorname{curl} \vec{v} = \operatorname{curl} \tilde{\vec{v}} - \tfrac{1}{3}\{&-\vec{x} \times \operatorname{grad}(\operatorname{div} \tilde{\vec{v}}) + \vec{x} \times \operatorname{grad}(\operatorname{div} \tilde{\vec{v}}) \\ &- \operatorname{curl} \tilde{\vec{v}} + 12 \operatorname{grad} \phi\},\end{aligned}$$

thus

$$\operatorname{curl} \tilde{\vec{v}} = \tfrac{3}{4} \operatorname{curl} \vec{v} + 3 \operatorname{grad} \phi. \tag{23}$$

Putting these formulae for $\operatorname{div} \tilde{\vec{v}}$ and $\operatorname{curl} \tilde{\vec{v}}$ into (4) yields

$$\begin{aligned}\tilde{\vec{v}} &= \vec{v} + \tfrac{1}{3}\{-\tfrac{3}{4}p\vec{x} + \tfrac{3}{4}\vec{x} \times \operatorname{curl} \vec{v} + 3\vec{x} \times \operatorname{grad} \phi\} \\ &= \vec{v} - \tfrac{1}{4}\{p\vec{x} - \vec{x} \times \operatorname{curl} \vec{v}\} + \vec{x} \times \operatorname{grad} \phi;\end{aligned}$$

i.e., (5) holds. Finally, the definition of ϕ by (21) and formula (23) imply that

$$\begin{aligned}4\phi + \vec{x} \cdot \operatorname{grad} \phi &= -\tfrac{1}{3}\vec{x} \cdot \operatorname{curl} \tilde{\vec{v}} + \tfrac{1}{3}\vec{x} \cdot \{\operatorname{curl} \tilde{\vec{v}} - \tfrac{3}{4} \operatorname{curl} \vec{v}\} \\ &= -\tfrac{1}{4}\vec{x} \cdot \operatorname{curl} \vec{v};\end{aligned}$$

i.e., (20) holds. This completes the proof of Proposition 3 and of the supplement. □

The next lemma shows that any Stokes function $\vec{v}$ can be represented by (4), where the auxiliary harmonic function $\tilde{\vec{v}}$ is given by (5) and (6). But for this lemma it is crucial to assume that the domain G is *star-shaped with respect to the origin* (and this assumption of Theorem 2 is needed only for this lemma).

LEMMA 2. *Assume that $G \subseteq \mathbb{R}^3$ is a domain which is star-shaped with respect to the origin, and that a function $\vec{v}: G \to \mathbb{R}^3$ satisfies $\vec{v} \in C_3(G)$ and* (22), *i.e.*, $\operatorname{curl}\{\Delta\vec{v}(\vec{x})\} \equiv 0$. *Then the function $\phi(\vec{x})$ given by* (6) *is harmonic in G and satisfies the differential equation* (20).

Proof. Consider the function $h(\vec{x}) := \vec{x} \cdot \operatorname{curl} \vec{v}(\vec{x})$. Then h is harmonic in G by (16) and (22). Just because G is star-shaped with respect to the origin the *function ϕ is well defined* by (6), and it follows that

$$\Delta\phi(\vec{x}) = \Delta\left\{-\frac{1}{4}\int_0^1 t^3 h(t\vec{x})\, dt\right\} = -\frac{1}{4}\int_0^1 t^5 (\Delta h)(t\vec{x})\, dt = 0.$$

Hence, ϕ is harmonic in G; and partial integration yields

$$\begin{aligned}\vec{x} \cdot \operatorname{grad} \phi(\vec{x}) &= -\frac{1}{4}\vec{x} \cdot \int_0^1 t^4 (\operatorname{grad} h)(t\vec{x})\, dt = -\frac{1}{4}\int_0^1 t^4 \frac{d}{dt}\{h(t\vec{x})\}\, dt \\ &= -\frac{1}{4}h(\vec{x}) + \int_0^1 t^3 h(t\vec{x})\, dt \\ &= -\frac{1}{4}\vec{x} \cdot \operatorname{curl} \vec{v}(\vec{x}) - 4\phi(\vec{x}) \quad \text{for } \vec{x} \in G.\end{aligned}$$

Thus, (20) holds. □

The *uniqueness* of $\tilde{\vec{v}}$ (compare Proposition 1 and Remark 3) in Theorem 2 is a consequence of the following proposition.

PROPOSITION 4. *Let $G \subseteq \mathbb{R}^3$ be a domain with $0 \in G$, and assume that $\vec{v}_1$ and $\vec{v}_2$ are harmonic functions in G such that*

$$\begin{aligned} &\vec{v}_1(\vec{x}) - \tfrac{1}{3}\{\operatorname{div} \vec{v}_1(\vec{x}) \cdot \vec{x} + \vec{x} \times \operatorname{curl} \vec{v}_1(\vec{x})\} \\ &\quad = \vec{v}_2(\vec{x}) - \tfrac{1}{3}\{\operatorname{div} \vec{v}_2(\vec{x}) \cdot \vec{x} + \vec{x} \times \operatorname{curl} \vec{v}_2(\vec{x})\} \quad \text{for } \vec{x} \in G. \end{aligned} \tag{24}$$

Then there exists $\alpha \in \mathbb{R}$ with

$$\vec{v}_1(\vec{x}) - \vec{v}_2(\vec{x}) = \alpha \vec{x} \quad \text{for } \vec{x} \in G. \tag{25}$$

Proof. Proposition 2 and equation (24) yield $0 = \operatorname{grad}\{\operatorname{div} \vec{v}_1 - \operatorname{div} \vec{v}_2\}$, thus

$$\operatorname{div}(\vec{v}_1 - \vec{v}_2) \equiv 3\alpha \quad \text{in } G \quad \text{for some } \alpha \in \mathbb{R}.$$

Then the function $\vec{v}_0(\vec{x}) := \vec{v}_1(\vec{x}) - \vec{v}_2(\vec{x}) - \alpha \vec{x}$ satisfies (observe that $\operatorname{div} \vec{x} = 3$, $\operatorname{curl} \vec{x} = 0$):

$$\operatorname{div} \vec{v}_0(\vec{x}) = 0, \quad \Delta \vec{v}_0(\vec{x}) = 0, \quad \vec{v}_0(\vec{x}) = \tfrac{1}{3}\vec{x} \times \operatorname{curl} \vec{v}_0(\vec{x}) \quad \text{for } \vec{x} \in G. \tag{26}$$

Setting $\psi(\vec{x}) := \vec{x} \cdot \operatorname{curl} \vec{v}_0(\vec{x})$, we obtain from (26), (16), and (17) the formulae

$$\Delta\psi(\vec{x}) = 0, \quad 4\psi(\vec{x}) + \vec{x} \cdot \operatorname{grad} \psi(\vec{x}) = 0, \quad \operatorname{grad} \psi(\vec{x}) = -4 \operatorname{curl} \vec{v}_0(\vec{x}). \tag{27}$$

Since $0 \in G$ we have that $U_\varepsilon(0) \subseteq G$ for some $\varepsilon > 0$. We consider the function $f(t) := \psi(t\vec{x})$ on $[0, 1]$ for a fixed $\vec{x} \in U_\varepsilon(0)$. Formulae (27) imply that $f(0) = 0$ and $4f(t) + tf'(t) = 0$ on $[0, 1]$. Hence, $f(t) \equiv 0$ on $[0, 1]$, in particular $\psi(\vec{x}) = f(1) = 0$; and it follows from (17) and (26) that $\operatorname{curl} \vec{v}_0(\vec{x}) = \frac{1}{3} \operatorname{curl}\{\vec{x} \times \operatorname{curl} \vec{v}_0(\vec{x})\} = -\frac{1}{3} \operatorname{curl} \vec{v}_0(\vec{x})$. Therefore, $\operatorname{curl} \vec{v}_0(\vec{x})$ and then also $\vec{v}_0(\vec{x})$ are identically zero in $U_\varepsilon(0)$. Since $\vec{v}_0$ is harmonic in G, it follows that $\vec{v}_0(\vec{x}) = 0$ for all $\vec{x} \in G$ by [2, Chap. X, Thm. IV], i.e., (25) holds. □

Remark 5. (i) Without the assumption $0 \in G$ the foregoing proof shows that

$$\vec{v}_1(\vec{x}) - \vec{v}_2(\vec{x}) = \alpha \vec{x} + \vec{v}_0(\vec{x}) \quad \text{for } \vec{x} \in G, \tag{25'}$$

where

$$\vec{v}_0(\vec{x}) = -\tfrac{1}{12}\vec{x} \times \operatorname{grad} \psi(\vec{x}) \quad \text{with } \psi(\vec{x}) = \vec{x} \cdot \operatorname{curl} \vec{v}_0(\vec{x}),$$

and where the function $\psi(\vec{x})$ satisfies

$$\Delta\psi(\vec{x}) = 0 \quad \text{and} \quad 4\psi(\vec{x}) + \vec{x} \cdot \operatorname{grad} \psi(\vec{x}) = 0 \quad \text{for } \vec{x} \in G; \tag{28}$$

i.e., $\psi(\vec{x})$ is harmonic in G with $\psi(\vec{x}) = r^{-4}\tilde{\psi}(\vartheta, \varphi)$, where (r, ϑ, φ) denote the usual spherical coordinates of $\vec{x}$. Any (separated) spherical harmonic of degree -4 satisfies (28). This discussion describes in general (i.e., if $0 \notin G$) the *exact freedom in the representation formula* (4). To prove this assume that $\psi \in C_2(G)$ satisfies (28); and define

$$\vec{v}_0(\vec{x}) := -\tfrac{1}{12}\vec{x} \times \operatorname{grad} \psi(\vec{x}).$$

Then we have (use (19))

$$\Delta \vec{v}_0(\vec{x}) = 0, \quad \operatorname{div} \vec{v}_0(\vec{x}) = 0, \quad \operatorname{curl} \vec{v}_0(\vec{x}) = -\tfrac{1}{4} \operatorname{grad} \psi(\vec{x});$$

thus,

$$\vec{v}_0(\vec{x}) - \tfrac{1}{3}\{\operatorname{div} \vec{v}_0(\vec{x}) \cdot \vec{x} + \vec{x} \times \operatorname{curl} \vec{v}_0(\vec{x})\} = 0$$

(compare formula (4) with $\vec{v} \equiv 0$, $p \equiv 0$, and $\tilde{\vec{v}} = \vec{v}_0$). In particular, the function $\tilde{\vec{v}}$ in (4) is *not* uniquely determined by $\vec{v}$ and p if $0 \notin G$.

(ii) The question whether Theorem 2 does not hold for more general domains is, by the preceding results, equivalent with the problem whether the differential equation (20) has a harmonic solution ϕ in G for any given function $\vec{v} \in C_3(G)$ that satisfies (22). In case that G is star-shaped with respect to the origin, Lemma 2 above answers this question affirmatively, and it even gives an explicit formula for ϕ (which is unique in this case by Proposition 4), i.e., (6). But the *question concerning more general domains remains open.* Concerning the solvability of (20) we have besides Lemma 2 only the following *local result* (where ε is certainly not the best possible).

PROPOSITION 5. *Given* $\vec{x}_0 \in \mathbb{R}^3$, $G := U_R(\vec{x}_0) = \{\vec{x}_0 \in \mathbb{R}^3 \,|\, |\vec{x} - \vec{x}_0| < R\}$ *with* $R > 0$, *and a function* $\vec{v} \in C_3(G)$ *that satisfies* (22). *Then there exists a function* ϕ, *which is harmonic and which satisfies the differential equation* (20) *in* $G' = U_\varepsilon(\vec{x}_0)$ *with* $\varepsilon := R/8e$.

Proof. Let $\gamma := |\vec{x}_0| \geqq R$, since otherwise $0 \in G$ and then the assertion follows from Lemma 2 (even with $\varepsilon = R$). Now there exists an orthogonal matrix U such that

$$U^T \vec{x}_0 = \begin{pmatrix} \gamma \\ 0 \\ 0 \end{pmatrix}.$$

For given functions $\vec{v}$ and ϕ consider the functions

$$h(\vec{x}) := \tfrac{1}{4}(U\vec{x} + \vec{x}_0) \operatorname{curl} \vec{v}(U\vec{x} + \vec{x}_0), \qquad \psi(\vec{x}) := \phi(U\vec{x} + \vec{x}_0). \tag{29}$$

Then $\Delta\psi(\vec{x}) = (\Delta\phi)(U\vec{x} + \vec{x}_0)$, since U is orthogonal, and $\operatorname{grad} \psi(\vec{x}) = (\operatorname{grad} \phi)(U\vec{x} + \vec{x}_0) \cdot U$ (where grad is a row-vector).

By (16) and (22) the function $\vec{x} \cdot \operatorname{curl} \vec{v}(\vec{x})$ is harmonic in G, thus

$$h(\vec{x}) \quad \text{is harmonic in} \quad U_R(0); \tag{30}$$

and our assertion is now equivalent with the existence of a function ψ satisfying

$$\begin{aligned} &\psi(\vec{x}) \text{ is harmonic in } U_\varepsilon(0), \quad \varepsilon = \frac{R}{8e} > 0, \quad \gamma \geqq R, \quad \text{with} \\ &4\psi(\vec{x}) + \vec{x} \cdot \operatorname{grad} \psi(\vec{x}) + \gamma\psi_z(\vec{x}) + h(\vec{x}) = 0 \quad \text{for } |\vec{x}| < \varepsilon. \end{aligned} \tag{31}$$

We construct $\psi(\vec{x}) = \psi(r, \vartheta, \varphi)$ by expansion with respect to spherical harmonics, where (r, ϑ, φ) denote the spherical coordinates of $\vec{x}$, i.e., $x = r \cos\varphi \sin\vartheta$, $y = r \sin\varphi \sin\vartheta$, $z = r \cos\vartheta$. By $Y_{nk}(\vartheta, \varphi)$, $-n \leqq k \leqq n$, we denote a complete, orthonormal system of spherical harmonics of degree n; more precisely:

$$\begin{aligned} Y_{nk}(\vartheta, \varphi) &:= c_{nk} \cos(k\varphi) P_n^k(\cos\vartheta) \qquad \text{for } 0 \leqq k \leqq n, \\ Y_{n,-k}(\vartheta, \varphi) &:= c_{nk} \sin(k\varphi) P_n^k(\cos\vartheta) \qquad \text{for } 1 \leqq k \leqq n, \end{aligned}$$

where

$$P_n^k(t) := \frac{1}{2^n \cdot n!} (1 - t^2)^{k/2} \left(\frac{d}{dt}\right)^{k+n} (t^2 - 1)^n$$

denote the Legendre functions (see [4, Chap. IV]) and where

$$c_{nk} := \left\{ \frac{2n+1}{2\pi} \frac{(n-k)!}{(n+k)!} \right\}^{1/2}.$$

Then we have

$$\int_{-\pi}^{\pi} \int_0^{\pi} Y_{nk}(\vartheta, \varphi) Y_{ml}(\vartheta, \varphi) \sin\vartheta \, d\vartheta \, d\varphi = \delta_{nm}\delta_{kl},$$

$$|Y_{nk}(\vartheta, \varphi)| \leqq \left\{ \frac{2n+1}{2\pi} \right\}^{1/2} \quad \text{for } (\vartheta, \varphi) \in [0, \pi] \times [-\pi, \pi] \tag{32}$$

by [5, Lemmas 8 and 14]. The recursion

$$ntP_n^k(t)+(1-t^2)\frac{d}{dt}P_n^k(t)=(n+k)P_{n-1}^k(t)$$

[4, p. 171] and $\partial r/\partial z=\cos\vartheta$, $\partial\varphi/\partial z=0$, $\partial\vartheta/\partial z=-\sin\vartheta/r$ yield the formula

$$\frac{\partial}{\partial z}\{r^nY_{nk}\}=\left\{\frac{2n+1}{2n-1}(n+k)(n-k)\right\}^{1/2}r^{n-1}Y_{n-1,k}\quad\text{for } |k|\leqq n-1, \tag{33}$$

$$=0\quad\text{for } k=\pm n,\quad n\geqq 0.$$

Since $h(\vec{x})$ is harmonic in $U_R(0)$ by (30) it can be expanded with respect to spherical harmonics (see [7] or [2]), i.e.,

$$h(\vec{x})=\sum_{n=0}^{\infty}\sum_{k=-n}^{n}b_{nk}r^nY_{nk}(\vartheta,\varphi)\quad\text{for } |\vec{x}|=r<R, \tag{34}$$

where the coefficients satisfy $b_{nk}=o(\rho^{-n})$ as $n\to\infty$ for all $\rho<R$. Hence, for *any fixed* $0<\rho<R$ we have

$$|b_{nk}|\leqq c\rho^{-n}\quad\text{for } |k|\leqq n,\ n\geqq 0\quad\text{with a constant } c=c(\rho)>0. \tag{35}$$

Now we construct ψ via the setting

$$\psi(\vec{x})=\sum_{n=0}^{\infty}\sum_{k=-n}^{n}a_{nk}r^nY_{nk}(\vartheta,\varphi).$$

Then ψ is automatically harmonic in $U_\varepsilon(0)$, provided we can show appropriate estimates of the coefficients. Now, by (33),

$$4\psi(\vec{x})+\vec{x}\cdot\operatorname{grad}\psi(\vec{x})+\gamma\psi_z(\vec{x})$$

$$=\sum_{n=0}^{\infty}\sum_{k=-n}^{n}\{(4+n)a_{nk}+\gamma\alpha_{nk}a_{n+1,k}\}r^nY_{nk}(\vartheta,\varphi)$$

with

$$\alpha_{nk}:=\left\{\frac{2n+3}{2n+1}(n+1+k)(n+1-k)\right\}^{1/2}.$$

Comparing coefficients, we find the differential equation (31) for ψ is equivalent with

$$(4+n)a_{nk}+\gamma\alpha_{nk}a_{n+1,k}+b_{nk}=0\quad\text{for } |k|\leqq n,\quad n\geqq 0. \tag{36}$$

These equations are fulfilled if we define the a_{nk} by

$$a_{n+1,k}=\frac{1}{\gamma\alpha_{nk}}\{-b_{nk}-(4+n)a_{nk}\}\quad\text{for } -n\leqq k\leqq n,\quad n\geqq 0,$$

$$a_{nn}=\frac{-1}{4+n}b_{nn},\quad a_{n,-n}=\frac{-1}{4+n}b_{n,-n}\quad\text{for } n\geqq 0. \tag{37}$$

We show recursively that

$$(4+n)|a_{n,\pm(n-k)}|\leqq(8/\rho)^nc\left\{\frac{n^k}{k!}\right\}^{1/2} \tag{38}$$

holds for $0 \leqq k \leqq n$, $n \geqq 0$. This is clear for $n = 0$, and for $k = 0$, $n \geqq 0$. For $1 \leqq k \leqq n+1$ it follows inductively from (35), (37), and (38) that

$$\begin{aligned}(4+n+1)|a_{n+1,n+1-k}| &\leqq \frac{4+n+1}{\gamma}\left\{\frac{2n+1}{2n+3}\cdot\frac{1}{k(2n+2-k)}\right\}^{1/2} \\ &\quad\cdot c\rho^{-n}\left\{1+8^n\left(\frac{n^{k-1}}{(k-1)!}\right)^{1/2}\right\} \\ &\leqq c\cdot\rho^{-n-1}\left\{\frac{n^{k-1}}{k!}\,\frac{(2n+1)(4+n+1)^2}{(2n+3)(n+1)}\right\}^{1/2} \\ &\quad\cdot\left\{8^n+\left(\frac{n^{k-1}}{(k-1)!}\right)^{-1/2}\right\} \\ &\leqq c(8/\rho)^{n+1}\left\{\frac{(n+1)^k}{k!}\right\}^{1/2} \qquad \text{(observe that } \gamma \geqq R > \rho\text{)}.\end{aligned}$$

Now, (38) yields

$$|a_{nk}| \leqq c(8/\rho)^n\left\{\frac{n^n}{n!}\right\}^{1/2}\frac{1}{4+n} \leqq c(8e/\rho)^n.$$

This estimate and (32) show that the series defining $\psi(\vec{x})$ converges absolutely (even after termwise differentiation by (33) and by corresponding formulae for the partial derivatives with respect to x and y) for $|\vec{x}| < R/8e$, and this completes the proof. □

Acknowledgment. The author records his thanks to the referees for several very helpful comments.

ISOLATED SINGULARITIES OF p-HARMONIC FUNCTIONS IN THE PLANE*

JUAN J. MANFREDI†

Dedicated to the memory of José Luis Rubio de Francia.

Abstract. A classification theorem for isolated singularities of p-harmonic functions is given and a precise asymptotic representation near the singularity is obtained. The approach is based on using the theory of quasiregular mappings to linearize the p-Laplacian by means of a hodographic transformation.

Key words. isolated singularities, p-harmonic functions, nonlinear elliptic equations

AMS(MOS) subject classifications. 35C20, 35J60

1. Introduction and statements of results.

Let Ω be a domain in $\mathbf{R}^n$, $n \geq 2$, and fix $p \in (1, \infty)$. A real function u defined in Ω is called p-harmonic if $u \in W^{1,p}_{\text{loc}}(\Omega)$ and

$$\int_{\Omega} |\nabla u|^{p-2} \langle \nabla u, \nabla \phi \rangle dx = 0 \tag{1.1}$$

for all $\phi \in W^{1,p}(\Omega)$ with compact support contained in Ω; that is, u is a weak solution of the p-Laplace equation

$$\operatorname{div}(|\nabla u|^{p-2} \nabla u) = 0. \tag{1.2}$$

It is well known [DB], [L] that $u \in C^{1,\alpha}_{\text{loc}}$, where $\alpha = \alpha(p, n) \in (0, 1]$. Indeed, in dimension two ($n = 2$) we have that

$$u \in C^{k,\alpha}_{\text{loc}}(\Omega) \cap W^{k+2,q}_{\text{loc}}(\Omega), \tag{1.3}$$

where the integer $k > 1$ and the exponent $\alpha \in (0, 1]$ are determined by the equation

$$k + \alpha = \frac{1}{6} \left(7 + \frac{1}{p-1} + \sqrt{1 + \frac{14}{p-1} + \frac{1}{(p-1)^2}} \right).$$

The integrability exponent q is any number such that

$$1 \leq q < \frac{2}{2 - \alpha} \leq 2.$$

Moreover, for $p \neq 2$ the regularity class in (1.3) is optimal. See [IM] for these results. To prove (1.3) we use complex analysis (quasiregular mappings) to linearize the p-Laplacian by means of a hodograph transformation [BI], [IM], [Ar].

†Department of Mathematics and Statistics, University of Pittsburgh, Pittsburgh, Pennsylvania 15260.

The purpose of this paper is to apply the ideas of [IM] to the study of isolated singularities of p-harmonic functions in two dimensions.

Let us begin by reviewing some known results. We will assume that u is a *singular p-harmonic* function; that is, u is p-harmonic in $(\mathbf{B}^n)' = \mathbf{B}^n\backslash\{0\} = \{x \in \mathbf{R}^n, 0 < |x| < 1\}$. An example is given by

$$u_1(x) = \begin{cases} |x|^{(p-n)/(p-1)} & \text{if } p \neq n \\ \log \frac{1}{|x|} & \text{if } p = n. \end{cases} \tag{1.4}$$

The function u_1 satisfies

$$\operatorname{div}(|\nabla u_1|^{p-2}\nabla u_1) = c\delta_0 \tag{1.5}$$

in the sense of distributions, where $c = c(p, n)$ is an appropriate constant. A classical result of Serrin [S] states that if $1 < p \leq n$ and u is a *nonnegative* singular p-harmonic function, then there exists a constant $c_1 > 0$ such that

$$\frac{1}{c_1} < \frac{u}{u_1} < c_1 \qquad \text{in } (\mathbf{B}^n)'.$$

Moreover, u satisfies (1.5) for a certain c.

Kichenassamy and Veron [KV] extended Serrin's result to cover the case $u/u_1 \in L^\infty$, in which case they proved the existence of a number $\gamma \in \mathbf{R}$ such that

$$\begin{aligned} &\text{(i)} \quad u - \gamma u_1 \in L^\infty, \\ &\text{(ii)} \quad |\nabla(u - \gamma u_1)| = o\left(|x|^{(1-n)/(p-1)}\right), \qquad \text{as } x \to 0, \text{ and} \\ &\text{(iii)} \quad -\operatorname{div}(|\nabla u|^{p-2}\nabla u) = \gamma|\gamma|^{p-2}\delta_0. \end{aligned} \tag{1.6}$$

A general question is whether these results, conveniently modified, continue to hold when u_1 is replaced by an *anisotropic* singularity v; that is, v is p-harmonic in $\mathbf{R}^n\backslash\{0\}$ of the form:

$$v(x) = |x|^\beta w\left(\frac{x}{|x|}\right), \qquad \beta < 0. \tag{1.7}$$

Veron [V] has shown the existence of plenty of anisotropic singularities in n-dimensions, where this general problem is posed.

In the plane all solutions of the form (1.6), now called *quasiradial* are known. For $N = 1, 2, \cdots$ there exists a real analytic 2π-periodic function Φ_N with $\Phi_N(0) = 1$ (a normalization) and a number μ_N (μ_N decreasing to $-\infty$ as $N \uparrow \infty$) such that

$$u_N(se^{i\alpha}) = \Phi_N(\alpha)s^{\mu_N} \tag{1.8}$$

is a singular p-harmonic function. Assuming $p \neq 2$, we find $\Phi_1(\alpha) \equiv 1$ and $\mu_1 = (p-2)/(p-1)$ so that u_1 coincides with the "fundamental solution" in (1.4). While $\mu_1 > 0$ for $p > 2$ (case of bounded singularities)

$$\mu_2 = \frac{p - (3 + \sqrt{p^2 - 3p + 3})}{3(p-1)} < 0 \tag{1.9}$$

for all p. These facts follow easily from the results of §5. See also [KV].

We can think of u_N as a nonlinear analogue of $Re(z^{-N})$. Our main result, Theorem 1, is a nonlinear version of the Laurent series development for harmonic functions.

THEOREM 1. *Let u be a singular p-harmonic function in $(\mathbf{B}^2)'$ such that 0 is not a removable singularity and for some $\beta \le (p-2)/(p-1)$ we have*

$$|u(x)| \le c|x|^{\beta} \qquad \text{for } |x| < \tfrac{1}{2}. \tag{1.10}$$

Then there exists $N \ge 1$ (N is the largest integer such that $\beta \le \mu_N$) and a constant $\gamma_N \ne 0$ such that

$$\sum_{|\nu|=m} |D^{\nu}u - \gamma_N D^{\nu}u_N|(x) \le c_m |x|^{\mu_N - m + \delta_N} \tag{1.11}$$

for $m = 1, 2, \cdots$. Here c_m are constants, $\delta_N > 0$ and the inequality holds for $0 < |x| < \delta = \delta(m)$.

Remark. If u satisfies (1.10) for some $\beta > (p-2)/(p-1)$ we will see in §6 that 0 is a removable singularity. Thus, we are in the situation treated in detail in [IM].

Note that $|D^{\nu}u_N(x)| \sim |x|^{\mu_N - m}$. The theorem is relevant because $\delta_N > 0$. The estimate (1.11) is an extension of (1.6–ii).

In §2 we will compute the explicit values of μ_N and δ_N. It turns out that

$$\begin{aligned} &\mu_N + \delta_N < 0 && \text{for } N \ge 3, \\ &\mu_N + \delta_N = 0 && \text{for } \begin{cases} N = 2, & p > 2, \\ N = 1, & 1 < p < 2, \end{cases} \\ &\mu_N + \delta_N = 1 && \text{for } N = 1, \quad p > 2. \end{aligned} \tag{1.12}$$

We can now integrate (1.10) to obtain the following.

THEOREM 2. *In the situation of Theorem 1, in a small ball centered at 0, we have:*

If $N \ge 3$,

$$|u(x) - \gamma_N u_N(x)| \le C|x|^{\mu_N + \delta_N}, \tag{1.13}$$

if $N = 2$, $p > 2$ or $N = 1$, $1 < p < 2$,

$$|u(x) - \gamma_N u_N(x)| \le C \log \frac{1}{|x|}, \tag{1.14}$$

and if $N = 1$, $p > 2$, $\lim_{x \to 0} u(x) = u(0)$ exists, $u - \gamma_1 u_1$ is Lipschitz in a neighborhood of 0 and

$$|u(x) - u(0) - \gamma_1 u_1(x)| \le C|x|. \tag{1.15}$$

When $p > 2$ we may have bounded singularities corresponding to the case of nonnegative β in (1.10). Theorem 2 says in this case that $u - \gamma_1 u_1$ is Lipschitz, that is, u is "as good as u_1" in terms of smoothness. This is an extension of Serrin and Kichenassamy–Veron results when $p > n = 2$. It would be very interesting to see whether some version of (1.15) holds in the case $p > n \ge 3$.

The next corollary answers the two-dimensional case of a question posed by Veron in [V].

COROLLARY 1. *With the hypothesis of Theorem* 1, *if* u *is unbounded at zero, for some* $N = 1, 2, \cdots$

$$\lim_{x\to 0} \frac{u(x)}{|x|^{\mu_N}} = \gamma_N \Phi_N\left(\frac{x}{|x|}\right) \tag{1.16}$$

and if u *is bounded at zero,* $\lim_{x\to 0} u(x) = u(0)$ *exists,* $p > 2$, *and*

$$\lim_{x\to 0} \frac{(u(x) - u(0))}{|x|^{(p-2)/(p-1)}} = \gamma_1. \tag{1.17}$$

This article is organized as follows. In §2 we linearize the p-Laplacian in the hodograph plane following [IM]. Next in §3 we find a series expansion of the solutions of the linearized p-Laplacian and use it to obtain several estimates. In §4 we study how to recover p-harmonic functions from their "hodograph transforms." This is used in §5 to construct the family u_N in (1.8) and find the μ_N's. The details of the proofs of Theorems 1 and 2 are presented in §6. Finally, in §7 we present an application of Theorem 2 to a problem of uniqueness.

2. The hodograph transformation. Let $u : (\mathbf{B}^2)' \to \mathbf{R}$ be a p-harmonic function. The complex gradient of u, $f = \partial u/\partial z$, is

$$f = \tfrac{1}{2}(u_x, -iu_y)$$

and it is a fundamental fact that f is a K-quasiregular mapping in $(\mathbf{B}^2)'$, where

$$K = \max\left\{p - 1, \frac{1}{p-1}\right\}.$$

See [IM], [M].

It follows from the existence theorem for the Beltrami equation [A, Chap. 5] and the chain rule for the complex dilatation [A, p. 9] that there exists $g_1 = \overline{\mathbf{R}^2} \to \overline{\mathbf{R}^2}$ K-quasiconformal fixing 0, 1, and ∞ and an analytic function h defined on $g_1((\mathbf{B}^2)')$ (itself a punctured neighborhood of 0) such that

$$f(z) = (h \circ g_1)(z) \tag{2.1}$$

for $z \in (\mathbf{B}^2)'$.

LEMMA 1. *Suppose* h *has a pole of order* N *at* 0, $N \geq 1$. *Then there exists a neighborhood of zero* $U \subset \mathbf{B}^2$ *and* $g : U \to U$ K*-quasiconformal, satisfying* $g(0) = 0$, *such that*

$$f(z) = (g(z))^{-N}$$

for $z \in U' = U\backslash\{0\}$.

In other words, near the singularity we may assume $h(\zeta) = \zeta^{-N}$.

Proof. This is an exercise in complex analysis. The function $\frac{1}{h}$ has a zero of order N at 0. So it has an N-rooth l, which is invertible in a neighborhood of 0. It is easily checked that $h \circ l^{-1}(\zeta) = \zeta^{-N}$ and $g = l \circ g_1$. □

As it is shown in [BI] and [IM], $f \in W^{1,2}_{\text{loc}}((\mathbf{B}^2)')$ and (1.2) translates into

$$\frac{\partial f}{\partial \bar{z}} = \left(\frac{1}{p} - \frac{1}{2}\right)\left\{\frac{\bar{f}}{f}\frac{\partial f}{\partial z} + \frac{f}{\bar{f}}\frac{\overline{\partial f}}{\partial z}\right\}. \tag{2.2}$$

Therefore, in a neighborhood of 0, g satisfies

$$\frac{\partial g}{\partial \bar{z}} = \left(\frac{1}{p} - \frac{1}{2}\right)\left\{\frac{g}{\bar{g}}\frac{\overline{\partial g}}{\partial z} + \frac{g^N}{\bar{g}^N}\frac{\partial g}{\partial z}\right\}.$$

We now apply the hodograph transformation; i.e., we set H the inverse of g, $z = H(g(z))$, $\xi = g(H(\xi))$ and $H(0) = 0$. We then obtain [IM] the following *linear* equation for H:

$$H_{\bar{\xi}} = \left(\frac{1}{2} - \frac{1}{p}\right)\left[\frac{\xi}{\bar{\xi}}H_\xi + \frac{\xi^N}{\bar{\xi}^N}\overline{H_\xi}\right]. \tag{2.3}$$

This equation is similar, but different from (17) in [IM]. The exponent of $\xi/\bar{\xi}$ has the opposite sign. This introduces some technical complications in the next section.

We shall call H the *hodograph transform* of u.

3. Series expansion for $H(\xi)$. We look for solutions of (2.3) in $W^{1,2}(U)$. Any such solution is a quasiregular mapping and is in $C^\infty(U')$. Write

$$H(r,\theta) = \sum_{k=-\infty}^{\infty} a_k(r)e^{i(k+N)\theta},$$

where

$$a_k(r) = \frac{1}{2\pi}\int_0^{2\pi} H(r,\theta)e^{-i(k+N)\theta}d\theta.$$

We have that $a_k \in C[0,\delta) \cap C^\infty(0,\delta)$ for some $\delta > 0$. Given $\xi = re^{i\theta}$, (2.3) becomes

$$2rH_r = -ipH_\theta + (p-2)ie^{2iN\theta}\bar{H}_\theta. \tag{3.1}$$

Compute Hr, H_θ, and substitute in (3.1) to get

$$2ra_k'(r) = p(k+N)a_k(r) - (p-2)(k-N)\overline{a_{-k}}(r) \tag{3.2}$$

for $k = 0, 1, 2, \cdots$. Proceed as in [IM] to obtain

$$r(ra_k')' - pNra_k' + (N^2 - k^2)(p-1)a_k = 0. \tag{3.3}$$

For $k \in \mathbf{Z}$ the solutions of (3.3) are

$$a_k(r) = A_k^+ r^{\lambda_k^+} + A_k^- r^{\lambda_k^-},$$

where

$$\lambda_k^\pm = \frac{pN \pm \sqrt{4k^2(p-1) + N^2(p-2)^2}}{2} \tag{3.4}$$

and A_k^+, A_k^- are arbitrary complex numbers. Note that λ_k^+ and λ_k^- are even functions of k, $\lambda_k^- < \lambda_k^+$, $\lambda_N^- = 0$, and $\lambda_N^+ = pN$.

If $|k| > N$, $\lambda_k^- < 0$ forcing $A_k^- = 0$ in this case. Furthermore, from (3.2) we obtain $A_N^- = 0$ and

$$\begin{aligned} A_{-k}^+ &= \varepsilon_k^+\overline{A_k^+}, \qquad k = 0, 1, 2, \cdots, \\ A_{-k}^- &= \varepsilon_k^-\overline{A_k^-}, \qquad k = 0, 1, 2, \cdots, N-1, \end{aligned} \tag{3.5}$$

where

$$\varepsilon_k^{\pm} = \frac{p(N+k) - 2\lambda_k^{\pm}}{(p-2)(k-N)} \quad \text{for } k \neq N, \tag{3.6}$$

$$\varepsilon_N^{+} = \frac{p-2}{p}, \tag{3.7}$$

and ε_N^{-} is not defined. Finally, $H(0) = 0$ implies that $A_N^{-} = 0$. We have the following variant of Theorem 2 in [IM], proved in exactly the same way.

THEOREM 3. *Suppose $H \in W^{1,2}(\mathbf{B}^2)$ is a solution of* (2.3) *satisfying $H(0) = 0$. Then*

$$\begin{aligned} H(r,\theta) = \sum_{k=0}^{N-1} & \left[\left\{A_k^{-} e^{i(k+N)\theta} + \varepsilon_k^{-} \bar{A}_k^{-} e^{-i(k-N)\theta}\right\} r^{\lambda_k^{-}}\right. \\ & \left. + \left\{A_k^{+} e^{i(k+N)\theta} + \varepsilon_k^{+} \bar{A}_k^{+} e^{-i(k-N)\theta}\right\} r^{\lambda_k^{+}}\right] \\ & + \sum_{K=N}^{\infty} \left\{A_k^{+} e^{i(k+N)\theta} + \varepsilon_k^{+} \bar{A}_k^{+} e^{-i(k-N)\theta}\right\} r^{\lambda_k^{+}}, \end{aligned} \tag{3.8}$$

where $\lambda_k^{\pm}$ and $\varepsilon_k^{\pm}$ are given by (3.4), (3.6), *and* (3.7), *$A_0^{\pm}, \cdots, A_{N-1}^{\pm}$ are arbitrary complex numbers, and $A_N^{+}, A_{N+1}^{+}, \cdots$ are arbitrary complex numbers satisfying*

$$\sum_{k=N}^{\infty} k|A_k^{+}|^2 < +\infty. \tag{3.9}$$

Moreover, the series (3.8) *is convergent in $W^{1,2}(\mathbf{B}^2)$. Conversely any series expansion like* (3.8) *with coefficients satisfying* (3.9) *gives a $W^{1,2}(\mathbf{B}^2)$ solution of* (2.3) *vanishing at the origin.*

Remarks. 1. Theorem 3 remains true if we replace $\mathbf{B}^2$ by another ball $B_R(0)$ for any $R > 0$ since (2.3) is invariant under $\xi \to \lambda\xi$, $\lambda > 0$.

2. A computation gives, for $k \neq N$,

$$\varepsilon_k^{\pm} = \frac{\lambda_k^{\pm} - N - k}{\lambda_k^{\pm} - N + k}. \tag{3.10}$$

Thus for $k > N$, $|\varepsilon_k^{+}| < 1$. Since $\lambda_k \sim k$ as $k \to \infty$ it follows that (3.9) is equivalent to $H \in W^{1,2}(\mathbf{B}^2)$.

3. It will be useful to rearrange the exponents $\lambda_k^{\pm}$ in increasing order. We obtain

$$0 < \lambda_{N-1}^{-} < \lambda_{N-2}^{-} < \cdots < \lambda_0^{-} < \lambda_0^{+} < \cdots < \lambda_N^{+} < \cdots. \tag{3.11}$$

4. Inverting the hodograph transform. We will now study the possibility of reversing the process

$$u \to f \to g \to H. \tag{4.1}$$

Let us start with a quasiconformal solution of (2.3) such that $H(0) = 0$. By inverting H in a neighborhood of zero we obtain g and $f = g^{-N}$. Since $f_{\bar{z}}$ is real, f is an

exact complex differential. Therefore, in any given simply connected region, we can find a function u with complex gradient f which will be p-harmonic. Since we allow singularities at zero, our domain is not simply connected and we have to be a little careful.

From the invertibility of H we deduce the invertibility of the leading term in the expansion (3.8). The building block in (3.8) is

$$H_k^{\pm} = \{A_k^{\pm} e^{i(k+N)\theta} + \varepsilon_k^{\pm} \bar{A}_k^{\pm} e^{-i(k-N)\theta}\} r^{\lambda_k^{\pm}}, \tag{4.2}$$

which is itself a quasiregular mapping. By using (3.10) and the argument principle it follows that $H_k^{\pm}$ is invertible only when $k = N-1$. Thus, if $N > 1$ we must have

(4.3)
$$A_{N-1}^- \neq 0 \text{ or } A_{N-1}^- = A_{N-2}^- = \cdots = A_0^- = A_0^+ = \cdots = A_{N-2}^+ = 0, \qquad A_{N-1}^+ \neq 0$$

and

$$|A_0^- + \varepsilon_0^- \overline{A_0^-}| + |A_0^+ + \varepsilon_0^+ \overline{A_0^+}| > 0 \tag{4.4}$$

when $N = 1$. We set for $N > 1$

$$H_{N-1}(r,\theta) = \{A_{N-1}^- e^{i(2N-1)\theta} + \varepsilon_{N-1}^- \bar{A}_{N-1}^- e^{i\theta}\} r^{\lambda_{N-1}^-}$$

and

$$H_0(r,\theta) = (A_0^- + \varepsilon_0^- \bar{A}_0^-) e^{i\theta} r^{\lambda_0^-} + (A_0^+ + \varepsilon_0^+ \bar{A}_0^+) e^{i\theta} r^{\lambda_0^+}.$$

Let us call α_N and β_N the first and second powers of r in the expansion (3.8). Observe that

$$\text{if } N \geq 2 \quad \begin{cases} \alpha_N = \lambda_{N-1}^+, & \beta_N = \lambda_N^+, \quad \text{in the + case,} \\ \alpha_N = \lambda_{N-1}^-, & \beta_N = \lambda_{N-2}^-, \quad \text{in the − case, and} \end{cases}$$

$$\text{if } N = 1 \quad \begin{cases} A_0^+ + \varepsilon_0^- A_0^- \neq 0, & \alpha_1 = \lambda_0^-, \beta_1 = \lambda_0^+, \\ A_0^- + \varepsilon_0^- A_0^- = 0, & \alpha_1 = \lambda_0^+, \beta_1 = \lambda_1^+. \end{cases}$$

In any case, we always have

$$|D^\nu H(r,\theta) - D^\nu H_{N-1}(r,\theta)| \leq C_m r^{\beta_N - m}, \tag{4.5}$$

where $|\nu| = m \geq 0$, $r \leq \delta(m)$ and C_m is a constant.

Denote by g_{N-1} the inverse of H_{N-1} and set

$$f_{N-1} = (g_{N-1})^{-N}.$$

Since H is close to H_{N-1} near zero, we expect g to be close to g_{N-1} and f to be close to f_{N-1} near zero. The next lemma corroborates this suspicion and provides us with the main estimate needed in the proof of Theorem 1.

LEMMA 2. *Let m be a nonnegative integer. There exists $\delta = \delta(m) > 0$ and a constant C_m such that*

$$\sum_{|\nu|=m} |D^\nu f(z) - D^\nu f_{N-1}(z)| \leq C_m |z|^{-(N/\alpha_N)-m+(\beta_N/\alpha_N)-1} \tag{4.6}$$

for $0 < |z| < \delta$.

Proof. The proof of this lemma is somewhat long and it will be divided into a series of steps:

Step 1 (Estimates for H and H_{N-1}). There exists $\rho = \rho(m) > 0$ and constants $C > 0$ and C_m such that

$$\begin{aligned} &\text{(i)} \quad (1/C)|\xi|^{\alpha_N} \le H(\xi) \le C|\xi|^{\alpha_N}, \\ &\text{(ii)} \quad (1/C)|\xi|^{2\alpha_N - 2} \le J_H(\xi) = |H_\xi|^2 - |H_{\bar\xi}|^2 \le C|\xi|^{2\alpha_N - 2}, \\ &\text{(iii)} \quad \textstyle\sum_{|\nu|=m} |D^\nu H(\xi)| \le C_m |\xi|^{\alpha_N - m} \end{aligned}$$

for $|\xi| \le \rho$. Moreover, H_{N-1} satisfies the same estimates.

Proof. It follows immediately from Corollary 1 in [IM].

Step 2 (Estimates for g and g_{N-1}). There exist $\delta = \delta(m) > 0$ and constants $C > 0$ and C_m such that

$$\begin{aligned} &\text{(i)} \quad \tfrac{1}{C}\,|z|^{1/\alpha_N} \le |g(z)| \le C|z|^{1/\alpha_N}, \\ &\text{(ii)} \quad C|z|^{-2+2/\alpha_N} \le J_g(z) = |g_z|^2 - |g_{\bar z}|^2 \le C|z|^{-2+2/\alpha_N}, \\ &\text{(iii)} \quad \textstyle\sum_{|\nu|=m} |D^\nu g(z)| \le C_m |z|^{-m+1/\alpha_N} \end{aligned}$$

for $|z| \le \delta$. Moreover g_{N-1} satisfies the same estimates.

Proof. The estimation of higher derivatives of an inverse function is done with a device introduced in [IM, Lemma 1] that we shall use below (Steps 4 and 5). As stated, Step 2 follows from Corollary 2 in [IM].

Step 3 (Estimates for f and f_{N-1}). There exists $\delta = \delta(m) > 0$ and constants $C > 0$ and C_m such that

$$\begin{aligned} &\text{(i)} \quad \tfrac{1}{C}\,|z|^{-N/\alpha_N} \le |f(z)| \le C|z|^{-N/\alpha_N}, \\ &\text{(ii)} \quad \textstyle\sum_{|\nu|=m} |D^\nu f(z)| \le C_m |z|^{-(N/\alpha_N)-m} \end{aligned}$$

for $0 < |z| < \delta$. Moreover, f_{N-1} satisfies the same estimates.

Proof. Since $f = g^{-N}$ (i) is clear and (ii) follows by induction.

Step 4 (Estimate for $g - g_{N-1}$). For $|z| \le \delta = \delta(m)$ and a constant C_m, we have

$$\sum_{|\nu|=m} |D^\nu g(z) - D^\nu g_{N-1}(z)| \le C_m |z|^{-m+1/\alpha_N + (\beta_N/\alpha_N) - 1}.$$

Proof. Given a positive integer s, let H^s denote one of the partials

$$\frac{\partial^s H}{\partial \xi^i \partial \bar\xi^j} \qquad \text{or} \qquad \frac{\overline{\partial^s H}}{\partial \xi^i \partial \bar\xi^j},$$

where $i+j = s$. Any expression of the form $H^{s_1} H^{s_2} \cdots H^{s_k}$, where $s_1+s_2+\cdots+s_k = s$, will be called a monomial of type (s,k). The set of all finite linear combinations of monomials of type (s,k) is denoted $\mathbf{P}(s,k)$ or $\mathbf{P}_H(s,k)$ if we want to emphasize the dependence on H. According to Lemma 1 in [IM] if $|\nu| = m \ge 1$, there exists $P^\nu \in \mathbf{P}(4m-3, 3m-2)$ such that

$$D^\nu g(H(\xi)) = (J_H(\xi))^{1-2m} P^\nu_H(\xi) \tag{4.7}$$

and

$$D^\nu g_{N-1}(H_{N-1}(\xi)) = (J_{H_{N-1}}(\xi))^{1-2m} P^\nu_{H_{N-1}}(\xi). \tag{4.8}$$

Put $z = H(\xi)$. We have

$$\begin{aligned}|D^\nu g(z) - D^\nu g_{N-1}(z)| &\le |D^\nu g(H(\xi)) - D^\nu g_{N-1}(H_{N-1}(\xi))| \\ &\quad + |D^\nu g_{N-1}(H_{N-1}(\xi)) - D^\nu g_{N-1}(H(\xi))| \\ &\equiv \mathrm{I} + \mathrm{II}.\end{aligned}$$

Estimate of I:

$$\begin{aligned}|\mathrm{I}| \le (J_H(\xi) J_{H_{N-1}}(\xi))^{1-2m} \big[&(J_{H_{N-1}}(\xi))^{2m-1} (P_H^\nu(\xi) - P_{H_{N-1}}^\nu(\xi)) \\ &+ P_{H_{N-1}}^\nu(\xi)(J_{H_{N-1}}^{2m-1}(\xi) - J_H^{2m-1}(\xi))\big].\end{aligned}$$

To estimate $P_H^\nu(\xi) - P_{H_{N-1}}^\nu(\xi)$ note that

$$|H^{s_1} H^{s_2} \cdots H^{s_k}(\xi) - H_{N-1}^{s_1} H_{N-1}^{s_2} \cdots H_{N-1}^{s_k}(\xi)| \le C|\xi|^{(k-1)\alpha_N + \beta_N - s}$$

for all monomials of type (s, k). Therefore

$$|P_H^\nu(\xi) - P_{H_{N-1}}^\nu(\xi)| \le C|\xi|^{(3m-3)\alpha_N + \beta_N - 4m + 3} \tag{4.9}$$

and

$$|P_{H_{N-1}}^\nu(\xi)| \le C|\xi|^{(3m-2)\alpha_N - 4m + 3}. \tag{4.10}$$

Now using Step 1, (4.9), and (4.10) we obtain

$$|\mathrm{I}| \le C|\xi|^{-(m+1)\alpha_N + \beta_N + 1}. \tag{4.11}$$

Estimate of II:

$$|\mathrm{II}| = |D^\nu g_{N-1}(H(\xi)) - D^\nu g_{N-1}(H(\xi) + 0(|\xi|^{\beta_N}))|.$$

Since $\beta_N > \alpha_N$ and $|\xi|$ is small, the mean value theorem gives

$$|\mathrm{II}| \le C \sum_{|\nu| = m+1} |D^\nu g_{N-1}(H(\xi) + 0(|\xi|^{\beta_N}))|\, |\xi|^{\beta_N}.$$

By Step 2,

$$|D^\nu g_{N-1}(z)| \le C|z|^{-(m+1)+1/\alpha_N}$$

for $|\nu| = m + 1$. Thus

$$|\mathrm{II}| \le C|H(\xi)|^{-(m+1)+1/\alpha_N} |\xi|^{\beta_N} \le C|\xi|^{-(m+1)\alpha_N + 1 + \beta_N}. \tag{4.12}$$

From (4.11), (4.12), and another application of Step 2 we obtain the estimate in Step 4.

Step 5 (Estimate for $f - f_{N-1}$). This is the final step in which we will prove (4.6).

Proof. Let us begin by observing that $D^\nu(g^{-N})$ is a linear combination of terms of the form

$$g^{-N-k} P_g(m, k), \tag{4.13}$$

where $k = 1, 2, \cdots, m$ and $P_g(m,k)$ is an element of $\mathbf{P}_g(m,k)$. Thus, it suffices to establish (4.6) for the difference of corresponding terms of the form (4.13). Writing

$$\begin{aligned} g^{-N-k}P_g(m,k) - g_{N-1}^{-N-k}P_{g_{N-1}}(m,k) \\ = (gg_{N-1})^{-N-k}\big[g_{N-1}^{N+k}(P_g(m,k) - P_{g_{N-1}}(m,k)) \\ + P_{g_{N-1}}(m,k)(g_{N-1}^{N+k} - g^{N+k})\big] \end{aligned}$$

and using

$$|Pg(m,k) - P_{g_{N-1}}(m,k)| \le C_m|z|^{-m+(k/\alpha_N)+(\beta_N/\alpha_N)-1}$$

and

$$|g^{N+k} - g_{N-1}^{N+k}| \le C_m|z|^{((N+k)/\alpha_N)+(\beta_N/\alpha_N)-1}$$

we can easily finish the proof. □

5. Quasiradial singular p-harmonic functions. Consider first the case $N \ge 2$. Then $H_{N-1}(r,\theta)$ is quasiradial; i.e.,

$$H_{N-1}(r,\theta) = \psi_{N-1}(\theta)r^{\alpha_N} \tag{5.1}$$

and so is its inverse g_{N-1}, and f_{N-1}. Indeed,

$$f_{N-1}(s,\alpha) = \varphi_{N-1}(\alpha)s^{-N/\alpha_N}. \tag{5.2}$$

In (5.1) and (5.2) ψ_{N-1} and φ_{N-1} are certain nontrivial real analytic functions of period 2π.

LEMMA 3A. *If $N \ge 2$ and $\alpha_N = \lambda_{N-1}^-$ the function f_{N-1} is the complex gradient of a p-harmonic function v_N with an isolated singularity at zero. Moreover, v_N is quasiradial and there exists a constant γ_N such that*

$$v_N(se^{i\alpha}) = \gamma_N u_N(se^{i\alpha}),$$

where

$$u_N(se^{i\alpha}) = \Phi_N(\alpha)s^{\mu_N}$$

is as in (1.8) *and $\mu_N = (-N/\alpha_N) + 1$.*

Proof. Write $f_{N-1} = p - iq$. It is enough to check that

$$\int_{|z|=\varepsilon} p\,dx + q\,dy = 0,$$

which follows since p and q are homogeneous functions of degree $-N/\alpha_N \ne -1$.

From the expression of μ_N it is clear that it decreases to $-\infty$ as $N \to \infty$.

LEMMA 3B. *If $N \ge 2$ and $\alpha_N = \lambda_{N-1}^+$ the function f_{N-1} is the complex gradient of a p-harmonic function $\bar{v}_N$ in a punctured neighborhood of zero. Moreover $\bar{v}_N$ is quasiradial and there exists a constant $\bar{\gamma}_N$ such that*

$$\bar{v}_N(se^{i\alpha}) = \bar{\gamma}_N\bar{u}_N(se^{i\alpha}),$$

where

$$\bar{u}_N(se^{i\alpha}) = \bar{\Phi}_N(\alpha)s^{\bar{\mu}_N}$$

and $\bar{\mu}_N = \frac{-N}{\alpha_N} + 1 > (p-2)^+/(p-1)$.

Proof. Again it is easy to check that $-N/\alpha_N \neq -1$. Therefore the existence of $\bar{v}_N$ follows as in Lemma 3A. From (3.4) we have

$$\bar{\mu}_N = \frac{-N}{\lambda_{N-1}^+} + 1 = \frac{-2}{p + \sqrt{4(1-\frac{1}{N})^2 + (p-2)^2}} + 1$$
$$> \frac{-2}{p+|p-2|} + 1 \geq \frac{(p-2)^+}{p-1}. \qquad \square$$

Remark. We will see in §6 that $\bar{v}_N$ are indeed p-harmonic in a neigborhood of zero. These functions are considered also in [Ar] and in [Kv].

We now consider the case $N = 1$. The previous argument does not work since we may have $\lambda_0^- = 1$. It is convenient to distinguish whether $1 < p < 2$ or $p > 2$.

Case $1 < p < 2$**.** For certain $\alpha, \beta \in \mathbf{R}$ we may write

$$H_0(r,\theta) = \alpha e^{i\theta} r^{p-1} + i\beta e^{i\theta} r. \tag{5.3}$$

If $\alpha = 0$, then $H_0(\xi) = i\beta\xi$, for $\xi \in \mathbf{C}$ and it is not hard to see that $f_0 = (g_0)^{-1}$ is not the complex gradient of a function in a neighborhood of zero.

If $\alpha \neq 0$, we redefine

$$H_0(r,\theta) = \alpha e^{i\theta} r^{p-1} \tag{5.4}$$

and check easily that H_0 is the hodograph transform of a multiple of

$$u_1(se^{i\alpha}) = s^{\mu_1},$$

where $\mu_1 = (p-2)/(p-1)$.

Case $p > 2$**.** In this case we write

$$H_0(r,\theta) = i\alpha e^{i\theta} r + \beta e^{i\theta} r^{p-1} \tag{5.5}$$

for certain $\alpha, \beta \in \mathbf{R}$. If $\alpha = 0$, H_0 is the hodograph transform of a multiple of u_1 and if $\alpha \neq 0$, we redefine

$$H_0(r,\theta) = i\alpha e^{i\theta} r, \tag{5.6}$$

which is not the hodograph transform of any function in a neighborhood of zero.

LEMMA 4. *Let* $N = 1$. *Then* H_0 (*redefined according to* (5.4) *and* (5.6)) *is the hodograph transform of a p-harmonic function if and only if* H *is the hodograph transform of a p-harmonic function in a neighborhood of zero.*

Proof. It is enough to show that $f - f_0$ is the gradient of a function in a punctured neighborhood of zero. From Lemma 2 we have

$$\int_{|z|=\varepsilon} |f - f_0| d|z| \leq C\varepsilon^{(-1+\beta_1)/\alpha_1}.$$

Since $\beta_1 = \lambda_0^+$ or $\beta_1 = \lambda_1^+$, it follows that $\beta_1 > 1$. Therefore

$$\int_{|z|=\varepsilon} (p - p_0)dx + (q - q_0)dy = 0. \qquad \square$$

From Lemma 4 we conclude that if H is the hodograph transform of some u, we must have

$$\begin{aligned} &\text{If } 1 < p < 2, \quad \operatorname{Re} A_0^- \neq 0, \quad \text{and} \\ &\text{if } p > 2, \quad \operatorname{Im} A_0^- = 0 \quad \text{and} \quad \operatorname{Re} A_0^+ \neq 0. \end{aligned} \tag{5.7}$$

In particular $\alpha_1 = p - 1$ and we also have $\mu_1 = (-1/\alpha_1) + 1$.

6. Proof of Theorems 1 and 2. Let u be a singular p-harmonic function in $(\mathbf{B}^2)'$ satisfying (1.10).

LEMMA 5. *For $0 < |x| < \frac{1}{2}$ we have*

$$|\nabla u(x)| \leq C|x|^{\beta-1}.$$

Proof. If a ball of radius $2R$, $B_{2R} \subset (\mathbf{B}^2)'$ Cacciopoli's inequality gives

$$\left(\fint_{B_R} |\nabla u|^p dx \right)^{1/p} \leq \frac{C}{R} \left(\fint_{B_{2R}} |u|^p \right)^{1/p}.$$

Fix $x, |x| < \frac{1}{2}$. For $y \in B_{|x|/2}(x)$ we have $|u(y)| \leq C|y|^\beta$, $|x|/2 \leq |y| \leq 3|x|/2$ and

$$\left(\fint_{B_{(|x|/4)}(x)} |\nabla u|^p dx \right)^{1/p} \leq \frac{C}{|x|} |x|^\beta = C|x|^{\beta-1}. \tag{6.1}$$

The lemma now follows from (6.1) and the L^∞-estimate for ∇u ([DB], [L]):

$$\sup_{B_{|x|/8}(x)} |\nabla u| \leq C \left(\int_{B_{|x|/4}(x)} |\nabla u|^p dx \right)^{1/p}. \qquad \square$$

Let $f = \frac{1}{2}(u_x - iu_y)$ and write $f = h \circ g_1$ as in (2.1). From Lemma 5 and the Hölder continuity of quasiconformal mappings ([LV], [A]) we infer that h has a pole at 0 of order $N \geq 0$.

If $N = 0$, f is indeed quasiregular in a neighborhood of the origin. Thus u is smooth at 0 and the singularity is removable.

Consider now the case where $N \geq 2$ and $\alpha_N = \lambda_{N-2}^+$. Applying Lemma 2 for $m = 0$ and Lemma 3B, we obtain

$$|\nabla u - \bar{\gamma}_N \nabla \bar{u}_N| \leq C_o |x|^{\bar{\mu}_N - 1 + ((\beta_N/\alpha_N)-1)}.$$

Therefore we have

$$|\nabla u(x)| \leq C|x|^{\mu_N - 1}.$$

Since $\bar{\mu}_N > (p-2)^+/(p-1) > (p-2)/p$, it follows that

$$\int_{|x|<\delta} |\nabla u|^p \, dx < \infty$$

for small $\delta > 0$. Let now $\phi \in C_0^\infty(|x| < \delta)$,

$$\int_{|x|<\delta} |\nabla u|^{p-2}\langle \nabla u, \nabla \phi\rangle \, dx = \int_{|x|<\epsilon} |\nabla u|^{p-2}\langle \nabla u, \nabla \phi\rangle \, dx + \int_{\epsilon<|x|<\delta} |\nabla u|^{p-2}\langle \nabla u, \nabla \phi\rangle \, dx.$$

By Hölder's inequality and the integrability of $|\nabla u|^p$ in $|x| < \delta$ the first integral tends to zero as $\epsilon \to 0$. Transform the second integral using the divergence theorem,

$$\int_{\epsilon<|x|<\delta} |\nabla u|^{p-2}\langle \nabla u, \nabla \phi\rangle \, dx = \int_{|x|=\epsilon} |\nabla u|^{p-2}\frac{\partial u}{\partial r}\phi \, dx.$$

Thus

$$\left| \int_{\epsilon<|x|<\delta} |\nabla u|^{p-2}\langle \nabla u, \nabla \phi\rangle \, dx \right| \le C\epsilon\epsilon^{(p-1)(\bar{\mu}_N - 1)}\|\phi\|_\infty,$$

which tends to zero as $\epsilon \to 0$ since $\bar{\mu}_N > (p-2)^+/(p-1) \ge (p-2)/(p-1)$. Therefore u is indeed p-harmonic in a neigborhood of zero, and the singularity is again removable.

Thus $N \ge 1$ of $N \ge 2$ and $\alpha_N = \lambda_{N-1}^-$ for a true singularity.

From Lemma 1 we write $f = g^{-N}$ in a neighborhood of zero, g quasiconformal satisfying $g(0) = 0$ and apply the results of §§3, 4, and 5. From Lemma 2 we obtain

$$\sum_{|\nu|=m+1} |D^\nu u - \gamma_N D^\nu u_N| \le C_m |x|^{-(N/\alpha_N)-m+((\beta_N/\alpha_N)-1)} \tag{6.2}$$

for m nonnegative integer. Set

$$\delta_N = \frac{\beta_N}{\alpha_N} - 1 > 0$$

and we have proved (1.11).

Combining Lemma 5 and the estimates in Step 3 of the proof of Lemma 2 we see that

$$|x|^{-N/\alpha_N} \le C|x|^{\beta-1}.$$

Therefore

$$\beta \le 1 - \frac{N}{\alpha_N} = \mu_N. \tag{6.3}$$

Indeed, N is the largest integer such that (6.3) holds. If $\beta > (p-2)/(p-1)$, N must be zero and so 0 is a removable singularity of u. This justifies the remark after Theorem 1 and finishes its proof.

To prove Theorem 2 all we have to do is to integrate (6.2) when $m = 0$. From the definitions of δ_N, μ_N, α_N, β_N, and (3.4) we can easily check (1.12).

Write (6.2) for $m = 0$,

$$|\nabla u(x) - \gamma_N \nabla u_N(x)| \le C|x|^{\mu_N - 1 + \delta_N}. \tag{6.4}$$

In particular,

$$|\nabla u(x)| \le C|x|^{\mu_N - 1}. \tag{6.5}$$

We now integrate (6.5). Let s be a small positive number and $|x| < s$,

$$\left|u(x) - u\left(s\frac{x}{|x|}\right)\right| \leq C\int_{|x|}^{s} t^{\mu_N - 1}dt \leq C|s^{\mu_N} - |x|^{\mu_N}| \tag{6.6}$$

since $\mu_N \neq 0$.

If $\mu_N < 0$, (6.6) implies

$$|u(x)| \leq C|x|^{\mu_N} \tag{6.7}$$

for small $|x|$. On the other hand, if $\mu_N > 0$ (Case $N = 1$, $p > 2$) we obtain

$$|u(x)| \leq C. \tag{6.8}$$

Similarly we integrate (6.4) to get

$$\left|u(x) - \gamma_N u_N(x) - u\left(s\frac{x}{|x|}\right) + \gamma_N u_N\left(s\frac{x}{|x|}\right)\right| \leq C\int_{|x|}^{s} t^{\mu_N - 1 + \delta_N}dt \tag{6.9}$$

for $|x| < \delta$. We will consider several cases:

(a) $N \geq 3$. Since $\mu_N + \delta_N < 0$, (1.13) follows from (6.9).

(b) $N = 2$, $p > 2$ and $N = 1$, $1 < p < 2$. Again (1.14) follows from (6.9).

(c) $N = 1$, $p > 2$. Since $\mu_N + \delta_N = 1$, (6.4) implies that $u - \gamma_1 u_1$ is Lipschitz across the origin. Thus (1.15) follows easily.

7. Remark on a uniqueness problem. Suppose $u \in W^{1,p-1}(\mathbf{B}^n)$ and u is p-harmonic in the following "ultra-weak" sense: (1.1) is required to hold only for test functions $\phi \in C_0^\infty(\mathbf{B}^n)$. Does it follow that u is in $W^{1,p}(\mathbf{B}^n)$ (and so that u is a classical p-harmonic function)?

Theorem 1 allows us to answer a particular case of this question in two dimensions.

THEOREM 4. *Suppose u is p-harmonic in $(\mathbf{B}^2)' = \mathbf{B}^2 - \{0\}$, $\nabla u \in L^{p-1}(\mathbf{B}^2)$ and*

$$\int_{\mathbf{B}^2} |\nabla u|^{p-2}\langle \nabla u, \nabla \phi\rangle dx = 0 \tag{7.1}$$

for all $\phi \in C_0^\infty(\mathbf{B}^2)$. Then u is p-harmonic in $\mathbf{B}^2$.

First we need the following lemma.

LEMMA 6. *Let u be a p-harmonic function in $(\mathbf{B}^2)'$ such that $\nabla u \in L^\epsilon(\mathbf{B}^2)$ for some $\epsilon > 0$. Then, there exists $\lambda > 0$ and a constant C such that*

$$|u(x)| \leq C|x|^{-\lambda} \tag{7.2}$$

for $|x| < \frac{1}{2}$.

Proof. Set $f = \partial u/\partial z$ as in §2 and write $f = h \circ g_1$ as in (2.1). Since g_1 is K-quasiconformal, where $K = \max\{p-1, 1/(p-1)\}$, there exists $\delta_p > 0$ such that

$$\int_{|x|<1/2} (J_{g_1}(x))^{1+\delta_p}\, dx < \infty. \tag{7.3}$$

Here J_{g_1} is the Jacobian of g_1 and (7.3) follows from the higher integrability of Jacobians of quasiconformal mappings [LV].

Let $\eta > 0$ be a small number such that $g_1^{-1}(\{w : |w| < \eta\})$ is contained in $\{x : |x| < \frac{1}{2}\}$, and set $q = 1+\delta_p$, $r = (1+\delta_p)/\delta_p$, $s = \epsilon\delta_p/(1+\delta_p)$, and $t = \delta_p/(1+\delta_p)$. Then

$$\begin{aligned}\int_{|w|<\eta} |h(w)|^s\, dw &= \int_{|w|<\eta} |h(w)|^s J^t_{g_1^{-1}}(w) J^{-t}_{g_1^{-1}}(w)\, dw \\ &\le \left(\int_{|w|<\eta} |h(w)|^{sr} J^{tr}_{g_1^{-1}}(w)\, dw\right)^{1/r} \left(\int_{|w|<\eta} \left(J_{g_1^{-1}}(w)\right)^{-tq}\, dw\right)^{1/q} \\ &= A^{1/r} B^{1/q}.\end{aligned}$$

To estimate A we change variables and use $f \in L^\epsilon(\mathbf{B}^2)$,

$$A = \int_{g_1^{-1}(|w|<\eta)} |h \circ g_1(x)|^\epsilon\, dx < \infty.$$

Similarly, after changing variables and using (7.3)

$$\begin{aligned}B &= \int_{g_1^{-1}(|w|<\eta)} \left[J_{g_1^{-1}}(g(x))\right]^{-\delta_p} J_{g_1}(x)\, dx \\ &= \int_{g_1^{-1}(|w|<\eta)} [J_{g_1}(x)]^{1+\delta_p}\, dx < \infty.\end{aligned}$$

Therefore h is a holomorphic function in a punctured neighborhood of zero satisfying

$$\int_{|w|<h} |h(w)|^{\epsilon\delta_p/(1+\delta_p)}\, dw < \infty. \tag{7.4}$$

For $|w| < \eta/2$ the subharmonicity of $|h|^{\epsilon\delta_p/(1+\delta_p)}$ gives

$$|h(w)|^{\epsilon\delta_p/(1+\delta_p)} \le \frac{4}{\pi|w|^2} \int\int_{|w-\eta|<|w|/2} |h(\eta)|^{\epsilon\delta_p/(1+\delta_p)}\, d\eta.$$

Thus $|h(w)| \le C|w|^\nu$ for some $\nu > 0$ and $|w| < \eta/2$. Since g_1 is Hölder continuous, it follows that

$$|\nabla u(x)| = |f(x)| \le C|x|^{-\lambda-1}$$

for some $\lambda > 0$ and $|x| < 1/2$. Upon integration we obtain the estimate (7.2). □

Proof of Theorem 4. From (7.1) and the divergence theorem we obtain

$$\lim_{\varepsilon\to 0} \int_{|x|=\varepsilon} |\nabla u|^{p-2} \frac{\partial u}{\partial r}\, d\sigma = 0. \tag{7.5}$$

If u is singular p-harmonic, from (1.11) we deduce

$$\nabla u(x) = \gamma_N \nabla u_N(x) + 0(|x|^{\mu_N - 1 + \delta_N})$$

for some constant $\gamma_N \neq 0$ and $N \geq 1$. It follows then that

$$\int_{|x|=\varepsilon} |\nabla u|^{p-2} \frac{\partial u}{\partial r}\, d\sigma = |\gamma_N|^{p-2}\gamma_N \int_{|x|=\varepsilon} |\nabla u_N|^{p-2} \frac{\partial u_N}{\partial r} + O(\varepsilon^{(\mu_N-1)(p-1)+\delta_N+1}).$$

Since

$$\int_{|x|=\varepsilon} |\nabla u_N|^{p-2} \frac{\partial u_N}{\partial r} = C\varepsilon^{(\mu_N-1)(p-1)+1}$$

and $\gamma_N \neq 0$, $C \neq 0$ we must have $(\mu_N-1)(p-1)+1 > 0$. Therefore $\mu_N > (p-2)/(p-1)$, which is impossible. Thus we have arrived at a contradiction if we assume that u is singular p-harmonic. So it must be that u is p-harmonic in $\mathbf{B}^2$. □

Acknowledgments. This paper was completed while the author was visiting the Department of Mathematics at Northwestern University. The author wishes to thank the members of this Department for the pleasant mathematical atmosphere they offered him. Especial thanks are due to Emmanuele DiBenedetto for enlightening conversations about p-harmonic functions and for suggesting the question treated in §7.

The author would like also to thank the referee who pointed out the need for Lemma 3B and Lemma 6.

APPROXIMATION OF SOLUTIONS OF SINGULAR SECOND-ORDER BOUNDARY VALUE PROBLEMS*

A. M. FINK†, JUAN A. GATICA‡, GASTON E. HERNANDEZ§, AND PAUL WALTMAN¶

Abstract. The boundary value problems

$$(P_1)\qquad y''+\frac{n-1}{x}y'+f(x,y)=0,\qquad y'(0)=y(1)=0,$$

and

$$(P_2)\qquad y''+f(x,y)=0,\quad \alpha y(0)-\beta y'(1)=0,\quad \gamma y(1)+\delta y'(1)=0$$

with the function $f(x, y)$ satisfying conditions that allow for singularities to be present are studied with the view of obtaining general existence, uniqueness, and approximation of positive solutions. Furthermore, the behavior of solutions near $x=1$ is described for the special case $f(x, y)=a(x)y^{-p}$.

Key words. singular nonlinear boundary value problems, radially symmetric solutions of nonlinear elliptic partial differential equations, order reversing operators, sequence of iterates, existence and uniqueness

AMS(MOS) subject classifications. primary 34B15; secondary 34A45, 35J65

1. Introduction. This paper deals with the existence, uniqueness, and approximation of solutions of boundary value problems of the following types:

$$(P_1)\qquad y''+\frac{n-1}{x}y'+f(x,y)=0,\qquad y'(0)=y(1)=0,$$

and

$$(P_2)\qquad y''+f(x,y)=0,\quad \alpha y(0)-\beta y'(1)=0,\quad \gamma y(1)+\delta y'(1)=0.$$

In both problems it is desired to include the case when $f(x, y)$ is singular at $y=0$; the conditions that are imposed on f are such that the special case $f(x, y)=a(x)y^{-p}$, $p>0$, $a(x)$ continuous is included in the results and the behavior of the solution of (P_1) in this special case is completely described for x near 1, i.e., near the point where the singularity occurs.

The paper is organized as follows. Section 2 deals with transforming these problems into fixed-point problems by using the appropriate Green's function integral operator and showing the equivalence of the problems. Once this is done the monotonicity introduced by the singularity in the dependent variable is used to determine a region

bounded between the graphs of two functions constructed iteratively where the graph of any solution must lie provided that certain initial inequalities hold; furthermore, it is shown that under slightly more restrictive conditions there can exist at most one solution.

Section 3 is devoted to finding a general approximation scheme, by regularizing the problems and showing that the conditions required in § 2 hold for the regularized problems. A general uniqueness result is obtained and general conditions are found that imply the existence of solutions to the problems and also some of their regularity properties.

Section 4 is devoted exclusively to the discussion of the special case $f(x, y) = a(x)y^{-p}$ for problem (P_1). The behavior of solutions when x is near 1 is described.

Section 5 simply shows how the approximation method used in the previous sections works for some specific examples. We describe the method used to compute the iterations and show graphs of the approximations for various specific examples.

The existence of positive solutions to (P_1) belonging to $C^1([0, 1]) \cap C^2((0, 1))$ was dealt with in [5] while those to (P_2), in the same class of functions, were studied in [4]: uniqueness results were given in both papers. An iterative procedure to approximate some positive solutions to (P_2) when $f(x, y) = a(x)y^{-p}$, $0 < p \leqq 1$, was described in [6].

Problem (P_1) comes from the study of existence of positive radially symmetric solutions to

$$\Delta u + f(x, u) = 0 \quad \text{in } \Omega,$$
$$u \,|\, \partial\Omega = 0,$$

where Ω is the open unit ball centered at the origin in $\mathbb{R}^n$; this partial differential equation with $f(x, u) = a(x)u^{-p}$, in more general domains but without radial symmetry, was studied in [13]. Problems with similar singularities were studied in [2].

Problem (P_2) is a generalized Emden-Fowler equation and has been extensively studied; [9] provides an excellent survey of the literature concerning Emden-Fowler equations. Equations with similar types of singularities were studied in [1], [3], [9], and [10].

2. Equivalent integral equation. In what follows it will be assumed, depending on the problem being considered, that the function f satisfies some of the following hypotheses:

- H_1 $f:[0, 1) \times (0, \infty) \to (0, \infty)$ is continuous.
- H_1' $f:(0, 1) \times (0, \infty) \to (0, \infty)$ is continuous.
- H_2 $f(x, y)$ is strictly decreasing in y for $x \in (0, 1)$, and integrable over $[0, 1]$ for each fixed $y > 0$.
- H_3 $\alpha, \beta, \gamma, \delta$ are nonnegative and $\rho = \gamma\beta + \alpha\gamma + \alpha\delta > 0$.

Note that none of these hypotheses implies the existence of a singularity.

It can be easily verified that the Green's function for the problem

$$y'' + \frac{n-1}{x} y' = 0, \qquad y'(0) = y(1) = 0,$$

is the function $G:(0, 1] \times (0, 1] \to [0, \infty)$ given by

$$G(x, t) = \begin{cases} \dfrac{1}{n-2} t^{n-1}(t^{2-n} - 1), & 0 < x \leqq t \leqq 1, \\ \dfrac{1}{n-2} t^{n-1}(x^{2-n} - 1), & 0 < t \leqq x \leqq 1, \end{cases} \tag{1}$$

if $n>2$ and

$$G(x,t)=\begin{cases}-t\ln(t), & 0<x\leqq t\leqq 1,\\ -t\ln(x), & 0<t\leqq x\leqq 1,\end{cases} \tag{2}$$

if $n=2$. It is clear that in either case $G(x,t)>0$ if $(x,t)\in(0,1)\times(0,1)$.

The Green's function for

$$\begin{aligned} &y''=0,\\ &\alpha y(0)-\beta y'(0)=0,\\ &\gamma y(1)+\delta y'(1)=0,\end{aligned} \tag{3}$$

assuming that $\rho>0$, is given by

$$G(x,t)=\begin{cases}\dfrac{1}{\rho}(\gamma+\delta-\gamma x)(\beta+\alpha t), & 0\leqq t\leqq x\leqq 1,\\ \dfrac{1}{\rho}(\beta+\alpha x)(\gamma+\delta-\gamma t), & 0\leqq x\leqq t\leqq 1,\end{cases}$$

and if H_3 is satisfied then $G(x,t)>0$ for $(x,t)\in(0,1)\times(0,1)$.

In what follows it will often be necessary to have that positive solutions of (P_1) or (P_2) are also solutions of the integral equation:

$$y(x)=\int_0^1 G(x,t)f(t,y(t))\,dt. \tag{4}$$

This may follow from the particular assumptions of the cases considered.

Before entering a detailed discussion of the particular results obtained, it will be convenient to establish a general principle which is the basis for what is to come. To avoid introducing excessive notation, X will stand for the space of real-valued continuous functions defined on $[0,1]$, with supremum norm, K will be the cone, in X, of nonnegative functions, $\leqq$ will denote the order induced in X by K, and D will be either the set

$$D=\{\phi\in K:\exists\theta>0 \text{ such that } \phi(x)\geqq\theta(1-x),\ x\in[0,1]\}, \tag{5}$$

when discussing (P_1), or the set

$$D=\{\phi\in K:\exists\theta>0 \text{ such that } \phi(x)\geqq g_\theta(x),\ x\in[0,1]\}, \tag{6}$$

where

$$g_\theta(x)=\begin{cases}\theta x, & 0\leqq x\leqq\frac{1}{2},\\ \theta(1-x), & \frac{1}{2}\leqq x\leqq 1,\end{cases}$$

when discussing (P_2). T will denote the Green's function operator

$$T\phi(x)=\int_0^1 G(x,t)f(t,\phi(t))\,dt \tag{7}$$

considered over its "natural domain," i.e., the set of all functions in K for which this formula defines a continuous function on $[0,1]$. Note that if f satisfies H_2 and if ϕ is in the natural domain of T, then any function $\psi\geqq\phi$ is also in the natural domain of T. If f is sufficiently well behaved, then D is contained in the natural domain of T and the restriction of T to D is easily seen to be such that $T:D\to D$; see [5].

It is important to note, however, that under very mild conditions any positive solution of (P_1) or (P_2) is a solution of the corresponding version of (4).

LEMMA 2.1. *If* H_1 *and* H_2 *hold, any positive solution of* (P_1) *is also a solution of* (4). *If* H_1', H_2 *and* H_3 *hold, any positive solution of* (P_2) *is also a solution of* (4).

Proof. If H_1 and H_2 hold and $\phi:[0,1]\to[0,\infty)$ is a solution of (P_1), then

$$(x^{n-1}\phi'(x))' = -x^{n-1}f(x,\phi(x)), \qquad x\in(0,1),$$

and $\phi'(0)=\phi(1)=0$. Thus, if $x\in(0,1]$,

$$x^{n-1}\phi'(x) = -\int_0^x t^{n-1}f(t,\phi(t))\,dt,$$

$$\phi'(x) = -\frac{1}{x^{n-1}}\int_0^x t^{n-1}f(t,\phi(t))\,dt$$

and, integrating again:

$$\phi(x)-\phi(0) = -\int_0^x\int_0^t \left(\frac{u}{t}\right)^{n-1} f(u,\phi(u))\,du\,dt$$

$$= -\int_0^x\int_u^x \left(\frac{u}{t}\right)^{n-1} f(u,\phi(u))\,dt\,du.$$

The cases $n=2$ and $n>2$ must be discussed separately. If $n=2$,

$$\phi(x)-\phi(0) = -\int_0^x\int_u^x \frac{u}{t}f(u,\phi(u))\,dt\,du$$

$$= -\int_0^x (\ln(x)-\ln(u))uf(u,\phi(u))\,du$$

$$= -\ln(x)\int_0^x uf(u,\phi(u))\,du + \int_0^x u\ln(u)f(u,\phi(u))\,du$$

and, in particular,

$$\phi(1)-\phi(0) = -\phi(0) = \int_0^1 u\ln(u)f(u,\phi(u))\,du.$$

This implies that

$$\int_0^1 |u\ln(u)|f(u,\phi(u))\,du<\infty$$

and the Green's function operator T may be applied to ϕ, obtaining

$$T\phi(x) = -\int_0^x t\ln(x)f(t,\phi(t))\,dt - \int_x^1 t\ln(t)f(t,\phi(t))\,dt.$$

This implies that $T\phi(1)=0$ and

$$(T\phi)'(x) = -\frac{1}{x}\int_0^x tf(t,\phi(t))\,dt,$$

$$(T\phi)''(x) = \frac{1}{x^2}\int_0^x tf(t,\phi(t))\,dt - f(x,\phi(x)), \qquad x\in(0,1),$$

so that

$$(T\phi)''(x) = -\frac{1}{x}(T\phi)'(x) - f(x, \phi(x)), \qquad x \in (0, 1),$$

which in turn implies that

$$(x(T\phi)'(x))' = -f(x, \phi(x)) = (x\phi'(x))', \qquad x \in (0, 1).$$

Since $T\phi(1) = \phi(1) = 0$, it must be the case that

$$x(T\phi)'(x) = x\phi'(x), \qquad x \in (0, 1),$$

and so

$$(T\phi)'(x) = \phi'(x), \qquad x \in (0, 1).$$

Since $T\phi(0) = \phi(0)$, the conclusion is that

$$T\phi(x) = \phi(x), \qquad x \in [0, 1].$$

The case $n > 2$ follows in identical fashion, the only difference being that

$$\int_u^x t^{-n+1}\, dt = \frac{1}{-n+2}[x^{-n+2} - u^{-n+2}].$$

If H_1', H_2, and H_3 hold, the discussion is simpler since then for any ψ in the domain of the Green's function operator:

$$(T\psi)''(x) = -f(x, \psi(x)), \qquad x \in (0, 1).$$

THEOREM 2.2. *If f satisfies H_1 or H_1', H_2 (and H_3 if considering (P_2)), and if there exists $\phi \in K$ such that $T\phi$, $T^2\phi$ are defined and either $T\phi \leqq \phi$, $T^2\phi \leqq \phi$ or $T\phi \geqq \phi$, $T^2\phi \geqq \phi$, then the sequence of iterates $\{T^n\phi\}_{n=0}^{\infty}$ is defined, the subsequences $\{T^{2n}\phi\}_{n=0}^{\infty}$, $\{T^{2n+1}\phi\}_{n=0}^{\infty}$ are monotone and uniformly convergent, with limits*

$$\psi_0 = \lim_{n\to\infty} T^{2n}\phi, \qquad \psi_1 = \lim_{n\to\infty} T^{2n+1}\phi.$$

Furthermore, if the function $yf(x, y)$ is strictly monotone for each x, then $\psi_0 = \psi_1$.

Proof. Consider the case when $T\phi \geqq \phi$ and $T^2\phi \geqq \phi$; the proof for the other case is analogous.

Since T is decreasing, it follows that

$$\phi \leqq T^2\phi \leqq T\phi$$

and hence

$$\phi \leqq T^2\phi \leqq T^3\phi \leqq T\phi.$$

It follows by induction that $\phi \leqq T^n\phi \leqq T\phi$ for all $n \geqq 1$ and that the subsequences $\{T^{2n}\phi\}_{n=0}^{\infty}$, $\{T^{2n+1}\phi\}_{n=0}^{\infty}$ are monotone increasing and monotone decreasing, respectively. Furthermore,

$$T^{2n+1}\phi \geqq T^{2n}\phi, \qquad n \geqq 0. \tag{8}$$

The monotone convergence theorem coupled with Dini's theorem imply that both subsequences are uniformly convergent on $[0, 1]$, so that ψ_0, ψ_1 exist and, by (8),

$$\psi_0 \leqq \psi_1.$$

It is immediate that $T\psi_0 = \psi_1$ and $T\psi_1 = \psi_0$. By definition of T it is the case that whenever φ is in the domain of T, then, in the case of problem (P_1),

$$(T\varphi)'(x) = -\int_0^x \left(\frac{t}{x}\right)^{n-1} f(t, \varphi(t))\, dt, \qquad 0 < x \leqq 1,$$

$$(T\varphi)'(0) = 0,$$

$$(T\varphi)''(x) = -\left(\frac{n-1}{x}\right)(T\varphi)'(x) - f(x, \varphi(x)), \qquad x \in (0, 1),$$

and for problem (P_2) an easy computation shows that

$$(T\varphi)''(x) = -f(x, \varphi(x)), \qquad x \in (0, 1).$$

To prove that $\psi_0 = \psi_1$ when $yf(x, y)$ is strictly increasing, recall that $\psi_0 \leqq \psi_1$ and, to proceed by contradiction, it is assumed that there exists $x \in (0, 1)$ such that $\psi_0(x) < \psi_1(x)$.

Define $\omega : [0, 1] \to \mathbb{R}$ by

$$\omega(x) = \psi_0(x)\psi_1'(x) - \psi_0'(x)\psi_1(x)$$

and observe that if the problem is (P_1) then $\omega(0) = \omega(1) = 0$; if the problem is (P_2) then it is the case that

$$\alpha\psi_i(0) - \beta\psi_i'(0) = 0, \qquad i = 0, 1,$$

$$\gamma\psi_i(1) + \delta\psi_i'(1) = 0,$$

and therefore, using the fact that $\rho = \gamma\beta + \gamma\alpha + \alpha\delta > 0$, it follows again that $\omega(0) = \omega(1) = 0$.

Also,

$$\omega'(x) = \psi_0'(x)\psi_1'(x) + \psi_0(x)\psi_1''(x) - \psi_0''((x)\psi_1(x) - \psi_0'(x)\psi_1'(x),$$

$$\omega'(x) = \psi_0(x)\psi_1''(x) - \psi_0''(x)\psi_1(x), \qquad x \in (0, 1),$$

and recalling that $\psi_0 = T\psi_1$, $\psi_1 = T\psi_0$, for (P_1):

$$\omega'(x) = \psi_0(x)\left[-\frac{(n-1)}{x}(T\psi_0)'(x) - f(x, \psi_0(x))\right]$$

$$- \psi_1(x)\left[-\frac{(n-1)}{x}(T\psi_1)'(x) - f(x, \psi_1(x))\right]$$

$$= -\frac{(n-1)}{x}\psi_0(x)\psi_1'(x) - \psi_0(x)f(x, \psi_0(x)) + \frac{(n-1)}{x}\psi_0'(x)\psi_1(x) + \psi_1(x)f(x, \psi_1(x))$$

$$= -\frac{(n-1)}{x}[\psi_0(x)\psi_1'(x) - \psi_0'(x)\psi_1(x)] + \psi_1(x)f(x, \psi_1(x)) - \psi_0(x)f(x, \psi_0(x)).$$

Thus, in this case:

$$\omega'(x) + \frac{n-1}{x}\omega(x) = \psi_1(x)f(x, \psi_1(x)) - \psi_0(x)f(x, \psi_0(x)), \qquad x \in (0, 1),$$

and the right-hand side is of one sign on $(0, 1)$. This is impossible since $\omega(0) = \omega(1) = 0$.

For (P_2), the discussion is even simpler since then

$$\omega'(x) = \psi_1(x)f(x, \psi_1(x)) - \psi_0(x)f(x, \psi_0(x)),$$

so ω' is of one sign on $(0, 1)$ and $\omega(0) = \omega(1) = 0$.

It should be pointed out that the convergence of the sequence of iterates to the solution of the integral equation in the case that $f(x, y) = a(x)y^{-p}$ with $p \in (0, 1)$ follows from a result in [12].

3. A general approximation result. This section is devoted to finding a large class of functions f for which it is easy to implement an iterative scheme to approximate the solutions of (P_1) or (P_2). The first step is to show that in many cases these problems have unique solutions; the following result generalizes the uniqueness criteria found in [3] and in [4].

THEOREM 3.1. *If* H_1 *and* H_2 *hold, then* (P_1) *has at most one positive solution. If* H_1', H_2, *and* H_3 *hold, then* (P_2) *has at most one positive solution.*

Proof. The monotonicity of the operator precludes the existence of two ordered solutions. If the problem has at least two distinct solutions ϕ_1, ϕ_2, it must be the case that there exist a, $b \in [0, 1]$, $a < b$, such that one of the solutions, say ϕ_1, is strictly greater than the other solution, ϕ_2, over $[a, b]$. Define $\omega : [0, 1] \to \mathbb{R}$ by

$$\omega(x) = \phi_1(x) - \phi_2(x).$$

It is the case that $\omega(x) > 0$ if $x \in [a, b]$; the claim is that $\omega(x) \geqq 0$ for $x \in [0, 1]$ for, if this were not the case, ω must have a point of minimum in $[0, 1]$, say x_0, with $\omega(x_0) < 0$.

The discussion now must be separated for the two problems. For problem (P_1), since $\omega(1) = 0$, it must be the case that $x_0 \in [0, 1)$; if $x_0 \in (0, 1)$ then $\omega(x_0) < 0$, $\omega'(x_0) = 0$, $\omega''(x_0) \geqq 0$. But

$$\omega''(x_0) = f(x_0, \phi_2(x_0)) - f(x_0, \phi_1(x_0)) < 0,$$

which is a contradiction. Thus the minimum must occur at $x = 0$ so there must exist $\varepsilon > 0$ such that if $x \in [0, \varepsilon)$, then $\phi_1(x) < \phi_2(x)$, and

$$\omega'(x) = \phi_1'(x) - \phi_2'(x) = \int_0^x \left(\frac{t}{x}\right)^{n-1} (f(t, \phi_2(t)) - f(t, \phi_1(t)))\, dt < 0,$$

which contradicts the fact that the minimum of ω occurs at $x = 0$.

For problem (P_2), we reason in the same way to eliminate the possibility of $x_0 \in (0, 1)$. If the minimum occurs at $x = 0$, then ω must be negative in a neighborhood $[0, \delta)$ of 0, and from the boundary conditions it follows that if $\beta = 0$ then $\omega(0) = 0$, so it may be assumed, in this case, that $\beta > 0$, obtaining:

$$\omega'(0) = \phi_1'(0) - \phi_2'(0) = \frac{\alpha}{\beta}(\phi_1(0) - \phi_2(0)) = \frac{\alpha}{\beta}\omega(0)$$

and

$$\omega'(x) - \omega'(0) = \int_0^x \omega''(t)\, dt = \int_0^x (f(t, \phi_2(t)) - f(t, \phi_1(t)))\, dt < 0,$$

so it follows that $\omega'(x) \leqq \omega'(0) = (\alpha/\beta)\omega(0) < 0$ on $[0, \delta)$, contradicting the fact that ω has its minimum at $x = 0$. Finally, if the minimum occurs at $x = 1$, ω must be negative in some neighborhood $(1 - \varepsilon, 1]$ of 1. For $x \in (1 - \varepsilon, 1]$,

$$\omega'(1) - \omega'(x) = \int_x^1 \omega''(t)\, dt = \int_x^1 (f(t, \phi_2(t)) - f(t, \phi_1(t)))\, dt < 0,$$

so that $\omega'(x) > \omega'(1)$ on $(1 - \varepsilon, 1)$. If $\delta = 0$ then the boundary conditions imply that $\omega(1) = 0$, so it must be the case that $\delta \neq 0$. In this situation $\omega'(1) = -(\gamma/\delta)\omega(1) > 0$ and $\omega'(x) > 0$ in $(1 - \varepsilon, 1)$, contradicting the fact that $x = 1$ is a minimum for ω.

For the rest of this section the focus will be the study of how good an approximation to the positive solution of (P_1) or (P_2) is the positive solution of the new problem

$$(P_1)_\varepsilon \qquad \begin{aligned} &y''+\frac{n-1}{x}y'+f(x, y+\varepsilon)=0,\\ &y'(0)=y(1)=0, \end{aligned}$$

or

$$(P_2)_\varepsilon \qquad \begin{aligned} &y''+f(x, y+\varepsilon)=0,\\ &\alpha y(0)-\beta y'(0)=0,\\ &\gamma y(1)+\delta y'(1)=0, \end{aligned}$$

respectively, for $\varepsilon>0$ and small.

Denoting $f_\varepsilon(x, y)=f(x, y+\varepsilon)$ and

$$T_\varepsilon\phi(x)=\int_0^1 G(x, t)f_\varepsilon(t, \phi(t))\,dt,$$

it is clear that if f satisfies H_1 then f_ε is continuous on $[0, 1)\times[0, \infty)$, if f satisfies H_1', then f_ε is continuous on $(0, 1)\times[0, \infty)$, and in both cases T_ε is defined on all of K and is monotone decreasing there if f satisfies H_1, and if f is continuous then f_ε satisfies appropriate integrability conditions (see [5]) for the problems to have solutions. Thus, problems $(P_1)_\varepsilon$ and $(P_2)_\varepsilon$ have a unique positive solution, denoted by ϕ_ε and if $yf_\varepsilon(x, y)$ is (strictly) monotone in y, then by Theorem 2.2 the sequence of iterates $\{T_\varepsilon^k 0\}_{k=1}^\infty$ converges uniformly to ϕ_ε, having in addition that the subsequence of even iterates is monotone decreasing and the subsequence of odd iterates is monotone increasing. It should be noted at this point that if $f(x, y)=a(x)y^{-p}$. $0<p\leqq 1$, and if $a(x)$ is continuous in its required domain, then $yf_\varepsilon(x, y)$ is strictly increasing in y for all $\varepsilon>0$, and therefore the convergence of the iterates of $T_\varepsilon 0$ to ϕ_ε is assured in this particular case.

THEOREM 3.2. *If* $0<\mu<\varepsilon$, *then* $0\leqq\phi_\mu(x)-\phi_\varepsilon(x)<\varepsilon-\mu$, $x\in[0, 1]$.

Proof. Let $\omega(x)=(\phi_\varepsilon(x)+\varepsilon)-(\phi_\mu(x)+\mu)$. It will be shown that $\omega(x)\geqq 0$ on $[0, 1]$.

Consider first problem (P_1). Define

$$h(x)=\frac{f(x, \phi_\mu(x)+\mu)-f(x, \phi_\varepsilon(x)+\varepsilon)}{(\phi_\mu(x)+\varepsilon)-(\phi_\mu(x)+\mu)}$$

when $\omega(x)\neq 0$, and $h(x)=0$ otherwise. Then $h(x)\geqq 0$, $x\in[0, 1]$, and ω satisfies

$$\omega''(x)+\frac{n-1}{x}\omega'(x)-h(x)\omega(x)=0.$$

It follows that ω cannot have an interior negative minimum (it would have to be the case that $x_0\in(0, 1)$, $\omega(x_0)<0$, $\omega'(x_0)=0$, $\omega''(x_0)\geqq 0$, but then $\omega''(x_0)=h(x_0)\omega(x_0)<0$, a contradiction). If $x=0$ is a point of minimum, then ω must be negative in a neighborhood $[0, \varepsilon)$ of 0, and proceeding as in the proof of Theorem 3.1, a contradiction results; the same argument as in the proof of Theorem 3.1 also shows that $x=1$ cannot be the point of minimum for ω. Thus, in the case of problem (P_1) it must be the case that $\omega(x)\geqq 0$ for $x\in[0, 1]$. The argument for (P_2) follows the same line of reasoning as in the proof of Theorem 3.1 to show that $\omega(x)\geqq 0$ for $x\in[0, 1]$.

Thus we have that if $0<\mu<\varepsilon$, then

$$\phi_\mu(x)+\mu \leqq \phi_\varepsilon(x)+\varepsilon, \qquad x\in[0,1],$$

and therefore

$$\phi_\mu(x)=\int_0^1 G(x,t)f(t,\phi_\mu(t)+\mu)\,dt \geqq \int_0^1 G(x,t)f(t,\phi_\varepsilon(t)+\varepsilon)=\phi_\varepsilon(x),$$

concluding that

$$0\leqq \phi_\mu(x)-\phi_\varepsilon(x)\leqq \varepsilon-\mu.$$

THEOREM 3.3.

(I) *If f satisfies* H_1 *and* H_2 *then* $\lim_{\varepsilon\to 0}\phi_\varepsilon=\phi$ *exists uniformly on* $[0,1]$ *and* ϕ *is a positive solution of* (P_1) *belonging to* $C^1([0,1))\cap C^2((0,1))$.

(II) *If f satisfies* H_1', H_2 *and* H_3 *holds, then* $\lim_{\varepsilon\to 0}\phi_\varepsilon=\phi$ *exists uniformly on* $[0,1]$ *and* ϕ *is a positive solution of* (P_2) *in*:

(a) $C([0,1])\cap C^2((0,1))$ *if* $\beta=\delta=0$,
(b) $C^1([0,1))\cap C^2((0,1))$ *if* $\alpha=0$,
(c) $C^1((0,1])\cap C^2((0,1))$ *if* $\gamma=0$,
(d) $C^1([0,1))\cap C^2((0,1))$ *if* $\alpha\neq 0$ *and* $\beta\neq 0$,
(e) $C^1((0,1])\cap C^2((0,1))$ *if* $\gamma\neq 0$ *and* $\delta\neq 0$,
(f) $C^1([0,1])\cap C^2((0,1))$ *if* α, β, γ, δ *are all positive.*

Proof. The existence of $\phi=\lim_{\varepsilon\to 0}\phi_\varepsilon$ uniformly on $[0,1]$ is an immediate consequence of Theorem 2.2, which also implies that if $0<\mu<\varepsilon$ then $\phi_\varepsilon\leqq\phi_\mu$ and $\phi_\mu+\mu<\phi_\varepsilon+\varepsilon$.

(I) For each $\varepsilon>0$, it is the case that

$$\phi_\varepsilon'(x)=-\int_0^x\left[\frac{t}{x}\right]^{n-1} f(t,\phi_\varepsilon(t)+\varepsilon)\,dt, \qquad x\in(0,1],$$

$$\phi_\varepsilon'(0)=0.$$

Let $\eta>0$, $\eta<1$ and consider $\{\phi_\varepsilon\}_{\varepsilon>0}$ on the interval $[0,1-\eta]$. Since $\phi_\varepsilon\leqq\phi_\mu$ if $0<\mu<\varepsilon$, it follows that fixing any $\varepsilon>0$, $\phi(x)\geqq\phi_\varepsilon(x)>0$ on $[0,1-\eta]$ and thus it is immediate that

$$\lim_{\varepsilon\to 0}\phi_\varepsilon'(x)=\phi'(x)$$

exists uniformly on $[0,1-\eta]$. This implies that $\phi\in C^1([0,1))$, $\phi'(0)=0$, and the same line of reasoning implies that $\phi\in C^2((0,1))$ with

$$\phi''(x)=-\frac{n-1}{x}\phi'(x)-f(x,\phi(x)), \qquad x\in(0,1).$$

Since $\phi(1)=0$, (I) follows.

(II) The existence of the uniform limit $\lim_{\varepsilon\to 0}\phi_\varepsilon(x)=\phi(x)$ on $[0,1]$ implies that if $0<\eta<\frac{1}{2}$, then

$$\lim_{\varepsilon\to 0} f(x,\phi_\varepsilon(x)+\varepsilon)=f(x,\phi(x))$$

uniformly on $[\eta,1-\eta]$, and $\phi(x)>0$ for $x\in[\eta,1-\eta]$.

Thus

$$-\int_{\eta}^{1-\eta}\int_{\eta}^{t} f(u,\phi(u))\,du\,dt = \lim_{\varepsilon\to 0}\left(-\int_{\eta}^{1-\eta}\int_{\eta}^{t} f(u,\phi_\varepsilon(u)+\varepsilon)\,du\,dt\right)$$

$$= \lim_{\varepsilon\to 0} -\int_{\eta}^{1-\eta}\int_{\eta}^{t} \phi_\varepsilon''\,du\,dt$$

$$= \lim_{\varepsilon\to 0} -\int_{\eta}^{1-\eta} (\phi_\varepsilon'(t)-\phi_\varepsilon'(\eta))\,dt$$

$$= \lim_{\varepsilon\to 0} [\phi_\varepsilon(1-\eta)-\phi_\varepsilon(\eta)-\phi_\varepsilon'(\eta)(1-2\eta)].$$

Since ϕ_ε converges uniformly on $[0,1]$, this implies that $\lim_{\varepsilon\to 0}\phi_\varepsilon'(\eta)$ exists. This, together with the fact that $\phi_\varepsilon''(x) = -f(x,\phi_\varepsilon(x)+\varepsilon)$, $x\in[0,1]$, and therefore $\lim_{\varepsilon\to 0}\phi_\varepsilon''(x)$ exists uniformly on compact subsets of $(0,1)$, implies that $\{\phi_\varepsilon'\}_{\varepsilon>0}$ converges uniformly on compact subsets of $(0,1)$ to a differentiable function with derivative $-f(x,\phi(x))$ on $[\eta,1-\eta]$. From this it follows that ϕ is twice differentiable on $[\eta,1-\eta]$ and that

$$\phi''(x) = -f(x,\phi(x)), \qquad x\in[\eta,1-\eta].$$

Thus $\phi\in C([0,1])\cap C^2((0,1))$ and is a positive solution of

$$y''+f(x,y)=0.$$

Now the validity of II(a) is obvious.

To prove II(b) it suffices to observe that since

$$\phi_\varepsilon'(x) = \frac{1}{\rho}\left[-\gamma\int_0^x (\beta+\alpha t)f(t,\phi_\varepsilon(t)+\varepsilon)\,dt+\alpha\int_x^1 (\gamma+\delta-\gamma t)f(t,\phi_\varepsilon(t)+\varepsilon)\,dt\right],$$

if $\alpha=0$ then $\phi_\varepsilon'(0)=0$ for all $\varepsilon>0$ and again by restricting attention to intervals of the form $[0,1-\eta]$ where $0<\eta<1$, it becomes apparent that $\{\phi_\varepsilon'\}_{\varepsilon>0}$ converges uniformly in this interval, and this in turn implies that $\phi\in C^1([0,1))\cap C^2((0,1))$ and $\phi'(0)=0$.

The argument for II(c) is entirely similar.

To prove II(d), observe that it cannot be the case, for any $\varepsilon>0$, that $\phi_\varepsilon(0)=0$ since this would imply that $\phi_\varepsilon'(0)=0$ and then, since

$$\phi_\varepsilon'(0) = \alpha\int_0^1 (\gamma+\delta-\gamma t)f(t,\phi_\varepsilon(t)+\varepsilon)\,dt,$$

it would have to be the case that $\gamma=\delta=0$, and this contradicts the assumption that $\rho>0$. Thus, it must be the case that $\phi_\varepsilon(0)>0$ for all $\varepsilon>0$, and hence $\phi(0)>0$, implying that the convergence of $f(x,\phi_\varepsilon(x)+\varepsilon)$ is uniform on compact subsets of $[0,1)$, yielding the desired result.

The proof of II(e) is analogous to that of II(d), and II(f) follows from II(d) and II(e).

Observation. Theorem 2.3 is a generalization of the existence results in [5], [6], and [11]. It also provides a good tool to approximate the solution of (P_1) or (P_2).

4. The case $f(x,y)=a(x)y^{-p}$. This section is devoted to understanding the behavior near $x=1$, that is to say, near the singularity, of the positive solution of (P_1)

in the special case when $f(x, y) = a(x)y^{-p}$, $p > 0$. Thus, the focus is on the positive solution ϕ of

$$y'' + \frac{n-1}{x} y' + a(x)y^{-p} = 0, \tag{9}$$
$$y'(0) = y(1) = 0,$$

with the aim of understanding its behavior near $x = 1$.

For the rest of this section it will be necessary to assume that $a : [0, 1] \to [0, \infty)$ is continuous and that $a(x) > 0$ if $x \in [0, 1)$.

THEOREM 4.1. *Let ϕ be the solution of* (9).

(I) *If $0 < p < 1$, there exist positive real numbers $0 < A < B$ such that*

$$A(1-x) \leqq \phi(x) \leqq B(1-x), \qquad x \in [0, 1].$$

(II) *If $p > 1$, there exist positive real numbers $0 < A < B$ such that*

$$A(1-x) \leqq \phi(x) \leqq B(1-x)^{2/p+1}, \qquad x \in [0, 1].$$

If in addition $a(1) > 0$, then there exist positive real numbers $A < B$ such that

$$A(1-x)^{2/p+1} \leqq \phi(x) \leqq B(1-x)^{2/p+1}, \qquad x \in [0, 1].$$

(III) *If $p = 1$, then given $q > 1$ there exist positive real numbers $A < B$ such that*

$$-Ax \ln x \leqq \phi(x) \leqq B(1-x)^{2/q+1}, \qquad x \in [0, 1].$$

If furthermore, $\int_0^1 a(x)/(1-x)\, dx < \infty$, then there exist positive real numbers $A < B$ such that

$$-Ax \ln x \leqq \phi(x) \leqq -Bx \ln (x), \qquad x \in [\tfrac{1}{2}, 1].$$

Proof. (I) It will first be established that, defining $\psi(x) = 1 - x$ for $x \in [0, 1]$, there exist constants $0 < C < D$ such that

$$C\psi(x) \leqq T\psi(x) \leqq D\psi(x), \qquad x \in [0, 1].$$

To see this, it is necessary to separate the discussion into two cases, namely, $n = 2$ and $n > 2$.

If $n = 2$, the integral operator is defined by

$$T\psi(x) = -\ln (x) \int_0^x ta(t)(\psi(t))^{-p}\, dt - \int_x^1 t \ln (t) a(t)(\psi(t))^{-p}\, dt.$$

The continuity of $a(x)$ implies that ψ belongs to the domain of T, and furthermore, it is clear that if $x \in [0, 1)$,

$$\frac{T\psi(x)}{\psi(x)} = -\frac{\ln (x)}{1-x} \int_0^x ta(t)(1-t)^{-p}\, dt - \frac{1}{1-x} \int_x^1 t \ln (t) a(t)(1-t)^{-p}\, dt,$$

and it is obvious that $T\psi(x)/\psi(x) > 0$ when $x \in [0, 1]$. Furthermore, by l'Hôpital's rule:

$$\lim_{x \to 1} \frac{\int_x^1 t \ln (t) a(t)(1-t)^{-p}\, dt}{1-x} = \lim_{x \to 1} \frac{x \ln (x) a(x)}{(1-x)^p}.$$

But

$$\lim_{x \to 1} \frac{x \ln (x)}{(1-x)^p} = \lim_{x \to 1} \frac{\ln (x) + 1}{p(1-x)^{p-1}} = 0,$$

so that

$$\lim_{x\to 1}\frac{\int_x^1 t\ln(t)a(t)(1-t)^{-p}\,dt}{1-x}=0.$$

Furthermore,

$$\lim_{x\to 1}\frac{\ln(x)}{1-x}=\lim_{x\to 1}-\frac{1}{x}=-1,$$

so, since $\int_0^1 ta(t)(1-t)^{-p}\,dt>0$,

$$\lim_{x\to 1}\frac{T\psi(x)}{\psi(x)}=\int_0^1 ta(t)(1-t)^{-p}\,dt>0,$$

and it follows that $T\psi/\psi$ can be considered as a continuous, strictly positive, function on $[0,1]$, and so there must exist $0<C<D$ such that

$$C\leqq\frac{T\psi(x)}{\psi(x)}\leqq D,$$

from which the assertion follows when $n=2$.

If $n>2$, then the integral operator is:

$$T\psi(x)=\frac{1}{n-2}\Big[(x^{2-n}-1)\int_0^x t^{n-1}a(t)(\psi(t))^{-p}\,dt + \int_x^1 t^{n-1}(t^{2-n}-1)a(t)(\psi(t))^{-p}\,dt\Big],$$

and again ψ is in the domain of T, with $T\psi(x)>0$ if $x\in[0,1)$. But

$$\begin{aligned}\frac{T\psi(x)}{\psi(x)}&=\frac{1}{n-2}\Big[\frac{(x^{2-n}-1)}{1-x}\int_0^x t^{n-1}a(t)(1-t)^{-p}\,dt - \frac{1}{1-x}\int_x^1 t^{n-1}(t^{2-n}-1)a(t)(1-t)^{-p}\,dt\Big]\\ &=\frac{1}{n-2}\Big[\frac{(1-x^{n-2})}{x^{n-2}(1-x)}\int_0^x t^{n-1}a(t)(1-t)^{-p}\,dt + \frac{1}{1-x}\int_x^1 t(1-t^{n-2})a(t)(1-t)^{-p}\,dt\Big]\\ &=\frac{1}{n-2}\Big[\frac{1+x+\cdots+x^{n-3}}{x^{n-2}}\int_0^x t^{n-1}a(t)(1-t)^{-p}\,dt + \frac{1}{1-x}\int_x^t t(1-t^{n-2})a(t)(1-t)^{-p}\,dt\Big],\end{aligned}$$

and, again by l'Hôpital's rule:

$$\lim_{x\to 1}\frac{T\psi(x)}{\psi(x)}=\int_0^x t^{n-1}a(t)(1-t)^{-p}\,dt<\infty,$$

and the existence of the positive numbers C and D is established in the same way as before.

Thus, in either case,

$$C\psi(x) \leqq T\psi(x) \leqq D\psi(x), \qquad x \in [0, 1].$$

For $\lambda > 0$, observe that

$$T(\lambda\psi) = \lambda^{-p} T\psi,$$

and setting $\psi_0 = \lambda\psi$, it follows that if $D/\lambda^{p+1} \leqq 1$ then $T\psi_0 \leqq \psi_0$. Furthermore,

$$T\psi_0 = \lambda^{-p} T\psi \geqq C\lambda^{-p}\psi,$$

and it follows that

$$T^2\psi_0 \leqq C^{-p}\lambda^{(p)^2} T\psi \leqq C^{-p}\lambda^{(p)^2} D\psi,$$

so that

$$T^2\psi_0 \leqq C^{-p}\lambda^{(p^2-1)} D\psi_0.$$

Thus, choosing λ large enough so as to have

$$\frac{D}{\lambda^{p+1}} \leqq 1 \quad \text{and} \quad C^{-p} D\lambda^{(p^2-1)} \leqq 1,$$

which is possible since $0 < p < 1$, it becomes the case that

$$T\psi_0 \leqq \psi_0 \quad \text{and} \quad T^2\psi_0 \leqq \psi_0.$$

This implies that the sequence of even iterates is monotone increasing and so, by Theorem 1.2, they converge to the solution ϕ of (9). This yields (I).

(II) The first thing to be shown is the existence of $B > 0$ such that

$$\phi(x) \leqq B(1-x)^{2/p+1}, \qquad x \in [0, 1].$$

To do this, for $\varepsilon > 0$ let ϕ_ε be the solution to

$$y'' + \frac{n-1}{x} y' + a(x)(y+\varepsilon)^{-p} = 0,$$

$$y'(0) = y(1) = 0,$$

and for $\lambda > 1$ define $\chi(x) = \lambda\phi(0)(1-x)^{2/(p+1)}$. Recall that $\phi(0) > \phi_\varepsilon(0)$ by Theorem 2.2, so that $\chi(0) > \phi_\varepsilon(0)$.

Define $\omega(x) = \chi(x) - \phi_\varepsilon(x)$ and observe that $\omega(0) > 0$, $\omega(1) = 0$. It will be shown, by contradiction, that $\omega(x) \geqq 0$ for $x \in [0, 1]$. If this were not the case, there would exist $x_0 \in (0, 1)$ such that $\omega(x_0) < 0$, $\omega'(x_0) = 0$, and $\omega'(x_0) \geqq 0$. But

$$\chi'(x) = -\frac{2}{p+1}\lambda\phi(0)(1-x)^{(1-p)/(p+1)},$$

$$\chi''(x) = \frac{2(1-p)}{(p+1)^2}\lambda\phi(0)(1-x)^{-(2p/(p+1))},$$

and the fact that $\omega'(x_0) = 0$ implies that

$$\chi'(x_0) = \phi'_\varepsilon(x_0),$$

so

$$\phi'_\varepsilon(x_0) = -\frac{2}{p+1}\lambda\phi(0)(1-x_0)^{(1-p)/(p+1)},$$

and this implies that

$$\phi_\varepsilon''(x_0) = -\frac{n-1}{x_0}\left(-\frac{2}{p+1}\lambda\phi(0)(1-x_0)^{(1-p)/(p+1)}\right) - \frac{a(x_0)}{(\phi_\varepsilon(x_0)+\varepsilon)^p}.$$

Thus

$$\begin{aligned}\omega''(x_0) &= -\frac{2(p-1)\lambda\phi(0)}{(p+1)^2}(1-x_0)^{-(2p/(p+1))} \\ &\quad -\frac{2(n-1)}{(p+1)x_0}\lambda\phi(0)(1-x_0)^{(1-p)/(1+p)} + \frac{a(x_0)}{(\phi_\varepsilon(x_0)+\varepsilon)^p} \\ &= -\frac{2\lambda\phi(0)(1-x_0)^{-(2p/(p+1))}}{p+1}\left[\frac{p-1}{p+1} + \frac{(n-1)}{x_0}(1-x_0)\right] + \frac{a(x_0)}{(\phi_\varepsilon(x_0)+\varepsilon)^p} \\ &\leqq -\frac{2(p-1)}{(p+1)^2}\lambda\phi(0)(1-x_0)^{-(2p/(p+1))} + \frac{\|a\|}{(\phi_\varepsilon(x_0))^p},\end{aligned}$$

where $\|a\| = \sup_{x\in[0,1]} a(x)$.

Since $0 < \chi(x_0) < \phi_\varepsilon(x_0)$, it follows that

$$\begin{aligned}\omega''(x_0) &\leqq -\frac{2(p-1)}{(p+1)^2}\lambda\phi(0)(1-x_0)^{-(2p/(p+1))} + \frac{\|a\|}{\lambda^p(\phi(0))^p(1-x_0)^{(2p/(p+1))}} \\ &= (1-x_0)^{-(2p/(p+1))}\left[\frac{\|a\|}{\lambda^p(\phi(0))^p} - \frac{2(p-1)}{(p+1)^2}\phi(0)\lambda\right].\end{aligned}$$

Hence, if λ is chosen so that

$$\frac{\|a\|}{\lambda^p(\phi(0))^p} < \frac{2(p-1)}{(p+1)^2}\phi(0)\lambda,$$

i.e., so that

$$\frac{\|a\|(p+1)^2}{2(p-1)(\phi(0))^{p+1}} < \lambda^{p+1},$$

it follows that $\omega''(x_0) < 0$, which is a contradiction. Since the selection of λ does not depend on ε, we have shown that for B sufficiently large

$$\phi_\varepsilon(x) \leqq B(1-x)^{2/p+1}, \qquad x\in[0,1], \quad \varepsilon > 0$$

and since $\phi(x) = \lim_{\varepsilon\to 0}\phi_\varepsilon(x)$, $x\in[0,1]$, the inequality

$$\phi(x) \leqq B(1-x)^{2/p+1}, \qquad x\in[0,1],$$

has been shown.

To complete the proof of the first part of (II), it suffices to observe that if $\varepsilon > 0$, then if $n > 2$ and $x\in[0,1)$,

$$\begin{aligned}\frac{\phi_\varepsilon(x)}{1-x} &= \frac{1}{n-2}\left[\frac{1-x^{n-2}}{x^{n-2}(1-x)}\int_0^x t^{n-1}a(t)(\phi_\varepsilon(t)+\varepsilon)^{-p}\,dt\right. \\ &\quad \left. + \frac{1}{1-x}\int_x^1 t(1-t^{n-2})a(t))(\phi_\varepsilon(t)+\varepsilon)^{-p}\,dt\right]\end{aligned}$$

and so

$$\frac{\phi_\varepsilon(x)}{1-x}=\frac{1}{n-2}\left[\frac{1+x+\cdots+x^{n-3}}{x^{n-2}}\int_0^x t^{n-1}a(t)(\phi_\varepsilon(t)+\varepsilon)^{-p}\,dt\right.$$
$$\left.+\frac{1}{1-x}\int_x^1 t(1-t^{n-2})a(t)(\phi_\varepsilon(t)+\varepsilon)^{-p}\,dt\right],$$

and hence

$$\lim_{x\to 1}\frac{\phi_\varepsilon(x)}{1-x}=\int_0^1 t^{n-1}a(t)(\phi_\varepsilon(t)+\varepsilon)^{-p}\,dt>0,$$

and thus, fixing $\varepsilon>0$, there exists $A>0$ such that

$$\frac{\phi_\varepsilon(x)}{1-x}\geqq A, \qquad x\in[0,1].$$

Thus, $\phi_\varepsilon(x)\geqq A(1-x)$, $x\in[0,1]$, and since $\phi_\varepsilon(x)\leqq\phi(x)$, $x\in[0,1]$, we have that

$$A(1-x)\leqq\phi(x)\leqq B(1-x)^{2/p+1}, \qquad x\in[0,1],$$

if $n>2$.

If $n=2$ and $x\in(0,1)$,

$$\frac{\phi_\varepsilon(x)}{1-x}=-\frac{\ln(x)}{1-x}\int_0^x ta(t)(\phi_\varepsilon(t)+\varepsilon)^{-p}\,dt-\frac{1}{1-x}\int_x^1 t\ln(t)a(t)(\phi_\varepsilon(t)+\varepsilon)^{-p}\,dt$$

and

$$\lim_{x\to 1}\frac{\phi_\varepsilon(x)}{1-x}=\int_0^1 ta(t)(\phi_\varepsilon(t)+\varepsilon)^{-p}\,dt>0,$$

and the same argument given above applies.

If it is known in addition that $a(1)>0$, then the proof of the existence of A such that

$$A(1-x)^{2/p+1}\leqq\phi(x), \qquad x\in[0,1]$$

goes as follows.

Define $\psi(x)=(1-x)^{2/p+1}$. The fact that there exists $B>0$ such that

$$\phi(x)\leqq B\psi(x), \qquad x\in[0,1],$$

implies that ψ is in the domain of the integral operator T, and that

$$B^{-p}T\psi(x)\leqq\phi(x), \qquad x\in[0,1].$$

Now, for $x\in(0,1)$, if $n>2$,

$$\frac{T\psi(x)}{\psi(x)}=\frac{1}{n-2}\left[\frac{1-x^{n-2}}{x^{n-2}(1-x)^{2/p+1}}\int_0^x t^{n-1}a(t)(1-t)^{-(2p/(p+1))}\,dt\right.$$
$$\left.+\frac{1}{(1-x)^{2/p+1}}\int_x^1 t(1-t^{n-2})a(t)(1-t)^{-(2p/(p+1))}\,dt\right],$$

so that

$$\frac{T\psi(x)}{\psi(x)}=\frac{1}{n-2}\left[\frac{(1-x)^{(p-1)/(p+1)}(1+x+\cdots+x^{n-3})}{x^{n-2}}\int_0^x t^{n-1}a(t)(1-t)^{-(2p/(p+1))}\,dt\right.$$
$$\left.+\frac{1}{(1-x)^{2/p+1}}\int_x^1 t(1-t)^{(p-1)/(p+1)}(1+t+\cdots+t^{n-3})a(t)\,dt\right].$$

Now observe that, by l'Hôpital's rule:

$$\lim_{x\to 1}\frac{\int_x^1 t(1-t)^{(1-p)/(1+p)}(1+t+\cdots+t^{n-3})a(t)\,dt}{(1-x)^{2/p+1}}$$

$$=\lim_{x\to 1}\frac{x(1-x)^{(p-1)/(p+1)}(1+\cdots+x^{n-3})a(x)}{(2/p+1)(1-x)^{(1-p)/(1+p)}}$$

$$=\lim_{x\to 1}\frac{(p+1)xa(x)(1+\cdots+x^{n-3})}{2}$$

$$=\frac{(n-2)(p+1)a(1)}{2},$$

and that if $\int_0^1 t^{n-1}a(t)(1-t)^{-(2p/(p+1))}\,dt<\infty$, then

$$\lim_{x\to 1}\frac{(1-x)^{(p-1)/(p+1)}(1+\cdots+x^{n-3})}{x^{n-2}}\int_0^x t^{n-1}a(t)(1-t)^{-(2p/(p+1))}\,dt=0,$$

and if the integral diverges, then by using l'Hôpital's rule again, it follows that

$$\lim_{x\to 1}\frac{\int_0^x t^{n-1}a(t)(1-t)^{-(2p/(1+p))}\,dt}{(x-1)^{(1-p)/(p+1)}}=\lim_{x\to 1}\frac{x^{n-1}a(x)(1-x)^{-(2p/(p+1))}}{-((1-p)/(p+1))(1-x)^{-(2p/(p+1))}}=\frac{a(1)}{p-1}.$$

Thus, if $a(1)>0$, it is the case that $\lim_{x\to 1}(T\psi(x)/\psi(x))>0$, and it follows that there exists $D>0$ for which

$$\frac{T\psi(x)}{\psi(x)}\geqq D,$$

so that $T\psi(x)\geqq D\psi(x)$.

Combining this with the fact that $B^{-p}T\psi(x)\leqq\phi(x)$, $x\in[0,1]$, the result follows if $n>2$.

If $n=2$, then

$$\frac{T\psi(x)}{\psi(x)}=-\frac{\ln(x)}{(1-x)^{2/p+1}}\int_0^x ta(t)(1-t)^{-(2p/(p+1))}\,dt$$

$$-\frac{1}{(1-x)^{2/p+1}}\int_x^1 t\ln(t)a(t)(1-t)^{-(2p/(p+1))}\,dt$$

and hence, since

$$\lim_{x\to 1}\frac{\int_x^1 t\ln(t)a(t)(1-t)^{-(2p/(1+p))}\,dt}{(1-x)^{2/p+1}}=\lim_{x\to 1}\frac{-x\ln(x)a(x)(1-x)^{-(2p/(p+1))}}{-(2/p+1)(1-x)^{-(1-p)/(p+1)}}$$

$$=\lim_{x\to 1}\frac{x\ln(x)a(x)}{(2/p+1)(1-x)}$$

and since $\lim_{x\to 1}(\ln(x)/(1-x))=-1$, we get that

$$\lim_{x\to 1}\frac{-\int_x^1 t\ln(t)a(t)(1-t)^{-(2p/(1+p))}\,dt}{(1-x)^{2/p+1}}=\frac{p+1}{2}a(1).$$

Similar computations show that

$$\lim_{x\to 1}\left[-\frac{\ln(x)}{(1-x)^{2/p+1}}\int_0^x ta(t)(1-t)^{-(2p/(p+1))}\,dt\right)=0$$

or

$$\lim_{x\to 1}\left(-\frac{\ln(x)}{(1-x)^{2/p+1}}\int_0^x ta(t)(1-t)^{-(2p/(p+1))}\,dt\right)=\frac{a(1)}{1-p},$$

and in either case the result now follows in the same way as for $n>2$.

Proof of (III). Let $\lambda>1$, ϕ_ε the solution

$$(9)_\varepsilon \qquad y''+\frac{n-1}{x}y'+a(x)(y+\varepsilon)^{-1}=0,$$
$$y'(0)=y(1)=0,$$

and define $\chi:[0,1]\to[0,\infty)$, $\omega:[0,1]\to\mathbb{R}$, by

$$\chi(x)=\lambda\phi(0)(1-x)^{2/q+1}, \qquad x\in[0,1]$$

and

$$\omega(x)=\chi(x)-\phi_\varepsilon(x), \qquad x\in[0,1].$$

Since $\phi(0)\geqq\phi_\varepsilon(0)>0$, it follows that $\omega(x_0)>0$, and it is obvious that $\omega(1)=0$. It will be proved, by contradiction, that $\omega(x)\geqq 0$ for all $x\in[0,1]$. If this were not true, there would exist $x_0\in(0,1)$ such that

$$\omega(x_0)<0, \quad \omega'(x_0)=0, \quad \omega''(x_0)\geqq 0.$$

Now

$$\chi'(x)=-\frac{2\lambda\phi(0)}{q+1}(1-x)^{(1-q)/(1+q)}$$

and

$$\chi''(x)=-\frac{2\lambda(q-1)}{(q+1)^2}\phi(0)(1-x)^{-(2q/(1+q))},$$

and therefore

$$\phi_\varepsilon'(x_0)=-\frac{2\lambda}{q+1}\phi(0)(1-x_0)^{(1-q)/(1+q)},$$
$$\phi_\varepsilon''(x_0)=-\frac{2(n-1)\lambda\phi(0)}{x_0(q+1)}(1-x_0)^{(1-q)/(1+q)}-\frac{a(x_0)}{\phi_\varepsilon(x_0)+\varepsilon},$$

so that

$$\begin{aligned}\omega''(x_0)&=-\frac{2\lambda(q-1)\phi(0)}{(q+1)^2}(1+x_0)^{-(2q/(q+1))}\\&\quad-\frac{2\lambda\phi(0)(n-1)}{(q+1)x_0}(1-x_0)^{(1-q)/(1+q)}+\frac{a(x_0)}{\phi_\varepsilon(x_0)+\varepsilon}\\&\leqq-\frac{2\lambda\phi(0)}{q+1}(1-x_0)^{-(2q/(q+1))}\left[\frac{q-1}{q+1}+\frac{n-1}{x_0}(1-x_0)\right]+\frac{\|a\|}{\phi_\varepsilon(x_0)}\\&\leqq-\frac{2\lambda\phi(0)}{q+1}(1-x_0)^{-(2q/(q+1))}\cdot\frac{q-1}{q+1}+\frac{\|a\|}{\lambda\phi(0)(1-x_0)^{2/q+1}}\\&=(1-x_0)^{-(2q/(q+1))}\left[\frac{\|a\|}{\lambda\phi(0)}-\frac{2\lambda\phi(0)(q-1)}{(q+1)^2}(1-x_0)^{(2(1-q)/(1+q))}\right]\\&\leqq(1-x_0)^{-(2q/(q+1))}\left[\frac{\|a\|}{\lambda\phi(0)}-\frac{2\lambda(q-1)\phi(0)}{(q+1)^2}\right],\end{aligned}$$

and therefore, if λ is chosen so that

$$\frac{\|a\|}{\lambda\phi(0)}-\frac{2\lambda(q-1)\phi(0)}{(q+1)^2}\leqq 0,$$

i.e.,

$$\lambda^2\geqq\frac{(q+1)^2\|a\|}{2(q-1)(\phi(0))^2},$$

then $\omega''(x_0)<0$, and this is a contradiction. Since the selection of λ does not depend on ε, it follows that

$$\phi_\varepsilon(x)\leqq B(1-x)^{(2/(q+1))},\qquad x\in[0,1],\quad \varepsilon>0,$$

and this implies that

$$\phi(x)\leqq B(1-x)^{(2/(q+1))},\qquad x\in[0,1].$$

To prove the other side of the inequality, recall that $\phi_\varepsilon\leqq\phi$, $\varepsilon>0$. Pick $\varepsilon>0$ and observe that if $n>2$ and $x\in[\frac{1}{2},1)$, then

$$\frac{\phi_\varepsilon(x)}{-x\ln(x)}=\frac{1}{n-2}\left[-\frac{1-x^{n-2}}{x^{n-2}x\ln(x)}\int_0^x t^{n-1}\frac{a(t)}{\phi_\varepsilon(t)+\varepsilon}\,dt\right.$$
$$\left.-\frac{1}{x\ln x}\int_x^1 t(1-t^{n-2})\frac{a(t)}{\phi_\varepsilon(t)+\varepsilon}\,dt\right]$$

and

$$\lim_{x\to 1}\frac{\phi_\varepsilon(x)}{-x\ln(x)}=\int_0^1 t^{n-1}\frac{a(t)}{\phi_\varepsilon(t)+\varepsilon}\,dt>0.$$

Thus, there must exist $A>0$ such that $\phi_\varepsilon(x)\geqq -Ax\ln(x)$, $x\in[\frac{1}{2},1]$ and therefore

$$\phi(x)\geqq -Ax\ln(x),\qquad x\in[\tfrac{1}{2},1].$$

If $n=2$, and $x\in[\frac{1}{2},1)$,

$$\frac{\phi_\varepsilon(x)}{-x\ln(x)}=\frac{1}{x}\int_0^x\frac{ta(t)}{\phi_\varepsilon(t)+\varepsilon}\,dt+\frac{1}{x\ln(x)}\int_x^1\frac{t\ln(t)a(t)}{\phi_\varepsilon(t)+\varepsilon}\,dt,$$

and the same argument applies.

For the proof of the last statement of (III), assume that

$$\int_0^1\frac{a(x)}{1-x}<\infty.$$

Under this hypothesis it has been shown in [5] that the unique solution ϕ of (9) is such that there exists $\theta>0$ for which

$$\theta(1-x)\leqq\phi(x),\qquad x\in[0,1].$$

Define $\psi:[0,1]\to[0,\infty)$ by

$$\psi(x)=\tfrac{1}{2}\ln(2),\qquad x\in[0,\tfrac{1}{2}],$$
$$\psi(x)=-x\ln(x),\qquad x\in[\tfrac{1}{2},1].$$

Consider first the case $n=2$. If $x\in[\frac{1}{2},1)$,

$$\frac{\phi(x)}{\psi(x)}=\frac{1}{x}\int_0^x\frac{ta(t)}{\phi(t)}\,dt+\frac{1}{x\ln(x)}\int_x^1\frac{t\ln(t)a(t)}{\phi(t)}\,dt$$

and

$$\lim_{x\to 1}\frac{\int_x^1 (t\ln(t)a(t)/\phi(t))\,dt}{x\ln(x)}=\lim_{x\to 1}\frac{(-x\ln(x)a(x)/\phi(x))}{1+\ln(x)}.$$

But

$$\lim_{x\to 1}\frac{-\ln(x)}{\phi(x)}=\lim_{x\to 1}\frac{1/x}{\int_0^x (t/x)(a(t)/\phi(t))\,dt}$$

$$=\frac{1}{\int_0^1 (ta(t)/\phi(t))\,dt},$$

and the conclusion is that

$$\lim\frac{\phi(x)}{\psi(x)}=\int_0^1\frac{ta(t)}{\phi(t)}\,dt+\frac{a(1)}{\int_0^1 (ta(t)/\phi(t))\,dt},$$

and hence the function ϕ/ψ can be defined to be continuous and positive on $[0, 1]$,

FIG. 1

so there exist positive real numbers $A < B$ such that

$$A \leqq \frac{\phi(x)}{\psi(x)} \leqq B, \qquad x \in [\tfrac{1}{2}, 1],$$

and therefore $-Ax \ln x \leqq \phi(x) \leqq -Bx \ln x$, $x \in [\frac{1}{2}, 1]$.

If $n > 2$, the argument is entirely similar, the change being in the Green's function, but the fact that

$$\lim \frac{1-x}{-x \ln (x)} = 1$$

is all that is needed to carry out the required computations.

Observation. Similar results for the case $p > 1$, but with a somewhat more restrictive assumption on the function $a(x)$, have been recently obtained in [7].

5. Numerical examples. Four figures will be presented that correspond to the graphs of several iterates of $T_\varepsilon(0)$, where T_ε is the operator arising from

$$y'' + \frac{1}{x} y' + (y+\varepsilon)^{-p} = 0,$$

$$y'(0) = y(1) = 0.$$

FIG. 2

These iterations were computed using a parallel program running on an Encore Multimax computer with 10 processors. Although parallel programs are not essential for these computations, we have larger problems in mind for the future.

The program uses Simpson's rule with 100 points in the interval [0, 1], and it is very easy to add more points to the subdivision. Two arrrays are used (both are shared memory), one of them to store the past iteration and one to store the current iteration. Each processor works one point at a time, computing the integral corresponding to that point. The shared memory allows all processors to access the values of the previous iteration.

Figure 1 corresponds to $p = 1/9$, $\varepsilon = 10^{-3}$, and the table that follows corresponds to the values of $T^i(0)$ evaluated at the indicated points of [0, 1], $i = 1, \cdots, 7$, where, for convenience, $T^i(0)$ has been denoted as Fl $(i-1)$. Figure 2 corresponds to $p = 1/9$,

SOME SINGULAR NONLINEAR BOUNDARY VALUE PROBLEMS*

JOHN V. BAXLEY†

Abstract. Two-point boundary value problems associated with the (possibly) singular nonlinear ordinary differential equation $y''+g(x, y')+f(x, y)=0$, $a \leqq x \leqq b$, are considered. The goal is to obtain rather general existence and uniqueness theorems for positive solutions. In the case of general separated linear boundary conditions, the results allow $f(x, y)$ to be singular as $y \to 0^+$ and at the endpoints, with significant nonlinearity in both f and g. For the special condition $y'(a)=0$, the results also allow g to be singular as $x \to a^+$. In this way, the case $g(x, y')=((N-1)/x)y'$, which arises when seeking radial solutions of $\nabla^2 y=f(x, y)$, is included. The results extend previous theorems of Taliaferro and more recent theorems of Gatica, Waltman, et al.

Key words. singular boundary value problems, existence and uniqueness

AMS(MOS) subject classifications. 34B15, 35J65

1. Introduction.

Two-point boundary value problems associated with the second-order equation

$$y''=F(x, y, y'), \qquad a<x<b, \tag{1.1}$$

can be singular in a variety of ways: a and/or b may be infinite, F may be unbounded near some $x_0 \in [a, b]$, or F may be unbounded near some particular value of y (or y'). This last possibility does not occur in linear problems and is the source of some added excitement in nonlinear problems.

Problems on infinite intervals have been studied by Granas et al. [8], Erbe and Schmitt [5], Berestycki, Lions, and Peletier (e.g., [4]), and by Baxley [1] and will not be considered here. Problems on finite intervals in which the singularity is caused by F being unbounded near a particular value of y have been studied by Luning and Perry [9], Nachman and Callegari [11], Taliaferro [13], Gatica, Oliker, and Waltman [7], and Baxley [2]. Recently, Gatica, Hernandez, and Waltman [6] have considered a finite interval problem which has singularities arising from F becoming infinite as $x \to a$ and also as $y \to 0$. We should also note that the problem considered by Erbe and Schmitt [5] on $0<x<\infty$ is singular at $x=0$.

It should be realized that a singularity of (1.1) at some finite value of y (or y') may only be bluffing: a solution of an associated boundary value problem might not come close enough to the singular value to be affected. Here are two such examples. A problem involving heat and mass transfer in a porous catalyst leads to the problem

$$y''=\alpha y \exp\left[\frac{\gamma\beta(1-y)}{1+\beta(1-y)}\right], \qquad 0<x<1,$$

$$y'(0)=0, \qquad y(1)=1,$$

where α, β, γ are positive constants. The apparent singularity at $y=1+1/\beta$ is only an idle threat because the solution actually satisfies $y(x) \leqq 1$ on $0 \leqq x \leqq 1$. Similar

† Department of Mathematics and Computer Science, Wake Forest University, Winston-Salem, North Carolina 27109. This research was done while the author was visiting the Department of Mathematics and Computer Science, Emory University, Atlanta, Georgia 30322, and was supported in part by National Science Foundation grant 86-01398.

behavior is encountered in this problem involving diffusion in a chemical catalytic converter:

$$y''=\frac{1}{y-2}(y')^2, \qquad 0<x<1,$$

$$y(0)=A, \qquad y(1)=B,$$

where $B<A<2$. The apparent singularity at $y=2$ does no real harm because the solution satisfies $B\leqq y(x)\leqq A$ on $0\leqq x\leqq 1$. These two examples from the engineering literature are discussed by Na [10] and Baxley [3]. The second example can actually be integrated by elementary methods after dividing by y'.

In almost all of the articles referenced above, attention has been confined to problems where $F(x, y, y')$ is independent of y', or at worst linear in y'. Motivation has come from interest in the problem

$$y''+a(x)y^{-p}=0, \qquad 0<x<1, \tag{1.2}$$

where $p>0$ and $a(x)>0$ and continuous on $[0, 1]$, and the problem

$$y''+\frac{N-1}{x}y'+a(x)y^{-p}=0, \qquad 0<x<1, \tag{1.3}$$

where again $p>0$ and $a(x)>0$ on $[0, 1]$, which is encountered in the search (see, e.g., [4]) for radial solutions of elliptic partial differential equations in R^N which have the form

$$\nabla^2 u+a(r)u^{-p}=0,$$

where $r=|x|$ is the radial coordinate and corresponds to the variable x in (1.3).

To facilitate comparison of our results, we state the existence and uniqueness theorems of Taliaferro [13]. He studied the equation (1.2) with the boundary conditions

$$y(0)=0, \qquad y(1)=0, \tag{1.4}$$

and proved that the problem (1.2), (1.4) has a positive solution $\phi\in C[0, 1]\cap C^2(0, 1)$ if and only if

$$\int_0^1 x(1-x)a(x)\,dx<\infty, \tag{1.5}$$

in which case such a positive solution is unique. Furthermore,

$$\lim_{x\to 0^+}\phi'(x) \quad \left(\text{respectively, } \lim_{x\to 1^-}\phi'(x)\right)$$

exists if and only if

$$\int_0^{1/2}\frac{a(x)}{x^p}\,dx \quad \left(\text{respectively, } \int_{1/2}^1\frac{a(x)}{(1-x)^p}\,dx\right)$$

is finite. Note that for existence of a continuous solution, the value of $p>0$ is otherwise unrestricted, but in order to have $\phi'(x)$ continuous at one of the endpoints, either p must not be too large, or $a(x)$ must tend to zero rather rapidly as x approaches that endpoint. In particular, (1.2), (1.4) has a positive solution $\phi\in C^1[0, 1]\cap C^2(0, 1)$ if and only if

$$\int_0^1\frac{a(x)}{(s(x))^p}\,dx<\infty \tag{1.6}$$

where $s(x) = x$ for $0 \leqq x \leqq \frac{1}{2}$ and $s(x) = 1 - x$ for $\frac{1}{2} < x \leqq 1$. Gatica, Oliker, and Waltman [7] extended the part of the above result regarding the existence of a $C^1[0, 1]$ solution in two ways: they replaced (1.2) by the more general equation

$$y'' + f(x, y) = 0, \tag{1.7}$$

where $f: (0, 1) \times (0, \infty) \to (0, \infty)$ continuously and $f(x, y)$ is nonincreasing in y for fixed $x \in (0, 1)$, and they dealt with the more general two-point boundary conditions

$$a_0 y(0) - a_1 y'(0) = 0, \qquad b_0 y(1) + b_1 y'(1) = 0, \tag{1.8}$$

where a_0, a_1, $b_1 \geqq 0$ and $a_0 b_0 + a_1 b_0 + a_0 b_1 > 0$. Assuming that $f(x, y) \to +\infty$ as $y \to 0^+$ uniformly on compact subsets of $(0, 1)$, and that

$$\int_0^1 f(x, \theta s(x))\, dx < \infty \tag{1.9}$$

for each $\theta > 0$, then Gatica, Oliker, and Waltman [7] prove existence of a positive solution $\phi \in C^1[0, 1] \cap C^2(0, 1)$ of (1.7), (1.8). They also provide a uniqueness theorem generalizing the corresponding statement of Taliaferro. Note that for $f(x, y) = a(x)/y^p$, (1.9) holds if and only if (1.6) holds.

In contrast to the shooting method used by Taliaferro, Gatica, Oliker, and Waltman [7] proved first an interesting fixed point theorem for decreasing maps on a Banach space and then applied it to the boundary value problem.

In [6], Gatica, Hernandez, and Waltman continued to exploit their fixed point theorem and attacked the more difficult problem (1.3) with the boundary conditions

$$y'(0) = 0, \qquad y(1) = 0. \tag{1.10}$$

Replacing $a(x)y^{-p}$ with $f: [0, 1) \times (0, \infty) \to (0, \infty)$ continuous (note the half-open interval), they assume f is decreasing in y for each x, $\int_0^1 f(x, y)\, dx < \infty$ for each $y > 0$, $f(x, y) \to +\infty$ as $y \to 0^+$ and $f(x, y) \to 0$ as $y \to +\infty$, both limits being uniform on compact subsets of $(0, 1)$, and finally that $\int_0^1 f(x, \theta(1-x))\, dx < \infty$ for each $\theta > 0$. They then prove existence of a positive solution $\phi \in C^1[0, 1] \cap C^2(0, 1)$ of (1.3), (1.10), and again provide a uniqueness theorem.

In this paper, we shall unify and extend these results in a two-stage procedure. Throughout, we assume our equation has the form

$$y'' + g(x, y') + f(x, y) = 0, \qquad a < x < b, \tag{1.11}$$

and we first study the problem (1.11) with the boundary conditions

$$a_0 y(a) - a_1 y'(a) = A, \qquad b_0 y(b) + b_1 y'(b) = B, \tag{1.12}$$

where a_0, a_1, b_0, b_1, A, $B \geqq 0$ and $a_0 b_0 + a_1 b_0 + a_0 b_1 > 0$. We extend the basic result of Taliaferro regarding the sufficiency of the condition (1.5) or (1.6) for existence to the equation (1.11) in which significant nonlinearity is allowed in the term $g(x, y')$, but no singularity. The result in [7] is also a special case. Our theorem does not require that the problem be either singular or nonlinear; after all, we would not expect nonsingular or linear problems to be worse than singular or nonlinear ones. We also include a uniqueness theorem which improves the one in [7].

Finally, we consider the problem studied in [6]. Modeling (1.3), we allow $g(x, y')$ in (1.11) to be singular at $x = a$. Our theorem allows, for example,

$$g(x, z) = -\frac{|z|^p}{(x-a)^q},$$

where $p \geqq 1$ and $q > 0$. We allow boundary conditions of the form

$$y'(a) = 0, \qquad b_0 y(b) + b_1 y'(b) = B, \tag{1.13}$$

where b_1, $B \geqq 0$ and $b_0 > 0$. Again we provide significant extensions of the existence and uniqueness theorems in [6].

Our strategy is to construct a sequence of problems which appproximate (1.11), (1.12), which are not singular, but which "converge" to the singular problem. We apply a previous result [3] to obtain existence of a positive solution ϕ_n of the nth approximating problem and use a priori estimates to justify application of Ascoli's theorem.

The approximating problems are constructed in § 2; § 3 contains basic information on qualitative behavior and a priori bounds for the approximating solutions. Existence and uniqueness for the problem (1.11), (1.12) with $g(x, y')$ nonsingular appear in §§ 4 and 5, while the results for $g(x, y')$ singular as $x \to a-$ appear in § 6.

This effort was motivated by the desire to understand the underlying differences in the problems studied in [6], [7] by Waltman and his colleagues, who very kindly placed preprints of their work at my disposal.

2. Basic assumptions and approximating problems. The context for our study of the problem (1.11), (1.12) will allow singular behavior as $x \to a+$, as $x \to b-$, and as $y \to 0+$, and we shall seek positive solutions of (1.11), (1.12). From the perspective of the singularity at $y = 0$, a solution $\phi(x)$ may keep its distance from zero and thereby render the singularity powerless, or the solution may approach zero as $x \to a+$ or as $x \to b-$, thus giving the singularity at $y = 0$ opportunity to cause havoc. If (1.11), (1.12) has a positive solution $\phi(x)$ which is bounded away from zero as $x \to a+$ (respectively, $x \to b-$), we shall say that the singularity at $y = 0$ is irrelevant at the endpoint $x = a$ (respectively, $x = b$).

Here are our basic assumptions regarding the differential equation (1.11):

(HF1) $f: (a, b) \times (0, \infty) \to (0, \infty)$ is continuous;

(HF2) $f(x, y)$ is nonincreasing in y for each fixed $x \in (a, b)$;

(HG1) $g: [a, b] \times (-\infty, \infty) \to (-\infty, \infty)$ is continuous;

(HG2) $zg(x, z) \geqq 0$ for all $(x, z) \in [a, b] \times (-\infty, \infty)$;

If, in (1.12), $b_0 > 0$, put $I = [a, b)$; if $b_0 = 0$ (Neumann data), put $I = [a, b]$.

(HG3) g satisfies a uniform Lipschitz condition in z on each compact subset $S \subset I \times (-\infty, \infty)$. That is, given such a set S, there exists $K > 0$ such that

$$|g(x, z_2) - g(x, z_1)| \leqq K|z_2 - z_1|$$

whenever (x, z_2), $(x, z_1) \in S$;

(HG4) If $a_1 = 0$ and $b_0 > 0$, then $g(x, z) = O(z^2)$, as $z \to +\infty$, uniformly for $x \in [a, b]$;

(HG5) If $b_0 = 0$, then $g(x, z) = O(z \log z)$ as $z \to +\infty$, uniformly for $x \in [a, b]$.

These conditions allow singular behavior of $f(x, y)$ near both endpoints of (a, b) and as $y \to 0^+$. The term $g(x, y')$ allows significant nonlinearity in y', but essentially no singularity; later we will allow $g(x, z)$ to be singular as $x \to a+$.

Our strategy for finding a solution of (1.11), (1.12) is to construct a sequence of approximate problems to which we can apply a previous existence theorem and then use Ascoli's theorem on the corresponding sequence of solutions.

We will encounter a technical problem in the course of our work which is easily dispatched if $f(x, y)$ satisfies the following more restrictive condition than (HF1).

(HF0) $f: (a, b] \times (0, \infty) \to (0, \infty)$ is continuous.

Our work will be facilitated if we keep this possibility in mind. We do this from the outset at follows. Define, for integers $n > 2/(b-a)$,

$$h_n(x) = \begin{cases} n^2(x-a) & \text{for } a \leqq x < a + \dfrac{1}{n}, \\ n & \text{for } a + \dfrac{1}{n} \leqq x \leqq b - \dfrac{1}{n}, \\ n^2(b-x) & \text{for } b - \dfrac{1}{n} < x \leqq b, \end{cases}$$

$$h_n^*(x) = \begin{cases} n^2(x-a) & \text{for } a \leqq x < a + \dfrac{1}{n}, \\ n & \text{for } a + \dfrac{1}{n} \leqq x \leqq b. \end{cases}$$

So $h_n(x)$, $h_n^*(x)$ are continuous (piecewise linear) functions on $a \leqq x \leqq b$. We shall use these functions to approximate $f(x, y)$ by bounded, continuous functions on $[a, b] \times (-\infty, \infty)$. If $f(x, y)$ satisfies the more restrictive condition (HF0), we put

$$f_n(x, y) = \min [h_n^*(x), f(x, y)] \quad \text{for } (x, y) \in (a, b] \times (0, \infty);$$

if f satisfies (HF1) but not (HF0), we put

$$f_n(x, y) = \min [h_n(x), f(x, y)] \quad \text{for } (x, y) \in (a, b) \times (0, \infty).$$

In either case, $f_n(x, y)$ has a unique continuous extension to $[a, b] \times (0, \infty)$, and since $f(x, y)$ is nonincreasing in y, then we may define

$$f_n(x, 0) \equiv \lim_{y \to 0^+} f_n(x, y) \quad \text{for } a \leqq x \leqq b$$

and then extend $f_n(x, y)$ to $[a, b] \times (-\infty, \infty)$ by

$$f_n(x, y) \equiv f_n(x, 0) \quad \text{if } y < 0.$$

It is clear that now

$$f_n : [a, b] \times (-\infty, \infty) \to (0, \infty) \text{ is continuous}$$

and $f_n(x, y)$ is nonincreasing in y for each fixed $x \in [a, b]$. It is important to note also that $f_n \leqq f_{n+1} \leqq f$.

For each integer $n > 2/(b-a)$, we view

$$\text{(ODE(n))} \qquad y'' + g(x, y') + f_n(x, y) = 0$$

as an approximation for (1.11). The existence of a solution $\phi_n \in C^2[a, b]$ of the boundary value problem consisting of (ODE(n)) and the boundary conditions (1.12) follows from existence theorems in [3]. In the case that $b_0 = 0$, then necessarily $a_0 b_1 > 0$ and existence follows from (HG5) and Theorem 2.1 of [3]. To conclude existence in case $b_0 > 0$, we first change variables, replacing x by $a + b - x$, to get the transformed problem

$$y'' + g(a + b - x, -y') + f_n(a + b - x, y) = 0, \qquad a < x < b,$$

$$b_0 y(a) - b_1 y'(a) = B, \qquad a_0 y(b) + a_1 y'(b) = A.$$

Note that $zg(a + b - x, -z) \leqq 0$. If $b_0 a_1 > 0$, existence is a simple consequence of Theorem 2.1 of [3]. If $b_0 > 0$ and $a_1 = 0$, then $b_0 a_0 > 0$ and existence follows from (HG4) and Theorem 2.2 of [3].

Before collecting some qualitative information about the graphs of these solutions $\phi_n(x)$, we state the following consequence of the maximum principle.

LEMMA 2.1. *Let* $T_n(y) = y'' + g(x, y') + f_n(x, y)$. *Suppose that* $T_n\phi(x) \geqq 0$, $T_n\psi(x) \leqq 0$, and $\phi(x) > \psi(x)$ *for* $x \in [c, d] \subset I$. *If* $\phi - \psi$ *is not constant on* $[c, d]$, *then* $\phi - \psi$ *cannot attain its maximum on* $[c, d]$ *at an interior point of* $[c, d]$. *This maximum can only occur at* c *with* $\phi'(c) < \psi'(c)$ *or at* d *with* $\phi'(d) > \psi'(d)$.

Proof. We use the standard procedure. Since $T_n\phi(x) \geqq 0$, $T_n\psi(x) \leqq 0$ *on* $[c, d]$, then $u = \phi - \psi$ satisfies

$$u'' + a(x)u' + b(x)u \geqq 0, \qquad c \leqq x \leqq d,$$

where

$$a(x) = \begin{cases} \dfrac{g(x, \phi'(x)) - g(x, \psi'(x))}{\phi'(x) - \psi'(x)} & \text{if } \phi'(x) \neq \psi'(x), \\ 0 & \text{if } \phi'(x) = \psi'(x). \end{cases}$$

and

$$b(x) = \frac{f_n(x, \phi(x)) - f_n(x, \psi(x))}{\phi(x) - \psi(x)}.$$

By (HG3), $a(x)$ is bounded on $[c, d]$ and since $f_n(x, y)$ is continuous and nonincreasing in y, then $b(x)$ is continuous and nonpositive on $[c, d]$. The maximum principle [12, pp. 6-7] therefore applies to complete the proof.

3. Approximating solutions: Behavior and estimates. We now describe qualitatively the graphs of $\phi_n(x)$.

LEMMA 3.1. $\phi_n(x)$ *has at most one critical point in* (a, b).

(a) *If such a critical point* $c_n \in (a, b)$ *exists, then* $a_0 b_0 > 0$ *and* ϕ_n *has an absolute maximum on* $[a, b]$ *at* c_n,

$$\phi_n'(x) < 0, \quad \phi_n(x) > (B - b_1\phi_n'(b))/b_0 \quad \text{for } c_n < x < b,$$

$$\phi_n'(x) > 0, \quad \phi_n(x) \geqq (a_1\phi_n'(a) + A)/a_0 \quad \text{for } a \leqq x < c_n.$$

(b) *If* ϕ_n *has no critical point in* (a, b), *then* ϕ_n *attains an absolute maximum on* $[a, b]$ *at exactly one endpoint* c_n *and either*

$$c_n = b, \quad a_0 > 0, \quad \phi_n'(x) > 0, \quad \phi_n(x) \geqq (a_1\phi_n'(a) + A)/a_0 \quad \text{for } a \leqq x < b,$$

or

$$c_n = a, \quad b_0 > 0, \quad \phi_n'(x) < 0, \quad \phi_n(x) > (B - b_1\phi_n'(b))/b_0 \quad \text{for } a < x < b.$$

Proof. If $\phi_n'(c) = 0$ for $c \in (a, b)$, then since (HG1), (HG2) imply $g(x, 0) = 0$, for $a \leqq x \leqq b$, it follows from (HF1) that

$$\phi_n''(c) = -f_n(c, \phi_n(c)) < 0$$

and thus c gives a strict local maximum. Clearly, at most one such c_n can exist. If such a c_n exists, then it certainly gives an absolute maximum and $\phi_n'(x) > 0$ on (a, c_n) and $\phi_n'(x) < 0$ on (c_n, b). If no such critical point in (a, b) exists, then $\phi_n'(x)$ has the same sign throughout (a, b). Suppose that $c_n > a$. By (HG2), we then have

$$\phi_n''(x) = -g(x, \phi_n'(x)) - f_n(x, \phi_n(x)) < 0 \quad \text{for } a < x < c_n,$$

and $\phi_n(x)$ is concave down on (a, c_n). Thus $\phi_n'(x)$ is decreasing on $[a, c_n]$ with $\phi_n'(a) > 0$. The boundary condition at $x = a$ gives $a_0\phi_n(a) = a_1\phi_n'(a) + A$. If $a_1 = 0$,

then $a_0 > 0$ by hypothesis; if $a_1 > 0$, then

$$a_0\phi_n(a) = a_1\phi_n'(a) + A \geq a_1\phi_n'(a) > 0$$

forces $a_0 > 0$. Thus for $a \leqq x \leqq c_n$,

$$\phi_n(x) \geqq \phi_n(a) = (a_1\phi_n'(a) + A)/a_0.$$

Suppose now that $c_n < b$ and focus attention on (c_n, b). It can no longer be concluded that $\phi_n''(x)$ is negative and ϕ_n may not be concave down on (c_n, b). (This loss of concavity is the root of technical difficulties with which (HF0) or some other alternative will assist later.) To show that $b_0 > 0$, suppose that $b_0 = 0$, $b_1 > 0$. Then the constant function $\phi(x) = \phi_n(c_n)$ satisfies $T_n(\phi) = f_n(x, \phi) \geqq 0$. We shall show that $\phi_n(x) \geqq \phi(x)$ on $[c_n, b]$, which contradicts the fact that c_n gives a strict maximum for $\phi_n(x)$. Assuming that $\phi_n(x) \geqq \phi(x)$ is false, we may suppose that $\phi - \phi_n$ attains a positive maximum at some point $x_0 \in [c_n, b]$. Clearly, $x_0 \neq c_n$ since $(\phi - \phi_n)(c_n) = 0$, and certainly $\phi - \phi_n$ is not constant on $(c_n, b]$. Choose $c \in (c_n, x_0)$ so that $\phi - \phi_n > 0$ on $[c, x_0]$. Since $b_1(\phi - \phi_n)'(b) = -B \leqq 0$, then surely $(\phi - \phi_n)'(x_0) \leqq 0$, contradicting Lemma 2.1. Thus $b_0 > 0$ and the boundary condition at $x = b$ gives $\phi_n(x) > \phi_n(b) = (B - b_1\phi_n'(b))/b_0$ for $c_n < x < b$, completing the proof.

Note that if the maximum of ϕ_n on $[a, b]$ occurs at $c_n < b$, we do not conclude that $\phi_n'(b) < 0$, in contrast to the fact that $\phi_n'(a) > 0$ if $c_n > a$. The possibility that $\phi_n'(b) = 0$ even though $c_n < b$ will be dealt with later.

LEMMA 3.2. *$\phi_n(x) \leqq \phi_{n+1}(x)$ for $a \leqq x \leqq b$ and integers $n \geqq 2/(b-a)$.*

Proof. Suppose on the contrary that for some n, the function $\phi_n - \phi_{n+1}$ attains a positive maximum at some point $x_0 \in [a, b]$. Since $\phi_n - \phi_{n+1}$ satisfies

$$a_0 y(a) - a_1 y'(a) = 0, \qquad b_0 y(b) + b_1 y'(b) = 0, \tag{3.1}$$

and $a_0 + b_0 > 0$, then $\phi_n - \phi_{n+1}$ is not constant on $[a, b]$. Note that $x_0 = b$ implies $b_0 = 0$ and thus $I = [a, b]$. Clearly, there exists an interval $[c, d] \subset [a, b]$ with $x_0 \in [c, d]$ and $\phi_n - \phi_{n+1}$ is positive and nonconstant on $[c, d]$. Since $T_n(\phi_n) = 0$ and $f_n(x, y) \leqq f_{n+1}(x, y)$ implies $T_n(\phi_{n+1}) \leqq T_{n+1}(\phi_{n+1}) = 0$, then Lemma 2.1 shows that $x_0 = a$ and $(\phi_n - \phi_{n+1})'(x_0) < 0$ or $x_0 = b$ and $(\phi_n - \phi_{n+1})'(x_0) > 0$. Each of these is impossible because $\phi_n - \phi_{n+1}$ satisfies (3.1).

We now obtain estimates on the derivatives ϕ_n' which will be central in allowing the use of Ascoli's theorem later.

LEMMA 3.3. *Suppose $c_n < b$ and $n > 2/(b-a)$. If $x_1 \in (a, b)$, $x_1 \geqq c_n$, then*

$$|\phi_n'(x)| \leqq |\phi_n'(x_1)| + 2\int_{x_1}^{x} f(s, \phi_n(s))\, ds \quad \text{for } x_1 \leqq x < b.$$

Proof. With x_1 as described, choose and fix $x \in (x_1, b)$. Then choose d so that $|\phi_n'(x)|$ assumes its maximum on $[x_1, x]$ at d. By Lemma 3.1, $\phi_n'(s) < 0$ on $[x_1, x]$ and (HG2) implies that

$$\phi_n''(s) = -g(s, \phi_n'(s)) - f_n(s, \phi_n(s)) \geqq -f_n(s, \phi_n(s)), \qquad x_1 \leqq s \leqq x.$$

Multiplying by $\phi_n'(s)$ and integrating over $[x_1, d]$, we obtain

$$|\phi_n'(d)|^2 \leqq |\phi_n'(x_1)|^2 - 2\int_{x_1}^{d} \phi_n'(s) f_n(s, \phi_n(s))\, ds.$$

Since $|\phi_n'(d)| = -\phi_n'(d)$ is the maximum value of $|\phi_n'(s)|$ on $[x_1, d]$, there follows

$$|\phi_n'(d)|^2 \leqq |\phi_n'(x_1)|^2 + 2|\phi_n'(d)| \int_{x_1}^{d} f_n(s, \phi_n(s))\, ds.$$

The desired result is obtained after division by $|\phi_n'(d)|$.

LEMMA 3.4. *Suppose* $c_n > a$.

(i) *If* $a_1 > 0$, *then* $0 \leqq \phi_n'(x) < a_0\phi_n(c_n)/a_1$, *for* $a \leqq x \leqq c_n$.

(ii) *If* $a_1 = 0$, $b_0 > 0$, *and* $x_2 \in (a, b)$, $x_2 \leqq c_n$, *then there exist positive numbers* K_1, z_1, *independent of* n, *so that*

$$0 \leqq \phi_n'(x) \leqq 2 \exp(2K_1\phi_n(c_n))\left\{z_1 + \phi_n'(x_2) + 2\int_x^{x_2} f(s, \phi_n(s))\, ds\right\}$$

for $a < x \leqq x_2$.

(iii) *If* $b_0 = 0$ *and* $x_2 \in (a, b)$, *then there exist positive numbers* K_2, z_2, *independent of* n, *so that*

$$\log\log \phi_n'(x) \leqq \log\log z_2 + K_2(b-a) + \frac{\int_x^{x_2} f(s, \phi_n(s))\, ds}{z_2 \log z_2}$$

for $a < x \leqq x_2$.

Proof. If $a_1 > 0$, the boundary condition at $x = a$ gives $\phi_n'(a) \leqq a_0\phi_n(a)/a_1$ and (i) follows from the facts that $\phi_n(a) < \phi_n(c_n)$ and ϕ_n is concave down on (a, c_n). We pass to (ii) and so may use (HG4). Thus there exist positive constants K_1, z_1 so that

$$g(x, z) \leqq K_1 z^2 \quad \text{for } z \geqq z_1.$$

Arguing by contradiction, suppose that there exists $x_0 \in (a, x_2)$ for which

$$\phi_n'(x_0) > 2 \exp(2K_1\phi_n(c_n))\left\{z_1 + \phi_n'(x_2) + 2\int_{x_0}^{x_2} f(s, \phi_n(s))\, ds\right\}.$$

Then we may choose $x_1 \in (x_0, x_2)$ so that

$$\phi_n'(x_1) = M \equiv \left\{z_1 + \phi_n'(x_2) + 2\int_{x_0}^{x_2} f(s, \phi_n(s))\, ds\right\},$$

and $\phi_n'(x) > M$ for $x_0 \leqq x < x_1$. The differential equation then gives

$$\phi_n''(x) = -g(x, \phi_n'(x)) - f_n(x, \phi_n(x)) \geqq -K_1(\phi_n'(x))^2 - f(x, \phi_n(x))$$

for $x_0 \leqq x \leqq x_1$. Dividing by $(\phi_n'(x))^2$ and integrating over $[x_0, x]$, where $x_0 < x \leqq x_1$, we get

$$\frac{1}{\phi_n'(x_0)} - \frac{1}{\phi_n'(x)} \geqq -K_1(x - x_0) - \frac{\int_{x_0}^{x} f(s, \phi_n(s))\, ds}{(\phi_n'(x))^2}$$

since $\phi_n'(x)$ is the minimum value of ϕ_n' on $[x_0, x]$. Then

$$\phi_n'(x) > 2\int_{x_0}^{x} f(s, \phi_n(s))\, ds$$

implies

$$\frac{1}{2\phi_n'(x)} \leqq \frac{1}{\phi_n'(x)}\left[1 - \frac{\int_{x_0}^{x} f(s, \phi_n(s))\, ds}{\phi_n'(x)}\right] \leqq K_1(x - x_0) + \frac{1}{\phi_n'(x_0)}.$$

Thus

$$2\phi_n'(x) \geqq \frac{\phi_n'(x_0)}{K_1\phi_n'(x_0)(x - x_0) + 1}, \qquad x_0 < x \leqq x_1. \tag{3.2}$$

Integrating (3.2) over $[x_0, x_1]$ and then using (3.2) again for the value $x = x_1$ produces

$$2(\phi_n(x_1) - \phi_n(x_0)) \geqq \frac{1}{K_1}\log(K_1\phi_n'(x_0)(x_1 - x_0) + 1)$$

and

$$2K_1\phi_n(c_n) \geqq \log\left[\frac{\phi_n'(x_0)}{2\phi_n'(x_1)}\right],$$

which leads to

$$\phi_n'(x_0) \leqq 2M \exp(2K_1\phi_n(c_n)),$$

a contradiction.

To prove (iii), we may use (HG5). So there exists $z_2 > 0$, $K_2 > 0$ such that

$$g(x, z) \leqq K_2 z \log z \quad \text{for } z \geqq z_2.$$

We may surely assume that $z_2 > B/b_1 = \phi_n'(b)$. If $\phi_n'(x) \leqq z_2$ on (a, x_2), there is nothing to prove. Otherwise there exists $x_1 \in (a, x_2)$ such that $\phi_n'(x_1) = z_2$ and $\phi_n'(x) > z_2$ for $a \leqq x < x_1$. Then

$$\phi_n''(s) \geqq -K_2\phi_n'(s) \log(\phi_n'(s)) - f(s, \phi_n(s)), \qquad a < s \leqq x_1.$$

After dividing by $\phi_n' \log \phi_n'$ and integrating from x to x_1, we obtain the desired conclusion.

4. Existence. We are now ready to formulate and prove our main result giving sufficient conditions for the existence of a solution ϕ of problem (1.11), (1.12). As might be expected, these conditions are less demanding if the singularity at $y = 0$ is irrelevant at one or both endpoints. Since we intend to construct our solution using Ascoli's theorem as the limit of the subsequence of the solutions $\{\phi_n\}$ of the approximating problems, we look to Lemmas 3.1 and 3.2 for guidance. Let N be the smallest integer larger than $2/(b-a)$ and suppose $n \geqq N$. If $A + a_1 > 0$, then Lemma 3.1 implies that $\phi_n(a) > 0$; from Lemma 3.2, it follows that $\phi(a)$ will also be positive and thus the singularity at $y = 0$ will be irrelevant at $x = a$. The other endpoint is more troublesome, because Lemma 3.1 does not guarantee that $\phi_n'(b)$ will be negative if $c_n < b$. If $B > 0$, then certainly $\phi_n(b) > 0$ and the singularity at $y = 0$ is also irrelevant at $x = b$. We immediately give simple conditions which force $\phi_n'(b) < 0$ when $c_n < b$. This can be accomplished via either the function $g(x, y')$ or the function $f(x, y)$. Here is the condition on g:

(HG6) There exists $\delta > 0$ so that $g(x, z) = O(|z|)$ as $z \to 0-$, uniformly for $x \in [b-\delta, b]$.

LEMMA 4.1. *Suppose $c_n < b$ and either that f satisfies the stronger condition* (HF0) *or that g satisfies* (HG6). *Then $\phi_n'(b) < 0$.*

Proof. By Lemma 3.1, ϕ_n attains its minimum on $[c_n, b]$ at b where $\phi_n'(b) \leqq 0$. Assuming that f satisfies (HF0) and $\phi_n'(b) = 0$, then

$$\phi_n''(b) = -f_n(b, \phi_n(b)) < 0,$$

which is clearly impossible. Thus $\phi_n'(b) < 0$. If $g(x, z)$ satisfies (HG6) and $\phi_n'(b) = 0$, then we may assume that $c_n < b - \delta$ and that there exists a constant k so that $|g(x, \phi_n'(x))| \leqq k|\phi_n'(x)|$ for $x \in [b-\delta, b)$. Thus

$$\phi_n''(x) + k\phi_n'(x) \leqq \phi_n''(x) + g(x, \phi_n'(x)) = -f(x, \phi_n(x)) < 0, \qquad b - \delta \leqq x < b.$$

Multiplying by $\exp(kx)$ and integrating, we get

$$\exp(kb)\phi_n'(b) < \exp(k(b-\delta))\phi_n'(b-\delta) < 0,$$

a contradiction. Thus $\phi_n'(b) < 0$.

If the hypotheses of Lemma 4.1 are satisfied, then Lemma 3.1 implies that the singularity at $y=0$ will be irrelevant at $x=b$ if $B=0$, $b_1>0$. In order to get a solution of (1.11), (1.12) which is sufficiently smooth at an endpoint of $[a, b]$, we shall need to impose certain integrability conditions on $f(x, y)$ near that endpoint. Let m be the midpoint of $[a, b]$. Here are the various conditions:

(a1) $\int_a^m f(x, \theta(x-a))\,dx<\infty$ for $\theta>0$,

(a2) $\int_a^m f(x, y)\,dx<\infty$ for $y>0$,

(a3) $\int_a^m (x-a)f(x, y)\,dx<\infty$ for $y>0$,

(b1) $\int_m^b f(x, \theta(b-x))\,dx<\infty$ for $\theta>0$,

(b2) $\int_m^b f(x, y)\,dx<\infty$ for $y>0$,

(b3) $\int_m^b (b-x)f(x, y)\,dx<\infty$ for $y>0$.

We say that $f(x, y)$ satisfies the strong integrability condition at $x=a$ if $f(x, y)$ satisfies (a2) in case $A+a_1>0$, and $f(x, y)$ satisfies (a1) in case $A+a_1=0$. Similarly, $f(x, y)$ satisfies the strong integrability condition at $x=b$ if $f(x, y)$ satisfies (b2) in the case where $B+b_1>0$, and $f(x, y)$ satisfies (b1) in the case where $B+b_1=0$; we also require that $f(x, y)$ satisfy HF0 if $B=0$, $b_0>0$, and $g(x, z)$ fails to satisfy (HG6). These are essentially the conditions used by Taliaferro in [13] and later in [7] in the case that $g(x, z)\equiv 0$.

To allow for the possibility that a solution's derivative is unbounded near a Dirichlet endpoint, we also consider "weak" integrability conditions analogous to those of Taliaferro [13]. We say that $f(x, y)$ satisfies the weak integrability condition at $x=b$ if $f(x, y)$ satisfies (b3). Similarly, $f(x, y)$ satisfies the weak integrability condition at $x=a$ if $f(x, y)$ satisfies (a3) when $g(x, z)=O(z)$ as $z\to+\infty$; otherwise, we must strengthen this condition to (a2). Since the weak conditions will only be considered at Dirichlet endpoints, it is clear that the weak condition at $x=a$ is no weaker than the strong condition if $A>0$ and $g(x, z)$ is not $O(z)$ for large z. We leave open the question of whether or not this strengthened condition is necessary.

For the purpose of easy reference and hopefully to make the proof transparent, we begin with several simple lemmas.

LEMMA 4.2. *If $f(x, y)$ satisfies the strong integrability condition at $x=a$, then $f(x, \phi_n(x))$ is integrable over the interval $[a, m]$. If $f(x, y)$ satisfies the strong integrability condition at $x=b$, then $f(x, \phi_n(x))$ is integrable over the interval $[m, b]$.*

Proof. If $A+a_1>0$, then Lemma 3.1 implies that there exists $y>0$ so that $\phi_n(x)\geqq y$ on $[a, m]$; thus by (HF2), $f(x, \phi_n(x))\leqq f(x, y)$ on $[a, m]$. If $A+a_1=0$, Lemma 3.1 implies that $\phi_n'(a)>0$ and so there exists $\theta>0$ for which $\phi_n(x)\geqq\theta(x-a)$ on $[a, m]$, so by (HF2) again, $f(x, \phi_n(x))\leqq f(x, \theta(x-a))$. The second statement follows similarly, but Lemma 4.1 must also be used.

LEMMA 4.3. *If $f(x, y)$ satisfies the weak integrability condition at $x=a$, then $\int_x^m f(s, y)\,ds$ is integrable over the interval $a\leqq x\leqq m$ for each fixed $y>0$. If $f(x, y)$ satisfies*

the weak integrability condition at $x = b$, then $\int_m^x f(s, y)\, ds$ is integrable over the interval $m \leqq x \leqq b$ for each fixed $y > 0$.

Proof. Fubini's theorem gives

$$\int_a^m \int_x^m f(s, y)\, ds\, dx = \int_a^m (s - a) f(s, y)\, ds,$$

implying that the first statement. The second statement is similar.

These integrability statements will be used in tandem with the next lemma to obtain equicontinuity.

LEMMA 4.4. *If $h(x)$ is integrable over some interval $[c, d]$, then given $\varepsilon > 0$, there exists $\delta > 0$ so that $c \leqq x_1 < x_2 \leqq d$ and $x_2 - x_1 < \delta$ implies $\int_{x_1}^{x_2} |h(x)|\, dx < \varepsilon$.*

Proof. This statement is the well-known fact from real analysis about absolute continuity of integrals.

Here are some intuitive remarks about our general strategy. To fix ideas, consider the case that c_n lies strictly between a and b. We want to use Lemma 3.3 to get uniform bounds on ϕ_n' to the right of c_n. If Lemma 4.2 applies, we expect uniform bounds up to b and we would like to integrate to get uniform bounds on $\phi_n(c_n)$; alternatively, we expect to integrate using Lemma 4.3 to get uniform bounds on $\phi_n(c_n)$. Then we want to use the estimates in Lemma 3.4 to obtain bounds to the left of c_n. But we have problems to overcome: if the c_n could accumulate at a and the strong integrability condition fails at a, the bound of Lemma 3.3 would fail us near c_n. Without an a priori bound on $\phi_n(c_n)$, the first two estimates in Lemma 3.4 are useless. Also, if the c_n could accumulate at b, the estimates of Lemma 3.4(ii) and (iii) would fail us near c_n. So an important part of the main proof is to show that the c_n cannot accumulate at a weak endpoint and the prevention of such accumulation at a is the technical problem to which we earlier referred. The extra assumption on $g(x, z)$ will be used via the following lemma.

LEMMA 4.5. *Suppose $c_n > a$ and $g(x, z) = O(z)$ as $z \to +\infty$. If $x_2 \in (a, b)$ and $x_2 \leqq c_n$, then there exist constants z_1 and K_1 so that*

$$\phi_n'(x) \leqq \exp\left(K_1(b - a)\right)\left\{ z_1 + \phi_n'(x_2) + \int_x^{x_2} f(s, \phi_n(s))\, ds \right\}$$

for $a < x < x_2$.

Proof. By hypothesis, there exist z_1 and K_1 so that $g(x, z) \leqq K_1 z$ for $z \geqq z_1$. If $\phi_n'(x) \leqq z_1 + \phi_n'(x_2)$ for $a \leqq x \leqq x_2$, there is nothing to prove. Otherwise, there exists $x_1 \in (a, x_2)$ such that $\phi_n'(x_1) = z_1 + \phi_n'(x_2)$. Then

$$\phi_n''(s) + K_1 \phi_n'(s) \geqq -f_n(s, \phi_n(s)) \quad \text{for } a < s < x_1,$$

and integration over $[x, x_1]$ leads quickly to the conclusion.

It will be convenient to have the following trivial extension of the usual Ascoli theorem.

LEMMA 4.6. *Suppose that $\{g_n\}$ is an equicontinuous sequence of functions on a finite interval $[c, d]$ and there exists a point x_0 in $[c, d]$ for which $\{g_n(x_0)\}$ is bounded. Then $\{g_n\}$ contains a uniformly convergent subsequence on $[c, d]$.*

Proof. The hypotheses imply that $\{g_n\}$ is uniformly bounded on $[c, d]$ so Ascoli's theorem applies.

Here is our main theorem.

THEOREM 4.1. *Suppose that f, g satisfy* (HF1)-(HF2) and (HG1)-(HG5). *At each endpoint of $[a, b]$, suppose either that $f(x, y)$ satisfies the strong integrability condition, or that the boundary condition at that endpoint is a Dirichlet condition and $f(x, y)$ satisfies*

the weak integrability condition. Let J denote the interval obtained by removing from $[a, b]$ any endpoint at which $f(x, y)$ fails to satisfy the strong integrability condition. Then the boundary value problem (1.11), (1.12) *has at least one solution* $\phi \in C^2(a, b) \cap C^1(J) \cap C[a, b]$. *Moreover, if* $A + a_0 = 0$, *then* ϕ' *satisfies the inequality*

$$|\phi'(x)| \leqq 2 \int_a^x f(s, \phi(s))\, ds < +\infty \quad \text{for } a \leqq x < b. \tag{4.1}$$

Proof. We shall show that some subsequence of $\{\phi_n\}$ satisfies the hypotheses of Lemma 4.6 and that the corresponding subsequence of $\{\phi_n'\}$ is uniformly bounded on each compact subset of J, and then use a slight modification of the familiar diagonalization argument with Ascoli's theorem. Because the argument differs if the point c_n where the maximum of ϕ_n occurs is an endpoint, we shall arrange our proof to deal conveniently with these special cases first. So we begin with the case that $c_n = b$ for infinitely many values of $n \geqq N$ and temporarily focus attention on these values of n.

Suppose $b_0 > 0$. Then the boundary condition at $x = b$ guarantees that $\phi_n(b) \leqq B/b_0$. If $a_1 > 0$, then $\{\phi_n'\}$ is uniformly bounded on $[a, b]$ by Lemma 3.4(i) and hence $\{\phi_n\}$ is equicontinuous on $[a, b]$. So we pass to the case that $a_1 = 0$. Here the concavity of ϕ_n on $[a, b]$ implies that

$$\phi_n'(m)(m - a) < \int_a^m \phi_n'(x)\, dx = \phi_n(m) - \phi_n(a) < \frac{B}{b_0} \tag{4.2}$$

so Lemma 3.4(ii) applies (with $x_2 = m$) to give constants C_1 and C_2 so that

$$\phi_n'(x) \leqq C_1 + C_2 \int_x^m f(s, \phi_n(s))\, ds \leqq C_1 + C_2 \int_x^m f(s, \phi_N(s))\, ds \tag{4.3}$$

for $a < x \leqq m$. Thus, using Lemma 4.2 if needed, we conclude from the concavity that $\{\phi_n'\}$ is uniformly bounded on each compact subset of J. To show the equicontinuity of $\{\phi_n\}$ on $[a, b]$, let $\varepsilon > 0$ be given. Define

$$h(x) = C_1 + C_2 \int_x^m f\left(s, \frac{\varepsilon}{2}\right) ds \quad \text{for } a < x \leqq m$$

and

$$h(x) = \frac{B}{(m - a)b_0} \quad \text{for } m < x \leqq b.$$

By Lemma 4.3, $h(x)$ is integrable over $[a, b]$. Let $\delta > 0$ be the number given by Lemma 4.4 (with ε replaced by $\varepsilon/2$ and $[c, d]$ replaced by $[a, b]$). We show that $a \leqq x_1 < x_2 \leqq b$ and $x_2 - x_1 < \delta$ implies

$$|\phi_n(x_2) - \phi_n(x_1)| < \varepsilon. \tag{4.4}$$

If $\phi_n(b) - \phi_n(a) < \varepsilon$, there is nothing to prove. Otherwise, choose $a_n \in (a, b)$ so that $\phi_n(a_n) = \phi_n(a) + \varepsilon/2$. Then if $x_1 \geqq a_n$, (4.2) and (4.3) imply $\phi_n'(x) \leqq h(x)$ on $[x_1, x_2]$ and integration gives (4.4) with ε replaced by $\varepsilon/2$. For $x_1 < a_n$, (4.4) follows immediately from the triangle inequality. If $b_0 = 0$, then $a_0 > 0$ and $b_1 > 0$. Thus from the boundary conditions, $\{\phi_n(a)\}$ is bounded by A/a_0 and $\{\phi_n'(b)\}$ is bounded by B/b_1. Also the strong integrability condition is satisfied at $x = b$. If $f(x, y)$ satisfies (a2), then Lemma 3.4(iii) applies (with x_2 replaced by b) to give a uniform bound for $\{\phi_n'\}$ on $[a, b]$ and equicontinuity of $\{\phi_n\}$ on $[a, b]$ is immediate. Otherwise, Lemma 4.5 may be applied to give (4.3) again and the argument in the case $b_0 > 0$ may be repeated. So we have the desired subsequence if $c_n = b$ for infinitely many n.

We now pass to the case that $c_n = a$ for infinitely many n. First suppose that $a_1 > 0$. Then $-A/a_1 < \phi_n'(a) \leqq 0$ and the strong integrability condition is satisfied at $x = a$. The bound for ϕ_n' of Lemma 3.3 may now be used for $h(x)$ with Lemmas 4.3 and 4.4 to show that $\{\phi_n\}$ is equicontinuous on $[a, b]$. If $x = b$ is a Dirichlet endpoint, then $\{\phi_n(b)\}$ is bounded and we are done; otherwise the strong integrability condition is also satisfied at $x = b$, Lemma 3.3 gives a uniform bound on $\{\phi_n'\}$ on $[a, b]$, and at least one of the boundary conditions then gives a bound on $\{\phi_n\}$ at the corresponding endpoint. Next suppose that $a_1 = 0$. Then $\phi_n(a) = A/a_0$ for every n of interest, providing a uniform bound for $\{\phi_n\}$ on $[a, b]$. With an eye to using Lemma 3.3, we shall show that if $x_1 \in (a, b)$, then $\{\phi_n'(x_1)\}$ is bounded. Choose x_0 as the midpoint of $[a, x_1]$. Applying Lemma 3.3 (with the roles of x and x_1 interchanged), we easily conclude that

$$\phi_n'(x) \leqq \phi_n'(x_1) + 2\int_{x_0}^{x_1} f(s, \phi_N(s))\, ds \quad \text{for } x_0 \leqq x \leqq x_1.$$

If $\{\phi_n'(x_1)\}$ was unbounded below, integration from x_0 to x_1 would force $\{\phi_n(x_0)\}$ to be unbounded, contradicting the uniform bound on $[a, b]$. To show the equicontinuity of $\{\phi_n\}$ on $[a, b]$, choose $\varepsilon > 0$. If $\phi_n(b) - \phi_n(a) < \varepsilon$, there is nothing to prove. Otherwise, choose x_1 so that $\phi_N(x_1) = A/a_0 - \varepsilon/3$ and b_n so that $\phi_n(b_n) < \phi_n(b) + \varepsilon$. With this choice of x_1, let

$$h(x) = \phi_n'(x_1) + \int_{x_1}^{x} f\left(s, \frac{\varepsilon}{3}\right) ds \quad \text{for } x_1 < x < b.$$

Then Lemma 3.3 shows that $h(x)$ is a bound for $\phi_n'(x)$ on $[x_1, b_n]$, and Lemmas 4.3 and 4.4 may be used as before to finish the proof. So now we have the desired subsequence in the case that $c_n = a$ for infinitely many n.

If neither of the earlier cases hold, then there exists $M > N$ for which $c_n \in (a, b)$ for all $n \geqq M$. It is necessary to know shortly that the sequence $\{c_n\}$ is bounded away from any weak endpoint, for $n \geqq M$. If b is a weak endpoint, then

$$\phi_n(c_n) - \phi_n(b) > \phi_M(c_M) - \phi_M(b) \equiv Q \quad \text{for } n > M.$$

Choose $b_n \in (c_n, b)$ so that $\phi_n(b_n) = \phi_n(b) + Q/2$. Integrating the bound of Lemma 3.3 (with x_1 replaced by c_n), we find that

$$\frac{Q}{2} < \phi_n(c_n) - \phi_n(b_n) \leqq 2\int_{c_n}^{b}\int_{c_n}^{x} f\left(s, \frac{Q}{2}\right) ds\, dx,$$

a clear contradiction of Lemma 4.4 if $\{c_n\}$ is not bounded away from $x = b$.

Suppose a is a weak endpoint. If $f(x, y)$ satisfies (a2), then the estimate of Lemma 3.3 (with $x_1 = c_n$) may be integrated to show that $\phi_n(c_n)$ is bounded and then the estimate of Lemma 3.4(ii) may be used (with $x_2 = c_n$) and integrated to contradict Lemma 4.4 if c_n is not bounded away from $x = a$; otherwise we may integrate the estimate of Lemma 4.5 and again contradict Lemma 4.4 if c_n is not bounded away from $x = a$.

If b is a strong endpoint, then Lemma 3.3 (with $x_1 = c_n$) implies that $\{\phi_n'(b)\}$ is bounded; here we use either that a is a strong endpoint or that $\{c_n\}$ is bounded away from a. Since $c_n < b$, Lemma 3.1 forces $b_0 > 0$. Whether or not b is a strong endpoint, the boundary condition at $x = b$ then gives a bound on $\{\phi_n(b)\}$ and integration of the estimate of Lemma 3.3 (with $x_1 = c_n$) over $[c_n, b]$ produces a bound on $\{\phi_n(c_n)\}$ for $n \geqq M$. The uniform boundedness of $\{\phi_n'\}$ on each compact subset of J now follows from Lemma 3.3 and either Lemma 3.4(i) or (ii) or Lemma 4.5.

To establish the equicontinuity of ϕ_n on $[a, b]$, let $\varepsilon > 0$ be given. It suffices to show that on each of $[a, c_n]$ and $[c_n, b]$, there exists $\delta > 0$ so that

$$|\phi_n(x_2) - \phi_n(x_1)| < \varepsilon/2$$

whenever $|x_2 - x_1| < \delta$. The argument is similar in each case. To illustrate, consider the interval $[a, c_n]$. If

$$\phi_n(c_n) - \phi_n(a) < \varepsilon/2$$

there is nothing to prove. Otherwise, choose $a_n \in [a, c_n]$ so that $\phi_n(a_n) = \phi_n(a) + \varepsilon/4$. Depending on the integrability hypothesis satisfied at $x = a$, either the estimate of Lemma 3.4(i) or (ii) or that of Lemma 4.5 may be integrated and Lemma 4.4 used to show that there exists $\delta > 0$ for which

$$\phi_n(x_2) - \phi_n(x_1) < \varepsilon/4$$

whenever $x_2 - x_1 < \delta$ on $[a_n, c_n]$, and the desired conclusion follows.

We thus conclude in all cases that there exists a subsequence of $\{\phi_n\}$ which satisfies the hypotheses of Lemma 4.6 and for which $\{\phi_n'\}$ is uniformly bounded on each compact subset of J. To apply Ascoli's theorem to $\{\phi_n'\}$, we need to know that $\{\phi_n'\}$ is equicontinuous on each compact subinterval J_1 of J. Since $\{\phi_n'\}$ is uniformly bounded on J_1 and $g(x, z)$ is continuous, $\{g(x, \phi_n'(x))\}$ is uniformly bounded on J_1. Using the differential equation, there then exists a constant C so that

$$|\phi_n''(x)| < C + f(x, \phi_N(x)) \quad \text{for } x \in J_1.$$

Using Lemmas 4.2 and 4.4, we may integrate this estimate to show that $\{\phi_n'\}$ is equicontinuous on J_1. The usual diagonalization argument now produces a further subsequence of $\{\phi_n\}$ which converges uniformly on $[a, b]$ and for which $\{\phi_n'\}$ converges uniformly on each compact subset of J. It is easy to see that the limit function ϕ satisfies all the desired properties, finally completing the proof.

5. Uniqueness. If $b_0 = 0$ in (1.12), then we encounter added technical problems in establishing uniqueness. So we begin with the case where $b_0 > 0$.

THEOREM 5.1. *Suppose that f satisfies* (HF1)-(HF2) *and that g satisfies* (HG1), (HG3), *and suppose that $g(x, z)$ is nondecreasing in z for each $x \in [a, b]$. If $b_0 > 0$, then the boundary value problem* (1.11), (1.12) *has at most one positive solution.*

Proof. Assume that (1.11), (1.12) has two distinct solutions ϕ, ψ and let $u = \phi - \psi$. We may suppose that u has a positive maximum at some $x_0 \in [a, b]$. Since u satisfies the boundary conditions

$$a_0 u(a) - a_1 u'(a) = 0, \qquad b_0 u(b) + b_1 u'(b) = 0, \tag{5.1}$$

then u cannot be a positive constant on $[a, b]$. The argument of Lemma 2.1 may be repeated to show that x_0 is not an interior point of $[a, b]$. Since $b_0 > 0$, the second of the conditions (5.1) shows that the positive maximum cannot occur at b. Thus $x_0 = a$ and from the first of conditions (5.1), we see that necessarily $a_0 = 0$ and $u'(a) = 0$. It is easy to see that $u(x) \geqq 0$ on $[a, b]$. Otherwise, $-u$ would have a positive maximum on $(a, b]$ and this is impossible by the same argument just used to show that u cannot have a positive maximum on $(a, b]$. Then $u'(x) \leqq 0$ on $[a, b]$ since otherwise we see that u has a positive maximum on $(a, b]$. Since $g(x, z)$ is nondecreasing in z, (HF2) implies

$$u''(x) = g(x, \psi'(x)) - g(x, \phi'(x)) + f(x, \psi(x)) - f(x, \phi(x)) \geqq 0$$

on (a, b), forcing u to be constant on $[a, b]$, which is impossible.

In our proof above, we used the assumption that $b_0 > 0$ to rule out a maximum at b. If $b_0 = 0$, we need some further hypothesis. Here are several possibilities, any one of which suffices:

(5.2) $f(x, y)$ satisfies (HF0),

(5.3) $g(x, z) \equiv 0$,

(5.4) $\liminf_{x \to b^-} [f(x, y_2) - f(x, y_1)] > 0, \qquad 0 < y_2 < y_1$.

THEOREM 5.2. *Suppose $f(x, y)$ satisfies* (HF1)-(HF2), *$g(x, z)$ satisfies* (HG1), (HG3), *and also $g(x, z)$ is nondecreasing in z for each $x \in [a, b]$. If $b_0 = 0$ and any one of* (5.2), (5.3), (5.4) *is satisfied, then the boundary value problem* (1.11), (1.12) *has at most one solution.*

Proof. The proof of Theorem 5.1 may be used if we can rule out a positive maximum for u at b. Assuming u has a positive maximum at b, the second condition in (5.1) now implies that $u'(b) = 0$. If (5.2) holds, the maximum principle applies as in the proof of Lemma 2.1 to show that $u'(b) > 0$, a contradiction. If (5.3) holds, we may assume that $u(x) > 0$ and nonconstant on some interval $[c, b]$ where $a < c < b$. Then

$$u''(x) = f(x, \psi(x)) - f(x, \phi(x)) \geqq 0 \quad \text{for } c \leqq x \leqq b,$$

and since $u'(x)$ must be positive somewhere in (c, b), we get $u'(b) > 0$, a contradiction. Finally if (5.4) is true, it is easy to see that $u''(x) > 0$ in some neighborhood of b and we again reach the contradiction that $u'(b) > 0$.

It seems likely that without some additional hypothesis, Theorem 5.1 does not remain true in the case that $b_0 = 0$.

6. Existence and uniqueness with $g(x, y')$ singular. We now turn attention to the problem (1.11), (1.13), allowing $g(x, z)$ to be singular at $x = a$. We continue to assume that f satisfies (HF1)-(HF2), but relax the hypotheses (HG1)-(HG3) to the following.

(HG1*) $g : (a, b] \times (-\infty, 0] \to (-\infty, 0]$ is continuous.

(HG2*) $g(x, 0) = 0$, for all $x \in (a, b]$.

(HG3*) g satisfies a uniform Lipschitz condition in z on each compact set $S \subset (a, b) \times (-\infty, 0]$.

THEOREM 6.1. *Suppose f, g satisfy* (HF1)-(HF2), (HG1*)-(HG3*), *and that f satisfies the strong integrability condition at $x = a$. Suppose that $f(x, y)$ satisfies the strong integrability condition at $x = b$ and let $J = [a, b]$, or that b is a Dirichlet endpoint and $f(x, y)$ satisfies the weak integrability condition at b and let $J = [a, b)$. Then the boundary value problem* (1.11), (1.13) *has at least one positive solution $\phi \in C^1(J) \cap C^2(a, b)$.*

Proof. For each integer $n > 1/(b - a)$, consider the boundary value problem

$$y'' + \hat{g}(x, y') + f(x, y) = 0, \qquad a + 1/n < x < b,$$

(BVP(n)) $$y'(a + 1/n) = 0,$$

$$b_0 y(b) + b_1 y'(b) = B,$$

where $\hat{g}(x, y) \equiv -g(x, -y)$, for $y > 0$, $\hat{g}(x, y) \equiv g(x, y)$, for $y \leqq 0$. We apply Theorem 4.1 with $A = 0$, $a_1 = 1$, $b_0 > 0$ to conclude the existence of a solution $\phi_n \in C^2(a + 1/n, b) \cap C^1([a + 1/n, b] \cap J) \cap C[a + 1/n, b]$ of (BVP(n)) for which

(6.1) $$|\phi_n'(x)| \leqq 2 \int_{a+1/n}^{x} f(s, \phi_n(s))\, ds < \infty$$

for $a+1/n \leqq x \leqq b$. Using the facts that $\phi_n'(a+1/n)=0$, $\phi_{n+1}'(a+1/n)<0$ and repeating the argument of Lemma 3.2, it is easy to see that $\phi_n(x) \leqq \phi_{n+1}(x)$ for $a+1/n \leqq x \leqq b$. Let N be the smallest integer larger than $1/(b-a)$ and put

$$\phi_0(x)=\begin{cases}\phi_N(x), & a+1/N \leqq x \leqq b,\\ \phi_N(a+1/N), & a \leqq x < a+1/N.\end{cases}$$

Since ϕ_n is decreasing on $[a+1/n, b]$, it follows that

$$\phi_n(x) \geqq \phi_0(x) \quad \text{for } a+1/n \leqq x \leqq b, \quad n \geqq N,$$

and (HF2) implies

$$|\phi_n'(x)| \leqq 2\int_a^x f(s, \phi_0(s))\, ds < \infty, \qquad a+\frac{1}{n} < x < b. \tag{6.2}$$

Thus we have a uniform bound for $\{\phi_n'\}$ on compact subsets of $J \cap (a, b]$ and integration of (6.2) produces a uniform bound for $\{\phi_n\}$ on $[a, b]$. Using Ascoli's theorem and the usual diagonalization argument, we complete the proof to get a solution ϕ of the differential equation on $(a, b]$ which satisfies the boundary condition at $x = b$. It remains to show that $\phi'(a)=0$. We may let $n \to \infty$ in (6.2) to get

$$|\phi'(x)| \leqq 2\int_a^x f(s, \phi_0(s))\, ds < \infty, \qquad a < x < b.$$

It follows that $\lim_{x \to a^+} \phi'(x)=0$. Since ϕ is monotone on $(a, b]$ and bounded, then $\phi(a) \equiv \lim_{x \to a^+} \phi(x)$ exists, and the mean value theorem shows that $\phi'(a)=0$.

The following uniqueness theorem is proved using the same argument as we used in Theorem 5.1.

THEOREM 6.2. *Suppose that f satisfies* (HF1)-(HF2) *and that g satisfies* (HG1*), (HG3*), *and suppose that $g(x, z)$ is nondecreasing in z for each $x \in (a, b]$. Then the boundary value problem* (1.11), (1.13) *has at most one positive solution.*

INVERSION OF DISCONTINUITIES FOR THE SCHRÖDINGER EQUATION IN THREE DIMENSIONS*

LASSI PÄIVÄRINTA† AND ERKKI SOMERSALO†

Abstract. This work deals with the inverse scattering problem for the Schrödinger operator in three dimensions. The following problem is studied: If the inverse scattering problem is solved approximately by using the linearizing Born approximation, what information about the true potential is obtained if the scatterer is not necessarily weak? It is shown that in a certain sense, the leading singularities of the potential are recovered exactly. More accurately, under certain a priori smoothness assumptions of the scattering potential, the difference of the potential and the one obtained by using the Born approximation is in a smoother class of functions. Especially, for bounded potentials the approximation agrees with the true potential up to a Lipschitz continuous function. For the a priori scale of function spaces we have chosen the Zygmund classes equipped with a suitable weight at infinity.

Key words. Schrödinger equation, Born approximation, inverse scattering

AMS(MOS) subject classifications. 35R30, 35J10, 81C05

Introduction. One of the most straightforward and widely used methods of approaching the multidimensional inverse scattering problems on various fields of physics is to use the Born approximation to linearize the typically nonlinear problem. The popularity of this approach is no doubt in the relative ease at which linear inverse problems are treated, both theoretically and numerically, as compared to nonlinear ones, where there are few standard methods available. Naturally, the problems then lie in the validation of the linearizing approximation. The general philosophy is that for weak potentials, or scatterers in general, the scattered field is well approximated by the Born approximation. Application to inverse scattering problems contains in principle a more difficult problem: Given a scattering amplitude of other scattering data, how do we decide whether the unknown scatterer is weak enough to justify the linearized scheme? This work is intended to contribute to this problem in the special case of three-dimensional inverse scattering of the Schrödinger equation. Explicitly, we ask the following question: Given the far field amplitude of the scattering solution of the Schrödinger equation, what information of the potential is retrieved if we blindly apply the Born inversion scheme to this data? The main result of the work is that, roughly, the Born inversion yields the singularities of the original potential exactly, up to a certain degree of smoothness. Similar results have been known for some time in other scattering configurations. One of the pioneering works that should be mentioned here is the important article by Beylkin [4], followed by a number of other works. The basic ideas of this work, however, come closer to those of [14]. In fact, it is not difficult to see that the results of [14] can be directly translated to the language of (one-dimensional) quantum scattering.

The plan of the present article is: In § 1 we discuss the background of the linearized inversion scheme and prove the main result (Theorem 1.8) of the work. In § 2 we show that in some cases it is possible to improve the general results of § 1. Especially, the calculus developed in § 1 is applied to show that the linearized inversion scheme is sufficient for inverting discontinuities of a bounded potential: The true potential is shown to differ from the approximation by a Lipschitz continuous function. There are two appendices. Appendix A is a quick reference on the results concerning certain

function spaces which are used in the work. Finally, some of the most technical proofs are collected in Appendix B.

1. Asymptotic expansion of the linearized equations. To fix the notations, we will review some basic definitions and facts from the scattering theory of the Schrödinger equation in $\mathbf{R}^3$. The general reference on quantum scattering theory is, e.g., [9]. Let q be a real valued potential in $\mathbf{R}^3$ appearing in the Schrödinger operator

$$H = -\Delta + q(x). \tag{1.1}$$

Since the aim of this work is mainly to establish certain general ideas, we will avoid extra complications, at the cost of some generality, by assuming that the potential has no (infinite) singularities. More precisely, let w_δ be a weight function

$$w_\delta(x) = (1+|x|^2)^\delta.$$

The general assumption in this work is

$$w_\delta q \in L^\infty \tag{1.2}$$

for some $\delta > \frac{3}{2}$, abbreviated as $q \in L^\infty_\delta$. In most of this work, the assumption about the rate of decay at infinity could be released. Our choice of δ is made to gain some notational convenience (see Remark 1.10 below). Later, we will study the smoothing properties of certain operators, so we need a scale of function spaces generalizing (1.2) to measure the degree of smoothness in q. For $s > 0$ we define the weighted Zygmund space Λ^s_δ by the condition

$$f \in \Lambda^s_\delta \quad \text{if } w_\delta f \in \Lambda^s, \tag{1.3}$$

where again $\delta > \frac{3}{2}$, and Λ^s denotes the classical Zygmund space with smoothness index s. In Appendix A, we have collected the definitions of the Zygmund spaces and some other closely related function spaces that will be used in this work. Also, some important results that would take us too far off the main topic are left to this Appendix. The useful property of the spaces Λ^s, and the reason why we have chosen to work with these spaces, is that they are obtained via interpolation from the simple spaces C^k, the space of k times continuously differentiable functions. More precisely, we will prove in Appendix A the following interpolation property.

THEOREM 1.1. *Let k_0 and k_1 be integers, $0 \leqq k_0 < k_1$. Further, let $0 < \theta < 1$ and $s = (1-\theta)k_0 + \theta k_1$. Then, for any $\varepsilon > 0$,*

$$\Lambda^{s+\varepsilon} \subset [C^{k_0}, C^{k_1}]_\theta \subset \Lambda^s,$$

with continuous embeddings.

In the sequel, we will also need the weighted L^2 spaces L^2_δ, $\delta \in \mathbf{R}$, defined as

$$L^2_\delta = \left\{ f \in L^2_{\text{loc}} \,\middle|\, \|f\|_\delta = \left(\int_{\mathbf{R}^3} |f(x)|^2 (1+|x|^2)^\delta \, dx \right)^{1/2} < \infty \right\}.$$

The following fundamental result of the stationary scattering theory, usually referred to as the *limiting absorption principle*, can be found in [1], [9].

PROPOSITION 1.2. *Assume that the potential q satisfies* (1.2). *Then for all $k > 0$ there exist the limits*

$$\lim_{\varepsilon \to 0+} (H - (k^2 \pm i\varepsilon))^{-1} =: \mathcal{R}^\pm(k) \tag{1.4}$$

in the uniform operator topology from L^2_δ to $L^2_{-\delta}$ as $\delta > \frac{1}{2}$. Moreover, for large k,

$$\|\mathcal{R}^\pm(k)\| \leqq \frac{C}{k}. \tag{1.5}$$

Although not explicitly stated, the estimate (1.5) follows from the a priori estimate (A.2′) of reference [1] (see also [11], [13]).

It should be noted that in [1], the conditions on the potential q are less restrictive than (1.2). From (1.4) it is evident that the operators $\mathscr{R}^+(k)$ and $\mathscr{R}^-(k)$ are adjoint, i.e.,

$$(\mathscr{R}^+(k))^* = \mathscr{R}^-(k).$$

The family of generalized eigenfunctions $\psi^\pm$ of the Schrödinger operator H with outgoing (+) and incoming (−) radiation condition at infinity are now defined as

$$\psi^\pm(x, k, \theta) = \psi_0(x, k, \theta) - \mathscr{R}^\pm(k)(q\psi_0)(x, k, \theta), \tag{1.6}$$

where $k>0$, θ is a unit vector, i.e., $\theta \in S^2$, and ψ_0 is the incident plane wave,

$$\psi_0(x, k, \theta) = e^{ik\theta\cdot x}.$$

It is well known that the wave functions satisfy the Lippmann-Schwinger equation

$$\begin{aligned}\psi^\pm(x, k, \theta) &= e^{ik\theta\cdot x} - \frac{1}{4\pi}\int_{\mathbf{R}^3} \frac{e^{\pm ik|x-y|}}{|x-y|} q(y)\psi^\pm(y, k, \theta)\, dy \\ &= \psi_0(x, k, \theta) - \mathscr{R}_0^\pm(k) q\psi^\pm(x, k, \theta).\end{aligned} \tag{1.7}$$

Asymptotically, ψ^+ admit the expansion

$$\psi^+(x, k, \theta) = e^{ik\theta\cdot x} - \frac{e^{ik|x|}}{4\pi|x|} A(k, \hat{x}, \theta) + o\left(\frac{1}{|x|}\right),$$

as $|x|$ tends to infinity, and $\hat{x} = x/|x|$. The *scattering amplitude* A is obtained as

$$A(k, \hat{x}, \theta) = \int_{\mathbf{R}^3} e^{-ik\hat{x}\cdot y} q(y)\psi^+(y, k, \theta)\, dy. \tag{1.8}$$

In [7], an estimate of the decay rate of the residual term is given in terms of the decay rate of the potential at infinity (see also [8]). For reasons of purely technical nature, we define the wave functions $\psi^\pm(x, k, \theta)$ for negative values of k also by extending the Lippmann-Schwinger equation (1.7) to negative k's. Then

$$\psi^+(x, -k, \theta) = \overline{\psi^+(x, k, \theta)} = \psi^-(x, k, -\theta). \tag{1.9}$$

Hence we can also extend (1.8) to negative values of k, and

$$A(-k, \hat{x}, \theta) = \overline{A(k, \hat{x}, \theta)} = A(-k, -\theta, -\hat{x}). \tag{1.10}$$

The latter equality is simply the well-known reciprocity relation. The classical inverse scattering problem is to reconstruct the potential q from the knowledge of the far field data $A(k, \hat{x}, \theta)$, when k, $\hat{x}$, and θ are restricted to some given set.

To state the linearized inverse scattering equations in a compact form, we introduce the cylinders $M_0 = \mathbf{R}\times S^2$ and $M = M_0 \times S^2$, S^2 being the surface of the unit ball, and the measures μ_θ and μ on M_0 and M, respectively, as

$$d\mu_\theta(k, \theta') = \frac{1}{4} k^2\, dk |\theta - \theta'|^2\, d\theta',$$

$$d\mu(k, \theta', \theta) = \frac{1}{4\pi}\, d\theta\, d\mu_\theta(k, \theta').$$

Here, $d\theta$ and $d\theta'$ denote the usual Lebesgue measure on S^2. Since the spaces M_0 and M will be treated as the Fourier spaces of $\mathbf{R}^3$, we will define the equivalent of the

usual inverse Fourier transform on M_0 and M. If $\varphi: M_0 \to \mathbf{C}$ is a smooth, rapidly decreasing function (with respect to $k(\theta - \theta')$), henceforth denoted as $\varphi \in S(M_0)$, we set

$$\mathcal{F}_{M_0}^{-1}\varphi(x) = \left(\frac{1}{2\pi}\right)^3 \int_{M_0} e^{-ik(\theta-\theta')\cdot x}\varphi(k, \theta')\, d\mu_\theta(k, \theta'), \qquad x \in \mathbf{R}^3.$$

Obviously, $\mathcal{F}_{M_0}^{-1}$ maps $S(M_0)$ to $S(\mathbf{R}^3)$. Similarly, we define $\mathcal{F}_M^{-1}: S(M) \to S(\mathbf{R}^3)$ by

$$\mathcal{F}_M^{-1}\varphi(x) = \left(\frac{1}{2\pi}\right)^3 \int_M e^{-ik(\theta-\theta')\cdot x}\varphi(k, \theta', \theta)\, d\mu(k, \theta', \theta).$$

Let u_θ be the coordinate mapping $M_0 \to \mathbf{R}^3$ given as

$$u_\theta(k, \theta') = k(\theta - \theta'), \tag{1.11}$$

where θ is considered as a fixed parameter. If we write $\xi = k(\theta - \theta')$, then k and θ' are obtained back as

$$k = \frac{|\xi|}{2\theta \cdot \hat{\xi}}, \qquad \theta \cdot \hat{\xi} \neq 0, \tag{1.12}$$
$$\theta' = \theta - 2(\theta \cdot \hat{\xi})\hat{\xi},$$

where $\hat{\xi} = \xi/|\xi|$. It is a simple matter to check that the measures μ_0 and μ are chosen to be compatible with the coordinate mapping u_θ in the sense that if $\varphi \in S(\mathbf{R}^3)$, then

$$\int_{M_0} \varphi \circ u_\theta(k, \theta')\, d\mu_\theta(k, \theta') = \int_M \varphi \circ u_\theta(k, \theta')\, d\mu(k, \theta, \theta') = \int_{\mathbf{R}^3} \varphi(x)\, dx.$$

Especially, for φ as above,

$$\mathcal{F}_{M_0}^{-1}(\varphi \circ u_\theta) = \mathcal{F}_M^{-1}(\varphi \circ u_\theta) = \mathcal{F}^{-1}\varphi,$$

the usual inverse Fourier transform in $\mathbf{R}^3$.

By duality, the operators $\mathcal{F}_{M_0}^{-1}$ and $\mathcal{F}_M^{-1}$ are extended to the spaces of tempered distributions $S'(M_0)$ and $S'(M)$, i.e., if $\varphi \in S(\mathbf{R}^3)$ and $T \in S'(M)$, then

$$\langle \mathcal{F}_M^{-1}T, \varphi\rangle_{\mathbf{R}^3} = \langle T, \mathcal{F}^{-1}\varphi(k(\theta - \theta'))\rangle_M.$$

Before the next definition, which is central in the whole work, some comments are in order. The measures μ_θ and μ as well as their compatibility with the change of variables (1.11), (1.12) has been found by several authors (see, e.g., [10] and references therein). An interesting generalization of the measure μ in M has been given recently in [5].

DEFINITION 1.3. The linearized inverse scattering equations or inverse Born approximations of q are defined as

$$\tilde{q}_\theta(x) = \mathcal{F}_{M_0}^{-1}(A(k, \theta', \theta))(x), \qquad \tilde{q}(x) = \mathcal{F}_M^{-1}(A(k, \theta', \theta))(x)$$

interpreted in the sense of distributions, where A is given as in (1.8).

The distribution $\tilde{q}_\theta$ is considered as an approximate solution to the inverse scattering problem when $A(k, \theta', \theta)$ is known with θ fixed. Similarly, in $\tilde{q}$ it is assumed that the data consist of the whole of $A(k, \theta', \theta)$.

Note that by using (1.10), we can write the definitions of $\tilde{q}_\theta$ and $\tilde{q}$ as

$$\tilde{q}_\theta(x) = \frac{1}{32\pi^3}\int_0^\infty k^2\, dk \int_{S^2} |\theta - \theta'|^2\, e^{-ik(\theta-\theta')\cdot x}(A(k, \theta', \theta) + \overline{A(k, -\theta, -\theta')}),$$

$$\tilde{q}(x) = \frac{1}{64\pi^4}\operatorname{Re}\left(\int_0^\infty k^2\, dk \int_{S^2\times S^2} d\theta\, d\theta' |\theta - \theta'|^2\, e^{-ik(\theta-\theta')\cdot x}A(k, \theta', \theta)\right).$$

These representations show that in the Definition 1.3 we use only physical data, and moreover, $\tilde{q}$ is real.

The above definitions are by no means new. Heuristically, they can be arrived at in a number of different ways (cf. [15]). One very straightforward approach is to note that if the scattering potential q is weak, we have approximately

$$\psi^+(x, k, \theta) = e^{ik\theta\cdot x} + O(q) \approx e^{ik\theta\cdot x},$$

and consequently

$$A(k, \theta', \theta) \approx \int_{\mathbf{R}^3} e^{ik(\theta-\theta')\cdot x} q(x)\, dx = \mathcal{F}q(k(\theta-\theta')).$$

Hence a natural candidate to approximate a weak potential q is, with an appropriate choice of variables, the inverse Fourier transform of A, which is the contents of Definition 1.3.

The objective of this work is to establish certain connections between the approximate solutions given above and the true potential q. We start with a simple uniqueness result. While the result in itself is not very deep, as it turns out, the formulation of the proof contains a key observation of the later discussion.

PROPOSITION 1.4. *For potentials q satisfying* (1.2) *with $\delta > \frac{3}{2}$, the knowledge of $\tilde{q}_\theta$ with θ restricted to a one-dimensional semicircle, defines q uniquely.*

Proof. Writing the definition of $\tilde{q}_\theta$ together with formula (1.8) for the scattering amplitude A we get

$$\begin{aligned}\tilde{q}_\theta(x) &= \left(\frac{1}{2\pi}\right)^3 \int_{M_0} e^{-ik(\theta-\theta')\cdot x} A(k, \theta', \theta)\, d\mu_\theta(k, \theta') \\ &= \left(\frac{1}{2\pi}\right)^3 \int_{M_0} d\mu_\theta(k, \theta') \int_{\mathbf{R}^3} dy\, e^{-ik(\theta-\theta')\cdot(x-y)} q(y) v(y, k, \theta),\end{aligned}$$

where $v(y, k, \theta) = e^{-ik\theta\cdot y}\psi^+(y, k, \theta)$. After the change of variables (1.12), we have

$$\tilde{q}_\theta(x) = \left(\frac{1}{2\pi}\right)^3 \int_{\mathbf{R}^3} d\xi \int_{\mathbf{R}^3} dy\, e^{-i\xi\cdot(x-y)} q(y) v\left(y, \frac{|\xi|}{2\hat{\xi}\cdot\theta}, \theta\right). \tag{1.13}$$

Hence, the Fourier transform of $\tilde{q}_\theta$ is simply

$$\begin{aligned}\mathcal{F}\tilde{q}_\theta(\xi) &= \int_{\mathbf{R}^3} dy\, e^{i\xi\cdot y} q(y) v\left(y, \frac{|\xi|}{2\hat{\xi}\cdot\theta}, \theta\right) \\ &= \mathcal{F}q(\xi) + \int_{\mathbf{R}^3} dy\, e^{i\xi\cdot y} q(y)\left(v\left(y, \frac{|\xi|}{2\hat{\xi}\cdot\theta}, \theta\right) - 1\right).\end{aligned}$$

Note that by assumption (1.2), q is in L^1 and thus $\mathcal{F}q$ is continuous. By (1.7) and Proposition 1.2 we get for $\delta > \frac{1}{2}$

$$\|v - 1\|_{L^2_{-\delta}} = \|\mathcal{R}^+(k)(q\psi_0)\|_{L^2_{-\delta}} \leqq \frac{C}{|k|}\|q\|_{L^2_\delta}.$$

Thus, as $\hat{\xi}\cdot\theta$ approaches zero, we have

$$\begin{aligned}\left|\int_{\mathbf{R}^3} dy\, e^{i\xi\cdot y} q(y)\left(v\left(y, \frac{|\xi|}{2\hat{\xi}\cdot\theta}, \theta\right) - 1\right)\right| &\leqq \|q\|_{L^2_\delta}\left\|v\left(\cdot, \frac{|\xi|}{2\hat{\xi}\cdot\theta}, \theta\right) - 1\right\|_{L^2_{-\delta}} \\ &\leqq C\|q\|^2_{L^2_\delta}\frac{|2\hat{\xi}\cdot\theta|}{|\xi|} \to 0.\end{aligned}$$

But the data $\{\mathcal{F}q(\xi) \mid \hat{\xi} \cdot \theta = 0\}$, when θ runs through a semicircle, is enough for the complete recovery of q. □

It is not hard to see that the above theorem is simply a restatement of the well-known fact that the high-frequency limit of the scattering amplitude determines the potential uniquely (see, e.g., [13]). In fact, the band limited data $\{A(k, \theta', \theta) \mid \theta' \in S^2, |k| \leqq M\}$ determines $\mathcal{F}\tilde{q}_\theta$ only in the so-called Ewald spheres $\{\xi \mid |\xi \pm M\theta| \leqq M\}$ that touch the plane $\xi \cdot \theta = 0$ only at the origin, no matter how large M is. The important point, however, is (1.13). If we momentarily forget the q dependence of the function v, (1.13) says that $\tilde{q}_\theta$ is obtained from q by applying a pseudodifferential operator with the amplitude $v(y, |\xi|/2\hat{\xi} \cdot \theta, \theta)$ on q. Also, from the proof of Proposition 1.4, it is evident that the principal part of this symbol is 1. In the discussion that follows, we will use this observation.

From now on, we will state all the results for $\tilde{q}$ only. Most of the results remain valid for $\tilde{q}_\theta$, too. The approximation $\tilde{q}$ is chosen to make some formulas more symmetric.

In the sequel, the following notation will be used. Let $\mathcal{K}(k)$ denote the operator

$$\mathcal{K}(k)\varphi(x) = \int_{\mathbf{R}^3} |q(x)|^{1/2} G_k^+(x-y) q(y)^{1/2} \varphi(y)\, dy,$$

where G_k^+ is the kernel of the operator $\mathcal{R}_0^+(k)$, i.e.,

$$G_k^+(x) = -\frac{e^{ik|x|}}{4\pi|x|},$$

and in the commonly used way, $q(y)^{1/2} = \operatorname{sign} q(y)\, |q(y)|^{1/2}$. It is known by Proposition 1.2 that $\mathcal{K}(k)$ is a continuous mapping in L^2 with the norm estimate

$$\|\mathcal{K}(k)\| \leqq \frac{C}{|k|}$$

for large $|k|$. Moreover, $\mathcal{K}(k)$ is a Hilbert–Schmidt operator, since its kernel, also denoted by $\mathcal{K}$, satisfies

$$\|\mathcal{K}(k)\|_{\mathrm{HS}} = \left(\int_{\mathbf{R}^3} \int_{\mathbf{R}^3} |\mathcal{K}(x, y)|^2\, dx\, dy \right)^{1/2} = \frac{1}{4\pi} \left(\int_{\mathbf{R}^3} \int_{\mathbf{R}^3} \frac{|q(x)||q(y)|}{|x-y|^2}\, dx\, dy \right)^{1/2}$$

$$= \|q\|_{\mathrm{R}} < \infty,$$

$\|q\|_{\mathrm{R}}$ denoting the Rollnik norm of q. Further, let $\Phi_0(k)$ be the operator

$$\Phi_0(k) f(x) = |q(x)|^{1/2} \int_{S^2} e^{ik\theta \cdot x} f(\theta)\, d\theta,$$

and similarly, $\Phi(k)$ defined as

$$\Phi(k) f(x) = |q(x)|^{1/2} \int_{S^2} \psi^+(x, k, \theta) f(\theta)\, d\theta,$$

both defined for square integrable functions on S^2. The following theorem is similar to Theorem 1.2(ii) in [13].

THEOREM 1.5. *The operators $\Phi_0(k)$ and $\Phi(k)$ are continuous operators from $L^2(S^2)$ to $L^2(\mathbf{R}^3)$ with norm bounded by $C/|k|$ as $|k|$ is large.*

Theorem 1.5 is a straightforward consequence of the following lemma, which is a version of the well-known optical theorem. For completeness, we include a simple proof of it, following the lines of [12].

LEMMA 1.6. *Assume that q is a potential satisfying* (1.2) *and f belongs to $S(\mathbf{R}^3)$. Then the function $v = \mathcal{R}^+(k)f$ solves the nonhomogenous Schrödinger equation*

$$(-\Delta + q - k^2)v = f \tag{1.14}$$

with the outgoing radiation condition at infinity, i.e.,

$$v(x, k) = \frac{e^{ik|x|}}{4\pi|x|} A_f(k, \hat{x}) + h(x, k), \qquad h(x, k) = o\left(\frac{1}{|x|}\right).$$

Furthermore, for the far-field pattern $A_f(k, \hat{x})$ we have

$$\int_{S^2} |A_f(k, \hat{x})|^2 \, d\hat{x} = -\frac{4\pi}{k} \operatorname{Im} \int_{\mathbf{R}^3} v(x, k)\overline{f(x)} \, dx.$$

Proof. Equation (1.14) follows trivially from the definition of v. To verify the asymptotic behavior of this solution at infinity, we employ the resolvent equation

$$\mathcal{R}^+(k) = \mathcal{R}_0^+(k) - \mathcal{R}_0^+(k)q\mathcal{R}^+(k),$$

proved in [1]. Since $f \in S(\mathbf{R}^3)$, we then have, by the estimates given in [7],

$$\begin{aligned}\mathcal{R}^+(k)f(x) &= \mathcal{R}_0^+(k)(f - q\mathcal{R}^+(k)f)(x) \\ &= \frac{e^{ik|x|}}{4\pi|x|} \int_{\mathbf{R}^3} e^{-ik\hat{x}\cdot y}(f(y) - q(y)\mathcal{R}^+(k)f(y)) \, dy + o\left(\frac{1}{|x|}\right),\end{aligned}$$

since $\mathcal{R}^+(k)f$ is bounded. Hence, v has the claimed asymptotic form at infinity.

Let ρ be a smooth cutoff function on $[0, \infty)$, i.e., $0 \leqq \rho \leqq 1$, $\rho(r) = 1$ as $0 \leqq r < 1$ and $\rho(r) = 0$ as $r \geqq 2$. We set $\rho_n(r) = \rho(r/n)$, for integers n. By multiplying (1.14) with $\overline{v(x)}\rho_n(|x|)$, integrating over $\mathbf{R}^3$ and taking imaginary parts, we get

$$\operatorname{Im} \int_{\mathbf{R}^3} \rho_n(|x|)f(x)\overline{v(x, k)} \, dx = \operatorname{Im} \int_{\mathbf{R}^3} -\Delta v(x, k)\rho_n(|x|)\overline{v(x, k)} \, dx.$$

As n tends to infinity, the left-hand side converges to $\int f(x)\overline{v(x, k)} \, dx$. To get the desired limit for the right-hand side, we integrate by parts to get

$$\begin{aligned}&\operatorname{Im} \int_{\mathbf{R}^3} -\Delta v(x, k)\rho_n(|x|)\overline{v(x)} \, dx \\ &= \operatorname{Im} \int_{\mathbf{R}^3} \hat{x} \cdot \nabla v(x, k)\rho_n'(|x|)\overline{v(x, k)} \, dx \\ &= \operatorname{Im} \int_{\mathbf{R}^3} (\hat{x} \cdot \nabla v(x, k) - ikv(x, k))\rho_n'(|x|)\overline{v(x, k)} \, dx + k \int_{\mathbf{R}^3} \rho_n'(|x|)|v(x, k)|^2 \, dx.\end{aligned}$$

Since v satisfies the Sommerfeld radiation condition (see [7] and references therein), the first term tends to zero, whereas the second term is

$$\begin{aligned}k \int_{\mathbf{R}^3} \rho_n'(|x|)|v(x, k)|^2 \, dx &= \frac{k}{(4\pi)^2} \int_{S^2} |A_f(k, \hat{x})|^2 \, d\hat{x} \int_n^{2n} \rho_n'(r) \, dr + o(1) \\ &= k/(4\pi)^2 \int_{S^2} |A_f(k, \hat{x})|^2 \, dx(\rho(2) - \rho(1)) + o(1),\end{aligned}$$

yielding the claim. □

To obtain the result in Theorem 1.5, let $\mathcal{A}_q(k)$ denote the linear mapping that takes the inhomogeneity f to the corresponding scattering amplitude, i.e.,

$$\mathcal{A}_q(k): f(x) \mapsto A_f(k, \hat{x}).$$

By Lemma 1.6, we have

$$\|\mathcal{A}_q(k)f\|^2_{L^2(S^2)} \leqq \frac{C}{|k|}\|v\|_{L^2_{-\delta}}\|f\|_{L^2_\delta} \leqq \frac{C}{|k|^2}\|f\|^2_{L^2_\delta},$$

so the operator $\mathcal{A}_q(k)$ extends continuously to the space L^2_δ. From the proof of Lemma 1.6 we can also read off the integral kernel of the operator $\mathcal{A}_q(k)$. Indeed, for $k>0$,

$$\begin{aligned}\mathcal{A}_q(k)f(\hat{x}) &= \int_{\mathbf{R}^3} e^{-ik\hat{x}\cdot y}(f(y) - q(y)\mathcal{R}^+(k)f(y))\,dy \\ &= \langle \psi_0(\cdot, k, \hat{x}), f - q\mathcal{R}^+(k)f\rangle \\ &= \langle \psi^-(\cdot, k, \hat{x}), f\rangle \\ &= \int_{\mathbf{R}^3} \psi^+(y, k, -\hat{x})f(y)\,dy,\end{aligned}$$

the last equality following from (1.9). By a density argument, this holds for all $f \in L^2_\delta$. Thus, if we denote by $\mathcal{A}_q(k)^t: L^2(S^2) \to L^2_{-\delta}(\mathbf{R}^3)$ the transpose of $\mathcal{A}_q(k)$, and by $Q: L^2(S^2) \to L^2(S^2)$ the operator $Qf(\hat{x}) = f(-\hat{x})$, we obtain

$$\Phi(k): L^2(S^2) \xrightarrow{\mathcal{A}_q(k)^t Q} L^2_{-\delta}(\mathbf{R}^3) \xrightarrow{|q|^{1/2}} L^2(\mathbf{R}^3),$$

with the norm estimate as claimed. The negative values of k are treated in the same way. Similarly,

$$\Phi_0(k) = |q|^{1/2}\mathcal{A}_0(k)^t Q.$$

Later we will use the notation

$$\tilde{\Phi}_0(k) = Q\mathcal{A}_0(k)q^{1/2} = \Phi_0(k)^t \operatorname{sign} q: L^2(\mathbf{R}^3) \to L^2(S^2).$$

Consider next the Lippmann–Schwinger equation (1.6), which after n iterations gives

$$\psi^+ = \sum_{j=0}^{n} (\mathcal{R}_0^+(k)q)^j\psi_0 + (\mathcal{R}_0^+(k)q)^{n+1}\psi^+.$$

Substituting this expression into the integral (1.14) defining the scattering amplitude $A(k, \theta', \theta)$ we get

$$\begin{aligned}A(k, \theta', \theta) = \sum_{j=0}^{n} &\int_{\mathbf{R}^3} e^{-ik\theta'\cdot y} q(y)(\mathcal{R}_0^+(k)q)^j\psi_0(y, k, \theta)\,dy \\ &+ \int_{\mathbf{R}^3} e^{-ik\theta'\cdot y} q(y)(\mathcal{R}_0^+(k)q)^{n+1}\psi^+(y, k, \theta)\,dy,\end{aligned}$$

or, interpreting A as an operator from $L^2(S^2)$ to itself with each $k \neq 0$ fixed, we get

$$A = \sum_{j=0}^{n} \tilde{\Phi}_0\mathcal{K}^j\Phi_0 + \tilde{\Phi}_0\mathcal{K}^{n+1}\Phi.$$

For brevity, the k dependence of the operators is suppressed. Hence, with some abuse of notation, we can write

$$\tilde{q} = \sum_{j=0}^{n} \mathcal{F}_M^{-1}\tilde{\Phi}_0\mathcal{K}^j\Phi_0 + \mathcal{F}_M^{-1}\tilde{\Phi}_0\mathcal{K}^{n+1}\Phi. \tag{1.15}$$

Above, $\tilde{\Phi}_0\mathcal{K}^j\Phi_0$ and $\tilde{\Phi}_0\mathcal{K}^{n+1}\Phi$ denote the kernels of the corresponding operators, and $\mathcal{F}_M^{-1}$ acts on this function of k, θ, and θ'. The following lemma gives estimates of the smoothness of the various terms in (1.15).

LEMMA 1.7. *Assume that q belongs to Λ_δ^s with $\delta > \frac{3}{2}$ and $s > 0$. (In the case $s = 0$ we assume that q is in the class L_δ^∞.) Then, for $j \geqq 1$, $\mathcal{F}_M^{-1}\tilde{\Phi}_0\mathcal{K}^j\Phi_0$ and $\mathcal{F}_M^{-1}\tilde{\Phi}_0\mathcal{K}^j\Phi$ are in the Sobolev space H^t for all $t < s + j - \frac{1}{2}$.*

Proof. We start with the elementary case when $w_\delta q$ is bounded. By using the change of variables (1.14), we get with $0 \leqq t < j - \frac{1}{2}$.

$$
\begin{aligned}
&\|(1+|\xi|^2)^{t/2}\mathcal{F}(\mathcal{F}_M^{-1}\tilde{\Phi}_0\mathcal{K}^j\Phi_0)(\xi)\|_{L^2(\mathbf{R}^3)}^2 \\
&\quad = \frac{1}{4\pi}\int_{\mathbf{R}^3}(1+|\xi|^2)^t \left|\int_{S^2}\tilde{\Phi}_0\mathcal{K}^j\Phi_0\left(\frac{|\xi|}{2\hat{\xi}\cdot\theta}, \theta - 2(\hat{\xi}\cdot\theta)\hat{\xi}, \theta\right) d\theta\right|^2 d\xi \\
&\quad \leqq \int_{\mathbf{R}^3}(1+|\xi|^2)^t \int_{S^2}\left|\tilde{\Phi}_0\mathcal{K}^j\Phi_0\left(\frac{|\xi|}{2\hat{\xi}\cdot\theta}, \theta - 2(\hat{\xi}\cdot\theta)\hat{\xi}, \theta\right)\right|^2 d\theta\, d\xi \qquad (1.16) \\
&\quad = 4\pi\int_M d\mu(k,\theta',\theta)(1+|k(\theta-\theta')|^2)^t|\tilde{\Phi}_0\mathcal{K}^j\Phi_0(k,\theta',\theta)|^2 \\
&\quad \leqq C\int_{-\infty}^{\infty} dk\, k^2(1+|k|^2)^t \int_{S^2} d\theta' \int_{S^2} d\theta|\tilde{\Phi}_0\mathcal{K}^j\Phi_0(k,\theta',\theta)|^2.
\end{aligned}
$$

Hence, it suffices to find an appropriately strongly converging bound for the Hilbert-Schmidt norm of the operator $\tilde{\Phi}_0\mathcal{K}^j\Phi_0$, as $|k|$ grows. But the class of Hilbert-Schmidt operators is a norm ideal, so by Proposition 1.5 and remarks before it we have the estimate

$$
\|\tilde{\Phi}_0\mathcal{K}^j\Phi_0\|_{\mathrm{HS}} \leqq \|\tilde{\Phi}_0\|\,\|\mathcal{K}\|_{\mathrm{HS}}\|\mathcal{K}\|^{j-1}\|\Phi_0\| \leqq \frac{C}{|k|^{j+1}}
$$

for large $|k|$. Especially, the integral (1.16) converges.

Next, assume that $w_\delta q$ belongs to C^k with $k > 0$ an integer. Then, by the particular form of the weight function w_δ,

$$
w_\delta|D^\alpha q| \in L^\infty \quad \text{for } 0 \leqq |\alpha| \leqq k. \qquad (1.17)
$$

To show that $\mathcal{F}_M^{-1}\tilde{\Phi}_0\mathcal{K}^j\Phi_0$ is in H^t for $t < k + j - \frac{1}{2}$ it is obviously sufficient to prove that $D^\alpha\mathcal{F}_M^{-1}\tilde{\Phi}_0\mathcal{K}^j\Phi_0$ which obviously equals to $\mathcal{F}_M^{-1}((k(\theta-\theta'))^\alpha\tilde{\Phi}_0\mathcal{K}^j\Phi_0)$ belongs to H^t, when $t < k - \frac{1}{2}$ and $0 \leqq |\alpha| \leqq j$. By writing $\tilde{\Phi}_0\mathcal{K}^j\Phi_0(k,\theta',\theta)$ explicitly as

$$
\begin{aligned}
\tilde{\Phi}_0\mathcal{K}^j\Phi_0 = \int_{\mathbf{R}^3} dx_1 \int_{\mathbf{R}^3} dx_2 \cdots \int_{\mathbf{R}^3} dx_{j+1}\, e^{-ik\theta'\cdot x_1} q(x_1) \\
\cdot G_k^+(x_1 - x_2)q(x_2)\cdots G_k^+(x_j - x_{j+1})q(x_{j+1})\, e^{ik\theta\cdot x_{j+1}}
\end{aligned}
$$

it is not hard to see that by successive integrations by parts we have

$$
\begin{aligned}
&(k(\theta-\theta'))^\alpha\tilde{\Phi}_0\mathcal{K}^j\Phi_0(k,\theta',\theta) \\
&\quad = \sum_{\alpha_1+\cdots+\alpha_{j+1}=\alpha}(-i)^{|\alpha|}\int_{\mathbf{R}^3} dx_1\cdots\int_{\mathbf{R}^3} dx_{j+1}\, e^{-ik\theta'\cdot x_1} D^{\alpha_1}q(x_1) \\
&\qquad \cdot G_k^+(x_1 - x_2)\cdots G_k(x_j - x_{j+1})D^{\alpha_{j+1}}q(x_{j+1})\, e^{ik\theta\cdot x_{j+1}}.
\end{aligned}
$$

By defining the operators $\Phi_{o,\alpha}$ and $\mathscr{K}_{\alpha,\beta}$ by the formulas

$$\Phi_{o,\alpha} f(x) = |D^\alpha q(x)|^{1/2} \int_{S^2} e^{ik\theta\cdot x} f(\theta)\, d\theta,$$

$$\mathscr{K}_{\alpha,\beta}\varphi(x) = \int_{\mathbf{R}^3} |D^\alpha q(x)|^{1/2} G_k^+(x-y)(D^\beta q(y))^{1/2}\varphi(y)\, dy,$$

we can write the above formula as

$$(k(\theta-\theta'))^\alpha \tilde{\Phi}_0 \mathscr{K}^j \Phi_0(k,\theta',\theta) = \sum_{(-i)^{|\alpha|}\alpha_1+\cdots+\alpha_{j+1}=\alpha} \tilde{\Phi}_{0,\alpha_1}\mathscr{K}_{\alpha_1,\alpha_2}\cdots\mathscr{K}_{\alpha_j,\alpha_{j+1}}\Phi_{0,\alpha_{j+1}}.$$

The same reasoning as in the first step, together with (1.17), now gives an appropriate estimate for the Hilbert–Schmidt norm of this operator and hence for the Sobolev norm.

Consider now the general case $w_\delta q \in \Lambda^s$, $s>0$. Denote by F_{j+1} the multilinear mapping defined as

$$\begin{aligned} &F_{j+1}(w_\delta q_1, w_\delta q_2, \cdots, w_\delta q_{j+1})(x) \\ &\quad = \int_M d\mu(k,\theta',\theta)\, e^{-ik(\theta-\theta')\cdot x} \int_{\mathbf{R}^3} dx_1 \int_{\mathbf{R}^3} dx_2 \cdots \int_{\mathbf{R}^3} dx_{j+1} \\ &\qquad \cdot e^{-ik\theta'\cdot x_1} q_1(x_1) G_k^+(x_1-x_2) q_2(x_2)\cdots G_k^+(x_j-x_{j+1}) q_{j+1}(x_{j+1})\, e^{ik\theta\cdot x_{j+1}}. \end{aligned}$$

This mapping is, by the same argument as above, a continuous mapping

$$F_{j+1}: \prod_{i=1}^{j+1} C^k \to H^{t_k}$$

for all integers $k \geqq 0$ and reals $t_k < k+j-\frac{1}{2}$. Assume that $0<t=s+j-\frac{1}{2}-\varepsilon$ for some $\varepsilon>0$. We shall choose integers k_0 and k_1 so that $0 \leqq k_0 < s < k_1$, and a parameter δ satisfying $0<\delta<\min(\varepsilon, s-k_0)$. Further, let θ be an interpolation parameter, $0<\theta<1$, with the property that $(1-\theta)k_0+\theta k_1 = s-\delta$. Since $\delta<\varepsilon$, we then have $t_n = k_n+j-\frac{1}{2}-(\varepsilon-\delta) < k_n+j-\frac{1}{2}$, where $n=0,1$. By the choice of θ, $(1-\theta)t_0+\theta t_1 = t$. Hence, invoking the multilinear complex interpolation theorem (see, e.g., [3]), we get for $(w_\delta q_1, w_\delta q_2, \cdots, w_\delta q_{j+1}) \in \prod \Lambda^s$ the estimate

$$\begin{aligned} \|F_{j+1}(w_\delta q_1, w_\delta q_2, \cdots, w_\delta q_{j+1})\|_{H^t} &= \|F_{j+1}(w_\delta q_1, w_\delta q_2, \cdots, w_\delta q_{j+1})\|_{[H^{t_0}, H^{t_1}]_\theta} \\ &\leqq C \prod_{i=1}^{j+1} \|w_\delta q_i\|_{[C^{k_0}, C^{k_1}]_\theta} \leqq C \prod_{i=1}^{j+1} \|w_\delta q_i\|_{\Lambda^s}. \end{aligned}$$

The last inequality follows from Theorem 1.1. Choosing $q_1 = q_2 = \cdots = q_{j+1} = q$ we get the desired result.

Finally, we have to establish the smoothness estimate for the residual term $\tilde{\Phi}_0 \mathscr{K}^{n+1}\Phi$. Obviously, as $s=0$, the same argument as in the first step above applies to this term too, so we have $\tilde{\Phi}_0\mathscr{K}^{n+1}\Phi \in H^t$ for $t<n+\frac{1}{2}$. The case $s>0$ can now be treated by writing

$$\mathscr{F}_M^{-1}\tilde{\Phi}_0\mathscr{K}^{n+1}\Phi = \sum_{j=n+2}^{N} \mathscr{F}_M^{-1}\tilde{\Phi}_0\mathscr{K}^j\Phi_0 + \mathscr{F}_M^{-1}\tilde{\Phi}_0\mathscr{K}^{N+1}\Phi$$

and choosing N large enough, say $N \leqq n+[s]+1$. □

Now consider the first term in expansion (1.16). We have

$$\mathscr{F}_M^{-1}\tilde{\Phi}_0\Phi_0 = \mathscr{F}_M^{-1}\left(\int_{\mathbf{R}^3} e^{ik(\theta-\theta')\cdot y} q(y)\, dy\right)(x) = q(x).$$

Hence, we have proved the following asymptotic series expansion for $\tilde{q}$.

THEOREM 1.8. *Let q satisfy the assumption of the previous lemma. The linearized approximation $\tilde{q}$ of q admits the asymptotic expansion*

$$\tilde{q} \sim q + \sum_{j=1}^{\infty} \mathscr{F}_M \tilde{\Phi}_0 \mathscr{K}^j \Phi_0,$$

where the asymptotic equivalence $\sim$ is to be understood in the sense of

$$\tilde{q} - q - \sum_{j=1}^{n} \mathscr{F}_M^{-1} \tilde{\Phi}_0 \mathscr{K}^j \Phi_0 \in H^t, \qquad t < s + n + \frac{1}{2}.$$

The importance of this result is, of course, in the fact that we are able to analyse how the singularities of q affect the degree of singularity of $\tilde{q}$. The first nonlinear term $q_1(x) = \mathscr{F}_M \tilde{\Phi}_0 \mathscr{K} \Phi_0(x)$ in the above expansion will be studied separately in the next section. It will be proved, among other things, that q_1 belongs to the space Λ^1 if the true potential q is in L^∞_δ for $\delta > \frac{3}{2}$. The proof is based on the explicit form of the term q_1. However, it is possible, by using the mapping properties of the operators discussed in this section, to establish a counterpart of this result to the higher-order terms, too. In the following theorem we use the notation

$$q_j = \mathscr{F}_M^{-1} \tilde{\Phi}_0 \mathscr{K}^j \Phi_0.$$

THEOREM 1.9. *If $\delta > \frac{3}{2}$ and $q \in L^\infty_\delta$ then q_j belongs to the Lipschitz class* Lip_1 *for $j > 2$ and q_2 belongs to* $\mathrm{Lip}_s = \Lambda^s$ *for all s, $0 < s < 1$.*

Proof. For x_1, x_2 in $\mathbf{R}^3$ we have

$$\begin{aligned} q_j(x_1) - q_j(x_2) &= \frac{1}{16\pi^3} \int_{-\infty}^{\infty} k^2\, dk \int d\theta \int d\theta' (1 - \theta \cdot \theta') \tilde{\Phi}_0 \mathscr{K}^j \Phi_0(k, \theta', \theta) \\ &\qquad \cdot (e^{-ik(\theta - \theta') \cdot x_1} - e^{-ik(\theta - \theta') \cdot x_2}) \\ &= \frac{1}{16\pi^3} \int_{-\infty}^{\infty} k^2\, dk ((e_{x_1}, \tilde{\Phi}_0 \mathscr{K}^j \Phi_0\, e_{x_1})_{L^2(S^2)} - (e_{x_2}, \tilde{\Phi}_0 \mathscr{K}^j \Phi_0\, e_{x_2})_{L^2(S^2)} \\ &\qquad - (E_{x_1}, \tilde{\Phi}_0 \mathscr{K}^j \Phi_0 E_{x_1})_{L^2(S^2)} + (E_{x_2}, \tilde{\Phi}_0 \mathscr{K}^j \Phi_0 E_{x_2})_{L^2(S^2)}). \end{aligned}$$

Here, $e_{x_j} = e^{ik\theta \cdot x_j} \in L^2(S^2)$ and $E_{x_j} = \theta\, e_{x_j} \in (L^2(S^2))^3$, the space of vector-valued L^2 functions. The inner products in these spaces are both denoted by $(\cdot, \cdot)_{L^2(S^2)}$. Because $\|E_{x_1} - E_{x_2}\|_{L^2(S^2)} = \|e_{x_1} - e_{x_2}\|_{L^2(S^2)}$ and $\|e_{x_j}\|_{L^2(S^2)} = 4\pi$, we obtain the estimate

$$|q_j(x_1) - q_j(x_2)| \leqq \frac{1}{\pi^2} \int_{-\infty}^{\infty} k^2\, dk \|e_{x_1} - e_{x_2}\|_{L^2(S^2)} \|\tilde{\Phi}_0 \mathscr{K}^j \Phi_0\|.$$

But according to Theorem 1.5 and Proposition 1.2,

$$\|\tilde{\Phi}_0 \mathscr{K}^j \Phi_0\| \leqq \frac{C}{1 + |k|^{j+2}}$$

and on the other hand,

$$\begin{aligned} \|e_{x_1} - e_{x_2}\|^2_{L^2(S^2)} &= 2 \int_{S^2} (1 - e^{ik\theta \cdot (x_1 - x_2)})\, d\theta \\ &= 8\pi (1 - j_0(|k(x_1 - x_2)|). \end{aligned}$$

Thus, by denoting $r = |x_1 - x_2|$, we need an estimate for the integral

$$\int_0^\infty \frac{k^2}{1 + k^{j+2}} \left(1 - \frac{\sin kr}{kr}\right)^{1/2} dk.$$

We split this integral into two parts and estimate the first as

$$\int_{1/r}^{\infty} \frac{k^2}{1+k^{j+2}} \left(1-\frac{\sin kr}{kr}\right)^{1/2} dk \leqq \int_{1/r}^{\infty} \frac{k^2}{1+k^{j+2}}\, dk \leqq Cr^{j-1}.$$

For the remaining part of the integral we get for $j>2$

$$\int_{0}^{1/r} \frac{k^2}{1+k^{j+2}} \left(1-\frac{\sin kr}{kr}\right)^{1/2} dk \leqq r \int_{0}^{1/r} \frac{k^3}{1+k^{j+2}}\, dk \leqq Cr,$$

proving the first claim in the theorem. For $j=2$ we get

$$r \int_{0}^{1/r} \frac{k^3}{1+k^4}\, dk \leqq Cr \log\left(\frac{1}{r}\right) \leqq Cr^s$$

for $0<s<1$. Hence the proof is complete if we can show that $q_j \in L^\infty$. But this is obvious, since

$$|q_j(x)| \leqq C \int_0^{\infty} \frac{k^2}{1+k^{j+2}} \left(\|e_x\|_{L^2(S^2)} + \|E_x\|_{L^2(S^2)}\right) dk \leqq C < \infty. \qquad \square$$

Remark 1.10. It is not hard to see that the argument of Lemma 1.7 holds for potentials with the asymptotic behavior $q(x)=\mathcal{O}(|x|^{-2-\varepsilon})$ at infinity. Also, Theorem 1.5 remains valid (see [12]]). Only the asymptotic behaviour of the solution ψ^+ as x goes to infinity should be interpreted in the $L^2(S^2)$ sense, causing some notational changes in the above analysis.

2. Analysis of the first nonlinear term. In this section it is shown that the smoothness estimates obtained in the previous section are not the best possible. Since the terms in the asymptotic expansion of $\tilde{q}$ contain only the potential and simple, analytically known functions, we can try to write them in a more explicit form to refine the analysis of the degree of smoothness. We shall carry out this kind of analysis for the first nonlinear term here.

THEOREM 2.1. *The first nonlinear term admits the integral representation*

$$q_1(x) = \mathcal{F}_M^{-1} \tilde{\Phi}_0 \mathcal{K} \Phi_0(x) = -\frac{1}{2} \left| \frac{1}{4\pi} \int_{\mathbf{R}^3} \frac{x-y}{|x-y|^3}\, q(y)\, dy \right|^2.$$

The proof of this result is a straightforward calculation, and we postpone it to Appendix B.

To estimate the smoothness of q_1 we will prove the following result.

LEMMA 2.2. *For $\delta>1$ the operators*

$$T_j u(x) = \int \frac{(x-y)_j}{|x-y|^3}\, u(y)\, dy, \qquad j=1,2,3,$$

map $L^\infty_\delta(\mathbf{R}^3)$ to Λ^1.

Proof. We will employ the *Riesz transform* R_j, *Riesz potential* I_s, and *Bessel potential* J_s defined as

$$R_j f(x) = \mathcal{F}^{-1}\left(\frac{\xi_j}{|\xi|}\hat{f}\right)(x), \qquad i=1,2,3,$$

$$I_s f(x) = \mathcal{F}^{-1}(|\xi|^s \hat{f})(x),$$

$$J_s f(x) = \mathcal{F}^{-1}((1+|\xi|^2)^{s/2}\hat{f})(x).$$

Here $\hat{f}$ is the Fourier transform of the function f. It is well known that $J_\sigma : \Lambda^s \to \Lambda^{s-\sigma}$ is an isomorphism for all real values of s and σ (see [16] and [18]). On the other hand, the Riesz transforms are bounded operators in Λ^s. Observing that $\mathcal{F}(x_j/|x|^3) = c\xi_j/|\xi|^2$ for some constant c, we see that in fact

$$T_j f = R_j I_{-1}.$$

Thus we have to show only that I_{-1} maps L^∞_δ to Λ^1. To do so, let φ be a compactly supported C^∞ function in $\mathbf{R}^3$, $\varphi(\xi) = 1$ in some neighborhood of the origin, and let

$$m_1(\xi) = \frac{\varphi(\xi)}{|\xi|}, \qquad m_2(\xi) = \frac{1-\varphi(\xi)}{|\xi|}.$$

If $f \in L^\infty_\delta \subset L^2$, we have $\hat{f} \in L^2$ and, consequently, $m_1 \hat{f} \in L^1$ implying especially that m_1 defines a continuous operator

$$T_{m_1} : f \mapsto \mathcal{F}^{-1}(m_1 \hat{f}), \qquad T_{m_1} : L^\infty_\delta \to L^\infty.$$

On the other hand, since

$$\mathcal{F}(D_j T_{m_1} f)(\xi) = \frac{\xi_j}{|\xi|}\varphi(\xi)\hat{f}(\xi),$$

we see that $D_j T_{m_1} f \in L^\infty$ as well, so that

$$T_{m_1} : L^\infty_\delta \to \Lambda^1$$

continuously. It remains to prove that m_2 also defines a continuous mapping,

$$T_{m_2} : f \mapsto \mathcal{F}^{-1}(m_2 \hat{f}), \qquad T_{m_2} : L^\infty_\delta \to \Lambda^1.$$

In fact, a slightly stronger result can be obtained, namely

$$T_{m_2} : \Lambda^s \to \Lambda^{s+1}$$

for all real values of s. Since $L^\infty_\delta \subset \Lambda^0$ as is shown in Appendix A, this is clearly more than enough. But since J_1 maps Λ^{s+1} to Λ^s, it remains to be shown that

$$\left\| \mathcal{F}^{-1}\left(\frac{(1+|\xi|^2)^{1/2}}{|\xi|}(1-\varphi(\xi))\hat{f}(\xi) \right) \right\|_{\Lambda^s} \leqq C \|f\|_{\Lambda^s}.$$

But this follows from the Mikhlin type of multiplier theorem (Theorem A3 in Appendix A). □

By the pointwise multiplier theorem (Proposition A2) we obtain immediately an estimate of smoothness for q_1 that is clearly better than the one obtained from Lemma 1.7.

COROLLARY 2.3. *If the potential q satisfies $w_\delta q \in L^\infty$, then*

$$q_1 \in H^t \cap \Lambda^1$$

for all t, $0 < t < 1$.

Finally, we combine the results from Theorems 1.8 and 1.9 with Corollary 2.3.

THEOREM 2.4. *For potentials belonging to the space L^∞_δ,*

$$q - \tilde{q} \in \Lambda^s$$

for every s, $0 < s < 1$.

Proof. Since

$$q - \tilde{q} = \sum_{j=1}^{n} q_j + q_n^r,$$

where q_n^r is in the Sobolev space $H^{n+(1/2)-\varepsilon}$, the claim follows from the Sobolev embedding theorem, if we choose n large enough. □

Appendix A. We start this Appendix by defining some classical, "constructive" function spaces. Let k be an integer, $k \geqq 0$. By $C^k = C^k(\mathbf{R}^3)$ we denote the classical Hölder space of k times continuously differentiable fucntions, endowed with the norm

$$\|f\|_{C^k} = \sup_x \sum_{|\alpha| \leqq k} |D^\alpha f(x)|.$$

There are several candidates to extend the definition above to noninteger values by using various moduli of continuity. A useful scale of function spaces is obtained in the following way: Let $s = k + t$, where k is an integer, $0 \leqq k < s$ and $0 < t \leqq 1$. Then f belongs to the classical Zygmund space Λ^s, if

$$\|f\|_{\Lambda^s} := \|f\|_{L^\infty} + \sum_{|\alpha| \leqq k} \sup_{x,h} \frac{|D^\alpha f(x+h) - 2D^\alpha f(y) + D^\alpha f(x-h)|}{|h|^t} < \infty.$$

In general, the symmetric difference cannot be replaced by a simple difference in the above definition. However, when $0 < s < 1$, we have $\Lambda^s = \mathrm{Lip}_s$ with equivalent norms, where the Lipschitz class Lip_s, $0 < s \leqq 1$ is characterized by the condition

$$\|f\|_{\mathrm{Lip}_s} := \|f\|_{L^\infty} + \sup_{x,h} \frac{|f(x+h) - f(x)|}{|h|^s} < \infty.$$

It turns out that for $s = 1$, the space Λ^1 is strictly larger than Lip_1. Similarly, for integer values of s, the space Λ^s is strictly larger than the corresponding Hölder space C^s. Next, we want to extend the definition of Λ^s for values $s \leqq 0$. Similarly to the usual Sobolev space scale, this is accomplished through Fourier analysis. We define first a smooth dyadic partition of unity in the following way: Let φ and φ_0 be C^∞ functions in $\mathbf{R}^3$, $0 \leqq \varphi, \varphi_0 \leqq 1$ such that $\mathrm{supp}\, \varphi = \{\xi \mid \frac{1}{2} \leqq |\xi| \leqq 2\}$ and $\mathrm{supp}\, \varphi_0 = \{\xi \mid |\xi| \leqq 1\}$. Furthermore, assume that the functions are scaled so that

$$\sum_{k=0}^{\infty} \varphi_k(\xi) = 1 \quad \text{for all } \xi \in \mathbf{R}^3,$$

where $\varphi_k(\xi) = \varphi(2^{k-1}\xi)$, $k = 1, 2, 3, \cdots$. Now, by definition, a function f belongs to the Besov space $B^s_{p,q} = B^s_{p,q}(\mathbf{R}^3)$, $0 \leqq p, q \leqq \infty$ and $-\infty < s < \infty$, if

$$\left(\sum_{k=0}^{\infty} (2^{ks} \|\mathscr{F}^{-1}(\varphi_k \hat{f})\|_{L^p})^q \right)^{1/q} < \infty.$$

(If $q = \infty$, the sum is to be replaced by the supremum.) It can be shown that the definition of the Besov spaces is independent of the specific choice of the resolution of unity $\{\varphi_k\}_{k=0}^\infty$ (see [3], [17], [18].) The important tool for us is the following.

PROPOSITION A1. *For $s > 0$,*

$$B^s_{\infty,\infty} = \Lambda^s$$

with equivalent norms.

Therefore, we can define $\Lambda^s = B^s_{\infty,\infty}$ for all s, $-\infty < s < \infty$. It should be noted that the space $B^0_{\infty,\infty}$ is strictly larger than L^∞. The inclusion $L^\infty \subset B^0_{\infty,\infty}$ is simple to verify. If $f \in L^\infty$, then

$$\|\mathscr{F}^{-1}(\varphi_k \hat{f})\|_{L^\infty} = \|\mathscr{F}^{-1}\varphi_k * f\|_{L^\infty} \leqq \|\mathscr{F}^{-1}\varphi_k\|_{L^1} \|f\|_{L^\infty} = C\|f\|_{L^\infty},$$

the constant C being independent of k.

Especially, it follows that for $\delta > 0$,

$$L^\infty_\delta \subset L^\infty \subset \Lambda^0.$$

The Besov spaces are known to have several multiplication properties. The following ones are used in § 2.

PROPOSITION A2. (a) *Let $0 \leqq t < s$. Then, for every $f \in H^t$ and $h \in \Lambda^s$, $hf \in H^t$, and*

$$\|hf\|_{H^t} \leqq C\|h\|_{\Lambda^s}\|f\|_{H^t}.$$

(b) *For $s > 0$ the space Λ^s is a multiplication algebra, i.e., if $h, f \in \Lambda^s$, then $hf \in \Lambda^s$ with the estimate*

$$\|hf\|_{\Lambda^s} \leqq C\|h\|_{\Lambda^s}\|f\|_{\Lambda^s}.$$

Part (a) of the above proposition is a special case of Theorem 2.4.2 of [18]; part (b) follows from Theorem 2.8.3 of the same work. One important property of the Besov spaces is that the Mikhlin–Hörmander type of Fourier multiplier theorem is valid. The following proposition is, again, a special case of the more general result proved in [18, Thm. 2.3.7].

PROPOSITION A3. *Assume that m is a C^∞ function in $\mathbf{R}^3$ satisfying for some integer N large enough the estimate*

$$|D^\alpha m(\xi)| \leqq C_\alpha (1+|\xi|^2)^{-|\alpha|/2}, \qquad 0 \leqq |\alpha| \leqq N.$$

Then, for $f \in \Lambda^s$, $-\infty < s < \infty$, there is a constant $C > 0$ depending only on the constants C_α such that for all $f \in \Lambda^s$,

$$\|\mathscr{F}^{-1}(m\hat{f})\|_{\Lambda^s} \leqq C\|f\|_{\Lambda^s}.$$

Finally, we close this Appendix by proving Theorem 1.1.

Proof of Theorem 1.1. It is well known (see [17, p. 201]) that the Zygmund spaces are obtained from the Hölder spaces by the real interpolation method as

$$(C^{k_0}, C^{k_1})_{\theta,\infty} = \Lambda^s, \qquad s = (1-\theta)k_0 + \theta k_1.$$

On the other hand, by the extremal property of the real interpolation method,

$$(C^{k_0}, C^{k_1})_{\theta,1} \subset [C^{k_0}, C^{k_1}]_\theta \subset (C^{k_0}, C^{k_1})_{\theta,\infty}.$$

Therefore, to obtain the claim, it suffices to prove the following embedding result: If $A_1 \subset A_0$, then

$$(A_0, A_1)_{\eta,\infty} \subset (A_0, A_1)_{\theta,1},$$

where $0 < \theta < \eta < 1$. But this follows relatively easily by using the standard K-functional techniques. By definition,

$$K(t, a) = \inf_{a = a_0 + a_1} (\|a_0\|_{A_0} + t\|a_1\|_{A_1})$$

for $a = a_0 + a_1 \in A_0 + A_1$. But since $A_0 + A_1 \subset A_0$, we get $K(t, a) \leqq \|a\|_{A_0}$. Therefore, applying the $\Phi_{\theta,1}$-functional to $K(t, a)$,

$$\begin{aligned}\Phi_{\theta,1}(K(\cdot, a)) &= \int_0^\infty t^{-\theta} K(t, a)\frac{dt}{t} \leqq \sup_{t \geqq 0} t^{-\eta}K(t, a)\int_0^1 t^{\eta-\theta}\frac{dt}{t} + \|a\|_{A_0}\int_1^\infty t^{-\theta}\frac{dt}{t} \\ &= C_1\Phi_{\eta,\infty}(K(\cdot, a)) + C_2\|a\|_{A_0} \leqq C\|a\|_{(A_0,A_1)_{\eta,\infty}}.\end{aligned}$$

The last inequality follows from the fact that $(A_0, A_1)_{\eta,\infty}$ is an intermediate space, i.e., $(A_0, A_1)_{\eta,\infty} \subset A_0 + A_1 \subset A_0$. □

Appendix B. In this section we derive the expression for q_1 as given in the Theorem 2.1. We start with two rather technical but straightforward lemmas.

LEMMA B1. *For $x, y \in \mathbf{R}^3$, $k \in \mathbf{R}$, we have*

$$\int_{S^2} d\theta\, e^{-ik\theta\cdot x} \int_{S^2} d\theta'\, \theta\cdot(\theta-\theta')\, e^{ik\theta'\cdot y} = (4\pi)^2(j_0(k|x|)j_0(k|y|) - \hat{x}\cdot\hat{y} j_1(k|x|)j_1(k|y|)).$$

Here, j_0 and j_1 are the spherical Bessel functions of orders zero and 1, *and $\hat{x} = x/|x|$, $\hat{y} = y/|y|$.*

Proof. Start with the θ' integral,

$$I(\theta, k, y) = \int_{S^2} d\theta'\, \theta\cdot(\theta-\theta')\, e^{ik\theta'\cdot y}.$$

Using the expansion of the exponential function in spherical harmonics,

$$e^{ik\theta'\cdot y} = e^{i|k||y|\theta\cdot(\operatorname{sign} k\hat{y})} = 4\pi \sum_{l=0}^{\infty}\sum_{m=-l}^{l} i^l j_l(|ky|)\, Y_l^m(\operatorname{sign} k\,\hat{y})\, \bar{Y}_l^m(\theta'),$$

and choosing the coordinates with the $\hat{e}_3$ axis is parallel to θ so that

$$1-\theta\cdot\theta' = 1-\cos(\theta,\theta') = \sqrt{4\pi}\left(Y_0^0(\theta') - \frac{1}{\sqrt{3}} Y_1^0(\theta')\right),$$

we get by the orthogonality of the spherical harmonics

$$I(\theta, k, y) = (4\pi)^{3/2}\left(j_0(|ky|)\, Y_0^0(\operatorname{sign} k\,\hat{y}) - \frac{i}{\sqrt{3}} j_1(|ky|)\, Y_1^0(\operatorname{sign} k\,\hat{y})\right)$$

$$= 4\pi(j_0(|ky|) - i \operatorname{sign} k\,\hat{y}\cdot\theta j_1(|ky|)).$$

Invoking the spherical harmonics expansion once more, this time choosing the $\hat{e}_3$ axis parallel to sign $k\,\hat{y}$,

$$\int_{S^2} d\theta\, e^{-ik\theta\cdot x} I(k, \theta, y)$$

$$= (4\pi)^{5/2} \sum_{l=0}^{l=\infty}\sum_{m=-l}^{m=l} i^l j_l(|kx|)\, Y_l^m(-\operatorname{sign} k\,\hat{x})$$

$$\cdot \int_{S^2} \bar{Y}_l^m(\theta)\left(j_0(|ky|)\, Y_0^0(\theta) - i\frac{1}{\sqrt{3}} j_1(|ky|)\, Y_1^0(\theta)\right) d\theta$$

$$= (4\pi)^2(j_0(|kx|)j_0(|ky|) - \hat{x}\cdot\hat{y} j_1(|kx|)j_1(|ky|)),$$

which yields the claim, since the products of the Bessel functions are even functions. □

To deal with the k-integral we prove the following result.

LEMMA B2. *For α, β, and γ positive, we have the following formulas for the distributional Fourier transforms of the products of Bessel functions*:

$$\int_{-\infty}^{\infty} e^{ik\alpha} j_0(\beta k) j_0(\gamma k)\, dk = -\frac{\pi}{2\beta\gamma}(\delta(\alpha+\beta+\gamma) + \delta(\alpha-\beta-\gamma)$$

$$- \delta(\alpha+\beta-\gamma) - \delta(\alpha-\beta+\gamma)),$$

and similarly

$$\int_{-\infty}^{\infty} e^{ik\alpha} j_1(\beta k) j_1(\gamma k)\, dk$$

$$= \frac{\pi}{2\beta\gamma}\Big(\delta(\alpha+\beta-\gamma)+\delta(\alpha-\beta-\gamma)+\delta(\alpha+\beta-\gamma)+\delta(\alpha-\beta+\gamma)$$

$$-\frac{1}{\beta}(\Theta(\beta-\alpha-\gamma)+\Theta(\beta-|\alpha-\gamma|))-\frac{1}{\gamma}(\Theta(\gamma-\alpha-\beta)+\Theta(\gamma-|\alpha-\beta|))$$

$$+\frac{1}{\beta\gamma}(\min(\beta,\alpha+\gamma)+\operatorname{sign}(\gamma-\alpha)\min(\beta,|\alpha-\gamma|))\Big).$$

Here, δ is the delta distribution and Θ is the Heaviside function.

Proof. By the explicit formula

$$j_0(t)=\frac{\sin t}{t}=\frac{1}{2it}(e^{it}-e^{-it}),$$

the first identity is immediate. Similarly, by the formula

$$j_1(t)=\left(\frac{\sin t}{t^2}-\frac{\cos t}{t}\right)$$

we obtain for the second term

$$j_1(\beta k)j_1(\gamma k)=\frac{1}{\beta\gamma k^2}\Big(\cos\beta k\cos\gamma k-\frac{1}{\beta k}\sin\beta k\cos\gamma k-\frac{1}{\gamma k}\sin\gamma k\cos\beta k$$

$$+\frac{1}{\beta\gamma k^2}\sin\beta k\sin\gamma k\Big).$$

We will integrate this expression term by term. The first term gives the δ-terms appearing in the claim. To evaluate the second term we write

$$\int_{-\infty}^{\infty}\frac{1}{k}e^{ik\alpha}\sin\beta k\cos\gamma k\,dk=2\int_0^{\infty}\frac{1}{k}\cos\alpha k\sin\beta k\cos\gamma k\,dk$$

$$=\int_0^{\infty}\frac{1}{k}\sin\beta k\cos(\alpha+\gamma)k\,dk+\int_0^{\infty}\frac{1}{k}\sin\beta k\cos(\alpha-\gamma)k\,dk$$

$$=\frac{\pi}{2}\Theta(\beta-\alpha-\gamma)+\frac{\pi}{2}\Theta(\beta-|\alpha-\gamma|).$$

The last equality follows from [6, p. 414].

The integral of the third term equals that of the second with the roles of β and γ interchanged. Finally, to integrate the fourth term, we write

$$\int_{-\infty}^{\infty}\frac{1}{k^2}e^{ik\alpha}\sin\beta k\sin\gamma k\,dk=2\int_0^{\infty}\frac{1}{k^2}\cos\alpha k\sin\beta k\sin\gamma k\,dk$$

$$=\int_0^{\infty}\frac{1}{k^2}\sin\beta k\sin(\alpha+\gamma)k\,dk+\operatorname{sign}(\gamma-\alpha)\int_0^{\infty}\frac{1}{k^2}\sin\beta k\sin|\gamma-\alpha|k\,dk$$

$$=\frac{\pi}{2}\min(\beta,\alpha+\gamma)+\frac{\pi}{2}\operatorname{sign}(\gamma-\alpha)\min(\beta,|\gamma-\alpha|)$$

by [6, p. 414]. The proof of the lemma is thus complete. □

Now we are ready to prove Theorem 2.1. Let $\varphi \in S(\mathbf{R}^3)$. By the distributional definition of $\mathscr{F}_M^{-1}$, we have

$$\begin{aligned}\langle \mathscr{F}_M^{-1}\tilde{\Phi}_0 \mathscr{K} \Phi_0, \varphi\rangle &= \int_M d\mu(k,\theta',\theta)\tilde{\Phi}_0\mathscr{K}\Phi_0(k,\theta',\theta)\mathscr{F}^{-1}\varphi(k(\theta-\theta')) \\ &= \int_M d\mu(k,\theta',\theta)\mathscr{F}^{-1}\varphi(k(\theta-\theta'))\int_{\mathbf{R}^3} dx\, e^{-ik\theta'\cdot x} q(x) \\ &\quad \cdot \int_{\mathbf{R}^3} dy \frac{e^{ik|x-y|}}{4\pi|x-y|} q(y)\, e^{ik\theta\cdot y}.\end{aligned}$$

It is not hard to see, by using the mapping properties of $\mathscr{R}_0^+(k)$, that we can use the Fubini theorem in the above integral to get

$$\begin{aligned}\langle \mathscr{F}_M^{-1}\tilde{\Phi}_0 \mathscr{K} \Phi_0, \varphi\rangle = \frac{1}{4\pi}\int dx\, q(x)\int dy\, q(y)\frac{1}{|x-y|}\int_M d\mu(k,\theta',\theta)\mathscr{F}^{-1}\varphi(k(\theta-\theta')) \\ \cdot e^{-ik\theta'\cdot x}\, e^{ik|x-y|}\, e^{ik\theta\cdot y}.\end{aligned}$$

To obtain the claimed result, we have to prove that for $x \neq y$,

$$\begin{aligned}&\frac{1}{4\pi}\int_M d\mu(k,\theta',\theta)\mathscr{F}^{-1}\varphi(k(\theta-\theta'))\, e^{-ik\theta'\cdot x}\, e^{ik|x-y|}\, e^{ik\theta\cdot y} \\ &\quad = -\frac{1}{32\pi}\int_{\mathbf{R}^3} dz\, \varphi(z)|x-y|\frac{(x-z)\cdot(y-z)}{|x-z|^3|y-x|^3}.\end{aligned}$$

By Lemma B1, we get

$$\begin{aligned}&\frac{1}{4\pi}\int_M d\mu(k,\theta',\theta)\mathscr{F}^{-1}\varphi(k(\theta-\theta'))\, e^{-ik\theta'\cdot x}\, e^{ik|x-y|}\, e^{ik\theta\cdot y} \\ &\quad = \frac{1}{16\pi^3}\lim_{n\to\infty}\int_{-n}^{n} dk\, k^2\int_{\mathbf{R}^3} dz\, \varphi(z)\, e^{ik|x-y|}(j_0(k|z-y|)j_0(k|z-x|) \\ &\quad\quad -(\widehat{z-y})\cdot(\widehat{z-x})j_1(k|z-y|)j_1(k|z-x|)).\end{aligned}$$

Further, by Lemma A2 with $\alpha = |x-y|$, $\beta = |z-y|$ and $\gamma = |z-x|$, the above integral equals to $I_1 + I_2$, where

$$\begin{aligned}I_1 = -\frac{1}{32\pi^2}\int_{\mathbf{R}^3} dz \frac{\varphi(z)}{|z-y||z-x|} \\ \cdot\{(1+(\widehat{z-y})\cdot(\widehat{z-x}))(\delta(|x-y|+|z-y|+|z-x|) \\ +\delta(|x-y|-|z-y|-|z-x|))+(1-(\widehat{z-y})\cdot(\widehat{z-x})) \\ \cdot(\delta(|x-y|-|z-y|+|z-x|)+\delta(|x-y|+|z-y|-|z-x|))\},\end{aligned}$$

and the remaining part contains the less singular terms, i.e.,

$$\begin{aligned}I_2 = -\frac{1}{16\pi^2}\int_{\mathbf{R}^3} dz \frac{\varphi(z)}{|z-y||z-x|}(\widehat{z-y})\cdot(\widehat{z-x}) \\ \cdot\left\{\frac{1}{|z-y|}(\Theta(|z-y|-|x-y|-|z-x|)+\Theta(|z-y|-\|x-y|-|z-x\|)) \right. \\ \left. +\frac{1}{|z-x|}(\Theta(|z-x|-|x-y|-|z-y|)+\Theta(|z-x|-\|x-y|-|z-y\|))\right.\end{aligned}$$

$$-\frac{1}{|z-y||z-x|}(\min(|z-y|, |x-y|+|z-x|)$$
$$+\operatorname{sign}(|z-x|-|x-y|)\min(|z-y|, \|x-y|-|z-x\|))\Big\}.$$

First we show that the first integral I_1 vanishes. To get an interpretation for the one-dimensional delta distributions appearing in the first integral I_1, we use the prolate spheroidal coordinates with foci at x and y. If $|x-y|=2a>0$, we choose the new coordinates (ξ, ζ, ω) as

$$2a\xi = |x-z|+|y-z|, \qquad 1 \leqq \xi < \infty,$$
$$2a\zeta = |x-z|-|y-z|, \qquad -1 \leqq \zeta \leqq 1,$$
$$\omega = \text{angle around, the axis passing through } x \text{ and } y, \qquad 0 \leqq \omega \leqq 2\pi.$$

The Jacobian of the change of variables $z=(z_1, z_2, z_3) \to (\xi, \zeta, \omega)$ is

$$\left|\frac{\partial(z_1, z_2, z_3)}{\partial(\xi, \zeta, \omega)}\right| = a|x-z||y-z|$$

(see [2, p. 105]). Finally, denoting $\alpha_\pm = 1 \pm (\widehat{z-y}) \cdot (\widehat{z-x})$ and by u the coordinate transform $z=u(\xi, \zeta, \omega)$, we have

$$I_1 = -\frac{1}{64\pi^2}\int_1^\infty d\xi \int_{-1}^1 d\zeta \int_0^{2\pi} d\omega\, \varphi \circ u(\xi, \zeta, \omega)$$
$$\cdot (\alpha_+(\delta(1+\xi)+\delta(1-\xi))+\alpha_-(\delta(1-\zeta)+\delta(1+\zeta))),$$

where the identity $\delta(at)=\delta(t)/a$ is used. From this representation we deduce that, in fact, $I_1=0$, because by a simple geometrical argument $\alpha_+=0$ when $\xi=1$, and $\alpha_-=0$ when $\zeta=\pm 1$. To simplify the I_2 integral, note that $|z-y| \leqq |z-x|+|x-y|$ and $\|y-x|-|z-x\| \leqq |z-y|$ and similarly with x and y interchanged, so I_2 reduces simply to

$$I_2 = -\frac{1}{32\pi^2}\int_{\mathbf{R}^3} dz\, \varphi(z) \frac{(\widehat{z-y}) \cdot (\widehat{z-x})}{|z-y||z-x|}$$
$$\cdot \left(\frac{1}{|z-y|}+\frac{1}{|z-x|}-\frac{1}{|z-y||z-x|}(|z-y|+|z-x|-|x-y|)\right)$$
$$= -\frac{1}{32\pi^2}\int_{\mathbf{R}^3} dz\, \varphi(z) \frac{(\widehat{z-y}) \cdot (\widehat{z-x})}{|z-y|^2|z-x|^2}|x-y|.$$

The proof of Theorem 2.1 is thus complete. □

TWO-DIMENSIONAL STATIONARY PHASE APPROXIMATION: STATIONARY POINT AT A CORNER*

J. P. McCLURE† AND R. WONG‡

Abstract. Asymptotic expansions are derived for the double integral

$$\int\int_D g(x, y) \exp(iNf(x, y))\, dx\, dy,$$

as $N \to +\infty$, where $f(x, y)$ has a stationary point at a corner of the boundary of D. Two different methods are given, one for the case of local extrema and one for saddlepoints. In the case of saddlepoints, our method allows the boundary of D to be tangent to a level curve of f.

Key words. stationary phase approximation, asymptotic expansion, double integral, stationary point at a corner

AMS(MOS) subject classification. primary 41A60

1. Introduction.

Consider the double integral

$$I(N) = \int\int_D g(x, y) \exp(iNf(x, y))\, dx\, dy, \tag{1.1}$$

where D is a bounded domain, f and g are real-valued C^∞-functions in D, and N is a large positive parameter. By a *stationary point* (x_0, y_0) of f, we mean a point at which the gradient of f vanishes, i.e., $f_x(x_0, y_0) = f_y(x_0, y_0) = 0$. A stationary point is said to be *nondegenerate* if the Hessian matrix of f is nonsingular, i.e.,

$$\det f''(x_0, y_0) \equiv (f_{xx}f_{yy} - f_{xy}^2)(x_0, y_0) \neq 0. \tag{1.2}$$

If (x_0, y_0) is the only stationary point of f in D, if it is nondegenerate, and if it lies in the interior of D, then it is well known that

$$I(N) \sim g(x_0, y_0) \exp(iNf(x_0, y_0)) |\det f''(x_0, y_0)|^{-1/2} \left(\frac{2\pi\sigma}{N}\right) \tag{1.3}$$

as $N \to \infty$, where σ is equal to i, $-i$, or 1 depending on whether (x_0, y_0) is a local minimum, local maximum, or saddlepoint, respectively; see, for example, [2, eq. 18] or [11, Chap. VIII].

If the stationary point (x_0, y_0) is nondegenerate and lies on the boundary of D, and if the boundary curve is smooth near this point, then it is also known that $I(N)$ is asymptotic to half of the above approximation, i.e.,

$$I(N) \sim g(x_0, y_0) \exp(iNf(x_0, y_0)) |\det f''(x_0, y_0)|^{-1/2} \left(\frac{\pi\sigma}{N}\right) \tag{1.4}$$

as $N \to \infty$; see [6, p. 22] or [11, p. 442]. However, in the case where the stationary point (x_0, y_0) is a saddlepoint (i.e., $(f_{xy}^2 - f_{xx}f_{yy})(x_0, y_0) > 0$), the level set $f(x, y) = f(x_0, y_0)$, near (x_0, y_0), can be shown to consist of a pair of smooth curves intersecting at (x_0, y_0).

The validity of (1.4) requires the additional assumption that the boundary curve $h(x, y) = 0$ not be tangent to either of these curves at (x_0, y_0). This condition can be expressed analytically by

$$\{h_x f_{yy} + h_y(-f_{xy} \pm \sqrt{f_{xy}^2 - f_{xx} f_{yy}})\}(x_0, y_0) \neq 0. \tag{1.5}$$

(This reduces to the more familiar condition $(h_x^2 f_{yy} + h_y^2 f_{xx})(x_0, y_0) \neq 0$ given in [6, p. 23], when $f_{xy}(x_0, y_0) = 0$.)

If the nondegenerate stationary point (x_0, y_0) occurs at a corner, i.e., at a point on the boundary where the tangent line has a jump, then there is no result that can claim any generality. The problem of deriving an asymptotic formula for the integral (1.1) in this case has been known for some time, and is explicitly mentioned in [1, p. 88]. (For a discussion of corners that are not stationary points, see [2], [5], and [6].) The purpose of this paper is to provide a solution to this problem, and our discussion will be divided into two separate cases. In one case, the corner point (x_0, y_0) is a local extremum of the phase function $f(x, y)$; and in the other case, (x_0, y_0) is a saddlepoint. The methods that we use in these two cases are quite different. In the first case, our method consists of a reduction of the double integral (1.1) to a one-dimensional Fourier transform and an application of a Taylor-type expansion of the Dirac δ-function. This approach is motivated by a method of Jones and Kline [6] as elaborated in [12]. In the second case, we make repeated use of Green's theorem and follow with an application of a result due to Erdélyi [4] concerning the stationary phase method in the presence of a logarithmic singularity. From our discussion below, it will become apparent that our method works even when the boundary curve is smooth at the stationary point but condition (1.5) fails to hold.

2. Local extremum at a corner. For convenience, we shall assume that the corner point (x_0, y_0) is at the origin, i.e., $x_0 = y_0 = 0$, and that near this point the domain D is bounded by two smooth curves intersecting only at $(0, 0)$. We will represent these curves by $h(x, y) = 0$ and $k(x, y) = 0$, where h and k are C^∞-functions with nonvanishing gradients. Since these two curves intersect with a positive angle at $(0, 0)$, i.e., they are not tangent to each other there, the gradients (h_x, h_y) and (k_x, k_y) are linearly independent at $(0, 0)$. Without loss of generality, it can be assumed that these gradients point into D for (x, y) near $(0, 0)$. By using a partition of unity [10, pp. 147, 246] or a neutralizer [11, p. 427], we can always isolate the stationary point $(0, 0)$ from other critical points by multiplying g by a C^∞-function with compact support, which may be taken arbitrarily small. Thus we may assume that g vanishes C^∞-smoothly off an arbitrarily small neighborhood of $(0, 0)$. The situation is as depicted in Fig. 1.

In the integral (1.1), we now make the change of variables

$$s = h(x, y), \qquad t = k(x, y). \tag{2.1}$$

Since (h_x, h_y) and (k_x, k_y) are linearly independent at $(0, 0)$,

$$\frac{\partial(s, t)}{\partial(x, y)} = h_x k_y - h_y k_x \equiv \Delta(x, y) \tag{2.2}$$

does not vanish at $(x, y) = (0, 0)$. Consequently, the transformation (2.1) is invertible near $(0, 0)$. By shrinking the support of g if necessary, we may assume without loss of generality that this transformation is invertible, with nonzero Jacobian, on $\operatorname{supp}(g)$. Thus

$$I(N) = \int\int_{D_1} g_1(s, t) \exp(iNf_1(s, t))\, ds\, dt, \tag{2.3}$$

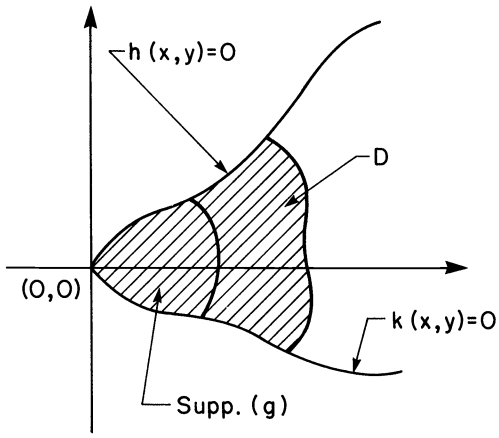

FIG. 1. *Domain D.*

where

$$f_1(s, t) = f(x, y), \qquad g_1(s, t) = \frac{g(x, y)}{|\Delta|}, \tag{2.4}$$

and D_1 is the image of D (see Fig. 2). Simple computation shows that $f_1(0, 0) = f(0, 0)$ and $(0, 0)$ is a stationary point of $f_1(s, t)$. Furthermore, near $(0, 0)$ we have

$$f_1(s, t) = f(0, 0) + \tfrac{1}{2}(\alpha s^2 + 2\beta st + \gamma t^2) + \cdots, \tag{2.5}$$

where

$$\alpha = \frac{\partial^2 f}{\partial x^2} k_y^2 - 2\frac{\partial^2 f}{\partial x\, \partial y} k_x k_y + \frac{\partial^2 f}{\partial y^2} k_x^2, \tag{2.6}$$

$$\beta = -\left(\frac{\partial^2 f}{\partial x^2} h_y k_y + \frac{\partial^2 f}{\partial y^2} h_x k_x\right) + \frac{\partial^2 f}{\partial x\, \partial y}(h_x k_y + h_y k_x), \tag{2.7}$$

$$\gamma = \frac{\partial^2 f}{\partial x^2} h_y^2 - 2\frac{\partial^2 f}{\partial x\, \partial y} h_x h_y + \frac{\partial^2 f}{\partial y^2} h_x^2, \tag{2.8}$$

all derivatives being evaluated at $(0, 0)$. Here we have also used the fact that the first-order partial derivatives of $f(x, y)$ vanish at $(0, 0)$.

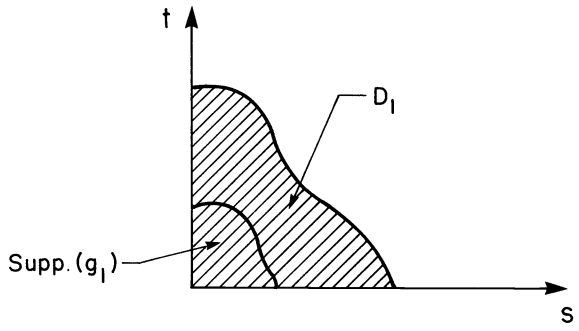

FIG. 2. *Domain* D_1.

Our next step is to eliminate the cross-product term st in the Maclaurin expansion (2.5). To do this, we make the second change of variables:

$$u = s + \frac{\beta}{\alpha} t \quad \text{and} \quad v = t. \tag{2.9}$$

It is easily verified that

$$\alpha s^2 + 2\beta st + \gamma t^2 = \lambda u^2 + \mu v^2,$$

where $\lambda = \alpha$ and $\mu = (\alpha\gamma - \beta^2)/\alpha$, and that the Jacobian of the transformation is 1. The integral $I(N)$ in (2.3) now becomes

$$I(N) = \int\int_{D_2} \psi(u, v) \exp(iN\phi(u, v))\, du\, dv, \tag{2.10}$$

where

$$\phi(u, v) = f(0, 0) + \frac{\lambda}{2} u^2 + \frac{\mu}{2} v^2 + \cdots, \tag{2.11}$$

$$\psi(u, v) = g_1(s, t). \tag{2.12}$$

The domain D_2 is as shown in Fig. 3.

We will apply the argument in [12] to the integral in (2.10). Before proceeding, we first observe that the nature of the stationary point $(0, 0)$ of $f(x, y)$ is preserved under the transformations (2.1) and (2.9). That is, if $(0, 0)$ is a local extremum of $f(x, y)$ then $(0, 0)$ is a local extremum of $\phi(u, v)$, and if $(0, 0)$ is a saddlepoint of $f(x, y)$ then $(0, 0)$ is a saddlepoint of $\phi(u, v)$. To demonstrate this, we let

$$a = \frac{\partial^2 f}{\partial x^2}(0, 0), \quad b = \frac{\partial^2 f}{\partial x\, \partial y}(0, 0), \quad c = \frac{\partial^2 f}{\partial y^2}(0, 0). \tag{2.13}$$

Simple computation yields

$$\alpha\gamma - \beta^2 = (ac - b^2)(k_x h_y - k_y h_x)^2, \tag{2.14}$$

$$\alpha = a\left[\left(k_y - \frac{b}{a} k_x\right)^2 + \frac{ac - b^2}{a^2} k_x^2\right], \tag{2.15}$$

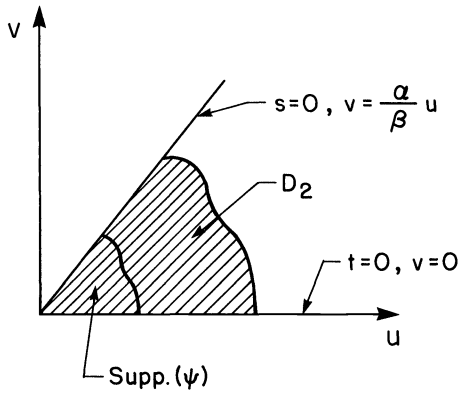

FIG. 3. *Domain* D_2.

where all derivatives are evaluated at $(0, 0)$. It is now evident that the signs of $\alpha\gamma - \beta^2$ and α, and hence those of λ and μ in (2.11), are determined by the signs of $ac - b^2$ and a. If, say, $(0, 0)$ is a local maximum of $f(x, y)$, then $ac - b^2 > 0$ and $a < 0$. Hence, $\alpha\gamma - \beta^2 > 0$ and $\alpha < 0$. Consequently, λ and μ are both negative, or equivalently, $(0, 0)$ is a local maximum of $\phi(u, v)$.

The argument in [12] first expresses the integral (2.10) in the form of a one-dimensional Fourier transform, using the method of resolution of double integrals [3, pp. 298–300]. Let m and M denote the infimum and supremum, respectively, of $\phi(u, v) - f(0, 0)$ in D_2. Then

$$I(N) = e^{iNf(0,0)} \int_m^M e^{iNt} h(t)\, dt, \tag{2.16}$$

where

$$h(t) = \int_\Gamma \frac{\psi(u, v)}{\sqrt{\phi_u^2 + \phi_v^2}}\, d\sigma \tag{2.17}$$

and Γ is the curve defined by

$$\Gamma = \{(u, v) \in D_2 : \phi(u, v) - f(0, 0) = t\}, \tag{2.18}$$

σ being the arclength of Γ.

Assume for the moment that $(0, 0)$ is a local minimum of $f(x, y)$. Then $(0, 0)$ is a local minimum of $\phi(u, v)$, in which case both λ and μ are positive. Put

$$u = \left(\frac{2\xi}{\lambda}\right)^{1/2} \cos\eta, \qquad v = \left(\frac{2\xi}{\mu}\right)^{1/2} \sin\eta. \tag{2.19}$$

Clearly

$$\xi = \frac{\lambda}{2} u^2 + \frac{\mu}{2} v^2, \tag{2.20}$$

$$\frac{\partial(u, v)}{\partial(\xi, \eta)} = \frac{1}{\sqrt{\lambda\mu}}. \tag{2.21}$$

In terms of the polar coordinates (ξ, η), the line integral becomes

$$h(t) = \int_{\Gamma'} \frac{\Phi(\xi, \eta)}{|\nabla(\xi + F)|}\, d\sigma', \tag{2.22}$$

where

$$\xi + F(\xi, \eta) = \phi(u, v) - f(0, 0), \qquad \Phi(\xi, \eta) = \frac{1}{\sqrt{\lambda\mu}} \psi(u, v), \tag{2.23}$$

$$\Gamma' = \{(\xi, \eta) \in D_3 : \xi + F(\xi, \eta) = t\}, \tag{2.24}$$

and $d\sigma'$ denotes the length of Γ'. The domain D_3 is shown in Fig. 4.

From (2.11), (2.19), and (2.23), it is easily seen that $F(\xi, \eta) = O(\xi^{3/2})$ and $F_\xi(\xi, \eta) = O(\xi^{1/2})$. Hence, by shrinking the support of Φ if necessary, we may assume without loss of generality that $1 + F_\xi > 0$. The implicit function theorem then ensures

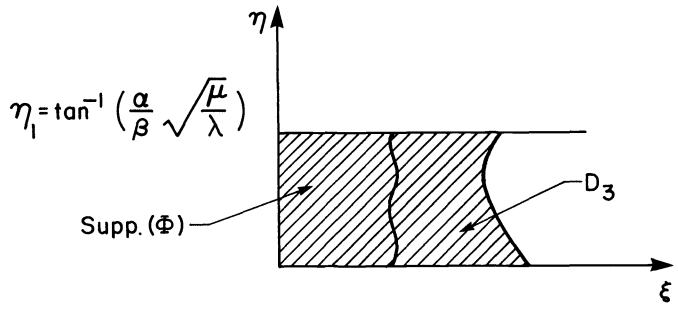

FIG. 4. *Domain* D_3.

that the equation $t = \xi + F(\xi, \eta)$ has a unique C^∞-solution $\xi_t(\eta)$. Consequently, we may write explicitly

$$d\sigma' = \frac{\sqrt{[1+F_\xi(\xi_t, \eta)]^2 + [F_\eta(\xi_t, \eta)]^2}}{1+F_\xi(\xi_t, \eta)}\, d\eta,$$

and the line integral in (2.22) becomes

$$h(t) = \int_0^{\eta_1} \frac{\Phi(\xi_t, \eta)}{1+F_\xi(\xi_t, \eta)}\, d\eta, \tag{2.25}$$

where $\eta_1 = \tan^{-1}[(\alpha/\beta)\sqrt{\mu/\lambda}]$. We will show next that $h(t)$ has an asymptotic expansion of the form

$$h(t) \sim a_0 + a_1 t^{1/2} + a_2 t + \cdots \quad \text{as } t \to 0^+. \tag{2.26}$$

To prove (2.26), we observe that in terms of generalized functions, the line integral (2.22) can be expressed as

$$h(t) = \langle \delta(t - \xi - F), \Phi \rangle,$$

where δ is the distribution concentrated on the curve Γ'; see [12, eqs. (3.5), (3.6)]. Thus the result of Lemma 2 in [12] applies immediately. Since Γ' lies inside domain D_3 (Fig. 4), the upper limit 2π in equation (4.6) of [12] is replaced by η_1. Consequently,

$$h(t) = \sum_{r=0}^{n} \frac{(-1)^r}{r!} \frac{\partial^r}{\partial t^r} \int_0^{\eta_1} \Phi(t, \eta) F^r(t, \eta)\, d\eta + R_{n+1}(t), \tag{2.27}$$

where the remainder satisfies

$$R_{n+1}(t) = O(t^{(n+1)/2}) \quad \text{as } t \to 0^+; \tag{2.28}$$

cf. [12, eq. (4.8)]. Since f and g are C^∞-functions, so are ϕ and ψ. Using (2.19), we can then write for any $p \geqq 1$

$$\Phi(\xi, \eta) F^r(\xi, \eta) = \sum_{\mu=0}^{p-1} c_{\mu r}(\eta) \xi^{\mu/2} + O(\xi^{p/2})$$

as $\xi \to 0^+$, where $c_{\mu r}(\eta)$ is a polynomial in $\cos\eta$ and $\sin\eta$, and the O-symbol is independent of η. From this it follows that each term in the series of (2.27) has an asymptotic expansion, as $t \to 0^+$, of the form $\sum_{\nu=0}^{\infty} a_{\nu r} t^{\nu/2}$. By rearranging the terms appropriately the desired result (2.26) is obtained.

In (2.10) it is tempting to make a nonlinear change of variables so that the phase function $\phi(u, v)$ becomes a sum of two squares. This would eliminate the use of the complicated expansion (2.27), and render the analysis much simpler; see [11, Chap. VIII, §§ 3, 6]. However, under this change of variable, the boundary curve $v=(\alpha/\beta)u$ of the domain D_2 would no longer be a straight line, and consequently D_3 would not be of the rectangular shape shown in Fig. 4.

The coefficients a_s in the expansion (2.26) can be calculated explicitly. The leading two are given by

$$a_0=\frac{1}{\sqrt{\lambda\mu}}\psi_{00}\eta_1, \tag{2.29}$$

$$\begin{aligned} a_1=\frac{1}{\sqrt{\lambda\mu}}\int_0^{\eta_1}\Bigg\{&\sqrt{\frac{2}{\lambda}}\psi_{10}\cos\eta+\sqrt{\frac{2}{\mu}}\psi_{01}\sin\eta \\ &-\frac{1}{4}\psi_{00}\Bigg[\left(\frac{2}{\lambda}\right)^{3/2}\phi_{30}\cos^3\eta+3\left(\frac{2}{\lambda}\right)\left(\frac{2}{\mu}\right)^{1/2}\phi_{21}\cos^2\eta\sin\eta \\ &+3\left(\frac{2}{\lambda}\right)^{1/2}\left(\frac{2}{\mu}\right)\phi_{12}\cos\eta\sin^2\eta+\left(\frac{2}{\mu}\right)^{3/2}\phi_{03}\sin^3\eta\Bigg]\Bigg\}\,d\eta, \end{aligned} \tag{2.30}$$

where $\psi_{ij}=\partial^{i+j}\psi/\partial u^i\,\partial v^j$ and a similar definition holds for ϕ_{ij}, all partial derivatives being evaluated at $(0, 0)$.

The asymptotic expansion of the integral in (2.16) will now follow from the theory for one-dimensional Fourier transforms. First, since in the present case $(0, 0)$ is a local minimum of $\phi(u, v)$, the lower limit m in (2.16) is zero. Second, since $\psi(u, v)$ vanishes outside the support of ψ and the support of ψ can be taken to be of any shape and arbitrarily small, the function $h(t)$ vanishes identically at the upper limit M. From (2.25), it is also evident that $h(t)$ is a C^∞-function for $0<t<M$. Therefore, upon termwise integration in the sense of Abel summability (see [9] or [11, p. 199]), we obtain

$$I(N)\sim e^{iNf(0,0)}\left[e^{i\pi/2}\frac{a_0}{N}+e^{i3\pi/4}\Gamma\left(\frac{3}{2}\right)\frac{a_1}{N^{3/2}}+e^{i\pi}\frac{a_2}{N^2}+\cdots\right] \tag{2.31}$$

as $N\to+\infty$.

The above analysis also works for the case when both λ and μ in (2.11) are negative, i.e., in the case when $(0, 0)$ is a local maximum for $f(x, y)$. The final result is

$$I(N)\sim e^{iNf(0,0)}\left[e^{-i\pi/2}\frac{a_0^*}{N}+e^{-i3\pi/4}\Gamma\left(\frac{3}{2}\right)\frac{a_1^*}{N^{3/2}}+e^{-i\pi}\frac{a_2^*}{N^2}+\cdots\right], \tag{2.32}$$

where

$$a_0^*=\frac{1}{\sqrt{\lambda\mu}}\psi_{00}\eta_1, \tag{2.33}$$

$$\begin{aligned} a_1^*=\frac{1}{\sqrt{\lambda\mu}}\int_0^{\eta_1}\Bigg\{&\psi_{10}\sqrt{\frac{2}{-\lambda}}\cos\eta+\psi_{01}\sqrt{\frac{2}{-\mu}}\sin\eta \\ &+\frac{1}{4}\psi_{00}\Bigg[\phi_{30}\left(\frac{2}{-\lambda}\right)^{3/2}\cos^3\eta+3\phi_{21}\left(\frac{2}{-\lambda}\right)\left(\frac{2}{-\mu}\right)^{1/2}\cos^2\eta\sin\eta \\ &+3\phi_{12}\left(\frac{2}{-\lambda}\right)^{1/2}\left(\frac{2}{-\mu}\right)\cos\eta\sin^2\eta \\ &+\phi_{03}\left(\frac{2}{-\mu}\right)^{3/2}\sin^3\eta\Bigg]\Bigg\}\,d\eta; \end{aligned} \tag{2.34}$$

cf. (2.29) and (2.30).

In terms of the original data f, g, h, and k, the leading term approximation in both (2.31) and (2.32) is

$$I(N) \sim e^{iNf(0,0)} \frac{g(0,0)}{\sqrt{ac-b^2}\,|k_x h_y - k_y h_x|^2} \tan^{-1}\left(\frac{1}{\beta}\sqrt{\alpha\gamma-\beta^2}\right)\frac{i}{N}, \tag{2.35}$$

where a, b, and c are given in (2.13) and α, β, and γ are given in (2.6)-(2.8). The partial derivatives in (2.35) are all evaluated at $(0, 0)$.

It is tempting to use the same method for the case of a saddlepoint at a corner, but it breaks down when one of the boundary curves $h(x, y) = 0$ or $k(x, y) = 0$ is tangent to the level curve $f(x, y) = 0$. To see this, we observe that the above procedure applies up to (2.16). Since the transformations (2.1) and (2.9) preserve the nature of the stationary point, if $(0, 0)$ is a saddlepoint of $f(x, y)$ then $(0, 0)$ is also a saddlepoint of $\phi(u, v)$, and consequently λ and μ have opposite signs. Suppose that $\lambda > 0$ and $\mu < 0$. Then the natural change of variable corresponding to (2.19) is

$$u = (2\xi)^{1/2}\frac{\cosh\eta}{\lambda^{1/2}}, \qquad v = (2\xi)^{1/2}\frac{\sinh\eta}{(-\mu)^{1/2}}.$$

The boundary curve $v = (\alpha/\beta)u$ of the domain D_2 is now mapped into the curve

$$\eta = \eta_1, \qquad \eta_1 = \tanh^{-1}\left(\frac{\alpha}{\beta}\sqrt{\frac{-\mu}{\lambda}}\right). \tag{2.36}$$

Suppose that the curve $h(x, y) = 0$ is tangent to the level curve $f(x, y) = 0$ at $(0, 0)$. Then (1.5) does not hold (with $x_0 = y_0 = 0$). In terms of the quantities α, β, and γ, this means that γ is zero, which in turn implies $\alpha/\beta = \sqrt{\lambda/-\mu}$, or equivalently, $\eta_1 = +\infty$ in (2.36). As a consequence, the arguments for the results corresponding to (2.26)-(2.28) are no longer valid. In particular, for the analogue of $F(\xi, \eta)$ as defined in (2.23), the estimate $F(\xi, \eta) = O(\xi^{3/2})$, as $\xi \to 0^+$, fails if $\eta_1 = \infty$.

Example. As a simple illustration, we consider the example in which

$$f(x, y) = (x^2 + xy + y^2)(1 - \tfrac{1}{2}x), \qquad g(x, y) = \cos(x + y), \tag{2.37}$$

and D is the domain bounded by the circles $(x-1)^2 + y^2 = 1$ and $x^2 + (y-1)^2 = 1$. It is easily verified that $f(x, y)$ has only two stationary points located at $(0, 0)$ and $(\frac{4}{3}, -\frac{2}{3})$. Hence, inside and on the boundary of D, $(0, 0)$ is the only stationary point of $f(x, y)$ and is a local minimum. Let $h(x, y) = x^2 - 2x + y^2$ and $k(x, y) = x^2 - 2y + y^2$. Simple calculations give

$$a = 2, \quad b = 1, \quad c = 2, \tag{2.38}$$

$$\alpha = 8, \quad \beta = 4, \quad \gamma = 8. \tag{2.39}$$

From (2.35) it follows that

$$\int\int_D g(x, y)\, e^{iNf(x,y)}\, dx\, dy \sim \frac{i}{48\sqrt{3}}\frac{\pi}{N} \tag{2.40}$$

as $N \to \infty$.

3. Saddlepoint at a corner: Transformation to canonical forms. As in § 2, we again assume that the corner point is at $(0, 0)$. By Theorem 4.1 in [7, p. 10], we may assume that the functions f, g, h, and k are extended to C^∞-functions in some neighborhood, say U of the origin. Although no actual use of the values of these extensions will be made outside the original domain D, the existence of these extensions will be a

convenience in our discussion. By shrinking the support of g, we may further assume that the support of g is contained in U. For definiteness, we also assume that for points in D we have $h(x, y) \geqq 0$ and $k(x, y) \geqq 0$, and that the angle of the corner of D at $(0, 0)$ is between 0 and π. The case of angles between π and 2π can be included by adding copies of the cases considered here. An illustration of the situation is depicted in Fig. 5.

Since $(0, 0)$ is a stationary point of $f(x, y)$, the initial terms in the Maclaurin expansion of $f(x, y)$ are

$$f(x, y) = f_{00} + f_{20}x^2 + f_{11}xy + f_{02}y^2 + \cdots,$$

where

$$f_{ij} = \frac{1}{i!\,j!} \frac{\partial^{i+j} f}{\partial x^i\, \partial y^j}(0, 0).$$

Without loss of generality, we may take $f_{00} = 0$, as it contributes only a factor $\exp\{iNf_{00}\}$ to the integral $I(N)$ in (1.1) (cf. (2.31)). Since it is always possible to eliminate the cross-product term xy by a linear change of variable, we may without loss of generality assume that

$$f(x, y) = f_{20}x^2 + f_{02}y^2 + O[(x^2 + y^2)^{3/2}] \tag{3.1}$$

as $(x, y) \to (0, 0)$.

The origin being a saddlepoint, the coefficients f_{20} and f_{02} have opposite signs. Hence, near $(0, 0)$, the level set, $f(x, y) = 0$ consists of two smooth curves intersecting at and only at $(0, 0)$; for a rigorous analysis, see the explanation following (3.9). We shall refer to these curves as the *critical curves* of $f(x, y)$. Also, we will assume that the following condition holds:

(C) Within the neighborhood U, each of the curves $h(x, y) = 0$ and $k(x, y) = 0$ meets the level set $f(x, y) = 0$ only at the point $(0, 0)$.

As indicated in § 1, previous treatments of a saddlepoint on a smooth boundary requires condition (1.5) to hold, i.e., that the critical curves of f not be tangent to the boundary of D at $(0, 0)$. Our condition (C) is much weaker; it allows the critical curves of f to meet the boundary of D tangentially, but rules out only situations in which a critical curve intersects the boundary infinitely often in the neighborhood U.

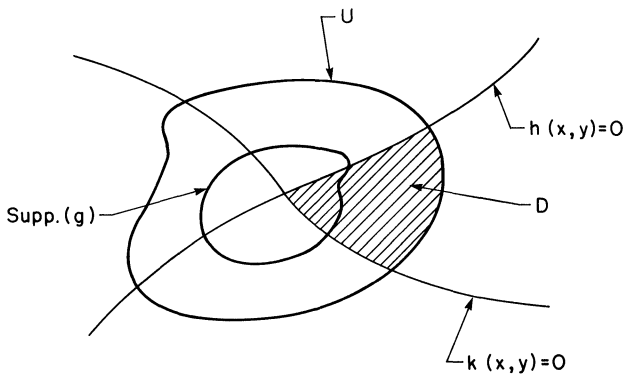

FIG. 5. *Neighborhood U.*

Since f_{20} and f_{02} have opposite signs, we may assume without loss of generality that $f_{20} > 0$ and $f_{02} < 0$. Define functions P and Q by

$$\begin{cases} P(x, y) = \dfrac{1}{x^2}[f(x, 0) + yf_y(x, 0) - f_{20}x^2] & \text{if } x \neq 0, \\ P(0, y) = \dfrac{1}{2} yf_{xxy}(0, 0), \end{cases} \tag{3.2}$$

$$\begin{cases} Q(x, y) = \dfrac{1}{y^2}[f(x, y) - f(x, 0) - yf_y(x, 0) - f_{02}y^2] & \text{if } y \neq 0, \\ Q(x, 0) = \dfrac{1}{2} f_{yy}(x, 0) - f_{02}. \end{cases} \tag{3.3}$$

By using l'Hôpital's rule, it is readily verified that each of P and Q is infinitely differentiable in U, and that $P(0, 0) = Q(0, 0) = 0$. It is also easily checked that

$$f(x, y) = f_{20}x^2 + x^2P(x, y) + f_{02}y^2 + y^2Q(x, y). \tag{3.4}$$

We now make the change of variables

$$s = x[f_{20} + P(x, y)]^{1/2}, \qquad t = y[-f_{02} - Q(x, y)]^{1/2}. \tag{3.5}$$

Clearly this transformation is infinitely differentiable in U, and from (3.4) we have

$$f(x, y) = s^2 - t^2. \tag{3.6}$$

Simple computation gives

$$\left.\frac{\partial(s, t)}{\partial(x, y)}\right|_{(0,0)} = \sqrt{-f_{20}f_{02}}. \tag{3.7}$$

By shrinking the neighborhood U in Fig. 5 if necessary, we may assume that the Jacobian $\partial(s, t)/\partial(x, y)$ is positive in U, and that the transformation (3.5) is one-to-one there. In terms of the variables s and t, the integral $I(N)$ in (1.1) becomes

$$I(N) = \int\int_{D_1} g_1(s, t) \exp(iN(s^2 - t^2))\, ds\, dt, \tag{3.8}$$

where D_1 is the image of D and

$$g_1(s, t) = g(x, y)\frac{\partial(x, y)}{\partial(s, t)}. \tag{3.9}$$

Let U_1 denote the image of U, and put $h_1(s, t) = h(x, y)$ and $k_1(s, t) = k(x, y)$. Parts of the curves $h_1(s, t) = 0$ and $k_1(s, t) = 0$ determine the boundary of D_1 near $(0, 0)$. For points (s, t) in D_1, we have $h_1(s, t) \geqq 0$ and $k_1(s, t) \geqq 0$. In view of (3.6), the set in U_1 corresponding to the level set $f(x, y) = 0$ is determined by $s^2 - t^2 = 0$. Consequently, as claimed earlier, $f(x, y) = 0$ determines, within U, two smooth curves intersecting non-tangentially at and only at $(0, 0)$. Since the transformation (3.5) is one-to-one in U, condition (C) implies that the curves $h_1(s, t) = 0$ and $k_1(s, t) = 0$ intersect each other, and the lines $s \pm t = 0$, at and only at $(0, 0)$ inside U_1.

To derive the asymptotic expansion of the integral (3.8), we make one further simple, linear change of variables:

$$u = s - t, \qquad v = s + t \tag{3.10}$$

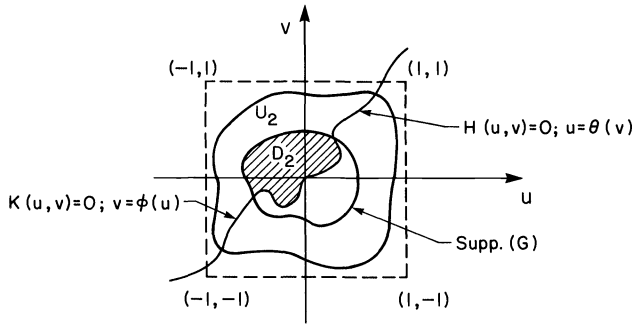

FIG. 6. *Neighborhood* U_2.

so that

$$I(N) = \int\int_{D_2} G(u, v)\, e^{iNuv}\, du\, dv, \tag{3.11}$$

where D_2 is the image of D_1 and

$$G(u, v) = g_1(s, t)\left|\frac{\partial(s, t)}{\partial(u, v)}\right| = \frac{1}{2}\, g_1(s, t). \tag{3.12}$$

Let U_2 denote the image of U_1, and put $H(u, v) = h_1(s, t)$ and $K(u, v) = k_1(s, t)$. For $(u, v) \in D_2$, we have $H(u, v) \geqq 0$ and $K(u, v) \geqq 0$.

By hypothesis, the gradients of $h(x, y)$ and $k(x, y)$ are both nonvanishing in U. Hence, in view of the nonsingularity of the transformations (3.5) and (3.10), each of the functions $H(u, v)$ and $K(u, v)$ has a nonvanishing gradient in U_2. As a consequence, locally within U_2, the equations $H(u, v) = 0$ and $K(u, v) = 0$ either determine v as a smooth function of u, say $v = \phi(u)$, or u as a function of v, say $u = \theta(v)$. We assume that U_2 is sufficiently small so that each of the curves $H(u, v) = 0$ and $K(u, v) = 0$ has such a representation globally within U_2. We also assume that U_2 is contained in the square with vertices at $(\pm 1, \pm 1)$; see Fig. 6. The integral (3.11) can then be written as a sum of not more than four terms, each of which is of one of the following forms:

$$\pm\int_0^{\pm 1}\int_0^{\phi(u)} G(u, v)\, e^{iNuv}\, dv\, du, \tag{3.13}$$

$$\pm\int_0^{\pm 1}\int_0^{\theta(v)} G(u, v)\, e^{iNuv}\, du\, dv, \tag{3.14}$$

$$\int_0^{\pm 1}\int_0^{\pm 1} G(u, v)\, e^{iNuv}\, du\, dv. \tag{3.15}$$

Note that the integral in (3.14) can be converted to that in (3.13). Thus our problem is solved if we can derive asymptotic expansions for the integrals in (3.13) and (3.15).

4. Saddlepoint at a corner: Derivation of expansions. We first consider the integral in (3.13), which we will rewrite as

$$I_1(N) = \int_0^1\int_0^{\phi(u)} G_0(u, v)\, e^{iNuv}\, dv\, du. \tag{4.1}$$

Recall that the function $\phi(u)$ corresponds to a part of the boundary of D_2 determined either by $H(u, v) = 0$ or $K(u, v) = 0$, and that it is a C^∞-function with $\phi(0) = 0$ and

$|\phi(u)| < 1$ for $0 \leqq u \leqq 1$. In view of (3.10), the curves corresponding to the critical curves of the original phase function $f(x, y)$ are determined by $u = 0$ and $v = 0$. By condition (C) in § 3, we have $\phi(u) \neq 0$ if $u \neq 0$. The function $G_0(u, v)$ is infinitely differentiable and has compact support inside the square with vertices at $(\pm 1, \pm 1)$.

Define

$$H_0^{(1)} = \frac{1}{v}[G_0(u, v) - G_0(u, 0)],$$
$$H_0^{(2)} = \frac{1}{u}[G_0(u, 0) - G_0(0, 0)], \tag{4.2}$$

and put $\mathbf{H}_0 = (H_0^{(1)}, H_0^{(2)})$. It is easily verified that

$$G_0(u, v) = G_0(0, 0) + (v, u) \cdot \mathbf{H}_0, \tag{4.3}$$

$$\nabla \cdot (\mathbf{H}_0 e^{iNuv}) = (\nabla \cdot \mathbf{H}_0) e^{iNuv} + iN[(v, u) \cdot \mathbf{H}_0] e^{iNuv}. \tag{4.4}$$

Inserting (4.3) and (4.4) into (4.1), we obtain

$$\begin{aligned} I_1(N) = G_0(0, 0) &\int_0^1 \int_0^{\phi(u)} e^{iNuv}\, dv\, du \\ &+ \frac{1}{iN} \int_0^1 \int_0^{\phi(u)} \nabla \cdot (\mathbf{H}_0 e^{iNuv})\, dv\, du \\ &+ \frac{i}{N} \int_0^1 \int_0^{\phi(u)} (\nabla \cdot \mathbf{H}_0) e^{iNuv}\, dv\, du. \end{aligned} \tag{4.5}$$

The first integral on the right can be written as

$$\frac{1}{iN} \int_0^1 \frac{1}{u}[e^{iNu\phi(u)} - 1]\, du. \tag{4.6}$$

In view of the fact that $G_0(u, v)$, and hence also $H_0^{(1)}(u, v)$, vanishes on the line $u = 1$, we readily verify by using Green's theorem that the second integral on the right-hand side of (4.5) is equal to

$$\begin{aligned} -\int_0^1 H_0^{(2)}(u, 0)\, du &+ \int_0^1 H_0^{(2)}(u, \phi(u))\, e^{iNu\phi(u)}\, du \\ &- \int_0^1 H_0^{(1)}(u, \phi(u))\, e^{iNu\phi(u)} \phi'(u)\, du, \end{aligned}$$

which in turn is equal to

$$\begin{aligned} -\int_0^1 \frac{1}{u}[G_0(u, 0) - G_0(0, 0)]\, du &\\ + \int_0^1 \frac{1}{u}[G_0(u, 0) - G_0(0, 0)]\, e^{iNu\phi(u)}\, du &\\ - \int_0^1 \frac{1}{\phi(u)}[G_0(u, \phi(u)) - G_0(u, 0)]\, e^{iNu\phi(u)} \phi'(u)\, du. & \end{aligned} \tag{4.7}$$

Combining the integral in (4.6) with the first two integrals in (4.7) gives

$$I_1(N)=\frac{1}{iN}\int_0^1 G_0(u,0)\frac{1}{u}[e^{iNu\phi(u)}-1]\,du$$

$$-\frac{1}{iN}\int_0^1 \frac{1}{\phi(u)}[G_0(u,\phi(u))-G_0(u,0)]\,e^{iNu\phi(u)}\phi'(u)\,du \tag{4.8}$$

$$+\frac{i}{N}\int_0^1\int_0^{\phi(u)} G_1(u,v)\,e^{iNuv}\,dv\,du,$$

where $G_1(u,v)=\nabla\cdot\mathbf{H}_0$. Note that the last integral on the right-hand side of (4.8) has exactly the same form as the integral $I_1(N)$ in (4.1), except that it is now multiplied by a factor $1/N$. Thus we may repeat the above procedure with $G_0(u,v)$ replaced by $G_1(u,v)$. Each time we perform this procedure, we produce a factor $1/N$ in the new "remainder term." Therefore, it suffices to consider just the two one-dimensional integrals in (4.8). To the first integral in (4.8), we apply an integration by parts. The result is

$$I_1(N)=-\int_0^1 (\log u)G_0(u,0)[\phi(u)+u\phi'(u)]\,e^{iNu\phi(u)}\,du$$

$$-\frac{1}{iN}\int_0^1 (\log u)\frac{\partial G_0}{\partial u}(u,0)\,e^{iNu\phi(u)}\,du+\frac{1}{iN}\int_0^1 (\log u)\frac{\partial G_0}{\partial u}(u,0)\,du$$

$$-\frac{1}{iN}\int_0^1 \frac{1}{\phi(u)}[G_0(u,\phi(u))-G_0(u,0)]\phi'(u)\,e^{iNu\phi(u)}\,du \tag{4.9}$$

$$+\frac{i}{N}\int_0^1\int_0^{\phi(u)} G_1(u,v)\,e^{iNuv}\,dv\,du.$$

Note that the third integral in (4.9) is independent of N; hence it is simply a coefficient of $1/N$ in the final expansion of $I_1(N)$. Here a comment is in order. Recall that the function $G_0(u,v)$ may involve an arbitrary C^∞-function used in isolating $(0,0)$ from other critical points. Thus it may seem strange that the coefficient

$$\int_0^1 (\log u)\frac{\partial G_0}{\partial u}(u,0)\,du$$

of $1/N$ in (4.9) depends on the values of $G_0(u,v)$ on the whole interval $[0,1]$. However, since $I_1(N)$ is only part of the original integral $I(N)$ in (1.1), there are contributions from other parts of $I(N)$ that in many cases will cancel this term in (4.9); see § 6 for a discussion of a complete case.

We now examine the three one-dimensional integrals in (4.9) which involve N. Observe that the first two are of the form

$$A(N)=\int_0^c (\log u)g(u)\,e^{iNh(u)}\,du, \tag{4.10}$$

to which we can apply the following result of Erdélyi [4], as corrected by McKenna [8].

Let $g(u)$ be an M times continuously differentiable function in $[0,c)$, which vanishes in some neighborhood of c; let $h(u)$ be differentiable and

$$h'(u)=u^{\rho-1}h_1(u), \tag{4.11}$$

where $\rho \geqq 1$, and $h_1(u)$ is positive and M times continuously differentiable for $0 \leqq u < c$. Introduce a variable w defined by

$$w^\rho = h(u) - h(0) \tag{4.12}$$

and put $w_1 = [h(c) - h(0)]^{1/\rho}$. Equation (4.12) can be inverted to give an expression of the form

$$u = w\left\{\left[\frac{\rho}{h_1(0)}\right]^{1/\rho} + R(w)\right\}, \tag{4.13}$$

where $R(0) = 0$, and $R(w)$ is M times continuously differentiable in $[0, w_1)$. Define functions $k_0(w)$ and $k_1(w)$ by

$$k_0(w) = g(u)\frac{du}{dw}, \tag{4.14}$$

$$k_1(w) = k_0(w)\log\left(\left[\frac{\rho}{h_1(0)}\right]^{1/\rho} + R(w)\right). \tag{4.15}$$

THEOREM (Erdélyi [4], McKenna [8]). *With the above conditions,*

$$A(N) = e^{iNh(0)}\sum_{n=0}^{M-1}\frac{1}{n!\rho}\Gamma\left(\frac{n+1}{\rho}\right) \cdot \exp\left(i(n+1)\pi/2\rho\right)A_n N^{-(n+1)/\rho} + o(N^{-M/\rho}) \tag{4.16}$$

as $N \to \infty$, *where*

$$A_n = k_0^{(n)}(0)\frac{1}{\rho}\left[\psi\left(\frac{n+1}{\rho}\right) - \log N + i\frac{\pi}{2}\right] + k_1^{(n)}(0), \tag{4.17}$$

ψ being the logarithmic derivative of the Gamma function.

In our application to the integrals in (4.9), we have $h(u) = u\phi(u)$ with $\phi(0) = 0$. We will assume

$$\phi(u) = u^{\rho-1}\phi_1(u), \tag{4.18}$$

where ρ is an integer, $\rho \geqq 2$, and $\phi_1(0) \neq 0$. This assumption is slightly stronger than condition (C); specifically, (C) would allow $\phi(u) = e^{-1/u}\phi_1(u)$, but (4.18) does not. We will first consider the case $\phi(u)$ positive in a neighborhood of the origin. By shrinking the support of $G_0(u, v)$, we may assume without loss of generality that

$$h'(u) = \phi(u) + u\phi'(u) = u^{\rho-1}[\rho\phi_1(u) + u\phi_1'(u)]$$

is positive in an interval $[0, c)$ for some $c \leqq 1$ so that the hypothesis of the above theorem for the phase function $h(u)$ is satisfied.

Since $h(u) = u\phi(u)$ in our case, coupling (4.12) and (4.18) gives

$$w = u[\phi_1(u)]^{1/\rho}, \tag{4.19}$$

from which we can compute dw/du and obtain

$$\frac{du}{dw} = \frac{\rho[\phi_1(u)]^{1-(1/\rho)}}{\rho\phi_1(u) + u\phi_1'(u)}. \tag{4.20}$$

A straightforward calculation then yields

$$\frac{du}{dw}(0) = [\phi_1(0)]^{-1/\rho}, \tag{4.21}$$

$$\frac{d^2u}{dw^2}(0) = -\frac{2\phi_1'(0)}{\rho[\phi_1(0)]^{1+(2/\rho)}}. \tag{4.22}$$

From (4.19), we also have

$$\log u = \log w - \frac{1}{\rho}\log \phi_1(u). \tag{4.23}$$

Thus the function $R(w)$ in (4.13) satisfies

$$\log\left(\left[\frac{\rho}{h_1(0)}\right]^{1/\rho} + R(w)\right) = -\frac{1}{\rho}\log \phi_1(u).$$

In the case of the first integral in (4.9), the amplitude function $g(u)$ in (4.10) is given by

$$g(u) = G_0(u, 0)[\phi(u) + u\phi'(u)].$$

Hence, in view of (4.18), the functions $k_0(w)$ and $k_1(w)$ in (4.14) and (4.15) are given by

$$k_0(w) = G_0(u, 0)u^{\rho-1}[\rho\phi_1(u) + u\phi_1'(u)]\frac{du}{dw},$$

$$k_1(w) = -\frac{1}{\rho}k_0(w)\log \phi_1(u).$$

Clearly, these functions vanish at least to order $\rho - 1$. Elementary computation yields

$$k_0^{(\rho-1)}(0) = \rho!\, G_0(0, 0),$$

$$k_0^{(\rho)}(0) = \frac{\rho!\rho}{[\phi_1(0)]^{1/\rho}}\frac{\partial G_0}{\partial u}(0, 0),$$

$$k_1^{(\rho-1)}(0) = -\frac{1}{\rho}k_0^{(\rho-1)}(0)\log \phi_1(0),$$

$$k_1^{(\rho)}(0) = -\frac{1}{\rho}k_0^{(\rho)}(0)\log \phi_1(0) - k_0^{(\rho-1)}(0)\frac{\phi_1'(0)}{[\phi_1(0)]^{(\rho+1)/\rho}}.$$

The above theorem of Erdélyi and McKenna then gives

$$\begin{aligned}\int_0^1 (\log u)G_0(u, 0)[\phi(u) + u\phi'(u)]\, e^{iNu\phi(u)}\, du \\ = (a_0 \log N + b_0)N^{-1} + (a_1 \log N + b_1)N^{-1-(1/\rho)} + o(N^{-1-(1/\rho)}),\end{aligned} \tag{4.24}$$

where

$$\begin{aligned} a_0 &= -\frac{i}{\rho}G_0(0, 0), \\ b_0 &= \frac{i}{\rho}G_0(0, 0)\left[\psi(1) + i\frac{\pi}{2} - \log \phi_1(0)\right], \\ a_1 &= -\frac{1}{\rho!\rho^2}\Gamma\left(\frac{\rho+1}{\rho}\right)\exp(i\pi(\rho+1)/2\rho)k_0^{(\rho)}(0), \\ b_1 &= \frac{1}{\rho!\rho^2}\Gamma\left(\frac{\rho+1}{\rho}\right)\exp(i\pi(\rho+1)/2\rho)\left\{k_0^{(\rho)}(0)\left[\psi\left(\frac{\rho+1}{2}\right) + i\frac{\pi}{2}\right] + \rho k_1^{(\rho)}(0)\right\}. \end{aligned} \tag{4.25}$$

In exactly the same manner, we have

$$\frac{1}{iN}\int_0^1 (\log u)\frac{\partial G_0}{\partial u}(u,0)\, e^{iNu\phi(u)}\, du \tag{4.26}$$
$$= (c_1 \log N + d_1)N^{-1-(1/\rho)} + o(N^{-1-(1/\rho)}),$$

where

$$c_1 = \frac{1}{\rho^2}\Gamma\left(\frac{1}{\rho}\right)\exp\left(i\pi(\rho+1)/2\rho\right)[\phi_1(0)]^{-1/\rho}\frac{\partial G_0}{\partial u}(0,0), \tag{4.27}$$
$$d_1 = c_1\left[\psi\left(\frac{1}{\rho}\right) + i\frac{\pi}{2} - \log\phi_1(0)\right].$$

For the penultimate integral on the right-hand side of (4.9), we need only the usual version of the stationary phase approximation [4, Thm. 3], and the result is

$$\frac{1}{iN}\int_0^1 \frac{1}{\phi(u)}[G_0(u,\phi(u)) - G_0(u,0)]\phi'(u)\, e^{iNu\phi(u)}\, du \tag{4.28}$$
$$= \frac{1}{\rho}\Gamma\left(\frac{1}{\rho}\right)\exp\left(-i\pi(\rho-1)/(2\rho)\right)\frac{\partial G_0}{\partial v}(0,0)\phi'(0)$$
$$\cdot[\phi_1(0)]^{-1/\rho}N^{-1-(1/\rho)} + o(N^{-1-(1/\rho)}).$$

(Note that $\rho \geqq 2$.) If $\rho > 2$, then $\phi'(0) = 0$ and hence the terms in (4.28) are of asymptotically smaller order than the terms in (4.26). A combination of (4.9), (4.24), (4.26), and (4.28) gives

$$I_1(N) \sim (\alpha_1 \log N + \beta_1)N^{-1} + (\gamma_1 \log N + \delta_1)N^{-1-(1/\rho)} + \cdots, \tag{4.29}$$

where

$$\alpha_1 = \frac{i}{\rho}G_0(0,0), \tag{4.30}$$

$$\beta_1 = -\frac{i}{\rho}G_0(0,0)\left[\psi(1) + i\frac{\pi}{2} - \log\phi_1(0)\right] - i\int_0^1 (\log u)\frac{\partial G_0}{\partial u}(u,0)\, du. \tag{4.31}$$

The coefficients γ_1 and δ_1 can be expressed in terms of the coefficients a_1, b_1, c_1, and d_1 given in (4.25) and (4.27). More precisely, we have $\gamma_1 = -a_1 - c_1$, $\delta_1 = -b_1 - c_1$, if $\rho > 2$, and

$$\delta_1 = -b_1 - c_1 - \frac{1}{\rho}\Gamma\left(\frac{1}{\rho}\right)\exp\left(-i\pi(\rho-1)/(2\rho)\right)\frac{\partial G_0}{\partial v}(0,0)\phi'(0)[\phi_1(0)]^{-1/\rho}$$

if $\rho = 2$.

5. Some variations. Recall that the integral $I_1(N)$ in (4.1) is only one of those in (4.13)-(4.15) that must be considered for the original problem. We now examine a number of simple variations of the computations leading to (4.29). First, note that by taking complex conjugates we have

$$I_1(-N) = \int_0^1\int_0^{\phi(u)} G_0(u,v)\, e^{-iNuv}\, dv\, du \tag{5.1}$$
$$\sim (\bar{\alpha}_1 \log N + \bar{\beta}_1)N^{-1} + (\bar{\gamma}_1 \log N + \bar{\delta}_1)N^{-1-(1/\rho)} + \cdots,$$

where a bar $^-$ denotes the complex conjugate.

Next, we consider the case in which $\phi(u)$ is negative for $0<u\leqq 1$. As in (4.18), we again write $\phi(u)=u^{\rho-1}\phi_1(u)$. Then $\phi_1(u)$ is negative and $|\phi_1(u)|=-\phi_1(u)$. The integral corresponding to (4.1) is now

$$\begin{aligned} I_2(N) &= \int_0^1 \int_{\phi(u)}^0 G_0(u, v)\, e^{iNuv}\, dv\, du \\ &= \int_0^1 \int_0^{|\phi(u)|} G_0(u, -v)\, e^{-iNuv}\, dv\, du. \end{aligned} \tag{5.2}$$

From (5.1) it follows that

$$I_2(N)\sim(\alpha_2\log N+\beta_2)N^{-1}+(\gamma_2\log N+\delta_2)N^{-1-(1/\rho)}+\cdots \tag{5.3}$$

as $N\to\infty$, where

$$\alpha_2=-\frac{i}{\rho}G_0(0,0), \tag{5.4}$$

$$\beta_2=\frac{i}{\rho}G_0(0,0)\left[\psi(1)-i\frac{\pi}{2}-\log|\phi_1(0)|\right]+i\int_0^1(\log u)\frac{\partial G_0}{\partial u}(u,0)\,du. \tag{5.5}$$

Explicit formulas can also be given for the coefficients γ_2 and δ_2.

If the domain of integration is bounded by the v-axis, the line $v=1$, and a smooth curve $u=\theta(v)$, where $\theta(v)$ is positive, then the integral corresponding to (4.1) is

$$I_3(N)=\int_0^1\int_0^{\theta(v)}G_0(u,v)\,e^{iNuv}\,du\,dv. \tag{5.6}$$

We assume, as in (4.18), that $\theta(v)=v^{\rho-1}\theta_1(v)$, where ρ is an integer greater than or equal to 2. Interchanging the variables u and v gives

$$I_3(N)=\int_0^1\int_0^{\theta(u)}G_0^*(u,v)\,e^{iNuv}\,dv\,du,$$

where $G_0^*(u,v)=G_0(v,u)$. By (4.29), we have

$$I_3(N)\sim(\alpha_3\log N+\beta_3)N^{-1}+(\gamma_3\log N+\delta_3)N^{-1-(1/\rho)}+\cdots, \tag{5.7}$$

where $\alpha_3=iG_0(0,0)/\rho$ and

$$\beta_3=-\frac{i}{\rho}G_0(0,0)\left[\psi(1)+i\frac{\pi}{2}-\log\theta_1(0)\right]-i\int_0^1(\log v)\frac{\partial G_0}{\partial v}(0,v)\,dv. \tag{5.8}$$

Similarly, if $\theta(v)<0$ for $0<v\leqq 1$, then by (5.3)

$$I_4(N)=\int_0^1\int_{\theta(v)}^0 G_0(u,v)\,e^{iNuv}\,du\,dv\sim(\alpha_4\log N+\beta_4)N^{-1}+\cdots, \tag{5.9}$$

where $\alpha_4=-iG_0(0,0)/\rho$ and

$$\beta_4=\frac{i}{\rho}G_0(0,0)\left[\psi(1)-i\frac{\pi}{2}-\log|\theta_1(0)|\right]+i\int_0^1(\log v)\frac{\partial G_0}{\partial v}(0,v)\,dv. \tag{5.10}$$

There are many other possibilities of this type. However, we will consider just one more; the reader can easily derive corresponding results for other types. For this case, we suppose we have the domain of integration in the second quadrant; specifically, we consider the integral

$$I_5(N)=\int_{-1}^0\int_0^{\phi(u)}G_0(u,v)\,e^{iNuv}\,dv\,du, \tag{5.11}$$

where the function $\tilde{\phi}(u)=\phi(-u)$ is positive for $0<u\leqq 1$ and of the form $\tilde{\phi}(u)=u^{\rho-1}\tilde{\phi}_1(u)$ with $\rho\geqq 2$; cf. (4.18). Changing variables by replacing u by $-u$, we get

$$I_5(N)=\int_0^1\int_0^{\tilde{\phi}(u)} G_0(-u, v)\, e^{-iNuv}\, dv\, du.$$

From (5.1) it follows that

$$I_5(N)\sim(\alpha_5\log N+\beta_5)N^{-1}+\cdots, \tag{5.12}$$

where $\alpha_5=-iG_0(0,0)/\rho$ and

$$\beta_5=\frac{i}{\rho}G_0(0,0)\left[\psi(1)-i\frac{\pi}{2}-\log\tilde{\phi}_1(0)\right]-i\int_{-1}^0(\log|u|)\frac{\partial G_0}{\partial u}(u,0)\,du. \tag{5.13}$$

Finally, we consider integrals of the form (3.15). Specifically, we consider the integral

$$I_6(N)=\int_0^1\int_0^1 G_0(u, v)\, e^{iNuv}\, du\, dv, \tag{5.14}$$

where G_0 has compact support inside the square with vertices at $(\pm1, \pm1)$. Clearly, we may write

$$I_6(N)=I_1(N)+I_3(N),$$

where $I_1(N)$ and $I_3(N)$ are the integrals given in (4.1) and (5.6), respectively, with $\phi(u)=u$ and $\theta(v)=v$. Thus, in both cases, we have $\rho=2$, and $\phi_1(u)=1$ and $\theta_1(v)=1$. By (4.29) and (5.7) we obtain

$$I_6(N)\sim(\alpha_6\log N+\beta_6)N^{-1}+\cdots, \tag{5.15}$$

where $\alpha_6=iG_0(0,0)$ and

$$\beta_6=-iG_0(0,0)\left[\psi(1)+i\frac{\pi}{2}\right]-i\int_0^1(\log w)\left[\frac{\partial G_0}{\partial u}(w,0)+\frac{\partial G_0}{\partial v}(0,w)\right]dw. \tag{5.16}$$

In exactly the same manner, we may write

$$I_7(N)\equiv\int_{-1}^0\int_0^1 G_0(u, v)\, e^{iNuv}\, dv\, du=I_5(N)+I_4(N), \tag{5.17}$$

where $I_5(N)$ and $I_4(N)$ are the integrals given in (5.11) and (5.9), respectively, with $\phi(u)=-u$ and $\theta(v)=-v$. Coupling (5.9) and (5.12) gives

$$I_7(N)\sim(\alpha_7\log N+\beta_7)N^{-1}+\cdots, \tag{5.18}$$

where $\alpha_7=-iG_0(0,0)$ and

$$\beta_7=iG_0(0,0)\left[\psi(1)-i\frac{\pi}{2}\right]+i\int_0^1(\log w)\left[\frac{\partial G_0}{\partial v}(0,w)-\frac{\partial G_0}{\partial u}(-w,0)\right]dw. \tag{5.19}$$

It is interesting to observe that by adding (5.15) and (5.18) we have

$$\int_{-1}^1\int_0^1 G_0(u, v)\, e^{iNuv}\, dv\, du\sim\left[\pi G_0(0,0)-i\int_{-1}^1(\log|u|)\frac{\partial G_0}{\partial u}(u,0)\,du\right]\frac{1}{N} \tag{5.20}$$

as $N\to\infty$. Carrying out calculations analogous to (5.15) and (5.18) for the other two quadrants, and adding, gives

$$\int_{-1}^1\int_{-1}^1 G_0(u, v)\, e^{iNuv}\, du\, dv\sim\frac{2\pi}{N}G_0(0,0) \tag{5.21}$$

as $N \to \infty$. Note that $(0, 0)$ is a saddlepoint of the phase function in (5.21) and lies in the interior of the support of G_0. Hence (5.21) follows directly from (1.3). However, (5.20) does not follow from (1.4), although $(0, 0)$ is a boundary saddlepoint. This is due to the fact that the boundary curve $v = 0$ in (5.20) is tangent to, and in fact coincides with, a level curve of the phase function at $(0, 0)$.

6. The final solution. From the above discussion, it is evident that the solution to our original problem depends on many factors. In this section we consider only a particular case, in which we derive the first term of the asymptotic expansion.

First we recall that the functions $\phi(u)$ and $\theta(v)$ in (4.1) and (5.6) are determined implicitly by the equations $H(u, v) = 0$ and $K(u, v) = 0$, which represent parts of the boundary of D_2 in a neighborhood of $(0, 0)$ (see Fig. 6). If these boundary curves are tangent to a coordinate axis, i.e., if the parameter ρ in (4.18) is greater than 2, then determining $\phi_1(0)$ or $\theta_1(0)$ will require higher-order implicit differentiation. Although this can be done for any specific example, it is difficult to give a formula for the general case. We will therefore make some simplifying assumptions. More precisely, we assume that after the transformations in (3.5) and (3.10), the domain D_2 is as depicted in Fig. 7, where $0 < \phi(u) < 1$ for $0 < u \leqq 1$, $\phi'(0) = \phi_1(0) > 0$, $-1 < \theta(v) < 0$ for $0 < v \leqq 1$, and $\theta'(0) = \theta_1(0) < 0$. In this case, the value of ρ for both ϕ and θ is 2. Since ϕ and θ are defined implicitly by $H(u, v) = 0$ and $K(u, v) = 0$, respectively, we have

$$\phi_1(0) = -\frac{H_u(0, 0)}{H_v(0, 0)}, \qquad \theta_1(0) = -\frac{K_v(0, 0)}{K_u(0, 0)}. \tag{6.1}$$

The integral (3.11) can be written as

$$\int\int_{D_2} G(u, v)\, e^{iNuv}\, du\, dv = I_6(N) - I_1(N) + I_4(N), \tag{6.2}$$

where $I_1(N)$ is given by (4.1), $I_4(N)$ by (5.9), and $I_6(N)$ by (5.14), with $G_0(u, v) = G(u, v)$ in all cases. A combination of (4.29), (5.9), and (5.15) gives

$$\int\int_{D_2} G(u, v)\, e^{iNuv}\, du\, dv \sim G(0, 0)[\pi - i \log \phi_1(0) - i \log |\theta_1(0)|]\, \frac{1}{2N} \tag{6.3}$$

as $N \to \infty$, where $\phi_1(0)$ and $\theta_1(0)$ are given in (6.1). Note that the terms involving integrals in (4.31), (5.10), and (5.16) all cancel out in the calculation of (6.3), confirming a remark made in § 4 following (4.9). Now, from § 3, we recall that

$$G(0, 0) = \tfrac{1}{2} g_1(0, 0) = \tfrac{1}{2} g(0, 0)/\sqrt{-f_{20} f_{02}}. \tag{6.4}$$

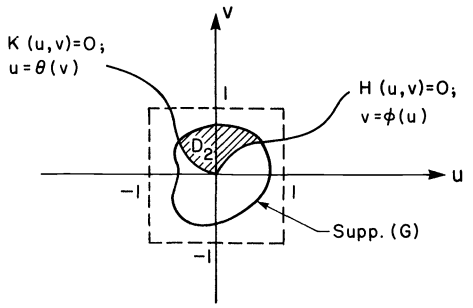

FIG. 7

Using (6.1), (3.10), and (3.5), we also find

$$\phi_1(0) = \frac{-\sqrt{-f_{02}}\, h_x(0,0) + \sqrt{f_{20}}\, h_y(0,0)}{\sqrt{-f_{02}}\, h_x(0,0) + \sqrt{f_{20}}\, h_y(0,0)}, \tag{6.5}$$

$$\theta_1(0) = \frac{\sqrt{-f_{02}}\, k_x(0,0) + \sqrt{f_{20}}\, k_y(0,0)}{-\sqrt{-f_{02}}\, k_x(0,0) + \sqrt{f_{20}}\, k_y(0,0)}. \tag{6.6}$$

Substituting (6.4)-(6.6) in (6.3), we obtain the leading term of an asymptotic expansion of the original integral $I(N)$ in terms of the original data f, g, h, and k.

The case where the boundary of D is smooth at the saddlepoint $(0, 0)$, but not tangent to a critical curve of the phase function $f(x, y)$, can be recovered from the result above. In the notation of § 5, a typical case of this would give

$$I(N) = I_6(N) + I_2(N) + I_4(N), \tag{6.7}$$

where $I_2(N)$, $I_4(N)$, and $I_6(N)$ are given, respectively, by (5.2), (5.9), and (5.14), with $G_0(u, v) = G(u, v)$ in all three cases. Since the boundary is not tangent to a critical curve of $f(x, y)$, the value of ρ for both ϕ and θ is again 2. The condition that the boundary of D be smooth at $(0, 0)$, i.e., have a tangent at that point, can be expressed in terms of ϕ_1 and θ_1 as

$$\phi_1(0) = \theta_1(0)^{-1}. \tag{6.8}$$

Noting that $\log|\phi_1(0)| = -\log|\theta_1(0)|$, it follows from (5.3), (5.9), and (5.15) that

$$I(N) \sim g(0,0)[-f_{20}f_{02}]^{-1/2}\left(\frac{\pi}{2N}\right) \tag{6.9}$$

as $N \to \infty$, in agreement with (1.4).

From the above discussion, it is now evident that our method is applicable when the boundary curve is smooth in a neighborhood of the saddlepoint and is tangent to a critical curve of f. For example, if in the uv-coordinates the boundary is smooth with a horizontal tangent at $(0, 0)$, then the integral can be expressed in the form $I_6(N) - I_1(N) + I_7(N) - I_5(N)$. The functions ϕ in $I_1(N)$ and $I_5(N)$ may be different, but both will have $\phi'(0) = 0$; or equivalently, $\rho > 2$. We emphasize that the result in such a case will be different from (6.9).

7. An example. As an illustration of the above calculation, we work out the first two terms in the asymptotic expansion of the integral

$$I(N) = \int_0^1 \int_{-x}^{x} \exp(iN \cosh x \cos y)\, dy\, dx, \tag{7.1}$$

which we will write in the form

$$I(N) = e^{iN} \int\int_D e^{iNf(x,y)}\, dx\, dy, \tag{7.2}$$

where D is the triangle with vertices at $(0, 0)$, $(1, -1)$, and $(1, 1)$, and

$$f(x, y) = \cosh x \cos y - 1 = \frac{x^2}{2} - \frac{y^2}{2} + O[(x^2+y^2)^2] \tag{7.3}$$

as $(x, y) \to (0, 0)$. Clearly, $f(x, y)$ has one and only one stationary point inside and on the boundary of D; it occurs at $(0, 0)$ and is a saddlepoint. Note that $(0, 0)$ is also a corner point of the domain D. By using a partition of unity (or neutralizers), we can

isolate it from the other two corner points $(1,-1)$ and $(1,1)$. Since the contribution from a corner point that is not a critical point of the phase function is $O(N^{-2})$ (see, e.g., [2]), we can rewrite (7.2) as

$$I(N)=e^{iN}\int\int_D g(x,y)\,e^{iNf(x,y)}\,dx\,dy+O(N^{-2}), \tag{7.4}$$

where $g(x,y)$ is a C^∞-function that is equal to 1 in a neighborhood of the origin and vanishes identically outside a disk with radius less than 1. From (7.3) it is clear that $f_{20}=\frac{1}{2}$ and $f_{02}=-\frac{1}{2}$. The functions P and Q in (3.2) and (3.3) are, in the present case, given by

$$P(x,y)=\frac{1}{x^2}\left[\cosh x-1-\frac{x^2}{2!}\right]=\frac{x^2}{4!}+O(x^4),$$

$$Q(x,y)=\frac{1}{y^2}\left[\cosh x(\cos y-1)+\frac{y^2}{2}\right]=-\frac{x^2}{(2!)^2}+\frac{y^2}{4!}+O[(x^2+y^2)^2].$$

Note that in this example $P(x,y)$ is independent of y. Define

$$\begin{aligned} p(x,y)&=\left[\frac{1}{2}+P(x,y)\right]^{1/2}=\left[\frac{1}{2}+\frac{x^2}{4!}+O(x^4)\right]^{1/2},\\ q(x,y)&=\left[\frac{1}{2}-Q(x,y)\right]^{1/2}=\left[\frac{1}{2}+\frac{x^2}{4}-\frac{y^2}{4!}+O\{(x^2+y^2)^2\}\right]^{1/2} \end{aligned} \tag{7.5}$$

so that the transformation (3.5) becomes

$$s=xp(x,y),\qquad t=yq(x,y). \tag{7.6}$$

Upon making the transformations (7.6) and (3.10), we have

$$I(N)=e^{iN}\int\int_{D_2} G(u,v)\,e^{iNuv}\,du\,dv, \tag{7.7}$$

where D_2 is the image of D and

$$G(u,v)=g(x,y)\frac{\partial(x,y)}{\partial(s,t)}\frac{\partial(s,t)}{\partial(u,v)}.$$

From (7.5), (7.6), and (3.12), it follows that

$$G(0,0)=g(0,0)=1. \tag{7.8}$$

Now we consider the boundary of D_2 near the corner $(0,0)$, which is determined by the two curves

$$H(u,v)=x+y=0,\qquad K(u,v)=x-y=0, \tag{7.9}$$

where $H(u,v)$ and $K(u,v)$ denote, respectively, the transforms of the functions $x+y$ and $x-y$ in terms of the variables u and v. From (7.9) and (3.10), we have

$$\begin{aligned} H_u(u,v)&=\tfrac{1}{2}(x_s+y_s)-\tfrac{1}{2}(x_t+y_t),\\ H_v(u,v)&=\tfrac{1}{2}(x_s+y_s)+\tfrac{1}{2}(x_t+y_t),\\ K_u(u,v)&=\tfrac{1}{2}(x_s-y_s)-\tfrac{1}{2}(x_t-y_t),\\ K_v(u,v)&=\tfrac{1}{2}(x_s-y_s)+\tfrac{1}{2}(x_t-y_t). \end{aligned} \tag{7.10}$$

Simple computation from (7.5) and (7.6) gives

$$x_s(0,0) = y_t(0,0) = \sqrt{2}, \qquad x_t(0,0) = y_s(0,0) = 0. \tag{7.11}$$

Hence

$$H_u(0,0) = 0, \qquad H_v(0,0) = \sqrt{2}, \tag{7.12}$$

$$K_u(0,0) = \sqrt{2}, \qquad K_v(0,0) = 0. \tag{7.13}$$

By the implicit function theorem, there exists $\phi(u)$ such that $v = \phi(u)$ satisfies $H(u, v) = 0$ near $(0, 0)$. Furthermore,

$$\phi'(u) = -\left.\frac{H_u(u,v)}{H_v(u,v)}\right|_{v=\phi(u)}, \tag{7.14}$$

and, in particular, $\phi'(0) = 0$. This means that the boundary curve $H(u, v) = 0$ is tangent to the u-axis at $(0, 0)$. Similarly, there exists $\theta(v)$ such that $u = \theta(v)$ satisfies $K(u, v) = 0$ near $(0, 0)$, with

$$\theta'(v) = -\left.\frac{K_v(u,v)}{K_u(u,v)}\right|_{u=\theta(v)} \tag{7.15}$$

and $\theta'(0) = 0$.

To apply our results, we need to determine a value of ρ for each of the boundary curves $v = \phi(u)$ and $u = \theta(v)$ so that $\phi(u) = u^{\rho-1}\phi_1(u)$ and $\theta(v) = v^{\rho-1}\theta_1(v)$, and the values of $\phi_1(0)$ and $\theta_1(0)$. (The value of ρ need *not* be the same for ϕ and θ.) Now, $\phi''(u)$ can be computed from (7.14). Using (7.12) and the fact that $\phi'(0) = 0$, we find

$$\phi''(0) = -\frac{1}{\sqrt{2}} H_{uu}(0,0). \tag{7.16}$$

To evaluate $H_{uu}(0, 0)$, we begin with the first equation in (7.10). From (3.10) we obtain

$$H_{uu}(u,v) = \tfrac{1}{4}(x_{ss} + y_{ss}) - \tfrac{1}{2}(x_{st} + y_{ts}) + \tfrac{1}{4}(x_{tt} + y_{tt}). \tag{7.17}$$

Differentiating the equations in (7.6) gives

$$\begin{aligned}
&1 = px_s + xp_s, \qquad 0 = px_t + xp_t,\\
&0 = px_{ss} + 2x_s p_s + xp_{ss},\\
&0 = px_{st} + p_t x_s + x_t p_s + xp_{st},\\
&0 = px_{tt} + 2x_t p_t + xp_{tt},\\
&0 = qy_s + yq_s, \qquad 1 = qy_t + yq_t,\\
&0 = qy_{ss} + 2q_s y_s + yq_{ss},\\
&0 = qy_{st} + q_t y_s + q_s y_t + yq_{st},\\
&0 = qy_{tt} + 2y_t q_t + yq_{tt}.
\end{aligned} \tag{7.18}$$

Since $(x, y) = (0, 0)$ corresponds to $(s, t) = (0, 0)$, and since $p(0, 0) = q(0, 0) = 1/\sqrt{2}$, we have from (7.11)

$$\begin{aligned}
&x_{ss} = -4p_s, \quad x_{st} = -2p_t, \quad x_{tt} = 0,\\
&y_{ss} = 0, \qquad y_{st} = -2q_s, \quad y_{tt} = -4q_t,
\end{aligned} \tag{7.19}$$

where it is understood that all derivatives are evaluated at $(0, 0)$. From (7.11), we also have $p_s = p_x x_s + p_y y_s = \sqrt{2}\, p_x$ at $(0, 0)$. Hence it follows from (7.5) that $p_s(0, 0) = \sqrt{2}\, p_x(0, 0) = 0$. Similarly, we find $p_t(0, 0) = 0$. (The argument for the latter case is actually simpler, since p is independent of y in this example.) By the same reasoning, we have $q_s = q_x x_s + q_y y_s = \sqrt{2}\, q_x$ and $q_s(0, 0) = \sqrt{2}\, q_x(0, 0) = 0$. Similarly, $q_t(0, 0) = 0$. A combination of (7.16), (7.17), and (7.19) gives

$$\phi''(0) = -\frac{1}{\sqrt{2}} H_{uu}(0, 0) = 0. \tag{7.20}$$

Our next step is to find $\phi^{(3)}(0)$, which can be computed from (7.14). The full expression is very complicated; however, since $\phi'(0) = \phi''(0) = 0$, we have from (7.12) and (7.20) the relatively simple equation

$$\phi^{(3)}(0) = -\frac{1}{\sqrt{2}} H_{uuu}(0, 0). \tag{7.21}$$

Differentiating (7.17), we obtain

$$H_{uuu}(u, v) = \tfrac{1}{8}(x_{sss} + y_{sss}) - \tfrac{3}{8}(x_{sst} + y_{sst}) + \tfrac{3}{8}(x_{stt} + y_{stt}) - \tfrac{1}{8}(x_{ttt} + y_{ttt}) \tag{7.22}$$

on account of (3.10). To evaluate the partial derivatives on the right-hand side, we turn to the equations in (7.18). First, from the third equation in (7.18), we have

$$p x_{sss} + 3 p_s x_{ss} + 3 p_{ss} x_s + x p_{sss} = 0.$$

Since $(x, y) = (0, 0)$ corresponds to $(s, t) = (0, 0)$, and since all the second-order partial derivatives in (7.19) vanish at $(0, 0)$, the last equation yields

$$x_{sss}(0, 0) = -6 p_{ss}(0, 0). \tag{7.23}$$

Now, $p_{ss} = p_{xx} x_s^2 + 2 p_{xy} x_s y_s + p_{yy} y_s^2 + p_x x_{ss} + p_y y_{ss}$. In view of the fact that p is independent of y, and again by the vanishing at $(0, 0)$ of all the second-order partial derivatives in (7.19), this gives

$$p_{ss}(0, 0) = 2 p_{xx}(0, 0) = \frac{1}{6\sqrt{2}}. \tag{7.24}$$

The last equality follows from (7.5). Coupling (7.23) and (7.24), we obtain

$$x_{sss}(0, 0) = -\frac{1}{\sqrt{2}}. \tag{7.25}$$

Similar computations, beginning with (7.18) and using analogues of (7.24), yield

$$\begin{aligned} &x_{sst} = 0, \quad x_{stt} = 0, \quad x_{ttt} = 0, \\ &y_{sss} = 0, \quad y_{sst} = -\sqrt{2}, \quad y_{stt} = 0, \quad y_{ttt} = \frac{1}{\sqrt{2}}, \end{aligned} \tag{7.26}$$

where all derivatives are again evaluated at $(0, 0)$. Returning to (7.21), we have from (7.22), (7.25), and (7.26)

$$\phi^{(3)}(0) = -\tfrac{1}{4}. \tag{7.27}$$

Hence it follows that for the boundary curve $H(u, v) = x + y = 0$ we have

$$\rho_H = 4, \qquad \phi_1(0) = -\tfrac{1}{24}. \tag{7.28}$$

In the same manner, beginning with (7.15), we find that for the boundary curve $K(u, v) = x - y = 0$, we have $\theta'(0) = \theta''(0) = 0$ and $\theta^{(3)}(0) = -\frac{1}{4}$. Consequently, we again have

$$\rho_K = 4, \qquad \theta_1(0) = -\tfrac{1}{24}. \tag{7.29}$$

Note that $\phi^{(3)}(0)$ and $\theta^{(3)}(0)$ negative implies that both $\phi(u)$ and $\theta(v)$ are negative for sufficiently small positive u and v. Consequently, (5.3), (5.9), and (5.15) apply, with the integral (7.1) taken in the form

$$I(N) = I_2(N) + I_6(N) + I_4(N).$$

Using these equations and (7.8), we obtain

$$I(N) \sim \frac{i}{2}\frac{\log N}{N} + \left\{\frac{3\pi}{4} + i\left[\frac{\gamma}{2} + \log(2\sqrt{6})\right]\right\}\frac{1}{N} \tag{7.30}$$

as $N \to \infty$, where $\gamma = -\psi(1)$ is the Euler constant.

The above example may seem to be too complicated for illustration purposes, and simpler examples could have been given instead. However, we find that this example is rather realistic, and demonstrates the fact that our method indeed works in practical situations. It also illustrates well the computations involved in our procedure, particularly in cases where parameter ρ is greater than 2.

ON THE ASYMPTOTIC BEHAVIOR OF THE COEFFICIENTS OF ASYMPTOTIC POWER SERIES AND ITS RELEVANCE TO STOKES PHENOMENA*

G. K. IMMINK†

Abstract. This paper discusses the relevance of the asymptotic behavior of the coefficients of asymptotic power series for the study of Stokes phenomena. By way of illustration a connection problem is considered in the theory of linear difference equations.

Key words. asymptotic expansion, isomorphism of Malgrange, Cauchy-Heine transform, saddle-point method, Stokes phenomenon, linear analytic functional equation, difference equation

AMS(MOS) subject classifications. 30E15, 39

Introduction. In this paper we extend and apply ideas of Malgrange [10] and Ramis [12] concerning the connection between Stokes phenomena, in a wider sense, and formal power series. We start with an illustrative example.

Let y be an analytic function on the Riemann surface of $\log z$, with the following properties.

(i) y admits an asymptotic expansion of the form $\sum_{n=0}^{\infty} y_n z^{-n}$ as $z \to \infty$ in the sector S: $-\pi/2 < \arg z < 5\pi/2$.

(ii) $y(z) - y(z e^{2\pi i}) = c e^{-z}$, $c \in \mathbb{C}^*$.

The second property implies that the asymptotic behavior of y changes abruptly as $\arg z$ becomes larger than $5\pi/2$ or less than $-\pi/2$. Such a change in asymptotic behavior will be called a Stokes phenomenon.

Now consider the function h defined by

$$h(z) = \frac{1}{2\pi i} \int_0^{\infty} \frac{e^{-t}}{t - z}\, dt, \qquad 0 < \arg z < 2\pi.$$

h is a Cauchy-Heine transform of e^{-z} (cf. [12]). By deformation of the path of integration it may be continued analytically to the Riemann surface of $\log z$. With the aid of residue calculus we readily verify that

$$h(z) - h(z e^{2\pi i}) = e^{-z}. \tag{0.1}$$

Moreover, h admits the asymptotic expansion $\sum_{n=1}^{\infty} h_n z^{-n}$ as $z \to \infty$, $z \in S$, where

$$h_n = -\frac{1}{2\pi i} \int_0^{\infty} e^{-t} t^{n-1}\, dt, \qquad n \in \mathbb{N}. \tag{0.2}$$

From (ii) and (0.1) we conclude that

$$y(z e^{2\pi i}) - ch(z e^{2\pi i}) = y(z) - ch(z).$$

Thus it turns out that $y - ch$ is a single-valued analytic function, admitting an asymptotic expansion of the form $\sum_{n=0}^{\infty} a_n z^{-n}$ as $z \to \infty$, $z \in S$, where

$$a_n = y_n - ch_n. \tag{0.3}$$

† University of Groningen, Institute of Econometrics, P.O. Box 800, 9700AV, Groningen, the Netherlands.

This implies that $y - ch$ is holomorphic at ∞ and, consequently, $\sum_{n=0}^{\infty} a_n z^{-n}$ is a convergent power series. From (0.2) and (0.3) it now follows that

$$c = -2\pi i \lim_{n\to\infty} \frac{y_n}{(n-1)!}.$$

Apparently, the constant c, which plays a central role in the Stokes phenomenon occurring in this example, is intimately related to the asymptotic behavior of the coefficients y_n. It is this relationship that forms the subject of this paper.

We shall consider the following situation. Suppose we are given a number of sectors S_ν, $\nu \in \{1, \cdots, N\}$, which cover a neighborhood of ∞ and a corresponding number of functions y_ν with the following properties: y_ν is analytic in S_ν and represented asymptotically by a series of the form $\sum_{n=0}^{\infty} \hat{y}_n z^{-n}$ (independent of ν) as $z \to \infty$, $z \in S_\nu$, $\nu \in \{1, \cdots, N\}$. Moreover, assume that

$$(0.4) \qquad y_{\nu+1}(z) - y_\nu(z) = \sum_{j=1}^{m} c_j^\nu \varphi_j^\nu(z), \qquad z \in S_\nu \cap S_{\nu+1}, \quad \nu \in \{1, \cdots, N\},$$

where $S_{N+1} = e^{2\pi i} S_1$, $y_{N+1}(z) \equiv y_1(z\, e^{-2\pi i})$, $c_j^\nu \in \mathbb{C}$, and the φ_j^ν belong to a certain class of analytic functions. We shall establish a relation between the complex numbers c_j^ν and the asymptotic behavior of $\hat{y}_n$ for $n \to \infty$. In some applications this relation may be exploited to "compute" at least part of the numbers c_j^ν from the coefficients $\hat{y}_n$ (cf. [9] and Remark 2 herein).

If the y_ν represent (sectorial models of) a resurgent function, our results could be derived from the work of Ecalle (cf. [4]). For the present purpose, however, this assumption is not needed and we shall establish the relation mentioned above in a more direct manner.

The argument is essentially the same as the one we used in [9]. It is based on the Propositions 1.1–1.3 herein. Proposition 1.1 concerns the properties of Cauchy–Heine transforms of functions like the φ_j^ν in (0.4). Proposition 1.2 enables us to construct, from the Cauchy–Heine transforms of the φ_j^ν, analytic functions H_ν with the same properties as the y_ν and only differing from the y_ν by a convergent power series in $1/z$. The coefficients of the asymptotic expansion $\hat{H}$ of the H_ν are given by the expression

$$\hat{H}_n = -\frac{1}{2\pi i} \sum_{\nu=1}^{N} \sum_{j=1}^{m} c_j^\nu \int_{\gamma_\nu} \varphi_j^\nu(t) t^{n-1}\, dt, \qquad \gamma_\nu \subset S_\nu.$$

Under certain conditions, like those mentioned in Proposition 1.3, the saddle-point method may be applied to the integral

$$\int_{\gamma_\nu} \varphi_j^\nu(t) t^{n-1}\, dt$$

to obtain its asymptotic behavior for $n \to \infty$. The main result is stated in Theorem 1.4. In § 2 this result is applied to a connection problem in the theory of homogeneous linear difference equations.

1. The general argument. Let $\mathbb{C}_\infty$ denote the Riemann surface of $\log z$. Let $z_0 \in \mathbb{C}_\infty$, $\alpha, \beta \in \mathbb{R}$, $\alpha < \beta$. By $S(\alpha, \beta)$ we denote the sector

$$S(\alpha, \beta) = \{z \in \mathbb{C}_\infty : \alpha < \arg z < \beta\}$$

and by $S(z_0, \alpha, \beta)$ the set

$$(1.1) \qquad S(z_0, \alpha, \beta) = \{z \in \mathbb{C}_\infty : \alpha < \arg (z - z_0) < \beta, |z| > |z_0|\}.$$

This will also be called a sector.

If S is a sector of the form $S=S(z_0, \alpha, \beta)$, then $\underline{S}$ will denote the sector $S(z_0, \alpha, \beta+2\pi)$.

Let $S=S(z_0, \alpha, \beta)$, $S'=S(z_1, \alpha', \beta')$ with $\alpha<\alpha'<\beta'<\beta$. We shall write

$$S' \Subset S$$

whenever $z_1 \in S$ and $S' \subset S(z_0, \alpha', \beta')$.

Let $\hat{h}=\sum_{n=0}^{\infty} h_n z^{-n}$ be a formal power series in z^{-1}, S a sector of the type (1.1), and h a function on S. We say that h is represented asymptotically by $\hat{h}$ as $z \to \infty$ in S, and write

$$h(z) \sim \sum_{n=0}^{\infty} h_n z^{-n}, \qquad z \to \infty \text{ in } S$$

if, for every $S' \Subset S$ and every $N \in \mathbb{N}$,

$$R_N(h; z) \equiv h(z) - \sum_{n=0}^{N-1} h_n z^{-n} = O(z^{-N}), \qquad z \to \infty, \quad z \in S'.$$

Any function φ which is analytic in a sector S and represented asymptotically by zero (i.e., the series with coefficients equal to zero) as $z \to \infty$ in S, may be written as the difference of two determinations of its Cauchy-Heine transform. The following proposition, due to Ramis, is concerned with the asymptotic properties of this Cauchy-Heine transform.

PROPOSITION 1.1 (cf. [12, Prop. 4.2]). *Let α and β be real numbers such that $\alpha<\beta$, $z_0 \in S(\alpha, \beta)$, and let φ be an analytic function on $S=S(z_0, \alpha, \beta)$. Suppose there exist positive numbers M_n, $n \in \mathbb{N}$, such that*

$$\sup_{z \in S} |z^n \varphi(z)| < M_n, \qquad n \in \mathbb{N}. \tag{1.2}$$

Then the function h defined by

$$h(z)=\frac{z}{2\pi i} \int_{\gamma} \frac{\varphi(\zeta)}{\zeta(\zeta-z)}\, d\zeta, \qquad z \in S(z_0, \Theta, \Theta+2\pi),$$

where γ is a half line in S from z_0 to ∞ with direction Θ, has the following properties:

(i) *h can be continued analytically to $\underline{S}$,*

(ii) *$h(z)-h(z e^{2\pi i})=\varphi(z)$ for all $z \in S$,*

(iii) *h is represented asymptotically by*

$$\sum_{n=0}^{\infty} -\frac{1}{2\pi i}\left(\int_{\gamma} \varphi(\zeta)\zeta^{n-1}\, d\zeta\right) z^{-n},$$

as $z \to \infty$ in $\underline{S}$. Moreover, for every $S' \Subset \underline{S}$ there exists a positive constant $C_{S'}$ such that

$$\sup_{z \in S'} |z^n R_n(h; z)| \leqq C_{S'} M_{n+1}, \qquad n \in \mathbb{N}.$$

Proof. Let us suppose that S is a convex set, i.e., $\beta-\pi/2<\arg z_0<\alpha+\pi/2$. In that case every half line from z_0 to ∞ with direction $\Theta \in (\alpha, \beta)$ lies in S. If γ has direction Θ, h is obviously analytic in $S(z_0, \Theta, \Theta+2\pi)$. The analytic continuation to $\underline{S}$ is obtained by varying Θ. Part (ii) follows immediately from Cauchy's theorem.

Now let $S'=S(z_1, \alpha', \beta') \Subset \underline{S}$. Then there is a number $\varepsilon \in (0, \pi/2)$ such that $\alpha+\varepsilon<\arg(z-z_0)<\beta+2\pi-\varepsilon$ for all $z \in S'$. Let $z \in S'$ and choose $\Theta \in (\alpha, \beta)$ in such

a way that $\Theta+\varepsilon<\arg(z-z_0)<\Theta+2\pi-\varepsilon$. Let γ_Θ be the half line from z_0 to ∞ with direction Θ. For all $\zeta\in\gamma_\Theta$ the following inequality holds:

$$|\zeta-z|>|z-z_0|\sin\varepsilon>|z|\left(1-\left|\frac{z_0}{z_1}\right|\right)\sin\varepsilon. \tag{1.3}$$

It is easily seen that

$$z^nR_n(h;z)=\frac{z}{2\pi i}\int_{\gamma_\Theta}\frac{\varphi(\zeta)}{\zeta-z}\,\zeta^{n-1}\,d\zeta,\qquad n\in\mathbb{N}.$$

With (1.2) and (1.3) it follows that

$$|z^nR_n(h;z)|<\frac{1}{2\pi\sin\varepsilon}\left(1-\left|\frac{z_0}{z_1}\right|\right)^{-1}\int_{\gamma_\Theta}\left|\frac{d\zeta}{\zeta^2}\right|M_{n+1}.$$

Hence

$$\sup_{z\in S'}|z^nR_n(h;z)|<\frac{1}{2\pi\sin\varepsilon}\left(1-\left|\frac{z_0}{z_1}\right|\right)^{-1}\sup_{\Theta\in(\alpha,\beta)}\int_{\gamma_\Theta}\left|\frac{d\zeta}{\zeta^2}\right|M_{n+1}$$

and this proves (iii).

If S is not convex the above argument must be adapted in an obvious manner.

PROPOSITION 1.2 (cf. [10], [12]). *Let $N\in\mathbb{N}$. Let α_ν, β_ν, $\nu\in\{1,\cdots,N\}$, be real numbers such that $\alpha_\nu\leqq\alpha_{\nu+1}<\beta_\nu\leqq\beta_{\nu+1}$ if $\nu<N$ and $\alpha_N\leqq\alpha_{N+1}\equiv\alpha_1+2\pi<\beta_N\leqq\beta_{n+1}\equiv\beta_1+2\pi$. Let $z_\nu\in S(\alpha_{\nu+1},\beta_\nu)$ and $S^\nu=S(z_\nu,\alpha_{\nu+1},\beta_\nu)$, $\nu=1,\cdots,N$.*

Suppose that, for every $\nu\in\{1,\cdots,N\}$, we are given an analytic function φ_ν on S^ν with the property that $\varphi_\nu(z)\sim0$ as $z\to\infty$ in S^ν. Let

$$h_\nu(z)=\frac{z}{2\pi i}\int_{\gamma_\nu}\frac{\varphi_\nu(\zeta)}{\zeta(\zeta-z)}\,d\zeta,\qquad z\in S(z_\nu,\Theta_\nu,\Theta_\nu+2\pi),\quad \nu\in\{1,\cdots,N\},$$

where γ_ν is a half line in S^ν from z_ν to ∞ with direction Θ_ν and let

$$H_\nu(z)=\sum_{\mu=1}^{\nu-1}h_\mu(z)+\sum_{\mu=\nu}^{N}h_\mu(z\,e^{2\pi i})\quad \text{if } \nu\in\{2,\cdots,N\},$$

$$H_1(z)=\sum_{\mu=1}^{N}h_\mu(z\,e^{2\pi i})\qquad \text{and}\qquad H_{N+1}(z)=\sum_{\mu=1}^{N}h_\mu(z).$$

The functions H_ν have the following properties:

(i) *For every $\nu\in\{1,\cdots,N+1\}$ there exists a $\tilde z_\nu\in S(\alpha_\nu,\beta_\nu)$ such that $\tilde z_{N+1}=\tilde z_1\,e^{2\pi i}$ and H_ν is analytic on $S_\nu=S(\tilde z_\nu,\alpha_\nu,\beta_\nu)$.*

(ii) *$H_{\nu+1}(z)-H_\nu(z)=\varphi_\nu(z)$ for all $z\in S_\nu\cap S_{\nu+1}$, $\nu\in\{1,\cdots,N\}$, and $H_{N+1}(z)=H_1(z\,e^{-2\pi i})$ for all $z\in e^{2\pi i}S_1$.*

(iii) *H_ν admits an asymptotic power series expansion $\hat H$ independent of ν, as $z\to\infty$ in S_ν.*

Moreover, if $\tilde H_\nu$, $\nu=1,\cdots,N+1$, are functions with the same properties, then there exists a function h, holomorphic at ∞, such that

$$\tilde H_\nu-H_\nu=h\quad \text{for all } \nu\in\{1,\cdots,N\}.$$

Proof. From Proposition 1.1(i) we deduce that H_ν is analytic in

$$\bigcap_{\mu=1}^{\nu-1}S(z_\mu,\alpha_{\mu+1},\beta_\mu+2\pi)\ \bigcap_{\mu=\nu}^{N}S(z_\mu,\alpha_{\mu+1}-2\pi,\beta_\mu)\quad \text{if } \nu\in\{2,\cdots,N\},$$

in

$$\bigcap_{\mu=1}^{N} S(z_\mu, \alpha_{\mu+1}-2\pi, \beta_\mu) \quad \text{if } \nu=1,$$

and in

$$\bigcap_{\mu=1}^{N} S(z_\mu, \alpha_{\mu+1}, \beta_\mu+2\pi) \quad \text{if } \nu=N+1,$$

and this set contains a sector of the form $S(\tilde{z}_\nu, \alpha_\nu, \beta_\nu)$ for a suitable choice of $\tilde{z}_\nu$. Part (ii) follows immediately from Proposition 1.1(ii) by observing that

$$H_{\nu+1}(z)-H_\nu(z)=h_\nu(z)-h_\nu(z\,e^{2\pi i}) \quad \text{for all } \nu\in\{1,\cdots,N\}.$$

Furthermore, Proposition 1.1(iii) implies that $H_\nu(z)\sim\sum_{n=0}^{\infty} H_n z^{-n}$, as $z\to\infty$ in S_ν, where

$$H_n=-\frac{1}{2\pi i}\sum_{\nu=1}^{N}\int_{\gamma_\nu}\varphi_\nu(\zeta)\zeta^{n-1}\,d\zeta, \qquad n\in\mathbb{N}. \tag{1.4}$$

Now suppose that $\tilde{H}_\nu$, $\nu=1,\cdots,N+1$, are functions with the properties (i)-(iii) mentioned in Proposition 1.2. Then there exist $z'_\nu\in S(\alpha_\nu,\beta_\nu)$ such that both H_ν and $\tilde{H}_\nu$ are analytic on $\tilde{S}_\nu=S(z'_\nu,\alpha_\nu,\beta_\nu)$ and we have

$$\tilde{H}_{\nu+1}(z)-\tilde{H}_\nu(z)=H_{\nu+1}(z)-H_\nu(z), \quad z\in\tilde{S}_\nu\cap\tilde{S}_{\nu+1}, \quad \nu\in\{1,\cdots,N\}$$

and

$$\tilde{H}_{N+1}(z)-\tilde{H}_1(z\,e^{-2\pi i})=H_{N+1}(z)-H_1(z\,e^{-2\pi i}), \qquad z\in\tilde{S}_{N+1}.$$

It follows that

$$\tilde{H}_{\nu+1}-H_{\nu+1}=\tilde{H}_\nu-H_\nu \quad \text{for all } \nu\in\{1,\cdots,N\}$$

and, moreover,

$$\tilde{H}_{N+1}(z)-H_{N+1}(z)=\tilde{H}_1(z\,e^{-2\pi i})-H_1(z\,e^{-2\pi i}).$$

Hence the function $h=\tilde{H}_1-H_1$ can be continued analytically to a reduced neighborhood of ∞. Furthermore, property (iii) implies that h admits an asymptotic power series expansion in z^{-1} as $z\to\infty$ in a neighborhood of ∞ and, consequently, h is analytic in a full neighborhood of ∞.

The next proposition concerns the asymptotic behavior of integrals of the type

$$\int_\gamma \varphi(z)z^n\,dz,$$

where γ is a half line and φ is an analytic function with the property that $\varphi(z)\sim 0$ as $z\to\infty$ in some sector S containing γ. The conditions (iii)-(v) below are purely technical and have been chosen in such a way that the result follows by a straightforward application of the saddle-point method. They might be relaxed or replaced by other conditions. We have merely tried to define a class of functions for which this method works.

PROPOSITION 1.3 (cf. [2, Thm. 7, Remark 6]). *Let α and β be real numbers such that $\alpha<\beta$, $z_0\in S(\alpha,\beta)$, and let ψ be an analytic function on $S=S(z_0,\alpha,\beta)$ with the property that*

(i) $\exp\psi(z)\sim 0$ *as* $z\to\infty$ *in* S.

Let $g: S\times\mathbb{N}\to\mathbb{C}$ be defined by

$$g(z,n)=\psi(z)+n\log z.$$

Suppose there exists $n_0 \in \mathbb{N}$ *such that for all* $n \geqq n_0$ *the following conditions hold*:

(ii) *The equation* $\partial g/\partial z = 0$ *has a solution* $s_n \in S$ *such that the half line* γ_n *from* z_0 *to* ∞ *through* s_n *is contained in* S. *Moreover,* $s_n \to \infty$ *as* $n \to \infty$.

(iii) *There exists a number* $\Theta \in (0, \pi/2)$ *such that*

$$\left| \arg - s_n^2 \frac{\partial^2 g}{\partial z^2}(s_n, n) \right| \leqq \Theta$$

and, furthermore, $s_n^2(\partial^2 g/\partial z^2)(s_n, n) \to \infty$ *as* $n \to \infty$.

(iv) *There exist positive numbers* ε_0 *and* K *such that*

$$\left| z \frac{\partial^3}{\partial z^3} g(z, n) \left\{ \frac{\partial^2}{\partial z^2} g(z, n) \right\}^{-1} \right| \leqq K$$

if $|z - s_n| < \varepsilon_0 |s_n|$.

(v) *Let* $\alpha_n = \arg(s_n - z_0) - \arg s_n$. *There exists a positive number* ε_1, *a function* $n_1 : (0, \varepsilon_1) \to \mathbb{N}$, *a bounded function* $g_1 : (0, \varepsilon_1) \times (-1, 0) \to \mathbb{R}$, *and a function* $g_2 : (0, \varepsilon_1) \times (0, \infty) \to \mathbb{R}$ *such that, for all* $\varepsilon \in (0, \varepsilon_1)$, $\exp g_2(\varepsilon, \cdot) \in \mathscr{L}(0, \infty)$, *and, for all* $n \geqq n_1(\varepsilon)$,

$$\operatorname{Re}\{g(s_n(1 + \tau e^{i\alpha_n}), n) - g(s_n(1 - \varepsilon e^{i\alpha_n}), n)\} \leqq g_1(\varepsilon, \tau)$$

if $\tau \in (-|1 - z_0/s_n|, -\varepsilon)$, *whereas*

$$\operatorname{Re}\{g(s_n(1 + \tau e^{i\alpha_n}), n) - g(s_n(1 + \varepsilon e^{i\alpha_n}), n)\} \leqq g_2(\varepsilon, \tau)$$

if $\tau \in (\varepsilon, \infty)$.

Furthermore, let f *be a bounded analytic function on* S *and suppose there exists a positive number* ε *such that*

(vi) $\sup_{z \in I_n(\varepsilon)} |f(z) - 1| \to 0$ *if* $n \to \infty$, *where* $I_n(\varepsilon)$ *denotes the segment between* $s_n(1 - \varepsilon e^{i\alpha_n})$ *and* $s_n(1 + \varepsilon e^{i\alpha_n})$.

Let

$$\varphi(z) = f(z) \exp \psi(z),$$

and

$$J_n = \frac{1}{2\pi i} \int_\gamma \varphi(z) z^n \, dz$$

where γ *is a half line in* S *from* z_0 *to* ∞. *Then we have*

$$J_n = \left\{ 2\pi s_n^2 \frac{\partial^2 g}{\partial z^2}(s_n, n) \right\}^{-1/2} s_n \exp g(s_n, n)(1 + o(1)), \quad n \to \infty,$$

where $\arg\{s_n^2(\partial^2 g/\partial z^2)(s_n, n)\}^{-1/2} \in (-\pi, 0)$.

Proof. We shall closely follow the proof of Theorem 7 in [2]. Let $n \geqq n_0$. Due to (i), (ii) and the properties of f, we may replace γ by γ_n. Let $\varepsilon > 0$. We begin by considering the integrand on the segment $I_n(\varepsilon)$. We put

$$\left| \frac{\partial^2 g}{\partial z^2}(z, n) - \frac{\partial^2 g}{\partial z^2}(s_n, n) \right| = h(z).$$

From (iv) we deduce that

$$h(z) \leqq K \left| \frac{\partial^2 g}{\partial z^2}(s_n, n) \right| \int_{s_n}^z \left| \frac{d\zeta}{\zeta} \right| + K \int_{s_n}^z h(\zeta) \left| \frac{d\zeta}{\zeta} \right|$$

provided $|z-s_n|<\varepsilon_0|s_n|$. With the aid of Gronwall's generalized inequality (cf. [5, p. 36]) we find

$$h(z)\leqq \tilde{K}\left|\frac{z-s_n}{s_n}\right|\left|\frac{\partial^2 g}{\partial z^2}(s_n, n)\right|,$$

where $\tilde{K}$ is a positive constant, provided $|z-s_n|<\varepsilon_0|s_n|$. Hence it follows that, for all $\varepsilon\in(0, \varepsilon_0)$,

$$\frac{\partial g}{\partial z}(z, n)=(z-s_n)\frac{\partial^2 g}{\partial z^2}(s_n, n)(1+\varepsilon O(1)), \qquad n\to\infty \tag{1.5}$$

$$g(z, n)-g(s_n, n)=\frac{1}{2}(z-s_n)^2\frac{\partial^2 g}{\partial z^2}(s_n, n)(1+\varepsilon O(1)), \qquad n\to\infty, \tag{1.6}$$

uniformly on $I_n(\varepsilon)$. Here $O(1)$ is uniformly bounded in ε.

We introduce a new variable w by means of

$$\tfrac{1}{2}w^2=g(s_n, n)-g(s_n(1+\tau e^{i\alpha_n}), n), \qquad |\tau|\leqq\varepsilon. \tag{1.7}$$

Due to (1.6) we have

$$w^2=-\tau^2 e^{2i\alpha_n}s_n^2\frac{\partial^2 g}{\partial z^2}(s_n, n)(1+\varepsilon O(1))$$

and we remove the ambiguity in the definition of w by demanding that

$$w=\tau e^{i\alpha_n}\left(-s_n^2\frac{\partial^2 g}{\partial z^2}(s_n, n)\right)^{1/2}(1+\varepsilon O(1)), \tag{1.8}$$

where the square root has its principal value. Equations (1.7) and (1.5) imply that

$$w\frac{dw}{d\tau}=-s_n e^{i\alpha_n}\frac{\partial g}{\partial z}(s_n(1+\tau e^{i\alpha_n}), n)=-s_n^2\tau e^{2i\alpha_n}\frac{\partial^2 g}{\partial z^2}(s_n, n)(1+\varepsilon O(1)).$$

Consequently,

$$\frac{dw}{d\tau}=e^{i\alpha_n}\left(-s_n^2\frac{\partial^2 g}{\partial z^2}(s_n, n)\right)^{1/2}(1+\varepsilon O(1)). \tag{1.9}$$

Let $w_\pm$ correspond to $\tau=\pm\varepsilon$. From (1.8) it follows that

$$w_\pm=\pm\varepsilon e^{i\alpha_n}\left(-s_n^2\frac{\partial^2 g}{\partial z^2}(s_n, n)\right)^{1/2}(1+\varepsilon O(1)). \tag{1.10}$$

From (1.7), (1.9), (1.10), and condition (vi) of Proposition 1.3 we deduce that

$$\begin{aligned}&\int_{s_n(1-\varepsilon e^{i\alpha_n})}^{s_n(1+\varepsilon e^{i\alpha_n})}\varphi(z)z^n\,dz\\ &\quad=s_n e^{i\alpha_n}\exp g(s_n, n)\int_{w_-}^{w_+}e^{-w^2/2}\left(\frac{dw}{d\tau}\right)^{-1}dw(1+o(1))\\ &\quad=\left(-s_n^2\frac{\partial^2 g}{\partial z^2}(s_n, n)\right)^{-1/2}s_n\exp g(s_n, n)\int_{w_-}^{w_+}e^{-w^2/2}\,dw(1+o(1))(1+\varepsilon O(1)).\end{aligned}$$

Using (1.10) and condition (iii) and noting that $\lim_{n\to\infty}\alpha_n=0$, we conclude that, for every $\varepsilon>0$,

$$\lim_{n\to\infty}\int_{w_-}^{w_+}e^{-w^2/2}\,dw=\sqrt{2\pi}.$$

Hence

$$\frac{1}{2\pi i}\int_{s_n(1-\varepsilon e^{i\alpha_n})}^{s_n(1+\varepsilon e^{i\alpha_n})}\varphi(z)z^n\,dz=\left(2\pi s_n^2\frac{\partial^2 g}{\partial z^2}(s_n,n)\right)^{-1/2}s_n$$
$$\cdot(\exp g(s_n,n)(1+o(1))(1+\varepsilon O(1)),$$

where $\arg\{s_n^2(\partial^2 g/\partial z^2)(s_n,n)\}^{-1/2}\in(-\pi,0)$.

Next we consider the integral

$$J_n^+(\varepsilon)=\int_{s_n(1+\varepsilon e^{i\alpha_n})}^{\infty}\varphi(z)z^n\,dz.$$

From (1.7), condition (v), and the properties of f we deduce that, for $n\geqq n_1(\varepsilon)$,

$$|J_n^+(\varepsilon)|\leqq C\left|s_n\exp\left\{g(s_n,n)-\frac{1}{2}w_+^2\right\}\right|\int_{\varepsilon}^{\infty}\exp g_2(\varepsilon,\tau)\,d\tau$$
$$\leqq C_1\left|s_n\exp\left\{g(s_n,n)-\frac{1}{2}w_+^2\right\}\right|,$$

where C and C_1 are positive constants. In view of (1.10) and condition (iii) this implies that

$$J_n^+(\varepsilon)=\left(s_n^2\frac{\partial^2 g}{\partial z^2}(s_n,n)\right)^{-1/2}s_n\exp g(s_n,n)o(1),\qquad n\to\infty$$

and the same property holds for the integral over the segment between z_0 and $s_n(1-\varepsilon e^{i\alpha_n})$. Combining the above estimates we find

$$J_n=\left(2\pi s_n^2\frac{\partial^2 g}{\partial z^2}(s_n,n)\right)^{-1/2}s_n\exp g(s_n,n)(1+\varepsilon O(1))(1+o(1)),\qquad n\to\infty.$$

Since this is true for every sufficiently small ε the result follows.

THEOREM 1.4. *Let $N\in\mathbb{N}$. Let α_ν, β_ν, $\nu\in\{1,\cdots,N\}$, be real numbers such that $\alpha_\nu\leqq\alpha_{\nu+1}<\beta_\nu\leqq\beta_{\nu+1}$ if $\nu<N$ and $\alpha_N\leqq\alpha_{N+1}\equiv\alpha_1+2\pi<\beta_N\leqq\beta_{N+1}\equiv\beta_1+2\pi$. Let $\tilde{z}_\nu\in S(\alpha_\nu,\beta_\nu)$ and $S_\nu=S(\tilde{z}_\nu,\alpha_\nu,\beta_\nu)$, $\nu=1,\cdots,N$, $S_{N+1}=e^{2\pi i}S_1$. Suppose that, for each $\nu\in\{1,\cdots,N\}$, we are given an analytic function y_ν on S_ν, admitting an asymptotic expansion $\sum_{n=0}^{\infty}\hat{y}_n z^{-n}$ as $z\to\infty$ in S_ν, independent of ν. Let*

$$y_{N+1}(z)=y_1(z\,e^{-2\pi i}),\qquad z\in S_{N+1},$$

and

$$\varphi_\nu(z)=y_{\nu+1}(z)-y_\nu(z),\qquad z\in S_\nu\cap S_{\nu+1},\quad \nu\in\{1,\cdots,N\}.$$

Suppose that for every $\nu\in\{1,\cdots,N\}$ there exists a sector $\tilde{S}^\nu\subset S_\nu\cap S_{\nu+1}$, a positive integer $m(\nu)$, and, for every $j\in\{1,\cdots,m(\nu)\}$, analytic functions ψ_j^ν and f_j^ν on $\tilde{S}^\nu$, satisfying the conditions of Proposition 1.3, and a complex number c_j^ν such that

$$\varphi_\nu(z)=\sum_{j=1}^{m(\nu)}c_j^\nu f_j^\nu(z)\exp\psi_j^\nu(z),\qquad z\in\tilde{S}^\nu.$$

Let $g_j^\nu(z,n)=\psi_j^\nu(z)+n\log z$, let $s_n^{\nu,j}$ denote its saddle point, and let

$$M_j^\nu(n)=\left\{2\pi(s_n^{\nu,j})^2\frac{\partial^2 g_j^\nu}{\partial z^2}(s_n^{\nu,j},n)\right\}^{-1/2}s_n^{\nu,j}\exp g_\nu(s_n^{\nu,j},n),$$
$$j\in\{1,\cdots,m(\nu)\},\quad \nu\in\{1,\cdots,N\},$$

where $\arg\{(s_n^{\nu,j})^2(\partial^2 g_j^\nu/\partial z^2)(s_n^{\nu,j}, n)\}^{-1/2} \in (-\pi, 0)$. *Then there exists a convergent power series* $\sum_{n=0}^{\infty} h_n z^{-n}$ *such that*

$$\hat{y}_n = h_n - \sum_{\nu=1}^{N} \sum_{j=1}^{m(\nu)} c_j^\nu \{M_j^\nu(n-1)(1+o(1))\}, \qquad n \to \infty. \tag{1.11}$$

Proof. There exists $z_\nu \in S_\nu \cap S_{\nu+1}$ such that $S_\nu \cap S_{\nu+1}$ contains the sector $S^\nu = S(z_\nu, \alpha_{\nu+1}, \beta_\nu)$. As y_ν and $y_{\nu+1}$ admit the same asymptotic expansion, it follows that

$$\varphi_\nu(z) = y_{\nu+1}(z) - y_\nu(z) \sim 0 \quad \text{as } z \to \infty \text{ in } S^\nu, \quad \nu \in \{1, \cdots, N\}.$$

Obviously, the functions y_ν possess the properties (i)–(iii) mentioned in Proposition 1.2.

According to Proposition 1.2 there exists a function h, holomorphic at ∞, such that $y_\nu = h + H_\nu$ for all $\nu \in \{1, \cdots, N\}$. Let $\sum_{n=0}^{\infty} h_n z^{-n}$ be the power series expansion of h. With (1.4) we find

$$\begin{aligned} \hat{y}_n &= h_n - \sum_{\nu=1}^{N} \frac{1}{2\pi i} \int_{\gamma_\nu} \varphi_\nu(z) z^{n-1}\, dz \\ &= h_n - \sum_{\nu=1}^{N} \sum_{j=1}^{m(\nu)} \frac{c_j^\nu}{2\pi i} \int_{\gamma_\nu} f_j^\nu(z) \exp \psi_j^\nu(z) z^{n-1}\, dz, \qquad n \in \mathbb{N}, \end{aligned}$$

where γ_ν is a half line $\tilde{S}^\nu$, $\nu \in \{1, \cdots, N\}$.

The proof is completed by application of Proposition 1.3 to each term of the sum in the right-hand side of the above identity.

Remark 1. If the y_ν as well as the functions $f_j^\nu \exp \psi_j^\nu$ are solutions of some homogeneous linear functional equation, the numbers c_j^ν play a role similar to the Stokes multipliers in the theory of linear differential equations.

Remark 2. If one of the functions M_j^ν in (1.11) dominates the rest for $n \to \infty$, the corresponding coefficient c_j^ν may be determined from the asymptotic behavior of $\hat{y}_n$.

Remark 3. Propositions 1.1 and 1.2 may also be used to obtain estimates of the growth of the remainder terms $R_n(y_\nu; z)$ as $n \to \infty$. This will be illustrated by the application to linear difference equations in the next section.

Example. The nonlinear differential equation

$$\frac{dy}{dz} = \frac{a}{z^2} + y + \frac{b}{z^2} y^3, \qquad a, b \in \mathbb{C}^* \tag{1.12}$$

possesses three formal solutions of the form $\sum_{n=-1}^{\infty} \hat{y}_n z^{-n}$. The coefficients $\hat{y}_n$ can be determined from the recursive relations

$$\begin{aligned} &-2\hat{y}_{n+2} + (n+4)\hat{y}_{n+1} + b \sum_{\substack{m_i \geqq n \\ m_1+m_2+m_3=n}} \hat{y}_{m_1}\hat{y}_{m_2}\hat{y}_{m_3} = 0, \qquad n \geqq -1, \\ &(\hat{y}_{-1})^2 = -\frac{1}{b}, \qquad \hat{y}_0 = -\frac{1}{2}\hat{y}_{-1} \end{aligned} \tag{1.13}$$

and

$$\begin{aligned} &\hat{y}_{n+2} + (n+1)\hat{y}_{n+1} + b \sum_{m_1+m_2+m_3=n} \hat{y}_{m_1}\hat{y}_{m_2}\hat{y}_{m_3} = 0, \qquad n \geqq 1, \\ &\hat{y}_{-1} = \hat{y}_0 = \hat{y}_1 = 0, \qquad \hat{y}_2 = -a. \end{aligned} \tag{1.14}$$

Let $\hat{y}$ denote one of the formal solutions and let S be a sector of aperture less than π. It is a well-known fact that there exists a solution of (1.12), analytic in S and

represented asymptotically by $\hat{y}$ as $z \to \infty$ in S, uniformly on S (cf. [13]). Suppose that y_1 and y_2 are two solutions with these properties. Obviously,

$$\frac{d}{dz}(y_1 - y_2) = y_1 - y_2 + \frac{b}{z^2}(y_1^2 + y_1 y_2 + y_2^2)(y_1 - y_2). \tag{1.15}$$

Let $\hat{y} = \sum_{n=-1}^{\infty} \hat{y}_n^- z^{-n}$ and suppose the coefficients $\hat{y}_n^-$ satisfy (1.13). Then we have

$$y_1^2 + y_1 y_2 + y_2^2 = -\frac{3}{b}(z^2 - z) + h(z), \tag{1.16}$$

where h is a bounded analytic function on S, admitting an asymptotic expansion as $z \to \infty$ in S. Inserting (1.16) into (1.15) we obtain

$$\frac{d}{dz}(y_1 - y_2) = \left\{-2 + \frac{3}{z} + \frac{b}{z^2} h(z)\right\}(y_1 - y_2)$$

and this implies that

$$y_1 - y_2 = c\, e^{-2z} z^3 \left(1 + O\left(\frac{1}{z}\right)\right) \quad z \to \infty \text{ in } S,$$

where c is a complex number. Hence it follows that (1.12) has a unique solution y^-, analytic in a left half plane and represented asymptotically by the series $\sum_{n=-1}^{\infty} \hat{y}_n^- z^{-n}$ as $z \to \infty$ in this half plane. Moreover, it is easily seen that y^- may be continued analytically to a sector of the form $S(z_1, -3\pi/2, 3\pi/2)$, with $z_1 \in \mathbb{C}_\infty$, without a change in asymptotic behavior.

Furthermore, we have

$$y^-(z) - y^-(z\, e^{2\pi i}) = c^-\, e^{-2z} z^3 \left(1 + O\left(\frac{1}{z}\right)\right), \qquad c^- \in \mathbb{C},$$

as $z \to \infty$ in $S(-3\pi/2 + \varepsilon, -\pi/2 - \varepsilon)$ for any $\varepsilon \in (0, \pi/2)$. Applying Theorem 1.4 we find

$$c^- = -2\pi i \lim_{n \to \infty} \frac{2^{n+3} \hat{y}_n^-}{(n+2)!}.$$

In a similar manner it is shown that (1.12) possesses a unique solution y^+ analytic in $S(z_2, -\pi/2, 5\pi/2)$ for some $z_2 \in \mathbb{C}_\infty$ and represented asymptotically by the series $\sum_{n=-1}^{\infty} \hat{y}_n^+ z^{-n}$ determined by (1.14), as $z \to \infty$ in this sector. Moreover, it turns out that

$$y^+(z) - y^+(z\, e^{2\pi i}) = c^+\, e^{z} \left(1 + O\left(\frac{1}{z}\right)\right), \qquad c^+ \in \mathbb{C},$$

as $z \to \infty$ in $S(-\pi/2 + \varepsilon, \pi/2 - \varepsilon)$ for any $\varepsilon \in (0, \pi/2)$. Application of Theorem 1.4 now yields the relation

$$c^+ = 2\pi i \lim_{n \to \infty} \frac{(-1)^{n-1} \hat{y}_n^+}{(n-1)!}.$$

2. An application to linear difference equations. We consider the mth-order homogeneous linear difference equation

$$\sum_{j=0}^{m} a_j(z) y(z + j) = 0, \tag{2.1}$$

where $a_j \in \mathbb{C}\{z^{-1}\}$, $j = 1, \cdots, m$ (or, equivalently, a system of m first-order difference equations). The "generic" case is when the characteristic equation of (2.1) has m distinct roots. This case has been treated in [8]. Here we shall deal with a more singular class of equations.

Under certain conditions, (2.1) possesses m linearly independent formal solutions of the form

$$\hat{y}_j(z) = \hat{h}_j(z) z^{\rho_j} \exp(d_j z \log z + \mu_j z), \qquad j = 1, \cdots, m, \tag{2.2}$$

where $\hat{h}_j(z) = \sum_{n=0}^{\infty} \hat{h}_{jn} z^{-n}$ with $\hat{h}_{j0} = 1$, $\rho_j \in \mathbb{C}$, $d_j \in \mathbb{Q}$ and $\mu_j \in \mathbb{C}$ for all $j \in \{1, \cdots, m\}$ (cf. [3], [11]).

We put

$$\rho_i - \rho_j = \rho_{ij}, \quad d_i - d_j = d_{ij}, \quad \text{and} \quad \mu_i - \mu_j = \mu_{ij}, \qquad i, j \in \{1, \cdots, m\}$$

and we assume that, for all $i, j \in \{1, \cdots, m\}$ such that $i \neq j$ and $d_{ij} = 0$,

$$\operatorname{Re} \mu_{ij} \neq 0. \tag{2.3}$$

For merely technical reasons we further assume that

$$\operatorname{Im} \mu_{ij} \notin \{0, -d_{ij}\pi\} \bmod 2\pi \quad \text{if } i \neq j, \quad i, j \in \{1, \cdots, m\} \tag{2.4}$$

but this condition can easily be removed. For all $i, j \in \{1, \cdots, m\}$ such that $i \neq j$ we shall denote by n_{ij} the integer determined by

$$\begin{aligned} &0 < \operatorname{Im} \mu_{ij} + 2n_{ij}\pi < 2\pi && \text{if } d_{ij} \leqq 0, \\ &0 < \operatorname{Im} \mu_{ij} + (2n_{ij} + d_{ij})\pi < 2\pi && \text{if } d_{ij} > 0. \end{aligned} \tag{2.5}$$

Let $S_1, \cdots, S_7$ be sectors of the following form:

$$S_1 = S(R e^{-i(\pi/2)}, -\pi, 0), \quad S_2 = e^{i(\pi/2)} S_1, \quad S_3 = S_4 = e^{i\pi} S_1,$$
$$S_5 = e^{i(3\pi/2)} S_1 \quad \text{and} \quad S_6 = S_7 = e^{2\pi i} S_1,$$

where $R > 0$. If R is chosen sufficiently large, equation (2.1) possesses, for each $j \in \{1, \cdots, m\}$ and $\nu \in \{1, 3, 4, 6, 7\}$, a unique solution y_j^{ν}, represented asymptotically by $\hat{y}_j$ as $z \to \infty$, uniformly on

$$\begin{aligned} &\left(\frac{\nu - 1}{3} - 1\right)\pi + \delta < \arg(z - R e^{(\nu/3 - 5/6)\pi i}) \leqq \frac{\nu - 1}{3}\pi \quad \text{if } \nu \in \{1, 4, 7\}, \\ &\left(\frac{\nu}{3} - 1\right)\pi \leqq \arg(z - R e^{(\nu/3 - 1/2)\pi i}) < \frac{\nu}{3}\pi - \delta \quad \text{if } \nu \in \{3, 6\} \end{aligned} \tag{2.6}$$

for every $\delta \in (0, \pi/2)$ (cf. [6, Thm. 2.4.5]; note that this is a stronger statement than $y_j^{\nu} \sim \hat{y}_j$ as $z \to \infty$ in S_{ν}). Moreover, we have

$$y_j^4 - y_j^3 = p_{jj}^3 y_j^3, \qquad y_j^7 - y_j^6 = p_{jj}^6 y_j^6, \tag{2.7}$$

where p_{jj}^3 and p_{jj}^6 are periodic functions of period 1 with the property that

$$\lim_{\operatorname{Im} z \to \infty} p_{jj}^3(z) = \lim_{\operatorname{Im} z \to -\infty} p_{jj}^6(z) = 0, \qquad j \in \{1, \cdots, m\}. \tag{2.8}$$

Furthermore, for each $j \in \{1, \cdots, m\}$, equation (2.1) possesses a unique solution y_j^2, analytic in S_2 and represented asymptotically by $\hat{y}_j$ as $z \to \infty$ in S_2, such that

$$y_j^2 - y_j^1 = \sum_{i=1}^{m} p_{ij}^1 y_i^1, \qquad y_j^3 - y_j^2 = \sum_{i=1}^{m} p_{ij}^2 y_i^2,$$

where p_{ij}^1 and p_{ij}^2 are periodic functions of period 1 with the following properties:

$$\begin{aligned} &p_{ij}^1 = p_{ij}^2 \equiv 0 \quad \text{if } d_{ij} > 0 \text{ or } d_{ij} = 0 \text{ and } \operatorname{Re} \mu_{ij} \geqq 0, \\ &\lim_{\operatorname{Im} z \to -\infty} p_{ij}^1(z) \exp\{-2(n_{ij} - 1)\pi i z\} \text{ and } \lim_{\operatorname{Im} z \to \infty} p_{ij}^2(z) \exp\{-2n_{ij}\pi i z\} \\ &\qquad \text{exist for all } i, j \in \{1, \cdots, m\} \text{ such that } i \neq j. \end{aligned} \tag{2.9}$$

Similarly, for each $j \in \{1, \cdots, m\}$, there exists a unique solution y_j^5, analytic in S_5 and represented asymptotically by $\hat{y}_j$ as $z \to \infty$ in S_5, such that

$$y_j^5 - y_j^4 = \sum_{i=1}^{m} p_{ij}^4 y_i^4, \qquad y_j^6 - y_j^5 = \sum_{i=1}^{m} p_{ij}^5 y_i^5,$$

where p_{ij}^4 and p_{ij}^5 are periodic functions of period 1 with the following properties:

$$p_{ij}^4 = p_{ij}^5 \equiv 0 \quad \text{if } d_{ij} < 0 \text{ or } d_{ij} = 0 \text{ and } \operatorname{Re} \mu_{ij} \leqq 0,$$

(2.10) $\lim_{\operatorname{Im} z \to \infty} p_{ij}^4(z) \exp\{-2n_{ij}\pi i z\}$ and $\lim_{\operatorname{Im} z \to -\infty} p_{ij}^5(z) \exp\{-2(n_{ij}-1)\pi i z\}$ exist for all $i, j \in \{1, \cdots, m\}$ such that $i \neq j$.

Now let

$$h_j^\nu(z) = y_j^\nu(z) z^{-\rho_j} \exp(-d_j z \log z - \mu_j z), \qquad j \in \{1, \cdots, m\}, \quad \nu \in \{1, \cdots, 7\}.$$

Obviously, h_j^ν is represented asymptotically by $\hat{h}_j$ as $z \to \infty$ in S_ν for all $j \in \{1, \cdots, m\}$ and all $\nu \in \{1, \cdots, 7\}$. Moreover, if $\nu \in \{1, 3, 4, 6, 7\}$, the asymptotic expansion is uniformly valid on (2.6) for every $\delta \in (0, \pi/2)$. The uniqueness of h_j^ν implies that

$$h_j^7(z) = h_j^1(z e^{-2\pi i}) \quad \text{for all } j \in \{1, \cdots, m\}. \tag{2.11}$$

Furthermore, we have, for all $j \in \{1, \cdots, m\}$ and $\nu \in \{1, \cdots, 6\}$,

$$h_j^{\nu+1}(z) - h_j^\nu(z) = \sum_{i=1}^{m} p_{ij}^\nu(z) h_i^\nu(z) z^{\rho_{ij}} \exp(d_{ij} z \log z + \mu_{ij} z). \tag{2.12}$$

For all $i, j \in \{1, \cdots, m\}$ and all $\nu \in \{1, \cdots, 6\}$ we define an integer n_{ij}^ν and complex numbers c_{ij}^ν and μ_{ij}^ν as follows:

(2.13)

$$n_{ij}^\nu = \begin{cases} \max\left\{ n \in \mathbb{Z} : \lim\limits_{\operatorname{Im} z \to \infty} p_{ij}^\nu(z) \exp(-2n\pi i z) \text{ exists} \right\} & \text{if } \nu \in \{2, 3, 4\} \text{ and } p_{ij}^\nu \not\equiv 0, \\ \min\left\{ n \in \mathbb{Z} : \lim\limits_{\operatorname{Im} z \to -\infty} p_{ij}^\nu(z) \exp(-2n\pi i z) \text{ exists} \right\} & \text{if } \nu \in \{1, 5, 6\} \text{ and } p_{ij}^\nu \not\equiv 0, \\ 0 \quad \text{otherwise,} \end{cases}$$

$$c_{ij}^\nu = \begin{cases} 0 & \text{if } p_{ij}^\nu \equiv 0, \\ \lim_{\operatorname{Im} z \to \pm\infty} p_{ij}^\nu(z) \exp(-2n_{ij}^\nu \pi i z) & \text{otherwise,} \end{cases} \tag{2.14}$$

$$\mu_{ij}^\nu = \mu_{ij} + 2n_{ij}^\nu \pi i z. \tag{2.15}$$

Furthermore, we define analytic functions f_{ij}^ν and φ_{ij}^ν by

$$f_{ij}^\nu(z) = \begin{cases} 0 & \text{if } c_{ij}^\nu = 0, \\ (c_{ij}^\nu)^{-1} p_{ij}^\nu(z) \exp(-2n_{ij}^\nu \pi i z) h_i^\nu(z) & \text{otherwise,} \end{cases} \tag{2.16}$$

$$\varphi_{ij}^\nu(z) = p_{ij}^\nu(z) h_i^\nu(z) z^{\rho_{ij}} \exp(d_{ij} z \log z + \mu_{ij} z). \tag{2.17}$$

Obviously,

$$\varphi_{ij}^\nu(z) = c_{ij}^\nu f_{ij}^\nu(z) z^{\rho_{ij}} \exp(d_{ij} z \log z + \mu_{ij}^\nu z), \qquad i, j \in \{1, \cdots, m\}, \quad \nu \in \{1, \cdots, 6\}. \tag{2.18}$$

In order to check whether the conditions of Theorem 1.4 are satisfied, we will first study the properties of the function $g : S \times \mathbb{N} \to \mathbb{C}$ defined by

$$g(z, n) = dz \log z + \mu z = (n + \rho) \log z,$$

where $d \in \mathbb{Q}$, $\mu \in \mathbb{C}$, $\rho \in \mathbb{C}$, and S is one of the sectors $S_\nu \cap S_{\nu+1}$, $\nu \in \{1, \cdots, 6\}$. From (2.18), (2.3), (2.7)-(2.10), and the definitions (2.13)-(2.15) we conclude that the following cases need to be considered:

1. $d = 0$, $\rho = 0$, $\mu = 2m\pi i$, $m \in \mathbb{N}$, $S = S_3$,
2. $d = 0$, $\rho = 0$, $\mu = -2m\pi i$, $m \in \mathbb{N}$, $S = S_6$,
3. $d = 0$, $\operatorname{Re} \mu < 0$, $\operatorname{Im} \mu < 0$, $S = S_1 \cap S_2$,
4. $d = 0$, $\operatorname{Re} \mu < 0$, $\operatorname{Im} \mu > 0$, $S = S_2 \cap S_3$,
5. $d = 0$, $\operatorname{Re} \mu > 0$, $\operatorname{Im} \mu > 0$, $S = S_4 \cap S_5$,
6. $d = 0$, $\operatorname{Re} \mu > 0$, $\operatorname{Im} \mu < 0$, $S = S_5 \cap S_6$,
7. $d < 0$, $\operatorname{Im} \mu < 0$, $S = S_1 \cap S_2$,
8. $d < 0$, $\operatorname{Im} \mu > 0$, $S = S_2 \cap S_3$,
9. $d > 0$, $\operatorname{Im} \mu + d\pi > 0$, $S = S_4 \cap S_5$,
10. $d > 0$, $\operatorname{Im} \mu + d\pi < 0$, $S = S_5 \cap S_6$.

In the first six cases, $\partial g / \partial z = 0$ has a unique solution s_n given by

$$s_n = -\frac{n+\rho}{\mu}. \tag{2.19}$$

Hence

$$\arg s_n = \arg\left(-\frac{1}{\mu}\right)(1+o(1)), \qquad n \to \infty. \tag{2.20}$$

Furthermore, we have

$$\frac{\partial^2 g}{\partial z^2}(s_n, n) = -\frac{\mu^2}{n+\rho}, \qquad s_n^2 \frac{\partial^2 g}{\partial z^2}(s_n, n) = -n-\rho, \tag{2.21}$$

$$z\frac{\partial^3 g}{\partial z^3}(z, n)\left\{\frac{\partial^2 g}{\partial z^2}(z, n)\right\}^{-1} = -2. \tag{2.22}$$

Let $S' \Subset S$. In each of the cases 1-6 there exists a positive number δ such that

$$\cos(\arg z + \arg \mu) < -\frac{\delta}{|\mu|} \quad \text{for all } z \in S'.$$

This implies that, for all $z \in S'$,

$$\operatorname{Re} g(z, n) \leqq -\delta|z| + (n + \operatorname{Re} \rho)\log|z| - \operatorname{Im} \rho \arg z.$$

Hence we easily deduce the existence of positive constants $A_{S'}$ and $C_{S'}$ such that

$$\sup_{z \in S'} |\exp g(z, n)| < C_{S'} A_{S'}^n n^n. \tag{2.23}$$

Now consider the cases 7-10. There $d \neq 0$ and the saddle point s_n is a solution of the equation

$$s_n\left(\log s_n + \frac{\mu}{d} + 1\right) = -\frac{n+\rho}{d}. \tag{2.24}$$

Let h be the inverse of the function $z \to z \log z$ (cf. [9, Ex. III], [4, § 3.6]). It has the following asymptotic behavior:

$$h(z) = \frac{z}{\log z}(1+o(1)), \qquad z \to \infty. \tag{2.25}$$

From (2.24) we deduce

$$
\begin{aligned}
s_n &= \exp\left(-\frac{\mu}{d}-1\right) h\left(-\frac{n+\rho}{d}\exp\left(\frac{\mu}{d}+1\right)\right) \\
&= -\frac{n+\rho}{d}\left\{\log h\left(-\frac{n+\rho}{d}\exp\left(\frac{\mu}{d}+1\right)\right)\right\}^{-1}.
\end{aligned} \tag{2.26}
$$

With (2.25) it follows that

$$
s_n = -\frac{n}{d\log n}(1+o(1)), \qquad n\to\infty. \tag{2.27}
$$

Equating the imaginary parts on both sides of (2.24), we get

$$
\operatorname{Im} s_n\left(\log|s_n|+\frac{\operatorname{Re}\mu}{d}+1\right)+\operatorname{Re} s_n\left(\arg s_n+\frac{\operatorname{Im}\mu}{d}\right)=\frac{\operatorname{Im}\rho}{d}.
$$

With (2.27) we find

$$
\operatorname{Im} s_n = \frac{n}{d(\log n)^2}\left(\arg s_n+\frac{\operatorname{Im}\mu}{d}\right)(1+o(1)), \qquad n\to\infty.
$$

Hence

$$
\operatorname{Im} s_n = \begin{cases} \dfrac{n}{d^2(\log n)^2}\operatorname{Im}\mu(1+o(1)), & n\to\infty \quad \text{if } d<0, \\ \dfrac{n}{d^2(\log n)^2}(\operatorname{Im}\mu+d\pi)(1+o(1)), & n\to\infty \quad \text{if } d>0. \end{cases} \tag{2.28}
$$

Furthermore, we have

$$
\frac{\partial^2 g}{\partial z^2}(s_n,n)=\frac{d}{s_n}-\frac{n+\rho}{s_n^2}=-\frac{d^2}{n+\rho}\log h\left(-\frac{n+\rho}{d}\exp\left(\frac{\mu}{d}+1\right)\right)(1+o(1)), \quad n\to\infty \tag{2.29}
$$

and hence

$$
s_n^2\frac{\partial^2 g}{\partial z^2}(s_n,n)=-n(1+o(1)), \qquad n\to\infty. \tag{2.30}
$$

We easily verify that

$$
z\frac{\partial^3 g}{\partial z^3}(z,n)\left\{\frac{\partial^2 g}{\partial z^2}(z,n)\right\}^{-1}=-\frac{2(n+\rho)-dz}{n+\rho-dz} \tag{2.31}
$$

and the expression on the right-hand side is obviously uniformly bounded on the half plane $-d\ \operatorname{Re} z>0$ and thus on S, provided $n\geqq n_0$, where n_0 is some sufficiently large number.

Let $S'\Subset S$. In each of the cases considered this implies the existence of a positive number δ such that

$$
d\cos\arg z<-\delta \quad \text{for all } z\in S'.
$$

Let $0<\varepsilon<\delta$. Then there exists a positive constant C such that

$$
|\exp g(z,n)|<C\exp(-\varepsilon|z|\log|z|)|z|^n, \qquad z\in S'.
$$

The expression to the right of the inequality sign attains its maximum as $|z| = h(ne/\varepsilon)/e$ and the maximum value is equal to

$$\exp\left(-2n+\frac{\varepsilon}{e}h\left(\frac{ne}{\varepsilon}\right)\right)h\left(\frac{ne}{\varepsilon}\right)^n.$$

In view of (2.25) it follows that there exist positive constants $A_{S'}$ and $C_{S'}$ such that

$$\sup_{z\in S'}|\exp g(z,n)| < C_{S'}A_{S'}^n\left(\frac{n}{\log n}\right)^n. \tag{2.32}$$

With the aid of (2.19), (2.21), (2.26), and (2.29) we can derive an explicit expression for the function $M:\mathbb{N}\to\mathbb{C}$ given by

$$M(n) = \left(2\pi s_n^2\frac{\partial^2 g}{\partial z^2}(s_n,n)\right)^{-1/2} s_n \exp g(s_n,n), \tag{2.33}$$

where $\arg\,(s_n^2(\partial^2 g/\partial z^2)(s_n,n))^{-1/2}\in(-\pi,0)$, in each of the cases considered above. With (2.30) we find

$$M(n) = \begin{cases} \{-2\pi(n+\rho)\}^{-1/2}\exp(-n-\rho)\left(\dfrac{n+\rho}{\mu}\right)^{n+\rho+1} & \text{if } d=0,\\ (-2\pi n)^{-1/2}\exp\{(n+\rho)\chi(n)^{-1}-1\}\left(\dfrac{n+\rho}{d\chi(n)}\right)^{n+\rho+1}(1+o(1)), & n\to\infty, \text{if } d\neq 0, \end{cases}$$

where $\chi(n) = \log h((n+\rho)/d\,\exp(\mu/d+1))$. Let us define a function $M_{d,\mu}:\mathbb{C}\to\mathbb{C}$ by

(2.34)

$$-2\pi i M_{d,\mu}(s) = \begin{cases} \Gamma(s)(-\mu)^{-s} & \text{if } d=0,\\ \Gamma(s)\exp\left\{\dfrac{s}{\log h(-s/d\,\exp(\mu/d+1))}\right\}\left\{-d\log h\left(-\dfrac{s}{d}\exp\left(\dfrac{\mu}{d}+1\right)\right)\right\}^{-s}, & \text{if } d\neq 0. \end{cases}$$

Using Stirling's formula and the properties of the function h, we readily verify that

$$-M(n-1) = M_{d,\mu}(n+\rho)(1+o(1)), \qquad n\to\infty. \tag{2.35}$$

Now let $\nu\in\{1,\cdots,6\}$, $\tilde{z}_\nu\in S_\nu\cap S_{\nu+1}$, and let $\tilde{S}^\nu$ be a sector of the following form:

$$\tilde{S}^\nu = S\left(\tilde{z}_\nu,\left(\frac{\nu}{3}-\frac{5}{6}\right)\pi+\delta,\frac{\nu-1}{3}\pi\right) \quad \text{if } \nu\in\{1,4\},$$

$$\tilde{S}^\nu = S\left(\tilde{z}_\nu,\frac{\nu-2}{3}\pi,\left(\frac{\nu}{3}-\frac{1}{6}\right)\pi\right) \quad \text{if } \nu\in\{2,5\},$$

$$\tilde{S}^\nu = S\left(\tilde{z}_\nu,\left(\frac{\nu}{3}-1\right)\pi+\delta,\frac{\nu}{3}\pi-\delta\right) \quad \text{if } \nu\in\{3,6\},$$

where $\delta\in(0,\pi/2)$. Let $i,j\in\{1,\cdots,m\}$ such that $c_{ij}^\nu\neq 0$, and let

$$g_{ij}^\nu(z,n) = d_{ij}z\log z+\mu_{ij}^\nu z+(n+\rho_{ij})\log z, \qquad z\in\tilde{S}^\nu,\quad n\in\mathbb{N}.$$

From (2.19)-(2.22) and (2.27)-(2.31) we deduce that conditions (ii)-(iv) of Proposition 1.3 are satisfied, provided δ is chosen sufficiently small. We readily verify that condition (v) holds as well (with $z_0=\tilde{z}_\nu$).

Next, we consider the function f_{ij}^{ν} defined by (2.16). The asymptotic properties of h_i^{ν} imply that

$$\lim_{z\to\infty} h_i^{\nu}(z) = 1 \quad \text{uniformly on } \tilde{S}^{\nu}. \tag{2.36}$$

Furthermore, from (2.14) and the fact that p_{ij}^{ν} is analytic on either a lower or an upper half plane it follows that

$$|p_{ij}^{\nu}(z)\exp(-2n_{ij}^{\nu}\pi i z) - c_{ij}^{\nu}| \leqq K\exp(-2\pi|\operatorname{Im} z|), \qquad z\in\tilde{S}^{\nu}, \tag{2.37}$$

where K is a positive constant. From (2.36) and (2.37) it is obvious that f_{ij}^{ν} is bounded on $\tilde{S}^{\nu}$. Moreover, with the aid of (2.20) it is easily seen that, in the case that $d_{ij}=0$, f_{ij}^{ν} satisfies condition (vi) of Proposition 1.3. Now suppose that $\nu\in\{1,2,4,5\}$ and $d_{ij}\neq 0$. Formulas (2.4) and (2.28) imply that $|\operatorname{Im} s_n|\to\infty$ as $n\to\infty$, where s_n denotes the saddle point of $g_{ij}^{\nu}(z,n)$. With (2.36) and (2.37) it follows that, also in this case, condition (vi) of Proposition 1.3 is fulfilled.

Apparently, all conditions of Theorem 1.4 are satisfied. Applying this theorem and using (2.33) and (2.35), we obtain the following result.

THEOREM 2.1. *For each $j\in\{1,\cdots,m\}$ there exists a convergent power series $\sum_{n=0}^{\infty} h_{jn}z^{-n}$ such that*

$$\hat{h}_{jn} = h_{jn} + \sum_{i=1}^{m}\sum_{\nu=1}^{6} c_{ij}^{\nu}\{M_{d_{ij},\mu_{ij}^{\nu}}(n+\rho_{ij})(1+o(1))\}, \qquad n\to\infty,$$

where c_{ij}^{ν} and $M_{d_{ij},\mu_{ij}^{\nu}}$ are defined by (2.14) *and* (2.34), *respectively.*

With the aid of Propositions 1.1 and 1.2 we are able to estimate the growth of the remainder terms $R_n(h_j^{\nu};z)$ for $n\to\infty$, $j\in\{1,\cdots,m\}$. Let $\nu\in\{1,\cdots,6\}$. $S_{\nu}\cap S_{\nu+1}$ is a sector of the form $S(z_{\nu},\alpha_{\nu},\beta_{\nu})$. We begin by considering the functions h_{ij}^{ν} defined by

$$h_{ij}^{\nu}(z) = \frac{z}{2\pi i}\int_{\gamma_{\nu}} \frac{\varphi_{ij}^{\nu}(\zeta)}{\zeta(\zeta-z)}\,d\zeta, \qquad i,j\in\{1,\cdots,m\}, \quad \nu\in\{1,\cdots,6\}, \tag{2.38}$$

where γ is a half line in $S_{\nu}\cap S_{\nu+1}$ from z_{ν} to ∞ and φ_{ij}^{ν} is defined by (2.17).

PROPOSITION 2.2. *Let $i,j\in\{1,\cdots,m\}$, $\nu\in\{1,\cdots,6\}$. The function h_{ij}^{ν} defined by* (2.38) *is analytic in $S_{\nu}\cap S_{\nu+1}$ and represented asymptotically by*

$$\sum_{n=0}^{\infty} -\frac{1}{2\pi i}\left(\int_{\gamma_{\nu}} \varphi_{ij}^{\nu}(\zeta)\zeta^{n-1}\,d\zeta\right) z^{-n}$$

as $z\to\infty$ in $S_{\nu}\cap S_{\nu+1}$. Moreover, for every $S'\Subset S_{\nu}\cap S_{\nu+1}$ there exist positive constants $A_{S'}$ and $C_{S'}$ such that, for all $n\in\mathbb{N}$,

$$\sup_{z\in S'}|z^n R_n(h_{ij}^{\nu};z)| \leqq \begin{cases} C_{S'}A_{S'}^n n! & \text{if } d_{ij}=0,\\ C_{S'}A_{S'}^n(n/\log n)^n & \text{if } d_{ij}\neq 0.\end{cases} \tag{2.39}$$

Proof. The first two statements follow immediately from Proposition 1.1 and the properties of φ_{ij}^{ν}. Now let $S'\Subset S_{\nu}\cap S_{\nu+1}$. We can choose a sector $S''\Subset S_{\nu}\cap S_{\nu+1}$ of the form $S''=S(\tilde{z}_{\nu},\tilde{\alpha}_{\nu},\tilde{\beta}_{\nu})$ such that $S'\Subset S''$. Let $\tilde{\gamma}_{\nu}$ be a half line in S'' from $\tilde{z}_{\nu}$ to ∞ and

$$\tilde{h}_{ij}^{\nu}(z) = \frac{z}{2\pi i}\int_{\tilde{\gamma}_{\nu}} \frac{\varphi_{ij}^{\nu}(\zeta)}{\zeta(\zeta-z)}\,d\zeta.$$

As $h_{ij}^{\nu}-\tilde{h}_{ij}^{\nu}$ is holomorphic at ∞, it is obviously sufficient to prove (2.39) for $\tilde{h}_{ij}^{\nu}$ instead of h_{ij}^{ν}. Using (2.18), (2.23), and (2.32) and noting that, due to (2.16), (2.36), and (2.37),

f_{ij}^{ν} is bounded on S'', we conclude that there exist positive numbers $A_{S''}$ and $C_{S''}$ such that, for all $n \in \mathbb{N}$,

$$\sup_{z \in S''} |z^n \varphi_{ij}^{\nu}(z)| \leqq \begin{cases} C_{S''} A_{S''}^n n! & \text{if } d_{ij} = 0, \\ C_{S''} A_{S''}^n (n/(\log n))^n & \text{if } d_{ij} \neq 0. \end{cases}$$

The result now follows by application of Proposition 1.1.

THEOREM 2.3 (cf. also [7]). *Let $j \in \{1, \cdots, m\}$, $\nu \in \{1, \cdots, 6\}$. For every $S' \Subset S_{\nu}$ there exist positive constants $A_{S'}$ and $C_{S'}$ such that*

$$\sup_{z \in S'} |z^n R_n(h_j^{\nu}; z)| < C_{S'} A_{S'}^n n!, \qquad n \in \mathbb{N}$$

Moreover, if the numbers c_{ij}^{μ} defined by (2.14) vanish for all $i \in \{1, \cdots, m\}$ such that $d_{ij} = 0$ and all $\mu \in \{1, \cdots, 6\}$, then there exist positive constants $\tilde{C}_{S'}$ and $\tilde{A}_{S'}$ such that

$$\sup_{z \in S'} |z^n R_n(h_j^{\nu}; z)| < \tilde{C}_{S'} \tilde{A}_{S'}^n \left(\frac{n}{\log n}\right)^n.$$

Proof. Using (2.11), (2.12), and the definitions (2.17) and (2.38), and applying Proposition 1.2, we conclude that there exists a function h_j, holomorphic at ∞, such that

$$h_j^{\nu}(z) = h_j(z) + \sum_{i=1}^{m} \left\{ \sum_{\mu=1}^{\nu-1} h_{ij}^{\nu}(z) + \sum_{\mu=\nu}^{6} h_{ij}^{\mu}(z\, e^{2\pi i}) \right\}.$$

Thus the statements of the theorem are seen to be an immediate corollary of Proposition 2.2.

To conclude this section we shall apply the above results to the second-order difference equation

$$\{(z+2)^2 + \alpha(z+2) + \beta\} y(z+2) - \{(z+1)^2 + \gamma(z+1)^2 + \gamma(z+1) + \delta\} y(z+1) + \sigma y(z) = 0,$$

where $\alpha, \beta, \gamma, \delta \in \mathbb{C}$, $\sigma \in \mathbb{C}^*$ (this is a particular case of the class of equations considered in [1]). This equation possesses two formal solutions $\hat{y}_1$ and $\hat{y}_2$ of the form

$$\hat{y}_1(z) = \hat{h}_1(z) z^{\gamma - \alpha - 2},$$

$$\hat{y}_2(z) = \hat{h}_2(z) z^{-\gamma - 2} \exp\{-2z \log z + (2 + \log \sigma) z\},$$

where $\hat{h}_j(z) = \sum_{n=0}^{\infty} \hat{h}_{jn} z^{-n}$ with $\hat{h}_{j0} = 1$, $j = 1, 2$. Thus we have

$$\rho_{12} = 2\gamma - \alpha = -\rho_{21}, \quad d_{12} = 2 = -d_{21}, \quad \mu_{12} = -(2 + \log \sigma) = -\mu_{21}.$$

Assumption (2.4) is equivalent to

$$\arg \sigma \neq 0 \bmod 2\pi.$$

We shall choose $\arg \sigma \in (0, 2\pi)$. With (2.5) it follows that $n_{12} = n_{21} = 0$. Hence, by (2.9) the following limits exist:

$$\lim_{\operatorname{Im} z \to -\infty} p_{21}^1(z) \exp 2\pi i z \quad \text{and} \quad \lim_{\operatorname{Im} z \to \infty} p_{21}^2(z).$$

From these and other considerations, based on the particular form of the equation, it can be deduced that the periodic functions p_{21}^1, p_{21}^2, p_{11}^3 and p_{11}^6 must be of the following form:

$$p_{11}^3(z) = \frac{c_{11}^3 \exp 2\pi i z + (\exp 2\pi i y - \exp 2\pi i \alpha) \exp 4\pi i z}{(1 - \exp 2\pi i (z - a))(1 - \exp 2\pi i (z - b))}, \tag{2.40}$$

$$p_{11}^6(z) = (1 + p_{11}^3(z))^{-1} \exp 2\pi i (\gamma - \alpha) - 1, \tag{2.41}$$

(2.42)

$$p_{21}^1(z) = -p_{21}^2(z)$$
$$= \frac{-c_{21}^2 + c_{21}^1 \exp 2\pi i(z-\gamma)}{1+\{c_{11}^3 - \exp(-2\pi i a) - \exp(-2\pi i b)\}\exp 2\pi i z + \exp 2\pi i(\gamma+2z)},$$

where a and b denote the roots of the polynomial $z^2+\alpha z+\beta$, and c_{21}^1, c_{21}^2, and c_{11}^3 are defined by (2.14). From (2.7), (2.9), and (2.10) it is seen that $c_{11}^\nu = 0$ for $\nu \in \{1, 2, 4, 5\}$ and $c_{21}^\nu = 0$ for $\nu \in \{3, 4, 5, 6\}$. According to Theorem 2.1 there exists a convergent power series $\sum_{n=0}^{\infty} h_{1n} z^{-n}$ such that

$$\begin{aligned}\hat{h}_{1n} = h_{1n} &+ c_{11}^3 M_{0,\mu_{11}^3}(n)(1+o(1)) + c_{11}^6 M_{0,\mu_{11}^6}(n)(1+o(1)) \\ &+ c_{21}^1 M_{-2,\mu_{21}^1}(n+\alpha-2\gamma)(1+o(1) \\ &+ c_{21}^2 M_{-2,\mu_{21}^2}(n+\alpha-2\gamma)(1+o(1)), \qquad n\to\infty.\end{aligned} \tag{2.43}$$

From (2.40)-(2.42) we deduce, with (2.13), that $n_{11}^3 = -n_{11}^6 = 1$, $n_{21}^1 = -1$, $n_{21}^2 = 0$ and hence, with (2.15), that

$$\mu_{11}^3 = -\mu_{11}^6 = 2\pi i, \quad \mu_{21}^1 = 2 + \log\sigma - 2\pi i, \quad \mu_{21}^2 = 2 + \log\sigma.$$

Using (2.34), we find

$$M_{0,\mu_{11}^3}(n) = (-1)^n M_{0,\mu_{11}^6}(n) = \Gamma(n)(-2\pi i)^{-n-1}.$$

As the dominating terms in (2.43) are the ones with coefficients c_{11}^3 and c_{11}^6 we conclude that

$$c_{11}^3 + c_{11}^6 = -\lim_{n\to\infty} \frac{\hat{h}_{12n}(2\pi i)^{2n+1}}{(2n-1)!},$$
$$c_{11}^3 - c_{11}^6 = \lim_{n\to\infty} \frac{\hat{h}_{12n+1}(2\pi i)^{2n+2}}{(2n)!}.$$

If $c_{11}^3 = 0$, then, by (2.41), $p_{11}^6 \equiv \exp 2\pi i(\gamma-\alpha) - 1$ and, in view of (2.8), this implies $c_{11}^6 = 0$ and $\gamma - \alpha \in \mathbb{Z}$. In that case (2.42) becomes

$$p_{21}^1(z) = -p_{21}^2(z) = \frac{-c_{21}^2 + c_{21}^1 \exp 2\pi i(z-\alpha)}{(1-\exp 2\pi i(z-a))(1-\exp 2\pi i(z-b))}$$

(where we have used the identity $a+b=-\alpha$), and the coefficient c_{21}^ν, $\nu \in \{1, 2\}$, of the dominating term in (2.43) may be determined from the asymptotic behavior of $\hat{h}_{1n}$ for $n\to\infty$.

On the other hand, if $c_{11}^3 \neq 0$, then the coefficients c_{21}^1 and c_{21}^2 cannot be determined by this method.

INVERTIBILITY OF SHIFTED BOX SPLINE INTERPOLATION OPERATORS *

C. K. CHUI†, J. STÖCKLER‡, AND J. D. WARD†

Abstract. Cardinal interpolation by integer-translates of shifted box splines $M_{n,\alpha} := M_{nnn}(\cdot + \alpha)$ on the three-direction mesh is studied. It was recently shown by Sivakumar that for even integers n the imaginary part of a certain rotation of the symbol of $M_{n,\alpha}$ does not vanish on the torus T^2 for all α in the shift region $\Lambda = (-\frac{1}{2}, \frac{1}{2})^2 \cap \{(s,t)\colon |s-t| < \frac{1}{2}\}$, and consequently, cardinal interpolation at $\mathbb{Z}^2$ by using $M_{n,\alpha}(\cdot - j), j \in \mathbb{Z}^2$, is poised for all even n and all $\alpha \in \Lambda$. For odd n, however, since both the real and imaginary parts of the rotated symbol have nonempty zero sets on T^2 for certain $\alpha \in \Lambda$ close to the corners of $\partial\Lambda$, the analysis in Sivakumar's work does not directly apply to the study of this situation. In this paper we prove that the above mentioned zero sets are disjoint for all odd integers n and all $\alpha \in \Lambda$, and hence, the symbol of $M_{n,\alpha}$ never vanishes on T^2. In other words, the cardinal interpolation operators corresponding to $M_{n,\alpha}, \alpha \in \Lambda$ and $n = 1, 2, \cdots$, are invertible.

1. Introduction and results.

Let ϕ be a piecewise continuous real-valued function with compact support in $\mathbb{R}^s, s \geq 1$, and let

$$S(\phi) := \left\{ \sum_{j \in \mathbb{Z}^s} a_j \phi(\cdot - j)\colon\ a_j \in \mathbb{R} \right\}.$$

The problem of *cardinal interpolation* from $S(\phi)$ is to study the existence and uniqueness of a bounded "coefficient" sequence $\{a_j\} \subset \mathbb{R}$ corresponding to any given bounded "data" sequence $\{f_j\} \subset \mathbb{R}$, such that the "spline" function $\Sigma a_j \phi(\cdot - j)$ from $S(\phi)$ agrees with $\{f_j\}$ on $\mathbb{Z}^s$; that is,

$$\sum_{j \in \mathbb{Z}^s} a_j \phi(i-j) = f_i, \qquad i \in \mathbb{Z}^s. \tag{1.1}$$

This problem is said to be *poised* (or *correct*) if corresponding to any bounded data sequence $\{f_j\}$ there exists a unique bounded coefficient sequence $\{a_j\}$ such that (1.1) is satisfied. The *discrete Fourier transform* $\tilde{\phi}$ of ϕ, defined by

$$\tilde{\phi}(x) = \sum_{j \in \mathbb{Z}^s} \phi(j) e^{-ij\cdot x}, \qquad x \in \mathbb{R}^s, \tag{1.2}$$

plays a central role in the study of the above problem. (Note that $\tilde{\phi}$ agrees with the restriction on the torus T^s of the *symbol* or *z-transform* $\Sigma \phi(j) z^{-j}$ of ϕ.) In fact, *the*

problem of cardinal interpolation from $S(\phi)$ is poised if and only if $\tilde{\phi}$ never vanishes (cf. [1], [6], and [3]). Hence, in this paper, we will concentrate on establishing the strict positivity of $|\phi(x)|, x \in \mathbb{R}^s$.

A somewhat stronger condition is the so-called "metric condition"

$$|1 - \tilde{\phi}(x)| < 1, \qquad x \in \mathbb{R}^s, \tag{1.3}$$

first considered in this context in [4]. If $\tilde{\phi}$ satisfies (1.3), then not only the cardinal interpolation problem has a unique solution to any given bounded data sequence, but this solution can also be constructed using the Neumann series (cf. [5] and [3]). Another important reason for considering a condition such as the metric condition in (1.3) is that since a multivariate analogue of the univariate "total positivity" does not exist, some condition which is not described in terms of sign changes, such as the metric condition (1.3) (or perhaps more suitably a somewhat weaker one), is needed to take place of total positivity in $\mathbb{R}^s, s \geq 2$. For instance, let $B = B_k := \chi_{(-\frac{1}{2},\frac{1}{2})} * \cdots * \chi_{(-\frac{1}{2},\frac{1}{2})}$ be the kth order centered B-spline, where a k-fold convolution of the characteristic function of $(-\frac{1}{2}, \frac{1}{2})$ is taken. Then by using total positivity, it was shown in Micchelli [7] and de Boor and Schoenberg [2] that the cardinal interpolation operator corresponding to the shifted B-spline $B_\alpha := B(\cdot + \alpha), |\alpha| \leq \frac{1}{2}$ is invertible if and only if $\alpha \neq \pm\frac{1}{2}$. In Sivakumar [8], this invertibility result was recovered by showing that $\widetilde{B}_\alpha$ never vanishes for $|\alpha| < \frac{1}{2}$. Recently, in Smith and Ward [10], it was further shown that the metric condition

$$|1 - \widetilde{B}_\alpha(x)| < 1, \qquad x \in \mathbb{R},$$

is satisfied for $|\alpha| \leq \frac{1}{2}$ if and only if $\alpha \neq \pm\frac{1}{2}$. Hence, it would seem to be hopeful that the metric condition can sometimes replace the total positivity property in certain multivariate derivations.

In this paper, we will restrict attention to bivariate box splines on a three-direction mesh. Let M_{nnn} denote the centered box spline with directions (1,0), (0,1), and (1,1), each repeated n times (cf. [3], Chap. 2). We will study the shifted box spline

$$M_{n,\alpha} := M_{nnn}(\cdot + \alpha), \tag{1.4}$$

where α is in the shift region

$$\Lambda := (-\tfrac{1}{2}, \tfrac{1}{2})^2 \cap \{(s,t)\colon\ |s - t| < \tfrac{1}{2}\}, \tag{1.5}$$

(cf. Fig. 1). Note that Λ is a largest connected region for the shift parameter α in the sense that for each $\alpha \in \partial\Lambda$, the zero set of $\widetilde{M}_{n,\alpha}$ is nonempty (cf. [9] and [12]). Recently, Sivakumar [9] showed that when n is even, $Im(e^{-i2\pi\alpha\cdot x}\widetilde{M}_{n,\alpha}(x)) \neq 0$ for all $x \in \mathbb{R}^2$. For odd $n > 1$, however, this conclusion no longer holds, and in fact, both of the zero sets of the real and imaginary parts of $e^{-i2\pi\alpha\cdot x}\widetilde{M}_{n,\alpha}(x)$ are nonempty. The objective of this paper is to show that these two sets are disjoint. More precisely, the following result will be established.

THEOREM 1. *For each $n = 1, 2, \cdots, \widetilde{M}_{n,\alpha}(x) \neq 0$ for all $x \in \mathbb{R}^2$ and $\alpha \in \Lambda$.*

Of course, as mentioned above, for even n this result was already established in [9]. It is interesting to note that due to the nature of the zero sets of the real and imaginary parts, the proof for odd integers n is much more involved, and in fact we used computer experiments to locate a separation of these zero sets.

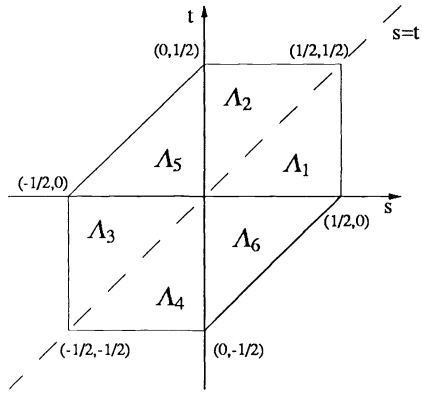

FIG. 1

A very brief outline of the proof of Theorem 1 will be given in §2. Necessary lemmas and Theorem 1 will be proved in §3. In the final section, numerical examples will be given to demonstrate that in contrast with the univariate B-spline situation, the metric condition (1.3) is not satisfied by every $\widetilde{M}_{n,\alpha}, \alpha \in \Lambda$, and this leaves room for further investigation.

2. Brief outline of proof. Let $\hat{\phi}$ denote, as usual, the Fourier transform of ϕ. Then by an application of the Poisson Summation formula (cf. [11, p. 49]), we have

$$\begin{aligned} \widetilde{M}_{n,\alpha}(x) &= \sum_{j\in\mathbb{Z}^s} \widehat{M}_{n,\alpha}(x+2\pi j) \\ &= \sum_{j\in\mathbb{Z}^s} \widehat{M}_{nnn}(x+2\pi j)e^{i\alpha\cdot(x+2\pi j)}, \end{aligned} \tag{2.1}$$

where $M_{n,\alpha}$ is the shift of M_{nnn} by α as defined in (1.4). Also, let $\mathcal{A}$ denote the multiplicative group of 2×2 matrices isomorphic to the permutation group S_3; that is, $\mathcal{A}$ has order 6 and consists of the matrices: $\left(\begin{smallmatrix}1&0\\0&1\end{smallmatrix}\right), \left(\begin{smallmatrix}0&-1\\-1&0\end{smallmatrix}\right), \left(\begin{smallmatrix}1&1\\0&-1\end{smallmatrix}\right), \left(\begin{smallmatrix}-1&0\\1&1\end{smallmatrix}\right), \left(\begin{smallmatrix}-1&-1\\1&0\end{smallmatrix}\right), \left(\begin{smallmatrix}0&1\\-1&-1\end{smallmatrix}\right)$. As noted in [9], the following identities hold for all $A \in \mathcal{A}$:

$$\begin{cases} M_{n,\pm\alpha A}(\pm xA) = M_{n,\alpha}(x), \\ \widetilde{M}_{n,\pm\alpha A}(x) = \widetilde{M}_{n,\alpha}(\pm xA^t), \\ \widehat{M}_{n,\pm\alpha A}(x) = \widehat{M}_{n,\alpha}(\pm xA^t), \end{cases} \tag{2.2}$$

where, as usual, A^t denotes the transpose of A. The identities in (2.2) allow us to restrict our attention to a certain subregion of $\mathbb{R}^2$ in establishing $\widetilde{M}_{n,\alpha}(x) \neq 0, x \in \mathbb{R}^2$.

Let $x = (2\pi u, 2\pi v)$ and let Δ denote the closed triangular region with vertices at (0,0), $(\frac{1}{2},0)$, and $(\frac{1}{3},\frac{1}{3})$. Then the set

$$F := \bigcup_{\pm A\in\mathcal{A}} \{(u,v)A^t\colon\ (u,v)\in\Delta\},$$

shown in Fig. 2, is a *fundamental region* in the sense that with a portion of its boundary removed, the translates of F over $\mathbb{Z}^2$ form a disjoint partition of $\mathbb{R}^2$. It is not difficult to verify that F is invariant under the transformations $\pm A^t$ for all $A \in \mathcal{A}$, and that

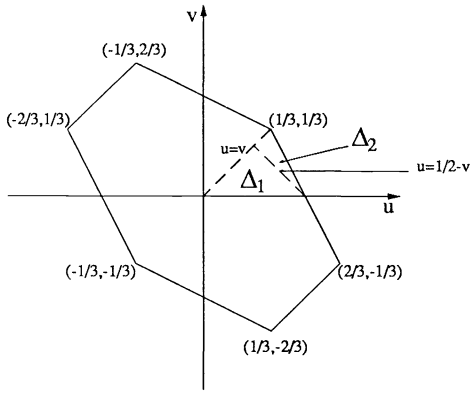

FIG. 2

the shift region Λ is invariant under the transformations $A \in \mathcal{A}$. Hence, in view of (2.2) and the definition of F, in order to prove that $\widetilde{M}_{n,\alpha}(x) \neq 0$ for all $x \in \mathbb{R}^2$ and $\alpha \in \Lambda$, it is sufficient to show that $\widetilde{M}_{n,\alpha}(x) \neq 0$ for all $x \in 2\pi\triangle$ and $\alpha \in \Lambda$. For this purpose, we divide $\triangle$ into two sub-triangles:

$$\begin{cases} \triangle_1 = \{(u,v) \in \triangle\colon\ u+v \leq \frac{1}{2}\}, \\ \triangle_2 = \left\{(u,v) \in \triangle\colon\ u+v > \frac{1}{2}\right\} \end{cases} \tag{2.3}$$

(cf. Fig. 2). Instead of showing that $\widetilde{M}_{n,\alpha}(x) \neq 0$, we follow [9] and show that a related series does not vanish on $\triangle$. First, consider the rotated symbol

$$\begin{aligned} P_{n,\alpha}(u,v) &:= e^{-i2\pi\alpha\cdot(u,v)}\widetilde{M}_{n,\alpha}(2\pi u, 2\pi v) \\ &= \sum_{j,k\in\mathbb{Z}} e^{i2\pi(js+kt)}\Big(\frac{\sin\pi u}{\pi(u+j)}\cdot\frac{\sin\pi v}{\pi(v+k)}\cdot\frac{\sin\pi(u+v)}{\pi(u+v+j+k)}\Big)^n. \end{aligned} \tag{2.4}$$

Here and throughout, we set $\alpha = (s,t)$. For $(u,v) \in \triangle$, the zero structure of $P_{n,\alpha}$ is the same as that of

$$\begin{aligned} Q_{n,\alpha}(u,v) &:= \Big(\frac{\pi u}{\sin\pi u}\cdot\frac{\pi v}{\sin\pi v}\cdot\frac{\pi(u+v)}{\sin\pi(u+v)}\Big)^n P_{n,\alpha}(u,v) \\ &= \sum_{j,k\in\mathbb{Z}} e^{i2\pi(js+kt)}\Big(\frac{u}{u+j}\Big)^n\Big(\frac{v}{v+k}\Big)^n\Big(\frac{u+v}{u+v+j+k}\Big)^n. \end{aligned} \tag{2.5}$$

We will first show that $Re\ Q_{n,\alpha}(u,v) > 0$ for $(u,v) \in \triangle_1$. To analyse $Q_{n,\alpha}$ on $\triangle_2$, we divide the shift region Λ into six parts $\Lambda_1, \cdots, \Lambda_6$ as shown in Fig. 1. Since we require $\Lambda = \Lambda_1 \cup \cdots \cup \Lambda_6$, the six edges separating $\Lambda_1, \cdots, \Lambda_6$ and joining the origin to the boundary of Λ must be included. For notational convenience, we simply include both such boundary edges of each Λ_i to Λ_i. For $(u,v) \in \triangle_2$ it will be shown that $Im\ Q_{n,\alpha}(u,v) < 0$ if $\alpha = (s,t) \in \Lambda_1 \cup \Lambda_2 \backslash \{0\}$ and $Im Q_{n,\alpha}(u,v) > 0$ if $\alpha = (s,t) \in \Lambda_3 \cup \Lambda_4 \backslash \{0\}$. On the other hand, for $\alpha = (s,t) \in \Lambda_5 \backslash \{0\}$ and $\alpha = (s,t) \in \Lambda_6 \backslash \{0\}$, we will see that $Im(e^{i2\pi t}Q_{n,\alpha}(u,v))$ is strictly positive and strictly negative, respectively, for all $(u,v) \in \triangle_2$. Of course the isolated situation $\alpha = 0$ not considered here corresponds to the centered box spline M_{nnn} result already established by de Boor, Höllig, and Riemenschneider in [1].

3. Proof of main result. Theorem 1 can be easily verified for $n = 1$, and, as mentioned above, has already been established by Sivakumar [9] for even n. In this section, we will present a proof for all integers $n \geq 3$, although some of the estimates still hold for $n = 2$. To facilitate our argument, several simple observations are included in the following lemma.

LEMMA 1. *Let* $k, \ell, m \in \mathbb{Z}\backslash\{0\}$ *and* $0 \leq v \leq u < 1$. *Then*

(a) $|\sin 2\pi yk| \leq |k||\sin 2\pi y|$ *for all* $y \in \mathbb{R}$;

(b) *The functions*

$$h_{\pm}(x,y,z) = (1-x)^{-|k|}(1-y)^{-|\ell|}(1-z)^{-|m|} \pm (1+x)^{-|k|}(1+y)^{-|\ell|}(1+z)^{-|m|}$$

are increasing in each of the variables x, y, z *on the interval* $[0,1)$; *moreover,* $|h_-(x,y,z)| \leq h_-(|x|,|y|,|z|)$ *for* $x, y, z \in (-1,1)$.

(c) $|\frac{1-u}{u+k}| \leq |\frac{1-v}{v+k}|$;

(d) $|\frac{v}{v+k}| \leq |\frac{u}{u+k}|$; *and*

(e) $|\frac{1+v}{v+k}| \leq |\frac{1+u}{u+k}|$.

Note that the inequalities (c), (d), and (e) were also used in [9]. We now proceed with our estimates.

LEMMA 2. *Let* $n \geq 2$ *be any integer. Then* $ReQ_{n,(s,t)}(u,v) > 0$ *for all* $(u,v) \in \triangle_1$ *and* $(s,t) \in \Lambda$.

Proof. From (2.5), we have

$$ReQ_{n,(s,t)}(u,v) = \sum_{j,k} \cos 2\pi(js+kt)\Big[\frac{u}{u+j}\cdot\frac{v}{v+k}\cdot\frac{u+v}{u+v+j+k}\Big]^n. \tag{3.1}$$

We split this series into two parts, namely:

$$\begin{aligned}\sum_{j,k} &= \sum_{j\in\mathbb{Z},k=0} + \sum_{j\in\mathbb{Z},k\neq 0} \\ &=: S + T,\end{aligned}$$

and will show that two terms in the series S dominate. To see this, the series S is again written as the sum of two subseries as follows:

$$\begin{aligned} S &= \sum_{j\in\mathbb{Z}} \cos 2\pi js\Big[\frac{u}{u+j}\cdot\frac{u+v}{u+v+j}\Big]^n \\ &= \sum_{j\in\mathbb{Z}}(-1)^j\Big[\frac{u}{u+j}\cdot\frac{u+v}{u+v+j}\Big]^n \\ &\quad + 2\sum_{j\in\mathbb{Z}}(-1)^{j+1}\sin^2\pi j\Big(\frac{1}{2}-s\Big)\Big[\frac{u}{u+j}\cdot\frac{u+v}{u+v+j}\Big]^n \\ &=: S_1 + S_2. \end{aligned} \tag{3.2}$$

For S_1, set $\varepsilon := \frac{1}{2} - u \geq 0$ and

$$\begin{aligned} a_j &:= (-1)^j\Big[\Big(\frac{u}{u+j}\cdot\frac{u+v}{u+v+j}\Big)^n - \Big(\frac{u}{u-j-1}\cdot\frac{u+v}{u+v-j-1}\Big)^n\Big] \\ &= (-1)^j\Big[\Big(\frac{1-2\varepsilon}{2j+1-2\varepsilon}\Big)^n\Big(\frac{1-2(\varepsilon-v)}{2j+1-2(\varepsilon-v)}\Big)^n \\ &\qquad - \Big(\frac{1-2\varepsilon}{2j+1+2\varepsilon}\Big)^n\Big(\frac{1-2(\varepsilon-v)}{2j+1+2(\varepsilon-v)}\Big)^n\Big]. \end{aligned}$$

Here, as a function of (u,v), a_0 is nonnegative and vanishes only when $(u,v)=(\frac{1}{2},0)$. Hence, it follows from Lemma 1(b) and $0 \le v \le \varepsilon \le \frac{1}{2}$ that

$$|a_j| \le \frac{1}{(2j+1)^{2n}} a_0$$

for all $j \ge 1$, and consequently, for all $n \ge 2$,

$$S_1 = \sum_{j=0}^{\infty} a_j \ge a_0 \left[1 - \sum_{j=1}^{\infty} \frac{1}{(2j+1)^{2n}}\right] \ge \frac{67}{68} a_0. \tag{3.3}$$

The subseries S_2 defined in (3.2) can be treated in a similar manner. Let

$$b_j := (-1)^{j+1} 2 \sin^2 \pi j \Big(\frac{1}{2} - s\Big) \Big[\Big(\frac{u}{j-u} \cdot \frac{u+v}{j-u-v}\Big)^n + \Big(\frac{u}{j+u} \cdot \frac{u+v}{j+u+v}\Big)^n\Big] \tag{3.4}$$

where $b_1 \ge 0$ and is strictly positive for $|s| < \frac{1}{2}$ and $(u,v) \ne (0,0)$. By factoring out j^{-2n} in (3.4) and applying Lemma 1 (a) and (b), we have

$$\begin{aligned} S_2 &\ge b_1 \left[1 - \sum_{j=2}^{\infty} \frac{1}{j^{2n}} \frac{\sin^2 \pi j(\frac{1}{2} - s)}{\sin^2 \pi(\frac{1}{2} - s)}\right] \\ &\ge b_1 \left[1 - \sum_{j=2}^{\infty} \frac{1}{j^{2n-2}}\right] \ge 0.35 b_1 \end{aligned} \tag{3.5}$$

for all $n \ge 2$. Hence, combining the information from (3.3) and (3.5), we have

$$S \ge \frac{67}{68} a_0 + 0.35 b_1, \tag{3.6}$$

which is strictly positive for all $(u,v) \in \triangle_1$ and $|s| < \frac{1}{2}$. To study the series T, note that for $(u,v) \in \triangle_1$, the inequalities

$$0 \le u, u+v \le \tfrac{1}{2} \quad \textit{and} \quad \tfrac{3}{4} \le 1 - v \le 1$$

hold. It follows that for $n \ge 2$,

$$\begin{aligned} |T| &\le \Big(\frac{v}{1-v}\Big)^n \sum_{j \in \mathbb{Z}, k \ne 0} \Big|\frac{1}{1+2j}\Big|^n \Big|\frac{1}{k}\Big|^n \Big|\frac{1}{1+2j+2k}\Big|^n \\ &\le \frac{4}{9} v \sum_{j \in \mathbb{Z}, k \ne 0} \Big|\frac{1}{1+2j}\Big|^2 \Big|\frac{1}{k}\Big|^2 \Big|\frac{1}{1+2j+2k}\Big|^2 \\ &\le \frac{5}{4} v. \end{aligned}$$

On the other hand, writing $\varepsilon = \frac{1}{2} - u$, we have

$$\begin{aligned} a_0 &\ge 1 - \Big(\frac{u}{1-u}\Big)^2 = \frac{(1+2\varepsilon)^2 - (1-2\varepsilon)^2}{(1+2\varepsilon)^2} \\ &\ge 2\varepsilon \ge 2v. \end{aligned}$$

This together with the lower bound estimate (3.6) gives

$$ReQ_{n,(s,t)}(u,v) \geq S - |T| \geq \Big(\frac{67}{68} - \frac{5}{8}\Big)a_0 + 0.35b_1 > 0$$

for all $|s| < \frac{1}{2}$, completing the proof of the lemma. □

For $(u,v) \in \triangle_2$, we first consider the shift region $\Lambda_1 \cup \Lambda_2 \cup \Lambda_3 \cup \Lambda_4$ as follows.

LEMMA 3. *Let $n \geq 3$ be an integer and $(u,v) \in \triangle_2$. Then*

$$ImQ_{n,\alpha}(u,v) < 0 \quad \text{for } \alpha \in \Lambda_1 \cup \Lambda_2 \backslash \{0\} \tag{3.7}$$

and

$$ImQ_{n,\alpha}(u,v) > 0 \quad \text{for } \alpha \in \Lambda_3 \cup \Lambda_4 \backslash \{0\}. \tag{3.8}$$

Proof. We first observe that since

$$Q_{n,\alpha}(u,v) = \overline{Q_{n,-\alpha}(u,v)},$$

the conclusions (3.7) and (3.8) are equivalent. To verify (3.7), write

$$ImQ_{n,(s,t)}(u,v) =: T_1 + T_2, \tag{3.9}$$

where

$$T_1 := \sum_{j,k\in\mathbb{Z}} \sin 2\pi sj \cos 2\pi tk \Big[\frac{u}{u+j} \cdot \frac{v}{v+k} \cdot \frac{u+v}{u+v+j+k}\Big]^n$$

and

$$T_2 := \sum_{j,k\in\mathbb{Z}} \cos 2\pi sj \sin 2\pi tk \Big[\frac{u}{u+j} \cdot \frac{v}{v+k} \cdot \frac{u+v}{u+v+j+k}\Big]^n.$$

Our plan is to show that $T_1, T_2 \leq 0$ on $\triangle_2$ and have disjoint zeros there. For the series T_1, we factor out the dominant term

$$c_{-1,0} := -\sin 2\pi s \Big[\frac{u}{1-u} \cdot \frac{u+v}{1-u-v}\Big]^n \leq 0, \tag{3.10}$$

and using the condition $u+v > \frac{1}{2}$ and $u > \frac{1}{4}$ for $(u,v) \in \triangle_2$ and applying Lemma 1 (c)–(e), we conclude that

$$\begin{aligned} T_1 &\leq c_{-1,0}\Big\{1 - \sum_{(j,k)\neq(-1,0)} \Big|\frac{\sin 2\pi sj}{\sin 2\pi s}\Big| |\cos 2\pi tk| \Big|\frac{1-u}{u+j}\Big|^n \Big|\frac{v}{v+k}\Big|^n \Big|\frac{1-u-v}{u+v+j+k}\Big|^n\Big\} \\ &\leq c_{-1,0}\Big\{1 - \sum_{(j,k)\neq(-1,0)} |j| \Big|\frac{3}{1+4j} \cdot \frac{1}{1+3k} \cdot \frac{1}{1+2j+2k}\Big|^n\Big\} \\ &\leq 0.96 c_{-1,0}, \end{aligned}$$

where the numerical constant is obtained by using $n = 3$. Hence, $T_1 \leq 0$ and has zeros in $\triangle_2$ (and in fact vanishes identically) if and only if $s = 0$. To study T_2, we first restrict our attention to $v \geq 0.05$. In this case, factoring out the dominant term

$$d_{0,-1} := -\sin 2\pi t \Big(\frac{v}{1-v} \cdot \frac{u+v}{1-u-v}\Big)^n \leq 0,$$

and applying Lemma 1 (c)–(e), we have, similarly,

$$T_2 \le d_{0,-1}\Big\{1 - \sum_{(j,k)\neq(0,-1)} |k|\Big|\frac{1}{1+2j}\cdot\frac{19}{1+20k}\cdot\frac{1}{1+2j+2k}\Big|^n\Big\}$$
$$\le 0.08 d_{0,-1},$$

where, in addition to the constraint $v \ge 0.05$, $n = 3$ has been used for computing the numerical constant. Note that $T_2 < 0$ if $t \neq 0$, and vanishes only if $t = 0$. Now suppose that $v \le 0.05$. We keep $(u, v) \in \triangle_2$ and t fixed and consider $g(s) := T_2(s, t, u, v)$ as a function of s. We will first show that $g(\frac{1}{2}) < 0$ for $t \neq 0$ and odd n, and $g(0) < 0$ for $t \neq 0$ and even n. Next we will verify that g is an increasing (respectively, decreasing) function on $[0, \frac{1}{2}]$ depending on n odd or even; hence, the proof of the lemma will be complete.

To establish the first claim for odd n, set $\varepsilon = \frac{1}{2} - u$ and consider the sum of the (j, k) and $(-j-1, -k)$ terms of $[uv(u+v)]^{-n} g(1/2)$, namely:

(3.11)
$$\begin{aligned} g_{jk} &:= (-1)^j 2^{2n} \sin 2\pi tk\{(2j+1-2\varepsilon)^{-n}(k+v)^{-n}(2j+2k+1+2(v-\varepsilon))^{-n} \\ &\qquad - (2j+1+2\varepsilon)^{-n}(k-v)^{-n}(2j+2k+1-2(v-\varepsilon))^{-n}\} \\ &= (-1)^j 2^{2n}(\sin 2\pi tk)(2j+1)^{-n}k^{-n}(2j+2k+1)^{-n} \\ &\quad \times \Big\{\Big(1-\frac{2\varepsilon}{2j+1}\Big)^{-n}\Big(1+\frac{v}{k}\Big)^{-n}\Big(1+\frac{2(v-\varepsilon)}{2j+2k+1}\Big)^{-n} \\ &\qquad - \Big(1+\frac{2\varepsilon}{2j+1}\Big)^{-n}\Big(1-\frac{v}{k}\Big)^{-n}\Big(1-\frac{2(v-\varepsilon)}{2j+2k+1}\Big)^{-n}\Big\}. \end{aligned}$$

Here, the assumption that n is odd has been used to determine the signs of both terms in the above formulation. By Lemma 1 (a),(b),

$$|g_{jk}| \le |2j+1|^{-n}|k|^{-n+1}|2j+2k+1|^{-n}|g_{-1,1}|,$$

where $g_{-1,1} \le 0$ and $= 0$ only for $t = 0$. Hence, it follows that

$$g\Big(\frac{1}{2}\Big) \le g_{-1,1}[uv(u+v)]^n\Big\{1 - \sum_{\substack{j\in\mathbb{Z}\\ k\ge 1}} |2j+1|^{-n}|k|^{-n+1}|2j+2k+1|^{-n}\Big\}$$
$$\le 0.89 g_{-1,1}[uv(u+v)]^n.$$

If n is even, then $g_{-1,1} \ge 0$ and the corresponding term in the series of $[uv(u+v)]^{-n}g(0)$ is $\tilde{g}_{jk} := (-1)^j g_{jk}$. Since $\tilde{g}_{-1,1} \le 0$ and $= 0$ only for $t = 0$, the above analysis directly applies to showing $g(0) \le 0$.

To establish the claim that g is a monotone function on $[0, \frac{1}{2}]$ for fixed $(u, v) \in \triangle_2$ with $v \le 0.05$ and $t \neq 0$, we note that

$$g'(s) = -2\pi \sum_{j,k\neq 0} j \sin 2\pi js \sin 2\pi kt\Big[\frac{u}{u+j}\cdot\frac{v}{v+k}\cdot\frac{u+v}{u+v+j+k}\Big]^n.$$

In particular, the series is dominated by the $(-1, 1)$ term

$$g'_{-1,1} := -2\pi \sin 2\pi s \sin 2\pi t\Big[\frac{u}{u-1}\cdot\frac{v}{1+v}\Big]^n,$$

which is positive for odd n and negative for even n. Assuming $0 \le v \le 0.05, 0.45 \le u \le 0.5$, and $0.5 \le u+v \le 0.525$, Lemma 1 (c)–(e) is used as follows:

$$\begin{aligned}
&\Big| \sum_{\substack{j,k\neq 0\\ (j,k)\neq(-1,1)}} j \sin 2\pi js \sin 2\pi kt \Big[\frac{u}{u+j}\cdot\frac{v}{v+k}\cdot\frac{u+v}{u+v+j+k}\Big]^n \Big| \\
&\qquad \le g'_{-1,1} \sum_{(j,k)\neq(-1,1)} j^2|k| \Big|\frac{1-u}{u+j}\cdot\frac{1+v}{v+k}\cdot\frac{u+v}{u+v+j+k}\Big|^n \\
&\qquad \le g'_{-1,1} \sum_{(j,k)\neq(-1,1)} j^2|k| \Big|\frac{1-u}{u+j}\cdot\frac{1+v}{v+k}\cdot\frac{u+v}{u+v+j+k}\Big|^3 \\
&\qquad \le 0.45 g'_{-1,1}.
\end{aligned}$$

Hence, combining the estimates for T_1 and T_2 into (3.9), we have established (3.7) and consequently completed the proof of the lemma. □

To complete the proof of Theorem 1, the only remaining task is to establish the following.

LEMMA 4. *Let $n \ge 3$. Then for all $(u,v) \in \triangle_2$,*

$$Im\ e^{i2\pi t} Q_{n,(s,t)}(u,v) > 0 \quad \text{if } (s,t) \in \Lambda_5 \backslash \{0\}, \tag{3.12}$$

$$Im\ e^{i2\pi t} Q_{n,(s,t)}(u,v) < 0 \quad \text{if } (s,t) \in \Lambda_6 \backslash \{0\}. \tag{3.13}$$

Proof. The proof adapts the method in [9] (cf. Case IV in the proof there) applied to a different $\triangle_2$ as follows. Again, it is sufficient to establish (3.12). Let $\alpha = (s,t) \in \Lambda_5 \backslash \{0\}$. Then

$$\begin{aligned}
&Im\ e^{i2\pi t} Q_{n,(s,t)}(u,v) \\
&\qquad = \sum_{j,k\in\mathbb{Z}} \sin 2\pi(js + (k+1)t) \Big\{\frac{u}{u+j}\cdot\frac{v}{v+k}\cdot\frac{u+v}{u+v+j+k}\Big\}^n \\
&\qquad =: T' + T'',
\end{aligned} \tag{3.14}$$

where T' and T'' are defined as in [9] (see also (3.15)–(3.16) to follow). For $(u,v) \in \triangle_2$, $0 \le u \le \frac{1}{2}, 0 \le v \le \frac{1}{3}$, and $0 \le u+v < \frac{2}{3}$, it follows from [9, Eq. (4.25)] that T' is dominated by $\sin 2\pi t$, and hence is nonnegative and vanishes only when $t = 0$. For T'', we must modify the argument in [9] and rely on the restrictions $u \ge \frac{1}{4}, v \le \frac{1}{3}$ and $u+v \ge \frac{1}{2}$ in applying Lemma 1 (c)–(d). With the dominant term

$$t''_{-1,0} := \Big(\frac{u}{1-u}\cdot\frac{u+v}{1-u-v}\Big)^n \sin 2\pi(t-s) \ge 0, \tag{3.15}$$

we have

$$\begin{aligned}
T'' &:= t''_{-1,0}\Big[1 - \sum_{\substack{(j,k)\neq\\ (0,0),(-1,0)}} \Big(\frac{1-u}{u+j}\cdot\frac{v}{v+k}\cdot\frac{1-u-v}{u+v+j+k}\Big)^n \\
&\qquad \times \frac{\sin 2\pi j(t-s)}{\sin 2\pi(t-s)} \cos 2\pi jt \cos 2\pi(k+1)t\Big] \qquad (3.16)\\
&\ge t''_{-1,0}\Big[1 - \sum_{\substack{(j,k)\neq\\ (0,0),(-1,0)}} \Big|\frac{3}{1+4j}\cdot\frac{1}{1+3k}\cdot\frac{1}{1+2j+2k}\Big|^n |j|\Big] \\
&\ge 0.96 t''_{-1,0},
\end{aligned}$$

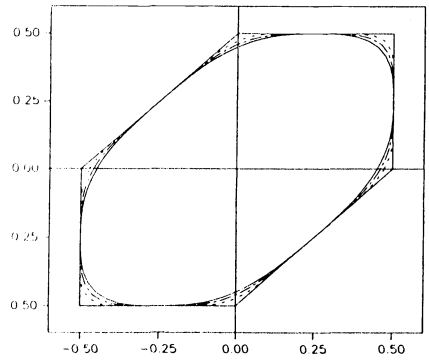

FIG. 3

where the numerical lower bound is obtained by using $n = 3$. In view of (3.15), $T'' \geq 0$ and vanishes only for $s = t$. Combining this with the estimate for T', we conclude that $Im\, e^{i2\pi t} Q_{n,(s,t)}(u,v)$ is strictly positive for all $(u,v) \in \triangle_2$ and all shift parameters $(s,t) \in \triangle_5 \backslash \{0\}$. This completes the proof of Lemma 4, and hence, of Theorem 1. □

4. The metric condition. The purpose of establishing $\tilde{\phi}(x) \neq 0$ for all $x \in \mathbb{R}^s$ is to guarantee that cardinal interpolation by using $\phi(\cdot - j), j \in \mathbb{Z}^s$ is poised. If $\tilde{\phi}$ satisfies the metric condition (1.3), then not only $\tilde{\phi}(x) \neq 0$ for all $x \in \mathbb{R}^s$, but the cardinal interpolants can also be constructed by using the Neumann series [5]. For B-splines B_k in one variable, it was shown in [10] that $|1 - \widetilde{B}_{k,\alpha}(x)| < 1$ for all x and $|\alpha| < \frac{1}{2}$, where $B_{k,\alpha} := B_k(\cdot + \alpha)$; hence, the important univariate notion of total positivity is not required in establishing invertibility of the cardinal interpolation operators corresponding to the shifted B-splines. Unfortunately, in the case of bivariate splines on the three-direction mesh considered in this paper, the metric condition

$$|1 - \widetilde{M}_{n,\alpha}(x)| < 1, \qquad x \in \mathbb{R}^2, \tag{4.1}$$

is no longer equivalent to the condition

$$\widetilde{M}_{n,\alpha}(x) \neq 0, \qquad x \in \mathbb{R}^2.$$

Let Λ^n denote the largest subregion of Λ on which the metric condition (4.1) holds. In Fig. 3, we have plotted subregions $\Lambda^1, \Lambda^2, \Lambda^3, \Lambda^4$ of the shift region Λ. Observe that $\Lambda = \Lambda^1 \supset \Lambda^2 \supset \Lambda^3 \supset \Lambda^4$, where all the containments are proper. However, at this writing, we do not know if $\{\Lambda^n\}$ is a monotone sequence. It would also be interesting to know its "limit" or "intersection."

Acknowledgment. The authors thank N. Sivakumar for several stimulating conversations.

A SIMPLE WILSON ORTHONORMAL BASIS WITH EXPONENTIAL DECAY*

INGRID DAUBECHIES†, STÉPHANE JAFFARD‡, AND JEAN-LIN JOURNÉ§

Abstract. Following a basic idea of Wilson ["Generalized Wannier functions," preprint] orthonormal bases for $L^2(\mathbb{R})$ which are a variation on the Gabor scheme are constructed. More precisely, $\phi \in L^2(\mathbb{R})$ is constructed such that the ψ_{ln}, $l \in \mathbb{N}$, $n \in \mathbb{Z}$, defined by

$$\psi_{0n}(x) = \phi(x-n)$$

$$\psi_{ln}(x) = \sqrt{2}\,\phi\left(x-\frac{n}{2}\right)\cos(2\pi l x) \quad \text{if } l \neq 0,\ l+n \in 2\mathbb{Z}$$

$$= \sqrt{2}\,\phi\left(x-\frac{n}{2}\right)\sin(2\pi l x) \quad \text{if } l \neq 0,\ l+n \in 2\mathbb{Z}+1,$$

constitute an orthonormal basis. Explicit examples are given in which both ϕ and its Fourier transform $\hat{\phi}$ have exponential decay. In the examples ϕ is constructed as an infinite superposition of modulated Gaussians, with coefficients that decrease exponentially fast. It is believed that such orthonormal bases could be useful in many contexts where lattices of modulated Gaussian functions are now used.

1. Introduction.

In several applications in quantum mechanics and in signal analysis, sets of functions generated from one single function by phase space translations are encountered:

$$g_{mn}(x) = e^{2\pi i \alpha m x} g(x-\beta n), \qquad m, n \in \mathbb{Z}. \tag{1.1}$$

If the function g and its Fourier transform $\hat{g}$,

$$\hat{g}(\xi) = \int dx\, e^{2\pi i x \xi} g(x),$$

are both centered around zero, then the function g_{mn} is centered around the phase space point $(\alpha m, \beta n)$. We can then hope to use the functions g_{mn} for expansions of functions with good phase space localization. More concretely, we would like expansions of the type

$$f = \sum_{m,n} c_{mn}(f) g_{mn}, \tag{1.2}$$

with the property that the $c_{mn}(f)$ are nonnegligible only for those values of (m, n) associated to phase space points where f is nonnegligible. For example, if $\int_{|t|\geq T} dt\, |f(t)|^2 \leqq \varepsilon \|f\|^2$ and $\int_{|\xi|\geq \Omega} d\xi\, |\hat{f}(\xi)|^2 = \varepsilon \|f\|^2$, then we would prefer most of the "content" of f to be concentrated in the $c_{mn}(f)$ with $(m\alpha, n\beta)$ within or close to the rectangle $[-\Omega, \Omega] \times [-T, T]$. More concretely, this can be translated into the

requirement

$$\sum_{\substack{|\alpha m|\geqq T+\Delta T \\ |\beta n|\geqq \Omega+\Delta\Omega}} |c_{mn}(f)|^2 \leqq C\varepsilon \|f\|^2, \tag{1.3}$$

where C should be independent of ε, T, and Ω, and where ΔT, $\Delta\Omega$ should only depend on the desired precision ε.

One example of a set of functions of type (1.1) are the phase space Wannier functions used in solid state physics. In the absence of a potential they are obtained by the choice

$$g(x) = \frac{\sin \pi x}{\pi x},$$

which corresponds to

$$\hat{g}(\xi) = \begin{cases} 1, & |\xi| < \frac{1}{2}, \\ 0, & \text{otherwise.} \end{cases}$$

(When the potential is nonzero, the Wannier functions are more complicated [1].) For this choice of g, and for the parameter choice $\alpha = \beta = 1$, the functions (1.1) constitute an orthonormal basis of $L^2(\mathbb{R})$. Expansions of type (1.2) are therefore simple to obtain: it suffices to take $c_{mn}(f) = \int dx\, \overline{g_{mn}(x)}\, f(x)$. Unfortunately, the localization of g is not very good. The function g has a rather long tail, so that

$$\int dx\, x^2 |g(x)|^2 = \infty.$$

As a consequence of this, expansions of functions with respect to the phase space Wannier functions do not have the good phase space localization features described above.

Another example of a set of functions of type (1.1) is given by the "Gabor expansions." These correspond to the choice

$$g(x) = 2^{1/4} \exp(-\pi x^2).$$

In the original proposal of Gabor [2], the parameter choice $\alpha = \beta = 1$ is made. Unfortunately, this parameter choice leads to numerically unstable expansions: for any $\varepsilon > 0$, there exists $f \in L^2(\mathbb{R})$ such that $\|f\| = 1$ but $\sum_{m,n} |c_{mn}(f)|^2 \leqq \varepsilon$. It can be shown that this phenomenon happens for any choice of α, β such that $\alpha\beta = 1$ [3a, b], [4a, b]. If $\alpha\beta > 1$, then the g_{mn} do not span all of $L^2(\mathbb{R})$ [5], [6]. If $\alpha\beta < 0.996$, then numerically stable expansions of type (1.2) do exist, with the "good" phase space localization described by (1.3) (see [7], [8]; it is conjectured that this situation persists for $\alpha\beta < 1$). There is, however, a price to pay: for $\alpha\beta < 1$, the g_{mn} are highly redundant, in the sense that any finite number of them lies in the closed linear span of all the others. While Gabor expansions with $\alpha\beta < 1$ are indeed used in practical computations in atomic and nuclear physics, this redundancy can be quite a nuisance.

These two examples illustrate how convenient it would be to have a nice orthonormal basis ($\rightarrow$ no redundancy) of type (1.1), based on a function g such that both g and $\hat{g}$ have good decay properties ($\rightarrow$ expansions with good phase space localization). Unfortunately, such an orthonormal basis does not exist. A theorem stated by Balian [9] and Low [10] asserts that a set of functions of type (1.1) can only constitute an orthonormal basis if either $\int dx\, x^2 |g(x)|^2 = \infty$ or $\int d\xi\, \xi^2 |\hat{g}(\xi)|^2 = \infty$. Balian's and Low's proofs contain a technical gap that was filled by Coifman and Semmes, as reported in [7]; a much simpler proof was subsequently found by Battle [11]. Even if the orthonormality, but not the "basis" requirement, is given up, the same conclusion still holds, as shown by the extension of Battle's argument in [12]. Both the original proof

and Battle's proof of the Balian-Low theorem rely heavily on the special structure of the g_{mn} as defined by (1.1). We might therefore wonder whether there exist more general bases, $\psi_{mn}(x)$, with phase space localizations distributed more or less regularly over phase space, and such that uniform bounds on the decay of all the ψ_{mn} and $(\psi_{mn})\hat{}$, away from their central value, would hold. It turns out that there is indeed improvement from giving up the simplicity of (1.1), but only very little. Bourgain [13] has constructed an orthonormal basis of ψ_{mn} such that

$$\begin{aligned} &\int dx\ (x-\bar{x}_{mn})^2|\psi_{mn}(x)|^2 \leqq C, \\ &\int d\xi\ (\xi-\bar{\xi}_{mn})^2|(\psi_{mn})\hat{}(\xi)|^2 \leqq C, \end{aligned} \tag{1.4}$$

uniformly in m, n, where $\bar{x}_{mn} = \int dx\, x|\psi_{mn}(x)|^2$, and $\bar{\xi}_{mn}$ is defined analogously. However, as soon as a slightly sharper localization is required, we hit another no-go-theorem, even for these more general constructions: Steger [14] proved that $L^2(\mathbb{R})$ does not admit an orthonormal basis ψ_{mn} satisfying

$$\begin{aligned} &\int dx\ (x-\bar{x}_{mn})^{2(1+\varepsilon)}|\psi_{mn}(x)|^2 \leqq C, \\ &\int d\xi\ (\xi-\bar{\xi}_{mn})^{2(1+\varepsilon)}|(\psi_{mn})\hat{}(\xi)|^2 \leqq C. \end{aligned} \tag{1.5}$$

Orthonormality, or, what is weaker, the existence of numerically stable expansions of type (1.2) with nonredundant functions ψ_{mn}, is therefore incompatible with good phase space localization.

In all the above, "good phase space localization" stands for strong decay properties of the ψ_{mn}, $(\psi_{mn})\hat{}$ away from the average values $\bar{x}_{mn}$, $\bar{\xi}_{mn}$. This corresponds to a picture in which both ψ_{mn} and $(\psi_{mn})\hat{}$ have essentially *one* peak. In [15] Wilson proposes instead to construct orthonormal bases ψ_{mn} of the type

$$\psi_{mn}(x) = f_m(x-n), \qquad m \in \mathbb{N}, \quad n \in \mathbb{Z}, \tag{1.6}$$

where $\hat{f}_m$ has *two* peaks, situated near $m/2$ and $-m/2$,

$$\hat{f}_m(\xi) = \phi_m^+\left(\xi - \frac{m}{2}\right) + \phi_m^-\left(\xi + \frac{m}{2}\right), \tag{1.7}$$

with ϕ_m^+, ϕ_m^- centered around zero. He proposes numerical evidence for the existence of such an orthonormal basis, with uniform exponential decay for f_m and ϕ_m^+, ϕ_m^-. In his numerical construction he further "optimizes" the localization by requiring

$$\int d\xi\, \xi^2 \overline{(\psi_{mn})\hat{}(\xi)}\, \psi_{m'n'}(\xi) = 0 \quad \begin{array}{l} \text{if } |m-m'|>1, \\ \text{or if } |m-m'|=1,\ |n-n'|>1. \end{array} \tag{1.8}$$

In [16] Sullivan et al. present arguments explaining both the existence of Wilson's basis and its exponential decay. In both [15] and [16] there are infinitely many functions $\phi_m^{\pm}$; as m tends to ∞, the $\phi_m^{\pm}$ tend to a limit function $\phi_\infty^{\pm}$.

The moral of Wilson's construction is that orthonormal bases with good phase space localization are possible after all if bimodal functions as in (1.7) are used. This is reminiscent of what happens for orthonormal wavelet bases, i.e., orthonormal bases of $L^2(\mathbb{R})$ of the type

$$h_{mn}(x) = 2^{-m/2} h(2^{-m}x - n), \qquad m, n \in \mathbb{Z}. \tag{1.9}$$

There exist functions h with excellent phase space localization properties such that the functions (1.9) constitute an orthonormal basis. In [17] Meyer constructs such a function h with compactly supported, C^∞ Fourier transform $\hat{h}$; [18]–[20] give examples of exponentially decaying $h \in C^k$; and [21] constructs compactly supported $h \in C^k$. In all these examples, $|\hat{h}|$ has two peaks, one for positive and one for negative frequencies. It has been shown [22] that these two peaks need not be symmetrical in order for the h_{mn} to constitute an orthonormal basis (the examples in [17]–[21] all have symmetric peaks for $|\hat{h}|$). However, there is no example, so far, of reasonably well-localized functions $h^\pm$ such that support $(h^\pm) \subset \mathbb{R}_\pm$ and such that the $h^\pm_{mn}$ constitute an orthonormal basis of $L^2(\mathbb{R})$, corresponding to wavelet bases with only one "peak" in frequency. (Equivalently, there is no example of a reasonably smooth function $\phi = \hat{h}^+$ such that the functions $2^{m/2} \exp(2\pi i 2^m n\xi)\phi(2^m\xi)$ are an orthonormal basis of $L^2(\mathbb{R}_+)$.) It is believed, without proof so far, that no such basis exists. This seems to be the analogue, for the wavelet situation, of the Balian–Low theorem.

In this paper we construct an explicit bimodal orthonormal basis of the type (1.6), (1.7). Our basis is especially simple because it is again generated by one single function, unlike the bases in [15], [16]. More explicitly, we construct a real function ϕ such that with the definitions

$$\hat{f}_1(\xi) = \phi(\xi),$$

$$\hat{f}_{2\ell+\kappa}(\xi) = \frac{1}{\sqrt{2}}[\phi(\xi-\ell) + (-1)^{\ell+\kappa}\phi(\xi+\ell)]\, e^{i\pi\kappa\xi}, \qquad \ell \in \mathbb{N}\setminus\{0\}, \quad \kappa = 0 \text{ or } 1, \tag{1.9a}$$

the family

$$\psi_{mn}(x) = f_m(x-n), \qquad m \in \mathbb{N}\setminus\{0\}, \quad n \in \mathbb{Z} \tag{1.9b}$$

constitutes an orthonormal basis. Both ϕ and its Fourier transform $\hat{\phi}$ have exponential decay. Moreover, ϕ can be explicitly constructed as a rapidly converging superposition of Gaussians. All these features should make the basis constructed here especially attractive for the computations in atomic and nuclear physics where the Gabor functions are now used. The price we pay for the simplicity of our Wilson basis is that the near-diagonalization (1.8) of ξ^2 no longer holds.

This paper is organized as follows. In § 2 we derive necessary and sufficient conditions on ϕ for the ψ_{mn}, defined by (1.9), to be an orthonormal basis of $L^2(\mathbb{R})$. In § 3 we rewrite these conditions in another form, via the Zak transform. In their new form, it is easy to see how to satisfy these conditions. We use this in § 4 to construct an explicit Wilson basis with all the properties mentioned above. It turns out that our construction is related to "tight frames" [23], [7]. We review this concept in § 5, and explain how it is linked to the present construction. This leads to an alternate construction method, given in § 6, which is easier to implement numerically. Finally § 7 gives some concluding remarks. In particular, we show how a relabelling of the ψ_{mn} in (1.9) reduces the construction to the formula given in the Abstract.

2. Necessary and sufficient conditions. It suffices to prove that

$$\|\psi_{mn}\| = 1, \qquad m \in \mathbb{N}\setminus\{0\}, \quad n \in \mathbb{Z}, \tag{2.1}$$

and

$$\sum_{m=1}^{\infty} \sum_{n=-\infty}^{\infty} \langle g, \psi_{mn}\rangle\langle\psi_{mn}, h\rangle = \langle g, h\rangle \tag{2.2}$$

for all $g, h \in L^2(\mathbb{R})$. Indeed, from (2.1) and (2.2) we obtain

$$1 = \|\psi_{m'n'}\|^2 = \sum_{m,n} |\langle \psi_{m'n'}, \psi_{mn}\rangle|^2$$

$$= 1 + \sum_{(m,n)\neq(m',n')} |\langle \psi_{m'n'}, \psi_{mn}\rangle|^2,$$

whence $\langle \psi_{mn}, \psi_{m'n'}\rangle = \delta_{mm'}\delta_{nn'}$. It follows that (2.1) and (2.2) imply that ψ_{mn} constitute a total orthonormal set.

We first concentrate on (2.2). Using Parseval's identity and the Poisson summation formula, we find

$$\sum_{m=1}^{\infty}\sum_{n=-\infty}^{\infty} \langle g, \psi_{mn}\rangle\langle \psi_{mn}, h\rangle = \sum_{m=1}^{\infty}\sum_{k=-\infty}^{\infty} \int d\xi\, \overline{\hat{g}(\xi)}\, \hat{h}(\xi+k)\hat{f}_m(\xi)\overline{\hat{f}_m(\xi+k)}.$$

(Note that we use the physicist's convention for the inner product in $L^2(\mathbb{R})$, which is linear in the *second* argument, $\langle g, h\rangle = \int dx\, \overline{g(x)}h(x)$.) In order to have (2.2), it is therefore necessary and sufficient that

$$\sum_{m=1}^{\infty} \hat{f}_m(\xi)\overline{\hat{f}_m(\xi+k)} = \delta_{k0}. \tag{2.3}$$

Let us write this out in terms of ϕ. For the time being, we disregard any convergence questions; for the function we will construct all series converge absolutely and uniformly. We also assume ϕ to be real.

$$\sum_{m=1}^{\infty} \hat{f}_m(\xi)\overline{\hat{f}_m(\xi+k)}$$

$$= \phi(\xi)\phi(\xi+k) + \frac{1}{2}\sum_{\ell=1}^{\infty}\sum_{\kappa=0}^{1} [\phi(\xi-\ell) + (-1)^{\ell+\kappa}\phi(\xi+\ell)]$$

$$\cdot [\phi(\xi\,\xi\varsigma\epsilon'' \eta\!\!\!/\, \ell + k) + (\overset{\ell+}{-}1) \quad \phi(\xi+\ell+k)]^{i\pi\kappa k} \tag{2.4}$$

$$= \phi(\xi)\phi(\xi+k) + \sum_{\ell\in\mathbb{Z},\ell\neq 0} \phi(\xi+\ell)\phi(\xi+\ell+k)\frac{1}{2}(1+(-1)^k)$$

$$+ \sum_{\ell\in\mathbb{Z},\ell\neq 0} (-1)^{\ell}\phi(\xi+\ell)\phi(\xi-\ell+k)\frac{1}{2}(1-(-1)^k).$$

If k is even, $k = 2j$, then

$$(2.4) = \sum_{\ell\in\mathbb{Z}} \phi(\xi+\ell)\phi(\xi+\ell+2j).$$

If k is odd, $k = 2j+1$, then

$$(2.4) = \sum_{\ell\in\mathbb{Z}} (-1)^{\ell}\phi(\xi+\ell)\phi(\xi-\ell+2j+1) = 0,$$

as is easily shown by the change of summation index $\ell' = -\ell + 2j + 1$. It follows that (2.3) is equivalent to

$$\sum_{\ell\in\mathbb{Z}} \phi(\xi+\ell)\phi(\xi+\ell+2j) = \delta_{j0}. \tag{2.5}$$

We now turn to (2.1). It clearly suffices to prove $\|\hat{f}_m\| = 1$, $m \in \mathbb{N}\setminus\{0\}$. For $m = 1$ this gives

$$\int d\xi\, |\phi(\xi)|^2 = 1.$$

For $m=2\ell+\sigma$, $\ell\geqq 1$, we find

$$\|\hat{f}_m\|^2=\frac{1}{2}\int d\xi\,|\phi(\xi-\ell)+(-1)^{\ell+\sigma}\phi(\xi+\ell)|^2$$

$$=1+(-1)^{\ell+\sigma}\int d\xi\,\phi(\xi-\ell)\phi(\xi+\ell).$$

It follows that (2.1) is equivalent to

$$\int d\xi\,\phi(\xi)\phi(\xi+2\ell)=\delta_{\ell 0}. \tag{2.6}$$

This condition is automatically satisfied if (2.5) holds:

$$\int_{-\infty}^{\infty} d\xi\,\phi(\xi)\phi(\xi+2\ell)=\sum_{k\in\mathbb{Z}}\int_0^1 d\xi\,\phi(\xi+k)\phi(\xi+k+2\ell)$$

$$=\int_0^1 d\xi\,\delta_{\ell 0}=\delta_{\ell 0}.$$

We have again assumed that ϕ is sufficiently well behaved so that the summation and integration may be commuted in this computation. It is easily checked that it is sufficient that ϕ decays faster than $|\xi|^{-1}$ for $|\xi|\to\infty$. For the examples we will construct, this is no problem. The following proposition summarizes our findings.

PROPOSITION 2.1. *Suppose that ϕ is a real function on $\mathbb{R}$ satisfying*

$$|\phi(\xi)|\leqq C(1+|\xi|)^{-1-\varepsilon}$$

for some C, $\varepsilon>0$. Then the functions ψ_{mn} defined by (1.9) *constitute an orthonormal basis for $L^2(\mathbb{R})$ if and only if*

$$\sum_{\ell\in\mathbb{Z}}\phi(\xi+\ell)\phi(\xi+\ell+2j)=\delta_{j0}.$$

We therefore have only one set of conditions, namely (2.5). This condition can be almost trivially satisfied if we choose ϕ to be supported in $[-1,1]$. In this case $\phi(\xi)\phi(\xi+2\ell)=0$ if $\ell\neq 0$, for any $\xi\in\mathbb{R}$. It follows that (2.5) is satisfied if $\sum_\ell \phi(\xi+\ell)^2=1$. Since this sum is periodic in ξ with period 1, we only need to check what happens for $0\leqq\xi\leqq 1$. For ϕ supported in $[-1,1]$, this means we only need to ascertain that $\phi(\xi)^2+\phi(\xi-1)^2=1$ for $0\leqq\xi\leqq 1$. Such ϕ are easy to construct: for any function F such that

$$F:\mathbb{R}\to\mathbb{R}$$

$$F(x)=\begin{cases}0, & x\leqq 0,\\ 1, & x\geqq 1,\end{cases}$$

$$0\leqq F(x)\leqq 1 \quad \text{for all } x,$$

the function ϕ defined by

$$\phi(\xi)=\begin{cases}\sin\left[\frac{\pi}{2}F(\xi+1)\right], & \xi\leqq 0,\\ \cos\left[\frac{\pi}{2}F(\xi)\right], & \xi\geqq 0\end{cases}$$

is a function supported in $[-1, 1]$ which satisfies (2.5), hence (2.1) and (2.2). If F is C^k (where k may be ∞), then ϕ is C^k. The corresponding ψ_{mn} are C^∞-functions; their decay at ∞ is regulated by the regularity of F. If F is C^∞, then the ψ_{mn} have "fast decay," i.e., for all $N \in \mathbb{N}$, there exists C_N such that

$$|\psi_{mn}(x)| \leqq C_N(1+|x-n|^2)^{-N}.$$

In practice, however, the constants C_N turn out to be rather large, so that the *numerical* localization of the ψ_{mn} is not very good. The examples we construct in § 4, corresponding to noncompactly supported ϕ, have better effective localization.

3. The Zak transform—rewriting the conditions. Using a unitary transformation, we will rewrite the infinitely many conditions (2.5) (one for every j) into a different form, reducing them to one single condition which is then easy to satisfy. The unitary map we shall use is the Zak transform. For the purposes of this paper, we define the Zak transform by

$$(U_Z g)(t, s) = \sqrt{2} \sum_{k \in \mathbb{Z}} e^{2\pi i t k} g(2(s-k)). \tag{3.1}$$

This is well defined for functions g with sufficient decay, $|g(x)| \leqq C(1+|x|^2)^{-1/2-\varepsilon}$. The two-variable function $G = U_Z g$ is periodic in the first and "semi-periodic" in the second variable,

$$\begin{aligned} G(t+1, s) &= G(t, s), \\ G(t, s+1) &= e^{2\pi i t} G(t, s). \end{aligned} \tag{3.2}$$

The set of all functions G of two variables satisfying the periodicity conditions (3.2) can be equipped with the norm

$$\|G\|^2 = \int_0^1 dt \int_0^1 ds\, |G(t, s)|^2. \tag{3.3}$$

We will denote the closure of this set, under the norm (3.3), by $\mathcal{Z}$. A function G is in $\mathcal{Z}$ if and only if its restriction to $[0, 1[\times [0, 1[$ is square integrable, and it satisfies the periodicity conditions (3.2) almost everywhere. It follows that $\mathcal{Z}$ is isomorphic with $L^2([0, 1]^2)$. The functions $E_{mn}(t, s)$, defined by

$$E_{mn}(t, s) = e^{2\pi i n t}\, e^{2\pi i m s} \quad \text{for } t, s \in [0, 1[,$$

extended by (3.2) to all of $\mathbb{R}^2$, constitute an orthonormal basis for $\mathcal{Z}$.

The map U_Z defined by (3.1) can be extended to a unitary map from $L^2(\mathbb{R})$ to $\mathcal{Z}$. This follows from the fact that U_Z maps the orthonormal basis $e_{mn}(x) = e^{\pi i m x} \chi(x-2n)$, where $\chi(x) = 2^{-1/2}$ if $0 \leqq x < 2$, $\chi(x) = 0$ otherwise, to the orthonormal basis E_{mn} of $\mathcal{Z}$, $U_Z e_{mn} = E_{mn}$.

The Zak transform has many interesting properties; it derives its name from its systematic study by J. Zak, who introduced it as a tool in solid state physics [24a-c]. It had already been studied sporadically before Zak's work, and it is claimed that even Gauss was already aware of some of its properties. An excellent review of the mathematical properties of U_Z and its applications to signal analysis is Janssen's paper [25], which also contains an extensive reference list.

The inverse transform of (3.1) is given by

$$(U_Z^{-1} G)(x) = \frac{1}{\sqrt{2}} \int_0^1 dt\, G\left(t, \frac{x}{2}\right). \tag{3.4}$$

Again this is only well defined for some G in $\mathscr{Z}$ (including all bounded G), but it can be extended to all of $\mathscr{Z}$.

There exists a relationship between $U_Z g$ and $U_Z \hat{g}$. Using the Poisson summation formula, we find

$$
\begin{aligned}
(U_Z\hat{g})(t,s) &= \sqrt{2}\sum_{\ell\in\mathbb{Z}} e^{2\pi i t\ell}\int_{-\infty}^{\infty} dx\, e^{4\pi i(s-\ell)x} g(x) \\
&= \frac{1}{\sqrt{2}} e^{2\pi i s t}\sum_{k\in\mathbb{Z}} e^{-2\pi i s k} g\left(\frac{t-k}{2}\right) \qquad \text{(3.5a)} \\
&= \frac{1}{2}\sum_{j=0}^{3} e^{2\pi i s(t+j)}(U_Z g)\left(-4s, \frac{t+j}{4}\right).
\end{aligned}
$$

Similarly,

$$
(U_Z g)(t,s) = \frac{1}{2}\sum_{j=0}^{3} e^{2\pi i s(t+j)}(U_Z \hat{g})\left(4s, -\frac{t+j}{4}\right). \qquad \text{(3.5b)}
$$

Let us now apply all this to the problem at hand. We define $\Phi = U_Z\phi$, and we rewrite (2.5) in terms of Φ. We have

$$
\begin{aligned}
\sum_{\ell\in\mathbb{Z}} \phi(\xi+\ell)\phi(\xi+\ell+2j) &= \frac{1}{2}\sum_{\ell\in\mathbb{Z}}\int_0^1 dt\int_0^1 dt'\,\Phi\left(t,\frac{\xi+\ell}{2}\right)\Phi\left(t',\frac{\xi+\ell}{2}+j\right) \\
&= \frac{1}{2}\sum_{k\in\mathbb{Z}}\int_0^1 dt\int_0^1 dt'\left[\Phi\left(t,\frac{\xi}{2}+k\right)\Phi\left(t',\frac{\xi}{2}+k+j\right)\right. \\
&\qquad \left. +\Phi\left(t,\frac{\xi+1}{2}+k\right)\Phi\left(t',\frac{\xi+1}{2}+k+j\right)\right] \\
&= \frac{1}{2}\sum_{k\in\mathbb{Z}}\int_0^1 dt\int_0^1 dt'\, e^{2\pi i k(t+t')}\, d^{2\pi i j t'} \\
&\qquad \cdot\left[\Phi\left(t,\frac{\xi}{2}\right)\Phi\left(t',\frac{\xi}{2}\right)+\Phi\left(t,\frac{\xi+1}{2}\right)\Phi\left(t',\frac{\xi+1}{2}\right)\right] \\
&\qquad\qquad \text{(use (3.2))} \\
&= \frac{1}{2}\int_0^1 dt\, e^{-2\pi i j t}\left[\left|\Phi\left(t,\frac{\xi}{2}\right)\right|^2+\left|\Phi\left(t,\frac{\xi+1}{2}\right)\right|^2\right].
\end{aligned}
$$

In the last step we have assumed that $\Phi(\cdot, s)$ is square integrable for all s; by the definition (3.1) of the Zak transform we easily check that this is equivalent to the requirement that $\sum_k |\phi(2s-2k)|^2$ be bounded for all s, which is certainly true if, as in Proposition 2.1, ϕ decays faster than $|\xi|^{-1}$. Note that we have used $\Phi(-t, s) = \overline{\Phi(t, s)}$, which is true for real functions ϕ. All this proves the following proposition.

PROPOSITION 3.1. *Let ϕ be as in Proposition* 2.1. *Then* (2.5) *is satisfied, i.e.,*

$$
\sum_{\ell\in\mathbb{Z}} \phi(\xi+\ell)\phi(\xi+\ell+2j) = \delta_{j0}
$$

if and only if the Zak transform $\Phi = U_Z\phi$ of ϕ, as defined by (3.1) *satisfies*

$$
|\Phi(t,s)|^2 + |\Phi(t, s+\tfrac{1}{2})|^2 = 2 \qquad \text{(3.6)}
$$

for almost all $t, s \in [0,1]^2$.

4. Constructing solutions. Now that we have reduced the infinitely many conditions (2.5) to the single condition (3.6), we can get down to the business of constructing explicit "nice" ϕ satisfying (2.5). Typically, we start with a real function g with exponential decay,

$$|g(x)| \leqq C e^{-\lambda|x|}, \tag{4.1}$$

such that its Fourier transform has exponential decay as well,

$$|\hat{g}(y)| \leqq C e^{-\mu|y|}. \tag{4.2}$$

Define $G = U_Z g$; G is well defined and continuous. Since g is real, we have, for all $t, s \in \mathbb{R}$,

$$G(-t, s) = \overline{G(t, s)}. \tag{4.3}$$

Assume that

$$\inf_{t,s\in[0,1]} [|G(t, s)|^2 + |G(t, s+\tfrac{1}{2})|^2] > 0. \tag{4.4}$$

We then define

$$\phi = U_Z^{-1}\Phi, \tag{4.5}$$

where

$$\Phi(t, s) = \sqrt{2}\,\frac{G(t, s)}{[|G(t, s)|^2 + |G(t, s+\tfrac{1}{2})|^2]^{1/2}}. \tag{4.6}$$

Then the following theorem holds.

THEOREM 4.1. *The function ϕ, defined by* (4.5), *is a real function, and satisfies* (2.5). *Furthermore, both ϕ and $\hat{\phi}$ have exponential decay.*

Proof. 1. It follows from (4.3) and (4.6) that

$$\Phi(-t, s) = \overline{\Phi(t, s)},$$

so that, using (3.4) and (3.2),

$$\begin{aligned}\overline{\phi(x)} &= \frac{1}{\sqrt{2}}\int_0^1 dt\, \overline{\Phi\left(t, \frac{x}{2}\right)} = \frac{1}{\sqrt{2}}\int_0^1 dt\, \Phi\left(-t, \frac{x}{2}\right) \\ &= \frac{1}{\sqrt{2}}\int_{-1}^0 dt\, \Phi\left(t, \frac{x}{2}\right) = \frac{1}{\sqrt{2}}\int_0^1 dt\, \Phi\left(t, \frac{x}{2}\right) = \phi(x).\end{aligned}$$

2. To prove that ϕ has exponential decay, we first extend the definition domain of G from $\mathbb{R}^2$ to $(\mathbb{R} + i(-\lambda/\pi, \infty)) \times \mathbb{R}$. From (4.1) we see that the series

$$G(t + i\tau, s) = \sqrt{2} \sum_{\ell\in\mathbb{Z}} e^{2\pi i(t+i\tau)\ell} g(2(s-l)) \tag{4.7}$$

converges absolutely for $\tau > -\lambda/\pi$. The function $G(z, s)$ is continuous on $(\mathbb{R} + i(-\lambda/\pi, \infty)) \times \mathbb{R}$, and $G(\cdot, s)$ is analytic on $\mathbb{R} + i(-\lambda/\pi, \infty)$ for every $s \in \mathbb{R}$. Moreover,

$$\begin{aligned} G(z, s+1) &= e^{2\pi i z} G(z, s), \\ G(z+1, s) &= G(z, s). \end{aligned} \tag{4.8}$$

We also define, for $z \in \mathbb{R} + i(-\lambda/\pi, \infty)$, $s \in \mathbb{R}$

$$\mathcal{G}(z, s) = G(z, s)G(-z, s) + G(z, s+\tfrac{1}{2})G(-z, s+\tfrac{1}{2}). \tag{4.9}$$

Then $\mathcal{G}(\cdot, s)$ is analytic on $\mathbb{R} + i(-\lambda/\pi, \infty)$ for every $s \in \mathbb{R}$, and

$$\mathcal{G}(z+1, s) = \mathcal{G}(z, s) = \mathcal{G}(z, s+\tfrac{1}{2}) \tag{4.10}$$

for all $z \in \mathbb{R} + i(-\lambda/\pi, \infty)$, $s \in \mathbb{R}$. Using (4.2), we can show that G is uniformly continuous on $(\mathbb{R} + i[-\lambda/\pi, \infty)) \times [0, 1]$; together with (4.10) this implies that $\mathcal{G}$ is uniformly continuous on $(\mathbb{R} + i[-\lambda/\pi, \infty)) \times \mathbb{R}$. On the other hand, the restriction of $\mathcal{G}$ to $\mathbb{R} \times \mathbb{R}$ is real, and bounded below away from zero by (4.4). It follows that there exists $\tilde{\lambda} > 0$ so that $|\mathcal{G}|$ is bounded below away from zero on $(\mathbb{R} + i[-\tilde{\lambda}, \tilde{\lambda}]) \times \mathbb{R}$. We can therefore define $\mathcal{G}^{-1/2}$ as a uniformly continuous function on $(\mathbb{R} + i[-\tilde{\lambda}, \tilde{\lambda}]) \times \mathbb{R}$; $\mathcal{G}(z, s)^{-1/2}$ is analytic in $z \in \mathbb{R} + i(-\tilde{\lambda}, \tilde{\lambda})$ for all $s \in \mathbb{R}$. We can therefore extend (4.6), and define for $z \in \mathbb{R} + i(-\tilde{\lambda}, \tilde{\lambda})$, $s \in \mathbb{R}$,

$$\Phi(z, s) = \sqrt{2}\, \mathcal{G}(z, s)^{-1/2} G(z, s).$$

By (4.8) and (4.10) this extension satisfies

$$\begin{aligned} &\Phi(z+1, s) = \Phi(z, s), \\ &\Phi(z, s+1) = e^{2\pi i z} \Phi(z, s). \end{aligned} \tag{4.11}$$

We can now use this extension to prove exponential decay of ϕ. By (4.5) and (3.4)

$$\phi(x) = \frac{1}{\sqrt{2}} \int_0^1 dt\, \Phi\left(t, \frac{x}{2}\right).$$

Assume that $x \geqq 0$. (We will treat $x \leqq 0$ afterwards.) Using the analyticity of Φ in $t + i\tau$, we can deform the integration path,

$$\phi(x) = \frac{1}{\sqrt{2}} \left[\int_0^\Lambda d\tau\, \Phi\left(i\tau, \frac{x}{2}\right) + \int_0^1 dt\, \Phi\left(t + i\Lambda, \frac{x}{2}\right) + \int_\Lambda^0 d\tau\, \Phi\left(1 + i\tau, \frac{x}{2}\right) \right],$$

where we assume $0 < \Lambda < \tilde{\lambda}$. Since $\Phi(1 + i\tau, x/2) = \Phi(i\tau, x/2)$, the first and third integral cancel out. If $x = 2n + 2x_1$, with $x_1 \in [0, 1]$, then, by (4.11),

$$\begin{aligned} |\phi(x)| &= \frac{1}{\sqrt{2}} \left| \int_0^1 dt\, e^{2\pi i n (t + i\Lambda)} \Phi(t + i\Lambda, x_1) \right| \\ &\leqq \frac{1}{\sqrt{2}}\, e^{-2\pi\Lambda n} \sup_{\substack{z \in [0,1] + i[-\tilde{\lambda}, \tilde{\lambda}] \\ s \in [0,1]}} |\Phi(z, s)| \\ &\leqq C'\, e^{-\pi\Lambda x}. \end{aligned}$$

For $x \leqq 0$ we use the same argument, but we deform the integration path by going into the Im $z < 0$ half plane. It follows that for all Λ such that

$$\Lambda < \min\left(\frac{\lambda}{\pi}, \inf\{|\tau|;\ \mathcal{G}(t + i\tau, s) = 0 \text{ for some } t, s \in [0, 1]\} \right),$$

there exists a constant C_Λ such that

$$|\phi(x)| \leqq C_\Lambda\, e^{-\pi\Lambda|x|}. \tag{4.12}$$

3. To prove the exponential decay of $\hat{\phi}$, we use the connection (3.5) between the Zak transforms of a function and of its Fourier transform. Because of (4.2) and (3.5b), arguments similar to those in step 2 above show that G can be extended to a uniformly continuous function on $\mathbb{R} \times (\mathbb{R} + i(\mu/4\pi, \infty))$, and that, for every $t \in \mathbb{R}$, $G(t, s + i\sigma)$ is analytic in $s + i\sigma \in \mathbb{R} + i(\mu/4\pi, \infty)$. We can now define, for $t \in \mathbb{R}$, $w = s + i\sigma \in \mathbb{R} + i(\mu/4\pi, \infty)$,

$$\Gamma(t, w) = G(t, w) G(-t, w) + G(t, w + \tfrac{1}{2}) G(-t, w + \tfrac{1}{2}).$$

Again $\Gamma(t, w)$ is analytic, and there exists $\tilde{\mu} > 0$ so that $|\Gamma|$ is bounded below away from zero on $\mathbb{R} \times (\mathbb{R} + i[-\tilde{\mu}, \tilde{\mu}])$. It follows that Φ has an extension to $\mathbb{R} \times (\mathbb{R} + i[-\tilde{\mu}, \tilde{\mu}])$,

$$\Phi(t, s+i\sigma) = \sqrt{2}\, G(t, s+i\sigma)\Gamma(t, s+i\sigma)^{-1/2},$$

which is analytic in $s+i\sigma$ for every fixed t, and which satisfies

$$\Phi(t, w+1) = e^{2\pi i t}\Phi(t, w),$$

$$\Phi(t+1, w) = \Phi(t, w).$$

By (3.4) and (3.5a) we have

$$\hat{\phi}(y) = \frac{1}{\sqrt{2}} \int_0^1 ds\, (U_Z \hat{\phi})\left(s, \frac{y}{2}\right)$$

$$= \frac{1}{2\sqrt{2}} \sum_{j=0}^{3} \int_0^1 ds\, e^{\pi i y(s+j)} \Phi\left(-2y, \frac{s+j}{4}\right).$$

We can now play the same game as before (deform the integral over s into the complex plane, $\cdots$). The result is that for all Δ such that

$$\Delta < \min\left(\frac{\mu}{\pi}, 4 \inf\{|\sigma|;\, \Gamma(t, s+i\sigma) = 0 \text{ for some } t, s \in [0, 1]\}\right),$$

there exists a constant $\hat{C}_\Delta$ such that

$$|\hat{\phi}(y)| \leqq \hat{C}_\Delta\, e^{-\pi\Delta|y|}. \tag{4.13}$$

4. It remains to show that ϕ satisfies (2.5). It is obvious from $|G(t, s+1)| = |G(t, s)|$ and from (4.6) that

$$|\Phi(t, s)|^2 + |\Phi(t, s+\tfrac{1}{2})|^2 = 2 \tag{4.14}$$

for all $t, s \in \mathbb{R}$. Because of the exponential decay of ϕ and $\hat{\phi}$, all the manipulations of § 3 are indeed allowed, and (4.14) implies (2.5). □

Any function g satisfying (4.1), (4.2), and (4.4) can therefore be used to construct an orthonormal Wilson basis of type (1.9). An explicit example is given by the Gaussian

$$g(x) = (2\nu)^{1/4}\, e^{-\nu\pi x^2}. \tag{4.15}$$

The Zak transform of g is related to one of Jacobi's theta functions,

$$\begin{aligned} G(t, s) &= \sqrt{2}\, (2\nu)^{1/4}\, e^{-4\nu\pi s^2} \sum_{\ell} e^{-4\nu\pi\ell^2}\, e^{2\pi\ell(4\nu s + it)} \\ &= \sqrt{2}\, (2\nu)^{1/4}\, e^{-4\nu\pi s^2} \theta_3(t - 4i\nu s \,|\, 4i\nu), \end{aligned} \tag{4.16}$$

with Bateman's notation [26]

$$\theta_3(z \,|\, \tau) = 1 + 2 \sum_{\ell=1}^{\infty} \cos(2\pi\ell z)\, e^{i\pi\tau\ell^2}.$$

As defined by (4.16), the function G has only one zero in $[0, 1]^2$, namely in $t = s = \frac{1}{2}$ [26]. Consequently, (4.4) is satisfied. Since g and $\hat{g}(y) = (2/\nu)^{1/4}\, e^{-\pi y^2/\nu}$ obviously have exponential decay, the construction (4.5)–(4.6) does lead to a Wilson basis with exponential phase space localization. For $\nu = 0.5$ we find

$$\inf\{|\tau|;\, \mathcal{G}(t + i\tau, s) = 0 \text{ for some } t, s \in [0, 1]\} = 0.5,$$

$$\inf\{|\sigma|;\, \Gamma(t, s+i\sigma) = 0 \text{ for some } t, s \in [0, 1]\} = 0.25.$$

Consequently, for every $\varepsilon > 0$ there exists C_ε such that

$$|\phi(x)| \leqq C_\varepsilon e^{-(\pi-\varepsilon)|x|/2}, \qquad |\hat{\phi}(y)| \leqq C_\varepsilon e^{-(\pi-\varepsilon)|x|}. \tag{4.17}$$

Remarks. 1. The decay rates in (4.17) can be adjusted by starting with a Gaussian different from (4.15). For $\nu = 2^{-1/2}$ e.g., we find that the corresponding ϕ and $\hat{\phi}$ are bounded by

$$|\phi(x)| \leqq C_\varepsilon \exp(-(\pi-\varepsilon)|x|/\sqrt{2}), \qquad |\hat{\phi}(y)| \leqq C_\varepsilon \exp(-(\pi-\varepsilon)|y|/\sqrt{2}). \tag{4.18}$$

2. It is easy to show that if g is an even function, then ϕ is even as well.

3. In [16] the explanation for the existence and exponential decay of the basis constructed by Wilson in [15] starts from an ansatz different from (1.9): the bimodal functions used as a starting point are of the form

$$g\left(\xi - \frac{2m+1}{4}\right) + (-1)^m g\left(\xi + \frac{2m+1}{4}\right). \tag{4.19}$$

For this ansatz the normalization (2.1) and the "completeness requirement" (2.2) do not reduce to the same condition. The orthonormalization of the functions in (4.19), starting from a "nice" g, results therefore in

$$\hat{f}_m(\xi) = \phi_m^1\left(\xi - \frac{2m+1}{4}\right) + \phi_m^2\left(\xi + \frac{2m+1}{4}\right),$$

where the $\phi_m^{1,2}$ depend on m. In the orthonormalization procedure in [16] the "overlap matrix" of the functions (4.19) is used. This overlap matrix also contains the quantity $|G(t, s)|^2 + |G(t, s+\frac{1}{2})|^2$, where G is the Zak transform of g (see Appendix B in [16]; the notation is very different, however). The merit of the present construction, starting from (1.9), is that the orthonormality (2.1) automatically follows once (2.2) is established; moreover, (2.1) + (2.2) are equivalent to the single condition (3.6), which enables us to construct, via (4.5)-(4.6) a *single* function ϕ generating the whole Wilson basis.

5. The link with tight frames. We start by briefly reviewing some material concerning "frames." Frames were introduced by Duffin and Schaeffer [27] in the context of nonharmonic Fourier series; in [23] and [7] special frames, constituted by families of functions of type (1.1), were studied in connection with the windowed Fourier transform. We review here some results from [7].

A family of g_{mn}, as defined in (1.1), constitutes a frame if there exist $A > 0$, $B < \infty$ such that, for all f in $L^2(\mathbb{R})$,

$$A\|f\|^2 \leqq \sum_{m,n} |\langle g_{mn}, f\rangle|^2 \leqq B\|f\|^2. \tag{5.1}$$

This condition can also be rewritten as

$$A\,\mathrm{Id} \leqq \mathbf{P} \leqq B\,\mathrm{Id}, \tag{5.2}$$

where $\mathbf{P}$ is the positive operator

$$\mathbf{P} = \sum_{m,n} P_{mn}, \qquad P_{mn} f = \langle g_{mn}, f\rangle g_{mn}. \tag{5.3}$$

If the g_{mn} constitute a frame, then functions $f \in L^2(\mathbb{R})$ can be completely characterized by the family of inner products $(\langle g_{mn}, f\rangle)_{m,n\in\mathbb{Z}}$, and there exists a numerically stable inversion procedure to reconstruct f from these inner products,

$$f = \sum_{m,n} \langle g_{mn}, f\rangle \tilde{g}_{mn},$$

with

$$\tilde{g}_{mn}(x) = e^{2\pi i\alpha mn}\tilde{g}(x-\beta n),$$
$$\tilde{g} = \mathbf{P}^{-1}g,$$

with $\mathbf{P}$ as defined by (5.3). Because of (5.2), $\mathbf{P}$ has a bounded inverse, so that $\tilde{g}$ is well defined. A special case arises when the frame is *tight*, i.e., when the frame bounds A and B are equal,

$$\sum_{m,n\in\mathbb{Z}} |\langle g_{mn}, f\rangle|^2 = A\|f\|^2.$$

It then follows that

$$\mathbf{P} = A\,\mathrm{Id},$$
$$\tilde{g} = A^{-1}g,$$
$$f = A^{-1}\sum_{m,n\in\mathbb{Z}} \langle g_{mn}, f\rangle g_{mn}.$$

In general, frames are redundant (they contain "too many" vectors, or more precisely, any frame vector lies in the closed linear span of all the others). If the frame is tight, then A indicates how redundant the frame is; for tight frames of type (1.1) we find [7]

$$A = (\alpha\beta)^{-1}\|g\|^2. \tag{5.4}$$

A frame of type (1.1) can only be an orthonormal basis if $\alpha\beta = 1$ (and if, moreover, g is chosen appropriately), corresponding to $A = 1$, or no redundancy. Tight frames with "nice" g exist if and only if $\alpha\beta < 1$; see [23] for a construction with compactly supported g.

Let us now specialize to the case $\alpha = .5$, $\beta = 1$,

$$g_{mn}(x) = e^{im\pi x}g(x-n).$$

The density of the phase space lattice corresponding to the g_{mn} is then twice as high as for an orthonormal basis. Suppose g is "nice," i.e., both g and $\hat{g}$ have fast decay at ∞. Let us investigate under which conditions on g the g_{mn} constitute a frame (respectively, tight frame). Because $(\alpha\beta)^{-1} = 2$ is an integer, the Zak transform is a natural tool to study these questions, as observed in [8]. Using (3.1), we find

$$(U_Z g_{m2n})(t, s) = e^{-2\pi itn}\, e^{2\pi ims} G(t, s),$$
$$(U_Z g_{m2n-1})(t, s) = e^{-2\pi itn}\, e^{2\pi ims} G(t, s+\tfrac{1}{2}),$$

where $G = U_Z g$. It follows that, for all $h_1, h_2 \in L^2(\mathbb{R})$,

$$\begin{aligned}\sum_{m,n\in\mathbb{Z}} \langle h_1, P_{m2n}h_2\rangle &= \sum_{m,n\in\mathbb{Z}} \langle h_1, g_{m2n}\rangle\langle g_{m2n}, h_2\rangle \\ &= \sum_{m,n\in\mathbb{Z}} \left[\int_0^1 dt \int_0^1 ds\, U_Z h_1(t, s)\overline{G(t, s)}\, e^{2\pi itn}\, e^{-2\pi ims}\right]^* \\ &\quad \cdot \left[\int_0^1 dt \int_0^1 ds\, U_Z h_2(t, s)\overline{G(t, s)}\, e^{2\pi itn}\, e^{-2\pi ims}\right] \\ &= \int_0^1 dt \int_0^1 ds\, \overline{U_Z h_1(t, s)}\, U_Z h_2(t, s)|G(t, s)|^2.\end{aligned}$$

Consequently, $U_Z[\sum_{m,n\in\mathbb{Z}} P_{m2n}]U_Z^{-1}$ is multiplication by $|G(t,s)|^2$ in $\mathscr{Z}$. Similarly, $U_Z[\sum_{m,n\in\mathbb{Z}} P_{m2n-1}]U_Z^{-1}$ is multiplication by $|G(t,s+\frac{1}{2})|^2$. Consequently, $\mathbf{P}=\sum_{m,n} P_{mn}$ is unitarily equivalent to multiplication by $|G(t,s)|^2+|G(t,s+\frac{1}{2})|^2$ on $\mathscr{Z}$. It follows that the g_{mn} constitute a frame, or equivalently that $\mathbf{P}$ satisfies (5.2), if and only if

$$0<A\leqq|G(t,s)|^2+|G(t,s+\tfrac{1}{2})|^2\leqq B<\infty$$

for all $t, s\in[0,1]$. All this is summarized in the following proposition.

PROPOSITION 5.1. *The functions $g_{mn}(x)=e^{im\pi x}g(x-n)$ constitute a frame if and only if the Zak transform $G=U_Zg$ of g, as defined by* (3.1), *satisfies*

$$A=\inf_{t,s\in[0,1]}[|G(t,s)|^2+|G(t,s+\tfrac{1}{2})|^2]>0$$

and

$$B=\sup_{t,s\in[0,1]}[|G(t,s)|^2+|G(t,s+\tfrac{1}{2})|^2]<\infty.$$

Note that if $|g(x)|\leqq C(1+|x|)^{-1-\varepsilon}$, then G is bounded, and B is automatically finite. There are other procedures than the Zak transform to check whether the g_{mn} constitute a frame [7]. The point of Proposition 5.1 is that any reasonably well-localized g such that the g_{mn} constitute a frame can be used as a starting point in the construction of ϕ in § 4. Note that the computations above also prove the following proposition.

PROPOSITION 5.2. *Let ϕ be a real function such that $|\phi(x)|\leqq C(1+|x|)^{-1-\varepsilon}$ and $\int dx\,|\phi(x)|^2=1$. Then the following are equivalent*:

(1) *The ψ_{mn}, as defined by* (1.9), *constitute an orthonormal basis,*

(2) *The Zak transform $\Phi=U_Z\phi$ of ϕ satisfies*

$$|\Phi(t,s)|^2+|\Phi(t,s+\tfrac{1}{2})|^2=2,$$

(3) *The functions $\phi_{mn}(x)=e^{im\pi x}\phi(x-n)$, $m, n\in\mathbb{Z}$, constitute a tight frame.*

Proof.

(1) $\Leftrightarrow$ (2) is proved in Proposition 5.2.

Define now $\mathbf{P}(\phi)$ by

$$\mathbf{P}(\phi)f=\sum_{m,n}\langle\phi_{mn},f\rangle\phi_{mn}.$$

Then, by the computation above,

$$\mathbf{P}(\phi)=U_Z^{-1}\{\text{multiplication with } [|\Phi(t,s)^2|+|\Phi(t,s+\tfrac{1}{2})|^2]\}U_Z. \tag{5.5}$$

If (2) holds, then it follows that $\mathbf{P}(\phi)=2\,\mathrm{Id}$, i.e.,

$$\sum_{m,n}|\langle\phi_{mn},f\rangle|^2=2\|f\|^2,$$

so the ϕ_{mn} constitute a tight frame.

On the other hand, if the ϕ_{mn} constitute a tight frame, i.e.,

$$\sum_{m,n}|\langle\phi_{mn},f\rangle|^2=A\|f\|^2,$$

then $A=2$ by (5.4) ($\alpha=.5$, $\beta=1$, and $\|g\|=1$). It follows that $\mathbf{P}(\phi)=2\,\mathrm{Id}$, which by (5.5) implies (2). □

Remark. From this analysis it follows that the construction in § 4 and § 6 below can also be used to generate tight frames with exponential localization in both time and frequency. The construction in § 6 can easily be extended to tight frames with arbitrary redundancy. These tight frames contrast with those constructed in [23], where either ϕ or $\hat{\phi}$ had compact support.

Proposition 5.2 leads to the following interpretation of our Wilson bases. Suppose that the ϕ_{mn} constitute a tight frame. Since $\alpha\beta = .5$, this tight frame has redundancy 2, i.e., it has "two times as many vectors" as an orthonormal basis. The Wilson basis vectors generated by ϕ via (1.9) are given by

$$(\psi_{mn})\hat{}(\xi) = e^{2\pi i n\xi}\hat{f}_m(\xi),$$

or

$$(\psi_{1n})\hat{}(\xi) = e^{2\pi i n\xi}\phi(\xi) = \phi_{02n}(\xi), \tag{5.6a}$$

$$(\psi_{2\ell+\kappa n})\hat{}(\xi) = \frac{1}{\sqrt{2}}\, e^{2\pi i n\xi}\, e^{i\pi\kappa\xi}[\phi(\xi-\ell)+(-1)^{\ell+\kappa}\phi(\xi+\ell)]$$

$$= \frac{1}{\sqrt{2}}(\phi_{\ell 2n+\kappa}+(-1)^{\ell+\kappa}\phi_{-\ell 2n+\kappa})(\xi), \tag{5.6b}$$

$$\ell \in \mathbb{N}\backslash\{0\}, \qquad \kappa = 0 \text{ or } 1.$$

Formula (1.9) can therefore be viewed as a procedure eliminating the redundancy factor 2 from the tight frame ϕ_{mn} by choosing only the ϕ_{0n} with even n, and replacing every pair $\phi_{\ell n}$, $\phi_{-\ell n}$ ($\ell \neq 0$) by one judiciously chosen linear combination of these two vectors. It seems a small miracle that the result is an orthonormal basis!

Note that (5.6) can be made even simpler by a relabelling of the ψ_{mn}. Denote

$$\Psi_{\ell 2n+\kappa} = \psi_{2\ell+\kappa n}, \qquad \ell \neq 0, \quad \kappa = 0 \text{ or } 1,$$

$$\Psi_{0n} = \psi_{1n}.$$

Then (5.6) becomes

$$(\Psi_{0n})\hat{} = \phi_{02n},$$

$$(\Psi_{\ell n})\hat{} = \frac{1}{\sqrt{2}}(\phi_{\ell n}+(-1)^{\ell+n}\phi_{-\ell n}), \qquad \ell \neq 0,$$

making the reduction from the right frame with redundancy 2 to the orthonormal basis even more elegant.

6. The construction revisited. The equivalence between (4.4) and the frame condition (5.1) leads to an alternate construction for the function ϕ which is very easy to implement numerically.

Choose g such that (4.1), (4.2), and (4.4) are satisfied. Then, by the argument in § 5,

$$U_Z \mathbf{P} U_Z^{-1} = \text{multiplication by } |G(t,s)|^2+|G(t,s+\tfrac{1}{2})|^2;$$

consequently,

$$\phi = U_Z^{-1}\frac{\sqrt{2}\,G}{\sqrt{|G(t,s)|^2+|G(t,s+\frac{1}{2})|^2}} = U_Z^{-1}U_Z\mathbf{P}^{-1/2}U_Z^{-1}\sqrt{2}\,G$$

$$= \sqrt{2}\,\mathbf{P}^{-1/2}U_Z^{-1}G = \sqrt{2}\,\mathbf{P}^{-1/2}g.$$

The operator $\mathbf{P}^{-1/2}$ can be written as a convergent series. Since

$$A\,\mathrm{Id} \leqq \mathbf{P} \leqq B\,\mathrm{Id}$$

for all $A>0$, $B<\infty$ satisfying

$$A \leqq \inf_{t,s\in[0,1]} [|G(t,s)|^2+|G(t,s+\tfrac{1}{2})|^2],$$

$$B \geqq \sup_{t,s\in[0,1]} [|G(t,s)|^2+|G(t,s+\tfrac{1}{2})|^2],$$

we have

$$\begin{aligned}\mathbf{P}^{-1/2} &= \left(\frac{2}{A+B}\right)^{1/2}\left[\mathrm{Id}-\left(\mathrm{Id}-\frac{2\mathbf{P}}{A+B}\right)\right]^{-1/2} \\ &= \left(\frac{2}{A+B}\right)^{1/2}\sum_{k=0}^{\infty}\frac{(2k)!}{2^{2k}(k!)^2}\left(\mathrm{Id}-\frac{2\mathbf{P}}{A+B}\right)^k,\end{aligned} \tag{6.1}$$

where the series converges because

$$\left\|\mathrm{Id}-\frac{2\mathbf{P}}{A+B}\right\| \leqq \frac{B-A}{B+A}<1.$$

This can be used to write ϕ as a combination of g_{mn}, with coefficients computed recursively. For instance, if g is Gaussian, $g^{\nu}(x)=(2\nu)^{1/4}\,e^{-\nu\pi x^2}$, then we find

$$\phi(x)=\frac{2}{\sqrt{A_\nu+B_\nu}}\sum_{m,n\in\mathbb{Z}} a_{mn}g^{\nu}_{mn}(x) \tag{6.2}$$

with

$$\begin{aligned}a_{mn} &= \sum_{k=0}^{\infty}\frac{(2k)!}{2^{2k}(k!)^2}\,b_{mn}^k, \\ b_{mn}^k &= \left(1-\frac{2}{A_\nu+B_\nu}\right)b_{mn}^{k-1}-\frac{2}{A_\nu+B_\nu}\sum_{(m',n')\neq(m,n)}\omega_{mn,m'n'}b_{m'n'}^{k-1},\end{aligned} \tag{6.3}$$

where

$$\omega_{mn,m'n'}=\exp\left[i(m'-m)(n+n')\frac{\pi}{2}-\frac{\nu\pi}{2}(n-n')^2-\frac{\pi}{8\nu}(m-m')^2\right],$$

$$b_{mn}^0=\delta_{m0}\delta_{n0}.$$

While this seems lengthy, it is very easy to program on a computer. The procedure converges at least as fast as a geometric series in $(B_\nu-A_\nu)/(B_\nu+A_\nu)$. For $\nu=.5$ we find $A_\nu=1.670$, $B_\nu=2.361$, $(B_\nu-A_\nu)/(B_\nu+A_\nu)=.1712$; for $\nu=2^{-1/2}$, we have $A_\nu=1.533$, $B_\nu=2.492$, $(B_\nu-A_\nu)/(B_\nu+A_\nu)=.2381$. Figures 1 and 2 give graphs of ϕ and $\hat{\phi}$, for $\nu=.5$ and $\nu=2^{-1/2}$, respectively.

Remarks. 1. A and B can be computed via the Zak transform:

$$A=\inf_{t,s\in[0,1]} [|(U_Zg)(t,s)|^2+|(U_Zg)(t,s+\tfrac{1}{2})|^2],$$

$$B=\sup_{t,s\in[0,1]} [|(U_Zg)(t,s)|^2+|(U_Zg)(t,s+\tfrac{1}{2})|^2].$$

In [7] an alternative way of estimating A and B is given, leading to a lower bound for A and an upper bound for B, without recourse to the Zak transform. Using the Poisson summation formula, we find

$$\mathbf{m}(g)-\mathbf{r}(g)\leqq A\leqq B\leqq \mathbf{M}(g)+\mathbf{r}(g), \tag{6.4}$$

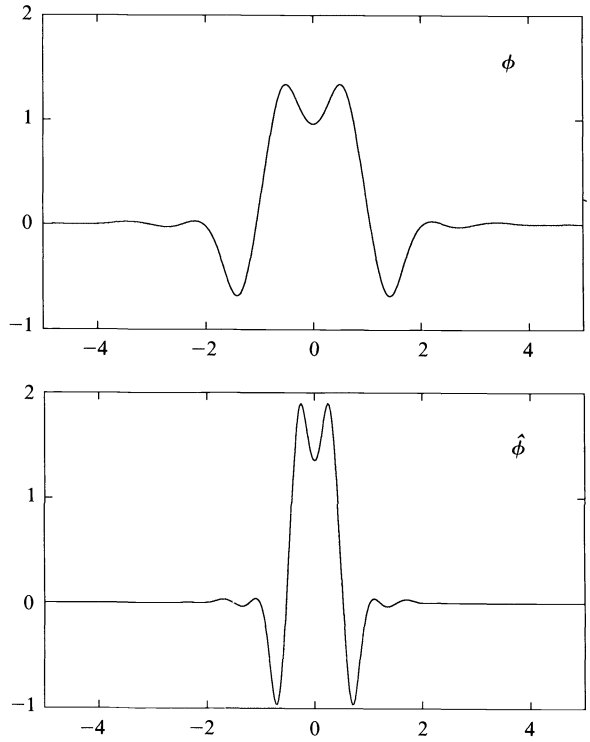

FIG. 1. *Plots of ϕ and $\hat{\phi}$, constructed from $g(x) = e^{-\pi x^2/2}$. For this choice of g, we have $\hat{\phi}(y) = \sqrt{2}\,\phi(2y)$ (see (6.6)). To draw these graphs, the recursive computation* (6.2), (6.3) *was used.*

where

$$\mathbf{m}(g) = \inf_{x\in[0,1]} \sum_n |g(x-n)|^2,$$

$$\mathbf{M}(g) = \sup_{x\in[0,1]} \sum_n |g(x-n)|^2,$$

$$\mathbf{r}(g) = 2\sum_{k=1}^{\infty} [\beta(2k)\beta(-2k)]^{1/2},$$

$$\beta(s) = \sup_{x\in[0,1]} \sum_n |g(x-n)g(x-n+s)|.$$

Note that the lower bound in (6.4) also gives a sufficient condition ensuring that (4.4) holds, without having to check the Zak transform. In some cases, more efficient bounds can be computed from the Fourier transform $\hat{g}$ of g. We obtain [7]

$$\tilde{\mathbf{m}}(g) - \tilde{\mathbf{r}}(g) \leqq A \leqq B \leqq \tilde{\mathbf{M}}(g) - \tilde{\mathbf{r}}(g)$$

with

$$\tilde{\mathbf{m}}(g) = \inf_{\xi\in[0,1/2]} \sum_n |\hat{g}(\xi - n/2)|^2,$$

$$\tilde{\mathbf{M}}(g) = \sup_{\xi\in[0,1/2]} \sum_n |\hat{g}(\xi - n/2)|^2,$$

$$\tilde{\mathbf{r}}(g) = 2\sum_{k=1}^{\infty} [\tilde{\beta}(k)\tilde{\beta}(-k)]^{1/2},$$

$$\tilde{\beta}(s) = \sup_{\xi\in[0,1/2]} \sum_n |\hat{g}(\xi - n/2)\hat{g}(\xi - n/2 + s)|.$$

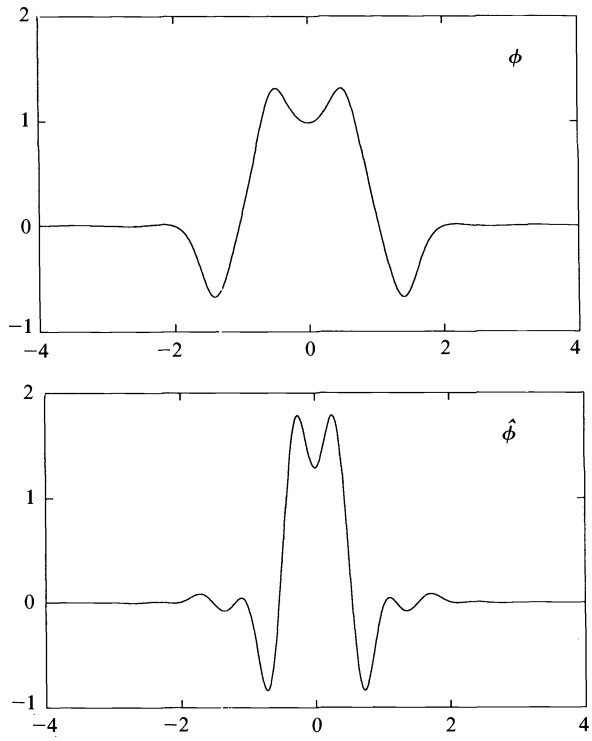

FIG. 2. *Plots of ϕ and $\hat{\phi}$ constructed from $g(x) = 2^{1/8} e^{-\pi x^2/\sqrt{2}}$. For this choice of g, the decay rates of ϕ and $\hat{\phi}$ are identical (see (4.18)). We have again used (6.2), (6.3) to compute ϕ; $\hat{\phi}$ is simply obtained by replacing g^{ν}_{mn} in (6.2) by $(g^{\nu}_{mn})\hat{}(y) = (-1)^{mn} e^{2\pi i y n} g^{1/\nu}(y + (m/2))$.*

2. Let us introduce the notation F for the Fourier transform and D_a for the dilations $(D_a f)(x) = |a|^{1/2} f(ax)$, and let us write $\mathbf{P}(g)$, $\phi(g)$ to make the dependence of the operator $\mathbf{P}$ and the function ϕ on the function g more explicit. Then we easily check that

$$D_{1/2} F \mathbf{P}(g) = \mathbf{P}(D_{1/2} F g) D_{1/2} F,$$

implying

$$D_{1/2} F \phi(g) = \phi(D_{1/2} F g). \tag{6.5}$$

Denoting $\phi(g^{\nu})$ by ϕ_{ν}, where $g^{\nu}(x) = (2\nu)^{1/4} \exp(-\pi \nu x^2)$, we find therefore

$$(\phi_{\nu})\hat{}(y) = \sqrt{2}\, \phi_{(4\nu)^{-1}}(2y). \tag{6.6}$$

In particular, for $\nu = .5$, $(\phi_{1/2})\hat{}(y) = \sqrt{2}\, \phi_{1/2}(2y)$.

7. Conclusion. We have shown how to construct very simple Wilson bases ψ_{mn}, generated by a single function ϕ, via

$$\begin{aligned} &\psi_{mn}(x) = f_m(x - n), \qquad n \in \mathbb{Z}, \quad m \in \mathbb{N}\backslash\{0\}, \\ &\hat{f}_1(\xi) = \phi(\xi), \\ &\hat{f}_{2\ell+\kappa}(\xi) = \frac{1}{\sqrt{2}} [\phi(\xi - \ell) + (-1)^{\ell+\kappa} \phi(\xi + \ell)]\, e^{i\pi\kappa\xi}, \qquad \ell \in \mathbb{N}\backslash\{0\}, \quad \kappa = 0 \text{ or } 1. \end{aligned} \tag{7.1}$$

We have explicitly constructed such bases; in order to obtain exponential decay for both the ψ_{mn} and their Fourier transforms $\hat{\psi}_{mn}$, it suffices to choose a function g such that g and $\hat{g}$ have exponential decay, and such that condition (4.4) is satisfied, or equivalently, such that the $g_{mn}(x) = e^{\pi i m x} g(x-n)$ constitute a frame. (For this it is sufficient that $\mathbf{m}(g) - \mathbf{r}(g) > 0$ or $\tilde{\mathbf{m}}(g) - \tilde{\mathbf{r}}(g) > 0$—see § 6.) The function ϕ can then be constructed from g either via the Zak transform (see § 4) or via a recursive algorithm (see § 6).

The functions f_m in (7.1) are given by the inverse Fourier transform of ϕ. If g is real and even, then so is ϕ, so that its Fourier transform and inverse Fourier transform coincide. We then have

$$f_1(x) = \hat{\phi}(x),$$

$$f_{2\ell+\kappa}(x) = \frac{1}{\sqrt{2}} \hat{\phi}\left(x + \frac{\kappa}{2}\right) e^{\pi i \ell \kappa} \left[e^{2\pi i \ell x} + (-1)^{\ell+\kappa} e^{-2\pi i \ell x} \right].$$

Using the relabelling

$$\Psi_{0n} = \psi_{1n}, \qquad \Psi_{\ell 2n+\kappa} = \psi_{2\ell+\kappa n}$$

we find

$$\Psi_{0n}(x) = \hat{\phi}(x-n),$$

$$\Psi_{\ell n}(x) = \sqrt{2}\, \hat{\phi}\left(x - \frac{n}{2}\right) \begin{cases} \cos(2\pi \ell x) & \text{if } \ell + n \text{ is even,} \\ \sin(2\pi \ell x) & \text{if } \ell + n \text{ is odd.} \end{cases}$$

It follows that the Wilson bases constructed here are very similar to the functions (1.1): the only difference is the alternate use of sines and cosines instead of complex exponentials. This trick is sufficient to beat the no-go Balian-Low theorem.

A HYPERBOLIC THEORY FOR THE EVOLUTION OF PLANE CURVES*

MORTON E. GURTIN† AND PAOLO PODIO-GUIDUGLI‡

Abstract. A theory is developed for the evolution of plane curves. This theory is based on balance laws for mass and momentum in conjunction with constitutive equations appropriate to a phase interface such as that between a crystal and its melt. The resulting evolution equation is hyperbolic and has solutions with aspects qualitatively reminiscent of the melting-freezing waves observed at the surface of He^4 crystals.

Key words. evolving curves, phase interfaces, melting-freezing waves

AMS(MOS) subject classifications. 35L70, 70K99

1. Introduction. It is the purpose of this paper to develop a theory for the evolution of plane curves which is based on balance laws for mass and momentum in conjunction with constitutive equations appropriate to a phase interface, and which leads to hyperbolic evolution equations. We have three reasons for presenting such a theory:

(1) The form of the balance laws is not at all obvious, and, in fact, represents an intriguing problem in continuum mechanics whose solution requires a nonstandard conceptual framework.

(2) The *parabolic* theory for the evolution of plane curves, which in its simplest form is based on the *curve-shortening equation*[1]

$$v = \kappa \tag{1.1}$$

(relating the normal velocity v and curvature κ) has been extremely successful, providing geometers with great insight; to our knowledge there is no *hyperbolic* version of (1.1).

(3) Crystals of helium in their melt exhibit a phenomenon generally not found in other materials: oscillations[2] of the solid-liquid interface in which atoms of the solid move only when they melt and enter the liquid. Motivated by Andreev and Parshin's [AP] classical discussion of such *melting-freezing waves*, a continuum model was developed in [G4][3] for a rigid crystal in an incompressible,[4] inviscid melt. This model, which we shall refer to as the **CM model**, leads to a free-boundary problem for the evolution of the interface; coupling between the interface and the melt renders this problem difficult, and it would seem useful to have a simple model in which the motion of the interface is governed by a hyperbolic analog of (1.1).

[1] See, e.g., Brakke [B], Gage and Hamilton [GH], and Grayson [Gr], as well as the references therein and those cited in § 5 of [AG].

[2] Such waves were predicted by Andreev and Parshin [AP] in 1978 and exhibited experimentally by Keshishev, Parshin, and Babkin [KPB] in 1979.

[3] Using, as a basis, a framework developed in [G1]-[G3], [AG], [GS].

[4] Andreev and Parshin [AP] note that the phase velocity of melting-freezing waves is generally well below the sound velocity.

Here we develop a theory in which *only the interface is endowed with mathematical structure*:[5] we model the inertia of the melt through an "*effective*" inertia for the interface, with the melt considered only as a source of atoms for the crystallization process; and we characterize this inertia constitutively through the corresponding interfacial mass density. As in the CM model, we restrict our attention to a purely mechanical[6] theory, and, to avoid the geometric complications that accompany evolving surfaces, to a two-dimensional theory in which the interface evolves as a plane curve.

Because of the presence of an "effective inertia," the balance laws for mass and momentum are not obvious. We derive these laws as a consequence of the requirement that the mechanical energy production—the rate at which the kinetic energy is changing minus the power expended by capillary forces—be invariant under Galilean changes in observer.

Constitutive equations, of the form derived in [G1] as a consequence of thermodynamical arguments, are assumed for the relevant interfacial fields. These equations and the underlying balance laws yield a single equation for the evolution of the interface:

$$\rho(\theta)v^\circ+\beta(\theta)v=[\psi(\theta)+\psi''(\theta)]\kappa-F. \tag{1.2}$$

Here $\psi(\theta)$, $\rho(\theta)$, and $\beta(\theta)$ are the energy, effective density, and kinetic coefficients for the interface; F is a constant which represents the driving force for crystallization; v° is the time derivative of v following the interface; and θ is the angle to the interface-normal $\mathbf{m}$. We assume that

$$\psi(\theta)+\psi''(\theta)>0, \qquad \rho(\theta)>0 \tag{1.3}$$

for all values of θ; this ensures that when (1.2) is combined with standard kinematical conditions for the evolution of a plane curve, the resulting partial differential equations are *hyperbolic*.

Equation (1.2) with $\beta(\theta)=0$, *linearized about a flat interface at equilibrium*, reduces to the classical wave equation

$$\rho_0 h_{tt}=(\psi+\psi'')_0 h_{xx} \tag{1.4}$$

for the interface expressed as a graph $y=h(x,t)$. This equation exhibits *melting-freezing waves*; that is, oscillatory solutions of the form

$$h(x,t)=C\,e^{i\lambda x}\,e^{-i\omega t} \tag{1.5}$$

with

$$\omega^2=\frac{(\psi+\psi'')_0\lambda^2}{\rho_0}. \tag{1.6}$$

As noted by Andreev and Parshin [AP] (cf. [G4]), the CM model exhibits melting-freezing waves of the form (1.5), but there ω^2 is proportional[7] to λ^3, rather than λ^2 as in (1.6). Thus the agreement between the simple model developed here and the more detailed CM model *is at most qualitative*; because of the simplified modeling of inertia, this is not unexpected.

[5] This is the point of view taken by Brower et al. [BK] and Ben-Jacob et al. [BG], who use equations involving only the interface to model interfacial evolution governed by bulk diffusion.

[6] As noted by Maris and Andreev [MA], for superconductors such as solid helium and its melt, solidification is "essentially a mechanical process, rather than a thermal process as it is for ordinary materials."

[7] This proporationality of ω^2 to λ^3 is confirmed by the experiments of Keshishev, Parshin, and Babkin [KPB].

For completeness we discuss the form the basic equations take when the interface is an evolving *surface* in $\mathbb{R}^3$. There (1.2) is replaced by

$$\rho(\mathbf{m})v^\circ+\beta(\mathbf{m})v=\psi(\mathbf{m})\kappa+\psi_{mm}(\mathbf{m})\cdot\mathbf{L}-F, \tag{1.7}$$

where $\mathbf{L}$ is the curvature tensor, $\kappa=\operatorname{tr}\mathbf{L}$ is twice the mean curvature, and $\psi_{mm}(\mathbf{m})$ is the second gradient of $\psi(\mathbf{m})$ on the surface of the unit ball.

We solve the problem (in $\mathbb{R}^2$ and $\mathbb{R}^3$) of radially symmetric crystallization of an isotropic crystal in an infinite melt. If the phase interface is initially at rest, then:

(i) For $F\geqq 0$ the crystal melts completely in finite time.

(ii) For $F<0$ there is a *critical radius* $R_{\text{crit}}:=(n-1)\psi/|F|$ (in $\mathbb{R}^n$) such that a crystal of radius $R(0)<R_{\text{crit}}$ melts in finite time, a crystal of radius $R(0)>R_{\text{crit}}$ grows unboundedly as $t\to\infty$.

An analogous problem is discussed in [G4] for the CM model in $\mathbb{R}^3$. The results are qualitatively the same as those described in (i) and (ii). In fact, if we identify F with the constant $\Psi_c+P-\zeta(\Psi+P)$ of the CM model, where Ψ_c and Ψ are the crystal and melt energies, ζ is the ratio of crystal density to melt density, and P is the far-field pressure in the melt, then the critical radii of the two theories coincide. As would be expected, the two theories exhibit quantitative differences: for example, during unbounded growth the radius grows asymptotically as t^2 within the present theory and as t within the CM model.

Although the CM model does exhibit oscillatory behavior, it is not clear whether or not shocks and other propagating discontinuities are possible.[8] To the contrary, such phenomena are generated within the present theory. We study the propagation of fronts across which the curvature is discontinuous. We show that, in the presence of anisotropy, fronts whose amplitude is sufficiently large and of the right sign grow to infinity in finite time, strongly suggesting that the interface develops a corner. Guided by other theories[9] of hyperbolic behavior, this result seems to indicate that there is global existence of classical solutions of (1.2) for initial data that are both sufficiently small and sufficiently smooth, but that smooth solutions corresponding to large data develop singularities in finite time.

2. Crystals. We consider an *infinite* **crystal lattice** modeled as a two-dimensional continuum, in fact as $\mathbb{R}^2$. A **crystal** $\mathscr{C}$ is then a compact subset of the lattice with boundary $\partial\mathscr{C}$, a smooth, simple closed curve. $\partial\mathscr{C}$ represents the **interface** between the crystal and its **melt**; we write $\mathbf{m}(\mathbf{x})$ for the outward unit normal to $\partial\mathscr{C}$ and define a unit tangent $\boldsymbol{\ell}(\mathbf{x})$ so that $\{\boldsymbol{\ell}(\mathbf{x}),\mathbf{m}(\mathbf{x})\}$ is a positively oriented basis of $\mathbb{R}^2$ (cf. Fig. 1). We let ds denote the element of arclength on $\partial\mathscr{C}$ and write f_s for the derivative, sometimes partial, of f with respect to arclength on $\partial\mathscr{C}$. (Our convention is that arclength increase in the direction of $\boldsymbol{\ell}$.) We then have the Frenet formulas

$$\mathbf{m}_s=-\kappa\boldsymbol{\ell},\qquad \boldsymbol{\ell}_s=\kappa\mathbf{m} \tag{2.1}$$

with $\kappa(\mathbf{x})$ the **curvature** of $\partial\mathscr{C}$. We define the **angle** $\theta(\mathbf{x})$, as a smooth function of $\mathbf{x}$, through

$$\mathbf{m}=(\cos\theta,\sin\theta),\qquad \boldsymbol{\ell}=(\sin\theta,-\cos\theta). \tag{2.2}$$

Our goal is to model situations in which crystals grow or shrink by processes such as solidification and melting. We therefore consider crystals $\mathscr{C}(t)$ that evolve with time

[8] Rogers [R] shows that such phenomena are not possible within the *linearized* CM theory.

[9] See, e.g., Renardy, Hrusa, and Nohel [RHN].

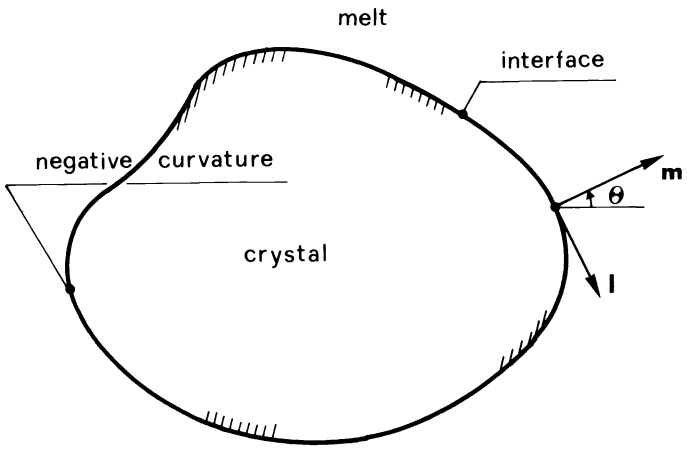

FIG. 1. *Sign conventions for interfacial motions.*

t, under the assumption that $\partial\mathscr{C}(t)$ is a smooth evolving curve (in the sense of [AG]). We write $v(\mathbf{x}, t)$ for the **normal velocity** of $\partial\mathscr{C}(t)$ in the direction $\mathbf{m}(\mathbf{x}, t)$, so that

$$\mathbf{v}(\mathbf{x}, t) = v(\mathbf{x}, t)\mathbf{m}(\mathbf{x}, t) \tag{2.3}$$

represents the **velocity** of $\partial\mathscr{C}(t)$. Fix t and $\mathbf{x} \in \partial\mathscr{C}(t)$ and (for τ sufficiently close to t) let $\mathbf{y}(\tau)$ denote the curve that passes through $\mathbf{x}$ at time t and has

$$\mathbf{y}^{\cdot}(\tau) = \mathbf{v}(\mathbf{y}(\tau), \tau)$$

($\mathbf{y}^{\cdot}(\tau) = d\mathbf{y}(\tau)/d\tau$; we use this notation for functions of time alone). Then the **normal time-derivative** $\Phi^{\circ}(\mathbf{x}, t)$ (following $\partial\mathscr{C}(t)$) of a scalar or vector function $\Phi(\mathbf{x}, t)$ is defined by

$$\Phi^{\circ}(\mathbf{x}, t) = \frac{d}{d\tau}\Phi(\mathbf{y}(\tau), \tau)|_{\tau=t}. \tag{2.4}$$

The identities

$$\begin{aligned} &\theta^{\circ} = \boldsymbol{\ell}^{\circ} \cdot \mathbf{m} = -\mathbf{m}^{\circ} \cdot \boldsymbol{\ell} = v_s, \\ &\boldsymbol{\ell}^{\circ} = \mathbf{m}\theta^{\circ} = \mathbf{v}_s + \kappa v \boldsymbol{\ell} \end{aligned} \tag{2.5}$$

are standard.[10]

By an **interfacial chunk** we mean a smoothly evolving curve $\sigma(t)$ with $\sigma(t) \subset \partial\mathscr{C}(t)$ at each time t; we say that $\sigma(t)$ *evolves normally* if its endpoints $\mathbf{x}_1(t)$ and $\mathbf{x}_2(t)$ evolve with the normal velocity of the interface:

$$\mathbf{x}_1^{\cdot}(t) = \mathbf{v}(\mathbf{x}_1(t), t), \qquad \mathbf{x}_2^{\cdot}(t) = \mathbf{v}(\mathbf{x}_2(t), t). \tag{2.6}$$

For any function $\Phi(\mathbf{x}, t)$ we write

$$\int_{\partial\sigma(t)} \Phi = \Phi(\mathbf{x}_2(t), t) - \Phi(\mathbf{x}_1(t), t). \tag{2.7}$$

[10] See, e.g., [AG, eqs. (2.4), (2.6), (2.18)].

We then have the identities[11]

$$\int_{\partial\sigma(t)} \Phi = \int_{\sigma(t)} \Phi_s \, ds,$$

$$\frac{d}{dt}\int_{\sigma(t)} \Phi \, ds = \int_{\sigma(t)} (\Phi^\circ - \Phi\kappa v) \, ds. \tag{2.8}$$

For convenience, we will generally omit the argument t when writing such integrals.

3. Interfacial forces. Inertia. Balance laws.

3.1. Basic concepts. We describe the **micromechanics** of an evolving crystal $\mathscr{C}(t)$ by four functions of $\mathbf{x} \in \partial\mathscr{C}(t)$ and t:

$\mathbf{C}(\mathbf{x}, t)$ **interfacial stress,**
$\mathbf{b}(\mathbf{x}, t)$ **interaction force,**
$\rho(\mathbf{x}, t)$ (effective) **inertial density,**
$r(\mathbf{x}, t)$ **mass supply.**

$\mathbf{C}(\mathbf{x}, t)$ represents the force *within the interface* exerted across $\mathbf{x}$ at time t; if we let σ^+ and σ^-, respectively, denote right and left neighborhoods of $\mathbf{x}$ in $\partial\mathscr{C}(t)$, then $\mathbf{C}(\mathbf{x}, t)$ is the force exerted *on* σ^- *by* σ^+. Concerning the remaining functions, $\mathbf{b}(\mathbf{x}, t)$ represents the net force exerted on the interface by the bulk material of the crystal and the melt; $\rho(\mathbf{x}, t)$ gives the inertial density of the interface; $r(\mathbf{x}, t)$ represents the *rate* at which mass is supplied to the interface.

We characterize forces by the manner in which they expend power, and inertia by the manner in which it affects kinetic energy. In particular, we assume that $\mathbf{C}(\mathbf{x}, t)$ and $\mathbf{b}(\mathbf{x}, t)$ expend power through the velocity[12] $\mathbf{v}(\mathbf{x}, t)$, and that it is this velocity that is appropriate to the kinetic energy of the interface. Precisely, given any normally evolving interfacial chunk $\sigma(t)$,

$$\frac{1}{2}\int_\sigma \rho|\mathbf{v}|^2 \, ds \tag{3.1}$$

is the **kinetic energy** of $\sigma(t)$,

$$\frac{1}{2}\int_\sigma r|\mathbf{v}|^2 \, ds \tag{3.2}$$

is the **rate at which kinetic energy is supplied** to $\sigma(t)$, and

$$\int_{\partial\sigma} \mathbf{C}\cdot\mathbf{v} + \int_\sigma \mathbf{b}\cdot\mathbf{v} \, ds \tag{3.3}$$

is the **power expended** on $\sigma(t)$. We will refer to

$$\mathscr{E}(\sigma)(t) = \frac{d}{dt}\left\{\frac{1}{2}\int_\sigma \rho|\mathbf{v}|^2 \, ds\right\} - \frac{1}{2}\int_\sigma r|\mathbf{v}|^2 \, ds - \int_{\partial\sigma} \mathbf{C}\cdot\mathbf{v} - \int_\sigma \mathbf{b}\cdot\mathbf{v} \, ds \tag{3.4}$$

as the **mechanical energy production** at time t. The first law of thermodynamics requires that this quantity be balanced by the addition of heat and by changes in the internal energy.

[11] Identities $(2.8)_2$ are generally not true if the chunk does *not* evolve normally: an additional term is needed to account for the flux of Φ across $\partial\sigma(t)$ (cf., e.g., [AG, eq. (2.34)]).

[12] See [G1, eq. (1.3) and § 3].

3.2. Invariance under observer changes. Balance laws for interfacial mass and momentum. A basic assumption of our theory is that

> The mechanical energy production be invariant
> under Galilean changes in observer;

precisely, we assume that, given any normally evolving interfacial chunk $\mathcal{S}(t)$ and any time t,

$$\begin{aligned}\frac{d}{dt}\left\{\frac{1}{2}\int_{\mathcal{S}}\rho|\mathbf{v}+\mathbf{c}|^2\,ds\right\}-\frac{1}{2}\int_{\mathcal{S}}r|\mathbf{v}+\mathbf{c}|^2\,ds-\int_{\partial\mathcal{S}}\mathbf{C}\cdot(\mathbf{v}+\mathbf{c})-\int_{\mathcal{S}}\mathbf{b}\cdot(\mathbf{v}+\mathbf{c})\,ds\\ =\frac{d}{dt}\left\{\frac{1}{2}\int_{\mathcal{S}}\rho|\mathbf{v}|^2\,ds\right\}-\frac{1}{2}\int_{\mathcal{S}}r|\mathbf{v}|^2\,ds-\int_{\partial\mathcal{S}}\mathbf{C}\cdot\mathbf{v}-\int_{\mathcal{S}}\mathbf{b}\cdot\mathbf{v}\,ds\end{aligned}\tag{3.5}$$

for any constant vector $\mathbf{c}$. Here $\mathbf{c}$ is the velocity defining an arbitrary observer change, and underlying (3.5) is the tacit assumption that ρ, $\mathbf{C}$, r, and $\mathbf{b}$ be invariant, while $\mathbf{v}$ transform to $\mathbf{v}+\mathbf{c}$.

If we expand the left side of (3.5) in terms of $\mathbf{c}$, we find that

$$\mathbf{c}\cdot\left\{\frac{d}{dt}\int_{\mathcal{S}}\rho\mathbf{v}\,ds-\int_{\mathcal{S}}r\mathbf{v}\,ds-\int_{\partial\mathcal{S}}\mathbf{C}-\int_{\mathcal{S}}\mathbf{b}\,ds\right\}+\frac{1}{2}|\mathbf{c}|^2\left\{\frac{d}{dt}\int_{\mathcal{S}}\rho\,ds-\int_{\mathcal{S}}r\,ds\right\}=0;\tag{3.6}$$

since $\mathbf{c}$ is *arbitrary*, this yields **balance of mass**

$$\frac{d}{dt}\int_{\mathcal{S}}\rho\,ds=\int_{\mathcal{S}}r\,ds\tag{3.7}$$

and **balance of momentum**

$$\frac{d}{dt}\left\{\int_{\mathcal{S}}\rho\mathbf{v}\,ds\right\}-\int_{\mathcal{S}}r\mathbf{v}\,ds=\int_{\partial\mathcal{S}}\mathbf{C}+\int_{\mathcal{S}}\mathbf{b}\,ds.\tag{3.8}$$

The relations (3.7) and (3.8) are required to hold for every normally evolving interfacial chunk $\mathcal{S}(t)$; using (2.8), we have the **local balance laws:**

$$\begin{aligned}\rho^{\circ}-\rho\kappa v&=r,\\ \rho\mathbf{v}^{\circ}&=\mathbf{C}_s+\mathbf{b}.\end{aligned}\tag{3.9}$$

We have taken the normal velocity as the kinematic variable that characterizes the manner in which power is expended: tangential motion does not expend power. As is consistent with a "constraint" of this type, *we leave as indeterminate the tangential component of the interaction* $\mathbf{b}$, *and therefore concern ourselves only with the normal component of the momentum balance law* $(3.9)_2$.

Using the local balance laws (3.9) in conjunction with (2.8), we can write the mechanical energy production (3.4) in the simple form

$$\mathscr{E}(\mathcal{S})(t)=-\int_{\mathcal{S}}\mathbf{C}\cdot\mathbf{v}_s\,ds.\tag{3.10}$$

For convenience, we decompose the interfacial stress into normal and tangential components:

$$\mathbf{C}=\sigma\boldsymbol{\ell}+\xi\mathbf{m}\tag{3.11}$$

with $\sigma(\mathbf{x}, t)$ the **surface tension** (line tension) and $\xi(\mathbf{x}, t)$ the **surface shear**. Then, writing

$$b=\mathbf{b}\cdot\mathbf{m}\tag{3.12}$$

for the **normal interaction**, the normal component of $(3.9)_1$ becomes

$$\rho v^\circ = \xi_s + \sigma\kappa + b. \tag{3.13}$$

4. Constitutive equations. To state the constitutive equations that form the basis of our theory, we associate, with each evolving crystal, an **interfacial energy** ψ. As **constitutive equations** we allow the interfacial energy, the interfacial stress, the inertial density, and the normal interaction to depend on the orientation of the interface through a dependence on the angle θ, and we allow the kinetics of the interface to affect the normal interaction through a dependence on the normal velocity[13] v:

$$\psi = \psi(\theta), \quad \mathbf{C} = \mathbf{C}(\theta), \quad \rho = \rho(\theta), \quad b = b(\theta, v). \tag{4.1}$$

We assume that:[14]

(i) $\psi(\theta)$ generates the interfacial stress through the thermodynamic relation[15]

$$\mathbf{C}(\theta) = \psi(\theta)\boldsymbol{\ell}(\theta) + \psi'(\theta)\mathbf{m}(\theta); \tag{4.2}$$

(ii) The normal interaction is given by a relation of the form

$$b(\theta, v) = -F - \beta(\theta)v, \tag{4.3}$$

with F a constant;

(iii) The following inequalities hold:

$$\rho(\theta), \psi(\theta), \beta(\theta) > 0. \tag{4.4}$$

Trivially, (4.2) implies that $\sigma = \sigma(\theta)$ and $\xi = \xi(\theta)$ with

$$\sigma(\theta) = \psi(\theta), \qquad \xi(\theta) = \psi'(\theta). \tag{4.5}$$

Concerning (4.3), the constant F represents a **driving force** for the crystallization process, while $-\beta(\theta)v$ represents a "drag force" which, by $(4.4)_3$, opposes interfacial motion.[16]

A consequence of (3.9) and the constitutive relations (4.2) and (4.3) is the *balance law for energy*:[17]

$$\frac{d}{dt}\left\{\int_{\partial\mathscr{C}}\left(\frac{1}{2}\rho|\mathbf{v}|^2 + \psi\right) ds + F \text{ area } (\mathscr{C})\right\} = \frac{1}{2}\int_{\partial\mathscr{C}} r|\mathbf{v}|^2\, ds - \int_{\partial\mathscr{C}} \beta v^2\, ds, \tag{4.6}$$

with $\partial\mathscr{C} = \partial\mathscr{C}(t)$. This result allows us to identify the last term as energy dissipated during crystal growth. The derivation of (4.6) is not difficult. First of all we have the standard relation

$$\frac{d}{dt}\text{area } (\mathscr{C}) = \int_{\partial\mathscr{C}} v\, ds, \tag{4.7}$$

as well as the following consequences of (2.5), (4.2), and (4.3):

$$\begin{aligned} &\mathbf{C}\cdot\mathbf{v}_s = \psi'(\theta)\theta^\circ - \psi(\theta)v\kappa = \psi(\theta)^\circ - \psi(\theta)v\kappa, \\ &bv = -Fv + \beta(\theta)v^2. \end{aligned} \tag{4.8}$$

---

[13] Here v represents the normal velocity of the interface relative to the crystal, so that v is trivially invariant under observer changes.

[14] See [G1] and [AG], where (4.2) and (4.3) (with $\beta = \beta(\theta, v) \geqq 0$) are derived using a thermodynamic argument.

[15] $\psi'(\theta) = d\psi(\theta)/d\theta$.

[16] See [G1, Remark 4.1].

[17] Generalizing (7.6) of [AG]. The integral involving ψ over $\partial\mathscr{C}$ plus F area $(\mathscr{C})$ represents a basic Gibbsian functional for the statical theory of crystals (cf. [G2, § 3.2]).

The relation (4.6) follows from (3.4) and (3.10) with $\mathscr{s} = \partial\mathscr{C}$ (so that $\partial\mathscr{s} = \varnothing$) in conjunction with (2.3), (3.12), (4.7), and (4.8).

5. Partial differential equations. The equations of our theory are balance of mass $(3.9)_1$ and the normal component (3.13) of balance of momentum in conjunction with the constitutive relations (4.2) and (4.3). Balance of mass $(3.9)_1$ coupled with $(2.5)_1$ yield

$$\rho'(\theta)v_s - \rho(\theta)\kappa v = r. \tag{5.1}$$

The melt serves only as a source of atoms for the evolving crystal,[18] so we may regard (5.1) as defining r. On the other hand, (3.13), by virtue of $(2.5)_3$, (4.3), and (4.4), yields the **evolution equation**

$$\rho(\theta)v^\circ + \beta(\theta)v = [\psi(\theta) + \psi''(\theta)]\kappa - F, \tag{5.2}$$

which forms the basis of our theory. Note that, for an *isotropic interface*, ψ, β, and ρ are constants and (5.2) reduces to

$$\rho^\circ + \beta v = \psi\kappa - F. \tag{5.3}$$

When the crystallization process takes place in $\mathbb{R}^3$, the interface evolves as a *surface*, rather than as a curve, but apart from notation the theory is identical. Following the notation and terminology of [G1], we write ∇_{surf} for the *surface gradient*, $\mathbf{L} = -\nabla_{\text{surf}}\mathbf{m}$ for the *curvature tensor*, and $\kappa = \operatorname{tr}\mathbf{L}$ for twice the *mean curvature*. Then the only essential changes regarding the theory presented thus far are the replacement of $\psi(\theta)$ by $\psi(\mathbf{m})$, $\beta(\theta)$ by $\beta(\mathbf{m})$, $\rho(\theta)$ by $\rho(\mathbf{m})$, and (5.2) by

$$\rho(\mathbf{m})v^\circ + \beta(\mathbf{m})v = \psi(\mathbf{m})\kappa + \psi_{mm}(\mathbf{m}) \cdot \mathbf{L} - F, \tag{5.4}$$

where $\psi_{mm}(\mathbf{m})$ is the second gradient of $\psi(\mathbf{m})$ on the surface of the unit ball.

Consider now the general theory in $\mathbb{R}^2$ as defined by (5.2). *Locally*, the interface may be represented as the graph of a function $y = h(x, t)$, provided the x and y axes are chosen appropriately. Consider the choice indicated in Fig. 2 (with orientation such that arclength increase with increasing x) and let

$$p = h_x, \tag{5.5}$$

where a subscript denotes partial differentiation with respect to the corresponding variable. Then

$$p \tan\theta = -1 \tag{5.6}$$

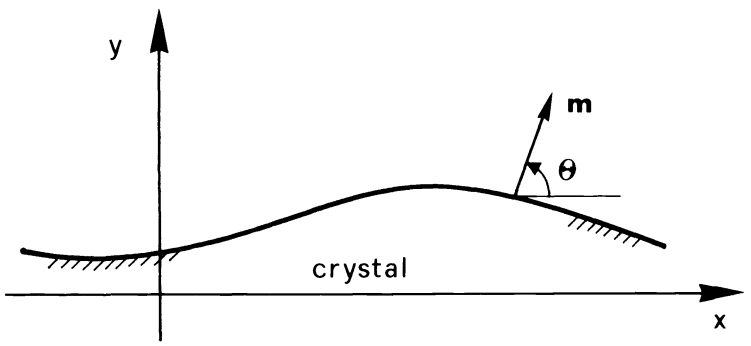

FIG. 2. *Sign conventions when the interface is a graph* $y = h(x, t)$.

[18] Reference [G4] considers a more detailed structure for the melt.

and, considering v as a function $v(x, t)$,

$$v = h_t \sin\theta, \qquad \kappa = h_{xx} \sin^3\theta, \tag{5.7}$$

$$v^\circ = v_t + v_x v \cos\theta = \sin\theta[h_{tt} + 2\sin\theta\cos\theta h_t h_{tx} + (h_t \sin\theta\cos\theta)^2 h_{xx}].$$

Thus, defining

$$B(\theta) = \beta(\theta)/\rho(\theta), \qquad G(\theta) = [\psi(\theta) + \psi''(\theta)]/\rho(\theta), \tag{5.8}$$
$$D(\theta) = F/[\rho(\theta)\sin\theta],$$

the evolution equation (5.2) takes the form

$$h_{tt} + B(\theta)h_t + 2\sin\theta\cos\theta h_t h_{tx} = \sin^2\theta[G(\theta) - (h_t\cos\theta)^2]h_{xx} - D(\theta), \tag{5.9}$$

with θ a function of h_x through (5.5) and (5.6).

Equation (5.9) is hyperbolic if and only if the discriminant Δ of the coefficients of its principal part is strictly positive. Since $\Delta = 4\sin^2\theta G(\theta)$, it is clear from (4.4) that (5.9) *is hyperbolic if and only if*

$$\psi(\theta) + \psi''(\theta) > 0. \tag{5.10}$$

We will assume that (5.10) *is satisfied for all angles of interest.*

Remark. The inequality (5.10) is essentially a condition of static stability for the interface: it follows from the requirement that straight line-segments locally minimize interfacial energy.[19] When the inequality (5.10) is reversed the partial differential equation (5.9) is elliptic and yields unstable behavior for standard initial value problems. There is no compelling physical reason to suppose that (5.10) is satisfied; in fact, material scientists often consider energies which violate (5.10) for particular ranges of θ (cf. Gjostein [G], Cahn and Hoffman [CH]). Since $\psi(\theta) > 0$ and is periodic, at worst we can have an equation which is elliptic for some but not all values of θ. Such elliptic intervals can be treated by introducing corners in the evolving crystal (cf. [AG]).

6. Some simple solutions.

6.1. Radial solutions for an isotropic crystal. In view of (5.3) and (5.4), isotropic, radially symmetric crystals in $\mathbb{R}^n$ $(n = 2, 3)$ evolve according to

$$\rho R^{\cdot\cdot}(t) + \beta R^{\cdot}(t) + (n-1)\psi R(t)^{-1} = -F, \tag{6.1}$$

with $R(t)$, the radius of the interface. Assuming that $R^{\cdot}(0) = 0$ and appealing to the phase portrait for (6.1), it is not difficult to verify that:

(i) For $F \geqq 0$, crystals melt completely in finite time;

(ii) For $F < 0$, crystals of radius $R(0) < R_{\text{crit}} := (n-1)\psi/|F|$ melt in finite time, while crystals of radius $R(0) > R_{\text{crit}}$ grow unboundedly as $t \to \infty$.

These conclusions are true whether or not $\rho = 0$ (provided we drop the initial condition $R^{\cdot}(0) = 0$ for $\rho = 0$). Furthermore, for $F < 0$ and $R(0) > R_{\text{crit}}$, $R(t)$ grows (for large t) as t when $\rho = 0$ and as t^2 when $\rho \neq 0$.

6.2. Small oscillations about a flat interface. Assume that

$$F = 0. \tag{6.2}$$

Then flat interfaces ($\kappa = 0$) describe equilibrium solutions of the general anisotropic equation (5.2). We now consider *interfacial motions which are close to equilibria of this*

[19] See Herring [H], Frank [Fr], Gjostein [G], Gruber (as referred to in [G]), Taylor [T], Fonseca [F], and Angenent and Gurtin [AG].

form. Precisely, we assume, without loss of generality, that the interface has angle $\theta = \pi/2$ at equilibrium and consider interfacial motions represented as a graph $y = h(x, t)$ with h and its derivatives "small." In view of (5.6), the angle $\theta(x, t)$, to first order in h, is given by

$$\theta = (\pi/2) + h_x. \tag{6.3}$$

Therefore (5.9) *linearized about this equilibrium* has the form

$$h_{tt} + B_0 h_t = G_0 h_{xx}, \tag{6.4}$$

where the subscript zero signifies that the corresponding quantity is to be evaluated at $\theta = \pi/2$. Equation (6.4) has the solution

$$\begin{aligned} &h(x, t) = C\, e^{i\lambda x}\, e^{-(i\omega+\zeta)t}, \\ &\omega^2 = G_0\lambda^2 - \zeta^2, \qquad \zeta = B_0/2, \end{aligned} \tag{6.5}$$

which represents *damped oscillations* of the interface.

6.3. Curvature waves advancing on a flat interface. In continuum mechanics the breakdown of solutions due to the formation of shocks (jumps in velocity) can be discussed qualitatively in terms of the blowup of waves involving jumps in acceleration.[20] An analogous discussion applies here with corners (jumps in angle) playing the role of shocks and curvature the role of acceleration.

We continue to assume that $F = 0$. We consider a front of discontinuous curvature advancing into a flat interface (with $\theta = \pi/2$). Precisely, we consider an interface described by a graph $y = h(x, t)$ and assume that there is a curve $\mathscr{K}$ in the (x, t)-plane which has the form $x = \xi(t)$ and is such that:

(W1) $h(x, t) = 0$ for $x \geqq \xi(t)$;

(W2) h and its first derivatives are continuous across $\mathscr{K}$, but second and higher derivatives of h suffer possible jump discontinuities across $\mathscr{K}$;

(W3) $[\kappa] \neq 0$.

Here and in what follows, $[g](t)$ denotes the **jump** in a function $g(x, t)$ across $\mathscr{K}$:

$$[g](t) = g(\xi(t)+0, t) - g(\xi(t)-0, t). \tag{6.6}$$

Because of (W3), we will refer to $\mathscr{K}$ as a **curvature wave**.

Standard kinematical conditions[21] give

$$[h_{tt}] = -c[h_{xt}] = c^2[h_{xx}], \tag{6.7}$$

where

$$c = \frac{d\xi}{dt} \tag{6.8}$$

is the **velocity of propagation**. Furthermore, by (W1) and (W2),

$$\theta = \pi/2 \quad \text{and} \quad h_t = h_x = 0 \quad \text{on } \mathscr{K}; \tag{6.9}$$

hence (5.6) and (5.7) yield

$$[\theta_t] = [h_{xt}], \qquad [\kappa] = [h_{xx}]. \tag{6.10}$$

[20] See, e.g., § 2 of [CG] for a discussion of such waves.

[21] See, e.g., [CG, eq. (2.5)].

As before, we write ϕ_0 for a function $\phi(\theta)$ evaluated at $\theta = \pi/2$. The jump in (5.9) across $\mathcal{K}$ then yields

$$c^2 = G_0 = (\psi + \psi'')_0/\rho_0, \tag{6.11}$$

and the *velocity of propagation is constant.*

We define the **amplitude** of the wave by

$$a = [\kappa] = [h_{xx}]; \tag{6.12}$$

a standard identity[22] then yields

$$2c^2 \frac{da}{dt} = [h_{ttt}] - c[h_{xxt}]. \tag{6.13}$$

Next, we differentiate (5.9) with respect to t and take the jump in the resulting equation; because of (6.9) and (6.10), this yields

$$[h_{ttt}] + B_0[h_{tt}] = G_0[h_{xxt}] + (G')_0[h_{xx}][h_{xt}]. \tag{6.14}$$

In deriving (6.14), we used the fact that, by (W1), $[h_{xx}\theta_t] = [h_{xx}][\theta_t]$. The relations (6.7) and (6.11)-(6.14) yield a nonlinear differential equation for the amplitude

$$\frac{2da}{dt} + B_0 a + \left[\frac{(G')_0}{c}\right] a^2 = 0. \tag{6.15}$$

For an isotropic crystal, $G(\theta)$ is independent of θ and $(G')_0 = 0$. In this case,

$$a(t) = a(0)\, e^{-B_0 t/2} \tag{6.16}$$

and curvature waves *decay.*

The results are far more interesting when the crystal is anisotropic. Assume that $(G')_0 \neq 0$. Then (6.15) has the explicit solution

$$a(t) = \frac{a(0)[1 - A]}{1 - A\, e^{B_0 t/2}}, \qquad A = 1 - \frac{\lambda}{a(0)}, \qquad \lambda = -\frac{B_0 c}{(G')_0}. \tag{6.17}$$

An elementary analysis of the solution (6.17) leads to the following conclusions:

(i) $a(0)/\lambda = 1$ implies $a(t) \equiv a(0)$;

(ii) $a(0)/\lambda < 1$ implies $a(t) \to 0$ monotonically as $t \to \infty$,

(iii) $a(0)/\lambda > 1$ implies $a(t) \to \infty$ in the finite time

$$t_\infty = -2(\ln A)/B_0. \tag{6.18}$$

The result (iii) asserts that if initially the jump in curvature is sufficiently large and of the right sign, then this jump becomes infinite in finite time, strongly suggesting that *the interface develops a corner*: $[\theta] \neq 0$. The number λ represents a *critical amplitude*: $a(t)$ grows without bound or decays to zero according as $a(0)/\lambda > 1$ or $a(0)/\lambda < 1$. This critical amplitude captures the competing effects of anisotropy and dissipation: anisotropy, measured by $(G')_0$, promotes blowup; dissipation, measured by B_0, promotes decay.

[22] See, e.g., [CG, eq. (2.10)].

BLOWUP ASYMPTOTICS FOR THE REACTIVE-EULER GAS MODEL*

ALBERTO BRESSAN†

Abstract. This paper is concerned with a semilinear hyperbolic system modeling the behavior of a reactive gas. Because of the presence of a nonlinear reaction term, solutions become unbounded within finite time; generically, the blowup occurs at a single point. As the explosion time is approached, a precise description of the asymptotic profile of a solution is obtained by the use of a rescaled set of coordinates. Relying on a topological argument, we prove that the rescaled solution has a nontrivial, nonsingular limit, whose analytical expression depends on a finite set of parameters, determined by the initial conditions.

Key words. reactive-Euler equations, blowup, asymptotic profile

AMS(MOS) subject classification. 35L40

1. Introduction.

A semilinear hyperbolic system of the form

$$\begin{cases} \vartheta_t - aP_t = be^{\vartheta} \\ v_t + cP_x = 0 \\ v_x + dP_t = be^{\vartheta} \end{cases} \tag{1.1}$$

was first derived in [4] and, independently, in [9] as a model for the behavior of a reactive gas where viscous and diffusive effects are sufficiently weak. See also [3], [11] for a unified treatment. Here the variables P, v, and ϑ denote the perturbations from a spatially uniform equilibrium state of pressure, velocity, and temperature, respectively, while a, b, c, d are positive constants. We first study the system (1.1) in the bounded domain $I = [-1, 1]$, with initial and boundary conditions

$$P(0,x) = \bar{P}(x), \quad v(0,x) = \bar{v}(x), \quad \vartheta(0,x) = \bar{\vartheta}(x), \tag{1.2}$$

$$v(t,1) = v(t,-1) = 0. \tag{1.3}$$

Here $\bar{P}, \bar{v}, \bar{\vartheta}$ are continuous functions on I, with $\bar{v}(1) = \bar{v}(-1) = 0$. The presence in (1.1) of a reaction term which grows exponentially with the temperature allows solutions to become unbounded within finite time. Our main concern is the location of the blowup and the description of the profile of a solution as the explosion time is approached. In §3 we prove that a generic solution of (1.1)–(1.3) blows up at a single point. In §4, assuming that the initial conditions are smooth and that the initial temperature has a sufficiently large and "well-focused" maximum (in a sense to be specified later), we determine the asymptotic profile of a solution close to the blowup point. A topological argument [8, p. 278] combined with standard comparison techniques shows that, in a suitable set of rescaled coordinates, the solution has a nontrivial nonsingular limit. This asymptotic limit depends on finitely many parameters, determined by the initial conditions. For a single parabolic equation, a similar rescaling of coordinates was studied in [7] and later in [2] for an exponential nonlinearity. The present paper supplies a rigorous proof to the formal computations

on the reactive-Euler model which appeared in [6], [10], relative to the case where the blowup occurs in the interior of the domain I. If the blowup point lies on the boundary of I, the variable rescaling and the consequent mathematical analysis will be different [10].

2. Preliminaries. The change of variables

$$\begin{cases} z_1 = \vartheta - aP \\ z_2 = \dfrac{a}{2}\,[P + (cd)^{-1/2} v] \\ z_3 = \dfrac{a}{2}\,[P - (cd)^{-1/2} v] \end{cases} \tag{2.1}$$

transforms (1.1), (1.3) into the system

$$\begin{cases} z_{1,t} = A\, e^{z_1+z_2+z_3} \\ z_{2,t} + \lambda z_{2,x} = B\, e^{z_1+z_2+z_3} \\ z_{3,t} - \lambda z_{3,x} = B\, e^{z_1+z_2+z_3} \end{cases} \tag{2.2}$$

with boundary conditions

$$z_2(t,1) = z_3(t,1), \qquad z_2(t,-1) = z_3(t,-1). \tag{2.3}$$

Here $A = b$, $B = ab/2d$, $\lambda = (c/d)^{1/2}$. Call $E \subset \mathcal{C}(I, \mathbb{R}^3)$ the Banach space of all continuous functions $z = (z_1, z_2, z_3)$ from $[-1,1]$ into $\mathbb{R}^3$ which satisfy

$$z_2(1) = z_3(1), \qquad z_2(-1) = z_3(-1),$$

with the usual norm

$$\| z \| = \max \{|z_i(x)|;\ |x| \leq 1,\ i = 1,2,3\}.$$

For a given set of initial conditions

$$z_i(0,x) = \bar{z}_i(x), \tag{2.4}$$

with $\bar{z} \in E$, it is well known [5], [12] that the system (2.2), (2.3) has a unique forward solution z defined on some maximal interval $[0,T)$. Using the semigroup notation, we write $S^t(\bar{z}) = z(t,\cdot) \in E$ for the value of this solution at time t. Observe that either $T = +\infty$ or $\| S^t(\bar{z}) \| \to \infty$ as $t \to T^-$. In this second case, we call $T = T(\bar{z})$ the blowup time for the initial conditions (2.4). A point $\bar{x} \in [-1,1]$ is a blowup point if there exist sequences $x_n \to \bar{x}$, $t_n \to T-$ such that $|z(t_n, x_n)| \to +\infty$. The set of blowup points, given the initial data $z(0,\cdot) = \bar{z}(x)$, is denoted by $\mathcal{B}\ell(\bar{z})$. On the space E, define the ordering

$$u \preceq v \quad \text{iff} \quad u_i(x) \leq v_i(x) \qquad \forall\, x \in I, \quad i = 1,2,3.$$

By a standard comparison theorem, if $u \preceq v$, then $S^t(u) \preceq S^t(v)$ for all $t \geq 0$ at which both are defined. In particular, $u \preceq v$ implies $T(u) \geq T(v)$.

In a metric space Y, $B(y,\delta)$ denotes the open ball centered at y with radius δ. We recall that a set-valued map F is upper semicontinuous [1, p. 66] if, for all $\bar{z}$ and $\varepsilon > 0$, there exists $\delta > 0$ such that

$$z \in B(\bar{z},\delta) \Longrightarrow F(z) \subseteq B(F(\bar{z}),\varepsilon).$$

Here $B(F(\bar{z}), \varepsilon)$ denotes the neighborhood of radius ε around the set $F(\bar{z})$. If Y is a complete metric space, a subset $R \subseteq Y$ is residual in Y (i.e., of second category) if and only if its complement $Y \setminus R$ lies in the union of countably many closed nowhere dense sets. A property $\mathcal{P}$ for the elements of Y is *generic* if it holds true for all y in a residual subset of Y. In the next section we prove that the property "$\mathcal{B}\ell(\bar{z})$ is a singleton" is generic in the space E. This is a mathematically precise way of expressing the fact that for "most" initial conditions $\bar{z} \in E$ the corresponding solution of (2.2) – (2.4) blows up at a single point. All of our results will be stated for the system (2.2), which is more tractable than (1.1). Performing the change of variables inverse of (2.1), analogous results for the original system (1.1) can be easily obtained.

3. Properties of the blowup set. As a preliminary, observe that for every initial condition $\bar{z} \in E$ the solution z of (2.2), (2.3) blows up in finite time. Indeed, following [3] define

$$c^+ = \max\{A, B\}, \qquad c^- = \min\{A, B\}, \tag{3.1}$$

$$\begin{aligned} m^+ &= \max\{\bar{z}_i(x); \quad x \in I, \quad i = 1,2,3\}, \\ m^- &= \min\{\bar{z}_i(x); \quad x \in I, \quad i = 1,2,3\}. \end{aligned} \tag{3.2}$$

Comparing the components of z with the solutions of the scalar Cauchy problems

$$y' = c^{\pm} e^{3y}, \qquad y(0) = m^{\pm} \tag{3.3}$$

we deduce

$$-\tfrac{1}{3}\ln[e^{-3m^-} - 3c^- t] \le z_i(t,x) \le -\tfrac{1}{3}\ln[e^{-3m^+} - 3c^+ t] \tag{3.4}$$

for $t > 0$, $x \in I$, $i = 1,2,3$. Hence the solution z blows up at some time $T = T(\bar{z})$ with

$$(3c^+ e^{3m^+})^{-1} \le T(\bar{z}) \le (3c^- e^{3m^-})^{-1}. \tag{3.5}$$

Observe, however, that all solutions can be extended backwards for all times $t \in (-\infty, 0]$. Indeed, another simple comparison argument yields

$$m^- + c^+ e^{3m^+} t \le z_i(t,x) \le m^+ \qquad \forall\, t \le 0.$$

In this section we study the dependence of the blowup time and of the blowup set on the initial data and prove that, generically, solutions blow up at a single point.

PROPOSITION 3.1. *The map $\bar{z} \to T(\bar{z})$ is continuous on E.*

Proof. Fix $\bar{z} \in E$. If $\tau < T(\bar{z})$, then $\| S^\tau(\bar{z}) \| < \infty$ and $S^{-\tau}$ provides a homeomorphism of a bounded neighborhood V of $S^\tau(\bar{z})$ onto a neighborhood U of $\bar{z}$. This implies $T(\bar{u}) > \tau$ for all $\bar{u} \in U$, hence

$$\liminf_{\bar{u} \to \bar{z}} T(\bar{u}) \ge T(\bar{z}). \tag{3.6}$$

To prove the converse inequality, fix $\varepsilon > 0$ and call $z = z(t,x), v = v(t,x)$ the solutions of (2.2), (2.3) with initial conditions $\bar{z}, \bar{v}$, respectively. For all t, x we have

$$v_i(t,x) \ge \min\{\bar{v}_i(x); \quad |x| \le 1, \ i = 1,2,3\}. \tag{3.7}$$

Define m^- as in (3.2) and choose $\tau < T(\bar z)$ and K large enough so that

$$e^{1-K}\, e^{2-2m^-} < \varepsilon c^-, \tag{3.8}$$

$$\max\{z_i(\tau, x); \quad |x| \leq 1,\ i = 1,2,3\} > K. \tag{3.9}$$

As before, $S^{-\tau}$ provides a homeomorphism between a neighborhood V of $S^\tau(\bar z)$ and a neighborhood U of $\bar z$. By possibly shrinking U and V, it is not restrictive to assume that

$$\| \bar v - \bar z \| < 1, \qquad \| S^\tau(\bar v) - S^\tau(\bar z) \| < 1 \quad \forall\, \bar v \in U. \tag{3.10}$$

From (3.9), (3.10) we deduce

$$\max\{v_i(\tau, x); \quad |x| \leq 1,\ i = 1,2,3\} > K - 1 \qquad \forall\, \bar v \in U. \tag{3.11}$$

Assume that this maximum is $v_j(\tau, \bar x)$. Integrating the jth equation in (2.2) along the jth characteristic line through $(\tau, \bar x)$ and estimating the other components v_i, $i \neq j$ by $v_i(t,x) \geq m^- - 1$ we obtain

$$\frac{d}{dt}\, v_j(\tau + t, \bar x + \lambda_j t) \geq c^-\, e^{2m^- - 2 + v_j}. \tag{3.12}$$

Here $\lambda_1 = 0$, $\lambda_2 = \lambda$, $\lambda_3 = -\lambda$. If $j = 2,3$, the corresponding characteristic may hit the boundary of $[-1,1]$. In such cases, the estimate can be continued along the reflected characteristic, through the same boundary point. A comparison with the solution of the Cauchy problem

$$y' = c^-\, e^{2m^- - 2 + y}, \qquad y(0) = K - 1$$

yields the estimate

$$v_j(\tau + t,\ \bar x + \lambda_j t) \geq -\ln[e^{1-K} - c^-\, e^{2m^- - 2} t]. \tag{3.13}$$

By (3.13), (3.8), every solution v with initial data $\bar v \in U$ blows up within time $\tau + \varepsilon$. This implies

$$\limsup_{\bar v \to \bar z} T(\bar v) \leq T(\bar z),$$

completing the proof.

PROPOSITION 3.2. *The map $\bar z \to \mathcal{B}\ell(\bar z)$ is upper semicontinuous, compact valued, from E into $[-1,1]$.*

Proof. It is clear that each set $\mathcal{B}\ell(\bar z)$ is closed, hence compact. The upper semicontinuity of the map $\mathcal{B}\ell$ will be established by proving that for each $\bar z \in E$ and each $\bar x \notin \mathcal{B}\ell(\bar z)$ there exists $\varepsilon > 0$ and a neighborhood U of $\bar z$ such that

$$[\bar x - \varepsilon, \bar x + \varepsilon] \cap \mathcal{B}\ell(\bar v) = \phi \qquad \forall\, \bar v \in U. \tag{3.14}$$

Let $\bar z, \bar x$ be given. Since $\bar x \notin \mathcal{B}\ell(\bar z)$, there exists $\delta > 0$ and L such that the solution $z = z(t,x)$ of (2.2) – (2.4) satisfies

$$z_i(t,x) < L - 1 \qquad \forall\, i = 1,2,3, \quad |x - \bar x| \leq \delta, \quad 0 \leq t < T(\bar z). \tag{3.15}$$

Set $\varepsilon = \min\{e^{-3L}/7c^+, \delta/3\lambda\}$, with c^+ as in (3.1), and define $\tau = T(\bar z) - \varepsilon$. Then $S^{-\tau}$ provides a homeomorphism from a neighborhood V of $S^\tau(\bar z)$ onto a neighborhood U of $\bar z$. By possibly shrinking U and V, in view of (3.15) and of Proposition 3.1, we can assume that

$$v_i(\tau, x) < L \qquad \forall\, i = 1,2,3, \quad |x - \bar x| \le \delta, \tag{3.16}$$

for all solutions v with initial conditions $\bar v \in U$, and that

$$T(\bar v) < T(\bar z) + \varepsilon \qquad \forall\, \bar v \in U. \tag{3.17}$$

Comparing the values of v_i with the solution of the Cauchy problem

$$y' = c^+ e^{3y}, \qquad y(\tau) = L \tag{3.18}$$

from (3.16) it follows that

$$v_i(t,x) \le -\tfrac{1}{3} \ln(3c^+(\tau - t) + e^{-3L}) \tag{3.19}$$

for $t \in [\tau, T(\bar v)]$, $|x - \bar x| \le \delta - \lambda(t - \tau)$. Since $T(\bar v) < \tau + 2\varepsilon$, (3.19) and the choice of ε imply that, for every initial condition $\bar v \in U$, the corresponding blowup set does not contain the interval $[\bar x - \varepsilon, \bar x + \varepsilon]$.

THEOREM 3.3. *The set E^* of all $\bar z \in E$ such that $\mathcal{B}\ell(\bar z)$ consists of a single point is residual in E.*

Proof. For every integer $m \ge 1$ define the set

$$A_m = \{\bar z \in E, \quad \operatorname{diam} \mathcal{B}\ell(\bar z) \ge m^{-1}\},$$

where $\operatorname{diam} V = \sup\{|x - y|;\ x, y \in V\}$ denotes the diameter of the set V. Clearly $E^* = E \setminus \bigcup_{m \ge 1} A_m$. It thus suffices to show that each A_m is closed and nowhere dense.

To see that A_m is closed, assume $v_n \in A_m$ for all $n \ge 1$, $v_n \to u$. Let $x_n, y_n \in \mathcal{B}\ell(v_n)$ with $|x_n - y_n| \ge m^{-1}$. Choosing a suitable subsequence, we can assume that $x_{n'} \to \bar x$, $y_{n'} \to \bar y$. By Proposition 3.2, $\bar x, \bar y \in \mathcal{B}\ell(u)$, hence $\operatorname{diam} \mathcal{B}\ell(u) \ge |\bar x - \bar y| \ge m^{-1}$ and $u \in A_m$.

It remains to prove that the complement A_m^c of A_m is everywhere dense. Fix $u \in E$ and let $\bar x \in \mathcal{B}\ell(u)$. Define $\varepsilon = 1/9m$, $\delta = \varepsilon/\lambda$. Let $\varphi : [-1,1] \to [0,1]$ be a continuous function such that $\varphi(x) = 1$ if $|x - \bar x| \le 2\varepsilon$, $\varphi(x) = 0$ if $|x - \bar x| \ge 3\varepsilon$. For each $n \ge 1$ define the functions $v_n = (v_{n1}, v_{n2}, v_{n3})$ and $\bar w_n$ by setting

$$v_{ni}(x) = u_i(T(u) - \delta, x) + n^{-1}\varphi(x), \qquad \bar w_n = S^{-T(u)+\delta}(v_n).$$

Clearly $v_n \to S^{T(u)-\delta}(u)$ and $\bar w_n \to u$ as $n \to \infty$. We claim that $\bar w_n \notin A_m$ for every $n \ge 1$. Call $w_n(t,x)$ the solution of (2.2), (2.3) with initial conditions $\bar w_n(x)$. Then

$$w_n(T(u) - \delta, x) = v_n(x) > u(T(u) - \delta, x)$$

for each $n \ge 1$, $|x - \bar x| \le 3\varepsilon$. By the continuity of u with respect to time, there exists $\delta' \in (0, \delta)$ such that

$$w_{ni}(T(u) - \delta, x) \ge u_i(T(u) - \delta + \delta', x) \tag{3.20}$$

for $|x - \bar{x}| \leq 2\varepsilon$. From (3.20) we deduce

$$w_{ni}(t,x) \geq u_i(t+\delta', x) \tag{3.21}$$

whenever $t \geq T(u) - \delta$, $|x - \bar{x}| \leq 2\varepsilon - \lambda(t - T(u) + \delta)$.

Since $\bar{x}$ is a blowup point for u, (3.21) implies $T(\bar{w}_n) \leq T(u) - \delta'$. All blowup points of $\bar{w}_n$, however, are contained inside the set $\{x;\ |x - \bar{x}| \leq 4\varepsilon\}$, because $w_n(t,x) = u(t,x)$ whenever $|x - \bar{x}| > 3\varepsilon + \lambda(t - T(u) + \delta)$, $T(u) - \delta \leq t < T(\bar{w}_n)$. Hence $\operatorname{diam} \mathcal{B}\ell(\bar{w}_n) > m^{-1}$ and $\bar{w}_n \notin A_m$, for all $n \geq 1$.

4. Asymptotic estimates. The aim of this section is to describe the asymptotic profile of a solution of (2.2) as the blowup time is approached. Since what matters here is just the local behavior, for simplicity we neglect the boundary conditions (2.3) and work with the Banach space $\mathcal{C}^3(\mathbb{R}, \mathbb{R}^3)$ of functions $z = (z_1, z_2, z_3)$ which are three times continuously differentiable on $\mathbb{R}$. Furthermore, we assume $A + 2B = 1$. This condition is clearly not restrictive, because it can always be achieved by the time rescaling $t' = (A + 2B)t$.

THEOREM 4.1. *There exists a nonempty open set $U \subset \mathcal{C}^3(\mathbb{R}, \mathbb{R}^3)$ such that, if $\bar{z} \in U$, the corresponding solution z of (2.2) – (2.4) blows up at an isolated point x_0. Moreover, if $T = T(\bar{z})$ is the blowup time, there exist constants $\Omega < 0$ and z_i^∞ such that $z_1^\infty + z_2^\infty + z_3^\infty = 0$, with the following property. For every $\varepsilon > 0$ there exists $\delta > 0$ such that*

$$\begin{aligned} &\left|z_1(t,x) - z_1^\infty + A \ln\left[(T-t) - \tfrac{\Omega}{2}(x - x_0)^2\right]\right| < \varepsilon, \\ &\left|z_i(t,x) - z_i^\infty + B \ln\left[(T-t) - \tfrac{\Omega}{2}(x - x_0)^2\right]\right| < \varepsilon \end{aligned} \tag{4.1}$$

$(i = 2, 3)$, whenever $T - \delta \leq t < T$, $|x - x_0| < \delta$.

Further estimates can be easily deduced from (4.1). For example, the temperature $\vartheta = z_1 + z_2 + z_3$ satisfies

$$\lim_{t \to T^-} \left[\vartheta(t,x) + \ln\left((T-t) - \frac{\Omega}{2}(x - x_0)^2\right)\right] = 0$$

uniformly on every domain of the form $|x| \leq \psi(T - t)$, ψ being any continuous function with $\psi(0) = 0$. Moreover, for $x \neq x_0$ the limit values of $z_i(t,x)$ as $t \to T^-$ are well defined. In particular, the final temperature profile $\vartheta(T, \cdot)$ satisfies

$$\lim_{x \to x_0} \left[\vartheta(T,x) + 2\ln|x - x_0| + \ln(-\Omega/2)\right] = 0. \tag{4.2}$$

A more precise version of the above theorem will be actually proved, providing computable conditions on the initial data $\bar{z}$ which imply (4.1). As a preliminary, observe that, given any $\alpha, \beta, \gamma > 0$, we can always find $\tilde{\tau}$ large enough so that the following conditions hold.

(C1) $e^{\tilde{\tau}/6} > \max\{2\lambda,\ 12\beta\lambda/\alpha,\ 4\gamma\lambda,\ e^{1/2}\}$,

(C2) The solution (μ, m, M, D) of the Cauchy problem

$$\begin{cases} \dot{\mu} = -4me^{-\tau/6} - \mu/2 & \mu(\tilde{\tau}) = \gamma/2, \\ \dot{m} = 2me^{-\tau/3} & m(\tilde{\tau}) = -\beta/2, \\ \dot{M} = 8m^2 e^{-\tau/3} & M(\tilde{\tau}) = -2\alpha, \\ \dot{D} = 2\beta + 8\beta^2 e^{-\tau/3} - D & D(\tilde{\tau}) = 2\beta, \end{cases} \tag{4.3}$$

satisfies

$$\mu(\tau) < \gamma, \quad m(\tau) > -\beta, \quad M(\tau) < -\alpha, \quad D(\tau) < 3\beta \qquad \forall \tau \geq \tilde{\tau}. \tag{4.4}$$

THEOREM 4.2. *Let $\alpha, \beta, \gamma, \tilde{\tau}$ be constants for which the conditions* (C1), (C2) *hold. Let $\bar{z} = (\bar{z}_1, \bar{z}_3, \bar{z}_3)$ be a $\mathcal{C}^3$ function such that $\bar{\vartheta} = \bar{z}_1 + \bar{z}_2 + \bar{z}_3$ attains a local maximum $\hat{\vartheta} > \tilde{\tau} + 1$ at a point $\hat{x}$. In addition, assume that*

(i) $\max |(\bar{z}_i)_x| < (\gamma/2) e^{(\hat{\vartheta}-1)/2}$,

(ii) $\max |(\bar{z}_i)_{xx}| < 2\beta\, e^{\hat{\vartheta}-1}$,

(iii) $-e^{\hat{\vartheta}-1}\beta/2 < \sum_i \min (z_i)_{xx} \leq \sum_i \max (z_i)_{xx} < -2\alpha\, e^{\hat{\vartheta}+1}$,

the max *and* min *being all taken over the set $|x - \hat{x}| \leq 2e^{2(1-\hat{\vartheta})/3}$. Then the solution z of* (2.2), (2.4) *blows up at an isolated point x_0, at some time T, with*

$$|\hat{x} - x_0| \leq e^{2(1-\hat{\vartheta})/3}, \qquad e^{-1-\hat{\vartheta}} \leq T \leq e^{1-\hat{\vartheta}}.$$

Moreover, the estimates (4.1) *hold with $-\beta \leq \Omega \leq -\alpha$.*

We outline here the main arguments in the proof, while the details will be worked out in §§5 and 6. Since all solutions of (2.2) have components which remain uniformly bounded from below, the blowup occurs precisely when their sum $\vartheta = z_1 + z_2 + z_3$ becomes unbounded. If ϑ blows up at $t = T$, $x = x_0$, we expect that a nontrivial, nonsingular asymptotic limit can be obtained using the rescaled variables

$$\tau = -\ln(T - t), \qquad \eta = \frac{x - x_0}{\sqrt{T - t}}, \tag{4.5}$$

$$\begin{cases} u = z_1 + A \cdot \ln(T - t), \\ v = z_2 + B \cdot \ln(T - t), \\ w = z_3 + B \cdot \ln(T - t), \end{cases} \tag{4.6}$$

$$S = u + v + w = \vartheta + \ln(T - t). \tag{4.7}$$

In these new variables, (2.2) takes the form

$$\begin{cases} u_\tau + \dfrac{\eta}{2} u_\eta = A(e^S - 1) \\ v_\tau + \left(\dfrac{\eta}{2} + \lambda e^{-\tau/2}\right) v_\eta = B(e^S - 1) \\ w_\tau + \left(\dfrac{\eta}{2} - \lambda e^{-\tau/2}\right) w_\eta = B(e^S - 1), \end{cases} \tag{4.8}$$

$$S_\tau + \frac{\eta}{2} S_\eta + \lambda e^{-\tau/2}(v_\eta - w_\eta) = e^S - 1. \tag{4.9}$$

The new initial conditions, at $\tau_0 = -\ln T$ are

$$u(\tau_0, \eta) = \bar{u}(\eta) = \bar{z}_1(x_0 + \eta T^{1/2}), \quad v(\tau_0, \eta) = \bar{v}(\eta) = \bar{z}_2(x_0 + \eta T^{1/2}),$$

$$w(\tau_0, \eta) = \bar{w}(\eta) = \bar{z}_3(x_0 + \eta T^{1/2}). \tag{4.10}$$

We remark, however, that the exact values of T and x_0 are now known a priori. Instead, we know the point $\hat{x}$ where the maximum value $\hat{\vartheta}$ of $\vartheta = z_1 + z_2 + z_3$ is initially attained. Of course, we expect $x_0 \simeq \hat{x}$ and $T \simeq e^{-\hat{\vartheta}}$, but equality need not hold, in general. For this reason, we have to consider a two-parameter family of transformations depending on T, x_0. Define the set

$$\mathcal{G} = \{(T, x_0);\ e^{-1-\hat{\vartheta}} \leq T \leq e^{1-\hat{\vartheta}},\ |\hat{x} - x_0| \leq e^{2(1-\hat{\vartheta})/3}\}. \tag{4.11}$$

Elements of $\mathcal{G}$ will be our "guesses" for the exact time and location of the blowup. For each fixed $(T, x_0) \in \mathcal{G}$, call $\xi(\tau)$ the point at which the rescaled variable $S(\tau, \cdot)$ attains its maximum. Assuming that $S_{\eta\eta}$ is negative at ξ, from (4.9) and the relations

$$S_\eta(\tau, \xi(\tau)) \equiv 0, \quad S_{\eta\tau}(\tau, \xi(\tau)) + S_{\eta\eta}(\tau, \xi(\tau))\dot{\xi}(\tau) \equiv 0, \tag{4.12}$$

$$S_{\eta\tau} + \frac{\eta}{2} S_{\eta\eta} + \frac{1}{2} S_\eta + \lambda e^{-\tau/2}(v_{\eta\eta} - w_{\eta\eta}) = e^S S_\eta, \tag{4.13}$$

we obtain

$$\frac{d\xi}{d\tau} = -\frac{S_{\eta\tau}(\tau, \xi)}{S_{\eta\eta}(\tau, \xi)} = \frac{\xi(\tau)}{2} + \frac{\lambda}{S_{\eta\eta}} e^{-\tau/2}(v_{\eta\eta} - w_{\eta\eta}), \tag{4.14}$$

$$\frac{d}{d\tau} S(\tau, \xi(\tau)) = S_\tau + S_\eta \dot{\xi} = e^{S(\tau,\xi)} - 1 - \lambda e^{-\tau/2}(v_\eta(\tau, \xi) - w_n(\tau, \xi)). \tag{4.15}$$

The initial conditions for $\xi, S(\xi)$ are

$$\xi(\tau_0) = (\hat{x} - x_0)T^{-1/2}, \qquad S(\xi(\tau_0)) = \hat{\vartheta} + \ln T. \tag{4.16}$$

In $\mathbb{R}^3$, define the tube with shrinking square section

$$\mathcal{T} = \{(\tau, \xi, S); |\xi|, |S| \leq e^{-\tau/3}\}. \tag{4.17}$$

As (T, x_0) range in $\mathcal{G}$, (4.14) – (4.16) determine a two-parameter family of trajectories $\tau \to (\xi(\tau), S(\tau, \xi(\tau)))$ depending continuously on T, x_0. We will show that these trajectories are well defined (in particular $S_{\eta\eta}(\tau, \xi(\tau)) < 0$) as long as they remain inside $\mathcal{T}$. Moreover, all boundary points of $\mathcal{T}$ are strict exit points. A topological argument thus implies the existence of some $T, x_0 \in \mathcal{G}$ whose corresponding solution of (4.14) – (4.16) remains forever inside $\mathcal{T}$. Such T and x_0 provide the exact timing and location of the blowup. In the second part of the proof we refine the estimates on u, v, w, and on their derivatives, and establish the limits (4.1) by means of a comparison theorem.

5. Proof of Theorem 4.2. Step 1. For $(T, x_0) \in \mathcal{G}$, let u, v, w, S be the corresponding solution of (4.8) – (4.10), defined for $\tau \geq \tau_0 = -\ln T$. Introduce the scalar quantities

$$\mu(\tau) = \max\{|u_\eta(\tau, \eta)|,\ |v_\eta(\tau, \eta)|,\ |w_\eta(\tau, \eta)|;\quad |\eta| \leq e^{-\tau/6}\} \tag{5.1}$$

$$\begin{cases} m^u(\tau) = \min u_{\eta\eta}(\tau, \eta) \\ m^v(\tau) = \min v_{\eta\eta}(\tau, \eta) \\ m^w(\tau) = \min w_{\eta\eta}(\tau, \eta) \end{cases} \qquad \begin{cases} M^u(\tau) = \max u_{\eta\eta}(\tau, \eta) \\ M^v(\tau) = \max v_{\eta\eta}(\tau, \eta) \\ M^w(\tau) = \max w_{\eta\eta}(\tau, \eta), \end{cases}$$

$$D(\tau) = \max\{|u_{\eta\eta}(\tau,\eta)|,\ |v_{\eta\eta}(\tau,\eta)|,\ |w_{\eta\eta}(\tau,\eta)|\}, \tag{5.2}$$

where the min and max are all taken over the set $|\eta| \le e^{-\tau/6}$. Defining

$$m = m^u + m^v + m^w, \qquad M = M^u + M^v + M^w, \tag{5.3}$$

we clearly have

$$m(\tau) \le S_{\eta\eta}(\tau,\eta) \le M(\tau) \tag{5.4}$$

whenever $|\eta| \le e^{-\tau/6}$. Estimates on the initial values of μ, m, M, and D can be derived from assumptions (i) – (iii) in Theorem 4.2. Recalling that

$$\hat\vartheta + 1 \ge \tau_0 = -\ln T \ge \hat\vartheta - 1 > \tilde\tau > 3, \tag{5.5}$$

if $|\eta| \le e^{-\tau_0/6}$, then

$$|x - x_0| = |\eta|\, e^{-\tau_0/2} \le e^{-2\tau_0/3} \le e^{2(1-\hat\vartheta)/3},$$

$$|x - \hat x| \le |x - x_0| + |x_0 - \hat x| \le 2\, e^{2(1-\hat\vartheta)/3}.$$

Hypotheses (i) – (iii) therefore imply

$$\begin{cases} \mu(\tau_0) < (\gamma/2)^{(\hat\vartheta-1)/2} \cdot e^{-\tau_0/2} \le \gamma/2 \\ m(\tau_0) > [-e^{\hat\vartheta-1} \cdot \beta/2] \cdot e^{-\tau_0} \ge -\beta/2 \\ M(\tau_0) < [-2\alpha\, e^{\hat\vartheta+1}] e^{-\tau_0} \le -2\alpha \\ D(\tau_0) < [e^{\hat\vartheta-1}\beta/2] e^{-\tau_0} \le \beta/2. \end{cases} \tag{5.6}$$

To estimate μ, m, M, D when $\tau > \tau_0$, we differentiate (4.8) and obtain

$$\begin{cases} u_{\eta\tau} + \dfrac{\eta}{2} u_{\eta\eta} + \dfrac{u_\eta}{2} = A\, e^S S_\eta \\ v_{\eta\tau} + \dfrac{\eta}{2} v_{\eta\eta} + \dfrac{v_\eta}{2} = B\, e^S S_\eta - \lambda\, e^{-\tau/2} v_{\eta\eta} \\ w_{\eta\tau} + \dfrac{\eta}{2} w_{\eta\eta} + \dfrac{w_\eta}{2} = B\, e^S S_\eta + \lambda\, e^{-\tau/2} w_{\eta\eta}, \end{cases} \tag{5.7}$$

$$\begin{cases} u_{\eta\eta\tau} + u_{\eta\eta} + \dfrac{\eta}{2} u_{\eta\eta\eta} = A\, e^S (S_\eta^2 + S_{\eta\eta}) \\ v_{\eta\eta\tau} + v_{\eta\eta} + \dfrac{\eta}{2} v_{\eta\eta\eta} = B\, e^S (S_\eta^2 + S_{\eta\eta}) - \lambda\, e^{-\tau/2} v_{\eta\eta\eta} \\ w_{\eta\eta\tau} + w_{\eta\eta} + \dfrac{\eta}{2} w_{\eta\eta\eta} = B\, e^S (S_\eta^2 + S_{\eta\eta}) + \lambda\, e^{-\tau/2} w_{\eta\eta\eta}. \end{cases} \tag{5.8}$$

Observe that the three families of characteristics for the system (4.8) are determined by the equations

$$\dot\eta = \frac{\eta}{2}, \quad \dot\eta = \frac{\eta}{2} + \lambda\, e^{-\tau/2}, \quad \dot\eta = \frac{\eta}{2} - \lambda\, e^{-\tau/2}.$$

By (5.5) and assumption (C1) on $\tilde{\tau}$, when $\tau \geq \tilde{\tau}$ all characteristics are flowing out from the domain $\{(\tau, \eta); |\eta| \leq e^{-\tau/6}\}$. Assume that $(\tau, \xi(\tau), S(\xi(\tau))) \in \mathcal{T}$ and $m(\tau) \leq M(\tau) < 0$ for τ in some initial interval $[\tau_0, \tau')$. Then the following estimates hold.

$$S(\tau, \eta) \leq e^{-\tau/3}, \qquad e^{S(\tau,\eta)} \leq 1 + 2\,e^{-\tau/3} \leq 2, \tag{5.9}$$

$$|S_\eta(\tau, \eta)| \leq |\eta - \xi(\tau)||m(\tau)| \leq 2|m(\tau)|e^{-\tau/6}. \tag{5.10}$$

Using (5.9), (5.10), from (5.7), (5.8) we deduce

$$\begin{aligned} \dot{\mu}(\tau) &\leq -\mu(\tau)/2 + \max\{|S_\eta(\tau, \eta)| \cdot e^{S(\tau,\eta)};\ |\eta| \leq e^{-\tau/6}\} \\ &\leq -\mu(\tau)/2 + 4|m(\tau)|e^{-\tau/6}, \end{aligned} \tag{5.11}$$

$$\begin{cases} \dot{m}^u(\tau) \geq -m^u(\tau) + A \cdot m(\tau)(1 + 2e^{-\tau/3}) \\ \dot{m}^v(\tau) \geq -m^v(\tau) + B \cdot m(\tau)(1 + 2e^{-\tau/3}) \\ \dot{m}^w(\tau) \geq -m^w(\tau) + B \cdot m(\tau)(1 + 2e^{-\tau/3}), \end{cases}$$

$$\dot{m}(\tau) \geq 2e^{-\tau/3} m(\tau), \tag{5.12}$$

$$\begin{cases} \dot{M}^u(\tau) \leq -M^u(\tau) + 2A(2|m(\tau)|e^{-\tau/6})^2 + A(1 + 2e^{-\tau/3})M(\tau) \\ \dot{M}^v(\tau) \leq -M^v(\tau) + 2B(2|m(\tau)|e^{-\tau/6})^2 + B(1 + 2e^{-\tau/3})M(\tau) \\ \dot{M}^w(\tau) \leq -M^w(\tau) + 2B(2|m(\tau)|e^{-\tau/6})^2 + B(1 + 2e^{-\tau/3})M(\tau), \end{cases}$$

$$\dot{M}(\tau) \leq 8m^2(\tau)e^{-\tau/3}. \tag{5.13}$$

Assumptions (C1), (C2) now imply

$$\mu(\tau) < \gamma, \quad m(\tau) > -\beta, \quad M(\tau) < -\alpha \tag{5.14}$$

for all $\tau \in [\tau_0, \tau')$. Since $S_{\eta\eta} < M(\tau) < 0$, (5.14) shows that solutions (ξ, S) of (4.14), (4.15) are well defined and depend continuously on the parameters T, x_0, as long as (ξ, S) remain inside the tube $\mathcal{T}$. Moreover, from (5.8) it follows

$$\begin{aligned} \dot{D}(\tau) &\leq -D(\tau) + 2\max\{(S_\eta^2 + |S_{\eta\eta}|);\ |\eta| \leq e^{-\tau/6}\} \\ &\leq -D(\tau) + 2[(2|m(\tau)|e^{-\tau/6})^2 + |m(\tau)|] \\ &\leq -D(\tau) + 8\beta^2 e^{-\tau/3} + 2\beta, \end{aligned} \tag{5.15}$$

hence, by condition (C2),

$$D(\tau) < 3\beta \qquad \forall\, \tau \in [\tau_0, \tau'). \tag{5.16}$$

We now define a continuous map φ from the unit square $Q = \{(y_1, y_2);\ |y_1|, |y_2| \leq 1\}$ onto its boundary as follows. Given $(y_1, y_2) \in Q$, there exists a unique $(T, x_0) \in \mathcal{G}$ such that, setting $\tau_0 = -\ln T$, we have

$$(y_1, y_2) = e^{\tau_0/3}(\xi(\tau_0), \qquad S(\xi(\tau_0))) = T^{-1/3}((\hat{x} - x_0)T^{-1/2},\ \hat{\vartheta} + \ln T). \tag{5.17}$$

If the corresponding solution of (4.14) – (4.16) escapes through the boundary of $\mathcal{T}$ at time τ, define

$$\varphi(y_1, y_2) = e^{\tau/3}(\xi(\tau), \qquad S(\tau, \xi(\tau))) \in \partial Q. \tag{5.18}$$

As customary, the continuity of φ can be proved by showing that every boundary point of $\mathcal{T}$ with $\tau \geq \tilde{\tau}$ is a strict exit point for solutions of (4.14) – (4.16). Indeed, if $|\xi(\tau)| = e^{-\tau/3}$, using (5.16) in (4.14) we obtain

$$\begin{aligned} \frac{d}{d\tau}|\xi| &\geq \frac{1}{2}e^{-\tau/3} - \frac{\lambda}{|M(\tau)|}e^{-\tau/3} \cdot 2D(\tau) \\ &\geq \frac{1}{2}e^{-\tau/3} - \frac{6\beta\lambda}{\alpha}e^{-\tau/2} > 0 \end{aligned}$$

because of (C1). On the other hand, if $|S(\tau, \xi(\tau))| = e^{-\tau/3}$, using (5.14) in (4.15) we now have

$$\frac{d}{d\tau}|S(\tau, \xi(\tau))| \geq \frac{1}{2}e^{-\tau/3} - \lambda e^{-\tau/2} \cdot 2\mu(\tau) > \frac{1}{2}e^{-\tau/3} - 2\lambda\gamma e^{-\tau/2} > 0.$$

If every choice $(T, x_0) \in \mathcal{G}$ yields a trajectory which escapes from $\mathcal{T}$ at some finite time τ, the map φ would then be a continuous surjection from Q onto ∂Q which leaves the points of ∂Q fixed. Since no such map exists, we have proved the existence of some $(T, x_0) \in \mathcal{G}$ whose corresponding trajectory $\tau \to (\xi(\tau), S(\tau, \xi(\tau)))$ remains inside $\mathcal{T}$ for all times $\tau \geq \tau_0$.

6. Proof of Theorem 4.2. Step 2. From now on, everything is referred to a unique coordinate transformation, i.e., the one determined by the element $(T, x_0) \in \mathcal{G}$ singled out at the end of §5. Differentiating (5.8) once again we find

$$\begin{cases} u_{\eta\eta\eta\tau} + \frac{3}{2}u_{\eta\eta\eta} + \frac{\eta}{2}u_{\eta\eta\eta\eta} = Ae^S S_{\eta\eta\eta} + Ae^S S_\eta(S_\eta^2 + 3S_{\eta\eta}) \\ v_{\eta\eta\eta\tau} + \frac{3}{2}v_{\eta\eta\eta} + \left(\frac{\eta}{2} + \lambda e^{-\tau/2}\right)v_{\eta\eta\eta\eta} = Be^S S_{\eta\eta\eta} + Be^S S_\eta(S_\eta^2 + 3S_{\eta\eta}) \\ w_{\eta\eta\eta\tau} + \frac{3}{2}w_{\eta\eta\eta} + \left(\frac{\eta}{2} - \lambda e^{-\tau/2}\right)w_{\eta\eta\eta\eta} = Be^S S_{\eta\eta\eta} + Be^S S_\eta(S_\eta^2 + 3S_{\eta\eta}). \end{cases} \tag{6.1}$$

Call $E^u(\tau)$ the maximum of $|u_{\eta\eta\eta}(\tau, \cdot)|$ over the set $|\eta| \leq e^{-\tau/6}$, and define $E^v(\tau)$, $E^w(\tau)$ similarly. Set $E = E^u + E^v + E^w$. Since $|S_{\eta\eta\eta}(\tau, \eta)| \leq E(\tau)$, by (6.1) E satisfies the differential inequality

$$\dot{E}(\tau) \leq \left(-\frac{3}{2} + \max_\eta e^{S(\tau,\eta)}\right)E(\tau) + \max_\eta |S_\eta| \cdot |e^S S_\eta^2 + 3e^S S_{\eta\eta}|. \tag{6.2}$$

The estimates (5.10) and (5.14) together imply

$$\lim_{\tau\to\infty} \max\{|S_\eta(\tau, \eta)|; |\eta| \leq e^{-\tau/6}\} = 0. \tag{6.3}$$

Using (6.3) and the uniform bounds on $S, |S_{\eta\eta}|$ in (6.2) we obtain

$$\lim_{\tau\to\infty} E(\tau) = 0,$$

therefore, recalling the definitions (5.3),

$$\lim_{\tau\to\infty} |M(\tau) - m(\tau)| = 0. \tag{6.4}$$

By (5.4), (5.14), from (6.4) it follows that

$$\Omega = \lim_{\substack{\tau\to\infty \\ |\eta|\leq e^{-\tau/6}}} S_{\eta\eta}(\tau,\eta) \tag{6.5}$$

exists and satisfies

$$-\beta \leq \Omega \leq -\alpha. \tag{6.6}$$

Using (6.5) in (5.8) we now obtain

$$\begin{cases} \lim_{\tau\to\infty} u_{\eta\eta} = A\Omega, \\ \lim_{\tau\to\infty} v_{\eta\eta} = \lim_{\tau\to\infty} w_{\eta\eta} = B\Omega, \end{cases} \tag{6.7}$$

all limits being taken inside the region $|\eta| \leq e^{-\tau/6}$. The equations (4.14), (4.15) in view of (6.5), (6.7) yield

$$|\xi(\tau)| \leq C\, e^{-\tau/2}, \qquad |S(\tau,\xi(\tau))| \leq C_1\, e^{-\tau/2} \tag{6.8}$$

for some constant C_1 and all τ large enough. Since $S_\eta(\tau,\xi(\tau)) \equiv 0$ and $|S_{\eta\eta}| < \beta$, (6.8) implies an estimate of the form

$$|S_\eta(\tau,\eta)| \leq C_2 e^{-\tau/2} \tag{6.9}$$

whenever $|\eta| \leq (C+2\lambda)e^{-\tau/2}$. In particular, (6.8) and (6.9) yield

$$|S(\tau,0)| \leq C_3 e^{-\tau/2}, \tag{6.10}$$

valid for some constant C_3 and all τ large enough. Define

$$\mu'(\tau) = \max\{|u_\eta(\tau,\eta)|,\ |v_\eta(\tau,\eta)|,\ |w_\eta(\tau,\eta)|;\ |\eta| \leq 2\lambda\, e^{-\tau/2}\}.$$

An estimate entirely similar to (5.11) now yields

$$\begin{aligned} \dot\mu' &\leq -\mu'(\tau)/2 + \max\{|S_\eta(\tau,\eta)|e^{S(\tau,\eta)};\ |\eta| \leq 2\lambda\, e^{-\tau/2}\} \\ &\leq -\mu'(\tau)/2 + 2C_2\, e^{-\tau/2}, \end{aligned}$$

which implies, in particular,

$$|u_\eta(\tau,0)|, \quad |v_\eta(\tau,0)|, \quad |w_\eta(\tau,0)| \leq C_4\tau\, e^{-\tau/2}. \tag{6.11}$$

To extend our estimates beyond the narrow strip $|\eta| \leq 2\lambda\, e^{-\tau/2}$ we rely on a comparison technique.

LEMMA. *Let (u,v,w) be a solution of* (5.2) *and let $Z = Z(\tau,\eta)$ be a scalar function such that*

$$Z_\tau + \frac{\eta}{2} Z_\eta = e^Z - 1. \tag{6.12}$$

Call

$$\begin{aligned} u^-(\tau,\eta) &= \min\{u(\tau,\eta');|\eta'-\eta| \leq 2\lambda\, e^{-\tau/2}\}, \\ u^+(\tau,\eta) &= \max\{u(\tau,\eta');|\eta'-\eta| \leq 2\lambda\, e^{-\tau/2}\} \end{aligned}$$

and similarly for v^-, v^+, w^-, w^+. *If at some point* (τ, η) *we have* $(u^-+v^-+w^-)(\tau,\eta) \geq Z(\tau, \eta)$, *then*

$$(u^- + v^- + w^-)(\tau + t,\ \eta e^{t/2}) \geq Z(\tau + t,\ \eta e^{t/2}) \qquad \forall t > 0. \tag{6.13}$$

On the other hand, if $(u^+ + v^+ + w^+)(\tau,\eta) \leq Z(\tau,\eta)$, *then*

$$(u^+ + v^+ + w^+)(\tau + t,\ \eta e^{t/2}) \leq Z(\tau + t,\ \eta e^{t/2}) \qquad \forall t > 0. \tag{6.14}$$

Indeed, (6.13) and (6.14) can be proved by defining

$$Y^{\pm}(t) = (u^{\pm} + v^{\pm} + w^{\pm})(\tau + t,\ \eta e^{t/2})$$

and checking that

$$\frac{dY^-(t)}{dt} \geq \frac{d}{dt} Z(\tau + t,\ \eta e^{t/2}),$$

$$\frac{dY^+(t)}{dt} \leq \frac{d}{dt} Z(\tau + t,\ \eta e^{t/2})$$

whenever $Y^- \geq Z$ or $Y^+ \leq Z$, respectively.

Using the lemma, we now prove that as $\tau \to \infty$ the functions u, v, w, S converge to some limit, uniformly on bounded sets. Fix $\varepsilon > 0$ and define

$$Z^+(\tau,\eta) = -\ln\left(1 - \frac{\Omega + \varepsilon}{2}\eta^2\right),$$

$$Z^-(\tau,\eta) = -\ln\left(1 - \frac{\Omega - \varepsilon}{2}\eta^2\right).$$

Observe that Z^+, Z^- are time-invariant solutions of (6.12), with $Z^+_{\eta\eta}(0) = \Omega + \varepsilon$, $Z^-_{\eta\eta}(0) = \Omega - \varepsilon$. For any $\varepsilon' > 0$, by (6.7) there exists τ_1 so large that

$$\begin{cases} u(\tau,\eta) \leq u(\tau,0) + u_\eta(\tau,0)\cdot\eta + (A\Omega + \varepsilon')\eta^2/2 \\ v(\tau,\eta) \leq v(\tau,0) + v_\eta(\tau,0)\cdot\eta + (B\Omega + \varepsilon')\eta^2/2 \\ w(\tau,\eta) \leq w(\tau,0) + w_\eta(\tau,0)\cdot\eta + (B\Omega + \varepsilon')\eta^2/2 \end{cases} \tag{6.15}$$

whenever $|\eta| \leq e^{-\tau/6}$, $\tau \geq \tau_1$.

Call $u_\infty, v_\infty, w_\infty$, respectively, the limits of $u(\tau,0), v(\tau,0), w(\tau,0)$ as $\tau \to \infty$. Using (6.10), (6.11) in (4.8), it is clear that these limits exist. In fact, we have the estimates

$$|u(\tau,0) - u_\infty|,\ |v(\tau,0) - v_\infty|, |w(\tau,0) - w_\infty| \leq C_5 \tau e^{-\tau/2} \tag{6.16}$$

for some constant C_5 and all τ large enough. Moreover,

$$u_\infty + v_\infty + w_\infty = \lim_{\tau\to\infty} S(\tau,0) = 0.$$

By (6.15), (6.16), there exists $\bar\tau$ so large that

$$u^+ - u_\infty \leq AZ^+, \quad v^+ - v_\infty \leq BZ^+, \quad w^+ - w_\infty \leq BZ^+, \tag{6.17}$$

at every point of the set $\{(\tau,\eta);\ \tau\geq\bar\tau,\ |\eta|=\frac12\,e^{-\tau/6}\}$. In particular,

$$(u^+ + v^+ + w^+)(\tau,\pm e^{-\tau/6}) \leq Z^+\left(\tau,\pm\tfrac12\,e^{-\tau/6}\right) \tag{6.18}$$

for all $\tau\geq\bar\tau$. The previous lemma now yields

$$S(\tau,\eta)\leq (u^+ + v^+ + w^+)(\tau,\eta)\leq Z^+(\tau,\eta) \tag{6.19}$$

on the region

$$\Sigma_{\bar\tau}=\left\{(\tau,\eta);\ \tau\geq\bar\tau,\ \tfrac12\,e^{-\tau/6}\leq|\eta|\leq\tfrac12\,e^{(\tau-\bar\tau)/2}\cdot e^{-\bar\tau/6}\right\}.$$

For $\bar\tau$ suitably large, an entirely similar argument yields

$$S(\tau,\eta)\geq (u^- + v^- + x^-)(\tau,\eta)\geq Z^-(\tau,\eta) \tag{6.20}$$

for all $(\tau,\eta)\in\Sigma_{\bar\tau}$. Since $S(\tau,\eta)\to 0$ as $\tau\to\infty$ on the strip $|\eta|\leq\frac12\,e^{-\tau/2}$, (6.19) and (6.20) prove the following. For every $\varepsilon>0$ there exists $\bar\tau$ large enough so that

$$\left|S(\tau,\eta)+\ln\left(1-\frac{\Omega}{2}\,\eta^2\right)\right|<\varepsilon \tag{6.21}$$

for every (τ,η) in the region

$$R_{\bar\tau}=\left\{(\tau,\eta);\ \tau\geq\bar\tau,\ |\eta|\leq\tfrac12\,e^{\tau/2}\,e^{-2\bar\tau/3}\right\}.$$

Using (6.19) and (6.20) in (4.8), another comparison argument shows that on $\Sigma_{\bar\tau}$ the functions $u^\pm$ satisfy

$$A\cdot Z^-(\eta)\leq u^-(\tau,\eta)-u_\infty\leq u^+(\tau,\eta)-u_\infty\leq A\cdot Z^+(\eta).$$

Similarly, the functions $v^\pm-v_\infty$ and $w^\pm-w_\infty$ are bounded by $B\cdot Z^\pm$. On the strip $|\eta|\leq\frac12\,e^{-\tau/6}$, estimates on u,v,w are already known. Therefore we conclude that for every $\varepsilon>0$ there exists $\bar\tau$ such that

$$\begin{aligned}
&\left|u(\tau,\eta)-u_\infty+A\cdot\ln\left(1-\frac{\Omega}{2}\,\eta^2\right)\right|<\varepsilon,\\
&\left|v(\tau,\eta)-v_\infty+B\cdot\ln\left(1-\frac{\Omega}{2}\,\eta^2\right)\right|<\varepsilon,\\
&\left|w(\tau,\eta)-w_\infty+B\cdot\ln\left(1-\frac{\Omega}{2}\,\eta^2\right)\right|<\varepsilon,
\end{aligned} \tag{6.22}$$

for every $(\tau,\eta)\in R_{\bar\tau}$. By setting $z_1^\infty=u_\infty$, $z_2^\infty=v_\infty$, $z_3^\infty=w_\infty$, the reinterpretation of (6.22) in the original variables t,x,z is the following. For every $\varepsilon>0$ there exists $\bar t<T$ such that the estimates (4.1) hold whenever $\bar t\leq t<T$, $|x-x_0|\leq\frac12\,(T-t)^{2/3}$. This proves Theorem 4.2.

The statements in Theorem 4.1 now follow as corollaries. Indeed, for any given $\alpha,\beta,\gamma,\tilde\tau$, the hypotheses in Theorem 4.2 are satisfied by a nonempty, open set of functions. The previous proof also indicates that the parameters T,x_0,z_i^∞, and Ω, which characterize the self-similar blowup, depend continuously on the initial data $\bar z$ in the $\mathcal{C}^2$ topology.

AN INTERIOR DISCONTINUITY OF A NONLINEAR ELLIPTIC-HYPERBOLIC SYSTEM*

SENHUEI E. CHEN† AND R. BRUCE KELLOGG‡

Abstract. A nonlinear elliptic-hyperbolic system of partial differential equations which is a simplified form of the equations of viscous, compressible, barotropic flow at steady-state is studied. A boundary value problem for the system on a strip $D = (0, a) \times (-\infty, \infty)$ is considered. Zero boundary conditions for the velocities u and v on the sides of the strip D are imposed, and for pressure $p(0, y) = p_0(y)$ is imposed, where $p_0(y)$ has a jump at $y = 0$. Jump conditions for the system show that u and v are continuous. However, their derivatives and pressure have a curve of discontinuity. With sufficient small width of the strip D the Schauder fixed-point theorem gives a solution with a curve of discontinuity. The results suggest that there are two-dimensional, viscous, barotropic, steady-state compressible flows with discontinuity.

Key words. viscous compressible flow, discontinuous solutions

AMS(MOS) subject classifications. 76N10, 35Q10

1. Introduction.

The mathematical theory of the compressible Navier–Stokes equations is far from complete, and there are many unsolved questions. Among these questions is the interior regularity of the solutions. There are some situations where it is quite clear what to expect. For example, in the case of compressible inviscid flow, the governing system of equations is hyperbolic and solutions will, in general, contain shock discontinuities. In the case of incompressible viscous flow, the governing system of equations may be thought of as elliptic, and it is reasonable to expect that the solutions will be regular interior to the flow region. In the case of viscous compressible flow, the governing system of equations is neither elliptic nor hyperbolic, and the issue of interior regularity is open. In this paper, we make a contribution to this problem.

There has been some work related to the problem of interior regularity of the solutions to the compressible flow equations. D. Hoff [1], [2] has considered the time-dependent, viscous, compressible flow equations in one space dimension. He shows that there are indeed solutions for which the pressure has a jump discontinuity; however, he also shows that this discontinuity decays as time goes to infinity. In [4] Valli considers the three-dimensional, steady-state, compressible flow equations. He shows that if the boundary data is small and smooth, then there is a smooth solution to the system. Kellogg [6] studies the two-dimensional, steady-state, viscous, compressible flow equations. The equations are linearized around an ambient nonzero solution to the nonlinear system. He shows that there is a solution to this linearized system that contains an interior discontinuity. The pressure takes a jump across this curve. The curve is a streamline of the ambient flow field that emanates from a jump in the specified boundary values of the pressure.

From the above discussion it seems possible that there are solutions to the steady-state, viscous, compressible flow equations which have an interior curve of discontinuity. We are unable to prove this result. Instead, we construct a simplified system of equations that still retains the "elliptic-hyperbolic" character of the original flow equations. Our simplification enables us to carry through an existence theorem for a

discontinuous solution, which is the purpose of this paper.

Let the primary unknowns be the velocity $u(x,y)$, $v(x,y)$ in the x, y directions, respectively, and the pressure $p(x,y)$, and let $\rho(p)$ be the density, which is related to the pressure through the equation of state. We consider the case of barotropic flow, in which there is no dependence on temperature. Let μ and λ denote the two coefficients of viscosity. The two-dimensional, barotropic, steady-state, compressible Navier–Stokes equations are:

$$-(2\mu+\lambda)u_{xx}-(\mu+\lambda)v_{xy}-\mu u_{yy}+(\rho u^2)_x+(\rho uv)_y+p_x=0, \tag{1.1a}$$

$$-\mu v_{xx}-(\mu+\lambda)u_{xy}-(2\mu+\lambda)v_{yy}+(\rho uv)_x+(\rho v^2)_y+p_y=0, \tag{1.1b}$$

$$(\rho u)_x+(\rho v)_y=0. \tag{1.1c}$$

To obtain the simplified system we set $\mu=-\lambda=1$ and we drop the convective terms in (1.1a,b). More crucially, we replace the continuity equation by a modified "continuity" equation, $u\rho_x+v\rho_y=0$. Thus, we have dropped the term $\rho u_x+\rho v_y$ from the continuity equation. This modified "continuity" equation has no physical meaning. Our only justification in considering it is that the elliptic-hyperbolic character of the system is unchanged, and that we are able to demonstrate the existence of a solution of the modified system with an interior discontinuity. The difficulties encountered in using (1.1c) are explained in §2. With the assumption that the system is barotropic, the density $\rho=\rho(p)$ is a function of pressure only and the system can be simplified further. Writing $\rho_x=(d\rho/dp)p_x$, $\rho_y=(d\rho/dp)p_y$, we obtain from (1.1c) the equation $up_x+vp_y=0$. We make a further notational change. The solution that we obtain will be such that the flow is close to uniform flow in the x direction. We therefore replace the unknown u by $1+u$. This leaves the modified momentum equations unchanged. The modified compressible flow equations studied in this paper are therefore

$$-u_{xx}-u_{yy}+p_x=0, \tag{1.2a}$$

$$-v_{xx}-v_{yy}+p_y=0, \tag{1.2b}$$

$$(1+u)p_x+vp_y=0. \tag{1.2c}$$

The system (1.2) will be considered in the strip $D=(0,a)\times(-\infty,\infty)$. The width a will be chosen later. We impose zero boundary conditions for u and v on the sides of the strip D, and we impose the boundary condition for the pressure on the side of the strip D through which the flow enters. Thus, we are led to the boundary conditions:

$$u(0,y)=u(a,y)=0, \tag{1.2d}$$

$$v(0,y)=v(a,y)=0, \tag{1.2e}$$

$$p(0,y)=p_0(y). \tag{1.2f}$$

The function $p_0(y)$ will be chosen to have a simple jump discontinuity at $y = 0$, to vanish outside $[0, a]$, and to be smooth for $y \geq 0$. We let $\delta p_0 = p_0(+0)$ denote the jump in $p_0(y)$ at $y = 0$. We will show that the system (1.2) has a solution with the property that $p(x, y)$ is discontinuous across a curve $\mathcal{C}$. The curve $\mathcal{C}$ is the streamline of the flow emanating from the point (0,0), which is the point of discontinuity of p_0. The first derivatives of u and v undergo jump discontinuities across $\mathcal{C}$, and satisfy certain jump conditions analogous to the Rankine–Hugoniot conditions for inviscid flow. The proof reformulates the problem as a fixed-point mapping T in a Banach space and uses the Schauder fixed-point theorem. In the course of the proof, we must choose a to be suitably small. The specific restriction on a is given below, and is used to guarantee that T is a self-mapping of a ball in the Banach space. Thus, both the width of the strip D and the support of p_0 are made small. On the other hand, there is no restriction on the size of the jump δp_0.

In §2 we define precisely what is meant by a weak solution of (1.2), we reformulate (1.2) as finding the fixed point of a map in a certain Banach space, and we state our existence theorem (Theorem 2.1). In addition, we derive in a heuristic way the jump conditions that the solution satisfies across the curve $\mathcal{C}$.

Section 3 presents a formula for the solution of the momentum equations (1.2a,b) in terms of certain weakly singular integrals. From this formula we obtain a modulus of continuity of u and v in the y variable of the form $r(|\ln|r||+1)$, which is just enough to ensure the unique solvability of the characteristic equations associated with (1.2c). Also in this section, we verify the jump conditions for a weak solution of (1.2), and we derive a formula for the solution of (1.2c).

In §4 an analysis of the interaction between the weakly singular integrals occurring in the solution of (1.2a,b) and the characteristic equation occurring in the solution of (1.2c) proves the continuity of the fixed-point mapping T. Following that, some a priori inequalities are derived.

In §5, a value of the width of the strip D is determined, and the Schauder fixed-point theorem (see, for example, [3]), is applied to give the existence of a solution with a curve $\mathcal{C}$ of discontinuity.

2. Existence theorem and jump conditions. In this section we define precisely what we mean by a weak solution of the system (1.2). We then state our main existence theorem as Theorem 2.1, whose proof is given in §5. The existence theorem establishes the existence of a weak solution (u, v, p) with the property that p has a curve $\mathcal{C}$ of discontinuity. The weak solution must satisfy certain jump conditions across the curve $\mathcal{C}$ of discontinuity, and we end this section with a discussion and heuristic derivation of these jump conditions.

Let $C^0(\bar{D})$ be the space of continuous functions in $\bar{D}$. Let

$$\mathcal{A} = \{(u, v) : u \in C^0(\bar{D}), v \in C^0(\bar{D}), ||u|| + ||v|| < \infty\},$$

where

$$||u|| = \sup_{x,y \in D} |u(x, y)| + \sup_{x,y,\bar{y} \in D, y \neq \bar{y}} \frac{|u(x, y) - u(x, \bar{y})|}{|y - \bar{y}|(|\ln|y - \bar{y}|| + 1)},$$

and similarly for $||v||$. It is easy to see that $\mathcal{A}$ is a Banach space with the norm $||(u, v)|| = ||u|| + ||v||$. The particular form of the norm $||u||$ reflects the elliptic-hyperbolic character of our system. The modulus of continuity of u in the y variable is $r[|\ln|r|| + 1]$. This modulus of continuity is just enough to guarantee the solvability

of the hyperbolic equation (1.2c), see the beginning of §3, and to provide the a priori estimates that arise from this solution (note Lemmas 4.1 and 4.2). On the other hand, this modulus of continuity is provided by estimates for the weakly singular integrals that occur in the solution of the elliptic equations (1.2a,b), and it seems that no better modulus of continuity arises from these weakly singular integrals.

For system (1.2), we say that (u, v, p) is a weak solution, if u and v belong to $\mathcal{A}$, p is a locally integrable function in D, and (u, v, p) satisfy the following conditions: for any $\phi(x, y) \in C_0^\infty(D)$, the equations

$$\int\int_D [-u\phi_{xx} - u\phi_{yy} - p\phi_x]dxdy = 0, \tag{2.1a}$$

$$\int\int_D [-v\phi_{xx} - v\phi_{yy} - p\phi_y]dxdy = 0 \tag{2.1b}$$

hold; on each curve $y = h(x, y_0)$ defined by the equation $h'(x, y_0) = v(x, h(x, y_0))/(1+u(x, h(x, y_0)))$, $h(0, y_0) = y_0$, p is constant and hence satisfies (1.2c). As mentioned above, since $(u, v) \in \mathcal{A}$, the function $h(x, y_0)$ is well defined. We now state the main existence theorem.

THEOREM 2.1. *Let p_0 be a function with $p_0(y) = 0$ for $y < 0$ and $y \geq a$, $p_0(y)$ infinitely differentiable for $y \geq 0$, and $\lim_{y \to +0} p_0(y) = \delta p_0 \neq 0$. Then there is a number $a^* > 0$, satisfying* (R1), (R2), *and* (R3) *defined in* §§4 *and* 5 *such that, if $0 < a < a^*$, the system* (1.2) *has a weak solution (u, v, p) with $(u, v) \in \mathcal{A}$. The solution has a curve C of discontinuity on which the jump conditions* (J1), (J2), *and* (J3) *defined below are satisfied.*

Let $\mathcal{B}$ be the closed ball in $\mathcal{A}$ with center 0 and radius 1/4. We define a mapping T on $\mathcal{B}$ as follows. Let $T_1 : (u, v) \to p$, where p is obtained by solving

$$(1 + u)p_x + vp_y = 0, \qquad p(0, y) = p_0(y),$$

and let $T_2 : p \to (\bar{u}, \bar{v})$, where $\bar{u}$, $\bar{v}$ satisfy

$$-\bar{u}_{xx} - \bar{u}_{yy} + p_x = 0, \qquad \bar{u}(0, y) = \bar{u}(a, y) = 0,$$

$$-\bar{v}_{xx} - \bar{v}_{yy} + p_y = 0, \qquad \bar{v}(0, y) = \bar{v}(a, y) = 0.$$

Let $T = T_2 \circ T_1$ be the composition of T_2 and T_1. Theorem 2.1 will be proved in §5 by showing that the mapping T has a fixed point in $\mathcal{B}$.

We may now explain the difficulties encountered in using the true continuity equation (1.1c), instead of (1.2c). Presumably, T_1 should be the solution operator of (1.1c). When written out, (1.1c) becomes $u\rho_x + v\rho_y + (u_x + v_y)\rho = 0$; if this equation were used, the space $\mathcal{A}$ would need to be replaced by a space of functions for which $u_x + v_y$ has meaning. Alternately, we could define a solution operator T_1 of (1.1c) by means of a weak solution. If this is the case, it is hard to get enough information concerning ρ to establish continuity results of the form given in Propositions 4.3 and 4.7.

Let $\Gamma = (x(s), y(s))$ be a smooth curve, parametrized by s, which divides D into two parts, D_1 and D_2. The unit normal vector to the curve is $n(s) = (-\dot{y}(s), \dot{x}(s))$. Suppose $n(s)$ points into D_2, so $n(s)$ is the outward pointing normal to D_1. In each

subregion we suppose that u, v, and p are smooth, but they or their derivatives may have a simple jump across Γ. Let u_t denote the tangential derivative along the curve Γ. Let $[u]_1$, $[u]_2$, $[u_x]_1$, $[u_x]_2$, etc., denote the one-sided limits of u, u_x, etc., on Γ. We use the notation $\delta u = [u]_2 - [u]_1$, $\delta u_x = [u_x]_2 - [u_x]_1$ to measure the jump. In the following theorem, we present jump conditions for solutions with a curve Γ of discontinuity. The proof uses the standard technique of integration by parts, but assumes that the solution is smooth on either side of Γ. In Theorem 3.1 these jump conditions are established for a weak solution.

THEOREM 2.2. *Let the domain D be divided into two parts D_1, D_2, by a smooth curve Γ. Let (u, v, p) be a weak solution of* (1.2). *Suppose u, v, p are smooth in each subdomain with one-sided limits on Γ, and suppose p has a jump on Γ. Then Γ is a streamline of the flow, the first derivatives of u and v have jumps on Γ, and u, v, p satisfy the jump conditions*

$$\delta u = \delta v = \delta u_t = \delta v_t = 0, \tag{J1}$$

$$\dot{y}\delta u_x - \dot{x}\delta u_y = \dot{y}\delta p, \tag{J2}$$

$$\dot{y}\delta v_x - \dot{x}\delta v_y = -\dot{x}\delta p. \tag{J3}$$

Proof. Let γ denote a curve that crosses Γ at a point q_0. Let $q \in \gamma$, and let Γ_q be the streamline through q. Then $p = p(q)$ on Γ_q. As q varies over $\gamma \cap D_1$, $p(q)$ is continuous, and as p varies over $\gamma \cap D_2$, $p(q)$ is continuous. Hence, for p to be discontinuous across Γ, we must have $\gamma = \Gamma_{q_0}$; that is, Γ is a streamline.

Since $(u, v) \in \mathcal{A}$, u and v are continuous. Hence $\delta u = \delta v = 0$, and since u and v are assumed to be smooth on either side of Γ, $\delta u_t = \delta v_t = 0$, and we have (J1).

Let ϕ be a smooth function of compact support contained in D_1. From a well-known property of the Laplacian operator and the fact that p is smooth in D_1, (2.1a) implies that u satisfies (1.2a) in D_1. Similarly, u satisfies (1.2a) in D_2. Next, let ϕ have support which intersects Γ. Applying (2.1a), we write the integral as a sum of integrals over D_1 and D_2. Integrating by parts and using (1.2a) in D_1 and D_2, we obtain

$$\int_\Gamma [\dot{y}\delta u_x - \dot{x}\delta u_y - \dot{y}\delta p + \delta u(\dot{y}\delta p_x - \dot{x}\delta p_y)]\phi ds = 0.$$

Since this is true for all smooth ϕ with compact support, and since $\delta u = 0$, we obtain (J2). The proof of (J3) is similar.

3. Properties of solutions. The aim of this section is to derive formulas for the mappings T_1 andT_2. These formula are then used to verify jump conditions and derive a formula for the modulus of continuity for a pair $(\bar{u}, \bar{v})$ in the range of T_2. First, we derive a formula for T_1 by solving (1.2c) and (1.2f) for p with (u, v) a given pair in $\mathcal{A}$. The characteristic curves $y = h(x, y_0)$ corresponding to the hyperbolic equation (1.2c) are those defined by the solutions of the nonlinear ordinary differential equation:

$$\frac{dh}{dx} = \frac{v(x, h(x, y_0))}{1 + u(x, h(x, y_0))}, \qquad h(0, y_0) = y_0. \tag{3.1}$$

In particular, when $y_0 = 0$, we obtain the characteristic curve $y = H(x)$ emanating from $(0,0)$:

$$\frac{dH}{dx} = \frac{v(x,H(x))}{1+u(x,H(x))}, \qquad H(0) = 0. \tag{3.2}$$

For the existence and uniqueness of solution of (3.1) and (3.2) we refer to Hartman [5]. Since u and v are continuous, the Peano existence theorem [5, Chap. II, Thm. 2.1] shows that solutions $h(x,y_0)$ and $H(x)$ exist. Since u and v are in $\mathcal{A}$, the Osgood criterion [5, Chap. III, Cor. 6.2] is satisfied and the solutions h and H are unique. As a consequence of this uniqueness, $h(x,y_0)$ is a strictly increasing function in y_0, so the inverse function exists. For each x, let the inverse function of $h(x,y_0)$ be $g(x,y)$, i.e.,

$$g(x,h(x,y_0)) = y_0, \qquad g(x,h(x,0)) = g(x,H(x)) = 0. \tag{3.3}$$

Through $g(x,y)$, the solution $p = T_1(u,v)$ can be expressed as

$$p(x,y) = p_0(g(x,y)).$$

In particular,

$$p(x,H(x)) = p_0(g(x,H(x))) = p_0(+0) = \delta p_0. \tag{3.4}$$

Thus, p is constant along each curve $y = h(x,y_0)$. Due to the jump discontinuity of $p_0(y)$ at $y = 0$, $p(x,y)$ has a jump discontinuity across the characteristic $y = H(x)$, that is, the one emanating from $(0,0)$ and denoted by $\mathcal{C}$. Moreover $p(x,y) = 0$, if $y < H(x)$, $p(x,y)$ is continuous and compactly supported in $y \geq H(x)$.

Now we are in position to solve (1.2a,b) subject to (1.2d,e) for $\bar{u}(x,y)$ and $\bar{v}(x,y)$ with given $p(x,y)$ in the range of T_1. We will take the Fourier transform of (1.2a,b) with respect to y. Since $p(x,y)$, and the first derivatives of $\bar{u}(x,y)$ and $\bar{v}(x,y)$ possibly are discontinuous on the curve $y = H(x)$, the usual formulas for the Fourier transform of the derivatives must be modified and the transformed equations include terms containing these jumps. When we apply the jump conditions (J1) and (J2), these extra terms cancel out and we obtain two linear ordinary differential equations in x with coefficients in t:

$$-\hat{u}_{xx} + t^2\hat{u} + \hat{p}_x = 0,$$

$$-\hat{v}_{xx} + t^2\hat{v} + it\hat{p} = 0,$$

where $\hat{u}$, $\hat{v}$, and $\hat{p}$ denote the Fourier transform of $\bar{u}$, $\bar{v}$, $\bar{p}$, and t denotes the transformed variable. These equations may be solved subject to boundary conditions.

For this, let

$$k_1(x-s,y-t) = \frac{-\sin \pi(x-s)/a}{8a(\sinh^2 \pi(y-t)/2a + \sin^2 \pi(x-s)/2a)},$$

$$k_2(x+s,y-t) = \frac{-\sin \pi(x+s)/a}{8a(\sinh^2 \pi(y-t)/2a + \sin^2 \pi(x+s)/2a)},$$

$$k_3(x-s,y-t)=\frac{-\sinh\pi(y-t)/a}{8a(\sinh^2\pi(y-t)/2a+\sin^2\pi(x-s)/2a)},$$

$$k_4(x+s,y-t)=\frac{-\sinh\pi(y-t)/a}{8a(\sinh^2\pi(y-t)/2a+\sin^2\pi(x+s)/2a)}.$$

Then, taking the inverse Fourier transform of the solutions and using some formulas in [7], we obtain the following formula for $(\bar{u},\bar{v})=T_2(p)$:

$$\begin{aligned}\bar{u}(x,y)&=\int\int_D p(s,t)(k_1(x-s,y-t)+k_2(x+s,y-t))dtds\\&\equiv\bar{u}_1(x,y)+\bar{u}_2(x,y),\end{aligned}\tag{3.5}$$

$$\begin{aligned}\bar{v}(x,y)&=\int\int_D p(s,t)(k_3(x-s,y-t)+k_4(x+s,y-t))dtds\\&\equiv\bar{v}_1(x,y)+\bar{v}_2(x,y).\end{aligned}\tag{3.6}$$

For some analysis in §4, it is convenient to introduce

$$k_7(x-s,y-t)=\frac{s-x}{2\pi((y-t)^2+(x-s)^2)}.$$

We may write $\bar{u}(x,y)$ as

$$\bar{u}(x,y)=[\bar{u}_1(x,y)-\bar{u}_3(x,y)]+\bar{u}_2(x,y)+\bar{u}_3(x,y),\tag{3.7}$$

where

$$\bar{u}_3(x,y)\equiv\int\int_D p(s,t)k_7(x-s,y-t)dtds.\tag{3.8}$$

Now we verify the jump conditions (J1), (J2), and (J3) for a pair $(\bar{u},\bar{v})$ in the range of T_2.

THEOREM 3.1. *Let u, v be in $\mathcal{A}$, and p the image of u, v under the mapping T_1, then $(\bar{u},\bar{v})=T_2(p)$ satisfies the jump conditions* (J1), (J2), *and* (J3).

Proof. Since $k_2(x+s,y-t)$ is C^1 as a function of x and y and bounded for all (s,t) in D, (x,y) in D, $\bar{u}_2(x,y)$ is C^1 in x and y. Hence $\bar{u}_2(x,y)$ takes no jump across $y=H(x)$. Using the fact that $p(s,t)$ is supported in $t\geq H(s)$ and making a change of variables $y-t=\tau$, $x-s=\sigma$ yields

$$\bar{u}_1(x,y)=\int_{x-a}^{x}\int_{-\infty}^{y-H(x-\sigma)}p(x-\sigma,y-\tau)k_1(\sigma,\tau)d\tau d\sigma.$$

We use this expression to evaluate the partial derivatives of $\bar{u}_1(x,y)$:

$$\begin{aligned}\frac{\partial\bar{u}_1}{\partial x}&=\int_{-\infty}^{y}p(0,y-\tau)k_1(x,\tau)d\tau-\int_{-\infty}^{y-H(a)}p(a,y-\tau)k_1(x-a,\tau)d\tau\\&\quad-\int_{x-a}^{x}H'(x-\sigma)p(x-\sigma,H(x-\sigma))k_1(\sigma,y-H(x-\sigma))d\sigma\\&\quad+\int_{x-a}^{x}\int_{-\infty}^{y-H(x-\sigma)}p_{,1}(x-\sigma,y-\tau)k_1(\sigma,\tau)d\tau d\sigma\end{aligned}$$

$$\equiv A_1 + A_2 + A_3 + A_4,$$

$$\frac{\partial \bar{u}_1}{\partial y} = \int_{x-a}^{x} \int_{-\infty}^{y-H(x-\sigma)} p_{,2}(x-\sigma, y-\tau) k_1(\sigma,\tau) d\tau d\sigma + \int_{x-a}^{x} p(x-\sigma, H(x-\sigma)) k_1(\sigma, y-H(x-\sigma)) d\sigma \equiv A_5 + A_6.$$

Here $p_{,i}$ means the partial derivative of p with respect to the ith variable. Terms A_1, A_2, A_4, A_5 are continuous across $y = H(x)$. However, A_3 and A_6 become singular as x, y approaches the curve $\mathcal{C}$, and these terms give rise to the jump discontinuity in $\partial \bar{u}_1/\partial x$ and $\partial \bar{u}_1/\partial y$. Using (3.4) we have

$$\begin{aligned}
A_3(x,y) &= -\int_0^a H'(s) p(s, H(s)) k_1(x-s, y-H(s)) ds \\
&= -\delta p_0 \int_0^a H'(s) k_1(x-s, y-H(s)) ds \\
&= -\delta p_0 \int_0^a (H'(s) - H'(x)) k_1(x-s, y-H(s)) ds \\
&\quad -\delta p_0 H'(x) \int_0^a \left(k_1(x-s, y-H(s)) - \frac{1}{2\pi} k_5(x-s, y-H(s)) \right) ds \\
&\quad \frac{-\delta p_0}{2\pi} H'(x) \int_0^a \left(k_5(x-s, y-H(s)) - k_6(x-s, y-H(s)) \right) ds \\
&\quad \frac{-\delta p_0}{2\pi} H'(x) \int_0^a k_6(x-s, y-H(s)) ds,
\end{aligned}$$

where

$$k_5(x-s, y-H(s)) = \frac{(s-x)}{((y-H(s))^2 + (x-s)^2)},$$

$$k_6(x-s, y-H(s)) = \frac{(s-x)}{(y-H(x)-H'(x)(s-x))^2 + (x-s)^2}.$$

Since $(H'(s) - H'(x))k_1$, $k_1 - k_5$, and $k_5 - k_6$ are continuous in x, y and bounded in D as a function of s, t for all (x, y) in D, $\int_0^a (H'(s) - H'(x)) k_1 ds$, $\int_0^a (k_1 - k_5) ds$ and $\int_0^a (k_5 - k_6) ds$ do not take a jump across $\mathcal{C}$. Further analysis of

$$-\frac{\delta p_0}{2\pi} H'(x) \int_0^a k_6(x-s, y-H(s)) ds$$

is needed to bring out the jump of $\partial u_1/\partial x$ across $\mathcal{C}$. By setting $x - s = \bar{s}$, $y - H(x) = \alpha$, and $\bar{s}/\alpha = \sigma$,

$$\begin{aligned}
\frac{-\delta p_0}{2\pi} H'(x) \int_0^a k_6(x-s, y-H(s)) ds &= \frac{\delta p_0}{2\pi} H'(x) \int_{x-a}^{x} \frac{\bar{s}}{(\alpha - H'(x)\bar{s})^2 + \bar{s}^2} d\bar{s} \\
&= \frac{\delta p_0}{2\pi} H'(x) \int_{(x-a)/\alpha}^{x/\alpha} \frac{\sigma}{(1 - H'(x)\sigma)^2 + \sigma^2} d\sigma \\
&\equiv \frac{\delta p_0}{2\pi} H'(x) \mathcal{F}(\alpha).
\end{aligned}$$

When $y - H(x) = \alpha > 0$,

$$\begin{aligned}\mathcal{F}^+(\alpha) = &\frac{1}{2(1+H'(x)^2)} \ln\left(\left(1 - H'(x)\frac{x}{\alpha}\right)^2 + H'(x)^2\left(\frac{x}{\alpha}\right)^2\right)\\ &+\frac{H'(x)}{1+H'(x)^2}\tan^{-1}\left((1+H'(x)^2)\frac{x}{\alpha} - H'(x)\right)\\ &-\frac{1}{2(1+H'(x)^2)} \ln\left(\left(1 - H'(x)\frac{x-a}{\alpha}\right)^2 + H'(x)^2\left(\frac{x-a}{\alpha}\right)^2\right)\\ &-\frac{H'(x)}{1+H'(x)^2}\tan^{-1}\left((1+H'(x)^2)\frac{x-a}{\alpha} - H'(x)\right).\end{aligned}$$

When $y - H(x) = -\alpha < 0$,

$$\begin{aligned}\mathcal{F}^-(\alpha) = &-\frac{1}{2(1+H'(x)^2)} \ln\left(\left(1 - H'(x)\frac{a-x}{\alpha}\right)^2 + H'(x)^2\left(\frac{a-x}{\alpha}\right)^2\right)\\ &-\frac{H'(x)}{1+H'(x)^2}\tan^{-1}\left((1+H'(x)^2)\frac{a-x}{\alpha} - H'(x)\right)\\ &+\frac{1}{2(1+H'(x)^2)} \ln\left(\left(1 - H'(x)\frac{-x}{\alpha}\right)^2 + H'(x)^2\left(\frac{-x}{\alpha}\right)^2\right)\\ &+\frac{H'(x)}{1+H'(x)^2}\tan^{-1}\left((1+H'(x)^2)\frac{-x}{\alpha} - H'(x)\right).\end{aligned}$$

Letting y go to $H(x)$ from above and below, we find that $\lim_{\alpha\to 0}\mathcal{F}^{\pm}(\alpha)$ exists and we obtain

$$\lim_{\alpha\to 0}\frac{\delta p_0}{2\pi}H'(x)(\mathcal{F}^+(\alpha) - \mathcal{F}^-(\alpha)) = \frac{\delta p_0 H'(x)H'(x)}{(1+H'(x)^2)} \tag{3.9}$$

Next, in the expression of $\partial u_1/\partial y$, $A_6(x,y)$ takes the same amount of jump across $\mathcal{C}$ as

$$-\frac{\delta p_0}{2\pi}\int_0^a k_6(x-s, y-H(s))ds.$$

By setting $x - s = \bar{s}$, $y - H(x) = \alpha$, $\bar{s}/\alpha = \sigma$,

$$\begin{aligned}\frac{-\delta p_0}{2\pi}\int_0^a k_6(x-s,y-H(s))ds &= \frac{\delta p_0}{2\pi}\int_0^a \frac{x-s}{(\alpha - H'(x)(x-s))^2 + (x-s)^2}ds\\ &= \frac{\delta p_0}{2\pi}\int_{x-a}^{x}\frac{\bar{s}}{(\alpha - H'(x)\bar{s})^2 + \bar{s}^2}d\bar{s}\\ &= \frac{\delta p_0}{2\pi}\int_{(x-a)/\alpha}^{x/\alpha}\frac{\sigma}{(1-H'(x)\sigma)^2+\sigma^2}d\sigma\\ &\equiv \frac{\delta p_0}{2\pi}\mathcal{G}(\alpha).\end{aligned}$$

When $y - H(x) = \alpha > 0$,

$$\begin{aligned}\mathcal{G}^+(\alpha) = &-\frac{1}{2(1+H'(x)^2)} \ln\left(\left(1 - H'(x)\frac{x}{\alpha}\right)^2 + H'(x)^2\left(\frac{x}{\alpha}\right)^2\right)\\ &-\frac{H'(x)}{1+H'(x)^2}\tan^{-1}\left(1+H'(x)^2)\frac{x}{\alpha} - H'(x)\right)\\ &+\frac{1}{2(1+H'(x)^2)} \ln\left(\left(1 - H'(x)\frac{x-a}{\alpha}\right)^2 + H'(x)^2\left(\frac{x-a}{\alpha}\right)^2\right)\\ &+\frac{H'(x)}{1+H'(x)^2}\tan^{-1}\left((1+H'(x)^2)\frac{x-a}{\alpha} - H'(x)\right).\end{aligned}$$

When $y - H(x) = -\alpha < 0$,

$$\begin{aligned}\mathcal{G}^-(\alpha) = &\frac{1}{2(1+H'(x)^2)} \ln\left(\left(1 - H'(x)\frac{a-x}{\alpha}\right)^2 + H'(x)^2\left(\frac{a-x}{\alpha}\right)^2\right)\\ &+\frac{H'(x)}{1+H'(x)^2}\tan^{-1}\left((1+H'(x)^2)\frac{a-x}{\alpha} - H'(x)\right)\\ &-\frac{1}{2(1+H'(x)^2)} \ln\left(\left(1 - H'(x)\frac{-x}{\alpha}\right)^2 + H'(x)^2\left(\frac{-x}{\alpha}\right)^2\right)\\ &-\frac{H'(x)}{1+H'(x)^2}\tan^{-1}\left((1+H'(x)^2)\frac{-x}{\alpha} - H'(x)\right).\end{aligned}$$

Letting y go to $H(x)$ from above and below, we find that $\lim_{\alpha\to 0}\mathcal{G}^{\pm}(\alpha)$ exists and we obtain

$$\lim_{\alpha\to 0}\frac{\delta p_0}{2\pi}(\mathcal{G}^+(\alpha) - \mathcal{G}^-(\alpha)) = -\frac{\delta p_0 H'(x)}{(1+H'(x)^2)} \quad . \tag{3.10}$$

Since $\dot{x} = 1$, $\dot{y} = H'(x)$, jump condition (J2) follows from equations (3.9) and (3.10), and (J3) is proved in a similar way. To verify (J1), note that from these formulas, $\bar{u}$ and $\bar{v}$ have one-sided derivatives on either side of $\mathcal{C}$, so (J1) follows from the continuity of $\bar{u}$ and $\bar{v}$ across $\mathcal{C}$. This completes the proof.

In the expression (3.7) for $\bar{u}(x,y)$, $\bar{u}_1(x,y) - \bar{u}_3(x,y)$ and $\bar{u}_2(x,y)$ are smoother than $\bar{u}_3(x,y)$. The crucial part concerning the modulus of the continuity of $\bar{u}(x,y)$ is $\bar{u}_3(x,y)$. We state the modulus of continuity of $\bar{u}_3(x,y)$ and give the proof as follows.

PROPOSITION 3.2. *Let $0 < a < 1$, and let p be a bounded function supported in $[0,a]\times[-2a,2a]$, then*

$$\bar{u}_3(x,y) = \int_0^a\int_{-2a}^{2a} p(s,t)k_7(x-s,y-t)dtds$$

satisfies

$$|\bar{u}_3(x,y) - \bar{u}_3(x,\bar{y})| \le aC_1||p|||y-\bar{y}|(|\ln|y-\bar{y}|| + 1), \tag{3.11}$$

where $||p|| = \sup_{(s,t)\in D}|p(s,t)|$, C_1 is a constant.

Proof. Define

$$f(x,y,\bar{y}) = \int_0^a \int_{-2a}^{2a} \frac{|(s-x)(y+\bar{y}-2t)|dtds}{((x-s)^2+(y-t)^2)((x-s)^2+(\bar{y}-t)^2)}.$$

Then

$$|\bar{u}_3(x,y) - \bar{u}_3(x,\bar{y})| \leq \frac{||p||}{2\pi}|y-\bar{y}|f(x,y,\bar{y}).$$

Consider, without loss of generality, the case $x = \bar{y} = 0$. Then,

$$f(0,y,0) \leq \int_0^a \int_{-2a}^{2a} \frac{|s||t|+|s||y-t|}{(s^2+(y-t)^2)(s^2+t^2)}dtds \equiv f_1(0,y,0) + f_2(0,y,0).$$

We rescale $f_1(0,y,0)$ by setting $s = y\sigma$, $t = ay\tau$. Then

$$f_1(0,y,0) \leq a\int_0^{a/y} \int_{-2/y}^{2/y} \frac{a|\sigma||\tau|d\tau d\sigma}{(\sigma^2+(1-a\tau)^2)(\sigma^2+a^2\tau^2)}.$$

Let

$$B_1 = \left\{(\sigma,\tau) : 0 \leq \sigma \leq \tfrac{a}{y}, \tfrac{-2}{y} \leq \tau \leq \tfrac{2}{y}\right\},$$

$$B_2 = \left\{(\sigma,\tau) : 0 \leq \sigma, 0 \leq \sigma^2+\tau^2 \leq \left(\tfrac{4}{y}\right)^2\right\},$$

$$B_3 = \left\{(\sigma,\tau) : 0 \leq \sigma, 0 \leq \sigma^2+\tau^2 \leq \tfrac{1}{4}\right\},$$

$$B_4 = \left\{(\sigma,\tau) : 0 \leq \sigma, \tfrac{1}{4} \leq \sigma^2+\tau^2 \leq \left(\tfrac{4}{y}\right)^2\right\},$$

$$B_5 = \left\{(\sigma,\tau) : 0 \leq \sigma, \tfrac{1}{4} \leq \sigma^2+(1-\tau)^2 \leq \left(\tfrac{4}{y}+1\right)^2\right\}.$$

Since $0 < a < 1$, $B_1 \subset B_2$, $a|\sigma||\tau|/(\sigma^2+a^2\tau^2) < \frac{1}{2}$, then

$$f_1(0,y,0) \leq \frac{a}{2}\int\int_{B_2} \frac{d\tau d\sigma}{\sigma^2+(1-a\tau)^2}.$$

With $B_2 = B_3 \cup B_4$,

$$\begin{aligned} f_1(0,y,0) &\leq \frac{a}{2}\int\int_{B_3} \frac{d\tau d\sigma}{(\sigma^2+(1-a\tau)^2)} + \frac{a}{2}\int\int_{B_4} \frac{d\tau d\sigma}{(\sigma^2+(1-a\tau)^2)} \\ &\equiv \frac{a}{2}((\mathrm{i})+(\mathrm{ii})). \end{aligned}$$

Since $B_4 \subset B_5$, $a < 1$, and

$$\frac{1}{(\sigma^2+(1-a\tau)^2)} \leq \frac{1}{(\sigma^2+(1-\tau)^2)},$$

we obtain

$$\begin{aligned}
\text{(i)} &\leq \int\int_{B_3} \frac{1}{(\sigma^2+(1-\tau)^2)} d\tau d\sigma \leq C_2, \\
\text{(ii)} &\leq \int\int_{B_4} \frac{d\sigma d\tau}{(\sigma^2+(1-\tau)^2)} \\
&\leq \int\int_{B_5} \frac{d\sigma d\tau}{(\sigma^2+(1-\tau)^2)} \\
&\leq \int_{-\pi}^{\pi} \int_{1/2}^{(4/y)+1} \frac{1}{r} dr d\theta \leq C_3(|\ln|y|| + 1),
\end{aligned}$$

for some constants C_2, C_3. Choosing $C_4 = \max(C_2, C_3)$,

$$f_1(0, y, 0) \leq \frac{a}{2} C_4(|\ln|y|| + 1).$$

Similarly,

$$f_2(0, y, 0) \leq \frac{a}{2} C_4(|\ln|y|| + 1).$$

We have shown that $f(x, y, \bar{y}) \leq aC_4(|\ln|y|| + 1)$. This completes the proof.

The functions $k_2(x-s, y-t)$ and $k_1(x-s, y-t) - k_7(x-s, y-t)$ are in C^1 as functions of x and y, and are bounded for all $(s,t) \in D$, $(x,y) \in D$. Hence $\bar{u}_2$ and $\bar{u}_1 - \bar{u}_3$ are continuously differentiable in D, so there is a constant C_5 such that

$$|\bar{u}_2(x,y) - \bar{u}_2(x,\bar{y})| \leq aC_5||p|||y-\bar{y}|, \tag{3.12}$$

$$|\bar{u}_1(x,y) - \bar{u}_3(x,y) - (\bar{u}_1(x,\bar{y}) - \bar{u}_3(x,\bar{y}))| \leq aC_5||p|||y-\bar{y}|. \tag{3.13}$$

In view of (3.11), (3.12), and (3.13) we have the following concerning the modulus of continuity of $\bar{u}(x,y)$. A similar analysis holds for $\bar{v}(x,y)$ andwe obtain the following proposition.

PROPOSITION 3.3. *There is a constant C_6 such that*

$$|\bar{u}(x,y) - \bar{u}(x,\bar{y})| \leq aC_6||p|||y-\bar{y}|(|\ln|y-\bar{y}|| + 1), \tag{3.14}$$

$$|\bar{v}(x,y) - \bar{v}(x,\bar{y})| \leq aC_6||p|||y-\bar{y}|(|\ln|y-\bar{y}|| + 1). \tag{3.15}$$

4. A priori estimates. By definition, $h(x, y_0)$ is the solution to the ordinary differential equation (3.1). Since $||u|| + ||v|| < \frac{1}{4}$, $|dh/dx| \leq (\frac{1}{4})/(1-\frac{1}{4}) < 1$. Thus, if $y > 2a$, $g(x,y) > 1$, then $p_0(g(x,y)) = 0$; if $y < -2a$, $g(x,y) < 0$, $p_0(g(x,y)) = 0$. Hence the support of p is contained in $[0,a] \times [-2a, 2a]$. Furthermore, the set of y_0 such that the curve $y = h(x, y_0)$ meets the rectangle $[0,a] \times [-2a, 2a]$ is contained in the interval $[-3a, 3a]$. For later purposes, we require this interval to have length less than 1; thus, we require

$$a < \tfrac{1}{6}. \tag{R1}$$

Let $(u^j, v^j) \in \mathcal{B}$, $j = 1, 2$, and let $h_j(x, y_0)$ be the corresponding characteristic curves satisfying (3.1). In particular, since $H_j(0) = 0$, we may write $H_j(x)$ as

$$H_j(x) = \int_0^x \frac{v^j(s, H_j(s))}{1 + u^j(s, H_j(s))} ds, \qquad j = 1, 2.$$

Let

$$||H(x)|| = \sup_{x \in (0,a)} |H(x)|, \qquad ||h(x, y_0)|| = \sup_{(x,y_0) \in D} |h(x, y_0)|.$$

With this notation we shall derive inequalities for perturbations $H_1 - H_2$ and $h_1 - h_2$ in terms of $u^1 - u^2$ and $v^1 - v^2$. For this, we first state and prove in Lemma 4.2 a variation of Gronwall's inequality.

LEMMA 4.1. *Let $K_4 > 0$, $K_5 > 0$, $1 > \varepsilon > 0$ be constants and let $L(x)$ solve*

$$(*) \qquad L'(x) = -K_4(L(x) \ln L(X) - L(x)), \quad L(0) = \varepsilon K_5 < 1,$$

then $L(x) \leq 3(\varepsilon K_5)^{e^{-aK_4}}$.

Proof. Equation $(*)$ has solution $L(x) = \exp[1 - e^{-xK_4} + e^{-xK_4} \ln(\varepsilon K_5)]$, so

$$L(x) \leq 3 \exp[e^{-xK_4} \ln(\varepsilon K_5)] \leq 3 \exp[e^{-aK_4} \ln(\varepsilon K_5)] = 3(\varepsilon K_5)^{e^{-aK_4}}.$$

LEMMA 4.2. *Let $f(x)$ be a nonnegative function satisfying*

$$f(x) = \int_0^x -K_4(f(s) \ln f(s) - f(s)) ds + \varepsilon K_5.$$

Suppose $\varepsilon K_5 < 1$ and $3(\varepsilon K_5)^{e^{-aK_4}} < 1$, then

$$f(x) \leq 3(\varepsilon K_5)^{e^{-aK_4}}.$$

Proof. It is sufficient to show that $L(x)$ dominates $f(x)$. We use the fact that $-x \ln x + x$ is an increasing function in $(0, 1)$. So we require $0 \leq L(x) \leq 1$. This is fulfilled by our assumption $3(\varepsilon K_5)^{e^{-aK_4}} < 1$. Define for $\delta > 0$,

$$L_\delta(x) = \int_0^x -K_4(L_\delta(s) \ln L_\delta(s) - L_\delta(s)) ds + K_5 \varepsilon + \delta, \qquad L_\delta(0) = \varepsilon K_5 + \delta > f(0).$$

Both $f(x)$ and $L_\delta(x)$ are continuous functions. Suppose $L_\delta(x) < f(x)$ for some x. Let $x^* > 0$ be the smallest number such that $L_\delta(x^*) = f(x^*)$. Of course, $x^* > 0$, since $L_\delta(0) > f(0)$. Hence $f(x) < L_\delta(x)$, $x \in (0, x^*)$. We have

$$\begin{aligned} 0 &= L_\delta(x^*) - f(x^*) \\ &= \int_0^{x^*} -K_4(L_\delta(s) \ln L_\delta(s) - L_\delta(s)) ds - \int_0^{x^*} -K_4(f(s) \ln f(s) - f(s)) ds + \delta > 0, \end{aligned}$$

a contradiction. Consequently, $f(x) \leq L_\delta(x)$. This is true for any $\delta > 0$. Therefore

$$f(x) \leq \lim_{\delta \to 0} L_\delta(x) = 3(\varepsilon K_5)^{e^{-aK_4}}.$$

PROPOSITION 4.3. *Let* (u^i, v^i) *be in* $\mathcal{B}$, *and let* H_i, h_i *be the corresponding solution of* (3.1), (3.2), *respectively, for* $i = 1, 2$. *Then*

$$||H_1 - H_2|| \leq K_1(||u^1 - u^2|| + ||v^1 - v^2||)^{K_2}, \tag{4.1}$$

$$||h_1 - h_2|| \leq K_1(||u^1 - u^2|| + ||v^1 - v^2||)^{K_2} \tag{4.2}$$

where $K_1 = 3(8a)^{K_2}$, $K_2 = e^{-4a}$.

Proof. Inequality (4.1) will be proved in detail. Similar arguments will derive (4.2), therefore we skip the proof of (4.2). We have

$$\begin{aligned}
&|H_1(x) - H_2(x)| \\
&\quad \leq \int_0^x |\frac{v^1(s, H_1(s))}{1 + u^1(s, H_1(s))} - \frac{v^2(s, H_2(s))}{1 + u^2(s, H_2(s))}| ds \\
&\quad \leq 4 \int_0^x [|v^1(s, H_1(s)) - v^1(s, H_2(s))| + |v^1(s, H_2(s)) - v^2(s, H_2(s))|] ds \\
&\qquad + 4 \int_0^x |v^1| \{|u^1(s, H_1(s)) - u^1(s, H_2(s))| + |u^1(s, H_2(s)) - u^2(s, H_2(s))|\} ds \\
&\qquad + 4 \int_0^x |u^2| \{|v^1(s, H_1(s)) - v^1(s, H_2(s))| + |v^1(s, H_2(s)) - v^2(s, H_2(s))|\} ds \\
&\quad \leq 8 \int_0^x \{|v^1(s, H_1(s)) - v^1(s, H_2(s))| + |u^1(s, H_1(s)) - u^1(s, H_2(s))|\} ds \\
&\qquad + 8 \int_0^x \{|v^1(s, H_2(s)) - v^2(s, H_2(s))| + |u^1(s, H_2(s)) - u^2(s, H_2(s))|\} ds.
\end{aligned}$$

Thus,

$$\begin{aligned}
|H_1(x) - H_2(x)| \leq 8 \int_0^x \{|v^1(s, H_1) - v^1(s, H_2)| + |u^1(s, H_1) - u^1(s, H_2)|\} ds \\
+ 8a(||v^1 - v^2|| + ||u^1 - u^2||).
\end{aligned} \tag{4.3}$$

Using (3.14) and (3.15) in the right-hand side of (4.3) yields

$$\begin{aligned}
|H_1(x) - H_2(x)| \leq \int_0^x -4(|H_1 - H_2| \ln |H_1 - H_2| - |H_1 - H_2|) ds \\
+ 8a(||v^1 - v^2|| + ||u^1 - u^2||).
\end{aligned} \tag{4.4}$$

It is sufficient to require

$$3(8a)^{K_2} < 1, \tag{R2}$$

to apply Lemma 4.2 to (4.4) with $\varepsilon = ||v^1 - v^2|| + ||u^1 - u^2||$, $f(x) = |H_1(x) - H_2(x)|$, $K_4 = 4$, $K_5 = 8a$. The proof is complete.

Next, two inequalities for $||\bar{u}^1 - \bar{u}^2||$ and $||\bar{v}^1 - \bar{v}^2||$ bounded in terms of $||H_1 - H_2||$, $||h_1 - h_2||$ are needed. These inequalities are given in Proposition 4.7. We first require some preliminary results.

LEMMA 4.4. *Suppose $f(x,y)$ is a function in D satisfying*

$$|f(x,y) - f(x,\bar{y})| \leq C_0|y-\bar{y}|(|\ln|y-\bar{y}|| + 1),$$

for all $x \in [0,a]$ and C_0 is a constant satisfying $0 < 2aC_0 < 1$. Let $z(x,z_0)$ and $\bar{z}(x,\bar{z}_0)$ be the solutions of

$$\frac{dz}{dx} = f(x,z), \quad z(0,z_0) = z_0, \quad x \in [0,a],$$

$$\frac{d\bar{z}}{dx} = f(x,\bar{z}), \quad \bar{z}(0,\bar{z}_0) = \bar{z}_0, \quad x \in [0,a],$$

respectively. Then, there are constants $\beta \in (0,1)$ and $K_6 > 0$, depending on a and C_0 only, such that

$$\bar{z}(x) - z(x) \geq K_6(\bar{z}_0 - z_0)^{1/\beta}, \quad \text{if } 0 \leq \bar{z}_0 - z_0 \leq 1.$$

Proof.

$$\bar{z}(x) - z(x) = \bar{z}_0 - z_0 + \int_0^x \frac{f(s,\bar{z}) - f(s,z)}{\bar{z} - z}(\bar{z} - z)ds.$$

Introducing $w(x) = \bar{z}(x) - z(x)$ and $(f(s,\bar{z}) - f(s,z))/(\bar{z} - z) = \zeta(s)$, we have

$$w(x) = w(0) + \int_0^x \zeta(s)w(s)ds,$$

which has the solution

$$w(x) = w(0)e^{\int_0^x \zeta(s)ds}.$$

Letting the max of $|\zeta|$ be assumed at x^*, we have

$$w(0)e^{-a|\zeta(x^*)|} \leq w(x) \leq w(0)e^{a|\zeta(x^*)|}.$$

Using the assumption in the case $x = x^*$, $|\zeta(x^*)| \leq C_0(1 + |\ln w(x^*)|)$, we obtain, for all x in $[0,a]$,

$$w(0)e^{-aC_0(1+|\ln w(x^*)|)} \leq w(x) \leq w(0)e^{aC_0(1+|\ln w(x^*)|)}. \tag{4.5}$$

If $0 \leq w(x^*) \leq 1$, the left side inequality in (4.5) becomes

$$w(x) \geq w(0)e^{-aC_0}w(x^*)^{aC_0}. \tag{4.6a}$$

In particular,

$$w(x^*) \geq w(0)e^{-aC_0}w(x^*)^{aC_0},$$

which implies

$$w(x^*) \geq w(0)^{1/(1-aC_0)}e^{-aC_0/(1-aC_0)}.$$

Then

$$w(x^*)^{aC_0} \geq w(0)^{aC_0/(1-aC_0)} e^{-a^2C_0^2/(1-aC_0)}.$$

Inserting this back into (4.6a), we obtain

$$w(x) \geq w(0)^{1/(1-aC_0)} e^{-aC_0/(1-aC_0)}. \tag{4.6b}$$

If $1 \leq w(x^*)$, the right-hand side inequality in (4.5) becomes

$$w(x) \leq w(0)e^{aC_0} w(x^*)^{aC_0}.$$

In particular,

$$w(x^*) \leq w(0)e^{aC_0} w(x^*)^{aC_0},$$

which implies

$$w(x^*) \leq w(0)^{1/(1-aC_0)} e^{aC_0/(1-aC_0)}.$$

Therefore,

$$w(x^*)^{-aC_0} \geq w(0)^{-aC_0/(1-aC_0)} e^{-a^2C_0^2/(1-aC_0)}. \tag{4.7a}$$

Meanwhile, the left-hand side inequality in (4.5) becomes

$$w(x) \geq w(0)e^{-aC_0} w(x^*)^{-aC_0}. \tag{4.7b}$$

Inserting (4.7a) into (4.7b), we obtain

$$w(x) \geq w(0)^{(1-2aC_0)/(1-aC_0)} e^{-aC_0/(1-aC_0)}. \tag{4.7c}$$

Since $0 \leq w(0) \leq 1$, (4.6b) and (4.7c) imply, for all x in $[0, a]$,

$$w(x) \geq w(0)^{1/(1-aC_0)} e^{-aC_0/(1-aC_0)}.$$

Let $\beta = 1 - aC_0$ and $K_6 = e^{-aC_0/(1-aC_0)}$, the proof is complete.

LEMMA 4.5. *Let (u^1, v^1) be in $\mathcal{B}$ and $g_1(s, t_j)$ be theinverse function of $h_1(x, y_j)$, which satisfies the differential equation* (3.1) *subject to initial value y_j, for $j = 1, 2$, and $0 \leq |y_1 - y_2| \leq 1$. Then*

$$|g_1(s, t_1) - g_1(s, t_2)| \leq K_7 |t_1 - t_2|^\beta, \tag{4.8}$$

for some constant K_7 and β as in the Lemma 4.4 *for all (s, t_1) and (s, t_2) in D.*

Proof. Since (u^1, v^1) is in $\mathcal{B}$, applying Lemma 4.4 to the differential equation (3.1) with $C_0 = \frac{1}{4}$ and using (R1), we find that $|y_1 - y_2|^{1/\beta} \leq K_6{}^{-1} |h_1(s, y_1) - h_1(s, y_2)|$. Through the definition of g_1 and h_1, this inequality is equivalent to (4.8) if $K_7 = K_6{}^{-\beta}$.

LEMMA 4.6. *Fix t_1, let (u^j, v^j) be in $\mathcal{B}$. Let $g_1(s, t_1)$ and $g_2(s, t_1)$ satisfy $0 \leq |g_1(s, t_1) - g_2(s, t_1)| \leq 1$. Let $h_j(s, y_j)$ be the inverse function of $g_j(s, t_1)$ for $j = 1, 2$, where $h_j(s, y_j)$ satisfies equation* (3.1). *Then*

$$|g_1(s, t_1) - g_2(s, t_1)| \leq K_7 |h_1(s, y_2) - h_2(s, y_2)|^\beta \tag{4.9}$$

for all (s, t_1) and (s, y_2) in D and constant K_7 as in Lemma 4.4.

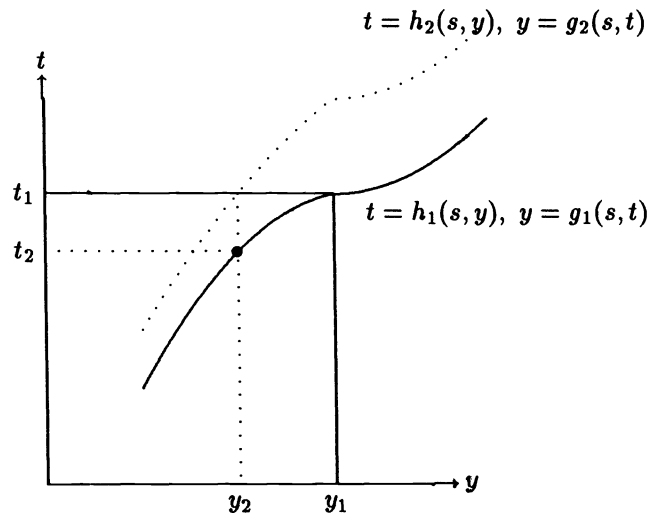

FIG. 4.1. *These curves show the relation between t and y for fixed s.*

Proof. Referring to Fig. 4.1 and applying Lemma 4.5, we have

$$|g_1(s,t_1) - g_2(s,t_1)| = |y_1 - y_2| = |g_1(s,t_1) - g_1(s,t_2)| \le K_7|t_1 - t_2|^\beta.$$

That is equivalent to (4.9).

As in (3.7), for $i = 1,2$, we write $\bar{u}^i = [\bar{u}_1^i - \bar{u}_3^i] + \bar{u}_2^i + \bar{u}_3^i$.

PROPOSITION 4.7.

$$\begin{aligned}(4.10)\qquad ||\bar{u}^1 - \bar{u}^2|| \le{}& K_{15}||p_0||||H_1 - H_2||^\alpha + K_{12}||p_0||||H_1 - H_2||^\alpha \\ &+K_{13}||p_0'||||h_1 - h_2||^\beta + K_7K_{10}||p_0'||||h_1 - h_2||^\beta\end{aligned}$$

$$\begin{aligned}(4.11)\qquad ||\bar{v}^1 - \bar{v}^2|| \le{}& K_{15}||p_0||||H_1 - H_2||^\alpha + K_{12}||p_0||||H_1 - H_2||^\alpha \\ &+K_{13}||p_0'||||h_1 - h_2||^\beta + K_7K_{10}||p_0'||||h_1 - h_2||^\beta,\end{aligned}$$

where $||p_0'|| = \sup_{y>0}|p_0'(y)|$, K_7, K_{10}, K_{12}, K_{13}, *and* K_{15} *are positive constants, with* $\alpha \in (0,1)$ *and* β *as in Lemma* 4.4.

Proof. Given $H_1(x)$ and $H_2(x)$, define $\bar{H}_1(x) = H_1(x) - 2||H_1 - H_2||$, $\bar{H}_2(x) = H_1(x) + 2||H_1 - H_2||$. Let us decompose D in the following way:

$$\begin{aligned}D_M &= \{(x,y) \in D, |y - H_1(x)| \le 2||H_1 - H_2||\},\\ D_U &= \{(x,y) \in D, y - \bar{H}_2(x) > 0\},\\ D_L &= \{(x,y) \in D, y - \bar{H}_1(x) < 0\}.\end{aligned}$$

$$\begin{aligned}\bar{u}_3^1(x,y)-\bar{u}_3^2(x,y) &= \int\int_{D_L}\frac{(x-s)(p_0(g_1(s,t))-p_0(g_2(s,t)))}{(x-s)^2+(y-t)^2}dtds\\ &\quad+\int\int_{D_M}\frac{(x-s)(p_0(g_1(s,t))-p_0(g_2(s,t)))}{(x-s)^2+(y-t)^2}dtds\\ &\quad+\int\int_{D_U}\frac{(x-s)(p_0(g_1(s,t))-p_0(g_2(s,t)))}{(x-s)^2+(y-t)^2}dtds\\ &\equiv \text{I+II+III}.\end{aligned}$$

For (s,t) in D_L, $p_0(g_1(s,t))=p_0(g_2(s,t))=0$, hence

$$|\text{I}|=0. \tag{4.12}$$

To estimate II we write

$$\begin{aligned}|\text{II}| &\le 2||p_0||\int_0^a\int_{\bar{H}_1(s)}^{\bar{H}_2(s)}\frac{dtds}{\sqrt{(x-s)^2+(y-t)^2}}\\ &\equiv 2||p_0||Q.\end{aligned}$$

Let $\bar{t}=t-\bar{H}_1(s)$, then

$$Q\le\int_0^a\int_0^{\bar{H}_2(s)-\bar{H}_1(s)}\frac{d\bar{t}ds}{\sqrt{(x-s)^2+(y-\bar{t}-\bar{H}_1(s))^2}}.$$

Making the further change of variables $\tau=y-\bar{t}-\bar{H}_1(s)$, $\sigma=x-s$, and setting $d=4||H_1-H_2||$,

$$\begin{aligned}Q &\le \int_{x-a}^{x}\int_{y-\bar{H}_1(x-\sigma)}^{y-\bar{H}_2(x-\sigma)}\frac{d\tau d\sigma}{\sqrt{\sigma^2+\tau^2}}\\ &\le \int_{-a}^{a}\int_{-d/2}^{d/2}\frac{dtds}{\sqrt{s^2+t^2}}\\ &= 4\int_0^a\int_0^d\frac{dtds}{\sqrt{s^2+t^2}}\\ &= 4\int_0^{\tan^{-1}d/a}\int_0^a\sec\theta dr d\theta+4\int_{\tan^{-1}d/a}^{\pi/2}\int_0^{d/2\sin\theta}dr d\theta\\ &\equiv \text{II}_1+\text{II}_2.\end{aligned}$$

Since $0\le\sec\theta\le 2$ in $0\le\theta\le\tan^{-1}d/a$, if $d/a<1$, and $\tan^{-1}d/a<C_7(d/a)^\alpha$ for $0<\alpha<1$, for some constant C_7 depending on α, we have

$$\text{II}_1\le C_8a^{1-\alpha}d^\alpha\equiv C_9d^\alpha.$$

$$\text{II}_2\le\pi d\int_{\tan^{-1}d/2a}^{\frac{\pi}{2}}\frac{1}{\theta}d\theta\le\pi d\left(\ln\frac{\pi}{2}-\ln\frac{d}{2a}\right)\le C_{10}d^\alpha,$$

for some constant C_{10}. Hence

$$|\text{II}|\le 2||p_0||(C_9+C_{10})d^\alpha\equiv K_{15}||p_0||||H_1-H_2||^\alpha. \tag{4.13}$$

It remains to estimate III. In D_U, both $g_1(s,t)$ and $g_2(s,t)$ are positive. They fall in the range in which $p_0(\cdot)$ is differentiable. Using $(R1)$, we see that $|g_1(s,t) - g_2(s,t)| < 1$. Hence we may use Lemma 4.6 to obtain $|p_0(g_1(s,t)) - p(g_2(s,t))| \leq ||p_0'||K_7|h_1 - h_2|^\beta$. Consequently, there is a constant K_{10} such that

$$|\mathrm{III}| \leq K_7 K_{10} ||p_0'|| |h_1 - h_2|^\beta. \tag{4.14}$$

Define

$$\begin{aligned}
&\bar{u}_3^1(x,y) - \bar{u}_3^2(x,y) - (\bar{u}_3^1(x,\bar{y}) - \bar{u}_3^2(x,\bar{y})) \\
&= \int\int_{D_U} (p_0(g_1) - p_0(g_2)) \frac{(y-\bar{y})(s-x)(y+\bar{y}-2t)dsdt}{s + ((x-s)^2 + (y-t)^2)((x-s)^2 + (\bar{y}-t)^2)} \\
&\quad + \int\int_{D_M} (p_0(g_1) - p_0(g_2)) \frac{(y-\bar{y})(s-x)(y+\bar{y}-2t)dsdt}{((x-s)^2 + (y-t)^2)((x-s)^2 + (\bar{y}-t)^2)} \\
&\equiv \mathrm{IV} + \mathrm{V}.
\end{aligned}$$

By Proposition 3.3 there is a constant K_{11} such that

$$|\mathrm{IV}| \leq ||p_0'|| ||g_1 - g_2|| K_{11} |y - \bar{y}| (|\ln |y - \bar{y}|| + 1).$$

By the proof of (4.13), there is a constant K_{12} such that

$$|\mathrm{V}| \leq ||p_0|| ||H_1 - H_2||^\alpha K_{12} |y - \bar{y}| (|\ln |y - \bar{y}|| + 1). \tag{4.15}$$

Finally, using (4.9),

$$|\mathrm{IV}| \leq ||p_0'|| ||h_1 - h_2||^\beta K_{13} |y - \bar{y}| (|\ln |y - \bar{y}|| + 1) \tag{4.16}$$

for some constant K_{13}. With these estimates of (4.12) through (4.16), the quantity $||\bar{u}_3^1 - \bar{u}_3^2||$ has been bounded by the right-hand side of (4.10). The other terms in the decomposition of $\bar{u}^1 - \bar{u}^2$ and $\bar{v}^1 - \bar{v}^2$ could be bounded in the same way, since they are more regular than $\bar{u}_3^1 - \bar{u}_3^2$. This completes the proof.

As a consequence of Propositions 4.3 and 4.7 we have Corollary 4.8.

COROLLARY 4.8. *The mapping T is continuous in $\mathcal{A}$.*

Proof. Inserting estimates (4.1), (4.2) into (4.10) and (4.11), we see that the mapping T is continuous in $\mathcal{A}$.

PROPOSITION 4.9. *There are constants C_6, K_{14} such that*

$$||\bar{u}|| + ||\bar{v}|| \leq 2aC_6 ||p_0|| + 8a||p_0|| + 2aK_{14} ||p_0||.$$

Proof. By the definition of $\bar{u}_3$, since $p(s,t)$ is supported in $[0,a] \times [-2a, 2a]$,

$$\bar{u}_3(x,y) = \int_0^a \int_{-2a}^{2a} p(s,t) k_7(x-s, y-t) dtds.$$

For those (x,y) such that $(y-t)^2 + (x-s)^2 > a^2$ for all (s,t) in $[0,a] \times [-2a, 2a]$ we have

$$\begin{aligned}
|\bar{u}_3(x,y)| &\leq ||p_0|| \int_0^a \int_{-2a}^{2a} \frac{|s-x|}{2\pi((y-t)^2 + (x-s)^2)} dsdt \\
&\leq ||p_0|| \int_0^a \int_{-2a}^{2a} \frac{1}{a\pi} dsdt \leq 4a||p_0||.
\end{aligned}$$

Otherwise, using the polar coordinate centered at (x, y),

$$|\bar{u}_3(x,y)| \le ||p_0|| \int_0^{4a} \int_{-\pi}^{\pi} \frac{1}{2\pi} d\theta dr = 4a||p_0||. \tag{4.17}$$

In either case, we conclude that

$$|\bar{u}_3(x,y)| \le 4a||p_0||. \tag{4.18}$$

Similarly, there is a constant K_{14} such that

$$|\bar{u}_1(x,y) - \bar{u}_3(x,y)| \le aK_{14}||p_0||, \tag{4.19}$$

$$|\bar{u}_2(x,y)| \le aK_{14}||p_0||. \tag{4.20}$$

Applying Proposition 3.3, we achieve

$$|\bar{u}(x,y) - \bar{u}(x,\bar{y})| + |\bar{v}(x,y) - \bar{v}(x,\bar{y})| \le 2aC_6||p_0|||y - \bar{y}|(|\ln|y - \bar{y}|| + 1). \tag{4.21}$$

By inequalities (4.18), (4.19), (4.20), and (4.21) the proof is complete.

In the next section, Proposition 4.9 will be used to show that T is self-mapping from $\mathcal{B}$ into $\mathcal{B}$. With Corollary 4.8 concerning the continuity of the mapping T, the Schauder fixed-point theorem will be applied to obtain the fixed point of T.

5. Proof of Theorem 2.1. First we show that T is a self-mapping on $\mathcal{B}$. Letting $(u, v) \in \mathcal{B}$, we construct $h(x, y_0)$, $H(x) = h(x, 0)$, $g(x, y)$ to obtain $p(x, y) = p_0(g(x, y)) = T_1(u, v)$. We must show that the pair $(\bar{u}, \bar{v}) = T_2(p)$ is in $\mathcal{B}$.

By Proposition 4.9 and choosing a small enough so that

$$2aC_6||p_0|| + 8a||p_0|| + 2aK_{14}||p_0|| \le \tfrac{1}{4}, \tag{R3}$$

for a given $||p_0||$, it follows that $T(\mathcal{B}) \subset \mathcal{B}$. The continuity of the mapping T is verified by the Corollary 4.8. To apply the Schauder fixed-point theorem, T must be a compact mapping from $\mathcal{B}$ into $\mathcal{B}$. To this end, we must show that any sequence in the image of T has a convergent subsequence. Given a sequence (u^j, v^j) in $\mathcal{B}$, through the mapping T_1, we have p_j, $h_j(x, y_0)$,$H_j(x)$, and $g_j(x, y)$; then through the mapping T_2, we end up with the sequence $(\bar{u}^j, \bar{v}^j)$. By the definitions of $h_j(x, y_0)$ and $H_j(x)$, it is easy to obtain

$$|H_j(x) - H_j(\bar{x})| \le C_{11}|x - \bar{x}|,$$

$$|h_j(x, y_0) - h_j(\bar{x}, \bar{y}_0)| \le C_{12}(|x - \bar{x}| + |y - \bar{y}_0|)$$

for some constants C_{11}, C_{12} independent of j. Thus $\{H_j(x)\}$ and $\{h_j(x, y_0)\}$ are equicontinuous families. Since $[0, a]$ is compact, by the Arzela–Ascoli theorem, there is a convergent subsequence $H_k(x)$ in $C[0, a]$. For the sequence $h_k(x, y_0)$, by the same argument, there is a convergent subsequence $h_l(x, y_0)$ in $C([0, a] \times [-2a, 2a])$. Therefore $\{H_l(x)\}$ and $\{h_l(x, y_0)\}$ are Cauchy sequences in the spaces $C[0, a]$, and $C([0, a] \times [-2a, 2a])$, respectively. Now we show that the sequence $(\bar{u}^l, \bar{v}^l)$ is Cauchy in $\mathcal{B}$. Let $R = [0, a] \times [-2a, 2a]$. Applying Proposition 4.7, we have

$$\begin{aligned} ||\bar{u}^{l+m} - \bar{u}^l|| \le{}& K_{15}||p_0||||H_{l+m} - H_l||^{\alpha} + K_7K_{10}||p_0'|| \sup_R |h_{l+m} - h_l|^{\beta} \\ &+ K_{12}||p_0||||H_{l+m} - H_l||^{\alpha} + K_{13}||p_0'|| \sup_R |h_{l+m} - h_l|^{\beta}, \end{aligned}$$

$$||\bar{v}^{l+m} - \bar{v}^{l}|| \leq K_{15}||p_0||||H_{l+m} - H_l||^{\alpha} + K_7 K_{10}||p_0'|| \sup_R |h_{l+m} - h_l|^{\beta}$$
$$+K_{12}||p_0||||H_{l+m}H_l||^{\alpha} + K_{13}||p_0'|| \sup_R |h_{l+m} - h_l|^{\beta}.$$

Hence $(\bar{u}^l, \bar{v}^l)$ is Cauchy in $\mathcal{B}$. Thus T is a continuous compact mapping from $\mathcal{B}$ into $\mathcal{B}$, if a is sufficiently small so that (R1), (R2), and (R3) are fulfilled. The Schauder fixed-point theorem completes the proof.

ON THE OBSTACLE PROBLEM FOR QUASILINEAR ELLIPTIC EQUATIONS OF p LAPLACIAN TYPE*

HI JUN CHOE† AND JOHN L. LEWIS†

Abstract. This article considers an obstacle problem for quasilinear elliptic equations of p Laplacian type. It is shown, under certain smoothness assumptions on the obstacle, that the solution to the corresponding obstacle problem has interior Hölder continuous derivatives.

Key words. p Laplacian, obstacle problem, Hölder continuity of the gradient, interior regularity

AMS(MOS) subject classifications. 35J70, 35J60

1. Introduction. In this paper we consider solutions to an obstacle problem for the following partial differential equation in a bounded domain Ω of Euclidean n space ($\mathbb{R}^n$):

$$\operatorname{div}(|\nabla w|^{p-2}\nabla w) = \hat{b}(x, w, \nabla w), \tag{1.1}$$

when $1 < p < \infty$. Here, ∇w denotes the gradient of w. The left-hand side of this equation is the so-called p Laplacian, and is interesting from a partial differential equation (P.D.E.) standpoint, essentially because of its degeneracy. Thus to obtain the results in this paper we cannot directly apply standard obstacle theorems for uniformly elliptic equations of divergence type.

As for our results, under certain regularity assumptions on $\hat{b}$ and the obstacle $\hat{\psi}$, we shall show that a bounded solution to the obstacle problem for (1.1) has Hölder continuous derivatives on compact subsets of Ω. These results generalize work of Fuchs [2], Lindqvist [6], and Norando [9], who obtained similar regularity results for an obstacle problem corresponding to (1.1) under more restrictive assumptions.

Indeed, Lindqvist assumes $\Omega \subset \mathbb{R}^2$ and uses quasi-conformal mapping techniques. Fuchs and Norando consider only the case when $p > 2$, $\hat{b} \equiv 0$, and $\hat{\psi}$ has essentially bounded distributional second partials in $\mathcal{R}^n[\hat{\psi} \in W_{2,\infty}(\mathbb{R}^n)]$. Moreover, their methods do not appear extendable to the case when $1 < p < 2$. In contrast we assume

(a) $1 < p < \infty$,

(b) $\hat{\psi}$ has distributional second partials on $\mathbb{R}^n$ which are qth power integrable for some $q > n$, i.e.,

$$\hat{\psi} \in W_{2,q}(\mathbb{R}^n), \tag{1.2}$$

(c) For some $c_1 > 0$, $\hat{b}$ satisfies the structure conditions:

$$|\hat{b}(x, z, h)| \leqq c_1(f(x) + |h|^p), \tag{1.3}$$

when $x \in \Omega$ and $(z, h) \in \mathbb{R} \times \mathbb{R}^n$. Here, $f \geqq 0$ is measurable and qth power integrable on $\mathbb{R}^n$ for some $q > n$, i.e.,

$$f \in L_q(\mathbb{R}^n). \tag{1.4}$$

(a)-(c) are well known to be optimal in the classical case, $p = 2$.

Our results are new even for weak subsolutions to (1.1) (so no obstacle is present). Previously DiBenedetto [1] has shown regularity of weak subsolutions to (1.1) when either $f \equiv 0$ in (1.3), or when $|h|^p$ in (1.3) is deleted and $f \in L_{p'n}(\Omega)$, $p' = p/(p-1)$. Also, Tolksdorf [11] obtained regularity as above when $f \equiv 1$ in (1.3).

To get our results we use, among other things, an improved version of a method originally used by Lewis in [5]. We essentially show that a certain function of the gradient of our solution (say $\nabla \hat{u}$) is a subsolution to a uniformly elliptic equation in divergence form, whose right-hand side involves terms in $\hat{\psi}$, f, and a function which satisfies an inequality of reverse Hölder type on balls contained in Ω. Using elliptic theory, we then get an integral inequality for $|\nabla \hat{u}|$ which can be iterated to get Hölder continuity of $\nabla \hat{u}$.

We remark that, as this paper was in preparation, Bill Ziemer informed the authors that Jun Mu has an independent and quite different proof of regularity for the obstacle problem corresponding to (1.1) when $1 < p < \infty$, $\hat{\psi} \in W_{2,\infty}(\mathbb{R}^n)$, and $\hat{b} \equiv 0$. Next, we remark that our arguments apply to more general partial differential equations than (1.1). For example, if $|\nabla w|^{p-2}\nabla w$ is replaced in (1.1) by $A(x, w, \nabla w)$, $A = (A_1, \cdots, A_n)$ and A satisfies the conditions in either [1] or [11], then solutions to the corresponding obstacle problem have the same regularity as for the p Laplacian. Moreover, the proof we give can be adapted to equations with the same principal part as in [3] and [7]. Finally, we emphasize that the ultimate generality of the structure assumptions on $\hat{b}$ in (1.3) forces us to assume our solutions are bounded and makes it considerably difficult to follow more or less standard P.D.E. procedure in approximating by smooth solutions and establishing L_∞ bounds on the gradient.

To be more specific, recall that $\hat{u}$ is a solution to the obstacle problem for (1.1) with obstacle $\hat{\psi}$, provided $\hat{u} \in W_{1,p}(\Omega)$,

$$\hat{u}(x) \geqq \hat{\psi}(x), \qquad x \in \Omega \text{ a.e.}, \tag{1.5}$$

and

$$\int_\Omega [(|\nabla \hat{u}|^{p-2}\nabla \hat{u}) \cdot \nabla \eta + \hat{b}(x, \hat{u}, \nabla \hat{u})\eta]\, dx \geqq 0, \tag{1.6}$$

whenever $\eta \in C_0^\infty(\Omega)$ with $\hat{u} + \eta \geqq \hat{\psi}$ (almost everywhere in Ω), and so in particular when $\eta \geqq 0$. We prove the following theorem.

THEOREM 1. *Let $\Omega \subset \mathbb{R}^n$ be a bounded domain and E a given compact subset of Ω. For fixed p, $1 < p < \infty$, suppose $\hat{u}$, $\hat{\psi}$, $\hat{b}$, f, satisfy* (1.2)-(1.6), *and*

$$|\hat{u}(x)| \leqq c_2 < \infty, \qquad x \in \Omega. \tag{1.7}$$

Then $\hat{u}$ has a representative in $W_{1,p}(\Omega)$ with continuous derivatives and for this representative: Given E, a compact subset of Ω, there exists $\alpha \in (0, 1)$, and $c < \infty$, depending only on p, n, q, c_1, c_2, $\|\hat{\psi}\|_{2,q}$, $\|f\|_q$, and the distance from E to the boundary of Ω such that

$$\max_{x \in E} |\nabla \hat{u}(x)| \leqq c,$$

$$|\nabla \hat{u}(x) - \nabla \hat{u}(y)| \leqq c|x - y|^\alpha, \qquad x, y \in E.$$

In Theorem 1, $\|\cdot\|_{2,q}$ and $\|\cdot\|_q$, denote the norm in $W_{2,q}(\mathbb{R}^n)$ and $L_q(\mathbb{R}^n)$, respectively. In the sequel, we shall let c denote a positive constant, with the same dependence as in Theorem 1, not necessarily the same at each occurrence. We say that c depends on the data. Also a denotes a positive constant depending only on p and n, not necessarily the same at each occurrence. As for our proof, let $\delta(F_1, F_2)$ denote the

distance between the sets F_1, F_2, and $B(x, R)=\{y: |y-x|<R\}$. If $0<\varepsilon\leqq 1/10 \min[\delta(E, \partial\Omega), 1]$ then we first consider functions $u=u(\cdot, \varepsilon)$, $\psi=\psi(\cdot, \varepsilon)$, such that $\psi\in C^\infty(\mathbb{R}^n)$, where (1.2), (1.5) hold with $\hat{u}$, $\hat{\psi}$ replaced by u, ψ, and Ω by $B=B(x_0, R_0)$. Also, $x_0\in E$ and $0<R_0\leqq 1/10 \min[\delta(E, \partial\Omega), 1]$. Moreover,

$$\|\psi\|_{2,q}\leqq c\|\hat{\psi}\|_{2,q} \tag{1.8}$$

and

$$\int_B [(\varepsilon+|\nabla u|^2)^{(p/2-1)}\nabla u\cdot\nabla\eta+b_\varepsilon(x, u, \nabla u)\eta]\,dx\geqq 0 \tag{1.9}$$

whenever $\eta\in \dot{W}_{1,p}(\Omega)$ with $u+\eta\geqq\psi$ almost everywhere in B. Here $\dot{W}_{1,p}(\Omega)$ denotes the closure of $C_0^\infty(\Omega)$ in the norm of $W_{1,p}(\Omega)$, and

$$|b_\varepsilon(x, z, h)|\leqq 2c_1 \min\left[\frac{1}{\varepsilon}, f(x)+|h|^p\right], \tag{1.10}$$

when $(x, z, h)\in\Omega\times\mathbb{R}\times\mathbb{R}^n$ (c_1 as in (1.3)). Next we suppose for fixed ε as above,

$$|u(x)|\leqq c_3, \qquad x\in B, \tag{1.11}$$

where c_3 depends only on the data.

We note that (1.9) is easier to work with than (1.6), since $u=u(\cdot, \varepsilon)$ is a supersolution to a nondegenerate elliptic equation. In § 2 we make some preliminary remarks concerning Hölder continuity of u, $\hat{u}$, and point out that a difference quotient argument of Tolksdorf can be used to show for fixed σ, $0<\sigma<1$, ε, and R_0 as above that $u\in W_{2,2}[B(x_0, \sigma R_0)]$ and $|\nabla u|\in L_\infty[B(x_0, \sigma R_0)]$. In § 3, we obtain L_∞ estimates on $|\nabla u|$ in $B(x_0, \sigma R_0)$ which depend only on σ, R_0, and the data (i.e., the same quantities as c in Theorem 1). Thus our estimates are independent of ε, $0<\varepsilon<1/10 \min[1, \delta(E, \partial\Omega)]$. In §§ 4 and 5 we use the argument of Lewis, mentioned earlier, to obtain Theorem 1 with $\hat{u}$ replaced by $u(\cdot, \varepsilon)$, $\Omega=B$, $E=B(x_0, \sigma R_0)$, and constants which depend only on σ, R_0 and the data. In § 6 we show the existence of $u=u(\cdot, \varepsilon)$ for $R_0>0$ sufficiently small (depending only on the data). We then let $\varepsilon\to 0$ and get Theorem 1 from local uniqueness type arguments and our previous work.

2. Preliminary reductions. Let $u=u(\cdot, \varepsilon)$, $b=b_\varepsilon$, and $\psi=\psi(\cdot, \varepsilon)$ be as in § 1 for fixed ε, R_0, with $0<\varepsilon$, $R_0<1/10 \min[1, \delta(E, \partial\Omega)]$ and p, $1<p<\infty$. Then $u\in W_{1,p}(B)$ and u, ψ, satisfy (1.2), (1.5), with $\hat{u}$, $\hat{\psi}$, replaced by u, ψ, and also (1.8)-(1.11). For $\hat{u}$ in Theorem 1 we claim there exists c, $\bar{\lambda}>0$, depending only on the data, such that $\hat{u}$ has a representative in $W_{1,p}(\Omega)$ with

$$|\hat{u}(x)-\hat{u}(y)|\leqq c|x-y|^{\bar{\lambda}}, \tag{2.1a}$$

whenever

$$\max[\delta(\{x\}, E), \delta(\{y\}, E)]\leqq\tfrac{1}{2}\delta(E, \partial\Omega).$$

We also claim for $\varepsilon>0$ as above and fixed σ, $0<\sigma<1$, that there exists d, $\lambda>0$ depending only on σ, R_0, and the data such that

$$|u(x)-u(y)|\leqq d|x-y|^{\lambda}, \tag{2.1b}$$

whenever $x, y\in B_1=B(x_0, R_1)$. Here, $R_1=(1/100)(99+\sigma)R_0$. To prove (2.1) observe from Sobolev's theorem that

$$|\nabla\psi(x)-\nabla\psi(y)|\leqq c\|\psi\|_{2,q}|x-y|^{(1-n/q)}, \tag{2.2}$$

$x, y \in \mathbb{R}^n$. Inequality (2.1) now follows from (2.2) and the argument in [8] with slight modification. Essentially the modification consists in using the estimates for bounded sub- and supersolutions in [12] rather than those in [10]. We omit the details. We assume, as we may, that $0<\lambda$, $\bar{\lambda}<\min[\frac{1}{4}, 1-(n/q)]$. In the rest of this section and §§ 3–5, σ and R_0 will be fixed. We let d denote a positive constant which may depend only on σ, R_0, and the same quantities as c in Theorem 1 (the data), not necessarily the same at each occurrence.

With ε still fixed as above, let $K=\{x: u(x)=\psi(x)\}$, and observe from (2.1b) that K is relatively closed in B. For fixed e in $\mathbb{R}^n$ with $|e|=1$, $h>0$, and g a function on $\mathbb{R}^n$, put

$$\tau_h g(x)=[g(x+he)-g(x)]/h, \qquad x\in\mathbb{R}^n,$$

$$\tau_{\bar{h}} g(x)=[g(x-he)-g(x)]/h, \qquad x\in\mathbb{R}^n.$$

Let $\xi(\gamma)=(\varepsilon+|\gamma|^2)^{(p/2-1)}\gamma$, $\gamma\in\mathbb{R}^n$, and note that

$$(\xi(\gamma)-\xi(\gamma'))\cdot(\gamma-\gamma')\geqq a(\varepsilon+|\gamma|+|\gamma'|)^{(p-2)}|\gamma-\gamma'|^2, \tag{2.3}$$

when $\gamma, \gamma'\in\mathbb{R}^n$, where $a=a(p,n)$ depends only on p and n. Next, let $\phi\in C_0^\infty[B]$ and put $A^+=\max(A,0)$. Since, $(u-\psi-\beta)^+\phi$ vanishes in a neighborhood of $K\cap\bar{B}$ for each $\beta>0$, we see upon letting $\beta\to 0$ that equality holds in (1.9) for $\eta=(u-\psi)\phi$. If $0<h<((1-\sigma)/400)R_0$, it follows from this observation and (1.9) that

$$\int_B \{\tau_h[\xi(\nabla u)]\cdot\nabla\tau_h(\eta)+\tau_{\bar{h}}[\tau_h(\eta)]b\}\,dx\leqq 0. \tag{2.4}$$

Using this inequality, (2.3), and arguing as in Tolksdorf [11, § 2.2] we deduce first that $u\in W_{2,2}[B_1]$ for $p\geqq 2$ and $u\in W_{2,p}[B_1]$ for $1<p\leqq 2$. Second, it follows as in [11, § 2.3] that $\nabla u\in L_\infty[B_1]$ for $1<p<\infty$ and thereupon that $u\in W_{2,2}(B_1)$ for $1<p<\infty$. Here the norm of u, ∇u, in each space may depend in addition to R_0, σ, and the data, on ε, the smoothness of ψ, and $\|b\|_\infty$. Additional terms in the iteration due to the obstacle are easily handled using the smoothness of ψ. Again we omit the details.

From the above facts and (1.9) we see that

$$\nabla\cdot[\xi(\nabla u(x))]-b(x,u,\nabla u)=0 \quad \text{for a.e. } x\in B_1-K. \tag{2.5}$$

Let $g_e=\nabla g\cdot e$, $e\in\mathbb{R}^n$, $|e|=1$. Then from (2.5) and integration by parts we get

$$\int[\xi(\nabla u)]_e\cdot\nabla\eta\,dx=\int(\nabla\cdot\bar{\xi})\eta_e\,dx=\int_{B_1-K} b\eta_e\,dx+\int_K(\nabla\cdot\bar{\xi})\eta_e\,dx, \tag{2.6}$$

where $\bar{\xi}(x)=\xi(\nabla u(x))$ in the last two integrals and $\eta\in\dot{W}_{1,2}[B_1]$. For almost every $x\in B_1$ we note that the ith component of $\bar{\xi}_e$ at x is

$$(\bar{\xi}_e)_i=a_{ij}(\nabla u)(u_e)_{x_j}, \qquad 1\leqq i\leqq n, \tag{2.7}$$

where repeated indexes denote summation from 1 to n and

$$a_{ij}(\gamma)=(\varepsilon+|\gamma|^2)^{(p/2-2)}[(p-2)\gamma_i\gamma_j+\delta_{ij}(\varepsilon+|\gamma|^2)] \tag{2.8}$$

for $1\leqq i, j\leqq n$, $\gamma\in\mathbb{R}^n$. In (2.8), δ_{ij} is the Kronnecker δ. Also for $\mu=(\mu_1,\cdots,\mu_n)\in\mathbb{R}^n$,

$$a_1(\varepsilon+|\gamma|^2)^{(p/2-1)}|\mu|^2\leqq a_{ij}(\gamma)\mu_i\mu_j\leqq a_2(\varepsilon+|\gamma|^2)^{(p/2-1)}|\mu|^2 \tag{2.9}$$

for some $a_1=a_1(p,n)$, $a_2=a_2(p,n)>0$.

3. L_∞ estimates on $|\nabla u|$. Let $R_2=(1/25)(24+\sigma)R_0$ and put $B_2=B(x_0,R_2)$. In this section we prove the following lemma.

LEMMA 1. *For R_0, ε, σ, p fixed as in* § 2,

$$\operatorname{ess.max}_{x\in B_2} |\nabla u(x)| \leqq d. \tag{3.1}$$

To prove (3.1) we use Moser iteration. We will need some notation. Let $\bar{E}$, ∂E, $|E|$, denote, respectively, the closure, boundary, and outer Lebesgue measure of E. If g is a function on $B(x, r)$, $r>0$, put

$$\fint_{B(x,r)} g\,dx = |B(x,r)|^{-1}\int_{B(x,r)} g\,dx,$$

$$M(r, g) = M(r, g, x) = \operatorname{ess.max}_{y\in B(x,r)} g(y).$$

The proof consists of two parts. In the first part we essentially estimate $M(R_2, |\nabla u|)$ in terms of the L_μ norm of ∇u over $B_3 = B(x_0, R_3)$, where $R_3 = (1/50)(49+\sigma)R_0$. Here, $\mu = \mu(p, n)$. The second part of the proof consists of estimating this norm in terms of the L_p norm of $|\nabla u|$ and ultimately in terms of the Hölder norm of u in B_1. Since the proof is more or less standard (see [1, § 3] or [11, § 3]), we will omit many details. Let $0<R<((1-\sigma)R_0)/1{,}000)$, $z\in B(x_0, R_2)$, $16R<\rho<t<32R$, $\phi\in C_0^\infty[B(z,t)]$, and $\phi\equiv 1$ on $B(z,\rho)$ with $|\nabla\phi|\leqq 1{,}000/(t-\rho)$. Let $w(x)=(\varepsilon+|\nabla u|^2)(x)$, $x\in B$, and let $\theta\geqq 0$ be a nondecreasing Lipschitz function on $\mathbb{R}$. We put $\eta(x)=u_e(x)\theta[w(x)]\phi^2(x)$ in (2.6) and use (2.7)-(2.9) with $e=e(k)$, $1\leqq k\leqq n$, where $\{e(k), 1\leqq k\leqq n\}$ is an orthonormal set of coordinate vectors. Summing, we get

$$\begin{aligned} I_1 &= \int w^{(p/2-1)}\left[\sum_i |\nabla u_{x_i}|^2\theta(w)+\theta'(w)|\nabla w|^2\right]\phi^2\,dx \\ &\leqq a\int w^{(p/2-1)}\theta(w)|u_{x_i}|\left(\sum_j |u_{x_ix_j}|\right)|\nabla\phi|\phi\,dx \\ &\quad + ac_1\int w^{p/2}|\nabla\eta|\,dx + ac_1\int f|\nabla\eta|\,dx + a\int_K |\nabla\cdot\xi||\nabla\eta|\,dx = I_2, \end{aligned} \tag{3.2}$$

where $a=a(p,n)$ and we have used (1.10). We first let $\theta(w)=w^s$, $s\geqq\frac{1}{2}(p+1)$ in (3.2). From

$$\begin{aligned} w^{p/2}|\nabla\eta| &\leqq w^{p/2}\{[|u_{x_ix_i}|w^s + sw^{(s-1)}|\nabla u||\nabla w|]\phi^2 + 2|\nabla u|w^s\phi|\nabla\phi|\} \\ &\leqq (4ac_1)^{-1}w^{(p/2-1)}\left[sw^{(s-1)}|\nabla w|^2 + \left(\sum_i |\nabla u_{x_i}|^2\right)w^s\right]\phi^2 \\ &\quad + a(c_1+1)[(s+1)w^{(p/2+s+1)}\phi^2 + w^{(p/2+s)}|\nabla\phi|^2], \end{aligned} \tag{3.3}$$

and Hölder's inequality, it follows that for a large enough

$$\begin{aligned} I_2 - \frac{1}{2}I_1 &\leqq c\left[\int (|\nabla\phi|^2+(s+1)w\phi^2)w^{(p/2+s)}\,dx\right] + c(s+1)\left(\int f^2 w^{(s-p/2+1)}\phi^2\,dx\right) \\ &\quad + csM(R_0, 1+|\nabla\psi|^2)^{s+p/2}\left\|\sum_{i,j}\psi_{x_ix_j}\phi\right\|_2^2 = I_3. \end{aligned} \tag{3.4}$$

In the last term of (3.4), the maximum of $1+|\nabla\psi|^2$ is relative to $B(x_0, R_0)$. Also,

$$I_1 \geqq as\int w^{(s+p/2-2)}|\nabla w|^2\phi^2\,dx \geqq as^{-1}\left(\int |\nabla w^{(s/2+p/4)}|^2\phi^2\,dx\right). \tag{3.5}$$

Combining (3.2), (3.4), and (3.5), we get

$$\|\nabla[w^{(s/2+p/4)}\phi]\|_2^2 \leqq c(s+1)I_3. \tag{3.6}$$

Let $2^* = 2n/(n-2)$, when $n > 2$. Then it follows from (3.6) and Sobolev's theorem when $n > 2$ that

$$\|w^{(s/2+p/4)}\phi\|_{2^*} \leqq c(s+1)^{1/2} I_3^{1/2}. \tag{3.7}$$

Let $\tilde{q} = \min(q, n/(1-\lambda))$ and $\bar{q} = 2\tilde{q}/(\tilde{q}-2) < 2^*$. Now using Hölder's inequality again we see from (3.7) that for $n > 2$ and $s \geqq (p+1)/2$,

$$\begin{aligned} &c(s+1)^{-1/2} R^{-n/2^*} \|w^{(s/2+p/4)}\phi\|_{2^*} \\ &\leqq J(\rho, t, R)\left[\fint_{B(z,t)} w^{(p/4+s/2)\bar{q}}\, dx\right]^{1/\bar{q}} + c^{(p/4+s/2)} k(R), \end{aligned} \tag{3.8}$$

where $\bar{f} = f + 1$,

$$k(R) = c\left[R^{(\tilde{q}-n)} \int_{B(z,32R)} \left\{\bar{f}^{\tilde{q}} + \sum_{i,j} |\psi_{x_i x_j}|^{\tilde{q}}\right\} dx\right]^{1/\tilde{q}},$$

and

$$J(\rho, t, R) = cR\left\{(t-\rho)^{-1} + \left[\int_{B(z,32R)} w^{\tilde{q}/2}\, dx\right]^{1/\tilde{q}}\right\} + k(R).$$

If $n = 2$ put $2^* = 2\bar{q}$. Then $w^{(p/4+s/2)}\phi$ is of bounded mean oscillation in $\mathbb{R}^2$(BMO) with BMO norm less than or equal to $a\|\nabla[w^{(p/4+s/2)}\phi]\|_2$. Using this fact and arguments similar to the above, we find that (3.8) is still true. We note from our assumptions on ρ, t that

$$k(R) \leqq cR^{(1-n/\tilde{q})} \leqq cR_0^{(1-n/\tilde{q})} = d. \tag{3.9}$$

From (3.9) it follows for properly chosen ρ, t, that (3.8) can be iterated in the usual way starting with $s = (p+1)/2$. Doing this we get

$$M(16R, w) \leqq \left[1 + \left(\int_{B(z,32R)} w^{\tilde{q}/2}\, dx\right)^{1/\tilde{q}}\right]^c \left[\fint_{B(z,20R)} (w+d)^\tau\, dx\right]^{1/\tau}, \tag{3.10}$$

where $\tau = (p + \frac{1}{2})\bar{q}/2$. From (3.10) we see that in order to prove (3.1) it suffices to show there exists $R = R(d) > 0$ such that

$$\left(\fint_{B(z,20R)} w^\alpha\, dx\right)^{1/\alpha} \leqq d(R)^{(2\lambda-2)}, \tag{3.11}$$

where $\alpha = \max[\tilde{q}/2, \tau]$. Indeed, from our choice of $\tilde{q}$, we then get

$$\int_{B(z,20R)} w^{\tilde{q}/2}\, dx \leqq dR^{[(\lambda-1)\tilde{q}+n]} \leqq d.$$

To prove (3.11) we need to estimate the term $\int w^{p/2+s+1}\phi^2\, dx$ in (3.4) in a different way. To do this we consider two cases depending on whether (A) $B(z, 64R) \cap K \neq \{\phi\}$ or (B) $B(z, 64R) \cap K = \{\phi\}$. If (A) holds we put $\eta = (u-\psi)\sigma(w)\phi^2$ in (1.9) where $\sigma(w) = (w^{s+1}-1)^+$, and use Hölder continuity of u, ψ, as well as Hölder's inequality, to get for $\tilde{w} = \max(w, 1)$, $0 < s \leqq \alpha$, and $R = R(d) > 0$ small enough that

$$\begin{aligned} L_1 = \int \tilde{w}^{(p/2+s+1)}\phi^2\, dx &\leqq dR^{2\lambda}\tilde{I}_1 + dR^{2\lambda} \int_{\{w \geqq 1\}} f^2 w^{(s+1-p/2)}\phi^2\, dx \\ &\quad + [dR^{2\lambda}(t-\rho)^{-2} + d]\left(\int_{B(z,t)} \tilde{w}^{(p/2+s)}\, dx\right) + dR^n, \end{aligned} \tag{3.12}$$

where $\tilde{I}_1 = \int_{\{w \geqq 1\}} w^{(p/2+s-2)} |\nabla w|^2 \phi^2 \, dx$. Next put $\theta(w) = [w^s - 1]^+$ in (3.2), $(p/2)((2^*/2)-1) \leqq s \leqq \alpha$. Arguing as in (3.2), (3.4), (3.5), and using (3.12), it follows for $R = R(d) > 0$ small enough that

$$\begin{aligned}\int |\nabla[\tilde{w}^{(s/2+p/4)}\phi]|^2 \, dx &\leqq d(t-\rho)^{-2}\left(\int_{B(z,t)} \tilde{w}^{(p/2+s)} \, dx\right) \\ &\quad + d\left[\int (f\phi)^2 \tilde{w}^{(p/2+s)} \, dx\right] \\ &\quad + d\left[\int_{B(z,t)} \sum_{i,j} (\psi_{x_i x_j})^2 \, dx\right] + dR^n.\end{aligned}$$

This inequality and Sobolev's and Hölder's inequalities imply as in (3.8) that for $(p/2)((2^*/2)-1) \leqq s \leqq \alpha$,

$$\begin{aligned} &R^{-n/2^*} \| \tilde{w}^{(s/2+p/4)}\phi \|_{2^*} \\ &\quad \leqq k(R)\left[\fint \phi^{\tilde{q}} \tilde{w}^{(p/4+s/2)\tilde{q}} \, dx\right]^{1/\tilde{q}} \\ &\quad\quad + dR(t-\rho)^{-1}\left[\fint_{B(z,t)} \tilde{w}^{(s+p/2)} \, dx\right]^{1/2} + k(R) \\ &\quad \leqq dR(t-\rho)^{-1}\left[\fint_{B(z,t)} \tilde{w}^{(s+p/2)} \, dx\right]^{1/2} + k(R)\end{aligned} \tag{3.14}$$

for R small, since (3.9) holds and $\tilde{q} < 2^*$. Now iterate (3.14), starting with $s = ((2^*/2)-1)(p/2)$. After at most $N = N(c)$ times, we obtain

$$\left(\fint_{B(z,20R)} \tilde{w}^{\alpha} \, dx\right)^{1/\alpha} \leqq d\left[\fint_{B(z,22R)} \tilde{w}^{(2^*p/4)} \, dx\right]^{4/(2^*p)} + dk(R). \tag{3.15}$$

Finally to estimate the right-hand side of (3.15) let

$$\begin{aligned} \bar{u}_{x_k} &= [u_{x_k} - (4n)^{-1}]^+, \qquad 1 \leqq k \leqq n, \\ u^*_{x_k} &= [-u_{x_k} - (4n)^{-1}]^+, \qquad 1 \leqq k \leqq n. \end{aligned}$$

First put $\eta = \bar{u}_{x_k}\phi^2$ in (2.6). By using (2.7)-(2.9) and summing, it follows that (3.2) is valid with $\theta(w) \equiv 1$ and u_{x_k} replaced by $\bar{u}_{x_k}$. Let $\bar{I}_1$ denote the left-hand side of (3.2) in this case. Using (3.2), (3.3), we get (3.4) with $s = 0$ and w replaced by $\tilde{w}$. To estimate, $\int \tilde{w}^{p/2+1}\phi^2 \, dx$, on the right-hand side of (3.4), put $(u-\psi)(\bar{u}_{x_k})^2\phi^2$, $1 \leqq k \leqq n$, in (1.9). Summing, we obtain an inequality analogous to (3.12) with $\tilde{I}_1$, L_1, replaced by $\bar{I}_1$ and

$$\bar{L}_1 = \sum_{k=1}^{n} \int w^{p/2}(\bar{u}_{x_k})^2\phi^2 \, dx.$$

Carrying out the same program for $u^*_{x_k}$, we obtain similar inequalities for L_1^*, I_1^*, which we define as above with $\bar{u}_{x_k}$ replaced by $u^*_{x_k}$. Now if $w > 1$, $0 < \varepsilon < \frac{1}{4}$, then for some k either $\bar{u}_{x_k} > (1/4n)w^{1/2}$ or $u^*_{x_k} > (1/4n)w^{1/2}$. From this fact and the above inequalities it follows that

$$\begin{aligned}\int \tilde{w}^{(p/2+1)}\phi^2 \, dx &\leqq c(R^n + \bar{L}_1 + L_1^*) \\ &\leqq dR^{2\lambda}(\bar{I}_1 + I_1^*) + [dR^{2\lambda}(t-\rho)^{-2} + d]\left(\int_{B(z,t)} \tilde{w}^{p/2} \, dx\right) \\ &\quad + dR^{2\lambda}\left(\int f^2 \tilde{w}^{(s+p/2)}\phi^2 \, dx\right) + dR^n.\end{aligned}$$

Using this inequality in the new versions of (3.2), we find that (3.13) is valid with $s=0$. From Sobolev's inequality, we conclude for properly chosen ϕ and $R=R(d)>0$ small enough that

$$\left[\fint_{B(z,22R)} \tilde{w}^{(2^*p)/4}\,dx\right]^{1/2^*} \leqq d\left[\fint_{B(z,24R)} \tilde{w}^{p/2}\,dx\right]^{1/2}. \tag{3.16}$$

The right-hand side of (3.16) can be estimated using $\eta=(u-\psi)\phi^p$ in (1.9). Doing this we deduce

$$\left(\fint \tilde{w}^{p/2}\,dx\right)^{1/2} \leqq dR^{p(1-\lambda)/2}. \tag{3.17}$$

Clearly (3.17), (3.16), and (3.15) imply (3.11) in case A. A similar proof holds in case B. We omit the details. The proof of Lemma 1 is now complete.

4. Reverse Hölder inequalities. In this section and § 5, we use a modification of the argument in [5, §§ 2–3]. The reader is advised to have this paper on hand, as we will often refer to it. We continue with the same notation as in §§ 2 and 3. Let $m=\max[p/2, 1]$, $s=m+p/2$, and put $v=w^s$. Let

$$b_{ij}(\gamma)=(\varepsilon+|\gamma|^2)^{(1-p/2)}a_{ij}(\gamma), \qquad \gamma\in\mathfrak{R}^n, \tag{4.1}$$

$1\leqq i, j\leqq n$, where a_{ij} is as in (2.8). We also put $\bar{\xi}(x)=\xi(\nabla u)(x)$ as in § 2 and

$$g_0(x)=(2s)[w^m(\bar{\xi}_{x_k}\cdot\nabla u_{x_k})+mw^{m-1}u_{x_k}(\bar{\xi}_{x_k}\cdot\nabla w)],$$

where repeated indices denote summation from 1 to n. Next put

$$g_1(x)=(2s)[b\chi_{\cdot(B_1-K)}+(\nabla\cdot\bar{\xi})\chi_{\cdot K}](u_{x_lx_l}w^m+mu_{x_l}w_{x_l}w^{(m-1)})$$

$$g_{l+1}(x)=(2s)[b\chi_{\cdot(B_1-K)}+(\nabla\cdot\bar{\xi})\chi_{\cdot K}](u_{x_l}w^m), \qquad 1\leqq l\leqq n.$$

Here, $\chi_{\cdot E}$ denotes the characteristic function of E. From (2.9) we see that

$$a^{-1}w^{(s-1)}\left(\sum_i |\nabla u_{x_i}|^2\right)\leqq g_0\leqq aw^{(s-1)}\left(\sum_i |\nabla u_{x_i}|^2\right) \tag{4.2}$$

for some $a=a(p, n)$. We prove the following lemma.

LEMMA 2. *If $\phi\in W_{1,2}(B_1)$ and $\bar{b}_{ij}(x)=b_{ij}(\nabla u(x))$, then*

$$\int \bar{b}_{ij}v_{x_j}\phi_{x_i}\,dx=\int(-g_0+g_1)\phi\,dx+\sum_{k=1}^{n}\int\phi_{x_k}g_{k+1}\,dx. \tag{4.3}$$

To prove (4.3) we put $\eta=u_{x_k}w^m\phi$ in (2.6) and choose $e=e(k)$ as in § 3. Summing, we find that

$$\begin{aligned} J_1&=\int[w^m(\bar{\xi}_{x_k}\cdot\nabla u_{x_k})+mw^{(m-1)}u_{x_k}(\bar{\xi}_{x_k}\cdot\nabla w)]\phi\,dx \\ &=-\int(u_{x_k}w^m)(\bar{\xi}_{x_k}\cdot\nabla\phi)\,dx+\int_{B_1-K}b\left(\sum_k\eta_{x_k}\right)dx+\int_K(\nabla\cdot\bar{\xi})\left(\sum_k\eta_{x_k}\right)dx \\ &=J_2+J_3+J_4. \end{aligned} \tag{4.4}$$

Now,

$$\int g_0\phi\,dx=(2s)J_1. \tag{4.5}$$

Next observe that if $\overline{a_{ij}}(x) = a_{ij}(\nabla u(x))$, then

$$\bar{b}_{ij} v_{x_j} = 2sw^{(s-1)} u_{x_k} (\bar{b}_{ij} u_{x_k x_j}) = 2sw^{(s-p/2)} u_{x_k} (\overline{a_{ij}} u_{x_k x_j}) = 2sw^m u_{x_k} (\bar{\xi}_{x_k})_i,$$

where $(\bar{\xi}_{x_k})_i$ denotes the ith component of $\bar{\xi}_{x_k}$. Using this observation, we obtain

$$-2sJ_2 = \int \bar{b}_{ij} v_{x_j} \phi_{x_i} \, dx. \tag{4.6}$$

Also,

$$\sum_k \eta_{x_k} = u_{x_k x_k} w^m \phi + m u_{x_k} w_{x_k} w^{(m-1)} \phi + u_{x_k} w^m \phi_{x_k}.$$

We put the right-hand side of this equality in the integrals defining J_3, J_4. Using (4.5), (4.6), and rearranging terms, we get Lemma 2. Next let $v_k = u_{x_k} w^{(s-1/2)}$, $1 \leqq k \leqq n$. We shall also need the following lemma.

LEMMA 3. *If* $\phi \in \dot{W}_{1,2}(B_1)$, *then for* $1 \leqq k \leqq n$

$$\left| \int \bar{b}_{ij} (v_k)_{x_j} \phi_{x_i} \, dx \leqq a \int (g_0 + G_0) |\phi| \, dx + a \int |\nabla \phi| G \, dx. \right. \tag{4.7}$$

Here $G_0(x) = (|b| \chi_{\cdot(B_1 - K)} + |\nabla \cdot \bar{\xi}| \chi_{\cdot K})(w^m \sum_{i,j} |u_{x_i x_j}|)$,

$$G(x) = [|b| \chi_{\cdot(B_1 - K)} + |\nabla \cdot \bar{\xi}| \chi_{\cdot K}] w^{m+1/2}.$$

The proof of Lemma 3 is similar to the proof of Lemma 2. We omit the details. Next we prove Lemma 4.

LEMMA 4. *There exists* $\beta = \beta(c)$, $0 < \beta < \frac{1}{4} \min(q/n - 1, 1)$ *with the property*: *If* $0 < R < ((1-\sigma)/1{,}000) R_0$, $z \in B_2$, *then*

$$\fint_{B(z,R)} g_0^{1+\beta} \, dx \leqq c \left(\fint_{B(z,2R)} g_0 \, dx \right)^{1+\beta} + c \fint_{B(z,2R)} E^{1+\beta} \, dx, \tag{4.8}$$

where $E = \tilde{w}^{(m-p/2+1)} \{ |b|^2 + \sum_{i,j} (\psi_{x_i x_j})^2 \}$.

Proof. In Lemma 4, $\tilde{w} = \max(w, 1)$ as usual. We begin by choosing orthonormal vectors $e_1, \cdots, e_{n-1}$ such that

$$\int_{B(z,3R/2)} w^{(m/2+p/4-1/2)} u_{e_k} \, dx = 0, \qquad 1 \leqq k \leqq n-1. \tag{4.9}$$

This choice is possible since if A_k denotes the integral in (4.9) with e_k replaced by x_k, $1 \leqq k \leqq n$, then the solutions to $A_i y_i = 0$ span at least an $(n-1)$-dimensional plane. Now if $e \in \{e_k\}$ we have as in (3.2) and (4.4) for $\eta = u_e w^m \phi^2$, $\phi \in C_0^\infty[B(z, 3R/2)]$,

$$\begin{aligned} H_1 = \int w^m (\bar{\xi}_e \cdot \nabla u_e) \phi^2 \, dx &\leqq \left| \int m w^{(m-1)} u_e (\bar{\xi}_e \cdot \nabla w) \phi^2 \, dx \right| \\ &+ \left| 2 \int \phi u_e w^m (\bar{\xi}_e \cdot \nabla \phi) \, dx \right| + \left| \int_{B_1 - K} b \eta_e \, dx \right| + \left| \int_K (\nabla \cdot \bar{\xi}) \eta_e \, dx \right| = H_2. \end{aligned} \tag{4.10}$$

We estimate H_2 slightly different than I_2 in § 3. Indeed, using Hölder's inequality once again, we deduce for given τ, $0 < \tau < \frac{1}{4}$,

$$\begin{aligned} H_2 - \frac{1}{2} H_1 &\leqq a\tau \int g_0 \phi^2 \, dx + a\tau^{(1-2m)} \int |u_e|^{2m} w^{(p/2-1)} |\nabla u_e|^2 \phi^2 \, dx \\ &+ a \int w^{(s-1)} (u_e)^2 |\nabla \phi|^2 \, dx + c\tau^{-1} \int E \phi^2 \, dx = H_3. \end{aligned} \tag{4.11}$$

Using (4.10), (4.11), and summing, we find that

$$\bar{H}_1 = \sum_{k=1}^{n-1} \int w^{(s-1)} |\nabla u_{e_k}|^2 \phi^2 \, dx \leqq \bar{H}_3, \tag{4.12}$$

where $\bar{H}_3$ is obtained from H_3 by summing over $e \in \{e_k\}$. If e_n is orthogonal to $\{e_k : 1 \leqq k \leqq n-1\}$ and of unit length, then from (4.2) we get

$$\int g_0 \phi^2 \, dx \leqq a\bar{H}_1 + a \int w^{(s-1)} (u_{e_n e_n})^2 \phi^2 \, dx. \tag{4.13}$$

Now for almost every $x \in B_1 - K$ we see from (2.5) that

$$w^{(s-1)} (u_{e_n e_n})^2 \leqq a w^{(m+1-p/2)} |b|^2 + a w^{(s-1)} \sum_{i=1}^{n} \sum_{j=1}^{n-1} (u_{e_i e_j})^2,$$

while if $x \in K$,

$$w^{(s-1)} (u_{e_n e_n})^2 \leqq c \sum_{i,j} (\psi_{x_i x_j})^2.$$

These inequalities and (4.13) imply that

$$\int g_0 \phi^2 \, dx \leqq a\bar{H}_1 + c \int E\phi^2 \, dx.$$

Putting this inequality in (4.12) we see for $\tau = \tau(a) > 0$ small enough that

$$\begin{aligned} \int g_0 \phi^2 \, dx \leqq c\tau^{(1-2m)} \sum_{k=1}^{n-1} \int |u_e|^{2m} w^{(p/2-1)} |\nabla u_e|^2 \phi^2 \, dx \\ \cdot \sum_{k=1}^{n-1} c \int w^{(s-1)} (u_e)^2 |\nabla \phi|^2 \, dx + c\tau^{-1} \int E\phi^2 \, dx. \end{aligned} \tag{4.14}$$

With $\tau = \tau(a)$ now fixed we can estimate the first term on the right-hand side of (4.14) by first putting $\eta = [(u_e)^+]^{(2m+1)} \phi^2$ in (2.6) and then $\eta = [(-u_e)^+]^{(2m+1)} \phi^2$ in (2.6). Using the resulting estimate in (4.14), we conclude

$$\int g_0 \phi^2 \, dx \leqq c \sum_{k=1}^{n-1} \int w^{(s-1)} (u_{e_k})^2 |\nabla \phi|^2 \, dx + c\tau^{-1} \int E\phi^2 \, dx. \tag{4.15}$$

From (4.15), (4.9), it follows as in [5, Lemma 1] that Lemma 4 is true. We omit the details.

5. Hölder continuity of $\nabla u(\cdot, \varepsilon)$. In this section we use Lemmas 1–4 to prove the following lemma for ε, R_0, σ, fixed as in § 1.

LEMMA 5. *There exists $\alpha = \alpha(d) > 0$ such that*

$$|\nabla u(x) - \nabla u(y)| \leqq d|x-y|^{\alpha}, \qquad x, y \in B(x_0, \sigma R_0). \tag{5.1}$$

Proof. Let v_k, $1 \leqq k \leqq n$, be as in Lemma 3, and put $v_0 = v$, v as in Lemma 2. Note from (4.1), (2.9) that the eigenvalues of $(\overline{b_{ij}})$ are uniformly bounded above and below. Suppose $z \in \bar{B}(x_0, \sigma R_0)$, and $0 < r \leqq ((1-\sigma)/10{,}000) R_0$. Then $v_k \in W_{1,2}(B_1)$, so by the usual variational argument there exists $h_k = h_k(\cdot, 4r)$, $0 \leqq k \leqq n$ with $h_k \in W_{1,2}[B(z, 4r)]$, $h_k = v_k$ on $\partial B(z, 4r)$ in the $W_{1,2}$ sense, and

$$Lh_k = (\overline{b_{ij}} h_{k x_j})_{x_i} = 0, \qquad 0 \leqq k \leqq n, \tag{5.2}$$

weakly in $B(z, 4r)$. Since $v_k - h_k \in \dot{W}_{1,2}[B(z, 4r)]$, $0 \leqq k \leqq n$, we have

$$\int_{B(z,4r)} \bar{b}_{ij} (h_k)_{x_i} (v_k - h_k)_{x_j} \, dx = 0,$$

so from (4.1), (2.9),

$$\begin{aligned}\int_{B(z,4r)} |\nabla h_k|^2\,dx &\leqq a\int_{B(z,4r)} |\nabla v_k|^2\,dx \\ &\leqq a\int_{B(z,4r)} \bar{b}_{ij}(v_k)_{x_i}(v_k)_{x_j}\,dx.\end{aligned} \tag{5.3}$$

From (5.3) and well-known ellipticity theory (see [5, (2.12)]), we find for $t<4r$

$$\begin{aligned}t^{2-n}\left(\sum\int_{B(z,t)} |\nabla h_k|^2\,dx\right) &\leqq a\left(\frac{t}{r}\right)^{2\mu}\left[r^{(2-n)}\left(\sum\int_{B(z,4r)} |\nabla h_k|^2\,dx\right)\right] \\ &\leqq a\left(\frac{t}{r}\right)^{2\mu}\left[\sum\int_{B(z,4r)} |\nabla v_k|^2\,dx\right] r^{2-n}\end{aligned} \tag{5.4}$$

for some μ, $0<\mu<1$, depending on the ellipticity constants. If $F_k = h_k - v_k$ in $B(z,4r)$ and $F_k = 0$ otherwise in $\mathfrak{R}^n$, we see from Lemmas 2 and 3,

$$\begin{aligned}\sum_{k=0}^{n}\left(\int |\nabla F_k|^2\,dx\right) &\leqq a\int \overline{b_{ij}}(h_k - v_k)_{x_i}(F_k)_{x_j}\,dx \\ &= -a\int (\overline{b_{ij}})(v_k)_{x_i}(F_k)_{x_j}\,dx \leqq a\int (g_0+G_0)\left(\sum_{k=0}^{n}|F_k|\right)dx \\ &\quad + a\int G\left(\sum_{k=0}^{n}|\nabla F_k|\right)dx \\ &\leqq a\int g_0\left(\sum_{k=0}^{n}|F_k|\right)dx + aM(4r, v_0)\int_{B(z,4r)} E\,dx \\ &\quad + a\int_{B(z,4r)} G^2\,dx + \frac{1}{2}\sum_{k=0}^{n}\left(\int |\nabla F_k|^2\,dx\right),\end{aligned} \tag{5.5}$$

where E is as in Lemma 4 and we have used that fact that $M(4r, F_k)\leqq 2M(4r, v_0)$, to estimate G_0. Let $\tau = (1+\beta)/\beta$ be the conjugate exponent to $1+\beta$ in Lemma 4. Then from Lemma 4 we have for $0\leqq k\leqq n$, $R = 4r$,

$$\begin{aligned}\fint_{B(z,4r)} g_0|F_k|\,dx &\leqq \left[\fint_{B(z,4r)} g_0^{1+\beta}\,dx\right]^{1/1+\beta}\left(\fint |F_k|^\tau\,dx\right)^{1/\tau} \\ &\leqq c\left(\fint_{B(z,8r)} g_0\,dx\right)\left(\fint |F_k|^\tau\,dx\right)^{1/\tau} + cQ_1,\end{aligned} \tag{5.6}$$

where

$$Q_1 \leqq aM(4r, v_0)\left[\fint_{B(z,16r)} E^{1+\beta}\,dx\right]^{1/1+\beta} \leqq aM(4r, v_0)r^{-n/\tilde{q}}\|E\chi\|_{\tilde{q}} \leqq dr^{-n/\tilde{q}}. \tag{5.7}$$

Here, $\tilde{q} = \min(n, q/2)$, $\chi = \chi_{\cdot B_2}$, and we have used Lemma 1. Using (5.6), (5.7), and the definition of G in (5.5), we deduce for $0<t\leqq 4r$,

$$\begin{aligned}\sum_{k=0}^{n}\left(\int_{B(z,t)} |\nabla F_k|^2\,dx\right) &\leqq \sum_{k=0}^{n}\left(\int_{B(z,4r)} |\nabla F_k|^2\,dx\right) \\ &\leqq d\left(\int_{B(z,16r)} g_0\,dx\right)\left(\fint |F_k|^\tau\,dx\right)^{1/\tau} + dr^{(n-2+\delta)},\end{aligned} \tag{5.8}$$

where $\delta = 2-(n/\tilde{q})>0$. Also as in [5, (3.11), (3.12)] we find that

$$M(8r, v_0)^{-1}\left[\sum_{k=0}^{n} \fint |F_k|^\tau \, dx\right]^{1/\tau} \leqq d\left[1-\frac{M(2r, v_0)}{M(8r, v_0)}+\frac{r^{1-n/2\tilde{q}}}{M(8r, v_0)}\right]^{1/\tau}. \tag{5.9}$$

Next let $\delta_1 = \frac{1}{4}\min(\delta, 2\mu)$ and suppose that

$$M(4r, v_0) > d_1 r^{\delta_1}. \tag{5.10}$$

If d_1 is large enough, it follows from ellipticity theory and an argument similar to [5, (3.9)] that

$$M(8r, v_0)\left(\int_{B(z,8r)} g_0 \, dx\right) \leqq a\left(\sum_{k=0}^{n} \int_{B(z,16r)} |\nabla v_k|^2 \, dx\right) + dr^{(n-2+\delta_1)}. \tag{5.11}$$

Using (5.9) and (5.11) in (5.8) we obtain

$$\begin{aligned}\sum_{k=0}^{n} \int_{B(z,t)} |\nabla F_k|^2 \, dx \leqq c&\left[\sum_{k=0}^{n} \int_{B(z,16r)} |\nabla v_k|^2 \, dx\right] \\ &\cdot\left[1-\frac{M(2r, v_0)}{M(8r, v_0)}+dr^{(n-2+\delta_1)}\right]^{1/\tau}+dr^{(n-2+\delta_1)},\end{aligned} \tag{5.12}$$

provided (5.10) is true. Multiplying (5.12) by t^{2-n} and adding the resulting inequality to (5.4) we obtain an inequality which can be iterated as in [5, p. 857], even though we now must also consider the case when (5.10) is false. Doing this and using Poincaré's inequality we find (see [5, 3.22]) that

$$\sum_{k=0}^{n} \fint_{B(z,\rho)} (v_k-\eta_k)^2 \, dx \leqq d\left(\frac{\rho}{R_0}\right)^{\delta_2}, \tag{5.13}$$

for some $\delta_2 = \delta_2(d) > 0$ and $0<\rho<((1-\sigma)/1{,}000)R_0$. Since $z \in B(x_0, \sigma R_0)$ is arbitrary it follows from (5.13) and Lemma 1, in a well-known way, that Lemma 5 is valid.

6. Proof of Theorem 1. We now construct $u(\cdot, \varepsilon)$ for $0<\varepsilon<1/10\times \min[1, \delta(E, \partial\Omega)]$ and show for sufficiently small $R_0>0$ that $\{u(\cdot, \varepsilon)\}$ satisfies (1.9) and (1.11). To do so, let $\phi \in C_0^\infty(\mathfrak{R}^n)$ with $\int \phi \, dx = 1$. Put $\phi_t(x) = t^{-n}\phi(x/t)$, $x \in \mathfrak{R}^n$, and let

$$\psi(x, \varepsilon) = \int_{\mathfrak{R}^n} \hat{\psi}(x-y)\phi_\varepsilon(y) \, dy = \hat{\psi} * \phi_\varepsilon(x), \qquad x \in \mathfrak{R}^n.$$

Then $\psi \in C^\infty(\mathfrak{R}^n)$ and (1.8) is valid. As in Tolksdorf [11, § 5] we let

$$\bar{b}(x, z, h) = \operatorname{sgn} \hat{b}(x, \hat{u}(x), \nabla\hat{u}(x)) \min\{|\hat{b}(x, \hat{u}(x), \nabla\hat{u}(x))|, 2c_1[|h|^p + f(x)]\}$$

for $(x, z, h) \in B \times \mathfrak{R} \times \mathfrak{R}^n$, where c_1, f are as in (1.3). Now put

$$b_\varepsilon(x, z, h) = \operatorname{sgn} \bar{b}(x, z, h) \min\left\{|\bar{b}(x, z, h)|, \frac{1}{\varepsilon}\right\}$$

for $(x, z, h) \in B \times \mathfrak{R} \times \mathfrak{R}^n$. Clearly, (1.10) holds. We claim there exists a solution $u = u(\cdot, \varepsilon)$ to (1.9) with $u - \hat{u} * \phi_\varepsilon \in \dot{W}_{1,p}(B)$, $u \geqq \psi$ in B, almost everywhere, and $u \leqq A < \infty$. The existence of $u(\cdot, \varepsilon)$ follows from standard ellipticity theory using the boundedness of b_ε (see [4, Chap. 10]). Next we prove the following lemma.

LEMMA 6. *There exists* $\rho_1 = \rho_1(c) > 0$, $\mu = \mu(c) > 0$, *depending only on the data such that if* $0 < R_0 \leqq \rho_1$, *then*

$$|u(x)| \leqq c, \qquad x \in B, \tag{6.1}$$

$$\left(\int_B |\nabla u|^p \, dx \right)^{1/p} \leqq c(\|\hat{u}\|_{1,p} + 1), \tag{6.2}$$

$$\operatorname*{osc}_B (u) \leqq c R_0^{\mu}. \tag{6.3}$$

To prove Lemma 6 let $\beta = M(R_0, \hat{u} * \phi_\varepsilon)$ and put $\eta = e^{\gamma(u-\beta)^+} - 1$. Then $\eta \in \dot{W}_{1,p}(B)$ and for this η equality holds in (1.9), since $\hat{u} * \phi_\varepsilon \geqq \psi(\cdot, \varepsilon)$ in B. Hence,

$$\begin{aligned} \gamma \int_{\{u \geqq \beta\}} |\nabla u|^p \, e^{\gamma(u-\beta)^+} \, dx &\leqq \int_B |b_\varepsilon| \eta \, dx + \gamma \int_B (\eta + 1) \, dx \\ &\leqq 2c_1 \int_{\{u \geqq \beta\}} |\nabla u|^p \, e^{\gamma(u-\beta)^+} \, dx \\ &\quad + (2c_1 + \gamma) \int_B \bar{f}(|\eta| + 1) \, dx, \end{aligned} \tag{6.4}$$

where again $\bar{f} = f + 1$. If $\gamma \geqq 4c_1$, then from (6.4) we conclude

$$\begin{aligned} \int_{\{u \geqq \beta\}} |\nabla \, e^{(\gamma/p)(u-\beta)^+}|^p \, dx &\leqq c\gamma^p \int_B \bar{f}(|\eta| + 1) \, dx \\ &\leqq c\gamma^p \left(\int_B \bar{f}(x)^q \, dx \right)^{1/q} \left[\int_B e^{\bar{q}\gamma(u-\beta)^+} \, dx \right]^{1/\bar{q}}, \end{aligned} \tag{6.5}$$

where $\bar{q} = q/(q-1) < n/(n-1)$.

We now consider the following cases (a) $p > n$, (b) $1 < p < n$, (c) $p = n$. In case (a), it follows from Sobolev's theorem and (6.5) that

$$\begin{aligned} \|e^{(\gamma/p)(u-\beta)^+} - 1\|_\infty &\leqq a \left[\int_B |\nabla \, e^{(\gamma/p)(u-\beta)^+}|^p \, dx \right]^{1/p} R_0^{1-n/p} \\ &\leqq c\gamma \|e^{(\gamma/p)(u-\beta^+)}\|_\infty R_0^{\xi}, \end{aligned}$$

where $\xi = 1 - (n/p) + (n/\bar{q}p)$. If $\gamma = 4c_1$ in the above inequality, then we first deduce that $(u-\beta)^+ \leqq c$ for ρ_1 small enough and second for $p > n$ that

$$u(x) \leqq \beta + cR_0^{\xi}, \qquad x \in B. \tag{6.6}$$

If $1 < p < n$, we use Sobolev's theorem again to deduce for $p^* = np/(n-p)$,

$$\left[\int_B (e^{(\gamma/p)(u-\beta)^+} - 1)^{p^*} \, dx \right]^{1/p^*} \leqq c\gamma R_0^{\sigma} \left[\int_B e^{\gamma\bar{q}(u-\beta)^+} \, dx \right]^{1/\bar{q}p}, \tag{6.7}$$

where $\sigma = (n/\bar{q}p) - (n/p^*) > 0$, since $(p^*/p) > \bar{q}$. If $p = n$, then $e^{(\gamma/p)(u-\beta)^+} - 1 \in$ BMO $(\mathfrak{R}^n)$ with BMO norm bounded by the $W_{1,n}$ norm of this function. Using this fact, we see that (6.7) remains valid with $p^* = 2\bar{q}n$. If $w = e^{\bar{q}(u-\beta)^+}$, $\alpha = p^*/(p\bar{q}) > 1$, then from (6.7) we deduce for $1 < p \leqq n$ and $\gamma \geqq 4c_1$,

$$\left[\fint_B w^{\gamma\alpha} \, dx \right]^{1/\alpha\gamma} \leqq c(\gamma^{1/\gamma})^{p\bar{q}} \left[\fint_B w^{\gamma} \, dx \right]^{1/\gamma}.$$

Iterating this inequality we conclude

$$M(R_0, w) \leqq c\left[\fint_B w^{\gamma_0}\, dx\right]^{1/\gamma_0},$$

where $\gamma_0 = 4c_1$. By using (6.7) again, it follows that

$$M(R_0, w)^{1/p} \leqq c\gamma_0 R_0^{\sigma} M(R_0, w)^{1/p} + c,$$

and hence

$$(u-\beta)^+ \leqq c \tag{6.8}$$

for $R_0 \leqq \rho_1$ in cases (b) and (c). To prove an analogue of (6.6) for $1 < p \leqq n$, we use (6.8). If $v = e^{\gamma_0(u-\beta)^+} - 1$, $\eta = v^s$, $s \geqq 1$, then as in (6.4), (6.5), we deduce using (6.8),

$$\int_B |\nabla v^{(s-1)/p+1}|^p\, dx \leqq cs^p \left[\int_B v^{(s-1)\bar{q}}\, dx\right]^{1/\bar{q}}.$$

From this inequality we see that the argument following (6.5) can be repeated to get

$$M(R_0, v) \leqq c\left[\int_B v^{s_0}\, dx\right]^{1/2s_0} R_0^{(1/2)\sigma_1} + cR_0^{\sigma_1} \leqq cM(R_0, v)^{1/2} R_0^{(1/2)\sigma_1} + cR_0^{\sigma_1}$$

for some $s_0 = s_0(c)$, $\sigma_1 = \sigma_1(c) > 0$. Clearly, this inequality implies for $\rho_1 > 0$ small enough that

$$u(x) \leqq \beta + cR_0^{\sigma_1}, \qquad x \in B, \tag{6.9}$$

when $1 \leqq p \leqq n$. Next put $\delta = \min_B (\hat{u} * \phi_\varepsilon)$ and let $\eta = e^{\gamma(\delta-u)^+} - 1 \in \dot{W}_{1,p}(B)$. Using (1.9) it follows that for $\gamma \geqq 4c_1$,

$$\int_B |\nabla e^{(\gamma/p)(\delta-u)^+}|^p\, dx \leqq c\gamma^p \left[\int_B e^{\bar{q}(\delta-u)^+}\, dx\right]^{1/\bar{q}}.$$

Repeating the argument following (6.5) we first get (6.6) with u replaced by $-u$ and β by $-\delta$, for $p > n$. Second, we find $(\delta - u)^+ \leqq c$ for $1 \leqq p \leqq n$. Using this fact, putting $\eta = (e^{(\delta-u)^+} - 1)^s$ in (1.9), and arguing as in the proof of (6.9) we deduce that (6.9) holds with u replaced by $-u$ and β by $-\delta$ when $1 < p \leqq n$. Combining these inequalities and using (1.5), (2.1a) we conclude first that

$$M(R_0, |u|) \leqq M(R_0, |\hat{u} * \phi_\varepsilon|) + cR_0^{\mu} \leqq c,$$

and second that

$$\operatorname*{osc}_B (u) \leqq \operatorname*{osc}_B (\hat{u} * \phi_\varepsilon) + CR_0^{\mu} \leqq cR_0^{\mu},$$

where $\mu = \min(\sigma_1, \bar{\lambda}, \xi)$. Thus (6.1) and (6.3) of Lemma 6 are true for ρ_1 small enough.

To prove (6.2) put $\eta = \hat{u} * \phi_\varepsilon - u$ in (1.9). If $\bar{u} = \hat{u} * \phi_\varepsilon$ it follows from (6.3), (1.5), and the definition of b_ε that

$$\begin{aligned} J_1 &= \int_B (\varepsilon + |\nabla u|^2)^{(p/2-1)} |\nabla u|^2\, dx \\ &\leqq c \int_B (\varepsilon + |\nabla u|^2)^{(p/2-1/2)} |\nabla \bar{u}|\, dx + \int |b_\varepsilon||\eta|\, dx \\ &\leqq \frac{1}{2} J_1 + c \int_B (|\nabla \bar{u}|^p + 1)\, dx + cR^{\mu} \int_B (|\nabla \bar{u}|^p + |\nabla \hat{u}|^p + f)\, dx. \end{aligned}$$

Since, $\int_B |\nabla \bar{u}|^p \leqq a \int_\Omega |\nabla \hat{u}|^p \, dx$, we see from the above inequality that (6.2) also holds when $\rho_1 = \rho_1(c) > 0$ is small enough. This completes the proof of Lemma 6.

We now prove Theorem 1. From Lemma 6, we see there is a subsequence $u_j = u(\cdot, \varepsilon_j)$ of $\{u(\cdot, \varepsilon)\}$ such that u_j converges weakly to a function v with $v - \hat{u}$ in $\dot{W}_{1,p}(B)$. Also from (6.1) we see that Lemmas 1 and 5 can be used to deduce that u_j, ∇u_j, converge uniformly to v, ∇v on compact subsets of B and that these functions are also Hölder continuous on compact subsets of B. We now show there exists $\rho_2 < \rho_1$ depending only on the data such that if $0 < R_0 \leqq \rho_2$, then $v = \hat{u}$. To do this, suppose $v + \zeta \geqq \hat{\psi}$, where $\zeta \in \dot{W}_{1,p}(B)$ is continuous and vanishes in a neighborhood of ∂B. Put

$$\bar{\zeta}_j(x) = \max [\psi(x, \varepsilon_j) - u(x, \varepsilon_j), \zeta(x)], \qquad x \in B,$$

$j = 1, 2, \cdots$. Then supp. $\bar{\zeta}_j \subset$ (supp. $\zeta \cap B$), $j = 1, 2, \cdots$, since $\psi(\cdot, \varepsilon) \leqq u(\cdot, \varepsilon)$ in B. Also, $\bar{\zeta}_j \in \dot{W}_{1,p}(B)$ and (1.9) holds with $\varepsilon = \varepsilon_j$, $\eta = \bar{\zeta}_j$, $j = 1, 2, \cdots$. Using these facts and uniform convergence of ∇u_j, u_j, to ∇v, v on compact subsets of B, we see that

$$\int [|\nabla v|^{(p-2)} \nabla v \cdot \nabla \zeta + \bar{b}(x, v, \nabla v) \zeta] \, dx \geqq 0. \tag{6.10}$$

Suppose now that $\zeta_j \in C_0^\infty(B)$ and $\|\zeta_j + v - \hat{u}\|_{1,p} \to 0$ as $j \to \infty$. Let $\bar{\zeta}_j = \min [\max (\hat{\psi} - v, \zeta_j), 2c]$, where c is chosen so large that $\|v - \hat{u}\|_\infty \leqq c$. Then $\bar{\zeta}_j \to \hat{u} - v$ in the norm of $W_{1,p}(B)$, and $\|\bar{\zeta}_j\|_\infty \leqq c$, $j = 1, 2, \cdots$. Since $\{b_\varepsilon\}$ is Lebesgue dominated by an integrable function, we deduce from these facts and (6.10) with $\zeta = \bar{\zeta}_j, j = 1, 2, \cdots$, that

$$\begin{aligned} &\int_B [|\nabla v|^{(p-2)} \nabla v \cdot \nabla(\hat{u} - v) + \bar{b}(x, v, \nabla v)(\hat{u} - v)] \, dx \\ &\quad = \lim_{j \to \infty} \int [|\nabla v|^{(p-2)} \nabla v \cdot \nabla \bar{\zeta}_j + \bar{b}(x, v, \nabla v) \bar{\zeta}_j] \, dx \geqq 0. \end{aligned} \tag{6.11}$$

Interchanging the roles of $\hat{u}$ and v, we also get

$$\int_B |\nabla \hat{u}|^{(p-2)} \nabla \hat{u} \cdot \nabla(v - \hat{u}) + \hat{b}(x, \hat{u}, \nabla \hat{u})(v - \hat{u}) \, dx \geqq 0. \tag{6.12}$$

By using (6.11), (6.12), it follows that

$$\begin{aligned} &\int_B (|\nabla \hat{u}| + |\nabla v|)^{(p-2)} |\nabla \hat{u} - \nabla v|^2 \, dx \\ &\quad \leqq a \int_B [|\nabla \hat{u}|^{(p-2)} \nabla \hat{u} - |\nabla v|^{(p-2)} \nabla v] \cdot \nabla(\hat{u} - v) \, dx \\ &\quad \leqq a \int_B |\bar{b}(x, v, \nabla v) - \hat{b}(x, \hat{u}, \nabla \hat{u})| \, |\hat{u} - v| \, dx \\ &\quad \leqq c R_0^\mu \int_B |\bar{b}(x, v, \nabla v) - \hat{b}(x, \hat{u}, \nabla \hat{u})| \, dx, \end{aligned} \tag{6.13}$$

where we have used Lemma 6 in the last inequality. Now $\hat{b}(x, \hat{u}(x), \nabla \hat{u}(x)) = \bar{b}(x, v(x), \nabla v(x))$ for $x \in B$ unless

$$2c_1(f(x) + |\nabla v(x)|^p) < \hat{b}(x, \hat{u}(x), \nabla \hat{u}(x)) \leqq c_1(f(x) + |\nabla \hat{u}(x)|^p),$$

thanks to (1.3). Thus

$$f(x)+|\nabla v(x)|^p \leqq \tfrac{1}{2}(f(x)+|\nabla u(x)|^p),$$

and so for $x \in B$,

$$|\hat{b}(x, \hat{u}(x), \nabla \hat{u}(x)) - \bar{b}(x, v(x), \nabla v(x))| \leqq a|\nabla \hat{u}(x) - \nabla v(x)|^2(|\nabla \hat{u}(x)| + (|\nabla v(x)|)^{(p-2)}.$$

Putting this inequality in (6.13), we find that

$$\int_B |\nabla \hat{u}| + |\nabla v|)^{p-2}|\nabla \hat{u} - \nabla v|^2 \, dx \leqq \frac{1}{2}\int_B |\nabla \hat{u} - \nabla v|^2(|\nabla \hat{u}| + |\nabla v|)^{(p-2)} \, dx,$$

provided $0 < R_0 \leqq \rho_2$, and $\rho_2(c) > 0$ is sufficiently small. Hence, $\nabla \hat{u} = \nabla v$ almost everywhere in B. Since $\hat{u} - v \in \dot{W}_{1,p}(B)$ we conclude $\hat{u} \equiv v$. Finally to get Theorem 1 take $R_0 = \rho_2(c)$ and put $\sigma = \frac{1}{2}$ in Lemmas 1 and 5. Then all constants depend only on the data and since $\hat{u}$, $\nabla \hat{u}$, are uniform limits on compact subsets of $u(\cdot, \varepsilon)$, $\nabla u(\cdot, \varepsilon)$, respectively, we see that Theorem 1 holds in $B(x_0, \frac{1}{2}R_0) \cap E$. Since E can be covered by at most $N = N(c)$ such balls, we conclude that Theorem 1 is true.

HOMOGENIZATION WITH SMALL PERFORATIONS OF INCREASINGLY COMPLICATED SHAPES*

ALAIN DAMLAMIAN† AND PATRIZIA DONATO‡

Abstract. The limit case for a domain perturbed with many small and periodically distributed inclusions (holes or cracks) with increasingly complicated shapes is studied for the Poisson problem. On each "perforation" the boundary condition relates the value of the unknown function, assumed to be constant, with the total flux of the same unknown.

The limit problem involves an extra term of order zero whose coefficient depends on all the parameters, in particular the capacity of the normalized inclusion and the measure of its boundary (or their behaviors as the size of the mesh goes to zero). Some examples involving fractal sets and cracks are given.

Key words. Poisson equation, homogenization, small inclusions, perforated domains, fractal cracks

AMS(MOS) subject classifications. 35J20, 35R05, 35J70

Introduction. A well-known application of homogenization theory consists in replacing a partial differential equation which has highly oscillatory coefficients or is posed on an oscillatory perturbation of a fixed domain by a smooth partial differential equation on a fixed domain (see, for example, De Giorgi and Spagnolo [12], Tartar [20], Sanchez-Palencia [19], Bensoussan, Lions, and Papanicolaou [3]).

In this paper we study the limit case for a perforated domain with many small and periodically distributed holes with increasingly complicated shapes. More precisely, we consider a domain Ω, perforated in an ε-periodic fashion by holes or cracks of size r_ε, similar to a reference hole or crack T_ε of unit size.

For simplicity, we consider the Poisson equation with homogeneous Dirichlet condition on the boundary Ω. On each perforation, we consider a boundary condition relating the total flux of the unknown to its value on the perforation (see (1.2)-(1.3)). This is the usual variational formulation on the boundary of a conductor in electrostatics. The purpose here is to consider holes and cracks with very complicated shapes, including some fractal behaviors (see § 6).

We prove that in general the limit problem is posed in the whole of Ω, with an extra term of order zero appearing in the limit equation, whose constant coefficient depends on all the parameters (see Theorem 4.1 and Remark 4.2), in particular on the limit behavior of the capacity of T_ε and of the measure of its boundary.

This problem was first introduced in Kaïzu [15], where a first partial answer is proposed. If the reference hole or crack T_ε does not vary with respect to ε (i.e., $T_\varepsilon \equiv T$), the similar problem with pointwise Dirichlet or Robin condition on the boundary of the perforations has already been studied by many authors (see Marchenko and Hruslov [17], Rauch and Taylor [18], Carbone and Colombini [5], Dal Maso and Longo [9], Cioranescu and Murat [7], Attouch and Picard [2], Conca [8], Cioranescu and Donato [6], Brillard [4], Kaïzu [14]).

Our method could be generalized to Robin conditions in the case of varying perforations only if the norm of the exterior trace operator on ∂T_ε and the exterior Wirtinger–Poincaré constant associated to T_ε are bounded with respect to ε. This seems to be false in the most interesting case, i.e., in the fractal construction of T_ε.

The plan of this paper is as follows. Section 1 gives notation and position of the problem; § 2 gives an approximation lemma; § 3 gives some auxiliary results; § 4 gives the asymptotic behavior; § 5 is a summary of the results; § 6 gives some fractal examples.

1. Notation and position of the problem. In what follows we will use the following notation:

ε = a positive parameter taking values in a sequence going to zero.
r_ε = a positive parameter such that $r_\varepsilon < \varepsilon/2$.
Ω = a bounded open set of $\mathbb{R}^N$, $N \geqq 2$.
B_r = the ball of $\mathbb{R}^N$ of radius r centered at the origin.
$B^k_{\eta_\varepsilon} = B_{\eta_\varepsilon} + 2\varepsilon k$, $k \in Z^N$, for $0 < \eta_\varepsilon \leqq \varepsilon$.
$\mathcal{K}_\varepsilon = \{k \in Z^N \mid \overline{B^k_{2r_\varepsilon}} \subset \Omega\}$.
$N(\varepsilon) = \operatorname{card} \mathcal{K}_\varepsilon$.
$\mathcal{B}_{\eta_\varepsilon} = \bigcup_{k \in \mathcal{K}_\varepsilon} B^k_{\eta_\varepsilon}$.
T_ε = an open set in B_1 with Lipschitz boundary ∂T_ε.
$T^k_\varepsilon = r_\varepsilon T_\varepsilon + 2\varepsilon k$, $k \in Z^N$.
$\mathcal{T}_\varepsilon = \bigcup_{k \in \mathcal{K}_\varepsilon} T^k_\varepsilon$.
$\Omega_\varepsilon = \Omega \setminus \overline{\mathcal{T}_\varepsilon}$.
χ_A = the characteristic function of A.
$\fint_A f$ denotes the mean value of f over the set A.
We will suppose in the following that

$$r_\varepsilon < \frac{\varepsilon}{2}, \quad \frac{r_\varepsilon}{\varepsilon} \to 0 \quad \text{as } \varepsilon \to 0. \tag{1.1}$$

Thus, Ω_ε denotes the perforated domain obtained removing the set $\mathcal{T}_\varepsilon$ of the "holes" from the domain Ω.

The holes are then periodically distributed in Ω with 2ε-periodicity and, for every ε, each hole is r_ε-homothetic to the unitary hole T_ε. See Fig. 1.

By (1.1) the size of the holes is of order smaller than the period. So, when $\varepsilon \to 0$, the number of the holes $N(\varepsilon) \to \infty$ as ε^{-N} and the N-dimensional measure of $\mathcal{T}_\varepsilon \to 0$ while the shape of the holes varies in general with ε.

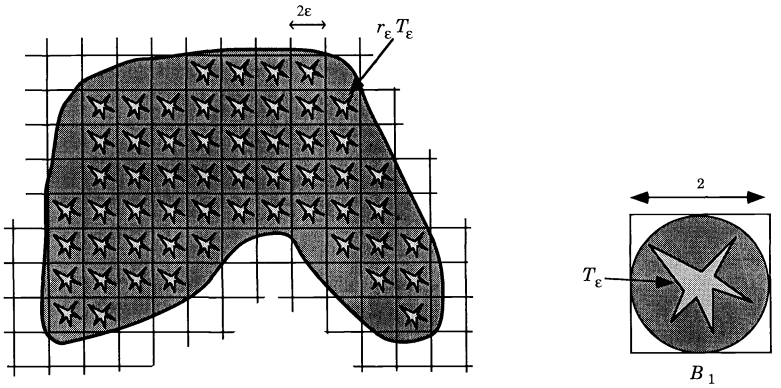

FIG. 1. *The set Ω_ε together with the normalized T_ε.*

Now let $a_\varepsilon \in [0, +\infty[$ and $f \in L^2(\Omega)$ and set for $p \in [1, +\infty]$

$$V^p = W_0^{1,p}(\Omega), \qquad V = V^2,$$

$$V_\varepsilon^p = \{u \in V^p \mid u \text{ constant on each } T_\varepsilon^k,\ k \in \mathcal{K}_\varepsilon \text{ in } T_\varepsilon\}, \qquad V_\varepsilon = V_\varepsilon^2.$$

It is easy to check that V_ε^p is a closed subspace of V^p, and consequently a Banach space when endowed with the $W_0^{1,p}(\Omega)$-norm.

Consider the problem:

$$\begin{aligned} &-\Delta u_\varepsilon = f \quad \text{in } \Omega_\varepsilon, \\ &u_\varepsilon = 0 \quad \text{on } \partial\Omega, \\ &\int_{\partial T_\varepsilon^k} \left(\frac{\partial u_\varepsilon}{\partial n} + a_\varepsilon u_\varepsilon\right) d\sigma = 0 \quad \forall k \in \mathcal{K}_\varepsilon, \\ &u_\varepsilon = V_\varepsilon, \end{aligned} \tag{1.2}$$

where n denotes the outward unit normal to Ω_ε.

The variational formulation of problem (1.2) is

$$\text{Find } u_\varepsilon \in V_\varepsilon \text{ such that}$$
$$\int_{\Omega_\varepsilon} \nabla u_\varepsilon \nabla \varphi \, dx = -\int_{\partial \mathcal{T}_\varepsilon} a_\varepsilon u_\varepsilon \varphi \, d\sigma + \int_{\Omega_\varepsilon} f\varphi \, dx \quad \forall \varphi \in V_\varepsilon. \tag{1.3}$$

The existence and uniqueness of the solution of (1.3) follows from Lax-Milgram's theorem, observing that

$$\|u_\varepsilon\|_{V_\varepsilon} \leqq C(V)\|\nabla u_\varepsilon\|_{L^2(\Omega_\varepsilon)} \leqq C(V)\|u_\varepsilon\|_{V_\varepsilon} \tag{1.4}$$

where $C(V)$ is the Poincaré constant of V.

Our purpose is to study the asymptotic behavior of the solutions u_ε as $\varepsilon \to 0$. It is clear from (1.3), (1.4) that u_ε is bounded in V, so that, by extraction of a subsequence, we can assume that there exists a u in V such that

$$u_\varepsilon \rightharpoonup u \quad \text{weakly in } V. \tag{1.5}$$

We are left with the task of identifying such u's, and determining the corresponding "limit problems," which is the aim of the remaining sections of this paper.

2. An approximate lemma. The following lemma shows that V is the proper variational space for the possible limit problems (see Kaïzu [15]).

LEMMA 2.1. *For every $p < \infty$ and $v \in V^p$, there exists a sequence $\{v_\varepsilon\}$ such that:*

(i) *For all ε, $v_\varepsilon \in V_\varepsilon^p$,*

(ii) *$v_\varepsilon \to v$ strongly in V^p,*

(iii) *If $v \in C^0(\bar{\Omega})$, then $v_\varepsilon \to v$ strongly in $C^0(\bar{\Omega})$.*

Proof. Let $\varphi \in \mathcal{D}(B_2)$ be such that $\varphi \equiv 1$ on B_1, and set

$$v_\varepsilon(x) = v(x) - \sum_{k \in \mathcal{K}_\varepsilon} \varphi\left(\frac{x-k}{r_\varepsilon}\right)\left(v(x) - \fint_{B_{r_\varepsilon}^k} v\right). \tag{2.1}$$

By the definition of $\mathcal{K}_\varepsilon$ we deduce that v_ε belongs to V_ε. We have

$$\begin{aligned} \|\nabla(v_\varepsilon - v)\|_{L^p(\Omega)}^p \leqq \sum_{k \in \mathcal{K}_\varepsilon} \Bigg[&\frac{1}{r_\varepsilon^p}\|\nabla\varphi\|_{L^\infty(B_2)}^p \left\| v - \fint_{B_{r_\varepsilon}^k} v \right\|_{L^p(B_{2r_\varepsilon}^k)}^p \\ &+ \|\varphi\|_{L^\infty(B_2)}^p \|\nabla v\|_{L^\infty(B_{2r_\varepsilon}^k)}^p \Bigg]. \end{aligned} \tag{2.2}$$

A straightforward modification of the classical Wirtinger-Poincaré-Friedrichs inequality for $W^{1,p}(B_2)$ yields a constant $C(B_2, B_1)$ such that

$$\forall \psi \in W^{1,p}(B_2) \quad \int_{B_2} \left[\psi - \fint_{B_1} \psi \right]^p dx \leqq C(B_2, B_1) \int_{B_2} |\nabla \psi|^p \, dx. \tag{2.3}$$

It follows that for every u in V^p satisfying $\fint_{B^k_{r_\varepsilon}} u = 0$ we have

$$\begin{aligned} \int_{B^k_{2r_\varepsilon}} u^p \, dx &= r_\varepsilon^N \int_{k+B_2} u^p(r_\varepsilon y) \, dy \\ &\leqq r_\varepsilon^N C(B_2, B_1) \int_{k+B_2} |\nabla_y u(r_\varepsilon y)|^p \, dy \\ &\leqq r_\varepsilon^p C(B_2, B_1) \int_{B^k_{2r_\varepsilon}} |\nabla u|^p \, dx. \end{aligned} \tag{2.4}$$

By (2.2) and (2.4), it follows that

$$\|\nabla(v_\varepsilon - v)\|^p_{L^p(\Omega)} \leqq C \|\nabla v\|^p_{L^p(\mathscr{B}_{2r_\varepsilon})}. \tag{2.5}$$

A similar calculation shows that

$$\|v_\varepsilon - v\|^p_{L^p(\Omega)} \leqq C r_\varepsilon^p \|\nabla v\|^p_{L^p(\mathscr{B}_{2r_\varepsilon})}. \tag{2.6}$$

Since by (1.1), the measure of $\mathscr{B}_{2r_\varepsilon} \to 0$ as $\varepsilon \to 0$, this implies (i) and (ii) of Lemma 2.1, while (iii) follows easily from the definition of v_ε, making use of the modulus of uniform continuity of v. □

Remark 2.2. In the case where r_ε is of the same order as ε, (2.5) and (2.6) still show the weak convergence of v_ε to v in V^p.

In this case, however, strong convergence does not hold for nonconstant v. Indeed if ∇v_ε converges strongly in $L^p(\Omega)$, then $\chi_{\mathscr{T}_\varepsilon} \nabla v_\varepsilon = 0$ in Ω together with the fact that $\chi_{\mathscr{T}_\varepsilon}$ converges to a nonzero constant weakly star in $L^{p'}(\Omega)$ implies that $\nabla v = 0$.

Remark 2.3. Actually, Lemma 2.1 yields the convergence of V_ε to V in the classical sense of Kuratowski [16].

Remark 2.4. We constructed the v_ε's to be constant in the balls $\mathscr{B}_{r_\varepsilon}$ in order to avoid the difficulty of estimating the Wirtinger-Poincaré constant of T_ε.

3. Some auxiliary results. In this section we introduce an auxiliary problem in order to construct test functions used in the process of passing to the limit in problem (1.2) as $\varepsilon \to 0$.

By (1.1) it follows that $\overline{T_\varepsilon} \subset B_{\varepsilon/r_\varepsilon}$. Consider the problem:

$$\begin{aligned} &-\Delta W_\varepsilon = 0 \quad \text{in } B_{\varepsilon/r_\varepsilon} \setminus \overline{T_\varepsilon}, \\ &W_\varepsilon = 0 \quad \text{on } \partial B_{\varepsilon/r_\varepsilon}, \\ &\int_{\partial T_\varepsilon} \left(\frac{\partial W_\varepsilon}{\partial n} + r_\varepsilon a_\varepsilon (W_\varepsilon - 1) \right) d\sigma = 0, \\ &W_\varepsilon \text{ constant on } T_\varepsilon, \\ &W_\varepsilon \in H^1(B_{\varepsilon/r_\varepsilon}). \end{aligned} \tag{3.1}$$

Set

$$A_\varepsilon = r_\varepsilon a_\varepsilon |\partial T_\varepsilon| \tag{3.2}$$

and

$$\text{cap}_\varepsilon = \text{cap}\,(T_\varepsilon, B_{\varepsilon/r_\varepsilon}) \tag{3.3}$$

where the capacity is in the H^1-sense, i.e.,

For all $A \subset B$ in $\mathbb{R}^N$

$$\text{cap}\,(A, B) = \inf_V \left\{ \int_{\mathbb{R}^N} |\nabla v|^2\, dy,\ \forall v \in H_0^1(B),\ v \equiv 1 \text{ on } A \text{ in the } H^1\text{-sense} \right\}. \tag{3.4}$$

Remark 3.1. If $N \geqq 3$, then

$$\text{cap}_\varepsilon \leqq \text{cap}\,(B_1, B_2) < \infty. \tag{3.5}$$

Moreover, if there exists $\beta > 0$ such that for all ε, T_ε contains a disk (of codimension one) D_β of radius β, then

$$\text{cap}_\varepsilon \geqq \text{cap}\,(D_\beta, \mathbb{R}^N) > 0, \tag{3.6}$$

hence cap_ε is bounded below away from 0.

If $N = 2$, we have

$$\text{cap}_\varepsilon \leqq \text{cap}\,(B_1, B_{\varepsilon/r_\varepsilon}) = \frac{2\pi}{\ln\,(\varepsilon/r_\varepsilon)}, \tag{3.7}$$

so that $\text{cap}_\varepsilon \to 0$ as $\varepsilon \to 0$. However, if there exists $\beta > 0$ such that for all ε, T_ε contains a segment S_β of length β, then (cf. Attouch and Picard [2, Prop. A3]):[1]

$$\text{cap}_\varepsilon \geqq \text{cap}\,(S_\beta, B_{\varepsilon/r_\varepsilon}) \simeq \frac{2\pi}{\ln\,(\varepsilon/\beta r_\varepsilon)} \simeq \frac{2\pi}{\ln\,(\varepsilon/r_\varepsilon)}, \tag{3.8}$$

which proves that, in this case, for $N = 2$, cap_ε is equivalent to $2\pi/\ln\,(\varepsilon/r_\varepsilon)$.

We denote by ψ_ε the capacitory potential of T_ε in $B_{\varepsilon/r_\varepsilon}$, i.e., the function achieving the minimum in (3.4) for $A = T_\varepsilon$ and $B = B_{\varepsilon/r_\varepsilon}$. Then ψ_ε satisfies

$$\begin{aligned} &-\Delta\psi_\varepsilon = 0 \quad \text{in } B_{\varepsilon/r_\varepsilon} \setminus \overline{T_\varepsilon}, \\ &\psi_\varepsilon = 0 \quad \text{on } B_{\varepsilon/r_\varepsilon}, \\ &\psi_\varepsilon = 1 \quad \text{on } \partial T_\varepsilon, \\ &\psi_\varepsilon \in H^1(B_{\varepsilon/r_\varepsilon}). \end{aligned} \tag{3.9}$$

The following lemma holds.

LEMMA 3.2. *There exists a unique solution W_ε for problem* (3.1) *and*

$$W_\varepsilon = \lambda_\varepsilon \psi_\varepsilon \tag{3.10}$$

with $\lambda_\varepsilon \in [0, 1]$ given by

$$\lambda_\varepsilon = \frac{A_\varepsilon}{A_\varepsilon + \text{cap}_\varepsilon} \tag{3.11}$$

where A_ε and cap_ε are defined by (3.2) *and* (3.3).

Proof. By uniqueness of the solution (3.1), there exists λ_ε such that (3.10) holds. To identify λ_ε, observe that

$$\text{cap}_\varepsilon = \int_{B_{\varepsilon/r_\varepsilon}} |\nabla \psi_\varepsilon|^2\, dy = \int_{\partial T_\varepsilon} \frac{\partial \psi_\varepsilon}{\partial n}\, d\sigma. \tag{3.12}$$

[1] The notation $\simeq$ indicates infinitesimal equivalence as $\varepsilon \to 0$.

Using (3.10) in (3.1), we get

$$\lambda_\varepsilon \operatorname{cap}_\varepsilon + r_\varepsilon a_\varepsilon(\lambda_\varepsilon - 1)|\partial T_\varepsilon| = 0 \tag{3.13}$$

where $|\partial T_\varepsilon|$ denotes the $(N-1)$-Lebesgue measure of ∂T_ε. By (3.13), we deduce (3.11) and, consequently, the uniqueness of W_ε. □

For $x \in B_\varepsilon$ set

$$w_\varepsilon(x) = W_\varepsilon\left(\frac{x}{r_\varepsilon}\right), \tag{3.14}$$

and extend w_ε by periodicity of period εZ^N to obtain an element of $H^1_{\text{loc}}(\mathbb{R}^N)$ still denoted as w_ε, which satisfies

$$\begin{aligned} &-\Delta w_\varepsilon = 0 \quad \text{in } \bigcup_{k\in Z^N} \{B_\varepsilon^k \setminus \overline{T_\varepsilon^k}\}, \\ &w_\varepsilon = 0 \quad \text{in } \mathbb{R}^N \Big\backslash \bigcup_{k\in Z^N} B_\varepsilon^k, \\ &\int_{\partial T_\varepsilon^k} \left(\frac{\partial w_\varepsilon}{\partial n} + a_\varepsilon(w_\varepsilon - 1)\right) d\sigma = 0 \quad \forall k \in Z^N, \\ &w_\varepsilon \text{ constant on each } \partial T_\varepsilon^k,\ k \in Z^N. \end{aligned} \tag{3.15}$$

Remark 3.3. Since $0 \leqq \psi_\varepsilon \leqq 1$, Lemma 3.2 with (3.14) implies that

$$0 \leqq W_\varepsilon \leqq \lambda_\varepsilon \leqq 1 \quad \text{a.e. in } B_{\varepsilon/r_\varepsilon},$$

$$0 \leqq w_\varepsilon \leqq \lambda_\varepsilon \leqq 1 \quad \text{a.e. in } \Omega.$$

PROPOSITION 3.4. *Assume that*

$$\frac{r_\varepsilon^{N-2}}{\varepsilon^N} \operatorname{cap}_\varepsilon \lambda_\varepsilon^2 \quad \textit{is bounded as } \varepsilon \to 0; \tag{3.16}$$

then

$$w_\varepsilon \rightharpoonup 0 \quad \textit{weakly in } H^1_{\text{loc}}(\mathbb{R}^N). \tag{3.17}$$

Furthermore, the following equivalence holds:

$$w_\varepsilon \to 0 \quad \textit{strongly in } H^1_{\text{loc}}(\mathbb{R}^N) \Leftrightarrow \frac{r_\varepsilon^{N-2}}{\varepsilon^N} \operatorname{cap}_\varepsilon \lambda_\varepsilon^2 \to 0 \quad \textit{as } \varepsilon \to 0. \tag{3.18}$$

Proof. By Remark 3.3 for any smooth bounded open set $\mathcal{O}$ in $\mathbb{R}^N$ we have

$$\|w_\varepsilon\|_{L^2(\mathcal{O})} \leqq C(\mathcal{O}) \tag{3.19}$$

where $C(\mathcal{O})$ is independent of ε.

On the other hand, Lemma 3.2 together with (3.5) yields

$$\begin{aligned} \int_{\mathcal{O}} |\nabla w_\varepsilon|^2\, dx &\simeq \frac{|\mathcal{O}|}{\varepsilon^N} \int_{B_\varepsilon} |\nabla w_\varepsilon|^2\, dx \\ &\simeq \frac{|\mathcal{O}|}{\varepsilon^N} \int_{B_{\varepsilon/r_\varepsilon}} \frac{1}{r_\varepsilon^2} |\nabla_y W_\varepsilon(y)|^2 r_\varepsilon^N\, dy \\ &\simeq |\mathcal{O}| \frac{r_\varepsilon^{N-2}}{\varepsilon^N} \operatorname{cap}_\varepsilon \lambda_\varepsilon^2. \end{aligned} \tag{3.20}$$

Hence, if (3.16) is satisfied, w_ε is bounded hence weakly relatively compact in $H^1(\mathcal{O})$. Observe that

$$w_\varepsilon \chi_{(\mathcal{O}\setminus \cup_{k\in Z^N} \overline{B_\varepsilon^k})} = 0 \quad \text{a.e. in } \mathcal{O}.$$

Since $\chi_{(\mathcal{O}\setminus \cup_{k\in Z^N} \overline{B_\varepsilon^k})}$ converges weakly star in $L^\infty(\mathcal{O})$ to some strictly positive constant, the whole sequence w_ε converges weakly to zero in $H^1(\mathcal{O})$. Finally, (3.18) is a direct consequence of (3.20). □

We now introduce some measures supported on the boundaries of the $\mathcal{B}_\varepsilon$ and $\mathcal{T}_\varepsilon$. Set

$$\mu_\varepsilon^* = -\left.\frac{\partial w_\varepsilon}{\partial n}\right|_{\partial \mathcal{B}_\varepsilon} \delta_{\partial \mathcal{B}_\varepsilon}, \tag{3.21}$$

$$\mu_\varepsilon = -\left.\frac{\partial w_\varepsilon}{\partial n}\right|_{\partial \mathcal{T}_\varepsilon} \delta_{\partial \mathcal{T}_\varepsilon} \tag{3.22}$$

where n denotes the outward unit normal to $\partial \mathcal{B}_\varepsilon$ and $\partial \mathcal{T}_\varepsilon$ respectively, and where δ denotes the $(N-1)$-dimensional surface measure. We now want to investigate the strong compactness of μ_ε^* in $H^{-1}(\Omega)$.

PROPOSITION 3.5. *If there exists a constant c independent of ε such that*

$$\begin{aligned} &\frac{\lambda_\varepsilon}{\varepsilon^2 \ln(\varepsilon/r_\varepsilon)} \leqq c \quad \text{if } N=2, \\ &\frac{r_\varepsilon^{N-2}}{\varepsilon^N}\lambda_\varepsilon \leqq c \qquad \text{if } N \geqq 3, \end{aligned} \tag{3.23}$$

then $\{\mu_\varepsilon^*\}$ is a compact set of $H^{-1}(\Omega)$.

If further there exists a nonnegative constant α such that

$$\frac{r_\varepsilon^{N-2}}{\varepsilon^N} \operatorname{cap}_\varepsilon \lambda_\varepsilon \to \alpha \quad \text{as } \varepsilon \to 0, \tag{3.24}$$

then

$$\mu_\varepsilon^* \to \alpha\, dx \quad \text{strongly in } H^{-1}(\Omega). \tag{3.25}$$

Remark 3.6. From (3.5) and (3.7) of Remark 3.1 it follows that (3.23) implies the boundedness of $(r_\varepsilon^{N-2}/\varepsilon^N)\operatorname{cap}_\varepsilon \lambda_\varepsilon$. The converse is true for $N \geqq 3$ (respectively, $N=2$) if and only if $\operatorname{cap}_\varepsilon$ (respectively $\operatorname{cap}_\varepsilon \ln(\varepsilon/r_\varepsilon)$) is bounded below away from zero. Thus (3.6) and (3.8) give sufficient conditions for this to occur.

Remark 3.7. If (3.24) holds, using (3.2) and (3.11) we obtain the following explicit formula:

$$\alpha = \lim_{\varepsilon\to 0} \frac{r_\varepsilon^{N-1}}{\varepsilon^N} \frac{a_\varepsilon |\partial T_\varepsilon| \operatorname{cap}_\varepsilon}{a_\varepsilon r_\varepsilon (\partial T_\varepsilon| + \operatorname{cap}_\varepsilon}, \tag{3.26}$$

which shows that all the parameters of the problem appear in the definition of α. In § 6 we will show examples where (3.23) or (3.24) hold. □

Proof of Proposition 3.5. We make use of test functions and a comparison lemma introduced by Cioranescu and Murat in [7].

Let ϖ_ε satisfy

$$\begin{aligned} &-\Delta \varpi_\varepsilon = 0 \quad \text{in } \mathcal{B}_\varepsilon \setminus \overline{\mathcal{B}_{r_\varepsilon}}, \\ &\varpi_\varepsilon = 0 \quad \text{in } \Omega \setminus \overline{\mathcal{B}_\varepsilon}, \\ &\varpi_\varepsilon = 1 \quad \text{in } \mathcal{B}_{r_\varepsilon}, \\ &\varpi_\varepsilon \in H^1(\Omega). \end{aligned} \tag{3.27}$$

By the maximum principle $w_\varepsilon \leqq \lambda_\varepsilon \varpi_\varepsilon$, so

$$0 \leqq -\frac{\partial w_\varepsilon}{\partial n}\,\delta_{\partial \mathscr{B}_\varepsilon} \leqq -\lambda_\varepsilon \frac{\partial \varpi_\varepsilon}{\partial n}\,\delta_{\partial \mathscr{B}_\varepsilon}.$$

By Lemma 2.8 of [7], the relative compactness of μ_ε^* is implied by that of $-\lambda_\varepsilon(\partial \varpi_\varepsilon/\partial n)\delta_{\partial \mathscr{B}_\varepsilon}$. On the other hand, Lemma 2.3 of [7] shows that

$$\lambda_\varepsilon \frac{\partial \varpi_\varepsilon}{\partial n} \simeq \begin{cases} \lambda_\varepsilon \dfrac{r_\varepsilon^{N-2}}{\varepsilon^{N-1}} & \text{if } N \geqq 3 \\ \dfrac{\lambda_\varepsilon}{\varepsilon \ln(\varepsilon/r_\varepsilon)} & \text{if } N = 2, \end{cases}$$

and that $\varepsilon \delta_{\partial \mathscr{B}_\varepsilon}$ is relatively compact in $H^{-1}(\Omega)$. Hence (3.23) implies the relative compactness of μ_ε^*. To show (3.25) let μ^* be a limit point in $H^{-1}(\Omega)$ of $\{\mu_\varepsilon\}$ as $\varepsilon \to 0$. From the ε-periodicity of μ_ε^*, it follows that μ^* is itself invariant under translations, which implies that it is a multiple of the Lebesgue measure.

From (3.2), (3.11), and (3.15), we have

$$\begin{aligned} \fint_\Omega d\mu_\varepsilon^* &= \frac{1}{|\Omega|}\int_{\partial \mathscr{B}_\varepsilon} -\frac{\partial w_\varepsilon}{\partial n}\,d\sigma \simeq \frac{1}{|\Omega|\varepsilon^N}\int_{\partial B_\varepsilon} -\frac{\partial w_\varepsilon}{\partial n}\,d\sigma \\ &= \frac{1}{|\Omega|\varepsilon^N}\int_{\partial T_\varepsilon} -\frac{\partial w_\varepsilon}{\partial n}\,d\sigma = \frac{1}{|\Omega|\varepsilon^N}\int_{\partial T_\varepsilon} a_\varepsilon(1-w_\varepsilon)\,d\sigma \\ &= \frac{r_\varepsilon^{N-1}}{|\Omega|\varepsilon^N} a_\varepsilon(1-\lambda_\varepsilon)|\partial T_\varepsilon| = \frac{r_\varepsilon^{N-2}}{|\Omega|\varepsilon^N}\lambda_\varepsilon \operatorname{cap}_\varepsilon, \end{aligned}$$

which implies that $\mu^* = \alpha\, dx_{|\Omega}$.

Remark 3.8. The above proof shows that if $\operatorname{cap}_\varepsilon$ (respectively, $\operatorname{cap}_\varepsilon \ln(\varepsilon/r_\varepsilon)$) is bounded below away from zero for $N \geqq 3$ (respectively, $N = 2$), then the boundedness of μ_ε^* in the space of measures on Ω implies its relative compactness in $H^{-1}(\Omega)$.

COROLLARY 3.9. *Under* (3.23), *a necessary and sufficient condition for* μ_ε *to converge strongly in* $H^{-1}(\Omega)$ *is that* $(r_\varepsilon^{N-2}/\varepsilon^N)\operatorname{cap}_\varepsilon \lambda_\varepsilon^2 \to 0$ *as* $\varepsilon \to 0$.

Proof. It is enough to note that $\mu_\varepsilon^* - \mu_\varepsilon = \Delta w_\varepsilon$ in $H^{-1}(\Omega)$ and to apply (3.18) with Proposition 3.5. □

4. The asymptotic behavior of problem (1.2). Set

$$X_\varepsilon = \frac{\operatorname{cap}_\varepsilon r_\varepsilon^{N-2}}{\varepsilon^N}, \qquad Y_\varepsilon = \frac{a_\varepsilon r_\varepsilon^{N-1}|\partial T_\varepsilon|}{\varepsilon^N}, \tag{4.1}$$

$$X'_\varepsilon = \begin{cases} \dfrac{r_\varepsilon^{N-2}}{\varepsilon^N} & \text{for } N \geqq 3, \\ \dfrac{2\pi}{\varepsilon^2 \ln(\varepsilon/r_\varepsilon)} & \text{for } N = 2, \end{cases} \tag{4.2}$$

and

$$Y'_\varepsilon = \begin{cases} \dfrac{a_\varepsilon r_\varepsilon^{N-1}|\partial T_\varepsilon|}{\varepsilon^N \operatorname{cap}_\varepsilon} & \text{for } N \geqq 3, \\ \dfrac{2\pi a_\varepsilon r_\varepsilon |\partial T_\varepsilon|}{\varepsilon^2 \ln(\varepsilon/r_\varepsilon)\operatorname{cap}_\varepsilon} & \text{for } N = 2. \end{cases} \tag{4.3}$$

We note that conditions (3.23) and (3.24) are equivalent to $X'_\varepsilon Y'_\varepsilon/(X'_\varepsilon + Y'_\varepsilon)$ bounded, and $\lim_{\varepsilon\to 0} X_\varepsilon Y_\varepsilon/(X_\varepsilon + Y_\varepsilon) = \alpha$, respectively. Our main result can now be stated as follows.

THEOREM 4.1. *Suppose that* (3.23) *and* (3.24) *hold, namely,* $X'_\varepsilon Y'_\varepsilon/(X'_\varepsilon + Y'_\varepsilon)$ *is bounded, and* $\lim_{\varepsilon\to 0} X_\varepsilon Y_\varepsilon/(X_\varepsilon + Y_\varepsilon) = \alpha$, *as* $\varepsilon \to 0$. *Then the solutions* u_ε *of problem* (1.2) *converge weakly in* V *to the unique solution* u *of the following problem*:

$$\begin{aligned} -\Delta u + \alpha u &= f \quad \text{in } \Omega, \\ u &= 0 \quad \text{on } \partial\Omega. \end{aligned} \tag{4.4}$$

Proof. By the uniqueness of the solution of (4.4) and referring to (1.5), it is enough to show that any weak limit point of $\{u_\varepsilon\}$ is a solution of (4.4).

Let φ be in $\mathcal{D}(\Omega)$ and let $\varphi_\varepsilon \in V_\varepsilon^p$ be the sequence given by Lemma 2.1 such that

$$\forall p \in [1, +\infty[, \quad \varphi_\varepsilon \to \varphi \text{ strongly in } V^p. \tag{4.5}$$

Choosing $\varphi_\varepsilon w_\varepsilon$ as test function in (1.3) yields

$$\int_\Omega w_\varepsilon \nabla u_\varepsilon \nabla \varphi_\varepsilon \, dx + \int_\Omega \varphi_\varepsilon \nabla u_\varepsilon \nabla w_\varepsilon \, dx + \int_{\partial\mathcal{T}_\varepsilon} a_\varepsilon u_\varepsilon \varphi_\varepsilon w_\varepsilon \, d\sigma = \int_\Omega f \varphi_\varepsilon w_\varepsilon \chi_{\Omega_\varepsilon} \, dx. \tag{4.6}$$

Also, multiplying (3.15) by $\varphi_\varepsilon u_\varepsilon$ and integrating by parts gives

$$\begin{aligned} &\int_{\mathcal{B}_\varepsilon \setminus \mathcal{T}_\varepsilon} u_\varepsilon \nabla w_\varepsilon \nabla \varphi_\varepsilon \, dx + \int_{\mathcal{B}_\varepsilon \setminus \mathcal{T}_\varepsilon} \varphi_\varepsilon \nabla w_\varepsilon \nabla u_\varepsilon \, dx \\ &\quad = \int_{\partial\mathcal{B}_\varepsilon} \frac{\partial w_\varepsilon}{\partial n} u_\varepsilon \varphi_\varepsilon \, d\sigma + \int_{\partial\mathcal{T}_\varepsilon} a_\varepsilon (1 - w_\varepsilon) u_\varepsilon \varphi_\varepsilon \, d\sigma. \end{aligned} \tag{4.7}$$

Combining (4.6) and (4.7), and since $w_\varepsilon = 0$ in $\Omega \setminus \mathcal{B}_\varepsilon$, we obtain

$$\begin{aligned} &\int_\Omega w_\varepsilon \nabla u_\varepsilon \nabla \varphi_\varepsilon \, dx - \int_\Omega u_\varepsilon \nabla \varphi_\varepsilon \nabla w_\varepsilon \, dx + \int_{\partial\mathcal{B}_\varepsilon} \frac{\partial w_\varepsilon}{\partial n} u_\varepsilon \varphi_\varepsilon \, d\sigma + \int_{\partial\mathcal{T}_\varepsilon} u_\varepsilon \varphi_\varepsilon a_\varepsilon \, d\sigma \\ &\quad = \int_\Omega \varphi_\varepsilon w_\varepsilon \chi_{\Omega_\varepsilon} \, dx. \end{aligned} \tag{4.8}$$

On the other hand, we can apply Proposition 3.4, which states that w_ε converges weakly to zero in $H^1_{\mathrm{loc}}(\mathbb{R}^N)$ because (3.24) is satisfied and $\lambda_\varepsilon \leqq 1$. In order to go to the limit as $\varepsilon \to 0$ in the first two terms of (4.8), we choose p such that $1/p + 1/q + \frac{1}{2} = 1$, for some $q < 2N/(N-2)$ (respectively, $q < \infty$ for $N = 2$), namely $p > N$, and use the fact that u_ε and w_ε converge strongly in $L^q(\Omega)$, the latter going to zero.

Consequently, because the right-hand side of (4.8) converges to zero, we obtain the following convergence for the remaining terms:

$$\lim_{\varepsilon\to 0} \left| \int_{\partial\mathcal{T}_\varepsilon} a_\varepsilon u_\varepsilon \varphi_\varepsilon \, d\sigma - \langle \mu_\varepsilon^*, u_\varepsilon \varphi_\varepsilon \rangle \right| = 0. \tag{4.9}$$

On the other hand, by Lemma 2.1, φ_ε converges to φ in $C^0(\Omega)$ and $\nabla\varphi_\varepsilon$ converges strongly to $\nabla\varphi$ in $L^p(\Omega)$ so that $u_\varepsilon \varphi_\varepsilon$ converges to $u\varphi$ weakly in V. By Proposition 3.5, μ^* converges strongly to $\alpha\, dx$ in $H^{-1}(\Omega)$, so

$$\lim_{\varepsilon\to 0} \int_{\partial\mathcal{T}_\varepsilon} a_\varepsilon u_\varepsilon \varphi_\varepsilon \, d\sigma = \alpha \int_\Omega u\varphi \, dx. \tag{4.10}$$

Finally, using φ_ε as a test function in (1.3) yields

$$\int_{\Omega_\varepsilon} \nabla u_\varepsilon \nabla \varphi_\varepsilon \, dx = -\int_{\partial \mathcal{T}_\varepsilon} a_\varepsilon u_\varepsilon \varphi_\varepsilon \, d\sigma + \int_{\Omega_\varepsilon} f\varphi_\varepsilon \, dx \quad \forall \varphi \in V_\varepsilon,$$

which, together with (4.10), gives as $\varepsilon \to 0$

$$\int_\Omega \nabla u \nabla \varphi \, dx + \alpha \int_\Omega u\varphi \, dx = \int_\Omega f\varphi \, dx$$

for all $\varphi \in \mathcal{D}(\Omega)$. This is the variational formulation of (4.4), and the proof is complete. □

Remark 4.2. In Theorem 4.1, we assume that the holes are modeled after an open set T_ε. However, it is easy to see that all the definitions and statements of the previous sections remain valid in the case of cracks, i.e., when T_ε is a piecewise C^1 set of codimension 1 (possibly with branchpoints), provided the following changes are performed:

— $\partial T_\varepsilon = T_\varepsilon$, $\partial \mathcal{T}_\varepsilon = \mathcal{T}_\epsilon$,

— The variational formulation (1.3) is preserved and in (1.2) the boundary condition is replaced by

$$\int_{T_\varepsilon^k} \left(-\left[\frac{\partial u_\varepsilon}{\partial n} \right]_n + a_\varepsilon u_\varepsilon \right) d\sigma = 0$$

where $[\partial u_\varepsilon / \partial n]_n$ denotes the jump of $\nabla u_\varepsilon \cdot n$ across the crack along the unit normal n (which is independent of the orientation chosen for n). An example of this situation is given in § 6.

5. Summary of the results. To present the results of the previous paragraph in a synthetic form we will combine them into Table 1, in which we use the following

TABLE 1

	$Y'=0$	$0<Y'<+\infty$	$Y'=+\infty$
$X'=0$	$X=Y=0$ $\alpha=0$	$X=0$ $\alpha=0$	$X=0$ $\alpha=0$
$0<X'<+\infty$	$Y=0$ $\alpha=0$	$\alpha=XY/(X+Y)$	$X<+\infty$ $\alpha=XY/(X+Y)$ Note 1
$X'=+\infty$	$Y=0$ $\alpha=0$	$Y<+\infty$ $\alpha=XY/(X+Y)$	Note 2 If $X=Y=+\infty$ then $\alpha=+\infty$

Note 1. If $\gamma>0$, then $X'=+\infty \Rightarrow X=+\infty$ and $Y'=+\infty \Rightarrow Y=+\infty$ so $\alpha=Y$ or $\alpha=X$, respectively.

Note 2. If $\gamma>0$, then $\alpha=+\infty$ can be obtained by a comparison method which is standard in the theory of Γ-convergence (see Di Giorgi [10], [11], Attouch [1]). Here $\alpha=+\infty$ means that the limit u is identically zero. However, we should note that the case of $\gamma=0$ can occur from two distinct possibilities: either a misjudgment of the values of r_ε (which may have been chosen too big, whereas $\gamma_\varepsilon \to 0$ leading to an indetermination), or a true difficulty for the case where r_ε is adjusted in such a way as to keep T_ε exactly inside a ball of unit radius and inside no smaller ball. In the latter case, the problem remains open.

notation to denote the "normalized" capacity of T_ε:

$$\gamma_\varepsilon = \begin{cases} \operatorname{cap}_\varepsilon & \text{for } N \geqq 3 \\ \dfrac{\operatorname{cap}_\varepsilon}{(2\pi/\ln(\varepsilon/r_\varepsilon))} & \text{for } N=2. \end{cases} \tag{5.1}$$

Note that from (3.5) and (3.7), γ_ε is bounded with respect to ε.

We assume (possibly taking subsequences) that the following convergences occur in $[0, +\infty]$:

$$\lim_{\varepsilon\to 0} X_\varepsilon = X, \qquad \lim_{\varepsilon\to 0} Y_\varepsilon = Y, \tag{5.2}$$

$$\lim_{\varepsilon\to 0} X'_\varepsilon = X', \qquad \lim_{\varepsilon\to 0} Y'_\varepsilon = Y', \tag{5.3}$$

$$\lim_{\varepsilon\to 0} \gamma_\varepsilon = \gamma < +\infty. \tag{5.4}$$

Clearly from (4.1)-(4.3) and provided the following operations make sense in $[0, +\infty]$ we have

$$X = X'\gamma \quad \text{and} \quad Y = Y'\gamma.$$

In this setting, conditions (3.23) and (3.24), which appear as the hypotheses of Theorem 4.1, are respectively equivalent to $\min(X', Y') < +\infty$ and $\alpha = (XY/(X+Y))$. The results of Theorem 4.1 are summarized in Table 1, where the main entries are X' and Y' and the conclusions bear on X, Y, and α. We only remark that the results of Theorem 4.1 can be applied in a more general setting without assuming the existence of the individual limits X, X', Y, and Y'.

6. Some fractal examples. In this section we give some examples involving some fractal sets, namely, the ones which can be defined as limits of recursive sequences of "normal" sets with a specific geometrical operation involved in the inductive step. Therefore, the limit set is self-similar. We refer to Falconer [13, Chap. 8] for a detailed presentation of such sets and the determination of their Hausdorff dimension.

In these constructions, it is more natural to use as a main parameter the induction index, an integer n which goes to ∞, and to consider three sequences $\{\varepsilon_n\}$, $\{a_n\}$, and $\{r_n\}$, in place of ε, a_ε, and r_ε, respectively. The normalized shape is then denoted T_n rather than T_ε.

In each construction, there is a number $\kappa > 0$ which determines the boundary measure of ∂T_n as a function of n:

$$|\partial T_{n+1}| = \kappa |\partial T_n|;$$

this number is intimately connected to the Hausdorff dimension of the boundaries of the limits of the T_n's.

Following the notation of the previous section, we set γ_n, X_n, Y_n, X'_n, and Y'_n in place of γ_ε, X_ε, etc. For simplicity we consider examples for which γ_n converges to a nonzero γ. Then the values of X and Y are obtained as the following limits:

$$X = \gamma \lim_{n\to\infty} \frac{r_n^{N-2}}{\varepsilon_n^N} \quad (N>2), \qquad X = \gamma \lim_{n\to\infty} \frac{2\pi}{\varepsilon_n^2 \ln(\varepsilon_n/r_n)} \quad (N=2),$$

$$Y = \lim_{n\to\infty} \frac{a_n r_n^{N-1} \kappa^n |\partial T_0|}{\varepsilon_n^N}.$$

In these formulas, both the capacity and the coefficient κ appear explicitly to give the limit coefficient α.

For a first example we take the twisted curve in the plane for which $\kappa = 2$ and whose boundary is of Hausdorff dimension 1.5. It is clear that γ is the normalized capacity of the limit of the sequence of sets T_n and is larger than zero. The first four iterations are given in Fig. 2.

Our second example concerns a set T_n in the plane which becomes more and more disconnected (see Fig. 3). It is not very hard to check that in this case also γ is not zero for any scaling factor q, $q \in (0, \frac{1}{2})$. Then, $\kappa = 4q$ and the Hausdorff dimension is $\ln 4/\ln(1/q)$. In Fig. 3, $q = \frac{1}{3}$ so that $\kappa = \frac{4}{3}$ and the Hausdorff dimension is $\ln 4/\ln 3$.

The third example is based on the well-known Koch curve in the plane, for which $\kappa = \frac{4}{3}$ and the Hausdorff dimension is $\ln 4/\ln 3$ (see Fig. 4).

The fourth example (Fig. 5) corresponds to the situation of a fractal cracks, with a similarity factor q and a given number of branches ν. Then $\kappa = 1 + (\nu - 1)q$ and the Hausdorff dimension of the tips is $\ln \nu / -\ln q$.

Each of these examples can be generalized to higher dimensions. In Fig. 6, we show the extension of the Koch curve to three dimensions, for which $\kappa = \frac{3}{2}$ and the Hausdorff dimension is $\ln 6/\ln 2$.

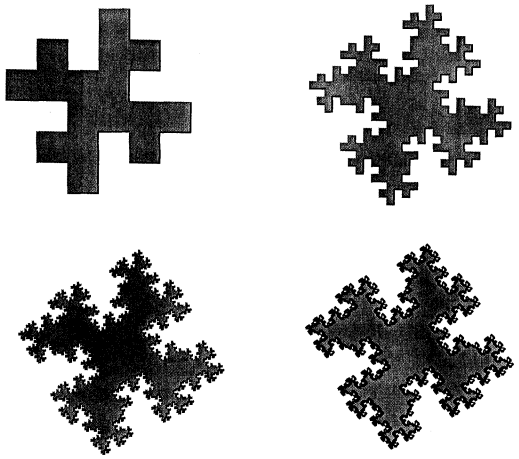

FIG. 2. *Twisted curve. Hausdorff dimension*: 1.5, $\kappa = 2$.

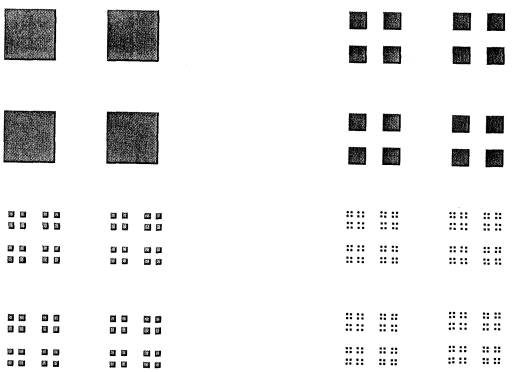

FIG. 3. *Hausdorff dimension*: $\ln 4/\ln 3$, $\kappa = \frac{4}{3}$.

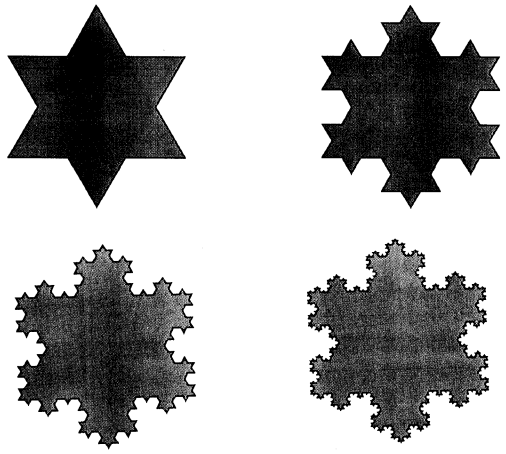

FIG. 4. *The Koch snowflake. Hausdorff dimension*: $\ln 4/\ln 3$, $\kappa = \frac{4}{3}$.

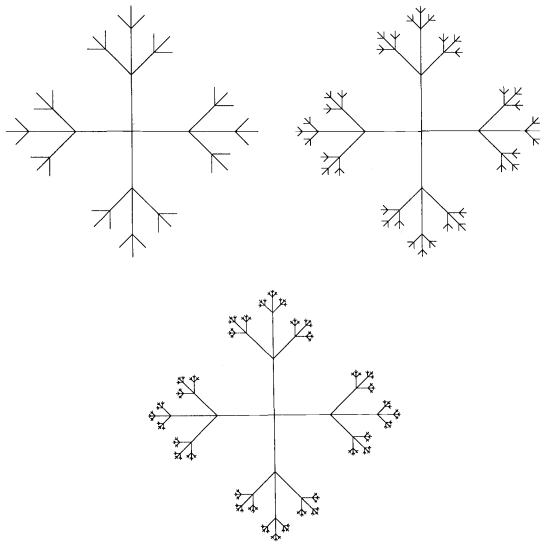

FIG. 5. *A fractal crack. Hausdorff dimension*: $\simeq \ln 3/\ln 2.5$, $\kappa \simeq 1.8$.

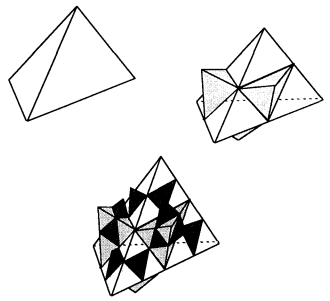

FIG. 6. *A three-dimensional Koch snowflake surface. Hausdorff dimension*: $\ln 6/\ln 2$, $\kappa = \frac{3}{2}$.

THE BIFURCATIONS OF COUNTABLE CONNECTIONS FROM A TWISTED HETEROCLINIC LOOP*

BO DENG†

Abstract. Codimension-two bifurcation phenomena associated with nondegenerate heteroclinic loops are studied. The bifurcation curves of homoclinic orbits in the parameter space are characterized by the twist structure of the heteroclinic loops at the bifurcation points. Among other things, it is shown that heteroclinic orbits with any given winding number around a doubly twisted heteroclinic loop must bifurcate. Applications of these bifurcation phenomena are also discussed.

Key words. twisted heteroclinic orbit, homoclinic orbit, periodic orbit, k-heteroclinic orbit, Sil'nikov's variables, exponential expansions, strong λ-lemmas, entrance sets, exit sets, bifurcation equations

AMS(MOS) subject classifications. 34A34, 34C28, 34C99

1. Introduction. A heteroclinic loop takes place for a vector field F when there exist two heteroclinic orbits $z_1^*(t)$ and $z_2^*(t)$, with z_1^* connecting an equilibrium point a_1, to another one a_2, and z_2^* connecting a_2 to a_1. To be precise,

$$z_i^*(t) \to a_i \quad \text{as } t \to -\infty \quad \text{and} \quad z_i^*(t) \to a_j \quad \text{as } t \to +\infty$$

for $i, j = 1, 2$ and $i \neq j$. Figures 1.1 and 1.2 heuristically illustrate what could happen to two structurally different loops when a planar vector field F is perturbed slightly. In Fig. 1.1, either a homoclinic orbit or a periodic orbit would possibly bifurcate from the loop, while in Fig. 1.2 a heteroclinic orbit winding around the original loop for any finite times before reaching its destinations in both backward and forward evolutions would also be possible under perturbation. The very structure distinguishing the second loop from the first one is that a given heteroclinic orbit arises from and tends to the equilibria from different "sides" of the other heteroclinic orbit. The purpose of this paper is to study the bifurcations of a generic two-parameter family of vector fields in $\mathbb{R}^d$, $d \geqq 2$ which exhibit the above heteroclinic phenomena.

The first obvious generalization is to assume that the equilibria a_i of the equation

$$\dot{z} = F(z) \tag{1.1}$$

have the same dimension, $m \geqq 1$, for the stable manifolds W_i^s and the same unstable dimension, $n = d - m \geqq 1$, for the unstable manifolds W_i^u for both $i = 1$ and 2. Moreover, the a_is are simple saddlepoints in the sense that

(1.2) There exist principal eigenvalues $\lambda_i < 0 < \mu_i$ for the linearization $D_z F(a_i)$ and constants $\bar{\lambda}_i < 0 < \bar{\mu}_i$ such that for any other eigenvalue ν of $D_z F(a_i)$ either $\operatorname{Re} \nu < \bar{\lambda}_i < \lambda_i$ or $\operatorname{Re} \nu > \bar{\mu}_i > \mu_i$, for $i = 1$ and 2.

Not as a generalization but as a generic restriction to all the cases, we assume that both equilibria are relatively contractive:

$$\lambda_i + \mu_i < 0 \quad \text{for } i = 1 \text{ and } 2. \tag{1.3}$$

That is, the principal attraction of a_i dominates the principal repelling.

Concerning the structure on the intersection of the unstable manifold W_i^u of a_i and the stable manifold W_j^s of a_j which must be nontransverse along the heteroclinic orbit $\Gamma_i := \{z_i^*(t) : t \in \mathbb{R}\}$, we assume that they are in general position:

$$\operatorname{codim} T_{z_i^*(t)} = 1 \quad \text{for all } t \in \mathbb{R}, \tag{1.4}$$

where

$$T_{z_i^*(t)} := T_{z_i^*(t)} W_i^u + T_{z_i^*(t)} W_j^s$$

and $T_p W$ means the tangent space of a given manifold W at a base point $p \in W$. Also, motivated by the strong λ-lemma from Deng (1989), the following strong inclination property, as another assumption, is also generic:

$$\begin{aligned} \lim_{t \to -\infty} T_{z_i^*(t)} &= T_{a_i} W_i^u + T_{a_i} W_i^{ss}, \\ \lim_{t \to +\infty} T_{z_i^*(t)} &= T_{a_j} W_j^{uu} + T_{a_j} W_j^s. \end{aligned} \tag{1.5}$$

Here, W_i^{ss} and W_i^{uu} are the strong stable and strong unstable manifolds of a_i, respectively. See Fig. 1.3. If the vector field F is C^r, then W^s and W^u are C^r as well (see, e.g., Shub (1987)). But, in general, W^{ss} and W^{uu} are proved to be C^{r-3} instead (see Deng (1989)). Moreover, W^{ss} and W^{uu} are $(m-1)$- and $(n-1)$-dimensional, respectively, characterized by the fact that the limits

$$\begin{aligned} \lim_{t \to -\infty} \frac{z(t) - a}{\|z(t) - a\|} &\neq 0 \quad \text{for } z(0) \in W^u \setminus W^{uu}, \\ \lim_{t \to +\infty} \frac{z(t) - a}{\|z(t) - a\|} &\neq 0 \quad \text{for } z(0) \in W^s \setminus W^{ss} \end{aligned} \tag{1.6}$$

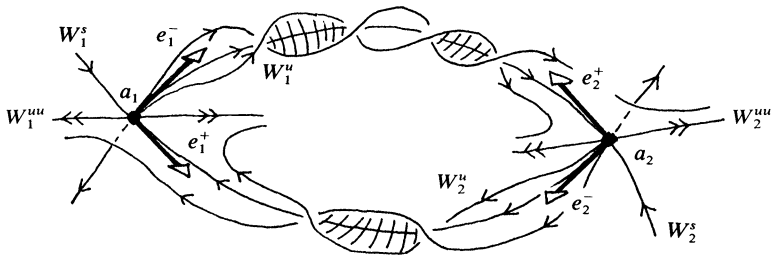
exist and are equal to unit eigenvectors for the principal unstable eigenvalue and principal stable eigenvalue, respectively. The strong inclination property is a generic property provided F is C^r with $r \geqq 7$. See Deng (1989) for the proof.

The last structural assumption reads

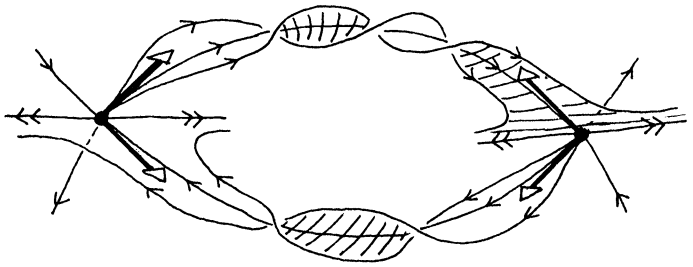
$$\Gamma_i \subset (W_i^u \setminus W_i^{uu}) \cap (W_j^s \setminus W_j^{ss}) \quad \text{for } i, j = 1, 2 \text{ and } i \neq j. \tag{1.7}$$

That is, by virtue of (1.6) this hypothesis says that the heteroclinic orbits arise from and tend to the equilibria along principal eigendirections. It is certainly a generic condition.

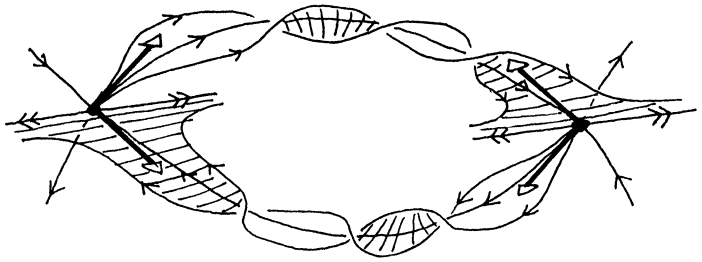
The assumptions (1.4), (1.5), and (1.7) together are referred to as nondegeneracy. They lead to our classifications of heteroclinic orbits into twisted and nontwisted as follows.



(a)



(b)



(c)

FIG. 1.3. (a) *a nontwisted loop,* (b) *a single twisted loop,* (c) *a double twisted loop.*

Let

$$
\begin{aligned}
e_j^+ &= \lim_{t\to+\infty} (z_i^*(t)-a_j)/\|z_i^*(t)-a_j\|, \\
e_i^- &= \lim_{t\to-\infty} (z_i^*(t)-a_i)/\|z_i^*(t)-a_i\|.
\end{aligned} \tag{1.8}
$$

By (1.6) and (1.7), they are unit principal eigenvectors. See Fig. 1.3. Choose $p_i \in \Gamma_i \cap W^u_{i\mathrm{loc}}$ sufficiently close to the equilibrium a_i and $q_j \in \Gamma_i \cap W^s_{j\mathrm{loc}}$ sufficiently close to the other equilibrium a_j. Let $p_i = z_i^*(0)$ and $q_j = z_i^*(T)$ for a large $T \geqq 0$. Because of the strong inclination property (1.5) and the principal asymptotic tangency (1.8), choosing p_i and q_j close enough to a_i and a_j, respectively, implies

$$
\begin{aligned}
&e_i^+ \notin T_{p_i}, \qquad \mathbb{R}^d = T_{p_i} + \mathrm{span}\,(e_i^+), \\
&e_j^- \notin T_{q_j}, \qquad \mathbb{R}^d = T_{q_j} + \mathrm{span}\,(e_j^-).
\end{aligned} \tag{1.9}
$$

Since $T_{z_1^*(t)}$, $0 \leqq t \leqq T$, defines a homotopy from T_{p_i} to T_{q_j}, the following definition is justified (see Fig. 1.3).

DEFINITION 1.1. Let Γ_i be a nondegenerate heteroclinic orbit connecting two simple saddles. Γ_i is said to be twisted if e_i^+ and e_j^- point to opposite sides of T_{p_i} and T_{q_j}, respectively. Otherwise, it is nontwisted.

For the heteroclinic loop, cl $(\Gamma_1 \cup \Gamma_2) = \{a_1, a_2\} \cup \Gamma_1 \cup \Gamma_2$, it is called double twisted if both Γ_1 and Γ_2 are twisted, single twisted if and only if one of them is twisted, and nontwisted if otherwise.

As the last assumption we assume

(1.10) $F: \mathbb{R}^d \times \mathbb{R}^2 \to \mathbb{R}^d$ is a generic C^r vector field with two parameters $\alpha = (\alpha_1, \alpha_2) \in \mathbb{R}^2$, having a nondegenerate heteroclinic loop at $\alpha = 0$. Here, the regularity $r \geqq 8$.

By genericity we mean that our results will hold for a residual subset of $C^r(\mathbb{R}^d \times \mathbb{R}^2, \mathbb{R}^d)$ in the weak Whitney topology of C^k-convergence (see, e.g., Hirsch (1976)). To be more precise, we include the following as equivalent conditions for (1.10):

(1.10a) The continuation of Γ_i: Given the fact that the heteroclinic orbit is a codimension 1 object by (1.4), we assume for every $(\alpha_1, 0)$ there exists a heteroclinic orbit $\Gamma_2(\alpha_1) = \{z_2^*(t, \alpha_1): t \in \mathbb{R}\}$ from a_2 to a_1 such that z_2^* is a C^r two-dimensional surface in the phase space. Similarly, $z_1^*(t, \alpha_2)$ forms a C^r surface in $\mathbb{R}^d$ as (t, α_2) takes all values from $\mathbb{R}^2$ and each of the t-curves is a heteroclinic orbit from a_1 to a_2;

(1.10b) The transverse crossing of the stable and unstable manifolds along Γ_i:

$$\lim_{\alpha_1 \to 0} \frac{d_1(\alpha_1, 0)}{|\alpha_1|} \neq 0 \quad \text{and} \quad \lim_{\alpha_2 \to 0} \frac{d_2(0, \alpha_2)}{|\alpha_2|} \neq 0,$$

where $d_1(\alpha_1, \alpha_2)$ denotes the continuously varying distance of $W_1^u(\alpha) \cap \Sigma$ and $W_2^s(\alpha) \cap \Sigma$ with $d_1(0, 0) = 0$ and Σ is an arbitrarily chosen Poincaré cross section to Γ_1. A similar description applies for d_2.

Note that since the Poincaré mapping introduced between any pair of two cross sections is diffeomorphism, the nonzero limiting property in (1.10b) above is independent of the choice of the cross section Σ.

Finally, to state our main theorems we need a few more terms. Let $\mathcal{U}$ be a small tubular neighborhood of the heteroclinic loop cl $(\Gamma_1 \cup \Gamma_2)$. A k-periodic (k-per) orbit is a periodic orbit which is contained in $\mathcal{U}$ and has winding number k in $\mathcal{U}$. Similarly, the closure of a k-homoclinic (k-hom) orbit has winding number k in $\mathcal{U}$. Accordingly, a k-heteroclinic (k-het$_1$) orbit Γ from a_1 to a_2 is such a heteroclinic orbit that cl $(\Gamma \cup \Gamma_2)$ has winding number $k+1$. Similarly, we define a k-heteroclinic (k-het$_2$) orbit from a_2 to a_1. Thus, Γ_1 and Γ_2 themselves are zero-heteroclinic orbits. Note that as long as $\mathcal{U}$ is chosen small enough, the above definition is independent of any particular choice of $\mathcal{U}$. Also, the terminology extends canonically to small perturbations of the vector field $F(\cdot, 0)$.

The first theorem, except for the directions of bifurcation and the k-heteroclinic orbits, is taken from Chow, Deng, and Terman (1990).

THEOREM A. *Suppose F is a generic two-parameter family of vector fields having a nondegenerate heteroclinic loop connecting two relatively contractive and simple saddle equilibria at $\alpha = 0$, i.e.,* (1.2)-(1.5), (1.7), *and* (1.10a, b) *are satisfied. Then there exists a small tubular neighborhood $\mathcal{U}$ of the heteroclinic loop* cl $(\Gamma_1 \cup \Gamma_2)$ *and a neighborhood*

Ω of the bifurcation point $\alpha = 0$ in the parameter space such that up to a nonsingular and differentiable change of the parameters, which leaves the axes invariant as sets, the following is satisfied (cf. the bifurcation diagram Fig. 1.4):

(i) *There exists a C^{r-7} curve $\alpha_2 = \hom_1(\alpha_1)$ with $\alpha_1 > 0$ in Ω such that there exists a homoclinic orbit to a_1 in $\mathcal{U}$ if and only if $\alpha \in \hom_1$. Moreover, $\hom_1$ is asymptotically tangent to the positive α_1-axis as $\alpha_1 \to 0^+$ and the direction of the bifurcation is determined by the twist of the heteroclinic orbit Γ_2 as follows:*

$$\hom_1 \begin{cases} > 0 & \text{if } \Gamma_2 \text{ is twisted,} \\ < 0 & \text{otherwise.} \end{cases}$$

(ii) *There does not exist any k-heteroclinic orbit from a_2 to a_1 for $k \geqq 1$ if Γ_2 is not twisted and there exists at least one 1-heteroclinic orbit from a_2 to a_1 on a C^{r-7} curve; $\alpha_2 = 1\text{-het}_2(\alpha_1)$ for $\alpha_1 > 0$ otherwise. Moreover, 1-het_2 is asymptotically tangent to the α_1-axis as $\alpha_1 \to 0^+$.*

(iii) *Analogous statements hold for homoclinic orbits to a_2 and k-heteroclinic orbits from a_1 to a_2.*

(iv) *Let $\Lambda = \{(\alpha_1, \alpha_2): \alpha_2 > \hom_1(\alpha_1)$ if $\alpha_1 > 0$ or $\alpha_1 > \hom_2(\alpha_2)$ if $\alpha_2 > 0\}$. Then there exists a periodic orbit in $\mathcal{U}$ if and only if $\alpha \in \Lambda$.*

(v) *The homoclinic and periodic orbits do not coexist in $\mathcal{U}$ for a given parameter. They are all unique and are 1-hom and 1-per orbits, respectively.*

Our main result is as follows.

THEOREM B. *In addition to the hypotheses of Theorem A, suppose the stable manifolds of the equilibria a_1 and a_2 are all one-dimensional; then the following is satisfied (cf. Fig. 1.4):*

(i) *If Γ_2 is twisted but Γ_1 is not, then the 1-heteroclinic orbit from a_2 to a_1 is the unique k-heteroclinic orbit for all $k \geqq 1$ and $\alpha \in \Omega$. Moreover,*

$$1\text{-het}_2(\alpha_1) > \hom_1(\alpha_1) \quad \text{for } \alpha_1 > 0.$$

(ii) *If the loop $\operatorname{cl}(\Gamma_1 \cup \Gamma_2)$ is double twisted, then there exist two sequences of C^{r-7} curves $\alpha_2 = k\text{-het}_2(\alpha_1)$ with $\alpha_1 > 0$ and $\alpha_1 = k\text{-het}_1(\alpha_2)$ with $\alpha_2 > 0$ in Ω, respectively, satisfying*

$$0 \leqq k\text{-het}_2 < (k+1)\text{-het}_2 < \hom_1$$

for all $k \geqq 0$ such that there exists a k-heteroclinic orbit from a_2 to a_1 if and only if $\alpha \in k\text{-het}_2$. Moreover, it is a unique heteroclinic orbit in $\mathcal{U}$ with respect to the parameter and $k\text{-het}_2$ is asymptotically tangent to the α_1-axis as $\alpha_1 \to 0^+$. Furthermore, the homoclinic bifurcation curve $\hom_1$ is inaccessible from below in the sense that for every α_1

$$k\text{-het}_2(\alpha_1) \to \hom_1(\alpha_1) \quad \text{as } k \to +\infty.$$

An analogous statement also holds for the $k\text{-het}_1$ curves.

Theorem A provides us with a useful clue to the twist of a given heteroclinic loop: the two zero-heteroclinic continuation curves (which are the parameter axes in our theorems) divide the neighborhood Ω into four sectors. The 1-homoclinic bifurcation curves $\hom_1$ and $\hom_2$ lie in one sector for a double twisted loop, or in two adjacent sectors for a single twisted loop, or in two opposite sectors for a nontwisted loop. Keeping this fact in mind, let us examine the following bifurcation diagram Fig. 1.5 for traveling waves of the FitzHugh–Nagumo equation

$$v_t = v_{xx} + f(v) - w, \quad w_t = \varepsilon(v - \gamma w), \quad \varepsilon, \gamma \geqq 0,$$

where $f(v) = -v + H(v - a)$ with H to be the Heaviside step function and $0 < a < \frac{1}{2}$.

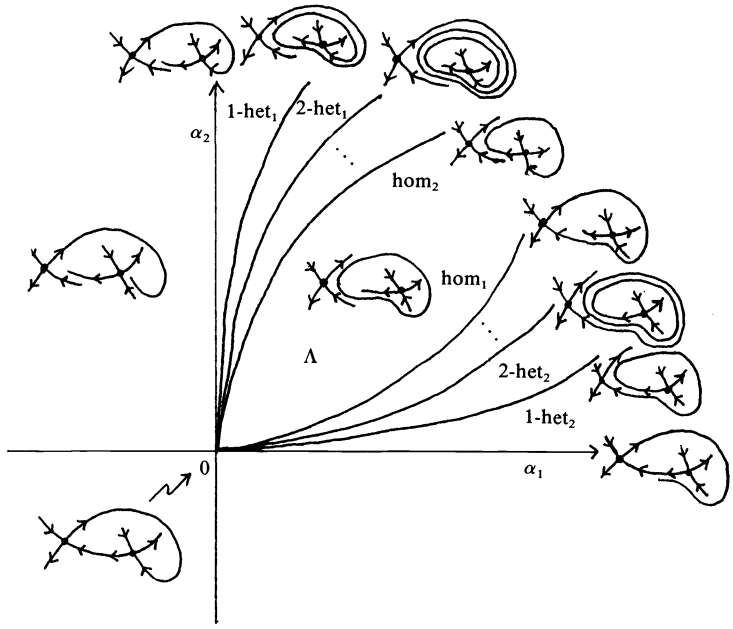
(b)

FIG. 1.4. *The bifurcation diagrams for* (a) *a nontwisted loop,* (b) *a single twisted loop,* (c) *a double twisted loop.*



(c)

FIG. 1.4.—continued

A traveling wave solution $(v, w)(x, t)$ is a function $(v, w)(z)$ of $z = x + ct$, $c \geqq 0$. Let $u(z) = v'(z)$, then $v_c = (v, u, w)(z)$ satisfies a first-order system of ODE

$$v' = u, \quad u' = cu - f(v) + w, \quad w' = \frac{\varepsilon}{c}(v - \gamma w). \tag{1.11}$$

For fixed $0 < a < \frac{1}{2}$ and $0 < \varepsilon \ll 1$, numerical as well as rigorous arguments from Rinzel and Terman (1982) show that the front curve θ_F, on which there exits a front wave connecting the rest steady state $\mathcal{O}$ to the exitable state $\mathcal{E}$ as shown in Fig. 1.6, crosses transversely the back curve θ_B, on which there is a back wave from $\mathcal{E}$ to $\mathcal{O}$. Thus, at the intersection point θ^* there exists a front wave and a back wave traveling at the same speed. This gives rise to a heteroclinic loop. Their numerical simulation also shows that the impulse curve $\theta_{\mathcal{O}}$, homoclinic to $\mathcal{O}$, and the $\mathcal{E}$-impulse curve $\theta_{\mathcal{E}}$, homoclinic to $\mathcal{E}$, also bifurcate from the loop at θ^*. Note that their bifurcation directions of asymptotic tangency are exactly opposite our bifurcation diagram Fig. 1.4 for Theorems A and B. This is due to the fact that the steady states $\mathcal{O}$ and $\mathcal{E}$ are relatively contractive simple saddles having one-dimensional stable manifolds only for the time reversed $(z \to -z)$ system (1.11). What is most remarkable about these two curves is that both of them lie in the same sector in the parameter space. In fact, this has been rigorously proved (see (3.8) and (3.10) from Rinzel and Terman (1982)). Unfortunately, however, we can only speculate that Theorem A suggests the double twist for the heteroclinic loop. Indeed, we are facing a tantalizing dilemma here: either it is feasible to check the transverse crossing condition (1.10b) and the double twist of the loop due to the piecewise linearity of f but the vector field is not smooth enough, or it becomes a fairly open problem to do so for a smooth vector field, e.g., the usual cubic function $f = v(v-1)(a-v)$. Nevertheless, the implication is interesting: for given

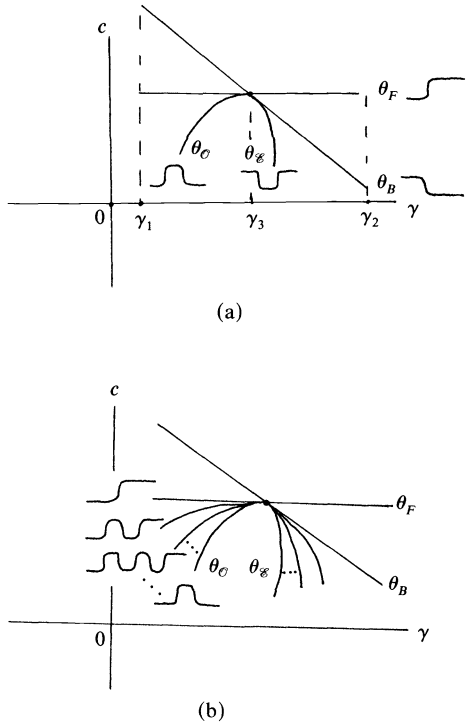


FIG. 1.5. (a) *A heuristic bifurcation diagram produced from Rinzel and Terman* (1982); (b) *The conjectured complete diagram.*

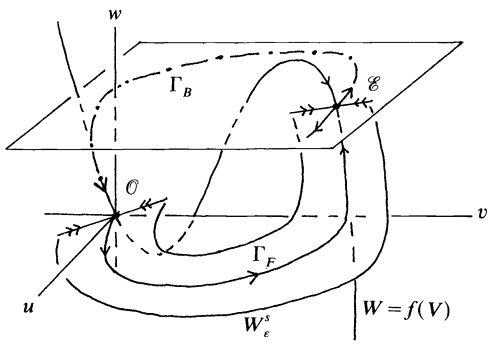

FIG. 1.6. *The conjectured twist for the front-back wave loop.*

parameters ε, $0 < a < \frac{1}{2}$ and $0 < \gamma_3 - \gamma \ll 1$ there would be infinitely many fronts traveling at different speeds. The more "humps" a front were to carry the slower it would travel. If the humps were "too many" (infinity) the traveling wave arising from the rest state would never be able to reach the exitable state $\mathscr{E}$ but would return to itself after a long excursion. Slowing down a little, it would become a traveling train, or periodic orbit for the ODE. On the other hand, push γ slightly to the right of γ_3, the above scenario would repeat for back waves and $\mathscr{E}$-impulses.

By their numerical evidence on the stability of the primary front and back waves with respect to the PDE, as well as other authors' results on somewhat related stability

problems, it has been demonstrated that the stability of a given impulse is closely related to the direction at which the stable and unstable manifolds cross transversely as the speed parameter c varies (see, e.g., Evans (1972), Jones (1984), Kokubu, Nishiura, and Oka (1988)). Thus, we find the second implication is most interesting: there would be infinitely many stable transition waves connecting two stable patterns.

However, all of these phenomena do not appear in the "chaotic" parameter region discussed by Evans, Fenichel, and Feroe (1982) and Hastings (1982), where for a given speed there are infinitely many impulses and traveling trains due to the Sil'nikov saddle-focus homoclinic explosion for (1.11) (see also Sil'nikov (1967)), whereas there would be a unique traveling front, or back, or impulse, or traveling train, except at the bifurcation point θ^* in our case. Indeed, as long as there are two bistable steady states as shown in Fig. 1.6, the equilibria are not saddle-focus. Nevertheless, we would probably not be too surprised by the enormous, stable, yet not "chaotical" transporting capability that a nerve axion would inherit if our conjectures were true.

In contrast to our conjectures above, we will discuss the existence of nontwisted heteroclinic orbits and thus the limited number of connections between two equilibrium states for another type of reaction diffusion systems in § 7. We will also discuss in that section some ways newly discovered by other authors to check all the nondegenerate and generic conditions (1.4), (1.5), (1.7), and (1.10a, b) for their examples to which our theory is immediately applicable.

2. Preliminaries. This section is devoted to introducing the Sil'nikov variables for a Poincaré map around the loop.

Let $0<\delta_0$ be a small number and $B(\delta_0)=\{z\colon z=(z^{(1)},\cdots,z^{(d)}), |z^{(i)}|\leqq\delta_0\}$ be the δ_0-box of the origin. Let the coordinate be locally normalized near the equilibria a_i so that $(x,y)=0$ corresponds to $z=a_i$ and the local stable, unstable manifolds are given by the x-axis and y-axis in $B(\delta_0)$, respectively; i.e., $W^s_{i\,\mathrm{loc}}=\{y=0\}\cap B(\delta_0)$ and $W^u_{i\,\mathrm{loc}}=\{x=0\}\cap B(\delta_0)$. In addition, the directions of the first x-component $x^{(1)}$ and the first y-component $y^{(1)}$ are chosen to be the unit principal eigenvectors e_i^+ and e_i^-, respectively, as in (1.8). Let the points p_i and q_i from (1.9) in the definition of twist be specifically given as $p_i=(x_{i*},0)$ and $q_i=(0,y_{i*})$. We can assume $x^{(1)}_{i*}=\delta_0$ and $y^{(1)}_{i*}=\delta_0$ because of assumption (1.7) for the asymptotic tangency of Γ_i along the principal eigendirections.

Let Σ_i^s and Σ_i^u be two small cross sections, or $(d-1)$-dimensional boxes $B(\delta_1)$ with $0<\delta_1<\delta_0$, centered at p_i and q_i and perpendicular to e_i^+ and e_i^-, respectively (see Fig. 2.1). They are Poincaré cross sections provided δ_0 and δ_1 are sufficiently small. Let σ_i^s be the subset of those initial points $(x_0,y_0)\in\Sigma_i^s$ whose trajectories in $B(\delta_0)$ first hit the exit cross section Σ_i^u at (x_1,y_1) at time $\tau=\tau(x_0,y_0)$. This correspondence gives rise to the local Poincaré map $\Pi_i\colon\sigma_i^s\to\Sigma_i^u$ by $(x_0,y_0)\to(x_1,y_1)$. Similarly, by the continuous dependence on initial data and parameters we can define a global Poincaré map $\Pi_{ij}\colon\Sigma_i^u\to\Sigma_j^s$. Here, without loss of generality Σ_i^u is taken to be the domain of definition for Π_{ij}, whereas σ_i^s is a proper subset of Σ_i^s not containing any point from the stable manifold $W^s_{i\,\mathrm{loc}}$.

Let $(\xi,y)\in\mathbb{R}^{d-1}$ and $(x,\eta)\in\mathbb{R}^{d-1}$ be the normalized local coordinates on Σ_i^s and Σ_i^u so that $(0,0)$ corresponds to the center points p_i and q_i, respectively. Indeed, $\xi=\hat{x}-\hat{x}_{i*}$ and $\eta=\hat{y}-\hat{y}_{i*}$, where $\hat{x}=(x^{(2)},\cdots,x^{(m)})$ and $\hat{y}=(y^{(2)},\cdots,y^{(n)})$ (see Fig. 2.1). Let $s=e^{-\mu_i(\alpha)\tau}$ be the Sil'nikov time near a_i, where $\mu_i(\alpha)$ is the principal unstable eigenvalue for $D_zF(a_i,\alpha)$. Then the Sil'nikov variable for the local map is (s,ξ,η) and the Sil'nikov domain is

$$\Delta_i:=\{(s,\xi,\eta)\colon 0<s<s_0(\alpha),|\xi|,|\eta|\leqq\delta_1\},$$

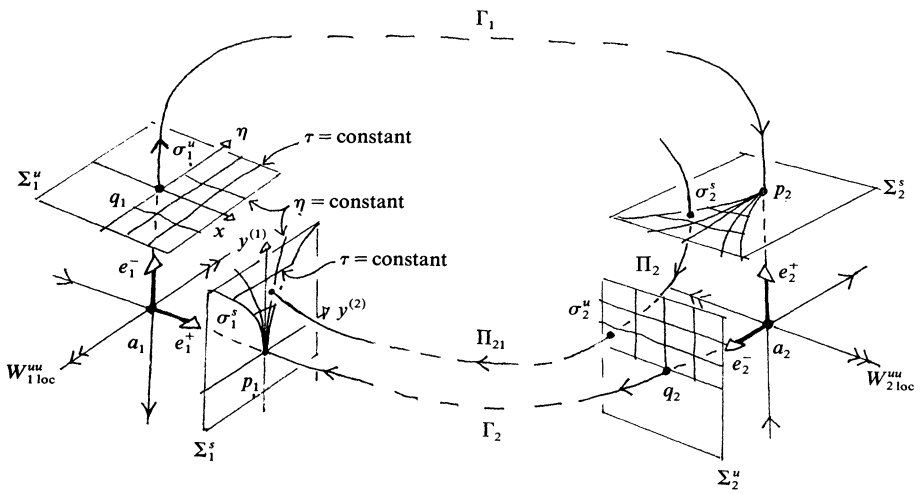

FIG. 2.1. *The cross sections and the corresponding Poincaré map when* $m = 1$, $n = 2$.

where $s_0(\alpha) = e^{-\mu_i(\alpha)\tau_0}$ for some large but fixed τ_0. Note that the dependence on α is suppressed from σ_i^s, σ_i^u, and Δ_i.

It has been proved by Sil'nikov (1967) that for the initial point $(x_0, y_0) \in \sigma_i^s$ and the end point $(x_1, y_1) \in \Sigma_i^u$ with $\tau = \tau(x_0, y_0)$ time units apart, the initial y_0 and the end x_1 components are functions of the Sil'nikov variable:

$$y_0 := Y_i(s, \xi, \eta, \alpha) \quad \text{and} \quad x_1 := X_i(s, \xi, \eta, \alpha).$$

Moreover, it has been observed by Deng (1989) that the maps $\rho_i^s : \Delta_i \to \sigma_i^s$ with $(s, \xi, \eta) \to (\xi, Y_i(s, \xi, \eta, \alpha))$ and $\rho_i^u : \Delta_i \to \sigma_i^s$ with $(s, \xi, \eta) \to (X_i(s, \xi, \eta, \alpha), \eta)$ are actually diffeomorphisms of class C^r. Thus, ρ_i^s gives rise to a smooth change of variables for the local Poincaré map Π_i, which in turn is ρ_i^u under the new Sil'nikov variable. See Fig. 2.2. More important, we have the following exponential expansion result.

PROPOSITION 2.1 (Deng (1988), (1989)). *Let the strong stable manifold and the strong unstable manifold also be normalized such that* $W_i^{ss} = \{x^{(1)} = 0, y = 0\}$ *and* $W_i^{uu} = \{x = 0, y^{(1)} = 0\}$ *locally. Let* $\nu_i(\alpha) = \lambda_i(\alpha)/\mu_i(\alpha) - 1$ *and* $\bar{\lambda}_i(\alpha)$ *and* $\bar{\mu}_i(\alpha)$ *be as in* (1.2). *Then for* δ_0 *sufficiently small there exist* C^{r-7} *functions* $\varphi_i(\xi, \eta, \alpha)$, $\psi_i(\xi, \eta, \alpha)$, $R_{i1}(s, \xi, \eta, \alpha)$, *and* $R_{i2}(s, \xi, \eta, \alpha)$ *over* Δ_i *such that*

$$\begin{aligned} X_i(s, \xi, \eta, \alpha) &= \varphi_i(\xi, \eta, \alpha) s^{1+\nu_i} + R_{i1}(s, \xi, \eta, \alpha), \\ Y_i(s, \xi, \eta, \alpha) &= \psi_i(\xi, \eta, \alpha) s + R_{i2}(s, \xi, \eta, \alpha) \end{aligned} \tag{2.1a}$$

with φ_i *and* ψ_i *satisfying*

$$\begin{aligned} \varphi_i(\xi, \eta, \alpha) &= e_m \delta_0 + O((|\xi| + |\eta| + \delta_0)\delta_0), \\ \psi_i(\xi, \eta, \alpha) &= e_n \delta_0 + O((|\xi| + |\eta| + \delta_0)\delta_0) \end{aligned} \tag{2.1b}$$

and $R_{ij} = R_{ij}(s, \xi, \eta, \alpha)$ *satisfying*

$$\begin{aligned} |D^k_{(\xi,\eta)} R_{i1}| &= O(s^{1+\nu_i+\bar{\nu}_i}), \qquad |D_s R_{i1}| = O(s^{\nu_i+\bar{\nu}_i}), \\ |D^k_{(\xi,\eta)} R_{i2}| &= O(s^{1+\bar{\nu}_i}), \qquad |D_s R_{i2}| = O(s^{\bar{\nu}_i}), \end{aligned} \tag{2.1c}$$

for all $(s, \xi, \eta) \in \Delta_i$, $0 \leqq k \leqq r - 7$, *where*

$$e_m = (1, 0, \cdots, 0)^T \in \mathbb{R}^m,$$

and

$$e_n = (1, 0, \cdots, 0)^T \in \mathbb{R}^n$$

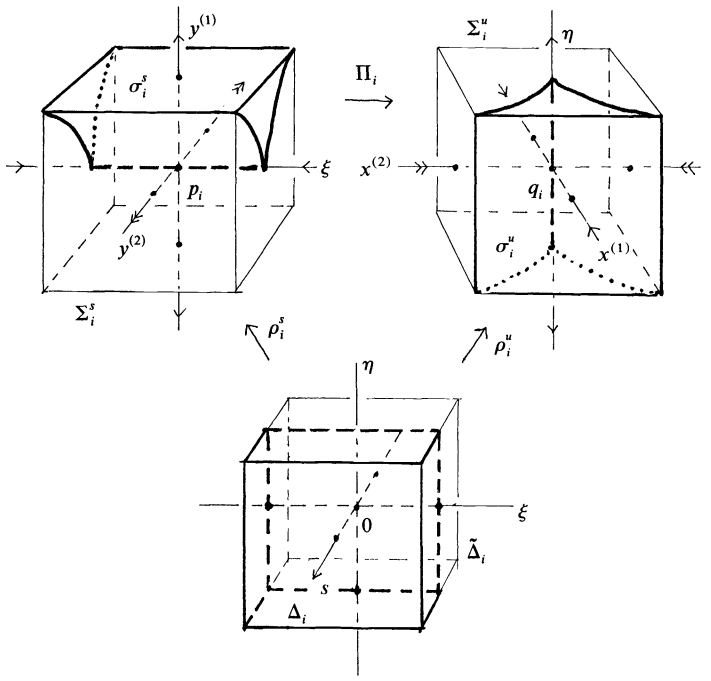

FIG. 2.2. *The Sil'nikov change of variables for the local map when* $m = n = 2$.

and $\bar{\nu}_i > 0$ *is a constant not greater than* $\min\{\bar{\mu}_i(\alpha)/\mu_i(\alpha), (\lambda_i(\alpha) - \bar{\lambda}_i(\alpha))/\mu_i(\alpha)\}$ *for all* $|\alpha| \leqq \delta_0$.

Equation (2.1a) is referred to as the exponential expansion, φ_i and ψ_i the expansion coefficient functions, and R_{ij}, the remainders. From this proposition we immediately have the following proposition.

PROPOSITION 2.2. *For sufficiently small but fixed* s_0, *the domain* σ_i^s *of the local map* Π_i *is contained in the vertical sector* $|\hat{y}| < y^{(1)}$ *on* Σ_i^s. *Moreover, for every boundary point* $(\xi, y) = (\xi, Y_i(s_0, \xi, \eta))$, $y^{(1)} \leqq \delta_0 s_0/2$. (*See Fig.* 2.2.)

It is also easy to see from (2.1c) that the functions X_i and Y_i, thus ρ_i^s and ρ_i^u, can be C^1 extended to $s \leqq 0$. From now on let us use the same notation for the extended functions, but $\tilde{\Delta}_i$ for the extended domain of Δ_i.

Let us conclude this section with two lemmas which will be frequently used later.

LEMMA 2.3. *Let the global map* Π_{ij} *be expressed as* $\xi = P_i(x, \eta, \alpha)$, $y = Q_i(x, \eta, \alpha)$, *under the new coordinates for* Σ_i^u *and* Σ_j^s. *Let*

$$M_i = \begin{bmatrix} D_\eta P_i(0,0,0) & 0 & -I \\ D_\eta Q_i(0,0,0) & e & 0 \end{bmatrix}_{(d-1)\times(d-1)} \quad \text{and} \quad \hat{M}_i = \begin{bmatrix} D_\eta P_i(0,0,0) & -I \\ D_\eta Q_i(0,0,0) & 0 \end{bmatrix}_{(d-2)\times(d-2)},$$

where $e = \psi_j(0,0,0)$, *or* e_n. *Then both* M_i *and* $\hat{M}_i$ *are nonsingular for sufficiently small* δ_0.

Proof. Note first that all the column vectors of M_i except the middle one $(0, e)$ span the linear subspace $T_{p_j}(W_i^u \cap \Sigma_j^s) + T_{p_j}(W_j^s \cap \Sigma_j^s)$, which has dimension $d-2$ by the hypothesis (1.4) and the choices of Σ_j, which are transverse to the flow. On the other hand, the remaining column vector is approximately parallel to the principal unstable eigenvector e_j^- by the exponential expansion property (2.1b). Thus, M_i achieves its maximal rank by (1.9). Moreover, the strong inclination property also implies $D_\eta \hat{Q}_i(0,0)$ is a diffeomorphism, thus the truncated square submatrix $\hat{M}_i$ achieves its maximal rank $d-2$ as well. □

LEMMA 2.4. *Let M_i be the same as in Lemma 2.3 above with $e=\psi_j(0,0,0)$ and*

$$N_i=\begin{bmatrix} D_\eta P_i(0,0,0) & 0 & -I \\ D_\eta Q_i(0,0,0) & f & 0 \end{bmatrix}_{(d-1)\times(d-1)}$$

with $f=(0,1,\cdots,0)^T,\cdots,(0,0,\cdots,1)^T$. Then there is a constant m_0 so that

$$\lim_{\delta_0\to 0}\frac{|\det M_i|}{\delta_0}\geqq m_0>0 \tag{2.2a}$$

and

$$\lim_{\delta_0\to 0}\det N_i=0. \tag{2.2b}$$

Proof. (2.2a) is true because of $\psi_j(0,0)/\delta\to e_n$ as $\delta_0\to 0$ and the strong inclination property (1.5) and (1.9). Since $(0,f)$ is contained in $T_{a_j}W_j^{uu}$, (2.2b) is also true for the same reason. □

3. Entrance and exit sets and their extensions. In this section we only consider the heteroclinic connections from a_2 to a_1. Analogous analysis and result can be immediately extended to the a_1 to a_2 connections. Again, the parameter α is suppressed from the text if no confusions arise.

Let $\mathrm{Ex}_2^0:=W_{2\mathrm{loc}}^u\cap\Sigma_2^u$ denote the intersection of the local unstable manifold of a_2 with the exit cross section Σ_2^u given in the previous section. Ex_2^0 is referred to as the initial exit set of W_2^u. It is obvious that there is a heteroclinic orbit (from a_2 to a_1) if and only if there is a solution of the initial exit set which also lies on the local stable manifold of the other equilibrium a_1. Thus, we need to closely follow the images of the initial exit set under those successive local and global Poincaré maps. To be precise, if we set the image of an empty set under a given map to be empty, then all the following sets are well defined:

$$\mathrm{En}_1^k:=\Pi_{21}(\mathrm{Ex}_2^{k-1}),\qquad \mathrm{En}_2^k:=\Pi_{12}(\mathrm{Ex}_1^k),$$
$$\mathrm{Ex}_i^k:=\Pi_i(\mathrm{En}_i^k\cap\rho_i^s(\Delta_i)),\qquad i=1,2,\quad k=1,2,\cdots,$$

where $\rho_i^s:\Delta_i\to\sigma_i^s$ is the Sil'nikov change of variables and $\rho_i^s(\Delta_i)$ is contained in the domain σ_i^s of Π_i. En_i^k and Ex_i^k are referred to as the kth entrance set and the kth exit set of W_2^u near a_i, respectively. They might be empty except for the initial exit set Ex_2^0 and the first entrance set En_1^1 near a_1. Nevertheless, we have the following.

PROPOSITION 3.1. *There exists a $(k-1)$-heteroclinic orbit from a_2 to a_1 sufficiently close to the loop $\Gamma_1\cup\Gamma_2$ if and only if $\mathrm{En}_i^j,\ \mathrm{Ex}_i^j\neq\varnothing$ for $1\leqq j\leqq k-1$, $i=1,2$, and $\mathrm{En}_1^k\cap W_{1\mathrm{loc}}^s\neq\varnothing$.*

By definition, for every point $(\xi,y)\in\mathrm{En}_1^k\neq\varnothing$ there exist $(0,\eta)\in\mathrm{Ex}_2^0$ and $z_i^j\in\sigma_i^s$ with $z_i^j=(\xi_i^j,y_i^j)$, $1\leqq j\leqq k-1$ and $i=1,2$ from the orbit of $(0,\eta)$ such that $\Pi_{21}(0,\eta)=z_1^1$, $\Pi_{12}\circ\Pi_1(z_1^1)=z_2^1,\cdots,\Pi_{21}\circ\Pi_2(z_2^{k-1})=(\xi,y)$. Using the "pull back," we have a unique $\zeta_i^j=(s_i^j,\xi_i^j,\eta_i^j)\in\Delta_i$ satisfying $z_i^j=\rho_i^s(\zeta_i^j)$. Thus, the following proposition is valid.

PROPOSITION 3.2. (3.2a) *The kth entrance set to a_1, En_1^k, is nonempty if and only if the following system of $l_1=(2k-1)(d-1)$ equations has solutions for the l_1+n-1 unknown variables $\eta,\zeta_1^1,\cdots,\zeta_2^{k-1},\xi,y$ with $\zeta_i^j=(s_i^j,\xi_i^j,\eta_i^j)\in\Delta_i$ satisfying the constraints $s_i^j>0$ for all $i=1,2$ and $1\leqq j\leqq k-1$:*

$$\Pi_{21}(0,\eta)=\rho_1^s(\zeta_1^1)$$
$$\vdots$$
$$\Pi_{21}(\rho_2^u(\zeta_2^{k-1}))=(\xi,y);$$

(3.2b) *The kth exit set from* a_1, Ex_1^k, *is nonempty if and only if after replacing* (ξ, y) *by* $\rho_1^s(\zeta_1^k)$ *with* $\zeta_1^k \in \Delta_1$ *the same statement of* (3.2a) *holds true*;

(3.2c) *The kth entrance set to* a_2, En_2^k, *is nonempty if and only if the following system of* $l_2 = 2k(d-1)$ *equations has solutions for the* $l_2 + n - 1$ *unknown variables*

$$\eta, \zeta_1^1, \cdots, \zeta_1^k, \xi, y$$

with $\zeta_i^j = (s_i^j, \xi_i^j, \eta_i^j) \in \Delta_i$ *satisfying the constraints* $s_i^j > 0$ *for all* $i = 1, 2$ *and* $1 \leqq j \leqq k$:

$$\Pi_{21}(0, y) = \rho_1^s(\zeta_1^1)$$
$$\vdots$$
$$\Pi_{12}(\rho_1^u(\zeta_1^k)) = (\xi, y);$$

(3.2d) *The kth exit set from* a_2, Ex_2^k, *is nonempty if and only if after replacing* (ξ, y) *by* $\rho_2^s(\zeta_2^k)$ *with* $\zeta_2^k \in \Delta_2$ *the same statement of* (3.2c) *holds true.*

Solving equations (3.2a-d) is more difficult with the constraints $s_i^j > 0$ than without them when those maps ρ_i^s and ρ_i^u are considered as the extended maps on the extended domain $\tilde{\Delta}_i$ introduced in the previous section. Let us now study the extended equations and leave the consideration of the constraints to the next section.

Note that each system of the extended equations (3.2a-d) might locally define an $(n-1)$-dimensional manifold near the origin of the l-dimensional Euclidean space $\mathbb{R}^l$, where $l = l_i + n - 1$. In fact, we have the following.

LEMMA 3.3. *Suppose the equilibria are simple saddle, relatively contractive, and the heteroclinic loop is nondegenerate. Then there exists a small constant* $\delta > 0$ *independent of k such that in the* δ*-box* $B(\delta)$ *of the origin in* $\mathbb{R}^l$ *each of the systems of the extended equations* (3.2a-d) *defines an* $(n-1)$*-dimensional manifold* $\mathcal{M}$ *in* $B(\delta)$ *which contains the origin and can be written as the graph of a* C^1 *vector-valued function of the last* $n-1$ *components, i.e., either* $\hat{y} = (y^{(2)}, \cdots, y^{(n)})$ *or* η_i, *where* $l = l_1 + n - 1$, *or* $l_2 + n - 1$, *accordingly.*

Proof. We prove the lemma by the implicit function theorem for equation (3.2a) only since the other cases are identical. By using the notation $\Pi_{ij} = (P_i, Q_i)^T$, $\rho_i^s = (\xi_i, Y_i)$ and $\rho_i^u = (X_i, \eta_i)$ from the last section, we see that solving equation (3.2a) is equivalent to solving the zero of the following equation:

$$\Phi(\zeta, \hat{y}) = 0,$$

where

$$\Phi(\zeta, \hat{y}) = \begin{bmatrix} -\xi_1^1 + P_2(0, \eta) \\ -Y_1^1 + Q_2(0, \eta) \\ -\xi_2^1 + P_1(X_1^1, \eta_1^1) \\ -Y_2^1 + Q_1(X_1^1, \eta_1^1) \\ \vdots \\ -\xi + P_2(X_2^{k-1}, \eta_2^{k-1}) \\ -y + Q_2(X_2^{k-1}, \eta_2^{k-1}) \end{bmatrix},$$

$$\zeta = (\eta, s_1^1, \xi_1^1, \eta_1^1, \cdots, s_2^{k-1}, \xi_2^{k-1}, \eta_2^{k-1}, \xi, y^{(1)}) \in \mathbb{R}^{l_1},$$

$X_i^j = X_i(s_i^j, \xi_i^j, \eta_i^j)$ and $Y_i^j = Y_i(s_i^j, \xi_i^j, \eta_i^j)$. It is obvious that the existence of the heteroclinic loop $\Gamma_1 \cup \Gamma_2$ (at $\alpha = 0$!) implies $\Phi(0, 0) = 0$. A simple calculation yields that the $l_1 \times l_1$ square Jacobian matrix $\partial\Phi/\partial\zeta$ at $(\zeta, \hat{y}) = (0, 0)$ has the following diagonal property

$$\left| \det \frac{\partial \Phi}{\partial \zeta}(0, 0) \right| = |\det \operatorname{diag}(M_2, M_1, \cdots, M_1, M_2)|,$$

where the diagonal blocks have the forms of Lemma 2.3 with all the blocks M_i except the last M_2 taking $e=-\psi_j(0,0,0)$. Therefore, the Jacobian matrix is nonsingular. Hence, by the implicit function theorem there exists a $\delta>0$ such that $\Phi(\zeta,\hat{y})=0$ defines in $B(\delta)$ an $(n-1)$-dimensional manifold $\mathcal{M}$ (containing the origin at $\alpha=0$) which is the graph of a C^1 function of the variable $\hat{y}$. Moreover, because of the diagonal block structure it is not difficult to see that δ can be chosen to be independent of the number of the equations $l_1=(2k-1)(d-1)$. □

Let $\mathbf{P}$ be the canonical projection from $\mathbb{R}^l=\mathbb{R}^{l-(d-1)}\times\mathbb{R}^{d-1}$ onto the last $d-1$ components. Then Lemma 3.3 implies that the projection $\mathbf{P}\mathcal{M}$ of the manifold $\mathcal{M}$ is also the graph of a C^1 function of the last $n-1$ coordinates. Therefore, we have the following.

DEFINITION 3.4. $\tilde{\mathrm{En}}_i^k:=\mathbf{P}\mathcal{M}$ and $\tilde{\mathrm{Ex}}_i^k:=\rho_i^u(\mathbf{P}\mathcal{M})$ are called the extended kth entrance set and the extended kth exit set (of W_2^u) near a_i, respectively, according to whether $\mathcal{M}$ is taken to be the manifold defined by the extended equations (3.2a–d) for the entrance sets or the exit sets in Lemma 3.3.

Since all the extended entrance and exit sets exist in some small but fixed δ-box $B(\delta)$ of the center points on the entrance and exit cross sections, respectively, we can easily construct a tubular neighborhood $\mathcal{U}$ of the heteroclinic loop $\mathrm{cl}(\Gamma_1\cup\Gamma_2)$ such that the intersections of $\mathcal{U}$ with the entrance and exit cross sections (Σ_i^s and Σ_i^u) are exactly those δ-boxes. Thus, we only need to consider the real entrance and exit sets (of W_2^u) in $B(\delta)$ and rename $E\beta^k:=E\beta^k\cap B(\delta)$ for simplicity of notation, where $\beta=n_i$ or x_i. Now we are ready to compare these sets with their extensions. Because the kth extended entrance set $\tilde{\mathrm{En}}_1^k$ near a_1 is a graph over the last $n-1$ coordinates $\hat{y}$ on Σ_1^s and the nonemptiness of its intersection with the local stable manifold W_1^s of a_1 forces $\hat{y}=0$, we have proved the following.

COROLLARY 3.5. *If a $(k-1)$-heteroclinic orbit from a_2 to a_1 exists in $\mathcal{U}$, then it must be unique (for the corresponding parameter).*

COROLLARY 3.6. *Let $\tilde{\mathrm{En}}_i^k=\mathrm{graph}(G,H)$ with $\xi=G(\hat{y})$ and $y^{(1)}=H(\hat{y})$. If $\dim W_1^s=\dim W_2^s=1$, $|H(\hat{y})|\leqq\delta_0 s_0/4$ and the derivative $|DH(\hat{y})|\leqq\frac{1}{2}$ for all $|\hat{y}|<\delta$, then $\tilde{\mathrm{En}}_i^k\cap\sigma_i^s\neq\varnothing$ if and only if $0<H(0)$, where δ_0 and s_0 are as in Proposition 2.2.*

Proof. Since $\dim W_1^s=\dim W_2^s=1$, $\xi=G(y)=\delta_0$, the x-component of the center of the entrance section Σ_i^s. Since the boundary point $(\delta_0,y_0)=(\delta_0,Y(s_0,0))\in\partial\sigma_1^s$ satisfies $y_0^{(1)}\geqq\delta_0 s_0/2>\max|H|$ by Proposition 2.2 and our assumption, the two boundary points (δ_0,y_0) and $(\delta_0,0)$ must be in different sides of $\tilde{\mathrm{En}}_i^k$ if $0<H(0)$. The path connectedness of σ_1^s implies there must be a point $(\delta_0,Y(s_1,\delta_0,0))\in\tilde{\mathrm{En}}_i^k$. This shows $0<H(0)$ is sufficient. To show that it also necessary, suppose it false, i.e., $H(0)\leqq 0$. Since $\tilde{\mathrm{En}}_1^k=\mathrm{graph}(H)$, then $y_0^{(1)}=H(0)\leqq 0$. Thus, $y^{(1)}-y_0^{(1)}\leqq|DH||\hat{y}|\leqq|\hat{y}|/2$ by our assumption. Let $y_1\in\tilde{\mathrm{En}}_i^k\cap\sigma_i^s\neq\varnothing$; then $|\hat{y}_1|<y_1^{(1)}$ holds true by Proposition 2.2. It follows that $|\hat{y}_1|-y_0^{(1)}<y_1^{(1)}-y_0^{(1)}\leqq|\hat{y}_1|/2$ and $0\leqq|\hat{y}_1|/2<y_0^{(1)}$, a contradiction. □

Our main result of this section is as follows.

THEOREM 3.7. *Let $\tilde{\mathrm{En}}_i^k=\mathrm{graph}(G,H)$ with $\xi=G(\hat{y})$ and $y^{(1)}=H(\hat{y})$. If the derivative of H satisfies $|DH|\leqq\frac{1}{2}$ for all k, $i=1,2$ and $E\beta^k$ is nonempty, then $E\beta^k=\tilde{E}\beta^k$, where $\beta=n_i$ or x_i.*

Proof. Suppose it is false; then there exists a first $E\beta^k$ such that $E\beta^k\neq\tilde{E}\beta^k$. We claim first $\beta=x_i$. If $\beta=n_i$ then there exists a point $p_0\in\tilde{\mathrm{En}}_i^k-\mathrm{En}_i^k$. Hence, there exists a point $(\zeta,\hat{y})\in\mathcal{M}$ with $p_0=\mathbf{P}(\zeta,\hat{y})$, and $(\zeta,\hat{y})$ has at least one $s_i^j\leqq 0$, where $\mathcal{M}$ and the projection $\mathbf{P}$ are as in Definition 3.4. To be precise, say $s_1^j\leqq 0$.

Let us first note the following: Denote $\mathcal{M}=\mathscr{E}\beta^k$ according to whether it is obtained by the extended equations for the kth entrance set when $\beta=n_i$ or the exit set when $\beta=x_i$. Now it is not difficult to see that if $p\in\mathscr{E}\beta^k$ then the point q, whose components consist of the first $(2j-1)(d-1)+n-1$ components of p, belongs to $\mathscr{E}x_1^j$ since q satisfies

the first $(2j-1)(d-1)$ equations (cf. Proposition 3.2). Similarly, if q is obtained by keeping the first $2j(d-1)+n-1$ components of p, then q is in $\mathscr{E}x_2^j$.

Now, resume our assumption $s_1^j \leqq 0$ and let q_0 be such a truncated point of p_0 which belongs to $\mathscr{E}x_1^j$. Then $\mathbf{P}(q_0) \in \tilde{E}x_1^j - \mathrm{Ex}_1^j$ since $s_1^j \leqq 0$. This contradicts our assumption for $\tilde{\mathrm{En}}_i^k$. Hence, the claim holds true.

Since we have $\varnothing \neq \mathrm{Ex}_i^k \neq \tilde{\mathrm{Ex}}_i^k$, it follows that there exist $\zeta_j = (s_j, \xi_j, \eta_j) \in \tilde{\Delta}_i$ with $j = 1, 2$, $s_1 \leqq 0$, and $s_2 > 0$ such that $\rho_i^s(\zeta_1) \in \tilde{\mathrm{En}}_i^k - \mathrm{En}_i^k$ and $\rho_i^s(\zeta_2) \in \mathrm{En}_i^k \cap \sigma_i^s$ for the same reason as above on the truncated point q. Since $\tilde{\mathrm{En}}_i^k$ is path connected, being a graph over the path connected set $|\hat{y}| < \delta$, there exists a $\zeta_0 = (s_0, \xi_0, \eta_0) \in \tilde{\Delta}_i$ with $s_0 = 0$. Hence, $\rho_i^s(\zeta_0) = (\xi_0, Y_i(0, \xi_0, \eta_0)) = (\xi_0, 0) \in \partial\sigma_i^s \cap W_{1\mathrm{loc}}^s$. That is, $(\xi_0, 0) \in \tilde{\mathrm{En}}_i^k =$ graph (G, H). This implies $|y^{(1)}| \leqq |DH||\hat{y}| \leqq |\hat{y}|/2$ by our assumption for all $(\xi, y) \in \tilde{\mathrm{En}}_i^k$. It follows that $\tilde{\mathrm{En}}_i^k \cap \sigma_i^s = \varnothing$, since by Proposition 2.2 $|\hat{y}| < y^{(1)}$ for all $(\xi, y) \in \sigma_i^s$. This contradicts $\rho_i^s(\zeta_2) \in \mathrm{En}_i^k \cap \sigma_i^s \subset \tilde{\mathrm{En}}_i^k \cap \sigma_i^s$. □

4. Bifurcation equations. From now on, we shall spell out the parameter explicitly wherever it is necessary. In this section we consider the constraints $s_i^j > 0$ in terms of their sign changes with the parameter, in particular the sign changes of $y^{(1)} = H(0)$. Here (G, H) gives the graph of the extended entrance set. For this reason, we consider the following equations:

$$\Pi_{21}(0, \eta, \alpha) = (\xi, y), \tag{4.1a}$$

$$\Pi_{21}(0, \eta, \alpha) = \rho_1^s(\zeta_1, \alpha), \tag{4.1b}$$

$$\Pi_{21}(\rho_2^u(\zeta_2, \alpha), \alpha) = (\xi, y), \tag{4.1c}$$

$$\Pi_{21}(\rho_2^u(\zeta_2, \alpha), \alpha) = \rho_1^s(\zeta_1, \alpha), \tag{4.1d}$$

$$\Pi_{12}(\rho_1^u(\zeta_1, \alpha), \alpha) = (\xi, y), \tag{4.1c'}$$

$$\Pi_{12}(\rho_1^u(\zeta_1, \alpha), \alpha) = \rho_2^s(\zeta_2, \alpha), \tag{4.1d'}$$

which introduce every new s_i^j or $y^{(1)}$ into our recursive construction of the entrance and exit sets in the last section, where $\zeta_i = (s_i, \xi_i, \eta_i)$.

Note that each of the systems above defines a system of $d-1$ equations with $l_1 = (d-1)+(n-1)+2$ unknown variables for (4.1a-b) or $l_2 = 2(d-1)+2$ variables for (4.1c-d'), including the parameters α_1 and α_2. Thus, presumably, each of them defines an $(l_i-(d-1))$-dimensional manifold in $\mathbb{R}^{l_i}$ accordingly. Indeed, we have the following lemma.

LEMMA 4.1. *Suppose the conditions of Theorem* A *are satisfied. Then there exists a small constant* $\delta > 0$ *such that in the* δ*-box* $B(\delta)$ *of the origin in* $\mathbb{R}^{l_i}$ *each of the extended equations* (4.1a-d) *defines an* $(l_i-(d-1))$*-dimensional differential manifold in* $B(\delta)$ *which can be written as the graph of a* C^1 *function of the last* $(n-1)+2$ *variables* $(\hat{y}, \alpha)$ *or* (η, α) *when* $l_i = l_1$ *or the first* m *and the last* $(n-1)+2$ *variables* $(s_i, \xi_i, \hat{y}, \alpha)$ *or* $(s_i, \xi_i, \eta, \alpha)$ *when* $l_i = l_2$, *accordingly. Moreover, up to only one nonsingular and differentiable change of the parameter for all the equations* (4.1a-d') *considered, the following bifurcation equations are satisfied for solutions to* (4.1a-d') *with the corresponding alphabetical order*:

$$m_1 y^{(1)} + \cdots + m_n y^{(n)} = \alpha_2 + O(|\hat{y}|^2), \tag{4.2a}$$

$$s_1 = \alpha_2 + O(|\eta_1||s_1| + |s_1|^{1+\bar{\nu}_1}), \tag{4.2b}$$

$$m_1 y^{(1)} + \cdots + m_n y^{(n)} = \alpha_2 + \tau_2(\alpha) s_2^{1+\nu_2} + O((|\xi_2| + |s_2|^{\bar{\nu}_2})|s_2|^{1+\nu_2} + |\hat{y}|^2), \tag{4.2c}$$

$$s_1 = \alpha_2 + \tau_2(\alpha) s_2^{1+\nu_2} + O((|\xi_2| + |s_2|^{\bar{\nu}_2})|s_2|^{1+\nu_2} + (|\eta_1| + |s_1|^{\bar{\nu}_1})|s_1|), \tag{4.2d}$$

$$\hat{m}_1 y^{(1)} + \cdots + \hat{m}_n y^{(n)} = \alpha_1 + \tau_1(\alpha) s_1^{1+\nu_1} + O((|\xi_1| + |s_1|^{\bar{\nu}_1})|s_1|^{1+\nu_1} + |\hat{y}|^2), \tag{4.2c'}$$

(4.2d′) $$s_2 = \alpha_1 + \tau_1(\alpha)s_1^{1+\nu_1} + O((|\xi_1| + |s_1|^{\bar{\nu}_1})|s_1|^{1+\nu_1} + (|\eta_2| + |s_2|^{\bar{\nu}_2})|s_2|),$$

where ν_i, $\bar{\nu}_i$ are as in Proposition 2.1. *Here $m_i = m_i(\alpha)$ are differentiable functions of α satisfying $1/(2\delta_0) < m_1 < 2/\delta_0$, $m_i/m_1 = o(1)$ as $\delta_0 \to 0$ for $i \neq 1$ and the analogous properties also hold for $\hat{m}_i$. Moreover, the scalar functions, $\tau_i = \tau_i(\alpha)$, called twist functions, are nonzero, differentiable, and satisfy*

(4.3) $$\tau_i(0)\begin{cases} <0 & \text{if } \Gamma_i \text{ is twisted,} \\ >0 & \text{otherwise.} \end{cases}$$

Furthermore, the change of the parameters leaves the parameter axes, as sets, invariant, but may reverse their directions.

The basic framework for the proof of this lemma, in particular, the derivation of the bifurcation equations through a modified Lyapunov-Schmidt reduction, has much in common with the spirit of Chow, Deng, and Terman (1990). Thus, we will prove it in the Appendix with necessary modifications given to the twist terms $\tau_i(\alpha)s_i^{1+\nu_i}$ and the order estimates on the higher-order terms.

The following corollaries concern the conditions of Corollary 3.6 and Theorem 3.7 when the parameter is taken into consideration.

COROLLARY 4.2. *Let $\tilde{\text{En}}_i^k = \text{graph}\,(G(\cdot, \alpha), H(\cdot, \alpha))$ with $\xi = G(\hat{y}, \alpha)$ and $y^{(1)} = H(\hat{y}, \alpha)$. Then δ_0 and δ can be chosen sufficiently small but fixed such that $|H(\hat{y}, \alpha)| \leqq \delta_0 s_0/4$ and $|DH(\hat{y}, \alpha)| \leqq \frac{1}{2}$ for all $|\hat{y}|$, $|\alpha| < \delta$ and $k \geqq 1$, where D is the differentiation operator in $\hat{y}$.*

Proof. Using (4.2c) or (4.2c′), we have

$$|y^{(1)}| \leqq \left[\max_{i \neq 1} |m_i(\alpha)|\delta + O(\delta)\right] \Big/ m_1(\alpha) = o(1)\delta + 2\delta_0 O(\delta),$$

and

$$|DH| \leqq \left[\max_{i \neq 1} |m_i(\alpha)| + O(\delta^{\nu_0})\right] \Big/ m_1(\alpha) = o(1) + 2\delta_0 O(\delta^{\nu_0}),$$

where $\nu_0 = \min\{\nu_1, \nu_2, \bar{\nu}_1, \bar{\nu}_2\}$. Choosing δ_0 and δ so small but fixed implies the desired estimates. □

COROLLARY 4.3. *δ can be chosen small so that if $\tilde{\text{En}}_i^k = \text{graph}\,(G(\cdot, \alpha), H(\cdot, \alpha))$ crosses the stable manifold $W^s_{i\,\text{loc}} \cap \Sigma_i^s$, then it does so transversely in α_j in the sense that $\partial H(0, \alpha)/\partial \alpha_j > 0$ for $|\alpha| < \delta$. In other words, if $H(0, \alpha^0) = 0$ then for the fixed ith component $\alpha_i = \alpha_i^0$, $H(0, \alpha) > 0$ if and only if $\alpha_j > \alpha_j^0$.*

Proof. Using (4.2c) or (4.2c′) again, we have $m_1(\alpha)H(0, \alpha) = \alpha_j + O(|\alpha|^{1+\nu_0})$ with $\nu_0 = \min\{\nu_1, \nu_2, \bar{\nu}_1, \bar{\nu}_2\}$. Thus

$$\partial H(0, \alpha)/\partial \alpha_j \geqq \left(1 - \left[\left|\frac{\partial m_1}{\partial \alpha_j} H(0, \alpha)\right| + O(|\alpha|^{\nu_0})\right]\right) \Big/ m_1(\alpha) > 0$$

for $|\alpha| < \delta$ by an appropriately chosen small δ. □

COROLLARY 4.4. *The first entrance set En_1^1 to a_1 intersects the domain σ_1^s of the local map nonempty if and only if $\alpha_2 > 0$.*

Proof. By (4.2b), $s_1 = \alpha_2 + O(|\eta_1||s_1| + |s_1|^{1+\nu_1})$, implying $s_1 > 0$ if and only if $\alpha_2 > 0$. □

5. Proof of Theorem A. As we mentioned earlier, Theorem A has been proved in Chow, Deng, and Terman (1990), except for the directions of homoclinic bifurcations and the k-heteroclinic orbits. Thus, we are going to outline the proof from that paper and provide the necessary details for the other part of the proof.

Consider the Poincaré map $\Pi_{11}=\Pi_{21}\circ\Pi_2\circ\Pi_{12}\circ\Pi_1$ from a subset of σ_1^s into the entrance section Σ_1^s near a_1. Using the Sil'nikov changes of variables, we can similarly reduce the problem of finding periodic points of Π_{11} into solving a system of equations for the unknown Sil'nikov variables with the constraints $s_i>0$. The conditions of the nondegenerate heteroclinic loop and the relative contraction for the simple saddle equilibria imply that the extended system has a unique solution parametrized by α by the implicit function theorem. This uniqueness allows us to consider the simple homoclinic, periodic orbits only. Thus, by the implicit function theorem, we solve $(\zeta_1^*, \xi_2^*)(\alpha)=(s_1^*, \xi_1^*, \eta_1^*, s_2^*, \xi_2^*, \eta_2^*)(\alpha)$ as the solution for the extended equations $\Pi_{12}(\rho_1^u(\zeta_1, \alpha), \alpha)=\rho_2^s(\zeta_2, \alpha)$ and $\Pi_{21}(\rho_2^u(\zeta_2, \alpha), \alpha)=\rho_1^s(\zeta_1, \alpha)$, where $\zeta_i=(s_i, \xi_i, \eta_i)$ with $|\zeta_i^*(\alpha)|=O(|\alpha|)$. Now, substituting ζ_1^* and ζ_2^* into the bifurcation equation (4.2d') and (4.2d), we have $s_2^*=\alpha_1+O(|\alpha|^{1+\nu_0})$ and $s_1^*=\alpha_2+O(|\alpha|^{1+\nu_0})$. It follows that the map $\alpha\to(s_1^*, s_2^*)$ is a diffeomorphism. Thus, the sector Λ for the periodic orbits is given by $s_1^*>0$ and $s_2^*>0$ and the curve $\hom_1$ for 1-homoclinic orbits from a_1 to a_1 is given as a piece of the boundary $\partial\Lambda$ with $s_1^*=0$ but $s_2^*>0$. Substituting $s_1^*=0$ and $s_2^*>0$ into (4.2d') and (4.2d), again we have $s_2^*=\alpha_1+O(|\alpha|)|s_2^*|^{1+\nu_0}$, implying $\alpha_1>0$, and

$$0=\alpha_2+\tau_2(\alpha)s_2^{*1+\nu_2}+O(|\alpha|)|s_2^*|^{1+\nu_2}, \tag{5.1}$$

implying $\alpha_2=\hom_1(\alpha_1)=[-\tau_2(\alpha)+O(|\alpha|)]|s_2^*|^{1+\nu_2}$. Therefore, the bifurcation directions in (i) hold true because of (4.3). Finally, to complete the proof, we only need to prove (ii).

Let us consider the $3(d-1)$ equations $\Pi_{21}(0, \eta, \alpha)=\rho_1^s(\zeta_1, \alpha)$,

$$\Pi_{12}(\rho_1^u(\zeta_1, \alpha), \alpha)=\rho_2^s(\zeta_2, \alpha), \text{ and } \Pi_{21}(\rho_2^u(\zeta_2, \alpha))=(\xi, 0) \quad \text{for } 3(d-1)+1 \text{ variables,}$$

including the two parameters α_1 and α_2, and assume Γ_2 is twisted first. We solve the following $3(d-1)-1$ equations first:

$$\Phi(\zeta, \alpha)=\begin{bmatrix} -\xi_1+P_2(0, \eta, \alpha) \\ -Y_1+Q_2(0, \eta, \alpha) \\ -\xi_2+P_1(X_1, \eta_1, \alpha) \\ -Y_2+Q_1(X_1, \eta_1, \alpha) \\ -\xi+P_2(X_2, \eta_2, \alpha) \\ \hat{Q}_2(X_2, \eta_2, \alpha) \end{bmatrix}=0, \tag{5.2}$$

with $\hat{Q}_2=(Q_2^{(2)}, \cdots, Q_2^{(n)})$, and solve the leftover equation $Q_2^{(1)}(X_2, \eta_2, \alpha)=0$ later, where $\zeta=(\eta, s_1, \xi_1, \eta_1, s_2, \xi_2, \eta_2, \xi)$. The existence of the heteroclinic loop implies $\Phi(0, 0)=0$ and a simple calculation shows the Jacobian square matrix satisfies

$$\left|\det\frac{\partial\Phi}{\partial\zeta}(0, 0)\right|=|\det \operatorname{diag}(M_2, M_1, \hat{M}_2)|,$$

where M_i and $\hat{M}_2$ are the same as in Lemma 2.3 with e being $\psi_j(0, 0)$ in M_i. Hence, it follows from Lemma 2.3 that the Jacobian $\partial\Phi/\partial\zeta(0, 0)$ is nonsingular and ζ can be solved as a C^1 function ζ^* of α satisfying $\zeta^*(0)=0$ by the implicit function theorem. Substituting $\zeta=\zeta^*(\alpha)$ into the remaining equation $Q_2^{(1)}(X_2^*, \eta_2^*, \alpha)=0$, we find it equivalent to solving α from

$$\begin{aligned} &\xi^*=P_2(X_2^*, \eta_2^*, \alpha), \\ &0=Q_2(X_2^*, \eta_2^*, \alpha). \end{aligned} \tag{5.3}$$

Notice that this equation has the form of the connecting equation (4.2c) and the corresponding bifurcation equation (4.2c) of Lemma 4.1 applies. Thus, it is equivalent to

$$0=\alpha_2+\tau_2(\alpha)|s_2^*|^{1+\nu_2}+O((|\xi_2^*|+|s_2^*|^{\bar\nu_2})|s_2^*|^{1+\nu_2}). \tag{5.4}$$

Since s_2^*, $\xi_2^*=O(|\alpha|)$, this equation always has a unique solution $\alpha_2:=1\text{-het}_2^{\wedge}(\alpha_1)$ for every α_1 by the implicit function theorem. Since Γ_2 is twisted, then $\tau_2(\alpha)<0$. This implies $1\text{-het}_2^{\wedge}>0$. Also $1\text{-het}_2^{\wedge}=O(|\alpha_1|^{1+\nu_2})$. To see if the constraint $s_1^*(\alpha)>0$ and $s_2^*(\alpha)>0$ are satisfied at $\alpha\in 1\text{-het}_2^{\wedge}$ we need to consider the other two bifurcation equations (4.2b) and (4.2d′) corresponding to the first two connections:

$$s_1^*=\alpha_2+O(|\eta_1^*||s_1^*|+|s_1^*|^{1+\bar\nu_1}), \tag{5.5a}$$

$$s_2^*=\alpha_1+\tau_1(\alpha)|s_1^*|^{1+\nu_1}+O((|\xi_1^*|+|s_1^*|^{\bar\nu_1})|s_1^*|^{1+\nu_1}+(|\eta_2^*|+|s_2^*|^{\bar\nu_2})|s_2^*|). \tag{5.5b}$$

From (5.5a) and $\alpha_2=1\text{-het}_2^{\wedge}(\alpha_1)>0$ it is obvious to see that $s_1^*>0$ is automatically satisfied. Moreover, $s_1^*=O(\alpha_2)=O(|\alpha_1|^{1+\nu_2})$. Substituting this order for s_1^* into (5.5b) yields $s_2^*>0$ if and only if $\alpha_1>0$ since α_1 is the leading term in the right-hand side when s_1^* and α_2 are of order $O(|\alpha_1|^{1+\nu_2})$. Let $1\text{-het}_2:=1\text{-het}_2^{\wedge}|_{\alpha_1>0}$ be the desired curve.

To show the nonexistence of k-heteroclinic orbits for $k\geqq 1$ under the nontwist assumption for Γ_2, let us solve a system of equations similar to (5.2). Analogously, it is equivalent to solving those α from the following bifurcation equations so that $s_i^{j^*}(\alpha)>0$ for all i,j:

$$\begin{aligned}
&s_1^{1^*}=\alpha_2+O((|\eta_1^{1^*}|+|s_1^{1^*}|^{\bar\nu_1})|s_1^{1^*}|)\\
&s_2^{1^*}=\alpha_1+\tau_1|s_1^{1^*}|^{1+\nu_1}+O((|\xi_1^{1^*}|+|s_1^{1^*}|^{\bar\nu_1})|s_1^{1^*}|^{1+\nu_1}+(|\eta_2^{1^*}|+|s_2^{1^*}|^{\bar\nu_2})|s_2^{1^*}|)\\
&\qquad\vdots\\
&0=\alpha_2+\tau_2|s_2^{k^*}|^{1+\nu_2}+O((|\xi_2^{k^*}|+|s_2^{k^*}|^{\bar\nu_2})|s_2^{k^*}|^{1+\nu_2}).
\end{aligned} \tag{5.6}$$

Since $\tau_2>0$, the last equation implies $\alpha_2<0$. This forces $s_1^{1^*}<0$ from the first equation. This completes the proof. □

6. Proof of Theorem B. To prove Theorem B we need the following three lemmas.

When $\dim W_i^s=1$, two given graphs $E_j=\text{graph}\,(H_j)$ over $\hat y$ on the entrance set Σ_i^s are denoted by $E_1\leqq E_2$ if $H_1(\hat y)\leqq H_2(\hat y)$, or $E_1<E_2$ if $H_1(\hat y)<H_2(\hat y)$ for all common $\hat y$. A point $p=(\delta_0,y)\in\Sigma_i^s$ is said to satisfy $p\leqq(<)E=\text{graph}\,(H)$ if $y^{(1)}\leqq(<)H(\hat y)$. In what follows, let $\text{Fx}_1^0:=W_{1\text{loc}}^u\cap\Sigma_1^u$ and Fn_1^1 be the corresponding first entrance set of W_1^u to a_1. Their definitions are analogous to Ex_2^0 and En_1^1, respectively. Now we have Lemma 6.1 (cf. Fig. 6.1).

LEMMA 6.1. *If* $\dim W_1^s=\dim W_2^s=1$ *and all the entrance sets* Fn_i^1 *and* En_i^j *to* a_i *up to a given number* $k\geqq j$ *are nonempty graphs over the* $\hat y$*-axis, then*

If Γ_2 *is twisted but* Γ_1 *is not, then*

$$\text{En}_1^2<\text{En}_i^j<\text{Fn}_1^1<\text{En}_1^1 \quad \textit{for } 3\leqq j\leqq k; \tag{6.1a}$$

If both Γ_1 *and* Γ_2 *are twisted, then*

$$\text{Fn}_1^1<\text{En}_i^k<\text{En}_i^{k-1}<\cdots<\text{En}_1^2<\text{En}_1^1. \tag{6.1b}$$

Proof. The proof is based on the following two simple observations: (1) The range σ_i^u of the local map Π_i contains all the exit sets and lies to one side of the corresponding initial exit graph (Fx_1^0 or Ex_1^0). The images of the exit sets under the global map Π_{ij}

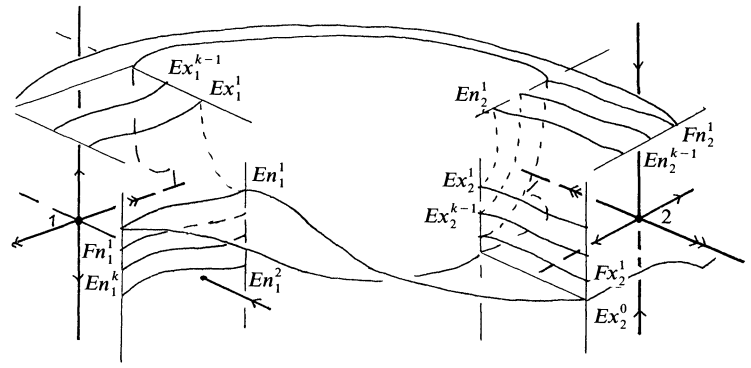
lie below (above), i.e., $<(>)$, the corresponding first entrance graph to the other equilibrium a_j if the connection Γ_i from a_i to a_j is twisted (nontwisted); (2) For a given pair of entrance graphs near a given equilibrium a_i ordered by $<$, the ordering $(<)$ for the consecutive entrance graphs near the other equilibrium a_j is (not) to be reversed if the connection Γ_i from a_i to a_j is (not) twisted.

To show (6.1(a)), we have $\mathrm{Ex}_2^j \subset \sigma_2^u$, thus $\mathrm{En}_1^{j+1} < \mathrm{En}_1^1$ for all $j \geqq 1$ by (1). By (2), the single twist and $\mathrm{En}_1^j < \mathrm{En}_1^1$ imply $\mathrm{En}_1^2 < \mathrm{En}_1^{j+1}$ for all $j \geqq 2$. Since $\mathrm{Fn}_2^1 < \mathrm{En}_2^j$ for $j \geqq 1$ by (1), we have $\mathrm{En}_1^{j+1} < \mathrm{Fn}_1^2$ by (2) (see Fig. 6.1(a)). To show (6.1(b)), we have $\mathrm{En}_2^j < \mathrm{Fn}_2^1$ and $\mathrm{En}_1^{j+1} < \mathrm{En}_1^1$ for all $j \geqq 1$ by (1). The twist of Γ_2 and $\mathrm{En}_2^j < \mathrm{Fn}_2^1$ imply $\mathrm{Fn}_1^1 < \mathrm{En}_1^{j+1}$ for all $j \geqq 0$ by (2). The double twists and $\mathrm{En}_1^2 < \mathrm{En}_1^1$ imply $\mathrm{En}_1^3 < \mathrm{En}_1^2$ by (2). Last, a simple inductive argument shows $\mathrm{En}_1^{j+1} < \mathrm{En}_1^j$ for all $j \geqq 1$ (see Fig. 6.1(b)). □

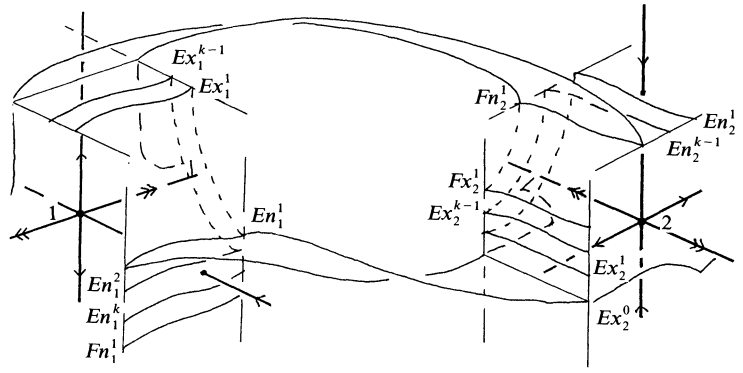
LEMMA 6.2. *If* $\dim W_1^s = \dim W_2^s = 1$ *and* $|\alpha_2| < \alpha_1$, *then the kth exit set* Ex_1^k *from* a_1 *is nonempty if all the previous* $k-1$ *exit sets* Ex_1^j *from* a_1 *are nonempty and the kth extended entrance set* $\tilde{\mathrm{En}}_1^k$ *near* a_1 *has nonempty intersection with the domain* σ_1^s *of the local map* Π_1.

Proof. We first claim that the $(k-1)$st exit set Ex_2^{k-1} from a_2 is nonempty. Since $\mathrm{Ex}_1^{k-1} \neq \varnothing$, the $(k-1)$st entrance set En_2^{k-1} to a_2 is nonempty. By $|DH(\cdot, \alpha)| \leqq \frac{1}{2}$ of Corollary 4.2 and Theorem 3.7, we have $\mathrm{En}_2^{k-1} = \tilde{\mathrm{En}}_2^{k-1} = \mathrm{graph}\,(G(\cdot, \alpha), H(\cdot, \alpha))$. Using the bifurcation equation (4.2c′) we have

$$H(0, \alpha) = [\alpha_1 + O(|\alpha|^{1+\nu_0})]/m_1(\alpha) > 0,$$



(a)



(b)

FIG. 6.1. (a) Γ_2 *is twisted but* Γ_1 *is not twisted*; (b) *Both* Γ_1 *and* Γ_2 *are twisted.*

since α_1 is dominating by our assumption $\alpha_1 > |\alpha_2|$. It follows from $|H(\hat{y}, \alpha)| \leqq \delta_0 s_0/4$ of Corollary 4.2 and Corollary 3.6 that $\tilde{\mathrm{En}}_2^{k-1} \cap \sigma_2^s \neq \emptyset$. Hence,

$$\mathrm{Ex}_2^{k-1} = \Pi_2(\mathrm{En}_2^{k-1} \cap \sigma_2^s) \neq \emptyset.$$

The claim is proved. Obviously, this claim implies the kth entrance set En_1^k to a_1 is nonempty and equal to its extension $\tilde{\mathrm{En}}_1^k$ by Corollary 4.2 and Theorem 3.7. Thus, the condition $\tilde{\mathrm{En}}_1^k \cap \sigma_1^s \neq \emptyset$ implies the kth exit set Ex_1^k near a_1 is nonempty. □

Combining Corollary 3.6, Theorem 3.7, and Corollaries 4.2, 4.3 above we have the following important result.

LEMMA 6.3. *If* $\dim W_1^s = \dim W_2^s = 1$ *and* $p_i = W_{i\,\mathrm{loc}}^s(\alpha) \cap \Sigma_i^s \in \tilde{\mathrm{En}}_i^k$ *at some* $\alpha = \alpha^0 = (\alpha_1^0, \alpha_2^0)$ *with* $k \geqq 1$, *then for the fixed ith component* $\alpha_i = \alpha_i^0$, $\tilde{\mathrm{En}}_i^k \cap \sigma_i^s \neq \emptyset$ *if and only if* $\alpha_j > \alpha_j^0$, *where* $|\alpha| < \delta$. *Moreover, if* En_i^k *is nonempty then the same statement holds true for* En_i^k.

Proof. Let $\tilde{\mathrm{En}}_i^k = \mathrm{graph}\,(H(\cdot, \alpha))$. Corollary 4.3 implies $H(0, \alpha) > 0$ for $\alpha_i = \alpha_i^0$ if and only if $\alpha_j > \alpha_j^0$. Since Corollary 4.2 implies the conditions $|DH| < \frac{1}{2}$ and $|H| \leqq \delta_0 s_0/4$ of Corollary 3.6, we conclude from Corollary 3.6 that $\tilde{\mathrm{En}}_i^k \cap \sigma_i^s \neq \emptyset$ for $\alpha_i = \alpha_i^0$ if and only if $\alpha_j > \alpha_j^0$. By the condition $|DH| < \frac{1}{2}$ of Corollary 4.2 and Theorem 3.7, we have $\mathrm{En}_i^k = \tilde{\mathrm{En}}_i^k$. □

Proof of Theorem B. (i) Corollary 4.2 implies the conditions of Corollary 3.6. The nonemptiness of the kth entrance set En_1^k with $k \geqq 3$ implies $\mathrm{En}_1^2 \cap \sigma_1^s \neq \emptyset$. Hence, by Corollary 3.6, $0 < H(0)$, where $\mathrm{En}_1^2 = \mathrm{graph}\,(H)$, implying the center point $p_1 = W_{1\,\mathrm{loc}}^s(\alpha) \cap \Sigma_1^s$ lies below the second entrance set En_1^2. It follows from (6.1a) that the existence of k-heteroclinic orbits from a_2 to a_1 is impossible for $k \geqq 2$. This together with Theorem A(ii) proves the uniqueness of the 1-heteroclinic orbit from a_2 to a_1.

Let 1-het$_2$ be as in Theorem A. To show 1-het$_2(\alpha_1) > \mathrm{hom}_1(\alpha_1)$ for $\alpha_1 > 0$, we notice that Fn_1^1 is nonempty in the spirit of Corollary 4.4. By (6.1a) we have $\mathrm{En}_1^2 < \mathrm{Fn}_1^1 < \mathrm{En}_1^1$. It follows that with α_2 increasing, the homoclinic connection $p_1 \in \mathrm{Fn}_1^1$ takes place before the single heteroclinic connection $p_1 \in \mathrm{En}_1^2$ does by the transverse crossing property of Corollary 4.3 and Lemma 6.3.

(ii) First we zoom in the region of the parameter where $(k-1)$-heteroclinic orbits (from a_2 to a_1) can take place. We first claim there exists a $(k-1)$-heteroclinic orbit only if $0 \leqq \alpha_2 < \mathrm{hom}_1(\alpha_1)$ with $\alpha_1 > 0$, where hom_1 is the bifurcation curve for the 1-homoclinic orbit at a_1. If $\alpha_1 < 0$ then $\mathrm{En}_2^k < \mathrm{Fn}_2^1 < p_2$ for all $k \geqq 1$ by Corollary 4.4 and the twist of Γ_1. Thus, $\mathrm{En}_2^k \cap \sigma_2^s = \emptyset$ by Corollary 3.6. Hence, $\mathrm{En}_1^{k+1} = \emptyset$ for $k \geqq 1$. If $\alpha_2 > \mathrm{hom}_1(\alpha_1)$ then $p_1 < \mathrm{Fn}_1^1$ by Corollary 4.3. By Lemma 6.1 $p_1 < \mathrm{Fn}_1^1 < \mathrm{En}_1^k$ for all $k \geqq 1$. This proves our claim.

The existence of these heteroclinic bifurcation curves $(k-1)$-het$_2$ in the region $0 \leqq \alpha_2 < \mathrm{hom}_1(\alpha_1)$ is an immediate consequence of the following claim: in $0 \leqq \alpha_2 < \mathrm{hom}_1(\alpha_1)$ there exists a unique $\alpha_2 = (k-1)$-het$_2(\alpha_1)$ for every $k \geqq 1$ such that $p_1 < \mathrm{En}_1^k$ if and only if $\alpha_2 > (k-1)$-het$_2(\alpha_1)$. We proceed by induction. When $k = 1$, it is trivial by the existence of the primary heteroclinic orbits and the transverse crossing property of Corollary 4.4. Suppose the claim holds true for $k-1$. Then, by Lemma 6.3 we have $\mathrm{En}_1^{k-1} \cap \sigma_1^s = \emptyset$ for $\alpha_2 < (k-2)$-het$_2(\alpha_1)$; hence, $(k-1)$-heteroclinic orbits do not exist. Again, by Lemma 6.2 and 6.3 we have $\mathrm{En}_1^k \neq \emptyset$ for $(k-2)$-het$_2(\alpha_1) < \alpha_2 \leqq \mathrm{hom}_1(\alpha_1) < \alpha_1$. On the other hand, Corollary 4.4 implies $\mathrm{Fn}_2^1 \cap \sigma_2^s \neq \emptyset$ and thus $\mathrm{Fn}_1^1 \neq \emptyset$ for these parameters. The transverse crossing properties of Lemma 6.3 and Corollary 3.6 imply $\mathrm{Fn}_1^1 < p_1$ for $\alpha_2 < \mathrm{hom}_1(\alpha_1)$. Lemma 6.1 implies $\mathrm{Fn}_1^1 < \mathrm{En}_1^k$. It follows from the continuity of En_1^1 on the parameter that when $0 < \alpha_2 - (k-2)$-het$_2(\alpha_1) \ll 1$, En_1^{k-1} is sufficiently close to the stable manifold W_1^s, and Ex_1^{k-1} is close to Fx_1^0. Therefore, $\mathrm{Fn}_1^1 < \mathrm{En}_1^k < p_1$ holds. Since $p_1 \in \mathrm{Fn}_1^1 < \mathrm{En}_1^k$ at $\alpha_2 = \mathrm{hom}_1(\alpha_1)$, there must be an α_2^{k-1}

such that $p_1 \in \mathrm{En}_1^k$ at $(\alpha_1, \alpha_2^{k-1})$. Because Lemma 6.3 implies this crossing is transverse, $p_1 < \mathrm{En}_1^k$ if and only if $\alpha_2 > \alpha_2^{k-1}$. Let $\alpha_2^{k-1} := (k-1)\text{-het}_2(\alpha_1)$. This completes the claim. Furthermore, by the property of transverse crossing, the function $(k-1)$-het_2 is also differentiable by the implicit function theorem.

Finally, to show the inaccessibility of the homoclinic bifurcation curve hom_1 from below, we suppose to the contrary that $(k-1)\text{-het}_2(\alpha_1^0) \to \alpha_2^0 < \mathrm{hom}_1(\alpha_1^0)$ for some α_1^0. Then, at $\alpha^0 = (\alpha_1^0, \alpha_2^0)$ $\mathrm{En}_1^k \neq \varnothing$ for all k. Let $\lim_{k\to\infty} \mathrm{En}_1^k = E^\infty$. Then $E^\infty \geqq p_1 > \mathrm{Fn}_1^1$ at α^0. Thus, $p_1 \notin E^\infty$ because otherwise $\mathrm{Fn}_1^1 < \mathrm{En}_1^k < p_1$ for sufficiently large k for En_1^k would be sufficiently close to the stable manifold W_1^s and En_1^{k+1} would be empty. Therefore, $p_1 < E^\infty$. But, in this case, by moving α_2 down a little, i.e., $0 < \alpha_2^0 - \alpha_2 \ll 1$, $p_1 < E^\infty \leqq \mathrm{En}_1^k$ would still hold true for all k and $\alpha = (\alpha_1^0, \alpha_2)$. Thus, there would exist a k such that $\alpha_2 < (k-1)\text{-het}_2(\alpha_1)$. This would imply $\mathrm{En}_1^k < p_1$ by our second claim above. This is a contradiction. □

7. Remarks. (a) It seems that the bifurcation equations (5.6) are solvable for $s_i^{j^*}(\alpha) > 0$ if the twist functions τ_1 and τ_2 are all negative. Incidentally, by neglecting the higher-order terms, the truncated recursive formulas do give rise to a monotone increasing set $s_2^{i^*}$ for $i = 1, \cdots, k-1$ with $s_2^{1^*} = \alpha_1 + \tau_1 \alpha_2^{1+\nu_1} > 0$ and a monotone decreasing set $s_1^{i^*}$ for $i = 1, \cdots, k$ with $s_1^{k^*} := \alpha_2 + \tau_2 |s_2^{k-1^*}|^{1+\nu_2} = 0$. Furthermore, the $(k-1)$-het_2 curve is then defined by the recursive formulas. Unfortunately, this argument fails when those fuzzy error terms are taken into consideration. A similar situation of our losing control over the full system appears in the homoclinic bifurcations with resonant principal eigenvalues (i.e., $\lambda_1(0) = \mu_1(0)$ in our notation) studied by Chow, Deng, and Fiedler (1990). This is the reason we impose the condition $\dim W^s = m = 1$ and approach our problem topologically by considering the entrance and exit sets and their extensions. We feel that this restriction may not be merely technical, since without it the position of Fn_1^1 relative to En_1^k may behave in an unpredictable way.

(b) It can be easily seen from the bifurcation equation (5.1) that the asymptotic tangency of the homoclinic curve hom_i is completely determined by the sign $\lambda_j + \mu_j$ for $i \neq j$. That is, hom_i is asymptotically tangent to the α_i-axis at $\alpha = 0$ for a relatively contractive a_j, or the α_j-axis for a relatively repelling a_j, or tangent to none of them for an a_j with principal resonant eigenvalues, i.e., $\lambda_j + \mu_j = 0$ at $\alpha = 0$. In all cases, however, k-heteroclinic orbits are expected to bifurcate at a twisted heteroclinic loop. In particular, as in the homoclinic doubling bifurcation for a twisted homoclinic orbit (see, e.g., Chow, Deng, and Fiedler (1990)), a double homoclinic bifurcation will also probably take place at a single twisted loop with the resonant eigenvalues, i.e., $(1+\nu_1)(1+\nu_2) = 1$ at $\alpha = 0$, or in the case where the heteroclinic loop is degenerate (see Yanagida (1986)).

Relaxing the equal dimensionality $\dim W_1^s = \dim W_2^s$ assumption will also lead to countable k-heteroclinic connections which, in contrast to Theorem B, take place in an open set of the parameter space. This was observed by Deng (1989). Also, as the principal eigenvalue (either stable or unstable) becomes a pair of complex, the system itself at $\alpha = 0$ becomes rather chaotically complicated (see Tresser (1984) for the case where $\dim W_1^s = \dim W_2^s$, and Bykov (1980) where $\dim W_1^s \neq \dim W_2^s$).

(c) The heteroclinic loop gives us another new bifurcation point which an oriented homoclinic path can hit globally in the parameter space (cf. Fig. 7.1). The orientation of a given homoclinic path is determined by the nonzero orbit index of the periodic orbits nearby. See Mallet-Paret and Yorke (1982), Fiedler (1985), and Chow, Deng, and Fiedler (1990) for more details on the orientation relative to the orbit index. Let us suppose the homoclinic paths hom_1 and hom_2 are oriented as shown in the figure.

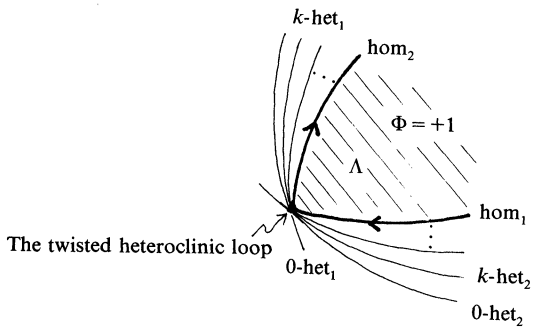


FIG. 7.1. *Φ is the orbit index. If it is assumed to be* 1 *then the region Λ is on the right of* hom$_i$ *curves.*

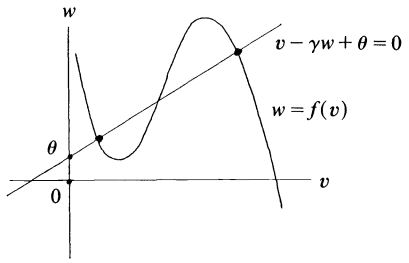

FIG. 7.2

Following hom$_1$, it will hit and terminate at the heteroclinic loop bifurcation point $\alpha = 0$. But, right at this point, the homoclinic orbit to a_1 trades itself to a homoclinic orbit to a_2 and the curve hom$_2$ arises from $\alpha = 0$ as if it is the continuation of hom$_1$. For this reason, we may also call our heteroclinic loop bifurcation the homoclinic trading bifurcation. However, if we "follow" (actually we do not know how at this moment) a heteroclinic path in the double twisted case, we will find doubly infinite heteroclinic trading partners at the homoclinic trading place $\alpha = 0$. Certainly, this immediately complicates any "global heteroclinic path following" attempt. But it also gives us one more hope that a global homoclinic path following result seems on its way (see a detailed discussion from Chow, Deng, and Fiedler (1990)).

(d) While writing these remarks, I received a preprint by Kokubu, Nishiura, and Oka (1988). I found that our notion of twisted heteroclinic loop has been propagating faster than I could finish writing this paper. Their work demonstrates that the non-degenerate conditions (1.4), (1.5), (1.7), and (1.10a, b) are verifiable. Indeed, motivated by the idea for the Mel'nikov function and the method of singular limit eigenvalue problem developed by Nishiura and Fujii (1987) and Nishiura (1989), they derive not only an analogous function to detect the transverse crossing of the stable and unstable manifolds (also see, e.g., Kokubu (1988)), but also a computable twist function to detect the strong inclination property and the twist of a given heteroclinic orbit at the same time for the system of ODE for the traveling waves, $(v, w)(x, t) = (v, w)(x + ct)$. The reaction diffusion system they consider is as follows:

$$\begin{aligned} \varepsilon\tau v_t &= \varepsilon^2 v_{xx} + f(v) - w, \\ w_t &= w_{xx} + v - \gamma w + \theta, \end{aligned} \tag{7.1}$$

where $f = -v^3 + v$. Starting at a standing front wave and a standing back wave which forms a heteroclinic loop (i.e., at $c = 0$), they manage to obtain the local codimension-three bifurcation unfoldings with c, θ, γ being the relevant parameters and globally

extend the local bifurcation diagram. Among the most interesting is the nontwistedness of all the resulting heteroclinic loops involved due to various symmetries exhibited by the system. According to Theorem A, this implies that there are no multiple heteroclinic connections other than the persistence of the zero-heteroclinic orbits from the loops. They also show that some of the finite connections are actually unstable.

Perhaps some comparisons between their system and the FitzHugh-Nagumo equation considered in the Introduction are worthwhile. First of all they model systems of different worlds—chemical reactions, predator and prey populations for the former while nerve impulses for the latter. Theoretically speaking, however, they are the same system but at different values of the diffusion parameter for the w dynamics. Indeed, if we move the origin to the left equilibrium state in Fig. 7.2, the parameter θ is the same as the parameter a in the FitzHugh-Nagumo equation (1.11). Rescaling the time and the space variables in (7.1) yields

$$v_t = v_{xx} + f(v) - w, \qquad w_t = \delta w_{xx} + \varepsilon(v - \gamma w),$$

where we renamed $\delta := \tau/\varepsilon$ and $\varepsilon := \varepsilon\tau$. Thus, it is the same FitzHugh-Nagumo equation except for a large diffusion coefficient δ for w. Since both systems have the same symmetries, I think the appearance of the second diffusion simply "untwists" the twisting structure somewhere. Thus, it is natural to ask whether it happens at some $\delta_0 > 0$ or just at $\delta_0 = 0$. Indeed, there are two types of bifurcations involved. When $\delta_0 = 0$ the system of the ODE is singularly perturbed. When $\delta_0 > 0$, however, to untwist a heteroclinic loop a heteroclinic orbit must be degenerate in general and, in particular, it must violate the strong inclination property. None of these bifurcations problems has ever been fully investigated. Nevertheless, the idea developed in this paper offers more hope for solving the bifurcation of twists than the problem of singular perturbation.

Appendix.

Proof of Lemma 4.1. The proof for the first half part of the lemma is identical to the proof of Lemma 3.3 in § 3. Thus, we omit it here. Using the notation from § 2, we write equations (4.1a-4.1d) in the following equivalent forms:

$$\Phi(\zeta, z, \alpha) = 0,$$

where $\Phi = \Phi_\iota$ with the subindex $\iota = a, b, c, d$ in correspondence with the alphabets in the equation numbers. Here $\zeta = (\eta_2, \xi_1)$ and z varies with equations as follows.

$$\Phi_a(\zeta, z, \alpha) = \begin{pmatrix} P_2(0, \eta_2, \alpha) - \xi_1 \\ Q_2(0, \eta_2, \alpha) - y_1 \end{pmatrix}, \qquad z = y_1,$$

$$\Phi_b(\zeta, z, \alpha) = \begin{pmatrix} P_2(0, \eta_2, \alpha) - \xi_1 \\ Q_2(0, \eta_2, \alpha) - Y_1 \end{pmatrix}, \qquad z = (s_1, \eta_1),$$

$$\Phi_c(\zeta, z, \alpha) = \begin{pmatrix} P_2(X_2, \eta_2, \alpha) - \xi_1 \\ Q_2(X_2, \eta_2, \alpha) - y_1 \end{pmatrix}, \qquad z = (s_2, \xi_2, y_1),$$

$$\Phi_d(\zeta, z, \alpha) = \begin{pmatrix} P_2(X_2, \eta_2, \alpha) - \xi_1 \\ Q_2(X_2, \eta_2, \alpha) - Y_1 \end{pmatrix}, \qquad z = (s_2, \xi_2, s_1, \eta_1),$$

where $X_2 = X_2(s_2, \xi_2, \eta_2, \alpha)$ and $Y_1 = Y_1(s_1, \xi_1, \eta_1, \alpha)$. Delete the mth component of Φ and let $\hat{\Phi} = (\Phi^{(1)}, \cdots, \Phi^{(m-1)}, \Phi^{(m+1)}, \cdots, \Phi^{(d-1)})^T$. We solve $\hat{\Phi} = 0$ first by the implicit function theorem for $\zeta = \zeta^*(z, \alpha)$ and then solve the reduced remaining equation $\Phi^{(m)}(\zeta^*, z, \alpha) = 0$ later.

Because of the existence of the heteroclinic loop we have $\hat{\Phi}(0, 0, 0) = 0$. Moreover, the square Jacobian $\partial\hat{\Phi}/\partial\zeta(0, 0, 0) = \hat{M}_2$ is nonsingular by Lemma 2.3. (Note that this

also implies $\partial\hat{Q}_2/\partial\eta(0,0,0)$ nonsingular.) Hence, by the implicit function theorem there exists a differentiable function ζ^* of $|z|, |\alpha| < \delta$ satisfying $\zeta^*(0,0)=0$ and $|\zeta^*| < \delta$ such that $\hat{\Phi}(\zeta, z, \alpha)=0$ if and only if $\zeta=\zeta^*(z,\alpha)$. To solve the reduced equation $\Phi^{(m)}(\zeta^*, z, \alpha)=0$, we need some important facts about ζ^*. Since ζ^* usually are not the same for different indexes $\iota = a, b, c,$ or d, we denote it by ζ_ι^*, accordingly. Since $\hat{\Phi}_a$ and $\hat{\Phi}_c$ do not depend on the first y-component $y_1^{(1)}$, ζ_a^* and ζ_c^* are functions of $\hat{y}_1$ and α only. Moreover, since $X_2(0,\xi_2,\eta_2,\alpha)=0$ and $Y_1(0,\xi_1,\eta_1,\alpha)=0$ by the property (2.1a) of exponential expansions, it is easy to see that when equations $\hat{\Phi}_\iota=0$ for all ι are restricted to $s_1=0$, $s_2=0$, and $\hat{y}_1=0$ (whichever applies) they are all reduced to the same equations as follows:

$$\text{(A.0)} \qquad \begin{cases} P_2(0,\eta_2,\alpha)-\xi_1=0, \\ Q_2(0,\eta_2,\alpha)=0, \end{cases} \qquad \zeta=(\eta_2,\xi_1).$$

Thus, the solution ζ depends only on α. Therefore, the following functions of restrictions $\zeta_a^*|_{\hat{y}_1=0}$, $\zeta_b^*|_{s_1=0}$, $\zeta_c^*|_{s_2=0,\hat{y}_1=0}$, and $\zeta_d^*|_{s_1=s_2=0}$ are in fact equal to the same function of α, say $(u,v)(\alpha)$, which is the solution to (A.0). Note also that $|\zeta_\iota^*-(u,v)^T|=O(|\hat{y}_1|+|s_2|)$ or $O(|s_1|+|s_2|)$, accordingly.

As another preparation, we need the following procedures one way or another. Expand $(P_2, Q_2)(x,\eta,\alpha)$ at $(x,\eta)=(0,u)$,

$$\text{(A.1)} \qquad \begin{pmatrix} P_2 \\ Q_2 \end{pmatrix}(x,\eta,\alpha)=\begin{pmatrix} P_{2\alpha} \\ Q_{2\alpha} \end{pmatrix}+\frac{\partial(P_2,Q_2)}{\partial(x,\eta)}(0,u,\alpha)\begin{pmatrix} x \\ \eta-u \end{pmatrix}+O(|x|^2+|\eta-u|^2),$$

where $(P_{2\alpha}, Q_{2\alpha})=(P_2,Q_2)(0,u,\alpha)$. Expand $\varphi(\xi,\eta,\alpha)$ at $(\xi,\eta)=(0,u)$ and $\psi(\xi,\eta,\alpha)$ at $(\xi,\eta)=(v,0)$, respectively:

$$\text{(A.2)} \qquad X(s_2,\xi_2,\eta_2,\alpha)=\varphi_{2\alpha}s_2^{1+\nu_2}+O[(|\xi_2|+|\eta_2-u|)|s_2|^{1+\nu_2}+|s_2|^{1+\nu_2+\bar{\nu}_2}],$$

$$\text{(A.3)} \qquad Y(s_1,\xi_1,\eta_1,\alpha)=\psi_{1\alpha}s_1+O[(|\xi_1-v|+|\eta_1|)|s_1|+|s_1|^{1+\bar{\nu}_1}],$$

where $\varphi_{2\alpha}=\varphi(0,u,\alpha)$ and $\psi_{1\alpha}=\psi(v,0,\alpha)$. Let

$$L_2(\alpha)=\begin{bmatrix} \dfrac{\partial P_2}{\partial\eta}(0,u,\alpha) & -I \\ \dfrac{\partial Q_2}{\partial\eta}(0,u,\alpha) & 0 \end{bmatrix}_{(d-1)\times(d-2)}$$

and

$$\hat{M}_2(\alpha)=\begin{bmatrix} \dfrac{\partial P_2}{\partial\eta}(0,u,\alpha) & -I \\ \dfrac{\partial \hat{Q}_2}{\partial\eta}(0,u,\alpha) & 0 \end{bmatrix}_{(d-2)\times(d-2)}.$$

Then, by the continuity of u on α and Lemma 2.3 we may assume that, without loss of generality, $L_2(\alpha)$ has the maximal rank $d-2$ which is attained by the submatrix $\hat{M}_2(\alpha)$. Note that this also implies $\partial\hat{Q}_2/\partial\eta(0,u,\alpha)$ nonsingular. Also, up to $m-1$ permutations we may still call

$$M_2(\alpha)=\left[L_2(\alpha),\begin{pmatrix} 0 \\ \psi_{1\alpha} \end{pmatrix}\right]_{(d-1)\times(d-1)}=\begin{bmatrix} \dfrac{\partial P_2}{\partial\eta}(0,u,\alpha) & -I & 0 \\ \dfrac{\partial Q_2}{\partial\eta}(0,u,\alpha) & 0 & \psi_{1\alpha} \end{bmatrix}$$

and we have $|\det M_2(\alpha)| > m_0\delta_0$ for $|\alpha|<\delta$ by Lemma 2.3 and Lemma 2.4.

Now we are ready to solve $\Phi^{(m)}(\zeta^*, z, \alpha) = 0$. Since $\hat{\Phi}(\zeta^*, z, \alpha) \equiv 0$, $\Phi(\zeta^*, z, \alpha) = (0, \cdots, \Phi^{(m)}, 0, \cdots, 0)(\zeta^*, z, \alpha)$. This implies

$$\det [L_2(\alpha), \Phi(\zeta^*, z, \alpha)] = (-1)^{(d-1)+m} \det \hat{M}_2(\alpha) \Phi^{(m)}(\zeta^*, z, \alpha).$$

Hence, $\Phi^{(m)}(\zeta^*, z, \alpha) = 0$ is equivalent to

$$\det [L_2(\alpha), \Phi(\zeta^*, z, \alpha)] = 0. \tag{A.4}$$

Since the simplifications for these equations are all identical we will only treat two typical cases $\iota = a$ and $\iota = c$ here, with emphasis on how the nonsingular change of parameters and the functions m_i and τ_i are obtained for all the bifurcation equations.

When $\iota = a$, substituting $(x, \eta) = (0, \eta_2^*)$ into the Taylor expansion (A.1) and using $|\eta_2^* - u| = O(|\hat{y}_1|)$, we have

$$\Phi_a(\xi^*, z, \alpha) = \begin{pmatrix} P_{2\alpha} \\ Q_{2\alpha} \end{pmatrix} + \frac{\partial (P_2, Q_2)}{\partial \eta} (0, u, \alpha)(\eta_2^* - u) + O(|\hat{y}_1|^2) - \begin{pmatrix} \xi_1^* \\ 0 \end{pmatrix} - \begin{pmatrix} 0 \\ y_1 \end{pmatrix}.$$

Since the second and the fourth terms all belong to the range of $L_2(\alpha)$, they will disappear in (A.4). This implies

$$\det \left[L_2(\alpha), \begin{pmatrix} 0 \\ y_1 \end{pmatrix} \right] = \det \left[L_2, \begin{pmatrix} P_{2\alpha} \\ Q_{2\alpha} \end{pmatrix} \right] + O(|\hat{y}_1|^2).$$

Dividing this equation by $\det M_2(\alpha)$ and expressing the left-hand side in terms of a homogeneous linear combination in $y_1^{(i)}$ we have

$$m_1(\alpha) y_1^{(1)} + \cdots m_n(\alpha) y_1^{(n)} = c_2(\alpha_1, \alpha_2) + O(|\hat{y}_1|^2),$$

where

$$m_i = \det \left[L_2(\alpha), \begin{pmatrix} 0 \\ e_i \end{pmatrix} \right] \Big/ \det M_2(\alpha),$$

and

$$c_2 = \det \left[L_2(\alpha), \begin{pmatrix} P_{2\alpha} \\ Q_{2\alpha} \end{pmatrix} \right] \Big/ \det M_2(\alpha), \tag{A.5}$$

and $e_i \in \mathbb{R}^n$ has zero components except for the ith component of 1. This has the form of (4.2a). Let us show that the functions m_i satisfy the required properties and postpone the discussion of c_2 until later.

Since $(0, \psi_j(0, 0))/\delta_0 \to (0, e_1)$ as $\delta_0 \to 0$ by the exponential expansion property (2.1b), $\det M_2(\alpha)$ is approximately the product of δ_0 and the numerator for m_1 as $\delta_0 \to 0$. Hence, for small but fixed δ_0 we have $1/2\delta_0 < m_1 < 2/\delta_0$. Also, it follows from Lemma 2.4 that

$$\frac{m_i}{m_1} = \det \left[L_2(\alpha), \begin{pmatrix} 0 \\ e_i \end{pmatrix} \right] \Big/ \det \left[L_2(\alpha), \begin{pmatrix} 0 \\ e_1 \end{pmatrix} \right] = o(1) \quad \text{as } \delta_0 \to 0.$$

Before we check the properties for c_2, let us first obtain the bifurcation equation (4.2d). Substitute $(x, \eta) = (X_2^*, \eta_2^*)$ with $X_2^* = X(s_2, \xi_2, \eta_2^*, \alpha)$ into (A.1) and use $|X_2^*| = O(|s_2|^{1+\nu_2})$ and $|\eta_2^* - u| = O(|s_1| + |s_2|)$. Then substitute the exponential expansion (A.2) for X_2^*. Finally, substitute the obtained (A.1) and (A.3) with $\xi_1 = \xi_1^*$ into the

function $\Phi_d(\zeta^*, z, \alpha)$. We have

$$\Phi_d(\zeta^*, z, \alpha) = \begin{pmatrix} P_{2\alpha} \\ Q_{2\alpha} \end{pmatrix} + \frac{\partial(P_2, Q_2)}{\partial x}(0, u, \alpha)\varphi_{2\alpha} s_2^{1+\nu_2} + \frac{\partial(P_2, Q_2)}{\partial \eta}(0, u, \alpha)(\eta_2^* - u) - \begin{pmatrix} 0 \\ \psi_{1\alpha} \end{pmatrix} s_1 + O((|\xi_2| + |s_2|^{\bar{\nu}_2})|s_2|^{1+\nu_2} + (|\eta_1| + |s_1|^{\bar{\nu}_1})|s_1|).$$

Similarly, the third and fourth terms belong to the range of $L_2(\alpha)$; hence, they disappear in equation (A.4). This yields

$$\det\left[L_2(\alpha), \begin{pmatrix} 0 \\ \psi_{1\alpha} \end{pmatrix}\right] s_1 = \det\left[L_2(\alpha), \begin{pmatrix} P_{2\alpha} \\ Q_{2\alpha} \end{pmatrix}\right] + \det\left[L_2(\alpha), \frac{\partial(P_2, Q_2)}{\partial x}(0, u, \alpha)\varphi_{2\alpha}\right] s_2^{1+\nu_2} + (\text{the same form of higher order}).$$

Dividing both sides by $\det M_2(\alpha) = \det[L_2(\alpha), \binom{0}{\psi_{1\alpha}}]$, we obtain the desired form

$$s_1 = c_2 + \tau_2 s_2^{1+\nu_2} + (\text{the same form of higher order}),$$

where the function c_2 of α is the same as (A.5), and

$$\tau_2 = \det\left[L_2(\alpha), \frac{\partial(P_2, Q_2)}{\partial x}(0, u, \alpha)\varphi_{2\alpha}\right] \Big/ \det M_2(\alpha).$$

Now we show $c_2(\alpha_1, 0) = 0$ and $\partial c_2/\partial\alpha_2(0, 0) \neq 0$ and (4.3). Recall that $\hat{Q}_{2\alpha} \equiv 0$. Thus, from (A.5) we obtain

$$c_2(\alpha_1, \alpha_2) = (-1)^{(m-1)m} \frac{\det \partial\hat{Q}_2/\partial\eta(0, u, \alpha)}{\det M_2(\alpha)} Q_{2\alpha}^{(1)}.$$

Because $\partial\hat{Q}_2/\partial\eta(0, u, \alpha)$ is nonsingular it suffices to show $Q_{2\alpha}^{(1)} = 0$ when $\alpha = (\alpha_1, 0)$ and $\partial Q_{2\alpha}^{(1)}/\partial\alpha_2 \neq 0$ at $\alpha = (0, 0)$ by the product rule of differentiation. It is trivial to check $Q_{2\alpha}^{(1)} = 0$ at $\alpha = (\alpha_1, 0)$ because of the existence of the primary heteroclinic connections from a_2 to a_1 on the α_1-axis. Also, since $(P_{2\alpha}, Q_{2\alpha})^T = (P_2, Q_2)^T(0, u, \alpha)$ is on the unstable manifold $W_2^u(\alpha) \cap \Sigma_1^s$ for $(0, u) \in W_{2\text{loc}}^u(\alpha) \cap \Sigma_2^u$, by (1.10b) for the distance between W_2^u and W_1^s on Σ_1^s and $\hat{Q}_{2\alpha} \equiv 0$ we have

$$0 \leqq d_2(\alpha_1, \alpha_2) \leqq \min_{(\xi, 0) \in W_{1\text{loc}}^s} |(P_{2\alpha}, Q_{2\alpha}) - (\xi, 0)| = |Q_{2\alpha}^{(1)}|.$$

This implies $Q_{2\alpha}^{(1)}$ at $\alpha = (0, \alpha_2)$ has a constant sign for $\alpha_2 > 0$, say > 0, since $0 < d_2(0, \alpha_2)$ by our assumptions. Therefore,

$$0 < \frac{d_2(0, \alpha_2)}{\alpha_2} \leqq \frac{Q_{2\alpha}^{(1)}}{\alpha_2} \quad \text{for } \alpha = (0, \alpha_2).$$

Passing the limit $\alpha_2 \to 0^+$ above, we have $\partial Q_{2\alpha}^{(1)}/\partial\alpha_2 > 0$ at $\alpha = (0, 0)$ by (1.10b). This completes the proof for c_2.

To show (4.3), we notice first that $u(0) = 0$ and the set of all the column vectors of $M_2(0)$ forms a base for $T_{p_1}\Sigma_1^s$ and

$$\frac{\partial(P_2, Q_2)}{\partial x}(0, 0, 0)\varphi_{20} = \frac{\partial(P_2, Q_2)}{\partial(x, \eta)}(0, 0, 0)\begin{pmatrix} \varphi_{20} \\ 0 \end{pmatrix}.$$

Project this vector onto the one-dimensional linear space span $\{(0, \psi_{10})^T\}$, which is complementary to the range of $L_2(0)$; namely, span $\{T_{p_1}(W_2^u \cap \Sigma_1^s), T_{p_1}(W_{1\text{loc}}^s \cap \Sigma_1^s)\}$. We obtain $\partial(P_2, Q_2)/\partial x(0,0,0)\varphi_{20} = \tilde{\tau}_2(0, \psi_{10})^T + h$ with $h \in \text{range } L_2(0)$. Hence,

$$\det[L_2(0), \partial(P_2, Q_2)/\partial x(0,0,0)\varphi_{20}] = \tilde{\tau}_2 \det M_2(0)$$

and $\tilde{\tau}_2 = \tau_2(0)$ follows. Of course, $\tau_2(0) > 0$ if and only if Γ_2 is not twisted by our Definition 1.1. This completes the proof. □

LAYERED VELOCITY INVERSION: A MODEL PROBLEM FROM REFLECTION SEISMOLOGY*

WILLIAM W. SYMES†

Abstract. A simple model problem in exploration seismology requires that a depth-varying sound velocity distribution be estimated from reflected sound waves. For various physical reasons, these reflected signals or echoes have very small Fourier coefficients at both very high and very low frequencies. Nonetheless, both geophysical practice, based on heuristic considerations, and recent numerical evidence indicate that a spectrally complete estimate of the velocity distribution is often achievable. We prove a theorem to this effect, showing that "sufficiently rough" velocity distributions may be recovered from reflected waves under some restrictions, independently of the very low- or high-frequency content of the data. The main restriction is that the velocity depend only on a single (depth) variable; only in this case are sufficiently refined propagation-of-singularity results available. The proof is based on a novel variational principle, from which numerical algorithms have been derived. These algorithms have been implemented and used to estimate velocity distributions from both synthetic and field reflection seismograms.

Key words. inverse problems, hyperbolic partial differential equations, sound velocity, reflection seismology

AMS(MOS) subject classification. 35R25

1. Introduction.

A simple model of the physical setting for reflection seismology is constant-density *linear acoustics*, in which the sound velocity field $c(x)$ ($x \in \mathbf{R}^3$) is connected to the pressure field $u(x,t)$ via the wave equation

$$\frac{1}{c^2(x)} \frac{\partial^2 u(x,t)}{\partial t^2} - \Delta u(x,t) = f(t)\delta(x),$$
$$u \equiv 0, \qquad t < 0.$$

The right-hand side represents an isotropic point dilatational energy source radiating with time-varying (transient) intensity $f(t)$ ("the *source wavelet*"). The *seismogram* is a sampling of the pressure u at a number of "receiver" points. We adopt the idealization that these points form the continuum $\{x_3 =: z = 0\}$ ("the surface (of the earth)") and that the measurement of u is also continuous in time for some time interval $0 \le t \le t_{\max}$. Regarding the source (i.e., $f(t)$) as known, the pressure field, hence the seismogram, becomes a function of the sound velocity:

$$s[c] := u|_{z=0}.$$

In this simple model, the fundamental problem of reflection seismology is to estimate c from $s[c]$, i.e., to solve a functional equation of the form

$$s[c] = s_{\text{data}}$$

possibly in some least-error sense accommodating the possibility (virtual certainty!) of inconsistent data error.

This model is grossly inadequate for some practical purposes, as it ignores significant physics of seismic wave generation and propagation. Nonetheless, it forms

* Received by the editors February 21, 1989; accepted for publication (in revised form) April 20, 1990. This work was partially supported by National Science Foundation grant DMS 8603614 and by Office of Naval Research contract N00014-85-0725.

† Department of Mathematical Sciences, Rice University, Houston, Texas 77251.

the basis for most contemporary seismic data processing (see, for instance, Yilmaz (1987)), and it exhibits two fundamental features of the "real" problem:

(i) $s[c]$ is nonlinear in c;

(ii) f should be chosen to suppress Fourier components in $s[c]$ at "low" and "high" frequencies.

Item (i) is simply the nonlinearity of solutions of linear equations as functions of their coefficients. Item (ii) is required by observations of the spectra of reflection seismograms: for various physical reasons, Fourier components at very low (<4Hz) and very high (> 80 Hz) temporal frequencies are essentially missing from real reflection seismograms.

The suppression of high-frequency components simply means that $c \mapsto s[c]$ is a smoothing operator. Techniques for management of the resulting high-frequency instability are well known (see, e.g., Tikhonov and Arsenin (1977), Miller (1970), Payne (1975)).

In contrast, the instability resulting from the lack of low-frequency data has been little discussed in the mathematical literature on inverse problems, even though it is nearly ubiquitous in real-world parameter-estimation problems based on wave propagation. This *low-frequency lacuna* is a striking feature of reflection seismology, in particular, and the possible ambiguities resulting from spectral incompleteness of data have sparked considerable discussion within the geophysical research community.

The present paper is devoted to the proof of a uniqueness and continuous dependence result for a restricted version of the inverse problem described above, in which the estimates are independent of the behaviour of $\hat{f}(\omega)$ near $\omega = 0$. We shall show that c is well determined by $s[c]$ when c is *sufficiently nonsmooth.*

This rather strange sounding requirement is natural in view of the application to reflection seismology: rapid changes in the mechanical properties of rock are entirely responsible for the return of substantial echoes to the surface, hence for the information content of seismic reflection data. The times of arrival of these echoes—or rather, the signals which simulate them in the model described above—carry information about the slowly varying components of c, completely independently of the low-frequency behavior of f. On the other hand, the identifiability of these echoes depends on the wave nature of the seismic disturbance, in other words on the propagation of singularity (or regularity), according to geometric optics. This propagation property clearly requires some smoothness of the coefficients; thus the conditions necessary for the creation of strong reflected signals are in tension with those necessary for their propagation.

We show in this paper that this tension can be resolved at least in a special case. The resolution requires certain estimates concerning propagation of regularity currently available only under the additional constraint:

> The sound velocity c is a function only of the "depth" variable $x_3(= z)$.

That is, the result detailed here applies to *layered* constant density fluid models only. The necessary technical results for this class of models were established in previous papers of Symes ((1981), (1983), (1985), (1986a), (1986b)). These are essentially energy estimates and are related to earlier work of Rauch and Taylor (1974) and Kreiss (1970) on mixed problems for linear hyperbolic systems in two independent variables. Other authors basing results about one-dimensional inverse problems for hyperbolic equations on the same ideas include Fawcett (1984) and Suzuki (1988).

As mentioned above the constant-density fluid model is severely oversimplified. For example, in reality the density of sedimentary rock is also variable, though much

less dramatically so than the compressional wave velocity. Also, density and compressional velocity are somewhat correlated in real rocks. Nonetheless the variation of density must be taken into account in explaining the details of real reflection seismograms. A natural extension of the problem considered here is therefore the determination of density and velocity profiles in a layered acoustic model. While treatment of this problem goes beyond the intention of the present paper, several conjectures seem plausible. First, based on the treatment of the linearized acoustic problem in Santosa and Symes (1988), we expect to recover in addition to the velocity, the oscillatory or rough part of the density profile (technically, we expect a Gårding-type estimate for small perturbations in density, similar to that stated in Theorem 4.1 below for the velocity). Second, we do *not* expect to gain control over the slowly varying part of the density, since the mechanism active in determination of the slowly varying part of the velocity is *inactive* for the density (that is, we do *not* expect analogues of Theorem 2.1 on Theorem 6.1 to hold for the density). The only hope for density trends appears to be that the above-mentioned correlation with velocity is accurate on long length scales. Third, we expect the inclusion of variable density to be quite important in accurate estimation of velocities. This last conclusion is based on the experience of Symes and others in velocity estimation from field seismograms.

More complicated (and so realistic) layered models (elastic, anelastic, ...) can doubtless be studied from the present point of view, but it is difficult to foresee the results. Of course the most interesting question is the possibility of extension of our results to *nonlayered* models—deviations from layering being the most dramatic way in which the real earth differs from our simple model. A few remarks concerning the prospects for weakening the layered medium assumption in these arguments may be found in the next section.

The paper is organized as follows. Section 2 gives a precise statement of the main results, a brief review of the literature, and discussion of related issues. Section 3 introduces the *plane-wave decomposition* and estimates for the plane-wave problems from Symes's previous work; this material forms the technical basis for the rest of the paper. As we are concerned mostly with the information independent of the low-frequency behaviour of f, we introduce in §4 the (temporary) assumption that f is a compactly supported measure, defining an elliptic convolution operator bounded on $L^2(\mathbf{R})$. Under this assumption, we prove an estimate of Gårding type for the derivative of the plane-wave seismogram map. In order to do more, it is necessary to consider the various plane-wave problems simultaneously. Each plane-wave *model* is parameterized by the vertical plane-wave velocity, viewed as a function of (its own) travel-time. These models are a priori independent. We derive a *coherency condition* in §5, equivalent to the existence of a (single) velocity profile $c(z)$ from which all of the plane-wave models are derived (i.e., "every (plane-wave) experiment sees the same earth"). In §6 we show that a least-squares version of the inverse problem stated above, posed in terms of the plane-wave models and augmented by the coherency condition (as a so-called penalty term) has a positive-definite Hessian (second derivative) operator at a consistent (zero-residual) solution provided that the corresponding velocity profile is sufficiently rough, as stated above. Our main result follows immediately via the implicit function theorem. So far we have maintained the elliptic assumption concerning f; this is dropped in §7, for the usual price, paid for the solution of compact operator equations, of a priori constraints on the smoothness of c.

2. Statement of main result and discussion. In this section we give a precise statement of the major result of this paper, followed by a brief review of the literature and a conceptual overview of the problem described above.

Since the principal goal of the present work is the production of a "solution" of the inverse problem stated above with continuity properties independent of the *low-frequency* behavior of the source wavelet f, we make the temporary assumption that:

> $f \in \mathcal{E}'(\mathbf{R})$ is a Borel measure, defining a bounded elliptic convolution operator on $H^1(\mathbf{R})$: i.e., for positive K_0, K_1, K^*, $\phi \in H^1(\mathbf{R})$

$$K_1 \left\| \frac{\partial \phi}{\partial t} \right\|_{L^2(\mathbf{R})} - K_0 \|\phi\|_{L^2(\mathbf{R})} \leq \left\| f * \frac{\partial \phi}{\partial t} \right\|_{L^2(\mathbf{R})} \leq K^* \left\| \frac{\partial \phi}{\partial t} \right\|_{L^2(\mathbf{R})}. \tag{2.1}$$

> Also, $\operatorname{supp} f \subset \{t \in \mathbf{R} : t \geq 0\}$.

Such a distribution necessarily has a finite *first moment*

$$m_f^1 = \sup_{\phi \in C^\infty} \frac{\langle f, t\phi \rangle}{\|\phi\|_{L^\infty}}.$$

The "elliptic" assumption (2.1) will be weakened, to the extent possible, in §7. Simple examples of wavelets (i.e., kernels) f having the elliptic property (2.1) are obtained by subtracting from a slightly shifted Dirac delta function a smooth approximation.

The conventional, though perhaps ill-founded, choice of measure for the seismogram error is some weighted version of the L^2-norm (see Tarantola (1987, Chap. 6)). We shall adopt this choice also. The elliptic nature of f precludes square-integrability of $s[c]$, however, as can easily be seen, so we choose what amounts to a very singular "weight": we define, for suitably small *slowness* p,

$$S[c](t,p) = \int\int dx_1 dx_2 \frac{\partial}{\partial t} s[c](x_1, x_2, t + px_1).$$

That is, S is a version of the Radon transform of s, which we shall further restrict to a rectangle $\{(t,p)\colon 0 < t \leq T_1, P_1 \leq p \leq P_2\} =: R_1$. It is easily seen that, for smooth c, any $T_1 > 0$, and P_2 sufficiently small, S is square integrable (Santosa and Symes (1988)). Thus the basic data set of this paper will be a member of $L^2(R_1)$.

Another piece of notation needed to state our main result is used in our method of measuring "roughness": as mentioned in the Introduction, a stable solution of the inverse problem can only be expected for sufficiently nonsmooth coefficient c.

The "roughness" measure depends on an arbitrary Dirac kernel $h_1 \in C_0^\infty(\mathbf{R})$ satisfying

$$h_1 \geq 0, \quad h_1(0) > 0, \quad \int h_1 = 1.$$

Set

$$h_\epsilon(z) = \frac{1}{\epsilon} h_1\left(\frac{z}{\epsilon}\right).$$

For $Z_0, \epsilon, \Delta > 0$, $c \in H^1_{\text{loc}}$, define

$$\bar{r}[c](Z_0, \Delta) = \sup_{0 \leq z \leq Z_0} \frac{1}{\Delta} \int_{z-\Delta/2}^{z+\Delta/2} |c'|^2,$$

$$r_*[c](Z_0,\epsilon,\Delta) = \inf_{0\le z\le Z_0} \frac{\epsilon^2}{\Delta}\int_{z-\Delta/2}^{z+\Delta/2} |h'_\epsilon * c'|^2,$$

$$r^*[c](Z_0,\epsilon,\Delta) = \sup_{0\le z\le Z_0} \frac{\epsilon^2}{\Delta}\int_{z-\Delta/2}^{z+\Delta/2} |h'_\epsilon * c'|^2.$$

These are local average measures of fluctuation. For example, r_* is a sizable fraction of $\bar{r}, r^*$ when c has significant Fourier components at frequencies proportional to $\frac{1}{\epsilon}$, locally uniformly on the length scale Δ.

The geometry of the plane-wave problem, which will occupy most of this paper, is determined by the travel-time function

$$\tau(z,p) = 2\int_0^z \sqrt{\frac{1}{c^2} - p^2},$$

which gives the time necessary for a point on a planar wavefront at slowness p, fixed horizontal coordinates, to travel to depth z and back to the surface.

The earlier results of Symes (1986a, 1986b) imply that S extends to a bounded, continuous map on the bounded set $\sum_c \subset H^1_{\text{loc}}(\mathbf{R})$ parameterized by positive numbers T_0, P_1, c_0, c_1, c^*, according to

$$\begin{aligned}\Sigma_c \quad = \quad & \{c \in H^1_{\text{loc}}(\mathbf{R}) : c(z) = c_0, z < 0; \quad \text{for} \\ & Z_0 > 0 \quad \text{so that} \quad T_0 = \tau(Z_0, P_1), \\ & \|\log c\|_{H^1[0,Z_0]} \le c^*; \\ & c(z) = c_1 \quad \text{for} \quad z \ge Z_0\}.\end{aligned}$$

We have also shown, however, that this extension is *not* locally Lipschitz-continuous, and certainly not differentiable, in these metrics. S does become differentiable when the domain is metricized more strictly (H^3), but then the derivative fails to have a lower bound. Thus the implicit function theorem does not apply to the solution of least-squares problems for S. The computational consequences of this pathology are also striking (Santosa and Symes 1989). Proofs of the above assertions, together with an incisive discussion of their consequences, are given in the 1989 thesis of R. M. Lewis in the Department of Mathematical Sciences at Rice University.

A suitable family of "rough" subsets Σ'_c of Σ_c depends on positive parameters $M_1, M_2, \bar{\epsilon}$, and $\bar{\Delta}$ according to

$$\begin{aligned}\Sigma'_c \quad = \quad & \{c \in \Sigma_c : \quad \text{for} \quad Z_0 > 0 \quad \text{such that} \\ & T_0 = \tau(Z_0, P_1) \quad \text{and some} \quad 0 < \epsilon \le \bar{\epsilon}, \quad 0 < \Delta \le \bar{\Delta}, \\ & \text{the following inequalities hold:} \\ & M_1 \le r_*(Z_0,\epsilon,\Delta), \\ & M_2 r_*(Z_0,\epsilon,\Delta) \ge \max(\bar{r}(Z_0,\Delta), r^*(Z_0,\epsilon,\Delta))\}.\end{aligned}$$

We shall verify that Σ'_c is nonempty for suitable choices of parameters.

The main result of our paper is Theorem 2.1.

THEOREM 2.1. *Suppose that* $0, T_0 < T_1$, $0 \leq P_1 < P_2$, $0 \leq K_0$, $0 < K_1 \leq K^*$ $0 < c_0, c_1, c^*$ *are given. Then there exist constants* $M_1, M_2, \bar{\epsilon}, \bar{\Delta}, \bar{m}$, *and* L^* *depending on* T_0, T_1, P_1, P_2, K_0, K_1, K^*, c_0, c_1, *and* c^* *so that if* $f \in \mathcal{E}'(\mathbf{R})$ *satisfies* (2.1) *and*

$$m_f^1 \leq \bar{m}$$

then Σ_c' *is nonempty and there exists an open neighborhood* U *of the set*

$$\{S[c] \in L^2(R_1) : c \in \Sigma_c'\}$$

and a map

$$I : U \longrightarrow L^2_{\text{loc}}(\mathbf{R})$$

so that

(i) *For* $c \in \Sigma_c'$, $IS[c] = c$;
(ii) *For* $D_1, D_2 \in U$, $Z_1 > 0$

$$\|I(D_1) - I(D_2)\|_{L^2[0,Z_1]} \leq L^* \|D_1 - D_2\|_{L^2(R_1)}.$$

Thus we obtain a continuous left inverse for S, under various constraints. The requirement that c be constant for large z is simply a way of controlling c at depths below the zone influencing the seismogram. That the zone of constancy begins at Z_0 such that $T_0 = \tau(Z_0, P_1)$, rather than $T_1 = \tau(Z_0, P_1)$, is an unfortunate side effect of the "width" of the source wavelet f: since supp f is not a point, the depth interval in which the seismogram gives sure control over the velocity coefficient is strictly smaller than the depth interval needed to compute the seismogram. Given an arbitrary velocity profile with mean c_1 near $z = Z_0$, we can, of course, truncate it to a member of Σ_c, i.e., by setting the velocity constant ($= c_1$) for $z > Z_0$, as in the definition. The corresponding seismograms are then different only in the "gap" ($T_0 \leq t \leq T_1$). If the original profile obeys the uniform roughness conditions as in the definition of Σ_c', then it follows from arguments similar to those in §§3 and 4 that the L^2-norm of the difference of seismograms is $O(m_f^1)$. The theorem then gives the same qualitative estimate for the error due to application of I. We leave to the reader the formulation of a theorem embodying this extension of our results.

A more subtle consequence of this gap is that the value of c in this "basement" region must be specified a priori, i.e., the condition that $c(z) = c_1$ for $z \geq Z_0$. It seems clear that this additional piece of data should have little influence on the values of c at shallower depths—and, to the extent that it does, should be determined by S as well. This may be a fruitful subject for further work; some related ideas are discussed in Sacks and Santosa (1987). In any case the author does not see at present how to formulate a convenient theorem without such a restriction.

It is easy to see that the Lipschitz estimate (ii) cannot be strengthened much. See Symes (1986b), for instance. In particular it is not possible to replace L^2 by H^1 on the left-hand side.

Estimates of the sort presented in Theorem 2.1 are only of qualitative importance. Numerical evidence (Symes (1988), (1990); Symes and Carazzone (1989), (1990)) indicates that typical values of the Lipschitz constant L^* are very large. On the other

hand, restriction to a submanifold of Σ_c' of small codimension diminishes L^* to a useful magnitude, while leaving enough freedom in the model that some information about c is still obtained from the data. Analysis of an approximation to S in Symes (1988), (1990) and Symes and Carazzone (1989) illustrates this feature. A full understanding of the need for this "residual regularization" is still lacking at this writing.

The significance of the present result lies in its reliance on the implicit function theorem: i.e., the stability follows directly from linearization stability, and any residual ill-conditioning can be improved by the straightforward addition of linear constraints. This is surprising—and, perhaps, of practical importance—since the implicit function theorem cannot be applied to S directly, as noted above, for elliptic f.

The left inverse I will be produced via the solution of an auxiliary least-squares problem, developed in §5. In §7 we remove the elliptic requirement on f, to a certain extent: for suitable $f \in C_0^\infty$, we obtain an approximate left inverse to replace I, which depends on a choice of regularization.

While a few previous papers (Symes (1983), (1986a), (1986b), Fawcett (1984), Suzuki (1988)) provide rigorous treatment of the central uniqueness, existence, and continuous dependence issues, none treat the "bandlimited" problem described in §1 in a satisfactory way: without exception these works either assume the low-frequency content problem away, or ignore it. The problem is well known to geophysical researchers, and its severity is explicitly illustrated in Pao, Santosa, and Symes (1984) and Gray and Symes (1985).

Note that even the known uniqueness theorems for several-dimensional inverse problems in wave propagation either require data in a frequency interval $[0, \omega)$ (Sacks and Symes (1985), Sun (1988), Ramm (1986)) or do not allow the reflection configuration (sources and receivers separated from the target region by a hyperplane (Nachman (1987), Rakesh and Symes (1988)). Thus the present paper is the only instance, to the author's knowledge, in which any version of the reflection inverse problem has been shown to be well posed in the presence of a low-frequency lacuna.

Nonetheless, evidence of two sorts indicates that velocities, at least, are quite well determined by bandlimited data. Conventional seismic data processing, as practiced by academic and industrial reflection seismologists, appears to produce such information. While based on numerous drastic approximations, the so-called "velocity analysis" procedures incorporate a great deal of data-driven insight (see, for example, Yilmaz (1987), Chap. 3). A side effect of our work is to provide a partial but rigorous mathematical basis for these important techniques.

A universal feature of "velocity analysis," as currently practiced, is the implicit separation of velocity (and other parameters) into slowly and rapidly varying parts. The influence of the rapid parameter variations is treated as a perturbation about the slowly varying trends. (We warn the reader that this linearization is seldom stated explicitly in the applied literature, but is simply assumed without comment.) To the author, one of the most gratifying features of the treatment given below is the *natural* emergence of this scale separation in the course of our analysis (Theorem 4.1, arguments in §6).

Other indications that velocities are well determined are to be found in recent numerical investigations of the nonlinear least-squares problem

$$\min_c \|s[c] - s_{\text{data}}\|_{L^2}^2 . \tag{2.2}$$

These have turned up more direct evidence that bandlimited seismograms determine velocity profiles (see Kolb, Collino, and Lailly (1986), McAulay (1985), Gauthier,

Tarantola, and Virieux (1986), and Mora (1987)). All of these papers also reveal that any reasonable setting of (2.2) results in a very difficult optimization problem. The reasons for both the success and the difficulty of this so-called "least-squares inversion" are noted briefly in §3, and explained in great detail in Santosa and Symes (1989), to which we refer the reader for extensive discussion. In any case, the computational difficulty of (2.2) was the main motivation for the work reported here, which relies on a different, "relaxed" least-squares problem (§5).

In this paper, we give only a qualitative analysis of this "relaxed" problem, which we call the *coherency optimization problem*, leading to Theorem 2.1. A quantitative analysis of an approximation appears in Symes (1988), (1990), and numerical experiments are reported there and in Symes and Carazzone (1989) establishing the feasibility of the optimization, its relative insensitivity to noise and its favorable comparison to (2.2) regarding computational efficiency. In Symes and Carazzone (1989), (1990) the technique is applied to field reflection seismograms with quite satisfactory results.

A very important remaining question concerns the extension of these results to other models, notably to nonlayered velocities (i.e., c depending on all space variables). As shown in Symes and Carazzone (1989), for example, an approximation to the coherency optimization problem can be formulated for the general nonlayered fluid model. Preliminary numerical experiments with an implementation for two-dimensional constant density acoustics will appear in Symes (1991). A full-blown extension of our results awaits better understanding of propagation of regularity for hyperbolic equations with nonsmooth coefficients, and implications for the relation between solutions and coefficients, analogous to the results for problems in two independent variables detailed in §3.

3. Preliminary considerations: Reduction to plane waves, properties of the one-dimensional forward map. We assume that seismograms are given on an open set Ω of the space-time boundary of cylinder form:

$$\Omega = \Omega' \times [0, t_{\max}]$$

with Ω' a neighborhood of the "source" point $x = 0$. We shall also assume that all velocity profiles $c : \mathbf{R} \to \mathbf{R}^+$ satisfy

$$0 < c_{\min} \leq c(z) \leq c_{\max}\,, \qquad z \geq 0 \tag{3.1}$$

for a priori fixed $c_{\min}, c_{\max}$. Whenever convenient we will also think of (3.1) as an $L^\infty(\mathbf{R})$-bound on $\log c$.

The principal technical device of this paper is the introduction of the Radon transformed field

$$U(p, z, t) := \int_{\mathbf{R}^2} dx\, u(x, z, t + p \cdot x_1), \qquad p \in \mathbf{R}.$$

Standard arguments show that U is well defined for small p, t under the assumptions made so far. For an attempt to maximize the domain of definition of U, see Santosa and Symes (1988). We remind the reader that the Radon transform is defined on natural classes of distributions as a *push-forward* (Duistermaat (1973, Prop. 1.3.4, p. 3), for example). It is commonplace to retain the integral notation even for distribution arguments, however, and we shall follow this practice.

A straightforward calculation shows that for suitably small $p \geq 0$ so that $c_{\max} p < 1$,

$$\begin{aligned} \frac{1}{v^2(z,p)} \frac{\partial^2 U}{\partial t^2}(z,t) - \frac{\partial^2 U}{\partial z^2}(z,t) &= \delta(z) f(t), \\ U \equiv 0, \qquad t << 0 & \end{aligned} \tag{3.2}$$

where the *vertical wave velocity* $v(z,p)$ (or $v[c]$, to emphasize the dependence on c) is defined by

$$v[c](z,p) = \frac{c(z)}{\sqrt{1 - c^2(z)p^2}}.$$

Because of the a priori bounds (3.1), the support of u, hence of s, is contained in a cone

$$c_{\max} t \geq \sqrt{|x|^2 + z^2}.$$

Therefore, for sufficiently small $p_{\max} (< 1/c_{\max})$ there exists $\tau_{\max} \geq 0$ so that for

$$R = \{(t,p) : 0 \leq t \leq \tau_{\max}, |p| \leq p_{\max}\}$$

we have for $(t,p) \in R$

$$\begin{aligned} S[c](t,p) &:= \frac{\partial U}{\partial t}(p,0,t) - f(t) \\ &= \int_{\mathbf{R}^2} dx \left(\mathbf{1}_\Omega \frac{\partial u}{\partial t}(x,z,t+px_1) - f(t+px_1)\delta(x) \right), \end{aligned} \tag{3.3}$$

i.e., the domains of integration of the Radon integrals intersect the support of u inside Ω. We assume tacitly in the sequel that all (t,p) domains satisfy this constraint.

Now we recall some facts about the one-dimensional seismogram map $S[c](\cdot,p) =: S_0[v]$ (fixed p) for which references are Symes (1986a), (1986b). It is convenient to include explicitly the source wavelet temporarily in the notation. That is, write $S_0[v,f]$ for the map defined by the solution of (3.2), (3.3) followed by restriction to fixed p. Recall that f is assumed to define an *elliptic convolution operator of order zero*. For the choice $f = \delta$, S_0 defines a bounded continuous map from

$$H^{1,+}_{\mathrm{loc}}(\mathbf{R}, v_0) = \left\{ v \in H^1(\mathbf{R}) : v \equiv v_0 \text{ for } z < 0, \log v \in H^1_{\mathrm{loc}}(\mathbf{R}) \right\}$$

into $L^2[0,T]$ for any $T > 0$, but $S_0[\cdot,\delta]$ is not locally uniformly continuous (Symes (1986b)). In order to recover the necessary degree of regularity for the arguments to follow, we introduce the "travel-time velocity" $\tilde{v}[c]$ defined by

$$\tilde{v} \circ \tau = v$$

where

$$\tau(z) = 2 \int_0^z \frac{1}{v}$$

is the (one-way) travel time. More discussion of the map $c \mapsto \tilde{v}[c]$ appears in § 5 (see also Symes (1986a)). A short calculation shows that $\tilde{U}$, defined by

$$\tilde{U}(\tau(z),t) = U(z,t),$$

satisfies

$$\frac{1}{\tilde{v}(x)}\frac{\partial^2 \tilde{U}}{\partial t^2}(x,t) - \frac{\partial}{\partial x}\frac{1}{\tilde{v}(x)}\frac{\partial \tilde{U}}{\partial x}(x,t) = \frac{1}{v_0} f(t)\delta(x).$$

Set

$$\tilde{S}_0[\tilde{v},f](t) = \frac{\partial \tilde{U}}{\partial t}(0,t).$$

We recapitulate a number of properties of $\tilde{S}_0$. With exceptions noted below, all of these may be found in Symes (1986a). Note that $\tilde{S}_0[\tilde{v},f] \equiv S_0[v,f]$ if $\tilde{v}\circ\tau = v$. $\tilde{S}_0$ also defines a bounded map: $H^{1,+}_{\text{loc}}(\mathbf{R},v_0) \to L^2_{\text{loc}}(\mathbf{R})$ for any $v_0 > 0$. Moreover, $\tilde{S}_0$ is actually of class C^2, viewed as a map: $H^{1,+}([0,T/2],v_0) \to L^2[0,T]$. The derivative is given by the formal perturbation ($\delta\tilde{v} \in H^1_{\text{loc}}(\mathbf{R})$, $\delta\tilde{v} \equiv 0, z < 0$)

$$\begin{aligned}\left(\frac{1}{\tilde{v}(x)}\right)\frac{\partial^2 \delta\tilde{U}}{\partial t^2}(x,t) - \frac{\partial}{\partial x}\left(\frac{1}{\tilde{v}(x)}\frac{\partial \delta\tilde{U}}{\partial x}\right)(x,t)&\\ = \frac{\partial}{\partial x}\left(\frac{\delta\tilde{v}}{\tilde{v}^2}\frac{\partial \tilde{U}}{\partial x}(x,t)\right), \qquad x \geq 0,&\\ \delta\tilde{U} = 0, \qquad t << 0,&\end{aligned}$$

$$D\tilde{S}_0[\tilde{v},f]\delta\tilde{v} = \left.\frac{\partial \delta\tilde{U}}{\partial t}\right|_{x=0},$$

so that

$$\begin{aligned}\|\tilde{S}_0[\tilde{v}+\delta\tilde{v},f] - \tilde{S}_0[\tilde{v},f] - D\tilde{S}_0[\tilde{v},f]\cdot\delta\tilde{v}\|_{L^2[0,T]}&\\ = o\left(\|\delta\tilde{v}\|_{H^1([0,T/2])}\right).&\end{aligned}$$

For $f = \delta$, more is true: for constants $C_-, C_+ > 0$ depending on $\|\log\tilde{v}\|_{H^1[0,T/2]}$ and on T,

$$\begin{aligned} C_-\left\|\frac{\partial\delta\tilde{v}}{\partial x}\right\|_{L^2[0,T/2]} &\leq \left\|D\tilde{S}_0[\tilde{v},\delta]\delta\tilde{v}\right\|_{L^2[0,T]} \\ &\leq C_+\left\|\frac{\partial\delta\tilde{v}}{\partial x}\right\|_{L^2[0,T/2]}. \end{aligned} \tag{3.4}$$

Also, for $f = H$ (the Heaviside function), there exists C_0 depending on $\|\log\tilde{v}\|_{H^1[0,T/2]}$ and on T so that

$$\|D\tilde{S}_0[\tilde{v},H]\delta\tilde{v}\|_{L^2[0,T]} \leq C_0\|\delta\tilde{v}\|_{L^2[0,T/2]}. \tag{3.5}$$

Note that for $\delta\tilde{v} \in H^1_{\text{loc}}$, $D\tilde{S}_0[\tilde{v},H]\delta\tilde{v} \in H^1_{\text{loc}}$ and

$$D\tilde{S}_0[\tilde{v},\delta] = \frac{\partial}{\partial t}D\tilde{S}_0[\tilde{v},H].$$

Also

$$\begin{aligned} \tilde{S}_0[\tilde{v}, f] &= f * \tilde{S}_0[\tilde{v}, \delta], \\ D\tilde{S}_0[\tilde{v}, f] &= f * D\tilde{S}_0[\tilde{v}, \delta]. \end{aligned}$$

All of these results are based on simple local energy estimates; with the exception of (3.5) they are stated explicitly in Symes (1986a). The Heaviside estimate (3.5) is not given there, but the proof presents no novelties.

4. Ellipticity for the one-dimensional forward map. We have assumed (until §7) that $f \in \mathcal{E}'(\mathbf{R})$ defines an elliptic convolution operator of order zero. Since $D\tilde{S}_0[\tilde{v}, \delta]$ for $\log \tilde{v} \in H^1_{\text{loc}}$ is invertible, ((3.6), (3.7)), it seems clear that $D\tilde{S}_0[\tilde{v}, f] = f * \tilde{S}_0[\tilde{v}, \delta]$ should be "elliptic" as well. The purpose of this section is to formulate and prove a precise result along these lines, keeping track of the dependence of various constants on the H^1-norm of $\tilde{v}$, the time and depth intervals used, etc. The result is a Gårding-type estimate for $D\tilde{S}_0$, which requires that $D\tilde{S}_0$ be given on $[0, T_1]$, $T_1 > T_0$, to estimate $\delta\tilde{v}$ on $[0, T_0]$. It is clear that a little "extra" data is required, since the support of f is not assumed to be a point. In fact, the principal constant intervening in the estimates is the first moment of f, which measures its "spread," and is related in the estimates to the size of the necessary "margin" $T_1 - T_0$.

Select a cutoff function $\psi \in C^\infty(\mathbf{R})$ with $\psi(t) \equiv 0$ for $t > T_1$ and $\psi(t) \equiv 1$ for $t \leq T_0$, and define the smoothly cutoff version of $\tilde{S}_0$:

$$\tilde{S}_\psi := \psi \tilde{S}_0$$

so also

$$D\tilde{S}_\psi := \psi D\tilde{S}_0.$$

In the following, we will apply the estimates of the previous section on various t-intervals. Since the constants C_-, C_+, etc. depend on the length of the interval, we will include the length explicitly in the notation, for the moment. Thus for estimates on the interval $[0, T]$, C_- becomes $C_-[T]$, etc. These constants depend on the H^1-norm of $\log \tilde{v}$ on the appropriate intervals.

Recall that "elliptic," applied to f, means the inequalities (2.1), which we recall here for convenience: for $\phi \in H^1(\mathbf{R})$,

$$\begin{aligned} K^* \left\| \frac{\partial \phi}{\partial x} \right\|_{L^2(\mathbf{R})} &\geq \left\| f * \frac{\partial \phi}{\partial x} \right\|_{L^2(\mathbf{R})} \\ &\geq K_1 \left\| \frac{\partial \phi}{\partial x} \right\|_{L^2(\mathbf{R})} - K_0 \|\phi\|_{L^2(\mathbf{R})}, \\ \text{supp} f \subset \mathbf{R}^+. \end{aligned} \tag{4.1}$$

From (3.5) and (3.6), for $\log \tilde{v} \in H^1_{\text{loc}}(\mathbf{R})$, $\delta\tilde{v} \in H^1_{\text{loc}}(\mathbf{R})$, $\tilde{v}(x) = v_0$ for $x < 0$:

$$\begin{aligned} \|D\tilde{S}_\psi[\tilde{v}, \delta]\delta\tilde{v}\|_{L^2(\mathbf{R})} &\leq \|D\tilde{S}_0[\tilde{v}, \delta]\delta\tilde{v}\|_{L^2[0,T_1]} \\ &\leq C_+[T_1] \left\| \frac{\partial \delta\tilde{v}}{\partial x} \right\|_{L^2[0,T_1/2]} \end{aligned} \tag{4.2}$$

while

$$\begin{aligned} \|D\tilde{S}_\psi[\tilde{v},\delta]\delta\tilde{v}\|_{L^2(\mathbf{R})} &\geq \|D\tilde{S}_0[\tilde{v},\delta]\delta\tilde{v}\|_{L^2[0,T_0]} \\ &\geq C_-[T_0]\left\|\frac{\partial\delta\tilde{v}}{\partial x}\right\|_{L^2[0,T_0/2]}. \end{aligned} \tag{4.3}$$

Also

$$\|D\tilde{S}_\psi[\tilde{v},H]\delta\tilde{v}\|_{L^2(\mathbf{R}^+)} \leq C_0[T_1]\|\delta\tilde{v}\|_{L^2[0,T_1/2]}. \tag{4.4}$$

Now

$$\begin{aligned} D\tilde{S}_\psi[\tilde{v},f]\delta\tilde{v} &= \psi(f * D\tilde{S}_0[\tilde{v},\delta]\delta\tilde{v}) \\ &= f * D\tilde{S}_\psi[\tilde{v},\delta]\delta\tilde{v} + e \end{aligned}$$

where for e we have the standard commutator estimate

$$\|e\|_{L^2(\mathbf{R})} \leq \|\psi'\|_{L^\infty} m_f^1 \|D\tilde{S}_0[\tilde{v},\delta]\delta\tilde{v}\|_{L^2[0,T_1]}.$$

Here m_f^1 denotes the measure norm of the distribution

$$\phi \longmapsto \langle |f|, t\phi\rangle,$$

i.e., the first moment of f, as explained in §2.

Combine this estimate with (4.1)–(4.4) to get

$$\begin{aligned} \|D\tilde{S}_0[v,f]\delta\tilde{v}\|_{L^2[0,T_1]} &\geq \|D\tilde{S}_\psi[\tilde{v},f]\delta\tilde{v}\|_{L^2(\mathbf{R})} \\ &\geq \|f * \psi\tfrac{\partial}{\partial t} D\tilde{S}_0[\tilde{v},H]\delta\tilde{v}\|_{L^2(\mathbf{R})} - \|e\|_{L^2(\mathbf{R})} \\ &\geq \|f * \tfrac{\partial}{\partial t}\psi D\tilde{S}_0[\tilde{v},H]\delta\tilde{v}\|_{L^2(\mathbf{R})} \\ &\quad -\|f * \tfrac{\partial\psi}{\partial t} D\tilde{S}_0[\tilde{v},H]\delta\tilde{v}\|_{L^2(\mathbf{R})} - \|e\|_{L^2(\mathbf{R})} \\ &\geq K_1\|\tfrac{\partial}{\partial t}\psi D\tilde{S}_0[\tilde{v},H]\delta\tilde{v}\|_{L^2(\mathbf{R})} - K_0\|\psi D\tilde{S}_0[\tilde{v},H]\delta\tilde{v}\|_{L^2(\mathbf{R})} \\ &\quad -K^*\|\tfrac{\partial\psi}{\partial t} D\tilde{S}_0[\tilde{v},H]\delta\tilde{v}\|_{L^2(\mathbf{R})} - \|e\|_{L^2(\mathbf{R})} \\ &\geq K_1\|D\tilde{S}_0[\tilde{v},\delta]\delta\tilde{v}\|_{L^2[0,T_0]} - K_0\|D\tilde{S}_0[\tilde{v},H]\delta\tilde{v}\|_{L^2[0,T_1]} \\ &\quad -K^*\|D\tilde{S}_0[\tilde{v},H]\delta\tilde{v}\|_{L^2[T_0,T_1]}\left\|\tfrac{\partial\psi}{\partial t}\right\|_{L^\infty(\mathbf{R})} \\ &\quad -m_f^1\|\tfrac{\partial\psi}{\partial t}\|_{L^\infty(\mathbf{R})}\|D\tilde{S}_0[\tilde{v},\delta]\delta\tilde{v}\|_{L^2[0,T_1]} \\ &\geq K_1 C_-[T_0]\|\tfrac{\partial\delta\tilde{v}}{\partial x}\|_{L^2[0,T_0/2]} \\ &\quad -C_0[T_1]\left(K_0 + K^*\left\|\tfrac{\partial\psi}{\partial t}\right\|_{L^\infty(\mathbf{R})}\right)\|\delta\tilde{v}\|_{L^2[0,T_1/2]} \\ &\quad -m_f^1\|\tfrac{\partial\psi}{\partial t}\|_{L^\infty(\mathbf{R})} C_+[T_1]\|\tfrac{\partial\delta\tilde{v}}{\partial x}\|_{L^2[0,T_1/2]}. \end{aligned}$$

The upshot of all of this is the inequality

$$\begin{aligned}\|D\tilde{S}_0[\tilde{v},f]\delta\tilde{v}\|_{L^2[0,T_1]} \quad \geq \quad & K_1 C_-[T_0] \left\| \tfrac{\partial \delta\tilde{v}}{\partial x} \right\|_{L^2[0,T_0/2]} \\ & - m_f^1 \left\| \tfrac{\partial \psi}{\partial t} \right\|_{L^\infty(\mathbf{R})} C_+[T_1] \left\| \tfrac{\partial \delta\tilde{v}}{\partial x} \right\|_{L^2[0,T_1/2]} \\ & - C_0[T_1] \left(K_0 + K^* \left\| \tfrac{\partial \psi}{\partial t} \right\|_{L^\infty(\mathbf{R})} \right) \|\delta\tilde{v}\|_{L^2[0,T_1/2]}.\end{aligned}$$

Remark. As noted in Symes (1986a), in general the constants $C_+[T]$, $C_0[T]$ increase with T, while $C_-[T]$ decreases.

Remark. It is worth noting the relation of the various bounds involving f to its Fourier transform. Indeed, obviously

$$K^* \geq \|\hat{f}\|_{L^\infty(\mathbf{R})}$$

whereas K_0, K_1 are related to the detailed behaviour of the Fourier transform near $\omega = 0$. Suppose that, for some K_*, $\omega > 0$,

$$|\hat{f}(\omega)| \geq K_* \quad \text{for } |\omega| > \omega \tag{4.5}$$

(i.e., $[\omega, \infty)$ constitutes the "passband" of $\hat{f}$, measured with tolerance K_*). Then for $\phi \in H^1(\mathbf{R})$, it is easy to see that

$$\left\| f * \frac{\partial \phi}{\partial t} \right\|_{L^2(\mathbf{R})} \geq K_* \left[\left\| \frac{\partial \phi}{\partial t} \right\|_{L^2(\mathbf{R})} - \omega \|\phi\|_{L^2(\mathbf{R})} \right]$$

which gives the relations

$$K_1 \geq K_*, \qquad K_0 \leq \omega K_*.$$

Note also the effect of scaling: if f satisfies (4.5), then

$$f_\epsilon(t) := \frac{1}{\epsilon} f\left(\frac{t}{\epsilon}\right)$$

satisfies (4.5) with $\omega_{\min}/\epsilon = \omega_{\min}/\epsilon$, while $m^1_{f_\epsilon} = \epsilon m^1_f$. Thus $K_1 = \mathcal{O}(1)$, $K_0 = \mathcal{O}(\frac{1}{\epsilon})$, and $m^1_{f_\epsilon} = \mathcal{O}(\epsilon)$ as $\epsilon \to 0$.

It is clear from the preceding discussion and the form of (4.5) that, for any prescribed $T_1 > T_0, \psi$ as above, and any "base" source wavelet f, a scaled version of f will have small enough first moment that

$$m_f^1 \left\| \frac{\partial \psi}{\partial t} \right\|_{L^\infty(\mathbf{R})} C_+[T_1] \leq \frac{1}{2} K_1 C_-[T_0]$$

with fixed K_1 (independent of scaling). Note that we can certainly choose ψ so that

$$\left\| \frac{\partial \psi}{\partial x} \right\|_{L^\infty(\mathbf{R})} \leq \frac{2}{T_1 - T_0}.$$

These obserations establish the nonvacuousness of Theorem 4.1.

THEOREM 4.1. *Choose* $T_1 > T_0 > 0$, *and* $K^* > K_1 > 0$. *Then for any* $\log \bar{v} \in H^1_{\text{loc}}(\mathbf{R})$, *there exists* $\bar{m}, L_2, L_1, L_0 > 0$ *depending on* $\tilde{v}$ *and on* T_1, T_0, K^*, K_1, *and so that if* f *satisfies* (4.1) *with some* $K_0 > 0$ *and*

$$m_f^1 \leq \bar{m}$$

then for $\delta\tilde{v} \in H^1_{\text{loc}}(\mathbf{R})$,

$$\|D\tilde{S}_0[\tilde{v}, f]\delta\tilde{v}\|_{L^2[0,T_1]} + m_f^1 L_2 \left\| \frac{\partial \delta\tilde{v}}{\partial x} \right\|_{L^2[T_0/2, T_1/2]} \geq L_1 \left\| \frac{\partial \delta\tilde{v}}{\partial x} \right\|_{L^2[0,T_0/2]} - L_0 \|\delta\tilde{v}\|_{L^2[0,T_1/2]}.$$

5. The optimum coherency principle. While we have shown that the linearized one-dimensional forward map is elliptic under the circumstances which concern us, it is certainly not boundedly invertible—or rather, the hypotheses concerning f do not imply any uniform bound on the inverse. This circumstance is widely remarked in the literature (for a sample, see Santosa and Symes (1989)), where numerical examples are also given (see especially Chapters 6 and 7). Recall, however, the provenance of the one-dimensional problem: it governs the propagation of a plane wave, the surface data for which are identical to the Radon transform of the point source surface data at fixed slowness (or angle). The possibility remains that the collection of *all* (precritical) plane-wave data might constrain the velocity estimate more severely than does a single plane-wave component.

In this and the next section we confirm this possibility. Since we will consider the data in an interval of slownesses $P_1 \leq p \leq P_2$, we will work with a suite of travel-time velocity models $\{\tilde{v}(t,p) : 0 \leq t \leq T,\ P_1 \leq p \leq P_2\}$. Recall from §3 that these are derived from velocity profiles $c(z)$; accordingly we begin with the question: what condition must $\tilde{v}(t,p)$ satisfy in order that $\tilde{v} = \tilde{v}[c]$ for some c? That is, we seek an operator whose kernel is identical to the range of $c \to \tilde{v}[c]$. We will call membership in the null space of the required operator (or in the range of $c \to \tilde{v}[c]$) the *coherency condition*, since coherence of the travel-time velocities $\tilde{v}$ is then forced across various values of p: all are representations of the same mechanical model, in different coordinate systems.

Denote by $\zeta(t,p)$ the inverse of the two-way travel time function $\tau(z,p)$, i.e.,

$$t = 2\int_0^{\zeta(t,p)} \frac{dz}{v(z,p)}.$$

Then clearly

$$\zeta(t,p) = \int_0^{t/2} d\tau \tilde{v}(\tau, p).$$

We will now regard ζ as being *defined* by this formula, hence as a functional of $\tilde{v}$. So, given $\tilde{v}$ we can compute ζ, whether $\tilde{v} = \tilde{v}[c]$ for some c, or not. Thus we can compute the quantity

$$\gamma[\tilde{v}] = \left[\frac{1}{(\tilde{v} \circ \zeta^{-1})^2} + p^2 \right].$$

(Here $\tilde{v} \circ \zeta^{-1}(z,p) = \tilde{v}(\zeta^{-1}(z,p),p)$.) Referring to the definitions (§3), we see that if $\tilde{v} = \tilde{v}[c]$, then

$$\gamma[\tilde{v}] = \frac{1}{c^2}$$

and it is thus independent of p: that is,

$$\tilde{v} = \tilde{v}[c] \Rightarrow \frac{\partial}{\partial p}\gamma[\tilde{v}] \equiv 0. \tag{5.1}$$

This last condition still involves the travel-time change of variables, so does not define a sufficiently regular function of $\tilde{v}$ (recall the discussion in §3). Define instead

$$\begin{aligned} \tilde{Q}[\tilde{v}] &= -\frac{\tilde{v}^3}{2}\left[\frac{\partial}{\partial p}\gamma[\tilde{v}]\right] \circ \zeta \\ &= -\frac{\tilde{v}^3}{2}\left(\left[\frac{\partial}{\partial p}(\tilde{v} \circ \zeta^{-1})^{-2}\right] \circ \zeta\right) - p\tilde{v}^3 \\ &= \left\{\frac{\partial \tilde{v}}{\partial p} + \left(\frac{\partial}{\partial p}\zeta^{-1}\right) \circ \zeta \frac{\partial \tilde{v}}{\partial t}\right\} - p\tilde{v}^3. \end{aligned} \tag{5.2}$$

A short chain-rule calculation gives

$$\left(\frac{\partial}{\partial p}\zeta^{-1}\right) \circ \zeta = -\frac{2}{\tilde{v}}\int_0^{t/2} \frac{\partial \tilde{v}}{\partial p},$$

which relation allows us to view $\tilde{Q}[\tilde{v}]$ as a functional of $\tilde{v}$. Clearly, from (5.1)

$$\tilde{v} = \tilde{v}[c] \Rightarrow \tilde{Q}[\tilde{v}] = 0.$$

It will be important to define the coherency condition in such a way as to have the largest possible domain contained in $H^{1,0}_{\text{loc}}(\mathbf{R} \times [P_1, P_2])$ (which will be the natural domain for the forward map, defined below). An obvious choice is H^1, but $\tilde{Q}$ is not continuous in that topology. As it happens, we can replace $\tilde{Q}$ with another operator having the same kernel, but which is continuous (even C^∞) in the H^1 sense.

Suppose temporarily that $\tilde{v} = \tilde{v}[c]$ for some c. Then

$$\begin{aligned} \frac{1}{\tilde{v}}\tilde{Q}[\tilde{v}] &= \frac{1}{\tilde{v}}\frac{\partial \tilde{v}}{\partial p} - \frac{2}{\tilde{v}^2}\left(\int_0^{t/2} \frac{\partial \tilde{v}}{\partial p}\right)\frac{\partial \tilde{v}}{\partial t} - p\tilde{v}^2 \\ &= \frac{\partial}{\partial t}\left(\frac{2}{\tilde{v}}\int_0^{t/2} \frac{\partial \tilde{v}}{\partial p} - 2p\int_0^{t/2} \tilde{v}^2\right) \\ &= 0. \end{aligned}$$

Thus

$$\tilde{v} = \tilde{v}[c] \Rightarrow \frac{2}{\tilde{v}}\int_0^{t/2} \frac{\partial \tilde{v}}{\partial p} = 2p\int_0^{t/2} \tilde{v}^2. \tag{5.3}$$

The map

$$Q[\tilde{v}] := \frac{\partial \tilde{v}}{\partial p} - 2p\left(\int_0^{t/2} \tilde{v}^2\right)\frac{\partial \tilde{v}}{\partial t} - p\tilde{v}^3$$

therefore also satisfies

$$\tilde{v} = \tilde{v}[c] :\Rightarrow Q[\tilde{v}] = 0. \tag{5.4}$$

On the other hand, for any $T > 0$, $R = [0,T] \times [P_1, P_2]$, Q obviously defines a C^2-map

$$Q : H^1(R) \to L^2(R).$$

The following converse to (5.4) shows that $Q = 0$ is an adequate coherency condition.

LEMMA 5.1. *Suppose that* $\log \tilde{v} \in H^1(R)$ *and* $Q[\tilde{v}] = 0$. *Then for some* $Z > 0$ *and some* $c \in H^1[0,Z]$,

$$\tilde{v} = \tilde{v}[c]|_R.$$

Proof. Integrate in t:

$$\begin{aligned} 0 &= \int_0^{t/2} dt' Q[\tilde{v}](t',p) \\ &= \int_0^{t/2} dt' \left\{ \frac{\partial \tilde{v}}{\partial p}(t',p) - 2p \left[\int_0^{t'/2} dt'' \tilde{v}^2(t'',p) \right] \frac{\partial \tilde{v}}{\partial t}(t',p) - p\tilde{v}^3(t',p) \right\} \\ &= \int_0^{t/2} dt' \frac{\partial \tilde{v}}{\partial p}(t',p) - 2p\tilde{v}(t,p) \int_0^{t/2} dt' \tilde{v}^2(t',p) \end{aligned}$$

after integration by parts, so we once again recover the relation

$$\frac{1}{\tilde{v}} \int_0^{t/2} \frac{\partial \tilde{v}}{\partial p} = 2p \int_0^{t/2} \tilde{v}^2.$$

It follows immediately that $\tilde{Q}[\tilde{v}] = 0$ as well, which is equivalent to

$$\frac{\partial}{\partial p} \gamma[\tilde{v}] = 0.$$

Set

$$\begin{aligned} R_\zeta &= \{(z,p) : P_1 \le p \le P_2,\ 0 \le z \le \zeta(T,p)\}, \\ v &= \tilde{v} \circ \zeta^{-1}. \end{aligned}$$

It is easily checked that $\log v \in H^1(R_\zeta)$. On the other hand, with

$$\begin{aligned} c(z) : &= \left(\frac{1}{v(z,p)^2} + p^2 \right)^{-1/2} \\ &= \gamma[\tilde{v}]^{-1/2}(z,p) \end{aligned}$$

we have $c \in H^1[0,Z]$, $Z = \sup_{P_1 \le p \le P_2} \zeta(T,p)$, and

$$v(z,p) = \frac{c(z)}{\sqrt{1 - c^2(z)p^2}},$$

$$\zeta^{-1}(z,p) = 2\int_0^z \frac{1}{v},$$

whence $\zeta^{-1} = \tau$, and the conclusion follows. □

We now turn to the definition of the multi-plane-wave forward map. For simplicity, define seismograms on the *data rectangle*

$$R_1 = [0,T_1] \times [P_1,P_2].$$

Choose $c_0, c_1 > 0$ with $c_0P_2, c_1P_2 < 1$, $T_2 \geq T_0$, and $\ell^* > 0$ and set

$$\sum = \{\tilde{v} \in H^1_{\text{loc}}(\mathbf{R} \times [P_1,P_2]) : \tilde{v}(x,p) = c_0/\left(1 - c_0p^2\right)^{1/2}, \quad x < 0,$$

$$\tilde{v}(x,p) = c_1/\left(1 - c_1^2p^2\right)^{1/2},$$

$$x \geq \tfrac{1}{2}T_2$$

$$\|\log \tilde{v}\|_{H^1([0,1/2T_2]\times[P_1,P_2])} < \ell^*\}$$

and its "tangent space"

$$T\sum = \{\delta\tilde{v} \in H^1_{\text{loc}}(\mathbf{R} \times [P_1,P_2]) :$$
$$\delta v(x,p) = 0, \quad x \leq 0 \text{ or } x \geq \tfrac{1}{2}T_2\}.$$

Only a finite interval in t is needed for the arguments which follow. With $T_2 > T_1$ to be determined below, set

$$\tilde{R}_2 = [0,T_2/2] \times [P_1,P_2].$$

Identify elements of $\sum$ and $T\sum$ with their restrictions to $\tilde{R}_2$, and topologize $\sum$ and $T\sum$ as subsets of $H^1(\tilde{R}_2)$.

With these conventions, define the forward map

$$\tilde{S} : \sum \longrightarrow L^2(R_1)$$

by

$$\tilde{S}[\tilde{v}](t,p) = \tilde{S}_0[\tilde{v}(\cdot,p), f](t)$$

with $\tilde{S}_0$ as in §4. From the results stated there and in §3, it follows that $\tilde{S}$ is of class C^2, with derivatives bounded in terms of c_0, T_1, f, and ℓ^*.

The derivative $D\tilde{S}[\tilde{v}]$ also obeys an "elliptic" estimate. To state this, set

$$\tilde{R}_0 = [0,T_0/2] \times [P_1,P_2], \qquad \tilde{R}_1 = [0,T_1/2] \times [P_1,P_2].$$

Then from Theorem 4.1 follows Theorem 5.2.

THEOREM 5.2. *Given $P_2 > P_1 \geq 0$, $T_1 > T_0 > 0$, $K^* \geq K_1 > 0$, and $\ell^* > 0$, there exist $\bar{m}, L_0, L_1, L_2, L_1 > 0$, so that for $K_0 > 0$ and $f \in \mathcal{E}'(\mathbf{R})$ satisfying* (4.1) *and*

$$m_f^1 \leq \bar{m}$$

so that for $\tilde{v} \in \sum, \delta\tilde{v} \in T\sum$

$$\|D\tilde{S}[\tilde{v}]\delta\tilde{v}\|_{L^2(R_1)} + m_f^1 L_2 \left\| \frac{\partial \delta\tilde{v}}{\partial x} \right\|_{L^2(\tilde{R}_1 \setminus \tilde{R}_0)} \geq L_1 \left\| \frac{\partial \delta\tilde{v}}{\partial x} \right\|_{L^2(\tilde{R}_0)} - L_0 \|\delta\tilde{v}\|_{L^2(\tilde{R}_1)}.$$

Moreover, for each $p \in [P_1, P_2]$,

$$\|D\tilde{S}[\tilde{v}]\delta\tilde{v}(\cdot, p)\|_{L^2[0,T_1]} + m_f^1 L_2 \left\| \frac{\partial \delta\tilde{v}}{\partial x}(\cdot, p) \right\|_{L^2[T_0/2, T_1/2]} \geq L_1 \left\| \frac{\partial \delta\tilde{v}}{\partial x}(\cdot, p) \right\|_{L^2[0,T_0/2]} - L_0 \|\delta\tilde{v}(\cdot, p)\|_{L^2[0,t_1/2]}.$$

In view of Lemma 5.1 and the obvious relation

$$\tilde{S}[\tilde{v}[c]] = S[c],$$

we can now state a version of the inverse problem closely related to the least-squares problem (2.2), as:

$$\begin{array}{ll} \min & \|\tilde{S}[\tilde{v}] - D\|^2_{L^2(R_1)} \quad \text{over } \tilde{v} \in \sum \\ \text{subject to} & Q[\tilde{v}] = 0. \end{array} \tag{5.5}$$

In fact, a solution to this problem clearly yields a solution to (2.2) on a suitable depth interval. On the other hand, this problem would appear to have the advantage of regularity: both the objective and constraint functions are of class $C^{2,1}$. Moreover, it is possible to show that, under the circumstances described in Theorem 6.1 below, the Hessian operator of the objective function is positive definite on the null space of the linearized constraints, at a consistent data set, i.e., when

$$D = S[c^*]$$

for suitable c^*.

Unfortunately these properties are insufficient to yield a stable local-existence result. To motivate the next step in the development, we digress, with a brief review of Lagrangian theory for constrained optimization, and a simple but closely related example.

Suppose that X, Y are Hilbert spaces, $f : U \to \mathbf{R}, g : U \to Y$ smooth on an open set $U \subset X$. As is well known (Luenberger (1973)), a local solution of the constrained optimization problem

$$\begin{array}{ll} \min\limits_{x \in U} & f(x) \\ \text{subject to} & g(x) = 0 \end{array}$$

is a critical point of the Lagrangian

$$\mathcal{L}(x, \lambda) = f(x) + \langle \lambda, g(x) \rangle.$$

We wish to apply the implicit function theorem, to assure that a solution is stable against $(C^{2,1})$ perturbations in f. The conditions necessary to apply the implicit function theorem to the critical-point problem

$$\operatorname{grad}_{x,\lambda} \mathcal{L}(x,\lambda) = 0$$

are also sufficient to ensure the convergence of Newton's method (and, generally, of its computationally efficient quasi-Newton relatives). These amount to

(i) $Dg(x)\delta x = 0 \Longrightarrow \langle \delta x, [\operatorname{Hess} f(x) + \langle \lambda, \operatorname{Hess} g(x)\rangle], \delta x\rangle \geq \ell_1 \|\delta x\|^2$,

(ii) $\|Dg(x)^*\lambda\| \geq \ell_2 \|\lambda\|$

for constants $\ell_1, \ell_2 > 0$. The so called "second-order sufficiency" condition (i) may be verified for the problem (5.3), as was mentioned above. The so-called "constraint qualification," however, fails, in the manner illustrated by the following simple example, which captures the main features of (5.5).

Let $X = \{u \in H^1(R) : \int \int_R u = 0\}$, $Y = L^2(R)$, $R = [0,1]^2$ the unit square in $\mathbf{R}^2$. Set for $u \in X$, $v \in Y$ given

$$f(u) = \left\| \frac{\partial u}{\partial x_1} - v \right\|^2_{L^2(R)}, \qquad g(u) = \frac{\partial u}{\partial x_2}$$

and let us suppose that $v = v(x_1)$, so that the problem

$$\begin{array}{ll} \min\limits_{u \in X} & \operatorname{grad} f(u) \\ \text{subject to} & g(u) = 0 \end{array}$$

has the unique, zero-residual solution

$$u(x_1, x_2) = \int_0^{x_1} dx\, v(x) + \text{const.}$$

The second-order sufficiency condition (i) is an immediate consequence of a form of Poincaré's inequality (Nečas (1967)). The adjoint $Dg^*(u)$ is given by

$$Dg^*(u) = -\mathcal{N} \frac{\partial}{\partial x_2}$$

where $\mathcal{N}$ is the solution operator of the Neumann problem: $\mathcal{N}b = w$, where

$$\begin{aligned} (I - \Delta)w &= b \quad \text{in } R, \\ \frac{\partial w}{\partial n} &= 0 \quad \text{on } \partial R. \end{aligned}$$

Set $\lambda_k(x) = \cos k_1 \pi x_1 \cos k_2 \pi x_2$ for $k \in \mathbf{Z}^2$. Then

$$\|Dg^*(u)\lambda_k\|_{H^1(R)} = \frac{2k_2}{\sqrt{1 + k_1^2 + k_2^2}},$$

which can be made as small as we like by taking k_1 large. Thus the constraint qualification (ii) fails.

For similar but nonlinear problems such as (5.5), the nonzero singular values of Dg are proportional to the instantaneous radii of curvature of the constraint set. The

failure of the constraint qualification could conceivably be associated with the presence of arbitrarily small radii of curvature—indeed, this must be the case for uniformly nonlinear problems like (5.5). In essence, the constraint set for such a problem has a cusp at every point! No reasonable stability properties can be expected for the solutions of such a problem.

On the other hand, the Hessian operator of the "penalized" cost functional

$$f(u) + \sigma^2 \|g(u)\|^2_{L^2(R)}$$

is positive-definite for any $\sigma > 0$—again, this is simply Poincaré's inequality. This observation motivates the following construction.

For choices of time and slowness intervals $T_2 > T_1 > T_0 > 0$, $P_2 > P_1 \geq 0$, "data set" $D \in L^2(R_1)$ and "tuning" parameters $\sigma, \lambda \geq 0$, define for $\tilde{v} \in \sum$

$$J_{\sigma,\lambda}[\tilde{v}] = \frac{1}{2}\left\{ \left\| \tilde{S}[\tilde{v}] - D \right\|^2_{L^2(R_1)} + \sigma^2 \|Q\tilde{v}\|^2_{L^2(\tilde{R}_2)} + \lambda^2 \left\| \frac{\partial \tilde{v}}{\partial x} \right\|_{L^2(\tilde{R}_2 \setminus \tilde{R}_0)} \right\}. \tag{5.6}$$

The first two summands in the definition of $J_{\sigma,\lambda}$ are motivated by analogy with the "Dirichlet" problem discussed above. The form of the "elliptic" estimate (Theorem 5.2) and the need, explained in the next section, to choose $T_2 > T_0$ motivate the last term. For example, the elliptic estimate gives a bound on $\delta\tilde{v}$ only on the shorter interval $[0, T_0]$, so $\delta\tilde{v}$ must be bounded a priori for $t > T_0$.

We shall call the three terms on the right-hand side of (5.6) "data," "coherency," and "extension" terms. Minimization of (5.6) is the "coherency optimization problem."

6. Proof of the main theorem. We begin this section with the proof that the Hessian operator of $J_{\sigma,\lambda}$ as defined in § 5 is *positive-definite* at a sufficiently rough, coherent $\tilde{v}$. The main idea is that the Hessian quadratic form consists of the "data" term dominating the high frequencies in $\delta\tilde{v}$, and a "coherency" term essentially consisting of the product of the indefinite integral (in x) of $\delta\tilde{v}$ and a derivative of $\tilde{v}$. This latter term is thus the product of a smooth factor (depending on $\delta\tilde{v}$) and a rough factor (derivative of $\tilde{v}$). When the rough factor is rough enough, uniformly on the length scale of significant change in the smooth factor, then the product dominates the smooth factor. Lemma 6.2 below makes this heuristic reasoning precise, and establishes a mathematical meaning for "sufficiently rough." The "smooth factor" discussed here is the indefinite (t-) integral of $\delta\tilde{v}$; the estimate for it, together with the elliptic estimate from § 5 and an interpolation argument, give a bound on $\delta\tilde{v}$ in terms of the "data," "coherency," and "extension" terms of the Hessian of $J_{\sigma,\lambda}$.

Recall from the preceding sections the geometry of the coherency optimization problem:

$$\begin{aligned} &0 < T_0 < T_1 < T_2 && \text{time limits} \\ &0 \leq P_1 < P_2 && \text{slowness limits,} \end{aligned}$$

$$\begin{aligned} R_\nu &= [0, T_\nu] \times [P_1, P_2], \\ \tilde{R}_\nu &= [0, T_\nu/2] \times [P_1, P_2], \end{aligned} \qquad \nu = 0, 1, 2$$

(data, model rectangles);

the function spaces involved in its setting:

$$\sum = \left\{ \tilde{v} \in H^1(\tilde{R}_2) : \tilde{v}(0,p) = \frac{c_0}{\sqrt{1-c_0^2p^2}}, \tilde{v}(T_2,p) = \frac{c_1}{\sqrt{1-c_1^2p^2}}, \| \log \tilde{v} \|_{H^1(\tilde{R}_2)} < \ell^* \right\},$$

$$\dot{\sum} = \left\{ \delta\tilde{v} \in H^1(\tilde{R}_2) : \delta\tilde{v}(0,p) = 0 = \delta\tilde{v}(T_2,p) \right\}$$

and the maps:

$$\begin{aligned} \tilde{S} : &\quad \sum \longrightarrow L^2(R_1), \\ D\tilde{S} : &\quad \sum \times \dot{\sum} \longrightarrow L^2(R_1), \\ Q : &\quad \sum \longrightarrow L^2(\tilde{R}_2), \\ DQ : &\quad \sum \times \dot{\sum} \longrightarrow L^2(\tilde{R}_2). \end{aligned}$$

It will be essential in the arguments given below that T_2 be related appropriately to T_0, as follows. For $\tilde{v} \in \sum$, the L^∞-bound on $\tilde{v}$ implies that

$$\begin{aligned} \zeta(T_0, P_2) &= \sup_{P_1 \le p \le P_2} \zeta(T_0, p) \\ &\le \frac{1}{2} T_0 e^{\ell^*} := Z \end{aligned}$$

whence

$$\begin{aligned} \tau(Z, P_1) &= \sup_{P_1 \le p \le P_2} \tau(Z, p) \\ &\le 2Ze^{\ell^*} = T_0 e^{2\ell^*}. \end{aligned}$$

Set $T_2 = T_0 e^{2\ell^*}$. Then it follows that for any $p_1, p_2 \in [P_1, P_2]$,

$$\tau(\zeta(T_0, p_1), p_2) \le T_2.$$

Define

$$R_Z = [0, Z] \times [P_1, P_2].$$

Then for $\delta\tilde{v} \in H^1_{\text{loc}}(\mathbf{R})$, $\tilde{v} \in \sum$

$$\begin{aligned} \|\delta\tilde{v}\|_{H^1(\tilde{R}_0)} &\le C \|\delta\tilde{v} \circ \tau\|_{H^1(R_Z)} \\ &\le C' \|\delta\tilde{v}\|_{H^1(\tilde{R}_2)} \end{aligned}$$

and similarly for L^2-norms.

Here we have introduced the habit, to which we shall uniformly adhere, of denoting by $C, C', \cdots$ constants which may be chosen uniformly over $\sum$. We shall make no attempt to identify optimum choices of such constants, so that the end result of our argument is only qualitative in nature.

Recall from §2 that the determination of c from bandlimited data requires that c be "rough" in some sense. For convenience, we restate the basic "roughness" criterion, phrased in terms of an (arbitrary) Dirac kernel

$$h_\epsilon(z) = \frac{1}{\epsilon} h_1\left(\frac{z}{\epsilon}\right)$$

where h_1 satisfies the usual requirements:

$$h_1 \in C_0^\infty(\mathbf{R}), \quad h_1(0) > 0, \quad h_1 \geq 0\,, \quad \int h_1 = 1\,.$$

Then $\{\epsilon h_\epsilon'\}$ is bounded in L^1, and defines a family of "low-cut" filters, i.e., convolution with $\epsilon h_\epsilon'$ suppresses Fourier components at frequencies less than or equal to $\mathcal{O}(1/\epsilon)$.

For $c \in H^1_{\text{loc}}(\mathbf{R})$, $\epsilon > 0, \Delta > 0$ define

$$\begin{aligned} r[c](z,\epsilon,\Delta) &= \frac{1}{\Delta}\int_{z-\Delta/2}^{z+\Delta/2} |\epsilon h_\epsilon' * c'|^2, \\ \bar{r}[c](z,\Delta) &= \frac{1}{\Delta}\int_{z-\Delta/2}^{z+\Delta/2} |c'|^2 \end{aligned}$$

and for any $Z_0 > 0$,

$$\begin{aligned} r_*[c](Z_0,\epsilon,\Delta) &= \inf_{0\leq z\leq Z_0} r[c](z,\epsilon,\Delta), \\ r^*[c](Z_0,\epsilon,\Delta) &= \sup_{0\leq z\leq Z_0} r[c](z,\epsilon,\Delta), \\ \bar{r}^*[c](Z_0,\Delta) &= \sup_{0\leq z\leq Z_0} \bar{r}[c](z,\Delta). \end{aligned}$$

The main step in the proof of Theorem 2.1 is embodied in Theorem 6.1.

THEOREM 6.1. *There exist constants $\bar{m}, M_1, M_2, \epsilon_0$, and $\Delta_0 > 0$ depending on $T_0, T_1, T_2, \ell^*, K_0, K_1$, and K^* so that if*

(i) *$f \in \mathcal{E}'$ satisfies (4.1) and $m_f^1 \leq \bar{m}$;*

(ii) *$\tilde{v} \in \sum$ is consistent with $D \in L^2(R_1)$, i.e., $S[\tilde{v}] = D$*

(iii) *$\tilde{v} \in \sum$ is coherent, $\tilde{v} = \tilde{v}[c]$ for $c \in H^1_{\text{loc}}(\mathbf{R})$;*

(iv) *For some ϵ, Δ, $Z_0 > 0$ with $\epsilon \leq \epsilon_0$, $\Delta \leq \Delta_0$, and $\tau(Z_0, P_1) = 2\int_0^{Z_0} dz \left(1/c^2(z) - p_1^2\right)^{1/2} \geq T_0$ the following inequalities hold: $r_*[c](Z_0,\epsilon,\Delta) \geq M_1$, $M_2 r_*[c](Z_0,\epsilon,\Delta) \geq \max(r^*[c](Z_0,\epsilon,\Delta),\ \bar{r}[c](Z_0,\Delta))$.*

Then there exists $\mu > 0$ depending on $T_0, T_1, T_2, \ell^*, K_0, K_1, \sigma$, and λ so that for $\delta\tilde{v} \in \dot{\sum}$,

$$\langle \delta\tilde{v}, \text{Hess}\, J_{\sigma,\lambda}\delta\tilde{v}\rangle_{H_1(\tilde{R}_2)} \geq \mu\|\delta\tilde{v}\|^2_{H^1(\tilde{R}_2)}.$$

Before giving the proof of Theorem 6.1, we digress to demonstrate the meaning of condition (iv) in the theorem, and show that the set of $\tilde{v}$ satisfying it is nonempty.

Let $c_0, \delta c_1 \in C^\infty(\mathbf{R}) \cap L^\infty(\mathbf{R})$, so that

$$0 < r_* \leq \int_{z-1}^{z+1} |h_1' * \delta c_1'|^2 \leq r^*, \qquad -\infty \leq z \leq \infty$$

and take $\bar{r} = \sup_{z \in \mathbf{R}} \int_{z-1}^{z+1} |\delta c_1'|^2$. Clearly we can choose δc_1 so that $r^* \geq r_*$, $\bar{r}$ achieve any prescribed values. On the other hand, set

$$\delta c_\epsilon(z) = 2\epsilon \delta c_1(\frac{z}{\epsilon}), \qquad c_\epsilon(z) = c_0(z) + \delta c_\epsilon(z)$$

for $0 \leq z \leq Z_0$, cut off to constants elsewhere. Then $\{\log c_\epsilon\}_{\epsilon \leq \epsilon_0}$ is bounded in $H^1[0, Z_0]$, for suitable ϵ_0, but

$$r_* - \mathcal{O}(\epsilon) \leq \frac{1}{2\epsilon} \int_{z-\epsilon}^{z+\epsilon} |\epsilon h_\epsilon' * c_\epsilon'|^2 \leq r^* + \mathcal{O}(\epsilon),$$

$$\frac{1}{2\epsilon} \int_{z-\epsilon}^{z+\epsilon} |c_\epsilon'| = \bar{r} + \mathcal{O}(\epsilon).$$

Thus with the choice $\Delta = 2\epsilon$, the quantities

$$r_*[c_\epsilon](Z_0, \epsilon, 2\epsilon),$$
$$r^*[c_\epsilon](Z_0, \epsilon, 2\epsilon), \qquad \bar{r}[c_\epsilon](Z_0, 2\epsilon)$$

stand in more or less fixed proportions throughout the set $\{c_\epsilon\}$. We conclude that, whatever the values of the constants $M_1, M_2, \bar{\epsilon}, \bar{\Delta}$ specified in Theorem 6.1, the set of travel-time velocities satisfying condition (iv) is nonempty—simply take $\tilde{v} = \tilde{v}[c_\epsilon]$ for sufficiently small ϵ, and a suitable choice of $c_0, \delta c_1$.
