Also the meaning of condition (iv) is clear from this construction. As $\epsilon \to 0$, the perturbation δc_ϵ becomes smaller, but its derivative has uniformly bounded (above and below) mean square over intervals of length ϵ, and this even after convolution with the oscillatory kernel $\epsilon h_\epsilon'$. Thus c_ϵ has significant oscillation everywhere on the scale ϵ, i.e., c_ϵ is "uniformly rough."

In the estimates which follow, we will write for convenience

$$\delta Q = DQ[\tilde{v}]\delta\tilde{v}, \qquad \delta\tilde{S} = D\tilde{S}[\tilde{v}]\delta\tilde{v}.$$

Also, for any function u of (t,p) or (z,p) we shall denote by $\int u$ the function

$$(t,p) \mapsto \int_0^t dt' u(t',p) \quad \text{or} \quad (z,p) \mapsto \int_0^z dz' u(z',p).$$

To begin the proof of Theorem 6.1, note that

$$\langle \delta\tilde{v}, \operatorname{Hess} J_{\sigma,\lambda}[\tilde{v}] \cdot \delta\tilde{v} \rangle = \|\delta\tilde{S}\|^2_{L^2(R_1)} + \sigma^2 \|\delta Q\|^2_{L^2(\tilde{R}_2)} + \lambda^2 \left\| \frac{\partial \delta\tilde{v}}{\partial x} \right\|_{L^2(\tilde{R}_2 \setminus \tilde{R}_0)} \tag{6.1}$$

because of the consistency and coherency assumptions.

The second term in (6.1) is the most interesting. It follows immediately from the definition of Q that

$$\begin{aligned}\delta Q &= \frac{\partial \delta\tilde{v}}{\partial p} - 2p\left(\int \tilde{v}^2\right)\frac{\partial \delta\tilde{v}}{\partial x} - 4p\left(\int \tilde{v}\delta\tilde{v}\right)\frac{\partial \tilde{v}}{\partial x} - 3p\tilde{v}^2\delta\tilde{v} \\ &= \left(\frac{\partial}{\partial p}(\delta\tilde{v}\circ\tau)\right)\circ\zeta - 4p\left(\int \tilde{v}\delta\tilde{v}\right)\frac{\partial \tilde{v}}{\partial x} - 3p\tilde{v}^2\delta\tilde{v} \\ &= \left\{\frac{\partial \delta v}{\partial p} - \frac{p}{2}\left(\int dz\,\delta v\right)\frac{\partial v^2}{\partial z} - 3pv^2\delta v\right\}\circ\zeta\end{aligned}$$

where we have written for convenience $\delta v = \delta\tilde{v}\circ\tau$. Note that δv is *not* the perturbation in v resulting from a perturbation in c.

Choose a test kernel $g \in C_0^\infty(\mathbf{R}_z)$ with $\|g\|_{L^1(\mathbf{R})} = 1$ and $\operatorname{supp} g \subset [0,\infty)$. Then

$$g * (\delta Q \circ \tau) = \frac{\partial}{\partial p} g * \delta v - \frac{1}{2} p\left(\int dz\,\delta v\right) g * \frac{\partial v^2}{\partial z} + E_1 - 3pg * (v^2\delta v).$$

The error term E_1 is the commutator of a multiplication operator and convolution with g:

$$E_1 = p\left\{\left(\int dz\,\delta v\right) g * \frac{\partial v^2}{\partial z} - g * \left(\left(\int dz\,\delta v\right)\frac{\partial v^2}{\partial z}\right)\right\}$$

for which a standard estimate gives

$$\|E_1(\cdot,p)\|_{L^2[0,T_2]} \le C m_g^1 \|\delta v(\cdot,p)\|_{L^\infty(\mathbf{R})}.$$

(We have used the notation

$$m_g^k = \int_{\mathbf{R}} dz\, z^k |g(z)|$$

for the moments of $|g|$ as explained before.)

Set

$$K_g = -\frac{1}{2} p\left(\int dz\,\delta v\right) g * \frac{\partial v^2}{\partial z}.$$

The next goal is an L^2 estimate for K_g on the domain $R_Z = [0,Z] \times [P_1, P_2]$. Recall that Z is chosen so that

$$T_0 \le \tau(Z,P_2) < \tau(Z,P_1) \le T_2.$$

First note that for its indefinite p-integral,

$$\int_{p_1}^{p_2} dp\, K_g = \int_{p_1}^{p_2} g * (\delta Q \circ \tau) - g * \delta v\Big|_{p=p_1}^{p_2} - \int_{p_1}^{p_2} dp\, E_1.$$

Since composition with τ and ζ, the indefinite p-integral, and z-convolution with g are all bounded operators on $L^2_{\mathrm{loc}}(\mathbf{R} \times [p_1,p_2])$,

$$\begin{aligned}\left\|\int_{p_1}^{p_2} dp K_g\right\|_{L^2[0,Z]} \le\ & C\Big\{\|g * \delta v(\cdot,p_1)\|_{L^2[0,Z]} + \|g * \delta v(\cdot,p_2)\|_{L^2[0,Z]} \\ & + \|\delta Q\|_{L^2(\tilde{R}_2)} + m_g^1\left\|\frac{\partial \delta v}{\partial z}\right\|_{L^2(R_Z)}\Big\}.\end{aligned}$$

Now assume that $\int g = 0$ and choose $\psi \in C_0^\infty(\mathbf{R})$ with $\psi \equiv 1$ on $[0, Z]$. For $p \in [P_1, P_2]$, denote by $\delta\tilde{v}$ the extension δv by a constant for $z > Z$. Then (since $\operatorname{supp} g \subset \mathbf{R}^+$)

$$\begin{aligned}
\|g * \delta v(\cdot, p)\|^2_{L^2[0,Z]} &\leq \|g * \psi\delta\bar{v}(\cdot, p)\|^2_{L^2[\mathbf{R}]} \\
&= \frac{1}{\sqrt{2\pi}} \int dk |\hat{g}(k)|^2 \widehat{\psi\delta\bar{v}}(k)|^2 \\
&= \frac{1}{\sqrt{2\pi}} \int dk \frac{|\hat{g}(k)|^2}{|k|^2} |ik\widehat{\psi\delta\bar{v}}(k)|^2 \\
&\leq \left(\sup_k \frac{|\hat{g}(k)|}{|k|}\right)^2 \left\| \frac{\partial}{\partial z}(\psi\delta\bar{v}(\cdot, p)) \right\|^2_{L^2(\mathbf{R})} \\
&\leq C \left(\sup_k \frac{|\hat{g}(k)|}{|k|}\right)^2 \left\| \frac{\partial \delta v}{\partial z}(\cdot, p) \right\|^2_{L^2([0,Z])},
\end{aligned}$$

since $\delta\bar{v}$ is constant for $z > Z$ and $\delta v(0, p) \equiv 0$.

Define

$$\epsilon_g := \sup_k \frac{|\hat{g}(k)|}{|k|}.$$

From the bound

$$\left\| \frac{\partial \delta v}{\partial z}(\cdot, p) \right\|_{L^2[0,Z]} \leq C \left\| \frac{\partial \delta\tilde{v}}{\partial x}(\cdot, p) \right\|_{L^2[0,T_2]}$$

valid for $\delta\tilde{v} \in \dot{\sum}$, we get for any $P_1 \leq p_1 \leq p_2 \leq P_2$,

$$\begin{aligned}
\left\| \int_{p_1}^{p_2} dp\, K_g \right\|^2_{L^2[0,Z]} \leq C \Bigg\{ \epsilon_g \Bigg[&\left\| \frac{\partial \delta\tilde{v}}{\partial x}(\cdot, p_1) \right\|^2_{L^2[0,T_2/2]} + \left\| \frac{\partial \delta\tilde{v}}{\partial x}(\cdot, p_2) \right\|^2_{L^2[0,T_2/2]} \Bigg] \\
&+ \|\delta Q\|^2_{L^2(\tilde{R}_2)} + m_g^1 \left\| \frac{\partial \delta\tilde{v}}{\partial x} \right\|^2_{L^2(\tilde{R}_2)} \Bigg\}. \qquad (6.2)
\end{aligned}$$

Next we estimate the p-derivative of K_g:

$$\begin{aligned}
\frac{\partial K_g}{\partial p} = -\frac{1}{2} \Bigg[&\left(\int dz\, \delta v \right) g * \frac{\partial v^2}{\partial z} \\
&+ p \left(\int dz \frac{\partial \delta v}{\partial p} \right) g * \frac{\partial v^2}{\partial z} + p \left(\int dz\, \delta v \right) g * \frac{\partial^2 v^2}{\partial p\, dz} \Bigg].
\end{aligned}$$

The first term is clearly dominated in $L^2[0, Z]$ for each p by a ($\dot{\sum}$-dependent) multiple of

$$\|\delta\tilde{v}(\cdot, p)\|_{L^2[0,T_2/2]}.$$

From the definition of δQ,

$$\int dz \frac{\partial \delta v}{\partial p} = \int dz \left\{ \delta Q \circ \tau - \frac{1}{2} p \left(\int dz\, \delta v \right) \frac{\partial v^2}{\partial z} - 3p \int v^2 \delta v \right\},$$

which is bounded by a ($\sum$-dependent) multiple of

$$\|\delta Q(\cdot, p)\|_{L^2[0,T_2]} + \|\delta \tilde{v}(\cdot, p)\|_{L^2[0,T_2/2]}.$$

Finally, we note that

$$v = \frac{c}{\sqrt{1 - c^2 p^2}}$$

for some c with

$$\|c\|_{H^1[0,Z]} \leq C$$

so that for any $p \in [P_1, P_2]$,

$$\left\| \frac{\partial^2 v^2}{\partial z \partial p}(\cdot, p) \right\|_{L^2[0,Z]} \leq C.$$

The upshot is the estimate

$$\left\| \frac{\partial K_g}{\partial p}(\cdot, p) \right\|_{L^2[0,Z]} \leq C \left\{ \|\delta Q(\cdot, p)\|_{L^2[0,T_2/2]} + \|\delta \tilde{v}(\cdot, p)\|_{L^2[0,T_2/2]} \right\}. \tag{6.3}$$

Integrating in p, we also get

$$\left\| \frac{\partial K_g}{\partial p} \right\|_{L^2(R_Z)} \leq C(\|\delta Q\|_{L^2(\tilde{R}_2)} + \|\delta \tilde{v}\|_{L^2(\tilde{R}_2)}). \tag{6.4}$$

Now we combine (6.2) and (6.4) to estimate K_g via a simple interpolation inequality, which is a special case of Gilbarg and Trudinger (1983, Theorem 7.28):

For $u \in H^2[a,b], \alpha > 0$:

$$\|u'\|^2_{L^2[a,b]} \leq \alpha \|u''\|^2_{L^2[a,b]} + \frac{C}{\alpha} \|u\|^2_{L^2[a,b]} \tag{6.5}$$

where $C = C(|b-a|)$.

Apply (6.5) to $u(p) = \int_{p_0}^{p} dp' K_g(z,p)$ for arbitrary $p_0 \in [P_1, P_2]$, integrate the result in z, and use (6.2) and (6.4) to obtain

$$\begin{aligned} \|K_g\|^2_{L^2(R_Z)} \leq\ & \frac{C}{\alpha} \left\{ \epsilon_g^2 \left([P_2 - P_1] \left\| \tfrac{\partial \delta \tilde{v}}{\partial x}(\cdot, p_0) \right\|^2_{L^2[0,T_2/2]} + \left\| \tfrac{\partial \delta \tilde{v}}{\partial x} \right\|^2_{L^2(\tilde{R}_2)} \right) \right. \\ & \left. + (m_g^1)^2 \left\| \tfrac{\partial \delta \tilde{v}}{\partial x} \right\|^2_{L^2(\tilde{R}_2)} + \|\delta Q\|^2_{L^2(\tilde{R}_2)} \right\} \\ & + \alpha C' \left\{ \|\delta Q\|^2_{L^2(\tilde{R}_2)} + \|\delta \tilde{v}\|^2_{L^2(\tilde{R}_2)} \right\}. \end{aligned}$$

With the choice

$$\alpha^* = \max(\epsilon_g, m_g^1), \qquad \alpha_* = \min(\epsilon_g, m_g^1),$$

this becomes after integration in p_0 from P_1 to P_2

$$\begin{aligned} ||K_g||^2_{L^2(R_Z)} &\leq C\tfrac{(\alpha^*)^2}{\alpha_*}\left\{\left\|\tfrac{\partial \delta\tilde{v}}{\partial x}\right\|^2_{L^2(\tilde{R}_2)} + \|\delta\tilde{v}\|^2_{L^2(\tilde{R}_2)}\right\} \\ &\quad + C'\left(\alpha^* + \tfrac{1}{\alpha_*}\right)\|\delta Q\|^2_{L^2(\tilde{R}_2)}. \end{aligned} \tag{6.6}$$

The next step is to show that K_g actually dominates the indefinite integral of $\delta\tilde{v}$. It is at this point that some constraints on $\tilde{v}$ (hence on c), other than coherency and membership in $\sum$, become necessary. Recall that

$$K_g = -\frac{1}{2}p\left(\int dz\, \delta v\right) g * \frac{\partial v^2}{\partial z}.$$

Thus K_g is the product of a relatively smooth factor (the indefinite integral) and a relatively rough factor (the derivative). Clearly, some estimate of the smooth factor must be possible, provided that the rough factor is sufficiently *uniformly* rough. The following simple lemma gives a crude criterion of this type.

LEMMA 6.2. *Suppose that* $u, \Phi \in C^\infty(\mathbf{R})$. *Set for* $\Delta > 0$, $a < b$

$$r(x,\Delta) = \frac{1}{\Delta}\int_{x-\Delta/2}^{x+\Delta/2} |u|^2,$$

$$r_*(\Delta) = \inf_{x\in[a,b]} r(x,\Delta), \qquad r^*(\Delta) = \sup_{x\in[a,b]} r(x,\Delta).$$

Then for any $\Delta > 0$ (L^2-*norms*) :

$$\|\Phi u\|^2_{L^2[a,b]} \geq \frac{r_*(\Delta)}{2}\|\Phi\|^2_{L^2[a,b]} - \frac{16}{9}(r_*(\Delta) + r^*(\Delta))\Delta^2\|\Phi'\|^2_{L^2[a,b]}.$$

Proof. Set

$$\bar{\Phi}_\Delta(x) = \frac{1}{\Delta}\int_{x-\Delta/2}^{x+\Delta/2} \Phi.$$

Then the Cauchy–Schwarz inequality gives

$$|\Phi(y) - \overline{\Phi}_\Delta(x)| \leq \frac{4}{3}\Delta^{1/2}\int_{x-\Delta/2}^{x+\Delta/2} |\Phi'|^2$$

for $x - \Delta/2 \leq y \leq x + \Delta/2$. Thus

$$\begin{aligned} \int_{x-\Delta/2}^{x+\Delta/2} |\Phi u|^2 &\geq \left[|\bar{\Phi}_\Delta(x)^2 - \frac{16}{9}\Delta\int_{x-\Delta/2}^{x+\Delta/2} |\Phi'|^2\right]\int_{x-\Delta/2}^{x+\Delta/2} |u|^2 \\ &\geq \Delta|\bar{\Phi}_\Delta(x)|^2 r_*(\Delta) - \frac{16}{9}\Delta^2 r^*(\Delta)\int_{x-\Delta/2}^{x+\Delta/2} |\Phi'|^2. \end{aligned}$$

Similarly,

$$\Delta|\bar{\Phi}_\Delta(x)|^2 \geq \frac{1}{2}\int_{x-\Delta/2}^{x+\Delta/2} |\Phi|^2 - \frac{16}{9}\Delta^2\int_{x-\Delta/2}^{x+\Delta/2} |\Phi'|^2.$$

Thus

$$\int_{x-\Delta/2}^{x+\Delta/2} |\Phi u|^2 \geq \frac{r_*(\Delta)}{2} \int_{x-\Delta/2}^{x+\Delta/2} |\Phi|^2 - \frac{16}{9}(r_*(\Delta) + r^*(\Delta))\Delta^2 \int_{x-\Delta/2}^{x+\Delta/2} |\Phi'|^2.$$

Now sum both sides over $x = (k + \frac{1}{2})\Delta$, $k = 0, \ldots [(b-a)/\Delta]$ to obtain the result. □

We shall apply Lemma 6.2 to K_g, with the identifications

$$\Phi \sim -\frac{1}{2}p \int \delta v(\cdot, p), \qquad u \sim g * \frac{\partial v^2}{\partial z}(\cdot, p).$$

Note that

$$\frac{\partial v^2}{\partial z} = (1 - c^2p^2)^{-2} c \frac{\partial c}{\partial z}$$

so that

$$g * \frac{\partial v^2}{\partial z} = (1 - c^2p^2)^{-2} cg * \frac{\partial c}{\partial z} + E_2.$$

We will assume that the length scale Δ is chosen so that supp $g \subset [\Delta/2, \Delta/2]$. Then a slight refinement of the standard error estimate gives

$$\frac{1}{\Delta} \int_{z-\Delta/2}^{z+\Delta/2} |E_2| \leq C\Delta^2 r_\delta^*(\Delta) a_g(\Delta)$$

where we have written, for any compactly supported measure h, and $Z_0 > 0$ to be determined:

$$\begin{aligned}
r_h^*(\Delta) &= \sup_{z \in [0, Z_0]} \frac{1}{\Delta} \int_{z-\Delta/2}^{z+\Delta/2} \left| h * \frac{dc}{dz} \right|^2, \\
r_{h,*}(\Delta) &= \inf_{z \in [0, Z_0]} \frac{1}{\Delta} \int_{z-\Delta/2}^{z+\Delta/2} \left| h * \frac{dc}{dz} \right|^2, \\
a_h(\Delta) &= \sup_{z \in [0, Z_0]} \frac{1}{\Delta} \int_{z-\Delta/2}^{z+\Delta/2} \left(|h| * \left| \frac{dc}{dz} \right| \right)^2.
\end{aligned}$$

For various $\sum$-dependent constants C_1–C_4, any $z \in [0, Z_0]$,

$$\begin{aligned}
C_1 r_{g,*}(\Delta) - C_2\Delta^2 r_\delta^*(\Delta) a_g(\Delta) &\leq \frac{1}{\Delta} \int_{z-\Delta/2}^{z+\Delta/2} \left| g * \frac{\partial v^2}{\partial z} \right|^2 \\
&\leq C_3 r_g^*(\Delta) + C_4\Delta^2 r_g^*(\Delta) a_g(\Delta).
\end{aligned}$$

Accordingly Lemma 6.2 implies, so long as $Z_0 \leq Z$, for $p_0 \in [P_1, P_2]$

$$\begin{aligned}
\|K_g(\cdot, p)\|^2_{L^2[0,Z]} &\geq Cp^2 r_{g,*}(\Delta) \left\| \int dz\, \delta v(\cdot, p) \right\|^2_{L^2[0,Z_0]} \\
&\quad - C'(r_{g,*}(\Delta) + r_g^*(\Delta) + r_g^*(\Delta) a_g(\Delta))\Delta^2 \|\delta v(\cdot, p)\|^2_{L^2[0,Z_0]}.
\end{aligned} \tag{6.7}$$

These estimates have no force unless the quantities $r_{g,*}(\Delta)$ and

$$r_t^*(\Delta) = (r_{g,*}(\Delta) + r_g^*(\Delta) + r_g^*(\Delta)a_g(\Delta))$$

are comparable. These quantities depend on the parameters Δ and Z_0 and on the kernel g (all of which are still to be chosen)—and, of course, on the velocity profile c.

To further manipulate the norms of $\delta v, \delta\tilde{v}$, we require an estimate on the p-derivative: after some algebra,

$$\begin{aligned}
&\frac{d}{dp}\left\|\int dz\, \delta v(\cdot,p)\right\|^2_{L^2[0,Z_0]} \\
&\quad = 2\left\langle \int dz\, \delta v(\cdot,p), \int dz \left(\delta C \circ \tau + \frac{1}{2}p\left(\int dz\, \delta v\right)\frac{\partial v^2}{\partial z} + 3pv^2\delta v\right)\right\rangle_{L^2[0,Z_0]} \\
&\quad \le C\left\|\int dz\, \delta v(\cdot,p)\right\|^2_{L^2[0,Z_0]} + C'\left\|\delta Q \circ \tau(\cdot,p)\right\|^2_{L^2[0,Z_0]}.
\end{aligned}$$

In the following lemma we have employed an estimate on norms of products.

LEMMA 6.3. *For $f \in H^1[a,b]$, $g \in L^2[a,b]$, define*

$$\int_a^z fg = h(z), \qquad a \le z \le b.$$

Then

$$\|h\|_0 \le C\|f\|_1 \left\|\int_a g\right\|_0$$

for a constant C depending on a, b.

Proof. Since

$$h(z) = f(z)\int_a^z g - \int_a^z dz' f'(z')\int_a^{z'} g$$

we have

$$\begin{aligned}
\|h\|_0 &\le \|f\|_{L^\infty}\left\|\int g\right\|_0 + \left(\int_a^b dz\left[\int_a^z dz' f'(z')\int_0^{z'} g\right]^2\right) \\
&\le C\|f\|_1\left\|\int g\right\|_0 + \int_a^b dz\left[\int_a^z dz'(f'(z'))^2\right]\left[\int_a^z dz'\left[\int_0^{z'} g\right]^2\right],
\end{aligned}$$

whence the required inequality follows. □

Thus Gronwall's inequality gives

$$\left|\left\|\int dz\, \delta v(\cdot,p)\right\|^2_{L^2[0,Z_0]} - \left\|\int dz\, \delta v(\cdot,p_0)\right\|^2_{L^2[0,Z_0]}\right| \le C\|\delta Q\|^2_{L^2(\tilde{R}_2)}$$

for any $p_0 \in [P_1, P_2]$. Thus

$$\int_{P_1}^{P_2} dp\, p^2 \left\| \int dz\, \delta v(\cdot,p) \right\|^2_{L^2[0,Z_0]} \geq \left(\left\| \int dz\, \delta v(\cdot,p_0) \right\|^2_{L^2[0,Z_0]} - C\|\delta Q\|^2_{L^2(\tilde{R}_2)} \right) \frac{P_2^3 - P_1^3}{3}$$

so that (6.7) implies, after integrating the preceding inequality in p_0 from P_1 to P_2,

$$\begin{aligned} C\|K_g\|^2_{L^2(R_Z)} \;\geq\; & C' r_{g,*}(\Delta) \| \int dz\, \delta v\|^2_{L^2([0,Z_0]\times[P_1,P_2])} \\ & - C'' \left\{ \|\delta Q\|^2_{L^2(\tilde{R}_2)} + r_t^*(\Delta)\Delta^2 \|\delta v\|^2_{L^2([0,Z_0]\times[p_1,p_2])} \right\}. \end{aligned}$$

Now concatenate the above inequality with (6.6) to get

$$\begin{aligned} & r_{g,*}(\Delta) \left\| \int \delta v \right\|^2_{L^2([0,Z_0]\times[P_1,P_2])} - C'' \left\{ \|\delta Q\|^2_{L^2(\tilde{R}_2)} + r_t^*(\Delta)\Delta^2 \|\delta v\|^2_{L^2([0,Z_0]\times[P_1,P_2])} \right\} \\ & \leq C \frac{(\alpha^*)^2}{\alpha_*} \|\delta\tilde{v}\|_{H^1(\tilde{R}_2)} + C' \left(\alpha^* + \frac{1}{\alpha_*} \right) \|\delta Q\|^2_{L^2(\tilde{R}_2')}. \end{aligned}$$

Next recall that the L^2-norms of δv and $\delta\tilde{v}$ are related by

$$\|\delta v\|_{L^2(R_Z)} \leq C\|\delta\tilde{v}\|_{L^2(\tilde{R}_2)}$$

as noted at the beginning of the section, which allows us to simplify the above inequality to

$$\begin{aligned} r_{g,*}(\Delta) \| \int dz\, \delta v\|^2_{L^2([0,Z_0]\times[P_1,P_2])} \leq\; & C \left(\frac{(\alpha^*)^2}{\alpha_*} + r_t^*(\Delta)\Delta^2 \right) \|\delta\tilde{v}\|^2_{H^1(\tilde{R}_2)} \\ & + C' \left(1 + \alpha^* + \frac{1}{\alpha_*} \right) \|\delta Q\|^2_{L^2(\tilde{R}_2)}. \end{aligned} \tag{6.8}$$

It is convenient at this point to put the left-hand side in terms of $\delta\tilde{v}$ also, by means of Lemma 6.3. Since

$$\int_0^z dz' \delta v(z',p) = \int_0^{\tau(z,p)} dx\, \tilde{v}(x,p)\delta\tilde{v}(x,p)$$

we can apply Lemma 6.3 with $f = (\tilde{v}(\cdot,p))^{-1}$, $g = \tilde{v}(\cdot,p)\delta\tilde{v}(\cdot,p)$, to get

$$\left\| \int \delta\tilde{v}(\cdot,p_0) \right\|_{L^2[0,\tau(Z_0,p_0)]} \leq C \left\| \int \delta v(\cdot,p_0) \right\|_{L^2[0,Z_0]}$$

whence (6.8) implies, after integration in p_0 from P_1 to P_2,

$$\begin{aligned} r_{g,*}(\Delta) \left\| \int \delta\tilde{v} \right\|^2_{L^2(A_3)} \;\leq\; & C \left(\frac{(\alpha^*)^2}{\alpha_*} + r_t^*(\Delta)\Delta^2 \right) \|\delta\tilde{v}\|^2_{H^1(\tilde{R}_2)} \\ & + C' \left(1 + \alpha^* + \frac{1}{\alpha_*} \right) \|\delta Q\|^2_{L^2(\tilde{R}_2)}. \end{aligned} \tag{6.9}$$

Here A_3 is the region

$$\{(x,p) : P_1 \leq p \leq P_2, \quad 0 \leq x \leq \tau(Z_0,p)\}.$$

At this point, we determine Z_0: set

$$Z_0 = \zeta\left(\frac{1}{2}T_0, P_1\right) = \inf_{p \in P_1, P_2} \zeta\left(\frac{1}{2}T_0, p\right).$$

Thus

$$A_3 \subset \tilde{R}_0.$$

The interpolation inequality (6.5) and (6.9) now yield

$$\begin{aligned} \|\delta\tilde{v}\|^2_{L^2(A_3)} \quad \leq \quad & \left[\beta + \frac{C}{\beta r_{g,*}(\Delta)}\left(\frac{(\alpha^*)^2}{\alpha_*} + r_t^*(\Delta)\Delta^2\right)\right] \|\delta\tilde{v}\|^2_{H^1(\tilde{R}_2)} \\ & + \frac{C'(1 + \alpha^* + (1/\alpha_*))}{\beta r_{g,*}(\Delta)} \|\delta Q\|^2_{L^2(\tilde{R}_2)}. \end{aligned} \tag{6.10}$$

It follows immediately from the Dirichlet condition at $x = T_2$ in the definition of $\sum$ that

$$\|\delta\tilde{v}\|^2_{H^1(\tilde{R}_2)} \leq \|\delta\tilde{v}\|^2_{H^1(\tilde{R}_0)} + C\left\|\frac{\partial\delta\tilde{v}}{\partial x}\right\|^2_{L^2(\tilde{R}_2\setminus\tilde{R}_0)}.$$

It is only slightly more difficult to estimate

$$\|\delta\tilde{v}\|^2_{L^2(\tilde{R}_1\setminus A_3)} \leq C\left\{\left\|\frac{\partial\delta\tilde{v}}{\partial x}\right\|^2_{L^2(\tilde{R}_2\setminus\tilde{R}_0)} + \|\delta Q\|^2_{L^2(\tilde{R}_2)}\right\}. \tag{6.11}$$

In fact, from the inequality

$$\left|\frac{\partial\delta v}{\partial p}\right|^2 + \left|\frac{\partial\delta v}{\partial x}\right|^2 \leq C\left(\left|\frac{\partial\delta v}{\partial x}\right|^2 + |\delta Q|^2\right),$$

which holds at every point in $\tilde{R}_2$, and the already-used inequality

$$\|\delta\tilde{v}\|_{L^2(\tilde{R}_2\setminus\tilde{R}_0)} \leq \sqrt{T_2 - T_0}\left\|\frac{\partial\delta v}{\partial x}\right\|_{L^2(\tilde{R}_2\setminus\tilde{R}_0)}$$

(Dirichlet condition at $x = T_2$!) follows the estimate

$$\|\delta\tilde{v}\|_{H^1(\tilde{R}_2\setminus\tilde{R}_0)} \leq C\left(\left\|\frac{\partial\delta v}{\partial x}\right\|_{L^2(\tilde{R}_2\setminus\tilde{R}_0)} + \|\delta Q\|_{L^2(\tilde{R}_2)}\right)$$

whence from the trace theorem

$$\|\delta\tilde{v}(\cdot, P_1)\|_{L^2[T_0,T_2]} \leq C\left\{\left\|\frac{\partial\delta\tilde{v}}{\partial x}\right\|_{L^2(\tilde{R}_2\setminus\tilde{R}_0)} + \|\delta Q\|_{L^2(\tilde{R}_2)}\right\}.$$

Any point in $\tilde{R}_1\setminus A_3$ lies on a curve of the family

$$p \mapsto \tau(z, p),$$

which joins it to the segment $[T_0, T_2] \times \{P_1\}$, and δQ is a first-order partial differential operator (acting on $\delta\tilde{v}$) whose principal part is a tangent vector field to this family of curves. Now (6.11) follows from the standard energy estimate for hyperbolic systems.

Combining (6.11) with (6.10), we get

$$\begin{aligned} \|\delta\tilde{v}\|^2_{L^2(\tilde{R}_1)} \quad \leq \quad & \left[\beta + \frac{C}{\beta r_{g,*}(\Delta)}\left(\frac{(\alpha^*)^2}{\alpha_*} + r_t^*(\Delta)\Delta^2\right)\right] \|\delta\tilde{v}\|^2_{H^1(\tilde{R}_0)} \\ & + C'\left[\|\delta Q\|^2_{L^2(\tilde{R}_2)} + \left\|\frac{\partial \delta\tilde{v}}{\partial x}\right\|^2_{L^2(\tilde{R}_2 \setminus \tilde{R}_0)}\right] \end{aligned}$$

where C' depends on $\beta, \alpha_*, \alpha^*$, and $r_{g,*}$ as well. Now recall the conclusion of Theorem 5.2 which we rewrite in a suggestive way:

$$\|\delta\tilde{S}\|^2_{L^2(R_1)} + (m_g^1)^2 L_2^2 \left\|\frac{\partial \delta\tilde{v}}{\partial x}\right\|^2_{L^2(\tilde{R}_1 \setminus \tilde{R}_0)} \geq L_1^2 \|\delta\tilde{v}\|^2_{H^1(\tilde{R}_0)} - (L_0^2 + L_1^2)\|\delta\tilde{v}\|^2_{L^2(\tilde{R}_1)}.$$

Evidently, Theorem 6.1 has been proved if we can make the various choices deferred above so that

$$(L_0^2 + L_1^2)\left[\beta + \frac{C}{\beta r_{g,*}(\Delta)}\left(\frac{(\alpha^*)^2}{\alpha_*} + r_t^*(\Delta)\Delta^2\right)\right] < L_1^2. \tag{6.12}$$

To understand the left-hand side of (6.12) we first examine $\alpha = \max(\epsilon_g, m_g^1)$. We relieve the reader's suspense by identifying the test kernel g with the kernel $\epsilon h'_\epsilon$ appearing in the statement of the theorem, so that the issue becomes one of choosing $\epsilon > 0$. Note that with this identification

$$m_g^1 = \int dz |z\epsilon h'_\epsilon(z)| = \mathcal{O}(\epsilon),$$

and similarly,

$$\epsilon_g = \mathcal{O}(\epsilon).$$

On the other hand, from the definitions,

$$\begin{aligned} r_g^*(\Delta) &= r^*(Z_0, \Delta, \epsilon), \\ r_{g,*}(\Delta) &= r_*(Z_0, \Delta, \epsilon), \\ r_g^*(\Delta) &= \bar{r}(Z_0, \Delta) \end{aligned}$$

while Young's inequality gives

$$a_g(\Delta) \leq C\bar{r}(Z_0, \Delta)$$

provided that $\epsilon \leq \Delta$, say, so that the support of h_ϵ is contained within a fixed number of Δ-intervals. In fact, we shall adopt the convention that $\epsilon \leq C\Delta^2$ and assume that Δ is sufficiently small that $\epsilon \leq \Delta$ as well. Then

$$r_{t,*}(\Delta) \leq C(r_*(Z_0, \epsilon, \Delta) + r^*(Z_0, \epsilon, \Delta) + \bar{r}(Z_0, \Delta)^2)$$

where the constant now depends on the test wavelet h_1 as well as on $\sum$—this will be the default dependence for constants "C" for the rest of the argument.

Note the uniform (over $c \in H^1_{\mathrm{loc}}$ corresponding to $\tilde{v} \in \sum$) constraints, for all $\epsilon, \Delta > 0$:

$$r_*(Z_0, \epsilon, \Delta) \le r^*(Z_0, \epsilon, \Delta) \le C,$$
$$\bar{r}(Z_0, \Delta) \le C,$$
$$r^*(Z_0, \epsilon, \Delta) \le C\bar{r}^*(Z_0, \Delta).$$

Choose a lower bound M_1 and a relative lower bound M_2, in the statement of Theorem 6.1, subject to these constraints, and assume that c satisfies condition (iv) of the theorem (recall that we have already met the constraint on Z_0, viz.

$$T_0 = \tau(Z_0, P_1) \ ).$$

That is,

$$\begin{aligned} &M_1 \le r_*(Z_0, \epsilon, \Delta), \\ &\bar{r}(Z_0, \Delta) \le M_2 r_*(Z_0, \epsilon, \Delta), \\ &r^*(Z_0, \epsilon, \Delta) \le M_2 r_*(Z_0, \epsilon, \Delta). \end{aligned} \tag{6.13}$$

Then the ratio

$$\frac{C}{r_{g,*}(\Delta)} \left(\frac{(\alpha^*)^2}{\alpha_*} + r_t^*(\Delta)\Delta^2 \right)$$

is $\mathcal{O}(\epsilon + \Delta^2) = \mathcal{O}(\Delta^2)$ for coherent $\tilde{v}\epsilon \sum$ for which the corresponding velocity profile c satisfies (6.13). Then we can choose $\beta = \mathcal{O}(\Delta)$ so that the left-hand side of (6.12) becomes $\mathcal{O}(\Delta)$ as well. In particular, for sufficiently small Δ, other choices as above, the left-hand side of (6.12) is

$$\le C(L_0^2 + L_1^2)\Delta \quad < \frac{1}{2}L_1^2$$

whence finally

$$\frac{1}{2}L_1^2 \|\delta\tilde{v}\|^2_{H^1(\tilde{R}_0)} \le \|\delta\tilde{S}\|^2_{L^2(R_1)} + C\|\delta Q\|^2_{L^2(\tilde{R}_2)} + C' \left\| \frac{\partial \delta\tilde{v}}{\partial x} \right\|_{L^2(\tilde{R}_2 \setminus \tilde{R}_0)}. \tag{6.14}$$

The right-hand side of (6.14) is bounded by a multiple of the Hessian quadratic form, the factor now depending on the penalty constants σ and λ as well. This completes the proof of Theorem 6.1. □

The proof of Theorem 2.1 is now immediate. Given appropriate $T_0, T_1, T_2, K_0, K_1, K^*$, P_1, P_2, c_0, c_1, and c^*, let $\sum_c$ denote the collection of $c \in H^1_{\mathrm{loc}}(\mathbf{R})$ satisfying

(i) $c(z) = c_0, \qquad z < 0,$

(ii) $\|\log c\|_{L^\infty(\mathbf{R})} \le c^* \qquad (\le -\log P_2),$

(iii) $c(z) = c_1 \quad \text{if} \quad 2\int_0^z \sqrt{\frac{1}{c^2} - P_1^2} \ge T_0.$

For some $\ell^* = \ell(c^*)$,

$$\|\log c\|_{H^1[0,Z]} \le c^* \longrightarrow \|\log \tilde{v}[c](\cdot, p)\|_{H^1[0,T_0/2]} \le \ell^*.$$

Then $c \in \sum_c \Rightarrow \tilde{v}[c] \in \sum$, as defined before the statement of Theorem 6.1.

Let $\bar{m}$ be as in the statement of Theorem 5.2 and assume that $f \in \mathcal{E}'(\mathbf{R})$ is chosen to satisfy

$$K^* \left\| \frac{\partial \phi}{\partial x} \right\|_{L^2(\mathbf{R})} \geq \left\| f * \frac{\partial \phi}{\partial x} \right\|_{L^2(\mathbf{R})} \geq K_1 \left\| \frac{\partial \phi}{\partial x} \right\|_{L^2(\mathbf{R})} - K_0 \|\phi\|_{L^2(\mathbf{R})}$$

for $\phi \in H^1(\mathbf{R})$,

$$m_f^1 \leq \bar{m}.$$

Choose a test wavelet h_1 as described above. Then choose $M_1, M_2, \bar{\Delta}$, and $\bar{\epsilon}$ as in the statement of Theorem 6.1 and define

$$\begin{aligned} \sum_c' \quad = \quad & \{c \in \textstyle\sum_c : \text{for } \Delta, \epsilon \text{ with } \ 0 < \Delta \leq \bar{\Delta}, \quad 0 < \epsilon \leq \bar{\epsilon}, \\ & \text{and } Z_0 \text{ satisfying } 2 \textstyle\int_0^{Z_0} \left(1/c_2 - p_1^2\right)^{1/2} = T_0, \\ & \text{the following inequalities hold: } M_1 \leq r_*(Z_0, \epsilon, \Delta) \\ & M_2 r_*(Z_0, \epsilon, \Delta) \geq \max(\bar{r}(Z_0, \Delta), r^*(Z_0, \epsilon, \Delta))\}. \end{aligned}$$

Then c is constant for $z > Z_0$, so $\tilde{v}[c]$ is constant (for each $p \in [P_1, P_2]$) for $t \geq \tau(Z_0, p)$, whence a fortiori for $t \geq T_0$.

The remarks after the statement of Theorem 6.1 show that, for arbitrary (but consistent) choices of the various parameters, the set $\sum_c'$ is nonempty.

Finally, assume that in the definition of $J_{\sigma,\lambda}$,

$$D = S[c] = \tilde{S}[\tilde{v}[c]]$$

for $c \in \sum_c'$. Then

$$J_{\sigma,\lambda}[\tilde{v}[c]] = 0$$

while Theorem 6.1 shows that the Hessian of $J_{\sigma,\lambda}$ at $\tilde{v}[c]$ is positive definite.

Therefore the implicit function theorem implies the existence of

(1) An open neighborhood U in $L^2(R_1)$ of the set

$$\{S[c] : c \in \textstyle\sum_c'\},$$

(2) An open neighborhood V in $\sum$ of the set

$$\{\tilde{v}[c] : c \in \textstyle\sum_c'\},$$

so that for each $D \in U$, the problem

$$\min_{\tilde{v} \in \sum} J_{\sigma,\lambda}[\tilde{v}]$$

has a unique solution $\tilde{v} = \tilde{I}[D] \in V$, which is moreover a Lipschitz continuous function of the data D.

Define the averaging operator

$$A : \sum \longrightarrow L^2_{\text{loc}}(\mathbf{R})$$

by

$$A\tilde{v}(z) = \frac{1}{P_2 - P_1}\int_{P_1}^{P_2} dp \left[\left(\frac{1}{\tilde{v}(\tau(z,p),p)}\right)^2 + p^2\right]^{-1/2}.$$

Remark. A performs a version of the operation "normal moveout correction, stack" from the reflection seismic data processing stream (see, e.g., Yilmaz (1987, §1.4)).

Then for $c \in \sum_c$,

$$A\tilde{v}[c] = c.$$

Also, A is Lipschitz continuous in the topologies indicated in its definition.

Set

$$I = A \circ \tilde{I} : U \to L^2_{\text{loc}}.$$

Then I has all of the properties indicated in the statement of Theorem 2.1. In particular, for $D_1, D_2 \in U$,

$$\|I(D_1) - I(D_2)\|_{L^2[0,Z]} \leq L^* \|D_1 - D_2\|_{L^2(R_1)}$$

for suitable L^*, depending on the various parameters defining $\sum_c'$ and on f. This completes the proof of Theorem 2.1. □

7. Nonelliptic sources. In this section we give a very brief sketch of the state of affairs when f is smooth. The necessary regularization arguments have become quite commonplace, so we shall concentrate on the steps necessary to modify the proof of Theorem 6.1.

Thus, suppose that $f \in C_0^\infty(\mathbf{R})$: then the best "near-elliptic" estimate might have the form

$$\left\| f * \frac{\partial \phi}{\partial x} \right\|_{L^2(\mathbf{R})} \geq K_1 \left\| \frac{\partial \phi}{\partial x} \right\|_{L^2(\mathbf{R})} - K_0 \|\phi\|_{L^2(\mathbf{R})} - K_2 \left\| \frac{\partial^2 \phi}{\partial x^2} \right\|_{L^2(\mathbf{R})} \tag{7.1}$$

for $\phi \in H^2(\mathbf{R})$. The size of K_2 measures the "passband" of f: i.e., if $|\hat{f}(\omega)|$ is uniformly large in an interval $\Omega_\ell \leq |\omega| \leq \Omega_h$, then $K_2 = \mathcal{O}(1/\Omega_h)$.

The analogue of Theorem 5.2 is Theorem 7.1.

THEOREM 7.1. *Given $P_2 > P_1 \geq 0$, $T_1 > T_0 > 0$, $K^* \geq K_1 > 0$, $K_0, K_2 \geq 0$, and $\ell^* > 0$, there exist $\bar{m}, L_0, L_1, L_2, L_3, > 0$, so that if $f \in C_0^\infty(\mathbf{R})$ satisfies (7.1) and $m_f^1 \leq \bar{m}$, then for $\tilde{v} \in \sum \cap H^2_{\text{loc}}(\mathbf{R})$, $\delta\tilde{v} \in \sum \cap H^2_{\text{loc}}(\mathbf{R})$*

$$\|D\tilde{S}[\tilde{v}]\delta\tilde{v}\|_{L^2(R_1)} \geq L_1 \left\| \frac{\partial \delta\tilde{v}}{\partial x} \right\|_{L^2(\tilde{R}_0)} - L_0 \|\delta\tilde{v}\|_{L^2(\tilde{R}_1)}$$
$$- m_f^1 L_3 \left\| \frac{\partial \delta\tilde{v}}{\partial x} \right\|_{L^2(\tilde{R}_1 \setminus \tilde{R}_0)} - L_2 \left\| \frac{\partial^2 \delta\tilde{v}}{\partial x^2} \right\|_{L^2(\tilde{R}_1)}.$$

The principal new ingredient in the proof is the higher-order estimate for the planewave problem

$$\|DS_0[\tilde{v}, \delta']\delta\tilde{v}\|_{L^2[0,T]} \leq C_2 \|\delta\tilde{v}\|_{H^2[0,\, T/2]}$$

for $\log \tilde{v} \in H^2_{\text{loc}}(\mathbf{R})$, $\delta\tilde{v} \in H^2_{\text{loc}}(\mathbf{R})$. See, for instance, Suzuki (1988) for similar estimates.

Most of the proof of Theorem 6.1 goes through as before, except that now the smoothness constraint implicit in Theorem 7.1 conflicts with the roughness conditions. For example, for a coherent $\tilde{v} \in \sum \cap H^2_{\text{loc}}(\mathbf{R})$, its corresponding $c \in H^2_{\text{loc}}(\mathbf{R})$ satisfies

$$\begin{aligned} \frac{1}{\Delta}\int_{z-\Delta/2}^{z+\Delta/2} |\epsilon h'_\epsilon * c'|^2 &= \frac{1}{\Delta}\int_{z-\Delta/2}^{z+\Delta/2} |\epsilon h_\epsilon * c''|^2 \\ &\leq C\frac{\epsilon^2}{\Delta}\|c''\|^2_{L^2[z-2\Delta,z+2\Delta]}. \end{aligned}$$

For the constraint $\epsilon = 0(\Delta)$, which we were bound to impose, this gives

$$\leq C\Delta\|c''\|_{L^2[0,Z_0]}.$$

So over any bounded set in $H^2(\tilde{R}_2)$, r_* is $\mathcal{O}(\Delta)$ over coherent travel-time velocities. Thus estimates of the sort developed in § 6 can only succeed if

(i) f is sufficiently "broadband" that (7.1) holds with small K_2 relative to $\sum, K_0$, K_1, K^*;

(ii) Target velocities exist in the intersection of $\sum'_c$ and a sufficiently large ball in $H^2(\tilde{R}_2)$, for which the regularized cost functional

$$\begin{aligned} J_{\sigma,\lambda,\rho}[\tilde{v}]: &= \frac{1}{2}\left\{\|\tilde{S}[\tilde{v}] - D\|^2_{L^2(R_1)} + \sigma^2\|C[\tilde{v}]\|^2_{L^2(\tilde{R}_1)}\right. \\ &\qquad \left. +\lambda^2\left\|\frac{\partial\tilde{v}}{\partial x}\right\|_{L^2(\tilde{R}_2\setminus\tilde{R}_0)} + \rho^2\left\|\frac{\partial\tilde{v}}{\partial x}\right\|_{L^2(\tilde{R}_2)}\right\} \end{aligned}$$

takes a sufficiently small value, with $\rho = \mathcal{O}(K_2)$.

Then the Hessian of $J_{\sigma,\lambda,\rho}$ will be positive-definite at target velocities as described in (ii), while the *value* of $J_{\sigma,\lambda,\rho}$ will be small enough to conclude the existence of a nearby local minimizer. Since it will no longer be possible to have $J = 0$, only an approximation will be obtained even for data corresponding exactly to $c \in \sum'_c \cap H^2_{\text{loc}}(\mathbf{R})$.

The reader is referred to Symes (1986b) for details of a similar construction.

SOLUTION OF THE INVERSE SCATTERING PROBLEM FOR THE THREE-DIMENSIONAL SCHRÖDINGER EQUATION USING A FREDHOLM INTEGRAL EQUATION*

TUNCAY AKTOSUN† AND CORNELIS VAN DER MEE‡

Abstract. It is shown that the inverse scattering problem for the three-dimensional Schrödinger equation with a potential having no spherical symmetry can be solved using a Fredholm integral equation. The integral operator studied here is shown to be compact and self-adjoint with its spectrum in $[-1,1]$. The relationship between solutions of this Fredholm equation and of a related Riemann–Hilbert problem is also clarified, and it is shown that the Fredholm integral equation is uniquely solvable if and only if the Riemann–Hilbert problem is uniquely solvable.

Key words. inverse scattering, three-dimensional Schrödinger equation, Fredholm integral equation

1. Introduction.

Consider the Schrödinger equation in three dimensions

$$\Delta\psi(k,x,\theta) + k^2\psi(k,x,\theta) = V(x)\psi(k,x,\theta), \tag{1.1}$$

where Δ is the Laplacian, $k^2 \in \mathbf{R}$ is energy, $x \in \mathbf{R}^3$ is the space coordinate, and $\theta \in S^2$ is a unit vector in $\mathbf{R}^3$. We assume that the potential $V(x)$ is real and decreases to zero sufficiently fast as $|x| \to \infty$. However, we do not assume any spherical symmetry on the potential. As $|x| \to \infty$, the wavefunction $\psi(k,x,\theta)$ satisfies

$$\psi(k,x,\theta) = e^{ik\theta\cdot x} + \frac{e^{ik|x|}}{|x|} A\left(k, \frac{x}{|x|}, \theta\right) + o\left(\frac{1}{|x|}\right) \tag{1.2}$$

where $A(k,\theta,\theta')$ is the scattering amplitude. The scattering operator $S(k,\theta,\theta')$ is then defined by

$$S(k,\theta,\theta') = \delta(\theta-\theta') - \frac{k}{2\pi i} A(k,\theta,\theta'), \tag{1.3}$$

where δ is the Dirac delta distribution on S^2. In operator notation (1.3) is written as

$$S(k) = \mathbf{I} - \frac{k}{2\pi i} A(k),$$

where the operators are all defined on $L^2(S^2)$, the Hilbert space of complex valued square integrable functions on the unit sphere S^2 in $\mathbf{R}^3$ with the usual inner product.

In this article we study the inverse scattering problem, which consists of recovering $V(x)$ when $S(k)$ is known. Since the main source of information about molecular, atomic, and subatomic particles consists of collision experiments, solving the inverse

scattering problem is equivalent to determining the forces among particles from scattering data.

For one-dimensional and radial Schrödinger equations, the inverse scattering problem is fairly well understood (at least for certain classes of potentials) [1]. In higher dimensions, however, the situation is quite different. The solution methods developed in higher dimensions include the Newton–Marchenko method [2]–[4], the generalized Gel'fand-Levitan method [2]–[5], the $\bar{\partial}$ method [6]–[9], a method that only relies on backward scattering data [10]–[13], a method that uses the Green's function of Faddeev [14]–[16], and the Wiener–Hopf factorization method [17]. There are still many open problems in multidimensional inverse scattering, and the methods developed are still far from being complete. Newton's recent book [18] gives a comprehensive review of the methods and related open problems in three-dimensional inverse scattering prior to 1989.

The main idea behind both the Newton–Marchenko and generalized Gel'fand–Levitan methods is to formulate the inverse scattering problem as a Riemann–Hilbert boundary value problem, to transform this Riemann–Hilbert problem into a nonhomogeneous integral equation where the kernel contains the Fourier transform of the scattering data, and to obtain the potential from the solution of the resulting integral equation. In this paper we give the solution of the three-dimensional inverse scattering problem by generalizing a method by Muskhelishvili and Vekua [19], [20] developed to solve Riemann–Hilbert problems with several unknown functions. In the radial case, Newton and Jost used this method to construct potentials from an $n \times n$ scattering matrix for a system of n ordinary differential equations [21]. Here we generalize the Muskhelishvili-Vekua method (and hence the Newton–Jost method) to solve an operator Riemann–Hilbert problem and thus to obtain the solution of the inverse scattering problem for the three-dimensional Schrödinger equation. In this method, the kernel of the key integral equation is an $n \times n$ matrix valued function whereas in our case we deal with an integral equation whose kernel is an operator valued function. In the Newton–Jost method the inverse scattering problem pertains to a system of n ordinary differential equations with an $n \times n$ scattering matrix; however, in this paper, we deal with the inverse scattering problem for a partial differential equation where the kernel of the key integral equation is an operator valued function. Contrary to the three-dimensional Newton–Marchenko and generalized Gel'fand–Levitan inversion methods, we do not use any Fourier transform in our solution of the inverse scattering problem.

The present paper is organized as follows. In §2 we identify the class of potentials for which all of the results in this paper are valid, and we state the key Riemann–Hilbert problem which helps to solve the inverse scattering problem for the three-dimensional Schrödinger equation. In §3, using the Riemann–Hilbert problem, we obtain our fundamental Fredholm integral equation (3.10). In §4, we show that the Fredholm integral operator of (3.10) is compact and self-adjoint and its spectrum is confined to $[-1, 1]$. In §5, we study the relationship between solutions of our Fredholm integral equation and of the Riemann–Hilbert problem and relate the unique solvability of the Fredholm equation to that of the Riemann–Hilbert problem. In §6, utilizing the solution of the fundamental Fredholm integral equation, we give the solution of the inverse scattering problem for the three-dimensional Schrödinger equation. Finally in §7, the conclusion is given.

2. Riemann–Hilbert problem. We first identify the class of potentials for which all of the results in this paper are valid. Except for the third condition given in

the following definition, these conditions are standard assumptions on the potential [18]. These conditions were instrumental in proving the Hölder continuity of the scattering operator and the existence of a Wiener–Hopf factorization of the scattering operator [17].

DEFINITION 2.1. A potential $V(x)$ is said to belong to the *Newton class* if $V(x)$ is real valued and measurable and satisfies

1. $\exists a, b > 0$ such that

$$\int_{\mathbf{R}^3} dx\, |V(x)| \left(\frac{|x| + |y| + a}{|x - y|} \right)^2 \leq b, \quad \forall y \in \mathbf{R}^3, \tag{2.1}$$

2. $\exists c > 0, s > \frac{1}{2}$ such that

$$|V(x)| \leq \frac{c}{(1 + |x|^2)^s}, \quad \forall x \in \mathbf{R}^3, \tag{2.2}$$

3. $\exists \alpha > 0$ and some $\beta \in (0, 1]$ such that

$$\int_{\mathbf{R}^3} dx\, |x|^\beta |V(x)| \leq \alpha, \tag{2.3}$$

4. $k = 0$ is not an exceptional point [22]. This condition is satisfied if at zero energy there are neither bound states nor half bound states.

In the Schrödinger equation (1.1), k appears as k^2 and hence $\psi(-k, x, \theta)$ is a solution whenever $\psi(k, x, \theta)$ is. These two solutions are related to each other as [2]

$$\psi(k, x, \theta) = \int_{S^2} d\theta'\, S(k, -\theta, \theta') \psi(-k, x, \theta'). \tag{2.4}$$

Define

$$f(k, x, \theta) = e^{-ik\theta \cdot x} \psi(k, x, \theta). \tag{2.5}$$

If the potential satisfies (2.1) and if there are no bound states, for fixed x and θ, the function $f(k, x, \theta)$ has an analytic extension in k to the upper half complex plane $\mathbf{C}^+$ and $f(k, x, \theta) = 1 + O(\frac{1}{|k|})$ as $|k| \to \infty$ there [2]. Similarly $f(-k, x, \theta)$ has an analytic extension in k to the lower half complex plane $\mathbf{C}^-$. Hence, using (2.4), we obtain the Riemann–Hilbert problem

$$f(k, x, \theta) = \int_{S^2} d\theta'\, e^{-ik\theta \cdot x} S(k, -\theta, \theta') e^{-ik\theta' \cdot x} f(-k, x, \theta'), \qquad k \in \mathbf{R}. \tag{2.6}$$

Let us define

$$G(k, x, \theta, \theta') = e^{-ik\theta \cdot x} S(k, -\theta, -\theta') e^{ik\theta' \cdot x}, \tag{2.7}$$

$$X_\pm(k) = f(\pm k, x, \pm\theta) - 1, \tag{2.8}$$

where $f(k, x, \theta)$ is as in (2.5). Then we can write (2.6) in vector form as

$$X_+(k) = G(k) X_-(k) + [G(k) - \mathbf{I}]\hat{1}, \qquad k \in \mathbf{R}, \tag{2.9}$$

where $G(k)$ is the operator on $L^2(S^2)$ with its kernel given in (2.7), $\mathbf{I}$ is the identity operator on this space, and $\hat{1}$ is the function on $L^2(S^2)$ defined as $\hat{1}(\theta) = 1$, $\forall \theta \in S^2$. Note that, since x enters (2.9) only as a parameter, we have suppressed the x-dependence of all the operators and vectors in (2.9).

If there are bound states, the extension of $f(k, x, \theta)$ in k to $\mathbf{C}^+$ becomes meromorphic with simple poles on the imaginary axis. A pole at $k = i\kappa$ corresponds to

a bound state of the Hamiltonian with energy $-\kappa^2$. It is possible to remove these simple poles from the Riemann–Hilbert problem by a reduction method [4]. Assume there is a bound state corresponding to a pole at $k = i\kappa$. Using a suitable orthogonal projection $\mathbf{B}$, we form the rational function

$$\Pi(k) = \mathbf{I} - \mathbf{B} + \frac{k + i\kappa}{k - i\kappa}\mathbf{B}$$

and define the corresponding reduced quantities

$$G^{\rm red}(k) = \Pi(k)^{-1} G(k) \Pi(k)$$

$$X_+^{\rm red}(k) = \Pi(k)^{-1} X_+(k) + [\Pi(k)^{-1} - \mathbf{I}]\hat{1} \tag{2.10}$$

$$X_-^{\rm red}(k) = \Pi(k) X_-(k) + [\Pi(k) - \mathbf{I}]\hat{1}. \tag{2.11}$$

As a result, $X_+^{\rm red}(k)$ does not have a pole at $k = i\kappa$ and $X_-^{\rm red}(k)$ does not have a pole at $k = -i\kappa$. If there is more than one bound state, this procedure must be repeated to remove the finitely many poles corresponding to the bound states; the details can be found in [4]. This eventually leads to the reduced Riemann–Hilbert problem

$$X_+^{\rm red}(k) = G^{\rm red}(k) X_-^{\rm red}(k) + [G^{\rm red}(k) - \mathbf{I}]\hat{1}, \qquad k \in \mathbf{R}. \tag{2.12}$$

Once the reduced Riemann–Hilbert problem (2.12) is solved, the solution of the original Riemann–Hilbert problem (2.9) can easily be obtained using (2.10) and (2.11). Hence, in the following sections, without any loss of generality, we will obtain the solution of the Riemann–Hilbert problem assuming that $X_+(k)$ and $X_-(k)$ have analytic extensions to $\mathbf{C}^+$ and $\mathbf{C}^-$, respectively, and vanish in the norm of $L^2(S^2)$ as $k \to \infty$ from that half plane.

3. Fredholm integral equation. In this section we show that the Riemann–Hilbert problem posed in (2.9) leads to a Fredholm integral equation, which will be the key equation to solve the inverse scattering problem.

From the Cauchy integral formula we have

$$X_+(k) = \frac{1}{\pi i}{\rm CPV}\int_{-\infty}^{+\infty} dt\, \frac{X_+(t)}{t - k}, \tag{3.1}$$

$$X_-(k) = -\frac{1}{\pi i}{\rm CPV}\int_{-\infty}^{+\infty} dt\, \frac{X_-(t)}{t - k}, \tag{3.2}$$

where CPV denotes the Cauchy principal value. Operating on (3.2) by $G(k)$ and adding the result to (3.1), we obtain

$$X_+(k) + G(k)X_-(k) = \frac{1}{\pi i}{\rm CPV}\int_{-\infty}^{+\infty} \frac{dt}{t - k}[X_+(t) - G(k)X_-(t)]. \tag{3.3}$$

Using (2.9) in (3.3) we obtain

$$\begin{aligned} &2X_+(k) + [\mathbf{I} - G(k)]\hat{1} \\ &\quad = \frac{1}{\pi i}{\rm CPV}\int_{-\infty}^{+\infty} \frac{dt}{t - k}\left([\mathbf{I} - G(k)G(t)^{-1}]X_+(t) + G(k)[\mathbf{I} - G(t)^{-1}]\hat{1}\right). \end{aligned} \tag{3.4}$$

Define the integral operator K whose kernel is given by

$$K(k,t) = \frac{1}{2\pi i}\frac{\mathbf{I} - G(k)G(t)^{-1}}{t - k}. \tag{3.5}$$

Then we can write (3.4) as

$$X_+(k) - \mathrm{CPV}\int_{-\infty}^{+\infty} dt\, K(k,t)X_+(t) = H(k), \tag{3.6}$$

where $H(k)$ is given by

$$H(k) = [G(k) - \mathbf{I} + \int_{-\infty}^{\infty} dt\, K(k,t)]\hat{1}.$$

If the potential $V(x)$ belongs to the Newton class defined in §2, the operator $G(k)^{-1}$ is Hölder continuous [17]. Hence the integral in (3.6) is no longer singular and we can drop CPV in front of this integral. Thus, we obtain the regular Fredholm integral equation of the second kind

$$X_+(k) - \int_{-\infty}^{+\infty} dt\, K(k,t)X_+(t) = H(k). \tag{3.7}$$

The Möbius transformation $k \to \xi = (k-i)/(k+i)$ maps the extended real axis onto the unit circle $\mathbf{T}$, the upper half complex plane $\mathbf{C}^+$ onto the unit disk $\mathbf{T}^+$, and the lower half complex plane $\mathbf{C}^-$ onto the exterior of the unit disk $\mathbf{T}^-$ where ∞ is considered to be a point of $\mathbf{T}^-$. Let $\tilde{S}(\xi) = S(k)$ under this transformation, and let us adopt this notation and use the tilde to denote the Möbius transformed quantity for other functions and operator valued functions throughout the paper.

Let $k \to \xi = (k-i)/(k+i)$ and $t \to \eta = (t-i)/(t+i)$ under this Möbius transformation. Defining

$$Y(\xi) = \frac{\tilde{X}_+(\xi)}{1-\xi} = \frac{k+i}{2i}X_+(k) \tag{3.8}$$

and

$$L(\xi) = \frac{\tilde{H}(\xi)}{1-\xi} = \frac{k+i}{2i}H(k), \tag{3.9}$$

we can transform (3.7) into

$$Y(\xi) - \int_{\mathbf{T}} d\eta\, \tilde{K}(\xi,\eta)Y(\eta) = L(\xi), \tag{3.10}$$

where the kernel of the integral operator $\tilde{K}$ is given by

$$\tilde{K}(\xi,\eta) = \frac{1}{2\pi i}\frac{\mathbf{I} - \tilde{G}(\xi)\tilde{G}(\eta)^{-1}}{\eta - \xi}. \tag{3.11}$$

Comparing (3.11) with (3.5) we see that $\tilde{K}$ is the Möbius transformed operator for K.

4. Properties of the integral operator. In this section we show that the integral operator $\tilde{K}$ in (3.10) is compact and self-adjoint and its spectrum lies in $[-1,1]$.

For $\alpha \in (0,1]$ let $\mathcal{H}_\alpha(\mathbf{T}; L^2(S^2))$ be the Banach space of Hölder continuous functions $W : \mathbf{T} \to L^2(S^2)$; i.e., the Banach space of all (strongly) continuous functions $W : \mathbf{T} \to L^2(S^2)$ which are bounded with respect to the norm

$$|||W|||_\alpha = \max_{\xi\in\mathbf{T}} \|W(\xi)\| + \sup_{\xi\neq\eta\in\mathbf{T}} \frac{\|W(\xi) - W(\eta)\|}{|\xi - \eta|^\alpha}.$$

Here and in the following $\|\cdot\|$ without any subscript denotes the operator norm on $L^2(S^2)$. Let $\mathcal{C}(\mathbf{T};L^2(S^2))$ denote the Banach space of (strongly) continuous functions $W:\mathbf{T}\to L^2(S^2)$ with norm $\|W\|_\infty=\max_{\xi\in\mathbf{T}}\|W(\xi)\|$. Finally, for $1\le p\le\infty$ let $L^p(\mathbf{T};L^2(S^2))$ denote the Banach space of all strongly measurable functions $W:\mathbf{T}\to L^2(S^2)$ such that $\|W(\cdot)\|$ belongs to $L^p(\mathbf{T})$ [23].

Let Γ be the singular integral operator on $L^2(S^2)$ defined by

$$(\Gamma f)(\xi)=\frac{1}{\pi i}\mathrm{CPV}\int_{\mathbf{T}}d\eta\,\frac{f(\eta)}{\eta-\xi}. \tag{4.1}$$

Then, from (3.10) and (3.11) it is seen that we can write $\tilde{K}$ as

$$\tilde{K}=\tfrac{1}{2}(\Gamma-\tilde{G}\Gamma\tilde{G}^{-1}), \tag{4.2}$$

where $\tilde{G}$ and $\tilde{G}^{-1}$ are operators of multiplication by the respective functions. The space $L^2(\mathbf{T};L^2(S^2))$ is a Hilbert space which allows the decomposition into the orthogonal closed subspaces $\mathcal{E}_+(\mathbf{T};L^2(S^2))$ and $\mathcal{E}_-(\mathbf{T};L^2(S^2))$. Here $\mathcal{E}_+(\mathbf{T};L^2(S^2))$ is the subspace of all L^2-functions which allow for an analytic continuation to $\mathbf{T}^+$, while $\mathcal{E}_-(\mathbf{T};L^2(S^2))$ is the subspace of L^2-functions which allow for an analytic continuation to $\mathbf{T}^-$ that vanishes at infinity. If $f(\xi)$ is an L^2-function defined on the unit circle $\mathbf{T}$, then using its Fourier series, we have the decomposition

$$f(\xi)=\sum_{n=-\infty}^{-1}f_n\xi^n+\sum_{n=0}^{\infty}f_n\xi^n$$

as a sum of elements in $\mathcal{E}_-(\mathbf{T};L^2(S^2))$ and $\mathcal{E}_+(\mathbf{T};L^2(S^2))$, and this decomposition is orthogonal. If we denote the two summations in the above decomposition as f_- and f_+, respectively, we obtain

$$\Gamma f=f_+-f_-. \tag{4.3}$$

Thus, Γ is self-adjoint and has unit norm on $L^2(\mathbf{T};L^2(S^2))$. More generally, Γ is a bounded linear operator on $\mathcal{E}(\mathbf{T};L^2(S^2))$, where $\mathcal{E}$ represents L^p with $1<p<\infty$ or $\mathcal{H}_\gamma$ with $0<\gamma<1$. This result can be derived from the boundedness of Γ on the spaces $\mathcal{E}(\mathbf{T})$ of scalar functions (Theorems I2.1 and I6.1 of [24]) and the density of the linear subspace $\{\sum_{j=1}^n\varphi_j(\cdot)h_j:n\in\mathbf{N},\varphi_j\in\mathcal{E}(\mathbf{T}),h_j\in L^2(S^2)\}$ in $\mathcal{E}(\mathbf{T};L^2(S^2))$ [23].

For potentials identified in Definition 2.1, we will prove the following three propositions.

PROPOSITION 4.1. *Let $V(x)$ belong to the Newton class. Then the Fredholm integral operator $\tilde{K}$ in (3.10) is compact on $L^p(\mathbf{T};L^2(S^2))$ for $1\le p\le\infty$, on $\mathcal{C}(\mathbf{T};L^2(S^2))$, and on $\mathcal{H}_\gamma(\mathbf{T};L^2(S^2))$ for $0<\gamma<\mu$. Here $\mu=\beta/2(1+\beta)$ for $s>1$ in (2.2) and $\mu=\beta(1-s)/(\beta-s+\frac{3}{2})$ for $\frac{1}{2}<s<1$ in (2.2), where $\beta\in(0,1]$ is the constant in (2.3)* [17].

Proof. Define the integral operator M acting on $L^2(S^2)$ as

$$(MZ)(\xi)=\frac{1}{2\pi i}\int_{\mathbf{T}}d\eta\,\frac{\tilde{G}(\eta)-\tilde{G}(\xi)}{\eta-\xi}Z(\eta). \tag{4.4}$$

Then $(\tilde{K}Y)(\xi)=(M\tilde{G}^{-1}Y)(\xi)$. Due to the fact that the scattering operator $S(k)$ is unitary, the operator $\tilde{G}(\xi)^{-1}$ is bounded with norm $\|\tilde{G}^{-1}\|=1$. Hence, to prove that $\tilde{K}$ is compact, it is sufficient to prove that M is compact, and we will prove this by showing that M can be approximated by a sequence of finite rank operators.

It is known [17] that $\tilde{G}(\xi) - \mathbf{I}$ is a compact operator on $L^2(S^2)$ depending continuously on $\xi \in \mathbf{T}$. Hence it can be approximated by a sequence of finite rank operators $\{\tilde{G}_n(\xi) - \mathbf{I}\}_{n=1}^{\infty}$ given by

$$\tilde{G}_n(\xi) - \mathbf{I} = \sum_{j=-n}^{n} \xi^j A_j,$$

where $\{A_j\}_{j=-\infty}^{\infty}$ is a sequence of mutually orthogonal finite rank operators on $L^2(S^2)$. We then obtain

$$\frac{\tilde{G}_n(\eta) - \tilde{G}_n(\xi)}{\eta - \xi} = \sum_{j=1}^{n} \sum_{l=0}^{j-1} (\xi^l \eta^{j-l-1} - \xi^{l-j} \eta^{-l-1}) A_j. \tag{4.5}$$

Using (4.5) in (4.4) we obtain a sequence of operators $\{M_n\}_{n=1}^{\infty}$ given by

$$(M_n Y)(\xi) = \frac{1}{2\pi i} \sum_{j=1}^{n} \left(\sum_{l=0}^{j-1} \xi^l - \sum_{l=j}^{2j-1} \xi^{l-2j} \right) A_j \int_{\mathbf{T}} d\eta\, \eta^{j-l-1} Y(\eta). \tag{4.6}$$

Hence, for each n, M_n is a finite rank operator. We will complete the proof of our proposition by showing that M_n converges to M as $n \to \infty$ in the function spaces $L^p(\mathbf{T}; L^2(S^2))$, $\mathcal{C}(\mathbf{T}; L^2(S^2))$, and $\mathcal{H}_\gamma(\mathbf{T}; L^2(S^2))$.

From (4.2) and (4.4), it is seen that $M = \frac{1}{2}(\Gamma\tilde{G} - \tilde{G}\Gamma)$ and $M_n = \frac{1}{2}(\Gamma\tilde{G}_n - \tilde{G}_n\Gamma)$. Hence, using the boundedness of Γ on $\mathcal{E}(\mathbf{T}; L^2(S^2))$, where $\mathcal{E}$ is equal to L^p with $1 < p < \infty$ or equal to $\mathcal{H}_\gamma$ with $0 < \gamma < \mu$, we have in the operator norm on $\mathcal{E}(\mathbf{T}; L^2(S^2))$

$$||M - M_n||_{\mathcal{E}} \leq ||\Gamma||_{\mathcal{E}}\, ||\tilde{G} - \tilde{G}_n||_{\mathcal{E}} \leq c\, |||\tilde{G} - \tilde{G}_n|||_\gamma$$

for some constant $c > 0$. Thus, $M_n \to M$ in the norm of $L^p(\mathbf{T}; L^2(S^2))$ for $1 < p < \infty$ and in the norm of $\mathcal{H}_\gamma(\mathbf{T}; L^2(S^2))$ for $0 < \gamma < \mu$.

It remains to prove the convergence of M_n to M as $n \to \infty$ in the operator norm on $\mathcal{E}(\mathbf{T}; L^2(S^2))$ where $\mathcal{E}$ is L^1, L^∞, or $\mathcal{C}$. First, from (4.4) we obtain

$$||(M - M_n)Y||_p \leq m_\gamma |||\tilde{G} - \tilde{G}_n|||_\gamma ||Y||_p, \qquad p = 1, \infty, \tag{4.7}$$

where

$$m_\gamma = \frac{1}{2\pi} \int_{\mathbf{T}} \frac{|d\eta|}{|\eta - \xi|^{1-\gamma}} = \frac{1}{2\pi} \int_0^{2\pi} \frac{dt}{(2 - 2\cos t)^{(1-\gamma)/2}}$$

is a constant independent of $\xi \in \mathbf{T}$. Then, from (4.7) it follows that $M_n \to M$ in the operator norm on $L^1(\mathbf{T}; L^2(S^2))$ and on $L^\infty(\mathbf{T}; L^2(S^2))$. Next, as a result of the dominated convergence theorem for Bochner integrals (Theorem II.3 of [23]), if $\xi \to \xi_0$ in $\mathbf{T}$, then for every $Y \in L^\infty(\mathbf{T}; L^2(S^2))$, $[(M - M_n)Y](\xi)$ converges to $[(M - M_n)Y](\xi_0)$ in the norm of $L^2(S^2)$. Therefore, M and M_n map $L^\infty(\mathbf{T}; L^2(S^2))$ into $\mathcal{C}(\mathbf{T}; L^2(S^2))$. Hence, we obtain from (4.7) that the convergence of M_n to M also holds in the operator norm on $\mathcal{C}(\mathbf{T}; L^2(S^2))$. Thus, the proof is complete. □

If λ is a nonzero eigenvalue of $\tilde{K}$, then, by the compactness of $\tilde{K}$ on $\mathcal{E}(\mathbf{T}; L^2(S^2))$, there exists some integer $N \geq 1$ such that the kernel of $(\tilde{K} - \lambda\mathbf{I})^n$ coincides with the kernel of $(\tilde{K} - \lambda\mathbf{I})^N$ if $n \geq N$. The finite dimension of this subspace is called the algebraic multiplicity of λ. The dimension of the kernel of $\tilde{K} - \lambda\mathbf{I}$ is called the geometric multiplicity of λ.

As a result of the compactness of $\tilde{K}$, we have the following result.

COROLLARY 4.2. *Let $V(x)$ belong to the Newton class. Then the nonzero eigenvalues of $\tilde{K}$ as well as their (algebraic) multiplicities do not depend on the choice of the function space on which they are defined. As a result, the eigenvectors and generalized eigenvectors of $\tilde{K}$ corresponding to its nonzero eigenvalues belong to each of the spaces $\mathcal{C}(\mathbf{T}; L^2(S^2))$, $L^p(\mathbf{T}; L^2(S^2))$ for $1 \leq p \leq \infty$, and $\mathcal{H}_\gamma(\mathbf{T}; L^2(S^2))$ for $0 < \gamma < \mu$, where μ is the constant specified in Proposition* 4.1.

Proof. Note that for $0 < \beta \leq \gamma$ and $1 \leq p \leq q < \infty$ we have

$$\mathcal{H}_\gamma \subset \mathcal{H}_\beta \subset \mathcal{C} \subset L^\infty \subset L^q \subset L^p.$$

Consider any of the four pairs of spaces $\{L^\infty, L^p\}$, $\{L^q, L^p\}$, $\{\mathcal{C}, L^p\}$, and $\{\mathcal{H}_\gamma, \mathcal{C}\}$. In each pair, let $\mathcal{E}_1$ denote the first space and $\mathcal{E}_2$ denote the second space for functions in $L^2(S^2)$. For example, for the first pair, we let $\mathcal{E}_1 = L^\infty(\mathbf{T}; L^2(S^2))$ and $\mathcal{E}_2 = L^p(\mathbf{T}; L^2(S^2))$. Then for all the pairs, $\mathcal{E}_1$ is continuously and densely imbedded in $\mathcal{E}_2$. Since $\tilde{K}$ is compact in $\mathcal{E}_1$ and in $\mathcal{E}_2$, for each nonzero complex number λ and natural number n, the closure in $\mathcal{E}_2$ of the image of $\mathcal{E}_1$ under $(\tilde{K} - \lambda \mathbf{I})^n$ coincides with the image of $\mathcal{E}_2$ under $(\tilde{K} - \lambda \mathbf{I})^n$. As a result, the complements of the ranges of $(\tilde{K} - \lambda \mathbf{I})^n$ in both $\mathcal{E}_1$ and in $\mathcal{E}_2$ have the same finite dimension. Since $(\tilde{K} - \lambda \mathbf{I})^n$ is a Fredholm operator of index 0, its kernels in $\mathcal{E}_1$ and $\mathcal{E}_2$ also have the same finite dimension. As a consequence, the dimensions of the (generalized) eigenspaces for each nonzero eigenvalue of $\tilde{K}$ are the same in $\mathcal{C}(\mathbf{T}; L^2(S^2))$, in $L^p(\mathbf{T}; L^2(S^2))$ for $1 \leq p \leq \infty$, and in $\mathcal{H}_\gamma(\mathbf{T}; L^2(S^2))$ for $0 < \gamma < \mu$, where μ is the constant specified in Proposition 4.1. □

PROPOSITION 4.3. *Let the potential $V(x)$ belong to the Newton class. Then $\tilde{K}$ is self-adjoint on $L^2(\mathbf{T}; L^2(S^2))$. As a result, all eigenvalues of $\tilde{K}$ are real and their algebraic and geometric multiplicities coincide.*

Proof. Due to the unitarity of the scattering operator $S(k)$, the operators $\tilde{G}$ and $\tilde{G}^{-1}$ are unitary. Because of (4.3), the singular integral operator Γ is self-adjoint. Thus, from (4.2) it follows that $\tilde{K}$ is self-adjoint on $L^2(\mathbf{T}; L^2(S^2))$. □

PROPOSITION 4.4. *Let the potential $V(x)$ belong to the Newton class. Then the norm of $\tilde{K}$ in $L^2(\mathbf{T}; L^2(S^2))$ is bounded above by* 1, *and all eigenvalues of $\tilde{K}$ belong to* $[-1, 1]$.

Proof. From (4.3) it is seen that the singular integral operator Γ has unit norm on $L^2(\mathbf{T}; L^2(S^2))$. Due to their unitarity, the multiplication operators $\tilde{G}$ and $\tilde{G}^{-1}$ each have unit norm. Thus, as seen from (4.2), $\tilde{K}$ has at most unit norm on $L^2(\mathbf{T}; L^2(S^2))$. Furthermore, by Proposition 4.3, $\tilde{K}$ is self-adjoint and hence its spectrum is real. Thus, the spectrum of $\tilde{K}$ lies in $[-1, 1]$, and by Corollary 4.2, the spectrum does not depend on the function space used. □

If ± 1 are not eigenvalues of $\tilde{K}$, the Fredholm integral equation (3.10) has a unique solution which can be obtained by iteration. Since we have shown in Corollary 4.2 that the spectral radius of $\tilde{K}$ does not depend on the function space used, the iteration converges in the norm of any of the spaces mentioned in Proposition 4.1.

5. Relationship between solutions of the Fredholm integral equation and of the Riemann–Hilbert problem. In this section we study the relationship between solutions of the Fredholm integral equation (3.10) and solutions of the Riemann–Hilbert problem on $\mathcal{E}(\mathbf{T}; L^2(S^2))$, where $\mathcal{E}$ is either L^p with $1 < p < \infty$ or $\mathcal{H}_\gamma$ with $0 < \gamma < \mu$, μ being the constant specified in Proposition 4.1. We also investigate the relationship between the partial indices of $\tilde{G}(\xi)$ [17] and the existence and uniqueness of the solution of (3.10).

Using $F(\xi) = (1/(1-\xi))[\tilde{G}(\xi) - \mathbf{I}]\hat{1}$, we can transform (2.9) into the Riemann–Hilbert problem on the unit circle $\mathbf{T}$ to obtain

$$Y_+(\xi) = \tilde{G}(\xi)Y_-(\xi) + F(\xi), \qquad \xi \in \mathbf{T}. \tag{5.1}$$

Let us write (3.10) as

$$(\mathbf{I} - \tilde{K})Y = L. \tag{5.2}$$

Note that the nonhomogeneous terms in (5.1) and in (5.2) are related to each other by

$$L = \tfrac{1}{2}\tilde{G}(\mathbf{I} + \Gamma)\tilde{G}^{-1}F. \tag{5.3}$$

We will relate the solutions of (5.1) with $F \in \mathcal{E}(\mathbf{T}; L^2(S^2))$ and $Y_\pm \in \mathcal{E}_\pm(\mathbf{T}; L^2(S^2))$ to the solutions of (5.2) with $L, Y \in \mathcal{E}(\mathbf{T}; L^2(S^2))$.

As mentioned prior to Proposition 4.1, the singular integral operator Γ defined in (4.1) is bounded on $\mathcal{E}(\mathbf{T}; L^2(S^2))$. Then $\frac{1}{2}(\mathbf{I}+\Gamma)$ and $\frac{1}{2}(\mathbf{I}-\Gamma)$ are complementary bounded projections onto the subspace $\mathcal{E}_+(\mathbf{T}; L^2(S^2))$ of all functions in $\mathcal{E}(\mathbf{T}; L^2(S^2))$ with an analytic continuation to $\mathbf{T}^+$ and onto the subspace $\mathcal{E}_-(\mathbf{T}; L^2(S^2))$ of all functions in $\mathcal{E}(\mathbf{T}; L^2(S^2))$ with an analytic continuation to $\mathbf{T}^-$ vanishing at infinity.

THEOREM 5.1. *Let $F \in \mathcal{E}(\mathbf{T}; L^2(S^2))$. If $Y_\pm$ is a solution of* (5.1) *in $\mathcal{E}_\pm(\mathbf{T}; L^2(S^2))$, then $Y = Y_+$ is a solution of* (5.2). *Conversely, if Y is a solution of* (5.2) *and $Y \in \mathcal{E}_+(\mathbf{T}; L^2(S^2))$, then $Y_\pm$, where $Y_+ = Y$ and $Y_- = \tilde{G}^{-1}(Y - F)$, is a solution of* (5.1) *with $Y_\pm \in \mathcal{E}_\pm(\mathbf{T}; L^2(S^2))$.*

Proof. Let $Y_\pm \in \mathcal{E}_\pm(\mathbf{T}; L^2(S^2))$ be a solution of (5.1). Then using (4.2), (5.3), and $(\mathbf{I} \pm \Gamma)Y_\mp = 0$, we have

$$\begin{aligned}(\mathbf{I} - \tilde{K})Y_+ &= \tfrac{1}{2}(\mathbf{I} - \Gamma)Y_+ + \tfrac{1}{2}\tilde{G}(\mathbf{I} + \Gamma)\tilde{G}^{-1}Y_+ \\ &= \tfrac{1}{2}\tilde{G}(\mathbf{I} + \Gamma)(Y_- + \tilde{G}^{-1}F) = \tfrac{1}{2}\tilde{G}(\mathbf{I} + \Gamma)\tilde{G}^{-1}F = L.\end{aligned}$$

Conversely, let $Y \in \mathcal{E}_+(\mathbf{T}; L^2(S^2))$ be a solution of (5.2). Clearly $Y_+ = Y$ and $Y_- = \tilde{G}^{-1}(Y - F)$ satisfy (5.1), provided $Y_- \in \mathcal{E}_-(\mathbf{T}; L^2(S^2))$. This follows from

$$(\mathbf{I} + \Gamma)Y_- = (\tilde{G}^{-1} + \Gamma\tilde{G}^{-1})Y - (\mathbf{I} + \Gamma)\tilde{G}^{-1}F = 2\tilde{G}^{-1}L - (\mathbf{I} + \Gamma)\tilde{G}^{-1}F = 0,$$

where we have used (4.2) and (5.3). □

From (4.2) and $\Gamma^2 = \mathbf{I}$ it is immediate that $\tilde{K}^2$ and Γ commute. Hence, $\tilde{K}^2$ maps $\mathcal{E}_+(\mathbf{T}; L^2(S^2))$ into $\mathcal{E}_+(\mathbf{T}; L^2(S^2))$ and $\mathcal{E}_-(\mathbf{T}; L^2(S^2))$ into $\mathcal{E}_-(\mathbf{T}; L^2(S^2))$. Thus, using the compactness of $\tilde{K}^2$, we can decompose the kernel and range of $\mathbf{I} - \tilde{K}^2$ as

$$\operatorname{Ran}(\mathbf{I} - \tilde{K}^2) = \{\operatorname{Ran}(\mathbf{I} - \tilde{K}^2) \cap \mathcal{E}_+(\mathbf{T}; L^2(S^2))\} \oplus \{\operatorname{Ran}(\mathbf{I} - \tilde{K}^2) \cap \mathcal{E}_-(\mathbf{T}; L^2(S^2))\} \tag{5.4}$$

and

$$\operatorname{Ker}(\mathbf{I} - \tilde{K}^2) = \{\operatorname{Ker}(\mathbf{I} - \tilde{K}^2) \cap \mathcal{E}_-(\mathbf{T}; L^2(S^2))\} \oplus \{\operatorname{Ker}(\mathbf{I} - \tilde{K}^2) \cap \mathcal{E}_-(\mathbf{T}; L^2(S^2))\}.$$

PROPOSITION 5.2. *Let $F \in \mathcal{E}(\mathbf{T}; L^2(S^2))$. Then there exists at least one solution of* (5.2) *if and only if there exists at least one solution of the equation*

$$(\mathbf{I} - \tilde{K}^2)Z = (\mathbf{I} + \tilde{K})L. \tag{5.5}$$

Moreover, if it exists, it is possible to choose the solution Z of (5.5) *in $\mathcal{E}_+(\mathbf{T}; L^2(S^2))$, but this solution may not satisfy* (5.2).

Proof. If Y is a solution of (5.2) in $\mathcal{E}(\mathbf{T}; L^2(S^2))$, then clearly it is also a solution of (5.5). To prove the converse, let us first take $\mathcal{E} = L^2$. The solution of (5.5) exists

provided $(\mathbf{I}+\tilde{K})L$ is orthogonal to $\mathrm{Ker}(\mathbf{I}-\tilde{K}^2)$. Let Z_0 be such that $(\mathbf{I}-\tilde{K}^2)Z_0 = 0$. Writing $Z_0 = Z_1+Z_2$ where $\tilde{K}Z_1 = Z_1$ and $\tilde{K}Z_2 = -Z_2$, and using the self-adjointness of $\tilde{K}$, we obtain

$$\langle(\mathbf{I}+\tilde{K})L, Z_2\rangle = \langle L, (\mathbf{I}+\tilde{K})Z_2\rangle = 0$$

and

$$\langle(\mathbf{I}+\tilde{K})L, Z_1\rangle = \langle L, (\mathbf{I}+\tilde{K})Z_1\rangle = 2\langle L, Z_1\rangle.$$

Hence, $(\mathbf{I}+\tilde{K})L$ is orthogonal to $\mathrm{Ker}(\mathbf{I}-\tilde{K}^2)$ if and only if L is orthogonal to $\mathrm{Ker}(\mathbf{I}-\tilde{K})$. Thus, a solution of (5.5) exists if and only if a solution of (5.2) exists.

Furthermore, from (4.2) and (5.3) we obtain

$$(\mathbf{I}+\tilde{K})L = \frac{1}{4}(\mathbf{I}+\Gamma)\tilde{G}(\mathbf{I}+\Gamma)\tilde{G}^{-1}F \in \mathcal{E}_+(\mathbf{T}; L^2(S^2)).$$

Then, since $N := \frac{1}{4}(\mathbf{I}+\Gamma)\tilde{G}(\mathbf{I}+\Gamma)\tilde{G}^{-1}$ has a closed range in each $\mathcal{E}(\mathbf{T}; L^2(S^2))$, the image of $L^2(\mathbf{T}; L^2(S^2))$ under N is the closure in $L^2(\mathbf{T}; L^2(S^2))$ of the image of $\mathcal{E}(\mathbf{T}; L^2(S^2))$ under N. Similarly, the image of $L^2(\mathbf{T}; L^2(S^2))$ under $\mathbf{I}+\tilde{K}$ is the closure in $L^2(\mathbf{T}; L^2(S^2))$ of the image of $\mathcal{E}(\mathbf{T}; L^2(S^2))$ under $\mathbf{I}+\tilde{K}$. Hence, if

$$N[L^2(\mathbf{T}; L^2(S^2))] \subset (\mathbf{I}+\tilde{K})[L^2(\mathbf{T}; L^2(S^2))]$$

as proven above, we also have

$$N[\mathcal{E}(\mathbf{T}; L^2(S^2))] \subset (\mathbf{I}+\tilde{K})[\mathcal{E}(\mathbf{T}; L^2(S^2))]$$

for $\mathcal{E} = L^p$ with $2 < p < \infty$ or $\mathcal{E} = \mathcal{H}_\gamma$ with $0 < \gamma < \mu$. The same conclusion may be drawn if $\mathcal{E} = L^p$ with $1 < p < 2$, but this time we use the fact that $L^2(\mathbf{T}; L^2(S^2))$ is continuously and densely imbedded in $\mathcal{E}(\mathbf{T}; L^2(S^2))$.

Finally, from (5.5) it is seen that a solution of (5.5) exists provided $(\mathbf{I}+\tilde{K})L \in \mathrm{Ran}(\mathbf{I}-\tilde{K}^2)$. Then using (5.4) and the invertibility of $(\mathbf{I}-\tilde{K}^2)$ on $\mathrm{Ran}(\mathbf{I}-\tilde{K}^2)$, it appears the solution of (5.5) can be chosen in $\mathrm{Ran}(\mathbf{I}-\tilde{K}^2)\cap\mathcal{E}_+$. □

The number of linearly independent solutions of the homogeneous Riemann–Hilbert problem

$$Y_+(\xi) = \tilde{G}(\xi)Y_-(\xi), \qquad \xi \in \mathbf{T} \tag{5.6}$$

is the sum of the positive partial indices of $\tilde{G}(\xi)$. Let $\{\rho_j\}$ denote the set of partial indices of $\tilde{G}(\xi)$. These partial indices arise in the Wiener–Hopf factorization of $\tilde{G}(\xi)$ [17].

A special case of Theorem 5.1 with $L = 0$ concludes that any solution Y_+ of (5.6) corresponds to a solution of the homogeneous Fredholm integral equation $(\mathbf{I}-\tilde{K})Y = 0$ in $\mathcal{E}_+(\mathbf{T}; L^2(S^2))$. As a result,

$$\sum_{\rho_j>0} \rho_j = \dim\{\mathrm{Ker}(\mathbf{I}-\tilde{K})\cap\mathcal{E}_+(\mathbf{T}; L^2(S^2))\}. \tag{5.7}$$

To obtain an expression for the sum of the negative indices, we consider the homogeneous Riemann–Hilbert problem which is adjoint to (5.6)

$$Z_+(\xi) = \tilde{G}(\xi)^{-1}Z_-(\xi), \quad \xi \in \mathbf{T} \tag{5.8}$$

where $Z_\pm \in \mathcal{E}_\pm(\mathbf{T}; L^2(S^2))$. Then the number of linearly independent solutions of (5.8) is the sum of the positive partial indices of $\tilde{G}(\xi)^{-1}$. Due to the unitarity of $\tilde{G}(\xi)$,

these indices coincide with the negatives of the negative partial indices of $\tilde{G}(\xi)$ [17]. Using (4.2) and (5.8) we have

$$(\mathbf{I}+\tilde{K})Z_- = (\mathbf{I}+\tfrac{1}{2}\Gamma-\tfrac{1}{2}\tilde{G}\Gamma\tilde{G}^{-1})Z_- = \tfrac{1}{2}(Z_- - \tilde{G}\Gamma Z_+) = 0.$$

Conversely, if $Z_- \in \mathcal{E}_-(\mathbf{T};L^2(S^2))$ and $(\mathbf{I}+\tilde{K})Z_- = 0$, then $\tilde{G}^{-1}Z_- = \tilde{G}^{-1}Z_- - \tilde{G}^{-1}(\mathbf{I}+\tilde{K})Z_- = \tilde{G}^{-1}Z_- - \tfrac{1}{2}\tilde{G}^{-1}(\mathbf{I}+\Gamma)Z_- - \tfrac{1}{2}(\mathbf{I}-\Gamma)\tilde{G}^{-1}Z_- = \tfrac{1}{2}(\mathbf{I}+\Gamma)\tilde{G}^{-1}Z_- \in \mathcal{E}_+(\mathbf{T};L^2(S^2))$. As a result, we find the expression

$$-\sum_{\rho_j<0}\rho_j = \dim\{\mathrm{Ker}(\mathbf{I}+\tilde{K})\cap\mathcal{E}_-(\mathbf{T};L^2(S^2))\}. \tag{5.9}$$

The norm of $\tilde{K}$ in $L^2(\mathbf{T};L^2(S^2))$, i.e., its spectral radius, can be expressed in terms of the gap between certain subspaces [25], [26] For Hilbert spaces the gap between two closed subspaces $\mathcal{M}_1$ and $\mathcal{M}_2$ equals $||P_1-P_2||$ where P_1 and P_2 are the orthogonal projections onto $\mathcal{M}_1$ and $\mathcal{M}_2$, respectively. Now notice that $\Gamma_\pm = \frac{1}{2}(\mathbf{I}\pm\Gamma)$ are the orthogonal projections of $\mathcal{E}(\mathbf{T};L^2(S^2))$ onto $\mathcal{E}_\pm(\mathbf{T};L^2(S^2))$ and $\Lambda_\pm = \frac{1}{2}\tilde{G}(\mathbf{I}\pm\Gamma)\tilde{G}^{-1}$ are the orthogonal projections of $\mathcal{E}(\mathbf{T};L^2(S^2))$ onto $\tilde{G}[\mathcal{E}_\pm(\mathbf{T};L^2(S^2))]$. In terms of these projections, from (4.2) we obtain

$$\tilde{K} = \Gamma_+ - \Lambda_+ \qquad \text{and} \qquad -\tilde{K} = \Gamma_- - \Lambda_-. \tag{5.10}$$

Hence, for $\mathcal{E} = L^2$ we have $||\tilde{K}|| = \mathrm{gap}\left(\mathcal{E}_\pm(\mathbf{T};L^2(S^2)), \tilde{G}[\mathcal{E}_\pm(\mathbf{T};L^2(S^2))]\right)$.

Using the projections $\Gamma_\pm$ and $\Lambda_\pm$, we will now derive more convenient expressions for the sums of the positive and negative partial indices of $\tilde{G}(\xi)$ than (5.7) and (5.9). Observe from (5.10) that

$$\mathbf{I}-\tilde{K} = \Gamma_- + \Lambda_+ \qquad \text{and} \qquad \mathbf{I}+\tilde{K} = \Gamma_+ + \Lambda_-. \tag{5.11}$$

Then we easily find from (5.7)

$$\sum_{\rho_j>0}\rho_j = \dim\{\mathcal{E}_+(\mathbf{T};L^2(S^2))\cap\tilde{G}[\mathcal{E}_-(\mathbf{T};L^2(S^2))]\}, \tag{5.12}$$

while we obtain from (5.9)

$$-\sum_{\rho_j<0}\rho_j = \dim\{\mathcal{E}_-(\mathbf{T};L^2(S^2))\cap\tilde{G}[\mathcal{E}_+(\mathbf{T};L^2(S^2))]\}. \tag{5.13}$$

We can now prove the following.

THEOREM 5.3. *The following statements are equivalent:*

(1) ±1 *are not eigenvalues of the Fredholm integral operator* $\tilde{K}$ *of* (5.2).

(2) *The Riemann–Hilbert problem* (5.1) *has a unique solution* $Y_\pm \in \mathcal{E}_\pm(\mathbf{T};L^2(S^2))$ *for every* $F \in \mathcal{E}(\mathbf{T};L^2(S^2))$.

(3) *There exists a right canonical Wiener–Hopf factorization*

$$\tilde{G}(\xi) = \tilde{G}_+(\xi)\tilde{G}_-(\xi), \qquad \xi\in\mathbf{T},$$

of $\tilde{G}(\xi)$ *where* $\tilde{G}_\pm(\xi)$ *and* $\tilde{G}_\pm(\xi)^{-1}$ *belong to* $\mathcal{H}_\gamma(\mathbf{T};\mathcal{L}(L^2(S^2)))$ *and have an analytic continuation to* $\mathbf{T}^\pm$, *where* γ *is the constant specified in Proposition* 4.1.

(4) *There exists a left canonical Wiener–Hopf factorization*

$$\tilde{G}(\xi) = \tilde{\mathcal{G}}_-(\xi)\tilde{\mathcal{G}}_+(\xi), \quad \xi\in\mathbf{T},$$

of $\tilde{G}(\xi)$ *where* $\tilde{\mathcal{G}}_\pm(\xi)$ *and* $\tilde{\mathcal{G}}_\pm(\xi)^{-1}$ *belong to* $\mathcal{H}_\gamma(\mathbf{T};\mathcal{L}(L^2(S^2)))$ *and have an analytic continuation to* $\mathbf{T}^\pm$.

(5) *The operator function* $\tilde{G}(\xi)$, *or equivalently the operator function* $G(k)$ *given in* (2.7), *has no partial indices* [17].

(6) *The three-dimensional Jost operator* [5] *exists and is unique* [17].

Proof. The equivalence of (2)–(6), as well as the existence of the left and right Wiener–Hopf factorizations of $\tilde{G}(\xi)$, has been proven in [17]. First, let us show that (1) implies (2). Note that from (5.11) we have

$$(\mathbf{I}-\tilde{K})[\mathcal{E}_{\pm}(\mathbf{T};L^2(S^2))]\subset\tilde{G}[\mathcal{E}_{\pm}(\mathbf{T};L^2(S^2))].$$

Since $\mathbf{I}-\tilde{K}$ is boundedly invertible in the absence of eigenvalues ± 1, it must act as a boundedly invertible operator from $\mathcal{E}_{\pm}(\mathbf{T};L^2(S^2))$ onto $\tilde{G}[\mathcal{E}_{\pm}(\mathbf{T};L^2(S^2))]$. As a result, the unique solution of (5.2) with right-hand side (5.3) belongs to $\mathcal{E}_{+}(\mathbf{T};L^2(S^2))$ for every $F\in\mathcal{E}(\mathbf{T};L^2(S^2))$. Then by Theorem 5.1, we can conclude that (1) implies (2).

To complete the proof of our theorem, it suffices to prove that (3) and (4) together imply (1). Indeed, let (3) and (4) be true. The canonical Wiener–Hopf factorization of $\tilde{G}(\xi)$ exists only when all the partial indices are zero. Thus, from (5.11) and (5.12) we obtain

$$\mathcal{E}_{\pm}(\mathbf{T};L^2(S^2))\cap\tilde{G}[\mathcal{E}_{\mp}(L^2(S^2))]=\{0\}. \tag{5.14}$$

Hence, if $Y\in\mathrm{Ker}(\mathbf{I}-\tilde{K})$, then using (5.11) one obtains

$$\Gamma_{-}Y=-\Lambda_{+}Y\in\mathcal{E}_{-}(\mathbf{T};L^2(S^2))\cap\tilde{G}[\mathcal{E}_{+}(\mathbf{T};L^2(S^2))].$$

and hence, by virtue of (5.14),

$$Y\in\mathcal{E}_{+}(\mathbf{T};L^2(S^2))\cap\tilde{G}[\mathcal{E}_{-}(\mathbf{T};L^2(S^2))],$$

which proves that $\mathrm{Ker}(\mathbf{I}-\tilde{K})=\{0\}$. Hence ± 1 are not eigenvalues of $\tilde{K}$, and our proof is complete. □

The following corollary gives a sufficient condition on the scattering operator so that the Fredholm integral equation (3.10) is uniquely solvable.

COROLLARY 5.4. *The Fredholm integral equation* (3.10) *and the Riemann–Hilbert problem* (2.9) *are uniquely solvable when the scattering operator satisfies* $\sup_{k\in\mathbf{R}}||S(k)-\mathbf{I}||<1$.

Proof. From (4.2) we have $\tilde{K}=\frac{1}{2}(\mathbf{I}-\tilde{G})\Gamma-\frac{1}{2}\tilde{G}\Gamma\tilde{G}^{-1}(\mathbf{I}-\tilde{G})$. Since Γ, $\tilde{G}$, and $\tilde{G}^{-1}$ have unit norms, we then obtain $||\tilde{K}||\leq||\mathbf{I}-\tilde{G}||$. However, we have $||\mathbf{I}-\tilde{G}(\xi)||=||\mathbf{I}-G(k)||=||S(k)-\mathbf{I}||$. Thus, if $\sup_{k\in\mathbf{R}}||S(k)-\mathbf{I}||<1$, we have $||\tilde{K}||<1$, and by Theorem 5.3 both the Riemann–Hilbert problem and the Fredholm integral equation are uniquely solvable.

6. Solution of the inverse problem. Once the Riemann–Hilbert problem posed in (2.9) is solved by solving the Fredholm integral equation (3.10), we obtain $f(k,x,\theta)$ given in (3.2) using (3.8) and (2.8). From the Schrödinger equation (1.1) we then obtain the potential as

$$V(x)=\frac{(\Delta+2ik\theta\cdot\nabla)X_{+}(k,x,\theta)}{1+X_{+}(k,x,\theta)}. \tag{6.1}$$

Note that the right-hand side of this equation contains θ and k whereas these two variables are absent from the left-hand side. Hence the solution of the Riemann–Hilbert problem will lead to a potential only if the right-hand side of (6.1) is independent of θ and k. Below we show that if the so-called miracle condition [2] occurs and the Riemann–Hilbert problem has a unique solution, then the right-hand side of (6.1) is

independent of θ and k and becomes equal to a potential function of x. In the absence of bound states the proof has been given in [17], and here we give the proof when the bound states are present.

From (2.10) we have

$$X_+(k) = X_+^{\mathrm{red}}(k) + [\Pi(k) - \mathbf{I}]\hat{1} + [\Pi(k) - \mathbf{I}]X_+^{\mathrm{red}}(k), \tag{6.2}$$

where we have again suppressed the x-dependence of $X_+(k)$, $X_+^{\mathrm{red}}(k)$, and $\Pi(k)$. Defining

$$\eta(\alpha, x, \theta) = \frac{1}{2\pi}\int_{-\infty}^{\infty} dk\, X_+(k)\, e^{-ik\alpha}, \tag{6.3}$$

$$\eta^{\mathrm{red}}(\alpha, x, \theta) = \frac{1}{2\pi}\int_{-\infty}^{\infty} dk\, X_+^{\mathrm{red}}(k)\, e^{-ik\alpha},$$

$$\Omega(\alpha, x, \theta) = \frac{1}{2\pi}\int_{-\infty}^{\infty} dk\, [\Pi(k) - \mathbf{I}]\, e^{-ik\alpha},$$

we can take the Fourier transform of (6.2) to obtain

$$\eta(\alpha, x, \theta) = \eta^{\mathrm{red}}(\alpha, x, \theta) + \Omega(\alpha, x, \theta)\hat{1} + \int_{-\infty}^{\infty} d\beta\, \Omega(\alpha - \beta, x, \theta)\, \eta^{\mathrm{red}}(\beta, x, \theta). \tag{6.4}$$

Note that $X_+(k) = O(\frac{1}{k})$ as $k \to \pm\infty$ and is analytic in $\mathbf{C}^+$; $\Pi(k) - \mathbf{I} = O(\frac{1}{k})$ as $k \to \pm\infty$ and is analytic in $\mathbf{C}^-$. As a result, $\eta^{\mathrm{red}}(\alpha, x, \theta) = 0$ for $\alpha < 0$ and $\Omega(\alpha, x, \theta) = 0$ for $\alpha > 0$. Thus, we can write (6.4) as

$$\eta(\alpha, x, \theta) = \eta^{\mathrm{red}}(\alpha, x, \theta) + \int_{\alpha}^{\infty} d\beta\, \Omega(\alpha - \beta, x, \theta)\, \eta^{\mathrm{red}}(\beta, x, \theta), \qquad \alpha > 0, \tag{6.5}$$

$$\eta(\alpha, x, \theta) = \Omega(\alpha, x, \theta)\hat{1} + \int_{0}^{\infty} d\beta\, \Omega(\alpha - \beta, x, \theta)\eta^{\mathrm{red}}(\beta, x, \theta), \qquad \alpha < 0. \tag{6.6}$$

In the Newton–Marchenko inversion theory [4], the potential $V(x)$ is obtained from (6.5) and (6.6) as

$$\begin{aligned} V(x) &= -2\theta \cdot \nabla \lim_{\alpha \to 0^+} [\eta(\alpha, x, \theta) - \eta(-\alpha, x, \theta)] \\ &= -2\theta \cdot \nabla \lim_{\alpha \to 0^+} [\eta^{\mathrm{red}}(\alpha, x, \theta) - \Omega(\alpha, x, \theta)]\hat{1}, \end{aligned} \tag{6.7}$$

provided the right-hand side is independent of θ; this θ-independence is known as the "miracle" identity of Newton [4]. If the miracle occurs and the Riemann–Hilbert problem (2.9) has a unique solution, $\eta(\alpha, x, \theta)$ satisfies the equation

$$\left[\Delta - 2\frac{\partial}{\partial \alpha}\theta \cdot \nabla - V(x)\right] \eta(\alpha, x, \theta) = 0. \tag{6.8}$$

Then we would like to show that (6.7) and (6.8) imply (6.1). To see this, note that from (6.3) we have

$$ikX_+(k) = \lim_{\alpha \to 0^+} [\eta(-\alpha, x, \theta) - \eta(\alpha, x, \theta)] - \int_{-\infty}^{\infty} d\alpha\, e^{ik\alpha} \frac{\partial \eta(\alpha, x, \theta)}{\partial \alpha}.$$

Thus, using (6.7) and (6.8) we obtain

$$[\Delta + 2ik\theta \cdot \nabla - V(x)]X_+(k) = V(x) + \int_{-\infty}^{\infty} d\alpha\, e^{ik\alpha} \left[\Delta - 2\frac{\partial}{\partial \alpha}\theta \cdot \nabla - V(x)\right] \eta(\alpha, x, \theta).$$

From this last equation, it is seen that (6.1) is implied by (6.7) and (6.8); hence, whenever the miracle condition of Newton is satisfied and the Riemann–Hilbert problem has a unique solution, the potential of the Schrödinger equation is given by (6.1).

Remark that whenever the scattering operator $S(k)$ is known to have a corresponding potential, it is guaranteed that the right-hand side of (6.1) is independent of k and θ. As a consequence, any of the statements in Theorem 5.3 is sufficient to guarantee that the right-hand side of (6.1) is independent of k and θ.

7. Concluding remarks. The results of this article remain true for any real measurable potential $V(x)$ on $\mathbf{R}^3$ without real exceptional points that leads to a scattering matrix $S(k)$ such that $S(k) - \mathbf{I}$ is compact for all $k \in \mathbf{R}$ and $\tilde{S}(\xi) = S(i(1+\xi)/(1-\xi))$ is Hölder continuous in ξ on $\mathbf{T}$. In that case we may generalize our results here to potentials on $\mathbf{R}^n$ with $n \geq 2$.

Acknowledgments. The authors are indebted to Roger Newton for his comments.

THE INVERSE EIGENVALUE PROBLEM WITH FINITE DATA*

DAVID C. BARNES†

Abstract. This work is concerned with the inverse eigenvalue problem for ordinary differential equations such as $y'' + (\lambda - q(x))y = 0$ and with some higher-order generalizations. A classical, well-known inverse problem is to reconstruct the coefficient function $q(x)$ in the differential equation using only spectral data, say $\lambda_n(q)$. Most treatments of this subject require an infinite amount of data which, of course, requires asymptotic formulae for the eigenvalues. Unfortunately, such formulae are sometimes very difficult or impossible to obtain. This work considers a different kind of inverse problem which ignores asymptotic formulae and uses only a *fixed and finite* amount of spectral data. The central problem considered in this paper is that of extracting from the finite amount of spectral data as much information as possible about the coefficient function $q(x)$.

It turns out that to understand such problems, it is necessary to examine the topological foundations of the continuity properties of the eigenvalues. This is done in §1. Based on these continuity theorems, a general theorem is given proving the convergence of some numerical approximations to the solution of the finite inverse problem.

In §2 a numerical algorithm for approximating a coefficient function using only a finite amount of spectral data is given. The method works by minimizing the l_2 norm of the difference between the eigenvalues $\lambda_i(q)$, $i = 1, 2, 3, \cdots, N$ and the spectral data.

Key words. inverse problem, eigenvalue problem, continuous dependence

1. Formulation of the finite inverse problem.

1.1. Introduction.

Consider the eigenvalue problem

$$y'' + (\lambda - q(x))y = 0, \qquad \begin{aligned} a_1y(0) + a_2y'(0) + a_3y(1) + a_4y'(1) &= 0, \\ b_1y(0) + b_2y'(0) + b_3y(1) + b_4y'(1) &= 0. \end{aligned} \tag{1}$$

We suppose that this is a self-adjoint problem and we denote the eigenvalues of (1) by $\lambda_n(q)$. Let $q^*(x)$ represent the unknown coefficient function and suppose spectral data $\boldsymbol{\lambda} = (\Lambda_1, \Lambda_2, \cdots)$ are given so that $\lambda_n(q^*) = \Lambda_n$.

There are (at least) two inverse problems which could be considered for this equation. The first, we call the *infinite inverse problem*; it consists of determining the function $q(x)$ given either an infinite amount of spectral data $\lambda_n(q)$, $n = 1, 2, \cdots \infty$, or at least enough data together with an asymptotic formula which may be used to approximate an infinite amount of data.

Various works have considered the problem of reconstructing $q(x)$ in such cases. The review article by McLaughlin [7] and the references given there provide many examples of such inverse problems. For example, Hald [4] has shown that if two functions q and q^* are close enough together and if both q and q^* are symmetric, $q(x) = q(1 - x)$, then

$$\|q - q^*\|_\infty \leq 2 \cdot 10^{8+38M+11M^2} \sum_{k=0}^{\infty} |\lambda_k - \lambda_k^*|. \tag{2}$$

Therefore, if the eigenvalues $\lambda_n(q)$ are close enough to those of q^* then the functions q and q^* are close in the $\|\cdot\|_\infty$ norm. This shows that (for symmetric functions) the information contained in an infinite amount of spectral data does, in fact, contain a uniform approximation to the unknown function $q^*(x)$. We will see that the situation is very different for the finite inverse problem. Although (2) is an interesting result, it is not useful for actual numerical estimates since for even small values of M (say $M \approx 1$) the constant in (2) is of order 10^{57}.

Another result of this type does not require the symmetry condition on $q(x)$ but uses the norming constants for (1) which are defined by $\rho_n(q) = \|y_n\|_2^2/y'_n(0)$. If q is close enough to q^*, then McLaughlin [8] has shown

$$\int_0^1 (q(x) - q^*(x))^2\,dx \le K \sum_{n=1}^{\infty} [(\lambda_n(q) - \lambda_n(q^*)]^2 + n^6\,[\rho_n(q) - \rho_n(q^*)]^2\,.$$

This result shows that, even without the symmetry condition on $q(x)$, an infinite amount of spectral data together with all of the norming constants still contains enough information to reconstruct an L_2 approximation to $q^*(x)$. The result of Sacks [10], which proves the L_2 convergence of certain numerical approximations to $q^*(x)$, is also of this general type.

These results can only be used if we have an infinite amount of data or, at least, an asymptotic formula and a sufficient amount of spectral data to make good approximations to the infinite data. In some cases, neither is available. This leads us to consider a second kind of inverse problem which we call the *finite inverse problem.* Here, we assume that only a finite amount of data has been collected and that asymptotic formulae are not available. Clearly, such an inverse problem cannot be solved uniquely since the set of all coefficient functions $q(x)$ is infinite-dimensional, whereas the set of vectors $\boldsymbol{\Lambda} = (\Lambda_1, \Lambda_2, \cdots, \Lambda_N)$ is finite dimensional. Therefore, we understand that to solve such a finite inverse problem simply means that we must produce a function $q(x)$ which has the correct spectral behavior. That is, $\lambda_n(q) = \lambda_n(q^*)$ for $n = 1, 2, 3, \cdots, N$. We must then provide a proper mathematical foundation and interpretation of the results. In particular, we need to know if this process produces an approximation to $q^*(x)$ in some suitable topology. If it does, we need to know something about the topology used and how accurate the approximation is. Theorem 1.2 provides a partial answer to this need. It shows that under certain conditions, as $N \to \infty$, the approximating function $q(x)$ converges to $q^*(x)$ in a certain topology. In addition, Theorem 1.1 indicates what kind of variation in the solution of such an inverse problem is still possible even after all of the requirements of a finite amount of spectral data have been satisfied. These results provide a proper mathematical foundation for the finite inverse problem.

Seidman [11] has studied a similar kind of finite inverse problem. He showed that if a sequence q_N satisfies $\lambda_n(q_k) = \Lambda_k$ for $k = 1, 2, 3, \cdots, N$ and if a certain norm $\|q_N\|_*$ is minimized over some class of functions, then $q_N \to q^*$ in a certain topology on the class of functions. This is analogous to the classical spline interpolation problem for real functions. Theorem 1.2 is also of this type. However, using the compactness of the class $\mathcal{C}(H)$ gives a much easier proof and it does not require the minimizing of a norm to achieve convergence of the interpolating sequence. Of course, such a minimizing condition could be tacked on to Theorem 1.2 if desired. We will also show that the topology used is stronger than that used in [11] so that Theorem 1.2 gives a better approximation to $q^*(x)$.

One of the tools we will need is the following variational characterization of the

eigenvalues using the Rayleigh quotient [3], [12]. Let $\mathcal{L}$ be a self-adjoint operator defined on a dense subspace $\mathbf{D}$ of a separable Hilbert space. Suppose that the lower part of the spectrum of $\mathcal{L}$ consists of isolated eigenvalues $\lambda_1 \leq \lambda_2 \leq \lambda_3 \leq \cdots$, each having finite multiplicity. Let y_i denote the eigenfunction corresponding to λ_i and let $\mathcal{U}_n$ be the subspace spanned by the first n eigenfunctions $y_1, y_2, \cdots, y_n$. Let $\mathcal{V}_n$ be any other n-dimensional subspace of $\mathbf{D}$. It follows that

$$\lambda_n \leq \max_{u \in \mathcal{V}_n} \frac{(\mathcal{L}u, u)}{(u, u)} \quad \text{and} \quad \lambda_n = \max_{u \in \mathcal{U}_n} \frac{(\mathcal{L}u, u)}{(u, u)}. \tag{3}$$

1.2. The topology of the finite inverse eigenvalue problem. A crucial part of the theory of the finite inverse problem is concerned with a norm $\|\cdot\|_{2L_1}$ which we define by

$$\|q\|_{2L_1} = \left|\int_0^1 q(x)\,dx\right| + \left|\int_0^1\int_0^x q(x_1)\,dx_1\,dx\right| + \int_0^1 \left|\int_0^x\int_0^{x_2} q(x_1)\,dx_1\,dx_2\right| dx. \tag{4}$$

The link between the $2L_1$ norm and eigenvalue problems is provided by the following theorem.

THEOREM 1.1. *Let $\lambda_n(q)$ denote the nth eigenvalue of* (1). *There is a constant $K_n(H)$ (which depends only on n and H) such that for any $q_1, q_2 \in C(H)$ we have*

$$|\lambda_n(q_1) - \lambda_n(q_2)| \leq K_n(H)\,\|q_1(s) - q_2(s)\|_{2L_1}. \tag{5}$$

We will give the proof in §1.3 below. From this, it follows that small changes in the $2L_1$ norm will produce small changes in the eigenvalues. However, it is vital to notice that the modulus of continuity depends on n. Roughly speaking then, the only information about q which can be extracted numerically from a finite number of eigenvalues is an L_1 approximation to the expression $\int_0^x \int_0^t q(s)ds\,dt$. Thus any numerical method that attempts to reconstruct, as its final product, a pointwise approximation to $q(x)$ using a fixed amount of spectral data will, implicitly, hinge on taking two derivatives of an L_1 approximation to $\int_0^x \int_0^t q(s)\,ds\,dt$. This stands in sharp contrast to the results dealing with the L_2 norm (and even the L_∞ norm) quoted above, which use an infinite amount of data.

To see how very different all of these norms really are and just how sharp this contrast is, consider a perturbation in $q^*(x)$ of the form $\Delta q(x) = A\cos Bx$ so that $q(x) = q^*(x) + \Delta q^*(x)$. A simple calculation shows, for large A and B, that $\|\Delta q^*(x)\|_{2l_1} = O(A/B^2)$. Thus, even if A is quite large, the size of the perturbation $A\cos Bx$ will be very small in the $2L_1$ norm if only B is also large. This is somewhat like the Riemann-Lebesgue lemma, in that, if the positive and negative oscillations tend to balance out, then the overall effect will be small. On the other hand, if A is large, then $\Delta q^*(x)$ will be large in the L_2 (or especially the L_∞) norms no matter what B is. Unfortunately, any candidate for $q^*(x)$ (perhaps obtained using some numerical approximation method) could be perturbed in this way and it would still be a good solution to the finite inverse problem. The penalty for dealing with only a finite amount of data and ignoring the infinite amount of high frequency spectral data is that we must put up with such high frequency noise in the determination of $q^*(x)$.

We will show later that, depending on how smooth q is, the eigenvalues may even be continuous in topologies much weaker than that defined by the $2L_1$ norm. Thus we may actually know even less about $q^*(x)$ than a $2L_1$ approximation. Of course, we should use the weakest topology in which all the eigenvalues are continuous since,

otherwise, we would be attempting to extract more information from the spectral data than it contains. This may very well result in ill-conditioned numerical procedures. However, this weak topology seems to be very difficult to determine exactly. In this work, we give some approximations to it.

Next, we will present a general convergence theorem which applies to the numerical solution of both the finite and infinite inverse eigenvalue problems. We first discuss the infinite inverse problem. Given a constant H, let $\mathcal{C}(H)$ be the set of all functions $q(x)$ which satisfy $|q(x)| \leq H$ and let $\mathcal{S}$ be the set of all infinite sequences $(\lambda_1, \lambda_2, \lambda_3, \cdots)$ of numbers. Define a mapping

$$\Phi : \mathcal{C}(H) \to \mathcal{S} \quad \text{by } \Phi(q) = (\lambda_1(q), \lambda_2(q), \lambda_3(q), \cdots),$$

and use the brief notation $\boldsymbol{\lambda}(q) = (\lambda_1(q), \lambda_2(q), \lambda_3(q), \cdots)$. Let $\mathcal{S}(H) \subset \mathcal{S}$ be the range of Φ. Define a topology on $\mathcal{S}(H)$ using the component-wise convergence criteria $\boldsymbol{\lambda}(q_j) \to \boldsymbol{\lambda}(q^*)$ if and only if, for each n, $\lambda_n(q_j) \to \lambda_n(q^*)$ as $j \to \infty$. We now topologize $\mathcal{C}(H)$ using the weakest topology in which all the eigenvalues are continuous. This simply means that $q_j \to q^*$ as $j \to \infty$ if and only if $\lambda_n(q_j) \to \lambda_n(q^*)$ for each n.

We say that a sequence q_N interpolates to the spectral data $\lambda_n(q^*)$ if, for each N, there is an ϵ_N such that

$$|\lambda_i(q_N) - \lambda_i(q^*)| < \epsilon_N \quad \text{for } i = 1, 2, \cdots, N \quad \text{and} \quad \epsilon_N \to 0 \quad \text{as } N \to \infty.$$

The theorem uses the $1Max$ norm which is defined by

$$\|q\|_{1Max} = \max_x \left| \int_0^x q(t)\, dt \right|. \tag{6}$$

THEOREM 1.2. *Given an eigenvalue problem and some spectral data $\lambda_n(q^*)$, suppose that the inverse eigenvalue problem has a unique solution. That is, given any two coefficient functions q_1 and q_2, if $\lambda_n(q_1) = \lambda_n(q_2)$ for all of the data then it follows that $q_1 = q_2$. Let q_N be any sequence of functions which interpolates to the data $\lambda_n(q^*)$. Then*

$$\|q_N - q^*\|_{1Max} \to 0 \quad \text{as } N \to \infty.$$

Furthermore, the range space $\mathcal{S}(H)$ is compact in the topology of component-wise convergence.

Proof. Consider the set of all functions $Q(x) = \int_0^x q(t)\, dt$ for $q \in \mathcal{C}(H)$. Such functions $Q(x)$ will satisfy the Lipschitz condition $|Q(x) - Q(y)| \leq H|x - y|$. Applying the Ascoli theorem shows that the space $\mathcal{C}(H)$ is compact in the $1Max$ norm. We will show below that the eigenvalues are continuous functionals in the $1Max$ norm. Let q_{N_k} denote a convergent subsequence, say $q_{N_k} \to \widehat{q}$. Then, if $N_k \geq n$, it follows that $|\lambda_n(q_{N_k}) - \lambda_n(q^*)| < \epsilon_{N_k}$. Letting $k \to \infty$ gives $\lambda_n(\widehat{q}) = \lambda_n(q^*)$. Uniqueness implies that $q^* = \widehat{q}$, so every convergent subsequence converges to q^*. Thus the original sequence q_N must converge to q^*.

We will now show that $\mathcal{S}(H)$ is compact. Unique solvability of the inverse problem implies that the mapping Φ has an inverse—say $\Psi : \mathcal{S}(H) \to \mathcal{C}(H)$. Since Φ and Ψ are one-to-one, the weak topology induced on $\mathcal{C}(H)$ by Φ and the strong topology induced on $\mathcal{C}(H)$ by Ψ are the same and both Φ and Ψ are homeomorphisms [2]. Since $\mathcal{C}(H)$ is compact in the $1Max$ topology, which is stronger than the weak topology, it follows that $\mathcal{C}(H)$ is compact in the weak topology. Thus $\mathcal{S}(H)$ is also compact. □

The theorem shows that an interpolating sequence converges. In fact, it shows that an infinite amount of spectral data contains a uniform approximation to $\int_0^x q^*(t)\,dt$ having arbitrarily high accuracy, however, the results [8], [4] show that such data actually contains much more than this. Our previous remarks regarding the information content of a finite amount of spectral data are, of course, still valid, since this theorem may require an arbitrarily large amount of data to produce such an approximation to $\int_0^x q(t)\,dt$. Even with such a large amount of data, this uniform approximation must still be differentiated in order to construct a pointwise approximation to $q(x)$.

Consider again the perturbation $\Delta q^*(x) = A\cos Bx$. It is easy to see that by choosing appropriate constants A and B, an example can be constructed which is small in the $2L_1$ norm but is not small in the $1Max$ norm. Even after the spectral data has been satisfied, a good $1Max$ approximation to $q^*(x)$ may not be obtained. However, Theorem 1.2 provides a (perhaps rough) $1Max$ approximation to q^* while Theorem 1.1 shows how much variability is still left in the unknown function $q^*(x)$ after using a finite amount of the data. In this sense, we have upper and lower bounds on the information content of the spectral data. Some of these compactness and continuity ideas have been used by Krein [5] to prove the existence of certain functions which maximize an eigenvalue.

We will now consider the finite inverse problem. Since the solution of this inverse problem is not unique, we must consider the isospectral equivalence classes on $\mathcal{C}(H)$. Call this set of classes $\mathcal{C}_N(H)$. Theorem 1.2 shows that if the infinite inverse problem has a unique solution then the diameter (as measured in the $1Max$ norm) of each equivalence class tends to zero as $N\to\infty$. Now $\mathcal{C}_N(H)$ inherits a natural topology from $\mathcal{C}(H)$, and there are natural extensions of Φ and Ψ to this context. These extensions will be both continuous and one-to-one. Thus, $\mathcal{C}_N(H)$ is homeomorphic to a subset of ordinary N-dimensional Euclidian space. This determines the weakest topology on $\mathcal{C}_N(H)$ in which the eigenvalues are continuous. Unfortunately, knowing the topology on $\mathcal{C}_N(H)$ still does not easily translate into usable conditions on the coefficient functions q which, of course, belong to $\mathcal{C}(H)$, not to $\mathcal{C}_N(H)$. The following section considers this very difficult problem.

1.3. Approximating the weak topology. We are now interested in extracting from the spectral data whatever information it contains about $q^*(x)$. Theorem 1.2 may provide only a rough approximation to $\int_0^x q(t)\,dt$ since we may not have the data to take N large enough. It would be best, of course, if we could completely characterize the weak topology on $\mathcal{C}(H)$ in terms of conditions on the functions $q(x)$. This seems to be very difficult to do, but we will give some partial answers. First, we will give the proof of Theorem 1.1.

Proof. Let $\mathcal{U}_n(q)$ denote the space spanned by the first n-eigenfunctions of (1) and use the notation $\Delta q(x) = q_1(x) - q_2(x)$, $\Delta\lambda_n = \lambda_n(q_1) - \lambda_n(q_2)$. Integrating by parts, we see that

$$\begin{aligned}\int_0^1 \Delta q(x)y^2(x)\,dx = y^2(1)\int_0^1 \Delta q(x_1)\,dx_1 \\ -y^{2\prime}(1)\int_0^1\int_0^{x_2} \Delta q(x_1)\,dx_1\,dx_2 \\ +\int_0^1 \left(y^2(x)\right)''\int_0^x\int_0^{x_2} \Delta q(x_1)\,dx_1\,dx_2\,dx.\end{aligned}$$

We will show below that there is a constant $K_n(H)$ such that for all $x \in [0,1]$, for all functions $q \in \mathcal{C}(H)$, and for all functions $y \in \mathcal{U}_n(q)$, it follows that y^2, y'^2, and y''^2 are uniformly[1] bounded by some term of the form $K_n(H)\int_0^1 y^2\,dx$. Substituting these bounds into the integration by parts formula and using (3) to compute the Rayleigh quotient for (1), we find that

$$\frac{-yy'\Big|_{x=0}^{x=1} + \int_0^1 y'^2 - q_2(x)y^2\,dx}{\int_0^1 y^2\,dx} \le \frac{-yy'\Big|_{x=0}^{x=1} + \int_0^1 y'^2 - q_1(x)y^2\,dx}{\int_0^1 y^2\,dx} + K_n(H)\,\|\Delta q\|_{2L_1}.$$

Next, take the maximum over all functions $y \in \mathcal{U}_n(q_1)$ and use the inequality (3). We find that $\lambda_n(q_2) \le \lambda_n(q_1) + K_n(H)\,\|\Delta q\|_{2L_1}$. This inequality, together with the one obtained by reversing the roles of q_1 and q_2, gives (5).

We need to prove the uniform boundedness property of y, y', and y'' for all $y \in \mathcal{U}_n(q)$. Let y_n be an eigenfunction of (1) and suppose that $(y,y) = (y_n,y_n) = 1$. We see that

$$(7) \qquad |y_n'(x)| = \left|y_n'(\xi) + \int_\xi^x y_n''(s)\,ds\right| \le |y_n'(\xi)| + \int_0^1 |(\lambda - q(s))y_n(s)|\,ds.$$

If y_n is not a monotone function, then we will select ξ to be some point for which $y_n'(\xi) = 0$. Otherwise, we may assume that y_n is an increasing function and there is a number m for which $y'(x) \ge m > 0$. It follows that there is some number c for which $y^2(x) \ge m^2(x-c)^2$. Thus, $1 = \int_0^1 y_n^2\,dx \ge \int_0^1 m^2(x-\frac{1}{2})^2\,dx = m^2/12$ with equality when $y_n = m(x-\frac{1}{2})$. Therefore, we must have $m < 4$. In this event, we select ξ to be some point for which $y_n'(\xi) < 4$. In either case, we obtain $|y_n'(x)| \le 4 + \int_0^1 |(\lambda - q(x))y_n(s)|\,ds$. Since $|q(x)| \le H$, it follows that $\lambda_n(q)$ is uniformly bounded, so the Schwarz inequality shows that $|y_n'(x)|$ is uniformly bounded. Thus, $|y_n|$ is uniformly bounded and (1) shows that y_n'' is also uniformly bounded. Since y is normalized and is a linear combination of the functions y_n, the theorem follows. □

It is well known (see [7] and the references given there) that two different sets of eigenvalues corresponding to different boundary conditions are sufficient to determine $q^*(x)$ uniquely. Furthermore, the results of McLaughlin and Rundell [9] show that if a fixed eigenvalue—say $\lambda_2(q^*)$—is known for an infinite number of distinct boundary conditions of the form $y(0) = y'(1) + \beta y(1) = 0$, then the function $q^*(x)$ is uniquely determined. However, the constant $K_n(H)$ of Theorem 1.1 is independent of the boundary conditions. It follows that no finite amount of spectral data corresponding to any number of different boundary conditions can reproduce an accurate pointwise approximation to the coefficient function $q(x)$. At most, the only information contained in such data is an L_1 approximation to $\int_0^x \int_0^s q(t)\,dt\,ds$ together with approximations of the two quantities $\int_0^1 q(x)\,dx$ and $\int_0^1 \int_0^x q(s)\,ds\,dx$.

Incidentally, it is easy to see that approximating these two quantities is equivalent to approximating the two Hausdorff moments $\int_0^1 q(x)\,dx$ and $\int_0^1 xq(x)\,dx$. That is, the norm

$$(8) \qquad \|q\|_{2H_1} = \left|\int_0^1 q(x)\,dx\right| + \left|\int_0^1 xq(x)\,dx\right| + \int_0^1 \left|\int_0^x \int_0^{x_2} q(x_1)\,dx_1\,dx_2\right| dx$$

[1] Throughout this work, "uniformly" refers to a property which holds for all functions $q \in \mathcal{C}(H)$ and for all of the functions $y \in \mathcal{U}_n(q)$, not just uniformly for $x \in [0,1]$.

is topologically equivalent to the norm $\|q\|_{2L_1}$. Furthermore, if boundary conditions for which either y or y' vanish at the endpoints are used, then the boundary terms in the integration by parts formula drop out. Thus, the first two terms in the $2L_1$ norm may be negelected and the much simpler norm

$$\|q\|^*_{2L_1} = \int_0^1 \left| \int_0^x \int_0^{x_2} q(x_1)\, dx_1\, dx_2 \right| dx$$

may be used.

Next, suppose that the coefficient functions q are all of uniformly bounded variation. This is only a slightly stronger assumption and still includes most of the applications of the inverse problem. It follows that y_n'' will also be of bounded variation and that we may now integrate by parts a third time to obtain

$$\begin{aligned}\int_0^1 \Delta q(x) y^2(x)\, dx = {} & y^2(1) \int_0^1 \Delta q(x_1)\, dx_1 - y^{2\prime}(1) \int_0^1 \int_0^{x_2} \Delta q(x_1)\, dx_1\, dx_2 \\ & + y^{2\prime\prime}(1) \int_0^1 \int_0^{x_3} \int_0^{x_2} \Delta q(x_1)\, dx_1\, dx_2\, dx_3 \\ & - \int_0^1 \int_0^x \int_0^{x_3} \int_0^{x_2} \Delta q(x_1)\, dx_1\, dx_2\, dx_3\, d(y^{2\prime\prime}).\end{aligned}$$

We will now use the norm defined by

$$\|q\|_{3Max} = \left| \int_0^1 q(x)\, dx \right| + \left| \int_0^1 \int_0^x q(x_1)\, dx_1\, dx \right| + \max_x \left| \int_0^x \int_0^{x_3} \int_0^{x_2} \Delta q(x_1)\, dx_1\, dx_2\, dx_3 \right|.$$

Note that $\|q\|_{3Max} \le \|q\|_{2L_1}$. It is then easy to prove the following theorem.

THEOREM 1.3. *Let V be a constant and let $\mathcal{C}(H, V)$ denote the class of functions $q \in \mathcal{C}(H)$ which have total variation at most V. Then there is a constant $K_n(H, V)$ such that, for any $q_1,\ q_2 \in \mathcal{C}(H, V)$, it follows that*

$$|\lambda_n(q_1) - \lambda_n(q_2)| \le K_n(H, V) \|q_1 - q_2\|_{3Max}. \tag{9}$$

Thus, we see that a finite amount of spectral data can yield, at most, an approximation to the first two Hausdorff moments and a uniform approximation to the quantity $\int_0^x \int_0^s \int_0^t q(z)\, dz\, dt\, ds$. Generating a pointwise approximation to $q(x)$ requires taking three derivatives of this uniform approximation.

If we use the subset of $\mathcal{C}(H)$ consisting of coefficient functions q which have bounded derivatives—say $|q'(x)| \le H_1$—then we can prove that

$$|\lambda_n(q_1) - \lambda_n(q_2)| \le K_n(H, H_1, V) \|q_1 - q_2\|_{3L_1}$$

where

$$\begin{aligned}\|q\|_{3L_1} = {} & \left| \int_0^1 q(x)\, dx \right| + \left| \int_0^1 \int_0^{x_2} q(x_1)\, dx_1\, dx_2 \right| \\ & + \left| \int_0^1 \int_0^{x_3} \int_0^{x_2} q(x_1)\, dx_1\, dx_2\, dx_3 \right| + \int_0^1 \left| \int_0^{x_4} \int_0^{x_3} \int_0^{x_2} q(x_1)\, dx_1\, dx_2\, dx_3 \right| dx_4.\end{aligned}$$

Generating a pointwise approximation to $q(x)$ requires taking three derivatives of an L_1 approximation to $\int_0^x \int_0^s \int_0^t q(z)\, dz\, dt\, ds$. Thus, we see a hierarchy of continuity conditions building. As q becomes smoother, we can build weaker topologies. We will investigate this idea further.

1.4. Some connections with weak convergence and other topologies. Define a norm similar to (4) but using only one integration by parts,

$$\|q\|_{1L_1} = \left|\int_0^1 q(x)\,dx\right| + \int_0^1 \left|\int_0^x q(x_1)\,dx_1\right| dx.$$

It is easy to show that $\|q\|_{2L_1} \le 2\|q\|_{1L_1}$. Thus, the norm $\|q\|_{2L_1}$ is weaker than $\|q\|_{1L_1}$. More generally, if the coefficient functions have $N-2$ uniformly bounded derivatives, then we can integrate by parts N times. Considering an appropriate norm $\|q\|_{(N+2)L_1}$ will then give continuity of the eigenvalues in a whole sequence of weaker topologies. If q is analytic, the process can be continued forever to give an infinite sequence of ever weaker topologies.

The norms used in these continuity results can be related to the concept of weak convergence using some fundamental facts of measure theory. For example, the following theorem holds.

THEOREM 1.4. *Let q, $q_n \in \mathcal{C}(H)$. The sequence $\int_0^x q_n(t)\,dt$ converges pointwise to the function $\int_0^x q(t)\,dt$ if and only if $(q_n, g)\to(q, g)$ for all functions $g \in L_2[0,1]$.*

The proof of this theorem hinges on taking $g(x)$ to be the characteristic function of the interval $[0, x]$. Therefore, the topology of weak convergence of $q_n(x)$ fits between the topologies defined by the two norms $\int_0^1 |\int_0^x q(t)\,dt|\,dx$ and $\max_x |\int_0^x q(t)\,dt|$.

Construct a topology τ on $\mathcal{C}(H)$ so that convergence of the sequence $q_n(x)\to q(x)$ means that $(q_n, G)\to(q, G)$ for every function G which satisfies $\int_0^1 G^2 + G'^2\,dx < \infty$. One of Seidman's [11] results is that the eigenvalues are continuous in the topology τ. We will now show that the $2L_1$ norm defines a topology weaker than τ and that the $1Max$ norm is stronger that τ.

Let $g \in L_2[0,1]$ and set $G(x) = \int_x^1 g(t)\,dt$. We see that $(q_n, G) = (\int_0^x q_n(t)\,dt, g)$. Thus, if $q_n\to q$ in the topology τ, then $\int_0^x q_n(t)\,dt$ converges weakly to $\int_0^x q(t)\,dt$. By Theorem 1.4, $\int_0^x \int_0^{x_1} q_n(t)\,dt\,dx_1$ converges pointwise to $\int_0^x \int_0^{x_1} q(t)\,dt\,dx_1$. Pointwise convergence implies L_1 convergence in $\mathcal{C}(H)$. Thus convergence in τ implies convergence in the norm $\int_0^1 |\int_0^x \int_0^{x_1} q_n(t)\,dt\,dx_1|\,dx$. Furthermore, we may take $G = 1$ and $G = x$ to show that

$$\int_0^1 q_n(x)\,dx \to \int_0^1 q(x)\,dx \quad \text{and} \quad \int_0^1\int_0^{x_2} q_n(x_1)dx_1\,dx_2 \to \int_0^1\int_0^{x_2} q(x_1)dx_1\,dx_2.$$

We now make use of (8) to finish the proof. Thus, Theorem 1.1 shows continuity of the eigenvalues in a topology weaker than τ. Theorem 1.4 can be easily adapted to show that $1Max$ is stronger than τ.

1.5. More general second-order equations. We may also apply these methods to the self-adjoint equation

$$y'' + \lambda p(x) y = 0, \qquad \begin{aligned} &a_1 y(0) + a_2 y'(0) + a_3 y(1) + a_4 y'(1) = 0,\\ &b_1 y(0) + b_2 y'(0) + b_3 y(1) + b_4 y'(1) = 0. \end{aligned} \tag{10}$$

We will need to use a slightly different class of coefficient functions $p(x)$ that are defined by

$$\mathcal{C}(H_1, H_2) = \{p(x) \mid H_1 \le p(x) \le H_2\} \qquad \text{where } H_1 > 0.$$

We have the following theorem.

THEOREM 1.5. *Let $\lambda_n(p)$ denote the nth eigenvalue of* (10). *There is a constant $K_n(H)$ which depends only on n, H_1, and H_2 such that for any $p_1, p_2 \in \mathcal{C}(H_1, H_2)$ we have*

$$|\lambda_n(p_1) - \lambda_n(p_2)| \leq K_n(H)\, \|p_1(s) - p_2(s)\|_{2L_1} \ . \tag{11}$$

Proof. First, we consider the Rayleigh quotient, $\mathcal{Q}(p, y) = (Ay, y)/(y, y)$, for (10). A short calculation yields

$$\mathcal{Q}(p, y) = \frac{\displaystyle\int_0^1 y'^2\, dx - yy'\Big|_{x=0}^{x=1}}{\displaystyle\int_0^1 p(x) y^2\, dx}.$$

A further calculation yields

$$\mathcal{Q}(p_1, y) = \mathcal{Q}(p_2, y) \left[1 + \frac{\displaystyle\int_0^1 \Delta p(x) y^2\, dx}{\displaystyle\int_0^1 p_1(x) y^2\, dx} \right] \qquad \text{where } \Delta p(x) = p_2(x) - p_1(x).$$

Next we develop an inequality for $\Delta p(x)$ just like we did for $\Delta q(x)$ in §1.3. It follows that there exists a constant A such that, uniformly for all functions $y \in \mathcal{U}_n$,

$$\int_0^1 \Delta p(x) y^2\, dx \leq A \|\Delta p(x)\|_{2L_1} \int_0^1 y^2\, dx.$$

Using this and the relation $p_1(x) \geq H_1$, we see that

$$\mathcal{Q}(p_1, y) \leq \mathcal{Q}(p_2, y) \left[1 + \frac{A}{H_1} \|\Delta p(x)\|_{2L_1} \right].$$

Applying the variational relation (3), we find that

$$\lambda_n(p_1) \leq \lambda_n(p_2) \left[1 + \frac{A}{H_1} \|\Delta p(x)\|_{2L_1} \right].$$

This result together with the one obtained by reversing the roles of p_2 and p_1 can be easily manipulated to finish the proof. □

Next, we will apply these methods to the equation

$$(r(x)y')' + \lambda y = 0, \qquad \begin{aligned} &a_1 y(0) + a_2 r(0) y'(0) + a_3 y(1) + a_4 r(1) y'(1) = 0, \\ &b_1 y(0) + b_2 r(0) y'(0) + b_3 y(1) + b_4 r(1) y'(1) = 0. \end{aligned} \tag{12}$$

We assume that this is a self-adjoint system. Integration by parts may be used on the expression $\int_0^1 y^2 \Delta r(x)\, dx$ just as in Theorem 1.2. In this case, y will be continuous but y' will have discontinuities if r does. We must also take account of the values of r at the endpoints since they occur in the boundary conditions. Given constants H, h, V, A, B, let $\mathcal{R}$ be the class of functions $r(x)$ which satisfy the following conditions:

1. $H \geq r(x) \geq h > 0$.
2. $r(x)$ has total variation at most V.
3. $r(x)$ has given values at the endpoints, $\lim_{x \downarrow 0} r(x) = A$, $\lim_{x \uparrow 1} r(x) = B$.

Using the $1Max$ norm we obtain the following theorem.

THEOREM 1.6. *Let $\lambda_n(r)$ denote the nth eigenvalue of* (12). *There is a constant $K = K_n(H, V, h)$ such that for any r_1, $r_2 \in \mathcal{R}(H, h, V)$, it follows that*

$$|\lambda_n(r_1) - \lambda_n(r_2)| \leq K\|r_1 - r_2\|_{1Max}. \tag{13}$$

Proof. Let y_n be the nth eigenfunction of (12). For any x, $\xi \in [0,1]$ we see that

$$r(x)y_n'(x) = r(\xi)y_n'(\xi) + \int_\xi^x (r(s)y_n'(s))'\,ds = r(\xi)y_n'(\xi) - \int_\xi^x \lambda y_n(s)\,ds. \tag{14}$$

Either the term $r(\xi)y_n'(\xi)$ is of one sign or not. If not, we may assume $r(\xi)y_n'(\xi) = 0$ for some ξ. If it is of one sign, we may assume that $r(\xi)y_n'(\xi) \geq m > 0$ for some constant m. As in Theorem 1.1, it follows that $m^2 \leq 12H^2$. The uniform boundedness properties follow from this and (14). We note that the differential equation shows

$$y'(x) = \frac{r(0)y'(0) - \int_0^x \lambda y(s)\,ds}{r(x)}.$$

Since $r(x)$ is of uniformly bounded variation, this equation shows that y_n' is also of uniformly bounded variation. So the following Stieltjes integral formula is valid:

$$\int_0^1 y_n'^2(\Delta r(x))\,dx = (y_n'^2)(1)\int_0^1 (\Delta r(x))\,dx - \int_0^1\int_0^x \Delta r(x)\,d(y_n'^2).$$

We now use this formula and the bounds on y to construct the Rayleigh quotient for (12) and obtain the relationship

$$\frac{-yr_1y'\Big|_{x=0}^{x=1} + \int_0^1 r_1(x)y'^2\,dx}{\int_0^1 y^2\,dx} \leq \frac{-yr_2y'\Big|_{x=0}^{x=1} + \int_0^1 r_2(x)y'^2\,dx}{\int_0^1 y^2\,dx} + K\,\|r_1(x) - r_2(x)\|_{1Max}.$$

The theorem follows, using (3). □

It is clear that these three examples can be extended to obtain theorems dealing with the most general Sturm–Liouville equation $(r(x)y')' + (\lambda p(x) - q(x))y = 0$. It is also clear that Theorem 1.2 can be generalized to include these equations.

1.6. Higher-order equations. Consider the fourth-order equation

$$y'''' - (\lambda - q(x))y = 0. \tag{15}$$

Suppose that four boundary conditions are given and that the resulting problem is self-adjoint. Since the eigenfunctions of such an equation are necessarily smoother than those for the second-order case, we may integrate by parts more times and

obtain continuity in much weaker topologies. The required formula is

$$\begin{aligned}\int_0^1 y^2\Delta q(x)\,dx &= y^2(1)\int_0^1 \Delta q(x_1)\,dx_1 - y^{2\prime}(1)\int_0^1\int_0^{x_2} \Delta q(x_1)\,dx_1\,dx_2\\ &\quad + y^{2\prime\prime}(1)\int_0^1\int_0^{x_3}\int_0^{x_2} \Delta q(x_1)\,dx_1\,dx_2\,dx_3\\ &\quad - y^{2\prime\prime\prime}(1)\int_0^1\int_0^{x_4}\int_0^{x_3}\int_0^{x_2} \Delta q(x_1)\,dx_1\,dx_2\,dx_3\,dx_4\\ &\quad + \int_0^1\int_0^{x}\int_0^{x_4}\int_0^{x_3}\int_0^{x_2} y^{2\prime\prime\prime\prime}\Delta q(x_1)\,dx_1\,dx_2\,dx_3\,dx_4\,dx.\end{aligned}$$

The new norm is given by

$$\begin{aligned}\|q\|_{4L_1} &= \left|\int_0^1 q(x)\,dx\right| + \left|\int_0^1\int_0^{x_2} q(x_1)\,dx_1\,dx_2\right| + \left|\int_0^1\int_0^{x_3}\int_0^{x_2} q(x_1)\,dx_1\,dx_2\,dx_3\right|\\ &\quad + \left|\int_0^1\int_0^{x_4}\int_0^{x_3}\int_0^{x_2} q(x_1)\,dx_1\,dx_2\,dx_3\,dx_4\right|\\ &\quad + \int_0^1\left|\int_0^{x}\int_0^{x_4}\int_0^{x_3}\int_0^{x_2} q(x_1)\,dx_1\,dx_2\,dx_3\,dx_4\right| dx.\end{aligned}$$

Methods like those used for Theorem 1.1 yield the following theorem.

THEOREM 1.7. *Let $\lambda_n(q)$ denote the nth eigenvalue of* (15) *subject to self-adjoint boundary conditions. Then there is a constant $M_n(H)$ such that, for any q_1, $q_2 \in C(H)$, we have*

$$|\lambda_n(q_1) - \lambda_n(q_2)| \le M_n(H)\|q_1 - q_2\|_{4L_1}. \tag{16}$$

The constant $M_n(H)$ is independent of the boundary conditions.

If we are willing to assume that the coefficients are of bounded variation, then we can integrate once more and imitate the procedure given in Theorem 1.2 above. Thus, the only information contained in a finite amount of spectral data for this fourth-order problem is a uniform approximation to the quantity $\int_0^x \int\int\int\int q$ together with approximations to the first four Hausdorff moments. Reconstructing a pointwise approximation to the coefficient function implicitly requires the numerical computation of five derivatives of this uniform approximation.

A generalization of Theorem 1.2 can also be obtained for higher-order equations.

2. Solving the finite inverse problem. We will now provide a numerical method for solving the finite inverse problem. We will also give a few examples and an analysis of the method. We will only consider the second-order equation (1) in any detail, although the methods will work for the general equation Sturm–Louville equation.

$$(r(x)y')' + (\lambda p(x) - q(x))y = 0, \qquad \begin{aligned} a_1y(0) + a_2y'(0) + a_3y(1) + a_4y'(1) &= 0,\\ b_1y(0) + b_2y'(0) + b_3y(1) + b_4y'(1) &= 0.\end{aligned} \tag{17}$$

The spectral data need not consist of the eigenvalues corresponding to one set of boundary conditions listed in increasing order. The data may, for example, consist of eigenvalues corresponding to several different sets of boundary conditions interlaced

in some manner or, perhaps, data like that considered by McLaughlin and Rundell [9].

This method works by minimizing the norm $\|\boldsymbol{\Lambda} - \boldsymbol{\lambda}(q)\|_2$ so that, if the inverse problem has nonunique solutions, then we can still produce an approximation to one of them. Even if there is no solution at all, then our method may produce a function which minimizes the norm $\|\boldsymbol{\Lambda} - \boldsymbol{\lambda}(q)\|_2$. We will need the following variational formula for the functionals $\boldsymbol{\lambda}(p, q, r)$ given by Barnes [1].

THEOREM 2.1. *For coefficient functions p, q, r and p^*, q^*, r^*, let y_i, λ_i and y_i^*, λ_i^* be corresponding eigenpairs for* (17). *Suppose that y_i^* is normalized so that $\int_0^1 p^* y_i^{*2}\, dx = 1$. For two sets of coefficient functions p^*, q^*, r^* and p, q, r define a functional $J(p, q, r)$ on the set $C(H)$ and define a boundary term BT by*

$$
\begin{aligned}
J(p, q, r) &= \int_0^1 [\lambda_i^* p y_i^{*2} + q y_i^{*2} - r y_i^{*'2}]\, dx, \\
BT &= r^* y_i^{*'} y_i - r y_i' y_i^* - r^* y_i^{*'} y_i^* \Big|_{x=0}^{x=1}.
\end{aligned} \tag{18}
$$

Then

$$
\lambda_i(p, q, r) = \lambda_i(p^*, q^*, r^*) + BT - J(p, q, r) + O_2, \tag{19}
$$

where the term O_2 is defined by

$$
O_2 = \int_0^1 [p^* y_i^* \Delta\lambda_i \Delta y_i + \lambda_i^* y_i^* \Delta p \Delta y_i + y_i^* \Delta q \Delta y_i - y_i^{*'} \Delta r \Delta y_i']\, dx.
$$

This theorem shows that the two functionals $\lambda_i(p, q, r)$ and $\lambda_i(p^*, q^*, r^*) + BT - J(p, q, r)$ are tangent to each other at $p = p^*, q = q^*$, and $r = r^*$ when considered as functionals depending on (p, q, r).

2.1. Minimizing the norm $\|\boldsymbol{\Lambda} - \boldsymbol{\lambda}(q)\|_2$. In order to simplify the presentation, we will restrict the following study to the simple equation (1) together with boundary conditions for which either y or y' vanish at both ends of the interval. However, it would be easy to generalize to other cases. Theorem 1.2 requires a sequence $q_N(x)$ which interpolates to the data. We will look for one in the class $C(M, H)$ of all functions of the general form

$$
q(x) = \sum_{k=1}^{M} \beta_k h_k(x) \quad \text{with } |q(x)| \le H. \tag{20}
$$

Here, the $h_k(x)$ can be any conveniently chosen basis functions and the β_k are constants. With this kind of representation we will sometimes use the notation $\boldsymbol{\lambda}(q) = \boldsymbol{\lambda}(\boldsymbol{\beta})$ where $\boldsymbol{\beta} = (\beta_1, \beta_2, \cdots, \beta_M)$.

For a given value of N, we will select a value of M (usually $M > N$) and take q_N^* to be a solution to the problem

$$
\min_{q \in C(M,H)} \|\boldsymbol{\Lambda} - \boldsymbol{\lambda}(q)\|_2 = \|\boldsymbol{\lambda} - \boldsymbol{\lambda}(q_N^*)\|_2 \qquad \text{where} \quad q_N^*(x) = \sum_{k=1}^{M} \beta_k^* h_k(x). \tag{21}
$$

Such a function always exists since there are only a finite number of the β_k. If the inverse problem does in fact have a unique solution, and if $N \to \infty$, then the sequence of minimums must approach zero. It follows that the functions q_N^* interpolate to the data. Therefore, $q_N^* \to q^*$ in the $1Max$ norm. If the solution of the inverse problem exists but is not unique, then the compactness of $\mathcal{C}(M, H)$ shows that a convergent subsequence of q_N^* can still be selected. Even if there is no solution of the inverse problem, there will still be a subsequence which will converge to some function which gives (at least a local) minimum to the norm $\|\boldsymbol{\Lambda} - \boldsymbol{\lambda}(q)\|_2$. Under the circumstances, this gives the best possible solution of the inverse problem.

The choice of M should be made large enough to allow $q_N^*(x)$ to approximate $q^*(x)$, which will make the norms (21) small. On the other hand, M should not be so large that it becomes difficult just to evaluate $q_N^*(x)$. According to Theorem 1.2, it does not make any real difference how large M is since we will always have at least a subsequence of q_N^* converging to q^*. In the numerical examples given below, selecting a value of M in the range $N \leq M \leq 2N$ seems to work well. We will give additional reasons for this choice later.

We will now show how to minimize the norm $\|\boldsymbol{\Lambda} - \boldsymbol{\lambda}(q)\|_2$. We first use (20) and (21) in the variational formula given by Theorem 2.1 to obtain the principal linear part of the eigenvalue functional $\lambda_i(q)$ in the form

$$
\begin{aligned}
&\lambda_i(q) = \lambda_i(q^*) - \int_0^1 q^*(x) y_i^{*2}\, dx + \int_0^1 q(x) y_i^{*2}\, dx + O_2, \\
&\lambda_i(q) = \lambda_i(q^*) - \sum_{k=1}^{M} \beta_k^* \int_0^1 h_k(x) y_i^{*2}\, dx + \sum_{k=1}^{M} \beta_k \int_0^1 h_k(x) y_i^{*2}\, dx + O_2.
\end{aligned} \tag{22}
$$

We now recast these equations in matrix form. Let data $\boldsymbol{\Lambda} = (\Lambda_1, \Lambda_2, \cdots, \Lambda_N)$ be given and let y_i^{*2} be the eigenfunctions corresponding to $\lambda_i(\boldsymbol{\beta}_N^*)$ and define a matrix Γ and a vector $\boldsymbol{R}$ by

$$
\Gamma = \left(\int_0^1 h_k(x) y_i^{*2}\, dx \right)_{N \times M}, \qquad \boldsymbol{R} = \boldsymbol{\Lambda} - \boldsymbol{\lambda}(\boldsymbol{\beta}_N^*) + \Gamma \boldsymbol{\beta}_N^*. \tag{23}
$$

We see that

$$
\boldsymbol{\lambda}(\boldsymbol{\beta}) = \boldsymbol{\lambda}(\boldsymbol{\beta}^*) - \Gamma \boldsymbol{\beta}^* + \Gamma \boldsymbol{\beta} + \boldsymbol{O}_2. \tag{24}
$$

We will now substitute this equation into the norm function. This converts the problem of minimizing a quantity involving the difficult functional $\lambda_i(q)$ into a sequence of simple least squares problems. The mathematical details of this conversion are based on the following theorem.

THEOREM 2.2. *For fixed values of N, M, let $\boldsymbol{\beta}_N^*$ be an approximate solution of the inverse problem in the sense that it minimizes the norm $\|\boldsymbol{\Lambda} - \boldsymbol{\lambda}(\boldsymbol{\beta})\|_2$. Then the choice $\boldsymbol{\beta} = \boldsymbol{\beta}_N^*$ also minimizes the norm $\|\boldsymbol{R} - \Gamma \boldsymbol{\beta}\|_2$. That is,*

$$
\|\boldsymbol{R} - \Gamma \boldsymbol{\beta}_N^*\|_2 \leq \|\boldsymbol{R} - \Gamma \boldsymbol{\beta}\|_2. \tag{25}
$$

Conversely, if some vector $\boldsymbol{\beta}_N^*$ satisfies the minimum condition (25), *then it must be an extremal of the norm $\|\boldsymbol{\Lambda} - \boldsymbol{\lambda}(\boldsymbol{\beta})\|_2$.*

Proof. Using (24), we find that

$$
\|\boldsymbol{\Lambda} - \boldsymbol{\lambda}(\boldsymbol{\beta})\|_2 = \|\boldsymbol{R} - \Gamma \boldsymbol{\beta}\|_2 + O_2. \tag{26}
$$

Equation (26) shows that the two norm functions are tangent to each other at $\boldsymbol{\beta} = \boldsymbol{\beta}_N^*$. The converse part of the theorem follows easily. Assuming that $\boldsymbol{\beta}_N^*$ is an extremal of the norm $\|\boldsymbol{\Lambda} - \boldsymbol{\lambda}(\boldsymbol{\beta})\|_2$, it follows that $\boldsymbol{\beta}_N^*$ is also an extremal of the norm $\|\boldsymbol{R} - \Gamma\boldsymbol{\beta}\|_2$. However, this norm is a nonnegative quadratic form in the components of $\boldsymbol{\beta}$. It can not have a maximum, so $\boldsymbol{\beta}_N^*$ must be a minimum for it. □

Except for the fact that both Γ and $\boldsymbol{R}$ depend on $\boldsymbol{\beta}_N^*$, it would follow that (25) is a simple least squares problem. As it is, finding a vector $\boldsymbol{\beta}_N^*$ which satisfies the minimizing condition is more difficult. Even so, we will set up an iterative scheme which can solve for such a vector having the required properties.

First, we pick an approximation to $\boldsymbol{\beta}_N^*$—call it $\boldsymbol{\beta}_{N,1}^*$—and solve the eigenvalue problem for $\lambda_i(\boldsymbol{\beta}_{N,1}^*)$, and the corresponding eigenfunctions. These quantities are then approximations to $\lambda_i(\boldsymbol{\beta}_N^*)$ and y_i^*, so we use them in (23) to compute approximations to Γ and to $\boldsymbol{C}$. Call them Γ_1 and $\boldsymbol{C}_1$. We then let $\boldsymbol{\beta}_{N,2}^*$ be the solution of the linear least squares problem of minimizing $\|\boldsymbol{C}_1 - \Gamma_1\boldsymbol{\beta}\|_2$ over all $\boldsymbol{\beta}$. This gives a better approximation to $\boldsymbol{\beta}^*$. Continue this iteration process.

In view of the compactness of $\mathcal{C}(H)$, the method must at least produce a convergent subsequence. It may not, however, produce a truly convergent sequence since there will always be infinitely many solutions $q(x)$ of the equations $\lambda_i(q) = \Lambda_i$ for $i = 1, 2, \cdots, N$, and it is possible that the sequence may oscillate among them. Note, however, that the convergence of the method comes from Theorem 1.2 by letting $N \to \infty$. Although it may seem strange, it is not necessary for the intermediate iterations producing the values of $\boldsymbol{\beta}_{N,k}^*$ to converge.

2.2. On the numerical conditioning of the finite inverse problem. The fundamental difficulty with the inverse eigenvlaue problem is caused by the fact that the eigenvalues are continuous functionals in some very weak topologies. However, we will now show that the inverse problem is, in fact, well conditioned if the validity of the solution is measured in terms of the proper topology. In order to simplify the presentation, we will deal only with boundary conditions for which either $y = 0$ or $y' = 0$ at both ends of the interval, although the methods can be generalized to cover the case of arbitrary self-adjoint boundary conditions.

The proper topology really means the smallest topology in which the eigenvalues are continuous functions. It seems very difficult to characterize this topology; however, a good approximation to it is the one defined by the $2L_1$ norm. As noted above, the only information contained in a finite number of eigenvalues is a $2L_1$ approximation to $q^*(x)$. Therefore, based only on spectral data, we should not even attempt to reconstruct an approximation using the $1Max$ norm, much less a pointwise approximation. Rather, we should only attempt to reconstruct an L_1 approximation to the function $Q(x)$ given by $Q(x) = \int_0^x \int_0^s q(z)\, dz\, ds$.

We may then change our viewpoint a little bit and consider the eigenvalues to depend on the function $Q(x)$ instead of $q(x)$. We therefore write $\lambda_i = \lambda_i(Q)$ rather than $\lambda_i = \lambda_i(q)$ to indicate this change in perspective. The direct eigenvalue problem now consists of calculating the eigenvalues $\boldsymbol{\lambda}$, given the function $Q(x)$, while the inverse problem is that of finding $Q^*(x)$, given spectral data $\boldsymbol{\Lambda} = \boldsymbol{\lambda}(Q^*)$. We will now show that the numerical behavior of this new problem based on $Q(x)$ is quite different from the behavior of the original problem based on $q(x)$. Both the direct and the inverse problem for $Q(x)$ are numerically well conditioned!

In order to investigate the conditioning of the inverse problem, we will suppose

that the functions $Q(x)$ and $q(x)$ are both expressed in the same general form:

$$Q(x) = \sum_{k=1}^{M} \alpha_k B_k(x), \qquad q(x) = \sum_{k=1}^{M} \beta_k B_k(x).$$

Any convenient set of functions $B_k(x)$ could be used for the basis; however, in order to avoid generalized functions (which, of course is *not* absolutely necessary), the functions $Q(x)$ must have piecewise continuous second derivatives. We will now consider the variation in the eigenvalues with small changes in the parameters α_k and β_k. We first integrate by parts twice in (22) to obtain the following relation:

$$\begin{aligned} \lambda_i(Q) &= \lambda_i(q^*) - \int_0^1 q^*(x) y_i^{*2}\, dx + \int_0^1 Q(x)(y_i^{*2})''\, dx + O_2, \\ \lambda_i(Q) &= \lambda_i(q^*) - \int_0^1 q^*(x) y_i^{*2}\, dx + \sum_{k=1}^{N} \alpha_k \int_0^1 B_k(x)(y_i^2)''\, dx + O_2. \end{aligned} \tag{27}$$

We now appeal to a version of (22) which uses the basis $B_k(x)$ and to (27) to take derivatives. We find that

$$\frac{\partial \lambda_i(Q)}{\partial \alpha_k} = \int_0^1 B_k(x)(y_i{}^2)''\, dx, \qquad \frac{\partial \lambda_i(q)}{\partial \beta_k} = \int_0^1 B_k(x)(y_i{}^2)\, dx. \tag{28}$$

These relations say a lot about the solution of the inverse problem. The asymptotic law for eigenvalues and eigenfunctions shows that the derivatives of $\lambda_i(Q)$ are larger than the derivatives of $\lambda_i(q)$ roughly by a multiple of i^2. This means that a small perturbation in $Q(x)$ will produce a much larger change in the eigenvalues than will the same perturbation applied to $q(x)$. Now consider this observation from the perspective of the inverse problem. It implies that the spectral data can be used to reconstruct the function $Q(x)$ much more easily than it can be used to find $q(x)$. The inverse problem for $Q(x)$ is much better conditioned than that for $q(x)$.

Suppose that i is large enough so that $\lambda_i(q) > |q(x)|$. The differential equation shows that the zeros of y_i and y_i'' coincide. Therefore, if the basis function $B_k(x)$ is positive and has its support concentrated in a very small interval, then some of the derivatives (28) will have a better chance of being large because it is less likely that the positive and negative parts of the integral involving $(y_i{}^2)''$ will cancel out. Also the large values of $B_k(x)$ will more readily match large values of the eigenfunctions. This is a good thing since it makes the derivatives larger and improves the conditioning of the inverse problem both for $\boldsymbol{\lambda}(q)$ and for $\boldsymbol{\lambda}(Q)$. This provides an intuitive foundation for the rule of thumb $N \le M \le 2N$ given in §2.1. This analysis also shows that the conditioning of a given inverse problem may depend on the location of the support of the basis functions and provides some guidelines for selection of the specific form of $B_k(x)$.

On the other hand, the direct problem of finding $\boldsymbol{\lambda}$ given $Q(x)$ would seem to require the computation of two numerical derivatives of $Q(x)$ in order to find $q(x)$ and use the differential equation. Perhaps the direct problem of using $Q(x)$ to calculate $\boldsymbol{\lambda}$ will now be ill-conditioned. However, Theorem 1.1 shows that this is not the case, in that *any* function which approximates $Q(x)$ well enough in the L_1 norm will give about the same eigenvalues. It simply does not matter if $Q''(x)$ is a good pointwise approximation to $q(x)$ or not. So we now have the best of both worlds in that the inverse problem and the direct problem connecting $Q(x)$ and $\boldsymbol{\lambda}(Q)$ are well

conditioned. Of course, the real difficulty with this point of view is that there are no well-known numerical algorithms for calculating $\lambda_n(q)$ when given only $Q(x)$.

Another way to think about the inverse problem for $\boldsymbol{\lambda}(q)$ is to break it into two separate steps. The first step is to use the spectral data to find an L_1 approximation to $Q(x)$. The second step is to use some kind of numerical differentiation procedure to compute $q(x) = Q''(x)$. It is only the second step which is ill-conditioned. The inverse eigenvalue problem is only ill-conditioned if we attempt to extract more information from the spectral data than it contains.

If it is known that the function $q(x)$ is differentiable, then Theorem 1.2 can be replaced with a stronger statement which involves three integrations by parts. The function $Q(x)$ can then be taken to be $Q(x) = \int_0^x \int_0^t \int_0^s q(z)\,dz\,ds\,dt$ and the above argument can be carried through using three derivatives rather than two.

2.3. Some numerical examples. To construct an example, we will use (1) with

$$q^*(x) = \begin{cases} 1 & \text{if } 0 \le x < \frac{1}{2}, \\ -1 & \text{if } \frac{1}{2} \le x \le 1, \end{cases} \qquad \text{and} \quad \boldsymbol{\Lambda} = \boldsymbol{\lambda}(q^*). \tag{29}$$

We choose as spectral data the first five eigenvalues of (1) using the boundary conditions $y(0) = y(1) = 0$ together with the first five eigenvalues of (1) using the boundary conditions $y(0) = y'(1) = 0$ for a total of 10 data values. We choose the representation (20) using the simple basis functions given by

$$h_k(x) = \begin{cases} 1 & \text{if } x \le \dfrac{k}{M}, \\ 0 & \text{otherwise,} \end{cases} \qquad k = 1, 2, \cdots, M.$$

Given $N = 10$, we choose $M = 15$ and we now take, as the first approximation to $q^*(x)$, the function $q_{15,1} \equiv .25$. Using (23) we compute $\boldsymbol{R}_1$ and Γ_1 and let $q_{15,2}(x)$ be the result of solving the least squares problem $\|\boldsymbol{R}_1 - \Gamma_1\boldsymbol{\beta}\| = \text{minimum}$.

A little computation shows that

$$\|q^*(x) - q_{15,2}(x)\|_{1Max} \approx .008\cdots, \qquad \int_0^1 |q^*(x) - q_{15,2}(x)|\,dx \approx 0.144\cdots,$$

$$\|q^*(x) - q_{15,2}(x)\|_{2L_1} \approx .002\cdots, \qquad \|\boldsymbol{\lambda}(q_{15,2}) - \boldsymbol{\Lambda}\|_2 \approx .041\cdots.$$

Thus, we have very good $1Max$ and $2L_1$ approximations but a very poor L_1 approximation. Graphs of the various functions are given in Fig. 1 where the following labels are used.

- The curve ① represents the function $q^*(x)$.
- The curve ④ represents the function $q_{15,2}(x)$.
- The two triangular shape curves ② and ⑤ represent, respectively, the functions $\int_0^x q^*(z)\,dz$ and $\int_0^x q^*_{15,2}(z)\,dz$.
- Graphically the three functions $\int_0^x\int_0^s q^*(z)\,dz\,ds\,dx$, $\int_0^x\int_0^s q{\downarrow_{15,2}}(z)\,dz\,ds\,dx$, and $\int_0^x\int_0^s q_{15,2}(z)\,dz\,ds\,dx$ are indistinguishable and the S-shape curve ③ represents all of them. Only a slight thickening of the curve can be detected.
- The curve ⑥ represents the function $q{\downarrow_{15,2}}(x)$ which will be defined in §2.4 below.

We may now use the function $q_{15,2}$ just obtained as a new approximation to $q^*(x)$ and repeat the minimization process. However, the new minimizing function $q_{15,3}$ obtained this way is, essentially, the same as $q_{15,2}$, at least as far as the $1Max$ and

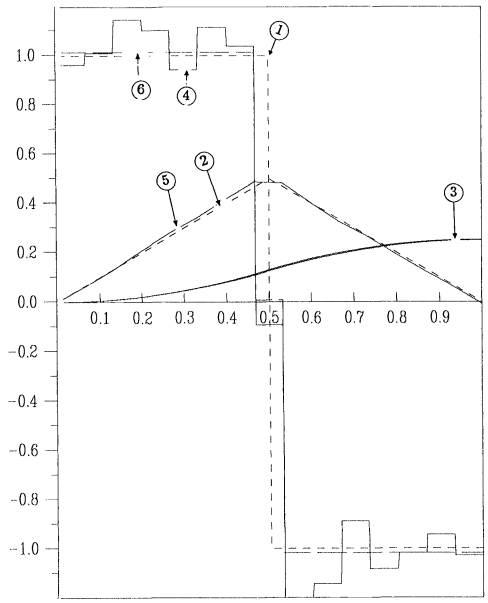

FIG. 1. *Graphs of the coefficient functions and some first and second integrals.*

$2L_1$ norms are concerned. Only some random roundoff error distinguishes them and the method converges in only one iteration step. This is typical of the method in that, depending on the choice of the first guess, it usually converges with only two or three steps. This is due to the fact that, for any choice of coefficient function $q(x)$, the eigenfunctions corresponding to the same set of boundary conditions look very much alike so that $\boldsymbol{R}$ and Γ are quite insensitive to changes in $q(x)$.

2.4. Constrained solutions using Hanson–Haskel's program LSEI. In view of the remarks in §§1.2 and 1.3, it seems impossible to extract pointwise information about $q(x)$ from a finite amount of spectral data. However, if it is possible to take advantage of some additional information about the unknown function, then we may very well be able to obtain good pointwise information. Consider, for example, the inverse problem associated with the free vibrations of the earth [6]. It seems quite reasonable to assume that the density of the earth is an increasing function of depth below the surface.

Such constraints can be used to eliminate the possibility of large oscillations like those given above by the example $\Delta q(x) = A \cos Bx$. In fact, there are many conditions which can be used to eliminate the oscillations. If, for example, the functions are also required to be monotone or convex or concave or even just unimodal, such oscillations will not be possible. Of course, the idea is to identify such an a priori constraint which will prevent the oscillations and, at the same time, still allow us to interpolate to the spectral data.

The CMLIB computing package contains a very useful FORTRAN program, written by R. J. Hanson and K. H. Haskel, called LSEI, which can solve constrained least

squares problems for matrices. Specifically, it solves the following problem:

$$\text{Minimize} \quad \|\boldsymbol{C} - \Gamma\boldsymbol{\beta}\|_2 \quad \text{subject to constraints}$$
$$E\boldsymbol{\beta} = \boldsymbol{F} \quad \text{and} \quad G\boldsymbol{\beta} \geq \boldsymbol{K}. \tag{30}$$

Other kinds of constraints on the coefficient functions, such as symmetry $q(x) = q(1-x)$, are sometimes used when dealing with inverse problems. Or the function could be given only for $0 \leq x \leq \frac{1}{2}$, and we might be required to find its unknown values for $\frac{1}{2} \leq x \leq 1$. Fortunately, this iterative least squares method can be easily adapted to take advantage of any such additional information.

We will now give an example which uses LSEI to solve a constrained inverse problem. We will use the same function $q^*(x)$ given in (29); however, in addition to the 10 spectral data values, we will now assume that $q^*(x)$ is also known to be a decreasing function of x. This condition is reflected in the constraint $\beta_k \geq 0$. Incidentally, this shows one good reason for using a local basis like $h_k(x)$. It would be very difficult to take advantage of the decreasing condition on $q(x)$ using a global basis such as a Fourier series. We now use LSEI to solve the constrained least squares problem with the same iterative procedure as before. Since the constraint eliminates the oscillations, we now get better results.

Using the previous solution $q_{15,2}(x)$ for the first guess, we solve the least squares problem subject to the decreasing condition to obtain a new function which we call $q{\downarrow}_{15,2}\ (x)$. Its graph, given in Fig. 1, clearly shows that it is a much better approximation. It even gives a fairly good pointwise approximation to $q^*(x)$ in that $|q^*(x) - q{\downarrow}_{15,2}\ (x)| < .019$ except for the short interval about the midpoint. Further computations show that

$$\|q^* - q{\downarrow}_{15,2}\|_{1Max} \approx .0034, \qquad \int_0^1 |q^*(x) - q{\downarrow}_{15,2}(x)|\,dx \approx .083,$$
$$\|q^* - q{\downarrow}_{15,2}\|_{2L_1} \approx .00092, \qquad \|\boldsymbol{\lambda}(q{\downarrow}_{15,2}) - \boldsymbol{\Lambda}\|_2 \approx .039.$$

Computing additional terms $q{\downarrow}_{15,n}$ in the sequence did not produce much better approximations, at least as far as the $2L_1$ norm is concerned.

2.5. Jump discontinuities in the coefficient functions. In the previous example, we obtained a solution which was very good at all points except near the jump discontinuity $x = \frac{1}{2}$. We will now develop a method of allowing the break points of the functions $h_k(x)$ to move around so as to better approximate a discontinuous function $q^*(x)$. To do this, we introduce the function $h_t(x)$ defined for any number t by

$$h_t(x) = \begin{cases} 1 & \text{if } x \leq t, \\ 0 & \text{if } t < x. \end{cases} \tag{31}$$

We then select points $t_k,\ t_k^* \in [0,1]$ and suppose that $q(x)$ and $q^*(x)$ are any two functions of the form

$$q^*(x) = \sum_{k=1}^{M} \beta_k^* h_{t_k^*}(x) \quad \text{and} \quad q(x) = \sum_{k=1}^{M} \beta_k h_{t_k}(x). \tag{32}$$

We suppose that both t_k and β_k are variables and introduce the new vector $\boldsymbol{\delta} = (\boldsymbol{\beta}, \boldsymbol{t})$. We then substitute the representation (32) into (22) and compute the principal linear

part of $\lambda_i(q)$ as a function of $\boldsymbol{\delta}$. Finally, we will apply the iterative process used previously to the new vector $\boldsymbol{\delta}$.

First, we derive the linear approximations to $\lambda_n(q)$. Putting (32) into (22) shows that

$$\lambda_i(q) = \lambda_i(q^*) - \int_0^1 q^*(x) y_i^{*2}\,dx + \sum_{k=1}^{M} \beta_k \int_0^1 h_{t_k}(x) y_i^{*2}\,dx + O_2. \tag{33}$$

We now use the relation

$$\beta_k \int_0^1 h_{t_k}(x) y_i^2\,dx = \beta_k^* \int_0^{t_k^*} y_i^{*2}\,dx + \Delta\beta_k \int_0^{t_k^*} y_i^{*2}\,dx + \Delta t_k \beta_k^* y_i^2(t_k^*) + O_2 \tag{34}$$

in (33) to obtain

$$\begin{aligned}\lambda_i(q) =& \lambda_i(q^*) - \int_0^1 q^*(x) y_i^{*2}\,dx - \sum_{k=1}^{M} t_k^* \beta_k^* y_i^{*2}(t_k^*) \\ &+ \sum_{k=1}^{M} \beta_k \int_0^1 h_{t_k^*}(x) y_i^{*2}\,dx + \sum_{k=1}^{M} t_k \beta_k^* y_i^{*2}(t_k^*) + O_2.\end{aligned}$$

We recast this equation in matrix form as $\boldsymbol{\lambda}(q) = -\boldsymbol{S} + \Gamma\boldsymbol{\delta} + O_2$ where

$$\begin{aligned}\boldsymbol{S}_i &= -\lambda_i(q^*) + \int_0^1 q^*(x) y_i^{*2}\,dx + \sum_{k=1}^{M} t_k^* \beta_k^* y_i^{*2}(t_k^*), \\ \Gamma_2 &= \left(\int_0^1 h_{t_k^*}(x) y_i^{*2}\,dx \right), \quad \Gamma_3 = \left(\beta_k^* y_i^{*2}(t_k^*) \right), \quad \Gamma = (\Gamma_2\ \Gamma_3).\end{aligned} \tag{35}$$

We may now take $\boldsymbol{R} = \boldsymbol{\Lambda} - \boldsymbol{S}$ and iterate in the minimum problem as before to solve for $\boldsymbol{\delta}$. However, a few important details need to be considered first.

In the process of allowing the values of t_k to move about, we may also use LSEI to impose constraints. One obvious constraint to use is that $t_1 \le t_2 \le \cdots \le t_M$, which serves to keep the indexing of the t's straight. However, there are other problems with using such a basis. If, for example, some of the t_k's are the same, then the "basis" will not be linearly independent. Even if the t_k's are allowed to come very close to each other, then the basis will become numerically ill-conditioned. To avoid this kind of problem, we will use LSEI to impose the restriction[2] $|t_k - \frac{k}{M}| \le \frac{1}{3M}$, which implies that $|t_k - t_j| \ge \frac{1}{3M}$.

However, problems may still arise with variable values for t. To see why this is so, consider the variation in the eigenvalues with changes in β and t. Taking derivatives as we did for (27) we find that at $\beta_k = \beta_k^*$ and $t_k = t_k^*$,

$$\frac{\partial\lambda_i(q)}{\partial\beta_k} = \int_0^1 h_{t_k^*}(x) y_i^2\,dx = \int_0^{t_k^*} y_i^2\,dx \quad \text{and} \quad \frac{\partial\lambda_i(q)}{\partial t_k} = \beta_k^* y_i^2(t_k^*). \tag{36}$$

These two relations explain a great deal about the behavior of the inverse problem in general. First notice that a small change in β_k^* will produce a change in λ_i^* which depends on a global quantity involving an integral over an entire interval of

[2] Actually, the example of §2.3 was implemented using the functions (31) and LSEI with the restriction $t_k = k/M$.

values. Such quantities are numerically well behaved. Now notice that a variation in t_k^* produces a variation in λ_i^* which depends on the local pointwise value of the eigenfunction $y_i^2(t_k^*)$. So small changes in t_k^* may or may not produce small changes in λ_i^*. It depends on whether $\beta_k^* y_i^2(t_k^*)$ is large or small, and this is unpredictable because of the rapid oscillations of the eigenfunctions.

If we attempt to solve an inverse eigenvalue problem and, by random bad luck, it happens that the discontinuity of the unknown coefficient $q^*(x)$ lies on or near some nodal point for each of the eigenfunctions corresponding to all of the known spectral data, then changes in t_k^* will produce very small changes in the eigenvalues. From the perspective of the inverse problem, we see that it would be impossible to locate such a discontinuity with any degree of accuracy using only spectral data. On the other hand, it is fortunate that the nodal points of any eigenfunction are almost uniformly spread out through the interval. Even with only a finite amount of data, we expect that at least some of the eigenfunctions will have their maximum values close to the point of discontinuity. Therefore, *even using only a finite amount of spectral data, we should still be able to accurately locate discontinuities in the coefficient function.* We only need to know a somewhat uniform sample of spectral data and to have a jump discontinuity for which β_k^*, the size of the jump, is not especially small.

We now give a numerical example of this process. We will use the same function $q^*(x)$ and the same spectral data used before. The solution $q{\downarrow}_{15,2}(x)$, obtained using the decreasing restriction, strongly suggests that $q^*(x)$ has a point of discontinuity in the interval $[t_7, t_8]$ where $t_7 = .466666$ and $t_8 = .533333$. We choose to let t_8 become a variable, but we will impose on $\boldsymbol{t}$ and $\boldsymbol{\beta}$ the restrictions

$$t_k = \frac{k}{15} \quad \text{for } k \neq 8 \quad \text{but} \quad .47 \leq t_8 \leq .54 \quad \text{and} \quad \beta_k \geq 0. \tag{37}$$

These constraints will insure that the basis is numerically well conditioned, but at the same time they will allow the discontinuity to be located.

Using the solution $q{\downarrow}_{15,2}(x)$ obtained in §2.4 as the first guess in the least squares iteration procedure, subject to (37), gives a sequence of functions—call them $\widehat{q}_n$—for which the points of discontinuity, called T_n, converge to .500. Some other important numbers are listed in Table 1.

TABLE 1

Concerning the sequence of iterations $\widehat{q}_n$.

n	T_n	$\|q^* - \widehat{q}_n\|_{1Max}$	$\|q^* - \widehat{q}_n\|_{2L_1}$	$\|\boldsymbol{\lambda}(\widehat{q}_n) - \boldsymbol{\Lambda}\|_2$
1	.53333333	$2.7457058{\cdot}10^{-02}$	$1.0778840{\cdot}10^{-03}$	$2.5811850{\cdot}10^{-03}$
2	0.4878601	$3.3297241{\cdot}10^{-02}$	$3.0311858{\cdot}10^{-03}$	$3.9687917{\cdot}10^{-02}$
3	0.5150741	$2.3708206{\cdot}10^{-03}$	$7.3498831{\cdot}10^{-04}$	$8.4827110{\cdot}10^{-02}$
4	0.5001864	$8.6408332{\cdot}10^{-03}$	$3.3640519{\cdot}10^{-03}$	$2.1405114{\cdot}10^{-02}$
5	0.5000984	$2.1051883{\cdot}10^{-03}$	$7.7785080{\cdot}10^{-05}$	$2.8585272{\cdot}10^{-02}$
6	0.5004199	$8.2593737{\cdot}10^{-04}$	$1.0909934{\cdot}10^{-04}$	$1.1293867{\cdot}10^{-03}$

At this point we must, subjectively, decide whether the unknown coefficient does or does not have a discontinuity. If it does, then we accept the solution given in Table 1. If we decide that there is no discontinuity, then we should construct a continuous approximation to the function $q{\downarrow}_{15,2}$ as the solution. Unfortunately, the size of $\|\boldsymbol{\lambda}(q) - \boldsymbol{\Lambda}\|_2$ cannot be used to make this decision because the norm can be

made small using many different functions q. Perhaps the strongest evidence for the existence of a discontinuity is the clear convergence of the sequence T_n indicated by the values in the table.

In this way, we have found a very good pointwise approximation to $q^*(x)$ using the spectral data and the additional decreasing information about $q^*(x)$. There is nothing special about the fact that there was only one discontinuity in this example. Several discontinuities could have been dealt with the same way.

These methods have also been used to solve some inverse problems for the equations $y'' + \lambda q(x)y = 0$ and $(r(x)y')' + \lambda y = 0$, and the numerical behavior was in most respects similar to that reported for (1). Theorem 2.1 must be used to obtain new approximation formulae, replacing (22). Otherwise, the procedure is identical. More generally, the method could be easily modified to study the equation $(r(x)y')' + (\lambda p(x) - q(x))y = 0$, together with arbitrary self-adjoint boundary conditions.

3. Summary and conclusions. We have provided an extensive mathematical analysis of the finite inverse problem, proving a convergence theorem for some approximations to its numerical solution. The most important tool used was the compactness of the set $\mathcal{C}(H)$ in the $1Max$ topology. Another major part of the analysis was introducing the idea of the weak topology on $\mathcal{C}(H)$ and approximating it using the $2L_1$ norm. The weak topology determines how much information about the coefficient function is contained in the spectral data. Finally, the application of Theorem 2.1 of [1] to develop (25), (28), and (36) yielded a very good intuitive understanding of the finite inverse eigenvalue problem.

Perhaps one of the most striking results of this analysis was to show the great disparity between the very weak approximations which must be used when given only a finite amount of data (a $2L_1$ approximation or worse) and the much stronger approximation (using the norms $\|\cdot\|_\infty$ or $\|\cdot\|_2$) which are possible when using an infinite amount of data [4], [8]. However, even if the approximation is quite weak in the finite case, it is still very a usable result. It is especially useful when combined with additional information about the coefficient function, such as monotonicity or convexity, which may frequently be available simply from the physics of the problem. In such cases, it may still be possible to generate good pointwise approximations using only finite data. This is an especially important development for equations of the form (10) and (12) which may have discontinuous coefficient functions since asymptotic formula are difficult to obtain in such cases. It would be interesting, and probably not especially difficult, to develop a set of theorems to the effect that "If $q_n(x)$ converges in the $2L_1$ norm and if $q_n(x)$ is a decreasing function of x or a convex function of x or $\cdots$ then $q_n(x)$ converges in a much stronger topology."

HALF-BOUND STATES AND LEVINSON'S THEOREM FOR DISCRETE SYSTEMS*

D. B. HINTON†, M. KLAUS‡, AND J. K. SHAW‡

Abstract. A second-order difference equation $-y_{n+1}+2y_n-y_{n-1}+q_ny_n=\lambda y_n$, $n=1,2,\cdots$ is considered. The perturbation terms q_n are assumed to satisfy the scattering condition $\sum_{n=1}^{\infty} n|q_n|<\infty$. A boundary condition $y_0+\alpha y_1=0$ is imposed, and a formula is derived for the number of eigenvalues of the associated self-adjoint operator. This formula, known as Levinson's theorem, is in terms of the change of phase of the complex amplitude function for solutions of the difference equation and of other factors whose value depends on the existence of so-called *half-bound states*, which are defined herein. An application is given to the equations of motion of a semi-infinite chain of masses connected by springs. It is established how the large-t asymptotics depend on the existence of half-bound states.

Key words. difference equation, Titchmarsh–Weyl theory, spectrum, half-bound state

AMS(MOS) subject classifications. 47E05, 34B25

1. Introduction. The spectral analysis of difference equations arises in many contexts. One such context is the dynamics of differential-difference equations. A simple example of this is an infinite chain of masses, each of which is connected by springs to its nearest neighbors. The same system of differential equations models certain large electrical systems and disordered crystals. In the case of a semi-infinite chain with identical springs, the difference equation

$$-y_{n+1}+2y_n-y_{n-1}+q_ny_n=\lambda y_n, \qquad n=1,2,\cdots, \tag{1.1}$$

arises in the computation of the vibrational frequencies or energy spectrum. Associated with (1.1) is a boundary condition

$$y_0+\alpha y_1=0 \tag{1.2}$$

where α is a real number. The coefficients q_n are real.

First we associate with (1.1)-(1.2) a self-adjoint operator T_α in the Hilbert space l_2 of square summable sequences $\{y_n\}_1^\infty$. Define T_α in l_2 by

$$(T_\alpha y)_n=-y_{n+1}+2y_n-y_{n-1}+q_ny_n, \qquad n=1,2,\cdots$$

with $y_0=-\alpha y_1$. Note that T_0 is associated with the boundary condition $y_0=0$. Furthermore, the domain of T_α is the set of all $y\in l_2$ such that $T_\alpha y\in l_2$. The operator T_α is known to be self-adjoint, e.g., [1], [2].

We consider T_α under the scattering condition

$$\sum_{n=1}^{\infty} n|q_n|<0, \tag{1.3}$$

which implies that T_α is a bounded operator on l_2. Under (1.3), it turns out that the essential spectrum of T_α is $[0,4]$ and that T_α may have finitely many eigenvalues in $(-\infty,0)\cup(4,\infty)$. In § 2 we derive a formula which counts the number of eigenvalues or bound states. This formula, of the type known as Levinson's theorem, is in terms of the change of phase of the complex amplitude function associated with a solution

of (1.1)-(1.2). Additional terms of $-\pi$ must be added when *half-bound states* are present; these are defined below (2.14). A good deal of work has recently been done on Levinson-type theorems in different contexts. The first such result was proved by Levinson for the Schrödinger operator [9]. Results have been obtained more recently for the Schrödinger equation [8], the Dirac equation [5], [12], and four-dimensional Hamiltonian systems [6], [11]. In [5], [6], and [8] the condition placed on the potentials is the scattering condition. For difference equations of the type considered here, a Levinson theorem has been formulated in [4]. But a proof under condition (1.3) was not given and the half-bound state case was not considered.

In § 3 the theory is applied to the equations of motion of a semi-infinite chain of masses connected by springs. It is found that the long-time behavior of a displacement is generically either of order $t^{-3/2}$ or $t^{-1/2}$ according to whether or not a half-bound state exists. (See the definition below (2.14).) Thus the influence of a half-bound state is exhibited in the rate of return of each mass to its equilibrium position.

2. Asymptotics of (1.1) and Levinson's theorem. For the sake of clarity we treat only the case where $\alpha = 0$ in (1.2). A basic role will be played by the two solutions $\theta(\lambda) = \{\theta_n(\lambda)\}$, $\phi(\lambda) = \{\phi_n(\lambda)\}$ of (1.1) defined by the initial conditions

$$\theta_0(\lambda) = \theta_1(\lambda) = 1, \quad \phi_0(\lambda) = 0, \quad \phi_1(\lambda) = 1. \tag{2.1}$$

For the unperturbed case, i.e., $q_n = 0$ for all n, we designate θ_n, ϕ_n by θ_n^0, ϕ_n^0, respectively. These sequences satisfy

$$y_{n+1} + (\lambda - 2)y_n + y_{n-1} = 0, \tag{2.2}$$

and we now calculate them. Setting $y_n = \tau^n$ in (2.2) gives that $\tau^2 + (\lambda - 2)\tau + 1 = 0$ so that

$$2 - \lambda = \tau + \frac{1}{\tau}, \qquad \tau = \frac{2 - \lambda \pm \sqrt{\lambda^2 - 4\lambda}}{2}. \tag{2.3}$$

We choose, for $\mathcal{I}\lambda \geqq 0$, a branch of square root in the following manner. Let

$$D_\gamma = \{\gamma \in \mathbb{C}: 0 \leqq \mathcal{R}\gamma \leqq \pi,\ 0 \leqq \mathcal{I}\gamma < \infty\},$$
$$D_\tau = \{\tau \in \mathbb{C}: |\tau| \leqq 1,\ \mathcal{I}\tau \geqq 0,\ \tau \neq 0\},$$
$$D_\lambda = \{\lambda \in \mathbb{C}: \mathcal{I}\lambda \geqq 0\}.$$

Then it is easily seen that the maps $\gamma \to \tau = e^{i\gamma} \to \lambda = 2 - \tau - 1/\tau$ are one to one and onto from $D_\gamma \to D_\tau \to D_\lambda$, respectively; furthermore, interiors are mapped onto interiors of these regions. Hence we see that for $\mathcal{I}\lambda > 0$ we may choose τ satisfying (2.3) so that $|\tau| < 1$ and $\mathcal{I}\tau > 0$. The map $\lambda = 2 - \tau - 1/\tau$ maps $(-1, 0)$ onto $(4, \infty)$ and $(0, 1)$ onto $(-\infty, 0)$, so we may continue the map analytically (by conjugation) from $\{|\tau| < 1: \tau \neq 0\}$ onto $\mathbb{C}\backslash[0, 4]$. This is the way we choose the solution τ of $\tau^2 + (\lambda - 2)\tau + 1 = 0$ for $\lambda \in \mathbb{C}\backslash[0, 4]$. The corresponding γ satisfies $-\pi < \mathcal{R}\gamma < \pi$, $\mathcal{I}\gamma > 0$.

Then for fixed $\lambda \in \mathbb{C}\backslash[0, 4]$, we have two solutions of the free problem, namely, $\tau^n = e^{in\gamma}$ and $\tau^{-n} = e^{-in\gamma}$. Note that $\tau^n \to 0$ as $n \to \infty$ since $\mathcal{I}\gamma > 0$. To compute $\{\theta_n^0(\lambda)\}$ and $\{\phi_n^0(\lambda)\}$ we express them as linear combinations of $\{e^{in\gamma}\}$ and $\{e^{-in\gamma}\}$ and substitute into (2.1). This yields, after some computation, that for $n = 0, 1, \cdots$,

$$\theta_n^0(\lambda) = \frac{\cos(n - \frac{1}{2})\gamma}{\cos \gamma/2} \quad \text{and} \quad \phi_n^0(\lambda) = \frac{\sin n\gamma}{\sin \gamma}.$$

To compute $\{\theta_n(\lambda)\}$ and $\{\phi_n(\lambda)\}$ we apply variation of constants to (1.1) written in the form

$$-y_{n+1} + (2 - \lambda)y_n - y_{n-1} = f_n, \qquad f_n = -q_n y_n. \tag{2.4}$$

This gives, for the solution of (2.4), that

$$y_n = c_1 \frac{\sin n\gamma}{\sin \gamma} + c_2 \frac{\cos (n-\frac{1}{2})\gamma}{\cos (\gamma/2)} + \sum_{k=1}^{n-1} \frac{\sin (n-k)\gamma}{\sin \gamma} q_k y_k$$

where a summation is zero when the upper limit is less than the lower limit. Using (2.1) now to compute c_1 and c_2, we obtain for $n = 1, 2, \cdots$

$$\phi_n(\lambda) = \frac{\sin n\gamma}{\sin \gamma} + \sum_{k=1}^{n-1} \frac{\sin (n-k)\gamma}{\sin \gamma} q_k \phi_k(\lambda), \tag{2.5}$$

$$\theta_n(\lambda) = \frac{\cos (n-\frac{1}{2})\gamma}{\cos \gamma/2} + \sum_{k=1}^{n-1} \frac{\sin (n-k)\gamma}{\sin \gamma} q_k \theta_k(\lambda). \tag{2.6}$$

Now we introduce the Jost functions and the asymptotics of solutions. Multiplying (2.5) by $e^{in\gamma}$, we get

$$e^{in\gamma}\phi_n(\lambda) = \frac{e^{2in\gamma} - 1}{2i \sin \gamma} + \sum_{k=1}^{n-1} \frac{e^{2i(n-k)\gamma} - 1}{2i \sin \gamma} q_k e^{ik\gamma} \phi_k(\lambda). \tag{2.7}$$

Since $\mathcal{I}\gamma > 0$ for $\lambda \in \mathbb{C}\backslash[0, 4]$, equation (2.7) implies that if $v_k = |e^{ik\gamma}\phi_k(\lambda)|$, then for $n = 1, 2, \cdots$,

$$v_n \leqq K\left(1 + \sum_{k=1}^{n-1} |q_k| v_k\right), \qquad K = \frac{1}{|\sin \gamma|}. \tag{2.8}$$

Application of the Gronwall inequality for difference equations to (2.8) yields that

$$\begin{aligned} v_n = |e^{in\gamma}\phi_n(\lambda)| &\leqq K \exp\left\{K \sum_{k=1}^{n-1} |q_k|\right\} \\ &\leqq K \exp\left\{K \sum_{k=1}^{\infty} |q_k|\right\}. \end{aligned} \tag{2.9}$$

Using the bound (2.9) in (2.7) it follows that

$$e^{in\gamma}\phi_n(\lambda) = -(2i \sin \gamma)^{-1}\left[1 + \sum_{k=1}^{\infty} e^{ik\gamma} q_k \phi_k(\lambda)\right] + o(1) \tag{2.10}$$

as $n \to \infty$. Similar calculations with $\theta_n(\lambda)$ in (2.6) yield that as $n \to \infty$,

$$e^{in\gamma}\theta_n(\lambda) = (2i \sin \gamma)^{-1}\left[(ie^{i\gamma/2} \sin \gamma)/(\cos \gamma/2) - \sum_{k=1}^{\infty} e^{ik\gamma} q_k \theta_k(\lambda)\right] + o(1). \tag{2.11}$$

Thus for $\lambda \in \mathbb{C}\backslash[0, 4]$, we define the Jost functions by

$$\begin{aligned} f_\phi(\lambda) &= 1 + \sum_{k=1}^{\infty} e^{ik\gamma} q_k \phi_k(\lambda), \\ f_\theta(\lambda) &= -(i e^{i\gamma/2} \sin \gamma)/(\cos \gamma/2) + \sum_{k=1}^{\infty} e^{ik\gamma} q_k \theta_k(\lambda). \end{aligned} \tag{2.12}$$

As in the differential equations case, the Jost function is the coefficient of the dominant asymptotic term. Its zeros therefore constitute the λ values corresponding to decaying solutions. Closely related to the Jost function is the Titchmarsh-Weyl function $m(\lambda)$ defined by

$$m(\lambda) = -\lim_{n \to \infty} \frac{\theta_n(\lambda)}{\phi_n(\lambda)}, \qquad \mathcal{I}\lambda \neq 0. \tag{2.13}$$

A general proof for the existence of the limit in (2.13) may be found in the text of Atkinson [1] and the papers of Asahi [2] and Bennewitz [3]; in our case the asymptotics of (2.10) and (2.11) give that

$$m(\lambda) = -f_\theta(\lambda)/f_\phi(\lambda), \tag{2.14}$$

provided $f_\phi(\lambda) \neq 0$ for $\mathcal{I}\lambda \neq 0$. That $f_\phi(\lambda) \neq 0$ for $\mathcal{I}\lambda \neq 0$ follows from the asymptotics of solutions of (1.1). Under the condition (1.3), the asymptotic methods of differential equations applied to difference equations yields solutions $\{z_n(\lambda)\}$, $\{w_n(\lambda)\}$ of (1.1) such that for $\lambda \in \mathbb{C}\backslash[0,4]$, as $n \to \infty$,

$$z_n(\lambda) = e^{in\gamma}[1+o(1)], \qquad w_n(\lambda) = e^{-in\gamma}[1+o(1)].$$

Since $\{z_n(\lambda)\}$, $\{w_n(\lambda)\}$ is a basis, it follows that $f_\phi(\lambda) = 0$ if and only if $\{z_n(\lambda)\}$ and $\{\phi_n(\lambda)\}$ are linearly dependent. This is equivalent to $\{\phi_n(\lambda)\} \in l_2$ since $\{z_n(\lambda)\} \in l_2$ and $\{w_n(\lambda)\} \notin l_2$. Thus $f_\phi(\lambda) = 0$ for $\lambda \in \mathbb{C}\backslash[0,4]$ if and only if λ is an eigenvalue for the self-adjoint operator T_α with $\alpha = 0$. Since T_α has no complex eigenvalues, we have another proof that $f_\phi(\lambda) \neq 0$ for $\mathcal{I}\lambda \neq 0$.

For $\lambda \in (0,4)$, $\theta_n(\lambda)$ and $\phi_n(\lambda)$ are asymptotically oscillatory, and we can show that this corresponds to the continuous spectrum of T_α (but we will not need this fact). Thus a point $\lambda \in \mathbb{C}\backslash[0,4]$ is in the resolvent set unless it is an eigenvalue, in which case $f_\phi(\lambda) = 0$ (for the $\alpha = 0$ case). From (2.9) and (2.12) we see that $f_\phi(\lambda) \to 1$ as $|\lambda| \to \infty$ so there are no eigenvalues sufficiently far out. We will presently show that the behaviour of $f_\phi(\lambda)$ as $\lambda \to 0$ rules out a clustering of eigenvalues at $\lambda = 0$, and similarly at $\lambda = 4$.

In particular, there will be only finitely many eigenvalues. This leaves only the points $\lambda = 0$ and $\lambda = 4$. We say that $\lambda = 0$ is a *half-bound state* (HBS) provided that $\{\phi_n(0)\}$ is a bounded sequence, and a non-half-bound state (non-HBS) otherwise. A similar definition may be given at $\lambda = 4$ in terms of $\{\phi_n(4)\}$. Sometimes it will be more convenient to say that $\phi(0)$ or $\phi(4)$ is a half-bound state. If instead $\{\theta_n(0)\}$ is bounded, we say that we have a θ-half-bound state (θ-HBS) at $\lambda = 0$, and similarly at $\lambda = 4$. It is the analysis of the Jost functions f_θ and f_ϕ at HBS that comprises the rest of this paper. We begin with f_ϕ near $\lambda = 0$.

THEOREM 2.1. *If* $\lambda = 0$ *is an* HBS, *then*

$$f_\phi(\lambda) = i\gamma a_\phi^{(1)} + o(|\gamma|) \quad \textit{where } a_\phi^{(1)} = \sum_{k=1}^{\infty} kq_k\phi_k(0) \neq 0. \tag{2.15}$$

If $\lambda = 0$ *is a non-*HBS, *then*

$$f_\phi(\lambda) = a_\phi^{(0)} + o(1) \quad \textit{where } a_\phi^{(0)} = 1 + \sum_{k=1}^{\infty} q_k\phi_k(0) \neq 0. \tag{2.16}$$

Proof. For $\lambda = 0$ we have $\gamma = 0$ and the unperturbed problem $-y_{n+1} + 2y_n - y_{n-1} = 0$ has solutions

$$\phi_n^0(0) = n, \quad \theta_n^0(0) = 1, \quad n = 0, 1, \cdots.$$

Equations (2.5) and (2.6) are replaced by

$$\begin{aligned} \phi_n(0) &= n + \sum_{k=1}^{n-1} (n-k)q_k\phi_k(0) \\ &= n\left[1 + \sum_{k=1}^{n-1} q_k\phi_k(0)\right] - \sum_{k=1}^{n-1} kq_k\phi_k(0), \end{aligned} \tag{2.17a}$$

$$\theta_n(0) = 1 + \sum_{k=1}^{n-1} (n-k) q_k \theta_k(0)$$

$$= \left[1 - \sum_{k=1}^{n-1} q_k \theta_k(0) \right] + n \sum_{k=1}^{n-1} k q_k \theta_k(0) \tag{2.17b}$$

for $n = 1, 2, \cdots$. Under the condition (1.3) with $\lambda = 0$, the methods of differential equations yield a pair of linearly independent solutions $\{z_n(0)\}$, $\{w_n(0)\}$ of (1.1) such that as $n \to \infty$, $z_n(0) = [1 + o(1)]$ and $w_n(0) = [n(1 + o(1)]$. Returning to $\{\phi_n(0)\}$, we see that if $\{\phi_n(0)\}$ is bounded, then by (2.17a) $1 + \sum_{k=1}^{\infty} q_k \phi_k(0) = 0$. On the other hand, since $\{\phi_n(0)\}$ is a linear combination of $\{z_n(0)\}$ and $\{w_n(0)\}$, it follows from (2.17a) that $\phi_n(0) = o(n)$ as $n \to \infty$ if $1 + \sum_{k=1}^{\infty} q_k \phi_k(0) = 0$. This then implies that $\{\phi_n(0)\}$ and $\{z_n(0)\}$ are linearly dependent, so that $\{\phi_n(0)\}$ is bounded. Thus $\{\phi_n(0)\}$ is bounded if and only if $1 + \sum_{k=1}^{\infty} q_k \phi_k(0) = 0$ in which case $\sum_{k=1}^{\infty} k q_k \phi_k(0) \neq 0$, for otherwise (2.17a) implies that as $n \to \infty$,

$$|\phi_n(0)| \leqq n \left| \sum_{k=n}^{\infty} q_k \phi_k(0) \right| + o(1)$$

$$\leqq \sum_{k=n}^{\infty} k |q_k| |\phi_k(0)| + o(1) = o(1),$$

contrary to $\{\phi_n(0)\}$ being a nonzero multiple of $\{z_n(0)\}$.

In a similar manner it follows that $\{\theta_n(0)\}$ is bounded if and only if $\sum_{k=1}^{\infty} q_k \theta_k(0) = 0$, in which case $1 - \sum_{k=1}^{\infty} k q_k \theta_k(0) \neq 0$.

We now examine the behaviour of $f_\phi(\lambda)$ as $\lambda \to 0$ in $\mathbb{C} \backslash [0, 4]$. First consider $f_\phi(\lambda)$ when $\phi(0)$ is not an HBS. Then

$$f_\phi(\lambda) = 1 + \sum_{k=1}^{\infty} e^{ik\gamma} q_k \phi_k(\lambda)$$

$$= \left[1 + \sum_{k=1}^{\infty} q_k \phi_k(0) \right] + \sum_{k=1}^{\infty} e^{ik\gamma} q_k [\phi_k(\lambda) - \phi_k(0)] + \sum_{k=1}^{\infty} (e^{ik\gamma} - 1) q_k \phi_k(0). \tag{2.18}$$

When $\phi(0)$ is an HBS we have

$$f_\phi(\lambda) = i\gamma \sum_{k=1}^{\infty} k q_k \phi_k(0) + \sum_{k=1}^{\infty} e^{ik\gamma} q_k [\phi_k(\lambda) - \phi_k(0)]$$

$$+ \sum_{k=1}^{\infty} (e^{ik\gamma} - 1 - ik\gamma) q_k \phi_k(0). \tag{2.19}$$

In both cases we need estimates on the differences $\phi_k(\lambda) - \phi_k(0)$. The difficult case is when ϕ is an HBS and we consider this estimate first.

From (2.5) and (2.17a) we have that for $n \geqq 1$,

$$\phi_n(\lambda) - \phi_n(0) = \left[\frac{\gamma}{\sin \gamma} - 1 \right] \phi_n(0) + \frac{\gamma}{\sin \gamma} D(\lambda) \tag{2.20}$$

where

$$
\begin{aligned}
D(\lambda) &= \frac{\sin\gamma}{\gamma}\phi_n(\lambda) - \phi_n(0) \\
&= \left[\frac{\sin n\gamma}{\gamma} - n\right]\left[1 + \sum_{k=1}^{n-1} q_k\phi_k(0)\right] \\
&\quad + \sum_{k=1}^{n-1} \gamma^{-1}\sin(n-k)\gamma\, q_k[\phi_k(\lambda) - \phi_k(0)] \\
&\quad + \sum_{k=1}^{n-1} \gamma^{-1}[-\sin n\gamma + k\gamma + \sin(n-k)\gamma] q_k\phi_k(0).
\end{aligned} \tag{2.21}
$$

For the sine function we have for some constant c,

$$
|\sin z - z| \leqq c|z|g(|z|)\, e^{\mathcal{I}z}, \qquad |\cos z - 1| \leqq cg(|z|)\, e^{\mathcal{I}z} \tag{2.22}
$$

on $\mathcal{I}z \geqq 0$, where $g(t) = t^2/(1+t^2)$. Also, for $\mathcal{I}\gamma \geqq 0$,

$$
|-\sin n\gamma + k\gamma + \sin(n-k)\gamma| = \left|\gamma \int_{n-k}^{n} [1-\cos\gamma t]\, dt\right| \leqq c|\gamma| kg(n|\gamma|)\, e^{\mathcal{I}n\gamma} \tag{2.23}
$$

by application of (2.22). Also by application of (2.22) and $g(t) \leqq 1$ we have

$$
\left|\frac{\sin n\gamma}{\gamma} - n\right| \leqq cng(n|\gamma|)\, e^{\mathcal{I}n\gamma}, \tag{2.24}
$$

$$
\left|\frac{\sin(n-k)\gamma}{\gamma}\right| \leqq n + cn\, e^{\mathcal{I}(n-k)\gamma} \leqq n(1+c)\, e^{\mathcal{I}n\gamma}. \tag{2.25}
$$

Define $\tilde{\phi}_n(\lambda) = e^{in\gamma}\phi_n(\lambda)$ and $\tilde{\phi}_n(0) = e^{in\gamma}\phi_n(0)$. Further note that for λ sufficiently small, $\lambda \in \mathbb{C}\backslash[0,4]$, we have for some constant c_1,

$$
|\gamma^{-1}\sin\gamma| \leqq c_1, \qquad |\gamma(\sin\gamma)^{-1} - 1| \leqq c_1|\gamma|^2. \tag{2.26}
$$

Multiplying (2.20) by $e^{in\gamma}$ and using (2.23)–(2.26) gives that

$$
\begin{aligned}
|\tilde{\phi}_n(\lambda) - \tilde{\phi}_n(0)| &\leqq c_1|\gamma|^2|\tilde{\phi}_n(0)| + c_1 cng(n|\gamma|)\left|1 + \sum_{k=1}^{n-1} q_k\phi_k(0)\right| \\
&\quad + c_1 \sum_{k=1}^{n-1} n(1+c)|q_k||\tilde{\phi}_k(\lambda) - \tilde{\phi}_k(0)| \\
&\quad + c_1 \sum_{k=1}^{n-1} ckg(n|\gamma|)|q_k||\tilde{\phi}_k(0)|.
\end{aligned} \tag{2.27}
$$

Suppose now $\phi(0)$ is an HBS. Then $\{\tilde{\phi}_n(0)\}$ is bounded and from (2.27) there is a constant d_1, independent of λ, such that (recall that $n[1+\sum_{k=1}^{n-1} q_k\phi_k(0)]$ is bounded from (2.17a))

$$
|\tilde{\phi}_n(\lambda) - \tilde{\phi}_n(0)| \leqq d_1\left\{|\gamma|^2 + g(n|\gamma|) + n\sum_{k=1}^{n-1} |q_k||\tilde{\phi}_k(\lambda) - \tilde{\phi}_k(0)|\right\}. \tag{2.28}
$$

To solve (2.28), let $\alpha_n = \sum_{k=1}^{n} |q_k||\tilde{\phi}_k(\lambda) - \tilde{\phi}_k(0)|$ for $n \geqq 1$. Then

$$
\alpha_n - \alpha_{n-1} = |q_n||\tilde{\phi}_n(\lambda) - \tilde{\phi}_n(0)| \leqq a_n + b_n\alpha_{n-1}
$$

where $a_n = |q_n|d_1[|\gamma|^2 + g(n|\gamma|)]$ and $b_n = d_1 n|q_n|$. Hence

$$
\alpha_n \leqq a_n + (1+b_n)\alpha_{n-1},
$$

and it follows by induction since $\alpha_1 = 0$ that for $n \geqq 2$,

$$\alpha_n \leqq a_n + \sum_{k=2}^{n-1} a_k(1+b_{k+1}) \cdots (1+b_n).$$

Since $(1+b_k) \leqq e^{b_k}$, it follows that

$$\alpha_n \leqq c_2 \sum_{k=1}^{n} a_k, \qquad c_2 = \exp\left\{ d_1 \sum_{n=1}^{\infty} n|q_n| \right\}$$

and thus

$$|\tilde{\phi}_n(\lambda) - \tilde{\phi}_n(0)| \leqq d_1 \left\{ |\gamma|^2 + g(n|\gamma|) + c_2 n \sum_{k=1}^{n-1} a_k \right\}. \tag{2.29}$$

We return now to (2.19). Using (2.29), we obtain

$$\left| \sum_{k=1}^{\infty} e^{ik\gamma} q_k [\phi_k(\lambda) - \phi_k(0)] \right| \leqq \sum_{k=1}^{\infty} |q_k| |\tilde{\phi}_k(\lambda) - \tilde{\phi}_k(0)|$$

$$\leqq d_1 \sum_{k=1}^{\infty} |q_k| [|\gamma|^2 + g(k|\gamma|)] + d_1 c_2 \sum_{k=1}^{\infty} k|q_k| \sum_{s=1}^{k} a_s.$$

The sum

$$\sum_{k=1}^{\infty} |q_k| q(k|\gamma|) = |\gamma| \sum_{k=1}^{\infty} (k|q_k|) \frac{k|\gamma|}{1+k^2|\gamma|^2} = o(|\gamma|)$$

as $|\gamma| \to 0$ by the Lebesgue dominated convergence theorem. The sum

$$\sum_{k=1}^{\infty} k|q_k| \sum_{s=1}^{k} a_s \leqq \sum_{s=1}^{\infty} d_1 |q_s| [|\gamma|^2 + g(s|\gamma|)] \sum_{k=1}^{\infty} k|q_k| = o(|\gamma|)$$

as $|\gamma| \to 0$ for the same reason. Hence

$$\sum_{k=1}^{\infty} e^{ik\gamma} q_k [\phi_k(\lambda) - \phi_k(0)] = o(|\gamma|)$$

as $|\gamma| \to 0$. Since $\mathcal{I}\gamma > 0$,

$$|e^{ik\gamma} - 1 - ik\gamma| \leqq d \frac{k^2|\gamma|^2}{1+k|\gamma|}$$

for some constant d independent of γ. Again by the Lebesgue dominated convergence theorem, as $|\gamma| \to 0$,

$$\sum_{k=1}^{\infty} (e^{ik\gamma} - 1 - ik\gamma) q_k \phi_k(0) = o(|\gamma|).$$

Substituting these estimates into (2.19) yields (2.15) for $\lambda = 0$ an HBS, as $\lambda \to 0$.

For $\lambda = 0$ not an HBS, then equation (2.28) is replaced by

$$|\tilde{\phi}_n(\lambda) - \tilde{\phi}_n(0)| \leqq d_1 \left\{ |\gamma|^2 + ng(n|\gamma|) + n \sum_{k=1}^{n-1} |q_k| |\tilde{\phi}_k(\lambda) - \tilde{\phi}_k(0)| \right\}.$$

An analysis like that above applied to (2.18) shows that as $\lambda \to 0$, (2.16) holds. This completes the proof of Theorem 2.1.

Remarks. A similar analysis applies to the solution $\theta(\lambda)$ at $\lambda = 0$, and we omit the details. The result is if $\theta(0)$ is an HBS, then as $\lambda \to 0$,

$$f_\theta(\lambda) = i a_\theta^{(1)} \gamma + o(|\gamma|), \qquad a_\theta^{(1)} = -1 + \sum_{k=1}^{\infty} k q_k \theta_k(0) \neq 0 \tag{2.30}$$

while if $\theta(0)$ is not an HBS, then

$$f_\theta(\lambda) = a_\theta^{(0)} + o(1), \qquad a_\theta^{(0)} = \sum_{k=1}^{\infty} q_k \theta_k(\lambda) \neq 0. \tag{2.31}$$

Note that as $\lambda \to 0$, series expansions of $i\gamma = \log \tau \approx (\tau - 1)$ and $-\lambda = (\tau - 1) + (\tau^{-1} - 1) \approx (\tau - 1)^2$ show that $\gamma/\sqrt{\lambda} \to 1$ as $\lambda \to 0$ in $\mathbb{C}\backslash[0, 4]$. Thus γ may be replaced by $\sqrt{\lambda}$ in the equations (2.15)-(2.16) and (2.30)-(2.31) where $\sqrt{\lambda}$ denotes the branchcut along the positive real axis. At $\lambda = 4$, the same analysis as above holds where γ is replaced in (2.15)-(2.16) and (2.30)-(2.31) by $\sqrt{\lambda - 4}$ and the branchcut for $\sqrt{}$ is along the negative real axis.

We are now ready to state Levinson's theorem for (1.1)-(1.3), and we do so for the general operator T_α. Let $y_\alpha(\lambda)$ be the solution of (1.1) satisfying $y_0 = -\alpha$ and $y_1 = 1$. Then $y_\alpha(\lambda) = \{y_n(\lambda)\}$ satisfies (1.2); furthermore, $y_\alpha(\lambda) = -\alpha\theta(\lambda) + (1+\alpha)\phi(\lambda)$ and $e^{in\gamma} y_n(\lambda) \to (1+\alpha) f_\phi(\lambda) - \alpha f_\theta(\lambda)$ as $n \to \infty$ for $\lambda \in \mathbb{C}\backslash[0, 4]$. Inspection of the bound (2.9) for $\phi(\lambda)$, and analogously for $\theta(\lambda)$, shows that the bound holds as $\lambda \to \lambda_0 \in (0, 4)$, $\mathcal{I}\lambda \neq 0$. Since the $\phi_k(\lambda)$ and $\theta_k(\lambda)$ are polynomials in λ, this means that the formulas (2.12) have a continuous extension from $\mathcal{I}\lambda > 0$ to include the interval $(0, 4)$.

Recall from the discussion above equations (2.15) that $f_\phi(\lambda) \to 1$ as $|\lambda| \to \infty$, $\lambda \in \mathbb{C}\backslash[0, 4]$.

THEOREM 2.2. *Let $f_\alpha(\lambda) = (1+\alpha) f_\phi(\lambda) - \alpha f_\theta(\lambda)$. Under the condition* (1.3), *the number N of eigenvalues of T_α is given by*

$$2\pi N = 2[\arg f_\alpha(4) - \arg f_\alpha(0)] + \Delta_0 + \Delta_4$$

where $f_\alpha(4)$, $f_\alpha(0)$ is the limiting argument of $f_\alpha(\lambda)$ as $\lambda \to 4$, 0, respectively, in $(0, 4)$ *($f_\alpha(\lambda)$ in* $(0, 4)$ *is the continuous extension of $f_\alpha(\lambda)$ from $\mathcal{I}\lambda > 0$) and*

$$\Delta_j = \begin{cases} -\pi & y_\alpha \text{ has an HBS at } j = \lambda, \\ 0 & y_\alpha \text{ does not have an HBS at } j = \lambda. \end{cases}$$

Proof. For simplicity we consider the $\alpha = 0$ case; the general proof is similar. We apply the argument to the contour $\Gamma = \Gamma_1 + \Gamma_2$, where Γ_1 is a circle about the origin of radius R, and Γ_2 consists of two circles of radius ε about $\lambda = 0, 4$ and joined by two intervals above and below the slit $0 < \lambda < 4$; orientation of Γ_1 and Γ_2 is counterclockwise. Since T_0 is bounded, for R sufficiently large, all eigenvalues are interior to Γ_1. Also the eigenvalues are exterior to Γ_2 for ε sufficiently small. The eigenvalues, which are zeros of $f_\phi(\lambda)$, must be finite in number, i.e., cannot have zero or four as an accumulation point, by the asymptotics (2.15)-(2.16). Let S_ε be the circle of radius ε at zero. By the asymptotics (2.15)-(2.16), with γ replaced by $\sqrt{\lambda}$, it is clear that [*change of argument in $f_\phi(\lambda)$ on S_ε*] $\to \pi$ or 0 as $\varepsilon \to 0$ according to whether or not $\phi(0)$ is an HBS. Similar calculations apply at $\lambda = 4$. By the argument principle

$$2\pi N = \int_{\Gamma_1} \frac{f_\phi'(\lambda)}{f_\phi(\lambda)}\, d\lambda - \int_{\Gamma_2} \frac{f_\phi'(\lambda)}{f_\phi(\lambda)}\, d\lambda.$$

Since $f_\phi(\lambda) \to 1$ as $\lambda \to \infty$, $\int_{\Gamma_1} f_\phi'/f_\phi \to 0$ as $R \to \infty$. Letting $R \to \infty$ as $\varepsilon \to 0$ completes the proof by recalling $f_\phi(\lambda)$ is analytic on $\mathbb{C}\backslash[0, 4]$ with $f_\phi(\bar{\lambda}) = \overline{f_\phi(\lambda)}$.

A simple example is obtained by taking one q_n nonzero, say $q_m \neq 0$ and $q_n = 0$ for $n \neq m$. Then from (2.12) we have

$$f_\phi(\lambda) = 1 + e^{im\gamma} q_m \phi_m(\lambda) = 1 + e^{im\gamma} q_m \sin m\gamma / \sin \gamma.$$

So for $\alpha = 0$ in (1.2), the eigenvalues of (1.1)-(1.2) are the solutions of $f_\phi(\lambda) = 0$. For

$m=1$ this is the simple equation $1+e^{i\gamma}q_1=1+\tau q_1=0$ or $\tau=-1/q_1$. Since $|\tau|<1$ we have a single eigenvalue given by $\lambda=2-\tau-1/\tau=2+q_1+1/q_1$ when $|q_1|>1$.

The asymptotics (2.15)-(2.16) may be substituted into (2.14) to yield asymptotics for $m(\lambda)$ at an endpoint of the essential spectrum. At $\lambda=0$ we obtain that as $\lambda\to 0$,

$$m(\lambda)\sim\begin{cases}-a_\theta^{(0)}/a_\phi^{(0)} & \text{neither } \phi(0) \text{ nor } \theta(0) \text{ an HBS},\\ -a_\theta^{(0)}/(ia_\phi^{(1)}\sqrt{\lambda}) & \phi(0) \text{ an HBS},\\ -ia_\theta^{(1)}\sqrt{\lambda}/a_\phi^{(0)} & \theta(0) \text{ an HBS}.\end{cases}$$

3. An application. In this section we consider the effect of half-bound states on the large-t asymptotics of a spring-mass system. Such a system is described by displacements $u_n(t)$ of the nth mass, where

$$M_n\ddot{u}_n=u_{n+1}-2u_n+u_{n-1},\quad n=1,2,\cdots,\quad \ddot{u}=d^2u/dt^2 \tag{3.1}$$

with $u_0\equiv 0$. Physically this represents a semi-infinite linear chain of springs (with spring constants equal to 1) and masses M_n where the first mass u_0 is attached on the left to a wall. The horizontal displacement at time t of the mass M_k from its rest position is $u_k(t)$. Let H denote the operator $(Hy)_n=y_{n+1}-2y_n+y_{n-1}$, $y_0=0$, $n=1,2,\cdots$, and let M be the operator $(My)_n=M_ny_n$. Assume $M_n=1+\delta_n$, where $\delta_n>-1$, and

$$\sum_{n=1}^{\infty} n|\delta_n|<\infty. \tag{3.2}$$

In l_2, H is the self-adjoint operator $-T_0$ where T_0 is as in § 2. Then H has continuous spectrum on $[-4,0]$. Let $l_{2,M}$ be the Hilbert space of sequences with inner product $\langle\{y_n\},\{z_n\}\rangle_M=\langle\{y_n\},M\{z_n\}\rangle$ where $\langle\cdot,\cdot\rangle$ is the inner product in l_2. Under (3.2) the norm $l_{2,M}$ is equivalent to the norm in l_2, and the operator

$$A=-M^{-1}H \tag{3.3}$$

is a bounded self-adjoint operator in $l_{2,M}$; furthermore, $A\geqq 0$, so $A^{1/2}$ exists. Since (3.1) is the same as $\ddot{u}+Au=0$, it can be solved by [10]

$$u(t)=(\cos A^{1/2}t)u(0)+(A^{-1/2}\sin A^{1/2}t)\dot{u}(0) \tag{3.4}$$

where $u(0)$ and $\dot{u}(0)$ denote the initial values. For simplicity we assume that

$$\dot{u}(0)=\{0\},\quad u(0)=\{\delta_{ns}\},\quad \delta_{ns}=\text{Kronecker delta}, \tag{3.5}$$

for some fixed s. Let $a^{(m)}$ denote the vectors with components $a_n^{(m)}=M_m^{-1}\delta_{nm}$, and let E_λ denote the spectral family for A in $l_{2,M}$. Then we have

$$u_m(t)=\langle a^{(m)},u(t)\rangle_M=\int_0^\infty \cos\sqrt{\lambda}\,t\,d_\lambda\langle a^{(m)},E_\lambda u(0)\rangle_M. \tag{3.6}$$

By Stone's formula, for a closed λ-interval Δ,

$$\langle h,E_\Delta g\rangle_M=\lim_{\varepsilon\to 0}\frac{1}{2\pi i}\int_\Delta\langle h,[(A-(\mu+i\varepsilon))^{-1}-(A-(\mu-i\varepsilon))^{-1}]g\rangle_M\,d\mu. \tag{3.7}$$

The resolvent of A can be constructed as follows. If $\Im\lambda\neq 0$ and

$$(A-\lambda)y=g, \tag{3.8}$$

then

$$(-H-\lambda\delta-\lambda)y=Mg \tag{3.9}$$

where δ is multiplication by δ_n in each component. The results of § 2 carry over in that the solution $\phi(\lambda)$ of the homogeneous equation (3.9) ($g=0$) is given by (2.5) with q_n replaced by $-\lambda\delta_n$. That is, we have

$$\phi_n(\lambda)=\frac{\sin n\gamma}{\gamma}-\sum_{k=1}^{n-1}\frac{\sin(n-k)\gamma}{\sin\gamma}\lambda\delta_k\phi_k(\lambda). \tag{3.10}$$

Also from (2.12),

$$f_\phi(\lambda)=1-\lambda\sum_{k=1}^{\infty}e^{ik\gamma}\delta_k\phi_k(\lambda). \tag{3.11}$$

The Jost solution $F(\lambda)$ of the homogeneous equation (3.9), i.e., the solution satisfying $F_n(\lambda)=e^{in\gamma}+o(1)$ as $n\to\infty$, may be calculated by the variation of constants formula to satisfy

$$F_n(\lambda)=e^{in\gamma}+\sum_{k=n+1}^{\infty}\frac{\sin(n-k)\gamma}{\sin\gamma}\lambda\delta_kF_k(\lambda). \tag{3.12}$$

Using the solutions $\phi(\lambda)$ and $F(\lambda)$ as a basis, we use variation of constants to solve (3.9), obtaining

$$y_n=-\phi_n(\lambda)W(\lambda)^{-1}\sum_{k=n}^{\infty}F_k(\lambda)M_kg_k-F_n(\lambda)W(\lambda)^{-1}\sum_{k=1}^{n-1}\phi_k(\lambda)M_kg_k \tag{3.13}$$

where $W(\lambda)$ is the Wronskian (independent of n),

$$W(\lambda)=\phi_n(\lambda)F_{n+1}(\lambda)-\phi_{n+1}(\lambda)F_n(\lambda). \tag{3.14}$$

Using $\phi_n(\lambda)=e^{-in\gamma}(2i\sin\gamma)^{-1}[f_\phi(\lambda)+o(1)]$ and $F_n(\lambda)=e^{in\gamma}[1+o(1)]$ as $n\to\infty$ gives that $W(\lambda)=-f_\phi(\lambda)$. Also note that $W(\lambda)=-F_0(\lambda)$. Suppose now that $\lambda\to\mu\pm i0$ with $0\leqq\mu\leqq4$. Using $F_n(\mu-i0)=\overline{F_n}(\mu+i0)$, $\phi_n(\mu-i0)=\phi_n(\mu+i0)$ (recall $\phi_n(\lambda)$ is a polynomial in λ [1, p. 97]) and $W(\mu-i0)=\bar{W}(\mu+i0)$, we have from (3.13) that

$$\begin{aligned}([(A-\lambda-i0)^{-1}-(A-\lambda+i0)^{-1}]g)_n&=-\phi_n(\mu)\sum_{k=n}^{\infty}\left[\frac{F_k(\mu)}{W(\mu)}-\frac{\overline{F_k}(\mu)}{\bar{W}(\mu)}\right]M_kg_k\\&\quad-\left[\frac{F_n(\mu)}{W(\mu)}-\frac{\overline{F_n}(\mu)}{\bar{W}(\mu)}\right]\sum_{k=1}^{n-1}\phi_k(\mu)M_kg_k\\&=\frac{2i\sin\gamma}{|W(\mu)|^2}\phi_n(\mu)\sum_{k=1}^{\infty}\phi_k(\mu)M_kg_k\end{aligned} \tag{3.15}$$

since by (3.14) and a calculation,

$$\begin{aligned}\bar{W}(\mu)F_n(\mu)-W(\mu)\overline{F_n}(\mu)&=\phi_n(\mu)[\bar{F}_{n+1}(\mu)F_n(\mu)-F_{n+1}(\mu)\overline{F_n}(\mu)]\\&=-2i\phi_n(\mu)\sin\gamma.\end{aligned}$$

The last equality follows from letting $n\to\infty$ in the Wronskian $\bar{F}_{n+1}(\mu)F_n(\mu)-F_{n+1}(\mu)\overline{F_n}(\mu)$ and using (3.12). For $\mu>4$, $f_\phi(\mu)$ is real and the arguments of § 2 show that the spectrum of A on $(4,\infty)$ consists of at most finitely many eigenvalues. Substitution of (3.15) into (3.7) for $0\leqq\lambda\leqq4$ gives

$$\langle h,E_\lambda g\rangle_M=\int_0^\lambda\frac{\sin\gamma}{\pi|W(\mu)|^2}\sum_{k=1}^{\infty}h_kM_k\phi_k(\mu)\sum_{k=1}^{\infty}g_kM_k\phi_k(\mu)\,d\mu$$

and thus (3.6) becomes

$$u_m(t) = M_s \int_0^4 \cos\sqrt{\lambda}\, t\, (\pi|W(\lambda)|^2)^{-1} \sin\gamma\phi_m(\lambda)\phi_s(\lambda)\, d\lambda + M_s \sum_{k=1}^{N} \cos\sqrt{\lambda_k}\, t\, \phi_s(\lambda_k)\phi_m(\lambda_k)\|\phi(\lambda_k)\|_M^{-2} \tag{3.16}$$

where the sum represents the contribution due to the possible eigenvalues in $(4, \infty)$ in (4.8). Below we will show that this sum never vanishes for any m and s when eigenvalues are present. First we determine the large-t asymptotics of the integral on the right of (3.16). In the following we only consider the case where $\{\delta_n\}$ has finite support, i.e.,

$$\delta_n = 0 \quad \text{for } n > N, \tag{3.17}$$

for some $N \geqq 1$.

Note that $\lambda = 0$ is not an HBS since $\phi_n(0) = n$. However $\lambda = 4$ may be an HBS and the analysis of § 2 shows that $W(\lambda) = -f_\phi(\lambda) \to W(4) \neq 0$ if $\lambda = 4$ is not an HBS and $(\lambda - 4)^{-1/2} W(\lambda) \to C \neq 0$ if $\lambda = 4$ is an HBS.

First suppose that $\lambda = 4$ is not an HBS. Suppose also that $\phi_m(4)\phi_s(4) \neq 0$. Let η_1, η_2 be nonnegative C^∞ functions such that $\eta_1(x) + \eta_2(x) = 1$, $\eta_1(x) = 1$ in a neighborhood of zero, and $\eta_1(x) = 0$ in a neighborhood of 4. Then $u_m(t) = I_1(t) + I_2(t)$ in (3.16), where

$$I_k(t) = M_s \int_0^4 \cos\sqrt{\lambda}\, t\, (\pi|W(\lambda)|^2)^{-1} \sin\gamma\, \phi_m(\lambda)\phi_s(\lambda)\eta_k(\lambda)\, d\lambda. \tag{3.18}$$

In I_1 put $u = \sqrt{\lambda}$ so that

$$\sin\gamma = \frac{(\tau - \tau^{-1})}{2i} = \frac{(\lambda^2 - 4\lambda)^{1/2}}{2i} = \frac{u(4-u^2)^{1/2}}{2}. \tag{3.19}$$

Then I_1 is of the form (for a certain function g)

$$I_1(t) = \int_0^2 (\cos ut) u^2 \eta_1(u^2) g(u)\, du. \tag{3.20}$$

Under condition (3.17), it follows from (3.11) and (3.19) that $W(u^2)$ is C^∞, in fact analytic, for $0 \leqq u < 2$. This allows us to integrate by parts twice in (3.20) with the result that $I_1(t) = O(t^{-2})$ as $t \to \infty$.

In $I_2(t)$ put $u = \sqrt{\lambda}$ again to obtain I_2 of the form

$$I_2(t) = \int_0^2 (\cos ut)(2-u)^{1/2} \eta_2(u) h(u)\, du \tag{3.21}$$

where $h(2) \neq 0$, because $\phi_m(4)\phi_s(4) \neq 0$ and h is C^∞ under (3.17). The substitution $s = 2 - u$ gives

$$I_2(t) = \int_0^2 (\cos(2-s)t) s^{1/2} g(s)\, ds, \qquad g(s) = \eta_2(2-s)h(2-s),$$

which after integration by parts reduces to

$$I_2(t) = \int_0^2 t^{-1}(\sin(2-s)t)(2^{-1}s^{-1/2}g(s) + s^{1/2}g'(s))\, ds. \tag{3.22}$$

In (3.22) write $g(s)=g(0)+s\tilde{g}(s)$ and then integrate by parts the terms with $\tilde{g}$ and g'. This gives

$$I_2(t)=\int_0^2 t^{-1}(\sin(2-s)t)2^{-1}s^{-1/2}g(0)\,ds+O(t^{-2})$$
$$=\left(\frac{1}{2t}\right)g(0)\left[\sin 2t\int_0^2 s^{-1/2}\cos st\,ds-\cos 2t\int_0^2 s^{-1/2}\sin st\,ds\right]+O(t^{-2}).$$

Since

$$\int_0^2 s^{-1/2}\cos st\,ds=t^{-1/2}\int_0^{2t} w^{-1/2}\cos w\,dw$$
$$=t^{-1/2}\left[\int_0^{\infty} w^{-1/2}\cos w\,dw-\int_{2t}^{\infty} w^{-1/2}\cos w\,dw\right]$$
$$=t^{-1/2}\left[\left(\frac{\pi}{2}\right)^{1/2}+O(t^{-1/2})\right]$$

with a similar expression for $\int_0^2 s^{-1/2}\sin st\,ds$, we have that

$$I_2(t)=\frac{g(0)\pi^{1/2}}{2t^{3/2}}\sin\left(2t-\frac{\pi}{4}\right)+O(t^{-2}),\qquad g(0)\neq 0, \tag{3.23}$$

as $t\to\infty$.

Now suppose $\lambda=4$ is an HBS. Then near $\lambda=4$, $W(\lambda)$ is of the form $|W(\lambda)|^2=\alpha|\lambda-4|+o(\lambda-4)$, $\alpha\neq 0$. Near $\lambda=0$ the situation is the same as in the non-HBS case and $I_1(t)=O(t^{-2})$ under (3.17). For I_2 however, we get in place of (3.21),

$$I_2(t)=\int_0^2(\cos ut)(2-u)^{-1/2}\eta_2(u)h(u)\,du$$

where again $h(2)\neq 0$ if $\phi_m(4)\phi_s(4)\neq 0$. With $s=2-u$ and $h(2-s)=h(2)+\tilde{h}(s)$ an analysis as in the non-HBS case shows that as $t\to\infty$

$$I_2(t)=h(2)\left[\cos 2t\int_0^2 s^{-1/2}\cos st\,ds+\sin 2t\int_0^2 s^{-1/2}\sin st\,ds\right]+O(t^{-1})$$
$$=\frac{h(2)\pi^{1/2}}{t^{1/2}}\sin\left(2t+\frac{\pi}{4}\right)+O(t^{-1}),\qquad h(2)\neq 0. \tag{3.24}$$

In both cases $u_m(t)\sim I_2(t)$ as $t\to\infty$.

The case where $\phi_m(4)\phi_s(4)=0$ can be handled in a similar manner. First note that $\phi_n(\lambda)$ is a polynomial and its zeros are simple [1, p. 100]. Thus $\phi_m(\lambda)\phi_s(\lambda)$ is $O(4-\lambda)$ or $O((4-\lambda)^2)$ near 4. Then two more integrations by parts are possible in $I_1(t)$ to show that $I_1(t)=O(t^{-4})$. The integral I_2 has the form

$$I_2(t)=\int_0^2(\cos ut)(2-u)^p\eta_2(u)h(u)\,du,\qquad p=\frac{3}{2}\text{ or }\frac{5}{2}, \tag{3.25}$$

in the non-HBS case and

$$I_2(t)=\int_0^2(\cos ut)(2-u)^p\eta_2(u)h(u)\,du,\qquad p=\frac{1}{2}\text{ or }\frac{3}{2}, \tag{3.26}$$

in the HBS case. This implies that $I_2(t)\sim t^{-5/2}$ or $I_2(t)\sim t^{-7/2}$ in the non-HBS case and that $I_2(t)\sim t^{-3/2}$ or $I_2(t)\sim t^{-5/2}$ in the HBS case. Again the large-t asymptotics of $u_m(t)$ are determined by $I_2(t)$.

We now know in what ways the continuous spectrum may affect the large-t asymptotics of $u_m(t)$. In the following discussion we make our results more precise. For this we need a lemma. Its proof uses an idea from [13].

LEMMA 3.1. (a) *Suppose A has $N \geqq 1$ eigenvalues in $(4, \infty)$ and let λ_1 denote the largest such eigenvalue. Then*

$$(-1)^{n+1}\phi_n(\lambda_1) > 0, \qquad n = 1, 2, \cdots. \tag{3.27}$$

(b) *Suppose A has no eigenvalue in $(4, \infty)$. Then*

$$(-1)^{n+1}\phi_n(4) > 0, \qquad n = 1, 2, \cdots. \tag{3.28}$$

Proof. Put $w(t) = e^{At}w(0)$ where $w(0) = \{\delta_{ns}\}$ (see (3.5)). Let $a^{(m)}$ be as in (3.6) so that $w_m(t) = \langle a^{(m)}, w(t)\rangle_M$. We proceed to determine the large-t behavior of $w_m(t)$. Of course, this can be done by essentially repeating the steps following (3.6) but with $\cos\sqrt{\lambda}\, t$ replaced by $e^{\lambda t}$. We therefore omit the details and just state the results. In case (a) we have

$$w_m(t) \sim M_s\, e^{\lambda_1 t}\phi_s(\lambda_1)\phi_m(\lambda_1)\|\phi(\lambda_1)\|_M^{-2}, \qquad t \to \infty, \tag{3.29}$$

again provided $\phi_s(\lambda_1)\phi_m(\lambda_1) \neq 0$. Now we introduce the unitary (in $l_{2,M}$) transformation $(Uy)_n = (-1)^n y_n$, and let $\tilde{A} = UAU^{-1}$. Then

$$(\tilde{A}y)_n = M_n^{-1}(y_{n+1} + 2y_n + y_{n-1}) \qquad (y_0 = 0). \tag{3.30}$$

Moreover,

$$w_m(t) = \langle a^{(m)}, w(t)\rangle_M = \langle Ua^{(m)}, e^{\tilde{A}t}Uw(0)\rangle_M = (-1)^{m+s}\langle a^{(m)}, e^{\tilde{A}t}w(0)\rangle_M. \tag{3.31}$$

It is clear from (3.30) that $\tilde{A}$ leaves invariant the cone of vectors with nonnegative components. Thus $\langle a^{(m)}, e^{\tilde{A}t}w(0)\rangle_M \geqq 0$ for $t > 0$ (in fact, we have strict inequality since $e^{\tilde{A}t}y$ has strictly positive components if y has nonnegative ones). Put $s = 1$, then $\phi_s(\lambda_1) = 1$, and compare (3.31) and (3.29). Clearly, if $\phi_m(\lambda_1) \neq 0$ then $(-1)^{m+1}\phi_m(\lambda_1) > 0$. If $\phi_m(\lambda_1) = 0$ then $\phi_{m-1}(\lambda_1) = -\phi_{m+1}(\lambda_1)$ $(\neq 0)$ since $A\phi = \lambda_1\phi$ and so $(-1)^m\phi_{m-1}(\lambda_1) = (-1)^{m+1}\phi_{m+1}(\lambda_1) = -(-1)^{m+2}\phi_{m+1}(\lambda_1) < 0$, a contradiction. In other words, $\phi_m(\lambda_1) = 0$ is impossible. This proves (3.27).

In case (b) we find that

$$w_m(t) \sim c_1\phi_m(4)\phi_s(4)t^{-3/2}\, e^{4t}, \quad \lambda = 4 \text{ is an HBS} \tag{3.32}$$

and

$$w_m(t) \sim c_2\phi_m(4)\phi_s(4)t^{-1/2}\, e^{4t} \qquad \lambda = 4 \text{ is not an HBS} \tag{3.33}$$

where $c_1, c_2 > 0$. Comparing (3.32) and (3.33) with (3.31) and arguing as in part (a) yields (3.28). Lemma 3.1 is proved.

The important conclusion from this lemma is that $\phi_n(\lambda_1)$ and $\phi_n(4)$ do not vanish in the situations described in part (a) and (b), respectively. Therefore we can say the following.

THEOREM 3.2. *Suppose* (3.5) *and* (3.17) *hold. Then*:

(a) *If A has $N \geqq 1$ eigenvalues $4 < \lambda_N < \cdots < \lambda_1$, then*

$$u_m(t) = \sum_{k=1}^{N} c_k \cos\sqrt{\lambda_k}\, t + \varepsilon_m(t) \tag{3.34}$$

*where $c_1 \neq 0$ and $\varepsilon_m(t) = O(t^{-3/2})$ in the non-*HBS *case and $\varepsilon_m(t) = O(t^{-1/2})$ in the* HBS *case.*

(b) *If A has no eigenvalues, then*

$$u_m(t) = \alpha_1 t^{-3/2} \sin\left(2t - \frac{\pi}{4}\right) + O(t^{-2}), \qquad \alpha_1 \neq 0, \tag{3.35}$$

*in the non-*HBS *case and*

$$u_m(t) = \alpha_2 t^{-1/2} \sin\left(2t - \frac{\pi}{4}\right) + O(t^{-1}), \qquad \alpha_2 \neq 0, \tag{3.36}$$

in the HBS *case.*

As an example, let $\delta_n = (\mu - 1)\delta_{nm}$ in (3.1). Then by direct calculation, or letting $\gamma \to \pi$ in (3.10), we have

$$\phi_n(4) = (-1)^{n+1} n, \qquad n \leqq m,$$

$$\begin{aligned}\phi_n(4) &= (-1)^{n+1} n - (-1)^{n-m+1}(n-m)4(\mu-1)(-1)^{m+1} m \\ &= (-1)^{n+1}(n + 4(n-m)m(\mu-1)), \qquad n > m.\end{aligned}$$

Thus we have an HBS at $\lambda = 4$ if $4m(\mu - 1) = -1$, i.e., $M_m = \mu = 1 - 1/4m$. Then $\phi_n(4) = (-1)^{n+1} n$ for $n \leqq m$ and $\phi_n(4) = (-1)^{n+1} m$ for $n > m$. Also from (3.11)

$$\begin{aligned}f_\phi(\lambda) &= 1 - \lambda(\mu - 1)\, e^{im\gamma}(-1)^{m+1} m \\ &= 1 + (1-\mu)(\tau - 1)^2 (-1)^m m \tau^{m-1},\end{aligned}$$

using $\tau = e^{i\gamma}$ and $\lambda\tau = -(\tau - 1)^2$. As τ goes from -1 to 0, λ goes from 4 to ∞. Hence there is a zero of $f_\phi(\lambda)$ in $(4, \infty)$, i.e., eigenvalue, if $f_\phi(4) = 1 - 4m(1-\mu) < 0$ since $f_\phi(\infty) > 0$. Thus there is an eigenvalue if $\mu < 1 - 1/4m$. For $m = 1$ this happens if $M_1 < \frac{3}{4}$. For $M_1 = \frac{1}{2}$ we have $\phi_n(4) = (-1)^{n+1}(n - 2(n-1)) = (-1)^{n+1}(2 - n)$ for $n \geqq 2$. Thus $\phi_2(4) = 0$ indeed happens, but we also have an eigenvalue in this case.

The $t^{-1/2}$ decay of the oscillations of a single mass also occurs in (3.1) with $n = 0, \pm 1, \pm 2, \cdots$, i.e., a doubly infinite chain of masses and springs. With no perturbation terms, this system is solved exactly in [7, pp. 385-387] where the solution $u_n(t) = J_{2n}(2t)$, J_{2n} the $2n$th order Bessel function, also exhibits $t^{-1/2}$ time decay. This is to be expected since $\lambda = 4$ is an HBS for the full line unperturbed problem ($\phi_n(4) = (-1)^{n+1}$). We refer to Chapter III of [14, §§ 2.1-2.4] for a discussion of a similar problem in the continuous case.

Abstract. By using z-transforms it is proved that every solution of a homogeneous system of linear difference equations with constant coefficient matrices oscillates componentwise if and only if its characteristic equation has no positive roots. This result is also applied to obtain necessary and sufficient conditions for the oscillation of all solutions of a linear system with piecewise constant arguments.

Key words. oscillation, difference equations, equations with piecewise constant arguments

AMS(MOS) subject classification. 39A12

1. Introduction.

Consider the homogeneous system of linear difference equations with constant coefficient matrices

$$y_{n+k} + P_1 y_{n+k-1} + \cdots + P_k y_n = 0 \tag{1}$$

for $n = 0, 1, \cdots$ where k is some positive integer, the coefficients P_i are real $r \times r$ matrices, and $\{y_n\}_{n=0}^{\infty}$ is a sequence of points in $\mathbf{R}^r$.

We associate with (1) its characteristic equation

$$\det(\lambda^k I + \lambda^{k-1} P_1 + \cdots + P_k) = 0. \tag{2}$$

Our aim in this paper is to establish the following result and then apply it to obtain necessary and sufficient conditions for the oscillation of all solutions of a linear system with piecewise constant arguments.

THEOREM 1. *Let k be a positive integer and let $P_1, \cdots, P_k$ be real $m \times m$ matrices. Then the following are equivalent:*

(a) *Every solution $\{y_n\}_{n=0}^{\infty}$ of equation (1) oscillates.*

(b) *The characteristic equation (2) has no positive roots.*

A sequence of real numbers $\{r_n\}_{n=0}^{\infty}$ is said to *oscillate* if the terms r_n are not eventually positive or eventually negative. Otherwise the sequence is called *nonoscillatory.*

For scalar equations, Theorem 1 was stated and proved (for $k \leq 3$) in [15], the proof being based on a lengthy analysis of the solution space of (1). A simple proof for scalar equations with positive coefficients was given in [12]. See also [11] for several applications of this theorem to scalar equations.

Our proof of Theorem 1 uses the method of z-transforms, the discrete analogue of the Laplace transform which has been recently used in [3] and [8] to establish the continuous analogue of Theorem 1 for delay differential equations. For more information about z-transforms, see, e.g., [14].

2. Proof of Theorem 1. The proof of (a) $\Rightarrow$ (b) is simple. If (a) holds, (2) cannot have a positive root since if λ_0 were such a root then there would be a nonzero vector $\xi \in \mathbf{R}^m$ such that

$$(\lambda^k I + \lambda^{k-1}P_1 + \cdots + P_k)\xi = 0.$$

But then, $y_n = {\lambda_0}^n \xi$ is a solution of (1) with at least one nonoscillatory component.

The proof of (b) $\Rightarrow$ (a) uses the z-transform. Assume that (b) holds and, for the sake of contradiction, assume that (1) has a solution $y_n = [y_n^1, \cdots, y_n^r]^T$ with at least one nonoscillatory component. With no loss of generality we assume that $\{y_n^1\}$ is eventually positive. As (1) is autonomous, we will assume in fact that $y_n^1 > 0$ for $n \geq 0$.

Clearly, there exists a $c \in (0, \infty)$ such that $\| y_n \| < c^n$. Then the z-transform of $\{y_n\}$,

$$Y(z) = \sum_{n=0}^{\infty} y_n z^{-n}$$

exists for $|z| > c$. From (1) we find that

$$F(z)Y(z) = \Phi(z) \tag{3}$$

holds for $|z| > c$ where, with $P_0 = I$,

$$F(z) = \sum_{i=0}^{k} P_i z^{k-i} \tag{4}$$

and

$$\Phi(z) = \sum_{i=0}^{k} P_i \sum_{j=0}^{k-i-1} z^{k-i-j} y_j. \tag{5}$$

By hypothesis

$$\det[F(z)] \neq 0 \tag{6}$$

for $z \in (0, \infty)$.

Let $Y_1(z)$ be the z-transform of y_n^1 and let M be the modulus of the largest zero of $\det[F(z)]$. Then by Cramer's rule, for $|z| > \max\{c, M\}$,

$$\det[F(z)]Y_1(z) = \det[D(z)] \tag{7}$$

where $D(z)$ has components of $F(z)$ and $\Phi(z)$ as its entries. Clearly, the determinants in (7) are polynomials in z.

Let $W(z) = Y_1(1/z)$ so that $W(z)$ is a power series with positive coefficients having radius of convergence $\rho > 0$. Equation (7) holds for $|z| > 1/\rho$, equivalently, $\det[F(1/z)]W(z) = \det[D(1/z)]$ for $0 < |z| < \rho$. Now it is known (see, e.g.,[9, p. 133]) that a power series with positive coefficients having radius of convergence $\rho < \infty$ has a singularity (in the sense of analytic continuation) at $z = \rho$. But since $\det[F(1/\rho)] \neq 0$ we see that $\det[D(1/z)]/\det[F(1/z)]$ is analytic in a disk centered at ρ and agrees with $W(z)$ on that part of the disk where $|z| < \rho$. This contradiction shows that we

must have $\rho = \infty$ and it follows that (7) holds for $|z| > 0$. But then $y_n^1 = 0$ for all sufficiently large n since otherwise the left side of (7), but not the right side, would have an essential singularity at $z = 0$. This contradicts the assumption that $\{y_n^1\}$ is nonoscillatory and the proof is complete.

Remark 1. It can easily be seen that the conclusion of Theorem 1 is also true when k is a negative integer and $\det P_k \neq 0$.

Remark 2. It should be observed that we proved a little more than we stated in Theorem 1. Namely, if (1) has a solution $\{y_n\}$ with one component eventually zero, then the characteristic equation (2) has a real root.

3. Application to linear systems with piecewise constant arguments. Let $[\cdot]$ denote the greatest-integer function, $\mathbf{N}$ the set of nonnegative integers, and $\mathbf{R}^{r\times r}$ the set of all $r \times r$ matrices with real components.

In this section we will apply Theorem 1 to obtain necessary and sufficient conditions for the oscillation of all solutions of the system of linear differential equations with piecewise constant arguments

$$\dot{x}(t) + \sum_{j=-k}^{\ell} Q_j x([t+j]) = 0, \qquad t \geq 0 \tag{8}$$

where

$$k,\ \ell \in \mathbf{N} \quad \text{and} \quad Q_j \in \mathbf{R}^{r\times r} \quad \text{for} \quad j = -k, \cdots, \ell. \tag{9}$$

With (8) we associate initial conditions of the form

$$x(j) = a_j \quad \text{for} \quad j \in \{-k, \cdots, 0\} \cup \{0, \cdots, \ell - 1\} \tag{10}$$

with the convention that if $\ell = 0$ the last set in (10) is empty.

By a solution of (8) we mean a function x defined on the set $\{-k, \cdots, 0\} \cup (0, \infty)$ with values in $\mathbf{R}^r$ and which satisfies the following properties:

(i) x is continuous on $[0, \infty)$.

(ii) The derivative $\dot{x}(t)$ exists at each point $t \in [0, \infty)$ with the possible exception of the points $t \in \mathbf{N}$ where finite one-sided derivatives exist.

(iii) Equation (2) is satisified on each interval $[n, n+1)$ for $n \in N$.

Let $a_j \in \mathbf{R}^r$ for $\{-k, \cdots, 0\} \cup \{0, \cdots, \ell - 1\}$ be given. Then, as we will show in Lemma 1, the intial value problem (8) and (10) has a unique solution provided that

$$\begin{aligned} &\text{if} \quad \ell = 1 \quad \text{then} \quad \det(Q_1 + I) \neq 0, \\ &\text{if} \quad \ell \geq 2 \quad \text{and} \quad k = 0 \quad \text{then} \quad \det Q_\ell \neq 0 \end{aligned} \tag{11}$$

with no restrictions for other values of k and ℓ, where I is the $r \times r$ identity matrix.

A solution $x(t) = [x_1(t), \cdots, x_r(t)]^T$ of (8) is called *oscillatory* if every component $x_i(t)$ has arbitrarily large zeros.

During the last few years there has been a lot of activity concerning the oscillation and asymptotic behavior of differential equations with piecewise constant arguments. See, for example, [1], [2], [5]–[8], and [10].

Among other things, equations with piecewise constant arguments provide the simplest examples of differential equations capable of displaying chaotic behavior. For example, as remarked in [10] the unique solution of the initial value problem

$$\begin{cases} \dot{y}(t) = 3y([t]) - y^2([t]), \\ y(0) = a_0 \end{cases}$$

has the property that

$$y(n+1) = 4y(n) - y^2(n), \qquad n = 0, 1, \cdots.$$

If we choose $a_0 = 4\sin^2(\pi/9)$ then the unique solution of this difference equation is $y(n) = 4\sin^2(2^n\pi/9)$ which has period 3 and hence exhibits chaotic behavior by the results of Li and Yorke [13]. See also [4].

The following lemma is the basic existence and uniqueness result for the initial value problem (8) and (10).

LEMMA 1. *Assume that* (9) *and* (11) *hold. Then the initial value problem* (8) *and* (10) *has a unique solution* $x(t)$. *Furthermore,* $x(t)$ *is given by*

$$x(t) = a_n - \left(\sum_{j=-k}^{\ell} Q_j a_{n+j}\right)(t-n) \quad \text{for} \quad n \le t < n+1 \quad \text{and} \quad n \in \mathbf{N} \tag{12}$$

where $\{a_n\}$ *is a sequence of vectors in* $\mathbf{R}^r$ *which satisfies the difference equation.*

$$a_{n+1} + a_n - \sum_{j=-k}^{\ell} Q_j a_{n+j} \quad \text{for} \quad n = 0, 1, \cdots. \tag{13}$$

Proof. Let $x(t)$ be a solution of (8) and (10). Then in the interval $n \le t < n+1$, for any $n \in \mathbf{N}$, (8) becomes

$$\dot{x}(t) + \sum_{j=-k}^{\ell} Q_j a_{n+j} = 0, \qquad n \le t < n+1 \tag{14}$$

where we use the notation

$$a_n = x(n) \quad \text{for} \quad n \in \{-k, \cdots, 0, 1, \cdots\}.$$

Clearly, the solution of (14) with $x(n) = a_n$ is given by (12). By continuity of the solution, as $t \to n+1$, (12) yields (13). So far we have proved that if $x(t)$ is a solution of (8) and (10) then $x(t)$ is given by (12) where the sequence $\{a_n\}$ satisfies (13).

Conversely, let $\{a_n\}$ be the solution of (13) with initial values $a_{-k}, \cdots, a_0, \cdots, a_{\ell-1}$. Note that this solution exists and is unique provided that (11) holds. Now define $x(t)$ by (10) and (12). The it can easily be shown by direct substitution that $x(t)$ satisfies (8). The proof is complete.

The characteristic equation associated with the difference equation (13) is

$$\det\left(\lambda I - I + \sum_{j=-k}^{\ell} Q_j \lambda^j\right) = 0. \tag{15}$$

The main result in this section is the following theorem. For the scalar case see [12] and [15].

THEOREM 2. *Assume that conditions* (9) *and* (11) *hold. Then the following statements are equivalent:*

(a) *Every solution of* (8) *oscillates.*

(b) *Every solution of* (13) *oscillates.*

(c) *The characteristic equation* (15) *has no positive roots.*

Proof. The fact that (b) is equivalent to (c) follows from Theorem 1. The proof of (b) $\Rightarrow$ (a) is an obvious consequence of the fact that $x(n) = a_n$. It remains to show that (a) $\Rightarrow$ (b). To this end, assume that every component of every solution of (8) oscillates but, for the sake of contradiction, assume that (13) has a solution $\{a_n\}$ which is nonoscillatory. Let

$$a_n = [a_n^1, \cdots, a_n^r].$$

Then one of the components of a_n is eventually positive or eventually negative. Without loss of generality we will assume that the first component a_n^1 is eventually positive; that is, there exists an n_0 such that $a_n^1 > 0$ for $n \geq n_0$. From (12) and (13) and the continuity of $x(t)$ we see that for $n \leq t \leq n+1$ and $n \in \mathbf{N}$

$$x(t) = a_n - (a_n - a_{n+1})(t-n) = [1-(t-n)]a_n + (t-n)a_{n+1}.$$

Hence the first component of $x(t) = [x^1(t), \cdots, x^r(t)]$ is such that

$$x^1(t) = [1-(t-n)]a_n^1 + (t-n)a_{n+1}^1 > 0.$$

This contradicts the hypothesis that every component of $x(t)$ oscillates, and the proof is complete.

ATKINSON'S SUPERLINEAR OSCILLATION THEOREM FOR MATRIX DIFFERENCE EQUATIONS*

ALLAN C. PETERSON† AND JERRY RIDENHOUR‡

Abstract. The concept of a generalized zero of a prepared solution of a superlinear matrix difference equation is introduced. Riccati techniques are used to establish necessary and sufficient conditions for all prepared solutions to be oscillatory.

Key words. generalized zero, oscillatory solution, superlinear equation, matrix difference equation, Riccati techniques

AMS(MOS) subject classifications. primary 34C10; secondary 34A34

1. Introduction. In 1955, Atkinson [3] proved that the second-order superlinear scalar ordinary differential equation

$$y''+f(t)y^{2n+1}=0, \qquad t\geqq 0$$

with $f(t)>0$ and continuous for each $t\geqq 0$ is oscillatory if and only if

$$\int_0^\infty tf(t)\,dt=\infty.$$

Versions of this result for the $m\times m$ matrix differential equation

$$Y''+(Y^nQ(t)Y^{*n})Y=0 \tag{1}$$

have recently been obtained by Kura [12], Butler and Erbe [4], and Ahlbrandt, Ridenhour, and Thompson [2]. In [2], it is shown that, when $Q(t)$ is Hermitian, positive definite, and continuous for each $t\geqq 0$, a necessary and sufficient condition for all prepared solutions of (1) which extend to infinity to be oscillatory is that

$$\int_0^\infty t\cdot\lambda_{\max}[Q(t)]\,dt=\infty.$$

Here, $\lambda_{\max}[Q(t)]$ denotes the maximum eigenvalue of $Q(t)$.

In the past few years, several papers (e.g., [8], [9], [11], [14], and [15]) have appeared on the oscillation theory of second-order scalar difference equations. Mingarelli [13] has shown that Atkinson's superlinear oscillation theorem is valid for second-order real scalar difference equations. The oscillation of second-order linear matrix differential equations has been studied extensively (see [5]–[7] and the several references therein). Ahlbrandt and Hooker [1] have studied the principal solutions of second-order matrix difference equations.

Our results show that Atkinson's theorem also carries over to the case of second-order superlinear matrix difference equations. In particular, we study the difference equation

$$\Delta^2Y(t-1)+[Y^n(t)Q(t)Y^{*n}(t)]Y(t)=0, \tag{2}$$

where $\mathbb{Z}^+$ is the set of positive integers, $t\in\mathbb{Z}^+$, $Y(t)$ and $Q(t)$ are $m\times m$ complex-valued matrices, $Y^*(t)$ is the Hermitian adjoint (i.e., conjugate transpose) of $Y(t)$, and $Q(t)$

* Received by the editors March 20, 1989; accepted for publication May 14, 1990.

is assumed to be Hermitian and positive definite for each $t \in \mathbb{Z}^+$. Since solutions are defined only at discrete points, the first consideration will be in arriving at an appropriate definition of zeros and generalized zeros of solutions. Once this is settled and a corresponding definition of an oscillatory prepared solution is made, the main result establishes that equation (2) is oscillatory if and only if

$$\sum_{t=1}^{\infty} t\lambda_{\max}[Q(t)] = \infty. \tag{3}$$

Although we employ Riccati techniques similar to those in [2], the arguments are different and more subtle. The difficulty presented by the generalized zeros and an important interplay between two different Riccati variables have no counterpart in the differential equations case.

2. Preliminaries and definitions. We see from (2) that specifying the values of $Y(t)$ at two consecutive positive integers leads iteratively to a unique solution $Y(t)$ defined for all $t \in \mathbb{Z}^+$. Hence, solutions always exist on all of $\mathbb{Z}^+$ even though (2) is nonlinear.

It is well known (see [2] and the references therein) that a satisfactory oscillation theory in the matrix case can be given only for the class of prepared solutions. A solution $Y(t)$ of (2) is said to be *prepared* if and only if

$$Y^*(t)\Delta Y(t) = \Delta Y^*(t)\, Y(t), \qquad t \in \mathbb{Z}^+.$$

It is easy to see that, for any solution $Y(t)$ of (2),

$$\Delta[\, Y^*(t)\Delta Y(t) - \Delta Y^*(t)\, Y(t)] = K,$$

and the solution $Y(t)$ is prepared only when K is the zero matrix.

Given a solution $Y(t)$ of (2), we introduce the Riccati functions $W(t)$ and $V(t)$, defined by

$$W(t) := \Delta Y(t-1)\, Y^{-1}(t-1)$$

and

$$V(t) := \Delta Y(t-1)\, Y^{-1}(t).$$

Obviously, $W(t)$ and $V(t)$ are defined only at integers t, where $Y^{-1}(t-1)$ and $Y^{-1}(t)$, respectively, exist. We have the following important identities relating Y, W, and V:

$$W(t) + I = Y(t)\, Y^{-1}(t-1), \tag{4}$$

$$I - V(t) = Y(t-1)\, Y^{-1}(t) = [\, W(t) + I]^{-1}. \tag{5}$$

Here, as elsewhere, I denotes the $m \times m$ identity matrix. We note that (4) follows from

$$W(t) = \Delta Y(t-1)\, Y^{-1}(t-1) = [\, Y(t) - Y(t-1)]\, Y^{-1}(t-1) = Y(t)\, Y^{-1}(t-1) - I$$

and (5) is proved in a similar fashion.

An absolutely essential fact in what follows is that, for a prepared solution of (2), Riccati functions $W(t)$ and $V(t)$ are Hermitian at points where they exist. The fact that $W(t)$ is Hermitian follows immediately from the definition of $W(t)$ and the fact that $Y(t)$ is prepared. We then see, from (5), that $V(t)$ is also Hermitian.

Let $Y(t)$ be a solution of (2). Using (2), (4), and the elementary formulas

$$\Delta[A(t)B(t)] = A(t+1)\Delta B(t) + \Delta A(t)B(t) = \Delta A(t)B(t+1) + A(t)\Delta B(t)$$

and

$$\Delta[A^{-1}(t)] = -A^{-1}(t)\Delta A(t)A^{-1}(t+1) = -A^{-1}(t+1)\Delta A(t)A^{-1}(t),$$

we obtain on intervals of integers where $W(t)$ exists that

$$\begin{aligned}\Delta W(t) &= \Delta^2 Y(t-1)Y^{-1}(t) - \Delta Y(t-1)Y^{-1}(t)\Delta Y(t-1)Y^{-1}(t-1)\\ &= -Y^n(t)Q(t)Y^{*n}(t) - \Delta Y(t-1)Y^{-1}(t-1)Y(t-1)Y^{-1}(t)W(t)\end{aligned}$$

or

$$\Delta W(t) = -Y^n(t)Q(t)Y^{*n}(t) - W(t)[W(t)+I]^{-1}W(t). \tag{6}$$

We will refer to (6) as the Riccati equation associated with (2). It will play a central role in the analysis to follow. We could just as well have derived a Riccati equation for $V(t)$ that is very similar to (6) and have based our analysis on it; however, either one of these equations together with (4) and (5) yields all the necessary information.

We are ready to define what we mean by generalized zeros and oscillatory solutions.

DEFINITION. We say a prepared solution $Y(t)$ of (2) has a *generalized zero* at $t_0 \in \mathbb{Z}^+$ if at least one of the eigenvalues of $W(t_0)+I$ is less than or equal to zero. A prepared solution $Y(t)$ of (2) is said to be *oscillatory* if, for any $n \in \mathbb{Z}^+$, $Y(t)$ has a generalized zero at some t_0 with $t_0 > n$; otherwise, we say the prepared solution $Y(t)$ is *nonoscillatory*. Equation (2) is said to be *oscillatory* if all prepared solutions are oscillatory and is said to be *nonoscillatory* if there exists at least one prepared solution which is *nonoscillatory*.

At first glance, our definition of a generalized zero seems unnatural. We justify it below, collecting our reasons under four headings.

I. *Real scalar equations.* Following Hartman [8], a discrete solution $y(t)$ of a real scalar difference equation is said to have a generalized zero at t if either $y(t)=0$ or $y(t-1)$ and $y(t)$ are of opposite signs. By (4), this occurs precisely when $w(t)+1 \leqq 0$.

II. *Complex scalar equations.* In this case, it follows from (4) and (2) that the function values of a prepared solution determine a set of points in the complex plane which all lie on a fixed line through the origin. When $w(t_0)+1<0$, the successive solution values $y(t_0-1)$ and $y(t_0)$ lie on opposite sides of the origin, a situation that agrees geometrically with the notion of a generalized zero.

III. *Hermitian solutions.* Suppose $Y(t)$ is a prepared Hermitian solution of (2) and t_0-1 is a positive integer for which $\det[Y(t_0-1)] \neq 0$. From matrix analysis [10, p. 229], if A and B are Hermitian with $AB=BA$, then there exists a unitary matrix U which simultaneously diagonalizes both A and B (i.e., $UAU^*=D$ and $UBU^*=\Lambda$, where D and Λ are diagonal matrices). Since $Y(t_0)=[W(t_0)+I]Y(t_0-1)$ is Hermitian, it follows that there is a unitary matrix $U(t_0)$ such that

$$U(t_0)[W(t_0)+I]U^*(t_0) = D(t_0) = \operatorname{diag}(d_1(t_0), \cdots, d_m(t_0))$$

and

$$U(t_0)Y(t_0-1)U^*(t_0) = \Lambda(t_0) = \operatorname{diag}(\lambda_1(t_0), \cdots, \lambda_m(t_0))$$

with $U(t_0)U^*(t_0)=I$. Therefore

$$\begin{aligned}Y(t_0) &= U^*(t_0)D(t_0)U(t_0)U^*(t_0)\Lambda(t_0)U(t_0)\\ &= U^*(t_0)\operatorname{diag}(d_1(t_0)\lambda_1(t_0), \cdots, d_m(t_0)\lambda_m(t_0))U(t_0).\end{aligned}$$

This shows that the eigenvalues of $Y(t_0)$ are products of eigenvalues of $W(t_0)+I$ with eigenvalues of $Y(t_0-1)$. That is, the unitary transformation $U(t_0)$ allows "tracking"

of eigenvalues in that the eigenvalue $\lambda_i(t_0)$ of $Y(t_0-1)$ is transformed into the eigenvalue $d_i(t_0)\lambda_i(t_0)$ of $Y(t_0)$. If some eigenvalue $d_i(t_0)$ of $W(t_0)+I$ is zero or negative, then the iteration from $Y(t_0-1)$ to $Y(t_0)$ either produces a singular matrix $Y(t_0)$ or an eigenvalue that changes sign. In a continuous evolution, an eigenvalue that changes sign must pass through zero yielding a point at which the matrix is singular. Therefore, a zero or negative eigenvalue of $W(t_0)+I$ implies the presence of a singularity of $Y(t)$ in passing from $Y(t_0-1)$ to $Y(t_0)$, thus supporting our definition of a generalized zero.

We now give an example which further illustrates the correctness of our definition in the case of Hermitian solutions. If there exists a constant unitary matrix U which diagonalizes $Q(t)$ for all $t\in\mathbb{Z}^+$, say, $UQ(t)U^*=D(t)=\operatorname{diag}(d_1(t),\cdots,d_m(t))$, then it is easy to see that $Y(t)=U^*Z(t)U$ is a prepared Hermitian solution of (2) provided that $Z(t)$ is a diagonal solution of

$$\Delta^2 Z(t-1)+Z^n(t)D(t)Z^{n+1}(t)=0.$$

If $Q(t)$ is the constant matrix given by

$$Q=\begin{bmatrix} 1.64 & -0.48 \\ -0.48 & 1.36 \end{bmatrix},$$

this technique can be used to find that $Y_0(t)$ given by

$$Y_0(t)=\left\{\begin{bmatrix} -0.28 & 0.96 \\ 0.96 & 0.28 \end{bmatrix},\begin{bmatrix} 0.56 & -1.92 \\ -1.92 & -0.56 \end{bmatrix},\begin{bmatrix} -5.96 & 6.72 \\ 6.72 & -2.04 \end{bmatrix},\begin{bmatrix} 1681.5 & -1275.4 \\ -1275.4 & 937.5 \end{bmatrix},\cdots\right\} \tag{7}$$

is a prepared Hermitian solution of

$$\Delta^2 Y(t-1)+Y(t)QY^*(t)Y(t)=0. \tag{8}$$

The sequence of eigenvalue pairs of $Y_0(t)$ is

$$\{(1,-1),(2,-2),(3,-1),(2638,-19),\cdots\}.$$

Since the eigenvalues of Q are $\lambda=1$ and $\lambda=2$ and (3) is consequently satisfied, all prepared solutions of (8), including $Y_0(t)$, ought to be oscillatory. Yet, simply by looking at $Y_0(t)$ as given in (7), or at the sequence of eigenvalue pairs, or perhaps at something like the sequence $\{\det(Y_0(t))\}$, it is difficult to detect why we ought to consider $Y_0(t)$ oscillatory. However, the sequence $\{W_0(t)+I\}$ has

$$\{(-2,-2),(-5.5,-1.5),(-239.82,-6.33),\cdots\}$$

as the corresponding sequence of eigenvalue pairs indicating that *both* eigenvalues of $Y_0(t)$ actually change sign at each iteration; hence, $Y_0(t)$ has infinitely many generalized zeros and is oscillatory by our definition.

IV. *The general case.* We will prove in the next section that (2) is oscillatory if and only if (3) holds. Therefore, the above definitions are appropriate for non-Hermitian as well as Hermitian solutions if the principal aim is to construct an oscillation theory for matrix difference equations which parallels the known results for matrix differential equations.

3. Main results. For any $m\times m$ Hermitian matrix H, we let $\lambda_1(H)\leqq\lambda_2(H)\leqq\cdots\leqq\lambda_m(H)$ denote the eigenvalues. Also, $\lambda_{\max}(H)$ and $\lambda_{\min}(H)$ will denote the maximum and minimum eigenvalues of H, respectively. We now mention three eigenvalue inequalities that will be used below. For the purpose of describing these inequalities,

assume H_1 and H_2 are any $m \times m$ Hermitian matrices, P is any $m \times m$ matrix that is Hermitian and positive definite, and A is any $m \times m$ matrix. The three inequalities are

$$\lambda_k(H_1)+\lambda_1(H_2) \leqq \lambda_k(H_1+H_2) \leqq \lambda_k(H_1)+\lambda_m(H_2),$$
$$\lambda_k(APA^*) \geqq \lambda_k(P)\lambda_1(AA^*),$$
$$\lambda_k(APA^*) \geqq \lambda_k(AA^*)\lambda_1(P),$$

all valid for $1 \leqq k \leqq m$. The first is due to Weyl [10, p. 181], the second is due to Ostrowski [10, pp. 224–225], and the third is an immediate consequence of the Courant–Fischer min-max theorem [10, p. 179].

We begin by proving a lemma which gives detailed information about the Riccati functions.

LEMMA. *Suppose $Y(t)$ is a nonoscillatory prepared solution of* (2). *Then there exists $t_0 \in \mathbb{Z}^+$ such that $W(t)$ and $V(t)$ are both positive definite and decreasing for $t \geqq t_0$ with*

$$\lim_{t\to\infty} W(t) = \lim_{t\to\infty} V(t) = 0. \tag{9}$$

Furthermore, multiplication of $W(t)$ and $V(t)$ is commutative at points where both exist and $W(t)V(t) = V(t)W(t)$ is positive definite for $t \geqq t_0$.

Proof. Since $Y(t)$ is nonoscillatory and prepared, we begin by choosing $t_0 \in \mathbb{Z}^+$ so that $W(t)+I>0$ for $t \geqq t_0$. Since $Q(t)$ is also positive definite, we see from the Riccati equation, Ostrowski's inequality, and Weyl's inequality that $\Delta W(t)<0$ for $t \geqq t_0$. Hence, by Weyl's inequality, each eigenvalue $\lambda_k[W(t)]$, $1 \leqq k \leqq m$, is a decreasing function of t for $t \geqq t_0$. Furthermore, each $\lambda_k[W(t)]$ is bounded below for $t \geqq t_0$ since $W(t)+I>0$. Therefore, $\lim_{t\to\infty} \lambda_k[W(t)]$ exists for $1 \leqq k \leqq m$. Since the eigenvalues of $W(t)+I$ decrease but remain positive, the eigenvalues of $[W(t)+I]^{-1}$ are positive and increasing for $t \geqq t_0$.

From the Riccati equation and the above-mentioned eigenvalue inequalities we obtain

$$\begin{aligned} \lambda_k[-\Delta W(t)] &> \lambda_k\{W(t)[W(t)+I]^{-1}W(t)\} \\ &\geqq \lambda_k[W^2(t)]\lambda_{\min}([W(t)+I]^{-1}) \\ &\geqq \{\lambda_k[W(t)]\}^2\lambda_{\min}([W(t_0)+I]^{-1}), \end{aligned} \tag{10}$$

valid for $1 \leqq k \leqq m$ and $t \geqq t_0$. We claim that

$$\lim_{t\to\infty} \lambda_k[W(t)] = 0 \tag{11}$$

holds for $1 \leqq k \leqq m$. Suppose not. We choose k_0 with $1 \leqq k_0 \leqq m$ such that

$$\lim_{t\to\infty} \lambda_{k_0}[W(t)] = \lambda_0 \neq 0. \tag{12}$$

In view of (10) and (12), we then choose an integer t_1 with $t_1 \geqq t_0$ and a positive number δ such that

$$\lambda_{k_0}[-\Delta W(t)] > \delta \quad \text{for } t \geqq t_1. \tag{13}$$

But this leads to (letting tr (A) denote the trace of A):

$$\begin{aligned} \lambda_{\max}[-W(t)+W(t_1)] &= \lambda_{\max}\left[\sum_{\tau=t_1}^{t-1} -\Delta W(\tau)\right] \geqq \frac{1}{m}\operatorname{tr}\left[\sum_{\tau=t_1}^{t-1} -\Delta W(\tau)\right] \\ &= \frac{1}{m}\sum_{\tau=t_1}^{t-1} \operatorname{tr}[-\Delta W(\tau)] \geqq \frac{1}{m}\sum_{\tau=t_1}^{t-1} \lambda_{k_0}[-\Delta W(\tau)]. \end{aligned}$$

By (13), this implies $\lambda_{\max}[-W(t)+W(t_1)]\to\infty$ and $\lambda_{\min}[W(t)]\to-\infty$ as $t\to\infty$. But this contradicts the fact that the eigenvalues of $W(t)$ are bounded below for $t\geqq t_0$.

This proves that (11) holds and, consequently, that $\lim_{t\to\infty} W(t)=0$. Therefore, $W(t)$ is positive for $t\geqq t_0$, $t\in\mathbb{Z}^+$. From (5),

$$V(t)=I-[W(t)+I]^{-1},$$

so the eigenvalues of $V(t)$ are also positive and decreasing for $t\geqq t_0$, with $\lim_{t\to\infty}\lambda_k[V(t)]=0$ for $1\leqq k\leqq m$ showing that (9) holds.

Finally, from (5), we see that

$$[W(t)+I][I-V(t)]=I=[I-V(t)][W(t)+I],$$

from which it follows that

$$W(t)V(t)=V(t)W(t)=W(t)-V(t)$$

at all integers t where both $W(t)$ and $V(t)$ exist. Since

$$\begin{aligned}V(t)[W(t)+I]V(t)&=V(t)W(t)V(t)+V^2(t)\\&=[W(t)-V(t)]V(t)+V^2(t)\\&=W(t)V(t),\end{aligned}$$

we see that $W(t)V(t)=V(t)W(t)$ is positive for $t\geqq t_0$ completing the proof of the lemma. □

The main result is the following theorem.

THEOREM 1. *Suppose $Q(t)$ is Hermitian and positive definite for all $t\in\mathbb{Z}^+$. Then equation* (2) *is oscillatory if and only if* (3) *holds.*

Proof. We first assume $n=1$ (a cubic nonlinearity) in (2). The general case will be treated later. Suppose (3) holds but (2) has a nonoscillatory prepared solution $Y(t)$. Applying the lemma, we choose $t_0\in\mathbb{Z}^+$ so that $Y(t)$ is invertible and the matrices $W(t)$, $V(t)$, and $W(t)V(t)=V(t)W(t)$ are all positive definite for $t\geqq t_0-1$, $t\in\mathbb{Z}^+$.

In the next few steps, we derive an identity relating $tQ(t)$ to $Y(t)$, $W(t)$, and $V(t)$. First,

$$\begin{aligned}\Delta[Y^{-1}(t-1)Y^{*-1}(t-1)]&=-Y^{-1}(t)\Delta Y(t-1)Y^{-1}(t-1)Y^{*-1}(t)\\&\quad-Y^{-1}(t-1)Y^{*-1}(t)\Delta Y^{*}(t-1)Y^{*-1}(t-1)\\&=-Y^{-1}(t)W(t)Y^{*-1}(t)\\&\quad-Y^{-1}(t-1)V(t)Y^{*-1}(t-1).\end{aligned}\tag{14}$$

Using the product rule

$$\begin{aligned}\Delta[A(t)B(t)C(t)D(t)E(t)]&=A(t+1)B(t+1)C(t+1)D(t+1)\Delta E(t)\\&\quad+A(t+1)\Delta B(t)C(t+1)D(t+1)E(t)\\&\quad+A(t+1)B(t)\Delta C(t)D(t+1)E(t)\\&\quad+A(t+1)B(t)C(t)\Delta D(t)E(t)\\&\quad+\Delta A(t)B(t)C(t)D(t)E(t),\end{aligned}$$

we obtain

$$
\begin{aligned}
&\Delta[(t-1)Y^{-1}(t)\Delta Y(t-1)Y^{-1}(t-1)Y^{*-1}(t)] \\
&\quad = -tY^{-1}(t+1)\Delta Y(t)Y^{-1}(t)Y^{*-1}(t)\Delta Y^{*}(t)Y^{*-1}(t+1) \\
&\qquad - tY^{-1}(t)\Delta Y(t)Y^{-1}(t+1)\Delta Y(t)Y^{-1}(t)Y^{*-1}(t) - tQ(t) \\
&\qquad - tY^{-1}(t)\Delta Y(t-1)Y^{-1}(t)\Delta Y(t-1)Y^{-1}(t-1)Y^{*-1}(t) \\
&\qquad + Y^{-1}(t)\Delta Y(t-1)Y^{-1}(t-1)Y^{*-1}(t) \\
&\quad = -tY^{-1}(t+1)W^{2}(t+1)Y^{*-1}(t+1) \\
&\qquad - tY^{-1}(t)V(t+1)W(t+1)Y^{*-1}(t) \\
&\qquad - tQ(t) - tY^{-1}(t)V(t)W(t)Y^{*-1}(t) + Y^{-1}(t)W(t)Y^{*-1}(t).
\end{aligned} \tag{15}
$$

Applying the following slightly different form of the product rule,

$$
\begin{aligned}
&\Delta[A(t)B(t)C(t)D(t)E(t)] \\
&\quad = A(t+1)B(t+1)C(t+1)\Delta D(t)E(t+1) \\
&\qquad + A(t+1)B(t+1)\Delta C(t)D(t)E(t+1) + A(t+1)\Delta B(t)C(t)D(t)E(t+1) \\
&\qquad + A(t+1)B(t)C(t)D(t)\Delta E(t) + \Delta A(t)B(t)C(t)D(t)E(t),
\end{aligned}
$$

we find that

$$
\begin{aligned}
&\Delta[(t-1)Y^{-1}(t-1)\Delta Y(t-1)Y^{-1}(t)Y^{*-1}(t-1)] \\
&\quad = -tY^{-1}(t)W(t+1)V(t+1)Y^{*-1}(t) - tQ(t) \\
&\qquad - tY^{-1}(t)W(t)V(t)Y^{*-1}(t) - tY^{-1}(t-1)V^{2}(t)Y^{*-1}(t-1) \\
&\qquad + Y^{-1}(t-1)V(t)Y^{*-1}(t-1).
\end{aligned} \tag{16}
$$

Combining (14)-(16), we have the identity

$$
\begin{aligned}
\Delta[Y^{-1}(t-1)Y^{*-1}(t-1)] = &-tH(t) - 2tQ(t) - \Delta[(t-1)Y^{-1}(t)W(t)Y^{*-1}(t)] \\
&- \Delta[(t-1)Y^{-1}(t-1)V(t)Y^{*-1}(t-1)],
\end{aligned} \tag{17}
$$

where

$$
\begin{aligned}
H(t) = &\, Y^{-1}(t+1)W^{2}(t+1)Y^{*-1}(t+1) + Y^{-1}(t-1)V^{2}(t)Y^{*-1}(t-1) \\
&+ Y^{-1}(t)[2V(t+1)W(t+1) + 2V(t)W(t)]Y^{*-1}(t).
\end{aligned}
$$

Summing both sides of (17) yields

$$
\begin{aligned}
2\sum_{\tau=t_0}^{t-1}\tau Q(\tau) = &-\sum_{\tau=t_0}^{t-1}\tau H(\tau) - Y^{-1}(t-1)Y^{*-1}(t-1) \\
&-(t-1)[Y^{-1}(t)W(t)Y^{*-1}(t) + Y^{-1}(t-1)V(t)Y^{*-1}(t-1)] + C,
\end{aligned} \tag{18}
$$

where C is a constant Hermitian matrix.

For $t \geqq t_0+1$, all terms except C on the right-hand side of (18) are negative definite and consequently there is a real constant K such that

$$
\lambda_{\max}\left(\sum_{\tau=t_0}^{t-1}\tau Q(\tau)\right) \leqq K \quad \text{for } t \geqq t_0+1.
$$

By Weyl's inequality, there is another constant K_1 so that

$$
\lambda_{\max}\left(\sum_{\tau=1}^{t-1}\tau Q(\tau)\right) \leqq K_1 \quad \text{for } t \geqq t_0+1. \tag{19}
$$

However,

$$\lambda_{\max}\left(\sum_{\tau=1}^{t-1}\tau Q(\tau)\right) \geqq \frac{1}{m}\operatorname{tr}\left(\sum_{\tau=1}^{t-1}\tau Q(\tau)\right)$$

$$= \frac{1}{m}\sum_{\tau=1}^{t-1}\operatorname{tr}[\tau Q(\tau)] \tag{20}$$

$$\geqq \frac{1}{m}\sum_{\tau=1}^{t-1}\lambda_{\max}[\tau Q(\tau)].$$

By (3), $\sum_{\tau=1}^{t-1}\lambda_{\max}[\tau Q(\tau)]\to\infty$ as $t\to\infty$, contradicting (19).

This proves that (3) is a sufficient condition for (2) to be oscillatory in the case $n=1$. We now prove the same in the case of a general positive integer n. Suppose to the contrary that (3) holds but there is a positive integer n such that (2) has a prepared nonoscillatory solution $Y_0(t)$. First, since $Y_0(t)$ is nonoscillatory, we choose $t_0\in\mathbb{Z}^+$ such that $Y_0(t)$ is invertible for $t\geqq t_0$ and the Riccati functions $W_0(t)$ and $V_0(t)$ are positive definite for $t\geqq t_0$. We let $Q_0(t)$ be defined by

$$Q_0(t) = Y_0^{n-1}(t)Q(t)Y_0^{*n-1}(t), \qquad t\in\mathbb{Z}^+.$$

We note that $Y_0(t)$ is also a nonoscillatory prepared solution of

$$\Delta^2 Y(t-1) + Y(t)Q_0(t)Y^*(t)Y(t) = 0, \qquad t\in\mathbb{Z}^+. \tag{21}$$

Now $Y_0^*(t)Y_0(t)$ and $Y_0(t)Y_0^*(t)$ have the same eigenvalues; furthermore, for $t\geqq t_0$ we have

$$\Delta[Y_0^*(t)Y_0(t)] = Y_0^*(t+1)\Delta Y_0(t) + Y_0^*(t)\Delta Y_0(t)$$

$$= Y_0^*(t+1)V_0(t+1)Y_0(t+1) + Y_0^*(t)W_0(t+1)Y_0(t). \tag{22}$$

From (22), we see that $\Delta[Y_0^*(t)Y_0(t)]>0$ for $t\geqq t_0$ so the eigenvalues of $Y_0(t)Y_0^*(t)$ are increasing; hence, we choose a positive real number δ so that $\lambda_{\min}[Y_0(t)Y_0^*(t)]>\delta$ for $t\geqq t_0$, $t\in\mathbb{Z}^+$. By Ostrowski's inequality,

$$\lambda_{\max}[Q_0(t)]\geqq\lambda_{\max}[Q(t)]\cdot\delta^{n-1} \quad \text{for } t\geqq t_0.$$

Hence, $Q_0(t)$ is Hermitian and positive definite for $t\geqq t_0$ with

$$\sum_{t=1}^{\infty} t\lambda_{\max}[Q_0(t)] = \infty.$$

Even though $Q_0(t)$ may only be positive semi-definite rather than positive definite for $t<t_0$ and $t\in\mathbb{Z}^+$, it is clear from the first part of the proof that (21) is oscillatory. Since $Y_0(t)$ is a nonoscillatory solution, we have reached a contradiction.

This completes the proof that (2) is oscillatory if (3) holds. Now we prove that (3) is a necessary condition if (2) is to be oscillatory.

Suppose that

$$\sum_{t=1}^{\infty} t\lambda_{\max}[Q_0(t)] < \infty. \tag{23}$$

We need to show that there is at least one nonoscillatory prepared solution of (2). Atkinson's original proof [3] in this direction can be recast as an application of the contraction mapping principle; our proof is in the same vein with some adjustment necessary because of the different matrix norms.

We begin by recalling some facts from elementary matrix analysis [10, Chap. 5]. Let $\mathcal{M}_m$ denote the set of $m \times m$ complex matrices, let $|z|$ denote the modulus of the complex number z, and let A_{ij} denote the entry in the ith row and jth column of a matrix A. Further, let $|||\cdot|||_\infty$, $|||\cdot|||_1$, and $|||\cdot|||_2$ be the matrix norms on $\mathcal{M}_m$ induced by the l_∞, l_1, and l_2 vector norms, respectively. Then $|||\cdot|||_\infty$ is the maximum row sum norm, $|||\cdot|||_1$ is the maximum column sum norm, and $|||\cdot|||_2$ is the spectral norm with $|||A|||_2 = [\lambda_{\max}(AA^*)]^{1/2}$ for $A \in \mathcal{M}_m$ and $|||H|||_2 = \lambda_{\max}(H)$ when H is Hermitian and positive semi-definite. The inequalities

$$|||A|||_\infty \leqq \sqrt{m}\, |||A|||_2, \qquad |||A|||_1 \leqq \sqrt{m}\, |||A|||_2, \quad \text{and} \quad |||A|||_1 \leqq m|||A|||_\infty$$

hold for all $A \in \mathcal{M}_m$. In addition, the submultiplicativity of matrix norms will play a key role.

If t_0 is a fixed positive integer, then a direct calculation shows that any $m \times m$ complex matrix-valued function $Y(t)$ defined for $t \geqq t_0$ and satisfying the equation

$$Y(t) = I - \sum_{s=t+1}^{\infty} (s-t)\, Y^n(s) Q(s) Y^{*n}(s) Y(s) \tag{24}$$

also satisfies (2) for $t \geqq t_0$. We will apply the contraction mapping principle to produce a solution of (24). First, we choose $t_0 \in \mathbb{Z}^+$ so large that

$$\sum_{s=t_0}^{\infty} s\lambda_{\max}[Q(s)] < m^{-5/2} 2^{-2n} (2n+1)^{-1}. \tag{25}$$

We let $\mathcal{X}_{t_0}$ denote the set of all $m \times m$ complex matrix-valued functions $U(t)$ defined for integers $t \geqq t_0$ and such that $\lim_{t\to\infty} U(t)$ exists as a finite matrix. For $U \in \mathcal{X}_{t_0}$, let

$$|||U||| = \sup_{t \geqq t_0} |||U(t)|||_\infty.$$

Then $\mathcal{X}_{t_0}$ equipped with this norm is a Banach space. Let $\mathcal{A} = \{U \in \mathcal{X}_{t_0} : |||U - I||| \leqq 1\}$. Then $\mathcal{A}$ is a closed and nonempty subset of $\mathcal{X}_{t_0}$. For $Y \in \mathcal{A}$, define TY by

$$TY(t) = I - \sum_{s=t+1}^{\infty} (s-t)\, Y^n(s) Q(s) Y^{*n}(s) Y(s). \tag{26}$$

Take $Y \in \mathcal{A}$. Then, for $s \geqq t$,

$$\begin{aligned} |[(s-t)\, Y^n(s) Q(s) Y^{*n}(s) Y(s)]_{ij}| &\leqq |||(s-t)\, Y^n(s) Q(s) Y^{*n}(s) Y(s)|||_\infty \\ &\leqq s|||Y(s)|||_\infty^{n+1} |||Y^n(s)|||_1 |||Q(s)|||_\infty \\ &\leqq sm|||Y|||^{n+1} \cdot m|||Y^n(s)|||_\infty \cdot \sqrt{m}\, |||Q(s)|||_2 \\ &\leqq 2^{2n+1} m^{3/2} s\lambda_{\max}[Q(s)]. \end{aligned} \tag{27}$$

From (27), we see that the series on the right-hand side of (26) is convergent for all $t \in \mathbb{Z}^+$. Moreover, from (25) and (26), we see that, for $t \geqq t_0$,

$$|||TY(t) - I|||_\infty \leqq 2^{2n+1} m^{5/2} \sum_{s=t_0+1}^{\infty} s\lambda_{\max}[Q(s)] < 1.$$

Therefore $|||TY - I||| \leqq 1$. Since $\lim_{t\to\infty} TY(t) = I$, we see that T is a mapping from $\mathcal{A}$ into $\mathcal{A}$.

For Y and Z in $\mathscr{A}$ and $t \geqq t_0$, we have

$$|[TY(t)-TZ(t)]_{ij}| \leqq \sum_{s=t_0+1}^{\infty} s \| Y^n(s)Q(s)Y^{*n}(s)Y(s) - Z^n(s)Q(s)Z^{*n}(s)Z(s) \|_\infty. \tag{28}$$

Shortening the notation in a self-evident way,

$$\begin{aligned} &\| Y^nQY^{*n}Y - Z^nQZ^{*n}Z \|_\infty \\ &\quad \leqq \| Y^nQY^{*n}Y - Y^nQY^{*n}Z \|_\infty \\ &\qquad + \| Y^nQY^{*n}Z - Y^nQZ^{*n}Z \|_\infty + \| Y^nQZ^{*n}Z - Z^nQZ^{*n}Z \|_\infty \\ &\quad \leqq \| Y \|_\infty^n \cdot \sqrt{m}\, \lambda_{\max}(Q) \cdot m \| Y^n \|_\infty \| Y - Z \|_\infty \\ &\qquad + \| Y^n \|_\infty \cdot \sqrt{m}\, \lambda_{\max}(Q) \cdot m \| Y^n - Z^n \|_\infty \| Z \|_\infty \\ &\qquad + \| Y^n - Z^n \|_\infty \cdot \sqrt{m}\, \lambda_{\max}(Q) \cdot m \| Z \|_\infty^{n+1}. \end{aligned} \tag{29}$$

Also,

$$\begin{aligned} \| Y^n - Z^n \|_\infty &\leqq \| Y^n - Y^{n-1}Z \|_\infty + \| Y^{n-1}Z - Y^{n-2}Z^2 \|_\infty + \cdots + \| YZ^{n-1} - Z^n \|_\infty \\ &\leqq \| Y^{n-1}(Y-Z) \|_\infty + \| Y^{n-2}(Y-Z)Z \|_\infty + \cdots + \| (Y-Z)Z^{n-1} \|_\infty \\ &\leqq n \cdot 2^{n-1} \| Y - Z \|_\infty. \end{aligned} \tag{30}$$

Combining (29) and (30) yields

$$\| Y^nQY^{*n}Y - Z^nQZ^{*n}Z \|_\infty \leqq (2n+1) \cdot 2^{2n} \cdot m^{3/2} \lambda_{\max}(Q) \| Y - Z \|_\infty. \tag{31}$$

From (28) and (31), we then find

$$\| TY - TZ \| \leqq \left[m^{5/2}(2n+1)2^{2n} \sum_{s=t_0+1}^{\infty} s \lambda_{\max}[Q(s)] \right] \| Y - Z \|.$$

Therefore, from (25), it follows that $T: \mathscr{A} \to \mathscr{A}$ is a contraction mapping.

Consequently, there is a solution $Y(t)$ of (24) which is also a solution of (2) for $t \geqq t_0$. Extending this solution backward to $t = 1$, we obtain a solution for all t satisfying (24) for $t \geqq t_0$. Since

$$\lim_{t \to \infty} Y(t) = I \quad \text{and} \quad \lim_{t \to \infty} \Delta Y(t) = 0,$$

it follows that $Y(t)$ is a prepared solution of (2). Finally

$$\lim_{t \to \infty} W(t) = \lim_{t \to \infty} \Delta Y(t-1) Y^{-1}(t-1) = 0,$$

so $W(t) + I \to I$ as $t \to \infty$, making $Y(t)$ a nonoscillatory solution of (2).

This completes the proof of Theorem 1. □

4. Extensions to more general equations. If equation (2) is altered slightly, the analysis changes somewhat. Let $H_n(t)$ denote a general nth degree product of $Y(t)$ and $Y^*(t)$; that is,

$$H_n(t) = Z_1(t)Z_2(t) \cdots Z_n(t),$$

where each $Z_i(t)$, $1 \leqq i \leqq n$, is either $Y(t)$ or $Y^*(t)$. Additionally, take $H_0(t) = I$. Consider the equations

$$\Delta^2 Y(t-1) + [Y(t)H_{n-1}(t)Q(t)H_{n-1}^*(t)Y^*(t)]Y(t) = 0, \tag{32}$$

$$\Delta^2 Y(t-1) + [Y^*(t)H_{n-1}(t)Q(t)H_{n-1}^*(t)Y(t)]Y(t) = 0. \tag{33}$$

Then (2) is a special case of (32) with $Z_i(t) = Y(t)$ for $1 \leqq i \leqq n-1$ and

$$\Delta^2 Y(t-1) + Y^{*n}(t) Q(t) Y^{n+1}(t) = 0$$

is a special case of (33) with $Z_i(t) = Y^*(t)$ for $1 \leqq i \leqq n-1$.

The definition of a prepared solution, the Riccati functions $W(t)$ and $V(t)$, and the definition of generalized zeros is the same as above. Following a development along the lines of that in [2] for matrix differential equations, we are led to Theorem 2 below. Since all the ideas that set the difference equations apart from the differential equations are already presented in the development of Theorem 1, we omit the proof.

THEOREM 2. *Suppose $Q(t)$ is Hermitian and positive definite for all $t \in \mathbb{Z}^+$. Then equation* (32) *is oscillatory if and only if* (3) *holds. Equation* (33) *is oscillatory provided that*

$$\sum_{t=1}^{\infty} t\lambda_{\min}[Q(t)] = \infty$$

and is nonoscillatory when

$$\sum_{t=1}^{\infty} t\lambda_{\max}[Q(t)] < \infty.$$

AN H_0^m INTERPOLATION RESULT*

S. JENSEN†

Abstract. This paper presents a proof of an interpolation result related to the approximation theory for higher-order finite element or spectral methods when C^1 (or higher) regularity is convenient for the finite-dimensional subspaces. This can be a natural choice, for example, for the Stokes problem, the biharmonic problem, or higher-order plate and shell models. It is shown that the same intermediate spaces are obtained whether one (1) interpolates between two Sobolev spaces defined on a domain with nonsmooth boundary first and then enforces the homogeneous boundary conditions afterwards or (2) interpolates between two Sobolev spaces where the homogeneous boundary conditions are enforced throughout the interpolation process.

Key words. interpolation, Peetre, boundary conditions, nonsmooth domains, small angle elliptic regularity

AMS(MOS) subject classifications. 65N30, 46E35, 35J40, 35B65

1. Introduction. The aim of this note is to prove an interpolation result for domains in $\mathbf{R}^2$ with finitely many corners and otherwise smooth boundary. We consider a bounded open set Ω of $\mathbf{R}^2$, whose boundary is a curvilinear polygon of class C^∞ (see [6]). We denote each of the C^∞ curves which constitute the boundary by $\overline{\Gamma_j}$ for some j ranging from 1 to N. The curve $\overline{\Gamma_{j+1}}$ follows $\overline{\Gamma_j}$ according to the positive orientation, on each connected component of Γ. We denote by C_j the vertex which is the end point of $\overline{\Gamma_j}$ and by α_j the measure of the angle at C_j (toward the interior of Ω). By a corner we mean a vertex C_j with an angle α_j not in the set $\{0, \pi, 2\pi\}$. The result is an extension to H_0^m of the one in [2], [1] for H_0^1 which would be useful in approximation theory for Sobolev spaces; see [8, Remark 2.2.9], [17, Remark 4.2], [7], and [14, the line following (III.26) in the proof of Thm. III.2]. For example, consider solving the Stokes problem via the p version of the finite element method or a polynomial spectral method. Then the discrete velocity $\vec{U}_p$ is an elliptic projection onto a finite-dimensional subspace Z_p of $Z = [H_0^1(\Omega)]^2 \cap \mathrm{Ker}(\mathrm{div})$ centering interest on the approximation problem. Introducing stream functions ($\vec{U} = \mathrm{rot}\phi, \vec{U}_p = \mathrm{rot}\phi_p$) will translate this approximation problem to $H_0^2(\Omega)$. Now an energy estimate is obtained for free — $\|\phi - \phi_p\|_2$ bounded when $\phi \in H_0^2$ only — and there exist constructive approximation estimates, $\|\phi - \phi_p\|_2 \leq Cp^{2-t}\|\phi\|_t$, when $\phi \in H^t(\Omega) \cap H_0^2(\Omega)$ for $t > 7/2$; see [17]. Now, one wishes to interpolate between these spaces and hopes to get spaces that coincide in some sense with the ones predicted by regularity theory, but the trace constraints on a nonsmooth boundary makes this identification nontrivial. If the boundary is smooth, the result can be deduced from [13]. In general such an identification is useful for higher-order finite element or spectral methods when C^1 (or higher) regularity is convenient for the finite-dimensional subspaces. This can be a natural choice, for example, also for the biharmonic problem or higher-order plate and shell models.

Let $H^s(\Omega)$ be the standard Sobolev space of order s based on L_2 with corresponding norm $\|\cdot\|_s$. For $m \in \mathbf{Z}_+$, $H_0^m(\Omega)$ is the set of functions in $H^m(\Omega)$ for which the traces of the function and its normal derivatives up to order $m-1$ vanish on $\partial\Omega$.

We shall use the interpolation spaces of Peetre (see, e.g., [3]) in the cases $1 \leq q \leq \infty$ and $0 < \theta < 1$ where we define $[H^t(\Omega) \cap H_0^m(\Omega), H_0^m(\Omega)]_{\theta,q}$ explicitly: For $u \in H^t \cap H_0^m$, we set

$$K(u,s) = \inf_{\substack{u = v + w \\ v \in H_0^m,\ w \in H^t \cap H_0^m}} (\|v\|_m + s\|w\|_t)$$

and we define the norm

$$\|u\|_{[\cdot,\cdot]_{\theta,q}} = \|s^{-1/q-\theta} K(u,s)\|_{L_q(0,\infty)}.$$

Then

$$[H^t(\Omega) \cap H_0^m(\Omega), H_0^m(\Omega)]_{\theta,q} = \{u \in H_0^m(\Omega) : \|u\|_{[\cdot,\cdot]_{\theta,q}} < \infty\}.$$

$[H^t(\Omega), H^m(\Omega)]_{\theta,q}$ is defined similarly. Note that this space will be a Sobolev space if we choose $q = 2$ and in general a Besov space.

2. The interpolation result. We state and prove the following proposition.

PROPOSITION 1. *Let $\Omega \subseteq \mathbf{R}^2$ be piecewise C^∞ with finitely many corners of angles in $(0, 2\pi) \setminus \{\pi\}$. Then the following identity holds for all $\theta \in (0,1)$, $1 \leq q \leq \infty$ and $t \geq m$, $t \notin m + \{\frac{1}{2}, \ldots, m - \frac{1}{2}\}$, $m \in \mathbf{Z}_+$:*

$$[H^t(\Omega) \cap H_0^m(\Omega), H_0^m(\Omega)]_{\theta,q} = [H^t(\Omega), H^m(\Omega)]_{\theta,q} \cap H_0^m(\Omega).$$

Proof. We follow the main ideas of [2] but have weights be unity for simplicity; see also [18] and [1].

The inclusion from left to right follows directly from the definition.

The proof of the reverse inclusion can through a partition of unity be reduced to considering a domain Ω with one corner of angle $\alpha \in (0, 2\pi) \setminus \{\pi\}$. We shall distinguish between two cases: whether $\alpha \in (0, \pi)$ or $(\pi, 2\pi)$.

Case 1. $\alpha \in (0, \pi)$. Then there exists a linear transformation from Ω to $\widetilde{\Omega}$ with a corner of angle $\tilde{\alpha} < \min\{\omega_0, \pi\}$ where ω_0 will be introduced in the next section as a sufficiently small angle that a certain shift theorem will hold. Let L be the associated map of functions defined on $\widetilde{\Omega}$ to functions defined on Ω. If $w \in H^t(\widetilde{\Omega})$, then we let $\tilde{v} = \Pi_{\widetilde{\Omega}} w$ denote the solution to

$$(2.1) \qquad \begin{aligned} (-\triangle)^m \tilde{v} + \tilde{v} &= (-\triangle)^m w + w \text{ in } \widetilde{\Omega}, \\ \tilde{v} &\in H_0^m(\widetilde{\Omega}). \end{aligned}$$

Thus $\Pi_{\widetilde{\Omega}}$ is a projection from $H^m(\widetilde{\Omega})$ to $H_0^m(\widetilde{\Omega})$. As proven in the next section on regularity, there exists ω_0, dependent on m and t, such that the following shift theorem holds provided $\tilde{\alpha} < \omega_0$:

$$\|\tilde{v}\|_{H^t} \leq C\|(-\triangle)^m w + w\|_{H^{t-2m}}.$$

In particular, $P_\Omega = L \circ \Pi_{\widetilde{\Omega}} \circ L^{-1} \in \mathcal{B}(H^m(\Omega), H_0^m(\Omega))$ and $P_\Omega \in \mathcal{B}(H^t(\Omega), H^t(\Omega) \cap H_0^m(\Omega))$. Thus, by interpolation,

$$P_\Omega \in \mathcal{B}([H^t(\Omega), H^m(\Omega)]_{\theta,q}, [H^t(\Omega) \cap H_0^m(\Omega), H_0^m(\Omega)]_{\theta,q}).$$

Since $P_\Omega|_{H_0^m(\Omega)} = I$ (the identity),

$$[H^t(\Omega), H^m(\Omega)]_{\theta,q} \cap H_0^m(\Omega) \subseteq [H^t(\Omega) \cap H_0^m(\Omega), H_0^m(\Omega)]_{\theta,q}. \tag{2.2}$$

Case 2. $\alpha \in (\pi, 2\pi)$. Let B be a ball centered at the corner and containing Ω. By E_Ω, we denote the Stein extension [16, Chap. VI, §3] of functions on Ω to functions on B vanishing at ∂B. Let $\Omega^c = B \setminus \Omega$ and let E_{Ω^c} be the Stein extension of functions on Ω^c to all of B. Theorem 5 in [16] states that $E_\Omega \in \mathcal{B}(H^k(\Omega), H^k(B))$ and $E_{\Omega^c} \in \mathcal{B}(H^k(\Omega^c), H^k(B))$, for all $k \in \mathbf{N}$. Now define

$$P_\Omega = E_{\Omega^c} \circ P_{\Omega^c} \circ E_\Omega + (I - E_{\Omega^c} \circ E_\Omega)$$

with P_{Ω^c} being the the same operator as P_Ω was in Case 1. Then $P_\Omega|_{H_0^m(\Omega)} = I$ and

$$P_\Omega \in \mathcal{B}([H^t(\Omega), H^m(\Omega)]_{\theta,q}, [H^t(\Omega) \cap H_0^m(\Omega), H_0^m(\Omega)]_{\theta,q})$$

which ends the proof of the proposition. □

Remark 1. We have explicitly excluded vertices of angles $0, \pi$, or 2π. In these cases it is not possible to map linearly onto a domain of sufficiently small angle. In case Ω is a polygon the exclusion only amounts to 2π.

Remark 2. The theorem and proof hold in $\mathbf{R}^3$ for conical points with smooth cross section almost verbatim.

3. Regularity for small angles. In [12] it is stated that, given $k \in \mathbf{N}$, if the domain contains only corners of sufficiently small angles and $f \in H_0^k$, then the solution (u) of a Dirichlet problem with zero boundary conditions and a $2m$ order, elliptic operator $(Lu = f, u \in H_0^m)$ belongs to H^{k+2m}. We present a proof here following and expanding upon the ideas in [12, pp. 292–294] and [4] extending to the case where $f \in H^k$, $k \geq -m$. We use the notation of [12].

Let L be strongly elliptic of order $2m$ with C^∞ coefficients and $u \in H_0^m$ be the solution of

$$Lu = f$$

in a plane sector with opening $\tilde{\alpha} > 0$ and the corner translated to the origin (a case of C^∞ sides may be reduced to this by a C^∞ diffeomorphism). In [12] a technique is used that involves a combination of (1) looking at $\mathcal{L}(0, \partial/\partial x)$: the principal part of the operator $L(x, \partial/\partial x)$ with coefficients fixed at the origin, (2) changing to polar variables (r, ω), so that $\mathcal{L}u = f$ takes the form:

$$\sum_{0 \leq i_2 \leq i_1 \leq 2m} \frac{a_{i_1 i_2}(\omega)}{r^{i_1}} \frac{\partial^{2m-i_2} u}{\partial r^{2m-i_1} \partial \omega^{i_1-i_2}} = f,$$

(3) making the change of the radial variable $(\varrho = \ln 1/r)$ so that $\mathcal{L}u = f$ now takes the form

$$\sum_{1 \leq k_1+k_2 \leq 2m, 0 \leq k_1, k_2} \breve{a}_{k_1 k_2}(\omega) \frac{\partial^{k_1+k_2} u}{\partial \varrho^{k_1} \partial \omega^{k_2}} = f \cdot e^{-2m\varrho} = F,$$

and (4) taking the Fourier transform with respect to the "radial" variable (ϱ). The domain then consists of angles $\omega \in \widetilde{D}$ — an interval on S^1 (for $\mathbf{R}^2$ — in dimension n a domain on S^{n-1} with smooth boundary). The final form of $\mathcal{L}u = f$ is

$$L_0\left(\omega, i\lambda, \frac{\partial}{\partial \omega}\right)\hat{u} = \hat{F}.$$

The boundary conditions undergo similar transformations. Steps 3 and 4 constitute a partial Mellin transform with respect to the r variable. Steps 2 through 4 are sometimes called the Kondrat'ev transform [9]. Let $R(\lambda)$ be the resolvent operator — a meromorphic function of λ — associated with the resulting boundary value problem. In [12], [11], and [4] it is shown that if $f \in H^k$, then $u \in H^m$ has the expansion

$$u = \sum_{h_0 < \mathrm{Im}\lambda_j < h} \sum_{s=0}^{n_j} \alpha_{js} r^{-i\lambda_j} \log^s r \sum_{q=0}^{s} P_{jsq}(r \log^q r) + w \tag{3.1}$$

where $h_0 = -1 + m$, $h = -1 + k + 2m$, λ_j are the poles of $R(\lambda)$ of multiplicity n_j, P_{jsq} are polynomials of degree $[h - \mathrm{Im}\lambda_j]$, whose coefficients are C^∞ functions of ω, and $w \in H^{k+2m}$. From this expansion we see that the smoothness of u depends on the poles λ_j of the function $R(\lambda)$ which lie above the straight line $\mathrm{Im}\lambda = -1 + m$. We will show that the following lemma holds.

LEMMA 1. *Given any positive h, there exists ω_0 such that, if the angle of the corner is smaller than ω_0, then the strip $-1 + m < \mathrm{Im}\lambda < h$ contains no poles of $R(\lambda)$.*

Proof. Let h be given and λ_0 be a pole of $R(\lambda)$ lying in the strip $-1+m < \mathrm{Im}\lambda < h$. When $\lambda = \lambda_0$, there exists a nonzero solution $u_0(\omega)$ to

$$\begin{aligned} L_0\left(\omega, i\lambda, \frac{\partial}{\partial\omega}\right) u_0 &= 0 \quad \text{in } \widetilde{D}, \\ u_0 = \frac{\partial u_0}{\partial\omega} = \cdots = \frac{\partial^{m-1} u_0}{\partial\omega^{m-1}} &= 0 \quad \text{on } \partial\widetilde{D}. \end{aligned}$$

Now, $L_0 u_0 = L_1 u_0 + \lambda L_2 u_0$, where the operator L_2 contains derivatives of order less than $2m$. Since this system is strongly elliptic for all real λ, it is strongly elliptic for $\lambda = 0$. So L_1 is strongly elliptic. Let

$$I(u) = \int_{\widetilde{D}} (L_0 u)\overline{u}\, d\omega$$

which at u_0 is zero: integrate by parts

$$\begin{aligned} &I_1(u_0) + I_2(u_0) + I_3(u_0) \\ &\quad = \int_{\widetilde{D}} \Bigg\{ \Bigg[\tilde{a}_{mm}(\omega) \frac{\partial^m u_0}{\partial\omega^m} \frac{\partial^m \overline{u_0}}{\partial\omega^m} \\ &\qquad + \sum_{0<i+j<2m, 0\le i,j\le m} \lambda^{i+j} \tilde{a}_{m-i,m-j}(\omega) \frac{\partial^{m-i} u_0}{\partial\omega^{m-i}} \frac{\partial^{m-j}\overline{u_0}}{\partial\omega^{m-j}} \Bigg] \\ &\qquad + \lambda^{2m} \tilde{a}_{00}(\omega) u_0 \overline{u_0} \Bigg\}\, d\omega \\ &\quad = 0. \end{aligned}$$

By strong ellipticity of L_1,

$$|\mathrm{Re} I_1(u_0)| \ge \gamma_0 \int_{\widetilde{D}} \left| \frac{\partial^m u_0}{\partial\omega^m} \right|^2 d\omega - C_0 \int_{\widetilde{D}} |u_0|^2 d\omega$$

where γ_0 and C_0 do not depend on u_0 or σ — the diameter of $\widetilde{D}$ $(= \tilde{\alpha})$.

$$|I_2(u_0)| \le \epsilon \int_{\widetilde{D}} \left| \frac{\partial^m u_0}{\partial\omega^m} \right|^2 d\omega + C(\epsilon)|\lambda|^{2(m-1)} \int_{\widetilde{D}} |u_0|^2 d\omega$$

by intermediate derivative inequalities as sketched in [12] and

$$|I_3(u_0)| \le C|\lambda|^{2m} \int_{\widetilde{D}} |u_0|^2 d\omega$$

where $C > 0$ does not depend on σ. Also

$$\int_{\widetilde{D}} \left| \frac{\partial^m u_0}{\partial \omega^m} \right|^2 d\omega \ge \frac{\gamma}{\sigma^{2m}} \int_{\widetilde{D}} |u_0|^2 \, d\omega.$$

Upon contracting like terms, substituting this last inequality, and cancelling $\int_{\widetilde{D}} |u_0|^2 d\omega$, we get from $|\mathrm{Re} I_1| \le |I_2| + |I_3|$

$$\gamma_1 \sigma^{-2m} \le 1 + |\lambda|^{2(m-1)} + |\lambda|^{2m}$$

for some $\gamma_1 > 0$ independent of σ. Since $\mathrm{Im}\lambda \in (-1+m, h)$, if $\lambda = \rho e^{i\theta}$, $\theta \in [-\pi/2, 3\pi/2)$, given any $\epsilon > 0$, there exists σ sufficiently small so that

$$\theta \in \left(-\frac{\epsilon}{2m}, \frac{\epsilon}{2m} \right) \cup \left(\pi - \frac{\epsilon}{2m}, \pi + \frac{\epsilon}{2m} \right)$$

and thus $2m\theta \in (-\epsilon, \epsilon) \cup (2m\pi - \epsilon, 2m\pi + \epsilon) = (-\epsilon, \epsilon)$ such that $\mathrm{Re}(\lambda^{2m}) > 0$. Thus $|\mathrm{Re}\ \lambda^{2m}|/|\lambda|^{2m} = \cos(2m\theta) \ge \cos\epsilon \ge \frac{1}{2}$ for $\epsilon < \pi/3$ so that for $\gamma_2 > 0$ independent of σ and u_0,

$$|\mathrm{Re} I_3| \ge \frac{\gamma_2}{2} |\lambda|^{2m} \int_{\widetilde{D}} |u_0|^2 d\omega.$$

If we again contract, substitute, and cancel as before, but now in $|\mathrm{Re}I_1 + \mathrm{Re}I_3| \le |I_2|$ (using that $\tilde{a}_{00}$ and $\tilde{a}_{mm}$ are of the same sign and $\mathrm{Re}(\lambda^{2m}) > 0$), we get with positive C_1, C_2

$$\sigma^{-2m} + C_1|\lambda|^{2m} \le C_2|\lambda|^{2(m-1)}$$

admitting no solutions λ for sufficiently small σ. □

Remark 3. Another way of proving this lemma for the biharmonic operator is by checking that the angle $\tilde{\alpha}$ can be chosen such that the roots of the equation

$$\sinh^2(\tau\omega) = \tau^2 \sin^2 \omega$$

see [6], (7,2,2,1), except for $-i$ and 0 all have sufficiently small (negative, large absolute value) imaginary value; cf. [5]. Note $1 + i\tau = -i\lambda$.

We finally employ a recent regularity theorem in [4].

LEMMA 2. *Assume that* $k \ge -m$, $k \notin -m + \{\frac{1}{2}, \frac{3}{2}, \cdots, m - \frac{1}{2}\}$. *Let* L *be a strongly elliptic partial differential operator of order* $2m$ *with* C^∞ *coefficients and let* $f \in H^k(\widetilde{\Omega})$ ($\widetilde{\Omega}$ *is defined above*). *Then, for sufficiently small* $\tilde{\alpha}$, *the solution* $u \in H_0^m(\widetilde{\Omega})$ *to*

$$Lu = f \text{ in } \widetilde{\Omega} \tag{3.2}$$

belongs to $H^{k+2m}(\widetilde{\Omega})$ *and* $\|u\|_{H^{k+2m}} \le C\|f\|_{H^k}$.

Proof. The statement is really a corollary of Lemma 1 and a recent shift theorem in [4, Cor. (5.2)] proven in [4, §10]. It is stated for a cone in Theorem (1.11). In order

to apply this result we select the angle $\tilde{\alpha}$ sufficiently small that Lemma 1 ensures that $R(\lambda)$ has no poles in the strip $\mathrm{Im}\lambda \in [m-1, t-2]$. This in turn implies Dauge's condition (C2*) ($\sim$ (R2)) as follows: If $-i\lambda \in \mathbf{N}$, then [4, Corollary (4.6′)] yields (C2*) and if $-i\lambda \notin \mathbf{N}$, then Corollary (4.9) along with Corollary (4.15) and the fact that $a = 2$ (see [4, p. 39]) concludes the proof. □

For the interpolation result we use this lemma with $L = (-\triangle)^m + I$.

Remark 4. For the H_0^2 interpolation to hold, it would have sufficed to quote [6, Theorem 7.2.2.3]. The H_0^2 interpolation result is thus essentially — along with the reasoning of the proof of the proposition and a localization of the poles of $R(\lambda)$ for the biharmonic — a consequence of the analysis in Grisvard's monograph [6]. Such an analysis was first done in [10] and [15] for the Stokes problem (which via the stream function connects to the biharmonic problem).

Remark 5. For $m > 2$ it is possible to prove Lemma 2 directly from [12] when $k \geq -1$, $k \in \mathbf{Z}$; [12] has the result for $f \in H_0^k$ and $k \in \mathbf{N}$. Then it is possible to prove for $f \in H^k$ when $k \geq -1$ by generalizing the trace Theorem 7.2.2.3 in [6] for a domain $\widetilde{\Omega}$ with one corner C of sufficiently small angle $\tilde{\alpha}$ between the two linear pieces Γ_j, $j = 1, 2$. First, by this, one finds $v \in H^{k+2m}(\widetilde{\Omega}) \cap H_0^m(\widetilde{\Omega})$ such that

$$(-\triangle)^m v + v - f \in H_0^k(\widetilde{\Omega}). \tag{3.3}$$

Then one applies to $w = u - v$ Kondrat'evs result (when $f \in H_0^k$) with Lemma 1 choosing $\tilde{\alpha}$ sufficiently small that $w \in H^{k+2m}$ where $v \in H^{k+2m}$ is the solution to (3.3). In [6] the generalization of Kondrat'ev's weighted spaces is given for $k = -1$. It seems difficult, however, to go to all the remaining negative integers.

Acknowledgments. The author wishes to expressly thank a number of people at the University of Maryland, College Park for some very helpful discussions: Michael Vogelius, Ivo Babuška, Bruce Kellogg, John Osborn, and Tobias von Petersdorff. Also thanks to the Institute for Physical Science and Technology, College Park, for giving me the opportunity for such discussions.

AN EXTREMAL PROBLEM CONCERNING A MARKOV-TYPE INEQUALITY*

P. DÖRFLER†

Abstract. For any polynomial f with complex coefficients let $\|f\|$ be the norm in $L^2[0,\infty)$ with the Laguerre weight function $w(t)=e^{-t}$. Let P_n be the set of all complex polynomials whose degree does not exceed n and $\gamma_n := \sup_{f\in P_n}(\|f'\|/\|f\|)$. We show that $\gamma_n/n \to 2/\pi$ as $n\to\infty$.

Key words. Markov inequality, L^2 norm, Laguerre weight

AMS(MOS) subject classifications. 33A65, 41A17, 41A44

1. For any polynomial f with complex coefficients we define the norm

$$\|f\| := \left\{\int_0^\infty |f(t)|^2 e^{-t}\,dt\right\}^{1/2}.$$

Let P_n denote the set of all complex polynomials whose degree does not exceed n and consider

$$\gamma_n := \sup_{f\in P_n}\frac{\|f'\|}{\|f\|}, \qquad n\in\mathbb{N}. \tag{1}$$

In [4] Schmidt obtained estimates for γ_n that are asymptotically sharp. Some years later, Turán [5] found the exact value of γ_n:

$$\gamma_n = \left(2\sin\frac{\pi}{4n+2}\right)^{-1}, \qquad n\in\mathbb{N}.$$

In the present paper we show the convergence of γ_n/n as $n\to\infty$ and determine the limit, which turns out to be $2/\pi$. This result is an immediate consequence of the above-mentioned results obtained by Schmidt and Turán. Now, it is the purpose of this paper to present a quite different approach to this problem by using a new method. This method is based on results developed in [1] and on some function-theoretic considerations derived from [2].

If P_n is restricted to certain smaller classes of polynomials, there exist several results concerning γ_n [6], [7]. For the class of polynomials with nonnegative coefficients, Milovanović [3] computed the exact value of γ_n even for the generalized Laguerre weight.

2. In [1] Dörfler proved that γ_n is the largest singular value of the $n\times(n+1)$ matrix

$$A_n^{(1)} = \begin{bmatrix} 0 & -1 & \cdots & -1 \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & -1 \end{bmatrix},$$

i.e., the square root of the largest eigenvalue of $(A_n^{(1)})^t A_n^{(1)}$.

† Institut für Mathematik und Angewandte Geometrie, Montanuniversität Leoben, A-8700 Leoben, Austria.

Since all the elements in the first row and the first column of $(A_n^{(1)})^t A_n^{(1)}$ are zero, it suffices to consider the eigenvalues of the $n \times n$ matrix

$$B_n := \begin{bmatrix} 1 & 1 & \cdots & 1 \\ 1 & 2 & \cdots & 2 \\ \vdots & \vdots & & \vdots \\ 1 & 2 & \cdots & n \end{bmatrix}, \qquad n \in \mathbb{N}.$$

First we derive a recurrence formula for the characteristic polynomial of B_n

$$Q_n(t) := \det(B_n - tI_n), \qquad n \in \mathbb{N}, \tag{2}$$

where I_n denotes the $n \times n$ identity matrix.

LEMMA 1. $Q_{n+1} = (1-2t)Q_n - t^2 Q_{n-1}$, $n \geqq 2$.

Proof. Consider $B_{n+1} - tI_{n+1}$. If we multiply the nth row by (-1) and then add it to the last row and, afterwards, multiply the nth column by (-1) and add it to the last column, we obtain

$$Q_{n+1} = \det \begin{bmatrix} 1-t & 1 & \cdots & 1 & 0 \\ 1 & 2-t & \cdots & 2 & 0 \\ \vdots & \vdots & & \vdots & \vdots \\ 1 & 2 & \cdots & n-t & t \\ 0 & 0 & \cdots & t & 1-2t \end{bmatrix}.$$

By expanding this determinant by the last row and expanding one of the subdeterminants by its last column, the above assertion follows instantly. □

With the aid of Lemma 1 we can compute Q_n explicitly.

LEMMA 2.

$$Q_n(t) = \sum_{k=0}^{n} \binom{n+k}{n-k} (-t)^{n-k}, \qquad n \in \mathbb{N}.$$

Proof. We use induction on n. By definition (2), $Q_1 = 1-t$ and $Q_2 = 1-3t+t^2$, so that the assertion is obviously true for $n=1$ and $n=2$. Suppose now that the assertion is also true for all n smaller than or equal to a fixed $N \geqq 2$. By substituting for Q_N and Q_{N-1} in the recurrence formula provided by Lemma 1, a lengthy but straightforward computation gives the desired result for Q_{N+1}. □

Remark. γ_n^2 is the largest root of Q_n. Although we know Q_n explicitly, it is difficult to determine γ_n from it. Its asymptotic behavior, however, can be studied by using function-theoretic methods.

3. First of all we introduce the rational functions

$$R_n(z) := \frac{Q_n(n^2 z)}{(-n^2 z)^n}, \qquad n \in \mathbb{N}, \tag{3}$$

which are well defined and analytic for all $z \in \mathbb{C} \setminus \{0\}$. By Lemma 2 we have

$$R_n(z) = \sum_{k=0}^{n} n^{-2k} \binom{n+k}{n-k} (-z)^{-k}, \qquad n \in \mathbb{N}. \tag{4}$$

LEMMA 3. *Let $n \in \mathbb{N}$ be arbitrary but fixed and let $n^2 w = z$. Then*

$$R_n(w) = 0 \Leftrightarrow Q_n(z) = 0.$$

Proof. This is clear by definition (3) and the fact that $Q_n(0) \neq 0$ for all $n \in \mathbb{N}$. □

LEMMA 4. *Let $G \subseteq \mathbb{C}$ be a region, $0 \notin G$. Then*

$$\lim_{n\to\infty} R_n(z) = \cos(z^{-1/2})$$

in G and this convergence is uniform on compact subsets of G.

Proof. (a) Let $k \in \mathbb{N} \cup \{0\}$ be fixed. Then

$$\lim_{n\to\infty} n^{-2k}\binom{n+k}{n-k} = \frac{1}{(2k)!}. \tag{5}$$

For $k = 0$ this is obviously true. Thus consider $k > 0$. If $n < k$, then $\binom{n+k}{n-k} = 0$ by definition. For $n \geqq k$ we have

$$n^{-2k}\binom{n+k}{n-k} = \frac{n+k}{n}\,\frac{n+k-1}{n}\cdots\frac{n-k+1}{n}\,\frac{1}{(2k)!}, \tag{6}$$

which implies (5) because k is fixed. Since

$$\cos(z^{-1/2}) = \sum_{k=0}^{\infty} \frac{1}{(2k)!}(-z)^{-k},$$

it follows from (4) and (5) that $R_n(z)$ converges to $\cos(z^{-1/2})$ in G as $n \to \infty$.

(b) Let $k \in \mathbb{N} \cup \{0\}$ and $n \in \mathbb{N}$ be arbitrary. Then

$$n^{-2k}\binom{n+k}{n-k} \leqq \frac{1}{k!}. \tag{7}$$

For $k = 0$ and $n < k$, this is evidently true. For $0 < k \leqq n$, equation (6) holds, from which we derive

$$n^{-2k}\binom{n+k}{n-k} = \left[1+\frac{k}{n}\right]\left[1-\left(\frac{k-1}{n}\right)^2\right]\cdots\left[1-\left(\frac{1}{n}\right)^2\right]\frac{1}{(2k)!},$$

and finally (7) follows.

Let $K \subseteq G$ be compact. Then by (4) and (7)

$$|R_n(z)| \leqq \sum_{k=0}^{\infty} \frac{1}{k!}|z|^{-k} \leqq \max_{z\in K} e^{1/|z|} =: C_K < \infty$$

for all $z \in K$ and all $n \in \mathbb{N}$, where C_K is a constant depending on K only. Hence, $\{R_n(z)\}$ is locally bounded and, by Vitali's theorem, the convergence of $R_n(z)$, shown in (a), is uniform on compact subsets of G. □

Now we are ready to state and prove our theorem.

THEOREM. *Let γ_n be defined as in* (1). *Then*

$$\lim_{n\to\infty} \frac{\gamma_n}{n} = \frac{2}{\pi}.$$

Proof. Let $z_{1n}, \cdots, z_{nn}$ be the roots of Q_n, the characteristic polynomial of B_n. Since $(A_n^{(1)})^t A_n^{(1)}$ is positive semidefinite, its eigenvalues are real and nonnegative. Hence, because $Q_n(0) \neq 0$, for all $n \in \mathbb{N}$ we can introduce the ordering $z_{1n} \geqq z_{2n} \geqq \cdots \geqq z_{nn} > 0$. Let, by Lemma 3, $w_{1n} \geqq w_{2n} \geqq \cdots \geqq w_{nn} > 0$ be the zeros of R_n corresponding to $z_{1n}, \cdots, z_{nn}$, respectively. Then, since $\gamma_n^2 = z_{1n}$,

$$w_{1n} = \left(\frac{\gamma_n}{n}\right)^2, \qquad n \in \mathbb{N}. \tag{8}$$

Let w_j denote the (positive) zeros of $\cos(z^{-1/2})$, that is,

$$w_j = \frac{4}{\pi^2(2j-1)^2}, \qquad j \in \mathbb{N},$$

which, in particular, implies $w_1 > w_2 > \cdots > w_j > \cdots > 0$. Then, by Lemma 4 and the theorem of Hurwitz we may conclude that for every fixed j

$$\lim_{n\to\infty} w_{jn} = w_j, \qquad j = 1, 2, 3, \cdots.$$

The case $j = 1$, combined with (8), proves the assertion of our theorem. □

MINIMAL EXTRAPOLATIONS OF FILTERS*

BENJAMIN B. WELLS†

Abstract. In this paper the following question is answered for the line and for the circle. When is a trapezoid t the graph of a function whose Fourier norm is smallest among functions whose graphs coincide with t on its intervals of constancy? When such functions are viewed as frequency responses of low-pass filters, they are optimally stable. In the periodic case this means that their Fourier transforms have the property that when implemented as digital filters, the least upper bound of all ratios of norms of output sequences to norms of corresponding input sequences is as small as possible.

Key words. absolutely convergent Fourier series, A-norm, quotient norm, pseudomeasure, low-pass filter

AMS(MOS) subject classifications. 42A16, 42A28

1. Introduction and preliminaries. We denote by $\mathbb{R}$ the group of real numbers under addition, by T the circle group of real numbers under addition modulo 2π, and by Z the group of integers. By an A-function we mean either a continuous complex-valued function f defined on $\mathbb{R}$ and expressed as the Fourier transform of an absolutely integrable function, or else a function f defined on the circle T and having absolutely convergent Fourier series. In the first case the A-norm of f is defined to be the L^1-norm of the absolutely integrable function giving rise to f; in the latter case the A-norm of f is defined to be the sum of the absolute values of the terms of the Fourier series of f.

Let E denote a fixed closed subset of the reals $\mathbb{R}$ or of the circle T, and let $I(E)$ denote those A-functions that are identically zero on E. An A-function f is said to be of *minimal extrapolation* from E provided

$$\|f\|_A = \inf\{\|f+g\|_A \mid g \text{ is in } I(E)\}. \tag{1}$$

The concept of minimal extrapolation was introduced by Beurling [2].

The expression on the right-hand side of (1) defines a norm on the quotient algebra $A(E) = A/I(E)$. The dual space of $A(E)$ may be identified with those pseudomeasures that annihilate $I(E)$. For the closed sets E considered in this paper, this class coincides with the pseudomeasures supported by E. Most of the pseudomeasures treated in this paper are discrete measures. To emphasize the duality with A, however, we shall use the term "pseudomeasure" throughout.

PROPOSITION 1.1. *The function f is of minimal extrapolation from E if and only if there is a pseudomeasure S of norm 1 whose support is contained in E such that*

$$(S, f) = \|f\|_A.$$

Proof. Suppose the existence of S. Thus,

$$(S, f+g) = (S, f) = \|f\|_A \tag{2}$$

for all g belonging to $I(E)$. An immediate consequence of (2) is that $\|f+g\|_A \geqq \|f\|_A$ for all g in $I(E)$, i.e., f is of minimal extrapolation.

* Received by the editors January 29, 1990; accepted for publication May 3, 1990.
† Science Applications International Corporation, 803 West Broad Street, Falls Church, Virginia 22046.

Conversely assume that f is of minimal extrapolation. Thus, the A-norm of f equals its quotient norm. By duality, we may select a pseudomeasure S, annihilating $I(E)$, such that $(S,f) = \|f\|_A$. This completes the proof of the proposition.

Let E denote the points of an equipartition of the circle T. A result of Herz (cf. [6, p. 58]) is that any continuous function that is piecewise linear on the intervals defined by E is of minimal extrapolation from E. Reference [1, Prop. 1] contains another proof of the Herz criterion. If the points of the partition E are not uniformly spaced, we might expect that a piecewise linear function need not be of minimal extrapolation relative to E. Indeed, it is no longer clear whether minimal extrapolation functions exist.

To guarantee the existence of minimal extrapolation functions, it is necessary to make some assumption about the set E. To see this, let E be a countable independent set having zero as an accumulation point. Let J be an interval containing zero such that $J \cap E$ and $J^c \cap E$ are both nonempty. Furthermore, let f be a function defined to be equal to 1 on $J \cap E$ and zero on $J^c \cap E$. The function f has no minimal extrapolation from the set E. This is a consequence of the fact that the quotient norm of f relative to E is equal to 1. It is easy to see that there can be no absolutely convergent Fourier series representing f and having A-norm equal to 1.

Esseen [3] pointed out that Lemma 1 of [2] implies that a minimal extrapolation always exists if E is the closure of its interior. By a standard convergence argument it is easy to demonstrate that a sufficient condition for the existence of minimal extrapolations relative to a set E is that every portion of E (i.e., every nonvoid intersection of E with an open interval) have positive measure. Thus, certainly, if E is a finite union of nondegenerate, closed intervals this condition would be met.

The question that led us to this study is the following. Among functions whose graphs are trapezoids symmetrical about the y-axis, which ones are of minimal extrapolation from their intervals of constancy? This problem is relevant to the subject of filter theory. For a detailed account of this subject, the reader is referred to the monograph [5]. A function whose graph is a trapezoid is an example of the amplitude of a bandpass filter. When such a filter is used as a multiplier, function values are "passed" in the pass band (where the amplitude of the filter is equal to 1), and function values in the stop band (where the values of the filter are equal to zero) are made equal to zero.

A function is said to define a *stable* filter if the operation defined by convolution with its Fourier coefficients is a bounded operator from the space of bounded sequences into itself. The stability of a filter is determined by what is happening in the transition bands. In the case of the trapezoid, these are the intervals where the function values give rise to the sides of the trapezoid. If a function defining a filter is an A-function, its A-norm is equal to the norm of the operator from the space of bounded sequences to itself defined by convolution with its Fourier coefficients. Indeed, the A-norm of the filter is exactly equal to the least upper bound of all ratios of norms of output sequences to norms of corresponding input sequences. Reference [1] contains estimates for lower bounds on the A-norms of filters having specified pass, stop, and transition bands.

For a given pass band and a given stop band, it is desirable to ensure that the least upper bound of all ratios of norms of output sequences to norms of corresponding input sequences is as small as possible. That is, we would like to know the minimal extrapolation of a filter from its intervals of constancy. For the case of trapezoids on the line, it is shown in § 2 that a necessary and sufficient condition is that the length of the pass band be an integral multiple of the length of the transition band. In § 3

the circle group is treated. It is shown that the only trapezoids that are minimal extrapolations from their intervals of constancy are those satisfying the Herz criterion. In the final section of the paper it is shown that in the case of the circle T, the trapezoid is never a unique minimal extrapolation from its intervals of constancy.

In the remainder of the paper we shall be dealing with extrapolations from the intervals of constancy of a function. The following definition will help make our statements more concise.

DEFINITION. We shall say that a function f has the M property if it is of minimal extrapolation from its intervals of constancy.

2. Filters defined by trapezoids on $\mathbb{R}$. In this section we prove that a necessary and sufficient condition that a trapezoid on $\mathbb{R}$ be a minimal extrapolation from its intervals of constancy is that the length of its pass band be an integral multiple of the length of its transition band.

For $0 \leqq \varepsilon \leqq \omega \leqq \omega + \varepsilon < \infty$, $t_{\omega,\varepsilon}$ will denote the function whose graph has the shape of a trapezoid of height 1, which is equal to 1 on the interval $[-\omega + \varepsilon, \omega - \varepsilon]$ and is equal to zero outside the interval $[-\omega - \varepsilon, \omega + \varepsilon]$:

$$\begin{aligned} t_{\omega,\varepsilon}(x) &= 1, \qquad -\omega + \varepsilon \leqq x \leqq \omega - \varepsilon, \\ &= 0, \qquad \omega + \varepsilon \leqq |x|. \end{aligned} \tag{3}$$

In the present setting, the Fourier transform of the function $t_{\omega,\varepsilon}$ is in $L^1(\mathbb{R})$, and its L^1-norm is the A-norm of $t_{\omega,\varepsilon}$. Fourier transforms of pseudomeasures are functions which belong to $L^\infty(\mathbb{R})$.

A straightforward computation yields that the Fourier transform of $t_{\omega,\varepsilon}$ is given by

$$\begin{aligned} t^{\wedge}_{\omega,\varepsilon}(y) &= 2(\sin \omega y \sin \varepsilon y)/\varepsilon y^2, \qquad y \neq 0, \\ &= 2\omega, \qquad y = 0. \end{aligned} \tag{4}$$

THEOREM 2.1. *The function $t_{\omega,\varepsilon}$ has the M property if and only if ω is an integral multiple of ε.*

LEMMA 2.2. *For positive α, $\|t_{\omega,\varepsilon}\|_{A(\mathbb{R})} = \|t_{\alpha\omega,\alpha\varepsilon}\|_{A(\mathbb{R})}$.*

Proof. The proof is an immediate consequence of the relation

$$t_{\alpha\omega,\alpha\varepsilon}(x) = t_{\omega,\varepsilon}(x/\alpha),$$

and the fact that $\|f(x/\alpha)\|_{A(\mathbb{R})} = \|f\|_{A(\mathbb{R})}$ for any $f \in A(\mathbb{R})$.

LEMMA 2.3. *For positive α, $t_{\omega,\varepsilon}$ has the M property if and only if $t_{\alpha\omega,\alpha\varepsilon}$ does.*

Proof. Apply Lemma 2.2.

We first prove that $t_{\omega,\varepsilon}$ has the M property when ω is an integral multiple of ε. By Lemma 2.3 there is no loss of generality in assuming that $\varepsilon/2\pi = 1$ and that $\omega/2\pi$ is an integer. Define the periodic function f by

$$f(y) = \operatorname{sign}(\sin \omega y).$$

A straightforward calculation yields that the Fourier coefficients of f are given by

$$\begin{aligned} f^{\wedge}(\omega n/2\pi) &= 4i/\omega n \quad \text{for } n \text{ odd}, \\ &= 0 \quad \text{for } n \text{ even}. \end{aligned}$$

Define the pseudomeasure S on $\mathbb{R}$ by setting its Fourier transform to be the periodic function

$$S^{\wedge}(y) = \operatorname{sign}(\sin \omega y \sin \varepsilon y). \tag{5}$$

It is evident from the expressions (4) and (5) of the Fourier transforms that S imparts its A-norm to $t_{\omega,\varepsilon}$. From the calculation of the last paragraph, we see that the nth Fourier coefficient of $S^\wedge$ is given by

$$S(n) = -\frac{8}{\pi\omega} \sum_{j\in\Lambda} 1/j(n - j\omega/2\pi), \tag{6}$$

where Λ is the set of odd integers j such that $n - j\omega/2\pi$ is an odd multiple of $\varepsilon/2\pi$. Since $\varepsilon/2\pi = 1$, this implies that $S(n)$ can be nonzero only when n and $\omega/2\pi$ have opposite parity.

It is easy to see from the definition of Λ that the support of S misses the intervals $(-\omega - \varepsilon, -\omega + \varepsilon)$ and $(\omega - \varepsilon, \omega + \varepsilon)$. For, suppose that $2\pi n = j\omega + k\varepsilon$ lies in the interval $(\omega - \varepsilon, \omega + \varepsilon)$ with j and k odd and $\omega = q\varepsilon$, then $-\varepsilon < \{(j-1)q + k\}\varepsilon < \varepsilon$. Since $(j-1)q + k$ is odd, this is not possible. It follows from Proposition 1.1 that $t_{\omega,\varepsilon}$ has the M property.

To complete the proof of the theorem, it is necessary to show that $t_{\omega,\varepsilon}$ fails to have the M property whenever ω is not an integral multiple of ε. Suppose, therefore, that $\omega/2\pi$ and $\varepsilon/2\pi$ are relatively prime positive integers, $\varepsilon \leqq \omega$, with $\varepsilon/2\pi \neq 1$. At least one of $\omega/2\pi$ and $\varepsilon/2\pi$ is odd. If $\varepsilon/2\pi$ is odd, it suffices to show that (6) is nonzero at $\omega/2\pi + 1$. A similar argument shows that (6) is nonzero at $\omega/2\pi$ in the case where $\omega/2\pi$ is odd and $\varepsilon/2\pi$ is even. Suppose that $\omega/2\pi + 1 = j_0\omega/2\pi + k_0\varepsilon/2\pi$ for odd integers j_0 and k_0. Except for the multiplicative constant in front, the sum in (6) may be written as

$$\sum_{\lambda=-\infty}^{\infty} 1/\{(j_1 + 2\lambda\varepsilon/2\pi)(\omega/2\pi + 1 - (j_1 + 2\lambda\varepsilon/2\pi)\omega/2\pi)\},$$

where j_1 is an odd integer such that $1 \leqq j_1 < 2\varepsilon/2\pi$, and $j_1 \equiv j_0$ modulo $2\varepsilon/2\pi$. It is clear that each of the terms of the above sum is negative, except possibly the $\lambda = 0$ term. Now, j_1 cannot be equal to 1, for if $j_0 \equiv 1$ modulo $2\varepsilon/2\pi$, it would follow that $\varepsilon/2\pi = 1$, contrary to assumption. Therefore, the term corresponding to $\lambda = 0$ is negative as well, and it follows that S has nonzero support in the transition intervals $(-\omega - \varepsilon, -\omega + \varepsilon)$ and $(\omega - \varepsilon, \omega + \varepsilon)$.

Since $t^\wedge_{\omega,\varepsilon}$ is zero on a discrete set, $S^\wedge$ is undefined only on a set of Lebesgue measure zero. If it were the case that $t_{\omega,\varepsilon}$ had the M property, by Proposition 1.1 there would exist a pseudomeasure S_0 such that $S_0^\wedge(x) = S^\wedge(x)$ almost everywhere with respect to Lebesgue measure and such that its support is disjoint from the transition intervals. That is to say, as L^∞-functions $S_0^\wedge$ and $S^\wedge$ are identical. Therefore, $t_{\omega,\varepsilon}$ fails to have the M property.

It follows from the last paragraph and Lemma 2.3 that $t_{\omega,\varepsilon}$ fails to enjoy the M property whenever the quotient ω/ε is rational and nonintegral. Suppose now that this quotient is irrational. By Lemma 2.3 there is no loss of generality in assuming that $\omega = 2\pi$. Any function in $L^\infty(\mathbb{R})$ of norm 1 which imparts its A-norm to $t_{\omega,\varepsilon}$ must be equal almost everywhere to the function $S^\wedge(y)$ defined by (5). Therefore, it only remains to check that the support of S is not disjoint from the transition intervals $(-\omega - \varepsilon, -\omega + \varepsilon)$ and $(\omega - \varepsilon, \omega + \varepsilon)$.

Recall that the Fourier coefficients of the $2\pi/\varepsilon$ periodic function

$$f(y) = \text{sign}\,(\sin \varepsilon y)$$

are given by

$$f^\wedge(\varepsilon n/2\pi) = 4i/\varepsilon n \quad \text{for } n \text{ odd},$$
$$= 0 \quad \text{for } n \text{ even}.$$

Therefore, the support of the pseudomeasure S will be at the points of the form $\{\varepsilon n/2\pi + k\}$ where n and k are odd integers. In fact, since $\varepsilon/2\pi$ is irrational, the sum $\varepsilon n/2\pi + k$ uniquely determines n and k, therefore

$$S(\varepsilon n/2\pi + k) = -8/(\pi\varepsilon nk), \qquad n \text{ and } k \text{ odd}.$$

Again using the irrationality of $\varepsilon/2\pi$, we see that the set of numbers of the form $\{\varepsilon n/2\pi + k\}$ as n and k range over odd integers is dense in $\mathbb{R}$, and certainly cannot be disjoint from the transition intervals $(-\omega - \varepsilon, -\omega + \varepsilon)$ and $(\omega - \varepsilon, \omega + \varepsilon)$. This completes the proof of Theorem 2.1.

3. Filters defined by trapezoids on T. In this section we shall characterize those trapezoids on the circle group that have the M property. The class of such trapezoids turns out to be a more narrow class than that defined on the line $\mathbb{R}$ and enjoying the same property. Indeed, beyond those guaranteed by the criterion of Herz, there are none.

Suppose that $0 \leqq \varepsilon \leqq \omega \leqq \omega + \varepsilon \leqq \pi$. The exact statement of the theorem is the following.

THEOREM 3.1. *The function $t_{\omega,\varepsilon}$ has the M property on T if and only if either $\omega = \varepsilon$ or there are positive integers j_0 and N, such that $\omega = \pi j_0/N$ and $\varepsilon = \pi/N$.*

The sufficiency of the condition is the Herz criterion applied to $t_{\omega,\varepsilon}$ and an equipartition of $(-\pi, \pi]$ having mesh equal to $2\pi/N$. If zero is a point of the equipartition, j_0 is odd, otherwise j_0 is even. The remainder of the section is devoted to a proof of Theorem 3.1.

Let S denote a pseudomeasure defined on $\mathbb{R}$. A pseudomeasure S_0 corresponding to S is defined on T by specifying that its Fourier transform be the restriction of $S^\wedge$ to Z. The pseudomeasure S_0 is defined by

$$S_0(x) = \sum_{k=-\infty}^{\infty} S((x/2\pi) + k). \tag{7}$$

Convergence of (7) is understood to mean pointwise convergence on evaluation at A-functions.

Let the pseudomeasure S be defined on $\mathbb{R}$ by the equality

$$S^\wedge(y) = \operatorname{sign}(\sin(\omega y)).$$

Recall from § 2 that S is given by

$$S(\omega n/2\pi) = 4i/\omega n \quad \text{for } n \text{ odd},$$
$$= 0 \quad \text{for } n \text{ even}.$$

If $\omega/2\pi$ is irrational, the pseudomeasure S_0 is given by

$$S_0(\omega n) = 4i/\omega n \quad \text{for } n \text{ odd}$$
$$= 0 \quad \text{for } n \text{ even}, \tag{8}$$

where the argument of S_0 is taken modulo 2π. If $\omega = \pi k_0/N$ for relatively prime integers k_0 and N, using (7) we obtain

$$S_0(\omega n) = \sum_{k=-\infty}^{\infty} \frac{4i}{\omega(n + 2Nk)} \quad \text{for } n \text{ odd}, \tag{9}$$
$$= (2i/k_0)\cot(n\pi/2N).$$

The last equality comes about from recognizing the Weierstrass partial fractions decomposition of the cotangent function.

We now let S be the pseudomeasure defined on $\mathbb{R}$ by the equality

$$S^{\wedge}(y) = \operatorname{sign}(\sin(\omega y)\sin(\varepsilon y)). \tag{10}$$

We first consider the case of ω/π irrational and $\varepsilon/\pi = k_0/N$ in lowest terms. In this case $S^{\wedge}$ is defined everywhere except at the points NZ where $\sin(\varepsilon y)$ vanishes. The points $\{j\omega + k\varepsilon\}$ modulo 2π as j and k range over odd integers are distinct and dense in T. From (8) and (9) we have for odd j and k:

$$S_0(j\omega + k\varepsilon) = -(8/\omega j k_0)\cot(k\pi/2N). \tag{11}$$

It is clear that the right-hand side of (11) is nonzero, except if N is odd and $k = \xi N$ for odd ξ. If μ is a pseudomeasure with spectrum contained in NZ, then μ is $2\pi/N$ periodic, i.e., $\mu(x) = \mu(x + 2\pi/N)$. It must be shown that no pseudomeasure of the form $S_0 - \mu$, where the spectrum of μ is contained in NZ, will have support disjoint from the transition intervals $(-\omega - \varepsilon, -\omega + \varepsilon)$ and $(\omega - \varepsilon, \omega + \varepsilon)$. However, this follows easily, since if $\zeta \in (\omega - \varepsilon, \omega + \varepsilon)$, $\zeta + 2\lambda\varepsilon$ belongs to the interval $(-\omega - \varepsilon, -\omega + \varepsilon)$ for some integer λ. The value of μ is the same at ζ as at $\zeta + 2\lambda\varepsilon$, although the values of S_0 are distinct at these two points. Therefore, by Proposition 1.1 $t_{\omega,\varepsilon}$ does not have the M property.

We next consider the case where ω/π and ε/π are both irrational with $\varepsilon \neq \omega$. Since $S_0^{\wedge}(n)$ is defined at *every* value of n, it follows that it is only necessary to show that the pseudomeasure S_0 has nonvoid support in the transition intervals $(-\omega - \varepsilon, -\omega + \varepsilon)$ and $(\omega - \varepsilon, \omega + \varepsilon)$. As a first subcase, assume that ε is not a rational multiple of ω. Then the points $\{j\omega + k\varepsilon\}$ modulo 2π as j and k range over odd integers are distinct and dense in T. We have from (8) that

$$S_0(j\omega + k\varepsilon) = -4^2/(j\omega k\varepsilon) \quad \text{for } j \text{ and } k \text{ odd integers,}$$

and therefore, the support of S_0 is nonvoid in the intervals $(-\omega - \varepsilon, -\omega + \varepsilon)$ and $(\omega - \varepsilon, \omega + \varepsilon)$.

Next consider the subcase where $\varepsilon = p\omega/q$ for relatively prime integers p and q. Then the points $\{j\omega + k\varepsilon\}$ modulo 2π are not distinct, but are still dense in T, since ω/π and ε/π are irrational. By using (8), it follows that the value of S_0 at $\zeta = j\omega + k\varepsilon$ for j and k odd is given by

$$\begin{aligned} S_0(j\omega + k\varepsilon) &= -4^2 \sum \frac{1}{\omega(j + 2np)} \frac{1}{\varepsilon(k - 2nq)}, \\ &= \frac{-4^2}{\zeta}\left[\sum \frac{1}{\omega j + 2n\omega p} + \sum \frac{1}{\varepsilon k - 2n\omega p}\right], \end{aligned} \tag{12}$$

where the sums are taken over all integers n.

Recognizing the Weierstrass decomposition of the cotangent function, we may rewrite (12) as

$$S_0(\zeta) = \frac{-4^2\pi}{2\zeta\omega p}\left[\cot\left(\frac{j\pi}{2p}\right) + \cot\left(\frac{k\pi}{2q}\right)\right]. \tag{13}$$

Note that (13) is equal to zero only when $jq + kp \equiv 0$ modulo $2pq$, i.e., when ζ is a multiple of $2p\omega$. Of course, if $\omega = \varepsilon$, then $p = q = 1$ and $S_0(\zeta) = 0$ for all such ζ except $\zeta = 0$. Thus, in the present case when $\varepsilon \neq \omega$, the support of S_0 intersects the intervals $(-\omega - \varepsilon, -\omega + \varepsilon)$ and $(\omega - \varepsilon, \omega + \varepsilon)$. Again, by Proposition 1.1 we conclude that $t_{\omega,\varepsilon}$ does not have the M property.

We now consider the final case, namely, where ω/π and ε/π are both rational numbers. In this case the support of S_0 is contained in the finite group $T_N = \{\pi k/N \mid 0 \leqq k < 2N\}$ for some integer N. For the remainder of the section, the appropriate setting for computations of the Fourier transform is the group T_N.

LEMMA 3.2. *For relatively prime positive integers p and N, set $\omega/\pi = p/N$, and let S be the pseudomeasure defined by the equality $S\hat{}(n) = \operatorname{sign}(\sin \omega n)$, for n not in NZ.*

(a) *If p is odd and $S\hat{}(Nk) = (-1)^k$ for $k \in Z$, S is given by*

$$S\left(\frac{\pi k}{N}\right) = \frac{4}{1 - e^{i\pi kp'/N}} \quad \text{for } k \text{ odd},$$

$$= 0 \quad \text{for } k \text{ even},$$

where p' denotes the multiplicative inverse of p modulo 2N.

(b) *If p is even and $S\hat{}(Nk) = 1$ for $k \in Z$, S is given by*

$$S\left(\frac{\pi k}{N}\right) = 4\left[\frac{1 - e^{i\pi kp'([N/2]+1)/N}}{1 - e^{i\pi kp'/N}}\right] \quad \text{for } k \text{ even},$$

$$= 0 \quad \text{for } k \text{ odd},$$

where p' denotes the multiplicative inverse of p/2 modulo N.

Proof. The result is a straightforward calculation starting with the Fourier transform of $S\hat{}$ on the finite group T_N. For the proof of part (a) we begin with the expression

$$\begin{aligned} S\left(\frac{\pi k}{N}\right) &= \sum_{n=0}^{2N-1} \operatorname{sign}\left(\sin\frac{\pi pn}{N}\right) e^{i\pi kn/N} \\ &= \sum_{m=0}^{2N-1} \operatorname{sign}\left(\sin\frac{\pi m}{N}\right) e^{i\pi kmp'/N} \\ &= \sum_{m=0}^{N-1} e^{i\pi kmp'/N} - \sum_{m=N}^{2N-1} e^{i\pi kmp'/N} \\ &= 2\sum_{m=0}^{N-1} e^{i\pi kmp'/N} \quad \text{for } k \text{ odd}, \\ &= 0 \quad \text{for } k \text{ even}. \end{aligned}$$

This may easily be expressed in the form of the conclusion of part (a).

For the proof of part (b) note that

$$S\left(\frac{\pi k}{N}\right) = \sum_{n=0}^{2N-1} \operatorname{sign}\left(\sin\frac{\pi pn}{N}\right) e^{i\pi kn/N} \quad \text{becomes}$$

$$S\left(\frac{\pi k}{N}\right) = 2\sum_{n=0}^{N-1} \operatorname{sign}\left(\sin\frac{\pi pn}{N}\right) e^{i\pi kn/N} \quad \text{when } k \text{ is even},$$

$$= 0 \quad \text{for } k \text{ odd}.$$

For k even, the substitution $n = mp'$ allows this to be expressed as

$$S\left(\frac{\pi k}{N}\right) = 2\sum_{m=0}^{[N/2]} e^{i\pi kmp'/N} - 2\sum_{m=[N/2]+1}^{N-1} e^{i\pi kmp'/N},$$

which is easily rewritten to conform to the conclusion of part (b).

We first assume that $\omega/\pi = p/N$, and $\varepsilon/\pi = q/N$, where p and q are odd and relatively prime to N. Later, we shall indicate changes in the proof to accommodate

the case of either p or q even and provide a proof for the case when p and q have common factors with N. Recall that the nth Fourier coefficient of the trapezoid $t_{\omega,\varepsilon}$ is given by

$$\begin{aligned} t^{\wedge}_{\omega,\varepsilon}(n) &= (\sin \omega n \sin \varepsilon n)/\pi\varepsilon n^2 \quad \text{for } n \neq 0, \\ &= \omega/\pi \quad \text{for } n = 0. \end{aligned} \tag{14}$$

LEMMA 3.3. *For λ and N positive integers, let the pseudomeasure S_0 be defined on $T_{\lambda N}$. The pseudomeasure S defined by the relation*

$$S\left(\frac{\pi n}{N}\right) = \frac{1}{\lambda} \sum_{\nu=0}^{\lambda-1} S_0\left\{\frac{\pi}{\lambda}\left(\frac{n}{N}+2\nu\right)\right\}, \qquad 0 \leqq n < 2N,$$

satisfies

$$S^{\wedge}(n) = S_0^{\wedge}(\lambda n), \qquad n \in Z.$$

Proof. A straightforward calculation gives the result. The Fourier transform of S is given by

$$\begin{aligned} S^{\wedge}(n) &= \frac{1}{N} \sum_{k=0}^{2N-1} \frac{1}{\lambda} \sum_{\nu=0}^{\lambda-1} S_0\left(\frac{\pi}{\lambda}\left(\frac{k}{N}+2\nu\right)\right) e^{-in\pi\lambda k/\lambda N} \\ &= \frac{1}{\lambda N} \sum_{k=0}^{2N-1} \sum_{\nu=0}^{\lambda-1} S_0\left(\frac{\pi}{\lambda N}(k+2\nu N)\right) e^{-i(k+2\nu N)\pi\lambda n/\lambda N} \\ &= S_0^{\wedge}(\lambda n). \end{aligned}$$

Take S to be the pseudomeasure defined by

$$\begin{aligned} S^{\wedge}(n) &= \operatorname{sign}(\sin \pi p n/N \sin \pi q n/N) \quad \text{for } n \neq 0, \\ &= 1 \quad \text{for } n = 0. \end{aligned} \tag{15}$$

Replace n by nq' in the right-hand side of (15), where q' denotes the multiplicative inverse of q modulo $2N$. Let $p^{\sim}$ denote the representative of pq' modulo $2N$, $1 \leqq p^{\sim} < 2N$. If $1 \leqq p^{\sim} < N$ set $r = p^{\sim}$. If $N < p^{\sim} < 2N$, set $r = 2N - p^{\sim}$. In the computations below we shall assume the former case. If the latter holds, except for the zeroth coefficient, the sign of each Fourier coefficient is reversed. This change of sign does not alter the arguments presented below.

The case where $r = 1$ corresponds to $p = q$ when the condition of the theorem holds. Therefore, assume that $1 < r$, and let r', $1 < r' < N$, denote the inverse of r modulo N, so that $rr' = 1 + \lambda N$ for some positive integer λ.

Under the above assumptions, for n even we have

$$\begin{aligned} S\left(\frac{\pi n}{N}\right) &= \sum_{\nu=0}^{2N-1} \operatorname{sign}\left\{\sin\left(\frac{\pi r\nu}{N}\right) \sin\left(\frac{\pi\nu}{N}\right)\right\} e^{i\pi\nu n/N} \\ &= 2\left[\sum_{\nu=0}^{N-1} \operatorname{sign}\left(\sin\frac{\pi r\nu}{N}\right) e^{i\pi\nu n/N}\right]. \end{aligned} \tag{16}$$

The constant coefficient of (16) is defined to be 1. Before proceeding to the evaluation of $S(\pi n/N)$, we replace N by λN, and evaluate $S_0(\pi n/\lambda N)$. For n even it is given by

$$\begin{aligned} 1 + \sum_{\nu=1}^{2\lambda N-1} \operatorname{sign}\left\{\sin\left(\frac{\pi r\nu}{\lambda N}\right) \sin\left(\frac{\pi\nu}{\lambda N}\right)\right\} e^{i\pi\nu n/\lambda N} \\ = 2\left[1 + \sum_{\nu=1}^{\lambda N-1} \operatorname{sign}\left(\sin\frac{\pi r\nu}{\lambda N}\right) e^{i\pi\nu n/\lambda N}\right]. \end{aligned} \tag{17}$$

The term inside the brackets of the right-hand side of (17) may be expressed in blocks with alternating sign:

$$\sum_{\nu=0}^{r'-1} e^{\pi i\nu n/\lambda N} - \sum_{\nu=r'}^{2r'-1} e^{\pi i\nu n/\lambda N} + \cdots + (-1)^{r-1} \sum_{\nu=(r-1)r'}^{rr'-1} e^{\pi i\nu n/\lambda N}. \tag{18}$$

This may be simplified to arrive at the expression

$$\left[\frac{1+e^{\pi in/\lambda N}}{1-e^{\pi in/\lambda N}}\right]\left[\frac{1-e^{\pi inr'/\lambda N}}{1+e^{\pi inr'/\lambda N}}\right] \quad \text{for } n \text{ even}, \quad n \neq 0,$$

which in turn is equal to

$$\cot(\pi n/2\lambda N)\tan(\pi r'n/2\lambda N). \tag{19}$$

By Lemma 3.3 and (19) it follows that for n even and not zero, except for a multiplicative constant, $S(\pi n/N)$ is given by

$$\frac{1}{\lambda}\sum_{j=0}^{\lambda-1} \cot\left\{\frac{\pi}{2\lambda}\left(\frac{n}{N}+2j\right)\right\}\tan\left\{\frac{\pi r'}{2\lambda}\left(\frac{n}{N}+2j\right)\right\}. \tag{20}$$

Set $x=\pi n/N$ and let φ denote the function defined by (19). The derivative of φ is given by

$$\varphi'(x)=\frac{r'\sin(x/\lambda)-\sin(r'x/\lambda)}{2^2\lambda\sin^2(x/2\lambda)\cos^2(r'x/2\lambda)}.$$

When $\lambda < r'$, $\varphi' > 0$ for $0 < x < \lambda\pi$. Since (20) is a sum of terms like (19), it follows that it defines an increasing function Ψ on intervals whose endpoints are points of discontinuity of at least one of the terms.

Under present assumptions p and q are odd integers. Furthermore, assume for the moment that $q \geqq 5$. In this case we may assume that $1 < r' < N/2$, for, if not, we replace r' by $N-r'$, so that $r(N-r')=-1+(r-\lambda)N$. Then proceed with the computations outlined above. In formulas (19) and (20) λ is replaced by $(r-\lambda)$, and a 1 is added.

From (16) and Proposition 1.1 it follows that to prove the theorem in the present case, it is enough to show that the polynomial $\sum_{\nu=0}^{N-1} \operatorname{sign}(\sin(\pi r\nu/N))X^{\nu}$ (the constant coefficient is defined to be 1) does not have each of the four roots of unity $e^{\pi i(p\pm1)q'/N}$ and $e^{\pi i(p\pm3)q'/N}$ as roots. Assume the contrary. These roots of unity are primitive roots of unity for some integers $N_1, \cdots, N_4$. Since this polynomial has integer coefficients and q' is relatively prime to N, it follows that it has $e^{\pi i(p\pm1)/N}$ and $e^{\pi i(p\pm3)/N}$ as additional roots, since they are primitive roots of unity for the same respective integers $N_1, \cdots, N_4$ (cf. [8, pp. 203–208]). Therefore (20) is zero for $n = p \pm 1$ and for $n = p \pm 3$. In view of the monotonicity of Ψ on the intervals of continuity of its terms, and since (20) is zero at each of these points, there exist odd integers, ξ_1, ξ_2, ξ_3 corresponding to endpoints of intervals of continuity of Ψ such that

$$\frac{p-3}{N} < \frac{\xi_3}{r'} < \frac{p-1}{N} < \frac{\xi_1}{r'} < \frac{p+1}{N} < \frac{\xi_2}{r'} < \frac{p+3}{N}.$$

Hence $4/r' \leqq (\xi_2-\xi_3)/r' \leqq 6/N$, which implies that $2N/3 < r'$, contrary to the assumption that $1 < r' < N/2$. Hence S is nonzero at one of the four points $\pi(p\pm1)/N$, $\pi(p\pm3)/N$, and by Proposition 1.1 it follows that $t_{\omega,\varepsilon}$ does not have the M property.

Assume now that $q=3$. It must be shown that (20) is not zero at one of $p\pm1$. Assume otherwise. By the same reasoning applied above, there exists an odd integer ξ such that either

(i) $(p-1)/N < \xi/r' < p/N$, or

(ii) $p/N < \xi/r' < (p+1)/N$.

Suppose that $1 < 3p' < N$. Set $r' = 3p'$, and suppose that case (i) holds. Now, by definition $pp' = 1 + \tau 2N$ for some integer τ. Therefore, (i) becomes

$$3(1 + \tau 2N) - r' < \xi N < 3(1 + \tau 2N).$$

This is clearly impossible in view of the fact that ξ is odd and $1 < r' < N$. In the case where (ii) holds, we have

$$3(1 + \tau 2N) < \xi N < 3(1 + \tau 2N) + r'.$$

If $N < 3p' < 2N$, set $r' = 2N - 3p'$; if $2N < 3p' < 3N$, set $r' = 3p' - 2N$; and if $3N < 3p' < 4N$, set $r' = 4N - 3p'$. In the first and third instances, λ is replaced by $2r - \lambda$ and $4r - \lambda$, respectively, and the proof proceeds as before. In each case the above inequalities (i) and (ii) result in contradiction, except possibly in the case where $3 + r' > N$. The cases where $r' = N - 1$ and $r' = N - 2$ must be examined separately.

In the case where $r' = N - 1$, we have that $r = N - 1$; in the case where $r' = N - 2$, we have that N must be odd and $r = (N - 1)/2$. In both cases the expression (17) with $\lambda = 1$ may be evaluated directly. In the first case (17) is constant and equal to 2 for n even and not zero. In the second case the expression inside the brackets of (17) is equal to

$$1 + 2\cos\frac{\pi n}{N}\frac{|1 + e^{i\pi n/N}|^2}{|1 + e^{2\pi i n/N}|^2}. \tag{21}$$

It is straightforward to check that (21) is zero only for $n/N = \pm\frac{2}{3}$, and therefore is zero for at most one of $n = p \pm 1$. By Proposition 1.1 it follows that $t_{\omega,\varepsilon}$ does not have the M property when p and q are odd and relatively prime to N.

If exactly one of p and q is even, the proof outlined above remains unchanged, except that formulas (16)–(21) are to be evaluated for n odd. If both p and q are even, but still relatively prime to N, we replace them by $N - p$ and $N - q$, respectively. Note that (15) is unchanged by this substitution. The proof then proceeds as above, except that the roots of unity of the new polynomial are $e^{\pi i(p\pm 1)(N-q)'/N}$ and $e^{\pi i(p\pm 3)(N-q)'/N}$. As in the previous paragraph, we conclude that $e^{\pi i(p\pm 1)/N}$ and $e^{\pi i(p\pm 3)/N}$ are additional roots and proceed as before. This completes the proof of the theorem for the case where p and q are relatively prime to N.

We now address the case when p and q have nontrivial factors common with N. Suppose that $\omega/\pi = p/N_1$, and $\varepsilon/\pi = q/N_2$ are written in lowest terms, and let N_3 denote the greatest common divisor of N_1 and N_2, so that $N_1 = cN_3$ and $N_2 = dN_3$ with c and d relatively prime and not both equal to 1. In this case the imaginary part of $S(\gamma)$ is nonzero. Let λ denote the least common multiple of p and q. We shall first evaluate S when $\omega/\pi = p/\lambda N_1$ and $\varepsilon/\pi = q/\lambda N_2$ and later apply Lemma 3.3 to get S when $\omega/\pi = p/N_1$ and $\varepsilon/\pi = q/N_2$. Set $\omega/\pi = M_1 = \lambda N_1/p$ and $M_2 = \lambda N_2/q$. By Lemma 3.2(a) (where p of the lemma is taken to be 1, and N is replaced by M_1 and M_2), the desired convolution is given by

$$S(\gamma) = \sum_{\substack{j \text{ even} \\ 0 \leqq j < 2N_3 - 1}} \frac{4}{1 - \exp(i\pi(r_1 + j\alpha)/M_1)} \frac{4}{1 - \exp(i\pi(r_2 - j\beta)/M_2)},$$

where $\gamma = r_1/M_1 + r_2/M_2$ (r_1 and r_2 odd integers), $\alpha = c\lambda/p$, $\beta = d\lambda/q$, and $S(\gamma) = 0$ for other γ. This may be rewritten in the form

$$4 \sum_{u=0}^{M_2-1} \sum_{\nu=0}^{M_1-1} \exp\left(i\pi\left\{\frac{r_1}{M_1}\nu + \frac{r_2}{M_2}u\right\}\right) \sum_{\substack{j \text{ even} \\ 0 \leqq j < 2N_3 - 1}} \exp(i\pi j(\nu - u)/N_3). \tag{22}$$

Make the substitutions $\nu = v + \xi_1 N_3$ and $u = w + \xi_2 N_3$, where $0 \leqq v, w < N_3$, and $0 \leqq \xi_1 \leqq \alpha - 1$ and $0 \leqq \xi_2 \leqq \beta - 1$. Expression (22) becomes

$$4N_3 \sum_{\xi_1=0}^{\alpha-1} \sum_{\xi_2=0}^{\beta-1} \sum_{\nu=0}^{N_3-1} e^{i\pi\gamma\nu} \exp\left(i\pi \frac{r_1}{\alpha} \xi_1\right) \exp\left(i\pi \frac{r_2}{\beta} \xi_2\right). \tag{23}$$

The real part of (23) is

$$\begin{aligned} &4N_3 \left[\frac{\sin \pi \dfrac{r_1}{\alpha}}{\left(1 - \cos \pi \dfrac{r_1}{\alpha}\right)} + \frac{\sin \pi \dfrac{r_2}{\beta}}{\left(1 - \cos \pi \dfrac{r_2}{\beta}\right)} \right] \frac{\sin \pi\gamma}{(1 - \cos \pi\gamma)} \\ &= 4N_3 \left[\cot \frac{\pi}{2} \frac{r_1}{\alpha} + \cot \frac{\pi}{2} \frac{r_2}{\beta} \right] \cot \frac{\pi\gamma}{2}. \end{aligned} \tag{24}$$

The imaginary part of (23) is

$$4N_3 \left[\cot \frac{\pi}{2} \frac{r_1}{\alpha} + \cot \frac{\pi}{2} \frac{r_2}{\beta} \right]. \tag{25}$$

We now consider $\omega/\pi = p/N_1$ and $\varepsilon/\pi = q/N_2$, where both fractions have been written in lowest terms. Suppose that $c \neq 1$. It follows from Lemma 3.3 and (25) that, except for a multiplicative constant, the imaginary part of $S(\gamma)$ is given by

$$\frac{1}{\lambda} \sum_{\nu=0}^{\lambda-1} \left[\cot \frac{\pi}{2} \frac{r_1}{\lambda} \frac{p}{c} + \cot \frac{\pi}{2} \frac{(r_2 q + 2\nu N_2)}{\lambda d} \right], \tag{26}$$

where $\gamma = r_1 p/N_1 + r_2 q/N_2$ (r_1 and r_2 are odd, and $r_1 p$ and $r_2 q$ are taken modulo N_1 and N_2, respectively, $-1 \leqq \gamma < 1$). The real part of $S(\gamma)$ has a similar expression. Furthermore, $S(\gamma) = 0$ for $\gamma = n/cdN_3$, when n has parity opposite to that of $d + c$.

Note that $S\hat{}(n)$ is not defined for n belonging to the union of the cosets $N_1 Z$ and $N_2 Z$. Therefore, to complete the proof of Theorem 3.1, by Proposition 1.1 it is necessary to show that for no two pseudomeasures μ_1 and μ_2 with spectra contained in $N_1 Z$ and $N_2 Z$, respectively, is it the case that $S - \mu_1 - \mu_2$ has support disjoint from the transition intervals. It suffices to show that either the real part of S or the imaginary part of S has no such representation on the transition intervals. Consider the imaginary part of S, and assume on the contrary that it may be expressed as $\mu_1(\gamma) + \mu_2(\gamma)$ for γ belonging to the transition intervals. Since the spectra of μ_1 and μ_2 are assumed to be contained in $N_1 Z$ and $N_2 Z$, respectively, it follows that μ_1 is $2\pi/N_1$-periodic and μ_2 is $2\pi/N_2$-periodic.

Except in the case where $c = 1$ and $q = 1$ (where the condition of the theorem is true), it is easy to show that for each ξ/N_1 ($-N_1 \leqq \xi < N_1$), except for $\xi \equiv p$ modulo $2c$ if $q = 1$, there are pairs of integers η_0, η_e (the subscripts indicate parity) such that $\pi[\xi/N_1 + \eta/N_2] \in (w - \varepsilon, \omega + \varepsilon)$, where the symbol η stands for those of either odd index "o" or even index "e." To see this, perform the division

$$pd - \xi d = Qc + r, \tag{27}$$

where the remainder r satisfies $0 < r < c$. If Q is even, set $\eta_e = Q$ and $\eta_o = Q + 1$, otherwise, set $\eta_o = Q$ and $\eta_e = Q + 1$. It is immediate that $\pi[\xi/N_1 + \eta/N_2] \in (\omega - \varepsilon, \omega + \varepsilon)$.

We shall assume in the following argument that p and q are both odd. Minor modifications to the proof allow for either p or q to be even. Let $\varphi(\gamma)$ denote the function defined by (26). Let ξ denote an odd integer. Now, by assumption,

$$\varphi\left(\frac{\xi}{N_1}+\frac{\eta_o}{N_2}\right)=\mu_2\left(\frac{\xi}{c}\right)+\mu_1\left(\frac{\eta_o}{d}\right). \tag{28}$$

If c and d are both odd, the sum $(\xi/N_1+\eta_e/N_2)$ does not have the form $r_1/N_1+r_2/N_2$ for r_1 and r_2 both odd integers. Therefore, $\mu_1(\eta_e/d)+\mu_2(\xi/c)=0$. Hence, (28) becomes

$$\varphi\left(\frac{\xi}{N_1}+\frac{\eta_o}{N_2}\right)=-\mu_1\left(\frac{\eta_e}{d}\right)+\mu_1\left(\frac{\eta_o}{d}\right). \tag{29}$$

Since $\pi[\xi/N_1+\eta_o/N_2]$ and $\pi[\xi/N_1+\eta_e/N_2]\in(\omega-\varepsilon,\omega+\varepsilon)$, it follows that $\pi[(\xi-2p)/N_1+\eta_o/N_2]$ and $\pi[(\xi-2p)/N_1+\eta_e/N_2]\in(-\omega-\varepsilon,-\omega+\varepsilon)$. By assumption,

$$\varphi\left(\frac{\xi-2p}{N_1}+\frac{\eta_o}{N_2}\right)=\mu_2\left(\frac{\xi-2p}{c}\right)+\mu_1\left(\frac{\eta_o}{d}\right). \tag{30}$$

Since c and d are both odd, it follows that $(\xi-2p)/N_1+\eta_e/N_2$ does not have the form $r_1/N_1+r_2/N_2$ for r_1 and r_2 both odd integers. Therefore, $\mu_1(\eta_e/d)+\mu_2((\xi-2p)/c)=0$. Hence, (30) becomes

$$\varphi\left(\frac{\xi-2p}{N_1}+\frac{\eta_o}{N_2}\right)=-\mu_1\left(\frac{\eta_e}{d}\right)+\mu_1\left(\frac{\eta_o}{d}\right). \tag{31}$$

Comparing (29) and (31), we obtain

$$\varphi\left(\frac{\xi}{N_1}+\frac{\eta_o}{N_2}\right)=\varphi\left(\frac{\xi-2p}{N_1}+\frac{\eta_o}{N_2}\right).$$

This is the equality

$$\begin{aligned}&\frac{1}{\lambda}\sum_{\nu=0}^{\lambda-1}\left[\cot\frac{\pi}{2}\frac{\xi}{\lambda c}+\cot\frac{\pi}{2}\frac{(\eta_o+2\nu N_2)}{\lambda d}\right]\\&\quad=\frac{1}{\lambda}\sum_{\nu=0}^{\lambda-1}\left[\cot\frac{\pi}{2}\frac{(\xi-2p)}{\lambda c}+\cot\frac{\pi}{2}\frac{(\eta_o+2\nu N_2)}{\lambda d}\right].\end{aligned} \tag{32}$$

Therefore, $\cot(\pi/2)\xi/\lambda c=\cot(\pi/2)(\xi-2p)/\lambda c$, which is clearly impossible.

We finally consider the case where one of c and d is even. If c is odd and d is even, the arguments are the same as in the preceding paragraph, since it is still true that $(\xi/N_1+\eta_e/N_2)$ does not have the form $r_1/N_1+r_2/N_2$ for ξ, r_1, and r_2 odd integers. However, if c is even and d is odd, $(\xi/N_1+\eta_e/N_2)$ does have the form $r_1/N_1+r_2/N_2$ for ξ, r_1, and r_2 odd integers, namely, $(\xi/N_1+\eta_e/N_2)=(\xi-c)/N_1+(\eta_e+d)/N_2$. Therefore, for the remainder of the argument assume that c is even and d is odd.

The functional expression analogous to (31) is

$$\varphi\left(\frac{\xi}{N_1}+\frac{\eta_e}{N_2}\right)-\varphi\left(\frac{\xi}{N_1}+\frac{\eta_o}{N_2}\right)=\mu_1\left(\frac{\eta_e}{d}\right)-\mu_1\left(\frac{\eta_o}{d}\right),$$

which leads to

$$\varphi\left(\frac{\xi}{N_1}+\frac{\eta_e}{N_2}\right)-\varphi\left(\frac{\xi}{N_1}+\frac{\eta_o}{N_2}\right)=\varphi\left(\frac{\xi-2p}{N_1}+\frac{\eta_e}{N_2}\right)-\varphi\left(\frac{\xi-2p}{N_1}+\frac{\eta_o}{N_2}\right),$$

since $(\xi-2p)/N_1+\eta/N_2$ belongs to the interval $(-\omega-\varepsilon, -\omega+\varepsilon)$. Using the definition of φ, this is the equality:

$$\begin{aligned}
&\frac{1}{\lambda}\sum_{\nu=0}^{\lambda-1}\left[\tan\frac{\pi}{2}\frac{\xi}{\lambda c}+\tan\frac{\pi}{2}\frac{(\eta_e+2\nu N_2)}{\lambda d}\right]\\
&\quad+\frac{1}{\lambda}\sum_{\nu=0}^{\lambda-1}\left[\cot\frac{\pi}{2}\frac{\xi}{\lambda c}+\cot\frac{\pi}{2}\frac{(\eta_o+2\nu N_2)}{\lambda d}\right]\\
&=\frac{1}{\lambda}\sum_{\nu=0}^{\lambda-1}\left[\tan\frac{\pi}{2}\frac{(\xi-2p)}{\lambda c}+\tan\frac{\pi}{2}\frac{(\eta_e+2\nu N_2)}{\lambda d}\right]\\
&\quad+\frac{1}{\lambda}\sum_{\nu=0}^{\lambda-1}\left[\cot\frac{\pi}{2}\frac{(\xi-2p)}{\lambda c}+\cot\frac{\pi}{2}\frac{(\eta_o+2\nu N_2)}{\lambda d}\right].
\end{aligned}\tag{33}$$

This reduces to

$$\tan\frac{\pi}{2}\frac{\xi}{\lambda c}+\cot\frac{\pi}{2}\frac{\xi}{\lambda c}=\tan\frac{\pi}{2}\frac{(\xi-2p)}{\lambda c}+\cot\frac{\pi}{2}\frac{(\xi-2p)}{\lambda c}$$

and hence to $\sin(\pi\xi)/\lambda c=\sin(\pi(\xi-2p)/\lambda c)$. The latter equality is easily seen to be false. This concludes the proof of Theorem 3.1.

4. Nonuniqueness of minimal extrapolations on T. In this section we will show that the trapezoids $t_{\omega,\varepsilon}$ on the circle T having the M property are not unique minimal extrapolations from their intervals of constancy. The proof of Theorem 3 of [4] applies to show uniqueness of the $t_{\omega,\varepsilon}$ for the case of the line $\mathbb{R}$.

Let φ be the function defined by

$$\begin{aligned}
\varphi(x)&=\sin(\pi x/\varepsilon), \qquad -\varepsilon\leqq x\leqq\varepsilon,\\
&=0, \qquad \varepsilon<|x|\leqq\pi.
\end{aligned}$$

Now define

$$f(x)=\varphi(x-\omega)-\varphi(x+\omega).$$

It is clear that f is supported on the intervals $(-\omega-\varepsilon, -\omega+\varepsilon)$ and $(\omega-\varepsilon, \omega+\varepsilon)$. Furthermore, the nth Fourier coefficient of f is given by

$$\begin{aligned}
f\hat{}(n)&=-(2\varepsilon/(\varepsilon^2n^2-\pi^2))\sin\varepsilon n\sin\omega n, \qquad n\neq\pm\pi/\varepsilon,\\
&=0, \qquad n=\pm\pi/\varepsilon.
\end{aligned}$$

Because n assumes only discrete values, it is easy to check that for sufficiently small positive λ

$$\lambda|f\hat{}(n)|<|t^{\wedge}_{\omega,\varepsilon}(n)| \quad \text{for all } n.$$

Hence

$$\begin{aligned}
\operatorname{sign}(t^{\wedge}_{\omega,\varepsilon}(n)+\lambda f\hat{}(n))&=\operatorname{sign}(t^{\wedge}_{\omega,\varepsilon}(n))\\
&=\operatorname{sign}(\sin\omega n\sin\varepsilon n) \quad \text{for all } n.
\end{aligned}$$

Since $t_{\omega,\varepsilon}$ has the M property, by Proposition 1.1 there exists a pseudomeasure S with support disjoint from the intervals $(-\omega-\varepsilon, -\omega+\varepsilon)$ and $(\omega-\varepsilon, \omega+\varepsilon)$ such that

$$\begin{aligned}
S\hat{}(n)&=\operatorname{sign}(\sin\omega n\sin\varepsilon n) \quad \text{for } n\neq 0,\\
&=1 \quad \text{for } n=0.
\end{aligned}$$

Therefore,

$$\|t_{\omega,\varepsilon}\|_A = (S, t_{\omega,\varepsilon}) = (S, t_{\omega,\varepsilon} + \lambda f)$$
$$= \|t_{\omega,\varepsilon} + \lambda f\|_A.$$

Therefore, both $t_{\omega,\varepsilon}$ and $t_{\omega,\varepsilon} + \lambda f$ have the M property and, of course, have the same intervals of constancy.

ASYMPTOTIC EXPANSION OF A CLASS OF FERMI-DIRAC INTEGRALS*

J. BOERSMA† AND M. L. GLASSER‡

Abstract. A procedure is presented for obtaining the complete asymptotic expansion of a class of fractional integrals (of Riemann-Liouville type), in which the integrand contains the product of two derivatives of the Fermi-Dirac integral. The procedure uses two-sided Laplace transforms and Abelian asymptotics of the inverse Laplace transform. The fractional integrals considered arise in various problems from statistical mechanics and solid state physics.

Key words. Fermi-Dirac integral, asymptotic expansion, Riemann-Liouville fractional integral, Laplace transform, Abelian asymptotics

AMS(MOS) subject classifications. 41A60, 33A70, 44A10, 26A33, 82

1. Introduction. This paper is concerned with the asymptotic expansion, as $\eta \to \infty$, of the class of integrals

$$G_{\mu,p}^{(m,n)}(\eta) = \frac{1}{\Gamma(\mu)} \int_{-\infty}^{n} (\eta - t)^{\mu-1} F_p^{(m)}(t) F_p^{(n)}(t)\, dt \qquad (\mu > 0). \tag{1.1}$$

Here, m and n are nonnegative integers, and $F_p^{(m)}(t)$ denotes the mth derivative of the Fermi-Dirac integral $F_p(t)$ defined by [1]

$$F_p(t) = \frac{1}{\Gamma(p+1)} \int_0^{\infty} \frac{x^p\, dx}{1 + e^{x-t}} \qquad (p > -1). \tag{1.2}$$

The class of Riemann-Liouville fractional integrals (1.1) is important in a number of areas of statistical mechanics and solid state physics. Two examples are the exchange energy of a d-dimensional electron gas [6] ($\mu = (d-1)/2$, $p = -\frac{1}{2}$, $m = n = 0$) and the temperature-dependent gradient expansion coefficients for the interaction functional of an inhomogeneous electron gas [5] ($\mu = 2$, $p = -\frac{1}{2}$, $m = n = 2$).

In the special case $p = -\frac{1}{2}$, $m = n = 0$, the asymptotics of the integral (1.1) has been treated by Glasser and Boersma [6]. Their procedure, which uses the two-sided Laplace transform, is generalized in the present paper to accommodate the additional parameters p, m, and n. The Laplace transform method is explained in § 2, where it is also shown that the asymptotic analysis may be restricted to the case $m = n$. Let the Laplace transform of $[F_p^{(m)}(t)]^2$ be denoted by $g(s)$ (with transform variable s), then the asymptotic expansion of $G(\eta)$ as $\eta \to \infty$ can be found by applying Abelian asymptotics to the series expansion of $g(s)$ around $s = 0$. By starting from a suitable integral representation for $g(s)$ as derived in § 3, the expansion of $g(s)$ around $s = 0$ is determined in §§ 4 and 5. In the final section, § 6, the corresponding complete asymptotic expansion of $G(\eta)$, as given by (1.1), is presented.

2. Laplace transform method. Following the procedure of § 3 of [6], we first determine the two-sided Laplace transform of (1.1):

$$\bar{G}_{\mu,p}^{(m,n)}(s) = \int_{-\infty}^{\infty} e^{-s\eta} G_{\mu,p}^{(m,n)}(\eta)\, d\eta = s^{-\mu} g_p^{(m,n)}(s) \tag{2.1}$$

where

$$g_p^{(m,n)}(s) = \int_{-\infty}^{\infty} e^{-st} F_p^{(m)}(t) F_p^{(n)}(t)\, dt. \tag{2.2}$$

From the known asymptotic behaviour [1]

$$F_p(t) = O(e^t), \quad t \to -\infty, \qquad F_p(t) = O(t^{p+1}), \quad t \to \infty, \tag{2.3}$$

it follows that the Laplace transforms $\bar{G}_{\mu,p}^{(m,n)}(s)$ and $g_p^{(m,n)}(s)$ are defined in the strip $0 < \operatorname{Re} s < 2$.

Assuming that $m \leqq n$ in (2.2) and integrating by parts, we establish the recurrence relations

$$g_p^{(m,m+1)}(s) = \tfrac{1}{2} s g_p^{(m,m)}(s), \tag{2.4}$$

$$g_p^{(m,n)}(s) = s g_p^{(m,n-1)}(s) - g_p^{(m+1,n-1)}(s), \qquad n \geqq m+2. \tag{2.5}$$

By repeated application of these relations we are led to

$$\begin{aligned} g_p^{(m,m+2)}(s) &= \tfrac{1}{2} s^2 g_p^{(m,m)}(s) - g_p^{(m+1,m+1)}(s), \\ g_p^{(m,m+3)}(s) &= \tfrac{1}{2} s^3 g_p^{(m,m)}(s) - \tfrac{3}{2} s g_p^{(m+1,m+1)}(s), \\ g_p^{(m,m+4)}(s) &= \tfrac{1}{2} s^4 g_p^{(m,m)}(s) - 2 s^2 g_p^{(m+1,m+1)}(s) + g_p^{(m+2,m+2)}(s). \end{aligned} \tag{2.6}$$

The coefficients in (2.4) and (2.6) are now used to form the polynomials

$$\begin{aligned} &p_0(s) = 1, \quad p_1(s) = \tfrac{1}{2} s, \quad p_2(s) = \tfrac{1}{2} s^2 - 1, \\ &p_3(s) = \tfrac{1}{2} s^3 - \tfrac{3}{2} s, \qquad p_4(s) = \tfrac{1}{2} s^4 - 2 s^2 + 1, \cdots, \end{aligned} \tag{2.7}$$

which, by (2.5), satisfy the recurrence relation

$$p_k(s) = s p_{k-1}(s) - p_{k-2}(s), \qquad k \geqq 2. \tag{2.8}$$

The latter recurrence relation is identical to that of the Chebyshev polynomials $T_k(s/2)$ (cf. [3, § 10.11]). Thus we find

$$p_k(s) = T_k\left(\frac{s}{2}\right) = \frac{1}{2} k \sum_{l=0}^{[k/2]} \frac{(-1)^l (k-l-1)!}{l!(k-2l)!} s^{k-2l}, \qquad k \geqq 1, \tag{2.9}$$

whereupon the results in (2.6) generalize to

$$g_p^{(m,m+k)}(s) = \frac{1}{2} k \sum_{l=0}^{[k/2]} \frac{(-1)^l (k-l-1)!}{l!(k-2l)!} s^{k-2l} g_p^{(m+l,m+l)}(s), \qquad k \geqq 1. \tag{2.10}$$

Consequently, without loss of generality we can restrict our further asymptotic analysis to the case $m = n$. Accordingly, we simplify the notation by setting $G_{\mu,p}^{(m,m)}(\eta) \equiv G_{\mu,p}^{(m)}(\eta)$ and $g_p^{(m,m)}(s) \equiv g_p^{(m)}(s)$.

In the Laplace transform method the asymptotic expansion of $G_{\mu,p}^{(m)}(\eta)$ as $\eta \to \infty$ is obtained by applying Abelian asymptotics [2, Kap. 7] to the series expansion of $g_p^{(m)}(s)$ around $s = 0$. To determine the latter expansion, we rewrite the integral (2.2) in a more convenient form by means of Parseval's formula:

$$g_p^{(m)}(s) = \int_{-\infty}^{\infty} e^{-st} [F_p^{(m)}(t)]^2\, dt = \int_{-\infty}^{\infty} f(u) f(-u)\, du \tag{2.11}$$

where

$$f(u) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-st/2} F_p^{(m)}(t)\, e^{iut}\, dt = \frac{(s/2 - iu)^m}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-st/2} F_p(t)\, e^{iut}\, dt. \tag{2.12}$$

The second integral in (2.12) is evaluated by inserting the integral representation (1.2) for $F_p(t)$, interchanging the order of integration, and applying the substitution $y = e^{x-t}$ in the t-integral:

$$\begin{aligned}\int_{-\infty}^{\infty} e^{-st/2} F_p(t)\, e^{iut}\, dt &= \frac{1}{\Gamma(p+1)} \int_0^{\infty} x^p\, e^{-(s/2-iu)x}\, dx \int_0^{\infty} \frac{y^{s/2-iu-1}}{1+y}\, dy \\ &= \frac{\pi(s/2-iu)^{-p-1}}{\sin[\pi(s/2-iu)]}.\end{aligned} \tag{2.13}$$

The result for $f(u)$ thus found is inserted into (2.11), and we have

$$g_p^{(m)}(s) = \pi \int_{-\infty}^{\infty} \frac{(s^2/4+u^2)^{m-p-1}}{\cosh(2\pi u) - \cos(\pi s)}\, du. \tag{2.14}$$

Obviously, $g_p^{(m)}(s)$ depends only on the difference $m-p$; this was to be expected from the basic recursion formula $F_p'(t) = F_{p-1}(t)$. Finally, for brevity we introduce

$$\nu = m - p - \tfrac{1}{2}, \qquad g_\nu(s) = g_p^{(m)}(s); \tag{2.15}$$

then the representation (2.14) becomes

$$g_\nu(s) = \pi \int_{-\infty}^{\infty} \frac{(s^2/4+u^2)^{\nu-1/2}}{\cosh(2\pi u) - \cos(\pi s)}\, du. \tag{2.16}$$

3. Integral representation for $g_\nu(s)$. The representation (2.16) for $g_\nu(s)$ is further reduced by another application of Parseval's formula. It is convenient to distinguish three cases.

Case i. $\nu < \frac{1}{2}$. From [4, Formulas 1.9(6), 1.3(7)] we quote the Fourier cosine transforms

$$\int_0^{\infty} \frac{\cos(xu)}{\cosh(2\pi u) - \cos(\pi s)}\, du = \frac{1}{2\sin(\pi s)} \frac{\sinh[(1-s)x/2]}{\sinh(x/2)}, \tag{3.1}$$

$$\int_0^{\infty} \left(\frac{s^2}{4}+u^2\right)^{\nu-1/2} \cos(xu)\, du = \frac{\pi^{1/2}}{\Gamma(\frac{1}{2}-\nu)} \left(\frac{x}{s}\right)^{-\nu} K_\nu\left(\frac{sx}{2}\right) \tag{3.2}$$

where we used that $K_{-\nu}(z) = K_\nu(z)$ by [7, Formula 3.71(8)]. Next, by means of Parseval's formula applied to (2.16) we are led to

$$g_\nu(s) = \frac{2\pi^{1/2}}{\Gamma(\frac{1}{2}-\nu)} \frac{s^\nu}{\sin(\pi s)} \int_0^{\infty} \frac{\sinh[(1-s)x/2]}{\sinh(x/2)}\, x^{-\nu} K_\nu\left(\frac{sx}{2}\right) dx. \tag{3.3}$$

It is easily seen that the integral (3.3) is convergent if $\nu < \frac{1}{2}$.

Case ii. $\nu > \frac{1}{2}$, $\nu - \frac{1}{2} \notin \mathbb{N}$. Let k be the smallest integer greater than or equal to ν; then we set $\nu = k - q$, where $0 \leqq q < 1$ and $q \neq \frac{1}{2}$. To apply Parseval's formula in (2.16), we need the Fourier cosine transform

$$\int_0^{\infty} \frac{(s^2/4+u^2)^k}{\cosh(2\pi u) - \cos(\pi s)} \cos(xu)\, du = \frac{1}{2\sin(\pi s)} \left(\frac{s^2}{4} - \frac{d^2}{dx^2}\right)^k \left\{\frac{\sinh[(1-s)x/2]}{\sinh(x/2)}\right\} \tag{3.4}$$

obtainable from (3.1), and the transform (3.2) with ν replaced by $-q$. As a result it is found that the representation (2.16) passes into

$$g_\nu(s) = \frac{2\pi^{1/2}}{\Gamma(q+\frac{1}{2})} \frac{s^{-q}}{\sin(\pi s)} \int_0^{\infty} \left(\frac{s^2}{4} - \frac{d^2}{dx^2}\right)^k \left\{\frac{\sinh[(1-s)x/2]}{\sinh(x/2)}\right\} x^q K_{-q}\left(\frac{sx}{2}\right) dx. \tag{3.5}$$

To further reduce (3.5), we would like to integrate by parts so that the differential operator acts on $x^q K_{-q}(sx/2)$. Here a difficulty comes up, since the resulting integral is divergent at the lower limit $x=0$ and the intermediate endpoint contributions at $x=0$ become infinite. To overcome this, we introduce the "finite part" (in the sense of Hadamard) of the resulting integral and end point contributions, defined as follows.

For $\delta \geqq 0$, let $f(\delta)$ have an asymptotic expansion as $\delta \downarrow 0$, that consists of terms $\delta^r(\log \delta)^j$ with real r and integer j. Suppose the expansion contains a finite number of singular terms (i.e., terms with $r<0$ or with $r=0$, $j \geqq 1$), and let $f_\infty(\delta)$ denote the sum of the singular terms. Then we define the finite part of $f(\delta)$ as $\delta \downarrow 0$ by

$$\operatorname*{fin}_{\delta \downarrow 0} f(\delta) = \lim_{\delta \downarrow 0} [f(\delta) - f_\infty(\delta)]. \tag{3.6}$$

Likewise, if $\int_0^\infty h(x)\,dx$ is divergent or convergent at $x=0$, we define the finite part of the integral as

$$\fint_0^\infty h(x)\,dx = \operatorname*{fin}_{\delta \downarrow 0} \int_\delta^\infty h(x)\,dx. \tag{3.7}$$

When integrating by parts in (3.5), the finite part of a typical endpoint contribution looks like

$$\operatorname*{fin}_{\delta \downarrow 0} \left(\frac{d}{dx}\right)^j \left\{\frac{\sinh[(1-s)x/2]}{\sinh(x/2)}\right\} \left(\frac{d}{dx}\right)^l \left\{x^q K_{-q}\left(\frac{sx}{2}\right)\right\}\Bigg|_{x=\delta} \tag{3.8}$$

where j and l are nonnegative integers with $j+l$ odd. We expand this in a power series in powers of $x=\delta$. Then the expansion is found to contain terms δ^{2n-j-l}, $\delta^{2n+2q-j-l}$ and, if $q=0$, also $\delta^{2n-j-l}\log\delta$, whereby $n=0,1,2,\cdots$. Because $q \neq \frac{1}{2}$ and $j+l$ is odd, none of the exponents $2n-j-l$ or $2n+2q-j-l$ is zero and the finite part (3.8) vanishes. In this way we find, through integration by parts in (3.5), that

$$g_\nu(s) = \frac{2\pi^{1/2}}{\Gamma(q+\frac{1}{2})} \frac{s^{-q}}{\sin(\pi s)} \fint_0^\infty \frac{\sinh[(1-s)x/2]}{\sinh(x/2)} \left(\frac{s^2}{4} - \frac{d^2}{dx^2}\right)^k \left\{x^q K_{-q}\left(\frac{sx}{2}\right)\right\} dx. \tag{3.9}$$

Setting $t=sx/2$, by repeated use of the recurrence formula [7, § 3.71]

$$\left(1-\frac{d^2}{dt^2}\right)\frac{K_\nu(t)}{t^\nu} = \frac{2\nu+1}{t}\frac{d}{dt}\left(\frac{K_\nu(t)}{t^\nu}\right) = -(2\nu+1)\frac{K_{\nu+1}(t)}{t^{\nu+1}} \tag{3.10}$$

we find

$$\left(\frac{s^2}{4} - \frac{d^2}{dx^2}\right)^k \left\{x^q K_{-q}\left(\frac{sx}{2}\right)\right\} = \frac{\Gamma(q+\frac{1}{2})}{\Gamma(q-k+\frac{1}{2})} s^k x^{q-k} K_{k-q}\left(\frac{sx}{2}\right). \tag{3.11}$$

Inserting (3.11) into (3.9) and restoring the notation $\nu = k-q$, we are led to the integral representation

$$g_\nu(s) = \frac{2\pi^{1/2}}{\Gamma(\frac{1}{2}-\nu)} \frac{s^\nu}{\sin(\pi s)} \fint_0^\infty \frac{\sinh[(1-s)x/2]}{\sinh(x/2)} x^{-\nu} K_\nu\left(\frac{sx}{2}\right) dx. \tag{3.12}$$

This result is identical to the corresponding representation (3.3) for Case i, except that now the finite part of the divergent integral is to be taken (as indicated by the notation $\fint$). From the original representation (2.16) it is clear that $g_\nu(s)$ is an analytic function of ν in the whole complex ν-plane. Therefore the finite part integral (3.12) is also the analytic continuation of the integral (3.3) which is analytic for $\operatorname{Re}\nu < \frac{1}{2}$.

Case iii. $\nu = n+\frac{1}{2}$, $n = 0, 1, 2, \cdots$. In this case the integral (2.16) can be evaluated by means of (3.4), viz.

$$g_{n+1/2}(s) = \pi \int_{-\infty}^{\infty} \frac{(s^2/4+u^2)^n}{\cosh(2\pi u)-\cos(\pi s)}\,du = \frac{\pi}{\sin(\pi s)}\left(\frac{s^2}{4}-\frac{d^2}{dx^2}\right)^n \left\{\frac{\sinh[(1-s)x/2]}{\sinh(x/2)}\right\}\Bigg|_{x=0}. \tag{3.13}$$

Thus for $n=0$, $\nu=\frac{1}{2}$, we have

$$g_{1/2}(s) = \frac{\pi}{\sin(\pi s)}(1-s). \tag{3.14}$$

To evaluate the derivative in (3.13), we substitute

$$\frac{\sinh[(1-s)x/2]}{\sinh(x/2)} = \frac{e^{(1-s/2)x}-e^{sx/2}}{e^x-1} = -2\sum_{k=0}^{\infty} B_{2k+1}\left(\frac{s}{2}\right)\frac{x^{2k}}{(2k+1)!} \tag{3.15}$$

where $B_{2k+1}(s/2)$ is the Bernoulli polynomial [3, § 1.13]. Then we find

$$g_{n+1/2}(s) = -\frac{2\pi}{\sin(\pi s)}\sum_{k=0}^{n}(-1)^k\binom{n}{k}\left(\frac{s^2}{4}\right)^{n-k}\frac{B_{2k+1}(s/2)}{2k+1}. \tag{3.16}$$

4. Expansion of $g_\nu(s)$ if $2\nu \notin \mathbb{Z}$. To determine the series expansion of $g_\nu(s)$ around $s=0$, we start from the integral representation (3.12) which includes the representation (3.3) as a special case. For convenience it is assumed that 2ν is not integral. By substitution of

$$\frac{\sinh[(1-s)x/2]}{\sinh(x/2)} = e^{-sx/2} - 2\sinh\left(\frac{sx}{2}\right)\frac{e^{-x}}{1-e^{-x}} \tag{4.1}$$

the representation (3.12) is rewritten as

$$g_\nu(s) = \frac{2\pi^{1/2}}{\Gamma(\frac{1}{2}-\nu)}\frac{s^\nu}{\sin(\pi s)}\int_0^\infty e^{-sx/2}x^{-\nu}K_\nu\left(\frac{sx}{2}\right)dx - \frac{4\pi^{1/2}}{\Gamma(\frac{1}{2}-\nu)}\frac{s^\nu}{\sin(\pi s)}\int_0^\infty \sinh\left(\frac{sx}{2}\right)K_\nu\left(\frac{sx}{2}\right)\frac{x^{-\nu}e^{-x}}{1-e^{-x}}\,dx. \tag{4.2}$$

From [4, Formula 6.8(28)] we have

$$\int_0^\infty e^{-sx/2}x^{-\nu}K_\nu\left(\frac{sx}{2}\right)dx = \frac{\pi^{1/2}\Gamma(1-2\nu)}{\Gamma(\frac{3}{2}-\nu)}s^{\nu-1}, \tag{4.3}$$

valid for $\operatorname{Re}\nu < \frac{1}{2}$. By analytic continuation the result (4.3) also holds for $\operatorname{Re}\nu \geqq \frac{1}{2}$, $2\nu \notin \mathbb{N}$, provided that the finite part of the integral is taken as in (4.2). To evaluate the second integral in (4.2), we expand the product $\sinh(sx/2)K_\nu(sx/2)$ in a power series. Starting from the definition

$$K_\nu(z) = \frac{\pi}{2\sin(\nu\pi)}[I_{-\nu}(z)-I_\nu(z)] \qquad (\nu \notin \mathbb{Z}) \tag{4.4}$$

we employ Watson's expansion [7, Formula 5.41(1)] for the products $J_\mu(z)J_{\pm\nu}(z)$ with $\mu=\frac{1}{2}$, $z=isx/2$. As a result, we obtain

$$\sinh\left(\frac{sx}{2}\right)K_\nu\left(\frac{sx}{2}\right) = \frac{\pi^{1/2}}{2\sin(\nu\pi)}\left[\sum_{k=0}^{\infty}\frac{\Gamma(2k-\nu+\frac{3}{2})}{(2k+1)!\Gamma(2k-2\nu+2)}(sx)^{2k-\nu+1} - \sum_{k=0}^{\infty}\frac{\Gamma(2k+\nu+\frac{3}{2})}{(2k+1)!\Gamma(2k+2\nu+2)}(sx)^{2k+\nu+1}\right]. \tag{4.5}$$

The latter expansion is inserted into the second integral in (4.2) and we apply a term-by-term integration using the auxiliary integral

$$\int_0^\infty x^\alpha \frac{e^{-x}}{1-e^{-x}}\,dx = \Gamma(\alpha+1)\zeta(\alpha+1) \qquad (\mathrm{Re}\,\alpha > 0) \tag{4.6}$$

where $\zeta(\alpha+1)$ denotes Riemann's zeta function [3, § 1.12]. By analytic continuation the result (4.6) also holds for $\mathrm{Re}\,\alpha \leqq 0$, $\alpha \notin \mathbb{Z}$, provided that the finite part of the integral is taken.

Finally, by compiling the previous results we are led to the desired expansion

$$g_\nu(s) = \frac{2\pi}{\Gamma(\frac{1}{2}-\nu)\sin(\nu\pi)}\frac{s}{\sin(\pi s)}\left[\sum_{k=0}^{\infty}\frac{\Gamma(2k+\nu-\frac{1}{2})}{\Gamma(2k+2\nu)}\zeta(2k)s^{2k+2\nu-2} - \sum_{k=0}^{\infty}\frac{\Gamma(2k-\nu+\frac{3}{2})}{(2k+1)!}\zeta(2k-2\nu+2)s^{2k}\right], \tag{4.7}$$

valid if $2\nu \notin \mathbb{Z}$. It is readily seen that the expansion (4.7) is convergent for $0<|s|<1$.

5. Expansion of $g_\nu(s)$ if $2\nu \in \mathbb{Z}$. Since $g_\nu(s)$ is a continuous function of the parameter ν, the series expansion of $g_\nu(s)$ when $2\nu = N \in \mathbb{Z}$ can be found by taking limits in (4.7) as $\nu \to N/2$. We distinguish four cases.

Case i. $\nu = n$, $n = 1, 2, 3, \cdots$. Rewrite the expansion (4.7) as

$$g_\nu(s) = \frac{2\pi}{\Gamma(\frac{1}{2}-\nu)}\frac{s}{\sin(\pi s)}\frac{1}{\sin(\nu\pi)} \cdot\left[-\sum_{k=0}^{n-2}\frac{\Gamma(2k-\nu+\frac{3}{2})}{(2k+1)!}\zeta(2k-2\nu+2)s^{2k} + \sum_{k=n-1}^{\infty}\left\{\frac{\Gamma(2k-2n+\nu+\frac{3}{2})}{\Gamma(2k-2n+2\nu+2)}\zeta(2k-2n+2)s^{2k-2n+2\nu} - \frac{\Gamma(2k-\nu+\frac{3}{2})}{(2k+1)!}\zeta(2k-2\nu+2)s^{2k}\right\}\right] \tag{5.1}$$

where it is noted that the terms of the finite sum and of the infinite series vanish when $\nu = n$. By properly taking limits as $\nu \to n$, the expansion (5.1) passes into

$$g_n(s) = \frac{4}{\pi}\Gamma\left(n+\frac{1}{2}\right)\frac{s}{\sin(\pi s)} \cdot\left[\sum_{k=0}^{n-2}\frac{\Gamma(2k-n+\frac{3}{2})}{(2k+1)!}\zeta'(2k-2n+2)s^{2k} + \sum_{k=n-1}^{\infty}\frac{\Gamma(2k-n+\frac{3}{2})}{(2k+1)!}\zeta(2k-2n+2)s^{2k} \cdot\left\{\log s + \psi\left(2k-n+\frac{3}{2}\right) - \psi(2k+2) + \frac{\zeta'(2k-2n+2)}{\zeta(2k-2n+2)}\right\}\right], \tag{5.2}$$

valid for $n = 1, 2, 3, \cdots$; here, $\psi(z)$ denotes the logarithmic derivative of the Γ-function, i.e., $\psi(z) = \Gamma'(z)/\Gamma(z)$. By means of [3, Formula 1.12(23)] we have

$$\zeta'(2k-2n+2) = (-1)^{n-k-1}\frac{(2n-2k-2)!}{2(2\pi)^{2n-2k-2}}\zeta(2n-2k-1) \qquad (k = 0, 1, \cdots, n-2), \tag{5.3}$$

which is used in the finite sum in (5.2).

Case ii. $\nu=-n$, $n=0,1,2,\cdots$. Rewrite the expansion (4.7) as

$$
\begin{aligned}
g_\nu(s)=&\frac{2\pi}{\Gamma(\frac12-\nu)}\,\frac{s}{\sin(\pi s)}\,\frac{1}{\sin(\nu\pi)}\\
&\cdot\Bigg[\sum_{k=0}^{n}\frac{\Gamma(2k+\nu-\frac12)}{\Gamma(2k+2\nu)}\zeta(2k)s^{2k+2\nu-2}\\
&\quad+\sum_{k=0}^{\infty}\Bigg\{\frac{\Gamma(2k+2n+\nu+\frac32)}{\Gamma(2k+2n+2\nu+2)}\zeta(2k+2n+2)s^{2k+2n+2\nu}\\
&\qquad-\frac{\Gamma(2k-\nu+\frac32)}{(2k+1)!}\zeta(2k-2\nu+2)s^{2k}\Bigg\}\Bigg]
\end{aligned}
\tag{5.4}
$$

and take limits as $\nu\to-n$. Then, as in Case i, we are led to the expansion

$$
\begin{aligned}
g_{-n}(s)=&\frac{4(-1)^n}{\Gamma(n+\frac12)}\,\frac{s}{\sin(\pi s)}\Bigg[\sum_{k=0}^{n}\Gamma\left(2k-n-\frac12\right)(2n-2k)!\,\zeta(2k)s^{2k-2n-2}\\
&+\sum_{k=0}^{\infty}\frac{\Gamma(2k+n+\frac32)}{(2k+1)!}\zeta(2k+2n+2)s^{2k}\\
&\cdot\left\{\log s+\psi\left(2k+n+\frac32\right)-\psi(2k+2)+\frac{\zeta'(2k+2n+2)}{\zeta(2k+2n+2)}\right\}\Bigg],
\end{aligned}
\tag{5.5}
$$

valid for $n=0,1,2,\cdots$. For $n=0$, the expansion (5.5) agrees with [6, Formula (33)]. Note that the expansion of $g_\nu(s)$ contains logarithmic terms in the case where ν is integral.

Case iii. $\nu=n+\frac12$, $n=0,1,2,\cdots$. When taking limits in (4.7) as $\nu\to n+\frac12$, proper care should be taken because some of the Γ- and ζ-functions become singular. First consider the case $\nu=\frac12$; then we find

$$
\begin{aligned}
g_{1/2}(s)=&\frac{2\pi s}{\sin(\pi s)}\lim_{\nu\to1/2}\frac{1}{\Gamma(\frac12-\nu)}\left[\frac{\Gamma(\nu-\frac12)}{\Gamma(2\nu)}\zeta(0)s^{2\nu-2}-\Gamma\left(\frac32-\nu\right)\zeta(2-2\nu)\right]\\
=&\frac{\pi s}{\sin(\pi s)}\left(\frac1s-1\right),
\end{aligned}
\tag{5.6}
$$

in accordance with (3.14). Generally, for $\nu=n+\frac12$, $n\geqq1$, the expansion (4.7) passes into

$$
\begin{aligned}
g_{n+1/2}(s)=&(-1)^n\frac{2\pi s}{\sin(\pi s)}\\
&\cdot\lim_{\nu\to n+1/2}\frac{1}{\Gamma(\frac12-\nu)}\Bigg[-\sum_{k=0}^{[(n-1)/2]}\frac{\Gamma(2k-\nu+\frac32)}{(2k+1)!}\zeta(2k-2\nu+2)s^{2k}\\
&\qquad-\frac{\Gamma(2n-\nu+\frac32)}{(2n+1)!}\zeta(2n-2\nu+2)s^{2n}\Bigg]\\
=&\frac{2\pi s}{\sin(\pi s)}\left[(-1)^n\sum_{k=0}^{[(n-1)/2]}\binom{n}{2k+1}\zeta(2k-2n+1)s^{2k}-\frac{(n!)^2}{2(2n+1)!}s^{2n}\right],
\end{aligned}
\tag{5.7}
$$

valid for $n=1,2,3,\cdots$. In the final line of (5.7) we may set, by [3, Formula 1.12(22)],

$$
\zeta(2k-2n+1)=-\frac{B_{2n-2k}}{2(n-k)}\qquad(k=0,1,\cdots,n-1)
\tag{5.8}
$$

where B_{2n-2k} is the Bernoulli number. It can be shown that the expansion (5.7) agrees with (3.16).

Case iv. $\nu = -n - \frac{1}{2}$, $n = 0, 1, 2, \cdots$. In this case the expansion (4.7) remains valid, provided that the ratio $\Gamma(2k+\nu-\frac{1}{2})/\Gamma(2k+2\nu)$ is handled with proper care. Thus by means of

$$\lim_{\nu \to -n-1/2} \frac{\Gamma(2k+\nu-\frac{1}{2})}{\Gamma(2k+2\nu)} = \begin{cases} 2(2k-2n-1)_n, & k \leqq n, \\ (2k-2n-1)_n, & k \geqq n+1 \end{cases} \tag{5.9}$$

we obtain the expansion

$$g_{-n-1/2}(s) = \frac{(-1)^n}{n!} \frac{2\pi s}{\sin(\pi s)} \left[-2 \sum_{k=0}^{n} (2k-2n-1)_n \zeta(2k) s^{2k-2n-3} + \sum_{k=1}^{\infty} (-1)^k (k)_n \zeta(k+2n+1) s^{k-2} \right], \tag{5.10}$$

valid for $n = 0, 1, 2, \cdots$. In the special case $n = 0$, $\nu = -\frac{1}{2}$, the expansion (5.10) reduces to

$$\begin{aligned} g_{-1/2}(s) &= \frac{2\pi s}{\sin(\pi s)} \left[s^{-3} + \sum_{k=1}^{\infty} (-1)^k \zeta(k+1) s^{k-2} \right] \\ &= -\frac{2\pi s^{-1}}{\sin(\pi s)} [\psi(s) + \gamma] \end{aligned} \tag{5.11}$$

by use of [3, Formula 1.17(5)]. The same result can also be found by a direct evaluation of the integral (3.3) with $\nu = -\frac{1}{2}$.

Finally, it is pointed out that the infinite series expansions of $g_\nu(s)$, as presented in (5.2), (5.5), and (5.10), are convergent for $0 < |s| < 1$. In Case iii the infinite series reduces to a finite sum; see (5.6) and (5.7).

6. Asymptotic expansion of $G^{(m)}_{\mu,p}(\eta)$. The asymptotic expansion of $G^{(m)}_{\mu,p}(\eta)$ as $\eta \to \infty$ is determined through a term-by-term conversion, based on theorems of Abelian asymptotics [2, Kap. 7], of the series expansion of $s^{-\mu} g_\nu(s)$ around $s = 0$. The conversion is most easily carried out by use of the "dictionary" in Table 1. The left column of the table shows a specific term of the expansion around $s = 0$; the right column shows the corresponding term of the asymptotic expansion as $\eta \to \infty$.

In the expansions of $g_\nu(s)$ as determined in §§ 4 and 5, replace $\pi s/\sin(\pi s)$ by

$$\frac{\pi s}{\sin(\pi s)} = 2 \sum_{k=0}^{\infty} (1 - 2^{1-2k}) \zeta(2k) s^{2k}, \qquad |s| < 1 \tag{6.1}$$

TABLE 1
Inverse Laplace transforms.

$f(s)$	$(1/2\pi i) \int_{c-i\infty}^{c+i\infty} f(s)\, e^{\eta s}\, ds$	
s^λ	$[1/\Gamma(-\lambda)]\eta^{-\lambda-1}$,	$\lambda \neq 0, 1, 2, \cdots$
	0,	$\lambda = 0, 1, 2, \cdots$
$s^\lambda \log s$	$-[1/\Gamma(-\lambda)]\eta^{-\lambda-1}[\log \eta - \psi(-\lambda)]$,	$\lambda \neq 0, 1, 2, \cdots$
	$(-1)^{\lambda+1}\lambda!\,\eta^{-\lambda-1}$,	$\lambda = 0, 1, 2, \cdots$

and multiply the series involved. Then for $2\nu \notin \mathbb{Z}$, the expansion (4.7) of $g_\nu(s)$ takes the form

$$g_\nu(s) = \sum_{k=0}^{\infty} A_k s^{2k+2\nu-2} + \sum_{k=0}^{\infty} B_k s^{2k}, \qquad 0<|s|<1 \tag{6.2}$$

with coefficients

$$\begin{aligned} A_k &= \frac{4}{\Gamma(\frac{1}{2}-\nu)\sin(\nu\pi)} \sum_{l=0}^{k} \frac{\Gamma(2l+\nu-\frac{1}{2})}{\Gamma(2l+2\nu)} \zeta(2l)(1-2^{1-2k+2l})\zeta(2k-2l), \\ B_k &= \frac{-4}{\Gamma(\frac{1}{2}-\nu)\sin(\nu\pi)} \sum_{l=0}^{k} \frac{\Gamma(2l-\nu+\frac{3}{2})}{(2l+1)!} \zeta(2l-2\nu+2)(1-2^{1-2k+2l})\zeta(2k-2l). \end{aligned} \tag{6.3}$$

Similar expansions hold in the case where $2\nu \in \mathbb{Z}$. From (5.2) and (5.5) it follows that the expansion of $g_\nu(s)$ contains logarithmic terms if ν is integral.

Starting from (6.2) multiplied by $s^{-\mu}$, we find by use of Table 1 the desired asymptotic expansion

$$\begin{aligned} G_{\mu,p}^{(m)}(\eta) \sim & \sum_{k=0}^{\infty} \frac{A_k}{\Gamma(\mu-2\nu-2k+2)} \eta^{\mu-2\nu-2k+1} \\ & + \sum_{k=0}^{\infty} \frac{B_k}{\Gamma(\mu-2k)} \eta^{\mu-2k-1} \qquad (\eta \to \infty), \end{aligned} \tag{6.4}$$

valid if $2\nu \notin \mathbb{Z}$. It is pointed out that the first (second) asymptotic series in (6.4) terminates to a finite sum if $\mu-2\nu$ (μ) is an integer. Similar asymptotic expansions hold in the case where $2\nu \in \mathbb{Z}$. If ν is an integer, it is found from (5.2) and (5.5) that the asymptotic expansion of $G_{\mu,p}^{(m)}(\eta)$ contains logarithmic terms $[1/\Gamma(\mu-2k)] \times \eta^{\mu-2k-1} \log \eta$, with $k \geqq \max(\nu-1, 0)$.

As an example, we determine the asymptotic expansion of the integral [5]

$$G_{2,-1/2}^{(2)}(\eta) = \int_{-\infty}^{\eta} (\eta - t)[F''_{-1/2}(t)]^2 \, dt, \tag{6.5}$$

for which $\nu = 2$. In the expansion (5.2) with $n=2$, replace $\pi s/\sin(\pi s)$ by (6.1), and multiply the series involved. Then the expansion of $g_2(s)$ takes the form

$$g_2(s) = \sum_{k=1}^{\infty} c_k s^{2k} \log s + \sum_{k=0}^{\infty} d_k s^{2k}, \qquad |s|<1 \tag{6.6}$$

with coefficients

$$\begin{aligned} c_k &= 6\pi^{-3/2} \sum_{l=1}^{k} \frac{\Gamma(2l-\frac{1}{2})}{(2l+1)!} \zeta(2l-2)(1-2^{1-2k+2l})\zeta(2k-2l), \\ d_k &= 6\pi^{-3/2} \sum_{l=0}^{k} \frac{\Gamma(2l-\frac{1}{2})}{(2l+1)!} \zeta(2l-2)\left[\psi\left(2l-\frac{1}{2}\right) - \psi(2l+2) + \frac{\zeta'(2l-2)}{\zeta(2l-2)}\right] \\ &\quad \cdot (1-2^{1-2k+2l})\zeta(2k-2l). \end{aligned} \tag{6.7}$$

Next, by use of Table 1 in a term-by-term conversion of the expansion of $s^{-2}g_2(s)$, we are led to the asymptotic expansion

$$G_{2,-1/2}^{(2)}(\eta) \sim d_0\eta - \sum_{k=1}^{\infty} (2k-2)! c_k \eta^{-2k+1} \qquad (\eta \to \infty). \tag{6.8}$$

By evaluating the leading terms in (6.8), we find

$$G^{(2)}_{2,-1/2}(\eta)=\frac{3\zeta(3)}{2\pi^3}\eta+\frac{1}{8\pi}\eta^{-1}+\frac{5\pi}{192}\eta^{-3}$$
$$+\frac{43\pi^3}{1920}\eta^{-5}+\frac{323\pi^5}{7168}\eta^{-7}+O(\eta^{-9}) \qquad (\eta\to\infty). \tag{6.9}$$

The asymptotic expansion (6.8) can also be derived in a more elementary manner. To that end we start from the two-sided Laplace transform

$$\int_{-\infty}^{\infty} e^{-st}F''_{-1/2}(t)\,dt=\frac{\pi s^{3/2}}{\sin(\pi s)}, \tag{6.10}$$

obtainable from (2.12) and (2.13). Using (6.1) and Table 1, we expand (6.10) in a power series around $s=0$, whereupon a term-by-term conversion yields the asymptotic expansion

$$F''_{-1/2}(t)\sim-\frac{2}{\pi}\sum_{k=0}^{\infty}(1-2^{1-2k})\Gamma\left(2k+\frac{3}{2}\right)\zeta(2k)t^{-2k-3/2} \qquad (t\to\infty). \tag{6.11}$$

By squaring (6.11) we find

$$[F''_{-1/2}(t)]^2\sim\sum_{k=0}^{\infty}b_k t^{-2k-3} \quad (t\to\infty) \tag{6.12}$$

with coefficients

$$b_k=\frac{4}{\pi^2}\sum_{l=0}^{k}(1-2^{1-2l})\Gamma\left(2l+\frac{3}{2}\right)\zeta(2l)$$
$$\cdot(1-2^{1-2k+2l})\Gamma\left(2k-2l+\frac{3}{2}\right)\zeta(2k-2l). \tag{6.13}$$

Next it is observed from (6.5) that $G^{(2)}_{2,-1/2}(\eta)$ is the repeated integral of order 2, of $[F''_{-1/2}(t)]^2$. As it has been shown in the Appendix of [6], the asymptotic expansion of $G^{(2)}_{2,-1/2}(\eta)$ can now be derived by a twice repeated termwise integration of the expansion (6.12). Thus we find

$$G^{(2)}_{2,-1/2}(\eta)\sim C_1\eta+C_0+\sum_{k=0}^{\infty}\frac{b_k}{(2k+1)(2k+2)}\eta^{-2k-1} \qquad (\eta\to\infty) \tag{6.14}$$

where the constants C_0 and C_1 are yet to be determined. By dividing (6.14) by η and taking limits as $\eta\to\infty$, it readily follows that

$$C_1=\int_{-\infty}^{\infty}[F''_{-1/2}(t)]^2\,dt=g_2(0)=\frac{3\zeta(3)}{2\pi^3} \tag{6.15}$$

where $g_2(0)$ has been evaluated by means of (2.16) and [4, Formula 6.6(4)]. In a similar manner it is found that

$$C_0=-\int_{-\infty}^{\infty}t[F''_{-1/2}(t)]^2\,dt=g'_2(0)=0. \tag{6.16}$$

The asymptotic expansion (6.14) does agree with (6.8) provided that

$$-(2k)!\,c_{k+1}=\frac{b_k}{(2k+1)(2k+2)}, \qquad k=0,1,2,\cdots. \tag{6.17}$$

The latter identity can be proved by a generating function technique.

CONTIGUITY RELATIONS OF AOMOTO-GEL'FAND HYPERGEOMETRIC FUNCTIONS AND APPLICATIONS TO APPELL'S SYSTEM F_3 AND GOURSAT'S SYSTEM ${}_3F_2$ *

TAKESHI SASAKI†

This paper is dedicated to the memory of Yutaka Se-ashi.

Abstract. Aomoto-Gel'fand hypergeometric functions $\Phi(Z, \alpha)$ [K. Aomoto, *Sci. Papers*, College of Arts and Sciences, University of Tokyo, 27 (1977), pp. 49-61], [I. M. Gel'fand, *Soviet Math. Dokl.*, 33 (1986), pp. 573-577] are functions of z defined on the Grassmannian $G_{k,n}$, the set of k-dimensional subspaces of an n-dimensional linear space, and with complex parameters (α). Such a class of functions contains certain classical hypergeometric functions (HGF), such as the HGF of Gauss, the generalized HGF ${}_{p+1}F_p$, and Appell's HGF's F_1, F_2, F_3. On the other hand, W. Miller [*J. Math. Phys.*, 13 (1972), pp. 1393-1399; *SIAM J. Appl. Math.*, 25 (1973), pp. 226-235; *SIAM J. Math. Anal.*, 3 (1972), pp. 31-44] has given contiguity relations for several HGF's, including the HGF's mentioned above, and has shown the Lie-algebraic structure of the equations satisfied by these functions. This paper first presents a principle of obtaining contiguity relations for Aomoto-Gel'fand HGF's and clarifies the Lie-algebraic structure among them. The contiguity relations for Lauricella's HGF F_D are known easily from this principle. The second part of this paper is an application to get complete tables of contiguity relations for F_3 and ${}_3F_2$, which complement the tables for these functions given by Miller in the papers cited above.

AMS(MOS) subject classifications. 33A30, 33A75, 33A70

Introduction. This paper is aimed at defining the contiguity relations of the Aomoto-Gel'fand hypergeometric functions and providing, as applications, a complete list of contiguity relations of Appell's hypergeometric function F_3 and that of Goursat's generalized hypergeometric function ${}_3F_2$. We use a short term HGF for "hypergeometric function."

Let us recall the contiguity relations of the Gauss HGF:

$$F(\alpha, \beta, \gamma; x) = \sum_{n=0}^{\infty} \frac{(\alpha, n)(\beta, n)}{(\gamma, n)n!} x^n,$$

where (α, n) denotes the factorial function

$$(\alpha, n) = \begin{cases} 1, & n = 0, \\ \alpha(\alpha+1)(\alpha+2)\cdots(\alpha+n-1), & n = 1, 2, 3, \cdots. \end{cases}$$

Functions such as $F(\alpha \pm 1, \beta, \gamma; x)$, $F(\alpha, \beta \pm 1, \gamma; x), \cdots$ are called *contiguous* to $F(\alpha, \beta, \gamma; x)$, and linear relations among contiguous functions and their derivatives are called *contiguity relations.* The following are typical examples:

$$\alpha F(\alpha+1, \beta, \gamma; x) = \alpha F(\alpha, \beta, \gamma; x) + x\frac{d}{dx} F(\alpha, \beta, \gamma; x),$$

$$(\alpha-\gamma+1)F(\alpha, \beta, \gamma; x) = (\gamma-\alpha-1-\beta x)F(\alpha+1, \beta, \gamma; x) + x(1-x)\frac{d}{dx} F(\alpha+1, \beta, \gamma; x). \tag{0.1}$$

* Received by the editors June 7, 1989; accepted for publication (in revised form) December 11, 1989.

Define differential operators H and B which appear in the right-hand sides by

$$H = x\frac{d}{dx} + \alpha \quad \text{and} \quad B = x(1-x)\frac{d}{dx} + (\gamma - \alpha - 1 - \beta x), \tag{0.2}$$

and denote by $S(\alpha, \beta, \gamma)$ the space of solutions of the Gauss hypergeometric differential equation (HGDE):

$$x(1-x)\frac{d^2u}{dx^2} + \{\gamma - (\alpha + \beta + 1)x\}\frac{du}{dx} - \alpha\beta u = 0. \tag{0.3}$$

Then these operators define linear homomorphisms:

$$\begin{aligned} &H : S(\alpha, \beta, \gamma) \to S(\alpha + 1, \beta, \gamma), \\ &B : S(\alpha + 1, \beta, \gamma) \to S(\alpha, \beta, \gamma), \end{aligned} \tag{0.4}$$

which are isomorphisms when $\alpha(\alpha + \gamma - 1) \neq 0$. The differential operator

$$\frac{d}{dx} : S(\alpha, \beta, \gamma) \to S(\alpha + 1, \beta + 1, \gamma + 1),$$

which has been basic in the study of the Gauss HGF in [GA], also reflects a contiguity relation

$$\frac{d}{dx} F(\alpha, \beta, \gamma, x) = \frac{\alpha\beta}{\gamma} F(\alpha + 1, \beta + 1, \gamma + 1; x).$$

As we have seen in [SY3], such relations form a part of the symmetry of the Gauss HGDE (0.3), and symmetry plays a fundamental role in the study of the HGF. It is thus important to understand how the contiguity relations arise for several HGF's. Refer also to [IKSY].

In this paper we first present a general principle of getting such relations and differential operators for a wider class of HGF's, i.e., a class of HGF's defined by Aomoto [A1] and Gel'fand [GE], which we call the Aomoto-Gel'fand HGF's (see § 1).

We next apply this principle to classical HGF's. Contiguity relations for the Appell-Lauricella HGF, denoted by F_D, are completely known by Miller [M1] in relation with the Lie-algebraic structure of the system of differential equations satisfied by these functions. Contiguity relations for Appell's HGF F_3 of two variables and those for Goursat's HGF ${}_pF_q$ are partly known by Miller [M2], [M3]. On the other hand, these functions F_D, F_3, and ${}_pF_q$ ($p = q + 1$) belong to the class of the Aomoto-Gel'fand HGF's. Therefore, as applications, we can reproduce contiguity relations of F_D by a simpler principle and complement those relations of F_3 and ${}_3F_2$ by Miller to yield a complete set of contiguity relations. The Lie-algebraic structure of the associated differential operators is also clarified by the same principle.

Here we give some remarks. Miller et al. in [M1]-[M4], [KMM1]-[KMM3] have determined the symmetry of Horn's two-variable systems. To each system they associated a constant coefficient system, called the canonical system, on a manifold that has fibering over the original two-manifold. In this instance they used (some) contiguity relations. Our present context is, put simply, in the opposite direction; we start with systems which are full of symmetry and then restrict our consideration to base manifolds to get contiguity relations of classical HGF's. This concept itself is not new. Hrabowski [H] introduced the canonical systems, which are generalizations of HGDE's, associated with certain simple Lie groups and classified the Lie-algebraic content of such systems. He also gave a principle, essentially the same as ours, for getting contiguity relations

(recurrence relations, in his terminology) for such systems. Recently, Gel'fand, Zelevinskii, and Kapranov [GZK] gave a precise description of algebraic structure of canonical systems, generalizing that by Hrabowski. So, by a method similar to that exhibited here we may find contiguity relations explicitly for several other HGF's. Appell's F_4, for example, is one such HGF since the function F_C that is a higher-dimensional generalization of F_4 is a special case of this general setting, although the actual computation needs some elaborate working. The author does not know, however, whether F_4 has a representation as one of Aomoto-Gel'fand HGF's. Refer to [T], where Takayama has given another method of obtaining contiguity relations for F_4.

It should be noted that Sato [SA] has already given a different approach to get a generalization of HGF's by referring to prehomogeneous vector spaces and b-functions.

In § 1 we recall the definition of the Aomoto-Gel'fand HGF and the system $E(k, n)$ of differential equations satisfied by this function. In § 2 contiguity relations for this system will be defined. From these relations we obtain *generalized Gauss relations*, namely, hypergeometric difference equations with respect to parameters. We treat in § 3 the system $E(2, n+3)$, which is associated with the Appell-Lauricella HGF F_D, and reproduce contiguity relations due to Miller (see Table 1).

In §§ 4–10 we deal with the system $E(3, 6)$, whose explicit expression is given in § 4. It is noteworthy that, while the system $E(3, 6)$ is defined on $\mathbf{CP}^4$ and of rank 6, it includes, as subsystems, Appell's systems F_1, F_2, and F_3, Gousat's system ${}_3F_2$, and the Gauss HGDE. This will be recalled in § 6. Moreover, this fact enables us to derive contiguity relations for these systems from the contiguity relations of $E(3, 6)$. Refer to [MSY2] for the algebraic-geometric implications of this fact. In § 5 and § 8 we give two representations of contiguity relations of $E(3, 6)$ (see Tables 2, 4). In § 7 we complete enumerating contiguity relations for Appell's F_3 (see Tables 3.1, 3.2). The list of those relations for ${}_3F_2$ will be given in § 9 (Table 5). Section 10 gives proofs of two technical lemmas.

1. The Aomoto–Gel'fand hypergeometric function. We recall the definition of the Aomoto-Gel'fand HGF following [GE] and [GG]. Fix integers n and k so that $k < n$. Let $Z_{k,n}$ denote the space of $k \times n$ complex matrices of rank k such that any column vector is nonzero; $G_{k,n}$ the Grassmannian manifold of k-subspaces in $\mathbf{C}^n$. Since each point in $Z_{k,n}$ defines an imbedding of $\mathbf{C}^k$ into $\mathbf{C}^n$, there is a natural projection $Z_{k,n} \to G_{k,n}$. We let (t^i) be coordinates of $\mathbf{C}^k$ and define a $(k-1)$-form ω by

$$\omega = \sum_{i=1}^{k} (-1)^{i+1} t^i \, dt^1 \wedge \cdots \wedge dt^{i-1} \wedge dt^{i+1} \wedge \cdots \wedge dt^k.$$

For a set of complex numbers $\alpha = (\alpha_1, \cdots, \alpha_n)$ with the property $\sum \alpha_j = n - k$ and for a point $z = (z_{ij})$ in $Z_{k,n}$ we put $\tau = \prod_{j=1}^{n} (\sum_{i=1}^{k} z_{ij} t^i)^{\alpha_j - 1} \omega$, which can be seen as a $(k-1)$-form on the projective space $\mathbf{CP}^{k-1}$. Then we take a suitable $(k-1)$-cycle C in $\mathbf{CP}^{k-1} - S$, where S is the union of n hyperplanes $\sum_{i=1}^{k} z_{ij} t^i = 0, j = 1, \cdots, n$, and define a function by the integral

$$\Phi(z, \alpha) = \int_C \tau, \tag{1.1}$$

which will be called the *Aomoto-Gel'fand hypergeometric function.*

This function is invariant under two kinds of group action. Since $Z_{k,n}$ is a principal GL_k-bundle over $G_{k,n}$, $g \in GL_k$ acts on $Z_{k,n}$ on the left. Under this action the integral

Φ changes as

$$\Phi(gz, \alpha) = (\det g)^{-1}\Phi(z, \alpha). \tag{1.2}$$

On the other hand, the Cartan subgroup H_n, consisting of diagonal matrices, acts on $Z_{k,n}$ on the right. Under this action, Φ transforms as

$$\Phi(zh, \alpha) = \prod_j (h_j)^{\alpha_j - 1}\Phi(z, \alpha), \tag{1.3}$$

where $h = \operatorname{diag}(h_1, \cdots, h_n)$.

Two points ζ and ζ' in $G_{k,n}$ are said to be *equivalent* if $\dim(P \cap \zeta) = \dim(P \cap \zeta')$ for any coordinate planes $P = \{(y^i) \in \mathbf{C}^n;\ y^{i_1} = y^{i_2} = \cdots = y^{i_j} = 0\}$ $(1 \leqq j \leqq n)$. Sets of equivalent points define a *stratification* of $G_{k,n}$. Note that each stratum is invariant under the action of the group H_n. It is of particular importance to study the restriction of the integral to each stratum; combinatorial information on the configuration of strata plays an essential role.

It is easy to see that the function Φ, viewed as a function on $Z_{k,n}$, satisfies the following system $E(k, n) = E(k, n; \alpha)$ of differential equations:

$$\sum_{i=1}^{k} z_{ij}\frac{\partial}{\partial z_{ij}}\Phi - (\alpha_j - 1)\Phi = 0, \tag{1.4}$$

$$\sum_{j=1}^{n} z_{ij}\frac{\partial}{\partial z_{lj}}\Phi + \delta_{il}\Phi = 0, \tag{1.5}$$

$$\frac{\partial^2}{\partial z_{ip}\,\partial z_{jq}}\Phi - \frac{\partial^2}{\partial z_{iq}\,\partial z_{jp}}\Phi = 0. \tag{1.6}$$

Equations (1.4) and (1.5) reflect the invariances (1.2) and (1.3), respectively. It is known [KN] that the rank of $E(k, n; \alpha)$ is generally not greater than $\binom{n-2}{k-1}$ and is equal to this number when z lies in the unique open stratum and when any α_j takes no integral value.

For the precise presentation of the above materials, refer to [A1], [A3], [GE], [GG], [KN].

2. Contiguity relations and Gauss relations. On the space $Z_{k,n}$ acts the general linear group GL_n on the right. We are interested in the associated infinitesimal transformation, which induces the vector fields L_{jl} on $Z_{k,n}$ given by

$$L_{jl} = \sum_{i=1}^{k} z_{ij}\frac{\partial}{\partial z_{il}} \quad \text{for } j, l = 1, \cdots, n. \tag{2.1}$$

The next lemma is a key to understanding what follows.

LEMMA 2.1. *The Lie algebra generated by vector fields L_{jl} is isomorphic to the Lie algebra $\mathfrak{gl}_n$ of general linear matrices.*

Proof. We have only to associate to L_{jl} the $n \times n$ matrix with 1 in the (jl)th component and zero in the others. □

Applying these differential operators on the integral (1.1), we easily see the following proposition.

PROPOSITION 2.2. *The integral Φ satisfies relations*

$$L_{jl}\Phi(z, \alpha) = (\alpha_l - 1)\Phi(z, \alpha + 1_j - 1_l), \tag{2.2}$$

where 1_j denotes the vector with 1 in the jth component and zero in the others.

While these identities are infinitesimal expressions of the right action, they can be seen as differential-difference relations among a solution of the system $E(k, n; \alpha)$

and a solution of another system $E(k, n; \alpha+1_j-1_l)$. So we introduce the following definition.

DEFINITION. We call the relations (2.2) the *contiguity relations* of the integral Φ or of the system $E(k, n)$.

We now look closer at these relations by the invariance (1.2). Take a point $z=(z_1, z_2)$ in $Z_{k,n}$, where z_1 is a nonsingular $k\times k$ matrix and z_2 is a $k\times(n-k)$ matrix. Put

$$u=(u_{ap})=z_1^{-1}z_2, \tag{2.3}$$

which can be seen as a point in $G_{k,n}$. The ranges of indices are supposed to be

$$1\leqq i, j, \cdots, \leqq n, \quad 1\leqq a, b, \cdots, \leqq k, \quad k+1\leqq p, q, \cdots, \leqq n.$$

We define

$$\varphi(u, \alpha)=\Phi((I_k, u), \alpha). \tag{2.4}$$

The invariance (1.2) implies

$$\Phi(z, \alpha)=(\det z_1)^{-1}\varphi(u, \alpha). \tag{2.5}$$

Hence the action of L_{jl} on Φ induces a differential operator $X_{jl}=(\det z_1)L_{jl}(\det z_1)^{-1}$ acting on φ; φ satisfies contiguity relations

$$X_{jl}\varphi(u, \alpha)=(\alpha_l-1)\varphi(u, \alpha+1_j-1_l). \tag{2.6}$$

LEMMA 2.3. *The operators X_{jl} are given by the formulae*

$$X_{jl}=\begin{cases} -\delta_{ab}-\sum_{p=k+1}^{n} u_{bp}\dfrac{\partial}{\partial u_{ap}}, & j=a, \quad l=b, \\ \dfrac{\partial}{\partial u_{ap}}, & j=a, \quad l=p, \\ -u_{ap}-\sum_{q=k+1}^{n} u_{aq}U_{pq}, & j=p, \quad l=a, \\ U_{pq}, & j=p, \quad l=q, \end{cases} \tag{2.7}$$

where

$$U_{pq}=\sum_{a=1}^{k} u_{ap}\frac{\partial}{\partial u_{aq}}.$$

Proof. Denote by (V_{ab}) the inverse matrix of z_1. Assume $1\leqq j, l\leqq k$. Then the derivation of (2.5) by L_{jl} gives

$$\begin{aligned} L_{jl}\Phi &= \sum z_{aj}\frac{\partial}{\partial z_{al}}((\det z_1)^{-1}\varphi(u, \alpha)) \\ &= \sum z_{aj}\frac{\partial}{\partial z_{al}}(\det z_1)^{-1}\cdot\varphi+\sum z_{aj}(\det z_1)^{-1}\frac{\partial u_{bp}}{\partial z_{al}}\frac{\partial\varphi}{\partial u_{bp}} \\ &= -\sum z_{aj}(\det z_1)^{-2}(\text{the } (al)\text{-cofactor})\varphi+\sum z_{aj}(\det z_1)^{-1}(-V_{ba}u_{lp})\frac{\partial\varphi}{\partial u_{bp}} \\ &= -\sum(\det z_1)^{-1}\delta_{jl}\varphi-\sum(\det z_1)^{-1}u_{lp}\frac{\partial\varphi}{\partial u_{jp}}. \end{aligned} \tag{2.8}$$

Hence we get the first formula. Other formulae are similarly shown. □

It is easy to see that these operators X_{jl} are linearly independent and form a Lie algebra isomorphic to $\mathfrak{gl}_n$, which we denote by $\mathfrak{g}$. The subspace $\mathfrak{g}_0 = \mathbf{C}\{U_{pq}\}$ is a subalgebra isomorphic to $\mathfrak{gl}_{n-k}$. The algebra $\mathfrak{g}$ is decomposed into the sum of $\mathfrak{g}_0$ and three subspaces.

$$\mathfrak{g}_1 = \mathbf{C}\{\partial/\partial u_{ap}\}, \quad \mathfrak{g}_{-1} = \mathbf{C}\{u_{ap} + \sum u_{aq} U_{pq}\}, \quad \text{and} \quad \mathfrak{g}_0' = \mathbf{C}\{\delta_{ab} + \sum u_{bp}\, \partial/\partial u_{ap}\}.$$

The triplet $\{\mathfrak{g}_{-1}, \mathfrak{g}_0 \oplus \mathfrak{g}_0', \mathfrak{g}_1\}$ gives a gradation of $\mathfrak{g}$.

The identity (2.6) for each X_{jl} gives

PROPOSITION 2.3. *The contiguity relations with respect to coordinates* (u_{ap}) *of* $G_{k,n}$ *are*

$$-\delta_{ab}\varphi(\alpha) - \sum_{p=k+1}^{n} u_{bp} \frac{\partial \varphi}{\partial u_{ap}}(\alpha) = (\alpha_b - 1)\varphi(\alpha + 1_a - 1_b), \tag{2.9}$$

$$\frac{\partial \varphi}{\partial u_{ap}}(\alpha) = (\alpha_p - 1)\varphi(\alpha + 1_a - 1_p), \tag{2.10}$$

$$-u_{ap}\varphi(\alpha) - \sum_{q=k+1}^{n} u_{aq} \left(\sum_{b=1}^{k} u_{bp} \frac{\partial \varphi}{\partial u_{bq}}(\alpha) \right) = (\alpha_a - 1)\varphi(\alpha + 1_p - 1_b), \tag{2.11}$$

$$\sum_{a=1}^{k} u_{ap} \frac{\partial \varphi}{\partial u_{aq}}(\alpha) = (\alpha_q - 1)\varphi(\alpha + 1_p - 1_q), \tag{2.12}$$

for $1 \leqq a, b \leqq k$, *and* $k+1 \leqq p, q \leqq n$.

In [A2] and [A3] Aomoto has given a general theory on the system of linear difference equations satisfied by the integral $\Phi(z, \alpha)$ viewed as a function of α. In our case the difference equations are obtained from the above formulae: it is enough to get rid of differential terms by using the second identity (2.10). Namely, we have the following proposition.

PROPOSITION 2.4. *The Aomoto-Gel'fand hypergeometric function* $\varphi(u, \alpha)$ *satisfies the system of difference equations with respect to* α:

$$\varphi(u, \alpha) = \sum_{a=1}^{k} u_{ap} \varphi(u, \alpha + 1_a - 1_p), \tag{2.13}$$

$$\alpha_a \varphi(u, \alpha) + \sum_{p=k+1}^{n} (\alpha_p - 1) u_{ap} \varphi(u, \alpha + 1_a - 1_p) = 0, \tag{2.14}$$

$$\begin{aligned} \alpha_p u_{ap} \varphi(u, \alpha) + \sum_{q=k+1, q \neq p}^{n} (\alpha_q - 1) u_{aq} \varphi(u, \alpha + 1_p - 1_q) \\ + (\alpha_a - 1)\varphi(u, \alpha + 1_p - 1_a) = 0, \end{aligned} \tag{2.15}$$

where $1 \leqq a \leqq k$ *and* $k+1 \leqq p \leqq n$.

Proof. By inserting (2.10) into (2.11), (2.9), and (2.12) we have (2.15) and

$$\delta_{ab}\varphi(u, \alpha) + \sum (\alpha_p - 1) u_{bp} \varphi(u, \alpha + 1_a - 1_p) + (\alpha_b - 1)\varphi(u, \alpha + 1_a - 1_b) = 0, \tag{2.16}$$

$$\varphi(u, \alpha + 1_p - 1_q) - \sum u_{ap} \varphi(u, \alpha + 1_a - 1_q) = 0, \tag{2.17}$$

respectively. Replacing $\alpha + 1_p - 1_q$ by α in (2.17) we get (2.13). Replacing $\alpha + 1_a - 1_b$ by α in (2.16) we get (2.14). □

Remark. Equations (2.13) and (2.14) have been given in [GZ].

DEFINITION. We call three systems of difference equations (2.13), (2.14), and (2.15) *generalized Gauss relations* (cf. [GA], [GZ]).

Example. The Goursat HGF ${}_kF_{k-1}$ is given by an integral associated with the one-dimensional stratum in $G_{k,2k}/H_{2k}$ consisting of points

$$\begin{pmatrix} 1 & & & & & 1 & & & & & 1 \\ & 1 & & & & -1 & 1 & & & & \\ & & 1 & & & & -1 & 1 & & & \\ & & & \ddots & & & & & \ddots & & \\ & & & & 1 & & & & & 1 & \\ & & & & & & & & & -1 & -x \end{pmatrix}.$$

In fact it is by definition

$$\begin{aligned} &{}_kF_{k-1}(\alpha_1, \cdots, \alpha_k; \beta_1, \cdots, \beta_{k-1}; x) \\ &\quad = \prod_{j=1}^{k-1} \frac{\Gamma(\beta_j)}{\Gamma(\alpha_j)\Gamma(\beta_j - \alpha_j)} \int t_1^{\alpha_1 - \beta_2} \times \prod_{j=2}^{k-2} t_j^{\alpha_j - \beta_{j+1}} t_{k-1}^{\alpha_{k-1} - 1} (1 - t_1)^{\beta_1 - \alpha_1 - 1} \\ &\qquad \cdot \prod_{j=2}^{k-1} (t_{j-1} - t_j)^{\beta_j - \alpha_j - 1} (1 - x t_{k-1})^{-\alpha_k} \, dt_1 \wedge \cdots \wedge dt_{k-1} \end{aligned} \tag{2.18}$$

integrated over the cycle $1 \geqq t_1 \geqq \cdots \geqq t_{k-1} \geqq 0$. The Gauss relations in Proposition 2.4 now consist of $k^2 + 2k$ difference relations, each of which contains three terms. Note that Rainville [R] has given a list of such relations; his list consists of $2k-2$ relations, each connecting three contiguous functions, and $k+1$ relations, each containing $k+1$ contiguous functions.

In the case $k = 2$, where the integral is the Gauss HGF F, we have eight relations; four of them are

$$\begin{aligned} &\gamma F - \alpha F(\alpha^+ \gamma^+) - (\gamma - \alpha) F(\gamma^+) = 0, \\ &\gamma F - \beta F(\beta^+ \gamma^+) - (\gamma - \beta) F(\gamma^+) = 0, \\ &\gamma F - \gamma F(\beta^+) + \alpha x F(\alpha^+ \beta^+ \gamma^+) = 0, \\ &\gamma F - \gamma F(\alpha^+) + \beta x F(\alpha^+ \beta^+ \gamma^+) = 0, \end{aligned}$$

where $F = F(\alpha, \beta, \gamma; x) = {}_2F_1(\alpha, \beta; \gamma; x)$ and $(\alpha^+) = (\alpha + 1, \beta, \gamma)$, $(\alpha^+ \gamma^+) = (\alpha + 1, \beta, \gamma + 1), \cdots$. The remaining four relations follow from these with certain translations of parameters. From the last two relations we have a well-known formula:

$$(\beta - \alpha) F - \beta F(\beta^+) + \alpha F(\alpha^+) = 0.$$

Another coordinate system on the stratum gives different relations; namely, because of the symmetry (1.2), we get relations transformed by so-called Kummer's identities. For example, consider a stratum of points

$$\begin{pmatrix} 1 & & 1 & 1 - x \\ & 1 & 1 & 1 \end{pmatrix}$$

in $G_{2,4}$. It is easy to see that the integral also defines the Gauss HGF with respect to the coordinate x. Then, in addition to the above relations, we have

$$\begin{aligned} &\gamma F - (\gamma - \alpha) F(\beta^+ \gamma^+) + \alpha(x - 1) F(\alpha^+ \beta^+ \gamma^+) = 0, \\ &\gamma F - (\gamma - \beta) F(\alpha^+ \gamma^+) + \beta(x - 1) F(\alpha^+ \beta^+ \gamma^+) = 0. \end{aligned}$$

In this way we can find 15 relations by Gauss [GA, p. 130].

The structure of the difference system for $k=3$ has been studied extensively by Aomoto in [A4]. Refer also to the definition of a generalized beta-function introduced in [GGR3]. The study for general k is interesting.

3. The Appell–Lauricella hypergeometric function F_D. The integral Φ can be determined by its value on the quotient space Γ/H_n of each stratum Γ by the invariance (1.2) and (1.3). We describe in this section contiguity relations (2.6) for the system $E(2, n+3)$ on the quotient of the open stratum.

We introduce coordinates on the open stratum by

$$(I_2, u)=\begin{pmatrix}1 & 0 & u_{13} & u_{14} & \cdots & u_{1,n+3}\\ 0 & 1 & u_{23} & u_{24} & \cdots & u_{2,n+3}\end{pmatrix},$$

where no 2×2 subdeterminants are zeros; to each point $u=(u_{ap})$ we associate a point in $\mathbf{C}^n$ with coordinates $(x^4, \cdots, x^{n+3})$ by

$$x^j=\frac{u_{13}u_{2j}}{u_{23}u_{1j}} \quad \text{for } 4\leqq j\leqq n+3.$$

The integral $\varphi(u, \alpha)=\Phi((I_2, u), \alpha)$ is by definition

$$\int t_1^{\alpha_1-1}t_2^{\alpha_2-1}\prod_{j=3}^{n+3}(u_{1j}t_1+u_{2j}t_2)^{\alpha_j-1}(-t_2\,dt_1+t_1\,dt_2).$$

Define ϕ by

$$\phi(u, \alpha)=u_{13}^{\alpha_2+\alpha_3-1}(-u_{23})^{-\alpha_2}\prod_{j=4}^{n+3}u_{1j}^{\alpha_j-1}.$$

Then the integrand is

$$\phi(u, \alpha)t^{\alpha_2-1}(1-t)^{\alpha_3-1}\prod_{j=4}^{n+3}(1-x^jt)^{\alpha_j-1}\,dt$$

for $t=-u_{23}t_2/u_{13}t_1$. Here recall the Appell–Lauricella HGF in n variables $(y^1, \cdots, y^n)$:

$$\begin{aligned}&F_D(\alpha, \beta_1, \cdots, \beta_n, \gamma; y^1, \cdots, y^n)\\ &\quad=\frac{\Gamma(\gamma)}{\Gamma(\alpha)\Gamma(\gamma-\alpha)}\int_0^1 t^{\alpha-1}(1-t)^{\gamma-\alpha-1}\prod_{j=1}^{n}(1-y^jt)^{-\beta_j}\,dt.\end{aligned}\tag{3.1}$$

Then, from the above consideration, if we take the interval $(0, 1)$ as a cycle in t-space, we have

$$\varphi(u, \alpha)=\phi(u, \alpha)w(x, \alpha),\tag{3.2}$$

where

$$w(x, \alpha)=\frac{\Gamma(\alpha)\Gamma(\gamma-\alpha)}{\Gamma(\gamma)}F_D(\alpha, \beta_4, \cdots, \beta_{n+3}, \gamma; x^4, \cdots, x^{n+3}),\tag{3.3}$$

$$\alpha=\alpha_2, \quad \beta_j=1-\alpha_j \quad (4\leqq j\leqq n+3), \quad \text{and} \quad \gamma=\alpha_2+\alpha_3.$$

Now it is easy to compute the action of X_{jl}. In the following we use the notation

$$\partial_j=\frac{\partial}{\partial x^j}, \quad \delta_j=x^j\partial_j, \quad \text{and} \quad \delta=\delta_4+\cdots+\delta_{n+3}.\tag{3.4}$$

Define Y_{jl} by

$$Y_{jl}w=\phi^{-1}X_{jl}\varphi\big|_{u_{23}=u_{13}=u_{14}=\cdots=u_{1,n+3}=1}.\tag{3.5}$$

We can see

$$\phi^{-1}X_{jl}\varphi = M_{jl}(u)\,Y_{jl}w, \tag{3.6}$$

where $M_{jl}(u)=\phi(u,\alpha+1_j-1_l)/\phi(u,\alpha)$, that is, equal to 1 when $u_{23}=u_{13}=\cdots=u_{1,n+3}=1$. The computation of Y_{jl} will be straightforward: we treat, for example, the case $(jl)=(13)$. Since $X_{13}=\partial/\partial u_{13}$,

$$X_{13}\varphi(u,\alpha)=\frac{\phi}{u_{13}}((\alpha_2+\alpha_3-1)w+\delta w).$$

The definition of ϕ implies

$$(\phi w)(\alpha+1_j-1_l)=\frac{1}{u_{13}}\phi(\alpha)w(\alpha+1_j-1_l).$$

Hence

$$Y_{13}w=(\alpha_2+\alpha_3-1)w+\delta w=(\alpha_3-1)w(\alpha+1_j-1_l)\quad\text{and}\quad M_{13}=1/u_{13}.$$

Thus we have the following proposition.

PROPOSITION 3.1. *The Appell-Lauricella* HGF $w(x,\alpha)$ *satisfies contiguity relations in Table* 1. *The diagonal operators* Y_{jj}, $1\leqq j\leqq n+3$, *induce scalar multiplications by* α_j-1.

TABLE 1

Index	Y	a_Y	α^Y	M
[13]	$\gamma-1+\delta$	$\gamma-\alpha-1$	γ^-	$1/u_{13}$
[23]	$-\alpha-\delta$	$-(\gamma-\alpha-1)$	α^+	$1/u_{23}$
[1j]	$-\beta_j-\delta_j$	$-\beta_j$	β_j^+	$1/u_{1j}$
[2j]	δ_j	β_j	$\alpha^+\beta_j^+\gamma^+$	$u_{13}/u_{23}u_{1j}$
[12]	$1-\gamma+\sum_j\beta_jx^j+\sum_j(x^j-1)\delta_j$	$-(\alpha-1)$	$\alpha^-\gamma^-$	u_{23}/u_{13}
[21]	$\alpha+\sum_j(x^j-1)\partial_j$	$-(\sum\beta_j-\gamma)$	$\alpha^+\gamma^+$	u_{13}/u_{23}
[3j]	$-\beta_j+(1-x^j)\partial_j$	$-\beta_j$	$\beta_j^+\gamma^+$	u_{13}/u_{1j}
[j3]	$\gamma-1+(1-x^j)\delta-\alpha x^j$	$\gamma-\alpha-1$	$\beta_j^-\gamma^-$	u_{1j}/u_{13}
[jl]	$-\beta_l+(x^j-x^l)\partial_l$	$-\beta_l$	$\beta_j^-\beta_l^+$	u_{1j}/u_{1l}
[31]	$\sum\beta_j-\gamma+\alpha+\sum_j(x^j-1)\partial_j$	$\sum\beta_j-\gamma$	γ^+	u_{13}
[32]	$\alpha-\gamma+\sum_j\beta_jx^j+\sum_j(x^j-1)\delta_j$	$-(\alpha-1)$	α^-	u_{23}
[j1]	$\sum\beta_j-\gamma+\alpha x^j+x^j\sum_l(x^l-1)\partial_l$	$\sum\beta_j-\gamma$	β_j^-	u_{1j}
[j2]	$(\alpha-1)x^j+\sum_l\beta_lx^l+1-\gamma+\sum(x^l-1)\delta_l$	$-(\alpha-1)$	$\alpha^-\beta_j^-\gamma^-$	$u_{23}u_{1j}/u_{13}$

Each line reads as $Yw(x,\alpha)=a_Yw(x,\alpha^Y)$. The first column denotes indices of Y_{jl}. We use parameters (α,β_j,γ) instead of (α_j) to make the formulae easy to refer to in classical notation. The notation (α^+) in the last column implies that the parameter α is increased by 1 and other parameters are unchanged. The range of indices in Table 1 for $j, l, \cdots$ is from 4 to $n+3$.

Remark. When $n=1$, F_D is the Gauss HGF. The operators H and B defined in (0.4) are $-Y_{23}$ and $-Y_{32}$, respectively.

Remark. The Lie-algebraic structure associated with the above operators given by Miller [M1] is the same as that of $\mathbf{C}\{X_{jl}\}$ (cf. the proof of Proposition 7.2).

Remark. Kametaka and Okamoto [O] introduced the notion of ladder structure and formulated a connection of this structure with the Toda equation. In the present case, their theory can be applied to subalgebras $\mathbf{C}\{X_{jl}, X_{lj}, X_{jj}-X_{ll}\}$ for $j\neq l$, each of

which is isomorphic to $\mathfrak{sl}_2$. For example, when $n=1$, the algebra for $j=2$ and $l=3$ associated with H and B as remarked above is used to give solutions of

$$\left((1-x)\frac{d}{dx}\right)^2 \log \chi_m = \chi_{m-1}\chi_{m+1}/\chi_m^2, \qquad m \in Z.$$

This remark works for each pair (k, n).

4. The system $E(3, 6)$. In this section we derive an explicit form of the system $E(3,6)$ on the quotient of the open stratum of $G_{3,6}$. We fix coordinates as follows. Consider the set of points

$$(I_3, u) = \begin{pmatrix} 1 & & & u_{14} & u_{15} & u_{16} \\ & 1 & & u_{24} & u_{25} & u_{26} \\ & & 1 & u_{34} & u_{35} & u_{36} \end{pmatrix} \tag{4.1}$$

in $Z_{3,6}$. Assume u_{14}, u_{15}, u_{16}, u_{24}, and u_{34} are not equal to zeros and define

$$x^1 = \frac{u_{14}u_{25}}{u_{15}u_{24}}, \quad x^2 = \frac{u_{14}u_{26}}{u_{16}u_{24}}, \quad x^3 = \frac{u_{14}u_{35}}{u_{15}u_{34}}, \quad x^4 = \frac{u_{14}u_{36}}{u_{16}u_{34}}. \tag{4.2}$$

Then $x=(x^i)$ is a system of coordinates around the single H_6-orbit $\{u_{25}=u_{26}=u_{35}=u_{36}=0\}$. It defines a local section of the projection $Z_{3,6} \to GL_3\backslash Z_{3,6}/H_6$ by associating a matrix

$$\begin{pmatrix} 1 & & & 1 & 1 & 1 \\ & 1 & & 1 & x^1 & x^2 \\ & & 1 & 1 & x^3 & x^4 \end{pmatrix}. \tag{4.3}$$

Remark here that this choice of coordinates is by no means the unique one. In § 8 we introduce another choice in order to study Goursat's HGF ${}_3F_2$, although the above choice is useful in the study of Appell's HGF F_3.

Put

$$\phi(u) = u_{14}^{\alpha_{234}-1} u_{24}^{-\alpha_2} u_{34}^{-\alpha_3} u_{15}^{\alpha_5-1} u_{16}^{\alpha_6-1}, \tag{4.4}$$

where $\alpha_{234} = \alpha_2+\alpha_3+\alpha_4$, and define a function w of (x^i) around the origin by

$$w(x, \alpha) = c(\alpha)F(x, \alpha),$$

where

$$c(\alpha) = \Gamma(1-\alpha_{234})\Gamma(\alpha_2)\Gamma(\alpha_3)/\Gamma(1-\alpha_4)$$

and

$$F(x, \alpha) = \sum \frac{(1-\alpha_5, k+l)(1-\alpha_6, m+n)(\alpha_2, k+m)(\alpha_3, l+n)}{(\alpha_{234}, k+l+m+n)(1, k)(1, l)(1, m)(1, n)} \cdot (x^1)^k (x^2)^l (x^3)^m (x^4)^n. \tag{4.5}$$

Summation is taken over nonnegative integers and $(a, k) = a(a+1)\cdots(a+k-1)$. Since the integral Φ is

$$\int \phi t_1^{\alpha_1-1} t_2^{\alpha_2-1} t_3^{\alpha_3-1} (t_1+t_2+t_3)^{\alpha_4-1} (t_1+x^1t_2+x^3t_3)^{\alpha_5-1} (t_1+x^2t_2+x^4t_3)^{\alpha_6-1}\, dt,$$

where $dt = t_1\, dt_2 \wedge dt_3 - t_2\, dt_1 \wedge dt_3 + t_3\, dt_1 \wedge dt_2$, the function $w = \phi^{-1}\Phi$ is a function only of x. Take $\{t_1+t_2+t_3=1,\ t_i \geqq 0\} \subset \mathbf{R}^3$ as the range of integration. Assume that the

real parts of α_2, α_3, α_5, α_6, and $1-\alpha_{234}$ are positive and that α_{234} and α_4 are not integers. Then, by use of the binomial expansion $(1-y)^{\alpha}=\sum((-\alpha, m)/(1, m))y^m$, we get the identity

$$\Phi(u, \alpha)=\phi(u, \alpha)w(x, \alpha). \tag{4.6}$$

We next rewrite the differential equations (1.4)-(1.6) with respect to w. Since equations (1.4) and (1.5) are trivial for w, thanks to the invariance (1.2) and (1.3), we deal with (1.6). Put

$$\theta_{ap}=u_{ap}\frac{\partial}{\partial u_{ap}} \quad \text{for } 1\leqq a\leqq 3 \quad \text{and} \quad 4\leqq p\leqq 6,$$

$$\delta_i=x^i\frac{\partial}{\partial x^i} \quad \text{for } 1\leqq i\leqq 4 \quad \text{and} \quad \delta=\delta_1+\delta_2+\delta_3+\delta_4.$$

LEMMA 4.1. *The vector fields* θ_{ap} $(1\leqq a\leqq 3, 4\leqq p\leqq 6)$ *acts on* $w=\phi^{-1}\Phi$ *as differential operators listed below*:

$$\begin{aligned}
&\theta_{14}=\alpha_{234}-1+\delta, && \theta_{15}=\alpha_5-1-\delta_1-\delta_3, && \theta_{16}=\alpha_6-1-\delta_2-\delta_4,\\
&\theta_{24}=-\alpha_2-\delta_1-\delta_2, && \theta_{25}=\delta_1, && \theta_{26}=\delta_2,\\
&\theta_{34}=-\alpha_3-\delta_3-\delta_4, && \theta_{35}=\delta_3, && \theta_{36}=\delta_4.
\end{aligned}$$

Proof. See (4.1)-(4.3). □

Assume $1\leqq a, b\leqq 3$, and $4\leqq p, q\leqq 6$. Then the identity (2.8) shows that the equations (1.6) become

$$\frac{\partial^2}{\partial u_{ap}\,\partial u_{bq}}-\frac{\partial^2}{\partial u_{bp}\,\partial u_{aq}}=0, \qquad 1\leqq a, b\leqq 3, \quad 4\leqq p, q\leqq 6. \tag{4.7}$$

It is not hard to see that the equations (1.6) for another set of indices reduce to (4.7). Notice that this presentation of the system is called the canonical system in [H]. In terms of θ_{ap}, (4.7) is written as

$$u_{aq}u_{bp}\theta_{ap}\theta_{bq}-u_{ap}u_{bq}\theta_{aq}\theta_{bp}=0.$$

So we have the following proposition.

PROPOSITION 4.2. *The system of equations for* w *consists of the following nine differential equations*:

$$\begin{aligned}
&(\alpha_{234}-1+\delta)\delta_1-x^1(\alpha_5-1-\delta_1-\delta_3)(-\alpha_2-\delta_1-\delta_2)=0,\\
&(\alpha_{234}-1+\delta)\delta_2-x^2(\alpha_6-1-\delta_2-\delta_4)(-\alpha_2-\delta_1-\delta_2)=0,\\
&(\alpha_{234}-1+\delta)\delta_3-x^3(\alpha_5-1-\delta_1-\delta_3)(-\alpha_3-\delta_3-\delta_4)=0,\\
&(\alpha_{234}-1+\delta)\delta_4-x^4(\alpha_6-1-\delta_2-\delta_4)(-\alpha_3-\delta_3-\delta_4)=0,\\
&x^1(\alpha_5-1-\delta_1-\delta_3)\delta_2-x^2(\alpha_6-1-\delta_2-\delta_4)\delta_1=0,\\
&x^3(\alpha_5-1-\delta_1-\delta_3)\delta_4-x^4(\alpha_6-1-\delta_2-\delta_4)\delta_3=0,\\
&x^1(\alpha_2+\delta_1+\delta_2)\delta_3-x^3(\alpha_3+\delta_3+\delta_4)\delta_1=0,\\
&x^2(\alpha_2+\delta_1+\delta_2)\delta_4-x^4(\alpha_3+\delta_3+\delta_4)\delta_2=0,\\
&x^2x^3\delta_1\delta_4-x^1x^4\delta_2\delta_3=0.
\end{aligned}$$

Since this system is of rank 6, by the general theory [SY2] for a system whose rank is greater than the number of independent variables by two, a *conformal structure* is attached to this system. The associated conformal tensor has an expression such as $g_{ij}\,dx^i\,dx^j$ when the equations are written in the form

$$\frac{\partial^2 w}{\partial x^i\,\partial x^j}=g_{ij}\frac{\partial^2 w}{\partial x^1\,\partial x^4}+\text{terms of lower degree of differentiation.}$$

It is known that the conformal class does not depend on the choice of variables. By an easy calculation we have the following proposition.

PROPOSITION 4.3. *The conformal tensor $g_{ij}\,dx^i\,dx^j$ associated with the above system is given by*

$$g_{11}=-\frac{(x^4-x^2)x^3}{(x^1-x^3)x^4}-\frac{(x^4-x^3)x^2}{(x^1-x^2)x^4}+\frac{x^2x^3-x^4}{(1-x^1)x^4},$$

$$g_{22}=-\frac{(x^4-x^3)x^2}{(x^1-x^2)x^4}-\frac{(x^1-x^3)x^2}{(x^4-x^2)x^1}+\frac{(x^1x^4-x^3)x^2}{(1-x^2)x^4x^1},$$

$$g_{33}=-\frac{(x^4-x^2)x^3}{(x^1-x^3)x^4}-\frac{(x^1-x^2)x^3}{(x^4-x^3)x^1}+\frac{(x^1x^4-x^2)x^3}{(1-x^3)x^4x^1},$$

$$g_{44}=-\frac{(x^1-x^3)x^2}{(x^4-x^2)x^1}-\frac{(x^1-x^2)x^3}{(x^4-x^3)x^1}+\frac{x^2x^3-x^1}{(1-x^4)x^1},$$

$$g_{12}=g_{21}=\frac{(x^4-x^3)x^2}{(x^1-x^2)x^4},\quad g_{13}=g_{31}=\frac{(x^4-x^2)x^3}{(x^1-x^3)x^4},\quad g_{14}=g_{41}=1,$$

$$g_{23}=g_{32}=\frac{x^2x^3}{x^1x^4},\quad g_{24}=g_{42}=\frac{(x^1-x^3)x^2}{(x^4-x^2)x^1},\quad g_{34}=g_{43}=\frac{(x^1-x^2)x^3}{(x^4-x^3)x^1}.$$

Remark. This tensor is conformally flat because of the following argument. Consider the mapping defined by six independent solutions of the system. When $\alpha_i=\frac{1}{2}$ for $1\leqq i\leqq 6$, this mapping is, as we have seen in [MSY1], the period map of a four-dimensional family of $K3$ surfaces. Since the period map satisfies Riemann's equality, the image is contained in a quadratic hypersurface in $\mathbf{CP}^5$. On the other hand, it was shown in [SY2] that the associated tensor is conformally flat if the image is contained in a quadratic hypersurface. Hence, the above tensor, which is independent of values of α_i, is conformally flat.

The system of differential equations for the integrals on the stratum $\{x^2=0\}$ of codimension 1 is computed similarly.

PROPOSITION 4.4. *The system of differential equations on the stratum $\{x^2=0\}$ is of rank 5 and consists of five equations*:

$$(\alpha_{234}-1+\delta')\delta_1-x^1(\alpha_5-1-\delta_1-\delta_3)(-\alpha_2-\delta_1)=0,$$

$$(\alpha_{234}-1+\delta')\delta_3-x^3(\alpha_5-1-\delta_1-\delta_3)(-\alpha_3-\delta_3-\delta_4)=0,$$

$$(\alpha_{234}-1+\delta')\delta_4-x^4(\alpha_6-1-\delta_4)(-\alpha_3-\delta_3-\delta_4)=0,$$

$$x^3(\alpha_5-1-\delta_1-\delta_3)\delta_4-x^4(\alpha_6-1-\delta_4)\delta_3=0,$$

$$x^1(\alpha_2+\delta_1)\delta_3-x^3(\alpha_3+\delta_3+\delta_4)\delta_1=0,$$

where $\delta'=\delta_1+\delta_3+\delta_4$.

5. Contiguity relations of $E(3,6)$. We will compute the contiguity relations of $E(3,6)$ with respect to the function $w(x,\alpha)$. For simplicity we use the notation $(\alpha_j^+\alpha_l^-)$ to denote the parameter $\alpha+1_j-1_l$ as in § 3.

Our task is to express (2.6) in terms of the operators θ_{ap}. Note that X_{ii} is a scalar multiplication and that this yields a trivial relation. Define Y_{jl} by

$$Y_{jl}w=\phi^{-1}X_{jl}(\phi w)|_{u_{14}=u_{24}=u_{34}=u_{15}=u_{16}=1}. \tag{5.1}$$

We can see that

$$\phi^{-1}X_{jl}(\phi w)=M_{jl}(u)\,Y_{jl}w, \tag{5.2}$$

where $M_{jl}(u)=\phi(u,\alpha+1_j-1_l)/\phi(u,\alpha)$. For the subspace $\mathfrak{g}_1$ generated by $\partial/\partial u_{ap}$, one of the contiguity relations is

$$\frac{\partial}{\partial u_{14}}(\phi w)(u,\alpha)=(\alpha_4-1)(\phi w)(\alpha_1^+\alpha_4^-)=\frac{1}{u_{14}}(\alpha_4-1)\phi(u,\alpha)w(\alpha_1^+\alpha_4^-).$$

By Lemma 4.1, this yields

$$Y_{14}w=(\alpha_{234}-1+\delta)w(x,\alpha)=(\alpha_4-1)w(x,\alpha_1^+\alpha_4^-) \quad \text{and} \quad M_{14}=1/u_{14}.$$

Similarly, for X_{pq} in $\mathfrak{g}_0$, the identity

$$X_{pq}=\frac{u_{1p}}{u_{1q}}\theta_{1q}+\frac{u_{2p}}{u_{2q}}\theta_{2q}+\frac{u_{3p}}{u_{3q}}\theta_{3q}$$

in Lemma 2.3 shows, for example,

$$X_{45}(\phi w)=\frac{u_{14}}{u_{15}}(\alpha_5-1)\phi w+\phi\left\{\frac{u_{24}}{u_{25}}\delta_1+\frac{u_{34}}{u_{35}}\delta_3-\frac{u_{14}}{u_{15}}(\delta_1+\delta_2)\right\}w.$$

On the other hand, this is equal to $(\alpha_5-1)(\phi w)(\alpha_4^+\alpha_5^-)$. Hence we have

$$Y_{45}w=(\alpha_5-1)w+\{(1-x^1)\partial_1+(1-x^3)\partial_3\}w=(\alpha_5-1)w(\alpha_4^+\alpha_5^-),$$
$$M_{45}=u_{14}/u_{15}.$$

As for the operator X_{ab} in $\mathfrak{g}_0'$, the identity

$$-X_{ab}=\delta_{ab}+\frac{u_{b4}}{u_{a4}}\theta_{a4}+\frac{u_{b5}}{u_{a5}}\theta_{a5}+\frac{u_{b6}}{u_{a6}}\theta_{a6}$$

gives, for example,

$$-X_{12}=\frac{u_{24}}{u_{14}}(\alpha_{234}-1+\delta)+\frac{u_{25}}{u_{15}}(\alpha_5-1-\delta_1-\delta_3)+\frac{u_{26}}{u_{16}}(\alpha_6-1-\delta_2-\delta_4),$$

which yields

$$Y_{12}w=-\{\alpha_{234}-1+\delta+x^1(\alpha_5-1-\delta_1-\delta_3)+x^2(\alpha_6-1-\delta_2-\delta_4)\}w=(\alpha_2-1)w(\alpha_1^+\alpha_2^-),$$
$$M_{12}=u_{24}/u_{14}.$$

We can similarly carry out the computation for the elements in $\mathfrak{g}_{-1}$. Thus we have the following proposition.

PROPOSITION 5.1. *The Aomoto-Gel'fand* HGF w *for the system* $E(3,6)$ *satisfies contiguity relations listed in Table* 2. *The diagonal operators* Y_{jj}, $1\leqq j\leqq 6$, *are scalar multiplications by* α_j-1.

Each line reads as $Y_{jl}w(x,\alpha)=(\alpha_j-1)w(x,\alpha_j^+\alpha_l^-)$. The first column denotes indices of Y_{jl}. The third column denotes the factor $M(u)$ that appears in equation (5.2). ∂_i denotes $\partial/\partial x^i$.

6. Strata in $G_{3,6}$. In the study of HGF's associated with $G_{3,6}$, Gel'fand and Graev [GGR1] gave explicit expressions of the integrals (1.1) for each stratum of $G_{3,6}$. They have shown that the space $G_{3,6}$ has 15 types of strata: one is the open stratum discussed in previous sections and the others are denoted by A, $B1$, $B2$, $B3$, $B4$, $C1$, $C2$, $C3$, $C4$, I, II, III, IV, and V. We do not cite their definitions here (refer to [GGR1, p. 299]), but we give a few remarks.

The dimension of a stratum belonging to respective types is 3 for A, 2 for B's, 1 for C's, and 0 for I-V. A stratum belonging to A is given by the equation $u_{14}=0$ in the coordinates (4.1) and the corresponding system of differential equations has been given in Proposition 4.4. Appell's system F_1, which is the system F_D in two variables,

TABLE 2

and Horn's system G_2 (cf. [E, § 5.7]) appear both for strata of types B1 and B2. Appell's systems F_2 and F_3 and Horn's system H_2 [E] appear for strata of type B3. The definition of F_3 will be recalled later. The system associated with a stratum of type B4 is a tensor product of two Gauss HGDE's with different parameters. Systems for $C1$, $C2$, or $C3$ are known to be the Gauss HGDE's. The final system associated with a stratum of type $C4$ is Goursat's (so-called generalized) HGF ${}_3F_2$ (cf. § 9). Refer to [GGR3] for these matters and to [MSY2] for another aspect of $G_{3,6}$.

The fact that HGF's F_2, F_3, and H_2 belong to the same type is remarkable. In view of the invariance (1.2) and (1.3), it says that the associated systems are related by certain transformations of coordinates and unknown functions. See [AK, p. 51] for the relation between functions F_2 and F_3 and [SY1, § 5.3] for the relations among systems F_2, F_3, and H_2. Moreover, one and the same function may appear on different strata of the same or different type and may have different expressions depending on the choice of coordinates; this fact explains certain transformation rules for this function such as Kummer's identities for the Gauss HGF. However, because we are concerned only with functions or systems and not with relations among their different expressions, we can restrict our consideration to the systems associated with strata chosen arbitrarily from each type, i.e., to the systems F_1, F_3, ${}_3F_2$, and the Gauss HGDE for types B and C. Since we have treated F_1 and the Gauss HGDE in § 3, we will consider F_3 and ${}_3F_2$ in the following sections.

Remark. A relation between the systems F_1 and G_2 is given as follows. Let $F_1(\alpha, \beta, \beta', \gamma)$ and $G_2(\alpha_1, \alpha_1', \beta_1, \beta_1')$ denote the systems of differential equations just given in [E, eq. (9), p. 233, and eq. (14), p. 234]. Then, for any solution $w(x, y)$ of G_2, the function $z(x, y) = y^{\alpha_1'} w(-x, -1/y)$ is a solution of F_1 and vice versa with the correspondence of parameters given by $\alpha = \alpha_1' + \beta_1'$, $\beta = \alpha_1$, $\beta' = \alpha_1'$, and $\gamma = \alpha_1' - \beta_1 + 1$.

7. Contiguity relations of Appell's F_3. Appel's HGF F_3 is given by the series

$$F_3(\alpha, \alpha', \beta, \beta', \gamma; x, y) = \sum_{m,n=0}^{\infty} \frac{(\alpha, m)(\alpha', n)(\beta, m)(\beta', n)}{(\gamma, m+n)(1, m)(1, n)} x^m y^n.$$

The definition of $F(x, \alpha)$ in (4.5) shows

$$F(x^1, 0, 0, x^4; \alpha_1, \cdots, \alpha_6) = F_3(\alpha, \alpha', \beta, \beta', \gamma; x^1, x^4)$$

and

$$c((\alpha_1, \cdots, \alpha_6)) = \Gamma(1-\gamma)\Gamma(\alpha)\Gamma(\alpha')/\Gamma(\alpha + \alpha' - \gamma + 1),$$

where

$$\alpha = \alpha_2, \quad \alpha' = \alpha_3, \quad \beta = 1 - \alpha_5, \quad \beta' = 1 - \alpha_6, \quad \gamma = \alpha_{234}. \tag{7.1}$$

We have seen in § 5 that the contiguity relation with respect to $w = c(\alpha)F(x, \alpha)$ is written in the form

$$Y(c(\alpha)F(x, \alpha)) = a_Y c(\alpha^Y) F(x, \alpha^Y) \tag{7.2}$$

for an operator Y; a_Y is a linear form on α and $\alpha^Y = \alpha + 1_j - 1_l = (\alpha_j^+ \alpha_l^-)$ for some j and l. If we can restrict both sides of this identity to the stratum $\{x^2 = x^3 = 0\}$, then this readily gives a part of contiguity relations of $F(x^1, 0, 0, x^4; \alpha)$ and thus of F_3. In reference to Table 2, the indices of such operators are

$$12, 13, 14, 15, 16, 24, 25, 34, 36, 52, 54, 63, 64. \tag{7.3}$$

Other operators contain terms like $\partial_2 F$ or $\partial_3 F$, whose restrictions will be examined later.

[66]	$-\beta'$	$-\beta'$	—

PROPOSITION 7.1. *The operators with indices listed in* (7.3) *yield the following contiguity relations in Table* 3.1 *with respect to the function* $\{\Gamma(\alpha)\Gamma(\alpha')\Gamma(1-\gamma)/\Gamma(\alpha+\alpha'-\gamma+1)\}F_3(\alpha, \alpha', \beta, \beta', \gamma; x, y)$. *Trivial relations for the operators* X_{ii} *are also listed.*

We use the notation $\partial_x = \partial/\partial x$, $\partial_y = \partial/\partial y$, $\delta_x = x\partial_x$, and $\delta_y = y\partial_y$.

Proof. Transformation from Table 2 to Table 3.1 is done by taking care of the identity (7.1) and the relation $\sum \alpha_i = 3$. The operator X_{14}, for example, increases (α_i) at $i=1$ and decreases at $i=4$. This implies the decrease of γ by 1, which is denoted by γ^-. The multiplier $\alpha_4 - 1$ is equal to $\gamma - \alpha - \alpha' - 1$. This shows the first line. □

The Lie-algebraic structure of the set of operators in this table will be recovered in the following way. Introduce supplementary variables v_{14}, v_{15}, v_{16}, v_{24}, v_{34} and define operators $\tau_{ij} = v_{ij}(\partial/\partial v_{ij})$. Put

$$
\begin{aligned}
&E_{11} = -\tau_{15} - \tau_{16} - \tau_{14} - 1, \quad E_{22} = -\tau_{24} - 1, \quad E_{33} = -\tau_{34} - 1,\\
&E_{44} = \tau_{14} + \tau_{24} + \tau_{34}, \quad E_{55} = \tau_{15}, \quad E_{66} = \tau_{16},\\
&E_{12} = \frac{v_{24}}{v_{14}}\{-\tau_{14} - \delta_x - \delta_y + x(-\tau_{15} + \delta_x)\},\\
&E_{13} = \frac{v_{34}}{v_{14}}\{-\tau_{14} - \delta_x - \delta_y + y(-\tau_{16} + \delta_y)\},\\
&E_{14} = \frac{1}{v_{14}}\{\tau_{14} + \delta_x + \delta_y\}, \quad E_{15} = \frac{1}{v_{15}}\{\tau_{15} - \delta_x\}, \quad E_{16} = \frac{1}{v_{16}}\{\tau_{16} - \delta_y\},\\
&E_{24} = \frac{1}{v_{24}}\{\tau_{24} - \delta_x\}, \qquad E_{25} = \frac{v_{14}}{v_{15}v_{24}}\partial_x,\\
&E_{34} = \frac{1}{v_{34}}\{\tau_{34} - \delta_y\}, \qquad E_{36} = \frac{v_{14}}{v_{16}v_{34}}\partial_y,\\
&E_{52} = \frac{v_{15}v_{24}}{v_{14}}\{x(1 + \tau_{15} - \tau_{24} + \delta_x) - \tau_{14} - \delta_x - \delta_y\},\\
&E_{54} = \frac{v_{15}}{v_{14}}\{\tau_{14} + \delta_x + \delta_y - x(-\tau_{24} + \delta_x)\},\\
&E_{63} = \frac{v_{16}v_{34}}{v_{14}}\{y(1 + \tau_{16} - \tau_{34} + \delta_y) - \tau_{14} - \delta_x - \delta_y\},\\
&E_{64} = \frac{v_{16}}{v_{34}}\{\tau_{14} + \delta_x + \delta_y - y(-\tau_{34} + \delta_y)\}.
\end{aligned}
\tag{7.4}
$$

Then we have the following proposition.

PROPOSITION 7.2. *Differential operators* E_{ij} *listed in* (7.4) *generate a Lie algebra of dimension* 19 *with relations*

$$[E_{ij}, E_{i'j'}] = \delta_{ji'}E_{ij'} - \delta_{j'i}E_{i'j}.$$

Proof. Let X be one of X_{jl} with indices in Table 3.1 and Y be the corresponding operator in Table 2. Then (5.2) says $\phi^{-1}X\phi \cdot w = M_X Y \cdot w$ for the corresponding factor M_X. The set of operators $\phi^{-1}X\phi$ for such X certainly forms a Lie algebra of dimension 19. Hence the proof will be completed by expressing $\phi^{-1}X\phi$ in terms of variables $u_{14}, \cdots, u_{34}$ and x^i and by restricting them onto $\{x^2 = x^3 = 0\}$. While $\phi^{-1}X\phi = X(\log\phi) + X$ as an operator, the operator $M_X^{-1}X$ acts on functions of x as a vector field $\underline{X}$ with respect to variables x and $M_X^{-1}X(\log\phi)$ is seen to be written as $\theta_{\underline{X}}(\log\phi)$,

where θ_X is a linear combination of τ_{jl} defined above. Here we use v for u to avoid confusion. Namely, we have $\phi^{-1}X\phi = M_X\theta_X(\log\phi) + M_X\underline{X} = \phi^{-1}\cdot M_X(\theta_X+\underline{X})\cdot\phi$. Explicit expressions of $E_X = M_X(\theta_X+\underline{X})$ are easily computed to get identities in (7.4). □

Remark. Miller in [M2] has already found nine contiguity relations in Table 3.1: 14, 15, 16, 24, 25, 34, 36, 52, 63. Relations with indices 12, 13, 54, and 64 follow from the Lie algebra structure; for example, $[E_{15}, E_{52}] = E_{12}$.

We next deal with the operators including ∂_x and/or ∂_y. Define two operators by

$$U_{26} = \alpha\beta' - \beta'(1-x)\partial_x - \alpha(1-y)\partial_y + \Delta\partial_x\partial_y, \tag{7.5}$$

$$U_{35} = \alpha'\beta - \alpha(1-x)\partial_x - \beta(1-y)\partial_y + \Delta\partial_x\partial_y, \tag{7.6}$$

where $\Delta = xy - x - y$. Then we see the following lemma.

LEMMA 7.3. *These operators give contiguity relations of second order*:

$$U_{26}\{cF_3\} = \beta'(\alpha' - \gamma + \beta)\{cF_3\}(\alpha^+\beta'^+\gamma^+),$$

$$U_{35}\{cF_3\} = \alpha'(\beta' - \gamma + \alpha)\{cF_3\}(\alpha'^+\beta^+\gamma^+).$$

A proof will be given in the last section. Now assume

$$(\gamma - \alpha' - \beta)(\gamma - \alpha - \beta') \neq 0 \tag{7.7}$$

and define operators by

$$Z_{26} = \frac{1}{\gamma - \alpha' - \beta}\,U_{26} \quad \text{and} \quad Z_{35} = \frac{1}{\gamma - \alpha - \beta'}\,U_{35}. \tag{7.8}$$

Then we have the remaining contiguity relations by the use of Table 2:

PROPOSITION 7.4. *Appell's* HGF $\{\Gamma(\alpha)\Gamma(\alpha')\Gamma(1-\gamma)/\Gamma(\alpha+\alpha'-\gamma+1)\}\times F_3(\alpha, \alpha', \beta, \beta', \gamma; x, y)$ *satisfies the contiguity relations listed in Table* 3.1 *and Table* 3.2.

Each line reads as $Z(cF_3) = a_Z\cdot(cF)(\alpha^Z)$. The first column in Table 3.2 gives the correspondence with Table 2.

TABLE 3.2

[26]	$\frac{1}{\gamma-\alpha'-\beta}(\alpha\beta' - \beta'(1-x)\partial_x - \alpha(1-y)\partial_y + \Delta\partial_{xy}^2) =: Z_{26}$	$-\beta'$	$\alpha^+\beta'^+\gamma^+$
[35]	$\frac{1}{\gamma-\beta'-\alpha}(\beta\alpha' - \alpha'(1-x)\partial_x - \beta(1-y)\partial_y + \Delta\partial_{xy}^2) =: Z_{35}$	$-\beta$	$\beta^+\alpha'^+\gamma^+$
[41]	$\alpha+\alpha'+\beta+\beta'-\gamma+(x-1)\partial_x+(y-1)\partial_y - Z_{26} - Z_{35}$	$\beta+\beta'-\gamma$	γ^+
[42]	$\alpha+\alpha'-\gamma+\beta x + x(x-1)\partial_x - xZ_{35}$	$\alpha-1$	α^-
[43]	$\alpha+\alpha'-\gamma+\beta' y + y(y-1)\partial_y - yZ_{26}$	$\alpha'-1$	α'^-
[51]	$\beta+\beta'-\gamma+\alpha x + x(x-1)\partial_x - xZ_{26}$	$\beta+\beta'-\gamma$	β^-
[61]	$\beta+\beta'-\gamma+\alpha' y + y(y-1)\partial_y - yZ_{35}$	$\beta+\beta'-\gamma$	β'^-
[53]	$1-\gamma+\alpha x+\beta' y + x(x-1)\partial_x + y(y-1)\partial_y - xyZ_{26}$	$\alpha'-1$	$\alpha'^-\beta^-\gamma^-$
[62]	$1-\gamma+\beta x+\alpha' y + x(x-1)\partial_x + y(y-1)\partial_y - xyZ_{35}$	$\alpha-1$	$\beta'^-\alpha^-\gamma^-$

Proof. From [26] in Table 2 we see

$$\frac{\partial}{\partial x^2}(cF)(\alpha)=(\alpha_6-1)(cF)(\alpha_2^+\alpha_6^-).$$

Restriction to $\{x^2=x^3=0\}$ then shows

$$\frac{\partial}{\partial x^2}(cF)(\alpha)\Big|_{x^2=x^3=0}=(\alpha_6-1)c(\alpha_2^+\alpha_6^-)F_3(\alpha_2^+\alpha_6^-;x,y).$$

The change of parameters $(\alpha_2^+\alpha_6^-)$ is equivalent to $(\alpha^+\beta'^+\gamma^+)$ by (7.1). Hence, by Lemma 7.3, the restriction of the function $(\partial/\partial x^2)(cF)$ onto the stratum $\{x^2=x^3=0\}$ can be replaced by the function $Z_{26}(cF)$. The same applies for [35]. Then, with reference to Table 2, we obtain whole relations. □

Remark. The relations in Tables 3.1 and 3.2 form a complete set of contiguity relations in the sense that every contiguous function of F_3 is representable as a linear combination of the original F_3 and its derivatives up to order 2 by a certain combination of differential operators appearing in these tables. See the last columns of these tables.

8. Different expression of contiguity relations of $E(3,6)$. The coordinate system (x^i) introduced in § 4 is not appropriate for the study of the system ${}_3F_2$. In this section we define new coordinate system (y^i) on the quotient of the open stratum in $G_{3,6}$.

Consider the set of points (I_3, u) defined in (4.1). Assume in this section that u_{14}, u_{16}, u_{24}, u_{25}, and u_{35} are not equal to zeros and define

$$y^1=\frac{u_{25}u_{34}}{u_{24}u_{35}},\quad y^2=\frac{u_{14}u_{26}}{u_{16}u_{24}},\quad y^3=\frac{u_{15}u_{24}}{u_{14}u_{25}},\quad y^4=\frac{u_{14}u_{25}u_{36}}{u_{16}u_{24}u_{35}}. \tag{8.1}$$

Then $y=(y^i)$ is a system of coordinates around the single H_6-orbit stratum $\{u_{15}=u_{26}=u_{34}=u_{36}=0\}$. It defines a local section of $Z_{3,6}\to GL_3\backslash Z_{3,6}/H_6$ by associating a matrix

$$\begin{pmatrix} 1 & & & 1 & y^3 & 1 \\ & 1 & & 1 & 1 & y^2 \\ & & 1 & y^1 & 1 & y^4 \end{pmatrix}. \tag{8.2}$$

The connection of y with x is seen to be

$$y^1=\frac{x^1}{x^3},\quad y^2=x^2,\quad y^3=\frac{1}{x^3},\quad y^4=\frac{x^1x^4}{x^3}. \tag{8.3}$$

We use the notation

$$\delta_i=y^i\frac{\partial}{\partial y^i}\quad\text{and}\quad \partial_i=\frac{\partial}{\partial y^i},\qquad 1\leqq i\leqq 4,$$

which should not be confused with that defined in § 4. The integral $\varphi(u,\alpha)=\Phi((I_3,u),\alpha)$ has the expression

$$\varphi(u,\alpha)=\phi(u,\alpha)w(y,\alpha), \tag{8.4}$$

where

$$\phi(u,\alpha)=u_{14}^{\alpha_{2345}-2}u_{24}^{1-\alpha_{235}}u_{25}^{\alpha_{35}-1}u_{35}^{-\alpha_3}u_{16}^{\alpha_6-1} \tag{8.5}$$

and

$$\begin{aligned} w(y,\alpha)=\int\prod_{i=1}^{3}t_i^{\alpha_i-1}(t_1+t_2+y^1t_3)^{\alpha_4-1}(y^3t_1+t_2+t_3)^{\alpha_5-1} \\ \cdot(t_1+y^2t_2+y^4t_3)^{\alpha_6-1}(t_1\,dt_2\wedge dt_3-t_2\,dt_1\wedge dt_3+t_3\,dt_1\wedge dt_2). \end{aligned} \tag{8.6}$$

Here $\alpha_{2345}=\alpha_2+\alpha_3+\alpha_4+\alpha_5$ and so on.

Recall operators $\theta_{ap} = u_{ap}(\partial/\partial u_{ap})$ defined in § 4. We denote the operator $\phi^{-1}\theta_{ap}\phi$ acting on w by the same letter θ_{ap}. Then we see the following lemma, similar to Lemma 4.1.

LEMMA 8.1. *The operators θ_{ap} are given as follows*:

$$\theta_{14} = \alpha_{2345} - 2 + \delta_2 - \delta_3 + \delta_4, \quad \theta_{15} = \delta_3, \quad \theta_{16} = \alpha_6 - 1 - \delta_2 - \delta_4,$$

$$\theta_{24} = 1 - \alpha_{235} - \delta_1 - \delta_2 + \delta_3 - \delta_4, \quad \theta_{25} = \alpha_{35} - 1 + \delta_1 - \delta_3 + \delta_4, \quad \theta_{26} = \delta_2,$$

$$\theta_{34} = \delta_1, \quad \theta_{35} = -\alpha_3 - \delta_1 - \delta_4, \quad \theta_{36} = \delta_4.$$

We next define operators Y_{jl} by

$$\phi^{-1}X_{jl}(\phi w) = M_{jl}(u)\, Y_{jl} w, \tag{8.7}$$

where $M_{jl}(u) = \phi(u, \alpha + 1_j - 1_l)/\phi(u, \alpha)$. Then, similar to Proposition 5.1, we get the following.

PROPOSITION 8.2. *The Aomoto-Gel'fand* HGF w *for the system* $E(3, 6)$ *relative to the coordinate* y *satisfies the contiguity relations listed in Table* 4. *The diagonal operators* Y_{jj}, $1 \leqq j \leqq 6$, *are scalar multiplications by* $\alpha_j - 1$.

The table is read in the same manner as Table 2.

TABLE 4

[61]	$-\alpha_6 - Y_{64} - y^3 Y_{65}$	u_{16}
[62]	$-\alpha_6 y^2 - Y_{64} - Y_{65}$	$u_{16}u_{24}/u_{14}$
[63]	$-\alpha_6 y^4 - y^1 Y_{64} - Y_{65}$	$u_{16}u_{24}u_{35}/u_{14}u_{25}$

9. Contiguity relations of Goursat's ${}_3F_2$. Goursat's HGF ${}_3F_2$ is given by the series

$$ {}_3F_2(a_1, a_2, a_3; b_1, b_2; y) = \sum_{n=0}^{\infty} \frac{(a_1, n)(a_2, n)(a_3, n)}{(b_1, n)(b_2, n)n!} y^n. $$

We use the abbreviation $(a) = (a_1, a_2, a_3; b_1, b_2)$. This function has an Euler integral representation (2.18) with a trivial change of notation. Hence the restriction of an integral of the form (8.2) to the one-dimensional stratum $\Gamma := \{y^1 = y^2 = y^3 = 0\}$ gives ${}_3F_2$:

$$ \begin{aligned} w(\alpha; 0, 0, 0, y^4) = & \int_{1+t_2 \geqq 0, t_2+t_3 \geqq 0, t_2 \leqq 0} t_2^{\alpha_2 - 1} t_3^{\alpha_3 - 1} \\ & \cdot (1+t_2)^{\alpha_4 - 1} (t_2+t_3)^{\alpha_5 - 1} (1+y^4 t_3)^{\alpha_6 - 1} \, dt_2 \wedge dt_3 \\ = & \gamma(\alpha) \cdot {}_3F_2(a; y), \end{aligned} \tag{9.1} $$

where

$$ \begin{aligned} & \gamma(\alpha) = (-1)^{\alpha_{25} - 1} \frac{\Gamma(\alpha_{235} - 1)\Gamma(\alpha_3)\Gamma(\alpha_4)\Gamma(\alpha_5)}{\Gamma(\alpha_{2345} - 1)\Gamma(\alpha_{35})}, \\ & y = -y^4, \\ & a_1 = \alpha_{235} - 1, \quad a_2 = \alpha_3, \quad a_3 = 1 - \alpha_6, \quad b_1 = \alpha_{2345} - 1, \quad b_2 = \alpha_{35}. \end{aligned} \tag{9.2} $$

With this notation the procedure of determining contiguity relations of ${}_3F_2$ is the same as that used in § 7. We first note that the operators Y_{jl} with indices

$$ 14,\ 16,\ 24,\ 25,\ 35,\ 36 \tag{9.3} $$

can be restricted to the stratum Γ. Namely we have the following proposition.

PROPOSITION 9.1. *The restriction of the differential operators Y_{jl} with indices in* (9.3) *to the stratum Γ yield the six contiguity relations of the function ${}_3F_2$:*

$$ \begin{aligned} & [14] \quad (\theta + b_1 - 1)_3F_2 = (b_1 - 1)_3F_2(b_1^-), \\ & [16] \quad (\theta + a_3)_3F_2 = a_3 \cdot {}_3F_2(a_3^+), \\ & [24] \quad (\theta + a_1)_3F_2 = a_1 \cdot {}_3F_2(a_1^+), \\ & [25] \quad (\theta + b_2 - 1)_3F_2 = (b_2 - 1)_3F_2(b_2^-), \\ & [35] \quad (\theta + a_2)_3F_2 = a_2 \cdot {}_3F_2(a_2^+), \\ & [36] \quad \frac{\partial}{\partial y} {}_3F_2 = \frac{a_1 a_2 a_3}{b_1 b_2} {}_3F_2(a_1^+ a_2^+ a_3^+; b_1^+ b_2^+). \end{aligned} \tag{9.4} $$

We next deal with the remaining operators. The key operators are Y_{15}, Y_{26}, and Y_{34}; namely, ∂_3, ∂_2, and ∂_1. We denote $y(\partial/\partial y)$ by θ and define three operators by

$$ Z_{15} = \frac{1}{1 - a_1} \{(1-y)\theta^2 + (b_{12} - 2 - a_{23}y)\theta - a_2 a_3 y + (b_1 - 1)(b_2 - 1)\}, \tag{9.5} $$

$$ Z_{26} = \frac{1}{(a_2 - b_1)y} \{(1-y)\theta^2 + (b_2 - 1 - a_{13}y)\theta - a_1 a_3 y\}, \tag{9.6} $$

$$ Z_{34} = \frac{1}{(a_3 - b_2)y} \{(1-y)\theta^2 + (b_1 - 1 - a_{12}y)\theta - a_1 a_2 y\}, \tag{9.7} $$

with the assumption

$$ (a_1 - 1)(a_2 - b_1)(a_3 - b_2) \neq 0, \tag{9.8} $$

and with abbreviations such as $b_{12} = b_1 + b_2$, $a_{23} = a_2 + a_3$. Then we can see the following lemma.

TABLE 5

Index	Z	c_Z	a^Z
[14]	$\theta+b_1-1$	b_1-1	b_1^-

LEMMA 9.2. *These operators yield the contiguity relations of second order for* $\underline{w} := \gamma_3 F_2$:

$$Z_{15}\underline{w}=(\alpha_5-1)\underline{w}(\alpha_1^+\alpha_5^-),\quad Z_{26}\underline{w}=(\alpha_6-1)\underline{w}(\alpha_2^+\alpha_6^-),\quad Z_{34}\underline{w}=(\alpha_4-1)\underline{w}(\alpha_3^+\alpha_4^-).$$

Proof will be given in § 10. Then, similar to Proposition 7.4, we have the following.

PROPOSITION 9.3. *Goursat's* HGF ${}_3F_2(a_1, a_2, a_3; b_1, b_2; y)$ *satisfies the contiguity relations listed in Table* 5.

Each line reads as $Z({}_3F_2(a; y)) = c_Z \cdot ({}_3F_2)(a^Z; y)$. We use parameters (a) in this table. Recall $\theta = y(\partial/\partial y)$ and $\partial = (\partial/\partial y)$. This set of relations is complete in the sense explained in the last remark of § 7.

10. Proof of Lemmas 7.3 and 9.2. We first prove Lemma 7.3. Restricting the system in Proposition 4.4 to the stratum $\{x^3=0\}$ we see that Appell's HGF $F_3(\alpha, \alpha', \beta, \beta', \gamma; x, y)$ satisfies the system

$$\begin{aligned}&(\delta_x+\delta_y+\gamma-1)\delta_x u - x(\delta_x+\alpha)(\delta_x+\beta)u=0,\\ &(\delta_x+\delta_y+\gamma-1)\delta_y u - y(\delta_x+\alpha')(\delta_x+\beta')u=0,\end{aligned}\tag{10.1}$$

where u is an unknown function and $\delta_x = x(\partial/\partial x)$, $\delta_y = y(\partial/\partial y)$. This system can be written in a Pfaffian form: put

$$e_0=u,\quad e_1=\delta_x u,\quad e_2=\delta_y u,\quad e_3=\delta_x\delta_y u$$

and define a column vector e by

$$e = {}^t(e_0, e_1, e_2, e_3).$$

Then the above system is equivalent to the equation for e:

$$de = \omega e, \tag{10.2}$$

where

$$\omega = \begin{pmatrix} 0 & \frac{dx}{x} & \frac{dy}{y} & 0 \\ -\frac{\alpha\beta}{x-1}dx & \left\{\frac{1-\gamma}{x} - \frac{\delta}{x-1}\right\}dx & 0 & \left\{\frac{1}{x-1} - \frac{1}{x}\right\}dx + \frac{1}{y}dy \\ -\frac{\alpha'\beta'}{y-1}dy & 0 & \left\{\frac{1-\gamma}{y} - \frac{\delta'}{y-1}\right\}dy & \left\{\frac{1}{y-1} - \frac{1}{y}\right\}dy + \frac{1}{x}dx \\ 0 & \alpha'\beta'\left\{\frac{dx}{x} - \frac{d\Delta}{\Delta}\right\} & \alpha\beta\left\{\frac{dy}{y} - \frac{d\Delta}{\Delta}\right\} & \delta'\frac{dx}{x} + \delta\frac{dy}{y} + \varepsilon\frac{d\Delta}{\Delta} \end{pmatrix},$$

$$\delta = \alpha + \beta + 1 - \gamma, \quad \delta' = \alpha' + \beta' + 1 - \gamma, \quad \varepsilon = \gamma - \alpha - \beta - \alpha' - \beta' - 1.$$

To denote the dependence of the vector e on the parameters we use the notation $e(\alpha, \alpha', \beta, \beta', \gamma)$; in the sequel we use abbreviations such as (α^+) for $(\alpha+1, \alpha', \beta, \beta', \gamma)$, $(\alpha^+\beta'^+\gamma^+)$ for $(\alpha+1, \alpha', \beta, \beta'+1, \gamma+1)$, and so on. Hence $e(\alpha^+)$ means $e(\alpha+1, \alpha', \beta, \beta', \gamma)$. The notation e always stands for $e(\alpha, \alpha', \beta, \beta', \gamma)$. We need the following lemma.

LEMMA 10.1. *Each solution u of* (10.1) *satisfies the equations*

$$x\Delta u_{xxy} = (\varepsilon y - (\alpha+\beta+1)\Delta)u_{xy} + \alpha\beta(1-y)u_y - \alpha'\beta' u_x,$$

$$y\Delta u_{xyy} = (\varepsilon x - (\alpha'+\beta'+1)\Delta)u_{xy} + \alpha'\beta'(1-y)u_y - \alpha\beta u_x.$$

The proof is straightforward and omitted.

The operator $L(\alpha^+\beta'^+\gamma^+)$ will be found by the following process. The relations [15], [16], and [25] in Table 3.1 provide us with relations expressing $e(\beta^+)$, $e(\beta'^+)$, and $e(\alpha^+\beta^+\gamma^+)$ by $e = e(\alpha, \alpha', \beta, \beta', \gamma)$, respectively. From the first relation we get a relation for (β^-), i.e., a relation expressing $e(\beta^-)$ by e. Then the composition

$$e(\alpha, \beta, \beta', \gamma) \xrightarrow{\beta'^+} e(\alpha, \beta, \beta'+1, \gamma)$$

$$\xrightarrow{\beta^-} e(\alpha, \beta-1, \beta'+1, \gamma)$$

$$\xrightarrow{\alpha^+\beta^+\gamma^+} e(\alpha+1, \beta, \beta'+1, \gamma+1)$$

gives a required operator.

Now let us follow this process. Put

$$\begin{aligned} e_0 &= c(\alpha, \alpha', \gamma)F_3(\alpha, \alpha', \beta, \beta', \gamma; x, y), \\ c(\alpha, \alpha', \gamma) &= \Gamma(1-\gamma)\Gamma(\alpha)\Gamma(\alpha')/\Gamma(\alpha+\alpha'-\gamma+1). \end{aligned} \tag{10.3}$$

The relation [15] in Table 3.1 reads

$$e_0(\beta^+) = e_0(\beta) + \frac{1}{\beta}e_1(\beta).$$

Hence (10.2) shows that we have

$$e(\beta^+) = Ae(\beta),$$

where

$$A = \begin{pmatrix} 1 & \frac{1}{\beta} & 0 & 0 \\ -\frac{\alpha x}{x-1} & \frac{1}{\beta}\left(1+\beta-\gamma-\frac{\delta x}{x-1}\right) & 0 & \frac{1}{\beta(x-1)} \\ 0 & 0 & 1 & \frac{1}{\beta} \\ 0 & -\frac{\alpha'\beta' y}{\beta\Delta} & -\frac{\alpha x(y-1)}{\Delta} & 1+\frac{\delta'}{\beta}+\frac{\varepsilon x(y-1)}{\beta\Delta} \end{pmatrix}.$$

The determinant of this matrix A is

$$\frac{(\alpha'+\beta+1-\gamma)(\beta+\beta'+1-\gamma)y}{\beta^2(x-1)\Delta}.$$

Hence, taking the inverse of this matrix and decreasing the value of β by 1, we get

$$e_0(\beta^-) = \left\{1+\frac{\alpha(\beta+\delta'-1)}{\lambda}x\right\}e_0+\frac{\beta+\delta'-1}{\lambda}(x-1)e_1+\frac{\alpha x(y-1)}{\lambda y}e_2+\frac{\Delta}{\lambda y}e_3,$$

provided that

$$\lambda := (\gamma-\alpha-\beta')(\gamma-\alpha'-\beta) \neq 0.$$

Namely, if we define a differential operator U_{51} by

$$U_{51} = \lambda+\alpha(\beta+\delta'-1)x+(\beta+\delta'-1)x(x-1)\partial_x+\alpha x(y-1)\partial_y+\Delta x\partial_x\partial_y, \tag{10.4}$$

then

$$U_{51}e_0 = \lambda e_0(\beta^-). \tag{10.5}$$

We next define an operator U_{21} by

$$U_{21} = -\frac{1}{\beta}U_{51}(\alpha^+\beta^+\gamma^+)\cdot Y_{25}, \tag{10.6}$$

where $Y_{25} = \partial_x$ in Table 3.1 and $U_{51}(\alpha^+\beta^+\gamma^+)$ denotes the operator U_{51} with parameters α, β, γ increased by 1. By using Lemma 10.1, we see

$$U_{21} = \alpha(\alpha'+\beta+\beta'-\gamma)-(\alpha'+\beta+\beta'-\gamma)(1-x)\partial_x-\alpha(1-y)\partial_y-\Delta\partial_x\partial_y,$$

and we have

$$U_{21}e_0 = \lambda e_0(\alpha^+\gamma^+). \tag{10.7}$$

We finally compute the composition U_{26} of U_{21} and Y_{16} in Table 3.1. A calculation shows

$$U_{26} = \frac{1}{\gamma-\beta-\beta'-1}U_{21}(\beta'^+)\cdot Y_{16},$$

and we have

$$U_{26}e_0 = \beta'(\alpha'+\beta-\gamma)e_0(\alpha^+\beta'^+\gamma^+),$$

which is the first assertion of Lemma 7.3. Note that we can forget the condition $\lambda \neq 0$ in the final step. The second assertion in Lemma 7.3 is obtained from the first one by the symmetry $\alpha \leftrightarrow \alpha'$, $\beta \leftrightarrow \beta'$, and $x \leftrightarrow y$. □

We next prove Lemma 9.2 by a similar method. The function $z = {}_3F_2(a; y)$ satisfies

$$\theta(\theta+b_1-1)(\theta+b_2-1)z - y(\theta+a_1)(\theta+a_2)(\theta+a_3)z = 0. \tag{10.8}$$

Put $e_0 = z$, $e_1 = \theta z$, and $e_2 = \theta^2 z$. Then $e = {}^t(e_0, e_1, e_2)$ is a solution of a Pfaffian equation

$$de = \omega e,$$

where

$$\omega = \begin{pmatrix} 0 & \frac{1}{y} & 0 \\ 0 & 0 & \frac{1}{y} \\ \frac{a_1a_2a_3y}{1-y} & \frac{Ay-B}{1-y} & \frac{a_{123}y-b_{12}+2}{1-y} \end{pmatrix} dy,$$

$$A = a_1a_2+a_2a_3+a_3a_1, \qquad B = (b_1-1)(b_2-1).$$

Recall the convention $a_{123} = a_1+a_2+a_3$ and $b_{12} = b_1+b_2$.

We will derive three operators (9.5)-(9.7) by the use of (9.4). Let us denote differential operators in (9.4) by Y_{14}, Y_{16}, and so on. If we find the inverse U_{42} or Y_{24}, then the composition of Y_{14}, U_{42}, and Y_{25}, in this order, yields Z_{15}. Similarly, denoting by U_{53} and U_{61} the inverses of Y_{35} and Y_{16}, we have Z_{26} and Z_{34} by certain composition of operators.

We follow the first case: By [24] of (9.4), we see

$$e(a_1^+) = \begin{pmatrix} 1 & \frac{1}{a_1} & 0 \\ 0 & 1 & \frac{1}{a_1} \\ \frac{a_2a_3y}{1-y} & \frac{Ay-B}{a_1(1-y)} & 1+\frac{a_{123}y-b_{12}+2}{a_1(1-y)} \end{pmatrix} e.$$

Then, inverting this identity, we see

$$e_0 = \frac{1}{(a_1-b_1+1)(a_1-b_2+1)}[\{(a_1-b_1+1)(a_1-b_2+1)-a_2a_3y\}e_0(a_1^+) \\ -\{a_{23}y+a_1-b_{12}+2\}e_1(a_1^+)+(1-y)e_2(a_1^+)].$$

Hence, by putting

$$U_{42} = \frac{1}{(a_1-b_1)(a_1-b_2)}[\{(a_1-b_1)(a_1-b_2)-a_2a_3y\}-\{a_{23}y+a_1-b_{12}+1\}\theta+(1-y)\theta^2],$$

we have

$$U_{42}e_0 = e_0(a_1^-).$$

Now define $U_{15} = Y_{25}(a_1^-b_1^-)\cdot U_{42}(b_1^-)\cdot Y_{14}$. Then a simple calculation shows

$$U_{15} = (1-y)\theta^2+(-a_{23}y+b_{12}-2)\theta-a_2a_3y+(b_1-1)(b_2-1)$$

and

$$U_{15}e_0 = (b_1-1)(b_2-1)e_0(a_1^-b_1^-b_2^-).$$

By multiplying a suitable constant, we get the operator Z_{15}, which satisfies the first relation in Lemma 9.2 in view of the relation of parameters (9.2).

For the second case look at the symmetry $a_1 \leftrightarrow a_2$ of (10.7). Then for the operator

$$U_{53} = \frac{1}{(a_2-b_1)(a_2-b_2)}[\{(a_2-b_1)(a_2-b_2)-a_1a_3y\}-(a_{13}y+a_2-b_{12}+1)\theta+(1-y)\theta^2],$$

the composition $U_{36} := Y_{36}(a_2^-b_2^-)\cdot U_{53}(b_2^-)\cdot Y_{25}$ gives

$$U_{36} = \frac{a_2-1}{(a_2-b_1)y}\{(y-1)\theta^2+(a_{13}y-b_2+1)\theta+a_1a_3y\}$$

and

$$U_{36}e_0 = -\frac{a_1a_3(a_2-1)}{b_1}e_0(a_1^+a_3^+b_1^+).$$

This is equivalent to the second identity of Lemma 9.2.

The third case can be treated similarly and we complete the proof. □

Acknowledgments. We express hearty thanks to Masaaki Yoshida for having several discussions on the subjects in this paper, and to the referee for showing the author papers [H] and [KMM1]-[KMM3] on canonical systems.

MEAN CONVERGENCE OF EXPANSIONS IN FREUD-TYPE ORTHOGONAL POLYNOMIALS*

H. N. MHASKAR† AND Y. XU‡

Abstract. Let $\{p_n\}$ be the system of polynomials orthonormal with respect to a weight function of the form $\exp(-2Q(x))$. Under some technical conditions on Q we prove certain norm inequalities for the partial sums of the orthogonal expansion of a function in a suitably weighted L^p- norm. These results are valid, in particular, when $Q(x) = x^m$, where m is an even positive integer.

Key words. orthogonal polynomials, mean convergence, Freud polynomials, Fourier orthogonal expansions

AMS(MOS) subject classifications. 41A25, 42C15, 33A65

1. Introduction.

A classical result of Riesz (cf. [21]) states that if f is a 2π-periodic function, $1 < p < \infty$, and $S_n(f, \bullet)$ is the nth partial sum of its trigonometric Fourier series, then

$$\int_{-\pi}^{\pi} |S_n(f,t)|^p dt \le c \int_{-\pi}^{\pi} |f(t)|^p dt \tag{1.1}$$

where c is a constant depending only on p. In the aperiodic case, the situation is quite different. Thus, for example, if $\int_{-1}^{1} |f(t)|^p dt < \infty$ and we consider the nth partial sum of its Legendre expansion instead of $S_n(f, \bullet)$, then an inequality of the form (1.1) holds only when $4/3 < p < 4$ [16]. Furthermore, if $\int_{-\infty}^{\infty} |f(x)|^p \exp(-x^2)dx < \infty$, and $s_n(f, \bullet)$ denotes the nth partial sum of the expansion of f in Hermite polynomials, then

$$\int_{-\infty}^{\infty} |s_n(f,x)|^p \exp(-x^2)dx \le c_2 \int_{-\infty}^{\infty} |f(x)|^p \exp(-x^2)dx \tag{1.2}$$

(with c_2 depending only on p) can hold only when $p = 2$ [16], [17]. Nevertheless, when $4/3 < p < 4$, then

$$\int_{-\infty}^{\infty} |s_n(f,x)\exp(-x^2/2)|^p dx \le c_3 \int_{-\infty}^{\infty} |f(x)\exp(-x^2/2)|^p dx \tag{1.3}$$

where c_3 depends only on p [1]. In 1970, Muckenhoupt [14] showed that an inequality of the form (1.1) can be proved for the Hermite expansions for all p in the range $1 < p < \infty$ if we take different weights on the two sides of the inequality. More precisely, he proved the following theorem.

THEOREM 1.1 [14]. *Let* $1 < p < \infty$,

$$U(x) := \exp(-x^2/2)(1 + |x|)^{\tilde{b}}$$

and

$$V(x) := \exp(-x^2/2)(1+|x|)^{\tilde{B}}(1+\log^+|x|)^{\beta}$$

where $\beta = 1$ *if* $\tilde{b} = \tilde{B}$ *and* $p = 4/3$ *or* 4, *and* $\beta = 0$ *otherwise. Assume that*

$$\begin{aligned} &\tilde{b} < 1 - 1/p, && 1 < p \le 4, \\ &\le \tfrac{2}{3} + 1/(3p), && 4 < p < \infty, \end{aligned} \tag{1.4a}$$

$$\begin{aligned} &\tilde{B} \ge -1 + 1/(3p), && 1 < p < 4/3, \\ &> -1/p, && 4/3 \le p < \infty, \end{aligned} \tag{1.4b}$$

$$\begin{aligned} &\tilde{b} \le \tilde{B} + 1 - 4/(3p), && 1 < p < 4/3, \\ &\le \tilde{B}, && 4/3 \le p \le 4, \\ &\le \tilde{B} - \tfrac{1}{3} + 4/(3p), && 4 < p < \infty, \end{aligned} \tag{1.4c}$$

and if equality occurs in (1.4c) *then equality does not occur in* (1.4a) *or* (1.4b). *Then there exists a constant* c_4 *independent of* f *and* n *such that*

$$\int_{-\infty}^{\infty} |s_n(f,x)U(x)|^p dx \le c_4 \int_{-\infty}^{\infty} |f(x)V(x)|^p dx \tag{1.5}$$

where $s_n(f,\bullet)$ *denotes the* n*th partial sum of the orthogonal expansion of* f *in terms of the Hermite polynomials.*

The proofs of these results concerning Hermite expansions utilize a very detailed knowledge about the asymptotic behavior of the Hermite polynomials.

In this paper, we obtain an analogue of Theorem 1.1 for expansions in Freud polynomials, i.e., polynomials orthogonal on the whole real line with respect to a weight function of the form $\exp(-2Q(x))$ where Q is a suitably chosen function. While several results concerning the asymptotic behavior of such polynomials and related quantities have been proved recently [6]–[9], [15], [18], [20], our knowledge concerning Freud polynomials with a general weight function is still limited to a few relatively imprecise estimations. Our interest, then, is not only in proving an analogue of Theorem 1.1, but also in exploring the extent to which various polynomial inequalities can be used in the study of orthogonal polynomial expansions.

We discuss our main results in § 2 and prove them in § 3.

2. Main results. Let Q be an even and convex function on $\mathbb{R}$, differentiable on $(0,\infty)$, and let $xQ'(x) \to \infty$ as $|x| \to \infty$. We consider a weight function of the form $w_Q^2(x) := \exp(-2Q(x))$ and the sequence of polynomials $\{p_n\}$ orthonormal on $\mathbb{R}$ with respect to w_Q^2. Thus, denoting the class of all polynomials of degree at most n by Π_n, we have

$$p_n(x) := p_n(w_Q^2,x) = \gamma_n x^n + \cdots \in \Pi_n, \quad \gamma_n := \gamma_n(w_Q^2) > 0, \quad n = 0,1,2,\cdots, \tag{2.1a}$$

$$\int_{-\infty}^{\infty} p_n p_m w_Q^2 dx = \delta_{nm}, \qquad n,m = 0,1,\cdots. \tag{2.1b}$$

If f is Lebesgue measurable function on $\mathbb{R}$, we define, when possible,

$$a_k(w_Q,f) := \int_{-\infty}^{\infty} f(t)p_k(t)w_Q^2(t)dt, \qquad k = 0,1,\cdots, \tag{2.2a}$$

$$s_n(w_Q, f, x) := \sum_{k=0}^{n-1} a_k(w_Q, f)p_k(x), \qquad n = 1, 2, \cdots. \tag{2.2b}$$

As usual, we also write

$$\|f\|_p := \begin{cases} \left(\int_{-\infty}^{\infty} |f(x)|^p dx\right)^{1/p}, & 1 \le p < \infty, \\ \operatorname{ess\,sup}_{x\in\mathbb{R}} |f(x)|, & p = \infty \end{cases} \tag{2.3}$$

and the space $L^p(\mathbb{R})$ then denotes the space of all Lebesgue measurable functions f for which $\|f\|_p < \infty$, two functions being considered equal when they are equal almost everywhere.

Our main theorem can now be formulated as follows.

THEOREM 2.1. *Let Q be an even, convex function on $\mathbb{R}$, differentiable on $(0, \infty)$ and $xQ'(x) \uparrow \infty$ as $|x| \to \infty$ and with suitably chosen constants c_5, c_6,*

$$1 < c_5 \le Q'(2x)/Q'(x) \le c_6 < \infty, \qquad x > 0.$$

For every integer $n > 0$, we let q_n be the least positive number satisfying the equation

$$q_n Q'(q_n) = n. \tag{2.4}$$

Suppose that the orthogonal polynomials $\{p_n\}$ satisfy each of the following inequalities where $K(\ge -1/2), A^*, c_7, c_8, c_9$ are suitably chosen constants depending on Q alone:

$$|p_n(x)w_Q(x)| \le c_7 q_n^K, \qquad x \in \mathbb{R}, \quad n = 1, 2, \cdots, \tag{2.5a}$$

$$|p_n(x)w_Q(x)| \le c_8 q_n^{-1/2}, \qquad |x| \le A^* q_n, \quad n = 1, 2, \cdots, \tag{2.5b}$$

$$|p_{n+1}(x) - p_{n-1}(x)|w_Q(x) \le c_9 q_n^{-1/2}, \qquad x \in \mathbb{R}, \quad n = 1, 2, \cdots. \tag{2.5c}$$

Let $1 < p < \infty$ and b, B be constants satisfying

$$b < \min\{1 - 1/p, -K + 1/2 - 1/p\}, \tag{2.6a}$$

$$B > \max\{-1/p, K + 1/2 - 1/p\}, \tag{2.6b}$$

$$B - b \ge 2K + 1. \tag{2.6c}$$

Then, for any Lebesgue measurable function f such that $(1 + |x|)^B w_Q f \in L^p(\mathbb{R})$, we have

$$\|(1 + |x|)^b w_Q(x) s_n(w_Q, f, x)\|_p \le c_{10} \|(1 + |x|)^B w_Q(x) f(x)\|^p \tag{2.7}$$

where c_{10} is a constant depending only on Q, p, b, B.

An estimate of the form (2.5a) can be proved easily using Nikolskii-type inequalities under very mild conditions on Q [11]. However, the constant K obtained in this way is usually not sharp. A sharp estimate of this form is known, at the time of this writing, only when $Q(x) = x^m$ where m is an even integer. In this case, $K = (m-3)/6$ [3]. In particular, in contrast to the Hermite polynomials ($m = 2$) Freud polynomials

for such weights are not uniformly bounded if $m \geq 4$. This fact is partly responsible for our inability to generalize Muckenhoupt's result completely.

Condition (2.5b) has been a subject of great interest in recent years [2], [3], [5], [7], [10]. In [7], it has been proved for the case when $Q(x) = |x|^\alpha$ when $\alpha > 3$. Lopez and Rahmanov have claimed to have proved it under very general conditions including the case of these weights when $\alpha > 0$.

Condition (2.5c) is currently known only in the case where $Q(x) = x^m$, m even positive integer [5]. The known proof requires an asymptotic expansion of quantities γ_{n-1}/γ_n. Thus, our theorem is currently valid only for the case when $Q(x) = x^m$, m even positive integer. Using the results in [7] and [8], it seems possible to obtain stronger results in this case. We hope to return to this in the near future, concentrating in this note on the general principles involved. It is conjectured that the inequalities (2.5) are true more generally, including the case where $Q(x) = |x|^\alpha$, $\alpha > 0$.

The conditions on Q imply that

$$\int_1^\infty \frac{Q(x)}{1+x^2}dx = \infty.$$

It is known [19] that expressions of the form $(1 + |x|)^B w_Q(x)P(x)$, where P is a polynomial, are dense in $L^p(\mathbb{R})$. Therefore, (2.7) easily implies that

$$||(1 + |x|)^b w_Q(x)\Big[s_n(w_Q, f, x) - f(x)\Big]||_p \to 0, \qquad n \to \infty.$$

An inequality similar to (2.7) with an L^1-norm on the left-hand side and an $L\log^+ L$ norm on the right-hand side can also be obtained using our techniques, but we do not intend to pursue this further since the proof does not add any deeper insights to the study of Freud polynomials.

3. Proof. In the sequel, we adopt the following conventions concerning constants. The letters $c, c_1, \cdots$ will denote constants depending only on Q and other fixed parameters involved, but their values may be different at different occurrences, even within the same formula. The notation adopted in § 2 will be continued except for the constants $c, c_1, \cdots$, etc. We also adopt the notation

$$\mathcal{P}_n(x) := p_n(x)w_Q(x), \qquad x \in \mathbb{R}, \quad n = 0, 1, \cdots. \tag{3.1}$$

To begin with, we recall certain facts concerning Freud polynomials and the Hilbert transform.

LEMMA 3.1. (a) [4] *We have*

$$xp_{n-1}(x) = \rho_n p_n(x) + \rho_{n-1}p_{n-2}(x), \quad \rho_n := \gamma_{n-1}/\gamma_n, \quad n = 1, 2, \cdots, \tag{3.2}$$

$$K_n(x, y) := \sum_{k=0}^{n-1} p_k(x)p_k(y) = \rho_n \frac{p_n(x)p_{n-1}(y) - p_n(y)p_{n-1}(x)}{x - y}. \tag{3.3}$$

(b) [10] *For the Freud polynomials, we have*

$$\tfrac{1}{4}q_n \leq \rho_n \leq 4q_n \tag{3.4}$$

where q_n is defined in (2.4).

(c) [12] *Let $0 < p, r < \infty$. Then there exists a constant $L := L(Q, p, r)$ with the following property. For every integer $n = 1, 2, \cdots$ and $P \in \Pi_n$,*

$$|w_Q(x)P(x)|^p \le c\exp(-c_1 n)\int_{|t|\le Lq_n} |w_Q(t)P(t)|^p dt, \qquad |x| \ge Lq_n, \tag{3.5a}$$

$$\left\{\int_{|x|\ge Lq_n} |w_Q(x)P(x)|^r dx\right\}^{p/r} \le c\exp(-c_1 n)\int_{|t|\le Lq_n} |w_Q(t)P(t)|^p dt. \tag{3.5b}$$

(d) [14] *If $1 < p < \infty$, $r < 1 - 1/p$, $R > -1/p$ and $r \le R$, and ϕ is Lebesgue measurable, then*

$$\int_{-\infty}^{\infty}\left|\int_{-\infty}^{\infty}\frac{\phi(y)}{x-y}dy\right|^p (1+|x|)^{rp}dx \le c\int_{-\infty}^{\infty}|\phi(x)(1+|x|)^R|^p dx, \tag{3.6}$$

where the singular integral is taken in the principal value sense.

We would like to warn the reader that the notation in Lemma 3.1(d) is different from the one used in Lemma 8 of [14]. As in [14], the starting point of our proof is the following lemma.

LEMMA 3.2. *We have, for $n = 1, 2, \cdots$,*

$$K_n(x,y)w_Q(x)w_Q(y) = h_1(x,y) + h_2(x,y) + h_3(x,y) \tag{3.7}$$

where

$$h_1(x,y) := \frac{\rho_n}{\rho_n + \rho_{n-1}}\mathcal{P}_{n-1}(x)\mathcal{P}_{n-1}(y), \tag{3.8a}$$

$$h_2(x,y) := \frac{\rho_{n-1}\rho_n}{\rho_n + \rho_{n-1}}\frac{\mathcal{P}_{n-1}(y)\Big[\mathcal{P}_n(x) - \mathcal{P}_{n-2}(x)\Big]}{x-y}, \tag{3.8b}$$

$$h_3(x,y) := h_2(y,x). \tag{3.8c}$$

Proof. Writing

$$D_n(x,y) := K_n(x,y)w_Q(x)w_Q(y), \tag{3.9}$$

we see from (3.3) that

$$\begin{aligned} 2D_n(x,y) &= D_n(x,y) + D_{n-1}(x,y) + \mathcal{P}_{n-1}(x)\mathcal{P}_{n-1}(y) \\ &= \rho_{n-1}\left[\frac{D_n(x,y)}{\rho_n} + \frac{D_{n-1}(x,y)}{\rho_{n-1}}\right] \\ &\quad + \frac{\rho_n - \rho_{n-1}}{\rho_n}D_n(x,y) + \mathcal{P}_{n-1}(x)\mathcal{P}_{n-1}(y). \end{aligned} \tag{3.10}$$

Transferring the middle term to the left-hand side and simplifying, we get

$$D_n(x,y) = \frac{\rho_n\rho_{n-1}}{\rho_n+\rho_{n-1}}\left[\frac{D_n(x,y)}{\rho_n}+\frac{D_{n-1}(x,y)}{\rho_{n-1}}\right]+\frac{\rho_n}{\rho_n+\rho_{n-1}}\mathcal{P}_{n-1}(x)\mathcal{P}_{n-1}(y). \tag{3.11}$$

Using (3.3) and the notation in formulas (3.8), we get (3.7). □

We write

$$u_r(x) := (1+|x|)^r, \qquad g(x) := w_Q(x)f(x). \tag{3.12}$$

Then (cf. [14]) with D_n as in (3.9),

$$u_b(x)w_Q(x)s_n(w_Q,f,x) = u_b(x)\int_{-\infty}^{\infty} g(y)D_n(x,y)dy.$$

Therefore, in order to prove Theorem 2.1, we need to show that

$$\int_{-\infty}^{\infty}\left|\int_{-\infty}^{\infty} g(y)D_n(x,y)u_b(x)dy\right|^p dx \le c\int_{-\infty}^{\infty}|g(y)u_B(y)|^p dy. \tag{3.13}$$

In view of Lemma 3.2, we see that it is enough to show that

$$\int_{-\infty}^{\infty}\left|\int_{-\infty}^{\infty} g(y)h_k(x,y)u_b(x)dy\right|^p dx \le c\int_{-\infty}^{\infty}|g(y)u_B(y)|^p dy, \qquad k=1,2,3. \tag{3.14}$$

The following lemma gives certain estimates on $\{\mathcal{P}_n\}$ which will be needed in the sequel. We note that our assumptions on Q imply that $\{q_{2n}/q_n\}$ is bounded from above and below by positive constants, and also that $K \ge -1/2$.

LEMMA 3.3. *Let $\sigma \in \mathbb{R}$, $0 < r \le \infty$. There exists a constant A depending only on σ, Q such that*

$$|u_\sigma(x)\mathcal{P}_n(x)| \le c\exp(-c_1 n), \qquad |x| \ge Aq_n. \tag{3.15}$$

Moreover,

$$||u_\sigma\mathcal{P}_n||_r \le \begin{cases} q_n^{-1/2}(\log n)^{1/r} & \text{if } \sigma = -1/r, \quad K=-1/2, \\ q_n^T & \text{otherwise} \end{cases} \tag{3.16a}$$

where

$$T := \max\{K+\sigma+1/r, -1/2\}. \tag{3.16b}$$

Proof. Let l be the least positive even integer greater than σ. Then, applying Lemma 3.1(c) to the polynomial $(1+x^l)p_n(x) \in \Pi_{n+l}$ with $p=2$, we get, for $|x| \ge Lq_{n+l}$,

$$\begin{aligned} |u_\sigma(x)\mathcal{P}_n(x)|^2 &\le |(1+x^l)p_n(x)w_Q(x)|^2 \\ &\le c\exp(-c_1 n)\int_{|t|\le Lq_{n+l}}(1+t^l)^2p_n^2(t)w_Q^2(t)dt \\ &\le cq_{n+l}^{2l}\exp(-c_1 n)\int_{-\infty}^{\infty}p_n^2(t)w_Q^2(t)dt \\ &\le c\exp(-c_1 n). \end{aligned} \tag{3.17}$$

Since $q_{n+l} \le cq_n$, (3.15) is now proved. Applying (3.15) with σ replaced by a larger number, we deduce that

$$\int_{|x|\ge A_1 q_n} |u_\sigma(x)\mathcal{P}_n(x)|^r dx \le c\exp(-c_1 n) \tag{3.18a}$$

for a suitably chosen A_1. Using (2.5a), we find that

$$\int_{A^* q_n \le |x| \le A_1 q_n} |u_\sigma(x)\mathcal{P}_n(x)|^r dx \le cq_n^{r\sigma+Kr+1}. \tag{3.18b}$$

Using (2.5b), we get

$$\begin{aligned}
&\int_{|x|\le A^* q_n} |u_\sigma(x)\mathcal{P}_n(x)|^r dx \\
&\qquad \le cq_n^{-r/2} \int_{|x|\le A^* q_n} u_\sigma^r(x)dx \\
&\qquad \le cq_n^{-r/2} \begin{cases} \log q_n & \text{if } \sigma = -1/r, \\ 1 & \text{if } \sigma < -1/r, \\ q_n^{r\sigma+1} & \text{if } \sigma > -1/r. \end{cases}
\end{aligned} \tag{3.18c}$$

The estimate (3.16) can be deduced from (3.18a), (3.18b), and (3.18c). □

Proof of Theorem 2.1. As we observed earlier, it is enough to prove (3.14). Using Hölder's inequality,

$$\begin{aligned}
&\int_{-\infty}^{\infty} \left| \int_{-\infty}^{\infty} g(y)\mathcal{P}_{n-1}(x)\mathcal{P}_{n-1}(y)u_b(x)dy \right|^p dx \\
&\qquad = \left(\int_{-\infty}^{\infty} \left| u_b(x)\mathcal{P}_{n-1}(x) \right|^p dx \right) \left(\int_{-\infty}^{\infty} \left| g(y)\mathcal{P}_{n-1}(y) \right| dy \right)^p \\
&\qquad \le ||u_b\mathcal{P}_{n-1}||_p^p ||u_B^{-1}\mathcal{P}_{n-1}||_q^p ||gu_B||_p^p
\end{aligned} \tag{3.19}$$

where

$$q := p/(p-1). \tag{3.20}$$

Next, we observe that $u_B^{-1} = u_{(-B)}$ and $q_{n-1} \le q_n$. If $K > -1/2$ then we may use (3.16) and the assumptions (2.6c) to conclude that

$$\int_{-\infty}^{\infty} \left| \int_{-\infty}^{\infty} g(y)\mathcal{P}_{n-1}(x)\mathcal{P}_{n-1}(y)u_b(x)dy \right|^p dx \le c||gu_B||_p^p. \tag{3.21}$$

If $K = -1/2$, then the estimation can be done by considering four simple cases. We omit these details. Thus, (3.14) is proved for $k = 1$.

Next, we let

$$R := B - 1/2 - K. \tag{3.22}$$

Then, in view of (2.6) and Lemma 3.1(d), for any ϕ with $u_R\phi \in L^p(\mathbb{R})$,

$$\int_{-\infty}^{\infty} \left| \int_{-\infty}^{\infty} \frac{\phi(y)}{x-y} dy \right|^p u_b(x)^p dx \le c||u_R\phi||_p^p. \tag{3.23}$$

So, using (2.5c) and (3.23), we get

(3.24)
$$\int_{-\infty}^{\infty}\left|\int_{-\infty}^{\infty} g(y)h_2(x,y)u_b(x)dy\right|^p dx$$
$$\le cq_n^p \int_{-\infty}^{\infty}\left|\int_{-\infty}^{\infty}\frac{g(y)\mathcal{P}_n(y)}{x-y}dy\right|^p \left|\mathcal{P}_n(x)-\mathcal{P}_{n-2}(x)\right|^p u_b(x)^p dx$$
$$\le cq_n^{p/2}\int_{-\infty}^{\infty}|g(y)\mathcal{P}_n(y)|^p u_R(y)^p dy.$$

Next, we apply (3.16) with $r=\infty$ and $\sigma = R-B$ and then use (3.22) to see that for $y\in(0,\infty)$,

(3.25)
$$|\mathcal{P}_n(y)u_R(y)| = |\mathcal{P}_n(y)u_{R-B}(y)||u_B(y)|$$
$$\le cq_n^{-1/2}|u_B(y)|.$$

Substituting from (3.25) into (3.24), we get

(3.26)
$$\int_{-\infty}^{\infty}\left|\int_{-\infty}^{\infty} g(y)h_2(x,y)u_b(x)dx\right|^p dy \le c||gu_B||_p^p.$$

We prove the estimate for h_3 in exactly the same way or by using a duality argument. □

Note added in proof. The authors have recently obtained more precise results similar to Theorem 1.1 in the case where $Q(x)=x^m$ (m an even integer).

Acknowledgments. The authors thank Professor Dr. Doron Lubinsky for pointing out a mistake in the original version of the paper and making various useful suggestions towards the improvement of the presentation in the paper.

REPRODUCING FORMULAS AND DOUBLE ORTHOGONALITY IN BARGMANN AND BERGMAN SPACES*

KRISTIAN SEIP†

Abstract. It is observed that the reproducing kernels of the Bargmann spaces in $\mathbf{C}^n$ act reproducingly over any polyball (apart, of course, from positive constants depending on the radii of the polyball). It is noticed likewise that the reproducing kernels of the Bergman spaces over the unit ball in $\mathbf{C}^n$ act reproducingly over any ball (that is, ball in the Bergman metric). From these observations the eigenvalues and eigenfunctions of certain concentration operators are found. These eigenfunctions can be viewed as analogues to the prolate spheroidal wave functions in the Paley-Wiener space, but they are simpler and have nice properties which the prolate spheroidal wave functions do not have. Such expansions are exploited to yield analogues to results on sampling of bandlimited signals: necessary density conditions for sampling and interpolation, and jittered sampling. These results can be interpreted as results on irregular discrete representations of particular short-time Fourier and wavelet transformations.

Key words. reproducing formula, double orthogonality, concentration operator, Bergman space, Bargmann space, wavelets, sampling, interpolation, jittered sampling

AMS(MOS) subject classifications. 94A05, 41A05, 44A15, 30C40

1. Introduction. Let $\mathcal{H}$ be a reproducing kernel Hilbert space being a subspace of $L^2(X, dm(x))$ where X is a measure space with positive measure m. We denote the reproducing kernel of $\mathcal{H}$ by $K(t, x)$. This is the unique Hermitian function defined on $X \times X$ with the following properties. $K(\cdot, x)$ belongs to $\mathcal{H}$ for each fixed x, and for each $f \in L^2(X, dm(x))$ we have

$$(Pf)(t) = \int_X K(t, x) f(x)\, dm(x),$$

where P denotes projection onto $\mathcal{H}$.

Let next q be some nonnegatively valued and essentially bounded function on X. We denote the inner product of $L^2(X, dm(x))$ by $(\cdot, \cdot)$ and that of $L^2(X, q(x)\, dm(x))$ by $(\cdot, \cdot)_q$. A sequence of elements in $\mathcal{H}$ will be said to be *doubly orthogonal* if it is orthogonal both with respect to $(\cdot, \cdot)$ and to $(\cdot, \cdot)_q$. Along with q we define the operator Q on $L^2(X, dm(x))$ by

$$(Qf)(x) = q(x) f(x).$$

We prove the following easy proposition.

PROPOSITION 1. *Let $\{f_k\}$ be an orthonormal basis of $\mathcal{H}$. Then $\{f_k\}$ is also orthogonal with respect to $(\cdot, \cdot)_q$ if and only if the functions f_k are eigenfunctions of PQ.*

Proof. Assume first double orthogonality. Then for any k,

$$0 = (f_i, f_k)_q = (f_i, PQf_k)$$

holds for all $i \neq k$, which by the assumed completeness of $\{f_k\}$ means that $PQf_k = \lambda_k f_k$.

Assume next that f_k are eigenfunctions of PQ. Then

$$(f_i, f_k)_q = (f_i, PQf_k) = (f_i, \lambda_k f_k),$$

which equals zero whenever $i \neq k$. □

A necessary and sufficient condition that $\mathscr{H}$ possess a doubly orthogonal basis is thus that the positive operator PQ have a purely discrete spectrum. This is definitely the case if PQ is compact. A sufficient condition that PQ be compact is

$$\int_X K(x, x)q(x)\, dm(x) < \infty. \tag{1}$$

Indeed, by the reproducing property of $K(t, x)$ we have

$$\int_X \int_X |K(t, x)q(x)|^2\, dm(t)\, dm(x) = \int_X K(x, x)q(x)^2\, dm(x),$$

which shows that (1) ensures square integrability of $K(t, x)q(x)$. Of course, (1) also implies that PQ is trace class.

If q is the characteristic function of some subset Y of X, PQ may be called a *concentration operator.* In the case that PQ is compact, eigenvalues and eigenfunctions can then be found by successively maximizing the *concentration*

$$\lambda = \frac{\int_Y |f(x)|^2\, dm(x)}{\int_X |f(x)|^2\, dm(x)}$$

over the orthogonal complement in $\mathscr{H}$ of the linear span of the previously determined eigenfunctions.

The first to consider such doubly orthogonal bases seems to have been Bergman in his study of the spaces that now commonly bear his name [4, pp. 14–18]. A later example are the celebrated prolate spheroidal wave functions of Landau, Slepian, and Pollak [40a–c]. By the work of Daubechies and Paul [11] we recognize a rather close connection between these two examples, both giving eigenfunctions of time-frequency-limiting operators.

Daubechies and Paul's problem of finding the eigenvalues and eigenfunctions of certain concentration operators is essentially the same as that of Bergman, but they formulate it in other spaces of functions than Bergman did. Being unaware of the connection to Bergman, they solve the problem in the same way as the prolate spheroidal wave functions were found, that is, by finding a differential operator commuting with the concentration operator.

We shall see below that in Bergman's formulation such problems are solved very easily in a direct manner. This will lead us to expansions with some rather nice properties. In addition to the double orthogonality and the concentration properties, the eigenfunctions will have certain reproducing properties, and the expansions are simply a kind of Taylor series. In the last part of this paper we present applications of such expansions yielding analogues of certain results on irregular sampling of bandlimited signals. These analogues are relevant for the theory of short-time Fourier and wavelet transformations.

We start our discussion of Bargmann and Bergman spaces in $\mathbf{C}^n$. We have chosen to treat the Bergman spaces over the unit ball. We could just as well have chosen the unit polydisk or more generally any unit polyball. To what class of symmetric domains in $\mathbf{C}^n$ our results can be extended we do not know. Our primary interest in these problems has been the above-mentioned applications, and for that purpose considering the ball has been more than sufficient.

It should be mentioned that what we have chosen to call concentration operators constitute a special class of Toeplitz operators, which in recent years have been studied quite extensively (see [6], [36] and the references therein).

Before turning to the main discussion, let us remark that some of the results of this paper are reported in [39].

2. Reproducing formulas and concentration operators. Below are listed some basic definitions and notational conventions that will be needed. For readers not familiar with the Bargmann and Bergman spaces [17] (Bargmann case) and [26] (Bergman case) might be good background references.

Notation. B will denote the unit ball in $\mathbf{C}^n$, $B(R)$ the ball of radius R centered at zero, $D(R_1, \cdots, R_n)$ the polydisk of radii $R_1, \cdots, R_n$ also centered at zero and S the unit sphere in $\mathbf{C}^n$, n a fixed positive integer. μ will denote Lebesgue measure on $\mathbf{C}^n$, normalized so that $\mu(B) = 1$, and σ will mean the rotation-invariant positive Borel measure on S for which $\sigma(S) = 1$. We use standard multi-index notation. If β is any multi-index then D_z^β is the corresponding differential operator, with the index indicating with respect to which variable one is differentiating.

We next introduce some symbols that will have different meaning depending on which case we have under consideration.

We start with the Bargmann case. We introduce the Bargmann kernel of $\mathbf{C}^n$ which is the function

$$K(z, \zeta) = e^{\langle z, \zeta \rangle}$$

defined on $\mathbf{C}^n \times \mathbf{C}^n$. We will use the weighted measure

$$d\omega_\alpha(z) = K(z, z)^{-\alpha}\, d\mu(z),$$

where $\alpha > 0$ is some fixed real number. We let $H(\mathbf{C}^n)$ be the class of all functions holomorphic in $\mathbf{C}^n$ and define the Bargmann spaces

$$F^\alpha = H(\mathbf{C}^n) \cap L^1(\mathbf{C}^n, d\omega_\alpha(z))$$

and

$$F^{\alpha,2}(\mathbf{C}^n) = H(\mathbf{C}^n) \cap L^2(\mathbf{C}^n, d\omega_\alpha(z)).$$

We define

$$T_z(\zeta) = z - \zeta.$$

We next turn to the Bergman case. The Bergman kernel of B is the function

$$K(z, \zeta) = (1 - \langle z, \zeta \rangle)^{-n-1}$$

defined on $B \times B$. We introduce the weighted measure

$$d\omega_\alpha(z) = K(z, z)^{-\alpha}\, d\mu(z),$$

where $\alpha > -1/(n+1)$ is some fixed real number. We let $H(B)$ be the class of all functions holomorphic in B and define the Bergman spaces

$$A^\alpha(B) = H(B) \cap L^1(B, d\omega_\alpha(z))$$

and

$$A^{\alpha,2}(B) = H(B) \cap L^2(B, d\omega_\alpha(z)).$$

The restriction on α is put to make these spaces nontrivial.

We shall denote the automorphism of B that interchanges z and zero (see [38, p. 25]) by T_z.

The Bargmann case. It is easy to show that the following holds.

THEOREM 2.1. *For any $f \in H(\mathbf{C}^n)$, any multi-index β, any $z \in \mathbf{C}^n$, and any $R > 0$ we have the following formula*:

$$\{D_\zeta^\beta [f(T_z\zeta)K(\zeta, z)^\alpha]\}_{\zeta=0} = C \int_{T_z B(R)} f(w)\overline{(T_z w)^\beta K(w, z)^\alpha}\, dw_\alpha(w) \tag{2}$$

with

$$C = C(R, |\beta|, \alpha) = \frac{(n+|\beta|-1)!}{n!}\left(\int_0^{R^2} r^{n+|\beta|-1} e^{-\alpha r}\, dr\right)^{-1}.$$

If $f \in F^\alpha$, the formula is also valid for $R = \infty$.

Proof. For arbitrary $f \in H(\mathbf{C}^n)$, we use the Cauchy formula [38, p. 39] for the function $f(rz)$ yielding

$$r^{|\beta|}\{[D^\beta f](\zeta)\}_{\zeta=0} = \frac{(n+|\beta|-1)!}{(n-1)!}\int_S f(rw)\bar{w}^\beta\, d\sigma(w).$$

We then multiply each side by $2nr^{2n-1}r^{|\beta|}e^{-\alpha r^2}\, dr$ and integrate over r from zero to R. Using the formula for integration in polar coordinates gives

$$\{[D^\beta f](\zeta)\}_{\zeta=0} = C\int_{B(R)} f(w)\overline{w^\beta}\, d\omega_\alpha(w). \tag{3}$$

We apply this formula to $f(T_z\zeta)K(\zeta, z)^\alpha$, then make a change of variables in the integral, and the result follows. □

THEOREM 2.2. *For any $f \in H(\mathbf{C}^n)$, any multi-index β, any $z \in \mathbf{C}^n$, and any $R_1, \cdots, R_n > 0$ we have the following formula*:

$$\{D_\zeta^\beta [f(T_z\zeta)K(\zeta, z)^\alpha]\}_{\zeta=0} = C \int_{T_z D(R_1,\cdots,R_n)} f(w)\overline{(T_z w)^\beta K(w, z)^\alpha}\, d\omega_\alpha(w) \tag{4}$$

with

$$C = C(R_1, \cdots, R_n, |\beta|, \alpha) = \prod_{k=1}^n \beta_k !\left(\int_0^{R_k^2} r^{\beta_k} e^{-\alpha r_k}\, dr_k\right)^{-1}.$$

If $f \in F^\alpha$, the formula is also valid when at least one R_k is infinite.

Proof. The proof is the easy and obvious variant of the proof of Theorem 2.1 where we use the Cauchy formula for polydisks. □

Remark 1. Note that when $\beta = 0$ the above theorems reduce to the following statement. The reproducing kernel of $F^{\alpha,2}$ acts reproducingly over any ball and over any polydisk, apart from positive factors depending only on the radii.

Remark 2. There is of course an obvious generalization of the statements above to "any polyball," which we have not made explicitly.

We shall now relate the discussion of the Introduction to the reproducing formulas above. This amounts merely to a simple extension of an observation made by Bergman [4, pp. 14].

Here I_Ω shall mean the operator of multiplication by the characteristic function of the set Ω.

THEOREM 2.3. *For $R < \infty$ the operator $P_{F^{\alpha,2}} I_{T_z B(R)}$ has eigenvalues*

$$\lambda_{|\beta|}(R) = \frac{C(R, |\beta|, \alpha)}{C(\infty, |\beta|, \alpha)} = \frac{1}{(n+|\beta|-1)!}\int_0^{\alpha R^2} r^{n+|\beta|-1} e^{-r}\, dr.$$

For $R_1, \cdots, R_n < \infty$ the operator $P_{F^{\alpha,2}(B)} I_{T_z D(R_1,\cdots,R_n)}$ has eigenvalues

$$\lambda_\beta(R_1, \cdots, R_n) = \frac{C(R_1, \cdots, R_n, \beta, \alpha)}{C(\infty, \cdots, \infty, \beta, \alpha)} = \prod_{k=1}^{n} \frac{1}{\beta_k!} \int_0^{\alpha R_k^2} r^{k+|\beta|-1} e^{-r}\, dr.$$

In either case the corresponding eigenfunctions are

$$f_\beta^z(\zeta) = \rho_\beta^z K(\zeta, z)^\alpha (T_z\zeta)^\beta,$$

the normalizing factor ρ_β^z being

$$\rho_\beta^z = \left(\frac{\beta! K(z, z)^\alpha}{C(\infty, |\beta|, \alpha)} \right)^{-1/2}. \tag{5}$$

Proof. The operator in question is clearly compact and trace class since, with the obvious definitions, (1) is satisfied.

For any $f \in F^{\alpha,2}(B)$, any $z \in B$, and any multi-index β, we have by Theorem 2.1

$$0 = \frac{\lambda_{|\beta|}(R)\rho_\beta^z}{C(\infty, |\beta|, \alpha)} \{\{D_\zeta^\beta [f(T_z\zeta) K(\zeta, z)^\alpha]\}_{\zeta=0} - \{D_\zeta^\beta [f(T_z\zeta) K(\zeta, z)^\alpha]\}_{\zeta=0}\}$$

$$= \int_{C^n} f(\zeta) \{\lambda_{|\beta|}(R) \overline{f_\beta^z(\zeta)} - \overline{(P_{F^{\alpha,2}} I_{T_z B(R)} f_\beta^z)(\zeta)}\}\, d\omega_\alpha(\zeta),$$

and consequently

$$\lambda_\beta(R) f_\beta^z(\zeta) = (P_{F^{\alpha,2}} I_{T_z B(R)} f_\beta^z)(\zeta).$$

In the case of polydisks, we use Theorem 2.2 in the same way.

The proof is completed by recalling that the set $\{f_\beta^z(\zeta)\}$ constitutes an orthonormal basis for $F^{\alpha,2}$ (the normalizing factor ρ_β^z is easily found using (2)). □

Remark. It may be observed that we have obtained the solutions to the eigenvalue problems considered in [11, I] avoiding the use of commuting second-order differential operators. Actually, we have gained a bit since [11, I] only covers the case of polydisks and not that of balls.

The Bergman case. Here we must work slightly harder. We find it convenient first to collect a few auxiliary facts.

Regarding the group of automorphisms of B and their relation to the Bergman kernel we note the following.

LEMMA 2.4. *For any $z, \zeta, w \in B$ and for any automorphism Φ of B we have*

$$T_z 0 = z, \qquad T_z z = 0, \tag{6}$$

$$T_z^{-1} = T_z, \tag{7}$$

$$K(\Phi z, \Phi\zeta) \det \Phi' z\, \overline{\det \Phi' \zeta} = K(z, \zeta), \tag{8}$$

$$K(T_z w, T_z \zeta) = \frac{K(z, z) K(w, \zeta)}{K(w, z) K(z, \zeta)}, \tag{9}$$

$$\det \Phi'(\Phi^{-1} z) = (\det (\Phi^{-1})'(z))^{-1}. \tag{10}$$

Proof. Equation (10) follows by the chain rule

$$I = (\Phi\Phi^{-1})'(z) = \Phi'(\Phi^{-1} z) \cdot (\Phi^{-1})'(z).$$

The rest are standard results which can be found in Chapter 2 of [38]. □

We next note the following.

LEMMA 2.5. *For any multi-index* β, *any* $f \in H(B)$, *and any* $0 < R < 1$, *we have*

$$\{[D^\beta f](\zeta)\}_{\zeta=0} = C(R, |\beta|, \alpha) \int_{B(R)} f(w)\bar{w}^\beta \, d\omega_\alpha(w) \tag{11}$$

with

$$C(R, |\beta|, \alpha) = \frac{(n+|\beta|-1)!}{n!} \int_0^{R^2} r^{n+|\beta|-1}(1-r)^\alpha \, dr. \tag{12}$$

Proof. This is proved in exactly the same way as formula (3). □

We are now ready to prove the following.

THEOREM 2.6. *For any* $f \in H(B)$, *any multi-index* β, *any* $z \in B$, *and any* $0 < R < 1$, *we have the following formula*:

$$\{D_\zeta^\beta[f(T_z\zeta)K(\zeta, z)^{1+\alpha}]\}_{\zeta=0} = C \int_{T_zB(R)} f(w)\overline{(T_zw)^\beta K(w, z)^{1+\alpha}} \, d\omega_\alpha(w) \tag{13}$$

with $C = C(R, |\beta|, \alpha)$ *as in Lemma* 2.5. *If* $f \in A^\alpha(B)$, *the formula is also valid for* $R = 1$.

Proof. Given $f \in H(B)$, $z \in B$, we form the function

$$g(\zeta) = f(T_z\zeta)(\det T_z'\zeta)^{1+\alpha}.$$

An application of Lemma 2.5 to g yields

$$\{D_\zeta^\beta[f(T_z\zeta)(\det T_z'\zeta)^{1+\alpha}]\}_{\zeta=0} = C(R, |\beta|, \alpha) \int_{B(R)} g(u)\overline{u^\beta K(u, 0)^{1+\alpha}} \, d\omega_\alpha(u). \tag{14}$$

We make the change of variables $u = T_zw$. By (8) you see that

$$dw_\alpha(u) = |\det T_z'w|^2 K(T_zw, T_zw)^{-\alpha} \, d\mu(w) = |\det T_z'w|^{2+2\alpha} \, d\omega_\alpha(w).$$

So we have

$$\begin{aligned} &\int_{B(R)} g(u)\overline{u^\beta K(u, 0)^{1+\alpha}} \, d\omega_\alpha(u) \\ &= \int_{T_zB(R)} f(w)\overline{(T_zw)^\beta K(T_zw, 0)^{1+\alpha}(\det T_z'w)^{1+\alpha}} \, d\omega_\alpha(w) \qquad (15) \\ &= \frac{1}{(\det T_z'z)^{1+\alpha}} \int_{T_zB(R)} f(w)\overline{(T_zw)^\beta K(w, z)^{1+\alpha}} \, d\omega_\alpha(w), \end{aligned}$$

where we have used (6), (7), (8), and (10). By (7), (10), and (8), we have

$$\det T_z'z = (\det T_z'0)^{-1} = K(z, z)\overline{\det T_z'0}. \tag{16}$$

By putting (16) into (15) and then (15) into (14), we get

$$\begin{aligned} &\{D_\zeta^\beta[f(T_z\zeta)K(z, z)^{1+\alpha}(\det T_z'\zeta)^{1+\alpha}\overline{(\det T_z'0)^{1+\alpha}}]\}_{\zeta=0} \\ &= C(R, |\beta|, \alpha) \int_{T_zB(R)} f(w)\overline{(T_zw)^\beta K(w, z)^{1+\alpha}} \, d\omega_\alpha(w). \end{aligned}$$

We finally use (8) and (9) to conclude that we have obtained the desired result. If $f \in A^\alpha(B)$, the validity of the formula for $R = 1$ is obvious. □

Remark 1. The above proof is based on a technique originally used by Bers [5], [29].

Remark 2. Note that when $\beta = 0$ the theorem reduces to the following statement. The reproducing kernel of $A^{\alpha,2}(B)$ acts reproducingly over any ball (ball is now to be understood in the Bergman metric), apart from a positive factor depending only on the radius of the ball.

As in the Bargmann case we shall relate the discussion of the Introduction to the reproducing formulas that we have found.

THEOREM 2.7. *For $R < 1$ the operator $P_{A^{\alpha,2}(B)} I_{T_z B(R)}$ has eigenvalues*

$$\lambda_{|\beta|}(R) = \frac{C(R, |\beta|, \alpha)}{C(1, |\beta|, \alpha)} = \frac{(\alpha+1)\cdots(\alpha+n+|\beta|)}{(n+|\beta|-1)!} \int_0^{R^2} r^{n+|\beta|-1}(1-r)^{\alpha}\, dr$$

with corresponding eigenfunctions

$$f_\beta^z(\zeta) = \rho_\beta^z K(\zeta, z)^{\alpha+1}(T_z\zeta)^\beta,$$

the normalizing factor ρ_β^z being

$$\rho_\beta^z = \left(\frac{\beta!\, K(z,z)^{1+\alpha}}{C(1, |\beta|, \alpha)}\right)^{-1/2}. \tag{17}$$

Proof. The proof is exactly like the proof of Theorem 2.3. □

Remark 1. It may be observed that we have obtained the solutions to the eigenvalue problems considered in [11, II], avoiding the use of commuting second-order differential operators.

Remark 2. To get a feeling for the behaviour of the eigenvalues it is instructive to consider the case $\alpha = 0$ in which they are particlarly simple: $\lambda_{|\beta|}(R) = R^{2(n+|\beta|)}$. For a general discussion on the asymptotics the reader should consult [11, II].

Both in the Bargmann and in the Bergman case the functions f_β^z provide us with a useful tool for a local analysis. We obtain "Taylor expansions," and we have the double orthogonality, the concentration properties, and the fact that the first function f_0^z acts reproducingly over any ball centered at z. In the next sections we shall present two examples of how these features may be exploited.

3. Preparation for two applications. For the sake of simplicity we restrict ourselves to the case where $n = 1$ for the rest of this paper.

We start by introducing some notation which, for much of the discussion that follows, will enable us not to distinguish between the Bargmann and the Bergman cases. From now on, unless otherwise specified, all statements should thus be read with respect to either of the two cases.

We should warn the reader that in doing this we will make some minor changes from the notational conventions of the previous section. This will be very convenient and should not cause any trouble if care is taken to note the differences.

We consider the Bargmann spaces $F^{\alpha,2}$ and the Bergman spaces $A^{\alpha,2}(\Delta)$ (we denote the unit disk in $\mathbf{C}$ by Δ). The reproducing kernels of these spaces will all be denoted by $R(z, \zeta)$, that is, for $F^{\alpha,2}$ we let

$$R(z, \zeta) = \alpha\, e^{\alpha z\bar{\zeta}}$$

and if we consider $A^{\alpha,2}(\Delta)$, we put

$$R(z, \zeta) = (2\alpha+1)(1-z\bar{\zeta})^{-2\alpha-2}.$$

We put $d\omega(\zeta) = d\omega_\alpha(\zeta)$, $(\cdot, \cdot)$ will mean the corresponding inner product and $\|\cdot\|$ the corresponding norm. Let distance $d(\cdot, \cdot)$ mean the Euclidean distance in the Bargmann

case and the hyperbolic distance in the Bergman case. Define

$$c_n = \begin{cases} \alpha^n/\pi & \text{Bargmann case,} \\ (2\alpha+1)(2\alpha+2)\cdots(2\alpha+n+1)/\pi & \text{Bergman case,} \end{cases}$$

$$\lambda_n(R) = \begin{cases} \dfrac{1}{n!}\displaystyle\int_0^{\alpha R^2} t^n e^{-t}\,dt & \text{Bargmann case,} \\ \dfrac{c_n\pi}{n!}\displaystyle\int_0^{\tanh^2 R/2} t^n(1-t)^{2\alpha}\,dt & \text{Bergman case,} \end{cases}$$

$$\Delta_z(R) = \{\zeta\colon d(z,\zeta) < R\}.$$

Note that in the Bergman case the argument R in $\lambda_n(R)$ is now a hyperbolic distance.

With this notation (2) (or (4)) and (13) can be written compactly as

$$\left[\frac{d^n}{dw^n}(f(T_z w)K(z,w))\right]_{w=0} = \frac{c_n}{\lambda_n(R)}\iint_{\Delta_z(R)} f(\zeta)\overline{(T_z\zeta)^n K(\zeta,z)}\,d\omega(\zeta). \tag{18}$$

Note in particular that this means

$$f(z) = \frac{1}{\lambda_0(R)}\iint_{\Delta_z(R)} f(\zeta)\overline{R(\zeta,z)}\,d\omega(\zeta). \tag{19}$$

The eigenfunctions of the concentration operators will now naturally be denoted

$$f_n^z(\zeta) = \rho_n^z R(z,\zeta)(T_z\zeta)^n$$

so that ρ_n^z is modified by a factor of $1/\alpha$ or $1/(2\alpha+1)$ from the definitions (5) or (17).

Let us now indicate the motivation for the applications that will be discussed in the last two sections of this paper. Our Bargmann spaces can be associated with the range of the short-time Fourier transformation when applying a Gaussian window function, as first proposed in [18]. For a discussion of this fact and for a short historical review of the importance of the Bargmann space in signal analysis and in different contexts in mathematical physics, see [12]. Another source of much information is [25].

By making the standard transformation from the upper halfplane to the unit disk, our Bergman spaces can be associated with the range of the wavelet transformation when choosing as wavelet the function $g(t)$ with Fourier transform

$$\hat{g}(\xi) = \xi^{\alpha+1/2}\,e^{-\xi}$$

[22]. During the last few years there has been a great deal of interest in such transformations, and interesting applications have been found in signal analysis, quantum mechanics, applied mathematics, and harmonic analysis [19], [21], [22], [32], [8]. This particular choice of wavelet has been studied extensively by Paul from a quantum mechanical point of view [33], [34]. It leads to coherent state representations related to the radial harmonic oscillator and the Coulomb potential problem for the hydrogen atom.

Discrete representations (or discrete transformations) are, of course, of great importance for various practical and theoretical reasons. In our formulation a discrete representation will be associated with some discrete set of points either in $\mathbf{C}$ or in Δ. For regular lattices we have now reached an almost complete understanding [1], [13], [12], [9]. We urge the reader to consult [9], which should give the necessary background for the present discussion.

A related story should be mentioned here. Different orthonormal bases of wavelets have been discovered recently [41], [32], [2], [10], [30], which have quite amazing

mathematical properties and which have turned out to be of interest for many applications. There is also a recent discovery of a class of orthonormal bases that is related to the Bargmann case [14].

The kinds of lattices that are chosen for discrete representations for short-time Fourier and wavelet transformations may be compared to the usual regular sampling of bandlimited signals. The question has been raised to which extent analogues to results on irregular sampling of bandlimited signals can be found. It seems natural to start such an investigation in a situation which is similar to that of bandlimited signals in the sense that we have available spaces of holomorphic functions.

Returning to our Bargmann and Bergman spaces, let us make precise what we mean by "discrete representations." We say that $\{z_n\}$ is a *set of uniqueness* if

$$f(z_n)=0 \quad \text{for all } z_n \Rightarrow f\equiv 0.$$

This is equivalent to saying that the set $\{R(z_n, z)/R(z_n, z_n)^{1/2}\}$ is complete in the space at hand. $\{z_n\}$ is said to be a *set of interpolation* if to any square-integrable sequence $\{c_n\}$ there exists an f such that $f(z_n)/R(z_n, z_n)^{1/2}=c_n$ for all n.

If the sequences $\{f(z_n)\}$ are to represent the vectors f, we should obviously require $\{z_n\}$ to be a set of uniqueness. But we should also require the inversion problem to be well posed. This means that we need the operator $f\mapsto\{f(z_n)/R(z_n, z_n)^{1/2}\}$ into l^2 to be bounded and to have a bounded inverse. We state this by requiring that for all f in the space in question we should have

$$A\|f\|^2\leqq\sum\frac{|f(z_n)|^2}{R(z_n, z_n)}\leqq B\|f\|^2 \tag{20}$$

with $0<A\leqq B<\infty$. Following Landau [27] we shall say that $\{z_n\}$ is a *set of sampling* if this is satisfied, which is seen to be equivalent to saying that the set $\{R(z_n, z)/R(z_n, z_n)^{1/2}\}$ is a *frame* [16], [42]. The numbers A and B will be denoted the *frame bounds* of $\{z_n\}$. We observe that a set of sampling is in particular a set of uniquenesses.

There exists a kind of duality between sets of sampling and sets of interpolation, which was clearly formulated by Landau [27], [28] in connection with bandlimited signals. This will also be made precise by Theorem 4.4 of the present work. We observe that if $\{z_n\}$ is both a set of sampling and a set of interpolation, then the sequence $\{R(z_n, z)/R(z_n, z_n)^{1/2}\}$ constitutes a Riesz basis in the space at hand [42, p. 188].

4. Necessary density conditions for sampling and interpolation. For a discrete set of points Γ to be one of sampling, must the "density" of points in any part of the domain in question exceed some lower bound? Such a lower bound would correspond to the Nyquist rate of information theory. From what we know about sampling of bandlimited signals [27], [28] we might expect this to be the case. Were it not, we could, at least theoretically, find discrete representations that were more economic than the ones used now. Similarly, for Γ to be a set of interpolation, we would expect that the "density" of points in any part of the domain under consideration could not exceed some upper bound.

Guided by the work of Landau [27], [28], we shall search for such necessary conditions. But first we should know if the word "density" can be given a reasonable meaning.

Following Beurling [28, p. 47] we shall only be concerned with *uniformly discrete sets*, those sets which are separated by some least positive distance (in the Bergman case that is hyperbolic distance). In the Bargmann case we can easily borrow the

concept of density used by Landau [28, p. 47]. We thus fix some "nice" two-dimensional set I of measure 1, like the unit square or the unit disk/π. To any uniformly discrete set Γ we define $n^+(r)$ and $n^-(r)$ to be the largest and smallest number of points of Γ to be found in a translate of rI. We define upper and lower (uniform) densities of Γ,

$$D^+(\Gamma) = \limsup_{r\to\infty} \frac{n^+(rI)}{r^2} \quad \text{and} \quad D^-(\Gamma) = \liminf_{r\to\infty} \frac{n^-(rI)}{r^2}.$$

Landau shows that if the boundary of I has measure zero this definition is independent of I. If the upper and lower densities are equal, we define Γ to have (uniform) density $D(\Gamma) = D^+(\Gamma) = D^-(\Gamma)$.

We shall prove an analogue of Landau's result for bandlimited L^2 functions [27]: If Γ is a set of sampling then $D^-(\Gamma) \geqq m(S)/2\pi$, and if Γ is a set of interpolation then $D^+(\Gamma) \leqq m(S)/2\pi$ (here S denotes the frequency band which can consist of any finite number of intervals and $m(S)$ denotes the measure of S).

In the Bergman case the above density definitions are not well suited. If we chose the disk of unit area as the basic set I, and defined upper and lower densities as above, we would find that the sets constructed below would not have densities, that is, $D^+(\Gamma) > D^-(\Gamma)$. But our intuition tells us that, if any, these "regular" sets should have densities.

Similar problems have been pointed out in slightly different contexts in [9, p. 69] and in [11, I]. It seems to be an interesting challenge to find a suitable density concept in the hyperbolic case.

In both the Bargmann and the Bergman cases we shall exploit the similarities with the Paley-Wiener case to use the ideas contained in [27]. It will be shown that for the Bergman case we can at least find analogies to two of Landau's important auxiliary results, and we will point out the difficulty in finding a "complete" analogy.

Before stating the results, let us quite informally explain the idea of connecting concentration operators to our sampling/interpolation problem. For some large compact set Ω the number of eigenvalues of the corresponding concentration operator significantly different from zero gives us the "dimension" of the space of functions "concentrated" on Ω. Thus if the number of points in Ω from some discrete set Γ was much smaller than this "dimension," we could find a function which was zero at all the points in Ω, and which was essentially zero outside Ω. If this were the case for arbitrarily large Ω, we would expect that the left inequality in (20) could not be satisfied. A similar argument can be made for interpolation.

The following lemmas give estimates reflecting this rather loose statement.

LEMMA 4.1. *Suppose $\{z_k\}_{k=1}^{\infty}$ is a set of sampling. Let ζ be any point (in* **C** *or in* Δ*) and let $\{z_k^\zeta\}_{k=1}^{\infty}$ denote a reordering of this set such that*

$$0 \leqq d(z_1^\zeta, \zeta) \leqq d(z_2^\zeta, \zeta) \leqq \cdots.$$

Furthermore, let r be any positive number and let $n = n(r, \zeta)$ be the number such that

$$d(z_n^\zeta, \zeta) < r + \frac{\delta_0}{2} \leqq d(z_{n+1}^\zeta, \zeta)$$

(if such a number does not exist, define $n = n(r, \zeta) = 0$). Then there exists a constant $\gamma < 1$, independent of r and ζ, such that

$$\frac{|\tilde{\alpha}_n^\zeta|^2 \lambda_n(r) + \cdots + |\tilde{\alpha}_0^\zeta|^2 \lambda_0(r)}{|\tilde{\alpha}_n^\zeta|^2 + \cdots + |\tilde{\alpha}_0^\zeta|^2} \leqq \gamma, \tag{21}$$

where $\alpha_n^\zeta z^n + \cdots + \alpha_1^\zeta z + \alpha_0^\zeta = \prod_{k=1}^n (z - T_\zeta(z_k^\zeta))$ *and*

$$\tilde{\alpha}_k^\zeta = \begin{cases} \left(\dfrac{k!}{\alpha^{k-1}}\right)^{1/2} \alpha_k^\zeta & \textit{Bargmann case,} \\ \left(\dfrac{k!}{2(\alpha+1)\cdot(2(\alpha+1)+1)\cdots(2(\alpha+1)+k-1)}\right)^{1/2} \alpha_k^\zeta & \textit{Bergman case.} \end{cases}$$

Proof. Let $\phi_n^\zeta(z) = R(z,\zeta)\prod_{k=1}^n (T_\zeta(z) - T_\zeta(z_k^\zeta))$. Then

$$A\|\phi_n^\zeta\|^2 \leqq \sum_{k=1}^\infty \frac{|\phi_n^\zeta(z_k^\zeta)|^2}{R(z_k^\zeta, z_k^\zeta)} = \sum_{k=n+1}^\infty \frac{|\phi_n^\zeta(z_k^\zeta)|^2}{R(z_k^\zeta, z_k^\zeta)}.$$

By (19) and the Schwarz inequality we thus get

$$A\|\phi_n^\zeta\|^2 \leqq \frac{1}{\lambda_0(\delta_0/2)}\left(\|\phi_n^\zeta\|^2 - \int\int_{d(z,\zeta)<r} |\phi_n^\zeta(z)|^2\, d\omega(z)\right). \tag{22}$$

From the definitions of ϕ_n^ζ and of the eigenfunctions we may write

$$\phi_n^\zeta(z) = \frac{\|\phi_n^\zeta\|^2}{\sum_{k=0}^n |\tilde{\alpha}_k^\zeta|^2} \sum_{k=0}^n \tilde{\alpha}_k^\zeta f_n^\zeta(z).$$

We put this into the integral of (22) and invoke the double orthogonality and the concentration properties of the eigenfunctions to obtain (21) with $\gamma = 1 - A\lambda_0(\delta_0/2)$. □

Due to the simplicity of the eigenfunctions we have here obtained a sharpening of Lemma 1 of [27], that is, we observe that the above lemma implies the statement analogous to Landau's result.

LEMMA 4.2. *Let the conditions and definitions be as in Lemma* 4.1. *Then we have*

$$\lambda_n(r) \leqq \gamma \tag{23}$$

with γ *as in Lemma* 4.1.

To prove a sharpening of Landau's corresponding result on interpolation seems harder, and we confine ourselves to prove an analogue of Lemma 2 in [27].

LEMMA 4.3. *Suppose* $\{z_k\}_{k=1}^\infty$ *is a set of interpolation. Let* ζ *be any point (in* $\mathbf{C}$ *or in* Δ*) and let* $\{z_k^\zeta\}_{k=1}^\infty$ *denote a reordering of this set such that*

$$0 \leqq d(z_1^\zeta, \zeta) \leqq d(z_2^\zeta, \zeta) \leqq \cdots.$$

Furthermore, let r be any positive number and let $n = n(r,\zeta)$ *be the number such that*

$$d(z_n^\zeta, \zeta) < r - \frac{\delta_0}{2} \leqq d(z_{n+1}^\zeta, \zeta)$$

(if such a number does not exist, define $n = n(r,\zeta) = 0$ *and* $\lambda_{-1}(r) = 1$*). Then there exists a constant* $\delta > 0$*, independent of r and* ζ*, such that*

$$\lambda_{n-1}(r) \geqq \delta. \tag{24}$$

Proof. First we note that it is possible to perform the interpolation in a stable way. This happens if we interpolate in $E_0^\perp$, the orthogonal complement to the space E_0 of functions vanishing on $\{z_k\}$. Hence there exists a constant $A < \infty$ such that to any square-summable sequence $\{a_k\}$ there is a function $\phi \in E_0^\perp$ with $\phi(z_k)/R(z_k, z_k) = a_k$ and

$$A\|\phi\|^2 \leqq \sum |a_k|^2 = \sum \frac{|\phi(z_k)|^2}{R(z_k, z_k)}. \tag{25}$$

For a proof of this fact, see the proof of Proposition 1 in [27].

Second, we need the following form of the Weyl-Courant lemma

$$\lambda_{n-1}(r) \geqq \inf_{\phi \in C_n} \frac{\iint_{d(z,\zeta)<r} |\phi(z)|^2 \, d\omega(z)}{\iint |\phi(z)|^2 \, d\omega(z)}, \tag{26}$$

with C_n any subspace of dimension n. A proof can again be found in [27].

Next, let $\phi_k^\zeta \in E_0^\perp$ be the function whose value is 1 at z_k^ζ and zero at every z_j^ζ, $j \neq k$, and let $\tilde{C}_n = \operatorname{span}\{\phi_k^\zeta\}_{k=1}^n$. For any $\phi \in \tilde{C}_n$ we thus have

$$A\|\phi\|^2 \leqq \sum_{k=1}^{\infty} \frac{|\phi(z_k^\zeta)|^2}{R(z_k^\zeta, z_k^\zeta)} \leqq \sum_{k=1}^{n} \frac{|\phi(z_k^\zeta)|^2}{R(z_k^\zeta, z_k^\zeta)}.$$

By (19) and the Schwarz inequality we find

$$A\|\phi\|^2 \leqq \frac{1}{\lambda_0(\delta_0/2)} \iint_{d(x,y)<r} |\phi(z)|^2 \, d\omega(z).$$

Now the result follows from (26) with $\delta = A\lambda_0(\delta_0/2)$. □

We are now prepared to prove the following general result for the Bargmann case, stating that the Nyquist rate is a critical density both for sampling and for interpolation.

THEOREM 4.4. *In the Bargmann case we have the following. If the uniformly discrete set $\{z_n\}$ is a set of sampling, then $D^-(\{z_n\}) \geqq \alpha/\pi$. If the uniformly discrete set $\{z_n\}$ is a set of interpolation, then $D^+(\{z_n\}) \leqq \alpha/\pi$.*

Proof. We make use of the asymptotic behaviour of the eigenvalues ($0 < \delta < \gamma < 1$)

$$\frac{\#\{\lambda_k(R): \delta \leqq \lambda_k(R) < \gamma\}}{\pi R^2} = O(R^{-1}),$$

$$\frac{\#\{\lambda_k(R): \lambda_k(R) \geqq \tfrac{1}{2}\}}{\pi R^2} = \frac{\alpha}{\pi} + O(R^{-1})$$

(see [11, I]). Thus

$$\frac{\#\{\lambda_k(R): \lambda_k(R) \geqq \gamma\}}{\pi R^2} = \frac{\alpha}{\pi} + O(R^{-1}),$$

and so for $n(R, \zeta)$ of Lemma 4.2 we have

$$\frac{n(R,\zeta)}{\pi R^2} \geqq \frac{\alpha}{\pi} + O(R^{-1}),$$

proving the first part of the theorem. The second part follows in the same way by applying Lemma 4.3. □

Remark 1. We may ask if the inequalities above can be substituted by strict inequalities.

Remark 2. The above result can be viewed as a generalization of what is known for regular lattices [9].

The situation is more delicate in the Bergman case. From the fact that

$$\frac{\#\{\lambda_k(R): \delta \leqq \lambda_k(R) < \gamma\}}{|\Delta_0(R)|} = O(1) \tag{27}$$

(see [11, II], $|\cdot|$ here meaning hyperbolic area) we realize that an attempt to copy the proof of Theorem 4.4 will fail. In view of (27) it is clear that Lemma 4.2 is too weak in this case, and we may ask what can be deduced from Lemma 4.1. At least to indicate the complexity of this problem we construct a special family of point sets below, to which Lemma 4.1 applies.

Note, however, that by Lemma 4.2 and (33) we can conclude that the number of points in any disk D must be $O(|D|)$.

A family of point sets in the Bergman case. In this paragraph we will construct a point set depending on a parameter M which is to represent a characteristic distance between the points. The purpose is to show that this set cannot be one of sampling for M larger than a certain critical bound.

The basic idea of the construction is to place the points regularly in distance M at concentric circles of radii M, $2M$, $3M, \cdots$. We choose $\zeta = 0$ as the center and number the circles accordingly $1, 2, 3, \cdots$ (the choice of the origin as the center is for convenience only, the construction works equally well with any point $\zeta \in \Delta$ playing this role). In Fig. 1 we have drawn the points at the four first circles for $M = 1.1$ with the outer circle indicating the unit circle. How to determine the number of points at each circle is explained below.

Of course, the distance between the points cannot in general be equal to M. We show how to approximate the number of points at circle k. For this purpose, we recall the cosine rule of hyperbolic geometry [3, p. 148] (see Fig. 2)

$$\cosh c = \cosh a \cosh b - \sinh a \sinh b \cos \alpha.$$

In our case we get

$$\cos \alpha_k = \frac{\cosh^2 kM - \cosh M}{\sinh^2 kM} = 1 - \frac{\cosh M - 1}{\sinh^2 kM},$$

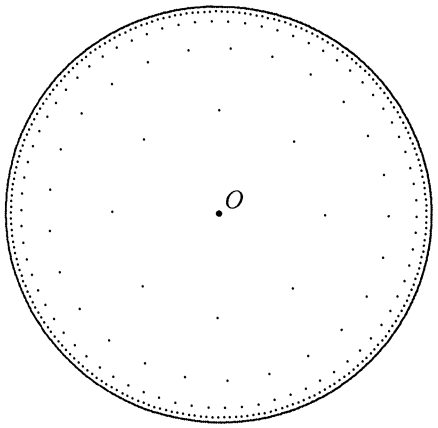

FIG. 1. *An example of a point set in the Bergman case.*

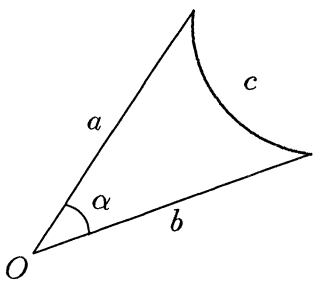

FIG. 2. *A hyperbolic triangle.*

α_k denoting the angle between the lines passing through two adjacent points at circle k and the origin. Since $\alpha_k \to 0$ as $k \to \infty$ we put

$$\alpha_k = \frac{\sqrt{2(\cosh M - 1)}}{\sinh kM}.$$

The number of points at circle k should therefore be approximately $2\pi/\alpha_k$. We define

$$n(k) = [C(M)\, e^{kM}], \tag{28}$$

where

$$C(M) = \frac{\pi}{\sqrt{2(\cosh M - 1)}},$$

and where we have defined $[x]$ to be the integer such that $x = [x] + \delta$ with $-\frac{1}{2} < \delta \leqq \frac{1}{2}$.

For computational ease we shall deviate a bit from the construction above. Let circle k have radius $(k+\varepsilon_k)M$, where ε_k is the solution of the equation

$$\left(\frac{1 - e^{-(k+\varepsilon_k)M}}{1 + e^{-(k+\varepsilon_k)M}}\right)^{[C(M)e^{kM}]} = e^{-2C(M)}.$$

It is easily seen that $\varepsilon_k \to 0$ as $k \to \infty$.

The introduction of the sequence $\{\varepsilon_k\}$ makes the polynomials associated with Lemma 4.1 comfortably simple. For a sufficiently large m, the polynomial $p_m(z)$ corresponding to $\zeta = 0$ and $r = mM$ takes the form

$$p_m(z) = \prod_{k=1}^{m} (z^{n(k)} - e^{-2C(M) + i\beta_k})$$

with $0 \leqq \beta_k < 2\pi$, depending on where we have chosen to arrange the points on each circle.

We next perform an ordering of the terms in this polynomial determined by the order of the exponents. We have

$$\sum_{j=1}^{l} n(j) = C(M)\, e^{M} \frac{e^{lM} - 1}{e^{M} - 1} + O(l) = O(n(l)). \tag{29}$$

Hence we see that the largest $n(k_i)$ appearing in the exponent of a term of the polynomial decides the order of this exponent. We add the coefficients (or rather the squares of the absolute values of the coefficients) of the terms of which $n(k)$ appears as the largest number in the exponent

$$\sum_{n(k)\,\text{largest}} |\alpha_l|^2 = \sum_{j=0}^{k-1} \binom{k-1}{j} e^{-4C(M)(m-j-1)} = e^{-4C(M)(m-1)}(1 + e^{4C(M)})^{k-1}. \tag{30}$$

For future use we note that the total sum of the coefficients is

$$\sum |\alpha_i|^2 = \sum_{k=1}^{m} \left(\sum_{n(k)\,\text{largest}} |\alpha_l|^2 \right) = e^{-4C(M)m}((1 + e^{4C(M)})^m - 1). \tag{31}$$

The scaling factor (cf. Lemma 4.1) of a term with exponent n can be approximated in the following way ($\theta = 2\alpha + 1$):

$$\begin{aligned} \frac{1 \cdot 2 \cdots n}{(\theta+1)\cdot(\theta+2)\cdots(\theta+n)} &= \frac{1 \cdot 2 \cdots n \cdot n^{\theta}}{(\theta+1)\cdot(\theta+2)\cdots(\theta+n)} \cdot n^{-\theta} \\ &= (\Gamma(\theta+1) + e_n) n^{-\theta}, \end{aligned} \tag{32}$$

with $e_n \geqq 0$ and $e_n = O(n^{-1})$. Thus we have for terms with exponent of order $n(k)$

$$\sum_{n(k)\,\text{largest}} |\tilde{\alpha}_l|^2 = O(\exp(-4C(M)m + k(\ln(1+e^{4C(M)}) - M\theta))).$$

This indicates that if our point set is one of sampling, we have

$$M < \theta^{-1} \ln(1+e^{4C(M)})$$

(otherwise the "larger" eigenvalues would dominate the left-hand side of (21) which then could not be expected to be bounded away from 1). We proceed to show that this is indeed the case.

We have

$$\lambda_n(r) = \frac{c_n \pi}{n!} \int_0^{\tanh^2 r/2} t^n (1-t)^{\theta-1}\, dt = 1 - \frac{c_n \pi}{n!} \int_{\tanh^2 r/2}^1 t^n (1-t)^{\theta-1}\, dt \tag{33}$$

$$\geqq 1 - \frac{c_n \pi}{\theta n!} \left(1 - \tanh^2 \frac{1}{2} r\right)^{\theta}.$$

From this we find

$$\frac{\sum |\tilde{\alpha}_i|^2 \lambda_i}{\sum |\tilde{\alpha}_i|^2} \geqq 1 - \cosh^{-2\theta}\left(\frac{1}{2} r\right) \frac{\sum |\alpha_i|^2}{\sum |\tilde{\alpha}_i|^2}. \tag{34}$$

From (30) and (32) we find

$$\sum_{n(k)\,\text{largest}} |\tilde{\alpha}_l|^2 \geqq A(M, \theta) \exp(-4C(M)m + (k-1)(\ln(1+e^{4C(M)}) - M\theta)), \tag{35}$$

where we can choose

$$A(M, \theta) = \Gamma(\theta+1) \left(\frac{C(M)\, e^M}{e^M - 1} + \frac{1}{2M}\right)^{-\theta} e^{4C(M) - M\theta}.$$

Here we have used the following estimate for the exponents l in (35):

$$l \leqq \sum_{j=1}^{k} n(j) \leqq C(M)\, e^M \frac{e^{kM} - 1}{e^M - 1} + \frac{1}{2} k \leqq \left(\frac{C(M)\, e^M}{e^M - 1} + \frac{1}{2M}\right) e^{kM}.$$

Thus we have

$$\sum |\tilde{\alpha}_i|^2 \geqq A(M, \theta)\, e^{-4C(M)m} \sum_{k=0}^{m-1} \exp(k(\ln(1+e^{4C(M)}) - M\theta)),$$

in other words,

$$\sum |\tilde{\alpha}_i|^2 \geqq \begin{cases} A'(M, \theta)\, e^{-4C(M)m}(1 - \exp(m(\ln(1+e^{4C(M)}) - M\theta))), & \\ & \ln(1+e^{4C(M)}) \neq M\theta, \\ A(M, \theta)\, e^{-4C(M)m} m, & \ln(1+e^{4C(M)}) = M\theta, \end{cases} \tag{36}$$

where

$$A'(M, \theta) = A(M, \theta)(1 - \exp(\ln(1+e^{4C(M)}) - M\theta))^{-1}.$$

The radius corresponding to $p_m(z)$ is mM, and consequently

$$\cosh^{-2\theta}(\tfrac{1}{2}r) \leqq 4^{\theta}\, e^{-mM\theta}.$$

We are now ready to draw the desired conclusion. For the case $\ln(1+e^{4C(M)}) < M\theta$ we have from (34) and (36) (with $B(M,\theta) = 4^{\theta}(A'(M,\theta))^{-1}$)

$$\frac{\sum |\tilde{\alpha}_i|^2 \lambda_i}{\sum |\tilde{\alpha}_i|^2} \geqq 1 - B(M,\theta) \frac{\exp(m(\ln(1+e^{4C(M)}) - M\theta)) - e^{-mM\theta}}{1 - \exp(m(\ln(1+e^{4C(M)}) - M\theta))} \to 1$$

as $m \to \infty$, contradicting Lemma 4.1.

For the case $M\theta = \ln(1+e^{4C(M)})$ we find from (34) and (36) (with $B(M,\theta) = 4^{\theta}(A(M,\theta))^{-1}$)

$$\frac{\sum |\tilde{\alpha}_i|^2 \lambda_i}{\sum |\tilde{\alpha}_i|^2} \geqq 1 - B(M,\theta) \frac{1 - e^{-mM\theta}}{m} \to 1$$

as $m \to \infty$, again contradicting Lemma 4.1.

We conclude that if a point set as constructed above is a set of sampling then we have $M/\ln(1+e^{4C(M)}) < (2\alpha+1)^{-1}$.

We remark that in a similar manner it can be proved that inequality (21) with $\zeta = 0$ is indeed satisfied when $M\theta < \ln(1+e^{4C(M)})$. This indicates that what has been found above is the sharpest result that can be deduced from Lemma 4.1.

We now prepare for an interesting observation on the asymptotics of the above inequality. First, we have

$$C(M) = \frac{2\pi}{\sinh(M/2)},$$

yielding for small M

$$M/\ln(1+e^{4C(M)}) = \frac{M^2}{4\pi} + O(M^3). \tag{37}$$

Next, as pointed out in the introduction of [23] the Bargmann case can formally be considered as the limiting case $\alpha \to \infty$. To see this we look at the scaled disk $R\Delta$, put $2\alpha = \tilde{\alpha}R^2$, let $R \to \infty$ and make use of the fact that $(1-|z|^2/R^2)^{\tilde{\alpha}R^2} \to e^{-\tilde{\alpha}|z|^2}$. Finally, observe that close to zero we have, loosely speaking, a Euclidean distance E corresponding to M with $M = 2E$.

We bring these remarks together, rewrite the necessary condition on M as

$$\frac{1}{(ER)^2} > \frac{\tilde{\alpha}}{\pi} + O(E),$$

and observe that formally we recapture the first part of Theorem 4.4.

The interest in the above calculation is not the fact that M cannot be too large since this is well known (for large M there are nonzero functions vanishing on these sets, see [20], [35]). What is interesting is the exact bound, the significance of which is indicated by our formal passage to the Nyquist density.

5. Jittered sampling. The purpose of this section is to show that the family of sets of sampling is in a sense an open set. This we will do by deducing estimates for the frame bounds for jitters of actual sets of sampling.

We should remark that there are available existence results of the following kind (incompletely quoted) [7], [37], [23], [31]. There exists a number $L_0 > 0$ such that if $\{z_n\}$ is any L-lattice (to be defined below) and $L < L_0$, then $\{z_n\}$ is a set of sampling. But we would like to know what is the value of L_0 and how we could estimate the frame bounds.

We shall borrow an idea from the theory of nonharmonic Fourier series [15]. It was used in the proof of one of the forerunners to Kadec's $\frac{1}{4}$-theorem [24]. In [15] it is shown that $\{e^{it_n\xi}\}$ is a Riesz basis for $L^2[-\pi, \pi]$ if $\sup_n |t_n - n| < \log 2/\pi \approx 0.22$ (by [24] the best possible constant is $\frac{1}{4}$). We combine this idea with the local analysis provided by our eigenfunction expansions.

We consider again uniformly discrete sets $\{z_n\}$ of complex numbers. Let us measure the distance between two such sets by

$$\rho(\{z_n\}, \{\zeta_n\}) = \sup_n d(z_n, \zeta_n).$$

We say that $\{\zeta_n\}$ is an *M-jitter* of $\{z_n\}$ if $\rho(\{z_n\}, \{\zeta_n\}) = M < \infty$.

Suppose $\{z_n\}$ has separating distance $2\delta_0 > 0$ and let $\{\zeta_n\}$ be an M-jitter of $\{z_n\}$ with $M < \delta_0$. In the Bargmann case define

$$D(M, \delta_0, A) = \frac{e^{\alpha\delta_0^2}}{(\alpha\delta_0)^2}(1 - A\lambda_0(\delta_0))\left(\left(1 - \frac{M^2}{\delta_0^2}\right)^{-2} - 1\right) \tag{38}$$

and in the Bergman case

$$D(M, \delta_0, A) = \frac{\min\{1, \cosh^{-4\alpha}(\delta_0/2)\}}{(2\alpha+1)\tanh^2(\delta_0/2)}(1 - A\lambda_0(\delta_0))\left(\left(1 - \frac{\tanh^2(M/2)}{\tanh^2(\delta_0/2)}\right)^{-2} - 1\right). \tag{39}$$

With this notation we have the following theorem.

THEOREM 5.1. *Suppose that $\{z_n\}$ with separating distance $2\delta_0$ is a set of sampling with frame bounds A and B. Let M_0 $(< \delta_0)$ be the positive number such that $D(M_0, \delta_0, A) = A$. Then any M-jitter $\{\zeta_n\}$ of $\{z_n\}$ with $M < M_0$ is a set of sampling, and for its frame bounds $\tilde{A}$ and $\tilde{B}$ we have*

$$\tilde{A} \geqq \begin{cases} e^{-\alpha M^2}(\sqrt{A} - \sqrt{D(M, \delta_0, A)})^2 & \text{Bargmann case,} \\ \cosh^{-4\alpha+4}(\tfrac{1}{2}M)(\sqrt{A} - \sqrt{D(M, \delta_0, A)})^2 & \text{Bergman case,} \end{cases} \tag{40}$$

$$\tilde{B} \leqq (\sqrt{B} + \sqrt{D(M, \delta_0, A)})^2. \tag{41}$$

Proof. Let $\{\zeta_n\}$ be an M-jitter of $\{z_n\}$ and f any function in the space at hand. The key to the proof is the following estimate:

$$\sum \left| \frac{R(z_n, z_n)^{1/2} f(\zeta_n)}{R(\zeta_n, z_n)} - \frac{f(z_n)}{R(z_n, z_n)^{1/2}} \right|^2 \leqq D(M, \delta_0, A)\|f\|^2. \tag{42}$$

Let us first show that (42) proves the theorem.

In the Bargmann case we have the identity

$$\frac{R(z, z)^{1/2}}{|R(\zeta, z)} = \frac{\exp(\frac{1}{2}\alpha|z - \zeta|^2)}{R(\zeta, \zeta)^{1/2}},$$

yielding

$$\frac{1}{R(\zeta_n, \zeta_n)^{1/2}} \leqq \frac{R(z_n, z_n)^{1/2}}{|R(\zeta_n, z_n)|} \leqq \frac{\exp(\frac{1}{2}\alpha M^2)}{R(\zeta_n, \zeta_n)^{1/2}}. \tag{43}$$

In the Bergman case we use the identity (see [3, p. 132])

$$\frac{R(z, z)^{1/2}}{|R(\zeta, z)|} = \frac{\cosh^{2\alpha+2}\frac{1}{2}d(z, \zeta)}{R(\zeta, \zeta)^{1/2}},$$

which leads to

$$\frac{1}{R(\zeta_n, \zeta_n)^{1/2}} \leqq \frac{R(z_n, z_n)^{1/2}}{|R(\zeta_n, z_n)|} \leqq \frac{\cosh^{2\alpha+2}\frac{1}{2}M}{R(\zeta_n, \zeta_n)^{1/2}}. \tag{44}$$

By (43) or (44) and Minkowski's inqeuality, (42) implies

$$\left(\sum \frac{|f(\zeta_n)|^2}{R(\zeta_n, \zeta_n)}\right)^{1/2} \leqq \sqrt{D(M, \delta_0, A)}\|f\| + \left(\sum \frac{|f(z_n)|^2}{R(z_n, z_n)}\right)^{1/2}.$$

By the definition of B we arrive at (41). Similarly, by (43) or (44) and Minkowski's inequality we see that (42) implies (40).

We next turn to the proof of (42). To this end we expand $f(z)$ into the eigenfunctions associated with z_n,

$$f(z) = \sum_{k=0}^{\infty} (f, f_k^{z_n}) f_k^{z_n}(z). \tag{45}$$

By the double orthogonality and the fact that $f_0^{z_n}$ acts reproducingly this gives

$$\int_{\Delta_{z_n}(\delta_0)} |f(z)|^2 \, d\omega(z) = \lambda_0(\delta_0) \frac{|f(z_n)|^2}{R(z_n, z_n)} + \sum_{k=1}^{\infty} \lambda_k(\delta_0) |(f, f_k^{z_n})|^2.$$

On summing over n and using the definition of A, we get

$$\sum_n \sum_{k=1}^{\infty} \lambda_k(\delta_0) |(f, f_k^{z_n})|^2 \leqq (1 - A\lambda_0(\delta_0)) \|f\|^2. \tag{46}$$

Let us now put $z = \zeta_n$ in (45). This yields

$$f(\zeta_n) = \frac{R(\zeta_n, z_n)}{R(z_n, z_n)} f(z_n) + R(\zeta_n, z_n) \sum_{k=1}^{\infty} \rho_k^{z_n} (f, f_k^{z_n}) (T_{z_n} \zeta_n)^k. \tag{47}$$

At this stage we split the discussion and treat the two cases separately.

In the Bargmann case (47) implies

$$\frac{R(z_n, z_n)^{1/2} f(\zeta_n)}{R(\zeta_n, z_n)} - \frac{f(z_n)}{R(z_n, z_n)^{1/2}} = \sum_{k=1}^{\infty} \sqrt{\frac{\alpha^{k-1}}{k!}} (f, f_k^{z_n}) (T_{z_n} \zeta_n)^k.$$

To estimate this sum we multiply and divide the kth term by $\delta_0^k / \sqrt{k+1}$ $(k = 1, 2, \cdots)$. By Hölder's inequality we then get

$$\left| \frac{R(z_n, z_n)^{1/2} f(\zeta_n)}{R(\zeta_n, z_n)} - \frac{f(z_n)}{R(z_n, z_n)^{1/2}} \right|^2 \leqq \sum_{k=1}^{\infty} \frac{\alpha^{k-1} \delta_0^{2k}}{k!(k+1)} |(f, f_k^{z_n})|^2 \sum_{j=1}^{\infty} (j+1) \frac{|z_n - \zeta_n|^{2j}}{\delta_0^{2j}}. \tag{48}$$

By the identity

$$\sum_{j=1}^{\infty} (j+1) x^j = \frac{1}{1-x} - 1$$

the last sum in (48) is found to be bounded by $(1 - M^2/\delta_0^2)^{-2} - 1$.

We next sum (48) over n. To apply (46) we use the estimate

$$\lambda_k(\delta_0) = \frac{1}{k!} \int_0^{\alpha\delta_0^2} t^k e^{-t} \, dt \geqq \frac{e^{-\alpha\delta_0^2} (\alpha\delta_0^2)^{k+1}}{k!(k+1)},$$

and we find we have arrived at (42).

The argument is exactly the same in the Bergman case. Here (47) implies

$$\frac{R(z_n, z_n)^{1/2} f(\zeta_n)}{R(\zeta_n, z_n)} - \frac{f(z_n)}{R(z_n, z_n)^{1/2}} = \sum_{k=1}^{\infty} \sqrt{\frac{c_k \pi}{k!(2\alpha+1)}} (f, f_k^{z_n}) (T_{z_n} \zeta_n)^k.$$

We use the estimate

$$\frac{k!(2\alpha+1)\lambda_k(\delta_0)}{c_k\pi} = (2\alpha+1)\int_0^{\tanh^2(\delta_0/2)} t^k(1-t)^2\,dt$$

$$\geqq (2\alpha+1)\min\left\{1, \cosh^{-4\alpha}\frac{\delta_0}{2}\right\}\frac{\tanh^{2(k+1)}(\delta_0/2)}{k+1}$$

and the identity

$$|T_z\zeta| = \tanh\left(\tfrac{1}{2}d(z,\zeta)\right)$$

(see [3, p. 132]) and obtain (42) in the same way as above. □

A slight modificaiton of the argument above shows that the frame bounds depend continuously on the jitters.

Let us now say that a uniformly discrete set $\{\zeta_n\}$ is an *L-lattice* if to any point z (in $\mathbf{C}$ or in Δ) there exists an n such that $d(z,\zeta_n)\leqq L$. With this notation we note the following, which gives us a numerical estimate for the number L_0 mentioned in the introduction to this section.

COROLLARY 5.2. *Let*

$$L_0 = \sup_{\{z_n\}}\{L\colon L<\delta_0(\{z_n\}) \text{ and } A(\{z_n\}) = D(L,\delta_0(\{z_n\}), A(\{z_n\}))\},$$

where the supremum is taken over all uniformly discrete sets $\{z_n\}$ *(each with separating distance* $2\delta_0(\{z_n\})$*) and where*

$$A(\{z_n\}) = \inf_{\|f\|\neq 0}\frac{\sum(|f(z_n)|^2/R(z_n,z_n))}{\|f\|^2}.$$

Then any L-lattice with $L<L_0$ *is a set of sampling.*

Proof. Let $\{\zeta_n\}$ be any L-lattice with $L<L_0$. By definition $\{\zeta_n\}$ is uniformly discrete, say with separating distance $2\tilde{\delta}_0$. So by (19) and the Schwarz inequality we have

$$\sum\frac{|f(z_n)|^2}{R(z_n,z_n))}\leqq\frac{1}{\lambda_0(\tilde{\delta}_0)}\|f\|^2.$$

Since $L<L_0$ we can find a set $\{z_k\}$ such that

$$A = A(\{z_k\}) > D(L,\delta_0,A) \tag{49}$$

and $L<\delta_0$ where we have assumed $\{z_k\}$ to have separating distance $2\delta_0$. Since $\{\zeta_n\}$ is an L-lattice we can pick a subsequence $\{\zeta_{n(k)}\}$ such that

$$\rho(\{\zeta_{n(k)}\},\{z_k\})\leqq L.$$

We have

$$\sum_n\frac{|f(\zeta_n)|^2}{R(\zeta_n,\zeta_n)}\geqq\sum_k\frac{|f(\zeta_{n(k)})|^2}{R(\zeta_{n(k)},\zeta_{n(k)})}$$

and since $\{\zeta_{n(k)}\}$ is an M-jitter of $\{z_k\}$ with $M\leqq L$, the existence of a lower frame bound follows from (49) and Theorem 5.1. □

We should remark that the existence of $L_0>0$ and the possibility of estimating it are ensured by the results in [9].

Acknowledgments. The author takes pleasure in thanking Henrik H. Martens for stimulating discussions throughout this work. Among the various valuable comments

of the referees the author is especially grateful for the one that led him to the formal passage from the Bergman to the Bargmann case at the end of § 4.

Note added in proof (Remark to Theorem 4.4.). Recently R. Wallstén and the author have proved that $D^- > \alpha/\pi$ and $D^+ < \alpha/\pi$ are also sufficient in the respective cases, a result that will appear in a forthcoming publication.

LONGTIME BEHAVIOUR OF STRONGLY DAMPED WAVE EQUATIONS, GLOBAL ATTRACTORS AND THEIR DIMENSION*

J. M. GHIDAGLIA† AND A. MARZOCCHI‡

Abstract. This paper contains some results on asymptotic behaviour of solutions to strongly damped abstract nonlinear wave equations. After reviewing sufficient hypotheses for existence and uniqueness, uniform time estimates are given and a global attractor for the trajectories of the associated dynamical system is constructed. Finally, applications are made to nonlinear wave equations such as Sine-Gordon equation, proving the finite dimensionality of the corresponding attractors.

Key words. nonlinear wave equations, attractors, asymptotic behaviour

AMS(MOS) subject classifications. 35L70, 35B40

Introduction. In this paper we study the longtime behaviour of strongly damped wave equations. We address the case where an external excitation drives the solutions and where nontrivial attractors occur. One of our main results concerns the dimension of these sets that we show to be finite. Let us begin by mentioning two applications that have motivated this work. Firstly, the perturbed Sine-Gordon equation

$$\frac{\partial^2 u}{\partial t^2} - \Delta u + \sin u = -\beta \frac{\partial u}{\partial t} + \alpha \frac{\partial(\Delta u)}{\partial t} + f, \tag{0.1}$$

where $u(x, t)$ is the current in a Josephson junction (see, e.g., [1]), x is the space variable and (0.1) is posed in a bounded domain Ω in $\mathbb{R}^n$ (with appropriate boundary conditions). The parameters α and β are nonnegative and correspond to loss effects. We are concerned in this work with the case where $\alpha > 0$ (refer to [2], [3] for the case $\alpha = 0$). The function $f, f(x, t)$, is time-periodic and figures the external current that drives the device. Another example reads

$$\frac{\partial^2 u}{\partial t^2} - \Delta u + |u|^q u = -\beta \left|\frac{\partial u}{\partial t}\right|^p \frac{\partial u}{\partial t} + \alpha \frac{\partial(\Delta u)}{\partial t} + f, \tag{0.2}$$

which is also a perturbed wave equation occurring in quantum mechanics.

These partial differential equations can be seen as infinite-dimensional dynamical systems, and the questions we address in this paper are related to determining whether or not these systems depend on a finite number of degrees of freedom after a transient period. A mathematical approach to this type of problem has been introduced for dissipative parabolic equations, motivated by the study of turbulence in fluids. It was proved that a global attractor exists and captures all the solutions as time goes to infinity, and that this set was finite dimensional. A bound on this dimension provides an estimate on the number of degrees of freedom in the longtime behaviour.

This point of view has been developed for many other types of partial differential equations such as (weakly) damped wave equations, coupled systems, etc. (see Temam [5] for a recent review), and more recently for nonlinear dispersive equations ([6], [7]).

In this article, we shall consider an abstract evolution equation which can be written as

$$\frac{d^2u}{dt^2}+\alpha A\frac{du}{dt}+Au+g(u)+h(u_t)=f, \tag{0.3}$$

where A is a linear positive operator (see below) and show, under several hypotheses, that its longtime behaviour is also described by a global attractor. Results in this direction were derived by Massatt [8] and Webb [9] under quite restrictive hypotheses on the nonlinear terms (g and h). Our techniques are completely different from those in [8] and [9] and we are able, for example, to handle nongradient systems or periodically driven equations. Then, in § 4 we give sufficient conditions on the nonlinear terms g and h that insure the finite dimension of this attractor.

1. Review and complements on the Cauchy problem.

1.1. Functional setting and the linear semigroup. Let H be a real Hilbert space and A a positive linear self-adjoint unbounded operator with domain $D(A)=\{v\in H\,|\,Av\in H\}$ which is dense in H. The space $D(A)$ is a Banach space when endowed with the graph norm $v\to\|v\|_H^2+\|Av\|_H^2$. We will suppose furthermore that $A: D(A)\to H$ is an isomorphism and that A^{-1} is a compact operator. Under these hypotheses it is possible to define the power A^s of $A(s\in\mathbb{R})$ and to see that the spaces

$$V_{2s}=D(A^s)\qquad(s\in\mathbb{R})$$

are Hilbert spaces with scalar products and norms:

$$(u,v)_{2s}=(A^su,A^sv)_H,$$
$$\|u\|_{V_{2s}}=(u,u)_{2s}^{1/2},$$

respectively.

For the sake of notational simplicity we will write throughout the paper

$$(\cdot,\cdot)\quad\text{for }(\cdot,\cdot)_H,$$
$$|\cdot|_{2s}\quad\text{for }\|\cdot\|_{V_{2s}},$$
$$|\cdot|\quad\text{for }|\cdot|_0,$$
$$\|\cdot\|\quad\text{for }|\cdot|_1.$$

Furthermore, we identify H with its dual, which leads to identify V_{-s} with the dual of V_s, and denote also by $(\cdot,\cdot)$ the duality pairing between these spaces.

Let $I\subset\mathbb{R}$ be an interval and X a Banach space with norm $\|\cdot\|_X$. Let $p\in[1,\infty]$ and

$$L^p(I;X)=\{f\,|\,f: I\to X\text{ such that }\|f\|_X(t)\in L^p(I)\}$$

be the space of all X-value functions and L^p-integrable on I. These spaces are Banach spaces when endowed with the norms

$$\|f\|_{L^p(I;X)}=\left[\int_I(\|f\|_X(t))^p\,dt\right]^{1/p}\quad\text{if }1\leqq p<\infty,$$
$$\|f\|_{L^\infty(I;X)}=\operatorname*{ess\,sup}_{t\in I}\{\|f\|_X(t)\}\quad\text{if }p=\infty.$$

Moreover, let $C(I;X)$ be the space of all continuous functions from I into X and $C_b(I;X)=C(I;X)\cap L^\infty(I;X)$ the subspace of the bounded ones.

When inserted in the abstract framework introduced above, the strongly damped wave equation we will consider generalizes as (u_t denote the time derivative)

$$\begin{aligned} &u_{tt}+\alpha Au_t+Au+g(u)+h(u_t)=f(t),\\ &u(0)=u_0, \qquad u_t(0)=u_1, \end{aligned} \tag{1.1}$$

where $\alpha\in\mathbb{R}^+$, f is a given function $I\to H$, and g, h represent given nonlinear mappings whose properties are to be specified later.

As it is well known (see, e.g., [5]) in the linear case, i.e., the case where f, g, and h vanish, (1.1) defines a linear semigroup on $V_1\times H$ which we denote by $\Sigma(t)$:

$$\Sigma(t):(u_0,u_1)\to(u(t),u_t(t)), \qquad t\geqq 0.$$

When $\alpha=0$ we recover the usual wave propagator (which is a unitary group) while when $\alpha>0$ (the dissipative case), the $\Sigma(t)$ are no longer invertible and the trajectory tends exponentially to zero as $t\to+\infty$, as we will see in Proposition 1.1.

1.2. The nonlinear semigroup. In this section we give sufficient conditions that ensure the existence and uniqueness of solutions to (1.1). Although it seems well known that the hypotheses below lead to the desired results, we have not been able to locate them in the literature (see, e.g., [8], [9] for related conditions). The results rely on the classical energy method, i.e., on some a priori estimates on the solutions of (1.1). We consider a smooth solution of (1.1), and assume that the nonlinear interaction term can be split as

$$g(v)=G'(v)+p(v), \tag{1.2}$$

where $G\in C^1(V,\mathbb{R})$ satisfies $G(0)=0$ and $p\in C^0(V, V_{-1})$. The scalar product of (1.1) with u_t in H leads to the "energy relation"

$$\frac{1}{2}\frac{d}{dt}(|u_t|^2+\|u\|^2+2G(u))+\alpha\|u_t\|^2+(h(u_t),u_t)+(p(u),u_t)=(f,u_t). \tag{1.3}$$

In order to deduce from this relation some estimates on the solutions we make the following hypotheses:

$$\text{(H1)} \qquad \liminf_{\|v\|\to\infty}\frac{G(v)}{\|v\|^2}\geqq 0;$$

$$\text{(H2)} \qquad \exists C_1>0,\quad \sigma_1>0 \quad \text{such that} \quad |p(v)|_{-1}^2\leqq C_1(1+|G(v)|)^{1-\sigma_1} \quad \forall v\in V;$$

$$\text{(H3)} \qquad \exists C_2>0,\quad \sigma_2>0 \quad \text{such that} \quad (h(v),v)\geqq -C_2(1+\|v\|^2)^{1-\sigma_2} \quad \forall v\in V.$$

Assuming that the external force term f satisfies $f\in L^2(0,T;V_{-1})$ for all $T>0$, it is straightforward to derive from the above hypotheses an a priori bound on the smooth solutions of (1.1). Existence of solutions can be then obtained via the usual Faedo-Galerkin method. However, supplementary hypotheses are needed in order to pass to the limit in the nonlinear terms. Hence we will assume furthermore that g and h are locally Lipschitzian in the following sense.

There exists $\delta\in]0,1]$ such that for every $R>0$, there exists $C_3=C_3(R)$ and $C_4=C_4(R)$ satisfying

$$\text{(H4)} \qquad |g(v)-g(w)|_{-1}\leqq C_3|v-w|_{1-\delta} \quad \forall v,w\in V \quad \|v\|,\|w\|\leqq R;$$

$$\text{(H5)} \qquad |h(v)-h(w)|_{-1}\leqq C_4(\|v\|+\|w\|)|v-w|_{1-\delta} \quad \forall v,w\in V \quad \|v\|,\|w\|\leqq R.$$

Under these hypotheses (i.e., (H1)-(H5)), for every $f \in L^2(0, T; V_{-1})$ for all $T > 0$ and $u_0 \in V$, $u_1 \in H$ there exists an unique function $u(t)$ such that

$$u \in C(\mathbb{R}^+; V), \qquad u_t \in C(\mathbb{R}^+, H) \cap L^2(0, T; V) \quad \forall T > 0$$

that satisfies (1.1).

Moreover, if f is time independent, i.e., $f(t) \equiv f \in V_{-1}$, the mappings

$$S(t) = \{u_0, u_1\} \to \{u(t), u_t(t)\}$$

form a semigroup on $V \times H$: that is, for fixed $t > 0$, $S(t)$ is continuous on $V \times H$ and

$$S(0) = I, \qquad S(t_1 + t_2) = S(t_1) \circ S(t_2), \quad t_1, t_2 > 0.$$

2. Bounded absorbing sets and attractors.

2.1. Time-uniform estimates in $V_1 \times H$.

2.1.1. The linear case. In this section we show the decay to zero of the linear operator $\Sigma(t)$ as $t \to +\infty$, as we have announced before.

PROPOSITION 2.1. *Let λ_1 be the first eigenvalue of A and set $\varepsilon_0 = \min(1/\alpha, \alpha\lambda_1/(2(1+\lambda_1)))$. Then, for every $\varepsilon \in]0, \varepsilon_0[$,*

$$|\{u, v\}|_\varepsilon^2 \equiv (1 - \varepsilon\alpha)\|u\|^2 + \varepsilon^2|u|^2 + |v + \varepsilon u|^2$$

induces a norm on $V_1 \times H$, equivalent to the usual one, and for every $\{u_0, u_1\} \in V_1 \times H$, we have

$$|\Sigma(t)\{u_0, u_1\}|_\varepsilon \leqq e^{-\varepsilon t}|\{u_0, u_1\}|_\varepsilon \quad \forall t \geqq 0. \tag{2.1}$$

Proof. Actually we are going to show a slightly stronger result than (2.1). We take $g = h = 0$ and $f \in V_{-1}$ and denote by $\{u(t), u_t(t)\}$ the solution of (1.1). Then

$$|\{u, v\}|_\varepsilon^2 \leqq |\{u_0, v_0\}|^2 \, e^{-2\varepsilon t} + \frac{(1 - e^{-2\varepsilon t})}{2\alpha\varepsilon}|f|_{-1}^2. \tag{2.2}$$

In order to prove (2.2) we set $v = u_t + \varepsilon u$, where $\varepsilon \leqq \varepsilon_0$. Thus

$$v_t = u_{tt} + \varepsilon u_t = u_{tt} + \varepsilon(v - \varepsilon u), \tag{2.3}$$

and making use of (1.1) we find

$$\begin{aligned} &v_t + (1 - \varepsilon\alpha)Au + \varepsilon^2 u + (\alpha A - \varepsilon)v = f, \\ &u_t = v - \varepsilon u. \end{aligned} \tag{2.4}$$

Taking the scalar product of $(2.4)_1$ with v we have

$$\frac{1}{2}\frac{d}{dt}|v|^2 + (1 - \varepsilon\alpha)(Au, v) + \varepsilon^2(u, v) + ((\alpha A - \varepsilon)v, u) = (f, v), \tag{2.5}$$

and using $(2.4)_2$, we can deduce that

$$(Au, v) = \frac{1}{2}\frac{d}{dt}\|u\|^2 + \varepsilon\|u\|^2,$$

$$(u, v) = \frac{1}{2}\frac{d}{dt}|u|^2 + \varepsilon|u|^2.$$

Substituting in (2.2) we get

$$\frac{1}{2}\frac{d}{dt}[(1 - \varepsilon\alpha)\|u\|^2 + |v|^2 + \varepsilon^2|u|^2] + \varepsilon(1 - \varepsilon\alpha)\|u\|^2 + ((\alpha A - \varepsilon)v, u) + \varepsilon^3|u|^2 = (f, v). \tag{2.6}$$

Now, we have that

$$\lambda_1|v|^2 \leqq \|v\|^2.$$

Thus, thanks to the hypotheses made on ε, it is easy to see that

$$((\alpha A-\varepsilon)u, v) \geqq \frac{\alpha}{2}\|v\|^2+\varepsilon|v|^2, \tag{2.7}$$

so that by (2.6) we get, setting $y=|\{u, v\}|_\varepsilon^2$,

$$\frac{1}{2}\frac{dy}{dt}+\varepsilon y+\frac{\alpha}{2}\|v\|^2 \leqq |f|_{L^\infty(\mathbb{R}^+, V_{-1})}\|v\| \leqq \frac{\alpha}{2}\|v\|^2+\frac{1}{2\alpha}|f|^2_{L^\infty(\mathbb{R}^+, H)}. \tag{2.8}$$

By this and Gronwall's lemma it is straightforward to derive (2.2). □

By (2.2) the following result also follows:

$$\|\Sigma_\varepsilon(t)\{u_0, u_1+\varepsilon u_0\}\|_{V_1\times H} \leqq e^{-2\varepsilon t}\|\{u_0, u_1+\varepsilon u_0\}\|_{V_1\times H} \quad \forall t \geqq 0, \quad \forall \varepsilon \in]0, \varepsilon_0]. \tag{2.9}$$

2.1.2. The nonlinear case. In order to obtain estimates similar to those of the preceding paragraph we need two more assumptions on the nonlinear terms. Hence we assume that there exists $C_5>0$ such that

$$\liminf_{\|v\|\to+\infty}\frac{(v, g(v))-C_5G(v)}{\|v\|^2} \geqq 0 \tag{H6}$$

and there exist $C_6>0$ and $\sigma_3>0$ such that

$$|h(v)|_{-1} \leqq C_4(1+\|v\|)^{1-\sigma_3} \quad \forall v \in V. \tag{H7}$$

This last hypothesis is somewhat restrictive but we shall relax it below; see Remark 2.2. We are now in position to prove the following.

PROPOSITION 2.2. *Let $f \in H$ and g, h satisfy hypotheses* (H1), (H2), (H3), (H6), *and* (H7). *Then there exists a bounded absorbing set B_0 in the space $V_1\times H$ for the dynamical system represented by* (1.1).

Proof. We are going to prove the following result: For every $\varepsilon \in]0, \varepsilon_1[$, where $\varepsilon_1=\min(1/\alpha, \alpha/3\lambda_1)$ there exist positive constants $k=k(\varepsilon)$ and ρ (independent of ε) such that the solution $u(t)$ of (1.1) satisfies

$$\begin{aligned}(1-\varepsilon\alpha)\|u\|^2+\varepsilon^2|u|^2+|u_t+\varepsilon u|^2+2G(u)\\ \leqq [(1-\varepsilon\alpha)\|u_0\|^2+\varepsilon^2|u_0|^2+|u_1+\varepsilon u_0|^2+2G(u_0)]\,e^{-\varepsilon\rho t}\\ +\frac{1}{\varepsilon\rho}(1-e^{-\varepsilon\rho t})\left(k+\frac{1}{\alpha}|f|^2\right).\end{aligned} \tag{2.10}$$

Proceeding similarly as in Proposition 2.1, it is easy to get

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}[(1-\varepsilon\alpha)\|u\|^2+\varepsilon^2|u|^2+|v|^2]+\varepsilon(1-\varepsilon\alpha)\|u\|^2+\varepsilon^2|u|^2\\ +\alpha\|v\|^2-\varepsilon|v|^2=(f, v)-(g(u), v)-(h(u), v).\end{aligned} \tag{2.11}$$

By $(2.4)_2$ and the decomposition (1.2), we have

$$\begin{aligned}(g(u), v)=\frac{d}{dt}G(u)+(p(u), v_t)+\varepsilon(g(u), u),\\ (h(u_t), v)=(h(u_t), u_t)+\varepsilon(h(u_t), u).\end{aligned} \tag{2.12}$$

Therefore equality (2.11) can be rewritten as

$$\begin{aligned}&\frac{d}{dt}[(1-\varepsilon\alpha)\|u\|^2+\varepsilon^2|u|^2+|v|^2+2G(u)]+\varepsilon[(1-\varepsilon\alpha)\|u\|^2+\varepsilon^2|u|^2]\\&\quad+\varepsilon[(1-\varepsilon\alpha)\|u\|^2+2(g(u),u)]+2\alpha\|v\|^2-2\varepsilon|v|^2+2(h(u_t),u_t)+\varepsilon^3|u|^2\\&\quad=2(p(u),u_t)-2\varepsilon(h(u_t),u).\end{aligned}\tag{2.13}$$

Now hypotheses (H2), (H3), (H6), and (H7) imply that for every choice of $\delta_i>0$ $(i=1,\cdots,4)$ there exist corresponding constants $k_i>0$ $(i=1,\cdots,4)$ such that

$$(g(u),u)\geqq C_5G(u)-\frac{\varepsilon^2\delta_1}{2}\|u\|^2+k_1,\tag{2.14}$$

$$(p(u),u_t)\leqq\|p(u)\|_*\|u_t\|\leqq[\delta_2(1+|G(u)|)^{1/2}+k_2]\|u_t\|,\tag{2.15}$$

$$(h(u_t),u_t)\geqq-\frac{\delta_3}{2}\left(1+\frac{1}{2}\|u_t\|^2\right)-k_3,\tag{2.16}$$

$$-(h(u_t),u)\leqq|h(u_t)|_{-1}\|u\|\leqq C_4(1+\|u_t\|)\|u\|.\tag{2.17}$$

Making use of the Cauch-Schwarz inequality and the fact that $\|u_t\|^2\leqq2\|v\|^2+2\varepsilon^2\|u\|^2$, it is easy to deduce from (2.15)-(2.17) that

$$2(h(u_t),u_t)\geqq-\delta_3(1+\|v\|^2+\varepsilon^2\|u\|^2),\tag{2.18}$$

$$|2\varepsilon(h(u_t),u)|\leqq k_5+\varepsilon^2(\delta_5\|u\|^2+\delta_4\|v\|^2),\tag{2.19}$$

where k_5 and δ_5 depend on $\varepsilon, k_4, \delta_3$,

$$-2(p(u),u_t)\leqq k_6+\varepsilon^2\delta_8\|u\|^2+2\varepsilon\delta_2G(u)+\varepsilon\delta_6\|v\|^2,\tag{2.20}$$

where k_6 and δ_6 depend on $\varepsilon, \delta_2, k_2, \delta_4$.

Inserting all these inequalities in (2.13) and setting $z=(1-\varepsilon\alpha)\|u\|^2+\varepsilon^2|u|^2+|v|^2+2G(u)$ we have

$$\begin{aligned}&\frac{dz}{dt}+\varepsilon[(1-\varepsilon\alpha)\|u\|^2+\varepsilon^2|u|^2+2(C_5-\delta_2)G(u)]\\&\quad+\varepsilon\{[1-\varepsilon(\alpha+\delta_1+\delta_3+\delta_4+\delta_6)]\|u\|^2+\varepsilon^2|u|^2\}\\&\quad+(2\alpha-\delta_2-\varepsilon^2\delta_3-\delta_6)\|v\|^2-2\varepsilon|v|^2\leqq2(f,v)+k_7,\end{aligned}\tag{2.21}$$

where $k_7=k_1+\delta_3+k_5+k_4$.

Now we note that if $\varepsilon<\min(1/\alpha,\alpha/3\lambda_1)$, then we can find $\delta_1, \delta_3, \delta_4, \delta_5, \delta_7$ such that

$$1-\varepsilon(\alpha+\delta_1+\delta_3+\delta_4+\delta_6)\geqq0,$$

$$\frac{1}{\lambda_1}\geqq\frac{3\varepsilon}{\alpha-\delta_3-\varepsilon\delta_4-\delta_6},$$

so that we can forget the term in $\{\}$ and that

$$(2\alpha-\delta_2-\varepsilon^2\delta_3-\delta_6)\|v\|^2\geqq\alpha\|v\|^2+\varepsilon|v|^2.$$

By this inequality and (2.21) we can deduce

$$\frac{dz}{dt}+\varepsilon\rho z\leqq k_7+\frac{|f|^2}{\alpha},\qquad0<\rho<\min\{1,C_3\},\tag{2.22}$$

and using Gronwall's lemma, (2.10) follows. Now hypothesis (H1) implies that for all $\delta_7 > 0$ there exists $k_8 > 0$ such that

$$2G(u) + \delta_7 \|u\|^2 \geqq -k_8,$$

so that from (2.10) we deduce that if $\varepsilon < \varepsilon_2 = \min(1/2\alpha, \alpha/3\lambda_1)$

$$\tfrac{1}{2}\|u\|^2 + \varepsilon^2 |u|^2 + |v|^2 \leqq k_9 + z(0)\, e^{-\varepsilon\rho t}, \tag{2.23}$$

where

$$k_9 = -k_8 + \frac{k_7}{\varepsilon\rho} + \frac{1}{\varepsilon\rho\alpha}|f|^2.$$

Now from (2.22) it readily follows that for every choice of u_0, u_1, $\varepsilon < \varepsilon_2$, and G (of course restricted by (H1) and (H6)), there exists $t_0 = t_0(\varepsilon, \|u_0\|, |u_1|, G)$ such that for $t \geqq t_0$

$$(u(t), u_t(t) + \varepsilon u(t)) \in \{(x, y) \in V \times H : \|(x, y)\|^2_{V\times H} \leqq 2k_9 + 1\} \equiv B_0, \tag{2.24}$$

i.e., B_0 is absorbing for the dynamical system (1.1). □

Remark 2.1. It is possible to assume $f \in C_b(\mathbb{R}^+; H)$ and easily modify the above proof so that $|f|$ is replaced by $|f|_{L^\infty(\mathbb{R}^+;H)}$.

Remark 2.2. The hypothesis (H7) is somewhat restrictive with respect to the applications we have in view. We relax this assumption by writing $h = h_1 + h_2$, where h_1 satisfies (H7) and h_2 is such that there exist $\delta_8 \in]0, \tfrac{1}{2}]$ and C_5 such that

$$|h_2(v)|_{-1} \leqq C_5 (h_2(v), v)^{1-\delta_8}. \tag{2.25}$$

Now Proposition 1.2 can be extended to this case.

PROPOSITION 2.3. *The conclusions of Proposition* 1.2 *hold true if we replace the fact that h satisfies* (H7) *by the assumptions* $h = h_1 + h_2$ *where* h_1 *satisfies* (H7) *and* h_2 *satisfies* (2.25).

Proof. From (2.24) it follows that

$$\varepsilon |(h_2(u_t), u)| \leqq \varepsilon |h_2(u_t)|_{-1} \|u\| \leqq \varepsilon C_5 (h_2(u_t), u_t) + \varepsilon^{2q} C_6 \|u\|^{2q},$$

with $2q = 1/\delta_8$, $q \geqq 1$. Then (2.22) reads as

$$\frac{dz}{dt} + \varepsilon\rho z \leqq k_7 + \frac{|f|^2}{\alpha} + C_6 \varepsilon^{2q} \|u\|^{2q}.$$

But, since for $\varepsilon \leqq 1/2\alpha$ we have $z \geqq \tfrac{1}{2}\|u\|^2$, it follows that

$$\frac{dz}{dt} + \varepsilon\rho z \leqq k_7 + \frac{|f|^2}{\alpha} + C_7 \varepsilon^{2q} z^{2q}.$$

Now, if we take ε sufficiently small, we can suppose

$$\varepsilon C_7^{1/q} \left(k_7 + \frac{2|f|^2}{\alpha} \right) \leqq \left(\frac{|f|^2}{2\alpha} \right)^{1/q}.$$

We choose z_0 and ε such that

$$C_7 \varepsilon^{2q} z_0 \leqq \frac{1}{2} \frac{|f|^2}{\alpha}, \qquad 0 \leqq t \leqq T, \tag{2.26}$$

so that

$$C_7 \varepsilon^{2q} z(t)^q \leqq \frac{|f|^2}{\alpha}, \qquad 0 \leqq t \leqq T, \tag{2.27}$$

and it can be that either

$$T<\infty \quad \text{and} \quad C_7\varepsilon^{2q}z^q(T)=\frac{|f|^2}{\alpha} \tag{2.28}$$

or

$$T=\infty. \tag{2.29}$$

In the interval $0\leqq t\leqq T$, by the previous assumption on ε, we have

$$\frac{dz}{dt}+\varepsilon\rho z\leqq k_7+\frac{2|f|^2}{\alpha},$$

and therefore

$$z(t)\leqq z_0\, e^{-\varepsilon\rho t}+\frac{1}{\varepsilon\rho}\left(k_7+\frac{2|f|^2}{\alpha}\right)(1-e^{-\varepsilon\rho t}), \qquad 0\leqq t\leqq T.$$

Now, since $x\to x^q$ is convex for $q\geqq 1$, we obtain

$$z(t)^q\leqq z_0^q\, e^{-\varepsilon\rho t}+\frac{1}{\varepsilon^q\rho^q}\left(k_7+\frac{2|f|^2}{\alpha}\right)^q(1-e^{-\varepsilon\rho t}),$$

so that

$$C_7\varepsilon^{2q}z(t)^q\leqq C_7\varepsilon^{2q}z_0^q\, e^{-\varepsilon\rho t}+\frac{C_7\varepsilon^q}{\rho^q}\left(k_7+\frac{2|f|^2}{\alpha}\right)(1-e^{-\varepsilon\rho t}), \qquad 0\leqq t\leqq T.$$

But from the assumptions (2.26) and (2.28) on z_0 and ε, it follows that

$$C_7\varepsilon^{2q}z^q(t)\leqq\frac{1}{2}\frac{|f|^2}{\alpha}, \qquad 0\leqq t\leqq T.$$

From this we deduce that (2.28) is impossible and $T=+\infty$, giving us

$$z(t)\leqq z_0\, e^{-\varepsilon\rho t}+\frac{1}{\varepsilon\rho}\left(k_7+\frac{|f|^2}{\alpha}\right)(1-e^{-\varepsilon\rho t}), \qquad 0\leqq t\leqq\infty, \tag{2.30}$$

and

$$C_7\varepsilon^{2q}z_0^q\leqq\frac{1}{2}\frac{|f|^2}{\alpha} \quad \text{for } \varepsilon\leqq\varepsilon_0.$$

Now we still need to prove that there exists an absorbing set in $V_1\times H$, since in the previous argument ε depends on z_0.

Then, if $|z_0|\geqq k_1$ with $R_1\geqq(1/\varepsilon_0^2)((1/2C_7)(|f|^2/\alpha))^{2/q}$, it follows that

$$z(t)\leqq z_0\, e^{-\varepsilon\rho t}+C_8\overline{z_0}(1-e^{-\varepsilon\rho t}) \quad \forall t\geqq 0, \quad \varepsilon\leqq\varepsilon_0.$$

Now, if $R_2=16C_8$, and $R\geqq R_1+R_2$, it is easy to see that

$$z(t)\leqq z_0\, e^{-\varepsilon\rho t}+\frac{R}{4}(1-e^{-\varepsilon\rho t}),$$

so that for $t\geqq t_1(R)$, $z(t)\leqq R/2$. At this point, if $R/2\geqq R_2$, we can continue the argument until $R/2\leqq R_2$. Thus $\{|z|\leqq R_2\}$ is absorbing. □

2.2. Construction of the global attractor. We will assume that the nonlinear mappings g and h, introduced in §§ 1.1–1.2, satisfy the following hypothesis:

(H8) $\exists \delta \in]0, \frac{1}{2}]$ such that $\forall (\xi, \eta) \in V \times V$ and $\forall \rho \geqq 0$,
$\|\xi\| \leqq \rho$ and $|\eta| \leqq \rho \Rightarrow \exists C_9(\rho)$ such that
$|g(\xi)|^2_{2\delta-1} + |h(\eta)|^2_{2\delta-1} \leqq C_9(\rho)(1 + \|\eta\|^2)$.

This section will be devoted to the proof of the following theorem.

THEOREM 2.1. *The ω-limit set of B_0,*

$$\mathscr{A} = \omega(B_0) = \bigcap_{s>0} \operatorname{cl}\left(\bigcup_{t \geqq s} S(t) B_0 \right),$$

where cl *stands for the closure with respect to the topology of $V_1 \times H$, which is the global attractor for $S(t)$ in that space, i.e.,*

(i) *$\mathscr{A}$ is a compact nonempty connected set in $V_1 \times H$;*

(ii) *$\mathscr{A}$ is invariant under $S(t)$; $S(t)\mathscr{A} = \mathscr{A}$ $\forall t \geqq 0$;*

(iii) *$\mathscr{A}$ is globally attracting: for every bounded set $\mathscr{B}$ in $V_1 \times H$, $\operatorname{dist}(S(t)B, \mathscr{A})$ tends to zero as $t \to \infty$.*

Remarks 2.3. (i) A similar result was obtained by Massatt [8] under more restrictive hypotheses on the nonlinear mappings g and h. We also notice that our techniques are completely different from those in [8].

(ii) We have denoted $\operatorname{dist}(X, Y) = \sup_{x \in X} \inf_{y \in Y} d(x, y)$.

(iii) The proof below will also show that $\mathscr{A}$ is bounded in the norm of $V_{1+\delta} \times V_\delta$, where δ is given in (H8).

Proof. The proof will be an easy consequence of the following abstract result [2], [4].

PROPOSITION 2.4. *If a semigroup $S(t)$ on a metric space $\mathscr{E}$ possesses a bounded absorbing set B_α and for every bounded set B in $\mathscr{E}$, there exists a compact set K in $\mathscr{E}$ such that $\lim_{t \to +\infty} \operatorname{dist}(S(t)B, K) = 0$ then the ω-limit set $\omega(B_\alpha)$ is the global attractor of $S(t)$.*

Therefore let $R \geqq 0$ be given with $u_0 \in V$, $u_1 \in H$ such that $\|u_0\| \leqq R$ and $|u_1| \leqq R$. We know from Proposition 1.2 that there exist C_0, $T_0(R)$, and $K_0(R)$ such that

$$\|u(t)\|^2 + |u_t(t)|^2 \leqq C_0 \quad \forall t \geqq T_0(R), \tag{2.31}$$

$$\|u(t)\|^2 + |u_t(t)|^2 \leqq K_0(R) \quad \forall t \geqq 0. \tag{2.32}$$

Let us write now $u = v + w$, where

$$v_{tt} + \alpha A v_t + A v = \varphi(t), \tag{2.33}$$

$$v(0) = 0, \qquad v_t(0) = 0, \tag{2.34}$$

$$\varphi(t) = f - g(u(t)) - h(u_t(t)), \tag{2.35}$$

and

$$w_{tt} + \alpha A w_t + A w = 0, \tag{2.36}$$

$$w(0) = u_0, \qquad w_t(0) = u_1. \tag{2.37}$$

Proposition 2.1 shows that there exist $C_\varepsilon > 0$ such that

$$\|w(t)\|^2 + |w_t(t)|^2 \leqq C_\varepsilon e^{-\varepsilon t} R^2 \quad \forall t \geqq 0. \tag{2.38}$$

Now hypothesis (H8) and (2.31) imply that

$$|g(u(t)) + h(u_t(t))|^2_{2\delta-1} \leqq C_9(R) \|u_t\|^2, \tag{2.39}$$

and integrating (2.21) between t and $t+1$ it is easy to deduce that

$$\int_t^{t+1} \|u_t(t)\|^2 \, d\tau \leqq C_{10}(R) \quad \forall t \geqq 0, \tag{2.40}$$

so that, by virtue of (2.35), we have

$$\begin{aligned} \int_t^{t+1} |\varphi(\tau)|_{2\delta-1}^2 \, d\tau &\leqq 2\left(\int_t^{t+1} |f|_{2\delta-1}^2 \, d\tau + \int_t^{t+1} |g(u(\tau)) + h(u(\tau))|_{2\delta-1}^2 \, d\tau \right) \\ &\leqq C_{11}(R). \end{aligned} \tag{2.41}$$

Suppose now that there exists $C_{12}(R)$ such that

$$|v(t)|_{2\delta+1} + |v_t(t)|_{2\delta} \leqq C_{12}(R); \tag{2.42}$$

then $\bigcup_{t\geqq 0, \|u_0\| \leqq R} \{v(t), v_t(t)\}$ is bounded in $V_{2\delta+1} \times V_\delta$ and being the injection $V_{2\delta+1} \times V_\delta \to V \times H$ compact, we have

$$\overline{\bigcup_{\substack{t\geqq 0 \\ \|u_0\| \leqq R}} \{v(t), v_t(t)\}} = K \quad \text{is compact in } V \times H.$$

But from (2.38) it follows that $\bigcup_{t\geqq 0, \|u_0\| \leqq R} \{u(t) - v(t), u_t(t) - v_t(t)\}$ is contained in the ball $B_{V\times H}(0, C e^{-\varepsilon t} R^2)$ which tends strongly to zero, so that $\overline{\bigcup_{t\geqq 0} S(t) B}^{V\times H}$ is compact in $V \times H$ and the theorem is proved.

It remains to prove (2.42). Setting $\xi = A^\delta v$, by (2.26) we have

$$\xi_{tt} + \alpha A \xi_t + A\xi = A^\delta \varphi, \tag{2.43}$$

from which, setting $\eta = \xi_t + \varepsilon \xi$ and $y = |\{\xi, \eta\}|_\varepsilon$, it is easy to derive

$$\frac{1}{2} \frac{dy}{dt} + \varepsilon y + \frac{\alpha}{2} \|\eta\|^2 = (A^\delta \varphi, \eta) = (A^{\delta - (1/2)} \varphi, A^{(1/2)} \eta) \leqq \|\eta\| \, |\varphi|_{2\delta-1}, \tag{2.44}$$

so that

$$\frac{dy}{dt} + 2\varepsilon y \leqq C_{13} |\varphi|_{2\delta-1}^2 = \zeta \tag{2.45}$$

with

$$\int_t^{t+1} \zeta(\tau) \, d\tau \leqq C_{14}(R). \tag{2.46}$$

Integration of (2.45) now yields

$$y(t) \, e^{2\varepsilon t} \leqq y(0) + \int_0^t \zeta(\tau) \, e^{2\varepsilon \tau} \, d\tau, \qquad n \leqq t \leqq n+1, \quad n \in \mathbb{N},$$

by which

$$\begin{aligned} y(t) \, e^{2\varepsilon t} &\leqq y(0) + \sum_{k=0}^{n} \int_k^{k+1} \zeta(\tau) \, e^{2\varepsilon \tau} \, d\tau \\ &\leqq y(0) + \sum_{k=0}^{n} e^{2\varepsilon(k+1)} \int_k^{k+1} \zeta(\tau) \, d\tau \\ &\leqq y(0) + C_{14}(R) \frac{e^{2\varepsilon(n+2)} - 1}{e^{2\varepsilon} - 1} \\ &\leqq y(0) + C_{14}(R) \frac{e^{2\varepsilon(t+2)}}{e^{2\varepsilon} - 1}, \end{aligned}$$

and, remembering that $y(0)=0$ by (2.35),

$$y(t) \leqq C_{14}(R)\frac{e^{4\varepsilon}}{e^{2\varepsilon}-1} \quad \forall t \geqq 0,$$

which rewrites as

$$\|\xi(t)\|^2+|\xi_t(t)+\varepsilon\eta(t)|^2 \leqq C_{15}(R); \tag{2.47}$$

but $v=A^{-\delta}\xi$, so (2.47) implies (2.42) and the proof is complete. □

3. Applications to wave equations.

3.1. Model problems. We want now to restrict ourselves to a class of model problems which fits in the abstract framework introduced in § 1 and to state sufficient conditions on the nonlinearities to guarantee that hypothesis (H8) and its subsequents be satisfied. Namely, we are going to set $A=-\Delta$ with Dirichlet boundary conditions and consider the mappings g, h as *real functions* acting on $u(x,t)$ and $u_t(x,t)$, respectively. Therefore let Ω be an open bounded connected domain in $\mathbb{R}^n$ with Lipschitz boundary. The model problems that will be considered are of the form

$$\begin{aligned} &\frac{\partial^2 u}{\partial t^2}(x,t)+\alpha\Delta\frac{\partial u}{\partial t}(x,t)-\Delta u(x,t)+g(u(x,t))+h\left(\frac{\partial u}{\partial t}(x,t)\right)=f(x,t), \\ &u(x,t)|_{\partial\Omega}=0, \\ &u(x,0)=u_0(x), \qquad \frac{\partial u}{\partial t}(x,0)=u_1(x). \end{aligned} \tag{3.1}$$

In this case $H=L^2(\Omega)$, $V_1=D(A^{1/2})=H_0^1(\Omega)$, $D(A)=H^2(\Omega)\cap H_0^1(\Omega)$ and $|\cdot|$, $\|\cdot\|$ will denote the $L^2(\Omega)$- and $H_0^1(\Omega)$-norms.

We assume that the functions g and h are such that (H1)-(H6) and (2.25) hold true. This will be the case if, e.g., $g(s)=\lambda|s|^{\beta-1}s$ and $h(s)=\mu|s|^{\gamma-1}s$ with $\lambda\geqq 0$, $\mu\geqq 0$, $\beta>0$, $\gamma>0$, and (for $n\geqq 3$), γ, $\beta<1+(n^2/n-2)$. Of course much more general functions g and h could be considered but we have restricted the exposition to homogeneous ones for the sake of simplicity.

It is merely worthwhile to note that the following results can be obtained in the general framework; we have left that framework only for a better readability of the proofs and theorems.

3.2. Further smoothness properties of the limit sets. The aim of this section is to prove that if the data are more regular, then so is the solution of (3.1), and that there exists an absorbing set for the system (3.1) in the space $V_1\times V_2\equiv H_0^1(\Omega)\times(H^2(\Omega)\cap H_0^1(\Omega))$.

To prove what follows let us make two supplementary hypotheses:

$$\begin{aligned} &\forall R\geqq 0\,\exists\sigma_4\geqq 0,\ \exists C_{16}=C_{16}(R) \text{ such that} \\ &\|v\|\leqq R\Rightarrow|g(v)|\leqq C_{16}(1+|\Delta v|)^{1-\sigma_4/2} \quad \forall v\in V; \end{aligned} \tag{H9}$$

$$\begin{aligned} &\forall R\geqq 0\,\exists\sigma_5>0,\ \exists C_{17}=C_{17}(R) \text{ such that} \\ &\|v\|\leqq R\Rightarrow|h(v)|\leqq C_{17}(1+|\Delta v|)^{1-\sigma_5} \quad \forall v\in V. \end{aligned} \tag{H10}$$

We then have the following proposition.

PROPOSITION 3.1. *Let $f\in H$ and g, h satisfy* (H9) *and* (H10). *Then there exists an absorbing set B_1 in the space $V_1\times V_2$ for the dynamical system* (1.1).

Proof. We begin to show that if $u_0 \in V_2$, $u_1 \in V_1$, then for every $R \geqq 0$ there exists $K_{10} = K_{10}(R)$ such that, for $0 < \varepsilon < \varepsilon_1$,

$$(1-\varepsilon\alpha)|\Delta u|^2 + \varepsilon\|u\|^2 + \|u_t + \varepsilon u\|^2 \leqq [(1-\varepsilon\alpha)|\Delta u_0|^2 + \|u_0\|^2 + \|u_1 + \varepsilon u_0\|^2]\, e^{-\varepsilon t} + \frac{1}{\varepsilon}(1-e^{-\varepsilon t})[K_{10}(R) + |f|]. \tag{3.2}$$

Taking the scalar product of (3.1) with $v = u_t + \varepsilon u$ in V_1, we easily get

$$\frac{1}{2}\frac{d}{dt}((1-\varepsilon\alpha)|\Delta u|^2 + \varepsilon^2\|u\|^2 + \|v\|^2) + \varepsilon(1-\varepsilon\alpha)|\Delta u|^2 + \varepsilon^3\|u\|^2 + ((-\alpha\Delta - \varepsilon)v, Av) = (f, Av) + (g(u), Av) + (h(u_t), \Delta v). \tag{3.3}$$

We choose now $R \geqq 0$ such that $|\Delta u_0|^2 + \varepsilon^2\|u\|^2 \leqq \lambda R^2$ so that, by Poincaré's inequality, we have

$$\|u_0\|^2 + |u_1|^2 \leqq R^2, \tag{3.4}$$

and then, according to the existence results we know that there exists $M = M(R)$ such that

$$\|u(t)\|^2 + |u_t(t)|^2 \leqq M(R) \quad \forall t \geqq 0.$$

From (3.4) and the hypotheses made above it follows that

$$\begin{aligned}(g(u), \Delta v) &\leqq |g(u)|\,|\Delta v| \leqq C_{16}(M(R))|\Delta v|(1+|\Delta u|)^{1-\sigma_4/2} \\ &\leqq \frac{\alpha}{4}|\Delta v|^2 + \frac{C_7(M(R))^2}{\alpha}(1+|\Delta u|)^{2-\sigma_2} \\ &\leqq \frac{\alpha}{4}|\Delta v|^2 + \frac{C_2(M(R))^2}{\alpha}\delta_{10}|\Delta u|^2 + K_{11}(\delta_{10}, R)\end{aligned} \tag{3.5}$$

for every $\delta_{10} > 0$, and

$$\begin{aligned}-(h(u_t), \Delta v) &\leqq |h(u_t)|\,|\Delta v| \leqq C_{17}(M(R))(1+|\Delta v|)^{1-\sigma_5/2}|\Delta v| \\ &\leqq \frac{\alpha}{4}|\Delta v|^2 + \frac{C_8(M(R))^2}{\alpha}(1+|\Delta u_t|)^{2-\sigma_1} \\ &\leqq \frac{\alpha}{4}|\Delta v|^2 + \frac{C_{17}(M(R))^2}{\alpha}\delta_{11}|\Delta u_t|^2 + K_{12}(\delta_{11}, R)\end{aligned} \tag{3.6}$$

for every $\delta_{11} > 0$.

Inserting these inequalities in (3.3) and using the fact that $|\Delta u_t|^2 \leqq |\Delta v|^2 + 2\varepsilon^2|\Delta u|^2$, we get

$$\begin{aligned}&\frac{d}{dt}[(1-\varepsilon\alpha)|\Delta u|^2 + \varepsilon^2\|u\|^2 + \|v\|^2] + \varepsilon[(1-\varepsilon\alpha)|\Delta u|^2 + \varepsilon^2\|u\|^2] \\ &\quad + \varepsilon\{[1-\varepsilon(\alpha+\delta_9)]|\Delta u|^2 + (2\alpha - \delta_{10})|\Delta v|^2 - 2\varepsilon\|v\|^2\} \\ &\quad \leqq \frac{\alpha}{2}|\Delta v|^2 + (f, \Delta v) + K_{13}(R) \leqq \alpha|\Delta v|^2 + \frac{|f|}{2\alpha} + K_{13}(R),\end{aligned} \tag{3.7}$$

where δ_9, δ_{10} depend on ε, C_{16}, C_{17} but can be otherwise chosen arbitrarily small. It is evident now that proceeding exactly as in Proposition 1.2 with the same bound on

ε, one can find (3.2). The proof of the existence of an absorbing set on $V_2 \times V_1$ of the form

$$B_1 = \{(x, y) \in V_2 \times V_1 : \|(x, y)\|_{V_2 \times V_1} \leqq 2K_{10} + 1\} \tag{3.8}$$

is exactly similar to that of the preceding proposition. □

Remark 3.1. If we assume $f, f_t \in C_b(\mathbb{R}^+; H)$ it is easy to prove the same result using the equality

$$-(f, \Delta v) = -\frac{d}{dt}(f, \Delta u) + (f_t, \Delta u) - \varepsilon(f, \Delta u). \tag{3.9}$$

3.3. Sufficient conditions on the nonlinearities. Let us now investigate the meaning of the abstract hypotheses (H8)-(H10) in the case of wave equations of the form (3.1).

We will suppose that the real function $g(\xi)$ satisfies the following conditions: There exists $C_{18} > 0$ such that

$$|g(\xi)| \leqq C_{18}(1 + |\xi|^2)^{\beta/2}, \tag{H11}$$

with

$$0 \leqq \beta < \infty \quad \text{if } n = 2,$$

$$0 \leqq \beta < 5 \quad \text{if } n = 3,$$

$$0 \leqq \beta < \frac{n+2}{n-2} \quad \text{if } n \geqq 4,$$

no such assumption is needed if $n = 1$.

Concerning $h(\xi)$, we will assume that there exists $C_{19} > 0$ such that

$$|h(\eta)| \leqq C_{19}(1 + |\eta|^2)^{\gamma/2}, \tag{H12a}$$

with

$$0 \leqq \gamma < \infty \quad \text{if } n = 2,$$

$$0 \leqq \gamma < \frac{7}{3} \quad \text{if } n = 3,$$

$$0 \leqq \gamma \leqq \frac{n+4}{n} \quad \text{if } n \geqq 2.$$

Now we want to show that (H11), (H12) imply (H9), (H10). We will distinguish four cases, always supposing that $\|u\| \leqq R$ and $|u_t| \leqq R$.

(i) $n = 1$. Since $H^1 \subset L^\infty$ in this case, we have

$$\|u\| \leqq R \Rightarrow |u|_{L^\infty} \leqq C' \Rightarrow |g(u)| \leqq C'' = \sup_{|w|_{L^\infty} \leqq C} |g(w)|,$$

and similarly

$$|u_t| \leqq R \Rightarrow |h(u_t)| \leqq C'''.$$

(ii) $n = 2$. By the Sobolev imbedding theorem, we have $H^1 \hookrightarrow L^{2\beta}$, for every $\beta > 0$. Then

$$|g(u)|^2 \leqq C_{18}(1 + |u|^{2\beta}) \leqq C_9(1 + C_\Omega \|u\|) \leqq C_9(1 + C_\Omega R)$$

and

$$|h(u_1)|^2 \leqq C_{19}(1+|u_t|^{2\beta}) \leqq C_{10}(1+R^{2\gamma}).$$

(iii) $n=3$. By the Sobolev imbedding theorem, we now have that if $\beta<5$,

$$|u_{2\beta}| \leqq C_1\|u\|_{H^{6/5}} \leqq M_2\|u\|^{4/5}|u|_2^{1/5} \leqq M_3R^{4/5}|\Delta u|^{1/5} \qquad (M_i>0),$$

so that

$$|g(u)|^2 \leqq C_9(1+M_3R^{4/5}|\Delta u|^{2\beta/5}) \leqq C_8(R)(1+|\Delta u|)^{2-\sigma_4/2}, \qquad \frac{2\beta}{5}<2.$$

As for h, we have similarly that if $\gamma<7/8$,

$$|u_t|_{2\gamma} \leqq M_4\|u_t\|_{H^{6/7}} \leqq M_5|u_t|^{4/7}|\Delta u|^{3/7},$$

so that

$$|h(u_t)|^2 \leqq C_{19}(1+M_5R^{4/7}|\Delta u_t|^{3\gamma/7}) \leqq C_9(R)(1+|\Delta u_t|)^{1-\sigma_5}, \qquad \frac{3\gamma}{7}<1.$$

(iv) $n \geqq 4$. We omit the calculations since they are exactly similar to the case where $n=3$.

As for hypothesis (H8), we will show that a stronger requirement on h is needed, namely,

(H12b) $$|h(\eta)| \leqq C(1+|\xi|^2)^{\gamma/2} \quad \forall \xi \in \mathbb{R}$$

with

$$\gamma \leqq 6 \quad \text{if } n=1,$$

$$\gamma<1+6/n \quad \text{if } n \geqq 2.$$

More precisely, (H11) and (H12b) imply (H8). To show this, the reasoning is similar to that used previously as concerns the part on $g(\xi)$, having noted that (H11) implies $|g(\xi)|<C(R)$ (that is, $\delta=\frac{1}{2}$) for $n=1,2$ and that, since $H^{-1}\subset L^{6/5}$, $\beta<5$ implies

$$|g(\xi)|_{-1+2\delta} \leqq C_{20}(R) \quad \text{for some } \delta>0.$$

The result for $n \geqq 4$ follows readily. As for $h(\eta)$ we will distinguish two cases: First, $n=1$: We have

$$|h(\eta)|_{-1} \leqq \sup_{\|\xi\| \leqq 1} \int_\Omega h(\eta)\xi\, dx \leqq C|h(\eta)|_{L^1}$$

$$\leqq \int (1+|\eta|)^\gamma\, dx \leqq |(1+|\eta|)|_{L^\infty}^{\gamma-2} \int (1+|\eta|)^2\, dx.$$

Since $(n=1)$ $|\xi|_{L^\infty} \leqq C|\xi|^{1/2}\|\xi\|^{1/2}$ the right-hand side is bounded by $C|\eta|^{(\gamma/2)+1}\|\eta\|^{(\gamma/2)-1}$. Hence (H13) implies that $|h(\eta)|_{-1} \leqq |(1+\|\eta\|^2)$.

Second, $n \geqq 2$: For every $\varepsilon>0$, there exists C_ε such that

$$|h(\eta)|_{-1} \leqq C_\varepsilon|h(\eta)|_{L^{(n+\varepsilon)/(n+2)}} \leqq C_\varepsilon(1+|\eta|_{L^{(2n+\varepsilon)\gamma/(n+2)}}^\gamma) \leqq C_{L^{(n+\varepsilon)/(n+2)}}(1+|\eta|_{H^s}^\gamma),$$

with $n+2/(2n+\varepsilon)\gamma=\frac{1}{2}-(s/n)$. Now, since $\gamma<1+(6/n)$, one can choose ε so that $s\gamma=2$. Therefore

$$|h(\eta)|_{-1} \leqq C_\varepsilon(1+|\eta|_{H^s}^\gamma \leqq C_\varepsilon(1+|\eta|_{L^2}^{\gamma(1-s)}|\eta|_{H^1}^{\gamma s})$$

and (H8) follows.

4. Finite dimensionality of the attractors. We consider a subset $X \subset V_1 \times H$, which satisfies the two following properties:

(4.1) X is included and bounded in $V_{1+\delta} \times V_\delta$ for some $\delta > 0$,

(4.2) X is invariant under (1.1), i.e., $S(t)X = X \quad \forall t \geqq 0$.

We shall supplement the previous hypotheses on g and h with the following ones.

For every $R > 0$, and $(u, \eta) \in V_{1+\delta} \times V_\delta$ with $|u|_{1+\delta} + |\eta|_\delta \leqq R$ there exist $\sigma_1 \in [0, 1[$ and $C \geqq 0$ such that

(H13) $$|\langle g'(u)v, \varphi\rangle| \leqq C|v|_{\sigma_1}\|\varphi\| \quad \forall v \in V, \quad \forall \varphi \in V;$$

there exist $\sigma_2 \in [0, 1[$ and $C \geqq 0$ such that

(H14) $$|\langle h'(\eta)\xi, \xi\rangle| \leqq C\|\xi\|^2_{\sigma_2} \quad \forall \xi \in V.$$

With these notations and hypotheses we can state the following theorem.

THEOREM 4.1. *Let X be a subset in $V_1 \times H$ which satisfies* (4.1) *and* (4.2). *Then X has finite Hausdorff and fractal dimensions.*

COROLLARY 4.1. *The global attractor constructed in Theorem* 2.1 *has finite Hausdorff and fractal dimensions.*

This corollary is obvious since the global attractor satisfies (4.2) by construction and we have noticed in Remark 2.3(ii) that it is bounded in $V_{1+\delta} \times V_\delta$ where $\delta > 0$ is given in (H5). Concerning the proof of Theorem 4.1, we will rely on an abstract result of Ghidaglia [7], which extends that of Constantin, Foias, and Temam [4]. First, we consider the linearized flow

$$v_{tt} + \alpha A v_t + Av + g'(u)v + h'(u_t)v_t = 0,$$

and introduce the quadratic forms $(0 < \varepsilon < 1/2\alpha)$

(4.3) $$q_\varepsilon\{v, v_t\} \equiv (1 - \alpha\varepsilon)\|v\|^2 + \varepsilon^2|v|^2 + |w + \varepsilon v|^2.$$

We immediately see that

(4.4) $$\frac{1}{2}\frac{d}{dt} q_\varepsilon\{v, v_t\} + \varepsilon(1 - \varepsilon\alpha)\|v\|^2 + \varepsilon^3|v|^2 + \alpha\|v_t + \varepsilon v\|^2$$
$$= -(g'(u)v + h'(u_t)v_t - \varepsilon^2 v, v_t + \varepsilon v).$$

Second, we use (H13) and (H14) in order to bound the right-hand side of (4.4) by

(4.5) $$\varepsilon^2|v|\,|v_t + \varepsilon v| + C\|v_t + \varepsilon v\|\,|v|_{\sigma_1} + C|v_t + \varepsilon v|^2_{\sigma_2} + \varepsilon C\|v\|\,\|v_t + \varepsilon v\|.$$

We have written $(h'(u_t)v_t, v_t + \varepsilon v) = (h'(u_t)(v_t + \varepsilon v), v_t + \varepsilon v) - \varepsilon(h'(u_t)v, v_t + \varepsilon v)$ and make use of (H14) in order to bound the last term.

Then combining (4.4) and (4.5) we deduce thanks to the Cauchy-Schwarz inequality that there exists $\varepsilon_0 < 1/2\alpha$ such that for $0 < \varepsilon \leqq \varepsilon$,

(4.6) $$\frac{d}{dt} q_\varepsilon\{v, v_t\} + \varepsilon(1 - \alpha\varepsilon)\|v\|^2 + 2\varepsilon^3|v|^2 + \alpha\|v_t + \varepsilon v\|^2 \leqq C(|v|^2_\sigma + |v_t|^2_\sigma),$$

where $\sigma = \max(\sigma_1, \sigma_2) < 1$.

Third, using the interpolation inequality

$$|\phi|_\sigma \leqq |\phi|^{(1-\sigma)/(2-\sigma)}_{\sigma-1} |\phi|^{1/(2-\sigma)}_1,$$

we deduce that (from now on $\varepsilon = \varepsilon_0$ is fixed)

$$C|v_t|_\sigma^2 \leqq \frac{\alpha}{2}\|v_t + \varepsilon v\|^2 + C|v_t|_{\sigma-1}^2,$$

so that (4.6) reads

$$\frac{d}{dt} q_{\varepsilon_0} + \gamma q_{\varepsilon_0} \leqq C[|v|_\sigma^2 + |v_t|_{\sigma-1}^2], \tag{4.7}$$

where $\gamma = \min(1/2\alpha, \alpha\lambda/2)$ and we have used the fact that

$$\lambda_1|w|^2 \leqq \|w\|^2.$$

Introducing the linear operator on $V_1 \times H$

$$K\{v, w\} = \{A^{\sigma-1}v, A^{\sigma-1}w\},$$

we can rewrite (4.7) as

$$\frac{dq_{\varepsilon_0}}{dt} + \gamma q_{\varepsilon_0} \leqq C(K\{v, v_t\}, \{v, v_t\})_{V_1 \times H}.$$

Finally, since the operator K is compact, we deduce from this inequality [7, Appendix] that X is finite dimensional. □

5. Applications, continued.

5.1. Time-periodic perturbed Sine–Gordon equation. In [1] the following equation, modelling the current in a Josephson junction, is introduced:

$$\frac{\partial^2 u}{\partial t^2} - \Delta u + \sin u = -\beta \frac{\partial u}{\partial t} + \alpha \frac{\partial(\Delta u)}{\partial t} + f(x, t), \tag{5.1}$$

$$\alpha > 0, \quad \beta > 0, \quad u(x, t) \in \mathbb{R}, \quad x \in \mathbb{R}^n.$$

Since $\sin u$ is a bounded function, we can apply the results of the preceding paragraphs to obtain the following theorem.

THEOREM 5.1. *Equation* (5.1), *together with initial and boundary conditions, defines a dynamical system which has a global attractor $\mathcal{A}$ of finite dimension.*

5.2. The power nonlinearity case. The following perturbed wave equation also occurs in quantum mechanics:

$$\frac{\partial^2 u}{\partial t^2} - \Delta u + |u|^q u = -\beta \left|\frac{\partial u}{\partial t}\right|^p \frac{\partial u}{\partial t} + \alpha \frac{\partial(\Delta u)}{\partial t} + f. \tag{5.2}$$

For this equation, bounds on p and q are required by the number of independent variables involved. Thus we have Theorem 5.2.

THEOREM 5.2. *Equation* (5.2), *together with initial and boundary condition, defines a dynamical system which has a finite-dimensional global attractor in the following cases*:

$$n = 1, \quad p \leqq 5, \quad q \text{ arbitrary},$$

$$n = 2, \quad p < 3, \quad q \text{ arbitrary},$$

$$n = 3, \quad p < 4/3, \quad q < 4,$$

$$n \geqq 4, \quad p < 4/n, \quad q < 4/(n-2).$$

A STRONGLY COUPLED SINGULARLY PERTURBED QUASILINEAR SECOND-ORDER SYSTEM*

JOHN S. JEFFRIES†

Abstract. A constructive existence proof is given for solutions of boundary layer type for the singularly perturbed quasilinear second-order system $\varepsilon(d^2x/dt^2) = F(t, x)(dx/dt) + g(t, x)$ subject to Dirichlet boundary conditions. The required assumptions involve only natural conditions that are induced by the O'Malley construction. In particular, restrictive conditions on the structure of $F(t, x)$ which seek to decouple the components of the system are avoided.

Key words. singular perturbations, boundary layer, strongly coupled

AMS(MOS) subject classifications. 34, 54

1. Introduction. We consider solutions exhibiting boundary layer behavior at one endpoint for the following vector differential equation:

$$\varepsilon \frac{d^2x}{dt^2} = F(t, x)\frac{dx}{dt} + g(t, x) \quad \text{for } 0 < t < 1 \tag{1.1}$$

for small values of ε $(\varepsilon \to 0^+)$ subject to the Dirichlet boundary conditions

$$x(0, \varepsilon) = \alpha, \qquad x(1, \varepsilon) = \beta, \tag{1.2}$$

where x and g are real n-dimensional vector-valued functions, α and β are real n-dimensional vectors, and F is a real $n \times n$ matrix-valued function.

The vector Dirichlet problem (1.1)-(1.2) has been considered in Hadlock [9], Chang [1]-[3], Habets [8], Freedman and Kaplan [7], Flaherty and O'Malley [6], O'Donnell [16], O'Malley [17], Chang and Howes [4], Kirschvink [15], Kelley [14], Smith [19], and Jeffries and Smith [11]. However, these works have either made rather strong restrictions on the size of the boundary layer jump or they have placed restrictions on the structure of $F(t, x)$ that effectively require the components to be only weakly coupled. In the present study we avoid these restrictions and thus allow the components of the system to be strongly coupled. It should be noted that the approach we use can be easily modified to handle the case in which $F(t, x)$, $g(t, x)$, α, and β are also functions of ε, i.e., $F = F(t, x, \varepsilon)$, $g = g(t, x, \varepsilon)$, $\alpha = \alpha(\varepsilon)$, and $\beta = \beta(\varepsilon)$. However, to ease the notational burden, we have assumed that F, g, α, and β are independent of ε. (See Smith [19] or Jeffries and Smith [11] for the required modifications if F, g, α, and β are not independent of ε.)

To prove the existence of a boundary layer solution to the problem (1.1)-(1.2) we use, with the aid of a Riccati transformation, the O'Malley construction to obtain an approximate solution. An additional Riccati transformation leads to an explicit construction of a suitable fundamental solution for the linearization of the problem about the proposed approximate solution. A resulting integral representation for the linearization provides directly the existence of a locally unique exact solution for the original problem along with error estimates of the difference between the exact solution and the approximate solution, thereby yielding precise information on the exact solution throughout the interval $0 \leqq t \leqq 1$ as $\varepsilon \to 0^+$.

† Department of Computer Science and Mathematics, New Mexico Highlands University, Las Vegas, New Mexico 87701.

Section 2 contains a discussion of our assumptions, and § 3 discusses the approximate solution provided by the O'Malley construction. A Riccati transformation is used in § 4 to obtain a fundamental solution for the linearization of the problem about the given approximate solution, resulting in an existence and local uniqueness theorem for the original problem along with error estimates.

2. Assumptions.

ASSUMPTION 1. There exists a continuous solution $X_0(t)$ to the reduced equation

$$F(t, X_0(t))\frac{dX_0}{dt}+g(t, X_0(t))=0 \tag{2.1}$$

such that the real parts of the eigenvalues of $F(t, X_0(t))$ are negative.

ASSUMPTION 2. There exists a decaying solution $\hat{X}_0$ to the boundary layer equation

$$\frac{d^2\hat{X}_0}{d\tau^2}=F(0, X_0(0)+\hat{X}_0(\tau))\frac{d\hat{X}_0}{d\tau}, \qquad \hat{X}_0(0)=\alpha-X_0(0). \tag{2.2}$$

It can be shown (see the discussion following formula (3.7)) that if $\hat{X}_0$ decays then it must decay exponentially. Before stating our next assumption, we must first consider the following $2n$-dimensional linear system:

$$\frac{d\hat{Z}}{d\tau}=\begin{pmatrix} 0 & I \\ \hat{A}(\tau) & \hat{B}(\tau)\end{pmatrix}\hat{Z}, \tag{2.3}$$

where

$$\begin{aligned}\hat{A}_{i,j}(\tau)&=\sum_{k=1}^{n}\frac{\partial F_{i,k}}{\partial x_j}(0, X_0(0)+\hat{X}_0(\tau))\frac{d\hat{X}_{0,k}}{d\tau},\\ \hat{B}(\tau)&=F(0, X_0(0)+\hat{X}_0(\tau)).\end{aligned} \tag{2.4}$$

It is shown in Lemma 1 that there exists a fundamental solution $\hat{Z}$ to the above linear system which satisfies the following dichotomy:

$$\begin{aligned}&\|\hat{Z}(\tau)P\hat{Z}^{-1}(u)\|\leqq K e^{-\nu(\tau-u)}, && \tau\geqq u,\\ &\|\hat{Z}(\tau)(I-P)\hat{Z}^{-1}(u)\|\leqq K, && u\geqq\tau,\end{aligned} \tag{2.5}$$

where K and ν are positive constants and $P=\left(\begin{smallmatrix} I_n & 0\\ 0 & 0\end{smallmatrix}\right)$. Essentially, this says that there are n linearly independent solutions to the system (2.3) that decay exponentially and n linearly independent solutions that are bounded in norm away from zero. Defining $P_1=\hat{Z}(0)P\hat{Z}^{-1}(0)$ we make the following assumption.

ASSUMPTION 3. The columns of $(I_n \quad 0)P_1$ span R^n.

The above assumption implies that the solution $\hat{X}_0(\tau)$ to the boundary value problem (2.2) is stable with respect to perturbations in the initial conditions. Assumption 3 is independent of the fundamental solution chosen provided the fundamental solution satisfies the dichotomy (2.5). (This follows from using arguments analogous to those given in Lemma 6.4 of [11] and letting $\varepsilon\to 0^+$.) Furthermore, if there exists a real n-dimensional vector-valued function f such that $F(t, x)=\nabla_x f(t, x)$ then Assumption 3 is always satisfied (see the discussion following formula (3.20)).

ASSUMPTION 4. The given data functions F and g are of class C^{N+1}, where $N\geqq 2$.

3. The approximate solution. In this section we construct an approximate solution to the problem (1.1)–(1.2) using the O'Malley construction. We write the approximate solution $X^N(t, \varepsilon)$ as the sum of an outer solution and a boundary layer correction function of the form

$$X^N(t, \varepsilon)=X(t, \varepsilon)+\hat{X}(\tau, \varepsilon), \qquad \tau:=t/\varepsilon, \tag{3.1}$$

where $X(t, \varepsilon)$ and $\hat{X}(\tau, \varepsilon)$ possess expansions in ε of the form

$$\begin{pmatrix} X(t, \varepsilon) \\ \hat{X}(\tau, \varepsilon) \end{pmatrix} = \sum_{k=0}^{N} \begin{pmatrix} X_k(t) \\ \hat{X}_k(\tau) \end{pmatrix} \varepsilon^k. \tag{3.2}$$

3.1. The outer solution. The outer solution coefficient functions $X_k(t)$, $k = 1, \cdots, N$, are determined by requiring that the outer solution satisfy the differential equation (1.1) and the right boundary conditions to Order (ε^N), i.e.,

$$\varepsilon \frac{d^2X}{dt^2} = F(t, X)\frac{dX}{dt} + g(t, X) + \bar{\rho}(t, \varepsilon), \qquad X(1, \varepsilon) = \beta - \bar{\psi}_N(\varepsilon), \tag{3.3}$$

where $\bar{\rho}(t, \varepsilon)$ and $\bar{\psi}_N(\varepsilon)$ are of Order (ε^{N+1}). A straightforward calculation shows that the outer coefficients functions must satisfy

$$\begin{aligned} &F(t, X_0(t))\frac{dX_k}{dt} = -[X_k(t) \cdot \nabla_x F(t, X_0(t))]\frac{dX_0}{dt} - g_x(t, X_0(t))X_k(t) + P_{k-1}(t), \\ &X_k(1) = 0, \end{aligned} \tag{3.4}$$

where $P_{k-1}(t)$ is known successively in terms of the preceding coefficient functions. Since $F(t, X_0(t))$ is nonsingular (see Assumption 1) there exists a unique solution to each of the above linear terminal value problems.

3.2. The boundary layer correction functions. The boundary layer correction functions are determined by requiring that the approximate solution $X^N(t, \varepsilon)$ satisfies the boundary value problem to Order (ε^N), i.e.,

$$\varepsilon \frac{d^2X^N}{dt^2} = F(t, X^N(t, \varepsilon))\frac{dX^N}{dt} + g(t, X^N(t, \varepsilon)) + \rho(t, \varepsilon), \tag{3.5}$$

$$X^N(0, \varepsilon) = \alpha - \phi_N(\varepsilon), \qquad X^N(1, \varepsilon) = \beta - \psi_N(\varepsilon), \tag{3.6}$$

where $\rho(t, \varepsilon)$ is a continuous function of t and satisfies $\int_0^1 |\rho(s, \varepsilon)|\, ds \leqq \text{Const. } \varepsilon^{N+1}$ and $|\phi_N(\varepsilon)|, |\psi_N(\varepsilon)| \leqq \text{Const. } \varepsilon^{N+1}$.

Using the results of § 3.1, changing variables from t to τ, and expanding about $\varepsilon = 0$, we find that the leading boundary layer correction function $\hat{X}_0$ must satisfy

$$\frac{d^2\hat{X}_0}{d\tau^2} = F(0, X_0(0) + \hat{X}_0(\tau))\frac{d\hat{X}_0}{d\tau}, \qquad \hat{X}_0(0) = \alpha - X_0(0). \tag{3.7}$$

In Assumption 2 we assumed that there exists a decaying solution $\hat{X}_0$ to the above problem. It follows, since $d\hat{X}_0/d\tau$ is a solution to the linear system

$$\frac{d}{d\tau}\left(\frac{d\hat{X}_0}{d\tau}\right) = D(\tau)\left(\frac{d\hat{X}_0}{d\tau}\right), \tag{3.8}$$

where $D(\tau) := F(0, X_0(0) + \hat{X}_0(\tau))$ and the real parts of the eigenvalues of $F(0, X_0(0))$ are negative, that $d\hat{X}_0/d\tau$ must be exponentially decaying. This, in turn, implies that $\hat{X}_0$ is also exponentially decaying, i.e., there exists a positive constant ν_0 such that

$$\left\| \frac{d\hat{X}_0}{d\tau} \right\|, \|\hat{X}_0(\tau)\| \leqq \text{Const. } e^{-\nu_0 \tau}. \tag{3.9}$$

The higher-order boundary layer correction terms must satisfy the following linear differential equations:

$$\begin{aligned}\frac{d^2\hat{X}_k}{d\tau^2} &= F(0, X_0(0)+\hat{X}_0(\tau))\frac{d\hat{X}_k}{d\tau}\\ &\quad +[\hat{X}_k(\tau)\cdot\nabla_x F(0, X_0(0)+\hat{X}_0(\tau))]\frac{d\hat{X}_0}{d\tau}+\hat{g}_{k-1}(\tau),\\ \hat{X}_k(0) &= -X_k(0),\end{aligned} \tag{3.10}$$

where $\hat{g}_{k-1}(\tau)$ is known in terms of the previous boundary layer correction terms and is exponentially decaying providing the previous terms are exponentially decaying.

Defining $\hat{Y}_k := d\hat{X}_k/d\tau$, and using $\hat{A}$ and $\hat{B}$ as defined in (2.4), we can rewrite the differential equation (3.10) as the following inhomogeneous linear system:

$$\frac{d}{d\tau}\begin{pmatrix}\hat{X}_k\\ \hat{Y}_k\end{pmatrix}=\begin{pmatrix}0 & I_n\\ \hat{A}(\tau) & \hat{B}(\tau)\end{pmatrix}\begin{pmatrix}\hat{X}_k\\ \hat{Y}_k\end{pmatrix}+\begin{pmatrix}0\\ \hat{g}_{k-1}(\tau)\end{pmatrix}. \tag{3.11}$$

Using the fundamental solution $\hat{Z}(\tau)$ (see Assumption 3) an exponentially decaying solution is given by

$$\begin{aligned}\begin{pmatrix}\hat{X}_k(\tau)\\ \hat{Y}_k(\tau)\end{pmatrix} &= \hat{Z}(\tau)P\hat{Z}^{-1}(0)d_k+\int_0^\tau \hat{Z}(\tau)P\hat{Z}^{-1}(u)\begin{pmatrix}0\\ \hat{g}_{k-1}(u)\end{pmatrix}du\\ &\quad -\int_\tau^\infty \hat{Z}(\tau)(I-P)\hat{Z}^{-1}(u)\begin{pmatrix}0\\ \hat{g}_{k-1}(u)\end{pmatrix}du,\end{aligned} \tag{3.12}$$

where d_k is a $2n$-dimensional vector. It follows from Assumption 3 that there exists a vector d_k such that $\hat{X}_k(0)=-X_k(0)$. We now turn to the proof of the existence of a fundamental solution $\hat{Z}(\tau)$, satisfying the dichotomy (2.5).

LEMMA 1. *There exists a fundamental solution $\hat{Z}$ to the linear system* (2.3) *satisfying the dichotomy* (2.5).

Proof. The strategy we use is to construct a fundamental solution on an interval of the form $[\tau_0, \infty)$, τ_0 a positive constant, that satisfies the dichotomy (2.5). We then extend this fundamental solution to the interval $[0, \infty)$. It follows from Coppel [5, p. 13] that the extended fundamental solution satisfies the dichotomy on the interval $[0, \infty)$.

Defining

$$\hat{Z}(\tau) := \begin{pmatrix}I_n & \hat{S}(\tau)\\ \hat{T}(\tau) & I_n+\hat{T}(\tau)\hat{S}(\tau)\end{pmatrix}\begin{pmatrix}\hat{\eta}(\tau) & 0\\ 0 & \hat{\xi}(\tau)\end{pmatrix}, \tag{3.13}$$

$$\hat{Z}^{-1}(\tau)=\begin{pmatrix}\hat{\eta}^{-1}(\tau) & 0\\ 0 & \hat{\xi}^{-1}(\tau)\end{pmatrix}\begin{pmatrix}I_n+\hat{S}(\tau)\hat{T}(\tau) & -\hat{S}(\tau)\\ -\hat{T}(\tau) & I_n\end{pmatrix} \tag{3.14}$$

for $\tau \geqq \tau_0$, the linear system decouples

$$\frac{d}{d\tau}\begin{pmatrix}\hat{\eta}\\ \hat{\xi}\end{pmatrix}=\begin{pmatrix}\hat{T} & 0\\ 0 & \hat{B}-\hat{T}\end{pmatrix}\begin{pmatrix}\hat{\eta}\\ \hat{\xi}\end{pmatrix}, \tag{3.15}$$

provided $\hat{T}$ and $\hat{S}$ satisfy the following differential equations for $\tau \geqq \tau_0$:

$$\frac{d\hat{T}}{d\tau}=\hat{B}\hat{T}-\hat{T}^2+\hat{A}, \tag{3.16}$$

$$\frac{d\hat{S}}{d\tau}=\hat{T}\hat{S}+\hat{S}[\hat{T}-\hat{B}]+I_n. \tag{3.17}$$

PROPOSITION 1. *There exists, for τ_0 sufficiently large, a bounded solution $\hat{T}$ to the differential equation* (3.16). *Furthermore, there exist positive constants K_0 and γ_0 such that*

$$\|\hat{T}(\tau)-\hat{B}(\tau)\| \leqq \gamma_0 e^{-\nu_0(\tau-\tau_0)}, \qquad \tau \geqq \tau_0, \tag{3.18}$$

$$\|\gamma_0\| \leqq K_0 e^{-\nu_0\tau_0}. \tag{3.19}$$

Proof. Letting $\hat{T}(\tau)=\hat{B}(\tau)+\hat{E}(\tau)$, we find that $\hat{E}(\tau)$ must satisfy

$$\frac{d\hat{E}}{d\tau}=-\hat{E}\hat{B}-\hat{E}^2+\hat{A}-\frac{d\hat{B}}{d\tau}. \tag{3.20}$$

(Note that if there exists an n-dimensional vector-valued function f such that $F=\nabla_x f$, then $\hat{A}-(d\hat{B}/d\tau)=0$ and so $T=\hat{B}$ is a solution to (3.16), and we may set $\tau_0=0$.) From Assumptions 1 and 2 it follows that there exists a fundamental solution $\hat{\eta}_1$ to the linear system $d\hat{\eta}_1/d\tau=\hat{B}(\tau)\hat{\eta}_1$ such that $\|\hat{\eta}_1(u)\hat{\eta}_1^{-1}(\tau)\| \leqq K_1 e^{-\nu_1(u-\tau)}$ for $u \geqq \tau$, where K_1 and ν_1 are positive constants. Using the fundamental solution $\hat{\eta}_1$ and imposing the terminal condition $\hat{E}(\infty)=0$, we find that $\hat{E}$ satisfies the following integral equation:

$$\hat{E}(\tau)=\int_\tau^\infty \left(\frac{d\hat{B}}{du}-\hat{A}\right)\hat{\eta}_1(u)\hat{\eta}_1^{-1}(\tau)\,du+\int_\tau^\infty \hat{E}^2(u)\hat{\eta}_1(u)\hat{\eta}_1^{-1}(\tau)\,du. \tag{3.21}$$

Letting $\gamma_0<\nu_1/2K_1$ and choosing τ_0 large enough so that $\|\hat{A}(\tau)-(d\hat{B}/d\tau)(\tau)\| \leqq \gamma_0\nu_1/2K_1$ for $u \geqq \tau_0$. (This is possible since $\|\hat{A}(\tau)-(d\hat{B}/d\tau)(\tau)\| \leqq \text{Const. } e^{-\nu_0\tau}$ for $\tau \geqq 0$.) By the Banach–Picard fixed point theorem there exists a solution $\hat{E}$ such that $\|\hat{E}(\tau)\| \leqq \gamma_0$ for $\tau \geqq \tau_0$. Furthermore, using repeated substitution starting with $\hat{E}_0(\tau) := \int_\tau^\infty ((d\hat{B}/du)-\hat{A})\hat{\eta}_1(u)\hat{\eta}_1^{-1}(\tau)\,du$, it can be shown that $\|\hat{E}(\tau)\| \leqq \gamma_0 \exp(-\nu_0(\tau-\tau_0))$ for $\tau \geqq \tau_0$, and since $\|\hat{A}-(d\hat{B}/d\tau)\| \leqq \text{Const. } e^{-\nu_0\tau}$ for $\tau \geqq 0$, γ_0 can be chosen so as to satisfy (3.19).

PROPOSITION 2. *The fundamental solution $\hat{\xi}$ satisfies $\|\hat{\xi}(u)\hat{\xi}^{-1}(u)\| \leqq \text{Const.}$ for $\tau, u \geqq \tau_0$.*

Proof. This follows from the boundedness of $\int_{\tau_0}^\infty \|\hat{B}-\hat{T}\|\,du$.

PROPOSITION 3. *The fundamental solution $\hat{\eta}(\tau)$ satisfies $|\hat{\eta}(\tau)\hat{\eta}^{-1}(u)| \leqq K_2 e^{-\nu_2(\tau-u)}$ for $\tau \geqq u \geqq \tau_0$, for some positive constants K_2 and ν_2.*

Proof. This follows from Assumption 1, the estimates (3.18)–(3.19), and Proposition 1 of [5].

PROPOSITION 4. *There exists a bounded solution $\hat{S}(\tau)$ to the differential equation* (3.17).

Proof. Imposing the initial condition $\hat{S}(\tau_0)=0$ and using the fundamental solutions $\hat{\eta}$ and $\hat{\xi}$ we find that

$$\hat{S}(\tau)=\int_{\tau_0}^\tau \hat{\eta}(\tau)\hat{\eta}^{-1}(u)\hat{\xi}(u)\hat{\xi}^{-1}(\tau)\,du. \tag{3.22}$$

It follows from Propositions 2 and 3 that $\hat{S}(\tau)$ is bounded for $\tau \geqq \tau_0$. Having shown that $\hat{S}$ is bounded we may express $\hat{S}$ as $\hat{S}(\tau)=\int_{\tau_0}^\tau \hat{\eta}(\tau)\hat{\eta}^{-1}(u)[I+\hat{S}(u)\hat{E}(u)]\,du$. This observation will be helpful later in the proof of the nonsingularity of $S(1/\varepsilon, \varepsilon)$. The proof of Lemma 1 now follows from Propositions 1–4.

4. Existence and local uniqueness. In this section we use a Riccati transformation to construct a fundamental solution for the linearization of the problem about the approximate solution $X^N(t, \varepsilon)$. An integral representation for the linearization is then used to prove the existence of an exact solution for (1.1)–(1.2) along with error estimates and local uniqueness.

THEOREM. *Assume there exists a continuous solution $X_0(t)$ to the reduced equation such that the eigenvalues of $F(t, X_0(t))$ have negative real parts* (*Assumption* 1). *If there exists a decaying solution $\hat{X}_0$ to the boundary layer problem* (*Assumption* 2), *the columns*

of $(I_n \;\; 0)P_1$ *span* R^n (*Assumption* 3), *and the given data are sufficiently smooth* (*Assumption* 4), *then there exist constants* ε_0 *and* C_N *such that* (1.1)-(1.2) *has an exact solution* $x(t, \varepsilon)$, *satisfying the estimates*

$$|x(t,\varepsilon)-X^N(t,\varepsilon)| \leqq C_N\varepsilon^N, \qquad \left|\frac{dx}{dt}(t,\varepsilon)-\frac{d}{dt}X^N(t,\varepsilon)\right| \leqq C_N\varepsilon^{N-1} \tag{4.1}$$

uniformly on the region $0 \leqq t \leqq 1, 0 < \varepsilon \leqq \varepsilon_0$. *Moreover,* $x(t, \varepsilon)$ *is unique subject to* (4.1).

Proof. Defining

$$\tilde{x} := x(t,\varepsilon)-X^N(t,\varepsilon), \qquad \tilde{y} := \varepsilon\frac{d\tilde{x}}{dt}, \tag{4.2}$$

a straightforward calculation (see Smith [18]) shows that $\tilde{x}$ and $\tilde{y}$ must satisfy

$$\frac{d}{dt}\begin{pmatrix}\tilde{x}\\ \tilde{y}\end{pmatrix} = \frac{1}{\varepsilon}\begin{pmatrix}0 & I_n\\ \varepsilon A(t,\varepsilon) & B(t,\varepsilon)\end{pmatrix}\begin{pmatrix}\tilde{x}\\ \tilde{y}\end{pmatrix} + \begin{pmatrix}0\\ H(t,\tilde{x},(1/\varepsilon)\tilde{y},\varepsilon)+\rho(t,\varepsilon)\end{pmatrix}, \tag{4.3}$$

subject to the boundary conditions

$$L\begin{pmatrix}\tilde{x}(0,\varepsilon)\\ \tilde{y}(0,\varepsilon)\end{pmatrix} + R\begin{pmatrix}\tilde{x}(1,\varepsilon)\\ \tilde{y}(1,\varepsilon)\end{pmatrix} = \begin{pmatrix}\phi_N(\varepsilon)\\ \psi_N(\varepsilon)\end{pmatrix}, \tag{4.4}$$

where

$$L := \begin{pmatrix}I_n & 0\\ 0 & 0\end{pmatrix}, \qquad R := \begin{pmatrix}0 & 0\\ I_n & 0\end{pmatrix}, \tag{4.5}$$

$$A_{i,j}(t,\varepsilon) := \sum_{k=1}^{n}\frac{\partial F_{i,k}}{\partial x_j}(t, X^N(t,\varepsilon))\frac{dX_k^N}{dt} + \frac{\partial g_i}{\partial x_j}(t, X^N(t,\varepsilon)), \tag{4.6}$$

$$B(t,\varepsilon) := F(t, X^N(t,\varepsilon)), \tag{4.7}$$

$$\begin{aligned} H(t,u,v,\varepsilon) := \int_0^1 \Bigg\{ &\left[\frac{d}{ds}F(t, X^N(t,\varepsilon)+su)\right]v + (1+s)\frac{d^2}{ds^2}\\ &\cdot\left[g(t, X^N(t,\varepsilon)+su) + F(t, X^N(t,\varepsilon)+su)\frac{d}{dt}X^N(t,\varepsilon)\right]\Bigg\}\, ds. \end{aligned} \tag{4.8}$$

Note that $H(t, u, v, \varepsilon)$ satisfies the inequality

$$|H(t,u,v,\varepsilon)| \leqq \text{Const.}\,(\varepsilon^{-1}|u|^2 + \varepsilon|v|^2) \tag{4.9}$$

uniformly as $\varepsilon \to 0^+$, for all $v \in R^n$ and for all u in a fixed compact subset of R^n.

We now construct a fundamental solution to the homogeneous portion of (4.3). Changing variables from t to τ we therefore consider the following linear system:

$$\frac{d}{d\tau}Z(\tau,\varepsilon) = \begin{pmatrix}0 & I_n\\ \varepsilon A(\varepsilon\tau,\varepsilon) & B(\varepsilon\tau,\varepsilon)\end{pmatrix}Z(\tau,\varepsilon). \tag{4.10}$$

As in Lemma 1 we employ a Riccati transformation so as to decouple the exponentially decaying solutions from the solutions bounded away from zero:

$$Z(\tau,\varepsilon) := \begin{pmatrix}I_n & S(\tau,\varepsilon)\\ T(\tau,\varepsilon) & I+T(\tau,\varepsilon)S(\tau,\varepsilon)\end{pmatrix}\begin{pmatrix}\eta(\tau,\varepsilon) & 0\\ 0 & \xi(\tau,\varepsilon)\end{pmatrix}, \tag{4.11}$$

$$Z^{-1}(\tau,\varepsilon) = \begin{pmatrix}\eta^{-1}(\tau,\varepsilon) & 0\\ 0 & \xi^{-1}(\tau,\varepsilon)\end{pmatrix}\begin{pmatrix}I+S(\tau,\varepsilon)T(\tau,\varepsilon) & -S(\tau,\varepsilon)\\ -T(\tau,\varepsilon) & I\end{pmatrix}. \tag{4.12}$$

It follows, using the method of analysis used in Lemma 1, that $Z(\tau, \varepsilon)$ satisfies the following dichotomy

$$\begin{aligned} &|Z(\tau, \varepsilon)PZ^{-1}(u, \varepsilon)| \leqq K e^{-\nu(\tau-u)}, \qquad \tau \geqq u, \\ &|Z(\tau, \varepsilon)(I-P)Z^{-1}(u, \varepsilon)| \leqq K, \qquad u \geqq \tau \end{aligned} \tag{4.13}$$

for positive constants K and ν. We now show that $S(1/\varepsilon, \varepsilon)$ is nonsingular for sufficiently small ε. Using the fundamental solution $\eta(\tau, \varepsilon)$ it follows that

$$S(\tau, \varepsilon) = \int_{\tau_0}^{\tau} \eta(\tau, \varepsilon)\eta^{-1}(u, \varepsilon)[I + S(u)E(u, \varepsilon)]\, du, \tag{4.14}$$

where $E(u, \varepsilon) = T(u, \varepsilon) - B(u, \varepsilon)$. Since $S(\tau, \varepsilon)$ is bounded, $\|E(\tau, \varepsilon)\| \leqq$ Const. $(e^{-\nu_0(\tau-\tau_0)} + \varepsilon)$, and $|\eta(\tau, \varepsilon)P\eta^{-1}(u, \varepsilon)| \leqq K e^{-\nu(\tau-u)}$ for $\tau \geqq u$, we find that

$$S\left(\frac{1}{\varepsilon}, \varepsilon\right) = \int_{1/\varepsilon - 1/\nu \ln 1/\varepsilon}^{1/\varepsilon} \eta\left(\frac{1}{\varepsilon}, \varepsilon\right)\eta^{-1}(u, \varepsilon)\, du + O(\varepsilon). \tag{4.15}$$

Since $(d/du)\eta^{-1} = -\eta^{-1}(u, \varepsilon)B(u, \varepsilon)$ and $B(u, \varepsilon) = F(1, X_0(1)) + O(\varepsilon \ln 1/\varepsilon)$ for $1/\varepsilon - 1/\nu \ln 1/\varepsilon \leqq u \leqq 1/\varepsilon$, it follows that $S(1/\varepsilon, \varepsilon) = -F(1, X_0(1)) + O(\varepsilon(\ln 1/\varepsilon)^2)$. Assumption 1 implies that $F(1, X_0(1))$ is nonsingular and hence, for all sufficiently small ε, $S(1/\varepsilon, \varepsilon)$ is also nonsingular.

We may now use $Z(\tau, \varepsilon)$ to construct a fundamental solution $\hat{Z}_1(\tau, \varepsilon)$ to the linear system

$$\frac{d\hat{Z}_1}{d\tau} = \begin{pmatrix} 0 & I_n \\ \hat{A}(\tau) & \hat{B}(\tau) \end{pmatrix} \hat{Z}_1, \qquad 0 \leqq \tau \leqq \kappa \ln \frac{1}{\varepsilon}, \tag{4.16}$$

κ a sufficiently large positive constant, satisfying the dichotomy

$$\begin{aligned} &\|\hat{Z}_1(\tau, \varepsilon)P\hat{Z}_1^{-1}(u, \varepsilon)\| \leqq K_4 e^{-\nu_4(\tau-u)}, \qquad u \leqq \tau \leqq \kappa \ln 1/\varepsilon, \\ &\|\hat{Z}_1(\tau, \varepsilon)(I-P)\hat{Z}_1^{-1}(u, \varepsilon)\| \leqq K_4, \qquad \tau \leqq u \leqq \kappa \ln 1/\varepsilon, \end{aligned} \tag{4.17}$$

where K_4 and ν_4 are positive constants, and the estimate

$$\hat{Z}_1(0, \varepsilon)P\hat{Z}^{-1}(0, \varepsilon) = Z(0, \varepsilon)PZ^{-1}(0, \varepsilon) + O(\varepsilon(\ln 1/\varepsilon)^2). \tag{4.18}$$

The proof follows from the arguments used in Lemma 6.3 of [11], Proposition 2 of [5], and the estimate $\|\varepsilon A(\varepsilon\tau, \varepsilon) - \hat{A}(\tau)\|$, $\|\hat{B}(\tau) - \hat{B}(\tau)\| \leqq$ Const. $(\varepsilon \ln 1/\varepsilon)$ for $0 \leqq \tau \leqq \kappa \ln 1/\varepsilon$.

We may now apply the arguments used in formulas (6.42)-(6.54) of Lemma 6.4 of [11] to conclude that there exists a bounded matrix $J(\varepsilon)$, with bounded inverse, such that

$$Z(0, \varepsilon)PZ^{-1}(0, \varepsilon) = P_1 J(\varepsilon) + O(\varepsilon(\ln 1/\varepsilon)^2). \tag{4.19}$$

Using the fundamental solution $\tilde{Z}(t, \varepsilon) := Z(t/\varepsilon, \varepsilon)$ we may write the problem (4.3)-(4.4) as the following integral equation:

$$\begin{aligned} \begin{pmatrix} \tilde{x}(t, \varepsilon) \\ \tilde{y}(t, \varepsilon) \end{pmatrix} &= \tilde{Z}(t, \varepsilon)PZ^{-1}(0, \varepsilon)C_L(\tilde{x}, \tilde{y}, \varepsilon) + \tilde{Z}(t, \varepsilon)(I-P)\tilde{Z}^{-1}(1, \varepsilon)C_R(\tilde{x}, \tilde{y}, \varepsilon) \\ &+ \int_0^t \tilde{Z}(t, \varepsilon)P\tilde{Z}^{-1}(s, \varepsilon)\begin{pmatrix} 0 \\ H(s, \tilde{x}(s, \varepsilon), (1/\varepsilon)\tilde{y}(s, \varepsilon), \varepsilon), \varepsilon) + \rho(s, \varepsilon) \end{pmatrix} ds \\ &- \int_t^1 \tilde{Z}(t, \varepsilon)(I-P)\tilde{Z}^{-1}(s, \varepsilon)\begin{pmatrix} 0 \\ H(s, \tilde{x}(s, \varepsilon), (1/\varepsilon)\tilde{y}(s, \varepsilon), \varepsilon) + \rho(x, \varepsilon) \end{pmatrix} ds, \end{aligned} \tag{4.20}$$

where $C_L(\tilde{x}, \tilde{y}, \varepsilon)$ and $C_R(\tilde{x}, \tilde{y}, \varepsilon)$ are determined by the boundary conditions. Imposing the boundary conditions we find that C_L and C_R must satisfy the following linear system:

$$M_L(\varepsilon)C_L(\tilde{x}, \tilde{y}, \varepsilon)+M_R(\varepsilon)C_R(\tilde{x}, \tilde{y}, \varepsilon)=\gamma(\tilde{x}, \tilde{y}, \varepsilon), \tag{4.21}$$

where

$$\begin{aligned} M_L(\varepsilon) &:= L\tilde{Z}(0, \varepsilon)P\tilde{Z}^{-1}(0, \varepsilon)+R\tilde{Z}(1, \varepsilon)P\tilde{Z}^{-1}(0, \varepsilon), \\ M_R(\varepsilon) &:= L\tilde{Z}(0, \varepsilon)(I-P)\tilde{Z}^{-1}(1, \varepsilon)+R\tilde{Z}(1, \varepsilon)(I-P)\tilde{Z}^{-1}(1, \varepsilon), \end{aligned} \tag{4.22}$$

and

$$\begin{aligned} \gamma(\tilde{x}, \tilde{y}, \varepsilon) := &\begin{pmatrix} \phi(\varepsilon) \\ \psi(\varepsilon) \end{pmatrix} + L\int_0^1 \tilde{Z}(0, \varepsilon)(I-P)\tilde{Z}^{-1}(s, \varepsilon) \\ &\cdot \begin{pmatrix} 0 \\ H(s, \tilde{x}(s, \varepsilon), (1/\varepsilon)\tilde{y}(s, \varepsilon), \varepsilon)+\rho(s, \varepsilon) \end{pmatrix} ds \\ &-R\int_0^1 \tilde{Z}(1, \varepsilon)P\tilde{Z}^{-1}(s, \varepsilon)\begin{pmatrix} 0 \\ H(s, \tilde{x}(s, \varepsilon), (1/\varepsilon)\tilde{y}(s, \varepsilon), \varepsilon)+\rho(s, \varepsilon) \end{pmatrix} ds. \end{aligned} \tag{4.23}$$

Since $|R\tilde{Z}(1, \varepsilon)P\tilde{Z}^{-1}(0, \varepsilon)| \leqq \text{Const. } e^{(\nu/\varepsilon)}$, the columns of $(I_n \quad 0)\tilde{Z}(0, \varepsilon)P\tilde{Z}^{-1}(0, \varepsilon) = (I_n \quad 0)P_1J(\varepsilon)+O(\varepsilon(\ln(1/\varepsilon)^2)$ span R^n (see Assumption 3 and (4.19)), and

$$\begin{aligned} &R\tilde{Z}(1, \varepsilon)(I-P)\tilde{Z}^{-1}(1, \varepsilon) \\ &= \begin{pmatrix} 0 & 0 \\ -F(1, X_0(1))T(1/\varepsilon, \varepsilon)T(1/\varepsilon, \varepsilon) & F(1, X_0(1)) \end{pmatrix} + O\left(\varepsilon\left(\ln\frac{1}{\varepsilon}\right)^2\right), \end{aligned} \tag{4.24}$$

it follows that for sufficiently small ε there exists a solution C_L and C_R to the above linear system. We may now apply the Banach-Picard fixed point theorem to conclude that there exists a fixed point to the integral equation and hence a solution to the problem (1.1)-(1.2) satisfying the estimates of (4.1). For the details of such a proof, including a discussion of local uniqueness, see [11, pp. 26-30].

EXISTENCE, UNIQUENESS, AND CONTINUOUS DEPENDENCE FOR A SYSTEM OF HYPERBOLIC CONSERVATION LAWS MODELING POLYMER FLOODING*

ASLAK TVEITO† AND RAGNAR WINTHER†

Abstract. The problem of well-posedness for a system of nonstrictly hyperbolic conservation laws is studied. A finite difference scheme is used to prove the existence of an entropy solution with bounded variation. It is proved that the entropy solution of the system is unique, and that the solution depends continuously on its initial data in a proper topology. The analysis is based on a smoothness property of one of the Riemann invariants of the system.

Key words. conservation laws, existence, uniqueness, continuous dependence

AMS(MOS) subject classifications. 65M10, 35L65

1. Introduction.

The purpose of this paper is to study the Cauchy problem for the hyperbolic system of conservation laws

$$\begin{aligned} s_t + f(s,c)_x &= 0, \\ (sc)_t + (c(f(s,c))_x &= 0. \end{aligned} \tag{1.1}$$

This model arises in enhanced oil recovery when oil is displaced in a porous rock by water containing dissolved polymer. The variable s denotes the saturation of the aqueous phase, consisting of water and polymer, while c denotes the concentration of polymer in the aqueous phase. The function $f = f(s,c)$ is usually referred to as the fractional flow function. For a discussion of the application of (1.1) as a model for polymer flooding, we refer to Pope [21], Isaacson [5], and Johansen and Winther [7].

The characteristic speeds of the system (1.1) are given by f_s and f/s. The system will be analyzed in regimes where the ordering of the characteristic speeds depends on the location in the state space. The hyperbolic problem (1.1) is therefore not strictly hyperbolic. Furthermore, the characteristic field associated with the speed f/s is linearly degenerate.

Riemann problems for the nonstrictly hyperbolic system (1.1) have been analyzed by Keyfitz and Kranzer [8] and Isaacson [5]. Temple [25] used these results to establish existence of a solution for the Cauchy problem by the random choice method. A parabolic regularization of the model (1.1) is studied in [29]. In [28], existence of a solution to the Cauchy problem was proved by applying finite difference approximations. However, the analysis given in [28] was limited by rather restrictive assumptions on the fractional flow function f. In particular these assumptions implied that the system was strictly hyperbolic, and they excluded physically relevant fractional flow functions. Generalizations of the problem (1.1) were studied by Serre [23].

It was observed in [28] that if the variable c is smooth initially, then c remains smooth for all time. This property is due to the fact that one of the characteristic fields is noninteracting, i.e., it does not generate discontinuities. This observation should be compared with the result of Keyfitz and Kranzer [9] that global smooth solutions of (1.1) can occur only if the variable f/s is constant for the initial data.

Hence, in general, discontinuities will develop, but in such a way that the variable c remains smooth.

In the present paper we significantly generalize the theory developed in [28]. The results derived in [28] is based on a simple form of the fractional flow function. In fact, for the model studied in [28], we could formulate the finite difference scheme equivalently in conservative variables and in the Riemann invariants. This simplified the derivation of the bounds on the approximate solutions. In the present paper we generalize the results to physically relevant fractional flow functions, for which we cannot formulate the finite difference scheme in Riemann invariants. In fact, since the system is nonstrictly hyperbolic, the Riemann invariants do not constitute a global coordinate system in the state-space. We also generalize the analysis presented in [28] by including uniqueness and continuous dependence results.

As in [28] the smoothness property of c is utilized. Existence of an entropy solution is derived under rather general assumptions on the fractional flow functions f. The existence argument uses finite difference approximations derived from the nonconservative form

$$\begin{aligned} s_t + f(s,c)_x &= 0, \\ c_t + g(s,c)c_x &= 0 \end{aligned} \tag{1.2}$$

of the system (1.1). Here $g = g(s,c)$ denotes the function $f(s,c)/s$. In order to prove convergence in L^1_{loc} of a subsequence the family (s_Δ, c_Δ) of approximate solutions generated by the finite difference scheme, it is sufficient to establish three estimates: (1) a uniform L^∞ bound, (2) a uniform total variation bound, and (3) L^1-continuity in time of the approximate solution. From these estimates we obtain convergence of a subsequence of the family (s_Δ, c_Δ) in L^1_{loc} (cf. Oleinik [19] or Smoller [24]). Glimm [4] applied this strategy in his famous existence proof for strictly hyperbolic systems of conservation laws with "small" data. He established the proper estimates for his random choice method. This scheme has also been applied by other authors in order to prove existence of weak solutions for special systems. In [15] LeVeque and Temple used this strategy to prove convergence of the Godunov scheme for strictly hyperbolic systems of conservation laws with "line fields." Serre [22] also studied such systems and proved convergence of the Godunov scheme, the random choice method, and the Lax–Friedrichs scheme.

For the present model, the estimates (1) and (3) are straightforward, whereas (2) depends strongly on the smoothness property of c_Δ derived in [28]. Having established the convergence, proving existence of an entropy solution is a matter of verifying that the limit satisfies the proper entropy condition. We remark that, to the author's knowledge, this is the first convergence result for a classical finite difference scheme applied to a nonstrictly hyperbolic system of conservation laws. Convergence of the random choice method for such system has been proved by Temple [25] and Liu and Wang [18].

However, the main contribution of this paper is a proof of uniqueness and continuous dependence results for the system (1.1). We show that, if the initial saturation s is a function of bounded variation and if the initial concentration c is sufficiently smooth, the entropy solution is unique. Furthermore, the solution depends continuously on the initial data in the proper topologies. These results should be compared with an observation done by Isaacson and Temple [6]. They observed, by combining two Riemann problem solutions, that if both the variables s and c are allowed to be discontinuous initially, then the solution would not depend continuously on the initial

data in L^1. Hence, a smoothness condition on c seems to be necessary in order to obtain a well-posed Cauchy problem.

We remark that, as a consequence of the uniqueness result, we obtain convergence of the entire family of approximate solutions, not only a subsequence of it. We hope to be able to investigate this convergence, with an eye to error estimates, in the future. We also remark that the method of proving the smoothness property of the c variable used in this paper also formally applies to more general systems of the form (1.2). The function g may depend on x, t, and other quantities in a model.

Our uniqueness and continuous dependence results are derived by introducing a "Kruzkov-form" for the saturation equation of (1.2). The results obtained from this form are combined with results obtained with the method of characteristics for the concentration equation. We recall that the "Kruzkov-form" for scalar conservation laws was introduced by Kruzkov [10] and used in [10] and Kuznetsov [11] in order to establish uniqueness and continuous dependence results for such problems. For systems of hyperbolic conservation laws there are, however, very few results addressing the question of uniqueness and continuous dependence. Some uniqueness results for rather general systems are derived by DiPerna [2] and Liu [16], and a uniqueness result for the p-system in gas dynamics is established by Oleinik (cf. Smoller [24]). Stability of the constant state for general systems is studied by Temple [26], [27].

The precise assumptions on the model and the main results are stated in §2. In §3 we derive the desired properties of the finite difference approximations, while the convergence arguments are given in §4. The uniqueness and continuous dependence results are proved in §5.

2. Preliminaries and statement of the main result. We begin by introducing some notation. If $\mathcal{K}$ is a domain in $\mathbb{R}$, then $L^p(\mathcal{K})$, $1 \le p \le \infty$, will denote the classical L^p spaces of real valued functions on $\mathcal{K}$. Instead of $L^p(\mathbb{R})$, we will simply write L^p, and the norms on L^p are denoted by $\|\cdot\|_p$. The localized versions of L^p, consisting of functions on $\mathbb{R}$ which are in $L^p(\mathcal{K})$ for any compact subset $\mathcal{K}$ of $\mathbb{R}$, are denoted by L^p_{loc}.

Furthermore, $BV = BV(\mathbb{R})$ denotes the subspace of L^1_{loc} consisting of functions with bounded variation; i.e.,

$$BV = \{v \in L^1_{\text{loc}} : TV(v) < \infty\},$$

where

$$TV(v) = \sup_{h \neq 0} \int_{\mathbb{R}} \frac{|v(x+h) - v(x)|}{|h|}\, dx.$$

The class of Lipschitz continuous functions on a domain $\mathcal{K} \subset \mathbb{R}$ is denoted by $\text{Lip}(\mathcal{K})$. More precisely

$$\text{Lip}(\mathcal{K}) = \{v \in L^\infty(\mathcal{K}) : \|v\|_{\text{Lip}(\mathcal{K})} < \infty\},$$

where

$$\|v\|_{\text{Lip}(\mathcal{K})} = \sup_{x \neq y} \frac{|v(x) - v(y)|}{|x - y|}.$$

As above, we will simply write Lip instead of $\text{Lip}(\mathbb{R})$.

If u is a function on a grid $\Delta = \{j\Delta x\}_{j\in\mathbb{Z}}$, with values u_j at the grid points $j\Delta x$, we define an associated piecewise constant function u_Δ on $\mathbb{R}$ by

$$u_\Delta(x) = u_j \quad \text{for } x \in [(j-\tfrac{1}{2})\Delta x, (j+\tfrac{1}{2})\Delta x).$$

The "discrete" L^1- and L^∞-norms of u are equal to the corresponding "continuous" norms; i.e.,

$$\|u\|_1 \equiv \Delta x \sum_{j\in\mathbb{Z}} |u_j| = \|u_\Delta\|_1,$$
$$\|u\|_\infty \equiv \sup_{j\in\mathbb{Z}} |u_j| = \|u_\Delta\|_\infty.$$

For a grid function u, we also let $TV(u)$ denote the associated "discrete" total variation given by

$$TV(u) \equiv \sum_{j\in\mathbb{Z}} |u_j - u_{j-1}|.$$

It can easily be seen (cf. [1]) that $TV(u)$ is finite if and only if $u_\Delta \in BV$, and that

$$TV(u) = TV(u_\Delta).$$

Consider now the flux-function $f = f(s,c)$ which defines our model (1.2). It will be assumed throughout the paper that there exists an S_0, $0 < S_0 < 1$, such that

$$f(S_0, c) \equiv 0 \quad \forall c \in [0,1]. \tag{2.1}$$

Furthermore we assume that

$$f(1, c) \equiv 1 \quad \forall c \in [0,1] \tag{2.2}$$

(cf. Fig. 1). The associated state-space $\mathcal{S}$ of the model is given by

$$\mathcal{S} = [S_0, 1] \times [0,1].$$

In addition to (2.1) and (2.2), we will also assume that $f(s,c)$ is an increasing and smooth function of s for all $c \in [0,1]$. In order to simplify our notation we introduce a positive constant M_f which bounds all the partial derivatives of f of order 1 or 2; i.e., we assume that $M_f > 0$ satisfies

$$0 \le f_s, |f_c|, |f_{ss}|, |f_{sc}|, |f_{cc}| \le M_f \tag{2.3}$$

for all $(s,c) \in \mathcal{S}$.

We emphasize that no assumptions are made concerning the sign of f_c or f_{ss}. Hence, the conditions here are more general than what has been assumed in some earlier papers on the model (1.2) (cf. [25], [5]).

The initial functions (s^0, c^0) of (1.2) are assumed to be given such that $(s^0(x), c^0(x)) \in \mathcal{S}$ for all $x \in \mathbb{R}$. In particular, this implies that $s^0(x) \ge S_0 > 0$ for all $x \in \mathbb{R}$. In addition we will assume that c^0 is a smooth function in the sense that $c^0 \in \text{Lip} \cap BV$. We recall that this assumption implies that c^0_x exists almost everywhere and, since c^0 is continuous, $c^0_x \in L^1$. Hence, for any bounded interval $\mathcal{K}$ of $\mathbb{R}$, the restriction of c^0 is an element of the Sobolev space $W^{1,1}(\mathcal{K})$ (cf. [30]).

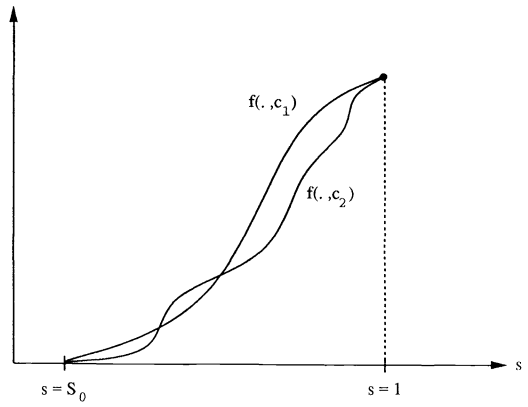

FIG. 1. *A fractional flow function f as a function of s for two values of c.*

Finally, it will be assumed that the functions s^0 and c_x^0 are elements of BV.

To be able to state the assumptions on the initial functions in a compact manner we introduce a subset $\mathcal{B}^0$ of $(L^\infty)^2$. A pair of functions (u, v) is said to be in the class $\mathcal{B}^0$ if

$$\begin{aligned} &\text{(a)} \quad (u(x), v(x)) \in \mathcal{S} \quad \forall x \in \mathbb{R}, \\ &\text{(b)} \quad v \in \mathrm{Lip} \cap BV, \\ &\text{(c)} \quad u, v_x \in BV. \end{aligned} \tag{2.4}$$

With this notation our assumptions on the functions s^0, c^0 can simply be written $(s^0, c^0) \in \mathcal{B}^0$. We also introduce a class $\mathcal{B}$ consisting of functions of two variables x and t; a pair of functions (u, v) is said to be in the class $\mathcal{B}$ if

$$\begin{aligned} &\text{(a)} \quad (u(\cdot, t), v(\cdot, t)) \in \mathcal{B}^0 \text{ for } t \in [0, T_0], \\ &\text{(b)} \quad \|u(\cdot, t) - u(\cdot, \tau)\|_1 + \|v(\cdot, t) - v(\cdot, \tau)\|_1 \le K|t - \tau| \\ &\qquad \text{for } 0 \le t, \tau \le T_0 < \infty, \\ &\text{(c)} \quad v(x, \cdot) \in \mathrm{Lip}[0, T_0] \text{ for } x \in \mathbb{R}. \end{aligned} \tag{2.5}$$

Here K is a finite constant. Throughout the paper T_0 will denote a fixed finite time. The main reason for introducing this notation is that we will show that

$$(s^0, c^0) \in \mathcal{B}^0 \Longrightarrow (s, c) \in \mathcal{B}.$$

Establishing this fundamental property of the solution of (1.2) is an essential part of our existence argument presented below.

Let us now turn to the precise formulation of the initial value problem for the model (1.2). Since we are working with a nonlinear system of hyperbolic conservation

laws, we expect that discontinuities in the solutions will occur. As indicated above, this is only the case for the saturation function s. The concentration function c will remain Lipschitz continuous for all time. Since c is continuous, the shocks in s can be considered, locally in space and time, as a shock of a scalar conservation law. We will therefore require these shocks to satisfy the proper generalization of a scalar entropy condition. This condition is formulated weakly by a modification of the Kruzkov form (cf. [10]).

DEFINITION 1. Let $(s^0, c^0) \in \mathcal{B}^0$ be given. A pair of functions (s, c) is called an entropy solution of (1.2) if they satisfy the following requirements:

1. $(s, c) \in \mathcal{B}$.

2. For all nonnegative C^∞-functions ϕ with compact support in $\mathbb{R} \times [0, T_0]$, all $q \in [S_0, 1]$ and all $T \in [0, T_0]$,

$$\int_0^T \int_{\mathbb{R}} \{|s-q|\phi_t + \operatorname{sign}(s-q)(f(s,c) - f(q,c))\phi_x - \operatorname{sign}(s-q) f(q,c)_x \phi\}\, dx\, dt$$
$$+ \int_{\mathbb{R}} |s^0(x) - q|\phi(x,0)\, dx - \int_{\mathbb{R}} |s(x,T) - q|\phi(x,T)\, dx \geq 0.$$

3. For almost all $(x, t) \in \mathbb{R} \times [0, T_0]$, $(s(x,t), c(x,t))$ satisfies

$$c_t + g(s,c)c_x = 0.$$

Furthermore,

$$\lim_{t \to 0^+} \|c(\cdot, t) - c^0\|_1 = 0.$$

This solution concept is a combination of a weak and a classical formulation. The inequality 2 is a generalization of the Kruzkov form (cf. [10]) for a scalar conservation law

$$s_t + f(s,c)_x = 0,$$

when c is a *given* function of x and t, while 3 is a classical formulation of the second equation of (1.2).

By using a finite difference approximation, we shall be able to prove the following existence result for the model (1.2).

THEOREM 2.1. *For any pair of initial functions $(s^0, c^0) \in \mathcal{B}^0$, there exists an entropy solution of* (1.2).

By assuming some extra regularity on the initial functions, we shall also prove that the entropy solution is unique. Recall that for $(s, c) \in \mathcal{S}$ we have $0 < S_0 \leq s \leq 1$; hence the function $k = c_x/s$ is well defined whenever c_x is. We also define $k^0 = c_x^0/s^0$. Assume that the initial data (s^0, c^0) satisfies the following requirements:

$$\text{(2.6)} \qquad \begin{aligned} &\text{(a)} \quad (s^0, c^0) \in \mathcal{B}^0, \\ &\text{(b)} \quad (s^0(x), c^0(x)) = \begin{cases} (s^L, c^L) & x \leq L, \\ (s^R, c^R) & x \geq R, \end{cases} \\ &\text{(c)} \quad k_x^0 \in L^\infty, \end{aligned}$$

where s^L, s^R, c^L, s^R, L, and R are finite constants. Let $(\bar{s}^0, \bar{c}^0)$ be another pair of initial functions satisfying (2.6) with the same constants; then we have the following uniqueness and continuous dependence result.

THEOREM 2.2. *Let (s^0, c^0) and $(\bar{s}^0, \bar{c}^0)$ be two pairs of initial data as described above, and let (s, c) and $(\bar{s}, \bar{c})$ be the corresponding entropy solutions of (1.2), coinciding for $|x|$ sufficiently large. Then there is a finite constant M such that*

$$\|s(\cdot,t) - \bar{s}(\cdot,t)\|_1 + \|c(\cdot,t) - \bar{c}(\cdot,t)\|_1 + \|c_x(\cdot,t) - \bar{c}_x(\cdot,t)\|_1 \leq M(\|s^0 - \bar{s}^0\|_1 + \|c^0 - \bar{c}^0\|_1 + \|c_x^0 - \bar{c}_x^0\|_1)$$

for $t \in [0, T_0]$.

This theorem shows that the system is well posed in the proper topology. We remark that, in view of the example given by Isaacson and Temple referred to above, the system is not well posed in the L^1-norm applied to the variables (s, c).

Theorem 2.1 will be proved in §4, while Theorem 2.2 will be proved in §5.

3. Properties of the approximate solutions. In order to prove the existence of a solution to the system (1.2), we generate a family (s_Δ, c_Δ) of approximate solutions to the system and prove that a subsequence of this family converges in L^1_{loc} and that the limit is a solution. The family of approximate solutions is generated by a nonconservative finite difference scheme (cf. [28]). The purpose of this section is to establish some bounds on these approximate solutions. First we prove that the approximate solutions remain in the state-space $\mathcal{S}$, and that the total variation of c_Δ is nonincreasing in time. Then, following [28], we show that c_Δ has a certain smoothness property. All these properties of the approximate solutions are used to prove that the total variation of s_Δ remains bounded for all finite time. As a corollary to the TV-estimates we establish the usual L^1-continuity in time for the approximate solutions. Finally we establish a discrete entropy condition.

Let Δx and Δt be the meshsize in space and time, respectively, and let (s_j^n, c_j^n) denote an approximation to $(s(j\Delta x, n\Delta t), c(j\Delta x, n\Delta t))$ for all $(j, n) \in \mathbb{Z} \times \mathbb{Z}^+$. The approximations are generated by the following finite difference scheme:

$$\begin{aligned} s_j^{n+1} &= s_j^n - \mu(f_j^n - f_{j-1}^n), \\ c_j^{n+1} &= c_j^n - \mu g_j^n (c_j^n - c_{j-1}^n), \end{aligned} \tag{3.1}$$

where $\mu = \Delta t/\Delta x$, $f_j^n = f(s_j^n, c_j^n)$, and $g_j^n = g(s_j^n, c_j^n)$. Recall that $g(s, c) = f(s, c)/s$. We assume that the mesh parameters satisfies the following CFL-condition:

$$\frac{\Delta t}{\Delta x} \sup_{(s,c)\in\mathcal{S}} \left(\frac{\partial f}{\partial s}, g \right) \leq 1. \tag{3.2}$$

The iteration is started by putting

$$s_j^0 = \frac{1}{\Delta x} \int_{(j-1/2)\Delta x}^{(j+1/2)\Delta x} s^0(x)\, dx \quad \text{and} \quad c_j^0 = \frac{1}{\Delta x} \int_{(j-1/2)\Delta x}^{(j+1/2)\Delta x} c^0(x)\, dx.$$

The family of approximate solutions (s_Δ, c_Δ) is defined by extending the finite difference solutions $\{(s_j^n, c_j^n)\}$ to a function on $\mathbb{R} \times [0, T_0]$,

$$\begin{aligned} &(s_\Delta(x,t), c_\Delta(x,t)) = (s_j^n, c_j^n) \\ &\qquad \text{for } (x,t) \in [(j - \tfrac{1}{2})\Delta x, (j + \tfrac{1}{2})\Delta x) \times [n\Delta t, (n+1)\Delta t). \end{aligned} \tag{3.3}$$

We start by showing that the finite difference solutions remain in the state-space, and that the total variation of c is nonincreasing as a function of time.

LEMMA 3.1. *Suppose that* $(s_j^0, c_j^0) \in \mathcal{S} \quad \forall j \in \mathbb{Z}$ *and that* $TV(c^0) < \infty$ *then*

(a) $(s_j^n, c_j^n) \in \mathcal{S} \quad \forall (j,n) \in \mathbb{Z} \times \mathbb{Z}^+$,

(b) $\min_i c_i^0 \leq c_j^n \leq \max_i c_i^0 \quad \forall (j,n) \in \mathbb{Z} \times \mathbb{Z}^+$,

(c) $TV(c^n) \leq TV(c^0) \quad \forall n \in \mathbb{Z}^+$.

Proof. Assume, for a fixed n, that $(s_j^n, c_j^n) \in \mathcal{S}$ for all $j \in \mathbb{Z}$. Since

$$c_j^{n+1} = (1 - \mu g_j^n) c_j^n + \mu g_j^n c_{j-1}^n,$$

it follows by the CFL-condition (3.2) that c_j^{n+1} is a convex combination of c_j^n and c_{j-1}^n. Hence

$$\min_i c_i^n \leq c_j^{n+1} \leq \max_i c_i^n \quad \forall j \in \mathbb{Z},$$

and

$$TV(c^{n+1}) \leq TV(c^n).$$

It remains to prove that

$$s_j^{n+1} \in [S_0, 1] \quad \forall j \in \mathbb{Z}. \tag{3.4}$$

Define the function $\sigma = \sigma(s^L, s^R, c^L, c^R)$ by

$$\sigma(s^L, s^R, c^L, c^R) = s^R - \mu(f(s^R, c^R) - f(s^L, c^L))$$

for $(s^L, c^L), (s^R, c^R) \in \mathcal{S}$. Then, by the CFL-condition (3.2) and the properties of f, we obtain

$$\frac{\partial \sigma}{\partial s^L} = \mu f_s(s^L, c^L) \geq 0,$$
$$\frac{\partial \sigma}{\partial s^R} = 1 - \mu f_s(s^R, c^R) \geq 0.$$

Consequently,

$$\sigma(s^L, s^R, c^L, c^R) \leq \sigma(1, 1, c^L, c^R) = 1,$$
$$\sigma(s^L, s^R, c^L, c^R) \geq \sigma(S_0, S_0, c^L, c^R) = S_0.$$

Since $s_j^{n+1} = \sigma(s_{j-1}^n, s_j^n, c_{j-1}^n, c_j^n)$, we have established (3.4), and the proof of the lemma is completed by induction on n. □

In [28] we established a smoothness property for the variable corresponding to our c-variable. In the present paper this property is of fundamental importance both for the existence and the uniqueness of a solution to the Cauchy problem. We will therefore, for completeness, briefly review the discussion of smoothness here.

Let us start by deriving this regularity in the case of classical solutions. We assume that (s, c) is a smooth solution of the system

$$\begin{aligned} s_t + (gs)_x &= 0, \\ c_t + gc_x &= 0, \end{aligned} \tag{3.5}$$

and that $(s(x,t), c(x,t)) \in \mathcal{S}$ for all $(x,t) \in \mathbb{R} \times [0, T_0]$. By differentiating the second equation of (3.5) with respect to x, we obtain the equation

$$(c_x)_t + (g\, c_x)_x = 0. \tag{3.6}$$

Now, let

$$k = c_x/s,$$

and recall that for $(s,c) \in \mathcal{S}$, we have $0 < S_0 \le s \le 1$. Then, by using (3.6), we get

$$0 = (ks)_t + (gks)_x = k(s_t + (gs)_x) + s(k_t + g\, k_x),$$

and then, by the first equation of (3.5), we obtain

$$k_t + g\, k_x = 0. \tag{3.7}$$

This equation is easily seen to satisfy the following maximum principle:

$$\|k(\cdot,t)\|_\infty \le \|k^0\|_\infty,$$

and consequently,

$$\|c_x(\cdot,t)\|_\infty \le \|c_x^0\|_\infty / S_0. \tag{3.8}$$

Thus we have established a uniform bound on the spatial derivative of the c-variable under the assumption of classical solutions. However, this is merely formalism since the solution of the system in general only exists in a weak sense, but these calculations clearly motivate a similar result for the approximate solutions. Using the regularity of the approximate solutions we prove, rigorously, that the function c obtained as the limit of c_Δ is Lipschitz continuous.

We remark that the method of deriving a uniform bound on the spatial derivative of c for smooth solutions outlined above is applicable for any systems that can be written on the form (3.5). It is not necessary for the function g to be a function of s and c only; it might also depend explicitly on x, t, and other quantities in a model.

To prove the regularity property for the approximate solutions, we introduce an auxiliary sequence

$$k_j^n = \frac{c_{j+1}^n - c_j^n}{\Delta x\, s_{j+1}^n} \quad \forall (j,n) \in \mathbb{Z} \times \mathbb{Z}^+. \tag{3.9}$$

Again we recall that $0 < S_0 \le s_j^n \le 1$ whenever $(s_j^n, c_j^n) \in \mathcal{S}$. We have the following result.

LEMMA 3.2. *Suppose that $(s_j^0, c_j^0) \in \mathcal{S}$ for all $j \in \mathbb{Z}$; then*

$$\left\| \frac{c_{j+1}^n - c_j^n}{\Delta x} \right\|_\infty \le \left\| \frac{c_{j+1}^0 - c_j^0}{\Delta x\, s_{j+1}^0} \right\|_\infty \le \frac{1}{S_0} \left\| \frac{c_{j+1}^0 - c_j^0}{\Delta x} \right\|_\infty \quad \forall n \in \mathbb{Z}^+.$$

Proof. We first observe that $(s_j^n, c_j^n) \in \mathcal{S}$ for all $(j,n) \in \mathbb{Z} \times \mathbb{Z}^+$ (cf. Lemma 3.1). By using the finite difference scheme (3.1) for (s_j^{n+1}, c_j^{n+1}), we obtain the following scheme for the auxiliary sequence $\{k_j^n\}$:

$$k_j^{n+1} = (1 - \mu g_{j+1}^n) \frac{s_{j+1}^n}{s_{j+1}^{n+1}} k_j^n + \mu g_j^n \frac{s_j^n}{s_{j+1}^{n+1}} k_{j-1}^n \tag{3.10}$$

(we refer to [28] for the details). By the CFL-condition (3.2), the coefficients of the scheme (3.10) are positive, and it follows from (3.1) that their sum is 1. Hence k_j^{n+1} is a convex combination of k_{j-1}^n and k_j^n, and then, by induction, we have

$$\|k^n\|_\infty \leq \|k^0\|_\infty.$$

By (3.9), this proves the lemma. □

From the proof above we collect the following results concerning the properties of the auxiliary sequence $\{k_j^n\}$.

COROLLARY 3.3. *Suppose that* $(s_j^0, c_j^0) \in \mathcal{S}\ \forall j \in \mathbb{Z}$, *and that* $TV(k^0) < \infty$, *then*

$$\text{(a)}\quad \|k^n\|_\infty \leq \|k^0\|_\infty \qquad \forall n \in \mathbb{Z}^+,$$
$$\text{(b)}\quad TV(k^n) \leq TV(k^0) \qquad \forall n \in \mathbb{Z}^+.$$

Both of these properties follow from the fact that k_j^{n+1} is a convex combination of k_{j-1}^n and k_j^n.

Next we prove that the total variation of s_Δ is bounded. We remark that this result depends strongly on the regularity of c_Δ.

LEMMA 3.4. *Suppose that* $(s_j^0, c_j^0) \in \mathcal{S}$ *for all* $j \in \mathbb{Z}$, *and that there is a finite constant* M_0 *such that*

$$TV(s^0), TV(k^0), TV(c^0), \|k^0\|_\infty \leq M_0.$$

Then

$$TV(s^n) \leq (2M_0 + \tfrac{1}{2})e^{2M_f M_0 n\Delta t},$$

where M_f *is defined by* (2.3).

Proof. From the finite difference scheme (3.1), we obtain

$$\begin{aligned} s_{j+1}^{n+1} - s_j^{n+1} &= s_{j+1}^n - s_j^n - \mu(f(s_{j+1}^n, c_{j+1}^n) - f(s_j^n, c_{j+1}^n) + f(s_j^n, c_{j+1}^n) - f(s_j^n, c_j^n)) \\ &\quad +\mu(f(s_j^n, c_j^n) - f(s_{j-1}^n, c_j^n) + f(s_{j-1}^n, c_j^n) - f(s_{j-1}^n, c_{j-1}^n)) \\ &= s_{j+1}^n - s_j^n - \mu f_s(s_{j+1/2}^n, c_{j+1}^n)(s_{j+1}^n - s_j^n) - \mu(f(s_j^n, c_{j+1}^n) - f(s_j^n, c_j^n)) \\ &\quad +\mu f_s(s_{j-1/2}^n, c_j^n)(s_j^n - s_{j-1}^n) + \mu(f(s_{j-1}^n, c_j^n) - f(s_{j-1}^n, c_{j-1}^n)), \end{aligned}$$

where $s_{j+1/2}^n \in \text{int}[s_j^n, s_{j+1}^n]$. Here $\text{int}[a, b]$ denotes the interval $[\min(a, b), \max(a, b)]$. By using a Taylor series expansion in the c-variable we get

$$\begin{aligned} TV(s^{n+1}) &= \sum_j |s_{j+1}^{n+1} - s_j^{n+1}| \\ &= \sum_j |(1 - \mu f_s(s_{j+1/2}^n, c_{j+1}^n))(s_{j+1}^n - s_j^n) + \mu f_s(s_{j-1/2}^n, c_j^n)(s_j^n - s_{j-1}^n) \\ &\quad -\mu f_c(s_j^n, c_j^n)(c_{j+1}^n - c_j^n) + \mu f_c(s_{j-1}^n, c_{j-1}^n)(c_j^n - c_{j-1}^n) \\ &\quad -\frac{\mu}{2} f_{cc}(s_j^n, c_{j+1/2}^n)(c_{j+1}^n - c_j^n)^2 + \frac{\mu}{2} f_{cc}(s_{j-1}^n, c_{j-1/2}^n)(c_j^n - c_{j-1}^n)^2|, \end{aligned}$$

where $c_{j+1/2}^n \in \text{int}[c_j^n, c_{j+1}^n]$. From the CFL-condition and the properties of f, we have

$$\begin{aligned} TV(s^{n+1}) &\leq TV(s^n) + \mu \sum_j |f_c(s_j^n, c_j^n)(c_{j+1}^n - c_j^n) - f_c(s_{j-1}^n, c_{j-1}^n)(c_j^n - c_{j-1}^n)| \\ &\quad +\mu M_f \|c_{j+1}^n - c_j^n\|_\infty \sum_j |c_{j+1}^n - c_j^n| = TV(s^n) + I + II. \end{aligned}$$

Here we bound I by using the properties of the auxiliary sequence $\{k_j^n\}$.

$$\begin{aligned} I &\equiv \frac{\Delta t}{\Delta x}\sum_j |f_c(s_j^n, c_j^n)(c_{j+1}^n - c_j^n) - f_c(s_{j-1}^n, c_{j-1}^n)(c_j^n - c_{j-1}^n)| \\ &= \Delta t \sum_j |f_c(s_j^n, c_j^n)k_j^n s_{j+1}^n - f_c(s_{j-1}^n, c_{j-1}^n)k_{j-1}^n s_j^n| \\ &= \Delta t \sum_j |k_j^n[f_c(s_j^n, c_j^n)(s_{j+1}^n - s_j^n) + s_j^n(f_c(s_j^n, c_j^n) - f_c(s_{j-1}^n, c_{j-1}^n))] \\ &\qquad + f_c(s_{j-1}^n, c_{j-1}^n)s_j^n(k_j^n - k_{j-1}^n)| \\ &\le \Delta t[\|k^n\|_\infty(M_f TV(s^n) + M_f TV(s^n) + M_f TV(c^n)) + M_f TV(k^n)]. \end{aligned}$$

Consequently, we have

$$I \le M_0 M_f(M_0 + 1)\Delta t + 2M_f M_0 \Delta t TV(s^n).$$

The term II is bounded by applying Lemmas 3.1 and 3.2:

$$II \equiv \Delta t M_f \|\frac{c_{j+1}^n - c_j^n}{\Delta x}\|_\infty TV(c^n) \le \Delta t M_f \|k^0\|_\infty TV(c^0) \le M_f M_0^2 \Delta t.$$

By using the bounds for I and II, we get

$$TV(s^{n+1}) \le (1 + 2M_f M_0 \Delta t)TV(s^n) + M_f M_0(2M_0 + 1)\Delta t,$$

and consequently we obtain, using induction, that

$$TV(s^n) \le (TV(s^0) + M_0 + \tfrac{1}{2})(1 + 2M_f M_0 \Delta t)^n - (M_0 + \tfrac{1}{2}).$$

Now the proof is completed by observing that

$$TV(s^n) \le (2M_0 + \tfrac{1}{2})e^{2M_f M_0 n \Delta t}. \qquad \square$$

An immediate consequence of Lemmas 3.1 and 3.4 and Corollary 3.3 is that the approximate solutions and the auxiliary sequence $\{k_j^n\}$ are L^1-Lipschitz continuous in time. For a proof of this fact we refer to [28].

LEMMA 3.5. *Suppose that $(s_j^0, c_j^0) \in \mathcal{S}$ for all $j \in \mathbb{Z}$, and that there is a finite constant M_0 such that*

$$TV(s^0), TV(k^0), TV(c^0), \|k^0\|_\infty \le M_0.$$

Then there exists a finite constant K depending only on M_0 and M_f such that

$$\|s^m - s^n\|_1, \|c^m - c^n\|_1, \|k^m - k^n\|_1 \le K|m - n|\Delta t$$

for $m, n \ge 0$ satisfying $m\Delta t, n\Delta t \le T_0 < \infty$.

We will conclude this section by proving that the approximate solutions satisfy a discrete entropy inequality. By using this discrete entropy inequality we will, in the next section, prove that the pair of functions (s, c), constructed as the limit of the family of approximate solutions, satisfies the entropy inequality formulated in Definition 1. In the discrete entropy condition, we will need a smooth approximation to the signum function. Let $\sigma_\epsilon = \sigma_\epsilon(s)$ be a family of nondecreasing C^∞-function satisfying $\sigma_\epsilon(s) = \text{sign}(s)$ for $|s| > \epsilon$.

LEMMA 3.6. *Suppose that* $(s_j^0, c_j^0) \in \mathcal{S}$ *for all* $j \in \mathbb{Z}$. *Let* ϕ *be a nonnegative* C^∞*-function with compact support on* $\mathbb{R} \times [0, T_0]$, *and let* N *be a positive integer such that* $N\Delta t \le T \le T_0$. *Then*

$$\begin{aligned}
\Delta t \sum_{n=0}^{N-1} \Delta x \sum_{j\in\mathbb{Z}} \Big\{ & \frac{\phi(j\Delta x,(n+1)\Delta t) - \phi(j\Delta x, n\Delta t)}{\Delta t} |s_j^{n+1} - q| \\
& + \frac{\phi((j+1)\Delta x, n\Delta t) - \phi(j\Delta x, n\Delta t)}{\Delta x} (f(s_j^n, c_j^n) - f(q, c_j^n))\operatorname{sign}(s_j^n - q) \\
& - \frac{f(q, c_j^n) - f(q, c_{j-1}^n)}{\Delta x} \sigma_\epsilon\left(s_j^{n+1} - q\right) \phi(j\Delta x, n\Delta t) \Big\} \\
+ \Delta x \sum_{j\in\mathbb{Z}} |s_j^0 - q| \phi(j\Delta x, 0) & - \Delta x \sum_{j\in\mathbb{Z}} |s_j^N - q| \phi(j\Delta x, N\Delta t) \\
& \ge \Delta t \sum_{n=0}^{N-1} \Delta x \sum_{j\in\mathbb{Z}} \Theta_\epsilon(s_j^{n+1} - q)\phi(j\Delta x, n\Delta t),
\end{aligned}$$

where

$$\Theta_\epsilon(s) = \sigma_\epsilon(s)s - |s|.$$

Proof. From the finite difference scheme (3.1), we have the following identity:

$$\begin{aligned}
s_j^{n+1} - q = s_j^n - q & - \mu(f(s_j^n, c_j^n) - f(q, c_j^n)) \\
& + \mu(f(s_{j-1}^n, c_{j-1}^n) - f(q, c_{j-1}^n)) \\
& - \mu(f(q, c_j^n) - f(q, c_{j-1}^n))
\end{aligned} \tag{3.11}$$

for any $q \in [S_0, 1]$. By multiplying this identity by $\sigma_\epsilon(s_j^{n+1} - q)$, we get $\sigma_\epsilon(s_j^{n+1} - q)(s_j^{n+1} - q)$ on the left-hand side of (3.11). By the definition of Θ_ϵ, this equals $|s_j^{n+1} - q| + \Theta_\epsilon(s_j^{n+1} - q)$. To estimate the resulting first term of the right-hand side, we introduce the function

$$\alpha(s) = s - q - \mu(f(s, c_j^n) - f(q, c_j^n)).$$

By the CFL-condition (3.2), we have

$$\alpha'(s) = 1 - \mu f_s(s, c_j^n) \ge 0,$$

hence $\operatorname{sign}(\alpha(s)) = \operatorname{sign}(s - q)$. By using this property of α and the fact that $\sigma_\epsilon(s) \le 1$, we obtain

$$\alpha(s)\sigma_\epsilon(s_j^{n+1} - q) \le |\alpha(s)| = \alpha(s)\operatorname{sign}(s - q).$$

Consequently, we have

$$\begin{aligned}
& (s_j^n - q - \mu(f(s_j^n, c_j^n) - f(q, c_j^n)))\sigma_\epsilon(s_j^{n+1} - q) \\
& \quad \le |s_j^n - q| - \mu(f(s_j^n, c_j^n) - f(q, c_j^n))\operatorname{sign}(s_j^n - q).
\end{aligned}$$

Since f is a nondecreasing function of s, the resulting second term of the right-hand side of (3.11) can be bounded in a similar manner:

$$\begin{aligned}
& \mu(f(s_{j-1}^n, c_{j-1}^n) - f(q, c_{j-1}^n))\sigma_\epsilon(s_j^{n+1} - q) \\
& \quad \le \mu |f(s_{j-1}^n, c_{j-1}^n) - f(q, c_{j-1}^n)| \\
& \quad = \mu(f(s_{j-1}^n, c_{j-1}^n) - f(q, c_{j-1}^n))\operatorname{sign}(s_{j-1}^n - q).
\end{aligned}$$

To summarize, we have derived from (3.11) the following pointwise discrete entropy inequality:

(3.12)
$$\begin{aligned}|s_j^{n+1}-q|-|s_j^n-q|+\Theta_\epsilon(s_j^{n+1}-q)\le&-\mu(f(s_j^n,c_j^n)-f(q,c_j^n))\operatorname{sign}(s_j^n-q)\\&+\mu(f(s_{j-1}^n,c_{j-1}^n)-f(q,c_{j-1}^n))\operatorname{sign}(s_{j-1}^n-q)\\&-\mu(f(q,c_j^n)-f(q,c_{j-1}^n))\sigma_\epsilon(s_j^{n+1}-q).\end{aligned}$$

By multiplying the inequality (3.12) by $\phi(j\Delta x,n\Delta t)$, we obtain, after summation in space and time, that

$$\begin{aligned}&\Delta t\sum_{n=0}^{N-1}\Delta x\sum_{j\in\mathbb{Z}}\Big\{\frac{|s_j^{n+1}-q|-|s_j^n-q|}{\Delta t}\phi(j\Delta x,n\Delta t)\\&+\frac{(f(s_j^n,c_j^n)-f(q,c_j^n))\operatorname{sign}(s_j^n-q)-(f(s_{j-1}^n,c_{j-1}^n)-f(q,c_{j-1}^n))\operatorname{sign}(s_{j-1}^n-q)}{\Delta x}\\&\qquad\cdot\phi(j\Delta x,n\Delta t)+\frac{f(q,c_j^n)-f(q,c_{j-1}^n)}{\Delta x}\sigma_\epsilon(s_j^{n+1}-q)\phi(j\Delta x,n\Delta t)\Big\}\\&\le-\Delta t\sum_{n=0}^{N-1}\Delta x\sum_{j\in\mathbb{Z}}\Theta_\epsilon(s_j^{n+1}-q)\phi(j\Delta x,n\Delta t).\end{aligned}$$

By applying summation by parts in time and space for the first and the second term, respectively, we get

$$\begin{aligned}&\Delta x\sum_{j\in\mathbb{Z}}|s_j^N-q|\phi(j\Delta x,N\Delta t)-\Delta x\sum_{j\in\mathbb{Z}}|s_j^0-q|\phi(j\Delta x,0)\\&-\Delta t\sum_{n=0}^{N-1}\Delta x\sum_{j\in\mathbb{Z}}\frac{\phi(j\Delta x,(n+1)\Delta t)-\phi(j\Delta x,n\Delta t)}{\Delta t}|s_j^{n+1}-q|\\&-\Delta t\sum_{n=0}^{N-1}\Delta x\sum_{j\in\mathbb{Z}}\frac{\phi((j+1)\Delta x,n\Delta t)-\phi(j\Delta x,n\Delta t)}{\Delta x}(f(s_j^n,c_j^n)-f(q,c_j^n))\operatorname{sign}(s_j^n-q)\\&+\Delta t\sum_{n=0}^{N-1}\Delta x\sum_{j\in\mathbb{Z}}\frac{f(q,c_j^n)-f(q,c_{j-1}^n)}{\Delta x}\sigma_\epsilon(s_j^{n+1}-q)\phi(j\Delta x,n\Delta t)\\&\le-\Delta t\sum_{n=0}^{N-1}\Delta x\sum_{j\in\mathbb{Z}}\Theta_\epsilon(s_j^{n+1}-q)\phi(j\Delta x,n\Delta t).\end{aligned}$$

which concludes the proof. □

4. Existence of an entropy solution. In the previous section we established some properties of the family of approximate solutions. In this section we will use these properties to prove that there exists a solution of the problem (1.2) in the sense of Definition 1. We start by showing that a subsequence of the family of approximate solutions (s_Δ,c_Δ) converges in L^1_{loc} to a pair of functions (s,c), and that this limit inherits the properties of the approximate solutions. Then we prove that in conservative variables, i.e., (s,sc), the limit is a weak solution of the Cauchy problem. Using this fact, and the regularity of c, we prove that the pair (s,c) is a solution according to Definition 1.

We start by stating the convergence result.

LEMMA 4.1. *Suppose that* (s^0, c^0) *is in the class* $\mathcal{B}^0$ (*cf.* (2.4)). *Then, as the meshsize tends to zero, there is a subsequence of* (s_Δ, c_Δ), *the family of approximate solutions generated by the finite difference scheme* (3.1), *converging in* L^1_{loc} *to a pair of functions* $(s, c) \in \mathcal{B}$.

Proof. In the previous section, we established the following properties of the approximate solutions:

$$\begin{aligned}
&(1)\quad (s_\Delta(x,t), c_\Delta(x,t)) \in \mathcal{S} \quad \forall (x,t) \in \mathbb{R} \times [0, T_0],\\
&(2)\quad TV(s_\Delta(\cdot,t)), TV(c_\Delta(\cdot,t)) \le K,\\
&(3)\quad \|s_\Delta(\cdot,t) - s_\Delta(\cdot,\tau)\|_1 + \|c_\Delta(\cdot,t) - c_\Delta(\cdot,\tau)\|_1 \le K(|t-\tau| + \Delta t)\\
&\text{for}\quad 0 \le t, \tau \le T_0 < \infty,
\end{aligned}$$

where K is a finite constant independent of Δ. Here (1) follows from Lemma 3.1, (2) follows from Lemmas 3.1 and 3.4, and (3) follows from Lemma 3.5. From these properties, it follows by an argument presented by Oleinik [19] (see also Smoller [24, Chap. 16]) that a subsequence, also denoted by (s_Δ, c_Δ), of the family of approximate solutions converges in L^1_{loc} for all $t \in [0, T_0]$ towards a pair of functions (s, c) as the meshsize tends to zero.

It remains to prove that the limit (s, c) is in the class $\mathcal{B}$ of functions (cf. (2.5)). Since convergence in L^1_{loc} implies pointwise convergence almost everywhere of a subsequence, we can deduce the properties of the limit (s, c) by appealing to the analogous discrete results. It might, however, be necessary to redefine (s, c) on a set of measure zero.

The fact that (s, c) remains in the state-space (cf. (a) of (2.4)), i.e.,

$$(s(x,t), c(x,t)) \in \mathcal{S} \quad \forall (x,t) \in \mathbb{R} \times [0, T_0],$$

follows from Lemma 3.1. The bound on the total variation and the Lipschitz continuity of c (cf. (b) of (2.4)), i.e.,

$$c(\cdot,t) \in \text{Lip} \cap BV \quad \text{for } t \in [0, T_0] \tag{4.1}$$

is a consequence of Lemmas 3.1 and 3.2. A detailed proof of (4.1) based on Lemma 3.2 is given in [28]. In a similar manner we deduce that

$$c(x,\cdot) \in \text{Lip}[0, \mathrm{T}_0] \quad \text{for } x \in \mathbb{R}$$

(cf. (c) of (2.5)), where in addition we have used the scheme (3.1) to derive an obvious bound on

$$\left\| \frac{c_j^{n+1} - c_j^n}{\Delta t} \right\|_\infty .$$

The L^1-Lipschitz continuity in time,

$$\|s(\cdot,t) - s(\cdot,\tau)\|_1 + \|c(\cdot,t) - c(\cdot,\tau)\|_1 \le K|t-\tau| \quad \text{for } 0 \le t, \tau \le T_0 < \infty$$

(cf. (b) of (2.5)) is a consequence of Lemma 3.5. From Lemma 3.4, it follows that

$$s(\cdot,t), \in BV \quad \text{for } t \in [0, T_0]$$

(cf. (c) of (2.4)).

To show that (c) of (2.4) are satisfied for almost all t, we define the family $\{k_\Delta\}$ of functions by

$$k_\Delta(x,t) = k_j^n \quad \text{for } (x,t) \in [(j-\tfrac{1}{2})\Delta x, (j+\tfrac{1}{2})\Delta x) \times [n\Delta t, (n+1)\Delta t).$$

Then, by the properties of k_Δ (cf. Corollary 3.3 and Lemma 3.5), there is a further subsequence, still denoted by k_Δ, converging in L^1_{loc} for all $t \in [0,T_0]$ to a function k satisfying $k(\cdot,t) \in BV \cap L^\infty$ for $t \in [0,T_0]$. Let ϕ be a smooth test function with compact support, and observe that

$$\begin{aligned}\Delta t \sum_{n=0}^{N} \Delta x \sum_{j\in\mathbb{Z}} k_j^n s_{j+1}^n \phi(j\Delta x, n\Delta t) &= \Delta t \sum_{n=0}^{N} \Delta x \sum_{j\in\mathbb{Z}} \frac{c_{j+1}^n - c_j^n}{\Delta x} \phi(j\Delta x, n\Delta t) \\ &= -\Delta t \sum_{n=0}^{N} \Delta x \sum_{j\in\mathbb{Z}} c_{j+1}^n \frac{\phi((j+1)\Delta x, n\Delta t) - \phi(j\Delta x, n\Delta t)}{\Delta x},\end{aligned}$$

where $N = \lceil T/\Delta t \rceil$, $T \le T_0$. Here $\lceil\cdot\rceil$ denotes the truncation operator. By Lebesgue dominated convergence theorem, we get

$$\int_0^T \int_{\mathbb{R}} ks\phi \, dx \, dt = -\int_0^T \int_{\mathbb{R}} c\phi_x \, dx \, dt.$$

Since c_x exists and is well defined almost everywhere, we have

$$\int_0^T \int_{\mathbb{R}} ks\phi \, dx \, dt = \int_0^T \int_{\mathbb{R}} c_x\phi \, dx \, dt.$$

Consequently,

$$ks = c_x,$$

where we, if necessary, have redefined k on a set of measure zero. This proves that (s,c) satisfies (c) of (2.4).

Thus we have verified that (s,c) is in the class $\mathcal{B}$. □

We have seen that a subsequence of the approximate solutions converges towards a pair of functions (s,c), and we will show that this limit is in fact an entropy solution. First, we will show that the limit is a weak solution of the system. Then, by using the smoothness of c, we prove that the second equation of (1.2) is satisfied in a classical sense almost everywhere. Finally, we prove that the limit is an entropy solution of the system.

We first establish that the limit is a weak solution of the system (1.2), i.e., a weak solution in the conservative variables (s, sc). The main difficulty in proving this is that our finite difference scheme is in nonconservative form. Hence, we cannot appeal to the classical theorem of Lax and Wendroff [18], stating that if a family of finite difference approximations generated by a conservative finite difference scheme converges boundedly almost everywhere, then the limit is a weak solution of the system. For our nonconservative scheme we proved a similar result in [28], taking advantage of the smoothness of the variable corresponding to c_Δ. In fact, the following proposition is a direct consequence of Lemma 2 in [28].

PROPOSITION 4.2. *Suppose that (s^0, c^0) is in the class $\mathcal{B}^0$ (cf. (2.4)). Then the pair of functions (s, sc) generated as the limit of the proper subsequence of the family*

of approximate solutions (cf. the previous lemma) is a weak solution of the system (1.1), *in the sense that*

$$\int_0^T \int_{\mathbb{R}} (s\phi_t + f(s,c)\phi_x)\,dx\,dt + \int_{\mathbb{R}} s^0(x)\phi(x,0)\,dx - \int_{\mathbb{R}} s(x,T)\phi(x,T)\,dx = 0,$$
$$\int_0^T \int_{\mathbb{R}} (sc\phi_t + cf(s,c)\phi_x)\,dx\,dt + \int_{\mathbb{R}} s^0(x)c^0(x)\phi(x,0)\,dx$$
$$- \int_{\mathbb{R}} s(x,T)c(x,T)\phi(x,T)\,dx = 0$$

for any smooth test function ϕ of compact support and any $0 \le T \le T_0$.

We next prove that (s,c) satisfies the second equation of (1.2) in a classical sense almost everywhere.

LEMMA 4.3. *Under the assumptions of Lemma* 4.1, *the pair of functions $(s,c) \in \mathcal{B}$ generated as the limit of the proper subsequence of (s_Δ, c_Δ) satisfies*

$$c_t + g(s,c)c_x = 0 \quad a.e.,$$

and

$$\lim_{t \to 0^+} \|c(\cdot,t) - c^0\|_1 = 0.$$

Proof. Let ϕ be a C^∞-function satisfying $\phi(x,t) \equiv 0$ for $|x| \ge R, t = 0, t \ge T$, where R is a finite real number. Then it follows from Proposition 4.2 that

$$\int_0^T \int_{\mathbb{R}} (s\phi_t + f(s,c)\phi_x)\,dx\,dt = 0 \tag{4.2}$$

and

$$\int_0^T \int_{\mathbb{R}} (sc\phi_t + cf(s,c)\phi_x)\,dx\,dt = 0. \tag{4.3}$$

Assume, for the moment, that

$$\int_0^T \int_{\mathbb{R}} (s(c\phi)_t + f(s,c)(c\phi)_x)\,dx\,dt = 0. \tag{4.4}$$

Then, since $(s,c) \in \mathcal{B}$, c_t and c_x exist almost everywhere,

$$\int_0^T \int_{\mathbb{R}} (s\phi c_t + f(s,c)\phi c_x)\,dx\,dt + \int_0^T \int_{\mathbb{R}} (sc\phi_t + cf(s,c)\phi_x)\,dx\,dt = 0,$$

which, by (4.3), implies

$$\int_0^T \int_{\mathbb{R}} s\phi(c_t + g(s,c)c_x)\,dx\,dt = 0.$$

Since $s(x,t) \ge S_0 > 0$, and ϕ is arbitrary, we have

$$c_t + g(s,c)c_x = 0 \quad \text{a.e.}$$

It remains to prove (4.4). Let ψ_n be a sequence of C^∞-functions with $\operatorname{supp}(\psi_n) \subset \operatorname{supp}(\phi)$ converging towards the function $c\phi$ in $W^{1,1}([-R,R]\times[0,T])$; such a sequence exists since C^∞ is dense in $W^{1,1}$ (cf. [30]) and $c\phi$ is easily seen to be in $W^{1,1}$. Consequently, by (4.2), we have

$$\begin{aligned}
&\left|\int_0^T\int_{\mathbb{R}}(s(c\phi)_t + f(s,c)(c\phi)_x)\,dx\,dt\right| \\
&= \left|\int_0^T\int_{\mathbb{R}}(s(c\phi)_t + f(s,c)(c\phi)_x)\,dx\,dt\right. \\
&\qquad \left. -\int_0^T\int_{\mathbb{R}}(s(\psi_n)_t + f(s,c)(\psi_n)_x)\,dx\,dt\right| \\
&\le M_f\int_0^T\int_{\mathbb{R}}(|(c\phi-\psi_n)_t| + |(c\phi-\psi_n)_x)|\,dx\,dt \longrightarrow 0 \quad \text{as } n\longrightarrow\infty.
\end{aligned}$$

We remark that $W^{1,1}$ denotes the Sobolev space with one derivative in L^1.

The second part of the lemma follows from the L^1-Lipschitz continuity in time of c (cf. property (b) of (2.5)), and the fact that $\|c_\Delta(\cdot,0)-c^0\|_1 \to 0$ as $\Delta\to 0$, by the construction. □

We finally prove that (s,c) satisfies the entropy inequality.

LEMMA 4.4. *Under the assumptions of Lemma* 4.1, *the pair of functions* $(s,c)\in\mathcal{B}$ *generated as the limit of the proper subsequence of* (s_Δ, c_Δ) *satisfies*

$$\begin{aligned}
&\int_0^T\int_{\mathbb{R}}\{|s-q|\phi_t + \operatorname{sign}(s-q)(f(s,c)-f(q,c))\phi_x - \operatorname{sign}(s-q)f(q,c)_x\phi\}\,dx\,dt \\
&+\int_{\mathbb{R}}|s^0(x)-q|\phi(x,0)\,dx - \int_{\mathbb{R}}|s(x,T)-q|\phi(x,T)\,dx \ge 0
\end{aligned}$$

for all nonnegative C^∞*-functions* ϕ *with compact support in* $\mathbb{R}\times[0,T_0]$, *all* $q\in[S_0,1]$, *and all* $T\in[0,T_0]$.

Proof. Let ϕ be a nonnegative C^∞-function with compact support on $\mathbb{R}\times[0,T_0]$ and let $N=\lceil T/\Delta t\rceil$. Then, by Lemma 3.6, we have

$$\begin{aligned}
&\Delta t\sum_{n=0}^{N-1}\Delta x\sum_{j\in\mathbb{Z}}\left\{\frac{\phi(j\Delta x,(n+1)\Delta t)-\phi(j\Delta x,n\Delta t)}{\Delta t}|s_j^{n+1}-q|\right. \\
&\quad +\frac{\phi((j+1)\Delta x,n\Delta t)-\phi(j\Delta x,n\Delta t)}{\Delta x}(f(s_j^n,c_j^n)-f(q,c_j^n))\operatorname{sign}(s_j^n-q) \\
&\qquad \left. -f_c(q,\tilde{c_j^n})k_{j-1}^n s_j^n\sigma_\epsilon\left(s_j^{n+1}-q\right)\phi(j\Delta x,n\Delta t)\right\} \\
&+\Delta x\sum_{j\in\mathbb{Z}}|s_j^0-q|\phi(j\Delta x,0) - \Delta x\sum_{j\in\mathbb{Z}}|s_j^N-q|\phi(j\Delta x,N\Delta t) \\
&\quad \ge \Delta t\sum_{n=0}^{N-1}\Delta x\sum_{j\in\mathbb{Z}}\Theta_\epsilon(s_j^{n+1}-q)\phi(j\Delta x,n\Delta t)
\end{aligned}$$

where we have used (3.9), and where $\tilde{c_j^n}\in\operatorname{int}[c_{j-1}^n,c_j^n]$.

Since $|\Theta_\epsilon(s)| \leq \epsilon$ for all s, the right-hand side is greater than

$$-\epsilon\Delta t \sum_{n=0}^{N-1} \Delta x \sum_{j\in\mathbb{Z}} \phi(j\Delta x, n\Delta t).$$

By the proof of Lemma 4.1, a subsequence of the family $(s_\Delta, c_\Delta, k_\Delta)$ converges pointwise almost everywhere towards (s, c, k), where $ks = c_x$; thus by passing to the limit in $(\Delta x, \Delta t)$ we obtain, using the Lebesque dominated convergence theorem, that

$$\begin{aligned}
&\int_0^T \int_{\mathbb{R}} \{|s-q|\phi_t + \operatorname{sign}(s-q)(f(s,c)-f(q,c))\phi_x - \sigma_\epsilon(s-q)f(q,c)_x\phi\}\,dx\,dt \\
&\quad + \int_{\mathbb{R}} |s^0(x)-q|\phi(x,0)\,dx - \int_{\mathbb{R}} |s(x,T)-q|\phi(x,T)\,dx \\
&\qquad \geq -\epsilon \int_0^T \int_{\mathbb{R}} \phi(x,t)\,dx\,dt.
\end{aligned}$$

Now the lemma follows by passing to the limit in ϵ and again using the Lebesgue dominated convergence theorem. □

Proof of Theorem 2.1. We can now summarize the proof of Theorem 2.1. We have constructed a pair of functions (s, c), which by Lemma 4.1 satisfies $(s, c) \in \mathcal{B}$. By Lemma 4.3 the second equation of (1.2) is satisfied in a classical sense almost everywhere, and the solution converges in L^1 towards the initial condition as the time tends to zero. Finally, we proved in Lemma 4.4 that (s, c) satisfies our entropy condition. Consequently, (s, c) is a solution according to Definition 1. □

5. Uniqueness and continuous dependence. The purpose of this section is to prove uniqueness of the entropy solution of (1.2). This result will be established under an extra smoothness assumption on the initial data (s^0, c^0). The technique we shall apply uses characteristics for the concentration equation of (1.2) together with a modification of the analysis given by Kruzkov [10] and Kuznetsov [11] applied to the saturation equation. As a consequence of our uniqueness argument, we will also obtain a continuous dependence result for the solution with respect to the initial data (s^0, c^0). Another consequence of the uniqueness is that the entire family of approximate solutions converges, not only a subsequence of it.

Before we consider the question of uniqueness, we will establish some elementary properties of an entropy solution of (1.2). These properties are based on the simple observation that the characteristic speed g of c is also the particle velocity of the aqueous phase.

Let (s, c) denote an entropy solution of (1.2) with initial data (s^0, c^0). Throughout this section it will be assumed that there exist two constant states (s^L, c^L) and (s^R, c^R) such that for $0 \leq t \leq T$, we have

$$(s(x,t), c(x,t)) = \begin{cases} (s^L, c^L) & x \leq x^L(t), \\ (s^R, c^R) & x \geq x^R(t), \end{cases} \tag{5.1}$$

where x^L and x^R are linear functions of t of the form

$$x^L(t) = L + g(s^L, c^L)t, \qquad x^R(t) = R + g(s^R, c^R)t$$

(cf. Fig. 2). In particular, we observe that the solution constructed above satisfies the condition (5.1) if the initial data is constant for $|x|$ sufficiently large.

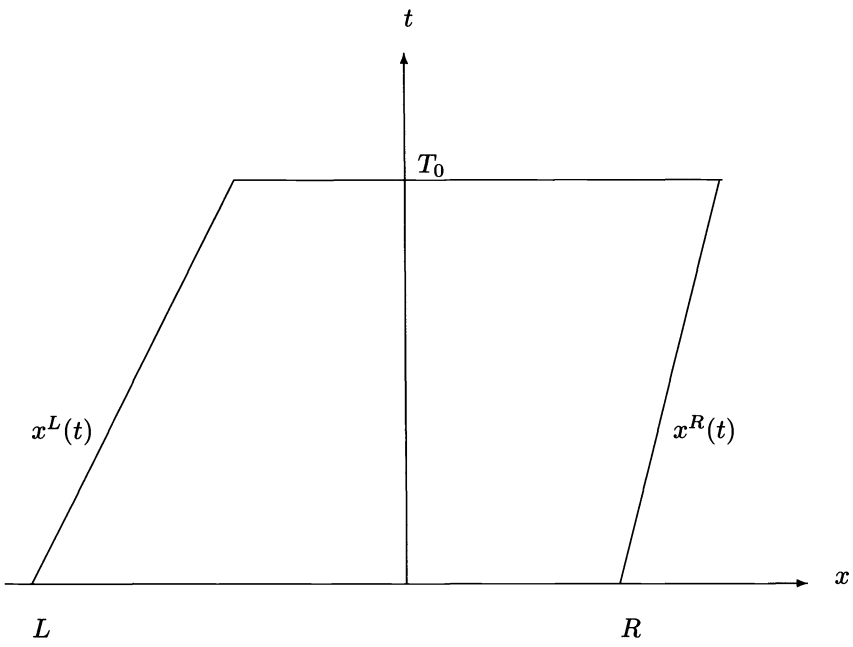

FIG. 2

Let $x(t)$, $0 \le t \le T$, be a smooth curve such that $x^L(t) \le x(t) \le x^R(t)$. From the entropy condition, it follows in particular that (s, c) satisfies the first equation of (1.2) weakly; hence (cf. Oleinik [20]) we have the following conservation relation:

$$\int_{x^L(t)}^{x(t)} s(\xi, t)\, d\xi - \int_L^{x(0)} s^0(\xi)\, d\xi = \int_0^t [s(x(\tau), \tau)x_\tau(\tau) - f(s(x(\tau), \tau), c(x(\tau), \tau))n(\tau)]\, d\tau, \tag{5.2}$$

where

$$n(\tau) = \frac{1}{\sqrt{1 + (x_\tau(\tau))^2}}.$$

For any $t \in [0, T_0]$ and $x \in [x^L(t), x^R(t)]$, define

$$m(x, t) = \int_{x^L(t)}^{x} s(\xi, t)\, d\xi.$$

For each $t \in [0, T_0]$, $m(\cdot, t)$ is a strictly increasing function of x with

$$m_x(x, t) = s(x, t) \ge S_0 > 0.$$

Furthermore, (5.2) implies that

$$m(x^R(t), t) = m(R, 0). \tag{5.3}$$

Also, for $t \in [0, T_0]$, we define a strictly increasing function $y(\cdot, t)$ from $[L, R]$ onto $[x^L(t), x^R(t)]$ by

$$m(y(x,t),t) = m(x,0). \tag{5.4}$$

Since m_x exists, y_x exists and

$$y_x(x,t) = \frac{m_x(x,0)}{m_y(y,t)} = \frac{s^0(x)}{s(y,t)} \geq S_0 > 0.$$

The identity (5.2) implies in particular that

$$m(x,t_1) - m(x,t_2) = -\int_{t_1}^{t_2} f(s(x,t),c(x,t))\,dt.$$

Hence, since the function $f(s(x,t),c(x,t))$ is bounded and measurable as a function of t for almost all x, it follows that $m_t(x,t)$ exists for almost all x and t, and

$$m_t(x,t) = -f(s(x,t),c(x,t)).$$

From (5.4) we therefore obtain that y_t exists for almost all (x,t), and

$$y_t(x,t) = -\frac{m_t(y,t)}{m_y(y,t)} = g(s(y,t),c(y,t)).$$

Note also that $y(x,0) = x$. Hence, the well-defined function $y(x,t)$, which is differentiable almost everywhere, corresponds to the desired characteristic for the concentration equation. In particular,

$$c(y(x,t),t) = c^0(x). \tag{5.5}$$

By differentiating this identity with respect to x, we obtain that

$$k(y(x,t),t) = k^0(x), \tag{5.6}$$

where $k = c_x/s$ and $k^0 = c_x^0/s^0$.

Assume now that $(\bar{s}, \bar{c})$ is another entropy solution of (1.2) with initial data $(\bar{s}^0, \bar{c}^0)$. Furthermore, we shall assume that $(\bar{s}, \bar{c})$ satisfies the condition (5.1), with the same boundary states (s^L, c^L) and (s^R, c^R) as the (s,c), and with the same curves $x^L(t)$ and $x^R(t)$. The difference between c and $\bar{c}$ can now be estimated by using the associated characteristics.

LEMMA 5.1. *Let (s,c) and $(\bar{s},\bar{c})$ be two entropy solutions of* (1.2), *with initial data $(s^0,c^0) \in \mathcal{B}^0$ and $(\bar{s}^0,\bar{c}^0) \in \mathcal{B}^0$, respectively, both satisfying the condition* (5.1). *Then there is a finite constant M such that*

$$\|(c-\bar{c})(\cdot,t)\|_1 \leq M\left\{\|c^0-\bar{c}^0\|_1 + \int_0^t (\|(s-\bar{s})(\cdot,\tau)\|_1 + \|(c-\bar{c})(\cdot,\tau)\|_1)\,d\tau\right\}$$

for $t \in [0, T_0]$.

Proof. Let S and C denote the differences $s - \bar{s}$ and $c - \bar{c}$, respectively. Then C clearly satisfies the following equation:

$$C_t + g(\bar{s},\bar{c})C_x = F(x,t),$$

where $F = c_x(g(\bar{s},\bar{c}) - g(s,c))$. Hence, if $\bar{y} = \bar{y}(x,t)$ represents the characteristic associated the solution $(\bar{s},\bar{c})$, then

$$C(\bar{y}(x,t),t) = C(x,0) + \int_0^t F(\bar{y}(x,\tau),\tau)\,d\tau. \tag{5.7}$$

Since

$$\int_{\mathbb{R}} |C(\bar{y}(x,t),t)|\,dx \geq S_0 \|C(\cdot,t)\|_1,$$

and

$$\int_0^t \int_{\mathbb{R}} |F(\bar{y}(x,\tau),\tau)|\,dx\,d\tau \leq \frac{M_g}{S_0}\|c_x\|_{L^\infty(\mathbb{R}\times[0,T_0])} \int_0^t (\|S(\cdot,\tau)\|_1 + \|C(\cdot,\tau)\|_1)\,d\tau,$$

the desired result follows. □

Recall that $k = c_x/s$, and let $\bar{k} = \bar{c}_x/\bar{s}$. Similarly, $k^0 = c_x^0/s^0$ and $\bar{k}^0 = \bar{c}_x^0/\bar{s}^0$. By assuming some extra regularity on the initial data, we obtain the following bound for the difference $c_x - \bar{c}_x$.

LEMMA 5.2. *Let (s,c) and $(\bar{s},\bar{c})$ be two entropy solutions of (1.2) as above, and assume in addition that $k_x^0 \in L^\infty$. Then there is a finite constant M such that*

$$\|(c_x - \bar{c}_x)(\cdot,t)\|_1 \leq M\Big\{\|s^0 - \bar{s}^0\|_1 + \|c_x^0 - \bar{c}_x^0\|_1 + \|s(\cdot,t) - \bar{s}(\cdot,t)\|_1 + \int_0^t (\|(s-\bar{s})(\cdot,\tau)\|_1 + \|(c-\bar{c})(\cdot,\tau)\|_1)\,d\tau\Big\}$$

for $t \in [0,T_0]$.

Proof. From (5.6), it follows that

$$k_t + g(s,c)k_x = 0.$$

A similar relation holds for $\bar{k}$. Since k_x is bounded by (5.6), an argument analogous to the argument given in the proof of Lemma 5.1 leads to the estimate

$$\|(k-\bar{k})(\cdot,t)\|_1 \leq M\left\{\|k^0 - \bar{k}^0\|_1 + \int_0^t (\|(s-\bar{s})(\cdot,\tau)\|_1 + \|(c-\bar{c})(\cdot,\tau)\|_1)\,d\tau\right\}.$$

Therefore, since

$$c_x - \bar{c}_x = s(k-\bar{k}) + \bar{k}(s-\bar{s}),$$

the estimate follows by a proper modification of the constant M. □

Finally, we estimate the difference $s - \bar{s}$ in L^1.

LEMMA 5.3. *Let (s,c) and $(\bar{s},\bar{c})$ be two entropy solutions of (1.2) as above. Then there is a finite constant K such that*

$$\|s(\cdot,t) - \bar{s}(\cdot,t)\|_1 \leq \|s^0 - \bar{s}^0\|_1 + K\int_0^t \{\|c_x(\cdot,\tau) - \bar{c}_x(\cdot,\tau)\|_1 + \|c(\cdot,\tau) - \bar{c}(\cdot,\tau)\|_1 + \|s(\cdot,\tau) - \bar{s}(\cdot,\tau)\|_1\}\,d\tau$$

for $t \in [0,T_0]$.

The proof of this lemma is given in the end of this section.

Proof of Theorem 2.2. We are now in position to prove Theorem 2.2. Define

$$\Phi(t) = \|c_x(\cdot,t) - \bar{c}_x(\cdot,t)\|_1 + \|c(\cdot,t) - \bar{c}(\cdot,t)\|_1 + \|s(\cdot,t) - \bar{s}(\cdot,t)\|_1.$$

By Lemmas 5.1, 5.2, and 5.3 we obtain

$$\Phi(t) \leq M\left(\Phi(0) + \int_0^t \Phi(\tau)\,d\tau\right)$$

for a finite constant M. Hence, by a proper modification of M, we get

$$\Phi(t) \leq M\Phi(0)$$

for $t \in [0, T_0]$, which is the stability result stated in Theorem 2.2. In particular, this implies the uniqueness result. □

As a consequence of the uniqueness of the entropy solution, we obtain convergence of the entire family (s_Δ, c_Δ) of approximate solutions.

5.1. Proof of Lemma 5.3. We will now prove Lemma 5.3, i.e., the stability estimate for the saturation variable s. The proof is motivated by the work of Kruzkov [10] and Kuznetsov [11] for scalar equations.

We introduce a nonnegative function $\omega \in C^\infty$ satisfying $\omega(\sigma) = \omega(-\sigma)$, $\omega(\sigma) \equiv 0$ for $|\sigma| \geq 1$, and $\int_{\mathbb{R}} \omega(\sigma)d\sigma = 1$. For $\epsilon > 0$, let

$$\omega_\epsilon(\sigma) = \frac{1}{\epsilon}\omega(\sigma/\epsilon);$$

then

$$\begin{aligned}
&\text{(a)} \quad \omega_\epsilon \in C^\infty, \quad \omega_\epsilon(\sigma) \geq 0 \quad \forall \sigma \in \mathbb{R},\\
&\text{(b)} \quad \int_{\mathbb{R}} \omega_\epsilon(\sigma)d\sigma = 1,\\
&\text{(c)} \quad \omega_\epsilon(\sigma) \equiv 0 \quad \text{for} \quad |\sigma| \geq \epsilon,\\
&\text{(d)} \quad \omega_\epsilon(\sigma) \leq M_\omega/\epsilon, \quad |\omega_\epsilon{}'(\sigma)| \leq M_\omega/\epsilon^2,
\end{aligned}$$

where M_ω is a finite constant independent ϵ.

We will need the following auxilary result concerning bounded and measurable functions of compact support.

LEMMA 5.4. (i) *Suppose $v = v(x)$ is a bounded and measurable function of compact support on $\mathbb{R}$; then*

$$\lim_{\epsilon\to 0} \frac{1}{\epsilon}\int_{\mathbb{R}}\int_{x-\epsilon}^{x+\epsilon} |v(x) - v(y)|dy\,dx = 0.$$

(ii) *Similarly, suppose $v = v(x,t)$ is a bounded and measurable function of compact support on $\mathbb{R}\times\mathbb{R}$; then*

$$\lim_{\epsilon\to 0} \frac{1}{\epsilon^2}\int_{\mathbb{R}}\int_{\mathbb{R}^+}\int_{x-\epsilon}^{x+\epsilon}\int_{t-\epsilon}^{t+\epsilon} |v(x,t) - v(y,\tau)|\,d\tau\,dy\,dt\,dx = 0.$$

We refer to Kruzkov [10, Lemma 2, p. 222] for a proof.

As above, (s,c) and $(\bar{s},\bar{c})$ are two pairs of solutions, in the sense of Definition 1, of the problem (1.2). Recall that

$$s(x,t)=\bar{s}(x,t) \quad \text{and} \quad c(x,t)=\bar{c}(x,t) \quad \text{for } x\notin[x^L(t),x^R(t)], \quad t\in[0,T_0].$$

For $q\in[S_0,1]$, we define

$$F_1(s,c,q)=\operatorname{sign}(s-q)(f(s,c)-f(q,c))$$

and

$$F_2(s,c,q)=\operatorname{sign}(s-q)f(q,c)_x.$$

Then the entropy condition for (s,c) reads

$$\int_0^T\int_{\mathbb{R}}\{|s-q|\phi_t+F_1(s,c,q)\phi_x-F_2(s,c,q)\phi\}\,dx\,dt + \int_{\mathbb{R}}|s^0(x)-q|\phi(x,0)\,dx-\int_{\mathbb{R}}|s(x,T)-q|\phi(x,T)\,dx\geq 0$$

for all $q\in[S_0,1]$, and all nonnegative C^∞-functions ϕ of compact support. We introduce the test functions

$$\psi_\epsilon(x,t,y,\tau)=\omega_\epsilon(t-\tau)\omega_\epsilon(x-y)$$

for $(x,t,y,\tau)\in(\mathbb{R}\times[0,T_0])^2$, and the form

$$\rho_\epsilon(w,z)=\int_{\mathbb{R}}\int_{\mathbb{R}}\omega_\epsilon(x-y)|w(x)-z(y)|\,dx\,dy.$$

By putting $q=\bar{s}(y,\tau)$ in the entropy condition for (s,c) and integrating with respect to y and τ, we get

$$\begin{aligned}(5.8)\quad 0\leq{}&\int_0^T\int_{\mathbb{R}}\int_0^T\int_{\mathbb{R}}\{|s(x,t)-\bar{s}(y,\tau)|(\psi_\epsilon)_t+F_1(s(x,t),c(x,t),\bar{s}(y,\tau))(\psi_\epsilon)_x\\&-F_2(s(x,t),c(x,t),\bar{s}(y,\tau))\psi_\epsilon\}\,dx\,dt\,dy\,d\tau\\&+\int_0^T\rho_\epsilon(s^0,\bar{s}(\cdot,\tau))\omega_\epsilon(\tau)\,d\tau-\int_0^T\rho_\epsilon(s(\cdot,T),\bar{s}(\cdot,\tau))\omega_\epsilon(T-\tau)\,d\tau\end{aligned}$$

for any $T\in[0,T_0]$. Similarly, by the entropy condition for $(\bar{s},\bar{c})$, we obtain

$$\begin{aligned}(5.9)\quad 0\leq{}&\int_0^T\int_{\mathbb{R}}\int_0^T\int_{\mathbb{R}}\{|s(x,t)-\bar{s}(y,\tau)|(\psi_\epsilon)_\tau+F_1(\bar{s}(y,\tau),\bar{c}(y,\tau),s(x,t))(\psi_\epsilon)_y\\&-F_2(\bar{s}(y,\tau),\bar{c}(y,\tau),s(x,t))\psi_\epsilon\}\,dx\,dt\,dy\,d\tau\\&+\int_0^T\rho_\epsilon(\bar{s}^0,s(\cdot,t))\omega_\epsilon(t)\,dt-\int_0^T\rho_\epsilon(\bar{s}(\cdot,T),s(\cdot,t))\omega_\epsilon(T-t)\,dt.\end{aligned}$$

We observe that

$$(\psi_\epsilon)_t=-(\psi_\epsilon)_\tau \quad \text{and} \quad (\psi_\epsilon)_x=-(\psi_\epsilon)_y.$$

Taking this into account, we obtain, by adding (5.8) and (5.9), that

$$\begin{aligned}
&\int_0^T \rho_\epsilon(s(\cdot,T),\bar{s}(\cdot,\tau))\omega_\epsilon(T-\tau)\,d\tau + \int_0^T \rho_\epsilon(\bar{s}(\cdot,T),s(\cdot,t)\omega_\epsilon(T-t))\,dt \\
&\le \int_0^T\int_{\mathbb{R}}\int_0^T\int_{\mathbb{R}} (F_1(s(x,t),c(x,t),\bar{s}(y,\tau)) \\
&\qquad\qquad -F_1(\bar{s}(y,\tau),\bar{c}(y,\tau),s(x,t)))(\psi_\epsilon)_x\,dx\,dt\,dy\,d\tau \\
&\quad -\int_0^T\int_{\mathbb{R}}\int_0^T\int_{\mathbb{R}} (F_2(s(x,t),c(x,t),\bar{s}(y,\tau)) \\
&\qquad\qquad +F_2(\bar{s}(y,\tau),\bar{c}(y,\tau),s(x,t)))\psi_\epsilon\,dx\,dt\,dy\,d\tau \\
&\quad +\int_0^T \rho_\epsilon(s^0,\bar{s}(\cdot,\tau))\omega_\epsilon(\tau)\,d\tau + \int_0^T \rho_\epsilon(\bar{s}^0,s(\cdot,t))\omega_\epsilon(t)\,dt.
\end{aligned}$$

For notational convenience we write this inequality as

$$L(\epsilon) \le R(\epsilon), \tag{5.10}$$

where

$$L(\epsilon) \equiv L_1(\epsilon) + L_2(\epsilon) \quad \text{and} \quad R(\epsilon) \equiv R_1(\epsilon) + R_2(\epsilon) + R_3(\epsilon) + R_4(\epsilon).$$

Observe that

$$\begin{aligned}
&\left| L_1(\epsilon) - \frac{1}{2}\int_{\mathbb{R}} \left| s(x,T) - \bar{s}(x,T) \right| dx \ \right| \\
&\quad = \left| \int_0^T\int_{\mathbb{R}}\int_{\mathbb{R}} |s(x,T) - \bar{s}(y,\tau)|\omega_\epsilon(T-\tau)\omega_\epsilon(x-y)\,dx\,dy\,d\tau \right. \\
&\qquad \left. - \int_0^T\int_{\mathbb{R}}\int_{\mathbb{R}} |s(x,T) - \bar{s}(x,T)|\omega_\epsilon(T-\tau)\omega_\epsilon(x-y)\,dx\,dy\,d\tau \right| \\
&\quad \le \int_0^T\int_{\mathbb{R}}\int_{\mathbb{R}} |\bar{s}(y,\tau) - \bar{s}(x,T)|\omega_\epsilon(T-\tau)\omega_\epsilon(x-y)\,dx\,dy\,d\tau \\
&\quad \le \int_0^T\int_{\mathbb{R}} |\bar{s}(y,\tau) - \bar{s}(y,T)|\omega_\epsilon(T-\tau)\,dy\,d\tau \\
&\qquad + \frac{1}{2}\int_{\mathbb{R}}\int_{\mathbb{R}} |\bar{s}(y,T) - \bar{s}(x,T)|\omega_\epsilon(x-y)\,dx\,dy \\
&\quad \le \frac{M_\omega}{\epsilon}\int_{T-\epsilon}^T\int_{\mathbb{R}} |\bar{s}(y,\tau) - \bar{s}(y,T)|\,dy\,d\tau + \frac{M_\omega}{2\epsilon}\int_{\mathbb{R}}\int_{x-\epsilon}^{x+\epsilon} |\bar{s}(y,T) - \bar{s}(x,T)|\,dy\,dx.
\end{aligned}$$

Hence, by Lemma 5.4, we have

$$\lim_{\epsilon\to 0} L_1(\epsilon) = \frac{1}{2}\int_{\mathbb{R}} |s(x,T) - \bar{s}(x,T)|\,dx.$$

By applying a similar argument for L_2, R_3, and R_4, we obtain

$$\lim_{\epsilon\to 0}(L_1(\epsilon) + L_2(\epsilon)) = \|s(\cdot,T) - \bar{s}(\cdot,T)\|_1 \tag{5.11}$$

and

$$\lim_{\epsilon\to 0}(R_3(\epsilon) + R_4(\epsilon)) = \|s^0 - \bar{s}^0\|_1. \tag{5.12}$$

It remains to estimate R_1 and R_2, and we start with the latter,

$$\begin{aligned}
|R_2(\epsilon)| &= \Big| \int_0^T \int_{\mathbb{R}} \int_0^T \int_{\mathbb{R}} (F_2(s(x,t), c(x,t), \bar{s}(y,\tau)) \\
&\qquad + F_2(\bar{s}(y,\tau), \bar{c}(y,\tau), s(x,t))) \psi_\epsilon \, dx \, dt \, dy \, d\tau \Big| \\
&\le \int_0^T \int_{\mathbb{R}} \int_0^T \int_{\mathbb{R}} |f(\bar{s}(y,\tau), c(x,t))_x - f(s(x,t), \bar{c}(y,\tau))_y| \psi_\epsilon \, dx \, dt \, dy \, d\tau \\
&\le \int_0^T \int_{\mathbb{R}} \int_0^T \int_{\mathbb{R}} \{ |f_c(\bar{s}(y,\tau), c(x,t))(c_x(x,t) - \bar{c}_y(y,\tau))| \psi_\epsilon + |f_c(\bar{s}(y,\tau), c(x,t)) \\
&\qquad - f_c(s(x,t), \bar{c}(y,\tau))| |\bar{c}_y(y,\tau)| \psi_\epsilon \} \, dx \, dt \, dy \, d\tau \\
&\le K \int_0^T \int_{\mathbb{R}} \int_0^T \int_{\mathbb{R}} (|c_x(x,t) - \bar{c}_y(y,\tau)| \\
&\qquad + |\bar{s}(y,\tau) - s(x,t)| + |c(x,t) - \bar{c}(y,\tau)|) \psi_\epsilon \, dx \, dt \, dy \, d\tau,
\end{aligned}$$

where K is a finite constant, depending on $\|c_y\|_\infty$, but independent of ϵ. Observe that

$$\begin{aligned}
&\int_0^T \int_{\mathbb{R}} \int_0^T \int_{\mathbb{R}} |c(x,t) - \bar{c}(y,\tau)| \psi_\epsilon \, dx \, dt \, dy \, d\tau \\
&\quad \le \int_0^T \int_{\mathbb{R}} \int_0^T \int_{\mathbb{R}} |c(x,t) - \bar{c}(x,t)| \omega_\epsilon(x-y) \omega_\epsilon(t-\tau) \, dx \, dt \, dy \, d\tau \\
&\qquad + \int_0^T \int_{\mathbb{R}} \int_0^T \int_{\mathbb{R}} |\bar{c}(x,t) - \bar{c}(y,\tau)| \omega_\epsilon(x-y) \omega_\epsilon(t-\tau) \, dx \, dt \, dy \, d\tau \\
&\quad \le \int_0^T \int_{\mathbb{R}} |c(x,t) - \bar{c}(x,t)| \, dx \, dt \\
&\qquad + \frac{M_\omega^2}{\epsilon^2} \int_0^T \int_{\mathbb{R}} \int_{\tau-\epsilon}^{\tau+\epsilon} \int_{y-\epsilon}^{y+\epsilon} |\bar{c}(x,t) - \bar{c}(y,\tau)| \, dx \, dt \, dy \, d\tau \\
&\quad \xrightarrow{\epsilon \to 0} \int_0^T \int_{\mathbb{R}} |c(x,t) - \bar{c}(x,t)| \, dx \, dt
\end{aligned}$$

by Lemma 5.4. (For simplicity, we have defined $\bar{c}(x,t) = \bar{c}^0(x)$ for $t < 0$.) In a similar manner, we obtain

$$\limsup_{\epsilon \to 0} \int_0^T \int_{\mathbb{R}} \int_0^T \int_{\mathbb{R}} |c_x(x,t) - \bar{c}_y(y,\tau)| \psi_\epsilon \, dx \, dt \, dy \, d\tau \le \int_0^T \int_{\mathbb{R}} |c_x(x,t) - \bar{c}_x(x,t)| \, dx \, dt$$

and

$$\limsup_{\epsilon \to 0} \int_0^T \int_{\mathbb{R}} \int_0^T \int_{\mathbb{R}} |\bar{s}(y,\tau) - s(x,t)| \psi_\epsilon \, dx \, dt \, dy \, d\tau \le \int_0^T \int_{\mathbb{R}} |s(x,t) - \bar{s}(x,t)| \, dx \, dt;$$

consequently

$$\begin{aligned}
\limsup_{\epsilon \to 0} |R_2(\epsilon)| \le K \int_0^T \{ &\|c_x(\cdot,t) - \bar{c}_x(\cdot,t)\|_1 \\
&+ \|c(\cdot,t) - \bar{c}(\cdot,t)\|_1 + \|s(\cdot,t) - \bar{s}(\cdot,t)\|_1 \} \, dt.
\end{aligned} \tag{5.13}$$

Next, we estimate R_1. We have

$$\begin{aligned} R_1(\epsilon) &= \int_0^T\int_{\mathbb{R}}\int_0^T\int_{\mathbb{R}} [F_1(s(x,t),c(x,t),\bar{s}(y,\tau)) \\ &\qquad -F_1(\bar{s}(y,\tau),\bar{c}(y,\tau),s(x,t))](\psi_\epsilon)_x\,dx\,dt\,dy\,d\tau \\ &\equiv \int_0^T\int_{\mathbb{R}}\int_0^T\int_{\mathbb{R}} Q(x,t,y,\tau)(\psi_\epsilon)_x\,dx\,dt\,dy\,d\tau, \end{aligned}$$

where

$$\begin{aligned} Q(x,t,y,\tau) = \operatorname{sign}(s(x,t)-\bar{s}(y,\tau))[&(f(s(x,t),c(x,t))-f(s(x,t),\bar{c}(y,\tau))) \\ &-(f(\bar{s}(y,\tau),c(x,t))-f(\bar{s}(y,\tau),\bar{c}(y,\tau)))]. \end{aligned}$$

Observe that

$$\int_0^T\int_{\mathbb{R}}\int_0^T\int_{\mathbb{R}} Q(y,\tau,y,\tau)(\psi_\epsilon)_x\,dx\,dt\,dy\,d\tau = 0$$

for all $\epsilon > 0$. Define the function

$$H(s,c,\bar{s},\bar{c}) = \operatorname{sign}(s-\bar{s})[(f(s,c)-f(s,\bar{c}))-(f(\bar{s},c)-f(\bar{s},\bar{c}))].$$

Then

$$\begin{aligned} &|Q(x,t,y,\tau)-Q(y,\tau,y,\tau)| \\ &\quad = |H(s(x,t),c(x,t),\bar{s}(y,\tau),\bar{c}(y,\tau))-H(s(y,\tau),c(y,\tau),\bar{s}(y,\tau),\bar{c}(y,\tau))| \\ &\quad \le |H(s(x,t),c(x,t),\bar{s}(y,\tau),\bar{c}(y,\tau))-H(s(y,\tau),c(x,t),\bar{s}(y,\tau),\bar{c}(y,\tau))| \\ &\qquad +|H(s(y,\tau),c(x,t),\bar{s}(y,\tau),\bar{c}(y,\tau))-H(s(y,\tau),c(y,\tau),\bar{s}(y,\tau),\bar{c}(y,\tau))| \\ &\quad \le |H_s(\tilde{s},c(x,t),\bar{s}(y,\tau),\bar{c}(y,\tau))||s(x,t)-s(y,\tau)| \\ &\qquad +|H_c(s(y,\tau),\tilde{c},\bar{s}(y,\tau),\bar{c}(y,\tau))||c(x,t)-c(y,\tau)|, \end{aligned}$$

where $\tilde{s} \in [S_0,1]$ and $\tilde{c} \in [0,1]$. Since

$$H_s(s,c,\bar{s},\bar{c}) = \operatorname{sign}(s-\bar{s})(f_s(s,c)-f_s(s,\bar{c}))$$

for almost all s, and

$$H_c(s,c,\bar{s},\bar{c}) = \operatorname{sign}(s-\bar{s})(f_c(s,c)-f_c(\bar{s},c)),$$

we obtain

$$\begin{aligned} &|Q(x,t,y,\tau)-Q(y,\tau,y,\tau)| \\ &\quad \le M_f\{|c(x,t)-\bar{c}(y,\tau)||s(x,t)-s(y,\tau)|+|s(y,\tau)-\bar{s}(y,\tau)||c(x,t)-c(y,\tau)|\}. \end{aligned}$$

Hence,

$$\begin{aligned} |R_1(\epsilon)| &= \left|\int_0^T\int_{\mathbb{R}}\int_0^T\int_{\mathbb{R}} (Q(x,t,y,\tau)-Q(y,\tau,y,\tau))(\psi_\epsilon)_x\,dx\,dt\,dy\,d\tau\right| \\ &\le M_f\int_0^T\int_{\mathbb{R}}\int_0^T\int_{\mathbb{R}} |c(x,t)-\bar{c}(y,\tau)||s(x,t)-s(y,\tau)| \\ &\qquad \cdot|\omega_\epsilon{}'(x-y)|\omega_\epsilon(t-\tau)\,dx\,dt\,dy\,d\tau \\ &\quad +M_f\int_0^T\int_{\mathbb{R}}\int_0^T\int_{\mathbb{R}} |s(y,\tau)-\bar{s}(y,\tau)||c(x,t)-c(y,\tau)| \\ &\qquad \cdot|\omega_\epsilon{}'(x-y)|\omega_\epsilon(t-\tau)\,dx\,dt\,dy\,d\tau \\ &\equiv I(\epsilon)+II(\epsilon). \end{aligned}$$

By using the Lipschitz continuity of $\bar{c}$, we get

$$\begin{aligned}
I(\epsilon) &= M_f \int_0^T \int_{\mathbb{R}} \int_0^T \int_{\mathbb{R}} (|c(x,t) - \bar{c}(y,\tau)||s(x,t) - s(y,\tau)|) \\
&\quad \cdot |\omega_\epsilon{}'(x-y)|\omega_\epsilon(t-\tau)\,dx\,dt\,dy\,d\tau \\
&\le M_f \int_0^T \int_{\mathbb{R}} \int_0^T \int_{\mathbb{R}} (|c(x,t) - \bar{c}(x,t)| + |\bar{c}(x,t) - \bar{c}(y,\tau)|) \\
&\quad \cdot |s(x,t) - s(y,\tau)||\omega_\epsilon{}'(x-y)|\omega_\epsilon(t-\tau)\,dx\,dt\,dy\,d\tau \\
&\le M_f \int_0^T \int_{\mathbb{R}} \int_0^T \int_{\mathbb{R}} |c(x,t) - \bar{c}(x,t)|(|s(x,t) - s(y,t)| \\
&\qquad\qquad + |s(y,t) - s(y,\tau)|)|\omega_\epsilon{}'(x-y)|\omega_\epsilon(t-\tau)\,dx\,dt\,dy\,d\tau \\
&\quad + \frac{M_f M_\omega^2}{\epsilon^2} \int_0^T \int_{\mathbb{R}} \int_{x-\epsilon}^{x-\epsilon} \int_{t-\epsilon}^{t-\epsilon} |s(x,t) - s(y,\tau)|\,dx\,dt\,dy\,d\tau.
\end{aligned}$$

(Recall that we defined $s(x,t) = s^0(x)$ for $t < 0$.) Here, by Lemma 5.4, the second term tends to zero as ϵ tends to zero. The first term is bounded by using the bound on the total variation and the L^1-Lipschitz continuity in time of s. Observe that

$$\begin{aligned}
&\int_0^T \int_{\mathbb{R}} \int_0^T \int_{\mathbb{R}} |c(x,t) - \bar{c}(x,t)|(|s(x,t) - s(y,t)| \\
&\qquad\qquad + |s(y,t) - s(y,\tau)|)|\omega_\epsilon{}'(x-y)|\omega_\epsilon(t-\tau)\,dx\,dt\,dy\,d\tau \\
&\le \int_0^T \int_0^T \omega_\epsilon(t-\tau)\|c(\cdot,t) - \bar{c}(\cdot,t)\|_\infty \left\{ \iint_{\mathbb{R}} |s(x,t) - s(y,t)||\omega_\epsilon{}'(x-y)|dx\,dy \right. \\
&\qquad\qquad \left. + \int_{\mathbb{R}} |s(y,t) - s(y,\tau)| \left[\int_{y-\epsilon}^{y+\epsilon} |\omega_\epsilon{}'(x-y)|dx \right] dy \right\} dt\,d\tau \\
&\le \int_0^T \int_0^T \omega_\epsilon(t-\tau)\|c(\cdot,t) - \bar{c}(\cdot,t)\|_\infty \left\{ \int_{\mathbb{R}} |\omega_\epsilon{}'(z)| \left(\int_{\mathbb{R}} |s(x,t) - s(x-z,t)|\,dx \right) dz \right. \\
&\qquad\qquad \left. + \frac{2M_\omega}{\epsilon}\|s(\cdot,t) - s(\cdot,\tau)\|_1 \right\} dt\,d\tau \\
&\le \int_0^T \|c(\cdot,t) - \bar{c}(\cdot,t)\|_\infty \left[\int_{\mathbb{R}} |\omega_\epsilon{}'(z)|\,TV(s(\cdot,t))\,|z|\,dz \right] dt \\
&\quad + \int_0^T \|c(\cdot,t) - \bar{c}(\cdot,t)\|_\infty \frac{\bar{K}}{\epsilon} \int_0^T \omega_\epsilon(t-\tau)|t-\tau|\,d\tau\,dt \\
&\le K \int_0^T \|c(\cdot,t) - \bar{c}(\cdot,t)\|_\infty\,dt,
\end{aligned}$$

where K and $\bar{K}$ are finite constants independent of ϵ. Since

$$\|c(\cdot,t) - \bar{c}(\cdot,t)\|_\infty \le \|c_x(\cdot,t) - \bar{c}_x(\cdot,t)\|_1,$$

we obtain, by a proper modification of K, that

$$\limsup_{\epsilon \to 0} I(\epsilon) \le K \int_0^T \|c_x(\cdot,t) - \bar{c}_x(\cdot,t)\|_1\,dt.$$

Finally we estimate $II(\epsilon)$ by using the Lipschitz continuity of c,

$$II(\epsilon) = M_f \int_0^T \int_{\mathbb{R}} \int_0^T \int_{\mathbb{R}} |s(y,\tau) - \bar{s}(y,\tau)||c(x,t) - c(y,\tau)|$$

$$
\begin{aligned}
&\cdot |\omega_\epsilon{}'(x-y)|\omega_\epsilon(t-\tau)\,dx\,dt\,dy\,d\tau \\
&\leq \bar{K}\int_0^T\int_{\mathbb{R}}\int_0^T\int_{\mathbb{R}} |s(y,\tau)-\bar{s}(y,\tau)|(|x-y|+|t-\tau|) \\
&\qquad \cdot |\omega_\epsilon{}'(x-y)|\omega_\epsilon(t-\tau)\,dx\,dt\,dy\,d\tau \\
&= \bar{K}\int_0^T\int_{\mathbb{R}} |s(y,\tau)-\bar{s}(y,\tau)|\Big\{ \int_{\mathbb{R}} |x-y||\omega_\epsilon{}'(x-y)|\,dx \int_0^T \omega_\epsilon(t-\tau)\,dt \\
&\qquad\qquad + \int_{\mathbb{R}} |\omega_\epsilon{}'(x-y)|\,dx \int_0^T |t-\tau|\omega_\epsilon(t-\tau)\,dt\Big\}\,dy\,d\tau \\
&\leq K\int_0^T \|s(\cdot,t)-\bar{s}(\cdot,t)\|_1\,dt.
\end{aligned}
$$

Consequently,

$$
\limsup_{\epsilon\to 0} R_1(\epsilon) \leq K\int_0^T (\|c_x(\cdot,t)-\bar{c}_x(\cdot,t)\|_1 + \|s(\cdot,t)-\bar{s}(\cdot,t)\|_1)\,dt. \tag{5.14}
$$

By applying (5.10)–(5.14) we obtain

$$
\begin{aligned}
\|s(\cdot,T)-\bar{s}(\cdot,T)\|_1 \leq \|s^0-\bar{s}^0\|_1 + K\int_0^T \{&\|c_x(\cdot,t)-\bar{c}_x(\cdot,t)\|_1 \\
&+\|c(\cdot,t)-\bar{c}(\cdot,t)\|_1 + \|s(\cdot,t)-\bar{s}(\cdot,t)\|_1\}\,dt,
\end{aligned}
$$

which concludes the proof of Lemma 5.3.

DIFFUSION OF PENETRANT IN A POLYMER: A FREE BOUNDARY PROBLEM*

BEI HU†

Abstract. A free boundary problem arising in modeling diffusion of a penetrant in a polymer is studied. The asymptotic behavior of the solution for short time and long time, for small and large physical parameter ϵ, and for small and large driving law exponent n are proved. Some explicit error estimates are also given.

Key words. free boundary, variational inequality, asymptotic behavior

AMS(MOS) subject classifications. 35B40, 35R35

1. Introduction.

A model describing the diffusion of a penetrant in a glassy polymer is given by

$$\epsilon u_t = u_{xx} \quad \text{for } 0 < x < s(t), \quad t > 0, \tag{1.1}$$

$$u(0,t) = 1, \tag{1.2}$$

$$[1 + \epsilon u(s(t),t)] \cdot s'(t) = -u_x(s(t),t), \tag{1.3}$$

$$s'(t) = u^n(s(t),t), \tag{1.4}$$

$$s(0) = 0, \tag{1.5}$$

where u is the penetrant concentration over its equilibrium value, s is the penetrant front driven by u. The driving law (1.4) expresses the kinetics of swelling and is assumed to be n-order type. $1/\epsilon$ is the diffusivity in the swollen polymer (see [1], [3]). In special examples in [3], n takes values varying from 10^{-2} to 10^2, ϵ need not be small, and it is an interesting problem to study the dependence of the solution on the parameter ϵ.

The problem with $\epsilon = 1$, (1.3) replaced by $[q + u(s(t),t)] \cdot s'(t) = -u_x(s(t),t)$ $(q \geq 0)$ and (1.4) replaced by $s'(t) = f(u(s(t),t))$ was studied in [4] by Fasano, Meyer, and Primicerio. Their results imply, in particular, the following theorem.

THEOREM 1.1. *Problem* (1.1)–(1.5) *has a unique classical solution* (u,s) *such that* $s \in C^2[0,\infty) \cap C^\infty(0,\infty)$, $u \in C^\infty(D_\infty) \cap C^{2,1}(\overline{D_\infty})$, *where* $D_\infty = \{(x,t) : 0 < x < s(t),\ 0 < t < \infty\}$; *furthermore,*

$$0 < u(x,t) < 1 \quad \textit{for } (x,t) \in D_\infty, \tag{1.6}$$

$$-1 - \epsilon < u_x(x,t) < 0 \quad \textit{for } (x,t) \in D_\infty, \tag{1.7}$$

$$u_t(x,t) > 0 \quad \textit{for } (x,t) \in D_\infty, \tag{1.8}$$

$$s''(t) < 0 \quad \textit{for } 0 \leq t < \infty. \tag{1.9}$$

They also studied the long time behavior of $s(t)$ $(t \to +\infty)$ and proved (for $\epsilon = 1$) that

$$\sqrt{\frac{3}{2}}(1 - o(t)) \leq \frac{s(t)}{\sqrt{t}} \leq \sqrt{2} \qquad \text{for } t \to \infty.$$

More recently, Cohen and Erneux [3] obtained more precise asymptotic behavior

$$\lim_{t\to\infty} s(t)s'(t) = \frac{M^2}{2},$$

$$\lim_{t\to\infty} u(ys(t),t) = 1 - \int_0^{My} \exp\left(-\frac{\epsilon}{4}\xi^2\right) d\xi \Big/ \int_0^{M} \exp\left(-\frac{\epsilon}{4}\xi^2\right) d\xi, \tag{1.10}$$

where M is given by

$$\exp\left(-\frac{\epsilon}{4}M^2\right) = \frac{1}{2}M\int_0^M \exp\left(-\frac{\epsilon}{4}\xi^2\right) d\xi;$$

note that (1.10) implies that

$$\lim_{t\to\infty} \frac{s(t)}{\sqrt{t}} = M. \tag{1.11}$$

They also obtained similar formulas for the asymptotic behavior of $u(x,t)$ and $s(t)$ as $t \to 0$ and as $\epsilon \to 0$:

$$u_0(x,t) - C_1\epsilon \le u_\epsilon(x,t) \le u_0(x,t) + C_2\epsilon \quad \text{for } 0 < x < s_\epsilon(t), \quad 0 < t < \infty, \tag{1.12}$$

$$1 - C_3\epsilon < \frac{s_0(t)}{s_\epsilon(t)} < 1 + C_4\epsilon \quad \text{for } 0 < t < \infty, \tag{1.13}$$

where (u_ϵ, s_ϵ) denotes the solution of (1.1)–(1.5); u_0, s_0 are indepedent of ϵ. However, all these results were obtained by formal power series expansions.

In §§1–4, we shall give rigorous justification to these facts. In §2 we consider the short time behavior for (u,s) and give explicit error estimates. In §3 we study the long time behavior and prove (1.10) and (1.11). In §4 we establish (1.12) and (1.13) with $C_1 = 5\max(n,1)$, $C_2 = 0$, $C_3 = 0$, and $C_4 = 4\max(n,1)$. And in §5 we shall prove that $\lim_{\epsilon\to\infty} s_\epsilon(t) = 0$.

Sections 6 and 7 are devoted to studying the effects of the driving law exponent n in (1.4). Denote by (u_n, s_n) the solution of (1.1)–(1.5). In §6 we shall show that $s_n(t) \to 0$ when $n \to \infty$. In §7, we investigate the case $n \to 0$. We shall prove that there exists a critical value $T^* > 0$ such that

$$\lim_{n\to 0}(u_n(x,t), s_n(t)) = (z(x,t),t) \quad \text{for } t \in [0,T^*] \tag{1.14}$$

and

$$\lim_{n\to 0}(u_n(x,t), s_n(t)) = (u_0(x,t), s_0(t)) \quad \text{for } t \in [T^*,\infty), \tag{1.15}$$

where (u_0, s_0) is the solution of an appropriate Stefan problem, and the formulas for $z(x,t)$ and T^* will also be given.

Consider next the case where condition (1.2) for maintaining constant concentration at $x = 0$ is replaced by flux control, namely,

$$u_x(0,t) = g(t). \tag{1.16}$$

THEOREM 1.2 (Anderucci and Ricci [2]). *If*

$$g \in C^1[0,\infty), \quad g(t) \le 0 \quad \text{for } t > 0, \quad g(0) < 0, \tag{1.17}$$

then the problem (1.1), (1.16), (1.3)–(1.5) *has a unique classical solution* (u,s) *with* $s \in C^1[0,\infty)$, $u \in C^{2,1}(D_\infty) \cap C^{1,0}(\overline{D_\infty})$, *where* $D_\infty = \{(x,t) : 0 < x < s(t),\ 0 < t < \infty\}$; *furthermore,*

$$u(x,t) > 0 \quad \text{for } (x,t) \in \overline{D_\infty}, \tag{1.18}$$

$$u_x(x,t) < 0 \quad \text{for } (x,t) \in D_\infty. \tag{1.19}$$

If in addition to (1.17), $g'(t) \ge 0$ *for* $t \ge 0$, *then*

$$s''(t) \le 0 \quad \text{for } 0 \le t < \infty. \tag{1.20}$$

It was also proved in [2] that if $\int_0^\infty g(t)dt > -\infty$, then $\lim_{t\to\infty} s(t)$ exists; the limit was also computed.

In §8 of this paper, we shall study the long time behavior of $s(t)$ when the condition $\int_0^\infty g(t)dt > -\infty$ is dropped. We shall prove that $x = s(t)$ approaches the free boundary of a Stefan problem; in particular, it follows that $\lim_{t\to\infty} s(t) = \infty$ in the case $\int_0^\infty g(t)dt = -\infty$, in contrast to the case $\int_0^\infty g(t)dt > -\infty$, where $\lim_{t\to\infty} s(t)$ is finite.

2. Short time behavior.

THEOREM 2.1. *For the solution of* (1.1)–(1.5), *we have*

$$0 \le u(x,t) - [1-(1+\epsilon)x] \le Ct^2 \quad \text{for } 0 \le x \le s(t), \quad 0 \le t \le \frac{1}{2(1+\epsilon)}, \tag{2.1}$$

$$-C_1(1+\epsilon)^2t^3 \le s(t) - \left(t - \frac{n}{2}(1+\epsilon)t^2\right) \le C_2(1+\epsilon)^2t^3 \quad \text{for } 0 \le t \le \frac{1}{2(1+\epsilon)}, \tag{2.2}$$

where $C = (1+\epsilon)(2n\epsilon+\epsilon+2n)$, $C_1 = 0$ *if* $n \ge 1$ *and* $C_1 = 1/6$ *if* $0 < n < 1$, *and* C_2 *is a constant depending only on* n.

Proof. Let $w(x,t) = 1-(1+\epsilon)x$; then obviously $\epsilon w_t - w_{xx} = 0$, $w(0,t) = u(0,t)$ and

$$w_x(s(t),t) + [1+\epsilon w(s(t),t)]w^n(s(t),t) \le -(1+\epsilon) + (1+\epsilon) = 0. \tag{2.3}$$

Hence, by maximum principle, $w(x,t) \le u(x,t)$ for $0 \le x \le s(t)$, $t \ge 0$.

Next, let $\widetilde{w}(x,t) = 1-(1+\epsilon)x + Cxt$; then $\epsilon\widetilde{w}_t - \widetilde{w}_{xx} = C\epsilon x \ge 0$ for $x \ge 0$ and $\widetilde{w}(0,t) = u(0,t)$. Since $s'(t) = u^n(s(t),t) \in (0,1)$, we have $0 < s(t) < t$, and hence

$$\begin{aligned}
\{\widetilde{w}_x + (1+\epsilon\widetilde{w})\widetilde{w}^n\}\Big|_{x=s(t)} &\ge -1-\epsilon+Ct+[1+\epsilon-\epsilon(1+\epsilon)s(t)][1-(1+\epsilon)s(t)]^n \\
&\ge -1-\epsilon+Ct+[1+\epsilon-\epsilon(1+\epsilon)t][1-(1+\epsilon)t]^n \\
&\equiv a(t) \quad \text{for } 0 \le x \le s(t), \quad 0 \le t \le \frac{1}{2(1+\epsilon)}.
\end{aligned}$$

For $0 \le t \le 1/[2(1+\epsilon)]$,

$$\begin{aligned}
a'(t) &= C - \epsilon(1+\epsilon)[1-(1+\epsilon)t]^n - n(1+\epsilon)[1+\epsilon-\epsilon(1+\epsilon)t][1-(1+\epsilon)t]^{n-1} \\
&\ge C - \epsilon(1+\epsilon) - n(1+\epsilon)^2 \cdot 2 \\
&= 0,
\end{aligned}$$

and thus $a(t) \geq a(0) = 0$ for $0 \leq t \leq 1/[2(1+\epsilon)]$. Now (2.1) follows by maximum principle.

By (2.1),

$$\begin{aligned} s'(t) &\geq [1-(1+\epsilon)s(t)]^n \\ &\geq 1-n(1+\epsilon)s(t)-3C_1[(1+\epsilon)s(t)]^2 \\ &\geq 1-n(1+\epsilon)t-3C_1[(1+\epsilon)t]^2, \end{aligned}$$

where we can take $C_1 = 0$ if $n \geq 1$ and $C_1 = 1/6$ if $0 < n < 1$. Hence

$$s(t) \geq t - \frac{n}{2}(1+\epsilon)t^2 - C_1(1+\epsilon)^2 t^3.$$

Next, using (2.1) again, we get

$$\begin{aligned} s'(t) &\leq [1-(1+\epsilon)s(t)+C[(1+\epsilon)t]^2]^n \\ &\leq 1-n(1+\epsilon)s(t)+C[(1+\epsilon)t]^2, \end{aligned}$$

where the constant C depends only on n. Solving the above inequality we obtain

$$\begin{aligned} s(t) &\leq \frac{1-\exp[-n(1+\epsilon)t]}{n(1+\epsilon)} + C(1+\epsilon)^2 \int_0^t \exp[-n(1+\epsilon)(t-\tau)]\tau^2 d\tau \\ &\leq t - \frac{n}{2}(1+\epsilon)t^2 + C(1+\epsilon)^2 t^3. \end{aligned}$$

□

3. Long time behavior. Define $\phi(x,t)$ to be the corresponding solution of the Stefan problem, i.e.,

$$\begin{aligned} &\epsilon\phi_t = \phi_{xx} \quad \text{for } 0 < x < h(t), \quad t > 0, \\ &\phi(0,t) = 1, \\ &h'(t) = -\phi_x(h(t),t), \\ &\phi(h(t),t) = 0, \\ &h(0) = 0. \end{aligned}$$

It is well known that

$$\phi(x,t) = 1 - \int_0^{x/\sqrt{t}} \exp\left(-\frac{\epsilon}{4}\xi^2\right) d\xi \Big/ \int_0^M \exp\left(-\frac{\epsilon}{4}\xi^2\right) d\xi,$$

(3.1)

$$h(t) = M\sqrt{t},$$

where $M = M(\epsilon)$ is such that

$$\exp\left(-\frac{\epsilon}{4}M^2\right) = \frac{1}{2}M \int_0^M \exp\left(-\frac{\epsilon}{4}\xi^2\right) d\xi. \tag{3.2}$$

The main result of this section is Theorem 3.1.

THEOREM 3.1. *Suppose* (u,s) *is a solution of* (1.1)–(1.5). *Then*

$$\lim_{t\to\infty} s(t)s'(t) = \frac{M^2}{2}, \tag{3.3}$$

which implies that

$$\lim_{t\to\infty} \frac{s(t)}{\sqrt{t}} = M. \tag{3.4}$$

Furthermore,

$$\lim_{t\to\infty} \sup_{0\le x\le s(t)} |u(x,t) - \phi(x,t)| = 0, \tag{3.5}$$

where ϕ is given by (3.1). □

In order to prove (3.3), we need to prove (3.4) first. We shall compare the solution (u, s) of (1.1)–(1.5) to the solution ϕ of the Stefan problem. Let us first transform our problem into a variational inequality. Set

$$\begin{aligned} v(x,t) &= \int_{s^{-1}(x)}^{t} \left[u(x,\tau) - (s'(\tau))^{1/n}\right] d\tau \quad \text{for } x < s(t) \\ &\equiv 0 \qquad\qquad\qquad\qquad\qquad\qquad\quad \text{for } x \ge s(t), \end{aligned} \tag{3.6}$$

where $s^{-1}(x)$ is the inverse function of $s(t)$; it is C^1 since $s'(t) > 0$. A calculation shows that v satisfies the following variational inequality:

$$\epsilon v_t - v_{xx} = -1 - \epsilon(s'(t))^{1/n} \quad \text{for } 0 < x < s(t), \quad t > 0, \tag{3.7}$$

$$v = v_x = 0 \quad \text{on } x = s(t), \quad t > 0, \tag{3.8}$$

$$v = \int_0^t \left[1 - (s'(\tau))^{1/n}\right] d\tau \quad \text{on } x = 0, \quad t > 0, \tag{3.9}$$

$$v = 0 > -1 - \epsilon(s'(t))^{1/n} \quad \text{for } x > s(t), \quad t > 0, \tag{3.10}$$

$$v > 0 \quad \text{for } x < s(t), \quad t > 0 \quad \text{(by using } v_x < 0 \text{ and (3.8))}. \tag{3.11}$$

LEMMA 3.2.

$$s(t) \le M\sqrt{t} \quad \textit{for all } t > 0. \tag{3.12}$$

Proof. Let

$$\begin{aligned} w(x,t) &= \int_{x^2/M^2}^{t} \phi(x,\tau)d\tau \quad \text{for } x < M\sqrt{t} \\ &\equiv 0 \qquad\qquad\qquad\quad \text{for } x \ge M\sqrt{t}. \end{aligned}$$

Then w satisfies the variational inequality:

$$\epsilon w_t - w_{xx} = -1 \quad \text{for } 0 < x < M\sqrt{t}, \quad t > 0, \tag{3.13}$$

$$w = w_x = 0 \quad \text{on } x = M\sqrt{t}, \quad t > 0, \tag{3.14}$$

$$w = t \quad \text{on } x = 0, \quad t > 0, \tag{3.15}$$

$$w = 0 > -1 \quad \text{for } x > M\sqrt{t}, \quad t > 0, \tag{3.16}$$

$$w > 0 \quad \text{for } x < M\sqrt{t}, \quad t > 0. \tag{3.17}$$

Therefore, by comparison principle for variational inequalities (see [7], for example) we get $v(x,t) \le w(x,t)$ for $0 < x < \infty, t > 0$, and hence $s(t) \le M\sqrt{t}$. □

Next, we prove Lemma 3.3.

LEMMA 3.3.

$$\lim_{t\to\infty} \frac{s(t)}{\sqrt{t}} = M. \tag{3.18}$$

Proof. By Theorem 5.2 of [4], we have

$$\lim_{t\to\infty} s'(t) = 0; \tag{3.19}$$

therefore for any $\eta > 0$, there exist $T > 0$ such that

$$0 < \epsilon(s'(t))^{1/n} \le \eta \quad \text{for } t \ge T. \tag{3.20}$$

Let N_η be the solution of

$$(1-\eta)\exp\left(-\frac{\epsilon}{4}N^2\right) = (1+\eta)\frac{1}{2}N\int_0^N \exp\left(-\frac{\epsilon}{4}\xi^2\right)d\xi; \tag{3.21}$$

it is then clear that $N_\eta < M$ and $N_\eta \to M$ as $\eta \to 0$. Next, set

$$\psi(x,t) = (1-\eta)\left(1 - \frac{\displaystyle\int_0^{x/\sqrt{t-T}} \exp\left(-\frac{\epsilon}{4}\xi^2\right)d\xi}{\displaystyle\int_0^{N_\eta} \exp\left(-\frac{\epsilon}{4}\xi^2\right)d\xi}\right) \quad \text{for } t \ge T. \tag{3.22}$$

Then

$$\begin{aligned}
&\epsilon\psi_t = \psi_{xx} \quad \text{for } 0 < x < N_\eta\sqrt{t-T}, \quad t > T,\\
&\psi(0,t) = 1-\eta \quad \text{for } t \ge T,\\
&\psi = 0, \quad -\psi_x = (1+\eta)\frac{d}{dt}\left(N_\eta\sqrt{t-T}\right) \quad \text{on } x = N_\eta\sqrt{t-T}.
\end{aligned}$$

Repeating the proof of Lemma 3.2 we find that

$$s(t) \ge N_\eta\sqrt{t-T} \quad \text{for } t \ge T; \tag{3.23}$$

it follows that

$$\liminf_{t\to\infty} \frac{s(t)}{\sqrt{t}} \ge N_\eta, \tag{3.24}$$

and we conclude the lemma by letting $\eta \to 0$. □

LEMMA 3.4.

$$\lim_{t\to\infty} \sup_{0\le x\le s(t)} |u(x,t) - \phi(x,t)| = 0, \tag{3.25}$$

where ϕ is given by (3.1).

Proof. Set

$$k(x,t) = \frac{1}{t^\alpha}\left(2 - \frac{x^2}{s^2(t)}\right),$$

where $\alpha > 0$ is to be determined. Then

$$\begin{aligned}
\epsilon k_t - k_{xx} &= -\frac{\epsilon\alpha}{t^{\alpha+1}}\left(2 - \frac{x^2}{s^2(t)}\right) + \frac{\epsilon}{t^\alpha}\frac{2x^2 s'(t)}{s^3(t)} + \frac{1}{t^\alpha}\frac{2}{s^2(t)} \\
&\geq \frac{2}{t^{\alpha+1}}\left(-\epsilon\alpha + \frac{t}{s^2(t)}\right) \\
&\geq \frac{2}{t^{\alpha+1}}\left(-\epsilon\alpha + \frac{1}{M^2}\right) \quad \text{(by Lemma 3.2)} \\
&> 0 \quad \text{for } t > 0,\ 0 < x < s(t)
\end{aligned}$$

if α is small enough. For $T > 0$, we set

$$w(x,t) = \phi(x,t) + \sup_{\tau \geq T}(s'(\tau))^{1/n} + T^\alpha k(x,t).$$

Then $\epsilon w_t - w_{xx} > 0$ for $0 < x < s(t), t > T$; $w(0,t) \geq 1 = u(0,t)$ for $t \geq T$; $w(s(t),t) \geq \sup_{\tau \geq T}(s'(\tau))^{1/n} \geq u(s(t),t)$ for $t \geq T$ and $w(x,T) \geq 1 \geq u(x,T)$ for $0 \leq x \leq s(t)$. Therefore by maximum principle,

$$w(x,t) \geq u(x,t) \quad \text{for } 0 \leq x \leq s(t), \quad t \geq T.$$

Hence

$$\limsup_{t\to\infty} \sup_{0\leq x\leq s(t)} [u(x,t) - \phi(x,t)] \leq \sup_{\tau \geq T}(s'(\tau))^{1/n}.$$

Letting $T \to \infty$, we obtain

$$\limsup_{t\to\infty} \sup_{0\leq x\leq s(t)} [u(x,t) - \phi(x,t)] \leq 0. \tag{3.26}$$

Next, by Lemma 3.3,

$$\lim_{t\to\infty} \phi(s(t),t) = 0.$$

Thus by using the subsolution

$$\widetilde{w}(x,t) = \phi(x,t) - \sup_{\tau \geq T} \phi(s(\tau),\tau) - T^\alpha k(x,t),$$

to estimate u from below and letting $T \to \infty$, we get the complement of (3.26), which completes the proof. □

LEMMA 3.5.

$$\limsup_{t\to\infty} s(t)s'(t) \leq \frac{M^2}{2}. \tag{3.27}$$

Proof. By (1.8), $u_{xx} = \epsilon u_t \geq 0$ for $0 \leq x \leq s(t)$, $t > 0$. Hence (as in [3, Prop. 5.1])

$$\begin{aligned}
u(x,t) &\geq u(s(t),t) + u_x(s(t),t)(x - s(t)) \\
&\geq -(1 + \epsilon u(s(t),t))s'(t)(x - s(t)).
\end{aligned}$$

Letting $x = \gamma s(t)$ $(0 < \gamma < 1)$ in the above inequality and letting $t \to \infty$, we obtain

$$\begin{aligned}(1-\gamma)\limsup_{t\to\infty} s(t)s'(t) &\le \limsup_{t\to\infty} \frac{u(\gamma s(t),t)}{1+\epsilon u(s(t),t)} \\ &\le \limsup_{t\to\infty} \phi(\gamma s(t),t) \quad \text{(by Lemma 3.4)} \\ &= 1 - \int_0^{\gamma M} \exp\left(-\frac{\epsilon}{4}\xi^2\right) d\xi \Big/ \int_0^{M} \exp\left(-\frac{\epsilon}{4}\xi^2\right) d\xi \\ &\qquad \text{(by Lemma 3.3).}\end{aligned}$$

Dividing by $1-\gamma$ and then letting $\gamma \to 1^-$, we immediately obtain (upon recalling (3.2)) the estimate (3.27). □

LEMMA 3.6. *There exist positive constants C and T such that*

$$u_t(x,t) \le \frac{C}{t} \quad \text{for } 0 \le x \le s(t), \quad T \le t < \infty. \tag{3.28}$$

Proof. It is clear that $\epsilon u_{tt} - u_{txx} = 0$ for $0 < x < s(t)$, $t > 0$, and $u_t(0,t) = 0$ for $t > 0$. Differentiating (1.4) and using $s''(t) < 0$ we get that $u_t(s(t),t) + u_x(s(t),t)s'(t) < 0$. Hence

$$\begin{aligned}u_t(s(t),t) &\le -u_x(s(t),t)s'(t) \\ &= (1+\epsilon u(s(t),t))(s'(t))^2 \quad \text{(by (1.3))} \\ &\le \frac{C^*}{t} \quad \text{for } 0 < t < \infty \quad \text{(by Lemmas 3.3 and 3.5).}\end{aligned}$$

Next, let

$$\theta(x,t) = -\int_0^{(x+1)/\sqrt{t}} \exp\left(-\frac{\epsilon}{4}\xi^2\right) d\xi.$$

Then $\epsilon\theta_t = \theta_{xx}$ for $t > 0$; and by Lemma 3.3, there exist $T, c_0 > 0$ such that

$$\begin{aligned}\theta_t(s(t),t) &= \exp\left(-\frac{\epsilon}{4}\frac{(s(t)+1)^2}{t}\right)\frac{s(t)+1}{2t\sqrt{t}} \\ &\ge \frac{c_0}{t} \quad \text{for } t \ge T.\end{aligned}$$

It is obvious that $\theta_t(0,t) > 0$ and

$$\inf_{0\le x\le s(T)} \theta_t(x,T) = \inf_{0\le x\le s(T)} \exp\left(-\frac{\epsilon}{4}\frac{(x+1)^2}{T}\right)\frac{x+1}{2T\sqrt{T}} \equiv c_1 > 0.$$

Therefore by maximum principle,

$$u_t(x,t) \le C\theta_t(x,t) \quad \text{for } 0 \le x \le s(t), \quad t \ge T$$

if C is large enough so that $Cc_0 \ge C^*$ and $Cc_1 \ge \max_{0\le x\le s(T)} u_t(x,T)$. It follows that (3.28) holds. □

Proof of Theorem 3.1. Since we have already proved (3.4), (3.5), and (3.27), it remains only to show that

$$\liminf_{t\to\infty} s(t)s'(t) \ge \frac{M^2}{2}. \tag{3.29}$$

By Lemma 3.6,

$$\begin{aligned} u(x,t) &= u(s(t),t) + u_x(s(t),t)(x-s(t)) + \int_x^{s(t)} (\xi - x) u_{xx}(\xi,t)\, d\xi \\ &\le u(s(t),t) + u_x(s(t),t)(x-s(t)) + \frac{C}{t}\frac{(s(t)-x)^2}{2} \quad \text{for } T \le t < \infty. \end{aligned}$$

Similarly to the proof of Lemma 3.5, we can now obtain, for $0 < \gamma < 1$ (note that $\lim_{t\to\infty} u(s(t),t) = 0$)

$$\begin{aligned} &(1-\gamma) \liminf_{t\to\infty} \left(s(t)s'(t) + \frac{C}{2}(1-\gamma)\frac{s^2(t)}{t} \right) \\ &\quad \ge 1 - \int_0^{\gamma M} \exp\left(-\frac{\epsilon}{4}\xi^2\right) d\xi \Big/ \int_0^{M} \exp\left(-\frac{\epsilon}{4}\xi^2\right) d\xi. \end{aligned}$$

Since $s^2(t)/t$ is bounded from above, the above inequality implies, after dividing by $1-\gamma$ and letting $\gamma \to 1^-$, that (3.29) holds. □

4. Small ϵ. As in [3], by formally letting $\epsilon \to 0$ in equations (1.1)–(1.5), we obtain equations for the limit functions (u_0, s_0):

$$u_0(x,t) = 1 - B(t)x, \tag{4.1}$$

$$s_0'(t) = (1 - B(t)s_0(t))^n = B(t), \tag{4.2}$$

$$B(0) = 1, \qquad s_0(0) = 0. \tag{4.3}$$

From this, we can uniquely determine $B(t)$ and $s_0(t)$; in particular $B(t)$ satisfies

$$t + \frac{1}{2} + \frac{n-1}{1-2n} = \frac{1}{2}B^{-2} + \frac{n-1}{1-2n}B^{(1/n)-2} \quad \text{if } n \ne \frac{1}{2}, \tag{4.4}$$

$$t + \frac{1}{2} = \frac{1}{2}B^{-2} + \log\frac{1}{B} \quad \text{if } n = \frac{1}{2}. \tag{4.5}$$

It easily follows that

$$0 < B(t) < 1, \qquad 0 < s_0(t)B(t) < 1, \tag{4.6}$$

$$\frac{dB}{dt} = -\frac{B^3}{1 + [(1-n)/n]B^{1/n}} < 0. \tag{4.7}$$

It is also clear that $\lim_{t\to\infty} s_0(t)/\sqrt{t} = \sqrt{2}$. Now we shall prove that the solution (u_ϵ, s_ϵ) of (1.1)–(1.5) converges to (u_0, s_0).

THEOREM 4.1. *We have, for $\epsilon > 0$,*

$$u_\epsilon(x,t) \le 1 - B(t)x \quad \textit{for } 0 \le x \le s_\epsilon(t), \quad 0 \le t < \infty, \tag{4.8}$$

$$s_\epsilon(t) < s_0(t) \quad \textit{for } 0 \le t < \infty. \tag{4.9}$$

Proof. (i) First we show that if (4.9) holds true for $0 < t < t_0$, then (4.8) must be true for $0 \le t \le t_0$. In fact, the function $w = 1 - B(t)x$ satisfies $w_t - \epsilon^{-1}w_{xx} =$

$-B'(t)x \geq 0$ for $0 < x < s_\epsilon(t)$, $t > 0$, and $w(0,t) = u_\epsilon(0,t)$ for $t \geq 0$. Since $1 - B(t)s_\epsilon(t) > 1 - B(t)s_0(t) > 0$ for $0 < t < t_0$,

$$\begin{aligned} \{w_x + (1+\epsilon w)w^n\}\Big|_{x=s_\epsilon(t)} &\geq -B(t) + (1 - B(t)s_\epsilon(t))^n \\ &\geq -B(t) + (1 - B(t)s_0(t))^n \\ &= 0 \quad \text{for } 0 \leq t \leq t_0. \end{aligned} \tag{4.10}$$

Therefore, by maximum principle, $u(x,t) \leq w(x,t)$ for $0 \leq t \leq t_0$, i.e., (4.8) holds for $0 \leq t \leq t_0$.

(ii) Next, we prove that (4.9) holds for small t. In fact, from (4.1)–(4.6) it follows that

$$\begin{aligned} s_0'(t) &\geq 1 - nB(t)s_0(t) - C[B(t)s_0(t)]^2 \\ &\geq 1 - nt - Ct^2; \end{aligned}$$

therefore $s_0(t) \geq t - (n/2)t^2 - Ct^3$. Hence, by (2.2), (4.9) holds for small $t > 0$.

(iii) It now follows that if the theorem is not true, then there exists a $T > 0$ such that

$$s_\epsilon(t) < s_0(t) \quad \text{for } 0 < t < T, \tag{4.11}$$

$$s_\epsilon(T) = s_0(T). \tag{4.12}$$

From (i), we obtain

$$s_\epsilon'(t) = u_\epsilon^n(s_\epsilon(t), t) \leq [1 - B(t)s_\epsilon(t)]^n \quad \text{for } 0 \leq t \leq T. \tag{4.13}$$

Note that $1 - B(t)s_\epsilon(t) \geq 1 - B(t)s_0(t) > c_0 > 0$ for $0 \leq t \leq T$, and the function $f(u) = u^n$ is Lipschitz continuous for $u \geq c_0$. Therefore, by using (4.2), (4.13), and (ii), we can apply the comparison principle of ODE and get

$$s_\epsilon(t) < s_0(t) \quad \text{for } 0 < t \leq T, \tag{4.14}$$

which contradicts (4.12) at $t = T$. □

THEOREM 4.2. *There exists a $\epsilon_0 > 0$ such that, for all $0 < \epsilon < \epsilon_0$,*

$$u_\epsilon(x,t) \geq 1 - B(t)x - 5\max(n,1)\epsilon \quad \textit{for } 0 \leq x \leq s_\epsilon(t), \quad 0 \leq t < \infty, \tag{4.15}$$

$$[1 + 4\max(n,1)\epsilon]s_\epsilon(t) > s_0(t) \quad \textit{for } 0 \leq t < \infty. \tag{4.16}$$

Proof. (i) Set

$$w = 1 - (1 + C^*\epsilon)B(t)x - \frac{C^*\epsilon}{4}B(t)\left(s_\epsilon(t) - \frac{x^2}{s_\epsilon(t)}\right), \tag{4.17}$$

where $C^* = 4\max(n,1)$, then

$$\begin{aligned} &w_t - \epsilon^{-1}w_{xx} \\ &\quad = -(1 + C^*\epsilon)B'(t)x - \frac{C^*\epsilon}{4}B'(t)\left(s_\epsilon(t) - \frac{x^2}{s_\epsilon(t)}\right) \end{aligned}$$

$$
\begin{aligned}
&-\frac{C^*\epsilon}{4}B(t)\left(s'_\epsilon(t)+\frac{x^2}{s^2_\epsilon(t)}s'_\epsilon(t)\right)-\epsilon^{-1}\frac{C^*\epsilon}{2}\frac{B(t)}{s_\epsilon(t)}\\
\le\ & -(1+C^*\epsilon)B'(t)s_\epsilon(t)-\frac{C^*\epsilon}{4}B'(t)s_\epsilon(t)-\frac{C^*}{2}\frac{B(t)}{s_\epsilon(t)}\\
=\ & \frac{1}{s_\epsilon(t)}\left[-\left(1+C^*\epsilon+\frac{C^*\epsilon}{4}\right)B'(t)s^2_\epsilon(t)-\frac{C^*}{2}B(t)\right]\\
\le\ & \frac{1}{s_\epsilon(t)}\left[\left(1+C^*\epsilon+\frac{C^*\epsilon}{4}\right)\frac{B^3(t)}{1+[(1-n)/n]B^{1/n}}s_0^2(t)-\frac{C^*}{2}B(t)\right]\\
& \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{(by (4.7), (4.9))}\\
\le\ & \frac{1}{s_\epsilon(t)}\left[\left(1+C^*\epsilon+\frac{C^*\epsilon}{4}\right)\max(n,1)B(t)-\frac{C^*}{2}B(t)\right]\quad \text{(by (4.6))}\\
<\ & 0
\end{aligned}
$$

if ϵ is small enough so that $C^*\epsilon + C^*\epsilon/4 < 1$.

Now we show that if (4.16) holds for $0 < t < t_0$, then

$$u_\epsilon(x,t) \ge w(x,t) \quad \text{for } 0 \le x \le s_\epsilon(t),\quad 0 \le t \le t_0, \tag{4.18}$$

which implies that (4.15) is valid for $0 \le t \le t_0$. Clearly, $w(0,t) = u(0,t)$ and

$$
\begin{aligned}
&\{w_x^+ + (1+\epsilon w)(w^+)^n\}\Big|_{x=s_\epsilon(t)}\\
&\quad\le\ -(1+C^*\epsilon)B(t)+\frac{C^*\epsilon}{2}B(t)+(1+\epsilon)\{[1-(1+C^*\epsilon)B(t)s_\epsilon(t)]^+\}^n\\
&\quad\le\ -\left(1+\frac{C^*\epsilon}{2}\right)B(t)+(1+\epsilon)[1-B(t)s_0(t)]^n\quad \text{(by (4.16))}\\
&\quad=\ -\left(1+\frac{C^*\epsilon}{2}\right)B(t)+(1+\epsilon)B(t)\\
&\quad<\ 0\qquad \text{for } 0\le t\le t_0.
\end{aligned}
$$

It follows by maximum principle that (4.18) holds.

(ii) It is clear that $(1+C^*\epsilon)s_\epsilon(t) = (1+C^*\epsilon)t + O(t^2)$ as $t \to 0$, and therefore (4.16) holds for small t. As in the proof of Theorem 4.1, if the theorem is not true, then there exists a $T > 0$ such that

$$(1+C^*\epsilon)s_\epsilon(t) > s_0(t) \quad \text{for } 0 < t < T, \tag{4.19}$$

$$(1+C^*\epsilon)s_\epsilon(T) = s_0(T). \tag{4.20}$$

From (4.18), we obtain

$$(1+C^*\epsilon)s'_\epsilon(t) > s'_\epsilon(t) = u^n_\epsilon(s_\epsilon(t),t) \ge \left\{[1-(1+C^*\epsilon)B(t)s_\epsilon(t)]^+\right\}^n. \tag{4.21}$$

Clearly,

$$\max_{0\le t\le T} B(t)s_0(t) \equiv \lambda < 1;$$

therefore, we can take $\lambda < \overline{\lambda} < 1$. Set

$$G = \{t \in [0,T] :\ (1+C^*\epsilon)B(t)s_\epsilon(t) \ge \overline{\lambda}\}. \tag{4.22}$$

Then for $t \in G$, we have

$$(1 + C^*\epsilon)s_\epsilon(t) \geq \frac{\overline{\lambda}}{B(t)} > s_0(t),$$

whereas for $t \in [0,T] \setminus G$ we have

$$1 - (1 + C^*\epsilon)B(t)s_\epsilon(t) \geq 1 - \overline{\lambda} > 0. \tag{4.23}$$

The set $[0,T] \setminus G$ is open and hence consists of open intervals with endpoints in G. The function $f(u) = u^n$ is Lipschitz continuous for $u \geq 1 - \overline{\lambda}$. Therefore by (4.2) and (4.21), we can apply the comparison principle of ODE and get that (4.19) holds also for $t \in [0,T] \setminus G$, which is a contradiction to (4.20) at $t = T$. □

Remark. Similar result of this section is obtained in [11].

5. Large ϵ. The diffusivity is small if ϵ is large. Therefore the penetrant front $s_\epsilon(t)$ should move very slowly when ϵ is large. This property is described in the following theorem.

THEOREM 5.1. *For the solution* (u_ϵ, s_ϵ) *of* (1.1)–(1.5), *we have*

$$\frac{s_\epsilon(t)}{\sqrt{t}} \to 0 \quad \text{as } \epsilon \to +\infty \tag{5.1}$$

uniformly for $t \in (0,\infty)$.

Proof. By Lemma 3.2,

$$\frac{s_\epsilon(t)}{\sqrt{t}} \leq M(\epsilon) \quad \text{for } 0 < t < \infty, \tag{5.2}$$

where $M(\epsilon)$ satisfies

$$\exp\left(-\frac{\epsilon}{4}M^2(\epsilon)\right) = \frac{1}{2}M(\epsilon)\int_0^{M(\epsilon)} \exp\left(-\frac{\epsilon}{4}\xi^2\right) d\xi. \tag{5.3}$$

If we set $K_\epsilon = \sqrt{\epsilon}M(\epsilon)$, then

$$\exp\left(-\frac{1}{4}K_\epsilon^2\right) = \frac{1}{2\epsilon}K_\epsilon\int_0^{K_\epsilon} \exp\left(-\frac{1}{4}\xi^2\right) d\xi. \tag{5.4}$$

It follows that

$$K_\epsilon \leq 2\sqrt{\log(2\epsilon)} \quad \text{for } \epsilon \geq \epsilon^*, \tag{5.5}$$

where $\epsilon^* \geq 1$ satisfies

$$\int_0^{2\sqrt{\log(2\epsilon^*)}} \exp\left(-\frac{1}{4}\xi^2\right) d\xi \geq 1. \tag{5.6}$$

We can easily check that $\epsilon^* = 1$ would satisfy (5.6). Therefore

$$M(\epsilon) \leq \frac{K_\epsilon}{\sqrt{\epsilon}} \leq \frac{2\sqrt{\log(2\epsilon)}}{\sqrt{\epsilon}} \quad \text{for } \epsilon \geq 1, \tag{5.7}$$

and (5.1) follows. □

6. The case $n \to \infty$. In the next two sections, we investigate the effects of the driving law exponent n. We shall fix ϵ and denote the solution of (1.1)–(1.5) by (u_n, s_n). The main result of this section is Theorem 6.1.

THEOREM 6.1. *For any $t^* > 0$,*

$$\lim_{n\to\infty} s_n(t) = 0 \tag{6.1}$$

uniformly for $t \in [0, t^*]$. □

We first list the available estimates for the solution (u_n, s_n) in the following lemma. Set

$$D_n = \{(x,t) : 0 < x < s_n(t),\ 0 < t < \infty\}.$$

LEMMA 6.2.

$$0 < u_n(x,t) < 1 \quad \textit{for } (x,t) \in D_n, \tag{6.2}$$

$$-1 - \epsilon < \frac{\partial u_n}{\partial x}(x,t) < 0 \quad \textit{for } (x,t) \in D_n, \tag{6.3}$$

$$0 < \frac{\partial u_n}{\partial t}(x,t) < 1 + \epsilon \quad \textit{for } (x,t) \in D_n, \tag{6.4}$$

$$0 < \frac{\partial^2 u_n}{\partial x^2}(x,t) < \frac{1}{\epsilon} + 1 \quad \textit{for } (x,t) \in D_n, \tag{6.5}$$

$$0 < s_n(t) < t \quad \textit{for } t > 0, \tag{6.6}$$

$$0 < s_n'(t) < 1 \quad \textit{for } t > 0, \tag{6.7}$$

$$s_n''(t) < 0 \quad \textit{for } t > 0. \tag{6.8}$$

Proof. (6.2), (6.3), and (6.6)–(6.8) are copied directly from Theorem 1.1. Formula (6.5) is equivalent to (6.4) by using the equation. We also know that $(u_n)_t > 0$. To prove (6.4), it suffices to note that $s_n''(t) < 0$ implies

$$\frac{\partial u_n}{\partial t}(s_n(t),t) + \frac{\partial u_n}{\partial x}(s_n(t),t)s_n'(t) < 0 \quad \text{for } t > 0, \tag{6.9}$$

and therefore by (6.3) and (6.7)

$$\frac{\partial u_n}{\partial t}(s_n(t),t) \le -\frac{\partial u_n}{\partial x}(s_n(t),t)s_n'(t) < 1 + \epsilon \quad \text{for } t > 0. \tag{6.10}$$

Now (6.4) follows by maximum principle. □

Next, we shall prove that $s_n(t)$ is monotone decreasing in n.

LEMMA 6.3. *If $n_1 > n_2$, then*

$$s_{n_1}(t) < s_{n_2}(t) \quad \textit{for } t > 0. \tag{6.11}$$

Proof. The transformation (see [4], for example)

$$v(x,t) = \int_x^{s(t)} (\epsilon u(\xi,t) + 1)d\xi \quad \text{for } 0 < x < s(t), \quad t > 0 \tag{6.12}$$

reduces (1.1)–(1.5) to the following problem:

$$\begin{aligned}
&\epsilon v_t = v_{xx} \quad \text{for } 0 < x < s(t), \quad t > 0,\\
&v_x(0,t) = -\epsilon - 1 \quad \text{for } t > 0,\\
&v(s(t),t) = 0 \quad \text{for } t > 0,\\
&v_x(s(t),t) = -\epsilon(s'(t))^{1/n} - 1 \quad \text{for } t > 0,\\
&s(0) = 0.
\end{aligned}$$

We shall denote by $v_{n_i}(x,t)$ $(i = 1,2)$ the functions obtained from $u_{n_i}(x,t)$ by formula (6.12).

It follows from (2.2) that (6.11) holds for small t. Therefore if (6.11) is not true, then there exists $T > 0$ such that

$$s_{n_1}(t) < s_{n_2}(t) \quad \text{for } 0 < t < T, \tag{6.13}$$

$$s_{n_1}(T) = s_{n_2}(T). \tag{6.14}$$

This implies that

$$s'_{n_1}(T) \geq s'_{n_2}(T), \tag{6.15}$$

and thus

$$\begin{aligned}
-\frac{\partial v_{n_1}}{\partial x}(s_{n_1}(T),T) &= \epsilon(s'_{n_1}(T))^{1/n_1} + 1\\
&\geq \epsilon(s'_{n_2}(T))^{1/n_1} + 1\\
&> \epsilon(s'_{n_2}(T))^{1/n_2} + 1 \quad (\text{since } 0 < s'_{n_2}(T) < 1,\ n_1 > n_2)\\
&= -\frac{\partial v_{n_2}}{\partial x}(s_{n_2}(T),T).
\end{aligned} \tag{6.16}$$

On the other hand, by the maximum principle, the maximum of $w \equiv v_{n_1} - v_{n_2}$ in the region $G \equiv \{(x,t) : 0 \leq x \leq s_{n_1}(t), 0 \leq t \leq T\}$ can only be obtained on $x = s_{n_1}(t), 0 \leq t \leq T$. Clearly,

$$w(0,0) = w(s_{n_1}(T),T) = 0, \tag{6.17}$$

and

$$w(s_{n_1}(t),t) = -v_{n_2}(s_{n_1}(t),t) < 0 \quad \text{for } 0 < t < T. \tag{6.18}$$

Hence w takes its maximum in G at $(x,t) = (s_{n_1}(T),T)$, which contradicts (6.16). Therefore (6.11) holds. □

Proof of Theorem 6.1. By Lemma 6.3 and (6.6)–(6.8), we get that, for any $t^* > 0$,

$$\lim_{n\to\infty} s_n(t) = s_\infty(t) \quad \text{uniformly for } t \in [0,t^*], \tag{6.19}$$

where $s_\infty(t)$ is some Lipschitz continuous function with the following properties:

$$0 \leq s'_\infty(t) \leq 1 \quad \text{a.e.,} \tag{6.20}$$

$$s''_\infty(t) \leq 0 \quad \text{in the distribution sense,} \tag{6.21}$$

$$s_\infty(t) < s_n(t) \quad \text{for } t > 0, \quad n > 0. \tag{6.22}$$

We claim that

(6.23) There exists $\delta > 0$ such that $s_\infty(t) \equiv 0$ for $0 \le t \le \delta$.

Note that (6.20), (6.21), and (6.23) imply that $s_\infty(t) \equiv 0$ for $t > 0$, and then the theorem follows.

If the claim (6.23) is not true, then in view of (6.20)

$$s_\infty(t) > 0 \quad \text{for } t > 0. \tag{6.24}$$

Set

$$D_\infty = \{(x,t) : 0 < x < s_\infty(t),\ 0 < t < t^*\}.$$

By Lemma 6.2 and the embedding theorem (see [10]), there exists a subsequence n_k's of n's ($n_k \to \infty$) such that, for any $0 < \alpha < \frac{1}{2}$ and any $\delta > 0$,

$$u_{n_k},\ \frac{\partial u_{n_k}}{\partial x} \to u_\infty,\ \frac{\partial u_\infty}{\partial x} \quad \text{in } C^\alpha(D_\infty \cap \{t > \delta\}) \text{ norm}, \tag{6.25}$$

$$\frac{\partial u_{n_k}}{\partial t},\ \frac{\partial^2 u_{n_k}}{\partial x^2} \rightharpoonup \frac{\partial u_\infty}{\partial t},\ \frac{\partial^2 u_\infty}{\partial x^2} \quad \text{weakly in } L^p(D_\infty \cap \{t > \delta\}) \text{ for any } p > 1, \tag{6.26}$$

where u_∞ is some function in $W^{2,1}_\infty(D_\infty)$.

Passing the limit in the equations in (1.1)–(1.5) as $n = n_k \to \infty$, we obtain

$$\epsilon(u_\infty)_t = (u_\infty)_{xx} \quad \text{in } D_\infty, \tag{6.27}$$

$$u_\infty(0,t) = 1 \quad \text{for } 0 < t < t^*. \tag{6.28}$$

Next, we compute

$$s_n'(t) = -\frac{(u_n)_x(s_\infty(t),t)}{1+\epsilon u_n(s_\infty(t),t)} + \left(\frac{(u_n)_x(s_\infty(t),t)}{1+\epsilon u_n(s_\infty(t),t)} - \frac{(u_n)_x(s_n(t),t)}{1+\epsilon u_n(s_n(t),t)}\right). \tag{6.29}$$

The first term of the above equality converges to $-(u_\infty)_x(s_\infty(t),t)/(1+\epsilon u_\infty(s_\infty(t),t))$ uniformly in any compact set of $(0,t^*]$, while the second term converges to zero uniformly for $t \in (0,t^*]$ since $(u_n)_x$, $(u_n)_{xx}$ are uniformly bounded. This shows that $s_{n_k}'(t)$ converges uniformly in any compact set of $(0,t^*]$ and the limit is continous. Hence we must have

$$s_{n_k}'(t) \to s_\infty'(t) \quad \text{uniformly in any compact set of } (0,t^*] \text{ as } n_k \to \infty; \tag{6.30}$$

$s_\infty'(t)$ is continuous and furthermore,

$$(1+\epsilon u_\infty(s_\infty(t),t))s_\infty'(t) = -(u_\infty)_x(s_\infty(t),t) \quad \text{for } t \in (0,t^*). \tag{6.31}$$

By (6.24) and (6.20),

$$s_\infty'(t_0) > 0 \quad \text{for some } t_0 \in (0,t^*). \tag{6.32}$$

It follows from (6.21) that

$$s_\infty'(t) \ge s_\infty'(t_0) > 0 \quad \text{for } t \in (0,t_0). \tag{6.33}$$

By virtue of (6.30) and concavity of s_{n_k}, there exists $N > 0$ such that

$$s'_{n_k}(t) \geq \tfrac{1}{2} s'_\infty(t_0) \quad \text{for } 0 < t \leq t_0, \quad n_k > N. \tag{6.34}$$

Since $s_\infty(t) < s_{n_k}(t)$,

$$1 \geq u_{n_k}(s_\infty(t), t) \geq u_{n_k}(s_{n_k}(t), t) = (s_{n_k}(t))^{1/n_k} \geq \left(\tfrac{1}{2} s'_\infty(t_0)\right)^{1/n_k} \tag{6.35}$$

for $0 < t \leq t_0$, $n_k > N$. Letting $n_k \to \infty$ in the above inequality, we obtain

$$u_\infty(s_\infty(t), t) \equiv 1 \quad \text{for } 0 < t \leq t_0.$$

Recalling (6.27) and (6.28), we get

$$u_\infty(x, t) \equiv 1 \quad \text{for } 0 \leq x \leq s_\infty(t), \quad 0 < t \leq t_0,$$

which contradicts (6.31) since $s'_\infty(t) > 0$ for $t \in (0, t_0)$. The proof of the theorem is now complete. □

7. The case $n \to 0$. We may guess that $\lim_{n \to 0} s_n(t) = t$ at the first glance of the driving law (1.4). However, this is not true when t is large enough by Lemma 3.2 (note that the constant M there is independent of n). The interesting result is that there exists a critical value $T^* > 0$ such that

$$\lim_{n \to 0} s_n(t) = t \quad \text{uniformly for } t \in [0, T^*] \tag{7.1}$$

and

$$\lim_{n \to 0} s_n(t) = s_0(t) \quad \text{uniformly for } t \in [T^*, t^*] \tag{7.2}$$

for any $t^* > T^*$, where $s_0(t)$ is the free boundary of an appropriate Stefan problem. In order to make the above statement more explicit, we consider the following problem:

$$\epsilon z_t = z_{xx} \quad \text{for } 0 < x < t, \tag{7.3}$$

$$z(0, t) = 1 \quad \text{for } t > 0, \tag{7.4}$$

$$1 + \epsilon z(t, t) = -z_x(t, t) \quad \text{for } t > 0. \tag{7.5}$$

It is clear that this problem has a unique smooth classical solution $z \in C^{2,1}(\overline{\Delta}) \cap C^\infty(\overline{\Delta} \setminus \{0\})$, where $\Delta = \{(x, t) : 0 < x < t < \infty\}$. The next lemma determines the critical value T^*.

LEMMA 7.1. *There exists a unique $T^* \in (0, 1]$ such that*

$$z(t, t) > 0 \quad \textit{for } 0 \leq t < T^*, \tag{7.6}$$

$$z(t, t) < 0 \quad \textit{for } t > T^*. \tag{7.7}$$

Note that by Lemma 7.1 and maximum principle, $z(x, T^*)$ is smooth and $z(x, T^*) > 0$ for $0 < x < T^*$ and $z(T^*, T^*) = 0$. □

We shall postpone the proof of Lemma 7.1 and first consider the solution (u_0, s_0) of the following Stefan problem:

$$\epsilon (u_0)_t = (u_0)_{xx} \quad \text{for } 0 < x < s_0(t), \quad t > T^*, \tag{7.8}$$

$$u_0(0, t) = 1 \quad \text{for } t > T^*, \tag{7.9}$$

$$s'_0(t) = -(u_0)_x(s_0(t), t) \quad \text{for } t > T^*, \tag{7.10}$$

$$u_0(s_0(t), t) = 0 \quad \text{for } t > T^*, \tag{7.11}$$

$$u_0(x, T^*) = z(x, T^*) \quad \text{for } 0 < x < T^*. \tag{7.12}$$

The main result of this section is Theorem 7.2.

THEOREM 7.2. *Denote by* (u_n, s_n) *the solution of* (1.1)–(1.5). *Suppose that* T^* *and* $z(x,t)$, (u_0, s_0) *are determined as above. Then* $T^* > 1/2(1+\epsilon)$ *and for any* $t^* > T^*$, *we have*

$$\lim_{n\to 0} s_n(t) = t \quad \textit{uniformly for } t \in [0, T^*], \tag{7.13}$$

$$\begin{aligned} &\lim_{n\to 0} u_n(x,t) = z(x,t) \\ &\textit{uniformly in any compact set of } \{(x,t):\ 0 \le x < t, 0 < t \le T^*\}; \end{aligned} \tag{7.14}$$

$$\lim_{n\to 0} s_n(t) = s_0(t) \quad \textit{uniformly for } t \in [T^*, t^*], \tag{7.15}$$

$$\begin{aligned} &\lim_{n\to 0} u_n(x,t) = u_0(x,t) \\ &\textit{uniformly in any compact set of } \{(x,t) : 0 \le x < s_0(t), T^* \le t \le t^*\}. \end{aligned} \tag{7.16}$$

□

Proof of Lemma 7.1. The linear function $w(x,t) \equiv 1 - x$ satisfies

$$w_x + \epsilon w \ge -1 \quad \text{for } 0 < x = t < 1. \tag{7.17}$$

Thus by maximum principle

$$z(x,t) \le w \equiv 1 - x \quad \text{for } 0 \le x \le t \le 1, \tag{7.18}$$

which implies that

$$z(1,1) \le 0. \tag{7.19}$$

It is clear that $z(t,t) > 0$ for t small. Hence in view of (7.19), there exists T^* $(0 < T^* \le 1)$ such that (7.6) holds and

$$z(T^*, T^*) = 0. \tag{7.20}$$

By maximum principle $z(x,t) \le 1$ for $0 \le x \le t < \infty$. Therefore

$$z_x(0,t) \le 0. \tag{7.21}$$

Let $\widetilde{w} = z_t + z_x$. Then

$$\epsilon \widetilde{w}_t = \widetilde{w}_{xx} \quad \text{for } 0 < x < t < \infty, \tag{7.22}$$

and, by (7.4) and (7.21),

$$\widetilde{w}(0,t) \le 0. \tag{7.23}$$

Differentiating (7.5) in t, we obtain

$$\widetilde{w}_x + \epsilon \widetilde{w} = 0 \quad \text{for } 0 < x = t < \infty. \tag{7.24}$$

Therefore by maximum principle

$$\widetilde{w} \le 0 \quad \text{for } 0 \le x \le t < \infty, \tag{7.25}$$

which implies that

$$\frac{d}{dt}z(t,t) \le 0 \quad \text{for } 0 < t < \infty. \tag{7.26}$$

Thus if (7.7) is not true, then

$$z(t,t) \equiv 0 \quad \text{for } T^* \le t \le T^* + \mu \tag{7.27}$$

for some $\mu > 0$. Hence

$$\widetilde{w}(t,t) \equiv 0 \quad \text{for } T^* < t < T^* + \mu. \tag{7.28}$$

Using (7.24), we get

$$\widetilde{w}_x(t,t) \equiv 0 \quad \text{for } T^* < t < T^* + \mu. \tag{7.29}$$

By (7.25) and (7.28), $\widetilde{w}$ takes its maximum on $(x,t) = (t,t)$, $T^* < t < T^* + \mu$. Now it follows from strong maximum principle that

$$\widetilde{w}(x,t) \equiv z_x(x,t) + z_t(x,t) \equiv 0 \quad \text{in } \Delta \cap \{t < T^* + \mu\}, \tag{7.30}$$

which implies that $z(t,t) \equiv z(0,0) = 1$ for $0 < t < T^* + \mu$. This is a contradiction to (7.20). □

Proof of Theorem 7.2. By Lemma 6.3 and (6.6)–(6.8),

$$\lim_{n \to 0} s_n(t) = s_\#(t) \quad \text{uniformly for } t \in [0, t^*], \tag{7.31}$$

where $s_\#(t)$ is some Lipschitz continuous function such that

$$0 \le s'_\#(t) \le 1 \quad \text{a.e.}, \tag{7.32}$$

$$s''_\#(t) \le 0 \quad \text{in the distribution sense}, \tag{7.33}$$

$$s_\#(t) > s_n(t) \quad \text{for } t > 0, n > 0. \tag{7.34}$$

By (2.1),

$$\begin{aligned} u_n(s_n(t),t) &\ge 1 - (1+\epsilon)s_n(t) \\ &\ge 1 - (1+\epsilon)t \\ &\ge \frac{1}{2} \quad \text{for } 0 < t < \frac{1}{2(1+\epsilon)}. \end{aligned} \tag{7.35}$$

Therefore

$$\begin{aligned} t \ge s_n(t) &= \int_0^t s'_n(\xi)\,d\xi \\ &= \int_0^t u_n^n(s_n(\xi),\xi)\,d\xi \\ &\ge \left(\frac{1}{2}\right)^n t \quad \text{for } 0 < t < \frac{1}{2(1+\epsilon)}. \end{aligned} \tag{7.36}$$

It follows by letting $n \to 0$ that

$$s_\#(t) \equiv t \quad \text{for } 0 < t < \frac{1}{2(1+\epsilon)}. \tag{7.37}$$

Define

$$T_{\#} = \sup\{b:\ s_{\#}(t) \equiv t \text{ for } 0 < t < b\} \tag{7.38}$$

and

$$D_{\#} = \{(x,t):\ 0 < x < s_{\#}(t), 0 < t < t^*\}. \tag{7.39}$$

Then $T_{\#} \geq 1/2(1+\epsilon)$. By (7.32) (7.33) and the definition for $T_{\#}$,

$$s_{\#}(t) \equiv t \quad \text{for } 0 \leq t < T_{\#}, \tag{7.40}$$

$$s_{\#}(t) < t \quad \text{for } T_{\#} < t < t^*. \tag{7.41}$$

Next, we introduce a scaling in the x direction so that the solutions u_n are defined in the same domain in the new variables. Let

$$v_n(x,t) = u_n\left(\frac{s_n(t)}{s_{\#}(t)}x, t\right) \qquad \text{for } (x,t) \in D_{\#}. \tag{7.42}$$

Then by Lemma 6.2 and (7.32),

$$\|v_n\|_{W^{2,1}_{\infty}(D_{\#}\cap\{t>\delta\})} \leq C_{\delta} \tag{7.43}$$

for any $\delta > 0$. Thus, for an appropriate subsequence n_k's of n's, we have, as $n_k \to 0$,

$$v_{n_k},\ \frac{\partial v_{n_k}}{\partial x} \to v_{\#},\ \frac{\partial v_{\#}}{\partial x} \quad \text{uniformly in } D_{\#} \cap \{t > \delta\} \text{ for any } \delta > 0, \tag{7.44}$$

$$\frac{\partial v_{n_k}}{\partial t},\ \frac{\partial^2 v_{n_k}}{\partial x^2} \rightharpoonup \frac{\partial v_{\#}}{\partial t},\ \frac{\partial^2 v_{\#}}{\partial x^2} \quad \text{weakly in } L^p(D_{\#} \cap \{t > \delta\}) \text{ for any } p > 1,\ \delta > 0, \tag{7.45}$$

for some function $v_{\#} \in W^{2,1}_{\infty}(D_{\#})$.

Note that

$$s_n'(t) = -\frac{(v_n)_x(s_{\#}(t),t)}{1+\epsilon v_n(s_{\#}(t),t)} \cdot \frac{s_{\#}(t)}{s_n(t)}. \tag{7.46}$$

Therefore, by using the same argument used in the proof of Theorem 6.1 we obtain

$$s_{n_k}'(t) \to s_{\#}'(t) \quad \text{uniformly in } t \in [\delta, t^*] \text{ as } n_k \to 0, \text{ for any } \delta > 0; \tag{7.47}$$

furthermore, $s_{\#}'(t)$ is continuous and

$$(1+\epsilon v_{\#}(s_{\#}(t),t))s_{\#}'(t) = -(v_{\#})_x(s_{\#}(t),t)). \tag{7.48}$$

A direct computation shows

$$\epsilon(v_n)_t = \left(\frac{s_{\#}}{s_n}\right)^2 (v_n)_{xx} + \epsilon x\left(\frac{s_n'}{s_n} - \frac{s_{\#}'}{s_{\#}}\right)(v_n)_x \quad \text{for } (x,t) \in D_{\#}. \tag{7.49}$$

By (7.31) and (7.47),

$$\lim_{n=n_k\to 0}\left|\frac{s_n'}{s_n} - \frac{s_{\#}'}{s_{\#}}\right| = 0 \quad \text{uniformly in } t \in [\delta, t^*] \text{ for any } \delta > 0. \tag{7.50}$$

Therefore, by letting $n = n_k \to 0$ in (7.49), using (7.31) and (7.50), we obtain

$$\epsilon(v_\#)_t = (v_\#)_{xx} \quad \text{for } (x,t) \in D_\#, \tag{7.51}$$

$$v_\#(0,t) = 1 \quad \text{for } 0 < t < t^*. \tag{7.52}$$

Since $s'_\#(t) \equiv 1$ for $0 < t < T_\#$, (7.48) implies that

$$1 + \epsilon v_\#(s_\#(t),t) = -(v_\#)_x(s_\#(t),t) \quad \text{for } 0 < t < T_\#. \tag{7.53}$$

Clearly also,

$$v_\#(s_\#(t),t) = \lim_{n\to 0} v_n(s_\#(t),t) \geq 0 \quad \text{for } 0 < t < t^*. \tag{7.54}$$

Recall that z is a solution of (7.3)–(7.5), and by uniqueness we have

$$v_\# = z \quad \text{for } 0 < t < x \leq T_\#. \tag{7.55}$$

Therefore (7.54) and (7.7) imply

$$T_\# \leq T^*. \tag{7.56}$$

Next, we shall prove that

$$v_\#(s_\#(t),t) = 0 \quad \text{for } T_\# < t < t^*. \tag{7.57}$$

Note that (7.57) implies $v_\#(s_\#(T_\#),T_\#) = 0$, by continuity; and hence $T_\# = T^*$ by Lemma 7.1.

Since $s'_\#(t)$ is continuous, (7.33), (7.40), and (7.41) imply that

$$s'_\#(t) < 1 \quad \text{for } T_\# < t < t^*. \tag{7.58}$$

Now we fix $t \in (T_\#, t^*)$ and take β with $s'_\#(t) < \beta < 1$. By virtue of (7.47),

$$s'_{n_k}(t) \leq \beta \quad \text{if } 0 < n_k < n_0 \tag{7.59}$$

for some sufficiently small n_0. It follows that

$$0 \leq v_n(s_\#(t),t) = (s'_n(t))^{1/n} \leq \beta^{1/n}. \tag{7.60}$$

Letting $n_k \to 0+$ in the above inequality, we obtain (7.57). Thus we have proved

$$T_\# = T^*. \tag{7.61}$$

Equations (7.51), (7.52), (7.57), (7.48), and (7.55), (7.61) imply that $(v_\#, s_\#)$ for $T_\# < t < t^*$ is a solution of the Stefan problem (7.8)–(7.12). Therefore by uniqueness

$$v_\# = u_0 \quad \text{for } T_\# < x < s_\#(t),\ T_\# < t < t^*, \tag{7.62}$$

$$s_\# = s_0 \quad \text{for } T_\# < t < t^*. \tag{7.63}$$

Now the limits in (7.44) and (7.45) are unique and independent of the choice of subsequences. And hence the whole sequences themselves converge. This implies that (7.13)–(7.16) hold. The theorem is proved. □

8. Neumann boundary condition. In this section we consider the Neumann boundary condition at $x = 0$. Taking for simplicity $\epsilon = 1$, the system becomes

$$u_t = u_{xx} \quad \text{for } 0 < x < s(t), \quad t > 0, \tag{8.1}$$

$$u_x(0,t) = g(t), \tag{8.2}$$

$$[1 + u(s(t),t)] \cdot s'(t) = -u_x(s(t),t), \tag{8.3}$$

$$s'(t) = u^n(s(t),t), \tag{8.4}$$

$$s(0) = 0. \tag{8.5}$$

It is shown in [2] that if

$$g \in C^2[0,\infty), \quad g(t) \le 0 \quad \text{for } t > 0, \quad g(0) < 0; \quad g'(t) \ge 0 \quad \text{for } t \ge 0, \tag{8.6}$$

then (1.18)–(1.20) hold. The asymptotic behavior of $s(t)$ as $t \to \infty$ is also studied in the case $\int_0^\infty g(t)dt > -\infty$.

We shall study the asymptotic behavior in the general case. Define $\psi_\eta = \psi_\eta(x,t)$, $h_\eta = h_\eta(t)$ to be the solution for the Stefan problem:

$$\psi_t = \psi_{xx} \quad \text{for } 0 < x < h(t), \quad t > 0, \tag{8.7}$$

$$\psi_x(0,t) = g(t), \tag{8.8}$$

$$\psi = 0, \ -\psi_x = (1+\eta)h'(t) \quad \text{on } x = h(t), \tag{8.9}$$

$$h(0) = 0, \tag{8.10}$$

where g satisfies (8.6) and $\eta \ge 0$.

THEOREM 8.1. *Assume in addition to assumption* (8.6) *that*

$$\lim_{t\to\infty} g(t) = 0. \tag{8.11}$$

Then

$$\lim_{t\to\infty} \frac{s(t)}{h_0(t)} = 1, \tag{8.12}$$

where $x = h_0(t)$ corresponds to the free boundary of the Stefan problem (8.7)–(8.10) *with $\eta = 0$.* □

We first establish several lemmas.

LEMMA 8.2. *For ψ_η and h_η defined in* (8.7)–(8.10), *we have*

$$(1+\eta)h_\eta(t) \ge h_0(t) \quad \textit{for } t > 0. \tag{8.13}$$

Proof. Let $w_\eta(x,t)$ be defined as

$$\begin{aligned} w_\eta(x,t) &= \int_{h_\eta^{-1}(x)}^{t} \psi_\eta(x,\tau)d\tau \quad \text{for } x < h_\eta(t) \\ &\equiv 0 \qquad\qquad\qquad\quad \text{for } x \ge h_\eta(t) \end{aligned} \tag{8.14}$$

($h_\eta^{-1}(x)$ exists since $h'(t) > 0$). Then

$$(w_\eta)_t - (w_\eta)_{xx} = -1 - \eta \quad \text{for } 0 < x < h_\eta(t), \quad t > 0, \tag{8.15}$$

$$w_\eta = (w_\eta)_x = 0 \quad \text{on } x = h_\eta(t), \quad t > 0, \tag{8.16}$$

$$(w_\eta)_x = \int_0^t g(\tau)d\tau \quad \text{on } x = 0, \quad t > 0, \tag{8.17}$$

$$w_\eta = 0 > -1 - \eta \quad \text{for } x > h_\eta(t), \quad t > 0. \tag{8.18}$$

Introducing the change of variables $y = (1+\eta)x$ and $\widetilde{w}_\eta(y,t) = (1+\eta)w_\eta(x,t)$, we find that (8.15) is equivalent to

$$(\widetilde{w}_\eta)_t - (\widetilde{w}_\eta)_{yy} = -1 + \left((1+\eta) - \frac{1}{1+\eta}\right)(w_\eta)_t(x,t) \quad \text{for } 0 < y < (1+\eta)h_\eta(t), \quad t > 0. \tag{8.19}$$

Since $(w_\eta)_t(x,t) = \psi_\eta(x,t) \geq 0$, it follows from the comparison principle for variational inequalities that

$$\widetilde{w}_\eta(y,t) \geq w_0(y,t) \quad \text{for all } y > 0, \quad t > 0. \tag{8.20}$$

Hence (8.13) holds. □

LEMMA 8.3. *For any* $T > 0$

$$\lim_{t\to\infty} \frac{h_\eta(t-T)}{h_\eta(t)} = 1. \tag{8.21}$$

Proof. We have $h_\eta(t) \geq h_\eta(t-T)$ since $h'_\eta \geq 0$. Equation (8.21) is obviously valid if $h_\eta(t)$ has a finite limit as $t \to \infty$. If, however, $\lim_{t\to\infty} h_\eta(t) = \infty$, then

$$\left|\frac{h_\eta(t-T)}{h_\eta(t)} - 1\right| \leq \frac{T|h'_\eta(\xi)|}{h_\eta(t)}, \tag{8.22}$$

where $\xi = \xi(t) \in (t-T, t)$. It is clear that $h'_\eta(t)$ is bounded as $t \to \infty$ since $g(t)$ is bounded. Therefore, the right-hand side of inequality (8.22) converges to zero as $t \to \infty$. □

Proof of Theorem 8.1. First we prove that

$$\lim_{t\to\infty} s'(t) = 0. \tag{8.23}$$

Since $s''(t) \leq 0$, $\lim_{t\to\infty} s'(t) = c_0$ exists. If $c_0 > 0$, then

$$\lim_{t\to\infty} \frac{s(t)}{t} = c_0 > 0.$$

However, by the mass balance

$$s(t) = -\int_0^{s(t)} u(x,t)dx - \int_0^t g(\tau)d\tau, \tag{8.24}$$

and hence

$$\frac{s(t)}{t} \leq -\frac{1}{t}\int_0^t g(\tau)d\tau \longrightarrow 0 \quad \text{as } t \to \infty$$

by (8.11), which is a contradiction.

Now, by using (8.23), Lemmas 8.2 and 8.3, we can proceed in the same proof as in Lemma 3.3 to finish the proof of this theorem. □

Having proved Theorem 8.1, we now reduce the asymptotic behavior of $s(t)$ near ∞ to that of the corresponding Stefan problem, which is well known. Therefore, using, for example, [6, Thm. 3, Chap. 8], we immediately get the behavior of $s(t)$ near ∞ if $g(t)$ is like $t^{-\delta}$ $(1/2 \leq \delta < 1)$ near ∞.

Acknowledgments. The author thanks Professor Avner Friedman for his directions and help. The author also thanks the referees for several helpful suggestions and comments.

THE ONE-DIMENSIONAL WIGNER-POISSON PROBLEM AND ITS RELATION TO THE SCHRÖDINGER-POISSON PROBLEM*

H. STEINRÜCK†

Abstract. This paper shows the existence of a solution of the Wigner-Poisson problem by expanding the solution into a series of solutions of the Schrödinger equation, and proves the convergence of the solutions of the Wigner-Poisson problem to a generalized solution of the Vlasov-Poisson problem in the classical limit.

Key words. quantum transport, nonlinear evolution equations

AMS(MOS) subject classifications. 35K22, 81C10, 82A70

1. Introduction. In this paper we consider the one-dimensional Wigner-Poisson problem

$$V(x) = \int_R |x-y| n(y)\, dy, \qquad n(y) = \int_R w(y, v)\, dv, \tag{1.1}$$

$$w_t + v.w_x - \Theta_\varepsilon[V]w = 0, \qquad x \in R_x, \qquad v \in R_v, \tag{1.2}$$

$$w(x, v, t=0) = w_I(x, v). \tag{1.3}$$

Equations (1.1)-(1.3) govern the temporal evolution of the Wigner function w, defined on the (x, v) phase space under the action of a self-consistent Coulomb potential $V(x)$. The particle density $n(x)$ is the mean value of w with respect to the velocity variable v. The pseudodifferential operator $\Theta_\varepsilon[V]$ is defined by

$$\Theta_\varepsilon[V]w = \frac{i}{2\pi\varepsilon} \int_R \int_R \left(V\left(x+\frac{\varepsilon\eta}{2}\right) - V\left(x-\frac{\varepsilon\eta}{2}\right)\right) w(x, v') \cdot e^{i\eta(v-v')}\, dv'\, d\eta. \tag{1.4}$$

Note that (1.1)-(1.3) are already in dimensionless form and that the parameter ε is the scaled (dimensionless) Planck constant. The Wigner function for a pure quantum mechanical state ϕ (a solution of the Schrödinger equation) was first introduced by Wigner in 1932 [14] and is defined by

$$w_\phi(x, v, t) = \frac{1}{\sqrt{2\pi\varepsilon}} \int_R \overline{\phi(x+\varepsilon\eta/2, t)}\phi(x-\varepsilon\eta/2, t)\, e^{i\eta v}\, d\eta.$$

An easy calculation shows that w_ϕ solves the Wigner equation (1.2). Therefore the Schrödinger and the Wigner equation are equivalent with respect to the temporal evolution of a pure state.

The advantage of the Wigner function is that it is defined on the (x, v) phase space and is therefore amenable to a comparison with the phase space formulation of classical mechanics. On the other hand, there are qualitative differences between the quantum and the classical case. While in classical mechanics the distribution function of particles in the phase space evolves according to the Liouville equation

$$w_t + v \cdot w_x - V_x \cdot w_v = 0, \tag{1.5}$$

which preserves the positivity of the initial function, the Wigner equation is in general not positivity preserving. That means that the solution w of (1.2) might assume negative values, though the initial function is nonnegative. Therefore the Wigner function cannot be interpreted as a distribution function of particles in the phase space. For a pure quantum state the mean values with respect to v (respectively, x) of w_ϕ are the probability densities to find a particle, which is described by its wave function ϕ at x (respectively, to have the velocity v). Therefore the Wigner function is referred as a "quasi distribution."

Note that for a harmonic oscillator (quadratic potential) the Wigner equation is identical to the classical Liouville equation. Considering the classical limit ($\varepsilon \to 0$) the Wigner equation tends at least formally to the Liouville equation. The pseudodifferential operator $\Theta_\varepsilon[V]$ then becomes the differential operator $V_x \, \partial/\partial v$.

Up to now, we have discussed the Wigner equation only as an equivalent alternative to the one particle Schrödinger equation. But starting with the many-body Schrödinger equation, using the density matrix formulation and an appropriate ansatz to get self-consistent equations we derive the Wigner–Poisson problem (1.1)–(1.3) (see [3]). Taking again the classical limit ($\varepsilon \to 0$), the Wigner–Poisson problem becomes at least formally the Vlasov–Poisson problem, which is a coupled system consisting of the Liouville and the Poisson equation.

The recent interest in the Wigner–Poisson problem is motivated by the miniaturization of semiconductor devices, where quantum effects in potential wells near heterojunctions [8] or tunneling effects [7] must be taken into account.

Mathematically the Wigner equation for a prescribed potential was analyzed in [9] and [10], using semigroup theory. In [2] these results are extended to the case of a particle with spin in a prescribed electromagnetic field. The existence of a solution of the coupled Wigner–Poisson problem has been shown for some special cases: periodic boundary conditions [1], and a bounded Brillouin zone [6], [13].

In this paper we will prove the existence of a unique globally defined solution of the Wigner–Poisson problem in the case of one space dimension. Due to the dimension dependence of the Green function of the Laplace operator the higher-dimensional cases have to be treated separately. An existence proof for the two-dimensional problem in the charge neutral case will be given by Arnold and Nier [4] and for the three-dimensional case by Brezzi and Markowich [5] in subsequent papers.

A second goal of this paper is the classical limit $\varepsilon \to 0$: A sequence of solutions of (1.1)–(1.3) has a subsequence, which converges weakly to a generalized solution of the Vlasov–Poisson problem as $\varepsilon \to 0$.

The paper is organized as follows. In § 2 we prove the existence of a solution of the one-dimensional Schrödinger–Poisson problem. In § 3 we use the relation between the Schrödinger and the Wigner equation to derive a solution representation of the Wigner equation in terms of the solution operator of the Schrödinger equation. The tools developed in §§ 2 and 3 will be used in § 4 to show the existence and uniqueness of a globally defined solution of the Wigner–Poisson problem. Section 5 is devoted to the classical limit.

2. The Schrödinger–Poisson problem. In this section we will prove the global existence of a solution of the Schrödinger-Poisson problem:

$$V(x) = \int_R |x-y|\,\overline{\psi(y)}\psi(y)\,dy, \tag{2.1}$$

$$i\varepsilon\psi_t = -\frac{\varepsilon^2}{2}\psi_{xx} + V\psi, \qquad x \in R, \quad t > 0, \tag{2.2}$$

$$\psi(x, t=0) = \psi_I(x). \tag{2.3}$$

THEOREM 2.1. *Let* $W := \{\psi \in L^2(R)\colon \|\psi\|_W := \|\psi\|_2 + \|\psi_x\|_2 + \|x\psi\|_2 < \infty\}$. *If* $\psi_I \in W$, *then the Schrödinger-Poisson problem has a unique mild solution* $\psi \in C([0,\infty) \to L^2(R))$. *If additionally* $\psi_I \in H_2$, *then the Schrödinger-Poisson problem has a unique classical solution.*

Remark. The term "mild" solution refers to the fact that the Schrödinger equation (2.2) is satisfied in the mild sense (see the definition on [11, p. 106]).

For the proof we first show that the Schrödinger equation (2.2)-(2.3) for a given sufficiently smooth potential, which is bounded by a polynomial of degree one, has a mild solution. Then inserting this solution into (2.1) we obtain a new potential, for which the Schrödinger equation can be solved and we will show that an iteration can be defined that way. Considering a sufficient small time interval this iteration contracts to a unique fixed point, which is a solution of the Schrödinger-Poisson problem. Using a priori estimates this solution can be extended for all positive times $t > 0$.

LEMMA 2.2. *Let* $V(x, t)$ *satisfy*:

$$|V(x, t)| \leqq \alpha(|x| + 1), \tag{2.4}$$

$$|V_x(x, t)| \leqq \beta, \tag{2.5}$$

$$|V_{xx}(x, t)| \leqq \gamma, \tag{2.6}$$

$$\limsup_{s \to t} \sup_{x \in R} \frac{|V(x, t) - V(x, s)|}{|x| + 1} = 0 \tag{2.7}$$

for some constants α, β, γ; *then there exists a strongly continuous family of unitary operators* $U(t, s)\colon L^2(R) \to L^2(R)$ *with*

$$U(t, r)U(r, s) = U(t, s) \quad \text{for } 0 \leqq s \leqq r \leqq t, \tag{2.8}$$

$$\frac{\partial^+}{\partial t} U(t, s)\psi|_{t=s} = i\frac{\varepsilon}{2}\psi_{xx} - \frac{i}{\varepsilon} V(\cdot, s)\psi \quad \text{for } \psi \in Y, \tag{2.9}$$

$$\frac{\partial}{\partial s} U(t, s)\psi = -U(t, s)\left(i\frac{\varepsilon}{2}\psi_{xx} - \frac{i}{\varepsilon} V(\cdot, s)\psi\right) \quad \text{for } \psi \in Y, \tag{2.10}$$

where $Y := \{\psi \in L^2$ *with* $x\psi, \psi_{xx} \in L^2\}$.

Proof. The conditions for the existence of an evolution system $U(t, s)$ satisfying (2.8)-(2.10) are the following [11]:

- (E1) The operators $H_s := (i\varepsilon/2)(\partial^2/\partial x^2) - (i/\varepsilon)V(\cdot, s)$ form a stable family of generators of C_0-semigroups. That is, let $0 \leqq s_1 \leqq s_2 \leqq \cdots \leqq s_n$ be a sequence of real numbers; then the estimate $\|\prod_{j=1}^n (H_{s_n} - \lambda)^{-1}\|_2 \leqq \lambda^{-n}$ for $\lambda > 0$ holds.
- (E2) The subspace $Y \subseteq D(H_s)$ is admissible. In other words, the restriction of H_s to Y generates a C_0-semigroup on Y for every fixed s.
- (E3) The mapping $t \to H_t$ is continuous in the norm of bounded operators from Y into L^2.

The operator iH_s is essentially self-adjoint (see the corollary to Theorem X.38 in [12]) and therefore H_s is the generator of a unitary C_0-group of operators on L^2.

Let $\lambda > 0$ and define ψ as the solution of $(H_s - \lambda)\psi = f$ for $f \in L^2$. Taking the inner product with $\bar{\psi}$ and using that H_s is skew symmetric yields

$$\|\psi\|_2 = \|(H_s - \lambda)^{-1} f\|_2 \leqq 1/\lambda \|f\|_2. \tag{2.11}$$

Since (2.11) holds independently of s, (E1) immediately follows.

To show (E2) we have to prove that H_s generates a *C_0-semigroup* on Y. We define a norm on Y by

$$\|\psi\|_Y := \|\psi\|_2 + \|x\psi\|_2 + \|\psi_x\|_2 + \|\psi_{xx}\|_2. \tag{2.12}$$

Since H_s is a closed operator on L^2, its restriction to Y is closed too, and it remains to estimate the resolvent $\|(H_s - \lambda)^{-1}\|_Y$.

Let $f \in Y$ and let ψ be the solution of

$$(H_s - \lambda)\psi = f, \qquad \lambda > 0;$$

then ψ_x is the solution of

$$(H_s - \lambda)\psi_x = f_x + i/\varepsilon V_x \psi. \tag{2.13}$$

We take the inner product of (2.13) with ψ_x, use that H_s is skew symmetric, and applying the Schwarz inequality we obtain

$$\begin{aligned} \|\psi_x\|_2 &\leqq \frac{1}{\lambda}\left(\|f_x\|_2 + \frac{\|V_x\|_\infty}{\varepsilon}\|\psi\|_2\right) \\ &\leqq \frac{1}{\lambda}\left(\|f_x\|_2 + \frac{\beta}{\lambda\varepsilon}\|f\|_2\right). \end{aligned} \tag{2.14}$$

Analogously we obtain from

$$(H_s - \lambda)\psi_{xx} = f_{xx} + 2i/\varepsilon V_x \psi_x + i/\varepsilon V_{xx}\psi \tag{2.15}$$

and (2.4)-(2.7)

$$\|\psi_{xx}\|_2 \leqq \frac{1}{\lambda}\left(\|f_{xx}\|_2 + \frac{2\beta}{\varepsilon\lambda}\|f_x\|_2 + \left(\frac{2\beta^2}{\varepsilon^2\lambda^2} + \frac{\gamma}{\varepsilon\lambda}\right)\|f\|_2\right). \tag{2.16}$$

In the same way we obtain

$$\|x\psi\|_2 \leqq \frac{1}{\lambda}\left(\|xf\|_2 + \frac{\varepsilon}{\lambda}\|f_x\|_2 + \frac{\beta}{\lambda^2}\|f\|_2\right). \tag{2.17}$$

Summing (2.14)-(2.17) yields

$$\|(H_s - \lambda)^{-1} f\|_Y = \|\psi\|_Y \leqq \frac{1}{\lambda}\left(1 + \frac{c}{\lambda} + \frac{c}{\lambda^2}\right)\|f\|_Y \quad \text{for } \lambda > 0 \tag{2.18}$$

with $c > \max\{2\beta/\varepsilon + \gamma/\varepsilon,\ 2\beta/\varepsilon + \varepsilon,\ 2\beta^2/\varepsilon^2 + \beta\}$, which implies

$$\|(H_s - \lambda)^{-n}\|_Y \leqq \frac{1}{(\lambda - c - 1)^n} \quad \text{for } \lambda > c + 1,$$

and by the Hille-Yoshida theorem [11] H_s generates a C_0-semigroup on Y.

It remains to check condition (E3). Let $\psi \in Y$; then we have

$$\begin{aligned} \lim_{t \to s} \|(H_t - H_s)\psi\|_2 &= \frac{1}{\varepsilon} \lim_{t \to s} \|(V(\cdot, t) - V(\cdot, s))\psi\|_2 \\ &\leqq \lim_{t \to s} \sup_x \frac{1}{\varepsilon} \frac{|V(\cdot, t) - V(\cdot, s)|}{|x| + 1} \|\psi\|_Y = 0. \end{aligned}$$

Therefore the mapping $t \to H_t$, $R^+ \to \mathcal{B}(Y, L^2)$, where $\mathcal{B}(Y, L^2)$ denotes the space of bounded operators from Y into L^2, is continuous. Therefore an evolution system $U(t, s)$ satisfying (2.8)-(2.10) exists.

Finally, we show that $U(t, s)$ is unitary. Let $\psi(t) = U(t, s)\psi_0$ and $\varphi(t) = U(t, s)\varphi_0$ with ψ_0 and $\varphi_0 \in Y$. Using the self-adjointness of iH_t we have

$$\frac{d}{dt}(\psi(t), \varphi(t)) = \left(\frac{d}{dt}\psi, \varphi\right) + \left(\psi, \frac{d}{dt}\varphi\right)$$

$$= (H_t\psi, \varphi) + (\psi, H_t\varphi) = (H_t\psi, \varphi) - (H_t\psi, \varphi) = 0.$$

Since Y is dense in L^2, we therefore have $(U(t, s)\psi, U(t, s)\varphi) = (\psi, \varphi)$ for $\psi, \varphi \in L^2$ and hence $U(t, s)$ is unitary. □

Now we can prove the following estimates.

LEMMA 2.3. *Let $V(x, t)$ satisfy* (2.4)-(2.7), *and let $\psi(t) = U(t, 0)\psi_I$ be the solution of* (2.2); *then the following estimates hold*:

$$\|\psi(t)\|_2 = \|\psi_I\|_2, \tag{2.19}$$

$$\|\psi_x(t)\|_2 \leqq \|\psi_{I,x}\|_2 + \frac{t\beta}{\varepsilon}\|\psi_I\|_2, \tag{2.20}$$

$$\|x\psi(t)\|_2 \leqq \|x\psi_I\|_2 + t\varepsilon\|\psi_{I,x}\|_2 + \frac{\beta t^2}{2}\|\psi_I\|_2. \tag{2.21}$$

Thus the subspace W is invariant under $U(t, s)$.

Proof. To prove (2.20) we differentiate (2.2) with respect to x:

$$\frac{\partial}{\partial t}\psi_x = \frac{i\varepsilon}{2}\frac{\partial^2}{\partial x^2}\psi_x - i/\varepsilon V\psi_x - i/\varepsilon V_x\psi.$$

Using the method of the variation of the constant we obtain

$$\psi_x = U(t, 0)\psi_{I,x} - i/\varepsilon \int_0^t U(t, s)V_x(\cdot, s)\psi(s)\, ds,$$

$$\|\psi_x\|_2 \leqq \|\psi_{I,x}\|_2 + t\beta/\varepsilon\|\psi_I\|_2,$$

which proves (2.20) and (2.21) is obtained similarly. □

In the next lemma we will show that the potential $V(x, t)$ satisfies the assumptions (2.4)-(2.7).

LEMMA 2.4. *Let $V(x)$ be defined in* (2.1) *with* (i) $\psi(t) \in W$ *and* (ii) *the mapping $t \to \psi(x, t)$ is continuous in $[0, \infty) \to L^2$; then the following estimates hold*:

$$|V(x)| \leqq (|x|\|\psi\|_2 + \|y\psi(y)\|_2)\|\psi\|_2, \tag{2.22}$$

$$|V_x(x)| \leqq \|\psi\|_2^2, \tag{2.23}$$

$$|V_{xx}| \leqq 2\|\psi\|_2\|\psi_x\|_2, \tag{2.24}$$

$$\limsup_{s \to t} \sup_{x \in R} \frac{|V(x, t) - V(x, s)|}{|x| + 1} = 0. \tag{2.25}$$

Proof. Statements (2.22) and (2.23) follow immediately from (2.1) and (2.24) is obtained from

$$|V_{xx}| = \left|\frac{\partial}{\partial x}\int_R \operatorname{sign}(y)|\psi(x + y)|^2\, dy\right| \leqq 2\|\psi\|_2\|\psi_x\|_2,$$

and (2.25) follows from

$$\limsup_{s\to t}\sup_{x\in R}\frac{|V(x,t)-V(x,s)|}{|x|+1}$$
$$\leqq \|\psi(t)-\psi(s)\|_2(\|(|y|+1)\psi(t)\|_2+\|(|y|+1)\psi(s)\|_2)=0. \qquad \square$$

Combining the estimates (2.20), (2.21) with (2.22), (2.24) we obtain the following a priori estimates.

LEMMA 2.5. *A solution $\psi(x,t)$, $V(x,t)$ of the Schrödinger–Poisson problem has to satisfy the a priori estimates*

$$\|\psi(t)\|_2=\|\psi_I\|_2, \tag{2.26}$$

$$\|\psi_x(t)\|_2\leqq\|\psi_{I,x}\|_2+\frac{t}{\varepsilon}\|\psi_I\|_2^3, \tag{2.27}$$

$$\|x\psi(t)\|_2\leqq\|x\psi_I\|_2+t\varepsilon\|\psi_{I,x}\|_2+\frac{t^2}{2}\|\psi_I\|_2^3, \qquad |V_{x,t}|\leqq\|\psi_I\|_2. \tag{2.28}$$

To show the existence of a solution of the Schrödinger–Poisson problem on the time interval $[0,T]$, we define the fixed point operator

$$F_T: C([0,T]\to W)\to C([0,T]\to L^2), \qquad F_T\psi(t)=U_{V_\psi}(t,0)\psi_I, \tag{2.29}$$

where $V_\psi:=\int_R|x-y||\psi(y)|^2\,dy$ and $U_V(t,s)$ is the evolution system associated with the family of operators $H_t(V):=(i\varepsilon/2)(d^2/dx^2)-(i/\varepsilon)V(t)$.

We prove the following lemma.

LEMMA 2.6. *The set*

$$S_T:=\{\psi\in C([0,T]\to W):\ \psi(t=0)=\psi_I,\ \psi \text{ satisfies } (2.26)\text{–}(2.28)\}, \tag{2.30}$$

is closed in $C([0,T]\to L^2)$ and invariant under the action of F_T.

Proof. Let $\psi_n\in S_T$ and $\psi_0\in C([0,T]\to L^2)$ with $\lim_{n\to\infty}\psi_n=\psi_0$ in the sense of $C([0,T]\to L^2)$, that is,

$$\lim_{n\to\infty}\sup_t\|\psi_n(t)-\psi_0(t)\|_2=0.$$

We have to show that $\psi_0\in S_T$. Since ψ_n converges to ψ_0 in L^2 for every fixed t, we have $\|\psi_0(t)\|_2=\|\psi_I\|_2$ and $\psi_0(0)=\psi_I$. Now consider t fixed. Since $\psi_n(t)$ converges in $L^2(R)$, $x\psi_n(t)$ converges in $L^2([-X,X])$ to $x\psi_0(t)$ for every $X>0$. Therefore we have

$$\|x\psi_0(t)\|_2^2=\lim_{x\to\infty}\lim_{n\to\infty}\int_{-X}^{X}x^2|\psi_n(x,t)|^2\,dx$$
$$\leqq(1+2\varepsilon t+t^2\|\psi_I\|_2^2)^2\|\psi_I\|_W^2.$$

To show that $\psi_0(t)$ has a derivative with respect to x, which is in L^2, we define $\psi_{0,x}$ in a distributional sense. Let $\phi\in C_0^\infty(R)$; then we define

$$\int_R\psi_{0,x}(x,t)\phi(x)\,dx=-\int_R\psi_0(x,t)\phi_x(x)\,dx$$
$$=-\lim_{n\to\infty}\int_R\psi_n(x,t)\phi_x\,dx$$
$$=\lim_{n\to\infty}\int_R\psi_{n,x}(x,t)\phi\,dx.$$

Using the estimate for $\|\psi_{n,x}\|_2$ we conclude that $\psi_{0,x}$ is a linear functional on L^2 and therefore a L^2-function itself with

$$\|\psi_{0,x}(t)\|_2 \leqq \|\psi_{I,x}\|_2 + \frac{t}{\varepsilon}\|\psi_I\|_2^3.$$

Therefore S_T is closed and applying (2.20), (2.21), (2.19), and (2.23) yields that S_T is invariant under F_T. □

Now we can prove the existence of a solution of the Schrödinger-Poisson problem.

LEMMA 2.7. *For T sufficiently small, the operator F_T has a unique fixed point in S_T.*

Proof. Since S_T is closed, it suffices to show that F_T is a contraction. Let $\phi_1, \phi_2 \in S_T$; then

$$F_T\phi_1 - F_T\phi_2 = \frac{i}{\varepsilon}\int_0^t U_{V_{\phi_1}}(t, s)(V_{\phi_1} - V_{\phi_2})F_T\phi_2\, ds.$$

We estimate

$$\begin{aligned}
&\|F_T\phi_1(t) - F_T\phi_2(t)\|_2 \\
&\quad \leqq \frac{t}{\varepsilon}\|(|x|+1)F_T\phi_2\|_2 \sup_{0\leqq\tau\leqq T, x\in R} \frac{|V_{\phi_1}(x,\tau) - V_{\phi_2}(x,\tau)|}{|x|+1} \\
&\quad \leqq \frac{2t}{\varepsilon}\left(2 + \frac{T}{\varepsilon} + \frac{T^2}{\|\psi_I\|_2^2}\right)^2 \|\psi_I\|_W^2 \sup_{0\leqq\tau\leqq T}\|\phi_1(\tau) - \phi_2(\tau)\|_2.
\end{aligned}$$

To get the last inequality we made use of

$$\begin{aligned}
|V_{\phi_1} - V_{\phi_2}| &= \int_R |x-y|(|\phi_1(y)|^2 - |\phi_2(y)|^2)\, dy \\
&\leqq (|x|+1)(\|(|y|+1)\phi_1\|_2 + \|(|y|+1)\phi_2\|_2)\|\phi_1 - \phi_2\|_2.
\end{aligned}$$

Choosing T sufficiently small, F_T is a contraction on S_T and has therefore a unique fixed point, which is a solution of the Schrödinger-Poisson problem. Using the a priori estimates (2.26)-(2.28) this solution can be extended for all positive times $t > 0$. □

3. The equivalence of the Schrödinger and the Wigner equation. In this section we assume that the potential $V(x, t)$ satisfying (2.4)-(2.7) is prescribed and that $U(t, s)$ is the family of operators defined in Lemma 2.2. We will use the evolution system U of the Schrödinger equation to construct a solution representation for the Wigner equation

$$w_t + v \cdot w_x - \Theta_\varepsilon[V]w = 0, \qquad w(t=0) = w_I. \tag{3.1}$$

By $\mathcal{F}$ we denote the Fourier transform with respect to the velocity variable v:

$$\mathcal{F}w(x, \eta, t) := \frac{1}{\sqrt{2\pi}}\int_R w(x, v, t)\, e^{-i\eta v}\, dv.$$

Then $\mathcal{F}w$ satisfies the Fourier transformed Wigner equation

$$\begin{aligned}
&\mathcal{F}w_t + i\mathcal{F}w_{x\eta} - i/\varepsilon(V(x+\varepsilon\eta/2, t) - V(x-\varepsilon\eta/2, t))\mathcal{F}w = 0, \\
&\mathcal{F}w(t=0) = \mathcal{F}w_I.
\end{aligned} \tag{3.2}$$

By employing the transform

$$p = x + \varepsilon\eta/2, \qquad q = x - \varepsilon\eta/2,$$
$$(Cg)(p, q) = \varepsilon^{-1} g(x, \eta), \qquad C : L^2(R_x \times R_\eta) \to L^2(R_p \times R_q), \tag{3.3}$$

and setting $z = C\mathcal{F}w$, $z_I = C\mathcal{F}w_I$, we obtain an evolution equation for z:

$$z_t := Qz, \qquad z(t=0) = z_I, \tag{3.4}$$

with

$$Qz := \left[i\frac{\varepsilon}{2}\frac{\partial^2}{\partial q^2} - \frac{i}{\varepsilon} V(q, t)) \right] z - \left[i\frac{\varepsilon}{2}\frac{\partial^2}{\partial p^2} - \frac{i}{\varepsilon} V(p, t) \right] z.$$

Using the notation of tensor products of Hilbert spaces [12] we can represent the operator Q as

$$Q = I \otimes H_t - H_t \otimes I. \tag{3.5}$$

Now we can write the solution operator of (3.4) by using the evolution system $U(t, s)$ defined in Lemma 2.2.

LEMMA 3.1. *The family of operators*

$$\{T(t, s) = \overline{U(t, s)} \otimes U(t, s) \; 0 \leqq s \leqq t\} \tag{3.6}$$

is a strongly continuous unitary evolution system with

$$\frac{\partial^+}{\partial t} T(t, s) z|_{t=s} = Qz \quad \textit{for } z \in Y \otimes Y, \tag{3.7}$$

$$\frac{\partial}{\partial s} T(t, s) z = -T(t, s) Qz \quad \textit{for } z \in Y \otimes Y. \tag{3.8}$$

The proof runs along the same lines as in [9]. This yields the following solution representation.

THEOREM 3.2. *Let $w_I \in L^2(R^2)$ be real valued; then there exists a complete orthonormal system $\varphi_{I,k}$, $k \in N$ of $L^2(R)$ and real numbers λ_k, $k \in N$, so that the solution of the Wigner equation is given by*

$$w(t) = \mathcal{F}^{-1} C^{-1} \sum_{k \in N} \lambda_k \overline{(U(t, 0)\varphi_k)(p)} (U(t, 0)\varphi_k)(q). \tag{3.9}$$

We associate with the initial condition $z_I = C\mathcal{F}w_I$ the operator

$$Z_I : L^2(R) \to L^2(R), \qquad (Z_I f)(p) = \int_R z_I(p, q) f(q)\, dq.$$

Since w_I is real valued, $z_I(p, q) = \overline{z_I(q, p)}$ and thus Z_I is self-adjoint. Since $z_I \in L^2(R \times R)$, Z_I is a Hilbert–Schmidt operator and therefore compact. Therefore Z_I has a complete orthogonal set of eigenfunctions $\varphi_{I,k}$, $k \in N$ and real eigenvalues λ_k with

$$z_I(p, q) = \sum_{k \in N} \lambda_k \overline{\varphi_{I,k}(p)}\, \varphi_{I,k}(q) \tag{3.10}$$

with $\sum_{k \in N} \lambda_k^2 < \infty$. Now (3.10) and (3.6) imply the assertion of the theorem. □

In other words, the solution of the Wigner equation (1.2) is equivalent to the solution of a countable series of Schrödinger equations:

$$i\varepsilon \frac{\partial}{\partial t} \psi_k = -\frac{\varepsilon^2}{2} \frac{\partial^2}{\partial x^2} \psi_k + V\psi_k, \quad \psi_k(t=0) = \varphi_{I,k}, \quad k \in N, \tag{3.11}$$

where $(\lambda_k, \varphi_{I,k})$ are eigenvalues and eigenfunctions of the operator Z_I associated with the initial condition $z_I = C\mathcal{F}w_I$.

We define the Hilbert space $\mathcal{H}$ of sequences of L^2-functions:

$$\mathcal{H} := \left\{ \psi = (\psi_1, \psi_2, \cdots),\ \psi_k \in L^2(R),\ \sum_{k=1}^{\infty} \lambda_k \|\psi_k\|_2^2 < \infty \right\},$$

with the inner product

$$(\varphi, \psi)_{\mathcal{H}} := \sum_{k=1}^{\infty} \lambda_k (\varphi_k, \psi_k).$$

We define the sequences $x\psi$, $(\partial/\partial x)\psi$ elementwise and using Lemma 2.3 we obtain for a solution of (3.11) the following lemma.

LEMMA 3.3. *Let* $\|\varphi_I\|_{\mathcal{H}} < \infty$, $\|x\varphi_I\|_{\mathcal{H}} < \infty$, $\|(\partial/\partial x)\varphi_I\|_{\mathcal{H}} < \infty$; *then a solution of* (3.11) *satisfies*

$$\|\psi(t)\|_{\mathcal{H}} = \|\varphi_I\|_{\mathcal{H}}, \tag{3.12}$$

$$\|\psi_x(t)\|_{\mathcal{H}} \leqq \left\| \frac{\partial}{\partial x} \varphi_I \right\|_{\mathcal{H}} + \frac{t\beta}{\varepsilon} \|\varphi_I\|_{\mathcal{H}}, \tag{3.13}$$

$$\|x\psi(t)\|_{\mathcal{H}} \leqq \|\varphi_I\|_{\mathcal{H}} + t\varepsilon \left\| \frac{\partial}{\partial x} \varphi_I \right\|_{\mathcal{H}} + t^2\beta/2 \|\varphi_I\|_{\mathcal{H}} \tag{3.14}$$

with $\beta \geqq \|V_x\|_\infty$.

The next lemma gives a criterion for $x\varphi_I$, $(\partial/\partial x)\varphi_I \in \mathcal{H}$ in terms of the initial condition z_I.

LEMMA 3.4. *Suppose that the operators* Z_I, Z_I^*, Z_I' *with the kernels* z_I, $p \cdot q \cdot z_I$, $(\partial^2/\partial p\, \partial q) z_I \in L^2$ *are self-adjoint, of trace class, and* $\lambda_k \geqq 0$; *then* $\sum_{k=1}^{\infty} \lambda_k \|x\varphi_{I,k}\|_2^2$, $\sum_{k=1}^{\infty} \lambda_k \|(\partial/\partial x)\varphi_{I,k}\|_2^2$ *converge.*

Proof. The trace of Z_I' is given by

$$\begin{aligned}
\operatorname{tr}(Z_I') &= \sum_{k=1}^{\infty} (\varphi_{I,k}, Z_I' \varphi_{I,k}) \\
&= \sum_{k=1}^{\infty} \int_R \int_R \varphi_{I,k}(p) \overline{\varphi_{I,k}(q)} \overline{\frac{\partial^2}{\partial p\, \partial q} z_I(p, q)}\, dp\, dq, \\
&\sum_{k=1}^{\infty} \int_R \int_R \overline{z_I(p, q)} \frac{\partial}{\partial p} \varphi_{I,k}(p) \frac{\partial}{\partial q} \overline{\varphi_{I,k}(q)}\, dp\, dq \\
&= \sum_{k=1}^{\infty} \int_R \int_R \sum_{n=1}^{\infty} \lambda_n \overline{\varphi_{I,n}(p)} \varphi_{I,n}(q) \frac{\partial}{\partial p} \varphi_{I,k}(p) \frac{\partial}{\partial q} \overline{\varphi_{I,k}(q)}\, dp\, dq \\
&= \sum_{k=1}^{\infty} \sum_{n=1}^{\infty} \lambda_n \left| \left(\varphi_{I,n}, \frac{\partial}{\partial p} \varphi_{I,k} \right) \right|^2 = \sum_{n=1}^{\infty} \lambda_n \left\| \frac{\partial}{\partial x} \varphi_{I,n} \right\|^2.
\end{aligned}$$

A similar calculation gives

$$\operatorname{tr}(Z_I^*) = \sum_{n=1}^{\infty} \lambda_n \|x\varphi_{I,n}\|_2^2. \qquad \square$$

4. The Wigner–Poisson problem. In the previous section we have considered the Wigner equation for a prescribed potential. The goal of this section is to show the existence of a solution of (1.1)–(1.3). To define the potential by the Poisson equation

in integral form (1.1) we need that the particle density $n(x)=\int_R w(x, v)\,dv$ and $xn(x)$ are L^1-functions. This fact is not guaranteed a priori if we assume that only the initial density n_I and xn_I are well-defined L^1 functions. To exploit the equivalence of the Schrödinger and Wigner equations we will define a generalized particle density. Suppose that $w_I(x, v)$ is sufficiently smooth and decays sufficiently fast; then we have formally

$$\begin{aligned} n(x,t) &= \int_R w(x,v,t)\,dv = \frac{1}{\sqrt{2\pi}}\,\mathcal{F}w(x,\eta=0,t) \\ &= \frac{\varepsilon}{\sqrt{2\pi}}\,z(x,x,t) = \frac{\varepsilon}{\sqrt{2\pi}}\sum_{k=1}^{\infty}\lambda_k|U(t,0)\varphi_{I,k}(x)|^2, \end{aligned} \tag{4.1}$$

where λ_k and $\varphi_{I,k}$ are defined in Theorem 3.2.

We say that an initial function z_I is of trace class (positive definite) if the associated operator Z_I is of trace class (positive definite). Now we define a generalized particle density in the following lemma.

LEMMA 4.1. *Let z_I be of trace class; then we define the generalized particle density by*

$$n_g(\cdot,t) := \frac{\varepsilon}{\sqrt{2\pi}}\sum_{k=1}^{\infty}\lambda_k|U(t,s)\varphi_{I,k}(\cdot)|^2 \in L^1(R).$$

If, additionally, z_I is positive definite, n_g is not negative.

Proof. Since z_I is of trace class, $\sum_{k=1}^{\infty}\lambda_k$ converges absolutely and therefore

$$\begin{aligned} \|n_g(t)\|_1 &= \frac{\varepsilon}{\sqrt{2\pi}}\int_R\left|\sum_{k=1}^{\infty}\lambda_k|(U(t,0)\varphi_{I,k})(x)|^2\right|dx \\ &\leqq \frac{\varepsilon}{\sqrt{2\pi}}\sum_{k=1}^{\infty}|\lambda_k|. \end{aligned}$$

If Z_I is positive definite, then the eigenvalues λ_k of Z_I are positive and therefore n_g is nonnegative. Note that the positive definiteness of z_I is not equivalent with $w_I \geqq 0$. □

LEMMA 4.2. *Let vw and $w_x \in L^2$ and $\sum_{k=1}^{\infty}\lambda_k < \infty$; then*

$$n_g(x) = n(x) = \int_R w(x,v)\,dv \in L^1(R).$$

Proof. From *vw*, $w_x \in L^2$ we conclude that $z \in H^1$, which implies that $n(x,t) = (\varepsilon/\sqrt{2\pi})z(x,x,t) \in L^1_{\text{loc}}$ and therefore coincides with n_g in the L^1-sense, and by Lemma 4.1 we have $n \in L^1(R)$. □

Now we can prove the existence theorem.

THEOREM 4.3. *Let w_I be real valued, so that $z_I = C\mathcal{F}w_I$ is positive definite and that z_I, pqz_I, $(\partial^2/\partial p\,\partial q)z \in L^2$ are of trace class; then the Wigner–Poisson problem*

$$V(x) = \int_R |x-y|n_g(y)\,dy, \tag{4.2}$$

$$w_t + v\cdot w_x - \Theta_\varepsilon[V]w = 0, \qquad x \in R_x, \quad v \in R_v, \tag{4.3}$$

$$w(x, v, t=0) = w_I(x, v), \tag{4.4}$$

where n_g is the generalized particle density, has a unique mild solution.

Remark. The term "mild solution" means that the Wigner equation is satisfied in the mild sense.

Proof. Let $\varphi_{I,k}$, λ_k be the eigenfunctions and eigenvalues of Z_I. Then the Wigner-Poisson problem is equivalent to

$$V(x) = \int_R |x-y| \sum_{k=1}^{\infty} \frac{\varepsilon}{\sqrt{2\pi}} \lambda_k |\psi_k(y)|^2 \, dy,$$

$$i\varepsilon \frac{\partial}{\partial t} \psi_k = -\frac{\varepsilon^2}{2} \frac{\partial^2}{\partial x^2} \psi_k + V\psi_k, \qquad \psi_k(t=0) = \varphi_{I,k}.$$

We define the set $\mathcal{S}_T \subset C([0, T] \to \mathcal{H})$:

$$\mathcal{S}_T := \Big\{ \psi(\cdot, t) \in \mathcal{H} \text{ for } 0 \leqq t \leqq T, \text{ with } \psi_k(t=0) = \varphi_{I,k},\ k \in N, \tag{4.5}$$
$$\cdot \left\| \frac{\partial}{\partial x} \psi(t) \right\|_{\mathcal{H}} \leqq B(t),\ \|x\psi(t)\|_{\mathcal{H}} \leqq C(t),\ \|\psi_k(t)\|_2 = 1 \Big\},$$

where

$$B(t) = \left\| \frac{\partial}{\partial x} \varphi_I \right\|_{\mathcal{H}} + t/\varepsilon \|\varphi_I\|_{\mathcal{H}}^3 \quad \text{and} \quad C(t) = \|\varphi_I\|_{\mathcal{H}} + t\varepsilon \left\| \frac{\partial}{\partial x} \varphi_I \right\|_{\mathcal{H}} + \frac{t^2}{2} \|\varphi_I\|_{\mathcal{H}}^3.$$

Proceeding analogously as in § 2, it follows that $\mathcal{S}_T$ is a closed set invariant under the operator F_T:

$$F_T : \mathcal{S}_T \to C([0, T] \to \mathcal{H}), \quad (F_T\psi)_k(t) = U_{V_\psi}(t, 0)\varphi_{I,k}, \quad k \in N.$$

In the next step we show that F_T is a contraction for T small enough.

From

$$\|(F\psi)_k(t) - (F\varphi)_k(t)\|_2$$
$$\leqq T \sup_{0 \leqq t \leqq T,\, x \in R} \frac{|V_\psi(x, t) - V_\varphi(x, t)|}{|x|+1} (\|x(F_T\psi)_k(t)\|_2 + \|(F_T\varphi)_k\|_2)$$

and

$$\left| \frac{V_\psi(x, t) - V_\varphi(x, t)}{|x|+1} \right| = \frac{\varepsilon}{\sqrt{2\pi}} \left| \int_R \frac{|x-y|}{|x|+1} \sum_{k=1}^{\infty} \lambda_k (|\varphi_k|^2 - |\psi_k|^2) \, dy \right|$$
$$\leqq \|\psi - \varphi\|_{\mathcal{H}} (\|\psi\|_{\mathcal{H}} + \|x\psi\|_{\mathcal{H}} + \|\varphi\|_{\mathcal{H}} + \|x\varphi\|_{\mathcal{H}}),$$

follows the estimate

$$\|F_T\psi - F_T\varphi\|_{\mathcal{H}}$$
$$\leqq \frac{\varepsilon}{\sqrt{2\pi}} T(\|\varphi\|_{\mathcal{H}} + \|x\varphi\|_{\mathcal{H}} + \|\psi\|_{\mathcal{H}} + \|x\psi\|_{\mathcal{H}})(\|F_T\varphi\|_{\mathcal{H}} + \|xF_T\psi\|_{\mathcal{H}}) \|\psi - \varphi\|_{\mathcal{H}}$$
$$\leqq \frac{\varepsilon}{\sqrt{2\pi}} 2C(T)^2 T \|\psi - \varphi\|_{\mathcal{H}}.$$

Now choosing T sufficiently small yields that F_T is a contraction and therefore has a unique fixed point in $\mathcal{S}_T$, which is a mild solution of the Wigner-Poisson problem on the interval $[0, T]$. Due to the a priori estimates (4.5) this solution can be extended to any $t \in R^+$.

5. The classical limit. In this section we will prove that solutions of the Wigner-Poisson problem (1.1)-(1.3) converge (after extracting a subsequence) to a generalized solution of the Vlasov-Poisson problem as $\varepsilon \to 0$. The analysis in this section is guided by the analysis in the corresponding sections in [13] and [1].

THEOREM 5.1. *Let $T>0$ and $(\varepsilon_m)_{m\in N}$ be a monotone decaying sequence of positive real numbers with limit zero (in the following we drop the index m) and let $w^{(\varepsilon)}$ be the solution of the Wigner–Poisson problem:*

$$V^{(\varepsilon)}(x)=\int_R |x-y|n^{(\varepsilon)}\,dy, \qquad n^{(\varepsilon)}(x)=\int_R w^{(\varepsilon)}(x,v)\,dv, \tag{5.1}$$

$$\frac{\partial}{\partial t}w^{(\varepsilon)}+v\cdot\frac{\partial}{\partial x}w^{(\varepsilon)}-\Theta_\varepsilon[V^{(\varepsilon)}]w^{(\varepsilon)}=0, \qquad x\in R,\quad v\in R, \tag{5.2}$$

$$w^{(\varepsilon)}(x,v,t=0)=w_I^{(\varepsilon)}(x,v) \tag{5.3}$$

with $w_I^{(\varepsilon)}$ satisfies the assumption of the existence Theorem 4.3 and the terms

$$\|w_I^{(\varepsilon)}\|_2, \quad \|xw_I^{(\varepsilon)}\|_2, \quad \|vw_I^{(\varepsilon)}\|_2, \tag{5.4}$$

$$\|w_I^{(\varepsilon)}\|_1, \quad \|x^2w_I^{(\varepsilon)}\|_1, \quad \|v^2w_I^{(\varepsilon)}\|_1, \quad \varepsilon^2\left\|\frac{\partial^2}{\partial x^2}w_I^{(\varepsilon)}\right\|_1, \tag{5.5}$$

are uniformly bounded with respect to ε. Then there exists a subsequence ε_{m_j} (which we denote as the original sequence) and functions $w^{(0)}$, $w_I^{(0)}$, $V_x^{(0)}$ with

$$\lim_{\varepsilon\to 0} w^{(\varepsilon)}=w^{(0)} \quad \text{in } L^2([0,T]\to L^2(R^2)) \text{ weakly}, \tag{5.6}$$

$$\lim_{\varepsilon\to 0} vw^{(\varepsilon)}=vw^{(0)} \quad \text{in } L^2([0,T]\to L^2(R^2)) \text{ weakly}, \tag{5.7}$$

$$\lim_{\varepsilon\to 0} w_I^{(\varepsilon)}=w_I^{(0)} \quad \text{in } L^2([0,T]\to L^2(R^2)) \text{ weakly}, \tag{5.8}$$

$$\lim_{\varepsilon\to 0} V_x^{(\varepsilon)}=V_x^{(0)} \quad \text{in } L^\infty(R\times[0,T]) \text{ weak}^*, \tag{5.9}$$

where $w^{(0)}$, $V^{(0)}$ is a generalized solution of the Vlasov–Poisson problem:

$$V^{(0)}(x)=\int_R |x-y|n^{(0)}\,dy, \qquad n^{(0)}(x)=\int_R w^{(0)}(x,v)\,dv, \tag{5.10}$$

$$\frac{\partial}{\partial t}w^{(0)}+v\cdot\frac{\partial}{\partial x}w^{(0)}-V_x^{(0)}\frac{\partial}{\partial v}w^{(0)}=0, \qquad x\in R,\quad v\in R, \tag{5.11}$$

$$w^{(0)}(x,v,t=0)=w_I^{(0)}(x,v). \tag{5.12}$$

In the following two lemmas we will show that certain quantities are bounded uniformly with respect to ε.

LEMMA 5.2. *Let the assumptions of Theorem 5.1 hold; then there exists a constant $D(T)$ independent of ε with*

$$\|vw^{(\varepsilon)}(t)\|_2\leqq D(\|w_I^{(\varepsilon)}\|_2+\|vw_I^{(\varepsilon)}\|_2) \quad \text{for } 0\leqq t\leqq T, \tag{5.13}$$

and

$$\|xw^{(\varepsilon)}(t)\|_2\leqq D(\|w_I^{(\varepsilon)}\|_2+\|xw_I^{(\varepsilon)}\|_2+\|vw_I^{(\varepsilon)}\|_2) \quad \text{for } 0\leqq t\leqq T. \tag{5.14}$$

Proof. The function $vw^{(\varepsilon)}$ solves the equation

$$(vw^{(\varepsilon)})_t+v(vw^{(\varepsilon)})_x-\Theta_\varepsilon[V^{(\varepsilon)}](vw^{(\varepsilon)})$$
$$=-\frac{1}{4\pi}\int_R\int_R\left(V_x^{(\varepsilon)}\left(x-\frac{\varepsilon\eta}{2}\right)+V_x^{(\varepsilon)}\left(x+\frac{\varepsilon\eta}{2}\right)\right)e^{i\eta(v-v')}w^{(\varepsilon)}(x,v',t)\,dv'\,d\eta.$$

Using $\|V_x^{(\varepsilon)}\|_\infty \leqq \|n_I^{(\varepsilon)}\|_1 \leqq \|w_I^{(\varepsilon)}\|_1$ we obtain

$$\|vw^{(\varepsilon)}(t)\|_2 \leqq \|vw_I^{(\varepsilon)}\|_2 + T\|w_I^{(\varepsilon)}\|_1 \|w_I^{(\varepsilon)}\|_2.$$

The second inequality is obtained similarly. □

LEMMA 5.3. *Let the assumptions of Theorem* 5.1 *hold; then there exists a constant* c *depending only on the quantities in* (5.5) *with*

$$\|xn(t)\|_1 \leqq (t^2+1)c. \tag{5.15}$$

Proof.

$$\begin{aligned}
\|xn\|_1 &= \frac{\varepsilon}{\sqrt{2\pi}} \int_R |xz^{(\varepsilon)}(x, x)|\, dx \\
&= \frac{\varepsilon}{\sqrt{2\pi}} \int_R \sum_{k=1}^{\infty} \lambda_k |xU(t,0)\varphi_{I,k}|\, |U(t,0)\varphi_{I,k}|\, dx \\
&\leqq \frac{\varepsilon}{\sqrt{2\pi}} \sum_{k=1}^{\infty} \lambda_k \|xU(t,0)\varphi_{I,k}\|_2 \\
&\leqq \frac{\varepsilon}{\sqrt{2\pi}} \sum_{k=1}^{\infty} \lambda_k \left(\|x\varphi_{I,k}\|_2 + t\varepsilon \left\| \frac{\partial}{\partial x} \varphi_{I,k} \right\|_2 + \frac{t^2\beta}{2} \|\varphi_{I,k}\|_2 \right)
\end{aligned} \tag{5.16}$$

with $\beta = \sup |V_x| = \|w_I\|_1$. Using the definition of the generalized particle density we estimate

$$\begin{aligned}
\frac{\varepsilon}{\sqrt{2\pi}} \sum_{k=1}^{\infty} \lambda_k \|x\varphi_{I,k}\|_2 &\leqq \sqrt{\frac{\varepsilon}{\sqrt{2\pi}} \sum_{k=1}^{\infty} \lambda_k \|x\varphi_{I,k}\|_2^2} \sqrt{\frac{\varepsilon}{\sqrt{2\pi}} \sum_{k=1}^{\infty} \lambda_k} \\
&\leqq \sqrt{\|x^2 w_I\|_1 \|w\|_1}
\end{aligned}$$

and similarly

$$\frac{\varepsilon^3}{\sqrt{2\pi}} \sum_{k=1}^{\infty} \lambda_k \left\| \frac{\partial}{\partial x} \varphi_{I,k} \right\|_2 \leqq \sqrt{\left\| \frac{\varepsilon^2}{4} w_{I,xx} + v^2 w_I \right\|_1 \|w_I\|_1}.$$

Inserting these estimates into (5.16) yields Lemma 5.3. □

Now we are able to prove Theorem 5.1. By (5.13), (5.14), and the assumption of Theorem 5.1 the functions $w^{(\varepsilon)}$, $vw^{(\varepsilon)}$, and $w_I^{(\varepsilon)}$ are uniformly bounded with respect to ε in the L^2-norm. Due to the weak compactness of a bounded set in L^2 there exist subsequences of $w^{(\varepsilon)}$, $vw^{(\varepsilon)}$, $w_I^{(\varepsilon)}$ which converge weakly to the functions $w^{(0)}$, $vw^{(0)}$, $w_I^{(0)}$. Since the L^1 norm of $n^{(\varepsilon)}$ is bounded uniformly, $V_x^{(\varepsilon)}$ is bounded uniformly and therefore there exist a subsequence of $V_x^{(\varepsilon)}$ and a limit function $V_x^{(0)}$ with

$$\lim_{\varepsilon \to 0} V_x^{(\varepsilon)} = V_{I,x}^{(0)} \quad \text{in } L^\infty(R \times [0, T]) \text{ weak*}.$$

It remains to show that $w^{(0)}$, $V_x^{(0)}$ satisfy the Vlasov-Poisson equation.

We multiply the Poisson equation by a test function $\sigma \in C_0^\infty(R \times [0, T])$ and choose a positive constant A:

$$\begin{aligned}
\int_0^T \int_R V_x^{(\varepsilon)} \sigma\, dx\, dt &= \int_0^T \int_R \int_R \operatorname{sign}(x-y) n^{(\varepsilon)}(y, t) \sigma(x, t)\, dy\, dx\, dt \\
&= \int_0^T \int_{-A}^{A} \int_R (1+|v|) w^{(\varepsilon)}(y, v, t) \frac{\int \operatorname{sign}(x-y)\sigma(x, t)\, dx}{1+|v|}\, dv\, dy\, dt \\
&\quad + \int_0^T \int_{R \setminus [-A, A]} \int_R \operatorname{sign}(x-y) n^{(\varepsilon)}(y, v, t) \sigma(x, t)\, dx\, dy\, dt.
\end{aligned}$$

We can estimate the second term by $\mu(\text{supp}(\sigma))\|\sigma\|_\infty\|xn^{(\varepsilon)}\|_1/A$. Note that μ denotes the Lebesgue measure. Using that $vw^{(\varepsilon)}$ converges weakly to $vw^{(0)}$, we obtain

$$\left|\int_0^T\int_R\left(V_x^{(0)}-\int_R \text{sign}(x-y)n^{(0)}(y,t)\,dy\right)\sigma(x,t)\,dx\,dt\right|$$
$$\leqq c(1+t^2)\mu(\text{supp}(\sigma))\|\sigma\|_\infty/A.$$

Taking the limit $A\to\infty$, we conclude that $V^{(0)}$, $n^{(0)}$ satisfy the Poisson equation.

We denote by $\Omega_A := [-A, A]^2$ and $\Omega_{A,T} := [-A, A]^2\times[0, T]$. Then we multiply the Fourier transformed Wigner equation by a test function $\varphi\in C_0^\infty(R^2\times[0,T])$ with $\text{supp}(\varphi)\subset\Omega_{A,T}$. Integration by parts yields

$$-\int_{\Omega_{A,T}}\mathcal{F}w^{(\varepsilon)}\varphi_t\,d\eta\,dx\,dt+i\int_{\Omega_{A,T}}\mathcal{F}w^{(\varepsilon)}\varphi_{x\eta}\,d\eta\,dx\,dt$$
$$-i/\varepsilon\int_{\Omega_{A,T}}\mathcal{F}w^{(\varepsilon)}(V^{(\varepsilon)}(x+\varepsilon\eta/2)-V^{(\varepsilon)}(x-\varepsilon\eta/2))\varphi\,d\eta\,dx\,dt$$
$$=\int_{\Omega_A}\mathcal{F}w_I^{(\varepsilon)}\pi(t=0)\,d\eta\,dx.$$

Now using the weak convergence of $w^{(\varepsilon)}$, $w_I^{(\varepsilon)}$ we obtain

$$\int_{\Omega_{A,T}}\mathcal{F}w^{(\varepsilon)}\varphi_t\,d\eta\,dx\,dt\to\int_{\Omega_{A,T}}\mathcal{F}w^{(0)}\varphi_t\,d\eta\,dx\,dt,$$
$$\int_{\Omega_{A,T}}\mathcal{F}w^{(\varepsilon)}\varphi_{x\eta}\,d\eta\,dx\,dt\to\int_{\Omega_{A,T}}\mathcal{F}w^{(0)}\varphi_{x\eta}\,d\eta\,dx\,dt,$$
$$\int_{\Omega_A}\mathcal{F}w_I^{(\varepsilon)}\varphi(t=0)\,d\eta\,dx\to\int_{\Omega_A}\mathcal{F}w_I^{(0)}\varphi(t=0)\,d\eta\,dx.$$

Only the third term on the left-hand side has to be taken care of. In the following we set $\delta_\varepsilon V=(V(x+\varepsilon\eta/2)-V(x-\varepsilon\eta/2))/\varepsilon$.

$$\int_{\Omega_{A,T}}\delta_\varepsilon V^{(\varepsilon)}\mathcal{F}w^{(\varepsilon)}\varphi\,dx\,d\eta\,dt$$

(5.17)
$$=\int_{\Omega_{A,T}}\eta V_x^{(0)}\mathcal{F}w_\varphi^{(0)}\,dx\,d\eta\,dt$$

(5.18)
$$+\int_{\Omega_{A,T}}(\eta V_x^{(\varepsilon)}-\eta V_x^{(0)})\mathcal{F}w^{(0)}\varphi\,dx\,d\eta\,dt$$

(5.19)
$$+\int_{\Omega_{A,T}}\eta V_x^{(\varepsilon)}(\mathcal{F}w^{(\varepsilon)}-\mathcal{F}w^{(0)})\varphi\,dx\,d\eta\,dt$$

(5.20)
$$+\int_{\Omega_{A,T}}(\delta_\varepsilon V^{(\varepsilon)}-\eta V_x^{(\varepsilon)})\mathcal{F}w^{(\varepsilon)}\varphi\,dx\,d\eta\,dt.$$

Since $V_x^{(\varepsilon)}$ converges in $L^\infty(R\times[0,T])$ weak* and $\eta\mathcal{F}w^{(0)}\in L^1$, the first term (5.18) converges to zero:

$$\int_{\Omega_{A,T}}(\eta V_x^{(\varepsilon)}-\eta V_x^{(0)})\mathcal{F}w^{(0)}\varphi\,dx\,d\eta\,dt\to 0\quad\text{as }\varepsilon\to 0.$$

Since $\mathcal{F}w_\eta^{(\varepsilon)}$ and $\delta_\varepsilon V^{(\varepsilon)}\mathcal{F}w^{(\varepsilon)}$ are uniformly bounded in $L^\infty([0, T]\to L^2(\Omega_A))$ and using

$$\mathcal{F}w_t^{(\varepsilon)} = -i\frac{\partial}{\partial x}\mathcal{F}w_\eta^{(\varepsilon)} + \delta_\varepsilon V^{(\varepsilon)}\mathcal{F}w^{(\varepsilon)},$$

we can interpret $\mathcal{F}w^{(\varepsilon)}(t)$ as a functional on $H^1(\Omega_A)$ with

$$\|\mathcal{F}w^{(\varepsilon)}\|_{W^{1,\infty}([0,T]\to H^{-1}(\Omega_A))} \leqq F,$$

where F is a constant independent of ε. Therefore we can extract a subsequence with

$$\mathcal{F}w^{(\varepsilon)} \to \mathcal{F}w^{(0)} \quad \text{strongly in } L^\infty([0, T]\to H^{-1}(\Omega_A)).$$

Since

$$\|V_{xx}^{(\varepsilon)}\|_2^2 = \|n^{(\varepsilon)}\|_2^2 \leqq \text{const. } \|(1+|v|)w^{(\varepsilon)}\|_2^2,$$

we conclude that $\eta V_x^{(\varepsilon)}\varphi$ is uniformly bounded in $L^\infty([0, T]\to H^1(\Omega_A))$ as $\varepsilon\to 0$ and therefore we have

$$\int_{\Omega_{A,T}} \eta V_x^{(\varepsilon)}(\mathcal{F}w^{(\varepsilon)} - \mathcal{F}w^{(0)})\varphi\, dx\, d\eta\, dt \to 0 \quad \text{as } \varepsilon\to 0.$$

To show the convergence of the fourth term (5.20), we estimate

$$\begin{aligned}
|\delta_\varepsilon V^{(\varepsilon)} - \eta V_x^{(\varepsilon)}| &= \int_R \left(\frac{|x-y+\varepsilon\eta/2| - |x-y-\varepsilon\eta/2|}{\varepsilon} - \eta \operatorname{sign}(x-y)\right) n^{(\varepsilon)}\, dy \\
&\leqq \int_{x-\varepsilon|\eta|/2}^{x+\varepsilon|\eta|/2} (2|x-y|/\varepsilon + |\eta|) n^{(\varepsilon)}(y)\, dy \\
&\leqq \text{const. } \varepsilon^{1/2}\eta^{3/2}\|(1+|v|)w^{(\varepsilon)}\|_2,
\end{aligned}$$

and we obtain

$$\int_{\Omega_{A,T}} (\delta_\varepsilon V^{(\varepsilon)} - \eta V_x^{(\varepsilon)})\mathcal{F}w^{(\varepsilon)}\varphi\, dx\, d\eta\, dt \to 0 \quad \text{as } \varepsilon\to 0,$$

which concludes the proof of Theorem 5.1. □

A BOUNDARY INTEGRAL EQUATION FOR THE TWO-DIMENSIONAL FLOATING-BODY PROBLEM*

Y. W. LIU†

Abstract. The time-harmonic two-dimensional finite-depth floating-body problem is reformulated as a boundary integral equation. As a result of choosing a simple kernel function, the integral equation extends over both the wetted portion of the floating body and the free surface. It is also shown that this integral equation suffers no irregular frequencies, that is, it has at most one solution.

Key word. floating-body problem

AMS(MOS) subject classification. 76B15

1. Introduction.

In 1950, Fritz John [4] published a paper analyzing time-harmonic motion of a fluid in which an impenetrable body is partially immersed. This floating-body problem was formulated mathematically as a boundary value problem for Laplace's equation in $\mathcal{R}^3$ with appropriate boundary and radiation conditions. The two-dimensional problem is formulated in a similar way with slight modification. Using the Green's function suggested by John, the boundary value problem can be reduced to an integral equation over the wetted portion of the floating body. Just as John demonstrated the existence of irregular frequencies for the three-dimensional case, the two-dimensional case also suffers irregular frequencies (e.g., Ursell [7] and Liu [6]). By irregular frequencies is meant frequencies for which the integral equation is not uniquely solvable even though the solution of the original boundary value problem is unique.

Another way to treat this problem is to employ a simpler Green's function, which only satisfies the boundary condition at the bottom of the fluid. Hence the corresponding integral equation is defined over the wetted surface of the floating body and the free surface as well. For both three- and two-dimensional problems, such integral equations have been derived and even solved numerically for certain cases, e.g., Yeung [9] and Bai and Yeung [2]. Numerical evidence indicates that these integral equations do not exhibit irregular frequencies but does not constitute a conclusive analytical argument to support this conjecture. Recently, Angell, Hsiao, and Kleinman [1] presented a proof of the conjecture that the integral equation for the three-dimensional problem has no irregular frequencies provided that the original boundary value problem is uniquely solvable.

The present paper provides a proof of the conjecture that an integral equation for a two-dimensional floating-body problem having no irregular frequencies is available. Making use of a proper Green's function, we arrive at an integral equation which has the same form as the one derived by Angell, Hsiao, and Kleinman. However, the proof of the uniqueness theorem is quite different. The unique solvability of the original boundary value problem is also required.

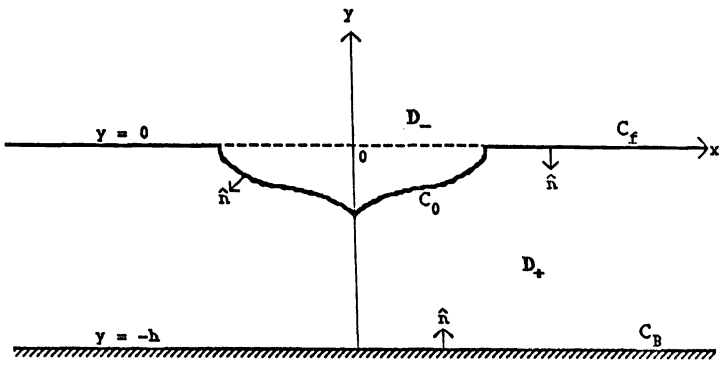

FIG. 1

2. Notation and statement of problem. The geometry of the two-dimensional floating-body problem with finite depth h is described as follows and is illustrated in Fig. 1. We denoted the fluid domain by $\mathbf{D}_+$, whose boundary consists of C_0, the wetted portion of the floating body, the free surface C_f, and the bottom C_B, and we denote by $\mathbf{D}_-$ the domain consisting of the upper half space and the interior of the floating body.

The function ϕ solves the floating-body problem if

$$\begin{aligned} &\nabla^2 \phi = 0 \quad \text{in } \mathbf{D}_+, \quad \frac{\partial \phi}{\partial n} = V \quad \text{on } C_0, \quad \frac{\partial \phi}{\partial n} = 0 \quad \text{on } C_B, \\ &\frac{\partial \phi}{\partial n} + k\phi = 0 \quad \text{on } C_f, \end{aligned} \tag{1}$$

and provided ϕ satisfies a radiation condition. Here $\partial/\partial n$ denotes the normal derivative pointing into $\mathbf{D}_+$ and V is a given function. The radiation condition is specified in the form

$$\frac{\partial \phi}{\partial |x|} - ik_0 = o(1) \quad \text{as } |x| \to \infty, \tag{2}$$

where k_0 is the root with largest real part of the transcendental equation

$$k = k_0 \tan h(k_o h). \tag{3}$$

Condition (2) may be shown to guarantee that

$$\phi(x, y) = e^{ik_0|x|} \cdot a(y) + O\left(e^{-\mu|x|}\right) \quad \text{as } |x| \to \infty, \tag{4}$$

uniformly in y, for some complex-valued function $a(y)$, (x, y) being rectangular coordinates and μ is a positive constant.

We now define the Green's function

$$\gamma(p, q) = \frac{1}{\pi} \left\{ \log \frac{|q|}{|p - q|} + \log \frac{|q_1|}{|p - q_1|} \right\}, \tag{5}$$

where $p = (x_p, y_p)$, $q = (x_q, y_q)$ and $q = (x_q, -2h - y_q)$. With this Green's function, Green's theorem for a solution of Laplace's equation in $\mathbf{D}_+$ which satisfies the radiation condition (2) then takes the form

$$\int_{C_0 \cup C_f \cup C_B} \left\{ \gamma(p, q) \frac{\partial \phi(q)}{\partial n_q} - \phi(q) \frac{\partial \gamma(p, q)}{\partial n_q} \right\} dS_q = \alpha(p)\phi(p), \tag{6}$$

with

$$\alpha(p) := \lim_{\varepsilon \to 0} \int_{[\partial B_\varepsilon(p)] \cap \mathbf{D}_+} \frac{\partial \gamma(p,q)}{\partial n_q} dS_q, \tag{7}$$

where $\partial B_\varepsilon(p)$ denotes the boundary of a disc of radius ε centered at p. If ϕ satisfies all the boundary conditions in (1) we arrive at the boundary integral equation

$$\begin{aligned} \alpha(p)\phi(p) + \int_{C_0} \phi(q) \frac{\partial \gamma}{\partial n_q}(p,q) dS_q + \int_{C_f} \phi(q) \left[\frac{\partial \gamma}{\partial n_q}(p,q) + k\gamma(p,q) \right] dS_q \\ = \int_{C_0} \gamma(p,q) V(q) dS_q, \end{aligned} \tag{8}$$

where p lies either on C_0 or C_f. The integral on C_B vanishes since both γ and ϕ satisfy the homogeneous Neumann condition there and the integrals over large enough artificial bounds $x = R$ and $x = -R$ can be shown to be of order $O(R^{-1})$ (see Liu [6]). This equation has irregular frequencies if there are real values of k for which the corresponding homogeneous equation ($V = 0$) has nontrivial solutions. We shall prove in the following that such irregular frequencies do not exist.

3. Uniqueness. Our result can be summarized as follows.

THEOREM. *If*

(a) $\phi(p) = e^{ik_0|x_p|} \cdot a(y_p) + O(e^{-\mu|x_p|})$ *as* $|p| \to \infty$, *uniformly in* y_p, $\mu > 0$;

(b) $\alpha(p)\phi(p) + \int_{C_0} \phi(q) \frac{\partial \gamma}{\partial n_q}(p,q)\, dS_q + \int_{C_f} \phi(q) [\frac{\partial \gamma}{\partial n_q}(p,q) + k\gamma(p,q)]\, dS_q = 0$ *for all* $p \in C_0 \cup C_f$; *and*

(c) ϕ *is continuous on* $C_0 \cup C_f$,

then $\phi(p) = 0$ *for all* $p \in C_0 \cup C_f$.

Proof. Assume that ϕ is a function satisfying (a), (b), and (c) of the theorem and define the functions u_+ and u_- in $\mathbf{D}_+$ and $\mathbf{D}_-$, respectively, as

$$\begin{aligned} \left.\begin{matrix} u_+ \\ u_- \end{matrix}\right\} := \int_{C_0} \phi(q) \frac{\partial \gamma}{\partial n_q}(p,q) dS_q \\ + \int_{C_f} \phi(q) \left[\frac{\partial \gamma}{\partial n_q}(p,q) + k\gamma(p,q) \right] dS_q, \qquad p \in \left\{ \begin{matrix} \mathbf{D}_+, \\ \mathbf{D}_-. \end{matrix} \right. \end{aligned} \tag{9}$$

It follows that

$$\nabla^2 u_\pm = 0, \qquad p \in \mathbf{D}_\pm, \tag{10}$$

since $p \neq q$ in either case. This property is inherited from the function $\gamma(p,q)$. Using the jump conditions for double layer potentials defined on $C_0 \cup C_f$, we have

$$\lim_{\substack{p \to C_0 \cup C_f \\ p \in \mathbf{D}_\pm}} \int_{C_0 \cup C_f} \phi(q) \frac{\partial \gamma}{\partial n_q}(p,q) dS_q = \left.\begin{matrix} (\alpha(p) - 2) \\ \alpha(p) \end{matrix}\right\} \phi(p) + \int_{C_0 \cup C_f} \phi(q) \frac{\partial \gamma}{\partial n_q}(p,q) dS_q, \tag{11}$$

$$p \in C_0 \cup C_f.$$

Together with the continuity of single layer potenials, this implies that

$$\lim_{\substack{p\to C_0\cup C_f\\ p\in\mathbf{D}_-}} u_-(p) = \alpha(p)\phi(p) + \int_{C_0} \phi(q)\frac{\partial\gamma}{\partial n_q}(p,q)\,dS_q + \int_{C_f} \phi(q)\left[\frac{\partial\gamma}{\partial n_q}(p,q) + k\gamma(p,q)\right] dS_q, \tag{12}$$

and hence

$$\lim_{p\to C_0\cup C_f} u_-(p) = 0, \qquad p\in\mathbf{D}_- \tag{13}$$

in view of (b). As is established in Appendix A, the growth of the function u_- in $\mathbf{D}_-$ is

$$u_-(p) = O(\log r_p) + O(1) + O(r_p^{-1}) \quad \text{as } r_p = |p| \to \infty, \tag{14}$$

for $p\in\mathbf{D}_-$. This together with (13) implies that

$$u_-(p) \equiv 0, \qquad p\in\mathbf{D}_- \tag{15}$$

by the maximum principle (see Appendix B). Consequently, we have

$$\frac{\partial u_-}{\partial n_-} = 0 \quad \text{on } C_0\cup C_f, \tag{16}$$

where $\partial/\partial n_-$ indicates the normal derivative from $\mathbf{D}_-$. From the definition of u_- in (9), it follows that

$$\frac{\partial}{\partial n_p}\int_{C_0\cup C_f} \phi(q)\frac{\partial\gamma}{\partial n_q}(p,q,)\,dS_q + k\int_{C_f}\phi(q)\frac{\partial\gamma}{\partial n_p}(p,q)\,dS_q + \beta(p)\phi(p) = 0, \tag{17}$$

with

$$\beta(p) = \begin{cases} 0, & p\in C_o,\\ -k, & p\in C_f, \end{cases} \tag{18}$$

where the jump condition of simple layer is employed. Note that the existence of the normal derivative of a double layer is not guaranteed for a merely continous density ϕ. But using the fact that $u_-\equiv 0$ in $\mathbf{D}_-$ and hence u_- has a ordinary normal derivative, $\partial u_-/\partial n_-\equiv 0$ on $C_0\cup C_f$, together with the fact that the single layers have ordinary normal derivatives, we conclude from definition (9) that

$$\frac{\partial}{\partial n_p}\int_{C_0\cup C_f}\phi(q)\frac{\partial\gamma}{\partial n_q}(p,q)\,dS_q$$

exists in the ordinary sense.

For properties of u_+, we find that

$$u_+(p) = (\alpha(p)-2)\phi(p) + \int_{C_0}\phi(q)\frac{\partial\gamma}{\partial n_q}(p,q)\,dS_q + \int_{C_f}\phi(q)\left[\frac{\partial\gamma}{\partial n_q}(p,q) + k\gamma(p,q)\right] dS_q, \qquad p\in C_0\cup C_f, \tag{19}$$

from the usual jump conditions. Consequently, using condition (b) we have that

$$u_+(p) = -2\phi(p), \qquad p \in C_0 \cup C_f. \tag{20}$$

Equation (20) means that $u_+(p)$ has the same growth as $\phi(p)$ on C_f, which is specified by (a). Taking the normal derivative yields

$$\begin{aligned}\frac{\partial u_+}{\partial n_+}(p) = \frac{\partial}{\partial n_p} \int_{C_0 \cup C_f} \phi(q) \frac{\partial \gamma}{\partial n_q}(p,q) dS_q \\ + k \int_{C_f} \phi(q) \frac{\partial \gamma}{\partial n_p}(p,q) dS_q - \beta(p)\phi(p).\end{aligned} \tag{21}$$

Since the normal derivatives of the double layer potential with continuous density are the same from either side provided that one of them exists, we obtain

$$\frac{\partial u_+}{\partial n_+} = -2\beta(p)\phi(p) = \beta(p)u_+(p) \tag{22}$$

from (17) and (20), or equivalently

$$\frac{\partial u_+}{\partial n_+} = 0, \qquad p \in C_0, \tag{23}$$

and

$$\frac{\partial u_+}{\partial n_+} = -ku_+(p), \qquad p \in C_f. \tag{24}$$

The function u_+ also satisfies

$$\frac{\partial u_+}{\partial n_+} = 0, \qquad p \in C_B, \tag{25}$$

which is inherited from $\gamma(p,q)$. Thus equations (10), (24), and (25) imply that u_+ satifies Laplace's equation in $\mathbf{D}_+$, together with the homogeneous Neumann and Robin condition on C_B and C_f, respectively. Following Weinstein [8] and Kreisel [5], u_+ has the representation

$$u_+(x,y) = \sum_{n=0}^{\infty} a_n(x) \cosh\left[k_n(y+h)\right], \qquad |x| \geq A, \tag{26}$$

where k_n's are the roots of the transcendental equation (3), and A is any number greater than the diameter of the wetted portion of the floating body. That is, $A > \max |x_p|, p \in C_0$. Hence the Fourier coefficients $a_n(x)$ in (26) are of the form

$$a_n(x) = C_n \int_{-h}^{0} u_+(x,y) \cosh\left[k_n(y+h)\right] dy \tag{27}$$

for some constant C_n, and they all have the same growth as $u_+(x,y)$ when $|x| \geq A$, i.e.,

$$a_n(x) = O(\log|x|) + O(1) + O(|x|^{-1}) \tag{28}$$

(see Appendix A). Recall that the most general form of $a_n(x)$ is

$$a_n(x) = C_{n,1} e^{ik_n|x|} + C_{n,2} e^{-ik_n|x|} \tag{29}$$

since $u_+(x,y)$ satisfies Laplace's equation. The fact that k_n has positive imaginary part for $n \geq 1$ makes the term $\exp(-ik_n|x|)$ grow exponentially. Computing $a_n(x)\exp(ik_n|x|)$ from both (27) and (28), we see that

$$e^{ik_n|x|}\{O(\log|x|) + O(1) + O(|x|^{-1})\} = C_{n,1}e^{i2k_n|x|} + C_{n,2}.$$

Hence $C_{n,2}$, being the only term that survives as $|x| \to \infty$, must be zero for $n \geq 1$. We may then rewrite the expression (26) as

$$u_+(x,y) = \sum_{n=0}^{\infty} C_{n,1}e^{ik_n|x|}\cosh[k_n(y+h)] + C_{n,2}e^{-ik_n|x|}\cosh[k_0(y+h)]. \tag{30}$$

Because $u_+(x,0)$ has the same asymptotic growth as ϕ, i.e., $0(\exp(ik_0|x|))$, we conclude that $C_{0,2} = 0$. Then the representation (30) can be further simplified as

$$u_+(x,y) = \sum_{n=0}^{\infty} C_n e^{ik_n|x|}\cosh[k_n(y+h)] \quad \text{for } |x| \geq A. \tag{31}$$

With this representation, it is obvious that u_+ satisfies the radiation condition (2). That is

$$\frac{\partial u_+}{\partial|x|} - ik_0u_+ = o(1) \quad \text{as} |x| \to \infty, \tag{32}$$

for $-h \leq y \leq 0$.

Now the uniqueness theorem for the two-dimensional floating-body problem (Liu [6]) implies that $u_+ \equiv 0$ in $\mathbf{D}_+$ and hence on $C_0 \cup C_f$, provided that C_0 satisfies the geometric restriction. Equation (24) then ensures that $\phi(p) = 0$ on $C_0 \cup C_f$. It means that the only solution of (a), (b), and (c) is $\phi \equiv 0$ and the integral equation (8) has no irregular frequencies. This completes the proof.

Appendix A. On the growth of $u\pm$. Here we establish the lemma regarding the growth of the functions u_+ and u_- defined in the uniqueness theorem. It is restated as follows.

LEMMA. *If*

(a) $\phi(p) = e^{ik_0|x_p|}.a(y) + O(e^{-\mu|x_p|})$ *as* $|p| \to \infty$ *uniformly in* y_p, $\mu > 0$;

(b) $$\alpha(p)\phi(p) + \int_{C_0} \phi(q)\frac{\partial\gamma}{\partial n_q}(p,q)\,dS_q + \int_{C_f} \phi(q)\left\{\frac{\partial\gamma}{\partial n_q}(p,q) + k\gamma(p,q)\right\}dS_q = 0$$
$$\forall p \in C_0 \cup C_f;$$

(c) ϕ *is continuous on* $C_0 \cup C_f$; *and*

(d) $$u_\pm(p) = \int_{C_0} \phi(q)\frac{\partial\gamma}{\partial n_q}(p,q)\,dS_q + \int_{C_f} \phi(q)\left\{\frac{\partial\gamma}{\partial n_q}(p,q) + k\gamma(p,q)\right\}dS_q,$$
$$p \in \mathbf{D}_\pm,$$

then $u_-(p) = O(\log r_p) + O(1) + O(r_p^{-1})$, *and* $u_+(p) = O(\log|x_p|) + O(1) + O(|x_p|^{-1})$, *as* $r_p \to \infty$, *where* $r_p = |p| = (x_p^2 + y_p^2)^{1/2}$.

Proof. With the Green's function $\gamma(p,q)$ defined in (5), we have

$$\gamma(p,q) = \frac{1}{2\pi}\left\{\log\frac{(x_q^2 + y_q^2)}{[(x_p - x_q)^2 + (y_p - y_q)^2]} + \log\frac{[x_q^2 + (2h + y_q)^2]}{[(y_p - x_q)^2 + (y_p + 2h + y_q)^2]}\right\} \tag{A.1}$$

and

$$\frac{\partial\gamma}{\partial y_q}(p,q) = \frac{1}{\pi}\left\{\frac{y_p - y_q}{(x_p - x_q)^2 + (y_p - y_q)^2} + \frac{y_q}{x_q^2 + y_q^2} - \frac{y_p + 2h + y_q}{(x_p - x_q)^2 + (y_p + 2h + y_q)^2} + \frac{2h + y_q}{x_q^2 + (2h + y_q)^2}\right\}; \tag{A.2}$$

hence

$$\int_{C_0} \phi(q)\frac{\partial\gamma}{\partial n_q}(p,q)dS_q = O(r_p^{-1}), \tag{A.3}$$

$$\int_{C_f \cap B_A} \phi(q)\frac{\partial\gamma}{\partial n_q}(p,q)dS_q = O(r_p^{-1}), \tag{A.4}$$

and

$$\int_{C_f \cap B_A} \phi(q)k\gamma(p,q)dS_q = O(\log r_p) + O(r_p^{-1}), \tag{A.5}$$

where $C_f \cap B_A$ is that portion on the free surface contained in the disc B_A centered at the origin with radius A, $A > \max\{|x_p|, p \in C_0\}$. We also have to establish the growth of

$$\int_{C_f \cap B_A^C} \phi(q)\left[\frac{\partial\gamma}{\partial n_q}(p,q) + k\gamma(p,q)\right]dS_q \tag{A.6}$$

with B_A^C being the complement of B_A. To examine the growth of the first piece in (A.6), it suffices to establish the growth of the integral

$$-\frac{1}{\pi}\int_{A'}^{\infty}\left[a(0)e^{ik_0x_q} + O(e^{-\mu|x_q|})\right]\left\{\frac{y_p}{(x_p - x_q)^2 + y_p^2} + \frac{y_p + 2h}{x_q^2 + (y_p + 2h)^2} - \frac{y_p + 2h}{(x_p - x_q)^2 + (y_p + 2h)^2}\right\}dx_q,$$

where the asymptotic behavior of ϕ has been employed, A' being a fixed number sufficiently large. Integrating by parts shows that its growth is of $O(r_p^{-1})$. Hence we conclude that

$$\int_{C_f \cap B_A^C} \phi(q)\frac{\partial\gamma}{\partial n_q}(p,q)dS_q = 0(r_p^{-1}) \quad \text{as } r_p \to \infty. \tag{A.7}$$

Next we consider the second piece in (A.6). As in the previous estimate, it suffices to examine the growth of

$$\int_{A'}^{\infty}\left[a(0)e^{ik_0x_q} + O(e^{-\mu|x_q|})\right]\log\frac{x_q^2}{(x_p - x_q)^2 + y_p^2}dx_q.$$

Integrating by parts twice, we see that

$$\int_{A'}^{\infty} e^{ik_o x_q} \log \frac{x_q^2}{(x_p - x_q)^2 + y_p^2} dx_q$$

$$= -\frac{e^{ik_o A'}}{ik_o} \log \frac{A'^2}{(x_p - A')^2 + y_p^2} - \frac{2}{ik_o} \int_{A'}^{\infty} e^{ik_o x_q} \left[\frac{1}{x_q} + \frac{x_p - x_q}{(x_p - x_q)^2 + y_p^2} \right] dx_q$$

$$= -\frac{e^{ik_o A'}}{ik_o} \log \frac{A'^2}{(x_p - A')^2 + y_p^2} - \frac{2}{(ik_o)^2} e^{ik_o A'} \left[\frac{1}{A'} + \frac{x_p - A'}{(x_p - A')^2 + y_p^2} \right]$$

$$+ \frac{2}{(ik_o)^2} \int_{A'}^{\infty} e^{ik_o x_q} \left[\frac{-1}{x_q^2} + \frac{(x_p - x_q)^2 + y_p^2}{[(x_p - x_q)^2 + y_p^2]^2} \right] dx_q.$$

Hence

$$\text{(A.8)} \qquad \int_{C_f \cap B_A^C} k\phi(q)\gamma(p,q) dS_q = O(\log r_p) + O(1) + O(r_p^{-1}) \quad \text{as } r_p \to \infty.$$

It follows from (A.3)–(A.5), (A.7), and (A.8) that

$$\text{(A.9)} \qquad u_-(p) = O(\log r_p) + O(1) + O(r_p^{-1}) \quad \text{as } r_p \to \infty, \quad p \in \mathbf{D}_-,$$

which is the required growth for the function $u_-(p)$ in $\mathbf{D}_-$. There are only two places where the estimate of u_+ is different from that of u_-.The first is that for every p in $\mathbf{D}_+$, y_p is always bounded, which results in the fact that $r_p \to \infty$ implies only $|x_p| \to \infty$. The second is that the normal derivatives on $C_0 \cup C_f$ have opposite sign to those of $u_-(p)$, but this will not affect any growth order. Thus we may arrive at

$$\text{(A.3)}' \qquad \int_{C_0} \phi(q) \frac{\partial \gamma}{\partial n_q}(p,q) dS_q = O(|x_p|^{-1}),$$

$$\text{(A.4)}' \qquad \int_{C_f \cap B_A} \phi(q) \frac{\partial \gamma}{\partial n_q}(p,q) dS_q = O(|x_p|^{-1}),$$

$$\text{(A.5)}' \qquad \int_{C_f \cap B_A} \phi(q) k\gamma(p,q) dS_q = O(\log |x_p|) + O(|x_p|^{-1}),$$

and

$$\text{(A.8)}' \qquad \int_{C_f \cap B_A^C} \phi(q) \left[\frac{\partial \gamma}{\partial n_q}(p,q) + k\gamma(p,q) \right] dS_q = O(\log |x_p|) + O(1) + O(|x_p|^{-1}).$$

Then it follows that

$$\text{(A.10)} \qquad u_+(p) = O(\log |x_p|) + O(1) + O(|x_p|^{-1}) \quad \text{as } r_p \to \infty, \quad p \in \mathbf{D}_+,$$

and the proof is complete.

Appendix B. Maximum principle on u_-. We wish to prove that the function $u_-(p)$ defined in (9) is a zero function in $\mathbf{D}_-$.

Proof. From (13) and (14) we know that $u_- = 0$ on $C_0 \cup C_f$ and that $u_-(p) = O(\log r_p)$ as $r_p \to \infty$ in $\mathbf{D}_-$. Choose r_0 large enough such that C_0 lies completely inside the circle $r = r_0$. Consider the potential u_- in the domain $\mathbf{D}_- \cap \{(r,\theta)|r > r_0\}$. Since $u_- = 0$ on C_f it follows that u_- can be continued, by Schwarz's symmetry principle, into the domain $\mathbf{D}_+ \cap \{(r,\theta)|r > r_0\}$ by the relation $u_-(x,y) = -u_-(x,-y)$. Because of the fact that $u_-(x,y)$ is an odd function of y as $r > r_0$, there is an expansion

$$u_-(r\cos\theta, r\sin\theta) = \sum_{m=1}^{\infty} b_m r^m \sin m\theta + \sum_{m=1}^{\infty} b_{-m} r^{-m} \sin m\theta$$

for $r > r_0$, $-\pi \le \theta \le \pi$, where the coefficients $\{b_m\}_{m=1}^{\infty}$ and $\{b_{-m}\}_{m=1}^{\infty}$ satisfy

$$b_m r^m - b_{-m} r^{-m} = \frac{1}{\pi} \int_{-\pi}^{\pi} u_-(r\cos\theta, r\sin\theta) \sin m\theta d\theta.$$

Let $r \to \infty$. We find that (14) requires $b_m = 0$ for $m \ge 1$, and hence

$$u_-(r\cos\theta, r\sin\theta) = \sum_{m=1}^{\infty} b_{-m} r^{-m} \sin m\theta.$$

We then have

$$|u_-(r\cos\theta, r\sin\theta)| < M/r$$

for r sufficiently large, say $r > 2r_0$.

Now we consider u_- in a bounded domain $\mathbf{D}_- \cap \{(r,\theta)|r < R\}$ where $R > 2r_0$. On the boundary we have

$$|u_-(R\cos\theta, R\sin\theta)| < M/R$$

when $-\pi < \theta < \pi$, while $u_- = 0$ on $C_0 \cup C_f$. Thus, for $p \in \mathbf{D}_-$ and $|p| < R$, we have

$$|u_-(p)| < M/R,$$

by the maximum principle. Let $R \to \infty$, keeping p fixed. We obtain $|u_-(p)| \le 0$, i.e., $u_-(p) \equiv 0$ in $\mathbf{D}_-$. This is the required result.

Acknowledgments. The author is indebted to his supervisors Professors G. C. Hsiao and R. E. Kleinman for their guidance, criticism, and suggestions.

A PRESCRIBED MEAN CURVATURE PROBLEM ON DOMAINS WITHOUT RADIAL SYMMETRY*

CHARLES V. COFFMAN† AND WILLIAM K. ZIEMER‡

Abstract. The existence is proved of a nontrivial solution to the problem

$$\operatorname{div}(\nabla u/\sqrt{1+|\nabla u|^2}) - \mu u + \lambda u^q = 0 \quad \text{in } \Omega, \qquad u = 0 \quad \text{on } \partial\Omega,$$

on a smooth, bounded but not necessarily radially symmetric domain Ω when λ is sufficiently large.

Key words. prescribed mean curvature problem, elliptic boundary value problem

AMS(MOS) subject classifications. 35J20, 35J25, 35J60

1. Introduction. This note is concerned with the existence of positive solutions to the Dirichlet problem for the so-called "prescribed mean curvature equation"

$$\operatorname{div}(\nabla u/\sqrt{1+|\nabla u|^2}) - \mu u + \lambda u^q = 0 \quad \text{in } \Omega, \qquad u = 0 \quad \text{on } \partial\Omega, \tag{1}$$

on a bounded $C^{1,1}$ domain $\Omega \subseteq R^N$, $N \geqq 2$. Here $\mu \geqq 0$; $1 < q < (N+2)/(N-2)$, and λ is a real parameter whose value will be assigned in advance. We stress that the domain Ω is not assumed to be radially symmetric. Our main result is that when μ, q, and Ω are fixed as above then (1) has a smooth positive solution for all sufficiently large λ.

The problem (1) has been treated in a number of recent works. The papers [1], [4], [5], [9] deal with radially symmetric ground states (positive symmetric solutions on R^N which tend to zero at ∞) in the case $\mu > 0$; it is shown in [4] that positive solutions vanishing at ∞ must be radially symmetric.

Radial symmetry of positive solutions on a ball is proved in [6]; the case when Ω is a ball is also treated in [8] and [11]. When $\mu = 0$ and Ω is a ball, Theorem 3.4 of [8] implies nonexistence of nontrivial solutions to (1) for supercritical q, i.e., for $q \geqq (N+2)/(N-2)$; a similar nonexistence result is given in [10] for $\mu > 0$ and Ω star-shaped. In [11] it is shown that when q is subcritical and Ω is a ball, then, independently of the radius of Ω, there is no nontrivial solution to (1) if

$$\mu > (2(q+1)/(q-1))^{(q-1)/(q+1)} \lambda^{2/(q+1)}.$$

Nonexistence is also proved in [11] for $\lambda = 1$ and $\mu > 0$ when the radius of Ω is too small; an existence result is given for the case where μ is sufficiently small and the radius of Ω sufficiently large.

It is instructive to compare (1) with the analogous semilinear problem in which the mean-curvature operator is replaced by the Laplacian

$$\Delta u - \mu u + \lambda u^q = 0 \quad \text{in } \Omega, \qquad u = 0 \quad \text{on } \partial\Omega. \tag{2}$$

The nonexistence results quoted above for the case of supercritical q of course apply also to (2), while the nonexistence results quoted from [11] reflect features special to the quasilinear problem (1). In particular, in the case of (2), unlike that of (1), we can limit attention to the case where $\lambda = 1$ and $\mu = 0$ or 1.

Our approach to (1) makes use of variational methods which generalize those that were introduced by Nehari [7] to treat boundary value problems for nonlinear ordinary differential equations; the application of these methods to (2) is described in [2]; see also [3].

We seek solutions to (1) as minima of the functional

$$H_\lambda(u)=\int_\Omega [2\sqrt{1+|\nabla u|^2}-2+\mu u^2-2\lambda(q+1)^{-1}|u|^{q+1}]\,dx \tag{3}$$

over nonzero functions subject to the constraint

$$N_\lambda(u)=\int_\Omega [|\nabla u|^2/\sqrt{1+|\nabla u|^2}+\mu u^2-\lambda|u|^{q+1}]\,dx=0. \tag{4}$$

We first note that (4) is necessarily satisfied by a solution to (1). Secondly, on a ray in $W_0^{1,2}(\Omega)$ emanating from the origin, $H_\lambda(u)$ achieves its maximum at the unique nonzero u that satisfies (4). Thus minimizing (3) subject to (4) is equivalent to maximizing (3) on rays from the origin and then finding a u that gives the minimum of these maxima.

The feature of (1) that enables one to extend Nehari's method is that the integrand on the right in (3) is concave in $(u^2, |\nabla u|^2)$. As a consequence, if $u\in W_0^{1,2}(\Omega)\backslash\{0\}$ with $N_\lambda(u)=0$ and we solve the linear boundary value problem

$$\operatorname{div}(\nabla v/\sqrt{1+|\nabla u|^2})-\mu v+\alpha u^q=0 \quad \text{in } \Omega, \qquad v=0 \quad \text{on } \partial\Omega, \tag{5}$$

adjusting $\alpha>0$ so that $N_\lambda(v)=0$, then the mapping

$$T_\lambda: u\to v \tag{6}$$

reduces H_λ. That is $H_\lambda(v)\leqq H_\lambda(u)$ and equality holds only if u and v are proportional; if the latter is the case then u satisfies (1) (μ and λ are assumed to be fixed throughout).

Several difficulties are encountered when one attempts to implement the method suggested above. First, the term

$$\int_\Omega (\sqrt{1+|\nabla|^2}-1)\,dx$$

(see (3)) is not coercive on $W_0^{1,p}(\Omega)$ for any $p>1$. Second, in contrast to the case of the semilinear analogue (2) (cf. [2]), the set

$$\{u\in W_0^{1,2}(\Omega): u\neq 0,\ N_\lambda(u)=0\}$$

is not bounded away from zero. Thus, in fact, the problem (3), (4), as formulated above, does not have a nontrivial global minimizer. We seek, therefore, to minimize H_λ under additional constraints. Assuming $\mu\geqq 0$ to be fixed, we construct a set

$$S(\lambda)\subseteq W^{2,r}(\Omega)\cap\{u: u\in W_0^{1,2}(\Omega)\backslash\{0\},\ N_\lambda(u)=0\} \qquad (r>N)$$

that is bounded in $W^{2,r}(\Omega)$, and such that when λ is sufficiently large we have the following: (i) $S(\lambda)$ is nonempty; (ii) H_λ has a positive lower bound on $S(\lambda)$; (iii) for $u\in S(\lambda)$, problem (5) is solvable and (iv) $S(\lambda)$ is invariant under the mapping T_λ or some iterate thereof. When λ is such that these latter four conditions hold, then H_λ can be minimized over $S(\lambda)$ and the resulting minimizer is a solution to (1).

2. Preliminaries. We shall actually consider a more general problem than (1), namely,

$$\operatorname{div}(\nabla u/\sqrt{1+|\nabla u|^2})-\mu u+\lambda f(u)=0 \quad \text{in } \Omega, \qquad u=0 \quad \text{on } \partial\Omega, \tag{7}$$

where the functional $f \in C[0, \infty)$ is assumed to satisfy the conditions

$$1 < s^{-q} f(s) < C \tag{8}$$

for some q such that

$$1 < q < (N+2)/(N-2), \tag{9}$$

and also to satisfy Nehari's condition, which in our notation takes the following form: for some $\varepsilon > 0$,

$$s^{-1-\varepsilon} f(s) < t^{-1-\varepsilon} f(t) \quad \text{for } 0 < s < t. \tag{10}$$

In place of (3) and (4) the definitions of H and N are

$$H_\lambda(u) = \int_\Omega [2(\sqrt{1+|\nabla u|^2} - 1) + \mu u^2 - 2\lambda F(u)]\, dx \tag{11}$$

and

$$N_\lambda(u) = \int_\Omega [|\nabla u|^2/\sqrt{1+|\nabla u|^2} + \mu u^2 - \lambda u f(u)]\, dx; \tag{12}$$

F in (11) is defined by

$$F(u) = \int_0^u f(s)\, ds. \tag{13}$$

3. Inequalities. Below K will be used to denote a generic constant that can depend on N and Ω but not on f, μ, or λ.

We find readily from (10) that F, defined by (13), satisfies

$$(2+\varepsilon) F(u) \leqq u f(u). \tag{14}$$

We will make frequent use below of the inequalities

$$p \geqq 2(\sqrt{1+p} - 1) \geqq p/\sqrt{1+p}. \tag{15}$$

From (11), (12), and (14) we conclude that for $u \in W_0^{1,2}(\Omega) \backslash \{0\}$ we have

$$H_\lambda(u) \geqq \varepsilon(2+\varepsilon)^{-1} \int_\Omega (2[\sqrt{1+|\nabla u|^2} - 1] + \mu u^2)\, dx, \tag{16}$$

when u is subject to the constraints

$$N_\lambda(u) = 0 \quad \text{and} \quad u \neq 0. \tag{17}$$

Next we observe that

$$2\sqrt{1+\|\nabla u\|_\infty^2} \int_\Omega [\sqrt{1+|\nabla u|^2} - 1]\, dx \geqq \int_\Omega |\nabla u|^2\, dx.$$

Combining this with (16) we have, when (17) holds,

$$\sqrt{1+\|\nabla u\|_\infty^2}\, H_\lambda(u) \geqq \varepsilon(2+\varepsilon)^{-1} \int_\Omega (|\nabla u|^2 + \mu u^2)\, dx. \tag{18}$$

Let $u \in W_0^{1,2}(\Omega) \backslash \{0\}$ satisfy (17) and define the formal operator $L = L_u$ by

$$Lw = -\operatorname{div}(\nabla w/\sqrt{1+|\nabla u|^2}) + \mu w. \tag{19}$$

We note that if $\|\nabla u\|_\infty < \infty$ and $h \in L^2(\Omega)$, then by the Lax-Milgram theorem, the boundary value problem

$$Lw = h \quad \text{in } \Omega, \qquad w = 0 \quad \text{on } \partial\Omega$$

has a unique weak solution in $W_0^{1,2}(\Omega)$; for elementary reasons w will be nonnegative if h is.

LEMMA 3.1. *Let λ be fixed and let $u \in W_0^{1,2}(\Omega)\backslash\{0\}$ and satisfy* (17). *Let $v \in W_0^{1,2}(\Omega)$ be the weak solution to*

$$Lv = \alpha\lambda f(u), \tag{20}$$

for any $\alpha > 0$. Then

$$H_\lambda(v) \leqq H_\lambda(u), \tag{21}$$

with equality only if $N_\lambda(v) = 0$ and u is a solution to (7).

Proof. By an elementary concavity inequality we have

$$H_\lambda(v) - H_\lambda(u) \leqq \int_\Omega [vLv - uLu - \lambda(v^2 - u^2)g(u)]\, dx,$$

where

$$g(0) = 0, \quad g(u) = f(u)/u, \qquad u \neq 0.$$

From (17) and (20) we have

$$H_\lambda(v) - H_\lambda(u) \leqq \lambda \int_\Omega [\alpha uv - v^2]g(u)\, dx. \tag{22}$$

Using (20), the Schwarz inequality, and (17) we get

$$\begin{aligned} \alpha\lambda \int_\Omega u^2 g(u)\, dx = \int_\Omega uLv\, dx &\leqq \left(\int_\Omega uLu\, dx\right)^{1/2} \left(\int vLv\right)^{1/2} \\ &\leqq \left(\lambda \int_\Omega u^2 g(u)\, dx\right)^{1/2} \left(\alpha\lambda \int_\Omega vug(u)\, dx\right)^{1/2}. \end{aligned} \tag{23}$$

We multiply through the last inequality by $(\int_\Omega vug(u)\, dx)^{1/2}$ and use the Schwarz inequality to get

$$\alpha \int_\Omega vug(u)\, dx \leqq \int_\Omega v^2 g(u)\, dx,$$

which, when substituted in (22), gives (21).

From the way in which the Schwarz inequality was used it is clear that for equality we must have v proportional to u; since $H_\lambda(v)$ achieves its maximum when $\alpha(>0)$ is chosen so that $N_\lambda(v) = 0$, the assertion follows.

Henceforth we assume that, in (20), $\alpha > 0$ is chosen so that $N_\lambda(v) = 0$. We seek a bound for this α. Using (17) we have from (23)

$$\alpha \left(\int_\Omega uLu\, dx\right)^{1/2} \leqq \left(\int_\Omega vLv\, dx\right)^{1/2}.$$

We also have

$$\sqrt{1 + \|\nabla u\|_\infty^2} \int_\Omega uLu\, dx \geqq H_\lambda(u),$$

and, since $N_\lambda(v)=0$,

$$\int_\Omega vLv\,dx \leqq \varepsilon^{-1}(2+\varepsilon)\sqrt{1+\|\nabla v\|_\infty^2}\,H_\lambda(v),$$

and thus, in view of (21),

$$\alpha \leqq (\varepsilon^{-1}(2+\varepsilon)\sqrt{1+\|\nabla v\|_\infty^2}\sqrt{1+\|\nabla u\|_\infty^2})^{1/2}. \tag{24}$$

If, in addition to the constraint (17), we also require that

$$\|\nabla u\|_\infty \leqq A,$$

then under these conditions $H_\lambda(u)$ will have a positive infimum. We seek upper and lower estimates for this infimum; these will be expressed as functions of μ and λ and in the case of the lower estimate also of A. Let $w\in C_0^\infty(\Omega)\backslash\{0\}$ be given and let $\beta=\beta(\lambda)>0$ be such that $N_\lambda(\beta w)=0$. Using the definition (12), it follows from (17) and (8) that

$$\int_\Omega (|\nabla w|^2+\mu w^2)\,dx \geqq \lambda\beta^{q-1}\int_\Omega |w|^{q+1}\,dx,$$

from which we conclude that

$$\beta \leqq K(1+\mu)^{1/(q-1)}\lambda^{-1/(q-1)}.$$

Thus we have shown the following.

LEMMA 3.2. *There exists a constant K such that for every $\lambda>0$ there is a $u\in C_0^\infty(\Omega)$ satisfying* (17) *and such that*

$$\|u\|_{1,2} \leqq K(1+\mu)^{1/(q-1)}\lambda^{-1/(q-1)} \tag{25}$$

(*here we are taking* $\|u\|_{1,2}=(\int_\Omega |\nabla u|^2\,dx)^{1/2}$).

From (25) there follows

$$H_\lambda(u) \leqq K^2(1+\mu)^{(q+1)/(q-1)}\lambda^{-2/(q-1)}; \tag{26}$$

this estimate then holds for the infimum of H_λ subject to (17).

Finally, if u satisfies (17) then we have

$$\begin{aligned}(\sqrt{1+\|\nabla u\|_\infty^2})^{-1}\int_\Omega (|\nabla u|^2+\mu u^2)\,dx &\leqq C\lambda\int_\Omega |u|^{q+1}\,dx\\ &\leqq KC\lambda\left(\int (|\nabla u|^2+\mu u^2)\,dx\right)^{(q+1)/2},\end{aligned}$$

from which we have

$$(1+\|\nabla u\|_\infty^2)^{1/(q-1)}\int_\Omega (|\nabla u|^2+\mu u^2)\,dx \geqq KC^{-2/(q-1)}\lambda^{-2/(q-1)}.$$

Thus we have the following.

LEMMA 3.3. *If $m_\lambda(A)$ denotes the infimum of H_λ subject to* (17) *and*

$$\|\nabla u\|_\infty \leqq A,$$

then

$$m_\lambda(\infty) \leqq K^2(1+\mu)^{(q+1)/(q-1)}\lambda^{-2/(q-1)}$$

and

$$m_\lambda(A) \geqq K\varepsilon(2+\varepsilon)^{-1}(1+A^2)^{(1-q)/2(1+q)}C^{-2/(q-1)}\lambda^{-2/(q-1)}.$$

LEMMA 3.4. *Let Ω be a region with $C^{1,1}$ boundary, let r: $N<r<\infty$ be given, and let*

$$1<s_0<r.$$

Then there is a constant $\delta>0$ and a constant M such that for

$$s_0 \leqq s \leqq r$$

if $u \in W^{2,r}(\Omega)$ and

$$\|u\|_{2,r}<\delta,$$

then the operator L_u defined by (19) *acts from $W^{2,s}(\Omega)\cap W_0^{1,2}(\Omega)$ to $L^s(\Omega)$ and is invertible with inverse*

$$L_u^{-1}: L^s(\Omega)\to W^{2,s}(\Omega)$$

satisfying the norm estimate

$$\|L_u^{-1}\|<M.$$

4. Determination of $S(\lambda)$. The set $S(\lambda)$ will be taken to be of the form

$$S(\lambda)=\{u:\ u\in W^{2,r}(\Omega)\cap W_0^{1,2}(\Omega),\ N_\lambda(u)=0,\ u\geqq 0,\ \text{a.e. in } \Omega,$$
$$0<\|u\|_{2,r}\leqq m_1\lambda^{-1/(q-1)},\ H_\lambda(u)\leqq m_2^2\lambda^{-2/(q-1)}\},$$

where r and the constant m_1 (which depends on μ, C, N, Ω, and the choice of r) are to be determined; m_2 is chosen in accordance with (26), i.e.,

$$m_2=K(1+\mu)^{(q+1)/2(q-1)}, \tag{27}$$

with K as in Lemma 3.2. Note that with the exception of the inequality on the $(2, r)$-norm all of the conditions in the definition are preserved by the operator T_λ.

We first determine the order of the iterate of the operator T_λ (defined by (5), (6); see also Lemma 3.1) that will leave $S(\lambda)$ invariant. What we actually seek is the number n such that, if we begin with $u\in W_0^{1,2}$, then after n iterations the resulting function will belong to $W^{2,r}(\Omega)$ with $r>N$. If $N=2$ then $r>2$ is chosen arbitrarily and we take $s_0=r$, $n=1$. If $N>2$ then we define inductively a finite sequence $s_0, s_1, \cdots, s_{n-1}$ by putting

$$s_0=p^*/q, \qquad p^*=2N/N-2,$$
$$s_{k+1}=Ns_k/q(N-2s_k), \qquad 0<k<n$$

(note that this sequence is strictly increasing only if (9) holds). We take n to be the least natural number such that

$$N/2<s_{n-2} \quad \text{or} \quad N<s_{n-1}<\infty,$$

we choose a finite $r>N$ arbitrarily in the former case and we take $r=s_{n-1}$ in the latter case. We have $n=1$ only if $N=2$ or $N=3$ and $q<2$.

Let $\lambda>0$ be fixed and let $u=u_0$ be an arbitrary element of $S(\lambda)$. Let the finite sequence

$$u_0, u_1, \cdots, u_n$$

be determined as follows: u_0 is as above and

$$Lu_{k+1}=\alpha_k\lambda f(u_k) \qquad (L=L_v,\ v=u_k),\quad 0<k<n, \tag{28}$$

where α_k is chosen so that $N(u_{k+1})=0$. We want to estimate the norms of the u_k simultaneously in $W^{2,s}(\Omega)$ $(s=s_{k-1})$ and $W^{2,r}(\Omega)$; more specifically, we shall derive estimates of the form

$$\|u_k\|_{2,s} \leqq \tau_k \lambda^{-1/(q-1)} \qquad (s=s_{k-1}), \tag{29}$$

$$\|u_k\|_{2,r} \leqq \tau_k \lambda^{-1/(q-1)}, \tag{30}$$

$k=1, 2, \cdots, n$. *In the course of this derivation we shall assume*

$$\|u_k\|_{2,r} < \delta, \qquad 0 \leqq k \leqq n, \tag{31}$$

where, with s_0 and r chosen as above, δ is as in Lemma 3.4; this assumption will be justified subsequently.

First, since $r > N$, (31) gives a uniform bound on the $\|\nabla u_k\|_\infty$; through (24) this gives a uniform estimate on the α_k,

$$\alpha_k \leqq a_0, \qquad 0 \leqq k < n. \tag{32}$$

We have from $u_0 \in S(\lambda)$,

$$H_\lambda(u_0) \leqq m_2^2 \lambda^{-2/(q-1)};$$

thus, in view of (18),

$$\begin{aligned} \|u_0\|_{1,2}^2 &\leqq a_0 \sqrt{(2+\varepsilon)/\varepsilon}\, H_\lambda(u_0) \\ &\leqq a_0 \sqrt{(2+\varepsilon)/\varepsilon}\, m_2^2 \lambda^{-2/(q-1)}, \end{aligned}$$

where a_0 is as in (32) (here we are taking $\|u\|_{1,2} = (\int_\Omega |\nabla u|^2\, dx)^{1/2}$). From the latter inequality, via (8),

$$\begin{aligned} \|f(u_0)\|_{s_0} &\leqq C \|u_0\|_{p^*}^q \\ &\leqq KCm_2^q (a_0^2(2+\varepsilon)/\varepsilon)^{q/4} \lambda^{-q/(q-1)}, \end{aligned}$$

and hence from (28), (32)

$$\|u_1\|_{2,s_0} \leqq KMCa_0^{1+q/2} m_2^q ((2+\varepsilon)/\varepsilon)^{q/4} \lambda^{-1/(q-1)} \leqq \tau_1 \lambda^{-1/(q-1)} \tag{33}$$

(here K incorporates an imbedding constant and M is as in Lemma 3.4).

Similarly we have

$$\begin{aligned} \|f(u_0)\|_r &\leqq CK \|u_0\|_\infty^q \\ &\leqq KCm_1^q \lambda^{-q/(q-1)}; \end{aligned}$$

hence

$$\|u_1\|_{2,r} \leqq KMCa_0 m_1^q \lambda^{-1/(q-1)} \leqq \bar{\tau}_1 \lambda^{-1/(q-1)}.$$

Proceeding inductively we get, for $1 \leqq k \leqq n$,

$$\|f(u_k)\|_{s_k} \leqq C \|u_k\|_{qs_k}^q \leqq CK^q \|u_k\|_{2,s_{k-1}}^q \leqq CK^q \tau_k^q \lambda^{-q/(q-1)},$$

and hence

$$\|u_{k+1}\|_{2,s_k} \leqq CMK^q a_0 \tau_k^q \lambda^{-1/(q-1)} \leqq \tau_{k+1} \lambda^{-1/(q-1)}.$$

Thus, with τ_1 defined implicitly by (33), the τ_k are determined recursively by

$$\tau_{k+1} = CMK^q a_0 \tau_k^q,$$

where K is an embedding constant that depends on k. The $\bar{\tau}_k$ satisfy a similar recursive relation with different values for K. The τ_k are completely determined and we now choose m_1 so that

$$m_2, \tau_n < m_1. \tag{34}$$

The $\bar{\tau}_k$ now also can be determined and we shall assume, as we can, that they are nondecreasing with $m_1 \leqq \bar{\tau}_1$.

Let $\Lambda > 0$ be such that

$$\bar{\tau}_n \Lambda^{-1/(q-1)} < \delta.$$

We easily see then that the assumption (31) is justified provided that $\lambda \geqq \Lambda$. Thus if $u_0, \cdots, u_n$ are as above then the inequalities (29) and (30) will hold provided $\lambda \geqq \Lambda$.

It follows from (34), (27), Lemma 3.2, and (25) that $S(\lambda) \neq \varnothing$. Let $\lambda \geqq \Lambda$, let $u = u_0 \in S(\lambda)$ be chosen arbitrarily and let u_n be related to u as above, i.e., let $u_n = T^n u$. Then we easily see that $u_n \in S(\lambda)$. Indeed $N_\lambda(u_n) = 0$ by the definition of T_λ, $H_\lambda(u_n) \leqq H_\lambda(u) \leqq m_2^2 \lambda^{2/(q-1)}$ by Lemma 3.1, $u_n \geqq 0$ almost everywhere for elementary reasons, and finally we have

$$\|u_n\|_{2,r} \leqq \tau_n \lambda^{-1/(q-1)} \leqq m_1 \lambda^{-1/(q-1)}$$

by (34). Thus, as claimed, T^n maps $S(\lambda)$ into itself provided $\lambda \geqq \Lambda$.

5. Statement of results. From the preceding section we deduce the following result.

THEOREM 5.1. *Let Ω be a bounded domain in $\mathbb{R}^N$ with $C^{1,1}$ boundary. Let $f \in C[0, \infty)$ satisfy* (8), *where* (9) *holds, and* (10). *Then there is a function $\Lambda = \Lambda(\Omega, \mu, f)$, monotone nondecreasing in μ for Ω, f fixed, such that for all $\lambda \geqq \Lambda(\Omega, \mu, f)$, the problem* (7) *has a nontrivial, nonnegative C^1-solution.*

Remarks. 1. It is clear from the proof that f need only be defined and/or satisfy (8), (10) on some interval $[0, c)$.

2. Explicit dependence of f on x can be allowed provided (8), (9) hold with the constant C independent of x and (10) is satisfied.

ON TRANSMISSION PROBLEMS FOR THE SCHRÖDINGER EQUATION*

G. F. ROACH† AND BO ZHANG†

Abstract. In this paper, weighted Sobolev spaces and the method of limiting absorption are used to settle questions of existence and uniqueness of solutions to transmission problems for the Schrödinger equation. The methods used here are suitable for problems in which there are inhomogeneous terms and variable coefficients that vanish asymptotically at infinity. Furthermore, it is shown that transmission solutions which satisfy the radiation condition

$$(1+r)^{-\mu/2}\left(\frac{\partial u_2}{\partial r}-iku_2\right)\in L_2(\Omega_2), \qquad r=|x|, \quad x\in\mathbf{R}^n, \quad 0\leqq\mu\leqq 1$$

also satisfy an integrability condition at infinity of the form

$$(1+r)^{-1/2}(\ln(e+r))^{-1/2-\delta/2}u_2\in L_2(\Omega_2), \qquad \delta>0.$$

Key words. transmission problem, Schrödinger equation, limiting absorption principle, radiation condition, weighted Sobolev space

1. Introduction.

Exterior boundary value problems involving compact boundaries associated with the Helmholtz equation

$$(\Delta+k^2)u=f, \qquad k^2>0 \tag{1.1}$$

have already been investigated by many authors. In these investigations a crucial role is played by the Sommerfeld radiation conditions. These were obtained by A. Sommerfeld from physical consideration and require that solutions should have the behaviour

$$u=O(r^{-(n-1)/2}), \tag{1.2}$$

$$\frac{\partial u}{\partial r}-iku=o(r^{-(n-1)/2}), \tag{1.3}$$

as $r=|x|\to\infty$. Examples of corresponding existence and uniqueness theorems can be found in the book by Kupradze [13]. Vekua [22] has shown that (1.2) is superfluous since (1.3) on its own guarantees uniqueness, while Rellich [19] has shown that (1.3) can be weakened to the following integral form:

$$\lim_{R\to\infty}\int_{s(R)}|\partial u/\partial r-iku|^2\,ds=0, \tag{1.4}$$

where $s(R)$ is a sphere of radius R. The existence of radiating solutions to (1.1) has been settled using, for instance, integral equation methods (see, for example, Jager [5]). Similar problems involving differential equations of more general elliptic type in the limiting case where the losses vanish have been studied by a number of Russian authors [2], [3], [21].

The existence and uniqueness of a radiating solution for boundary value problems involving an infinite boundary for general elliptic differential equations has been

* Received by the editors August 7, 1989; accepted for publication (in revised form) May 3, 1990.
† Department of Mathematics, University of Strathclyde, Glasgow G1 1XH, Scotland.

considered by Vogelsang [23] and Saranen [20]. These authors require that radiating solutions should satisfy the following conditions: a finiteness condition

$$(1+|x|^2)^{-1/4-\delta/2}u \in L_2(\Omega) \tag{1.5}$$

and a radiating condition

$$(1+|x|^2)^{-\delta/2}\nabla(e^{-ikr}u) \in (L_2(\Omega))^n. \tag{1.6}$$

In Neittaanmaki and Roach [15] it is shown that under the assumption $(1+|x|)\times(\ln(e+|x|))^{\delta/2}f \in L_2(\Omega)$ there exists a unique solution u of (1.1) satisfying the radiation condition

$$\frac{\partial u}{\partial r} - iku \in L_2(\Omega). \tag{1.7}$$

In [15] it is also shown that the radiation solution has the following integrability property:

$$(1+|x|)^{-1/2}(\ln(e+|x|))^{-1/2-\delta/2}u \in L_2(\Omega), \tag{1.8}$$

where δ is some fixed number satisfying $0<\delta<\frac{1}{2}$.

Transmission problems for the Helmholtz equation (1.1) have also been studied. In [11] Kress and Roach considered the existence and uniqueness of transmission solutions for (1.1), (1.2), and (1.3), with $f=0$ and established existence and uniqueness theorems using integral equation methods. In this connection we also mention the works of Kittappa and Kleinman [9], Kleinman and Martin [10], Kupradze [13], Ramm [18], and Werner [25], [26]. In particular, we remark that in [25] and [26] Werner used integral equation methods to study the existence and uniqueness of transmission solutions to the reduced wave equation in which the smooth coefficients and inhomogeneous terms are assumed to be constants and zero, respectively, outside a sphere of sufficiently large radius. Jones [6] established a uniqueness theorem for elastodynamics, with spatially varying parameters, by making extensive use of the properties of the spherical harmonics. Kristensson [12] obtained a uniqueness theorem for Helmholtz equation in penetrable media with an infinite interface in the lossless case, and in this connection we also mention the results of Odeh [16]. Beck [1] studied a transmission problem for a second-order uniformly elliptic differential operator of Helmholtz type in the case of a more general geometry compared to [12]. Here he derived a Rellich-type estimate for the transmission solutions and established the uniqueness theorem using this estimate in the case where the field u and its covariant derivative are continuous on the interface.

In the present paper we study the uniqueness and existence of transmission solutions to a non-selfadjoint differential equation of Schrödinger type. In [4] Eidus proved that under certain conditions the non-selfadjoint differential operator in $L_2(\mathbf{R}^n)$ defined by

$$L := -\Delta + B(x)\nabla + q(x) \tag{1.9}$$

has no positive eigenvalues. Using this result of Eidus and a radiation condition of the form

$$(1+r)^{-\mu/2}\left(\frac{\partial u_2}{\partial r} - iku_2\right) \in L_2(\Omega_2), \qquad 0 \leqq \mu \leqq 1, \tag{1.10}$$

we can obtain a uniqueness theorem for transmission problems for the Schrödinger equation

$$-\Delta u + B(x)\nabla u + q(x)u - k^2 u = f, \qquad k^2 > 0. \tag{1.11}$$

This is achieved by imposing suitable conditions on the coefficients and by using the unique continuation principle [14]. Weighted Sobolev spaces are then used to prove the limiting absorption principle, from which an existence theorem for transmission solutions can be derived. Furthermore, it is shown that transmission solutions satisfy the integrability property

$$(1+|x|)^{-1/2}(\ln(e+|x|))^{-1/2-\delta/2}u_2 \in L_2(\Omega_2), \tag{1.12}$$

where δ is some fixed number and $0<\delta\leqq 1$.

2. Statement of the problem and notation. Let $\Omega_1 \subset \mathbf{R}^n$ be a bounded domain and Ω_2 be the exterior. The interface boundary $\Gamma := \partial\Omega_1 = \partial\Omega_2$ is assumed to be of class C^2. We denote by $\nu=(\nu_1, \nu_2, \cdots, \nu_n)$ the unit normal to Γ drawn in the direction from Ω_1 to Ω_2.

We are concerned with the uniqueness and existence of solutions to the following problem.

Transmission problem. Find $u=(u_1, u_2)\in C^2(\Omega_1)\times C^2(\Omega_2)$ such that

$$\begin{gathered} -\Delta u_j + B_j\nabla u_j + q_j u_j - k^2 u_j = f_j \quad \text{in } \Omega_j, \quad j=1,2, \\ \alpha u_1 - u_2 = g_1 \quad \text{on } \Gamma, \\ \beta\,\partial u_1/\partial\nu - \partial u_2/\partial\nu = g_2 \quad \text{on } \Gamma, \\ (1+r)^{-\mu/2}\left(\frac{\partial u_2}{\partial r} - iku_2\right) \in L_2(\Omega_2), \qquad 0\leqq\mu\leqq 1, \end{gathered} \tag{2.1}$$

where B_j, q_j, f_j, and u_j are complex-valued functions on Ω_j, $j=1,2$, g_j, $j=1,2$ are complex-valued functions on Γ, $k^2>0$, $\alpha, \beta\in\mathbf{C}\backslash\{0\}$ are constants. In Ω_j, $j=1,2$, we assume that the following relations hold:

$$|B_j|+|q_j|\leqq C, \qquad j=1,2, \tag{2.2}$$

$$q_1, B_1\in C(\Omega_1), \qquad q_2, B_2\in C(\Omega_2), \tag{2.3}$$

$$|q_2|+|B_2| = O(r^{-2}(\ln r)^{-1-\delta}), \qquad 0<\delta\leqq 1, \quad r\to\infty, \tag{2.4}$$

$$f_j\in L_2(B(R)\cap\Omega_j) \quad \forall R>0, \quad j=1,2, \quad g_1\in H^{1/2}(\Gamma), \quad g_2\in H^{-1/2}(\Gamma).$$

With $D\subset\mathbf{R}^n$ an open set, we introduce complex Sobolev spaces $H^k(D)$, $k=0,1,2,\cdots$, and $H^l(\Gamma)$, $l\in\mathbf{R}$. The inner product on $H^k(D)$ is denoted by

$$(u, v)_{k,D} = \sum_{|\alpha|\leqq k}\int_D \partial^\alpha u\,\partial^\alpha\bar{v}\,dx,$$

where $\partial^\alpha = \partial_1^{\alpha_1}\cdots\partial_n^{\alpha_n}$, $\partial_i = \partial/\partial x_i$, and the corresponding norm by $\|u\|_{k,D}=\sqrt{(u,u)_{k,D}}$. The duality relation between $H^l(\Gamma)$ and $H^{-l}(\Gamma)$ will be denoted by $\langle\circ,\circ\rangle$. By $\mathcal{D}(D)$ we denote the space of infinitely continuously differential functions having compact support in D.

It is convenient to introduce the following weight functions:

$$\begin{aligned} P_\delta(x) &:= (1+|x|)^{-1/2}(\ln(e+|x|))^{-1/2-\delta/2}, \\ q_\delta(x) &:= (\ln(e+|x|))^{-\delta/2}, \\ \rho(x) &:= (1+|x|)(\ln(e+|x|))^{\delta/2}, \end{aligned} \tag{2.5}$$

and for any weight function g the following weighted Sobolev spaces:

$$\begin{aligned} L_g^2(D) &:= \{u\in L_2(D\cap B(R)) \ \forall R>0 \,|\, gu\in L_2(D)\}, \\ H_g^k(D) &:= \{u\in H^k(D\cap B(R)) \ \forall R>0 \,|\, g\partial^\alpha u\in L_2(D), \ |\alpha|\leqq k\}, \end{aligned}$$

with the weighted norm

$$\|u\|_{k,g,D} := \left(\sum_{|\alpha| \leqq k} \int_D g^2 |\partial^\alpha u|^2 \, dx \right)^{1/2},$$

and the Sobolev space

$$L_g^2(\Omega) := L_g^2(\Omega_1) \times L_g^2(\Omega_2),$$

with the norm

$$\|u\|_{0,g,\Omega} := \left(\sum_{j=1}^{2} \|u_j\|_{0,g,\Omega_j}^2 \right)^{1/2},$$

where $\Omega = \Omega_1 \cup \Omega_2$.

Let $r = |x|$, $\hat{x} = x/r$, and $\partial_r u = \partial u / \partial r = \hat{x} \nabla u$, where $\nabla u = (\partial_1 u, \cdots, \partial_n u)$. We introduce the abbreviations

$$E(R) := \{x \in \mathbf{R}^n \,|\, |x| > R\},$$
$$B(R) := \{x \in \mathbf{R}^n \,|\, |x| < R\},$$
$$S(R) := \{x \in \mathbf{R}^n \,|\, |x| = R\},$$
$$D(R) := \{x \in \Omega_2 \,|\, |x| \leqq R\}.$$

For convenience, we suppose that $0 \in \Omega_1$ and that R_0 is a fixed number such that $\bar{\Omega}_1 \subset B(R_0)$. Thus, let

$$\Omega(R) := \{x \in E(R_0) \,|\, |x| < R\},$$
$$\Omega(R_1, R_2) := \{x \in E(R_0) \,|\, R_1 < |x| < R_2\}.$$

To give a definition of a weak formulation of (2.1) we introduce the following bounded, bilinear, and linear functionals:

$$a_j(u_j, v_j) := \int_{\Omega_j} (\nabla u_j \nabla \bar{v}_j + B_j \nabla u_j \bar{v}_j + q_j u_j \bar{v}_j - k^2 u_j \bar{v}_j) \, dx \qquad \forall u_j, v_j \in H^1(\Omega_j), \quad j = 1, 2, \tag{2.6}$$

$$a(u, v) := \bar{\alpha}\beta a_1(u_1, v_1) + a_2(u_2, v_2), \qquad \forall u = (u_1, u_2), \quad v = (v_1, v_2) \in H^1(\Omega_1) \times H^1(\Omega_2), \tag{2.7}$$

$$F(v) := \bar{\alpha}\beta \int_{\Omega_1} f_1 \bar{v}_1 \, dx + \int_{\Omega_2} f_2 \bar{v}_2 \, dx + \int_\Gamma g_2 \bar{v}_2 \, ds \qquad \forall v = (v_1, v_2) \in H^1(\Omega_1) \times H^1(\Omega_2), \tag{2.8}$$

together with the sets

$$H_E := \{v = (v_1, v_2) \,|\, v_j \in H^1(B(R) \cap \Omega_j) \ \forall R > 0, \ j = 1, 2, \ \alpha v_1 = v_2 \text{ on } \Gamma\}$$

and

$$H_E^* := \{v = (v_1, v_2) \,|\, v_j \in H^1(B(R) \cap \Omega_j) \ \forall R > 0, \ j = 1, 2, \ \alpha v_1 - v_2 = g_1 \text{ on } \Gamma\}.$$

With the above notation, a weak formulation of (2.1) is given:

$$\text{Find } u = (u_1, u_2) \in H_E^* \quad \text{such that } a(u, \phi v) = F(\phi v) \quad \forall v \in H_E, \quad \phi \in \mathcal{D}(\mathbf{R}^n),$$
$$(1 + r)^{-\mu/2} (\partial u_2 / \partial r - iku_2) \in L_2(\Omega_2). \tag{2.9}$$

Solutions of (2.9) are called weak solutions of (2.1). In what follows we are concerned with showing that weak solutions of the transmission problem (2.1) exist and, moreover, are unique.

3. On the uniqueness of the transmission solutions. To establish the required uniqueness of the solutions to (2.9), we make use of the following result due to Eidus [4, Thm. 3.2].

LEMMA 3.1 [4]. *Under the assumptions* (2.2)-(2.4), *every solution* $u \in H^2(E(R_1) \cap B(R))$ *for all* $R > R_1$ *of the equation*

$$-\Delta u + B_2 \nabla u + q_2 u = k^2 u, \qquad k^2 > 0 \quad \text{in } E(R_1), \quad R_1 \geqq R_0$$

is equal to zero almost everywhere in $E(R_1)$ *if* $u \in L_2(E(R_1))$.

THEOREM 3.1. *The transmission problem* (2.9) *has at most one solution.*

Proof. Let $u = (u_1, u_2) \in H_E$ be such that

$$a(u, \phi v) = 0 \quad \forall v \in H_E, \quad \phi \in \mathcal{D}(\mathbf{R}^n) \tag{3.1}$$

and

$$(1+r)^{-\mu/2}\left(\frac{\partial u_2}{\partial r} - iku_2\right) \in L_2(\Omega_2). \tag{3.2}$$

Then we have

$$u_j \in H^1(B(R) \cap \Omega_j) \quad \forall R > 0, \qquad a_j(u_j, \phi) = 0 \quad \forall \phi \in \mathcal{D}(\Omega_j), \quad j = 1, 2. \tag{3.3}$$

Furthermore, by the coerciveness estimates [14, Thm. 2.7], we see that

$$u_j \in H^2(B(R) \cap \Omega_j) \quad \forall R > 0, \tag{3.4}$$

and that for any $R > 0$ there is a constant C_R such that

$$|\Delta u_j| \leqq C_R(|u_j| + |\nabla u_j|) \quad \text{a.e. in } B(R) \cap \Omega_j \quad \forall R > 0, \tag{3.5}$$

and

$$-\Delta u_j + B_j \nabla u_j + q_j u_j - k^2 u_j = 0 \quad \text{a.e. in } B(R) \cap \Omega_j \quad \forall R > 0, \quad j = 1, 2. \tag{3.6}$$

Hence we can obtain from the definition of H_E and (3.1) the transmission conditions

$$\alpha u_1 = u_2 \qquad \text{on } \Gamma, \tag{3.7}$$

$$\frac{\beta\, \partial u_1}{\partial n} = \frac{\partial u_2}{\partial \nu} \quad \text{on } \Gamma. \tag{3.8}$$

Bearing in mind Lemma 3.1 and (3.6), it remains to prove that $u_2 \in L_2(\Omega_2)$.

Step 1. We prove that

$$(1+r)^{-1/2}(\ln(e+r))^{-1/2-\delta/2}(|u_2| + |\nabla u_2|) \in L_2(\Omega_2)$$

and

$$(1+r)^{-1/2}|\nabla(e^{-ikr}u_2)| \in L_2(\Omega_2).$$

Let $R > R_1 > R_0 + 1$, $\eta(r) = r^{-1/2}(\ln r)^{-1/2-\delta/2}$ and $g(r) = r^{-1/2}$ for $r > 1$. By direct calculation with $w = e^{-ikr}u_2$, we see from (3.6) that

$$(-\Delta - ik(2\partial_r + (n-1)r^{-1}) + B_2\nabla + q_2 + ikB_2\hat{x})w = 0 \quad \text{a.e. in } \Omega_2. \tag{3.9}$$

On multiplying the equation (3.9) by $(\ln r)^{-\delta}\bar{w}$, integrating over $\Omega(R_1, R)$, and taking the imaginary part of both sides of the equation thus obtained, we get by appropriate partial integration that

$$\begin{aligned}&\delta k\|u_2\|^2_{0,\eta,\Omega(R_1,R)}+k(\ln R)^{-\delta}\|u_2\|^2_{0,s(R)}\\&=\operatorname{Im}\int_{\Omega(R_1,R)}[B_2\nabla w\bar{w}+q_2|w|^2+ikB_2\hat{x}|w|^2-\delta(r\ln r)^{-1}\partial_r w\bar{w}](\ln r)^{-\delta}\,dx\\&\quad-(\ln R)^{-\delta}\operatorname{Im}(\partial_r w, w)_{0,s(R)}+K_{R_1}(w),\end{aligned}\tag{3.10}$$

where $|K_{R_1}(w)|\leqq C\|w\|^2_{1,s(R_1)}<+\infty$. By (2.4) and Cauchy's inequality we obtain from (3.10) that

$$\begin{aligned}&\delta k\|u_2\|^2_{0,\eta,\Omega(R_1,R)}+k(\ln R)^{-\delta}\|u_2\|^2_{0,s(R)}\\&\leqq C(\ln R_1)^{-\delta}\{\|\nabla w\|^2_{0,g,\Omega(R_1,R)}+\|u_2\|^2_{0,\eta,\Omega(R_1,R)}+(\ln R)^{-\delta}\|u_2\|^2_{0,s(R)}\}\\&\quad+\|\partial_r w\|^2_{0,s(R)}+K_{R_1}(w).\end{aligned}\tag{3.11}$$

On the other hand, multiply (3.9) by $2g^2(r\partial_r\bar{w}+(n-1)/2\bar{w})$, integrate over $\Omega(R_1, R)$, and make use of the basic identity

$$\begin{aligned}2\operatorname{Re}[\Delta w r h(r)\partial_r\bar{w}]&=\operatorname{div}[2\operatorname{Re}\nabla w r h(r)\partial_r\bar{w}-h(r)|\nabla w|^2x]+(n-2)h(r)|\nabla w|^2\\&\quad+r\partial_r h(r)(|\nabla w|^2-2|\partial_r w|^2)\quad\text{a.e. in } E(R_0),\end{aligned}\tag{3.12}$$

with $h(r)=g^2=r^{-1}$ to obtain, after integrating by parts, the result

$$\begin{aligned}&2\|\nabla w\|^2_{0,g,\Omega(R_1,R)}-2\|\partial_r w\|^2_{0,g,\Omega(R_1,R)}-(n-1)\operatorname{Re}(\partial_r w, r^{-2}w)_{0,\Omega(R_1,R)}\\&\quad+2\operatorname{Re}((B_2\nabla+q_2+ikB_2\hat{x})w, g^2(r\partial_r+(n-1)/2)w)_{0,\Omega(R_1,R)}\\&\quad-\int_{s(R)}(2|\partial_r w|^2-|\nabla w|^2)\,ds-(n-1)R^{-1}\operatorname{Re}\int_{s(R)}\bar{w}\partial_r w\,ds\\&\quad+\int_{s(R_1)}(2|\partial_r w|^2-|\nabla w|^2)\,ds+(n-1)R_1^{-1}\operatorname{Re}\int_{s(R_1)}\bar{w}\partial_r w\,ds=0.\end{aligned}\tag{3.13}$$

Taking into account (2.4) and the fact that $|\nabla w|^2-|\partial_r w|^2\geqq 0$, we obtain from (3.13) that

$$\begin{aligned}\|\nabla w\|^2_{0,g,\Omega(R_1,R)}&\leqq CR_1^{-1/2}\{\|\nabla w\|^2_{0,g,\Omega(R_1,R)}+\|u_2\|^2_{0,\eta,\Omega(R_1,R)}\\&\quad+(\ln R)^{-\delta}\|u_2\|^2_{0,s(R)}\}+\|\partial_r w\|^2_{0,s(R)}\\&\quad+\|\partial_r w\|^2_{0,g,\Omega(R_1,R)}+K_{R_1}(w).\end{aligned}\tag{3.14}$$

Thus for R_1 sufficiently large we get from (3.11) and (3.14) that

$$\|u_2\|^2_{0,\eta,\Omega(R_1,R)}+\|\nabla w\|^2_{0,g,\Omega(R_1,R)}\leqq C(R_1)\{\|\partial_r w\|^2_{0,s(R)}+\|\partial_r w\|^2_{0,g,\Omega(R_1,R)}\}+K_{R_1}(w).$$

As $(1+r)^{-\mu/2}\partial_r w\in L_2(\Omega_2)$ and $0\leqq\mu\leqq 1$, there is a sequence $R_j\to\infty$ such that $\|\partial_r w\|^2_{0,s(R_j)}$ tends to zero. Thus, we get

$$\|u_2\|^2_{0,\eta,E(R_1)}+\|\nabla w\|^2_{0,g,E(R_1)}\leqq C(R_1)\|\partial_r w\|^2_{0,g,E(R_1)}+K_{R_1}(w)<+\infty.$$

Consequently, $(1+r)^{-1/2}(\ln(e+r))^{-1/2-\delta/2}u_2\in L_2(\Omega_2)$ and $(1+r)^{-1/2}|\nabla(e^{-ikr}u_2)|\in L_2(\Omega_2)$. This, combined with (3.6), implies that $(1+r)^{-1/2}(\ln(e+r))^{-1/2-\delta/2}|\nabla u_2|\in L_2(\Omega_2)$.

Step 2. To show that $|\nabla w|\in L_2(\Omega_2)$, we need the following.

In the equation (3.13), integrating

$$\operatorname{Re}\int_{\Omega(R_1,R)}r^{-2}\bar{w}\partial_r w\,dx$$

by parts and letting $R \to \infty$, we get

$$2\int_{E(R_1)} r^{-1}\{|\nabla w|^2 - |\partial_r w|^2\}\,dx + \int_{s(R_1)} \{2|\partial_r w|^2 - |\nabla w|^2 + (n-1)R_1^{-1}\,\mathrm{Re}\,\bar{w}\partial_r w\}\,ds$$
$$= -(n-1)/2\left\{(n-3)\int_{E(R_1)} r^{-3}|u_2|^2\,dx + \int_{s(R_1)} r^{-2}|u_2|^2\,ds\right\}$$
$$-\mathrm{Re}\,((B_2\nabla + q_2 + ikB_2\hat{x})w, (2\partial_r w + (n-1)r^{-1}w))_{0,E(R_1)}.$$

From the assumption (2.4) and Step 1 we infer that the right-hand side of the above equality is integrable with respect to R_1 from R to ∞ and, therefore, so is the left-hand side. Integrating both sides of the above equality with respect to R_1 from R to ∞ and denoting the left-hand side and the right-hand side of the equality thus obtained by $LH(R)$ and $RH(R)$, respectively, we then have $RH(R) < +\infty$, while

$$LH(R) = \liminf_{R_2\to\infty}\left\{\int_{\Omega(R,R_2)} [|\nabla w|^2 + (n-1)r^{-1}\,\mathrm{Re}\,\bar{w}\partial_r w]\,dx\right.$$
$$+2R_2\int_{E(R_2)} r^{-1}[|\nabla w|^2 - |\partial_r w|^2]\,dx$$
$$\left.-2R\int_{E(R)} r^{-1}[|\nabla w|^2 - |\partial_r w|^2]\,dx\right\}$$
$$\geqq \liminf_{R_2\to\infty}\left\{\frac{1}{2}\int_{\Omega(R,R_2)} |\nabla w|^2\,dx - (n-1)^2/2\int_{\Omega(R,R_2)} r^{-2}|u_2|^2\,dx\right.$$
$$\left.-2R\int_{E(R)} r^{-1}[|\nabla w|^2 - |\partial_r w|^2]\,dx\right\},$$

where we have used Young's inequality and the fact that

$$|\nabla w|^2 - |\partial_r w|^2 \geqq 0.$$

Hence, from the above inequality and Step 1 it follows immediately that $|\nabla w| \in L_2(\Omega_2)$.

Step 3. To show that $\liminf_{R\to\infty}\int_{s(R)}(|u_2|^2 + |\nabla u_2|^2)\,ds = 0$, we need the following.

Let $R > R_0$ and j be an arbitrary integer with $j > R$. Choose $\phi_j(r) \in \mathscr{D}(\mathbf{R}^n)$, satisfying

$$\phi_j(r) = 1, \quad r \leqq R, \quad \phi_j(r) = 0, \quad r \geqq j, \quad 0 \leqq \phi_j \leqq 1 \quad \text{in } \mathbf{R}^n, \tag{3.15}$$

$$|\partial_r \phi_j| \leqq C(j-R)^{-1}, \qquad \partial_r \phi_j \leqq 0, \quad R < r < j, \tag{3.16}$$

where C is a constant independent of r, R, j, and ϕ_j. The existence of suitable ϕ_j is indicated in Remark 3.1 below. On multiplying (3.9) by $\phi_j \bar{w}$ and integrating it over $\Omega(R,j)$, we have

$$\mathrm{Im}\,(\partial_r u_2, u_2)_{0,s(R)} = -\mathrm{Im}\int_{\Omega(R,j)} \{[B_2\nabla w + q_2 w + ikB_2\hat{x}w]\phi_j\bar{w} + \partial_r\phi_j\partial_r w\bar{w}\}\,dx$$
$$-k\int_{\Omega(R,j)} \partial_r\phi_j|u_2|^2\,dx. \tag{3.17}$$

By assumption (2.4), Step 1, Step 2, (3.15), and (3.16), we see that the first term of the right-hand side of (3.17) remains finite as $j \to \infty$ and therefore the second one is finite as well. Define

$$f_j(r) := k|\partial_r\phi_j|\,\|u_2\|^2_{0,s(r)} \quad \text{for all } r \geqq R;$$

then $f_j(r) \to 0$ almost everywhere in $[R, \infty)$ as $j \to \infty$ from (3.15) and (3.16) and

$$I_j(R) := -k \int_{\Omega(R,j)} \partial_r \phi_j |u_2|^2 \, dx = \int_R^\infty f_j(r) \, dr$$

is uniformly bounded for $j \geqq R$ and is convergent as $j \to \infty$ from (3.17). For all $j > R$ let $g_j = \sup\{f_j, f_{j+1}, \cdots\}$. Then g_j is integrable. In fact, $Mf_{jk} := \max\{f_j, f_{j+1}, \cdots, f_{j+k}\}$ is integrable. Moreover, $Mf_{jk} \to g_j$ as $k \to \infty$ and for any $j > R$ there is a constant $A(j) > 0$, independent of k and Mf_{jk}, such that

$$\int_R^\infty Mf_{jk} \, dr \leqq A(j) \quad \text{for all positive integer } k \tag{3.18}$$

for $G_j(x) := \sup_k \int_x^\infty Mf_{jk} \, dr$ with $x \geqq R$ is a nonincreasing positive function of x, and thus for any $j > R$, $G_j(x)$ tends to M_j, with $0 \leqq M_j < \infty$ as $x \to \infty$. Therefore the function g_j is indeed integrable by Levi's theorem (see [24, p. 368]). The sequence $\{g_j\}$ is nonincreasing, the integrals $\int g_j \, dr \geqq 0$ and $g_j \to 0$ almost everywhere in $[R, \infty)$. Hence,

$$\int_R^\infty g_j \, dr \to 0 \tag{3.19}$$

as $j \to \infty$ by Levi's theorem. The inequalities $f_j \leqq g_j$ for all $j > R$ imply that $I_j(R) \to 0$ as $j \to \infty$. This combined with (3.17) yields

$$\operatorname{Im} (\partial_r u_2, u_2)_{0,s(R)} \to 0$$

as $R \to \infty$. From this and the fact that

$$|\nabla w|^2 = |\nabla u_2|^2 + k^2 |u_2|^2 - 2k \operatorname{Im} \partial_r u_2 \bar{u}_2, \qquad |\nabla w| \in L_2(\Omega_2),$$

the required result follows.

Step 4. We prove that $u_2 \in L_2(\Omega_2)$ and $u_j = 0$ almost everywhere in Ω_j, $j = 1, 2$.

Multiply the equation (3.6) by $2\partial_r \bar{u}_2 + (n-1) r^{-1} \bar{u}_2$, integrate it over $E(R)$, and take the real part of both sides of the equality thus obtained to get

$$\begin{aligned} 2(\|\nabla u_2\|^2_{0,g,E(R)} - \|\partial_r u_2\|^2_{0,g,E(R)}) &- (n-1) \operatorname{Re} (\partial_r u_2, r^{-2} u_2)_{0,E(R)} \\ &+ \operatorname{Re} ((B_2 \nabla + q_2) u_2, 2\partial_r u_2 + (n-1) r^{-1} u_2)_{0,E(R)} \\ &+ \int_{s(R)} \{2|\partial_r u_2|^2 + k^2 |u_2|^2 - |\nabla u_2|^2\} \, ds \\ &+ (n-1) \operatorname{Re} \int_{s(R)} r^{-1} \bar{u}_2 \partial_r u_2 \, ds = 0. \end{aligned}$$

From this equality, (2.4), Step 1, and Step 2 we are able to obtain $u_2 \in L_2(\Omega_2)$ by following the same argument used in Step 2. Consequently, we have $u_2 = 0$ almost everywhere in $E(R)$ for some fixed $R > R_0$ by Lemma 3.1. The unique continuation principle [14, p. 65] and the transmission conditions (3.7) and (3.8) imply that $u_1 = 0$ almost everywhere in Ω_1 and $u_2 = 0$ almost everywhere in Ω_2. The theorem is proved.

Remark 3.1. Define $\phi_j \in \mathscr{D}(\mathbf{R}^n)$ as follows:

$$\phi_j(r) = \begin{cases} 1, & r \leqq R, \\ 0, & r \geqq j, \end{cases} \qquad \phi_j(r) = \exp\{1 - (j-R)^2 [(j-R)^2 - (r-R)^2]^{-1}\}, \quad R < r < j.$$

Then ϕ_j satisfies (3.15) and (3.16).

4. On the existence of the transmission solutions. The existence of the transmission solutions will be established by the principle of limiting absorption as given by Eidus [2], [3]. To this end, we introduce the following bilinear functionals:

$$a_{2\varepsilon}(u_2, v_2) = a_2(u_2, v_2) - i\varepsilon(u_2, v_2)_{0,\Omega_2} \quad \forall u_2, v_2 \in H^1(\Omega_2),$$

$$a_\varepsilon(u, v) = \bar{\alpha}\beta a_1(u_1, v_1) + a_{2\varepsilon}(u_2, v_2) \quad \forall u, v \in H^1(\Omega_1) \times H^1(\Omega_2), \quad 0 < \varepsilon \leqq 1,$$

the Hilbert space

$$H := \{v = (v_1, v_2) \mid v_i \in H^1(\Omega_i),\ i = 1, 2,\ \alpha v_1 - v_2 = 0, \text{ on } \Gamma\},$$

with the inner product

$$(u, v)_{1,\Omega} := \sum_{i=1}^{2} (u_i, v_i)_{1,\Omega_i},$$

and the set

$$H^* := \{v = (v_1, v_2) \mid v_i \in H^1(\Omega_i),\ i = 1, 2,\ \alpha v_1 - v_2 = g_1 \text{ on } \Gamma\}.$$

In this section we will consider the following problem:

$$\begin{aligned} &\text{Find } u_\varepsilon = (u_{1\varepsilon}, u_{2\varepsilon}) \in H^* \quad \text{such that} \\ &a_\varepsilon(u_\varepsilon, v) = F(v) \quad \forall v \in H. \end{aligned} \tag{4.1}$$

We will prove that (4.1) has a unique solution $u_\varepsilon \in H^*$ and, with respect to some suitable weighted norm, the limit

$$\lim_{\varepsilon \to 0^+} u_\varepsilon = u \tag{4.2}$$

exists. The limit function u will turn out to be the solution of the transmission problem (2.9) and will be seen to possess certain integrability properties. Finally, we introduce the bounded linear operator $A_\varepsilon : H \to H$ as follows:

$$(A_\varepsilon u, v)_{1,\Omega} = a_\varepsilon(u, v) \quad \forall u, v \in H. \tag{4.3}$$

To settle the existence and uniqueness of solutions to (4.1), we shall need the following lemmas.

LEMMA 4.1. *If either* $\operatorname{Re}(\bar{\alpha}\beta) > 0$ *or* $\operatorname{Im}(\bar{\alpha}\beta) \neq 0$, *then there is a constant* $C > 0$ *such that for every* $u \in H$

$$\|u\|_{1,\Omega} \leqq C(\|A_\varepsilon u\|_{1,\Omega} + (1+\varepsilon)\|u\|_{0,\Omega}), \tag{4.4}$$

where C *is independent of* ε, u, *and* A_ε.

Proof. Let $a = \operatorname{Re}(\bar{\alpha}\beta)$ and $b = \operatorname{Im}(\bar{\alpha}\beta)$. We distinguish the following two cases:

Case 1. $a > 0$. Since

$$\begin{aligned} \bar{\alpha}\beta \|u\|_{1,\Omega}^2 = (A_\varepsilon u, u)_{1,\Omega} &+ \bar{\alpha}\beta \int_{\Omega_1} (1 + k^2 - q_1)|u_1|^2\, dx - \bar{\alpha}\beta \int_{\Omega_1} B_1 \nabla u_1 \bar{u}_1\, dx \\ &+ (\bar{\alpha}\beta - 1) \int_{\Omega_2} |\nabla u_2|^2\, dx + \int_{\Omega_2} (\bar{\alpha}\beta + k^2 + i\varepsilon - q_2)|u_2|^2\, dx \\ &- \int_{\Omega_2} B_2 \nabla u_2 \bar{u}_2\, dx, \end{aligned}$$

by taking the real part in the above equality and using Cauchy's and Young's inequalities, we obtain

$$\|u\|_{1,\Omega}^2 \leqq C(|(A_\varepsilon u, u)_{1,\Omega}| + \|u\|_{0,\Omega}^2). \tag{4.5}$$

The estimate (4.4) follows from (4.5) and Cauchy's inequality.

Case 2. $b \neq 0$. From the equality

$$\begin{aligned}\|u\|_{1,\Omega}^2 = (A_\varepsilon u, u)_{1,\Omega} + (1-\bar{\alpha}\beta)\int_{\Omega_1} |\nabla u_1|^2\,dx + \int_{\Omega_1} (1+\bar{\alpha}\beta k^2 - \bar{\alpha}\beta q_1)|u_1|^2\,dx \\ -\bar{\alpha}\beta\int_{\Omega_1} B_1\nabla u_1 \bar{u}_1\,dx + \int_{\Omega_2}(1+k^2+i\varepsilon-q_2)|u_2|^2\,dx \\ -\int_{\Omega_2} B_2\nabla u_2\bar{u}_2\,dx,\end{aligned} \tag{4.6}$$

we obtain, by multiplying the imaginary part by $b^{-1}a$, adding the result to the real part of (4.6), and using the Young's inequality, that

$$\|u\|_{1,\Omega}^2 \leqq C[|(A_\varepsilon u, u)_{1,\Omega}| + (1+\varepsilon)\|u\|_{0,\Omega}^2], \tag{4.7}$$

which gives the estimate (4.4).

LEMMA 4.2. *If either* $\operatorname{Re}(\bar{\alpha}\beta) > 0$ *or* $\operatorname{Im}(\bar{\alpha}\beta) \neq 0$, *then for any* $R \geqq R_0$ *there exists a constant* $C > 0$ *such that for every* $u \in H$

$$\|u\|_{1,B(R)} \leqq C(\|A_\varepsilon u\|_{1,B(R+1)} + (1+\varepsilon)\|u\|_{0,B(R+1)}), \tag{4.8}$$

where C *is independent of* ε, u, *and* A_ε.

Proof. For any $R \geqq R_0$ let $\phi(r) \in \mathscr{D}(\mathbf{R}^n)$ be such that

$$\phi(r) = \begin{cases} 1, & r \leqq R, \\ 0, & r \geqq R+1, \end{cases} \quad 0 \leqq \phi(r) \leqq 1, \quad |\partial_r \phi| \leqq C\phi^{1/2}, \quad R < r < R+1, \tag{4.9}$$

where C is a constant independent of R, r, and ϕ. From (4.5) and (4.7) we have

$$\|\phi u\|_{1,B(R+1)}^2 \leqq C[|(A_\varepsilon(\phi u), \phi u)_{1,B(R+1)}| + (1+\varepsilon)\|\phi u\|_{0,B(R+1)}^2]. \tag{4.10}$$

By making use of (4.3), (4.10), Cauchy's inequality and a direct calculation, the required inequality (4.8) follows from (4.10).

Remark 4.1. The same arguments used to prove (4.4) and (4.8) can also be used to obtain similar results when A_ε is replaced by $A_\varepsilon + \lambda I$ with $\operatorname{Re}\lambda \geqq 0$ and $\operatorname{Im}\lambda \geqq 0$, where I denotes the identity operator on H.

To deal with nonhomogeneous data we reduce (4.1) to an equivalent problem involving homogeneous data as follows. First, we note that for $g_1 \in H^{1/2}(\Gamma)$ there is a $w_0 \in H^1(\Omega_1)$ such that $w_0 = g_1$ on Γ and $\|w_0\|_{1,\Omega_1} \leqq C\|g_1\|_{1/2,\Gamma}$ [17, p. 141]. We then set

$$u'_{1\varepsilon} = u_{1\varepsilon} - w_0/\alpha$$

and

$$F'(v) = F(v) - (\bar{\alpha}\beta/\alpha)a_1(w_0, v_1) \quad \forall v = (v_1, v_2) \in H.$$

Consequently, (4.1) is equivalent to the following problem:

$$\begin{aligned}&\text{Find } u'_\varepsilon = (u'_{1\varepsilon}, u'_{2\varepsilon}) \in H \quad \text{such that} \\ &a_\varepsilon(u'_\varepsilon, v) = F'(v) \quad \forall v \in H\end{aligned} \tag{4.11}$$

and

$$u_\varepsilon = (u_{1\varepsilon}, u_{2\varepsilon}) = (u'_{1\varepsilon} + w_0/\alpha, u'_{2\varepsilon}). \tag{4.12}$$

If u'_ε are solutions of (4.11) with $f_2 \in L_2(\Omega_2)$, then it follows from the fact that $|F'(v)| \leqq C(\sum_{j=1}^{2} \|f_j\|_{0,\Omega_j} + \|g_1\|_{1/2,\Gamma} + \|g_2\|_{-1/2,\Gamma})\|v\|_{1,\Omega}$ for all $v \in H$, the definition of A_ε, (4.3), and (4.11) that

$$\|A_\varepsilon u'_\varepsilon\|_{1,\Omega} \leqq C\left(\sum_{j=1}^{2} \|f_j\|_{0,\Omega_j} + \|g_1\|_{1/2,\Gamma} + \|g_2\|_{-1/2,\Gamma}\right). \tag{4.13}$$

To prove that (4.1), or equivalently, (4.11), has a unique solution and that (4.2) exists in an appropriate weighted Sobolev space, we need the following a priori estimate for solutions to (4.1).

LEMMA 4.3. *Let $u_\varepsilon \in H^*$, $0 < \varepsilon \leqq 1$, be a solution of* (4.1) *with $f_2 \in L^2_\rho(\Omega_2)$. If either* $\operatorname{Re}(\bar{\alpha}\beta) > 0$ *or* $\operatorname{Im}(\bar{\alpha}\beta) \neq 0$, *then*

$$\begin{aligned} &\|\nabla(e^{-ikr}u_\varepsilon)\|_{0,\Omega} + \|u_\varepsilon\|_{0,P_\delta,\Omega} \\ &\qquad \leqq C\left(\sum_{j=1}^{2} \|f_j\|_{0,\rho,\Omega_j} + \|g_1\|_{1/2,\Gamma} + \|g_2\|_{-1/2,\Gamma} + \|u_\varepsilon\|_{0,B(R_2)}\right) \end{aligned} \tag{4.14}$$

for some fixed $R_2 > R_0$ and $C > 0$ independent of ε, u_ε, f_j, and g_j, $j = 1, 2$.

Proof. We first note that, by coerciveness estimates [14, Thm. 2.7], we have

$$u_2 \in H^2(B(R) \cap \Omega_2) \quad \forall R > 0$$

and

$$(-\Delta + B_2\nabla + q_2 - k^2 - i\varepsilon)u_2 = f_2 \quad \text{a.e. in } \Omega_2.$$

Lemma 4.3 is proved in several steps following [15] and [23]. For $R_1 > R_0$ set $\phi \in C^\infty(\mathbf{R}^n)$ be such that $\phi(x) = 0$, $|x| \leqq R_1$, $\phi(x) = 1$, $|x| \geqq 2R_1$, and $0 \leqq \phi \leqq 1$, $R_1 < |x| < 2R_1$. Let $w = (w_1, w_2) = e^{-ikr}\phi(u_{1\varepsilon}, u_{2\varepsilon})$. Then $w \in H$ and by a direct calculation we find that w_2 satisfies

$$(A_1 + A_2 + A_3 + B_2\nabla)w_2 = \tilde{f}, \tag{4.15}$$

where $A_1 = -\Delta$, $A_2 = -ik(2\partial_r + (n-1)/r)$, $A_3 = q_2 + ikB_2\hat{x} - i\varepsilon$, $\tilde{f} = e^{-ikr}[-\Delta(\phi u_{2\varepsilon}) + B_2\nabla(\phi u_{2\varepsilon}) + q_2\phi u_{2\varepsilon} - (k^2 + i\varepsilon)\phi u_{2\varepsilon}]$.

Step 1. We show that there exists a constant $C_1 > 0$, independent of ε, w_2, $\tilde{f}$, and R, such that for $R > R_1$

$$\begin{aligned} &k\|\nabla w_2\|^2_{0,\Omega(R)} + \varepsilon\|\sqrt{r}\,\nabla w_2\|^2_{0,\Omega(R)} \\ &\quad \leqq C_1\{(\ln R_1)^{\delta/2}\|\tilde{f}\|^2_{0,\rho,\Omega(R)} + (\ln R_1)^{-\delta/2}(\|\nabla w_2\|^2_{0,\Omega(R)} + \|w_2\|^2_{0,P_\delta,\Omega(R)}) \\ &\qquad + \varepsilon(\ln R_1)^{-\delta/2}(\|\sqrt{r}\,\nabla w_2\|^2_{0,\Omega(R)} + \|w_2\|^2_{0,q_\delta,\Omega(R)})\} + K_R(w_2), \end{aligned} \tag{4.16}$$

where $K_R(w_2)$ denotes a functional satisfying

$$|K_R(w_2)| \leqq CR(\|\nabla w_2\|^2_{0,s(R)} + \|w_2\|^2_{0,s(R)}).$$

Step 2. We show that for $R_2 > R_1$, arbitrarily, the following estimate holds:

$$\begin{aligned} &k\|w_2\|^2_{0,P_\delta,\Omega(R_1,R_2)} + (\varepsilon/\delta)\|w_2\|^2_{0,q_\delta,\Omega(R_1,R_2)} \\ &\quad \leqq C_1\{\|\tilde{f}\|^2_{0,\rho,\Omega(R_1,R_2)} + (\ln R_1)^{-\delta/2}(\|\nabla w_2\|^2_{0,\Omega(R_1,R_2)} + \|w_2\|^2_{0,P_\delta,\Omega(R_1,R_2)})\} \\ &\qquad + (\varepsilon/\delta)(\ln R_2)^{-\delta}\|w_2\|^2_{0,\Omega(R_1,R_2)}, \end{aligned} \tag{4.17}$$

where $C_1 > 0$ is independent of ε, w_2, $\tilde{f}$, R_1, and R_2.

The estimates (4.16) and (4.17) can be easily proved by using the same arguments as used in [15] and (2.3), (2.4), and (2.5).

Step 3. We now combine Step 1 and Step 2 to obtain the required estimate (4.14). By (4.16) and (4.17) we know, for any $R_2 > R_1 \geqq R_0$, that

$$\begin{aligned} & k\|\nabla w_2\|^2_{0,\Omega(R_1,R_2)} + \varepsilon\|\sqrt{r}\,\nabla w_2\|^2_{0,\Omega(R_1,R_2)} \\ & \quad + (\varepsilon/\delta)\|w_2\|^2_{0,q_\delta,\Omega(R_1,R_2)} + k\|w_2\|^2_{0,P_\delta,\Omega(R_1,R_2)} \\ & \leqq C\{(\ln R_1)^{\delta/2}\|\tilde{f}\|^2_{0,\rho,\Omega(R_1,R_2)} \\ & \quad + (\ln R_1)^{-\delta/2}(\|\nabla w_2\|^2_{0,\Omega(R_1,R_2)} + \|w_2\|^2_{0,P_\delta,\Omega(R_1,R_2)}) \\ & \quad + \varepsilon(\ln R_1)^{-\delta/2}(\|\sqrt{r}\,\nabla w_2\|^2_{0,\Omega(R_1,R_2)} + \|w_2\|^2_{0,q_\delta,\Omega(R_1,R_2)})\} \\ & \quad + \varepsilon\delta^{-1}(\ln R_2)^{-\delta}\|w_2\|^2_{0,\Omega(R_1,R_2)} + K_{R_2}(w_2), \end{aligned}$$

which implies that, for $R_1 \geqq R_0$ sufficiently large,

$$\begin{aligned} & \|\nabla w_2\|^2_{0,\Omega(R_1,R_2)} + \|w_2\|^2_{0,P_\delta,\Omega(R_1,R_2)} \\ & \quad \leqq C(\|\tilde{f}\|^2_{0,\rho,\Omega(R_1,R_2)} + (\ln R_2)^{-\delta}\|w_2\|^2_{0,\Omega(R_1,R_2)}) + K_{R_2}(w_2). \end{aligned} \tag{4.18}$$

Since $|K_{R_2}(w_2)| \leqq CR_2(\|w_2\|^2_{0,s(R_2)} + \|\nabla w_2\|^2_{0,s(R_2)})$ and $w_2 \in H^1(\Omega_2)$, there exists a sequence $\{R_{2j}\}_{j=1}^{\infty}$ such that $R_{2j} \to \infty$ and $K_{R_{2j}}(w_2) \to 0$ as $j \to \infty$. From this, the definition of ϕ, (4.18), and (4.15), we obtain by taking $R_2 = R_{2j}$ and passing to the limit in (4.18) as $j \to \infty$ that for some fixed $R_1 > 0$

$$\|\nabla(e^{-ikr}\phi u_{2\varepsilon})\|_{0,E(R_1)} + \|\phi u_{2\varepsilon}\|_{0,P_\delta,E(R_1)} \leqq C\|\tilde{f}\|_{0,\rho,E(R_1)}.$$

From this and by making use of the definition of ϕ and $\tilde{f}$, we arrive at the following inequality:

$$\|\nabla(e^{-ikr}u_{2\varepsilon})\|_{0,E(2R_1)} + \|u_{2\varepsilon}\|_{0,P_\delta,E(2R_1)} \leqq C(\|f_2\|_{0,\rho,E(R_1)} + \|u_{2\varepsilon}\|_{1,\Omega(R_1,2R_1)}). \tag{4.19}$$

On the other hand, since in any bounded region the weighted norms are equivalent to similar norms with unit weight, by Lemma 4.2 and (4.12), (4.13) we get

$$\begin{aligned} & \|\nabla(e^{-ikr}u_\varepsilon)\|_{0,B(2R_1)} + \|u_\varepsilon\|_{0,P_\delta,B(2R_1)} + \|u_{2\varepsilon}\|_{1,\Omega(R_1,2R_1)} \\ & \quad \leqq C\|u_\varepsilon\|_{1,B(2R_1)} \\ & \quad \leqq C\left[\sum_{j=1}^{2}\|f_j\|_{0,\rho,\Omega_j} + \|g_1\|_{1/2,\Gamma} + \|g_2\|_{-1/2,\Gamma} + \|u_\varepsilon\|_{0,B(2R_1+1)}\right]. \end{aligned} \tag{4.20}$$

Then (4.19) and (4.20) imply the required estimate (4.14).

With Lemma 4.3 we can now establish the principle of limiting absorption in the following form.

THEOREM 4.1. *Let* $f_j \in L^2_\rho(\Omega_j)$, $j = 1, 2$, *and either* $\operatorname{Re}(\bar{\alpha}\beta) > 0$ *or* $\operatorname{Im}(\bar{\alpha}\beta) \neq 0$. *Let* u_ε, $0 < \varepsilon \leqq 1$, *be a solution to* (4.1). *Then there exists a* $u \in H^*_E \cap L^2_{P_\delta}(\Omega)$ *such that* $\lim_{\varepsilon\to 0^+} u_\varepsilon = u$ *weakly in* $L^2_{P_\delta}(\Omega)$ *and* u *is the unique solution to the transmission problem* (2.9). *Moreover,* u *satisfies the estimate*

$$\|\nabla(e^{-ikr}u)\|_{0,\Omega} + \|u\|_{0,P_\delta,\Omega} \leqq C\left(\sum_{j=1}^{2}\|f_j\|_{0,\rho,\Omega_j} + \|g_1\|_{1/2,\Gamma} + \|g_2\|_{-1/2,\Gamma} + \|u\|_{0,B(R_2)}\right) \tag{4.21}$$

where C *is a positive constant independent of* $u, f_j, g_j, j = 1, 2$ *and* R_2 *is some fixed number chosen as in Lemma* 4.3.

Proof. We distinguish the following two cases.

Case 1. $\operatorname{Sup}_\varepsilon \|u_\varepsilon\|_{0,B(R_2)} < \infty$.

By Lemma 4.3 we find

$$\sup_{\varepsilon} [\|\nabla(e^{-ikr}u_\varepsilon)\|_{0,\Omega} + \|u_\varepsilon\|_{0,P_\delta,\Omega}] < \infty. \tag{4.22}$$

Define the Hilbert space Ξ as follows:

$$\Xi := \{v \in L^2(B(R) \cap \Omega_1) \times L^2(B(R) \cap \Omega_2) \ \forall R > 0 \,|\, \|\nabla(e^{-ikr}v)\|_{0,\Omega} + \|v\|_{0,P_\delta,\Omega} < \infty\},$$

with the norm

$$\|v\|_\Xi := [\|\nabla(e^{-ikr}v)\|^2_{0,\Omega} + \|v\|^2_{0,P_\delta,\Omega}]^{1/2}.$$

Then, by the reflexive property of Hilbert spaces and (4.22) we can find a $u \in \Xi \subset L^2_{P_\delta}(\Omega)$ and a subsequence which we simply denote by $\{u_\varepsilon\}_{0<\varepsilon\leqq 1}$ such that u_ε converges weakly to u in Ξ. This implies that u_ε converges weakly to u in $L^2_{P_\delta}(\Omega)$ and that u_ε converges weakly to u in $L_2(B(R))$ with $R \geqq 0$, arbitrarily. On the other hand, from (4.22) we see $\sup_\varepsilon \|u_\varepsilon\|_{0,B(R)} < \infty$ for arbitrary $R \geqq 0$, which, together with Lemma 4.2, gives $\sup_\varepsilon \|u_\varepsilon\|_{1,B(R)} < \infty$ for arbitrary $R \geqq 0$. Rellich's selection theorem asserts that there is a subsequence $\{u_{\varepsilon_i}\}_{i=1}^\infty$ and a $v \in L_2(B(R))$ such that u_{ε_i} converges strongly to v in $L_2(B(R))$ for arbitrary $R \geqq 0$. Hence $v = u$ in $L_2(B(R))$ for arbitrary $R \geqq 0$. Lemma 4.2 yields that u_{ε_i} also converges strongly to u in $H^1(B(R))$ for arbitrary $R \geqq 0$. Combining this with (4.1), we obtain that $u \in H^*_E \cap L^2_{P_\delta}(\Omega)$ is the unique solution to (2.9). By the weak lower semicontinuity of $\|v\|_\Xi$ on Ξ, we get

$$\|u\|_\Xi \leqq \liminf_{i\to\infty} \|u_{\varepsilon_i}\|_\Xi.$$

Then, from (4.14) we obtain that u satisfies the estimate (4.21). Furthermore, the same argument as above and Theorem 3.1 imply that the original sequence $\{u_\varepsilon\}_{0<\varepsilon\leqq 1}$ weakly converges to u in $L^2_{P_\delta}(\Omega)$.

Case 2. $\operatorname{Sup}_\varepsilon \|u_\varepsilon\|_{0,B(R_2)} = \infty$.

Let $v_\varepsilon = \|u_\varepsilon\|^{-1}_{0,B(R_2)} u_\varepsilon$. Then v_ε satisfies (4.1) with f_j and g_j replaced by $f_{j\varepsilon} = \|u_\varepsilon\|^{-1}_{0,B(R_2)} f_j$ and $g_{j\varepsilon} = \|u_\varepsilon\|^{-1}_{0,B(R_2)} g_j$, respectively, $j = 1, 2$, and $\|v_\varepsilon\|_{0,B(R_2)} = 1$, where $f_{j\varepsilon}$ and $g_{j\varepsilon}$, $j = 1, 2$, tend to zero as $\varepsilon \to 0$. The same argument as in Case 1 can be used to prove that there is a $v \in L^2_{P_\delta}(\Omega)$ such that v_ε converges to v weakly in $L^2_{P_\delta}(\Omega)$, where v is a solution of the homogeneous problem corresponding to (2.9) and $\|v\|_{0,B(R_2)} = 1$. By Theorem 3.1 the solution of this homogeneous problem is unique, and therefore $v = 0$ almost everywhere in Ω. This is a contradiction. The proof is complete.

To prove the existence of solutions to the transmission problem we have to prove that at least for $\varepsilon > 0$ sufficiently small (4.1) has indeed a unique solution. With the help of Theorems 3.1 and 4.1, (4.11), and (4.12), this can be established as follows.

THEOREM 4.2. *Let $f_j \in L_2(\Omega_j)$, $j = 1, 2$ and either* $\operatorname{Re}(\bar{\alpha}\beta) > 0$ *or* $\operatorname{Im}(\bar{\alpha}\beta) \neq 0$. *Then there is an $\varepsilon_0 > 0$ such that for $0 < \varepsilon \leqq \varepsilon_0$ problem* (4.1) *has a unique solution $u_\varepsilon \in H^*$, satisfying*

$$\|u_\varepsilon\|_{1,\Omega} \leqq C(\varepsilon)\left(\sum_{j=1}^{2} \|f_j\|_{0,\Omega_j} + \|g_1\|_{1/2,\Gamma} + \|g_2\|_{-1/2,\Gamma}\right). \tag{4.23}$$

Proof. (a) *Uniqueness.* Consider the following homogeneous problem corresponding to (4.1):

$$\begin{aligned} &\text{Find } v_\varepsilon = (v_{1\varepsilon}, v_{2\varepsilon}) \in H \quad \text{such that} \\ &a_\varepsilon(v_\varepsilon, v) = 0 \quad \forall v \in H. \end{aligned} \tag{4.24}$$

To prove the uniqueness of solutions to (4.1) it is sufficient to prove that there is an $\varepsilon_0 > 0$ such that for $0 < \varepsilon \leqq \varepsilon_0$ problem (4.24) has only a trivial solution. If this is false,

then there will be a subsequence $\{v_{\varepsilon_i}\}$ such that $\varepsilon_i \to 0$ as $i \to \infty$, $v_{\varepsilon_i} \neq 0$ almost everywhere in Ω, and v_{ε_i} is a solution to (4.24) with ε replaced by ε_i. We now see that $\|v_{\varepsilon_i}\|_{0,B(R_2)} \neq 0$, because otherwise we get $\|v_{\varepsilon_i}\|_{0,P_\delta,\Omega} = 0$ from Lemma 4.3, which implies that $v_{\varepsilon_i} = 0$ almost everywhere in Ω. Thus, we can assume that $\|v_{\varepsilon_i}\|_{0,B(R_2)} = 1$. Theorem 3.1 and the same argument as used in Case 1 in the proof of Theorem 4.1 imply that v_{ε_i} converges to zero in $L_2(B(R_2))$. This contradicts the fact that $\|v_{\varepsilon_i}\|_{0,B(R_2)} = 1$, $i = 1, 2, \cdots$. Uniqueness is proved.

(b) *Existence.* Using (4.3) and the uniqueness property we find that the kernel of the operator A_ε satisfies $\operatorname{Ker}(A_\varepsilon) = \{0\}$. On the other hand, since A_ε is a bounded linear operator, $A_\varepsilon + \lambda I$ is invertible for all $\lambda \in C$ with $|\lambda|$ sufficiently large. Therefore, if we can also prove that $A_\varepsilon + \lambda I$ is a semi-Fredholm operator for all $\lambda \in C$ with $\operatorname{Re} \lambda \geqq 0$ and $\operatorname{Im} \lambda \geqq 0$, well-known results from perturbation theory imply that $A_\varepsilon + \lambda I$ is not only semi-Fredholm but also Fredholm with index zero for all $\lambda \in C$ with $\operatorname{Re} \lambda \geqq 0$ and $\operatorname{Im} \lambda \geqq 0$ [8, Thm. 5.17]. In particular, if $\lambda = 0$, we will obtain that A_ε is a Fredholm operator with index zero, which, together with $\operatorname{Ker}(A_\varepsilon) = \{0\}$ implies that A_ε is bijective from H onto H. Therefore, (4.11) has a unique solution. Thus by (4.11) and (4.12), (4.1) also has a unique solution and the estimate (4.23) follows from (4.12) and (4.13). Hence, we only have to prove that $A_\varepsilon + \lambda I$ is a semi-Fredholm operator with $\operatorname{Re} \lambda \geqq 0$ and $\operatorname{Im} \lambda \geqq 0$, that is, that $R(A_\varepsilon + \lambda I) = \overline{R(A_\varepsilon + \lambda I)}$ and the dimension of $\operatorname{Ker}(A_\varepsilon + \lambda I)$ is finite. To this end we first derive a coerciveness estimate. From (4.3) we find for $0 < t \leqq 1$ and $u \in H$ that

$$
\begin{aligned}
\sqrt{2}|((A_\varepsilon + \lambda I)u, u)_{1,\Omega}| &\geqq t|\operatorname{Re}((A_\varepsilon + \lambda I)u, u)_{1,\Omega}| + |\operatorname{Im}((A_\varepsilon + \lambda I)u, u)_{1,\Omega}| \\
&\geqq t\|\nabla u_2\|^2_{0,\Omega_2} - tk^2\|u_2\|^2_{0,\Omega_2} + \varepsilon\|u_2\|^2_{0,\Omega_2} - C\|u_1\|^2_{1,\Omega_1} \\
&\quad - |(B_2 \nabla u_2, u_2)_{0,\Omega_2}| - |(q_2 u_2, u_2)_{0,\Omega_2}|.
\end{aligned} \tag{4.25}
$$

Since by (2.4) we have

$$
\begin{aligned}
&|(B_2 \nabla u_2, u_2)_{0,\Omega_2}| + |(q_2 u_2, u_2)_{0,\Omega_2}| \\
&\quad \leqq CR_1^{-1}(\ln R_1)^{-1-\delta}(\|\nabla u_2\|^2_{0,E(R_1)} + \|u_2\|^2_{0,E(R_1)}) + C\|u_2\|^2_{1,D(R_1)},
\end{aligned}
$$

it follows from (4.25) that there is an $R_1 > 0$ sufficiently large and a $t > 0$ sufficiently small such that

$$
\|u\|_{1,\Omega} \leqq C(\varepsilon, R_1)[\|(A_\varepsilon + \lambda I)u\|_{1,\Omega} + \|u\|_{1,B(R_1)}] \quad \forall u \in H. \tag{4.26}
$$

On the other hand, by Remark 4.1 we have

$$
\|u\|_{1,B(R_1)} \leqq C[\|(A_\varepsilon + \lambda I)u\|_{1,\Omega} + (1+\varepsilon)\|u\|_{0,B(R_1+1)}] \quad \forall u \in H. \tag{4.27}
$$

Now combine (4.26) and (4.27) to obtain the coerciveness estimate

$$
\|u\|_{1,\Omega} \leqq C(\varepsilon)[\|(A_\varepsilon + \lambda I)u\|_{1,\Omega} + \|u\|_{0,B(R_1+1)}] \quad \forall u \in H. \tag{4.28}
$$

From (4.28) and Rellich's selection theorem it follows that $\dim \operatorname{Ker}(A_\varepsilon + \lambda I)$ is finite.

To prove that $R(A_\varepsilon + \lambda I)$ is closed, we consider the operator $T: H/\operatorname{Ker}(A_\varepsilon + \lambda I) \to H$, defined as follows:

$$
T[u] := (A_\varepsilon + \lambda I)u \quad \forall u \in H,
$$

where $H/\operatorname{Ker}(A_\varepsilon + \lambda I)$ denotes the quotient space with the norm $\|[u]\| = \inf\{\|u - v\|_{1,\Omega} | v \in \operatorname{Ker}(A_\varepsilon + \lambda I)\}$ and $[u] \in H/\operatorname{Ker}(A_\varepsilon + \lambda I)$, an equivalence class such that for arbitrary $u', u'' \in [u]$ we have $u' - u'' \in \operatorname{Ker}(A_\varepsilon + \lambda I)$. Evidently, $R(T) = R(A_\varepsilon + \lambda I)$ and T is a bounded linear operator satisfying $\operatorname{Ker}(T) = \{[0]\}$; that is, T

is invertible. Consequently, to prove $R(A_\varepsilon+\lambda I)=\overline{R(A_\varepsilon+\lambda I)}$ it is enough to prove that T^{-1} is continuous, that is,

$$\|[u]\| \leqq C\|T[u]\|_{1,\Omega} \quad \forall u \in H. \tag{4.29}$$

However, by (4.28) we know that

$$\|u-v\|_{1,\Omega} \leqq C(\varepsilon)(\|(A_\varepsilon+\lambda I)u\|_{1,\Omega}+\|u-v\|_{0,B(R_1+1)}) \quad \forall v \in \operatorname{Ker}(A_\varepsilon+\lambda I), \quad u \in H,$$

which, together with Rellich's selection theorem and the fact that $T[u]=(A_\varepsilon+\lambda I)u$ and $\operatorname{Ker}(T)=\{[0]\}$, implies that

$$\|u-v\|_{1,\Omega} \leqq C(\varepsilon)\|(A_\varepsilon+\lambda I)u\|_{1,\Omega} \quad \forall v \in \operatorname{Ker}(A_\varepsilon+\lambda I), \quad u \in H.$$

From this, (4.29) follows. Hence, the proof is complete.

As a direct consequence of Theorems 4.1 and 4.2, we obtain the existence of solutions to the transmission problem (2.9).

THEOREM 4.3. *Let* $f_j \in L^2_\rho(\Omega_j)$, $j=1,2$ *and either* $\operatorname{Re}(\bar{\alpha}\beta)>0$ *or* $\operatorname{Im}(\bar{\alpha}\beta)\neq 0$. *Then* (2.9) *has a unique solution* $u \in H^*_E \cap L^2_{P_\delta}(\Omega)$ *such that*

$$\|\nabla(e^{-ikr}u)\|_{0,\Omega}+\|u\|_{0,P_\delta,\Omega} \leqq C\left(\sum_{j=1}^{2}\|f_j\|_{0,\rho,\Omega_j}+\|g_1\|_{1/2,\Gamma}+\|g_2\|_{-1/2,\Gamma}+\|u\|_{0,B(R_2)}\right). \tag{4.30}$$

Remark 4.2. If $g_1 \in H^{3/2}(\Gamma)$ and $g_2 \in H^{1/2}(\Gamma)$, then, by coerciveness estimates [14, Thm. 2.7], we find that the transmission solution $u=(u_1,u_2)$ has the regularity that $u_j \in H^2(B(R)\cap\Omega_j)$ for all $R>0$, $j=1,2$.

Remark 4.3. For exterior boundary value problems, that is, Dirichlet, Neumann, and Robin problems, our methods are still applicable and similar results hold.

Remark 4.4. If the Laplace operator Δ is replaced by the operator $\sum_{k,j=1}^{n}(\partial/\partial x_k)\times(a_{kj}^{(i)}\partial/\partial x_j)$, $i=1,2$, with $a_{kj}^{(i)}$ satisfying the following conditions:

(1) The $a_{kj}^{(i)}$ are real-valued functions, $a_{kj}^{(i)}=a_{jk}^{(i)}$, $a_{kj}^{(i)} \in C^1(\Omega_i)$, $i=1,2$;

(2) For all $x \in \Omega_i$ and for all $\xi \in \mathbf{R}^n$ the following inequality holds:

$$\sum_{k,j=1}^{n} a_{kj}^{(i)}(x)\xi_k\xi_j \geqq C_0|\xi|^2,$$

where C_0 is a positive constant;

(3) There is a $R_1 \geqq R_0$ such that $a_{kj}^{(i)}(x)=\delta_{kj}$ for $|x| \geqq R_1$, $i=1,2$, $k,j=1,\cdots,n$;

(4) In (2.1) the transmission condition $\beta\partial u_1/\partial\nu-\partial u_2/\partial\nu=g_2$ on Γ is replaced by the condition $\beta a_{kj}^{(1)}\nu_k\partial u_1/\partial x_j-a_{kj}^{(2)}\nu_k\partial u_2/\partial x_j=g_2$ on Γ.

Then Theorems 3.1, 4.1, and 4.3 still hold.

Acknowledgment. The authors thank the referee for his constructive comments on this problem and for his pointing out an error in the proof of Lemma 4.3 in the original version of this paper.

NONTRIVIAL SOLUTIONS TO NONLINEAR VOLTERRA INTEGRAL EQUATIONS*

W. OKRASIŃSKI†

Abstract. The Volterra integral equation

$$u(x)=\int_0^x k(x-s)g(u(s))\,ds \qquad (x\geqq 0)$$

is considered, where $k\geqq 0$ is a monotonic integrable function and g is an increasing, continuous function such that $g(0)=0$. Some necessary and sufficient conditions for the existence of nontrivial solutions to the above equation are presented. Physical problems that motivate these results are also discussed.

Key words. nonlinear Volterra equation, existence of nontrivial solutions

AMS(MOS) subject classifications. 45D05, 45G10

1. Introduction and statement of results. We consider the nonlinear Volterra integral equation

$$u(x)=\int_0^x k(x-s)g(u(s))\,ds \qquad (x\geqq 0), \tag{1.1}$$

where

(k) $k:(0,\delta\rangle\to(0,+\infty)$ $(\delta>0)$ is a monotonic absolutely continuous function such that $\int_0^\delta k(s)\,ds<\infty$,

(g) g is a nondecreasing absolutely continuous function such $g(0)=0$, $g(u)>0$ for $u>0$ and $u/g(u)\to 0$ as $u\to 0+$.

Equation (1.1) has been studied recently in connection with nonlinear diffusion and shock-wave propagation problems (see the Appendix). A typical example of g considered in applications is $g(u)=u^p$ $(p\in(0,1))$. Obviously, $u\equiv 0$ is the trivial solution to (1.1). But the question of physical interest is the existence of nontrivial solutions to (1.1), i.e., continuous functions u such that $u(x)>0$ for $x>0$.

The purpose of this paper is to present some sufficient and necessary conditions for the existence of nontrivial solutions to (1.1) on an interval $\langle 0,\delta_1\rangle$ $(\delta_1>0)$. We formulate the results which will be proved in this paper. Let K^{-1} denote the inverse function to $K(x)\doteq\int_0^x k(s)\,ds$. At first, we present two theorems involving sufficient conditions for the existence of nontrivial solutions to (1.1).

THEOREM 1.1. *Suppose k is an increasing function satisfying* (k). *Let g satisfy* (g). *If*

$$\int_0^{\delta_0}[g'(s)/g(s)]K^{-1}(s/g(s))\,ds<\infty \qquad (\delta_0>0), \tag{1.2}$$

then equation (1.1) *has a nontrivial solution on an interval* $\langle 0,\delta_1\rangle$ $(\delta_1>0)$.

THEOREM 1.2. *Suppose k is a decreasing function satisfying* (k) *such that* $\ln k$ *is convex. Let g satisfy* (g). *If*

$$\int_0^{\delta_0}[g(s)k\circ K^{-1}(s/g(s))]^{-1}\,ds<\infty \qquad (\delta_0>0), \tag{1.3}$$

then equation (1.1) *has a nontrivial solution on an interval* $\langle 0,\delta_1\rangle$ $(\delta_1>0)$.

† Institute of Mathematics, University of Wrocław, Pl. Grunwaldzki 2/4, 50-384 Wrocław, Poland.

We now present two necessary conditions for the existence of nontrivial solutions to (1.1).

THEOREM 1.3. *Suppose k is an increasing function satisfying* (k) *such that* $\ln k$ *is concave. Let g satisfy* (g). *If equation* (1.1) *has a nontrivial solution on an interval* $\langle 0, \delta_1\rangle$ $(\delta_1 > 0)$, *then*

$$\int_0^{\delta_0} [g(s)k \circ K^{-1}(s/g(s))]^{-1}\, ds < \infty \qquad (\delta_0 > 0). \tag{1.4}$$

THEOREM 1.4. *Suppose k is a decreasing function satisfying* (k). *Let g satisfy* (g). *If equation* (1.1) *has a nontrivial solution on an interval* $\langle 0, \delta_1\rangle$ $(\delta_1 > 0)$, *then*

$$\int_0^{\delta_0} [g'(s)/g(s)]K^{-1}(s/g(s))\, ds < \infty \qquad (\delta_0 > 0). \tag{1.5}$$

Proofs of the theorems presented above are given in § 3.

In [5] Gripenberg considered the following special case of (1.1):

$$u(x) = \int_0^x (x-s)^{\alpha-1} g(u(s))\, ds \qquad (\alpha > 0), \tag{1.6}$$

where

(i) $g(u)/u$ is continuous positive and nonincreasing on $(0, a\rangle$ $(a > 0)$,

(ii) for each $q > 0$ the function $u[g(u)/u]^q$ is nondecreasing on $\langle 0, a_q\rangle$ $(a_q > 0)$.

In [5] it is shown that $u \equiv 0$ is the unique solution to (1.6) if and only if

$$\int_0^{\delta_0} [s[g(s)/s]^{1/\alpha}]^{-1}\, ds = \infty \qquad (\delta_0 > 0). \tag{1.7}$$

Let us note that for $\alpha = 1$ from (1.7) we obtain the famous Osgood condition. On the basis of Gripenberg's results it can be concluded that (1.6) has a nontrivial solution if and only if

$$\int_0^{\delta_0} [s[g(s)/s]^{1/\alpha}]^{-1}\, ds < \infty \qquad (\delta_0 > 0). \tag{1.8}$$

It is easy to see that in the case where $\lim_{u\to 0+} u/g(u) > 0$, equation (1.6) only has the trivial solution. We must emphasize that under Gripenberg's assumptions the case where $g(u) = u^p$ $(p \in (0, 1))$ is not allowed. Results similar to Gripenberg's are presented in [2], [3], and [10] under weaker assumptions of g and such g's as mentioned above are admissible. In § 2 of this paper we show that Theorems 1.1–1.4 generalize condition (1.8).

2. Some consequences and comments. On the basis of Theorem 1.1 we can formulate the corollary.

COROLLARY 2.1. *Suppose the assumptions of Theorem* 1.1 *and* (i) *are satisfied. If*

$$\int_0^{\delta_0} K^{-1}(s/g(s))/s\, ds < \infty, \tag{2.1}$$

then equation (1.1) *has a nontrivial solution on an interval* $\langle 0, \delta_1\rangle$ $(\delta_1 > 0)$.

By (g) *and* (i) *we have*

$$g'(s) \leqq g(s)/s \quad \text{a.e.} \tag{2.2}$$

By (2.2) *we obtain*

$$[g'(s)/g(s)]K^{-1}(s/g(s)) \leqq K^{-1}(s/g(s))/s \quad \text{a.e.} \tag{2.3}$$

By (2.1) and (2.3) we infer (1.2) is fulfilled. The corollary is true.

Now we show Corollary 2.2.

COROLLARY 2.2. *Suppose the assumptions of Theorem* 1.4 *and* (i) *are satisfied. Moreover, there exists a number* $q_0 > 1$ *such that* $u[g(u)/u]^{q_0}$ *is nondecreasing. If equation* (1.1) *has a nontrivial solution on an interval* $\langle 0, \delta_1\rangle$ $(\delta_1 > 0)$, *then*

$$\int_0^{\delta_0} K^{-1}(s/g(s))/s \, ds < \infty. \tag{2.4}$$

As in [5] it can be shown that

$$g'(s) \geqq (1 - 1/q_0)g(s)/s \quad \text{a.e.} \tag{2.5}$$

By (1.5) and (2.5) we infer (2.4) is satisfied.

Now we present results concerning the special kernel $k(x) = x^{\alpha-1}$ $(\alpha > 0)$.

Remark 2.1. Let us note that for the kernel $k(x) = x^{\alpha-1}$ $(\alpha > 0)$ conditions (1.3), (1.4), (2.1), and (2.4) are equivalent to Gripenberg's condition (1.8).

We can generalize Gripenberg's results as follows.

COROLLARY 2.3. *Let* $\alpha > 0$. *Suppose g satisfies* (g), (i) *and there exists a number* $q_0 > 1$ *such that* $u[g(u)/u]^{q_0}$ *is nondecreasing. Equation* (1.6) *has a nontrivial solution if and only if* (1.8) *is fulfilled.*

This corollary is a consequence of Theorems 1.2–1.3, Corollaries 2.1–2.2, and Remark 2.1.

Remark 2.2. Function $g(u) = u^p$ $(p \in (0, 1))$ satisfies the assumptions of Corollary 2.3.

In [3] it is shown that the equation

$$u(x) = \int_0^x \exp(-1/(x-s)^{\alpha})[u(s)]^p \, ds \qquad (\alpha \geqq 1,\ p \in (0, 1))$$

has a nontrivial solution. In this case our sufficient conditions do not work. This suggests that we must look for other kinds of conditions.

3. Proofs of theorems. We start with two remarks, which are consequences of theorems presented in [2], [7], and [8].

Remark 3.1. Let (k) and (g) be satisfied. If there exists a nontrivial solution to (1.1), then it is the unique nontrivial solution on an interval $\langle 0, \delta_1\rangle$ $(\delta_1 > 0)$. Moreover, it is a strictly increasing absolutely continuous function. We shall denote this solution by u_0.

Remark 3.2. Let (k) and (g) be satisfied. Consider the equation

$$u(x) = \varepsilon x + \int_0^x k(x-s)g(u(s)) \, ds. \tag{3.1}$$

For every $\varepsilon \in (0, 1)$ there exists a unique strictly increasing absolutely continuous solution u_ε to (3.1) on an interval $\langle 0, \delta_1\rangle$, where $\delta_1 > 0$ is independent of ε. Moreover, $u_{\varepsilon_1} \leqq u_{\varepsilon_2}$ for $\varepsilon_1 \leqq \varepsilon_2$.

Now we can formulate the following lemma.

LEMMA 3.1. *Let* $\varepsilon \in \langle 0, 1)$. *Let k satisfy* (k) *and g satisfy* (g). *If equation* (3.1) *has a nontrivial solution* u_ε *on* $\langle 0, \delta_1\rangle$ $(\delta_1 > 0)$, *then there exists a function* $v_\varepsilon \in L(0, u_\varepsilon(\delta_1))$

such that $v_\varepsilon > 0$ *almost everywhere and*

$$v_\varepsilon(x) = 1 \Big/ \left(\int_0^x k \int_s^x v_\varepsilon(\xi)\, d\xi\, g'(s)\, ds + \varepsilon \right) \quad \text{a.e.} \tag{3.2}$$

Proof. Let u_ε be the nontrivial solution to (3.1) mentioned in Remarks 3.1 and 3.2. It is an increasing absolutely continuous function. Differentiating (3.1) we get

$$u'_\varepsilon(x) = \int_0^x k(x-s) g'(u_\varepsilon(s)) u'_\varepsilon(s)\, ds + \varepsilon \tag{3.3}$$

for almost all $x \in \langle 0, \delta_1 \rangle$. By assumptions and (3.3) we have $u'_\varepsilon > 0$ almost everywhere. We infer u_ε^{-1} is an absolutely continuous function. From (3.3) we get

$$u'_\varepsilon(x) = \varepsilon + \int_0^{u_\varepsilon(x)} k(x - u_\varepsilon^{-1}(s)) g'(s)\, ds \quad \text{a.e.}$$

Substituting $u_\varepsilon^{-1}(x)$ instead of x, we obtain

$$u'_\varepsilon(u_\varepsilon^{-1}(x)) = \varepsilon + \int_0^x k(u_\varepsilon^{-1}(x) - u_\varepsilon^{-1}(s)) g'(s)\, ds \quad \text{a.e.} \tag{3.4}$$

Let $v_\varepsilon \doteq [u_\varepsilon^{-1}]$ almost everywhere. Since $v_\varepsilon = 1/u'_\varepsilon \circ u_\varepsilon^{-1}$ almost everywhere and $u_\varepsilon^{-1}(x) - u_\varepsilon^{-1}(s) = \int_s^x v_\varepsilon(\xi)\, d\xi$, by (3.4) we get (3.2).

COROLLARY 3.1. *If* u_ε *is the nontrivial solution mentioned in Remarks* 3.1 *and* 3.2, *then we put* $v_\varepsilon \doteq [u_\varepsilon^{-1}]'$ *almost everywhere. Since* u_ε^{-1} *is absolutely continuous,* $u_\varepsilon^{-1}(x) = \int_0^x v_\varepsilon(s)\, ds$.

COROLLARY 3.2. *Let* $\varepsilon > 0$. *If the integrable function* v_ε *satisfies* (3.2), *then*

$$\int_0^x K\left(\int_s^x v_\varepsilon(\xi)\, d\xi \right) g'(s)\, ds \leqq x. \tag{3.5}$$

Let $\varepsilon = 0$. *If the integrable function* v_0 *satisfies* (3.2), *then*

$$\int_0^x K\left(\int_s^x v_0(\xi)\, d\xi \right) g'(s)\, ds = x. \tag{3.6}$$

From (3.2) *we have*

$$v_\varepsilon(x) \int_0^x k\left(\int_s^x v_\varepsilon(\xi)\, d\xi \right) g'(s)\, ds + \varepsilon v_\varepsilon(x) = 1 \quad \text{a.e.} \tag{3.7}$$

Integrating (3.7) *we get*

$$\int_0^x K\left(\int_s^x v_\varepsilon(\xi)\, d\xi \right) g'(s)\, ds + \varepsilon \int_0^x v_\varepsilon(s)\, ds = x. \tag{3.8}$$

From (3.8) *we obtain* (3.5) *and* (3.6).

Proof of Theorem 1.1. Consider (3.1). Let $\{u_\varepsilon\}$ $(\varepsilon \in (0, 1))$ denote the family of increasing absolutely continuous solutions to (3.1) on $\langle 0, \delta_1 \rangle$ mentioned in Remark 3.2. By Corollary 3.1 the function $v_\varepsilon \doteq [u_\varepsilon^{-1}]'$ almost everywhere on $\langle 0, u_\varepsilon(\delta_1) \rangle$ satisfies (3.5). Since K is convex then from (3.5) by the Jensen inequality, we get

$$g(x) K\left(\int_0^x \int_s^x v_\varepsilon(\xi)\, d\xi\, g'(s)\, ds / g(x) \right) \leqq x$$

or after simple calculations

$$V_\varepsilon(x) \leqq K^{-1}(x/g(x)), \tag{3.9}$$

where

$$V_\varepsilon(x) \doteq \int_0^x v_\varepsilon(s)g(s)\,ds/g(x).$$

We have

$$V'_\varepsilon(x) = v_\varepsilon(x) - [g'(x)/g(x)]V_\varepsilon(x) \quad \text{a.e.} \tag{3.10}$$

From (3.9) and (3.10) we get

$$V'_\varepsilon(x) \geqq v_\varepsilon(x) - [g'(x)/g(x)]K^{-1}(x/g(x)) \quad \text{a.e.} \tag{3.11}$$

From (3.11) we obtain

$$v_\varepsilon(x) \leqq V'_\varepsilon(x) + [g'(x)/g(x)]K^{-1}(x/g(x)) \quad \text{a.e.} \tag{3.12}$$

Since $u_\varepsilon^{-1}(x) = \int_0^x v_\varepsilon(s)\,ds$ and (1.2) holds, integrating (3.12) we get

$$u_\varepsilon^{-1}(x) \leqq V_\varepsilon(x) + \int_0^x [g'(s)/g(s)]K^{-1}(s/g(s))\,ds.$$

Hence by (3.9) we obtain

$$u_\varepsilon^{-1}(x) \leqq K^{-1}(x/g(x)) + \int_0^x [g'(s)/g(s)]K^{-1}(s/g(s))\,ds. \tag{3.13}$$

Let

$$F^{-1}(x) \doteq K^{-1}\left(\sup_{s\in\langle 0,x\rangle}(s/g(s))\right) + \int_0^x [g'(s)/g(s)]K^{-1}(s/g(s))\,ds + x.$$

It is a strictly increasing continuous function such that $F^{-1}(0) = 0$. By (3.13) we have

$$u_\varepsilon^{-1}(x) \leqq F^{-1}(x) \quad \text{on } \langle 0, u_\varepsilon(\delta_1)\rangle$$

or

$$u_\varepsilon(x) \geqq F(x) \quad \text{on } \langle 0, \delta_1\rangle. \tag{3.14}$$

Let $\varepsilon \searrow 0+$. Since the sequence u_ε is decreasing with respect to ε, we infer that

$$u(x) \doteq \lim_{\varepsilon\searrow 0+} u_\varepsilon(x) \qquad (x \in \langle 0, \delta_1\rangle)$$

is a nondecreasing continuous solution to (1.1). Since (3.14) holds for any $\varepsilon \in (0, 1)$, $u(x) \geqq F(x)$ on $\langle 0, \delta_1\rangle$. It means we have found a nontrivial solution u to (1.1).

Proof of Theorem 1.2. Consider (3.1). Let $\{u_\varepsilon\}$ $(\varepsilon \in (0, 1))$ denote the family of increasing absolutely continuous solutions to (3.1) on $\langle 0, \delta_1\rangle$ mentioned in Remark 3.2. By Corollary 3.1 and (3.2) we infer that the function $v_\varepsilon \doteq [u_\varepsilon^{-1}]'$ almost everywhere on $\langle 0, u_\varepsilon(\delta_1)\rangle$ must satisfy the following inequality:

$$v_\varepsilon(x) \leqq 1 \Big/ \int_0^x k\left(\int_s^x v_\varepsilon(\xi)\,d\xi\right) g'(s)\,ds \quad \text{a.e.} \tag{3.15}$$

We can write (3.15) as

$$v_\varepsilon(x) \leqq 1 \Big/ \int_0^x k \circ K^{-1}\left(K\left(\int_s^x v_\varepsilon(\xi)\,d\xi\right)\right) g'(s)\,ds \quad \text{a.e.} \tag{3.16}$$

Since $\ln k$ is convex it follows that $k \circ K^{-1}$ is convex. By the Jensen inequality from (3.16) we obtain

$$v_\varepsilon(x) \leqq 1/g(x) k \circ K^{-1}\left(\int_0^x K\left(\int_s^x v_\varepsilon(\xi)\, d\xi\right) g'(s)\, ds/g(x)\right) \quad \text{a.e.} \tag{3.17}$$

The function $1/k \circ K^{-1}$ is increasing because k is decreasing and K is increasing. By (3.6) and (3.17) we obtain

$$v_\varepsilon(x) \leqq 1/g(x) k \circ K^{-1}(x/g(x)) \quad \text{a.e. on } \langle 0, u_\varepsilon(\delta_1)\rangle. \tag{3.18}$$

Let

$$G^{-1}(x) \doteq \int_0^x [g(s) k \circ K^{-1}(s/g(s))]^{-1}\, ds. \tag{3.19}$$

By assumption (1.3) the function G^{-1} is well defined. Integrating (3.18), we get

$$u_\varepsilon^{-1}(x) \leqq G^{-1}(x) \quad \text{on } \langle 0, u_\varepsilon(\delta_1)\rangle$$

or

$$u_\varepsilon(x) \geqq G(x) \quad \text{on } \langle 0, \delta_1\rangle. \tag{3.20}$$

Let $\varepsilon \searrow 0+$. Since the sequence u_ε is decreasing with respect to ε, we infer that

$$u(x) \doteq \lim_{\varepsilon \searrow 0+} u_\varepsilon(x) \qquad (x \in \langle 0, \delta_1\rangle)$$

is a nondecreasing continuous solution to (1.1). Since (3.20) holds for any $\varepsilon \in (0, 1)$, $u(x) \geqq G(x)$ on $\langle 0, \delta_1\rangle$. It means that the function u is a nontrivial solution to (1.1).

Proof of Theorem 1.3. Let u_0 be the nontrivial solution to (1.1) mentioned in Remark 3.1. Let $v_0 \doteq [u_0^{-1}]'$ almost everywhere on $\langle 0, u_0(\delta_1)\rangle$. By Corollary 3.1 and (3.2) we have

$$v_0(x) = 1 \Big/ \int_0^x k \circ K^{-1}\left(K\left(\int_s^x v_0(\xi)\, d\xi\right)\right) g'(s)\, ds \quad \text{a.e.} \tag{3.21}$$

Since $\ln k$ is concave it follows that $k \circ K^{-1}$ is concave. From (3.21) by the Jensen inequality we get

$$v_0(x) \geqq 1/g(x) k \circ K^{-1}\left(\int_0^x K\left(\int_s^x v_0(\xi)\, d\xi\right) g'(s)\, ds/g(x)\right) \tag{3.22}$$

and by (3.6)

$$v_0(x) \geqq 1/g(x) k \circ K^{-1}(x/g(x)). \tag{3.23}$$

Since v_0 is integrable, we infer that (1.4) holds.

Proof of Theorem 1.4. Let u_0 be the nontrivial solution to (1.1) mentioned in Remark 3.1. Let $v_0 = [u_0^{-1}]'$ almost everywhere on $\langle 0, u_0(\delta_1)\rangle$. By Corollary 3.1 the function v_0 satisfies (3.6). Since K is convex, then from (3.6) by the Jensen inequality we get

$$x \leqq g(x) K\left(\int_0^x \int_s^x v_0(\xi)\, d\xi\, g'(s)\, ds/g(x)\right),$$

or after simple calculations,

$$V_0(x) \geqq K^{-1}(x/g(x)), \tag{3.24}$$

where

$$V_0(x) \doteq \int_0^x v_0(s)g(s)\,ds/g(x).$$

We have

$$V_0'(x) = v_0(x) - [g'(x)/g(x)]V_0(x) \quad \text{a.e.} \tag{3.25}$$

From (3.24) and (3.25) we get

$$V_0'(x) \leqq v_0(x) - [g'(x)/g(x)]K^{-1}(x/g(x)) \quad \text{a.e.} \tag{3.26}$$

or

$$[g'(x)/g(x)]K^{-1}(x/g(x)) \leqq v_0(x) - V_0'(x) \quad \text{a.e.} \tag{3.27}$$

Since v_0 and V_0' are integrable, then by (3.27) we get (1.5).

Appendix. We present two physical problems leading to nonlinear Volterra integral equations having the form (1.1) and satisfying (k) and (g).

A.1. Travelling wave solutions to shock-wave problems. We consider shock waves in gas-filled shock-wave tubes [6]. We want to find the axial component of the particle velocity behind the shock wave. We assume that the x-axis of the coordinate system is directed along the axis of the tube. Moreover, the shock-wave front passes through the origin of the x-axis at time $t=0$. Let $c_s \geqq c_0$ (c_0 is the sound speed) denote the speed of the shock-wave front. We denote by $v(x, t)$ the axial component of the particle velocity behind the wave front at point x and time t. The function v must satisfy the following equation (see [6]):

$$D_t v + c_s D_x v = -(B_1 v + (c_0 - c_s))D_x v + \frac{1}{2} B_2 \int_0^{t-x/c_s} D_t v(x, t-s)s^{\alpha-1}\,ds, \tag{A1}$$

where B_1, B_2, $\alpha > 0$ are physical parameters, and must also satisfy the condition

$$v(x, x/c_s) = (c_s - c_0)/B_1. \tag{A2}$$

This last condition describes the discontinuity of the axial velocity at the wave front. We look for so-called travelling wave solutions of (A1)-(A2) having the form

$$v(x, t) = v(t - x/c_s). \tag{A3}$$

In the case of such solutions the problem (A1)-(A2) will be reduced to

$$\frac{B_1}{c_s}([v(x) - (c_s - c_0)/B_1]^2)' = B_2 \int_0^x v'(x-s)s^{\alpha-1}\,ds, \tag{A4}$$

where $v = v(x)$ is the unknown function such that

$$v(0) = (c_s - c_0)/B_1. \tag{A5}$$

Substituting into (A4) and (A5) instead of v the function $B_2 c_s[v - (c_s - c_0)/B_1]/B_1$, we get

$$([v(x)]^2)' = \int_0^x v'(x-s)s^{\alpha-1}\,ds \tag{A6}$$

and

$$v(0) = 0. \tag{A7}$$

Integrating (A6) and using (A7), we get

$$[v(x)]^2 = \int_0^x (x-s)^{\alpha-1} v(s)\, ds \tag{A8}$$

or after substituting $v = u^{1/2}$, we obtain

$$u(x) = \int_0^x (x-s)^{\alpha-1} [u(s)]^{1/2}\, ds \tag{A9}$$

for $x \geqq 0$. With respect to physical meaning only nonnegative nontrivial solutions are interesting. Such solutions are considered in [6] and [11].

A.2. Subsolutions of nonlinear diffusion problems. We study the following diffusion problem [1], [9]:

$$D_t h = r^{-1} D_r (r D_r (h^{1/p})) \qquad (p \in (0, 1)) \tag{A10}$$

with conditions

$$h(r, 0) = 0 \quad \text{for } r > 1, \tag{A11}$$

$$h(1, t) = 1 \quad \text{for } t > 0. \tag{A12}$$

Let us note that in the case $p = \frac{1}{2}$ the problem (A10)-(A12) may describe the infiltration of the fluid from a cylindrical reservoir. It may be shown that (A10) with conditions (A11)-(A12) has a unique so-called weak solution $h(r, t)$ in the domain $(1, +\infty) \times (0, +\infty)$ (for details see [4]). It is important for applications that the weak solution is classical at these points (r, t) for which $h(r, t) > 0$. Moreover, it is shown that $\operatorname{supp} h(\cdot, t) = \langle 1, r_0(t) \rangle$ for $t > 0$, where $r_0(t)$ is a continuous increasing function. With respect to applications it is interesting to give even approximate information about the function h. We try to construct an auxiliary function approximating the exact solution h from below. This new function will be a so-called subsolution. We try to construct a subsolution $\underline{h}$ having the form

$$\underline{h}(r, t) = \begin{cases} \dot{A}(t) f(r/[A(t)]^{1/2}, & r \leqq [A(t)]^{1/2}, \\ 0, & r > [A(t)]^{1/2}. \end{cases} \tag{A13}$$

The above function will be a subsolution if there exist both a sufficiently smooth decreasing function f satisfying the problem

$$s^{-1}(s(f^{1/p})')' = -\tfrac{1}{2} s f' \quad \text{for } s \in (0, 1\rangle \tag{A14}$$

with

$$f(1) = 0 \quad \text{and} \quad \lim_{s \to 1-} [f^{1/p}(s)]' = 0 \tag{A15}$$

and the function A satisfying the differential equation

$$\dot{A} f(1/A^{1/2}) = 1 \quad \text{with } A(0) = 1. \tag{A16}$$

To solve (A14)-(A15) we use the substitution

$$f(s) = w(-\log s). \tag{A17}$$

We reduce (A14) and (A15) to

$$(w^{1/p})'' = \tfrac{1}{2} e^{-2x} w' \quad \text{for } x \geqq 0 \tag{A18}$$

with conditions

$$w(0)=0 \quad \text{and} \quad \lim_{x\to 0+}[w^{1/p}(x)]'=0. \tag{A19}$$

Integrating (A18) twice and using (A19), we get

$$[w(x)]^{1/p}=\int_0^x e^{-2s}\left[\frac{1}{2}+x-s\right]w(s)\,ds \qquad (x\geqq 0). \tag{A20}$$

Substituting $e^{-2px/(1-p)}w(x)$ instead of $w(x)$, we get

$$[w(x)]^{1/p}=\int_0^x k(x-s)w(s)\,ds \tag{A21}$$

where

$$k(x)=[\tfrac{1}{2}+x]\,e^{2x/(1-p)}. \tag{A22}$$

We look for continuous solutions w of (A21) such that $w(x)>0$ for $x>0$. We substitute

$$w=u^p \tag{A23}$$

into (A21) to obtain

$$u(x)=\int_0^x k(x-s)[u(s)]^p\,ds \qquad (p\in(0,1)). \tag{A24}$$

Mathematical considerations concerning the existence of nontrivial solutions to (A24), or more exactly to (A20), are presented in [9].

STABILITY OF TRAVELING WAVEFRONTS FOR THE DISCRETE NAGUMO EQUATION*

B. ZINNER†

Abstract. It has been shown that the discrete Nagumo equation

$$\dot{u}_n = d(u_{n-1} - 2u_n + u_{n+1}) + f(u_n), \qquad n \in \mathbb{Z},$$

has a traveling wavefront solution for sufficiently strong coupling d. In this paper it is shown that such a traveling wavefront is unique (up to a shift in time) and globally stable.

Key words. traveling waves, lower solution technique, myelinated axon, discrete cells

AMS(MOS) subject classifications. 34K20, 35K57

1. Introduction. Consider the infinite system of coupled nonlinear differential equations

$$\dot{u}_n = d(u_{n-1} - 2u_n + u_{n+1}) + f(u_n), \qquad n \in \mathbb{Z} \tag{1}$$

where d is a positive real number.

A typical example for the nonlinearity f is the cubic polynomial $f(x) = x(x-a)(1-x)$, $0 < a < \frac{1}{2}$. Equation (1) is the discrete analogue to the well-known Nagumo equation [5]

$$\frac{\partial u}{\partial t} = D\frac{\partial^2 u}{\partial x^2} + f(u). \tag{2}$$

The discrete Nagumo equation is interesting because it has been used to derive (2) [8] and it has also been proposed as a model for conduction in myelinated nerve axons [1]. The continuous Nagumo equation (2) is well studied [4] and it has been proven that there exist globally stable monotone traveling wavefront solutions.

The analytic approach has been less developed for the discrete than for the continuous Nagumo equation. The first results about the discrete Nagumo equation were concerned with threshold properties, that is, conditions forcing nonconvergence to zero of solutions as time approaches infinity, and bounds on the speed of propagation of a "wave of excitation" [1], [2]. The next results were concerned with wave propagation, that is, with solutions of the form

$$u_n(t) = U(n + ct).$$

In particular, failure of propagation for small d and local stability of traveling wavefronts were shown in [6] and [7].

Then traveling wavefronts were analyzed numerically for certain cubic polynomials f [3]. Only recently has the existence of monotone traveling wavefronts for sufficiently large d been proved in [9] and [10]. It is the purpose of this paper to prove that such traveling wavefronts are globally stable.

By a *traveling wavefront* with *velocity* c, $c > 0$, we mean a solution $\{u_n(t)\}_{n=-\infty}^{\infty}$ of (1) for which there exists $U \in C^1(\mathbb{R}, (0,1))$, $U(-\infty) = 0$, $U(\infty) = 1$, such that $u_n(t) = U(n + ct)$ for all $t \in \mathbb{R}$. If in addition $U'(z) > 0$ for all $z \in \mathbb{R}$, then the wavefront is *monotone*. The following theorem allows f to have several zeros in $(0, 1)$ even though

* Received by the editors September 18, 1989; accepted for publication (in revised form) June 21, 1990.
† Division of Mathematics, 120 Mathematics Annex, Auburn University, Auburn, Alabama 36849-5307.

existence of a monotone traveling wavefront has only been shown for the case where f has exactly one zero in $(0, 1)$.

THEOREM 1.1. *Suppose* $f \in C^1([0,1], \mathbb{R})$, *satisfies*

(i) $f(0) = f(1) = 0$, $f'(0) < 0, f'(1) < 0$,

(ii) $f(u) < 0$ *for* $0 < u < \alpha_0$,

(iii) $f(u) > 0$ *for* $\alpha_1 < u < 1$, $0 < \alpha_0 \leqq \alpha_1 < 1$,

and suppose there exists a monotone traveling wavefront $\{v_n(t)\}$, $v_n(t) = U(n + ct)$. *Then for any solution* $\{u_n(t)\}$ *of* (1) *which satisfies*

$$0 \leqq u_n(0) \leqq 1 \quad \textit{for all integers } n, \quad \textit{and}$$

$$\limsup_{n \to -\infty} u_n(0) < \alpha_0 \leqq \alpha_1 < \liminf_{n \to \infty} u_n(0),$$

there exists a constant s *such that*

$$\lim_{t \to \infty} \left(\sup_{n \in \mathbb{Z}} |u_n(t) - U(n + ct - s)| \right) = 0.$$

The following corollary is a direct consequence of Theorem 1.1.

COROLLARY 1.2. *Suppose* $\{u_n(t)\}$ *and* $\{v_n(t)\}$ *are traveling wavefronts of* (1). *Then there exists a constant* t_0 *such that* $\{u_n(t)\} = \{v_n(t - t_0)\}$. *In particular, there is a unique speed* c *for traveling wavefronts.*

2. Proof of the theorem. We will make use of the following lemma [6, Thms. 4.1, 4.2].

LEMMA 2.1. *If the hypotheses of Theorem* 1.1 *hold, then there are constants* z_1, z_2, q_0, μ_0 (*the last two positive*) *such that*

$$U(n + ct - z_1) - q_0 e^{-\mu_0 t} \leqq u_n(t) \leqq U(n + ct - z_2) + q_0 e^{-\mu_0 t}. \tag{3}$$

Furthermore, if there are constants t_0, z_0, *and* ε *for which*

$$\sup_{n \in \mathbb{Z}} |u_n(t_0) - U(n + ct_0 - z_0)| < \varepsilon,$$

then there is a number $\omega(\varepsilon)$ *with* $\lim_{\varepsilon \to 0} \omega(\varepsilon) = 0$ *such that*

$$\sup_{n \in \mathbb{Z}} |u_n(t) - U(n + ct - z_0)| < \omega(\varepsilon) \quad \textit{for all } t \geqq t_0.$$

Lemma 2.1 says that $\{u_n(t)\}$ is "more or less" bounded between two shifted wavefronts and if $\{u_n(t)\}$ is close to a wavefront U at some instant then it will remain close to U. The main idea for the following proof is the attempt to replace the constants z_1, z_2 in (3) by functions $z_1(t)$, $z_2(t)$ with $\lim_{t \to \infty} z_1(t) = \lim_{t \to \infty} z_2(t)$.

Let

$$w_n^s(t) := u_n(t) - U(n + ct - s),$$

$$A := \left\{ s \in [z_2, z_1] : \limsup_{t \to \infty} \left[\sup_{n \in \mathbb{Z}} w_n^s(t) \right] \leqq 0 \right\}, \quad \textit{and}$$

$$B := \left\{ s \in [z_2, z_1] : \limsup_{t \to \infty} \left[\sup_{n \in \mathbb{Z}} -w_n^s(t) \right] \leqq 0 \right\}.$$

Note that $z_2 \in A$, $z_1 \in B$, and Theorem 1.1 will be proved if we show that $A \cap B \neq \varnothing$.

By assumption (i) of Theorem 1.1 there exist positive constants μ and δ_0 such that

$$f(x) - f(y) \leqq -\mu(x - y) \quad \text{for all } x, y \in [0, \delta_0], \quad \text{and} \tag{4a}$$

$$f(x) - f(y) \leqq -\mu(x - y) \quad \text{for all } x, y \in [1 - \delta_0, 1]. \tag{4b}$$

Choose $\delta \in (0, \delta_0)$, arbitrary. Since $U(-\infty)=0$ and $U(\infty)=1$, we may choose $n_0 \in \mathbb{Z}$ and $n_1 \in \mathbb{Z}$ such that

$$U(n_0 - z_2) \leqq \frac{\delta}{2} \quad \text{and} \quad U(n_1 - z_1) \geqq 1 - \frac{\delta}{2}.$$

Now let $I(t) := \{n \in \mathbb{Z}: n_0 - ct \leqq n \leqq n_1 - ct\}$,

$$A_f := \left\{ s \in [z_2, z_1]: \limsup_{t\to\infty} \left[\sup_{n \in I(t)} w_n^s(t) \right] \leqq 0 \right\},$$

$$B_f := \left\{ s \in [z_2, z_1]: \limsup_{t\to\infty} \left[\sup_{n \in I(t)} -w_n^s(t) \right] \leqq 0 \right\}.$$

LEMMA 2.2. *$A_f = A$ and $B_f = B$.*

Proof. From the definition of A_f, A, B_f, and B it is clear that $A \subset A_f$ and $B \subset B_f$. It suffices to show $A_f \subset A$, since the proof of $B_f \subset B$ is identical.

So suppose $s \in A_f$. Then

$$\limsup_{t\to\infty} \left[\sup_{n \in I(t)} w_n^s(t) \right] \leqq 0$$

and we have to show that

$$\limsup_{t\to\infty} \left[\sup_{n \in \mathbb{Z}} w_n^s(t) \right] \leqq 0,$$

i.e., given $\varepsilon > 0$ there exists T such that

$$w_n^s(t) \leqq \varepsilon \quad \text{for all } n \in \mathbb{Z}, \quad t \geqq T. \tag{5}$$

Fix $\varepsilon > 0$. Then there exists T_0 such that

$$w_n^s(t) \leqq \varepsilon \quad \text{for all } n \in I(t), \quad t \geqq T_0$$

and

$$u_n(t) \notin [\delta, 1-\delta] \quad \text{for all } n \notin I(t), \quad t \geqq T_0. \tag{6}$$

Let $q \in (0, 1)$ be such that

$$d\left(\frac{1}{q} + \frac{1}{q} - 2\right) \leqq \frac{1}{2}\mu. \tag{7}$$

We will show that the existence of a number $T_k \geqq T_0$, $k \in \mathbb{N}_0$, such that

$$w_n^s(t) \leqq \max\{q^k\delta, \varepsilon\} \quad \text{for all } n \in \mathbb{Z}, \quad t \geqq T_k, \tag{8}$$

will imply the existence of $T_{k+1} \geqq T_0$ such that

$$w_n^s(t) \leqq \max\{q^{k+1}\delta, \varepsilon\} \quad \text{for all } n \in \mathbb{Z}, \quad t \geqq T_{k+1}. \tag{9}$$

Note that (9) only needs to be shown for $n \notin I(t)$. Suppose (8) holds and for some index n we have

$$\max\{q^{k+1}\delta, \varepsilon\} \leqq w_n^s(t) \leqq \max\{q^k\delta, \varepsilon\}, \qquad t \geqq T_k. \tag{10}$$

Since u_n and U satisfy (1) we obtain

$$\dot{w}_n^s = d(w_{n-1}^s - 2w_n^s + w_{n+1}^s) + f(u_n) - f(U), \tag{11}$$

which can be rewritten to

$$\dot{w}_n^s = d\left(\frac{w_{n-1}^s}{w_n^s}+\frac{w_{n+1}^s}{w_n^s}-2\right)w_n^s+\frac{f(u_n)-f(U)}{w_n^s}\,w_n^s. \tag{12}$$

From (7), (8), and (10), we deduce

$$d\left(\frac{w_{n-1}^s}{w_n^s}+\frac{w_{n+1}^s}{w_n^s}-2\right)\leqq\frac{1}{2}\mu \tag{13}$$

and from (4a), (4b), and (6) we get

$$\frac{f(u_n)-f(U)}{w_n^s}\leqq-\mu. \tag{14}$$

Finally, from (12), (13), and (14) we estimate

$$\dot{w}_n^s\leqq-\tfrac{1}{2}\mu w_n^s. \tag{15}$$

With Gronwall's lemma we deduce (9) where T_{k+1} is determined by

$$\exp\left(-\tfrac{1}{2}\mu(T_{k+1}-T_k)\right)=q.$$

The claim (5) then follows by induction. □

Because of Lemma 2.2 it now suffices to show that $A_f\cap B_f\neq\varnothing$. To reach a contradiction suppose $A_f\cap B_f=\varnothing$.

We consider A_f and B_f as topological subspaces of the interval $[z_2, z_1]$. It is easy to check that B_f is closed and therefore we may pick $s\in\partial B_f\backslash A_f$. Since $s\in\partial B_f$ there exist sequences $\{t_k\}_{k=1}^{\infty}$, $\lim_{k\to\infty}t_k=\infty$, $\{n_k\}_{k=1}^{\infty}$, $n_k\in I(t_k)$, such that

$$\lim_{k\to\infty}w_{n_k}^s(t_k)=0. \tag{16}$$

Since $s\notin A_f\cap B_f=A\cap B$ there exists $\varepsilon>0$ such that

$$\sup_{n\in\mathbb{Z}}|w_n^s(t_k)|\geqq\varepsilon \tag{17}$$

in view of Lemma 2.1.

It follows from the definition of $I(t)$ that there exists T_0 such that

$$|w_n^s(t)|<\delta\quad\text{for all } n\notin I(t),\quad t\geqq T_0. \tag{18}$$

Either

$$\begin{aligned}&\lim_{k\to\infty}w_{m_k}^s(t_k)=0\text{ implies }\lim_{k\to\infty}\left(|w_{m_k-1}^s(t_k)|+|w_{m_k+1}^s(t_k)|\right)=0\\&\text{holds for all sequences }\{m_k\}_{k=1}^{\infty},\ m_k\in I(t_k),\end{aligned} \tag{19}$$

or (19) does not hold.

If (19) holds, then it follows from (16) and by induction that $\lim_{k\to\infty}\sup_{n\in I(t_k)}|w_n^s(t_k)|=0$. Together with (18) this implies that there exists $K\in\mathbb{N}$ such that $\sup_{n\in\mathbb{Z}}|w_n^s(t_k)|<\delta$ for all $k\geqq K$. Since δ may be chosen to be less than ε, this contradicts (17).

Therefore (19) does not hold and hence there exist a subsequence of $\{t_k\}$, which we also denote by $\{t_k\}$, a sequence $\{m_k\}$, $m_k\in I(t_k)$, and $\varepsilon_0>0$ such that

$$\lim_{k\to\infty}w_{m_k}^s(t_k)=0\quad\text{and}\quad|w_{m_k-1}^s(t_k)|+|w_{m_k+1}^s(t_k)|\geqq\varepsilon_0. \tag{20}$$

It follows from (20) and $s \in \partial B_f \subset B$ that there exists $K \in \mathbb{N}$ such that

$$-2w^s_{m_k}(t_k) > -\frac{\varepsilon_0}{4},$$

$$w^s_{m_k-1}(t_k) + w^s_{m_k+1}(t_k) > \frac{\varepsilon_0}{2},$$

and

$$f(u_{m_k}(t_k)) - f(U(m_k - ct_k - s)) > -\frac{d\varepsilon_0}{8}$$

holds for all $k \geqq K$. Therefore (11) implies

$$\dot{w}^s_{m_k}(t_k) > \frac{d\varepsilon_0}{8} \quad \text{for all } k \geqq K. \tag{21}$$

It also follows from (11) that there exists $M > 0$ such that

$$\ddot{w}_n(t) < M \quad \text{for all } n \in \mathbb{N} \text{ and } t \geqq 0,$$

which implies together with (21) that there exists $h > 0$ such that

$$\dot{w}_{m_k}(t) > \frac{d\varepsilon_0}{16} \quad \text{for all } t \in [t_k - h, t_k], \quad k \geqq K.$$

Therefore $-w^s_{m_k}(t_k - h) > (hd\varepsilon_0/16) - w^s_{m_k}(t_k)$ for all $k \geqq K$ which implies together with (20) that

$$\limsup_{t \to \infty} \sup_{m \in \mathbb{N}} -w^s_n(t) \geqq \frac{hd\varepsilon_0}{16} > 0,$$

in contradiction to $s \in B_f$.

AN OSCILLATION METHOD FOR FOURTH-ORDER, SELF-ADJOINT, TWO-POINT BOUNDARY VALUE PROBLEMS WITH NONLINEAR EIGENVALUES*

LEON GREENBERG†

Abstract. An oscillation method is presented for finding the eigenvalues of a fourth-order, self-adjoint, two-point boundary value problem. The eigenvalue may occur nonlinearly in the differential equation, and may occur in the boundary conditions. The method can approximate the nth eigenvalue without consideration of other eigenvalues. It provides an a posteriori error estimate for the approximate eigenvalue.

Key words. eigenvalue, eigenfunction, self-adjoint, oscillation, energy inner product, Wronskian, Sturm-Liouville equation

AMS(MOS) classification. 65L15

1. Introduction. Physical problems often lead to linear two-point boundary value problems in which the eigenvalue occurs nonlinearly in the differential equation, and may occur in the boundary conditions. Typically, this type of equation arises when we linearize a nonlinear equation and look for normal modes. Examples of such problems occur in acoustics (Porter and Reiss [10]), mechanics of beams (Roseau [12]), and hydrodynamics (Drazin and Reid [5], Chandrasekhar [2], [3]).

A classical example of this kind of problem is a Sturm-Liouville equation

$$\begin{aligned} &(p(x,\lambda)u')'+q(x,\lambda)u=0 \quad \text{for } 0<x<1,\\ &\alpha_0(\lambda)u(0)+\beta_0(\lambda)u'(0)=0,\\ &\alpha_1(\lambda)u(1)+\beta_1(\lambda)u'(1)=0. \end{aligned} \tag{1.1}$$

In [8], Greenberg and Babuška studied the problem (1.1) by means of a function $N(\lambda)$, which is related to the number of oscillations of a solution of the differential equation. Under suitable conditions, (1.1) has $N(\lambda'')-N(\lambda')$ eigenvalues in the interval $[\lambda', \lambda'')$. This enables us to decide whether or not a given interval $[\lambda', \lambda'')$ contains an eigenvalue. Furthermore, if $N(\lambda')\leqq n-1$ and $N(\lambda'')\geqq n$, then the nth eigenvalue satisfies $\lambda'\leqq\lambda_n<\lambda''$. Thus we can determine if λ_n lies in a given interval. By applying the bisection method to $N(\lambda)$, we can approximate the nth eigenvalue without consideration of other eigenvalues, and with an a posteriori error estimate.

In this paper, the above results will be extended to fourth-order boundary value problems. $N(\lambda)$ will be related to the oscillations of the Wronskian of two solutions of the differential equation. In [8], the analysis for the second-order problem was based on the Sturm comparison and oscillation theorems and on Sturm sequences for tridiagonal matrices. These methods are not applicable to the fourth-order problem. An entirely different analysis is given here, based on variational properties of eigenvalues and inertial properties of the energy inner product. It seems likely that these methods can be applied to higher-order problems.

We shall consider two types of fourth-order problems: A scalar equation

$$\text{(I)} \qquad L(u;\lambda)=(p(x,\lambda)u'')''-(q(x,\lambda)u')'+r(x,\lambda)u=0 \quad \text{for } 0<x<1$$

* Received by the editors December 11, 1989; accepted for publication (in revised form) August 2, 1990.
† Mathematics Department, University of Maryland, College Park, Maryland 20742.

with boundary conditions of the form

$$\mathrm{BC}_0(u;\lambda)=\begin{bmatrix}\alpha_{01}(\lambda) & \alpha_{02}(\lambda) & \alpha_{03}(\lambda) & \alpha_{04}(\lambda)\\ \beta_{01}(\lambda) & \beta_{02}(\lambda) & \beta_{03}(\lambda) & \beta_{04}(\lambda)\end{bmatrix}\begin{bmatrix}u(0)\\ u'(0)\\ u''(0)\\ u'''(0)\end{bmatrix}=0$$

and

$$\mathrm{BC}_1(u;\lambda)=\begin{bmatrix}\alpha_{11}(\lambda) & \alpha_{12}(\lambda) & \alpha_{13}(\lambda) & \alpha_{14}(\lambda)\\ \beta_{11}(\lambda) & \beta_{12}(\lambda) & \beta_{13}(\lambda) & \beta_{14}(\lambda)\end{bmatrix}\begin{bmatrix}u(1)\\ u'(1)\\ u''(1)\\ u'''(1)\end{bmatrix}=0;$$

and a vector equation

$$\text{(II)}\qquad L(u;\lambda)=-(P(x,\lambda)u'+Q(x,\lambda)u)'+Q^T(x,\lambda)u'+R(x,\lambda)u=0 \quad \text{for } 0<x<1$$

with boundary conditions of the form

$$\mathrm{BC}_0(u;\lambda)=\begin{bmatrix}\alpha_{01}(\lambda) & \alpha_{02}(\lambda) & \alpha_{03}(\lambda) & \alpha_{04}(\lambda)\\ \beta_{01}(\lambda) & \beta_{02}(\lambda) & \beta_{03}(\lambda) & \beta_{04}(\lambda)\end{bmatrix}\begin{bmatrix}u_1(0)\\ u_2(0)\\ u_1'(0)\\ u_2'(0)\end{bmatrix}=0$$

and

$$\mathrm{BC}_1(u;\lambda)=\begin{bmatrix}\alpha_{11}(\lambda) & \alpha_{12}(\lambda) & \alpha_{13}(\lambda) & \alpha_{14}(\lambda)\\ \beta_{11}(\lambda) & \beta_{12}(\lambda) & \beta_{13}(\lambda) & \beta_{14}(\lambda)\end{bmatrix}\begin{bmatrix}u_1(1)\\ u_2(1)\\ u_1'(1)\\ u_2'(1)\end{bmatrix}=0.$$

In problem (II) $u(x)=(u_1(x), u_2(x))^T$ and $P(x,\lambda)$, $Q(x,\lambda)$, and $R(x,\lambda)$ are 2×2 matrices. (Note that $Q^T(x,\lambda)$ denotes the transpose of $Q(x,\lambda)$.) The boundary conditions are required to be self-adjoint. This will be discussed in § 3.

We shall need to make certain assumptions about the coefficient functions in problems (I) and (II). As indicated below, these occur in several categories. The standard assumptions will always be implicitly assumed. The other assumptions will be explicitly assumed when needed. (The monotonicity and limit assumptions are similar to assumptions in the Sturm oscillation theorem for second-order problems.) The reader may wish to skip over or scan through these assumptions at first. The monotonicity and limit assumptions will only be used in § 4. In the following, λ will vary in an interval (Λ_1, Λ_2). We do not exclude the possibilities $\Lambda_1=-\infty$ or $\Lambda_2=\infty$.

Standard assumptions for problem (I).

(S1) $p(x,\lambda)$, $(\partial/\partial x)p(x,\lambda)$, $(\partial^2/\partial x^2)p(x,\lambda)$, $q(x,\lambda)$, $(\partial/\partial x)q(x,\lambda)$, and $r(x,\lambda)$ are continuous functions on $[0,1]\times(\Lambda_1,\Lambda_2)$.

(S2) $p(x,\lambda)\geqq k>0$ for $0\leqq x\leqq 1$, $\Lambda_1<\lambda<\Lambda_2$.

Standard assumptions for problem (II).

(S1a) $P(x,\lambda)$, $(\partial/\partial x)P(x,\lambda)$, $Q(x,\lambda)$, $(\partial/\partial x)Q(x,\lambda)$, and $R(x,\lambda)$ are continuous matrix functions on $[0,1]\times(\Lambda_1,\Lambda_2)$.

(S1b) $P(x, \lambda) = P^T(x, \lambda)$ and $R(x, \lambda) = R^T(x, \lambda)$ for $0 \leqq x \leqq 1$, $\Lambda_1 < \lambda < \Lambda_2$.

(S2) There is a number $k > 0$ such that for any vector $\xi = (\xi_1, \xi_2)^T$, $\xi^T P(x, \lambda)\xi \geqq k(\xi_1^2 + \xi_2^2)$ for $0 \leqq x \leqq 1$, $\Lambda_1 < \lambda < \Lambda_2$.

Standard assumptions for problems (I) *and* (II).

(S3) The coefficients in the boundary conditions are continuous functions of λ on (Λ_1, Λ_2).

(S4) At each endpoint $x = 0, 1$, the two given boundary conditions are linearly independent for $\Lambda_1 < \lambda < \Lambda_2$.

(S5) Any essential boundary conditions have constant coefficients (see Remark 2, below).

Remark 1. We do not need the full strength of assumption (S1). It would be enough to assume that these functions are piecewise smooth in x (up to the indicated degree of smoothness), and continuous in λ. We assume (S1) for simplicity.

Remark 2. Regarding (S5), recall that an essential boundary condition for (I) involves u and u', but no higher derivatives. An essential boundary condition for (II) involves u_1 and u_2, but no derivatives. The relevant Hilbert space for problem (I) (respectively, (II)) is a subspace of the Sobolev space $H^2[0, 1]$ (respectively, $H^1[0, 1] \times H^1[0, 1]$) that depends on the essential boundary conditions. We have assumed condition (S5) in order to prevent this space from changing as λ varies. This will enable us to apply well-known monotonicity properties of eigenvalues.

The energy inner product for (I) is of the form

$$B(u, v; \lambda) = -\beta_0(u, v; \lambda) + \beta_1(u, v; \lambda) + \int_0^1 [p(x, \lambda)u''v'' + q(x, \lambda)u'v' + r(x, \lambda)uv]\, dx. \tag{1.2}$$

Here the inner product $\beta_i(u, v; \lambda)$ (for $i = 0, 1$) arises from the natural boundary conditions at the endpoint $x = i$, and has the form

$$\beta_i(u, v; \lambda) = a_i(\lambda)u(i)v(i) + b_i(\lambda)(u(i)v'(i) + u'(i)v(i)) + c_i(\lambda)u'(i)v'(i). \tag{1.3}$$

For problem (II), we shall use the "dot product" notation: $\xi \cdot \eta = \xi_1\eta_1 + \xi_2\eta_2$, where $\xi = (\xi_1, \xi_2)^T$ and $\eta = (\eta_1, \eta_2)^T$. The energy inner product for (II) has the form

$$B(u, v; \lambda) = -\beta_0(u, v; \lambda) + \beta_1(u, v; \lambda) + \int_0^1 [P(x, \lambda)u' \cdot v' + Q(x, \lambda)u \cdot v' + Q(x, \lambda)v \cdot u' + R(x, \lambda)u \cdot v]\, dx, \tag{1.4}$$

where

$$\beta_i(u, v; \lambda) = a_i(\lambda)u_1(i)v_1(i) + b_i(\lambda)(u_1(i)v_2(i) + u_2(i)v_1(i)) + c_i(\lambda)u_2(i)v_2(i). \tag{1.5}$$

(These inner products will be discussed in § 3, where we shall classify the boundary conditions.)

Please note that the inner products in this paper are often indefinite. For a linear eigenvalue problem, the number of negative eigenvalues equals the negative index of inertia of the energy inner product $B(u, v)$.

We shall assume monotonicity conditions on the coefficients of (I) and (II) in order to force $B(u, u; \lambda)$ to be a strictly decreasing function of λ for each $u \neq 0$.

Monotonicity assumptions for (I).

(M1) For each x, $r(x, \lambda)$ is a strictly decreasing function of λ.

(M2) For each x, $p(x, \lambda)$ and $q(x, \lambda)$ are nonincreasing functions of λ.

Monotonicity assumptions for (II).

(M1) For each x and for $\xi = (\xi_1, \xi_2)^T \neq 0$, $R(x, \lambda)\xi \cdot \xi$ is a strictly decreasing function of λ.

(M2) For each x and for any vectors $\xi = (\xi_1, \xi_2)^T$, $\eta = (\eta_1, \eta_2)^T$, $P(x, \lambda)\xi \cdot \xi + 2Q(x, \lambda)\eta \cdot \xi + R(x, \lambda)\eta \cdot \eta$ is a nonincreasing function of λ.

Monotonicity assumptions for (I) *and* (II).

(M3) For each vector $\xi = (\xi_1, \xi_2)^T$, the boundary term $\beta_0 = a_0(\lambda)\xi_1^2 + 2b_0(\lambda)\xi_1\xi_2 + c_0(\lambda)\xi_2^2$ is a nondecreasing function of λ.

(M4) For each vector $\xi = (\xi_1, \xi_2)^T$, the boundary term $\beta_1 = a_1(\lambda)\xi_1^2 + 2b_1(\lambda)\xi_1\xi_2 + c_1(\lambda)\xi_2^2$ is a nonincreasing function of λ.

Remark 3. If $A(\lambda)$ is an $n \times n$ symmetric matrix whose coefficients $a_{ij}(\lambda)$ are differentiable functions of λ, and $\xi = (\xi_1, \xi_2, \cdots, \xi_n)^T \neq 0$, then $\xi^T A(\lambda)\xi$ is a strictly decreasing function of λ if $(d/d\lambda)A(\lambda)$ is negative definite. (If $A(\lambda)$ is not differentiable, an analogous condition is that $A(\lambda'') - A(\lambda')$ be negative definite for $\lambda' < \lambda''$.) Suppose that the coefficients in (I) and (II) are differentiable functions of λ. Then (M1) is satisfied for (II) if $(\partial/\partial\lambda)R(x, \lambda)$ is negative definite. (M2) is satisfied for (II) if $(\partial/\partial\lambda)\left[\begin{smallmatrix} P & Q \\ Q^T & R \end{smallmatrix}\right]$ is negative semidefinite. (M3) is satisfied if $(d/d\lambda)\left[\begin{smallmatrix} a_0 & b_0 \\ b_0 & c_0 \end{smallmatrix}\right]$ is positive semidefinite. (M4) is satisfied if $(d/d\lambda)\left[\begin{smallmatrix} a_1 & b_1 \\ b_1 & c_1 \end{smallmatrix}\right]$ is negative semidefinite.

The main result in this paper is Theorem 4.2, which indicates how $N(\lambda)$ can be used to locate eigenvalues. It is an analogue for fourth-order problems of Theorem 2.1 in [8], which deals with second-order problems. The condition (L1) below will be needed to ensure that $B(u, v; \lambda)$ is positive definite when λ is near Λ_1. In a companion paper [7], an existence theorem, similar to the Sturm oscillation theorem, will be proved. The condition (L2) below will be needed to guarantee the existence of infinitely many eigenvalues. For (I), we can place the burden for this either on $r(x, \lambda)$ or $q(x, \lambda)$, and so we shall give two possible conditions for each of these cases. We shall use the following notation:

$$f^*(\lambda) = \max_{0 \leqq x \leqq 1} f(x, \lambda), \qquad f_*(\lambda) = \min_{0 \leqq x \leqq 1} f(x, \lambda). \tag{1.6}$$

Limit assumptions for (I).

(L1) Either (a) $\lim_{\lambda \to \Lambda_1} r_*(\lambda) = \infty$ or (b) $\lim_{\lambda \to \Lambda_1} q_*(\lambda) = \infty$ and there exists λ_+ in (Λ_1, Λ_2) such that $r_*(\lambda_+) > 0$, $a_0(\lambda_+) \leqq 0$, and $a_1(\lambda_+) \geqq 0$.[1]

(L2) Either (a) $\lim_{\lambda \to \Lambda_2} r^*(\lambda) = -\infty$ or (b) $\lim_{\lambda \to \Lambda_2} q^*(\lambda) = -\infty$.

In problem (II), let $R(x, \lambda)$ have eigenvalues $\mu_R(x, \lambda) \leqq \nu_R(x, \lambda)$, and let $\mu_R(\lambda) = \min_{0 \leqq x \leqq 1} \mu_R(x, \lambda)$, $\nu_R(\lambda) = \max_{0 \leqq x \leqq 1} \nu_R(x, \lambda)$. The matrix $\left[\begin{smallmatrix} 0 & Q(x, \lambda) \\ Q^T(x, \lambda) & 0 \end{smallmatrix}\right]$ has eigenvalues $\pm\mu_Q(x, \lambda)$ and $\pm\nu_Q(x, \lambda)$, where $0 \leqq \mu_Q(x, \lambda) \leqq \nu_Q(x, \lambda)$. Let $\nu_Q(\lambda) = \max_{0 \leqq x \leqq 1} \nu_Q(x, \lambda)$.

[1] The functions $a_0(\lambda)$ and $a_1(\lambda)$ in (L1b) are coefficients in the boundary terms $\beta_0(u, v; \lambda)$ and $\beta_1(u, v; \lambda)$ in (1.2) and (1.3).

Limit assumptions for (II).

(L1) $$\lim_{\lambda \to \Lambda_1} \frac{\mu_R(\lambda)}{1+\nu_Q(\lambda)^2} = \infty.$$

(L2) $$\lim_{\lambda \to \Lambda_2} \frac{\nu_R(\lambda)}{1+\nu_Q(\lambda)} = -\infty.$$

Remark 4. For (II), the denominator in (L1) is $1+\nu_Q(\lambda)^2$ rather than $\nu_Q(\lambda)^2$ in order to counteract the effect of small $\nu_Q(\lambda)$, and similarly for (L2). If $\nu_Q(\lambda)$ is bounded, then (L1) may be replaced by $\lim_{\lambda \to \Lambda_1} \mu_R(\lambda) = \infty$, and (L2) replaced by $\lim_{\lambda \to \Lambda_2} \nu_R(\lambda) = -\infty$.

The construction of the function $N(\lambda)$ begins in § 2, where we consider linear eigenvalue problems of the form $Lu = \lambda u$. Here λ does not appear in the coefficients of L or the boundary conditions. A number $N_0(L)$ is defined, using the Wronskian $w(x)$ of two solutions of the differential equation $Lu = 0$. $N_0(L)$ is related to the zeros of $w(x)$. Theorem 2.2 asserts that $N_0(L)$ equals the number of negative eigenvalues of L if L has Dirichlet boundary conditions at $x = 1$. This theorem was proved (for problem (II)) by Morse [9], in the context of extremal curves in the calculus of variations. It is also one of the main theorems in Edwards [6], where it is proved by topological methods. The proof given in § 2 is simpler and more direct than previous proofs. It uses only standard tools from eigenvalue theory.

In order to deal with operators that do not have Dirichlet boundary conditions, a "correction term" $\sigma(L)$ is defined, using an orthogonal decomposition of the energy inner product. The integer $\sigma(L)$ can have values 0, 1, or 2. Theorem 2.5 asserts that the number $N(L) = N_0(L) + \sigma(L)$ equals the number of negative eigenvalues of L. This theorem is due to Edwards [6]. However, it should be mentioned that Edwards never explicitly addresses the boundary conditions, and so $\sigma(L)$ cannot be related to the coefficients of the boundary value problem. Here we emphasize the detailed calculation of formulas, which enables numerical computation.

In § 3 we classify the separated, self-adjoint boundary conditions for (I) and (II) into four types (for each problem). The inner products $\beta_0(u, v)$ and $\beta_1(u, v)$ are calculated for each type of boundary condition. We also calculate the inner product $B_s(u, v)$, which is used to compute $\sigma(L)$.

By its definition in (2.22), $B_s(u, v)$ is an integral. But an important feature of our method is that $B_s(u, v)$ and $\sigma(L)$ depend only on values (of u, v their derivatives, and the coefficients of L) at $x = 1$. In this respect, $\sigma(L)$ is analogous to the term $\sigma(\lambda)$ in [8], for Sturm–Liouville problems. The main purpose of § 3 is to calculate $B_s(u, v)$ and $\sigma(L)$ for the different types of boundary conditions.

In § 4, we turn to the case where the operator L and the boundary conditions depend on λ. Let L_λ denote the operator L for fixed λ, and let $\mu_k(\lambda)$ be the kth eigenvalue of L_λ. The monotonicity assumptions imply that the $\mu_k(\lambda)$ are strictly decreasing functions of λ. The zeros of these functions are the eigenvalues of L. These are the key facts that allow the theorems of § 2 to carry over to the λ-dependent case. We define $N(\lambda) = N(L_\lambda)$, and Theorem 4.2 shows that $N(\lambda)$ has properties similar to those proved in [8] for Sturm–Liouville problems.

In § 5 we discuss properties of the Wronskians that are used to calculate $N(\lambda)$. Our method requires the calculation of $n(x; \lambda) = \text{nullity } W(x; \lambda)$, where $W(x; \lambda)$ is a certain Wronskian matrix. The integers $n(x; \lambda)$ can be 0, 1, or 2, and $n(x_0; \lambda) > 0$ if and only if x_0 is a zero of the Wronskian determinant $w(x) = w(x; \lambda) = \det W(x; \lambda)$. An important fact established in § 5 is that $w(x)$ changes sign at x_0 if $n(x_0; \lambda) = 1$, but

does not change sign if $n(x_0; \lambda) = 2$. This enables us to distinguish the two cases numerically.

2. Linear eigenvalue problems. In this section, we shall consider differential operators L of types (I) and (II) in the case that the coefficients (in L and in the boundary conditions) do not depend on λ. Our main objective in this section is to prove two formulas (Theorems 2.2 and 2.5) for the number of negative eigenvalues of L.

Let $H^k[a, b]$ be the Sobolev space of functions $u(x)$ that have derivatives $u^{(j)}(x) \in L^2[a, b]$ for $0 \leqq j \leqq k$. The basic Hilbert space for (I) is

$$H = \{u \in H^2[0, 1] \mid u \text{ satisfies the essential boundary conditions at } x = 0, 1\}. \tag{2.1}$$

The basic Hilbert space for (II) is

$$H = \{u \in H^1[0, 1] \times H^1[0, 1] \mid u \text{ satisfies the essential boundary conditions at } x = 0, 1\}. \tag{2.2}$$

The energy inner products in these spaces are given in (1.2) and (1.4). (Note that the above spaces are the relevant Hilbert spaces for (I) and (II) whether or not the coefficients depend on λ. The standard assumption (S5) implies that these spaces do not change when λ varies. In the present section, the operator L and the energy inner product B do not depend on λ.) Let $\|u\|$ denote the norm $(\int_0^y u(x)^2\,dx)^{1/2}$ in $L^2[0, y]$. The following estimates are immediate consequences of the fundamental theorem of calculus and Schwarz's inequality.

LEMMA 2.1. *Let $u(x)$ be a function in $H^1[0, y]$ such that $u(x_0) = 0$ for some $x_0 \in [0, y]$. Then*

(1) $u(x)^2 \leqq y\|u'\|^2$ *for* $0 \leqq x \leqq y$, *and*

(2) $\|u\| \leqq y\|u'\|$.

DEFINITION 2.1. Let L be an operator of type (I) or (II), where we assume that the coefficients in L and in the boundary conditions do not depend on λ. For $0 < y \leqq 1$, let $L|_{[0,y]}$ denote the operator L restricted to the interval $[0, y]$, with the given boundary conditions $BC_0(u) = 0$ at $x = 0$, and Dirichlet boundary conditions at $x = y$. (Recall that Dirichlet conditions for problem (I) are $u(y) = u'(y) = 0$, and for problem (II) are $u_1(y) = u_2(y) = 0$.)

THEOREM 2.1. *Let $\lambda_1(y)$ be the smallest eigenvalue of $L|_{[0,y]}$. Then* $\lim_{y \to 0} \lambda_1(y) = \infty$.

Proof. We shall use the formula

$$\lambda_1(y) = \min_{u \in H, u \neq 0} \frac{B(u, u)}{\|u\|^2}, \tag{2.3}$$

where the Hilbert space H, energy inner product B, and norm $\|u\|$ have all been restricted to the interval $[0, y]$ (and $u \in H$ is required to satisfy Dirichlet conditions at $x = y$). Thus, for example, $\|u\|^2 = \int_0^y u(x)^2\,dx$.

For (I), the energy inner product is

$$B(u, u) = -\beta_0(u, u) + \int_0^y [p(x)u''(x)^2 + q(x)u'(x)^2 + r(x)u(x)^2]\,dx, \tag{2.4}$$

where

$$\beta_0(u) = a_0 u(0)^2 + 2b_0 u(0)u'(0) + c_0 u'(0)^2. \tag{2.5}$$

(The term $\beta_y(u, u)$ is absent because we have Dirichlet conditions at $x = y$.) Using the notation $f_* = \min_{0\leqq x\leqq 1} f(x)$, and recalling that $p(x) \geqq k > 0$, we have

$$B(u, u) \geqq -\beta_0(u, u) + k\|u''\|^2 + q_*\|u'\|^2 + r_*\|u\|^2. \tag{2.6}$$

By Lemma 2.1,

$$\|u'\| \leqq y\|u''\|, \qquad \|u\| \leqq y^2\|u''\|, \tag{2.7}$$

$$|\beta_0(u, u)| \leqq (|a_0|y^3 + 2|b_0|y^2 + |c_0|y)\|u''\|^2. \tag{2.8}$$

Therefore,

$$\frac{B(u, u)}{\|u\|^2} \geqq \frac{(k - \alpha y - \beta y^2 - \gamma y^3 - \delta y^4)\|u''\|^2}{y^4\|u''\|^2}, \tag{2.9}$$

where $\alpha = |c_0|$, $\beta = |q_*| + 2|b_0|$, $\gamma = |a_0|$, and $\delta = |r_*|$. This implies that

$$\lambda_1(y) \geqq \frac{(k - \alpha y - \beta y^2 - \gamma y^3 - \delta y^4)}{y^4}, \tag{2.10}$$

and so $\lim_{y\to 0} \lambda_1(y) = \infty$. This proves the theorem for (I).

For (II), the energy inner product is

$$B(u, u) = -\beta_0(u, u) + \int_0^y [P(x)u' \cdot u' + 2Q(x)u \cdot u' + R(x)u \cdot u]\, dx, \tag{2.11}$$

where

$$\beta_0(u, u) = a_0 u_1(0)^2 + 2b_0 u_1(0)u_2(0) + c_0 u_2(0)^2. \tag{2.12}$$

The matrix $\begin{bmatrix} 0 & Q(x) \\ Q^T(x) & 0 \end{bmatrix}$ has eigenvalues $\pm\mu_Q(x)$ and $\pm\nu_Q(x)$, where $0 \leqq \mu_Q(x) \leqq \nu_Q(x)$. Let $\nu_Q = \max_{0\leqq x\leqq 1} \nu_Q(x)$. Then, for any $\varepsilon > 0$,

$$2|Q(x)u \cdot u'| = 2\left| Q(x)\left(\frac{u}{\varepsilon}\right) \cdot (\varepsilon u') \right| \leqq \nu_Q\left(\frac{u \cdot u}{\varepsilon^2} + \varepsilon^2 u' \cdot u'\right).$$

Let $\mu_R(x)$ be the smallest eigenvalue of $R(x)$, and $\mu_R = \min_{0\leqq x\leqq 1} \mu_R(x)$. Then

$$R(x)u \cdot u \geqq \mu_R u \cdot u.$$

Recall that $P(x)u' \cdot u' \geqq ku' \cdot u'$, where $k > 0$. The above remarks imply that

$$B(u, u) \geqq -\beta_0(u, u) + \int_0^y \left[(k - \varepsilon^2\nu_Q)u' \cdot u' + \left(\mu_R - \frac{\nu_Q}{\varepsilon^2}\right) u \cdot u \right] dx. \tag{2.13}$$

Let $\|u\|^2 = \int_0^y u \cdot u\, dx = \|u_1\|^2 + \|u_2\|^2$, and similarly $\|u'\|^2 = \int_0^y u' \cdot u'\, dx = \|u_1'\|^2 + \|u_2'\|^2$. Lemma 2.1 implies that $\|u\|^2 \leqq y^2\|u'\|^2$. Therefore,

$$B(u, u) \geqq -\beta_0(u, u) + \left[(k - \varepsilon^2\nu_Q) - \left| \mu_R - \frac{\nu_Q}{\varepsilon^2} \right| y^2 \right] \|u'\|^2. \tag{2.14}$$

We can estimate $\beta_0(u, u)$ as in (I) to obtain

$$|\beta_0(u, u)| \leqq (|a_0| + 2|b_0| + |c_0|)y\|u'\|^2. \tag{2.15}$$

Therefore,

$$B(u, u) \geqq (\alpha - \beta y - \gamma y^2)\|u'\|^2, \tag{2.16}$$

where $\alpha = k - \varepsilon^2\nu_Q$, $\beta = |a_0| + 2|b_0| + |c_0|$, and $\gamma = |\mu_R - (\nu_Q/\varepsilon^2)$. Now choose ε small enough so that $k - \varepsilon^2\nu_Q > 0$, and the proof concludes as for (I). □

Remark. Inequalities (2.9) and (2.16) show that the Rayleigh quotient has a lower bound, and so the eigenvalues are bounded from below on any interval $[0, y]$. This is a well-known property of elliptic equations.

DEFINITION 2.2. Let L be a differential operator of type (I) or (II) on the interval $[0, 1]$. (We assume that the coefficients in L and the boundary conditions do not depend on λ.) For a given number λ_0, let u, v be linearly independent solutions of $Lz = \lambda_0 z$ that satisfy the boundary conditions at $x = 0$. Let $W(x) = W(x; L, \lambda_0) = W[u, v](x; L, \lambda_0)$ be the Wronskian matrix, and $w(x) = w(x; L, \lambda_0) = w[u, v](x; L, \lambda_0)$ the Wronskian determinant. Thus, for problem (I), $W(x) = \begin{bmatrix} u & v \\ u' & v' \end{bmatrix}$, and for problem (II), $W(x) = \begin{bmatrix} u_1 & v_1 \\ u_2 & v_2 \end{bmatrix}$. In each case, $w(x) = \det W(x)$.

Please note that these Wronskian matrices and determinants have size 2×2. This is in contrast to the standard practice for a fourth-order problem, where four independent solutions are used, so that the Wronskians have size 4×4.

We now define the following functions:

$$n(x; L, \lambda_0) = \text{nullity } W(x) = 2 - \text{rank } W(x), \tag{2.17}$$

$$N_0(L, \lambda_0) = \sum_{0<x<1} n(x; L, \lambda_0), \tag{2.18}$$

$$N_0(L) = N_0(L, 0). \tag{2.19}$$

Remark. The integer $n(x; L, \lambda_0)$ can be 0, 1, or 2. Moreover, there can be only finitely many points $x \in (0, 1)$ such that $n(x; L, \lambda_0) > 0$. (This will be verified in the proof of the following theorem.) Thus, the right-hand side of (2.18) is a finite sum.

THEOREM 2.2. *Let L be a differential operator of type* (I) *or* (II). (*We assume that the coefficients in L and in the boundary conditions do not depend on λ.*) *Suppose that L has Dirichlet boundary conditions at $x = 1$. Then L has exactly $N_0(L, \lambda_0)$ eigenvalues* (*counting multiplicity*) *that are less than λ_0. In particular, L has $N_0(L)$ negative eigenvalues.*

Proof. For $0 < y \leqq 1$, consider the restricted operator $L|_{[0,y]}$ defined in Definition 2.1. Let u, v be linearly independent solutions of $Lz = \lambda_0 z$ that satisfy the boundary conditions at $x = 0$ (as in Definition 2.2). The given number λ_0 is an eigenvalue of $L|_{[0,y]}$ if and only if there exist constants a, b (not both zero) such that $z = au + bv$ satisfies the Dirichlet conditions at $x = y$. Such constants exist if and only if the Wronskian $w[u, v](y; L, \lambda_0) = 0$. The integer $n(y; L, \lambda_0)$ is the multiplicity of the eigenvalue λ_0 for $L|_{[0,y]}$.

Let $\lambda_k(y)$ be the kth eigenvalue of $L|_{[0,y]}$. Then $n(y; L, \lambda_0) > 0$ if and only if $\lambda_k(y) = \lambda_0$ for some k. Furthermore, $n(y; L, \lambda_0)$ is the number of functions $\lambda_k(y)$ (i.e., the number of indices k) such that $\lambda_k(y) = \lambda_0$.

It is well known that $\lambda_k(y)$ is a continuous, strictly decreasing function of y. (See, for example, Weinberger [13].) Therefore, for each k, there can be at most one y such that $\lambda_k(y) = \lambda_0$. Theorem 2.1 implies that all of the functions $\lambda_k(y)$ decrease from ∞ to $\lambda_k(1)$ as y varies from 0 to 1. Therefore there exists $y \in (0, 1)$ such that $\lambda_k(y) = \lambda_0$ if and only if $\lambda_k(1) < \lambda_0$. But the numbers $\lambda_k(1)$ are the eigenvalues of L. Therefore, there are only finitely many indices k such that $\lambda_k(1) < \lambda_0$. This shows that only finitely many terms $n(x; L, \lambda_0)$ in (2.18) can be nonzero. It also shows that $N_0(L, \lambda_0)$ equals the number of eigenvalues $\lambda_k(1)$ that are less than λ_0. □

The formula given in Definition 2.2 and Theorem 2.2 is the first objective of this section. It deals with the case where L has Dirichlet conditions at $x = 1$. Next we shall find a formula that deals with more general boundary conditions. A "correction term" $\sigma(L)$ will be constructed that depends on the boundary conditions at $x = 1$. It will be

shown that the function $N(L) = N_0(L) + \sigma(L)$ counts the negative eigenvalues of L.

Let H be one of the spaces (2.1) or (2.2) (corresponding to (I) or (II)), and let $B(u, v)$ be the energy inner product in H. The negative eigenvalues of L are, of course, related to the inertial properties of $B(u, v)$. This point of view is based on the following theorem, which is easily proved by using eigenfunction expansions. The proof will be omitted. We state the theorem to set the mood for the subsequent discussion.

THEOREM 2.3. *The following numbers are equal*:

(1) *The maximum dimension of a subspace* $V \subset H$ *on which* $B(u, v)$ *is negative definite*;

(2) *The dimension of a maximal subspace* $V \subset H$ *on which* $B(u, v)$ *is negative definite*;

(3) *The number of negative eigenvalues of* L (*counted with multiplicity*).

DEFINITION 2.3. We shall consider the following subspaces of H:

$$H_0 = \{u \in H \mid u \text{ satisfies Dirichlet conditions at } x = 1\}. \tag{2.20}$$

$$S(L) = \{u \in H \mid Lu = 0 \text{ and } u \text{ satisfies the given boundary conditions at } x = 0\}. \tag{2.21}$$

The restrictions of the energy inner product B to these subspaces will be denoted as follows:

$$B_0 = B|_{H_0},\ B_s = B|_{S(L)}. \tag{2.22}$$

We shall also consider the following operator:

(2.23) L_0 is the differential operator that has the same differential expression as L, with the given boundary conditions at $x = 0$, and Dirichlet boundary conditions at $x = 1$.

Remarks. In the notation of Definition 2.1, $L_0 = L|_{[0,1]}$. H_0 is the relevant Hilbert space for L_0 and B_0 is the energy inner product in H_0. The condition in brackets on the right-hand side of (2.21) should be interpreted in the weak sense: $B(u, v) = 0$ for all $v \in H_0$. This forces u to have enough smoothness so that the condition in (2.21) can be interpreted and is valid in the classical sense. Note that the functions in $S(L)$ are required to satisfy the essential boundary conditions at $x = 1$ (if any), since this is part of the definition of H. Thus dim $S(L)$ can be 0, 1, or 2. If zero is not an eigenvalue of L_0, then dim $S(L) = 2 - \nu$, where ν is the number of independent essential boundary conditions at $x = 1$. In this case dim $S(L) =$ codim H_0.

THEOREM 2.4. (a) $S(L)$ *is the subspace of* H *that is orthogonal to* H_0 *with respect to the energy inner product* B.

(b) *If* 0 *is not an eigenvalue of* L_0, *then* $H = H_0 \oplus S(L)$ (*orthogonal decomposition*).

Proof. (a) The equation

$$B(u, v) = 0 \quad \text{for all } v \in H_0 \tag{2.24}$$

is the weak form of

$$Lu = 0 \tag{2.25}$$

and u satisfies the given boundary conditions at $x = 0$.

(b) Since zero is not an eigenvalue of L_0, dim $S(L) =$ codim H_0 (as was remarked above). Furthermore $H_0 \cap S(L) = \{0\}$, because any nontrivial function $u \in H_0 \cap S(L)$ is an eigenfunction of L_0 with eigenvalue zero. This shows that $H = H_0 \oplus S(L)$. □

DEFINITION 2.4. If $F(u, v)$ is an inner product on a space X, the index of F is

$$\text{Ind } F = \sup \{\dim V \mid V \text{ is a subspace of } X \text{ on which } F \text{ is negative definite}\}. \tag{2.26}$$

We now define

$$\sigma(L) = \text{Ind } B_s \tag{2.27}$$

and

$$N(L) = N_0(L) + \sigma(L), \tag{2.28}$$

if zero is not an eigenvalue of L_0;

$$N(L) = \lim_{\varepsilon \to 0^+} N(L+\varepsilon), \tag{2.29}$$

if zero is an eigenvalue of L_0.

Remarks. Theorem 2.2 asserts that Ind $B_0 = N_0(L)$. Note that $\sigma(L)$ can be 0, 1, or 2. One way to calculate $\sigma(L)$ is to represent B_s by a (symmetric) matrix A, with respect to some basis of $S(L)$. Then $\sigma(L)$ is the number of negative eigenvalues of A.

Note that to calculate $N(L+\varepsilon)$, we would find solutions of $Lz = -\varepsilon z$.

THEOREM 2.5. *Let L be a differential operator of type* (I) *or* (II). (*We assume that the coefficients in L and in the boundary conditions do not depend on λ.*) *Then L has exactly $N(L)$ negative eigenvalues* (*counting multiplicity*).

Proof. First suppose that zero is not an eigenvalue of L_0. Then $N(L) = N_0(L) + \sigma(L)$. By Theorem 2.3, the number of negative eigenvalues of L is Ind B. The orthogonal decomposition $H = H_0 \oplus S(L)$ (in Theorem 2.4) implies that Ind $B =$ Ind $B_0 +$ Ind B_s, which equals $N_0(L) + \sigma(L) = N(L)$.

If zero is an eigenvalue of L_0, then it is not an eigenvalue of $L_0 + \varepsilon$ for small ε. Let $\lambda_1, \lambda_2, \cdots, \lambda_n$ be the negative eigenvalues of L. Then $\lambda_1 + \varepsilon, \cdots, \lambda_n + \varepsilon$ are eigenvalues of $L + \varepsilon$, and for small ε they remain negative. Thus Ind $B = n = N(L+\varepsilon)$, for small ε. □

Remark. In the next section we shall express the inner product B_s explicitly in terms of the boundary conditions.

3. Self-adjoint boundary conditions. The separated, self-adjoint boundary conditions for problems (I) and (II) will now be classified. The inner products $\beta_0(u, v)$, $\beta_1(u, v)$ (that occur in (1.2)-(1.4)) and $B_s(u, v)$ (in (2.22)) will be calculated for each type of boundary condition. As in the previous section, we assume that the operator L and the boundary conditions do not depend on λ.

LEMMA 3.1. *Let V be a two-dimensional subspace of $\mathbb{R}^4$ such that*

$$(x_2y_3 - x_3y_2) + (x_4y_1 - x_1y_4) = 0 \tag{*}$$

for all $x, y \in V$. Then V is the solution space of one of the following systems of equations:

(1) $$\begin{cases} x_1 = 0, \\ x_2 = 0; \end{cases}$$

(2) $$\begin{cases} x_1 = 0, \\ cx_2 + x_3 = 0; \end{cases}$$

(3) $$\begin{cases} ax_1 + bx_3 - x_4 = 0, \\ bx_1 - x_2 = 0; \end{cases}$$

$$\begin{cases} ax_1 + bx_2 - x_4 = 0, \\ bx_1 + cx_2 + x_3 = 0. \end{cases} \tag{4}$$

The above coefficients a, b, c can be arbitrary real numbers.

Proof. Using the Euclidean inner product $\langle x, y\rangle = \sum_{i=1}^{4} x_i y_i$ in $\mathbb{R}^4$, let $V^\perp$ be the orthogonal complement of V. Consider the matrix

$$S = \begin{bmatrix} 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix}. \tag{3.1}$$

Note that

$$\langle x, Sy\rangle = (x_2y_3 - x_3y_2) + (x_4y_1 - x_1y_4). \tag{3.2}$$

The equation (*) says that $\langle x, Sy\rangle = 0$ for all $x, y \in V$. This implies that $S(V) = V^\perp$. Since $S^2 = -I$, $S(V^\perp) = S^2(V) = V$. Thus S interchanges V and $V^\perp$. Therefore if $x, y \in V^\perp$, then $S(y) \in V$ and so $\langle x, S(y)\rangle = 0$. This shows that equation (*) is satisfied for all $x, y \in V^\perp$.

Now let $\alpha = (\alpha_1, \alpha_2, \alpha_3, \alpha_4)^T$, $\beta = (\beta_1, \beta_2, \beta_3, \beta_4)^T$ be a basis for $V^\perp$. Then V is the solution space of the system of equations

$$\begin{aligned} &\alpha_1x_1 + \alpha_2x_2 + \alpha_3x_3 + \alpha_4x_4 = 0, \\ &\beta_1x_1 + \beta_2x_2 + \beta_3x_3 + \beta_4x_4 = 0. \end{aligned} \tag{3.3}$$

Since α, β satisfy equation (*), we have

$$\alpha_2\beta_3 - \alpha_3\beta_2 = \alpha_1\beta_4 - \alpha_4\beta_1. \tag{3.4}$$

Using (3.4), the lemma can be proved by considering several cases, depending on the rank of the matrix $A = \left[\begin{smallmatrix} \alpha_3 & \alpha_4 \\ \beta_3 & \beta_4 \end{smallmatrix}\right]$. The details are left to the reader. □

Notation 3.1. The boundary conditions for (I) will be given using the following functions: $u_0 = u$, $u_1 = u'$, $u_2 = pu''$, $u_3 = (pu'')' - qu'$.

THEOREM 3.1. *For problem* (I), *self-adjoint* (*separated*) *boundary conditions at* $x = i$ (*where* $i = 0, 1$) *are equivalent to one of the following types.* (*The conditions at* $x = 0$ *and* $x = 1$ *are independent of each other.*)

(1) $$\begin{cases} u_0(i) = 0 \quad (\textit{Dirichlet conditions}), \\ u_1(i) = 0; \end{cases}$$

(2) $$\begin{cases} u_0(i) = 0, \\ cu_1(i) + u_2(i) = 0, \end{cases}$$

(3) $$\begin{cases} au_0(i) + bu_2(i) - u_3(i) = 0, \\ bu_0(i) - u_1(i) = 0; \end{cases}$$

(4) $$\begin{cases} au_0(i) + bu_1(i) - u_3(i) = 0, \\ bu_0(i) + cu_1(i) + u_2(i) = 0. \end{cases}$$

Proof. Let L be the operator of (I). Integration by parts shows that

$$\int_0^1 (Lu)v\,dx = -\gamma_0(u, v) + \gamma_1(u, v) + \int_0^1 u(Lv)\,dx,$$

where (for $i = 0, 1$)

$$\gamma_i(u, v) = (u_1(i)v_2(i) - u_2(i)v_1(i)) + (u_3(i)v_0(i) - u_0(i)v_3(i)). \tag{3.5}$$

The boundary conditions

$$\begin{aligned} &\alpha_{0i}u_0(i) + \alpha_{1i}u_1(i) + \alpha_{2i}u_2(i) + \alpha_{3i}u_3(i) = 0, \\ &\beta_{0i}u_0(i) + \beta_{1i}u_1(i) + \beta_{2i}u_2(i) + \beta_{3i}u_3(i) = 0 \end{aligned} \tag{3.6}$$

at $x = i$ are self-adjoint if and only if $\gamma_i(u, v) = 0$ for all u, v satisfying (3.6). Setting $(x_1, x_2, x_3, x_4) = (u_0(i), u_1(i), u_2(i), u_3(i))$, we see that Lemma 3.1 implies that the equations (3.6) are equivalent to one of the types listed in the theorem. □

Notation 3.2. The boundary conditions for (II) will be given using the functions $u = (u_1, u_2)^T$ and $\dot{u} = (\dot{u}_1, \dot{u}_2)^T = Pu' + Qu$.

The following theorem is proved similarly to the previous one by setting $(x_1, x_2, x_3, x_4) = (u_1(i), u_2(i), \dot{u}_2(i), -\dot{u}_1(i))$ in Lemma 3.1.

THEOREM 3.2. *For* (II), *self-adjoint* (*separated*) *boundary conditions at* $x = i$ (*where* $i = 0, 1$) *are equivalent to one of the following types*: (*The conditions at* $x = 0$ *and* $x = 1$ *are independent of each other.*)

(1) $\begin{cases} u_1(i) = 0 & (\textit{Dirichlet conditions}), \\ u_2(i) = 0; \end{cases}$

(2) $\begin{cases} u_1(i) = 0, \\ cu_2(i) + \dot{u}_2(i) = 0; \end{cases}$

(3) $\begin{cases} au_1(i) + \dot{u}_1(i) + b\dot{u}_2(i) = 0, \\ bu_1(i) - u_2(i) = 0; \end{cases}$

(4) $\begin{cases} au_1(i) + bu_2(i) + \dot{u}_1(i) = 0, \\ bu_1(i) + cu_2(i) + \dot{u}_2(i) = 0. \end{cases}$

The following two theorems can be proved using integration by parts. The details are left for the reader.

THEOREM 3.3. *For* (I), *the following formulas give the inner products* $\beta_i(u, v)$ *and* $B_s(u, v)$, *corresponding to the different types of boundary conditions.*

(1) $\begin{cases} u_0(i) = 0, \\ u_1(i) = 0; \end{cases}$

$\beta_i(u, v) = 0$. *If* $i = 1$, *then* $B_s(u, v) = 0$.

(2) $\begin{cases} u_0(i) = 0, \\ cu_1(i) + u_2(i) = 0; \end{cases}$

$\beta_i(u, v) = cu_1(i)v_1(i)$. *If* $i = 1$, *then* $B_s(u, v) = [cu_1(1) + u_2(1)]v_1(1)$.

(3) $\begin{cases} au_0(i) + bu_2(i) - u_3(i) = 0, \\ bu_0(i) - u_1(i) = 0; \end{cases}$

$\beta_i(u, v) = au_0(i)v_0(i)$.

If $i = 1$, *then* $B_s(u, v) = [au_0(1) + bu_2(1) - u_3(1)]v_0(1)$.

(4) $\begin{cases} au_0(i) + bu_1(i) - u_3(i) = 0, \\ bu_0(i) + cu_1(i) + u_2(i) = 0; \end{cases}$

$\beta_i(u, v) = au_0(i)v_0(i) + b(u_0(i)v_1(i) + u_1(i)v_0(i)) + cu_1(i)v_1(i)$.

If $i = 1$, *then*

$$B_s(u, v) = [au_0(1) + bu_1(1) - u_3(1)]v_0(1) + [bu_0(1) + cu_1(1) + u_2(1)]v_1(1).$$

THEOREM 3.4. *For* (II), *the following formulas give the inner products* $\beta_i(u, v)$ *and* $B_s(u, v)$, *corresponding to the different types of boundary conditions.*

(1) $$\begin{cases} u_1(i) = 0, \\ u_2(i) = 0; \end{cases}$$

$\beta_i(u, v) = 0$. *If* $i = 1$, *then* $B_s(u, v) = 0$.

(2) $$\begin{cases} u_1(i) = 0, \\ cu_2(i) + \dot{u}_2(i) = 0; \end{cases}$$

$\beta_i(u, v) = cu_2(i)v_2(i)$. *If* $i = 1$, *then* $B_s(u, v) = [cu_2(1) + \dot{u}_2(1)]v_2(1)$.

(3) $$\begin{cases} au_1(i) + \dot{u}_1(i) + b\dot{u}_2(i) = 0, \\ bu_1(i) - u_2(i) = 0; \end{cases}$$

$\beta_i(u, v) = au_1(i)v_1(i)$.

If $i = 1$, *then* $B_s(u, v) = [au_1(1) + \dot{u}_1(1) + b\dot{u}_2(1)]v_1(1)$.

(4) $$\begin{cases} au_1(i) + bu_2(i) + \dot{u}_1(i) = 0, \\ bu_1(i) + cu_2(i) + \dot{u}_2(i) = 0; \end{cases}$$

$\beta_i(u, v) = au_1(i)v_1(i) + b(u_1(i)v_2(i) + u_2(i)v_1(i)) + cu_2(i)v_2(i)$.

If $i = 1$, *then*

$$B_s(u, v) = [au_1(1) + bu_2(1) + \dot{u}_1(1)]v_1(1) + [bu_1(1) + cu_2(1) + \dot{u}_2(1)]v_2(1).$$

Remark. The inner products $B_s(u, v)$ do not appear to be symmetric in the above formulas. But this is only an illusion, since $B(u, v)$ is symmetric.

4. Nonlinear eigenvalues. We now turn to the case where the operator L and the boundary conditions depend on λ. The coefficients a, b, c in the boundary conditions (see Theorems 3.1 and 3.2) may now be functions of λ. But in the type (3) boundary conditions (for (I) and (II)) the coefficient b is assumed to be constant, because essential boundary conditions are assumed to have constant coefficients. (See the standard assumption (S5) in § 1.) The type of boundary condition does not change as λ varies, because the type is determined by the essential boundary conditions.

We begin with the following estimates, which will be needed in the proof of Theorem 4.1. As before, we use the notation $\|u\|^2 = \int_0^1 u(x)^2\,dx$.

LEMMA 4.1. *Let* $\varepsilon > 0$.

(1) *If* $u \in H^1[0, 1]$, *then* $u(x)^2 \leqq \varepsilon^2\|u'\|^2 + (1 + 1/\varepsilon^2)\|u\|^2$.

(2) *There exists* $C(\varepsilon) > 0$ *so that if* $u \in H^2[0, 1]$ *then* $\|u'\|^2 \leqq \varepsilon^2\|u''\|^2 + C(\varepsilon)\|u\|^2$.

Proof. (1) Let $\min_{0\leqq x\leqq 1} u(x)^2 = m^2 = u(x_0)^2$. Then $\|u\|^2 = \int_0^1 u(x)^2\,dx \geqq m^2$, so $m \leqq \|u\|$.

$$\begin{aligned} u(x)^2 &= u(x_0)^2 + \int_{x_0}^{x} 2u(x)u'(x)\,dx \\ &\leqq m^2 + 2\left(\frac{\|u\|}{\varepsilon}\right)(\varepsilon\|u'\|) \\ &\leqq m^2 + \left(\varepsilon^2\|u'\|^2 + \frac{1}{\varepsilon^2}\|u\|^2\right) \\ &\leqq \varepsilon^2\|u'\|^2 + \left(1 + \frac{1}{\varepsilon^2}\right)\|u\|^2. \end{aligned}$$

(2) Integrating by parts, we have

$$\|u'\|^2 = \int_0^1 u'(x)^2\,dx = u(1)u'(1) - u(0)u'(0) - \int_0^1 uu''\,dx,$$

and therefore,

$$\|u'\|^2 \leqq |u(1)u'(1)| + |u(0)u'(0)| + \|u\|\,\|u''\|. \tag{4.1}$$

Let $\varepsilon_1, \varepsilon_2, \delta > 0$ be constants to be determined later. For $i = 0, 1$ we have

$$|u(i)u'(i)| \leqq \frac{1}{2}\left(\varepsilon_1^2 u'(i)^2 + \frac{1}{\varepsilon_1^2}u(i)^2\right), \tag{4.2}$$

$$\|u\|\,\|u''\| \leqq \frac{1}{2}\left(\varepsilon_2^2\|u''\|^2 + \frac{1}{\varepsilon_2^2}\|u\|^2\right). \tag{4.3}$$

Part (1) of the lemma implies that

$$u(i)^2 \leqq \delta^2\|u'\|^2 + \left(1+\frac{1}{\delta^2}\right)\|u\|^2, \tag{4.4}$$

$$u'(i)^2 \leqq \|u''\|^2 + 2\|u'\|^2. \tag{4.5}$$

The above inequalities imply that

$$\left(1-2\varepsilon_1^2-\frac{\delta^2}{\varepsilon_1^2}\right)\|u'\|^2 \leqq \left(\varepsilon_1^2+\frac{\varepsilon_2^2}{2}\right)\|u''\|^2 + \left[\frac{1}{\varepsilon_1^2}\left(1+\frac{1}{\delta^2}\right)+\frac{1}{2\varepsilon_2^2}\right]\|u\|^2. \tag{4.6}$$

We may assume that $\varepsilon < 1$ (or else replace ε by $\varepsilon' = \frac{1}{2}$). Now let $\varepsilon_1 = \varepsilon/2$ and $\varepsilon_2 = \varepsilon/\sqrt{2}$, so that $\varepsilon_1^2 + (\varepsilon_2^2/2) = \varepsilon^2/2$. Define δ so that $1 - 2\varepsilon_1^2 - (\delta^2/\varepsilon_1^2) = \frac{1}{2}$ (i.e., $\delta^2 = \varepsilon^2(1-\varepsilon^2)/8$), and let $C(\varepsilon) = 2[(1/\varepsilon_1^2)(1+1/\delta^2)+1/(2\varepsilon_2^2)]$. Now (4.6) implies that $\|u'\|^2 \leqq \varepsilon^2\|u''\|^2 + C(\varepsilon)\|u\|^2$. □

LEMMA 4.2. *Let Q be an $n \times 2n$ matrix and let $|Q|$ be its norm with respect to the Euclidean norm in $\mathbb{R}^n$. Let $\hat{Q}$ be the $2n \times 2n$ matrix $\begin{bmatrix} 0 & Q \\ Q^T & 0 \end{bmatrix}$ and let λ_0 be the maximum eigenvalue of $\hat{Q}$. Then $|Q| = \lambda_0$.*

Proof. Let $x, y \in \mathbb{R}^n$ and $z = \begin{pmatrix} x \\ y \end{pmatrix} \in \mathbb{R}^{2n}$. The equation $\hat{Q}z = \lambda z$ is equivalent to the pair of equations

$$Q^T x = \lambda y, \qquad Qy = \lambda x, \tag{4.7}$$

which imply that

$$QQ^T x = \lambda^2 x, \qquad Q^T Q y = \lambda^2 y. \tag{4.8}$$

Therefore, if λ is an eigenvalue of $\hat{Q}$, then λ^2 is an eigenvalue of Q^TQ. Conversely, if $Q^TQy = \lambda^2 y$, let $Qy = \lambda x$. Then $\lambda Q^T x = Q^T Q y = \lambda^2 y$. If $\lambda \neq 0$, then $Q^T x = \lambda y$. Since $Qy = \lambda x$ and $Q^T x = \lambda y$, it follows that λ is an eigenvalue of $\hat{Q}$. If $\lambda = 0$, then Q and Q^T have a zero eigenvalue, so $\hat{Q}$ does also. Thus λ is an eigenvalue of $\hat{Q}$ if and only if λ^2 is an eigenvalue of Q^TQ. Since λ_0 is the maximum eigenvalue of $\hat{Q}$, λ_0^2 is the maximum eigenvalue of Q^TQ.

Let $\langle x, y\rangle$ denote the Euclidean inner product in $\mathbb{R}^n$, and $|x|^2 = \langle x, x\rangle$. Then

$$|Q|^2 = \max_{x\neq 0}\frac{|Qx|^2}{|x|^2} = \max_{x\neq 0}\frac{\langle Qx, Qx\rangle}{|x|^2} = \max_{x\neq 0}\frac{\langle Q^TQx, x\rangle}{|x|^2} = \lambda_0^2.$$

Therefore, $|Q| = \lambda_0$. □

Remark. The above proof shows that if λ is an eigenvalue of $\hat{Q}$, then $-\lambda$ is also an eigenvalue. In fact, the characteristic polynomial $p(\lambda) = \det(\lambda I - \hat{Q})$ is an even function. This can be seen by multiplying the first n rows and the last n columns of $\det(\lambda I - \hat{Q})$ by -1.

The lemma shows that the norm $|Q|$ of the matrix $Q(x, \lambda)$ (which occurs in (II)) equals the maximum eigenvalue $\nu_Q(x, \lambda)$ of $\hat{Q} = \begin{bmatrix} 0 & Q \\ Q^T & 0 \end{bmatrix}$. This implies that

$$|Q(x, \lambda)u \cdot u'| \leqq \nu_Q(\lambda)|u||u'|, \tag{4.9}$$

where $\nu_Q(\lambda) = \max_{0\leqq x\leqq 1} \nu_Q(x, \lambda)$. This fact will be used in the proof of the following theorem.

THEOREM 4.1. *Let L be a differential operator of type* (I) *or* (II). *Suppose that L satisfies the monotonicity assumptions and the limit assumption* (L1). *Then the energy inner product $B(u, v; \lambda)$ is positive definite for λ near Λ_1.*

Proof. Suppose that L is of type (I). Recall that

$$B(u, u; \lambda) = -\beta_0(u, u; \lambda) + \beta_1(u, u; \lambda) + \int_0^1 (p(x, \lambda)(u'')^2 + q(x, \lambda)(u')^2 + r(x, \lambda)u^2)\, dx, \tag{4.10}$$

where, for $i = 0, 1$,

$$\beta_i(u, u; \lambda) = a_i(\lambda)u(i)^2 + 2b_i(\lambda)u(i)u'(i) + c_i(\lambda)u'(i)^2. \tag{4.11}$$

Suppose that L satisfies the limit assumption (L1a): $\lim_{\lambda\to\Lambda_1} r_*(\lambda) = \infty$. Let $\Lambda_1 < \lambda_0 < \Lambda_2$. The standard assumption (S2) and the monotonicity assumptions imply that for $\Lambda_1 < \lambda < \lambda_0$,

$$B(u, u; \lambda) \geqq -\beta_0(u, u; \lambda_0) + \beta_1(u, u; \lambda_0) + \int_0^1 (k(u'')^2 + q(x, \lambda_0)(u')^2 + r(x, \lambda)u^2)\, dx, \tag{4.12}$$

and therefore,

$$B(u, u; \lambda) \geqq -|\beta_0(u, u; \lambda_0)| - |\beta_1(u, u; \lambda_0)| + k\|u''\|^2 + q_*(\lambda_0)\|u'\|^2 + r_*(\lambda)\|u\|^2. \tag{4.13}$$

Letting $a_i = a_i(\lambda_0)$, $b_i = b_i(\lambda_0)$, and $c_i = c_i(\lambda_0)$, we have

$$|\beta_i(u, u; \lambda_0)| \leqq |a_i|u(i)^2 + 2|b_i||u(i)u'(i)| + |c_i|u'(i)^2, \tag{4.14}$$

$$2|u(i)u'(i)| \leqq u(i)^2 + u'(i)^2. \tag{4.15}$$

Let $\varepsilon > 0$ be a constant to be chosen later. Lemma 4.1 implies that

$$u(i)^2 \leqq \|u'\|^2 + 2\|u\|^2, \tag{4.16}$$

$$u'(i)^2 \leqq \varepsilon^2\|u''\|^2 + \left(1 + \frac{1}{\varepsilon^2}\right)\|u'\|^2. \tag{4.17}$$

These inequalities imply that

$$|\beta_i(u, u; \lambda_0)| \leqq A_i\varepsilon^2\|u''\|^2 + B_i(\varepsilon)\|u'\|^2 + C_i\|u\|^2, \tag{4.18}$$

where $A_i = |b_i| + |c_i|$, $B_i(\varepsilon) = (|a_i| + |b_i|) + (|b_i| + |c_i|)(1 + 1/\varepsilon^2)$ and $C_i = 2(|a_i| + |b_i|)$. Letting $A = A_0 + A_1$, $B(\varepsilon) = B_0(\varepsilon) + B_1(\varepsilon)$, and $C = C_0 + C_1$, the above inequalities imply that for $\Lambda_1 < \lambda < \lambda_0$,

$$B(u, u; \lambda) \geqq (k - A\varepsilon^2)\|u''\|^2 + (q_*(\lambda_0) - B(\varepsilon))\|u'\|^2 + (r_*(\lambda) - C)\|u\|^2. \tag{4.19}$$

Let $\delta > 0$ be a constant to be determined later. Lemma 4.1 implies that there exists $D(\delta) > 0$ so that

$$\|u'\|^2 \leqq \delta^2\|u''\|^2 + D(\delta)\|u\|^2. \tag{4.20}$$

By letting $E(\varepsilon) = |q_*(\lambda_0) - B(\varepsilon)|$, the inequalities (4.19) and (4.20) imply that

$$B(u, u; \lambda) \geqq (k - A\varepsilon^2 - E(\varepsilon)\delta^2)\|u''\|^2 + (r_*(\lambda) - C - D(\delta)E(\varepsilon))\|u\|^2, \tag{4.21}$$

for $\Lambda_1 < \lambda < \lambda_0$. Now choose ε and δ so that $A\varepsilon^2 < k/2$ and $E(\varepsilon)\delta^2 < k/2$. Then $k - A\varepsilon^2 - E(\varepsilon)\delta^2 > 0$ and (L1a) implies that $r_*(\lambda) - C - D(\delta)E(\varepsilon) > 0$ for λ near Λ_1. This concludes the proof under the assumption (L1a).

Next we suppose that L is of type (I) and satisfies (L1b): $\lim_{\lambda \to \Lambda_1} q_*(\lambda) = \infty$ and there exists λ_+ such that $r_*(\lambda_+) > 0$, $a_0(\lambda_+) \leqq 0$, and $a_1(\lambda_+) \geqq 0$. The standard assumption (S2) and the monotonicity assumptions imply that for $\Lambda_1 < \lambda < \lambda_+$,

$$\begin{aligned} B(u, u; \lambda) \geqq & -\beta_0(u, u; \lambda_+) + \beta_1(u, u; \lambda_+) + k\|u''\|^2 \\ & + q_*(\lambda)\|u'\|^2 + r_*(\lambda_+)\|u\|^2. \end{aligned} \tag{4.22}$$

Letting $a_i = a_i(\lambda_+)$, $b_i = b_i(\lambda_+)$, $c_i = c_i(\lambda_+)$ and using

$$2|u(i)u'(i)| \leqq \varepsilon^2 u(i)^2 + \frac{1}{\varepsilon^2} u'(i)^2, \tag{4.23}$$

$$u(i)^2 \leqq \|u'\|^2 + 2\|u\|^2, \tag{4.24}$$

and

$$u'(i)^2 \leqq \delta^2\|u''\|^2 + \left(1 + \frac{1}{\delta^2}\right)\|u'\|^2, \tag{4.25}$$

we obtain

$$\beta_1(u, u; \lambda_+) \geqq a_1 u(1)^2 - A_1(\varepsilon)\delta^2\|u''\|^2 - B_1(\varepsilon, \delta)\|u'\|^2 - C_1\varepsilon^2\|u\|^2, \tag{4.26}$$

$$-\beta_0(u, u; \lambda_+) \geqq -a_0 u(0)^2 - A_0(\varepsilon)\delta^2\|u''\|^2 - B_0(\varepsilon, \delta)\|u'\|^2 - C_0\varepsilon^2\|u\|^2, \tag{4.27}$$

where

$$A_i(\varepsilon) = |c_i| + \frac{|b_i|}{\varepsilon^2}, \quad B_i(\varepsilon, \delta) = |b_i|\varepsilon^2 + \left(|c_i| + \frac{|b_i|}{\varepsilon^2}\right)\left(1 + \frac{1}{\delta^2}\right), \quad \text{and } C_i = 2|b_i|.$$

Letting $A = A_0 + A_1$, $B = B_0 + B_1$, and $C = C_0 + C_1$, (4.22) now implies that

$$\begin{aligned} B(u, u; \lambda) \geqq & -a_0 u(0)^2 + a_1 u(1)^2 + (k - (A(\varepsilon)\delta^2)\|u''\|^2 \\ & + (q_*(\lambda) - B(\varepsilon, \delta))\|u'\|^2 + (r_*(\lambda_+) - C\varepsilon^2)\|u\|^2 \end{aligned} \tag{4.28}$$

for $\Lambda_1 < \lambda < \lambda_+$. Choose ε and δ so that $r_*(\lambda_+) - C\varepsilon^2 > 0$ and $k - A(\varepsilon)\delta^2 > 0$. The assumption (L1b) implies that $q_*(\lambda) - B(\varepsilon, \delta) > 0$ for λ near Λ_1. This concludes the proof under the assumption (L1b).

Now suppose that L is of type (II). Recall that

$$\begin{aligned} B(u, u; \lambda) = & -\beta_0(u, u; \lambda_0) + \beta_1(u, u; \lambda_0) \\ & + \int_0^1 (P(x, \lambda)u' \cdot u' + 2Q(x, \lambda)u \cdot u' + R(x, \lambda)u \cdot u)\, dx, \end{aligned} \tag{4.29}$$

where

$$\beta_i(u, u; \lambda) = a_i(\lambda)u_1(i)^2 + 2b_i(\lambda)u_1(i)u_2(i) + c_i(\lambda)u_2(i)^2. \tag{4.30}$$

The standard assumption (S2) and the monotonicity assumptions imply that for $\Lambda_1 < \lambda < \lambda_0$,

$$\begin{aligned} B(u, u; \lambda) \geqq & -\beta_0(u, u; \lambda_0) + \beta_1(u, u; \lambda_0) \\ & + \int_0^1 (ku' \cdot u' + 2Q(x, \lambda)u \cdot u' + R(x, \lambda)u \cdot u)\, dx. \end{aligned} \tag{4.31}$$

The eigenvalues of $R(x,\lambda)$ are $\mu_R(x,\lambda) \leqq \nu_R(x,\lambda)$, and $\mu_R(\lambda) = \min_{0\leqq x\leqq 1} \mu_R(x,\lambda)$. For $u=(u_1,u_2)^T$, let $|u|^2 = u_1^2+u_2^2$ and $\|u\|^2 = \int_0^1 |u|^2\,dx$. Then

$$\int_0^1 R(x,\lambda)u\cdot u\,dx \geqq \mu_R(\lambda)\|u\|^2. \tag{4.32}$$

The eigenvalues of $\begin{bmatrix} 0 & Q(x,\lambda) \\ Q^T(x,\lambda) & 0 \end{bmatrix}$ are $\pm\mu_Q(x,\lambda)$ and $\pm\nu_Q(x,\lambda)$, where $0 \leqq \mu_Q(x,\lambda) \leqq \nu_Q(x,\lambda)$ and $\nu_Q(\lambda) = \max_{0\leqq x\leqq 1} \nu_Q(x,\lambda)$. It follows from (4.9) that

$$2|Q(x,\lambda)u\cdot u'| \leqq 2\nu_Q(\lambda)|u||u'| \leqq \varepsilon^2|u'|^2 + \frac{\nu_Q(\lambda)^2}{\varepsilon^2}|u|^2,$$

and therefore,

$$\int_0^1 2Q(x,\lambda)u\cdot u'\,dx \geqq -\left(\varepsilon^2\|u'\|^2 + \frac{\nu_Q(\lambda)^2}{\varepsilon^2}\|u\|^2\right). \tag{4.33}$$

The inequalities (4.31), (4.32), and (4.33) imply

$$\begin{aligned} B(u,u;\lambda) \geqq & -\beta_0(u,u;\lambda_0)+\beta_1(u,u;\lambda_0) \\ & +(k-\varepsilon^2)\|u'\|^2 + \left[\mu_R(\lambda) - \frac{\nu_Q(\lambda)^2}{\varepsilon^2}\right]\|u\|^2 \end{aligned} \tag{4.34.}$$

for $\Lambda_1 < \lambda < \lambda_0$. Using the estimates

$$2|u_1(i)u_2(i)| \leqq u_1(i)^2 + u_2(i)^2, \tag{4.35}$$

and

$$u_j(i)^2 \leqq \varepsilon^2\|u_j'\|^2 + \left(1+\frac{1}{\varepsilon^2}\right)\|u_j\|^2, \tag{4.36}$$

we obtain

$$|\beta_i(u,u;\lambda_0)| \leqq A_i\left(\varepsilon^2\|u'\|^2 + \left(1+\frac{1}{\varepsilon^2}\right)\|u\|^2\right), \tag{4.37}$$

where $A_i = |a_i(\lambda_0)| + |b_i(\lambda_0)| + |c_i(\lambda_0)|$. Letting $A = 1 + A_0 + A_1$ and using the fact that $\nu_Q(\lambda)^2/\varepsilon^2 + A(1+1/\varepsilon^2) \leqq A(1+\nu_Q(\lambda)^2)(1+1/\varepsilon^2)$, the inequalities (4.34) and (4.37) imply that

$$\begin{aligned} B(u,u;\lambda) \geqq & (k-A\varepsilon^2)\|u'\|^2 \\ & +(1+\nu_Q(\lambda)^2)\left[\frac{\mu_R(\lambda)}{1+\nu_Q(\lambda)^2} - A\left(1+\frac{1}{\varepsilon^2}\right)\right]\|u\|^2 \end{aligned} \tag{4.38}$$

for $\Lambda_1 < \lambda < \lambda_0$. Now choose $\varepsilon > 0$ so that $k - A\varepsilon^2 > 0$. The limit assumption (L1) implies that

$$\frac{\mu_R(\lambda)}{1+\nu_Q(\lambda)^2} - A\left(1+\frac{1}{\varepsilon^2}\right) > 0 \quad \text{for } \lambda \text{ near } \Lambda_1. \qquad \square$$

Remark. If (I) has a boundary condition of type (1) or (2) at $x=0$ or 1 (see Theorem 3.1 for the types of boundary conditions), then Lemma 2.1 implies that $u(x)^2 \leqq \|u'\|^2$ and $\|u\|^2 \leqq \|u'\|^2$ for $u \in H$. In this case, estimates similar to those in the the previous proof show that $B(u,v;\lambda)$ is positive definite for λ near Λ_1 if $\lim_{\lambda\to\Lambda_1} q_*(\lambda) = \infty$.

DEFINITION 4.1. L_λ will denote the operator L for fixed λ, and

$$N_0(\lambda) = N_0(L_\lambda), \tag{4.39}$$

$$\sigma(\lambda) = \sigma(L_\lambda), \tag{4.40}$$

$$N(\lambda) = N(L_\lambda) = N_0(\lambda) + \sigma(\lambda). \tag{4.41}$$

The following theorem is the main result of this paper. It is analogous to Theorem 2.1 in [8], which applies to second-order problems.

THEOREM 4.2. *Let L be an operator of type* (I) *or* (II).

(1) *Let $\Lambda_1 < \lambda' < \lambda'' < \Lambda_2$. If L satisfies the monotonicity assumptions, then L has exactly $N(\lambda'') - N(\lambda')$ eigenvalues (counting multiplicity) in the interval $[\lambda', \lambda'')$.*

(2) *Let $\Lambda_1 < \lambda < \Lambda_2$. If L also satisfies the limit assumption* (L1), *then L has exactly $N(\lambda)$ eigenvalues (counting multiplicity) in the interval (Λ_1, λ).*

Proof. (1) Let $\mu_1(\lambda) \leqq \mu_2(\lambda) \leqq \cdots \leqq \mu_n(\lambda) \leqq \cdots$ be the eigenvalues of L_λ. The following statements are equivalent:

(a) λ_0 is an eigenvalue of L;

(b) zero is an eigenvalue of L_{λ_0};

(c) $\mu_k(\lambda_0) = 0$, for some k.

Furthermore, λ_0 is a double eigenvalue of L if and only if $\mu_k(\lambda_0) = \mu_{k+1}(\lambda_0) = 0$, for some k.

The monotonicity assumptions imply that for each $u \in H$, $u \neq 0$, $B(u, u; \lambda)$ is a strictly decreasing function of λ. This implies that the $\mu_k(\lambda)$ are strictly decreasing functions. By Theorem 2.5, L_λ has exactly $N(\lambda)$ negative eigenvalues. As λ increases from λ' to λ'', the number of negative eigenvalues increases from $N(\lambda')$ to $N(\lambda'')$. Thus $N(\lambda'') - N(\lambda')$ new eigenvalues $\mu_k(\lambda)$ have become negative, thereby passing through zero. This shows that L has $N(\lambda'') - N(\lambda')$ eigenvalues in the interval $[\lambda', \lambda'')$.

(2) If L satisfies the limit assumption (L1), then Theorem 4.1 shows that $N(\lambda_0) = 0$ for λ_0 near Λ_1. Part (1) of the present theorem implies that there are no eigenvalues in the interval (Λ_1, λ_0), and $N(\lambda) = 0$ for $\Lambda_1 < \lambda \leqq \lambda_0$. If $\lambda_0 < \lambda < \Lambda_2$, then any eigenvalues in (Λ_1, λ) are in the interval $[\lambda_0, \lambda)$, and the number of these eigenvalues is $N(\lambda) - N(\lambda_0) = N(\lambda)$. □

Remark. In [7] it is shown that if L satisfies the limit assumption (L2), then $\lim_{\lambda \to \Lambda_2} N(\lambda) = \infty$ and L has infinitely many eigenvalues.

5. Wronskians. The Wronskians used to calculate $N(\lambda)$ will now be considered in greater detail. We shall define six Wronskians that are related to each other by a system of differential equations. Let the given boundary conditions at $x = 0$ be denoted by $\mathrm{BC}_0(y; \lambda) = 0$. For a given λ_0, let u, v be linearly independent solutions of

$$\begin{aligned} L(y; \lambda_0) &= 0, \\ \mathrm{BC}_0(y; \lambda_0) &= 0. \end{aligned} \tag{5.1}$$

For problem (I) we continue to use the notation $u_0 = u$, $u_1 = u'$, $u_2 = pu''$, and $u_3 = (pu'')' - qu'$. Now let

$$\begin{aligned} w_1 &= u_0 v_1 - u_1 v_0, & w_2 &= u_0 v_2 - u_2 v_0, \\ w_3 &= u_0 v_3 - u_3 v_0, & w_4 &= u_1 v_2 - u_2 v_1, \\ w_5 &= u_1 v_3 - u_3 v_1, & w_6 &= u_2 v_3 - u_3 v_2. \end{aligned} \tag{5.2}$$

For problem (II) let $u = (u_1, u_2)^T$, $\dot{u} = (\dot{u}_1, \dot{u}_2)^T = Pu' + Qu$, and let

$$\begin{aligned} w_1 &= u_1 v_2 - u_2 v_1, & w_2 &= u_1 \dot{v}_1 - \dot{u}_1 v_1, \\ w_3 &= u_1 \dot{v}_2 - \dot{u}_2 v_1, & w_4 &= u_2 \dot{v}_1 - \dot{u}_1 v_2, \\ w_5 &= u_2 \dot{v}_2 - \dot{u}_2 v_2, & w_6 &= \dot{u}_1 \dot{v}_2 - \dot{u}_2 \dot{v}_1. \end{aligned} \tag{5.3}$$

Note that the Wronskian determinant $w(x)$ (that occurs in Definition 2.2) is the same as $w_1(x)$ for both (I) and (II). The self-adjointness of the problems implies the following fact.

THEOREM 5.1. (1) *For* (I), $w_4 = w_3$.

(2) *For* (II), $w_5 = -w_2$.

Proof. (1) Integration by parts shows that

$$\int_0^x (Lu)v\,dt - \int_0^x u(Lv)\,dt = [(u_3v_0 - u_0v_3) + (u_1v_2 - u_2v_1)]_0^x. \tag{5.4}$$

(Here we have abbreviated $L(u;\lambda_0)$ by Lu.) If u and v are solutions of (5.1), then $Lu = 0 = Lv$, and (5.4) shows that

$$(u_3v_0 - u_0v_3) + (u_1v_2 - u_2v_1) = \text{constant}. \tag{5.5}$$

But the boundary conditions at $x = 0$ are self-adjoint precisely when the left-hand side of (5.5) is zero at $x = 0$ (see the proof of Theorem 3.1). Therefore, the constant in (5.5) is zero. Referring to (5.2), this implies that $w_4 = w_3$.

(2) Similarly, for (II), integration by parts shows that

$$\int_0^x (Lu)\cdot v\,dt - \int_0^x u\cdot(Lv)\,dt = [u\cdot\dot{v} - \dot{u}\cdot v]_0^x. \tag{5.6}$$

As before, this leads to the equation

$$u\cdot\dot{v} - \dot{u}\cdot v = \text{constant}. \tag{5.7}$$

Since the boundary conditions at $x = 0$ are self-adjoint, the constant in (5.7) is zero, which implies that $w_5 = -w_2$. □

Theorem 5.1 allows us to reduce the system of six Wronskians to five by omitting w_4 for (I) and w_5 for (II). A simple calculation now shows that for (I), the Wronskians satisfy the following equations:

$$\begin{aligned} w_1' &= (1/p)w_2, \\ w_2' &= qw_1 + 2w_3, \\ w_3' &= w_5, \\ w_5' &= rw_1 + (1/p)w_6, \\ w_6' &= rw_2 + qw_5. \end{aligned} \tag{5.8}$$

In (II), the equation $L(u;\lambda_0) = 0$ can be split into a first-order system:

$$\begin{aligned} u' &= -P^{-1}Qu + P^{-1}\dot{u}, \\ \dot{u}' &= (-Q^TP^{-1}Q + R)u + Q^TP^{-1}\dot{u}. \end{aligned} \tag{5.9}$$

Let

$$\begin{aligned} A &= \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} = -P^{-1}Q, \\ B &= \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix} = P^{-1}, \\ C &= \begin{bmatrix} c_{11} & c_{12} \\ c_{21} & c_{22} \end{bmatrix} = -Q^TP^{-1}Q + R. \end{aligned} \tag{5.10}$$

Note that $B = B^T$ and $C = C^T$. Equation (5.9) may be rewritten as

$$\begin{aligned} u' &= Au + B\dot{u}, \\ \dot{u}' &= Cu - A^T\dot{u}. \end{aligned} \tag{5.11}$$

Using (5.11), a calculation shows that the Wronskians for (II) satisfy the following equations:

$$\begin{aligned} w_1' &= (a_{11}+a_{22})w_1 + 2b_{12}w_2 + b_{22}w_3 - b_{11}w_4, \\ w_2' &= c_{12}w_1 - a_{21}w_3 + a_{12}w_4 - b_{12}w_6, \\ w_3' &= c_{22}w_1 - 2a_{12}w_2 + (a_{11}-a_{22})w_3 + b_{11}w_6, \\ w_4' &= -c_{11}w_1 + 2a_{21}w_2 + (-a_{11}+a_{22})w_4 - b_{22}w_6, \\ w_6' &= -2c_{12}w_2 + c_{11}w_3 - c_{22}w_4 - (a_{11}+a_{22})w_6. \end{aligned} \tag{5.12}$$

Recall that $n(x; \lambda_0) = \text{nullity } W(x; \lambda_0)$, where $W(x; \lambda_0) = \left[\begin{smallmatrix} u_0 & v_0 \\ u_1 & v_1 \end{smallmatrix}\right]$ for (I) and $W(x; \lambda_0) = \left[\begin{smallmatrix} u_1 & v_1 \\ u_2 & v_2 \end{smallmatrix}\right]$ for (II).

THEOREM 5.2. *For* (I) *and* (II), *the following are equivalent.*

(1) $n(x_0; \lambda_0) = 2$,

(2) $w_1(x_0; \lambda_0) = w_2(x_0; \lambda_0) = w_3(x_0; \lambda_0) = w_4(x_0; \lambda_0) = w_5(x_0; \lambda_0) = 0$.

Proof. Statement (1) is true for (I) if and only if $u_0(x_0) = u_1(x_0) = v_0(x_0) = v_1(x_0) = 0$. It is true for (II) if and only if $u_1(x_0) = u_2(x_0) = v_1(x_0) = v_2(x_0) = 0$. Referring to (5.2) and (5.3), we see that (1) implies (2).

Conversely, suppose that (2) is true for (I). If $(u_0(x_0), v_0(x_0)) \neq (0, 0)$, then, since $w_2(x_0) = w_3(x_0) = 0$, it follows that there are constants α, β such that $(u_2(x_0), v_2(x_0)) = \alpha(u_0(x_0), v_0(x_0))$ and $(u_3(x_0), v_3(x_0)) = \beta(u_0(x_0), v_0(x_0))$. This implies that $w_6(x_0) = 0$. Since all six Wronskians are zero at $x = x_0$, the vectors $(u_0(x_0), u_1(x_0), u_2(x_0), u_3(x_0))$ and $(v_0(x_0), v_1(x_0), v_2(x_0), v_3(x_0))$ are linearly dependent. This implies that $u(x)$ and $v(x)$ are linearly dependent. This contradiction implies that $u_0(x_0) = v_0(x_0) = 0$.

Similarly, if $(u_1(x_0), v_1(x_0)) \neq (0, 0)$, then $w_4(x_0) = w_5(x_0) = 0$ implies that $(u_2(x_0), v_2(x_0)) = \alpha(u_1(x_0), v_1(x_0))$ and $(u_3(x_0), v_3(x_0)) = \beta(u_1(x_0), v_1(x_0))$. This again implies that $w_6(x_0) = 0$, which leads to a contradiction. Therefore $u_1(x_0) = v_1(x_0) = 0$, and $n(x_0; \lambda_0) = 2$.

A similar argument shows that (2) implies (1) for (II). □

THEOREM 5.3. *The following are true for* (I).

(1) *If* $n(x_0; \lambda_0) = 1$, *then* $w(x)$ *has a zero of order* 1 *or* 3 *at* x_0.

(2) *If* $n(x_0; \lambda_0) = 2$, *then* $w(x)$ *has a zero of order* 4 *at* x_0.

Proof. Using equations (5.8), the derivatives of w can be expressed in the form

$$\begin{aligned} w &= w_1, \\ w' &= (1/p)w_2, \\ w'' &= \alpha_{21}w_1 + \alpha_{22}w_2 + (2/p)w_3, \\ w''' &= \alpha_{31}w_1 + \alpha_{32}w_2 + \alpha_{33}w_3 + (2/p)w_5, \\ w^{(iv)} &= \alpha_{41}w_1 + \alpha_{42}w_2 + \alpha_{43}w_3 + \alpha_{45}w_5 + (2/p^2)w_6. \end{aligned} \tag{5.13}$$

By Theorem 5.2, $n(x_0; \lambda_0) = 2$ if and only if $w_1(x_0) = w_2(x_0) = w_3(x_0) = w_4(x_0) = w_5(x_0) = 0$. Recalling that $w_3 = w_4$, (5.13) shows that $n(x_0; \lambda_0) = 2$ if and only if $w(x_0) = w'(x_0) = w''(x_0) = w'''(x_0) = 0$. Moreover, if $w^{(iv)}(x_0) = 0$ also, then (5.13) shows that $w_6(x_0) = 0$, so that all six Wronskians are zero at x_0. This leads to a contradiction (as in the proof of Theorem 5.2). Therefore, $w(x)$ has a zero of order 4 at x_0 if $n(x_0; \lambda_0) = 2$.

Now suppose that $n(x_0; \lambda_0) = 1$. Then $w(x_0) = 0$, and we may suppose that $u_0(x_0) = u_1(x_0) = 0$. This implies that $w_2(x_0) = -u_2(x_0)v_0(x_0)$, $w_3(x_0) = -u_3(x_0)v_0(x_0)$ and $w_4(x_0) = -u_2(x_0)v_1(x_0)$. If $w'(x_0) \neq 0$, then $w(x)$ has a zero of order 1 at x_0. Suppose that $w'(x_0) = 0$. Then (5.13) shows that $w_2(x_0) = 0$, which implies that either $v_0(x_0) = 0$ or $u_2(x_0) = 0$. Therefore, either $w_3(x_0) = 0$ or $w_4(x_0) = 0$. But $w_3 = w_4$, by Theorem 6.1. Thus, $w_3(x_0) = 0$, and (5.13) implies that $w''(x_0) = 0$. If $w'''(x_0) = 0$ also, then $n(x_0; \lambda_0) = 2$, as shown above. Therefore, $w(x)$ has a zero of order 1 or 3 at x_0 if $n(x_0; \lambda_0) = 1$. □

THEOREM 5.4. *For problem* (II), $n(x_0; \lambda_0)$ *equals the order of the zero of* $w(x)$ *at* x_0.

Proof. We know that $n(x_0; \lambda_0) > 0$ if and only if $w(x_0) = 0$. We claim that $n(x_0; \lambda_0) = 2$ if and only if $w(x_0) = w'(x_0) = 0$. If $n(x_0; \lambda_0) = 2$, then $w_1(x_0) = w_2(x_0) = w_3(x_0) = w_4(x_0) = w_5(x_0) = 0$, by Theorem 5.2. The first equation in (5.12), which is

$$w' = (a_{11} + a_{22})w_1 + 2b_{12}w_2 + b_{22}w_3 - b_{11}w_4, \tag{5.14}$$

now implies that $w'(x_0) = 0$.

Conversely, suppose that $w(x_0) = w'(x_0) = 0$. We may assume that $u_1(x_0) = u_2(x_0) = 0$. Therefore, $w_2(x_0) = -\dot{u}_1(x_0)v_1(x_0)$, $w_3(x_0) = -\dot{u}_2(x_0)v_1(x_0)$ and $w_4(x_0) = -\dot{u}_1(x_0)v_2(x_0)$. Equation (5.14) implies that

$$\begin{aligned} w'(x_0) = &-2b_{12}(x_0)\dot{u}_1(x_0)v_1(x_0) - b_{22}(x_0)\dot{u}_2(x_0)v_1(x_0) \\ &+ b_{11}(x_0)\dot{u}_1(x_0)v_2(x_0). \end{aligned} \tag{5.15}$$

By Theorem 6.1, $w_5 = -w_2$. Since $u_1(x_0) = u_2(x_0) = 0$, this implies that

$$\dot{u}_1(x_0)v_1(x_0) + \dot{u}_2(x_0)v_2(x_0) = 0. \tag{5.16}$$

Substituting in (5.15), and setting $w'(x_0) = 0$, we obtain

$$\begin{aligned} &b_{11}(x_0)\dot{u}_1(x_0)v_2(x_0) + b_{12}(x_0)[\dot{u}_2(x_0)v_2(x_0) - \dot{u}_1(x_0)v_1(x_0)] \\ &\quad - b_{22}(x_0)\dot{u}_2(x_0)v_1(x_0) = 0. \end{aligned} \tag{5.17}$$

Let $\langle \xi, \eta \rangle$ denote the Euclidean inner product for vectors $\xi, \eta \in \mathbb{R}^2$, and consider the vectors $\dot{u}(x_0) = (\dot{u}_1(x_0), \dot{u}_2(x_0))^T$ and $v(x_0)^\perp = (v_2(x_0), -v_1(x_0))^T$. Note that $\dot{u}(x_0) \neq (0, 0)$, since $u(x)$ is not the trivial solution of $L(u; \lambda_0) = 0$. Let

$$B_0 = B(x_0) = \begin{bmatrix} b_{11}(x_0) & b_{12}(x_0) \\ b_{21}(x_0) & b_{22}(x_0) \end{bmatrix} = P(x_0)^{-1}. \tag{5.18}$$

Since B_0 is positive definite, $B_0\dot{u}(x_0) \neq 0$. Equation (5.17) is equivalent to

$$\langle B_0\dot{u}(x_0), v(x_0)^\perp \rangle = 0. \tag{5.19}$$

Since $B_0\dot{u}(x_0)$ and $v(x_0) = (v_1(x_0), v_2(x_0))^T$ are both orthogonal to $v(x_0)^\perp$, and $B_0\dot{u}(x_0) \neq 0$, it follows that there is a constant c such that $v(x_0) = cB_0\dot{u}(x_0)$. This implies that

$$P_0 v(x_0) = c\dot{u}(x_0), \tag{5.20}$$

where $P_0 = P(x_0)$. Equation (5.16) says that $\langle \dot{u}(x_0), v(x_0) \rangle = 0$. By (5.20), $\langle P_0 v(x_0), v(x_0) \rangle = c\langle \dot{u}(x_0), v(x_0) \rangle = 0$, and therefore, $v(x_0) = 0$. This shows that $n(x_0; \lambda_0) = 2$ if $w(x_0) = w'(x_0) = 0$.

We now know that $n(x_0; \lambda_0) = 2$ if and only if $w(x_0) = w'(x_0) = 0$. Furthermore, we claim that $w''(x_0) \neq 0$ in this case. To see this, differentiate (5.14) and use (5.12) to obtain

$$w'' = \alpha_1 w_1 + \alpha_2 w_2 + \alpha_3 w_3 + \alpha_4 w_4 + 2(b_{11}b_{22} - b_{12}^2)w_6. \tag{5.21}$$

Since $n(x_0; \lambda_0) = 2$,

$$w_1(x_0) = w_2(x_0) = w_3(x_0) = w_4(x_0) = w_5(x_0) = 0.$$

If $w''(x_0) = 0$, then (5.21) implies that $w_6(x_0) = 0$ also. This leads to a contradiction (as in the proof of Theorem 5.2). Therefore, x_0 is a zero of order 2 (of $w(x)$) if $n(x_0; \lambda_0) = 2$, and it must be a zero of order 1 if $n(x_0; \lambda_0) = 1$. □

Theorems 5.3 and 5.4 imply the important fact that $w(x)$ changes sign at x_0 if $n(x_0; \lambda_0) = 1$, and does not change sign if $n(x_0; \lambda_0) = 2$.

DIFFUSIVE LOGISTIC EQUATIONS WITH INDEFINITE WEIGHTS: POPULATION MODELS IN DISRUPTED ENVIRONMENTS II*

ROBERT STEPHEN CANTRELL† AND CHRIS COSNER†

Abstract. The dynamics of a population inhabiting a strongly heterogeneous environment are modeled by diffusive logistic equations of the form $u_t = \nabla \cdot (d(x, u)\nabla u) - \mathbf{b}(x) \cdot \nabla u + m(x)u - cu^2$ in $\Omega \times (0, \infty)$, where u represents the population density, $d(x, u)$ the (possibly) density dependent diffusion rate, $\mathbf{b}(x)$ drift, c the limiting effects of crowding, and $m(x)$ the local growth rate of the population. The growth rate $m(x)$ is positive on favorable habitats and negative on unfavorable ones. The environment Ω is bounded and surrounded by uninhabitable regions, so that $u = 0$ on $\partial\Omega \times (0, \infty)$. In a previous paper, the authors considered the special case $d(x, u) = d$, a constant, and $\mathbf{b} = 0$, and were able to make an analysis based on variational methods. The inclusion of density dependent diffusion and/or drift makes for more flexible and realistic models. However, variational methods are mathematically insufficient in these more complicated situations. By employing methods based on monotonicity and positive operator theory, many previous results on the dependence on m of the overall suitability of the environment can be recovered and some new results can be established concerning environmental quality dependence on $\mathbf{b}$. In the process, a bifurcation and stability analysis is made of the model which includes some new estimates on eigenvalues for associated linear problems.

1. Introduction.

Reaction-diffusion equations have been widely used as models for populations whose densities vary with location as well as time. If the environment is strongly heterogeneous, the coefficients describing the growth and diffusion of the population may vary with location as well. In an earlier article, we studied a diffusive logistic model in which the diffusion rate of the population was constant but the growth rate was assumed to vary with position, being positive in regions of favorable habitat and negative in unfavorable regions. The present article is devoted to extending our results to models in which the diffusion rate varies with position and population density, and the population may be subject to drift in addition to pure diffusion. These more complicated models incorporate effects which are often present in real situations, and thus can give more complete descriptions of biological phenomena. Since these models are quasilinear rather than semilinear, and in general are not in variational form, the technical aspects of the analysis are somewhat different and more difficult than in the case of simple Fickian diffusion. The technical complexity is inherent in the models we consider, and cannot be avoided if we are to give a rigorous analysis. However, we have introduced into our models only the sorts of effects which theoretical ecologists have suggested to us as being especially important.

Since the implications of our analysis should be of some interest to biological scientists, we give a brief summary of them in the last section, and conclude each section of the paper with a fairly detailed discussion of the main results from a biological viewpoint. Some of the discussion overlaps that given in [6], [7], and [9]. Additional references are given in [6] and [9]. In [7] we use relatively simple mathematics to analyze a number of special cases of the general models considered here and give a

† Department of Mathematics and Computer Science, University of Miami, Coral Gables, Florida 33124.

moderately detailed biological discussion of their interpretation. A reader whose primary interest is in the biological aspects of the work may find the present article more accessible after reading [7].

The situation we wish to model is that of a species inhabiting a bounded region of variable habitat, and dispersing throughout that region via a process of diffusion which may be affected by population density and location and which may also involve drift due to wind, current, or environmental gradients. The questions we address are those of deciding how environmental factors and/or the density dependence of the diffusion affect the population. Obviously, if the overall environment includes too much poor habitat the population cannot be expected to persist. However, the *arrangement* of favorable and unfavorable regions turns out to play an important role in determining the overall suitability of an environment. Questions about the effects of the arrangement of favorable and unfavorable regions are especially important in refuge theory; for example, is one large preserve likely to be more or less effective in sustaining a population than several small preserves? Of course, the answers to such questions will depend on the details of the biology but models can suggest answers in some cases and serve to sharpen discussion in others. Island biogeography theory has been widely used in the context of refuge theory. The sort of models we consider provide an alternative approach. We discuss this point in some detail and give a number of references in [6]. One object of the present work is to extend the results of [6] to include models with more complex and realistic sorts of diffusion and drift processes. Another object is to study directly the effects of density dependent diffusion and of drift. We find that density dependence in the diffusion rate may have effects similar to those of depensation in the growth dynamics, as studied in [20]. Specifically, models with density dependent diffusion may admit multiple equilibria even if the corresponding dynamics with constant diffusion yield a unique equilibrium. The effects of drift in the case of a homogeneous environment and constant diffusion are discussed in [22]. We extend some of the results of [22] to models with variable diffusion and growth coefficients, but we have so far been unable to give a complete description of the effects of drift on the population dynamics.

There is a vast literature on traveling waves in reaction-diffusion models. Most of that literature is not directly relevant to our work, because we are concerned exclusively with bounded regions. A general overview of the literature on waves is given in [10] and [28]. Some specific problems related to wavelike propagation in ecological models and to considerations of domain size are studied in [4]. Another class of models which have a more direct relation to our work are patch models, where a population is assumed to inhabit a number of discrete patches rather than a continuous region. Some topics similar to those we consider are discussed from the viewpoint of patch models in [26]. (Threshold results for propagation through an infinite number of patches are derived in [3]; the specific model in [3] arises in neurophysiology, but the same methods would also apply to ecological models.) Our present work is most closely related to the ideas discussed in [20], [22], and [27], and of course [6], [9], where the models are primarily reaction-diffusion equations on bounded spatial domains.

The viewpoint we take in our modeling is essentially that taken in the pioneering work of Skellam [27], who deduced reaction-diffusion models for population growth and dispersal from the random-walk problem, and analyzed some of those models via classical methods. A representative result is that the density u of a population with linear growth law inhabiting a uniform disc of radius r_0 surrounded by a completely inhospitable region can be described by the equation $u_t = d\Delta u + mu$ with homogeneous Dirichlet boundary conditions, and hence will grow rather than decline provided

$m-(dj_1^2/r_0^2)>0$, where j_1 is the first zero of the Bessel function J_0. Another way to state this result is that the population will grow if the first eigenvalue λ_1 for the problem $-d\Delta\phi=\lambda m\phi$ on the disc of radius r_0 with homogeneous Dirichlet conditions satisfies $\lambda_1<1$. Skellam considered several other models, the most complicated being of the general form $u_t=d\Delta u+m(x)u-c(x)u^2$. Of such models, Skellam wrote (in 1951) that "orthodox analytical methods appear inadequate." (See [27, p. 212].) Since that time, there has been much work on reaction-diffusion models for population dynamics, and a number of new analytical methods have been introduced. For general background on the modeling aspects of population dynamics, see [19] or [24]; for mathematical methods and results, see [9], [10], or [28]. In our previous article [6], we study models that include those considered by Skellam, and discuss their biological interpretation.

The models in [6] have the form

$$u_t=d\Delta u+f(x,u)u \quad \text{in } \Omega, \qquad u=0 \quad \text{on } \partial\Omega, \tag{1.1}$$

where f is decreasing in u and Ω is a bounded domain in $\mathbb{R}^n$, with $n\leqq 3$ in applications. The intrinsic local growth rate of the population is given by $f(x,0)$, which is assumed to change sign on Ω, with positive values indicating favorable habitat and negative ones unfavorable habitat. Our results imply that (1.1) has a unique positive steady state which is a global attractor for nonnegative, nontrivial solutions, provided the first positive eigenvalue $\lambda_1(d,f(x,0))$ of the problem

$$-d\Delta\phi=\lambda f(x,0)\phi \quad \text{in } \Omega, \qquad \phi=0 \quad \text{on } \partial\Omega,$$

satisfies $\lambda_1(d,f(x,0))<1$. We also examined the question of how $\lambda_1(d,m(x))$ depends on the arrangement of positive and negative regions for $m(x)$. We showed that for a sequence $\{m_j(x)\}$ of weights, a necessary and sufficient condition for having

$$\lim_{j\to\infty}\lambda_1(d,m_j(x))=\infty \text{ is that } \limsup_{j\to\infty}\int_\Omega \psi m_j\leqq 0$$

for any $\psi\in L^1(\Omega)$ with $\psi\geqq 0$ almost everywhere. (This result is Theorem 3.1 of [6].) One implication of these results is that if the unfavorable regions are greater than or equal to the favorable ones in strength and extent, and the two sorts of regions are too closely interspersed, the population will not persist, *even though it might persist if the favorable habit formed a single larger region.* We also showed that in a certain sense, the most favorable situations will occur if there is a relatively large favorable region located some distance away from the boundary of Ω.

In the present article we consider models of the form

$$u_t=\nabla\cdot d(x,u)\nabla u-\mathbf{b}\cdot\nabla u+m(x)u-cu^2 \quad \text{in } \Omega, \qquad u=0 \quad \text{on } \partial\Omega, \tag{1.2}$$

and attempt to recover some of the results of [6]. Since the analysis of [6] was based largely on variational methods, we have had to substantially modify our techniques. In many cases, we replace ideas and results based on variational principles with others based on monotonicity or positive operator theory. Also, since we assume only $m(x)\in L^\infty(\Omega)$ (for various reasons which are discussed in [6]), we must work with weak solutions, so the standard Hopf maximum principle must generally be replaced by the maximum and comparison principles for weak solutions of elliptic equations discussed in [11, Chaps. 8, 9], or the corresponding results for the parabolic case which follow readily from similar arguments. (We do not always state this explicitly, and in some

cases we will simply cite references where the Hopf maximum principle is used but whose results extend directly to our situation via maximum principles for weak solutions.)

Models such as (1.2) display some different features than those of the form (1.1). In particular, if $d(x, u)$ is not monotone nondecreasing in u, (1.2) may have multiple positive solutions. (We give an example in § 3.) It is known that a similar phenomenon can occur in (1.1) in the presence of depensation (that is, if $f(x, u)$ is allowed to be increasing in u for some values of x and/or u) but not in the case of logistic growth. This situation is not surprising, since the equation $\nabla \cdot d(u)\nabla u + g(u) = 0$ can be converted to the form $\Delta U + G(U) = 0$ by letting $U = D(u)$ where $D(0) = 0$ and $D'(u) = d(u)$, and such a change of variables may destroy monotonicity or concavity properties of $g(u)$.

To analyze (1.2) we observe that the recent work of Hirsch [16] on monotone flows implies that the dynamics of (1.2) are determined by its steady states, we "unfold" the steady-state problem by introducing a parameter λ multiplying the undifferentiated terms, and we then analyze the steady states by using λ as a bifurcation parameter and applying the results of Rabinowitz [25]. Our main results state that under suitable restrictions on d, $\mathbf{b}$, and m, the problem (1.2) has a unique, stable, positive steady state provided $\lambda_1(d(x, 0), \mathbf{b}(x), m(x)) < 1$, where $\lambda_1(d, \mathbf{b}, m)$ is the first positive eigenvalue of

$$-\nabla d\nabla\phi + \mathbf{b}\cdot\nabla\phi = \lambda m\phi \quad \text{in } \Omega, \qquad \phi = 0 \quad \text{on } \partial\Omega, \tag{1.3}$$

and give a partial description of how that eigenvalue depends on d, $\mathbf{b}$, and m. In particular, we show that under a mild coercivity assumption on the left side of (1.3), the necessary and sufficient condition for $\lambda_1(d, 0, m_j(x)) \to \infty$ as $j \to \infty$ given in Theorem 3.1 of [6] extends to the case of $\lambda_1(d(x), \mathbf{b}(x), m_j(x))$. Since environments may vary in ways best described by discontinuous functions (for example, if a field is crossed by a paved road with sharp boundaries) we consider the case of $m \in L^\infty(\Omega)$ with $m > 0$ on a set of positive measure, but with m taking both positive and negative values. In that situation, we have to extend known results somewhat to obtain the existence of a first positive eigenvalue $\lambda_1(d, \mathbf{b}, m)$. The analysis is based on work of Hess and Kato [15] and Hess [14]. Our results on the behavior of $\lambda_1(d, \mathbf{b}, m)$ overlap slightly with those of Murray and Sperb [22], who considered the case of $\lambda_1(1, \mathbf{b}, 1)$. Other results implying bounds for eigenvalues for $\lambda_1(d, \mathbf{b}, m)$ under various hypotheses are given in [12], [13], [15], and [17], but they either do not apply in our situation or do not appear to be sharp enough for our purposes. We have observed that the presence of a drift term can either raise or lower $\lambda_1(d, \mathbf{b}, m)$. Our analysis of the existence problem for positive steady states of (1.2) is fairly complete, but to obtain uniqueness we must make additional structure assumptions (specifically that either $\partial d/\partial u \equiv 0$ or $\mathbf{b} \equiv 0$), and there remain many open questions about the dependence of $\lambda_1(d, \mathbf{b}, m)$ on d, $\mathbf{b}$, and m.

The paper is structured as follows. We derive the basic existence theory for positive equilibria in § 2, and obtain conditions on the uniqueness and stability of equilibria in § 3. Many of the results are somewhat technical, but they have some interesting biological implications. In § 4 we examine how the eigenvalue $\lambda_1(d, \mathbf{b}, m)$, whose size determines whether the model predicts extinction or persistence for the population, depends on the environment, drift, and diffusion. In § 5 we obtain some population estimates, again in terms of $\lambda_1(d, \mathbf{b}, m)$. Since the answers to the questions of greatest biological interest are determined by the size of $\lambda_1(d, \mathbf{b}, m)$, we consider the results of § 4 to have the greatest applied significance because they relate $\lambda_1(d, \mathbf{b}, m)$ to the physical conditions in the model. In § 6 we give a biologically oriented summary of

our conclusions. We also conclude each section with a description of the biological interpretation of the main results of that section.

2. A qualitative overview. In this section, we consider the positive steady-state solutions of the parabolic problem

$$\begin{aligned} &u_t = \nabla \cdot (d(x,u)\nabla u) - \mathbf{b}(x)\cdot\nabla u + \lambda(m(x)u - cu^2) && \text{in } \Omega\times(0,\infty),\\ &u(x,0) = u_0(x) \geqq 0 && \text{for } x\in\Omega,\\ &u(x,t) = 0 && \text{on } \partial\Omega\times(0,\infty). \end{aligned} \tag{2.1}$$

Here, as noted in the Introduction, λ is a real parameter and we wish to observe the structure of said solutions when viewed as a subset of an appropriate function space via global bifurcation theory [25] as well as determine the stability properties of the solution when viewed as solutions to (2.1). We assume that $d\in C^2(\bar{\Omega}\times\mathbb{R})$ such that $d(x,s)\geqq d_1>0$ for all $(x,s)\in\bar{\Omega}\times\mathbb{R}$, $\mathbf{b}\in[C^1(\bar{\Omega})]^n$, and $m\in L^\infty(\bar{\Omega})$ and consider

$$\begin{aligned} &-\nabla\cdot(d(x,u)\nabla u) + \mathbf{b}(x)\cdot\nabla u = \lambda(m(x)u - cu^2) && \text{in } \Omega,\\ &u = 0 && \text{on } \partial\Omega. \end{aligned} \tag{2.2}$$

Observe first of all that (2.2) can be expressed as

$$\begin{aligned} &-\Delta u + \left[\frac{\mathbf{b}(x) - \mathbf{d}_x(x,0)}{d(x,0)}\right]\cdot\nabla u\\ &\quad = \lambda\frac{m(x)}{d(x,0)}u + \left[\frac{d_u(x,u)}{d(x,u)}|\nabla u|^2 + \left(\frac{\mathbf{d}_x(x,u)}{d(x,u)} - \frac{\mathbf{d}_x(x,0)}{d(x,0)}\right)\cdot\nabla u\right.\\ &\quad\quad + \left(\frac{1}{d(x,0)} - \frac{1}{d(x,u)}\right)(\mathbf{b}(x)\cdot\nabla u) + \lambda\left(\frac{1}{d(x,u)} - \frac{1}{d(x,0)}\right)m(x)u - \left.\frac{\lambda cu^2}{d(x,u)}\right] \quad \text{in } \Omega,\\ &u = 0 \quad \text{on } \partial\Omega. \end{aligned} \tag{2.3}$$

Denote the expression in brackets in (2.3) by $H(\lambda,u)$. Then for a sufficiently large p, $H:\mathbb{R}\times W_0^{1,p}(\Omega)\to L^{p/2}(\Omega)$ is continuous and $\lim_{\|u\|_{1,p}\to 0} H(\lambda,u)/\|u\|_{1,p} = 0$, where $\|\ \|_{1,p}$ denotes the norm in $W_0^{1,p}(\Omega)$ and the limit is uniform for λ contained in compact intervals. (That such is the case relies on the fact $W_0^{1,p}(\Omega)$ embeds into $C_0^\alpha(\bar{\Omega})$ for sufficiently large p.) Consequently, if L denotes the elliptic operator on the left-hand side of (2.3) subject to zero Dirichlet boundary data and M/D denotes multiplication by $m(x)/d(x,0)$, a solution u to (2.3) is equivalent to a solution u of

$$u = \lambda L^{-1}\left(\frac{M}{D}\right)u + L^{-1}H(\lambda,u). \tag{2.4}$$

Since $L^{-1}: L^{p/2}(\Omega)\to W^{2,p/2}(\Omega)\cap W_0^{1,p/2}(\Omega)$ is continuous, $W^{2,p/2}(\Omega)\cap W_0^{1,p/2}(\Omega)$ embeds compactly into $C_0^{1+\alpha}(\bar{\Omega})$, $0<\alpha<1$ for p sufficiently large, and $C_0^{1+\alpha}(\bar{\Omega})$ embeds into $W_0^{1,p}(\Omega)$ for any p, the right-hand side of (2.4) may be viewed as a completely continuous operator on $W_0^{1,p}(\Omega)$ for a sufficiently large p with $\lim_{\|u\|_{1,p}\to 0}\|L^{-1}H(\lambda,u)\|_{1,p}/\|u\|_{1,p} = 0$ uniformly for λ in compact intervals. Consequently, $\mathbb{R}\times W_0^{1,p}(\Omega)$ is an appropriate space in which to apply global bifurcation theory [25].

In order to invoke global bifurcation theory to guarantee the existence of a continuum of positive solutions to (2.2) in $\mathbb{R}\times W_0^{1,p}(\Omega)$, it suffices to establish that there is a unique $\lambda = \lambda_1(m) > 0$ such that

$$v = \lambda L^{-1}\left(\frac{M}{D}\right)v \tag{2.5}$$

has as generalized null space the span of a positive function. Note that (2.5) is equivalent

to

$$\begin{aligned} &-\nabla\cdot(d(x,0)\nabla v)+\mathbf{b}(x)\cdot\nabla v=\lambda m(x)v \quad \text{in } \Omega,\\ &v=0 \qquad\qquad\qquad\qquad\qquad\qquad\quad \text{on } \partial\Omega. \end{aligned} \tag{2.6}$$

In the special cases $\mathbf{b}\equiv\mathbf{0}$ or $m\in C(\bar{\Omega})$, the result follows from the results of [21] and [15], respectively, provided that $\{x\in\Omega: m(x)>0\}$ has positive measure. In the case that $\mathbf{b}\not\equiv\mathbf{0}$ and $m\in(L^{\infty}(\Omega)-C(\bar{\Omega}))$, to our knowledge, the result does not explicitly appear in the literature. Since such is the case and since the result is of independent interest, we include a brief proof.

THEOREM 2.1. *Suppose that d, $\mathbf{b}$, and m are as described above and that $\{x\in\Omega: m(x)>0\}$ has positive measure. Then there is a unique $\lambda=\lambda_1(m)>0$ such that*

$$\begin{aligned} &-\Delta v+\left[\frac{\mathbf{b}(x)-\mathbf{d}_x(x,0)}{d(x,0)}\right]\cdot\nabla v=\lambda\frac{m(x)}{d(x,0)}v \quad \text{in } \Omega,\\ &v=0 \qquad\qquad\qquad\qquad\qquad\qquad\quad \text{on } \partial\Omega \end{aligned} \tag{2.7}$$

has a solution $v\in C_0^{1+\alpha}(\bar{\Omega})$ with $v(x)>0$ in Ω and $(\partial v/\partial n)(x)<0$ on $\partial\Omega$. Moreover, $\cup_{r\geqq 1}N\{(I-\lambda L^{-1}(M/D))^r\}=\langle v\rangle$.

Proof. The uniqueness and simplicity assertions of the theorem follow as in [15] once the existence of such a λ has been established. To this end, let $R>0$ be such that $m(x)/d(x,0)+R>0$ on Ω almost everywhere and consider the operator $A_\lambda=\lambda(L+R\lambda)^{-1}(M/D+R)$, which may be viewed as a compact positive operator on $C_0^0(\bar{\Omega})$. A_λ is continuous in λ and consequently so is its spectral radius $r(A_\lambda)$ [23]. Moreover, $\lim_{\lambda\to 0}r(A_\lambda)=0$. Hence, as in [8], the existence of an eigenvalue λ with the required properties follows from the Krein–Rutman theorem and the maximum principle as long as there is a $\lambda>0$ so that $r(A_\lambda)\geqq 1$. The assumption that $\{x\in\Omega: m(x)>0\}$ has positive measure guarantees that (2.7) has infinitely many eigenvalues with positive real part [14, Thm. 2]. For any such eigenvalue λ^* and any associated eigenfunction v, Lemma 3 of [15] implies that

$$|v|\leqq A_{\mathrm{Re}\,\lambda^*}|v|.$$

Hence $r(A_{\mathrm{Re}\,\lambda^*})\geqq 1$, and the result is established.

It is of substantial interest from the biological point of view not only to have the existence of an unbounded continuum of positive solutions to (2.2) but also to know there is a solution (λ,u) on the continuum for all $\lambda>\lambda_1(m)$. Such an observation requires information in addition to that provided by global bifurcation theory. The *a priori* estimates given in the following theorem are sufficient for this purpose.

THEOREM 2.2. *Suppose (λ,u) is a positive solution to (2.2) and that $\lambda\in[a,b]$, where $0\leqq a\leqq b<\infty$. Then there is a constant $K>0$ such that $\|u\|_{1,p}\leqq K$.*

Proof. We know that $u\in W^{2,p}(\Omega)\cap W_0^{1,p}(\Omega)$ and consequently $u\in C_0^{1+\alpha}(\bar{\Omega})$. Hence, as in § 2 of [6], the maximum principle implies that $\|u\|_{\infty}\leqq$ ess $\sup_{x\in\bar{\Omega}}(m^+(x)/c)$. The result then will follow if we can show $\|\nabla u\|_{\infty}$ is bounded uniformly with respect to $\lambda\in[a,b]$.

To this end, we employ results in §§ 4 and 5 of Chapter 4 and in § 2 of Chapter 6 of [18]. Equation (2.2) satisfies the ellipticity and structure conditions there imposed, with ellipiticity (and other constants) bounded for $\lambda\in[a,b]$. Moreover, as noted, $0\leqq u(x)\leqq$ ess $\sup_{x\in\bar{\Omega}}(m^+(x)/c)$. By the proof of Theorem 4.1 of [18, Chap. 4], ess $\sup_{\Omega}|\nabla u|$ can then be bounded in terms of ess $\sup_{\partial\Omega}|\nabla u|$ and integrals which are in essence $\|u\|_{2,2}^2$ and $\|u\|_{1,4}^2$. Theorem 5.1 of [18, Chap. 4] implies that these last integrals are bounded in terms of $\|u\|_{\infty}$ and constants depending on Ω and the coefficients of (2.2), all of which are uniformly bounded for $\lambda\in[a,b]$.

In order to see that ess $\sup_{\partial\Omega} |\nabla u|$ is uniformly bounded with respect to $\lambda \in [a, b]$, we employ Lemma 4.1 of [18, Chap. 4] or Lemma 2.1 of [18, Chap. 6]. (These are two statements of the same result.) The idea behind the lemmas is Bernstein's, namely, to compare u with an appropriate auxiliary function via differential inequalities and the maximum principle to obtain bounds on $\partial u/\partial n$ on subsets of $\partial\Omega$. In [18], the classical maximum principle is used, and u is assumed to have classical second derivatives throughout Ω. However, we may replace the classical maximum principle with the maximum principle for weak solutions as stated in Chapter 8 of [11] and only require that $u \in W^{2,p}(\Omega) \cap W_0^{1,p}(\Omega)$. The bound we obtain depends only on Ω, $\|u\|_\infty$, and ellipticity and structure constants which are bounded as long as $\|u\|_\infty$ and λ are uniformly bounded so the result follows.

Consequently, there is an unbounded continuum $\mathscr{C}$ in $\mathbb{R} \times W_0^{1,p}(\Omega)$ of positive solutions to (2.2) with the property that if $(\lambda, u) \in \mathscr{C}$ and $\lambda \in [a, b]$, where $0 \leqq a < b < \infty$, there is a $K > 0$ such that $\|u\|_{1,p} \leqq K$. Furthermore, it is evident that (2.2) has only the trivial solution when $\lambda = 0$. Hence, the projection $\Pi(\mathscr{C})$ into $\mathbb{R}$ of $\mathscr{C}$ must satisfy $(\lambda_1(m), \infty) \subseteq \Pi(\mathscr{C}) \subseteq (0, \infty)$. In particular, there is at least one positive solution of (2.2) for every $\lambda > \lambda_1(m)$.

For any fixed λ, $(\lambda, u) \in \mathscr{C}$ of course implies that u is an equilibrium solution to (2.1). It is sometimes possible to determine that u is globally asymptotically stable with respect to smooth initial data $u_0(x) \geqq 0$. We first observe that if $\lambda > \lambda_1(m)$, then the zero solution of (2.2) is unstable. To this end, observe that the linearization A of $-\nabla \cdot (d(x, u)\nabla u) + \mathbf{b}(x) \cdot \nabla u - \lambda(m(x)u - cu^2)$ with respect to u at $u = 0$ is given by $A(\phi) = -\nabla \cdot (d(x, 0)\nabla\phi) + \mathbf{b}(x) \cdot \nabla\phi - \lambda m(x)\phi$ and that the zero solution is unstable provided that

$$A\phi = \sigma\phi \quad \text{in } \Omega,$$

$$\phi = 0 \quad \text{on } \partial\Omega,$$

and $\phi(x) > 0$ in Ω implies that $\sigma < 0$. If $\sigma \geqq 0$, then $v = \phi$ is a positive solution to the inhomogeneous boundary value problem

$$-\nabla \cdot (d(x, 0)\nabla v) + \mathbf{b}(x) \cdot \nabla v = \lambda m(x)v + h \quad \text{in } \Omega,$$

$$v = 0 \quad \text{on } \partial\Omega,$$

where $h = \sigma\phi \geqq 0$. As $\lambda > \lambda_1(m)$, Proposition 3 of [15] is violated. As a consequence, the zero solution of (2.2) is unstable as an equilibrium to (2.1) if $\lambda > \lambda_1(m)$, and we are able to establish the following theorem.

THEOREM 2.3. *Suppose that for some $\lambda > \lambda_1(m)$, there is a unique positive solution $\bar{u}$ to* (2.2). *Then $\bar{u}$ is a globally asymptotically stable equilibrium for* (2.1) *provided we require the initial data u_0 to lie in an appropriate Sobolev–Slobedickii space $W_0^{\sigma,p}$. This will be the case if $u_0 \in C_0^2(\bar{\Omega})$, for example.*

Proof. The methods of Amann [1], [2] imply that (2.1) generates a monotone flow on a Sobolev–Slobedickii space $W_0^{\sigma,p}(\Omega)$ with $W_0^{\sigma,p}(\Omega) \subseteq W^{2,p}(\Omega) \cap W_0^{1,p}(\Omega) \subseteq C^1(\bar{\Omega})$. (See also [16, Thm. 4.6]. We assume slightly less regularity than Amann since $m(x) \in L^\infty(\Omega)$, but a comparison principle for weak solutions to quasilinear parabolic problems can be readily obtained by modifying the proof of Theorem 9.5 of [11] to treat the parabolic case, so this is not a problem.) Consequently, the results of [16] are applicable in this situation. Since the zero solution of (2.2) is an unstable equilibrium and since $[0, \bar{u}]$ is an order interval containing no other equilibria, Theorem 0.6 of [16] implies that if $0 \leqq \bar{u}_0(x) \leqq \bar{u}(x)$ and $u_0(x) \not\equiv 0$, then the solution $u(x, t)$ of (2.1) corresponding to $u_0(x)$ converges to $\bar{u}(x)$ as $t \to \infty$, uniformly on $\bar{\Omega}$. Moreover, for any sufficiently

large constant K, Theorem 0.7 of [16] implies that the solution $u_K(x,t)$ of (2.1) corresponding to initial condition K converges to $\bar{u}(x)$ as $t\to\infty$, uniformly on $\bar{\Omega}$. The result now follows from monotonicity, since for any smooth initial data $v(x)>0$ and $v\not\equiv 0$, we can find $u_0(x)\in[0,\bar{u}]$ and K sufficiently large so that $u_0(x)\leqq v(x)\leqq K$. We conclude this section with the following result, which is a corollary to Theorems 2.1–2.3.

THEOREM 2.4. *Consider equation* (2.6) *and let* $\lambda_1(d,\mathbf{b},m)$ *be as in Theorem* 2.1. *If* $\lambda_1(d,\mathbf{b},m)<1$, *then the problem* (2.1) *with* $\lambda=1$ *has a positive equilibrium solution* $\bar{u}$. *If* $\bar{u}$ *is unique, then it is globally asymptotically stable with respect to smooth initial data* $u_0(x)$.

2.1. Biological interpretation. The primary result of biological interest in this section is Theorem 2.4. That result asserts that there exists a positive equilibrium density for the population being modeled provided that the eigenvalue $\lambda_1(d,\mathbf{b},m)$ is less than 1. The significance of the result lies in the fact that $\lambda_1(d,\mathbf{b},m)$ depends directly on the terms in the model describing biological properties of the population and the environment. Thus Theorem 2.4 provides a criterion for the possible persistence of a population in terms of diffusion, drift, and growth rates which vary with location. In some simple cases it is possible to compute $\lambda_1(d,\mathbf{b},m)$ as the solution of an equation involving trigonometric and hyperbolic functions (which can be approximated by Newton's method). This is discussed in [7]; an example is given below.

In general, the numerical problem of finding $\lambda_1(d,\mathbf{b},m)$ is fairly difficult but has been studied extensively. Approximation schemes for the case $\mathbf{b}=0$ (no drift) are discussed in detail in [29]. There is a substantial literature on numerical approximation for solutions of eigenvalue problems with or without drift terms; [29] gives a large number of references. It is not surprising that the computation of the eigenvalue λ_1 may be complicated, since if λ_1 gives a reasonable synthesis of the various factors such as the size, shape, and quality of the environment and the effects of winds, currents, temperature or chemical gradients, it must reflect a large number of complex biological factors. In giving an accurate description of a complex phenomenon, a certain amount of mathematical sophistication may be required. Even so, the computational problem of finding $\lambda_1(d,\mathbf{b},m)$ is likely to be simpler than that of evaluating the results of a comparably detailed simulation.

A major advantage of having a criterion for persistence based on $\lambda_1(d,\mathbf{b},m)$ is that it is possible to make a number of *qualitative* statements about the ways in which changes in the environment affect a population. That is the main theme of [6] and [7] and of § 4 of this article. We discuss the topic at some length in § 4.

As an example, suppose that we consider a one-dimensional region $\Omega=(0,\ell)$, with no drift, constant diffusion rate, and a growth rate $m(x)$ which is a positive constant on a subinterval of Ω and a negative constant on the remainder of Ω. For appropriate d, this problem can easily be rescaled into the form

$$\begin{aligned} &u''+m(x)u-cu^2=0 \quad \text{on } (0,1),\\ &u(0)=u(1)=0 \end{aligned} \tag{2.8}$$

with

$$m(x)=\begin{cases} -1, & 0<x<a,\\ k, & a<x<a+T,\\ -1, & a+T<x<1, \end{cases} \tag{2.9}$$

for some $T<1$ describing the relative size of the favorable region, some $a\in[0,1-T]$ describing its location relative to the boundary, and some k describing the relative

quality of the favorable habitat compared with the unfavorable. (The diffusion coefficient is scaled into $m(x)$; the carrying capacity relative to habitat quality is described by c but does not directly enter the computation of λ_1.) We show in [7] that for (2.8), (2.9), we have $\lambda_1 = \alpha^2$ where α is the smallest positive solution of

$$\cot \alpha\sqrt{k}\, T = \frac{k \tanh[\alpha(1-a-T)] \tanh \alpha a - 1}{\sqrt{k}\,[\tanh \alpha a + \tanh \alpha(1-a-T)]}. \tag{2.10}$$

Note that for a uniformly favorable environment we have $\lambda_1 = \alpha^2 = \pi^2/k$ so that we can expect persistence only for $k > \pi^2$. For $k = 16$, $T = 1$, $a = 0$ (indicating a uniformly favorable environment), we have $\lambda_1 \approx .61$. For $k = 16$, $a = .1$, $T = .8$ we find by solving (2.10) that $\lambda_1 \approx .63$. For $k = 16$, $a = .3$, $T = .4$, $\lambda_1 \approx .86$. The results of [7] show how in (2.8) a number of other forms of $m(x)$ can be treated via equations similar to (2.10).

3. Uniqueness. In this section we shall consider the question of uniqueness for positive steady states in our model. Our analysis includes some results on the direction of bifurcation with respect to the unfolding parameter λ, and on the linearized stability of the steady state. We begin with an example that shows that some restrictions are needed if uniqueness is to hold. In the general semilinear problem $\Delta u + f(x, u) = 0$, some conditions must be imposed on f to obtain uniqueness, and the problem $\nabla \cdot d(u)\nabla u + m(x)u - cu^2 = 0$ is equivalent to the semilinear problem $\Delta U + m(x)D^{-1}(U) - c[D^{-1}(U)]^2 = 0$ where $U = D(u)$ with $D'(s) = d(s)$, $D(0) = 0$; so we must expect that some conditions will be needed on $d(s)$ if the corresponding semilinear problem is to have a unique solution. The nature of those conditions is indicated by the problem

$$(d(u)u')' + \lambda(u - u^2) = 0, \qquad u > 0 \quad \text{on } (0, \pi), \qquad u(0) = u(\pi) = 0, \tag{3.1}$$

where $d(s) = 1 - 2d_0 s$ for $0 \leqq s \leqq d_0/4$, $d(s)$ is smooth for $0 \leqq s < \infty$, and $d(s) \geqq d_1 > 0$. By the analysis in § 2, a branch of positive solutions to (3.1) bifurcates from the trivial solution at $\lambda = 1$. If we multiply the equation in (3.1) by u, integrate by parts, and use the fact that

$$\int_0^\pi u'(x)^2\, dx \geqq \int_0^\pi u(x)^2\, dx,$$

then we obtain the relation

$$d_1 \int_0^\pi u^2\, dx \leqq d_1 \int_0^\pi (u')^2\, dx \leqq \int_0^\pi d(u)(u')^2\, dx = \lambda \int_0^\pi u^2\, dx - \lambda \int_0^\pi u^3\, dx.$$

Since $u > 0$ on $(0, \pi)$, it follows that $\lambda \geqq d_1 > 0$. Also, $0 < u < 1$ on $(0, \pi)$ by the maximum principle, so a standard application of the Rabinowitz global bifurcation theorem implies that the branch of positive solutions emanating from the zero solution at $\lambda = 1$ must meet infinity in λ. However, if we multiply (3.1) by $\sin x$ and integrate by parts, then as long as $0 \leqq u \leqq d_0/4$ (which will be true locally near the bifurcation point) we have

$$\begin{aligned}
\lambda \int_0^\pi u \sin x\, dx - \lambda \int_0^\pi u^2 \sin x\, dx &= -\int_0^\pi (d(u)u')' \sin x\, dx \\
&= -\int_0^\pi u'' \sin x\, dx + \int_0^\pi (2d_0 uu')' \sin x\, dx \\
&= \int_0^\pi u \sin x\, dx - \int_0^\pi d_0 u^2 \sin x\, dx.
\end{aligned}$$

Hence, as long as $0 < u \leqq d_0/4$, we have

$$\lambda \int_0^\pi (u-u^2)\sin x\,dx = \int_0^\pi (u-u^2)\sin x\,dx + (1-d_0)\int_0^\pi u^2 \sin x\,dx,$$

so if $d_0 > 1$, we must have $\lambda < 1$. But the branch of solutions must meet infinity in λ, so there must be a solution with $\sup u > d_0/4$ corresponding to $\lambda = 1$. It follows from the fact that the branch of positive solutions is a continuum and the leftward direction of bifurcation that for some $\varepsilon > 0$, the problem (3.1) has at least two solutions, one with $\sup u \leqq d_0/4$ and one with $\sup u > d_0/4$, for $\lambda = 1-\varepsilon$.

To avoid the phenomenon observed in this example, we must ensure that the bifurcation is to the right rather than to the left. If we have $\lambda > \lambda_1(d(x,0), \mathbf{b}, m)$ for all positive solutions and they are all linearly stable, that is enough for uniqueness.

THEOREM 3.1. *Assume that $d(x,u)$ is of class C^1. Suppose that for any solution of*

$$\begin{aligned} &\nabla d(x,u)\nabla u - \mathbf{b}(x)\cdot\nabla u + \lambda(m(x)u - cu^2) = 0 && \text{in } \Omega, \\ &u = 0 && \text{on } \partial\Omega, \\ &\lambda > 0, \quad u > 0 && \text{in } \Omega, \end{aligned} \tag{3.2}$$

we have $\lambda > \lambda_1(d(x,0), \mathbf{b}, m)$, and that the first eigenvalue of the linearized problem

$$\begin{aligned} &-\nabla\cdot d(x,u)\nabla\phi - \nabla\cdot\phi\frac{\partial d(x,u)}{\partial u}\nabla u + \mathbf{b}\cdot\nabla\phi + \lambda(2cu-m)\phi = \sigma\phi \quad \text{in } \Omega, \\ &\phi = 0 \qquad\qquad \text{on } \partial\Omega \end{aligned} \tag{3.3}$$

satisfies $\sigma_1 > 0$ for any positive solution u. Then the positive solution for (3.2) *is unique for any given λ.*

Remarks. Combined with the comparison principle for the corresponding parabolic problem and the results of Hirsch [16], uniqueness implies stability. The condition $\sigma_1 > 0$ already implies linearized (and hence local) stability.

Proof. Choose $p > 1$ large enough that $W^{2,p}(\Omega) \cap W_0^{1,p}(\Omega)$ embeds in $C_0^{1+\alpha}(\Omega)$ and $W^{1,p/2}(\Omega)$ embeds in $C^\beta(\Omega)$ for some $\alpha, \beta \in (0,1)$. Then the nonlinear function $F(\lambda, u) = \nabla\cdot d(x,u)\nabla u - \mathbf{b}(x)\cdot\nabla u + \lambda(m(x)u - cu^2)$ maps $\mathbb{R}\times(W^{2,p}(\Omega)\cap W_0^{1,p}(\Omega)) \to L^p(\Omega)$. The map is continuously differentiable, and the derivative with respect to the second variable is the negative of the operator on the left side of (3.3). If $\sigma_1 > 0$ in (3.3), then the linearized operator is invertible from L^p to $W^{2,p}\cap W_0^{1,p}$ by standard elliptic theory. Thus, if (λ_0, u_0) satisfies $F(\lambda, u) = 0$ and $u_0 > 0$ in Ω, then there is a bounded neighborhood U of u_0 in $W^{2,p}\cap W_0^{1,p}$, an interval $\Lambda = (\lambda_0 - \delta, \lambda_0 + \delta)$ with $\delta > 0$, and a function $g: \Lambda \to U$ such that for any $\lambda \in \Lambda$, the unique solution in U of (3.2) is $u = g(\lambda)$. Let $\lambda_k \uparrow \lambda_0 + \delta$ as $k \to \infty$. By (3.2), we have for $u_k = g(\lambda_k)$

$$\begin{aligned} u_k &= -\Delta^{-1}[(\nabla d(x,u_k)\cdot\nabla u_k - \mathbf{b}\cdot\nabla u_k + \lambda_k(mu_k - cu_k^2))/d(x,u_k)] \\ &\equiv -\Delta^{-1} w_k. \end{aligned} \tag{3.4}$$

Since U is bounded in $W^{2,p}\cap W_0^{1,p}$, so is $\bar{U}$; thus the right side of (3.4) is of the form $-\Delta^{-1}w_k$, where $\{w_k\}$ is uniformly bounded in $W^{1,p/2}$. (Here the $p/2$ is due to the presence on the right side of (3.4) of terms of the form $(\partial d/\partial u)|\nabla u|^2$; also, we have used the fact that $d \geqq d_1 > 0$, the embedding $W^{2,p}\cap W_0^{1,p} \hookrightarrow C_0^{1+\alpha}$, and the differentiability of d.) Our choice of p is such that $W^{1,p/2} \hookrightarrow C^\beta$, so since C^β embeds compactly in

C^0, we may choose a subsequence and reindex so that $\{w_k\}$ converges in C^0, and hence in L^p. Then (3.4) implies that the sequence $\{u_k\}$ converges in $W^{2,p} \cap W_0^{1,p}$, thus producing a nonnegative solution to (3.2) at $\lambda = \lambda_0 + \delta$. A similar argument applies at $\lambda = \lambda_0 - \delta$. For these values of λ, the solution can be extended further if it is positive. However, if we choose $K > 0$ sufficiently large we have from (3.2) that

$$-\nabla \cdot d(x, u)\nabla u + \mathbf{b}(x) \cdot \nabla u + Ku = [\lambda m(x) - \lambda cu + K]u \geqq 0,$$

so if $u \geqq 0$ and $u = 0$ somewhere in Ω, then $u = 0$ almost everywhere by the strong maximum principle for weak solutions (see [11, Thm. 8.19]). Hence, the only way that continuation in λ can fail is if λ is a bifurcation point from the branch of trivial solutions. The unique point where positive solutions can bifurcate from that branch is $\lambda = \lambda_1(d(x, 0), \mathbf{b}, m)$. It follows that if (3.2) has a positive solution u_0 for some λ_0, then there is a curve $(\lambda, u(\lambda))$ of positive solutions passing through (λ_0, u_0) which can be extended at least until $\lambda = \lambda_1(d(x, 0), \mathbf{b}, m)$. Suppose that for some $\lambda_0 > \lambda_1(d(x, 0), \mathbf{b}, m)$ there are two distinct positive solutions of (3.2). Then each lies on an arc which extends until $\lambda = \lambda_1(d(x, 0), \mathbf{b}, m)$, and the arcs cannot intersect as long as the solutions to (3.2) remain positive. If an arc contains a positive solution to (3.2) at $\lambda = \lambda_1(d(x, 0), \mathbf{b}, m)$, then the preceding argument based on the implicit function theorem implies that there are positive solutions of (3.2) on $\lambda \in (\lambda_1 - \delta, \lambda_1)$, for some $\delta > 0$, contradicting our hypotheses. But both branches cannot connect to the zero solution at the point $\lambda = \lambda_1(d(x, 0), \mathbf{b}, m)$, since the Crandall–Rabinowitz constructive bifurcation theorem for simple eigenvalues implies that there is a unique branch of positive solutions in some neighborhood of the bifurcation point. Hence, assuming the existence of two distinct positive solutions for some λ yields a contradiction, so for any λ the positive solution of (3.2) must be unique.

Remark. A similar argument is used to obtain a uniqueness theorem for a diffusive Lotka–Volterra competition model in [5].

So far, we have been unable to establish that the hypotheses of Theorem 3.1 are satisfied, in general, for equations of the form (3.2). However, we can show that they will be met if the differential operator in (3.2) is either linear or in divergence form. The two cases require different arguments, so we consider them separately.

COROLLARY 3.2. *Suppose that* $\mathbf{b} \equiv 0$ *and* $\partial d(x, u)/\partial u \geqq 0$ *for all* $x \in \Omega$ *and* $u \in [0, \operatorname{ess\,sup}(m^+/c)]$. *Then* (3.2) *has a unique positive solution for* $\lambda > \lambda_1(d(x, 0), 0, m)$.

Proof. Suppose that (3.2) has a positive solution for some $\lambda > 0$. Multiplying by u, integrating by parts, and using the hypothesis that $d(x, u)$ is monotone increasing in u, we have

$$0 < \int_\Omega d(x, 0)|\nabla u|^2 \, dx < \int_\Omega d(x, u)|\nabla u|^2 + \lambda c \int_\Omega u^3 \, dx = \lambda \int_\Omega m(x)u^2 \, dx.$$

Since $\int_\Omega mu^2 \, dx > 0$, it follows from results in [16] that

$$\int_\Omega d(x, 0)|\nabla u|^2 \, dx \geqq \lambda_1(d(x, 0), 0, m) \int_\Omega m(x)u^2 \, dx,$$

so that

$$\lambda_1(d(x, 0), 0, m) \int_\Omega mu^2 \, dx < \lambda \int_\Omega mu^2 \, dx$$

and

$$\lambda_1(d(x, 0), 0, m) < \lambda,$$

as required.

Suppose that $\phi_1 > 0$ is an eigenfunction for (3.3) corresponding to the principa eigenvalue σ_1. Multiplying (3.3) by u and integrating by parts yields

$$\sigma_1 \int_\Omega u\phi_1 \, dx = \int_\Omega \left[-\nabla \cdot d(x, u)\nabla u + \frac{\partial d(x, u)}{\partial u} |\nabla u|^2 + 2\lambda cu^2 - \lambda mu \right] \phi_1 \, dx,$$

so by (3.2) we have

$$\sigma_1 \int_\Omega u\phi_1 \, dx = \int_\Omega \left[\frac{\partial d(x, u)}{\partial u} |\nabla u|^2 + \lambda cu^2 \right] \phi_1 \, dx > 0$$

and hence $\sigma_1 > 0$ as required.

COROLLARY 3.3. *Suppose that* $d(x, u) \equiv d(x, 0)$, *so that* (3.2) *is semilinear. The* (3.2) *has a unique positive solution for* $\lambda > \lambda_1(d(x, 0), \mathbf{b}, m)$.

Proof. Suppose that (3.2) has a positive solution for some $\lambda > 0$. Then we have

$$-\nabla \cdot d(x, 0)\nabla u + \mathbf{b}(x) \cdot \nabla u = \lambda(m(x) - cu)u,$$

where $u > 0$ in Ω and $u = 0$ on $\partial\Omega$, so that

$$\lambda = \lambda_1(d(x, 0), \mathbf{b}, m - cu) > \lambda_1(d(x, 0), \mathbf{b}, m)$$

by the monotonicity of the positive principal eigenvalue with respect to the weigh (see [11]). In this case, (3.2) can be written as

$$-\nabla \cdot d(x, 0)\nabla u + \mathbf{b} \cdot \nabla u + \lambda(2cu - m)u = \lambda cu > 0. \tag{3.5}$$

Since (3.5) admits a positive solution u for the positive inhomogeneous term λcu it follows that the principal eigenvalue for the operator $L\phi \equiv -\nabla \cdot d(x, 0)\nabla\phi - \mathbf{b} \cdot \nabla\phi + \lambda(2cu - m)\phi$ must be positive. Since $\partial d(x, u)/\partial u \equiv 0$, that eigenvalue is σ_1 so $\sigma_1 > 0$.

Remark. It would be of interest to find a natural set of conditions including thos of both corollaries under which the hypotheses of Theorem 3.1 are satisfied. So far w have been unable to find such general conditions. It is well known that results fo quasilinear problems not in divergence form are typically much weaker and/or mor difficult than for either linear or divergence form problems (see the discussion in [7 and [14]). There are numerous open questions about uniqueness even in the case o ordinary differential equations.

3.1. Biological interpretation. The results of this section serve largely to sharpe those of the previous section by giving criteria for the uniqueness of the positive stead state for the population. Uniqueness is important in the context of our models becaus it implies the global stability of the positive steady state and thus the persistence o the population. Perhaps the most interesting observation from a biological viewpoir is that uniqueness may *fail* if the rate of diffusion is allowed to decrease with respec to the population density. Such a phenomenon occurs when the diffusion rate i constant but the logistic growth term is replaced by something of the form $uf(x, u$ with $f(x, u)$ sometimes increasing with u; in other words, in the presence of depensatio in the growth rate. That observation is made in [20] in connection with a model fo the population dynamics of the spruce budworm. As far as we know, it has not bee observed previously that the same sort of effect can be induced by density depender diffusion, which can sometimes produce multiple steady states even with a simpl logistic growth term. In the absence of drift, we show that such an effect can onl occur if the diffusion rate decreases relative to the population density at some densities We have not been able to determine the effects of drift terms on this phenomenon. I

the case of a density independent diffusion rate, we show that a positive steady state is unique and stable if it exists, and similarly for models with no drift and a diffusion rate which increases with population density.

4. Properties of the principal eigenvalue. We have seen that under fairly general hypotheses, the condition $\lambda_1(d(x,0), \mathbf{b}(x), m(x)) < 1$ is sufficient for the existence of a positive steady state for our model, and under somewhat stronger hypotheses the condition is also necessary and the positive steady state is unique and hence stable. Thus, it is natural to ask how $\lambda_1(d(x,0), \mathbf{b}(x), m(x))$ depends on d, $\mathbf{b}$, and m. Some results for the case $d(x,0) \equiv 1$, $m(x) \equiv 1$ are given in [21], and for the case $d(x,0) \equiv 1$ and $\mathbf{b} \equiv 0$ in [6].

Our first result is an extension of Theorem 3.1 of [6].

THEOREM 4.1. *Suppose that* $d(x) = d(x,0) \in C^{1+\alpha}(\bar{\Omega})$, $\mathbf{b}(x) = (b_1, \cdots, b_n)$ *with* $b_i(x) \in C^{\alpha}(\bar{\Omega})$ *for* $i = 1, \cdots, n$, *and* $m_j(x) \in L^{\infty}(\Omega)$ *for* $j = 1, 2, \cdots$. *Suppose that* d *and* $\mathbf{b}$ *are such that for any* $\phi \in W_0^{1,2}(\Omega)$ *we have*

$$\int_{\Omega} d|\nabla\phi|^2 + (\mathbf{b}\cdot\nabla\phi)\phi \geqq d_0 \int_{\Omega} |\nabla\phi|^2 \tag{4.1}$$

for some $d_0 > 0$, *and for each* j,

$$\|m_j\|_{\infty} \leqq m_0 \quad \text{and} \quad m_j > 0 \quad \text{on a set of positive measure.} \tag{4.2}$$

To have $\lim_{j\to\infty} \lambda_1(d, \mathbf{b}, m_j) = \infty$, *it is necessary and sufficient that*

$$\limsup_{j\to\infty} \int_{\Omega} m_j\beta \leqq 0 \tag{4.3}$$

for all $\beta \in L^1(\Omega)$ *with* $\beta \geqq 0$ *almost everywhere.*

Proof. Suppose that (4.1), (4.2), and (4.3) hold but $\lambda_1(d, \mathbf{b}, m_j) \not\to \infty$ as $j \to \infty$. We may then choose a subsequence $\{\lambda_1(d, \mathbf{b}, m_k)\}$ which is bounded. Let ϕ_k be the positive eigenfunction corresponding to $\lambda_1(d, \mathbf{b}, m_k)$ and normalized so that $\int_{\Omega} |\nabla\phi_k|^2 = 1$. Then the sequence $\{\phi_k\}$ is uniformly bounded in $W_0^{1,2}(\Omega)$, and since $W_0^{1,2}(\Omega)$ embeds compactly in $L^2(\Omega)$, we may choose a subsequence $\{\phi_l\}$ which converges in $L^2(\Omega)$ to some function ϕ. We have

$$\begin{aligned} d_0 = d_0 \int_{\Omega} |\nabla\phi_l|^2 &\leqq \int_{\Omega} d(x)|\nabla\phi_l|^2 + \phi_l \mathbf{b}(x)\cdot\nabla\phi_l \\ &= \lambda_1(d, \mathbf{b}, m_l) \int_{\Omega} m_l\phi_l^2 \\ &= \lambda_1(d, \mathbf{b}, m_l)\left(\int_{\Omega} m_l(\phi_l^2 - \phi^2) + \int_{\Omega} m_l\phi^2 \right). \end{aligned} \tag{4.4}$$

Letting $l \to \infty$, the first integral in the last formula goes to zero since $\|m_l\|_{\infty} \leqq m_0$ and $\phi_l \to \phi$ in $L^2(\Omega)$; the second goes to zero by (4.3). Since $\{\lambda_1(d, \mathbf{b}, m_l)\}$ is bounded, this implies $d_0 \leqq 0$, which is a contradiction, so we must have $\lambda_1(d, \mathbf{b}, m_j) \to \infty$.

To show that our hypotheses are necessary as well as sufficient, we use a device due to Holland [17] in a form similar to that used by Hess [13] in the context of periodic-parabolic problems. (In fact, this device provides a method for estimating the size of $\lambda_1(d, \mathbf{b}, m)$ from above for fixed d, $\mathbf{b}$, and m, but we shall not pursue this.) Consider the problem

$$-\nabla d(x)\nabla\psi + \mathbf{b}\cdot\nabla\psi - \lambda m\psi = \mu\psi \quad \text{in } \Omega, \qquad \psi = 0 \quad \text{on } \partial\Omega, \tag{4.5}$$

where $m \in L^\infty(\Omega)$ and $m > 0$ on a set of positive measure. The first eigenvalue $\mu_1(\lambda)$ admits an eigenfunction with $\psi > 0$ on Ω. Let $\theta = -\ln \psi$; then θ is defined on Ω and satisfies

$$d\Delta\theta - d|\nabla\theta|^2 - (\mathbf{b} - \nabla d)\cdot\nabla\theta - \lambda m = \mu_1(\lambda). \tag{4.6}$$

Suppose that $\phi \in C_0^\infty(\Omega)$ satisfies $\int_\Omega m\phi^2 > 0$ and $\int_\Omega \phi^2 = 1$. (We will return to the question of deciding if such functions exist later.) Multiplying (4.6) by ϕ^2 and using the divergence theorem, we have

$$\int_\Omega \nabla\cdot d\phi^2\nabla\theta - \int_\Omega [d\phi^2|\nabla\theta|^2 + 2d\phi\nabla\phi\cdot\nabla\theta + \phi^2\mathbf{b}\cdot\nabla\theta] - \lambda\int_\Omega m\phi^2 = \mu_1(\lambda). \tag{4.7}$$

Another application of the divergence theorem shows that the first term in (4.7) is zero. Adding the quantity

$$\int_\Omega d|\phi\nabla\theta + [\phi\mathbf{b} + 2d\nabla\phi]/2d|^2 \geqq 0$$

to the left side of (4.7) and rearranging terms, we have

$$\int_\Omega [|\phi\mathbf{b} + 2d\nabla\phi|^2/4d] - \lambda\int m\phi^2 \geqq \mu_1(\lambda). \tag{4.8}$$

If we let

$$\lambda = \Lambda(\phi, m) \equiv \int_\Omega [|\phi\mathbf{b} + 2d\nabla\phi|^2/4d] \Big/ \int_\Omega m\phi^2,$$

then (4.8) implies $\mu_1(\lambda) \leqq 0$; but since $\psi > 0$, it then follows from (4.5) and the positivity lemma of [15] that $\lambda_1(d, \mathbf{b}, m) \leqq \Lambda(\phi, m)$. Now suppose that $\limsup_{j\to\infty}\int_\Omega m_j\beta = \varepsilon_0 > 0$ for some $\beta \in L^1(\Omega)$ with $\beta \geqq 0$ almost everywhere. Then we can take a subsequence $\{m_k\}$ so that $\int_\Omega m_k\beta \geqq \varepsilon_0/2$, and we can approximate $\sqrt{\beta}$ as closely as we wish in $L^2(\Omega)$ with a function $\phi \in C_0^\infty(\Omega)$. If we choose ϕ so that $\int_\Omega |\beta - \phi^2| \leqq \varepsilon_0/4m_0$, we obtain $\int m_k\phi^2 \geqq \varepsilon_0/4 > 0$. It follows that for such ϕ the denominator of $\Lambda(\phi, m_k)$ is uniformly bounded away from zero, and since the numerator is independent of m, we have $\lambda_1(d, \mathbf{b}, m_k) \leqq \Lambda_0 < \infty$ for some Λ_0 and all m_k in the subsequence. Hence we cannot have $\lim_{j\to\infty}\lambda_1(d, \mathbf{b}, m_j) = \infty$ if (4.3) does not hold.

Remarks. If we consider a set of weights $\{m_j\}$ with $\int m_j \geqq m_1 > 0$ for all j, then (4.3) fails for $\beta \equiv 1$, so the corresponding set of principal eigenvalues $\lambda_1(d, \mathbf{b}, m_j)$ must be bounded, since otherwise we could find a sequence m_l with $\lambda_1(d, \mathbf{b}, m_l) \to \infty$ as $l \to \infty$. There are various conditions on d and $\mathbf{b}$ under which (4.1) must hold. For example, if we assume $d \geqq d_1 > 0$ and $|\mathbf{b}| \leqq b_0$, then we have for any $\varepsilon > 0$

$$\left|\int_\Omega (\mathbf{b}\cdot\nabla\phi)\phi\right| \leqq \int_\Omega (\varepsilon(\mathbf{b}\cdot\nabla\phi)^2/2) + (\phi^2/2\varepsilon) \leqq [(\varepsilon b_0^2/2) + (1/2\varepsilon\lambda_0)]\int_\Omega |\nabla\phi|^2$$

where $\lambda_0 \equiv \lambda_1(1, 0, 1)$. If we minimize with respect to ε, we obtain $|\int_\Omega (\mathbf{b}\cdot\nabla\phi)\phi| \leqq b_0/\sqrt{\lambda_0}$, so that (4.1) is satisfied if $d_1 > b_0/\sqrt{\lambda_0}$. If we assume $\mathbf{b} \in [C^1(\bar{\Omega})]^n$, we have

$$\int_\Omega (\mathbf{b}\cdot\nabla\phi)\phi = \frac{1}{2}\int_\Omega \mathbf{b}\cdot\nabla(\phi^2) = -\frac{1}{2}\int_\Omega (\nabla\cdot\mathbf{b})\phi^2.$$

If $\nabla\cdot\mathbf{b} \leqq b_1$ and $d \geqq d_1 > 0$, then (4.1) must hold provided $d_1 > b_1/2\lambda_0$.

Next we consider the problem of how $\mathbf{b}$ affects $\lambda_1(d, \mathbf{b}, m)$. For the case where $d \equiv 1$, $m \equiv 1$, and $\mathbf{b} = -\nabla B$, $B \in C^2(\bar{\Omega})$, Murray and Sperb [22] showed that if γ_1, γ_2 are such that $\gamma_1 \leqq \frac{1}{2}\Delta B + \frac{1}{4}|\nabla B|^2 \leqq \gamma_2$, then

$$\lambda_1(1, 0, 1) + \gamma_1 \leqq \lambda_1(1, \mathbf{b}, 1) \leqq \lambda_1(1, 0, 1) + \gamma_2. \tag{4.9}$$

They also showed that if $\Omega \subseteq \mathbb{R}^2$ is convex, the matrix $((\partial b_i/\partial x_j))$ is positive semidefinite in Ω, $\omega = \max_{\partial\Omega} |\mathbf{b}|$, $\alpha(\lambda, \omega) = \omega((\lambda + \omega^2)^{1/2} + \omega)$, and ρ is the radius of the largest disc contained in Ω, then $\lambda_1(\mathbf{1}, \mathbf{b}, 1)$ is greater than or equal to the first positive root λ of $\alpha(\lambda, \omega)/(\lambda + \alpha(\lambda, \omega)) = \cos(\rho\sqrt{\lambda})$.

Inequality (4.9) is obtained via a change of variables. If we have $\mathbf{b}(x)/d(x) = -\nabla B$ for some B, we can make the corresponding change of variables; letting $\psi = e^{B/2}\phi$ converts the problem $-\nabla \cdot d\nabla\phi + \mathbf{b} \cdot \nabla\phi = \lambda m\phi$ to

$$-\nabla \cdot d\nabla\psi + [(\nabla \cdot d\nabla B/2) + (d|\nabla B|^2/4)]\psi = \lambda m\psi, \tag{4.10}$$

while preserving the homogeneous Dirichlet boundary condition. If $\lambda = \lambda_1(d, \mathbf{b}, m)$ then since $\psi = e^{B/2}\phi > 0$, λ is also the first eigenvalue for (4.10), which has the variational characterization (see [21])

$$\lambda = \inf_{\substack{\psi \in W_0^{1,2}(\Omega) \\ \int m\psi^2 > 0}} \frac{\int_\Omega [d|\nabla\psi|^2 + \gamma\psi^2]}{\int_\Omega m\psi^2}, \tag{4.11}$$

where $\gamma = [(\nabla \cdot d\nabla B/2) + (d|\nabla B|^2/4)]$. In the special case $d \equiv 1$, $m \equiv 1$, (4.11) implies the bound (4.9). In general, if $\mathbf{b}$ satisfies $\mathbf{b} = -d\nabla B$, with B such that $\gamma \geqq 0$, then we may conclude $\lambda_1(d, \mathbf{b}, m) \geqq \lambda_1(d, 0, m)$, and if $\gamma \leqq 0$, $\lambda_1(d, \mathbf{b}, m) \leqq \lambda_1(d, 0, m)$. Since m is indefinite, it is not clear how to obtain bounds analogous to (4.9).

In the case where $\mathbf{b}$ is not a gradient, we can still obtain some information if $\mathbf{b} \in [C^1(\Omega)]^n$. If we multiply the equation $-\nabla \cdot d\nabla\phi + \mathbf{b} \cdot \nabla\phi = \lambda_1 m\phi$ by ϕ, integrate by parts, and use the boundary condition, we obtain

$$\int_\Omega [d|\nabla\phi|^2 - (\nabla \cdot \mathbf{b}/2)\phi^2] = \lambda_1 \int_\Omega m\phi^2. \tag{4.12}$$

If condition (4.1) is satisfied (which will clearly be the case if $\nabla \cdot \mathbf{b} \leqq 0$) then we have $\int_\Omega m\phi^2 > 0$, so that we may again use the variational formulation of [21] to see that if $\nabla \cdot \mathbf{b} \leqq 0$, then

$$\begin{aligned} \lambda_1(d, \mathbf{b}, m) &\geqq \inf_{\substack{\psi \in W_0^{1,2}(\Omega) \\ \int_\Omega m\psi^2 > 0}} \frac{\int_\Omega [d|\nabla\psi|^2 - (\nabla \cdot \mathbf{b}/2)\psi^2]}{\int_\Omega m\psi^2} \\ &\geqq \inf_{\substack{\psi \in W_0^{1,2}(\Omega) \\ \int_\Omega m\psi^2 > 0}} \frac{\int_\Omega d|\nabla\psi|^2}{\int_\Omega m\psi^2} = \lambda_1(d, 0, m). \end{aligned}$$

We have thus proved the following result.

THEOREM 4.2. *Suppose that either* $\mathbf{b} \in [C^1(\bar{\Omega})]^n$ *and* $\nabla \cdot \mathbf{b} \leqq 0$, *or that* $\mathbf{b} = -d\nabla B$ *for some* $B \in C^2(\bar{\Omega})$ *such that* $\gamma \equiv [(\nabla \cdot d\nabla B/2) + (d|\nabla B|^2/4)] \geqq 0$. *Then* $\lambda_1(d, \mathbf{b}, m) \geqq \lambda_1(d, 0, m)$.

Theorem 4.2 generalizes a result of [22] which implies that adding a constant drift term to the Laplacian always raises the principal eigenvalue. It can be shown via a perturbation argument that if $\mathbf{b} \in [C^1(\bar{\Omega})]^n$ with $\nabla \cdot \mathbf{b} > 0$, then for $\varepsilon > 0$ sufficiently small, $\lambda_1(1, \varepsilon\mathbf{b}, m) \leqq \lambda_1(1, 0, m)$. The general question of deciding how $\lambda_1(d_1, \mathbf{b}_1, m_1)$ and $\lambda_1(d_2, \mathbf{b}_2, m_2)$ are related is to our knowledge an open problem.

THEOREM 4.3. *Suppose that* $d \geqq d_1 > 0$ *and that* $\mathbf{b} \in [C^1(\bar{\Omega})]^n$ *with* $\nabla \cdot \mathbf{b} \leqq 0$. *Let* $M(x)$ *be any solution to*

$$\nabla \cdot d\nabla M + \mathbf{b} \cdot \nabla M + (\nabla \cdot \mathbf{b})M = m. \tag{4.13}$$

Suppose $M_1 \geqq \sup_\Omega M$ *and* $M_2 \geqq \operatorname{ess\,sup}_\Omega (-Mm)$. *If* $M_2 \leqq 0$, *then* $\lambda_1(d, \mathbf{b}, m) \geqq 1/2M_1$. *If* $M_2 > 0$, *then*

$$\lambda_1(d, \mathbf{b}, m) \geqq \frac{-2M_1 + [4M_1^2 + (8M_2/d_1\lambda_1(1, 0, 1))]^{1/2}}{(4M_2/d_1\lambda_1(1, 0, 1))}.$$

Remarks. Observe that no boundary condition is imposed on M in (4.13). Since $\nabla \cdot \mathbf{b} \leqq 0$, there will exist a solution for any reasonable boundary data.

Proof. Suppose ϕ satisfies

$$\begin{aligned} -\nabla \cdot d\nabla\phi + \mathbf{b} \cdot \nabla\phi &= \lambda_1(d, \mathbf{b}, m)m\phi \quad \text{in } \Omega, \\ \phi &= 0 \qquad\qquad\qquad\quad \text{on } \partial\Omega. \end{aligned} \tag{4.14}$$

Then we have via integration by parts

$$0 = \int_\Omega M(\nabla \cdot d\nabla\phi^2) - \phi^2(\nabla \cdot d\nabla M).$$

Since

$$\begin{aligned} \nabla \cdot d\nabla\phi^2 &= 2\phi\nabla \cdot d\nabla\phi + 2d|\nabla\phi|^2 \\ &= 2\phi\mathbf{b} \cdot \nabla\phi - 2\lambda_1 m\phi^2 + 2d|\nabla\phi|^2 \end{aligned}$$

and

$$\int_\Omega 2M\phi(\mathbf{b} \cdot \nabla\phi) = \int_\Omega M\mathbf{b} \cdot \nabla\phi^2 = -\int_\Omega \phi^2[\nabla M \cdot \mathbf{b} + M\nabla \cdot \mathbf{b}],$$

it follows that

$$0 = 2\int_\Omega Md|\nabla\phi|^2 - \int_\Omega \phi^2[\nabla \cdot d\nabla M + \mathbf{b} \cdot \nabla M + (\nabla \cdot \mathbf{b})M] - 2\lambda_1 \int_\Omega Mm\phi^2. \tag{4.15}$$

From (4.14) it follows that

$$\begin{aligned} \lambda_1 \int_\Omega m\phi^2 &= \int_\Omega [d|\nabla\phi|^2 + (\mathbf{b} \cdot \nabla\phi)\phi] \\ &= \int_\Omega [d|\nabla\phi|^2 - (\nabla \cdot \mathbf{b}/2)\phi^2] > 0, \end{aligned}$$

and we may assume that ϕ is normalized so that $\lambda_1 \int_\Omega m\phi^2 = 1$. By (4.13) we may replace the middle term in (4.15) by $-\int_\Omega m\phi^2$; if we then rearrange terms and multiply by λ_1, we obtain

$$1 = \lambda_1 \int_\Omega m\phi^2 = -2\lambda_1^2 \int_\Omega Mm\phi^2 + 2\lambda_1 \int_\Omega Md|\nabla\phi|^2. \tag{4.16}$$

Since

$$\nabla \cdot \mathbf{b} \leqq 0, \qquad 0 < \int_\Omega d|\nabla \phi|^2 \leqq \lambda_1 \int_\Omega m\phi^2 = 1;$$

also,

$$\int_\Omega \phi^2 \leqq \frac{1}{\lambda_1(1,0,1)d_1} \int_\Omega d|\nabla \phi|^2.$$

If we estimate the two integrals on the right of (4.16), we obtain

$$\int_\Omega d|\nabla \phi|^2 \leqq 1 \leqq 2M_2\lambda_1^2 \int_\Omega \phi^2 + 2M_1\lambda_1 \int_\Omega d|\nabla \phi|^2.$$

If $M_2 \leqq 0$, we have $1 \leqq 2M_1\lambda_1$. If $M_2 > 0$, then we have

$$1 \leqq (2M_2/\lambda_1(1,0,1)d_1)\lambda_1^2 + 2M_1\lambda_1.$$

The bounds on λ_1 follow immediately.

Example. Let $\Omega = (0, \pi)$, $d \equiv 1$, $\mathbf{b} \equiv b_0$, and $M = \sin nx$. Then (4.13) becomes $M'' + bM' = \sin nx$, which has a solution

$$M = -[b_0/n(n^2+b_0^2)] \cos nx - [1/(n^2+b_0^2)] \sin nx.$$

We may use $M_1 = 1/n(n^2+b_0^2)^{1/2}$ and $M_2 = (n+b_0)/n(n^2+b_0^2)$. Theorem 4.3 then yields

$$\lambda_1(1, b_0, \sin nx) \geqq \frac{1}{2}\left[\frac{-(n^2+b_0^2)^{1/2}}{n+b_0} + \left(\frac{n^2+b_0^2}{(n+b_0)^2} + \frac{2n(n^2+b_0^2)}{n+b_0}\right)^{1/2}\right], \tag{4.17}$$

which implies that $\lambda_1(1, b_0, \sin nx) \to \infty$ with order n as $n \to \infty$ and with order $\sqrt{b_0}$ as $b_0 \to \infty$.

4.1. Biological interpretation. While the results of this section are technical in appearance in the sense that they represent extensions of existing results, they are potentially the most relevant for studying the effects of environmental factors on population dynamics. In previous sections we established that the size of the eigenvalue $\lambda_1(d, \mathbf{b}, m)$ gives a criterion for persistence, namely, $\lambda_1(d, \mathbf{b}, m) < 1$, so that $\lambda_1(d, \mathbf{b}, m)$ serves as a reasonable measure of the overall suitability of an environment. In the next section we shall strengthen the case for using λ_1 as such a measure by deriving a population estimate in terms of λ_1. The results of this section give some information on how $\lambda_1(d, \mathbf{b}, m)$ is affected by the aspects of the environment described by the diffusion rate, drift, and local growth rate. Thus, they provide a means of using our models to infer the likely effects of certain environmental changes. The first two major results are qualitative, in that they describe the general behavior of λ_1 when the environment is perturbed in certain ways. The third is quantitative and allows a comparison of the relative impact of different effects, at least in simple cases. Our biological conclusions are somewhat tentative because of the enormous complexity of the problems they address, but they provide a starting point and direction for further work. We undertake a much more detailed analysis of some specific situations in [7].

Theorem 4.1 is a generalization of a result in [6]. Its main significance, we believe, is that it allows us to gain some insight into the effects of habitat fragmentation via reaction-diffusion models. The problem of understanding habitat fragmentation on populations is one of the most important topics in conservation biology. The theory

of island biogeography has been used to a considerable extent in the theoretical work on this problem, and it generally suggests that a few large regions of favorable habitat can be expected to sustain more species than a great many very small regions of the same total area. Theorem 4.1 allows us to consider the question at the species level rather than the community level, but leads to conclusions which are similar in spirit. Specifically, if we consider an environment in which the average habitat quality (as measured by the integral of the growth rate $m(x)$) is zero and vary the spatial distribution of favorable habitat so that it becomes more and more fragmented and more closely interspersed with unfavorable regions, then λ_1 will eventually tend to infinity so that our model predicts extinction.

As a simple example, if we consider a one-dimensional environment with fixed diffusion and drift coefficients and take $m_j(x) = \sin(jx)$, then $\lambda_1(d, b, \sin(jx)) \to \infty$ as $j \to \infty$. Whenever j is large enough that $\lambda_1(d, b, \sin(jx)) > 1$, the population cannot be expected to persist. It is important to keep in mind the asymptotic nature of this result; some of our work in [7] indicates that under certain conditions a few medium-sized favorable regions may provide a more suitable overall environment than a single large one. In some cases, we can obtain more precise quantitative information from Theorem 4.3. We have given an example immediately prior to this discussion. For more details on the connections between our work, island biogeography theory, and conservation biology, along with some references, see [6].

Theorem 4.2 gives some information on the effects of drift on the population. It is well known that (in the presence of a hostile exterior) increasing the diffusion rate tends to cause a more rapid loss of population across the boundary of the environment. Under certain conditions the effects of drift can produce the same results, and the theorem described some of those conditions. The case of constant growth and diffusion rates was treated by Murray and Sperb [22], and our results can be viewed as an extension of theirs to the case of variable diffusion. In realistic models we should expect $\nabla \cdot \mathbf{b}$ to change sign unless $\mathbf{b}$ is constant, since otherwise the drift term itself acts as a source or a sink. The condition $\mathbf{b} = -d\nabla B$ with B satisfying $(\nabla \cdot d\nabla B/2) + (d|\nabla B|^2/4) \geqq 0$ says roughly that the drift acts to augment the effects of diffusion. This condition can be checked via standard techniques from vector calculus. It was shown in [22] that for constant diffusion and growth rates, constant drift always makes the environment less suitable for the population under the assumption of a hostile exterior. Our results show that the same conclusion holds in the case of variable growth and diffusion rates. In both situations, the effect is due essentially to the drift pushing the population toward the hostile exterior region in one direction, while contributing no inward flux from the other since there will be no population in the hostile exterior region.

The qualitative results of Theorems 4.1 and 4.2 are augmented by the quantitative bounds on λ_1 given by Theorem 4.3. The example following the proof of that theorem shows how it can be used to draw conclusions about the persistence of a population from data on the diffusion, drift, and growth coefficients in a specific case. If the lower bound given in (4.17) is larger than 1, our model predicts extinction for the population. Other situations could be treated in a similar way. Of course, more complicated situations will require more effort in the analysis, but the estimate is based on the well-developed theory of linear differential equations. The specific bound (4.17) is already of some interest biologically since it gives an indication of the relative significance of drift and environmental heterogeneity. If we consider a one-dimensional environment, the estimate increases with the same order as the number of fragments of equal size into which the regions of favorable and unfavorable habitat are divided. It increases with the order of the square root of the coefficient describing the drift.

5. Population estimates. In the situations covered by Corollary 3.2 (density dependent diffusion in divergence form) and Corollary 3.3 (density independent diffusion not necessarily in divergence form), we are able to estimate the total size $\int_\Omega u\,dx$ of the positive steady states to (2.1) in a manner analogous to that in Theorem 4.1 of [6]. Since the results for these two cases are different from each other, we include them in this paper for the sake of completeness. We begin with the case of density independent diffusion.

THEOREM 5.1. *Suppose that u is the positive solution to*

$$\begin{aligned} -\nabla\cdot(d(x)\nabla u)+\mathbf{b}(x)\cdot\nabla u &= \lambda[m(x)u-u^2] \quad \text{in } \Omega, \\ u &= 0 \quad \text{on } \partial\Omega \end{aligned} \tag{5.1}$$

where $\lambda>\lambda_1(d,\mathbf{b},m)$. Suppose that the differential operator satisfies the coercivity condition (4.1) *and that $\tilde\lambda>0$ is the principal eigenvalue for*

$$\begin{aligned} -d_0\Delta z &= \mu m z \quad \text{in } \Omega, \\ z &= 0 \quad \text{on } \partial\Omega. \end{aligned}$$

Then $\tilde\lambda\leqq\lambda_1(d,\mathbf{b},m)$ and

$$\|u\|_1\leqq\left(1-\frac{\tilde\lambda}{\lambda}\right)\|m_+\|_3|\Omega|^{2/3}.$$

Proof. Suppose that $w>0$ on Ω and satisfies

$$\begin{aligned} -\nabla\cdot(d(x)\nabla w)+\mathbf{b}(x)\cdot\nabla w &= \lambda_1(d,\mathbf{b},m)m(x)w \quad \text{in } \Omega, \\ w &= 0 \quad \text{on } \partial\Omega. \end{aligned}$$

Then

$$\lambda_1(d,\mathbf{b},m)\int_\Omega m(x)w^2=\int_\Omega w(-\nabla\cdot(d(x)\nabla w)+\mathbf{b}(x)\cdot\nabla w)\geqq d_0\int_\Omega|\nabla w|^2.$$

Consequently, $\int_\Omega m(x)w^2>0$ and $d_0\int_\Omega|\nabla w|^2\geqq\tilde\lambda\int_\Omega m(x)w^2$ by the variational characterization of $\tilde\lambda$ [21]. Hence $\tilde\lambda\leqq\lambda_1(d,\mathbf{b},m)$. Multiplying (5.1) by u and integrating gives

$$\begin{aligned} \int_\Omega u^3 &= \int_\Omega m(x)u^2-\int_\Omega u\left[\frac{-\nabla\cdot(d(x)\nabla u)+\mathbf{b}(x)\cdot\nabla u}{\lambda}\right] \\ &\leqq \int_\Omega m(x)u^2-\frac{d_0}{\lambda}\int_\Omega|\nabla u|^2 \\ &\leqq \left(1-\frac{\tilde\lambda}{\lambda}\right)\int_\Omega m(x)u^2, \end{aligned}$$

since $\int_\Omega m(x)u^2>0$ by (4.1). Since $\int_\Omega mu^2\leqq\int_\Omega m_+u^2\leqq\|m_+\|_3\|u\|_3^2$ and $\|u\|_1\leqq\|u\|_3|\Omega|^{2/3}$, the result follows.

Two comments are in order at this point. The first is that the reader will recall that § 4 contains a discussion of conditions under which the coercivity condition (4.1) obtains. The second is that Theorem 5.1 does not provide an estimate of the rate at which $\|u\|_1$ approaches zero as $\lambda\to\lambda_1(d,\mathbf{b},m)$ which we know must be the case by the results of §§ 2 and 3. This limitation is due to the presence of the drift term. However, Theorem 5.1 does provide the useful global estimate $\|u\|_1\leqq\|m+\|_3|\Omega|^{2/3}$. In the density dependent case in divergence form, we can obtain the same global estimate

as well as estimate the rate at which $\|u\|_1$ tends to zero as $\lambda \to \lambda_1(d(x,0),0,m)$ as the next result shows.

THEOREM 5.2. *Suppose that u is the positive solution to*

$$-\nabla \cdot (d(x,u)\nabla u) = \lambda[m(x)u - u^2] \quad \text{in } \Omega,$$
$$u = 0 \quad \text{on } \partial\Omega,$$

where $\lambda > \lambda_1(d(x,0),0,m)$ and we assume that $\partial d/\partial u \geqq 0$. Then

$$\|u\|_1 \leqq \left(1 - \frac{\lambda_1(d(x,0),0,m)}{\lambda}\right)\|m_+\|_3 |\Omega|^{2/3}.$$

Proof.

$$0 < \int_\Omega \frac{d(x,u)|\nabla u|^2}{\lambda} + \int_\Omega u^3 = \int_\Omega mu^2.$$

So $\int_\Omega mu^2 > 0$, and hence

$$\begin{aligned}\int_\Omega u^3 &= \int_\Omega mu^2 - \int_\Omega \frac{d(x,u)}{\lambda}|\nabla u|^2 \\ &\leqq \int_\Omega mu^2 - \int_\Omega \frac{d(x,0)}{\lambda}|\nabla u|^2 \\ &\leqq \left(1 - \frac{\lambda_1(d(x,0),0,m)}{\lambda}\right)\int_\Omega mu^2\end{aligned}$$

by the positivity of $\int_\Omega mu^2$ and the variational characterization of $\lambda_1(d(x,0),0,m)$. The remainder of the proof follows as in the proof of Theorem 5.1.

Finally, we note that in both these situations, we can obtain estimates on the rate of decay of solutions to (2.1) which are analogous to the result of Theorem 4.7 in [6]. The modifications needed to obtain these results from Theorem 4.7 of [6] are similar to those needed to obtain Theorems 5.1 and 5.2 above from Theorem 4.1 of [6]. Consequently, we omit them from this paper.

5.1. Biological interpretation. The immediate biological interpretation of the results of this section is clear. They yield bounds on the total population which our models predict a given environment can sustain. Theorem 5.1 is less sharp than Theorem 5.2, but for regions with simple geometry $\tilde{\lambda}$ may be easier to compute than λ_1. A deeper interpretation of Theorem 5.2 is that $\lambda_1(d, \mathbf{b}, m)$ is, in fact, an appropriate measure of environmental suitability, for in the original form of our models with $\lambda = 1$, Theorem 5.2 gives a bound on the population in which $1 - \lambda_1(d, \mathbf{b}, m)$ appears as a factor. Thus, if we vary d, $\mathbf{b}$, and m so that $\lambda_1(d, \mathbf{b}, m)$ approaches 1, the bound on the population goes to zero. (We have considered only the case where the carrying capacity is taken to be 1, but that can always be achieved by a rescaling if the carrying capacity is a constant.)

6. Conclusions. Reaction-diffusion models have been widely used to model population dynamics (see [4]–[7], [9], [10], [19], [20], [24], [27], [28]). We consider a class of such models which incorporate environmental variation, drift, and density dependent diffusion. We establish that in many cases the eigenvalue $\lambda_1(d, \mathbf{b}, m)$ for an associated linear problem is a reasonable measure of environmental suitability by showing that the condition $\lambda_1(d, \mathbf{b}, m) < 1$ implies persistence and obtaining upper bounds for the population in which $1 - \lambda(d, \mathbf{b}, m)$ appears as a factor. The significance of this

observation is that $\lambda_1(d, \mathbf{b}, m)$ is a quantity which depends directly on the diffusion, drift, and growth rates for the population and which can be computed by using well-known (although sometimes fairly sophisticated) mathematical techniques. In some cases we can calculate $\lambda_1(d, \mathbf{b}, m)$ fairly easily, but what is perhaps more important is that we can make qualitative inferences about the effects of changing various aspects of the environment on its overall suitability for a population as measured by λ_1. Specifically, our models predict that a high degree of fragmentation of favorable habitat increases λ_1 and thus decreases environmental suitability, and that the presence of drift may either increase or decrease environmental suitability. (It turns out that under the assumption of a hostile exterior region that constant drift always decreases the overall environmental suitability, but a spatially varying drift term may actually increase it.) Similar conclusions have been drawn in other ways, but largely on the basis of either heuristic arguments or different modeling viewpoints. A conclusion that does not rely on properties of λ_1 is that the presence of density dependent diffusion can lead to multiple equilibria. A similar effect has been observed for models with constant diffusion but depensatory growth rate, but the observation that multiple equilibria can occur with a logistic growth term and density dependent diffusion is apparently new.

GLOBAL BEHAVIOR OF AN AGE-STRUCTURED EPIDEMIC MODEL*

STAVROS N. BUSENBERG†, MIMMO IANNELLI‡, AND HORST R. THIEME§

Abstract. The global behavior of the general $s \to i \to s$ age-structured epidemic model in a population of constant size is obtained. It is shown that there is a sharp threshold which determines the existence and global stability of an endemic state; hence, periodic solutions are ruled out. The threshold is identified as the spectral radius of a positive linear operator. The analysis employs the theory of semigroups and positive operator methods, and is based on the formulation of the problem as an abstract differential equation in a Banach space.

Key words. epidemic model, age structure, semigroup, monotone operator, global behavior

1. Introduction.

Periodic oscillations in the incidence rates of infectives occur for a number of diseases, and there are several dynamic mechanisms that could be the cause of this oscillatory behavior. For example, there is a pronounced biennial oscillation in the occurence of measles that is reported in the data of several large cities [7], [10], [13], and these have been variously attributed to the incubation delays [10], to the age-structured seasonal interaction rates that are due to school attendance [13], and to more complicated nonlinear transmission dynamics [7]. The simplest epidemiological interactions occur for diseases which do not impart immunity and which can be described by models that include only two epidemiological classes composed of the susceptible and infective parts of the population, that is, they are of the $s \to i \to s$ type. Since it has been suggested that the age dependence of the transmission rate of a disease may cause oscillations that do not occur in the corresponding situation without age structure, a basic problem in epidemic modeling is to rigorously establish either the possibility or the impossibility of the occurence of such oscillations.

The purpose of this and of a subsequent paper, where we will include vertical transmission, is to show that, for the general $s \to i \to s$ age-structured model, periodic oscillations do not occur. In fact, we give the complete global dynamic behavior for such a model when the total population is at its equilibrium distribution. To our knowledge, this is the first general age-structured epidemic model for which the global dynamic behavior is resolved. Global behavior results for this model have recently been obtained by Busenberg, Cooke, and Iannelli [2] when the force of infection term assumes certain particular age-dependent forms. These forms represent the cases where the disease transmission interactions are limited to members of the same age group (the *intracohort* case), and the other extreme possibility where the age of the infectives does not affect their contact rates with other individuals (the *intercohort* case.) In fact, for the intercohort case, periodic oscillations are ruled out in [2], only

with additional assumptions on the form of the age-dependent probability that a contact of a susceptible with an infective will lead to the transmission of the disease.

There is a recent surge of interest in analyzing the effects of age-structure on the dynamics of epidemics [1]–[6], [8], [11], [12] because of the recognition that the transmission dynamics of certain diseases could not be correctly described by the traditional epidemic models with no age dependence. Much of the work in this area has been limited to the derivation of threshold conditions for the existence of endemic steady states and, in some cases, to the the study of the local stability of these endemic states. Global stability analyses of such models have been obtained only in special cases [2], [4]. Even though the $s \to i \to s$ model exhibits one of the simplest types of disease transmision interactions, its complete analysis which we provide here settles a basic open question in the modeling of epidemics.

The model that we consider divides the affected population into two epidemiologically distinct classes, composed of the susceptible and the infective individuals. The age-specific densities of the susceptibles at time t and age a is denoted by $s(a,t)$, and that of the infectives by $i(a,t)$. Thus

$$\int_{a_1}^{a_2} s(a,t)\,da \quad \text{and} \quad \int_{a_1}^{a_2} i(a,t)\,da,$$

are the respective numbers of susceptible and infective individuals at time t whose ages fall between a_1 and a_2. Let $K(a,a')$ denote the rate at which an infective individual of age a' comes into a disease transmitting contact with a susceptible individual of age a also let $K_0(a)$ be the infection rate for pure intracohort interaction. Then the rate at which susceptible individuals of age a are moved over into the infective class is given by

$$s(a,t)\lambda[a|u(\cdot,t)] = s(a,t)\left[K_0(a)i(a,t) + \int_0^\infty K(a,a')i(a',t)\,da'\right].$$

The decomposition of the trasmission rate into the two parts K_0 and K allows us to include a pure intracohort term without using kernels which are measures.

Denoting the age-specific mortality, birth rate, and cure rate by $\mu(a)$, $\beta(a)$, and $\gamma(a)$, respectively, and using the notation $\lambda(a,t)$ for $\lambda[a|u(\cdot,t)]$, we obtain the following system of equations that describe the dynamics of this model:

$$\begin{aligned} &\frac{\partial s(a,t)}{\partial t} + \frac{\partial s(a,t)}{\partial a} + \mu(a)s(a,t) = -s(a,t)\lambda(a,t) + \gamma(a)i(a,t), \\ &\frac{\partial i(a,t)}{\partial t} + \frac{\partial i(a,t)}{\partial a} + \mu(a)i(a,t) = s(a,t)\lambda(a,t) - \gamma(a,t)i(a,t) \end{aligned} \tag{1.1}$$

with initial and boundary conditions

$$\begin{aligned} &s(0,t) = \int_0^\infty \beta(a)s(a,t)\,da, \qquad i(0,t) = 0, \\ &s(a,0) = s_0(a), \qquad i(a,0) = i_0(a). \end{aligned} \tag{1.2}$$

We note that in our assumption the disease does not affect the natural mortality and fertility rates.

We shall be dealing with these equations under the hypothesis that the total population, $p(a,t) = s(a,t) + i(a,t)$, has reached a steady-state distribution $p_\infty(a)$. From the classical theory of the linear McKendrick–Von Foerster equation which $p(a,t)$ satisfies, this occurs when the basic reproductive number R of the total population is equal to 1. That is,

$$R = \int_0^\infty \beta(a) \exp\left(-\int_0^a \mu(a')\,da'\right) da = 1. \tag{1.3}$$

It is worth noting that, if the parameters β, μ, γ, and K in the model did not depend on age, the corresponding equations for the total populations $S(t)$ and $I(t)$, can be obtained by integrating (1.1) from $a = 0$ to ∞, and using the conditions (1.2), and $s(\infty,t) = i(\infty,t) = 0$. These last conditions simply mean that no individual in the population can survive to infinite age. The resulting equations are

$$\begin{aligned} \frac{dS(t)}{dt} &= (\beta - \mu)S(t) + \gamma I(t) - KS(t)I(t), \\ \frac{dI(t)}{dt} &= -(\mu + \gamma)I(t) + KS(t)I(t). \end{aligned} \tag{1.4}$$

This is the standard $S \to I \to S$ epidemic model with vital dynamics. The condition (1.3) implies that $\beta = \mu$. Hence, we are in the case where the births and deaths are in balance, and consequently, the total population $S(t) + I(t) = P$ is constant. Writing $S(t) = P - I(t)$, and substituting in the second equation in (1.4), we obtain a first-order equation in the single variable $I(t)$ which can be explicitly integrated by elementary methods. The system (1.4) cannot exhibit time-periodic behavior, and the main result of this paper shows that the introduction of age dependence, with a general form $K(a,a')$ of the contact rate, does not produce a model which has periodic solutions, regardless of the choice of the age-dependent parameters entering in (1.1)–(1.2).

In the next section we transform the problem (1.1)–(1, 2) to one that involves only a single dependent variable $u(a,t) = i(a,t)/p_\infty(a)$. We then proceed to show that the problem can be viewed as a dynamical system for which we prove the existence of an appropriate unique solution, under mild restrictions on the parameters appearing in the equations. In the other sections we exploit the monotonicity and convexity properties of our formulation of the problem to show that all solutions stabilize to steady states, regardless of their initial data. The conditions we impose on the contact rate $K(a,a')$ include all epidemiologically significant cases. Thus, for the general $s \to i \to s$ age structured model, the global behavior of solutions is settled, and oscillatory solutions do not occur. In the final section we discuss the epidemiological implications of our results and of the hypotheses that we need to place on the pertinent parameters in the model.

2. Setting the problem. Let us first state the assumptions on the demographic parameters $\beta(a)$ and $\mu(a)$, namely, we assume that there is a maximum age $a_\dagger$ for the population so that we can restrict ourselves to the age interval $[0, a_\dagger]$, and

(2.1) $\beta(a)$ is nonnegative and belongs to $L^\infty(0, a_\dagger)$,

(2.2) $\mu(a)$ is nonnegative and measurable,

$$R = \int_0^{a_\dagger} \beta(a) \exp\left(-\int_0^a \mu(a')\,da'\right) da = 1. \tag{2.3}$$

This last parameter R is the basic reproductive number of the population and represents the mean number of newborns from an individual, during his whole lifespan. Thus, by (2.3) we are assuming that the demographic parameters are such that a steady asymptotic state exists:

$$p_\infty(a) = b_0 \exp\left(-\int_0^a \mu(\sigma)\,d\sigma\right), \tag{2.4}$$

where

$$b_0 = \int_0^{a_\dagger} \beta(a) p_\infty(a)\,da. \tag{2.5}$$

Now we assume that the total population $p(a,t) = s(a,t) + i(a,t)$ has reached the steady-state distribution (2.4). Thus we have

$$s(a,t) = p_\infty(a) - i(a,t) \tag{2.6}$$

and the system can be reduced to a single equation for $i(a,t)$. In fact, fitting (2.6) into the second equation in (1.1), we have

$$\begin{aligned}
&\frac{\partial i(a,t)}{\partial t} + \frac{\partial i(a,t)}{\partial a} + \mu(a) i(a,t) = \lambda[a \mid i(.,t)][p_\infty(a) - i(a,t)] - \gamma(a) i(a,t),\\
&\lambda[a \mid i(.,t)] = K_0(a) i(a,t) + \int_0^{a_\dagger} K(a,a') i(a',t)\,da',\\
&i(0,t) = 0, \qquad i(a,0) = i_0(a).
\end{aligned}$$

Furthermore, we perform the following change $u(a,t) = i(a,t)/p_\infty(a)$ so that

$$\begin{aligned}
&\frac{\partial u(a,t)}{\partial t} + \frac{\partial u(a,t)}{\partial a} = \lambda[a \mid u(\cdot,t)][1 - u(a,t)] - \gamma(a) u(a,t),\\
&\lambda[a \mid u(\cdot,t)] = K_0(a) p_\infty(a) u(a,t) + \int_0^{a_\dagger} K(a,a') p_\infty(a') u(a',t)\,da',\\
&u(0,t) = 0, \qquad u(a,0) = \frac{i_0(a)}{p_\infty(a)} = u_0(a),
\end{aligned} \tag{2.7}$$

and this is the problem that we are going to consider in the sequel.

Let us now state the assumptions on $\gamma(a)$ and on the contact rates $K_0(a)$ and $K(a,a')$. We assume that

$$\gamma(a), K_0(a) \quad \text{are nonnegative and belong to } L^\infty(0,a_\dagger); \tag{2.8}$$

moreover, $K(a,a')$ is measurable, and there exist a positive constant ϵ and nonnegative functions $K_1(a), K_2(a)$ such that

$$\epsilon\, K_1(a) K_2(a') \le K(a,a') p_\infty(a') \le K_1(a) K_2(a'), \tag{2.9}$$

$$K_1 \in L^1(0,a_\dagger)\,, \qquad K_2 \in L^\infty(0,a_\dagger). \tag{2.10}$$

There are $0 \le a_1, a_2, b_1, b_2 \le a_\dagger$ such that

$$a_1 < b_1, \quad a_2 < b_2, \quad a_1 < b_2, \tag{2.11}$$

$$K_1(a) > 0 \quad \text{if } a_1 < a < b_1, \tag{2.12}$$

$$K_2(a) > 0 \quad \text{if } a_2 < a < b_2. \tag{2.13}$$

The implications of these hypotheses from the viewpoint of the biological model will be discussed in §6.

3. Resetting the problem. We now identify the problem as an abstract semilinear equation. To this purpose we consider the Banach space $E = L^1(0, a_\dagger)$ and define

$$A = \begin{cases} D_A = \{f \in E \mid f \text{ is absolutely continuous; } f(0) = 0\}, \\ (Af)(a) = -f'(a), \end{cases} \tag{3.1}$$

$$F(f)(a) = \lambda[a \mid f(.)][1 - f(a)] - \gamma(a)f(a), \tag{3.2}$$

where

$$\lambda[a \mid f(.)] = K_0(a)p_\infty(a)f(a) + \int_0^{a_\dagger} K(a, a')p_\infty(a')f(a')\,da'.$$

Thus (2.2) can be expressed as the following Cauchy problem in E:

$$\frac{d}{dt}u(t) = Au(t) + F(u(t)), \qquad u(0) = u_0, \tag{3.3}$$

and, due to the meaning of $u(a, t)$, we look for a solution in the closed convex set:

$$C = \{f \in L^1(0, a_\dagger);\ 0 \le f(a) \le 1 \text{ a.e.}\}. \tag{3.4}$$

Concerning the operator A we have that it is the generator of the C_0-semigroup on E:

$$(e^{tA}u_0)(a) = \begin{cases} u_0(a - t) & \text{for} \quad t < a, \\ 0 & \text{for} \quad t > a \end{cases} \tag{3.5}$$

with the following properties:

$$e^{tA}(C) \subset C, \tag{3.6}$$

$$\text{if } u_0 \le v_0, \quad \text{then } e^{tA}u_0 \le e^{tA}v_0, \tag{3.7}$$

where $\le$ denotes the usual ordering in L^1.

We also note that if $\alpha > 0$ the resolvent $(I - \alpha A)^{-1}$ is given by the formula:

$$((I - \alpha A)^{-1}f)(a) = \frac{1}{\alpha}\int_0^a e^{-\frac{1}{\alpha}(a-s)}f(s)\,ds \tag{3.8}$$

and satisfies:

$$(I - \alpha A)^{-1}(C) \subset C \tag{3.9}$$

$$\text{if } u \le v, \quad \text{then } (I - \alpha A)^{-1}u \le (I - \alpha A)^{-1}v. \tag{3.10}$$

Concerning F we have Proposition 3.1.

PROPOSITION 3.1. *The function $F : C \to E$ is Lipschitz continuous and there exists a constant $\alpha \in (0,1)$ such that*

$$\text{if } u \le v, \quad \text{then } u + \alpha F(u) \le v + \alpha F(v), \tag{3.11}$$

$$(I + \alpha F)(C) \subset C. \tag{3.12}$$

Proof. Lipschitz continuity is a simple matter. Moreover, let γ^+ and λ^+ be such that $\gamma(a) < \gamma^+$ and $\lambda[a \mid f(.)] < \lambda^+$ for any $f \in C$. Take

$$\alpha < \frac{1}{\gamma^+ + \lambda^+}, \tag{3.13}$$

then, if $u \le v$,

$$\begin{aligned}
(u + \alpha F(u))(a) &= u(a) + \alpha\lambda[a \mid u(\cdot)][1 - u(a)] - \alpha\gamma(a)u(a) \\
&\le u(a) + \alpha\lambda[a \mid v(\cdot)][1 - u(a)] - \alpha\gamma(a)u(a) \\
&= u(a)[1 - \alpha\lambda[a \mid v(\cdot)] - \alpha\gamma(a)] + \alpha\lambda[a \mid v(\cdot)] \\
&\le v(a)[1 - \alpha\lambda[a \mid v(\cdot)] - \alpha\gamma(a)] + \alpha\lambda[a \mid v(\cdot)] \\
&= (v + \alpha F(v))(a)
\end{aligned}$$

with the last estimate being possible because the square bracket is nonnegative, thanks to the choice of α.

Finally (3.12) is a consequence of (3.11), in fact if $0 \le u(a) \le 1$ then, by (3.2),

$$0 \le \alpha F(0) \le u + \alpha F(u) \le 1 + \alpha F(1) = 1 - \alpha\gamma(a) \le 1. \tag{3.14}$$

□

Now we are ready to prove existence of a mild solution to problem (3.3), namely, we look for a solution of the integral equation (see A. Pazy [12]):

$$u(t) = e^{tA}u_0 + \int_0^t e^{(t-s)A}F(u(s))\,ds. \tag{3.15}$$

We then have Theorem 3.2.

THEOREM 3.2. *Let $u_0 \in C$; then problem* (3.3) *has a unique mild solution in C. This defines a flow $S(t)u_0$ which has the following properties:*

$$S(t)(C) \subset C, \tag{3.16}$$

$$\text{if } u_0 \le v_0, \quad \text{then } S(t)u_0 \le S(t)v_0, \tag{3.17}$$

$$\text{if } 0 \le \xi \le 1, \quad \text{then } \xi S(t)u_0 \le S(t)(\xi u_0). \tag{3.18}$$

Proof. It is easy to prove that problem (3.15) is equivalent to the following one:

$$u(t) = e^{-\frac{1}{\alpha}t}e^{tA}u_0 + \frac{1}{\alpha}\int_0^t e^{-\frac{1}{\alpha}(t-s)}e^{(t-s)A}[u(s) + \alpha F(u(s))]\,ds, \tag{3.19}$$

where α is chosen as in (3.13). We start the standard iterative procedure:

$$
\begin{aligned}
&u^0(t) = u_0,\\
&u^{n+1}(t) = e^{-\frac{1}{\alpha}t}e^{tA}u_0 + \frac{1}{\alpha}\int_0^t e^{-\frac{1}{\alpha}(t-s)}e^{(t-s)A}[u^n(s) + \alpha F(u^n(s))]\,ds.
\end{aligned}
\tag{3.20}
$$

Now, thanks to (3.6) and (3.12), $u^{n+1}(t) \in C$; in fact, the right-hand side of (3.20) is a convex linear combination of $e^{tA}u_0$ and $[u^n(s) + \alpha F(u^n(s))]$ (note that $e^{-\frac{1}{\alpha}t} + \frac{1}{\alpha}\int_0^t e^{-\frac{1}{\alpha}(t-s)}ds = 1$); thus, because of the Lipschitz continuity of F, the sequence $u^n(t)$ converges uniformly to $S(t)u_0 \in C$.

Furthermore, if we start the procedure with $v_0 \geq u_0$, thanks to (3.7) and (3.11), the iterates v^n and u^n satisfy $v^n \geq u^n$ so that, in the limit, we have (3.17).

Finally, let u_ξ^n be the iterates (3.20) with u_0 replaced by ξu_0. Since $0 \leq \xi \leq 1$, we have

$$\xi u + \alpha F(\xi u) \geq \xi(u + \alpha F(u))$$

so that

$$u_\xi^n \geq \xi u^n$$

and, going to the limit, we obtain (3.18). □

4. Existence and uniqueness of an endemic equilibrium. We are now concerned with existence and uniqueness of a nontrivial equilibrium point to problem (3.3); namely, we look for a solution to the equation

$$Au_\infty + F(u_\infty) = 0. \tag{4.1}$$

We use the symbol u_∞ because we shall show below that any such fixed point is a limit of other solutions of (3.3). This is equivalent to looking for a fixed point of the flow:

$$S(t)u_\infty = u_\infty. \tag{4.2}$$

In fact, if u_∞ satisfies (4.2), from equation (3.15) we get

$$u_\infty = e^{tA}u_\infty + \int_0^t e^{(t-s)A}\,ds\; F(u_\infty) \quad \forall t \geq 0, \tag{4.3}$$

that is,

$$e^{tA}u_\infty = u_\infty - \int_0^t e^{sA}\,ds\; F(u_\infty), \tag{4.4}$$

which implies that $e^{tA}u_\infty$ is differentiable, and consequently, that $u_\infty \in D_A$. Differentiating (4.4) at $t = 0$, we obtain (4.1). This argument can be followed backward proving (4.2), starting from (4.1).

We now state a necessary condition which should be satisfied by any nontrivial solution of (4.1).

PROPOSITION 4.1. *Let u_∞ be a nontrivial solution of* (4.1)*; then*

$$\int_0^{a_\dagger} K_2(a)u_\infty(a)da > 0. \tag{4.5}$$

Proof. If (4.5) is not fulfilled, then

$$\int_0^{a_\dagger} K(a,a')p_\infty(a')u_\infty(a')\,da' = 0 \quad \forall a \in [0,a_\dagger] \tag{4.6}$$

and u_∞ satisfies

$$u'_\infty(a) = -\gamma(a)u_\infty(a) + K_0(a)p_\infty(a)u_\infty(a)[1-u_\infty(a)],$$

thus $u_\infty(a)$ is either identically zero or positive on $[0,a_\dagger]$, and this latter case is not compatible with (4.6) and (2.9)–(2.13). □

We next state a preliminary estimate that must be satisfied by any possible nontrivial fixed point. Our estimate involves a comparison function, namely,

$$m(a) = \int_0^a K_1(a')\,da'. \tag{4.7}$$

PROPOSITION 4.2. *Let u_∞ be a nontrivial solution to* (4.1). *Then*

$$\epsilon_1 m(a) \le u_\infty(a) \le \epsilon_2 m(a), \tag{4.8}$$

where ϵ_1, ϵ_2 are positive constants depending on u_∞.

Proof. As u_∞ is a nontrivial solution, (4.5) is satisfied so that

$$c_1K_1(a) \le \lambda[a \mid u_\infty(.)] \le k_0^+u_\infty(a) + c_2K_1(a),$$

where c_1, c_2 are positive and $k_0^+ \ge b_0K_0(a)$. Hence u_∞ satisfies the inequality

$$c_1K_1(a) - (\lambda^+ + \gamma^+)u_\infty(a) \le u'_\infty(a) \le k_0^+u_\infty(a) + c_2K_1(a)$$

and, since $u_\infty(0) = 0$, we can find positive ϵ_1, ϵ_2 such that (4.8) is satisfied. □

To deal with problem (4.1) it is convenient to transform this problem into the following one:

$$u_\infty = (I - \alpha A)^{-1}(I + \alpha F)u_\infty,$$

where α is as in (3.13). Thus we are led to investigate fixed points of the mapping

$$T = (I - \alpha A)^{-1}(I + \alpha F),$$

which by (3.9)–(3.12) has the following properties:

$$T(C) \subset C, \tag{4.9}$$

$$\text{if } u \le v, \quad \text{then } Tu \le Tv. \tag{4.10}$$

We first show the uniqueness of a nontrivial equilibrium by following the line of reasoning in Krasnosel'skii [9]. In order to do this, we need some more estimates.

LEMMA 4.3. *Let $u_\infty \in C$ be a nontrivial fixed point of T. Let ξ be a constant and $v \in C$, such that $0 < \xi < 1$, $v \ge 0$, and*

$$\xi u_\infty + v \in C, \qquad \int_0^{a_\dagger} K_2(a)v(a)\,da > 0; \tag{4.11}$$

then there exists a constant $\epsilon_3 > 0$ *such that*

$$T(\xi u_\infty + v) \geq \xi u_\infty + \epsilon_3(1-\xi)m. \tag{4.12}$$

Proof. Note that (see (3.13))

$$\begin{aligned}
&(\xi u_\infty + v + \alpha F(\xi u_\infty + v))(a)\\
&\quad = \xi u_\infty(a) + v(a) + \alpha[1 - \xi u_\infty(a) - v(a)]\lambda[a \mid \xi u_\infty(\cdot) + v(\cdot)]\\
&\qquad - \alpha\gamma(a)(\xi u_\infty(a) + v(a))\\
&\quad = \xi u_\infty(a) + \alpha F(\xi u_\infty)(a)\\
&\qquad + v(a)(1 - \alpha\lambda[a \mid \xi u_\infty(\cdot) + v(\cdot)] - \alpha\gamma(a)) + \alpha[1 - \xi u_\infty(a)]\lambda[a \mid v(\cdot)]\\
&\quad \geq \xi u_\infty(a) + \alpha\xi F(u_\infty)(a) + \alpha(1-\xi)\lambda[a \mid v(\cdot)]\\
&\quad \geq \xi(u_\infty + \alpha F u_\infty)(a) + \alpha\epsilon(1-\xi)K_1(a)\int_0^{a_\dagger} K_2(a')v(a')\,da'.
\end{aligned}$$

Then by (3.8), (3.10), and (4.7), we obtain (4.12). □

LEMMA 4.4. *Let* $u_\infty \in C$ *be a nontrivial fixed point of* T *and let* $0 < \xi < 1$. *Then there exists a constant* $\epsilon_4 > 0$ *such that*

$$T(\xi u_\infty) \geq \xi u_\infty + \xi(1-\xi)\epsilon_4 m_1, \tag{4.13}$$

where $m_1(a) = m^2(a)$.

Proof. Note that

$$\begin{aligned}
&(\xi u_\infty + \alpha F(\xi u_\infty))(a)\\
&\quad = \xi(u_\infty + \alpha F(u_\infty))(a) + \alpha\xi(1-\xi)u_\infty(a)\lambda[a \mid u_\infty(.)]\\
&\quad \geq \xi(u_\infty + \alpha F(u_\infty))(a) + \alpha\xi(1-\xi)\epsilon u_\infty(a)K_1(a)\int_0^{a_\dagger} K_2(a')u_\infty(a')da'\\
&\quad \geq \xi(u_\infty + \alpha F(u_\infty))(a) + \alpha\xi(1-\xi)\epsilon_4\frac{d}{da}\left[\int_0^a K_1(a')\,da'\right]^2,
\end{aligned}$$

where we have used (4.8). Thus, by (3.8) and (3.10) we get (4.13). □

Note that by (4.13) it follows that

$$\xi u_\infty + \xi(1-\xi)\epsilon_4 m_1 \in C,$$

and moreover, since $a_1 < b_2$, it follows that

$$\int_0^{a_\dagger} K_2(a')m_1(a')\,da' > 0.$$

Finally, we have Theorem 4.5.

THEOREM 4.5. *T has at most one nontrivial fixed point.*

Proof. Let $u_\infty \not\equiv v_\infty$ be two nontrivial fixed points. Without losing generality we can assume that we do not have $u_\infty \leq v_\infty$. By (4.8), $v_\infty \geq (\epsilon_1/\epsilon_2)u_\infty$. Let ξ be the maximum constant such that

$$v_\infty \geq \xi u_\infty. \tag{4.14}$$

It must be that $0 < \xi < 1$. Then, by Lemma 4.4

$$v_\infty = T^2(v_\infty) \geq T^2(\xi u_\infty) \geq T(\xi u_\infty + \xi(1-\xi)\epsilon_4 m_1) \tag{4.15}$$

and by Lemma 4.3 (take $v = \xi(1-\xi)\epsilon_4 m_1$)

$$v_\infty \geq \xi u_\infty + (1-\xi)\epsilon_3 m$$

so that

$$v_\infty \geq \xi u_\infty + (1-\xi)\frac{\epsilon_3}{\epsilon_2} u_\infty,$$

which is impossible because it contradicts the definition of ξ. □

The existence of a nontrivial equilibrium is related to the Fréchet derivative of T, which we denote by $DT[u]$, and depends on the spectral radius ρ of $DT[0]$; actually we have Proposition 4.6.

PROPOSITION 4.6. *Let $\rho \leq 1$; then the mapping T has no nontrivial fixed points in C.*

Proof. Suppose that u_∞ is a nontrivial fixed point of T and let $0 < \xi < 1$. Then, by Lemmas 4.3 and 4.4

$$T^2(\xi u_\infty) \geq T(\xi u_\infty + \xi(1-\xi)\epsilon_4 m_1) \geq \xi u_\infty + (1-\xi)\frac{\epsilon_3}{\epsilon_2} u_\infty = \xi(1+\delta)u_\infty$$

and, by noting that

$$(Tu)(a) = (DT[0]u)(a) - \int_0^a e^{-\frac{1}{\alpha}(a-s)} \lambda[s \mid u(\cdot)]u(s)\, ds, \tag{4.16}$$

which implies

$$T(u) \leq DT[0]u \quad \text{for any } u \in C,$$

we have

$$\xi \left(DT[0]\right)^2 u_\infty \geq T^2(\xi u_\infty) \geq \xi(1+\delta)u_\infty$$

so that

$$\left(DT[0]\right)^2 u_\infty \geq (1+\delta)u_\infty,$$

which implies $\rho > 1$, thus contradicting the assumption. □

On the other hand, we also have Proposition 4.7.

PROPOSITION 4.7. *If $\rho > 1$, T has at least one nontrivial fixed point.*

Proof. $DT[0]$ is linear, completely continuous, and leaves the positive cone $K \equiv \{h \in E \mid h \geq 0\}$ invariant. Then by the Krein–Rutman theorem, there exists an eigenvector $h^* \geq 0$ with eigenvalue ρ. Since h^* satisfies the problem:

$$\begin{aligned} &\alpha\rho \frac{d}{da} h^*(a) = [1 - \alpha\gamma(a) - \rho]h^*(a) + \alpha\lambda[a \mid h^*(\cdot)], \\ &h^*(0) = 0. \end{aligned}$$

Proceeding as in the proof of Proposition 4.2, we can find positive constants c_1, c_2 such that

$$c_1\, m(a) \leq h^*(a) \leq c_2\, m(a).$$

This, in particular, implies that h^* belongs to $L^\infty(0, a_\dagger)$, so that, without loss of generality, we can assume that $h^* \in C$. Moreover, by (4.16), we have, for $0 < \xi < 1$,

$$T(\xi h^*)(a) = \xi \rho h^*(a) - \xi^2 \int_0^a e^{-\frac{1}{\alpha}(a-s)} \lambda[s \mid h^*(\cdot)] h^*(s)\, ds.$$

Since

$$\int_0^a \lambda[s \mid h^*(\cdot)] h^*(s) ds \le \lambda^+ c_2 m(a) \le \lambda^+ \frac{c_2}{c_1} h^*(a),$$

we have

$$T(\xi h^*)(a) \ge \xi h^*(a) + \xi \left[(\rho - 1) - \xi \lambda^+ \frac{c_2}{c_1} \right] h^*(a),$$

and, if ξ is sufficiently small,

$$T(\xi h^*) \ge \xi h^*.$$

Thus the sequence

$$u_n = T^n(\xi h^*) \in C$$

is monotonic nondecreasing and converges to some u_∞ which is a nontrivial fixed point of T. □

5. Convergence to the equilibrium. Our first statement concerns the case when only the trivial equilibrium exists.

THEOREM 5.1. *Assume that no nontrivial equilibrium exists; then*

$$\forall u_0 \in C, \quad S(t)u_0 \longrightarrow 0 \quad \text{as } t \to \infty. \tag{5.1}$$

Proof. Assume that (5.1) is not true for some initial datum u_0, then define

$$\bar{u} = \limsup_{t \to \infty} S(t)u_0.$$

This $\bar{u} \not\equiv 0$ does exist in C because $L^1(0, a_\dagger)$ is a complete lattice. Moreover, since $\sup_{s \ge r} S(s)u_0$ is nonincreasing as a function of r, then

$$\bar{u} = \lim_{r \to \infty} \sup_{s \ge r} S(s)u_0.$$

Now

$$\begin{aligned} S(t)\bar{u} &= \lim_{r \to \infty} S(t) \sup_{s \ge r} S(s)u_0 \ge \lim_{r \to \infty} \sup_{s \ge r} S(t+s)u_0 \\ &= \lim_{r \to \infty} \sup_{s \ge t+r} S(s)u_0 = \lim_{r \to \infty} \sup_{s = r} S(s)u_0 = \bar{u}, \end{aligned}$$

which implies that $S(t)\bar{u}$ is nondecreasing as a function of t; in fact, if $h > 0$,

$$S(t+h)\bar{u} = S(t)S(h)\bar{u} \ge S(t)\bar{u}.$$

Then

$$u_\infty = \lim_{t \to \infty} S(t)\bar{u}$$

exists and is a nontrivial fixed point of $S(t)$, i.e., it is a nontrivial equilibrium. This contradicts the assumptions and proves that (5.1) is true. □

Let us now consider the case in which a (unique) nontrivial equilibrium u_∞ exists. In this case we have to introduce the following condition:

$$\int_t^{a\dagger} K_2(a)u_0(a-t)\,da > 0 \quad \text{for some } t \geq 0. \tag{5.2}$$

If this condition is satisfied, we say that u_0, with support in $[0, a_\dagger]$, is a *nontrivial initial datum.*

Then we have Proposition 5.2.

PROPOSITION 5.2. *Let u_0 be a nontrivial initial datum. Then there exist $t_0 > 0$ and $\xi > 0$ such that*

$$S(t_0)u_0 \geq \xi u_\infty.$$

Proof. We start from equation (3.19) (where $u(t) = S(t)u_0$), which yields

$$u(t) \geq \frac{1}{\alpha}\int_0^t e^{-\frac{1}{\alpha}(t-s)}e^{(t-s)A}[u(s) + \alpha F(u(s))]\,ds. \tag{5.3}$$

Now, since $\alpha < 1/(\lambda^+ + \gamma^+)$ we have

$$u(s) + \alpha F(u(s)) \geq w(s),$$

where

$$(w(s))(a) = \alpha\epsilon K_1(a)\int_0^{a_\dagger} K_2(a')(u(s))(a')\,da'$$

so that

$$\left(e^{(t-s)A}w(s)\right)(a) \geq \begin{cases} \alpha\epsilon K_1(a+s-t)\displaystyle\int_0^{a_\dagger} K_2(a')(u(s))(a')\,da' & \text{for } a > t-s, \\ 0 & \text{for } a < t-s, \end{cases}$$

and, plugging this into (5.3), we obtain

$$(u(t))(a) \geq \epsilon e^{-\frac{1}{\alpha}t}\int_{(t-a)\vee 0}^t K_1(a+s-t)h(s)\,ds \tag{5.4}$$

with

$$h(s) = \int_0^{a_\dagger} K_2(a')(u(s))(a')\,da'.$$

We will prove that

$$\text{There exists } s_\infty \text{ such that } h(s) > 0 \text{ for } s > s_\infty. \tag{5.5}$$

To this aim, we first prove that

$$\text{If } h(s) > 0 \text{ for } s \in [s_1, s_2], \text{ then } h(s) > 0 \text{ for } s \in [s_1 + c_1, s_2 + c_2], \tag{5.6}$$

where $c_1 = (a_1 \vee a_2) - b_1$ and $c_2 = b_2 - a_1$.

Note first that $u(t)(a) > 0$ if

$$a > a_1, \quad t > s_1, \quad s_1 - b_1 < t - a < s_2 - a_1. \tag{5.7}$$

In fact, if these are fulfilled then $(t-a)\vee s_1 < t\wedge s_2$ and, setting $I \equiv [(t-a)\vee s_1, t\wedge s_2]$ we have

$$I \subset [s_1, s_2], \qquad \{a - t + I\} \cap [a_1, b_1] \neq \emptyset \tag{5.8}$$

so that from (5.4)

$$(u(t))(a) \geq \epsilon e^{-\frac{1}{\alpha}t} \int_{(t-a)\vee s_1}^{t\wedge s_2} K_1(a+s-t)h(s)\,ds > 0 \tag{5.9}$$

because by (5.8) the integrand is positive on some interval contained in I.

Finally, fix $t \in [s_1 + c_1, s_2 + c_2]$ and note that

$$h(t) \geq \int_{a_2}^{b_2} K_2(a')(u(t))(a')\,da' > \int_{a_1\vee a_2}^{b_2} K_2(a')(u(t))(a')\,da'.$$

Now, K_2 is positive on $[a_1 \vee a_2, b_2]$ and, by (5.7), $u(t)(a)$ is positive for $a > a_1$ and $a \in J \equiv [a_1 + t - s_2, t + b_1 - s_1]$ but our choice of t yields

$$a_1 + t - s_2 < a_1 + c_2 = b_2,$$

$$t + b_1 - s_1 > b_1 + c_1 = a_1 \vee a_2,$$

so that $J \cap [a_1 \vee a_2, b_2] \neq \emptyset$, and $h(t) > 0$.

Now that (5.6) is proven, note that if u_0 is a nontrivial initial datum, then from (3.19) we see that for some positive constant δ

$$h(s) = \int_0^{a_\dagger} K_2(a)u(s)(a)\,da \geq \delta \int_0^{a_\dagger} K_2(a)(e^{sA}u_0)(a) = \delta \int_s^{a_\dagger} K_2(a)u_0(a-s)\,da > 0$$

for s in some interval $[s_1, s_2]$. Thus, iterating statement (5.6) we have, for any integer n

$$h(s) > 0 \quad \text{in } [s_1 + nc_1, s_2 + nc_2] \tag{5.10}$$

so that, since $c_2 - c_1 > 0$ and $c_2 > 0$ by (2.11), if n is sufficiently large, successive intervals are overlapping, and consequently statement (5.5) is proven.

We now use (5.5) in order to prove that

$$\text{There exists } t_\infty \text{ such that } (u(t))(a) > 0 \text{ for } a > a_1 \text{ and } t > t_\infty. \tag{5.11}$$

In fact, if $t > s_\infty + a_\dagger + b_1$, we have $t - a > s_\infty$ and, by (5.4)

$$\begin{aligned}(u(t))(a) &\geq \epsilon e^{-\frac{1}{\alpha}t} \int_{(t-a)}^{t} K_1(a+s-t)h(s)\,ds \\ &\geq \epsilon e^{-\frac{1}{\alpha}t} \int_{a_1}^{a\wedge b_1} K_1(\sigma)h(\sigma+t-a)\,d\sigma > 0.\end{aligned}$$

Now let $t_0 > s_\infty + a_\dagger$; then $t_0 - a > s_\infty$ and

$$\begin{aligned}(u(t_0))(a) &\geq \epsilon e^{-\frac{1}{\alpha}t_0} \int_{(t_0-a)}^{t_0} K_1(a+s-t_0)h(s)ds \\ &> \epsilon e^{-\frac{1}{\alpha}t_0} h_- \int_{(t_0-a)}^{t_0} K_1(a+s-t_0)ds \\ &= \epsilon e^{-\frac{1}{\alpha}t_0} h_- \int_0^a K_1(s)ds = \epsilon e^{-\frac{1}{\alpha}t_0} h_- m(a),\end{aligned}$$

where $h_- = \inf_{s\in[s_\infty,t_0]} h(s)$. Finally, by (4.8) we have

$$(u(t_0))(a) \geq \xi u_\infty(a), \tag{5.12}$$

where $\xi = (\epsilon/\epsilon_2)e^{-\frac{1}{\alpha}t_0}h_-$, and the proof is done. □

Finally, we come to the following theorem.

THEOREM 5.3. *Let u_∞ be the unique nontrivial equilibrium; then for any nontrivial initial datum u_0*

$$S(t)u_0 \longrightarrow u_\infty \quad \text{as } t \to \infty. \tag{5.13}$$

If u_0 is not nontrivial, then

$$S(t)u_0 = 0 \quad \text{for } t \geq a_\dagger. \tag{5.14}$$

Proof. Let ξ and t_0 be as in the previous proposition; then letting **1** denote the function equal to 1 almost everywhere on $[0, a_\dagger]$,

$$\xi u_\infty \leq S(t_0)u_0 \leq \mathbf{1}$$

and

$$S(t)\xi u_\infty \leq S(t+t_0)u_0 \leq S(t)\mathbf{1}. \tag{5.15}$$

Now

$$\xi u_\infty = \xi S(t)u_\infty \leq S(t)\xi u_\infty \quad \text{and} \quad S(t)\mathbf{1} \leq \mathbf{1}.$$

Consequently, $S(t)\xi u_\infty$ and $S(t)\mathbf{1}$ are monotonic with respect to t (nondecreasing and nonincreasing, respectively) and converge to a nontrivial equilibrium which coincides with u_∞ by the uniqueness Theorem 4.5; then (5.13) follows from (5.15).

Now let

$$\int_t^{a_\dagger} K_2(a)u_0(a-t)da = 0 \quad \text{for all } t \geq 0.$$

Let us show that the iterates $u^n(t)$ defined in (3.20) also satisfy

$$\int_s^{a_\dagger} K_2(a)u^n(t)(a-s)\,da = 0 \quad \text{for all } t \geq 0 \text{ and } s \geq 0. \tag{5.16}$$

Actually, if (5.16) is true, then

$$\begin{aligned}\lambda[a \mid u^n(t)(\cdot)] &\leq K_0(a)p_\infty(a)u^n(t)(a) + K_1(a)\int_0^{a_\dagger} K_2(a)u^n(t)(a)\,da \\ &= K_0(a)p_\infty(a)u^n(t)(a)\end{aligned}$$

and

$$u^n(t) + \alpha F(u^n(t)) \leq (1+\alpha k_0^+)u^n(t).$$

This implies that

$$u^{n+1}(t) \leq e^{tA}u_0 + c\int_0^t e^{(t-\sigma)A}u^n(\sigma)\,d\sigma,$$

where $c > 0$; and, consequently,

$$\int_s^{a_\dagger} K_2(a)u^{n+1}(t)(a-s)\,da \le \int_{s+t}^{a_\dagger} K_2(a)u_0(a-t-s)da + c\int_0^t \int_{s+t-\sigma}^{a_\dagger} K_2(a)u^n(\sigma)(a-t-s+\sigma)\,da\,d\sigma = 0.$$

Thus (5.16) is true by induction.

Now (5.16) implies that

$$\int_s^{a_\dagger} K_2(a)u(t)(a-s)da = 0 \quad \text{for all } t \ge 0 \text{ and } s \ge 0 \tag{5.17}$$

so that if $t > a_\dagger$

$$u(t) \le c\int_0^t e^{(t-s)A}u(s)\,ds, \tag{5.18}$$

which implies (5.14). In fact, fix $t > a_\dagger, a \in [0, a_\dagger]$ and define

$$\phi(x) = u(t-a+x)(x) \quad \text{for } x \in [0, a_\dagger];$$

then by (5.18)

$$\phi(x) \le c\int_0^x \phi(s)\,ds,$$

which implies $\phi(x) \equiv 0$. □

6. Conclusion. As noted in the Introduction, our results provide a complete global stability analysis and show that sustained periodic behavior is not possible in the general $s - i - s$ age-dependent epidemic model with constant total population size. Consequently, the addition of age-structure does not change the gross dynamics of this model, even though it adds considerable demographic detail and realism to the model. We demonstrate the existence of a sharp endemic threshold and our results can be used to obtain the age distribution of the susceptible and the infective subpopulations. The basic endemic threshold for this model is identified as the spectral radius of an explicit linear operator which depends on the pertinent demographic and epidemiological parameters. It generalizes the explicit expressions that were obtained for this threshold by Busenberg, Cooke, and Iannelli [2] for the two special cases of purely intercohort and intracohort forces of infection. The proof that we provide for the existence and uniqueness of the endemic state, when it exists, is constructive. It can be used as the basis of an iterative method for obtaining approximations, within prescribed error bounds, of the subpopulation age distributions at the endemic state.

The generality of our results is limited only by the restrictions (2.9)–(2.13) on the age-dependent force of infection term. The conditions (2.10)–(2.13) do not place any essential restrictions on $K(a, a')$ that go beyond what would be dictated by the biological situation that is being modeled. However, from (2.9) it is seen that if $K(\tilde{a}, \tilde{a}') = 0$ for some fixed $(\tilde{a}, \tilde{a}') \in [0, a_\dagger] \times [0, a_\dagger]$, then either $K_1(\tilde{a}) = 0$, or $K_2(\tilde{a}') = 0$. Hence, we either have $K(\tilde{a}, a) = 0$ or $K(a, \tilde{a}') = 0$ for all $a \in [0, a_\dagger]$. That is, if the disease is never transmitted to any age $\tilde{a}$ individual from every age $\tilde{a}'$ individual, then either it cannot be transmitted from any age group $a \ne \tilde{a}$ to age $\tilde{a}$ individuals, or it

cannot be transmitted from any age $\tilde{a}'$ individual to an age $a \neq \tilde{a}'$ individual for all $a \in [0, a_\dagger]$. Since we are dealing with densities which are defined almost everywhere, this represents a real restriction only when there exist two age-class intervals $I_1, I_2 \subset [0, a_\dagger]$, for which $K(a, a') = 0$ for all $(a, a') \subset I_1 \times I_2$. In the epidemiological situtation that we are modeling, such complete immunity to disease transmission across two separate age classes is extremely unlikely. Hence, condition (2.9) includes the situations that are of interest from the viewpoint of the epidemiological model. In particular, asymmetric forms of K with $K(a, a') \neq K(a', a)$ are included in our result, as well as cases where individuals from two separate age groups have only limited, but nonvanishing, disease transmitting interactions. Nevertheless, it would be interesting to explore the dynamic implications of any substantial weakening of condition (2.9).

We finally note that we have excluded the possibility of vertical transmission in our model by requiring that $i(0, t) = 0$ in (1.2). This restriction is not essential, and was made for technical reasons since the inclusion of vertical transmission adds complications to the the model equations. Similar results to the ones that we have proved here also hold for the model with vertical transmission and they will be taken up in a separate paper.

CONVERGENCE FOR STRONGLY ORDER-PRESERVING SEMIFLOWS*

HAL L. SMITH†‡ AND HORST R. THIEME†§

Abstract. Convergence of almost all trajectories of strongly order-preserving semiflows is derived under suitable additional assumptions. These essentially consist in slightly sharpening the strongly order-preserving property and in the continuous differentiability of the flow with respect to the state variable. Required spectral properties of the linearizations of the flow around equilibria usually follow in the same way as the compactness and monotonicity assumptions for the flow itself. The proofs are based on sharpened versions of the limit set dichotomy and the sequential limit set trichotomy.

Key words. monotone dynamical system, strongly order-preserving semiflow, open dense set of (stable) convergent points, limit set dichotomy, nonordering principle, sequential limit set trichotomy, spectral theory of strongly positive linear operators

AMS(MOS) subject classifications. 34C35, 34G20, 47H20

Introduction. In the fundamental paper [7], Hirsch establishes that most orbits of a strongly monotone semiflow on a strongly ordered space X tend to the set E of the equilibria. Somewhat more precisely, Hirsch shows that the set of all $x \in X$ for which $\omega(x)$, the omega (positive) limit set of x, satisfies $\omega(x) \subset E$, is a "large" (open dense, residual, set of full measure) subset of X. Points x for which $\omega(x) \subset E$ are called *quasi-convergent* points; they are called *convergent* points if $\omega(x)$ consists of a single point of E.

The results in [7] extend earlier work of Hirsch [4], [5] for competitive and cooperative ordinary differential equations to infinite-dimensional semiflows. Applications are made to parabolic partial differential equations.

Matano pioneered the monotone dynamical systems approach to parabolic equations in [12] and [13] where he introduces the notion of upward (downward) stability of equilibria and considers the dynamics near such equilibria using monotonicity arguments. In his more recent work [13]-[16], he outlines an alternative approach to monotone dynamical systems, parallel to Hirsch's, which does not require that the space be strongly ordered and is, therefore, more suitable for applications to parabolic equations. One of the main results of Matano's theory, like that of Hirsch's, provides sufficient conditions for "most" points to be quasi-convergent.

In a recent paper [27], Smith and Thieme combine ideas from Hirsch and Matano to obtain a theory which improves several of the results of both authors while at the same time being conceptually simpler. We adopt (a slight generalization of) Matano's idea of a *strongly order-preserving* semiflow, but base our results on modified versions of two fundamental results due to Hirsch, namely, the *nonordering principle* for limit sets [7] and the *limit set dichotomy* [7]. These two principles also hold under Matano's weaker assumptions (see [16]) and can actually be shown by modifying Hirsch's proofs accordingly.

In this paper we present conditions for the existence of a dense open set of convergent points, i.e., any trajectory starting in that dense open set converges to a single equilibrium.

Trivial conditions consist in assuming that the set of equilibria E is discrete or totally ordered. Both assumptions guarantee that any quasi-convergent point is convergent: in the first case because the ω limit set is connected, in the second because the ω limit set cannot contain two different order-related points due to the *nonordering principle.*

These two trivial conditions do not harmonize with the spirit of the theory, namely, finding general structural conditions (e.g., strongly order preserving) under which almost all solutions have a very simply asymptotic behavior. For systems of equations and particularly for infinite-dimensional problems, it can be very difficult to verify one of the two trivial conditions above.

Our aim is to obtain general structural conditions that guarantee the existence of a dense open set of convergent points. These conditions do not imply that any quasi-convergent point is convergent (though this holds if we assume that it is a stable point). Essentially they consist in strengthening the notion of a *strongly order-preserving semiflow* (remaining more general than *strongly monotone*) and, more importantly, assuming that the semiflow is C^1, i.e., continuously differentiable in the state variable, at least in a neighborhood of each point of E. We also require spectral conditions for the linearization of the semiflow around equilibria, but these usually follow from the same considerations which establish the strengthened strongly order-preserving properties and the compactness properties of the semiflow.

Our approach has been inspired by the work of Poláčik [20], who finds conditions for abstract semilinear parabolic evolution equations to have a residual set of convergent points. In setting down these conditions, he is able to exploit the special framework for semilinear parabolic equations, as described by Henry [3]. Our approach is more general in the sense that we make no assumptions on the underlying system of equations generating the semiflow. Our abstract results, applied to the case considered by Poláčik, yield stronger conclusions than those in [20], assuming less smoothness but more compactness. We conclude that the set of stable convergent points is open and dense, whereas Poláčik concludes that the set of convergent points is a residual set.

In the remainder of this section we describe some basic ideas and notation and preview several of the main results.

Let X be an ordered metric space with metric d and order relation $\leqq$. We write $x < y$ if $x \leqq y$ and $x \neq y$. Points x and y in X are *ordered* if either $x < y$ or $y < x$. Given two subsets A and B of X we write $A \leqq B$ ($A < B$) whenever $x \leqq y$ ($x < y$) for each choice of $x \in A$ and $y \in B$. If $x < y$ then $[x, y] = \{z \in X : x \leqq z \leqq y\}$. A subset Y of X is *order convex* if $[y_1, y_2] \subset Y$ whenever $y_1, y_2 \in Y$ and $y_1 < y_2$.

We assume that the order and the topology on X are compatible in the sense that $x \leqq y$ whenever $x_n \to x$, $y_n \to y$, and $x_n \leqq y_n$ for all n. If $x \in X$ we say that x can be approximated from below (above) in X if there exists a sequence $\{x_n\}$ in X satisfying $x_n < x_{n+1} < x$ ($x < x_{n+1} < x_n$) for $n \geqq 1$ and $x_n \to x$.

The space X is said to be normally ordered if there exists a constant $k > 0$ such that

$$d(u, v) \leqq k d(x, y)$$

for all x, y, u, v with $u, v \in [x, y]$.

For simplicity here, we assume that Φ is a global semiflow on X. More precisely, let $\Phi : X \times \mathbf{R}^+ \to X$ be a semiflow on X, that is, Φ is continuous and $\Phi_t(x) \equiv \Phi(x, t)$ satisfies $\Phi_0(x) = x$ for every x and $\Phi_t \Phi_s = \Phi_{t+s}$ for every $t, s \geqq 0$. For $x \in X$, let

$$\mathcal{O}^+(x) = \{\Phi_t(x) : t \geqq 0\},$$
$$\omega(x) = \bigcap_{t \geqq 0} \overline{\mathcal{O}^+(\Phi_t(x))}$$

be the orbit initiating at x and the omega (positive) limit set of $\mathcal{O}^+(x)$, respectively. If $\mathcal{O}^+(x)$ has compact closure in X, then $\omega(x)$ is nonempty, compact, connected, and invariant, i.e., $\Phi_t(\omega(x)) = \omega(x)$, $t \geqq 0$, and $\Phi_t(x) \to \omega(x)$ as $t \to \infty$. We let $E = \{x \in X: \Phi_t(x) = x, t \geqq 0\}$ be the set of equilibria. The set of quasi-convergent points is denoted by $Q = \{x \in X: \omega(x) \subset E\}$ and the set of convergent points by $C = \{x \in Q: \omega(x)$ is a singleton set$\}$.

The semiflow Φ is said to be *monotone* provided

$$\Phi_t(x) \leqq \Phi_t(y) \quad \text{whenever } x \leqq y.$$

Following Matano [15], [16], Φ is said to be *strongly order-preserving* if Φ is monotone and whenever $x, y \in X$ with $x < y$, there exist open sets U and V, $x \in U$, $y \in V$, and $t_0 \geqq 0$ such that $\Phi_{t_0}(U) \leqq \Phi_{t_0}(V)$. By monotonicity, it follows that

$$\Phi_t(U) \leqq \Phi_t(V) \quad \text{for } t \geqq t_0.$$

In almost every case in which the strong order-preserving property can be verified, it results from the fact that the semiflow Φ eventually operates as a strongly monotone semiflow on some subset Z of an ordered Banach space $(Y, \|\cdot\|)$ with cone Y_+ and where Int $Y_+ \neq \varnothing$. We write $\leqq_Y$ for the partial order on Y generated by Y_+ and $\ll$ for the strong ordering induced by Int Y_+; that is, $y_1 \ll y_2$ if and only if $y_2 - y_1 \in$ Int Y_+. We assume that Z is a common subset of Y and of X, that the two partial orders $\leqq$ and $\leqq_Y$ induced on Z by the ordering on X and the ordering on Y agree, and that the inclusion $Z \hookrightarrow X$ is continuous, where Z is given the topology induced by the norm on Y. In order to simplify the statement of our results here, we assume that Z is order convex.

Additional hypotheses intertwine the set Z and the semiflow Φ:

(I) $\Phi_t(Z) \subseteq Z$ for $t \geqq 0$.

(J) There exists $\tau \geqq 0$ such that $\Phi_\tau(X) \subseteq Z$ and $\Phi_\tau: X \to Z$ is continuous.

(M) If $x_1, x_2 \in X$ satisfy $x_1 < x_2$, then $\Phi_\tau(x_1) \ll \Phi_\tau(x_2)$.

(D) Φ_τ is continuously differentiable on Z with derivative $\Phi'_\tau(z)$.

(Σ) For any equilibrium e of Φ satisfying $\rho(e) := \operatorname{spr}(\Phi'_\tau(e)) \geqq 1$, $\rho(e)$ is a pole of the resolvent of $\Phi'_\tau(e)$ with finite rank and $N(\rho(e)I - \Phi'_\tau(e))$ is spanned by an element of Int Y_+.

Here we use the notation spr L for the spectral radius of a bounded linear operator L and $N(L)$ for the null space of L. Less restrictive hypotheses are stated with more care and detail in § 3.

The spectral hypothesis (Σ) is crucial to our result. It may appear very restrictive until we realize that the monotonicity of Φ implies that the derivative $\Phi'_\tau(e)$ is a positive linear operator on Y. In applications we usually can establish the compactness of $\Phi'_\tau(e)$ which implies that $\rho(e)$ is a pole of the resolvent with finite rank. The same consideration that checks the strong monotonicity assumption (M) usually provides that the operator $\Phi'_\tau(z)$ is strongly positive, i.e., maps nonzero positive elements into Int Y_+. This implies [22] that the eigenspace associated with $\rho(e)$ is one-dimensional and spanned by a vector in Int Y_+.

Hypotheses (D) and (Σ) can be replaced by an alternative hypothesis that $\Phi'_t(e)$ generates a strongly continuous semigroup for each $e \in E$ and where spectral conditions are assumed to hold for the generator of this semigroup instead of for the semigroup itself. This approach is more appropriate for applications to semilinear parabolic equations.

It turns out that (J) and (M), together with the monotonicity of Φ on X, imply (see Lemma 2.1) that Φ is strongly order preserving on X. The additional assumptions allow a significant improvement of the *limit set dichotomy* in [27] (see Proposition 2.2).

PROPOSITION. *Let Φ be a monotone semiflow on X satisfying* (I), (J), (M), (D), *and* (Σ). *If $x_1, x_2 \in X$ are such that $\mathcal{O}^+(x_1)$ and $\mathcal{O}^+(x_2)$ have compact closure in X and $x_1 < x_2$, then either*

(a) $\omega(x_1) < \omega(x_2)$, *or*

(b) $\omega(x_1) = \omega(x_2) = \{e\}$ *for some equilibrium $e \in E$.*

Armed with this sharpened limit set dichotomy, we improve our sequential limit set trichotomy of [27] in Proposition 2.3 and this, in turn, leads to two of our main results stated below.

THEOREM 1. *Suppose that for each $x \in X$, $\mathcal{O}^+(x)$ has compact closure in X and that x can be approximated either from above or from below in X by a sequence $\{x_n\}$ such that $\bigcup_{n \geq 1} \omega(x_n)$ has compact closure in X. Then* Int C *is dense in X.*

In fact, under minimal additional hypotheses we can show that X contains an open and dense set of stable convergent points (see Theorem 2.6). A point $x \in X$ is called a *stable point* if for every $\varepsilon > 0$ there exists $\delta > 0$ such that $d(\Phi_t(x), \Phi_t(y)) < \varepsilon$ for $t \geqq 0$ whenever $y \in X$ and $d(x, y) < \delta$.

In many applications, however, it is unreasonable to assume that we have a global semiflow on the space X. We typically have a local semiflow on X (see § 3 for precise definitions) and can show that $\mathcal{O}^+(x)$ has compact closure in X only for some subset X_0 of points of X. In § 3 we show that, by suitably modifying assumptions (I), (J), (M), (D), and (Σ), we can obtain the following result.

THEOREM 2. *Let X_0 be an open subset of X such that every point of X_0 can be approximated both from above and from below in X. Assume either*

(a) *X is normally ordered, every orbit starting in X_0 has compact closure in X, and for any convergent monotone sequence x_n in X_0, $\bigcup_{n \geq 1} \omega(x_n)$ has compact closure in X, or*

(b) *Each point of X_0 belongs to a neighborhood U such that $U \times [0, \infty) \subset \operatorname{Dom} \Phi$ and $\Phi(U \times [t_0, \infty))$ has compact closure in X for some $t_0 > 0$.*

Then X_0 contains a dense open subset of stable convergent points.

The modified versions of assumptions (I), (J), (M), (D), and (Σ) are assumed to hold in Theorem 2.

The compactness assumptions contained in both (a) and (b) of Theorem 2 are rather mild for most applications. However, these assumptions are not made in [7] or [20]. In § 3 we show that neither of these compactness assumptions is required for the weaker result that there are at most a countable number of nonconvergent points on any totally ordered arc of points of X having precompact orbits in X. Such a result for quasi-convergent points was obtained by Hirsch [7, Thm. 7.3].

For applications of the results of monotone dynamical systems theory, we refer the reader to [4]–[6], [23], and [24] for applications to systems of ordinary differential equations, to [7], [12]–[17], [20], and [21] for applications to parabolic initial-boundary value problems, to [25], [26], and [28] for applications to functional differential equations, and to [10] and [11] for applications to systems of parabolic equations with time delays. In these applications the stronger results of this paper are typically obtained by finding additional conditions that guarantee that the induced semiflow is continuously differentiable in the state variable.

The organization of this paper is as follows. In § 1 we establish the key result, Proposition 1.2, leading to the improved limit set dichotomy. Proposition 1.2 states that for a strongly order-preserving discrete dynamical system with certain smoothness and compactness properties, any compact, connected, unordered, and nonempty set

of equilibria which attracts two orbits $\{u_n\}$ and $\{v_n\}$ with $u_n \ll v_n$ must be a singleton. In § 2, we use this result to establish the improved limit set dichotomy (the proposition above) and Theorem 1. In this section we assume that Φ is a global semiflow on X. In § 3 we show how to modify the ideas of § 2 to apply in case the semiflow is a local one. Theorem 2 is a corollary of the main result of this section. Finally, in § 4 we consider two applications of our results. The first application is to semilinear parabolic equations. Here we compare our results to those of Poláčik [20]. The second is to systems of functional differential equations, following [25].

1. Discrete prelude. Let Y be an ordered Banach space with cone Y_+ such that Int $Y_+ \neq \emptyset$. Let $Z \subset Y$ and $S: Z \to Y$ be a mapping which is order preserving and has the following property. If $e \in Z$ is a fixed point of S, i.e., $Se = e$ and l a natural number, then there exists a neighborhood U of e in Z which is order convex in Y such that (i) S^l is defined on U and (ii) S is continuously differentiable on U; that is, there exists a continuous mapping $S': U \to L_+(Y)$ such that

$$S(z) - S(z_0) = S'(z_0)(z - z_0) + \phi(z, z_0)\|z - z_0\|$$

with $\phi(z, z_0) \to 0$ as $z \to z_0$ where $z_0, z \in U$. Here $L_+(Y)$ denotes the cone of bounded linear operators on Y mapping Y_+ into itself. The reader may think of S as the map Φ_τ where Φ is the semiflow in the Introduction.

We assume the existence of a compact connected set K of fixed points of S in Z with the following properties:

(A) For any $e \in K$ with $\rho_e \equiv \operatorname{spr}(S'(e)) \geqq 1$, ρ_e is a pole of the resolvent of $S'(e)$ of order m_e and $N((\rho_e I - S'(e))^{m_e})$ is finite-dimensional. Moreover, $N(\rho_e I - S'(e))$ is spanned by a vector in Int Y_+.

(B) If $e_1, e_2 \in K$ and $e_1 \leqq e_2$, then $e_1 = e_2$, i.e., K contains no pair of distinct order-related points.

If an isolated point α of the spectrum of a closed linear operator L is a pole of the resolvent of L of finite order and $\cup_{k \geqq 1} N((\alpha I - L)^k)$ is finite-dimensional, we say that α is a pole of the resolvent of *finite rank.*

Assumption (A) has several consequences that are conveniently described here. First, we note that $\rho_e \geqq 1$ for all $e \in K$ unless K is a singleton. For if $e \in K$ is a limit point of K, then necessarily one belongs to the spectrum of $S'(e)$. So let us assume that $\rho_e \geqq 1$ for all $e \in K$. It follows that ρ_e depends continuously on $e \in K$. In fact, the upper semicontinuity follows from the well-known upper semicontinuity of the spectrum as a function of the operator and the lower semicontinuity is a result of the lower semicontinuity of isolated parts of the spectrum [8, Thm. 3.1, Remark 3.3, Thm. 3.16, Chap. IV]. As ρ_e is a pole of the resolvent of the order $m = m_e$

$$Y = N((\rho_e I - S'(e))^m) \oplus \operatorname{Im}((\rho_e I - S'(e))^m)$$

where both subspaces are invariant under $S'(e)$ and ρ_e does not belong to the spectrum of the restriction of $S'(e)$ to Im $((\rho_e I - S'(e))^m)$. Let $P(e)$ denote the projection onto $N((\rho_e I - S'(e))^m)$ along Im $((\rho_e I - S'(e))^m)$. Then $P(e)$ depends continuously on $e \in K$ [8, Thm. 3.16, Chap. IV].

Finally, let $z(e)$ denote the unique eigenvector of $S'(e)$ associated with ρ_e of unit norm belonging to Int Y_+. We establish the continuity of $z(e)$ on K as follows. Let $e_n \to e$ as $n \to \infty$ where e_n, $e \in K$, and let $z_n = z(e_n)$, $z = z(e)$. Then $(I - P(e))z_n = [P(e_n) - P(e)]z_n \to 0$ as $n \to \infty$, and $\{P(e)z_n\}$ is precompact in the finite-dimensional

space $N((\rho_e I - S'(e))^m)$. Hence, $\{z_n\}$ is precompact, and, if $z_{n_i} \to u$ for some subsequence $\{n_i\}$, then $S'(e)u = \lim_{i\to\infty} S'(e)z_{n_i} = \lim_{i\to\infty} \rho_{e_{n_i}} z_{n_i} = \rho_e u$. It follows that $u = z$ and that $z_n \to z$ as $n \to \infty$.

PROPOSITION 1.1. *If K is not a singleton, then $\rho_e > 1$ for all $e \in K$.*

Proof. Assume K is not a singleton. Then $\rho_e \geqq 1$ for all $e \in K$ as noted above. Suppose that $\rho_e = 1$ for some $e \in K$. Choose a sequence $e_n \in K$, $e_n \neq e$, $e_n \to e$ as $n \to \infty$. Then

$$e - e_n = S(e) - S(e_n) = S'(e)(e - e_n) + o(\|e - e_n\|).$$

Put $v_n = (e - e_n / \|e - e_n\|)$. We have

$$v_n = S'(e)v_n + r_n, \quad r_n \to 0 \quad \text{as } n \to \infty.$$

In view of our hypothesis (A) and the discussion following it, we may conclude that $I - S'(e)$, restricted to $(I - P(e))Y$, is invertible where $P(e)$ is the spectral projection defined in the discussion preceding the proposition. Let $w_n = (I - P(e))v_n$ and observe that

$$(I - S'(e))w_n = (I - P(e))r_n \to 0$$

which implies that $w_n \to 0$. As in a previous argument, this implies that $\{v_n\}$ is precompact in Y and any limit point belongs to $P(e)Y$. If $v_{n_i} \to v$ as $i \to \infty$ for some subsequence, then $v = S'(e)v$. Thus, $v = \pm z(e)$, and this implies that $e_{n_i} = e - \|e - e_{n_i}\| v_{n_i}$ is related to e for large i, contradicting (B) and completing our proof.

Proposition 1.1 is the only place where we require that $N(\rho_e I - S'(e))$ be spanned by a vector in Int Y_+ (see (A)). The proof of Proposition 1.2 below requires only that the null space $N(\rho_e I - S'(e))$ contain a vector in Int Y_+.

PROPOSITION 1.2. *If there exist sequences $\{u_n\}$ and $\{v_n\}$ in Z, $u_{n+1} = S(u_n)$, $v_{n+1} = S(v_n)$, $u_n \gg v_n$ and $\operatorname{dist}(u_n, K) \to 0$, $\operatorname{dist}(v_n, K) \to 0$ as $n \to \infty$, then K is a singleton.*

Proof. Suppose K is not a singleton set but that there exist two sequences as in the hypotheses. Let $w \in \text{Int } Y_+$ and define a new norm $\|\cdot\|_w$ on Y by $\|y\|_w = \inf\{\lambda > 0 : -\lambda w \leqq y \leqq \lambda w\}$. Since $w \in \text{Int } Y_+$, there exists $\delta > 0$ such that for all $y \in Y$, $y \neq 0$, it follows that $w \pm \delta(y/\|y\|) \geqq 0$. From this, we conclude that $\|y\|_w \leqq \delta^{-1}\|y\|$ for all $y \in Y$, i.e., the w-norm is weaker than the original norm. All convergence and continuity statements below are with respect to the original norm. The $\|\cdot\|_w$ norm is used only for order purposes.

Define $\alpha_n = \sup\{\alpha > 0 : u_n \geqq v_n + \alpha w\}$ and note that $\alpha_n > 0$ and $u_n \geqq v_n + \alpha_n w$. We observe that $\alpha_n \to 0$ as $n \to \infty$. If not, $\alpha_{n_i} \geqq \alpha > 0$ for some subsequence $\{n_i\}$ and, by the compactness of K and the fact that $u_n, v_n \to K$ as $n \to \infty$, we may as well assume that $u_{n_i} \to u \in K$ and $v_{n_i} \to v \in K$ as $i \to \infty$. Then $u \geqq v + \alpha w$ so u and v are distinct order-related points of K in contradiction to our hypothesis (B).

Choose $e_n \in K$ such that $v_n - e_n \to 0$ as $n \to \infty$. Now K is assumed not to be a singleton, so $\rho_e > 1$ for all $e \in K$ by Proposition 1.1. As K is compact and $e \mapsto \rho_e$ is continuous, there exists $r > 1$ such that $\rho_{e_n} \geqq r$ for all n. Let $z_n \in \text{Int } Y_+$, $\|z_n\|_w = 1$ be the normalized positive eigenvector of $S'(e_n)$ corresponding to ρ_{e_n} so $z_n \leqq w$. There is an $\varepsilon > 0$ such that $z_n \geqq \varepsilon w$ holds for all n. This follows from the continuity of the map $e \mapsto z(e) \in \text{Int } Y_+$ assigning to each $e \in K$ the normalized ($\|z(e)\|_w = 1$) positive eigenvector of $S'(e)$ corresponding to ρ_e, which, in turn, implies the continuity of the map $\beta : K \to (0, \infty)$ defined by $\beta(e) = \sup\{\beta > 0 : z(e) \geqq \beta w\}$. As K is compact, there exists $\varepsilon > 0$ such that $\beta(K) \geqq \varepsilon$.

Choose l, a positive integer, such that $r^l \varepsilon > 1$. By (i) and (ii) and the compactness of K there is a cover of K by order-convex open $U \subset Z$ such that S^l is differentiable on U and for each sufficiently large n, the entire segment $v_n + \xi\alpha_n w$, $0 \leqq \xi \leqq 1$, belongs

to one of the U. Hence

$$S^l(v_n+\alpha_n w)-S^l v_n=(S^l)'(e_n)\alpha_n w+\alpha_n\Delta_n$$

where

$$\Delta_n\equiv\int_0^1[(S^l)'(v_n+\xi\alpha_n w)-(S^l)'(e_n)]w\,d\xi.$$

Since $v_n+\alpha_n w-e_n\to 0$, K is compact, and $(S^l)'$ is continuous, it follows that $\delta_n\equiv\|\Delta_n\|_w\to 0$ as $n\to\infty$. Thus we have

$$\begin{aligned}S^l(v_n+\alpha_n w)-S^l v_n&\geqq[S'(e_n)]^l\alpha_n w-\alpha_n\delta_n w\\&\geqq[S'(e_n)]^l\alpha_n z_n-\alpha_n\delta_n w\\&\geqq r^l\alpha_n z_n-\alpha_n\delta_n w\\&\geqq(r^l\varepsilon-\delta_n)\alpha_n w\\&\geqq\alpha_n w\end{aligned}$$

for all large n. We have used that $\varepsilon w\leqq z_n\leqq w$ and $e_n\in E$ in the estimate above. From this last estimate, we obtain

$$\begin{aligned}u_{n+1}=S^l u_n&\geqq S^l(v_n+\alpha_n w)\\&\geqq S^l v_n+\alpha_n w\\&=v_{n+l}+\alpha_n w\end{aligned}$$

for all large n. This implies that

$$\alpha_{n+l}\geqq\alpha_n$$

for large n, contradicting that $0<\alpha_n\to 0$ as $n\to\infty$ and completing our proof.

2. Stable convergence. Returning to the continuous scenario outlined in the Introduction, consider an order-preserving (or monotone) semiflow Φ on an ordered metric space X. We assume that for each $x\in X$, $\mathcal{O}^+(x)$ has compact closure in X.

Suppose that there is an ordered Banach space Y with order $\leqq_Y$ generated by a cone Y_+ having nonempty interior, Int Y_+, and that Y and X have a common subset Z with the following properties:

(i) The metric d_Z induced by the norm in Y on Z is stronger than the metric induced by d, the metric on X, i.e., the embedding from (Z, d_Z) to (Z, d) is continuous.

(ii) The restriction of $\leqq_Y$ to Z agrees with the restriction of $\leqq$ to Z.

In the following, the topology on Z will be assumed to be that induced by d_Z unless otherwise indicated. Additional hypotheses intertwine the set Z and the semiflow Φ:

(I) $\Phi_t(Z)\subseteq Z$ for $t\geqq 0$.

(J) There exists $\tau\geqq 0$ such that $\Phi_\tau(X)\subseteq Z$ and $\Phi_\tau: X\to Z$ is continuous.

(M) If $x_1, x_2\in X$ satisfy $x_1<x_2$, then $\Phi_\tau(x_1)\ll\Phi_\tau(x_2)$ where τ is as in (J) and the strong order $\ll$ is induced by Int Y_+ on Z.

(D) For any $e\in E$, there exists a neighborhood U of e in Z which is order convex in Y and a $\tau>0$ such that Φ_τ is continuously differentiable on U, i.e., there exists a continuous mapping

$$\Phi'_\tau: U\to L_+(Y)$$

such that

$$\Phi_\tau(z)-\Phi_\tau(z_0)=\Phi'_\tau(z_0)(z-z_0)+\phi(z,z_0)\|z-z_0\|_Y$$

for $z, z_0 \in U$ with $\|\phi(z,z_0)\|_Y \to 0$ as $z \to z_0$.

(Σ) For any equilibrium e of Φ satisfying $\rho(e) := \operatorname{spr}(\Phi'_\tau(e)) \geqq 1$, $\rho(e)$ is a pole of the resolvent of $\Phi'_\tau(e)$ with finite rank and $N(\rho(e)I-\Phi'_\tau(e))$ is spanned by an element of Int Y_+, where τ is as in (D) above.

Remark 1. As mentioned in the Introduction, assumption (Σ) is less restrictive than it appears. In applications some compactness property of Φ will typically imply that $\Phi'_\tau(e)$ (or one of its powers) can be represented as a sum of a compact operator and an operator with norm strictly less than 1. This implies that $\rho(e) \geqq 1$ is a pole of the resolvent with finite rank [18]. The same consideration which derives (M) usually shows that $\Phi'_\tau(e)$ is a strongly positive operator, i.e., maps positive nonzero elements into Int Y_+. In particular, $\Phi'_\tau(e)$ is irreducible, implying that the eigenspace of $\Phi'_\tau(e)$ associated with $\rho(e)$ is one-dimensional and spanned by a vector in Int Y_+. See Theorem 3.2 of [22, p. 270]. It is possible to give alternative conditions for (Σ) to hold which are weaker in certain respects (see [2, §§ 8, 9], [18], [22]), but the above appears to be most appropriate in the applications.

Remark 2. In many cases of interest, Z will be order convex, and, in this case, it is possible to verify (M) and (Σ) by establishing the following:

(Σ') For any $z \in Z$, $\Phi'_\tau(z)$ is a strongly positive operator, i.e., maps any positive nonzero element in Y into Int Y_+. Moreover, for $e \in E$, $\Phi'_\tau(e)$ is compact.

Observe that (M) follows from (Σ') by the integral version of Taylor's formula.

Remark 3. In many applications, semilinear parabolic equations, for example, $\Phi'_\tau(e)$, $e \in E$, will usually be a strongly continuous semigroup. In this case, it is more natural to replace the spectral condition (Σ) involving $\Phi'_t(e)$ by one which involves the infinitesimal generator $A(e)$ of $\Phi'_t(e)$. We will show, at the end of this section, how our results may also be obtained by replacing (D) and (Σ) by the assumption (S) below.

(S) For any $e \in E$, $t > 0$, Φ_t can be continuously differentiated in a neighborhood of e in Z which is order convex in Y and $\Phi'_t(e)$, $t \geqq 0$, forms a strongly continuous semigroup on Y. Assume that, for $e \in E$, there exists $\varepsilon > 0$ and a neighborhood U of e such that Φ' is defined and bounded on $U \times [0, \varepsilon]$ as an $L(Y)$-valued map. Assume that the generator $A(e)$ has compact resolvent. If the spectral bound $s(e) = \sup\{\operatorname{Re}\lambda : \lambda \in \sigma(A(e))\}$ of $A(e)$ satisfies $s(e) \geqq 0$, let $N(s(e)I-A(e))$ be spanned by an element $z(e) \in \operatorname{Int} Y^+$.

It turns out that (J) and (M), together with the monotonicity of Φ on X, imply that Φ is strongly order preserving on X.

LEMMA 2.1. *Assuming the hypotheses above, we have*

(a) Φ_t *maps* X *continuously into* Z *for* $t \geqq \tau$.

(b) *For any* $x_1, x_2 \in X$ *with* $x_1 < x_2$, $\Phi_t(x_1) < \Phi_t(x_2)$ *for* $t \geqq 0$ *and* $\Phi_t(x_1) \ll \Phi_t(x_2)$ *for* $t \geqq \tau$.

(c) *Any compact invariant set in* X *is also compact and invariant in* Z.

(d) Φ *is strongly order preserving on* X.

Proof. We prove (d) as the other statements are obvious. If $x_1 < x_2$ then $\Phi_\tau(x_1) \ll \Phi_\tau(x_2)$ so we may find neighborhood U_Y, V_Y in Z with $U_Y \leqq V_Y$ and $\Phi_\tau(x_1) \in U_Y$, $\Phi_\tau(x_2) \in V_Y$. As Φ_τ maps X continuously into Z, we have $\Phi_\tau(U) \subseteq U_Y$, $\Phi_\tau(V) \subseteq V_Y$ for suitable neighborhoods U, V of x_1, x_2 in X.

We next prove the following improvement of the *limit set dichotomy* in [27]. For the remainder of this section, we assume the existence of a space Z satisfying (i) and (ii) above and we assume (I), (J), (M), (D), and (Σ) hold.

PROPOSITION 2.2. *If $x_1, x_2 \in X$ and $x_1 < x_2$, then either*

(a) $\omega(x_1) < \omega(x_2)$, *or*

(b) $\omega(x_1) = \omega(x_2) = \{e\}$ *for some equilibrium $e \in E$.*

Proof. We only need to show that if $\omega(x_1) = \omega(x_2) \subseteq E$, then (b) holds. Let $K = \omega(x_1)$ and note that K is compact in Y by Lemma 2.1(c). By the nonordering principle, K contains no pair of order-related points. Let $v_n = \Phi_{n\tau}(x_1)$, $u_n = \Phi_{n\tau}(x_2)$ and $S: Z \to Z$ be given by $S = \Phi_\tau$. Then K is a compact connected set of fixed points of S, $u_{n+1} = Su_n$, $v_{n+1} = Sv_n$ and $u_n \ll v_n$ holds for $n \geqq 2$. Moreover, $\operatorname{dist}_Z(u_n; K) \to 0$ and $\operatorname{dist}_Z(v_n; K) \to 0$ as $n \to \infty$. In fact, (J) implies that $\Phi_t(x_1) \to K$ in Z as $t \to \infty$. In order to apply Proposition 1.2, it remains only to check (A) of § 1, as the fact that S is continuously differentiable and order preserving is inherited from the corresponding properties of Φ_τ. But (Σ) implies (A) of § 1, so by Proposition 1.2, K is a singleton.

Armed with this sharpened limit set dichotomy, we improve our sequential limit set trichotomy of Proposition 3.1 of [27]. Observe that only alternative (c) of the earlier version is affected. Note also that we include explicitly in the hypotheses only the compactness hypotheses required for the proof, rather than assuming hypothesis (C) as in [27].

PROPOSITION 2.3 (sequential limit set trichotomy). *Let $x_0 \in X$ have the property that it can be approximated from below in X by a sequence $\tilde{x}_n$ such that $\overline{\bigcup_{n\geqq 1} \omega(\tilde{x}_n)}$ is compact in X. Then there exists a subsequence x_n of $\tilde{x}_n$ such that $x_n < x_{n+1} < x_0$, $n \geqq 1$, with $x_n \to x_0$ satisfying one of the following*:

(a) *There exists $u_0 \in E$ such that*

$$\omega(x_n) < \omega(x_{n+1}) < u_0 = \omega(x_0), \qquad n \geqq 1$$

and

$$\lim_{n\to\infty} \operatorname{dist}(\omega(x_n), u_0) = 0.$$

(b) *There exists $u_0 \in E$ such that*

$$\omega(x_n) = u_0 < \omega(x_0), \qquad n \geqq 1.$$

If $u \in E$ and $u < \omega(x_0)$, then $u \leqq u_0$.

(c) *There exists $u_0 \in E$ such that $\omega(x_n) = \omega(x_0) = u_0$ for $n \geqq 1$.*

The special property "$\overline{\bigcup_{n\geqq 1} \omega(\tilde{x}_n)}$ is compact in X" of the sequence $\tilde{x}_n$ approximating x from below will be required for several results of this and the next section. It is convenient to have some notation for it. We say x has property (ω_-) ((ω_+)) if it can be approximated from below (above) by a sequence x_n such that $\overline{\bigcup_{n\geqq 1} \omega(x_n)}$ is compact in X. We say x has property (ω) if it has both property (ω_-) and (ω_+).

Repeating the proof of Theorem 3.3 in [27] and using the stronger sequential limit set trichotomy in Proposition 2.3 in place of Proposition 3.1 in [27], we find that there is an open dense subset of X which consists of convergent points.

THEOREM 2.4. *Suppose each point of X has property (ω_-) or (ω_+). Then* Int C *is dense in X.*

In fact, under minimal additional hypotheses, we can show that X contains an open and dense set of stable convergent points. A point $x \in X$ is called a *stable point* if, for every $\varepsilon > 0$, there exists $\delta > 0$ such that $d(\Phi_t(x), \Phi_t(y)) < \varepsilon$ for $t \geqq 0$ whenever $y \in X$ and $d(x, y) < \delta$. The set of stable points in X is denoted by S.

PROPOSITION 2.5. *Let $x \in S$ be a stable point which has property (ω_-) or (ω_+). Then $x \in C$.*

Proof. Consider an approximating sequence $\{x_n\}$. Then, after passing to a subsequence only alternatives (a) or (c) of Proposition 2.3 are possible because points close to x have limit sets which are close to the limit set of x. Thus $x \in C$.

Proposition 2.5 implies the following conclusion from Theorem 3.9 in [27].

THEOREM 2.6. *Let X be a normally ordered metric space. Suppose that each point $x \in X$ has property (ω_-) or (ω_+) and that X contains an open and dense subset X_0 of points which have property (ω). Then $S \subseteq C$ and* Int S *is dense in X.*

In [27], Theorem 3.13, we give conditions under which the set of asymptotically stable points A is dense in X. This theorem cannot be improved by adding the assumptions of this paper, but note that we now have $A \subseteq C$ instead of $A \subseteq Q$. Recall that $A \subseteq S \subseteq C$ by Proposition 2.5 and that, by its definition, A is open.

We conclude this section by sketching modifications of the arguments in the proofs of Propositions 1.1 and 1.2, now in the continuous setting of the semiflow Φ_t, which are required in order to establish that assumptions (I), (J), (M), and (S) imply the limit set dichotomy (Proposition 2.2). We begin with the analogue of Proposition 1.1.

PROPOSITION 2.7. *Assume* (I), (J), (M), *and* (S) *hold. Let K be a nonempty, compact, connected, unordered set of equilibria of Φ_t which is not a singleton. Then $s(e) > 0$ for all $e \in K$.*

Proof. Let $e \in K$. As in Proposition 1.1, we can find a sequence $e_n \in K$ such that $e_n \neq e$ and $e_n \to e$ as $n \to \infty$. We have

$$e - e_n = \Phi_t(e) - \Phi_t(e_n).$$

Set $v_n = (e - e_n / \|e - e_n\|)$. Then

$$v_n = \Phi_t'(e) v_n + r_n(t) \tag{2.1}$$

where $r_n(t) \to 0$ as $n \to \infty$ pointwise in t. By our boundedness assumption concerning Φ' in (S), we can assume that the

$$r_n(t) = \int_0^1 [\Phi_t'(se + (1-s)e_n) - \Phi_t'(e)] v_n \, ds, \qquad n \geqq 1,$$

are uniformly bounded for t in $[0, \varepsilon]$. Multiplying through (2.1) by $e^{-\lambda t}$ where λ is chosen sufficiently large, and integrating the result from zero to ε, we obtain

$$\begin{aligned} \lambda^{-1}(1 - e^{-\lambda\varepsilon}) v_n &= \int_0^\varepsilon e^{-\lambda t} \Phi_t'(e) v_n \, dt + \int_0^\varepsilon e^{-\lambda t} r_n(t) \, dt \\ &= (\lambda I - A(e))^{-1} v_n - \int_\varepsilon^\infty e^{-\lambda t} \Phi_t'(e) v_n \, dt + \int_0^\varepsilon e^{-\lambda t} r_n(t) \, dt, \end{aligned}$$

where, in the second equality, we have used the Laplace transform formula for the resolvent of the generator of the semigroup $\Phi_t'(e)$ (see [19, proof of Remark 5.4, Chap. 1]). By the uniform boundedness of the $r_n(t)$ on $[0, \varepsilon]$ and the fact that they converge pointwise to zero, $\int_0^\varepsilon e^{-\lambda t} r_n(t) \, dt \to 0$ as $n \to \infty$. Let α denote the measure of noncompactness [9]. Using the compactness of the resolvent and standard properties of α, we obtain from the last formula

$$\begin{aligned} \lambda^{-1}(1 - e^{-\lambda\varepsilon}) \alpha\{v_n\} &\leqq \alpha\left\{ \int_\varepsilon^\infty e^{-\lambda t} \Phi_t'(e) v_n \, dt \right\} \\ &\leqq \frac{M e^{(\omega(\varepsilon) - \lambda)\varepsilon}}{\lambda - \omega(e)} \alpha\{v_n\}, \end{aligned}$$

where we use that $\|\Phi_t'(e)\| \leqq M e^{\omega(e)t}$ for some $M \geqq 1$ and $\omega(e)$. Choosing λ sufficiently large in the inequality above establishes that $\alpha\{v_n\} = 0$. Hence, v_n has a subsequence converging to a point u and, by (2.1),

$$u = \Phi_t'(e)u, \qquad t \geqq 0.$$

Multiplying through by $e^{-\lambda t}$ and integrating over $t \in [0, \infty)$, we get

$$\lambda^{-1}u = (\lambda I - A(e))^{-1}u$$

for large λ. In particular, $r_\lambda(e)$, the spectral radius of $(\lambda I - A(e))^{-1}$, satisfies $r_\lambda(e) \geqq \lambda^{-1}$ for large λ. As $r_\lambda(e) = (\lambda - s(e))^{-1} \geqq \lambda^{-1}$, it follows that $s(e) \geqq 0$. If $s(e) = 0$, then it follows that $r_\lambda(e) = \lambda^{-1}$ and so u is an eigenvector of $A(e)$ associated with $s(e)$. By (S), $u = \pm z(e)$, where $z(e)$ is as in (S). But then $e_n = e - \|e - e_n\| v_n$ is related to e for some large n, contradicting that K is unordered. This proves the proposition.

Now, the proof of Proposition 2.2 can be followed to obtain the sequences $u_{n+1} = Su_n$ and $v_{n+1} = Sv_n$ where $S = \Phi_\tau$, τ as in (M), $u_n \ll v_n$ and $\operatorname{dist}_Z(u_n; K) \to 0$, $\operatorname{dist}_Z(v_n; K) \to 0$ as $n \to \infty$ with $K = \omega(x_1)$, a nonempty compact, connected, unordered set of equilibria. Now we need Proposition 1.2 to conclude that K is a singleton. Let us see how to modify the proof of Proposition 1.2 so that we may apply it. Indeed, we can follow the proof of Proposition 1.2 through the first paragraph without change. For the remainder of the proof we take z_n as the eigenvector of $A(e_n)$ corresponding to $s(e_n) > 0$. Clearly z_n is an eigenvector of $\Phi_\tau'(e_n)$ associated with the eigenvalue $r(e_n) = e^{s(e_n)\tau} > 1$, although $r(e_n)$ need not be the spectral radius of $\Phi_\tau'(e_n)$. We need only to establish the continuity of the maps $e \mapsto z(e)$ and $e \mapsto s(e)$ in order to conclude the existence of $r > 1$ and $\varepsilon > 0$ such that $r(e_n) > r$ and $z(e_n) \geqq \varepsilon w$ hold for all n. The remainder of the proof of Proposition 1.2 can then be followed to obtain the desired contradiction.

In order to establish the continuity of the maps $e \mapsto z(e)$, $e \mapsto s(e)$, we show that for sufficiently large λ, the resolvents $(\lambda I - A(e))^{-1}$ depend continuously on $e \in K$. Indeed, if $e_n \to e$, $A = A(e)$, $A_n = A(e_n)$, $T_n(t) = \Phi_t'(e_n)$, and $T(t) = \Phi_t'(e)$, then from the boundedness of Φ' in $U \times [0, \varepsilon]$, where U is a neighborhood of e (see (S)), it follows that $\|T_n(t)\|, \|T(t)\| \leqq M e^{\omega t}$, $n \geqq 1$, for some $M \geqq 1$ and ω (see the proof of Theorem 2.2 [19, Chap. 1]). Since $T_n(t) \to T(t)$ in the uniform operator topology as $n \to \infty$, we can argue as in Theorem 4.2 of [19, Chap. 3] to conclude that $(\lambda I - A(e_n))^{-1} \to (\lambda I - A(e))^{-1}$ as $n \to \infty$ in the uniform operator topology. Note that part (b) of Theorem 4.2 of [19, Chap. 3] proves that if $T_n(t) \to T(t)$ in the strong topology, then the resolvents converge in the strong topology. We obtain the stronger conclusion above by virtue of the stronger hypothesis that $T_n(t) \to T(t)$ in the uniform topology. The spectral radius $r_\lambda(e)$ of $(\lambda I - A(e))^{-1}$ depends continuously on e by the same arguments establishing the continuity of the spectral radius ρ_e in § 1. Moreover, $r_\lambda(e) = (\lambda - s(e))^{-1}$ and $z(e)$ spans the eigenspace of $(\lambda I - A(e))^{-1}$ corresponding to $r_\lambda(e)$. Thus, the continuity of $s(e)$ and $z(e)$ follows as in the arguments preceding Proposition 1.1. This completes our sketch of the validity of Proposition 2.2 under the hypotheses (I), (J), (M), and (S). In particular, these assumptions can replace (I), (J), (M), (D), and (Σ) in all the results of this section.

3. Stable convergence for local semiflows. In this section we consider the case that the semiflow Φ may not be globally defined on X. We assume only that $\Phi : \operatorname{Dom} \Phi \subseteq X \times \mathbf{R}^+ \to X$ is a local semiflow as defined below. Our aim will be to show that, through slight modification of the ideas in [27] and the previous section, a stable convergence result may still be obtained in this more general setting. As in § 2, we assume that X is an ordered metric space.

Following Hirsch [7], we assume that $\Phi: \operatorname{Dom}\Phi \to X$, where $\operatorname{Dom}\Phi$ is an open subset in $X \times \mathbf{R}^+$ containing $X \times \{0\}$, and Φ is continuous on $\operatorname{Dom}\Phi$ and satisfies

(i) $\Phi_0 = \Phi(\cdot, 0) = \mathrm{id}_X$

(ii) For all $s, t \geqq 0$, $\operatorname{Dom}\Phi_{s+t} = \Phi_t^{-1}(\operatorname{Dom}\Phi_s)$ and

$$\Phi_{s+t} = \Phi_t \circ \Phi_s$$

where $\Phi_t: \operatorname{Dom}\Phi_t \to X$, $\operatorname{Dom}\Phi_t = \{x: (x, t) \in \operatorname{Dom}\Phi\}$ and $\Phi_t(x) = \Phi(x, t)$ for $x \in \operatorname{Dom}\Phi_t$.

For each $x \in X$, $\{t \geqq 0: x \in \operatorname{Dom}\Phi_t\} = [0, \sigma_x)$ is a half-open interval with right-hand endpoint $\sigma_x \leqq +\infty$. The orbit of x is $\mathcal{O}^+(x) = \{\Phi_t(x): 0 \leqq t < \sigma_x\}$. A set $K \subset X$ is positively invariant if it contains the orbit of each of its points. If K is compact and positively invariant, then $\sigma_x = +\infty$ for each $x \in K$. In particular, if $\overline{\mathcal{O}^+(x)}$ is compact in X, then $\sigma_x = +\infty$ and the omega limit set $\omega(x)$ has the properties described in the Introduction.

We assume hereafter that Φ is monotone (order preserving) in the sense that $\Phi_t(x) \leqq \Phi_t(y)$ holds whenever $x \leqq y$ and $0 \leqq t < \min\{\sigma_x, \sigma_y\}$.

As in § 2, we assume that there is an ordered Banach space Y with order $\leqq_Y$ generated by a cone Y_+ with $\operatorname{Int} Y_+ \neq \varnothing$ and that Y and X have a common subset Z with the assumptions (i) and (ii) of § 2 holding.

We modify the assumptions (I)-(M) of § 2 as follows:

(I) $\Phi_t(z) \in Z$, $0 \leqq t < \sigma_z$, for each $z \in Z$.

(J) There exists $\tau \geqq 0$ such that, for any $x \in X$ with $\sigma_x > \tau$, there is a neighborhood U of x in X such that Φ_τ is defined on U and maps U, with the X topology, continuously into Z, with the Y topology.

(M) There exists $\tau > 0$ such that if $x_1, x_2 \in X$ satisfy $x_1 < x_2$ and $\sigma_{x_i} > \tau$, then $\Phi_\tau(x_1) \ll \Phi_\tau(x_2)$, where the strong order $\ll$ is induced by $\operatorname{Int} Y_+$ on Z.

Assumptions (D) and (Σ) of § 2 are assumed to hold as well, where τ in assumption (Σ) is the same as τ in (D). Alternatively, assumption (S) of Remark 3 may be assumed in place of (D) and (Σ).

By taking τ sufficiently large, we may assume that the τ of (J) and (M) are identical. Indeed, if in (J), $\tau < t < \sigma_x$, then there exists a neighborhood V contained in U such that $V \times [0, t] \subset \operatorname{Dom}\Phi$ and Φ_t maps V, with the X topology, continuously into Z, with the Y topology. From (M), it is easily deduced that $\Phi_t(x_1) \ll \Phi_t(x_2)$ holds for all t satisfying $\tau \leqq t < \min\{\sigma_{x_1}, \sigma_{x_2}\}$. As (D) and ($\Sigma$) remain valid with τ replaced by any integral multiple of itself, it is clear that we may assume, by passing to a sufficiently large τ if necessary, that the τ of (J), (M), (D), and (Σ) are identical.

The strong order-preserving property of Φ must be understood in a slightly modified form. Arguing as in Lemma 2.1, we can show that if $x_1, x_2 \in X$ satisfy $\sigma_{x_1}, \sigma_{x_2} > \tau$ and $x_1 < x_2$, then there exist neighborhoods U of x_1 and V of x_2 in X such that $U \times [0, \tau]$ and $V \times [0, \tau]$ are contained in $\operatorname{Dom}\Phi$ and $\Phi_\tau(U) \leqq \Phi_\tau(V)$. Since we will usually assume that the points x with which we work belong to orbits having compact closure in X, this modification of the strong order-preserving property will not have a significant effect.

The reader may check that the limit set dichotomy in Proposition 2.3 of [27] remains valid in the present context provided that we assume that $\overline{\mathcal{O}^+(x)}$ and $\overline{\mathcal{O}^+(y)}$ are compact in X. Similarly, the sequential limit set trichotomy in Proposition 3.1 of [27] is valid if we assume that $\overline{\mathcal{O}^+(x_0)}$ is compact in X, $\overline{\mathcal{O}^+(\tilde{x}_n)}$ is compact in X for each n, corresponding to the sequence $\tilde{x}_n$ approximating x_0 from below in X, and $\overline{\bigcup_{n \geqq 1} \omega(x_n)}$ is compact in X.

It is now easy to check that the improved limit set dichotomy (Proposition 2.2) and the sequential limit set trichotomy (Proposition 2.3) of § 2 remain valid, provided that we assume that the appropriate points (x and y in Proposition 2.2 and x_0 and $\tilde{x}_n$ in Proposition 2.3) belong to orbits having compact closure in X. Note that hypothesis (i) of § 1 is automatically satisfied since for any $t>0$ and $e\in E$ there exists an open set U such that $U\times[0, t)\subset \operatorname{Dom}\Phi$.

We now introduce a local uniform compactness-of-orbits assumption on Φ which will allow us to obtain strong stability results as in Theorem 2.6 without the normality assumption of that theorem. This is important for applications to semilinear parabolic equations where the usual interpolation spaces fail to have the normality property.

We say that orbits of Φ are locally uniformly compact at x_0, provided there exists a neighborhood U of x_0 such that $\sigma_y=+\infty$ for all $y\in U$ and

$$\Phi(U\times[t_0,\infty))$$

has compact closure in X for some $t_0>0$. Observe that this assumption implies that $\overline{\cup_{n\geqq 1}\omega(x_n)}$ is compact in X if x_n is a sequence approximating x_0 from below (above) in X and $x_n\in U$ for $n\geqq 1$.

Let $x\in X$ belong to a neighborhood U in X such that $\overline{\mathcal{O}^+(y)}$ is compact in X for each $y\in U$. Then we say x is stable provided for each $\varepsilon>0$ there exists $\delta>0$ such that $d(\Phi_t(x),\Phi_t(y))<\varepsilon$ for $t\geqq 0$ whenever $y\in X$ satisfies $d(x, y)<\delta$. Let S denote the set of stable points in X. We say that x is asymptotically stable if there is a neighborhood V of x, contained in U, with the property that for every $\varepsilon>0$, there exists $t_\varepsilon>0$ such that $d(\Phi_t(x),\Phi_t(y))<\varepsilon$ if $t\geqq t_\varepsilon$ and $y\in V$. Let A denote the set of asymptotically stable points in X. Note that A is open and that $A\subset S$.

The next two lemmas prepare the way for a main result of this section, Theorem 3.3 below.

LEMMA 3.1. *Assume that x_0 is contained in a neighborhood U such that $\sigma_y=+\infty$ for $y\in U$ and*

$$\Phi(U\times[t_0,\infty))$$

has compact closure in X for some $t_0>0$. Furthermore, assume that $x_0\in X$ can be approximated from below such that either alternative (b) *or* (c) *of the sequential limit set trichotomy holds.*

Then there exists a neighborhood $W\subset U$ of x_0 such that any point $x\in W$, $x<x_0$, is an asymptotically stable point.

Proof. Let (b) hold. From Corollary 3.2 of [27] we find a neighborhood W of x_0 contained in U with the following property: For each $x\in W$, $x<x_0$, there is a neighborhood $V=V_x$ of x in W, a positive integer $N=N_x$ and a time $T=T_x>0$ such that

$$u_0\leqq\Phi_t(V)\leqq\Phi_t(x_N)\quad\text{for } t\geqq T.$$

We claim that, for any $\varepsilon>0$, there is some $t_\varepsilon>0$ such that

$$d(\Phi_t(v), u_0)<\varepsilon,\qquad t>t_\varepsilon,\quad v\in V.$$

If this does not hold, we find sequences $t_j\to\infty$, $j\to\infty$ and $v_j\in V$ such that, for each j,

$$d(\Phi_{t_j}(v_j), u_0)>\varepsilon>0.$$

By our compactness assumption we can assume, possibly after choosing a subsequence, that $\Phi_{t_j}(v_j)$ converges towards an element $w\in X$, $d(w, u_0)\geqq\varepsilon$. As

$$u_0\leqq\Phi_{t_j}(v_j)\leqq\Phi_{t_j}(x_N)\to u_0,\qquad j\to\infty,$$

we conclude that $w=u_0$, a contradiction.

We now consider alternative (c). From Corollary 3.2 of [27] we find a neighborhood W of x_0 contained in U with the following property. For each $x \in W$, $x < x_0$, there is a neighborhood $V = V_x$ of x in W, a positive integer $N = N_x$ and a time $T = T_x > 0$, such that

$$\Phi_t(x_1) \leqq \Phi_t(V) \leqq \Phi_t(x_N) \quad \text{for } t \geqq T.$$

We claim that, for any $\varepsilon > 0$, there is some $t_\varepsilon > 0$ such that

$$d(\Phi_t(v), \Phi_t(x_1)) < \varepsilon, \qquad t > t_\varepsilon, \quad v \in V.$$

If this does not hold, we find sequences $t_j \to \infty$, $j \to \infty$, and $v_j \in V$ such that

$$d(\Phi_{t_j}(v_j), \Phi_{t_j}(x_1)) > \varepsilon > 0.$$

By our compactness assumption we can assume, after possibly choosing subsequences, that

$$\Phi_{t_j}(x_1) \to w_1, \quad \Phi_{t_j}(v_j) \to w_2, \quad \Phi_{t_j}(x_N) \to w_3, \quad j \to \infty$$

and

$$d(w_2, w_1) \geqq \varepsilon > 0, \qquad w_1, w_3 \in \omega(x_1) = \omega(x_N).$$

From the compatibility between order and topology we conclude that

$$w_1 \leqq w_2 \leqq w_3.$$

The nonordering principle implies $w_1 = w_3$; hence $w_1 = w_2$, a contradiction.

LEMMA 3.2. *Let $x_0 \in X$ be such that it can be approximated both from below and from above. Furthermore, assume that x_0 is contained in a neighborhood U such that $\sigma_y = +\infty$ for $y \in U$ and*

$$\Phi(U \times [t_0, \infty))$$

has compact closure in X for some $t_0 > 0$.

(a) *Let alternative* (a) *of the sequential limit set trichotomy hold both below and above x_0. Then x_0 is a stable point.*

(b) *Let alternative* (c) *of the sequential limit set trichotomy hold both below and above x_0. Then x_0 is an asymptotically stable point.*

Proof. We first consider (a). So we have sequences

$$x_n < x_{n+1} < x_0 < y_{n+1} < y_n, \qquad x_n \to x_0, \quad y_n \to x_0, \quad n \to \infty,$$
$$\omega(x_n) < \omega(x_{n+1}) < u_0 = \omega(x_0) < \omega(y_{n+1}) < \omega(y_n),$$

where

$$\lim_{n\to\infty} \operatorname{dist}(\omega(x_n), u_0) = \lim_{n\to\infty} \operatorname{dist}(\omega(y_n), u_0) = 0.$$

By Corollary 3.2 of [27] we have neighborhoods U_n of x_0 in U and times $t_n > 0$ such that

$$\Phi_t(x_n) \leqq \Phi_t(U_n) \leqq \Phi_t(y_n), \qquad t \geqq t_n.$$

If x_0 is not a stable point, we find $z_j \to x_0$, $s_j \to \infty$, such that, for all j,

$$d(\Phi_{s_j}(z_j), \Phi_{s_j}(x_0)) > \varepsilon > 0.$$

After choosing appropriate subsequences we can assume that $s_j > t_j$, $z_j \in U_j$, hence

$$\Phi_{s_j}(x_j) \leqq \Phi_{s_j}(z_j) \leqq \Phi_{s_j}(y_j).$$

By our compactness assumption, we can assume, after choosing subsequences, that

$$\Phi_{s_j}(x_j) \to w_1, \quad \Phi_{s_j}(z_j) \to w_2, \quad \Phi_{s_j}(y_j) \to w_3, \quad j \to \infty.$$

In particular,

$$w_1 \leqq w_2 \leqq w_3, \qquad d(w_2, u_0) \geqq \varepsilon.$$

The monotonicity of the flow implies that, for each j,

$$\omega(x_j) < w_1 \leqq w_2 \leqq w_3 < \omega(y_j).$$

This implies $w_1 = u_0 = w_2 = w_3$, a contradiction.

We consider the situation in (b). So we have the sequences

$$x_n < x_{n+1} < x_0 < y_{n+1} < y_n, \qquad x_n \to x_0, \quad y_n \to x_0, \quad n \to \infty,$$

where

$$\omega(x_n) = \omega(x_0) = \omega(y_n).$$

Using that the semiflow is strongly order preserving we find a neighborhood V of x_0 in U and a time $T > 0$ such that

$$\Phi_t(x_1) \leqq \Phi_t(V) \leqq \Phi_t(y_1), \qquad t > T.$$

Arguing as in the proof of Lemma 3.1 case (c), we find: For any $\varepsilon > 0$ there is some $t_\varepsilon > 0$ such that

$$d(\Phi_t(v), \Phi_t(x_0)) < \varepsilon, \qquad t > t_\varepsilon, \quad v \in V.$$

This completes our proof.

We can now state the main result of this section.

THEOREM 3.3. *Let X_0 be an open subset of X such that every point of X_0 can be approximated both from above and from below in X. Assume that either*

(a) *X is normally ordered, every orbit starting in X_0 has compact closure in X and, for any convergent monotone sequence x_n in X_0, $\bigcup_{n \geq 1} \omega(x_n)$ has compact closure in X, or*

(b) *Each point of X_0 belongs to a neighborhood U such that $U \times [0, \infty) \subset \operatorname{Dom} \Phi$ and*

$$\Phi(U \times [t_0, \infty)) \text{ has compact closure in } X \text{ for some } t_0 > 0.$$

Then $A \subset S \subset C$ and

$$X_0 \cap (A \cup \operatorname{Int} S)$$

is dense in X_0. In particular, X_0 contains a dense open subset of stable convergent points.

Proof. We consider only the case where (b) holds, since the other case follows simply as in Theorem 3.9 of [27]. It is sufficient to show that

$$U \cap (A \cup \operatorname{Int}(S \cap C)) \neq \varnothing$$

for any open subset U of X_0. Assume that $U \cap A = \varnothing$. Let x_0 be an arbitrary element in U. By assumption x_0 can be approximated from below and above. If the alternatives (b) or (c) of the limit set trichotomy hold below x_0 or above x_0, $U \cap A \neq \varnothing$, because x_0 is then approximated by asymptotically stable points. See Lemma 3.1. Hence, alternative (a) has to hold below x_0 and above x_0. Therefore, x_0 is a stable convergent point by Lemma 3.2(a). Since x_0 was an arbitrary point in U we have $U \subset S \cap C$. As U is open we have $U \subset \operatorname{Int}(S \cap C)$. This implies the assertion. Note that $A \subset S \subset C$ follows as in Proposition 2.5.

COROLLARY 3.4. *Let X contain a dense open set X_0 satisfying one of the assumptions* (a) *or* (b) *of the previous theorem. Then $A \cup \operatorname{Int} S$ is open and dense in X.*

Theorem 2.4 and Corollary 3.4 imply that, from a topological point of view, convergence to equilibrium occurs for a "large" set of initial data for strongly order-preserving semiflows enjoying the properties assumed to hold in this paper. Another notion of a "large" set, in finite dimensions, is a set whose complement has Lebesgue measure zero. We can establish that the set of nonconvergent points has measure zero in finite dimensions by showing that the set of such points on any totally ordered arc is at most countable and then applying Fubini's theorem. Thus, a natural extension of this notion of the scarcity of nonconvergent points, to infinite dimensions, is that any totally ordered arc contains at most countably many nonconvergent points. Such a result for quasi-convergent points was obtained by Hirsch [7, Thm. 7.3]. If we restrict ourselves to totally ordered arcs as opposed to sets, this result does not require the separability of the space X. Below we extend this result to convergent points as well as obtain a stronger result with the additional compactness hypothesis required for the sequential limit set trichotomy.

Recall that a totally ordered arc is the continuous image of a nontrivial interval $I \subseteq \mathbf{R}$ under a map $\psi: I \to X$ such that $\psi(s) < \psi(t)$ whenever $s, t \in I$ and $s < t$.

THEOREM 3.5. *Let J be a totally ordered arc of points belonging to orbits with compact closure in X. Then $J \setminus C$ is at most countable. If, furthermore, for every convergent sequence $x_n \in J$, $\overline{\bigcup_{n \geq 1} \omega(x_n)}$ is compact in X, then $J \setminus C$ consists of isolated points of J.*

Proof. Let $W = \overline{\Phi([0, \infty) \times J)}$. Then the continuity of Φ implies that W is a separable metric space which is positively invariant under Φ. Hence, we may as well assume from the beginning that X is separable since we can always pass to the space W.

We next establish that if $x \in J$ and

$$\inf \{\operatorname{dist}(\omega(x), \omega(y)): y \in J, y \neq x\} = 0,$$

then $x \in C$. Choose a sequence $x_n \in J$, $x_n \neq x$, such that $\operatorname{dist}(\omega(x_n), \omega(x)) \to 0$, $n \to \infty$. We may assume that $x_n < x$ for all n. Taking a subsequence, we can conclude from Proposition 2.2 that either $\omega(x_n) = \omega(x)$ holds for some n or $\omega(x_n) < \omega(x)$ holds for all n. In the first case x is convergent. In the second case we choose $y_n \in \omega(x_n)$, $z_n \in \omega(x)$, such that $d(y_n, z_n) \to 0$, $n \to \infty$. As $\omega(x)$ is compact we can assume, possibly by passing to a subsequence, that $y_n, z_n \to z \in \omega(x)$. As $y_n \leqq \omega(x)$, we conclude that $z \leqq \omega(x)$ and $z \in \omega(x)$ implies that $\omega(x) = \{z\}$ by the nonordering principle [27, Prop. 22]. Again, x is a convergent point, establishing our claim.

Now, if $x \in J \setminus C$, we find, by the claim of the previous paragraph, that there exists a neighborhood U_x of $\omega(x)$ such that $U_x \cap \omega(y) = \varnothing$ for every $y \in J$, $y \neq x$. By the axiom of choice we have a mapping $x \mapsto u_x \in \omega(x) \subset U_x$ from $J \setminus C$ into X which is injective. As X is separable, it has a countable base and we may obtain a neighborhood $V_x \subset U_x$ for each $x \in J \setminus C$, where V_x belongs to the countable base. A second application of the axiom of choice gives an injective mapping from $J - C$ into the countable base by $x \mapsto V_x$. This establishes the countability of $J - C$.

Assume the stronger assumption holds that for each convergent sequence $x_n \in J$, $\overline{\bigcup_{n \geq 1} \omega(x_n)}$ is compact in X. If x were not an isolated point of $J - C$ relative to J, then we could approximate x by a monotone sequence of points of $J - C$. But, as $x \in J - C$, this violates the sequential limit set trichotomy.

4. Applications. In this section we apply our theory to an abstract parabolic evolution equation and a concrete parabolic initial/boundary problem as well as to a system of quasi-monotone functional differential equations.

4.1. An abstract parabolic evolution equation. We consider the Cauchy problem

$$\text{(SPE)} \qquad \frac{du}{dt} + Au = f(u)$$

and compare the results provided by our theory with those obtained by Poláčik [20].

We assume that A is a sectorial operator on a Banach space X^0 with compact resolvent $(\lambda I - A)^{-1}$ and $\operatorname{Re}\sigma(A) > 0$, where $\sigma(A)$ denotes the spectrum of A.

For $\nu > 0$, X^ν denotes the domain of the fractional power A^ν with the corresponding graph norm which makes it a Banach space.

We fix some $0 \leqq \alpha < 1$. X^α is going to be our basic state space.

We require the following properties for f:

(f1) $f: X^\alpha \to X$ is C^1.

(f2) f maps bounded sets in X^α onto bounded sets in X.

By Theorems 3.3.3 and 3.3.4 of [3] the solutions u of (SPE) induce a local semiflow Φ on X^α by $\Phi_t(u(0)) = u(t)$. The maximal interval of existence of $\Phi_t(x)$ is denoted by σ_x.

It follows from Corollary 3.4.6 of [3] that Φ is continuously differentiable as a mapping from $X^\alpha \times (0, \infty)$ into X^α on its domain of existence. (SPE) then implies that $\Phi_t(x)$ is a continuous function of t from $(0, \sigma_x)$ into X^1.

As A has a compact resolvent and we have assumed (f2), Φ_t, for $t > 0$, maps bounded sets in X^α into bounded sets in X^β, $\alpha < \beta < 1$, and, hence, into compact sets in X^α. See the proof of Theorem 3.3.6 and Theorem 1.4.8 of [3]. In particular, sets $\Phi(B \times [\varepsilon, \infty))$ with $B \subset X^\alpha$, which are defined and bounded in X^α for $\varepsilon = 0$, are relatively compact in X^α for $\varepsilon > 0$.

We assume that X^0 is an ordered Banach space under a partial ordering $\leqq$. Our essential requirement is that there is some $\beta \in [\alpha, 1)$ such that X^β is strongly ordered by the induced ordering $\leqq$, i.e., the positive cone X^β_+ has nonempty open interior in X^β and that

$$\text{(P)} \qquad \Phi_t(y) - \Phi_t(x) \in \operatorname{Int} X^\beta_+, \qquad t > 0, \quad x < y,$$

$x, y \in X^\alpha$, t in the common interval of existence. (P) is formally weaker than Poláčik's assumption (M4) because it only involves solutions and not subsolutions to (SPE). (P) implies, in particular, assumptions (J) and (M) in § 3.

Φ_t restricts to a continuously differentiable (in the state variable) local semiflow on X^β since f restricts to a C^1 map on X^β. Hence (I) holds.

We verify that (S) of Remark 3, § 2 holds. For $e \in E$, we have already noted that Φ_t is continuously differentiable in an X^β neighborhood of e. From Theorem 3.4.4 of [3], it follows that $\Phi'_t(e)$ defines a strongly continuous semiflow on X^β generated by $A(e) = -A + f'(e)$. $A(e)$ is sectorial and $(\mu I - A(e))^{-1}$ maps X^0 continuously into X^1 and hence restricts to a compact operator on X^β. Thus $A(e)$ has compact resolvent. For each $e \in E$ and $\varepsilon > 0$ there exists a neighborhood U' of e such that $U' \times [0, \varepsilon] \subset \operatorname{Dom}\Phi$. Using again Theorem 3.4.4 of [3], standard Gronwall estimates, and continuity of Φ_t on X^β, we can verify that there is a neighborhood U containing e in U' such that $\Phi'(U \times [0, \varepsilon])$ is a bounded set in $L(X^\beta)$.

The remaining hypotheses in (S) concerning the spectrum of $A(e)$ must be added to our hypothesis:

(SP) For each $e \in E$, the spectral bound $s(e) = \sup\{\operatorname{Re}\lambda : \lambda \in \sigma(A(e))\}$ has the property that if $s(e) \geqq 0$, then $N(s(e)I - A(e))$ is spanned by an element $z(e)$ belonging to $\operatorname{Int} X^\beta$.

We note that (SP) follows immediately from (M3) of Poláčik (see [20, beginning of § 3]).

In the following results we assume that (f1), (f2), (P), and (SP) hold. Theorem 4.1 follows from the first assertion of Theorem 3.5 and Theorem 4.2 from Theorem 3.3 with hypothesis (b).

THEOREM 4.1. *Let J be a totally ordered arc of points in X^α, the orbits of which are defined for all $t \geqq 0$, and are bounded. Then the set of nonconvergent points on J is at most countable.*

THEOREM 4.2. *Let U be an open subset of X^α with the following property. For any $u \in U$ there is a neighborhood V of u in U such that $V \times [0, \infty) \subset \operatorname{Dom} \Phi$ and*

$$\Phi(V \times [0, \infty))$$

is bounded in X^α. Then U contains a dense open subset of stable convergent points.

Theorems 4.1 and 4.2 express that the set of nonconvergent points is small. They should be compared to Poláčik's Corollary 5.3 in [20]. We obtain a stronger conclusion in Theorem 4.2 than [20, Cor. 5.3], namely, that U contains a dense open set of stable convergent points rather than a residual set of convergent points, assuming more compactness. We can dispense with the technical conditions (SM1) and (SM2) in [20] and, more importantly, need $f \in C^1$ rather than $f \in C^2$ as in [20].

The results for abstract parabolic evolution equations can be applied to scalar parabolic initial boundary value problems

$$\begin{aligned} &\partial_t u - \mathcal{A}u = g(x, u, \nabla u), \qquad x \in \Omega, \\ &Bu = 0, \qquad x \in \partial\Omega, \\ &u(0, x) = u_0(x), \qquad x \in \Omega, \end{aligned}$$

where Ω is a bounded domain in $\mathbf{R}^N$ with sufficiently smooth boundary $\partial\Omega$ and $\mathcal{A}$ is a uniformly elliptic second-order operator and B a suitable boundary operator, in essentially the same way as done by Poláčik. Our hypotheses (P) and (SP) can be verified by application of the strong maximum principle for parabolic equations. We need $g \in C^1$ instead of C^2 and can dispense with Poláčik's assumption (6.8) in the case of Dirichlet boundary conditions.

4.2. Quasi-monotone functional differential equations. Consider the functional differential equation

$$\text{(FDE)} \qquad x'(t) = f(x_t)$$

where $f: C_r \to \mathbf{R}^n$ is C^1, $r = (r_1, r_2, \cdots, r_n) > 0$, $C_r = \prod_{i=1}^n C([-r_i, 0], \mathbf{R})$. If $x^i(t)$ is defined and continuous on $[-r_i, \sigma)$, $\sigma > 0$, $1 \leqq i \leqq n$, and $0 \leqq t < \sigma$, then $x_t \in C_r$ is given by $x_t = (x_t^1, x_t^2, \cdots, x_t^n)$ where $x_t^i(\theta) = x_i(t + \theta)$, $-r_i \leqq \theta \leqq 0$. Given $\phi \in C_r$, (FDE) has a unique solution $x(t; \phi)$ on a maximal interval of existence $[0, \sigma_\phi)$ satisfying $x_0^i = \phi^i$. The system (FDE) generates a (local) semiflow Φ on C_r given by

$$\Phi_t(\phi) = x_t(\phi), \qquad 0 \leqq t < \sigma_\phi.$$

Let $C_r^+ = \prod_{i=1}^n C([-r_i, 0], \mathbf{R}_+)$ be the cone of nonnegative functions in C_r and note that $\operatorname{Int} C_r^+$ consists of the functions each of whose components is positive on its domain.

Let U be an open subset of C_r which is positively invariant for (FDE); that is, $\Phi_t(\phi) \in U$ for $0 \leqq t < \sigma_\phi$, for all $\phi \in U$. Following [24], we introduce the following hypotheses:

(K) For all $\psi \in U$ and $\phi \in C_r^+$ with $\phi_i(0) = 0$,

$$f_i'(\psi)(\phi) \geqq 0.$$

The derivative $f_i'(\psi)$, of f_i, appearing in (K) can be represented as

$$f_i'(\psi)(\phi) = \sum_{j=1}^{n} \int_{-r_j}^{0} \phi_j(\theta)\, d\eta_{ij}(\theta)$$

where $\eta_{ij} = \eta_{ij}(\theta; \psi)$: $\mathbf{R} \to \mathbf{R}$ satisfy

$$\eta_{ij}(\theta) = \eta_{ij}(0), \qquad \theta \geqq 0,$$

$$\eta_{ij}(\theta) = 0, \qquad \theta \leqq -r_j,$$

$\eta_{ij} \in BV[-r_j, 0]$ and is continuous from the left on $(-r_j, 0)$.

As noted in [24], (K) is equivalent to assuming that η_{ij} is nondecreasing on $[-r_j, 0]$, $i \neq j$, and η_{ii} is nondecreasing on $[-r_i, 0)$.

In addition, we introduce the following hypotheses.

(R) For each $\psi \in U$, the $n \times n$ matrix

$$(\eta_{ij}(0; \psi))$$

is irreducible.

(S) For every j for which $r_j > 0$, there exists i such that for all $\psi \in U$ and all small $\varepsilon > 0$

$$\eta_{ij}(-r_j + \varepsilon; \psi) > 0.$$

We refer the reader to [24] for additional motivation for the hypotheses above. Recall that a matrix is irreducible if it does not leave invariant any nontrivial coordinate subspaces. If f satisfies (K), (R), and (S) on U, then f is cooperative and irreducible in U.

In order to insure that (FDE) generates a (global) semiflow with appropriate compactness hypotheses we will also assume the following:

(T) f maps bounded subsets of U to bounded sets in $\mathbf{R}^n$. For each $\psi \in U$ the orbit $\mathcal{O}^+(\psi) = \{x_t(\psi): t \geqq 0\}$ exists and is bounded. Moreover, assume that there is a closed bounded subset $B \subset U$ such that $\omega(\psi) \subset B$ for all $\psi \in U$, where $\omega(\psi)$ is the omega limit set of $\mathcal{O}^+(\psi)$.

Hypothesis (T) is easily seen to imply that the compactness assumptions of Theorem 3.3(a) hold. Indeed, if $\{\psi_n\}$ is a convergent sequence, then $\bigcup_{n \geqq 1} \omega(\psi_n)$ is an invariant set contained in the closed and bounded subset B. Since f is bounded on bounded sets, Φ_t is completely continuous for large t [24] so it follows that $\bigcup_{n \geqq 1} \omega(\psi_n)$ has compact closure in B.

In the following result, we summarize several important consequences of our assumptions.

PROPOSITION 4.3. *Let f satisfy* (K), (R), (S), *and* (T). *Then Φ_t is an eventually strongly monotone C^1-semiflow on U; that is, if $\psi, \phi \in U$, and $\phi < \psi$, then*

$$x_t(\phi) \ll x_t(\psi) \quad \textit{for } t \geqq (n+1) \max r_i.$$

If $e \in U$ is an equilibrium point of (FDE), *then $\{T_e(t) \equiv \Phi_t'(e)\}_{t \geqq 0}$ is a strongly continuous semigroup and $y_t = \Phi_t'(e)\phi$ satisfies*

$$y'(t) = L(y_t), \quad L(\psi) = f'(e)\psi, \quad y_0 = \phi.$$

Moreover, $T_e(t)$ is compact and strongly positive for $t \geqq (n+1) \max r_i$.

Proof. The proof follows immediately from Theorem 3.1 of [24].

THEOREM 4.4. *Let f satisfy* (K), (R), (S), *and* (T). *Then U contains an open and dense set of stable convergent points.*

Theorem 4.4 follows from Theorem 3.3(a) using the normality of C_r. Concrete examples where the above result applies appear in [24], [25], and [27].

Acknowledgment. The authors thank an anonymous reviewer who stimulated us to significantly improve our original manuscript.

PERIODIC TRIDIAGONAL COMPETITIVE AND COOPERATIVE SYSTEMS OF DIFFERENTIAL EQUATIONS*

HAL L. SMITH†

Abstract. J. Smillie [*J. Differential Equations*, 64 (1986), pp. 165-194] proves that a bounded solution of a smooth autonomous tridiagonal competitive or cooperative system of differential equations converges to an equilibrium. This result is extended to ω-periodic systems, showing that every bounded solution is asymptotic to an ω-periodic solution, at the same time relaxing Smillie's smoothness requirements. In addition, it is shown that the Floquet multipliers of an ω-periodic solution are positive, simple, and have distinct absolute values.

Key words. periodic competitive system, periodic cooperative system, monotone dynamical systems, integer-valued Lyapunov function

AMS(MOS) subject classifications. 34C25, 34C15

Introduction. We consider the nonlinear periodic tridiagonal system

$$\begin{aligned} y_1' &= f_1(t, y_1, y_2), \\ y_j' &= f_j(t, y_{j-1}, y_j, y_{j+1}), \qquad 2 \leqq j \leqq n-1, \\ y_n' &= f_n(t, y_{n-1}, y_n), \end{aligned} \tag{0.1}$$

where $f=(f_1, f_2, \cdots, f_n)$ is defined on $\mathbf{R}\times\mathcal{O}$, $\mathcal{O}$ a nonempty open subset of $\mathbf{R}^n$. We assume that the f_i and their partial derivatives with respect to the y_j are continuous in $\mathbf{R}\times\mathcal{O}$ and that there exist $\delta_i \in \{-1, +1\}$, $1 \leqq i \leqq n-1$, such that

$$\delta_i \frac{\partial f_i}{\partial y_{i+1}} > 0, \quad \delta_i \frac{\partial f_{i+1}}{\partial y_i} > 0, \qquad 1 \leqq i \leqq n-1 \tag{0.2}$$

holds for all values of the arguments $(t, y) \in \mathbf{R}\times\mathcal{O}$. It will be assumed that there exists $\omega > 0$ such that

$$f(t+\omega, y) = f(t, y), \qquad (t, y) \in \mathbf{R}\times\mathcal{O}. \tag{0.3}$$

Finally, concerning the open set $\mathcal{O}$, we assume that each of the coordinate projections $\mathcal{O}_1 \subseteq \mathbf{R}^2$ of $\mathcal{O}$ onto the (y_1, y_2) plane, $\mathcal{O}_n \subseteq \mathbf{R}^2$ of $\mathcal{O}$ onto the (y_{n-1}, y_n) plane, and $\mathcal{O}_j \subseteq \mathbf{R}^3$ of $\mathcal{O}$ onto the (y_{j-1}, y_j, y_{j+1}) space, $2 \leqq j \leqq n-1$, are nonempty convex subsets.

Autonomous systems of the form (0.1) satisfying (0.2) where f_i was assumed to be $n-1$ times differentiable with respect to the y_j were considered by Smillie [18]. With these hypotheses, Smillie shows that every bounded orbit converges to an equilibrium. We extend this result by showing that every bounded orbit of (0.1) is asymptotic to an ω-periodic solution of (0.1), at the same time relaxing Smillie's smoothness assumptions. In the autonomous case, we obtain his result with only the assumption that $f \in C^1$.

The requirement (0.2) implies that the Jacobian matrix, $\partial f/\partial y$, corresponding to (0.1), is tridiagonal and sign symmetric in the sense that $\partial f_i/\partial y_{i+1}$ and $\partial f_{i+1}/\partial y_i$ have the same sign, namely, δ_i. In case $\delta_i = -1$ for all i, (0.1) is called competitive and if $\delta_i = +1$ for all i then (0.1) is called cooperative. The change of variables $\bar{y}_i = \mu_i y_i$,

$\mu_i \in \{-1, +1\}$, $1 \leqq i \leqq n$, transforms (0.1) to a new system of the same type, satisfying (0.2), where now $\bar{\delta}_i = \mu_i \mu_{i+1} \delta_i$. It is clear that we may choose the μ_i, $1 \leqq i \leqq n$, so that $\mu_i \mu_{i+1} = \delta_i$ for $1 \leqq i \leqq n-1$. Indeed, set $\mu_1 = 1$, $\mu_i = \delta_{i-1} \mu_{i-1}$, $2 \leqq i \leqq n$. After such a change of variables we may always assume that (0.1) is cooperative. Note also that the time reversed system is again a system of type (0.1) satisfying (0.2) and (0.3) with the signs of δ_i reversed.

System (0.1) with the assumption (0.2) can be viewed as a monotone dynamical system in the sense that the Poincaré (period) map preserves a partial ordering on $\mathbf{R}^n$. There is now an extensive literature on monotone dynamical systems, beginning with the path-breaking work of M. W. Hirsch [9]–[12] for monotone semiflows. The results of Hirsch and later improvements by Matano [15], Smith and Thieme [22], [23], and Poláčik [17] established that most orbits of a strongly order-preserving semiflow converge to the set of equilibria. These results, of course, apply only to autonomous systems. Smillie's result stands out in that all bounded orbits converge.

The theory of discrete-time monotone dynamics is significantly more complicated than its continuous-time counterpart. There has been much recent work following the early studies of Alikakos and Hess [1] and Alikakos, Hess, and Matano [2]. Examples of stable k-cycles, $k \geqq 2$, for strongly order-preserving discrete-time dynamical systems have been given by Takáč [26], [27] and by Dancer and Hess [28]. In the example given in [27], the dynamics is generated by the Poincaré map for a cooperative and irreducible time-periodic four-dimensional vector field. These examples show that the limit set dichotomy of Hirsch [9], [10], [12] for strongly monotone semiflows does not carry over to strongly monotone discrete-time dynamical systems and that we cannot expect to prove that "most orbits" of a strongly monotone discrete-time dynamical system converge to the set of equilibria (fixed points). Convergence for strongly monotone discrete-time dynamical systems has been established by Takáč [25] in the case that all equilibria are Lyapunov stable and additional technical assumptions. This result improved the previously mentioned work of Alikakos and Hess [1] and Alikakos, Hess, and Matano [2].

In a certain sense, our results here are natural generalizations of the results of de Mottoni and Schiaffino [4] and Hale and Somolinos [7], who proved that all solutions of two-dimensional ω-periodic competitive or cooperative systems are asymptotic to ω-periodic solutions. See also [19] and [20] for extensions of this work.

The proof of our main result, namely, that every bounded solution $y(t)$ of (0.1) is asymptotic to an ω-periodic solution, uses the main technique introduced by Smillie and which is also used in a related form by Smith with Mallet-Paret in [13], by Fusco and Oliva in [6], and by Smith in [21]. An integer-valued function is introduced which has the property that it is a Lyapunov function for a certain class of linear systems including the variational equation corresponding to (0.1). In other words, this function is defined for all but an at most finite set of points t along a nontrivial solution of the linear system, is locally constant near points where it is defined, and strictly decreases as t increases through points where it is not defined. The nature of the domain of this Lyapunov function, together with the fact that the solution of the linear system belongs to this domain for almost all values of t, places strong restrictions on the signs of components of the solution and leads to the proof of our main result, Theorem 2.2. The Lyapunov function also places strong restrictions on the Floquet multipliers of an ω-periodic solution of (0.1). In Theorem 1.3 we show that all multipliers are distinct and positive.

The idea of using integer-valued Lyapunov functions in dynamical systems seems to go back to the work of Nickel [16] and later to that of Matano [14], where the

so-called lap number is introduced as a count of the number of sign changes of a solution $u(t, x)$ of a scalar reaction diffusion equation on an interval $0 \leqq x \leqq L$. As t increases this number cannot increase. The lap number has been used by Henry [8] and Angenent [3] to establish the Morse-Smale property for scalar reaction diffusion equations. See also Fiedler and Mallet-Paret [5].

The paper is organized as follows. In § 1 we introduce the Lyapunov function and use it to study certain linear systems which include the variational equation along a solution of (0.1). Theorem 1.3 concerning Floquet multipliers is also proved. In § 2 we prove our main result, Theorem 2.2, by applying the results of § 1 to the difference of two solutions of (0.1), which satisfies an appropriate linear system.

1. Linear systems. Consider the linear system

$$\begin{aligned} x_1' &= a_{11}x_1 + a_{12}x_2, \\ x_j' &= a_{jj-1}x_{j-1} + a_{jj}x_j + a_{jj+1}x_{j+1}, \qquad 2 \leqq j \leqq n-1, \\ x_n' &= a_{nn-1}x_{n-1} + a_{nn}x_n, \end{aligned} \tag{1.1}$$

where the a_{ij} are continuous functions defined on a nontrivial interval I and

$$\begin{aligned} a_{jj+1}(t) &> 0 \quad \text{on } I, \quad 1 \leqq j \leqq n-1, \\ a_{jj-1}(t) &> 0 \quad \text{on } I, \quad 2 \leqq j \leqq n. \end{aligned} \tag{1.2}$$

Following [18], we define the continuous map

$$\sigma : \Lambda \to \{0, 1, 2, \cdots, n-1\}$$

on

$$\begin{aligned} \Lambda = \{v \in \mathbf{R}^n &: v_1 \neq 0,\ v_n \neq 0 \text{ and if } v_i = 0 \\ &\text{for some } i,\ 2 \leqq i \leqq n-1, \text{ then } v_{i-1}v_{i+1} < 0\} \end{aligned}$$

by

$$\sigma(v) = \#\{i : v_i v_{i+1} < 0\}.$$

Here, # denotes the cardinality of the set. Note that Λ is open and dense in $\mathbf{R}^n$ and Λ is the maximal domain on which σ is continuous.

A second integer-valued function was introduced in [13] and in [6]. In [21], Smith extends the applicability of this function to a class of linear systems including (1.1). This map is defined by

$$N : \mathcal{N} \to \{0, 1, 2, \cdots, n\}$$

on

$$\mathcal{N} = \{v \in \mathbf{R}^n : \text{if } v_i = 0 \text{ for some } i,\ 1 \leqq i \leqq n, \text{ then } v_{i-1}v_{i+1} < 0\},$$

where i is to be interpreted modulo n ($0 \sim n$, $n+1 \sim 0$), and

$$N(v) = \#\{i : v_i v_{i-1} < 0\}.$$

It is not hard to see that N is continuous on its domain $\mathcal{N}$, which is open, and that N takes only even values in $\{0, 1, 2, \cdots, n\}$.

Clearly, we have

$$\Lambda \subset \mathcal{N} \tag{1.3}$$

and

$$N(v)=\begin{cases}\sigma(v), & v_1v_n>0,\\ \sigma(v)+1, & v_1v_n<0\end{cases} \tag{1.4}$$

for all $v\in\Lambda$.

A special case of the main result in [21] is the following.

PROPOSITION 1.1. *If $x(t)$ is a nontrivial solution of* (1.1) *on I then*

(i) $x(t)\in\mathcal{N}$ *except possibly for isolated values of t.*

(ii) *If $x(s)\notin\mathcal{N}$ for some $s\in\operatorname{int} I$ then $N(x(s+))<N(x(s-))$.*

Assertion (i) implies that if $x(s)\notin\mathcal{N}$ then there exists $\varepsilon>0$ such that $x(t)\in\mathcal{N}$ for $0<|t-s|<\varepsilon$. The continuity of N on $\mathcal{N}$ implies that $N(x(t))$ is constant on $(s-\varepsilon, s)$ and on $(s, s+\varepsilon)$. $N(x(t))$ decreases by a positive multiple of 2 as t increases through s. The notation int I denotes the interior of the interval I and $N(x(s+))$ denotes the limit of $N(x(t))$ as t approaches s from the right and similarly for $N(x(s-))$.

The next result was proved by Smillie [18] in the case where a_{ij} are $n-2$ times differentiable.

PROPOSITION 1.2. *If $x(t)$ is a nontrivial solution of* (1.1) *on I then*

(i) $x(t)\in\Lambda$ *except possibly for isolated values of t.*

(ii) *If $x(s)\notin\Lambda$ for some $s\in\operatorname{int} I$ then $\sigma(x(s+))<\sigma(x(s-))$.*

Corresponding remarks to those following Proposition 1.1 can be made here as well. In particular, $\sigma(x(t))$ decreases (not necessarily by a multiple of 2) as t increases through a point $s\in\operatorname{int} I$ at which $x(s)\notin\Lambda$. Note that as $\sigma(x(t))$ can assume at most n values for $t\in I\cap x^{-1}(\Lambda)$, it follows that there can be at most $n-1$ values of $t\in I$ for which $x(t)\notin\Lambda$.

Proof of Proposition 1.2. We use Proposition 1.1 in the proof. Let $t_1\in\operatorname{int} I$ be such that $x(t_1)\notin\Lambda$. Suppose first that $x(t_1)\in\mathcal{N}$. Then $x_1(t_1)=0$ or $x_n(t_1)=0$ or both. But $x(t_1)\in\mathcal{N}$ implies that if $x_1(t_1)=0$ then $x_n(t_1)x_2(t_1)<0$ and if $x_n(t_1)=0$ then $x_{n-1}(t_1)x_1(t_1)<0$. We suppose $x_n(t_1)=0$, the other case being similar. Now $x_n'(t_1)=a_{nn-1}x_{n-1}(t_1)\neq 0$ so t_1 is an isolated point at which $x(t_1)\notin\Lambda$ and

$$\left.\frac{d}{dt}\right|_{t=t_1} x_1(t)x_n(t)=a_{nn-1}(t_1)x_{n-1}(t_1)x_1(t_1)<0.$$

By (1.4) and the fact that $N(t)=N(t_1)$ in a neighborhood of t_1, it is clear that

$$\sigma(x(t_1-))=\sigma(x(t_1+))+1.$$

Thus the conclusion of the proposition holds in this case.

Suppose $x(t_1)\notin\mathcal{N}$. Then by Proposition 1.1 there exists $\varepsilon>0$ such that $x(t)\in\mathcal{N}$ for $0<|t-t_1|<\varepsilon$ and $N(x(t_1-))-N(x(t_1+))$ is a positive multiple of 2. We claim that $x_1(t)x_n(t)$ can vanish at at most two points of $0<|t-t_1|<\varepsilon$. At a zero of x_1x_n in $0<|t-t_1|<\varepsilon$, $d/dt\, x_1x_n<0$ since $x\in\mathcal{N}$ at such a point. Thus x_1x_n can vanish at most at one point of $(t_1-\varepsilon, t_1)$ and at most at one point of $(t_1, t_1+\varepsilon)$, proving our claim. Hence we may find $\varepsilon_0\leqq\varepsilon$ such that $x(t)\in\Lambda$ for $0<|t-t_1|<\varepsilon_0$. As N decreases by a positive multiple of 2 as t increases through t_1, (1.4) implies that σ must decrease by at least 1. Our proof is complete. □

As Proposition 1.1 had important implications for Floquet theory for periodic linear monotone cyclic feedback systems in [13], Proposition 1.2 has similar implications for Floquet theory for (1.1) when the system is periodic. Hereafter in this section, we assume that $a_{ij}(t+\omega)=a_{ij}(t)$ holds for all t and all i, j, where $\omega>0$. Let $X(t)$ denote the fundamental matrix solution of (1.1) satisfying $X(0)=I$, where I is the identity matrix. Recall that the eigenvalues of $X(\omega)$ are the Floquet multipliers of

(1.1). The proof of the next result follows closely the proof of related results in [13] and so we merely sketch the proof, making use of results and notation in [13, § 2].

THEOREM 1.3. *The ω-periodic linear system* (1.1) *has n distinct positive Floquet multipliers $\alpha_1, \cdots, \alpha_n$, satisfying*

$$\alpha_1 > \alpha_2 > \cdots > \alpha_{n-1} > \alpha_n > 0. \tag{1.5}$$

If E_{α_i} are the corresponding one-dimensional eigenspaces of $X(\omega)$ then $E_{\alpha_i}\backslash\{0\} \subset \Lambda$ and

$$\sigma(E_{\alpha_i}\backslash\{0\}) = i-1, \qquad 1 \leqq i \leqq n. \tag{1.6}$$

Proof. It is easy to see that Lemmas 2.1 through 2.4 of [13] hold with σ replacing N. Let α be a multiplier of (1.1) and $G_\alpha = \ker (X(\omega) - \alpha I)^m$ be the generalized eigenspace corresponding to α (here m is chosen sufficiently large). By Lemma 2.2 in [13], for each $\sigma_0 > 0$ which is the modulus of some Floquet multiplier of (1.1), we have

$$\mathcal{G}_{\sigma_0}\backslash\{0\} \subseteq \Lambda$$

and σ is constant on $\mathcal{G}_{\sigma_0}\backslash\{0\}$ where

$$\mathcal{G}_{\sigma_0} = \operatorname{Re} \bigoplus_{|\alpha|=\sigma_0} G_\alpha.$$

If $\dim \mathcal{G}_{\sigma_0} \geqq 2$ then we could find linearly independent vectors $v, w \in \mathcal{G}_{\sigma_0}$ such that $\beta v_1 + w_1 = 0$ for a suitable scalar $\beta \neq 0$. But this contradicts that $\beta v + w \in \mathcal{G}_{\sigma_0}\backslash\{0\} \subset \Lambda$. Hence, $\dim \mathcal{G}_{\sigma_0} = 1$ and $\mathcal{G}_{\sigma_0} = G_{\alpha_0} = E_{\alpha_0}$ for some Floquet multiplier α_0. Moreover, α_0 is the only Floquet multiplier with modulus $|\alpha_0| = \sigma_0$. Thus α_0 is real.

Recall that for a Floquet multiplier α of (1.1) there corresponds a nontrivial solution $x(t)$ of (1.1) satisfying $x(\omega) = \alpha x(0)$. If α were negative then necessarily $x_1(t)(x_n(t))$ must vanish for some t, contradicting that $E_\alpha\backslash\{0\} \subseteq \Lambda$. Thus, every Floquet multiplier of (1.1) is positive.

Lemmas 2.4 and 2.5 in [13], where now $\dim \operatorname{span}_{\sigma_0 \in S} \mathcal{G}_{\sigma_0} \leqq 1$ replaces the estimate in Lemma 2.5, by the argument above, imply that σ takes different values on different eigenspaces E_α (more precisely on $E_\alpha\backslash\{0\}$). Lemma 2.3 in [13] then implies (1.6). □

2. Main results. In this section we establish our main result concerning the nonlinear periodic system

$$\begin{aligned} y_1' &= f_1(t, y_1, y_2), \\ y_j' &= f_j(t, y_{j-1}, y_j, y_{j+1}), \qquad 2 \leqq j \leqq n-1, \\ y_n' &= f_n(t, y_{n-1}, y_n), \end{aligned} \tag{2.1}$$

where $f = (f_1, f_2, \cdots, f_n)$ is defined on $\mathbf{R} \times \mathcal{O}$ where $\mathcal{O}$ is a nonempty open set in $\mathbf{R}^n$ with the property that each of the coordinate projections $\mathcal{O}_1 \subseteq \mathbf{R}^2$ of $\mathcal{O}$ onto the (y_1, y_2) plane, $\mathcal{O}_n \subseteq \mathbf{R}^2$ of $\mathcal{O}$ onto the (y_{n-1}, y_n) plane, and $\mathcal{O}_j \subseteq \mathbf{R}^3$ of $\mathcal{O}$ onto the (y_{j-1}, y_j, y_{j+1}) space, $2 \leqq j \leqq n-1$, are convex. We assume that the f_i and each of their partial derivatives with respect to the y_j exist and are continuous on $\mathbf{R} \times \mathcal{O}$ and

$$f(t+\omega, y) = f(t, y) \tag{2.2}$$

for all $(t, y) \in \mathbf{R} \times \mathcal{O}$ for some positive number ω (not necessarily the minimal period). In addition, we assume that f is cooperative:

$$\frac{\partial f_j}{\partial y_{j-1}} > 0, \qquad \frac{\partial f_j}{\partial y_{j+1}} > 0, \tag{2.3}$$

$2 \leqq j \leqq n-1$, and the first inequality holds for $j = n$ and the second holds for $j = 1$. In the introduction we showed that the more general assumption (0.2) can be transformed to (2.3) by a change of variables.

LEMMA 2.1. *Let $y(t)$ and $\bar{y}(t)$ be distinct solutions of* (2.1) *on an interval I. Then $y(t)-\bar{y}(t)\in\Lambda$ except possibly at finitely many values of $t\in I$. $\sigma(y(t)-\bar{y}(t))$ is locally constant and strictly decreases as t increases through a value s at which it is not defined.*

Proof. $x(t)=y(t)-\bar{y}(t)$ satisfies the linear system (1.1), where

$$a_{ij}(t)=\int_0^1 \frac{\partial f_i}{\partial y_j}(t, u_{i-1}(s,t), u_i(s,t), u_{i+1}(s,t))\,ds$$

with $u_i(s,t)=sy_i(t)+(1-s)\bar{y}_i(t)$, $j=i-1, i, i+1$. The result now follows from (2.3) and Proposition 1.2. □

THEOREM 2.2. *Let $\bar{y}(t)$ be a solution of* (2.1) *for $t\geqq 0$ which is not ω-periodic but which is bounded for $t\geqq 0$. Then $\bar{y}(t)$ is asymptotic to an ω-periodic solution of* (2.1).

Proof. Define the Poincaré map corresponding to (2.1) by $Py(0)=y(\omega)$ for those points $y(0)$ for which it is defined. The omega limit set of the orbit $\mathcal{O}^+(\bar{y}(0))=\{\bar{y}(n\omega)=P^n\bar{y}(0)\colon n=0,1,2,\cdots\}$ of $\bar{y}(0)$ under the map P, $\Omega(\bar{y}(0))$, is defined, compact, nonempty, invariant under P, and $\bar{y}(n\omega)\to\Omega(\bar{y}(0))$ as $n\to\infty$. The proof will be complete if we establish that $\Omega(\bar{y}(0))$ is a singleton.

By our hypotheses and (2.2), $\bar{y}(t)$ and $\bar{y}(t+\omega)$ are distinct solutions of (2.1) for $t\geqq 0$. Lemma 2.1 implies that $\bar{y}(t+\omega)-\bar{y}(t)\in\Lambda$ for all large t. This implies that $\bar{y}_1(t+\omega)-\bar{y}_1(t)(\bar{y}_n(t+\omega)-\bar{y}_n(t))$ cannot vanish for all large t and so must be of constant sign, say, $\bar{y}_1(t+\omega)-\bar{y}_1(t)>0$ for $t\geqq m\omega$ where m is some positive integer. Putting $t=k\omega$, $k\geqq m$, into this inequality, we find that

$$\bar{y}_1(k\omega)<\bar{y}_1((k+1)\omega), \qquad k\geqq m.$$

In particular, $\lim_{k\to\infty}\bar{y}_1(k\omega)=\bar{p}_1$ and $\lim_{k\to\infty}\bar{y}_n(k\omega)=\bar{p}_n$ exist.

If $p\in\Omega(\bar{y}(0))$ then it follows that $p_1=\bar{p}_1$ and $p_n=\bar{p}_n$. If $p\neq q$ and $p, q\in\Omega(\bar{y}(0))$, then the solutions $p(t)$ and $q(t)$ of (2.1) with $p(0)=p$ and $q(0)=q$ are defined for all $t\in\mathbf{R}$ and $p(l\omega)$, $q(k\omega)$ belong to $\Omega(\bar{y}(0))$ for all integers l and k. Since $p(t)$ and $q(t)$ are distinct solutions of (2.1), Lemma 2.1 implies that $p(t)-q(t)\in\Lambda$ for all large values of t. In particular, $p_1(k\omega)-q_1(k\omega)\neq 0$ for all large positive integers k. But this contradicts that $p_1(k\omega)=\bar{p}_1=q_1(k\omega)$, which was established above. Thus $\Omega(\bar{y}(0))$ must be a singleton set, establishing the theorem. □

According to Theorem 1.3, if $p(t)=p(t+\omega)$ is an ω-periodic solution of (2.1), its Floquet multipliers, determined by the periodic linear variational system (1.1) where

$$a_{ij}(t)=\frac{\partial f_i}{\partial y_j}(t, p_{i-1}(t), p_i(t), p_{i+1}(t))$$

for $j=i-1, i, i+1$, are positive and distinct.

Theorem 1.3 has an important additional implication if we assume that every ω-periodic solution $p(t)$ of (2.1) is nondegenerate, that is, that one is not a Floquet multiplier. Of course, this implies that $p(t)$ is hyperbolic by Theorem 1.3, that is, there are no Floquet multipliers of unit modulus. In this case, if there is a heteroclinic (homoclinic) solution $z(t)$, asymptotic to an ω-periodic solution $p(t)$ as $t\to+\infty$ and to an ω-periodic solution $q(t)$ as $t\to-\infty$, then $\dim W^s(q(0))<\dim W^s(p(0))$ where $W^s(q(0))$ denotes the stable manifold of the fixed point $q(0)$ for the Poincaré map P corresponding to (2.1). In particular, there can be no homoclinic solution $z(t)$ corresponding to an ω-periodic solution of (2.1) nor a set of heteroclinic solutions forming a cycle. See [29] for an application of this result. In order to see that $\dim W^s(q(0))<\dim W^s(p(0))$, assume $q(0)\neq p(0)$, a similar argument applies if $p(0)=q(0)$, and suppose $z(t)$ is a heteroclinic solution so that $z(n\omega)\to p(0)$ ($z(n\omega)\to q(0)$) as $n\to+\infty$ ($n\to-\infty$). Then $z(t)-q(t)\in\Lambda$ for $|t|$ large and $p(t)-q(t)\in\Lambda$ for all t by Lemma 2.1

and periodicity. It follows that $\sigma(z(t)-q(t))\to\sigma(p(0)-q(0))$ as $t\to+\infty$ and $\sigma(z(t)-q(t))\geqq\sigma(p(0)-q(0))$ by Lemma 2.1 and continuity of σ. Now, a subsequence of $(z(n\omega)-q(0))/|z(n\omega)-q(0)|$ approaches a unit vector in $E^{q(0)}_{\alpha_j}$, the eigenspace corresponding to some Floquet multiplier α_j of the periodic solution $q(t)$, where the multipliers are ordered as in Theorem 1.3. Thus, $\sigma(z(t)-q(t))=j-1$ for large negative t. Hence $j-1\geqq\sigma(p(0)-q(0))$ and note also that dim $W^u(q(0))\geqq j$ since $\alpha_j>1$. Arguing similarly with $p(t)-z(t)$, we obtain $\sigma(p(0)-q(0))\geqq k-1$ where a subsequence of $(p(0)-z(n\omega))/|p(0)-z(n\omega)|$ approaches a unit vector in some $E^{p(0)}_{\alpha_k}$, the eigenspace corresponding to a Floquet multiplier α_k of the periodic solution $p(t)$. Now, $\alpha_k<1$ so dim $W^s(p(0))\geqq n-k+1$. The inequality $j-1\geqq\sigma(p(0)-q(0))\geqq k-1$ implies that dim $W^s(q(0))=n-$dim $W^u(q(0))\leqq n-j\leqq n-k<n-k+1\leqq$ dim $W^s(p(0))$, completing the argument.

In the special case where (2.1) is autonomous, (2.2) holds for all ω, we obtain the result of Smillie [18]. Smillie required f to be $n-1$-times differentiable. Our result removes that restriction.

COROLLARY 2.3 (C^1 version of Smillie's theorem [18]). *Let f be independent of t in* (2.1). *Then every solution $y(t)$ of* (2.1), *bounded on $t\geqq 0$, converges to an equilibrium of* (2.1).

THE SPHERICAL WIENER-PLANCHEREL FORMULA AND SPECTRAL ESTIMATION

JOHN J. BENEDETTO†

Abstract. The d-dimensional spherical analogues of Wiener's "s-function" and difference operator are defined, and the role of the iterated Laplacian is explained. The corresponding spherical Wiener-Plancherel formula is formulated and proved. A recipe for spectral estimation is extracted from the formula.

Key words. Wiener-Plancherel, Tauberian theorems, iterated Laplacian, Besov and Besicovich spaces, spherical mean value, difference operators

AMS(MOS) subject classifications. 42B10, 46F10, 62M15

Introduction. We shall prove a spherical Wiener-Plancherel formula for d-dimensional Euclidean space $\mathbb{R}^d$. This formula is an analogue of the Plancherel formula in the case of functions that are not square-integrable. Wiener developed such a formula for $\mathbb{R}$ [W2], and it became a beacon in his perception and formulation of the statistical theory of communication, e.g., [W3], [Le]. Wiener even chose to have the formula appear on the cover of his autobiography, *I Am a Mathematician.*

What exactly is a Wiener-Plancherel formula? Given a function φ defined on $\mathbb{R}^d$ having Fourier transform $\hat{\varphi}$ defined on $\hat{\mathbb{R}}^d$ $(=\mathbb{R}^d)$. Suppose the distribution $\hat{\varphi}$ is intractable, as is likely for poorly behaved φ. Let s be an operable integral of $\hat{\varphi}$, i.e., suppose that s is a well-behaved function and that $Ls = \hat{\varphi}$, distributionally, for some differential operator L. Wiener's idea was to deal with a computable function s instead of the more esoteric distribution $\hat{\varphi}$, and to relate the quadratic behavior of φ and s. In particular, for the spherical case dealing with balls $B(0, R) = \{t \in \mathbb{R}^d : |t| \leqq R\}$ having volumes $|B(0, R)|$, a Wiener-Plancherel formula has the form

$$\lim_{R\to\infty} \frac{1}{|B(0, R)|} \int_{B(0,R)} |\varphi(t)|^2 \, dt = Q(s),$$

where $Q(s)$ is an explicit quadratic expression and Q, s, and L are interdependent (cf. (1.1) for the exact formula). In Wiener's original result ($d = 1$), Ls can be correctly formulated as a first distributional derivative of s, e.g., [B1, § 2.1], and

$$Q(s) = \lim_{\lambda\to 0} \frac{1}{2\lambda} \int_{-\infty}^{\infty} |s(\gamma+\lambda) - s(\gamma-\lambda)|^2 \, d\gamma$$

(cf. [La], [M]).

The Plancherel formula allows us to define the Fourier transform of a square-integrable function f, and, at certain levels of abstraction, it is considered to characterize what is meant by an harmonic analysis of f. On the other hand, for most applications in $\mathbb{R}^d$, the Plancherel formula assumes the workaday role of an effective tool used to obtain quantitative results. It is this latter role we envisage for Wiener-Plancherel formulas in the non-square-integrable case. After all, distribution theory (in $\mathbb{R}^d$) gives the proper definition of the Fourier transform of tempered distributions. The real issue

* Received by the editors January 7, 1990; accepted for publication (in revised form) July 30, 1990.
† The MITRE Corporation and the Department of Mathematics, University of Maryland, College Park, Maryland 20742.

is to obtain quantitative results for problems where an harmonic analysis of a non-square-integrable function is desired. A host of such problems comes under the heading of an harmonic (spectral) analysis of signals containing non-square-integrable noise and/or random components, whether it be speech recognition, image processing, geophysical modeling, or turbulence in fluid mechanics. Such problems can be attacked by Beurling's profound theory of spectral synthesis, e.g., [B1], as well as by the extensive multifaceted theory of time series, e.g., [P]. Beurling's spectral synthesis does not deal with energy and power considerations, i.e., quadratic criteria, and time series relies on a stochastic point of view. Our goal is to implement Wiener-Plancherel formulas to address the above-mentioned group of problems. These formulas are well suited to deal with energy and power; they provide an analytic device which should dovetail with spectral estimation methods (from time series) developed since Wiener's time.

Our title is misleading in that we do not obtain results in spectral estimation. However, our Wiener-Plancherel formula contains a critical recipe for power spectrum estimation that is discussed in § 7. This recipe is the basis for our forthcoming work on multidimensional spectral estimation.

The paper is organized as follows. In § 1 we state our spherical Wiener-Plancherel formula, viz. (1.1), without going into any detail concerning hypotheses and motivation. We feel that the technicalities in proof are sufficiently complex to warrant a displayed version of our goal at the outset. We also remark on some previous work and the relevance of the spherical case. Section 2 provides the required Fourier analysis on multiplicative groups, including the Tauberian theorem, as well as some examples of special functions that are used in the proof of (1.1). It turns out that the differential operator L is an iterated Laplacian Δ^k in our case, and the Wiener s-function described above is defined by $\Delta^k s = \hat{\varphi}$. Section 3 deals with these notions and the subtleties required to define distributional convolution properly for this setting (cf. (1.2), Theorem 3.8, and the hypotheses of Theorem 5.7). The expression $Q(s)$ combines a spherical mean-value operator and spherical difference operator. These ideas and accompanying technicalities are the subject of § 4. At this point we are ready to prove our spherical Wiener-Plancherel formula. This is accomplished in Theorem 5.7 of § 5. Besides the Tauberian theorem and the material in §§ 3 and 4, we also utilize the space of functions having bounded quadratic means over spheres as well as the Beurling algebra, which is its predual. Because the Tauberian theorem is required, § 6 contains a preliminary result and example concerning zeros of Fourier transforms of relevant special functions.

Besides the usual notation in analysis as found in the books by Hörmander [Hö], Schwartz [S], and Stein and Weiss [SW], we shall use the conventions and notation described at the end of the paper.

1. Statement of the spherical Wiener–Plancherel formula.

Formula 1.1. The spherical Wiener-Plancherel formula is

$$\lim_{R\to\infty} \frac{1}{|B(0,R)|} \int_{B(0,R)} |\varphi(t)|^2\, dt = \lim_{\lambda\to 0} \frac{c(d,k)(2\pi)^{4k}}{\omega_{d-1}\lambda^{4k-d}} \int |D_\lambda s_k(\gamma)|^2\, d\gamma. \tag{1.1}$$

The function s_k is the Wiener s-function

$$s_k = \hat{\varphi} * E_k, \tag{1.2}$$

where $\Delta^k E_k = 1$, ω_{d-1} is the surface area of the unit sphere Σ_{d-1}, $c(d,k)^{-1}$ is the L^1-norm of a special function related to the Fourier transform of the restriction of surface measure σ_{d-1} to Σ_{d-1}, e.g., Example 2.5,

$$D_\lambda s_k = s_k - \mathcal{M}_\lambda s_k,$$

and

$$\mathcal{M}_\lambda s_k(\gamma) = \frac{1}{\omega_{d-1}} \int_{\Sigma_{d-1}} s_k(\gamma + \lambda\theta)\, d\sigma_{d-1}(\theta).$$

The integer k is related to the dimension d, and there must be control of the quadratic means of φ over spheres in order to verify (1.1). The operator L described in the Introduction is the iterated Laplacian Δ^k.

Remark 1.2. (a) In a previous work [BBE], we proved a rectilinear version of (1.1). The rectilinear result is easier to prove than the spherical one, although by no means elementary. Also, in the case of "rectilinear geometry" the operator L is the hyperbolic operator

$$L = \partial_1 \partial_2 \cdots \partial_d,$$

whereas the "spherical geometry" of (1.1) gives rise to the elliptic operator $L = \Delta^k$. This remark indicates there is a range of Wiener-Plancherel formulas according to the number of degrees of freedom available in various convergence criteria.

(b) It is natural to expect significant differences between the rectilinear and spherical cases.

The analogous situation with the convergence problem for multiple Fourier series makes this point clear. There are several natural rectilinear convergence criteria for multiple Fourier series, and there exist positive results in some cases. For example, using the Carleson-Hunt theorem for $d = 1$, Fefferman [F] proved that

$$\lim_{R\to\infty} \sum_{m \in RP \cap \mathbb{Z}^d} a_m e^{2\pi i t \cdot m} = \varphi(t) \quad \text{a.e.} \tag{1.3}$$

for $\varphi \in L^p(\mathbb{R}^d/\mathbb{Z}^d)$, $1 < p \leqq \infty$, where $P \subseteq \mathbb{R}^d$ is a d-dimensional polygon. The rectilinear convergence we used in [BBE] is analogous to the so-called "restricted rectangular" convergence criterion in the theory multiple Fourier series; this criterion is different from that of (1.3). If the polygonal convergence of (1.3) is replaced by spherical convergence, then it is not known whether all the elements of $L^2(\mathbb{R}^d/\mathbb{Z}^d)$, $d > 1$, have a Fourier series representation pointwise almost everywhere. There are negative results if $p < 2$. The problem of multiple Fourier series with spherical convergence criteria is closely related to deep problems associated with Bochner-Riesz multipliers. There are some positive results, and we close this discussion with one such recent theorem written in terms of Fourier transforms [CS]: if $d \geqq 2$, $\alpha > 0$, $2 \leqq p < 2d/(d-1)$, and φ is an element of the Sobolev space $L^p_\alpha(\mathbb{R}^d)$, then

$$\lim_{R\to\infty} \int_{B(0,R)} \hat{\varphi}(\gamma)\, e^{2\pi i t \cdot \gamma}\, d\gamma = \varphi(t) \quad \text{a.e.}$$

Example 1.3. A formula such as (1.1) established a mapping between spaces of functions. For example, if the left side of (1.1) is finite then $\|\varphi | B^2(\mathbb{R}^d)\| < \infty$, where $B^2(\mathbb{R}^d)$ consists of functions having bounded quadratic means over spheres, e.g., (5.1). There is a hierarchy of Besicovich spaces $B(p, q)$ of which $B^2 = B(2, \infty)$. For the right side of (1.1) the corresponding hierarchy $V(p, q)$ is related to Besov spaces. In the case $d = 1$, the mappings $B(2, 1) \to V(2, 1)$ and $B(2, \infty) \to V(2, \infty)$, established by Wiener's original Wiener-Plancherel formula, are topological isomorphisms, e.g., [Be] and [CL], respectively. Taking $d \geqq 1$ and using the rectilinear Wiener-Plancherel formula in [BBE], Heil [He] proved that the mapping $B(2, q) \to V(2, q)$ is a topological isomorphism for $1 \leqq q \leqq \infty$.

2. The Fourier transform on $\mathbb{R}_+^*$. Let $\mathbb{R}_+^*$ denote the set, $\{r \in \mathbb{R}: r \in (0, \infty)\}$, considered as a multiplicative group under ordinary multiplication. $\mathbb{R}_+^*$ is a locally compact Abelian group taken with the usual topology from $\mathbb{R}$. Haar measure μ on $\mathbb{R}_+^*$ is defined by the formula

$$\forall \Theta \in C_c(\mathbb{R}_+^*), \quad \int_{\mathbb{R}_+^*} \Theta \, d\mu = \int_0^\infty \Theta(r) \frac{dr}{r},$$

and convolution on $\mathbb{R}_+^*$ is written as

$$\Theta \otimes \Phi(r) = \int_0^\infty \Theta\left(\frac{r}{s}\right) \Phi(s) \frac{ds}{s}.$$

$(\mathbb{R}_+^*)^\wedge$, the dual group of $\mathbb{R}_+^*$, consists of elements $\rho \in \hat{\mathbb{R}}$ under the mapping $\rho: \mathbb{R}_+^* \to \mathbb{C}$, $r \mapsto r^{i\rho}$.

DEFINITION 2.1. The *Fourier transform* of $\Theta \in L^1(\mathbb{R}_+^*)$ is the function on $(\mathbb{R}_+^*)^\wedge$ defined as

$$\forall \rho \in (\mathbb{R}_+^*)^\wedge, \quad \mathscr{F}(\Theta)(\rho) = \int_0^\infty r^{i\rho} \Theta(r) \frac{dr}{r}.$$

Formally, the *Mellin transform* of Θ, a function on $\mathbb{R}_+^*$, is

$$M(\Theta)(z) = \int_0^\infty r^{z-1} \Theta(r) \, dr, \qquad z \in \mathbb{C}.$$

Thus,

$$\mathscr{F}(\Theta)(\rho) = M(\Theta)(i\rho).$$

Wiener's Tauberian theorem and its generalizations are valid on any locally compact Abelian group [B1]. The form we use in § 5 is the following.

THEOREM 2.2. *Given $\Psi \in L^1(\mathbb{R}_+^*)$ for which $|\mathscr{F}\Psi(\rho)| > 0$ on $(\mathbb{R}_+^*)^\wedge$, let $\Phi \in L^\infty(\mathbb{R}_+^*)$ and assume there is a constant C_Φ for which*

$$\lim_{r \to \infty} \Psi \otimes \Phi(r) = C_\Phi \int_0^\infty \Psi(s) \frac{ds}{s}.$$

Then

$$\forall \Theta \in L^1(\mathbb{R}_+^*), \quad \lim_{r \to \infty} \Theta \otimes \Phi(r) = C_\Phi \int_0^\infty \Theta(s) \frac{ds}{s}.$$

Example 2.3. Define the function

$$K_A(r) = \begin{cases} 0 & \text{for } r \in (0, 1), \\ 1/r^d & \text{for } r \geqq 1, \end{cases}$$

where $d > 0$. The subscript A is used to designate "arithmetic mean" (cf. (2.1)).

First, note that $K_A \in L^1(\mathbb{R}_+^*)$ since $\int_0^\infty K_A(r) \, dr/r = 1/d$. Also, if $\Phi \in L^\infty(\mathbb{R}_+^*)$ then

$$K_A \otimes \Phi(r) = \frac{1}{R^d} \int_0^R r^{d-1} \Phi(r) \, dr \tag{2.1}$$

since $K_A(R/r)=0$ if and only if $r>R$. Finally, $\mathcal{F}(K_A)(\rho)=1/(d-i\rho)$, so that $|\mathcal{F}(K_A)(\rho)|>0$ on $(\mathbb{R}_+^*)^\wedge$.

Example 2.4. Given an integer $d\geqq 2$, define the function

$$K_k(r)=r^{4k-d}\left(1-\frac{2\pi}{\omega_{d-1}}\left(\frac{1}{r}\right)^{-(d-2)/2}J_{(d-2)/2}\left(\frac{2\pi}{r}\right)\right)^2$$

for a given integer $k\geqq 0$. K_k plays a critical role in the definition of the spherical difference operator (§ 4) used in our formulation of the Wiener-Plancherel theorem (§ 5) (cf. Example 6.3). We have

$$\forall r>0 \text{ and } \forall \beta\in\Sigma_{d-1},\quad K_k(r)=r^{4k-d}\left(\frac{\hat{\mu}_{d-1}(0)-\hat{\mu}_{d-1}(\beta/r)}{\omega_{d-1}}\right)^2,$$

where μ_{d-1} is the restriction of surface area measure σ_{d-1} to $\Sigma_{d-1}\subseteq\mathbb{R}^d$.

Observe that $\|K_k|L^1(\mathbb{R}_+^*)\|<\infty$ for $4(k-1)<d<4k$, and that

$$\|K_k|L^1(\mathbb{R}_+^*)\|=\infty \quad \text{for } d\notin(4(k-1),4k).$$

3. The Wiener *s*-function and iterated Laplacian. Let $\chi_R(t)$ be the characteristic function of $B(0,R)^\sim$, $R>0$.

Definition/Remark 3.1. (a) Given $\varphi\in L^1_{\text{loc}}(\mathbb{R}^d)$, assume there is an integer $k\geqq 0$ such that $(\varphi(t)/|t|^{2k})\chi_R(t)\in L^1(\mathbb{R}^d)$ for all $R>0$. The corresponding *k-spherical Wiener s-mean determined by* $R>0$ is defined by

$$s_{k,R}(\gamma)=\left(\frac{i}{2\pi}\right)^{2k}\int e^{-2\pi it\cdot\gamma}\varphi(t)\frac{1}{|t|^{2k}}\chi_R(t)\,dt,\qquad \gamma\in\hat{\mathbb{R}}^d,$$

for each $R>0$. Clearly, $s_{k,R}\in A(\hat{\mathbb{R}}^d)$.

(b) Formally, we have

$$\Delta^k s_{k,R}(\gamma)=\int e^{-2\pi it\cdot\gamma}\varphi(t)\chi_R(t)\,dt, \tag{3.1}$$

where k is a positive integer and Δ^k is the kth iterate of the Laplacian Δ in $\hat{\mathbb{R}}^d$.

(c) Let $\varphi\in\mathcal{S}'(\mathbb{R}^d)\cap L^1_{\text{loc}}(\mathbb{R}^d)$. Because of (3.1) we consider the well-known equation $\Delta^k s_k=\hat{\varphi}$. We write

$$s_k=\hat{\varphi}*E_k, \tag{3.2}$$

where $\Delta^k E_k=\delta$, and formally compute

$$(-1)^k(2\pi)^{2k}|t|^{2k}E_k^\vee(t)=1.$$

The *Wiener s-function* corresponding to φ is the distribution s_k defined by (3.2) when this distributional convolution exists.

The verification of the following result is standard.

THEOREM 3.2. *Given $k\geqq 1$ for which $d>2k$, define*

$$E_k^\vee(t)=\frac{(-1)^k}{(2\pi|t|)^{2k}}.$$

(a) $E_k^\vee\in\mathcal{S}'(\mathbb{R}^d)\cap L^1_{\text{loc}}(\mathbb{R}^d)$ *and its Fourier transform is*

$$E_k(\gamma)=\frac{(-1)^k\lambda(d-2k)}{(2\pi|\gamma|)^{d-2k}}\in L^1_{\text{loc}}(\hat{\mathbb{R}}^d), \tag{3.3}$$

where $\lambda(\alpha)=\pi^{d/2}\Gamma(\alpha/2)/\Gamma((d-\alpha)/2)$, *e.g.*, [St, *Chap.* 3.3.3].

(b) *If* $d < 4k$ *then* $E_k \in L^2_{\mathrm{loc}}(\hat{\mathbb{R}}^d)$ *and, for each* $R > 0$, $E_k^\vee \in L^2(\mathbb{R}^d \setminus B(0, R))$.

(c) *If* $\varphi \in L^\infty_{\mathrm{loc}}(\mathbb{R}^d)$ *and* $\chi_R(t)\varphi(t)/|t|^{2k} \in L^1(\mathbb{R}^d)$ *for each* $R > 0$ *then* $\varphi \in \mathcal{S}'(\mathbb{R}^d)$ *and* $\varphi E_k^\vee \in L^1(\mathbb{R}^d)$.

The hypotheses of Theorem 3.2 were made in light of the requirements to prove the Wiener–Plancherel formula in § 5. In case the convolution (3.2) does not exist for $\varphi \in L^2_{\mathrm{loc}}(\mathbb{R}^d)$, but $\varphi E_k^\vee \in \mathcal{S}'(\mathbb{R}^d)$, then it will be convenient to refer to $(\varphi E_k^\vee)^\wedge$ as the Wiener s-function corresponding to φ. If the hypotheses of Theorem 3.2(c) are satisfied, then

$$s_k = (\varphi E_k^\vee)^\wedge \in A(\hat{\mathbb{R}}^d) \tag{3.4}$$

(cf. Theorem 3.8 and Example 4.6).

Remark 3.3. Suppose $\varphi \in \mathcal{S}'(\mathbb{R}^d) \cap L^1_{\mathrm{loc}}(\mathbb{R}^d)$. Our proof of the Wiener–Plancherel formula requires k for which $4k > d$; $d > 2k$ is required in order that $E_k^\vee$, $E_k \in \mathcal{S}' \cap L^1_{\mathrm{loc}}$. In attempting to define the s-function by means of (3.2), it is easy to see that there are no integers k for which $2k < d < 4k$ in the cases $d = 1, 2, 4$, but that for all other dimensions there are solutions. There is no problem in defining the s-function by means of (3.2) for $d = 1$. In fact, $s = H * \hat{\varphi}$, H the Heaviside function, and Δ^k is replaced by ordinary one-dimensional distributional differentiation. In particular, $s' = \hat{\varphi}$ distributionally [B1].

If $d = 2, 4$ then we can take $E_k(\gamma) = C \log|\gamma|$ by classical distributional methods, e.g., [GS, Chap. 2.3.3 and 2.4.2].

THEOREM 3.4. *If* $\varphi \in L^\infty_{\mathrm{loc}}(\mathbb{R}^d)$, $\chi_R(t)\varphi(t)/|t|^{2k} \in L^1(\mathbb{R}^d)$ *for all* $R > 0$, *and* $d > 2k$ $(k \geqq 1)$ *then*

$$\lim_{R \to 0} \| s_k - s_{k,R} | A(\hat{\mathbb{R}}^d) \| = 0$$

and

$$\forall f \in \mathcal{S}(\hat{\mathbb{R}}^d), \quad \lim_{R \to 0} \Delta^k s_{k,R}(f) = \Delta^k s_k(f) = \hat{\varphi}(f)$$

(*cf.* (3.2)).

Proof. Since s_k, $s_{k,R} \in A(\hat{\mathbb{R}}^d)$ (Theorem 3.2(c) and (3.4)), the norm estimate is a consequence of estimating $\| \varphi(t)\chi_{B(0,R)}(t)/|t|^{2k} | L^1(\mathbb{R}^d) \|$.

If $f \in \mathcal{S}(\hat{\mathbb{R}}^d)$ then distributional differentiation and Fubini's theorem allow us to write

$$\Delta^k s_{k,R}(f) = s_{k,R}(\Delta^k f) = \left(\frac{i}{2\pi}\right)^{2k} \int_{|t| \geqq R} \frac{\varphi(t)}{|t|^{2k}} (\Delta^k f)^\wedge(t)\, dt = \int_{|t| \geqq R} \varphi(t) \hat{f}(t)\, dt,$$

and so

$$\lim_{R \to 0} \Delta^k s_{k,R}(f) = \int \varphi(t) \hat{f}(t)\, dt = \hat{\varphi}(f).$$

We have

$$\lim_{R \to 0} \Delta^k s_{k,R}(f) = \lim_{R \to 0} s_{k,R}(\Delta^k f) = s_k(\Delta^k f) = \Delta^k s_k(f)$$

by distributional differentiation and the weak convergence, $\lim_{R \to 0} s_{k,R}(g) = s_k(g)$, $g \in \mathcal{S}(\hat{\mathbb{R}}^d)$. This weak convergence is a consequence of our $A(\hat{\mathbb{R}}^d)$-norm estimate. □

The situation is more complicated if $d \leqq 2k$, $k \geqq 1$, but there is a result analogous to Theorem 3.4. For example, if $\varphi \in \mathcal{S}'(\mathbb{R}^d)$ is Borel measurable and $\chi_R(t)\varphi(t)/|t|^{2k} \in L^1(\mathbb{R}^d)$ for all $R > 0$ then $\lim_{R\to 0} \Delta^k s_{k,R}(f) = \hat{\varphi}(f)$ for each f in the "moment space" $\mathcal{S}_0(\hat{\mathbb{R}}^d)$. Of course, $\mathcal{S}_0(\hat{\mathbb{R}}^d)^\vee$ is not dense in $L^1(\mathbb{R}^d)$ since $\{0\} \subseteq \hat{\mathbb{R}}^d$ is a set of spectral synthesis, e.g., [B1].

Example 3.5. Suppose $d > 2k$.

(a) Give $p \in [1, \infty)$. It is not true that $f * E_k \in L^p(\mathbb{R}^d)$ for all $f \in C_c^\infty(\hat{\mathbb{R}}^d)$. In fact, if $f \geqq 0$ then, by Fubini's theorem and translation invariance, we compute

$$\|f * E_k | L^p(\hat{\mathbb{R}}^d)\|^p = C\|f|L^p(\hat{\mathbb{R}}^d)\| \int_0^\infty \rho^{(2k-d)p+d-1}\, d\rho = \infty.$$

(b) On the other hand, $f * E_k \in L^\infty(\hat{\mathbb{R}}^d)$ for all $f \in \mathcal{S}(\mathbb{R}^d)$. In fact,

$$|f * E_k(\gamma)| \leqq C \int_{|\lambda|\leqq 1} \frac{1}{|\lambda|^{d-2k}} |f(\gamma - \lambda)|\, d\lambda + C \int_{|\lambda|>1} |f(\gamma-\lambda)|\, d\lambda$$

$$\leqq C\|f|L^\infty(\hat{\mathbb{R}}^d)\|\omega_{d-1} \int_0^1 \rho^{2k-1}\, d\rho + C\|f|L^1(\hat{\mathbb{R}}^d)\|.$$

Because of (3.2) and (3.4) it is desirable to define $\hat{\varphi} * E_k$ for a large class of functions $\varphi \in \mathcal{S}'(\mathbb{R}^d) \cap L^1_{\text{loc}}(\mathbb{R}^d)$. To this end, it is useful to know that $f * \hat{\varphi} \in L^1(\hat{\mathbb{R}}^d)$ for all $f \in \mathcal{S}(\hat{\mathbb{R}}^d)$, in light of the fact that $f * E_k \in L^\infty(\mathbb{R}^d)$ (see, e.g., Definition/Remark 3.7(a)).

Definition/Remark 3.6. (a) $\mathcal{O}_c(\hat{\mathbb{R}}^d)$ is the space of infinitely differentiable functions g for which there is $m \in \mathbb{Z}$ such that

$$\forall \alpha, \quad (1+|\gamma|^2)^m\, \partial^\alpha g(\gamma) \in C_0(\hat{\mathbb{R}}^d).$$

(b) If $\varphi \in \mathcal{S}'(\mathbb{R}^d) \cap L^1_{\text{loc}}(\mathbb{R}^d)$ then $f * \hat{\varphi} \in \mathcal{O}_c(\hat{\mathbb{R}}^d)$ for all $f \in \mathcal{S}(\hat{\mathbb{R}}^d)$ (see, e.g., [H, Prop. 4.11.7]); the exchange formula $(f^\vee \varphi)^\wedge = f * \hat{\varphi}$ is valid [S].

(c) Further, if $\varphi \in \mathcal{S}'(\mathbb{R}^d) \cap L^1_{\text{loc}}(\mathbb{R}^d)$ then $f^\vee \varphi \in L^1(\mathbb{R}^d)$ for all $f \in \mathcal{S}(\hat{\mathbb{R}}^d)$. In fact, $|\varphi|$ is a positive tempered measure so that

$$\int \frac{|\varphi(t)|}{(1+|t|^2)^m}\, dt < \infty$$

for some m, e.g., [S, Thm. 7.7.4]; hence,

$$\int |(f^\vee \varphi)(t)|\, dt = \int |f^\vee(t)|(1+|t|^2)^m \frac{|\varphi(t)|}{(1+|t|^2)^m}\, dt$$

$$\leqq \|f^\vee(t)(1+|t|^2)^m | L^\infty(\hat{\mathbb{R}}^d)\| \int \frac{|\varphi(t)|}{(1+|t|^2)^m}\, dt < \infty.$$

Definition/Remark 3.7. (a) Given $S, T \in \mathcal{S}'(\hat{\mathbb{R}}^d)$, suppose $(S*f)(\tilde{T}*g) \in L^1(\hat{\mathbb{R}}^d)$ for all $f, g \in \mathcal{S}(\hat{\mathbb{R}}^d)$, where $\tilde{T}(g) = T(\gamma)(g(-\gamma))$. Then there is a unique element $S * T \in \mathcal{S}'(\hat{\mathbb{R}}^d)$, the *$\mathcal{S}'$-convolution* of S and T, satisfying the equation

$$\forall f, g \in \mathcal{S}(\hat{\mathbb{R}}^d), \quad ((S*T)*f)(g) = \int (S*f)(\gamma)(\tilde{T}*g)(\gamma)\, d\gamma. \tag{3.5}$$

The fact that (3.5) determines a well-defined element of $\mathcal{S}'(\hat{\mathbb{R}}^d)$ and the subsequent definition of convolution are due to [HO, p. 148].

(b) Note that (3.5) is automatic if $S, T \in \mathcal{S}(\hat{\mathbb{R}}^d)$ and $S * T$ is usual convolution:

$$\begin{aligned}((S*T)*f)(g) &= \int \left(\int S*T(\lambda) f(\gamma-\lambda)\, d\lambda \right) g(\gamma)\, d\gamma \\ &= \int\int\int S(\lambda-\mu) T(\mu) f(\gamma-\lambda) g(\gamma)\, d\mu\, d\lambda\, d\gamma \\ &= \int\int\int S(\lambda-\mu) T(\mu) f(\gamma-\lambda) g(\gamma)\, d\lambda\, d\gamma\, d\mu \\ &= \int\int\int S(\gamma-\mu-\eta) T(\mu) f(\eta) g(\gamma)\, d\eta\, d\gamma\, d\mu \\ &= \int\int\int S(\nu-\eta) T(\mu) f(\eta) g(\nu+\mu)\, d\eta\, d\nu\, d\mu \\ &= \int \left(\int S(\nu-\eta) f(\eta)\, d\eta \right) \left(\int T(\mu) g(\nu+\mu)\, d\mu \right) d\nu \\ &= \int (S*f)(\nu)(\tilde{T}*g)(\nu)\, d\nu.\end{aligned}$$

(c) Given $S, T \in D'(\mathbb{R}^d)$, the *product* ST is defined as

$$\lim_{n\to\infty} (S*\theta_n)(T*\theta_n) = ST, \qquad \sigma(D'(\mathbb{R}^d), C_c^\infty(\mathbb{R}^d)),$$

if the left side exists for each sequence $\{\theta_n\} \subseteq C_c^\infty(\mathbb{R}^d)$ with the properties that $\bigcap \operatorname{supp} \theta_n = \{0\}$ and $\int \theta_n(t)\, dt = 1$ for all n.

THEOREM 3.8. *Suppose $d > 2k$, $k \geqq 1$. Assume $\varphi \in \mathcal{S}'(\mathbb{R}^d)$ and*

$$\forall f \in \mathcal{S}(\hat{\mathbb{R}}^d), \quad (1+|\gamma|^2)^{k+1} (f * \hat{\varphi})(\gamma) \in L^1(\hat{\mathbb{R}}^d). \tag{3.6}$$

Then the $\mathcal{S}'$ convolution $s_k = \hat{\varphi} * E_k$ exists and

$$(\hat{\varphi} * E_k)^\vee = \varphi E_k^\vee. \tag{3.7}$$

Proof. (a) We can verify that

$$\forall f \in \mathcal{S}(\hat{\mathbb{R}}^d), \quad (1+|\gamma|^2)^{-(k+1)} f * E_k(\gamma) \in C_b(\hat{\mathbb{R}}^d), \tag{3.8}$$

noting that $f * E_k(\gamma)$ clearly exists for each $\gamma \in \hat{\mathbb{R}}^d$.

(b) Using (3.6) and (3.8), Definition/Remark 3.7(a) allows us to define the $\mathcal{S}'$-convolution of $\hat{\varphi}$ and E_k.

(c) Take any $\psi \in C_c^\infty(\mathbb{R}^d)$. Then $\psi\varphi \in \mathcal{E}'(\mathbb{R}^d)$ and it is easy to check that

$$(\psi\varphi) * E_k^\vee \in \mathcal{S}'(\mathbb{R}^d).$$

Furthermore, by a closure argument, e.g., [S, Thm. 7.8.15], we have

$$((\psi\varphi) * E_k^\vee)^\wedge = (\hat{\psi} * \hat{\varphi}) E_k$$

and $\hat{\psi} * \hat{\varphi} \in \mathcal{O}_c(\hat{\mathbb{R}}^d)$ (see, e.g., Definition/Remark 3.6(b)).

Using (3.6), there is $g \in L^1(\hat{\mathbb{R}}^d)$ for which

$$(\hat{\psi} * \hat{\varphi})(\gamma) E_k(\gamma) = \frac{g(\gamma)}{(1+|\gamma|^2)^{k+1} |\gamma|^{d-2k}},$$

and, in particular, $(\hat{\psi} * \hat{\varphi}) E_k \in L^1(\hat{\mathbb{R}}^d \setminus N)$, where N is a neighborhood of zero. Moreover, since $\hat{\psi} * \hat{\varphi} \in \mathcal{C}_c(\hat{\mathbb{R}}^d)$, we know it is bounded on N and hence $(\hat{\psi} * \hat{\varphi}) E_k \in L^1(N)$. Thus, $(\hat{\psi} * \hat{\varphi}) E_k \in L^1(\hat{\mathbb{R}}^d)$, and so, $(\psi\varphi) * E_k^\vee \in A(\mathbb{R}^d)$. The continuity allows us to use [IS, Prop. 5] to conclude that $\varphi E_k^\vee$ exists and

$$(\varphi E_k^\vee)(\psi) = ((\psi\varphi) * E_k^\vee)(0).$$

Consequently, we have

$$(\varphi E^\vee)(\psi) = ((\psi\varphi) * E^\vee)(0) = \int \hat{\psi} * \hat{\varphi}(\gamma) E_k(\gamma)\, d\gamma = (\hat{\varphi} * E_k(\lambda))(\hat{\psi}(-\lambda)) = (\hat{\varphi} * E_k)^\vee(\psi),$$

and this is (3.7). □

The procedure we have used to verify the exchange formula (3.7) after showing that the product $\varphi E_k^\vee$ exists is quite general and is due to [IS]. More recent related work is due to members of the Polish school including Antosik, Burzyk, Kaminski, and Wawak. The proof of Theorem 3.8 is easier if we know $\varphi E_k^\vee \in L^1(\mathbb{R}^d)$.

Example 3.9. (a) Condition (3.6) is automatically satisfied if φ is a trigonometric polynomial.

(b) Further, if $\hat{\varphi} = \mu \in M_b(\hat{\mathbb{R}}^d)$ has the property that

$$\int (1+|\gamma|^2)^{k+1}\, d|\mu|(\gamma) < \infty$$

then (3.6) is satisfied for all $f \in \mathcal{S}(\hat{\mathbb{R}}^d)$.

(c) On the other hand, if $\hat{\varphi} = \mu \in M_{b+}(\hat{\mathbb{R}}^d)$ and

$$\int (1+|\gamma|^2)^{k+1}\, d\mu(\gamma) = \infty \tag{3.9}$$

then (3.6) fails for all nonnegative $f \in \mathcal{S}(\hat{\mathbb{R}}^d)$.

It is easy to construct positive-definite elements $\varphi = \mu^\vee \in A(\mathbb{R}^d)$ that satisfy (3.9). For example, if $g(\gamma) = |\gamma|^{-d+1}(1+|\gamma|^2)^{-1}$ then $\|g|L^1(\hat{\mathbb{R}}^d)\| = \pi\omega_{d-1}/2$, whereas the left side of (3.9) for the case $\varphi = g^\vee$ is

$$\omega_{d-1} \int_0^\infty (1+\rho^2)^k\, d\rho = \infty.$$

4. Spherical mean value and difference operators.

Definition/Remark 4.1. (a) The d-dimensional *spherical mean-value operator* $\mathcal{M}_\lambda$ of radius λ is defined as

$$\mathcal{M}_\lambda f(\gamma) = \frac{1}{\omega_{d-1}} \int_{\Sigma_{d-1}} f(\gamma + \lambda\theta)\, d\sigma_{d-1}(\theta), \tag{4.1}$$

where $f: \hat{\mathbb{R}}^d \to \mathbb{C}$, $\gamma \in \hat{\mathbb{R}}^d$, $\lambda > 0$, and $\theta \in \Sigma_{d-1}$. Thus, $\mathcal{M}_\lambda f(\gamma)$ is a mean-value of f at the point γ. In fact, if $d = 2$ and f is analytic within and on a circle of radius λ about γ then the Cauchy integral formula implies that $f(\gamma) = \mathcal{M}_\lambda f(\gamma)$. Furthermore, if $d \geqq 2$ and f is harmonic in a domain containing $\gamma \in \hat{\mathbb{R}}^d$ and the closed ball of radius λ then $f(\gamma) = \mathcal{M}_\lambda f(\gamma)$ [SW, p. 38].

(b) Each operator $\mathcal{M}_\lambda$ is a continuous linear mapping $\mathcal{M}_\lambda: \mathcal{S}(\hat{\mathbb{R}}^d) \to \mathcal{S}(\hat{\mathbb{R}}^d)$. The dual mapping $\mathcal{M}_\lambda^*: \mathcal{S}'(\hat{\mathbb{R}}^d) \to \mathcal{S}'(\hat{\mathbb{R}}^d)$ is well defined by the duality $(\mathcal{M}_\lambda^* f)(\bar{g}) = f(\mathcal{M}_\lambda g)^-$, where $g \in \mathcal{S}(\hat{\mathbb{R}}^d)$.

(c) $\mathcal{M}_\lambda^*: \mathcal{S}'(\hat{\mathbb{R}}^d) \to \mathcal{S}'(\hat{\mathbb{R}}^d)$ is the unique continuous linear mapping on $\mathcal{S}'(\hat{\mathbb{R}}^d)$ that extends $\mathcal{M}_\lambda$ defined on $\mathcal{S}(\hat{\mathbb{R}}^d) \subseteq \mathcal{S}'(\hat{\mathbb{R}}^d)$; as such we designate $\mathcal{M}_\lambda^*$ by $\mathcal{M}_\lambda$ for each $\lambda > 0$.

To see that $\mathcal{M}_\lambda^*$ is an extension of $\mathcal{M}_\lambda$, take $f, g \in \mathcal{S}(\hat{\mathbb{R}}^d)$ and compute

$$(\mathcal{M}_\lambda^* f)(\bar{g}) = f(\mathcal{M}_\lambda g)^- = \int f(\gamma)\overline{(\mathcal{M}_\lambda g)(\gamma)}\, d\gamma$$

$$= \frac{1}{\omega_{d-1}} \int_{\Sigma_{d-1}} \left(\int f(\gamma)\overline{g(\gamma+\lambda\theta)}\, d\gamma \right) d\sigma_{d-1}(\theta)$$

$$= \frac{1}{\omega_{d-1}} \int_{\Sigma_{d-1}} \left(\int f(\gamma+\lambda(-\theta))\overline{g(\gamma)}\, d\gamma \right) d\sigma_{d-1}(\theta)$$

$$= \int \left(\frac{1}{\omega_{d-1}} \int_{\Sigma_{d-1}} f(\gamma+\lambda(-\theta))\, d\sigma_{d-1}(\theta) \right) \overline{g(\gamma)}\, d\gamma = (\mathcal{M}_\lambda f)(\bar{g}).$$

To verify uniqueness, take $f \in \mathcal{S}'(\hat{\mathbb{R}}^d)$ and let $f_n \to f$ in the $\sigma(\mathcal{S}'(\hat{\mathbb{R}}^d), \mathcal{S}(\hat{\mathbb{R}}^d))$ topology, where $\{f_n\} \subseteq \mathcal{S}(\hat{\mathbb{R}}^d)$. Then

$$(\mathcal{M}_\lambda^* f)(\bar{g}) = f(\mathcal{M}_\lambda g)^- = \lim f_n(\mathcal{M}_\lambda g)^- = \lim (\mathcal{M}_\lambda f_n)(\bar{g}).$$

Remark 4.2. In [BBE], we defined a symmetric difference operator Δ_λ which was a unimodular weighted mean-value operator. An analogue for the present situation is

$$\frac{1}{\omega_{d-1}} \int_{\Sigma_{d-1}} w(\theta) f(\gamma+\lambda\theta)\, d\sigma_{d-1}(\theta),$$

where $|w(\theta)| = 1$ and

$$\lim_{\lambda \to 0} \frac{1}{\omega_{d-1}} \int_{\Sigma_{d-1}} w(\theta) f(\gamma+\lambda\theta)\, d\sigma_{d-1}(\theta) = 0.$$

PROPOSITION 4.3. *Let $g \in L^2(\hat{\mathbb{R}}^d)$, $\alpha \in \mathbb{C}$, and $f \in \mathcal{S}'(\hat{\mathbb{R}}^d)$. Assume f satisfies the following conditions: $f^\vee \in \mathcal{S}'(\hat{\mathbb{R}}^d)$ is a Borel measurable function,*

$$\exists R > 0, \quad \text{such that } f^\vee \in L^2(B(0, R)^\sim)$$

and

$$|t|^2 f^\vee(t) \in L^2_{\text{loc}}(\mathbb{R}^d).$$

Then $f - \mathcal{M}_\lambda f \in L^2(\hat{\mathbb{R}}^d)$ and

$$\|g - \alpha(f - \mathcal{M}_\lambda f) | L^2(\hat{\mathbb{R}}^d)\|$$

$$= \left\| g^\vee(t) - \alpha f^\vee(t) \left(1 - \frac{2\pi}{\omega_{d-1}} (|t|\lambda)^{-(d-2)/2} J_{(d-2)/2}(2\pi|t|\lambda) \right) \middle| L^2(\mathbb{R}^d) \right\|. \tag{4.2}$$

Proof. (a) The hypothesis $|t|^2 f^\vee(t) \in L^2_{\text{loc}}(\mathbb{R}^d)$ implies that $f^\vee \in L^2_{\text{loc}}(\mathbb{R}^d \setminus \{0\})$. In fact, if $K \subseteq \mathbb{R}^d$ is compact and $0 \notin K$ then

$$\int_K |f^\vee(t)|^2\, dt = \int_K \frac{|t|^4}{|t|^4} |f^\vee(t)|^2\, dt \leqq C \int_K |t|^4 |f^\vee(t)|^2\, dt < \infty.$$

If we did not assume $f^\vee$ to be a Borel measurable function, then it could contain terms of the form $\partial^\beta \delta$.

(b) We now prove

$$f^\vee(t)\theta_\lambda(t) = f^\vee(t) \left(1 - \frac{2\pi}{\omega_{d-1}} (|t|\lambda)^{-(d-2)/2} J_{(d-2)/2}(2\pi|t|\lambda) \right) \in L^2(\mathbb{R}^d). \tag{4.3}$$

Since $f^\vee(t) \in L^2(B(0,R)^\sim)$ and

$$\sup_{|t|\geqq R} |t|^{-d+2} J_{(d-2)/2}(2\pi|t|\lambda)^2 \leqq C \sup_{|t|\geqq R} |t|^{-d+2}(2\pi|t|\lambda)^{-1} \leqq C_\lambda \sup_{|t|\geqq R} |t|^{-d+1} \leqq C_\lambda R^{-d+1},$$

it is sufficient for (4.3) to dominate

$$I = \int_{B(0,R)} \left| f^\vee(t)\left(1 - \frac{2\pi}{\omega_{d-1}}(|t|\lambda)^{-(d-2)/2} J_{(d-2)/2}(2\pi|t|\lambda)\right)\right|^2 dt. \tag{4.4}$$

This integral is

$$\int_{B(0,R)} \left| f^\vee(t)\left\{\left(1 - \frac{2\pi}{\omega_{d-1}}(|t|\lambda)^{-(d-2)/2}\left(\frac{2\pi|t|\lambda}{2}\right)^{(d-2)/2} \frac{1}{\Gamma(d/2)}\right)\right.\right.$$
$$\left.\left. - \frac{2\pi}{\omega_{d-1}}(|t|\lambda)^{-(d-2)/2}\left(\frac{2\pi|t|\lambda}{2}\right)^{(d-2)/2} \sum_{k=1}^{\infty} \frac{(-(1/4)(2\pi|t|\lambda)^2)^k}{k!\Gamma(((d-2)/2)+k+1)}\right\}\right|^2 dt$$
$$= \int_{B(0,R)} \left| f^\vee(t)\left\{\frac{2\pi^{d/2}}{\omega_{d-1}} \sum_{k=1}^{\infty} \frac{(-\pi^2|t|^2\lambda^2)^k}{k!\Gamma((d/2)+k)}\right\}\right|^2 dt$$

(see, e.g., Example 2.4). Thus, by Minkowski's inequality, we have

$$I^{1/2} \leqq \sum_{k=1}^{\infty} \left\| f^\vee(t) \frac{2\pi^{d/2}}{\omega_{d-1}} \frac{(\pi|t|\lambda)^{2k}}{k!\Gamma((d/2)+k)} \right| L^2(B(0,R))\Big\|$$
$$= \Gamma\left(\frac{d}{2}\right) \sum_{k=1}^{\infty} \frac{(\pi\lambda)^{2k}}{k!\Gamma((d/2)+k)} \|f^\vee(t)|t|^{2k} | L^2(B(0,R))\|,$$

and this is finite since $|t|^2 f^\vee(t) \in L^2_{\text{loc}}(\mathbb{R}^d)$. Consequently, (4.3) is valid.

(c) Distributionally, we have

$$\forall \psi \in \mathcal{S}(\mathbb{R}^d), \quad (f^\vee \theta_\lambda)(\bar{\psi}) = (f^\vee \theta_\lambda)^\wedge(\tilde{\hat{\psi}}).$$

The left-hand side is

$$\int f^\vee(t)(\theta_\lambda \bar{\psi})(t)\, dt = \int f^\vee(t)\overline{(\theta_\lambda(t)\psi(t))}\, dt = \overline{f(\theta_\lambda \psi)^\wedge}$$
$$= f(\gamma)\left(\int \left(1 - \frac{1}{\omega_{d-1}} \int_{\Sigma_{d-1}} e^{-2\pi i t\cdot\lambda\theta}\, d\sigma_{d-1}(\theta)\right)\psi(t)\, e^{-2\pi i t\cdot\gamma}\, dt\right)^-$$
$$= f(\gamma)\left(\hat{\psi}(\gamma) - \frac{1}{\omega_{d-1}} \int_{\Sigma_{d-1}} \left(\int \psi(t)\, e^{-2\pi i t\cdot(\gamma+\lambda\theta)}\, dt\right) d\sigma_{d-1}(\theta)\right)^-$$
$$= f(\hat{\psi} - \mathcal{M}_\lambda \hat{\psi})^- = f(\hat{\psi})^- - (\mathcal{M}_\lambda^* f)(\hat{\psi})^- = (f - \mathcal{M}_\lambda f)(\tilde{\hat{\psi}}).$$

Thus, $f - \mathcal{M}_\lambda f = (f^\vee \theta_\lambda)^\wedge$.

Since $f^\vee \theta_\lambda \in L^2(\mathbb{R}^d)$ we know that $(f^\vee \theta_\lambda)^\wedge \in L^2(\hat{\mathbb{R}}^d)$, and hence, $f - \mathcal{M}_\lambda f \in L^2(\hat{\mathbb{R}}^d)$. Equation (4.2) is a consequence of the Plancherel theorem. □

The operator (on the function f)

$$-\frac{2d}{\lambda^2}(f - \mathcal{M}_\lambda f)$$

corresponds to the Laplacian in $\hat{\mathbb{R}}^d$ in the same way that the difference operator

$$\frac{1}{2\lambda}(\tau_{-\lambda} f - \tau_\lambda f) \tag{4.5}$$

corresponds to the ordinary derivative in $\hat{\mathbb{R}}$ (cf. [BBE] for the rectangular generalization of (4.5) to $\hat{\mathbb{R}}^d$ and § 1 for the corresponding differential operator). Wiener made the following calculation for the case $d=3$ [W1].

Formal calculation 4.4. Given $f\in\mathcal{S}'(\hat{\mathbb{R}}^d)$ for which $\Delta f\in L^2(\hat{\mathbb{R}}^d)$ and $f^\vee$ is Borel measurable, then

$$\lim_{\lambda\to 0}\left\|\Delta f-\left(-\frac{2d}{\lambda^2}\right)(f-\mathcal{M}_\lambda f)\,\middle|\,L^2(\hat{\mathbb{R}}^d)\right\|=0. \tag{4.6}$$

Proof. Since Δf is a convolution of $f\in\mathcal{S}'(\hat{\mathbb{R}}^d)$ and a distribution having compact support, the exchange formula is valid and $\Delta f^\vee(t)=-4\pi^2|t|^2 f^\vee(t)\in\mathcal{S}'(\mathbb{R}^d)$. The hypothesis $\Delta f\in L^2(\hat{\mathbb{R}}^d)$ allows us to conclude that $-4\pi^2|t|^2 f^\vee(t)\in L^2(\mathbb{R}^d)$. In particular, the hypotheses of Proposition 4.3 are satisfied and thus we have

$$\begin{aligned}&\left\|\Delta f-\left(-\frac{2d}{\lambda^2}\right)(f-\mathcal{M}_\lambda f)\,\middle|\,L^2(\hat{\mathbb{R}}^d)\right\|\\&=\left\|f^\vee(t)\left(\frac{2d}{\lambda^2}\left\{1-\frac{2\pi^2|t|^2\lambda^2}{d}-\frac{2\pi}{\omega_{d-1}}(|t|\lambda)^{-(d-2)/2}J_{(d-2)/2}(2\pi|t|\lambda)\right\}\right)\,\middle|\,L^2(\mathbb{R}^d)\right\|.\end{aligned} \tag{4.7}$$

Using the series representation of J_ν, the right side of (4.7) becomes

$$\begin{aligned}&\left\|f^\vee(t)\left(\frac{2d}{\lambda^2}\left\{\left[1-\frac{2\pi}{\omega_{d-1}}(|t|\lambda)^{-(d-2)/2}\left(\frac{2\pi|t|\lambda}{2}\right)^{(d-2)/2}\frac{1}{\Gamma(d/2)}\right]\right.\right.\\&\quad+\left[-\frac{2(\pi|t|\lambda)^2}{d}-\frac{2\pi}{\omega_{d-1}}(|t|\lambda)^{-(d-2)/2}\left(\frac{2\pi|t|\lambda}{2}\right)^{(d-2)/2}\left(\frac{-(\pi|t|\lambda)^2}{\Gamma((d/2)+1)}\right)\right]\\&\quad\left.\left.-\frac{2\pi^{d/2}}{\omega_{d-1}}\sum_{k=2}^{\infty}\frac{(-(\pi|t|\lambda)^2)^k}{k!\Gamma((d/2)+k)}\right\}\right)\,\middle|\,L^2(\mathbb{R}^d)\right\|\\&=2d\Gamma\left(\frac{d}{2}\right)\left\|f^\vee(t)\frac{1}{\lambda^2}\sum_{k=2}^{\infty}\frac{(-(\pi|t|\lambda)^2)^k}{k!\Gamma((d/2)+k)}\,\middle|\,L^2(\mathbb{R}^d)\right\|,\end{aligned} \tag{4.8}$$

where we use the fact that $\Gamma((d/2)+1)=(d/2)\Gamma(d/2)$ to eliminate the $k=1$ term.

The right side of (4.8) *formally* tends to zero as $\lambda\to 0$ since $k\geqq 2$. □

Naturally, the final and only formal step of the preceding calculation is verifiable for many functions $f^\vee$.

Also, in light of the role of iterated Laplacians it is natural to ask if this calculation can be adapted to deal with $\sum_1 a_j\Delta^j f$ instead of Δf. Since $(\sum_1 a_j\Delta^j f)^\vee(t)=\sum_1(-1)^j(2\pi)^{2j}a_j|t|^{2j}$, the cancellation analogous to that indicated in (4.8) is not possible if $\alpha=-2d/\lambda^2$ and $j\geqq 2$. Similar problems arise when α is adjusted. For example, if $\alpha=c/\lambda^{2j}$, $j\geqq 2$, so that the $|t|^{2j}$ terms cancel, then there is no cancellation for the $|t|^{2k}$ terms, $k<j$. Progress can be made when $\mathcal{M}_\lambda$ is replaced by more complicated means.

DEFINITION 4.5. The d-dimensional *spherical difference operator* D_λ of radius λ is defined by

$$D_\lambda f(\gamma)=f(\gamma)-(\mathcal{M}_\lambda f)(\gamma). \tag{4.9}$$

If the hypotheses of Proposition 4.3 are satisfied for a function f then the spherical difference operator gives rise to an $L^2(\mathbb{R}^d)$-valued function of λ, the path of which is a *helix* (in $L^2(\mathbb{R}^d)$) in the sense of Masani's theory of helices (see, e.g., [M, pp. 351–359]). The helical theory is more complicated for our rectangular Wiener–Plancherel formula (see, e.g., [He]).

Because of the Wiener–Plancherel formulas in Theorems 5.6 and 5.7, it is natural to investigate the relationship between $D_\lambda s_k$ and $s_{k,R}$. We do this in the following example.

Example 4.6. Let $\psi(t) = (i/2\pi)^{2k}\varphi(t)/|t|^{2k}$, where $\varphi \in \mathcal{S}'(\mathbb{R}^d) \cap L^1_{\text{loc}}(\mathbb{R}^d)$, and let f and g be functions defined on $\hat{\mathbb{R}}^d$. We have the following formal relations which are valid for a large class of functions:

$$s_{k,R} = \hat{\psi} * \hat{\chi}_R = s_k * (\delta - \hat{\chi}_{B(0,R)}) = s_k - s_k * \hat{\chi}_{B(0,R)}, \tag{4.10}$$

where $\hat{\psi} = s_k$;

$$\lim_{\lambda \to 0} \mathcal{M}_\lambda f = f \tag{4.11}$$

and

$$\mathcal{M}_\lambda(f * g) = (\mathcal{M}_\lambda f) * g. \tag{4.12}$$

Let $R = 1/\lambda$. Because of (4.11), the mean $\mathcal{M}_\lambda$ of the right side of (4.10) is approximated by $s_k - \mathcal{M}_\lambda(s_k * \hat{\chi}_{B(0,R)})$. Using (4.12) and the weak convergence to δ by $\hat{\chi}_{B(0,R)}$, we see that this approximation is in turn an estimation of $D_\lambda s_k$. Thus, $D_\lambda s_k \approx \mathcal{M}_\lambda s_{k,R}$ (cf. Example 6.3).

5. Proof of the spherical Wiener–Plancherel formula.

Definition/Remark 5.1. (a) The space $B^2(\mathbb{R}^d)$ of functions having *bounded quadratic means over spheres* is the set of all functions $\varphi \in L^2_{\text{loc}}(\mathbb{R}^d)$ for which

$$\|\varphi | B^2(\mathbb{R}^d)\| = \sup_{R>0} \left(\frac{1}{|B(0,R)|} \int_{B(0,R)} |\varphi(t)|^2 \, dt \right)^{1/2} < \infty. \tag{5.1}$$

$B^2(\mathbb{R}^d)$ is a Banach space with norm defined by (5.1).

(b) Given $\varphi \in L^2_{\text{loc}}(\mathbb{R}^d)$. The *spherical average of* φ is the function Φ defined on $\mathbb{R}^*_+$ by

$$\Phi(r) = \frac{1}{\omega_{d-1}} \int_{\Sigma_{d-1}} |\varphi(r\theta)|^2 \, d\sigma_{d-1}(\theta). \tag{5.2}$$

(c) A basic property of spherical averages, and one that is relevant for comparison with the classical and rectangular Wiener–Plancherel formulas [W2], [BBE], is that

$$\Phi \in L^\infty(\mathbb{R}^*_+) \quad \text{implies} \quad \varphi \in B^2(\mathbb{R}^d). \tag{5.3}$$

The verification of (5.3) is immediate:

$$\begin{aligned} \frac{1}{|B(0,R)|} \int_{B(0,R)} |\varphi(t)|^2 \, dt &= \frac{\omega_{d-1}}{|B(0,R)|} \int_0^R r^{d-1} \Phi(r) \, dr \\ &\leqq \frac{\|\Phi | L^\infty(\mathbb{R}^*_+)\|}{d|B(0,R)|} \omega_{d-1} R^d = \|\Phi | L^\infty(\mathbb{R}^*_+)\|. \end{aligned}$$

(d) Clearly, $B^2(\mathbb{R}^d) \setminus L^\infty(\mathbb{R}^d) \neq \varnothing$. In fact we can choose a continuous radial element $\varphi \in L^2(\mathbb{R}^d)$ for which $\overline{\lim}_{r \to \infty} |\varphi(r)| = \infty$. This function also shows that the converse of (5.3) fails since $\Phi(r) = |\varphi(r)|^2$. Furthermore, this observation shows that, for the class of radial continuous functions, $\Phi \in L^\infty(\mathbb{R}^*_+)$ if and only if $\varphi \in L^\infty(\mathbb{R}^d)$.

We quote the following important result of Beurling which is related to one of his deep investigations of spectral synthesis [Be].

THEOREM 5.2 [Be, Thms. I, II] (cf. [BDD]). (a) *$B^2(\mathbb{R}^d)$ is the Banach space dual of the convolution Banach algebra $A^2(\mathbb{R}^d)$ defined as follows*:

$$A^2(\mathbb{R}^d) = \bigcup_{\omega\in\Omega} L^2_{1/\omega}(\mathbb{R}^d) \subseteq L^1(\mathbb{R}^d),$$

where $\Omega = \{\omega \in L^1(\mathbb{R}^d)$: $\omega > 0$, $\|\omega | L^1(\mathbb{R}^d)\| = 1$, ω is radial, and $\omega(|t|)$ decreases on $\mathbb{R}^*_+\}$ and $L^2_{1/\omega}(\mathbb{R}^d)$ is the Banach space of Borel measurable functions φ defined by the norm

$$\|\varphi | L^2_{1/\omega}(\mathbb{R}^d)\| = \left(\int \frac{|\varphi(t)|^2}{\omega(t)}\, dt\right)^{1/2}.$$

The Banach space norm of $\varphi \in A^2(\mathbb{R}^d)$ is

$$\|\varphi | A^2(\mathbb{R}^d)\| = \inf_{\omega\in\Omega} \|\varphi | L^2_{1/\omega}(\mathbb{R}^d)\|,$$

and the duality between $A^2(\mathbb{R}^d)$ and $B^2(\mathbb{R}^d)$ is defined by the relation

$$\forall \theta \in A^2(\mathbb{R}^d) \quad \text{and} \quad \forall \varphi \in B^2(\mathbb{R}^d), \quad \varphi(\theta) = \int \varphi(t)\overline{\theta(t)}\, dt.$$

(b) *$B^2(\mathbb{R}^d)$ is characterized by the intersection*

$$B^2(\mathbb{R}^d) = \bigcap_{\omega\in\Omega} L^2_\omega(\mathbb{R}^d). \tag{5.4}$$

DEFINITION 5.3. The spherical *Wiener space* $W(\mathbb{R}^d)$ consists of all functions $\varphi \in L^2_{\text{loc}}(\mathbb{R}^d)$ for which

$$\|\varphi | W(\mathbb{R}^d)\| = \left(\int \frac{|\varphi(t)|^2}{(1+|t|^2)^d}\, dt\right)^{1/2} < \infty$$

(cf. [BBE, Ex. 4.3]). Clearly, $W(\mathbb{R}^d) = \hat{H}^{-d}$, where H^α is the Hilbert Sobolev space $L^2_\alpha(\mathbb{R}^d)$.

We could prove the first inclusion of the following result directly, analogous to the method used in [BBE, Thm. 3.2], or by invoking the well-known inclusion $B^2(\mathbb{R}^d) \subseteq \hat{H}^\alpha$, for each $\alpha < -d/2$. Instead we use (5.4); this application of Beurling's theorem is due to Heil [He].

THEOREM 5.4. $B^2(\mathbb{R}^d) \subseteq W(\mathbb{R}^d) \subseteq \mathcal{S}'(\mathbb{R}^d)$.

Proof. (a) We shall first prove that $B^2(\mathbb{R}^d) \subseteq W(\mathbb{R}^d)$. The weight $\omega(t) = c/(1+|t|^2)^d$ is an element of Ω, for the proper choice of $c > 0$, and $L^2_\omega(\mathbb{R}^d) = W(\mathbb{R}^d)$. The assertion follows from (5.4).

(b) The proof of the inclusion $W(\mathbb{R}^d) \subseteq \mathcal{S}'(\mathbb{R}^d)$ follows from definitions. □

LEMMA 5.5. *Let $\varphi \in L^2_{\text{loc}}(\mathbb{R}^d)$ for which $\Phi \in L^\infty(\mathbb{R}^*_+)$, and suppose we are given k for which $4k > d$. Then*

$$\forall R > 0, \quad \varphi E^\vee_k \in L^2(\mathbb{R}^d \setminus B(0, R)).$$

Proof.

$$\int_{B(0,R)^\sim} |\varphi(t) E^\vee_k(t)|^2\, dt = \frac{1}{(2\pi)^{4k}} \int_R^\infty r^{d-4k-1} \Phi(r)\, dr \leqq \frac{\|\Phi | L^\infty(\mathbb{R}^*_+)\|}{(2\pi)^{4k}(4k-d)} R^{d-4k}. \qquad \square$$

THEOREM 5.6. *Given $\varphi \in L^2_{\text{loc}}(\mathbb{R}^d)$ and an integer k for which $4k > d$, assume $\Phi \in L^\infty(\mathbb{R}^*_+)$. Then*

$$\begin{aligned} \lim_{R\to\infty} \frac{1}{|B(0,R)|} \int_{B(0,R)} |\varphi(t)|^2\, dt &= \lim_{\lambda\to 0} \frac{(4k-d)(2\pi)^{4k}}{\omega^2_{d-1}\lambda^{4k-d}} \int |s_{k,1/\lambda}(\gamma)|^2\, d\gamma \\ &= \lim_{R\to\infty} \frac{(4k-d)R^{4k-d}}{\omega^2_{d-1}} \int_{B(0,R)^\sim} |\varphi(t)|^2 \frac{1}{|t|^{4k}}\, dt, \end{aligned} \tag{5.5}$$

in the sense that if any one limit exists, then the others exist and they are all equal.

Proof. We compute

$$(2\pi)^{4k}\int |s_{k,R}(\gamma)|^2\,d\gamma = \int_{B(0,R)^\sim} |\varphi(t)|^2 \frac{1}{|t|^{4k}}\,dt$$

$$= \omega_{d-1}\int_R^\infty r^{d-4k-1}\left(\frac{1}{\omega_{d-1}}\int_{\Sigma_{d-1}} |\varphi(r\theta)|^2\,d\sigma_{d-1}(\theta)\right)dr$$

$$= \omega_{d-1}\lambda^{4k-d}\int_R^\infty (\lambda r)^{d-4k}\Phi(r)\frac{dr}{r}$$

$$= \omega_{d-1}\lambda^{4k-d}\int_0^\infty \chi_{(0,1)}\left(\frac{R}{r}\right)\left(\frac{R}{r}\right)^{4k-d}\Phi(r)\frac{dr}{r}$$

$$= \omega_{d-1}\lambda^{4k-d}\Theta\otimes\Phi(R),$$

where $\lambda = 1/R$ and $\Theta(s) = \chi_{(0,1)}(s)s^{4k-d} \in L^1(\mathbb{R}_+^*)$. The calculation is valid because of the Plancherel theorem and because the hypotheses allow us to use Lemma 5.5.

Also,

$$\mathscr{F}(\Theta)(\rho) = \int_0^\infty r^{i\rho}\Theta(r)\frac{dr}{r} = \frac{1}{4k-d+i\rho},$$

so that $|\mathscr{F}(\Theta)| > 0$ on $(\mathbb{R}_+^*)\hat{}$.

Next, we have

$$\frac{1}{|B(0,R)|}\int_{B(0,R)} |\varphi(t)|^2\,dt = \frac{1}{|B(0,R)|}\int_0^R r^{d-1}\Phi(r)\,dr$$

$$= \frac{d}{\omega_{d-1}R^d}\int_0^R r^{d-1}\Phi(r)\,dr = \frac{d}{\omega_{d-1}}K_A\otimes\Phi(R),$$

where the last step follows from Example 2.3 and where $|B(0,R)| = \omega_{d-1}R^d/d$. Thus,

$$\frac{1}{|B(0,R)|}\int_{B(0,R)} |\varphi(t)|^2\,dt = \left(\frac{d}{\omega_{d-1}}K_A\right)\otimes\Phi(R).$$

Recall that $|\mathscr{F}(K_A)| > 0$ on $(\mathbb{R}_+^*)\hat{}$.

We now apply the Tauberian theorem, Theorem 2.2. If

$$\lim_{R\to\infty}\left(\frac{d}{\omega_{d-1}}K_A\right)\otimes\Phi(R) = C_\Phi\int_0^\infty \frac{d}{\omega_{d-1}}K_A(r)\frac{dr}{r},$$

then

$$\lim_{R\to\infty}\Theta\otimes\Phi(R) = C_\Phi\int_0^\infty \Theta(r)\frac{dr}{r},$$

and vice versa. Consequently,

$$\frac{1}{\int_0^\infty K_A(r)\,dr/r}\lim_{R\to\infty}K_A\otimes\Phi(R) = \frac{1}{\int_0^\infty \Theta(r)\,dr/r}\lim_{R\to\infty}\Theta\otimes\Phi(R)$$

and so,

$$\lim_{R\to\infty}\frac{\omega_{d-1}}{|B(0,R)|}\int_{B(0,R)}|\varphi(t)|^2\,dt=\lim_{R\to\infty}(4k-d)(2\pi)^{4k}R^{4k-d}\int|s_{k,R}(\gamma)|^2\,d\gamma$$

$$=\lim_{R\to\infty}(4k-d)R^{4k-d}\int_{B(0,R)^{\sim}}|\varphi(t)|^2\frac{1}{|t|^{4k}}\,dt. \qquad \square$$

The limit in (5.5) involving $s_{k,1/\lambda}$ can be replaced by one involving $\mathcal{M}_\lambda s_{k,1/\lambda}$ at least in the case where the first limit of (5.5) is assumed to exist, e.g., Example 6.3.

THEOREM 5.7. *Let $\varphi\in L^2_{\mathrm{loc}}(\mathbb{R}^d)$, which is bounded in a neighborhood of the origin, and given an integer k for which $4(k-1)<d<4k$ and $d>2k$ ($d>4(k-1)$ implies $d>2k$ for $k\geqq 2$). Assume $\Phi\in L^\infty(\mathbb{R}^*_+)$. Then $s_k=(\varphi E_k^\vee)^\wedge\in\mathcal{S}'(\hat{\mathbb{R}}^d)$ and*

$$\lim_{R\to\infty}\frac{1}{|B(0,R)|}\int_{B(0,R)}|\varphi(t)|^2\,dt=\lim_{\lambda\to 0}\frac{c(d,k)(2\pi)^{4k}}{\omega_{d-1}\lambda^{4k-d}}\int|D_\lambda s_k(\gamma)|^2\,d\gamma, \tag{5.6}$$

where $c(d,k)^{-1}=\|K_k|L^1(\mathbb{R}^*_+)\|$. Equation (5.6) signifies that if the left side exists then the right side exists and they are equal.

Proof. (a) The hypotheses allow us to invoke Proposition 4.3. To see this we proceed as follows. The function $s_k^\vee=\varphi E_k^\vee$ is Borel measurable, and $s_k^\vee\in L^2(B(0,R)^{\sim})$ since $\Phi\in L^\infty(\mathbb{R}^*_+)$ and $4k>d$. Furthermore, $|t|^2 s_k^\vee(t)\in L^2_{\mathrm{loc}}(\mathbb{R}^d)$ since

$$\int_{B(0,R)}\frac{|\varphi(t)|^2}{|t|^{4(k-1)}}\,dt\leqq\omega_{d-1}\|\Phi|L^\infty(\mathbb{R}^*_+)\|\int_0^R r^{d-4k+3}\,dr$$

and $4(k-1)<d$.

Finally, we must show $s_k^\vee\in\mathcal{S}'(\mathbb{R}^d)$. Since $d>2k$ we know from Theorem 3.2(a) that $E_k^\vee\in\mathcal{S}'(\mathbb{R}^d)\cap L^1_{\mathrm{loc}}(\mathbb{R}^d)$. For $\theta\in\mathcal{S}(\mathbb{R}^d)$ we have the estimate

$$|s_k^\vee(\theta)|\leqq\frac{C(\varphi,R)}{(2\pi)^{2k}}\int_{B(0,R)}\frac{|\theta(t)|}{|t|^{2k}}\,dt$$

$$+\frac{1}{(2\pi)^{2k}}\|\varphi|W(\mathbb{R}^d)\|\left(\int_{B(0,R)^{\sim}}|\theta(t)|^2\frac{(1+|t|^2)^d}{|t|^{4k}}\,dt\right)^{1/2},$$

where $|\varphi(t)|\leqq C(\varphi,R)$ on $B(0,R)$. The right side is finite by Theorem 5.4, the hypothesis $d>2k$, and the fact $\theta\in\mathcal{S}(\mathbb{R}^d)$. If $\lim_{m\to\infty}\theta_m=0$ in $\mathcal{S}(\mathbb{R}^d)$ then it is clear that the right side of the inequality tends to zero with θ replaced by θ_m. Thus, $s_k^\vee\in\mathcal{S}'(\mathbb{R}^d)$.

Therefore, Proposition 4.3 applies and thus $D_\lambda s_k\in L^2(\hat{\mathbb{R}}^d)$ for all $\lambda>0$, and (4.2) is valid for $f=s_k$.

(b) We can now compute

$$\int|D_\lambda s_k(\gamma)|^2\,d\gamma=\int\left|s_k^\vee(t)\left(1-\frac{2\pi}{\omega_{d-1}}(|t|\lambda)^{-(d-2)/2}J_{(d-2)/2}(2\pi|t|\lambda)\right)\right|^2 dt$$

$$=\frac{1}{(2\pi)^{4k}}\int_0^\infty r^{d-4k}\Phi(r)\left(1-\frac{2\pi}{\omega_{d-1}}(r\lambda)^{-(d-2)/2}J_{(d-2)/2}(2\pi r\lambda)\right)^2\frac{dr}{r}.$$

Therefore, if $R=1/\lambda$ then

$$\frac{(2\pi)^{4k}}{\lambda^{4k-d}}\int|D_\lambda s_k(\gamma)|^2\,d\gamma=\int_0^\infty\Phi(r)\left(\frac{R}{r}\right)^{4k-d}\left(1-\frac{2\pi}{\omega_{d-1}}\left(\frac{r}{R}\right)^{-(d-2)/2}J_{(d-2)/2}\left(\frac{2\pi r}{R}\right)\right)^2\frac{dr}{r}$$

$$=K_k\otimes\Phi(R).$$

(c) Recall from the proof of Theorem 5.6 that

$$\frac{1}{|B(0,R)|}\int_{B(0,R)}|\varphi(t)|^2\,dt=\left(\frac{d}{\omega_{d-1}}K_A\right)\otimes\Phi(R)$$

and $|\mathcal{F}(K_A)|>0$ on $(\mathbb{R}^*_+)^\wedge$. Therefore, we can apply the Tauberian theorem, Theorem 2.2, to conclude that if

$$\lim_{R\to\infty}\frac{\omega_{d-1}}{|B(0,R)|}\int_{B(0,R)}|\varphi(t)|^2\,dt=C_\Phi,$$

then

$$\lim_{\lambda\to 0}\frac{c(d,k)(2\pi)^{4k}}{\lambda^{4k-d}}\int|D_\lambda s_k(\gamma)|^2\,d\gamma=C_\Phi. \qquad \square$$

6. Computations and zeros of Fourier transforms. The following lemma plays a role in Logan's incisive analysis of bandlimited functions [L]; the method used to prove the accompanying proposition is standard. The proposition is of the type that can be used to study the function L_k defined in Example 6.3. The function L_k arises in the Wiener–Plancherel formula involving the mean of $s_{k,R}$.

LEMMA 6.1. *Given $L>0$, there exists a real and even function $\varphi_L\in L^2(\mathbb{R})$ having the following properties: $\varphi_L<0$ on $(-\infty,-(1/2L))\cup((1/2L),\infty)$, $\hat{\varphi}_L>0$ on $(-L,0)\cup(0,L)$, and* supp $\hat{\varphi}_L=[-L,L]$, *e.g.,*

$$\varphi_L(t)=\frac{L}{\pi}\frac{\cos^2(\pi tL)}{1-(2tL)^2}$$

and

$$\hat{\varphi}_L(\gamma)=\begin{cases}\dfrac{1}{4}\sin\dfrac{\pi\gamma}{L}, & |\gamma|<L,\\ 0, & |\gamma|\geqq L.\end{cases}$$

PROPOSITION 6.2. *Given a nonnegative function $\psi\in(L^1(\mathbb{R})\cap L^2(\mathbb{R}))\backslash\{0\}$ and assuming $\psi=0$ on $(-1/2L,1/2L)$, there is $\rho_0\in(-L,L)$ for which* $(\operatorname{Re}\hat{\psi})(\rho_0)=0$.

Proof. Choose φ_L as in Lemma 6.1. By Parseval's formula and hypothesis, we compute

$$\begin{aligned}0&>\int_{|t|>(1/2L)}\psi(t)\varphi_L(t)\,dt=\int\psi(t)\varphi_L(t)\,dt\\&=\int\hat{\psi}(\gamma)\hat{\varphi}_L(-\gamma)\,d\gamma=\int_{-L}^{L}\hat{\psi}(t)\hat{\varphi}_L(-\gamma)\,d\gamma\\&=\int_{-L}^{L}(\operatorname{Re}\hat{\psi}(\gamma))\hat{\varphi}_L(-\gamma)\,d\gamma+i\int_{-L}^{L}(\operatorname{Im}\hat{\psi}(\gamma))\hat{\varphi}_L(-\gamma)\,d\gamma=a+ib.\end{aligned}$$

Clearly, $a<0$ and $b=0$. Also, $\hat{\psi}(0)=\int\psi(t)\,dt>0$ and so $\hat{\psi}(0)=(\operatorname{Re}\hat{\psi})(0)$. Since $a<0$ and $\hat{\varphi}_L(-\gamma)>0$ on $(-L,0)\cup(0,L)$, we can conclude that $\operatorname{Re}\hat{\psi}<0$ on some subset of positive measure of $(-L,L)$. This combines with the continuity of $\hat{\psi}$ and the fact that $(\operatorname{Re}\hat{\psi})(0)>0$ to yield the result. $\square$

Example 6.3. Define the function

$$L_k(r)=\begin{cases}\dfrac{1}{r^{d-4k}}\,I\left(\dfrac{1}{r}\right) & \text{for } r\in(0,1),\\ 0 & \text{for } r\geqq 1,\end{cases}$$

where

$$I(s)=\left|\frac{2\pi}{\omega_{d-1}}\,s^{-(d-2)/2}J_{(d-2)/2}(2\pi s)\right|^2=\frac{1}{\omega_{d-1}^2}\,|\hat{\mu}_{d-1}(2\pi s)|^2.$$

Clearly, $L_k(R/r)=0$ if $r<R$ and

$$\forall r>R,\quad L_k\left(\frac{R}{r}\right)=\left(\frac{2\pi}{\omega_{d-1}}\right)^2\left(\frac{R}{r}\right)^{4k-2}J_{(d-2)/2}\left(\frac{2\pi r}{R}\right)^2. \tag{6.1}$$

(a) We first observe that $L_k\in L^1(\mathbb{R}_+^*)$ if $4k>1$:

$$\int_0^\infty |L_k(r)|\frac{dr}{r}=\int_1^\infty r^{d-4k}|I(r)|\frac{dr}{r}\leqq\int_1^\infty r^{d-4k-1}\left|\frac{2\pi C}{\omega_{d-1}}\,r^{-(d-2)/2}r^{-1/2}\right|^2 dr$$

$$=\left(\frac{2\pi C}{\omega_{d-1}}\right)^2\int_1^\infty r^{d-4k-1}r^{-(d-1)}\,dr=\left(\frac{2\pi C}{\omega_{d-1}}\right)^2\frac{1}{4k-1}<\infty$$

if $4k>1$.

(b) Next, if $\Phi\in L^\infty(\mathbb{R}_+^*)$ and $4k>1$ then $L_k\otimes\Phi(r)$ exists and

$$L_k\otimes\Phi(r)=\int_r^\infty L_k\left(\frac{r}{s}\right)\Phi(s)\frac{ds}{s}=\int_r^\infty\left(\frac{s}{r}\right)^{d-4k}I\left(\frac{s}{r}\right)\Phi(s)\frac{ds}{s}.$$

(c) The reason for considering the function L_k is that the limit in (5.5) involving $s_{k,1/\lambda}$ can be replaced by one involving $\mathcal{M}_\lambda s_{k,1/\lambda}$, at least in the case where the first limit of (5.5) is assumed to exist. This follows from the proof of Theorem 5.6 and the following calculations:

$$\mathcal{M}_{1/R}s_{k,R}(\gamma)=\left(\frac{i}{2\pi}\right)^{2k}\int e^{-2\pi i t\cdot\gamma}\left(\frac{2\pi}{\omega_{d-1}}\left(\frac{|t|}{R}\right)^{-(d-2)/2}J_{(d-2)/2}\left(\frac{2\pi|t|}{R}\right)\frac{\varphi(t)}{|t|^{2k}}\,\chi_R(t)\right)dt$$

and, by Plancherel's theorem,

$$(2\pi)^{4k}\int|\mathcal{M}_{1/R}s_{k,R}(\gamma)|^2\,d\gamma$$

$$=\left(\frac{2\pi}{\omega_{d-1}}\right)^2\int_{B(0,R)^\sim}\left(\frac{R}{|t|}\right)^{d-2}J_{(d-2)/2}\left(\frac{2\pi|t|}{R}\right)^2\frac{|\varphi(t)|^2}{|t|^{4k}}\,dt$$

$$=\left(\frac{2\pi}{\omega_{d-1}}\right)^2\int_R^\infty\frac{r^{-4k+2}}{R^{-d+2}}J_{(d-2)/2}\left(\frac{2\pi r}{R}\right)^2\Phi(r)\frac{dr}{r}$$

$$=\left(\frac{2\pi}{\omega_{d-1}}\right)^2R^{d-4k}\int_R^\infty\left(\frac{R}{r}\right)^{4k-2}J_{(d-2)/2}\left(\frac{2\pi r}{R}\right)^2\Phi(r)\frac{dr}{r}=R^{d-4k}L_k\otimes\Phi(R),$$

where we have used (6.1) in the last step and where Φ is defined in terms of φ as in § 5.

7. Remarks on spectral estimation.

DEFINITION 7.1. Given $\varphi\in L^2_{\mathrm{loc}}(\mathbb{R}^d)$, define

$$\forall R>0,\quad P_{\varphi,R}(t)=\frac{1}{|B(0,R)|}\int_{B(0,R)}\varphi(t+x)\overline{\varphi(x)}\,dx.$$

Suppose that there is a continuous positive definite function P_φ for which $\lim_{R\to\infty} P_{\varphi,R} = P_\varphi$ in the $\sigma(M(\mathbb{R}^d), C_c(\mathbb{R}^d))$ topology, where $M(\mathbb{R}^d)$ is the space of measures on $\mathbb{R}^d$. Then $P_\varphi \in L^\infty(\mathbb{R}^d)$ is the *autocorrelation* of φ, and the positive measure $\mu_\varphi = \hat{P}_\varphi$ is the *power spectrum* of φ.

Remark 7.2. (a) Depending on the particular problem, the weak topology in Definition 7.1 can be replaced by various other convergence criteria, including pointwise convergence.

(b) Given $\varphi \in L^2_{\text{loc}}(\mathbb{R}^d)$ with power spectrum μ_φ, assume there is an increasing function $i(R)$ on $(0,\infty)$ for which $\sup_{|t|\leqq R} |\varphi(t)| \leqq i(R)$ and $\lim_{R\to\infty} i(R)^2/R = 0$. Then we can prove that

$$\forall \psi \in C_c(\mathbb{R}^d), \quad \lim_{R\to\infty} \frac{1}{|B(0,R)|} \int_{B(0,R)} |\psi * \varphi(t)|^2 \, dt = \int |\hat{\psi}(\gamma)|^2 \, d\mu_\varphi(\gamma), \tag{7.1}$$

[B2, § 5].

If we take $\psi = \delta$ in (7.1) then the left side of (7.1) is the arithmetic mean on the left side of our Wiener–Plancherel formula (5.6). Given $\varphi \in L^2_{\text{loc}}(\mathbb{R}^d)$ and combining formulas (5.6) and (7.1), it is then reasonable to expect that

$$\lim_{\lambda\to 0} \frac{c(d,k)(2\pi)^{4k}}{\omega_{d-1}\lambda^{4k-d}} |D_\lambda s_k|^2 = \mu_\varphi \tag{7.2}$$

in some weak topology, e.g., [B1, § 2.1] for the case $d = 1$. In this same spirit we provide the following calculation which Wiener made for the case $d = 1$ [W2, pp. 155–159].

Formal calculation 7.3. Given $\varphi \in L^2_{\text{loc}}(\mathbb{R}^d)$ with autocorrelation P_φ, for $t \in \mathbb{R}^d$,

$$\lim_{\lambda\to 0} \frac{c(d,k)(2\pi)^{4k}}{\omega_{d-1}\lambda^{4k-d}} \int |D_\lambda s_k(\gamma)|^2 \, e^{2\pi i t\cdot\gamma} \, d\gamma = P_\varphi(t). \tag{7.3}$$

Proof. (a) A direct calculation gives

$$\begin{aligned} P_\varphi(t) &= \lim_{R\to\infty} \frac{1}{|B(0,R)|} \int_{B(0,R)} \varphi(t+x)\overline{\varphi(x)} \, dx \\ &= \frac{1}{4} \lim_{R\to\infty} \frac{1}{|B(0,R)|} \int_{B(0,R)} \{|\varphi(t+x)+\varphi(x)|^2 - |\varphi(t+x)-\varphi(x)|^2 \\ &\qquad + i|\varphi(t+x)+i\varphi(x)|^2 - i|\varphi(t+x)-i\varphi(t)|^2\} \, dt \\ &\equiv \frac{1}{4}(K_1 - K_2 + iK_3 - iK_4). \end{aligned} \tag{7.4}$$

(b) Let $\psi(x) = \varphi(t+x) + c\varphi(x)$, where $|c| = 1$, and write $s_k(\theta)(\gamma) = (\theta E_k^\vee)\hat{}\,(\gamma)$, so that $s_k(\varphi) = s_k$. By the Wiener–Plancherel formula we compute

$$\begin{aligned} &\lim_{R\to\infty} \frac{1}{|B(0,R)|} \int_{B(0,R)} |\psi(x)|^2 \, dx \\ &\quad = \lim_{\lambda\to 0} \frac{c(d,k)(2\pi)^{4k}}{\omega_{d-1}\lambda^{4k-d}} \int |D_\lambda s_k(\tau_{-t}\varphi)(\gamma) + D_\lambda s_k(c\varphi)(\gamma)|^2 \, d\gamma \\ &\quad = \lim_{\lambda\to 0} \frac{c(d,k)(2\pi)^{4k}}{\omega_{d-1}\lambda^{4k-d}} \int |D_\lambda s_k(\tau_{-t}\varphi)(\gamma) - e^{2\pi i t\cdot\gamma} D_\lambda s_k(\varphi)(\gamma) \\ &\qquad\qquad + (c + e^{2\pi i t\cdot\gamma}) D_\lambda s_k(\varphi)(\gamma)|^2 \, d\gamma \\ &\quad = E + \lim_{\lambda\to 0} \frac{c(d,k)(2\pi)^{4k}}{\omega_{d-1}\lambda^{4k-d}} \int |D_\lambda s_k(\varphi)(\gamma)|^2 |c + e^{2\pi i t\cdot\gamma}|^2 \, d\gamma, \end{aligned} \tag{7.5}$$

where the "error" E is estimated by

$$\lim_{\lambda\to 0}\frac{c(d,k)(2\pi)^{4k}}{\omega_{d-1}\lambda^{4k-d}}\int |D_\lambda s_k(\tau_{-t}\varphi)(\gamma)-e^{2\pi it\cdot\gamma}D_\lambda s_k(\varphi)(\gamma)|^2\,d\gamma. \tag{7.6}$$

Under natural hypotheses, and implementing Example 2.4 and Proposition 4.3, we can show that the limit in (7.6) vanishes, i.e., $E=0$.

(c) We now combine the right side of (7.4) and (7.5) with $E=0$ for the four cases $c=\pm 1, \pm i$. Thus,

$$\begin{aligned}P_\varphi(t)=\frac{1}{4}\lim_{\lambda\to 0}\frac{c(d,k)(2\pi)^{4k}}{\omega_{d-1}\lambda^{4k-d}}\int |D_\lambda s_k(\gamma)|^2\\ \cdot\{(2+e_{-t}(\gamma)+e_t(\gamma))-(2-e_{-t}(\gamma)-e_t(\gamma))\\ +i(2+ie_{-t}(\gamma)-ie_t(\gamma))-i(2-ie_{-t}(\gamma)+ie_t(\gamma))\}\,d\gamma,\end{aligned}$$

where $e_u(\gamma)=e^{2\pi iu\cdot\gamma}$. Combining terms, we obtain (7.3). □

Formally, (7.2) and (7.3) are compatible. If we are given data φ_S on a set S, these formulas lead us to consider multidimensional *spectral estimators* molded from expressions of the form

$$\frac{c(d,k)(2\pi)^{4k}}{\omega_{d-1}\lambda^{4k-d}}|D_\lambda(\hat{\varphi}_S * E_k)|^2. \tag{7.7}$$

Instead of continuing this section with a quodlibetic discussion of spectral estimation, we shall view (7.7) as the prologue to our forthcoming work on the subject vis a vis classical algorithms, e.g., [IEa-d], [Ma], and evolutionary spectra for nonstationary processes, e.g., [AGT], [P, Chap. 11].

7.1. Notation. If G is a locally compact Abelian group, then $L^1_{\text{loc}}(G)$ is the space of locally integrable functions with respect to Haar measure and $L^1(G)$ is the subspace of integrable functions. $C_c(G)$ consists of all continuous functions on G having compact supports and $C_b(G)$ consists of all continuous bounded functions on G.

The Fourier transform $\hat{\psi}$ of $\psi\in L^1(\mathbb{R}^d)$ is defined by $\hat{\psi}(\gamma)=\int e^{-2\pi it\cdot\gamma}\psi(t)\,dt$, where $\int$ designates integration over $\mathbb{R}^d$; $f^\vee$ is the inverse Fourier transform of f. $A(\hat{\mathbb{R}}^d)$ is the set $\{\hat{\varphi}\colon \varphi\in L^1(\mathbb{R}^d)\}$ and $\mathcal{S}_0(\hat{\mathbb{R}}^d)$ is the set $\{f\in\mathcal{S}(\hat{\mathbb{R}}^d)\colon f^\vee=0$ on a neighborhood of $0\}$. If $\psi\in L^p(\mathbb{R}^d)$, then its usual L^p-norm is denoted by

$$\|\psi|L^p(\mathbb{R}^d)\|.$$

If S is a set then $S^\sim$ is its complement and χ_S is its characteristic function. For $R>0$,

$$\chi_R=\chi_{B(0,R)^\sim}.$$

We denote translation by $(\tau_\lambda f)(\gamma)=f(\gamma-\lambda)$. Finally, the unit sphere in $\mathbb{R}^d$ is $\Sigma_{d-1}=\{t\in\mathbb{R}^d\colon |t|=1\}$.

Acknowledgments. The author thanks two MITRE colleagues and former students, George Benke and Christopher Heil, for sharing their expertise and providing several valuable insights on this material. Also, besides our program on spectral estimation and Wiener-Plancherel formulas, further work on spherical Wiener-Plancherel formulas is forthcoming from George Benke. The referee suggested eliminating calculations in §§ 2 and 3, and kindly pointed out a number of places throughout the paper where Sobolev spaces might be used to advantage over our essentially L^1 approach.

SPECTRAL THEORY OF JACOBI MATRICES IN $l^2(\mathbb{Z})$ AND THE $su(1,1)$ LIE ALGEBRA*

D. R. MASSON† AND J. REPKA†

Abstract. The connection between orthogonal polynomials, continued fractions, difference equations, and self-adjoint Jacobi matrices acting in $l^2(\mathbb{Z}^+)$ and the extension of these connections to $l^2(\mathbb{Z})$ are reviewed. This yields three different representations for the resolvent of the Jacobi matrix: an integral representation in terms of orthogonal polynomials, a representation in terms of continued fractions, and a representation in terms of the subdominant (or minimal) solution to the associated difference equation. This latter representation is given explicitly in terms of hypergeometric functions for the cases of associated Meixner, Meixner-Pollaczek, and Laguerre polynomials. It is also shown that it is precisely these cases that occur in the unitary irreducible representations of $su(1,1)$ for the resolvent of a real linear combination of the generators of the algebra.

Key words. orthogonal polynomials, continued fractions, difference equations, Jacobi matrices, spectral theory, resolvent, Lie algebra, $su(1,1)$

AMS(MOS) subject classifications. 33A65, 17B15, 30B70, 40A15, 47B39

1. Introduction.

The classical moment problem [2] provides a natural link between properties of Jacobi matrices, continued fractions, and second-order difference equations. The usual setting for these connections is the Hilbert space $l^2(\mathbb{Z}^+)$, the space of all square summable complex sequences. With standard basis vectors $\{e_n\}_{n=0}^{\infty}$, elements of $l^2(\mathbb{Z}^+)$ are written $u=\sum_{n=0}^{\infty} u_n e_n$ and $v=\sum_{n=0}^{\infty} v_n e_n$ and the inner product is $(u, v)=\sum_{n=0}^{\infty} \bar{u}_n v_n$.

Here we will extend these connections to the case of bilaterally infinite Jacobi matrices acting in $l^2(\mathbb{Z})$, but limit our considerations to Jacobi matrices which are essentially self-adjoint on the domain of finite vectors, i.e., the case of deficiency indices (0, 0). We could also consider the cases of deficiency indices (1, 1) or (2, 2) and weighted l^2 spaces. For all of these in the case of Jacobi matrices associated with bilateral birth and death processes, we refer the reader to Pruitt [16], [17] (see also [7], [10]).

We first recall some results associated with unilaterally infinite Jacobi matrices and the classical moment problem. Consider the symmetric Jacobi matrix

$$A := \begin{pmatrix} a_0 & b_1 & & 0 \\ b_1 & a_1 & \ddots & \\ & \ddots & \ddots & \\ 0 & & & \end{pmatrix}, \qquad \begin{aligned} a_n &= (e_n, Ae_n) \in \mathbb{R}, \\ b_n &= (e_{n-1}, Ae_n) > 0, \end{aligned} \tag{1.1}$$

acting in $l^2(\mathbb{Z}^+)$, the associated continued fraction

$$\frac{1}{CF(z)} := \frac{1}{z - a_0 + K_{n=1}^{\infty}(-b_n^2/(z-a_n))}, \tag{1.2}$$

and the difference equation

$$b_{n+1} Y_{n+1}(z) - (z-a_n) Y_n(z) + b_n Y_{n-1}(z) = 0, \qquad n \geqq 0. \tag{1.3}$$

* Received by the editors November 20, 1989; accepted for publication (in revised form) June 11, 1990. This research was partially supported by the Natural Sciences and Engineering Research Council of Canada.

† Department of Mathematics, University of Toronto, Toronto, Canada, M5S 1A1.

If A is closed, with minimal domain, and self-adjoint (the determined case for the moment problem with moments $c_n = (e_0, A^n e_0)$) then for $z \notin \sigma(A)$, the spectrum of A, [20],

$$(e_0, (zI - A)^{-1} e_0) = \frac{1}{CF(z)}. \tag{1.4}$$

Also

$$\frac{1}{CF(z)} = \lim_{n\to\infty} \frac{Q_n(z)}{P_n(z)}. \tag{1.5}$$

Here $Q_n(z)/P_n(z)$ is the nth approximant of the continued fraction (1.2) (see [21]); $\{P_n\}_{n=0}^{\infty}$, $\{Q_n\}_{n=0}^{\infty}$ are orthogonal polynomial sets (of the first and second kind, respectively) satisfying the difference equations (1.3) subject to the initial conditions $P_0 = Q_1 = 1$, $P_{-1} = Q_0 = 0$. These polynomials are closely related to properties of A. In particular, $\{P_n(z)\}_{n=0}^{\infty}$ are orthogonal with respect to a probability measure $dw(x) = d(e_0, E_A(x)e_0)$, where $E_A(x)$ is the spectral family of orthogonal projections associated with the diagonalization of A. This follows from the fact that (1.1), (1.3) and the initial conditions for P_n imply that

$$e_n = P_n(A)e_0. \tag{1.6}$$

Thus using the functional calculus for self-adjoint operators [20] and (1.6) we obtain

$$(e_m, (zI - A)^{-1} e_n) = \int_{-\infty}^{\infty} \frac{P_m(x)P_n(x)}{z - x}\, dw(x), \qquad z \notin \sigma(A), \tag{1.7}$$

$$w(x) = (e_0, E_A(x)e_0).$$

The leading term in the large z asymptotic expansion of (1.7) gives the claimed orthogonality

$$\delta_{mn} = (e_m, e_n) = \int_{-\infty}^{\infty} P_m(x)P_n(x)\, dw\,(x). \tag{1.7'}$$

Another useful representation for $(zI - A)^{-1}$ can be obtained in terms of a subdominant (minimal) solution to (1.3) (cf. [12]). Let $\{Y_n^{(s)}(z)\}$ be a solution to (1.3) which is in $l^2(\mathbb{Z}^+)$. Since for a determined moment problem with $z \notin \sigma(A)$, we have that such l^2-solutions exist and are unique to within a constant multiple, this implies the subdominant property

$$\lim_{n\to\infty} Y_n^{(s)}(z)/\, Y_n^{(d)}(z) = 0, \qquad z \notin \sigma(A),$$

so long as $Y_n^{(s)}(z)$, $Y_n^{(d)}(z)$ are linearly independent solutions to (1.3). Pincherle's theorem [9] then yields

$$\frac{1}{CF(z)} = \frac{Y_0^{(s)}(z)}{b_0 Y_{-1}^{(s)}(z)}, \qquad z \notin \sigma(A), \tag{1.8}$$

so that (1.4) and (1.7) then give

$$(e_0, (zI - A)^{-1} e_0) = \int_{-\infty}^{\infty} \frac{dw\,(x)}{z - x} = \frac{Y_0^{(s)}(z)}{b_0 Y_{-1}^{(s)}(z)}. \tag{1.9}$$

More generally ([12]; see also Wall [21, Chap. 12]) we have

$$(e_m, (zI-A)^{-1}e_n) = \frac{P_m(z)\,Y_n^{(s)}(z)}{b_0\,Y_{-1}^{(s)}(z)}, \qquad m \leqq n. \tag{1.10}$$

In § 2 we extend the representations (1.4), (1.7), (1.9), and (1.10) for the resolvent of A to the case of bilaterally infinite Jacobi matrices acting in $l^2(\mathbb{Z})$. In § 3 these formulas are made explicit for the bilateral Jacobi matrices connected with associated Meixner, Meixner-Pollaczek, and Laguerre polynomials. In § 4 we give a purely algebraic calculation for the resolvent of a finite Jacobi matrix; it can be combined with Pincherle's theorem to give (1.4) and (1.5). In § 5 these results are applied to the discrete, principal, and complementary (supplementary) series representations of the Lie algebra $su(1,1)$.

2. Resolvent representations in $l^2(\mathbb{Z})$. Consider the complex Hilbert space of square summable bilateral sequences (column vectors)

$$l^2(\mathbb{Z}) := \left\{ u = (u_m) \mid u_m \in \mathbb{C},\ \sum_{m=-\infty}^{\infty} |u_m|^2 < \infty \right\}$$

with inner product

$$(u, v) := \sum_{m=-\infty}^{\infty} \bar{u}_m v_m$$

and standard orthonormal basis $\{e_n\}_{n=-\infty}^{\infty}$, $e_n := (\delta_{nm})$.

Let

$$A := \begin{pmatrix} \ddots & & & & & 0 \\ & a_{-1} & b_0 & & & \\ & b_0 & a_0 & b_1 & & \\ & & b_1 & a_1 & & \\ 0 & & & & \ddots & \end{pmatrix}, \qquad a_n \in \mathbb{R}, \quad b_n > 0 \tag{2.1}$$

be a closed symmetric minimal domain operator acting in $l^2(\mathbb{Z})$. That is, $a_n = (e_n, Ae_n)$, $b_{n+1} = (e_n, Ae_{n+1}) = (e_{n+1}, Ae_n)$, and

$$Ae_n = b_{n+1}e_{n+1} + a_n e_n + b_n e_{n-1}. \tag{2.2}$$

Associated with A we have the difference equation

$$b_{n+1}Y_{n+1}(z) - (z-a_n)Y_n(z) + b_n Y_{n-1}(z) = 0, \qquad n \in \mathbb{Z} \tag{2.3}$$

and the polynomial solutions $\{Y_n = P_n^{(k)}(z)\}_{n=-\infty}^{\infty}$, $k = 0, 1$ satisfying the initial conditions

$$P_n^{(k)}(z) = \delta_{nk}, \qquad n, k = 0, 1.$$

THEOREM 2.1. *A is self-adjoint if and only if*

$$\sum_{n=0}^{\infty} |P_n^{(1)}(z)|^2 = \infty, \qquad \sum_{n=-\infty}^{0} |P_n^{(0)}(z)|^2 = \infty \tag{2.4}$$

for some (and hence all) z such that $\operatorname{Im} z \neq 0$.

Proof. Condition (2.4) implies that the left and right lateral sections of A yield determined moment problems. We show that this is necessary and sufficient in order for A to be self-adjoint. Recall that A is self-adjoint if and only if A has deficiency

indices (0, 0). That is, if and only if $AY = zY$ has no nontrivial solution $Y \in l^2(\mathbb{Z})$ for some, and hence all, z with $\operatorname{Im} z \neq 0$, since by complex conjugation A must have equal deficiency indices [18, Thm. X.3]. Now $AY(z) = zY(z)$, $Y(z) = (Y_n(z))$ is equivalent to (2.3). Hence $Y_n(z) = c_0 P_n^{(0)}(z) + c_1 P_n^{(1)}(z)$. If $\sum_{n=0}^{\infty} |P_n^{(1)}(z)|^2 < \infty$, $\sum_{n=-\infty}^{0} |P_n^{(0)}(z)| < \infty$, then from the classical moment problem [2] it follows that all solutions to (2.2) are in $l^2(\mathbb{Z})$ and A has deficiency indices (2, 2). If $\sum_{n=0}^{\infty} |P_n^{(1)}(z)|^2 < \infty$, $\sum_{n=-\infty}^{0} |P_n^{(0)}(z)|^2 = \infty$, then all solutions to (2.3) are in $l^2(\mathbb{Z}^+)$ and a special choice of c_0, c_1 ($c_1/c_0 = -\lim_{n\to-\infty} P_n^{(0)}(z)/P_n^{(1)}(z)$) yields $Y(z) \in l^2(\mathbb{Z})$ so that A has deficiency indices (1, 1). If $\sum_{n=0}^{\infty} |P_n^{(1)}(z)| = \infty$, $\sum_{n=-\infty}^{0} |P_n^{(0)}(z)| < \infty$, then the special choice $c_0/c_1 = -\lim_{n\to\infty} P_n^{(1)}(z)/P_n^{(0)}(z)$ yields $Y(x) \in l^2(\mathbb{Z})$ so that A again has deficiency indices (1, 1). If $\sum_{n=0}^{\infty} |P_n^{(1)}(z)|^2 = \sum_{n=-\infty}^{0} |P_n^{(0)}(z)|^2 = \infty$, then for no choice of c_0, c_1 can we have $Y \in l^2(\mathbb{Z})$ ($\lim_{n\to\infty} P_n^{(0)}(z)/P_n^{(1)}(z) \neq \lim_{n\to-\infty} P_n^{(0)}(z)/P_n^{(1)}(z)$ since the former limit is $O(1/z)$ while the latter is $O(z)$), and A has deficiency indices (0, 0). □

COROLLARY 2.2. *A is self-adjoint if*

$$\sum_{n=0}^{\infty} \frac{1}{b_n} = \infty, \qquad \sum_{n=-\infty}^{0} \frac{1}{b_n} = \infty. \tag{2.5}$$

Proof. Condition (2.5) is sufficient for the determinate cases for the right and left lateral sections of A [2, p. 24]. □

Assuming that A is self-adjoint, we now derive three different representations for the resolvent of A. The first two have also been derived by Pruitt for the special case of bilaterally infinite birth and death processes [16], [17]. (See also [7], [10].)

2.1. Integral representation.

THEOREM 2.3. *Let A given by* (2.1) *be self-adjoint. Let $E_A(x)$, $x \in \mathbb{R}$, be its spectral family of orthogonal projections. Then*

$$\begin{aligned}(e_m, (zI - A)^{-1} e_n) &= \int_{\mathbb{R}} (z-x)^{-1} \{P_m^{(0)}(x) P_n^{(0)}(x)\, d\mu_{00}(x) + P_m^{(1)}(x) P_n^{(1)}(x)\, d\mu_{11}(x) \\ &\qquad + [P_m^{(0)}(x) P_n^{(1)}(x) + P_m^{(1)}(x) P_n^{(0)}(x)]\, d\mu_{01}(x)\}, \qquad z \notin \sigma(A) \end{aligned} \tag{2.6}$$

$$\mu_{ij}(x) = (e_i, E_A(x) e_j).$$

Proof. From (2.2) and (2.3) it follows that

$$e_n = P_n^{(0)}(A) e_0 + P_n^{(1)}(A) e_1 \tag{2.7}$$

and from the spectral theorem [20]

$$(zI - A)^{-1} = \int_{\mathbb{R}} (z-x)^{-1}\, dE_A(x). \tag{2.8}$$

From (2.7), (2.8) and the functional calculus for self-adjoint operators we obtain (2.6) with $\mu_{01}(x) = \mu_{10}(x)$ since A is real symmetric. □

Note that as $z \to \infty$ the leading $1/z$ term in (2.6) yields a four-term orthogonality

$$\delta_{nm} = (e_m, e_n) = \int_{\mathbb{R}} \sum_{i,j=0}^{1} P_m^{(i)}(x) P_n^{(i)}(x)\, d\mu_{ij}(x) \tag{2.9}$$

involving four sets of polynomials $\{P_n^{(i)}(x)\}$, $i = 0, 1$, $n \geqq 0$, $n < 0$ and four measures $d\mu_{ij}$, $i, j = 0, 1$ (with $d\mu_{00}$, $d\mu_{11}$ positive and two equal-signed measures $d\mu_{01} = d\mu_{10}$).

This is in contrast with the single set of orthogonal polynomials and positive measure associated with a semi-infinite Jacobi matrix and a determined classical moment problem given by (1.7).

2.2. Subdominant representation. Let $Y_n^{(R)}(z)$, $Y_n^{(L)}(z)$ be solutions to (2.3) satisfying the boundary conditions

$$\lim_{n\to\infty} Y_n^{(R)}(z)/Y_n^{(L)}(z)=0,$$

$$\lim_{n\to-\infty} Y_n^{(L)}(z)/Y_n^{(R)}(z)=0.$$

These will be called right and left subdominant solutions, respectively. Their existence and uniqueness to within a constant multiple is assured for $\operatorname{Im} z\neq 0$ when condition (2.4) is satisfied since the moment problem associated with the left and right lateral portions of A are then determined [2].

THEOREM 2.4. *If A given by* (2.1) *is self-adjoint and* $\operatorname{Im} z\neq 0$, *then*

$$(e_m,(zI-A)^{-1}e_n)=\begin{cases}\dfrac{Y_m^{(L)}(z)\,Y_n^{(R)}(z)}{b_{k+1}W(Y_k^{(R)}(z),\,Y_k^{(L)}(z))}, & m\leqq n,\\[2ex] \dfrac{Y_m^{(R)}(z)\,Y_n^{(L)}(z)}{b_{k+1}W(Y_k^{(R)}(z),\,Y_k^{(L)}(z))}, & n\leqq m,\end{cases} \tag{2.10}$$

where

$$W(Y_k^{(R)}(z),\,Y_k^{(L)}(z))=Y_k^{(R)}(z)\,Y_{k+1}^{(L)}(z)-Y_{k+1}^{(R)}(z)\,Y_k^{(L)}(z).$$

Proof. Let $R_{m,n}(z)=(e_m,(zI-A)^{-1}e_n)$. Then since A is symmetric we have $R_{m,n}(z)=R_{n,m}(z)$. From (2.2) we have

$$\begin{aligned} &zR_{m,n}(z)-b_{n+1}R_{m,n+1}(z)-a_nR_{m,n}(z)-b_nR_{m,n-1}(z)\\ &\quad=(e_m,(zI-A)^{-1}(zI-A)e_n)=\delta_{mn}.\end{aligned} \tag{2.11}$$

Thus for $m\neq n$ we have

$$(e_m,(zI-A)^{-1}e_n)=\begin{cases}\displaystyle\sum_{i,j=1}^{2} c_{i,j}\,Y_m^{(i)}(z)\,Y_n^{(j)}(z), & m<n,\\[2ex] \displaystyle\sum_{i,j=1}^{2} c_{i,j}\,Y_n^{(i)}(z)\,Y_m^{(j)}(z), & n<m,\end{cases}$$

where $Y_n^{(i)}(z)$, $i=1,2$, are solutions to (2.3). Now $R_{m,n}$ is a Fourier coefficient with respect to either subscript. That is $\sum_{n=-\infty}^{\infty}|R_{m,n}(z)|^2<\infty$. Since the right and left subdominant solutions are, to within a constant multiple, the unique right and left lateral square summable solutions we must have

$$(e_m,(zI-A)^{-1}e_n)=\begin{cases}cY_m^{(L)}(z)\,Y_n^{(R)}(z), & m<n,\\ cY_n^{(L)}(z)\,Y_m^{(R)}(z), & n<m.\end{cases}$$

The constant c is determined from (2.11) for $m=n$. This yields

$$c(zY_n^{(L)}(z)\,Y_n^{(R)}(z)-b_{n+1}Y_{n+1}^{(L)}(z)\,Y_{n+1}^{(R)}(z)-a_nY_n^{(L)}(z)\,Y_n^{(R)}(z)-b_nY_n^{(R)}(z)\,Y_{n-1}^{(L)}(z))=1.$$

That is, using (2.3) for $Y_n=Y_n^{(L)}(z)$, $c(b_{n+1}Y_n^{(R)}(z)\,Y_{n+1}^{(L)}(z)-b_{n+1}Y_n^{(L)}(z)\,Y_{n+1}^{(R)}(z))=1$. Thus $c=1/b_{n+1}W(Y_n^{(R)}(z),\,Y_n^{(L)}(z))$, which is independent of n. □

2.3. Continued fraction representation. The resolvent elements may be expressed in terms of continued fractions either by taking the limits of the resolvent elements of the finite portions of A derived in § 4 or by applying Pincherle's theorem [9] to the representation (2.10). Here we choose the latter.

Recall that Pincherle's theorem yields a continued fraction representation for a ratio of subdominant terms. Thus

$$-\frac{b_{n+1}Y_{n+1}^{(R)}(z)}{Y_n^{(R)}(z)} = K_{k=1}^{\infty}\left(\frac{-b_{n+k}^2}{z-a_{n+k}}\right), \tag{2.12}$$

$$\frac{b_{n+1}Y_{n+1}^{(L)}(z)}{Y_n^{(L)}(z)} = z-a_n+K_{k=1}^{\infty}\left(\frac{-b_{n+1-k}^2}{z-a_{n-k}}\right), \tag{2.13}$$

where we use the standard notation

$$K_{k=1}^{\infty}\left(\frac{u_k}{v_k}\right) := \lim_{N\to\infty} \cfrac{u_1}{v_1+\cfrac{u_2}{v_2+\ddots\cfrac{}{\cfrac{u_N}{v_N}}}}.$$

THEOREM 2.5. *If A given by* (2.1) *is self-adjoint and* $\operatorname{Im} z \neq 0$, *then*

$$(e_n,(zI-A)^{-1}e_n) = \frac{1}{z-a_n+K_{k=1}^{\infty}(-b_{n+k}^2/(z-a_{n+k}))+K_{k=1}^{\infty}(-b_{n+1-k}^2/(z-a_{n-k}))}. \tag{2.14}$$

Proof. Since A is self-adjoint we have the existence of right and left subdominant solutions $Y_n^{(R)}(z)$, $Y_n^{(L)}(z)$ to (2.3) for $\operatorname{Im} z \neq 0$. From (2.10) with $k=n$ we have

$$(e_n,(zI-A)^{-1}e_n) = \frac{1}{b_{n+1}(Y_{n+1}^{(L)}(z)/Y_n^{(L)}(z)-Y_{n+1}^{(R)}(z)/Y_n^{(R)}(z))}.$$

The representations (2.12), (2.13) then yield (2.14). □

Remarks. (1) The off-diagonal elements of the resolvent are considerably more complicated and involve sums and products of continued fractions. We do not derive them here. However, an expression for the general matrix element of the resolvent for finite portions of A is given in § 4.

(2) Note that for a semi-infinite Jacobi matrix one of the two continued fractions in (2.14) reduces to a finite fraction. In particular, if $b_0=0$ we have the standard expression (see (1.2), (1.4))

$$(e_0,(zI-A)^{-1}e_0) = \frac{1}{z-a_0+K_{k=1}^{\infty}(-b_k^2/(z-a_k))}.$$

(3) Note that (2.14) is the Stieltjes transform of a positive measure. It would be interesting to find the semi-infinite Jacobi matrix

$$A' = \begin{pmatrix} a_0' & b_1' & & 0 \\ b_1' & a_1' & \ddots & \\ & \ddots & \ddots & \\ 0 & & & \end{pmatrix}$$

such that

$$(e_n,(zI-A)^{-1}e_n) = \frac{1}{z-a_0'+K_{k=1}^{\infty}(-b_k'^2/(z-a_k'))}$$

and relate the elements a_n' and b_{n+1}', $n\in\mathbb{Z}^+$ to the original a_n and b_n, $n\in\mathbb{Z}$.

3. Explicit cases. We derive explicit formulas for the resolvent in cases related to associated Meixner, Meixner-Pollaczek, and Laguerre polynomials. That is the cases $a_n = dn$, $b_n^2 = an^2 + bn + c$ with a, b, c, d real, $a, c \neq 0$, and $b_n^2 > 0$.

The resolvent representation (2.10) of § 2 is made explicit through the use of hypergeometric solutions to the associated difference equation and their asymptotic behaviour. These solutions are given in [5] and [12].

3.1. Associated Meixner. Let $a_n = dn$, $b_n^2 = an^2 + bn + c > 0$, $d^2 > 4a > 0$ and consider the difference equation

$$b_{n+1} Y_{n+1}(z) - (z - a_n) Y_n(z) + b_n Y_{n-1}(z) = 0. \tag{3.1}$$

By renormalizing the solutions in [12, eq. (2.3)] we obtain a pair of linearly independent solutions

$$\begin{aligned} Y_{n-1}^{(1),\pm}(z) &= \left(\frac{\pm\sqrt{a}}{\mu}\right)^n \frac{\sqrt{\Gamma(n+\alpha)\Gamma(n+\beta)}}{\Gamma(n+\gamma_\pm(z))}\, {}_2F_1\left(\begin{matrix} n+\alpha, n+\beta \\ n+\gamma_\pm(z) \end{matrix}; \delta_\pm\right), \\ \mu &= \sqrt{d^2-4a}, \qquad an^2+bn+c = a(n+\alpha)(n+\beta), \\ \delta_\pm &= \frac{1 \pm d/\mu}{2}, \qquad \gamma_\pm(z) = (1+\alpha+\beta)\delta_\pm \pm \frac{z}{\mu}. \end{aligned} \tag{3.2}$$

Note that if $d > 0$ then $\delta_- < \frac{1}{2}$. Thus the $Y_n^{(1),-}$ solution is then well defined either through the power series expansion of ${}_2F_1(\delta_-)$ or its analytic continuation. However, the $Y_n^{(1),+}$ solution will have an ambiguity if $\delta_- < 0$ since we then have $\delta_+ > 1$ and evaluation of ${}_2F_1(\delta_+)$ on the branchcut $[1, \infty)$. This ambiguity is resolved by a consistent evaluation of ${}_2F_1$ and does not affect the final result. For $d < 0$ the situation is similar except that we have $\delta_+ < \frac{1}{2}$ and $\delta_- > 1$ if $\delta_+ < 0$.

The $n \to \infty$ asymptotic behaviour of these solutions is obtained through the use of the transformation

$${}_2F_1\left(\begin{matrix} a, b \\ c \end{matrix}; z\right) = (1-z)^{c-a-b}\, {}_2F_1\left(\begin{matrix} c-a, c-b \\ c \end{matrix}; z\right),$$

and the estimate

$${}_2F_1\left(\begin{matrix} a, b \\ c \end{matrix}; z\right) = 1 + O\left(\frac{1}{\operatorname{Re} c}\right), \qquad z \notin [1, \infty), \quad \operatorname{Re} c \to \infty.$$

Thus we obtain as $n \to \infty$

$$Y_n^{(1),\pm}(z) = \left(\pm\frac{\sqrt{a}}{\mu}\right)^{n+1} n^{(\alpha+\beta-2\gamma_\pm)/2} (\delta_\mp)^{\gamma_\pm - (\alpha+\beta+n+1)} \left(1 + O\left(\frac{1}{n}\right)\right). \tag{3.3}$$

A second pair of linearly independent solutions is given by

$$Y_n^{(2),\pm}(z) = \left(\mp\frac{\mu}{\sqrt{a}}\right)^{n+1} \frac{\sqrt{\Gamma(-n-\alpha)\Gamma(-n-\beta)}}{\Gamma(1-n-\gamma_\pm(z))}\, {}_2F_1\left(\begin{matrix} -n-\alpha, -n-\beta \\ 1-n-\gamma_\pm(z) \end{matrix}; \delta_\pm\right). \tag{3.4}$$

This follows from a renormalization of [12, eq. (2.7)] after correcting a misprint (replace $(\pm\mu)^n$ by $(\mp\mu)^n$). The $n \to -\infty$ asymptotic behaviour of these solutions follows similarly and is given by

$$Y_n^{(2),\pm}(z) = \left(\mp\frac{\mu}{\sqrt{a}}\right)^{n+1} (-n)^{(2\gamma_\pm - (\alpha+\beta+1))/2} (\delta_\mp)^{n+\alpha+\beta-\gamma_\pm} \left(1 + O\left(\frac{1}{n}\right)\right). \tag{3.5}$$

From the above asymptotics it is clear that we have right and left subdominant solutions

$$Y_n^{(R)}(z)=\begin{cases} Y_n^{(1),-}(z), & d>0,\\ Y_n^{(1),+}(z), & d<0,\end{cases} \tag{3.6}$$

$$Y_n^{(L)}(z)=\begin{cases} Y_n^{(2),-}(z), & d>0,\\ Y_n^{(2),+}(z), & d<0.\end{cases} \tag{3.7}$$

To apply the resolvent formula (2.10) of § 2 it remains only to calculate $b_{k+1}W(Y_k^{(R)}(z), Y_k^{(L)}(z))$. To this end we use the identity [8, eq. (34), p. 107]

$$u_2=\frac{\Gamma(a+b+1-c)\Gamma(1-c)}{\Gamma(a+1-c)\Gamma(b+1-c)}u_1+\frac{\Gamma(a+b+1-c)\Gamma(c-1)}{\Gamma(a)\Gamma(b)}u_5,$$

$$u_1={}_2F_1\left(\begin{matrix}a,b\\c\end{matrix};z\right),\qquad u_2={}_2F_1\left(\begin{matrix}a,b\\a+b+1-c\end{matrix};1-z\right),$$

$$u_5=z^{1-c}(1-z)^{c-a-b}{}_2F_1\left(\begin{matrix}1-a,1-b\\2-c\end{matrix};z\right)$$

to obtain the connecting formula

$$\begin{aligned} &Y_n^{(1),\pm}(z)=C_\pm Y_n^{(1),\mp}(z)+D_\pm Y_n^{(2),\pm}(z),\\ &C_\pm=\pi^{-1}\Gamma(1+\alpha-\gamma_\pm(z))\Gamma(1+\beta-\gamma_\pm(z))\sin\pi\gamma_\pm(z),\\ &D_\pm=\pi^{-1}\delta_\pm^{1-\gamma_\pm}\delta_\mp^{1-\gamma_\mp}\Gamma(1+\alpha-\gamma_\pm(z))\Gamma(1+\beta-\gamma_\pm(z))\sqrt{\sin\pi\alpha\sin\pi\beta}\,. \end{aligned} \tag{3.8}$$

From (3.5)-(3.8) it now follows that (by calculating $b_{k+1}W(Y_k^{(R)}(z), Y_k^{(L)}(z))$ asymptotically as $k\to\infty$)

$$b_{k+1}W(Y_k^{(R)}(z), Y_k^{(L)}(z))=\begin{cases}\dfrac{\mu\sin\pi\gamma_-(z)}{\sqrt{\sin\pi\alpha\sin\pi\beta}}, & d>0,\\[2ex] \dfrac{-\mu\sin\pi\gamma_+(z)}{\sqrt{\sin\pi\alpha\sin\pi\beta}}, & d<0.\end{cases} \tag{3.9}$$

We summarize these calculations with Theorem 3.1.

THEOREM 3.1. *Let $A=(A_{m,n})$ be a closed symmetric tridiagonal matrix acting in $l^2(\mathbb{Z})$ with $A_{n,n}=dn$, $A_{n,n-1}=A_{n-1,n}=\sqrt{a(n+\alpha)(n+\beta)}$, and $d^2>4a>0$. Then A is self-adjoint and for $m\leqq n$,*

$$\begin{aligned}((zI-A)^{-1})_{m,n}=&\frac{(-1)^{n+1}\mu^{m-n-1}a^{(n-m)/2}\sqrt{\sin\pi\alpha\sin\pi\beta}}{\sin\pi\gamma_-(z)}\\ &\times\frac{\sqrt{\Gamma(-m-\alpha)\Gamma(-m-\beta)}}{\Gamma(1-m-\gamma_-(z))}{}_2F_1\left(\begin{matrix}-m-\alpha,-m-\beta\\1-m-\gamma_-(z)\end{matrix};\delta_-\right)\\ &\times\frac{\sqrt{\Gamma(1+n+\alpha)\Gamma(1+n+\beta)}}{\Gamma(1+n+\gamma_-(z))}{}_2F_1\left(\begin{matrix}1+n+\alpha,1+n+\beta\\1+n+\gamma_-(z)\end{matrix};\delta_-\right),\end{aligned} \tag{3.10}$$

$$\delta_-=\frac{1-d/\mu}{2},\qquad \gamma_-(z)=(1+\alpha+\beta)\delta_--\frac{z}{\mu},$$

where

$$\mu=\begin{cases}\sqrt{d^2-4a}, & d>0,\\ -\sqrt{d^2-4a}, & d<0.\end{cases} \tag{3.11}$$

Proof. Formula (3.10) follows from (2.10), (3.3)-(3.7), and (3.9). □

COROLLARY 3.2. *With the assumptions of Theorem* 3.1, *A has a discrete spectrum of isolated eigenvalues* $\{z_m\}_{m=-\infty}^{\infty}$ *given by*

$$z_m = m\mu + \tfrac{1}{2}(1+\alpha+\beta)(\mu - d), \qquad m \in \mathbb{Z}. \tag{3.12}$$

Proof. We have ${}_2F_1(\begin{smallmatrix}a,b\\c\end{smallmatrix}; z)/\Gamma(c)$ an entire function of c. It follows that the only resolvent singularities of (3.10) are given by the vanishing of $\sin \pi\gamma_-(z)$. That is, $\gamma_-(z) = m$, $m \in \mathbb{Z}$. Solving for z yields (3.12). □

Remarks. (1) It is curious that the eigenvalues given by (3.12) depend only on $\alpha+\beta$ while the off-diagonal elements of A involve both $\alpha+\beta$ and $\alpha\beta$. Thus, in terms of the original parameters a, b, c, d, we have the surprising fact that the eigenvalues depend only on a, b, d and are independent of c.

(2) Note that as $\mu \to 0+$ the eigenvalue spacing tends to zero and we obtain the associated Laguerre case of § 3.3.

3.2. Associated Meixner–Pollaczek. Let $a_n = dn$, $b_n^2 = an^2 + bn + c > 0$, $d^2 < 4a$. The solutions to (3.1) and their asymptotics are again given by (3.2)-(3.5) with $\mu = i\sqrt{4a - d^2}$. However, the right and left subdominant solutions are now changed because $\delta_\pm$ is complex with $\operatorname{Re}\delta_\pm = \frac{1}{2}$ and $|\delta_\pm| = a/(4a-d^2)$. Thus the asymptotic behaviour of (3.4) and (3.5) now dictates

$$Y_n^{(R)}(z) = \begin{cases} Y_n^{(1),-}(z), & \operatorname{Im} z < 0, \\ Y_n^{(1),+}(z), & \operatorname{Im} z > 0, \end{cases} \tag{3.13}$$

$$Y_n^{(L)}(z) = \begin{cases} Y_n^{(2),+}(z), & \operatorname{Im} z < 0, \\ Y_n^{(2),-}(z), & \operatorname{Im} z > 0. \end{cases} \tag{3.14}$$

The connecting formula (3.8) and its asymptotic behaviour now yields

$$b_{k+1} W(Y_k^{(R)}(z), Y_k^{(L)}(z)) = \begin{cases} \pi\mu/\Gamma(1+\alpha-\gamma_-)\Gamma(1+\beta-\gamma_-)\sqrt{\sin\pi\alpha \sin\pi\beta}, & \operatorname{Im} z > 0, \\ -\pi\mu/\Gamma(1+\alpha-\gamma_+)\Gamma(1+\beta-\gamma_+)\sqrt{\sin\pi\alpha \sin\pi\beta}, & \operatorname{Im} z < 0. \end{cases} \tag{3.15}$$

The application of (3.13)-(3.15) to (2.10) then gives Theorem 3.3.

THEOREM 3.3. *Let* $A = (A_{m,n})$ *be a closed symmetric tridiagonal matrix acting in* $l^2(\mathbb{Z})$ *with* $A_{n,n} = dn$, $A_{n,n-1} = A_{n-1,n} = \sqrt{a(n+\alpha)(n+\beta)}$ *and* $d^2 < 4a$. *Then A is self-adjoint and for* $m \leqq n$ *and* $\operatorname{Im} z \neq 0$ *we have*

$$\begin{aligned} ((zI - A)^{-1})_{m,n} = {} & \frac{\Gamma(1+\alpha-\gamma_-(z))\Gamma(1+\beta-\gamma_-(z))\sqrt{\sin\pi\alpha \sin\pi\beta}}{\pi\mu} \\ & \times \left(\frac{\sqrt{a}}{\mu}\right)^{n+1} \frac{\sqrt{\Gamma(1+n+\alpha)\Gamma(1+n+\beta)}}{\Gamma(1+n+\gamma_+(z))} {}_2F_1\left(\begin{matrix}1+n+\alpha, 1+n+\beta \\ 1+n+\gamma_+(z)\end{matrix}; \delta_+\right) \\ & \times \left(\frac{\mu}{\sqrt{a}}\right)^{m+1} \frac{\sqrt{\Gamma(-m-\alpha)\Gamma(-m-\beta)}}{\Gamma(1-m-\gamma_-(z))} {}_2F_1\left(\begin{matrix}-m-\alpha, -m-\beta \\ 1-m-\gamma_-(z)\end{matrix}; \delta_-\right), \end{aligned} \tag{3.16}$$

$$\delta_\pm = \frac{1}{2}\left(1 \pm \frac{d}{\mu}\right), \qquad \gamma_\pm(z) = (1+\alpha+\beta)\delta_\pm \pm \frac{z}{\mu},$$

$$\mu = \begin{cases} i\sqrt{4a-d^2}, & \operatorname{Im} z > 0, \\ -i\sqrt{4a-d^2}, & \operatorname{Im} z < 0. \end{cases}$$

3.3. Associated Laguerre. Let $a_n = dn$, $b_n^2 = an^2 + bn + c > 0$, $d^2 = 4a \neq 0$. Then by renormalizing the solutions (2.16), (2.17), (2.19), and (2.20) in [12] we obtain pairwise linearly independent solutions to (3.1) given by

$$Y_n^{(1)}(z) = (-1)^{n+1}\sqrt{\Gamma(1+n+\alpha)\Gamma(1+n+\beta)}\; U(1+n+\alpha;\, \alpha-\beta+1;\, x), \tag{3.17}$$

$$Y_n^{(2)}(z) = (-1)^{n+1}\frac{\Gamma(1+n+\alpha)}{\sqrt{\Gamma(1+n+\alpha)\tau(1+n+\beta)}}\,{}_1F_1(1+n+\alpha;\, \alpha-\beta+1;\, x), \tag{3.18}$$

$$Y_n^{(3)}(z) = \sqrt{\Gamma(-n-\alpha)\Gamma(-n-\beta)}\; U(-n-\alpha;\, \beta-\alpha+1;\, -x), \tag{3.19}$$

$$Y_n^{(4)}(z) = \frac{\sqrt{\Gamma(-n-\alpha)\Gamma(-n-\beta)}}{\Gamma(-n-\beta)}\,{}_1F_1(-n-\alpha;\, \beta-\alpha+1;\, -x),$$

$$\begin{aligned} &x = -\frac{2z}{d} - \frac{4b}{d^2} - 1, \\ &-x = e^{-i\pi\varepsilon}x, \qquad \varepsilon = \begin{cases} 1, & \arg x > 0, \\ -1, & \arg x \leqq 0, \end{cases} \\ &an^2 + bn + c = a(n+\alpha)(n+\beta). \end{aligned} \tag{3.20}$$

In the above we have used Slater's notation [19] for the confluent hypergeometric functions. Again following Slater, we have confluent hypergeometric functions y_i, $i = 1, \cdots, 8$ with

$$y_1 = {}_1F_1(a;\, b;\, x), \qquad y_4 = x^{1-b}e^x\,{}_1F_1(1-a;\, 2-b;\, -x),$$
$$y_5 = U(a;\, b;\, x), \qquad y_8 = e^x x^{1-b}U(1-b;\, 2-b;\, -x),$$

and $y_3 = y_1$, $y_4 = y_2$, $y_6 = y_5$, $y_7 = e^{-i\pi\varepsilon(1-b)}y_8$. Thus

$$\begin{aligned} Y_n^{(1)} &= (-1)^{n+1}\sqrt{\Gamma(n+1+\alpha)\Gamma(n+1+\beta)}\; y_5, \\ Y_n^{(2)} &= (-1)^{n+1}\frac{\Gamma(1+n+\alpha)}{\sqrt{\Gamma(1+n+\alpha)\Gamma(1+n+\beta)}}\, y_1, \\ Y_n^{(3)} &= \sqrt{\Gamma(-n-\alpha)\Gamma(-n-\beta)}\; e^{-x}x^{\alpha-\beta}y_8, \\ Y_n^{(4)} &= \frac{\sqrt{\Gamma(-n-\alpha)\Gamma(-n-\beta)}}{\Gamma(-n-\beta)}\, e^{-x}x^{\alpha-\beta}y_4 \end{aligned}$$

with confluent parameters $a = 1+n+\alpha$, $b = \alpha-\beta+1$.

From the connecting formula [19, eq. (2.1.54)]

$$y_1 = \frac{\Gamma(b)}{\Gamma(b-a)}\, e^{i\pi\varepsilon a}y_5 + \frac{\Gamma(b)}{\Gamma(a)}\, e^{\varepsilon i\pi(a-b)}y_7,$$

we then have

$$Y_n^{(2)}(z) = \Gamma(\alpha-\beta+1)\; e^{\varepsilon\pi i\alpha}[\sin\pi\beta\, Y_n^{(1)}(z) - e^x x^{\beta-\alpha}\sqrt{\sin\pi\alpha\,\sin\pi\beta}\; Y_n^{(3)}(z)] \tag{3.21}$$

and three other connecting formulas which follow from [19, eqs. (2.1.55)-(2.1.57)].

The large n asymptotic behaviour of $Y_n^{(1)}$, $Y_n^{(2)}$ is obtained from [19, eqs. (4.5.42), (4.6.43)], This yields

$$Y_n^{(2)}(z) = (-1)^{n+1}\; e^{x/2}x^{(\beta-\alpha)/2}\Gamma(\alpha-\beta+1)I_{\alpha-\beta}(2\sqrt{nx})\left(1 + O\left(\frac{1}{\sqrt{n}}\right)\right), \tag{3.22}$$

$$Y_n^{(1)}(z) = 2(-1)^{n+1}\; e^{x/2}x^{(\beta-\alpha)/2}K_{\alpha-\beta}(2\sqrt{nx})\left(1 + O\left(\frac{1}{\sqrt{n}}\right)\right) \tag{3.23}$$

in terms of Bessel functions of imaginary argument.

Now for $|\arg u| < \pi/2$, we have

$$I_\nu(u) \sim \frac{e^u}{\sqrt{2\pi u}}, \qquad K_\nu(u) \sim \sqrt{\frac{\pi}{2u}}\, e^{-u}.$$

Thus

$$Y_n^{(R)}(z) = Y_n^{(1)}(z), \qquad -\pi < \arg x < \pi. \tag{3.24}$$

Similarly, we obtain the $n \to -\infty$ asymptotic behaviour of $Y_n^{(3)}$, $Y_n^{(4)}$ so that

$$Y_n^{(L)}(z) = Y_n^{(3)}(z), \qquad -\pi < \arg(-x) < \pi. \tag{3.25}$$

Thus $b_{n+1} W(Y_n^{(R)}(z), Y_n^{(L)}(z)) = b_{n+1} W(Y_n^{(1)}(z), Y_n^{(3)}(z))$, $\operatorname{Im} z \neq 0$, and from (3.21)

$$b_{n+1} W(Y_n^{(1)}(z), Y_n^{(3)}(z)) = \frac{-\pi\, e^{-\pi i \varepsilon \alpha}\, e^{-x} x^{\alpha-\beta}}{\Gamma(\alpha-\beta+1)\sqrt{\sin \pi\alpha \sin \pi\beta}}\, b_{n+1} W(Y_n^{(1)}(z), Y_n^{(2)}(z)).$$

The right-hand side may then be calculated from the asymptotic behaviour of (3.22) and (3.23). This yields

$$b_{n+1} W(Y_n^{(R)}(z), Y_n^{(L)}(z)) = \frac{\pi\sqrt{a}\, e^{-i\pi\varepsilon\alpha}}{\sqrt{\sin \pi\alpha \sin \pi\beta}}. \tag{3.26}$$

The above calculations are summarized by Theorem 3.4.

THEOREM 3.4. *Let $A = (A_{m,n})$ be a closed symmetric tridiagonal matrix acting in $l^2(\mathbb{Z})$ with $A_{n,n} = dn$, $A_{n-1,n} = A_{n,n-1} = \sqrt{a(n+\alpha)(n+\beta)}$, $d^2 = 4a \neq 0$. Then A is self-adjoint and for $m \leqq n$ and* $\operatorname{Im} z \neq 0$,

$$\begin{aligned}((zI - A)^{-1})_{m,n} = {} & 2(-1)^{n+1} \frac{\sqrt{\sin \pi\alpha \sin \pi\beta}}{\pi d}\, e^{i\pi\varepsilon\alpha} \\ & \times \sqrt{\Gamma(-m-\alpha)\Gamma(-m-\beta)}\; U(-m-\alpha; \beta-\alpha+1; -x) \\ & \times \sqrt{\Gamma(1+n+\alpha)\Gamma(1+n+\beta)}\; U(1+n+\alpha; \alpha-\beta+1; x),\end{aligned} \tag{3.27}$$

$$x = -\frac{2z}{d} - \frac{4b}{d^2} - 1,$$

$$-x = e^{-i\pi\varepsilon} x, \qquad \varepsilon = \begin{cases} 1, & \arg x > 0, \\ -1, & \arg x \leqq 0. \end{cases}$$

Remark. We should also be able to obtain explicit expressions for the polynomials and measures in the resolvent representation (2.6). The polynomials are, of course, the associated polynomials of Meixner, Meixner-Pollaczek, or Laguerre. The measures would be obtained by applying the Stieltjes-Perron inversion formula to the resolvent representations obtained above. We do not attempt this here.

4. Finite matrices. In this section we give an algebraic development for the resolvent formula (2.14), based on a calculation of the inverse of a truncated Jacobi matrix. Beginning with the doubly infinite Jacobi matrix A of (2.1), for each $M \leqq N$ we form the finite truncated Jacobi matrix

$$A_N^M = \begin{pmatrix} a_M & b_{M+1} & & 0 \\ b_{M+1} & \ddots & \ddots & \\ & \ddots & \ddots & b_N \\ 0 & & b_N & a_N \end{pmatrix}. \tag{4.1}$$

We calculate its inverse by Cramer's rule. If $i<j$, the ijth minor is

$$\det\begin{pmatrix} \underline{A_{i-1}^M\,|} & & & & & & \\ & b_i & 0 & 0 & & & \\ & b_{i+1} & a_{i+1} & b_{i+2} & & & \\ & 0 & b_{i+2} & \ddots & \ddots & & \\ & & & \ddots & a_{j-2} & b_{j-1} & 0 \\ & & & & b_{j-1} & a_{j-1} & 0 \\ & & & & & b_j & \dfrac{b_{j+1}}{|A_N^{j+1}} \end{pmatrix} \tag{4.2}$$

$$= \left(\prod_{k=i}^{j-1} b_{k+1}\right) \cdot \det(A_{i-1}^M) \cdot \det(A_N^{j+1}).$$

By symmetry, this also equals the jith minor. The iith minor is

$$\det\left(\begin{array}{c|c} A_{i-1}^M & 0 \\ \hline 0 & A_N^{i+1} \end{array}\right) = \det(A_{i-1}^M)\det(A_N^{i+1}),$$

which is consistent with (4.2) if we interpret $\prod_{k=i}^{i-1} b_{k+1}$ as 1.

Expanding by cofactors along the ith column, we find that

$$\det A_N^M = a_i \det(A_{i-1}^M)\cdot\det(A_N^{i+1}) - b_i^2 \det(A_{i-2}^M)\cdot\det(A_N^{i+1}) - b_{i+1}^2 \det(A_{i-1}^M)\cdot\det(A_N^{i+2}).$$

Cramer's rule gives the following formula for the entries of the inverse $(A_N^M)^{-1}$. For $i \leqq j$,

$$(A_N^M)_{ij}^{-1} = (-1)^{i+j}\left(\prod_{k=i}^{j-1} b_{k+1}\right)\cdot\det(A_{i-1}^M)\cdot(A_N^{j+1})\cdot\det(A_N^M)^{-1}$$

$$= (-1)^{i+j}\left(\prod_{k=i}^{j-1} b_{k+1}\right)\left[\frac{a_i \det(A_{i-1}^M)\det(A_N^{i+1}) - b_{i+1}^2\det(A_{i-2}^M)\det(A_N^{i+1}) - b_{i+1}^2\det(A_{i-1}^M)\det(A_N^{i+2})}{\det(A_{i-1}^M)\det(A_N^{j+1})}\right]^{-1} \tag{4.3}$$

$$= (-1)^{i+j}\left(\prod_{k=1}^{j-1} b_{k+1}\right)\left[a_i\frac{\det(A_N^{i+1})}{\det(A_N^{j+1})} - b_i^2\frac{\det(A_{i-2}^M)\det(A_N^{i+1})}{\det(A_{i-1}^M)\det(A_N^{j+1})} - b_{i+1}^2\frac{\det(A_N^{i+2})}{\det(A_N^{j+1})}\right]^{-1}$$

Using the cofactor expansion, it is easy to show the following relations with continued fractions. For $M \leqq i,\ j \leqq N$,

$$\frac{\det(A_N^i)}{\det(A_N^{i+1})} = a_i + K_{k=i}^N\left(\frac{-b_{k+1}^2}{a_{k+1}}\right),$$
$$\frac{\det(A_j^M)}{\det(A_{j-1}^M)} = a_j + K_{k=j}^M\left(\frac{-b_k^2}{a_{k-1}}\right). \tag{4.4}$$

With these formulas it is possible to express the entries of $(A_N^M)^{-1}$ with products of continued fractions. The simplest case is the diagonal entry:

$$[(A_N^M)^{-1}]_{ii} = \frac{1}{a_i - b_i^2(a_{i-1} + K_{k=i-1}^M(-b_k^2/a_{k-1}))^{-1} - b_{i+1}^2(a_{i+1} + K_{k=i+1}^N(-b_{k+1}^2/a_{k+1}))^{-1}}.$$

For the case of interest in this paper, we replace the diagonal entries of (4.1) with $a_i - z$; we then have formulas for the entries of the resolvent $(A_N^M - zI)^{-1}$.

For the case of an infinite matrix we can justify the convergence of the infinite continued fractions using Pincherle's theorem [9]. This gives an alternate proof of formula (2.14).

5. Applications. The explicit cases of § 3 and their classical limits with $b_0^2 = 0$ are closely related to the representation theory of the Lie algebra $so(2, 1)$ or $su(1, 1)$. We detail this connection here.

Let T_j, $j = 1, 2, 3$ be the generators of the Lie algebra $so(2, 1)$ or $su(1, 1)$ with

$$[T_1, T_2] = -iT_3, \quad [T_2, T_3] = iT_1, \quad [T_3, T_1] = iT_2. \tag{5.1}$$

Consider an irreducible unitary representation with T_3 diagonal and the operator

$$T = \alpha_1 T_1 + \alpha_2 T_2 + \alpha_3 T_3, \qquad \alpha_j \in \mathbb{R}. \tag{5.2}$$

For the highest and lowest weight representations (i.e., "discrete series"; cf. [1]) we have T represented as a one-sidedly infinite Jacobi matrix connected with the classical polynomial cases of § 1 having $a_n = dn$ and $b_n^2 = an^2 + bn$, $n \in \mathbb{Z}^+$.

However, for the principal or complementary series representations we have T represented as a bilaterally infinite Jacobi matrix of the form given by the associated polynomial cases of § 3.

The results of § 3 and their $c \to 0$ classical limits allow us to calculate the resolvent and spectral properties of T. Since there are a variety of differential operators which obey the commutation properties (5.1) (cf. [1], [3], [4], [6], [11], [13]-[15]), this also gives a unified approach to the properties of a class of differential operators.

5.1. Discrete series. The lowest-weight representation $D_+(q)$ with lowest weight $q > 0$ has basis $\{\phi_m\}_{n=0}^{\infty}$ and action

$$\begin{aligned} T_3\phi_m &= (q+m)\phi_m, \\ T_1\phi_m &= \frac{1}{2}([(m+1)(2q+m)]^{1/2}\phi_{m+1} + [m(2q+m-1)]^{1/2}\phi_{m-1}), \\ T_2\phi_m &= \frac{1}{2i}([(m+1)(2q+m)]^{1/2}\phi_{m+1} - [m(2q+m-1)]^{1/2}\phi_{m-1}). \end{aligned} \tag{5.3}$$

Relative to this basis the matrix for the operator T in (5.3) is $(T_{m,n})$ with

$$\begin{aligned} T_{m,m} &= \alpha_3(q+m), \\ \bar{T}_{m,m+1} &= T_{m+1,m} = [(m+1)(2q+m)]^{1/2}\left(\frac{\alpha_1 - i\alpha_2}{2}\right). \end{aligned}$$

Letting $e_m = \exp(mi \arg(\alpha_1 - i\alpha_2))\phi_m$, we see that relative to the basis $\{e_m\}_{m=0}^{\infty}$, the operator $T - \alpha_3 qI$ has a one-sided Jacobi matrix representation A, where

$$\begin{aligned} A_{m,m} &= a_m = \alpha_3 m, \\ A_{m,m+1} &= A_{m+1,m} = b_{m+1} = \tfrac{1}{2}[(m+1)(2q+m)]^{1/2}\sqrt{\alpha_1^2 + \alpha_2^2}. \end{aligned} \tag{5.4}$$

In terms of the parameters a, b, c, d of § 3, we then have

$$a = \frac{\alpha_1^2 + \alpha_2^2}{4}, \quad b = \left(\frac{\alpha_1^2 + \alpha_2^2}{4}\right)(2q-1), \quad c = 0, \quad d = \alpha_3. \tag{5.5}$$

This corresponds to the classical Meixner polynomial case when $\alpha_1^2 + \alpha_2^2 - \alpha_3^2 < 0$, to the Meixner-Pollaczek case when $\alpha_1^2 + \alpha_2^2 - \alpha_3^2 > 0$, and to the case of Laguerre polynomials when $\alpha_1^2 + \alpha_2^2 - \alpha_3^2 = 0$.

The highest-weight representation $D_-(q)$ with highest weight $q<0$ has basis $\{\phi_m\}_{m=-\infty}^{0}$ and action

$$T_3\phi_m = (q+m)\phi_m,$$

$$T_1\phi_m = \frac{1}{2}([(m-1)(2q+m)]^{1/2}\phi_{m-1} + [m(2q+m+1)]^{1/2}\phi_{m+1}), \tag{5.6}$$

$$T_2\phi_m = -\frac{1}{2i}([(m-1)(2q+m)]^{1/2}\phi_{m-1} - [m(2q+m+1)]^{1/2}\phi_{m+1}).$$

Letting $e_m = \exp(-mi \arg(\alpha_1 - i\alpha_2))\phi_{-m}$ we see that relative to the basis $\{e_m\}_{m=0}^{\infty}$, the operator $T - \alpha_3 qI$ has a one-sided Jacobi matrix representation A, where

$$A_{m,m} = a_m = \alpha_3 m,$$
$$A_{m,m+1} = A_{m+1,m} = b_{m+1} = \tfrac{1}{2}[(m+1)(m-2q)]^{1/2}\sqrt{\alpha_1^2+\alpha_2^2}, \qquad m \in \mathbb{Z}^+. \tag{5.7}$$

The parameters of § 3 are now

$$a = \frac{\alpha_1^2+\alpha_2^2}{4}, \quad b = \left(\frac{\alpha_1^2+\alpha_2^2}{4}\right)(-2q-1), \quad c = 0, \quad d = -\alpha_3. \tag{5.8}$$

Thus the classical polynomial correspondence, depending on $\alpha^2 = \alpha_1^2+\alpha_2^2-\alpha_3^2$, is the same for both the lowest- and highest-weight cases.

In summary, the discrete series representations correspond precisely to the classical polynomial cases of Meixner ($\alpha^2<0$), Meixner-Pollaczek ($\alpha^2>0$), and Laguerre ($\alpha^2=0$).

5.2. Principal series. The (unitary) principal series representation $D_p(\sigma)$, $\sigma \in \mathbb{R}$ has basis $\{\phi_m\}_{m=-\infty}^{\infty}$ and action

$$T_3\phi_m = \left(m+\frac{1}{2}\right)\phi_m,$$

$$T_1\phi_m = \frac{1}{2}([(m+1)^2+\sigma^2]^{1/2}\phi_{m+1} + [m^2+\sigma^2]^{1/2}\phi_{m-1}), \tag{5.9}$$

$$T_2\phi_m = \frac{1}{2i}([(m+1)^2+\sigma^2]^{1/2}\phi_{m+1} - [m^2+\sigma^2]^{1/2}\phi_{m-1}).$$

The representations $D_p(\sigma)$ and $D_p(-\sigma)$ are clearly equivalent.

Letting $e_m = \exp(im \arg(\alpha_1 - i\alpha_2))\phi_m$ and with T as in (5.2), we see that relative to the basis $\{e_m\}_{m=-\infty}^{\infty}$, the operator $T - \frac{1}{2}\alpha_3 I$ has a bilateral Jacobi matrix representation A, where

$$A_{m,m} = a_m = \alpha_3 m,$$
$$A_{m,m+1} = A_{m+1,m} = b_{m+1} = \tfrac{1}{2}[(m+1)^2+\sigma^2]^{1/2}\sqrt{\alpha_1^2+\alpha_2^2}. \tag{5.10}$$

In the notation of § 3 we then have

$$a = \frac{\alpha_1^2+\alpha_2^2}{4}, \quad b = 0, \quad c = \frac{\alpha_1^2+\alpha_2^2}{4}\sigma^2, \quad d = \alpha_3. \tag{5.11}$$

5.3. Complementary series. The complementary series (sometimes called supplementary series) representations $D_c(s, t)$ are parameterized by $s, t \in \mathbb{R}$ satisfying

$$-1+|t| < s < -|t|. \tag{5.12}$$

Relative to a basis $\{\phi_m\}_{m=-\infty}^{\infty}$ the action is given by

$$
\begin{aligned}
T_3\phi_m &= (t+m)\phi_m,\\
T_1\phi_m &= \frac{1}{2}([s+t+m)(s+t+m+1)]^{1/2}\phi_{m+1}\\
&\qquad +[(s+t+m)(-s+t+m-1)]^{1/2}\phi_{m-1}),\\
T_2\phi_m &= \frac{1}{2i}([(-s+t+m)(s+t+m+1)]^{1/2}\phi_{m+1}\\
&\qquad -[(s+t+m)(-s+t+m-1)]^{1/2}\phi_{m-1}).
\end{aligned}
\tag{5.13}
$$

Letting $e_m = \exp(im \arg(\alpha_1 - i\alpha_2))\phi_m$ and with T as in (5.2) we find that, relative to the basis $\{e_m\}_{m=-\infty}^{\infty}$, the operator $T-\alpha_3 tI$ has a bilateral Jacobi matrix representation A, with

$$
\begin{aligned}
&A_{m,m} = a_m = \alpha_3 m,\\
&A_{m,m+1} = A_{m+1,m} = b_{m+1} = \tfrac{1}{2}[(-s+t+m)(s+t+m+1)]^{1/2}\sqrt{\alpha_1^2+\alpha_2^2}.
\end{aligned}
\tag{5.14}
$$

In the notation of § 3 we now have

$$
\begin{aligned}
&a = \frac{\alpha_1^2+\alpha_2^2}{4}, \qquad b = \frac{\alpha_1^2+\alpha_2^2}{4}(2t-1),\\
&c = \frac{\alpha_1^2+\alpha_2^2}{4}(s+t)(t-s-1), \qquad d = \alpha_3.
\end{aligned}
\tag{5.15}
$$

Thus both the principal and complementary series cases correspond to the bilateral associated polynomial cases of § 3 of Meixner ($\alpha^2 = \alpha_1^2+\alpha_2^2-\alpha_3^2<0$), Meixner-Pollaczek ($\alpha^2>0$), and Laguerre ($\alpha^2=0$).

Other associated polynomial cases of Charlier, Hermite, and Bessel order related to representations of H_4 and T_3 can also be made explicit (compare [12] and [13]).

ORTHOGONAL FUNCTIONS FROM GRAM DETERMINANTS*

JAMES A. WILSON†

Abstract. Generalized Gram determinants are used to derive explicit hypergeometric series or basic hypergometric series formulas for orthogonal polynomials and biorthogonal rational functions. The computations involve some new determinant evaluations.

Key words. orthogonal polynomials, biorthogonal rational functions, hypergeometric series, basic hypergeometric series, Gram determinants

AMS(MOS) subject classifications. 33A65, 33A30

1. Introduction and example. It is well known that the orthogonal polynomials p_n for a given distribution $d\mu$ can be expressed as determinants

$$p_n(x) = \begin{vmatrix} \mu_0 & \mu_1 & \cdots & \mu_n \\ \mu_1 & \cdots & & \mu_{n+1} \\ \vdots & & & \vdots \\ \mu_{n-1} & \cdots & & \mu_{2n-1} \\ 1 & x & \cdots & x^n \end{vmatrix} \tag{1.1}$$

with $\mu_n = \int x^n d\mu(x)$. What is surprising is that many of the usual explicit formulas for orthogonal polynomials can be derived by directly evaluating determinants similar to this. We demonstrate here how simple determinant reductions lead naturally to the classical orthogonal polynomials and the related hypergeometric and basic hypergeometric orthogonal polynomials [1], even the ${}_4F_3$ polynomials in [7] and [8] and their basic analogues in [2]. In fact, the technique is the source of the ${}_9F_8$ and ${}_{10}\phi_9$ biorthogonal functions referred to in [5] and [6], the proof in §2 being the original derivation from my thesis [8].

Let $\{\phi_k\}_{k=0}^{\infty}$ and $\{\psi_k\}_{k=0}^{\infty}$ be sequences of polynomials, ϕ_k and ψ_k of exact degree k. Then an alternative to (1.1) is

$$p_n(x) = C \cdot \begin{vmatrix} \mu_{0,0} & \mu_{0,1} & \cdots & \mu_{0,n} \\ \mu_{1,0} & \cdots & & \mu_{1,n} \\ \vdots & & & \vdots \\ \mu_{n-1,0} & \cdots & & \mu_{n-1,n} \\ \phi_0(x) & \phi_1(x) & \cdots & \phi_n(x) \end{vmatrix} \tag{1.2}$$

with $\mu_{i,j} = \int \psi_i \phi_j d\mu$. Indeed,

$$\int p_n \psi_k d\mu = C \cdot \begin{vmatrix} \mu_{0,0} & \mu_{0,1} & \cdots & \mu_{0,n} \\ \mu_{1,0} & \cdots & & \vdots \\ \vdots & & & \\ \mu_{n-1,0} & \cdots & & \mu_{n-1,n} \\ \mu_{k,0} & \mu_{k,1} & \cdots & \mu_{k,n} \end{vmatrix}$$

and this is zero if $k < n$.

*Received by the editors July 28, 1990; accepted for publication August 27, 1990.
†Department of Mathematics, Iowa State University, Ames, Iowa 50011.

Here and elsewhere in the paper, C represents a factor which affects only the normalization of the orthogonal functions.

To illustrate the technique, we take $d\mu(x) = (1-x)^\alpha(1+x)^\beta\,dx; -1 < x < 1$; $\alpha, \beta > -1$; and derive the explicit series formula for the Jacobi polynomials $P_n^{(\alpha,\beta)}$. Start with the beta integral

$$\int d\mu(x) = \int_{-1}^{1}(1-x)^\alpha(1+x)^\beta\,dx = 2^{\alpha+\beta+1}\Gamma(\alpha+1)\Gamma(\beta+1)/\Gamma(\alpha+\beta+2).$$

We see that good choices for the basis polynomials are $\phi_k(x) = (1-x)^k$ and $\psi_k(x) = (1+x)^k$, since these combine with the weight function in a simple way:

$$\mu_{i,j} = \int \psi_i\phi_j d\mu = \int_{-1}^{1}(1-x)^{\alpha+j}(1+x)^{\beta+i}dx \tag{1.3}$$
$$= 2^{\alpha+\beta+1+i+j}\Gamma(\alpha+1+j)\Gamma(\beta+1+i)/\Gamma(\alpha+\beta+2+i+j).$$

(The computations which follow would be a little longer with $\phi_k(x) = \psi_k(x) = (1 \pm x)^k$.) In using (1.2), we multiply the columns and rows by appropriate factors to simplify the μ_{ij}'s and make 1's in the first column:

$$P_n^{(\alpha,\beta)} = C \cdot \begin{vmatrix} \tilde{\mu}_{0,0} & \tilde{\mu}_{0,1} & \cdots & \tilde{\mu}_{0,n} \\ \tilde{\mu}_{1,0} & \cdots & & \vdots \\ \vdots & & & \\ \tilde{\mu}_{n-1,0} & \cdots & & \tilde{\mu}_{n-1,n} \\ \tilde{\phi}_0 & \tilde{\phi}_1 & \cdots & \tilde{\phi}_n \end{vmatrix}$$

with $\tilde{\mu}_{ij} = 1/(\alpha+\beta+2+i)_j$ and $\tilde{\phi}_j(x) = (1-x)^j/2^j(\alpha+1)_j$. Now expand along the bottom row:

$$P_n^{(\alpha,\beta)} = C \cdot \sum_{k=0}^{n}(-1)^k\tilde{\phi}_k \cdot \det\left[\tilde{\mu}_{i,j}\right]_{\substack{0\le i\le n-1 \\ 0\le j\le n, j\ne k}}. \tag{1.4}$$

The problem now is to evaluate determinants of the form

$$\Delta(A,n,k) = \det\left[1/(A+i)_j\right]_{\substack{0\le i\le n-1 \\ 0\le j\le n, j\ne k}}$$

($\Delta(A,0,0) = 1$). Begin by making zeros in the first column by subtracting row $n-1$ from row n, row $n-2$ from row $n-1$, etc. Then expand along the first column to get

$$\Delta(A,n,k) = \det\left[\frac{1}{(A+i+1)_{j+1}} - \frac{1}{(A+i)_{j+1}}\right]_{\substack{0\le i\le n-2 \\ 0\le j\le n-1, j\ne k-1}}.$$

The general entry in this determinant simplifies to $-(j+1)/(A+i)_{j+2} = -(j+1)/(A+i)(A+i+1)(A+i+2)_j$, so that

$$\Delta(A,n,k) = \left[(-1)^{n-1}\prod_{\substack{j=0 \\ j\ne k}}^{n-1}(j+1) \Big/ \prod_{i=0}^{n-2}(A+i)(A+i+1)\right]\Delta(A+2,n-1,k-1)$$
$$= [(-1)^{n-1}n!/k(A)_{n-1}(A+1)_{n-1}]\,\Delta(A+2,n-1,k-1).$$

Iterate this k times:

$$(1.5)\quad \Delta(A,n,k) = \left\{\frac{1}{k!}\prod_{r=0}^{k-1}\frac{(n-r)!(-1)^{n-r-1}}{(A+2r)_{n-r-1}(A+2r+1)_{n-r-1}}\right\}\Delta(A+2k,n-k,0).$$

In the right-hand determinant, the index j runs from 1 to $n-k$. If we shift the index, we get

$$\begin{aligned}\Delta(A+2k,n-k,0) &= \det\left[1/(A+2k+i)_{j+1}\right]_{\substack{0\le i\le n-k-1\\ 0\le j\le n-k-1}}\\ &= \det\left[1/(A+2k+i)(A+2k+1+i)_j\right]_{\substack{0\le i\le n-k-1\\ 0\le j\le n-k-1}}\\ &= \Delta(A+2k+1,n-k,n-k)\ /\ (A+2k)_{n-k}.\end{aligned}$$

Finally, the last determinant can be evaluated by formula (1.5). These reductions give

$$(1.6)\qquad \Delta(A,n,k) = (\text{factor indep. of } k)\cdot(-1)^k(-n)_k(A+n-1)_k/k!$$

and from (1.4)

$$\begin{aligned}P_n^{(\alpha,\beta)}(x) &= C\cdot\sum_{k=0}^{n}(-1)^k\Delta(\alpha+\beta+2,n,k)\left(\frac{1-x}{2}\right)^k/(\alpha+1)_k\\ &= C\cdot\sum_{k=0}^{n}\frac{(-n)_k(n+\alpha+\beta+1)_k}{(\alpha+1)_k\ k!}\left(\frac{1-x}{2}\right)^k.\end{aligned}$$

This is a well-known and valuable representation of the Jacobi polynomials. (For the usual normalization, put $C=(\alpha+1)_n/n!$.)

The derivations of the explicit hypergeometric or basic hypergeometric formulas for other classical and related orthogonal polynomials differ little from this. Whether $\int d\mu$ is an ordinary integral or a finite or infinite sum, we choose the basis polynomials ϕ_k and ψ_k so that, as in (1.3), multiplying the weight function by $\psi_i\phi_j$ has the effect of shifting parameters. There are interesting determinant evaluations which arise in these computations, more general than $\Delta(A,n,k)$. Some are given explicitly in §3.

2. Rational function biorthogonalities. After seeing orthogonal polynomials derived in this way from series or integrals containing parameters, it is natural to try for something new using more general formulas. Dougall's theorem [3, p. 27] is

$$\begin{aligned}&{}_7F_6\left[\begin{matrix}2a,a+1,a+b,a+c,a+d,a+e,a+f;\ 1\\ a,a-b+1,a-c+1,a-d+1,a-e+1,a-f+1\end{matrix}\right]\\ (2.1)\qquad &= \sum_{k=0}^{N}w_k(a,b,c,d,e,f)\\ &= \frac{(2a+1)_N(1-c-d)_N(1-c-e)_N(1-d-e)_N}{(a-c+1)_N(a-d+1)_N(a-e+1)_N(b+f)_N},\end{aligned}$$

provided $a+b+c+d+e+f=1$ and $a+b=-N$. Here

$$(2.2)\quad w_k(a,b,c,d,e,f) = \frac{(2a)_k(a+k)(a+b)_k(a+c)_k(a+d)_k(a+e)_k(a+f)_k}{(1)_k\ a\ (a-b+1)_k\ \dots\ (a-f+1)_k}.$$

The simplest functions ϕ_j, ψ_i by which we can multiply w_k to shift parameters (while preserving the condition $a+b+c+d+e+f=1$) are not polynomials, but rational functions of a quadratic function of k. We choose

$$\begin{aligned}\phi_j(z^2) &= (c-z)_j(c+z)_j/(1-e+z)_j(1-e-z)_j,\\ \psi_i(z^2) &= (d-z)_i(d+z)_i/(1-f+z)_i(1-f-z)_i.\end{aligned}$$

Then

$$\begin{aligned}\mu_{ij} &= \sum_{k=0}^{N} w_k(a,b,c,d,e,f)\phi_j\left((a+k)^2\right)\psi_i\left((a+k)^2\right)\\ &= \frac{(c-a)_j(c+a)_j(d-a)_i(d+a)_i}{(1-e+a)_j(1-e-a)_j(1-f+a)_i(1-f-a)_i}\\ &\qquad\cdot\sum_{i=0}^{N} w_k(a,b,c+j,d+i,e-j,f-i)\\ &= \text{(factor indep. of } j)\cdot\frac{(a+c)_j(b+c)_j(c+d+i)_j(c+f-i)_j}{(1-e-a)_j(1-e-b)_j(1-d-e-i)_j(1-e-f+i)_j}\end{aligned}$$

by Dougall's theorem. We define for $0 \le n \le N$

$$R_n(z^2) = \begin{vmatrix} \mu_{0,0} & \mu_{0,1} & \cdots & \mu_{0,n} \\ \mu_{1,0} & & & \mu_{1,n} \\ \vdots & & & \vdots \\ \mu_{n-1,0} & \cdots & & \mu_{n-1,n} \\ \phi_0(z^2) & \cdots & & \phi_n(z^2) \end{vmatrix}, \tag{2.3}$$

$$S_n(z^2) = \begin{vmatrix} \mu_{0,0} & \cdots & \mu_{n,0} \\ \mu_{0,1} & \cdots & \mu_{n,1} \\ \vdots & & \vdots \\ \mu_{0,n-1} & \cdots & \mu_{n,n-1} \\ \psi_0(z^2) & \cdots & \psi_n(z^2) \end{vmatrix}$$

so that

$$\begin{aligned}&\sum_{k=0}^{N} w_k R_n\left((a+k)^2\right)\psi_m\left((a+k)^2\right)\\ &\qquad = \sum_{k=0}^{N} w_k S_n\left((a+k)^2\right)\phi_m\left((a+k)^2\right) = 0\end{aligned}$$

for $0 \le m < n \le N$, and we have a biorthogonality relation

$$\sum_{k=0}^{N} w_k R_m\left((a+k)^2\right) S_n\left((a+k)^2\right) = 0$$

for $m, n \in \{0, 1, \cdots, N\}, m \ne n$.

The hope is, of course, that the computation in §1 generalizes to give hypergeometric series formulas for the determinants (2.3).

Multiplying the columns and rows by appropriate factors and expanding along the last row, as in the Jacobi polynomial case, gives

$$\begin{aligned}R_n(z^2) &= C\cdot\sum_{k=0}^{n}\frac{(-1)^k\,(1-e-a)_k(1-e-b)_k}{(a+b)_k(b+c)_k}\\ &\qquad\cdot\phi_k(z^2)\Delta(c+d,c+f,1-e-f,1-e-d,n,k)\end{aligned} \tag{2.4}$$

where

$$\Delta(A,B,C,D,n,k) = \det\left[\frac{(A+i)_j(B-i)_j}{(C+i)_j(D-i)_j}\right]_{\substack{0\le i\le n-1\\ 0\le j\le n, j\ne k}} \tag{2.5}$$

for $0 \le k \le n$. ($\Delta(A,B,C,D,0,0) = 1$.)

We need to evaluate (2.5) when $A + D = B + C$. This time, subtracting rows leads to

$$\begin{aligned}\Delta(A,B,C,D,n,k) &= \det\Bigg[\frac{(A+i+1)_j(B-i)_j}{(C+i)_{j+2}(D-i-1)_{j+2}} \\ &\quad \{(A+i+j+1)(B-i-1)(C+i)(D-i+j) \\ &\qquad -(A+i)(B-i+j)(C+i+j+1)(D-i-1)\}\Bigg]_{\substack{0\le i\le n-2\\ 0\le j\le n-1, j\ne k-1}}.\end{aligned}$$

The expression in braces factors into $(j+1)(B+C+j)(A-C)(A-B+2i+1)$ when $A + D = B + C$. Because of this fortuitous factorization, the procedure used in §1 may be followed to the conclusion

(2.6)
$$\begin{aligned}&\Delta(A,B,C,D,n,k) \\ &= (\text{factor indep. of } k)\frac{(-1)^k(-n)_k(B+C-1)_k(B+C-1+2k)(C+n-1)_k(D)_k}{k!\,(A)_k(B-n+1)_k(B+C+n)_k}.\end{aligned}$$

Upon substituting the value of $\Delta(A,B,C,D,n,k)$ into (2.3), we find

(2.7)
$$R_n(z^2) = C \cdot {}_9F_8\left[\begin{matrix} c-e,(c-e)/2+1,c-z,c+z,1-e-a,1-e-b,1-e-d,n-e-f,-n;1 \\ (c-e)/2,1-e+z,1-e-z,c+a,c+b,c+d,c+f-n+1,c-e+n+1.\end{matrix}\right]$$

A ${}_9F_8$ of this special type satisfies Bailey's transformation identity [3, p. 27]:

(2.8)
$$\begin{aligned}&{}_9F_8\left[\begin{matrix} a,a/2+1,b,c,d,e,f,g,-n;\ 1 \\ a/2,a-b+1,\cdots,a-g+1,a+n+1\end{matrix}\right] \\ &= \frac{(a+1)_n(a'-e+1)_n(a'-f+1)_n(a'-g+1)_n}{(a'+1)_n(a-e+1)_n(a-f+1)_n(a-g+1)_n} \\ &\quad \cdot {}_9F_8\left[\begin{matrix} a',a'/2+1,a'-a+b,a'-a+c,a'-a+d,e,f,-n;1 \\ a'/2,a-b+1,a-c+1,a-d+1,a'-e+1,a'-g+1,a'+n+1\end{matrix}\right]\end{aligned}$$

with $a' = 2a - b - c - d + 1$, provided $b + c + d + e + f + g - n = 3a + 2$. In terms of the rational functions, Bailey's transformation says that $R_n(z^2)$ is symmetric is a, b, c, and d when we put $C = (c+a)_n(c+b)_n(c+d)_n(-c-f)_n/(c-e+1)_n$ in (2.7). In fact, an iterate of (2.8) gives

$$\begin{aligned}R_n(z^2) &= \frac{(a-z)_n(b-z)_n(c-z)_n(d-z)_n(z-f)_n}{(-2z)_n\,(1-e-z)_n} \\ &\cdot {}_9F_8\left[\begin{matrix} 2z-n,z-n/2+1,a+z,b+z,c+z,d+z,e-n+z,f-n+1+z,-n;\ 1 \\ z-n/2,z-a-n+1,z-b-n+1,z-c-n+1,z-d-n+1,z-e+1,z-f,2z+1\end{matrix}\right]\end{aligned}$$

(with the same choice for C). By symmetry, $S_n(z^2)$ is given by the same formula with e and f interchanged.

The biorthogonality just derived may be written

$$\sum_{k=0}^{N} w_k\, R_m\left((a+k)^2;a,b,c,d,e,f\right) R_n\left((a+k)^2;a,b,c,d,f,e\right) = \delta_{m,n}\cdot h_n \tag{2.9}$$

if $a+b+c+d+e+f=1$; $a+b=-N$, $m,n\in\{0,1,\cdots,N\}$, the weights w_k are given by (2.2), and

$$R_n(z^2) = \frac{(a+b)_n(a+c)_n(a+d)_n(-a-f)_n}{(a-e+1)_n} \cdot {}_9F_8\left[\begin{matrix} a-e,(a-e)/2+1,a-z,a+z,1-e-b,1-e-c,1-e-d,n-e-f,-n;1 \\ (a-e)/2,1-e+z,1-e-z,a+b,a+c,a+d,a+f-n+1,a-e+n+1 \end{matrix}\right].$$

Once the formula for $R_n(z^2)$ is given, direct verification of the biorthogonality is much easier than the derivation, and carrying this out is one way to find that

$$h_n = M\cdot\frac{n!(n-e-f)_n(a+b)_n(a+c)_n(a+d)_n(b+c)_n(b+d)_n(c+d)_n}{(1-e-f)_{2n}}$$

with

$$M = \frac{(2a+1)_N(1-c-d)_N(1-c-e)_N(1-d-e)_N}{(a-c+1)_N(a-d+1)_N(a-e+1)_N(b+f)_N}.$$

Interchanging a and b in (2.9) is equivalent to summing in the reverse order.

If we let e and f become infinite while preserving the condition $a+b+c+d+e+f=1$, the biorthogonality (2.9) reduces to a discrete case of the polynomial orthogonality relation for

$$p_n(z^2) = (a+b)_n(a+c)_n(a+d)_n\ {}_4F_3\left[\begin{matrix} -n,n+a+b+c+d-1,a-z,a+z \\ a+b,a+c,a+d \end{matrix};1\right]$$

($a+b=-N, 0\le n\le N$), which polynomials in turn contain the classical polynomials and others as limiting cases [1], [2], [4], [7], [8].

The rational functions $R_n(z^2)$ have basic hypergeometric analogues. We use the notation $(a;q)_k=(1-a)(1-aq)\cdots(1-aq^{k-1})$ if $k\ge 1$; $(a;q)_0=1$; and

$${}_{r+1}\phi_r\left[\begin{matrix} a_0,a_1,\cdots,a_r \\ b_1,\cdots,b_r \end{matrix};q,z\right] = \sum_{k=0}^{\infty}\frac{(a_0;q)_k\cdots(a_r;q)_k}{(q;q)_k(b_1;q)_k\cdots(b_r;q)_k}z^k.$$

The sums we encounter will actually be terminating ones, a_r being q^{-n} for some nonnegative integer n. Suppose $abcdef=q$, and for $n=0,1,\cdots$ let

(2.10)

$$r_n\left((z+z^{-1})/2;a,b,c,d,e,f;q\right) = \frac{(ab;q)_n(ac;q)_n(ad;q)_n(1/af;q)_n}{(aq/e;q)_n} \cdot {}_{10}\phi_9\left[\begin{matrix} a/e,q\sqrt{a/e},-q\sqrt{a/e},a/z,az,q/be,q/ce,q/de,q^n/ef,q^{-n} \\ \sqrt{a/e},-\sqrt{a/e},qz/e,q/ez,ab,ac,ad,q^{1-n}af,q^{n+1}a/e \end{matrix};q,q\right].$$

Then $r_n\left((z+z^{-1})/2\right)$ is a rational function of degree n/n in the variable $(z+z^{-1})/2$, since

$$\frac{(a/z;q)_k(az;q)_k}{(qz/e;q)_k(q/ez;q)_k} = \prod_{j=0}^{k-1}\frac{1-aq^j(z+z^{-1})+a^2q^{2j}}{1-q^{j+1}e^{-1}(z+z^{-1})+q^{2j+2}e^{-2}}$$

and the series terminates with the $k=n$ term. Replacing a,b,c,d,e,f,z by $q^a,\cdots,q^f$, q^z and then letting $q\to 1$ yields the ${}_9F_8$ functions $R_n(z^2)$. In the same way, the biorthogonality for $r_n\left((z+z^{-1})/2\right)$ contains relation (2.9). The basic analogue of

transformation (2.8) is [3, p. 68]

$$
{}_{10}\phi_9\left[\begin{matrix} a, q\sqrt{a}, -q\sqrt{a}, b, c, d, e, f, g, q^{-n}; q, q \\ \sqrt{a}, -\sqrt{a}, aq/b, aq/c, \cdots ; aq^{n+1} \end{matrix}\right]
$$

$$
= \frac{(aq;q)_n(aq/ef;q)_n(aq/eg;q)_n(aq/fg;q)_n}{(aq/e;q)_n(aq/f;q)_n(aq/g;q)_n(aq/efg;q)_n}
$$

$$
\cdot {}_{10}\phi_9\left[\begin{matrix} s, q\sqrt{s}, -q\sqrt{s}, sb/a, sc/a, sd/a, e, f, g, q^{-n}; q, q \\ \sqrt{s}, -\sqrt{s}, aq/b, aq/c, aq/d, sq/e, sq/f, sq/g, sq^{n+1} \end{matrix}\right]
$$

with $s = a^2q/bcd$, provided $a^3q^{n+2} = bcdefg$. This says that r_n is symmetric in a, b, c, and d, and an iterate of this transformation gives

$$
r_n\left((z+z^{-1})/2\right) = \frac{(a/z)_n(b/z)_n(c/z)_n(d/z)_n(z/f)_n}{(z^{-2})_n(q/ez)_n}
$$

$$
\cdot {}_{10}\phi_9\left[\begin{matrix} z^2q^{-n}, zq^{1-n/2}, -zq^{1-n/2}, az, bz, cz, dz, eq^{-n}z, fq^{-n+1}z, q^{-n}; q, q \\ zq^{-n/2}, -zq^{-n/2}, zq^{1-n}/a, zq^{1-n}/b, zq^{1-n}/c, zq^{1-n}/d, zq/e, z/f, z^2q \end{matrix}\right].
$$

In place of Dougall's theorem (2.1) we need Jackson's theorem [3, p. 67]:

$$
{}_8\phi_7\left[\begin{matrix} a^2, aq, -aq, ab, ac, ad, ae, af; q, q \\ a, -a, aq/b, aq/c, aq/d, aq/e, aq/f \end{matrix}\right] = \frac{(a^2q;q)_N(q/cd;q)_N(q/ce;q)_N(q/de;q)_N}{(aq/c;q)_N(aq/d;q)_N(aq/e;q)_N(bf;q)_N},
$$

provided $abcdef = q$ and $ab = q^{-N}$. Mimicking the derivation in §3 leads to a biorthogonality relation for $r_n\left((z+z^{-1})/2\right)$ on the $N+1$ points $(z+z^{-1})/2 = (a+a^{-1})/2, (aq+a^{-1}q^{-1})/2, \cdots, (aq^N+a^{-1}q^{-N})/2$. The determinant formulas produced in the computation are given in the next section.

The biorthogonality is again easier to verify directly:

(2.11)

$$
\sum_{k=0}^{N} w_k r_n\left(\frac{aq^k+a^{-1}q^{-k}}{2}; a, b, c, d, e, f; q\right) r_m\left(\frac{aq^k+a^{-1}q^{-k}}{2}; a, b, c, d, f, e; q\right)
$$

$$
= M \cdot \delta_{m,n} \frac{(q;q)_n(q^n/ef;q)_n(ab;q)_n(ac;q)_n(ad;q)_n(bc;q)_n(bd;q)_n(cd;q)_n}{(q/ef;q)_{2n}}
$$

with $abcdef = q$; $ab = q^{-N}$; $m, n \in \{0, 1, \cdots, N\}$;

$$
w_k = \frac{(a^2;q)_k(1-a^2q^{2k})(ab;q)_k(ac;q)_k(ad;q)_k(ae;q)_k(af;q)_k q^k}{(q;q)_k(1-a^2)(aq/b;q)_k(aq/c;q)_k(aq/d;q)_k(aq/e;q)_k(aq/f;q)_k}
$$

and

$$
M = \frac{(aq;q)_N(q/cd;q)_N(q/ce;q)_N(q/de;q)_N}{(aq/c;q)_N(aq/d;q)_N(aq/e;q)_N(bf;q)_N}.
$$

As in (2.9), interchanging a and b in (2.11) is equivalent to summing in reverse order. If we let $e \to 0$ and $f \to \infty$ with $abcdef = q$, this relation reduces to the discrete case of the orthogonality relation for the ${}_4\phi_3$ polynomials in [2].

3. The determinant formulas. New determinant formulas may have value in a variety of contexts. The determinants involved in the preceding computations seem particularly promising because of their intimate connection with hypergeometric and basic hypergeometric series. Therefore, it is worthwhile to record the complete evaluation formulas.

The determinants involved with the ${}_{10}\phi_9$'s are

$$\Delta_{n,k} = \det[(Aq^i;q)_j(Bq^{-i};q)_j/(Cq^i;q)_j(Dq^{-i};q)_j]_{\substack{0\le i\le n-1\\ 0\le j\le n, j\ne k}} \tag{3.1}$$

with $AD = BC$, $0 \le k \le n$. ($\Delta_{0,0} = 1$.) For these, we have

$$\Delta_{n,n} = \prod_{r=0}^{n-1} \frac{q^{-r}(q;q)_r D^r (1-AC^{-1}q^{-n+1+r})^r (AB^{-1}q^{n-r};q^2)_r (ADq^{n-1-r};q^2)_r}{(Cq^r;q)_{n-1}(Dq^{-r};q)_{n-1}}$$

$$= \prod_{r=1}^{n-1} \frac{q^{-r(r+1)/2}(q;q)_r(-B)^r(CA^{-1};q)_r(AB^{-1}q^{n-r};q^2)_r(ADq^{n-1-r};q^2)_r}{(Cq^{n-1-r};q)_{2r}(Dq^{-r};q)_{2r}}$$

(we have given two of many ways to group the factors) and

$$\Delta_{n,k} = \Delta_{n,n} \cdot \pi_k/\pi_n$$

with

$$\pi_k = \frac{(ADq^{-1};q)_k(1-ADq^{2k-1})(D;q)_k(Cq^{n-1};q)_k(q^{-n};q)_k}{(q;q)_k(1-ADq^{-1})(A;q)_k(Bq^{-n+1};q)_k(ADq^n;q)_k}(-q)^k.$$

All the similar generalized Gram determinants we have evaluated are limiting cases of this one. We now give some examples. If A, B, C, D are replaced by q^A, q^B, q^C, q^D, then as $q \to 1$, we get the determinants involved in the $R_n(z^2)$ computation:

$$\Delta_{n,k} = \det\left[\frac{(A+i)_j(B-i)_j}{(C+i)_j(D-i)_j}\right]_{\substack{0\le i\le n-1\\ 0\le j\le n, j\ne k}}, \tag{3.2}$$

$A + D = B + C$. For these, we have

$$\Delta_{n,k} = \Delta_{n,n}\pi_k/\pi_n,$$

$$\Delta_{n,n} = \prod_{r=0}^{n-1} \frac{(-1)^r r!(C-A)_r 2^{2r}\left((A-B+n-r)/2\right)_r\left((A+D+n-1-r)/2\right)_r}{(C+r)_{n-1}(D-r)_{n-1}},$$

$$\pi_k = \frac{(A+D-1)_k(A+D-1+2k)(D)_k(C+n-1)_k(-n)_k(-1)^k}{k!(A+D-1)(A)_k(B-n+1)_k(A+D+n)_k}.$$

It is interesting that, with a change of variable, these formulas evaluate the more symmetric determinants with entries $(a;q)_{i+j}(b;q)_{i'+j}(c;q)_{i+j'}(d;q)_{i'+j'}$ if $ad = bc$, or $(a)_{i+j}\ (b)_{i'+j}\ (c)_{i+j'}\ (d)_{i'+j'}$ if $a + d = b + c$, $i' = n-1-i$, $j' = n-1-j$.

In the limit as $B, D \to \infty$, (3.2) becomes

$$\begin{aligned}\Delta_{n,k} &= \det[(A+i)_j/(C+i)_j]_{\substack{0\le i\le n-1\\ 0\le j\le n, j\ne k}} \\ &= \Delta_{n,n}\pi_k/\pi_n, \\ \Delta_{n,n} &= \prod_{r=0}^{n-1} r!(C-A)_r/(C+r)_{n-1}, \\ \pi_k &= (C+n-1)_k(-n)_k(-1)^k/k!(A)k.\end{aligned} \tag{3.3}$$

The basic analogue is ($B, D \to 0$ in (3.1))

$$\begin{aligned}\Delta_{n,k} &= \det[(Aq^i;q)_j/(Cq^i;q)_j]_{\substack{0\le i\le n-1\\ 0\le j\le n, j\ne k}}\\ &= \Delta_{n,n}\cdot \pi_k/\pi_n,\\ \Delta_{n,n} &= \prod_{r=0}^{n-1}(q;q)_r(C/A;q)_r A^r q^{r(r-1)}/(Cq^r;q)_{n-1},\\ \pi_k &= (Cq^{n-1};q)_k(q^{-n};q)_k(-q)^k/(q;q)_k(A;q)_k.\end{aligned}$$

The symmetrized versions of these determinants have entries $(a)_{i+j}(d)_{i'+j'}$ and $(a;q)_{i+j}$ $(d;q)_{i'+j'}q^{-ij}$.

Other limiting cases are the determinants with entries $(A+i)_j/(D-i)_j$ or $(B-i)_j/(C+i)_j$, or their basic analogues.

The entries in the determinants become rational functions of i and j (or of q^i and q^j in the basic versions) when $A-C$ and $B-D$ are integers (or when A/C and B/D are integer powers of q). For example, with $C = A+1$ in (3.3), we can calculate

$$\det[1/(A+i+j)]_{\substack{0\le i\le n-1\\ 0\le j\le n-1}} = \prod_{r=0}^{n-1}(r!)^2/(A+r)_n.$$

CONVERGENT FACTORIAL SERIES EXPANSIONS FOR BESSEL FUNCTIONS*

T. M. DUNSTER† AND D. A. LUTZ†

Abstract. Solutions of Bessel's equation and the modified Bessel equation are examined where the argument $z \to \infty$. Convergent series representations are derived for all of the standard Bessel and modified Bessel functions. These representations involve (inverse) factorial series of the form

$$\sum_{m=0}^{\infty} \frac{c_m(\nu) m!}{z(z+1)\cdots(z+m)},$$

and are uniformly and absolutely convergent in the half plane $\mathrm{Re}\,(z) \geqq \varepsilon > 0$ (ε arbitrary). Error bounds, explicit in the Bessel parameter ν, are derived for the difference between the infinite series and the truncated series.

It is shown that the factorial coefficients have the asymptotic behavior $c_m(\nu) = O(\{\ln(m)\}^{\nu-5/2}/m)$ as $m \to \infty$. The coefficients are also shown to satisfy certain recursion relations, which provide a means of calculating them in a numerically satisfactory manner.

Key words. Bessel functions, asymptotic expansions

AMS(MOS) subject classifications. 33A40, 34E05

1. Introduction. A general theory for factorial series expansions of solutions of linear differential equations has long been available, originating with the work of Horn. However, it does not seem to be widely known, nor used often in practice. This is perhaps partly due to the fact that while the general theory implies the convergence of a factorial series (in some half plane), it does not immediately provide all the information needed to analyze the convergence. Moreover, it does not provide a means of determining the order of magnitude of the factorial coefficients in a satisfactory manner.

The purpose of this paper is to investigate factorial series expansions for Bessel functions. We shall determine factorial series expansions for all the standard Bessel functions (§ 2), each of which converges in a half plane. We will also provide numerically satisfactory procedures for calculating the coefficients in these factorial series expansions (§§ 2, 3), give error bounds for the remainder, including explicit dependence on the parameter ν (§ 4), and determine the asymptotic behavior of the coefficients (§ 5).

A natural question regarding these factorial series expansions would be to ask how good the resulting convergence is for various fixed values of z, especially with respect to the parameter ν. We shall investigate questions such as these and, as a result, learn enough about the calculation and convergence of the factorial series so that their numerical effectiveness can be ascertained. We compare calculations based on factorial series with other standard types of convergent and asymptotic expansions in § 6.

The procedure we follow is based on the general theory (see, for example, [3] or [7]) that goes back to Horn and Norlünd, in which the Laplace transform plays a key role. Other types of convergent expansions for Bessel functions have been considered. J. Hadamard gave an expansion for the modified Bessel equation $I_\nu(z)$ which is particularly useful (see [8, pp. 204-205]). Hadamard's series representations for the other Bessel functions, while convergent, determine the solutions only to within the addition of an exponentially small error term.

In a relatively recent paper Rosser [6] discussed a third type of series expansion, for the modified Bessel function $K_\nu(z)$, which involves quotients of gamma functions (see (5.17) below). The coefficients in such an expansion, which turn out to be somewhat more elusive than the factorial series coefficients, have been conjectured by Rosser to have a similar rate of growth. Using the same kind of argument as in § 5, we are also able to prove Rosser's conjecture, including the form of their complete asymptotic expansion.

2. Factorial representations for unmodified Bessel functions. In this section we examine solutions of Bessel's equation

$$\frac{d^2w}{dz^2}+\frac{1}{z}\frac{dw}{dz}+\left(1-\frac{\nu^2}{z^2}\right)w=0. \tag{2.1}$$

We assume throughout that ν is real and nonnegative, and furthermore is not equal to $\frac{1}{2}$ (in which case the solutions can be expressed in terms of elementary functions). Extensions of the following results to complex ν are feasible, but we shall not pursue this.

We shall derive a factorial series expansion for $H_\nu^{(1)}(z)$, and from this we derive corresponding results for the Bessel functions $H_\nu^{(2)}(z)$, $J_\nu(z)$, and $Y_\nu(z)$. We seek a factorial series representation for $u(\nu, z)$, defined by

$$H_\nu^{(1)}(z)=\left(\frac{2}{\pi z}\right)^{1/2} e^{-\nu\pi i/2-\pi i/4}\, e^{iz}[1+u(\nu, z)]. \tag{2.2}$$

Note that $u(\nu, z)$ possesses the following asymptotic expansion as $z\to\infty$ (e.g., see [5, p. 238]):

$$u(\nu, z)\sim\sum_{s=1}^{\infty} i^s\frac{A_s(\nu)}{z^s} \qquad (-\pi+\delta\leqq\arg z\leqq 2\pi-\delta), \tag{2.3a}$$

where

$$A_s(\nu)=\frac{(4\nu^2-1^2)(4\nu^2-3^2)\cdots(4\nu^2-(2s-1)^2)}{s!8^s}. \tag{2.3b}$$

Following Horn, consider the function $f(\nu, t)$ defined implicitly by

$$u(\nu, z)=\int_0^\infty e^{-zt}f(\nu, t)\,dt. \tag{2.4}$$

We make the following assumptions on $f(\nu, t)$ a priori, and these will be justified below. We assume

$$\lim_{t\to\infty}(tf(\nu, t))'\,e^{-\kappa t}=\lim_{t\to\infty} tf(\nu, t)\,e^{-\kappa t}=0, \qquad \text{arbitrary } \kappa>0. \tag{2.5}$$

We shall also need the following information, which follows from (2.3) and (2.4) and integration by parts:

$$f(\nu, 0)=iA_1(\nu)=i\sigma/2, \qquad \sigma=\nu^2-\tfrac{1}{4} \quad (\neq 0). \tag{2.6}$$

Here we have introduced a new parameter σ for later convenience.

From (2.4)-(2.6), and the following inhomogeneous differential equation for $u(\nu, z)$

$$z^2\frac{d^2u}{dz^2}+2iz^2\frac{du}{dz}-\sigma u=\sigma, \tag{2.7}$$

we find that $f(\nu, t)$ satisfies

$$t(t-2i)\frac{d^2f}{dt^2}+4(t-i)\frac{df}{dt}+(2-\sigma)f=0. \tag{2.8}$$

This is a form of the hypergeometric equation. From (2.6) we see that

$$f(\nu, t)=\frac{i\sigma}{2}F\left(\frac{3}{2}+\nu, \frac{3}{2}-\nu; 2; -\frac{it}{2}\right), \tag{2.9}$$

with the usual notation. This representation is very closely related to some well-known integral transforms (e.g., see [2, p. 212, eqs. (1), (4)]).

The hypergeometric function $f(\nu, t)$ given by (2.9) has a simple pole at $t=2i$ (see [5, p. 166, eq. (10.11)]). Its behavior at the regular singularity at infinity is given by (see [5, p. 167])

$$f(\nu, t)\sim a_0(\nu)t^{\nu-3/2}, \tag{2.10a}$$

where

$$a_0(\nu)=\begin{cases}\dfrac{\sigma\pi 2^{1/2-\nu}\, e^{(2\nu-1)\pi i/4}}{\sin(2\pi\nu)\Gamma(\frac{3}{2}+\nu)\Gamma(\frac{1}{2}+\nu)\Gamma(1-2\nu)} & (2\nu\neq 0, 1, 2, \cdots), \\ \dfrac{\sigma\Gamma(2\nu)2^{1/2-\nu}\, e^{(2\nu-1)\pi i/4}}{\Gamma(\frac{3}{2}+\nu)\Gamma(\frac{1}{2}+\nu)} & (2\nu=1, 2, 3, \cdots),\end{cases} \tag{2.10b}$$

and

$$f(0, t)=O(t^{-3/2}\ln(t)). \tag{2.10c}$$

The cut associated with the branchpoint at infinity runs along the imaginary axis from $t=i\infty$ to $t=2i$.

To derive a factorial series expansion formally, use

$$\int_0^\infty (1-e^{-t})^m e^{-zt}\,dt=\frac{m!}{z(z+1)\cdots(z+m)}, \qquad (m=0, 1, 2, \cdots), \tag{2.11}$$

and expand $f(\nu, t)$ in terms of a new independent variable $\xi(t)$ defined by

$$\xi=1-e^{-t}. \tag{2.12}$$

A region T in the t plane bounded by the parametric curve $t=-\ln(2\cos(\theta/2))+i\theta/2$ $(-\pi<\theta<\pi)$ is mapped to the unit disk $|\xi|\leqq 1$ in the ξ plane; see Fig. 1. The singularities $t=0, 2i, \infty$ are mapped to $\xi=0, 1-e^{-2i}, 1$, respectively. For this section we confine our attention to t lying in T, or correspondingly, ξ lying in the unit disk $|\xi|\leqq 1$.

Regarding $f(\nu, t)$ as a function of ξ, i.e.,

$$f(\nu, t)=f(\nu, -\ln(1-\xi))\equiv\phi(\nu, \xi), \tag{2.13}$$

it follows that $\phi(\nu, \xi)$ is analytic throughout $|\xi|\leqq 1$ except at $\xi=1$, where it has a logarithmic singularity:

$$\phi(\nu, \xi)=O([-\ln(1-\xi)]^{\nu-3/2}), \qquad \xi\to 1^-. \tag{2.14}$$

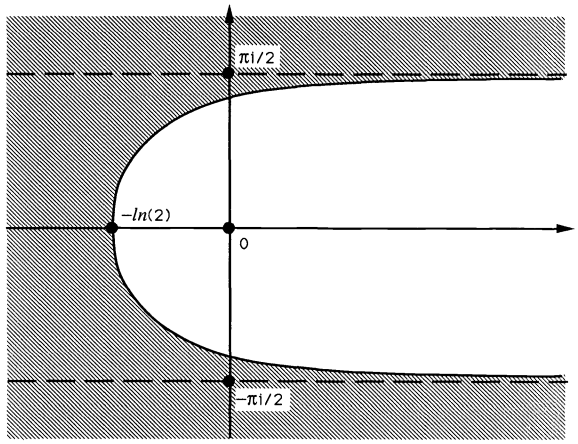

FIG. 1. *Domain T in t plane.*

Therefore, $\phi(\nu, \xi)$ possesses a Maclaurin expansion of the form

$$f(\nu, t) \equiv \phi(\nu, \xi) = \sum_{m=0}^{\infty} c_m(\nu)\xi^m, \tag{2.15}$$

which is convergent for $|\xi| < 1$. On substitution of (2.15) into (2.4), interchanging the summation and integral, and then employing (2.11), we formally arrive at the factorial series representation

$$u(\nu, z) = \sum_{m=0}^{\infty} \frac{c_m(\nu)m!}{z(z+1)\cdots(z+m)}. \tag{2.16}$$

For a justification of this formal process see § 4.

A necessary and sufficient condition for absolute convergence in a half plane $\mathrm{Re}\,(z) \geqq \kappa$ is that the coefficients satisfy

$$c_m(\nu) = O(m^{\kappa-1})$$

as $m \to \infty$; see [3] or [7]. In § 5 we shall show that $c_m(\nu) = o(m^{\varepsilon-1})$ as $m \to \infty$ for arbitrary positive ε. This implies uniform absolute convergence of the series for $\mathrm{Re}\,(z) \geqq \varepsilon > 0$.

One way of determining the Maclaurin coefficients is to employ the differential equation for $\phi(\nu, \xi)$ together with the initial condition $\phi(\nu, 0) = i\sigma/2$. From (2.8) and (2.12) we readily find that the equation is given by

$$p(\xi)\phi_{\xi\xi} + q(\xi)\phi_{\xi} + (2-\sigma)\phi = 0, \tag{2.17}$$

where

$$p(\xi) = (\xi-1)^2 t(t-2i), \qquad q(\xi) = (t^2 - 2it - 4t + 4i)(\xi - 1), \tag{2.18}$$

with $t = -\ln(1-\xi)$. Clearly $p(\xi)$ and $q(\xi)$ possess Maclaurin expansions of the form

$$p(\xi) = \sum_{r=1}^{\infty} p_r \xi^r, \quad q(\xi) = \sum_{r=0}^{\infty} q_r \xi^r, \quad |\xi| < 1.$$

Substituting these series and (2.15) into (2.17) we obtain

$$c_0(\nu)=\frac{i\sigma}{2}, \qquad c_1(\nu)=\frac{\sigma(2-\sigma)}{8}, \tag{2.19a, b}$$

$$\begin{aligned} c_{m+1}(\nu)=&\frac{1}{2i(m+1)(m+2)} \\ &\cdot\left\{q_m c_1(\nu)+\sum_{j=2}^{m}\{jc_j(\nu)[(j-1)p_{m+2-j}+q_{m+1-j}]\}+(2-\sigma)c_m(\nu)\right\} \\ &(m=1,2,\cdots), \end{aligned} \tag{2.20}$$

with the understanding that the summation in (2.20) is null for $m=1$.

Explicit formulas for the coefficients $\{p_r\}$ and $\{q_r\}$ can be derived by differentiating the expression for $p(\xi)$ r-times, and then using Taylor's formula $p_r=p^{(r)}(0)/r!$; the same holds for $q(\xi)$. After simplification using the binomial theorem, we find

$$\begin{aligned} &p_1=-2i, \quad p_2=1+3i, \quad p_3=-1-\frac{2}{3}i, \\ &p_r=\frac{1}{r(r-1)(r-2)}\left\{4\sum_{j=1}^{r-3}\frac{1}{j}-6-4i\right\} \qquad (r\geqq 4); \end{aligned} \tag{2.21}$$

$$\begin{aligned} &q_0=-4i, \quad q_1=4+6i, \quad q_2=-3-i, \\ &q_r=\frac{1}{r(r-1)}\left\{2\sum_{j=1}^{r-2}\frac{1}{j}-6-2i\right\} \qquad (r\geqq 3). \end{aligned} \tag{2.22}$$

The above recursion scheme provides a simple and numerically satisfactory means of evaluating the factorial coefficients $\{c_m(\nu)\}$ $(m=0,1,2,\cdots)$.

The factorial coefficients can also be expressed explicitly in terms of Stirling numbers of the first kind $S_n^{(m)}$ and the coefficients $\{A_s(\nu)\}$ in the asymptotic expansion (2.3) of the Hankel function. Following [7, pp. 329–330] we find

$$c_0(\nu)=iA_1(\nu), \qquad c_m(\nu)=\frac{(-1)^m i}{m!}\sum_{j=1}^{m}(-i)^j A_{j+1}(\nu)S_m^{(j)} \qquad (m=1,2,\cdots). \tag{2.23}$$

These formulas are more difficult to implement in numerical calculations as they require calculation of large individual terms to a high degree of accuracy. Another procedure for recursively calculating the coefficients can be derived by substituting the expansion (2.16) into equation (2.7) and using known formulas for derivatives of factorial series.

Finally, to obtain factorial series representations for the other standard Bessel function we use the well-known relations

$$H_\nu^{(1)}(z)=\overline{H_{\bar\nu}^{(2)}(\bar z)}, \qquad J_\nu(z)=\frac{1}{2}\{H_\nu^{(1)}(z)+H_\nu^{(2)}(z)\},$$

$$Y_\nu(z)=\frac{1}{2i}\{H_\nu^{(1)}(z)-H_\nu^{(2)}(z)\}.$$

We find

$$H_\nu^{(2)}(z)=\left(\frac{2}{\pi z}\right)^{1/2} e^{\nu\pi i/2+\pi i/4}\, e^{-iz}\left[1+\sum_{m=0}^{\infty}\frac{\overline{c_m(\nu)}m!}{z(z+1)\cdots(z+m)}\right], \tag{2.24}$$

$$\begin{aligned} J_\nu(z)=\left(\frac{2}{\pi z}\right)^{1/2}&\left\{\cos(z-\nu\pi/2-\pi/4)\left[1+\sum_{m=1}^{\infty}\frac{\mathrm{Re}\{c_m(\nu)\}m!}{z(z+1)\cdots(z+m)}\right]\right. \\ &\left.-\sin(z-\nu\pi/2-\pi/4)\sum_{m=0}^{\infty}\frac{\mathrm{Im}\{c_m(\nu)\}m!}{z(z+1)\cdots(z+m)}\right\}, \end{aligned} \tag{2.25}$$

$$Y_\nu(z)=\left(\frac{2}{\pi z}\right)^{1/2}\left\{\sin(z-\nu\pi/2-\pi/4)\left[1+\sum_{m=1}^{\infty}\frac{\mathrm{Re}\{c_m(\nu)\}m!}{z(z+1)\cdots(z+m)}\right]\right.$$
$$\left.+\cos(z-\nu\pi/2-\pi/4)\sum_{m=0}^{\infty}\frac{\mathrm{Im}\{c_m(\nu)\}m!}{z(z+1)\cdots(z+m)}\right\}. \tag{2.26}$$

3. Factorial representations for modified Bessel functions. The standard solutions of the modified Bessel equation

$$\frac{d^2w}{dz^2}+\frac{1}{z}\frac{dw}{dz}-\left(1+\frac{\nu^2}{z^2}\right)w=0, \tag{3.1}$$

are the modified Bessel functions $K_\nu(z)$ and $I_\nu(z)$. The purpose of this section is to derive factorial series expansions for these two functions which are uniformly and absolutely convergent in the half plane $\mathrm{Re}(z)\geqq\varepsilon>0$.

Consider $K_\nu(z)$ first. The derivation of a factorial series expansion for this function follows in a similar manner to that of the Hankel functions. We define $\tilde{u}(\nu, z)$ by

$$K_\nu(z)=\left(\frac{\pi}{2z}\right)^{1/2}e^{-z}[1+\tilde{u}(\nu, z)]. \tag{3.2}$$

Proceeding in a manner similar to the previous section we find that

$$\tilde{u}(\nu, z)=\int_0^\infty e^{-zt}\tilde{f}(\nu, t)\,dt, \tag{3.3}$$

where

$$\tilde{f}(\nu, t)=\frac{\sigma}{2}F\left(\frac{3}{2}+\nu, \frac{3}{2}-\nu; 2; -\frac{t}{2}\right). \tag{3.4}$$

The hypergeometric function $\tilde{f}(\nu, t)$ has a simple pole at $t=-2$ and a regular singularity at infinity. It therefore has no finite singularities inside the region T (defined in § 2). Thus, proceeding as before, we find that

$$\tilde{u}(\nu, z)=\sum_{m=0}^{\infty}\frac{d_m(\nu)m!}{z(z+1)\cdots(z+m)}. \tag{3.5}$$

The factorial coefficients $\{d_m(\nu)\}$ are found to be real, with $d_0(\nu)=-ic_0(\nu)$, $d_1(\nu)=-c_1(\nu)$, and the other coefficients satisfying the recursion relations (2.20)-(2.22) with i replaced by -1 in each equation.

We now turn our attention to the modified Bessel function $I_\nu(z)$. Unlike $H_\nu^{(1)}(z)$, $H_\nu^{(2)}(z)$, and $K_\nu(z)$, this function is dominant at infinity for all values of $\arg(z)$. The dominance makes the construction of a factorial series representation for it less straightforward than for the other three Bessel functions. We shall use the following representation:

$$I_\nu(z)=-\frac{i}{\pi}\{K_\nu(z\,e^{-\pi i})-e^{\nu\pi i}K_\nu(z)\}, \tag{3.6}$$

seeking a factorial series expansion for the modified Bessel function $K_\nu(z\,e^{-\pi i})$. Clearly, $K_\nu(z\,e^{-\pi i})$ is recessive at infinity in the sector $\pi/2<\arg(z)<3\pi/2$.

We next define $u^+(\nu, z)$ by

$$K_\nu(z\,e^{-\pi i})=i\left(\frac{\pi}{2z}\right)^{1/2}e^{z}[1+u^+(\nu, z)]. \tag{3.7}$$

Again, we could write $u^+(\nu, z)$ as a Laplace transform

$$u^+(\nu, z) = \int_\Gamma e^{-zt} f(\nu, t)\, dt \qquad (\mathrm{Re}\,(z) \geqq \kappa > 0), \tag{3.8}$$

where the path of integration Γ runs from $t = 0$ to infinity such that $\mathrm{Re}\,(zt) \to +\infty$. For any choice of Γ satisfying these requirements we find that $f(\mu, t)$ is a hypergeometric function which is regular at $t = 0$, but has a simple pole on the real axis at $t = 2$, which lies inside the region T. The presence of this singularity prevents us from proceeding exactly as before. If the pole were lying inside T, but not on the real axis, an appropriate (real) scaling of the variables t and z could reduce the problem to an equivalent one where the pole lies outside T (see [7, p. 326]).

Also we do not have enough information on $u^+(\nu, z)$ to determine the precise path of integration Γ in (3.8). This is because Γ can be taken to lie above or below the pole at $t = 2$ (the integrand remains unchanged in both circumstances). The two choices of Γ result in two different functions for the right-hand side, which differ by the residue of the integrand at $t = 2$. It is seen that this residue is $O(e^{-2z})$ as $\mathrm{Re}\,(z) \to \infty$, and therefore the asymptotic behavior of the integral at $z = \infty$ will be identical for either path. (The path Γ could also be chosen to loop the pole a number of times, or pass through it as a Cauchy principal value.)

The above difficulties arise from the fact that $K_\nu(z\, e^{-\pi i})$ is dominant in the half plane $|\arg(z)| < \pi/2$. In order to overcome the difficulty we seek a factorial series representation for $K_\nu(z\, e^{-\pi i})$ in the half plane $\mathrm{Re}\,(z\, e^{-\pi i/4}) \geqq \varepsilon > 0$. To do this we introduce the scaling factor

$$\omega = \frac{\pi}{4} + i\frac{\pi}{4} = \frac{\pi}{2\sqrt{2}}\, e^{i\pi/4}, \tag{3.9}$$

and seek a factorial series in terms of the variable $z^+ = z/\omega$. In place of (3.8) we therefore define

$$u^+(\nu, z) = \int_0^\infty e^{-z^+ t} f^+(\nu, t)\, dt. \tag{3.10}$$

where the path of integration is along the real axis. The pole of $f^+(\nu, t)$ is then found to be at $t = 2\omega$, which lies outside the region T. The modulus of ω was chosen to ensure this. Then, proceeding as before, we find that

$$u^+(\nu, z) = \sum_{m=0}^{\infty} \frac{d_m^+(\nu) m!}{z(z/\omega + 1) \cdots (z/\omega + m)}, \tag{3.11}$$

where

$$d_0^+(\nu) = -\frac{\sigma}{2}, \qquad d_1^+(\nu) = \frac{\sigma(\sigma - 2)}{8\omega}, \tag{3.12}$$

and where the other coefficients satisfy (2.20)–(2.22) with i replaced by ω, throughout. Thus from (3.6) we have the compound expansion

$$\begin{aligned} I_\nu(z) = \left(\frac{1}{2\pi z}\right)^{1/2} \Bigg\{ & e^z \left[1 + \sum_{m=0}^{\infty} \frac{d_m^+(\nu) m!}{z(z/\omega + 1) \cdots (z/\omega + m)} \right] \\ & + i\, e^{\nu\pi i}\, e^{-z} \left[1 + \sum_{m=0}^{\infty} \frac{d_m(\nu) m!}{z(z+1) \cdots (z+m)} \right] \Bigg\} \\ & \left(\mathrm{Re}\,(z) \geqq \varepsilon > 0, \quad -\frac{\pi}{4} + \delta \leqq \arg(z) \leqq \frac{\pi}{2} \right). \end{aligned} \tag{3.13}$$

A similar expansion, convergent in the conjugate region $\mathrm{Re}\,(z)\geqq\varepsilon>0$, $-\pi/2\leqq\arg z\leqq\pi/4-\delta$, can be derived from (3.13) and the relation $I_\nu(z)=\overline{I_{\bar\nu}(\bar z)}$.

When $z=x$ is real and positive both expansions are valid. A useful formula for $I_\nu(x)$ comes from adding these two formulas and dividing by 2. This yields

$$I_\nu(x)=\left(\frac{1}{2\pi x}\right)^{1/2}\left\{e^x\left[1+\sum_{m=0}^{\infty}\mathrm{Re}\left\{\frac{d_m^+(\nu)m!}{x(x/\omega^++1)\cdots(x/\omega^++m)}\right\}\right]\right.$$

(3.14)

$$\left.-\sin(\nu\pi)\,e^{-x}\left[1+\sum_{m=0}^{\infty}\frac{d_m(\nu)m!}{x(x+1)\cdots(x+m)}\right]\right\}$$

$$(x\geqq\varepsilon>0).$$

4. Error bounds. We seek a bound for $\delta_n(\nu,z)$ defined by

$$u(\nu,z)=\sum_{m=0}^{n-1}\frac{c_m(\nu)m!}{z(z+1)\cdots(z+m)}+\delta_n(\nu,z). \tag{4.1}$$

We concern ourselves here with the unmodified Bessel functions. Bounds for the modified Bessel functions can be derived in a similar manner.

Following [9, pp. 142–144] we derive

$$\delta_n(\nu,z)=\frac{1}{z(z+1)\cdots(z+n-1)}\int_0^1(1-\xi)^{z+n-1}\phi^{(n)}(\nu,\xi)\,d\xi. \tag{4.2}$$

Next, introduce the supremum

$$M(\nu,\alpha)=\sup_{t\in T}\{|f(\nu,t)\,e^{-\alpha t}|\}. \tag{4.3}$$

Because of (2.10a–c) it is seen that the supremum exists for all positive values of α. For our purposes it is necessary to impose the restriction that $0<\alpha<\mathrm{Re}\,(z)$. From (2.12) and (2.13) we find

$$|\phi(\nu,\xi)|\leqq M(\nu,\alpha)|1-\xi|^{-\alpha}\qquad(|\xi|\geqq1). \tag{4.4}$$

Therefore, for $0\leqq\xi<1$, we have from Cauchy's integral formula and (4.4)

$$|\phi^{(n)}(\nu,\xi)|\leqq\frac{M(\nu,\alpha)(1-\rho)^{-\alpha}n!}{\rho^n}\qquad(0<\rho<1-\xi). \tag{4.5}$$

Setting $\rho=(1-\xi)n/(n+1)$ in (4.5) and noting that $(1+n^{-1})^n<e$ $(n>0)$, we obtain from (4.2) and (4.5) the bound

$$|\delta_n(\nu,z)|\leqq\frac{M(\nu,\alpha)\,en!}{|z(z+1)\cdots(z+n-1)|(\mathrm{Re}\,(z)-\alpha)}. \tag{4.6}$$

Incidentally, it can be confirmed from this bound that that factorial series is absolutely convergent for $\mathrm{Re}\,(z)>\alpha$.

Since we know that the convergence becomes slow for large ν we now examine the asymptotic behavior of $M(\nu,\alpha)$ as $\nu\to\infty$. The asymptotic behavior of $f(\nu,t)$ can be established from the differential equation (2.8) written in the normalized form

$$\frac{d^2\hat f}{dt^2}=\left\{\nu^2\frac{1}{t(t-2i)}-\frac{1}{4t(t-2i)}\right\}\hat f, \tag{4.7a}$$

$$\hat f(\nu,t)\equiv t(t-2i)f(\nu,t). \tag{4.7b}$$

This equation is characterized in T by having a simple pole at $t=0$ and a regular singularity at $t=\infty$. To obtain an asymptotic approximation that is uniformly valid at

both singularities we shall apply an asymptotic theory of differential equations having a simple pole in the complex plane [5, Chap. 12, § 9]. *Note that Olver's parameter u corresponds to our parameter ν, and in this application Olver's ν is equal to* 1.

The Liouville transformation given by (see [5, pp. 438-439])

$$\zeta^{1/2}=\int_0^t \frac{d\tau}{\tau^{1/2}(\tau-2i)^{1/2}}=\ln\left[it+1+i(t^2-2it)^{1/2}\right], \tag{4.8}$$

$$W(\nu,\zeta)=\left(\frac{4\zeta}{t(t-2i)}\right)^{1/4}\hat{f}(t), \tag{4.9}$$

takes (4.7a) into the form

$$\frac{d^2W}{d\zeta^2}=\left\{\frac{\nu^2}{4\zeta}-\frac{1}{4\zeta^2}+\frac{\psi(\zeta)}{\zeta}\right\}W, \tag{4.10}$$

where

$$\psi(\zeta)=-\frac{3}{16}\left\{\frac{1}{\zeta}+\frac{1}{t(t-2i)}\right\}. \tag{4.11}$$

With regard to (4.8) and (4.9) we introduce a branchcut along the imaginary t axis from $t=2i$ to $t=i\infty$, and a temporary cut along the negative t axis from $t=0$ to $t=-\infty$. With these cuts the integrand of (4.8) is taken to be positive for $\tau=$ is $(0<s<2)$ and continuous elsewhere. The ζ domain Δ corresponding to the t domain T is depicted in Fig. 2. The asymptote at infinity (dashed line) is the parabola

$$\mathrm{Re}\,(\zeta)=\left(\frac{\mathrm{Im}\,(\zeta)}{\pi}\right)^2-\left(\frac{\pi}{2}\right)^2. \tag{4.12}$$

The $t\leftrightarrow\zeta$ transformation (4.8) is analytic and $1\leftrightarrow1$ at all points in T, including the singularity $t=0$ ($\zeta=0$). The Schwarzian $\psi(\zeta)$ is holomorphic within Δ.

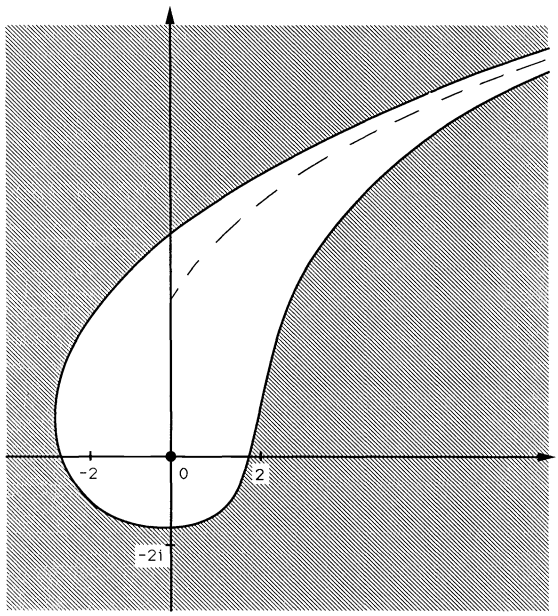

FIG. 2. *Domain Δ in ζ plane.*

The following can be deduced from the above equations:

$$\zeta = 2it + \tfrac{1}{3}t^2 - \tfrac{4}{45}it^3 + O(t^4) \quad \text{as } t \to 0, \tag{4.13}$$

$$\psi(\zeta) = -\tfrac{1}{16} + \tfrac{1}{80}\zeta - \tfrac{1}{504}\zeta^2 + O(\zeta^3) \quad \text{as } \zeta \to 0, \tag{4.14}$$

$$\exp(\zeta^{1/2}) \sim 2it \quad \text{as } t \to \infty. \tag{4.15}$$

We now apply Theorem 9.1 of [5, Chap. 12] to obtain the following solution of (4.10):

$$W(\nu, \zeta) = \zeta^{1/2} I_1(\nu\zeta^{1/2}) + \varepsilon_1(\nu, \zeta), \tag{4.16}$$

where $I_1(z)$ is the modified Bessel function of order 1 and $\varepsilon_1(\nu, \zeta)$ is uniformly bounded for $\zeta \in \Delta$ and $\nu > 0$ by

$$|\varepsilon_1(\nu, \zeta)| \leqq \mu_2 |\zeta|^{1/2} \mathscr{E}_1(\nu\zeta^{1/2}) \mathscr{M}_1(\nu\zeta^{1/2}) \exp\left\{\frac{\mu_1}{\nu} V\right\} \frac{V}{\nu}, \tag{4.17a}$$

with

$$V = \int_{\mathscr{P}} |v^{-1/2}\psi(v)|\, dv. \tag{4.17b}$$

The path of integration $\mathscr{P}$ of (4.18) links zero to ζ in the v plane subject to the first of the conditions (i) and (ii) of [5, p. 457]. The convergence of this integral at $\zeta = 0$ and $\zeta = \infty$ in Δ is readily verified from (4.11), (4.14), and (4.15); compare also equation (4.7a) with Example 4.1 of [5, p. 369].

In (4.17) $\mathscr{E}_1(z)$ and $\mathscr{M}_1(z)$ are auxiliary functions for modified Bessel functions of complex argument, satisfying

$$|I_1(z)| = \mathscr{E}_1(z)\mathscr{M}_1(z) \cos(\theta_1(z)) \qquad (|\arg(z)| \leqq \pi/2), \tag{4.18}$$

where $\theta_1(z)$ is a real function of z. The constants μ_1 and μ_2 are certain suprema involving these auxiliary functions (see [5, pp. 454–456]). The significance of the bound (4.17a, b) is that it establishes the fact that

$$\frac{\varepsilon_1(\nu, \zeta)}{\zeta^{1/2} I_1(\nu\zeta^{1/2})} = \begin{cases} O(\zeta) & \text{as } \zeta \to 0; \\ O(1/\nu) & \text{uniformly in } \Delta \text{ except} \\ & \text{near the zeros of } I_1(\nu\zeta^{1/2}). \end{cases} \tag{4.19}$$

The function (4.16) is the solution of (4.10) that is recessive at $\zeta = 0$. As such it can be directly identified with the hypergeometric function of (2.9), since that function is also recessive at $t = 0$. On comparing then both solutions at $t = 0$ ($\zeta = 0$) we deduce that for $\nu > 0$ ($\nu \neq \frac{1}{2}$), $t \in T$ ($\zeta \in \Delta$),

$$\begin{aligned} f(\nu, t) &= \frac{i\sigma}{2} F\left(\frac{3}{2} + \nu, \frac{3}{2} - \nu; 2; -\frac{it}{2}\right) \\ &= i\left\{\frac{4\nu^2 - 1}{4\nu}\right\} \frac{\zeta^{1/4}}{[t(2i - t)]^{3/4}} [I_1(\nu\zeta^{1/2}) + \zeta^{-1/2}\varepsilon_1(\nu, \zeta)]. \end{aligned} \tag{4.20}$$

In deriving this asymptotic formula we employed (2.6), (4.7b), (4.9), (4.13), (4.16), (4.19), together with the well-known asymptotic behavior of $I_1(z)$ near $z = 0$ (e.g., see [5, p. 435]).

Before applying the above results to bound $M(\nu, \alpha)$ we prove the following result.

LEMMA 1. *For* $\nu > \alpha(\pi/2 + 1) > 0$,

$$\begin{aligned} N(\nu, \alpha) &\equiv \sup_{t \in T} |\exp(\nu\zeta^{1/2} - \alpha t)| \\ &\leqq \max\{2^\nu \nu^\nu \alpha^{-\nu} e^{-\nu + \alpha\pi/2 + \alpha}, 2^\alpha [2(\ln(2) + (\pi/2) + 1)]^\nu\}. \end{aligned} \tag{4.21}$$

Proof. We seek an upper bound on $\mathrm{Re}\,(\nu\zeta^{1/2}-\alpha t)$ for $t\in T$. First, from the parametric equation for the boundary of T (see the paragraph following equation (2.12)) we have for $t\in T$

$$|t|\leqq|x|+\frac{\pi}{2},\qquad x\equiv\mathrm{Re}\,(t). \tag{4.22}$$

Thus, for $t\in T$, $x\geqq 0$,

$$\begin{aligned}\mathrm{Re}\,(\nu\zeta^{1/2}-\alpha t)&=\nu\ln\{|it+1+i(t^2-2it)^{1/2}|\}-\alpha x\\&\leqq\nu\ln\{|t|+1+(|t|^2+2|t|+1)^{1/2}\}-\alpha x\\&\leqq\nu\ln\{2(x+(\pi/2)+1)\}-\alpha x\equiv m(x).\end{aligned} \tag{4.23}$$

The only stationary point of $m(x)$ in $0<x<\infty$ is $x=x_c=\nu/\alpha-(\pi/2)-1$ (note the hypothesis of this lemma). It is readily verified that the absolute maximum of $m(x)$ in $[0,\infty)$ occurs at $x=x_c$. Therefore it follows that

$$\mathrm{Re}\,(\nu\zeta^{1/2}-\alpha t)\leqq m(x)\leqq m\left(\frac{\nu}{\alpha}-\frac{\pi}{2}-1\right)\qquad(t\in T,\ \mathrm{Re}\,(t)\geqq 0).$$

On exponentiation and simplification we arrive at the first of the maxima of the right-hand side of (4.21).

For the complementary case $-\ln(2)<x<0$ we find

$$\begin{aligned}\mathrm{Re}\,(\nu\zeta^{1/2}-\alpha t)&\leqq\nu\ln\{2(|x|+(\pi/2)+1)\}-\alpha x\\&\leqq\nu\ln\{2(\ln(2)+(\pi/2)+1)\}+\alpha\ln(2)\qquad(t\in T,\ \mathrm{Re}\,(t)<0),\end{aligned}$$

noting the monotonicity of the middle expression. Again we exponentiate, and the second of the maxima of the right-hand side of (4.21) is obtained. This completes the proof of Lemma 1.

Finally, from (4.17), (4.18), and (4.20), we derive for $t\in T$ the bound

$$\begin{aligned}|f(\nu,t)\,e^{-\alpha t}|\leqq\left|\left\{\frac{4\nu^2-1}{4}\right\}\left\{\frac{\zeta}{t(2i-t)}\right\}^{3/4}\left\{\frac{\mathscr{E}_1(\nu\zeta^{1/2})\mathscr{M}_1(\nu\zeta^{1/2})\exp\{-\nu\zeta^{1/2}\}}{\nu\zeta^{1/2}}\right\}\right.\\\left.\cdot\{\exp(\nu\zeta^{1/2}-\alpha t)\}\left\{1+\mu_2\exp\left(\frac{\mu_1}{\nu}V\right)\frac{V}{\nu}\right\}\right|.\end{aligned}$$

Hence, from (4.3),

$$M(\nu,\alpha)\leqq\left|\frac{4\nu^2-1}{4}\right|\lambda_1\lambda_2\lambda_3(\nu)N(\nu,\alpha), \tag{4.24}$$

where

$$\lambda_1=\sup_{t\in T}\left|\frac{\zeta}{t(2i-t)}\right|^{3/4}, \tag{4.25}$$

$$\lambda_2=\sup_{\mathrm{Re}\,(z)\geqq 0}\left\{\left|\frac{e^{-z}}{z}\right|\mathscr{E}_1(z)\mathscr{M}_1(z)\right\}, \tag{4.26}$$

$$\lambda_3(\nu)=1+\mu_2\exp\left(\frac{\mu_1}{\nu}V_\infty\right)\frac{V_\infty}{\nu}\qquad\left(V_\infty=\int_0^\infty|v^{-1/2}\psi(v)|\,dv\right), \tag{4.27}$$

and where $N(\nu,\alpha)$ is defined and bounded by (4.21). The existence of λ_1 is seen from (4.13) and (4.15). From (8.09), (8.16), and (8.25) of [5, Chap. 12] it can also be verified that λ_2 exists.

5. Asymptotic behavior of the factorial coefficients. For the convergence of the factorial series derived in § 2, it is helpful to obtain some information on the size of the factorial coefficients $c_m(\nu)$ as $m \to \infty$, including the dependence on the parameter ν. The purpose of this section is to investigate this behavior. We shall suppose that $\nu \neq 0, \frac{1}{2}$.

To determine the asymptotic behavior we use the representation

$$c_m(\nu) = \frac{1}{2\pi i} \oint_{|\xi|=\rho<1} \frac{\phi(\nu, \xi)}{\xi^{m+1}} \, d\xi, \tag{5.1}$$

which comes from (2.15) and Cauchy's formula, or equivalently

$$c_m(\nu) = \frac{1}{2\pi i} \oint_{|t|=\delta>0} \frac{f(\nu, t)\, e^{-t}}{(1-e^{-t})^{m+1}} \, dt, \tag{5.2}$$

where $t = -\ln(1-\xi)$. As it turns out, the asymptotic behavior of $f(\nu, t)$ as $t \to \infty$ determines the behavior of $c_m(\nu)$ as $m \to \infty$.

First deform the contour in (5.2) into a path γ consisting of a finite segment γ_0 from $t = i\pi$ to $t = -i\pi$, and two semi-infinite lines γ^+ and γ^- as depicted in Fig. 3. The integrals along the infinite segments converge because of the behavior of $f(\nu, t)$ near $t = \infty$ (see (2.10a-c)). The only finite singularity of $f(\nu, t)$ is a simple pole at $t = 2i$, and in deforming the contour we have taken into account the location of that pole. Note also that the integrand has an infinite number of poles along the imaginary axis at $t = 2n\pi i$ $(n = 0, \pm 1, \pm 2, \cdots)$.

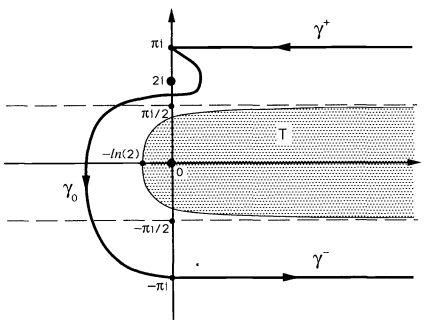

FIG. 3. *Integration path γ in t plane.*

Along the finite segment γ_0 the numerator of the integrand is bounded, while the modulus of the denominator is bounded below by c^m, for some real constant c which is greater than 1. Hence the integral along γ_0 contributes a term of order $O(c^{-m})$ as $m \to \infty$. All such terms of order $O(c^{-m})$, $c > 1$, will be considered from now on as *asymptotically negligible.* The main contributions come from the integrals along γ^+ and γ^-, since we shall see that they are of much larger order of magnitude. Any further information about the value of c is therefore unnecessary.

Note that we could have chosen the segments $\gamma^\pm$ to be semi-infinite lines along $\text{Im}\,(t) = A^\pm$, for any constants $A^+ > 0$ and $A^- < 0$. However, in order that the contribution from the path γ_0 be asymptotically negligible it is necessary that $\pi/2 \leqq |A^\pm| \leqq 3\pi/2$, since otherwise γ_0 would pass through at least one region in which $|1 - e^{-t}| < 1$. Our particular choices $A^\pm = \pm\pi$ were taken for convenience.

Now consider the contribution from the paths $\gamma^{\pm}$. We parameterize $\gamma^{\pm}$ by $t = \pm i\pi + \tau$ $(0 \leqq \tau < \infty)$. Integration along γ^{+} and γ^{-} then gives

$$\frac{1}{2\pi i}\int_0^{\infty} \frac{[f(\nu, i\pi+\tau) - f(\nu, -i\pi+\tau)]\, e^{-\tau}}{(1+e^{-\tau})^{m+1}}\, d\tau. \tag{5.3}$$

In (5.3) we now make the change of variable $1+e^{-\tau} = e^{u}$, which yields

$$\frac{1}{2\pi i}\int_0^{\ln(2)} g(\nu, u)\, e^{-mu}\, du, \tag{5.4}$$

where

$$g(\nu, u) = f(\nu, i\pi - \ln(e^{u}-1)) - f(\nu, -i\pi - \ln(e^{u}-1)). \tag{5.5}$$

The behavior of (5.4) as $m \to \infty$ depends upon the asymptotic behavior of $g(\nu, u)$ as $u \to 0^{+}$, which in turn corresponds to the behavior of $f(\nu, t)$ as $t \to \infty$ along γ^{+} and γ^{-}. For this we use the following representation of $f(\nu, t)$:

$$f(\nu, t) t^{\nu-3/2} \sum_{k=0}^{\infty} a_k(\nu) t^{-k} + t^{-\nu-3/2} \sum_{k=0}^{\infty} b_k(\nu) t^{-k}, \tag{5.6}$$

where both series converge for $|t| > 2$. The coefficients $\{a_k(\nu)\}$ and $\{b_k(\nu)\}$ $(k = 0, 1, 2, \cdots)$ can be determined explicitly from (2.9) and a connection formula (see [5, p. 167, eq. (10.15)]).

Then, setting $t = \pm i\pi + \tau$ in (5.6) and reexpanding yields

$$f(\nu, \pm i\pi + \tau) = \tau^{\nu-3/2} \sum_{k=0}^{\infty} a_k^{\pm}(\nu) \tau^{-k} + \tau^{-\nu-3/2} \sum_{k=0}^{\infty} b_k^{\pm}(\nu) \tau^{-k}, \tag{5.7}$$

which converges for $\tau > \pi$. In this expression $a_0^{\pm}(\nu) = a_0(\nu)$, $b_0^{\pm}(\nu) = b_0(\nu)$, and the other coefficients in (5.7) can be expressed explicitly in terms of those in (5.6).

If we now write

$$\begin{aligned} g(\nu, u) = {} & f\left(\nu, i\pi - \ln(u) + \ln\left\{\frac{u}{e^{u}-1}\right\}\right) \\ & - f\left(\nu, -\pi - \ln(u) + \ln\left\{\frac{u}{e^{u}-1}\right\}\right), \end{aligned} \tag{5.8}$$

and use the fact that $\ln(u/(e^{u}-1))$ is regular at $u = 0$ and vanishes there, we find (observing that the leading terms cancel)

$$\begin{aligned} g(\nu, u) = {} & (-\ln(u))^{\nu-5/2} \sum_{k=0}^{\infty} \frac{\hat{a}_k(\nu)}{(-\ln(u))^{k}} + (-\ln(u))^{-\nu-5/2} \sum_{k=0}^{\infty} \frac{\hat{b}_k(\nu)}{(-\ln(u))^{k}} \\ & + O(u(-\ln(u))^{\nu-5/2}). \end{aligned} \tag{5.9}$$

The series in (5.9) converge uniformly for $0 < u \leqq \varepsilon$, for sufficiently small ε. Each of the coefficients $\hat{a}_k(\nu)$ and $\hat{b}_k(\nu)$ is expressible in terms of the coefficients $\{a_k^{\pm}(\nu)\}$ and $\{b_k^{\pm}(\nu)\}$.

For ε as above let

$$\int_0^{\ln(2)} g(\nu, u)\, e^{-mu}\, du = \int_0^{\varepsilon} g(\nu, u)\, e^{-mu}\, du + \int_{\varepsilon}^{\ln(2)} g(\nu, u)\, e^{-mu}\, du. \tag{5.10}$$

Since the contribution of the second integral is easily seen to be asymptotically negligible, it remains to determine the asymptotic behavior of

$$\int_0^\varepsilon g(\nu,u)\,e^{-mu}\,du=\sum_{k=0}^{\infty}\hat{a}_k(\nu)\int_0^\varepsilon(-\ln(u))^{\nu-5/2-k}\,e^{-mu}\,du$$

$$+\sum_{k=0}^{\infty}\hat{b}_k(\nu)\int_0^\varepsilon(-\ln(u))^{-\nu-5/2-k}\,e^{-mu}\,du \tag{5.11}$$

$$+\int_0^\varepsilon O(u(-\ln(u))^{\nu-5/2})\,e^{-mu}\,du,$$

as $m\to\infty$. Clearly integrals of the form

$$L(m,\lambda,\alpha)=\int_0^\varepsilon(-\ln(u))^{\alpha}u^{\lambda-1}\,e^{-mu}\,du \tag{5.12}$$

play a key role. Such integrals have been discussed by Erdélyi [4] for the parameters $0<\varepsilon<1$, $\lambda>0$, and α real. Erdélyi has shown that

$$L(m,\lambda,\alpha)\sim\textstyle\sum_{n=0}^{\infty}(-1)^n\binom{\alpha}{n}\Gamma^{(n)}(\lambda)m^{-\lambda}(\ln(m))^{\alpha-n}, \tag{5.13}$$

as $m\to\infty$. Hence setting $\lambda=1$ and 2, $\alpha=\pm\nu-\frac{5}{2}-k$ in (5.13), we finally obtain as $m\to\infty$

$$c_m(\nu)\sim\frac{(\ln(m))^{\nu-5/2}}{m}\sum_{k=0}^{\infty}\frac{\alpha_k(\nu)}{(\ln(m))^k}+\frac{(\ln(m))^{-\nu-5/2}}{m}\sum_{k=0}^{\infty}\frac{\beta_k(\nu)}{(\ln(m))^k}$$

$$+O\left(\frac{(\ln(m))^{\nu-5/2}}{m^2}\right), \tag{5.14}$$

where the coefficients $\{\alpha_k(\nu)\}$ and $\{\beta_k(\nu)\}$ are, in principle, computable in terms of those in the expansion for $f(\nu,t)$ given by (5.7) above. For example, the leading coefficient is found to be

$$\alpha_0(\nu)=\tfrac{1}{4}(\nu-\tfrac{3}{2})^2a_0(\nu), \tag{5.15}$$

where $a_0(\nu)$ is given in (2.10b).

By using the same analysis it can be shown that the coefficients $\{d_m(\nu)\}$ appearing in the factorial series expansions of the modified Bessel functions have similar asymptotic representations. Also, when ν is complex the factorial coefficients (in the modified and unmodified cases) have similar asymptotic representations. This can be shown using an analogue of Erdélyi's result (5.13) for α complex, due to Wong and Wyman [10].

The above procedure can also be used to analyze other similarly constructed series expansions and their coefficients. For example, Rosser [6] started with the integral representation

$$K_\nu(z)=\frac{\sqrt{\pi}\,(z/2)^\nu\,e^{-z}}{\Gamma(\nu+\frac{1}{2})}\int_0^1 s^{z-1}(\ln^2(s)-2\ln(s))^{\nu-1/2}\,ds, \tag{5.16}$$

and obtained the convergent (factorial-like) series expansion

$$\int_0^1 s^{z-1}(\ln^2(s)-2\ln(s))^{\nu-1/2}\,ds=\sum_{m=0}^{\infty}E_m(\nu)\frac{\Gamma(z)\Gamma(m+\nu+\frac{1}{2})}{\Gamma(z+m+\nu+\frac{1}{2})}, \tag{5.17}$$

where the coefficients $\{E_m(\nu)\}$ are defined implicitly by means of the auxiliary function

$$h(\nu, t)=\left[\frac{\ln^2(1-t)-2\ln(1-t)}{t}\right]^{\nu-1/2}=\sum_{m=0}^{\infty} E_m(\nu)t^m. \tag{5.18}$$

Rosser conjectured that the coefficients should satisfy

$$E_m(\nu)=O\left(\frac{\{\ln(m)\}^{M(\nu)}}{m}\right) \quad \text{as } m\to\infty, \tag{5.19}$$

where $M(\nu)$ is some number independent of m. With a similar analysis as above it can easily be shown that this is indeed the case. In fact the coefficients $\{E_m(\nu)\}$ have asymptotic expansions of the form

$$E_m(\nu)\sim\frac{(\ln(m))^{2\nu-2}}{m}\sum_{k=0}^{\infty}\frac{e_k(\nu)}{(\ln(m))^k} \quad \text{as } m\to\infty, \tag{5.20}$$

where the coefficients $\{e_k(\nu)\}$ can also be explicitly given. When ν is half an odd integer (5.17) reduces to an ordinary factorial series, but otherwise there do not exist explicit means for computing the coefficients $\{E_m(\nu)\}$. A reason for this is that when ν is not half an odd integer the integral (5.16) does not possess an asymptotic expansion involving only powers of $1/z$.

6. Numerical calculations and conclusions. While the factorial series converge in principle for $\mathrm{Re}\,(z)>0$ and for all $\nu\geqq 0$, in practice the error bounds (§ 4) and the behavior of the coefficients (§ 5) indicate that the convergence becomes quite slow when $\mathrm{Re}\,(z)$ is small, or when ν is large with respect to $\mathrm{Re}\,(z)$. For small $|z|$ the ascending power series converge well, and for moderate to large ν the large-order asymptotic expansions [5, pp. 377, 423–424] are particularly powerful since they are doubly asymptotic: they are uniformly valid at both $z=0$ and at $z=\infty$.

Tables 1(a) ($\nu=0$) and 2(a) ($\nu=2$) contain, for various values of n and real values of z (denoted by x), the following partial factorial sums which appear in the representation for $K_\nu(x)$:

$$\left[1+\sum_{m=0}^{n}\frac{d_m(\nu)m!}{x(x+1)\cdots(x+m)}\right]. \tag{6.1}$$

The coefficients $\{d_m(\nu)\}$ were calculated using the recurrence relations (2.20)–(2.22) with i replaced by -1, and all calculations were performed in double precision. (The rows labeled "A & S" are values of $(2x/\pi)^{1/2}e^xK_\nu(x)$ calculated from tables in Abramowitz and Stegun [1, Chap. 9].) As a comparison, partial sums of the corresponding ascending power series [1, p. 375] for $(2x/\pi)^{1/2}e^xK_0(x)$ are given in Table 1(b).

Tables 1(c) and 2(b) contain calculations for $(2x/\pi)^{1/2}e^xK_\nu(x)$ using asymptotic expansions for large argument, and Table 2(c) contains calculations for $(2x/\pi)^{1/2}e^xK_2(x)$ using the uniform asymptotic expansion for large order; see [1, p. 378, eqs. (9.7.2), (9.7.8)]). In these tables the values in parentheses are the number of terms taken in the expansion to attain the indicated value.

For small $\mathrm{Re}\,(z)$ the convergence of the factorial series, while predictably slow, appears to be numerically stable. For $\mathrm{Re}\,(z)$ large the factorial coefficients are not significantly more difficult to calculate than the coefficients in the large argument asymptotic expansions, and the two series have roughly comparable errors after a moderate number of terms. If better accuracy than available from the asymptotic expansions is required, the convergent factorial series are a reasonable alternative, particularly when ν is small.

In summary, factorial series expansions for Bessel functions are good for small parameter values and moderate to large values of $\mathrm{Re}\,(z)$, $0 \leqq \nu \leqq 2$ and $\mathrm{Re}\,(z) \geqq 10$, say. Special contiguous relations for Bessel functions have been successfully used for their efficient numerical calculation; see [1, pp. 385–388]. Factorial series could possibly be employed in conjunction with these other procedures. For example, as an alternative means of providing starting values in forward recursion schemes or continued fraction iterations [8, p. 153], particularly when the usual normalization procedure is not numerically satisfactory (such as Neumann's series for $K_0(x)$ when x is large [1, p. 377, eq. (9.6.53)]).

POLYNOMIALS WITH NONNEGATIVE COEFFICIENTS WHOSE ZEROS HAVE MODULUS ONE*

RONALD EVANS† AND JOHN GREENE‡

Abstract. Define $p(z) = \prod_{j=0}^{n-1} \left(z - e^{i(\theta+\alpha j)}\right)\left(z - e^{-i(\theta+\alpha j)}\right)$ for $\alpha > 0$ and $\theta \geq 0$ with $\pi/2 - (n-1)\alpha/2 \leq \theta \leq \pi - (n-1)\alpha/2$. It is proved that if $0 < \alpha < \pi/n$, then the $2n+1$ coefficients of $p(z)$ are all positive. It is also proved that if for some point θ, all coefficients of $p(z)$ are nonnegative, then each coefficient is an increasing function of θ in a neighborhood of this point. A similar result is conjectured for more general polynomials $p(z)$.

Key words. orthogonal polynomials, q-ultraspherical polynomials, absolutely monotonic polynomials

1. Introduction.

For

$$\alpha > 0 \quad \text{and} \quad \theta \geq 0, \tag{1.1}$$

consider the monic polynomial $p(z)$ of degree $2n$ whose zeros consist of the n equally spaced points

$$\exp(i(\theta + \alpha j)), \qquad 0 \leq j \leq n-1, \tag{1.2}$$

along with their n complex conjugates, i.e.,

$$p(z) = \prod_{j=0}^{n-1} \left(z - e^{i(\theta+\alpha j)}\right)\left(z - e^{-i(\theta+\alpha j)}\right). \tag{1.3}$$

We assume *throughout* that the variable θ in (1.3) is restricted to the interval

$$\pi/2 - (n-1)\alpha/2 \leq \theta \leq \pi - (n-1)\alpha/2. \tag{1.4}$$

Equivalently,

$$\pi/2 \leq \theta + (n-1)\alpha/2 \leq \pi, \tag{1.5}$$

so that the geometric mean of the n zeros in (1.2) lies in the second quadrant. Condition (1.5) automatically holds, for example, if each of the n zeros in (1.2) has Argument $\in (0, \pi)$ and the coefficient of z in $p(z)$ is positive; this is easily seen from (2.12) and (2.17). When (1.5) holds, the geometric mean of the n zeros in (1.2) is closer to -1 than to $+1$, and it moves (together with at least half of the zeros of $p(z)$) towards -1 along the unit circle as θ increases.

The coefficients of $p(z)$ are not necessarily increasing functions of θ, even if each of the n zeros in (1.2) has Argument $\in (0, \pi)$ (in which case each of the n quadratic factors in (1.3) has increasing coefficients). For example, if $n = 3$, $\alpha = 5\pi/12$, then the coefficient of z^3 in $p(z)$ is negative and *decreasing* at $\theta = \pi/8$, while $\pi/8$ is in the interval (1.4). However, the following theorem holds for all n. The proof, given in §3, depends on properties of q-ultraspherical polynomials discussed in §2.

THEOREM 1. *If for some nonnegative $\theta = \theta_0$ in the interval* (1.4), *all coefficients of $p(z)$ are nonnegative, then they are each increasing functions of θ for $\theta_0 \leq \theta < \pi - (n-1)\alpha/2$. Except for the coefficients* 1 *of the leading and constant terms, the coefficients are in fact strictly increasing, unless $\alpha = 2\pi/n$.*

For $\alpha = 2\pi/n$, we have

$$p(z) = z^{2n} - 2\cos(\theta n) z^n + 1,$$

which has nonnegative coefficients for $\pi/(2n) \leq \theta \leq \pi/n$, but if $n > 1$, the coefficient of z is zero, which is not strictly increasing. This formula for $p(z)$ is proved in §3 (see (3.10)).

Consider for the moment the general polynomial

$$P(z) = \prod_{j=0}^{n-1} \left(z - e^{i(\theta + a_j)}\right)\left(z - e^{-i(\theta + a_j)}\right) \tag{1.6}$$

where

$$\theta \geq 0, \qquad 0 = a_0 < a_1 < \cdots < a_{n-1}. \tag{1.7}$$

The polynomial $P(z)$ reduces to $p(z)$ when $a_j = j\alpha$, $0 \leq j \leq n-1$. In view of Theorem 1, we might ask if nonnegativity of the coefficients of $P(z)$ for some $\theta = \theta_0$ always implies that the coefficients are increasing for $\theta \geq \theta_0$, when θ is restricted to the interval

$$\pi/2 - (a_1 + \cdots + a_{n-1})/n \leq \theta \leq \pi - (a_1 + \cdots + a_{n-1})/n. \tag{1.8}$$

The answer is no. For example, if $n = 3$, $a_1 = \pi/2$, $a_2 = 7\pi/12$, then the coefficients of $P(z)$ are all positive for $\pi/4 < \theta < 23\pi/36$, yet the coefficients of z^2, z^3, z^4 are each decreasing at $\theta = 2$. However, we believe the following.

CONJECTURE. *If the coefficients of $P(z)$ are all nonnegative for some $\theta = \theta_0 \geq 0$, then they are each increasing functions of θ on the interval $\theta_0 \leq \theta < \pi - a_{n-1}$.*

For convenient application of Theorem 1, we would like to have a simple necessary condition for the nonnegativity of the coefficients of $p(z)$. This is given in Theorem 2.

THEOREM 2. *Suppose that*

$$0 < \alpha < \pi/n. \tag{1.9}$$

Then each coefficient of $p(z)$ is positive (*and hence increasing in θ, by Theorem* 1).

This theorem was motivated by the fact that for sufficiently small α, all zeros of $p(z)$ are closer to -1 than to $+1$ (because of (1.5)), and so all coefficients of $p(z)$ are positive. The question is how small α must be.

For $n > 1$, the upper bound in (1.9) is best possible, i.e., if $\alpha > \pi/n$, the coefficients of $p(z)$ cannot all be positive on the interval (1.4). If $\alpha \geq 2\pi/n$, there is *no* θ

in the interval (1.4) for which all coefficients of $p(z)$ are positive. If $\pi/n \le \alpha < 2\pi/n$, the coefficients of $p(z)$ are all positive only on a subinterval

$$r_\alpha < \theta < \pi - (n-1)\alpha/2 \tag{1.10}$$

of the interval (1.4). These remarks will be proved in §4. Also in §4 we prove Theorem 2 and the following related result.

THEOREM 3. *Let $0 < \alpha < \pi/n$. Then all coefficients of*

$$p(u,v) := \prod_{j=(1-n)/2}^{(n-1)/2} (1 + ue^{i\alpha j} + ve^{-i\alpha j}) \tag{1.11}$$

are positive, i.e.,

$$p(u,v) = \sum_{\substack{0 \le r,s \le n \\ r+s \le n}} a_{rs} u^r v^s, \qquad a_{rs} > 0. \tag{1.12}$$

(The variable j in (1.11) ranges over halves of odd integers if n is even.)

As an application of Theorem 2, we give in §5 a short proof of Theorem 4 below in the special case

$$f(z) = (z^{mk} - 1)/(z^k - 1), \tag{1.13}$$

where m, k are positive integers.

THEOREM 4. *Let $f(z)$ denote a monic polynomial of degree N with nonnegative coefficients and with zeros $z_1, z_2, \cdots, z_N$. For fixed $t \ge 0$, write*

$$f_t(z) = \prod_{\substack{1 \le j \le N \\ |\operatorname{Arg} z_j| > t}} (z - z_j). \tag{1.14}$$

Then if $f(z) \ne f_t(z)$, all coefficients of $f_t(z)$ are positive.

Theorem 4 had been open for several years until a proof was found recently by Barnard et al. [2].

In the special cases $f(z) = z^N + 1$ or $f(z) = 1 + z + \cdots + z^N$, we can say a bit more about the polynomials $f_t(z)$ in (1.14), namely, the following theorem [4].

THEOREM 5. *If $f(z) = z^N + 1$ or $f(z) = 1 + z + \cdots + z^N$, and if $f_t(z) \ne f(z)$, then $f_t(z)$ is a strictly unimodal polynomial. (In particular, all coefficients of $f_t(z)$ are ≥ 1.)*

If $f(z)$ is given by (1.13), it is not generally true that $f_t(z)$ is unimodal when $f_t(z) \ne f(z)$.

2. The coefficients of $p(z)$ in terms of q-ultraspherical polynomials. We will use the following additional notation throughout:

$$q = e^{i\alpha}, \tag{2.1}$$

$$\beta = \theta + (n-1)\alpha/2 - \pi/2, \tag{2.2}$$

and

$$x = \sin\beta. \tag{2.3}$$

Observe that (1.5) is equivalent to

$$0 \le \beta \le \pi/2, \tag{2.4}$$

which implies that

$$0 \le x \le 1, \qquad \frac{dx}{d\theta} \ge 0. \tag{2.5}$$

In order to relate $p(z)$ to q-ultraspherical polynomials (see (2.12)–(2.13)), we begin by replacing j by $j + (n-1)/2$ in (1.3) to obtain

$$p(z) = \prod_{j=(1-n)/2}^{(n-1)/2} \left(z - e^{i(\beta+\alpha j+\pi/2)}\right)\left(z - e^{-i(\beta+\alpha j+\pi/2)}\right). \tag{2.6}$$

Since the range of values of j in (2.6) is symmetric about zero, we have

$$\begin{aligned} p(z) &= \prod_{j=(1-n)/2}^{(n-1)/2} \left(z - e^{i(\beta+\alpha j+\pi/2)}\right)\left(z - e^{-i(\beta-\alpha j+\pi/2)}\right) \\ &= \prod_{j=(1-n)/2}^{(n-1)/2} (z^2 - 2zq^j\cos(\beta+\pi/2) + q^{2j}) \\ &= \prod_{j=(1-n)/2}^{(n-1)/2} (z^2 + 2zq^j\sin\beta + q^{2j}). \end{aligned} \tag{2.7}$$

Replace j by $-j$ and multiply each factor by q^{2j} to obtain

$$p(z) = \prod_{j=(1-n)/2}^{(n-1)/2} (z^2q^{2j} + 2zxq^j + 1). \tag{2.8}$$

Note that the coefficients of $p(z)$ are symmetric about the middle, as

$$z^{2n}p(1/z) = p(z), \tag{2.9}$$

and the leading and constant coefficients of $p(z)$ are 1 for all θ, α.

The generating function for the q-ultraspherical polynomials $C_k(x;t|q)$ is [1, eq. (3.4), p. 179]

$$\sum_{k=0}^{\infty} C_k(x;t|q)w^k = \prod_{k=0}^{\infty} \frac{(1 - 2twxq^k + t^2w^2q^{2k})}{(1 - 2wxq^k + w^2q^{2k})}, \qquad 0 < q < 1. \tag{2.10}$$

In particular, with $t = q^{-n}$,

$$\sum_{k=0}^{\infty} C_k(x; q^{-n}|q) w^k = \prod_{k=-n}^{-1} (1 - 2wxq^k + w^2 q^{2k}). \tag{2.11}$$

The polynomials $C_k(x; q^{-n}|q)$ are well defined by (2.11) for $q = e^{i\alpha}$. Replace w by $-zq^{(n+1)/2}$ in (2.11) and use (2.8) to see that

$$p(z) = \sum_{k=0}^{2n} E_k(x; q^{-n}|q) z^k, \tag{2.12}$$

where

$$E_k := E_k(x) = E_k(x; q^{-n}|q) = (-1)^k q^{k(n+1)/2} C_k(x; q^{-n}|q). \tag{2.13}$$

The $C_k(x; t|q)$ satisfy the recurrence relation [1, eq. (1.1), p. 176]

$$2x(1 - tq^k) C_k(x; t|q) = (1 - q^{k+1}) C_{k+1}(x; t|q) + (1 - t^2 q^{k-1}) C_{k-1}(x; t|q) \tag{2.14}$$

for $k \geq 1$, with

$$C_0(x; t|q) = 1, \qquad C_1(x; t|q) = 2x(1 - t)/(1 - q). \tag{2.15}$$

In view of (2.1) and (2.13)–(2.15), the E_k satisfy the recurrence

$$\begin{aligned} E_k = {} & 2x \frac{\sin((n+1-k)\alpha/2)}{\sin(k\alpha/2)} E_{k-1} \\ & + \frac{\sin((2n+2-k)\alpha/2)}{\sin(k\alpha/2)} E_{k-2} \qquad (k \geq 2) \end{aligned} \tag{2.16}$$

with

$$E_0 = 1, \qquad E_1 = 2x \frac{\sin(n\alpha/2)}{\sin(\alpha/2)}. \tag{2.17}$$

3. Proof of Theorem 1. Theorem 1 is trivial for $n = 1$, so let $n > 1$. For brevity, write

$$A_k = \frac{\sin((n+1-k)\alpha/2)}{\sin(k\alpha/2)}, \quad B_k = \frac{\sin((2n+2-k)\alpha/2)}{\sin(k\alpha/2)}, \quad k \geq 1, \tag{3.1}$$

so by (2.16),

$$E_k = 2xA_k E_{k-1} + B_k E_{k-2}, \qquad k \geq 2. \tag{3.2}$$

By hypothesis, for some x_0 with $0 \leq x_0 < 1$,

$$E_k(x_0) \geq 0 \quad \text{for } 0 \leq k \leq 2n. \tag{3.3}$$

By (2.9), it suffices to show that the polynomials $E_k(x)$ are strictly increasing on $x_0 < x < 1$ for $1 \leq k \leq n$.

Case 1. $\alpha < 2\pi/n$. In this case,

$$A_k > 0 \quad \text{for } 1 \leq k \leq n. \tag{3.4}$$

In particular, the leading coefficient of $E_k(x)$ is positive for each k, $1 \leq k \leq n$.

Suppose there is an integer m with $2 \leq m \leq n$ such that

$$B_m < 0, \tag{3.5}$$

and choose the maximal such m. By (3.1),

$$B_k < 0 \quad \text{for } 2 \leq k \leq m. \tag{3.6}$$

By (3.2) and Favard's theorem [3, Thm. 4.4, p. 21], $E_1, E_2, \cdots, E_m$ are orthogonal polynomials with respect to a positive-definite operator. Thus we can apply the theorem on separation of zeros [3, Thm. 5.3, p. 28] to conclude that the zeros of $E_1, \cdots, E_m$ are all real and simple, and that a zero of E_{k-1} lies strictly between every two consecutive zeros of E_k, $2 \leq k \leq m$.

We proceed to prove by induction on k that if $1 \leq k \leq m$, then the largest zero of E_k is $\leq x_0$. This holds for $k = 1$ since $E_1 = 2A_1 x$ and $0 \leq x_0$. Let $k > 1$. By induction hypothesis, the largest zero of E_{k-1} is $\leq x_0$, so by separation of zeros, x_0 exceeds the second largest zero of E_k. For x between the largest and second largest zeros of E_k, $E_k(x)$ is negative. Thus, by (3.3), the largest zero of E_k is $\leq x_0$, and the induction is complete.

It follows for $1 \leq k \leq m$ that

$$E_k(x) = c_k \prod_{j=1}^{k} (x - \alpha_{jk}) \tag{3.7}$$

with $c_k > 0$ and $\alpha_{jk} \leq x_0$ $(1 \leq j \leq k)$. Thus $E_k(x)$ is strictly increasing on $x_0 < x < 1$ for $1 \leq k \leq m$.

If there is no integer m with $2 \leq m \leq n$ for which (3.5) holds, set $m = 1$. It remains to prove that $E_k(x)$ is strictly increasing on $x_0 < x < 1$ for $n \geq k > m$. This follows from (3.2), since $A_k > 0$ and $B_k \geq 0$.

Case 2. $\alpha = 2\pi/n$. In this case, by (2.16) and (2.17), $E_1(x) = E_2(x) = \cdots = E_{n-1}(x) = 0$. Thus by (2.9) and (2.12),

$$p(z) = z^{2n} + E_n z^n + 1. \tag{3.8}$$

It is easily seen from (1.3) that

$$p(1) = (e^{i\theta n} - 1)(e^{-i\theta n} - 1) = 2 - 2\cos(\theta n). \tag{3.9}$$

By (3.8) and (3.9), $E_n = -2\cos(\theta n)$, so

$$p(z) = z^{2n} - 2\cos(\theta n) z^n + 1. \tag{3.10}$$

For $\pi/(2n) \leq \theta \leq \pi/n$, the coefficients of $p(z)$ are nonnegative and they are increasing functions of θ.

Case 3. $\alpha > 2\pi/n$. In this case, $x_0 > 0$ by (2.2) and (2.3). Moreover, by (1.1) and (1.5), we may suppose that

$$2\pi/n < \alpha < 2\pi/(n-1). \tag{3.11}$$

By (2.17) and (3.11),

$$E_1(x_0) = 2x_0 \sin(n\alpha/2)/\sin(\alpha/2) < 0. \tag{3.12}$$

This contradicts (3.3), so Case 3 is vacuous.

4. Proofs of Theorems 2 and 3.

Proof of Theorem 2. Let $0 < \alpha < \pi/n$. By (2.9) and (2.12), it suffices to prove

$$E_k > 0, \qquad 0 \le k \le n. \tag{4.1}$$

This follows for $k = 0, 1$ by (2.17). For $2 \le k \le n$, all sines in (3.1) are positive, so

$$A_k > 0, \quad B_k > 0 \quad \text{for } 2 \le k \le n. \tag{4.2}$$

Thus (4.1) follows by (3.2) and induction on k.

Proof of Theorem 3. Let $0 < \alpha < \pi/n$. The proof of (4.1) actually yields the stronger result

$$E_k = \sum_{i=0}^{M} b_{ik} x^i, \qquad 0 \le k \le 2n, \tag{4.3}$$

with

$$\begin{aligned} &b_{ik} > 0, \quad \text{if } i \equiv k (\mathrm{mod}\, 2), \\ &b_{ik} = 0, \quad \text{otherwise}, \end{aligned} \tag{4.4}$$

where

$$M = \min(k,\ 2n-k). \tag{4.5}$$

Thus, by (2.8) and (2.12),

$$p(z) = \prod_{j=(1-n)/2}^{(n-1)/2} (z^2 q^j + 2zx + q^{-j}) = \sum_{k=0}^{2n} \sum_{i=0}^{M} b_{ik} x^i z^k. \tag{4.6}$$

Replace x by $x/(2z)$ to get

$$\sum_{k=0}^{2n} \sum_{i=0}^{M} b_{ik} 2^{-i} x^i z^{k-i} = \prod_{j=(1-n)/2}^{(n-1)/2} (z^2 q^j + x + q^{-j}). \tag{4.7}$$

Replace z^2 by z, then x by x^{-1}, and multiply by x^n to get

$$\sum_{k=0}^{2n} \sum_{i=0}^{M} b_{ik} 2^{-i} x^{n-i} z^{(k-i)/2} = \prod_{j=(1-n)/2}^{(n-1)/2} (zxq^j + 1 + xq^{-j}). \tag{4.8}$$

Replace z by z/x to get

$$\sum_{k=0}^{2n}\sum_{i=0}^{M} b_{ik}2^{-i}x^{n-(i+k)/2}z^{(k-i)/2} = \prod_{j=(1-n)/2}^{(n-1)/2}(zq^j + 1 + xq^{-j}). \tag{4.9}$$

Now (1.12) follows easily from (4.9), completing the proof of Theorem 3.

We close this section by proving the remarks made in §1 between the statements of Theorems 2 and 3.

Let $n > 1$. Then the upper bound π/n in (1.9) is best possible. For, if α is slightly larger than π/n, then $E_2 < 0$ for sufficiently small x, since

$$E_2 = 4x^2\frac{\sin(n\alpha/2)\sin((n-1)\alpha/2)}{\sin(\alpha/2)\sin(\alpha)} + \frac{\sin(n\alpha)}{\sin(\alpha)}. \tag{4.10}$$

If $\alpha \geq 2\pi/n$, there is no θ in the interval (1.4) for which all coefficients of $p(z)$ are positive, by (3.11) and (3.12). Finally, suppose that

$$0 < \alpha < 2\pi/n. \tag{4.11}$$

Then all coefficients of $p(z)$ are positive on a small interval (1.10), i.e., for x sufficiently close to 1. To see this, it suffices to show that when $x = 1$ (and (4.11) holds), all coefficients of $p(z)$ are positive.

By (2.8), when $x = 1$,

$$p(z) = \prod_{j=(1-n)/2}^{(n-1)/2}(q^j z + 1)^2, \tag{4.12}$$

so

$$p(z) = \left(\sum_{\nu=0}^{n} C(n,\nu)z^\nu\right)^2, \tag{4.13}$$

where the $C(n,\nu)$ are central Gaussian coefficients (see [5, p. 449]). By (4.11) and Theorem 3 of [5, p. 449], all of the $C(n,\nu)$ are positive. Thus, by (4.13), all coefficients of $p(z)$ are positive when $x = 1$, $0 < \alpha < 2\pi/n$.

5. Application to Theorem 4. Let $f(z), f_t(z)$ be given by (1.13) and (1.14), and suppose that $f(z) \neq f_t(z)$. We will use Theorem 2 to show that all coefficients of $f_t(z)$ are positive.

Case 1. $t < 2\pi/k$. We have

$$f(z) = g(z)/h(z), \tag{5.1}$$

where

$$g(z) = \frac{z^{mk}-1}{z-1}, \qquad h(z) = \frac{1-z^k}{1-z}, \tag{5.2}$$

so

$$f_t(z) = g_t(z)/h_t(z). \tag{5.3}$$

However, in Case 1, $h_t(z) = h(z)$, so by (5.3),

$$f_t(z) = g_t(z)/h(z) = (g_t(z)(1-z))\,(1 + z^k + z^{2k} + \cdots)\,. \tag{5.4}$$

Let

$$d = \text{degree}\,(g_t(z)). \tag{5.5}$$

By Theorem 5 with $N = mk$, $g_t(z)$ is strictly unimodal, so all terms of $g_t(z)(1-z)$ of degree $\leq d/2$ have positive coefficients. Therefore, by (5.4), all terms of $f_t(z)$ of degree $\leq d/2$ have positive coefficients. However, $f_t(z)$ has degree $d-(k-1) \leq d$ by (5.4), so since the coefficients of $f_t(z)$ are symmetric about the middle one, they are all positive.

Case 2. $t \geq 2\pi/k$. If m is even, say $m = 2M$, then

$$f(z) = \frac{z^{Mk}-1}{z^k-1} \cdot (z^{Mk}+1)\,. \tag{5.6}$$

Applying Theorem 5, we could then deduce the result by induction on m. Thus assume that m is odd, so -1 is not a zero of $f(z)$. We have

$$f(z) = \prod_{r=1}^{m-1} A^{(r)}(z), \tag{5.7}$$

where

$$A^{(r)}(z) = \prod_{\substack{0<\nu<mk/2 \\ \nu \equiv r \pmod m}} \left(z - e^{2\pi i\nu/mk}\right)\left(z - e^{-2\pi i\nu/mk}\right). \tag{5.8}$$

Thus,

$$f_t(z) = \prod_{r=1}^{m-1} A_t^{(r)}(z), \tag{5.9}$$

with

$$A_t^{(r)}(z) = \prod_{\substack{mkt/2\pi<\nu<mk/2 \\ \nu \equiv r \pmod m}} \left(z - e^{2\pi i\nu/mk}\right)\left(z - e^{-2\pi i\nu/mk}\right). \tag{5.10}$$

For any fixed r, the zeros of $A_t^{(r)}(z)$ on the upper half of the unit circle can be written in the form

$$\exp(i(\theta_r + \alpha j)), \qquad 0 \leq j \leq n_r - 1, \tag{5.11}$$

where

$$\theta_r > t \geq 2\pi/k = \alpha \tag{5.12}$$

and

$$\theta_r + \alpha(n_r - 1) < \pi < \theta_r + \alpha n_r. \tag{5.13}$$

Therefore $A_t^{(r)}(z)$ has the same form as $p(z)$ in (1.3), and furthermore,

$$\pi/2 < \theta_r + (n_r - 1)\alpha/2 < \pi \tag{5.14}$$

as in (1.5). Since, moreover, $0 < \alpha < \pi/n_r$, Theorem 2 implies that all coefficients of $A_t^{(r)}(z)$ are positive. Thus all coefficients of $f_t(z)$ are positive by (5.9).

CONVEXITY PRESERVING APPROXIMATION BY FREE KNOT SPLINES*

YINGKANG HU†

Abstract. In this paper the order of shape-preserving approximation of functions f in Sobolev space by free knot splines is studied. The main result is that the k-convexity of f for general k can be preserved, and the optimal order of approximation n^{-r} can be retained at the same time.

Key words. shape preserving, approximation order, free knot spline, nonlinear approximation

1. Introduction.

In many applications, it is desired that the mathematical model preserve certain geometric properties of the data, such as monotonicity and convexity. We shall give some results which show it is possible to preserve these properties without deteriorating the order of approximation by free knot splines. More precisely, we shall prove a theorem about the approximation order of k-convex functions in the Sobolev space $\mathbf{W}_1^r[0, 1]$ by k-convex spline functions with n free knots of order r. We say a function $f \in \mathbf{C}[0, 1]$ is k-convex if its k-th forward differences $\Delta_h^k(f, x)$ are nonnegative for all choices of x and $h > 0$ such that $0 \le x < x + kh \le 1$. If f has k continuous derivatives, then f is k-convex if and only if $f^{(k)} \ge 0$. It is clear that k-convexity means f is nonnegative if $k = 0$, nondecreasing if $k = 1$, and convex if $k = 2$. We will develop our results for the interval $[0, 1]$, but they hold also for any finite interval $[a, b]$ by a linear change of variable.

Let Σ_n be the space of all splines of order r on $[0, 1]$ with n knots:

$$\Sigma_n := \Sigma_n[0, 1] := \cup\, \mathcal{S}_r(\mathbf{T}, [0, 1]) \tag{1.1}$$

with the union taken over all knot sequences $\mathbf{T}$ on $[0, 1]$ of length n. For any $f \in \mathbf{C}[0, 1]$ which is k-convex for some $0 \le k < r$, let

$$\sigma_{n,k}^*(f) := \inf\{\|f - s\|_\infty : s \in \Sigma_n, s^{(k)} \ge 0\}. \tag{1.2}$$

We now state the main theorem of this paper, whose proof will be given in §3. In this theorem and throughout the paper, M will denote $\|f^{(r)}\|_1[0, 1]$ exclusively.

THEOREM 1.1. *If f is in the Sobolev space $\mathbf{W}_1^r[0, 1]$, and if $f^{(k)} \ge 0$ for some $0 \le k < r$, then there exists an $s_0 \in \mathbf{C}^{r-2} \cap \Sigma_n$ such that $s_0^{(k)} \ge 0$ and*

$$\|f - s_0\|_\infty \le C\,\frac{M}{n^r} \tag{1.3}$$

with C depending only on r, i.e.,

$$\sigma_{n,k}^* = \mathcal{O}\,(n^{-r})\,.$$

Theorem 1.1 says that there is a free knot approximation to f which preserves k-convexity of f, has the highest smoothness of all splines of order r which are not polynomials, and retains the optimal order of approximation n^{-r} at the same time. We

should point out that for nonconstrained free knot approximation the optimal order is achievable for a wider class of functions than $\mathbf{W}_1^r$. It would be nice if we could prove our theorem for the same class of functions, but $\mathbf{W}_1^r$ is the largest function space contained in that class whose seminorm is suitable for our constructive proof.

There are many similar results in the literature for the case of fixed knot spline approximation. DeVore [6] proved that the optimal order is achievable by monotone spline approximation with equally spaced knots in $\mathbf{L}_\infty$. He also proved in [7] a similar result about monotone approximation by polynomials. Several years later, Chui, Smith, and Ward [5] gave a simpler proof of DeVore's result in [6] and also proved the corresponding result in $\mathbf{L}_p$, $1 \le p < \infty$. More recently, Beatson gave corresponding results on k-convex approximation for $k = 0$ and 1 with arbitrary fixed knots ([2], [3]), and $k = 2$ with equally spaced knots [1]. But [3] has never been published since he found an elegant short proof to treat the cases $k = 1$ and 2 (for an arbitrary fixed knot sequence) simultaneously [4]. We emphasize again that the distinction with these results and our Theorem 1.1 is that Theorem 1.1 is for free knot spline approximation for which the same order of approximation $n^{-\alpha}$ is achievable for a wider class of functions. The simplest example of this is Kahane's theorem which says that a continuous function f can be approximated by free knot piecewise constants with the optimal order n^{-1} if and only if $f \in \mathbf{BV}$, while in the case of equally spaced knots the condition becomes $f \in \mathrm{Lip}1$, which is obviously smaller than $\mathbf{BV}$ [10].

Theorem 1.1 deals with convexity of a general order k. The proof consists of three steps. In Step 1, we construct an approximating spline $g \ge 0$ of order $r_0 := r - k$ to $f^{(k)}$ with $0 \le f^{(k)} - g = \mathcal{O}(n^{-r_0})$. This step is long and the notation is a little cumbersome but the idea is simple. We cut the interval in an appropriate way, construct some overlapping approximating polynomials on the subintervals obtained, then use a "blending lemma" (Lemma 2.5) to put them together and obtain the spline g. The k-fold integral of g is a k-convex approximation to f, but its approximation order is only n^{-r_0}. In Step 2 we first modify g, then integrate it k times on $[0, 1]$. *The key step in the proof is modifying g so as to prevent the error from building up when integrating back.* In Step 3 we estimate the error. In the proof we need some preparatory theorems and lemmas which we discuss in the section that follows.

2. Preliminary results. We begin with the following result on approximation by splines with free knots.

THEOREM 2.1. *If $f \in \mathbf{W}_1^r[0, 1]$, then for any $n \ge 1$, there exists a partition $\mathbf{T}$: $0 = t_0 < t_1 < \cdots < t_n = 1$, and a piecewise polynomial s of order $\le r$ on $\mathbf{T}$, such that*

$$\|f - s\|_\infty \le \frac{1}{(r-1)!}\frac{M}{n^r}. \tag{2.1}$$

Theorem 2.1 is well known, save for the value of the constant on the right-hand side of (2.1), [9, Thm. 7.2]. Our new proof is based on the following two lemmas which show that a good partition can be obtained by balancing the values of a certain "interval function." This idea will also be important in the proof of Theorem 1.1 in §3.

Let $\mathbf{T} := \{t_i\}$ be a partition of $[0, 1]$, and k a nonnegative integer. Let $I_i := [t_{i-1}, t_i]$ and

$$C(\mathbf{T}) := \left(\sum_{i=1}^{n} \frac{1}{|I_i|^k}\right)^{-1}.$$

We define the interval function

$$F_i := F(t_{i-1}, t_i) := F^{(k)}(t_{i-1}, t_i) := |I_i|^k \|f^{(r)}\|_1(I_i),$$

and the ratio of its largest and smallest values

$$R(\mathbf{T}) := \frac{\max_i F_i}{\min_i F_i}. \tag{2.2}$$

This R is considered 1 whenever all F_i are equal, even if they are all equal to zero.

LEMMA 2.2. *For any partition* $\mathbf{T}$ *of* $[0, 1]$, *we have*

$$C(\mathbf{T}) \leq \frac{1}{n^{k+1}} \tag{2.3}$$

and

$$F_i \leq R(\mathbf{T})C(\mathbf{T})M \leq R(\mathbf{T})\frac{M}{n^{k+1}}. \tag{2.4}$$

Proof. We can assume $k \geq 1$ and $\min_i F_i > 0$, for the cases $k = 0$ or $\min_i F_i = 0$ are trivial. We make use of the following inequality, which is a special case of (2.9.1) in [8]:

$$\left(\frac{1}{n}\sum_{i=1}^{n} a_i{}^{\alpha}\right)^{1/\alpha} \leq \left(\prod_{i=1}^{n} a_i\right)^{1/n} \leq \left(\frac{1}{n}\sum_{i=1}^{n} a_i{}^{\beta}\right)^{1/\beta}, \tag{2.5}$$

which holds whenever $\alpha < 0 < \beta$, $a_i > 0$, $i = 1, \cdots, n$. In (2.5) we set $\alpha = -k$, $a_i = |I_i|$, $\beta = 1$, and obtain

$$\left(\frac{1}{n}\sum_i \frac{1}{|I_i|^k}\right)^{-1/k} \leq \frac{1}{n}\sum_i |I_i| = \frac{1}{n},$$

or

$$\left(\frac{1}{n}\sum_i \frac{1}{|I_i|^k}\right)^{-1} \leq \frac{1}{n^k}.$$

This gives (2.3). For (2.4), we simply note

$$M = \sum_i \|f^{(r)}\|_1(I_i) = \sum_i \frac{F_i}{|I_i|^k} \geq \frac{\min_i F_i}{C(\mathbf{T})}. \tag{2.6}$$

Thus

$$1 \leq \frac{C(\mathbf{T})M}{\min_i F_i},$$

and

$$F_i \leq \max_i F_i \leq \frac{\max_i F_i}{\min_i F_i} C(\mathbf{T})M = R(\mathbf{T})C(\mathbf{T})M. \qquad \square$$

Remark. With $k = r - 1$, the above lemma and Taylor's theorem give

$$\|f - s\|_\infty \leq \frac{R(\mathbf{T})}{(r-1)!}\frac{M}{n^r} \tag{2.7}$$

for some piecewise polynomial s on $\mathbf{T}$. Therefore the ratio $R(\mathbf{T})$ (with $k = r - 1$) measures the quality of a partition $\mathbf{T}$ with respect to this error bound.

LEMMA 2.3. *There exists a partition* $\mathbf{T}^*$: $0 = t_0^* < t_1^* < \cdots < t_n^* = 1$, *such that* $R(\mathbf{T}^*) = 1$, *and*

$$F_i = C(\mathbf{T}^*)M, \qquad i = 1, \cdots, n. \tag{2.8}$$

If $M > 0$ *and* $k \geq 1$, *the partition is unique.*

Proof. The cases $M = 0$ or $k = 0$ are trivial. So we suppose $M > 0$ and $k \geq 1$. We observe that for any t_{i-1} and t_i, $F(t_{i-1}, t_i)$ continuously increases when t_{i-1} decreases and/or t_i increases. If $F(t_{i-1}, t_i) > 0$, it increases strictly.

Now we consider the continuous function $g(t_1, \cdots, t_{n-1}) := \max_i F_i - \min_i F_i$ defined on the compact subset $D := \{(t_1, \cdots, t_{n-1}) : 0 \leq t_1 \leq \cdots \leq t_{n-1} \leq 1\}$ of $\mathbf{R}^{n-1}$, and suppose g assumes its minimum at $(t_1^*, \cdots, t_{n-1}^*)$. We also suppose, towards a contradiction, that this minimum is not zero. Let $A := \max_i F(t_{i-1}^*, t_i^*) > 0$ and $\Lambda := \{j : F_j = A\}$. There must be an index j such that $j \in \Lambda$ but one of its neighbors, say $j - 1$, is not. That is, $F_{j-1} < F_j = A$. We slightly increase the point t_{j-1}^* so that $F_{j-1} \leq F_j < A$. This makes $\#\Lambda$ smaller by one. We keep doing this until Λ is empty, and end up with a new point in D which gives a smaller value for g than that at $(t_1^*, \cdots, t_{n-1}^*)$, i.e., than the minimum of g. This contradiction shows that $\min_D g = 0$, or $R(\mathbf{T}^*) = 1$. It is obvious from the definition that all $F_i > 0$ for such $\mathbf{T}^*$, thus all t_i^* must be distinct. For $\mathbf{T}^*$, we have $|I_i|^k \|f^{(r)}\|_1(I_i) = F_i =: C_0$ with C_0 a constant. Therefore by (2.6) $M = C_0 \sum |I_i|^{-k} = C_0 C(\mathbf{T}^*)^{-1}$ which is (2.8). The uniqueness is due to the (strict) monotonicity of F_i. □

Theorem 2.1 follows from the lemma and (2.7).

In Step 1 of the proof of our main theorem, after finding a partition by balancing subintervals, we shall construct some nonnegative overlapping polynomials which approximate $f^{(k)}$ from below, then construct the spline g by putting these local approximants together. The following lemma from Beatson [2] will be used to guarantee the existence of the local polynomials with the required properties.

LEMMA 2.4 (Beatson, [2, Lemma 2.1]). *Let* $g \in \mathbf{C}^n[a, b]$ *be nonnegative. Let* p^* *be a best restricted uniform approximation to* g *from* $W := \{p \in \mathbf{P}_n[a, b] : 0 \leq p(x) \leq g(x), x \in [a, b]\}$, *and let* $r := g - p^*$. *Then*

$$\|r^{(i)}\|_\infty \leq (b - a)^{n-i} \omega(g^{(n)}, [a, b], b - a), \qquad i = 0, \cdots, n. \tag{2.9}$$

Lemma 2.5 below enables us to put the local polynomials together to get the smooth spline g, which, roughly speaking, approximates the function no worse than those polynomials. The first version of the lemma was established by Beatson in the special case of $g_1 = 0$, and equally spaced knots. DeVore then gave a simpler proof of the special case. The proof of Beatson in [2] is a modification of this one.

LEMMA 2.5 (Beatson, [2, Lemma 3.2]). *Let* $r \geq 2$ *be an integer and* $d = 2(r-1)^2$. *Let* $\mathbf{T} = \{t_i\}_{i=-\infty}^{\infty}$ *be a strictly increasing knot sequence with* $t_0 = a$ *and* $t_d = b$. *Let* g_1, g_2 *be two polynomials of degree* $< r$. *Then there exists a spline* $g \in \mathcal{S}_r(\mathbf{T})$ *such that*

(1) $g(x)$ *is a number between* $g_1(x)$ *and* $g_2(x)$ *for each* $x \in [a, b]$,

(2) $g = g_1$ *on* $(-\infty, a]$ *and* $g = g_2$ *on* $[b, \infty)$.

In Step 2 of the proof of Theorem 1.1, we shall modify the spline g, without destroying its positivity, of course, before integration to prevent the error from building up. This will lead to a system of linear equations with some undetermined coefficients. The undetermined coefficients should be chosen so that the system has a nonnegative solution, but it is not trivial to do so directly. We shall make use of the following Banach perturbation lemma (Theorem 2.6) to change the system into a limiting form

which is relatively easier to solve. The final stage of the proof was greatly helped by DeVore, who pointed out that this is a moment problem and so made it possible for the author to solve it beyond the case of $k \leq 3$. The author then studied the moment theory and related areas, which resulted in the final elegant proof for the case of general k, based on the well-known Gauss–Jacobi quadrature (Theorem 2.7.)

THEOREM 2.6 [11, Thm. 4.3.6]. *Let $\|\cdot\|$ be a matrix norm such that $\|XY\| \leq \|X\| \cdot \|Y\|$ for any $n \times n$ matrices X and Y, and $\|I\| = 1$, where I is the identity matrix. Let A and E be two $n \times n$ matrices with A invertible. If $\|A^{-1}E\| < 1$ then $A + E$ is also invertible and*

$$\frac{\|A^{-1} - (A+E)^{-1}\|}{\|A^{-1}\|} \leq \frac{\|A^{-1}E\|}{1 - \|A^{-1}E\|}.$$

THEOREM 2.7 [12, Thms. 3.3.1, 3.4.1, 3.4.2]. *If $y_1, y_2, \cdots, y_n$ denote the zeros of the nth orthogonal polynomial p_n with respect to the positive distribution $d\alpha$ on $[a, b]$, then*

(1) *They are all real, distinct, and located in (a, b);*

(2) *There exist positive numbers (Christoffel numbers) $\lambda_1, \lambda_2, \cdots, \lambda_n$ such that*

$$\int_a^b p(x)\, d\alpha(x) = \sum_{j=1}^{n} \lambda_j p(y_j)$$

for all polynomials p of degree $\leq 2n-1$. The distribution $d\alpha$ and the integer n uniquely determine these numbers λ_j.

3. Proof of the main theorem. We begin with some comments which will simplify our analysis. We shall define below an integer l, depending only on r and k and bounded by a function of r, and prove that if $n = ml$, $m = 1, 2, \cdots$, then $\sigma^*_{n,k}(f) \leq CMm^{-r}$. The theorem then holds for general n, because if $n < l$, we can enlarge the constant C; if $lm \leq n < l(m+1)$ for some $m \geq 1$, then

$$\begin{aligned}\sigma^*_{n,k}(f) \leq \sigma^*_{lm,k}(f) \leq CMm^{-r} &= \left[C\left(l\frac{m+1}{m}\right)^r\right] M[l(m+1)]^{-r} \\ &< [C(2l)^r]Mn^{-r} =: C'Mn^{-r}.\end{aligned}$$

We can also assume that $M > 0$. Otherwise $f \in \mathbf{P}_{r-1}[0, 1]$ and we simply set $s_0 = f$. As mentioned before, we prove the theorem in three steps. We shall use our previous notation $r_0 := r - k$ for the order of the spline function g below.

Step 1. We shall construct a nonnegative spline g of order r_0 which approximates $f^{(k)}$ *from below* and whose k-fold definite integral has an approximation order n^{-r_0}. Later, in Step 2, we shall make corrections to this g and integrate the resulting spline $\hat{g}$ to obtain the desired approximant to f. The reason we approximate $f^{(k)}$ *from below* is that the corrections will be in the positive direction and the positivity of g will then be automatically preserved.

Case 1. $r_0 = 1$ (i.e., $k = r - 1$). This is a trivial case in which g is a nonnegative piecewise constant approximant to $f^{(r-1)}$. Let $l = k(r_0+1)+1 = 2r-1$. By Lemmas 2.2 and 2.3, there exists a partition $\mathbf{X}$: $0 = x_0 < x_1 < \cdots < x_m = 1$ such that

$$F^{(r-1)}(x_{i-1}, x_i) := |J_i|^{r-1}\|f^{(r)}\|_1(J_i) = C(\mathbf{X})M \leq Mm^{-r},$$

where $J_i := [x_{i-1}, x_i]$, $1 \leq i \leq m$. This estimate, and (3.1) in Case 2, will control the local errors of the final approximant s_0 to f. We apply Lemma 2.4 to $f^{(k)}$ on each J_i. Then there is a constant $\alpha_i \geq 0$ such that on J_i

$$0 \leq f^{(k)} - \alpha_i \leq \omega(f^{(k)}, J_i, |J_i|) \leq \|f^{(r)}\|_1(J_i) = F^{(r_0-1)}(x_{i-1}, x_i).$$

Define $g(x) := \alpha_i$, for $x \in (x_{i-1}, x_i)$, we obtain the desired approximant to $f^{(k)}$.

Case 2. $r_0 \geq 2$. Let $l = 2[2(r_0-1)^2 + 1 + k(r_0+1)] + 1 \leq 6r^2 + 2r + 3$. Then, as in Case 1, there is a partition (which we index by even integers): $0 = x_0 < x_2 < \cdots < x_{2m} = 1$ such that

$$F^{(r-1)}(x_{2i-2}, x_{2i}) := |J_{2i}|^{r-1}\|f^{(r)}\|_1(J_{2i}) \leq Mm^{-r}, \tag{3.1}$$

where $J_i := [x_{i-2}, x_i]$. Since $M > 0$, we have $F^{(r-1)}(x_{2i-2}, x_{2i}) > 0$ (see the proof of Lemma 2.3). We choose the points $x_1, x_3, \cdots, x_{2m-1}$ in the following way. We choose x_1 as the midpoint of $[x_0, x_2]$. We then find x_3 such that $F^{(r-1)}(x_1, x_3) = F^{(r-1)}(x_0, x_2)$. Since $r = r_0 + k \geq 2$, we have $r - 1 \geq 1$ and therefore the F_i are strictly increasing as the first variable decreases and/or the second increases (see the proof of Lemma 2.3 again). We have $x_2 < x_3 < x_4$. We continue in this way to find $x_5, x_7, \cdots, x_{2m-1}$, and end up with a partition $\mathbf{X}$: $0 = x_0 < x_1 < x_2 < \cdots < x_{2m} = 1$ such that $F^{(r-1)}(x_{i-2}, x_i)$ are all equal for $2 \leq i \leq 2m$.

If we apply Lemma 2.4 to $f^{(k)}$ on each $J_i := [x_{i-2}, x_i]$, $2 \leq i \leq 2m$, we know there is a polynomial $p_i \geq 0$ of degree $< r_0$ such that

$$\begin{aligned} 0 \leq f^{(k)} - p_i &\leq |J_i|^{r_0-1}\omega(f^{(r-1)}, J_i, |J_i|) \\ &\leq |J_i|^{r_0-1}\|f^{(r)}\|_1(J_i) = F^{(r_0-1)}(x_{i-2}, x_i). \end{aligned}$$

We then blend these overlapping polynomials as follows: We insert $2(r_0-1)^2 + 1$ simple knots in each $I_i := (x_{i-1}, x_i)$ for $1 \leq i \leq 2m$ in an arbitrary way, and then apply Lemma 2.5 to each pair p_i, p_{i+1}, $2 \leq i \leq 2m-1$, to obtain a spline g_i of order r_0 satisfying the conditions (1) and (2) in the lemma. Define g by setting $g := g_i$ on I_i, $2 \leq i \leq 2m-1$, $g := g_2 = p_2$ on I_1, and $g := g_{2m-1} = p_{2m}$ on I_{2m}. Then g is a spline on the knot sequence consisting of the knots inserted above as well as those in $\mathbf{X}$.

From the construction of g, Lemmas 2.4 and 2.5 show that $g \geq 0$ and on I_i

$$0 \leq f^{(k)} - g \leq \begin{cases} \max\limits_{j \in \{i, i+1\}} F^{(r_0-1)}(x_{j-2}, x_j), & 2 \leq i \leq 2m-1, \\ F^{(r_0-1)}(x_0, x_2), & i = 1, \\ F^{(r_0-1)}(x_{2m-2}, x_{2m}), & i = 2m. \end{cases} \tag{3.2}$$

Step 2 (error correction). Having constructed g, a natural candidate for our s_0 is the solution $\bar{s}_0$ of the following initial value problem:

$$\begin{aligned} &\bar{s}_0^{(k)}(x) = g(x), \\ &\bar{s}_0^{(j)}(0) = f^{(j)}(0), \qquad j = 0, \cdots, k-1. \end{aligned}$$

First we take a look at what kind of errors this choice would give. Denote the error function by $r(x) := f(x) - \bar{s}_0(x)$, then $r^{(k)}(x) = f^{(k)}(x) - g(x)$. The first k derivatives of $r(x)$ at x_1, for example, will be

$$\begin{aligned} r^{(k-1)}(x_1) &= \int_{x_0}^{x_1} r^{(k)}(t)\,dt \quad =: e_0, \\ r^{(k-2)}(x_1) &= \int_{x_0}^{x_1} (x_1 - t)\, r^{(k)}(t)\,dt \quad =: e_1, \\ &\vdots \\ r(x_1) &= \frac{1}{(k-1)!}\int_{x_0}^{x_1} (x_1 - t)^{k-1}\, r^{(k)}(t)\,dt =: \frac{1}{(k-1)!} e_{k-1}. \end{aligned} \tag{3.3}$$

Here we have used the Taylor's expansions at x_0. In the trivial case that $r^{(k)}$ is identically zero on $[x_0, x_1]$ no correction is necessary. Hence, attention can now be restricted to the case where $\int_{x_0}^{x_1} r^{(k)}(t)\,dt > 0$. In this case we have to control all of them or they would build up and end up with, roughly speaking, order $n^{-r_0} = n^{k-r}$.

To correct these errors, we will add some spline $m_1(x) = \sum_{j=1}^{k} \bar{\lambda}_j M_j(x)$ to g, where $\bar{\lambda}_j \geq 0$, M_j are the B-splines of order r_0 on some knots which will be inserted into I_1 later, with $\int M_j(t)\,dt = 1$, such that

$$\int_{x_0}^{x_1} (x_1 - t)^i m_1(t)\,dt = e_i, \qquad i = 0, \cdots, k-1, \tag{3.4}$$

i.e., we will add a nonnegative spline supported on I_1 to g which will eliminate all the errors in the first k derivatives at x_1. We need to show that there exist coefficients $\bar{\lambda}_j$ and knots for the B-splines M_j which satisfy (3.4). For this we use the mean value theorem to rewrite (3.4) as

$$e_i = \sum_{j=1}^{k} \bar{\lambda}_j \int_{x_0}^{x_1} (x_1 - t)^i M_j(t)\,dt = \sum_{j=1}^{k} \bar{\lambda}_j (x_1 - \xi_{i,j})^i \tag{3.5}$$

or

$$\bar{A}\bar{\lambda} = \mathbf{e}, \tag{3.6}$$

where $\bar{\lambda} := (\bar{\lambda}_1, \cdots, \bar{\lambda}_k)^T$, $\mathbf{e} := (e_0, \cdots, e_{k-1})^T$, and $\bar{A}$ is the $k \times k$ matrix $((x_1 - \xi_{i,j})^i)_{i,j}$, with $\xi_{i,j}$ lying in $\mathrm{Supp}(M_j)$. We shall choose in I_1 the supporting knots for M_j such that (3.6) has a *nonnegative* solution $\bar{\lambda}$. This is difficult to solve directly, so we first consider an ideal problem in which the knots of M_j are allowed to coalesce. That is, suppose $M_j = \delta_{y_j}$ are the Dirac functions with a unit mass at some $y_j \in I_1$, then $\xi_{i,j} = y_j$ will depend only on j. In this case it is easy to see that we can choose the points y_j so that (3.5) has a solution $\lambda := (\lambda_1, \cdots, \lambda_k)^T$ with $\lambda_j > 0$:

$$A\lambda = \mathbf{e}, \quad \text{where } A = ((x_1 - y_j)^i)_{i,j}\,. \tag{3.7}$$

Namely, we apply the Gauss–Jacobi quadrature (Theorem 2.7) to the integrals in (3.3) with $n := k$, and $d\alpha(t) := r^{(k)}(t)\,dt \geq 0$, and find

$$e_i = \int_{x_0}^{x_1} (x_1 - t)^i r^{(k)}(t)\,dt = \sum_{j=1}^{k} \lambda_j (x_1 - y_j)^i, \qquad i = 0, \cdots, k-1,$$

for some $y_j \in I_1$ and $\lambda_j > 0$. Since all the y's are distinct, A is a Vandermonde matrix, thus invertible. We can write the solution as $\lambda = A^{-1}\mathbf{e}$.

We can now solve the original system (3.6) as a perturbation of this ideal problem. By Theorem 2.6, if we insert into I_1 for each M_j $r_0 + 1$ simple knots which are sufficiently close to y_j, then $\bar{A}$ will be so close to A (in the ∞-norm) that it will also be invertible, and the solution $\bar{\lambda} = \bar{A}^{-1}\mathbf{e}$ of (3.6) will be so close to λ that it will be nonnegative. This proves the existence of m_1.

We call m_1 a correcting function on I_1 since it completely corrects all the errors in the first k derivatives of g accumulated on I_1. We are now ready to construct the final approximant s_0 to f: we find a correcting function $m_i(x)$ for each I_i, and let $\hat{g}(x) = g(x) + \sum_i m_i(x) \geq 0$. Since $\mathrm{Supp}(m_i) \subset I_i$, we have

$$\hat{g}(x) = g(x) + m_i(x) \quad \text{for } x \in I_i. \tag{3.8}$$

Let $s_0(x)$ be the solution of the initial value problem

$$\begin{aligned} s_0^{(k)}(x) &= \hat{g}(x), \\ s_0^{(j)}(0) &= f^{(j)}(0), \qquad 0 \le j < k. \end{aligned} \tag{3.9}$$

Then s_0 is a k-convex $\mathbf{C}^{r-2}$ spline function of order r on the knot sequence consisting of all the knots we inserted: x_i's (called the test points), those inserted in the blending, and those for M_j's. The only thing that remains to show is the approximation order of s_0, which we will establish in Step 3 below.

Step 3 (error estimate). It is easy to see from our construction that s_0 interpolates f k times at each test point x_i, that is to say, the situation at each x_i is exactly the same as that at $x_0 = 0$. Therefore the errors on different subintervals I_i are independent of each other, and can be estimated locally. We shall do this on I_1 for the case $r_0 \ge 2$ only. Estimates for other I_i and the case $r_0 = 1$ are similar.

Since $r^{(k)}(x) \ge 0$, we have

$$\begin{aligned} 0 \le e_{k-1} &:= \int_{x_0}^{x_1} (x_1 - t)^{k-1} r^{(k)}(t)\, dt \le |I_1|^{k-1} \int_{x_0}^{x_1} (f^{(k)} - g)(t)\, dt \\ &\le |I_1|^{k-1}\, |I_1|\, F^{(r_0-1)}(x_0, x_2) \le |J_2|^{r-1} \|f^{(r)}\|_1(J_2) \le M m^{-r}. \end{aligned}$$

Here (3.2) and (3.1) have been used. Therefore, using the Taylor expansion at x_0, (3.9), and (3.8), we have, for any $x \in [x_0, x_1]$,

$$\begin{aligned} |f(x) - s_0(x)| &= C_0 \left| \int_{x_0}^{x} (x - t)^{k-1} (f^{(k)} - s_0^{(k)})(t)\, dt \right| \\ &= C_0 \left| \int_{x_0}^{x} (x - t)^{k-1} (f^{(k)} - g - m_1)(t)\, dt \right| \\ &\le C_0 \left| \int_{x_0}^{x_1} (x_1 - t)^{k-1} r^{(k)}(t)\, dt \right| + C_0 \left| \int_{x_0}^{x_1} (x_1 - t)^{k-1} m_1(t)\, dt \right|, \end{aligned}$$

where $C_0 := 1/(k-1)!$. The last two integrals are both equal to e_{k-1} by (3.3) and (3.4), therefore

$$|f(x) - s_0(x)| \le 2C_0\, e_{k-1} \le \frac{2}{(k-1)!} \frac{M}{m^r}.$$

This finishes our proof. □

Acknowledgments. I would like to thank Professor Ronald A. DeVore for interesting me in this problem, and for his patient guidance and valuable ideas, especially those for the case of general k.

THE LARGE DEFORMATION OF NONLINEARLY ELASTIC TUBES IN TWO-DIMENSIONAL FLOWS*

MASSIMO LANZA DE CRISTOFORIS† AND STUART S. ANTMAN‡

Abstract. This paper treats the large deformation of closed nonlinearly elastic cylindrical tubes (rings) under an external pressure field generated by the steady, irrotational, two-dimensional flow of an incompressible, inviscid fluid. The flow is assumed to have a prescribed velocity U and pressure P at infinity. The deformation of the tubes is described by a geometrically exact theory of rods. The parameters U and P and the deformed shape of the ring uniquely determine the velocity field of the steady flow exterior to the tube. It is shown that velocity of the flow on the tube depends continuously and compactly on the function describing the shape. The pressure field on the ring, depending on U, P, and the velocity field on the tube, is substituted into the equilibrium equations for the tube, yielding a system of ordinary functional-differential equations. These are converted into a fixed-point form, which is analyzed by a global implicit function theorem. Refined results from conformal mapping theory are used to handle serious technical difficulties with regularity, which apparently do not arise in the study of flows past rigid obstacles.

Key words. fluid-solid interactions, two-dimensional perfect flows, nonlinearly elastic tubes, global continuation theory, boundary behavior of conformal mappings

1. Introduction.

In this paper we study the large deformation of closed nonlinearly elastic cylindrical shells (tubes) produced by the action of an external pressure field generated by the steady, irrotational, two-dimensional flow of an incompressible, inviscid fluid. The flow is assumed to have a prescribed velocity U and pressure P at infinity. The two-dimensionality of our problem means that the generators of the cylindrical shell in any deformed configuration remain perpendicular to the flow so that every section of the shell perpendicular to the generators suffers the same deformation. The equations for the deformation of a typical section are those for the planar deformation of a ring. We accordingly refer to such a section as a *ring*. We describe the deformation of these rings with a geometrically exact theory of rods (cf. Antman and Rosenfeld (1978)) that accounts for flexure, compression, and shear. We allow the material properties of the ring to be described by a very general class of nonlinear constitutive relations. We limit our attention to problems having a line of symmetry.

We begin our analysis by observing that U, P, and the deformed shape of the ring uniquely determine the velocity field of the steady flow exterior to the ring. Then we

show that the velocity of the flow on the ring depends continuously and compactly on the function describing the shape. We use Bernoulli's theorem to express the pressure field on the ring in terms of U, P, and the velocity field on the ring. We substitute this pressure into the equilibrium equations for the elastic ring. We transform these equations into a fixed-point equation for the shape, involving a compact operator and depending parametrically upon U and P. We apply a generalization of the Global Implicit Function Theorem of Alexander and Yorke (1976) to these equations to deduce the existence of connected families of solutions. In this program we encounter serious technical difficulties in showing that the pressure on the rod depends continuously and compactly on an appropriate function describing the shape and in constructing a suitable fixed point equation. To handle these difficulties we determine detailed regularity properties of the operator describing the dependence of the boundary values of the pressure field on the shape of the rod. (These properties can be and, to the best of our knowledge, have been ignored in the study of flows past rigid obstacles. Consequently, the presence of a deformable obstacle raises the fluid mechanical part of our problem to a level of difficulty higher than that for rigid obstacles.) To obtain the requisite properties of the pressure field we exploit refined results from conformal mapping theory. For clarity of exposition we relegate this technical analysis of compactness to §6.)

Thus we replace the coupled problem for the deformation of the ring and the external flow of the fluid with a single problem for the deformation of the ring in which the pressure field on it depends nonlocally on its shape. In this process it is necessary to marry the material (Lagrangian) description, which is natural for the ring, with the spatial (Eulerian) description, which is natural for the fluid. This fact contributes to the complexity of the formulation.

Two of the goals of this paper are to treat the nonlinear deformation of a solid under the pressure field arising from a correctly posed theory of fluid mechanics (rather than by some ad hoc approximation of the pressure) and to develop effective methods for treating well set nonlinear problems from mechanics with nonlocal terms. (Similar problems arise in electromagnetism.) Finnila and Sloss (1966) discussed a problem related to ours for a solid linearly elastic cylinder by reducing it to an integral equation.

Let us define a *solution-parameter pair* to consist of the parameters (U, P) and a set of functions that determine a configuration of the ring. (Each solution-parameter pair determines the flow.) Our fundamental result is Theorem 5.38. Informally it says that there is a connected two-dimensional family of classical solution-parameter pairs of our problem that has some very nice topological properties.

Notation. Partial derivatives are denoted by subscripts and ordinary derivatives by primes. If f and g are functions of u and v, then $\partial(f, g)/\partial(u, v)$ denotes the *matrix* of partial derivatives of f and g with respect to u and v. We denote the closure of a set $\mathcal{E}$ by $\operatorname{cl}\mathcal{E}$ and the set of elements belonging to set $\mathcal{A}$ and not belonging to set $\mathcal{B}$ by $\mathcal{A} \setminus \mathcal{B}$.

The space of m-times continuously differentiable functions on a compact set (usually the interval $[-L, L]$) with the usual norm $\|\cdot\|_m$ is denoted C^m. The domain of the functions under consideration will be evident from the context. The subspace of C^m whose functions have mth derivatives that are Hölder continuous with exponent α are denoted $C^{m,\alpha}$; If u is in $C^{0,\alpha}$ on a region Ω, then its α-Hölder quotient is

$$|u|_\alpha \equiv \sup\left\{\frac{|u(x) - u(y)|}{|x - y|^\alpha},\ x, y \in \Omega,\ x \neq y\right\}.$$

The space $C^{m,\alpha}$ on an interval of $\mathbb{R}$ or on a region of $\mathbb{C}$ is equipped with the usual norm :$\|u\|_{m,\alpha} \equiv \|u\|_m + |u^{(m)}|_\alpha$ where $u^{(m)}$ is the mth derivative of u.

To conduct the analysis effectively, especially in §6, it is necessary to employ a very precise notation. For example, the pressure at a material point s on the ring depends on the whole shape of the ring, defined by ζ, and on U and P. We denote it by $p[\zeta, U, P](s)$. We need such a notation in §6, where we must carry out limit processes simultaneously in the variables ζ and s.

2. Equilibrium equations for nonlinearly elastic rings. Since the problems we treat are two-dimensional, we express all vectorial quantities in complex notation. We describe the deformation of the ring by the planar equations for a rod that can suffer flexure, extension, and shear (cf. Antman and Rosenfeld (1978)). The configuration of such a (Cosserat) rod is a plane curve every point of which is equipped with a coplanar unit vector. The theory is geometrically exact in that no variable characterizing such a configuration (such as the sine of an angle) is ever approximated (by the angle itself or any finite Taylor sum for the sine). The plane curve characterizes the gross behavior of a slender body and can be identified with the deformed shape of some material base curve. The unit vector characterizes the deformed configuration of a material cross-section. Such a body can sustain forces and torques. Indeed, the theory we employ is the most general for which equilibrium can be completely described by equations involving no stress resultants other than the classical contact force and contact couple. (Moreover, it is more than adequate for many practical purposes.)

Formally, a *configuration of a ring* is specified by the pair of continuously differentiable functions

$$[-L, L] \ni s \mapsto \big(\zeta(s),\ \theta(s)\big) \in \mathbb{C} \times \mathbb{R} \tag{2.1a}$$

with $\zeta \equiv x(s) + iy(s)$ a simple closed curve having positive (counterclockwise) orientation so that

$$\zeta(-L) = \zeta(L),\quad \zeta'(-L) = \zeta'(L),\quad \theta(L) = \theta(-L) + 2\pi. \tag{2.1b,c,d}$$

Such a configuration is an intrinsically one-dimensional concept. Solely for the sake of interpretation, we can regard (ζ, θ) as defining a deformation of the two-dimensional body

$$\mathcal{B} \equiv \{Z(s) + \xi e^{i\Theta(s)} \in \mathbb{C} :\ -L \le s \le L,\ 0 \le \xi \le h(s)\} \tag{2.2}$$

where $s \mapsto (Z(s), \Theta(s)) \in \mathbb{C} \times \mathbb{R}$ is a prescribed continuously differentiable function satisfying (2.1b,c,d) and

$$Z' = -ie^{i\Theta} \tag{2.3}$$

and h is a prescribed positive-valued continuous function representing the thickness of the ring. (Equation (2.2) defines the reference (undeformed) configuration of the body.) h must satisfy the relation $h(-L) = h(L)$. (See Fig. 2.4.) A point in $\mathcal{B}$ is called a *material point.* Equation (2.3) requires that $Z'(s)$ be a unit vector normal to $e^{i\Theta(s)}$. This condition is not critical; it can be relaxed at the cost of complicating a few formulas. The requirement that there be a locally one-to-one orientation-preserving correspondence between the material points of $\mathcal{B}$ and pairs (s, ξ) of curvilinear coordinates in $\{(s, \xi) : -L \le s < L,\ 0 \le \xi \le h(s)\}$ is ensured by

$$h(s)\Theta'(s) < 1. \tag{2.5}$$

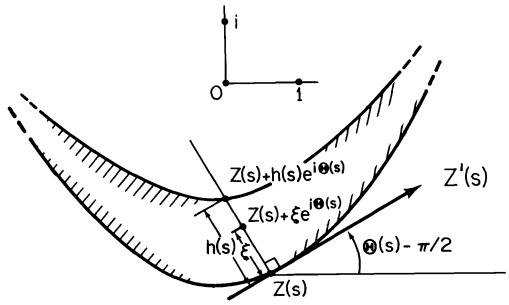

FIG. 2.4. *Reference configuration $\mathcal{B}$ of the ring regarded as a two-dimensional body.*

This condition implies that the curvature vectors from nearby points of Z do not intersect inside $\mathcal{B}$. One could formulate mild additional geometric restrictions on $\mathcal{B}$ to ensure that the correspondence be global. We assume that this is so.

s may be interpreted as the scaled arc length parameter of the bounding curve Z of the ring $\mathcal{B}$ in its undeformed reference configuration. Thus s identifies a *material section* $\xi \mapsto Z(s)+\xi e^{i\Theta(s)}$ of the ring. The configuration (ζ, θ) may then be interpreted as defining the deformation

$$\mathcal{B} \ni Z(s) + \xi e^{i\Theta(s)} \mapsto \zeta(s) + \xi e^{i\theta(s)}. \tag{2.6}$$

Thus $\zeta(s)$ may be interpreted as the deformed position of the material point $Z(s)$ originally on the bounding curve Z of the ring in its reference configuration $\mathcal{B}$, and θ may be interpreted as characterizing the orientation of the deformed configuration of the section s with respect to the positive real axis. $\Theta(s)$ is the given value of $\theta(s)$ in the reference configuration. (It is more common to interpret Z not as a bounding curve of $\mathcal{B}$, but rather as its curve of centroids. Since the material points of Z are those in contact with the fluid, our choice of interpretation proves to be more natural for the problems we study.)

We can regard (2.6) as constraining the deformations of $\mathcal{B}$ to be those for which plane sections remain plane and do not change their length. Since we are not confined to representations of the form (2.6), we can assign more general interpretations to (ζ, θ). A virtue of the abstract definition (2.1a) is that it admits any one of a multitude of such interpretations and is not tied to (2.6).

We denote differentiation with respect to s by a prime. We decompose the vector $\zeta'(s)$ tangent to the curve ζ at $\zeta(s)$ by

$$\zeta'(s) \equiv -i(\nu + i\eta)e^{i\theta} \tag{2.7}$$

where ν and η are real-valued. The function ν can be thought of as measuring elongation. (It actually contributes to the volume change; see (2.10).) The function η

measures shear. We set

$$\psi \equiv \theta - \Theta, \qquad \mu \equiv \psi'(s). \tag{2.8a,b}$$

μ measures the amount of bending. Then

$$\mathbf{q} \equiv (\nu, \eta, \mu) \tag{2.9}$$

is the set of *strains* for our rings.

If we adopt the two-dimensional interpretation (2.6) of (ζ, θ) given above, then the requirement that the local ratio of deformed-to-reference volume be positive leads to the inequality

$$\nu(s) - \xi\theta'(s) > 0 \quad \forall \xi \in [0, h(s)], \tag{2.10}$$

which is equivalent to

$$\nu(s) > \max\{0, h(s)[\mu(s) + \Theta'(s)]\} \equiv \kappa\big(\mu(s), s\big). \tag{2.11}$$

$\kappa(\cdot, s)$ is convex. This is the essential property of κ that we require in our analysis. (This convexity arises no matter what reasonable interpretation is given to (ζ, θ); cf. Antman (1976).) We require that (2.11) hold and for simplicity we take κ to have the specific form shown there. The positivity of ν following from (2.11) ensures that the local ratio of deformed to reference length of ζ at s be positive and that the section at s not be sheared so severely that $e^{i\theta(s)}$ is parallel to $\zeta'(s)$. We require ζ to be simple. We do not bother to impose a global injectivity restriction on (2.6).

Let $-i[\check{N}(s) + i\check{H}(s)]e^{i\theta(s)}$ denote the resultant contact force and $\check{M}(s)$ the resultant contact couple acting across the section s of the ring exerted by the material of $(s, s+\epsilon]$ on the material of $[s-\epsilon, s]$ where ϵ is a small positive number. By definition of contact force and couple, these resultants are independent of ϵ. ($\check{N}$, $\check{H}$, $\check{M}$ are each real-valued.) We assume that the only external force applied to the ring at s is a hydrodynamical pressure of intensity $p(s)$ per unit deformed length acting in the direction $i\zeta'(s)$. (This assumption means that the fluid lies to the right of the oriented curve ζ. A natural sign convention allows for the possibility, remote from the focus of our analysis, that the pressure be negative.) Then the equilibrium equations for the ring are

$$\{[\check{N}(s) + i\check{H}(s)]e^{i\theta(s)}\}' = p(s)\zeta'(s), \tag{2.12}$$

$$\check{M}'(s) - \operatorname{Re}\{\zeta'(s)[\check{N}(s) - i\check{H}(s)]e^{-i\theta(s)}\} = 0. \tag{2.13}$$

We can put these equations into the componential forms

$$\check{N}'(s) = \theta'(s)\check{H}(s) + p(s)\eta(s), \tag{2.14}$$

$$\check{H}'(s) = -\theta'(s)\check{N}(s) - p(s)\nu(s), \tag{2.15}$$

$$\check{M}'(s) = \eta(s)\check{N}(s) - \nu(s)\check{H}(s). \tag{2.16}$$

Let

$$\mathcal{Q}(s) \equiv \{\mathbf{q} \in \mathbb{R}^3 : \nu > \kappa(\mu, s)\}, \tag{2.17}$$

$$\mathcal{Q} \equiv \{(\mathbf{q}, s) : \mathbf{q} \in \mathcal{Q}(s), s \in [-L, L]\}. \tag{2.18}$$

The material of the ring is *elastic* if there are constitutive functions

$$\mathbf{Q} \equiv (N, H, M) : \mathcal{Q} \to \mathbb{R}^3 \tag{2.19}$$

such that

$$\check{N}(s) = N\big(\mathbf{q}(s), s\big), \text{ etc.} \tag{2.20}$$

We assume that the constitutive functions (2.19) are thrice continuously differentiable. In particular, in consonance with (2.1) we assume that $\mathbf{Q}(\mathbf{q}, \cdot)$, when extended to $\mathbb{R}$ by periodicity, is twice continuously differentiable. $\mathbf{Q}$ is required to satisfy the *monotonicity condition*:

$$\text{The matrix } \mathbf{Q}_{\mathbf{q}}(\mathbf{q}, s) \equiv \frac{\partial(N, H, M)}{\partial(\nu, \eta, \mu)}(\mathbf{q}, s) \text{ is positive definite } \forall\ (\mathbf{q}, s) \in \mathcal{Q}. \tag{2.21}$$

This assumption can be shown to be inherited from the strong ellipticity condition of three-dimensional elasticity in the process by which rod theories are constructed from the three-dimensional theory (cf. Antman (1976)). It ensures, e.g., that an increase in the bending strain μ is accompanied by a corresponding increase in the bending couple M. We require that:

$$\eta \mapsto N(\nu, \eta, \mu, s) \text{ is even}, \qquad \eta \mapsto H(\nu, \eta, \mu, s) \text{ is odd}, \tag{2.22a,b}$$

$$\eta \mapsto M(\nu, \eta, \mu, s) \text{ is even}, \tag{2.22c}$$

$$N(1, 0, 0, s) = 0, \qquad M(1, 0, 0, s) = 0. \tag{2.23a,b}$$

Conditions (2.22b), (2.23) ensure that the reference configuration is stress-free.

Remark. There is no obstacle to extending our entire analysis to a rod theory with any level of complexity. (Such theories can be interpreted as replacing (2.6) with any expression having more degrees of freedom.) We would merely have to augment our geometrical and mechanical variables with a larger set, many of whose members would lack simple interpretations; cf. Antman (1976) and Antman and Carbone (1977).

3. Steady, two-dimensional, irrotational flows of incompressible, inviscid fluids. The force acting on the ring is generated by the two-dimensional, steady, irrotational flow of an incompressible inviscid fluid. No body force (such as gravity) acts on the fluid. The velocity and pressure fields are assumed to have limits at infinity (in the complex plane $\mathbb{C}$). In this section we formulate the governing equations for the motion of these fluids. The derivations can be found in standard books on fluid dynamics (cf., e.g., Serrin (1959) and Milne-Thomson (1968)).

Let $\mathcal{F}$ denote the (open) domain of $\mathbb{C}$ occupied by the fluid. We assume that $\mathcal{F}$ is of class C^1. Let $w(z) = u(z) - iv(z)$, $p(z)$, ρ denote the complex velocity, pressure, and density at point $z = x + iy$ in the closure $\mathrm{cl}\,\mathcal{F}$ of $\mathcal{F}$. ρ is a given positive number. u, v, p are real-valued. Under our assumptions, Euler's equations for the flow in $\mathcal{F}$ are the *momentum equations*

$$\rho(uu_x + vu_y) = -p_x, \qquad \rho(uv_x + vv_y) = -p_y \ \text{ in } \mathcal{F}, \tag{3.1}$$

the *incompressibility condition*

$$u_x + v_y = 0 \ \text{ in } \mathcal{F}, \tag{3.2}$$

and the *irrotationality condition*

$$u_y - v_x = 0 \ \text{ in } \mathcal{F}. \tag{3.3}$$

Note that (3.2), (3.3) are the Cauchy–Riemann equations so that w must be a holomorphic function in $\mathcal{F}$.

We assume that

(3.4a,b) $$w(z) \to U, \qquad p(z) \to P \quad \text{as } z \to \infty$$

where U, P are given nonnegative real numbers. Then (3.1), (3.3), (3.4) yield Bernoulli's equation

(3.5) $$p(z) = -\frac{\rho}{2}|w(z)|^2 + \frac{\rho}{2}U^2 + P \quad \text{in } \mathcal{F},$$

which shows that p in $\mathcal{F}$ is determined by w, U, P. This formula can be extended by continuity to $\operatorname{cl}\mathcal{F}$ whenever w can be so extended.

Equations (3.2) and (3.3) imply that on any simply-connected subset of $\mathcal{F}$ there exists a holomorphic function $\Omega = \Phi + i\Psi$ such that

(3.6) $$w(z) = \Omega'(z).$$

Φ is the *velocity potential*, Ψ is the *stream function*, and Ω is the *complex potential*. In §6 we observe that under the assumptions we shall impose on the flow, the *circulation*

(3.7) $$\int_\zeta w(z)\,dz = 0,$$

which is precisely the supplementary condition needed to show that for this problem Ω is also defined on all of $\mathcal{F}$. Thus Ω is holomorphic on $\mathcal{F}$ while Φ and Ψ satisfy the Cauchy–Riemann equations here.

Since the boundary $\partial\mathcal{F}$ of $\mathcal{F}$ is solid, fluid cannot penetrate it, i.e.,

(3.8) $$\operatorname{Re}(nw) = 0 \quad \text{on } \partial\mathcal{F}$$

where n is the unit inner normal to $\partial\mathcal{F}$. It follows from (3.6) and (3.8) that $\Psi =$ const. on $\partial\mathcal{F}$. Since $\mathcal{F}$ is at worst doubly connected, there is no loss in generality in taking this constant to be zero:

(3.9) $$\Psi = 0 \quad \text{on } \partial\mathcal{F}.$$

The solution of (3.1)–(3.4), (3.8) can thus be effected by finding a holomorphic function Ω on $\mathcal{F}$ that together with its derivative admits a continuous extension to $\operatorname{cl}\mathcal{F}$ and that satisfies (3.9) and

(3.10) $$\Omega'(z) \to U \quad \text{as } z \to \infty.$$

Then w and p can be found from (3.6), (3.5).

In the sequel, when it is necessary to emphasize the dependence of $\mathcal{F}$, Ω, etc., on ζ, U, we write $\mathcal{F}[\zeta]$, $\Omega[\zeta, U]$, etc.

4. The symmetrically deformed ring. In this section we give a detailed description of the class of functions in which we seek solutions of our equations. In the next section we carry out a global analysis of the symmetric deformation of a ring in a symmetric flow under the assumption that the pressure field on the ring has the right form. We deduce the properties of the pressure field in §6, where we analyze the flow problem.

We record (2.1b,c,d):

(4.1a,b,c) $$\zeta(-L) = \zeta(L), \quad \zeta'(-L) = \zeta'(L), \quad \theta(L) = \theta(-L) + 2\pi.$$

To ensure that the flow does not apply a net torque to the ring and that the complex potential Ω is well defined, we consider only configurations that are symmetric with respect to the x-axis and have the property that $\operatorname{Re}\zeta(\pm L) > \operatorname{Re}\zeta(0)$ (see Fig. 4.2):

(4.3a,b) $$\zeta(-s) = \overline{\zeta}(s), \qquad \theta(s) = -\theta(-s).$$

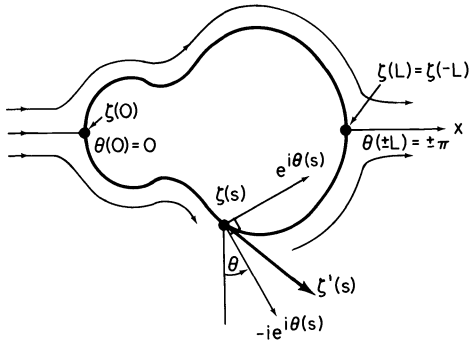

FIG. 4.2. *Flow about a symmetrically deformed ring.*

Using (2.7), we readily deduce from (4.3) that

(4.4a,b,c) $$\nu(s) = \nu(-s), \quad \eta(s) = -\eta(-s), \quad \mu(s) = \mu(-s).$$

By comparing (4.1) with (4.3), we obtain the obvious conditions

(4.5a,b,c) $$y(0) = 0, \quad x'(0) = 0, \quad \theta(0) = 0$$

together with

(4.6a,b,c) $$y(\pm L) = 0, \quad x'(\pm L) = 0, \quad \theta(\pm L) = \pm\pi.$$

Note that (4.3) and (those equations of) (4.6) (with a plus sign) imply (4.1). For (4.3) to be reasonable, we require that the reference configuration satisfy it and that the constitutive functions N, H, M, h be even in s. It is convenient to fix the rigid translation of ζ by requiring that

(4.7) $$\zeta(0) = Z(0).$$

In order to carry out compactness proofs needed to meet the hypotheses of the Global Implicit Function Theorem (stated below), we require a convenient characterization of simple, closed, continuously differentiable ζ's. Let us extend ζ to $\mathbb{R}$ by periodicity. Let

(4.8a) $$\sigma(s_1, s_2) \equiv \min\{|t_1 - t_2| : e^{i\pi t_\alpha/L} = e^{i\pi s_\alpha/L}, \ \alpha = 1, 2\},$$

(4.8b) $$l[\zeta] \equiv \inf\left\{\left|\frac{\zeta(s) - \zeta(t)}{\sigma(s,t)}\right| : s, t \in [-L, L], \ s \neq t\right\}.$$

For $\delta > 0$, we set

(4.9) $$\mathcal{Z}(\delta) \equiv \{\zeta \in C^1 : (4.1a,b) \text{ holds}, \ l[\zeta] > \delta\},$$

(4.10) $$\mathcal{Z} \equiv \bigcup_{\delta>0} \mathcal{Z}(\delta).$$

LEMMA 4.11. *$\mathcal{Z}$ is precisely the set of all simple, closed, continuously differentiable ζ's (with $|\zeta'|$ everywhere positive).*

Proof. It is a straightforward exercise to show that an element of $\mathcal{Z}(\delta)$, and hence of $\mathcal{Z}$, is a simple, closed, continously differentiable curve with a nowhere vanishing derivative. Let us prove the converse. Suppose for contradiction that ζ is such a curve with $l[\zeta] = 0$. Then by the definition of l (and by the Bolzano–Weierstrass theorem) there are sequences$\{s_k\}$ and $\{t_k\}$ in $[-L, L]$ with $s_k \leq t_k$ converging to s_∞ and t_∞ such that

$$\lim_{k\to\infty} \frac{|\zeta(s_k) - \zeta(t_k)|}{|\sigma(s_k, t_k)|} = 0. \tag{4.12}$$

If $s_\infty \neq t_\infty \mod 2L$, then $\zeta(s_\infty) \neq \zeta(t_\infty)$ and (4.12) cannot hold. If $s_\infty = t_\infty$, then (4.12) implies that $\zeta'(s_\infty) = 0$, a contradiction. If $s_\infty = -L$, $t_\infty = L$, then for k sufficiently large, $\sigma(s_k, t_k) = |t_k - s_k - 2L|$. Since $\zeta(t_k) = \zeta(t_k - 2L)$, equation (4.12) implies that $\zeta'(-L) = 0$, another contradiction. □

LEMMA 4.13. *$\mathcal{Z}(\delta)$ and $\mathcal{Z}$ are open in $\{\zeta \in C^1 : (4.1a,b)\ holds\}$.*

Proof. Let $\zeta \in \mathcal{Z}(\delta)$ with $\delta > 0$, let $\chi \in \{\zeta \in C^1 : (4.1a,b)\ \text{holds}\}$, and let$\|\zeta - \chi\|_1 < \frac{1}{2}(l[\zeta] - \delta)$. We show that $\chi \in \mathcal{Z}(\delta)$ by showing that $l[\chi] > \delta$. Definitions (4.8) imply that

$$\begin{aligned} l[\chi] &\geq \inf\left\{\left|\frac{\zeta(s) - \zeta(t)}{\sigma(s,t)}\right| - \left|\frac{(\zeta - \chi)(s) - (\zeta - \chi)(t)}{\sigma(s,t)}\right| : s, t \in [-L, L],\ s \neq t\right\} \\ &\geq l[\zeta] - \|\zeta - \chi\|_1 > \frac{1}{2} l[\zeta] + \frac{\delta}{2} > \delta. \end{aligned} \tag{4.14}$$

In deriving this inequality we have used the inequality for the mean value. □

Remark. When interpretation (2.6) is used, it would be physically appropriate to require the deformed inner boundary curve $s \mapsto \zeta(s) + h(s)e^{i\theta(s)}$ of the annular region $\mathcal{B}$ of (2.2) to be simple, closed, and positively oriented. We do not bother to pursue the technical adjustments needed to accommodate this requirement.

In §6 we prove the following theorem.

THEOREM 4.15. *Let* (4.1a,b) *and* (4.3a) *hold. For $\zeta \in \mathcal{Z}$ let $w[\zeta, U](s)$, which is independent of P, denote the complex velocity of the (symmetric) flow at the point $\zeta(s)$. Then $U^{-1}w[\zeta, U]$ is independent of U (and is thus solely determined by ζ). The function $s \mapsto U^{-1}w[\zeta, U](s)$ is continuous. The operator $C^2 \cap \{\zeta \in \mathcal{Z} :$ (4.3a) holds$\} \ni \zeta \mapsto |U^{-1}w[\zeta, U]| \in C^0$ is continuous. It is compact on $C^2 \cap \{\zeta \in \mathcal{Z}(\delta) :$ (4.3a) holds$\}$ for every $\delta > 0$. The pressure on the ring at $\zeta(s)$ is given by*

$$p[\zeta, U, P](s) = P + \tfrac{\rho}{2} U^2 \{1 - U^{-2}|w[\zeta, U](s)|^2\} \tag{4.16}$$

and satisfies $p[\zeta, U, P](s) = p[\zeta, U, P](-s)$. Moreover,

$$p[\cdot, \cdot, \cdot] : [C^2 \cap \{\zeta \in \mathcal{Z} :\ (4.3a)\ holds\}] \times \mathbb{R}^2 \to C^0 \tag{4.17}$$

is continuous and is compact on $[C^2 \cap \{\zeta \in \mathcal{Z}(\delta) :\ (4.3a)\ holds\}] \times \mathbb{R}^2$ for every $\delta > 0$.

Note that these fluid-dynamical variables are independent of θ, i.e., independent of the state of shear in the rod.

We introduce the Banach space

$$\mathcal{V} \equiv \{(\zeta, \psi) \in C^2 : (4.1a,b),\ (4.3)\ \text{hold}\} \tag{4.18}$$

endowed with the C^2–norm. (We need this norm in order to use Theorem 4.15.) We define the operators $\hat{\mathbf{q}} \equiv (\hat{\nu}, \hat{\eta}, \hat{\mu})$, $\hat{\theta}$ by

$$\hat{\mu}[\psi] \equiv \psi', \quad \hat{\theta}[\psi](s) \equiv \Theta(s) + \int_0^s \psi'(\xi)\, d\xi, \tag{4.19}$$

$$\hat{\nu}[\zeta, \psi] + i\hat{\eta}[\zeta, \psi] \equiv ie^{-i\hat{\theta}[\psi]}\zeta'. \tag{4.20}$$

Let us set

$$\begin{aligned} &\mathcal{Z}^+(\delta) \equiv \{\zeta \in \mathcal{Z}(\delta) : \zeta \text{ has positive orientation}\}, \\ &\mathcal{Z}^+ \equiv \{\zeta \in \mathcal{Z} : \zeta \text{ has positive orientation}\}. \end{aligned} \tag{4.21}$$

We define $\mathcal{Z}^-(\delta)$ and $\mathcal{Z}^-$ analogously for ζ's having negative orientation. Lemma 4.13 holds with $\mathcal{Z}^\pm(\delta)$, $\mathcal{Z}^\pm$ replacing $\mathcal{Z}(\delta)$, $\mathcal{Z}$. We shall seek solutions of our operator equations in the following subset of $\mathcal{V}$:

$$\mathcal{A} \equiv \{(\zeta, \psi) \in \mathcal{V} : \zeta \in \mathcal{Z}^+,\ \operatorname{Re}\zeta(\pm L) > \operatorname{Re}\zeta(0),\ \hat{\mathbf{q}}[\zeta, \psi](s) \in \mathcal{Q}(s)\ \forall s\}. \tag{4.22a}$$

Clearly $\mathcal{A}$ contains the pair $(Z, 0)$ corresponding to the reference configuration (Z, Θ). Note that $\mathcal{A}$ does not account for (4.1c). We accordingly define

$$\mathcal{A}^\sharp \equiv \{(\zeta, \psi) \in \mathcal{A} : (4.1c) \text{ holds}\}. \tag{4.22b}$$

We assume that $\Theta \in C^2$. In the reference configuration $\mathbf{q} = (1, 0, 0)$ (by definition of this configuration). It then follows from (2.7) that Z is in C^3. Our *boundary value problem* (BVP) is to find $(\zeta, \psi) \in \mathcal{A}^\sharp$ such that the strain-configuration relations (4.19), (4.20), the equilibrium equations (2.14)–(2.16) with $p(s)$ replaced with $p[\zeta, U, P](s)$, defined in (4.16), and the constitutive equations (2.20) hold. Note that the reference configuration (Z, Θ) satisfies BVP for $U = 0, P = 0$. In the rest of the paper we regard (2.8a) as an identity and express restrictions on ψ in terms of θ or vice versa.

5. The fixed-point problem. We now recast BVP as a fixed-point problem to which we can apply the following theorem, whose interpretation follows its statement.

THEOREM 5.1 (Global Implicit Function Theorem). *Let $\mathcal{X}$ be a Banach space and let $\{\mathcal{O}(\epsilon), 0 < \epsilon < E\}$ be a family of open sets (not necessarily bounded) in $\mathcal{X} \times \mathbb{R}^m$ for which*

$$(0, 0) \in \mathcal{O}(\epsilon), \qquad 0 < \epsilon < E, \tag{5.2}$$

$$\operatorname{cl}\mathcal{O}(\epsilon_2) \subset \mathcal{O}(\epsilon_1) \quad \text{for } 0 < \epsilon_1 < \epsilon_2 < E. \tag{5.3}$$

Let

$$\mathcal{O} \equiv \bigcup_{0<\epsilon<E} \mathcal{O}(\epsilon). \tag{5.4}$$

Let $F : \mathcal{O} \to \mathcal{X}$ be continuous, let $F(0, 0) = 0$, and let $F : \mathcal{O}(\epsilon) \to \mathcal{X}$ be compact for $0 < \epsilon < E$, where E is a given positive number. Let I denote the identity operator on $\mathcal{X}$. Let the Fréchet derivative $I - F_x(0, 0) : \mathcal{X} \to \mathcal{X}$ of $x \mapsto x - F(x, \lambda)$ at $(0, 0)$ exist and be invertible. Let $\mathcal{S} \equiv \{(x, \lambda) \in \mathcal{O} : x = F(x, \lambda)\}$ and let $\mathcal{S}_0$ be the connected component of $\mathcal{S}$ containing $(0, 0)$. (In a neighborhood of $(0, 0)$ $\mathcal{S}$ agrees with $\mathcal{S}_0$.) Then one of the following statements is true:

(i) *$\mathcal{S}_0$ is bounded and there is an $\epsilon^* \in (0, E)$ such that $\mathcal{S}_0 \subset \mathcal{O}(\epsilon^*)$. There is an essential map (i.e., a continuous map not homotopic to a constant) σ from $\mathcal{S}_0$ onto the m-dimensional sphere $\mathbb{S}^m$ whose restriction to $\mathcal{S}_0 \setminus \{(0, 0)\}$ is inessential. Moreover, $\mathcal{S}_0$ contains a connected subset $\mathcal{S}_{00}$*

that contains $(0,0)$*, that has the same properties as* $\mathcal{S}_0$ *with respect to* σ*, and that has the property that each point of it has Lebesgue dimension at least* m*.*

(ii) $\mathcal{S}_0 \setminus \mathcal{O}(\epsilon) \neq \emptyset$ *for all* $\epsilon \in (0,E)$ *or* $\mathcal{S}_0$ *is unbounded. For each* $\epsilon \in (0,E)$ *there is a modified equation* $x = \varphi(x,\lambda,\epsilon)F(x,\lambda)$ *(cf.* (7.4)*) defined on all of* $\mathcal{X} \times \mathbb{R}^m$ *that agrees with* $x = F(x,\lambda)$ *on* $\mathcal{O}(\epsilon)$*. The one-point compactification* $\mathcal{S}_0^+(\epsilon)$ *of the connected component* $\mathcal{S}_0(\epsilon)$ *containing* $(0,0)$ *of the set of solution pairs of the modified equation has the same properties as* $\mathcal{S}_0$ *in statement* (i)*.*

We prove this theorem, which generalizes results of Alexander and Yorke (1976), in §7. Without comment we shall shift the base point $(0,0)$ in this theorem to any other point. In our problem the role of λ is played by (U,P). In case (i) the theorem states that the set of solution-parameter pairs (x,λ) of the equation $x = F(x,\lambda)$ has a connected subset $\mathcal{S}_{00}$ containing $(0,0)$ and having dimension at least 2 at each point. This means that $\mathcal{S}_{00}$ contains a subset that looks like a surface. The statement about the essential map roughly means that $\mathcal{S}_0$ cannot abruptly terminate and that it looks like a sphere to which are possibly attached further solution pairs.

We set

$$\mathbf{f}(\mathbf{q},p,s) \equiv \big(-N_s+(\Theta'(s)+\mu)H+p\eta, -H_s-(\Theta'(s)+\mu)N-p\nu, -M_s+\eta N-\nu H\big) \tag{5.5}$$

where the arguments of N, N_s, etc., are $\mathbf{q}$, s. By substituting the constitutive equations (2.20) and the pressure equation (4.16) into the equilibrium equations (2.14)–(2.16), and then carrying out the indicated differentiations, we find that the system (2.14)–(2.16), (2.20), (4.16) is formally equivalent to

$$\mathbf{q}(s) = \mathbf{q}(0) + \int_0^s \mathbf{Q}_{\mathbf{q}}\big(\mathbf{q}(\xi),\xi\big)^{-1}\mathbf{f}\big(\mathbf{q}(\xi),p[\zeta,U,P](\xi),\xi\big)\,d\xi \tag{5.6}$$

$$\equiv \mathbf{q}(0) + \mathbf{g}[\mathbf{q},\zeta,U,P](s). \tag{5.7}$$

In consonance with (4.4b) we take

$$\eta(0) = 0. \tag{5.8}$$

We define the operators $\mathbf{q}^\sharp \equiv (\nu^\sharp,\eta^\sharp,\mu^\sharp)$ by

$$\mathbf{q}^\sharp[\zeta,\psi,U,P](s) \equiv \mathbf{g}\big[\hat{\mathbf{q}}[\zeta,\psi],\zeta,U,P\big](s). \tag{5.9}$$

We now use (4.7), (4.19), (4.20) to convert (5.5), (5.6) to

$$\begin{aligned}\zeta(s) &= Z(0) - i\int_0^s e^{i\hat{\theta}(\xi)}\{\nu_0 + \nu^\sharp[\zeta,\psi,U,P](\xi) + i\eta^\sharp[\zeta,\psi,U,P](\xi)\}\,d\xi \\ &\equiv Z(0) + x^\sharp[\zeta,\psi,\nu_0,U,P](s) + iy^\sharp[\zeta,\psi,\nu_0,U,P](s),\end{aligned} \tag{5.10}$$

$$\psi(s) = \mu_0 s + \int_0^s \mu^\sharp[\zeta,\psi,U,P](\xi)\,d\xi, \tag{5.11}$$

where the unknown constants ν_0 and μ_0 are equal to $\hat{\nu}(0)$ and $\hat{\mu}(0)$.

Remark. System (5.10), (5.11) would have a fixed-point form if the constants ν_0 and μ_0 were chosen to depend on (ζ,ψ). To get a useful fixed-point form in $\mathcal{V} \cap \{(\zeta,\psi) : \text{(4.1c) holds}\}$, we should like to choose ν_0 and μ_0 to ensure that the

right-hand sides of (5.10), (5.11) satisfy (4.6), i.e., so that

$$y^\sharp[\zeta,\psi,\nu_0,U,P](L)=0, \tag{5.12a}$$

$$x^\sharp[\zeta,\psi,\nu_0,U,P]'(L)=0, \tag{5.12b}$$

$$\mu_0 L+\int_0^L \mu^\sharp[\zeta,\psi,U,P](\xi)\,d\xi=0. \tag{5.12c}$$

Unfortunately, we have only two constants available to satisfy three relations. The situation is actually somewhat worse: If we compute the matrix of partial derivatives of the left-hand sides of (5.12) with respect to ν_0 and μ_0, we get

$$\begin{pmatrix} -\int_0^L \cos\hat\theta(\xi)\,d\xi & 0\\ \sin\hat\theta(L) & 0\\ 0 & L\end{pmatrix}, \tag{5.13}$$

which reduces to

$$\begin{pmatrix} 0 & 0\\ 0 & 0\\ 0 & L\end{pmatrix} \tag{5.14}$$

in the trivial state with $(U,P)=(0,0)$. Thus there is no way to use the classical implicit function theorem directly to solve (5.12) for ν_0 and μ_0 as functionals of (ζ,ψ) near the trivial solution or to get any such representation for ν_0. We could solve for μ_0 as a functional of (ζ,ψ), by defining it to be the solution of (5.12c) so that (4.6c) would hold. But while this definition of μ_0 is useful for certain problems with *constant* hydrostratic pressure (cf. Antman (1973)), it does not compensate for the degeneracy inherent in (5.14). We could replace the $\hat\theta(\xi)$ in the integrand in (5.10) with $\mu_0\xi+\int_0^\xi \mu^\sharp[\zeta,\psi,U,P](\omega)\,d\omega$ and thus introduce the parameter μ_0 elsewhere in our equations, but such a step does not ameliorate the situation. In short, the complexity of our class of admissible configurations satisfying (2.1) prevents us from setting up our fixed-point problem in the most obvious way. We now exploit the underlying mechanics and geometry of our problem to resolve this difficulty by a less straightforward procedure.

Since we have no assurance that the right-hand sides of (5.10), (5.11) take $\mathcal{A}$ or even $\mathcal{A}^\sharp$ into $\mathcal{V}$, we contrive to cast our problem in a more suitable form. We let α and β play the roles of ν_0 and μ_0. Then in place of (5.10)–(5.12) we consider

$$\begin{aligned}
x(s)&=X(0)+x^\sharp[\zeta,\psi,\alpha,U,P](s)+\frac{2L}{\pi}x^\sharp[\zeta,\psi,\alpha,U,P]'(L)\cos\frac{\pi s}{2L},\\
y(s)&=y^\sharp[\zeta,\psi,\alpha,U,P](s)-y^\sharp[\zeta,\psi,\alpha,U,P](L)\sin\frac{\pi s}{2L},\\
\psi(s)&=\beta s+\int_0^s \mu^\sharp[\zeta,\psi,U,P](\xi)\,d\xi,\\
\alpha&=\alpha+x^\sharp[\zeta,\psi,\alpha,U,P]'(L),\\
\beta&=\beta+y^\sharp[\zeta,\psi,\alpha,U,P](L).
\end{aligned} \tag{5.15a}$$

We abbreviate (5.15a) as

$$(\zeta,\psi,\alpha,\beta)=\mathbf{k}[\zeta,\psi,\alpha,\beta,U,P]. \tag{5.15b}$$

It is easy to see that $\mathbf{k}[\zeta,\psi,\alpha,\beta,U,P]$ satisfies (4.1a,b), (4.3) (and thus $\mathbf{k}$ takes $\mathcal{A}\times\mathbb{R}^4$ into $\mathcal{V}\times\mathbb{R}^2$) and that if $(\zeta,\psi,\alpha,\beta)$ in $\mathcal{A}\times\mathbb{R}^2$ satisfies (5.15), then (ζ,ψ) satisfies all the conditions of BVP, except possibly (4.1c), which is equivalent to (4.6c).

Furthermore, $\alpha = \hat{\nu}(0)$ and $\beta = \hat{\mu}(0)$ and conversely, if (ζ, ψ, U, P) in $\mathcal{A} \times \mathbb{R}^2$ satisfies BVP, except for (4.1c), then $(\zeta, \psi, \hat{\nu}(0), \hat{\mu}(0), U, P)$ satisfies (5.15). We now show that under mild conditions (ζ, ψ) must satisfy (4.6c) as well.

PROPOSITION 5.16. *Let* $(\zeta, \psi, \alpha, \beta) \in \mathcal{A} \times \mathbb{R}^2$ *satisfy* (5.15) *and*

(5.17)
$$\frac{N(\hat{\mathbf{q}}[\zeta,\psi](L), L)}{\hat{\nu}[\zeta,\psi](L)} < \frac{H(\hat{\mathbf{q}}[\zeta,\psi](L), L)}{\hat{\eta}[\zeta,\psi](L)} \equiv \int_0^1 H_\eta\big(\hat{\nu}[\zeta,\psi](L), \alpha\hat{\eta}[\zeta,\psi](L), \hat{\mu}[\zeta,\psi](L), L\big)\, d\alpha$$

(*when* $\hat{\eta}[\zeta,\psi](L) \neq 0$). *Then* (ζ, ψ) *satisfies* BVP.

Remarks. The identity in (5.17), which is used to define the limit of the second quotient as $\eta \to 0$, follows from (2.22b) and the Mean Value Theorem. By virtue of (2.21), condition (5.17) holds in the trivial state, in which its left-hand side is zero, and therefore holds in a neighborhood of this state. It also holds when $\check{N}(L) < 0$, i.e., when the material of the ring at L is in compression. We might expect this condition to hold, at least for moderate deformations, because such a compression of the ring is a likely effect of a positive pressure exerted on it by the surrounding fluid (when $P > 0$). The violation of (5.17), which could occur when the ring is under sufficiently large tension at its trailing point, is associated with a shear instability (cf. Antman and Carbone (1977)). We could show that such a possibility is precluded either by obtaining a suitable a priori estimate or else by elevating (5.17) into the (reasonable) constitutive restriction:

$$\frac{N(\mathbf{q}, L)}{\nu} < \frac{H(\mathbf{q}, L)}{\eta} \quad \forall \mathbf{q} \in \mathcal{Q}(L), \quad \eta \neq 0. \tag{5.18}$$

PROOF OF PROPOSITION 5.16. In view of the remarks preceding the statement of the proposition, it suffices to show that (4.1c) holds. Let ϕ be the angle between ζ' and the negative y-axis:

$$\zeta' = -i|\zeta'|e^{i\phi} \tag{5.19}$$

with $\phi(0) = 0$. Equation (4.20) then implies that

$$\hat{\nu} + i\hat{\eta} = |\zeta'|e^{i(\phi - \hat{\theta})}. \tag{5.20}$$

Since ζ is a simple, closed, positively oriented, continuously differentiable curve, it follows that

$$\phi(\pm L) = \pm\pi. \tag{5.21}$$

Since the membership of (ζ, ψ) in $\mathcal{A}$, defined in (4.22a), implies that (2.11) holds, it follows that $\hat{\nu}(s)$ must be positive for all s. It then follows from (5.20) that $\cos\big(\phi(s) - \hat{\theta}(s)\big) > 0$, and since $\hat{\theta}(0) = 0 = \phi(0)$ by (4.5), it follows from the continuity of $\phi - \hat{\theta}$ that $|\phi(s) - \hat{\theta}(s)| < \pi/2$. Thus (5.21) yields

$$|\hat{\theta}(L) - \pi| < \frac{\pi}{2}. \tag{5.22}$$

Now the integral of (2.12) over $(-L, L)$ yields

$$(\check{N} + i\check{H})e^{i\hat{\theta}}\Big|_{-L}^{L} = \int_{-L}^{L} p[\zeta, U, P](s)\zeta'(s)\, ds. \tag{5.23}$$

The Kutta–Joukowski Theorem stated in §6 implies that the integral on the right-hand side of (5.23), which is the net force exerted by the inviscid fluid on the deformed ring, must vanish, and consequently the left-hand side must vanish. (The fundamental "stress principle" or law of action and reaction embodied in the integrals of (2.12) over arbitrary intervals would directly imply that the left-hand side of (5.23) would vanish, were it not for the distinguished role we have assigned to $\pm L$.) We now use (2.20), (2.22a,b), (4.4a,c), and the evenness of H in s to deduce from (5.23) that

$$N\big(\hat{\mathbf{q}}(L),L\big)\sin\hat{\theta}(L)+H\big(\hat{\mathbf{q}}(L),L\big)\cos\hat{\theta}(L)=0. \tag{5.24}$$

From (2.7), (4.6b) we obtain

$$\hat{\nu}(L)\sin\hat{\theta}(L)+\hat{\eta}(L)\cos\hat{\theta}(L)=0. \tag{5.25}$$

Since (5.24), (5.25), regarded as a linear system for $\sin\hat{\theta}(L)$, $\cos\hat{\theta}(L)$, cannot have a trivial solution, we conclude that

$$\hat{\eta}(L)N\big(\hat{\mathbf{q}}(L),L\big)=\hat{\nu}(L)H\big(\hat{\mathbf{q}}(L),L\big). \tag{5.26}$$

(The arguments of the functions in (5.26) are understood to equal those of (5.17).) Condition (5.17) implies that (5.26) is satisfied if and only if $\hat{\eta}(L)=0$. From (5.20) we thus find that $\sin\big(\phi(L)-\hat{\theta}(L)\big)=0$. It follows from (5.22) that $\hat{\theta}(L)=\phi(L)=\pi$. □

We now introduce the subsets $\mathcal{O}(\epsilon)$ of the domain of definition of $\mathbf{k}$ that are used in Theorem 5.1. Let $(\zeta,\psi)\in\mathcal{A}$. We define

$$\hat{\epsilon}[\zeta,\psi]\equiv\min\big\{l[\zeta],\min\{\hat{\nu}[\zeta,\psi](s)-\kappa\big(\psi'(s),s\big)\}\big\}, \tag{5.27a}$$

$$E\equiv\hat{\epsilon}[Z,0]. \tag{5.27b}$$

For each $\epsilon\in[0,E)$, we define

$$\mathcal{O}(\epsilon)\equiv\{(\zeta,\psi,\alpha,\beta,U,P)\in\mathcal{V}\times\mathbb{R}^4:\hat{\epsilon}[\zeta,\psi]>\epsilon,\ \zeta\text{ has positive orientation}\}. \tag{5.28}$$

(Note that $\mathcal{O}(\epsilon)\subset\mathcal{A}\times\mathbb{R}^4$.) Clearly $\mathcal{O}(\epsilon)$ satisfies (5.2)–(5.4) with $\mathcal{O}=\mathcal{O}(0)=\mathcal{A}\times\mathbb{R}^4$ and with $(0,0)$ replaced with $(Z,0,1,0,0,0)$.

PROPOSITION 5.29. $\mathbf{k}$ *is continuous on* $\mathcal{A}\times\mathbb{R}^4$ *and is continuously Fréchet differentiable with respect to* $(\zeta,\psi,\alpha,\beta,P)$ *if* $U=0$. *The restriction of* $\mathbf{k}$ *to* $\mathcal{O}(\epsilon)$ *is compact for every* $\epsilon\in(0,E)$.

Proof. The continuity and Fréchet differentiability follow immediately from their definitions and from Theorem 4.15. The compactness follows from the Arzelà–Ascoli Theorem and Theorem 4.15 in a straightforward way. (Note that for arbitrary $\epsilon>0$ the set $\{(\nu,\eta,\mu,s)\in\mathcal{Q}:\nu-\kappa(\mu,s)\geq\epsilon,\ \nu+|\eta|+|\mu|\leq 1/\epsilon\}$ is a compact subset of $\mathcal{Q}$.) □

The way we have replaced $\hat{\nu}(0)$, $\hat{\mu}(0)$ with α, β was designed precisely to compensate for the degeneracy inherent in (5.14) and to enable us to prove the following proposition.

PROPOSITION 5.30. *The Fréchet derivative of* $\mathbf{I}-\mathbf{k}$ *with respect to* $(\zeta,\psi,\alpha,\beta)$ *about the trivial state* $(\zeta,\psi,\alpha,\beta,U,P)=(Z,0,1,0,0,0)$ *is an invertible linear mapping of* $\mathcal{V}\times\mathbb{R}^2$ *onto itself.*

Proof. In view of Proposition 5.29, we can use the Open Mapping Theorem and the Fredholm Alternative to reduce the proof to showing that this derivative is injective, i.e., to showing that the linearization of (5.15) about the trivial solution has the unique zero solution. By an argument analogous to that leading up to Proposition 5.16, we can show that the linearization of (5.15) is equivalent to the linearization of BVP. (In particular, the treatment of the linearization of (4.6c) follows that for (4.6c)

itself.) This linearization of (5.15) can be formally obtained by assuming that all the variables depend upon a small parameter τ with the trivial state corresponding to $\tau = 0$, then by differentiating the governing equations with respect to τ, and finally by setting $\tau = 0$. The value of the derivative of a variable such as ν with respect to τ at $\tau = 0$ is denoted $\dot{\nu}$. Variables with dots are the unknowns of the linearization. The values of constitutive functions at the trivial state are identified by the superscript 0. Thus, e.g., $N_\nu^0(s) \equiv N_\nu(1,0,0,s)$. In deriving the linearization we have used (4.4) and the evenness of $\mathbf{Q}(\mathbf{q},\cdot)$ to show that various constitutive functions, such as N_η are zero in the trivial state. We use (4.16) to show that $\dot{p} = 0$. The linearization of BVP is accordingly given by

$$\dot{x}' = \dot{\nu}\sin\Theta + (\dot{\eta}+\dot{\theta})\cos\Theta, \quad \dot{y}' = -\dot{\nu}\cos\Theta + (\dot{\eta}+\dot{\theta})\sin\Theta, \quad \dot{\theta}' = \dot{\mu}, \tag{5.31a}$$

$$\begin{aligned} &\dot{x}(s) = \dot{x}(-s), \quad \dot{y}(s) = -\dot{y}(-s), \quad \dot{\theta}(s) = -\dot{\theta}(-s),\\ &\dot{\nu}(s) = \dot{\nu}(-s), \quad \dot{\eta}(s) = -\dot{\eta}(-s), \quad \dot{\mu}(s) = \dot{\mu}(-s),\\ &\dot{y}(\pm L) = 0, \qquad \dot{x}'(\pm L) = 0, \qquad \dot{\theta}(\pm L) = 0, \end{aligned} \tag{5.31b}$$

$$\dot{N}' = \Theta'\dot{H}, \quad \dot{H}' = -\Theta'\dot{N}, \quad \dot{M}' = -\dot{H}, \tag{5.31c}$$

$$\dot{N} = N_\nu^0\dot{\nu} + N_\mu^0\dot{\mu}, \quad \dot{H} = H_\eta^0\dot{\eta}, \quad \dot{M} = M_\nu^0\dot{\nu} + M_\mu^0\dot{\mu}. \tag{5.31d}$$

From (5.31c) we obtain (the principle of virtual work)

$$\int_{-L}^{L} [\dot{y}(-\dot{N}\cos\Theta + \dot{H}\sin\Theta)' + \dot{x}(\dot{N}\sin\Theta + \dot{H}\cos\Theta)' + \dot{\theta}(\dot{M}' + \dot{H})]\,ds = 0. \tag{5.32}$$

We integrate (5.32) by parts and then use (5.31a,b,d) to obtain

$$\int_{-L}^{L} [(N_\nu^0\dot{\nu} + N_\mu^0\dot{\mu})\dot{\nu} + H_\eta^0\dot{\eta}^2 + (M_\nu^0\dot{\nu} + M_\mu^0\dot{\mu})\dot{\mu}]\,ds = 0. \tag{5.33}$$

Since the integrand of (5.33) is positive definite by (2.21), we find that $\dot{\nu} = \dot{\eta} = \dot{\mu} = 0$, whence the triviality of the solution follows. □

From Propositions 5.29, 5.30 and the Implicit Function Theorem in Banach space we deduce the following theorem.

THEOREM 5.34. *Let $U = 0$. There exists a neighborhood $\mathcal{E}$ of $(\zeta,\psi,\alpha,\beta) = (Z,0,1,0)$ in $\mathcal{A}\times\mathbb{R}^2$ and a number $\tilde{P} > 0$ such that if $|P| < \tilde{P}$, then (5.15) has exactly one solution $\big(\tilde{\zeta}(P)(\cdot),\tilde{\psi}(P)(\cdot),\tilde{\alpha}(P),\tilde{\beta}(P)\big)$ in $\mathcal{E}$. The mapping taking P into this solution is continuously differentiable.*

Since the set of bounded linear invertible mappings is open in the space of bounded linear mappings of a Banach space into itself, we can choose $\tilde{P}$ so small that the Fréchet derivative $\mathbf{I}-\mathbf{k}_{(\zeta,\psi,\alpha,\beta)}\big(\tilde{\zeta}(P)(\cdot),\tilde{\psi}(P)(\cdot),\tilde{\alpha}(P),\tilde{\beta}(P),0,P\big)$ of $\mathbf{I}-\mathbf{k}$ is invertible. Accordingly, we define

$$\begin{aligned} \mathcal{P} \equiv \{P\in\mathbb{R} :\ &(5.15) \text{ has a solution } \big(\zeta^\star(P)(\cdot),\psi^\star(P)(\cdot),\alpha^\star(P),\beta^\star(P)\big) \text{ for } U = 0,\\ &\mathbf{I}-\mathbf{k}_{(\zeta,\psi,\alpha,\beta)}\big(\zeta^\star(P)(\cdot),\psi^\star(P)(\cdot),\alpha^\star(P),\beta^\star(P),0,P\big) \text{ is invertible}\}. \end{aligned} \tag{5.35}$$

By Theorem 5.34 we know that $\mathcal{P}$ contains a nonempty interval containing zero. Let

$$\mathcal{S} \equiv \{(\zeta,\psi,\alpha,\beta,U,P)\in\mathcal{A}\times\mathbb{R}^4 : (5.15) \text{ holds}\}. \tag{5.36}$$

It is the set of solution-parameter pairs of (5.15). Let $P_0 \in \mathcal{P}$ and let

$$(\zeta_0, \psi_0, \alpha_0, \beta_0) = \big(\zeta^\star(P_0)(\cdot), \psi^\star(P_0)(\cdot), \alpha^\star(P_0), \beta^\star(P_0)\big) \tag{5.37}$$

be defined as in (5.35). We define $\mathcal{S}_0$ to be the connected component of $\mathcal{S}$ containing $(\zeta_0, \psi_0, \alpha_0, \beta_0, 0, P_0)$. Proposition 5.29, the membership of P_0 in $\mathcal{P}$, and Theorem 5.1 now yield our fundamental result, which asserts the existence of a two-dimensional connected set of solution-parameter pairs of (5.15) having nice topological properties.

THEOREM 5.38. *At least one of the following statements holds:*

(5.39a) $\exists\ \epsilon_1 \in (0, E)$ *such that* $\mathcal{S}_0 \subset \mathcal{O}(\epsilon_1)$, $\mathcal{S}_0$ *is bounded,*

(5.39b) $\mathcal{S}_0 \cap [\mathcal{O} \setminus \mathcal{O}(\epsilon)] \neq \emptyset \quad \forall\ \epsilon \in (0, E)$ *or* $\mathcal{S}_0$ *is unbounded.*

If (5.39a) *holds, then there is an essential mapping* σ *from* $\mathcal{S}_0$ *to* $\mathbb{S}^2$ *whose restriction to* $\mathcal{S}_0 \setminus \{(\zeta_0, \psi_0, \alpha_0, \beta_0, 0, P_0)\}$ *is inessential. Moreover,* $\mathcal{S}_0$ *contains a subset* $\mathcal{S}_{00}$ *each point of which has topological dimension at least* 2. *The restriction of* σ *to* $\mathcal{S}_{00}$ *is essential. If* (5.39b) *holds, then for each* ϵ *there is a compact and continuous operator* $\mathbf{k}_\epsilon$ *on* $\mathcal{V} \times \mathbb{R}^4$ *such that the equation* $(\zeta, \psi, \alpha, \beta) = \mathbf{k}_\epsilon[\zeta, \psi, \alpha, \beta, U, P]$ *on* $\mathcal{V} \times \mathbb{R}^4$ *agrees with* (5.15b) *on* $\mathcal{O}(\epsilon)$. *The one-point compactification* $\mathcal{S}_0^+(\epsilon)$ *of the connected component* $\mathcal{S}_0(\epsilon)$ *of its solution pairs containing* $(0, 0)$ *has the same properties as* $\mathcal{S}_0$ *in statement* (i).

Remark. We have not yet been able to show that $\mathbf{k}$ is Fréchet differentiable with respect to $(\zeta, \psi, \alpha, \beta)$ when $U \neq 0$. For this reason we cannot invoke the local Implicit Function Theorem in Banach space to assert that $\mathcal{S}_0$ (or $\mathcal{S}$) is a C^1-surface of dimension 2 near $(\zeta_0, \psi_0, \alpha_0, \beta_0, 0, P_0)$. Such a result would be necessary to justify the most primitive of perturbation methods.

We now study solutions of (5.15) with P fixed at a value P_0 in $\mathcal{P}$.

THEOREM 5.40. *Let* $P_0 \in \mathcal{P}$ *and let* (5.37) *hold. Then there is a number* $U_1 > 0$, *depending on* P_0, *such that the set*

$$\mathcal{S}_*(P_0) \equiv \bigcup_{|U| \leq U_1} \{(\zeta, \psi, \alpha, \beta, U, P_0) \in \mathcal{S}\} \tag{5.41}$$

contains a connected subset joining the planes $U = \pm U_1$. (*Thus there is a solution for each* U *with* $|U| \leq U_1$.)

Proof. The existence of a branch bifurcating from (5.37) follows from a one-parameter version of Theorem 5.38. Since $\mathbf{I} - \mathbf{k}_{(\zeta,\psi,\alpha,\beta)}(\zeta_0, \psi_0, \alpha_0, \beta_0, 0, P)$ is invertible, it follows that $(\zeta_0, \psi_0, \alpha_0, \beta_0, 0, P)$ is an isolated solution of (5.15) in the space $\mathcal{V} \times \mathbb{R}^2 \times \{0\} \times \{P_0\}$. Thus the values of U on the branch cannot be confined to zero. Since (5.15) is even in U, the values of U must be symmetrically disposed about $U = 0$. □

Remark. These theorems describe the connectivity properties of solution sextuples $(\zeta, \psi, \alpha, \beta, U, P)$ of the modified problem (5.15). It is easy to use the relations $\alpha = \hat{\nu}(0)$ and $\beta = \hat{\mu}(0)$ to show that the same results apply to the solution quadruples (ζ, ψ, U, P) of the original BVP, except possibly for (4.1c), which can be handled with Proposition 5.16.

Remark. For P held fixed at a positive $P_0 \in \mathcal{P}$, the continuity of $p[\cdot, \cdot, \cdot]$, defined in (4.16), ensures that the pressure on the ring is everywhere positive if U is small enough. If the pressure becomes negative on part of the ring, then cavitation occurs. Note that the speed $|w|$ of the flow has a strict maximum on $\operatorname{cl}\mathcal{F}[\zeta]$ on its boundary ζ (as can be shown by mapping $\mathcal{F}[\zeta]$ onto a bounded region and applying a maximum principle). Thus the second summand in (4.16) is negative somewhere on the ring.

For P held fixed at 0 and $U \neq 0$, there must be a place on the ring where the pressure is negative.

6. The conformal mapping problem for the flow about a symmetric ring. Our main goal in this section is to prove Theorem 4.15. We use the results of §3. Let $\zeta \in C^{1,\alpha} \cap \mathcal{Z}^+$ be a simple closed positively oriented curve satisfying (4.3a). Without loss of generality we assume that 0 lies inside of ζ. Our *flow problem* FP is to find a complex potential $\Omega = \Phi + i\Psi$ holomorphic on $\mathcal{F}[\zeta]$ with Ω' continuous on $\operatorname{cl}\mathcal{F}[\zeta]$ that satisfies (3.9), (3.10), and the symmetry condition

$$\Omega(\overline{z}) = \overline{\Omega}(z) \text{ or, equivalently, } \Phi(x,y) = \Phi(x,-y). \tag{6.1a}$$

By virtue of (3.6a), this condition is in turn equivalent to

$$u(x,y) = u(x,-y), \qquad v(x,y) = -v(x,-y). \tag{6.1b}$$

Condition (6.1b) ensures (3.7), which states that the flow has zero circulation (cf. Brezis and Stampacchia (1976)). The Kutta–Joukowski Theorem states that the resultant force on the ring produced by the flow $w[\zeta,U]$ is $-i\rho U \int_\zeta w[\zeta,U](z)\,dz$. This vanishes when (3.7) holds (in which case we have d'Alembert's paradox that the resultant force on the ring is zero). The Blasius Theorem states that the resultant moment on the ring produced by the flow $w[\zeta,U]$ is $-\frac{\rho}{2}\operatorname{Re}\int_\zeta zw[\zeta,U](z)^2\,dz$. That (6.1) forces this integral to vanish is our main motivation for adopting this restriction. We can prove Theorem 4.15 when the circulation is zero without invoking (6.1), but we do not emphasize this point. At several places our analysis makes contact with standard results on existence and uniqueness of solutions to FP. It is nevertheless necessary for us to reiterate some of the steps in order to show precisely how the boundary values of solutions depend on ζ.

Let

$$\mathcal{D} \equiv \{\omega \in \mathbb{C} : |\omega| < 1\}. \tag{6.2}$$

We shall reduce FP to finding a conformal mapping f from $\mathcal{F}[\zeta]$ to $\mathbb{C}\backslash\operatorname{cl}\mathcal{D}$.

For technical reasons it is convenient to study conformal mappings from bounded sets to bounded sets. For this purpose we express f as a composition of the inversion $\mathcal{F}[\zeta] \ni z \mapsto 1/z$ followed by a mapping $g[\zeta]^{-1}$ and then followed by another inversion $\omega \mapsto 1/\omega$. See Fig. 6.3. Since our aim is to determine precisely how the flow variables depend on ζ, we must determine precisely how $g[\zeta]$ depends on ζ. Nevertheless, for notational simplicity we shall often suppress the dependence of variables on ζ in our computations, but not in the statements of important results.

We now introduce a class of boundary shapes that are compatible with the analysis of the ring problem in §§4 and 5 and that promote the analysis of the conformal mapping problem formulated below. For $0 < \alpha \leq 1$, $0 < h_1 < h_2$, $0 < \delta$ we define

$$\begin{aligned} &\mathcal{Z}^{\pm}(\alpha,h_1,h_2,\delta) \equiv \mathcal{A}(h_1,h_2) \cap C^{1,\alpha} \cap \mathcal{Z}^{\pm}(\delta), \\ &\mathcal{Z}^{\pm}(\alpha,h_1,h_2) \equiv \mathcal{A}(h_1,h_2) \cap C^{1,\alpha} \cap \mathcal{Z}^{\pm}, \\ &\mathcal{A}(h_1,h_2) \equiv \{\zeta : h_1 < |\zeta| < h_2,\ (4.3a) \text{ holds, } \operatorname{Re}\zeta(\pm L) > \operatorname{Re}\zeta(0)\}. \end{aligned} \tag{6.4}$$

DEFINITION 6.5. For $\zeta \in \mathcal{Z}^+(\alpha,h_1,h_2)$, $\mathcal{I}[\zeta]$ is the domain of $\mathbb{C}$ enclosed by the curve $1/\zeta$.

The following result is immediate.

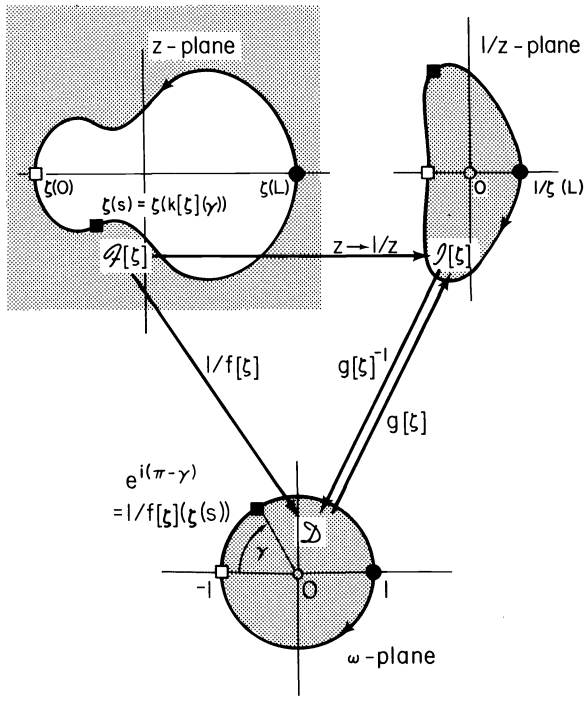

FIG. 6.3. *Conformal mappings. The positive (counterclockwise) orientation we have adopted for ς is a negative orientation for the boundary of $\mathcal{F}$. The counterclockwise orientation of ς is reversed by the inversion $z \mapsto 1/z$ so that the boundaries of $\mathcal{I}$ and $\mathcal{D}$ are shown with clockwise orientations. The parameter γ for $\partial\mathcal{D}$ corresponds to this orientation.*

LEMMA 6.6. *Let $0 < \alpha \leq 1$, $0 < h_1 < h_2$. The mapping $\mathcal{Z}^+(\alpha, h_1, h_2) \ni \zeta \mapsto 1/\zeta \in \mathcal{Z}^-(\alpha, h_2^{-1}, h_1^{-1})$ is continuous in the $C^{1,\alpha}$-norm.*

For $0 < \alpha \leq 1$, $0 < h_1 < h_2$, let $\zeta \in \mathcal{Z}^+(\alpha, h_1, h_2)$. Our *conformal mapping problem* (CMP) is to find a continuously differentiable homeomorphism

$$f : \mathrm{cl}\,\mathcal{F}[\zeta] \to \mathbb{C} \setminus \mathcal{D}, \tag{6.7a}$$

with

$$f(\partial\mathcal{F}[\zeta]) = \partial\mathcal{D}, \tag{6.7b}$$

$$f(\infty) = \infty, \tag{6.7c}$$

$$f'(\infty) \text{ exists and is a positive real number,} \tag{6.7d}$$

$$f(\overline{z}) = \overline{f}(z) \tag{6.7e}$$

such that the restriction of f to $\mathcal{F}[\zeta]$ is conformal. This problem is equivalent to that of finding a continuously differentiable homeomorphism

$$g : \operatorname{cl}\mathcal{D} \to \operatorname{cl}\mathcal{I}[\zeta] \tag{6.8a}$$

with

$$g(\partial\mathcal{D}) = \partial\mathcal{I}[\zeta], \tag{6.8b}$$

$$g(0) = 0, \tag{6.8c}$$

$$g'(0) \text{ is a positive real number,} \tag{6.8d}$$

$$g(\overline{z}) = \overline{g}(z) \tag{6.8e}$$

such that the restriction of g to $\mathcal{D}$ is conformal. We denote the solutions to these problems, each designated CMP, by $f[\zeta]$ and $g[\zeta]$. They are related by

$$f[\zeta](z) = \frac{1}{g[\zeta]^{-1}(1/z)}. \tag{6.9a}$$

We readily find that

$$f[\zeta]'(\infty) = g[\zeta]'(0). \tag{6.9b}$$

THEOREM 6.10. *Let $f[\zeta]$ satisfy* CMP. *Then* FP *has a solution*

$$\Omega[\zeta, U] = \frac{U}{f[\zeta]'(\infty)}\left\{f[\zeta] + \frac{1}{f[\zeta]}\right\}, \tag{6.11}$$

unique to within a real constant.

Proof. All the assertions, except the uniqueness, follow from direct computation. To prove uniqueness, let $\tilde{\Omega}$ be the difference of two solutions of FP. Set

$$H(\omega) \equiv \tilde{\Omega}\big(1/g(\omega)\big), \qquad \omega \in \operatorname{cl}\mathcal{D} \setminus \{0\}. \tag{6.12}$$

Since $\omega \mapsto \tilde{\Omega}'(1/g(\omega))$ is holomorphic on $\mathcal{D} \setminus \{0\}$ and tends to zero as ω tends to zero by (3.4a), it follows that

$$\lim_{\omega\to 0} \omega H'(\omega) = -\lim_{\omega\to 0} \frac{\omega^2 g'(\omega)}{g(\omega)^2} \lim_{\omega\to 0} \frac{\tilde{\Omega}'(1/g(\omega))}{\omega} \in \mathbb{C}. \tag{6.13}$$

Since (6.1a) implies that $\int_{\partial\mathcal{D}} H'(\omega)\,d\omega = \int_{\zeta} \tilde{\Omega}'(z)\,dz = 0$, it follows that H' is holomophic in $\mathcal{D}$. Conditions (3.9) and (6.8b) imply that $\operatorname{Im} H = 0$ on $\partial\mathcal{D}$. Therefore H and consequently $\tilde{\Omega}$ are real constants. □

We now obtain some preliminary lemmas that will enable us not only to solve CMP, but also to determine how solutions depend on the shape ζ of the deformed ring. Our attention is focused on the boundary behavior of g.

LEMMA 6.14. *Let $0 < \alpha \le 1$ and let $\zeta \in C^{1,\alpha}$ satisfy $|\zeta'(s)| > 0$ everywhere. Let $\phi[\zeta](s)$ be (a branch of) the angle from the negative imaginary axis to $\zeta'(s)$. Let $\phi[\zeta]$ be continuous. Then there is a positive constant a depending only on $\phi[\zeta](0)$, L, α (and otherwise independent of ζ) such that*

$$\|\phi[\zeta]\|_{0,\alpha} \le a\big(\|\zeta\|_{1,\alpha} + 1\big)^{4/\alpha}\big(\min|\zeta'|\big)^{-4/\alpha}. \tag{6.15}$$

Proof. $\phi[\zeta](s)$ satisfies $\zeta' = -i|\zeta'|e^{i\phi}$. Without loss of generality we take $\phi[\zeta](0) = 0$. Therefore,

(6.16)
$$|\sin(\phi(s) - \phi(t))| = \left|\mathrm{Re}\left\{-i\frac{\zeta'(s)}{|\zeta'(s)|}\frac{\overline{\zeta}'(t)}{|\zeta'(t)|}\right\}\right| = \left|\mathrm{Re}\left\{i\left[\frac{\zeta'(s)}{|\zeta'(s)|} - \frac{\zeta'(t)}{|\zeta'(t)|}\right]\frac{\overline{\zeta}'(t)}{|\zeta'(t)|}\right\}\right|$$
$$\leq \left|\frac{\zeta'(s)}{|\zeta'(s)|} - \frac{\zeta'(t)}{|\zeta'(t)|}\right| \leq \frac{2\|\zeta\|_{1,\alpha}^2|s-t|^\alpha}{\min|\zeta'(s)|^2}.$$

Let us choose an integer $k[\zeta] \geq 1$ so that

$$\frac{L}{k} \leq 4^{-1/\alpha}\left(\min|\zeta'(s)|\right)^{2/\alpha}\|\zeta\|_{1,\alpha}^{-2/\alpha} < \frac{L}{k-1}. \tag{6.17}$$

Then

$$\left|\sin(\phi(s) - \phi(t))\right| \leq \frac{1}{2} \quad \text{when } |s-t| \leq \frac{L}{k}. \tag{6.18}$$

It follows that ϕ can vary at most by $\pi/3$ on an interval of the form $[jL/k, (j+1)L/k]$, $j = -k, \cdots, k-1$. Therefore,

$$|\phi| \leq \frac{k\pi}{3}. \tag{6.19}$$

Thus

$$|\phi(s) - \phi(t)| = \frac{|\phi(s) - \phi(t)|}{\left|\sin(\phi(s) - \phi(t))\right|}\left|\sin(\phi(s) - \phi(t))\right| \leq \frac{2\pi}{3}\left|\sin(\phi(s) - \phi(t))\right| \tag{6.20}$$
$$\text{when } |s-t| \leq \frac{L}{k}.$$

We combine (6.16) and (6.20) to estimate the Hölder quotient for ϕ when $|s-t| \leq L/k$. Otherwise, we find that $|\phi(s) - \phi(t)| \leq (2k/L^\alpha)\|\phi\|_0|s-t|^\alpha \leq (2k^2\pi/3L^\alpha)|s-t|^\alpha$ by (6.19). We now estimate k from the second inequality of (6.17) to obtain (6.15). □

We now state some results from complex function theory that are needed in the ensuing analysis.

LEMMA 6.21. *Let κ be a simple closed continuously differentiable curve in $\mathbb{C}$ with $|\kappa'|$ everywhere positive. If h is a one-to-one holomorphic function taking $\mathcal{D}$ onto the interior of κ, then h can be extended to $\mathrm{cl}\,\mathcal{D}$ so that the extension is a continuous bijection of $\mathrm{cl}\,\mathcal{D}$ onto $h(\mathrm{cl}\,\mathcal{D})$.*

The proof is given by Hille (1962, p. 367).

LEMMA 6.22 (Warschawski (1932), (1961), (1968)). *Let $\kappa : [-L, L] \to \mathbb{C}$ and h be as in Lemma 6.21. Let $\phi(\sigma)$ be the angle* (mod 2π) *that the tangent vector $\kappa'(s)$ makes with the negative imaginary axis at the point s with arc length parameter*

$$\sigma = \int_0^s |\kappa'(t)|\,dt.$$

If the function ϕ is Hölder continuous with exponent $\alpha \in (0, 1]$, then h' has a continuous extension to $\mathrm{cl}\,\mathcal{D}$ with h' vanishing nowhere on $\mathrm{cl}\,\mathcal{D}$.

LEMMA 6.23 (Radó (1923, p. 182); cf. Gattegno and Ostrowski (1949, p. 29)). *Let κ, $\kappa_n : [-L, L] \to \mathbb{C}$, $n = 1, 2, \cdots$ be simple closed continuously differentiable curves enclosing 0 with with $|\kappa'|$, $|\kappa_n'|$ everywhere positive. Let $h[\kappa]$, $h[\kappa_n]$ be one-to-one holomorphic mappings from $\mathcal{D}$ onto the interiors of κ, κ_n, respectively, with*

$h[\kappa](0) = h[\kappa_n](0) = 0$, $h[\kappa]'(0) > 0$, $h[\kappa_n]'(0) > 0$. *If* κ_n *converges uniformly to* κ *on* $[-L, L]$, *then* $h[\kappa_n]$ *converges uniformly to* $h[\kappa]$ *on* $\operatorname{cl}\mathcal{D}$.

We can now prove our first basic result about the solvability of CMP and the regularity of its solution.

THEOREM 6.24. *Let* $0 < \alpha \leq 1$, $0 < h_1 < h_2$, $\zeta \in \mathcal{Z}^{\pm}(\alpha, h_1, h_2)$. *Then there is a unique conformal mapping* $g[\zeta]$ *satisfying* CMP *such that* $g[\zeta]'$ *can be continuously extended to* $\operatorname{cl}\mathcal{D}$ *and vanishes nowhere on* $\operatorname{cl}\mathcal{D}$. *Moreover, if* $\{\zeta_k\}$ *is a sequence in* $\mathcal{Z}^{\pm}(\alpha, h_1, h_2)$ *converging to* ζ *in the* $C^{1,\alpha}$*-norm, then* $g[\zeta_k]$ *converges uniformly to* $g[\zeta]$ *on* $\operatorname{cl}\mathcal{D}$ *and* $g[\zeta_k]^{-1}(1/\zeta_k(\cdot))$ *converges pointwise to* $g[\zeta]^{-1}(1/\zeta(\cdot))$ *on* $[-L, L]$.

Proof. The existence and uniqueness of a conformal mapping $g[\zeta]$ from $\mathcal{D}$ to $\mathcal{I}[\zeta]$ such that (6.8c,d) hold is ensured by the Riemann Mapping Theorem. Condition (6.8b) follows from Lemma 6.21. By (4.3a), $z \mapsto \overline{g[\zeta](\bar{z})}$ satisfies (6.8a–d). Hence (6.8e) is satisfied by the uniqueness ensured by the Riemann Mapping Theorem. That $g[\zeta]$ enjoys the regularity properties at the boundary follows from Lemmas 6.14, 6.21, 6.22. The uniform convergence of $g[\zeta_k]$ follows from Lemmas 6.6 and 6.23. To prove the last statement, let $\sigma_0 = 1/\zeta(s)$, $s \in [-L, L]$. Then $g[\zeta_k]^{-1}(1/\zeta_k(s)) \in \partial\mathcal{D}$ and is accordingly bounded. By the Bolzano–Weierstrass Theorem, it has a subsequence (denoted the same way) converging to $\omega_0 \in \partial\mathcal{D}$. Now

(6.25)
$$\begin{aligned}|\sigma_0 - g[\zeta](\omega_0)| \leq{}& |\sigma_0 - 1/\zeta_k(s)| + \left|g[\zeta_k]\left(g[\zeta_k]^{-1}(1/\zeta_k(s))\right) - g[\zeta]\left(g[\zeta_k]^{-1}(1/\zeta_k(s))\right)\right| \\ &+ \left|g[\zeta]\left(g[\zeta_k]^{-1}(1/\zeta_k(s))\right) - g[\zeta](\omega_0)\right|.\end{aligned}$$

As $k \to \infty$ the terms on the right of (6.25) approach 0 because $g[\zeta_k]$ and ζ_k converge uniformly to $g[\zeta]$ and ζ and because $g[\zeta]$ is continuous. Hence $\omega_0 = g[\zeta]^{-1}(\sigma_0)$. Since this argument holds for all subsequences, the last statement of the theorem is established. □

We must supplement the results of Theorem 6.24 in order to prove the assertions about compactness made in Theorem 4.15. The next lemma introduces a function k, which intimately connects g and ζ and which intervenes in the explicit formulas, like (6.33) below, for the boundary values of fluid mechanical variables.

LEMMA 6.26. *Let* $0 < \alpha \leq 1$, $0 < h_1 < h_2$, $\zeta \in \mathcal{Z}^{+}(\alpha, h_1, h_2)$. *Let a typical point of* $\partial\mathcal{D}$ *be denoted by* $e^{i(\pi-\gamma)}$ (*cf. Fig.* 6.3). *Then there exists a unique function*

$$k[\zeta] : [-\pi, \pi] \to [-L, L] \tag{6.27}$$

(*which associates the parameter* s *of* ζ *with the angle* γ *parametrizing* $\partial\mathcal{D}$) *such that*

$$g[\zeta]\left(e^{i(\pi-\gamma)}\right) = 1/\zeta\left(k[\zeta](\gamma)\right). \tag{6.28}$$

$k[\zeta]$ *is continuously differentiable and* $k[\zeta]'$ *is everywhere positive. Moreover, if* $\zeta_l \in \mathcal{Z}^{+}(\alpha, h_1, h_2)$ *and if* $\zeta_l \to \zeta$ *in the* $C^{1,\alpha}$*-norm, then* $k[\zeta_l]$ *converges pointwise to* $k[\zeta]$.

Proof. Since ζ is simple, the mapping $[-L, L) \ni s \mapsto 1/\zeta(s) \in \partial\mathcal{I}$ has an inverse $j[\zeta]$. We define $k[\zeta](\gamma) \equiv j[\zeta]\left(g[\zeta](e^{i(\pi-\gamma)})\right)$. Thus (6.28) is satisfied. Since ζ' vanishes nowhere, the classical Implicit Function Theorem enables us to deduce from (6.28) that $k[\zeta]$ is continuously differentiable. Since g' does not vanish on $\partial\mathcal{D}$ by Theorem 6.24, we obtain from (6.28) that k' does not vanish on $[-\pi, \pi]$. Since conformal mappings preserve orientation, we conclude that $k[\zeta]'$ is everywhere positive.

We now turn to the convergence properties of k. We fix γ. Since $\{k[\zeta_l](\gamma)\}$ is bounded, it has a subsequence, denoted the same way, that converges to $s \in [-L, L]$. Now

$$\left|\frac{1}{\zeta_l\left(k[\zeta_l](\gamma)\right)} - \frac{1}{\zeta(s)}\right| \leq \left|\frac{1}{\zeta_l\left(k[\zeta_l](\gamma)\right)} - \frac{1}{\zeta\left(k[\zeta_l](\gamma)\right)}\right| + \left|\frac{1}{\zeta\left(k[\zeta_l](\gamma)\right)} - \frac{1}{\zeta(s)}\right|. \tag{6.29}$$

It follows from the uniform convergence of $\zeta_l \to \zeta$ and from the properties of our subsequence that the right-hand side of (6.29) approaches zero as $l \to \infty$. It then follows from this observation, from (6.28), and from Theorem 6.24 that

$$1/\zeta(s) = \lim g[\zeta_l]\big(e^{i(\pi-\gamma)}\big) = g[\zeta]\big(e^{i(\pi-\gamma)}\big). \tag{6.30}$$

Therefore $s = k[\zeta](\gamma)$. Since our argument holds for all subsequences, we conclude that $\lim k[\zeta_l](\gamma) = k[\zeta](\gamma)$. □

From (6.9) and (6.11) we compute

$$\Omega'(z) = \frac{U\big[1 - g^{-1}(\frac{1}{z})^2\big]}{g'(0)g^{-1}(\frac{1}{z})^2 g'\big(g^{-1}(\frac{1}{z})\big)z^2}. \tag{6.31}$$

Let $z = \zeta(s)$, $s = k(\gamma)$, so that $g^{-1}(\frac{1}{z}) = e^{i(\pi-\gamma)}$. Provided that the hypotheses of Lemma 6.26 hold, we find that the complex velocity at $\zeta(s)$ is

$$\Omega'\big(\zeta(s)\big) = \frac{2U\sin\gamma}{g'(0)\zeta'(s)k'(\gamma)}, \qquad s = k(\gamma). \tag{6.32}$$

From Bernoulli's equation (3.5), we thus obtain a form of (4.16) that makes the role of ζ explicit:

$$p[\zeta, U, P](s) = P + \frac{\rho}{2}U^2\left\{1 - \frac{4\,|\sin k[\zeta]^{-1}(s)|^2}{\big|g'(0)\zeta'(s)k[\zeta]'\big(k[\zeta]^{-1}(s)\big)\big|^2}\right\}. \tag{6.33}$$

To obtain Hölder and C^1 bounds needed to establish Theorem 4.15 we employ the following lemma.

LEMMA 6.34 (Warschawski (1932, pp. 451–452)). *Let κ, h, ϕ be as in Lemmas 6.22 and 6.23 and let $0 < \alpha < 1$. If there exists a positive number A such that*

$$\operatorname{diam} h(\mathcal{D}) < A, \tag{6.35a}$$

$$h(\mathcal{D}) \text{ contains the disk } (1/A)\mathcal{D} \text{ of radius } 1/A \text{ centered at } 0, \tag{6.35b}$$

$$\frac{1}{A} \le \inf\left\{\frac{|z_1 - z_2|}{\lambda(z_1, z_2)} \;:\; z_1, z_2 \in h(\partial\mathcal{D}), \quad z_1 \ne z_2\right\} \tag{6.35c}$$

where $\lambda(z_1, z_2)$ is the length of the shortest arc of κ joining z_1 to z_2,

$$\frac{1}{A} \le \int_{-L}^{L} |\kappa'(s)|\,ds, \tag{6.35d}$$

$$\|\phi\|_{0,\alpha} < A, \tag{6.35e}$$

then there exists a positive number C depending only on A and α (and independent of κ) such that

$$1/C < |h'(\omega)| < C \quad \forall\,\omega \in \operatorname{cl}\mathcal{D}, \tag{6.36a}$$

$$\|h\|_{C^{1,\alpha}(\operatorname{cl}\mathcal{D})} < C. \tag{6.36b}$$

We now convert these results to those for g.

LEMMA 6.37. *Let $0 < \alpha < 1$, $0 < h_1 < h_2$, $c > 0$, $\delta > 0$ and let $\zeta \in \mathcal{Z}^{\pm}(\alpha, h_1, h_2, \delta)$ with $\|\zeta\|_{1,\alpha} \le c$. Then there exists a positive number C depending only on c, α, h_1, h_2, δ (and independent of ζ) such that*

$$1/C < |g[\zeta]'(\omega)| < C \quad \forall\,\omega \in \operatorname{cl}\mathcal{D}, \tag{6.38a}$$

$$\|g[\zeta]\|_{C^{1,\alpha}(\operatorname{cl}\mathcal{D})} < C. \tag{6.38b}$$

Proof. We identify h and κ of Lemma 6.34 with $g[\zeta]$ and $\partial\mathcal{I}[\zeta]$. (In particular, (6.30) holds.) The properties of g listed in Theorem 6.24 imply that (6.38) is a consequence of (6.36). Thus we need only find an A, depending only on c, α, h_1, h_2, δ such that (6.35) holds. Since $\operatorname{diam} g(\mathcal{D}) < \sup\{|\zeta(s)^{-1} - \zeta(t)^{-1}| : s \neq t\} \leq 2ch_1^{-2}$ and since $\int_{-L}^{L} |(1/\zeta)'|\, ds \geq 2L\delta h_2^{-2}$, we ensure (6.35a,d) by taking $A > 2ch_1^{-2}, h_2^2 L^{-1}\delta^{-1}2^{-1}$. We ensure (6.35b) by taking $A > h_2$. To verify (6.35c) we let $s < t$ and observe that

(6.39)
$$\begin{aligned}
&\lambda\big(\zeta(s)^{-1}, \zeta(t)^{-1}\big) \\
&\quad = \min\left\{\int_{-L}^{s} |\zeta'(u)\zeta(u)^{-2}|\, du + \int_{t}^{L} |\zeta'(u)\zeta(u)^{-2}|\, du,\ \int_{s}^{t} |\zeta'(u)\zeta(u)^{-2}|\, du\right\} \\
&\quad \leq \|\zeta'\|_0 h_1^{-2} \min\{2L - (t-s), t-s\} = \|\zeta'\|_0 h_1^{-2}\sigma(t,s)
\end{aligned}$$

where σ is defined in (4.8a). Since $\zeta \in \mathcal{Z}(\delta)$, we have

$$\frac{|\zeta(s)^{-1} - \zeta(t)^{-1}|}{\lambda\big(\zeta(s)^{-1}, \zeta(t)^{-1}\big)} \geq \frac{\delta h_1^2 \sigma(t,s)}{ch_2^2\sigma(t,s)} = \frac{\delta h_1^2}{ch_2^2}. \tag{6.40}$$

Thus we ensure (6.35c) by taking $A > ch_2^2/\delta h_1^2$. We now use (6.15) with ζ replaced by $1/\zeta$ and use the definition of $\mathcal{Z}(\delta)$ to ensure (6.35e) by taking $A > a[h_1^{-1} + ch_1^{-2} + c^3(1 + 2(2L)^{1-\alpha})h_1^{-4} + 1]^{4/\alpha}(\delta h_2^{-2})^{-4/\alpha}$. □

We need the following technical and intrinsically interesting lemma (a proof of which we could not find in the literature).

LEMMA 6.41. *Let $0 < \beta < \alpha \leq 1$ and let m be a nonnegative integer. Let $\{f_k\}$ be a sequence of functions on $[-L, L]$ that is bounded in $C^{m,\alpha}$. If f_k converges to $f \in C^0$ either pointwise almost everywhere or in the sense of distributions on $(-L, L)$, then $f \in C^{m,\alpha}$ and f_k converges to f in the norm of $C^{m,\beta}$.*

Proof. By hypothesis there is a positive number C such that $\|f_k\|_{m,\alpha} \leq C$. Since $C^{m,\alpha}$ is compactly embedded in $C^{m,\beta}$, the sequence $\{f_k\}$ has a subsequence, denoted the same way, that converges to a limit $g \in C^{m,\beta}$ in the $C^{m,\beta}$-norm. (A fortiori f_k approaches g pointwise almost everywhere and in the sense of distributions.) Our bound on $\|f_k\|_{m,\alpha}$ implies that

$$\left|\frac{d^m}{ds^m} f_k(s_1) - \frac{d^m}{ds^m} f_k(s_2)\right| \leq C|s_1 - s_2|^\alpha \quad \forall\, s_1, s_2, \tag{6.42a}$$

whence we obtain

$$\left|\frac{d^m}{ds^m} g(s_1) - \frac{d^m}{ds^m} g(s_2)\right| \leq C|s_1 - s_2|^\alpha \quad \forall\, s_1, s_2. \tag{6.42b}$$

Thus $g \in C^{m,\alpha}$. Since f_k converges to both f and g either pointwise almost everywhere or in the sense of distributions and since both f and g are continuous, we conclude that $f = g$. The full sequence $\{f_k\}$ converges to f in the norm of $C^{m,\beta}$, for if not, there would be a number $\epsilon > 0$ and another subsequence $\{f_k\}$ such that $\|f_k - f\|_{m,\beta} \geq \epsilon$. We apply the preceding argument to this subsequence to derive a contradiction. □

The following lemma is the culmination of our analysis of of the function k, which plays a central role in determining the boundary behavior of the fluid-mechanical variables.

LEMMA 6.43. *Let $c > 0$, $0 < \beta < \alpha \leq 1$. For all positive integers n let ζ_n, $\zeta \in \{\zeta \in \mathcal{Z}^+ : (4.3a)\ holds\} \cap C^{1,\alpha}$; $0 \in \mathcal{I}[\zeta]$, $\mathcal{I}[\zeta_n]$; $\|\zeta_n\|_{1,\alpha}$, $\|\zeta\|_{1,\alpha} < c$. Let $\zeta_n \to \zeta$ in*

the C^1-norm. Then

$$k[\zeta_n]^{-1} \to k[\zeta]^{-1}, \tag{6.44}$$

$$k[\zeta_n]'\big(k[\zeta_n]^{-1}(\cdot)\big) \to k[\zeta]'\big(k[\zeta]^{-1}(\cdot)\big) \tag{6.45}$$

in the $C^{0,\beta}$-norm.

Proof. Since $\zeta_n \to \zeta$ in the C^1-norm, there is a number N such that $\|\zeta_n - \zeta\|_0 < \frac{1}{2}\min_s|\zeta(s)|$ for $n > N$. We define

$$\begin{aligned} h_1[\zeta] &\equiv \min\Big\{\tfrac{1}{2}\min_s|\zeta(s)|,\ \min_s|\zeta_n(s)|,\ n = 1,\cdots,N\Big\} > 0,\\ h_2[\zeta] &\equiv \max\Big\{2\max_s|\zeta(s)|,\ \max_s|\zeta_n(s)|,\ n = 1,\cdots,N\Big\} < \infty. \end{aligned} \tag{6.46}$$

Thus we find that

$$h_1[\zeta] \le |\zeta_n(s)| \le h_2[\zeta] \quad \forall n, s. \tag{6.47a}$$

Using Lemma 4.13 we likewise show that there is a $\delta[\zeta] > 0$ such that

$$l[\zeta],\ l[\zeta_n] > \delta \tag{6.47b}$$

(cf. (4.8)) and that there is an $\epsilon[\zeta] > 0$ such that

$$\min_s|\zeta'(s)|,\quad \min_s|\zeta_n'(s)| > \epsilon. \tag{6.47c}$$

Thus $\zeta,\ \zeta_n \in \mathcal{Z}^+(\alpha, h_1[\zeta], h_2[\zeta], \delta[\zeta])$.

We now show that

$$\|k[\zeta]\|_{1,\alpha},\ \sup_n\big\{\|k[\zeta_n]\|_{1,\alpha}\big\} < \infty. \tag{6.48}$$

Clearly, $\|k[\zeta_n]\|_0 = L$. From (6.28) we obtain

$$\begin{aligned} &\|k[\zeta_n]'\|_0 = \|r_n(\gamma)\|_0 < \infty,\\ &r_n(\gamma) \equiv ig[\zeta_n]'\big(e^{i(\pi-\gamma)}\big)\zeta_n\big(k[\zeta_n](\gamma)\big)^2/\zeta_n'\big(k[\zeta_n](\gamma)\big), \end{aligned} \tag{6.49}$$

the inequality following from (6.38a), (6.47c). From (6.28) we also obtain

$$|k[\zeta_n]'(\gamma_1) - k[\zeta_n]'(\gamma_2)| \le |r_n(\gamma_1) - r_n(\gamma_2)| + |r_n(\gamma_2)||e^{i(\pi-\gamma_1)} - e^{i(\pi-\gamma_2)}|. \tag{6.50}$$

The continuity of $k[\zeta_n]'$ (ensured by Lemma 6.26), the hypothesis that $\|\zeta_n\|_{1,\alpha}, \|\zeta\|_{1,\alpha} < c$, and the inequalities (6.38b), (6.47c) ensure that there is a positive number C independent of n such that

$$|r_n(\gamma_1) - r_n(\gamma_2)| \le C|e^{i(\pi-\gamma_1)} - e^{i(\pi-\gamma_2)}|^\alpha. \tag{6.51}$$

Since $|e^{i(\pi-\gamma_1)} - e^{i(\pi-\gamma_2)}| = 2|\sin\frac{\gamma_2-\gamma_1}{2}| \le |\gamma_2 - \gamma_1|$, we readily deduce that (6.48) holds.

We now prove that (6.44) holds pointwise. Let us assume for contradiction that it does not. Then there would be a number $t \in [-L, L]$, a number $\epsilon > 0$, and a subsequence such that $|k[\zeta_n]^{-1}(t) - k[\zeta]^{-1}(t)| > \epsilon$. Since $\{k[\zeta_n]^{-1}(t)\}$ is bounded, it has a further subsequence converging to $\tau \in [-\pi, \pi]$. Since

$$(6.52)\quad |t - k[\zeta](\tau)| \leq |k[\zeta_n]\big(k[\zeta_n]^{-1}(t)\big) - k[\zeta]\big(k[\zeta_n]^{-1}(t)\big)| + |k[\zeta]\big(k[\zeta_n]^{-1}(t)\big) - k[\zeta](\tau)|,$$

we can use Lemma 6.26, Lemma 6.41, and inequality (6.48) to deduce that $t = k[\zeta](\tau)$, a contradiction. Thus $k[\zeta_n]^{-1}$ converges pointwise to $k[\zeta_n]^{-1}$. That this convergence is actually in the norm of $C^{0,\beta}$ follows from Lemma 6.41 because the inequality

$$(6.53)\quad |k[\zeta_n]^{-1}(s_1) - k[\zeta_n]^{-1}(s_2)| \leq \frac{|s_1 - s_2|}{\min_s k[\zeta_n]'\big(k[\zeta_n]^{-1}(s)\big)} \leq \frac{\max_s |\zeta_n'(s)||s_1 - s_2|}{\min_s |\zeta_n(s)|^2 \min_{\mathrm{cl}\,\mathcal{D}} |g[\zeta_n]'(\omega)|}$$

together with (6.38a), (6.46), and the hypothesis that $\|\zeta_n\|_{1,\alpha},\ \|\zeta\|_{1,\alpha} < c$ imply that there is a number C depending on ζ such that

$$(6.54)\qquad \|k[\zeta_n]^{-1}\|_{0,1},\ \|k[\zeta_n]^{-1}\|_{0,1} \leq C.$$

We now turn to the proof of (6.45). In view of (6.48), we can use Lemmas 6.26 and 6.41 to show that $k[\zeta_n]'$ converges uniformly to $k[\zeta]'$. Since

$$(6.55)\quad \begin{aligned} &|k[\zeta_n]'\big(k[\zeta_n]^{-1}(s)\big) - k[\zeta]'\big(k[\zeta]^{-1}(s)\big)| \\ &\quad \leq |k[\zeta_n]'\big(k[\zeta_n]^{-1}(s)\big) - k[\zeta]'\big(k[\zeta_n]^{-1}(s)\big)| \\ &\qquad + |k[\zeta]'\big(k[\zeta_n]^{-1}(s)\big) - k[\zeta]'\big(k[\zeta]^{-1}(s)\big)| \end{aligned}$$

we can use the continuity of $k[\zeta]'$, the uniform convergence of $k[\zeta_n]'$ to $k[\zeta]'$, and the pointwise convergence of $k[\zeta_n]^{-1}$ to $k[\zeta]^{-1}$ to deduce that (6.45) holds pointwise. Conditions (6.48), (6.54) imply that there is a number C depending on ζ such that

$$(6.56)\qquad \|k[\zeta_n]'\big(k[\zeta_n]^{-1}(\cdot)\big)\|_{0,\alpha},\ \|k[\zeta]'\big(k[\zeta]^{-1}(\cdot)\big)\|_{0,\alpha} \leq C.$$

Property (6.45) now follows from another application of Lemma 6.41. □

Having collected these technical results, we are now ready to put them together in the following lemma, which leads immediately to the proof of Theorem 4.15.

LEMMA 6.57. *Let* $\{\zeta_n, U_n, P_n\}$ *be a sequence bounded in* $[\{\zeta \in \mathcal{Z}^+\colon$ (4.3a) *holds*$\}$ $\cap C^{1,1}] \times \mathbb{R}^2$ *and let there be a number* $\alpha \in (0,1]$ *such that this sequence converges in the norm of* $C^{1,\alpha} \times \mathbb{R}^2$ *to* $\{\zeta, U, P\} \in [\{\zeta \in \mathcal{Z}^+ :$ (4.3a) *holds*$\} \cap C^{1,1}] \times \mathbb{R}^2$. *Then for each* $\beta \in (0,\alpha)$, *the functions* $\Omega'\big(\zeta_n(\cdot)\big)$ *and* $p[\zeta_n, U_n, P_n]$, *defined in* (6.32), (6.33) *converge to* $\Omega'\big(\zeta(\cdot)\big)$ *and to* $p[\zeta, U, P]$ *in the norm of* $C^{0,\beta}$.

Proof. Since $\Omega[\zeta]'(z) = \Omega[\zeta + a]'(z + a)$ for all real a, there is no loss of generality in assuming that $0 \in \mathcal{I}[\zeta],\ \mathcal{I}[\zeta_n]$ for all n. Then just as in the proof of Lemma 6.43, we can show that there are positive numbers h_1, h_2, depending on ζ, such that $\zeta,\ \zeta_n \in \mathcal{Z}^+(\alpha, h_1, h_2)$ for n sufficiently large. In particular, $|\zeta'|,\ |\zeta_n'|$ are everywhere positive. It follows from Theorem 6.24 that $g[\zeta]'(0),\ g[\zeta_n]'(0) \neq 0$ and from Lemma 6.26 that $k[\zeta]',\ k[\zeta_n]'$ are everywhere positive. Consequently the corresponding flow variables can be defined as in (6.32), (6.33). The convergence of the terms involving the function k follows from Lemmas 6.26 and 6.43. Let us identify $g[\zeta_n]$ with f_n of Lemma 6.41. We choose $m = 1$ and replace $[-L, L]$ with $\mathrm{cl}\,\mathcal{D}$. By (6.38b) and Lemma 6.23, f_n meets the hypotheses of Lemma 6.41. We thus conclude that $g[\zeta_n]'(0) \to g[\zeta]'(0)$. □

Proof of Theorem 4.15. Clearly $\mathcal{Z} = \mathcal{Z}^+ \cup \mathcal{Z}^-$, $\mathcal{Z}^+ \cap \mathcal{Z}^- = \emptyset$, and $\mathcal{Z}^+$ and $\mathcal{Z}^-$ are both open and closed in $\mathcal{Z}$ with respect to the C^1-norm. Hence it suffices to prove the statement when $\mathcal{Z}$ is replaced with $\mathcal{Z}^+$. Now $\mathcal{Z}^+$ is the disjoint union of those ζ's

for which $\operatorname{Re}\zeta(\pm L) > \operatorname{Re}\zeta(0)$ and of those ζ's for which the reverse inequality holds. It suffices to consider just the former subset of $\mathcal{Z}^+$.

We must verify that (6.32), (6.33) have the requisite properties. We use (3.6a). That $U^{-1}\Omega'\big(\zeta(\cdot)\big)$ is independent of U follows immediately from (6.32). Let δ be any positive number. The continuity of

(6.58)
$$C^2 \cap \{\zeta \in \mathcal{Z}^+(\delta) : \text{ (4.3) holds, } \operatorname{Re}\zeta(\pm L) > \operatorname{Re}\zeta(0)\} \ni \zeta \mapsto |U^{-1}w[\zeta, U]| \in C^0$$
$$p[\cdot,\cdot,\cdot] : C^2 \cap \{\zeta \in \mathcal{Z}^+(\delta) : (4.3) \text{ holds, } \operatorname{Re}\zeta(\pm L) > \operatorname{Re}\zeta(0)\} \times \mathbb{R}^2 \to C^0$$

follows from Lemma 6.57. To prove the compactness, let $\{\zeta_n, U_n, P_n\}$ be a sequence bounded in $C^{1,1} \cap \{\zeta \in \mathcal{Z}^+(\delta) : (4.3a) \text{ holds, } \operatorname{Re}\zeta(\pm L) > \operatorname{Re}\zeta(0)\} \times \mathbb{R}^2$. Since $C^{1,1}$ is compactly embedded in $C^{1,\alpha}$ for $\alpha \in (0,1)$, there is a subsequence converging in the norm of $C^{1,\alpha} \times \mathbb{R}^2$ to $\{\zeta, U, P\}$. Since $|\zeta_n'(s_1) - \zeta_n'(s_2)| \le \sup \|\zeta_n\|_{1,1} |s_1 - s_2|$ and since $|\zeta_n(s_1) - \zeta_n(s_2)| \ge \delta\sigma(s_1, s_2)$ (cf. (4.8)), we find that $\zeta \in C^{1,1} \cap \mathcal{Z}^+(\delta/2)$. Since $\operatorname{Re}\zeta_n(\pm L) > \operatorname{Re}\zeta_n(0)$, it follows that $\operatorname{Re}\zeta(\pm L) \ge \operatorname{Re}\zeta(0)$. Hence the injectivity of $\zeta \in \mathcal{Z}^+(\delta/2)$ implies that $\operatorname{Re}\zeta(\pm L) > \operatorname{Re}\zeta(0)$.

Lemma 6.57 thus implies that $|U^{-1}w[\zeta_n, U]|$ and $p[\zeta_n, U_n, P_n]$ converge in the norm of $C^{0,\beta}$, which is compactly embedded in C^0. □

7. Proof of the Global Implicit Function Theorem. We deduce the Global Implicit Function Theorem 5.1 from the following theorem.

THEOREM 7.1 (Alexander and Yorke (1976)). *Let $\mathcal{X}$ be a Banach space. Let $F : \mathcal{X} \times \mathbb{R}^m \to \mathcal{X}$ be continuous and compact with $F(0,0) = 0$. Let I denote the identity operator on $\mathcal{X}$. Let the Fréchet derivative $I - F_x(0,0) : \mathcal{X} \to \mathcal{X}$ of $x \mapsto x - F(x,\lambda)$ at $(0,0)$ exist and be invertible. Let $\mathcal{S} \equiv \{(x,\lambda) \in \mathcal{X} \times \mathbb{R}^m : x = F(x,\lambda)\}$, let $\mathcal{S}_0$ be the connected component of $\mathcal{S}$ containing $(0,0)$, and let $\mathcal{S}_0^+$ be the one-point compactification of $\mathcal{S}_0$. Then there is an essential map (i.e., a continuous map not homotopic to a constant) from $\mathcal{S}_0^+$ onto the m-dimensional sphere $\mathbb{S}^m$ whose restriction to $\mathcal{S}_0 \setminus \{(0,0)\}$ is inessential. Moreover, $\mathcal{S}_0^+$ contains a connected subset $\mathcal{S}_{00}^+$ that contains $(0,0)$, that has the same properties as $\mathcal{S}_0^+$ with respect to essential maps onto $\mathbb{S}^m$, and that has the property that each of its points has topological dimension m.*

Remarks. That each point of $\mathcal{S}_{00}^+$ has topological dimension m was observed by Alexander and Antman (1981). Alexander and Yorke (1976) actually stated the somewhat stronger result that the conclusion of Theorem 7.1 holds when the domain of F is a set $\mathcal{U}$ in $\mathcal{X} \times \mathbb{R}^m$ that is homeomorphic to $\mathcal{X} \times \mathbb{R}^m$. (Alexander and Antman (1981) made an analogous assertion.) We could reduce the more general problem to Theorem 7.1 provided that $\mathcal{U}$ and F admit a homeomorphism from $\mathcal{U}$ to $\mathcal{X} \times \mathbb{R}^m$ that preserves (i) the fixed-point form of the equation and the distinguished role of the parameter in $\mathbb{R}^m$, (ii) the compactness of the appropriate operator, and (iii) the existence of an invertible partial Fréchet derivative at a base point. Problems that admit such homeomorphisms must have very special forms. Thus we believe that the stronger result of Alexander and Yorke (and the corresponding result of Alexander and Antman) do not hold without further qualification. Since our problem apparently fails to have the requisite special form, we resort to Theorem 5.1, a corollary of Theorem 7.1, which not only retains much of the force of the stronger version, but also applies to a wider class of domains and operators. Continuation theorems related to Theorem 7.1 are given by Fitzpatrick, Massabò, and Pejsachowicz (1983) and by Ize, Massabò, Pejsachowicz, and Vignoli (1985).

Proof of Theorem 5.1. The result about $\mathcal{S}$ in a neighborhood of $(0,0)$ is a consequence of the classical Implicit Function Theorem in Banach space. Let us first suppose that the first statements of (ii) and (iii) do not hold. Then the first statement of (i) must hold. We prove the rest of statement (i).

Let $E > 0$ be given. We choose ϵ^* accordingly. Since $\mathcal{X} \times \mathbb{R}^m$ is a Banach space and thus a normal topological space, Urysohn's lemma implies that there exists a continuous function

$$\mathcal{X} \times \mathbb{R}^m \ni (x, \lambda) \mapsto \varphi(x, \lambda, \epsilon) \in [0,1] \tag{7.2}$$

such that

$$\begin{aligned} &\varphi(x,\lambda,\epsilon) = 1 \quad \text{for } (x,\lambda) \in \mathcal{O}(\epsilon), \\ &\varphi(x,\lambda,\epsilon) = 0 \quad \text{for } (x,\lambda) \in \mathcal{X} \times \mathbb{R}^m \setminus \mathcal{O}(\epsilon/2), \end{aligned} \tag{7.3}$$

for each $\epsilon \in (0, \epsilon^*)$ (provided that $\mathcal{O}(\epsilon/2) \neq \mathcal{X} \times \mathbb{R}^m$, which we may assume. We shall apply Theorem 7.1 to the mollified equation

$$x = \varphi(x, \lambda, \epsilon) F(x, \lambda). \tag{7.4}$$

Let

$$\mathcal{S}(\epsilon) \equiv \{(x,\lambda) \in \mathcal{X} \times \mathbb{R}^m : (7.4) \text{ holds}\} \tag{7.5}$$

and let $\mathcal{S}_0(\epsilon)$ be the connected component of $\mathcal{S}(\epsilon)$ containing $(0,0)$. We reduce our proof to a sequence of lemmas. The properties of φ imply the following lemmas.

LEMMA 7.6. *Let* $0 < \epsilon < \epsilon^*/4$. *Then* $\mathcal{S} \cap \mathcal{O}(\epsilon^*) = \mathcal{S}(\epsilon) \cap \mathcal{O}(\epsilon^*)$.

LEMMA 7.7. *Let* $\mathcal{A}$ *be an open subset of a metric space* $\mathcal{Y}$ *and let* $\mathcal{C}$ *be a closed connected subset of* $\mathcal{Y}$ *with* $\mathcal{C} \cap \operatorname{cl}\mathcal{A}$ *compact and* $\mathcal{C} \setminus \mathcal{A} \neq \emptyset$. *Let* $x \in \mathcal{C} \cap \mathcal{A}$. *Then there exists a connected subset* $\mathcal{C}_1$ *of* $\mathcal{C} \cap \operatorname{cl}\mathcal{A}$ *such that* $x \in \mathcal{C}_1$, $\mathcal{C}_1 \cap \partial\mathcal{A} \neq \emptyset$.

Proof. The connectedness of $\mathcal{C}$ suppports a simple proof by contradiction that $\mathcal{C} \cap \partial\mathcal{A}$ and x are not separated in $\mathcal{C} \cap \operatorname{cl}\mathcal{A}$. Hence a well-known result from topology (cf. Alexander (1981, Cor. 4)) implies that x and $\mathcal{C} \cap \partial A$ are connected in $\mathcal{C} \cap \operatorname{cl}\mathcal{A}$. □

LEMMA 7.8. *Let* $\mathcal{S}_0$ *be bounded, let* $\mathcal{S}_0 \subset \mathcal{O}(\epsilon^*)$, *and let* $0 < \epsilon < \epsilon^*/4$. *Then* $\mathcal{S}_0 = \mathcal{S}_0(\epsilon)$.

Proof. By Lemma 7.6 $\mathcal{S}_0 \subset \mathcal{S} \cap \mathcal{O}(\epsilon^*) = \mathcal{S}(\epsilon) \cap \mathcal{O}(\epsilon^*) \subset \mathcal{S}(\epsilon)$. The connectivity properties of $\mathcal{S}_0$ and $\mathcal{S}_0(\epsilon)$ then imply that $\mathcal{S}_0 \subset \mathcal{S}_0(\epsilon)$.

We now prove the reverse inclusion. The compactness of F on $\mathcal{O}(\epsilon)$ and the boundedness of $\mathcal{S}_0$ imply that $\mathcal{S}_0$ is compact. Since $\mathcal{S}_0 \subset \mathcal{S} \cap \mathcal{O}(\epsilon^*)$, it follows that

$$d \equiv \operatorname{dist}\{\mathcal{S}_0,\ \mathcal{X} \times \mathbb{R}^m \setminus \mathcal{O}(\epsilon^*)\} > 0. \tag{7.9}$$

Let

$$\mathcal{A} \equiv \{(x,\lambda) \in \mathcal{X} \times \mathbb{R}^m : \operatorname{dist}\{(x,\lambda), \mathcal{S}_0\} < d/4\}. \tag{7.10}$$

Clearly, $\mathcal{A}$ is open and bounded and $\mathcal{S}_0 \subset \mathcal{A} \subset \mathcal{O}(\epsilon^*)$. We now prove by contradiction that $\mathcal{S}_0(\epsilon) \subset \operatorname{cl}\mathcal{A}$. Suppose that there were a $p \in \mathcal{S}_0(\epsilon) \setminus \operatorname{cl}\mathcal{A}$. Since φF is compact on $\mathcal{X} \times \mathbb{R}^m$, we find that $\mathcal{S}_0(\epsilon) \cap \operatorname{cl}\mathcal{A}$ is compact. Lemma 7.7 implies that there would exist a connected subset $\mathcal{S}_1(\epsilon)$ of $\mathcal{S}_0(\epsilon) \cap \operatorname{cl}\mathcal{A}$ such that $(0,0) \in \mathcal{S}_1(\epsilon)$, $\mathcal{S}_1(\epsilon) \cap \partial\mathcal{A} \neq \emptyset$. Since $0 < \epsilon < \epsilon^*/4$, Lemma 7.6 implies that $\mathcal{S}_1(\epsilon) \subset \mathcal{S}_0(\epsilon) \cap \mathcal{O}(\epsilon^*) \subset \mathcal{S}(\epsilon) \cap \mathcal{O}(\epsilon^*) = \mathcal{S} \cap \mathcal{O}(\epsilon^*)$. Thus $\mathcal{S}_1(\epsilon) \subset \mathcal{S}$. Since $(0,0) \in \mathcal{S}_1(\epsilon)$ and $\mathcal{S}_1(\epsilon)$ is connected, it follows that $\mathcal{S}_1(\epsilon) \subset \mathcal{S}_0$. Hence, $\mathcal{S}_0 \cap \partial\mathcal{A} \neq \emptyset$. But this is impossible because $\mathcal{A}$ is an open neighborhood of $\mathcal{S}_0$. Thus $\mathcal{S}_0(\epsilon) \subset \operatorname{cl}\mathcal{A} \subset \mathcal{O}(\epsilon^*)$. Lemma 7.6 now implies that

$\mathcal{S}_0(\epsilon) \subset \mathcal{S}(\epsilon) \cap \mathcal{O}(\epsilon^*) = \mathcal{S} \cap \mathcal{O}(\epsilon^*) \subset \mathcal{S}$. Since $\mathcal{S}_0(\epsilon)$ is connected, contains $(0,0)$, and is contained in $\mathcal{S}$, it follows that $\mathcal{S}_0(\epsilon) \subset \mathcal{S}_0$. □

Since Lemma 7.8 and the compactness of $\mathcal{S}_0$ imply that $\mathcal{S}_0(\epsilon) \cup \{\infty\} = \mathcal{S}_0 \cup \{\infty\} = \mathcal{S}_0^+$ (with ∞ isolated), we can apply Theorem 7.1 to (7.4) to deduce statement (i) of Theorem 5.1. The mollification argument we have used enables us to apply Theorem 7.1 directly to (7.4) in order to obtain statement (ii). □

Acknowledgment. We are grateful to J. C. Alexander and J. A. Hummel for a number of helpful comments. The work reported here represents a significant extension of part of the doctoral dissertation of Lanza de Cristoforis (1987).

THE POISSON EQUATION WITH NONAUTONOMOUS SEMILINEAR BOUNDARY CONDITIONS IN DOMAINS WITH MANY TINY HOLES*

SATOSHI KAIZU†

Abstract. This paper discusses asymptotic behaviors of the solution of the Poisson equation in domains with many tiny holes, where the number of holes grows to infinity and the diameter of each hole tends to zero. The solution satisfies a nonautonomous semilinear boundary condition on fragmentary boundaries of many tiny holes. Sufficient conditions are given, under which an extension of the solution to the domain with no hole converges, and the equation satisfied by the limit of the extension of the solution is determined. The convergence properties of Radon measures are applied, and also the convergence properties of the resolvent of subdifferentials together with variational inequalities are applied.

Key words. Poisson equation, semilinear boundary condition, domains with many tiny holes, homogenization, variational inequalities, subdifferentials, asymptotic behavior

AMS(MOS) subject classifications. 35B25, 35B40, 35J05, 35J20

Introduction. Let Ω be a bounded domain in $\mathbb{R}^N$, $N \geqq 2$, with smooth boundary $\partial\Omega$ and let $Y = [-\frac{1}{2}, \frac{1}{2}]^N$. Let T be a starlike, subdomain of Y, with smooth boundary ∂T, such that $T \ni 0$ and, with some $c^* > 1$,

$$c^* T \subset Y. \tag{0.0}_a$$

We simply denote by ε and r_ε the values of each sequence of $\{\varepsilon\}$ and $\{r_\varepsilon\}$ of positive numbers decreasing to zero, such that $\varepsilon/2 \geqq r_\varepsilon$. Let $Y_\varepsilon^i = p_\varepsilon^i + \varepsilon Y$ and $T_\varepsilon^i = p_\varepsilon^i + r_\varepsilon T$, where $p_\varepsilon^i \in \mathbb{R}^N$, $i \in \mathbb{N}$, are lattice points of edge length ε, by measurement in a parallel direction to each coordinate axis, i.e., $\varepsilon\mathbb{Z}^N = \{p_\varepsilon^i;\ i \in \mathbb{N}\}$. Let

$$T_\varepsilon = \bigcup \{T_\varepsilon^i;\ p_\varepsilon^i + c^* r_\varepsilon T \subset \Omega^-\} \quad \text{and} \quad \Omega_\varepsilon = \Omega \setminus T_\varepsilon. \tag{0.0}_b$$

We call T_ε the holes in Ω_ε, and Ω_ε a domain with holes (Fig. 1). Let β be a maximal monotone graph in $\mathbb{R} \times \mathbb{R}$ such that $\beta(0) \ni 0$. Let $f \in L^2(\Omega)$ and $g \in H^{1/2}(\partial T)$. We set $g_\varepsilon(x) = g((x - p_\varepsilon^i)/r_\varepsilon)$ for $x \in \partial T_\varepsilon^i$.

We consider the boundary value problem (P_ε):

$$-\Delta u_\varepsilon = f \quad \text{a.e. in } \Omega_\varepsilon, \tag{0.1}$$

$$\partial u_\varepsilon / \partial \nu + \alpha_\varepsilon \beta(u_\varepsilon) \ni g_\varepsilon \quad \text{on } \partial T_\varepsilon, \tag{0.2}$$

$$u_\varepsilon = 0 \quad \text{on } \partial\Omega, \tag{0.3}$$

where ν denotes the outer unit normal to $\partial\Omega_\varepsilon$ and α_ε denotes a positive constant. We call g_ε a nonautonomous term, which is usually called a nonhomogeneous term in linear cases. Let $V_\varepsilon = \{v \in H^1(\Omega_\varepsilon);\ v|\partial\Omega = 0\}$. Let us recall that there exists a unique weak solution $u_\varepsilon \in V_\varepsilon \cap H^2(\Omega_\varepsilon)$ (see Brezis [4]). In particular, the boundary condition (0.2) includes the following conditions:

(a) Dirichlet's homogeneous boundary condition (an autonomous boundary condition), $\beta_D(\xi) = \varnothing$ for $\xi \neq 0$ and $\beta_D(0) = \mathbb{R}$.

(b) Neumann's boundary condition, $\beta_N(\xi) = \{0\}$.

(c) Robin's boundary condition, $\beta_R(\xi) = \xi$.

$(d)_p$ $\beta(\xi) = \xi|\xi|^{p-1}$ with $p > 0$.

(e) $C_1|\xi| \leqq |\beta(\xi)| \leqq C_2|\xi|$ and $\beta(\xi) \in C(\mathbb{R})$ with positive constants C_1 and C_2.

(f) Heaviside's boundary condition:

$$\beta_H(\xi) = \begin{cases} \{1\} & \text{for } \xi > 0, \\ [0, 1] & \text{for } \xi = 0, \\ \{0\} & \text{for } \xi < 0. \end{cases}$$

(g) Signorini's boundary condition:

$$\beta_S(\xi) = \begin{cases} \phi & \text{for } \xi > 0, \\ [0, \infty) & \text{for } \xi = 0, \\ \{0\} & \text{for } \xi < 0. \end{cases}$$

Thus, condition (0.2) covers a wide class of nonautonomous nonlinear boundary conditions (see Remark 0.1).

Remark 0.1. The type of (0.2) contains the homogeneous Dirichlet boundary condition as seen in the above (a). But it does not contain the nonhomogeneous Dirichlet boundary condition, which is represented by (a)′ below using β_D with $c \neq 0$.

(a)′ Dirichlet's nonhomogeneous boundary condition (a nonautonomous boundary condition), $\beta(\xi) = \beta_D(\xi - c)$ for $\xi - c \in D(\beta_D)$ $(= D(\beta))$ with $c \neq 0$.

For the definition (0.0) of the domain Ω_ε, later we show that there exists a sequence $\{\tilde{u_\varepsilon} \in H_0^1(\Omega)\}$ of extensions of $\{u_\varepsilon\}$, bounded in the space $H_0^1(\Omega)$. Our aim is to seek sufficient conditions, under which $\tilde{u_\varepsilon}$ converges weakly in $H_0^1(\Omega)$ as $\varepsilon \to 0$, and to determine the equation in Ω, satisfied by the weak limit u of $\tilde{u_\varepsilon}$.

For the autonomous case in condition (0.2) with β such as (b), (c), $(d)_p$, and (e) we have three parameters $\bar{\alpha}$, a, and θ_λ, $0 \leqq \lambda \leqq N$, that play an important role in determining the behavior of u_ε. Here

$$\theta_\lambda = \lim_{\varepsilon \to 0} \theta_{\lambda,\varepsilon},$$

where

$$\theta_{\lambda,\varepsilon} = \begin{cases} r_\varepsilon^\lambda / \varepsilon^N & \text{for } 0 < \lambda \leqq N, \\ \varepsilon^{-N} (\log r_\varepsilon^{-1})^{-1+N} & \text{for } \lambda = 0, \end{cases} \tag{0.4}$$

$$\bar{\alpha} = \lim_{\varepsilon \to 0} \bar{\alpha}_\varepsilon \quad \text{and} \quad \bar{\alpha}_\varepsilon = \alpha_\varepsilon r_\varepsilon, \tag{0.5}$$

and

$$a = \lim_{\varepsilon \to 0} a_\varepsilon \quad \text{and} \quad a_\varepsilon = \alpha_\varepsilon \theta_{N-1,\varepsilon}. \tag{0.6}$$

All limit equations on $\tilde{u_\varepsilon}$ are drawn in a picture (see Kaizu [15]).

Thus our question is whether these parameters $\bar{\alpha}$, a, and θ_λ are still available for the nonautonomous case in (0.2) with β such as (b), (c), $(d)_p$, and (e), and whether they are also applicable even for (0.2) with β such as (f) and (g).

Recently, Conca and Donato [10] and Cioranescu and Donato [6] have shown that no different limit equation on $u_\varepsilon^\sim$ appears in the nonautonomous case of (0.2) with β such as (b) and (c), provided that $I_g = 0$, where $I_h = \int_{\partial T} g \, d\sigma$. However, if $I_g \neq 0$, the behavior of $u_\varepsilon^\sim$ differs greatly from that in the autonomous case.

The other purpose of this paper is to understand the works of Conca, Donato, and Cioranescu [6], [10] in a unified way under the boundary condition (0.2).

We review some works around the case of homogeneous linear boundary conditions, i.e., autonomous linear boundary conditions. Systematic works are done by Khruslov in [17] and [18] for the Dirichlet boundary condition, and in [19] and [20] for the Neumann boundary condition. In his work [18], strongly elliptic operators of order $2m$, $m \geqq 1$, are considered. He shows that the parameter θ_{N-2m} plays an important role together with the notion of capacity, in the process $\varepsilon \to 0$. Vanninathan [24], [25] and Cioranescu and Saint Jean Paulin [8] have studied the Neumann boundary condition case. In particular, Vanninathan [24], [25] has considered the behavior of eigenvalues of the Laplacian. The homogenized operator $\mathscr{H}$ is introduced by each study of Cioranescu and Saint Jean Paulin [8], Khruslov [19], and Vanninathan [24], [25] for "the Laplacian in domains with many tiny holes," and there it is shown that θ_N is critical. Different approaches are given by Rauch and Taylor [23] for the Laplacian with a general linear boundary condition, and by Cioranescu and Murat [7] and Ozawa [22] also for the same operator with the Dirichlet boundary condition. For the Robin boundary condition Kaizu considered in [12], under the special form of T (i.e., T is a ball) the author has shown that the parameter θ_{N-1} is important. We see in [15] that it remains true even for a general T.

The Laplacian under autonomous nonlinear boundary conditions is considered by Kaizu [13]–[16]. In [16], Kaizu has shown that the Hausdorff dimension and the Hausdorff measure play some roles, where domains $\{\Omega_\varepsilon\}$ in [16] are more complicated than those presented here. An interesting family of domains has also been studied recently by Damlamian and Donato [11].

Among various methods for our asymptotic problem, we apply and extend those of the notion of epi-convergence of functionals. Several ideas, inequalities, and some special test functions have appeared in Attouch [1], Cioranescu and Donato [6], Cioranescu and Murat [7], Cioranescu and Saint Jean Paulin [8], Conca [9], Conca and Donato [10], and Vanninathan [25].

Notation. We denote by $C, C_1, C_2, \cdots$, positive constants which are independent of ε. By $\|v\|_{p,G}$ we denote the L^p norm, $(\int_G |v|^p \, dx)^{1/p}$. In particular, we simply denote the norm by $\|v\|_G$ if $p = 2$.

1. Theorems. Let $E_\varepsilon : V_\varepsilon \to H_0^1(\Omega)$ be a linear bounded extension operator such that

$$\|\nabla(E_\varepsilon v)\|_{T_\varepsilon} \leqq C\|\nabla v\|_{\Omega_\varepsilon} \quad \text{and} \quad \|E_\varepsilon v\|_{T_\varepsilon} \leqq C(\|\nabla v\|_{\Omega_\varepsilon} + \|c\|_{\Omega_\varepsilon}),$$

where C is independent of ε. For the existence of $\{E_\varepsilon\}$ see Corollary 3.3 (for a special case $p = 2$ and $\varepsilon \sim r_\varepsilon$ as $\varepsilon \to 0$; see also § 4 of Cioranescu and Saint Jean Paulin [8]). All the results in our paper are available for such a family of extension operators. But, to fix the extensions $V_\varepsilon \to H_0^1(\Omega)$ in a simple and quick way, we adopt the following special mapping.

Let $u_\varepsilon^\sim \in H_0^1(\Omega)$ be the extension of the solution u_ε of (P_ε) defined by

$$\Delta u_\varepsilon^\sim = 0 \quad \text{on } T_\varepsilon \quad \text{and} \quad u_\varepsilon^\sim = u_\varepsilon \quad \text{on } \partial T_\varepsilon.$$

We consider the following conditions.

$(\beta\text{-}0)_a$ β is a monotone graph in $\mathbb{R}\times\mathbb{R}$, i.e., for $\eta_i\in\beta(\xi_i)$, $\xi_i\in D(\beta)=\{\xi\in\mathbb{R};\ \beta(\xi)\neq\emptyset\}$, $i=1, 2$, we have

$$(\eta_2-\eta_1)(\xi_2-\xi_1)\geqq 0.$$

$(\beta\text{-}0)_b$ β is maximal in the family of all monotone graphs in $\mathbb{R}\times\mathbb{R}$, and further we suppose that $\beta(0)\ni 0$ and $D(\beta)\neq\{0\}$.

$(\beta\text{-}1)$ β is continuous in $D(\beta)$ except at finite points.

$(\beta\text{-}2)$ Let $\beta^0(\xi)=\eta$, where $\eta\in\beta(\xi)$ and $|\eta|=\min\{|\eta'|;\ \eta'\in\beta(\xi)\}$ for $\xi\in D(\beta)$. We have $C_1\geqq 0$, $C_2>0$, and $r\geqq 0$ such that

$$|\beta^0(\xi)|\leqq C_1+C_2|\xi|^r \quad \text{for all } \xi\in D(\beta).$$

$(\beta\text{-}3)$ We have that $C>0$ and $s>0$ such that

$$|\beta^0(\xi)|\geqq C|\xi|^s \quad \text{for all } \xi\in D(\beta).$$

We do not consider Dirichlet's boundary condition (see (a) in § 0); thus, $D(\beta)\neq\{0\}$ in $(\beta\text{-}0)$ is supposed. The nonnegative value r is regarded as the minimum exponent satisfying $(\beta\text{-}2)$, while we regard s as a certain positive number satisfying $(\beta\text{-}3)$. If $D(\beta)\cap(0,\infty)$ is a bounded interval, C_2 and r are determined by the graph of $\beta^0(\xi)$, $\xi\in D(\beta)\cap(-\infty, 0)$. Now, for a fixed r we simply set

$$\rho=\begin{cases}\rho(r) & \text{for } N\geqq 3,\\ 2 & \text{for } N=2 \text{ and } r=0,\\ a \text{ number of } [c(r), 2) & \text{for } N=2 \text{ and } 0<r<\infty,\end{cases} \tag{1.1}$$

where $\rho(r)=2N(N+r(N-2))^{-1}$ and $c(r)=\max\{1, 2/(1+r)\}$ (see the proof of Lemma 4.2). For $N\geqq 3$ we have $2\geqq\rho(r)\geqq 1$ if and only if $0\leqq r\leqq N/(N-2)$. Let $\rho^*=\rho/(\rho-1)$ with convention $1^*=\infty$, and let

$$\kappa_{\varepsilon,\rho}=\begin{cases}(r_\varepsilon/\varepsilon)^{(\rho-1)N/\rho} & \text{for } 1\leqq\rho<N,\\ (r_\varepsilon/\varepsilon)^{N-1}[\log(c_0\varepsilon/r_\varepsilon)]^{(N-1)/N} & \text{for } \rho=N,\end{cases} \tag{1.2}$$

where $c_0=\max\{N^{1/2}/(2|y|);\ y\in\partial T\}$. We give $r_\varepsilon^{(\lambda)}$, which plays a scale for the size of each hole T_ε^i in Ω_ε, as follows:

$$r_\varepsilon^{(\lambda)}=\varepsilon^{N/\lambda} \quad \text{for } 0<\lambda\leqq N \quad \text{and} \quad r_\varepsilon^{(0)}=\exp\{-\varepsilon^{-N/(N-1)}\}.$$

The inequality $0\leqq\lambda<\mu\leqq N$ implies that $r_\varepsilon^{(\lambda)}\ll r_\varepsilon^{(\mu)}$ as $\varepsilon\to 0$. We get $r_\varepsilon^{(\lambda)}\sim r_\varepsilon$ as $\varepsilon\to 0$ if and only if $0<\theta_\lambda<\infty$, $r_\varepsilon^{(\lambda)}\ll r_\varepsilon$ as $\varepsilon\to 0$ if and only if $\theta_\lambda=\infty$, where θ_λ is determined by (0.4).

1.1. Estimates.

THEOREM A. *We suppose condition* $(\beta\text{-}0)$ *holds. Then we have*

$$\|\nabla u_\varepsilon\|_{\Omega_\varepsilon}\leqq C\left(\|f\|_\Omega+\theta_{N-1,\varepsilon}\left|\int_{\partial T} g\,d\sigma\right|+\|g\|_{\partial T}\kappa_{\varepsilon,2}\right).$$

Let

$$b=\lim_{\varepsilon\to 0} b_\varepsilon \quad \text{and} \quad b_\varepsilon=\theta_{N-1,\varepsilon}/\alpha_\varepsilon^{1/s}. \tag{1.3}$$

THEOREM B. *In Theorem* A *we suppose condition* $(\beta\text{-}3)$ *holds. Let* $\sigma=s+1$ *and* $\sigma'=\min\{s, 1\}+1$. *We further suppose that* $f\in L^{\sigma'*}(\Omega)$, $g\in L^{\sigma^*}(\partial T)$, (0.6) *with* $a=\infty$, (1.3) *with* $b=0$, *and*

$$r_\varepsilon^{(N-\sigma')}\ll r_\varepsilon\leqq\varepsilon \quad \text{as } \varepsilon\to 0.$$

Then $u_\varepsilon^{\sim}$ *converges strongly to zero in* $W_0^{1,\sigma'}(\Omega)$. *Furthermore, we get*

$$\|\nabla u_\varepsilon\|_{\sigma',\Omega_\varepsilon}^2 \leqq C[\|f\|_{\sigma'^*,\Omega}^2 \theta_{N-\sigma',\varepsilon}^{-2/\sigma'} + \|f\|_{\sigma'^*,\Omega}^{\sigma^*} a_\varepsilon^{-1/s} + b_\varepsilon \|g\|_{\sigma^*,\partial T}^{\sigma^*}].$$

THEOREM C. *In Theorem* A *we suppose that* $\int_{\partial T} g\, d\sigma \neq 0$ *and*

$$r_\varepsilon^{(N-1)} \ll r_\varepsilon \leqq \varepsilon \quad \text{as } \varepsilon \to 0.$$

(I) *We have*

$$\|\nabla u_\varepsilon\|_{\Omega_\varepsilon} \leqq C\theta_{N-1,\varepsilon}.$$

(II) *In addition to* (I) *we suppose that* $D(\beta) = \mathbb{R}$, (β-2) *with* $0 \leqq r \leqq 1$, *and* (0.6) *with* $0 \leqq a < \infty$. *Then we have*

$$\|\nabla u_\varepsilon\|_{\Omega_\varepsilon} \geqq C\theta_{N-1,\varepsilon}.$$

(III) *In* (I) *we suppose condition* (β-3) *and* (0.6) *holds with* $a = \infty$, $0 < b \leqq \infty$. *Then we have*

$$\|\nabla u_\varepsilon\|_{\sigma',\Omega_\varepsilon} \leqq C b_\varepsilon^{1/2}, \tag{1.4}$$

$$\|u_\varepsilon\|_{\sigma',\Omega_\varepsilon} \leqq C b_\varepsilon^{1/\sigma'} (\theta_{N-\sigma',\varepsilon}^{-1/\sigma'} + a_\varepsilon^{-1/\sigma}), \tag{1.5}$$

and

$$u_\varepsilon^{\sim}/b_\varepsilon^{1/\sigma'} \xrightarrow{w} 0 \quad \text{in } W_0^{1,\sigma'}(\Omega) \quad \text{as } \varepsilon \to 0.$$

Remark 1.1. For the bounds in (1.4) and Theorem C(I) we want to know $\lim \theta_{N-1,\varepsilon}/b_\varepsilon^{1/\sigma'}$. Let

$$a_{h,\varepsilon} \equiv \alpha_\varepsilon (\theta_{N-1,\varepsilon})^h. \tag{1.6}$$

Then we have $\theta_{N-1,\varepsilon}/b_\varepsilon^{1/\sigma'} = a_{s,\varepsilon}^{1/2s}$ for $s \geqq 1$ and $\theta_{N-1,\varepsilon}/b_\varepsilon^{1/\sigma'} = a_{\sigma'',\varepsilon}^{1/s\sigma'}$, $\sigma'' = s^2$, for $0 < s < 1$.

1.2. Convergence.

THEOREM a. *We suppose* (β-0), (β-1), *and* (β-2) *with*

$$\begin{aligned} &0 \leqq r \leqq 1 \quad \text{for } N \geqq 3, \\ &r = 0 \quad \text{for } N = 2. \end{aligned}$$

In the case where $1 > r \geqq 0$ *with* $N \geqq 3$, *using* (0.5) *and* (1.1) *we suppose that*

$$\bar{\alpha} < \infty, \quad \bar{\alpha}\theta_{N-\rho^*} = 0 \quad \text{and} \quad r_\varepsilon \leqq C r_\varepsilon^{(N-\rho^*)} \quad \text{as } \varepsilon \to 0. \tag{1.7}$$

Let $\tilde{\alpha}_\varepsilon = \bar{\alpha}_\varepsilon (\log r_\varepsilon^{-1})^{(N-1)/N^*}$. *In the case where* $r = 1$ *with* $N \geqq 3$, *we suppose that*

$$\tilde{\alpha} = \lim_{\varepsilon \to 0} \tilde{\alpha}_\varepsilon < \infty, \ \tilde{\alpha}\theta_0 = 0 \quad \text{and} \quad r_\varepsilon \leqq C r_\varepsilon^{(0)} \quad \text{as } \varepsilon \to 0. \tag{1.8}$$

Let $\hat{\alpha}_\varepsilon = \tilde{\alpha}_\varepsilon (\log (c_0 \varepsilon / r_\varepsilon))^{1/2}$. *In the case where* $r = 0$ *with* $N = 2$ *we suppose that*

$$\hat{\alpha} = \lim_{\varepsilon \to 0} \hat{\alpha}_\varepsilon < \infty, \quad \hat{\alpha}\theta_0 = 0, \quad \text{and} \quad r_\varepsilon \leqq C r_\varepsilon^{(0)} \quad \text{as } \varepsilon \to 0. \tag{1.9}$$

Then $u_\varepsilon^{\sim}$ *weakly converges to* u *in* $H_0^1(\Omega)$, *where* u *is the solution of*

$$-\Delta u = f \quad \text{a.e. in } \Omega.$$

THEOREM b. *We suppose conditions* (β-0), (β-1), *and* (β-2) *hold with*

$$\begin{aligned} &0 \leqq r < N/(N-2) \quad \text{for } N \geqq 3, \\ &0 \leqq r < \infty \quad \text{for } N = 2. \end{aligned} \tag{1.10}$$

We suppose (0.6) *holds with* $0 \leqq a \leqq \infty$, *and*

$$r_\varepsilon^{(N-\rho)} \ll r_\varepsilon \leqq C r_\varepsilon^{(N-1)} \quad \text{as } \varepsilon \to 0.$$

Let $S(\partial T)$ *be the surface area of* ∂T. *Then* $u_\varepsilon^{\sim}$ *converges to* u *weakly in* $H_0^1(\Omega)$, *where* u *satisfies*

$$-\Delta u + aS(\partial T)\beta(u) \ni f + \theta_{N-1} \int_{\partial T} g \, d\sigma \quad \text{a.e. in } \Omega, \tag{1.11}$$

for $0 \leqq a < \infty$, *otherwise, if* $a = \infty$, *then*

$$u = 0 \quad \text{a.e. in } \Omega,$$

provided that

$$\int_0^{\pm\delta} \beta(\xi)\, d\xi > 0 \quad \text{for any } \delta > 0. \tag{β-4}$$

1.3. Convergence after renormalization. We have renormalization on u_ε as follows:

$$z_\varepsilon \equiv u_\varepsilon / \theta_{N-1,\varepsilon}.$$

We recall (I) and (II) in Theorem C. It is natural to consider the behavior of z_ε when $\theta_{N-1,\varepsilon} \to \infty$ as $\varepsilon \to 0$.

(A) Let h be a fixed positive number such that $h \geqq r$ and let

$$\beta^\varepsilon(\xi) \equiv \beta(\theta_{N-1,\varepsilon}\xi)/\theta_{N-1,\varepsilon}^h \quad \text{for } \xi \in D(\beta^\varepsilon),$$

where $D(\beta^\varepsilon) = \{\xi \in \mathbb{R};\ \theta_{N-1,\varepsilon}\xi \in D(\beta)\}$. A multivalued function β^ε satisfies (β-0) and (β-1) as β. Each element β^ε of $\{\beta^\varepsilon;\ \theta_{N-1,\varepsilon} \to \infty\}$ also satisfies (β-2) with the same r as β. We have $\beta^\varepsilon \equiv \beta$ for a homogeneous function of degree h. In this section, one of the following conditions, (γ-1), (γ-2), (γ-3), is supposed.

(B) Conditions.

(γ-1) β satisfies (β-2) with (1.10). Besides, $D(\beta^0) = D(\beta^\varepsilon) = \mathbb{R}$ and $|\beta^\varepsilon(\xi) - \beta^0(\xi)| \leqq c_\varepsilon(1+|\xi|)^t$ with $c_\varepsilon \to 0$ as $\varepsilon \to 0$ and $0 \leqq t \leqq r$.

(γ-2) β satisfies (β-2) with (1.10). Besides, $D(\beta^0) = D(\beta^\varepsilon) = \mathbb{R}$ and $\beta^\varepsilon \uparrow \beta^0$ or $\beta^\varepsilon \downarrow \beta^0$ as $\varepsilon \downarrow 0$.

(γ-3) β satisfies (β-2) with $r = 0$, $D(\beta^0) = \liminf_{\varepsilon \to 0} D(\beta^\varepsilon)$ and β^ε converges to β^0 as $\varepsilon \to 0$ pointwise in $D(\beta^0)$ except at discontinuous points of β^0.

(γ-4) β^0 satisfies (β-0) and (β-1).

Example 1.2. Let $\theta_\varepsilon = \theta_{N-1,\varepsilon}$. For $\beta(\xi) = |\xi|^{r-1}\xi$, we get $\beta^\varepsilon(\xi) = \theta_\varepsilon^{r-h}\beta(\xi)$. We have ($\gamma$-1) with $\beta^0 = \beta$ for $h = r$, and $\beta^0 = \beta_N$ for $h > r$. For

$$\beta(\xi) = \begin{cases} 1 & \text{for } \xi \geqq 1, \\ \xi & \text{for } 0 \leqq \xi \leqq 1, \\ 0 & \text{for } \xi \leqq 0, \end{cases}$$

which satisfies (β-0), (β-1), and (β-2) with $r = 0$, we have

$$\beta^\varepsilon(\xi) = \begin{cases} \theta_\varepsilon^{-h} & \text{for } \xi \geqq \theta_\varepsilon^{-1}, \\ \theta_\varepsilon^{1-h}\xi & \text{for } 0 \leqq \xi \leqq \theta_\varepsilon^{-1}, \\ 0 & \text{for } \xi \leqq 0; \end{cases}$$

(γ-2): $\beta^\varepsilon \uparrow \beta_H$ as $\varepsilon \downarrow 0$ for $h=0$; (γ-2): $\beta^\varepsilon \downarrow \beta_N$ as $\varepsilon \uparrow 0$ for $h \geqq 1$; (γ-1): $\|\beta^\varepsilon - \beta_N\|_\infty \to 0$ as $\varepsilon \to 0$ for $0<h<1$. If

$$\beta(\xi)=\begin{cases}\infty & \text{for } \xi \geqq 1,\\ \xi & \text{for } 0 \leqq \xi \leqq 1,\\ 0 & \text{for } \xi \leqq 0\end{cases}$$

is chosen, we have (β-0), (β-1), and (β-2) with $r=0$. Then

$$\beta^\varepsilon(\xi)=\begin{cases}\infty & \text{for } \xi \geqq \theta_\varepsilon^{-1},\\ \theta_\varepsilon^{1-h}\xi & \text{for } 0 \leqq \xi \leqq \theta_\varepsilon^{-1},\\ 0 & \text{for } \xi \leqq 0.\end{cases}$$

Thus (γ-3) is satisfied with $\beta^0=\beta_S$.

(C) The homogenized operator. Let $Y^* = Y \setminus T^*$ and $T^* = \theta_N^{1/N} T$. Let $|Y^*|$ be the Lebesgue measure of Y^*, and let

$$\mathcal{H}=\begin{cases}-\Delta & \text{for } \theta_N=0,\\ -\sum\limits_{i,j=1}^{N} q_{ij}\dfrac{\partial^2}{\partial x_i \partial x_j} & \text{for } 0<\theta_N \leqq 1,\end{cases}$$

where q_{ij}, $1 \leqq i, j \leqq N$, are constants defined by $q_{ij}=|Y^*|\delta_{ij}-\int_{Y^*} \nabla \kappa_i \nabla \kappa_j \, dy$. Here $\kappa_i \in W_0$, is defined by

$$\int_{Y^*} \nabla \kappa_i \nabla v \, dy + \int_{\partial T^*} \nu_i v \, d\sigma = 0 \quad \text{for all } v \in W_0,$$

where $W_0=\{v \in H^1(Y^*); \int_{Y^*} v\,dy=0$ and v is Y-periodic$\}$ and $\nu=\{\nu_i; 1 \leqq i \leqq N\}$ is the outer unit normal to ∂Y^*.

(D) THEOREM c. *In Theorem* C(I) *we further suppose conditions* (β-0), (β-1), *and* (γ-4) *hold and one of the conditions* (γ-1), (γ-2), (γ-3) *holds.*

(I) *We suppose that* $a_h=\lim_\varepsilon a_{h,\varepsilon}<\infty$ *with* (1.6). *Then* $z_\varepsilon^\sim$ *weakly converges in* $H_0^1(\Omega)$ *to* z, *where* z *is a unique solution of*

$$\mathcal{H}z + a_h S(\partial T)\beta^0(z) \ni \int_{\partial T} g \, d\sigma \quad \text{a.e. in } \Omega. \tag{1.12}$$

(II) *If* $a_h=\infty$ *and* (β-4) *is satisfied by* β^0, *then* $z_\varepsilon^\sim$ *converges weakly to zero in* $H_0^1(\Omega)$.

1.4. Convergence for continuous functions β. For continuous functions β we have more results as below for the case where $Cr_\varepsilon^{(N-2)} \geqq r_\varepsilon$ than in Theorem a, and for the case where $r_\varepsilon^{(N-2)} \ll r_\varepsilon \leqq Cr_\varepsilon^{(N-1)}$ than in Theorem b, respectively.

THEOREM a′. *We suppose that* $N \geqq 3$, *and conditions* (β-0), (β-2), *and* (β-3) *hold with* $C_1=0$, $r=1=s$, *and* (β-1)$_0$ *below.*

(β-1)$_0$ $D(\beta)=\mathbb{R}$ *and* β *is continuous in* $\mathbb{R}$.

Besides, we suppose (0.5) *holds with* $\bar{\alpha}=\infty$, *and* $Cr_\varepsilon^{(N-2)} \geqq r_\varepsilon$ *with a fixed* θ_{N-2} *as* $\varepsilon \to 0$. *Then* $u_\varepsilon^\sim$ *converges weakly to* u *in* $H_0^1(\Omega)$ *as* $\varepsilon \to 0$, *where* u *satisfies either*

$$-\Delta u + \theta_{N-2} C_T u = f \quad \text{a.e. in } \Omega \quad \text{for } \theta_{N-2}<\infty,$$

or

$$u=0 \quad \text{a.e. in } \Omega \quad \text{for } \theta_{N-2}=\infty,$$

where C_T denotes the capacity of T defined by

$$C_T = \inf\left\{\int_{\mathbb{R}^N} |\nabla v|^2\, dx;\ v \in H^1(\mathbb{R}^N) \text{ and } v \geqq 1 \text{ on } T\right\}.$$

For $\bar{\alpha} < \infty$, we can have a value $C(\bar{\alpha}, T)$ also like the capacity of T (for more detail see Theorem A.1 in Kaizu [15]).

THEOREM b′. *We suppose* (β-0), (β-3), *and* (β-1)$_1$ *below hold.*

(β-1)$_1$ $D(\beta) = \mathbb{R}$ *and* β *is Lipschitz continuous.*

We also suppose (0.6) *holds with* $0 \leqq a \leqq \infty$, $r_\varepsilon^{(N-2)} \ll r_\varepsilon \leqq C r_\varepsilon^{(N-1)}$. *Then* $u_\varepsilon^{\sim}$ *converges in* $H_0^1(\Omega)$ *weakly to* u, *where* u *is the solution of*

$$-\Delta u + aS(\partial T)\beta(u) = f + \theta_{N-1}\int_{\partial T} g\, d\sigma \quad \text{a.e. in } \Omega \quad \text{for } a < \infty,$$

$$u = 0 \quad \text{a.e. in } \Omega \quad \text{for } a = \infty.$$

Remark 1.3. The range $r_\varepsilon^{(N-2)} \ll r_\varepsilon \leqq C r_\varepsilon^{(N-1)}$ of r_ε in Theorem b′ is slightly wider than that of r_ε in Theorem b.

2. Convergence of subdifferentials. To our asymptotic problem we shall apply the theory of the convergence of a sequence of subdifferentials, described below.

Let H be a real Hilbert space of lower semicontinuous convex functions $\varphi^n : H \to [0, \infty]$ with $\varphi^n(0) = 0$. We set $D(\varphi^n) = \{x \in H;\ \varphi^n(x) < \infty\}$, which we call the effective domain of φ^n. Let H^n be a closed linear subspace which contains the closure of $D(\varphi^n)$ in the topology of H. Let p^n be the projection from H onto H^n (see Example 2.3). Let φ^0 be a lower semicontinuous convex function from H into $[0, \infty]$, with $\varphi^0(0) = 0$. Let $D(\varphi^0)$ be the effective domain of φ^0. We suppose the following conditions:

(c-1) There exists a sequence $\{E^n\}$ of linear mappings E^n: $D(\varphi^n) \to D(\varphi^0)$, satisfying the following properties:
  (i) $p^n E^n = p^n$ and $(x, y) = (E^n x, p^n y)$ for all $x, y \in D(\varphi^n)$;
  (ii) If $\limsup_{n\to\infty} \varphi^n(x^n) < \infty$, then the sequence $\{E^n x^n\}$ is totally bounded.

(c-2) There exists a positive constant η such that the strong convergence $x^n \to x$, implies the weak convergence $p^n x^n \xrightarrow{w} \eta x$.

Now, we write $\varphi^n \xrightarrow{(e)} \varphi^0$, if and only if the following two conditions are satisfied:

(e-1) For any $x \in D(\varphi^0)$ we have $x^n \in D(\varphi^n)$ such that $E^n x^n \xrightarrow{s} x$ and

$$\varphi^0(x) \geqq \limsup_{n\to\infty} \varphi^n(x^n).$$

(e-2) The convergence $E^n x^n \xrightarrow{s} x$, implies the inequality

$$\varphi^0(x) \leqq \liminf_{n\to\infty} \varphi^n(x^n).$$

It is clear that, for the case $E^n \equiv$ the identity map, we have $\varphi^n \xrightarrow{(e)} \varphi^0$ if and only if φ^0 is the τ-epi-limit of φ^n, where τ is the topology of H (see Attouch [1, Prop. 1.14, p. 30]).

The subdifferential $\partial\varphi$ of a lower semicontinuous convex function φ is defined as follows: $\partial\varphi(x) = \{y \in H;\ \varphi(z) \geqq \varphi(x) + (y, z - x) \text{ for all } z \in H\}$. It is well known that we have the equivalent relation between Mosco's convergence and the convergence of the resolvent mappings of the subdifferentials (see [1, Thm. 3.26, p. 305]). Even for the above convergence we still get the following theorem.

THEOREM 2.1. *We suppose conditions* (c-1) *and* (c-2) *hold. Then the following statements are equivalent*:

(I) $\varphi^n \xrightarrow{(e)} \varphi^0$.

(II) *Let* $f^n \xrightarrow{s} f^0$ *and* x^n *be the solution of* $(\lambda\partial\varphi^n + I)x^n \ni f^n$, $\lambda > 0$. *Then* $E^n x^n$ *converges strongly and the limit* x *satisfies* $(\lambda\partial\varphi^0 + \eta I)x \ni \eta f^0$.

(III) *Let* x^n *be the solution of* $(\lambda\partial\varphi^n + I)x^n \ni f$, $\lambda > 0$. *Then* $E^n x^n$ *converges strongly and the limit* x *satisfies* $(\lambda\partial\varphi^0 + \eta I)x \ni \eta f$.

PROPOSITION 2.2. (a) *The following statement* (IV) *is sufficient for the statement* (III).

(IV) *Let* $f^n \xrightarrow{s} f^0$ *and* x^n *be the solution of* $\partial\varphi^n(x^n) \ni f^n$. *Then* $E^n x^n$ *converges strongly and the limit* x *satisfies* $\partial\varphi^0(x) \ni \eta f^0$.

(b) *If* $\{(\partial\varphi^n)^{-1}\}$ *is uniformly bounded, the statement* (IV) *is necessary for* (II).

Example 2.3. Let $H = L^2(\Omega)$ and $V^0 = H_0^1(\Omega)$. We denote by $\{\varepsilon_n\}$ a sequence of positive numbers decreasing to zero. Let Ω^n be a subdomain of Ω defined by (0.0). We consider $H^n = L^2(\Omega^n)$, as a subspace of H, which consists of functions of H, vanishing outside Ω^n. We write $V^n = V_\varepsilon$ with $\varepsilon = \varepsilon_n$. Let φ^n, φ^0: $H \to [0, \infty]$, be lower semicontinuous convex functions defined by

$$\varphi^n(v) = \begin{cases} \displaystyle\int_{\Omega^n} |\nabla v|^2 \, dx/2 & \text{for } v \in V^n, \\ \infty & \text{otherwise,} \end{cases}$$

$$\varphi^0(v) = \begin{cases} \displaystyle\int_{\Omega} (\nabla v, \nabla v)_Q \, dx/2 & \text{for } v \in V^0, \\ \infty & \text{otherwise,} \end{cases}$$

where

$$(\nabla v, \nabla v)_Q = \sum_{i,j=1}^{N} Q_{ij} \frac{\partial v}{\partial x_i} \frac{\partial v}{\partial x_j}$$

and

$$Q_{ij} = \begin{cases} \delta_{ij}, & \text{the Kronecker delta} \quad \text{for } \theta_N = 0, \\ q_{ij}, & \text{constants given in §§ 1.3} \quad \text{for } 0 < \theta_N \leqq 1. \end{cases}$$

For $v \in V^n$ we define $E^n(v) = v^\sim \in V^0$, where $\Delta v^\sim = 0$ on T_ε and $v^\sim = v$ on ∂T_ε with $\varepsilon = \varepsilon_n$ (we can choose another extension family $\{E^n\}$ in Corollary 3.3). Let $p^n v = \chi^n v$, $v \in H$, where χ^n denotes the characteristic function of Ω^n. Then (c-1) is satisfied by combining Corollary 3.3 with the Rellich theorem. We see that $\chi^n \to |Y^*|(=\eta)$ weakly star in $L^\infty(\Omega)$ as $n \to \infty$. We consider (P_ε) with $\alpha_\varepsilon \equiv 0$ and $g \equiv 0$, and have $\partial\varphi^n(u^n) \ni f$. According to Cioranescu and Saint Jean Paulin [8] and Khruslov [19], we have that $u_n^\sim \to u$ weakly in $H_0^1(\Omega)$ as $\varepsilon \to 0$, where

$$-\Delta u = f \quad \text{in } \Omega \quad \text{for } \theta_N = 0,$$

$$\mathcal{H}u = \eta f \quad \text{in } \Omega \quad \text{for } \theta_N > 0.$$

The convergence of $u_n^\sim$ to u remains true, even if f is replaced with f^n, which strongly converges to f, in the equation $\partial\varphi^n(u^n) \ni f$. By Proposition 2.2(a), we get

$$\varphi^n \xrightarrow{(e)} \varphi^0. \tag{2.1}$$

We consider a perturbation of (2.1) as follows.

PROPOSITION 2.4. *We suppose that* $\varphi^n \xrightarrow{(e)} \varphi^0$. *Besides we suppose that* $j^n, j^0 : H \to [0, \infty]$, *satisfy the following conditions*:

(i) $\varphi^n + j^n$ *is a lower semicontinuous convex function for each* $n \in \mathbb{N} \cup \{0\}$.

(ii) *We have maps* $F^n : D(\varphi^n) \to D(\varphi^n + j^n)$, *such that* $\varphi^n(F^n x) \leqq \varphi^n(x)$ *for* $x \in D(\varphi^n)$, *and* $E^n F^n x^n \to x^0$ *for any* $E^n x^n \to x^0 \in D(\varphi^0 + j^0)$ *as* $n \to \infty$.

(iii) $j^n(x^n) \to j^0(x)$ *as* $n \to \infty$ *for any sequence* $\{x^n\}$ *such that* $\sup\{\varphi^n(x^n) + j^n(x^n)\} < \infty$ *and* $E^n x^n \to x$.

Then we get

$$\varphi^n + j^n \xrightarrow{(e)} \varphi^0 + j^0.$$

Proof of Theorem 2.1. It is trivial that (II) $\to$ (III). We show (III) $\to$ (I). Let $J_\lambda^n = (\lambda \partial \varphi^n + I)^{-1}$. The Yosida approximation of φ_λ^n, $\lambda > 0$, is defined by

$$\varphi_\lambda^n(x) = \inf\{\varphi^n(y) + \|y - x\|^2/(2\lambda);\ y \in H\}$$

for all $x \in H$. The following properties are fundamental.

(a) φ_λ^n is of class C^1 and its derivative A_λ^n is Lipschitz continuous with constant $1/\lambda$. Besides we have $|A_\lambda^n x| \leqq |y|$ for all $y \in \partial^n \varphi(x)$, $x \in D(\partial \varphi^n)$.

(b) $\varphi_\lambda^n(x) \uparrow \varphi^n(x)$ as $\lambda \downarrow 0$.

(c) $\varphi_\lambda^n(x) = \lambda \|A_\lambda^n x\|^2/2 + \varphi^n(J_\lambda^n x)$.

(d) $\lambda A_\lambda^n + J_\lambda^n = I$.

(e) $p^n = s - \lim_{\lambda \to 0} J_\lambda^n$.

(f) $A^n J_\lambda^n \supset A_\lambda^n$.

LEMMA 2.5. *Under* (c-2) *and* (III), *we have*

(a) $(A_\lambda^n y, x^n) \to (A_{\lambda/\eta}^0 y, x)$ *as* $n \to \infty$, *for any* $y \in H$, $x^n \in D(\varphi^n)$, $E^n x^n \to x$,

(b) $(A_\lambda^n y, x) - (y - p^n y, x)/\lambda \to (A_{\lambda/\eta}^0 y, x)$ *as* $n \to \infty$, *for any* x *and* $y \in H$,

(c) $(A_\lambda^n y, x) \to (A_{\lambda/\eta}^0 y, x) + (1 - \eta)(y, x)/\lambda$ *as* $n \to \infty$, *for any* x *and* $y \in H$.

Proof. By (c-2) and (III), we have $E^n J_\lambda^n y \to J_{\lambda/\eta}^0 y$, $x^n \xrightarrow{w} \eta x$ and $p^n y \xrightarrow{w} \eta y$ as $n \to \infty$. By (d) we get Lemma 2.5(a) as follows:

$$\begin{aligned}(A_\lambda^n y, x^n) &= [(y, p^n E^n x^n) - (E^n J_\lambda^n y, p^n E^n x^n)]/\lambda \\ &\to \eta[(y, x) - (J_{\lambda/\eta}^0 y, x)]/\lambda = (A_{\lambda/\eta}^0 y, x).\end{aligned}$$

Combining (d), (c-2), and (III) with $(J_\lambda^n y, x) = (p^n E^n J_\lambda^n y, x)$, we get

$$(A_\lambda^n y, x) = [(p^n y - p^n E^n J_\lambda^n y, x) + (y - p^n y, x)]/\lambda,$$

$$(A_\lambda^n y, x) - (y - p^n y, x)/\lambda \to (A_{\lambda/\eta}^0 y, x) \quad \text{as } n \to 0.$$

Lemma 2.5(b) implies (c) together with (c-2). □

LEMMA 2.6. *Under* (c-2), (III) *implies the following*:

(a) $\lim_{n \to \infty} \varphi_\lambda^n(x) - (\|x\|^2 - \lim_{n \to \infty} \|p^n x\|^2)/(2\lambda) = \varphi_{\lambda/\eta}^0(x)$,

(b) $\lim_{n \to \infty} \varphi_\lambda^n(x) = \varphi_{\lambda/\eta}^0(x) + (1 - \eta)\|x\|^2/(2\lambda)$.

Proof. By (a), Lemma 2.5(b), the Lebesgue convergence theorem and $\varphi^n(0) = 0 = \varphi^0(0)$, we get

$$\begin{aligned}&\varphi_\lambda^n(x) - (\|x\|^2 - \|p^n x\|^2)/(2\lambda) \\ &\quad = \int_0^1 [(A_\lambda^n(sx), x) - s\lambda^{-1}(x - p^n x, x)]\, ds \\ &\quad \to \int_0^1 (A_{\lambda/\eta}^0(sx), x)\, dx = \varphi_{\lambda/\eta}^0(x).\end{aligned}$$

This shows (a) of this lemma. So, we get (b) of this lemma. □

First we show (e-2). By (c), (d), and (f) we get

$$\begin{aligned}\varphi^n(x^n) &\geqq \varphi^n(J_\lambda^n x)+(A_\lambda^n x, x^n - J_\lambda^n x)\\ &= (\varphi_\lambda^n(x)-\lambda\|A_\lambda^n x\|^2/2)+(A_\lambda^n x, x-J_\lambda^n x)+(A_\lambda^n x, x^n - x)\\ &= \varphi_\lambda^n(x)+\lambda\|A_\lambda^n x\|^2/2+(A_\lambda^n x, x^n - x)\\ &= \varphi_\lambda^n(x)+(x-J_\lambda^n x, A_\lambda^n x)/2+(A_\lambda^n x, x^n - x) = B_\lambda^n(x).\end{aligned}$$

Applying (d), Lemma 2.6(b), and (a) and (c) of Lemma 2.5 we have

$$B_\lambda^n(x) \to \varphi_{\lambda/\eta}^0(x)+\lambda\|A_{\lambda/\eta}^0 x\|^2/(2\eta)+(1-\eta)(1-\lambda)\|x\|^2/(2\lambda)$$

as $n\to\infty$. Thus, we get

$$\liminf_{n\to\infty} \varphi_\lambda^n(x^n) \geqq \varphi_{\lambda/\eta}^0(x).$$

By (b) we have shown condition (e-2).

Next we show (e-1). It suffices to show that, for any subsequence, still denoted by $\{\varphi^n\}$, there exists a subsequence of $\{\varphi^n\}$ satisfying (e$-$1). By (e) we have λ_n such that $\|x - J_{\lambda/\eta}^0 x\| \leqq (2n)^{-1}$, $\lambda < \lambda_n$, $n\in\mathbb{N}$. By (III) and Lemma 2.6(a) we get $m'(n)$ such that $\|J_{\lambda_n/\eta}^0(x) - E^m J_{\lambda_n}^m(x)\| \leqq (2n)^{-1}$ and $\varphi_{\lambda_n}^m(x)-(\|x\|^2-\|p^m x\|^2)/(2\lambda_n) \leqq \varphi_{\lambda_n/\eta}^0(x)+1/n$ for $m\geqq m'(n)$. For $x^{n'} = J_{\lambda_n}^{m'}(x)$, $n'\equiv m'(n)$, we get $\|E^{n'}x^{n'}-x\|\leqq 1/n$. By (c), we have

$$\begin{aligned}\varphi_{\lambda_n/\eta}^0(x)+\frac{1}{n} &\geqq \varphi_{\lambda_n}^{n'}(x)+(\|p^{n'}x\|^2-\|x\|^2)/(2\lambda_n)\\ &= \varphi^{n'}(x^{n'})+(\|\lambda_n A_{\lambda_n}^{n'}x\|^2+\|p^{n'}x\|^2-\|x\|^2)/(2\lambda_n)\\ &= \varphi^{n'}(x^{n'})+C_\lambda^n(x)/(2\lambda_n).\end{aligned}$$

By (d) we have $C_\lambda^n(x) = \|J_{\lambda_n}^{n'}x\|^2+\|p^{n'}x\|^2-2(x, J_{\lambda_n}^{n'}x)$. Since $p^{n'}x = x+(p^{n'}x-x)$, we get

$$\begin{aligned}C_\lambda^{n'}(x) &= (J_{\lambda_n}^{n'}x, J_{\lambda_n}^{n'}x-x)-(J_{\lambda_n}^{n'}x-p^{n'}x, x)\\ &= \|J_{\lambda_n}^{n'}x-x\|^2-\|(I-p^{n'})x\|^2\\ &= \|J_{\lambda_n}^{n'}x-p^{n'}x\|^2 \geqq 0.\end{aligned}$$

Thus, by (b) we have

$$\varphi^0(x) \geqq \limsup_{n\to\infty}\left(\varphi_{\lambda_n/\eta}^0(x)+\frac{1}{n}\right) \geqq \limsup_{n\to\infty}\varphi^{n'}(x^{n'}).$$

Since $E^{n'}x^{n'}\to x$, we have shown (e-1), and so, (I).

Finally, we show the implication (I)$\to$(II). We have

$$\varphi^n(z) \geqq \varphi^n(x^n)+\lambda^{-1}(f^n-x^n, z-x^n) \tag{2.2}$$

for all $z\in H$. Since J_λ^n is contractive, $\{x^n\}$ is bounded. By $\varphi^n(0)=0$, together with (c-1) and (2.2), $\{E^n x^n\}$ is totally bounded. We extract a subsequence, still denoted by $\{E^n x^n\}$ such that $E^n x^n \to x$ as $n\to\infty$. By (e-1), for $z\in D(\varphi^0)$ we have z^n such that $E^n z^n \to z$ as $n\to\infty$, and $\limsup_{n\to\infty}\varphi^n(z^n)\leqq\varphi^0(z)$. Applying (c-2), we get

$$(f^n-x^n, z^n) = (f^n - E^n x^n, p^n E^n z^n) \to \eta(f^0-x, z),$$

$$\|x^n\|^2 = (p^n x^n, E^n x^n) \to \eta\|x\|^2 \quad \text{as } n\to\infty.$$

Putting $z = z^n$ into (2.2) and applying (e-1) and (e-2), we have

$$\begin{aligned}\varphi^0(z) &\geqq \limsup_{n\to\infty} \varphi^n(z^n)\\ &\geqq \liminf \varphi^n(x^n) + \lambda^{-1}\eta(f^0 - x, z - x)\\ &\geqq \varphi^0(x) + \lambda^{-1}\eta(f^0 - x, z - x).\end{aligned}$$

This shows $J^0_{\lambda/\eta} f^0 = x$. Thus, the full sequence $\{E^n x^n\}$ converges to $J^0_{\lambda/\eta} f^0$ as $n \to \infty$. This means that (I) $\to$ (II). □

Proof of Proposition 2.2. (a) Let x^n be the solution of $(\lambda \partial\varphi^n + I)x^n \ni f$, i.e., $\partial\varphi^n(x^n) \ni (f - x^n)/\lambda$. Since J^n_λ is contractive, $\{x^n\}$ is bounded. By the definition of $\partial\varphi^n$ with (c-1), we see that $\{E^n x^n\}$ is totally bounded. We extract a subsequence such that $E^n x^n \to x$, and we also have that $\partial\varphi^n(x^n) \ni (f - E^n x^n)/\lambda$. By (IV) we get $\partial\varphi^0(x) \ni \eta(f - x)/\lambda$. This means that (III) is true.

(b) Let x^n be the solution of $\partial\varphi^n(x^n) \ni f^n$. Since $\{f^n\}$ is bounded and $\{(\partial\varphi^n)^{-1}\}$ is uniformly bounded, $\{x^n\}$ is bounded. By the defintion of $\partial\varphi^n$ with (c-1), $\{E^n x^n\}$ is totally bounded. We suppose $E^n x^n \to x$. We have $(\partial\varphi^n + I)(x^n) \ni f^n + E^n x^n$ and $f^n + E^n x^n \to f^0 + x$ as $n \to \infty$. By (II) we get $(\partial\varphi^0 + \eta I)(X) \ni \eta(f^0 + x)$. This means that (IV) is true. □

3. Lemmas. Recall that c^* be a constant larger than one given in (0.0). Let $A(T)$ be an annular set $c^*T \setminus T$.

LEMMA 3.1 (Rauch and Taylor [23, Ex. 1, p. 40]).

(a) *For $p \in [1, \infty)$, we have a constant C and extension operators $E_{T,p}: W^{1,p}(A(T)) \to W^{1,p}(c^*T)$, such that*

(i) $\|\nabla(E_{T,p}v)\|_{p,T} \leqq C\|\nabla v\|_{p,A(T)}$,

(ii) $\|E_{T,p}v\|_{p,T} \leqq C(\|\nabla v\|_{p,A(T)} + \|v\|_{p,A(T)})$

for all $v \in W^{1,p}(A(T))$.

(b) *For $p = 2$, we can replace $E_{T,p}v$ with $v^\sim$ in* (i) *and* (ii) *above.*

Remark. The extension operators in Lemma 3.1(b) are used in [15]. There is another way to construct extension operators, satisfying properties in Lemma 3.1, due to Cioranescu and Saint Jean Paulin [8].

Let $r^*_\varepsilon = r_\varepsilon/\varepsilon$, $T^*_\varepsilon = r^*_\varepsilon T$ and $Y^*_\varepsilon = Y \setminus T(\varepsilon)^*$. We often write $T^*(\varepsilon) = T^*_\varepsilon$ and $Y^*(\varepsilon) = Y^*_\varepsilon$.

COROLLARY 3.2.

(a) *For $p \in [1, \infty)$, we have a constant C and an extension operator $E_{\varepsilon,p}: W^{1,p}(Y^*_\varepsilon) \to W^{1,p}(Y)$, such that*

(i) $\|\nabla(E_{\varepsilon,p}v)\|_{p,T^*(\varepsilon)} \leqq C\|\nabla v\|_{p,Y^*(\varepsilon)}$,

(ii) $\|E_{\varepsilon,p}v\|_{p,T^*(\varepsilon)} \leqq C(\|\nabla v\|_{p,Y^*(\varepsilon)} + \|v\|_{p,Y^*(\varepsilon)})$

for all $v \in W^{1,p}(Y^*_\varepsilon)$.

(b) *For $p = 2$, we can replace $E_{\varepsilon,p}v$ with $v^\sim$ in* (i) *and* (ii) *above.*

By the method of scaling together with Lemma 3.1 we see

$$\|\nabla(E_{\varepsilon,p}v)\|_{p,T^*(\varepsilon)} \leqq C\|\nabla v\|_{p,r^*_\varepsilon A(T)}$$

and

$$\|E_{\varepsilon,p}v\|_{p,T^*(\varepsilon)} \leqq C(r^*_\varepsilon\|\nabla v\|_{p,r^*_\varepsilon A(T)} + \|v\|_{p,r^*_\varepsilon A(T)}).$$

Thus, the above corollary is true. By the same way we also obtain the following corollary under (0.0) for our sequence $\{\Omega_\varepsilon\}$.

COROLLARY 3.3 (uniform extension property, [15, § 4]).

(a) *We suppose* (0.0) *holds on* $\{\Omega_\varepsilon\}$. *Then for* $p \in [1, \infty)$, *we have a constant* C *and extensions* $E_\varepsilon : \{v \in W^{1,p}(\Omega_\varepsilon);\ v|\partial\Omega = 0\} \to W_0^{1,p}(\Omega)$, *such that*

(i) $\|\nabla(E_\varepsilon v)\|_{p,T_\varepsilon} \leqq C\|\nabla v\|_{p,\Omega_\varepsilon}$, *and*

(ii) $\|E_\varepsilon v\|_{p,T_\varepsilon} \leqq C(\|\nabla v\|_{p,\Omega_\varepsilon} + \|v\|_{p,\Omega_\varepsilon})$.

(b) *For* $p = 2$ *we can replace* $E_\varepsilon v$ *with* $\tilde{v}$ *in* (i) *and* (ii) *above.*

Remark. Corollary 3.3(a) with $p = 2$ and $\varepsilon \sim r_\varepsilon$ as $\varepsilon \to 0$, is introduced by Cioranescu and Saint Jean Paulin [8] and Khruslov [19]. Their results are also extended to the case where $\varepsilon \gg r_\varepsilon$. The method of scaling for extension mappings in domains with many tiny holes has been previously applied by Rauch and Taylor [23, p. 40].

COROLLARY 3.4. *For* $p \in [1, \infty)$, *we have a constant* C *such that*

$$\|v\|_{p,\Omega_\varepsilon} \leqq C\|\nabla v\|_{p,\Omega_\varepsilon}$$

for all $v \in W^{1,p}(\Omega_\varepsilon)$ *such that* $v|\partial\Omega = 0$.

LEMMA 3.5. *For* $p \in (1, \infty)$, *we have a constant* C *such that*

$$\|v\|_{p,Y^*(\varepsilon)} \leqq C\|\nabla v\|_{p,Y^*(\varepsilon)}$$

for all $v \in W^{1,p}(Y_\varepsilon^*)$ *such that* $\int_{Y^*(\varepsilon)} v\, dy = 0$.

Proof. We suppose the contrary. Let $u_n \in W^{1,p}(Y_n^*)$ and a sequence $\varepsilon_n \downarrow 0$ as $n \uparrow \infty$, such that $\int_{Y^*(n)} u_n\, dy = 0$ and $\|u_n\|_{p,Y^*(n)} = 1 > n\|\nabla u_n\|_{p,Y^*(n)}$ for $n \in \mathbb{N}$, where $Y^*(n) = Y_\varepsilon^*$ with $\varepsilon = \varepsilon_n$. We have extensions $v_n = E_n u_n \in W^{1,p}(Y)$ satisfying (i) and (ii) in Corollary 3.2, where $E_n = E_{p,\varepsilon}$ with $\varepsilon = \varepsilon_n$. Note that $\int_Y v_n\, dy = \int_{T^*(n)} v_n\, dy = c_n$ and

$$\left|\int_Y v_n\, dy\right| \leqq C|T^*(n)|^{1/p^*}\|v_n\|_{p,Y^*(n)} \to 0 \quad \text{as } \varepsilon \to 0.$$

For $v_{n,0} = v_n - c_n$, we have $\int_Y v_{n,0}\, dy = 0$, $\|v_{n,0}\|_{p,Y} \to 1$ and $\|\nabla v_{n,0}\|_{p,Y} \to 0$ as $n \to \infty$. There exists a subsequence, still denoted by $v_{n,0}$, such that $v_{n,0} \to v_0$ in $L^p(Y)$. Then $v_0 \equiv 0$ almost everywhere in Y and this contradicts to $\|v_0\|_{p,Y} = 1$. □

The next lemma appeared as Lemma 6.1 of Conca [9] in the case where $r_\varepsilon = \varepsilon$. It is proved by the same spirit as in [9].

LEMMA 3.6. *Let* $p \in [1, N]$. *We have a constant* C *such that*

$$\|v\|_{p,\Omega_\varepsilon} \leqq C\{\theta_{N-p,\varepsilon}^{-1/p}\|\nabla v\|_{p,\Omega_\varepsilon} + \theta_{N-1,\varepsilon}^{-1/p}\|v\|_{p,\partial T_\varepsilon}\}$$

for all $v \in V_\varepsilon$.

LEMMA 3.7 (Conca and Donato [10, Lemma 2.1]). *For* $p \in [1, \infty)$ *we have a constant* C *such that*

$$\|v\|_{p,\partial T_\varepsilon} \leqq C\{c(r_\varepsilon, \varepsilon)^{1/p}\|\nabla v\|_{p,\Omega_\varepsilon} + \theta_{N-1,\varepsilon}^{1/p}\|v\|_{p,\Omega_\varepsilon}\}.$$

Here $c(r_\varepsilon, \varepsilon) = r_\varepsilon^{N-1}\varepsilon^{p-N}$ *for* $p > N$, $c(r_\varepsilon, \varepsilon) = c_1(r_\varepsilon)$ *for* $p \leqq N$,

$$c_1(r_\varepsilon) = \frac{\theta_{N-1,\varepsilon}}{\theta_{N-p,\varepsilon}} = \begin{cases} r_\varepsilon^{p-1} & \text{for } 1 \leqq p < N, \\ (r_\varepsilon \log r_\varepsilon^{-1})^{N-1} & \text{for } p = N. \end{cases}$$

We consider test functions introduced first in the case where $r_\varepsilon \sim \varepsilon$ with $p=2$, by Vanninathan [25]. Let $\nu=\{\nu_i; 1\leqq i\leqq N\}$ be the unit outer normal to $\partial(Y\setminus T_\varepsilon^*)$ and let

$$Av=-\sum_{i=1}^{N}\partial\left(\left|\frac{\partial v}{\partial y_i}\right|^{p-2}\frac{\partial v}{\partial y_i}\right)\Big/\partial y_i\in L^{p^*}(Y_\varepsilon^*),$$

$$Bv=\sum_{i=1}^{N}\nu_i\left|\frac{\partial v}{\partial y_i}\right|^{p-2}\frac{\partial v}{\partial y_i}\in L^{p^*}(\partial T_\varepsilon^*)$$

for $v\in W^{1,p}(Y_\varepsilon^*)$ (note that the mapping $v\in L^p(Y_\varepsilon^*)\to|v|^{p-2}v\in L^{p^*}(Y_\varepsilon^*)$, is the singly valued duality mapping). We consider (Q_ε^*):

$$A\Phi_\varepsilon=-C(\varepsilon),\quad \text{a constant, in } Y_\varepsilon^*,$$

$$(B\Phi_\varepsilon)(y)=g(y/r_\varepsilon^*)\quad \text{for } y\in\partial T_\varepsilon^*,$$

$$\int_{Y^*(\varepsilon)}\Phi_\varepsilon\,dy=0,$$

$$\Phi_\varepsilon\quad \text{is } Y \text{ periodic},$$

where $C(\varepsilon)$ satisfies the compatibility condition, i.e., $C(\varepsilon)=(r_\varepsilon^*)^{N-1}|Y_\varepsilon^*|^{-1}\int_{\partial T}g\,d\sigma$. Let $X=\{v\in W^{1,p}(Y_\varepsilon^*);\ v \text{ is } Y \text{ periodic}\}$. We consider (Q_ε^*) in a general form.

We consider the following problem. For $h_1\in L^{p^*}(Y_\varepsilon^*)$ and $h_2\in L^{p^*}(\partial T_\varepsilon^*)$, find $v\in X/\mathbb{R}$ such that

$$Av=h_1\quad \text{in } Y_\varepsilon^*\quad \text{and}\quad Bv=h_2\quad \text{on } \partial T_\varepsilon^*. \tag{3.1}$$

When there exists a solution v, we get a compatibility condition

$$\int_{Y_\varepsilon^*}h_1\,dy+\int_{\partial T_\varepsilon^*}h_2\,d\sigma=0. \tag{3.2}$$

We show that there exists a unique solution $v\in X/\mathbb{R}$ of (3.1) under (3.2).

Let X^* be the dual space of X, which is reflexive. Generally, for a fixed reflexive (respectively, uniformly convex) normed space E, we can say that any closed subspace of E, or any quotient space modulo a closed subspace is also reflexive (respectively, uniformly convex). Let $F=\{l\in X^*;\langle l,1\rangle=0\}$. We have $\mathbb{R}=\{v\in X;\langle l,v\rangle=0 \text{ for all } l\in F\}$ and $\{X/\mathbb{R},F\}$ as a dual pairing. Let φ be a lower semicontinuous convex function, $X/\mathbb{R}\to[0,\infty]$, defined by

$$\varphi(v)=p^{-1}\int_{Y_\varepsilon^*}|\nabla v|^p\,dy.$$

Since $\|\nabla v\|_{p,Y_\varepsilon^*}$ is a norm on $X/\mathbb{R}$, we have $\varphi(v)/\|\nabla v\|_{p,Y_\varepsilon^*}\to\infty$ as $\|\nabla v\|_{p,Y_\varepsilon^*}\to\infty$. We have $A(=\partial\varphi):X/\mathbb{R}\to F$ with its range, $R(A)=F$ and have the bounded inverse of A, A^{-1} (see, for example, Barbu [2, Prop. 2.6, p. 56]). Generally, if we denote by $|\cdot|$ a norm on a reflexive space E with its dual E^*, we have the duality mapping $E\ni x\to G(x)=\partial(|\cdot|^p/p)(x)\in E^*$, $1<p<\infty$. When E^* is strictly convex, G is single-valued and demicontinuous (see [2, pp. 13, 53]). In our case $X/\mathbb{R}$ is isometrically isomorphic to a closed subspace Z of $L^p(Y_\varepsilon^*)^N$ and the dual space F is isometrically isomorphic to the space $L^q(Y_\varepsilon^*)^N/Z^\perp$, where $Z^\perp$ is the polar set of Z in $L^q(Y_\varepsilon^*)^N$. Thus, F is uniformly convex, so, strictly convex. We see that A and A^{-1} are single-valued.

The operator A with $2\leqq p<\infty$, is frequently considered, while A with general p, $1<p<\infty$, and the boundary operator B is not so often seen. Here, for this point we cite only Proposition 4.1 of Lions [21, p. 205].

Therefore, we have a solution Φ_ε of (Q_ε^*), which satisfies

$$\int_{Y^*(\varepsilon)} \sum_{i=1}^{N} \left|\frac{\partial \Phi_\varepsilon}{\partial y_i}\right|^{p-2} \frac{\partial \Phi_\varepsilon}{\partial y_i} \frac{\partial v}{\partial y_i}\, dy = -C(\varepsilon) \int_{Y^*(\varepsilon)} v\, dy + \int_{\partial T^*(\varepsilon)} g\left(\frac{y}{r_\varepsilon^*}\right) v(y)\, d\sigma(y) \tag{3.3}$$

for all $v \in X$.

Let

$$\tilde{\kappa}_{\varepsilon,p} = \begin{cases} \kappa_{\varepsilon,p} & \text{for } p \in [1, N], \\ (r_\varepsilon^*)^{N-1} & \text{for } p \in (N, \infty). \end{cases}$$

LEMMA 3.8. *Let $I_g = \int_{\partial T} g\, d\sigma$ and $g \in L^{p^*}(\partial T)$ with $1 < p < \infty$.*

(a) *We have a constant C such that, for all $v \in W^{1,p}(Y_\varepsilon^*)$,*

$$\left| \int_{Y^*} \sum_{i=1}^{N} \left|\frac{\partial \Phi_\varepsilon}{\partial Y_i}\right|^{p-2} \frac{\partial \Phi_\varepsilon}{\partial y_i} \frac{\partial v}{\partial y_i}\, dy \right| \leqq C(|I_g| + \|g\|_{p^*,\partial T}) \tilde{\kappa}_{\varepsilon,p} \|\nabla v\|_{p,Y^*}.$$

(b) *Let $\gamma_\varepsilon = \{\gamma_\varepsilon^i;\ 1 \leqq i \leqq N\}$ be a vector function defined by*

$$\gamma_\varepsilon^i(x) = \left(\left|\frac{\partial \Phi_\varepsilon}{\partial y_i}\right|^{p-2} \frac{\partial \Phi_\varepsilon}{\partial y_i} \right)(y)$$

where $y = (x - p_\varepsilon^i)/\varepsilon$ and $x \in p_\varepsilon^i + (\varepsilon Y \setminus r_\varepsilon T)$ for all $i \in \mathbb{N}$. Then, for $v \in W_0^{1,p}(\Omega_\varepsilon)$, we have

$$\left| \int_{\Omega_\varepsilon} \gamma_\varepsilon \nabla v\, dx \right| \leqq C(|I_g| + \|g\|_{p^*,\partial T}) \tilde{\kappa}_{\varepsilon,p} \|\nabla v\|_{p,\Omega_\varepsilon}.$$

To show this we need the lemma below, which is proved as in the proof of Lemma 3.7.

LEMMA 3.9. *For $q \in [1, \infty)$ we have a constant C such that*

$$\|w\|_{q,\partial T^*(\varepsilon)}^q \leqq C\{\tilde{c}(r_\varepsilon^*) \|\nabla w\|_{q,Y^*(\varepsilon)}^q + (r_\varepsilon^*)^{N-1} \|w\|_{q,Y^*(\varepsilon)}^q\}$$

for all $w \in W^{1,q}(Y_\varepsilon^*)$, where $\tilde{c}(r_\varepsilon^*) = c(r_\varepsilon^*, 1)$, $c(\cdot,\cdot)$ is as in Lemma 3.7.

Proof of Lemma 3.8(a). We suppose $v \in X$. By (3.3), Lemmas 3.5 and 3.9 with the Hölder inequality applied to $\int_{Y^*} v\, dy$ and $\int_{\partial T^*(\varepsilon)} g(y/r_\varepsilon^*) v(y)\, d\sigma(y)$, we get

$$\begin{aligned} &\left| \int_{Y^*} \sum_{i=1}^{N} \left|\frac{\partial \Phi_\varepsilon}{\partial y_i}\right|^{p-2} \frac{\partial \Phi_\xi}{\partial y_i} \frac{\partial v}{\partial y_i}\, dy \right| \\ &\quad \leqq C \|\nabla v\|_{p,Y^*(\varepsilon)} [|C(\varepsilon)| + \|g\|_{p^*,\partial T} \{(r_\varepsilon^*)^{N-1} + (r_\varepsilon^*)^{(N-1)/p^*} \tilde{c}(r_\varepsilon^*)^{1/p}\}] \\ &\quad \leqq C(|I_g| + \|g\|_{p^*}) \tilde{\kappa}_{\varepsilon,p} \|\nabla v\|_{p,Y^*}. \end{aligned}$$

Substituting $v = \Phi_\varepsilon$ into the above inequality, we have

$$\|\nabla \Phi_\varepsilon\|_{p,Y^*(\varepsilon)}^{p-1} \leqq C(|I_g| + \|g\|_{p^*}) \tilde{\kappa}_{\varepsilon,p}. \tag{3.4}$$

For $v \in W^{1,p}(Y_\varepsilon^*)$, the inequality in (a) also stands. □

Proof of Lemma 3.8(b). *This directly follows* (3.4). □

Let $\mathcal{T}_\varepsilon = \cup \{T_\varepsilon^i;\ i \in \mathbb{N}\}$ and $\mathcal{T}_\varepsilon^c = \mathbb{R}^N \setminus \mathcal{T}_\varepsilon$. Let $g_\varepsilon \delta_\varepsilon$ be a signed measure defined by

$$\langle g_\varepsilon \delta_\varepsilon, \zeta \rangle = \int_{\partial \mathcal{T}_\varepsilon} g_\varepsilon \zeta\, d\sigma \quad \text{for } \zeta \in C_0(\mathbb{R}^N).$$

Using Φ_ε we introduce test functions $\varphi_\varepsilon \in W^{1,p}_{\mathrm{loc}}(\mathcal{T}_\varepsilon)$ and $\gamma_\varepsilon \in L^{p^*}_{\mathrm{loc}}(\mathcal{T}_\varepsilon)^N$ by $\varphi_\varepsilon(x) = \Phi_\varepsilon((x-p^i_\varepsilon)/\varepsilon)$, $\gamma_\varepsilon(x) = (\nabla\varphi_\varepsilon)((x-p^i_\varepsilon)/\varepsilon)$ for all $x \in p^i_\varepsilon + (\varepsilon Y \setminus r_\varepsilon T)$, $i \in \mathbb{N}$. We get

$$\varepsilon^p A\varphi_\varepsilon = -C(\varepsilon) \quad \text{in } \mathcal{T}_\varepsilon,$$

$$\varepsilon^{p-1} B\varphi_\varepsilon = g_\varepsilon(x) \quad \text{on } \partial\mathcal{T}_\varepsilon,$$

$$\varphi_\varepsilon \quad \text{is } \varepsilon Y \text{ periodic, and}$$

$$\langle g_\varepsilon \delta_\varepsilon, v\rangle = \theta_{N-1,\varepsilon} I_g \int_{\mathcal{T}^c_\varepsilon} v\,dx/|Y^*_\varepsilon| + \int_{\mathcal{T}^c_\varepsilon} \gamma_\varepsilon \nabla v\,dx \tag{3.5}$$

for all $v \in W^{1,p}(\mathbb{R}^N)$ such that supp v is compact (for (3.5) with $p=2$ and $\varepsilon \sim r_\varepsilon$ see (11.6) of Vanninathan [25]).

LEMMA 3.10. Let $p \in (1, \infty)$.

(a) *In the case where $p > N$ we suppose only that $\varepsilon \to 0$. In the case where $p \in [1, N]$, we suppose that $\theta_{N-p} = \infty$, as $\varepsilon \to 0$. Then we have*

$$g_\varepsilon \delta_\varepsilon / \theta_{N-1,\varepsilon} \xrightarrow{s} I_g\,dx \quad \text{in } W^{-1,p^*}(\Omega) \quad \text{as } \varepsilon \to 0. \tag{3.6}$$

(b) *If $\alpha_\varepsilon \tilde{\kappa_\varepsilon} \to 0$ and $a < \infty$ as $\varepsilon \to 0$, then we have*

$$\alpha_\varepsilon \delta_\varepsilon \to a\,dx \quad \text{as } \varepsilon \to 0 \quad \text{in } W^{-1,p^*}(\Omega). \tag{3.7}$$

(c) *Let $\langle g_\varepsilon \bar{\delta}_\varepsilon, \zeta\rangle = \int_{\partial T_\varepsilon} g_\varepsilon \zeta\,d\sigma$ for $\zeta \in C^\infty_0(\Omega)$. Then we have all the results in* (a), (b), *even if δ_ε is replaced with $\bar{\delta}_\varepsilon$.*

Assertions (a) and (b) follow from (3.5) with Lemma 3.8(b), while (c) follows from the estimate $|\Omega \cap (\mathcal{T}_\varepsilon \setminus T_\varepsilon)| \leqq C|\partial\Omega|\varepsilon$.

It is a generalization of Theorem 2.2 of [15] from a case where $g \equiv 1$ to $g \in L^{p^*}(\partial T)$. Another generalization is considered in [16].

4. Proofs of theorems. Let $I_g = \int_{\partial T} g\,d\sigma$, $\theta_\varepsilon = \theta_{N-1,\varepsilon}$ and $\theta = \theta_{N-1}$. Let $B(\xi) = \int_0^\xi \beta^0(\xi')\,d\xi'$ for $\xi \in D(\beta)^-$ and $B(\xi) = \infty$ for $\xi \in \mathbb{R} \setminus D(\beta)^-$ (for β^0 see § 1; β^0 is single-valued, monotonously increasing in $D(\beta)$). Let $m_\beta = \inf\{\xi \in D(\beta)\}$ and $M_\beta = \sup\{\xi \in D(\beta)\}$. We can define B^ε, m^ε_β, M^ε_β, and B^0, m^0_β, M^0_β, in the same way as B, m_β, and M_β, using β^ε, β^0, instead of using β in the integrand above or the region in which the infimum and the supremum are taken. We see $\theta_\varepsilon m^\varepsilon_\beta = m_\beta$, $\theta_\varepsilon M^\varepsilon_\beta = M_\beta$, and $B^\varepsilon(\xi) = B(\theta_\varepsilon\xi)/\theta^{h+1}_\varepsilon$ (see §§ 1.3).

Let $K^\varepsilon = \{v \in V_\varepsilon;\ B(v)|\partial T_\varepsilon \in L^1(\partial T_\varepsilon)\}$. The weak solution $u_\varepsilon \in K^\varepsilon$ of (P_ε), satisfies the next inequality:

$$\int_{\Omega_\varepsilon} [\nabla u_\varepsilon \nabla(v-u_\varepsilon) - (v-u_\varepsilon)f]\,dx - \langle g_\varepsilon \bar{\delta}_\varepsilon, v-u_\varepsilon\rangle + \alpha_\varepsilon\langle \bar{\delta}_\varepsilon, B(v) - B(u_\varepsilon)\rangle \geqq 0 \quad \text{for all } v \in K^\varepsilon. \tag{4.1}$$

4.1. Estimate. Theorems A, B, C, follow from (4.1) combining with estimates in § 3.

(A) *Proof of Theorem* A. Let $\kappa_\varepsilon = \kappa_{\varepsilon,2}$. After substituting $v = 0$ into (4.1) and applying (3.5) and Lemma 3.8(b) we get

$$\|\nabla u_\varepsilon\|^2_{\Omega_\varepsilon} + \alpha_\varepsilon\langle \bar{\delta}_\varepsilon, B(u_\varepsilon)\rangle \leqq \|f\|_\Omega \|u_\varepsilon\|_{\Omega_\varepsilon} + C\theta_\varepsilon |I_g|\,\|u_\varepsilon\|_{\Omega_\varepsilon} + (|I_g| + \|g\|_{\partial T})\kappa_\varepsilon \|\nabla u_\varepsilon\|_{\Omega_\varepsilon}. \tag{4.2}$$

Corollary 3.4 implies that

$$\|\nabla u_\varepsilon\|_{\Omega_\varepsilon} \leqq C(\|f\|_\Omega + \theta_\varepsilon |I_g| + \kappa_\varepsilon |I_g| + \kappa_\varepsilon \|g\|_{\partial T})$$

and

$$(4.2)_b \qquad \alpha_\varepsilon \langle \delta_\varepsilon, B(u_\varepsilon)\rangle \leqq C(\|f\|_\Omega + \theta_\varepsilon |I_g| + \kappa_\varepsilon |I_g| + \kappa_\varepsilon \|g\|_{\partial T})^2$$

(B) *Proof of Theorem* B. By Hölder's inequality we get

$$(4.3)_a \qquad \|u_\varepsilon\|^2_{\sigma',\Omega_\varepsilon} \leqq C \|u_\varepsilon\|^2_{\Omega_\varepsilon}$$

and

$$(4.3)_b \qquad \theta_\varepsilon^{-(\sigma-\sigma')/\sigma'} \|u_\varepsilon\|^\sigma_{\sigma',\partial T_\varepsilon} \leqq C \|u_\varepsilon\|^\sigma_{\sigma,\partial T_\varepsilon},$$

where $u_\varepsilon \in L^\sigma(\partial T_\varepsilon)$. By (4.1) with $v=0$, together $(4.3)_a$, (β-3) with Lemma 3.6 we get

$$\begin{aligned}\|\nabla u_\varepsilon\|^2_{\sigma',\Omega_\varepsilon} + \alpha_\varepsilon \|u_\varepsilon\|^\sigma_{\sigma,\partial T_\varepsilon} \leqq C(&\|f\|_{\sigma'^*,\Omega_\varepsilon} \|\nabla u_\varepsilon\|_{\sigma',\Omega_\varepsilon} / \theta^{1/\sigma'}_{N-\sigma',\varepsilon} \\ &+ \|f\|_{\sigma'^*,\Omega_\varepsilon} \|u_\varepsilon\|_{\sigma',\partial T_\varepsilon} / \theta_\varepsilon^{1/\sigma'} \\ &+ \theta_\varepsilon^{1/\sigma^*} \|g\|_{\sigma^*,\partial T} \|u_\varepsilon\|_{\sigma,\partial T_\varepsilon}).\end{aligned}$$

Young's inequality with $(4.3)_b$ implies

$$(4.4) \qquad \begin{aligned}&\|\nabla u_\varepsilon\|^2_{\sigma',\Omega_\varepsilon} + \alpha_\varepsilon \|u_\varepsilon\|^\sigma_{\sigma,\partial T_\varepsilon} \\ &\leqq C(\|f\|^2_{\sigma'^*,\Omega} / \theta^{2/\sigma'}_{N-\sigma',\varepsilon} + \|f\|^{\sigma^*}_{\sigma'^*,\Omega} / a_\varepsilon^{\sigma^*/\sigma} + \|g\|^{\sigma^*}_{\sigma^*,\partial T} \theta_\varepsilon / \alpha_\varepsilon^{\sigma^*/\sigma}).\end{aligned}$$

By Corollary 3.3 we have $u_\varepsilon^\sim \xrightarrow{s} 0$ in $W_0^{1,\sigma'}(\Omega)$ as $\varepsilon \to 0$. □

(C) *Proof of Theorem* C(I). This directly follows Theorem A with $\theta = \infty$. □

(D) *Proof of Theorem* C(II). Note that $\beta = \partial B$. Let γ_λ be the Yosida approximation of $(\partial B)_\lambda$ and let v_λ be the solution of

$$-\Delta v_\lambda = f \quad \text{in } \Omega_\varepsilon,$$

$$\frac{\partial v_\lambda}{\partial \nu} + \gamma_\lambda(v_\lambda) = g_\varepsilon \quad \text{on } \partial T_\varepsilon \quad \text{and} \quad v_\lambda = 0 \quad \text{on } \partial\Omega.$$

By a slight modification of the proof of Théorème I.10 of Brezis [4], to a nonautonomous boundary condition on ∂T_ε, we have $v_\lambda \xrightarrow{W} u_\varepsilon$ in $H^2(\Omega_\varepsilon)$ as $\lambda \to +0$. Thus, we can extract $\{v_\varepsilon\}$ such that $\|\nabla(v_\varepsilon - u_\varepsilon)\|_{\Omega_\varepsilon} + \|v_\varepsilon - u_\varepsilon\|_{\Omega_\varepsilon} \to 0$ as $\varepsilon \to 0$, where $v_\varepsilon = v_\lambda$ with $\lambda = \lambda_\varepsilon$. It suffices to show that $\|\nabla v_\varepsilon\|_{\Omega_\varepsilon} \geqq C\theta_\varepsilon$. We get

$$\int_{\Omega_\varepsilon} [\nabla v_\varepsilon \nabla \zeta - f\zeta]\, dx + \alpha_\varepsilon \langle \bar{\delta}_\varepsilon, \gamma_\varepsilon(v_\varepsilon)\zeta\rangle = \langle g_\varepsilon \bar{\delta}_\varepsilon, \zeta\rangle \quad \text{for } \zeta \in C_0^\infty(\Omega),$$

where $\gamma_\varepsilon = \gamma_\lambda$ with $\lambda = \lambda_\varepsilon$. For ζ, $0 \leqq \zeta \leqq 1$, and $\zeta \equiv 1$ on a nonempty open set $G \Subset \Omega$, we have C such that $\int_{\Omega_\varepsilon} \zeta\, dx \geqq C > 0$. Property (a) in § 2 implies that $|\gamma_\varepsilon(\xi)| \leqq |\beta^0(\xi)|$ for all $\xi \in \mathbb{R}$. Thus, (β-2) with $0 \leqq r \leqq 1$, $\beta_m = -\infty$, and $\beta_M = \infty$, give an estimate,

$$|\alpha_\varepsilon \langle \bar{\delta}_\varepsilon, \gamma_\varepsilon(v_\varepsilon)\zeta\rangle| \leqq C_1 \alpha_\varepsilon \langle \bar{\delta}_\varepsilon, |v_\varepsilon| + 1\rangle.$$

Applying (3.5) to $\alpha_\varepsilon \bar{\delta}_\varepsilon$ and $g_\varepsilon \bar{\delta}_\varepsilon$ together with Lemma 3.10(b), (c), we get

$$\theta_\varepsilon |I_g| \leqq C_2(\|\nabla v_\varepsilon\|_{\Omega_\varepsilon} + a_\varepsilon \|v_\varepsilon\|_{\Omega_\varepsilon} + \alpha_\varepsilon \kappa_\varepsilon \|\nabla v_\varepsilon\|_{\Omega_\varepsilon} + \|f\|_\Omega + \alpha_\varepsilon S(\partial T_\varepsilon) + \kappa_\varepsilon).$$

But $\alpha_\varepsilon S(\partial T_\varepsilon) \leqq a_\varepsilon |\partial T|$ and $\lim_{\varepsilon \to 0} \alpha_\varepsilon \kappa_\varepsilon = 0$. Using Corollary 3.4, we then have

$$\theta_\varepsilon |I_g| \leqq C_3 \|\nabla v_\varepsilon\|_{\Omega_\varepsilon} + C_4.$$

But $\theta = \infty$ and so we get $\theta_\varepsilon |I_g| \leqq C_5 \|\nabla v_\varepsilon\|_{\Omega_\varepsilon}$. □

(E) *Proof of Theorem* C(III). The estimate (4.4) with $\theta_{N-\sigma'}=\infty=a$, implies (1.4) and $\|u_\varepsilon\|^{\sigma}_{\sigma,\partial T_\varepsilon}\leqq Cb_\varepsilon/\alpha_\varepsilon$. By $(4.3)_b$ we get $\|u_\varepsilon\|^{\sigma'}_{\sigma',\partial T_\varepsilon}\leqq C\|u_\varepsilon\|^{\sigma'}_{\sigma,\partial T_\varepsilon}\theta_\varepsilon^{(\sigma-\sigma')/\sigma}$. Lemma 3.6 implies

$$\begin{aligned}\|u_\varepsilon\|_{\sigma',\Omega_\varepsilon}&\leqq C_1\|\nabla u_\varepsilon\|_{\sigma',\Omega_\varepsilon}/\theta^{1/\sigma'}_{N-\sigma',\varepsilon}+C_2\|u_\varepsilon\|_{\sigma',\partial T_\varepsilon}/\theta^{1/\sigma'}_\varepsilon\\&\leqq C_1 b_\varepsilon^{1/2}\theta^{-1/\sigma'}_{N-\sigma',\varepsilon}+C_2(b_\varepsilon/\alpha_\varepsilon)^{1/\sigma}\theta_\varepsilon^{(\sigma-\sigma')/\sigma\sigma'-1/\sigma'}\\&\leqq C_3 b_\varepsilon^{1/\sigma'}(\theta^{-1/\sigma'}_{N-\sigma',\varepsilon}+a_\varepsilon^{-1/\sigma}).\end{aligned}$$

Thus we get (1.5). The estimates (1.4), (1.5), with Corollary 3.3 imply $\tilde{u_\varepsilon}/b_\varepsilon^{1/\sigma'}\xrightarrow{w}0$ in $W_0^{1,\sigma'}(\Omega)$ as $\varepsilon\to 0$. □

4.2. Convergence. Theorems from §§ 1.2–1.4 follow Theorem 2.1 combining with Propositions 2.2, 2.4 and Lemma 3.10.

Problem (P_ε) is rewritten with a subdifferential. Let $H=L^2(\Omega)$. We then use the terminology in Example 2.3. Let $\varphi^\varepsilon=\varphi^n$ and $\mathbf{j}^\varepsilon=\mathbf{k}^\varepsilon+\mathbf{m}^\varepsilon$, $\varepsilon=\varepsilon_n$, where $\mathbf{k}^\varepsilon(\xi)=-\langle g_\varepsilon\bar{\delta}_\varepsilon,\xi\rangle$ for $\xi\in L^2(\partial T_\varepsilon)$ and

$$m^\varepsilon(\xi)=\begin{cases}\alpha_\varepsilon\langle\bar{\delta}_\varepsilon, B(\xi)\rangle & \text{for } \xi\in L^2(\partial T_\varepsilon) \text{ and } B(\xi)\in L^1(\partial T_\varepsilon),\\ \infty & \text{for others } \xi \text{ in } L^2(\partial T_\varepsilon).\end{cases}$$

We see that $D(\partial\mathbf{j}^\varepsilon)=\{\xi\in L^2(\partial T_\varepsilon)$; there exists $\xi'\in L^2(\partial T_\varepsilon)$ such that $\xi'(x)\in\alpha_\varepsilon\beta(\xi(x))-g_\varepsilon(x)$ almost everywhere on $\partial T_\varepsilon\}$. Let $\Phi^\varepsilon: H\to[0,\infty]$ be

$$\Phi^\varepsilon(v)=\begin{cases}\varphi^\varepsilon(v)+\mathbf{j}^\varepsilon(v|\partial T_\varepsilon) & \text{for } v\in K^\varepsilon,\\ \infty & \text{otherwise.}\end{cases}$$

We set $\tilde{\mathbf{j}}^\varepsilon=\mathbf{j}^\varepsilon\,|\,H^{1/2}(\partial T_\varepsilon)$ as in Brezis [4, p. 32]. A basic fact below follows the argument in I.2.1, Théorème I.10 of [4, p. 33] and Theorem 12 of [5, p. 112].

PROPOSITION 4.1. (I) *For $f\in L^2(\Omega_\varepsilon)$ and $g\in L^2(\partial T_\varepsilon)$, there exists a unique solution u_ε of* (4.1). *This u_ε is also the solution of the problem*:

$$-\Delta u_\varepsilon=f \quad \text{in } \mathcal{D}(\Omega)',$$

$$\frac{\partial u_\varepsilon}{\partial\nu}+\partial\tilde{\mathbf{j}}^\varepsilon(u_\varepsilon)\ni 0 \quad \text{in } H^{-1/2}(\partial T_\varepsilon),$$

$$u_\varepsilon=0 \quad \text{on } \partial\Omega,$$

where $\mathcal{D}(\Omega)'$ is the space of distributions.

(II) *In addition to* (I), *if we suppose $g\in H^{1/2}(\partial T)$, then $u_\varepsilon\in H^2(\Omega_\varepsilon)\cap V_\varepsilon$, and u_ε satisfies* (0.2).

(III) *If $g\in H^{1/2}(\partial T)$, then we have that $D(\partial\Phi^\varepsilon)=\{v\in H^2(\Omega_\varepsilon)\cap V_\varepsilon$; v satisfies* (0.2)*\} and $\partial\Phi^\varepsilon(v)=-\Delta v$ for $v\in D(\partial\Phi^\varepsilon)$.*

The condition $g\in H^{1/2}(\partial T)$ in the Introduction implies

$$\partial\Phi^\varepsilon(u_\varepsilon)\ni f. \tag{4.5}$$

As seen in (2.1), we have

$$\varphi^\varepsilon\xrightarrow{(e)}\varphi^0, \tag{4.6}$$

if $\varepsilon\to 0$ with a fixed value θ_N. When $\{\Phi^\varepsilon\}$ and a certain Φ^0 satisfy the conditions in Proposition 2.4 and $\{(\partial\Phi^\varepsilon)^{-1}\}$ is uniformly bounded, Proposition 2.2(b) is applied to $\{\Phi^\varepsilon\}$.

LEMMA 4.2. (a) *Let* $F^\varepsilon : v \in V_\varepsilon \to F^\varepsilon v = \max\{\min\{v, c_\varepsilon\}, C_\varepsilon\}$, c_ε, $C_\varepsilon \in \mathbb{R}$. *Then* $\varphi^\varepsilon(F^\varepsilon v) \leqq \varphi^\varepsilon(v)$ *and* $(F^\varepsilon v_\varepsilon)^\sim \xrightarrow{w} v$ *for* $v_\varepsilon^\sim \xrightarrow{w} v$ *in* $H_0^1(\Omega)$, $c_0 \leqq v \leqq C_0$ *provided that* $c_\varepsilon \to c_0$ *and* $C_\varepsilon \to C_0$ *as* $\varepsilon \to 0$.

(b) *We suppose* (β-1) *and* (β-2) *with* (1.10). *Then,* $B(v_\varepsilon) \to B(v_0)$ *weakly in* $W_0^{1,\rho}(\Omega)$ *as* $\varepsilon \to 0$, *for any* $v_\varepsilon \xrightarrow{w} v_0$ *in* $H_0^1(\Omega)$ *as* $\varepsilon \to 0$ *such that* $\beta_m \leqq v_\varepsilon(x) \leqq \beta_M$ *almost everywhere in* Ω, *where for* ρ *given in* (1.1).

Proof. We can easily see (a). The boundedness of $\{B(v_\varepsilon)\}$ in $W_0^{1,\rho}(\Omega)$ follows the growth condition of β together with the Hölder inequality. By this argument we get $\rho = 2q(q+2r)^{-1}$, where q is taken as the injection, $H_0^1(\Omega) \to L^q(\Omega)$, is bounded. The continuity of B in (b) follows the growth condition on $B: |B(\xi)| \leqq C(1+|\xi|^{r+1})$, combining with the compact imbedding, $H_0^1(\Omega) \to L^{q'}(\Omega)$, $1 \leqq q' < q = 2N/(N-2)$ for $N \geqq 3$ and $1 \leqq q' < \infty$ for $N = 2$. The mapping, $B: L^{q'}(\Omega) \to L^\rho(\Omega)$, is continuous, if $r+1 \leqq q'/\rho < r + q'/2$, which implies $q \geqq 2$ for $N = 2$ (from here we get $c(r) \leqq \rho$). Thus, we have (1.1) for ρ (see the proof of [15, Lemma B.1].

(A) *Proofs of Theorems* a *and* b. Before giving the proofs we consider the relation between the value r and the value $\alpha_\varepsilon \kappa_{\varepsilon,\rho}$, which plays a key role in Lemma 3.10(b). The definition of ρ implies $\rho^* > 1$. In Theorem a we see that $r \leqq 1$ if and only if $\rho^* \leqq N$ for $N \geqq 3$. For $N = 2$, we get $r = 0$ if and only if $\rho^* = N(=2)$. Using $\bar{\alpha}_\varepsilon$, $\tilde{\alpha}_\varepsilon$, and $\hat{\alpha}_\varepsilon$, we have $(a)_1$ $\alpha_\varepsilon \kappa_{\varepsilon,\rho} = \bar{\alpha}_\varepsilon \theta_{N-\rho^*,\varepsilon}^{1/\rho^*}$ for $N \geqq 3$ and $0 \leqq r < 1$, $(a)_2$ $\alpha_\varepsilon \kappa_{\varepsilon,\rho} \sim \tilde{\alpha}_\varepsilon \theta_{0,\varepsilon}^{1/N}$ as $\varepsilon \to 0$, for $N \geqq 3$ and $r = 1$, $(a)_3$ $\alpha_\varepsilon \kappa_{\varepsilon,\rho} \sim \hat{\alpha}_\varepsilon \theta_{0,\varepsilon}^{1/2}$ as $\varepsilon \to 0$, for $N = 2$ and $r = 0$. These relations are used for Theorem a. In Theorem b we again consider the relation between r and the value $\alpha_\varepsilon \kappa_{\varepsilon,\rho}$. For the case $N \geqq 3$ and $r \geqq 0$, we always have $\rho < N$ and note that $1 \leqq \rho$ if and only if $N/(N-2) \geqq r$. For the case $N = 2$ and $r \geqq 0$ we have $2 \geqq \rho \geqq 1$. The relation, (b) $\alpha_\varepsilon \kappa_{\varepsilon,\rho} = a_\varepsilon \theta_{N-\rho}^{-1/\rho}$, holds and is useful in Theorem b. The relations $(a)_1$, $(a)_2$, and $(a)_3$ work well for the case where $r_\varepsilon \leqq C r_\varepsilon^{(N-2)}$ and we get Theorem a, while the relation (b) is applied to the case $r_\varepsilon \gg r_\varepsilon^{(N-2)}$ and we get Theoerem b. In more detail, we describe the proofs as follows.

Proof of Theorem A. Since $r_\varepsilon \leqq C r_\varepsilon^{(N-\rho^*)} \ll r_\varepsilon^{(N-1)}$, Theorem A, and Corollary 3.4 hold true, $\{(\partial\Phi^\varepsilon)^{-1}\}$ is uniformly bounded. By Proposition 2.2(b) it suffices to show that

$$(4.6)_1 \qquad \Phi^\varepsilon \xrightarrow{(e)} \varphi^0.$$

To show this we take F^n in Proposition 2.4 as F^ε in Lemma 4.2. Besides for $\varepsilon = \varepsilon_n$ we put $j^n(v) = \mathbf{j}^\varepsilon(v|\partial T_\varepsilon)$ for $v \in K^\varepsilon$. The condition $\alpha_\varepsilon \kappa_\varepsilon \to 0$ in Lemma 3.10(b) follows any one of (1.7), (1.8), or (1.9). We get $a = 0 < \infty$ from $N - \rho^* \leqq N - 2$ and $a_\varepsilon = \bar{\alpha}_\varepsilon \theta_{N-2,\varepsilon}$. The assertion $(4.6)_1$ follows (4.6), Propositions 2.2(b) and 2.4, Lemma 3.10(b), (c), and Lemma 4.2.

We prove Theorem b. For $a < \infty$ let $\Phi^0 = \varphi^0 + j^0$ and $j^0 = k^0 + m^0$, where the functionals k^0, $m^0 : H \to [0, \infty]$, are defined by

$$k^0(v) = -\theta I_g \int_\Omega v \, dx \quad \text{for } v \in L^2(\Omega)$$

and

$$m^0(v) = \begin{cases} aS(\partial T) \displaystyle\int_\Omega B(v)\, dx & \text{for } v \in L^2(\Omega) \text{ and } B(v) \in L^1(\Omega), \\ \infty & \text{otherwise.} \end{cases}$$

The uniform boundedness of $\{(\partial\Phi^\varepsilon)^{-1}\}$ follows the same reason as in the previous argument. As in the proof of Theorem a, the convergence (4.6), Propositions 2.2(b) and 2.4, and Lemmas 3.10(b) and 4.2 imply that $\Phi^\varepsilon \xrightarrow{(e)} \Phi^0$. This shows Theorem b in the case where $a < \infty$.

In the above argument, the point is as follows. For any $m_\beta \leqq v_\varepsilon \leqq M_\beta$, $v_\varepsilon \overset{w}{\to} v$ in $H_0^1(\Omega)$ we have $B(v_\varepsilon)$, $B(v) \in W_0^{1,\rho}(\Omega)$, $B(v_\varepsilon) \overset{w}{\to} B(v)$ in $W_0^{1,\rho}(\Omega)$ and $\alpha_\varepsilon \bar{\delta}_\varepsilon \overset{s}{\to} a\,dx$ in $W^{-1,\rho^*}(\Omega)$.

Now, it remains to prove Theorem b with $a = \infty$. Even in this case, $\{u_\varepsilon^\sim\}$ is bounded in $H_0^1(\Omega)$. After dividing both sides of $(4.2)_b$ by a_ε and applying (3.6), we get $\int_\Omega B(u)\,dx = 0$. By (β-4) we see that $u = 0$ almost everywhere in Ω. □

(B) *Proof of Theorem* c. We suppose $a_h < \infty$. First recall the definition of m_β^ε, M_β^ε and B^ε in the first paragraph in this section. We take $w \in K_*^\varepsilon \equiv \{v \in V_\varepsilon;\ B^\varepsilon(w) \in L^1(\partial T_\varepsilon)\}$; i.e., $m_\beta^\varepsilon \leqq w \leqq M_\beta^\varepsilon$ on ∂T_ε. After substituting $v = \theta_\varepsilon w$ into (4.1) and dividing both sides of (4.1) by θ_ε^2, we get

$$\int_{\Omega_\varepsilon} [\nabla z_\varepsilon \nabla(w - z_\varepsilon) - (w - z_\varepsilon)\theta_\varepsilon^{-1} f]\,dx + a_{h,\varepsilon}\langle \theta_\varepsilon^{-1}\bar{\delta}_\varepsilon, B^\varepsilon(w) - B^\varepsilon(z_\varepsilon)\rangle - \langle g_\varepsilon \bar{\delta}_\varepsilon, w - z_\varepsilon\rangle / \theta_\varepsilon \geqq 0. \tag{4.7}$$

Let $\mathbf{k}_*^\varepsilon$ and $\mathbf{m}_*^\varepsilon$ be the new functionals defined by

$$\mathbf{k}_*^\varepsilon(\xi) = -\theta_\varepsilon^{-1}\langle g_\varepsilon \bar{\delta}_\varepsilon, \xi\rangle \quad \text{for } \xi \in L^2(\partial T_\varepsilon),$$

$$\mathbf{m}_*^\varepsilon(\xi) = \begin{cases} a_{h,\varepsilon}\theta_\varepsilon^{-1}\langle \bar{\delta}_\varepsilon, B^\varepsilon(\xi)\rangle & \text{for } \xi \in L^2(\partial T_\varepsilon),\quad B(\xi) \in L^1(\partial T_\varepsilon), \\ \infty & \text{otherwise.} \end{cases}$$

Let $\mathbf{j}_*^\varepsilon : L^2(\partial T_\varepsilon) \to [0, \infty]$ and $j_*^\varepsilon : L^2(\Omega_\varepsilon) \to [0, \infty]$ defined by $\mathbf{j}_*^\varepsilon = \mathbf{k}_*^\varepsilon + \mathbf{m}_*^\varepsilon$ and $j_*^\varepsilon(v) = \mathbf{j}_*^\varepsilon(v|\partial T_\varepsilon)$ for $v \in V_\varepsilon$ with $\mathbf{j}_*^\varepsilon(v|\partial T_\varepsilon) < \infty$, $\mathbf{j}_*^\varepsilon(v) = \infty$, otherwise. Furthermore,

$$\Phi_*^\varepsilon(v) = \begin{cases} \varphi^\varepsilon(v) + j_*^\varepsilon(v) & \text{for } v \in K_*^\varepsilon, \\ \infty & \text{otherwise.} \end{cases}$$

We set $k_*^0(v) = -I_g \int_\Omega v\,dx$ for $v \in H$, $m_*^0(v) = a_h S(\partial T) \int_\Omega B_*^0(v)\,dx$ for $v \in H_0^1(\Omega)$, and $B_*^0(v) \in L^1(\Omega)$ and $m_*^0(v) = \infty$, otherwise. Let $j_*^0 = k_*^0 + m_*^0$ and $\Phi_*^0 = \varphi^0 + j_*^0$. Inequality (4.7) and (1.12) are rewritten by using subdifferentials as $\partial\Phi_*^\varepsilon(z_\varepsilon) \ni \theta_\varepsilon^{-1} f$ and $\partial\Phi_*^0(z) \ni 0$, respectively. It suffices to see the convergence of $w_\varepsilon^\sim$ to w in H, where $\partial\Phi_*^\varepsilon(w_\varepsilon) \ni f_\varepsilon$, $\partial\Phi_*^0(w) \ni \eta f$ and $f_\varepsilon \to f$ as $\varepsilon \to 0$, where $\eta = |Y^*|$. $\{(\partial\Phi_*^\varepsilon)^{-1}\}$ is uniformly bounded by the inequality obtained from (4.7) replacing f/θ_ε with f_ε, where f_ε belongs to a bounded set in H. By Proposition 2.2(b) it suffices to show that

$$\Phi_*^\varepsilon \xrightarrow{(e)} \Phi_*^0. \tag{4.8}$$

It suffices to show the conditions in Proposition 2.4. By the definition of m_β^ε and M_β^ε we see that $m_\beta^\varepsilon \to m_\beta^0$ and $M_\beta^\varepsilon \to M_\beta^0$ as $\varepsilon \to 0$. We regard F^ε in Lemma 4.2 with $c_\varepsilon = m_\beta^\varepsilon$ and $C_\varepsilon = M_\beta^\varepsilon$ as F^n in Proposition 2.4 with $\varepsilon = \varepsilon_n$. Lemma 4.2(a) implies (ii) of Proposition 2.4. We have to show (iii) of Proposition 2.4.

For this aim we need some p such that

$$B_*^\varepsilon(v_\varepsilon), B_*^0(v) \in W_0^{1,p}(\Omega),\ B_*^\varepsilon(v_\varepsilon) \overset{w}{\to} B_*^0(v) \quad \text{in } W_0^{1,p}(\Omega) \tag{4.8}_1$$

and

$$a_{h,\varepsilon}\theta_\varepsilon^{-1}\bar{\delta}_\varepsilon \overset{s}{\to} a_h|\partial T|\,dx \quad \text{in } W^{-1,p^*}(\Omega) \tag{4.8}_2$$

for any $\{v_\varepsilon\}$ such that

$$m_\beta^\varepsilon \leqq v_\varepsilon \leqq M_\beta^\varepsilon \quad \text{and} \quad v_\varepsilon \overset{w}{\to} v \quad \text{in } H_0^1(\Omega) \quad \text{as } \varepsilon \to 0.$$

LEMMA 4.3. (i) *We have* $(4.8)_1$ *with* $p=\rho$ *provided that* $(\gamma\text{-}1)$ *or* $(\gamma\text{-}2)$ *are satisfied; in this case,* $m_\beta^\varepsilon=-\infty$ *and* $M_\beta^\varepsilon=\infty$.

(ii) *We also have* $(4.8)_1$ *with* $p=2$ *provided that* $(\gamma\text{-}3)$ *are satisfied.*

Proof. The functions β^ε and β^0 satisfy $(\beta\text{-}2)$ with the same r and coefficients C_1 and C_2, as those of β, because $\theta_\varepsilon\to\infty$ and $h\geqq r$.

For β satisfying $(\beta\text{-}1)$ or $(\beta\text{-}2)$ with (1.10), the inclusion, $B^\varepsilon(v_\varepsilon)$, $B^0(v)\in W_0^{1,\rho}(\Omega)$, and the boundedness of $\{B^\varepsilon(v_\varepsilon)\}$ in $W_0^{1,\rho}(\Omega)$, is derived from the definition of $B^\varepsilon(v_\varepsilon)$ using the Sobolev imbedding theorem together with Hölder's inequality as in the proof of Lemma 4.2. The convergence of $\{B^\varepsilon(v_\varepsilon)\}$ in $L^\rho(\Omega)$ under $(\gamma-1)$, is implied by the growth condition of β^0 (cf. [15, Lemma B.1]).

The case $(\gamma\text{-}2)$ is proved by analogy with the proof of Dini's theorem for a monotone sequence of continuous functions defined on a compact set as follows.

We get $B^0(v_\varepsilon)\overset{w}{\to}B^0(v)$ in $W_0^{1,\rho}(\Omega)$ by Lemma 4.2(b). It suffices to show that

$$\|B^\varepsilon(v_\varepsilon)-B^0(v_\varepsilon)\|_{\rho,\Omega}\to 0 \quad \text{as } \varepsilon\to 0. \tag{4.9}$$

We see that $\{B^\varepsilon(\cdot)-B^0(\cdot)\}$ is a continuous mapping from $L^{q'}(\Omega)$ into $L^\rho(\Omega)$, where $2\leqq q'\leqq 2N/(N-2)$ for $N\geqq 3$, and $2\leqq q'<\infty$ for $N=2$, because of $|B^\varepsilon(\xi)|\leqq C(1+|\xi|^{r+1})$ with (1.10) (see [15, Lemma B.1, p. 78]. Suppose that (4.9) is not true. Let $B^n=B^\varepsilon$ with $\varepsilon=\varepsilon_n$ and $v_m=v_\varepsilon$ with $\varepsilon=\varepsilon_m$, $n, m\in\mathbb{N}$. There exists $\{v_m\}$ such that $\|B^n(v_m)-B^0(v_m)\|_{\rho,\Omega}\geqq\delta>0$ for all $m, n\in\mathbb{N}$ with some $\delta>0$, where the sequence $\{v_m\}$ converges to v_0 in $L^{q'}(\Omega)$. Let $I_n=\{v_m, m\in\mathbb{N}, v_0;\ \|B^n(v_m)-B^0(v_m)\|_{\rho,\Omega}\geqq\delta/2\}$. By $(\gamma\text{-}2)$ we get $I_n\supset I_{n+1}$. Since $\{v_m, m\in\mathbb{N}, v_0\}$ is compact, B^n-B^0 is continuous, and $\bigcap_{n=1}^\infty I_n=\varnothing$, we have n_0 such that $I_{n_0}=\varnothing$. This is a contradiction.

We suppose $(\gamma\text{-}3)$ holds. Then we have $B^\varepsilon(v_\varepsilon)-B^\varepsilon(v_0)\in L^2(\Omega)$, $\partial B^\varepsilon(v_\varepsilon)/\partial x_i=\beta^\varepsilon(v_\varepsilon)\partial v_\varepsilon/\partial x_i\in L^2(\Omega)$, and $B^\varepsilon(v_\varepsilon)-B^\varepsilon(v_0)\in H_0^1(\Omega)$. The class $\{B^\varepsilon\}$ is equicontinuous because $\|B^\varepsilon(v_\varepsilon)-B^\varepsilon(v_0)\|_\Omega^2\leqq C\|v_\varepsilon-v_0\|_\Omega^2$. On the other hand, we have

$$\|B^\varepsilon(v_0)-B^0(v_0)\|_\Omega\to 0 \quad \text{as } \varepsilon\to 0. \tag{4.10}$$

In fact, since

$$\partial(B^\varepsilon(v_0)-B^0(v_0))/\partial x_i=(\beta^\varepsilon(v_0)-\beta^0(v_0))\partial v_0/\partial x_i,$$
$$|(\beta^\varepsilon(v_0)-\beta^0(v_0))\partial v_0/\partial xi|^2\leqq C|\partial v_0/\partial x_i|^2,$$

and $(\beta^\varepsilon(v_0)-\beta^0(v_0))\partial v_0/\partial x_i\to 0$ as $\varepsilon\to 0$, we have $\|\nabla(B^\varepsilon(v_0)-B^0(v_0))\|_\Omega\to 0$ as $\varepsilon\to 0$ by the Lebesgue convergence theorem. Thus, (4.10) follows from the Poincaré inequality. We have shown the lemma. □

Since $\theta_{N-\rho}=\infty=\theta_{N-2}$ for $r_\varepsilon\gg r_\varepsilon^{(N-1)}$, $(4.8)_2$ is implied from Lemma 3.10(a) with $a_h<\infty$, where $p=\rho$ for $(\gamma\text{-}1)$ and $(\gamma\text{-}2)$ and $p=2$ for $(\gamma\text{-}3)$. Thus, we have (4.8).

For the case where $a_h=\infty$, $\{z_\varepsilon^\sim\}$ is bounded in $H_0^1(\Omega)$. We take a subsequence, denoted by $\{z_\varepsilon^\sim\}$ again, such that $z_\varepsilon^\sim\overset{w}{\to}z$ in $H_0^1(\Omega)$ as $\varepsilon\to 0$. We substitute $w=0$ into (4.7), and divide both sides of the inequality by $a_{h,\varepsilon}$. We apply Lemma 3.10(a) with $\theta_{N-2}=\infty$, and get $\int_\Omega B_*^0(z)\,dx=0$. By $(\beta\text{-}4)$ we get $z=0$. This concludes the proof of Theorem c.

(C) *Proof of Theorem* a′. The proof is done in the same way as the proof of Theorem A.2 of [15], because, in that proof the differentiability of β is not used at all. Thus, we can omit the proof of Theorem a′.

(D) *Proof of Theorem* b′. This proof is also derived directly from the proof of Theorem B in [15] together with Lemma 3.10. Thus, we omit it.

5. Asymptotic behavior in $\mathbb{R}^2$. Theorem a′ says nothing for the case where $N=2$, nor does Theorem a cover the case where

$$N=2, \quad r_\varepsilon\leqq Cr_\varepsilon^{(0)} \quad \text{with } \hat{\alpha}=\infty. \tag{5.1}$$

Let $\hat{\alpha}_\varepsilon = \tilde{\alpha}_\varepsilon(\log r_\varepsilon^{-1})^{1/2}$ and $\hat{\alpha}_* = \lim \hat{\alpha}_\varepsilon$. We have $\hat{\alpha} < \infty$ if and only if $\hat{\alpha}_* < \infty$. Let $c_\varepsilon = \theta_{0,\varepsilon}/a_\varepsilon$ and $c = \lim c_\varepsilon$. We also have

$$\hat{\alpha}_\varepsilon = 2(\log r_\varepsilon^{-1})^{1/2}/c_\varepsilon.$$

Here, $r_\varepsilon T$ is supposed to be a ball $\{x \in \mathbb{R}^N; |x| \leqq r_\varepsilon/2\}$ together with $\beta(\xi) = \xi$ in (0.2). We are interested in the case where $0 < c < \infty$, and the case where $c = 0$. The state $c = 0$ follows both

(i) $\theta_0 \in [0, \infty)$ and $a = \infty$,

and

(ii) $\theta_0 = 0$ and $a \in (0, \infty]$.

The state $0 < c < \infty$ follows

(iii) θ_0, $a \in (0, \infty)$.

The remaining case of (θ_0, a) such that $\theta_0 = 0$ and $a = 0$ may imply various values of c.

The test function in [12], $w_\varepsilon(r) = [1 - \alpha_\varepsilon \bar{r}_\varepsilon(\log(r_\varepsilon/\varepsilon) - \log(r/\bar{\varepsilon}))]/(1 - \alpha_\varepsilon \bar{r}_\varepsilon \log(r_\varepsilon/\varepsilon))$ with $r = |x|$, $\bar{\varepsilon} = \varepsilon/2$, and $\bar{r}_\varepsilon = r_\varepsilon/2$, is useful. Let $\theta_{0,\varepsilon}^{\sim} = (\varepsilon^2 \log(\varepsilon/r_\varepsilon))^{-1}$. The formula $\partial w_\varepsilon/\partial r|_{r=\varepsilon} = \bar{\varepsilon}\theta_{0,\varepsilon}^{\sim}(1 + \theta_{0,\varepsilon}^{\sim}/a_\varepsilon)^{-1}$, together with the method in Cioranescu and Murat [7], imply the proposition below.

PROPOSITION 5.1. *We suppose* $r_\varepsilon \leqq Cr_\varepsilon^{(0)}$, (0.4) *with a fixed* $\theta_0 < \infty$ *and a fixed* $c \in [0, \infty]$ *as* $\varepsilon \to 0$. *Then* $u_\varepsilon^{\sim} \to u$ *weakly in* $H_0^1(\Omega)$, *where* u *is determined by the equation*

$$-\Delta u + 2\pi\theta_0(c+1)^{-1}u = f \quad \text{a.e. in } \Omega. \tag{5.2}$$

Remark 5.2. If instead of (0.2) we consider the Dirichlet boundary condition, we get (5.2) with $c = 0$, using the method in Cioranescu and Murat [7].

6. Applications.

Application 6.1. The theorems in § 1 are applied to monotone functions β such as (b), (c), $(d)_p$, (e), (f), and (g) described in the Introduction. We give Table 1 for $N \geqq 3$.

Application 6.2. Let C_1, $C_2 > 0$. We suppose $\int_{\partial T} g\, d\sigma \neq 0$,

$$\beta(\xi) = \begin{cases} C_1\xi & \text{for } \xi \leqq 0, \\ C_2\xi & \text{for } \xi \geqq 0, \end{cases}$$

TABLE 1

Theorem	To be applicable	Not to be applicable
A	(b) (c) $(d)_p$ (e) (f) (g)	(a)

10	$u_\varepsilon^{\sim} \to 0$		

and relations among ε, r_ε, and α_ε as follows:

$$\varepsilon = r_\varepsilon^m, \qquad m \in (0, 1],$$
$$\alpha_\varepsilon = r_\varepsilon^n, \qquad n \in \mathbb{R}.$$

Let $\mu = Nm \in (0, N]$. Then all the limit equations are displayed as points having coordinates (μ, n) in $(0, N] \times \mathbb{R}$. Theorem a′ derives limit equations number 1, 2 in Fig. 2, for points of $\{(\mu, n);\ \mu \leqq N-2 \text{ and } n \in \mathbb{R}\}$. Theorem b′ also derives the equations number 2, 3, 4, which are settled in the region, $\{(u, n);\ N-2 < \mu \leqq N-1 \text{ and } n \in \mathbb{R}\}$. Theorems B and c concern the set $\{(\mu, n);\ N-2 < \mu \leqq N,\ n < \mu - N + 1 \text{ and } n < -\mu + N - 1\}$ and $\{(\mu, n);\ N-1 < \mu \leqq N \text{ and } n \geqq \mu - N + 1\}$, respectively (number 4, 5, 6, 7, and 8). Last, by Theorem C(III) we get limit equations (number 9, 10) for points of $\{(\mu, n);\ N-1 < \mu \leqq N,\ n < \mu - N + 1 \text{ and } n \geqq -\mu + N - 1\}$. Thus, limit equations are drawn in one picture as Fig. 2 in [15]. Unfortunately, by our theorems we can show no limit equation corresponding to a point $(N-2, -1)$ (number 0), when $C_1 \neq C_2$. The exact equation corresponding to each number is described in Table 2.

ON THE NEWTONIAN POTENTIAL OF A HETEROGENEOUS ELLIPSOID*

HENRIK SHAHGHOLIAN†

Abstract. In this note the Newtonian potential of a heterogeneous ellipsoid in $\mathbb{R}^n$ is calculated. It turns out that for polynomial densities the potential is also a polynomial in the interior of the ellipsoid. As an application, it is shown that the solution of $\Delta u = P$ near ∂E and $u = |\nabla u| = 0$ on ∂E, where E is an ellipsoid and P a polynomial, has a harmonic continuation to $\mathbb{R}^n \setminus E_0$, where E_0 is the focal ellipsoid of E.

Key words. Newtonian potential, Schwarz potential, ellipsoid

AMS(MOS) subject classifications. 31C99, 35J05

Introduction. This paper consists of two parts:

(1) Calculation of the Newtonian potential of a heterogeneous ellipsoid, at an internal point. Here we prove that the Newtonian potential of an ellipsoid in $\mathbb{R}^n$ with polynomial density is a polynomial in the interior of the ellipsoid. This was proved in $\mathbb{R}^3$ by Ferrers (see [Fe]) using special techniques of ellipsoidal coordinates; it seems difficult to extend this method to more than three dimensions.

In any case, it seems of interest to give a new proof of this fundamental result in $\mathbb{R}^n$. We do this by adapting the celebrated method of Dirichlet [Di], based on Fourier's integral, combined with Ferrer's [Fe] idea that any polynomial can be expressed by a finite linear combination of P, $P^2, \cdots$ and their derivatives of different degrees (see Lemma 1.4).

(2) Application to the Cauchy problem for the Laplace equation. Here we use part (1) to solve the following Cauchy problem:

$$\begin{aligned} &\Delta u = 0 \quad \text{near } \partial E \\ &u \equiv P \quad \text{on } \partial E \end{aligned} \qquad E \text{ is an ellipsoid in } \mathbb{R}^n.$$

It turns out that the solution of this problem is harmonic in $\mathbb{R}^n \setminus E_0$.

Notation. We will use the following notation.

(i) By $g \equiv f$, we mean $g = f$ and $\nabla g = \nabla f$, where f, $g \in C^1(\mathbb{R}^n)$ and ∇ denotes gradient.

(ii) The solution of the following Cauchy problem, when it exists, will be called the *Schwarz potential* U_Γ of Γ, where Γ is a hypersurface in $\mathbb{R}^n$,

$$\begin{aligned} &\Delta u = 0 \quad \text{near } \Gamma, \\ &u \equiv \tfrac{1}{2}|x|^2 \quad \text{on } \Gamma. \end{aligned}$$

(iii) $K_m(x, y)$ is defined as follows. Set $\psi(x-y) = \omega_n^{-1}|x-y|^{2-n}$, where $\omega_n = (2-n) \cdot A_n$; A_n is the surface area of the $(n-1)$-dimensional unit sphere. For $a \in \mathbb{R}^n$, $x \in \mathbb{R}^n$, and $x \neq a$ set

$$K_m^a(x, y) := \psi(x-y) - \sum_{|\alpha|<m} \frac{(y-a)^\alpha}{\alpha!} \frac{\partial^\alpha}{\partial z^\alpha} \psi(x-z)\big|_{z=a},$$

$$K_m(x, y) := K_m^0(x, y).$$

* Received by the editors November 28, 1989; accepted for publication (in revised form) October 3, 1990.
† Department of Mathematics, Royal Institute of Technology, Stockholm, Sweden.

(iv) Let $\Omega \subset \mathbb{R}^n$ and $\bar{\Omega} \neq \mathbb{R}^n$. Then we define the *generalized Newtonian potential* with polynomial density R, with respect to $a \in \mathbb{R}^n$ by

$$\int_\Omega K_m^a(x, y) R(x)\, dx, \quad \text{where } m = \deg R + 3 \text{ and } a \notin \bar{\Omega}.$$

(v) For $a_1 \geqq a_2 \geqq \cdots \geqq a_n > 0$ we define E and E_0:

$$E = \left\{ x \in \mathbb{R}^n : \sum_{j=1}^n \frac{x_j^2}{a_j^2} \leqq 1 \right\},$$

$$E_0 = \left\{ x \in \mathbb{R}^n : \sum_{j=1}^{n-1} \frac{x_j^2}{a_j^2 - a_n^2} \leqq 1 \text{ and } x_n = 0 \right\}.$$

E_0 is the so-called *focal ellipsoid* of E.

(vi) We also define φ, S, and P as follows:

$$\varphi^2(s) = (s + a_1^2)(s + a_2^2) \cdots (s + a_n^2),$$

$$S(s, y) = \sum_{j=1}^n \frac{y_j^2}{a_j^2 + s} \quad \text{and} \quad P(x) = 1 - \sum_{j=1}^n \frac{x_j^2}{a_j^2}.$$

1. Calculation of the Newtonian potential of a heterogeneous ellipsoid, at an internal point. Here we calculate the potential of E (ellipsoid) with polynomial density. To do this we begin with the following theorem.

THEOREM 1.1. *Let $m \geqq 0$; then*

$$\int_E \frac{P^m(x)\, dx}{|x - y|^{n-2}} = \frac{c_n}{m+1} \int_\lambda^\infty \left(1 - \sum_{j=1}^n \frac{y_j^2}{s + a_j^2} \right)^{m+1} \varphi(s)^{-1}\, ds$$

where $c_n = \pi^{n/2} a_1 \cdots a_n \cdot (n-2)/2\Gamma(n/2)$, and λ is the largest of the ellipsoidal coordinates of $y \notin E$ and $\lambda = 0$ if $y \in E$. Consequently, if m is a nonnegative integer then the Newtonian potential of E with density $P^m(x)$ is a polynomial of degree $m+2$ in the interior of E.

Proof. Set

$$V(y) = \int_E \frac{P^m(x)}{|x - y|^{n-2}}\, dx \quad \text{and} \quad V_k := \frac{\partial V}{\partial y_k}(y).$$

We first calculate $V_k(y)$ for $y \in \mathbb{R}^n$, and $m > 0$. Define

$$f(\xi) = \begin{cases} (1 - |\xi|)^m, & |\xi| < 1, \\ 0, & |\xi| \geqq 1, \end{cases} \quad \xi \in \mathbb{R}.$$

Then

$$f(\xi) = \operatorname{Re} \int_0^\infty \frac{\hat{f}(t)}{\pi} e^{it\xi}\, dt, \tag{1}$$

where

$$\hat{f}(t) = \int_{-\infty}^\infty f(\xi)\, e^{-it\xi}\, d\xi$$

is in $L^1(\mathbb{R})$, for $m > 0$. We have

$$\frac{V_k}{n-2} = \int_{\mathbb{R}^n} f\left(\sum_{j=1}^n \frac{x_j^2}{a_j^2} \right) (x_k - y_k) |x - y|^{-n}\, dx.$$

Here we want to use (1) with $\xi = \sum_{j=1}^{n} (x_j^2/a_j^2)$ and then change the order of integration, but since $(x_k - y_k)|x-y|^n$ is not integrable over $\mathbb{R}^n$, we first introduce a convergence factor $\exp(-\delta|x|^2)$ which gives

$$\frac{V_k}{n-2} = \lim_{\delta \to 0} \int_{\mathbb{R}^n} f\left(\sum_{j=1}^{n} \frac{x_j^2}{a_j^2}\right)(x_k - y_k)|x-y|^{-n} e^{-\delta|x|^2}\, dx. \tag{2}$$

Now we insert (1) into (2) which implies that (2) becomes

$$\operatorname{Re}\left[\lim_{\delta \to 0} \int_{\mathbb{R}^n} \int_0^\infty \frac{\hat{f}(t)}{\pi} I_1(x, y, t)\, dt\, dx\right], \tag{2'}$$

where $I_1(x, y, t) = (x_k - y_k)|x-y|^{-n} \exp[it \sum_{j=1}^{n} (x_j^2/a_j^2) - \delta|x|^2]$. Here we change the order of integration, so (2') becomes

$$\lim_{\delta \to 0} \operatorname{Re} \int_0^\infty \frac{\hat{f}(t)}{\pi} \int_{\mathbb{R}^n} I_1(x, y, t)\, dx\, dt. \tag{2''}$$

The idea is to split the integration over $\mathbb{R}^n$ into n products of one-dimensional integrals. For this we will use the following known formula:

$$\int_0^\infty \exp[-(\varepsilon - i\beta)\nu] \cdot \nu^{r-1}\, d\nu = (\varepsilon - i\beta)^{-r} \cdot \Gamma(r),$$

where $r > 0$, $\varepsilon > 0$, $\beta \in \mathbb{R}^n$, and Γ is the gamma function (see [GH, p. 62]). To make the formula applicable to our purposes, we set $\beta = |x-y|^2$ and $r = n/2$. Then

$$\begin{aligned} &\int_{\mathbb{R}^n} I_1(x, y, t)\, dx \\ &= \lim_{\varepsilon \to 0} (-i)^{n/2} \int_{\mathbb{R}^n} [\varepsilon - i|x-y|^2]^{-n/2}(x_k - y_k) \exp\left[it \sum_{j=1}^{n} \frac{x_j^2}{a_j^2} - \delta|x|^2\right] dx \qquad (3) \\ &= \lim_{\varepsilon \to 0} (-i)^{n/2} (\Gamma(n/2))^{-1} \int_{\mathbb{R}^n} \int_0^\infty \exp(I_2) \cdot (x_k - y_k) \cdot \nu^{(n-2)/2}\, d\nu\, dx, \end{aligned}$$

where

$$\begin{aligned} I_2 &= -(\varepsilon - i|x-y|^2)\nu + it \sum_{j=1}^{n} \frac{x_j^2}{a_j^2} - \delta|x|^2 \\ &= -\varepsilon\nu + i|y|^2\nu + \sum_{j=1}^{n} \left[\left(i\nu + \frac{it}{a_j^2} - \delta\right)x_j^2 - 2iy_j\nu x_j\right]. \end{aligned}$$

Set

$$P_j = \left(\nu + \frac{t}{a_j^2}\right) \quad \text{and} \quad Q_j = -y_j\nu, \quad j = 1, 2, \cdots, n;$$

then

$$I_2 = -\varepsilon\nu + i|y|^2\nu + \sum_{j=1}^{n} [(iP_j - \delta)x_j^2 + 2iQ_j x_j].$$

Now changing the order of integration in (3) we can reduce it to

$$\lim_{\varepsilon \to 0} (-i)^{n/2} (\Gamma(n/2))^{-1} \int_0^\infty \nu^{(n-2)/2} \exp[-\varepsilon\nu + i|y|^2\nu] G(t, y, \nu)\, d\nu, \tag{3'}$$

where

$$G(t, y, \nu) = \int_{\mathbb{R}^n} \exp \sum_{j=1}^{n} [(iP_j - \delta)x_j^2 + 2iQ_j x_j] \cdot (x_k - y_k)\, dx$$
$$= \left(\prod_{\substack{j=1 \\ j \neq k}}^{n} \int_{-\infty}^{\infty} \exp [(iP_j - \delta)x_j^2 + 2iQ_j x_j]\, dx_j \right)$$
$$\cdot \int_{-\infty}^{\infty} (x_k - y_k) \exp [(iP_k - \delta)x_k^2 + 2iQ_k x_k]\, dx_k.$$

By calculating these integrals we find

$$\int_{-\infty}^{\infty} \exp [(iP_j - \delta)x_j^2 + 2iQ_j x_j]\, dx_j = \frac{\exp [-Q_j^2/(\delta - iP_j)]}{\sqrt{\delta - iP_j}} \cdot \sqrt{\pi}$$

and

$$\int_{-\infty}^{\infty} (x_k - y_k) \exp [(iP_k - \delta)x_k^2 + 2iQ_k x_k]\, dx_k$$
$$= \left(\frac{iQ_k}{\delta - iP_k} - y_k \right) \frac{\exp [-Q_k^2/(\delta - iP_k)] \cdot \sqrt{\pi}}{\sqrt{\delta - iP_k}}$$
$$= \frac{-\delta + (it/a_k^2)}{(\delta - iP_k)} y_k \frac{\exp [-Q_k^2/(\delta - iP_k)] \cdot \sqrt{\pi}}{\sqrt{\delta - iP_k}},$$

i.e.,

$$G(t, y, \nu) = \pi^{n/2} \frac{(-\delta + (it/a_k^2))}{\delta - iP_k} \cdot y_k \cdot \frac{\exp [-\sum_{j=1}^{n} Q_j^2/(\delta - iP_j)]}{\sqrt{(\delta - iP_1) \cdots (\delta - iP_n)}}. \tag{4}$$

Now, inserting (4) in (3′) and making the variable changes $s = t/\nu$ we get, after recalling the definition of P_j and Q_j, that (3′) is reduced to

$$\lim_{\varepsilon \to 0} d_n \int_0^{\infty} \frac{((-ia_k^2\delta/t) - 1)y_k}{R_k} \cdot \frac{\exp [-\varepsilon t/s + i \sum_{j=1}^{n} ((i\delta a_j^2 + t)/R_j)y_j^2]}{\sqrt{R_1 \cdot R_2 \cdots R_n}}\, ds$$
$$= d_n \int_0^{\infty} \frac{((-ia_k^2\delta/t) - 1)y_k}{R_k} \cdot \frac{\exp [i \sum_{j=1}^{n} ((i\delta a_j^2 + t)/R_j)y_j^2]}{\sqrt{R_1 \cdots R_n}}\, ds, \tag{3″}$$

where $R_j = ((i\delta a_j^2 s/t) + a_j^2 + s)$ and

$$d_n = \pi^{n/2} \cdot (\Gamma(n/2))^{-1} \cdot a_1 \cdots a_n = \frac{2c_n}{n-2}.$$

Summing up we arrive at

$$\int_{\mathbb{R}^n} I_1(x, y, t)\, dx = d_n \int_0^{\infty} F\, ds,$$

where

$$F = F(y, s, t, \delta) = \frac{((-ia_k^2\delta/t) - 1)y_k}{R_k} \cdot \frac{\exp [i \sum_{j=1}^{n} ((i\delta a_j^2 + t)/R_j)y_j^2]}{\sqrt{R_1 \cdots R_n}}.$$

Now we put this into (2″); then we have

$$\frac{V_k}{n-2} = \operatorname{Re} \lim_{\delta \to 0} d_n \int_0^{\infty} \int_0^{\infty} \frac{\hat{f}(t)}{\pi} F\, ds\, dt.$$

Since $\int_0^\infty |F|\,ds<\infty$ we can change the order of integration and let $\delta\to 0$. This gives

$$\frac{V_k}{n-2}=d_n\int_0^\infty \operatorname{Re}\int_0^\infty \frac{\hat f(t)}{\pi}F_0\,dt\,ds,$$

where

$$F_0=F(x,y,t,0)=\frac{-y_k\exp\left[it\sum_{j=1}^n y_j^2/(a_j^2+s)\right]}{(a_k^2+s)\cdot[(a_1^2+s)\cdots(a_n^2+s)]^{1/2}}.$$

Recall the definition of S and φ; then we observe

$$V_k=(2-n)d_n y_k\int_0^\infty[\varphi(s)(s+a_k^2)]^{-1}\int_{-\infty}^\infty\frac{\hat f(t)}{2\pi}\exp\left[itS(s,y)\right]dt\,ds. \tag{5}$$

Now let λ be the positive root of $S(s,y)=1$ for fixed y, i.e., $\lambda=\lambda(y)$. Then the inner integral in (5) is zero for $s<\lambda$ and is equal to $f(S(s,y))$ for $s\geqq\lambda$. Therefore

$$\begin{aligned}V_k&=(2-n)d_n y_k\int_\lambda^\infty\frac{f(S(s,y))}{\varphi(s)(s+a_k^2)}\,ds\\&=(2-n)d_n y_k\int_\lambda^\infty\left(1-\sum_{j=1}^n\frac{y_j^2}{s+a_j^2}\right)^m\cdot[\varphi(s)(s+a_k^2)]^{-1}\,ds,\end{aligned}\qquad k=1,2,\cdots,n \tag{5'}$$

and, integrating,

$$V(y)=\frac{(n-2)d_n}{2(m+1)}\int_\lambda^\infty\left(1-\sum_{j=1}^n\frac{y_j^2}{s+a_j^2}\right)^{m+1}\varphi^{-1}(s)\,ds+c. \tag{6}$$

For $y\in E$, λ is replaced by zero in the above integral. The case $m=0$ could be obtained by letting m go to zero in (6). Thus the proof is completed.

Remark. In (6) we see, by letting $|y|\to\infty$, that $V(y)\to 0$ and the absolute value of the integral on the right is bounded by

$$A\int_\lambda^\infty\varphi^{-1}(s)\,ds,\quad\text{where } A=\frac{(n-2)d_n}{2(m+1)}$$

and this goes to zero, as $|y|\to\infty$ (since $\lambda=\lambda(y)\to\infty$). Thus $c=0$.

Remark. Theorem 1.1 is a special case of a much more general theorem, which we state without proof (the proof is similar to the proof of Theorem 1.1). Let g have compact support in $(0,\infty)$ and be (for example) piecewise continuous. Set

$$G(t)=\int_t^\infty g(\tau)\,d\tau.$$

Then

$$\int_{\mathbb{R}^n}\frac{g(\sum_{j=1}^n(x_j^2/a_j^2))\,dx}{(n-2)A_n}=\frac{\varphi(0)}{4}\int_0^\infty\frac{G(\sum_{j=1}^n(y_j^2/(a_j^2+s))\,ds}{\varphi(s)}.$$

We also want to mention that the case $m=0$ (for $n=3$) is the goal of classical papers such as those by Lagrange, Gauss, Chasles, and Dirichlet. For references see § 3.

COROLLARY 1.2. *Let P be as in the notation, and let m be a nonnegative integer. Then the Newtonian potential of E with density P^m is harmonic in the exterior of E and has a harmonic continuation into $E\setminus E_0$.*

Proof. Define

$$W(y)=\frac{c_n}{m+1}\int_\lambda^\infty\varphi^{-1}(s)\left(1-\sum_{j=1}^n\frac{y_j^2}{a_j^2+s}\right)^{m+1}ds,$$

where $c_n = \pi^{n/2} a_1 \cdots a_n (n-2)/2\Gamma(n/2)$, $\lambda = \lambda(y)$ is such that $\sum_{j=1}^{n} (y_j^2/(a_j^2+\lambda)) = 1$. Then it is easy to show that W is real analytic in $\mathbb{R}^n \setminus E_0$. Moreover, by Theorem 1.1, we have $W = V$ in $\mathbb{R}^n \setminus E$, where $V = \int_E (P^m(x)/|x-y|^{n-2})\, dx$. Thus V can be continued into $E \setminus E_0$ as a harmonic function.

THEOREM 1.3. *The Newtonian potential of the ellipsoid E in $\mathbb{R}^n (n \geq 3)$ with polynomial density Q of degree m is a polynomial of degree $m+2$ in the interior of E.*

To prove this theorem we need the following two lemmas, which are essentially due to Ferrers [Fe].

LEMMA 1.4. *Define $\mathcal{B}$ to be*

$$\mathcal{B} = \operatorname{span} \left\{ \sum_{j=0}^{m'} \sum_{|\alpha|=m-2j} b_\alpha \partial^\alpha P^{m-j} \right\}_{m=0}^{\infty},$$

whence

$$m' = \begin{cases} m/2 & m \text{ even}, \\ (m-1)/2 & m \text{ odd}, \end{cases}$$

$$b_\alpha \in \mathbb{R}, \quad \partial^\alpha = \partial_1^{\alpha_1} \partial_2^{\alpha_2} \cdots \partial_n^{\alpha_n}, \quad \partial_j = \frac{\partial}{\partial x_j}$$

and P is as in the notation. Set

$$\mathcal{P} = \{\textit{polynomials in } n \textit{ variables with real coefficients}\}.$$

Then $\mathcal{B} = \mathcal{P}$.

LEMMA 1.5. *Let $m \geqq 0$ be an integer. Then for $|\alpha| \leqq m$,*

$$\int_{P>0} \frac{\partial^\alpha P^m(x)}{\partial x^\alpha} |x-y|^{2-n}\, dx = \frac{\partial^\alpha}{\partial y^\alpha} \int_{P>0} \frac{P^m}{|x-y|^{n-2}}\, dx \quad \forall y \in \mathbb{R}^n. \tag{7}$$

The lemmas will be proved by induction.

Remark. That the derivative in (7) exists depends on the fact that the function $\int_{P>0} P(x)^m |x-y|^{2-n}\, dx$ is of class $C^m(\mathbb{R}^n)$. This in turn depends on the following. Set $g = P^m$ for $P > 0$ and $g = 0$ for $P > 0$. Then $\int_{\mathbb{R}^n} g(x)|x-y|^{2-n}\, dx = \int_{P>0} P^m(x)|x-y|^{2-n}\, dx$ and $g \in C_0^{m-1}(\mathbb{R}^n)$, which implies that $\int_{\mathbb{R}^n} g(x)|x-y|^{2-n}\, dx$ is of class $C^m(\mathbb{R}^n)$.

Proof of Lemma 1.4. Define

$$\mathcal{P}_k = \{\text{polynomials of degree} \leqq k \text{ in } n \text{ variables with real coefficients}\}:$$

(i) $\mathcal{P}_0 \subset \mathcal{B}$ is clear.

(ii) Suppose $\mathcal{P}_k \in \mathcal{B}$. Then we will show that every monomial of the form $x_j x^\gamma$ for $|\gamma| = k$ and $j = 1, 2, \cdots, n$ is in $\mathcal{B}$. Set (without loss of generality) $j = 1$, then $x^\gamma \in \mathcal{B}$ implies

$$x_1 x^\gamma = x_1 \sum_{j=0}^{k'} \sum_{|\alpha|=k-2j} b_\alpha \partial^\alpha P^{k-j} = \sum_{j=0}^{k'} \sum_{|\alpha|=k-2j} b_\alpha [x_1 \partial^\alpha P^{k-j}], \tag{8}$$

where

$$k' = \begin{cases} k/2 & \text{if } k \text{ even}, \\ (k-1)/2 & \text{if } k \text{ odd}. \end{cases}$$

We introduce the notation $\beta = (\alpha_1 + 1, \alpha_2, \cdots, \alpha_n)$, $\sigma = (\alpha_1 - 1, \alpha_2, \cdots, \alpha_n)$. Then by the Leibniz formula

$$-x_1 \partial^\alpha P^{k-j} = \frac{a_1^2}{2(k+1-j)} \partial^\beta P^{k+1-j} + \alpha_1 \partial^\sigma P^{k-j}. \tag{9}$$

Substituting (9) into (8) we have

$$-x_1x^\gamma = \sum_{j=0}^{k'} \sum_{|\alpha|=k-2j} b_\alpha \left(\frac{a_1^2}{2(k+1-j)} \partial^\beta P^{k+1-j} + \alpha_1 \partial^\sigma P^{k-j} \right),$$

i.e., $x_1x^\gamma \in \mathcal{B}$ for all $\gamma = (\gamma_1, \gamma_2, \cdots, \gamma_n)$ and $|\gamma| = k$, which gives that $\mathcal{P}_{k+1} \in \mathcal{B}$, and the proof is completed.

Proof of Lemma 1.5. For $m = 0$ there is nothing to prove. Now let $m > 0$ and $|\alpha| \leqq m$. If $|\alpha| = 0$, then there is nothing to prove, so let $|\alpha| > 0$. Then $\alpha_j > 0$ for some j. So let $j = 1$ and $\alpha' = (\alpha_1 - 1, \alpha_2, \cdots, \alpha_n)$, then

$$\begin{aligned} &\int_{P>0} \frac{\partial^\alpha P^m(x)}{\partial x^\alpha} |x-y|^{2-n}\, dx \\ &\quad = \int_{P>0} \frac{\partial}{\partial x_1} \frac{\partial^{\alpha'} P^m(x)}{\partial x^{\alpha'}} \cdot |x-y|^{2-n}\, dx \\ &\quad = \int_{P>0} \frac{\partial}{\partial x_1} \left(\frac{\partial^{\alpha'} P^m(x)}{\partial x^{\alpha'}} \cdot |x-y|^{2-n} \right) dx - \int_{P>0} \frac{\partial^{\alpha'} P^m(x)}{\partial x^{\alpha'}} \cdot \frac{\partial}{\partial x_1} |x-y|^{2-n}\, dx \\ &\quad = \frac{\partial}{\partial y_1} \int_{P>0} \frac{\partial^{\alpha'} P^m(x)}{\partial x^{\alpha'}} \cdot |x-y|^{2-n}\, dx. \end{aligned} \tag{10}$$

Summing up,

$$\int_{P>0} \frac{\partial^\alpha P^m(x)}{\partial x^\alpha} |x-y|^{2-n}\, dx = \frac{\partial}{\partial y_1} \int_{P>0} \frac{\partial^{\alpha'} P^m(x)}{\partial x^{\alpha'}} \cdot |x-y|^{2-n}\, dx.$$

Proceeding in this way we can move the differential operator ∂^α outside the integral sign, and this will complete the proof of the lemma.

Proof of Theorem 1.3. By Lemma 1.4

$$Q(x) = \sum_{j=0}^{m'} \sum_{|\alpha|=m-2j} b_\alpha \partial^\alpha P^{m-j}$$

and

$$m' = \begin{cases} m/2 & m \text{ even}, \\ (m-1)/2 & m \text{ odd}. \end{cases}$$

Thus

$$\begin{aligned} \int_E Q(x)|x-y|^{2-n}\, dx &= \sum_{j=0}^{m'} \sum_{|\alpha|=m-2j} b_\alpha \int_E \frac{\partial^\alpha P^{m-j}}{\partial x^\alpha} \cdot |x-y|^{2-n}\, dx \\ &= \sum_{j=0}^{m'} \sum_{|\alpha|=m-2j} b_\alpha \frac{\partial^\alpha}{\partial y^\alpha} \int P^{m-j} |x-y|^{2-n}\, dx \quad \text{(by Lemma 1.5).} \end{aligned}$$

Now by Theorem 1.1 the last integral is a polynomial of degree $2m-2j+2$ in the interior of E, and since $|\alpha| = m-2j$, $(\partial^\alpha/\partial y^\alpha) \int P^{m-j}(x)|x-y|^{2-n}\, dx$ is a polynomial of degree $m+2$ in the interior of E. Thus $\int_E Q(x)|x-y|^{2-n}\, dx$ is a polynomial of degree $m+2$ in the interior of E.

Remark. In [DF] the authors prove the following theorem.

THEOREM [DiBenedetto, Friedman]. *Let Ω be a bounded domain in $\mathbb{R}^n$ and suppose that the Newtonian potential of Ω with constant density is a polynomial in the interior of Ω. Then Ω is an ellipsoid.*

It is very natural to ask whether or not this is true when the density is a polynomial. In the following proposition we will show that this is generally not true. But we still have the following problem.

PROBLEM. Give conditions on R (= polynomial) such that

$$\int_\Omega \frac{R(x)}{|x-y|^{n-2}}\,dx = \text{polynomial for } y\in\Omega \Rightarrow \Omega \text{ is an ellipsoid.}$$

PROPOSITION 1.6. *Let $\Omega\subset\mathbb{R}^n$ be a bounded domain and suppose Q is a polynomial such that*

$$Q\equiv 0 \quad \text{on } \partial\Omega. \tag{11}$$

Then the Newtonian potential of Ω with density ΔQ is a constant multiple of Q.

Proof. The proof is an easy consequence of the fact that $\Delta_x|x-y|^{n-2} = c\delta_y$ where δ is the Dirac distribution, and that $Q\equiv 0$ (on $\partial\Omega$). Thus

$$\int_\Omega \frac{\Delta Q}{|x-y|^{n-2}}\,dx = \omega_n Q(y), \qquad y\in\Omega.$$

ω_n is defined in the notation.

2. Application to Cauchy's problem for the Laplace equation. In [KS] the authors conjecture the following.

CONJECTURE [KS]. Let Γ be an analytic hypersurface in $\mathbb{R}^n$ whose Schwarz potential $U_\Gamma(x)$ is real analytic in the domain Ω. Then, for any polynomial $R(x) = R(x_1,\cdots,x_n)$ the solution of the following initial value problem can be continued analytically into Ω:

$$\begin{aligned} &\Delta u = 0 \quad \text{near } \Gamma,\\ &u\equiv R \quad \text{on } \Gamma. \end{aligned} \tag{12}$$

Here we want to prove this conjecture in some special cases, namely $\Gamma=\partial\Omega$, and Ω is such that there exists an increasing sequence of ellipsoids E_i with

$$\Omega = \mathbb{R}^n \Big\backslash \bigcup_{i=1}^{\infty} E_i.$$

(In particular, this holds if Γ is an ellipsoid.) It is not difficult to show that $\partial\Omega$ is a hyperplane or a (elliptic or parabolic) quadratic hypersurface if $\partial\Omega$ is not empty.

First we prove the following lemma.

LEMMA 2.1. *Let E_i be an increasing sequence of ellipsoids such that*

$$\mathbb{R}^n \neq \overline{\bigcup_{i=1}^{\infty} E_i}.$$

Set $\Omega' := \bigcup_{i=1}^{\infty} E_i$ and let (without loss of generality) $0^\delta \notin \bar{\Omega}'$. Then the generalized Newtonian potential of Ω' with respect to $a=0$ with polynomial density R is a polynomial of degree deg $R+2$, *in the interior of Ω'.*

Remark. Since $K_m^a(x,y) = O(|y|^m/|x|^{m+n-2})$ for $|x|$ large, the generalized Newtonian potential is well defined.

Proof. Define $N_i(y) = \int_{E_i} K_m(x,y)R(x)\,dx$ and $N(y) = \int_\Omega K_m(x,y)R(x)\,dx$. Then by Theorem 1.3, $N_i(y)$ is a polynomial in E_i and $N_i(y)$ converges uniformly to $N(y)$ on each compact subset of Ω'. Thus, $N(y)$ is a polynomial in the interior of Ω'.

THEOREM 2.2. *Let E_i, $i=1,2,\cdots$, and Ω' be as in Lemma* 2.1. *Then the solution of* (12) *is real analytic in $\Omega := \mathbb{R}^n\backslash\Omega'$.*

Proof (without loss of generality $0 \notin \bar{\Omega}'$). Let R be the polynomial in (12). Then, by Lemma 2.1, the generalized Newtonian potential of Ω' with respect to zero with density ΔR is a polynomial in the interior of $\mathbb{R}^n \setminus \Omega = \Omega'$. Define Q to be the polynomial such that

$$Q(y) = \int_{\Omega'} K_m(x, y) \Delta R \, dx \quad \forall y \in \Omega' = \mathbb{R}^n \setminus \Omega.$$

Set $u_0 = Q(y) - \int_{\Omega'} K_m(x, y) \Delta R \, dx$ in Ω, and let u be the solution of (12) with $\Gamma = \partial\Omega$, i.e.,

$$\begin{aligned} \Delta u &= 0 \quad \text{near } \partial\Omega, \\ u &\equiv R \quad \text{on } \partial\Omega. \end{aligned}$$

Since $Q(y) \equiv \int_{\Omega'} K_m(x, y) \Delta R(x) \, dx$ on $\partial\Omega$ we have

$$\begin{aligned} \Delta u_0 &= \Delta R \quad \text{in } \Omega, \\ u_0 &\equiv 0 \quad \text{on } \partial\Omega. \end{aligned} \tag{13}$$

Define

$$v = \begin{cases} R - u_0 & \text{in } \Omega, \\ u & \text{in } \Omega' = \mathbb{R}^n \setminus \Omega. \end{cases}$$

Since $u \equiv R - u_0$ on $\partial\Omega$, u is harmonic near $\partial\Omega$ and $R - u_0$ is harmonic in Ω. They are the harmonic continuations of each other (see [Ke, p. 261]), and v will be harmonic in a neighborhood of $\partial\Omega$. Now, by the uniqueness part of the Cauchy-Kowalevsky theorem, $u = v$, that is, $u = R - u_0$ in Ω. Then by (13), $\Delta u = 0$ in Ω, i.e., u is harmonic in Ω and the proof is completed.

Remark. In Theorem 2.2 when $E_i = E$ for all i we obtain $u_0 = Q(y) - \omega_n^{-1} \int_E \Delta R \cdot |x - y|^{2-n} \, dx$, where Q is a polynomial such that

$$Q(y) = \omega_n^{-1} \int_E |x - y|^{2-n} \Delta R(x) \, dx$$

for all $y \in E$. Now define

$$v = \begin{cases} R - u_0 & \text{in } \Omega = \mathbb{R}^n \setminus E, \\ u & \text{in } E. \end{cases}$$

Then as in the above theorem, $u = v$ in $\mathbb{R}^n$, and u_0 is analytic in $\Omega = \mathbb{R}^n \setminus E$, and by Corollary 1.2, in conjunction with Lemmas 1.4 and 1.5, it has a continuation into $E \setminus E_0$. Thus the Schwarz potential of ∂E is harmonic in $\mathbb{R}^n \setminus E_0$.

Remark. For a ball B centered at x_0, we get that the solution of (12) with

Γ = the boundary of B has a harmonic continuation into $\mathbb{R}^n \setminus \{x_0\}$.

3. Concluding remarks. The kernel K_m appears, for a general elliptic operator, earlier in L. Nirenberg and H. F. Walker [NW].

The following are some references mentioned earlier. A. Wangerin, ed., *Über die Anziehung homogener Ellipsoide, Abhandlungen von Laplace* (1782), *Ivory* (1809), *Gauss* (1813), *Chasles* (1838) *and Dirichlet* (1839) [W].

As for the case $n = 2$, the only reason we left it out is the passage of formula (5′) to (6). In (6) we obtain that

$$v(0) = \frac{c_n}{m+1} \int_\lambda^\infty \frac{ds}{\varphi(s)},$$

where $\varphi^2(s) = (a_1^2 + s)(a_2^2 + s)$, i.e., $\varphi^{-1} \notin L^1(\lambda, \infty)$, hence $v(0) = \infty$. Thus this formula ceases to be true for $n = 2$. But at any rate we do have an explicit formula for v_k (which

is (5')). All other results here are true for $n = 2$, and we just have to replace the potential $|x-y|^{2-n}$ by $\log|x-y|^{-1}$.

Acknowledgments. I thank Professor Harold S. Shapiro for suggesting the problem to me and encouraging me during this work. I also thank Lavi Karp for showing me his (unpublished) work on the generalized Newtonian potential and D. Khavinson for suggesting some improvements in an earlier version of this report.

ARTIFICIAL BOUNDARY CONDITIONS FOR INCOMPLETELY PARABOLIC PERTURBATIONS OF HYPERBOLIC SYSTEMS*

LAURENCE HALPERN†

Abstract. Artificial boundary conditions are devised for small incompletely parabolic perturbations of hyperbolic systems, which are local, consistent with the hyperbolic equation, well posed, and produce weak boundary layers. The general strategy is applied to the Navier-Stokes system.

Key words. artificial boundary conditions, Navier-Stokes equations

AMS(MOS) subject classifications. 35B25, 35Q10, 35G10

Introduction. A general model for a fluid motion is the following time-dependent compressible Navier-Stokes system:

$$\frac{\partial \rho}{\partial t} + \operatorname{div} \rho v = 0,$$

$$\frac{\partial \rho v}{\partial t} + \operatorname{div} (\rho v \cdot v + pI) = \rho g + \operatorname{div} \mu\tau,$$

$$\frac{\partial e}{\partial t} + \operatorname{div} (e+p)v = \rho g \cdot v + \operatorname{div} (K \operatorname{grad} T + \mu v \cdot \tau),$$

where ρ represents the density, p the pressure, T the temperature, and v the velocity of the fluid. τ is the momentum flux density tensor due to friction: $\tau = -\frac{2}{3} I \operatorname{div} v + \operatorname{grad} v + (\operatorname{grad} v)^{\tau}$. μ and K are the coefficients of viscosity and heat conductivity, respectively. An equation of state relating ρ, p, and T is added to close the system. Those equations are a special case of a class of equations called incompletely parabolic equations.

Although the mathematical analysis of these nonlinear equations is not entirely satisfactory, and due to the increasing complexity of the physical problems involved, the Navier-Stokes model is more and more widely used in today's computational fluid dynamics.

In many problems of interest, the computational domain is infinite, so that an important task is the design and analysis of reliable numerical boundary conditions. Very often the Euler equations have replaced the Navier-Stokes system in computations (i.e., assuming the viscosity and heat conductivity coefficients negligible). In that case stable boundary conditions are provided by prescribing the entering characteristic quantities (see, for instance, [OS]). For better accuracy strategies were described in [EM1], [EM2], and [BT1], [BT2], [BT3], which led to higher-order differential operators on the boundary.

For the Navier-Stokes system, it is well known that more boundary conditions are needed to ensure the well posedness. Considering the Navier-Stokes equation as a perturbation of the Euler system, it has been suggested that extra boundary conditions

* Received by the editors August 7, 1989; accepted for publication (in revised form) August 28, 1990. This work was completed while the author was visiting the University of California, Berkeley, California, and was supported by Office of Naval Research grant N00014-86-K-0691.

† Ecole Polytechnique, Centre de Mathématiques appliquées, 91128 Palaiseau Cedex, France, and Département de Mathématiques et Informatique, Centre Scientifique et Polytechnique, Université Paris Nord, 93430 Villetaneuse, France.

be added to those derived for the Euler system [OS]. The artificial boundary is usually set in a "smooth" region, where the equations can be linearized about a regular state (in general, it is supposed to be constant). The derivation and analysis can then be carried out for the linear equation. In [GS] boundary conditions were built by adding conditions on the normal derivatives to the "hyperbolic" boundary conditions to produce dissipation. In [RS1] and [RS2] "hyperbolic" boundary conditions were tested for a flow over a flat plate to force the convergence to the steady state. More recently in [ABL] Abarbanel, Bayliss, and Lustman worked directly on the Navier-Stokes equation for the flow past an airplane. They decoupled the domain into the boundary layer region and the hyperbolic region, and in the former region used a modal expansion and an approximation of the solution. This approximation is made in the regime of long wavelength.

We develop here a general strategy for the derivation of artificial boundary conditions for incompletely parabolic perturbations of hyperbolic systems. Because of the remark above we shall consider linear systems with constant coefficients. Using the Fourier transform as an essential tool, we shall write artificial boundary conditions for a half-space in such a way that the well posedness and the convergence to the hyperbolic equation are ensured by the well posedness of a reduced hyperbolic problem. The strategy has been introduced in [H] and [HS] for incompressible flows and consists of expanding the modes in terms of the small parameter ν. For the analysis of these boundary conditions we shall rely on the results by Strikwerda in [S] on the well posedness of incompletely parabolic systems, and by Michelson in [M] on the boundary layer expansion and convergence to the "inviscid" equation. This strategy theoretically allows for a convergence up to any accuracy, but the well posedness is not guaranteed (note that in the hyperbolic case, no well-posedness proof is available for general artificial boundary condition; see [EM1]).

Consider an incomplete singular perturbation of a hyperbolic system, i.e.,

$$\frac{\partial w}{\partial t} = \sum_{j=1}^{N} A^{(j)} \frac{\partial w}{\partial x_j} + \nu \sum_{j,k=1}^{N} P^{(jk)} \frac{\partial^2 w}{\partial x_j \, \partial x_k} + F(x, t), \tag{0.1}$$

where the $n \times n$ matrices $P^{(jk)}$ are assumed of the form

$$P^{(jk)} = \begin{pmatrix} \bar{P}^{(jk)} & 0 \\ 0 & 0 \end{pmatrix} \tag{0.2}$$

with rank $\bar{P}^{(jk)} = r$, $\bar{P}^{(jk)}$ is nonsingular, and $P^{(jk)} = P^{(kj)}$. The matrices $A^{(j)}$ are partitioned in the same way:

$$A^{(j)} = \begin{pmatrix} B^{(j)} & C^{(j)} \\ D^{(j)} & \bar{A}^{(j)} \end{pmatrix}. \tag{0.3}$$

We require the operator $\partial_t - \sum_{j=1}^{N} A^{(j)} \partial_j$ to be hyperbolic, the partial operator $\partial_t - \nu \sum_{j=1}^{N} \bar{P}^{(jk)} \partial_{jk}$ to be Petrovski parabolic, and the reduced operator $\partial_t - \sum_{j=1}^{N} \bar{A}^{(j)} \partial_j$ to be strictly hyperbolic. These assumptions ensure the well posedness of the Cauchy problem. In order to consider an initial boundary value problem in a half-space $x_1 > 0$ or $x_1 < 0$, we shall assume that the boundary $\Gamma = \{x_1 = 0\}$ is noncharacteristic, i.e., that $A^{(1)}$ is nonsingular. Its eigenvalues are denoted by $\lambda_1, \cdots, \lambda_n$ where $\lambda_1, \cdots, \lambda_m$ are negative and $\lambda_{m+1}, \cdots, \lambda_n$ are positive. The corresponding eigenvectors are $\Lambda^1, \cdots, \Lambda^n$. For convenience and simplicity, we shall assume that $\bar{A}^{(1)}$ is a diagonal matrix, with p negative eigenvalues:

$$\bar{A}^{(1)} = \begin{pmatrix} \bar{A}^{(1)^-} & 0 \\ 0 & \bar{A}^{(1)^+} \end{pmatrix} \tag{0.4}$$

where

$$\bar{A}^{(1)^-} = \begin{pmatrix} \bar{\lambda}_{1+r} & & \\ & \ddots & \\ & & \bar{\lambda}_{p+r} \end{pmatrix} < 0, \qquad \bar{A}^{(1)^+} = \begin{pmatrix} \bar{\lambda}_{p+r+1} & & \\ & \ddots & \\ & & \bar{\lambda}_{n} \end{pmatrix} > 0.$$

We further assume the existence of a symmetrizer S for the full operator

$$Q = \sum_{j=1}^{N} A^{(j)} \frac{\partial}{\partial x_j} + \nu \sum_{j=1}^{N} P^{(jk)} \frac{\partial^2}{\partial x_j \, \partial x_k}, \tag{0.5}$$

which implies in particular that the symbol of Q,

$$Q(i\xi) = i \sum_{j=1}^{N} A^{(j)} \xi_j - \nu \sum_{j=1}^{N} P^{(jk)} \xi_j \xi_k, \tag{0.6}$$

is diagonalizable through a transformation analytic in ξ. S is a symmetric positive-definite matrix. We shall denote by $\tilde{A}^{(j)}$ and $\tilde{P}^{(jk)}$ the symmetrized matrices $\tilde{A}^{(j)} = SA^{(j)}$, $\tilde{P}^{(jk)} = SP^{(jk)}$. Both the Navier-Stokes and shallow-water systems fulfill all the conditions above.

In § 1 we shall recall the modal analysis for the Cauchy problem. Most results in this section are known (see, for instance, [YS] for Navier-Stokes, [S] for the general case), but we need to set our notation clearly.

In § 2 we derive the local and nonlocal boundary conditions for a half-space. The transparent boundary condition is first written in terms of generalized eigenvalues and eigenfunctions for the system. It is then approximated with respect to the small parameter ν we shall call viscosity for obvious reasons. This yields boundary conditions that are differential of first order in the normal direction, but still integral in time and the tangential derivatives (like the transparent boundary condition for the pure hyperbolic problem). Those boundary conditions are, in turn, approximated by differential operators which are of order zero in time and one in the tangential direction, using the strategy in [EM1].

In § 3, necessary and sufficient conditions for the well posedness of the corresponding initial boundary value problem are set. The same conditions ensure the convergence to the unperturbed hyperbolic problem, with an error estimate. These results are a direct application of the general analysis in [M].

In § 4 the construction above is carried out explicitly for the two-dimensional compressible Navier-Stokes system.

Finally in § 5, we indicate how to produce more accurate boundary conditions. For the sake of clarity, explicit calculations are made in the special case of the two-dimensional linearized shallow water equation. Nevertheless, the construction carries over to any incompletely parabolic system provided the diagonalizability assumption (0.6) is fulfilled.

1. The Cauchy problem.

1.1. Normal modes for the Cauchy problem. The following analysis can be partly found in [S], but we include it here in order to set our notation and to study more particularly the eigenmodes as functions of the parameter ν.

The normal modes are the solutions of (0.1) with $F \equiv 0$, of the type

$$w = e^{st + \xi x_1 + i\eta \cdot y} \Phi, \qquad \text{Re } s \geqq 0,$$

where

$$x=(x_1,\cdots,x_N),\qquad y=(x_2,\cdots,x_N).$$

They satisfy the equation

$$(Q(\xi, i\eta)-sI)\Phi=0. \tag{1.1}$$

Here s and $i\eta$ are the independent variables and ξ is considered as a function of (s,η). The equation in ξ is of order $n+r$. By an abuse of notation, but for simplicity, we shall often refer to ξ as a "generalized eigenvalue."

We shall first need a general lemma on matrices.

LEMMA 1.1. *Let M and S be two matrices of same order n. If M is nonnegative, if S is symmetric positive definite, and moreover if SM is symmetric, then SM is nonnegative.*

Let us recall that a matrix M is nonnegative if for any u, $(Mu,u)\geqq 0$, where $(\cdot,\cdot)$ denotes the usual scalar product. M is positive definite if there exists a constant $\alpha>0$ such that for any u, $(Mu,u)\geqq\alpha\|u\|^2$.

Proof. For convenience, we choose a basis where S is diagonal: $S=\operatorname{diag}(s_1,\cdots,s_n)$, $M=(m_{ij})$. Using the identity $SM=M^TS$, we can write $(Mu,u)=(Nv,v)$, where $u=Sv$, and N is defined by

$$n_{ij}=\frac{1}{2}s_is_j\left(1+\frac{s_i}{s_j}\right)m_{ij},\qquad i\leqq j,$$

$$n_{ij}=n_{ji},\qquad i>j.$$

On the other hand, we can express SM as

$$(SMu,u)=2(Cu,u),$$

where

$$c_{ij}=\frac{1}{s_i+s_j}n_{ij}.$$

We know that a matrix defines a nonnegative bilinear form if and only if all the principal minors are nonnegative. For the matrix $1/(s_i+s_j)$, they are equal for $k\leqq n$ to

$$\frac{\prod_{i<j\leqq k}(s_i-s_j)^2}{2^k\Pi s_i\prod_{i<j\leqq k}(s_i+s_j)^2}.$$

We now use the following classical result: if A and B are two symmetric nonnegative matrices, the matrix whose general term is $a_{ij}b_{ij}$ is also nonnegative. Hence C is nonnegative and the proof is complete.

LEMMA 1.2. *For* $\operatorname{Re} s>0$, *there are precisely $(r+p)$ generalized eigenvalues ξ with a negative real part, and $n-p$ with a positive real part.*

Proof. We first prove that there are no purely imaginary generalized eigenvalues. Let us assume that $\xi=i\zeta$, where ζ is a real number. We apply S to (1.1) and multiply by Φ. We now take the real part of the Hermitian product:

$$\nu\left(\left(\sum\tilde{P}^{(jk)}\psi_j\psi_k\right)\Phi,\Phi\right)+\operatorname{Re}s(S\Phi,\Phi)=0,\qquad \psi=(\zeta,\eta_2,\cdots,\eta_n).$$

By assumption, the matrix $\sum P^{(jk)}\psi_j\psi_k$ is nonnegative, and so is $\sum\tilde{P}^{(jk)}\psi_j\psi_k$ by Lemma 1.1. If $\operatorname{Re}s>0$, since $(S\Phi,\Phi)$ is positive, we obtain the contradiction.

Now let N_+ be the number of eigenvalues ξ such that $\operatorname{Re}\xi<0$, and N_- the number of eigenvalues ξ such that $\operatorname{Re}\xi>0$. We have $N_+ + N_- = r+n$, from above. N_+ and N_- are constant functions of η and s. Furthermore, they are constant functions of A and P, as long as, for instance, $P^{(11)} \neq 0$.

Let us choose $\eta = 0$ and $B^{(1)} = C^{(1)} = D^{(1)} = 0$. Equation (1.1) for ξ reads

$$\det[\nu P^{(11)}\xi^2 + A^{(1)}\xi - sI] = 0 \quad \text{or}$$

$$\det[\nu \bar{P}^{(11)}\xi^2 - sI] \cdot \det[\bar{A}^{(1)}\xi - sI] = 0.$$

N_+ (respectively, N_-) is then the number of solutions with positive real part (respectively, negative) of the equations

$$\det[\nu \bar{P}^{(11)}\xi^2 - sI] = 0, \qquad \det[\bar{A}^{(1)}\xi - sI] = 0.$$

The first equation is even in ξ. Hence there are r solutions with positive real part and r with negative real part. Moreover, the second equation reduces to $\xi = s/\bar{\lambda}_i$, which gives p values with a negative real part and $n-r-p$ with a positive real part. So

$$N^+ = r+p, \qquad N^- = r+n-r-p = n-p.$$

We now turn to the behavior of these generalized eigenvalues ξ as the parameter ν tends to zero.

THEOREM 1.1. *If* $\operatorname{Re} s>0$, *as* ν *tends to zero,* r *values of* ξ *tend to infinity as* $1/\nu$, *and* n *values have a finite limit.*

Proof. Let us write $\xi = \alpha + 0(\nu)$, where α is a solution to

$$\det\left[A^{(1)}\alpha + \sum_{j\neq 1} iA^{(j)}\eta_j - sI\right] = 0. \tag{1.2}$$

By assumption this equation has n solutions, denoted by $\alpha_1(s,\eta), \cdots, \alpha_n(s,\eta)$, and

$$\begin{aligned} &1 \leqq j \leqq m, \qquad \operatorname{Re}\frac{\alpha_j}{s} \leqq 0, \\ &m+1 \leqq j \leqq n, \qquad \operatorname{Re}\frac{\alpha_j}{s} \geqq 0 \end{aligned} \tag{1.3}$$

to any α_j is associated an eigenvector $\Pi^j(s,\eta)$, and $\Pi^1, \cdots, \Pi^n$ span $\mathbf{R}^n$

$$\left(A^{(1)}\alpha_k + \sum_{j\neq 1} iA^{(j)}\eta_j - sI\right)\Pi^k = 0. \tag{1.4}$$

If now $\xi = \theta/\nu + O(1)$, θ is a solution of

$$\det(P^{(11)}\theta + A^{(1)}) = 0, \tag{1.5}$$

which is an equation of degree r in θ, and has r roots $\theta_1 \cdots \theta_r$, then $\theta_1, \cdots, \theta_{r+p-m}$ are such that $\operatorname{Re}\theta_j < 0$, and $\theta_{r+p-m+1}, \cdots, \theta_r$ are such that $\operatorname{Re}\theta_j > 0$. The corresponding generalized eigenvectors $\Theta^1 \cdots \Theta^r$ are defined by

$$(P^{(11)}\theta_j + A^{(1)})\Theta^j = 0. \tag{1.6}$$

In summary, every solution (ξ, Φ) of $(Q(\xi, i\eta) - sI)\Phi = 0$ for $\operatorname{Re} s>0$ is such that either

$$\xi(s,\eta,\nu) = \alpha(s,\eta) + O(\nu), \qquad \Phi(s,\eta,\nu) = \Pi(s,\eta) + O(\nu),$$

where

$$\left[A^{(1)}\alpha+\sum_{j\neq 1} i\eta_j A^{(j)}-sI\right]\Pi=0$$

or

$$\xi(s,\eta,\nu)=\frac{1}{\nu}\theta+O(1),\qquad \Phi(s,\eta,\nu)=\Theta+O(\nu),$$

where

$$(P^{(11)}\theta+A^{(1)})\Theta=0.$$

We shall denote by $\xi_1\cdots\xi_m$ the values of ξ of the first form with negative real part, i.e., corresponding to "propagating modes," and $\xi_{m+1}\cdots\xi_{r+p}$ the values of ξ of the second form with negative real parts. We define $\zeta_j(s,\eta)$ and $\psi_j(s,\eta)$ as follows:

$$\begin{aligned} &1\leqq j\leqq m, \qquad \xi_j(s,\eta,\nu)=\zeta_j(s,\eta)+O(\nu),\\ &m+1\leqq j\leqq r+p, \qquad \xi_j(s,\eta,\nu)=\frac{1}{\nu}\zeta_j(s,\eta)+O(1) \end{aligned} \tag{1.7}$$

(ζ_j does not actually depend on s and η if $j\geqq m+1$) and

$$1\leqq j\leqq r+p, \qquad \Phi^j(s,\eta,\nu)=\Psi^j(s,\eta)+O(\nu), \tag{1.8}$$

so that

$$\begin{aligned} &1\leqq j\leqq m, \quad \zeta_j(s,\eta)=\alpha_j(s,\eta), \quad \Psi^j(s,\eta)=\Pi^j(s,\eta),\\ &m+1\leqq j\leqq r+p, \quad \zeta_j(s,\eta)=\theta_{j-m}, \quad \Psi^j(s,\eta)=\Theta^{j-m}. \end{aligned} \tag{1.9}$$

1.2. The transmission conditions. Let us first write a weak formulation of (0.1) in a domain Ω with smooth boundary $\partial\Omega$. For any v sufficiently smooth, we multiply (0.1) by S, apply it to v, and integrate on Ω. Using the Green formulas

$$\int_\Omega\left(\tilde{A}^{(j)}\frac{\partial w}{\partial x_j},v\right)+\int_\Omega\left(\tilde{A}^{(j)}w,\frac{\partial v}{\partial x_j}\right)=\int_{\partial\Omega}(\tilde{A}^{(j)}w,v)n_j,$$

$$\sum_{j,k=1}^N\int_\Omega\left(\tilde{P}^{(j,k)}\frac{\partial^2 w}{\partial x_j\,\partial x_k},v\right)+\sum_{j,k=1}^N\int_\Omega\left(\tilde{P}^{(j,k)}\frac{\partial w}{\partial x_j},\frac{\partial v}{\partial x_k}\right)$$
$$=\sum_{j,k=1}^N\int_{\partial\Omega}\left(\tilde{P}^{(j,k)}\frac{\partial w}{\partial x_j},v\right)n_k,$$

where n is the normal exterior to $\partial\Omega$, we get

$$\int_\Omega\left(S\frac{\partial w}{\partial t},v\right)+\nu\sum_{j,k=1}^N\int_\Omega\left(\tilde{P}^{(j,k)}\frac{\partial w}{\partial x_j},\frac{\partial v}{\partial x_k}\right)$$
$$+\frac{1}{2}\sum_{j=1}^N\int_\Omega\left[\left(\tilde{A}^{(j)}\frac{\partial v}{\partial x_j},w\right)-\left(\tilde{A}^{(j)}\frac{\partial w}{\partial x_j},v\right)\right]$$
$$=\nu\int_\Gamma\sum_{j,k=1}^N\left(\tilde{P}^{(jk)}\frac{\partial w}{\partial x_j},v\right)n_k+\frac{1}{2}\int_\Gamma\sum_{j=1}^N(A^{(j)}w,v)n_j+\int_\Omega Fv.$$

We define two bilinear forms a and p, by

$$
\begin{aligned}
a(v, w) &= \frac{1}{2}\int_\Omega \sum_{j=1}^{N}\left[\left(\tilde{A}^{(j)}\frac{\partial v}{\partial x_j}, w\right)-\left(\tilde{A}^{(j)}\frac{\partial w}{\partial x_j}, v\right)\right] dx,\\
p(v, w) &= \int_\Omega \sum_{j,k=1}^{N}\left(\tilde{P}^{(j,k)}\frac{\partial w}{\partial x_j}, \frac{\partial v}{\partial x_k}\right),
\end{aligned}
\tag{1.10}
$$

where a is antisymmetric and p is symmetric, nonnegative (Lemma 1.1).

S being symmetric definite positive, defines a scalar product

$$
s(w, v) = \int_\Omega (Sw, v)\, dx \tag{1.11}
$$

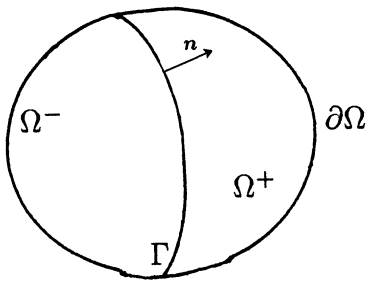
and we can write

$$
s\left(\frac{\partial w}{\partial t}, v\right) + \nu p(v, w) + a(v, w) - \int_{\partial\Omega} (S\mathscr{E}w, v)\, d\gamma = \int_\Omega Fv, \tag{1.12}
$$

where $\mathscr{E}w$ is the normal stress

$$
\mathscr{E}w = \sum_{k=1}^{n}\left(\nu\sum_j P^{(jk)}\frac{\partial w}{\partial x_j} + \frac{1}{2}A^{(k)}w\right)n_k. \tag{1.13}
$$

Suppose now that $\Omega = \Omega^- \cup \Omega^+$,



the orientation of n being from Ω^- to Ω^+. We define a^-, a^+, p^-, p^+, s^-, s^+ as we did for a, p, s, but the integral being taken over Ω^- and Ω^+, respectively. Let v be compactly supported in Ω. We thus have

$$
s\left(\frac{\partial w}{\partial t}, v\right) + \nu p(v, w) + a(v, w) = \int_\Omega Fv, \tag{1.14}
$$

but

$$
\begin{aligned}
p(v, w) &= p^+(v, w) + p^-(v, w),\\
a(v, w) &= a^+(v, w) + a^-(v, w),\\
s\left(\frac{\partial w}{\partial t}, v\right) &= s^+\left(\frac{\partial w}{\partial t}, v\right) + s^-\left(\frac{\partial w}{\partial t}, v\right),
\end{aligned}
$$

and we can write

$$
s^\pm\left(\frac{\partial w^\pm}{\partial t}, v\right) + \nu p^\pm(w^\pm, v) + a^\pm(w^\pm, v) - \int_{\partial\Omega^\pm} (S\mathscr{E}w^\pm, v)\, d\gamma = \int_{\Omega^\pm} F^\pm v, \tag{1.15}^\pm
$$

where $F^\pm = F/\Omega^\pm$ and $w^\pm = w/\Omega^\pm$, so that adding $(1.15)^+$ and $(1.15)^-$, and subtracting

from (1.14) we get

$$\int_{\partial\Omega^+} (S\mathscr{E}w, v)\, d\gamma + \int_{\partial\Omega^-} (S\mathscr{E}w, v)\, d\gamma = 0.$$

Since v is compactly supported in Ω, $\partial\Omega^{\pm}$ reduces to Γ and $(\mathscr{E}w)^- = (\mathscr{E}w^-)|_\Gamma$ if w is defined in Ω^-, $(\mathscr{E}w)^+ = (\mathscr{E}w^+)|_\Gamma$ if w is defined in Ω^+, and the normal on Γ is exterior to Ω^- (thus interior to Ω^+). The transmission conditions then read

$$\begin{aligned} &(\mathscr{E}w)^- = (\mathscr{E}w)^+ \\ &w^- = w^+ \end{aligned} \quad \text{on } \Gamma, \tag{1.16}$$

or

$$\sum_{k=1}^{N} \left(\nu \sum_j P^{(jk)} \frac{\partial w^-}{\partial x_j} + \frac{1}{2} A^{(k)} w^- \right) n_k = \sum_{k=1}^{N} \left(\nu \sum_j P^{(jk)} \frac{\partial w^+}{\partial x_j} + \frac{1}{2} A^{(k)} w^+ \right) n_k. \tag{1.17}$$

In particular, if $\Omega = \mathbf{R}^n$, $\Omega^- = \{x_1 < 0\}$, $\Omega^+ = \{x_1 > 0\}$, so that $\Gamma = \{x_1 = 0\}$, then the transmission conditions are

$$\begin{cases} \nu \sum_{j=1}^{N} \bar{P}^{(j1)} \dfrac{\partial w^-}{\partial x_j} = \nu \sum_{j=1}^{N} \bar{P}^{(j1)} \dfrac{\partial w^+}{\partial x_j} \\ w^- = w^+ \end{cases} \quad \text{on } \Gamma. \tag{1.18}$$

Condition (1.18) is equivalent to (1.16). The Green formula with the constraints is more useful when we want to prove the well posedness through energy estimates, and it is the reason we include it here. Again, (1.18) can also be written

$$w^- = w^+, \qquad \frac{\partial w^{-I}}{\partial x_1} = \frac{\partial w^{+I}}{\partial x_1}, \tag{1.19}$$

where (w^I, w^{II}) corresponds to the decomposition of the matrices $P^{(jk)}$, i.e.,

$$w^I = (w_1, \cdots, w_r), \qquad w^{II} = (w_{r+1}, \cdots, w_n), \tag{1.20}$$

but we prefer to use the form (1.18), which seems more fitted to the multidimensional case.

2. Derivation of the artificial boundary conditions. We shall use the transmission conditions we wrote above to derive the transparent boundary condition. Let F and w^0 be compactly supported in Ω^-; consider the Cauchy problem:

$$\begin{cases} \dfrac{\partial w}{\partial t} = \sum_{j=1}^{N} A^{(j)} \dfrac{\partial w}{\partial x_j} + \nu \sum_{j,k=1}^{N} P^{(jk)} \dfrac{\partial^2 w}{\partial x_j\, \partial x_k} + F(x, t), \\ w(0) = w^0. \end{cases} \tag{2.1}$$

It is equivalent to the transmission problem

$$\begin{cases} \dfrac{\partial w^-}{\partial t} - Qw^- = F(x, t) \quad \text{in } \Omega^-, \\ w^-(0) = w^0, \end{cases} \tag{2.2}$$

$$\begin{cases} \dfrac{\partial w^+}{\partial t} - Qw^+ = 0 \quad \text{in } \Omega^+, \\ w^+(0) = 0 \end{cases} \tag{2.3}$$

with the transmission conditions

$$\begin{cases} \nu \sum_1^N \bar{P}^{(j1)} \dfrac{\partial w^-}{\partial x_j} = \nu \sum_1^N \bar{P}^{(j1)} \dfrac{\partial w^+}{\partial x_j} \\ w^- = w^+ \end{cases} \quad \text{on } \Gamma. \tag{2.4}$$

2.1. The transparent boundary condition. We introduce the initial boundary value problem in Ω^+:

$$\frac{\partial w}{\partial t} - Qw = 0 \quad \text{in } \Omega^+, \tag{2.5a}$$

$$w(t=0) = 0, \tag{2.5b}$$

$$\begin{pmatrix} w_1 \\ \vdots \\ w_{r+p} \end{pmatrix} = g \quad \text{on } \Gamma. \tag{2.5c}$$

THEOREM 2.1. *The boundary value problem* (2.5) *is strongly well posed. The solution is given in Fourier variables* (η, s) *by*

$$\hat{w}(x_1, \eta, s) = \sum_{i=1}^{r+p} \lambda_i e^{\xi_i x_1} \Phi^i, \tag{2.6}$$

where (ξ_i, Φ^i) *are defined in* (1.1) *and the coefficients* λ_i *are determined by the boundary conditions.*

Proof. According to Strikwerda [S], the problem is strongly well posed if and only if the two initial boundary value problems

$$\begin{cases} \dfrac{\partial w^I}{\partial t} = \nu \sum_{j,k=1}^N \bar{P}^{(jk)} \dfrac{\partial^2 w^I}{\partial x_j \, \partial x_k}, \\ w^I = g^I \quad \text{on } \Gamma, \end{cases}$$

and

$$\begin{cases} \dfrac{\partial w^{II}}{\partial t} = \sum_{j=1}^N \bar{A}^{(j)} \dfrac{\partial w^{II}}{\partial x_j}, \\ \begin{pmatrix} w_{r+1} \\ \vdots \\ w_{r+p} \end{pmatrix} = \begin{pmatrix} g_{r+1} \\ \vdots \\ g_{r+p} \end{pmatrix} \quad \text{on } \Gamma \end{cases}$$

are strongly well posed. The first problem is a strongly parabolic problem with a Dirichlet boundary condition, and hence is strongly well posed. As for the second one, since $\bar{A}^{(j)}$ is diagonal, the boundary condition reduces to specifying the entering characteristics which is, again, a strongly well posed problem.

Let us now consider Fourier-Laplace transform (2.5a) with respect to t and y. The corresponding variables are (s, η), with $\operatorname{Re} s > 0$. We then get a second-order ordinary differential equation, whose solution is

$$\hat{w} = \sum \lambda_i e^{\xi_i x_1} \Phi^i,$$

where (ξ_i, Φ^i) are given in (1.1), since we supposed that $Q(i\xi)$ was diagonalizable. In order for $\hat{w}$ to be in L^2, the coefficients λ_i must vanish when $\operatorname{Re} \xi_i \geqq 0$. We thus are led to (2.6).

Remark. We have assumed that Q was diagonalizable, so the $(\Phi_k^i)_{1 \leqq i,k \leqq r+p}$ is a nonsingular matrix and thus the boundary condition determines the λ_i's.

THEOREM 2.2. *The transparent boundary condition at* Γ *for the half-space* Ω^- *is*

$$\nu \sum_{j=1}^{N} \bar{P}^{(1j)} \frac{\partial \hat{w}^I}{\partial x_j} = \nu \sum_{j=1}^{r+p} \bar{P}^{(11)} \sum_{i=1}^{r+p} \xi_i M_{ij}^{-1} \Phi^{iI} \hat{w}_j + \nu \sum_{l \neq 1} i\eta_l \bar{P}^{(l1)} \hat{w}^I, \tag{2.7a}$$

$$\hat{w}_k = \sum_{i=1}^{r+p} \sum_{j=1}^{r+p} M_{ij}^{-1} \hat{w}_j \Phi_k^i, \qquad k = r+p+1, \cdots, n, \tag{2.7b}$$

where (M_{ij}) *is the* $(r+p)\times(r+p)$ *matrix defined by*

$$M_{ij} = \Phi_i^j, \quad \textit{and} \quad M^{-1} \textit{ is the inverse of } M. \tag{2.8}$$

Proof. w^+ is the solution in Ω^+ of the initial boundary problem (2.5) with $g_k = w_k^-$, $1 \leqq k \leqq r+p$. Theorem 2.1 then enables us to calculate explicitly w_k^+, $r+p+1 \leqq k \leqq n$ and $\partial w^{+I}/\partial x_j$. The transmission conditions then give the result

$$\nu \sum_{j=1}^{N} \bar{P}^{(1j)} \frac{\partial \hat{w}^I}{\partial x_j} = \nu \bar{P}^{(11)} \frac{\partial \hat{w}^I}{\partial x_1} + \nu \sum_{j \neq 1} \bar{P}^{(1j)} i\eta_j \hat{w}^I.$$

From (2.6) we deduce that

$$\frac{\partial \hat{w}^+}{\partial x_1} = \sum_{i=1}^{r+p} \lambda_i \xi_i \Phi^i \quad \text{on } \Gamma,$$

so that

$$\nu \sum_{j=1}^{N} \bar{P}^{(1j)} \frac{\partial \hat{w}^{+I}}{\partial x_j} = \nu \bar{P}^{(11)} \sum_{j=1}^{r+p} \lambda_j \xi_j \Phi^{jI} + \nu \sum_{j \neq 1} \bar{P}^{(1j)} i\eta_j \sum_{i=1}^{r+p} \lambda_i \Phi^{iI},$$

$$\hat{w}_k^+ = \sum_{i=1}^{r+p} \lambda_i \Phi_k^i, \qquad k = r+p+1, \cdots, n.$$

The coefficients λ_j are determined by

$$\sum_{i=1}^{r+p} \lambda_i \Phi_j^i = \hat{w}_j^-, \qquad j = 1, \cdots, r+p.$$

So, if the matrix M is defined by (2.8), we have

$$\lambda_i = \sum_{j=1}^{r+p} M_{ij}^{-1} \hat{w}_j^-$$

and finally $\hat{w}^-$ satisfies (2.7a), (2.7b): (2.7a), (2.7b) is actually the transparent boundary condition.

Remark. If $\bar{A}^{(1)}$ were not diagonal, the same study could be carried over, by choosing an admissible boundary condition (2.5c).

Remark. If $n = r+p$, the transparent boundary condition reduces to (2.7a): the "hyperbolic" part does not require any boundary conditions. (It is the case for instance for Navier-Stokes equation when the flow is supersonic and the boundary is on the outflow.)

2.2. Nonlocal approximate boundary condition. Since we are seeking boundary conditions that are consistent with the hyperbolic problem (i.e., $\nu = 0$), we shall approximate the transparent boundary condition (2.7) with respect to the parameter ν. We thus shall obtain boundary condition relating w and $\partial w^I/\partial x_1$, whose kernel is a nonrational function of s and η, and thus integral in the time variable and the boundary variables. This boundary condition will eventually be approximated by local

boundary conditions in § 2.3, using the techniques in [EM1] for hyperbolic problems.

Let us consider the limits as ν tends to zero of the various terms in the right-hand side of (2.7). By (1.8) the vectors Φ^i tend to the corresponding Ψ^i, and hence the matrix M tends to N, where

$$N_{ij} = \Psi^j_i, \qquad 1 \leqq i, j \leqq r+p. \tag{2.9}$$

As for the coefficients $\nu\xi_i$, by (1.9) if $1 \leqq i \leqq m$, $\nu\xi_i$ tends to zero, and if $m+1 \leqq i \leqq n$, $\nu\xi_i$ tends to a finite limit $\zeta_i(s, \eta)$ (which actually does not depend on s, η). Taking the limits in the right-hand side of (2.7) as described, we are led to the boundary condition

$$\nu \sum_{j=1}^{N} \bar{P}^{(1,j)} \frac{\partial \hat{w}^I}{\partial x_j} = \sum_{i=m+1}^{r+p} \bar{P}^{(11)} \sum_{j=1}^{r+p} \zeta_i N^{-1}_{ij} \Psi^{iI} \hat{w}_j, \tag{2.10a}$$

$$\hat{w}_k = \sum_{i=1}^{r+p} \sum_{j=1}^{r+p} N^{-1}_{ij} \hat{w}_j \Psi^i_k, \qquad r+p+1 \leqq k \leqq n. \tag{2.10b}$$

We shall see in the next section how this boundary condition leads to a well-posed problem in the left half-space Ω^-, whose solution converges as ν tends to zero toward the restriction to Ω^- of the solution of the full hyperbolic problem in $\mathbf{R}^n$. The latter will be done using a boundary layer expansion and the criterion in [M]. Before carrying over the analysis we shall write local boundary conditions. In order to make the mechanisms clear, and since we shall need it later, we shall first recall the derivation of transparent and approximate boundary conditions for the hyperbolic problem.

2.3. Absorbing boundary conditions for the hyperbolic problem. Here we will follow the lines drawn in [EM1]. We keep the notation and assumptions set in the first section. The hyperbolic system is

$$\frac{\partial w}{\partial t} = \sum_{j=1}^{N} A^{(j)} \frac{\partial w}{\partial x_j} + F. \tag{2.11}$$

By Laplace-Fourier transform in t and y, the solutions of this equation in the full space when $F = 0$ are given by

$$\hat{w} = \sum_{i=1}^{N} \lambda_i e^{\alpha_i x_1} \Pi^i, \tag{2.12}$$

where (α_i, Π^i) are the eigenvalues and eigenvectors defined in § 1

$$\left(A^{(1)} \alpha_k + \sum_{j \neq 1} i A^{(j)} \eta_j - sI \right) \Pi^k = 0. \tag{2.13}$$

If $(\operatorname{Re} s \operatorname{Re} \alpha_j) \leqq 0$ (respectively, $(\operatorname{Re} s \operatorname{Re} \alpha_j) \geqq 0$), the corresponding mode in (2.12) propagates in the $(x_1 > 0)$-direction (respectively, $x_1 < 0$).

The transparent boundary condition at $x_1 = 0$ for the half-space Ω^- expresses that no wave can propagate from the boundary toward the interior of Ω^-, i.e.,

$$i = m+1, \cdots, n, \qquad \lambda_i = 0. \tag{2.14}$$

Let us define T as the matrix of the eigenvectors:

$$T_{ij}(s, \eta) = \Pi^j_i(s, \eta). \tag{2.15}$$

By (2.15), (2.14) can be rewritten as

$$\forall i = m+1, \cdots, n \quad (T^{-1} \hat{w})_i = 0. \tag{2.16}$$

This is the transparent boundary condition at $x_1 = 0$ for the half-space Ω^-, i.e., the

equivalent of (2.7) for $\nu = 0$. We shall see in the next section that (2.7) (or (2.10)) actually reduces to (2.16) when ν tends to zero, so that the solution of (0.1) coupled with (2.7) (or (2.10)) tends to the solution of (2.11) with the boundary condition (2.16). This boundary condition is nonlocal in time and space. Following [EM1], we shall make an approximation with respect to the angle of incidence of the wave on the boundary. This is easily achieved by letting $\eta = 0$ in (2.13), so that α_k is nothing but s/λ_k where λ_k is an eigenvalue of $A^{(1)}$, and $\Pi^k = \Lambda^k$.

Thus, the first absorbing boundary condition for (2.11) in Ω^- is

$$\forall i = m+1, \cdots, n \quad (\tilde{T}^{-1} w)_i = 0, \tag{2.17}$$

where

$$\tilde{T}_{ij} = \Lambda_i^j, \qquad 1 \leqq i, \quad j \leqq n,$$

which is simply writing that the entering characteristics of the system are prescribed the value zero on the boundary.

2.4. Local boundary conditions for the full problem. We thus want to make the same kind of approximation in (2.10), and it is now clearer: for $m+1 \leqq j \leqq r+p$, neither ζ_j nor Ψ^j depends on (s, η) and therefore both remain unchanged. For $1 \leqq j \leqq m$, ζ_j and Ψ^j are approximated by s/λ_j and Λ^j, respectively.

We then define the vector $\tilde{\Psi}^j$, $1 \leqq j \leqq r+p$ by

$$\begin{aligned} &\tilde{\Psi}^j = \Lambda^j, \qquad 1 \leqq j \leqq m, \\ &\tilde{\Psi}^j = \Psi^j, \qquad m+1 \leqq j \leqq r+p \end{aligned} \tag{2.18}$$

and the matrix $\tilde{N}$ by

$$\tilde{N}_{ij} = \tilde{\Psi}_i^j, \qquad 1 \leqq i, \quad j \leqq r+p. \tag{2.19}$$

The approximate boundary condition takes the form

$$\begin{cases} \nu \sum_{j=1}^{N} \bar{P}^{(1,j)} \dfrac{\partial w^I}{\partial x_j} = \sum_{i=m+1}^{r+p} \bar{P}^{(11)} \sum_{j=1}^{r+p} \zeta_i \tilde{N}_{ij}^{-1} \Psi^{i^I} w_j, \\ w_k = \sum_{i=1}^{r+p} \sum_{j=1}^{r+p} \tilde{N}_{ij}^{-1} \tilde{\Psi}_k^i w_j, \qquad r+p+1 \leqq k \leqq n. \end{cases} \tag{2.20}$$

This is our local boundary condition. It is of first order in x, and zero order in time. For (2.7) and (2.16), we shall see that it converges to (2.17) when ν tends to zero, so that the solution of (0.1) coupled with (2.20) tends to the solution of (2.11) coupled with the first absorbing boundary condition (2.17).

We shall discuss in § 5 further approximations to these boundary conditions, with respect to either parameters ν or the angle of incidence on the boundary. These boundary conditions will involve higher derivatives in time and the tangential variables.

3. Analysis of the approximate boundary conditions. We shall use here the analysis by Michelson [M] of the well posedness and boundary layer for initial boundary value problems related to parabolic perturbations of hyperbolic equations.

3.1. Well posedness of the boundary value problems. As already pointed out by Strikwerda [S], the well posedness of the initial boundary value problem for (0.1) is equivalent to the well posedness of the purely parabolic problem for $\bar{P}$ and purely hyperbolic problem for $\bar{A}$, provided the boundary conditions satisfy certain decoupling conditions, which are automatically satisfied for boundary conditions of the form (2.7).

Furthermore, if the problem satisfies a uniform Lopatinski condition stated by Michelson in [M], then we can get estimates uniform in ν. Let us define in Ω^- the weighted norms:

$$\|u\|^2_{m_1,m_2,\eta} = \sum_{\substack{|\beta|\leqq m_2 \\ |\alpha|+|\beta|\leqq m_1}} \|(\nu D, \nu\eta)^\alpha (\chi D_{x_1}, D_y, D_t, \eta)^\beta e^{-\eta t} u\|^2_{L^2}, \tag{3.1}$$

where $\chi = \chi(x_1)$ is a fixed smooth nondecreasing function of x_1 such that $\chi(x_1) = x_1$ for $|x_1| < \frac{1}{2}$, and $\chi(x_1) = 1$ for $|x_1| > 1$. Denote by $|u(x_1, \cdot)|^2_{m_1,m_2,\eta}$ the obvious restriction of the above norm to the hyperplane $x_1 = \text{const}$. Let σ be the pseudodifferential operator with symbol $\operatorname{Re}(1+\nu s+|\nu\eta|^2)^{1/2}$ $(s = i\omega + \eta)$. If w is partitioned in the natural way mentioned before $w = \binom{w^I}{w^{II}}$, we define v by

$$v = \begin{pmatrix} v^I \\ v^{II} \end{pmatrix}, \quad v^{II} = w^{II}, \quad v^I = \begin{pmatrix} \sigma^{-1}\nu D_{x_1} w^I \\ \sigma w^I \end{pmatrix}. \tag{3.2}$$

We start by writing the decoupled problems.

The parabolic problem is

$$\frac{\partial w^I}{\partial t} = \sum_{j,k=1}^{N} \bar{P}^{(jk)} \frac{\partial^2 w^I}{\partial x_j \, \partial x_k} + F^I, \tag{3.3a}$$

$$\begin{aligned} &\sum_{j=1}^{N} \bar{P}^{(1j)} \frac{\partial w^I}{\partial x_j} = 0 \quad \text{on } \Gamma, \\ &w^I(t=0) = 0, \end{aligned} \tag{3.3b}$$

and the hyperbolic problem is

$$\frac{\partial w^{II}}{\partial t} = \sum_{j=1}^{N} \bar{A}^{(j)} \frac{\partial w^{II}}{\partial x^j} + F^{II}, \tag{3.4a}$$

$$\begin{aligned} &\hat{w}_k = \sum_{i=1}^{r+p} \sum_{j=r+1}^{r+p} N^{-1}_{ij} \hat{w}_j \Psi^i_k, \qquad k = r+p+1, \cdots, n \quad \text{on } \Gamma, \\ &w^{II}(t=0) = 0, \end{aligned} \tag{3.4b}$$

for the boundary conditions (2.10). For the boundary conditions (2.20) N and Ψ must be replaced by $\tilde{N}$ and $\tilde{\Psi}$, respectively.

Then we have Theorem 3.1.

THEOREM 3.1. *The boundary value problem* (0.1) *coupled with either boundary condition* (2.10) *or* (2.20) *is well posed if and only if the reduced hyperbolic problem* (3.4) *is well posed. Furthermore, if* (3.4) *is well posed in the sense of Kreiss, let integers* $m_1 \geqq m_2 \geqq 0$ *be such that* $m_1 - m_2 \geqq 1$. *Then there exist positive constants* k, ν_0, η_0 *such that for all* $\eta > \eta_0$ *and* $0 \leqq \nu < \nu_0$ *the following a priori estimate holds*:

$$\begin{aligned} &\eta\|w\|^2_{m_1,m_2,\eta} + \nu\|D_x w^I\|^2_{m_1,m_2,\eta} + |v(0,\cdot)|^2_{m_1,m_2,\eta} + |\sigma^{1/2} v^I(0,\cdot)|^2_{m_1,m_2,\eta} \\ &\quad + \sup_{x_1} \left(|w(x_1,\cdot)|^2_{m_1-1,m_2-1,\eta} + |\nu D_x w^I(x_1,\cdot)|^2_{m_1-1,m_2-1,\eta}\right) \\ &\quad \leqq k\eta^{-1}\|F\|^2_{m_1,m_2,\eta}. \end{aligned} \tag{3.5}$$

Proof. The first assertion is a mere consequence of the result by Strikwerda in [S]. As for the second a priori estimate, it follows directly from the general theory on parabolic perturbations for hyperbolic systems by Michelson in [M].

The a priori estimate justifies the boundary layer expansion and proves the

convergence of the initial boundary value problems (0.1) coupled with either of the boundary conditions (2.10) or (2.11) as described in § 3.2.

3.2. Boundary layer; Convergence results. A physical phenomenon related to incompletely parabolic approximations of hyperbolic equations with a small parameter ν is the formation of a boundary layer. It is mathematically represented by a formal expansion

$$w(x, t, \nu) = \sum_{i \geqq 0} \nu^i \left(w_i^{(1)}(x, t) + w_i^{(2)}\left(\frac{x_1}{\nu}, y, t\right)\right). \tag{3.6}$$

The functions $w_i^{(1)}$ represent the smooth part of the solution, while the functions $w_i^{(2)}$ represent the boundary layer: they are exponentially decreasing in x_1/ν. Michelson proved in [M] that under the same hypothesis as in Theorem 3.1, the expansion (3.6) was actually valid. We shall apply this result to our particular case.

THEOREM 3.2. *Let $w(x, t, \nu)$ be the solution of* (0.1), (2.10) (*respectively*, (2.20)) *with a sufficiently smooth F. Suppose, as in Theorem* 3.2, *that the reduced hyperbolic problem* (3.4) *is well posed. Then, as ν tends to zero, w converges to the solution u of the hyperbolic problem* (2.11), (2.16) (*respectively*, (2.17)). *More precisely, if $m_1 \geqq m_2 \geqq m_3 \geqq 0$ and $m_1 - m_2 \geqq 1$, we have*

$$\| w(x, t, \nu) - u(x, t) \|_{m_1, m_2, m_3, \eta} \leqq c(\nu + \nu^{(3/2)-m_3}), \tag{3.7}$$

where the norm above is defined by

$$\| u \|^2_{m_1, m_2, m_3, \eta} = \sum_{i=0}^{m_3} \| D^i_{x_1} u \|^2_{m_1 - i, m_2 - i, \eta}. \tag{3.8}$$

Remarks. (1) This result tells even more about the boundary layer: it says that in expansion (3.6) the first term $w_0^{(1)}$ is indeed the solution of the associated hyperbolic problem, and the first term $w_0^{(2)}$ vanishes: the boundary layer is "weak."

(2) Boundary condition (2.16) is actually the transparent boundary condition for the hyperbolic problem, so that the solution of (0.1), (2.10) converges to the solution of the Cauchy problem for (2.1).

Proof of Theorem 3.2. According to Michelson [M], the following estimate holds:

$$\| w(x, t, \nu) - w_0^{(1)}(x, t) - w_0^{(2)}(x_1/\nu, y, t) \|_{m_1, m_2, m_3, \eta} \leqq c(\nu + \nu^{(3/2)-m_3}). \tag{3.9}$$

We merely need to check that $w_0^{(1)}$ is u and $w_0^{(2)}$ is zero. These terms are obtained by substituting the expansion (3.6) into the equation and the boundary condition, separating the scales x_1 and x_1/ν, and equating to zero the successive coefficients of the resulting series:

From the equation we deduce that $w_0^{(1)}$ and $w_0^{(2)}$ are solutions of the following equations:

$$A^{(1)} w_0^{(2)} + P^{(11)} \frac{\partial w_0^{(2)}}{\partial (x_1/\nu)} = 0, \tag{3.10}$$

$$\frac{\partial w_0^{(1)}}{\partial t} = \sum_{j=1}^{N} A^{(j)} \frac{\partial w_0^{(1)}}{\partial x_j} + F, \tag{3.11}$$

and $w_i^{(1)}$ and $w_i^{(2)}$ are solutions of

$$\frac{\partial w_i^{(1)}}{\partial t} = \sum_{j=1}^{N} A^{(j)} \frac{\partial w_i^{(1)}}{\partial x_j} + \sum_{j,k=1}^{N} P^{(jk)} \frac{\partial^2 w_{i-1}^{(1)}}{\partial x_j \, \partial x_k}, \tag{3.12}$$

$$
\begin{aligned}
&A^{(1)}\frac{\partial w_i^{(2)}}{\partial(x_1/\nu)}+P^{(11)}\frac{\partial^2 w_i^{(2)}}{\partial(x_1/\nu)^2}\\
&=\frac{\partial w_{i-1}^{(2)}}{\partial t}-\sum_{j\neq 1}A^{(j)}\frac{\partial w_{i-1}^{(2)}}{\partial x_j}-2\sum_{j\neq 1}P^{(1j)}\frac{\partial^2 w_{i-1}^{(2)}}{\partial(x_1/\nu)\partial x_j}-\sum_{j,k\neq 1}P^{(jk)}\frac{\partial^2 w_{i-2}^{(2)}}{\partial x_j\,\partial x_k}
\end{aligned}
\tag{3.13}
$$

with the convention that $w_{i-2}^{(2)}\equiv 0$ if $i=1$. We shall assume here the boundary conditions (2.10) are imposed. The calculations are the same for (2.20). For $x_1=0$ we have

$$
\frac{\partial \hat{w}_0^{(2)I}}{\partial(x_1/\nu)}=\sum_{i=m+1}^{r+p}\sum_{j=1}^{r+p}\zeta_i N_{ij}^{-1}\Psi^{iI}(\hat{w}_{0,j}^{(1)}+\hat{w}_{0,j}^{(2)}),
\tag{3.14}
$$

$$
\hat{w}_{0,k}^{(1)}+\hat{w}_{0,k}^{(2)}=\sum_{i,j=1}^{r+p}N_{ij}^{-1}\Psi_k^i(\hat{w}_{0,j}^{(1)}+\hat{w}_{0,j}^{(2)}),\qquad r+p+1\leqq k\leqq n.
\tag{3.15}
$$

For $l\geqq 1$,

$$
\begin{aligned}
&\bar{P}^{(11)}\left[\frac{\partial \hat{w}_l^{(2)I}}{\partial(x_1/\nu)}-\sum_{i=m+1}^{r+p}\sum_{j=1}^{r+p}\zeta_i N_{ij}^{-1}\Psi^{iI}(\hat{w}_{lj}^{(1)}+\hat{w}_{lj}^{(2)})\right]\\
&\quad+\sum_{j\neq 1}\bar{P}^{(1j)}\left(\frac{\partial \hat{w}_{l-1}^{(1)}}{\partial x_j}+\frac{\partial \hat{w}_{l-1}^{(2)}}{\partial x_j}\right)+\bar{P}^{(11)}\frac{\partial \hat{w}_{l-1}^{(1)}}{\partial x_1}=0,
\end{aligned}
\tag{3.16}
$$

$$
\hat{w}_{l,k}^{(1)}+\hat{w}_{l,k}^{(2)}=\sum_{i,j=1}^{r+p}N_{ij}^{-1}\Psi_k^i(\hat{w}_{l,j}^{(1)}+\hat{w}_{l,j}^{(2)}),\qquad r+p+1\leqq k\leqq n.
\tag{3.17}
$$

Let us start with (3.10). From this form, we deduce that $w_0^{(2)}$ is a linear combination of the "exponential modes" defined in (1.6). Here $w_0^{(2)}$ is supposed to be exponentially decreasing in Ω^-, so that

$$
w_0^{(2)}=\sum_{j=r+p-m+1}^{r}\lambda_j\Theta^j e^{\theta_j x_1},\qquad x_1\leqq 0.
$$

We substitute into (3.14), remembering that for $i=m+1,\cdots,r+p$, (ζ_i,Ψ^i) is actually $(\theta_{i-m},\Theta^{j-m})$. We thus get

$$
\sum_{j=r+p-m+1}^{r}\theta_j\lambda_j\Theta^{jI}=\sum_{j=1}^{r+p-m}\sum_{i=1}^{r+p}\theta_j N_{j+m,i}^{-1}(\hat{w}_{0,1}^{(1)}+\hat{w}_{0,i}^{(2)})\Theta^{jI}.
$$

This amounts to stating that there exist coefficients α_k such that $\sum_{k=1}^{r}\alpha_k\Theta^{kI}=0$. It implies that $\sum_{k=1}^{r}\alpha_k\Theta^k=0$, for equation (1.6) can be written

$$
\begin{aligned}
&\bar{P}^{(11)}\theta_k\Theta^{kI}+B^{(1)}\Theta^{kI}+\mathbf{C}^{(1)}\Theta^{kII}=0,\\
&D^{(1)}\Theta^{kI}+\bar{A}^{(1)}\Theta^{kII}=0.
\end{aligned}
$$

And if $\sum\alpha_k\Theta^{kI}=0$, then $\sum\alpha_k D^{(1)}\Theta^{kI}=0$, so that $\sum\alpha_k\bar{A}^{(1)}\Theta^{kII}=0$, and since $\bar{A}^{(1)}$ is nonsingular, the result follows. From the assumptions (0.5) on the operator Q, the Θ^k's are independent, and hence the α_k's vanish for any k.

Then $\lambda_j=0$ for $r+p-m+1\leqq j\leqq r$, and thus $w_0^{(2)}$ vanishes identically in Ω^-. We substitute into (3.14) and (3.15), which indicates that $w_0^{(1)}$ is a solution of the following problem in Ω^-:

$$
\frac{\partial u}{\partial t}=\sum_{j=1}^{n}A^{(j)}\frac{\partial u}{\partial x_j}+F,\qquad x\in\Omega^-
$$

with the boundary conditions

$$
\sum_{j=1}^{r+p}N_{ij}^{-1}\hat{u}_j=0,\qquad i=m+1,\cdots,r+p,
\tag{3.18a}
$$

(3.18b) $$\hat{u}_k = \sum_{i,j=1}^{r+p} N_{ij}^{-1}\Psi_k^i \hat{u}_j, \qquad k = r+p+1, \cdots, n.$$

We will now prove that (3.18) implies the transparent boundary condition (2.16) $(T^{-1}\hat{u})_i = 0$, $m+1 \leqq i \leqq n$:

$$(T^{-1}\hat{u})_i = \sum_{j=1}^{n} T_{ij}^{-1}\hat{u}_j = \sum_{j=1}^{r+p} T_{ij}^{-1}\hat{u}_j + \sum_{j=r+p+1}^{n} T_{ij}^{-1}\hat{u}_j.$$

In the second term of the right-hand side we substitute (3.18b):

$$\sum_{k=r+p+1}^{n} T_{ik}^{-1}\hat{u}_k = \sum_{k=r+p+1}^{n} T_{ik}^{-1} \sum_{l=1}^{r+p}\sum_{j=1}^{r+p} N_{lj}^{-1}\Psi_k^l \hat{u}_j,$$

$$\sum_{k=r+p+1}^{n} T_{ik}^{-1}\hat{u}_k = \sum_{k=1}^{n}\sum_{l=1}^{r+p}\sum_{j=1}^{r+p} N_{lj}^{-1}T_{ik}^{-1}\Psi_k^l \hat{u}_j - \sum_{k=1}^{r+p}\sum_{l=1}^{r+p}\sum_{j=1}^{r+p} N_{lj}^{-1}T_{ik}^{-1}\Psi_k^l \hat{u}_j,$$

but

$$\sum_{l=1}^{r+p} N_{lj}^{-1}\Psi_k^l = \delta_{kj} \quad \text{and} \quad \sum_{k=1}^{r+p}\sum_{l=1}^{r+p}\sum_{j=1}^{r+p} N_{lj}^{-1}\Psi_k^l T_{ik}^{-1}\hat{u}_j = \sum_{j=1}^{r+p} T_{ij}^{-1}\hat{u}_j,$$

so that

$$(T^{-1}\hat{u})_i = \sum_{k=1}^{n}\sum_{l=1}^{r+p}\sum_{j=1}^{r+p} N_{lj}^{-1}T_{ik}^{-1}\Psi_k^l \hat{u}_j.$$

On account of (3.18), the latter reduces to

$$(T^{-1}\hat{u})_i = \sum_{l=1}^{m}\sum_{j=1}^{r+p} N_{lj}^{-1}\hat{u}_j \sum_{k=1}^{n} T_{ik}^{-1}\Psi_k^l.$$

For $1 \leqq l \leqq m$, Ψ^l corresponds to the hyperbolic part of Q, so that $\sum_{k=1}^{n} T_{ik}^{-1}\Psi_k^l = \delta_{il}$ and

$$(T^{-1}\hat{u})_i = 0 \quad \text{for } m+1 \leqq i \leqq n. \qquad \square$$

4. Application to Navier–Stokes equations. We consider here the two-dimensional compressible Navier-Stokes equations:

(4.1a) $$\rho\frac{du_i}{dt} = -\frac{\partial p}{\partial x_i} + \sum_{j=1}^{2}\frac{\partial}{\partial x_j}\left[\mu\left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} - \frac{2}{3}\delta_{ij}\operatorname{div} u\right)\right], \qquad i = 1, 2,$$

(4.1b) $$\rho\frac{dc_v T}{dt} = -p \operatorname{div} u + \mu\sum_{i,j=1}^{2}\left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} - \frac{2}{3}\delta_{ij}\operatorname{div} u\right)\frac{\partial u_i}{\partial x_j} + \sum_{j=1}^{2}\frac{\partial}{\partial x_j}\left(k\frac{\partial T}{\partial x_j}\right),$$

(4.1c) $$\frac{d\rho}{dt} = -\rho \operatorname{div} u.$$

Here ρ is the density, u_i is the velocity component, p is the pressure, T is the temperature, μ and k are the coefficients of viscosity and heat conductivity, respectively, and c_v is the specific heat at constant volume. The pressure p is related to ρ and T by $p = \rho RT$, where R is the gas constant. We shall introduce γ as the ratio of specific heats, i.e., $\gamma = c_p/c_v$ (recall that $R = c_p - c_v$), and the Prandtl number of the gas $P_r = \mu c_p/k$. P_r is supposed to be constant here. As usual $d/dt = \partial/\partial t + u_1(\partial/\partial x_1) + u_2(\partial/\partial x_2)$. We shall assume that the artificial boundary is sufficiently far from any turbulent regime, so that we can consider (u, ρ, T, p) as a small perturbation of a smooth regime (u, ρ, T, p). Since in our analysis the lower-order derivatives are not of much importance, and the

results of Michelson carry over to variable coefficients as well by freezing the coefficients, we shall concentrate here on the case where the reference regime is constant as a function of time and space. Let us call $(\tilde{u}, \tilde{\rho}, \tilde{T}, \tilde{p})$ the perturbation. It is a solution of the following problem:

$$\rho\frac{d\tilde{u}_1}{dt}+RT\frac{\partial\tilde{\rho}}{\partial x_1}+\rho R\frac{\partial\tilde{T}}{\partial x_1}=\mu\left[\frac{4}{3}\frac{\partial^2\tilde{u}_1}{\partial x_1^2}+\frac{\partial^2\tilde{u}_1}{\partial x_2^2}+\frac{1}{3}\frac{\partial^2\tilde{u}_2}{\partial x_1\,\partial x_2}\right], \tag{4.2a}$$

$$\rho\frac{d\tilde{u}_2}{dt}+RT\frac{\partial\tilde{\rho}}{\partial x_2}+\rho R\frac{\partial\tilde{T}}{\partial x_2}=\mu\left[\frac{\partial^2\tilde{u}_2}{\partial x_1^2}+\frac{4}{3}\frac{\partial^2\tilde{u}_2}{\partial x_2^2}+\frac{1}{3}\frac{\partial^2\tilde{u}_1}{\partial x_1\,\partial x_2}\right], \tag{4.2b}$$

$$\rho\frac{d\tilde{T}}{dt}+(\gamma-1)\rho T\ \mathrm{div}\ \tilde{u}=\gamma P_r^{-1}\mu\Delta\tilde{T}, \tag{4.2c}$$

$$\frac{d\tilde{\rho}}{dt}+\rho\ \mathrm{div}\ \tilde{u}=0. \tag{4.2d}$$

We shall normalize these equations by redefining $\tilde{\rho}$ as $\tilde{\rho}/\rho$ and introducing the undisturbed kinematic viscosity $\nu=\mu/\rho$. So that the equations can be written in the form (0.1)

$$\frac{\partial U}{\partial t}=A^{(1)}\frac{\partial U}{\partial x_1}+A^{(2)}\frac{\partial U}{\partial x_2}+\nu\sum_{j,k=1}^{2}P^{(jk)}\frac{\partial^2 u}{\partial x_j\,\partial x_k}+F(x,t), \tag{4.3}$$

where $U=(\tilde{u}_1, \tilde{u}_2, \tilde{T}, \tilde{\rho})$

$$A^{(1)}=\begin{pmatrix} -u_1 & 0 & -R & -RT \\ 0 & -u_1 & 0 & 0 \\ -(\gamma-1)T & 0 & -u_1 & 0 \\ -1 & 0 & 0 & -u_1 \end{pmatrix},$$

$$A^{(2)}=\begin{pmatrix} -u_2 & 0 & 0 & 0 \\ 0 & -u_2 & -R & -RT \\ 0 & -(\gamma-1)T & -u_2 & 0 \\ 0 & -1 & 0 & -u_2 \end{pmatrix},$$

$$P^{(11)}=\begin{pmatrix} \frac{4}{3} & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & \gamma P_r^{-1} & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

$$P^{(22)}=\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & \frac{4}{3} & 0 & 0 \\ 0 & 0 & \gamma P_r^{-1} & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

$$P^{(12)}=\begin{pmatrix} 0 & \frac{1}{6} & 0 & 0 \\ \frac{1}{6} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

They satisfy all the assumptions we made in the Introduction. We shall write here the precise formulation for the local boundary conditions (2.20). We shall start by studying

the eigenvalues of $A^{(1)}$, and recalling the corresponding boundary conditions for the Euler equations (cf., for instance, [EM1]).

4.1. The Euler system. It is well known that the eigenvalues of $A^{(1)}$ are

$$\lambda_1 = -u_1 - c, \quad \lambda_2 = \lambda_3 = -u_1, \quad \lambda_4 = -u_1 + c. \tag{4.4}$$

The corresponding eigenvectors are

$$\Lambda^1 = \begin{pmatrix} c \\ 0 \\ (\gamma-1)T \\ 1 \end{pmatrix}, \qquad \Lambda^2 = \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \end{pmatrix},$$
$$\Lambda^3 = \begin{pmatrix} 0 \\ 0 \\ T \\ -1 \end{pmatrix}, \qquad \Lambda^4 = \begin{pmatrix} c \\ 0 \\ -(\gamma-1)T \\ -1 \end{pmatrix}. \tag{4.5}$$

So that $A^{(1)}$ is diagonalizable and the matrix $\tilde{T}$ in (2.17) is

$$\tilde{T} = \begin{pmatrix} c & 0 & 0 & c \\ 0 & 1 & 0 & 0 \\ (\gamma-1)T & 0 & T & -(\gamma-1)T \\ 1 & 0 & -1 & -1 \end{pmatrix} \tag{4.6}$$

and

$$A^{(1)} = \tilde{T} \begin{pmatrix} \lambda_1 & & & 0 \\ & \lambda_2 & & \\ & & \lambda_3 & \\ 0 & & & \lambda_4 \end{pmatrix} \tilde{T}^{-1}.$$

The number of boundary conditions required by the system at $x_1 = 0$ in Ω^- depends on whether the flow is super or subsonic and the boundary is inflow or outflow, as summarized below.

The **subsonic** case: $|u_1| < c$.

- **inflow:** $u_1 < 0$.

$$\lambda_1 < 0, \lambda_2, \lambda_3, \lambda_4 > 0, \quad m = 1: \quad \textbf{3 boundary conditions.}$$
$$(\tilde{T}^{-1}u)_i = 0, \qquad i = 2, 3, 4.$$

- **outflow:** $u_1 > 0$.

$$\lambda_1, \lambda_2, \lambda_3 < 0, \quad \lambda_4 > 0, \quad m = 3: \quad \textbf{1 boundary condition.}$$
$$(\tilde{T}^{-1}u)_4 = 0.$$

The **supersonic case:** $|u_1| > c$.

- **inflow:** $u_1 < 0$.

$$\lambda_1, \lambda_2, \lambda_3, \lambda_4 > 0, \quad m = 0: \quad \textbf{4 boundary conditions.}$$
$$u_i = 0, \qquad i = 1, 2, 3, 4.$$

- **outflow:** $u_1 > 0$.

$$\lambda_1, \lambda_2, \lambda_3, \lambda_4 > 0, \quad m = 4: \quad \textbf{0 boundary conditions.}$$

The matrix $\tilde{T}^{-1}$ is given by

$$\tilde{T}^{-1}=\begin{pmatrix} \frac{1}{2c} & 0 & \frac{1}{2\gamma T} & \frac{1}{2\gamma} \\ 0 & 1 & 0 & 0 \\ 0 & 0 & \frac{1}{\gamma T} & -\frac{\gamma-1}{\gamma} \\ \frac{1}{2c} & 0 & -\frac{1}{2\gamma T} & -\frac{1}{2\gamma} \end{pmatrix} \tag{4.7}$$

so that the boundary conditions are as follows.

- *Subsonic inflow*:

$$\frac{\tilde{u}_1}{c}-\frac{1}{\gamma}\frac{\tilde{T}}{T}-\frac{1}{\gamma}\frac{\tilde{\rho}}{\rho}=0,$$

$$\tilde{u}_2=0, \tag{4.8a}$$

$$\frac{1}{\gamma}\frac{\tilde{T}}{T}-\frac{\gamma-1}{\gamma}\frac{\tilde{\rho}}{\rho}=0.$$

- *Subsonic outflow*:

$$\frac{\tilde{u}_1}{c}-\frac{1}{\gamma}\frac{\tilde{T}}{T}-\frac{1}{\gamma}\frac{\tilde{\rho}}{\rho}=0. \tag{4.8b}$$

- *Supersonic inflow*:

$$\tilde{u}_1=\tilde{u}_2=\tilde{T}=\tilde{\rho}=0. \tag{4.8c}$$

- *Supersonic outflow*:

no boundary condition.

We reintroduced here the density ρ for the sake of consistency. These boundary conditions are stable in the sense of Kreiss (see [EM1]).

4.2. The Navier–Stokes system. Here the number of boundary conditions is $n-p$, where p is the number of negative eigenvalues of $\bar{A}^{(1)}$. $\bar{A}^{(1)}$ reduces to $-u_1$, so that we must distinguish only between the inflow and the outflow cases:

- **Inflow** boundary: $u_1<0$.

$$p=0: \quad \textbf{4 boundary conditions.}$$

- **Outflow** boundary: $u_1>0$

$$p=1: \quad \textbf{3 boundary conditions.}$$

We must determine the other part of the family (Ψ^j), i.e., the θ_j and Θ_j solutions of

$$[P^{(1,1)}\theta+A^{(1)}]\Theta=0.$$

The cubic equation for θ has an immediate root we shall call θ_3:

$$\theta_3=u_1. \tag{4.9}$$

The two other roots are solutions of the quadratic equation

$$-u_1(\tfrac{4}{3}\theta-u_1)(\alpha\theta-u_1)-RT(\alpha\theta-\gamma u_1)=0, \tag{4.10}$$

where, for simplicity, we set

$$\alpha=\gamma P_r^{-1}.$$

We have

$$\theta_1\theta_2=\frac{3}{4\alpha}(u_1^2-c^2), \qquad \theta_1+\theta_2=\frac{3}{4}\frac{[\alpha(u_1^2-c^2/\gamma)+\frac{4}{3}u_1^2]}{\alpha u_1}$$

with $c^2=\gamma RT$.

Recalling that $\gamma>1$, we can determine the signs of the roots. We order θ_1 and θ_2 so that $\theta_1<\theta_2$ (θ_1 cannot be equal to θ_2).

Subsonic case: $\theta_1<0<\theta_2$.

- Inflow case: $\theta_3<0$;
- Outflow case: $\theta_3>0$.

Supersonic case.

- Inflow case: $\theta_1<\theta_2<0$, $\theta_3<0$;
- Outflow case: $0<\theta_1<\theta_2$, $\theta_3>0$.

The corresponding generalized eigenvalues are

$$\Theta^i=\begin{pmatrix} u_1 \\ 0 \\ (\gamma-1)Tu_1/(\alpha\theta_i-u_1) \\ -1 \end{pmatrix}, \quad i=1,2, \qquad \Theta^3=\begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \end{pmatrix} \tag{4.11}$$

We now have all the elements to (2.20).

- *Subsonic inflow*: $m=1$, $p=0$, $r+p=3$.

$$\zeta_1=\lambda_1, \quad \tilde{\Psi}^1=\Lambda^1, \quad \zeta_2=\theta_1, \quad \tilde{\Psi}^2=\Theta^1, \quad \zeta_3=\theta_3, \quad \tilde{\Psi}^3=\Theta^3$$

and

$$\tilde{N}=\begin{pmatrix} c & u_1 & 0 \\ 0 & 0 & 1 \\ (\gamma-1)T & U_1 & 0 \end{pmatrix}, \qquad \tilde{N}^{-1}=\frac{1}{\det\tilde{N}}\begin{pmatrix} -U_1 & 0 & u_1 \\ (\gamma-1)T & 0 & -c \\ 0 & \det\tilde{N} & 0 \end{pmatrix},$$

where $U_i=(\gamma-1)Tu_1/(\alpha\theta_i-u_1)$, $\det\tilde{N}=(\gamma-1)Tu_1-U_1c$

$$\begin{aligned}
&\nu\frac{\partial\tilde{u}_1}{\partial x_1}+\frac{1}{8}\nu\frac{\partial\tilde{u}_2}{\partial x_2}=\frac{\theta_1}{1-c/(\gamma P_r^{-1}\theta_1-u_1)}\left(\tilde{u}_1-\frac{c}{\gamma-1}\frac{\tilde{T}}{T}\right),\\
&\nu\frac{\partial\tilde{u}_2}{\partial x_1}+\frac{1}{6}\nu\frac{\partial\tilde{u}_1}{\partial x_2}=u_1\tilde{u}_2,\\
&\nu\frac{\partial\tilde{T}}{\partial x_1}=\frac{(\gamma-1)T\theta_1}{\gamma P_r^{-1}\theta_1-u_1-c}\left(\tilde{u}_1-\frac{c}{\gamma-1}\frac{\tilde{T}}{T}\right),\\
&\frac{\tilde{\rho}}{\rho}=\frac{-1}{u_1(1-c/(\gamma P_r^{-1}\theta_1-u_1))}\left[\frac{\gamma P_r^{-1}\theta_1}{\gamma P_r^{-1}\theta_1-u_1}\tilde{u}_1-\frac{u_1+c}{\gamma-1}\frac{\tilde{T}}{T}\right].
\end{aligned} \tag{4.12a}$$

This system reduces to (4.8a) when $\nu=0$.

- *Subsonic outflow*: $m=3$, $p=1$, $r+p=4$.

$$\zeta_i=\lambda_i,\quad \tilde{\Psi}^i=\Lambda^i,\quad i=1,2,3,\quad \zeta_4=\theta_1,\quad \tilde{\Psi}^4=\Theta^1,$$

$$\tilde{N}=\begin{pmatrix} c & 0 & 0 & u_1 \\ 0 & 1 & 0 & 0 \\ (\gamma-1)T & 0 & T & U_1 \\ 1 & 0 & -1 & -1 \end{pmatrix},$$

$$\tilde{N}^{-1}=\frac{1}{TZ}\begin{pmatrix} T-U_1 & 0 & u_1 & u_1T \\ 0 & TZ & 0 & 0 \\ T-U_1-\gamma T & 0 & u_1+c & T(u_1+c)-ZT \\ +\gamma T & 0 & -c & -cT \end{pmatrix},$$

where $Z=\gamma u_1-c(U_1/T-1)$. Condition (2.20) reduces to

$$\nu\sum_{j=1}^{2}\bar{P}^{(1j)}\frac{\partial w^I}{\partial x_j}=\bar{P}^{(11)}\theta_1\left(\sum_{j=1}^{4}\tilde{N}^{-1}_{4j}w_j\right)\Theta^{1I},$$

or

$$\nu\frac{\partial\tilde{u}_1}{\partial x_1}+\frac{1}{8}\nu\frac{\partial\tilde{u}_2}{\partial x_2}=\frac{c\theta_1u_1}{Z}\left(\frac{\gamma}{c}\tilde{u}_1-\frac{\tilde{T}}{T}-\frac{\tilde{\rho}}{\rho}\right),$$

$$\nu\frac{\partial\tilde{u}_2}{\partial x_1}+\frac{1}{6}\nu\frac{\partial\tilde{u}_1}{\partial x_2}=0, \tag{4.12b}$$

$$\nu\frac{\partial\tilde{T}}{\partial x_1}=\frac{c\theta_1U_1}{Z}\left(\frac{\gamma}{c}\tilde{u}_1-\frac{\tilde{T}}{T}-\frac{\tilde{\rho}}{\rho}\right).$$

Again, these equations reduce to (4.8b) when $\nu=0$.

- *Supersonic inflow*: $m=0$, $p=0$, $r+p=3$.

$$\zeta_i=\theta_i,\quad \tilde{\Psi}^i=\Theta^i,\quad i=1,\cdots,3,$$

and

$$\tilde{N}=\begin{pmatrix} u_1 & u_1 & 0 \\ 0 & 0 & 1 \\ U_1 & U_2 & 0 \end{pmatrix}\quad \tilde{N}^{-1}=\frac{1}{u_1(U_1-U_2)}\begin{pmatrix} -U_2 & 0 & u_1 \\ +U_1 & 0 & -u_1 \\ 0 & u_1(U_1-U_2) & 0 \end{pmatrix}.$$

The boundary conditions are

$$\nu\frac{\partial\tilde{u}_1}{\partial x_1}+\frac{1}{8}\nu\frac{\partial\tilde{u}_2}{\partial x_2}=\frac{3}{4u_1}\left(u_1^2-\frac{c^2}{\gamma}\right)\tilde{u}_1+\frac{3c^2}{4\gamma}\frac{\tilde{T}}{T},$$

$$\nu\frac{\partial\tilde{u}_2}{\partial x_1}+\frac{1}{6}\nu\frac{\partial\tilde{u}_1}{\partial x_2}=u_1\tilde{u}_2, \tag{4.12c}$$

$$\nu\frac{\partial\tilde{T}}{\partial x_1}=\frac{(\gamma-1)}{\alpha}Tu_1\left(\frac{\tilde{u}_1}{u_1}+\frac{1}{\gamma-1}\frac{\tilde{T}}{T}\right),$$

$$\frac{\tilde{\rho}}{\rho}=-\frac{\tilde{u}_1}{u_1}.$$

If $\nu = 0$, the system reduces to $\tilde{u}_1 = \tilde{u}_2 = \tilde{T} = \tilde{\rho} = 0$.

- *Supersonic outflow*: $m = 4$, $p = 1$, $r + p = 4$.

$$\zeta_i = \lambda_i, \qquad i = 1, \cdots, 4$$

so that the boundary condition is

$$\begin{aligned} &\frac{\partial \tilde{u}_1}{\partial x_1} + \frac{1}{8}\frac{\partial \tilde{u}_2}{\partial x_2} = 0, \\ &\frac{\partial \tilde{u}_2}{\partial x_1} + \frac{1}{6}\frac{\partial \tilde{u}_1}{\partial x_2} = 0, \\ &\frac{\partial \tilde{T}}{\partial x_1} = 0. \end{aligned} \tag{4.12d}$$

The results in § 3 apply to these equations as follows.

THEOREM 4.1. *The initial boundary value problem for* (4.2) *and the zero-order boundary conditions* (4.12) *is well posed in* Ω^-. *As the viscosity* ν *tends to zero, the solution converges to the solution of the Euler equation with the corresponding boundary conditions* (4.8), *the* L^2 *norm of the error decreases linearly in* ν.

Proof. We merely need to check that the reduced hyperbolic problem is well posed, which is extremely simple here since $\bar{A}^{(1)} = -u_1$. The boundary condition then reduces to $\tilde{\rho} = 0$ (when there is a boundary condition for $\tilde{\rho}$) and the following problem:

$$\begin{aligned} &\frac{\partial \tilde{\rho}}{\partial t} = -u_1 \frac{\partial \tilde{\rho}}{\partial x_1} - u_2 \frac{\partial \tilde{\rho}}{\partial x_2}, \qquad x_1 \leqq 0, \\ &\tilde{\rho} = 0, \qquad x_1 = 0 \end{aligned}$$

for $u_1 < 0$ is obviously well posed.

Remark. In [GS] the authors introduced for the Navier–Stokes compressible equation artificial boundary conditions by requiring them to be dissipative. Furthermore, these boundary conditions produce a weak boundary layer. Therefore Theorem 4.1 also holds in that case. We have not been able to decide whether our boundary conditions are dissipative or not. However for more general systems or higher dimensions, it seems difficult to extend their techniques which consist of studying the boundary form $(\mathscr{E}w, w)$ and matching coefficients of the boundary condition to get the right sign. It does not allow for higher-order boundary conditions either.

5. Higher-order boundary conditions. We discussed earlier the goals of our work: provide boundary conditions which would be (1) local and (2) consistent with the Euler equation. A first step was made in § 3 by an approximation of order zero of the right-hand side in (2.10). We now want to increase the accuracy of our boundary conditions. This means, from our point of view, expand first the transparent boundary condition (2.10) up to higher order in ν. By doing this, we shall keep terms like $\alpha_i(s, \eta)$, for $1 \leqq i \leqq m$, where α_i is the traveling mode defined in (1.3). These will correspond to pseudodifferential operators of order 1 on the boundary, which are, of course, far from being local. We thus shall in turn approximate these modes with the techniques described in [EM]. The first realistic approximation is similar to (2.17): we shall set $\eta = 0$, and approximate the quantities in (2.7) to first order in ν.

We shall restrict ourselves here to the particular case of the viscous linearized shallow-water system, though the procedure carries over without modification to more general systems, provided they possess a symmetrizer. This property ensures that the eigenvalues ξ_i for the system have an expansion $\xi_i(s, \eta, \nu) = \zeta_i(s, \eta) + \nu\chi_i(s, \eta) + O(\nu^2)$,

$1 \leqq i \leqq m$, and $\xi_i(s, \eta, \nu) = (\zeta_i + \nu\chi_i + O(\nu^2))/\nu$, $m+1 \leqq i \leqq r+p$, with a corresponding expansion for the eigenvectors Ψ_j.

Let us consider the shallow-water equations, linearized about the steady-state $(U, 0)$:

$$\frac{\partial w}{\partial t} = A^{(1)} \frac{\partial w}{\partial x_1} + A^{(2)} \frac{\partial w}{\partial x_2} + \nu \left(P^{(11)} \frac{\partial^2 w}{\partial x_1^2} + P^{(22)} \frac{\partial^2 w}{\partial x_2^2} \right), \tag{5.1}$$

where $w = (u_1, u_2, \varphi)$.

$$A^{(1)} = \begin{pmatrix} -U & 0 & -1 \\ 0 & -U & 0 \\ -c^2 & 0 & -U \end{pmatrix}, \tag{5.2}$$

$$A^{(2)} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & -c^2 & 0 \end{pmatrix}, \tag{5.3}$$

$$P^{(11)} = P^{(22)} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix} \tag{5.4}$$

with $c > 0$.

In our notation of § 0, $r = 2$, $\bar{P}^{(ij)} = \delta_{ij} I_2$, and $\bar{A}^{(1)} = -U$. The eigenvalues of $A^{(1)}$ are

$$\lambda_1 = -U - c, \quad \lambda_2 = -U, \quad \lambda_3 = -U + c \tag{5.5a}$$

and the corresponding eigenvectors are

$$\Lambda_1 = \begin{pmatrix} 1 \\ 0 \\ c \end{pmatrix}, \quad \Lambda_2 = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}, \quad \Lambda_3 = \begin{pmatrix} 1 \\ 0 \\ -c \end{pmatrix}. \tag{5.5b}$$

The solutions of $(P^{(1,1)}\theta + A^{(1)})\Theta = 0$ are

$$\theta_1 = \frac{U^2 - c^2}{U}, \qquad \theta_2 = U, \tag{5.6a}$$

and the corresponding generalized eigenvectors are

$$\Theta_1 = \begin{pmatrix} U \\ 0 \\ -c^2 \end{pmatrix}, \qquad \Theta_2 = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}. \tag{5.6b}$$

The signs of the λ's and θ's depend on whether the flow is sub or supersonic, and ingoing or outgoing, as in the case of the full Navier–Stokes equations.

We shall approximate the generalized eigenvalues and eigenvectors $\xi_i(s, 0, \nu)$ and $\Phi^i(s, 0, \nu)$ up to first order in ν.

For $1 \leqq i \leqq m$:

$$\begin{aligned} &\xi_i(s, \nu) = \zeta_i(s) + \nu\chi_i s^2 + O(\nu^2), \\ &\zeta_i(s) = \frac{s}{\lambda_i}, \end{aligned} \tag{5.7a}$$

$$\begin{aligned} &\Phi^i(s, \nu) = \Psi^i + \nu \Xi^i s + O(\nu^2), \\ &\Psi^i = \Lambda^i; \end{aligned} \tag{5.7b}$$

For $m+1 \leqq i \leqq r+p$:

$$\xi^i(s,\nu) = \frac{1}{\nu}\zeta_i + \chi_{i-m}s + O(\nu),$$

(5.8a)

$$\zeta_i = \theta_{i-m},$$

$$\Phi^i(s,\nu) = \Psi^i + \nu\Xi^{i-m}s + O(\nu^2),$$

(5.8b)

$$\Psi^i = \Theta^{i-m}$$

(in the formulas above, the variable η, being zero, has been omitted).

The χ_i's and Ξ_i's are obtained by substitution of the expressions above in formula (11) for $\eta = 0$:

$$(\xi A^{(1)} + \nu\xi^2 P^{(11)} - sI)\Phi = 0.$$

To λ_1, λ_2, λ_3 are associated three values of ξ and vectors Φ:

$$\tilde{\xi}_1 = \frac{s}{\lambda_1} - \frac{\nu s^2}{2\lambda_1^3} + O(\nu^2),$$

(5.9a)

$$\tilde{\xi}_2 = \frac{s}{\lambda_2} - \frac{\nu s^2}{\lambda_2^3} + O(\nu^2),$$

$$\tilde{\xi}_3 = \frac{s}{\lambda_3} - \frac{\nu s^2}{2\lambda_2^3} + O(\nu^2),$$

$$\tilde{\Phi}^1 = \Lambda^1 + \nu s\begin{pmatrix} -1/2\lambda_1 c \\ 0 \\ 0 \end{pmatrix} + O(\nu^2) = \begin{pmatrix} 1 - \nu s/2\lambda_1 c \\ 0 \\ c \end{pmatrix} + O(\nu^2),$$

(5.9b)

$$\tilde{\Phi}_2 = \Lambda^2 + O(\nu^2) = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} + O(\nu^2),$$

$$\tilde{\Phi}_3 = \Lambda^3 + \nu s\begin{pmatrix} -1/2\lambda_3 c \\ 0 \\ 0 \end{pmatrix} + O(\nu^2) = \begin{pmatrix} 1 - \nu s/2\lambda_3 c \\ 0 \\ -c \end{pmatrix} + O(\nu^2),$$

and to θ_1, θ_2 are associated two values of ξ and Φ:

$$\tilde{\tilde{\xi}}_1 = \frac{U^2 - c^2}{\nu U} + s\frac{U^2 + c^2}{U(U^2 - c^2)} + O(\nu),$$

(5.10a)

$$\tilde{\tilde{\Phi}}^1 = \Theta^1 + \nu s\begin{pmatrix} 0 \\ 0 \\ c^2/(U^2 - c^2) \end{pmatrix} + O(\nu^2)$$

$$= \begin{pmatrix} U \\ 0 \\ -c^2(1 - \nu s/(U^2 - c^2)) \end{pmatrix} + O(\nu^2),$$

$$\tilde{\tilde{\xi}}_2 = \frac{U}{\nu} + \frac{s}{U} + O(\nu),$$

(5.10b)

$$\tilde{\tilde{\Phi}}^2 = \Theta^2 + O(\nu^2) = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} + O(\nu^2).$$

We cannot go any further without dividing the analysis into four cases: subsonic or supersonic, inflow or outflow.

—*Subsonic inflow case*: $-c < U < 0$, $p = 0$.

$$\lambda_1 < 0, \quad \lambda_2, \lambda_3 > 0: \quad m = 1,$$
$$\theta_1 > 0, \qquad \theta_2 < 0.$$

p is equal to zero. We have three boundary conditions

$$\xi_1 = \tilde{\xi}_1, \qquad \Phi^1 = \tilde{\Phi}^1,$$
$$\xi_2 = \tilde{\tilde{\xi}}^2, \qquad \Phi^2 = \tilde{\tilde{\Phi}}^2.$$

By a zero-order approximation of the ξ_i's and Φ^i's, we get the first set of approximated boundary conditions:

$$(5.11)_0 \qquad \begin{cases} \nu \dfrac{\partial u_1}{\partial x_1} = 0, \\ \nu \dfrac{\partial u_2}{\partial x_1} - U u_2 = 0, \\ \varphi - c u_1 = 0. \end{cases}$$

By a first-order approximation in ν, we obtain a new set of boundary conditions, which contains differentiation in time:

$$(5.11)_1 \qquad \begin{cases} \nu \dfrac{\partial u_1}{\partial x_1} = -\dfrac{\nu}{U+c} \dfrac{\partial u_1}{\partial t}, \\ \nu \dfrac{\partial u_2}{\partial x_1} = U u_2 + \dfrac{\nu}{U} \dfrac{\partial u_2}{\partial t}, \\ \varphi = c u_1 - \dfrac{\nu}{2(U+c)} \dfrac{\partial u_1}{\partial t}. \end{cases}$$

—*Subsonic outflow case*: $0 < U < c$, $p = 1$.

$$\lambda_1, \lambda_2 < 0, \quad \lambda_3 > 0: \quad m = 2,$$
$$\theta_1 < 0, \qquad \theta_2 > 0.$$

The generalized eigenvalues and eigenvectors with negative real parts (when $\operatorname{Re} s > 0$) are

$$\xi_1 = \tilde{\xi}_1, \quad \xi_2 = \tilde{\xi}_2, \quad \xi_3 = \tilde{\tilde{\xi}}_1,$$
$$\Phi^1 = \tilde{\Phi}^1, \quad \Phi^2 = \tilde{\Phi}^2, \quad \Phi^3 = \tilde{\tilde{\Phi}}^1.$$

The analogue to $(5.11)_0$ becomes

$$(5.12)_0 \qquad \nu \frac{\partial u_1}{\partial x_1} = \frac{c-U}{c}(-c u_1 + \varphi), \qquad \nu \frac{\partial u_2}{\partial x_1} = 0,$$

and the first-order boundary condition is

$$(5.12)_1 \qquad \begin{cases} \nu \dfrac{\partial u_1}{\partial x_1} = \dfrac{c-U}{c}(-c u_1 + \varphi) + \dfrac{\nu}{2c^2(c-U)} \dfrac{\partial}{\partial t}(-c^2 u_1 + U\varphi), \\ \nu \dfrac{\partial u_2}{\partial x_1} = -\dfrac{\nu}{U} \dfrac{\partial u_2}{\partial t}. \end{cases}$$

In the supersonic case, the calculations are much easier.

—*Supersonic inflow case*: $U<-c$, $p=0$.

$$\lambda_1, \lambda_2, \lambda_3>0: \quad m=0,$$
$$\theta_1, \theta_2<0.$$

We have three boundary conditions:

$(5.13)_0$
$$\begin{cases} \nu\dfrac{\partial u_1}{\partial x_1}=\dfrac{U^2-c^2}{U}u_1; \\ \nu\dfrac{\partial u_2}{\partial x_1}=Uu_2, \\ \varphi=-\dfrac{c^2}{U}u_1, \end{cases}$$

and

$(5.13)_1$
$$\begin{cases} \nu\dfrac{\partial u_1}{\partial x_1}=\dfrac{U^2-c^2}{U}u_1+\nu\dfrac{U^2+c^2}{U(U^2-c^2)}\dfrac{\partial u_1}{\partial t}, \\ \nu\dfrac{\partial u_2}{\partial x_1}=Uu_2+\dfrac{\nu}{U}\dfrac{\partial u_2}{\partial t}, \\ \varphi=-\dfrac{c^2}{U}u_1+\dfrac{\nu c^2}{U(U^2-c^2)}\dfrac{\partial u_1}{\partial t}. \end{cases}$$

—*Supersonic outflow case*: $U>c$, $p=1$.

$$\lambda_1, \lambda_2, \lambda_3<0: \quad m=3,$$
$$\theta_1, \theta_2>0.$$

Here we have two boundary conditions:

$(5.14)_0$
$$\nu\frac{\partial u_1}{\partial x_1}=0, \qquad \nu\frac{\partial u_2}{\partial x_1}=0,$$

$(5.14)_1$
$$\begin{cases} \nu\dfrac{\partial u_1}{\partial x_1}=\dfrac{\nu}{U^2-c^2}\dfrac{\partial}{\partial t}(-Uu_1+\varphi), \\ \nu\dfrac{\partial u_2}{\partial x_1}=-\dfrac{\nu}{U}\dfrac{\partial u_2}{\partial t}. \end{cases}$$

We shall not repeat here the calculations for the inviscid case, i.e., $\nu=0$. They are identical to those for the full Euler equations. The local boundary condition (2.17) is in this case:

Subsonic inflow case:

(5.15) $$u_2=0, \qquad \varphi-cu_1=0;$$

Subsonic outflow case:

(5.16) $$\varphi-cu_1=0;$$

Supersonic inflow case:

(5.17) $$u_1=u_2=\varphi=0;$$

Supersonic outflow case:

(5.18) no boundary conditions.

The analogue of Theorem 4.1 holds.

THEOREM 5.1. *The initial boundary value problem for* (5.1) *and any of the boundary conditions* $(5.11+i)_0$, $i=0,\cdots,3$ *is well posed in* Ω^-. *As the viscosity* ν *tends to zero, the solution converges to the solution of the inviscid equation with the corresponding boundary condition* $(5.14+i)$, *and the* L^2*-norm of the error decreases as* $O(\nu)$.

The proof is exactly the same as for Theorem 4.1.

Remark. In this case, the well posedness in the classical sense can be expressed by energy estimates, using the variational formula (1.14). Let us denote by $E(t)$ the quantity defined by

$$E(t)=\frac{1}{2}\int\int_{\Omega^-}[c^2(u_1^2+u_2^2)+\varphi^2]\,dx \tag{5.19}$$

and the analogue on Γ:

$$E_\Gamma(t)=\frac{1}{2}\int_\Gamma[c^2(u_1^2+u_2^2)+\varphi^2]\,dx_2. \tag{5.20}$$

The energy equality then reads

$$\begin{aligned}&\frac{dE}{dt}+\nu\int\int_{\Omega^-}(\nabla u_1^2+\nabla u_2^2)\,dx\\&\quad=-UE_\Gamma(t)+c^2\int_\Gamma\left(\nu u\cdot\frac{\partial u}{\partial x_1}-u_1\varphi\right)dx_2+\int\int_{\Omega^-}Fu\,dx.\end{aligned} \tag{5.21}$$

It can be easily checked in each case that the quantity integrated on Γ is negative.

Unfortunately, the decoupling conditions prescribed in [M] to obtain the well posedness and the error estimates do not apply to our higher-order boundary conditions $(5.11+i)_1$. We have not been able to establish a priori estimates in this case either. However, the formal expansion (3.6) is still available. It is an easy matter to check that for the higher-order boundary conditions $(5.11+i)_1$, the next term in the expansion vanishes. For instance, in the subsonic inflow case, it is due to the fact that $(\partial/\partial x_1+1/(U+c)\,\partial/\partial t)(w_0^{(1)})=0$. *So the boundary layer is weaker than in the former case, and the solution of the corresponding initial boundary value problem converges formally to the solution of the inviscid equation with boundary condition* $(5.14+i)$, *the error being* $O(\nu^2)$.

Remark. Consider the boundary conditions derived from $(5.11+i)_1$ in the four cases by neglecting certain terms:

$$\begin{cases}\nu\dfrac{\partial u_1}{\partial x_1}=-\dfrac{\nu}{U+c}\dfrac{\partial u_1}{\partial t},\\[2ex]\nu\dfrac{\partial u_2}{\partial x_1}=Uu_2+\dfrac{\nu}{U}\dfrac{\partial u_2}{\partial t},\qquad \varphi=cu_1,\end{cases} \tag{5.22}$$

$$\nu\frac{\partial u_1}{\partial x_1}=\frac{c-U}{c}(-cu_1+\varphi),\qquad \nu\frac{\partial u_2}{\partial x_1}=-\frac{\nu}{U}\frac{\partial u_2}{\partial t}, \tag{5.23}$$

$$\begin{cases}\nu\dfrac{\partial u_1}{\partial x_1}=\dfrac{U^2-c^2}{U}u_1+\nu\dfrac{U^2+c^2}{U(U^2-c^2)}\dfrac{\partial u_1}{\partial t},\\[2ex]\nu\dfrac{\partial u_2}{\partial x_1}=u_2+\dfrac{\nu}{U}\dfrac{\partial u_2}{\partial t},\qquad \varphi=-\dfrac{c^2}{U}u_1,\end{cases} \tag{5.24}$$

$$\nu\frac{\partial u_1}{\partial x_1}=0,\qquad \nu\frac{\partial u_2}{\partial x_1}=-\frac{\nu}{U}\frac{\partial u_2}{\partial t}. \tag{5.25}$$

These boundary conditions are well posed in the classical sense: we have neglected the terms which could prevent the energy from decreasing in time. Furthermore, they still give an approximation to the inviscid problem with boundary conditions $(5.14+i)$ in $O(\nu^2)$: the relevant equations are unchanged. However, the last statement remains formal, since the decoupling conditions still do not hold.

So far we have considered approximations to the inviscid equations with the "zero-order" boundary conditions (2.17), which are those used in practice. It is tempting to try to approximate the Euler problem better. This adds new important difficulties: as pointed out in [EM] the choice of the "good" boundary condition in the hyperbolic case is not canonical, and furthermore, it is not clear whether or not it is well posed in the sense of Kreiss. An analysis of such boundary conditions, together with numerical experiments, will be presented in a forthcoming paper.

ADMISSIBILITY CONDITIONS FOR SHOCKS IN CONSERVATION LAWS THAT CHANGE TYPE*

BARBARA LEE KEYFITZ†

Abstract. Systems of conservation laws which are not of classical hyperbolic type appear in models for some complex flows. To formulate admissibility conditions for shocks, a single shock is regularized between a point where the system is hyperbolic and a point where it is not, by the addition of a higher-order term ("viscosity matrix"), to obtain an admissibility criterion based on the existence of connecting orbits in a related dynamical system. This criterion is more sensitive to the structure of the viscosity matrix than in the classical hyperbolic case.

Key words. conservation laws, viscous profiles, shock admissibility

AMS(MOS) subject classifications. 35L65, 35L67, 35M05, 58F14

1. Introduction.

We consider a pair of conservation laws,

$$w_t + h_x \equiv w_t + A(w)w_x = 0, \tag{1.1}$$

where

$$h = h(w), \quad w = (u, v), \quad h = (f, g).$$

The characteristic speeds λ_i satisfy

$$\lambda^2 - \operatorname{tr} A\lambda + \det A = 0.$$

They are ordered, by convention, $\lambda_1 < \lambda_2$, when they are real. The system is hyperbolic or elliptic according to whether

$$D(w) = (\operatorname{tr} A)^2 - 4 \det A$$

is positive or negative. We assume that there are open sets

$$\mathscr{H} = \{w \mid D(w) > 0\}, \qquad \mathscr{E} = \{w \mid D(w) < 0\}$$

representing each type, and that their common boundary,

$$\mathscr{B} = \{w \mid D(w) = 0\}, \tag{1.2}$$

is a smooth curve.

Systems with this feature appear as models for propagation of phase boundaries in elasticity [10], in fluids of van der Waals type near the critical temperature [19], and in the dynamics of some models for shape-memory alloys or austenitic to martensitic transitions in solids [1]. Change of type has also been noted in models for pressure-driven, convection-dominated, three-phase flow in porous media [3]. Some unusual models of flows have also led to systems that change type; these include a kinematic model for two-directional traffic flow [4] and an ecological model [9].

The theory we formulate in this work indicates that there are at least two classes of flows that change type, and we observe that this corresponds to a distinction in the observed phenomena. In models for the dynamics of phase transitions, the presence

† Department of Mathematics, University of Houston, Houston, Texas 77204-3476.

of an elliptic region is coexistent with a physically unstable range of the order variable (density or strain), as manifested by the behavior of the constitutive relation. A typical system is

$$u_t - v_x = 0, \qquad v_t - \sigma(u)_x = 0. \tag{1.3}$$

This system is a nonlinear wave equation whose characteristic speeds $\pm\sqrt{\sigma'}$ are real and opposite when $\sigma(u)$ is an increasing function of u, and complex, with real part zero, when $\sigma(u)$ is decreasing. The symmetry of the wave speeds expresses Galilean invariance of the system: this system is of *wave equation type*. Symmetry is absent in three-phase porous medium flow, where the pressure differential breaks the reflectional symmetry; it is absent also in the kinematic model of traffic flow and in abstract models, such as general perturbations of quadratic flux functions [8]. Also, there is no obvious physical instability connected with the elliptic region in these models. The theory presented here finds the second class to be *generic*; all wave-equation-type examples exhibit a degeneracy.

Change of type occurs also in steady transonic flow; the model equations are of the form

$$h_x + k_y \equiv A(w)w_x + B(w)w_y = 0, \tag{1.4}$$

and the characteristic directions (ξ, η), which are the roots of

$$\det|\xi A(w) + \eta B(w)| = 0,$$

are real on one side of the sonic line and complex on the other.

There are significant mathematical differences between (1.4) and (1.1).

An attempt to formulate admissibility conditions for systems of mixed type based on the model (1.4) was made by Mock [17]. Although there is some overlap, the results in [17] cannot be applied without modification to (1.1). Conversely, the normal form analysis which is the main result of the present paper can be applied to (1.4), but a different normal form is required [16].

2. Conservation law considerations. We study the admissibility of *uniform planar shocks*: solutions of (1.1) of the form

$$w(x, t) = \begin{cases} w_0, & x < st, \\ w_1, & x > st \end{cases} \tag{2.1}$$

where w_0 and w_1 are constant states, related to the shock speed s by the *Rankine-Hugoniot relation*:

$$s[w] - [h] \equiv s(w_1 - w_0) - (h(w_1) - h(w_0)) = 0, \tag{2.2}$$

which makes (2.1) a weak solution of (1.1). For fixed w_0, the set of values w such that (2.2) is satisfied for some s forms the *wave locus*,

$$W(w_0) = \{w \mid \exists s \ni s(w - w_0) = h(w) - h(w_0)\}. \tag{2.3}$$

Locally, W is a curve, parameterized by s.

Not every configuration (2.1) that satisfies (2.2) is an admissible solution. In the equations of isentropic gas dynamics in Lagrangian coordinates (equation (1.3) with σ a monotone function) W comprises four branches, which may be labeled S_i and S_i^*, $i = 1$ or 2. Each extends from w_0 to infinity; S_i and S_i^* are tangent to r_i, the right eigenvector of A corresponding to λ_i, and $s \to \lambda_i$ as $w \to w_0$ along each branch. In addition, s is monotonically decreasing on S_i^*, and increases along S_i, as $w \to w_0$. Admissibility is determined by the *Lax geometric entropy condition* (LGEC):

$$\lambda_i(w_0) > s > \lambda_i(w)$$

for $i=1$ or 2, where w is the state on the right in (2.1). Figure 1 illustrates the situation schematically: points on the S_i branches correspond to admissible shocks in (2.1), while if $w_1 \in S_i^*(w_0)$, then an admissible shock is obtained if left and right are reversed in (2.1). (See [20] or [11] for a discussion.)

The LGEC cannot be applied to equations that change type. In this paper we apply a well-known method that is not sensitive to type, the *viscous profile* criterion: admissible shocks are those solutions of (2.1) that are limits as $\varepsilon \to 0$ of self-similar solutions of

$$w_t + h_x = \varepsilon (M w_x)_x, \tag{2.4}$$

$$w = w(\xi) \equiv w\left(\frac{x-st}{\varepsilon}\right), \qquad w(\xi) \to \begin{cases} w_0, & \xi \to -\infty, \\ w_1, & \xi \to \infty. \end{cases} \tag{2.5}$$

Such a $w(\xi)$ is a heteroclinic orbit of the vector field

$$M\frac{dw}{d\xi} = h(w) - sw + c, \tag{2.6}$$

where c is the value $sw_0 - h(w_0) = sw_1 - h(w_1)$, from (2.2). The matrix M is called the *viscosity matrix.*

3. The Hugoniot loop. The fact that there are solutions of (2.2) with real s for which one state is in $\mathcal{H}$ and the other in $\mathcal{E}$ is well known from many examples. The first theorem of this section is a local result which gives a qualitative description of the wave locus $W(w_0)$ when w_0 is near $\mathcal{B}$.

A nondegeneracy hypothesis $\nabla_w D(w) \neq 0$ on $\mathcal{B}$, which guarantees that $\mathcal{B}$ is a smooth curve, will be assumed throughout. This implies that

$$N(w) = A(w) - \lambda(w) I$$

is a nilpotent matrix of rank one on $\mathcal{B}$ [15]. Thus N has a unique right eigenvector r and left eigenvector l on $\mathcal{B}$. We impose a second nondegeneracy condition

$$l^T d^2 h(r, r) > 0 \tag{3.1}$$

on $\mathcal{B}$. (Points where this condition fails are interesting, and are discussed in [15].) If (3.1) holds, then (1.1) is genuinely nonlinear in $\mathcal{H}$, sufficiently close to $\mathcal{B}$, and also

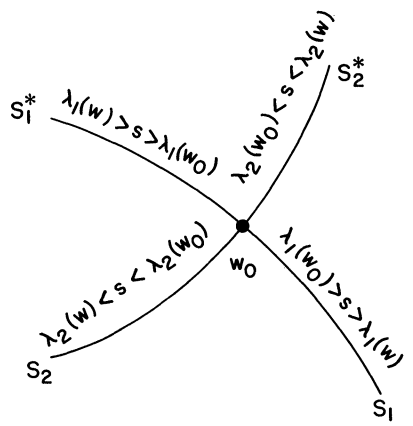

FIG. 1. *Admissibility for hyperbolic systems.*

satisfies the Smoller-Johnson interaction condition [11]:

$$l_j^T d^2h(r_i, r_i) > 0 \quad \text{for } i, j = 1, 2.$$

Here r_i and l_i are right and left unit eigenvectors of $A = dh$ corresponding to λ_i, normalized by $r_i \cdot \nabla\lambda_i > 0$ and $l_i \cdot r_i > 0$. Figure 2 illustrates $W(w_0)$ in a neighborhood of w_0 when w_0 is near $\mathcal{B}$. (Necessarily, S_1^* and S_2 are the branches that turn toward $\mathcal{B}$.) It can be seen that

$$\lim r_1(w) = r(w_*), \quad \lim r_2(w) = -r(w_*), \quad \lim l_i(w) = l(w_*)$$

as $w \to w_* \in \mathcal{B}$ through points in $\mathcal{H}$. Also, writing N as $\beta\alpha^T$, we have $r = \beta/|\beta|$ and $l = -\alpha/|\alpha|$. Finally, r is directed strictly into $\mathcal{E}$.

THEOREM 3.1. *Let w_* be a point in $\mathcal{B}$ where* (3.1) *holds. Then for w_0 in a neighborhood $\mathcal{N}$ of w_*, $W(w_0)$ has the following structure:*

— *If $w_0 \in \mathcal{B}$, then W forms a cusp opening into $\mathcal{H}$, with axis tangent to $r(w_0)$. The value of s at w_0 is $\lambda(w_0)$, and $ds/d\mu = \mathcal{O}(1/\sqrt{\mu})$ near w_0, where μ is arclength on W.*

— *If $w_0 \in \mathcal{E}$, then W is the union of w_0 itself and a smooth curve lying entirely in $\mathcal{H}$ (and therefore disconnected from w_0); s is monotonic on W.*

— *If $w_0 \in \mathcal{H}$, then W consists of a loop which crosses $\mathcal{B}$, and two segments which leave $\mathcal{N}$ in the opposite direction; thus, W is a curve with a self-intersection; s is monotonic along the entire curve.*

Remark. The first and third possibilities are illustrated in Fig. 2. We shall refer to the segment between the two self-intersections as the *Hugoniot loop.*

Proof. The zero-set of (2.2),

$$G(w, w_0, s) \equiv h(w) - h(w_0) - s(w - w_0) = 0,$$

can be analyzed as a bifurcation problem, using the singularity theory approach of Golubitsky and Schaeffer and the notion of t-equivalence [5, p. 129]. This type of equivalence reflects the persistence of the trivial solution $w = w_0$ for all values of the bifurcation parameter s. Since dG has rank greater than or equal to 1, G can be reduced to a one-state-variable problem; we use a Lyapunov-Schmidt reduction that preserves the t-equivalence. Fixing $w_0 = w_* \in \mathcal{B}$, $dG|_0 = N(w_*)$; a basis for $\ker N$ is r and a basis for $(\text{Range } N)^\perp$ is l. We express w implicitly in terms of a reduced variable x as

$$w = xr + w_p(x, \nu) + w_0$$

where $\nu = s - \lambda$ is the bifurcation parameter. A straightforward calculation shows that G is t-equivalent to

$$\eta x^2 + \delta x \nu^2 = 0,$$

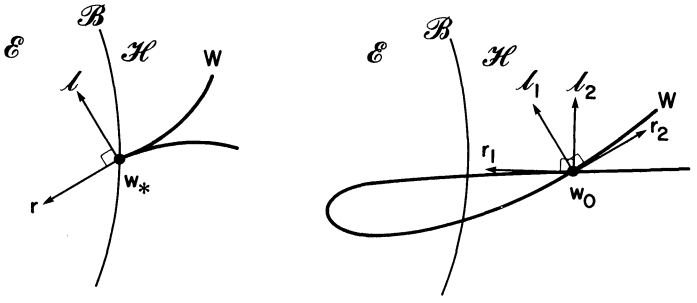

FIG. 2. *The Hugoniot loop.*

where

$$\eta = l^T d^2 h(r, r) > 0, \qquad \delta = \frac{2}{|\alpha||\beta|} > 0.$$

This normal form has t-codimension 1, and an unfolding,

$$\eta x^2 + \delta x \nu^2 + ax = 0, \tag{3.2}$$

is obtained by perturbing w_0 away from $\mathcal{B}$, say

$$w_0 = w_* + ar.$$

The conclusions of the theorem now follow upon examining the nontrivial solution of (3.2), $x = -\nu^2 - a$, and noting that x and a refer to distances along the vector r.

When $a < 0$, so that $w_0 \in \mathcal{H}$, the solution x has two zeros at $\nu = \pm\sqrt{(-a)}$ corresponding to the two ends of the loop. We can parameterize the loop by arclength so that s is monotonically decreasing on the loop. At $\nu = 0$, $x > 0$, so that the loop contains a subinterval inside $\mathcal{E}$.

A similar theorem was proved by Mock [17], using expansions of h near $\mathcal{B}$. Theorem 3.1 clarifies the hypotheses and shows that the size of $\mathcal{N}$ depends on the region of validity of the Lyapunov-Schmidt procedure, which can be determined in specific examples.

To study the vector field (2.6) for w_0 in $\mathcal{N}$ and w_1 in $W(w_0)$, we again choose a degenerate case and unfold it, this time using vector field unfoldings.

THEOREM 3.2. *Under assumption* (3.1) *and an additional nondegeneracy condition*

$$l^T d^2 h(r, l) + r^T d^2 h(r, r) \neq 0; \tag{3.3}$$

then (2.6) *at* $w_0 = w_1 = w_* \in \mathcal{B}$, *and* $M = I$ *is equivalent* (*in the sense of vector field equivalence*) *to*

$$\begin{aligned} \dot{x} &= y, \\ \dot{y} &= Ax^2 + 2Bxy, \end{aligned} \qquad A, B, \neq 0. \tag{3.4}$$

Furthermore, varying w_0, w_1, *and* M *in a neighborhood of these values gives a universal unfolding of the vector field.*

Remarks. (1) System (3.4) is the Takens-Bogdanov normal form. It has codimension two, in the sense of vector field unfoldings, and is discussed in detail by Guckenheimer and Holmes [6, p. 365]. For the application to (2.6), we wish to unfold under t-equivalence, so that the solution $w_0 = w_1$ is preserved. The unfolding in this case was worked out by Hirschberg and Knobloch [7]. Unfolding theory for vector fields (as in [6] and [7]) does not consider a distinguished parameter, so an interpretation in the spirit of Theorem 3.1 requires further discussion. This follows the proof.

(2) It is not necessary to vary M to obtain the universal unfolding, but it is useful to recognize that $M \neq I$ is included in the application of this theorem.

(3) The additional nondegeneracy condition (3.3) is necessary to obtain the normal form (3.4), and it is not always satisfied. For example, the nonlinear wave equation (1.3) is always degenerate. On the other hand, the model equation devised in [12] to explain some features of a three-phase porous medium flow system and quadratic models, such as [4], [8], and [9], satisfy this condition, except for special values of the parameters. For this reason, such systems were called generic in the Introduction.

Proof. Without loss of generality, let $c=0$ and $w_0=w_1=w_*=0$ in (2.6). By subtracting $\lambda(0)w$ from h we may assume $\lambda(0)=0$ also, and so $s=0$. The linearization of (2.6) at the critical point $w=0$ is

$$\frac{dw}{d\xi}=dh(0)w\equiv Nw, \tag{3.5}$$

where N is the nilpotent matrix previously encountered. By performing a linear change of coordinates, $w\mapsto Pw$, if necessary, we may assume $r=(-1,0)^T$, $l=(0,1)^T$ and

$$N=\begin{pmatrix}0 & 1\\ 0 & 0\end{pmatrix}.$$

Expanding h through quadratic powers of w now yields

$$h(w)=Nw+d^2h(w,w).$$

Write $w=xr-yl$, and expand d^2h, which is bilinear in its arguments. Equation (2.6) (with signs reversed) now agrees with (3.4) through linear terms; the higher-order terms must be removed by a nonlinear change of variables. Noting that

$$d^2h(w,w)=x^2d^2h(r,r)-2xyd^2h(r,l)+y^2d^2h(l,l)$$

and that multiplication by r and $-l$, respectively, gives the contribution to the first and second equations, we obtain

$$A=-l^Td^2h(r,r),\qquad B=l^Td^2h(r,l)+r^Td^2h(r,r) \tag{3.6}$$

upon carrying out the nonlinear change of variables explicitly.

A universal unfolding of (3.4) that respects the trivial solution but has no other symmetries is [7]

$$\dot{x}=y,\qquad \dot{y}=Ax^2+2Bxy+\mu_1x+\mu_2y. \tag{3.7}$$

The fixed points are $(0,0)$ and $(-\mu_1/A,0)$, and the linearization at zero is

$$\begin{pmatrix}0 & 1\\ \mu_1 & \mu_2\end{pmatrix}.$$

In identifying unfolding variables, we may choose $\mu_1=(w_1-w_0)\cdot r$. If we specify $\mu_1\gtrless 0$, we avoid some redundancy. Now w_0 is the origin, and is a saddle in the dynamics, while $w_1\in W(w_0)$ is to the left of it in the Hugoniot loop. As discussed earlier, we must have $w_0\in\mathscr{H}$ if $w_1\to w_0$, and then the approach is along a 1- or 2-shock branch. If $w_0\notin\mathscr{B}$, then the steady-state bifurcation as w_1 crosses w_0 is transcritical, and μ_2 is any parameter that measures the nondegeneracy of this bifurcation: for example, $\mu_2=\lambda_2(w_0)-\lambda_1(w_0)$ is adequate locally. As $w_0\to\mathscr{B}$, we use a smooth determination $\mu_2=\lambda_i(w_0)-\lambda_j(w_0)$ of the eigenvalues. We did not attempt to find an unfolding using the minimum number of variables.

If $M\neq I$, the linearized system (3.5) is associated with the matrix $M^{-1}N$, which may not have a double zero eigenvalue. However, if M is close to I, there will be a codimension-2 bifurcation point near $w_1=w_0=w_*$: perturbing M is yet another way of unfolding the singularity.

This completes the proof of Theorem 3.2. We now turn to a qualitative analysis of the vector field (2.6) for w_0 and w_1 in $\mathscr{N}$. Assume w_0 to be in $\mathscr{H}$, and w_1 in the Hugoniot loop of w_0; allow w_0 to represent either the forward or the backward limit in (2.5). We describe the sequence of vector field bifurcations as w_1 traverses the Hugoniot loop, introducing s as a distinguished parameter; this gives a path

$(\mu_1(s), \mu_2(s))$ through unfolding space. We refer to Fig. 3, which follows [7]. The coordinate axes are μ_1 and μ_2. The Hugoniot loop traces a path in this space beginning on the negative μ_2 axis (when $w_1 = w_0$ and $s = \lambda_2$) and ending on the positive μ_2 axis ($w_1 = w_0$ and $s = \lambda_1$), and traversing three open regions in the right half plane. For s near λ_2, there is a connecting orbit: a solution of (2.4), (2.5) with limit (2.1) as $\varepsilon \to 0$. In this region, states w_1 near w_0 are on the classical S_2 branch of $W(w_0)$, and these are classical 2-shocks as long as w_1 remains in $\mathcal{H}$. The transition of w_1 into $\mathcal{E}$ does not affect the existence or qualitative properties of the orbit. It is true that if $M = I$, then $w_1 \in \mathcal{B}$ marks a change of type of the unstable critical point, from a node to a spiral, but this transition occurs at a different value of w_1 if $M \neq I$.

The other end of the loop, near the positive μ_2 axis, corresponds to a state w_1 in S_1^*: the admissible shock wave represented by this pair is

$$w(x, t) = \begin{cases} w_1, & x < st, \\ w_0, & x > st. \end{cases}$$

This orbit also persists as w_1 crosses $\mathcal{B}$ into $\mathcal{E}$.

Two curves B_h and B_{sc}, which separate the S_2 and S_1^* branches, enclose an open region in which there is no orbit connecting the fixed points of (3.7). According to the sign of B in (3.7), B_h and B_{sc} are as shown here ($B < 0$) or interchanged. At a point on B_h, a Hopf bifurcation occurs at w_1. For $M = I$, a simple calculation in (2.6) shows that this occurs when

$$s(w_1, w_0) = \operatorname{Re} \lambda_1(w_1) = \operatorname{Re} \lambda_2(w_1), \tag{3.8}$$

and hence that w_1 is in $\mathcal{E}$ at this point. For any other choice of M, the point may be similarly calculated; this is always a local condition.

In the wedge between B_h and B_{sc}, w_1 is a stable spiral, and an unstable limit cycle separates all orbits containing w_1 from any orbit reaching w_0. Geometrically, this limit cycle grows in size as the point $(\mu_1(s), \mu_2(s))$ moves away from B_h. The curve B_{sc} represents a line of saddle connections: the limit cycle coincides with a homoclinic loop at w_0, which disappears on the other side of B_{sc} (the "blue sky catastrophe"). The existence of B_{sc} could be inferred from the necessity of continuous transitions of the vector field along the Hugoniot loop, but the fact that it is unique, under the

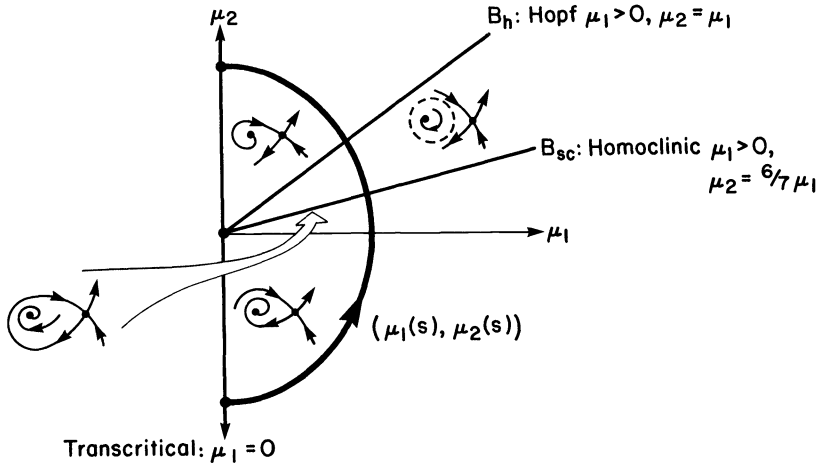

FIG. 3. *The vector field bifurcations.*

nondegeneracy conditions holding for (3.4) and its unfolding, is a consequence of the theory in [6] and [7]. Furthermore, it is theoretically quite difficult to find the point on the Hugoniot loop at which $w_1 \in B_{sc}$, since this, unlike (3.8), is not a local condition.

4. The viscous profile criterion and shock admissibility. We restate the conclusion of Theorem 3.2 as it applies to a shock configuration on the Hugoniot loop. (See Fig. 4.)

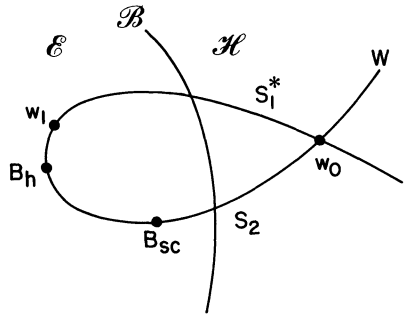

FIG. 4. *Admissibility conditions on the Hugoniot loop.*

COROLLARY TO THEOREM 3.2. *Under the nondegeneracy conditions* $\nabla D(w) \neq 0$ *at* w_* *on* $\mathscr{B}$, *and* (3.1) *and* (3.3), *and for* w_0 *and* w_1 *in a neighborhood* $\mathscr{N}(w_*)$ *in which the reduction to normal form is valid, the Hugoniot loop of* w_0 *is divided by two points,* B_{sc} *and* B_h, *into three open intervals: in* S_2 *and* S_1^*, *there are connecting orbits that give shock profiles that extend the* 2- *and* 1-*shocks, respectively. These profiles are not necessarily monotone.*

Between B_h and B_{sc} is an open interval where no connecting orbit exists.

For a given value of w_0, the locations of B_{sc} and B_h depend on the choice of M. When M is near I, both points are in $\mathscr{E}$.

Existence of traveling wave orbits for (2.6) can be related to other admissibility criteria. In [13], Keyfitz suggested an extension of the LGEC for states in $\mathscr{E}$: for a 2-shock with $w_1 \in \mathscr{E}$,

$$\lambda_2(w_0) > s > \operatorname{Re} \lambda_2(w_1), \quad \lambda_1(w_0) < s, \quad \operatorname{Re} \lambda_1(w_1) < s. \tag{4.1}$$

This condition is insufficient: it does not take into account B_{sc} and the possibility of a limit cycle. Furthermore, while the analogous condition for a 1-shock appears correct for the case where $M = I$ and $B < 0$, it is incorrect when $M \neq I$. A simple geometric condition equivalent to the viscous profile criterion does not exist in this case. Since the LEGC is based on properties of initial boundary-value problems, we can pose such a problem when change of type occurs. We have some preliminary results in [2] that are consistent with the present paper.

The results in § 3 explicitly exclude system (1.3), for which $B = 0$. For $M = I$, the curve B_h exists and along this curve the system is Hamiltonian. Perturbation to $M \neq I$ will introduce both the cases $B > 0$ and $B < 0$. The normal form for this singularity requires third-order terms.

For some model problems, such as (1.3), a singular viscosity matrix may be appropriate. For example, Shearer used this as an admissibility condition in [18]. We have excluded singular viscosities from the theorems by requiring M to be near I, but have examined them in numerical experiments. We conjecture that they describe a limiting case for the S_2 and S_1^* intervals on the Hugoniot loop.

Acknowledgments. In applying bifurcation theory, both steady state and dynamic, to find and describe the local form of the wave locus and orbit structure, I benefited from discussions with Marty Golubitsky and Bill Farr. These results were first presented at the GAMM International Conference in honor of Jack Hale on Problems Involving Change of Type; a summary appears in [14].

BEST POSSIBLE UPPER BOUND FOR BLOWUP SOLUTIONS OF THE QUASILINEAR HEAT CONDUCTION EQUATION WITH SOURCE*

VICTOR A. GALAKTIONOV†

Abstract. This article studies the behavior of the weak solution of the Cauchy problem to quasilinear degenerate parabolic equation $u_t = (u^\sigma u_x)_x + u^{\sigma+1}$, where $\sigma > 0$ is a fixed constant, with a nonnegative bounded compactly supported initial function. Let T_0 be the finite blowup time for solution $u(x, t)$. The estimate $\sup_x u(x, t) \leqq M(t)$ for all $t \in (0, T_0)$, where $M(t)$ is defined from some nonlinear ordinary differential equation, is proved by the comparison of intersection methods (based on the theory of lap number or zero set) with explicit noninvariant blowup solution.

Key words. quasilinear heat conduction equation with source, blowup solution, localization, noninvariant explicit solution, upper bound

AMS(MOS) subject classification. 35K

1. Introduction. Main results. In this paper we consider the Cauchy problem for the quasilinear degenerate parabolic equation

$$u_t = (u^\sigma u_x)_x + u^{\sigma+1} \quad \text{for } x \in \mathbf{R} = (-\infty, \infty), \quad t > 0, \tag{1.1}$$

$$u(x, 0) = u_0(x) \quad \text{in } \mathbf{R}. \tag{1.2}$$

Here $\sigma > 0$ is a fixed constant. We assume that the initial function satisfies the hypotheses

$$\begin{aligned} &u_0 \geqq 0 \quad \text{in } \mathbf{R}, \quad u_0 \not\equiv 0, \quad \sup u_0 < \infty, \\ &u_0 \text{ has compact support } \operatorname{supp} u_0 = \{x \in \mathbf{R} \mid u_0(x) > 0\}, \\ &u_0^\sigma \text{ is uniformly Lipschitz continuous in } \mathbf{R}. \end{aligned} \tag{1.3}$$

Equation (1.1) describes the evolution of initial temperature u_0 in a medium with nonlinear heat conduction coefficient $k(u) = u^\sigma$ and heat source $Q(u) = u^{\sigma+1}$ depending on the temperature $u = u(x, t) \geqq 0$.

It is well known [4], [20, p. 208] that for any nonzero, nonnegative, initial function problem (1.1), (1.2) has no global (in time) solution and $u(x, t)$ blows up in finite time T_0, i.e., the weak solution $u(x, t)$ exists in $\mathbf{R} \times [0, T_0)$ and

$$\overline{\lim_{t \to T_0^-}} \sup_{x \in \mathbf{R}} u(x, t) = +\infty. \tag{1.4}$$

Here $T_0 = T_0(u_0)$, depending upon the initial function u_0, is called the finite blowup time of the unbounded solution $u(x, t)$.

In this paper some global properties of the unbounded solution of the Cauchy problem (1.1), (1.2) on the whole time interval $(0, T_0)$ are investigated. Detailed information concerning different properties of unbounded blowup solutions of (1.1) and of the equation with power nonlinearities of a more general kind,

$$u_t = (u^\sigma u_x)_x + u^\beta, \qquad x \in \mathbf{R}, \quad t > 0, \tag{1.5}$$

where $\sigma > 0$ and $\beta > 1$ are arbitrary fixed constants, are given in [20, Chaps. IV, V, VII]; see also the list of references given there. Properties of blowup solutions of the

Cauchy problem for (1.5) are quite different for three cases: (i) so-called LS evolution of blowup solution, $\beta > \sigma+1$, when $u(x, t)$ may go to infinity as $t \to T_0$ in a domain of zero measure or single point blowup (see [7], [20, p. 253]); (ii) S evolution, $\beta = \sigma+1$, when under the hypothesis (1.3) the spatial blowup set for the solution $u(x, t)$ is a bounded domain of nonzero measure (see [20, p. 230], [3]); (iii) HS evolution, $\beta < \sigma+1$, when $u(x, t) \to +\infty$ as $t \to T_0$ for any $x \in \mathbf{R}$ (see [20, p. 238]). This classification (LS, S, and HS evolutions) of different types of unbounded blowup solutions was introduced approximately twenty years ago. See a full list of references in [20].

Thus the case $\beta = \sigma+1$ is the interesting "boundary" one between the region $\{\beta > \sigma+1\}$ of single point localization of blowup solutions and region $\{\beta < \sigma+1\}$ of nonlocalized solutions of total blowup.

We now state the main result of the paper.

THEOREM 1. *Let the hypotheses* (1.3) *hold and let* $T_0 \in (0, \infty)$ *be the finite blowup time of the solution to* (1.1), (1.2). *Then*

$$\|u(\cdot, t)\|_{L^\infty(\mathbf{R})} \equiv \sup_{x \in \mathbf{R}} u(x, t) \leqq \{\varphi(t)[\psi(t)+1]\}^{1/\sigma}, \qquad t \in (0, T_0), \tag{1.6}$$

where the function $\psi(t) \in (-1, 1)$ *satisfies the ordinary differential equation*

$$\psi' = \sigma(\sigma+1)^{-1} C_0 (1-\psi^2)^{-\sigma/2}, \quad t \in (0, T_0), \quad \psi(0) = -1, \tag{1.7}$$

$$C_0 = C_0(T_0) \equiv [(\sigma+1)/\sigma] T_0^{-1} B(1+\sigma/2, \tfrac{1}{2}) \tag{1.8}$$

($B(p, q)$ *is the beta-function*), *and*

$$\varphi(t) = C_0[1-\psi^2(t)]^{-(\sigma+2)/2}, \qquad t \in (0, T_0). \tag{1.9}$$

Note that the upper bound (1.6) holds for the arbitrary blowup solution and the right side of (1.6) depends only on the finite blowup time T_0 and does not depend on the initial function satisfying (1.3) (except through the value of T_0).

Estimate (1.6) allows for the possibility that the amplitude of the solution may be nonmonotonic in time. For example, $\sup_x u(x, t)$ may decrease for small $t > 0$ and $\sup_x u(x, t) \to \infty$ as $t \to T_0$. Under some additional conditions on the initial function ($u_0(-x) = u_0(x)$ in $\mathbf{R}$ and $u_0 \not\equiv$ const. is a nonincreasing function in $\mathbf{R}_+ = (0, \infty)$) the same result was proved in [3]. In order to avoid these restrictive conditions on u_0 and to prove the estimate (1.6) for sufficiently arbitrary initial functions satisfying (1.3), we use the idea of the so-called "comparison of intersection" of blowup solutions from [5] and [6] (see also [10]).

If we define asymptotics of the function

$$M(t) := \{\varphi(t)[\psi(t)+1]\}^{1/\sigma}, \qquad t \in (0, T_0) \tag{1.10}$$

as $t \to 0$ and $t \to T_0$ using (1.6) we get the following estimates.

COROLLARY 1. *Under the hypotheses of Theorem* 1 *there exists* $\tau_1 > 0$, *depending on* σ *and* T_0, *such that*

$$\|u(\cdot, t)\|_{L^\infty(\mathbf{R})} \leqq a_0 t^{-1/(\sigma+2)}(1+o(1)), \qquad 0 < t < \tau_1, \tag{1.11}$$

where

$$a_0 = a_0(T_0) \equiv 2^{-1/\sigma}[(\sigma+1)/\sigma]^{1/\sigma}(\sigma+2)^{-1/(\sigma+2)} \cdot T_0^{-2/\sigma(\sigma+2)}[B(1+\sigma/2, \tfrac{1}{2})]^{2/\sigma(\sigma+2)}. \tag{1.12}$$

COROLLARY 2. *Under the hypotheses of Theorem* 1 *there exists* $\tau_2 > 0$, *depending on* σ *and* T_0, *such that*

$$\|u(\cdot, t)\|_{L^\infty(\mathbf{R})} \leqq [A_0^{-1}(T_0 - t)]^{-1/\sigma}(1 + o(1)), \qquad T_0 - \tau_2 < t < T_0, \tag{1.13}$$

where $A_0 = 2(\sigma+1)/\sigma(\sigma+2)$.

We shall show that the upper estimates (1.11) and (1.13) of the asymptotic behavior of the solution near $t = 0$ and near finite blowup time $t = T_0$ are the best possible.

The plan of the paper is as follows. In § 2 we give some preliminary information and results. In § 3 some basic properties of the noninvariant explicit solution of the equation (1.1) [8], [9] are described. The main result is obtained by the comparison of intersection (see [20, Chap. IV]) of the solution $u(x, t)$ with the above-mentioned explicit solution which has the same finite blowup time. Necessary preliminary information about the comparison of such an intersection is given in § 4. Theorem 1 is proved in § 5.

The explicit solution from § 3 shows the existence of the weak solution of the Cauchy problem for (1.1) with singular initial function

$$u(x, 0) = \delta(x) \quad \text{in } \mathbf{R} \tag{1.14}$$

($\delta(x)$ is Dirac's measure). It is shown that the weak solution $u_*(t, x)$ of (1.1), (1.14) exists in $\mathbf{R} \times [0, T_*)$ where

$$T_* = 2^{-1}\sigma^{-(\sigma+1)}(\sigma+1)^{(\sigma+2)/2}B(1+\sigma/2, \tfrac{1}{2})B^\sigma(1+1/\sigma, \tfrac{1}{2}) \tag{1.15}$$

and $u_*(x, t) \to +\infty$ as $t \to T_*^-$ in the localization domain $\omega_L = (-L_s/2, L_s/2)$, where $L_s = 2\pi(\sigma+1)^{1/2}/\sigma$ is the so-called fundamental length of the nonlinear medium described by (1.1) [20, Chap. IV], and $u_*(x, t) = 0$ in $(\mathbf{R} \setminus \omega_L) \times [0, T_*)$.

The explicit solution $u_*(x, t)$ gives another general property of the localization of blowup solutions to (1.1). It was shown in [3] by the comparison of intersection that the right front $h_+(t) \equiv \sup\{x \in \mathbf{R} \mid u(x, t) > 0\}$ of any unbounded solution satisfies the estimate

$$h_+(t) \leqq h_+(0) + (L_s/2\pi) \cdot [\pi/2 + \arcsin \psi(t)] < h_+(0) + L_s/2$$

in $(0, T_0)$, where the function $\psi(t)$ is as defined in (1.7), (1.8). Hence the right heat front does not move more than a distance $L_s/2$ from its initial position. This upper estimate is exact since the right front of the explicit solution $u_*(x, t)$ moves exactly through the distance $L_s/2$ as $t \to T_*^-$. Therefore L_s is really a fundamental characteristic of the nonlinear equation (1.1), since the property of the heat front mentioned above does not depend on the initial function.

The explicit solution (from § 3) illustrates several of the most general properties of a wide class of blowup solutions, i.e., it possesses the "fundamental" characteristics of the nonlinear equation (1.1).

2. Preliminary results. In the general case, the Cauchy problem for the quasilinear degenerate parabolic equation (1.1) admits a weak blowup solution.

A bounded continuous function $u(x, t)$ satisfying (1.2) is said to be a weak solution of the problem (1.1), (1.2) in $Q_T = \mathbf{R} \times [0, T]$ if there exists a weak derivative $(u^{\sigma+1})_x \in L^2_{\mathrm{loc}}(Q_T)$, and if the identity

$$\iint_{Q_T} \{(\sigma+1)^{-1}(u^{\sigma+1})_x f_x - u^{\sigma+1} f - u f_t\}\, dx\, dt = 0 \tag{2.1}$$

holds for arbitrary test functions $f \in C_0^1(Q_T)$. The function $u(x, t)$ is said to be a blowup weak solution of the problem (1.1), (1.2) in $\mathbf{R} \times [0, T_0)$ if it is a weak solution in Q_T for all $T \in (0, T_0)$ and if (1.4) holds.

Local existence, uniqueness, and the comparison theorems for quasilinear degenerate parabolic equations of type (1.1) are proved, for instance, in [17]-[19] and [14]. See the detailed survey in [11]. For any points where $u > 0$ and where the equation is uniformly parabolic with smooth coefficients, the weak solution is classical and has derivatives of arbitrary order. Nonexistence of the global weak solution to the problem (1.1), (1.2) for $u_0 \not\equiv 0$ was proved in [4]. See also [20, p. 208]. We shall use the well-known property of finite speed of propagation of disturbances for the degenerate equation (1.1), i.e., under hypotheses (1.3), $u(x, t)$ has compact support for any $t \in (0, T_0)$. See the references in [11].

3. Explicit solution. It has been shown in [8] and [9] that for arbitrary $\sigma > 0$ the quasilinear parabolic equation (1.1) admits an explicit weak blowup solution of the form

$$
\begin{aligned}
&u_*(x, t) = \{\varphi(t)[\psi(t) + \cos(2\pi x / L_s)]\}^{1/\sigma} \quad \text{for } x \in (-L_s/2, L_s/2), \\
&u_* \equiv 0 \quad \text{for } x \in \mathbf{R} \setminus (-L_s/2, L_s/2), \quad t \in (0, T_0),
\end{aligned} \tag{3.1}
$$

where the function $\psi(t)$ satisfies the ordinary differential equation (1.7), (1.8) and the function $\varphi(t)$ is defined in (1.9). It can easily be shown that this explicit solution (for C_0 from (1.8)) has the finite blowup time T_0.

Consider the main evolution properties of the explicit solution (3.1). It describes the behavior of the blowup heat structure with nonmonotone spatial amplitude

$$
\|u_*(\cdot, t)\|_{L^\infty(\mathbf{R})} \equiv u_*(0, t) = M(t) \equiv \{\varphi(t)[\psi(t) + 1]\}^{1/\sigma}, \qquad t \in (0, T_0), \tag{3.2}
$$

and $u_*(0, t) = M(t) \to +\infty$ as $t \to T_0$. Using (1.7)-(1.9), we have that

$$
u_*(0, t) = M(t) = a_0 t^{-1/(\sigma+2)}(1 + o(1)) \to +\infty \quad \text{as } t \to 0, \tag{3.3}
$$

$$
u_*(0, t) = [A_0^{-1}(T_0 - t)]^{-1/\sigma}(1 + o(1)) \to +\infty \quad \text{as } t \to T_0^-, \tag{3.4}
$$

where constants a_0, A_0 are as defined in Corollaries 1 and 2.

Thus, the formulas above show that the spatial amplitude $M(t)$ of the solution $u_*(x, t)$ is a nonmonotone function. It is easy to calculate that

$$
\min_{(0, T_0)} M(t) = T_0^{-1/\sigma} B^{1/\sigma}(1 + \sigma/2, \tfrac{1}{2})[\sigma(\sigma+2)/(\sigma+1)^2]^{-(\sigma+2)/2\sigma}
$$

for

$$
t = t_m = T_0 B^{-1}(1 + \sigma/2, \tfrac{1}{2}) \int_{1/(\sigma+1)}^{1} (1 - z^2)^{\sigma/2}\, dz \in (0, T_0/2).
$$

For any $t \in (0, T_0)$ this explicit solution has the compact support with the right front

$$
x = h_+^*(t) \equiv g(t) \equiv (L_s/2\pi)[\pi/2 + \arcsin \psi(t)], \qquad t \in (0, T_0). \tag{3.5}
$$

Therefore $u_*(x, t)$ is the localized solution, since $h_+^*(t) < L_s/2$ for all $t \in (0, T_0)$ and $h_+^*(T_0^-) = L_s/2$. Note that (3.5) leads to the following behavior of the right heat front:

$$
h_+^*(t) = b_0^{1/2} t^{1/(\sigma+2)}(1 + o(1)) \quad \text{as } t \to 0, \tag{3.6}
$$

where

$$
b_0 = b_0(T_0) \equiv (\sigma+1)\sigma^{-2}(\sigma+2)^{2/(\sigma+2)} T_0^{-2/(\sigma+2)}[B(1 + \sigma/2, \tfrac{1}{2})]^{2/(\sigma+2)}.
$$

Consider now a more detailed asymptotic space-time structure of $u_*(x, t)$ near $t=0$. Such results are important for comparison of intersection. First, we note that $u_*(x, t)$ is the nonnegative bounded weak solution of (1.1) in $\mathbf{R}\times[\tau, T]$ for arbitrary fixed $\tau\in(0, T_0)$ and $T\in(\tau, T_0)$. From (1.7) and (1.9) it follows that $\psi(t)=-1+b_0t^{2/(\sigma+2)}(1+o(1))$ and $\varphi(t)=A_0t^{-1}(1+o(1))$ as $t\to 0$. Therefore

$$u_*(x, t)=(A_0t^{-1}(1+o(1))[b_0t^{2/(\sigma+2)}(1+o(1))+\cos(2\pi x/L_s)-1])_+^{1/\sigma} \quad \text{as } t\to 0.$$

Since $1-\cos(2\pi x/L_s)=2\sin^2(\pi x/L_s)=2\pi^2x^2/L_s^2+o(x^2)$ as $x\to 0$ we get

$$u_*(x, t)=a_0t^{-1/(\sigma+2)}([(1+\lambda_1(t, x))-(x/b_0^{1/2}t^{1/(\sigma+2)})^2](1+\lambda_2(t, x)))_+^{1/\sigma}, \tag{3.7}$$

where $\lambda_1(t, x)$ and $\lambda_2(t, x)$ are sufficiently smooth functions such that $\lambda_i(t, x)=o(1)$ as $t+|x|\to 0$, $i=1, 2$.

Hence, for $T_0=T_*$ (see (1.15)) the explicit solution $u_*(x, t)$ satisfies the initial condition (1.14) in the weak sense:

$$\lim_{t\to 0}\int_{-\infty}^{\infty}u_*(x, t)\xi(x)\,dx=\xi(0)$$

for arbitrary test functions $\xi\in C_0^\infty(\mathbf{R})$.

4. Comparison of intersection. Main preliminary statements. We now give some preliminary statements concerning the comparison of intersection of the solution of the problem (1.1), (1.2) with the explicit solution $u_*(x, t)$.

Let $u(x, t)$ be the solution of the Cauchy problem (1.1), (1.2) in $\mathbf{R}\times(0, T_0)$ with the initial function satisfying (1.3), and let T_0 be the finite blowup time. We suppose that $\operatorname{supp}_x u(x, t)\equiv\{x\in\mathbf{R}\,|\,u(x, t)>0\}=(h_-(t), h_+(t))$, i.e., the support of $u(x, t)$ is the finite connected interval for any $t\in[0, T_0)$. Then $h_\pm(t)$ are continuous functions in $[0, T_0)$, $h_+(t)$ is a nondecreasing function, and $h_-(t)$ is a nonincreasing one. See the references in [11]. By the results of localization [3] (see also [20, p. 230]) we have the estimate $\operatorname{supp}_x u(x, t)\subset(h_-(0)-L_s/2, h_+(0)+L_s/2)$ for all $t\in(0, T_0)$.

Let $v(x, t)$ be the weak solution of the Cauchy problem for (1.1) in $\mathbf{R}\times(0, T_0)$ with some initial function $v(0, x)=v_0(x)$ satisfying the same hypotheses. We suppose that $v(x, t)$ has bounded connected support for any $t\in(0, T_0)$.

Proof of the main results of this paper are based on the following preliminary lemmas concerning the comparison of intersection method of different solutions $u(x, t)$ and $v(x, t)$ of the equation (1.1) [20, Chap. IV].

The functions $u(x, t_0)$ and $v(x, t_0)$ for fixed $t_0\in[0, T]$ are said to be intersected on the finite interval $[a, b]$, if the difference $w(x, t_0)\equiv u(x, t_0)-v(x, t_0)=0$ in $[a, b]$, $w(x, t_0)\not\equiv 0$ in $[a-\varepsilon, a]$ and $[b, b+\varepsilon]$ and $w(x, t_0)$ changes sign in the interval $[a-\varepsilon, b+\varepsilon]$ for arbitrarily small $\varepsilon>0$. In other words, the finite interval $[a, b]$ is said to be an intersection if $w(x, t_0)\equiv 0$ on $[a, b]$, and for any small $\varepsilon>0$ there exist $x_1\in[a-\varepsilon, a]$, $x_2\in[b, b+\varepsilon]$, such that $w(x_1, t_0)w(x_2, t_0)<0$. If $a=b$ then this is the point of intersection. However, for the quasilinear degenerate parabolic equation (1.1) with weak compactly supported solutions there exist intervals of intersection.

We shall denote by $N(t)$, the number of intersections for fixed $t\in[0, T_0)$. Evidently, $N(t)$ is equal to the number of sign changes in $\mathbf{R}$ of the function $w(x, t)$.

The first statement of the comparison of intersection is the most general one.

LEMMA 1 (see [20, p. 240]). *Let $N(0)<\infty$. Then $N(t)$ is a nonincreasing function and in particular*

$$N(t)\leqq N(0) \quad \textit{for all } t\in(0, T_0). \tag{4.1}$$

This result is well known for linear and quasilinear parabolic equations (see other such results in [1], [2], [5], [6], [10], [15], [16], [21]).

The second statement is a specific comparison theorem for different weak blowup solutions with the same finite blowup times.

LEMMA 2 (see [20, p. 231]). *Let T_0 be the finite blowup time for $v(x, t)$. Then*

$$\{t \in [0, T_0) \mid \overline{\operatorname{supp}}_x v(x, t) \subset \operatorname{supp}_x u(x, t) \text{ and } v(x, t) \leqq u(x, t) \text{ in } \mathbf{R}\} = \varnothing. \tag{4.2}$$

From the simple properties of weak solutions it follows that if (4.2) is not valid and for some $t_0 \in [0, T_0)$

$$\overline{\operatorname{supp}}_x v(x, t_0) \subset \operatorname{supp}_x u(x, t_0), \quad v(x, t_0) \leqq u(x, t_0) \quad \text{in } \mathbf{R} \tag{4.3}$$

then blowup time for $v(x, t)$ is greater than blowup time for $u(x, t)$. It is easy to show by the strong maximum principle and comparison theorems that under conditions (4.3) there exist small $\tau_1 > 0$, $\tau_2 > 0$ such that $v(x, t_0 + \tau_1 + \tau_2) \leqq u(x, t_0 + \tau_1)$ in $\mathbf{R}$, and hence by the usual comparison theorem $v(x, t + \tau_2) \leqq u(x, t)$ in $\mathbf{R} \times [t_0 + \tau_1, T_0)$ (see [20, p. 231]). Letting $t = T_0 - \tau_2$, we get $v(x, T_0) \leqq u(x, T_0 - \tau_2) < +\infty$ in $\mathbf{R}$, i.e., T_0 is not the blowup time for $v(x, t)$, which leads to a contradiction of the hypothesis of Lemma 2.

5. Proof of Theorem 1. We shall compare the solution of the Cauchy problem (1.1), (1.2) with the explicit solution (3.1) (more precisely, with the two-parametric family of such explicit solutions).

Consider, for fixed arbitrary $\varepsilon > 0$ and $\delta \in \mathbf{R}$, the function $v(x, t; \varepsilon, \delta) \equiv u_*(x - \delta, t + \varepsilon)$, where $\psi(t)$, $\varphi(t)$ satisfy (1.7), (1.9), and $C_0 = C_0(T_0 + \varepsilon)$ is given in (1.8). Then $v(x, t; \varepsilon, \delta)$ is the weak blowup solution in $\mathbf{R} \times (0, T_0)$ of the Cauchy problem for (1.1) with the initial function $v(x, 0; \varepsilon, \delta) \equiv u_*(x - \delta, \varepsilon)$ satisfying hypotheses (1.3). Clearly, $v(x, t; \varepsilon, \delta)$ is the continuous function with respect to x, t and ε, δ. By construction, for any fixed $\varepsilon > 0$ and $\delta \in \mathbf{R}$, solutions $u(x, t)$ and $v(x, t; \varepsilon, \delta)$ have the same blowup time T_0.

Let $N(t; \varepsilon, \delta)$ be the number of intersections of the functions $u(x, t)$ and $v(x, t; \varepsilon, \delta)$.

LEMMA 3. *There exists sufficiently small $\varepsilon_0 > 0$ such that for any $\varepsilon \in (0, \varepsilon_0]$, $\delta \in \mathbf{R}$*

$$\sup_{x \in \mathbf{R}} v(x, 0; \varepsilon, \delta) \equiv v(\delta, 0; \varepsilon, \delta) \equiv u_*(0, \varepsilon) > \sup_{x \in \mathbf{R}} u_0(x) \tag{5.1}$$

and

$$N(0; \varepsilon, \delta) \leqq 2. \tag{5.2}$$

Proof. Estimates (5.1), (5.2) for arbitrary fixed $\varepsilon \in (0, \varepsilon_0]$, $\delta \in \mathbf{R}$ follow from asymptotic behavior of $u_*(x, t)$ near $t = 0$, given in (3.7).

From (5.2) and Lemma 1 it follows that

$$N(t; \varepsilon, \delta) \leqq 2 \quad \text{for } 0 < t < T_0 \quad \text{for any } \varepsilon \in (0, \varepsilon_0], \quad \delta \in \mathbf{R}. \tag{5.3}$$

We now prove that

$$\sup_{x \in \mathbf{R}} u(x, t) \leqq \sup_{x \in \mathbf{R}} v(x, t; \varepsilon, \delta) \equiv v(\delta, t; \varepsilon, \delta) \tag{5.4}$$

for all $t \in [0, T_0)$.

Let

$$t_* = \sup \{s \in (0, T_0) \mid (5.4) \text{ hold for all } 0 \leqq t \leqq s\} < T_0 \tag{5.5}$$

($t_* > 0$ by (5.1)). Then there exists $x_* \in \mathbf{R}$ such that

$$\sup_{x \in \mathbf{R}} u(x, t_*) = u(x_*, t_*)$$

and hence for $\delta = x_*$

$$\sup_{x \in \mathbf{R}} v(x, t_*; \varepsilon, x_*) \equiv v(x_*, t_*; \varepsilon, x_*),$$

i.e., $x = x_*$ is the maximum point for $u(x, t_*)$ and $v(x, t_*; \varepsilon, x_*)$. Without loss of generality we suppose that $x = x_*$ is the point of strict maximum for $u(x, t_*)$, i.e., $u(x, t_*) < u(x_*, t_*)$ in a small deleted neighborhood of $x = x_*$. Evidently, the same assertion holds for the explicit solution $v(x, t_*; \varepsilon, x_*)$. This assumption about zeros or maximum points is valid for arbitrary classical solutions of parabolic equations with sufficiently smooth coefficients. See different results in this direction [2], [5], [15], [21]. Note that all coefficients of (1.1) are smooth (and analytic) functions for $u > 0$ and therefore we may assume that solutions of the Cauchy problems considered are C^∞ (and analytic in x) functions at any point of positivity of the solution [12], [13] (see also [1] where analyticity results were obtained for a wide class of nonlinear degenerate parabolic equation including our quasilinear equation (1.1)). Under these hypotheses any positive maximum of $u(x, t_*)$ is the isolated point. The same holds for any intersection of $u(x, t_*)$ and $v(x, t_*; \varepsilon, \delta)$ if these solutions are strictly positive near the intersection. But the above-mentioned assumptions are not the principal parts of our proof.

Two cases are possible. Certainly, we may assume that $u(x, t_*) \not\equiv v(x, t_*; \varepsilon, x_*)$.

Case 1. $x = x_*$ is the point of *inflection* (see [6], [10]) of functions $u(x, t_*)$ and $v(x, t_*; \varepsilon, x_*)$, i.e., $x = x_*$ is the isolated point of intersection and the function $w(x, t_*; \varepsilon, x_*) \equiv u(x, t_*) - v(x, t_*; \varepsilon, x_*)$ changes sign in any small neighborhood of the point $x = x_*$ and

$$w(x_*, t_*; \varepsilon, x_*) = w_x(x_*, t_*; \varepsilon, x_*) = 0. \tag{5.6}$$

Since $w(x, t_*; \varepsilon, x_*)$ is not of constant sign near $x = x_*$, we suppose that $w(x, t_*; \varepsilon, x_*) > 0$ in a small left neighborhood of $x = x_*$ and $w(x, t_*; \varepsilon, x_*) < 0$ in a small right one. Then there exist $x_1 < x_* < x_2$ such that

$$w(x_1, t_*; \varepsilon, x_*) > 0, \qquad w(x_2, t_*; \varepsilon, x_*) < 0. \tag{5.7}$$

Fix small $\lambda > 0$ and consider the function $v(x, t_*; \varepsilon, x_* - \lambda)$. Since $x = x_*$ is the point of strict maximum for functions $u(x, t_*)$ and $v(x, t_*; \varepsilon, x_*)$ we can see that the difference $w(x, t_*; \varepsilon, x_* - \lambda) \equiv u(x, t_*) - v(x, t_*; \varepsilon, x_* - \lambda)$ satisfies

$$w(x_*, t_*; \varepsilon, x_* - \lambda) > 0, \qquad w(x_* - \lambda, t_*; \varepsilon, x_* - \lambda) < 0. \tag{5.8}$$

The function $v(x, t_*; \varepsilon, x_* - \lambda)$ is continuous with respect to λ. Hence, inequalities (5.7) hold for any small $\lambda > 0$, i.e.,

$$w(x_1, t_*; \varepsilon, x_* - \lambda) > 0, \qquad w(x_2, t_*; \varepsilon, x_* - \lambda) < 0. \tag{5.9}$$

From (5.8), (5.9) we see that $w(x, t_*; \varepsilon, x_* - \lambda)$ has at least three sign changes in the interval (x_1, x_2) near the point $x = x_*$, i.e., $N(t_*; \varepsilon, x_* - \lambda) \geqq 3$, which contradicts (5.3) for $\delta = x_* - \lambda$.

Case 2. $x = x_*$ is the point of *tangency* of the functions $u(x, t_*)$ and $v(x, t_*; \varepsilon, x_*)$, and in particular $w(x_*, t_*; \varepsilon, x_*) = 0$ but $w(x, t_*; \varepsilon, x_*)$ does not change sign near $x = x_*$.

If $v(x, t_*; \varepsilon, x_*) \geqq u(x, t_*)$ near $x = x_*$ and $v(x, t_*; \varepsilon, x_*) \not\equiv u(x, t_*)$, then by the strong maximum principle and the usual comparison theorem the same inequality

holds for any $t > t_*$, where $t - t_*$ is sufficiently small, which contradicts the choice of t_* in (5.5).

Thus, it remains to consider the case where $v(x, t_*; \varepsilon, x_*) \leqq u(x, t_*)$ and $v(x, t_*; \varepsilon, x_*) \not\equiv u(x, t_*)$ in a small neighborhood of $x = x_*$. Then we can choose $x_1 < x_* < x_2$ such that

$$w(x_1, t_*; \varepsilon, x_*) > 0, \qquad w(x_2, t_*; \varepsilon, x_*) > 0. \tag{5.10}$$

If $v(x, t_*; \varepsilon, x_*) \leqq u(x, t_*)$ in $\mathbf{R}$ and $\overline{\operatorname{supp}}_x v(x, t_*; \varepsilon, x_*) \subset \operatorname{supp}_x u(x, t_*)$, then we get a contradiction to Lemma 2 since, by construction, T_0 is the finite blowup time for $u(x, t)$ and $v(x, t; \varepsilon, x_*)$.

Consider now the case where

$$v(x, t_*; \varepsilon, x_*) \leqq u(x, t_*) \quad \text{in } \mathbf{R}, \tag{5.11}$$

i.e., $N(t_*; \varepsilon, x_*) = 0$ (the difference $w(x, t_*; \varepsilon, x_*)$ does not change sign in $\mathbf{R}$), but the condition $\overline{\operatorname{supp}}_x v(x, t_*; \varepsilon, x_*) \subset \operatorname{supp}_x u(x, t_*)$ is not valid. Clearly, (5.11) means that $\operatorname{supp}_x v(x, t_*; \varepsilon, x_*) \subseteq \operatorname{supp}_x u(x, t_*)$ and one or two boundary points of the supports $\operatorname{supp}_x v(x, t_*; \varepsilon, x_*) \equiv (x_* - g(t_*), x_* + g(t_*))$ (see (3.5)) and $\operatorname{supp}_x u(x, t_*) \equiv (h_-(t_*), h_+(t_*))$ coincide. For instance, let the right heat fronts of $v(x, t_*; \varepsilon, x_*)$ and $u(x, t_*)$ coincide, i.e., $x_* + g(t_*) = h_+(t_*)$. Then we can obtain that for any small $\lambda > 0$ the number of intersections $N(t_*; \varepsilon, x_* + \lambda)$ of the functions $v(x, t_*; \varepsilon, x_* + \lambda)$ and $u(x, t_*)$ satisfies the inequality $N(t_*; \varepsilon, x_* + \lambda) \geqq 3$. Evidently, since $\operatorname{supp}_x v(x, t_*; \varepsilon, x_* + \lambda) = (x_* + \lambda - g(t_*), x_* + \lambda + g(t_*))$ and hence $w(h_+(t_*), t_*; \varepsilon, x_* + \lambda) \equiv -v(h_+(t_*), t_*; \varepsilon, x_* + \lambda) < 0 = u(h_+(t_*), t_*)$, one new intersection arises near the right heat front $x = h_+(t_*)$ of the function $u(x, t_*)$. Using the second inequality (5.10), we get that for any small $\lambda > 0$ there exists at least one intersection of the functions $v(x, t_*; \varepsilon, x_* + \lambda)$ and $u(x, t_*)$ on the interval $(x_2, h_+(t_*))$. Two new intersections arise near the point $x = x_*$. Since $x = x_*$ is the point of strict maximum of the functions $v(x, t_*; \varepsilon, x_*)$ and $u(x, t_*)$, it follows that

$$w(x_* + \lambda, t_*; \varepsilon, x_* + \lambda) < 0. \tag{5.12}$$

By continuity of $w(x, t_*; \varepsilon, x_* + \lambda)$ with respect to λ, inequalities (5.10) remain valid for all small $\lambda > 0$, i.e.,

$$w(x_1, t_*; \varepsilon, x_* + \lambda) > 0, \qquad w(x_2, t_*; \varepsilon, x_* + \lambda) > 0. \tag{5.13}$$

From (5.12), (5.13) we get that $w(x, t_*; \varepsilon, x_* + \lambda)$ has at least two sign changes on the interval (x_1, x_2).

Thus, $N(t_*; \varepsilon, x_* + \lambda) \geqq 3$ for all sufficiently small $\lambda > 0$ and we arrive at a contradiction to (5.3) for $\delta = x_* + \lambda$.

Consider the last situation where $v(x, t_*; \varepsilon, x_*) \leqq u(x, t_*)$ in a small neighborhood of the point $x = x_*$ and $N(t_*; \varepsilon, x_*) \geqq 1$. Then we can see by the same "λ-translation the x-axis of the function $v(x, t_*; \varepsilon, x_*)$" that two new intersections arise near the maximum point $x = x_*$. Together with the intersections for $\lambda = 0$ which do not disappear for any small $\lambda > 0$ this leads to the estimate $N(t_*; \varepsilon, x_* + \lambda) \geqq 3$, which contradicts (5.3) for $\delta = x_* + \lambda$.

Thus, $t_* = T_0$, and (5.4) holds for all $t \in [0, T_0)$. Letting $\varepsilon \to 0$ and $\delta = 0$, we get (1.6) which completes the proof of Theorem 1.

Using (3.3), (3.4), we obtain results for Corollaries 1 and 2. Evidently, these estimates are the best possible since the explicit solution $u_*(x, t)$ satisfies (1.11) and (1.13) with equality signs instead of inequality signs.

Remark 1. Equation (1.1) admits the weak blowup self-similar solution of the form (see, e.g., [20, p. 175])

$$u_A(x, t) = (T_0 - t)^{-1/\sigma} \cdot \theta(x),$$

where

$$\theta(x) = \left(\frac{2(\sigma+1)}{\sigma(\sigma+2)} \cos^2\left(\frac{\pi x}{L_s}\right)\right)^{1/\sigma} \quad \text{for } |x| < L_s/2 = \pi(\sigma+1)^{1/2}/\sigma,$$

$$\theta(x) = 0 \quad \text{for } |x| \geqq L_s/2.$$

This solution is localized in the bounded domain $\{|x| < L_s/2\}$, $u_A(x, t) = 0$ in $\mathbf{R}\backslash\{|x| < L_s/2\}$ for all $t \in (0, T_0)$ and $u_A(0, t) = [A_0^{-1}(T_0 - t)]^{-1/\sigma}$ for $t \in (0, T_0)$. The last equality coincides with the right-hand side of (1.13).

Remark 2. It follows from the proof of the Theorem 1 that the estimate (1.6) holds for any blowup solution $u(x, t)$ such that $\sup_x u(x, t)$ is attained at a finite point $x = x_* \in \mathbf{R}$ for arbitrarily fixed $t \in [0, T_0)$. Hence, for instance, Theorem 1 is valid for an arbitrary initial function u_0 such that $u(x, t) \to 0$ as $|x| \to \infty$ for any fixed $t \in [0, T_0)$, i.e., (1.6) holds for more general initial functions u_0 than those with compact support.

INVERSE PROBLEMS IN MULTIDIMENSIONS*

LI-YENG SUNG† AND A. S. FOKAS†

Abstract. The direct and inverse problems associated with off-diagonal $N \times N$ matrix-valued potentials in $\mathbb{R}^{n+1}$ are studied rigorously. For $N = 2$ and $n = 1$, they are related to the Davey–Stewartson II equation. The components of the potentials are assumed to be rapidly decreasing Schwartz functions. Under small norm conditions, both the direct and the inverse problems are shown to be uniquely solvable. The inverse data are characterized by certain nonlinear equations. Furthermore, the general problem of reconstructing the potential is reduced to the reconstruction of 2×2 potentials.

Key words. inverse problems, multidimensions

AMS(MOS) subject classification. 35R30

1. Introduction.

In this paper we shall study rigorously an inverse problem formally discussed in [5]. Let $Q(x_0, x)$ be an off-diagonal $N \times N$-matrix-valued function defined on $\mathbb{R}^{n+1}$. To facilitate the discussion, we shall assume that the components of Q are rapidly decreasing Schwartz functions. The space of such matrix-valued functions will be denoted by $S^o_{N\times N}$. We want to reconstruct Q from solutions of the following system:

$$\psi_{x_0} + \sigma \sum_{\ell=1}^{n} J_\ell \psi_{x_\ell} = Q\psi, \qquad \sigma = \sigma_R + i\sigma_I, \quad \sigma_I \neq 0, \quad n > 1, \tag{1.1}$$

where the J_ℓ's are constant real diagonal $N \times N$ matrices and ψ is an $N \times N$-matrix-valued function.

We assume that $n \leq N$, otherwise (1.1) can be reduced to a problem with fewer variables. In order to reconstruct the potential Q we look for bounded solutions of (1.1) in the following form:

$$\psi(x_0, x, k) = \mu(x_0, x, k) \exp\left[i \sum_{\ell=1}^{n} k_\ell (x_\ell I - \sigma x_0 J_\ell) \right], \tag{1.2}$$

where $k \in \mathbb{C}^n$ and I is the $N \times N$ identity matrix. Direct substitution yields the following equation for the Jost function μ:

$$\mu_{x_0} + \sigma \sum_{\ell=1}^{n} (J_\ell \mu_{x_\ell} + i k_\ell [J_\ell, \mu]) = Q\mu. \tag{1.3}$$

In view of the decay of Q, it is natural to require that

$$\lim_{|x_0|+|x|\to\infty} \mu = I. \tag{1.4}$$

†Department of Mathematics and Computer Science, Clarkson University, Potsdam, New York 13699.

In §2 we consider the direct problem: In Proposition 2.1 we show that if $Q \in S^o_{N\times N}$ and certain norms of Q are small enough (see (2.11)), then (1.3) with the boundary condition (1.4) has a unique bounded solution for each $k \in \mathbb{C}^n$. In Propositions 2.2 and 2.3 we study the regularity of μ and its asymptotic behavior for large k. The inverse data T is introduced in Definition 2.2, and in Proposition 2.4 we derive the $\bar\partial$ equations expressing $\partial\mu/\partial\bar k_p$ in terms of μ and T. We show in Proposition 2.5 that T satisfies the characterization equations, i.e., $2(n-1)$ constraints. In Definitions 2.3 and 2.4 we define the Fréchet space $D^o_{N\times N}$ of inverse data and the scattering map § that takes Q to T. The results of §2 are summarized in Theorem 2.1.

In §3 we study the inverse problem: In Proposition 3.1 we show that if $T \in D^o_{N\times N}$ and certain norms of T are small enough (see (3.8)), then the $\bar\partial$ equations have unique bounded solutions μ_p $(1 \le p \le n)$. The regularity of μ_1 is discussed in Proposition 3.2. In Proposition 3.3 we show that $\mu_1 = \mu_2 = \cdots = \mu_n$, and hence the $\bar\partial$ equations have a unique simultaneous solution μ. The asymptotics of μ for large k is studied in Proposition 3.4. In Propositions 3.5 and 3.6 and Corollary 3.1 we show that if Q_p is defined in terms of μ via

$$Q_p = \frac{i\sigma}{\pi}\left[J_p, \int_{\mathbb{R}^2} \frac{\partial\mu}{\partial\bar k_p}(x_0, x, k)\, dk_{p_R}\, dk_{p_I}\right], \qquad 1 \le p \le n,$$

then $Q_1 = Q_2 = \cdots = Q_n = Q$ (Q is therefore independent of k), $Q \in S^o_{N\times N}$, and Q and μ solve (1.3)–(1.4). We define the inverse scattering map $\hat{\mathbf{S}}$, which takes T to Q in Definition 3.2. The results of §3 are summarized in Theorem 3.1.

In §4 we study the relation between $\mathbf{S}$ and $\hat{\mathbf{S}}$: We show in Proposition 4.1 that $\mathbf{S}$ and $\hat{\mathbf{S}}$ are inverses of each other. As a result, we obtain Theorem 4.1, which states that $\mathbf{S}$ is a homeomorphism from a neighborhood of $0 \in S^o_{N\times N}$ onto a neighborhood of $0 \in D^o_{N\times N}$.

In §5 we consider the problem of reducing the reconstruction of $N \times N$ potentials to the case of 2×2 potentials: In Proposition 5.1 and Corollary 5.1 we show that the 2×2 matrix

$$\hat\mu = \lim_{k\to\infty} \begin{pmatrix} \mu_{aa} & \mu_{ab} \\ \mu_{ba} & \mu_{bb} \end{pmatrix}$$

(the limit is taken in a certain direction determined by the indices a and b) satisfies (1.3)–(1.4) where the coefficient matrices $\hat J_\ell$ and the potential $\hat Q$ are the restrictions of J_ℓ and Q to the aa, ab, ba, and bbth components, and the inverse data $\hat T$ of the 2×2 system can be obtained from the limits of the inverse data of the original system. In Proposition 5.2 we obtain an equivalent characterization of inverse data. An efficient way of reconstructing the potential is then discussed.

There exist several physically significant cases of the above problem: (1) Equation (1.1) with $\sigma = i$, $N = 2$, $n = 1$, and $Q_{21} = \pm\overline{Q}_{12}$ can be used to integrate the Davey–Stewartson (DS) II equation. This equation is a two-spatial dimensional generalization of the celebrated nonlinear Schrödinger equation. DSII was discussed formally in [4] and [6] and rigorously in [1]. Furthermore, it is shown in [2] that for the case of $Q_{21} = \overline{Q}_{12}$, the small norm assumption for both the direct and the inverse problem can be relaxed. (2) Equation (1.1) with $\sigma = 1$, $N = 2$, $n = 1$, and $Q_{21} = \pm\overline{Q}_{12}$ is associated with the DSI equation while (1.1) with $\sigma = 1$, $n = 1$, and arbitrary N is associated with the N-wave interaction equations (see [4], [9]). Although the case $\sigma = 1$ can be considered as the limit $\sigma \to 1 + i0^+$, it is more convenient to study this case directly. This problem is rigorously discussed in [19].

The novelty associated with inverse problems in greater than two spatial dimensions stems from the fact that the inverse data depends on more variables than the potential. Indeed, in the case studied here the potential $Q(x_0, x)$ depends on $n+1$ real variables, while the inverse data $T(k_R, k_I, m)$, $k_R \in \mathbb{R}^n$, $k_I \in \mathbb{R}^n$, $m \in \mathbb{R}^{n-1}$, depends on $3n-1$ variables. This has important implications: (1) The inverse data must be appropriately constrained. Actually, the "characterization" of the inverse data now becomes the central problem. Such a characterization problem was first considered by Faddeev [3] in connection with the multidimensional Schrödinger equation, and later by Newton [13]–[17], who introduced the so-called miracle condition. This problem has recently been studied using the $\bar{\partial}$ approach [10], [11], [18], which is the approach followed here. (2) The existence of redundant scattering parameters can be used to simplify the problem of reconstruction. Indeed, in the case of the Schrödinger equation, this redundancy yields the well-known Born "approximation," which implies that the potential can be reconstructed in closed form. The novelty associated with (1.1) is that, although the reconstruction problem can be simplified, it remains nontrivial: We reduce the general problem of reconstructing an $N \times N$ potential Q in $n+1$ dimensions to one with $N = n = 2$. Henkin and Novikov [7] have subsequently shown that a similar situation arises in a number of physically important cases.

Equation (1.1) was also discussed in [12], where the characterization problem was formally solved but the reconstruction of Q remained open (see the discussion in [5]).

2. The direct problem. We will make the following nondegeneracy assumptions on the coefficient matrices J_ℓ.

$$J_1^a \neq 0 \quad \text{for } 1 \leq a \leq N. \tag{2.1}$$

$$J_\ell^a - J_\ell^b \neq 0 \quad \text{for } 1 \leq \ell \leq n \text{ and } 1 \leq a < b \leq N. \tag{2.2}$$

For the moment we shall concentrate on the abth component of (1.3). It can be simplified by the following change of variables:

$$\begin{aligned} x_0 &= 2y_0, \\ x_1 &= 2J_1^a[\sigma_R y_0 + \sigma_I y_1], \\ x_\ell &= y_\ell + 2J_\ell^a[\sigma_R y_0 + \sigma_I y_1], \quad 2 \leq \ell \leq n. \end{aligned} \tag{2.3}$$

In the y-coordinates, the equation for the abth component in (1.3) is

$$\frac{1}{2}\left[\frac{\partial}{\partial y_0} + i\frac{\partial}{\partial y_1}\right]\tilde{\mu}_{ab} + i\sigma k_{ab}\tilde{\mu}_{ab} = [\widetilde{Q\mu}]_{ab}, \tag{2.4}$$

where $k_{ab} = \sum_{\ell=1}^n k_\ell \left(J_\ell^a - J_\ell^b\right)$. Note that the partial differential operator on the left-hand side of (2.4) is just the $\bar{\partial}$ operator for the complex variable $z = y_0 + iy_1$.

There exists a bounded fundamental solution

$$G(z, k_{ab}) = \frac{1}{\pi z} \cdot \exp\left[-i\left(\sigma k_{ab}\bar{z} + \overline{\sigma k_{ab}} z\right)\right] \tag{2.5}$$

for the operator $\partial/\partial\bar{z} + i\sigma k_{ab}$. Observe that

$$\lim_{|z|\to\infty} G(z, k_{ab}) = 0. \tag{2.6}$$

Therefore, if (2.4) is satisfied (in the sense of distributions) by a continuous and bounded μ, then it will follow from (2.6), (1.4), and Liouville's theorem that

$$\tilde{\mu}_{ab}(y_0,y,k)=\delta^{ab}+\int_{\mathbb{R}^2}G(\xi,k_{ab})[\widetilde{Q\mu}]_{ab}(y_0-\xi_0,y_1-\xi_1,y_2,\cdots,y_n,k)d\xi_0d\xi_1, \tag{2.7}$$

where $\xi=\xi_0+i\xi_1$ and δ^{ab} is the Kronecker symbol.

In the original coordinates, we have

$$\mu_{ab}(x_0,x,k)=\delta_{ab}+\int_{\mathbb{R}^2}G(\xi,k_{ab})[Q\mu]_{ab}(x_0-2\xi_0,x_1-J_1^a(\sigma\bar{\xi}+\bar{\sigma}\xi),\cdots, x_n-J_n^a(\sigma\bar{\xi}+\bar{\sigma}\xi),k)d\xi_0d\xi_1. \tag{2.8}$$

In summary, if μ is a bounded continuous (generalized) solution of (1.3) with boundary conditions (1.4), then μ satisfies

$$\mu=I+\mathbf{N}_{Q,k}\mu, \tag{2.9}$$

where $\mathbf{N}_{Q,k}: C^b_{N\times N}(\mathbb{R}^{n+1})\longrightarrow C^b_{N\times N}(\mathbb{R}^{n+1})$ is defined by

$$[\mathbf{N}_{Q,k}(\phi)]_{ab}=\int_{\mathbb{R}^2}G(\xi,k_{ab})[Q\phi]_{ab}\Big(x_0-2\xi_0,x_1-J_1^a(\sigma\bar{\xi}+\bar{\sigma}\xi),\cdots, x_n-J_n^a(\sigma\bar{\xi}+\bar{\sigma}\xi)\Big)d\xi_0d\xi_1. \tag{2.10}$$

Here $C^b_{N\times N}(\mathbb{R}^{n+1})$ is the Banach space of bounded continuous $N\times N$-matrix-valued functions on $\mathbb{R}^{n+1}$ equipped with the norm defined by

$$||\phi||_\infty=\max_{1\le a,b\le N}\sup_{\mathbb{R}^{n+1}}|\phi_{ab}(x_0,x)|.$$

Conversely, if μ is a solution of (2.9) in $C^b_{N\times N}(\mathbb{R}^{n+1})$, then μ is a generalized solution of (1.3). Moreover, the decay of $Q(x_0,x)$ and (2.6) imply that μ will also satisfy the boundary condition (1.4).

PROPOSITION 2.1. (Existence and uniqueness of the solution of the direct problem.) *If Q satisfies*

$$||Q||_\infty\cdot\max_{1\le a,b\le N}\sup_{\mathbb{R}^{n+1}}\int_{\mathbb{R}^2}|Q_{ab}\big(x_0-2\xi_0,x_1-J_1^a(\sigma\bar{\xi}+\bar{\sigma}\xi),\cdots, x_n-J_n^a(\sigma\bar{\xi}+\bar{\sigma}\xi)\big)|d\xi_0d\xi_1<\frac{\pi}{8(N-1)^2}, \tag{2.11}$$

then equation (2.9) *has a unique solution in* $C^b_{N\times N}(\mathbb{R}^{n+1})$.

Proof. For each (a,b),

$$\sup_{\mathbb{R}^{n+1}}|[\mathbf{N}_{Q,k}\phi]_{ab}|\le||\phi||_\infty\sum_{j=1}^N\int_{\mathbb{R}^2}|G(\xi,k_{ab})Q_{aj}\big(x_0-2\xi_0,x_1-J_1^a(\sigma\bar{\xi}+\bar{\sigma}\xi),\cdots, x_n-J_n^a(\sigma\bar{\xi}+\bar{\sigma}\xi)\big)|d\xi_0d\xi_1.$$

Note that there are only $(N-1)$ terms on the right-hand side of the inequality because $Q(x_0,x)$ is off-diagonal. For simplicity of expression, we shall suppress the arguments of the integrand Q_{aj}. From (2.5), we have

$$\int_{\mathbb{R}^2} |G(\xi,k_{ab})Q_{aj}|d\xi_0 d\xi_1 \le \int_{|\xi|\le r} \frac{|Q_{aj}|}{\pi|\xi|}d\xi_0 d\xi_1 + \int_{|\xi|\ge r} \frac{|Q_{aj}|}{\pi|\xi|}d\xi_0 d\xi_1$$
$$\le 2A\cdot r + \frac{B}{\pi r},$$

where

$$A = ||Q||_\infty \quad \text{and}$$
$$B = \max_{1\le a,b\le N}\left[\sup_{\mathbb{R}^{n+1}}\int_{\mathbb{R}^2} |Q_{ab}(x_0-2\xi_0, x_1 - J_1^a(\sigma\bar{\xi}+\bar{\sigma}\xi),\cdots,$$
$$x_n - J_n^a(\sigma\bar{\xi}+\bar{\sigma}\xi))|d\xi_0 d\xi_1\right].$$

The minimum of $2Ar + \frac{B}{\pi r}$ is attained at $r = \sqrt{B/2A\pi}$. For this choice of r, we have $\int_{\mathbb{R}^2} |G(\xi,k_{ab})Q_{aj}|d\xi_0 d\xi_1 \le \sqrt{8AB/\pi}$ and the proposition follows from the contraction mapping theorem. □

From now on we assume that (2.11) holds. Therefore there exists a number τ such that

$$||\mathbf{N}_{Q,k}|| \le \tau < 1 \quad \text{for all } k\in\mathbb{C}^n. \tag{2.12}$$

So far k is acting as a parameter, but we can also consider $\mu(x_0,x,k)$ as the unique solution in $C^b_{N\times N}(\mathbb{R}^{n+1}\times\mathbb{C}^n)$ of

$$\mu = I + \mathbf{N}_Q\mu, \tag{2.13}$$

where $\mathbf{N}_Q : C^b_{N\times N}(\mathbb{R}^{n+1}\times\mathbb{C}^n) \to C^b_{N\times N}(\mathbb{R}^{n+1}\times\mathbb{C}^n)$ is defined by $(\mathbf{N}_Q\phi)(x_0,x,k) = [\mathbf{N}_{Q,k}\phi(\cdot,\cdot,k)](x_0,x)$. In view of (2.12), $\mathbf{N}_Q$ is also a contraction on $C^b_{N\times N}(\mathbb{R}^{n+1}\times\mathbb{C}^n)$.

In fact, $\mathbf{N}_Q\phi$ makes sense for a wide range of spaces.

DEFINITION 2.1. For each nonnegative integer ℓ, let $X^\ell_{N\times N} = \{\phi : \phi$ is an $N\times N$ matrix-valued function on $\mathbb{R}^{n+1}\times\mathbb{C}^n$ such that (i) ϕ is uniformly continuous on $K\times\mathbb{C}^n$ for any compact subset K of $\mathbb{R}^{n+1}$ and (ii) $\{\sup_{\mathbb{R}^{n+1}\times\mathbb{C}^n}[|\phi_{ab}(x_0,x,k)| \cdot(1+|x_0|+|x|)^{-\ell}] < \infty\}$ for $1\le a,b\le N$. The norm on $X^\ell_{N\times N}$ is defined by $\|\phi\|_\ell = \max_{1\le a,b\le N}\sup_{\mathbb{R}^{n+1}\times\mathbb{C}^n}[|\phi_{ab}(x_0,x,k)|(1+|x_0|+|x|)^{-\ell}]$.

Remark 2.1. It is easy to see that (i) $X^\ell_{N\times N}$ is a Banach space, (ii) $X^0_{N\times N}$ is a closed subspace of $C^b_{N\times N}$, (iii) $X^0_{N\times N}$ contains I and hence μ (see Lemma 2.1 below), and (iv) the natural embedding of $X^\ell_{N\times N}$ into $X^{\ell+1}_{N\times N}$ is bounded.

Moreover, if a bounded sequence $\{\phi_n\}$ in $X^\ell_{N\times N}$ converges uniformly to ϕ on sets of the form $K\times\mathbb{C}^n$ where K is a compact subset of $\mathbb{R}^{n+1}$, then $\phi\in X^\ell_{N\times N}$ and $\lim_{n\to\infty}\phi_n = \phi$ in $X^{\ell+1}_{N\times N}$.

LEMMA 2.1.

(i) $\mathbf{N}_W$ *is a bounded map from* $X^\ell_{N\times N}$ *into* $X^0_{N\times N}$ *for any* $W\in S^o_{N\times N}$.

(ii) $p(x_0,x)\mathbf{N}_W\phi \in X^0_{N\times N}$ *for any* $W\in S^o_{N\times N}$, $\phi\in X^\ell_{N\times N}$ *and polynomial* p *with degree* ≤ 1.

(iii) $(\mathbf{I}-\mathbf{N}_Q) : X^\ell_{N\times N}\to X^\ell_{N\times N}$ *is invertible and* $(\mathbf{I}-\mathbf{N}_Q)^{-1}\phi = \sum_{m=0}^\infty \mathbf{N}_Q^m\phi$.

Proof. (i) and (ii) follow from the decay of W and the definition of $G(\xi,k_{ab})$. Since $\mathbf{N}_Q\phi$ is in $X^0_{N\times N}$ by (i), $\sum_{m=1}^\infty \cdot\mathbf{N}_Q^m\phi$ converges in $X^0_{N\times N}$. Therefore $\sum_{m=1}^\infty$

$\mathbf{N}_Q^m\phi$, and hence $\sum_{m=0}^{\infty}\mathbf{N}_Q^m\phi$ also converges in $X^{\ell}_{N\times N}$. It is then straightforward to show that $(\mathbf{I}-\mathbf{N}_Q)\sum_{m=0}^{\infty}\mathbf{N}_Q^m\phi=\phi=\sum_{m=0}^{\infty}\mathbf{N}_Q^m[(\mathbf{I}-\mathbf{N}_Q)\phi]$. □

LEMMA 2.2. *Let $W_j\in S^o_{N\times N}$, $\partial^\alpha\phi_j\in X^{\ell-1}_{N\times N}$ $(\ell\geq 1)$ for $|\alpha|\leq 1$, and $p_j(x_0,x)$ be a polynomial of degree $\leq\ell$ for $1\leq j\leq m$. Suppose that $\theta\in X^{\ell-1}_{N\times N}$ satisfies*

$$\theta=\sum_{j=1}^{m}p_j\mathbf{N}_{W_j}\phi_j+\mathbf{N}_Q\theta; \tag{2.14}$$

then the following statements hold.

(i) *θ is C^1 on $\mathbb{R}^{n+1}\times\mathbb{C}^n$.*

(ii) *If χ is a first-order derivative of θ in the (x_0,x) variables, then $\chi\in X^{\ell-1}_{N\times N}$ and it satisfies an equation of the form*

$$\chi=\sum_{j=1}^{m'}p'_j\mathbf{N}_{W'_j}\phi'_j+\mathbf{N}_Q\chi, \tag{2.15}$$

where $W'_j\in S^o_{N\times N}$, $\phi'_j\in X^{\ell-1}_{N\times N}$ is either θ or a derivative of the ϕ_j's of order ≤ 1, and $\deg p'_j\leq\ell$.

(iii) *If ψ is a first-order derivative of θ in the k variables, then $\psi\in X^{\ell}_{N\times N}$ and it satisfies an equation of the form*

$$\psi=\sum_{j=1}^{\tilde m}\tilde p_j\mathbf{N}_{\tilde W_j}\tilde\phi_j+\mathbf{N}_Q\psi, \tag{2.16}$$

where $\tilde W_j\in S^o_{N\times N}$, $\tilde\phi_j\in X^{\ell-1}_{N\times N}$ is either θ or a derivative of the ϕ_j's of order ≤ 1, and $\deg\tilde p_j\leq\ell+1$.

Proof. We will only discuss the case of the k_{1_R}-derivative of θ. The same argument can be applied to the other derivatives.

Let $\delta_\epsilon F=\frac{1}{\epsilon}\big[F(x_0,x,k+\epsilon e_1)-F(x_0,x,k)\big]$ for any function $F(x_0,x,k)$, where $e_1=(1,0,\cdots,0)\in\mathbb{C}^n$. From (2.14), we have

$$\delta_\epsilon\theta=\sum_{j=1}^{m}p_j\delta_\epsilon\big(\mathbf{N}_{W_j}\phi_j\big)+\frac{1}{\epsilon}\big(\mathbf{N}_{Q,k+\epsilon e_1}-\mathbf{N}_{Q,k}\big)\theta(x_0,x,k+\epsilon e_1)+\mathbf{N}_Q\delta_\epsilon\theta.$$

Therefore,

$$\delta_\epsilon\theta=\big(\mathbf{I}-\mathbf{N}_Q\big)^{-1}\Psi_\epsilon, \tag{2.17}$$

where $\Psi_\epsilon=[\sum_{j=1}^{m}p_j\delta_\epsilon\big(\mathbf{N}_{W_j}\phi_j\big)+\frac{1}{\epsilon}\big(\mathbf{N}_{Q,k+\epsilon e_1}-\mathbf{N}_{Q,k}\big)\theta(x_0,x,k+\epsilon e_1)]$.

By the decay of W_j and Q, $\{\Psi_\epsilon:|\epsilon|\leq 1\}$ is a bounded subset of $X^{\ell}_{N\times N}$. Let K be a compact subset of $\mathbb{R}^{n+1}$. From (2.5), the decay of W_j and Q, and the assumptions on ϕ_j and its first-order derivatives, it follows that Ψ_ϵ converges uniformly on $K\times\mathbb{C}^n$ as $\epsilon\to 0$ to a sum of the form $\sum_{j=1}^{\tilde m}\tilde p_j\mathbf{N}_{\tilde W_j}\tilde\phi_j$. Each $\tilde W_j$ is the product of one of the W_ℓ's with a polynomial in (x_0,x_1) of degree ≤ 1, $\tilde\phi_j$ is either θ or a derivative of the ϕ_ℓ's of order ≤ 1, and $\deg\tilde p_j\leq\ell+1$. Therefore, Ψ_ϵ converges to $\sum_{j=1}^{\tilde m}\tilde p_j\mathbf{N}_{\tilde W_j}\tilde\phi_j$ in $X^{\ell+1}_{N\times N}$ by Remark 2.2. Part (iii) of Lemma 2.1 and (2.17)

then implies that $\delta_\epsilon\theta$ converges to $\left(\mathbf{I}-\mathbf{N}_Q\right)^{-1}\left(\sum_{j=1}^{\tilde m}\tilde p_j\mathbf{N}_{\tilde W_j}\tilde\phi_j\right)$ in $X^{\ell+1}_{N\times N}$. Hence $\partial\theta/\partial k_{1_R}$ exists and is continuous on $\mathbb{R}^{n+1}\times\mathbb{C}^n$. Since $\sum_{j=1}^{\tilde m}\tilde p_j\mathbf{N}_{\tilde W_j}\tilde\phi_j\in X^{\ell}_{N\times N}$ by part (ii) of Lemma 2.3, $\partial\theta/\partial k_{1_R}$ actually belongs to $X^{\ell}_{N\times N}$. Moreover, $\partial\theta/\partial k_{1_R}$ satisfies

$$\frac{\partial\theta}{\partial k_{1_R}}=\sum_{j=1}^{\tilde m}\tilde p_j\mathbf{N}_{\tilde W_j}\tilde\phi_j+\mathbf{N}_Q\frac{\partial\theta}{\partial k_{1_R}}. \qquad \square$$

We are now ready to prove results for the regularity and growth of $\mu(x_0,x,k)$.

PROPOSITION 2.2. (Regularity and growth of μ.) *Let μ solve* (2.13), *where Q satisfies* (2.11). *Then*

(i) *μ is C^∞ on $\mathbb{R}^{n+1}\times\mathbb{C}^n$, and*

(ii) $\partial^\alpha_{(x_0,x)}\partial^\beta_k\mu\in X^{\max(|\beta|-1,0)}_{N\times N}$.

Proof. We can rewrite (2.13) as

$$(\mu-I)=\mathbf{N}_QI+\mathbf{N}_Q(\mu-I).$$

Lemma 2.2 implies that $\mu-I\in X^0_{N\times N}$. Repeated applications of Lemma 2.2 yield that $\partial^\alpha_{(x_0,x)}\partial^\beta_k\mu\in X^{\max(|\beta|-1,0)}_{N\times N}$ and it satisfies an equation of the form

$$\partial^\alpha_{(x_0,x)}\partial^\beta_k\mu=\sum_{j=1}^{m}p_j\mathbf{N}_{W_j}\phi_j+\mathbf{N}_Q\left(\partial^\alpha_{(x_0,x)}\partial^\beta_k\mu\right), \tag{2.18}$$

where $\deg p_j\le|\beta|$, $W_j\in S^o_{N\times N}$ is the product of a polynomial in (x_0,x_1) of degree $\le|\beta|$ with a derivative of Q of order $\le|\alpha|+|\beta|$ and ϕ_j is either I or a derivative of μ of order $\le|\alpha|+|\beta|-1$. $\square$

Remark 2.2. By tracing the dependence of $\partial^\alpha_{(x_0,x)}\partial^\beta_k\mu$ on Q (cf. (2.18)), it is easy to see that $\|\partial^\alpha_{(x_0,x)}\partial^\beta_k\mu\|_{\max(|\beta|-1,0)}$ only depends on finitely many seminorms of Q of the form $\sup_{\mathbb{R}^{n+1}}\left[(1+|x_0|+|x|)^m|\partial^\gamma Q(x_0,x)|\right]$.

PROPOSITION 2.3. (Asymptotics of μ for large k.) *For fixed (x_0,x) and $(k_1,\cdots,k_{p-1},k_{p+1},\cdots,k_n)$, we have*

$$\lim_{k_p\to\infty}\mu(x_0,x,k)=I, \tag{2.19}$$

$$\lim_{k_p\to\infty}\frac{\partial\mu}{\partial x_\ell}(x_0,x,k)=0,\qquad 0\le\ell\le n, \tag{2.20}$$

$$\mu(x_0,x,k)=I+\frac{1}{k_p}\mu_p+o\left(\frac{1}{|k_p|}\right), \tag{2.21}$$

where $(\mu_p)_{ab}=\left[Q_{ab}(x_0,x)\right]/\left[i\sigma(J^a_p-J^b_p)\right]$ for $a\ne b$.

Proof. Recall that $\mu=\sum_{j=0}^\infty\mathbf{N}^j_QI$ and the convergence is uniform on $\mathbb{R}^{n+1}\times\mathbb{C}^n$. To prove (2.19) it therefore suffices to show that $\lim_{k_p\to\infty}\mathbf{N}^j_QI=0$ for $j\ge1$.

By (2.10) and the Riemann–Lebesgue lemma, $\lim_{k_p\to\infty}\mathbf{N}_QI=0$. The other limits follow inductively from the Lebesgue dominated convergence theorem.

The limit (2.20) can be proved similarly.

We now prove (2.21). From (2.8) we have, for $a \neq b$,

$$\begin{aligned}
&k_p[\mu - I]_{ab} \\
&= \frac{k_p}{i\sigma k_{ab}} \int_{\mathbb{R}^2} i\sigma k_{ab} G(\xi, k_{ab})[Q\mu]_{ab} d\xi_0 d\xi_1 \\
&= \frac{k_p}{i\sigma k_{ab}} \left\{ \int_{\mathbb{R}^2} \left[\left(\frac{\partial}{\partial \bar{\xi}} + i\sigma k_{ab} \right) G(\xi, k_{ab}) \right] [Q\mu]_{ab} d\xi_0 d\xi_1 \right. \\
&\qquad \left. + \int_{\mathbb{R}^2} G(\xi, k_{ab}) \frac{\partial}{\partial \bar{\xi}} \left([Q\mu]_{ab} \right) d\xi_0 d\xi_1 \right\} \\
&= \frac{k_p}{i\sigma k_{ab}} [Q\mu]_{ab}(x_0, x, k) + \frac{k_p}{i\sigma k_{ab}} \int_{\mathbb{R}^2} G(\xi, k_{ab}) \frac{\partial}{\partial \bar{\xi}} \left([Q\mu]_{ab} \right) d\xi_0 d\xi_1.
\end{aligned}$$

It is obvious that $\lim_{k_p \to \infty} (k_p / i\sigma k_{ab})[Q\mu]_{ab}(x_0, x, k) = \left[Q_{ab}(x_0, x) \right] / \left[i\sigma (J_p^a - J_p^b) \right]$. (Recall that $k_{ab} = \sum_{\ell=1}^{n} k_\ell (J_\ell^a - J_\ell^b)$.) On the other hand, the integral

$$\begin{aligned}
\int_{\mathbb{R}^2} G(\xi, k_{ab}) \frac{\partial}{\partial \bar{\xi}} \big([Q\mu]_{ab} \big(& x_0 - 2\xi_0, x_1 - J_1^a(\sigma\bar{\xi} + \bar{\sigma}\xi), \\
& \cdots, x_n - J_n^a(\sigma\bar{\xi} + \bar{\sigma}\xi) \big) \big) d\xi_0 d\xi_1
\end{aligned}$$

converges to zero as $k_p \to \infty$, by (2.19), (2.20), and the Riemann–Lebesgue lemma. Hence we have

$$[\mu - I]_{ab} = \frac{1}{k_p} \frac{Q_{ab}(x_0, x)}{i\sigma (J_p^a - J_p^b)} + o\left(\frac{1}{|k_p|} \right).$$

The asymptotic expansion (2.21) now follows from (2.8) and the fact that $Q(x_0, x)$ is off-diagonal. □

We next introduce the inverse data for problem (1.3)–(1.4) by relating $\partial\mu / \partial \bar{k}_p$ and μ.

By differentiating (2.13), we have

$$\frac{\partial \mu}{\partial \bar{k}_p} = H_p + \mathbf{N}_Q \frac{\partial \mu}{\partial \bar{k}_p}, \tag{2.22}$$

where

$$\frac{\partial}{\partial \bar{k}_p} = \frac{1}{2} \left[\frac{\partial}{\partial k_{p_R}} + i \frac{\partial}{\partial k_{p_I}} \right],$$

and

$$\begin{aligned}
[H_p]_{ab} = \frac{1}{i} \frac{\bar{\sigma}(J_p^a - J_p^b)}{\pi} \int_{\mathbb{R}^2} & \exp\left[-i \left(\sigma k_{ab} \bar{\xi} + \bar{\sigma} \bar{k}_{ab} \xi \right) \right] \\
& \cdot [Q\mu]_{ab}\big(x_0 - 2\xi_0, x_1 - J_1^a(\sigma\bar{\xi} + \bar{\sigma}\xi), \cdots, \\
& x_n - J_n^a(\sigma\bar{\xi} + \bar{\sigma}\xi), k \big) d\xi_0 d\xi_1.
\end{aligned}$$

By a change of variables, we can rewrite $[H_p]_{ab}$ in the following form.

$$\begin{aligned}
[H_p]_{ab} = & \gamma^a (J_p^a - J_p^b) \int_{\mathbb{R}^2} \exp\left[i\beta^a (x_0 - \xi_0, x_1 - \xi_1, k_{ab}) \right] \\
& \cdot [Q\mu]_{ab} \left(\xi_0, \xi_1, x_2 - \frac{J_2^a}{J_1^a}(x_1 - \xi_1), \cdots, x_n - \frac{J_n^a}{J_1^a}(x_1 - \xi_1), k \right) d\xi_0 d\xi_1,
\end{aligned} \tag{2.23}$$

where

$$\beta^a(x_0,x_1,\kappa)=\frac{1}{\sigma_I}\left[|\sigma|^2\kappa_I x_0-\frac{(\sigma\kappa)_I}{J_1^a}x_1\right]\quad\text{and}\quad\gamma^a=\frac{\bar\sigma}{4\pi i J_1^a|\sigma_I|}. \tag{2.24}$$

As a consequence of Proposition 2.2, $[Q\mu]$ is rapidly decreasing in (x_0,x) for fixed k. Therefore, by the Fourier inversion formula, $[H_p]_{ab}$ can be represented as

$$\begin{aligned}[H_p]_{ab}=&\frac{\gamma^a(J_p^a-J_p^b)}{(2\pi)^{n-1}}\int_{\mathbb{R}^{n-1}}\int_{\mathbb{R}^{n+1}}\exp\left[i\beta^a(x_0-\xi_0,x_1-\xi_1,k_{ab})\right.\\&\left.+i\alpha^a(x_1-\xi_1,x^{(2)}-\eta,m)\right]\cdot[Q\mu]_{ab}(\xi_0,\xi_1,\eta,k)d\xi_0d\xi_1d\eta dm,\end{aligned} \tag{2.25}$$

where $m=(m_2,\cdots,m_n)$, $x^{(2)}=(x_2,\cdots,x_n)$, $\eta=(\eta_2,\cdots,\eta_n)$, $d\eta=d\eta_2\cdots d\eta_n$, $dm=dm_2\cdots dm_n$, and

$$\alpha^a(x_1,x^{(2)},m)=\sum_{\ell=2}^n m_\ell\left(x_\ell-x_1\frac{J_\ell^a}{J_1^a}\right). \tag{2.26}$$

DEFINITION 2.2. (Inverse data.) T is an off-diagonal $N\times N$ matrix-valued function defined on $\mathbb{C}^n\times\mathbb{R}^{n-1}$ such that

$$\begin{aligned}T_{ab}(k,m)=&\int_{\mathbb{R}^{n+1}}\exp\left[-i\beta^a(\xi_0,\xi_1,k_{ab})-i\alpha^a(\xi_1,\eta,m)\right]\\&\cdot[Q\mu]_{ab}(\xi_0,\xi_1,\eta,k)d\xi_0d\xi_1d\eta\quad\text{for } a\neq b,\end{aligned} \tag{2.27}$$

where β^a, α^a are defined in (2.24) and (2.26).

Remark 2.3. In view of the decay of Q and Proposition 2.2, $T(k,m)$ is C^∞ on $\mathbb{C}^n\times\mathbb{R}^{n-1}$. For each multi-index α with $3n-1$ components, $\sup_{\mathbb{C}^n\times\mathbb{R}^{n-1}}[(1+|k_{ab}|+|m|)^j|\partial^\alpha T_{ab}(k,m)|]<\infty$ for $j=0,1,2,\cdots$ and $1\le a,b\le N$.

PROPOSITION 2.4. ($\bar\partial$ equation associated with inverse data.) *For* $1\le p\le n$,

$$\begin{aligned}\frac{\partial\mu}{\partial\bar k_p}(x_0,x,k)=&\sum_{a,b=1}^N\frac{\gamma^a(J_p^a-J_p^b)}{(2\pi)^{n-1}}\exp\left[i\beta^a(x_0,x_1,k_{ab})\right]\\&\cdot\int_{\mathbb{R}^{n-1}}\exp\left[i\alpha^a(x,m)\right]T_{ab}(k,m)\mu\big(x_0,x,\lambda^{ab}(k,m)\big)E^{ab}dm,\end{aligned} \tag{2.28}$$

where

$$\lambda_1^{ab}(k,m)=k_1-\left[\frac{(\sigma k_{ab})_I}{\sigma_I J_1^a}+\sum_{\ell=2}^n m_\ell\frac{J_\ell^a}{J_1^a}\right], \tag{2.29}$$

$$\lambda_\ell^{ab}(k,m)=k_\ell+m_\ell\quad\textit{for } 2\le\ell\le n. \tag{2.30}$$

Proof. By using (2.25) and the definition of T_{ab}, $[H]_{ab}$ can be expressed in the following simple form:

$$[H]_{ab}=\frac{\gamma^a(J_p^a-J_p^b)}{(2\pi)^{n-1}}\int_{\mathbb{R}^{n-1}}\exp\left[i\beta^a(x_0,x_1,k_{ab})+i\alpha^a(x,m)\right]T_{ab}(k,m)dm. \tag{2.31}$$

From (2.22), we have

$$\frac{\partial \mu}{\partial \bar{k}_p} = (\mathbf{I} - \mathbf{N}_Q)^{-1} H = \sum_{a,b} (\mathbf{I} - \mathbf{N}_Q)^{-1} (H_{ab} E^{ab}), \tag{2.32}$$

where E^{ab} is the $N \times N$ matrix with zeros in all its entries except the abth, which equals 1. Note that the summation is actually only over $a \neq b$, since $H_{aa} = 0$.

Since $(\mathbf{I} - \mathbf{N}_Q)^{-1}$ is a linear operator in the (x_0, x, k) variable, it commutes with integration in m. Therefore, in order to compute H_{ab}, it suffices to find $F^{ab} = (\mathbf{I} - \mathbf{N}_Q)^{-1} (\exp[i\beta^a(x_0, x_1, k_{ab}) + i\alpha^a(x, m)] E^{ab})$, which is the unique solution of the following equation.

$$F^{ab} = \exp\left[i\beta^a(x_0, x_1, k_{ab}) + i\alpha^a(x, m)\right] E^{ab} + \mathbf{N}_Q F^{ab}. \tag{2.33}$$

Note that the integral equation (2.33) is equivalent to the following boundary value problem:

$$(F^{ab})_{x_0} + \sigma \sum_{\ell=1}^{n} \{J_\ell (F^{ab})_{x_\ell} + i k_\ell [J_\ell, F^{ab}]\} = Q\mu, \tag{2.34}$$

$$\lim_{|x_0|+|x| \to \infty} \exp\left[-i\beta^a(x_0, x, k_{ab}) - i\alpha^a(x, m)\right] F^{ab}(x_0, x, k) = E^{ab}. \tag{2.35}$$

Since F^{ab} satisfies the same equation as μ but with a different boundary condition, it is natural to look for a solution in the form

$$F^{ab} = \exp\left[i\beta^a(x_0, x_1, k_{ab}) + i\alpha^a(x, m)\right] \mu(x_0, x, \lambda^{ab}(k, m)) E^{ab}, \tag{2.36}$$

where the function $\lambda^{ab}(k, m)$ will compensate for the oscillatory factor $\exp[i(\beta^a + \alpha^a)]$. Note that the boundary conditions (2.33) are automatically satisfied since $\lim_{|x_0|+|x| \to \infty} \mu = I$.

Observe that the only nonzero column in $\mu(x_0, x, \lambda^{ab}(k, m)) E^{ab}$ is the bth one with entries identical to those of the ath column of $\mu(x_0, x, \lambda^{ab}(k, m))$. If we substitute (2.36) into (2.34) and use (1.3), we see that (2.34) is reduced to

$$\begin{aligned} \Bigg\{ &\frac{\partial}{\partial x_0} \beta^a(x_0, x_1, k_{ab}) + \sigma \sum_{\ell=1}^{n} J_\ell^r \frac{\partial}{\partial x_\ell} \left[\beta^a(x_0, x_1, k_{ab}) + \alpha^a(x, m)\right] \\ &+ \sigma \sum_{\ell=1}^{n} k_\ell (J_\ell^r - J_\ell^b) - \sigma \sum_{\ell=1}^{n} \lambda_\ell^{ab}(k, m) (J_\ell^r - J_\ell^a) \Bigg\} \\ &\cdot \mu_{ra}(x_0, x, \lambda^{ab}(k, m)) = 0 \quad \text{for } 1 \leq r \leq N. \end{aligned} \tag{2.37}$$

From (2.24) and (2.26) we obtain

$$\begin{aligned}
&\frac{\partial}{\partial x_0}\beta^a(x_0,x_1,k_{ab})+\sigma\sum_{\ell=1}^{n}J_\ell^r\frac{\partial}{\partial x_\ell}\left[\beta^a(x_0,x_1,k_{ab})+\alpha^a(x,m)\right]\\
&\quad=\frac{1}{\sigma_I}|\sigma|^2(k_{ab})_I-\sigma\left[\frac{(\sigma k_{ab})_I}{\sigma_I J_1^a}+\sum_{\ell=2}^{n}m_\ell\frac{J_\ell^a}{J_1^a}\right]J_1^r+\sigma\sum_{\ell=2}^{n}m_\ell J_\ell^r\\
&\quad=\sigma\Bigg\{\frac{\bar\sigma}{\sigma_I}(k_{ab})_I-\left[\frac{(\sigma k_{ab})_I}{\sigma_I J_1^a}+\sum_{\ell=2}^{n}m_\ell\frac{J_\ell^a}{J_1^a}\right]J_1^a+\sum_{\ell=2}^{n}m_\ell J_\ell^a\\
&\qquad\qquad-\left[\frac{(\sigma k_{ab})_I}{\sigma_I J_1^a}+\sum_{\ell=2}^{n}m_\ell\frac{J_\ell^a}{J_1^a}\right](J_1^r-J_1^a)+\sum_{\ell=2}^{n}m_\ell(J_\ell^r-J_\ell^a)\Bigg\}\\
&\quad=\sigma\Bigg\{\frac{\bar\sigma}{\sigma_I}(k_{ab})_I-\frac{(\sigma k_{ab})_I}{\sigma_I}-\left[\frac{(\sigma k_{ab})_I}{\sigma_I J_1^a}+\sum_{\ell=2}^{n}m_\ell\frac{J_\ell^a}{J_1^a}\right](J_1^r-J_1^a)+\sum_{\ell=2}^{n}m_\ell(J_\ell^r-J_\ell^a)\Bigg\}\\
&\quad=\sigma\Bigg\{-k_{ab}-\left[\frac{(\sigma k_{ab})_I}{\sigma_I J_1^a}+\sum_{\ell=2}^{n}m_\ell\frac{J_\ell^a}{J_1^a}\right](J_1^r-J_1^a)+\sum_{\ell=2}^{n}m_\ell(J_\ell^r-J_\ell^a)\Bigg\}.
\end{aligned}$$

Recall that $k_{ab}=\sum_{\ell=1}^{n}k_\ell(J_\ell^a-J_\ell^b)$. Therefore $-k_{ab}+\sum_{\ell=1}^{n}k_\ell(J_\ell^r-J_\ell^b)=\sum_{\ell=1}^{n}k_\ell(J_\ell^r-J_\ell^a)$. At this point, we see that (2.37) follows from (2.29) and (2.30).

We have just proved that

$$\begin{aligned}
&(\mathbf{I}-\mathbf{N}_Q)^{-1}\left(\exp\left[i\beta^a(x_0,x_1,k_{ab})+i\alpha^a(x,m)\right]E^{ab}\right)\\
&\qquad=\exp\left[i\beta^a(x_0,x_1,k_{ab})+i\alpha^a(x,m)\right]\mu\left(x_0,x,\lambda^{ab}(k,m)\right)E^{ab}.
\end{aligned}\tag{2.38}$$

Equation (2.28) now follows from (2.31), (2.32), and (2.38). □

From Proposition 2.4, Remark 2.3, and (1.4), we have the following two corollaries.

COROLLARY 2.1. *$\partial\mu/\partial\bar k_p$ is rapidly decreasing in k_p, with all the other variables fixed.*

COROLLARY 2.2. (T as asymptotics of μ in large x_0.) *For $1\le a,b\le N$ and $a\ne b$,*

$$\begin{aligned}
&\lim_{x_0\to\infty}\left\{\exp[-i\beta^a(x_0,0,k_{ab})]\frac{\partial\mu_{ab}}{\partial\bar k_p}(x_0,0,x_2,\cdots,x_n,k)\right\}\\
&\qquad=\frac{\gamma^a(J_p^a-J_p^b)}{(2\pi)^{n-1}}\int_{\mathbb{R}^{n-1}}\exp\left(\sum_{\ell=2}^{n}m_\ell x_\ell\right)T_{ab}(k,m)\,dm.
\end{aligned}\tag{2.39}$$

COROLLARY 2.3. (Reconstruction of Q.)

$$Q(x_0,x)=\frac{i\sigma}{\pi}\left\{J_p,\int_{\mathbb{R}^2}\frac{\partial\mu}{\partial\bar k_p}(x_0,x,k_1,\cdots,k_{p-1},k_p,k_{p+1},\cdots,k_n)dk_{p_R}dk_{p_I}\right\}\tag{2.40}$$

for $p=1,\cdots,n$.

Proof. From Corollary 2.1 and the inversion formula for the $\bar\partial$ operator, we have

$$\begin{aligned}
&\mu(x_0,x,k)\\
&\quad=I+\frac{1}{\pi}\int_{\mathbb{R}^2}\frac{(\partial\mu/\partial\bar k_p)(x_0,x,k_1,\cdots,k_{p-1},k'_p,k_{p+1},\cdots,k_n)}{k_p-k'_p}dk'_{p_R}dk'_{p_I}\\
&\quad=I+\frac{1}{k_p}\left[\frac{1}{\pi}\int_{\mathbb{R}^2}\frac{\partial\mu}{\partial\bar k_p}(x_0,x,k_1,k_{p-1},\cdots,k'_p,k_{p+1},\cdots,k_n)dk'_{p_R}dk'_{p_I}\right]\\
&\qquad+o\left(\frac{1}{|k_p|}\right).
\end{aligned}\tag{2.41}$$

Equation (2.40) follows by comparing (2.41) with (2.21). □

PROPOSITION 2.5. (Characterization of T.) *For any (a,b) such that $1 \le a,b, \le N$ and $a \ne b$, we have*

$$\mathbf{L}_r^{ab} T_{ab} = \mathbf{L}_p^{ab} T_{ab}, \qquad 1 \le r, \quad p \le n, \tag{2.42}$$

where

$$\begin{aligned} &\big(\mathbf{L}_\ell^{ab} T_{ab}\big)(k,m) \\ &\quad = \frac{1}{J_\ell^a - J_\ell^b} \frac{\partial T_{ab}}{\partial \bar{k}_\ell}(k,m) - \sum_{j=1}^{N} \frac{\gamma^j}{(2\pi)^{n-1}} \int_{\mathbb{R}^{n-1}} \Big(\frac{J_\ell^j - J_\ell^b}{J_\ell^a - J_\ell^b}\Big) \\ &\qquad \cdot T_{jb}(k,M) T_{aj}\big(\lambda^{jb}(k,m), m - M\big) dM. \end{aligned} \tag{2.43}$$

Proof. Define

$$\mathbf{L}_{rp}^{ab} = \big(J_p^a - J_p^b\big) \frac{\partial}{\partial \bar{k}_r} - \big(J_r^a - J_r^b\big) \frac{\partial}{\partial \bar{k}_p} \tag{2.44}$$

and

$$\begin{aligned} \varepsilon^{ab}(x_0,x,k,m) &= \beta^a(x_0,x_1,k_{ab}) + \alpha^a(x,m) \\ &= \frac{1}{\sigma_I} \left[|\sigma|^2 (k_{ab})_I x_0 - \frac{(\sigma k_{ab})_I}{J_1^a} x_1 \right] + \sum_{\ell=2}^{n} m_\ell \Big(x_\ell - x_1 \frac{J_\ell^a}{J_1^a} \Big). \end{aligned} \tag{2.45}$$

It follows from (2.29), (2.30), and the definition of k_{ab} that

$$\mathbf{L}_{rp}^{ab} \varepsilon^{ab} = 0, \tag{2.46}$$

and

$$\mathbf{L}_{rp}^{ab} \Big[\mu\big(x_0,x,\lambda^{ab}(k,m)\big) \Big] = \Big[\mathbf{L}_{rp}^{ab} \mu \Big] \big(x_0,x,\lambda^{ab}(k,m)\big). \tag{2.47}$$

Applying (2.28), (2.46), and (2.47), we have

$$\begin{aligned} 0 &= \frac{\partial}{\partial \bar{k}_r} \Big(\frac{\partial \mu}{\partial \bar{k}_p} \Big) - \frac{\partial}{\partial \bar{k}_p} \Big(\frac{\partial \mu}{\partial \bar{k}_r} \Big) \\ &= \sum_{a,b} \frac{\gamma^a}{(2\pi)^{n-1}} \int_{\mathbb{R}^{n-1}} \exp\big[i \varepsilon^{ab}(x_0,x,k,m) \big] \\ &\quad \cdot \Big[\big(\mathbf{L}_{rp}^{ab} T_{ab} \big)(k,m) \mu\big(x_0,x,\lambda^{ab}(k,m)\big) \\ &\qquad + T_{ab}(k,m) \big(\mathbf{L}_{rp}^{ab} \mu \big) \big(x_0,x,\lambda^{ab}(k,m)\big) \Big] E^{ab} dm\,. \end{aligned}$$

Therefore, (2.28) implies that

$$\begin{aligned} 0 = &\sum_{a,b} \frac{\gamma^a}{(2\pi)^{n-1}} \int_{\mathbb{R}^{n-1}} \exp\big[i \varepsilon^{ab}(x_0,x,k,m) \big] \big(\mathbf{L}_{rp}^{ab} T_{ab} \big)(k,m) \\ &\qquad \cdot \mu\big(x_0,x,\lambda^{ab}(k,m)\big) E^{ab} dm \\ &+ \sum_{a,b} \frac{\gamma^a}{(2\pi)^{n-1}} \int_{\mathbb{R}^{n-1}} \exp\big[i \varepsilon^{ab}(x_0,x,k,m) \big] T_{ab}(k,m) \\ &\quad \cdot \Big\{ \sum_{j=1}^{n} \frac{\gamma^j}{(2\pi)^{n-1}} \Big[\big(J_p^a - J_p^b\big)\big(J_r^j - J_r^a\big) - \big(J_r^a - J_r^b\big)\big(J_p^j - J_p^a\big) \Big] \\ &\qquad \cdot \int_{\mathbb{R}^{n-1}} \exp\big[i \varepsilon^{ja}(x_0,x,\lambda^{ab}(k,m),M) \big] T_{ja}\big(\lambda^{ab}(k,m),M\big) \\ &\qquad\quad \cdot \mu\Big(x_0,x,\lambda^{ja}\big(\lambda^{ab}(k,m),M\big)\Big) E^{jb} dM dm \Big\}. \end{aligned} \tag{2.48}$$

It is straightforward (cf. [5]) to show that

$$\lambda^{ja}(\lambda^{ab}(k,m),M) = \lambda^{jb}(k,m+M), \tag{2.49}$$

$$\varepsilon^{ab}(x_0,x,k,m) + \varepsilon^{ja}\big(x_0,x,\lambda^{ab}(k,m),M\big) = \varepsilon^{jb}(x_0,x,k,m+M). \tag{2.50}$$

If we multiply (2.48) by $(2\pi)^{n-1}(\gamma^a)^{-1}\exp\big[-i|\sigma|^2\sigma_I^{-1}(k_{ab})_I x_0\big]$ and then let $x_1 = 0$ and $x_0 \to \infty$ in the resulting equation, we have by looking at the abth component the following equation:

$$\begin{aligned} 0 = {} & \int_{\mathbb{R}^{n-1}} \exp\Big[i\sum_{\ell=2}^{n} m_\ell x_\ell\Big]\big(\mathbf{L}_{rp}^{ab}T_{ab}\big)(k,m)dm \\ & + \sum_{j=1}^{N} \frac{\gamma^j}{(2\pi)^{n-1}}\Big[\big(J_r^a - J_r^j\big)\big(J_p^j - J_p^b\big) - \big(J_p^a - J_p^j\big)\big(J_\gamma^j - J_\gamma^b\big)\Big] \\ & \cdot \int_{\mathbb{R}^{n-1}}\int_{\mathbb{R}^{n-1}} \exp\Big[i\sum_{\ell=2}^{n}(m_\ell + M_\ell)x_\ell\Big]T_{jb}(k,m) \\ & \cdot T_{aj}\big(\lambda^{jb}(k,m),M\big)dMdm. \end{aligned} \tag{2.51}$$

We have used (2.45), (2.49), (2.50), and the boundary conditions (1.4) in deriving (2.51). From the Fourier inversion formula and (2.51), we obtain

$$\begin{aligned} 0 = {} & \big(\mathbf{L}_{rp}^{ab}T_{ab}\big)(k,m) \\ & + \sum_{j=1}^{N} \frac{\gamma^j}{(2\pi)^{n-1}}\Big[\big(J_r^a - J_r^j\big)\big(J_p^j - J_p^b\big) - \big(J_p^a - J_p^j\big)\big(J_r^j - J_r^b\big)\Big] \\ & \cdot \int_{\mathbb{R}^{n-1}} T_{jb}(k,M)T_{aj}\big(\lambda^{jb}(k,M),m-M\big)dM. \end{aligned} \tag{2.52}$$

Since

$$\begin{aligned} & \frac{1}{\big(J_p^a - J_p^b\big)\big(J_r^a - J_r^b\big)}\sum_{j=1}^{N}\Big[\big(J_r^a - J_r^j\big)\big(J_p^j - J_p^b\big) - \big(J_p^a - J_p^j\big)\big(J_r^j - J_r^b\big)\Big] \\ & \quad = \sum_{\ell=1}^{N}\Big[\frac{J_p^\ell - J_p^b}{J_p^a - J_p^b} - \frac{J_r^\ell - J_r^b}{J_r^a - J_r^b}\Big], \end{aligned}$$

equation (2.52) is equivalent to (2.42). □

DEFINITION 2.3. Let $D_{N\times N}^{o}$ be the space of off-diagonal $N\times N$-matrix-valued functions $\Phi(k,m)$ that satisfy the following conditions.

(i) $\Phi(k,m)$ is C^∞ on $\mathbb{C}^n\times\mathbb{R}^{n-1}$.

(ii) For each multi-index α with $3n-1$ components, $\sup_{\mathbb{C}^n\times\mathbb{R}^{n-1}}\big(1+|k_{ab}|+|m|\big)^j\cdot\ |\partial^\alpha\Phi_{ab}(k,m)| < \infty$ for $j = 0,1,2,\cdots$ and $1\le a,b\le N$.

(iii) $\mathbf{L}_r^{ab}\Phi_{ab} = \mathbf{L}_p^{ab}\Phi_{ab}$, $1\le r,\ p\le n$.

$D_{N\times N}^{o}$ becomes a Fréchet space if we equip it with the seminorms

$$|\Phi|_{(a,b,\alpha,j)} = \sup_{\mathbb{C}^n\times\mathbb{R}^{n-1}}\big(1+|k_{ab}|+|m|\big)^j\cdot\ |\partial^\alpha\Phi_{ab}(k,m)|.$$

DEFINITION 2.4. (Scattering map.)

$$\mathbf{S}(Q) = T. \tag{2.53}$$

Remark 2.4. $\mathbf{S}$ is defined on a neighborhood of $0 \in S^o_{N\times N}$. In view of Remark 2.3 and Proposition 2.5, the range of $\mathbf{S}$ is a subset of $D^o_{N\times N}$. By (2.27) and Remark 2.2, $\mathbf{S}$ is continuous with respect to the Fréchet space topologies on $S^o_{N\times N}$ and $D^o_{N\times N}$.

The results of this section are summarized in the following theorem.

THEOREM 2.1. *The direct problem is uniquely solvable if Q satisfies* (2.11). *If the inverse data T is defined by* (2.27), *then $T \in D^o_{N\times N}$ (cf. Definition* 2.3) *and the $\bar\partial$ equation* (2.28) *is valid. The scattering map $\mathbf{S}$ that takes Q to T is a continuous map from a neighborhood of $0 \in S^o_{N\times N}$ into $D^o_{N\times N}$. Both the potential Q and the inverse data T can be expressed directly in terms of the Jost function μ via* (2.39) *and* (2.40).

Remark 2.5. $\mathbf{S}$ is actually infinitely Fréchet differentiable.

3. The inverse problem. Let $T \in D^o_{N\times N}$. The fundamental equations ($1 \le p \le n$) for the inverse problem are

$$\begin{aligned}\frac{\partial \mu_p}{\partial \bar k_p}(x_0,x,k) = \sum_{a,b} \frac{\gamma^a(J^a_p - J^b_p)}{(2\pi)^{n-1}} \int_{\mathbb{R}^{n-1}} \exp\left[i\varepsilon^{ab}(x_0,x,k,m)\right] \\ \cdot T_{ab}(k,m)\mu_p\big(x_0,x,\lambda^{ab}(k,m)\big)E^{ab}dm,\end{aligned} \tag{3.1}$$

with boundary conditions

$$\lim_{k_p\to\infty} \mu_p(x_0,x,k) = I \quad \text{for fixed } (x_0,x,k_1,\cdots,k_{p-1},k_{p+1},\cdots,k_n). \tag{3.2}$$

Note that ε^{ab} is defined in (2.45). It is useful to observe that any first-order derivative of ε^{ab} in the (x_0,x) variables is a linear combination of $\{(k_{ab})_R,(k_{ab})_I, m_2,\cdots,m_n\}$ and that each of the (x_0,x) variables can be represented as a linear combination of $\{(\partial\varepsilon^{ab}/\partial k_{p_R}),(\partial\varepsilon^{ab}/\partial k_{p_I}),(\partial\varepsilon^{ab}/\partial m_2),\cdots,(\partial\varepsilon^{ab}/\partial m_n)\}$.

Let the differential-integral operator $\mathbf{L}^p_{(x_0,x)}$ be defined by

$$\begin{aligned}\left[\mathbf{L}^p_{(x_0,x)}\nu\right](k) = \frac{\partial \nu}{\partial \bar k_p}(k) - \sum_{a,b} \frac{\gamma^a(J^a_p - J^b_p)}{(2\pi)^{n-1}} \int_{\mathbb{R}^{n-1}} \exp\left[i\varepsilon^{ab}(x_0,x,k,m)\right] \\ \cdot T_{ab}(k,m)\nu\big(\lambda^{ab}(k,m)\big)E^{ab}dm,\end{aligned} \tag{3.3}$$

so that (3.1) can be written in the simple form $\mathbf{L}^p_{(x_0,x)}\mu(x_0,x,\cdot) = 0$.

The goal of the inverse problem is to find a potential whose scattering data is T. We start with the solvability of (3.1)–(3.2).

Henceforth we shall denote $(k_1,\cdots,k_{p-1},k'_p,k_{p+1},\cdots,k_n)$ by $k'_{(p)}$. The following lemma is a direct consequence of the inversion formula for the $\bar\partial$ operator and Liouville's theorem.

LEMMA 3.1. *$\mu_p(x_0,x,k)$ is a bounded continuous generalized solution of* (3.1) *and* (3.2) *if and only if it is a solution of the following integral equation:*

$$\begin{aligned}\mu_p = I + \sum_{a,b} \frac{\gamma^a\big(J^a_p - J^b_p\big)}{\pi(2\pi)^{n-1}} \int_{\mathbb{R}^{n+1}} \frac{1}{k_p - k'_p} \exp\left[i\varepsilon^{ab}(x_0,x,k'_{(p)},m)\right] \\ \cdot T_{ab}(k'_{(p)},m)\mu_p\big(x_0,x,\lambda^{ab}(k'_{(p)},m)\big)E^{ab}dm dk'_{p_R}\,dk'_{p_I}.\end{aligned} \tag{3.4}$$

Let $\mathbf{P}^p_{(x_0,x)}$ be the operator on $C^b_{N\times N}(\mathbb{C}^n)$ defined by

$$[\mathbf{P}^p_{(x_0,x)}\nu](k) = \sum_{a,b} \frac{\gamma^a(J^a_p - J^b_p)}{\pi(2\pi)^{n-1}} \int_{\mathbb{R}^{n+1}} \frac{1}{k_p - k'_p} \exp\left[i\varepsilon^{ab}(x_0, x, k'_{(p)}, m)\right] \cdot T_{ab}(k'_{(p)}, m)\nu\big(\lambda^{ab}(k'_{(p)}, m)\big)E^{ab}dm dk'_{p_R} dk'_{p_I}. \tag{3.5}$$

Remark 3.1. Equation (3.4) is therefore just $\mu_p = I + \mathbf{P}^p_{(x_0,x)}\mu_p$. Note that by property (ii) of Definition 2.3, $\mathbf{P}^p_{(x_0,x)}$ is also defined on any continuous function $\nu(k)$ with polynomial growth. Moreover, for such ν we have

$$\frac{\partial}{\partial \bar{k}_p}(\mathbf{P}^p_{(x_0,x)}\nu)(k) = \sum_{a,b} \frac{\gamma^a(J^a_p - J^b_p)}{(2\pi)^{n-1}} \exp\left[i\beta^a(x_0, x_1, k_{ab})\right] \cdot \int_{\mathbb{R}^{n-1}} \exp\left[i\alpha^a(x,m)\right] T_{ab}(k,m)\nu\big(\lambda^{ab}(k,m)\big)E^{ab}dm, \tag{3.6}$$

and

$$\lim_{k_j\to\infty} \mathbf{P}^p_{(x_0,x)}\nu = 0 \ (1 \le p \le n) \tag{3.7}$$

for fixed $(x_0, x, k_1, \cdots, k_{j-1}, k_{j+1}, \cdots, k_n)$.

A sufficient condition for (3.4) (equivalently (3.1)–(3.2)) to be uniquely solvable is stated in the next proposition whose proof is omitted due to its similarity to the proof of Proposition 2.1.

PROPOSITION 3.1. (Contracting property of $\mathbf{P}^p_{(x_0,x)}$.) *Assume that* $T \in D^o_{N\times N}$ *and that it satisfies*

$$\int_{\mathbb{R}^{n-1}} \sup_{\mathbb{C}^n} |T(k,m)|dm \cdot \int_{\mathbb{R}^{n-1}} \left[\int_{\mathbb{R}^2} \sup_{\mathbb{C}^{n-1}} |T(k,m)|dk_{p_R} dk_{p_I}\right] dm < \frac{\pi}{8\omega_p^2(N-1)^2}, \tag{3.8}$$

where $\omega_p = \max_{a,b}\left(|\gamma^a||J^a_p - J^b_p|\right)/(2\pi)^{n-1}$ *and* $|T(k,m)| = \max_{1\le a,b\le N}|T_{ab}(k,m)|$. *Then* $\mathbf{P}^p_{(x_0,x)}$ *is a contraction on* $C^b_{N\times N}(\mathbb{C}^n)$ *with*

$$\|\mathbf{P}^p_{(x_0,x)}\| \le \tau_p < 1 \quad \forall (x_0, x) \in \mathbb{R}^{n+1}. \tag{3.9}$$

From now on we shall assume that (3.8) holds for $1 \le p \le n$ and denote by $\mu_p(x_0, x, k)$ the unique solution in $C^b_{N\times N}(\mathbb{C}^n)$ of

$$\mu_p = I + \mathbf{P}^p_{(x_0,x)}\mu_p. \tag{3.10}$$

Since the operator $\mathbf{P}^p_{(x_0,x)}$ depends continuously on (x_0, x), μ_p is bounded and continuous on $\mathbb{R}^{n+1}\times\mathbb{C}^n$. It is a solution of (3.1) in the sense of distribution, and we also have by (3.6)

$$\lim_{k_j\to\infty} \mu_p(x_0, x, k) = I, \qquad 1 \le p \le n, \tag{3.11}$$

for fixed $(x_0, x, k_1, \cdots, k_{j-1}, k_{j+1}, \cdots, k_n)$.

By the same argument in the proof of (2.19), we obtain

$$\lim_{|x_0|+|x|\to\infty} \mu_p(x_0,x,k) = I \tag{3.12}$$

for fixed k.

PROPOSITION 3.2. (Properties of μ_1.) $\mu_1 \in C^\infty(\mathbb{R}^{n+1}\times\mathbb{C}^n)$. *All the derivatives of μ_1 that only involve the (x_0,x) variables are bounded on $\mathbb{R}^{n+1}\times\mathbb{C}^n$. All the derivatives that involve the k variables are bounded on $\mathbb{C}^n$ for fixed (x_0,x). All the first-order derivatives of $\mu_1 \to 0$ as $k_p \to \infty$ with all the other variables fixed.*

Proof. We will employ techniques similar to those in the proof of Lemma 2.2 and Proposition 2.2. But special care must be taken for the k_1-derivatives because of the function $\lambda_1^{ab}(k,m)$ (cf. (2.29)) that appears in the definition of $P^1_{(x_0,x)}$.

Starting with (3.1) for $p=1$, it is easy to show by induction that

$$\left(\frac{\partial}{\partial\bar{k}_1}\right)^\ell \mu_1(x_0,x,k) \quad \text{is continuous on } \mathbb{R}^{n+1}\times\mathbb{C}^n \tag{3.13}$$

for $\ell = 1,2,\cdots$, and

$$\left(\frac{\partial}{\partial\bar{k}_1}\right)^\ell \mu_1(x_0,x,k) \in C^b_{N\times N}(\mathbb{C}^n) \tag{3.14}$$

for $\ell = 1,2,\cdots$ and fixed (x_0,x). Here the derivatives are taken in the sense of distributions.

By elliptic regularity (cf. [8]), $\partial\mu_1/\partial k_{1_R}$ and $\partial\mu_1/\partial k_{1_I}$ exist in the classical sense. Let $\tilde{\mathbf{L}} = \sigma_R(\partial/\partial k_{1_R}) - \sigma_I(\partial/\partial k_{1_I})$. It follows from (2.29) that

$$\tilde{\mathbf{L}}\Big[\mu_1\big(x_0,x,\lambda^{ab}(k,m)\big)\Big] = \big(\tilde{\mathbf{L}}\mu_1\big)\big(x_0,x,\lambda^{ab}(k,m)\big). \tag{3.15}$$

By the technique in the proof of Lemma 2.2, $\tilde{\mathbf{L}}\mu_1$ is the solution in $C^b_{N\times N}(\mathbb{C}^n)$ of

$$\tilde{\mathbf{L}}\mu_1 = W + \mathbf{P}^1_{(x_0,x)}\big(\tilde{\mathbf{L}}\mu_1\big), \tag{3.16}$$

where

$$W = \sum_{a,b} \frac{\gamma^a\big(J_1^a - J_1^b\big)}{(2\pi)^{n-1}} \int_{\mathbb{R}^{n+1}} \tilde{\mathbf{L}}\Big\{ \exp\big[i\varepsilon^{ab}(x_0,x,k_1-k_1',k_2,\cdots,k_n,m)\big] \cdot T_{ab}(k_1-k_1',k_2,\cdots,k_n,m)\Big\} \cdot \frac{1}{k_1'}\mu_1\big(x_0,x,\lambda^{ab}(k_1-k_1',k_2,\cdots,k_n,m)\big)E^{ab}dm dk_{1_R}' dk_{1_I}'.$$

Since W depends continuously on (x_0,x), it follows from (3.16) that $\tilde{\mathbf{L}}\mu_1$ is continuous on $\mathbb{R}^{n+1}\times\mathbb{C}^n$. As $\partial\mu_1/\partial k_{1_R}$ and $\partial\mu_1/\partial k_{1_I}$ can be represented as linear combinations of $\partial\mu_1/\partial\bar{k}_1$ and $\tilde{\mathbf{L}}\mu_1$, we see that both $\partial\mu_1/\partial k_{1_R}$ and $\partial\mu_1/\partial k_{1_I}$ are continuous on $\mathbb{R}^{n+1}\times\mathbb{C}^n$ and bounded on $\mathbb{C}^n$ for fixed (x_0,x).

The other first-order derivatives can now be handled easily. The same arguments are then applied inductively as in the proof of Proposition 2.2 to higher-order derivatives.

Let ζ be one of the first-order derivatives of μ_1. Then ζ satisfies an equation of the form

$$\zeta = K + \mathbf{P}^1_{(x_0,x)}\zeta,$$

where by property (ii) of Definition 2.3, $\lim_{k_p\to\infty} K = 0$ with $(x_0, x, k_1, \cdots, k_{p-1}, k_{p+1}, \cdots, k_n)$ fixed. Since ζ is bounded on $\mathbb{C}^n$ for fixed (x_0, x), we also have in view of (3.7) that $\lim_{k_p\to\infty} P^1_{(x_0,x)}\zeta = 0$ for fixed $(x_0, x, k_1, \cdots, k_{p-1}, k_{p+1}, \cdots, k_n)$. Hence $\lim_{k_p\to\infty}\zeta = 0$. □

Our next goal is to prove that $\mu_1 = \mu_2 = \cdots = \mu_n$, actually.

LEMMA 3.2. *If $\nu(k) \in C^2(\mathbb{C}^n)$ and $\partial^\alpha\nu$ is bounded on $\mathbb{C}^n$ for $|\alpha| \le 1$, then*

$$\left[\mathbf{L}^p_{(x_0,x)}, \mathbf{L}^r_{(x_0,x)}\right]\nu = 0. \tag{3.17}$$

Proof. The commutativity of $\mathbf{L}^p_{(x_0,x)}$ and $\mathbf{L}^r_{(x_0,x)}$ is the consequence of the constraint $\mathbf{L}^{ab}_r T_{ab} = \mathbf{L}^{ab}_p T_{ab}$ in the definition of the space $D^o_{N\times N}$ (cf. (iii) of Definition 2.3). The following computations are similar to those in the proof of Proposition 2.5 and we shall use the notation introduced there.

From (2.46) and (2.47), we have

$$\begin{aligned}
&\left[\mathbf{L}^p_{(x_0,x)}, \mathbf{L}^r_{(x_0,x)}\right]\nu \\
&\quad = \mathbf{L}^p_{(x_0,x)}\mathbf{L}^r_{(x_0,x)}\nu - \mathbf{L}^r_{(x_0,x)}\mathbf{L}^p_{(x_0,x)}\nu \\
&\quad = \sum_{a,b}\frac{\gamma^a}{(2\pi)^{n-1}}\int_{\mathbb{R}^{n-1}}\exp\left[i\varepsilon^{ab}(x_0,x,k,m)\right]\left[\mathbf{L}^{ab}_{rp}T_{ab}\right]\nu\left(\lambda^{ab}(k,m)\right)E^{ab}dm \\
&\qquad + \sum_{a,b}\left\{\sum_j \frac{\gamma^{j+a}}{(2\pi)^{2n-2}}\left[\left(J^j_p - J^b_p\right)\left(J^a_r - J^j_r\right) - \left(J^j_r - J^b_r\right)\left(J^a_p - J^j_p\right)\right]\right. \\
&\qquad\quad \cdot\int_{\mathbb{R}^{2n-2}}\exp\left[i\varepsilon^{jb}(x_0,x,k,M) + i\varepsilon^{aj}\left(x_0,x,\lambda^{jb}(k,M),m\right)\right]T_{jb}(k,M) \\
&\qquad\quad \left.\cdot T_{aj}\left(\lambda^{jb}(k,M),m\right)\nu\left(\lambda^{aj}\left(\lambda^{jb}(k,M),m\right)\right)E^{ab}dmdM\right\}.
\end{aligned}$$

Using (2.49) and (2.50), we can rewrite the second sum as

$$\begin{aligned}
&\sum_{a,b}\frac{\gamma^a}{(2\pi)^{n-1}}\int_{\mathbb{R}^{n-1}}\exp\left[i\varepsilon^{ab}(x_0,x,k,m)\right] \\
&\quad\cdot\left\{\sum_j \frac{\gamma^j\left[\left(J^j_p - J^b_p\right)\left(J^a_r - J^j_r\right) - \left(J^j_r - J^b_r\right)\left(J^a_p - J^j_p\right)\right]}{(2\pi)^{n-1}}\int_{\mathbb{R}^{n-1}} T_{jb}(k,M)\right. \\
&\qquad\left.\cdot T_{aj}\left(\lambda^{jb}(k,M), m-M\right)\nu\left(\lambda^{ab}(k,m)\right)E^{ab}dM\right\}dm.
\end{aligned}$$

The proof of the lemma is then completed by observing that (2.52) holds because $\mathbf{L}^{ab}_r T_{ab} = \mathbf{L}^{ab}_p T_{ab}$. □

PROPOSITION 3.3. (Existence and uniqueness of the solution of the inverse problem.) *Assuming that* (3.8) *holds for $1 \le p \le n$, there is a unique μ which satisfies* (3.1) *and* (3.2) *simultaneously for $1 \le p \le n$.*

Proof. Since $\mathbf{L}^1_{(x_0,x)}\mu_1 = 0$, Lemma 3.2 implies that for $2 \le p \le n$

$$\mathbf{L}^1_{(x_0,x)}\left[\mathbf{L}^p_{(x_0,x)}\mu_1\right] = 0.$$

For fixed $(x_0, x, k_2, \cdots, k_n)$, $\lim_{k_1\to\infty} \partial\mu_1/\partial\bar{k}_p = 0$ by Proposition 3.2. Since the integral in the definition of $\mathbf{L}^p_{(x_0,x)}$ also tends to zero as $k_1 \to \infty$ by the decay of T, we have

$$\lim_{k_1\to\infty} \mathbf{L}^p_{(x_0,x)}\mu_1 = 0$$

for fixed $(x_0, x, k_2, \cdots, k_n)$.

Therefore the inversion formula for the $\bar{\partial}$ operator and Liouville's theorem imply that

$$\mathbf{L}^p_{(x_0,x)}\mu_1 = \mathbf{P}^1_{(x_0,x)}\left[\mathbf{L}^p_{(x_0,x)}\mu_1\right].$$

Hence $\mathbf{L}^p_{(x_0,x)}\mu_1 = 0$ for $2 \le p \le n$, by the contraction property of $\mathbf{P}^1_{(x_0,x)}$. In view of (3.11), μ_1 satisfies the boundary condition (3.2) for $2 \le p \le n$ which means that μ_1 also satisfies (3.4) for $2 \le p \le n$. By the contraction property of $\mathbf{P}^p_{(x_0,x)}$, we have $\mu_1 = \mu_p$ for $2 \le p \le n$. □

PROPOSITION 3.4. (Asymptotics of μ for large k.) *For fixed* $(x_0, x, k_1, \cdots, k_{p-1}, k_{p+1}, \cdots, k_n)$ *and* $1 \le p \le n$,

$$\mu(x_0, x, k) = I + \frac{1}{\pi k_p}\int_{\mathbb{R}^2} \frac{\partial\mu}{\partial\bar{k}_p}(x_0, x, k)\,dk_{p_R}\,dk_{p_I} + o\left(\frac{1}{|k_p|}\right). \tag{3.18}$$

Proof. We have

$$\begin{aligned} k_p(\mu - I) &= \sum_{a,b} \frac{\gamma^a\left(J^a_p - J^b_p\right)}{\pi(2\pi)^{n-1}} \int_{\mathbb{R}^{n+1}} \exp\left[i\varepsilon^{ab}\left(x_0, x, k'_{(p)}, m\right)\right] \\ &\quad \cdot T_{ab}(k'_{(p)}, m)\mu\left(x_0, x, \lambda^{ab}(k'_{(p)}, m)\right)E^{ab}\,dm\,dk'_{p_R}\,dk'_{p_I} \\ &\quad + \sum_{a,b} \frac{\gamma^a\left(J^a_p - J^b_p\right)}{\pi(2\pi)^{n-1}} \int_{\mathbb{R}^{n+1}} \frac{k'_p}{k_p - k'_p} \exp\left[i\varepsilon^{ab}\left(x_0, x, k'_{(p)}, m\right)\right] \\ &\quad \cdot T_{ab}(k'_{(p)}, m)\mu\left(x_0, x, \lambda^{ab}(k'_{(p)}, m)\right)E^{ab}\,dm\,dk_{p_R}\,dk_{p_I}. \end{aligned}$$

The second sum goes to zero as $k_p \to \infty$, by the decay of T. In view of (3.1), the first sum is just $(1/\pi)\int_{\mathbb{R}^2}(\partial\mu/\partial\bar{k}_p)(x_0, x, k)\,dk_{p_R}\,dk_{p_I}$. □

In view of (2.40), it is natural to define the potential Q by

$$Q = \frac{i\sigma}{\pi}\left[J_p, \int_{\mathbb{R}^2} \frac{\partial\mu}{\partial\bar{k}_p}(x_0, x, k)\,dk_{p_R}\,dk_{p_I}\right].$$

The problem with this definition is twofold: (i) it is not clear that Q is a function of (x_0, x) alone and (ii) Q apparently depends on the choice of p. Therefore we begin instead with the matrix-valued functions Q_p $(1 \le p \le n)$ defined by

$$Q_p = \frac{i\sigma}{\pi}\left[J_p, \int_{\mathbb{R}^2} \frac{\partial\mu}{\partial\bar{k}_p}(x_0, x, k)\,dk_{p_R}\,dk_{p_I}\right], \tag{3.19}$$

or equivalently (using (3.1)),

$$Q_p = \frac{i\sigma}{\pi} \sum_{a,b} \frac{\gamma^a (J_p^a - J_p^b)}{\pi (2\pi)^{n-1}} \Bigg[J_p, \int_{\mathbb{R}^{n+1}} \exp\left[i\varepsilon^{ab}(x_0, x, k, m) \right] \cdot T_{ab}(k, m) \mu\big(x_0, x, \lambda^{ab}(k, m)\big) E^{ab} \Bigg] dm dk_{p_R} dk_{p_I}. \tag{3.20}$$

Hence Q_p is C^∞ and bounded on $\mathbb{R}^{n+1} \times \mathbb{C}^n$. Note that Q_p is independent of k_p.

Let $\mathbf{L}_k$ be the differential operator defined by

$$\mathbf{L}_k \theta = \frac{\partial \theta}{\partial x_0} + \sigma \sum_{\ell=1}^{n} \left(J_\ell \frac{\partial \theta}{\partial x_\ell} + i k_\ell [J_\ell, \theta] \right), \tag{3.21}$$

where θ is an $N \times N$-matrix-valued function defined on $\mathbb{R}^{n+1}$. Note that (1.3) can be rewritten as $\mathbf{L}_k \mu = Q\mu$.

LEMMA 3.3. *Let $\nu \in C^2(\mathbb{R}^{n+1} \times \mathbb{C}^n)$ and $\partial^\alpha_{(x_0,x)} \nu$ be bounded for $|\alpha| \le 1$. Then*

$$\big[\mathbf{L}^p_{(x_0,x)}, \mathbf{L}_k \big] \nu = 0. \tag{3.22}$$

Proof. It is clear that $\partial(\mathbf{L}_k \mu)/\partial \bar{k}_p = \mathbf{L}_k (\partial \mu / \partial \bar{k}_p)$. On the other hand, the decay of T allows differentiation under the integral sign:

$$\begin{aligned} \mathbf{L}_k \Bigg\{ \sum_{a,b} \frac{\gamma^a (J_p^a - J_p^b)}{\pi (2\pi)^{n-1}} \int_{\mathbb{R}^{n-1}} & \exp\left[i\varepsilon^{ab}(x_0, x, k, m) \right] \\ & \cdot T_{ab}(k, m) \nu\big(x_0, x, \lambda^{ab}(k, m)\big) E^{ab} dm \Bigg\} \\ = \sum_{a,b} \frac{\gamma^a (J_p^a - J_p^b)}{(2\pi)^{n-1}} \int_{\mathbb{R}^{n-1}} & T_{ab}(k, m) \mathbf{L}_k \Big\{ \exp\left[i\varepsilon^{ab}(x_0, x, k, m) \right] \\ & \cdot \nu\big(x_0, x, \lambda^{ab}(k, m)\big) E^{ab} \Big\} dm. \end{aligned}$$

Recall (cf. proof of Proposition 2.4) that $\lambda^{ab}(k, m)$ is defined so that

$$\begin{aligned} \mathbf{L}_k \Big\{ \exp\big[i\varepsilon^{ab}(x_0, x, k, m) \big] \nu(x_0, x, \lambda^{ab}(k, m)) E^{ab} \Big\} \\ = \exp\left[i\varepsilon^{ab}(x_0, x, k, m) \right] (\mathbf{L}_k \nu)\big(x_0, x, \lambda^{ab}(k, m)\big). \end{aligned}$$

The proof of the lemma is therefore complete. □

PROPOSITION 3.5. (Equivalence of the reconstruction formulas.)

$$Q_1 = Q_2 = \cdots = Q_n.$$

Proof. From (3.22) we have $\mathbf{L}^p_{(x_0,x)}(\mathbf{L}_k \mu) = 0$ for $1 \le p \le n$, and it follows from (3.18) that

$$\lim_{k_p \to \infty} i\sigma \sum_{\ell=1}^{n} k_\ell [J_\ell, \mu] = Q_p \tag{3.23}$$

for fixed $(x_0, x, k_1, \cdots, k_{p-1}, k_{p+1}, \cdots, k_n)$. Hence Proposition 3.2 implies that

$$\lim_{k_p \to \infty} \mathbf{L}_k \mu = Q_p \tag{3.24}$$

for fixed $(x_0, x, k_1, \cdots, k_{p-1}, k_{p+1}, \cdots, k_n)$.

Since $\mathbf{L}_k \mu$ has polynomial growth in k, we have by Remark 3.1 the inversion formula for the $\bar{\partial}$ operator and Liouville's theorem that

$$\mathbf{L}_k \mu = Q_p + \mathbf{P}^p_{(x_0,x)}(\mathbf{L}_k \mu) \quad \text{for } 1 \le p \le n. \tag{3.25}$$

Recall that Q_p is independent of k_p. On the other hand, if we keep $(x_0, x, k_1, \cdots, k_{p-1}, k_{p+1}, \cdots, k_n)$ fixed and then let $k_p \to \infty$ in the equation $\mathbf{L}_k \mu = Q_j + \mathbf{P}^j_{(x_0,x)} \cdot (\mathbf{L}_k \mu)$, it follows from (3.7) that

$$Q_p = \lim_{k_p \to \infty} \mathbf{L}_k \mu = \lim_{k_p \to \infty} Q_j. \tag{3.26}$$

Therefore Q_p is also independent of k_j. Since j is arbitrary, Q_p is a function of (x_0, x) alone, for $1 \le p \le n$. But then (3.26) implies that $Q_p = Q_j$ for any p and j, i.e., $Q_1 = Q_2 = \cdots = Q_n$. □

COROLLARY 3.1. (Differential equation relating Q and μ.)

$$\mu_{x_0} + \sigma \sum_{\ell=1}^{n} (J_\ell \mu_{x_\ell} + i k_\ell [J_\ell, \mu]) = Q\mu. \tag{3.27}$$

Proof. Since Q is a function of (x_0, x) alone, it follows from (3.10) that

$$Q\mu = Q + \mathbf{P}^p_{(x_0,x)}(Q\mu) \quad \text{for } 1 \le p \le n. \tag{3.28}$$

Equation (3.27) then follows by comparing (3.28) with (3.25). □

It is clear that Q is off-diagonal and C^∞ on $\mathbb{R}^{n+1}$. To study the decay of Q, we exploit the following integral equation, which is a consequence of (3.1), (3.4), and (2.30).

$$\begin{aligned} &\frac{\partial \mu}{\partial \bar{k}_1}(x_0, x, k) \\ &= G + \sum_{a,b} \frac{\gamma^a (J_1^a - J_1^b)}{\pi (2\pi)^{n-1}} \int_{\mathbb{R}^{n+1}} \exp\left[i\varepsilon^{ab}(x_0, x_1, k, m)\right] \frac{1}{\lambda_1^{ab}(k,m) - k_1'} \\ &\quad \cdot T_{ab}(k,m) \frac{\partial \mu}{\partial \bar{k}_1'}(x_0, x, k_1', k_2 + m_2, \cdots, k_n + m_n) E^{ab} dk_{1_R}' dk_{1_I}' dm, \end{aligned} \tag{3.29}$$

where

$$G = \sum_{a,b} \frac{\gamma^a (J_1^a - J_1^b)}{\pi (2\pi)^{n-1}} \int_{\mathbb{R}^{n-1}} \exp\left[i\varepsilon^{ab}(x_0, x, k, m)\right] T_{ab}(k,m) E^{ab} dm. \tag{3.30}$$

DEFINITION 3.1. Let $L^1_{N\times N}(\mathbb{C})$ be the Banach space of $N \times N$ matrices whose entries belong to $L^1(\mathbb{C})$. If $\nu \in L^1_{N\times N}(\mathbb{C})$, then $\|\nu\|_{L^1_{N\times N}} = \max_{1\le a,b\le N} \|\nu_{ab}\|_{L^1(\mathbb{C})}$. Let $C^b(\mathbb{C}^{n-1}, L^1_{N\times N}(\mathbb{C}))$ be the Banach space of bounded continuous func-

tions on $\mathbb{C}^{n-1}$ with value in $L^1_{N\times N}(\mathbb{C})$. If $\nu(k_2,\cdots,k_n)\in C^b\big(\mathbb{C}^{n-1},L^1_{N\times N}(\mathbb{C})\big)$, $|||\nu|||=\sup_{\mathbb{C}^{n-1}}\|\nu(k_2,\cdots,k_n)\|_{L^1_{N\times N}}$. We shall also write $\nu(k_2,\cdots,k_n)(k_1)$ as $\nu(k_1,k_2,\cdots,k_n)$.

Let $\mathbf{R}_{(x_0,x)}$ be the operator on $C^b\big(\mathbb{C}^{n-1},L^1_{N\times N}(\mathbb{C})\big)$ defined by

$$\begin{aligned}\Big[\mathbf{R}_{(x_0,x)}\nu\Big](k)&\\ =\sum_{a,b}\frac{\gamma^a\big(J_1^a-J_1^b\big)}{\pi(2\pi)^{n-1}}\int_{\mathbb{R}^{n+1}}&\exp\big[i\varepsilon^{ab}(x_0,x,k,m)\big]\frac{1}{\lambda_1^{ab}(k,m)-k_1'}T_{ab}(k,m)\\ &\cdot\nu\big(k_1',k_2+m_2,\cdots,k_n+m_n\big)E^{ab}dk_{1_R}'dk_{1_I}'dm\,.\end{aligned}\tag{3.31}$$

It is clear from (3.1) that $(\partial\mu/\partial\bar{k}_1)\in C^b\big(\mathbb{C}^{n-1},L^1_{N\times N}(\mathbb{C})\big)$. We can therefore regard (3.29) as an equation in $C^b\big(\mathbb{C}^{n-1},L^1_{N\times N}(\mathbb{C})\big)$ and rewrite it as

$$\frac{\partial\mu}{\partial\bar{k}_1}=G+\mathbf{R}_{(x_0,x)}\Big(\frac{\partial\mu}{\partial\bar{k}_1}\Big).\tag{3.32}$$

LEMMA 3.4. *$\mathbf{R}_{(x_0,x)}$ is a contraction on $C^b\big(\mathbb{C}^{n-1},L^1_{N\times N}(\mathbb{C})\big)$ if (3.8) holds for $p=1$.*

Proof. Note that by (2.29),

$$\big[\lambda_1^{ab}(k_1,0)\big]_I=k_{1_I}\tag{3.33}$$

and

$$\big[\lambda_1^{ab}(k_1,0)\big]_R=\frac{J_1^b}{J_1^a}k_{1_R}-\frac{\sigma_R\big(J_1^a-J_1^b\big)}{\sigma_I J_1^a}k_{1_I}\,.\tag{3.34}$$

From (2.24),

$$\begin{aligned}\omega_1&=\max_{a,b}\frac{|\gamma^a||J_1^a-J_1^b|}{(2\pi)^{n-1}}\\ &=\max_{a,b}\frac{|\gamma^a||J_1^a-J_1^b||J_1^a|}{(2\pi)^{n-1}|J_1^b|}\,.\end{aligned}\tag{3.35}$$

Using (3.33)–(3.35) and an argument similar to the one in the proof of Proposition 2.1, we find

$$\begin{aligned}&\Big\|\Big[\mathbf{R}_{(x_0,x)}\nu\Big]_{ab}(\cdot,k_2,\cdots,k_n)\Big\|_{L^1_{N\times N}}\\ &\quad\le\sum_{j=1}^N\frac{|\gamma^j||J_1^j-J_1^b|}{\pi(2\pi)^{n-1}}\int_{\mathbb{R}^{n+3}}\frac{1}{|\lambda_1^{jb}(k,m)-k_1'|}|T_{jb}(k,m)|\\ &\qquad\cdot|\nu_{aj}(k_1',k_2+m_2,\cdots,k_n+m_n)|dk_{1_R}'dk_{1_I}'dmdk_{1_R}dk_{1_I}\\ &\quad\le\frac{(N-1)8^{\frac12}\omega_1}{\pi^{\frac12}}|||\nu|||\int_{\mathbb{R}^{n-1}}\Big[\sup_{\mathbb{C}^n}|T(k,m)|\Big]^{\frac12}\Big[\sup_{\mathbb{C}^{n-1}}\int_{\mathbb{R}^2}|T(k,m)|dk_{1_R}dk_{1_I}\Big]^{\frac12}dm\\ &\quad\le\frac{(N-1)8^{\frac12}\omega_1}{\pi^{\frac12}}|||\nu|||\Big[\int_{\mathbb{R}^{n-1}}\sup_{\mathbb{C}^n}|T(k,m)|dm\Big]^{\frac12}\\ &\qquad\cdot\Big[\int_{\mathbb{R}^{n-1}}\Big[\sup_{\mathbb{C}^{n-1}}\int_{\mathbb{R}^2}|T(k,m)|dk_{1_R}dk_{1_I}\Big]dm\Big]^{\frac12}.\end{aligned}$$

□

Since we assume that (3.8) holds for $1 \leq p \leq n$, we can control the norm of $R_{(x_0,x)}$ by the same constant that appears in (3.9):

$$||\mathbf{R}_{(x_0,x)}|| \leq \tau_1 < 1 \quad \forall\, (x_0,x) \in \mathbb{R}^{n+1}. \tag{3.36}$$

PROPOSITION 3.6. (Decay of Q.)

$$Q \in S^o_{N\times N}.$$

Proof. From (3.32), we obtain

$$\begin{aligned}(1+|x_0|^2+|x|^2)^j \frac{\partial \mu}{\partial \bar{k}_1} &= (1+|x_0|^2+|x|^2)^j G \\ &\quad + \mathbf{R}_{(x_0,x)}\left((1+|x_0|^2+|x|^2)^j \frac{\partial \mu}{\partial \bar{k}_1}\right)\end{aligned} \tag{3.37}$$

for $j = 0, 1, 2, \cdots$.

Using integration by parts and (3.30), property (ii) of Definition 2.3 implies that there exists $C_j > 0$ such that

$$|||(1+|x_0|^2+|x|^2)G(x_0,x,k)||| \leq C_j \quad \forall\, (x_0,x) \in \mathbb{R}^{n+1}. \tag{3.38}$$

It follows from (3.36)–(3.38) that

$$|||(1+|x_0|^2+|x|^2)^j \frac{\partial \mu}{\partial \bar{k}_1}(x_0,x,k)||| \leq \frac{C_j}{1-\tau_1} \quad \forall\, (x_0,x) \in \mathbb{R}^{n+1}. \tag{3.39}$$

Inductively, we have

$$\partial^\alpha_{(x_0,x)} \frac{\partial \mu}{\partial \bar{k}_1} = G_\alpha + \mathbf{R}_{(x_0,x)}\left(\partial^\alpha_{(x_0,x)} \frac{\partial \mu}{\partial \bar{k}_1}\right), \tag{3.40}$$

where

$$|||(1+|x_0|^2+|x|^2)^j G_\alpha(x_0,x,k)||| \leq C_{\alpha,j} \quad \forall\, (x_0,x) \in \mathbb{R}^{n+1}. \tag{3.41}$$

Hence

$$|||(1+|x_0|^2+|x|^2)^j \partial^\alpha_{(x_0,x)} \frac{\partial \mu}{\partial \bar{k}_1}(x_0,x,k)||| \leq \frac{C_{\alpha,j}}{1-\tau_1} \quad \forall\, (x_0,x) \in \mathbb{R}^{n+1}. \tag{3.42}$$

Since $Q = (i\sigma/\pi)\left[J_1, \int_{\mathbb{R}^2} \frac{\partial \mu}{\partial k_1}(x_0,x,k) dk_{1_R} dk_{1_I}\right]$, the proposition follows from (3.42). □

DEFINITION 3.2. (Inverse scattering map.)

$$\hat{\mathbf{S}}(T) = Q. \tag{3.43}$$

Remark 3.2. If we trace the dependence of Q on T through the arguments in the proof of Proposition 3.6, we see that $\hat{\mathbf{S}}$ is a continuous map from a neighborhood of $0 \in D^o_{N\times N}$ into $S^o_{N\times N}$.

The results of this section are summarized in the following theorem.

THEOREM 3.1. *The inverse problem has a unique simultaneous solution* μ *if* (3.8) *holds for* $1 \le p \le n$. *The reconstruction formulas in* (3.19) *are equivalent, and the potential* $Q(x_0, x)$ *defined by these formulas belongs to* $S^o_{N\times N}$. *Moreover,* (1.3)–(1.4) *are satisfied by* Q *and* μ. *The inverse scattering map* $\hat{\mathbf{S}}$ *that takes* T *to* Q *is a continuous map from a neighborhood of* $0 \in D^o_{N\times N}$ *into* $S^o_{N\times N}$.

Remark 3.3. $\hat{\mathbf{S}}$ is actually infinitely Fréchet differentiable.

4. Relation between S and $\hat{\mathbf{S}}$.

PROPOSITION 4.1.

$$\hat{\mathbf{S}} \circ \mathbf{S} = \mathbf{I} \quad \textit{on the domain of} \quad \hat{\mathbf{S}} \circ \mathbf{S}, \tag{4.1}$$

and

$$\mathbf{S} \circ \hat{\mathbf{S}} = \mathbf{I} \quad \textit{on the domain of} \quad \mathbf{S} \circ \hat{\mathbf{S}}. \tag{4.2}$$

Proof. Given $Q \in S^o_{N\times N}$ belonging to the domain of $\hat{\mathbf{S}} \circ \mathbf{S}$, let $T = \mathbf{S}(Q)$ and $Q' = \hat{\mathbf{S}}(T)$. Let μ be the unique solution of (1.3)–(1.4). Then μ is also the unique solution of the $\bar\partial$ problem (3.1)–(3.2) by Proposition 2.4. In view of Corollary 2.3, Q' defined by

$$Q' = \frac{i\sigma}{\pi}\left[J_p, \int_{\mathbb{R}^2} \frac{\partial \mu}{\partial \bar k_p}(x_0, x, k) dk_{p_R} dk_{p_I}\right], \qquad 1 \le p \le n,$$

must coincide with Q.

Given $T \in D^o_{N\times N}$ belonging to the domain $\mathbf{S} \circ \hat{\mathbf{S}}$, let $Q = \hat{\mathbf{S}}(T)$ and $T' = \mathbf{S}(Q)$. Let μ be the unique solution of (3.1)–(3.2). Then it follows immediately that

$$\begin{aligned} \lim_{x_0\to\infty} &\left\{\exp[-i\beta^a(x_0, 0, k_{ab})]\frac{\partial \mu_{ab}}{\partial \bar k_p}(x_0, 0, x_2, \cdots, x_n, k)\right\} \\ &= \frac{\gamma^a(J^a_p - J^b_p)}{(2\pi)^{n-1}} \int_{\mathbb{R}^{n-1}} \exp\left(\sum_{\ell=2}^n m_\ell x_\ell\right) T_{ab}(k, m)\, dm. \end{aligned} \tag{4.3}$$

By Corollary 3.1 and (3.12), μ is also the unique solution of (1.3)–(1.4). Hence Corollary 2.2 implies that

$$\begin{aligned} \lim_{x_0\to\infty} &\left[\exp[-i\beta^a(x_0, 0, k_{ab})]\frac{\partial \mu_{ab}}{\partial \bar k_p}(x_0, 0, x_2, \cdots, x_n, k)\right] \\ &= \frac{\gamma^a(J^a_p - J^b_p)}{(2\pi)^{n-1}} \int_{\mathbb{R}^{n-1}} \exp\left(\sum_{\ell=2}^n m_\ell x_\ell\right) T'_{ab}(k, m)\, dm. \end{aligned} \tag{4.4}$$

Comparing (4.3) and (4.4), we conclude that $T = T'$. □

Combining Remarks 2.4 and 3.2 and Proposition 4.1, we obtain the following theorem.

THEOREM 4.1. *The scattering map* $\mathbf{S}$ *is a homeomorphism from a neighborhood of* $0 \in S^o_{N\times N}$ *onto a neighborhood of* $0 \in D^o_{N\times N}$.

Remark 4.1. $\mathbf{S}$ is actually a diffeomorphism.

5. Reduction to 2×2 potentials. We shall show in this section how the reconstruction of the potential from the scattering data can be reduced to the special

case of 2×2 potentials and 2×2 inverse data. As mentioned in the Introduction, this means that the number of variables involved can be reduced to 3, i.e., $n = 2$.

Throughout this section we assume appropriate *smallness* conditions so that all the equations involved are uniquely solvable. We first take a quick look at the simplification of the theory developed in §§2 and 3 when $N = 2$. Let $\hat{Q}(x_0, x)$ be a 2×2 potential. The equations for the direct problem are

$$\frac{\partial \hat{\mu}_{11}}{\partial x_0} + \sigma \sum_{\ell=1}^{n} \hat{J}_\ell^1 \frac{\partial \hat{\mu}_{11}}{\partial x_\ell} = \hat{Q}_{12}\hat{\mu}_{21}, \tag{5.1}$$

$$\frac{\partial \hat{\mu}_{12}}{\partial x_0} + \sigma \sum_{\ell=1}^{n} \hat{J}_\ell^1 \frac{\partial \hat{\mu}_{12}}{\partial x_\ell} + i\sigma \left[\sum_{\ell=1}^{n} k_\ell (\hat{J}_\ell^1 - \hat{J}_\ell^2) \right] \hat{\mu}_{12} = \hat{Q}_{12}\hat{\mu}_{22}, \tag{5.2}$$

$$\frac{\partial \hat{\mu}_{21}}{\partial x_0} + \sigma \sum_{\ell=2}^{n} \hat{J}_\ell^2 \frac{\partial \hat{\mu}_{21}}{\partial x_\ell} + i\sigma \left[\sum_{\ell=1}^{n} k_\ell (\hat{J}_\ell^2 - \hat{J}_\ell^1) \right] \hat{\mu}_{21} = \hat{Q}_{21}\hat{\mu}_{11}, \tag{5.3}$$

and

$$\frac{\partial \hat{\mu}_{22}}{\partial x_0} + \sigma \sum_{\ell=1}^{n} \hat{J}_\ell^2 \frac{\partial \hat{\mu}_{22}}{\partial x_\ell} = \hat{Q}_{21}\hat{\mu}_{12} \tag{5.4}$$

with the boundary condition

$$\lim_{|x_0|+|x| \to \infty} \hat{\mu} = I. \tag{5.5}$$

It is clear that there is really only one complex variable involved, namely, $\chi = \sum_{\ell=1}^{n} k_\ell (\hat{J}_\ell^1 - \hat{J}_\ell^2)$. In particular, the characterization problem does not exist.

$(\partial \hat{\mu}/\partial \bar{\chi})$ and $\hat{\mu}$ are related through

$$\begin{aligned} \frac{\partial \hat{\mu}}{\partial \bar{\chi}} = \frac{\bar{\sigma}}{4\pi i |\sigma_I| (2\pi)^{n-1}} \Bigg\{ & \frac{1}{\hat{J}_1^1} \int_{\mathbb{R}^{n-1}} \exp\left[i\hat{\beta}^1(x_0, x_1, \chi) + i \sum_{\ell=2}^{n} m_\ell \left(x_\ell - x_1 \frac{\hat{J}_\ell^1}{\hat{J}_1^1} \right) \right] \\ & \cdot \hat{T}_{12}(\chi, m) \hat{\mu}\big(x_0, x, \hat{\lambda}^1(\chi, m)\big) E^{12} dm \\ & + \frac{-1}{\hat{J}_1^2} \int_{\mathbb{R}^{n-1}} \exp\left[i\hat{\beta}^2(x_0, x_1, -\chi) + i \sum_{\ell=2}^{n} m_\ell \left(x_\ell - x_1 \frac{\hat{J}_\ell^2}{\hat{J}_1^2} \right) \right] \\ & \cdot \hat{T}_{21}(\chi, m) \hat{\mu}\big(x_0, x, \hat{\lambda}^2(\chi, m)\big) E^{21} dm \Bigg\}, \end{aligned} \tag{5.6}$$

where

$$\hat{\beta}^j(x_0, x_1, \chi) = \frac{1}{\sigma} \left[|\sigma|^2 \chi_I x_0 - \frac{(\sigma\chi)_I}{\hat{J}_1^j} x_1 \right], \qquad j = 1, 2, \tag{5.7}$$

$$\begin{aligned} \hat{T}_{12}(\chi, m) = \int_{\mathbb{R}^{n+1}} & \exp\left[-i\hat{\beta}^1(\xi_0, \xi_1, \chi) - i \sum_{\ell=2}^{n} m_\ell \left(\eta_\ell - \xi_1 \frac{\hat{J}_\ell^1}{\hat{J}_1^1} \right) \right] \\ & \cdot \hat{Q}_{12}(\xi_0, \xi_1, \eta) \hat{\mu}_{22}(\xi_0, \xi_1, \eta, \chi) d\xi_0 d\xi_1 d\eta, \end{aligned} \tag{5.8}$$

$$\begin{aligned} \hat{T}_{21}(\chi, m) = \int_{\mathbb{R}^{n+1}} & \exp\left[-i\hat{\beta}^2(\xi_0, \xi_1, -\chi) - i \sum_{\ell=2}^{n} m_\ell \left(\eta_\ell - \xi_1 \frac{\hat{J}_\ell^2}{\hat{J}_1^2} \right) \right] \\ & \cdot \hat{Q}_{21}(\xi_0, \xi_1, \eta) \hat{\mu}_{11}(\xi_0, \xi_1, \eta, \chi) d\xi_0 d\xi_1 d\eta, \end{aligned} \tag{5.9}$$

and

$$\hat{\lambda}^j(\chi,m)=\frac{\chi}{\hat{J}_1^1-\hat{J}_1^2}+\sum_{\ell=2}^{n}m_\ell\frac{\hat{J}_\ell^1\hat{J}_1^2-\hat{J}_1^1\hat{J}_\ell^2}{\hat{J}_1^j\left(\hat{J}_1^1-\hat{J}_1^2\right)}-(-1)^j\frac{(\sigma\chi)_I}{\sigma_I\hat{J}_1^j},\qquad j=1,2. \tag{5.10}$$

Equation (5.6) is essentially the same as (2.28) except for the minor changes due to the fact that the derivative is taken with respect to $\bar{\chi}$ instead of the individual $\bar{k}_p$.

In the inverse problem, $\hat{\mu}$ is obtained by solving (5.6) with boundary condition

$$\lim_{\chi\to\infty}\hat{\mu}(x_0,x,\chi)=I. \tag{5.11}$$

The potential is then given by

$$\hat{Q}_{12}(x_0,x)=\frac{i\sigma}{\pi}\int_{\mathbb{R}^2}\frac{\partial\hat{\mu}_{12}}{\partial\bar{\chi}}(x_0,x,\chi)d\chi_R d\chi_I \tag{5.12}$$

and

$$\hat{Q}_{21}(x_0,x)=\frac{i\sigma}{\pi}\int_{\mathbb{R}^2}\frac{\partial\hat{\mu}_{21}}{\partial\bar{\chi}}(x_0,x,\chi)d\chi_R d\chi_I. \tag{5.13}$$

We now show how the general $N\times N$ case can be reduced to the special case above. We shall impose the following additional nondegeneracy condition.

$$\left(J_1^a-J_1^b\right)\left(J_p^c-J_p^b\right)\neq\left(J_1^c-J_1^b\right)\left(J_p^a-J_p^b\right) \tag{5.14}$$

for all distinct a,b,c and for $p\neq 1$.

Let μ satisfy (1.3) and (1.4). For fixed $\hat{a}$ and $\hat{b}$ such that $\hat{a}<\hat{b}$, let $\hat{Q}_{12}(x_0,x)=Q_{\hat{a}\hat{b}}(x_0,x),\hat{Q}_{21}(x_0,x)=Q_{\hat{b}\hat{a}}(x_0,x),\hat{J}_\ell^1=J_\ell^a$, and $\hat{J}_\ell^2=J_\ell^b$ for $1\leq\ell\leq n$.

PROPOSITION 5.1. *The reduced 2×2 system*

$$\hat{\mu}_{x_0}+\sum_{\ell=1}^{n}\sigma\left(\hat{J}_\ell\hat{\mu}_{x_\ell}+ik_\ell\left[\hat{J}_\ell,\hat{\mu}\right]\right)=\hat{Q}\hat{\mu} \tag{5.15}$$

with boundary condition

$$\lim_{|x_0|+|x|\to\infty}\hat{\mu}=I \tag{5.16}$$

is satisfied (uniquely) by

$$\hat{\mu}_{11}=\lim_{k_p\to\infty}\mu_{\hat{a}\hat{a}},\qquad \hat{\mu}_{12}=\lim_{k_p\to\infty}\mu_{\hat{a}\hat{b}},$$
$$\hat{\mu}_{21}=\lim_{k_p\to\infty}\mu_{\hat{b}\hat{a}},\qquad \hat{\mu}_{22}=\lim_{k_p\to\infty}\mu_{\hat{b}\hat{b}}. \tag{5.17}$$

Here the limit is taken with fixed $(x_0,x,\chi,k_2,\cdots,k_{p-1},k_{p+1},\cdots,k_n)$, where $\chi=\sum_{\ell=1}^{n}k_\ell\left(\hat{J}_\ell^1-\hat{J}_\ell^2\right)=k_{\hat{a}\hat{b}}$ and $p\geq 2$.

Proof. Observe that (5.14) implies that

$$\lim_{k_p\to\infty} k_{ab} = \infty \tag{5.18}$$

for $b = \hat{a}$ or $\hat{b}$, $1 \le a \le N$, and $(a,b) \notin \{(\hat{a},\hat{a}),(\hat{a},\hat{b}),(\hat{b},\hat{a}),(\hat{b},\hat{b})\}$.

Assume that as $k_p \to \infty$, $\mu_{ab}(x_0,x,\chi,k_2,\cdots,k_n)$ converges uniformly on compact subsets of $\mathbb{R}^{n+1}$ to $\psi_{ab}(x_0,x,\chi,k_2,\cdots,k_{p-1},k_{p+1},\cdots,k_n)$ for $b = \hat{a}$ or $\hat{b}$ and for $1 \le a \le N$. By (2.8), (5.18), the boundedness of μ, the decay of Q, and the Riemann–Lebesgue lemma, we find for $(a,b) \notin \{(\hat{a},\hat{a}),(\hat{a},\hat{b}),(\hat{b},\hat{a}),(\hat{b},\hat{b})\}$

$$\begin{aligned}
&\psi_{ab}(x_0,x,\chi,k_2,\cdots,k_{p-1},k_{p+1},\cdots,k_n)\\
&\quad = \lim_{k_p\to\infty} \mu_{ab}(x_0,x,\chi,k_2,\cdots,k_n)\\
&\quad = \lim_{k_p\to\infty} \int_{\mathbb{R}^2} G(\xi,k_{ab})[Q\psi]_{ab}(x_0-2\xi_0, x_1 - J_1^a(\sigma\bar{\xi}+\bar{\sigma}\xi),\cdots,\\
&\qquad\qquad x_n - J_n^a(\sigma\bar{\xi}+\bar{\sigma}\xi),\chi,k_2,\cdots,k_n)d\xi_0 d\xi_1 \qquad (5.19)\\
&\quad = 0\,.
\end{aligned}$$

It also follows from (2.8), (5.18) and (5.19) that

$$\begin{aligned}
&\psi_{\hat{a}\hat{a}}(x_0,x,\chi,k_2,\cdots,k_{p-1},k_{p+1},\cdots,k_n)\\
&\quad = 1 + \int_{\mathbb{R}^2} G(\xi,0)[Q_{\hat{a}\hat{b}}\psi_{\hat{b}\hat{a}}](x_0-2\xi_0, x_1 - J_1^a(\sigma\bar{\xi}+\bar{\sigma}\xi),\cdots, \qquad (5.20)\\
&\qquad\qquad x_n - J_n^a(\sigma\bar{\xi}+\bar{\sigma}\xi),\chi,k_2,\cdots,k_{p-1},k_{p+1},\cdots,k_n)d\xi_0 d\xi_1,\\
&\psi_{\hat{a}\hat{b}}(x_0,x,\chi,k_2,\cdots,k_{p-1},k_{p+1},\cdots,k_n)\\
&\quad = \int_{\mathbb{R}^2} G(\xi,\chi)[Q_{\hat{a}\hat{b}}\psi_{\hat{b}\hat{b}}](x_0-2\xi_0, x_1 - J_1^a(\sigma\bar{\xi}+\bar{\sigma}\xi),\cdots, \qquad (5.21)\\
&\qquad\qquad x_n - J_n^a(\sigma\bar{\xi}+\bar{\sigma}\xi),\chi,k_2,\cdots,k_{p-1},k_{p+1},\cdots,k_n)d\xi_0 d\xi_1,\\
&\psi_{\hat{b}\hat{a}}(x_0,x,\chi,k_2,\cdots,k_{p-1},k_{p+1},\cdots,k_n)\\
&\quad = \int_{\mathbb{R}^2} G(\xi,-\chi)[Q_{\hat{b}\hat{a}}\psi_{\hat{a}\hat{a}}](x_0-2\xi_0, x_1 - J_1^a(\sigma\bar{\xi}+\bar{\sigma}\xi),\cdots, \qquad (5.22)\\
&\qquad\qquad x_n - J_n^a(\sigma\bar{\xi}+\bar{\sigma}\xi),\chi,k_2,\cdots,k_{p-1},k_{p+1},\cdots,k_n)d\xi_0 d\xi_1,\\
&\psi_{\hat{b}\hat{b}}(x_0,x,\chi,k_2,\cdots,k_{p-1},k_{p+1},\cdots,k_n)\\
&\quad = 1 + \int_{\mathbb{R}^2} G(\xi,0)[Q_{\hat{b}\hat{a}}\psi_{\hat{a}\hat{b}}](x_0-2\xi_0, x_1 - J_1^a(\sigma\bar{\xi}+\bar{\sigma}\xi),\cdots, \qquad (5.23)\\
&\qquad\qquad x_n - J_n^a(\sigma\bar{\xi}+\bar{\sigma}\xi),\chi,k_2,\cdots,k_{p-1},k_{p+1},\cdots,k_n)d\xi_0 d\xi_1.
\end{aligned}$$

In other words, $\hat{\mu} = \begin{pmatrix} \psi_{\hat{a}\hat{a}} & \psi_{\hat{a}\hat{b}} \\ \psi_{\hat{b}\hat{a}} & \psi_{\hat{b}\hat{b}} \end{pmatrix}$ is the unique solution of (5.15) and (5.16). In particular, ψ_{ab} only depends on (x_0,x,χ).

It remains to show that $\mu_{ab}(x_0,x,\chi,k_2,\cdots,k_n)$ actually converges uniformly on compact subsets of $\mathbb{R}^{n+1}$ for $1 \le a \le N$, $b = \hat{a}$ or $\hat{b}$, and for fixed $(\chi,k_2,\cdots,k_{p-1},k_{p+1},\cdots,k_n)$. Since $\partial^\alpha \mu \in C^b_{N\times N}(\mathbb{R}^{n+1}\times C^n)$ for $|\alpha| \le 1$, the Arzela–Ascoli theorem implies that given any sequence $\kappa_j \to \infty$, $\mu_{ab}(x_0,x,\chi,k_2,\cdots,k_{p-1},\kappa_j,k_{p+1},\cdots,k_n)$ has a subsequence that converges uniformly on compact subsets of $\mathbb{R}^{n+1}$. But we have shown that these limit functions must satisfy (5.19)–(5.23), i.e., they are uniquely determined.

Therefore, $\mu_{ab}(x_0, x, \kappa, k_2, \cdots, k_n)$ converges uniformly on compact subsets of $\mathbb{R}^{n+1}$ as the continuous variable $k_p \to \infty$. □

Let T be the inverse data of Q, and let

$$\hat{T}(\chi, m) = \begin{pmatrix} 0 & \hat{T}_{12}(\chi, m) \\ \hat{T}_{21}(\chi, m) & 0 \end{pmatrix}$$

be the inverse data of $\hat{Q}$. By comparing (5.8) and (5.9) with (2.27), we have by (5.19) the following corollary.

COROLLARY 5.1. (Relation between the inverse data.)

$$\hat{T}_{12}(\chi, m) = \lim_{k_p \to \infty} T_{\hat{a}\hat{b}}(k, m), \tag{5.24}$$

and

$$\hat{T}_{21}(\chi, m) = \lim_{k_p \to \infty} T_{\hat{b}\hat{a}}(k, m), \tag{5.25}$$

where the limit is taken with fixed $(\chi, k_2, \cdots, k_{p-1}, k_{p+1}, \cdots, k_n)$.

The characterization equations in (2.42) can be rewritten as

$$\frac{1}{J_p^a - J_p^b} \frac{\partial T_{ab}}{\partial \bar{k}_p}(k, m) - \frac{1}{J_1^a - J_1^b} \frac{\partial T_{ab}}{\partial \bar{k}_1}(k, m) = N_{1p}^{ab}[T], \qquad 2 \le p \le n, \tag{5.26}$$

where

$$\begin{aligned} &N_{1p}^{ab}[T](k, m) \\ &= \sum_{j=1}^{N} \frac{\gamma^j}{(2\pi)^{n-1}} \int_{\mathbb{R}^{n-1}} \left[\frac{J_p^j - J_p^b}{J_p^a - J_p^b} - \frac{J_1^j - J_1^b}{J_1^a - J_1^b} \right] T_{jb}(k, M) \\ &\qquad \cdot T_{aj}(\lambda^{jb}(k, m), m - M)\, dM. \end{aligned} \tag{5.27}$$

Denote by $\tilde{T}_{ab}$ and $\tilde{N}_{1p}^{ab}[\tilde{T}]$ the functions representing T_{ab} and $N_{1p}^{ab}[T]$ in the $(k_{ab}, k_2, \cdots, k_n, m)$ coordinates. Then (5.26) is equivalent to

$$\begin{aligned} &\frac{\partial \tilde{T}_{ab}}{\partial \bar{k}_p}(k_{ab}, k_2, \cdots, k_n, m) = (J_p^a - J_p^b) \tilde{N}_{1p}^{ab}[\tilde{T}](k_{ab}, k_2, \cdots, k_n, m), \\ &\qquad\qquad 2 \le p \le n. \end{aligned} \tag{5.28}$$

PROPOSITION 5.2. (Equivalent characterization of the inverse data.) *Given any* a *and* b *such that* $1 \le a \ne b \le n$,

$$\begin{aligned} &\tilde{T}_{ab}(k_{ab}, k_2, \cdots, k_n, m) - \frac{1}{\pi} \int_{\mathbb{R}^2} \frac{(J_p^a - J_p^b)}{k_p - k_p'} \\ &\qquad \cdot \tilde{N}_{1p}^{ab}[\tilde{T}](k_{ab}, k_2, \cdots, k_{p-1}, k_p', k_{p+1}, \cdots, k_n, m)\, dk_{p_k}'\, dk_{p_I}' \end{aligned} \tag{5.29}$$

represent the same function $\Phi_{ab}(k_{ab}, m)$ *for* $2 \le p \le n$.

Proof. By the inversion formula for the $\bar{\partial}$ operator and Liouville's theorem, (5.28) is equivalent to

$$\begin{aligned} &\tilde{T}_{ab}(k_{ab}, k_2, \cdots, k_n, m) \\ &= \lim_{k_p \to \infty} \tilde{T}_{ab}(k_{ab}, k_2, \cdots, k_n, m) + \frac{1}{\pi} \int_{\mathbb{R}^2} \frac{(J_p^a - J_p^b)}{k_p - k_p'} \\ &\qquad \cdot \tilde{N}_{1p}^{ab}[T](k_{ab}, k_2, \cdots, k_{p-1}, k_p', k_{p+1}, \cdots, k_n, m)\, dk_{p_k}'\, dk_{p_I}'. \end{aligned} \tag{5.30}$$

Here the limit is taken with $(k_{ab}, k_2, \cdots, k_{p-1}, k_{p+1}, \cdots, k_n, m)$ fixed. Corollary 5.1 implies that $\lim_{k_p \to \infty} \tilde{T}_{ab}(k_{ab}, k_2, \cdots, k_n, m) = \lim_{k_r \to \infty} \tilde{T}_{ab}(k_{ab}, k_2, \cdots, k_n, m)$ for $2 \leq p, r \leq n$. Their common value is the inverse data of the reduced system, and therefore only depends on (k_{ab}, m).

Conversely, if (5.29) holds for $1 \leq a, b \leq N$, then (5.28) and hence the characterization equations (2.42) are obviously satisfied. □

Combining these results we can treat the reconstruction problem by the following procedures. Let $T(k, m)$ be an off-diagonal $N \times N$-matrix-valued function that satisfies conditions (i) and (ii) of Definition 2.3. If condition (5.29) is satisfied, then $T \in D^o_{N \times N}$ and T belongs to the range of $\mathbf{S}$ if it is small enough. Let $1 \leq \hat{a} < \hat{b} \leq N$. Proposition 5.1 and Corollary 5.1 imply that the $\hat{a}\hat{b}$th and $\hat{b}\hat{a}$th component of the potential Q can be reconstructed through (5.6), (5.12), and (5.13) by letting $\hat{T}_{12}(\chi, m) = \Phi_{\hat{a}\hat{b}}(\chi, m)$ and $\hat{T}_{21}(\chi, m) = \Phi_{\hat{b}\hat{a}}(\chi, m)$.

In other words, we can replace condition (iii) of Definition 2.3 by (5.29). If (5.29) is satisfied, we can reconstruct the components of Q two at a time by solving a 2×2 inverse problem, and the inverse data of such 2×2 systems are already computed in the checking of condition (5.29).

THERMOSTAT SYSTEMS HAVING STABLE PERIODIC SOLUTIONS WITH SHORT PERIODS*

GUSTAF GRIPENBERG†

Abstract. The local stability of periodic solutions of a system controlled by a thermostat is studied in the case where the periods are arbitrarily short. If the system is modeled by the equation $y(t) = \int_{-\infty}^{t} a(t-s)u(s)\,ds$ and the kernel a satisfies certain crucial smoothness assumptions, then such solutions exist if (and in most cases only if) $\hat{a}(w) \neq 0$ for $\Re w \geq 0$ and either $a(0) > 0$ or $a(0) = 0$, $a'(0) > 0$, and $a''(0) < 0$.

Key words. thermostat control, short period, stability, hysteresis

1. Introduction and statement of results.

The purpose of this paper is to study the local stability of periodic solutions of the equation

$$y(t) = \int_{-\infty}^{t} a(t-s)u(s)\,ds, \qquad t \in \mathbf{R}, \tag{1}$$

when the period approaches zero. Here $u : \mathbf{R} \to \{0, 1\}$ is determined by the requirement that, if $u(t) = 1$ and y reaches an upper level θ_{high} at time t, then $u(t+) = 0$, and conversely, if $u(t) = 0$ and y reaches a lower level θ_{low} at time t, then $u(t+) = 1$, or, in other words, the system functions like a thermostat. Thus we see that if the period is short, then $\theta_{\text{high}} - \theta_{\text{low}}$ must be small and $y(t)$ must stay close to the interval $[\theta_{\text{low}}, \theta_{\text{high}}]$. This is, of course, the reason why we would want to have a short period.

The main motivation for equation (1) is that it is a reasonable model for a system controlled by a thermostat. For example, consider a situation where a heater is turned on if the temperature at some fixed point drops to a level θ_{low} and is turned off if the temperature rises to a level θ_{high} where we have $\theta_{\text{low}} < \theta_{\text{high}}$. It is convenient to normalize the equation in such a way that without heating the temperature is zero and with uninterrupted heating it is 1. The function a is determined by the requirement that if the heating is turned on at time zero for the first time, then the temperature should be $\int_0^t a(s)\,ds$ at time $t > 0$. Some external influences can also be added to (1).

Models of this kind have earlier been studied in, e.g., [2]–[9] and [13], but in many of these references the state equation is not explicitly written in the form (1). In [4] and [5], the main emphasis is on questions of existence of solutions and on a precise description of the heating process involving diffusion. In [9] this work is continued and some sufficient conditions for the existence of periodic solutions are given. In [3] thermostat control in a diffusion model is considered, and the existence—and in some cases uniqueness—of periodic solutions is established. In [2] the question of how to choose parameters optimally (e.g., θ_{low} and θ_{high}) is considered. In [8] the existence and asymptotic behavior of solutions of a diffusion problem is studied, and in [13] it is shown that there are infinitely many periodic solutions of a heat-control problem where $\theta_{\text{low}} = \theta_{\text{high}}$.

*Received by the editors April 16, 1990; accepted for publication September 6, 1990.

†Department of Mathematics, University of Helsinki, Regeringsgatan 15, 00100 Helsingfors, Finland.

In [1] and [10]–[12] a class of related switching systems is considered. In [1] the state equation is written as $L(y, s) = 0$ where L is a differential operator (for example, the heat operator) with respect to y and s is a switching variable and in [10]–[12] it is of the form $y'(t) = f_j(y(t))$ where the index j, and hence the state equation, is changed when the solution reaches a "switching surface." In [12] sufficient conditions for the existence of periodic solutions for this kind of system are given.

Equation (1) is an example of a system involving hysteresis, but in this paper no results from the general theory of such systems will be used.

In [6] the existence of periodic solutions of equation (1) is established, but there the dependence of u on y is in general a slightly weaker form of thermostat control (although the difference appears only in the case where y has a local maximum equal to θ_{high} or a local minimum equal to θ_{low}). In [7] a criterion for the local stability of these periodic solutions is given, and the present paper is based on these results.

Here we will use the following notion of thermostat control (which could also be formulated in many other equivalent ways).

DEFINITION 1. If $I \subset \mathbf{R}$ is an interval and $y : I \to \mathbf{R}$ is a continuous function, then a function $u : I \to \{0, 1\}$ is (strictly) *thermostat controlled* by y with respect to the higher limit θ_{high} and the lower limit θ_{low} on the interval I provided that u is left-continuous with right-hand limits on I and the following conditions hold for all $t \in I$:

(i) $u(t) = 1$ if $y(t) < \theta_{\text{low}}$,
(ii) $u(t) = 0$ if $y(t) > \theta_{\text{high}}$,
(iii) If $y(t) = \theta_{\text{high}}$ and $u(t) = 1$, then $u(t+) = 0$, and if $u(t) - u(t+) = 1$, then $y(t) = \theta_{\text{high}}$,
(iv) If $y(t) = \theta_{\text{low}}$ and $u(t) = 0$, then $u(t+) = 1$, and if $u(t) - u(t+) = -1$, then $y(t) = \theta_{\text{low}}$.

The question that is asked and (at least to some extent) answered in this paper is the following. When are there arbitrarily small positive numbers T and S such that there exists a locally stable periodic solution (y_*, u_*) of (1) with $u_* = 1$ on intervals of length T, $u_* = 0$ on intervals of length S, and u_* is strictly thermostat controlled by y_* on $\mathbf{R}$ with respect to θ_{high} and θ_{low}.

In order to define what we mean by stability, we consider the equation

$$y(t) = \int_{-\infty}^{t} a(t-s)u(s)\,ds + e(t), \qquad t \geq 0, \tag{2}$$

where u is given on $(-\infty, 0]$ and u is strictly thermostat controlled by y on $(0, \infty)$. To fix the notation we define the sequences $\{v_n(u)\}$ and $\{w_n(u)\}$ by the requirement that

$$u(t) = \begin{cases} 1, & t \in (v_n(u), w_n(u)], \\ 0, & t \in (w_n(u), v_{n+1}(u)], \end{cases} \qquad n \in \mathbf{Z}.$$

No generality is lost by requiring that $v_0(u) = 0$, i.e., $u(0) = 0$ and $u(0+) = 1$. We define the numbers $T_n(u)$ and $S_n(u)$ by

$$T_n(u) = w_n(u) - v_n(u),$$
$$S_n(u) = v_{n+1}(u) - w_n(u),$$

so that u is 1 on intervals of length $T_n(u)$ and zero on intervals of length $S_n(u)$.

DEFINITION 2. If (y_*, u_*) is a periodic solution of (1) on $\mathbf{R}$ with $u_* = 1$ on intervals of length T, $u_* = 0$ on intervals of length S, and u_* is strictly thermostat

controlled by y_* on $\mathbf{R}$ (with respect to θ_{low} and θ_{high}), then (y_*, u_*) is locally stable provided that for each $\epsilon > 0$ there exists $\delta > 0$ such that, if $e \in C(\mathbf{R}^+, \mathbf{R})$, if $u : \mathbf{R} \to \{0, 1\}$ is left-continuous with right-hand limits, $u(0) = 0$, $u(0+) = 1$, and if u is strictly thermostat controlled by the solution y of (2) on $(0, \infty)$, then the inequalities

$$\begin{aligned} &|T_i(u) - T| + |S_i(u) - S| \le \delta, \qquad i < 0, \\ &|e(t)| \le \delta, \qquad t \ge 0, \end{aligned}$$

imply that for every $n \ge 0$,

$$|T_n(u) - T| + |S_n(u) - S| \le \epsilon,$$

and in the case where $\lim_{t\to\infty} e(t) = 0$ it follows that

$$T_n(u) \to T \quad \text{and} \quad S_n(u) \to S \quad \text{as } n \to \infty.$$

In [7] it is shown that the following condition is a sufficient condition for local stability (in fact, a slightly stronger result is obtained): The function

$$\begin{aligned} f(z) \overset{\text{def}}{=} {} & \frac{1}{z}\sum_{j=1}^{\infty} a\big(j(T+S) - S\big)z^j \sum_{j=1}^{\infty} a\big(j(T+S) - T\big)z^j \\ & - \left(\sum_{j=1}^{\infty}\Big(a\big(j(T+S)\big)z^j - a\big(j(T+S)\big) + a\big(j(T+S) - T\big)\Big)\right) \\ & \times \left(\sum_{j=1}^{\infty}\Big(a\big(j(T+S)\big)z^j - a\big(j(T+S)\big) + a\big(j(T+S) - S\big)\Big)\right) \end{aligned} \tag{3}$$

has a simple zero at $z = 1$ and no other zeros in $\{\, z \in \mathbf{C} \mid |z| \le 1 \,\}$.

Therefore, the main part of the paper consists of a detailed analysis of this function f when T and S are close to zero.

Some of the assumptions that we use are unnecessarily strong, but the main weakness in the assumptions is that, kernels a of the form $t^\alpha b(t)$ with $b(0) \ne 0$ and $\alpha > -1$ not equal to an integer they do not include.

THEOREM 3. *Let $\theta_* \in (0, 1)$, let $m \ge 0$ be an integer and assume that*

(i) *$a \in L^1(\mathbf{R}^+; \mathbf{R})$, $\int_0^\infty a(t)\,dt = 1$, $a^{(j)} \in BV(\mathbf{R}^+; \mathbf{R}) \bigcap AC(\mathbf{R}^+; \mathbf{R})$ for $j = 0, \cdots, m$, $a^{(j)}(0) = 0$ for $j = 0, \cdots, m-1$, $a^{(m)}(0) \ne 0$, and $\int_0^\infty t^2 |a'(t)|\,dt < \infty$;*

(ii) *If $m = 0$ or 1, then $a^{(j)} \in BV(\mathbf{R}^+; \mathbf{R}) \bigcap AC(\mathbf{R}^+; \mathbf{R})$ for $j = 0, \cdots, 2m+1$, and $\int_0^\infty t\big|a^{(2m+2)}(t)\big|\,dt < \infty$;*

(iii) *There are positive numbers T and S such that there exists a periodic solution (y_*, u_*) of (1) with $u_* = 1$ on intervals of length T, $u_* = 0$ on intervals of length S, $u_*(0) = 0$, $u_*(0+) = 1$, and u_* is (strictly) thermostat controlled by y_* on $\mathbf{R}$ with respect to θ_{low} and θ_{high}, satisfying $0 < \theta_{\text{low}} < \theta_* < \theta_{\text{high}} < 1$.*

Then the following conclusions hold.

(a) *If $\hat{a}(w) \ne 0$ for $w \in \mathbf{C}$ with $\Re w \ge 0$ and either $m = 0$, or $m = 1$ and $a''(0) < 0$, then there exists a number $\mu > 0$ such that (y_*, u_*) is locally stable provided $T + S < \mu$.*

(b) *If $\hat{a}(w_0) = 0$ for some $w_0 \in \mathbf{C}$ with $\Re w_0 > 0$, or $m = 1$ and $a''(0) > 0$, or $m > 1$, then there exists a number $\mu > 0$ such that (y_*, u_*) is not locally stable provided $T + S < \mu$.*

We see from the proof that in some of the cases where instability is claimed, it is due to the fact that there are no periodic solutions at all, so that the assumptions of the theorem are not satisfied. Note also that if $m = 0$ and $a(0) < 0$, or $m = 1$ and $a'(0) < 0$, then there exists a number $\sigma > 0$ such that $\hat{a}(\sigma) = 0$, but in these cases it is also true that there are no periodic solutions with short periods.

When proving part (b) we have to extend some of the results found in [7]. Therefore we consider the discrete equation

$$\sum_{j=-\infty}^{n} \alpha_{n-j}\xi_j = \Phi_n\left(\{\xi_{n-j}\}_{j=0}^{\infty}\right) + \varphi_n, \qquad n \geq 0; \tag{4}$$

$$\xi_i = \psi_i, \qquad i < 0.$$

The criterion for stability of the linear part of (4) is $\det[\sum_{n=0}^{\infty} z^n\alpha_n] \neq 0$ when $|z| \leq 1$, so it is no surprise that the trivial solution is unstable if there is a zero inside the unit circle. (If there are zeros on the unit circle, then we can at least show as in [7] that a certain stronger kind of stability cannot hold.)

For completeness we state and prove the result that we need concerning (4). Let us denote the set of integers by $\mathbf{Z}$, the set of negative integers by $\mathbf{Z}_-$, and the set of natural numbers, i.e., the nonnegative integers, by $\mathbf{N}$. By $|\cdot|$ we denote some norm in $\mathbf{R}^m$, and also the corresponding matrix norm.

PROPOSITION 4. *Assume that the following conditions hold:*

(i) $\alpha \in l^1(\mathbf{N}; \mathbf{R}^{m\times m})$;

(ii) *For each* $j \geq 0$ *the mapping* $\zeta \in l^\infty(\mathbf{N}; \mathbf{R}^m) \mapsto \Phi_j(\zeta) \in \mathbf{R}^m$ *is continuous and* $\|\Phi(\zeta)\|_{l^\infty(\mathbf{N})} = o\big(\|\zeta\|_{l^\infty(\mathbf{N})}\big)$ *as* $\|\zeta\|_{l^\infty(\mathbf{N})} \to 0$;

(iii) $\varphi \in l^\infty(\mathbf{N}; \mathbf{R}^m)$;

(iv) $\psi \in l^\infty(\mathbf{Z}_-; \mathbf{R}^m)$;

(v) $\det[\sum_{n=0}^{\infty} z_0^n\alpha_n] = 0$ *for some* $z_0 \in \mathbf{C}$ *with* $|z_0| < 1$.

Then there exists a number $\epsilon > 0$ *such that there is no* $\delta > 0$ *for which the inequalities*

$$|\psi_i| \leq \delta, \qquad i < 0, \tag{5}$$
$$|\varphi_n| \leq \delta, \qquad n \geq 0$$

imply that, if ξ *is a solution of* (4), *then*

$$|\xi_n| \leq \epsilon, \qquad n \geq 0. \tag{6}$$

2. Proof of Theorem 3(a). It is a consequence of the assumptions that $\lim_{\sigma\to\infty} \sigma^{m+1}\hat{a}(\sigma) = a^{(m)}(0)$ and $\hat{a}(0) = 1$. Since, moreover, $\hat{a}(\sigma) \neq 0$ when $\sigma \geq 0$, it follows that

$$a^{(m)}(0) > 0. \tag{7}$$

Let us introduce the following abbreviations:

$$\mathcal{T} = T + S,$$
$$q = \frac{T}{T+S},$$
$$t_j(q) = (j - q)(T + S).$$

Because $\int_0^\infty a(t)\,dt = 1$ it follows from (iii) that $\lim_{\mathcal{T}\downarrow 0}\bigl(\int_{-\infty}^t a(t-s)u_*(s)\,ds - q\bigr) = 0$, uniformly for $t \in \mathbf{R}$. Hence q is close to θ_* when $\mathcal{T}$ is small, and this guarantees that q and $1-q$ remain bounded away from zero and 1. We may assume that $u_*(0) = 0$ and $u_*(0+) = 1$.

It follows from the results in [7] that, if we want to show that the periodic solution is stable, then we have to prove that (3) holds. Let $\mathcal{D} = \{\, z \in \mathbf{C} \mid |z| \le 1 \,\}$. First we consider the case where

$$z \in \mathcal{D}_{\mathcal{T}} \stackrel{\text{def}}{=} \{\, z \in \mathcal{D} \mid |z-1| \le \gamma(\mathcal{T}) \,\},$$

where $\gamma : \mathbf{R}^+ \to [0, \frac{1}{2}]$ is some continuous function with $\gamma(0) = 0$ that will be fixed later. Define

$$w = -\frac{\log(z)}{\mathcal{T}} \quad \text{and} \quad \mathcal{H}_{\mathcal{T}} = \{\, w \in \mathbf{C} \mid \exp(-\mathcal{T}w) \in \mathcal{D}_{\mathcal{T}} \,\}.$$

We let

$$A(t,w) = a(t)\mathrm{e}^{-wt}, \qquad t \ge 0, \quad \Re w \ge 0,$$

and by $A'(t,w)$ we denote the derivative with respect to t.

Using an integration by parts we get the following result for $p \in [0,1)$:

$$\begin{aligned} z^{-p}\sum_{j=1}^{\infty} a\bigl(t_j(p)\bigr)z^j &= \sum_{j=1}^{\infty} a\bigl(t_j(p)\bigr)\mathrm{e}^{-t_j(p)w} \\ &= \frac{1}{\mathcal{T}}\hat{a}(w) + \frac{1}{\mathcal{T}}\sum_{j=1}^{\infty}\int_{t_{j-1}(0)}^{t_j(0)} \Bigl(a\bigl(t_j(p)\bigr)\,\mathrm{e}^{-t_j(p)w} - a(s)\,\mathrm{e}^{-sw}\Bigr)\,ds \\ &= \frac{1}{\mathcal{T}}\hat{a}(w) + \sum_{j=1}^{\infty} z^{j-1}\int_{t_{j-1}(0)}^{t_j(0)} h_0\Bigl(\frac{s-t_{j-1}(0)}{\mathcal{T}}, p\Bigr)A'(s,w)\,ds, \end{aligned} \tag{8}$$

where h_0 is defined by

$$h_0(t,p) = t - \chi_{[1-p,1]}(t), \qquad t \in [0,1], \quad p \in [0,1]. \tag{9}$$

For $k \ge 0$ we let

$$\begin{aligned} c_k(p) &= \int_0^1 h_k(s,p)\,ds, \\ h_{k+1}(t,p) &= -\int_0^t \bigl(h_k(s,p) - c_k(p)\bigr)\,ds, \end{aligned} \tag{10}$$

and then we define

$$R_k(p,\mathcal{T}) = \sum_{j=1}^{\infty}\int_{t_{j-1}(0)}^{t_j(0)} h_k\Bigl(\frac{s-t_{j-1}(0)}{\mathcal{T}}, p\Bigr)A^{(k+1)}(s,w)\,ds. \tag{11}$$

Provided $a^{(j)}$ is integrable for $0 \le j \le k+2$ we get from an integration by parts that

$$R_k(p,z,\mathcal{T}) = -c_k(p)A^{(k)}(0,w) + \mathcal{T}R_{k+1}(p,z,\mathcal{T}). \tag{12}$$

By (8) we therefore have

$$z^{-p}\sum_{j=1}^{\infty} a\big(t_j(p)\big)z^j = \frac{1}{\mathcal{T}}\hat{a}(w) - \sum_{k=0}^{n} c_k(p)A^{(k)}(0,w)\mathcal{T}^k + \mathcal{T}^{n+1}R_{n+1}(p,z,\mathcal{T}), \tag{13}$$

where $n = m-1$ if $m > 1$ and $n = 2m$ if $m = 0$ or 1.

Using an approximation argument we conclude that

$$R_k(p,z,\mathcal{T}) \to -c_k(p)A^{(k)}(0,w) \text{ as } \mathcal{T} \downarrow 0 \text{ uniformly for } w \in \mathcal{H}_{\mathcal{T}} \text{ and } p \in [0,1], \tag{14}$$

for $0 \le k \le m$ if $m > 1$, and $0 \le k \le 2m+1$ otherwise. Since $\mathcal{T}w/(z-1) \to -1$ as $\mathcal{T} \downarrow 0$ we see from a similar argument that when $m = 0$ or 1, and $k = 0, \cdots, 2m+1$,

$$\frac{\mathcal{T}}{z-1}\big(R_k(p,z,\mathcal{T}) - R_k(p,1,\mathcal{T})\big) \to c_k(p)\frac{1}{w}\big(A^{(k)}(0,w) - A^{(k)}(0,0)\big) \tag{15}$$
$$\text{as } \mathcal{T} \downarrow 0 \text{ uniformly for } w \in \mathcal{H}_{\mathcal{T}} \text{ and } p \in [0,1].$$

Note that the moment assumption in (ii) is needed for the case $k = 2m+1$ and once this is established the remaining cases follow from (12).

It is an immediate consequence of definitions (9) and (10) that

$$h_{k+1}(t,p) = \frac{(-1)^{k+1}}{k!}\int_0^t (t-s)^k h_0(s,p)\,ds - \sum_{j=0}^{k} c_j(p)\frac{(-t)^{k-j+1}}{(k-j+1)!},$$

and since $h_{k+1}(1,p) = 0$ by the definition of $c_k(p)$, we get

$$\sum_{j=0}^{k} c_j(p)\frac{(-1)^{k-j+1}}{(k-j+1)!} = \frac{(-1)^{k+1}}{(k+2)!} - \frac{(-p)^{k+1}}{(k+1)!}. \tag{16}$$

From this equation it is easy to solve the coefficients $c_j(p)$ recursively.

It follows from (3), (11), and (13) that

$$\begin{aligned} f(z) &= \Big[\frac{\hat{a}(w)}{\mathcal{T}} + R_0(q,z,\mathcal{T})\Big]\Big[\frac{\hat{a}(w)}{\mathcal{T}} + R_0(1-q,z,\mathcal{T})\Big] \\ &\quad - \Big[\frac{\hat{a}(w)}{\mathcal{T}} + \Big(R_0(0,z,\mathcal{T}) - R_0(0,1,\mathcal{T}) + R_0(q,1,\mathcal{T})\Big)\Big] \\ &\quad \times \Big[\frac{\hat{a}(w)}{\mathcal{T}} + \Big(R_0(0,z,\mathcal{T}) - R_0(0,1,\mathcal{T}) + R_0(1-q,1,\mathcal{T})\Big)\Big] \\ &= \frac{\hat{a}(w)}{\mathcal{T}}D(q,z,\mathcal{T}) + E(q,z,\mathcal{T}) + F(q,z,\mathcal{T}), \end{aligned} \tag{17}$$

where

$$\begin{aligned} D(q,z,\mathcal{T}) &\overset{\text{def}}{=} R_0(q,z,\mathcal{T}) + R_0(1-q,z,\mathcal{T}) - 2R_0(0,z,\mathcal{T}) \\ &\quad - R_0(q,1,\mathcal{T}) - R_0(1-q,1,\mathcal{T}) + 2R_0(0,1,\mathcal{T}), \\ E(q,z,\mathcal{T}) &\overset{\text{def}}{=} \big(R_0(q,z,\mathcal{T}) - R_0(q,1,\mathcal{T})\big)R_0(1-q,z,\mathcal{T}) \\ &\quad + \big(R_0(1-q,z,\mathcal{T}) - R_0(1-q,1,\mathcal{T})\big)R_0(q,1,\mathcal{T}), \end{aligned}$$

and

$$F(q,z,\mathcal{T}) \stackrel{\text{def}}{=} \Big(R_0(0,z,\mathcal{T}) - R_0(0,1,\mathcal{T})\Big)^2 - \Big(R_0(0,z,\mathcal{T}) - R_0(0,1,\mathcal{T})\Big)\Big(R_0(q,1,\mathcal{T}) + R_0(1-q,1,\mathcal{T})\Big).$$

Assume first that $m = 0$. If $z \in \mathcal{D}_{\mathcal{T}}$, then $w\mathcal{T} \to 0$ as $\mathcal{T} \to 0$. On the other hand, we know that $w\hat{a}(w) \to a(0)$ as $|w| \to \infty$ with $\Re w \geq 0$. Therefore it follows from the fact that $\hat{a}(w) \neq 0$ for $\Re w \geq 0$ that

$$\inf_{w \in \mathcal{H}_{\mathcal{T}}} \left| \frac{\hat{a}(w)}{\mathcal{T}} \right| \to \infty \quad \text{as } \mathcal{T} \downarrow 0. \tag{18}$$

From (12), (15), and (16) we get

$$\begin{aligned} \frac{D(q,z,\mathcal{T})}{z-1} &\to \big(c_1(q) + c_1(1-q) - 2c_1(0)\big)\frac{1}{w}\big(A'(0,w) - A'(0,0)\big) \\ &= a(0)q(1-q) \quad \text{as } \mathcal{T} \downarrow 0 \text{ uniformly for } w \in \mathcal{H}_{\mathcal{T}} \text{ and } p \in [0,1]. \end{aligned} \tag{19}$$

Because $A(0,w) = a(0)$ we get from (12) that

$$R_0(p,z,\mathcal{T}) - R_0(p,1,\mathcal{T}) = \mathcal{T}\big(R_1(p,z,\mathcal{T}) - R_1(p,1,\mathcal{T})\big). \tag{20}$$

Therefore it follows from (14) and (15) that

$$\frac{E(q,z,\mathcal{T})}{z-1} = O(1) \quad \text{as } \mathcal{T} \downarrow 0 \text{ uniformly for } w \in \mathcal{H}_{\mathcal{T}}. \tag{21}$$

Moreover, since $c_0(p) = \frac{1}{2} - p$, we see from (12) that

$$R_0(q,1,\mathcal{T}) + R_0(1-q,1,\mathcal{T}) = \mathcal{T}\big(R_1(q,1,\mathcal{T}) + R_1(1-q,1,\mathcal{T})\big), \tag{22}$$

and hence we conclude from (14), (15), and (20) that

$$\frac{F(q,z,\mathcal{T})}{z-1} = O(\mathcal{T}) \quad \text{as } \mathcal{T} \downarrow 0 \text{ uniformly for } w \in \mathcal{H}_{\mathcal{T}}.$$

Combining this result with (19) and (21) we get from (17) and (18) that

$$\frac{f(z)}{z-1} = \big(1 + o(1)\big)\frac{\hat{a}(w)}{\mathcal{T}} \quad \text{as } \mathcal{T} \downarrow 0, \quad w \in \mathcal{H}_{\mathcal{T}}. \tag{23}$$

Thus we see that if $m = 0$ then $f(z)/(z-1)$ has no zeros in a neighborhood of the point 1.

Next we consider the case where $m = 1$. By using the fact that now $a(0) = 0$ and $c_2(q) + c_2(1-q) - 2c_2(0) = 0$ we get from an argument similar to the one used above that

$$\begin{aligned} \frac{D(q,z,\mathcal{T})}{z-1} &\to \mathcal{T}^2\Big(c_3(q) + c_3(1-q) - 2c_3(0)\Big)\frac{1}{w}\Big(A^{(3)}(0,w) - A^{(3)}(0,0)\Big) \\ &= \mathcal{T}^2\big(-a''(0) + wa'(0)\big)\frac{q^2(1-q)^2}{4} \\ &\qquad \text{as } \mathcal{T} \downarrow 0 \text{ uniformly for } w \in \mathcal{H}_{\mathcal{T}} \text{ and } p \in [0,1]. \end{aligned}$$

Since $a(0) = 0$ we get instead of (20) that

$$R_0(p,z,\mathcal{T}) - R_0(p,1,\mathcal{T}) = \mathcal{T}^2\big(R_2(p,z,\mathcal{T}) - R_2(p,1,\mathcal{T})\big), \tag{24}$$

and also that $R_0(p,z,\mathcal{T}) = \mathcal{T}R_1(p,z,\mathcal{T})$. This implies that

$$\frac{E(q,z,\mathcal{T})}{z-1} = O(\mathcal{T}^2) \quad \text{as } \mathcal{T} \downarrow 0 \text{ uniformly for } w \in \mathcal{H}_{\mathcal{T}}.$$

From (14), (22), and (24) it also follows that

$$\frac{F(q,z,\mathcal{T})}{z-1} = O(\mathcal{T}^2) \quad \text{as } \mathcal{T} \downarrow 0 \text{ uniformly for } w \in \mathcal{H}_{\mathcal{T}}.$$

Now we know that $w^2\hat{a}(w) \to a'(0)$ as $|w| \to \infty$ with $\Re w \geq 0$ and that $-a''(0) + wa'(0) \neq 0$ when $\Re w \geq 0$. Therefore we have by an argument similar to the one used in deriving (18) that

$$\inf_{w \in \mathcal{H}_{\mathcal{T}}} \left| \frac{\hat{a}(w)}{\mathcal{T}}\big(-a''(0) + wa'(0)\big) \right| \to \infty \quad \text{as } \mathcal{T} \downarrow 0.$$

Thus we see that

$$\frac{f(z)}{z-1} = \big(1 + o(1)\big)\frac{\mathcal{T}}{4}\hat{a}(w)\big(-a''(0) + wa'(0)\big) \quad \text{as } \mathcal{T} \downarrow 0 \text{ and } w \in \mathcal{H}_{\mathcal{T}}. \tag{25}$$

This completes the proof in the case $m = 1$ as well.

Next we consider the case where z does not lie in a neighborhood of 1 in the unit disk. Define the function b by

$$b(t) = \begin{cases} a\Big(\frac{t\mathcal{T}}{2\pi}\Big)\mathrm{e}^{t\log(z)/(2\pi)}, & t \geq 0, \\ 0, & t < 0 \end{cases}$$

and let

$$B(t) = \sum_{k=-\infty}^{\infty} b(t + 2k\pi), \qquad t \in [0, 2\pi].$$

It follows from our assumptions that B is of bounded variation and therefore we have (note that all sums $\sum_{n=-\infty}^{\infty}$ are to be interpreted as $\lim_{N\to\infty}\sum_{n=-N}^{N}$)

$$\frac{1}{2}\big(B(t-) + B(t+)\big) = \sum_{n=-\infty}^{\infty} \mathrm{e}^{int}\tilde{B}(n), \tag{26}$$

where the Fourier coefficients $\tilde{B}(n)$ are given by

$$\tilde{B}(n) = \frac{1}{2\pi}\int_0^{2\pi} \mathrm{e}^{-int} \sum_{k=-\infty}^{\infty} b(t + 2k\pi)\,dt = \frac{1}{2\pi}\int_0^{\infty} \mathrm{e}^{-int}b(t)\,dt. \tag{27}$$

Choosing $t = 2\pi(1-p)$ in (26) we get (assuming for the moment that $p \in (0,1)$)

$$\begin{aligned} B(t) &= \sum_{k=0}^{\infty} a\big((1-p)\mathcal{T} + k\mathcal{T}\big)z^k z^{1-p} \\ &= z^{-p}\sum_{j=1}^{\infty} a\big(t_j(p)\big)z^j = \sum_{n=-\infty}^{\infty} \mathrm{e}^{\mathrm{i}2n\pi(1-p)}\tilde{B}(n). \end{aligned} \tag{28}$$

Invoking the definition of b and performing a change of variables we conclude from (27) that the Fourier coefficients $\tilde{B}(n)$ are given by

$$\begin{aligned}\tilde{B}(n) =&\frac{1}{2\pi}\int_0^\infty \mathrm{e}^{-\mathrm{i}nt}a\Big(\frac{t\mathcal{T}}{2\pi}\Big)\mathrm{e}^{t\log(z)/(2\pi)}\,dt\\ =&\frac{1}{\mathcal{T}}\int_0^\infty \mathrm{e}^{-t(\mathrm{i}2n\pi-\log(z))/\mathcal{T}}a(t)\,dt=\frac{1}{\mathcal{T}}\hat{a}\Big(\frac{\mathrm{i}2n\pi-\log(z)}{\mathcal{T}}\Big).\end{aligned}\tag{29}$$

Since we assume that $a^{(j)}\in BV(\mathbf{R}^+;\mathbf{R})$ for $j=0,\cdots,m$, we get

$$\hat{a}(w)=\frac{\widehat{a^{(m+1)}}(w)}{w^{m+1}}+\sum_{j=0}^{m}\frac{a^{(j)}(0)}{w^{j+1}}.\tag{30}$$

Let

$$H_j(w,p)=\frac{\mathrm{d}^j}{\mathrm{d}w^j}\frac{\mathrm{e}^{w(1-p)}}{1-\mathrm{e}^w},\qquad j\geq 0,\quad p\in[0,1].\tag{31}$$

For $p\in(0,1)$ we have

$$H_j(w,p)=j!\sum_{n=-\infty}^{\infty}\frac{\mathrm{e}^{\mathrm{i}2n\pi(1-p)}}{(\mathrm{i}2n\pi-w)^{j+1}}.$$

Because $a^{(m)}\in AC(\mathbf{R}^+;\mathbf{R})$ we see from the Riemann–Lebesgue lemma that we have $\widehat{a^{(m+1)}}(w)\to 0$ as $|w|\to\infty$ with $\Re w\geq 0$. Therefore, from (28)–(30) and the assumptions that $a^{(j)}(0)=0$ for $j=0,\cdots,m-1$ (and $a'\in BV(\mathbf{R}^+;\mathbf{R})$ when $m=0$), it follows that there exists a continuous function γ with $\gamma(0)=0$ such that

$$\begin{aligned}\sum_{j=1}^{\infty}a\big(t_j(p)\big)z^j=z^p a^{(m)}(0)H_m(\log(z),p)\frac{\mathcal{T}^m}{m!}+o\big(\mathcal{T}^m\big)\\ \text{as } \mathcal{T}\downarrow 0 \text{ and } |z|\leq 1,\quad |z-1|\geq\gamma(\mathcal{T}).\end{aligned}\tag{32}$$

It is easy to check that this formula holds in the case $p=0$ as well. (The function B may have a discontinuity at zero, but the expression for $H_0(w,0)$ is modified in a corresponding way.)

Now let us consider the stability condition (3). In order to simplify the notation we define

$$d_k(p)=k!\big(c_k(0,1)-c_k(p,1)\big),\qquad k\geq 0,\quad p\in[0,1].\tag{33}$$

If we use (13), (14), and (32), then we see that the stability condition (3) becomes

$$f(z)=a^{(m)}(0)^2P_m(z,q)\mathcal{T}^{2m}+o\big(\mathcal{T}^{2m}\big)\neq 0,\tag{34}$$

where

$$\begin{aligned}P_m(z,q)=&H_m(\log(z),q)H_m(\log(z),1-q)\\ &-\big(H_m(\log(z),0)+d_m(q)\big)\big(H_m(\log(z),0)+d_m(1-q)\big).\end{aligned}\tag{35}$$

A simple calculation shows that

$$P_0(z,q) = -q(1-q) \quad \text{and} \quad P_1(z,q) = -\tfrac{1}{4}q^2(1-q)^2.$$

We conclude from (34) that, if $m = 0$ or 1 and if $\mathcal{T}$ is sufficiently small, then $f(z) \neq 0$ when $z \in \mathcal{D} \setminus \mathcal{D}_{\mathcal{T}}$.

Now the conclusion of part (a) follows from the results in [7] once we have proved that $y_*'(0-) < 0$ and $y_*'(T-) > 0$. Clearly, $y_*'(0-) = \sum_{j=1}^{\infty}\big(a(t_j(0) - a(t_j(q))\big)$ and $y_*'(T-) = \sum_{j=1}^{\infty}\big(a(t_j(1-q) - a(t_j(0))\big)$. Thus we see that it suffices to show that

$$\sum_{j=1}^{\infty}\big(a(t_j(0) - a(t_j(p))\big) < 0, \qquad p = q, \quad 1-q. \tag{36}$$

By (13) and (14) we have

$$\operatorname{sign}\left(\sum_{j=1}^{\infty}\big(a(t_j(0) - a(t_j(p))\big)\right) = -\operatorname{sign}\big(a^{(m)}(0)\big)\operatorname{sign}\big(d_m(p)\big) \tag{37}$$

for sufficiently small $\mathcal{T}$. Because $d_0(p) = p$ and $d_1(p) = p(1-p)/2$ we see that (36) follows from (7) and the proof is completed.

3. Proof of Theorem 3(b). We use the same notation as in the proof of part (a). First we prove that if $\mathcal{T}$ is sufficiently small, then either there exists a complex number z_0 with $|z_0| < 1$ such that $f(z_0) = 0$ or there is no periodic solution (y_*, u_*) such that u_* is thermostat controlled by y_*.

When $m = 0$ or 1 there exists a complex number w_0 with $\Re w_0 > 0$ such that $\hat{a}(w_0) = 0$ if $m = 0$ and such that $\hat{a}(w_0)(-a''(0) + w_0 a'(0)) = 0$ if $m = 1$. In the argument above it was assumed that $\hat{a}(w) \neq 0$ or $\hat{a}(w)(-a''(0) + wa'(0)) \neq 0$ when $\Re w \geq 0$, but it is easy to see that (23) or (25) holds if w is restricted to some compact set in the right half plane on which this expression does not vanish. Hence we can invoke the argument principle to show that the desired point z_0 exists.

Let $m > 1$. First we formulate some results on the coefficients $d_k(p)$ defined in (33).

LEMMA 5. *For each integer $k \geq 1$ and each $p \in (0,1)$,*

$$\begin{aligned}
&d_{2k}(p) = -d_{2k}(1-p),\\
&d_{2k-1}(p) = d_{2k-1}(1-p),\\
&d_{2k}(p)d_{2k}(1-p) < 0, \qquad p \neq \tfrac{1}{2},\\
&d_{4k-1}(p) < 0,\\
&d_{4k+1}(p) > 0.
\end{aligned}$$

Proof. It is a consequence of (16) and the definition of $d_j(p)$ that

$$\sum_{j=0}^{\infty} d_j(p)\frac{s^j}{j!} = \frac{1 - \mathrm{e}^{-ps}}{1 - \mathrm{e}^{-s}} \stackrel{\text{def}}{=} \varphi(p,s).$$

The first two claims follow from the fact that

$$\varphi(1-p,s) = 1 - \varphi(p,-s).$$

It is easy to see that the functions $d_k(p)$ can be expressed with the aid of Bernoulli polynomials in the following way:

$$d_k(p) = \frac{(-1)^k}{k+1}\big(B_{k+1}(p) - B_{k+1}(0)\big), \qquad k \geq 0.$$

Since the Bernoulli polynomials satisfy $B_n'(p) = nB_{n-1}(p)$, $\int_0^1 B_n(p)\,dp = 0$, and $B_1(p) = p - \frac{1}{2}$ we can use an induction argument to prove that for all $k \geq 1$ and all $p \in (0,1)$ we have

$$\begin{aligned}
&d_k(0) = d_k(1) = 0,\\
&d_{4k-3}(p) > 0,\\
&\big(p - \tfrac{1}{2}\big)d_{4k-2}(p) < 0, \qquad p \neq \tfrac{1}{2},\\
&d_{4k-1}(p) < 0,\\
&\big(p - \tfrac{1}{2}\big)d_{4k}(p) > 0, \qquad p \neq \tfrac{1}{2}.
\end{aligned}$$

This gives the last three claims and the proof of Lemma 5 is complete.

It follows from the argument principle and (34) that, if there exists a point z_1 such that $|z_1| < 1$ and $P_m(z_1, q) = 0$, then there exists, at least when $\mathcal{T}$ is sufficiently small, a point z_0 with $|z_0| < 1$ such that $f(z_0) = 0$.

In the case where m is an even positive number and $q \neq \frac{1}{2}$, it follows from Lemma 5, that $d_m(q)$ and $d_m(1-q)$ have opposite signs. This implies, in view of (37) that, for sufficiently small $\mathcal{T}$ there cannot be any periodic solutions satisfying the conditions of thermostat control, and hence no locally stable ones either. If, on the other hand, $q = \frac{1}{2}$, then we use the fact that by Lemma 5 we have $d_m(\frac{1}{2}) = 0$ and therefore $P_m(0, \frac{1}{2}) = 0$. It follows that there exists a zero of f in the interior of the unit disc when $\mathcal{T}$ is sufficiently small.

In order to treat the remaining cases where $m > 1$ is odd, we note that, because

$$\frac{\mathrm{e}^{-(1-p)w}}{1 - \mathrm{e}^{-w}} = -\frac{\mathrm{e}^{pw}}{1 - \mathrm{e}^{w}},$$

it follows that

$$H_m(-w, p) = (-1)^{m+1} H_m(w, 1-p).$$

When we combine this result with Lemma 5 we get, since $H_m(w,0) = H_m(w,1)$ when $m > 0$, that

$$P_m(z, q) = P_m\Big(\frac{1}{z}, q\Big). \tag{38}$$

Next we observe that by (31)

$$H_k(w,q) = \frac{\mathrm{d}^k}{\mathrm{d}w^k}\Big(\mathrm{e}^{-qw}\frac{\mathrm{e}^w}{1-\mathrm{e}^w}\Big) \quad \text{and} \quad H_k(w,1-q) = \frac{\mathrm{d}^k}{\mathrm{d}w^k}\Big(\mathrm{e}^{qw}\Big(\frac{\mathrm{e}^w}{1-\mathrm{e}^w} + 1\Big)\Big).$$

Moreover,

$$\frac{\mathrm{d}^k}{\mathrm{d}w^k}\frac{\mathrm{e}^w}{1-\mathrm{e}^w} = g_k\Big(\frac{\mathrm{e}^w}{1-\mathrm{e}^w}\Big),$$

where the functions g_j are defined by $g_0(u) = u$ and $g_{j+1}(u) = g_j'(u)(u^2+u)$. Thus we see from (35) that

$$P_m(z,q) = \left[\sum_{j=0}^{m}\binom{m}{j}(-q)^j g_{m-j}\Big(\frac{z}{1-z}\Big)\right]\left[q^m + \sum_{j=0}^{m}\binom{m}{j}q^j g_{m-j}\Big(\frac{z}{1-z}\Big)\right] - \Big[g_m\Big(\frac{z}{1-z}\Big) + d_m(q)\Big]\Big[g_m\Big(\frac{z}{1-z}\Big) + d_m(1-q)\Big]. \tag{39}$$

By induction we easily prove that

$$g_j(u) = u + (2^j - 1)u^2 + \cdots.$$

Therefore we conclude from (39) that when m is odd

(40)

$$\begin{aligned} P_m(z,q) = &-\Big[d_m(q)^2 + \Big(2d_m(q) - q^m(1-q)^m\Big)\frac{z}{1-z} \\ &+ \Big(2(2^m-1)d_m(q) + 1 - q^m(2-q)^m + q^m(1-q)^m \\ &-(1-q^2)^m\Big)\Big(\frac{z}{1-z}\Big)^2 + \cdots + c_n\Big(\frac{z}{1-z}\Big)^n\Big] \\ = &-\frac{1}{(1-z)^n}\Big[d_m(q)^2 - \Big(nd_m(q)^2 + q^m(1-q)^m - 2d_m(q)\Big)z \\ &+ \Big(\frac{n(n-1)}{2}d_m(q)^2 + (n-1)\big(q^m(1-q)^m - 2d_m(q)\big) + 2(2^m-1)d_m(q) \\ &+ 1 - q^m(2-q)^m + q^m(1-q)^m - (1-q^2)^m\Big)z^2 + \cdots\Big]. \end{aligned}$$

It is clear that $n \le 2m+1$ since the degree of g_j is $j+1$ and at least the terms of degree $2m+2$ cancel. By (38) we know that if there is no zero of $P_m(z)$ inside the unit circle, then all the zeros are on the unit circle. If $p(z)$ is a polynomial of degree n with real coefficients such that all zeros of p are on the unit circle, then $p(z) = a_0 + a_1 z + a_2 z^2 + \cdots$ where $|a_1/a_0| \le n$ and $|a_2/a_0| \le n(n-1)/2$. Applying these observations to $P_m(z,q)$ we conclude from (40) that unless it has a zero inside the unit circle, we must have

$$\begin{aligned} &n + \frac{q^m(1-q)^m}{d_m(q)^2} - \frac{2}{d_m(q)} \le n, \\ &\frac{n(n-1)}{2} + (n-1)\frac{q^m(1-q)^m}{d_m(q)^2} - (n-1)\frac{2}{d_m(q)} \\ &\quad + \frac{2(2^m-1)}{d_m(q)} - \frac{q^m(2-q)^m - q^m(1-q)^m + (1-q^2)^m - 1}{d_m(q)^2} \le \frac{n(n-1)}{2}. \end{aligned}$$

If $m = 4k-1$, then it follows from Lemma 5 that $d_m(q) < 0$ and the first inequality above gives a contradiction. Hence we assume that $m = 4k+1$ so that $d_m(q) > 0$. The second inequality above implies that

$$d_m(q) \le \frac{q^m(2-q)^m - nq^m(1-q)^m + (1-q^2)^m - 1}{2(2^m - n)}. \tag{41}$$

A straightforward calculation shows that $q^3(2-q)^3 + (1-q^2)^3 < 1$ when $q \in (0,1)$, and since $q(2-q) \leq 1$ and $1-q^2 \leq 1$ it follows that $q^m(2-q)^m + (1-q^2)^m < 1$ for $m \geq 3$. But then it follows from (41) that $d_m(q) < 0$ and we have a contradiction. This completes the proof of the fact that, if $m > 1$ is odd, then there exists a point z_1 with $|z_1| < 1$ such that $P_m(z_1, q) = 0$.

Now we know that if there exists a periodic solution, then there exists a complex number z_0 with $|z_0| < 1$ such that $f(z_0) = 0$. To complete the proof we use the same argument as in [7] to show that the problem can be reduced to an equation of the type (4) with $f(z)/(1-z) = \sum_{n=0}^{\infty} z^n \alpha_n$, and then we invoke Proposition 4. Note that what is needed for the reduction to (4) is not necessarily that $y_*'(0-) < 0$ and $y_*'(T-) > 0$ but that u_* is strictly thermostat controlled by y_* and that each switching time depends continuously on the data. If this last condition is not satisfied, then the periodic solution is clearly not locally stable.

4. Proof of Proposition 4. We use the following notation: if $n \in \mathbf{Z}$ and if $\{\zeta_j\}$ is a sequence of elements in $\mathbf{R}^m$ defined at least for all indices $j \leq n$, then the sequence $H_n\zeta : \mathbf{N} \to \mathbf{R}^m$ is defined by $(H_n\zeta)_j = \zeta_{n-j}$, i.e., $H_n\zeta$ consists of the part of ζ "before" n.

Let us first assume that $\det[\alpha_0] \neq 0$. The resolvent kernel ρ associated with α is defined to be the solution of the equation

$$\sum_{j=0}^{n} \alpha_{n-j}\rho_j = \sum_{j=0}^{n} \rho_{n-j}\alpha_j = \delta_{0n}, \qquad n \geq 0.$$

(Here $\delta_{ij} = I$ if $i = j$ and zero otherwise.)

Since there exists a complex number z_0 such that $|z_0| < 1$, $\det[\sum_{n=0}^{\infty} z_0^n \alpha_n] = 0$, and $\det[\alpha_0] \neq 0$, we may assume that there exists real numbers $0 < r_0 < r_1 < 1$ so that

$$\left[\sum_{n=0}^{\infty} z^n \alpha_n\right]^{-1} = \sum_{l=1}^{L} \sum_{k=0}^{p_l-1} \left(\frac{1}{2} \frac{1}{(z_l - z)^{k+1}} A_{l,k} + \frac{1}{2} \frac{1}{(\overline{z_l} - z)^{k+1}} \overline{A_{l,k}} \right) + F(z), \tag{42}$$

where $L \geq 1$, $p_l \geq 1$, $|z_l| = r_0$, $l = 1, \cdots, L$, and F is (a matrix of functions) analytic in $\{ z \in \mathbf{C} \mid |z| \leq r_1 \}$.

It follows from (42) that the resolvent ρ can be expressed in the form

$$\rho_n = u_n + \varrho_n, \qquad n \geq 0, \tag{43}$$

where

$$u_n = \Re \left[\sum_{l=1}^{L} \sum_{k=0}^{p_l-1} \binom{n+k}{k} z_l^{-(n+k+1)} A_{l,k} \right]$$

and

$$\sum_{n=0}^{\infty} r_1^n |\varrho_n| \leq c_\varrho < \infty.$$

(Observe that here $\Re M$ is the matrix with each element equal to the real part of the corresponding element in M.)

Let $P = \max\{ p_l \mid l = 1, \cdots, L \}$ and define

$$b_n = \sum_{k=0}^{P-1} \left| \binom{k-n}{k} \right| r_0^{-(k+1)} \left(\frac{r_0}{r_1} \right)^n, \qquad n \geq 0.$$

We choose numbers B_∞ and B_1 such that

$$B_\infty \geq r_0^P \sup_{n\geq 0} b_n, \qquad B_1 \geq \sum_{n=1}^{\infty} b_n.$$

We shall later use the fact that B_∞ and B_1 can be chosen independently of r_0 when r_0 is close to zero.

We take the constant c_A to be such that

$$|A_{l,k}| \leq c_A.$$

We may, without loss of generality, assume that $p_1 = P$. It is easy to see that there exists a vector $v \in \mathbf{R}^m$ with $|v| = 1$ and a number $\gamma > 0$ such that

$$\left| \Re \left[\sum_{k=0}^{P-1} z_1^{-(k+1)} A_{1,k} v \right] \right| \geq r_0^{-P} \gamma B_\infty c_A. \tag{44}$$

Let $\Gamma = (2+\gamma)/\gamma$ and let ϵ be a positive number such that if $\|\zeta\|_{l^\infty(\mathbf{N})} \leq \Gamma\epsilon$, then

$$\|\Phi(\zeta)\|_{l^\infty(\mathbf{N})} \leq \|\zeta\|_{l^\infty(\mathbf{N})} \frac{1}{2\Gamma} \min\left\{ \frac{1}{c_\varrho}, \frac{1}{Lc_A B_1} \right\}. \tag{45}$$

If the conclusion of Proposition 4 does not hold, then there exists a number δ such that (5) implies (6). Pick a positive integer N such that

$$r_1^{N+1} \leq \frac{\delta}{\Gamma\epsilon}. \tag{46}$$

Define the set Ω by

$$\begin{aligned} \Omega = &\left\{ \{\vartheta_n\}_{n=0}^N \;\middle|\; \vartheta_n \in \mathbf{R}^m, \quad |\vartheta_n| \leq \Gamma\epsilon r_1^{N-n}, \quad 0 \leq n \leq N \right\} \\ &\times \left\{ \{\theta_n\}_{n=0}^N \;\middle|\; \theta_n \in \mathbf{R}^m, \quad |\theta_n| \leq \frac{\epsilon r_1^{N-n}}{Lc_A B_1}, \quad 0 \leq n \leq N \right\}. \end{aligned}$$

Next we consider a mapping $(\vartheta, \theta) \in \Omega \mapsto (G(\vartheta,\theta), g(\vartheta,\theta))$ defined as follows.

$$\begin{aligned} G_n(\vartheta,\theta) =& \frac{2\epsilon r_0^P}{\gamma c_A B_\infty} \Re \left[\sum_{k=0}^{P-1} \binom{n-N+k}{k} z_1^{N-n-k-1} A_{1,k} v \right] \\ &- \sum_{j=n+1}^{N} u_{n-j} \Phi_j(H_j\xi) + \sum_{j=0}^{n} \varrho_{n-j} \Phi_j(H_j\xi), \qquad 0 \leq n \leq N; \\ g_n(\vartheta,\theta) =& \Phi_n(H_n\xi), \qquad 0 \leq n \leq N, \end{aligned} \tag{47}$$

where

$$\xi_n = \begin{cases} \dfrac{2\epsilon r_0^P}{\gamma C_a B_\infty} \Re \left[\displaystyle\sum_{k=0}^{P-1} \binom{n-N+k}{k} z_1^{N-n-k-1} A_{1,k} v \right] - \displaystyle\sum_{j=0}^{N} u_{n-j}\theta_j, & n < 0; \\ \vartheta_n, & 0 \leq n \leq N. \end{cases} \tag{48}$$

It is obvious that the mapping $(\vartheta,\theta)\mapsto(G(\vartheta,\theta),g(\vartheta,\theta))$ is continuous (in the topology of $\mathbf{R}^{m\times(2N+2)}$), and we must show that it maps Ω into itself.

We clearly have for all $n\le N$

$$\left|\frac{2\epsilon r_0^P}{\gamma c_A B_\infty}\Re\left[\sum_{k=0}^{P-1}\binom{n-N+k}{k}z_1^{N-n-k-1}A_{1,k}v\right]\right|\le\frac{2\epsilon c_A r_0^P b_{N-n}r_1^{N-n}}{\gamma c_A B_\infty}\le\frac{2\epsilon r_1^{N-n}}{\gamma}.$$

Next we observe that, if $(\vartheta,\theta)\in\Omega$, then it follows that

$$|\xi_i|\le\frac{2\epsilon r_1^{N-i}}{\gamma}+\sum_{j=0}^{N}Lc_A r_1^{N-i}b_{j-i}\frac{\epsilon}{Lc_A B_1}\le\Gamma\epsilon r_1^{N-i},\qquad i<0.$$

Because $r_1<1$ and $N-i\ge N+1\ge N-n$ when $i<0\le n$, we therefore see that (46) and the definitions of ξ and Ω imply that

$$\sup_{n<0}|\xi_n|\le\delta\quad\text{and}\quad\|H_n\xi\|_{l^\infty(\mathbf{N})}\le\Gamma\epsilon r_1^{N-n},\quad 0\le n\le N. \tag{49}$$

An easy calculation shows that

$$\begin{aligned}\left|\sum_{j=n+1}^{N}u_{n-j}\Phi_j(H_j\xi)\right|&\le\sum_{j=n+1}^{N}Lc_A\sum_{k=0}^{P-1}\left|\binom{n-j+k}{k}\right|r_0^{j-n-k-1}\frac{\Gamma\epsilon r_1^{N-j}}{2\Gamma Lc_A B_1}\\&=\frac{\epsilon r_1^{N-n}}{2B_1}\sum_{j=n+1}^{N}b_{j-n}\le\frac{\epsilon r_1^{N-n}}{2}.\end{aligned} \tag{50}$$

In the same way we get

$$\left|\sum_{j=0}^{n}\varrho_{n-j}\Phi_j(H_j\xi)\right|\le\sum_{j=0}^{n}|\varrho_{n-j}|\Gamma\epsilon r_1^{N-j}\frac{1}{2\Gamma c_\varrho}\le\frac{\epsilon r_1^{N-n}}{2}. \tag{51}$$

It is immediately clear from (45) and (49) that

$$|g_n(\vartheta,\theta)|\le\frac{\epsilon r_1^{N-n}}{2Lc_A B_1},\qquad 0\le n\le N.$$

This inequality combined with (50) and (51) shows that Ω is mapped into itself.

Since Ω is convex, we can apply Schauder's fixed point theorem and find a point $(\vartheta^*,\theta^*)\in\Omega$ such that $G(\vartheta^*,\theta^*)=\vartheta^*$ and $g(\vartheta^*,\theta^*)=\theta^*$. Define ξ^* by replacing (ϑ,θ) in (48) by (ϑ^*,θ^*) and let

$$\psi_n=\frac{2\epsilon r_0^P}{\gamma C_a B_\infty}\Re\left[\sum_{k=0}^{P-1}\binom{n-N+k}{k}z_1^{N-n-k-1}A_{1,k}v\right]-\sum_{j=0}^{N}u_{n-j}\theta_j^*,\quad n\le N.$$

Since $\xi_n^*=G_n(\vartheta^*,\theta^*)$ and $\theta_n^*=\Phi_n(H_n(\xi^*))$ for $0\le n\le N$, we get

$$\xi_n^*=\psi_n+\sum_{j=0}^{n}(u_{n-j}+\varrho_{n-j})\Phi_j(H_j\xi^*),\qquad 0\le n\le N.$$

Let $\hat{\alpha}(z) = \sum_{n=0}^{\infty} z^n \alpha_n$. For every $l = 1, 2, \cdots, L$ we have

$$\begin{aligned} &\lim_{z \to z_l} \frac{\mathrm{d}^{p_l - 1}}{\mathrm{d}z^{p_l - 1}} \frac{(-1)^{p_l - 1}}{(p_l - 1)!} \sum_{k=0}^{p_l - 1} \hat{\alpha}(z) z^{-n-1} (z_l - z)^{p_l - k - 1} A_{l,k} \\ &= \lim_{z \to z_l} \sum_{k=0}^{p_l - 1} \frac{(-1)^k}{k!} \frac{\mathrm{d}^k}{\mathrm{d}z^k} \sum_{j=-\infty}^{n} \alpha_{n-j} z^{-j-1} A_{l,k} \\ &= \sum_{j=-\infty}^{n} \alpha_{n-j} \sum_{k=0}^{p_l - 1} \binom{j+k}{k} z_l^{-(j+k+1)} A_{l,k}. \end{aligned} \tag{52}$$

On the other hand, it follows from (42) that there exists a function G, analytic at z_l such that

$$\sum_{k=0}^{p_l - 1} \hat{\alpha}(z) z^{-n-1} (z_l - z)^{p_l - k - 1} A_{l,k} = (z_l - z)^{p_l} G(z).$$

We combine this result with (52) and note that the argument can be repeated with z_l and $A_{l,k}$ replaced by $\overline{z_l}$ and $\overline{A_{l,k}}$, respectively. This shows that for every $l = 1, 2, \cdots, L$ we have

$$\sum_{j=-\infty}^{n} \alpha_{n-j} \Re \left[\sum_{k=0}^{p_l - 1} \binom{j+k}{k} z_l^{-(j+k+1)} A_{l,k} \right] = 0, \qquad n \in \mathbf{Z}.$$

It follows that $\sum_{j=-\infty}^{n} \alpha_{n-j} \psi_j = 0$, and therefore we conclude from (43) that ξ^* satisfies the equation

$$\begin{aligned} &\sum_{j=-\infty}^{n} \alpha_{n-j} \xi_j = \Phi_n(H_n \xi), \qquad 0 \le n \le N, \\ &\xi_i = \psi_i, \qquad i < 0. \end{aligned}$$

In order to get the desired contradiction we note that by (44), (47), and (51),

$$|\xi_N^*| = |G_N(\vartheta^*, \theta^*)| \ge \frac{2\epsilon r_0^P r_0^{-P} \gamma c_A B_\infty}{\gamma c_A B_\infty} - \frac{\epsilon}{2} = \frac{3\epsilon}{2}.$$

This completes the proof in the case where $r_0 > 0$.

Finally we have to consider the case where $r_0 = 0$ (and therefore $L = 1$). We construct a continuous function $t \in [0,1] \mapsto \alpha(t) \in l^1(\mathbf{N}; \mathbf{R}^{m \times m})$ such that $\alpha(0) = \alpha$ and so that

$$\left[\sum_{n=0}^{\infty} z^n \alpha_n(t) \right]^{-1} = \sum_{k=0}^{P-1} \left(\frac{1}{2} \frac{1}{(z(t) - z)^{k+1}} A_k(t) + \frac{1}{2} \frac{1}{(\overline{z(t)} - z)^{k+1}} \overline{A_k(t)} \right) + F(z,t),$$

where $z \mapsto F(z,t)$ is analytic for $|z| \le r_1(t)$ and $z(t) \ne 0$ for $t > 0$. Moreover, we require that $z(t)$, $r_1(t)$, $A_k(t)$, and $F(z,t)$ are continuous functions of t. As a consequence we can in the above take the constants c_ϱ, c_A, γ, B_1, and B_∞ to be independent of t. These constants determine the number ϵ that we choose. We assume that $\delta > 0$ is such that (5) implies (6). Now we take a number $t > 0$ to be so small that

$$\sum_{n=0}^{\infty} |\alpha_n(t) - \alpha_n| < \frac{\delta}{\Gamma \epsilon}. \tag{53}$$

By the argument above, there exists a sequence $\{\psi_i\}_{i=-\infty}^{-1}$ with $\sup_{i\le -1}|\psi_i| \le \delta$ and a solution ξ of the equation

$$\sum_{j=-\infty}^{n} \alpha_{n-j}(t)\xi_j = \Phi(H_n\xi), \qquad 0 \le n \le N,$$
$$\xi_i = \psi_i, \qquad i < 0,$$

such that $|\xi_N| > \epsilon$. But then ξ is also a solution of the equation

$$\sum_{j=-\infty}^{n} \alpha_{n-j}\xi_j = \Phi(H_n\xi) + \varphi_n, \qquad 0 \le n \le N,$$
$$\xi_i = \psi_i, \qquad i < 0,$$

where $\varphi_n = \sum_{j=-\infty}^{n}(\alpha_{n-j} - \alpha_{n-j}(t))\xi_j$. Since $|\varphi_n| \le \delta$ by (53) and the definition of the set Ω, we have a contradiction. This completes the proof of Proposition 4.

Acknowledgment. The author thanks the referees for pointing out some errors in an earlier version of the paper.

EXCHANGE OF STABILITIES FOR FLOW ALONG A CONCAVE WALL*

ISOM H. HERRON†

Abstract. The equations of hydrodynamical stability derived by Görtler for flow along a concave wall are proved to satisfy the principle of exchange of stabilities (PES). The case where a constant suction normal to the wall is present is also treated in the same formulation.

Key words. Görtler flow, suction, linear operators

AMS(MOS) subject classifications. 76E05, 47E05

1. Introduction. The first study of the instability of the boundary layer due to the curvature of the flow along a concave wall is attributed to Görtler [4]. Interest in this type of instability has only increased with time. The purpose here is to prove exchange of stabilities in the following sense. *Principle of exchange of stabilities* (PES): *The first unstable eigenvalue has imaginary part equal to zero.* By means of a technique due to Weinberger [5], our previous work on this problem [2] proved exchange of stabilities for flow near a free surface with small curvature, ignoring the effects of surface tension. As a sequel, the wall bounded case is now solved. Since most of the details are developed in the previous paper [2], this work will simply show how the wall bounded case may be transformed to the case already treated.

The governing disturbance equations are

$$(D^2 - v_0 D - a^2 - \sigma)(D^2 - a^2)v + a^2 \mu U u = 0, \tag{1.1a}$$

$$(D^2 - v_0 D - a^2 - \sigma)u - U'v = 0 \tag{1.1b}$$

for the components $u(\eta)$ along the wall and $v(\eta)$ perpendicular to the wall, with boundary conditions

$$v(0) = v'(0) = u(0) = 0, \tag{1.1c}$$

and decay at infinity

$$v, v', u \to 0 \quad \text{as } \eta \to \infty. \tag{1.1d}$$

This is the notation of Drazin and Reid [1], where $D = d/d\eta$, $U(\eta)$ is the velocity component of the basic flow along the wall, a is the wave number, μ is the small gap Taylor number (linearly proportional to curvature), σ is the eigenvalue, and $v_0 = 0$ (no suction) or $v_0 = -1$ (suction). The two cases $v_0 = 0$ and $v_0 = -1$ are handled in one formulation. As in the previous work [2], it is assumed that $U \geqq 0$ and $U' \geqq 0$ for $0 \leqq \eta < \infty$.

2. Abstract formulation and PES. In operator form the differential equations may be written

$$(S^* + \sigma)Mv + a^2 \mu U u = 0, \tag{2.1a}$$

$$U'v + (\tilde{S} + \sigma)u = 0, \tag{2.1b}$$

* Received by the editors July 2, 1990; accepted for publication October 30, 1990. This work was supported by the Office of Naval Research.

† Department of Mathematics, Howard University, Washington, DC 20059.

where

$$Mv = mv = (-D^2 + a^2)v, \qquad v \in \text{dmn } M,$$
$$(S^* + \sigma)Mv = (-D^2 + v_0 D + a^2 + \sigma)Mv, \qquad v \in \text{dmn } (S^* M),$$
$$(\tilde{S} + \sigma)u = (-D^2 + v_0 D + a^2 + \sigma)u, \qquad u \in \text{dmn } \tilde{S}.$$

Next define the operator M^* by

$$M^* v = mv = (-D^2 + a^2)v, \qquad v \in \text{dmn } M^*,$$

where

$$\text{dmn } M^* = \{v \in L_2[0, \infty) \mid v, v' \text{ abs. cont.}, mv \in L_2[0, \infty)\}. \tag{2.2a}$$

Thus M^* has no boundary conditions; it is the adjoint of M given above and

$$\text{dmn } M = \{v \in \text{dmn } M^* \mid v(0) = v'(0) = 0\}. \tag{2.2b}$$

Consequently, M is symmetric and positive definite, but not maximal and not invertible. Another operator needed in what follows is $\tilde{M}$, a positive-definite self-adjoint extension of M: $\tilde{M}v = mv$, $v \in \text{dmn } \tilde{M}$, where

$$\text{dmn } \tilde{M} = \{v \in \text{dmn } M^* \mid v(0) = 0\}. \tag{2.3}$$

A *generalized inverse* [3] to M is $M^\dagger$. The null space of M^*, nul M^* is spanned by $e^{-a\eta}$. The projection operator Q onto nul M^* is defined by

$$(Q\varphi)(\eta) = \int_0^\infty g_Q(\eta, \xi)\varphi(\xi)\, d\xi, \tag{2.4a}$$

where

$$g_Q(\eta, \xi) = e^{-a\eta}\left[\int_0^\infty e^{-2as}\, ds\right]^{-1} e^{-a\xi} = 2a\, e^{-a(\eta+\xi)}. \tag{2.4b}$$

Then $g^\dagger$, the kernel of the generalized inverse, satisfies

$$\left(-\frac{\partial^2}{\partial \eta^2} + a^2\right) g^\dagger(\eta, \xi) = \delta(\eta - \xi) - g_Q(\eta, \xi), \tag{2.5a}$$

$$g^\dagger(0, \xi) = \frac{\partial g^\dagger}{\partial \eta}(0, \xi) = 0, \quad g^\dagger, \frac{\partial g^\dagger}{\partial \eta} \to 0 \quad \text{as } \eta \to \infty, \tag{2.5b}$$

so that

$$(M^\dagger \varphi)(\eta) = \int_0^\infty g^\dagger(\eta, \xi)\varphi(\xi)\, d\xi. \tag{2.6}$$

Some properties of $M^\dagger$ are

$$MM^\dagger = I - Q, \tag{2.7a}$$

$$M^\dagger M = I, \tag{2.7b}$$

since nul M is trivial.

When (2.1a, b) are considered in more detail, S^* has no boundary conditions, while $\tilde{S}$ has boundary conditions and is maximal. The space of functions on which the operators act is weighted (if $v_0 \neq 0$) defined as

$$H_{v_0} = \left\{\varphi \;\middle|\; \int_0^\infty e^{-v_0\eta}|\varphi|^2\, d\eta < \infty\right\}, \tag{2.8a}$$

with inner product

$$\langle \varphi, \psi \rangle_{v_0} = \int_0^\infty \varphi(\eta)\bar{\psi}(\eta)\, e^{-v_0\eta}\, d\eta, \qquad \varphi, \psi \in H_{v_0}, \tag{2.8b}$$

and norm

$$\|\varphi\|_{v_0} = (\langle \varphi, \varphi \rangle_{v_0})^{1/2}. \tag{2.8c}$$

The projection Q onto the null space of M^* is employed. Define $\zeta = Mv \Rightarrow v = M^\dagger \zeta$, and let

$$Z(y) = \zeta(\eta) - T\zeta(\eta) = (I - T)\zeta, \tag{2.9a}$$

such that $Z \in \operatorname{dmn} \tilde{M}$. This is done by setting

$$T\zeta(\eta) = \zeta(0)\, e^{-a\eta}, \tag{2.9b}$$

which is an element of the null space of M^*. Thus, $I - T$ maps the range of M onto the domain of $\tilde{M}$. Then

$$QZ = Q\zeta - QT\zeta = -T\zeta. \tag{2.10}$$

From (2.7) we have

$$M^\dagger(Z - QZ) = M^\dagger Z, \tag{2.11}$$

where Q is given by (2.4). Then (2.1) may be written in terms of Z as

$$(\tilde{S} + \sigma)Z + a^2\mu Uu = (S^* + \sigma)QZ, \tag{2.12a}$$

$$U'M^\dagger Z + (\tilde{S} + \sigma)u = 0. \tag{2.12b}$$

It is not difficult to show that $\tilde{S}$ is maximal positive definite; $u \in \operatorname{dmn} \tilde{S}$, $\langle \tilde{S}u, u \rangle_{v_0} \geqq (v_0^2/4 + a^2)\langle u, u \rangle_{v_0}$. Thus $(\tilde{S} + \sigma)^{-1}$ exists for $\sigma \notin \Sigma = \{\sigma \in \mathbb{C} \,|\, \operatorname{Re}(\sigma) \leqq -(v_0^2/4 + a^2), \operatorname{Im}(\sigma) = 0\}$. The operation of $(\tilde{S} + \sigma)^{-1}$ is [2]

$$(\tilde{S} + \sigma)^{-1}\varphi = \int_0^\infty h(\eta, \xi; \sigma)\varphi(\xi)\, d\xi, \tag{2.13a}$$

where

$$h(\eta, \xi; \sigma) = \left[\frac{e^{-p|\eta - \xi|} - e^{-p(\eta + \xi)}}{2p}\right] e^{v_0(\eta - \xi)/2}, \tag{2.13b}$$

and

$$p = \sqrt{a^2 + v_0^2/4 + \sigma} \quad \text{is the positive square root.}$$

Application of $(\tilde{S} + \sigma)^{-1}$ to (2.12a) gives

$$Z + a^2\mu B(\sigma)Uu = B(\sigma)(S^* + \sigma)QZ, \tag{2.14a}$$

where

$$B(\sigma) = (\tilde{S} + \sigma)^{-1}. \tag{2.14b}$$

Integration by parts on the right side of (2.14a) leads to

$$\begin{aligned} Z(\eta) + (a^2\mu B(\sigma)Uu)(\eta) = \Bigg[h(\eta, \xi; \sigma)\left(-\frac{\partial}{\partial \xi}(QZ)(\xi) + v_0(QZ)(\xi)\right) \\ + \frac{\partial}{\partial \xi} h(\eta, \xi; \sigma)(QZ)(\xi)\Bigg]_{\xi=0}^{\infty} + (QZ)(\eta). \end{aligned} \tag{2.15}$$

From (2.13b) we have

$$Z(\eta)+(a^2\mu BUu)(\eta)=-\frac{\partial}{\partial\xi}h(\eta,0;\sigma)(QZ)(0)+(QZ)(\eta). \tag{2.16}$$

It is possible to rewrite (2.16) as

$$Z+(a^2\mu BU)u=(I-A(\sigma))QZ, \tag{2.17}$$

where $A(\sigma)$ is the projection onto nul $(S^*+\sigma)$. With (2.12b), (2.17) becomes

$$Z-a^2\mu BUBU'M^\dagger Z=(I-A)QZ. \tag{2.18}$$

Application of Q to both sides of (2.18) gives

$$a^2\mu QBUBU'M^\dagger Z=QAQZ. \tag{2.19}$$

The left side of (2.19) depends explicitly (linearly) on μ; the right side does not. Let $\mu\to 0$. Then $QAQZ\to 0$, which is not unexpected.

The condition $QAQZ=0$, interpreted in the light of (2.13) and (2.16), means

$$(QZ)(0)\int_0^\infty g_Q(\eta,\gamma)\frac{\partial h}{\partial\xi}(\gamma,0;\sigma)\,d\gamma=0. \tag{2.20}$$

When this calculation is carried out the result is

$$\frac{2a\,e^{-a\eta}}{a+p-v_0/2}(QZ)(0)=0. \tag{2.21}$$

This can only hold if $(QZ)(0)=0$, which from (2.10) means $QZ\equiv 0$, and this implies $Z\equiv 0$.

Next, by considering the norms of both sides of (2.19), the relation $QAQZ=0$ must hold for $\mu\neq 0$ as well. To see this, first set

$$J\equiv QBUBU'M^\dagger \tag{2.22}$$

so that from (2.19)

$$\|QAQZ\|_{v_0}=a^2\mu\|JZ\|_{v_0}$$

and the ratio

$$\frac{\|QAQZ\|_{v_0}}{\|JZ\|_{v_0}}=a^2\mu\geqq\frac{\|QAQZ\|_{v_0}}{\|J\|_{v_0}\|Z\|_{v_0}}. \tag{2.23}$$

Thus, as $\mu\to 0$, the right side of (2.23) must approach zero as $\|Z\|_{v_0}\to 0$, and this requires $\|QAQZ\|_{v_0}\to 0$ faster than $\|Z\|_{v_0}\to 0$, which for a linear operator cannot be true, unless $QAQZ\equiv 0$.

The calculations which led to (2.20) and (2.21) can be carried out again, giving the same result: $QZ\equiv 0\Rightarrow Z\equiv 0$, so the system (2.12) is really homogeneous. Furthermore, $\tilde{M}M^\dagger Z=(I-Q)Z=Z$, so $M^\dagger=\tilde{M}^{-1}$ when operating on Z.

The system (2.12) may be written as a single equation:

$$(\tilde{S}+\sigma)Z-a^2\mu UB(\sigma)U'\tilde{M}^{-1}Z=0, \tag{2.24}$$

or

$$Z-K(\sigma)Z=0, \tag{2.25a}$$

where

$$K(\sigma)=a^2\mu B(\sigma)UB(\sigma)U'B(0). \tag{2.25b}$$

The formulation (2.25) is a reduction to the form considered in the previous article [2]. It is true that $K(\sigma)$ will be a *compact* operator if the decay of U' to zero as $\eta \to \infty$ is sufficiently strong. By the technique of Weinberger [5], PES thereby follows. Now our earlier discussion (between equations (2.12) and (2.13)) has shown that the original system (2.1) and the transformed system (2.24) have spectra that agree, except on a set Σ, which is a subset of the negative real halfline. Consequently, PES will hold for the original system as well.

GENEALOGY AND BIFURCATION SKELETON FOR CYCLES OF THE ITERATED TWO-EXTREMUM MAP OF THE INTERVAL*

J. RINGLAND†‡ AND M. SCHELL†

Abstract. It is shown how the skeleton of the bifurcation structure of iterated maps of the interval with two extrema may be constructed without reference to kneading sequences. This construction of the skeleton is based on local rules and is accomplished by considering not just the bones, i.e., the curves in the parameter plane that correspond to the existence of superstable cycles, but also the curves that correspond to the existence of itineraries from one turning point to the other: curves called ligaments here. A graphical genealogy of the cycles ensues.

Key words. genealogy, periodic orbits, skeleton, superstability, bimodal map

AMS(MOS) subject classifications. 58C25, 58F14, 58F22, 34C35

1. Introduction. Analysis of the dynamics of iterated maps of the interval with two extrema has focused on the parameter-plane curves that correspond to the existence of superstable cycles.[1] The curves have been termed the *bones* [1] of the regions in the parameter-plane where cycles are stable. The way in which the bifurcation structure hangs on these bones has been described [1], [2]. A more difficult problem is determining the arrangement of the *skeleton*—the collection of all the bones. Mackay and Tresser [2] have shown how it may be solved by applying the kneading theory [2]–[6]. Here we present an alternative solution that is much simpler and, due to its radically different character, quite complementary to the previous work. In our approach, no reference is made to the lexicology of kneading sequences. Impossible cycles that in the kneading theory approach must be excluded case by case, using a rather laborious admissibility test, simply do not arise. More importantly, the result of our construction is a graphical genealogy of the cycles that embodies their intricately knitted relationships and provides a locally causal explanation of the existence and arrangement of the bones.

Our construction of the skeleton is accomplished by considering not only the bones, but also the parameter-plane curves that correspond to the existence of itineraries from one turning point to the other: curves we call *ligaments*. As we intend the name to suggest, the ligaments serve to connect the bones. We stress that while each ligament is in fact the locus of occurrence of specific (finite) kneading sequence, at no point do we make use of the kneading sequences themselves. And parenthetically we note that while bones correspond to attractors of the map, ligaments do not.

The construction is founded on the local analysis of three classes of singular point of the parameter plane from which bones and ligaments can be considered to emanate. The three corresponding kinds of singular[2] condition of the map, which for brevity we denote (arbitrarily) by the letters α, χ, and ψ, are exemplified in Fig. 1. These

* Received by the editors November 27, 1989; accepted for publication (in revised form) September 10, 1990. This research was supported by the Petroleum Research Fund, administered by the American Chemical Society.

† Department of Chemistry and Center for Nonequilibrium Structures, Southern Methodist University, Dallas, Texas 75275.

‡ Department of Mathematics, State University of New York at Buffalo, Buffalo, New York 14214.

[1] These are cycles that include a turning point of the map, and hence have eigenvalue zero.

[2] The term does not imply that the map lacks smoothness (see Fig. 1).

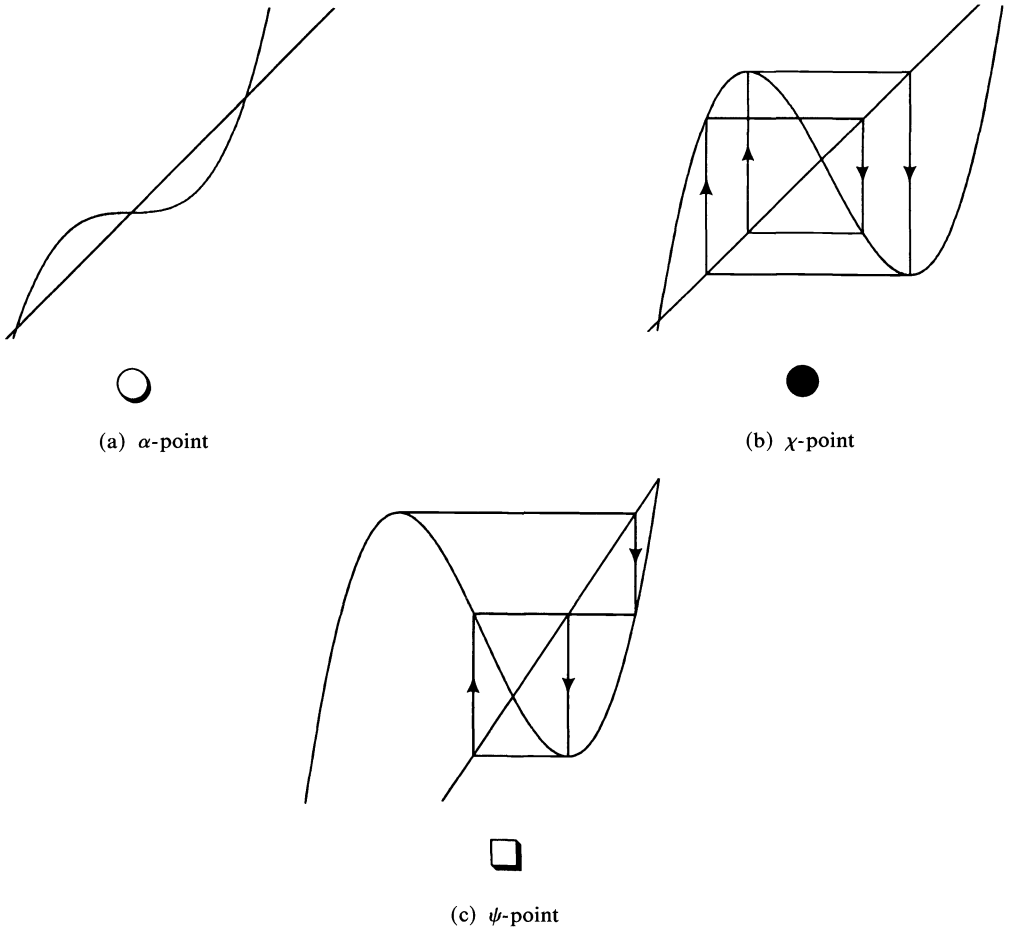

FIG. 1. *Maps (sketched) in the three kinds of condition that correspond to sources of bones and/or ligaments.* (a) *At an α-point, a point of degeneracy of two turning points.* (b) *At a χ-point, the location of a doubly superstable cycle, i.e., a cycle that contains both of the turning points of the map.* (c) *At a ψ-point, where an itinerary from one turning point to the other coexists with a cycle that contains the terminal turning point of that itinerary. The symbols appearing below the sketches are used in later figures to mark points in the parameter plane where the respective conditions arise.*

singular points will be discussed in detail in the next section, but first we mention briefly their attributes in order to sketch the logic of our approach. The α-point is a source of ligaments, the χ-point is a point of intersection of two ligaments and is the source of a pair of bones and of additional ligaments, and the ψ-point is a point of intersection of a ligament and a bone and is the source of additional ligaments. The idea of the construction is that the ligaments emanating from the α-point participate in intersections that constitute χ-points. The bones and ligaments that emanate from these χ-points participate in intersections that constitute additional χ-points and ψ-points. These points in turn are the sources of bones and ligaments which give rise to more χ-points and ψ-points, and so on. In this way the entire skeleton is generated, and in what follows we develop the specific prescription. Related methods have been applied in other dynamical systems contexts [7], [8].

In § 2 we describe the singular points, and derive the existence and arrangement of the bones and/or ligaments that emanate from them. In § 3 we investigate the

consequences of these results for map families that are *full* and *nice*: properties defined in that section that, in the spirit of the previous work [2], ensure, respectively, the completeness and maximal simplicity of the skeleton. Consideration of the possibility of other kinds of interaction of ligaments and bones then permits the completion of the set of rules for constructing the skeleton. We carry out the construction as far as to include all bones corresponding to cycles of length 6 or less.

2. Local analysis of the three points of origin of bones and/or ligaments. We consider analytic two-parameter families of maps $x \to \Phi(x, \lambda, \mu)$ of the interval into itself (coordinate x, parameters λ, μ), with $\partial\Phi/\partial x > 0$ except at two turning points (where $\partial\Phi/\partial x = 0$) and between them where $\partial\Phi/\partial x < 0$.

2.1. The α-point. In order to consider the starting point of the skeleton, we broaden slightly the class of maps considered and allow the turning points to merge.

DEFINITION. A point (λ_0, μ_0) of the parameter plane of the map $\Phi(x, \lambda, \mu)$ is an *α-point* if there exists x_0 such that $\Phi(x_0, \lambda_0, \mu_0) = x_0$, $\partial\Phi(x_0, \lambda_0, \mu_0)/\partial x = \partial^2\Phi(x_0, \lambda_0, \mu_0)/\partial x^2 = 0$, and $\partial^3\Phi(x_0, \lambda_0, \mu_0)/\partial x^3 > 0$.

The graph of a map at an α-point is pictured in Fig. 1(a).

THEOREM 1. *Generically, a sufficiently small parameter-plane circle centered at an α-point is intersected (transversally) by ligaments $\{\mathcal{L}_n\}$ corresponding to itineraries of lengths $n = 0, 1, 2, \cdots$ between turning points, and by a bone $\mathcal{B}$ corresponding to fixture of a turning point (equivalently, superstability of a fixed point), in the following (cyclic) order: $\mathcal{L}_0(L \to R)$, $\mathcal{B}(R)$, $\cdots$, $\mathcal{L}_3(L \to R)$, $\mathcal{L}_2(L \to R)$, $\mathcal{L}_1(L \to R)$, $\mathcal{L}_1(R \to L)$, $\mathcal{L}_2(R \to L)$, $\mathcal{L}_3(R \to L)$, $\cdots$, $\mathcal{B}(L)$, $\mathcal{L}_0(R \to L)$, where the arguments indicate the association with the left (L) and right (R) turning points. In other words, the generic unfolding of an α-point is qualitatively as depicted in Fig.* 2(a).

The proof follows a description of Fig. 2(a). The ligament corresponding to an inter-turning-point itinerary of length zero, i.e., the locus of emergence of the turning points, is labeled zero. The hatching indicates the side of this curve where the map is monotonic. On the other side is the bone (unbroken curve), on which exists a superstable fixed point of the map, and the bundle of ligaments, each labeled by the length of the corresponding itinerary. Ligaments corresponding to longer itineraries are closer to the bone. The asterisk in Fig. 2(a) corresponds to a situation like that depicted in Fig. 3(a).

In Fig. 2 (and Figs. 4 and 5) we use dashed and dotted curves to distinguish between the two *types* of ligament: those that correspond to itineraries from the left turning point to the right one, and those that correspond to itineraries from the right turning point to the left one.

The ligaments emanating from an α-point change type at the α-point: this fact is associated with the coincidence there of the two turning points. So on one "side" of the α-point the ligaments correspond to itineraries from the left turning point to the right one, and on the other side they correspond to itineraries from the right turning point to the left one. As discussed in detail in § 2.2, two ligaments of opposite type can intersect, giving rise to a χ-point: the location of a cycle that includes both turning points, and a source of bones and additional ligaments.

Proof of Theorem 1. Let us write the map as

$$\Phi(x, \lambda, \mu) = \Sigma a_{ijk} x^i \lambda^j \mu^k. \tag{2.1.1}$$

Here, as elsewhere below, the sum is on all indices over the nonnegative integers. An α-point at $x = \lambda = \mu = 0$ is obtained if we set $a_{000} = a_{100} = a_{200} = 0$. Generically, $a_{300} \neq 0$, and therefore $a_{300} > 0$ by the previously stated requirements on $\partial\Phi/\partial x$. Also generically

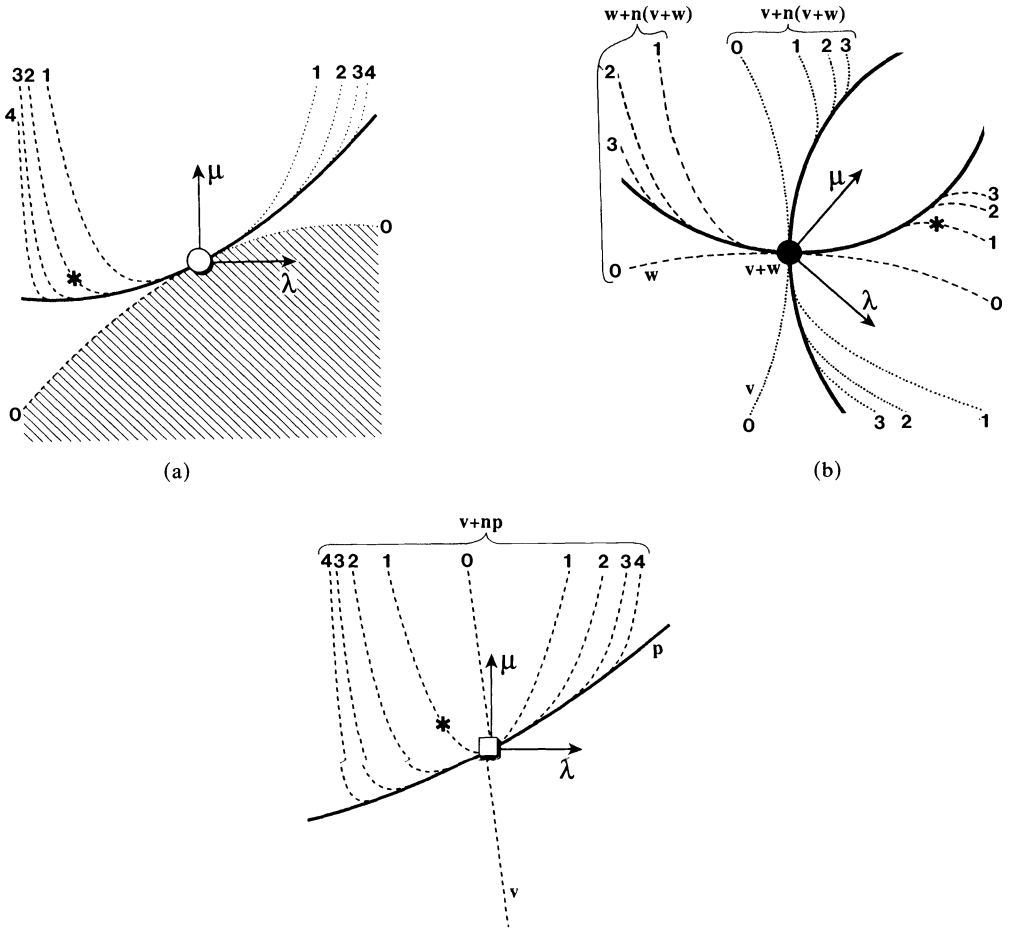

FIG. 2. *Sketches of the parameter-plane neighborhoods of each of the three kinds of condition depicted in Fig.* 1. *Unbroken curves represent bones (existence loci of superstable cycles). Broken curves represent ligaments (existence loci of itineraries from one turning point to the other); dashed and dotted are used to distinguish between the two types.* (a) *The α-point. Ligaments are labeled with the length of the corresponding itinerary. The ligament* 0 *is the locus of degeneracy of the two turning points; on the hatched side of this curve the map is monotonic. On the other side exist the (period-*1*) bone and bundle of ligaments which emanate from the α-point. The ligaments are ordered by length of corresponding itinerary, with the longer ones closer to the bone, as proved in* § 2.1. (b) *the χ-point. Two bones and two bundles of ligaments emanate from each χ-point. The ligaments are labeled with the value of n in the respective formulas for the length of the corresponding itinerary. That the local qualitative arrangement of the bones and ligaments is generically as pictured is proved in* § 2.2. (c) *The ψ-point, from which a bundle of ligaments emanates. The ligaments are labeled with the value of n in the formula v + np for the length of the corresponding itinerary. That this is the generic picture is proved in* § 2.3.

$a_{101} \neq 0$, so the implicit function theorem locally guarantees the existence of a unique analytic function

$$\mu^*(r, \lambda) = \Sigma b_{ij} r^i \lambda^j \tag{2.1.2}$$

($b_{00} = 0$) that satisfies

$$\frac{\partial \Phi}{\partial x}(r, \lambda, \mu^*(r, \lambda)) = 0, \tag{2.1.3}$$

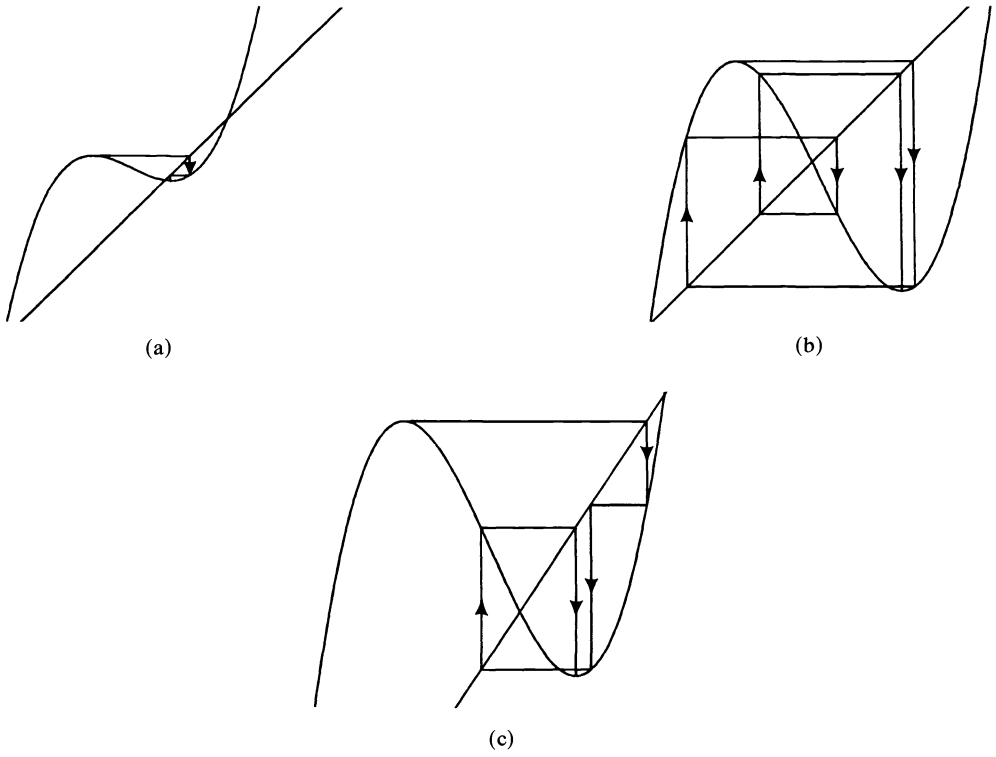

FIG. 3. *Sketches of maps near each of the three conditions depicted in Fig.* 1, *showing itineraries between turning points which exist on ligaments emanating from the singular points.* (a) *Near an* α*-point, an itinerary of length* 2 *from the left to the right turning point.* (b) *Near the* χ*-point of Fig.* 1(b), *an itinerary from the left to the right turning point of length* 5, *which at the* χ*-point is degenerate with itineraries of length* 1, 5, 9, 13, $\cdots$, *the increment being the period* (4) *of the doubly superstable cycle that exists at the* χ*-point.* (c) *Near the* ψ*-point of Fig.* 1(c), *an itinerary* (*length* 4) *that at the* ψ*-point consists of the direct itinerary* (*length* 2) *plus one loop around the superstable cycle* (*period* 2).

i.e., that makes r a turning point of Φ. Substitution of (2.1.1) and (2.1.2) into (2.1.3), and equating like terms yields $b_{10} = -2a_{200}/a_{101} = 0$.

There also exists another turning point given by an analytic function

$$s(r, \lambda) = \Sigma c_{ij} r^i \lambda^j \tag{2.1.4}$$

($c_{00} = 0$) satisfying

$$\frac{\partial \Phi}{\partial x}(s(r, \lambda), \lambda, \mu^*(r, \lambda)) = 0. \tag{2.1.5}$$

Since $a_{200} = 0$ and $a_{300} \neq 0$, $s(r, \lambda)$ as defined is double-valued. One value is simply the turning point r itself: $s(r, \lambda) = r$. We are interested in the other value, which by substitution of (2.1.1) and (2.1.4) into (2.1.5) has $c_{10} = -1$.

The implicit function theorem also guarantees the existence of a set of analytic functions $r_n(\lambda)$, $n = 0, 1, 2, \cdots$, with $r_n(0) = 0$, for all n, that satisfy

$$I_n(r_n(\lambda), \lambda) = 0, \tag{2.1.6}$$

where

$$I_n(r,\lambda)\equiv\Phi^n(r,\lambda,\mu^*(r,\lambda))-s(r,\lambda), \tag{2.1.7}$$

since $\partial I_0(0,0)/\partial r=1-c_{10}=2\ (\neq 0)$ and $\partial I_{n>0}(0,0)/\partial r=-c_{10}=1\ (\neq 0)$. (By Φ^n we mean the n-fold composition of Φ with itself.) Then the set of analytic functions $\{\mu_n(\lambda)\equiv\mu^*(r_n(\lambda),\lambda),\ n=0,1,2,\cdots\}$ represents a bundle of ligaments emanating from the α-point. We conclude that the itineraries of all lengths that degenerately exist at the α-point persist each on a unique curve in the unfolding.

Similarly, a bone is represented by the analytic function $\mu_{ss}(\lambda)\equiv\mu^*(r_{ss}(\lambda),\lambda)$ where

$$r_{ss}(\lambda)=\Sigma d_j\lambda^j \tag{2.1.8}$$

($d_0=0$) is defined by

$$I_{ss}(r_{ss}(\lambda),\lambda)=0, \tag{2.1.9}$$

where

$$I_{ss}(r,\lambda)\equiv\Phi(s(r,\lambda),\lambda,\mu^*(r,\lambda))-s(r,\lambda). \tag{2.1.10}$$

(Existence and uniqueness of $r_{ss}(\lambda)$ are guaranteed by $\partial I_{ss}(0,0)/\partial r=-c_{10}=1\neq 0$.) Note that $r_{ss}(\lambda)$ is the selection of the turning point such that the *other* turning point s is a fixed point of Φ.

To determine the *arrangement* of the ligaments and the bone we compute the deviations of the ligaments $\{\mu_n(\lambda)\}$ from the bone $\mu_{ss}(\lambda)$. That is, we compute the differences

$$\Delta\mu_n(\lambda)\equiv\mu^*(r_n(\lambda),\lambda)-\mu^*(r_{ss}(\lambda),\lambda). \tag{2.1.11}$$

If we define $\Delta r_n(\lambda)\equiv r_n(\lambda)-r_{ss}(\lambda)$, then

$$\Delta\mu_n(\lambda)=\mu^*(r_{ss}(\lambda)+\Delta r_n(\lambda),\lambda)-\mu^*(r_{ss}(\lambda),\lambda). \tag{2.1.12}$$

Substituting $r_{ss}(\lambda)+\Delta r_n(\lambda)$ for r in (2.1.2), using (2.1.8), and recalling that $b_{10}=d_0=0$, we obtain

$$\Delta\mu_n(\lambda)=s\lambda\Delta r_n(\lambda)+T\Delta r_n^2(\lambda)+\text{h.o.t.}, \tag{2.1.13}$$

where

$$S=2d_1b_{20}+b_{11},\qquad T=b_{20}, \tag{2.1.14}$$

and by h.o.t. we mean terms of higher order in λ than the leading term of the expressions to the left. Straightforward substitution of the series expansions of μ_{ss}, s, and r_{ss} into the definitions of these quantities ((2.1.2), (2.1.4), and (2.1.8), respectively), and equating like terms yields the following identities required for the evaluation of S and T:

$$\begin{aligned}
&d_1=c_{01}-b_{01}a_{001}-a_{010},\\
&c_{01}=(b_{11}a_{101}-2b_{01}a_{201}-2a_{210})/6a_{300},\\
&b_{01}=-a_{110}/a_{101},\\
&b_{11}=-2(b_{01}a_{201}+a_{210})/a_{101},\\
&b_{20}=-3a_{300}/a_{101}.
\end{aligned} \tag{2.1.15}$$

Now, from (2.1.6),

$$\begin{aligned}
0&=I_n(r_{ss}(\lambda)+\Delta r_n(\lambda),\lambda)\\
&=\Phi^n(r_{ss}(\lambda)+\Delta r_n(\lambda),\lambda,\mu(r_{ss}(\lambda)+\Delta r_n(\lambda),\lambda))-s(r_{ss}(\lambda)+\Delta r_n(\lambda),\lambda).
\end{aligned} \tag{2.1.16}$$

Substituting (2.1.8) into (2.1.4), and applying Φ, we get

$$0=\begin{cases} I_n(r_{ss}(\lambda),\lambda)+(1-c_{10})\Delta r_n(\lambda)+O(\Delta r_n(\lambda)^2), & n=0,\\ I_n(r_{ss}(\lambda),\lambda)+(-c_{10})\Delta r_n(\lambda)+O(\Delta r_n(\lambda)^2), & n>0. \end{cases} \tag{2.1.17}$$

Since $c_{10}=-1$, (2.1.17) implies that

$$\Delta r_n(\lambda)=\begin{cases} -\frac{1}{2}I_n(r_{ss}(\lambda),\lambda)+\text{h.o.t.}, & n=0,\\ -I_n(r_{ss}(\lambda),\lambda)+\text{h.o.t.}, & n>0. \end{cases} \tag{2.1.18}$$

By using (2.1.1), a recursion formula may be obtained for the $\{I_n(r_{ss}(\lambda),\lambda)\}$ as follows:

$$\begin{aligned} I_{n+1}(r_{ss}(\lambda),\lambda)&=\Phi(\Phi^n(r_{ss}(\lambda),\lambda,\mu(r_{ss}(\lambda),\lambda)),\lambda,\mu(r_{ss}(\lambda),\lambda))-s(r_{ss}(\lambda),\lambda),\\ &=\Phi(I_n(r_{ss}(\lambda),\lambda)+s(r_{ss}(\lambda),\lambda),\lambda,\mu(r_{ss}(\lambda),\lambda))-s(r_{ss}(\lambda),\lambda). \end{aligned} \tag{2.1.19}$$

Expanding, we then obtain

$$\begin{aligned} I_{n+1}(r_{ss}(\lambda),\lambda)&=\Phi(s(r_{ss}(\lambda),\lambda),\lambda,\mu(r_{ss}(\lambda),\lambda))-s(r_{ss}(\lambda),\lambda)\\ &\quad+Q\lambda I_n^2(r_{ss}(\lambda),\lambda)+RI_n^3(r_{ss}(\lambda),\lambda)+\text{h.o.t.}\\ &=Q\lambda I_n^2(r_{ss}(\lambda),\lambda)+RI_n^3(r_{ss}(\lambda),\lambda)+\text{h.o.t.}, \end{aligned} \tag{2.1.20}$$

where

$$Q=3a_{300}(c_{01}-d_1)+b_{01}a_{201}+a_{210},\qquad R=a_{300}. \tag{2.1.21}$$

(Recall that s is the location of a quadratic extremum of Φ except at $\lambda=\mu=0$ where Φ has a cubic inflection at s.)

The starting point for our recursive determination of the $\{\Delta\mu_n(\lambda)\}$ is, from (2.1.7) with $n=0$, (2.1.4) and (2.1.8),

$$I_0(r_{ss}(\lambda),\lambda)=U\lambda, \tag{2.1.22}$$

where

$$U=2d_1-c_{01}. \tag{2.1.23}$$

Combining the results (2.1.13), (2.1.18), (2.1.20), and (2.1.22), we have

$$\begin{aligned} &\Delta\mu_0(\lambda)=(-\tfrac{1}{2}SU+\tfrac{1}{4}TU^2)\lambda^2+\text{h.o.t.},\\ &\Delta\mu_1(\lambda)=-S(Q+RU)U^2\lambda^4+\text{h.o.t.},\\ &\Delta\mu_n(\lambda)=-SQQ^{(2^{n-1}-2)}(Q+RU)^{2^{n-1}}U^{2^n}\lambda^{2^{n+1}}+\text{h.o.t.},\qquad n>1. \end{aligned} \tag{2.1.24}$$

Thus the ligaments $\mu_n(\lambda)$ deviate from the bone $\mu_{ss}(\lambda)$ at orders λ^2, λ^4, λ^8, $\lambda^{16},\cdots$, for $n=0,1,2,3,\cdots$. The arrangement of the curves is ascertained by considering that for $n>1$, the sign of the leading order term of $\Delta\mu_n(\lambda)$ is always the same: the sign of $-SQ$. Moreover, the sign of $\Delta\mu_1(\lambda)$ is also the same, since the product of coefficients

$$[-S(Q+RU)][-SQ]=\frac{S^2V^2}{3a_{101}^2}, \tag{2.1.25}$$

where $V=3a_{300}(a_{101}a_{010}-a_{110}a_{001})+a_{210}a_{101}-a_{201}a_{110}$, is not less than zero. In contrast, $\mu_0(\lambda)$, the locus of turning point coalescence, deviates from the bone on the opposite side since the product

$$\left[-\frac{1}{2}SU+\frac{1}{4}TU^2\right][-SQ]=-\frac{2}{3}\frac{1}{a_{300}}\left[\frac{1}{a_{101}}\right]^6V^4 \tag{2.1.26}$$

is not *greater* than zero if $a_{300}>0$ as originally posited. Thus the qualitative arrangement of the ligaments and the bone is universal, and is as specified in Theorem 1. □

2.2. The χ-point. An intersection of two ligaments of opposite type, that is to say, of a ligament corresponding to an itinerary from the left turning point of the map to the right one and a ligament corresponding to an itinerary from the right turning point of the map to the left one, is a point of existence of a doubly superstable cycle (a cycle that includes both turning points). We show below that such a point is the source of a pair of bones, and of two bundles of additional ligaments. For the purposes of our construction of the skeleton we regard the intersection mentioned above as "causative" of the doubly superstable point and of the bones and other ligaments which emanate from it. But for purposes of analysis it is more convenient to define the point as follows.

DEFINITION. A point (λ_0, μ_0) of the parameter plane of the map $\Phi(x, \lambda, \mu)$ is a *χ-point* if there exist v, $w \in \mathbb{N}$ such that $\Phi^v(r_0, \lambda_0, \mu_0) = s_0$, and $\Phi^w(s_0, \lambda_0, \mu_0) = r_0$, where r_0, s_0 are (distinct) quadratic turning points of $\Phi(x, \lambda_0, \mu_0)$.

The existence of the two "causative" ligaments, as well as of the other ligaments and the bones, follows from the definition as we now demonstrate.

THEOREM 2. *Let (λ_0, μ_0) be a χ-point of $\Phi(x, \lambda_0, \mu_0)$ for which the turning points are r_0 and s_0, and let $v = \min(v' \in \mathbb{N} | \Phi^{v'}(r_0, \lambda_0, \mu_0) = s_0)$ and $w = \min(w' \in \mathbb{N} | \Phi^{w'}(s_0, \lambda_0, \mu_0) = r_0)$. Generically, a sufficiently small parameter-plane circle centered at (λ_0, μ_0) is intersected (transversally) by ligaments $\{\mathcal{L}_n^{r\to s}\}$ and $\{\mathcal{L}_n^{s\to r}\}$, $n = 0, 1, 2, \cdots$, corresponding to itineraries between the turning points (r and s) of lengths $v + n(v+w)$ and $w + n(v+w)$, respectively, and by bones $\mathcal{B}^r$ and $\mathcal{B}^s$ corresponding to (superstable) cycles containing r and s respectively, in the following (cyclic) order: $\mathcal{L}_0^{r\to s}$, $\mathcal{B}^s, \cdots, \mathcal{L}_3^{r\to s}$, $\mathcal{L}_2^{r\to s}$, $\mathcal{L}_1^{r\to s}$, $\mathcal{L}_0^{s\to r}$, $\mathcal{L}_1^{s\to r}$, $\mathcal{L}_2^{s\to r}, \cdots, \mathcal{B}^r$, $\mathcal{B}^s, \cdots, \mathcal{L}_2^{r\to s}$, $\mathcal{L}_1^{r\to s}$, $\mathcal{L}_0^{r\to s}$, $\mathcal{L}_1^{s\to r}$, $\mathcal{L}_2^{s\to r}$, $\mathcal{L}_3^{s\to r}, \cdots, \mathcal{B}^r$, $\mathcal{L}_0^{s\to r}$. In other words, the generic unfolding of a χ-point is qualitatively as depicted in the sketch of Fig. 2(b).*

The proof follows a brief description of Fig. 2(b). The pair of unbroken curves tangent at the χ-point to the causative ligaments (itinerary lengths v and w) are the bones, one associated with each turning point. The two bundles of emanating ligaments, one tangent to each bone at the χ-point, are represented by the first four members of each. In both bundles, ligaments corresponding to longer itineraries are closer to the respective bone: the ligaments are marked with the value of the index n of Theorem 1. The asterisk corresponds to a situation like that depicted in Fig. 3(b).

Proof of Theorem 2. Let there be a doubly superstable cycle of Φ, period $v+w$, at $\lambda = \mu = 0$ with

$$\Phi^v(r_0, 0, 0) = s_0, \qquad \Phi^w(s_0, 0, 0) = r_0 \tag{2.2.1}$$

(with no smaller v or w satisfying these equations), where

$$\frac{\partial \Phi}{\partial x}(r_0, 0, 0) = \frac{\partial \Phi}{\partial x}(s_0, 0, 0) = 0, \quad \frac{\partial^2 \Phi}{\partial x^2}(r_0, 0, 0) \neq 0, \quad \frac{\partial^2 \Phi}{\partial x^2}(s_0, 0, 0) \neq 0. \tag{2.2.2}$$

We write the v- and w-fold compositions of Φ as

$$\begin{aligned} f(x, \lambda, \mu) &= \Sigma a_{ijk} x^i \lambda^j \mu^k \equiv \Phi^v(r_0 + x, \lambda, \mu), \\ g(x, \lambda, \mu) &= \Sigma b_{ijk} x^i \lambda^j \mu^k \equiv \Phi^w(s_0 + x, \lambda, \mu), \end{aligned} \tag{2.2.3}$$

with $a_{000} = b_{000} = a_{100} = b_{100} = 0$ from (2.2.1) and (2.2.2). Since by stipulation (and generically) $a_{200} \neq 0$ and $b_{200} \neq 0$, there exist unique analytic functions $r(\lambda, \mu)$ and

$s(\lambda, \mu)$ for the turning points, defined, respectively, by

$$\frac{\partial f}{\partial x}(r(\lambda, \mu), \lambda, \mu) = 0, \qquad \frac{\partial g}{\partial x}(s(\lambda, \mu), \lambda, \mu) = 0. \tag{2.2.4}$$

We write them as

$$r(\lambda, \mu) = \Sigma c_{jk} \lambda^j \mu^k, \qquad s(\lambda, \mu) = \Sigma d_{jk} \lambda^j \mu^k \tag{2.2.5}$$

(with $c_{00} = d_{00} = 0$). We define the functions $\mu_{ss}(\lambda)$, $\mu_{rr}(\lambda)$, representing the bones (associated with s and r, respectively) as follows:

$$\begin{aligned} fg(s(\lambda, \mu_{ss}(\lambda)), \lambda, \mu_{ss}(\lambda)) - s(\lambda, \mu_{ss}(\lambda)) = 0, \\ gf(r(\lambda, \mu_{rr}(\lambda)), \lambda, \mu_{rr}(\lambda)) - r(\lambda, \mu_{rr}(\lambda)) = 0, \end{aligned} \tag{2.2.6}$$

and expand them as

$$\mu_{ss}(\lambda) = \Sigma e_m \lambda^m, \qquad \mu_{rr}(\lambda) = \Sigma \overline{e_m} \lambda^m. \tag{2.2.7}$$

Unique analytic functions $\mu_{ss}(\lambda)$ and $\mu_{rr}(\lambda)$ are guaranteed since $d_{01} = -b_{101}/2b_{200} \neq a_{001}$ generically, and $c_{01} = -a_{101}/2a_{200} \neq b_{001}$ generically. The fact that the two equations in (2.2.6) are related by interchanging the coefficients $\{a_{ijk}\} \leftrightarrow \{b_{ijk}\}$, i.e., by switching the identification of the turning points, means that the $\{e_m\}$ and $\{\overline{e_m}\}$ are related by the same interchange (once they have been evaluated in terms of those problem-defining coefficients). In what follows an overbar will denote the interchange operation.

We now define for the $n = 0, 1, 2, \cdots$,

$$\begin{aligned} I_n^{r \to s}(\lambda, \mu) \equiv (fg)^n f(r, \lambda, \mu) - s, \\ I_n^{s \to r}(\lambda, \mu) \equiv (gf)^n g(s, \lambda, \mu) - r. \end{aligned} \tag{2.2.8}$$

Since $\partial I_n^{r \to s}(0, 0)/\partial \mu = a_{001} - d_{01}$ (for all n) is generically nonzero, as is $\partial I_n^{s \to r}(0, 0)/\partial \mu = b_{001} - c_{01}$, ligaments represented by analytic functions $\mu_n^{r \to s}(\lambda)$, $\mu_n^{s \to r}(\lambda)$, $n = 0, 1, 2, \cdots$, that are the unique solutions of

$$I_n^{r \to s}(\lambda, \mu_n^{r \to s}(\lambda)) = 0, \qquad I_n^{s \to r}(\lambda, \mu_n^{s \to r}(\lambda)) = 0, \tag{2.2.9}$$

respectively, are guaranteed. We write the deviations of the ligaments from the respective bones as

$$\Delta \mu_n^{r \to s}(\lambda) \equiv \mu_n^{r \to s}(\lambda) - \mu_{ss}(\lambda), \qquad \Delta \mu_n^{s \to r}(\lambda) \equiv \mu_n^{s \to r}(\lambda) - \mu_{rr}(\lambda). \tag{2.2.10}$$

It is the leading terms of these deviations in which we are interested. The first step is to derive a relation between $\Delta \mu_n^{r \to s}(\lambda)$ and the ligament-defining function $I_n^{r \to s}(\lambda, \mu)$, *evaluated on the bone* $\mu_{ss}(\lambda)$, as follows using (2.2.8) and (2.2.9):

$$\begin{aligned} 0 \equiv I_n^{r \to s}(\lambda, \mu_n^{r \to s}(\lambda)) = I_n^{r \to s}(\lambda, \mu_{ss}(\lambda) + \Delta \mu_n^{r \to s}(\lambda)), \\ = I_n^{r \to s}(\lambda, \mu_{ss}(\lambda)) - P \Delta \mu_n^{r \to s}(\lambda) + O(\lambda) \Delta \mu_n^{r \to s}(\lambda) + O((\Delta \mu_n^{r \to s}(\lambda))^2), \end{aligned} \tag{2.2.11}$$

where

$$P = -(a_{001} - d_{01}). \tag{2.2.12}$$

Substituting (2.2.5) into (2.2.4) yields $d_{01} = -b_{101}/2b_{200}$. Thus

$$\Delta \mu_n^{r \to s}(\lambda) = \frac{1}{P} I_n^{r \to s}(\lambda, \mu_{ss}(\lambda)) + \text{h.o.t.}, \tag{2.2.13}$$

where, as before, by h.o.t. we mean terms of higher order than that of the leading term of the quantity to the left. Next we obtain a recursion relation for the $\{I_n^{r\to s}(\lambda, \mu_{ss})\}$ using (2.2.8):

$$\begin{aligned} I_{n+1}^{r\to s}(\lambda,\mu) &= (fg)^{n+1} f(r,\lambda,\mu) - s \\ &= fg(fg)^n f(r,\lambda,\mu) - s \\ &= fg(I_n^{r\to s}+s,\lambda,\mu) - s. \end{aligned} \tag{2.2.14}$$

Expanding, we obtain

$$\begin{aligned} I_{n+1}^{r\to s}(\lambda,\mu_{ss}) &= fg(s(\lambda,\mu_{ss}) + I_n^{r\to s}(\lambda,\mu_{ss}),\lambda,\mu_{ss}) - s(\lambda,\mu_{ss}) \\ &= Q\lambda(I_n^{r\to s}(\lambda,\mu_{ss}))^2 + O(\lambda^2)(I_n^{r\to s}(\lambda,\mu_{ss}))^2 + O((I_n^{r\to s}(\lambda,\mu_{ss}))^4) \end{aligned} \tag{2.2.15}$$

(recall that s is a turning point of fg that is quadratic except at $0=\lambda=\mu_{ss}(0)$ where it is quartic) where, by substituting into (2.2.3), it is found that

$$Q = b_{200}[e_1(2a_{200}b_{001} + a_{101}) + 2a_{200}b_{010} + a_{110}]. \tag{2.2.16}$$

From the definition of μ_{ss} (2.2.6a),

$$e_1 = -(a_{010} - d_{10})/(a_{001} - d_{01}), \tag{2.2.17}$$

where, from the definition of s (2.2.5), $d_{10} = -b_{110}/2b_{200}$. Combining the two results (2.2.13) and (2.2.15), we obtain a recursion relation for the deviations $\{\Delta\mu_n^{r\to s}(\lambda)\}$:

$$\begin{aligned} \Delta\mu_{n+1}^{r\to s}(\lambda) &= \frac{1}{P} I_{n+1}^{r\to s}(\lambda,\mu_{ss}) + \text{h.o.t.} \\ &= \frac{Q}{P}\lambda[I_n^{r\to s}(\lambda,\mu_{ss})]^2 + \text{h.o.t.}, \\ &= \frac{Q}{P}\lambda[P\Delta\mu_n^{r\to s}(\lambda)]^2 + \text{h.o.t.}, \\ &= PQ\lambda[\Delta\mu_n^{r\to s}(\lambda)]^2 + \text{h.o.t.} \end{aligned} \tag{2.2.18}$$

The first element of this sequence, $\Delta\mu_0^{r\to s}(\lambda)$, may be evaluated directly from (2.2.3), (2.2.9), and (2.2.13) as

$$\Delta\mu_0^{r\to s}(\lambda) = \frac{R^2}{S}\lambda^2 + O(\lambda^3), \tag{2.2.19}$$

where

$$\begin{aligned} R = {} & +4b_{200}b_{001}a_{200}a_{010} + 2b_{200}a_{101}a_{010} - 4a_{200}a_{001}b_{200}b_{010} - 2a_{200}b_{101}b_{010} \\ & + 2a_{200}b_{110}b_{001} + a_{101}b_{110} - 2b_{200}a_{110}a_{001} - b_{101}a_{110}, \end{aligned} \tag{2.2.20}$$

and

$$S \equiv 2\frac{a_{200}}{b_{200}}[a_{001}^2 b_{200}^2(12b_{101} + 8a_{001}b_{200}) + b_{101}^2(6a_{001}b_{200} + b_{101})]. \tag{2.2.21}$$

Noting that in fact $PQ = R/2$, we have finally that

$$\Delta\mu_n^{r\to s}(\lambda) = \frac{2}{R}\left[\frac{R^3}{2S}\right]^{2^n} \lambda^{3(2^n)-1} + \text{h.o.t.} \tag{2.2.22}$$

So we find that the leading orders of the deviations $\{\Delta\mu_n^{r\to s}(\lambda)\}$ are λ^2, λ^5, λ^{11}, $\lambda^{23}, \cdots$, for $n=0, 1, 2, 3, \cdots$: all odd powers for $n>0$. Moreover, the sign of the leading order coefficients for $n>0$ are all the same: the sign of R. This means that if we consider the quadrants into which the neighborhood of the χ-point is divided by the bones $\mu_{ss}(\lambda)$, $\mu_{rr}(\lambda)$ (note that $e_1 \neq \overline{e_1}$ generically), the $r\to s$ ligaments for $n>0$ run from one quadrant to the opposing one and, as n increases, accumulate on $\mu_{ss}(\lambda)$, just as depicted in Fig. 2(b). The $n=0$, or causative, ligament is quadratically tangent to the bone (thus occupying a pair of adjacent quadrants).

By symmetry, the results derived for the $r\to s$ ligaments and the s-bone apply equally to the $s\to r$ ligaments and the r-bone; the analogous quantitative relations are obtained by interchanging the coefficients $\{a_{ijk}\}\leftrightarrow\{b_{ijk}\}$.

To complete the analysis we first observe that for $n>0$, the sign of $\Delta\mu_n^{r\to s}(\lambda)\Delta\mu_n^{s\to r}(\lambda)=\Delta\mu_n^{r\to s}(\lambda)\overline{\Delta\mu_n^{r\to s}(\lambda)}$ is the sign of $R\bar{R}$. But R is, by inspection, antisymmetric under the interchange operation. Therefore

$$R\bar{R}\leqq 0. \tag{2.2.23}$$

This result implies that the bundles of ligaments given by $\mu_n^{r\to s}(\lambda)$ and $\mu_n^{s\to r}(\lambda)$, $n>0$, occupy the same pair of quadrants, leaving two quadrants unoccupied by ligaments with $n>0$.

To determine the relative placement of the $n=0$ (causative) ligaments, we consider the product of coefficients:

$$[\mu_0^{r\to s}(\lambda)-\mu_0^{s\to r}(\lambda)]\Delta\mu_1^{r\to s}(\lambda)\Delta\mu_0^{r\to s}(\lambda)\overline{\Delta\mu_0^{r\to s}(\lambda)}=T\lambda^{10}+O(\lambda^{11}), \tag{2.2.24}$$

where

$$\begin{aligned} T&=(e_1-\overline{e_1})\frac{R}{2}\left(\frac{R^2}{S}\right)^2\frac{R^2}{S}\frac{\bar{R}^2}{\bar{S}}\\ &=(e_1-\overline{e_1})\frac{R}{2}\frac{1}{S\bar{S}}\frac{R^4}{S^2}\bar{R}^2. \end{aligned} \tag{2.2.25}$$

But from (2.2.17),

$$(e_1-\overline{e_1})=-\frac{R}{U}, \tag{2.2.26}$$

where

$$U=[4a_{200}a_{001}b_{200}b_{001}+2a_{101}a_{001}b_{200}+a_{101}b_{101}+2b_{101}b_{001}a_{200}], \tag{2.2.27}$$

and from (2.2.21),

$$S\bar{S}=4U^3, \tag{2.2.28}$$

whence

$$T=-\frac{1}{8}\left[\frac{R^4\bar{R}}{SU^2}\right]^2\leqq 0. \tag{2.2.29}$$

Examination of Fig. 2(b) shows that any arrangement of the curves which is in accord with the result $R\bar{R}\leqq 0$, but which is qualitatively different from that shown (other than in orientation with respect to the λ, μ axes, and the sign of T is invariant under such orientation changes) will contradict $T\leqq 0$. Thus the qualitative arrangement of the ligaments and bones is universal, and is as specified in Theorem 2. □

2.3. The ψ-point. The intersection of a ligament with a bone that is associated with the terminal turning point of the ligament's itinerary, a situation such as the one

sketched in Fig. 1(c), constitutes the third kind of singular point of the parameter plane that we consider. We show below that such a point is the source of a bundle of additional ligaments. As in the case of the χ-point, for purposes of construction of the skeleton we consider the intersection of the ligament and bone to be "causative" of the bundle of additional ligaments, but for analytical convenience we define the point as follows.

DEFINITION. A point (λ_0, μ_0) of the parameter plane of the map $\Phi(x, \lambda, \mu)$ is a *ψ-point* if there exist v, $p \in \mathbb{N}$ such that $\Phi^v(r_0, \lambda_0, \mu_0) = s_0$, $\Phi^p(s_0, \lambda_0, \mu_0) = s_0$, where r_0, s_0 are (distinct) quadratic turning points of $\Phi(x, \lambda_0, \mu_0)$, and there does not exist $w(<p) \in \mathbb{N}$ such that $\Phi^w(s_0, \lambda_0, \mu_0) = r_0$.

The existence of the causative ligament and bone, as well as of the bundle of additional ligaments, follows from this definition as we demonstrate below. The additional ligaments correspond to itineraries that at the ψ-point are degenerate and consist of the direct inter-turning-point itinerary plus a some number of circuits around the superstable cycle. Figure 3(c) sketches the situation near a ψ-point on one such ligament.

THEOREM 3. *Let (λ_0, μ_0) be a ψ-point of $\Phi(x, \lambda, \mu)$ for which the turning points are r_0 and s_0, and let $v = \min(v' \in \mathbb{N} | \Phi^{v'}(r_0, \lambda_0, \mu_0) = s_0)$ and $p = \min(p' \in \mathbb{N} | \Phi^{p'}(s_0, \lambda_0, \mu_0) = s_0)$. Generically, a sufficiently small parameter-plane circle centered at (λ_0, μ_0) is intersected (transversally) by ligaments $\{\mathscr{L}_n^{r\to s}\}$, $n = 0, 1, 2, \cdots$, corresponding to itineraries of lengths $v + np$ from turning point r to turning point s, and by a bone $\mathscr{B}^s$ corresponding to a superstable cycle containing s, in the following (cyclic) order: $\mathscr{L}_0^{r\to s}$, $\mathscr{B}^s, \cdots, \mathscr{L}_3^{r\to s}$, $\mathscr{L}_2^{r\to s}$, $\mathscr{L}_1^{r\to s}$, $\mathscr{L}_0^{s\to r}$, $\mathscr{L}_1^{r\to s}$, $\mathscr{L}_2^{r\to s}$, $\mathscr{L}_3^{r\to s}, \cdots, \mathscr{B}^s$. In other words, the generic unfolding of a ψ-point is qualitatively as depicted in the sketch of Fig.* 2(c).

In Fig. 2(c) the unbroken curve represents the bone, and in the bundle of ligaments the ones corresponding to longer itineraries are closer to the bone. The asterisk corresponds to a situation like that depicted in Fig. 3(c).

Proof of Theorem 3. At $\lambda = \mu = 0$ let there exist an itinerary of length v between turning points of the map $\Phi(x, \lambda, \mu)$ and a superstable cycle of period p that includes the terminal turning point of that itinerary:

$$\Phi^v(r_0, 0, 0) = s_0, \qquad \Phi^p(s_0, 0, 0) = s_0 \tag{2.3.1}$$

(with v, p the smallest numbers satisfying these equations) where

$$\frac{\partial \Phi}{\partial x}(r_0, 0, 0) = \frac{\partial \Phi}{\partial x}(s_0, 0, 0) = 0, \quad \frac{\partial^2 \Phi}{\partial x^2}(r_0, 0, 0) \neq 0, \quad \frac{\partial^2 \Phi}{\partial x^2}(s_0, 0, 0) \neq 0. \tag{2.3.2}$$

In a fashion similar to that of § 2.2, we write the v- and p-fold composites of Φ as

$$\begin{aligned} f(x, \lambda, \mu) &= \Sigma a_{ijk} x^i \lambda^j \mu^k \equiv \Phi^v(r_0 + x, \lambda, \mu), \\ g(x, \lambda, \mu) &= \Sigma b_{ijk} x^i \lambda^j \mu^k \equiv \Phi^p(s_0 + x, \lambda, \mu), \end{aligned} \tag{2.3.3}$$

with $a_{000} = b_{000} = a_{100} = b_{100} = 0$ from (2.3.2), and the analytic functions $r(\lambda, \mu)$, $s(\lambda, \mu)$, representing the two turning points, defined, respectively, by

$$\frac{\partial f}{\partial x}(r(\lambda, \mu), \lambda, \mu) = 0, \qquad \frac{\partial g}{\partial x}(s(\lambda, \mu), \lambda, \mu) = 0 \tag{2.3.4}$$

(and guaranteed, respectively, by $a_{200} \neq 0$, $b_{200} \neq 0$) as

$$r(\lambda, \mu) = \Sigma c_{jk} \lambda^j \mu^k, \qquad s(\lambda, \mu) = \Sigma d_{jk} \lambda^j \mu^k \tag{2.3.5}$$

($c_{00} = d_{00} = 0$). The existence of a bone associated with s, represented by the function $\mu_{ss}(\lambda)$ that satisfies

$$g(s(\lambda, \mu_{ss}(\lambda)), \lambda, \mu_{ss}(\lambda)) - s(\lambda, \mu_{ss}(\lambda)) = 0, \tag{2.3.6}$$

is guaranteed by the generic inequality of b_{001} and d_{01}. We expand $\mu_{ss}(\lambda)$ as

$$\mu_{ss}(\lambda) = \Sigma e_j \lambda^j. \tag{2.3.7}$$

We then define for $n = 0, 1, 2, \cdots$

$$I_n^{r\to s}(\lambda, \mu) \equiv g^n f(r, \lambda, \mu) - s. \tag{2.3.8}$$

Since $\partial I_n^{r\to s}(0, 0)/\partial\mu = a_{001} - d_{01}$ (for all n) is generically nonzero, we are guaranteed, for each n, a ligament represented by the unique function $\mu_n^{r\to s}(\lambda)$ that satisfies

$$I_n^{r\to s}(\lambda, \mu_n^{r\to s}(\lambda)) = 0. \tag{2.3.9}$$

We write the deviations of the ligaments from the bone as

$$\Delta\mu_n^{r\to s}(\lambda) \equiv \mu_n^{r\to s}(\lambda) - \mu_{ss}(\lambda). \tag{2.3.10}$$

As before, we compute the leading terms of these deviations. Setting $n = 0$ in (2.3.10), substituting the series expansions for the various quantities, and collecting coefficients yields

$$\Delta\mu_0^{r\to s}(\lambda) = \frac{R}{S}\lambda + O(\lambda^2), \tag{2.3.11}$$

where

$$R = 2b_{200}[2b_{200}(a_{001}b_{010} - b_{001}a_{010}) + b_{110}(a_{001} - b_{010}) - b_{101}(a_{010} - b_{010})], \tag{2.3.12}$$

and

$$S = (2b_{200}a_{001} + b_{101})(2b_{200}b_{001} + b_{101}). \tag{2.3.13}$$

A recursion relation is obtained as follows:

$$\begin{aligned} 0 \equiv I_n^{r\to s}(\lambda, \mu_n^{r\to s}(\lambda)) &= I_n^{r\to s}(\lambda, \mu_{ss}(\lambda) + \Delta\mu_n^{r\to s}(\lambda)), \\ &= I_n^{r\to s}(\lambda, \mu_{ss}(\lambda)) - P_n\Delta\mu_n^{r\to s}(\lambda) + O(\lambda)\Delta\mu_n^{r\to s}(\lambda) + O((\Delta\mu_n^{r\to s}(\lambda))^2), \end{aligned} \tag{2.3.14}$$

where

$$P_n = \begin{cases} -(a_{001} - d_{01}), & n = 0, \\ -(b_{001} - d_{01}), & n > 0, \end{cases} \tag{2.3.15}$$

and $d_{01} = -b_{101}/2b_{200}$. Thus

$$\Delta\mu_n^{r\to s}(\lambda) = \frac{1}{P_n} I_n^{r\to s}(\lambda, \mu_{ss}(\lambda)) + \text{h.o.t.} \tag{2.3.16}$$

We have also that

$$\begin{aligned} I_{n+1}^{r\to s}(\lambda, \mu) &= g^{n+1} f(r, \lambda, \mu) - s \\ &= g g^n f(r, \lambda, \mu) - s \\ &= g(I_n^{r\to s} + s, \lambda, \mu) - s. \end{aligned} \tag{2.3.17}$$

Thus

$$\begin{aligned} I_{n+1}^{r\to s}(\lambda, \mu_{ss}) &= g(s(\lambda, \mu_{ss}) + I_n^{r\to s}(\lambda, \mu_{ss}), \lambda, \mu_{ss}) - s(\lambda, \mu_{ss}) \\ &= Q[I_n^{r\to s}(\lambda, \mu_{ss})]^2 + O(\lambda^2)[I_n^{r\to s}(\lambda, \mu_{ss})]^2 + O([I_n^{r\to s}(\lambda, \mu_{ss})]^4), \end{aligned} \tag{2.3.18}$$

where

$$Q = b_{200}. \tag{2.3.19}$$

(Recall that s is a turning point of g that is quadratic even at $\lambda = \mu = 0$.) We thus obtain

$$\begin{aligned}
\Delta\mu_{n+1}^{r\to s}(\lambda) &= \frac{1}{P_{n+1}} I_{n+1}^{r\to s}(\lambda, \mu_{ss}) + \text{h.o.t.} \\
&= \frac{Q}{P_{n+1}} \lambda [I_n^{r\to s}(\lambda, \mu_{ss})]^2 + \text{h.o.t.} \\
&= \frac{Q}{P} \lambda [P_n \Delta\mu_n^{r\to s}(\lambda)]^2 + \text{h.o.t.} \\
&= \begin{cases} \dfrac{Q}{P_1} P_0^2 \lambda [\Delta\mu_n^{r\to s}(\lambda)]^2 + \text{h.o.t.}, & n = 0, \\ P_1 Q \lambda [\Delta\mu_n^{r\to s}(\lambda)]^2 + \text{h.o.t.}, & n > 0. \end{cases}
\end{aligned} \tag{2.3.20}$$

And finally,

$$\Delta\mu_n^{r\to s}(\lambda) = \begin{cases} \dfrac{R}{S}\lambda + O(\lambda)^2, & n = 0, \\ \left[\dfrac{(P_1 Q)^{2^{n-1}}}{P_1 Q}\right]\left[\dfrac{Q}{P_1}\right]^{2^{n-1}}\left[\dfrac{P_0 R}{S}\right]^{2^n} \lambda^{2^n} + O(\lambda^{2^n+1}), & n > 0. \end{cases} \tag{2.3.21}$$

The $n = 0$ result indicates the generic transversal intersection of the ligament and bone which we think of as causing the ψ-point. The leading orders of the $\{\Delta\mu_n^{r\to s}(\lambda)\}$ representing the ligaments which emanate from the ψ-point are $\lambda^2, \lambda^4, \lambda^8, \lambda^{16}, \cdots$ for $n = 1, 2, 3, 4, \cdots$: all even powers. The sign of the leading order coefficients for $n > 0$ are all the same: the signs of $P_1 Q$. (Note that for $n = 1$, it is the sign of Q/P_1, which is of course the same.) Thus the qualitative arrangement of the ligaments and bones is universal, and is as specified in Theorem 3. □

3. Extending the bones and ligaments away from the neighborhood of their point of origin. Having determined the manner in which bones and ligaments originate, we now consider the rules which govern their behavior *away* from their points of origin, and examine the consequences.

In the present paper we restrict our attention to "full" two-parameter families of maps.

DEFINITION. A two-parameter family of two-extremum maps is *full* if there is complete transversal self-intersection of the ligament bundle emanating from an α-point.

The cubic family $\Phi(x, \lambda, \mu) = x^3 - \lambda x + \mu$, for example, with α-point at $\lambda = \mu = 0$, is full. The ligaments emanating from an α-point of a full family are sketched in Fig. 4(a). The χ-points caused by the intersections of these ligaments are marked by large dots. We can proceed with the derivation of the qualitative form of the rest of the skeleton by adding, according to the local rules derived in § 2, the bones and secondary ligaments that originate from each χ-point. The addition of the ligaments generates additional χ-points, and ψ-points are generated by the addition of the bones. Then at each of these points, the emanating bones and/or ligaments are again added. This procedure has a topologically unique result (independent of the order in which we choose to deal with the χ- and ψ-points) if, following [2], we insist that the family is "nice."

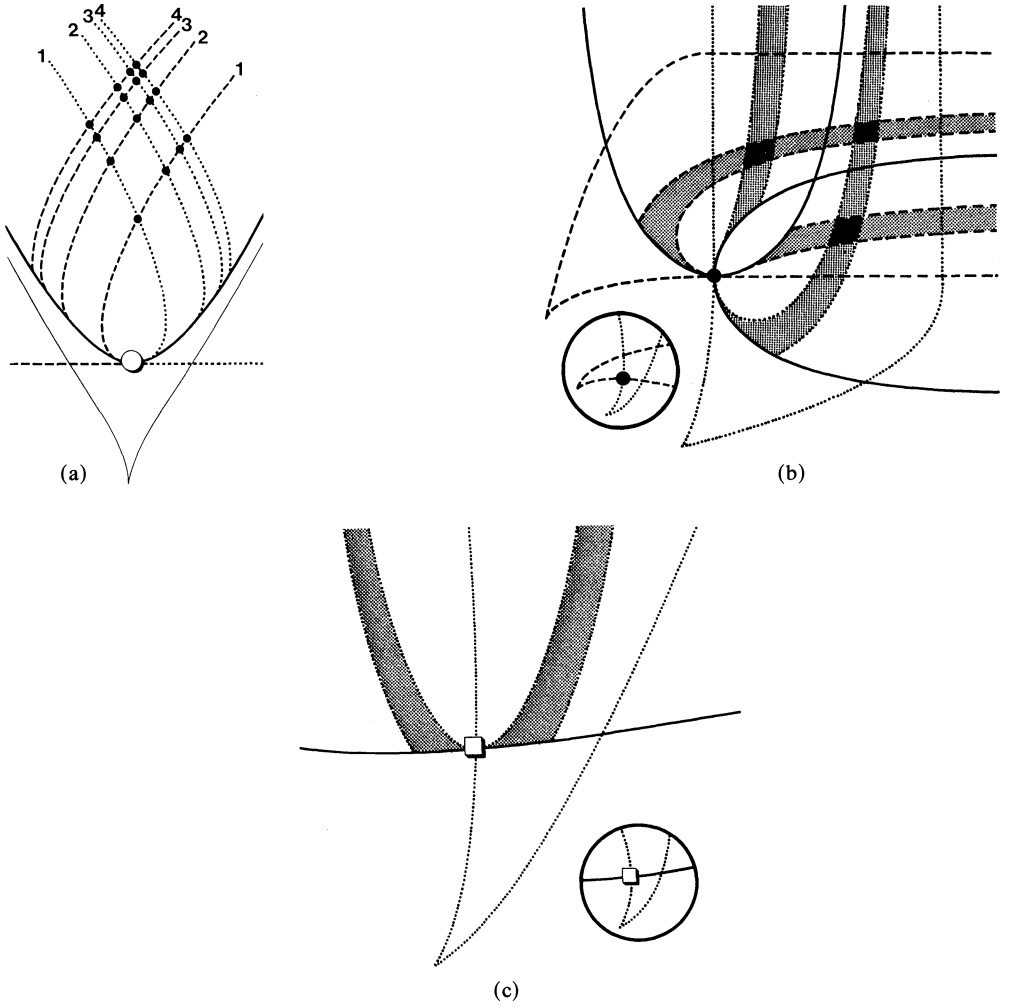

FIG. 4. (a) *A "full" two-parameter family of maps: the ligament bundle (broken curves) emanating from the α-point intersects itself completely (only first four ligaments shown) and transversally. This diagram is the starting point for the construction of the skeleton pursued in Fig. 5. The unbroken curve is the period-1 bone, as in Fig.* 2(a). *The thin* v*-shaped curve is a locus of tangent bifurcation which is commonly present (see* [1], *for example).* (b) *Inset: environment of every χ-point in Fig.* 4(a). *Main figure: necessary paths of ligaments and bones emanating from a χ-point situated as in the inset. The shaded bands represent the ligament bundles.* (c) *Inset: environment of every ψ-point in Fig.* 4(b). *Main figure: necessary paths of ligaments and bones emanating from a ψ-point situated as in the inset. The shaded band represents the ligament bundle.*

DEFINITION. A two-parameter family is *nice* if each bone and ligament has only one point of origin in the sense of § 2 (cf. [2]).

This property, which is imposed to guarantee that things are as simple as possible, implies the following:

(1) Two ligaments of the same type may not touch except at the point of origin of at least one of them, for it can easily be shown that a point of coincidence of two ligaments of the same type is necessarily an α-, χ-, or ψ-point; and

(2) Away from its point of origin, a bone may not touch a ligament whose itinerary begins at the turning point with which the bone is associated, for such a point of coincidence would necessarily be another χ-point of origin of the bone.

TABLE 1
Rules of contact and intersection of curves (r denotes one turning point, s the other).

	$s \to r$ ligament	$r \to s$ ligament	r-bone	s-bone
r-bone	ψ-point	forbidden[2]	forbidden	unrestricted[3]
$s \to r$ ligament	forbidden[1]	χ-point		

[1] By niceness, unless point of origin of at least one of the ligaments.
[2] Other than at χ-point of origin of bone.
[3] May be χ-point of origin of the bones, otherwise no interaction.

Additionally, it is a proximate consequence of the implicit function theorem that (without assumption) the coincidence of two bones associated with the same turning point is structurally unstable in two-parameter families. So generically no two bones associated with the same turning point intersect or touch. On the other hand, two bones can cross with no restriction and no interaction if they are associated with different turning points.

The rules of contact and interaction of bones and ligaments we have established are summarized in Table 1, and are sufficient to guide the construction of the skeleton unambiguously, as is now explained. We start with Fig. 4(a). Consider that the environment of each χ-point in Fig. 4(a) is as depicted in the circular inset of Fig. 4(b). That is, each causative ligament is intersected "downstream" by a ligament which has the same point of origin as the other causative ligament. We make three observations. First, of the two ways that the local picture of Fig. 2(b) can be oriented at the marked χ-point, only one does not lead to a conflict with the "crossability" rules described above when the emanating curves are extended; a ligament or bone cannot emanate into a sealed box of uncrossable walls. The unique orientation that is possible is as sketched in the main part of Fig. 4(b), where the shaded bands represent the bundles of emanating ligaments. Second, the way the emanating curves are extended in Fig. 4(b) away from the locality of the χ-point is the only way of reconciling the local picture with the crossability rules. Third, the environment of every additional χ-point caused by the emanating ligaments is exactly analogous to that of the marked χ-point in the inset; the same arguments thus apply to the curves emanating from these points.

Similarly, consider that the environment of each ψ-point generated by the introduction of the bones in Fig. 4(b) is as depicted in the circular inset of Fig. 4(c). That is, it has a neighboring ψ-point, with common bone, whose causative ligament has the same point of origin as its own. The ψ-point's ligament bundle cannot emanate "downwards" into the sealed trilateral box, but must emanate "upwards" as sketched in the main part of Fig. 4(c). (The shaded band represents the bundle of emanating ligaments.) All the χ-points and additional ψ-points caused by the ligaments emanating from the ψ-point again have environments analogous to those depicted in the insets of Figs. 4(b) and 4(c), respectively, and so the above arguments apply recursively to all the χ- and ψ-points generated. Thus if we start with Fig. 4(a), and follow the rules described, a topologically unique network of bones and ligaments will be generated.

In Fig. 5 we show this network constructed as far as to include all bones up to period 6. (A true sketch was drawn according to the rules: the figure as presented is a fair copy of that sketch with the spacing of the curves adjusted for better clarity.) A subset of this picture (bones up to period 5, no ligaments) was generated by Mackay and Tresser [2] following an entirely different procedure based on ordering of kneading

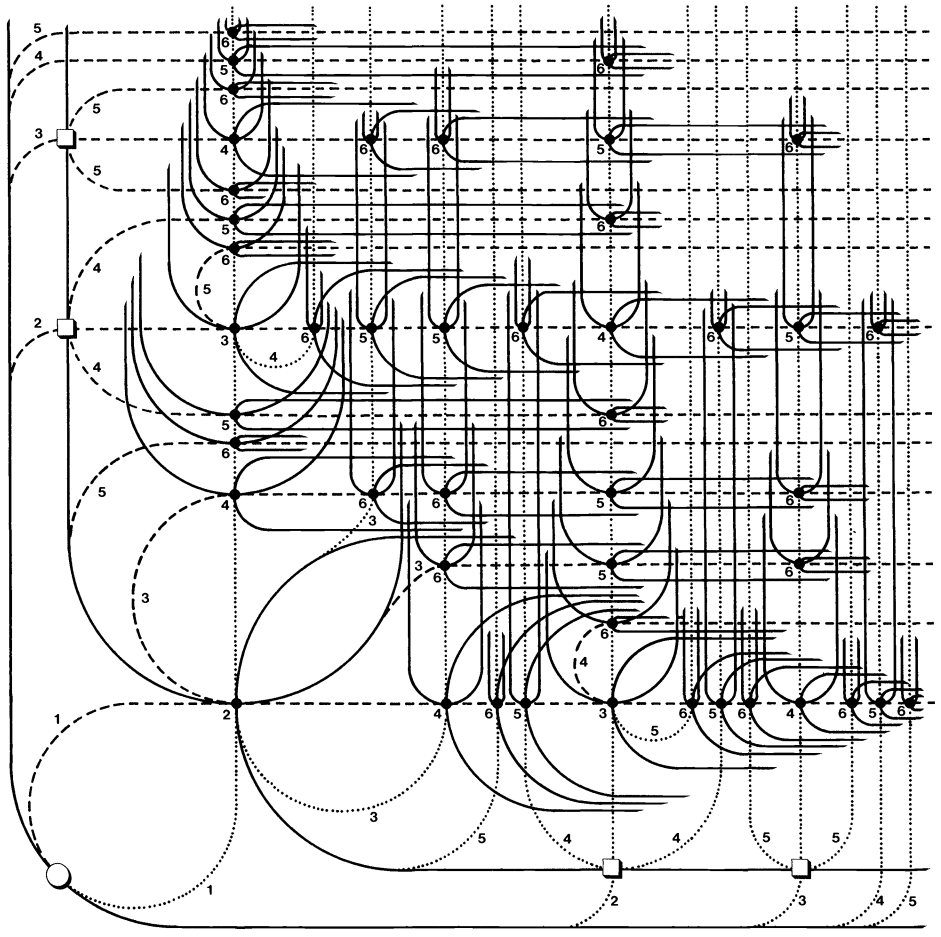

FIG. 5. *The skeleton of bones and ligaments constructed, according to the rules developed, to the extent of including every bone of period* 6 *and less. The figure constitutes a genealogy of the cycles. The length of the itinerary associated with each ligament, and the period of the cycle associated with each* χ*-point and its emanating bones, are marked. The reader is invited to check the arithmetic of these numbers. The same symbols as before are used for the* α*-,* χ*-, and* ψ*-points. (Only four* ψ*-points participate at this level; this number increases greatly if period-*7 *bones are to be included.) In order to avoid a dense mass of bones at the upper right, bones are produced only as far as is necessary to visually establish their positions relative to other bones.*

sequences. Bones of the inadmissible cycles of [2] do not arise in our construction simply because the loci (ligaments) of the would-be constituent kneading sequences do not get an opportunity to intersect, due to the relative positions of their (α-, χ-, or ψ-) points of origin.

Of the numerous interesting structural features of the skeleton of bones and ligaments, we mention two. One is the substructure responsible for the *U*-sequence [5] of doubly superstable (χ-) points which occurs along each causative ligament of every doubly superstable point. The lexical self-similarity of the U-sequence is reflected in structural self-similarity of the parameter-plane skeleton. This can be seen, for example, in Fig. 5 on either of the ligaments of itinerary length 1 that emanate from the α-point. Consider the U-sequence based on the period-2 χ-point and the one based

on the neighboring period-4 χ-point. The ligaments (itinerary lengths 3, 5, (7, 9, $\cdots$)) emanating from the period-2 χ-point can be seen to play the role for the latter analogous to that played for the former by the ligaments (itinerary lengths 1, 2, 3, 4, $\cdots$) emanating from the α-point. A more extensive development of the U-sequence substructure appears in Fig. 5 of [9], where the results of the present paper, Theorems 2 and 3, are used. A second self-similar substructure of the bone-and-ligament skeleton is the two-parameter Farey tree, as developed in [9] using Theorem 2 of the present paper.

The great ease of constructing the parameter-plane skeleton using our method is a facet of the method's value.[3] But more significant is that the genealogy of the cycles is realized and manifest in our skeleton of bones and ligaments, and that the emergence of the global structure upon the application of local rules offers a new perspective on the dynamics of two-extremum maps.

Acknowledgment. The authors thank C. Frenzen for useful discussions.

CONSTRUCTING SYMMETRIC NONNEGATIVE MATRICES WITH PRESCRIBED EIGENVALUES BY DIFFERENTIAL EQUATIONS*

MOODY T. CHU† AND KENNETH R. DRIESSEL‡

Abstract. The inverse eigenvalue problem is solved for symmetric nonnegative matrices by means of a differential equation. If the given spectrum is feasible, then a symmetric nonnegative matrix can be constructed simply by following the solution curve of the differential system. The choice of the vector field is based on the idea of minimizing the distance between the cone of symmetric nonnegative matrices and the isospectral surface determined by the given spectrum. The projected gradient of the objective function is explicitly described. Using center manifold theory, it is also shown that the ω-limit set of any solution curve is a single point. Some numerical examples are presented.

Key words. nonnegative matrix, eigenvalue, projected gradient, stable manifold

AMS(MOS) subject classifications. 58F10, 49D10, 15A18, 65F15

1. Introduction.

A matrix $A \in R^{n\times n}$ is said to be nonnegative if no entry of A is negative. Nonnegative matrices arise frequently in various applied areas [3]. The Perron–Frobenius theorem concerning the spectrum of nonnegative matrices may be regarded as the central result in the theory of nonnegative matrices. It is, therefore, of great interest to study the following inverse eigenvalue problem.

PROBLEM 1. *Given a set $\sigma := \{\lambda_1, \cdots, \lambda_n\} \subset C$, find necessary and sufficient conditions for σ to be the spectrum of some nonnegative matrix.*

In practice, the prescribed eigenvalues $\lambda_1, \cdots, \lambda_n$ often are real numbers. Thus it is also interesting to ask the following.

PROBLEM 2. *Given a set $\sigma = \{\lambda_1, \cdots, \lambda_n\} \subset R$, find necessary and sufficient conditions for σ to be the spectrum of some symmetric nonnegative matrix.*

For decades researchers have been trying to answer these problems. A few necessary and a few sufficient conditions can be found, for example, in [2], [10]–[14], [16], [18], or more recently in [4]. To our knowledge, however, neither Problem 1 nor Problem 2 has been completely solved.

In this paper we want to address the problem of constructing a nonnegative matrix with prescribed spectrum. The problem is stated as follows.

PROBLEM 3. *Given a set σ of n real values that is known a priori to be the spectrum of some nonnegative matrix, numerically construct a symmetric nonnegative matrix whose spectrum is exactly σ.*

We have not found much discussion of Problem 3 in the literature. The most constructive result we have seen is the sufficient condition studied by Soules [18]. But Soules' condition is still limited because his construction depends on the specification of the Perron eigenvector—in particular, the components of the Perron eigenvector need to satisfy certain inequalities in order for his construction to work.

For our consideration, we shall need the following notation. Let $\mathcal{O}(n)$ denote the set of all orthogonal matrices in $R^{n\times n}$. Let Λ denote the diagonal matrix with

diagonal entries $\lambda_1, \cdots, \lambda_n$; in symbols,

$$\Lambda := \operatorname{diag}\{\lambda_1, \cdots, \lambda_n\}. \tag{1}$$

The set

$$\mathcal{M}(\Lambda) := \{Q^T \Lambda Q | Q \in \mathcal{O}(n)\} \tag{2}$$

will be called the isospectral surface corresponding to Λ. Although the assumption is not required in our discussion, it can be shown that $\mathcal{M}(\Lambda)$ is indeed a smooth manifold with dimension $n(n-1)/2$ if all λ_i are distinct. The set of all symmetric nonnegative matrices in $R^{n\times n}$ is denoted by $\pi_s(R_+^n)$. We note that Problem 2 is equivalent to the following.

PROBLEM 2′. *Find necessary and sufficient conditions for the intersection of the isospectral surface $\mathcal{M}(\Lambda)$ and the cone $\pi_s(R_+^n)$ to be nonempty.*

Thus we are motivated to explore the idea of developing a way to systematically reduce the distance between $\pi_s(R_+^n)$ and $\mathcal{M}(\Lambda)$. If $\mathcal{M}(\Lambda)$ does intersect $\pi_s(R_+^n)$, then, of course, the distance is zero. Otherwise, our approach still finds a matrix from $\mathcal{M}(\Lambda)$ and a matrix from $\pi_s(R_+^n)$ such that their distance is a local minimum. In the latter case, the matrix from $\pi_s(R_+^n)$ is expected to be on a face of the cone $\pi_s(R_+^n)$, i.e., some of the entries of the nonnegative matrix are zero. We shall see that this property indeed shows up naturally in the development of our theory. Another fact, obvious from the geometry, is also worth mentioning: if $\mathcal{M}(\Lambda)$ intersects $\pi_s(R_+^n)$ at an interior point, then $\mathcal{M}(\Lambda)$ intersects $\pi_s(R_+^n)$ in a relative neighborhood of that point. In this case there are infinitely many symmetric nonnegative matrices corresponding to the given spectrum.

We can precisely formulate our idea as a constrained optimization problem. We first note that the set $\pi(R_+^n)$ of all nonnegative matrices in $R^{n\times n}$ can be formed as

$$\pi(R_+^n) = \{B * B | B \in R^{n\times n}\}, \tag{3}$$

where $X * Y$ denotes the Hadamard product of matrices X and Y. Let $\mathcal{S}(n)$ denote the set of all symmetric matrices in $R^{n\times n}$. Let

$$\langle A, B\rangle := \operatorname{trace}(AB^T) = \sum_{i,j} a_{ij} b_{ij} \tag{4}$$

denote the Frobenius inner product of two matrices $A, B \in R^{n\times n}$. We shall consider the following minimization problem.

PROBLEM 4. *Minimize*

$$F(Q, R) := \tfrac{1}{2}\|Q^T \Lambda Q - R * R\|^2, \tag{5}$$

subject to

$$(Q, R) \in \mathcal{O}(n) \times \mathcal{S}(n),$$

where $\|\cdot\|$ represents the Frobenius matrix norm. We shall show that the projection of the gradient vector of the objective function F onto the manifold $\mathcal{O}(n) \times \mathcal{S}(n)$ can be calculated explicitly. Consequently, we can introduce a steepest descent vector field on $\mathcal{O}(n) \times \mathcal{S}(n)$. This vector field can easily be transformed into a "flow" on the isospectral surface $\mathcal{M}(\Lambda)$ and a "flow" in the cone $\pi_s(R_+^n)$. Both flows are moving

in the steepest descent direction to minimize their distance until an equilibrium is reached. Our approach to Problem 4, *therefore, is a continuous realization process.*

In our earlier works, we have applied similar ideas to tackle the inverse Toeplitz eigenvalue problems [9] and other least squares matrix approximation problems subject to spectral constraint [8]. Our approach there proves to be quite successful. In this paper, we shall use some of our previously developed ideas. In §2 we develop the differential system; this is our main result. In §3 we use center manifold theory to study the stability properties of the resulting differential system. We argue that generically the ω-limit set of a solution flow contains only a single point. This proves the global convergence of our method. In §4, we study in detail the stability of equilibria for the case $n = 2$. Although this represents the simplest case, the stability analysis should shed some light on the behavior of our flow for higher-dimension cases. We present some numerical examples in the last section.

2. Projected gradient. In the product space $R^{n\times n} \times R^{n\times n}$, we shall use the induced Frobenius inner product:

$$\langle (A_1, A_2), (B_1, B_2) \rangle := \langle A_1, B_1 \rangle + \langle A_2, B_2 \rangle. \tag{6}$$

With this topology, the feasible set $\mathcal{O}(n) \times \mathcal{S}(n)$ of Problem 4 is clearly a smooth manifold. It is not difficult to show [8] that the space tangent to $\mathcal{O}(n) \times \mathcal{S}(n)$ at a point $(Q, R) \in \mathcal{O}(n) \times \mathcal{S}(n)$ is given by

$$\mathcal{T}_{(Q,R)}\mathcal{O}(n) \times \mathcal{S}(n) = \mathcal{T}_Q\mathcal{O}(n) \times \mathcal{T}_R\mathcal{S}(n) = Q\mathcal{S}(n)^\perp \times \mathcal{S}(n), \tag{7}$$

where $\mathcal{S}(n)^\perp$ denotes the orthogonal complement of $\mathcal{S}(n)$ and is composed of all skew-symmetric matrices in $R^{n\times n}$.

We first extend the definition of the function F in (5) in an obvious way to the entire space $R^{n\times n} \times R^{n\times n}$. A straightforward calculation shows that the Fréchet derivative of F at a general point $(A, B) \in R^{n\times n} \times R^{n\times n}$ acting on $(H, K) \in R^{n\times n} \times R^{n\times n}$ is

$$\begin{aligned} F'(A,B)(H,K) &= \langle A^T\Lambda A - B * B, H^T\Lambda A + A^T\Lambda H - K * B - B * K \rangle \\ &= \langle \Lambda A[(A^T\Lambda A - B * B)^T + (A^T\Lambda A - B * B)], H \rangle \\ &\quad + \langle -2(A^T\Lambda A - B * B) * B, K \rangle. \end{aligned} \tag{8}$$

The adjoint property $\langle A, BC \rangle = \langle AC^T, B \rangle = \langle B^T A, C \rangle$ has been used to rearrange terms in (8). It follows that, with respect to the inner product (6), the gradient of F at (A, B) is a pair of matrices; in fact, we have

$$\begin{aligned} \nabla F(A,B) &= \big(\Lambda A[(A^T\Lambda A - B * B)^T + (A^T\Lambda A - B * B)], \\ &\qquad - 2(A^T\Lambda A - B * B) * B\big). \end{aligned} \tag{9}$$

We are interested only in the case when $(A, B) = (Q, R) \in \mathcal{O}(n) \times \mathcal{S}(n)$. In this case, (9) is simplified to

$$\nabla F(Q,R) = (2\Lambda Q(Q^T\Lambda Q - R * R), -2(Q^T\Lambda Q - R * R) * R). \tag{10}$$

We now calculate the projection of $\nabla F(Q, R)$ on the manifold $\mathcal{O}(n) \times \mathcal{S}(n)$. Because we are using a product topology, the projection of $\nabla F(Q, R)$ on $\mathcal{O}(n) \times \mathcal{S}(n)$ is the direct product of the projections of the two components of $\nabla F(Q, R)$ on $\mathcal{O}(n)$

and $\mathcal{S}(n)$, respectively. Each of these projections can be calculated easily. In [8] we presented a simple way to do the projection on $\mathcal{O}(n)$: Since

$$R^{n\times n} = \mathcal{T}_Q\mathcal{O}(n) \oplus \mathcal{N}_Q\mathcal{O}(n) = Q\mathcal{S}(n)^{\perp} \oplus Q\mathcal{S}(n), \tag{11}$$

any matrix $A \in R^{n\times n}$ has a unique orthogonal splitting

$$A = Q\{\tfrac{1}{2}(Q^TA - A^TQ)\} + Q\{\tfrac{1}{2}(Q^TA + A^TQ)\} \tag{12}$$

as the sum of elements from $\mathcal{T}_Q\mathcal{O}(n)$ and $\mathcal{N}_Q\mathcal{O}(n)$. In particular, the projection of $2\Lambda Q(Q^T\Lambda Q - R*R)$ onto $\mathcal{T}_Q\mathcal{O}(n)$ is

$$\begin{aligned}&\tfrac{1}{2}Q\left\{Q^T[2\Lambda Q(Q^T\Lambda Q - R*R)] - [2\Lambda Q(Q^T\Lambda Q - R*R)]^TQ\right\}\\ &\quad = Q\left\{-Q^T\Lambda Q(R*R) + (R*R)Q^T\Lambda Q\right\}.\end{aligned} \tag{13}$$

On the other hand, $\mathcal{S}(n)$ is a vector space already, so the projection of $-2(Q^T\Lambda Q - R*R)*R$ onto $\mathcal{S}(n)$ is just itself. Thus we have found that the projection $g(Q,R)$ of $\nabla F(Q,R)$ onto the manifold $\mathcal{O}(n)\times\mathcal{S}(n)$ is given by the pair of matrices,

$$g(Q,R) = \left(Q\left\{-Q^T\Lambda Q(R*R) + (R*R)Q^T\Lambda Q\right\}, -2(Q^T\Lambda Q - R*R)*R\right). \tag{14}$$

The differential equation

$$\frac{d(Q,R)}{dt} = -g(Q,R), \tag{15}$$

therefore, defines a "steepest" descent vector field on $\mathcal{O}(n)\times\mathcal{S}(n)$ for the objective function $F(Q,R)$.

We now transport the flow (15) to the surface $\mathcal{M}(\Lambda)$ and the cone $\pi_s(R^n_+)$. For $Q(t)\in\mathcal{O}(n)$ and $R(t)\in\mathcal{S}(n)$, let

$$X(t) := Q(t)^T\Lambda Q(t), \tag{16}$$

$$Y(t) := R(t)*R(t). \tag{17}$$

Upon differentiating $X(t)$ and $Y(t)$ with respect to the variable t and using (15), we find that $X(t)$ and $Y(t)$ are governed by the differential system

$$\frac{dX}{dt} = [X,[X,Y]], \tag{18}$$

$$\frac{dY}{dt} = 4Y*(X-Y). \tag{19}$$

In (18) we have used the Lie bracket notation $[A,B] := AB - BA$. Together with an initial value $(X(0),Y(0))\in\mathcal{M}(\Lambda)\times\pi_s(R^n_+)$, we have reformulated Problem 4 as an initial value problem for (X,Y). The initial value problem is readily solved by available software.

The vector field on the right-hand sides of (18) and (19) is well defined for every $(X,Y)\in R^{n\times n}\times R^{n\times n}$. However, it is important to note that we intend to start the flow from an initial value $(X(0),Y(0))$ in $\mathcal{M}(\Lambda)\times\pi_s(R^n_+)$. Then $X(t)\in\mathcal{M}(\Lambda)$ and $Y(t)\in\pi_s(R^n_+)$ throughout the interval of existence. By the way these flows are

constructed, we know both $X(t)$ and $Y(t)$ are bounded and, hence, exist for $t \in [0, \infty)$. In fact, if we define

$$G(t) := F(X(t), Y(t)) = \tfrac{1}{2}\|X(t) - Y(t)\|^2 \geq 0, \tag{20}$$

then it is easy to calculate that

$$\frac{dG}{dt} = -\langle [X, Y], [X, Y] \rangle - 4\langle (X - Y), Y * (X - Y) \rangle \leq 0. \tag{21}$$

According to Lyapunov's second method [5, Thm. 5.5], the limit points of $(X(t), Y(t)) \in \mathcal{M}(\Lambda) \times \pi_s(R_+^n)$ must satisfy the equation $dG/dt = 0$. That is, $(\hat{X}, \hat{Y})$ will be a limit point only if

$$[\hat{X}, \hat{Y}] = 0 \tag{22}$$

and

$$\hat{Y} * (\hat{X} - \hat{Y}) = 0. \tag{23}$$

It is crucial to note from (18) and (19) that the conditions (22) and (23) are also sufficient for the condition that $(\hat{X}, \hat{Y})$ be an equilibrium point for the system. (In fact, if all eigenvalues in σ are distinct, then it can be shown that conditions (22) and (23) are also necessary.) Let

$$\mathcal{L} := \{(X, Y) \in \mathcal{M}(\Lambda) \times \pi_s(R_+^n) | [X, Y] = 0, Y * (X - Y) = 0\}. \tag{24}$$

We conclude that if we start with any $(X(0), Y(0)) \in \mathcal{M}(\Lambda) \times \pi_s(R_+^n)$, then the solution flow $(X(t), Y(t))$ approaches the set $\mathcal{L}$ as $t \longrightarrow \infty$ [5, Lemma 5.4]. That is, for every $\epsilon > 0$, there exists a $T > 0$ such that for every $t > T$ there exist a point $(\hat{X}, \hat{Y}) \in \mathcal{L}$ (possibly depending on t) such that $\|(X(t), Y(t)) - (\hat{X}, \hat{Y})\| < \epsilon$.

The above convergence result is not entirely satisfactory. For example, the flow $(X(t), Y(t))$ might oscillate around a nontrivial limit set. It will be interesting and important if we can show that the ω-limit set of any orbit $(X(t), Y(t))$ contains only a singleton. In the next section we shall use center manifold theory to prove that if the ω-limit set of an orbit $(X(t), Y(t))$ contains a point of the type $(\hat{X}, \hat{X})$, then $(X(t), Y(t))$ indeed converges to $(\hat{X}, \hat{X})$.

For computation, we obviously may choose $X(0) = \Lambda$. We note (using (19)) that if one component of $Y(t)$ is zero, then that component remains zero. For a feasible set of "generic" values, therefore, we should begin the flow $Y(t)$ with an interior point (i.e., a positive matrix) of the cone $\pi_s(R_+^n)$. Other than this restriction, the choice of $Y(0)$ is arbitrary. Different initial values of $Y(0)$ may lead to different limit points. We shall see some numerical examples in the last section.

Finally, we remark that a limit point $\hat{Y}$ of a flow $Y(t)$ could lie in one of the faces of $\pi_s(R_+^n)$ even if the flow starts from the interior of $\pi_s(R_+^n)$. We expect this situation when $\mathcal{M}(\Lambda) \cap \pi_s(R_+^n) = \emptyset$, i.e., when the given spectrum σ is not associated with any element of $\pi_s(R_+^n)$. But the most interesting case occurs when no component of the limit point $\hat{Y}$ is zero. Then, by (23), the symmetric nonnegative matrix $\hat{Y}$ must be the same as the isospectral matrix $\hat{X}$. In this case, we have numerically constructed a symmetric nonnegative matrix that has a prescribed spectrum.

3. Convergence. We have pointed out earlier that the ω-limit set of any orbit $(X(t), Y(t))$ is nonempty and invariant and that the orbit approaches its ω-limit set. In this section we shall take a closer look at the convergence behavior of the solution flow $(X(t), Y(t))$. We first use center manifold theory [6] to study the behavior of $(X(t), Y(t))$ near an equilibrium point. We then argue that the ω-limit set of any orbit $(X(t), Y(t))$ contains only a singleton.

Let $(\hat{X}, \hat{Y})$ be an equilibrium point of the system (18) and (19). If $\hat{X} \neq \hat{Y}$ or if $(\hat{X}, \hat{Y})$ does not belong to $\mathcal{M}(\Lambda) \times \pi_s(R_+^n)$, then we have not yet solved the inverse eigenvalue problem. We shall consider only the opposite case, namely, $\hat{X} = \hat{Y} \in \pi_s(R_+^n)$.

Our first approach is similar to the work done in [7]. For convenience, we first briefly review center manifold theory: Consider the system

$$\frac{dx}{dt} = Ax + f(x, y), \tag{25}$$

$$\frac{dy}{dt} = By + g(x, y), \tag{26}$$

where $x \in R^n$, $y \in R^m$, and A, B are constant matrices such that all eigenvalues of A have zero real parts while all those of B have negative real parts, the functions f and g are C^2 with $f(0,0) = 0, f'(0,0) = 0, g(0,0) = 0$, and $g'(0,0) = 0$. Then there exists an invariant manifold, called the center manifold, for the system (25) and (26). The center manifold is characterized by a C^2 function h from R^n to R^m with the property

$$y = h(x), \quad h(0) = 0, \quad h'(0) = 0. \tag{27}$$

Furthermore, the stability of $(0,0) \in R^n \times R^m$ for the system (25) and (26) is equivalent to the stability of $0 \in R^n$ for the system

$$\frac{dz}{dt} = Az + f(z, h(z)). \tag{28}$$

In addition, if $0 \in R^n$ is stable for (28), then with $(x(0), y(0))$ sufficiently small, there exists a solution $z(t)$ of (28) such that as $t \longrightarrow \infty$,

$$x(t) = z(t) + O(e^{-\mu t}), \tag{29}$$

$$y(t) = h(z(t)) + O(e^{-\mu t}) \tag{30}$$

for some constant $\mu > 0$.

We now apply these results to (18) and (19). Near an equilibrium point $(\hat{X}, \hat{X})$, we define

$$U(t) := X(t) - \hat{X}, \tag{31}$$

$$W(t) := X(t) - Y(t). \tag{32}$$

It is easy to see that (18) and (19) are equivalent to the following equations:

$$\frac{dU}{dt} = [\hat{X}, [W, \hat{X}]] + [U, [W, \hat{X}]] + [\hat{X}, [W, U]] + [U, [W, U]], \tag{33}$$

$$\frac{dW}{dt} = [\hat{X}, [W, \hat{X}]] - 4\hat{X} * W + [U, [W, \hat{X}]] + [\hat{X}, [W, U]] + [U, [W, U]] - 4W * (U - W). \tag{34}$$

Readers should distinguish between the linear and the nonlinear terms in each of the above expressions. We note that (33) is not quite in the same form as (25) since the linear term in (33) is in the variable W. But this discrepancy can easily be fixed through a simple linear transformation. Additionally, we are more interested in knowing whether $W(t)$ converges to zero than what $X(t)$ converges to. Thus we shall not be bothered to perform the transformation explicitly.

Since all underlying matrices are symmetric, it suffices to consider only the upper triangular parts of the matrices. Let Ω be the $n(n+1)/2 \times n(n+1)/2$ matrix representing the upper triangular part of the linear operator $[\hat{X},[W,\hat{X}]] - 4\hat{X} * W$. Applying center manifold theory, we first study the behavior of a solution flow near an equilibrium point.

LEMMA 3.1. *Suppose that all eigenvalues of Ω at an equilibrium point $(\hat{X},\hat{X})$ have negative real part. Then, starting with any matrix $(X(0),Y(0))$ sufficiently close to $(\hat{X},\hat{X})$, the solution flow $(X(t),Y(t))$ of (18) and (19) converges to a constant matrix of the form $(\hat{Z},\hat{Z})$. (Note that $\hat{Z}$ may not be the same as $\hat{X}$.)*

Proof. If all eigenvalues of Ω have negative real part, then obviously (see [6, Thm. 3, p. 5])

$$W \equiv h(U) \equiv 0 \tag{35}$$

is a center manifold for the system (33) and (34). It follows that the corresponding system (28) on the center manifold has constant solution. From (29) and (30), we conclude that $U(t)$ converges to a constant matrix while $W(t)$ converges to the zero matrix as $t \longrightarrow \infty$. We note that center manifold theory does not provide any information regarding which limit point $U(t)$ (and hence $X(t)$) is converging to, although it does guarantee that $X(t)$ and $Y(t)$ are converging to the same point.

The critical supposition that all eigenvalues of Ω have negative real part is difficult to justify in general. Even for the special case $n = 2$ to be discussed in the next section, the explicit expressions for eigenvalues of Ω are very complicated. Nonetheless, we have observed the following fact concerning this supposition.

LEMMA 3.2. *At any equilibrium point $(\hat{X},\hat{X}) \in \mathcal{M}(\Lambda) \times \pi_s(R_+^n)$, no eigenvalue of the corresponding Ω can have positive real part.*

Proof. We recall the definition $W(t) = X(t) - Y(t)$ and the fact that the differential equations (18) and (19) are designed to fulfill the specific purpose of reducing $\|X(t) - Y(t)\|$. Thus the Frobenius norm of the upper triangular part of $W(t)$ cannot grow as a function of t. Since $W(t)$ is related to its derivative by (34), the assertion follows.

In order that some eigenvalues of Ω have zero real parts, the components of $\hat{X}$ must satisfy certain algebraic equations. (Some examples are demonstrated in the next section.) The algebraic constraint, therefore, limits these special matrices, denoted by $(\tilde{X},\tilde{X})$, to a lower dimensional manifold in $\mathcal{M}(\Lambda) \times \pi_s(R_+^n)$. Forming a set of measure zero in the relative topology of $\mathcal{M}(\Lambda) \times \pi_s(R_+^n)$, points like $(\tilde{X},\tilde{X})$ should be regarded as nongeneric. Thus, for *almost all* equilibrium points of the kind $(\hat{X},\hat{X})$, all eigenvalues of the corresponding Ω have negative real part. Lemma 3.1, therefore, serves to explain the generic behavior of the dynamics of (18) and (19).

Near an equilibrium point of the kind $(\tilde{X},\tilde{X})$, the corresponding center manifold becomes much more complicated than (35). However, it can be proved that any flow, starting sufficiently close to $(\tilde{X},\tilde{X})$, still converges to a single point $(\tilde{Z},\tilde{Z})$. The proof is tedious but straightforward. We shall not give the full account of details here. But examples in the next section should illustrate our point.

It should be noted that Lemma 3.1 proves only a *local* convergence result. But we also know in the earlier discussion that the semiorbit of $(X(t), Y(t))$ approaches arbitrarily close to its ω-limit set which is a subset of all equilibrium points. These observations together imply that a solution flow $(X(t), Y(t))$ converges *globally* to a single point [1, Thm. 2.3]. Indeed, we have the following result.

LEMMA 3.3. *Let $(X(t), Y(t))$ be a solution flow of the differential system* (18) *and* (19). *Suppose $(\hat{X}, \hat{X})$ is an ω-limit point of the orbit $(X(t), Y(t))$ where all eigenvalues of the corresponding Ω have negative real parts. Then $(X(t), Y(t)) \longrightarrow (\hat{X}, \hat{X})$ as $t \longrightarrow \infty$.*

Proof. Since $(\hat{X}, \hat{X})$ is an ω-limit point of $(X(t), Y(t))$, there exists $T > 0$ such that $(X(T), Y(T))$ is sufficiently close to $(\hat{X}, \hat{X})$. By Lemma 3.1, the solution flow that begins at $(X(T), Y(T))$ converges to a single point $(\hat{Z}, \hat{Z})$. It follows that $(X(t), Y(t))$ converges to $(\hat{Z}, \hat{Z})$. Since $(\hat{X}, \hat{X})$ is an ω-limit point, it must be that $\hat{X} = \hat{Z}$.

In the above lemma, the assumption that all eigenvalues of Ω have negative real parts can be weakened. In fact, all we need in the proof of global convergence is the fact of local convergence to a single point. Thus, we restate the lemma as follows.

LEMMA 3.4. *Let $(X(t), Y(t)) \in \mathcal{M}(\Lambda) \times \pi_s(R_+^n)$ be a solution of the differential system* (18) *and* (19). *If $(\hat{X}, \hat{X})$ is an ω-limit point of this solution, then* $\lim_{t \to \infty}(X(t), Y(t)) = (\hat{X}, \hat{X})$.

We conclude this section with one final remark on Lemma 3.4. It is obvious that not every given set σ of n real values can be the spectrum of some nonnegative matrix. If a nonfeasible spectrum is given, we cannot expect the ω-limit set of any solution $(X(t), Y(t)) \in \mathcal{M}(\Lambda) \times \pi_s(R_+^n)$ to contain a point of the form $(\hat{X}, \hat{X})$. But even if σ is feasible, it is possible that an orbit $(X(t), Y(t))$ contains *no* limit point of the form $(\hat{X}, \hat{X})$. We have not analyzed this type of equilibrium points yet. In either case, however, our numerical experiment seems to suggest that the ω-limit set of $(X(t), Y(t))$ still contains a single point.

4. Stability analysis for $n = 2$. We shall now analyze the differential system (18) and (19) for the case $n = 2$ in detail. The answers to Problems 2 and 3 are obviously known for this simple case. But we hope the following study will provide some interesting insight into the understanding of the higher-dimensional case.

First we explain the geometry of $\mathcal{M}(\Lambda)$ and $\pi_s(R_+^n)$. Due to symmetry, it suffices to study the behavior of the six variables $(x_{11}, x_{12}, x_{22}; y_{11}, y_{12}, y_{22})$ only. We note that the set $\mathcal{O}(2)$ consists of two kinds of orthogonal matrices

$$\begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix}, \qquad \begin{bmatrix} \cos\theta & \sin\theta \\ \sin\theta & -\cos\theta \end{bmatrix}$$

with $\theta \in [0, 2\pi)$. From (16), it follows that

$$\begin{aligned} x_{11} &= \lambda_1 \cos^2\theta + \lambda_2 \sin^2\theta, \\ x_{12} &= (\lambda_1 - \lambda_2)\cos\theta \sin\theta, \\ x_{22} &= \lambda_1 \sin^2\theta + \lambda_2 \cos^2\theta. \end{aligned} \tag{36}$$

These equations provide a parametric representation of the ellipse in R^3 formed by the intersection of the plane Π with equation $x_{11} + x_{22} = \lambda_1 + \lambda_2$ and the ellipsoid with equation $x_{11}^2 + 2x_{12}^2 + x_{22}^2 = \lambda_1^2 + \lambda_2^2$. If $\lambda_1 = \lambda_2$, then this ellipse is degenerate. Thus, the isospectral surface $\mathcal{M}(\Lambda)$ for $n = 2$ is represented by an ellipse. The distance from the plane Π to the origin is $\frac{1}{2}|\lambda_1 + \lambda_2|$. The cone $\pi_s(R_+^2)$ is the set of points in the

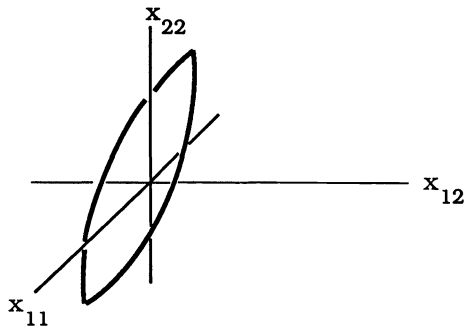

FIG. 1. *The set* $\mathcal{M}(\Lambda)$.

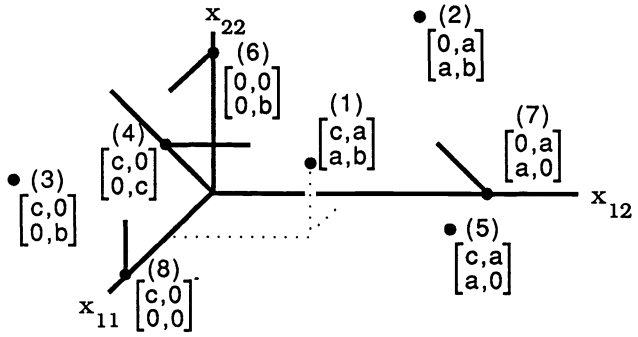

FIG. 2. *Representation of points in* $\mathcal{L}$.

first octant of R^3. The inverse eigenvalue problem will have a solution if and only if the ellipse intersects the first octant (see Fig. 1). It is clear from the geometry that this condition is equivalent to $\lambda_1 + \lambda_2 \geq 0$.

For $n = 2$, the set $\mathcal{L}$ defined in (24) contains points of the following eight types:

(1) $(y_{11}, y_{12}, y_{22}; y_{11}, y_{12}, y_{22})$; y_{ij} arbitrary but > 0;
(2) $(0, y_{12}, y_{22}; 0, y_{12}, y_{22})$; y_{ij} arbitrary but > 0;
(3) $(y_{11}, 0, y_{22}; y_{11}, 0, y_{22})$; y_{ij} arbitrary but > 0, $y_{11} \neq y_{22}$;
(4) $(y_{11}, x_{12}, y_{11}; y_{11}, 0, y_{11})$; x_{12}, y_{ij} arbitrary, but $y_{11} > 0$;
(5) $(y_{11}, y_{12}, 0; y_{11}, y_{12}, 0)$; y_{ij} arbitrary but > 0;
(6) $(x_{11}, 0, y_{22}; 0, 0, y_{22})$; x_{11}, y_{22} arbitrary, but $y_{22} > 0$;
(7) $(x_{11}, y_{12}, x_{11}; 0, y_{12}, 0)$; x_{11}, y_{12} arbitrary, but $y_{12} > 0$;
(8) $(y_{11}, 0, x_{22}; y_{11}, 0, 0)$; x_{22}, y_{11} arbitrary, but $y_{11} > 0$.

We note that the set $\mathcal{L}$ is the union [15] of one three-dimensional manifold (points of type (1)) and several two-dimensional manifolds (points of types (2)–(8)). The set $\mathcal{L}$ is represented in Fig. 2. For convenience, we have identified a representative for each type of point in Fig. 2. For example, the first open octant represents type (1) points; the first open quadrant in the yz-plane represents type (2) points, and so on. The extra lines sticking out from the coordinate axes or planes represent the freedom of variables for the matrix X. These are types (4), (6), (7), and (8) points, respectively.

For these types of limit points, note that the matrix Y is fixed to be the single point at the foot of these lines.

We consider the case when

$$\hat{X} = \hat{Y} = \begin{bmatrix} c & a \\ a & b \end{bmatrix}.$$

The corresponding matrix Ω in (19) is given by

$$\Omega = \begin{bmatrix} -4c - 2a^2 & 2ca - 2ba & 2a^2 \\ ca - ba & 2cb - c^2 - b^2 - 4a & -ca + ba \\ 2a^2 & -2ca + 2ba & -2a^2 - 4b \end{bmatrix}. \tag{37}$$

A general formula for eigenvalues of Ω is difficult to compute even with the help of a symbolic package. However, we already know from Lemma 3.2 that all eigenvalues of Ω have nonpositive real part. As an example, when $a = 2$, $b = 3$, and $c = 5$, we find the eigenvalues of Ω are approximately -35.53793480, -15.53700242, and -8.925062779. It can be seen easily from the characteristic polynomial that Ω will have two purely imaginary eigenvalues only if a, b, and c come from a very special two-dimensional hypersurface in R^3.

It turns out that some eigenvalues of Ω can be zero when $\hat{X}$ is on the faces or edges of the cone $\pi_s(R_+^n)$. In the following, we consider the local convergence for some of the following special cases.

Case 1. Type (8) limit point where

$$\tilde{X} = \tilde{Y} = \begin{bmatrix} c & 0 \\ 0 & 0 \end{bmatrix}.$$

In this case, $\Omega = \operatorname{diag}\{-4c, -c^2, 0\}$. So Lemma 3.1 cannot be applied. We give below a somewhat extended argument to demonstrate how the convergence of a flow near $(\tilde{X}, \tilde{X})$ can be reached. The differential system (33) and (34) becomes

(38)

$$\begin{aligned}
u_{11}' &= 2u_{12}w_{12}c + 2u_{12}w_{12}u_{11} + 2w_{22}u_{12}^2 - 2w_{11}u_{12}^2 - 2u_{12}w_{12}u_{22};\\
u_{12}' &= -w_{12}c^2 - 2w_{12}u_{11}c + 2u_{22}w_{12}c + cw_{11}u_{12} - cw_{22}u_{12} + u_{11}w_{11}u_{12}\\
&\quad +2u_{11}w_{12}u_{22} - w_{12}u_{11}^2 - u_{11}w_{22}u_{12} - w_{11}u_{12}u_{22} - w_{12}u_{22}^2 + w_{22}u_{12}u_{22};\\
u_{22}' &= -2u_{12}w_{12}c + 2w_{11}u_{12}^2 + 2u_{12}w_{12}u_{22} - 2u_{12}w_{12}u_{11} - 2w_{22}u_{12}^2;\\
w_{11}' &= -4w_{11}c + 2u_{12}w_{12}c + 2u_{12}w_{12}u_{11} + 2w_{22}u_{12}^2 - 2w_{11}u_{12}^2\\
&\quad -2u_{12}w_{12}u_{22} - 4w_{11}u_{11} + 4w_{11}^2;\\
w_{12}' &= -w_{12}c^2 - 2w_{12}u_{11}c + 2u_{22}w_{12}c + cw_{11}u_{12} - cw_{22}u_{12} + u_{11}w_{11}u_{12}\\
&\quad +2u_{11}w_{12}u_{22} - w_{12}u_{11}^2 - u_{11}w_{22}u_{12} - w_{11}u_{12}u_{22} - w_{12}u_{22}^2\\
&\quad +w_{22}u_{12}u_{22} - 4w_{12}u_{12} + 4w_{12}^2;\\
w_{22}' &= -2u_{12}w_{12}c + 2w_{11}u_{12}^2 + 2u_{12}w_{12}u_{22} - 2u_{12}w_{12}u_{11} - 2w_{22}u_{12}^2\\
&\quad -4w_{22}u_{22} + 4w_{22}^2.
\end{aligned}$$

We note there are two negative linear terms in w_{11}' and w_{12}'. So the convergence is contingent upon how the flow behaves on the center manifold. By center manifold theory, the center manifold of (38) is given by

$$(w_{11}, w_{12}) = h(u_{11}, u_{12}, u_{22}, w_{22}) \tag{39}$$

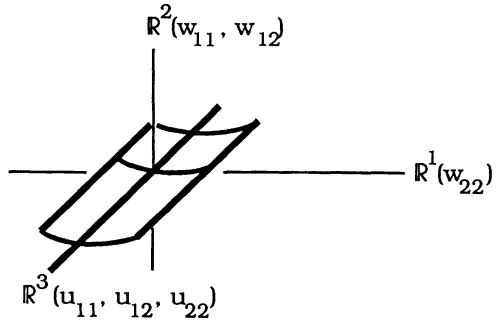

FIG. 3. *Four-dimensional center manifold.*

for some smooth function h. The geometry is illustrated in Fig. 3 where we use the x-axis to represent the three variables $(u_{11}, u_{12}, u_{22}) \in R^3$, the y-axis to represent the variable $w_{22} \in R$, and the z-axis to represent the two variables $(w_{11}, w_{12}) \in R^2$. We note that the x-axis where $W \equiv 0$ also represents the three-dimensional equilibrium points of type (1). Although h is difficult to compute explicitly, the following function can be shown to be an $O(\|(U, W)\|^3)$ approximation to h [6] near the origin:

$$
\begin{aligned}
w_{11} &:= \frac{u_{12}^2 w_{22}}{2c}; \\
w_{12} &:= \frac{-cu_{12}w_{22} - u_{11}u_{12}w_{22} + u_{12}u_{22}w_{22}}{c^2}.
\end{aligned} \tag{40}
$$

Upon substitution, we find the flow (28) on the center manifold is given by

$$
\begin{aligned}
u_{11}' &= -w_{22}u_{12}^2(-4u_{22}c + 4u_{11}c - 4u_{22}u_{11} + 2u_{11}^2 + u_{12}^2c + 2u_{22}^2)/c^2; \\
u_{12}' &= w_{22}u_{12}(-12u_{22}u_{11}c + 6u_{11}^2c + 4u_{11}c^2 + 6u_{22}^2c - 4u_{22}c^2 \\
&\qquad + u_{12}^2c^2 + u_{12}^2u_{11}c + 6u_{22}^2u_{11} - 6u_{11}^2u_{22} + 2u_{11}^3 \\
&\qquad - u_{12}^2u_{22}c - 2u_{22}^3)/(2c^2); \\
u_{22}' &= w_{22}u_{12}^2(-4u_{22}c + 4u_{11}c - 4u_{22}u_{11} + 2u_{11}^2 + u_{12}^2c + 2u_{22}^2)/c^2; \\
w_{22}' &= w_{22}(-4u_{12}^2u_{22}c + 4u_{12}^2u_{11}c + u_{12}^4c + 2u_{12}^2u_{22}^2 - 4u_{12}^2u_{22}u_{11} \\
&\qquad + 2u_{12}^2u_{11}^2 - 4u_{22}c^2 + 4w_{22}c^2)/c^2.
\end{aligned} \tag{41}
$$

The most dominant term in (41) is

$$
w_{22}' = 4w_{22}(w_{22} - u_{22}) + \text{ higher-order terms.} \tag{42}
$$

It is also obvious that

$$
(w_{22} - u_{22})' = 4w_{22}(w_{22} - u_{22}). \tag{43}
$$

We are interested only in the case where $Y(t) \in \pi_s(R_+^n)$. Therefore, $w_{22} = x_{22} - y_{22} = u_{22} - y_{22} \leq u_{22}$ since $y_{22} \geq 0$. By checking the signs of the right-hand sides of (42) and (43), we find that the projection of the vector field (41) at any point $(u_{11}, u_{12}, u_{22}, w_{22}) \in R^4$ onto the (u_{22}, w_{22})-plane must be within the shaded region as shown in Fig. 4. It is obvious from the geometry that $u_{22}(t)$ converges to a fixed

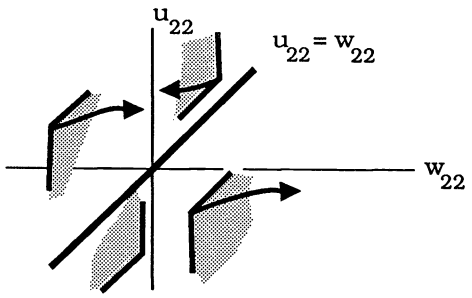

FIG. 4. *Projection of flows.*

point and $w_{22}(t)$ converges to zero as t converges to infinity. In other words, we have shown that near a equilibrium point $(\tilde{X}, \tilde{X})$ of type (8), the solution flow $(X(t), Y(t))$ with $Y(0) \in \pi_s(R_+^n)$ converges to a fixed point of the form $(\tilde{Z}, \tilde{Z})$. This should manifest our point made in the preceding section concerning the convergence when Ω has zero eigenvalues. In Fig. 4 we have also drawn the projection of vector field of (41) when $Y(0)$ is not in $\pi_s(R_+^n)$. This corresponds to the region below the diagonal $u_{22} = w_{22}$. It is interesting to note that $w_{22}(t)$ may diverge to infinity. This is because the differential system (18) and (19) has the descending property only if $Y(t) \in \pi_s(R_+^n)$.

Case 2. Type (3) limit points where

$$\hat{X} = \hat{Y} = \begin{bmatrix} c & 0 \\ 0 & b \end{bmatrix}$$

and $b \neq c$. We find $\Omega = \operatorname{diag}\{-4c, -(b-c)^2, -4b\}$. Thus Lemma 3.1 can be applied.

Case 3. Type (7) limit points where

$$\tilde{X} = \tilde{Y} = \begin{bmatrix} 0 & a \\ a & 0 \end{bmatrix}.$$

At such a limit point, the matrix Ω has eigenvalues $\{0, -4a, -4a^2\}$. An argument similar to the one given in Case 1 can be made. The center manifold should become more complicated because the eigenvectors, $[1,0,1]^T, [0,1,0]^T$, and $[1,0,-1]^T$, of Ω indicate that there are couplings between components. Instead of using center manifold theory, we now take a geometric viewpoint to study this limit point. Limit points of Type (7) have a unique feature that makes them special—that is, the ellipse $\mathcal{M}(\Lambda)$ containing $(\tilde{X}, \tilde{X})$ intersects the first octant only at $(\tilde{X}, \tilde{X})$. Therefore, the ellipse corresponding to a slightly perturbed spectrum, say $\sigma = \{a - \epsilon, -a\}$ with $\epsilon > 0$, will not intersect the first octant at all. This observation perhaps explains why we experience some numerical difficulty in constructing the second example in [18] by our method. We shall report this difficulty in the next section.

Case 4. Type (2) limit points where

$$\hat{X} = \hat{Y} = \begin{bmatrix} 0 & a \\ a & b \end{bmatrix}.$$

It can be checked that the characteristic polynomial of Ω is given by $p(\lambda) = \lambda^3 + (4a^2 + b^2 + 4a + 4b)\lambda^2 + (4b^3 + 16a^3 + 8a^2b + 16ab)\lambda + 32a^3b$. Clearly, $p(\lambda)$ must have

one negative real root. The other two roots can be purely imaginary numbers only if $(4a^2 + b^2 + 4a + 4b)(4b^3 + 16a^3 + 8a^2b + 16ab) = 32a^3b$. We therefore conclude that for almost all values of a and b, all three roots of $p(\lambda)$ have negative real part.

5. Numerical results. In this section we briefly report some of our numerical experiments with the differential equations (18) and (19).

We use the subroutine ODE in [17] as the integrator. Both local control parameters ABSERR and RELERR are set to be 10^{-12}. This criterion is used to control the accuracy in following the solution path. We examine the output values at time interval of 1. Normally, we should expect the loss of one or two digits in the global error. Thus, when the norm of the difference between two consecutive output points becomes less than 10^{-9}, we assume the path has converged to an equilibrium point. The execution is then terminated automatically. We always use $X(0) = \Lambda$ as the starting value for $X(t)$.

Example 1. We consider the spectrum $\sigma = \{5, 0, -2, -2\}$ which satisfies the so-called condition (K) in [10]. Let E denote the matrix whose components are all 1's. We report below various choices of $Y(0)$ and the corresponding approximate equilibrium points $\hat{Y}$. We also report the approximate length of t for convergence. These lengths may depend on the initial values and the integrators, but they should be independent of the computing machine.

(a) $Y(0) = E$, $\hat{Y} \approx Y(120) \approx$

$$\begin{bmatrix} .3035817600D{+}0 & .5849737957D{+}0 & .2062366873D{+}1 & .2062366873D{+}1 \\ .5849737957D{+}0 & .5568227490D{+}0 & .1257189377D{+}1 & .1257189377D{+}1 \\ .2062366873D{+}1 & .1257189377D{+}1 & .6979774550D{-}1 & .2069797746D{+}1 \\ .2062366873D{+}1 & .1257189377D{+}1 & .2069797746D{+}1 & .6979774550D{-}1 \end{bmatrix};$$

(b) $Y(0) = 2E$, $\hat{Y} \approx Y(120) \approx$

$$\begin{bmatrix} .2384681793D{+}0 & .5682102400D{+}0 & .2008259297D{+}1 & .2008259297D{+}1 \\ .5682102400D{+}0 & .6025576213D{+}0 & .1336108181D{+}1 & .1336108181D{+}1 \\ .2008259297D{+}1 & .1336108181D{+}1 & .7948709968D{-}1 & .2079487100D{+}1 \\ .2008259297D{+}1 & .1336108181D{+}1 & .2079487100D{+}1 & .7948709968D{-}1 \end{bmatrix};$$

(c) $Y(0) = 12E$, $\hat{Y} \approx Y(120) \approx$

$$\begin{bmatrix} .2054687518D{+}0 & .5725349916D{+}0 & .1995497108D{+}1 & .1995497108D{+}1 \\ .5725349916D{+}0 & .6259762947D{+}0 & .1349043940D{+}1 & .1349043940D{+}1 \\ .1995497108D{+}1 & .1349043940D{+}1 & .8427747670D{-}1 & .2084277477D{+}1 \\ .1995497108D{+}1 & .1349043940D{+}1 & .2084277477D{+}1 & .8427747670D{-}1 \end{bmatrix};$$

(d) $Y(0) = 200E$, $\hat{Y} \approx Y(120) \approx$

$$\begin{bmatrix} .2002571961D{+}0 & .5800168336D{+}0 & .2000122546D{+}1 & .2000122546D{+}1 \\ .5800168336D{+}0 & .6302391750D{+}0 & .1339883371D{+}1 & .1339883371D{+}1 \\ .2000122546D{+}1 & .1339883371D{+}1 & .8475181443D{-}1 & .2084751814D{+}1 \\ .2000122546D{+}1 & .1339883371D{+}1 & .2084751814D{+}1 & .8475181442D{-}1 \end{bmatrix};$$

(e) $Y(0) =$ a randomly generated symmetric positive matrix, $\hat{Y} \approx Y(240) \approx$

$$\begin{bmatrix} .5806553062D{+}0 & .8075689805D{+}0 & .2354051323D{+}1 & .2276884031D{+}1 \\ .8075689805D{+}0 & .5285565377D{-}1 & .1981177836D{+}0 & .4150231898D{+}0 \\ .2354051323D{+}1 & .1981177836D{+}0 & .3084574129D{+}0 & .2165951279D{+}1 \\ .2276884031D{+}1 & .4150231898D{+}0 & .2165951279D{+}1 & .5803162721D{-}1 \end{bmatrix}.$$

It is interesting to note that different choices of $Y(0)$ lead to different equilibrium points. It is also interesting to note that it takes about the same length of integration to reach convergence, although this observation is not conclusive.

Example 2. We consider the spectrum $\sigma = \{3 - t, 1 + t, -1, -1, -1, -1\}$ for $0 < t < 1$. It can be checked easily that the sufficient condition (K) in [10] is not satisfied. But in [18] it is proved that the set σ is indeed the spectrum of the nonnegative matrix

$$N := \begin{bmatrix} A & B \\ B & A \end{bmatrix},$$

where

$$A = \begin{bmatrix} 1 & 0 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix}$$

and

$$B = \frac{(1-t)}{3} \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}.$$

Considering $t = \frac{1}{2}$, we find the matrix $\Omega \in R^{21\times 21}$ at the point $(\tilde{X}, \tilde{X})$ with $\tilde{X} = N$ has one zero eigenvalue. Thus, this example is one of the exceptional cases we mentioned earlier. Furthermore, the sum of elements of σ is equal to zero for every value of t. A slight perturbation of σ, therefore, may make the spectrum unfeasible. We think this is a situation similar to Case 3 discussed in the previous section. Indeed, the matrix N has zeros on its diagonal, which indicates that N is at the intersection of n faces of $\pi_s(R^6_+)$.

(a) Suppose $Y(0) = N$. It can be calculated that $\|X(0) - Y(0)\| = 5$. We find $\hat{Y} \approx Y(130) \approx$

$$\begin{bmatrix} .0000D{+}0 & .9928D{+}0 & .9978D{+}0 & .2279D{+}0 & .2279D{+}0 & .2279D{+}0 \\ .9928D{+}0 & .0000D{+}0 & .9985D{+}0 & .1096D{+}0 & .1096D{+}0 & .1096D{+}0 \\ .9978D{+}0 & .9985D{+}0 & .0000D{+}0 & .1631D{+}0 & .1631D{+}0 & .1631D{+}0 \\ .2279D{+}0 & .1096D{+}0 & .1631D{+}0 & .0000D{+}0 & .1000D{+}1 & .1000D{+}1 \\ .2279D{+}0 & .1096D{+}0 & .1631D{+}0 & .1000D{+}1 & .0000D{+}0 & .1000D{+}1 \\ .2279D{+}0 & .1096D{+}0 & .1631D{+}0 & .1000D{+}1 & .1000D{+}1 & .0000D{+}0 \end{bmatrix},$$

where $\|X(130) - Y(130)\| \approx 7.9105 \times 10^{-11}$. We note this nonnegative matrix is different from the one constructed in [18] even though $Y(0)$ itself is already a solution to Problem 3.

(b) Suppose $Y(0) = E$. Then $\|X(0) - Y(0)\| \approx 6.9642$. We are surprised to find that our flow does not converge to an equilibrium point of the form $(\hat{X}, \hat{X})$, but rather $X(t)$ converges to $\hat{X} \approx$

$$\begin{bmatrix} -.3000D{+}0 & -.2041D{-}3 & .7000D{+}0 & .7000D{+}0 & .7000D{+}0 & .7000D{+}0 \\ -.2041D{-}3 & .1500D{+}1 & .5867D{-}3 & .5867D{-}3 & .5867D{-}3 & .5867D{-}3 \\ .7000D{+}0 & .5867D{-}3 & -.3000D{+}0 & .7000D{+}0 & .7000D{+}0 & .7000D{+}0 \\ .7000D{+}0 & .5867D{-}3 & .7000D{+}0 & -.3000D{+}0 & .7000D{+}0 & .7000D{+}0 \\ .7000D{+}0 & .5867D{-}3 & .7000D{+}0 & .7000D{+}0 & -.3000D{+}0 & .7000D{+}0 \\ .7000D{+}0 & .5867D{-}3 & .7000D{+}0 & .7000D{+}0 & .7000D{+}0 & -.3000D{+}0 \end{bmatrix},$$

while $Y(t)$ converges to $\hat{Y} \approx$

$$\begin{bmatrix} .5909-307 & .3325D-6 & .7000D+0 & .7000D+0 & .7000D+0 & .7000D+0 \\ .3325D-6 & .1500D+1 & .6963D-3 & .6963D-3 & .6963D-3 & .6963D-3 \\ .7000D+0 & .6963D-3 & .7348-307 & .7000D+0 & .7000D+0 & .7000D+0 \\ .7000D+0 & .6963D-3 & .7000D+0 & .7348-307 & .7000D+0 & .7000D+0 \\ .7000D+0 & .6963D-3 & .7000D+0 & .7000D+0 & .7348-307 & .7000D+0 \\ .7000D+0 & .6963D-3 & .7000D+0 & .7000D+0 & .7000D+0 & .7348-307 \end{bmatrix}$$

with $\|X(9120) - Y(9120)\| \approx .6708$. It is interesting to note that the eigenvalues of $\hat{Y}$ are $\{2.8, 1.5, -.7, -.7 - .7, -.7\}$. The true equilibrium point $(\hat{X}, \hat{Y})$ is where all the small components in the second row and the second column except the $(2,2)$-position of the above two matrices are zero. We have observed that all the significant components of $(\hat{X}, \hat{Y})$ are reached as early as $t \approx 500$. The overall slow convergence is due to the slow rate of change of components in the second row and the second column. To see this, we rerun the code by choosing

$$Y(0) = \begin{bmatrix} 1 & 0 & 1 & 1 & 1 & 1 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 1 & 1 & 1 \end{bmatrix}$$

so that the small components become zero. Then the corresponding orbit converges to the limit point within $t \approx 80$. This example also illustrates that an orbit $(X(t), Y(t))$ may not necessarily have a limit point of the form $(\hat{X}, \hat{X})$.

(c) Suppose $Y(0) = 12E$. Then $\|X(0) - Y(0)\| \approx 72.0868$. Again, we find that $X(t)$ converges to

$$\begin{bmatrix} -.3000D+0 & -.2487D-3 & .7000D+0 & .7000D+0 & .7000D+0 & .7000D+0 \\ -.2487D-3 & .1500D+1 & .7158D-3 & .7158D-3 & .7158D-3 & .7158D-3 \\ .7000D+0 & .7158D-3 & -.3000D+0 & .7000D+0 & .7000D+0 & .7000D+0 \\ .7000D+0 & .7158D-3 & .7000D+0 & -.3000D+0 & .7000D+0 & .7000D+0 \\ .7000D+0 & .7158D-3 & .7000D+0 & .7000D+0 & -.3000D+0 & .7000D+0 \\ .7000D+0 & .7158D-3 & .7000D+0 & .7000D+0 & .7000D+0 & -.3000D+0 \end{bmatrix}$$

while $Y(t)$ converges to

$$\begin{bmatrix} .7206-307 & .7133D-6 & .7000D+0 & .7000D+0 & .7000D+0 & .7000D+0 \\ .7133D-6 & .1500D+1 & .8494D-3 & .8494D-3 & .8494D-3 & .8494D-3 \\ .7000D+0 & .8494D-3 & .7205-307 & .7000D+0 & .7000D+0 & .7000D+0 \\ .7000D+0 & .8494D-3 & .7000D+0 & .7205-307 & .7000D+0 & .7000D+0 \\ .7000D+0 & .8494D-3 & .7000D+0 & .7000D+0 & .7205-307 & .7000D+0 \\ .7000D+0 & .8494D-3 & .7000D+0 & .7000D+0 & .7000D+0 & .7205-307 \end{bmatrix}$$

with $\|X(7140) - Y(7140)\| \approx .6708$. We believe the true limit point is the same as the one in (b).

Example 3. We consider the spectrum $\sigma = \{11, -3, -2, -2, -1, -1\}$ which satisfies a sufficient condition in [10, Thm. 2.4]. Then,

(a) With $Y(0) = 2E$, then $\|X(0) - Y(0)\| \approx 16.6132$ and $\hat{Y} \approx Y(70) \approx$

$$\begin{bmatrix} .5514D+0 & .1920D+1 & .2194D+1 & .1620D+1 & .1551D+1 & .1920D+1 \\ .1920D+1 & .2243D+0 & .2550D+1 & .2265D+1 & .1920D+1 & .2224D+1 \\ .2194D+1 & .2550D+1 & .1158D+0 & .3058D+1 & .2194D+1 & .2550D+1 \\ .1620D+1 & .2265D+1 & .3058D+1 & .3328D+0 & .1620D+1 & .2265D+1 \\ .1551D+1 & .1920D+1 & .2194D+1 & .1620D+1 & .5514D+0 & .1920D+1 \\ .1920D+1 & .2224D+1 & .2550D+1 & .2265D+1 & .1920D+1 & .2243D+0 \end{bmatrix}$$

with $\|X(70) - Y(70)\| \approx 4.3653 \times 10^{-10}$.

(b) With $Y(0) = 12E$, then $\|X(0) - Y(0)\| \approx 72.6360$ and $\hat{Y} \approx Y(70) \approx$

$$\begin{bmatrix} .5741D{+}0 & .1946D{+}1 & .2206D{+}1 & .1604D{+}1 & .1574D{+}1 & .1946D{+}1 \\ .1946D{+}1 & .2292D{+}0 & .2550D{+}1 & .2230D{+}1 & .1946D{+}1 & .2229D{+}1 \\ .2206D{+}1 & .2550D{+}1 & .1100D{+}0 & .3025D{+}1 & .2206D{+}1 & .2550D{+}1 \\ .1604D{+}1 & .2230D{+}1 & .3025D{+}1 & .2833D{+}0 & .1604D{+}1 & .2230D{+}1 \\ .1574D{+}1 & .1946D{+}1 & .2206D{+}1 & .1604D{+}1 & .5741D{+}0 & .1946D{+}1 \\ .1946D{+}1 & .2229D{+}1 & .2550D{+}1 & .2230D{+}1 & .1946D{+}1 & .2292D{+}0 \end{bmatrix}$$

with $\|X(70) - Y(70)\| \approx 6.0561 \times 10^{-10}$.

TWO-SCALE DIFFERENCE EQUATIONS I. EXISTENCE AND GLOBAL REGULARITY OF SOLUTIONS*

INGRID DAUBECHIES†‡ AND JEFFREY C. LAGARIAS†

Abstract. A *two-scale difference equation* is a functional equation of the form $f(x)=\sum_{n=0}^{N} c_n f(\alpha x-\beta_n)$, where $\alpha>1$ and $\beta_0<\beta_1<\cdots<\beta_n$ are real constants, and c_n are complex constants. Solutions of such equations arise in spline theory, in interpolation schemes for constructing curves, in constructing wavelets of compact support, in constructing fractals, and in probability theory. This paper studies the existence and uniqueness of L^1-solutions to such equations. In particular, it characterizes L^1-solutions having compact support. A time-domain method is introduced for studying the special case of such equations where $\{\alpha, \beta_0, \cdots, \beta_n\}$ are integers, which are called *lattice two-scale difference equations.* It is shown that if a lattice two-scale difference equation has a compactly supported solution in $C^m(\mathbb{R})$, then $m<(\beta_n-\beta_0)/(\alpha-1)-1$.

1. Introduction.

A *two-scale difference equation* is a functional equation of the form

$$f(x)=\sum_{n=0}^{N} c_n f(\alpha x-\beta_n) \tag{1.1}$$

where $\alpha>1$ and $\beta_0<\beta_1<\cdots<\beta_n$ are real constants, and x takes real values, while the c_n are complex constants. The right side of (1.1) is typical for difference equations, and the name two-scale difference equation reflects the fact that (1.1) relates translates of scaled versions of the same function, involving two different scales. A *lattice two-scale difference equation* is the special case where α and all β_n are integers, i.e.,

$$f(x)=\sum_{n=0}^{N} c_n f(kx-n) \tag{1.2}$$

where $k\geqq 2$ is an integer. The apparently more general equation

$$f(x)=\sum_{n=-N_1}^{N_2} c_n f(kx-n) \tag{1.3}$$

can be reduced to the form (1.2) by the change of variable $y=x-N_1/(k-1)$.

This paper and its sequel (Daubechies and Lagarias (1988), hereafter called part II) study L^1-solutions of two-scale difference equations, and of lattice two-scale difference equations in particular. The basic questions concern the existence, uniqueness, and degree of regularity of solutions for a given equation. We treat in detail L^1-solutions having compact support. In fact, two-scale difference equations always have solutions in the sense of distributions and may also possess functions not in $L^1(\mathbb{R})$ as solutions, e.g., if $\sum_{n=0}^{N} c_n=1$, then the constant functions are solutions. However, only for special sets of $\{\alpha, \beta_n, c_n\}$ will (1.1) have any nonzero L^1-solutions.

Functions that satisfy lattice two-scale difference equations arise in several different contexts. G. de Rham is credited with an example of a continuous,

nowhere-differentiable function which satisfies (1.2) with $k=3$ and $c_0=1$, $c_1=c_{-1}=\frac{1}{3}$, $c_2=c_{-2}=\frac{2}{3}$, and all other $c_n\equiv 0$. (This was communicated to us by Meyer (1987). We have not found a direct reference to this function in de Rham's papers but similar functions appear in de Rham (1947), (1956), (1957), (1959).) Such functions also arise as limits of "uniform subdivision schemes" for constructing curves and surfaces. As observed and generalized in the work of Dahmen and Micchelli (1984), (1988) and Micchelli and Prautzsch (1987a), (1987b), (1989), normalized B-splines and d-dimensional box splines each satisfy a lattice two-scale difference equation with $k=2$. They point out that this two-scale property is really the basic ingredient in a subdivision algorithm for numerically evaluating B-spline curves and surfaces, given by Lane and Riesenfeld (1980). This can be exploited to define and study other subdivision schemes for the design of curves and surfaces, also characterized by a lattice two-scale equation (Cavaretta and Micchelli (1989)). Dyn and Levin (1989) similarly link subdivision algorithms with the study of a lattice two-scale equation. Dubuc (1986) proposed a dyadic interpolation scheme where the "fundamental function" satisfies an equation of type (1.3) with $k=2$. For special values of the parameters, he proved smoothness results of this fundamental function. Dyn, Gregory, and Levin (1987) independently and by different techniques proved similar results for the same dyadic interpolation schemes. In Deslauriers and Dubuc (1987) this interpolation scheme was applied to the construction of fractal objects and functions with fractal properties. Deslauriers and Dubuc (1989) extend the dyadic interpolation scheme to other integer values of k; they use the properties of solutions of (1.3) corresponding to specific values of the c_n to study Lagrange iterative interpolation processes. In another field, Daubechies (1988) constructed orthonormal bases of compactly supported wavelets, i.e., orthonormal bases $\{h_{mn}(x)\}$ of $L^2(\mathbb{R})$ generated by translating and dilating a single compactly supported function h via

$$h_{mn}(x)=2^{-m/2}h(2^{-m}x-n).$$

The construction of such h requires an auxiliary function which is a solution of a lattice two-scale difference equation, and our interest in these equations arose from these functions. All of these examples actually involve L^1-solutions having compact support.

Solutions of general two-scale difference equations (1.1) arise in other areas of mathematics as well. Kershner and Wintner (1935) considered symmetric Bernoulli convolutions $d\lambda(x,\beta)$ whose Fourier transform $\Lambda(u,\beta)=\int_{-\infty}^{\infty} e^{iux}\,d\lambda(x,\beta)$ has

$$\Lambda(u,\beta)=\prod_{n=0}^{\infty}\cos(\beta^n u). \tag{1.4}$$

For certain values of β in $(0,1)$ the measure $d\lambda(x,\beta)=\lambda'(x,\beta)\,dx$ is absolutely continuous, and $\lambda'(x,\beta)$ then satisfies the two-scale difference equation

$$\lambda'(x)=\frac{\beta}{2}\left(\lambda'\left(\frac{1}{\beta}x-1\right)+\lambda'\left(\frac{1}{\beta}x+1\right)\right).$$

Smoothness properties of this and related Bernoulli convolutions were studied by Jessen and Wintner (1935), Erdös (1939), (1940), Garsia (1962), and Brown and Moran (1973). It remains a difficult open problem to characterize the set of β for which $d\lambda(x,\beta)$ is absolutely continuous. More recently, Barnsley and Demko (1985, Ex. 21) in studying iterated function systems construct a function $f_\beta(z)$ defined on $\mathbb{C}-A$ where

A is the Cantor set, satisfying the two-scale difference equation

$$f_\beta(z) = \frac{3^\beta}{2}\,(f_\beta(3z-2)+f_\beta(3z)).$$

Here $f_\beta(z) = \int_A d\mu(x)/(z-x)^\beta$, where $d\mu$ is uniform measure on the Cantor set.
