Proof of Theorem 2.1. Let $M \geqq \delta$ be given according to (ii) of Lemma 3.3. By (i) of Lemma 3.3, we can find a constant $M_1 > M+1$ such that $\delta \leqq \varphi(\theta) \leqq M+1$ on $[-\tau^*, 0]$ implies $\delta \leqq x(t; \varphi) \leqq M_1$ for all $t \geqq 0$. By (ii) of Lemma 3.3, we can find a constant $T_1 > 0$ such that $\delta \leqq \varphi(\theta) \leqq M_1 + 1$ on $[-\tau^*, 0]$ implies $\delta \leqq x(t; \varphi) \leqq M$ for all $t \geqq T_1$. Similarly, we can find constants M_2 and $M_3 > \delta$ such that

$$\delta \leqq \varphi(\theta) \leqq M_1 + 1 \quad \text{on } [-\tau^*, 0] \quad \text{implies } \delta \leqq x(t; \varphi) \leqq M_2$$

for all $t \geqq 0$, *and*

$$\delta \leqq \varphi(\theta) \leqq M_2 \quad \text{on } [-\tau^*, 0] \quad \text{implies } \delta \leqq x(t; \varphi) \leqq M_3$$

for all $t \geqq 0$.

Define

$$L = M_3 \sup_{t \in [0, \omega]} \{a(t) + b(t) M_3 + c(t) M_3\}$$

and

$$S_0 = \{\varphi \in C;\ \delta \leqq \varphi(\theta) \leqq M+1, |\varphi(\theta) - \varphi(\eta)| \leqq L|\theta - \eta| \quad \text{for } \theta, \eta \in [-\tau^*, 0]\},$$

$$S_1 = \{\varphi \in C;\ \delta \leqq \varphi(\theta) < M_1+1, |\varphi(\theta) - \varphi(\eta)| \leqq L|\theta - \eta| \quad \text{for } \theta, \eta \in [-\tau^*, 0]\},$$

$$S_2 = \{\varphi \in C;\ \delta \leqq \varphi(\theta) \leqq M_2, |\varphi(\theta) - \varphi(\eta)| \leqq L|\theta - \eta| \quad \text{for } \theta, \eta \in [-\tau^*, 0]\}.$$

As well, define a Poincaré map $P: S_2 \to C$ by

$$P(\varphi) = x_\omega(\varphi) \quad \text{for } \varphi \in S_2.$$

Then by the uniqueness and continuous dependence of solutions and the periodicity of a, b, c and τ, we have $P^n(\varphi) = x_{n\omega}(\varphi)$ for all integers $n \geqq 0$, and furthermore P is a continuous map. Evidently, $S_0 \subset S_1 \subset S_2$ are convex subsets of the Banach space C, with S_0 and S_2 compact (Arzola-Ascoli's theorem) and S_1 open relative to S_2. Choose an integer $m > 0$ such that $m\omega > T_1$. Then

$$P^j(S_1) \subseteq S_2 \quad \text{for all } j \geqq 1$$

and

$$P^j(S_1) \subseteq S_0 \quad \text{for all } j \geqq m.$$

Now by Horn's asymptotic fixed point theorem, P has a fixed point in S_0. That is, there is a ω-periodic solution $Q(t)$ of (2.1) with $Q(t) \geqq \delta$ for $t \in [0, \omega]$.

To prove the global asymptotic stability of $Q(t)$ with respect to positive solutions of (2.1), we note that

$$\left[\ln \frac{x(t)}{Q(t)}\right]' = -b(t)[x(t) - Q(t)] + c(t)[x(t - \tau(t)) - Q(t - \tau(t))].$$

Let $u(t)=x(t)-Q(t)$. We get

$$\left[\ln\left(1+\frac{u(t)}{Q(t)}\right)\right]'=-b(t)u(t)+c(t)u(t-\tau(t)).$$

The change of variable

$$\ln\left(1+\frac{u(t)}{Q(t)}\right)=y(t)$$

or equivalently,

$$u(t)=[e^{y(t)}-1]Q(t)$$

leads to the equation

$$\dot{y}(t)=-b(t)Q(t)[e^{y(t)}-1]+c(t)Q(t-\tau(t))[e^{y(t-\tau(t))}-1]. \tag{3.5}$$

Consider the function $W(t)=[e^{y(t)}-1]^2$ and choose a constant $\rho^*>1$ such that

$$\rho^*c(t)Q(t-\tau(t))<b(t)Q(t) \quad \text{for } t\in[0,\omega].$$

If at an instant $t\geqq 0$, we have

$$W(y(s))\leqq \rho^* W(y(t)) \quad \text{for all } s\in[t-\tau(t),t],$$

then

$$\begin{aligned}\frac{d}{dt}W(y(t))&=-2\,e^{y(t)}\{b(t)Q(t)[e^{y(t)}-1]^2-c(t)Q(t-\tau(t))[e^{y(t-\tau(t))}-1][e^{y(t)}-1]\}\\ &\leqq -2\,e^{y(t)}\{b(t)Q(t)[e^{y(t)}-1]^2-\rho^*c(t)Q(t-\tau(t))[e^{y(t)}-1]^2\}\\ &\leqq -2\varepsilon\, e^{y(t)}[e^{y(t)}-1]^2,\end{aligned}$$

where $\varepsilon=\inf_{t\in[0,\omega]}\{b(t)Q(t)-\rho^*c(t)Q(t-\tau(t))\}>0$. Therefore, by the uniform asymptotic stability theorem of Lyapunov-Razumikhin type, we are assured that the zero solution of (3.5) is globally uniformly asymptotically stable, that is, the ω-periodic solution $Q(t)$ of (2.1) is uniformly globally asymptotically stable with respect to positive solutions of (2.1). The proof is completed.

Proof of Theorem 2.2. First of all, using an argument similar to that for Lemma 3.1, we can show that if $\delta>0$ is sufficiently small, so that $a(t)-b(t)\delta>0$ for $t\in[0,\omega]$, then for any $\varphi\in C_\gamma$ with $\varphi(\theta)\geqq\delta$ for $\theta\leqq 0$, we have $x(t;\varphi)\geqq\delta$ for $t\geqq 0$.

Let $BC_\gamma=\{\varphi\in C_\gamma;\ \sup_{\theta\leqq 0}|\varphi(\theta)|<\infty\}$. We next prove that for any $\xi\geqq\delta$ there exists $d(\xi)>0$ such that if $\varphi\in BC_\gamma$ is given, so that $\delta\leqq\varphi(\theta)\leqq\xi e^{-\gamma\theta}$ for $\theta\leqq 0$, then $\delta\leqq x(t;\varphi)\leqq d(\varphi)$ for $t\geqq 0$. In fact, for the function $V: R\times(0,\infty)\to R$ defined by $V(t,x)=(x/K(t))-\ln(x/K(t))$, and for $x(t):=x(t;\varphi)$, we have

$$\begin{aligned}\frac{d}{dt}V(t,x(t))&=-\frac{x(t)-K(t)}{K(t)}\\ &\quad\cdot\left\{b(t)[x(t)-K(t)]-\int_{-\infty}^{t}p(t,s)[x(s)-K(s)]\,ds-\frac{\dot{K}(t)}{K(t)}\right\}.\end{aligned}$$

Since $u-\ln u$ is an increasing and unbounded function for $u\geqq 1$, we can find a constant $N_1\geqq\max_{\delta\leqq\varphi(0)\leqq\xi}V(0,\varphi(0))$ such that if $\max\{N_1, V(s,x(s))\}\leqq V(t,x(t))$ for $s\leqq t$, then $\max\{N_2, x(s)/K(s)\} \leqq x(t)/K(t)$ for $s \leqq t$, where

$$N_2 = \max_{t\in[0,\omega]} \frac{|\dot{K}(t)|/K(t)}{b(t) - \int_{-\infty}^{t} p(t,s)[K(s)/K(t)]\,ds}.$$

Therefore, if $\max\{N_1, V(s, x(s))\} \leqq V(t, x(t))$ for $s \leqq t$, then $x(s) - K(s) \leqq (K(s)/K(t))[x(t) - K(t)]$ for $s \leqq t$, and

$$\begin{aligned} &\frac{d}{dt} V(t, K(t)) \\ &\quad \leqq -\frac{1}{K(t)}\left\{\left[b(t) - \int_{-\infty}^{t} p(t,s)\frac{K(s)}{K(t)}\,ds\right][x(t)-K(t)]^2 - \frac{|\dot{K}(t)|}{K(t)}|x(t)-K(t)|\right\} \\ &\quad \leqq 0. \end{aligned}$$

Therefore, $V(t, x(t)) \leqq N_1$ for $t \geqq 0$, which implies the existence of $d(\xi)$.

We then show that there exists a constant $M \geqq \delta$ such that for any $\xi \geqq \delta$ there is a constant $T(\xi) > 0$ such that if $\varphi \in BC_\gamma$ and $\delta \leqq \varphi(\theta) \leqq \xi e^{-\gamma\theta}$ for $\theta \leqq 0$, then $\delta \leqq x(t; \varphi) \leqq M$ for all $t \geqq T(\xi)$. In fact, from the condition (2.4), for any $\varphi \geqq \delta$, we can choose $q(\xi) > 0$ such that

$$\int_{-\infty}^{-q(\xi)} p(t, t+\theta)\, e^{-\gamma\theta}\, d\theta \leqq \frac{1}{\xi + d(\varphi) + |K_0|_\gamma + \max_{0\leqq s\leqq\omega} K(s)}, \quad t \in [0, \omega].$$

Therefore,

$$\begin{aligned} &\int_{-\infty}^{-q(\xi)} p(t, t+\theta)|x(t+\theta) - K(t+\theta)|\, d\theta \\ &\quad \leqq \int_{-\infty}^{-q(\xi)} p(t, t+\theta)\, e^{-\gamma\theta}\, d\theta \left[\sup_{s\leqq -t} |x(t+s) - K(t+s)|\, e^{\gamma(t+s)}\, e^{-\gamma t}\right. \\ &\qquad\qquad\qquad\qquad \left. + \sup_{-t\leqq s\leqq 0} |x(t+s) - K(t+s)|\right] \\ &\quad \leqq \int_{-\infty}^{-q(\xi)} p(t, t+\theta)\, e^{-\gamma\theta}\, d\theta \left[\xi + |K_0|_{C_\gamma} + d(\xi) + \max_{0\leqq s\leqq\omega} K(s)\right] \\ &\quad \leqq 1. \end{aligned}$$

We now find a constant $\rho > 1$ such that

$$\min_{t\in[0,\omega]} \left\{b(t) - \rho \int_{-\infty}^{t} p(t,s)\frac{K(s)}{K(t)}\,ds\right\} = \delta_1 > 0$$

and define

$$M^* = \frac{2}{\delta_1}\left[1 + (\rho - 1) \sup_{0\leqq t\leqq\omega} \left\{\int_{-\infty}^{t} p(t,s)K(s)\,ds + \frac{|\dot{K}(t)|}{K(t)}\right\}\right].$$

Then using an argument similar to that for Lemma 3.3, we can see that if at some $t \geqq 0$, $V(s, x(s)) \leqq (\rho - \ln\rho)V(t, x(t))$ for $s \in [t - q(\xi), t]$ and $x(t) \geqq M^*$, then

$$x(s) - K(s) \leqq \frac{K(s)}{K(t)}\rho[x(t) - K(t)] + (\rho - 1)K(s)$$

for $s \in [t-q(\xi), t]$, and hence

$$\begin{aligned} -K(t)\frac{d}{dt}V(t, x(t)) &\geqq b(t)[x(t)-K(t)]^2 - \int_{-\infty}^{t-q(\xi)} p(t, s)[x(s)-K(s)]\,ds|x(t)-K(t)| \\ &\quad -\int_{t-q(\xi)}^{t} p(t, s)\frac{K(s)}{K(t)}\rho[x(t)-K(t)]^2\,ds \\ &\quad -\int_{t-q(\xi)}^{t} p(t, s)(\rho-1)K(s)|x(t)-K(t)|\,ds \\ &\quad -\frac{|\dot{K}(t)|}{K(t)}|x(t)-K(t)| \\ &\geqq \frac{\delta_1}{2}|x(t)-K(t)|^2. \end{aligned}$$

Therefore, employing a variation of the standard argument of the uniform ultimate boundedness theorem of Lyapunov-Razumikhin type [25], we can prove the existence of M.

The rest of the proof is similar to the proofs for Theorem 2.1 and Theorem 3.1 of [1], and therefore is omitted.

Proof of Theorem 2.3. We construct a Lyapunov function $V(t, x) = (x/K(t)) - \ln(x/K(t))$ for $(t, x) \in R \times (0, \infty)$, and select a constant $\rho > 0$ such that

$$\inf_{x\in R^+} D_x(t, x) - \rho \sup_{\varphi\in C} \|B_\varphi(t, \varphi)\| \frac{\max_{\theta\in[0,\omega]} K(\theta)}{K(t)} \geqq \delta_1 > 0,$$

where $\delta_1 > 0$ is a constant. It is easy to obtain

$$\begin{aligned} \frac{d}{dt}V(t, x(t)) &= -\frac{x(t)-K(t)}{K(t)}[D(t, x(t)) - B(t, x_t)] - \frac{x(t)-K(t)}{K^2(t)}\dot{K}(t) \\ &= -\frac{x(t)-K(t)}{K(t)}[D(t, x(t)) - D(t, K(t))] \\ &\quad + \frac{x(t)-K(t)}{K(t)}[B(t, x_t) - B(t, K_t)] - \frac{x(t)-K(t)}{K^2(t)}\dot{K}(t) \\ &\leqq -\frac{[x(t)-K(t)]^2}{K(t)} \inf_{x\in R^+} D_x(t, x) \\ &\quad + \sup_{\varphi\in C} \|B_\varphi(t, \varphi)\| \frac{|x(t)-K(t)|}{K(t)} \|x_t - K_t\| - \frac{x(t)-K(t)}{K^2(t)}\dot{K}(t). \end{aligned}$$

Therefore, if

$$V(t+s, x(t+s)) \leqq (\rho - \ln \rho) V(t, x(t)) \quad \text{for } s \in [-\tau^*, 0]$$

and

$$\begin{aligned} x(t) \geqq M^* = \frac{2}{\delta_1} \sup_{t\in[0,\omega]} &\left\{(\rho-1) \sup_{\varphi\in C} \|B_\varphi(t, \varphi)\| \max_{\varphi\in[0,\omega]} K(\theta) + \frac{|\dot{K}(t)|}{K(t)}\right\} \\ &+ \max_{\theta\in[0,\omega]} K(\theta). \end{aligned}$$

Then by Lemma 3.2, we can obtain

$$\frac{dV(t, x(t))}{dt} \leqq -\frac{\delta_1}{2\max_{\theta\in[0,\omega]} K(\theta)}|x(t)-K(t)|^2.$$

Hence results in Lemma 3.3 are valid. The rest of the proof is exactly the same as that for Theorem 2.1 and therefore is omitted.

Discussion. In this paper we have considered several single-species models with time delays where both the coefficients and the delays are periodic functions. These models are based on laboratory evidence in observing the population growth of rotifers.

The model given by (2.1) is of retarded type, whereas the model described by (2.3) incorporates a distributed periodic delay. However, both of these are of Lotka-Volterra type. It would be of interest to consider equations of single-species which are more general. Unfortunately, we are not able to do so at this time, since some of the technical steps in our method of proofs of the existence of positive periodic solutions require the Lotka-Volterra format.

It would also be of interest to consider higher-dimensional systems with periodic delays, representing predator-prey or competitive systems. Again, this is likely to be considerably more difficult, and we leave this for future work.

Acknowledgment. The authors thank the referees for their valuable comments and suggestions which led to a substantial improvement of our original manuscript.

HOMOCLINIC SOLUTIONS FOR AUTONOMOUS DYNAMICAL SYSTEMS IN ARBITRARY DIMENSION*

JOSEPH GRUENDLER†

Abstract. An autonomous differential equation in $\mathcal{R}^n$ with two parameters, μ_1, μ_2, is considered and it is assumed that when both parameter values are zero the equation has a hyperbolic equilibrium and a homoclinic solution. Curves are sought through the origin in the μ_1-μ_2 plane along which the homoclinic solution persists for nonzero parameter values. By using the method of Lyapunov–Schmidt, a function, H, is obtained between two finite-dimensional spaces where the zeros of H represent homoclinic solutions for nonzero parameter values. The implicit function theorem is applied to H in various cases. For $n = 2$ a single curve is obtained as in the work of Melnikov. When $n > 2$ and the stable and unstable manifolds of the hyperbolic equilibrium have an intersection of dimension one, a result of Palmer is achieved which, again, yields a single curve. When this dimension of intersection is greater than one, original results give multiple curves. The various cases of the theory are illustrated by seven examples: one in $\mathcal{R}^2$, one in $\mathcal{R}^3$, four in $\mathcal{R}^4$, and one in $\mathcal{R}^6$.

Key words. differential equations, dynamical systems, homoclinic solutions, bifurcations

AMS(MOS) subject classification. 34C35

1. Introduction.

The problem of determining parameter values for which an autonomous dynamical system possesses a homoclinic or heteroclinic solution arises in a variety of applications. Some of these are predator-prey systems [3], diffusion problems [7], traveling waves in neurons [8], [12], [13], shock waves in gas dynamics [9], [15], climate models [10], [24], chemical stirred tank reactors [16], [17], and chemical kinetics [22].

Various techniques have been used for detecting homoclinic solutions. In [4], Carr uses bifurcation from a center equilibrium. In [18], Kopell and Howard follow the bifurcation of one equilibrium to two, which can produce a heteroclinic solution. In [21], Mock uses topological degree.

In this work we consider an autonomous dynamical system involving two parameters, μ_1, μ_2, and assume that when both parameter values are zero the system has a known homoclinic solution. We then locate curves through the origin in the μ_1-μ_2 plane along which the homoclinic solution persists for small nonzero values of the parameters.

The seminal work along these lines is by Melnikov [20]. He assumes that the dynamical system is in $\mathcal{R}^2$ and is analytic, that the unperturbed system is autonomous, and that the perturbation is periodic. A generalization of [20] to $\mathcal{R}^n$ can be found in [11].

In the present work we consider a $\mathcal{C}^3$, autonomous system in $\mathcal{R}^n$ and utilize the method of Lyapunov–Schmidt. Previous work of a similar nature is by Chow and Hale [5] and Chow, Hale, and Mallet–Paret [6]. Our work is a generalization, in the autonomous case, of [5, §11.3] from $\mathcal{R}^2$ to $\mathcal{R}^n$.

*Received by the editors November 8, 1989; accepted for publication (in revised form) September 18, 1991.

†Department of Mathematics, North Carolina A&T State University, Greensboro, North Carolina 27401.

We assume the unperturbed system has a hyperbolic equilibrium and a homoclinic solution. The assumption of a homoclinic solution is equivalent to the assumption that the stable and unstable manifolds for the equilibrium intersect. Now, in the plane the intersection of the stable and unstable manifolds is equal to the homoclinic orbit itself (or, possibly, two homoclinic orbits).

In higher dimensions, on the other hand, the invariant manifolds need not meet along a single orbit. We give examples below where the invariant manifolds in $\mathcal{R}^4$ meet along an entire family of homoclinic orbits. Another way of describing this situation is in terms of the dimension of intersection of the stable and unstable manifolds. In $\mathcal{R}^2$ or $\mathcal{R}^3$ this dimension of intersection is always one. In general, the dimension of intersection in $\mathcal{R}^n$ can be as much as $n/2$.

We consider a dynamical system in $\mathcal{R}^n$ with the dimension of intersection of the stable and unstable manifolds arbitrary and use the method of Lyapunov–Schmidt to obtain a function, H, between two finite-dimensional spaces where the zeros of H represent homoclinic solutions. The independent variables for H include the parameters from the dynamical system along with some additional variables. These additional variables represent excess tangent directions for the intersection of the stable and unstable manifolds; that is, directions tangent to both manifolds other than the tangent direction provided by the homoclinic orbit itself.

When the invariant manifolds meet in dimension one the extra variables drop out. We can then apply the implicit function theorem to H and obtain, when $n = 2$, an autonomous version of Melnikov's result [20] or, when $n > 2$, a result of Palmer [23]. These results are illustrated in the first three examples below.

When the invarient manifolds meet in dimension greater than one the function H has a singularity at the origin which can result in multiple curves through the origin along which H is zero. The latter three examples below have, respectively, two, three, and five such curves.

Theory. We shall consider dynamical systems of the form

$$\dot{x}(t) = f(x(t), \mu), \tag{1}$$

where $x \in \mathcal{R}^n, \mu \in \mathcal{R}^2$. We could just as easily consider μ restricted to some connected open set containing the origin.

We make the following assumptions about (1):

(i) f is $\mathcal{C}^3$ in all its arguments.

(ii) $x = 0$ is a hyperbolic equilibrium. That is, $f(0, \mu) = 0$ for all μ and the eigenvalues of $D_1 f(0,0)$ lie off the imaginary axis.

(iii) The system has a homoclinic solution when $\mu = 0$. That is, there exists a differentiable function $t \rightarrow \gamma(t)$ such that $\dot{\gamma}(t) = f(\gamma(t), 0)$ and $\lim_{t\rightarrow+\infty} \gamma(t) = \lim_{t\rightarrow-\infty} \gamma(t) = 0$.

We shall adopt the standard notation of W^s, W^u for the stable and unstable manifolds, respectively, of the origin and $d_s = \dim(W^s)$, $d_u = \dim(W^u)$. Since $x = 0$ is a hyperbolic equilibrium, γ must approach the origin along W^s as $t \rightarrow +\infty$ and along W^u as $t \rightarrow -\infty$. Thus, γ lies on $W^s \cap W^u$. Letting $P = \gamma(0)$ we shall denote $d_b = \dim(T_P W^s \cap T_P W^u)$.

Our approach in locating homoclinic solutions for nonzero values of μ will be to define two Banach spaces, $\mathcal{Z}^1$ and $\mathcal{Z}^0$, consisting of homoclinic paths in $\mathcal{R}^n$ and try to use the usual function $F : \mathcal{Z}^1 \times \mathcal{R}^2 \rightarrow \mathcal{Z}^0$ defined as $F(z, \mu) = \dot{\gamma} + \dot{z} - f(\gamma + z, \mu)$. The idea will be to solve the equation $F(z, \mu) = 0$ for z as a function of μ. Actually, modifications of this idea will be necessary, but we introduce the basic concept here to motivate our preliminary results.

Let $\{\lambda_1, \cdots, \lambda_n\}$ denote the eigenvalues of $D_1 f(0,0)$. Since $x = 0$ is a hyperbolic equilibrium we can choose $M > 0$ such that $|\Re(\lambda_i)| \geq 4M$ for all i. For sufficiently small $|\mu|$ any homoclinic solution which exists must decay at least as fast as e^{-Mt} as $t \to +\infty$ and e^{Mt} as $t \to -\infty$. Accordingly, we define

$$\mathcal{Z}^0 = \left\{ z \in \mathcal{C}^0(\mathcal{R}, \mathcal{R}^n) : \sup_t |z(t)| e^{M|t|} < \infty \right\},$$

$$\mathcal{Z}^1 = \left\{ z \in \mathcal{C}^1(\mathcal{R}, \mathcal{R}^n) : \sup_t |z(t)| e^{M|t|} < \infty, \sup_t |\dot{z}(t)| e^{M|t|} < \infty \right\}.$$

We take as a norm on each space the maximum of the sups in the respective definition. With these norms each $\mathcal{Z}^r$ is a Banach space.

Once the function F above has been properly defined we will need to look at the derivative, $D_1 F(0,0)$. To determine the Kernel of this map we must solve the variational equation $\dot{u} = D_1 f(\gamma, 0) u$. Note that $\dot{\gamma}$ is one solution in $\mathcal{Z}^1$ to this equation. There may be others.

THEOREM 1. *Let $\dot{x} = f(x, \mu)$ be as in (1). Let $\{\lambda_1, \cdots, \lambda_n\}$ denote the eigenvalues of $D_1 f(0,0)$. Then there exists a fundamental solution, U, for the variational equation $\dot{u}(t) = D_1 f(\gamma(t), 0) u(t)$; nonnegative integers k_i; real, continuous, bounded functions v_i^+, v_i^-; and a permutation, σ, on n symbols such that, if u_j denotes the jth column of U,*

$$\lim_{t \to +\infty} \left(u_j(t) t^{-k_j} \exp(-\Re(\lambda_j) t) - v_j^+(t) \right) = 0,$$

$$\lim_{t \to -\infty} \left(u_j(t) t^{-k_{\sigma(j)}} \exp(-\Re(\lambda_{\sigma(j)}) t) - v_j^-(t) \right) = 0.$$

Proof. Let $\{\lambda_1, \lambda_2, \cdots, \lambda_n\}$ denote the eigenvalues of $D_1 f(0,0)$ repeated according to algebraic multiplicity and numbered so that $\Re(\lambda_j) \geq \Re(\lambda_{j+1})$ and so that $k_j \geq k_{j+1}$ when $\Re(\lambda_j) = \Re(\lambda_{j+1})$. By standard asymptotic theory we have the existence of two real fundamental solutions, $\{\alpha_1, \cdots, \alpha_n\}$ and $\{\beta_1, \cdots, \beta_n\}$, to the variational equation such that, for $j = 1, \cdots, n$, we have

$$\lim_{t \to +\infty} (\alpha_j(t) t^{-k_j} \exp(-\Re(\lambda_j) t) - w_j(t)) = 0,$$

$$\lim_{t \to -\infty} (\beta_j(t) t^{-k_{n-j+1}} \exp(-\Re(\lambda_{n-j+1}) t) - w_{n-j+1}(t)) = 0$$

for some set of nonnegative integers k_j and nonzero, continuous, periodic functions w_j.

We denote by $A(t)$ and $B(t)$ the matrices with, respectively, $\alpha_j(t)$ and $\beta_j(t)$ as column j. Since these are both fundamental solutions we can write $A = BP$ for some constant matrix P. We now operate on P by means of elementary column operations. The objective is to obtain $AQ = B\tilde{P}$ with Q lower-triangular and $\tilde{P}$ such that the first nonzero entry in each column is one with each column-leading one in a different row.

Suppose we have reached the point where the transformed P has the following property: there exist distinct integers $j_1, j_2, \cdots, j_{r-1}$ such that

$$\begin{aligned} &p_{ij_k} = 0 \quad \text{if } i < k, \\ &p_{kj_k} = 1, \\ &p_{ik} = 0 \quad \text{for } 1 \leq i < r-1, \quad k \notin \{j_1, j_2, \cdots, j_{r-1}\}. \end{aligned}$$

In row r pick the maximum $j_r \notin \{j_1, \cdots j_{r-1}\}$ such that $p_{rj_r} \neq 0$. Such a j_r must exist as P is nonsingular. Now divide column j_r by p_{rj_r} so now $p_{rj_r} = 1$. Next, use column operations to get $p_{rk} = 0$ for $k \notin \{j_1, j_2, \cdots, j_r\}$. Notice we need operate only on columns to the left of column j_r.

Continuing this process through $r = n$ yields a non-singular, lower triangular constant matrix Q such that $A(t)Q = B(t)\tilde{P}$ where $\tilde{P}$ has the property that given j, $1 \leq j \leq n$, there exists $\sigma(j)$ defined by $j_{\sigma(i)} = i$ such that $\sigma(i) \neq \sigma(j)$ for $i \neq j$, $\tilde{p}_{ij} = 0$ for $i < \sigma(j)$, and $\tilde{p}_{\sigma(j),j} = 1$.

Let u_j denote column j of the matrix $U = A(t)Q = B(t)\tilde{P}$. Then

$$u_j(t) = \sum_{r=j}^{n} q_{rj}\alpha_r(t) = \sum_{r=\sigma(j)}^{n} \tilde{p}_{rj}\beta_r(t),$$

so that

$$\lim_{t \to +\infty} \left(u_j(t)t^{-k_j} \exp(-Re(\lambda_j)t) - v_j^+(t)\right) = 0$$

where $v_j^+ = \sum q_{rj}w_r$, the sum taken over

$$\{r : j \leq r \leq n, \Re(\lambda_r) = \Re(\lambda_j), k_r = k_j\}.$$

Also,

$$\lim_{t \to -\infty} \left(u_j(t)t^{-k_{\sigma(j)}} \exp(-\Re(\lambda_{\sigma(j})t) - v_j^-(t)\right) = 0$$

where $v_j^- = \sum \tilde{p}_{rj}w_r$, the sum taken over

$$\{r : \sigma(j) \leq r \leq n, \Re(\lambda_r) = \Re(\lambda_j), k_r = k_j\}. \qquad \square$$

We shall refer to U as a dichotomous variational solution along γ. We classify the solutions into four types and introduce notation useful for solution of the nonhomogeneous variational equation.

DEFINITION 2. Let $\dot{x} = f(x, \mu)$ be as in (1). Let U denote a dichotomous variational solution along γ with u_j the jth column of U.

(i) We shall say that u_j connects λ_j to $\lambda_{\sigma(j)}$.

(ii) We write the index set, $I = \{1, 2, \cdots, n\}$, as the disjoint union of four sets according to the behavior of the u_j's at $+\infty$ and $-\infty$:

$$\begin{aligned}
j \in I_{ab}, \quad a = s \quad &\text{iff} \lim_{t \to +\infty} u_j(t) = 0,\\
j \in I_{ab}, \quad a = u \quad &\text{iff} \lim_{t \to +\infty} u_j(t) = \infty,\\
j \in I_{ab}, \quad b = s \quad &\text{iff} \lim_{t \to -\infty} u_j(t) = 0,\\
j \in I_{ab}, \quad b = u \quad &\text{iff} \lim_{t \to -\infty} u_j(t) = \infty.
\end{aligned}$$

(iii) We let n_{ab} denote the order of I_{ab} and use "u_j is of type ab" to mean $j \in I_{ab}$.

(iv) For each $i = 1, \cdots, n$ we define $u_i^\perp(t)$ by $\langle u_i^\perp(t), u_j(t)\rangle = \delta_{ij}$.

It may occur that $\dot{\gamma} = u_k$ for some k. The actual numbering of the u_j's is unimportant. The essential thing is that each u_j connects a distinct pair of eigenvalues.

The vectors $u_j^\perp$ can be computed from the formula $U^{\perp t} = U^{-1}$, where $U^\perp$ denotes the matrix with $u_j^\perp$ as column j. Differentiating $UU^{\perp t} = I$ we obtain $\dot{U}U^{\perp t} + U\dot{U}^{\perp t} = 0$ so that $\dot{U}^\perp = -(U^{-1}\dot{U}U^{\perp t})^t = -D_1 f(\gamma, 0)^t U^\perp$. Thus, $U^\perp$ is the adjoint of U.

We also have

$$\det(U(t)) = \det(U(0)) \exp\left(\int_0^t (\nabla \cdot f)(\gamma(s), 0)\, ds\right),$$

and, for $w \in \mathcal{C}^r(\mathcal{R}, \mathcal{R}^n)$, the formula

$$\langle u_i^\perp(t), w(t)\rangle = \det(u_1(t), \cdots, u_{i-1}(t), w(t), u_{i+1}(t), \cdots, u_n(t)) \det(U(t))^{-1}. \tag{2}$$

We shall construct a solution to the nonhomogeneous variational equation $\dot{x} = D_1 f(\gamma, 0)x + w$ in the form

$$x = \sum_{j=1}^n u_j(t) \int \langle u_j^\perp(s), w(s)\rangle\, ds = U(t) \int U^{-1}(s) w(s)\, ds. \tag{3}$$

For breaking up this formula over the various I_{ab} we define, for each $a = s, u$, $b = s, u$, an $n \times n$ matrix, P_{ab}, defined as $(P_{ab})_{ii} = 1$ if $i \in I_{ab}$ and $(P_{ab})_{ij} = 0$, otherwise. We have then

$$\sum_{j \in I_{ab}} u_j(t) \int \langle u_j^\perp(s), w(s)\rangle\, ds = U(t) \int P_{ab} U^{-1}(s) w(s)\, ds. \tag{4}$$

LEMMA 3. *There exists a constant K_0 such that for every $z \in \mathcal{Z}^0$ we have:*

(i) $$\left|\langle u_i^\perp(t), z(t)\rangle\right| \leq K_0 \|z\| e^{-Mt}$$
for $t \geq 0$ when $i \in I_{us} \cup I_{uu}$.

(ii) $$\left|\langle u_i^\perp(t), z(t)\rangle\right| \leq K_0 \|z\| e^{Mt}$$
for $t \leq 0$ when $i \in I_{su} \cup I_{uu}$.

(iii) $$\left|\int_0^t U(t)(P_{ss} + P_{su}) U^{-1}(s) z(s)\, ds\right| \leq K_0 \|z\| e^{-Mt}$$
for $t \geq 0$.

(iv) $$\left|\int_t^\infty U(t)(P_{us} + P_{uu}) U^{-1}(s) z(s)\, ds\right| \leq K_0 \|z\| e^{-Mt}$$
for $t \geq 0$.

(v) $$\left|\int_0^t U(t)(P_{ss} + P_{us}) U^{-1}(s) z(s)\, ds\right| \leq K_0 \|z\| e^{Mt}$$
for $t \leq 0$.

(vi) $$\left|\int_{-\infty}^t U(t)(P_{su} + P_{uu}) U^{-1}(s) z(s)\, ds\right| \leq K_0 \|z\| e^{Mt}$$
for $t \leq 0$.

Proof. Choose $K_0 > 0$ such that

$$|u_i(t)| \leq K_0^{1/n} \exp\left(\left(\Re(\lambda_i) + M/(n-1)\right) t\right)$$

for all $t \geq 0$ and

$$\det\left(U^{-1}(t)\right) = \det(U(0)) \exp\left(-\int_0^t (\nabla \cdot f)(\gamma(s), 0)\, ds\right) \leq K_0^{1/n} e^{(-\lambda+M)t},$$

where $\lambda = \Re(\lambda_1) + \cdots + \Re(\lambda_n)$. Since $i \in I_{us} \cup I_{uu}$, $\Re(\lambda_i) \geq 4M$, so, using (2),

$$\left\langle u_i^{\perp}(t), z(t) \right\rangle \leq K_0 \|z\| \exp((-\Re(\lambda_i))t) \leq K_0 \|z\| e^{-Mt}.$$

This proves (i). Part (ii) follows similarly. Note that (i) and (ii) imply the convergence of the improper integrals in (iv) and (vi) when these are viewed via (4).

We now turn to (iii). Assume the eigenvalues are numbered so that $I_{ss} \cup I_{su} = \{1, 2, \cdots, d_s\}$. Then $P_{ss} + P_{su} = \left(\begin{smallmatrix} I & 0 \\ 0 & 0 \end{smallmatrix}\right)$ where I is the $d_s \times d_s$ identity matrix. Let $A = D_1 f(0,0)$ and let Q be a real, $n \times n$ matrix such that the matrix $B = Q^{-1}AQ$ has the form $B = \left(\begin{smallmatrix} B_1 & 0 \\ 0 & B_2 \end{smallmatrix}\right)$ with B_1 a $d_s \times d_s$ matrix whose eigenvalues all have negative real parts. We can choose $K_B > 0$ such that

$$\left|\begin{pmatrix} e^{tB_1} & 0 \\ 0 & 0 \end{pmatrix}\right| \leq |e^{tB_1}| \leq K_B e^{-2Mt}.$$

Since

$$Q^{-1}\dot{U} = \left(Q^{-1} D_1 f(\gamma, 0) Q\right) Q^{-1} U$$

and

$$\lim_{t \to \infty} Q^{-1} D_1 f(\gamma, 0) Q = B$$

we can choose $K_1 > 0$ such that $|Q^{-1}U - e^{tB}| \leq K_1 e^{-2Mt}$, and using the adjoint equation we obtain $|U^{-1}Q - e^{-tB}| \leq K_2 e^{-2Mt}$, both for all $t \geq 0$.

Now write

$$\begin{aligned}
&U(t)(P_{ss} + P_{su})U^{-1}(s)z(s) \\
&\quad = Q\left[\left(Q^{-1}U(t) - e^{tB}\right)(P_{ss} + P_{su})\left(U^{-1}(s)Q - e^{-sB}\right)\right. \\
&\qquad + \left(Q^{-1}U(t) - e^{tB}\right)(P_{ss} + P_{su})e^{-sB} + e^{tB}(P_{ss} + P_{su})e^{-sB} \\
&\qquad \left. + e^{tB}(P_{ss} + P_{su})\left(U^{-1}(s)Q - e^{-sB}\right)\right] Q^{-1}z(s) \\
&\quad = Q\left[\left(Q^{-1}U(t) - e^{tB}\right)(P_{ss} + P_{su})\left(U^{-1}(s)Q - e^{-sB}\right)\right. \\
&\qquad + \left(Q^{-1}U(t) - e^{tB}\right)\begin{pmatrix} e^{-sB_1} & 0 \\ 0 & 0 \end{pmatrix} + \begin{pmatrix} e^{(t-s)B_1} & 0 \\ 0 & 0 \end{pmatrix} \\
&\qquad \left. + \begin{pmatrix} e^{tB_1} & 0 \\ 0 & 0 \end{pmatrix}\left(U^{-1}(s)Q - e^{-sB}\right)\right] Q^{-1}z(s).
\end{aligned}$$

From this we obtain

$$|U(t)(P_{ss} + P_{su})U^{-1}(s)z(s)| \leq K_3 \|z\| e^{-2Mt} e^{-3Ms} + K_B \|z\| e^{-2Mt} e^{Ms},$$

where $K_3 = K_1 \left|P_{ss} + P_{su}\right| K_2 + K_1 K_B + K_B K_2$.

Integration of the preceding estimate yields (iii) with $K_0 = \frac{K_3}{3M} + \frac{K_B}{M}$. This proves (iii). Parts (iv)–(vi) follow similarly. □

One consequence of the preceding result is that the integrals $\int_{-\infty}^{\infty} \left\langle u_i^\perp, z \right\rangle dt$ are convergent for $z \in \mathcal{Z}^0, i \in I_{uu}$.

Furthermore, since

$$\begin{aligned}\left\langle u_i^\perp, \dot{z} - D_1 f(\gamma, 0) z \right\rangle &= \left\langle u_i^\perp, \dot{z} \right\rangle - \left\langle D_1 f(\gamma, 0)^t u_i^\perp, z \right\rangle \\ &= \left\langle u_i^\perp, \dot{z} \right\rangle + \left\langle \dot{u}_i^\perp, z \right\rangle \\ &= \frac{d}{dt} \left\langle u_i^\perp, z \right\rangle,\end{aligned}$$

it follows that

$$\int_{-\infty}^{\infty} \left\langle u_i^\perp, \dot{z} - D_1 f(\gamma, 0) z \right\rangle dt = 0 \quad \text{for } z \in \mathcal{Z}^1,\ i \in I_{uu}. \tag{5}$$

THEOREM 4. *Let $\dot{x} = f(x, \mu)$ be as in* (1) *and consider the nonhomogeneous variational equation*

$$\dot{h}(t) = D_1 f(\gamma(t), 0) h(t) + w(t) \tag{6}$$

with $w \in \mathcal{Z}^0$. Then (6) *has a solution in $\mathcal{Z}^1$ if and only if*

$$\int_{-\infty}^{\infty} \left\langle u_i^\perp, w \right\rangle dt = 0$$

for all $i \in I_{uu}$. In this case (6) *has a unique solution in $\mathcal{Z}^1$ satisfying $\left\langle u_i^\perp(0), h(0) \right\rangle = 0$ for all $i \in I_{ss}$.*

Proof. If (6) has a solution $h \in \mathcal{Z}^1$ then $\int_{-\infty}^{\infty} \left\langle u_i^\perp, w \right\rangle dt = 0$ for all $i \in I_{uu}$ by (5). Now suppose $\int_{-\infty}^{\infty} \left\langle u_i^\perp, w \right\rangle dt = 0$ for all $i \in I_{uu}$. Then using variation of parameters we get a particular solution, h_p, to (6) given by

$$\begin{aligned} & h_p(t) \\ &= U(t) \left[\int_{-\infty}^{0} P_{su} U^{-1}(s) w(s)\, ds + \int_0^t (P_{ss} + P_{su}) U^{-1}(s) w(s)\, ds \right. \\ &\qquad \left. - \int_t^{\infty} (P_{us} + P_{uu}) U^{-1}(s) w(s)\, ds \right] \\ &= U(t) \left[- \int_0^{\infty} P_{us} U^{-1}(s) w(s)\, ds + \int_0^t U(t)(P_{ss} + P_{us}) U^{-1}(s) w(s)\, ds \right. \\ &\qquad \left. + \int_{-\infty}^{t} U(t)(P_{su} + P_{uu}) U^{-1}(s) w(s)\, ds \right], \end{aligned}$$

where the first and second forms are intended for $t \geq 0$ and $t \leq 0$, respectively.

Now $h_p \in \mathcal{Z}^1$ by Lemma 3. The general solution in $\mathcal{Z}^1$ to (6) is $h = h_p + \sum_{i \in I_{ss}} c_i u_i$ for constants c_i. But $\left\langle u_i^\perp(0), h(0) \right\rangle = c_i$ for $i \in I_{ss}$ so h_p is the unique solution in $\mathcal{Z}^1$ to (6), satisfying $\left\langle u_i^\perp(0), h(0) \right\rangle = 0$ for all $i \in I_{ss}$. □

The preceding result has two consequences. First, it characterizes the image of $D_1F(0,0)$ as $\{w \in \mathcal{Z}^0 : \int_{-\infty}^{\infty} \langle u_i^\perp, z\rangle\, dt = 0,\ i \in I_{uu}\}$. Further, we see that we can make $D_1F(0,0)$ injective by restricting the domain of F to the subspace

$$\tilde{\mathcal{Z}}^1 = \{z \in \mathcal{Z}^1 : \langle u_i^\perp(0), z(0)\rangle = 0,\ i \in I_{ss}\}.$$

As the Kernel of a continuous linear map $\tilde{\mathcal{Z}}^1$ is closed and hence a Banach space.

We can proceed to our main result once we settle the question of the domain for F. On the one hand, F cannot be defined on all $\mathcal{Z}^1$ since this would distinguish solutions in $\mathcal{Z}^1$ which are time-translates of each other. There is a way to handle this problem. Let U be a dichotomous variational solution along γ and choose $k \in I_{ss}$ so that $\langle u_k^\perp(0), \dot\gamma(0)\rangle \neq 0$. We then require z to satisfy $\langle u_k^\perp(0), z(0)\rangle = 0$ so that $\langle u_k^\perp(0), \gamma(0) + z(0)\rangle$ is independent of z. This construction has a geometric meaning. Since $\langle u_i^\perp(0), \dot\gamma(0)\rangle$ is the coordinate of $\dot\gamma(0)$ along $u_i(0)$, the vectors $u_i(0)$, $i \neq k$ span an affine linear subspace, Π, in $\mathcal{R}^n$ through $P = \gamma(0)$ and transverse to $\dot\gamma(0)$. We are requiring that $\gamma(0) + z(0)$ remain in Π. In each example below we have $u_k = \dot\gamma$ for some k so then $\langle u_k^\perp(0), \dot\gamma(0)\rangle = \langle u_k^\perp(0), u_k(0)\rangle = 1$. This situation can always be assumed for $d_b = 1$ but not necessarily when $d_b > 1$.

On the other hand, for $D_1F(0,0)$ to be injective we need to have $z \in \tilde{\mathcal{Z}}^1$. Now, when $d_b = 1$ these two requirements agree but, for $d_b > 1$, requiring z to be in $\tilde{\mathcal{Z}}^1$ is unnecessarily restrictive. We reconcile this by taking $z \in \tilde{\mathcal{Z}}^1$ but then adding extra variables to take into account the tangent directions $u_j(0)$, $j \in I_{ss}$, $j \neq k$.

THEOREM 5. *Let $\dot x = f(x,\mu)$ be as in (1). Let U be a dichotomous variational solution along γ numbered so that $I_{uu} = \{1, \cdots, d_b\}$ along with a bijection $\alpha : \{1, \cdots, d_b\} \to I_{ss}$ and such that $\left\langle u_{\alpha(d_b)}^\perp(0), \dot\gamma(0)\right\rangle \neq 0$. Then there exists a connected open set $V \subset \mathcal{R}^{d_b-1} \times \mathcal{R}^2$ with $(0,0) \in V$ and a differentiable function $H : V \to \mathcal{R}^{d_b}$ denoted $(\beta,\mu) \to H(\beta,\mu)$ with the following properties:*

(i) *If $H(\beta^*,\mu^*) = 0$ then $\dot x = f(x,\mu^*)$ has a homoclinic solution*

(ii) $H(0,0) = 0.$

(iii) $$\frac{\partial H_i}{\partial \mu_j}(0,0) = -\int_{-\infty}^{\infty} \left\langle u_i^\perp, \frac{\partial f}{\partial \mu_j}(\gamma,0)\right\rangle dt.$$

(iv) $$\frac{\partial H_i}{\partial \beta_j}(0,0) = 0.$$

(v) $$\frac{\partial^2 H_i}{\partial \beta_j \partial \beta_k}(0,0) = -\int_{-\infty}^{\infty} \langle u_i^\perp, D_{11}f(\gamma,0)u_{\alpha(j)}u_{\alpha(k)}\rangle\, dt.$$

Proof. We define a differentiable function $F : \tilde{\mathcal{Z}}^1 \times \mathcal{R}^{d_b-1} \times \mathcal{R}^2 \to \mathcal{Z}^0$ as follows:

$$F(z,\beta,\mu)(t) = \dot\gamma(t) + \dot z(t) + \sum_{i=1}^{d_b-1} \beta_i \dot u_{\alpha(i)}(t) - f\left(\gamma(t) + z(t) + \sum_{i=1}^{d_b-1} \beta_i u_{\alpha(i)}(t), \mu\right).$$

A sufficient condition for a homoclinic solution is $F(z,\beta,\mu) = 0$. We use the method of Lyapunov–Schmidt to eliminate z from this equation.

Let $\phi : \mathcal{R} \to \mathcal{R}$ be a continuous function satisfying $\sup_t |\phi(t)|e^{M|t|} < \infty$ and $\int_{-\infty}^{\infty} \phi(t)dt = 1$. Then define a projection $P : \mathcal{Z}^0 \to \mathcal{Z}^0$ by

$$P(z) = \phi \sum_{i \in I_{uu}} \left(\int_{-\infty}^{\infty} \langle u_i^{\perp}, z \rangle \, dt \right) u_i.$$

It is easy to check that for any $z \in \mathcal{Z}^0$ we have

$$\int_{-\infty}^{\infty} \langle u_i^{\perp}, (I-P)z \rangle \, dt = 0 \quad \text{for } i \in I_{uu}. \tag{7}$$

So now F resolves into two parts:

$$\begin{aligned} (I-P)F &: \tilde{\mathcal{Z}}^1 \times \mathcal{R}^{d_b - 1} \times \mathcal{R}^2 \to \mathrm{Im}(I-P), \\ PF &: \tilde{\mathcal{Z}}^1 \times \mathcal{R}^{d_b - 1} \times \mathcal{R}^2 \to \mathrm{Im}(P). \end{aligned}$$

The idea is to solve the equation $(I-P)F = 0$ for z and substitute the result into $PF = 0$. Using (5) we find that the equation

$$D_1[(I-P)F](0)h = w$$

is

$$\dot{h} = D_1 f(\gamma, 0)h + w.$$

Combining (7) and Theorem 4 we see that this last equation has a unique solution in $\tilde{\mathcal{Z}}^1$ since $w \in \mathrm{Im}(I-P)$. We can now apply the implicit function theorem to obtain a connected open set $V \subset \mathcal{R}^{d_b - 1} \times \mathcal{R}^2$ and a differentiable function $\psi : V \to \tilde{\mathcal{Z}}^1$ such that $\psi(0,0) = 0$ and

$$((I-P)F)(\psi(\beta, \mu), \beta, \mu) = 0 \tag{8}$$

for all $(\beta, \mu) \in V$.

The conditions for a homoclinic solution now become

$$(PF)(\psi(\beta, \mu), \beta, \mu) = 0.$$

These conditions can be stated in the form $H(\beta, \mu) = 0$ by defining the differentiable function $H : V \to \mathcal{R}^{d_b}$ as follows:

$$\begin{aligned} H_i(\beta, \mu) = \int_{-\infty}^{\infty} \Bigg\langle u_i^{\perp}, \dot{\gamma} + \dot{\psi}(\beta, \mu) + \sum_{j=1}^{d_b - 1} \beta_j \dot{u}_{\alpha(j)} \\ - f\left(\gamma + \psi(\beta, \mu) + \sum_{j=1}^{d_b - 1} \beta_j u_{\alpha(j)}, \mu \right) \Bigg\rangle \, dt. \end{aligned}$$

Result (ii) follows from the fact that $\psi(0,0) = 0$. Differentiation of H combined with (5) yields (iii) and (iv).

To show (v) we first differentiate (8) with respect to β and use (5) to obtain

$$\frac{\partial\dot{\psi}}{\partial\beta_j}(0,0) = D_1 f(\gamma,0)\frac{\partial\psi}{\partial\beta_j}(0,0),$$

and this result combined with Theorem 4 yields

$$\frac{\partial\psi}{\partial\beta_j}(0,0) = 0.$$

We now obtain (v) by differentiation of H twice with respect to β, combined with this last result and (5). □

Let us look at some special cases of the preceding theorem. If $x \in \mathcal{R}^2$ we must have $d_b = 1$, $I_{uu} = \{1\}$, $I_{ss} = \{2\}$, and $u_2 = \dot{\gamma}$. Denoting $\gamma = (\gamma_1, \gamma_2)$ we can take

$$u_1^{\perp}(t) = (-\dot{\gamma}_2(t), \dot{\gamma}_1(t)) \exp\left(-\int_0^t (\nabla \cdot f)(\gamma(s),0)\,ds\right),$$

and knowledge of u_1 is not required. There is no β and the condition for a homoclinic solution is the scalar equation $H(\mu_1, \mu_2) = 0$. With the appropriate hypothesis the implicit function theorem can be used to solve this last equation for μ_1 in terms of μ_2. This yields the following result which is an autonomous version of Melnikov's theorem [20]. See also [5] and [6]. This next result is illustrated in Example 1 below.

COROLLARY 6. *Let $\dot{x} = f(x,\mu)$ be as in* (1) *with $x \in \mathcal{R}^2$. Let*

$$a_i = -\int_{-\infty}^{\infty} \det\left(\dot{\gamma}(t), \frac{\partial f}{\partial\mu_i}(\gamma(t),0)\right) \exp\left(-\int_0^t (\nabla \cdot f)(\gamma(s),0)\,ds\right) dt$$

for $i = 1,2$ and suppose $a_1 \neq 0$. Then there exists an open interval W containing zero and a differentiable function $\phi : W \to \mathcal{R}$ such that $\phi(0) = 0$, $\phi'(0) = -a_2/a_1$ and such that (1) *has a homoclinic solution for $\mu_1 = \phi(\mu_2)$, $\mu_2 \in W$.*

The preceding result generalizes with little difficulty to higher n as long as we have $d_b = 1$. The difference is that for $n > 2$ it is necessary to utilize a dichotomous variational solution. This leads to the following result obtained by Palmer [23]. This next result is illustrated in Examples 2 and 3 below.

COROLLARY 7. *Let $\dot{x} = f(x,\mu)$ be as in* (1) *with $d_b = 1$. Let U be a dichotomous variational solution along γ with $I_{uu} = \{1\}$. Let*

$$a_i = \frac{\partial H}{\partial\mu_i}(0,0) = -\int_{-\infty}^{\infty} \left\langle u_1^{\perp}, \frac{\partial f}{\partial\mu_i}(\gamma,0)\right\rangle dt$$

for $i = 1,2$ and suppose $a_1 \neq 0$. Then there exists an open interval W containing zero and a differentiable function $\phi : W \to \mathcal{R}$ such that $\phi(0) = 0$, $\phi'(0) = -a_2/a_1$ and such that (1) *has a homoclinic solution for $\mu_1 = \phi(\mu_2)$, $\mu_2 \in W$.*

We now wish to consider $d_b > 1$. A special case occurs for $d_b = 2$ for then we have $\beta \in \mathcal{R}$, $\mu \in \mathcal{R}^2$, and the conditions for a homoclinic solution are $H_i(\beta, \mu_1, \mu_2) = 0$; $i = 1,2$. With the appropriate assumption these equations can be solved for μ in terms of β to yield the following result.

COROLLARY 8. *Let $\dot{x} = f(x,\mu)$ be as in* (1) *with $d_b = 2$. Let U be a dichotomous variational solution along γ with $I_{uu} = \{1,2\}$, $I_{ss} = \{3,4\}$, $\left\langle u_4^\perp(0), \dot{\gamma}(0)\right\rangle \neq 0$. Define a 2×2 matrix $A = [a_{ij}]$ by*

$$a_{ij} = \frac{\partial H_i}{\partial \mu_j}(0,0) = -\int_{-\infty}^{\infty} \left\langle u_i^\perp, \frac{\partial f}{\partial \mu_j}(\gamma, 0)\right\rangle dt, \qquad i = 1,2, \quad j = 1,2$$

and a 2-vector $b = [b_i]$ by

$$b_i = \frac{\partial^2 H_i}{\partial \beta^2}(0,0) = -\int_{-\infty}^{\infty} \langle u_i^\perp, D_{11} f(\gamma, 0) u_3 u_3\rangle \, dt, \qquad i = 1,2.$$

If $\det(A) \neq 0$ *then there exists an open interval W containing zero and a differentiable function $\phi : W \to \mathcal{R}^2$ such that $\phi(0) = 0$, $\phi'(0) = 0$, $\phi''(0) = -A^{-1}b$ and such that* (1) *has a homoclinic solution for $\mu = \phi(\beta)$, $\beta \in W$.*

When this result is interpreted in terms of the μ's we obtain a curve in the μ_1–μ_2 plane passing through the origin with slope

$$m = \lim_{\beta \to 0} \frac{\mu_2(\beta)}{\mu_1(\beta)} = \frac{-a_{21}b_1 + a_{11}b_2}{a_{22}b_1 - a_{12}b_2}.$$

This is illustrated in Example 4 below.

The case of $d_b \geq 3$ is a bit harder. Our approach is, first, to set to zero the terms of lowest degree in $H(\beta, \mu)$.

DEFINITION 9. Let $\dot{x} = f(x,\mu)$ be as in (1). Let U be a dichotomous variational solution along γ numbered in such a way that $I_{uu} = \{1, \cdots, d_b\}$ together with a bijection $\alpha : \{1, \cdots, d_b\} \to I_{ss}$ such that $\left\langle u_{\alpha(d_b)}^\perp(0), \dot{\gamma}(0)\right\rangle \neq 0$. Let $V \subset \mathcal{R}^{d_b - 1} \times \mathcal{R}^2$ and $H : V \to \mathcal{R}^{d_b}$ be as in Theorem 5.

(i) We define

$$a_{ij} = \frac{\partial H_i}{\partial \mu_j}(0,0) = -\int_{-\infty}^{\infty} \left\langle u_i^\perp, \frac{\partial f}{\partial \mu_j}(\gamma, 0)\right\rangle dt$$

$$\text{for } i = 1, \cdots, d_b, \quad j = 1,2.$$

$$b_{ijk} = \frac{\partial^2 H_i}{\partial \beta_j \partial \beta_k}(0,0) = -\int_{-\infty}^{\infty} \langle u_i^\perp, D_{11} f(\gamma, 0) u_{\alpha(j)} u_{\alpha(k)}\rangle \, dt$$

$$\text{for } i = 1, \cdots, d_b, \quad j,k = 1, \cdots, d_b - 1.$$

(ii) We define a second degree map $M : \mathcal{R}^{d_b - 1} \times \mathcal{R}^2 \to \mathcal{R}^{d_b}$ by

$$M_i(\beta, \mu) = \sum_{j=1}^{2} a_{ij}\mu_j + \frac{1}{2} \sum_{j=1}^{d_b - 1} \sum_{k=1}^{d_b - 1} b_{ijk}\beta_j\beta_k.$$

(iii) We shall say that $(\beta^0, \mu^0) \in \mathcal{R}^{d_b - 1} \times \mathcal{R}^2$ is a characteristic vector for (1) if $M(\beta^0, \mu^0) = 0$.

If (β^0, μ^0) is a characteristic vector for (1) then $(s\beta^0, s^2\mu^0)$ is a characteristic vector for (1) for all scalars s. We can specify a choice for s by requiring $\|\beta^0\|^2 + \|\mu^0\| = 1$. We now use the implicit function theorem to find a solution to the exact equation $H(\beta, \mu) = 0$.

THEOREM 10. *Let $\dot{x} = f(x, \mu)$ be as in* (1). *Let a_{ij}, b_{ijk}, and $M(\beta, \mu)$ be as in Definition* 9. *Let (β^0, μ^0) be a characteristic vector for* (1) *and define a $d_b \times (d_b + 1)$ matrix $C = [c_{ij}]$ by*

$$\begin{aligned} c_{ij} &= \sum_{k=1}^{d_b-1} b_{ijk}\beta_k^0, && i = 1, \cdots, d_b, \quad j = 1, \cdots, d_b - 1, \\ c_{ij} &= a_{i,j-d_b+1}, && i = 1, \cdots, d_b, \quad j = d_b, \ d_b + 1. \end{aligned}$$

If C has maximal rank there exists an open interval W containing zero and a differentiable function $\phi : W \to \mathcal{R}^2$ with $\phi(0) = 0$ such that $\dot{x} = f(x, \mu)$ has a homoclinic solution for $\mu = s^2(\mu^0 + \phi(s))$, $s \in W$.

Proof. Let $V \subset \mathcal{R}^{d_b-1} \times \mathcal{R}^2$ and $H : V \to \mathcal{R}^{d_b}$ be as in Theorem 5. Let $V_1 \subset \mathcal{R}^{d_b-1} \times \mathcal{R}^2 \times \mathcal{R}$ be a sufficiently small open neighborhood of $(0,0)$ and define a differentiable function $F : V_1 \to \mathcal{R}^{d_b}$ by

$$F(\psi, \phi, s) = \begin{cases} \dfrac{1}{s^2} H(s\beta^0 + s\psi, s^2\mu^0 + s^2\phi) & \text{for } s \neq 0, \\ M(\beta^0 + \psi, \mu^0 + \phi) & \text{for } s = 0. \end{cases}$$

Observe that $F(0) = 0$ and $\tilde{D}F(0) = C$, where $\tilde{D}$ denotes differentiation with respect to (ψ, ϕ). By hypothesis, C has maximal rank which means that it has an invertible $d_b \times d_b$ submatrix. One of the columns of this submatrix must correspond to one of the components ϕ_1, ϕ_2 of ϕ. Assume the component is ϕ_1. Then from the implicit function theorem we can solve the equation $F(\psi_1, \cdots, \psi_{d_b-1}, \phi_1, 0, s) = 0$ for ψ and ϕ_1 in terms of s. The result now follows from Theorem 5. □

Note that Theorem 10 can yield multiple curves in the μ_1–μ_2 plane along which we have a homoclinic solution. For each (β^0, μ^0) we get a curve passing through the origin with slope $m = \mu_2^0 / \mu_1^0$. This is illustrated in Example 5.

Case of a manifold of homoclinic orbits. The preceding results utilize the second derivatives of H with respect to β; when these derivatives are zero we need an alternate approach. One situation worth considering occurs when all or part of $W^s \cap W^u$ is a manifold which we can term the bistable manifold, W^b. This case arises in certain integrable Hamiltonian systems [19].

Suppose $W^s \cap W^u$ has a branch which is a manifold, denoted W^b, of dimension d_b; let $P : \mathcal{R}^{d_b-1} \to W^b$ be differentiable; and let γ_θ denote a homoclinic solution for $\dot{x} = f(x, 0)$ satisfying $\gamma_\theta(0) = P(\theta)$. Assume P is constructed so that $(\theta, t) \to \gamma_\theta(t)$ establishes local coordinates on W^b. Since

$$\dot{\gamma}_\theta(t) = f(\gamma_\theta(t), 0),$$

differentiation with respect to θ yields

$$\frac{\partial \dot{\gamma}_\theta}{\partial \theta_i}(t) = D_1 f(\gamma_\theta(t), 0) \frac{\partial \gamma_\theta}{\partial \theta_i}(t).$$

Thus, the functions $\partial \gamma_\theta / \partial \theta_j$, along with $\dot{\gamma}_\theta$ provide a natural set of solutions of type ss to the variational equation along γ_θ.

Let U_θ denote a dichotomous variational solution along γ_θ with $u_{\theta j}$ the jth column of U_θ, and define $u_{\theta i}^\perp$ by $\langle u_{\theta i}^\perp(t), u_{\theta j}(t) \rangle = \delta_{ij}$.

Also, let $A(\theta) = [a_{ij}(\theta)]$ denote the $d_b \times 2$ matrix defined as

$$a_{ij}(\theta) = -\int_{-\infty}^{\infty} \left\langle u_{\theta i}^\perp, \frac{\partial f}{\partial \mu_j}(\gamma_\theta, 0) \right\rangle dt.$$

THEOREM 11. *Let $\dot{x} = f(x,\mu)$ be as in* (1). *Suppose $W^s \cap W^u$ has a branch, W^b, which is a manifold and let $A(\theta)$ be as above. Suppose there exist $\theta^0 \in \mathcal{R}^{d_b-1}$ and a nonzero $\mu^0 \in \mathcal{R}^2$ such that $A(\theta^0)\mu^0 = 0$. Define a $d_b \times (d_b+1)$ matrix $C = [c_{ij}]$ by*

$$c_{ij} = \begin{cases} \sum_{k=1}^2 \dfrac{\partial a_{ik}}{\partial \theta_j}(\theta^0)\mu_k^0 & \textit{for } i = 1, \cdots, d_b, \quad j = 1, \cdots, d_b - 1 \\ a_{i,j-d_b+1}(\theta^0) & \textit{for } i = 1, \cdots, d_b, \quad j = d_b,\ d_b+1. \end{cases}$$

If C has maximal rank there exists an open interval W containing zero and a differentiable function $\phi : W \to \mathcal{R}^2$ with $\phi(0) = 0$ such that (1) *has a homoclinic solution for $\mu = s(\mu^0 + \phi(s))$, $s \in W$.*

Proof. We begin by modifying the proof of Theorem 5. We define a map F : $\tilde{\mathcal{Z}}^1 \times \mathcal{R}^{d_b-1} \times \mathcal{R}^2 \to \mathcal{Z}^0$ by

$$F(z,\theta,\mu)(t) = \dot{\gamma}_\theta(t) + \dot{z}(t) - f(\gamma_\theta(t) + z(t), \mu).$$

In other words, we replace the β coordinates in Theorem 5 with the local manifold coordinates θ. Proceeding as before we obtain a connected open set $V \subset \mathcal{R}^{d_b-1} \times \mathcal{R}^2$ with $(0,0) \in V$ and a differentiable function $H : V \to \mathcal{R}^{d_b}$ denoted $(\theta,\mu) \to H(\theta,\mu)$ with the following properties:

(i) If $H(\theta^*,\mu^*) = 0$, then $\dot{x} = f(x,\mu^*)$ has a homoclinic solution;

(ii) $H(\theta,0) = 0$;

(iii) $$\frac{\partial H_i}{\partial \mu_j}(\theta,0) = -\int_{-\infty}^{\infty} \left\langle u_{\theta i}^{\perp}, \frac{\partial f}{\partial \mu_j}(\gamma_\theta, 0) \right\rangle dt = a_{ij}(\theta).$$

The next step is to modify the proof of Theorem 10. For a sufficiently small neighborhood $V_1 \subset \mathcal{R}^{d_b-1} \times \mathcal{R}^2 \times \mathcal{R}$ we define a differentiable map $G : V_1 \to \mathcal{R}^{d_b}$ by

$$G(\psi,\phi,s) = \begin{cases} \dfrac{1}{s} H(\theta^0 + \psi, s\mu^0 + s\phi) & \text{for } s \neq 0, \\ A(\theta^0 + \psi)(\mu^0 + \phi) & \text{for } s = 0. \end{cases}$$

We have $G(0) = A(\theta^0)\mu^0 = 0$ and $\tilde{D}G(0) = C$, where $\tilde{D}$ denotes differentiation with respect to (ψ,ϕ). As in the proof of Theorem 10 we can, after renumbering if necessary, use the implicit function theorem to solve the equation $G(\psi_1, \cdots, \psi_{d_b-1}, \phi_1, 0, s) = 0$ for ψ and ϕ_1 in terms of s. □

This result is very similar to Theorem 10 and generalizes Theorem 1 of [19]. In terms of parameter space we have, for each (θ^0, μ^0), a curve in the μ_1–μ_2 plane passing through the origin with slope $m = \mu_2^0/\mu_1^0$. Note that here there is no restriction on the number of resulting curves. Theorem 11 is illustrated in Examples 6 and 7 below with, respectively, three and five curves.

Examples. We now proceed to illustrate the above theory with a number of examples. We begin with a well-known example in $\mathcal{R}^2$ and consider various generalizations to higher dimensions. In all the following calculations we adopt the notation $r(t) = \operatorname{sech} t$. Note that we have $\ddot{r} = r - 2r^3$. The following numerical values and defined functions will be needed.

$$\int_{-\infty}^{\infty} r^2\,dt = 2, \qquad \int_{-\infty}^{\infty} r^3\,dt = \frac{\pi}{2},$$

$$\int_{-\infty}^{\infty} \dot{r}^2\,dt = \frac{2}{3}, \qquad \int_{-\infty}^{\infty} r\dot{r}^2\,dt = \frac{\pi}{8}, \qquad \int_{-\infty}^{\infty} r^2\dot{r}^2\,dt = \frac{4}{15},$$

$$
\begin{aligned}
I_1(\theta) &= -\int_{-\infty}^{\infty} \dot r(t) r(t-\theta)\,dt = 2\left(\frac{\theta\cosh\theta - \sinh\theta}{\sinh^2\theta}\right),\\
I_2(\theta) &= \int_{-\infty}^{\infty} \dot r(t)\dot r(t-\theta)\,dt = 2\left(\frac{2\sinh\theta\cosh\theta - 2\theta - \theta\sinh^2\theta}{\sinh^3\theta}\right),\\
I_3(\theta) &= -\int_{-\infty}^{\infty} r(t)^2\dot r(t) r(t-\theta)\,dt\\
&= 2\left(\frac{2\sinh^3\theta - 3\sinh\theta\cosh^2\theta + 3\theta\cosh\theta}{\sinh^4\theta}\right).
\end{aligned}
$$

Example 1. Consider the equation

$$\ddot x = x - 2x^3 + \mu_1\dot x(1-x^2) - \mu_2\dot x \tag{9}$$

which we regard as a first-order system in phase space $(x,\dot x)$. This equation has been studied by Holmes and Rand [14]. Similar equations appear in [1], [2, p. 280], and [4]. In meteorology this equation is sometimes referred to as the Saltzman oscillator [24].

Equation (9) has a hyperbolic fixed point at $(0,0)$ for all sufficiently small $|\mu|$. When $\mu = 0$ we get the familiar Duffing's equation with negative stiffness, which has two homoclinic solutions. We will consider the one given by $x = r$.

In the notation of Corollary 6 we compute $a_1 = -\frac{2}{5}$ and $a_2 = \frac{2}{3}$. Thus, the corollary applies so there exists a function ϕ with $\phi(0) = 0$ and $\phi'(0) = \frac{5}{3}$ such that (9) has a homoclinic solution when $\mu_1 = \phi(\mu_2)$.

Example 2. We now wish to generalize to $\mathcal{R}^3$ the equation of the preceding example. We do this by using the μ_2 term to couple the equation to an additional first-order equation which maintains the hyperbolic equilibrium. Thus consider

$$
\begin{aligned}
\ddot x &= x - 2x^3 + \mu_1\dot x(1-x^2) + \mu_2(\dot y - \dot x),\\
\dot y &= -2y + \mu_2(\dot x - \dot y).
\end{aligned}
$$

Letting $x_1 = x,\ x_2 = \dot x,\ x_3 = y$ we get

$$
\begin{aligned}
\dot x_1 &= x_2,\\
\dot x_2 &= x_1 - 2x_1^3 + \mu_1 x_2(1-x_1^2) - \left(\frac{2\mu_2}{1+\mu_2}\right)x_3 - \left(\frac{\mu_2}{1+\mu_2}\right)x_2,\\
\dot x_3 &= \left(\frac{\mu_2}{1+\mu_2}\right)x_2 - \left(\frac{2}{1+\mu_2}\right)x_3.
\end{aligned}
$$

The eigenvalues of $D_1 f(0,0)$ are $\lambda_1 = -2$, $\lambda_2 = -1$, $\lambda_3 = 1$. When $\mu = 0$ this system has a homoclinic solution given by $\gamma = (r, \dot r, 0)$. For a dichotomous variational solution along γ we first take $u_2 = \dot\gamma = (\dot r, \ddot r, 0)$. Using variation of parameter we obtain a second solution of the form $u_1 = (P\dot r, (P\dot r)^{\cdot}, 0)$, where P is a differentiable function which satisfies $(P\dot r)^{\cdot}\dot r - P\dot r\ddot r = \dot P\dot r^2 = 1$, an arbitrary constant.

For a third solution we have $u_3 = (0, 0, e^{-2t})$.

Notice that u_1 connects λ_3 to λ_2 (type uu), u_2 connects λ_2 to λ_3 (type ss), and u_3 connects λ_1 to λ_1 (type su). Thus, we have a dichotomous variational solution, necessarily, with $n_{ss} = d_b = 1$.

Using $u_1^{\perp} = (-\ddot{r}, \dot{r}, 0)$ we compute $a_1 = -\frac{2}{5}$ and $a_2 = \frac{2}{3}$ so Corollary 7 applies. There exists a function ϕ such that $\phi(0) = 0$, $\phi'(0) = \frac{5}{3}$ and such that the dynamical system has a homoclinic solution for $\mu_1 = \phi(\mu_2)$.

Example 3. The preceding example can easily be generalized to higher dimension. For example, consider the equations

$$\begin{aligned}\ddot{x} &= x - 2x^3 + \mu_1\dot{x}(1 - x^2) + \mu_2(\dot{y} - \dot{x}),\\ \ddot{y} &= y + \mu_2(\dot{x} - \dot{y}).\end{aligned}$$

The phase space for this system is $\mathcal{R}^4$ with coordinates $(x, \dot{x}, y, \dot{y})$. The eigenvalues of $D_1 f(0,0)$ are $\lambda_1 = -1$, $\lambda_2 = -1$, $\lambda_3 = 1$, $\lambda_4 = 1$ and, when $\mu = 0$, a homoclinic solution is given by $\gamma = (r, \dot{r}, 0, 0)$. A dichotomous variational solution is given by

$u_1 = (P\dot{r}, (P\dot{r})^{\cdot}, 0, 0),$	connects λ_3 to λ_2,	type uu,
$u_2 = (\dot{r}, \ddot{r}, 0, 0),$	connects λ_2 to λ_3,	type ss,
$u_3 = (0, 0, e^{-t}, -e^{-t}),$	connects λ_1 to λ_1,	type su,
$u_4 = (0, 0, e^{t}, e^{t}),$	connects λ_2 to λ_2,	type us,

where P is as in the preceding example. Things are numbered so that $I_{uu} = \{1\}$, $I_{ss} = \{2\}$, and $u_2 = \dot{\gamma}$. Since $n_{ss} = 1$, $d_b = 1$, and Corollary 7 still applies. A straightforward calculation with $u_1^{\perp} = (-\ddot{r}, \dot{r}, 0, 0)$ yields the same values for each a_i as in the previous examples.

Example 4. We now turn to some examples with $d_b = 2$. The most natural way to achieve this is to replace the second equation in Example 3 with a Duffing's equation. The problem with this is that then $W^s \cap W^u$ is a manifold which is a higher degree of degeneracy. Such a system is considered in Example 7 below. For now we consider

$$\begin{aligned}\ddot{x} &= x - \tfrac{4}{3}x^3 - \tfrac{2}{3}y^3 + \mu_1(x + a\dot{x}),\\ \ddot{y} &= y - \tfrac{4}{3}y^3 - \tfrac{2}{3}x^3 + \mu_2(y + b\dot{y}),\end{aligned}$$

where a, b are constants.

A homoclinic solution, when $\mu = 0$, is given by $x = y = r$. We work in the phase space $(x, \dot{x}, y, \dot{y})$ and find the eigenvalues of $D_1 f(0,0)$ to be $\lambda_1 = -1$, $\lambda_2 = -1$, $\lambda_3 = 1$, $\lambda_4 = 1$. Letting $u = (v, \dot{v}, w, \dot{w})$ denote a typical solution to the variational equation we get

$$\begin{aligned}\ddot{v} &= v - 4r^2 v - 2r^2 w,\\ \ddot{w} &= w - 4r^2 w - 2r^2 v.\end{aligned}$$

One variational solution is given by $v = w = \dot{r}$, and variation of parameter leads to a second of the form $v = w = P\dot{r}$, where P is as in Example 2. A third solution is given by $v = -w = r$ and, once again turning to variation of parameter, a solution $v = -w = Qr$, where Q satisfies $(Qr)^{\cdot} r - Qr\dot{r} = \dot{Q}r^2 = 1$, an arbitrary constant.

We now have a dichotomous variational solution:

$u_1 = (Qr, (Qr)^{\cdot}, -Qr, -(Qr)^{\cdot}),$	connects λ_3 to λ_2,	type uu,
$u_2 = (P\dot{r}, (P\dot{r})^{\cdot}, P\dot{r}, (P\dot{r})^{\cdot}),$	connects λ_4 to λ_1,	type uu,
$u_3 = (r, \dot{r}, -r, -\dot{r}),$	connects λ_2 to λ_3,	type ss,
$u_4 = (\dot{r}, \ddot{r}, \dot{r}, \ddot{r}),$	connects λ_1 to λ_4,	type ss.

The u_i's have been numbered so that $I_{uu} = \{1, 2\}$, $I_{ss} = \{3, 4\}$, and $u_4 = \dot{\gamma}$. We see that $n_{ss} = 2$ which implies that $d_b = 2$. In the notation of Corollary 8 we compute

$$\begin{aligned} u_1^{\perp} &= \tfrac{1}{2}(-\dot{r}, r, \dot{r}, -r), \\ u_2^{\perp} &= \tfrac{1}{2}(-\ddot{r}, \dot{r}, -\ddot{r}, \dot{r}) \end{aligned}$$

and $a_{11} = -1$, $a_{12} = 1$, $a_{21} = -a/3$, $a_{22} = -b/3$, $b_1 = 2\pi$, $b_2 = 0$.

Since $\det(A) = (a + b)/3$ and

$$\langle u_4^{\perp}(0), \dot{\gamma}(0)\rangle = \langle u_4^{\perp}(0), u_4(0)\rangle = 1,$$

Corollary 8 applies as long as $a + b \neq 0$. In this case, there exists an interval, W, containing zero and a function $\phi : W \to \mathcal{R}^2$ with $\phi(0) = 0$, $\phi'(0) = 0$, $\phi''(0) = \frac{2\pi}{a+b}(b, -a)$ such that the dynamical system has a homoclinic solution when $\mu = \phi(\beta)$. We have a curve in the μ_1–μ_2 plane passing through the origin with slope $m = \phi_2''(0)/\phi_1''(0) = -a/b$.

Example 5. To obtain a value of $d_b = 3$ requires a minimum of $n = 6$ and, hence, the possibility of extensive calculations. We present a model problem which illustrates the principle. Consider the system:

$$\begin{aligned} \ddot{x} &= x - 2xz^2 + \dot{x}^2 + \mu_1 z, \\ \ddot{y} &= y - 2yz^2 + \dot{x}\dot{y}, \\ \ddot{z} &= z - 2z^3 + y\dot{y} + \mu_2 \dot{z}. \end{aligned}$$

We work in the phase space $(x, \dot{x}, y, \dot{y}, z, \dot{z})$ and easily compute the eigenvalues of $D_1 f(0, 0)$ to be $\lambda_1 = \lambda_2 = \lambda_3 = -1$, $\lambda_4 = \lambda_5 = \lambda_6 = 1$. A homoclinic solution when $\mu = 0$ is given by $x = y = 0$, $z = r$, i.e., $\gamma = (0, 0, 0, 0, r, \dot{r})$. The variational equation along γ uncouples so that it is easy to compute the following dichotomous variational solution:

$$\begin{array}{lll} u_1 = (Qr, (Qr)^{\cdot}, 0, 0, 0, 0), & \text{connects } \lambda_4 \text{ to } \lambda_1, & \text{type uu,} \\ u_2 = (0, 0, Qr, (Qr)^{\cdot}, 0, 0), & \text{connects } \lambda_5 \text{ to } \lambda_1, & \text{type uu,} \\ u_3 = (0, 0, 0, 0, P\dot{r}, (P\dot{r})^{\cdot}), & \text{connects } \lambda_6 \text{ to } \lambda_3, & \text{type uu,} \\ u_4 = (r, \dot{r}, 0, 0, 0, 0), & \text{connects } \lambda_1 \text{ to } \lambda_4, & \text{type ss,} \\ u_5 = (0, 0, r, \dot{r}, 0, 0), & \text{connects } \lambda_2 \text{ to } \lambda_5, & \text{type ss,} \\ u_6 = (0, 0, 0, 0, \dot{r}, \ddot{r}), & \text{connects } \lambda_3 \text{ to } \lambda_6, & \text{type ss.} \end{array}$$

The functions P and Q are as in earlier examples. Since u_4, u_5, and u_6 are each of type ss we have $d_b = n_{ss} = 3$. Things are numbered so that $I_{uu} = \{1, 2, 3\}$, $I_{ss} = \{4, 5, 6\}$, and $u_6 = \dot{\gamma}$. We take $\alpha(1) = 4$, $\alpha(2) = 5$, $\alpha(3) = 6$ so then $\langle u_{\alpha(3)}^{\perp}(0), \dot{\gamma}(0)\rangle = \langle u_6^{\perp}(0), u_6(0)\rangle = 1$.

Using

$$\begin{aligned} u_1^{\perp} &= (-\dot{r}, r, 0, 0, 0, 0), \\ u_2^{\perp} &= (0, 0, -\dot{r}, r, 0, 0), \\ u_3^{\perp} &= (0, 0, 0, 0, -\ddot{r}, \dot{r}), \end{aligned}$$

the equations $\sum a_{ij}\mu_j + \frac{1}{2}\sum\sum b_{ijk}\beta_j\beta_k = 0$ in Definition 9 become:

$$\begin{aligned} -2\mu_1 - \frac{\pi}{8}{\beta_1}^2 &= 0, \\ -\frac{\pi}{8}\beta_1\beta_2 &= 0, \\ -\tfrac{2}{3}\mu_2 - \frac{\pi}{8}{\beta_2}^2 &= 0. \end{aligned}$$

We see that these equations yield two characteristic vectors which, in the notation of Theorem 10, are summarized below.

$$\text{(i)} \qquad \beta^0 = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \qquad \mu^0 = \begin{pmatrix} -\frac{\pi}{16} \\ 0 \end{pmatrix}, \qquad C = \begin{pmatrix} -\frac{\pi}{4} & 0 & -2 & 0 \\ 0 & -\frac{\pi}{8} & 0 & 0 \\ 0 & 0 & 0 & -\frac{2}{3} \end{pmatrix},$$

$$\text{(ii)} \qquad \beta^0 = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \qquad \mu^0 = \begin{pmatrix} 0 \\ -\frac{3\pi}{16} \end{pmatrix}, \qquad C = \begin{pmatrix} 0 & 0 & -2 & 0 \\ -\frac{\pi}{8} & 0 & 0 & 0 \\ 0 & -\frac{\pi}{4} & 0 & -\frac{2}{3} \end{pmatrix}.$$

In each case $\text{rank}(C) = 3$ so there are two curves through the origin in the μ_1-μ_2 plane along which the perturbed system has a homoclinic solution. The curves have slopes 0 and ∞; that is, each curve is tangent to one of the axes.

Example 6. Example 4 used reflective symmetry to obtain $d_b = 2$. We now use rotational symmetry. Consider:

$$\begin{aligned} \ddot{x} &= x + 2x(x^2 + y^2) + \mu_1(x + \dot{x}), \\ \ddot{y} &= y + 2y(x^2 + y^2) + \mu_2(y - \dot{y}). \end{aligned}$$

A similar example is given in [19]. When $\mu = 0$ the eigenvalues of the origin are $\lambda_1 = -1$, $\lambda_2 = -1$, $\lambda_3 = 1$, $\lambda_4 = 1$ and the system has a homoclinic solution given by $x(t) = r(t)\cos\theta$, $y(t) = r(t)\sin\theta$ for all θ. We have a 2-manifold of homoclinic solutions so, necessarily, $d_b = 2$.

The necessary calculations are simplified by introduction of the rotated coordinates $\tilde{x} = x\cos\theta + y\sin\theta$, $\tilde{y} = -x\sin\theta + y\cos\theta$. In the phase space $(\tilde{x}, \dot{\tilde{x}}, \tilde{y}, \dot{\tilde{y}})$ we have $\gamma_\theta = (r, \dot{r}, 0, 0)$ and $\partial\gamma/\partial\theta = (0, 0, r, \dot{r})$. A dichotomous variational solution is given by

$$\begin{aligned} &u_1 = (0, 0, Qr, (Qr)^{\cdot}), && \text{connects } \lambda_3 \text{ to } \lambda_2, && \text{type uu}, \\ &u_2 = (P\dot{r}, (P\dot{r})^{\cdot}, 0, 0), && \text{connects } \lambda_4 \text{ to } \lambda_1, && \text{type uu}, \\ &u_3 = (0, 0, r, \dot{r}), && \text{connects } \lambda_2 \text{ to } \lambda_3, && \text{type ss}, \\ &u_4 = (\dot{r}, \ddot{r}, 0, 0), && \text{connects } \lambda_1 \text{ to } \lambda_4, && \text{type ss}. \end{aligned}$$

In the notation preceding Theorem 11 we use

$$\begin{aligned} u_1^{\perp} &= (0, 0, -\dot{r}, r), \\ u_2^{\perp} &= (-\ddot{r}, \dot{r}, 0, 0), \end{aligned}$$

and compute $a_{11} = \sin 2\theta$, $a_{12} = -\sin 2\theta$, $a_{21} = -\frac{2}{3}\cos^2\theta$, $a_{22} = \frac{2}{3}\sin^2\theta$. We find that the equation $A(\theta)\mu^0 = 0$ has a nontrivial solution for μ^0 when $\det(A(\theta)) = -\frac{2}{3}\sin 2\theta \cos 2\theta = 0$. We get three distinct results for $-\pi \leq \theta \leq \pi$, summarized as follows:

$$\text{(i)} \qquad \theta^0 = \pm\tfrac{\pi}{2}; \qquad \mu^0 = \begin{pmatrix} 1 \\ 0 \end{pmatrix}; \qquad C = \begin{pmatrix} -2 & 0 & 0 \\ 0 & 0 & \frac{2}{3} \end{pmatrix},$$

$$\text{(ii)} \qquad \theta^0 = 0, \pi; \qquad \mu^0 = \begin{pmatrix} 0 \\ 1 \end{pmatrix}; \qquad C = \begin{pmatrix} -2 & 0 & 0 \\ 0 & -\frac{2}{3} & 0 \end{pmatrix},$$

$$\text{(iii)} \qquad \theta^0 = \pm\tfrac{\pi}{4}, \mp\tfrac{3\pi}{4}; \qquad \mu^0 = \begin{pmatrix} 1 \\ 1 \end{pmatrix}; \qquad C = \begin{pmatrix} 0 & \pm 1 & \mp 1 \\ \pm\frac{4}{3} & -\frac{1}{3} & \frac{1}{3} \end{pmatrix}.$$

In each case $\operatorname{rank}(C) = 2$ so Theorem 11 can be applied three times. The result is three curves in the μ_1–μ_2 plane along which the system has a homoclinic solution. There is a curve tangent to each axis and one with a slope of one.

Example 7. When a system in $\mathcal{R}^4$ is such that the unperturbed system uncouples into a pair of equations, each with a homoclinic solution, there is always a 2-manifold of homoclinic solutions. For example, consider

$$\begin{aligned} \ddot{x} &= x - 2x^3 + \mu_1 y + \mu_2(3\dot{y} - \dot{x}), \\ \ddot{y} &= y - 2y^3 + \mu_1 x + \mu_2(\dot{x} + 2\dot{y}). \end{aligned}$$

The phase space for this system is $(x, \dot{x}, y, \dot{y})$. When $\mu = 0$ the eigenvalues are $\lambda_1 = -1$, $\lambda_2 = -1$, $\lambda_3 = 1$, $\lambda_4 = 1$, and a 2-manifold of homoclinic solutions is given by $x(t) = r(t)$, $y(t) = r(t - \theta)$. Using the function P from Example 2 we get a dichotomous variational solution:

$$\begin{aligned} u_{\theta 1}(t) &= ((P\dot{r})(t), (P\dot{r})^{\cdot}(t), 0, 0), && \lambda_3 \text{ to } \lambda_2, && \text{type uu}, \\ u_{\theta 2}(t) &= (0, 0, (P\dot{r})(t - \theta), (P\dot{r})^{\cdot}(t - \theta)), && \lambda_4 \text{ to } \lambda_1, && \text{type uu}, \\ u_{\theta 3}(t) &= (\dot{r}(t), \ddot{r}(t), 0, 0), && \lambda_2 \text{ to } \lambda_3, && \text{type ss}, \\ u_{\theta 4}(t) &= (0, 0, \dot{r}(t - \theta), \ddot{r}(t - \theta)), && \lambda_1 \text{ to } \lambda_4, && \text{type ss}. \end{aligned}$$

From this we get

$$\begin{aligned} u_{\theta 1}^{\perp}(t) &= (-\ddot{r}(t), \dot{r}(t), 0, 0), \\ u_{\theta 2}^{\perp}(t) &= (0, 0, -\ddot{r}(t - \theta), \dot{r}(t - \theta)). \end{aligned}$$

For the purposes of Theorem 11 we compute

$$\begin{aligned} A(\theta) &= \begin{pmatrix} I_1(\theta) & \frac{2}{3} - 3I_2(\theta) \\ -I_1(\theta) & -\frac{4}{3} - I_2(\theta) \end{pmatrix}, \\ \frac{dA}{d\theta}(\theta) &= \begin{pmatrix} I_1(\theta) & -3(I_1(\theta) - 6I_3(\theta)) \\ -I_2(\theta) & -I_1(\theta) + 6I_3(\theta) \end{pmatrix}. \end{aligned}$$

We have introduced the definitions preceding Example 1 and have used the relationships $dI_1/d\theta = I_2$, $dI_2/d\theta = I_1 - 6I_3$. Application of Theorem 11 requires the solution of the equation $\det(A(\theta)) = -\frac{2}{3}I_1(\theta)(6I_2(\theta) + 1) = 0$. It is easy to check that

$I_1(\theta) = 0$ has the solution $\theta = 0$ and a little computer work shows that this is the only solution. The equation $6I_2(\theta) + 1 = 0$ can be shown by computer calculation to have four solutions. The resulting five solutions to $A(\theta^0)\mu^0 = 0$ are:

$$\text{(i)} \qquad \theta^0 = 0, \qquad \mu^0 = \begin{pmatrix} 1 \\ 0 \end{pmatrix},$$

$$\text{(ii)} \qquad \theta^0 = \pm 2.199071, \qquad \mu^0 = \begin{pmatrix} .9005686 \\ \mp .4347139 \end{pmatrix},$$

$$\text{(iii)} \qquad \theta^0 = \pm 3.741983, \qquad \mu^0 = \begin{pmatrix} .9759556 \\ \mp .2179694 \end{pmatrix}.$$

In each case a computer calculation determines that $\operatorname{rank}(C) = 2$ so Theorem 12 can be applied five times. In the μ_1–μ_2 plane we have five curves through the origin along which the system has a homoclinic solution. One curve is tangent to the μ_1–axis, the others have slopes ±.4827105 and ±.2233395.

Acknowledgments. This work has benefitted greatly from the generous assistance of Stephen Schecter who read countless earlier drafts and pointed out errors and means of improvement. In addition, the SIAM referee provided two sets of useful comments including an additional reference.

DIFFERENTIAL OPERATORS AND THE LAGUERRE TYPE POLYNOMIALS*

W. N. EVERITT†, A. M. KRALL‡, L. L. LITTLEJOHN§, AND V. P. ONYANGO-OTIENO¶

Abstract. In 1940, all fourth-order differential equations which have a sequence of orthogonal polynomial eigenfunctions were classified by H. L. Krall, up to a linear change of variable. One of these equations was subsequently named the Laguerre type equation and various properties of the orthogonal polynomial solutions and the right-definite boundary value problem were studied by A. M. Krall in 1981. In this paper, the Laguerre type expression is further studied in the right-definite setting and the appropriate left-definite problem associated with the fourth-order Laguerre type differential expression is discussed in detail.

Key words. orthogonal polynomials, differential equations, right-definite boundary value problems, left-definite boundary value problems, self-adjoint operators

AMS(MOS) subject classifications. 33A65, 34B20, 41A10

1. Introduction. The existence of the Laguerre type differential equation and the corresponding orthogonal polynomial solutions was first observed by H. L. Krall in 1940; see [15] and [16] for the methods used by Krall to discover this and other differential equations having orthogonal polynomial solutions. Of course, these polynomials may be constructed by using the standard definition given in Szegö [23, §§ 2.1 and 2.2] with respect to the nondecreasing function $\hat{\sigma}$ where, for some given positive number A,

$$\hat{\sigma}(x)=\begin{cases}-1/A & \text{if } x\in(-\infty,0],\\ 1-e^{-x} & \text{if } x\in(0,\infty).\end{cases}\tag{1.1}$$

Let σ denote the regular, nonnegative measure generated by $\hat{\sigma}$ on the Borel sets of the real line $\mathbb{R}$. Further, let $L^2_\sigma[0,\infty)$ denote the Hilbert function space derived from this measure σ, i.e., if $\mathbb{C}$ represents the complex field,

$$L^2_\sigma[0,\infty):=\left\{f\colon[0,\infty)\to\mathbb{C}\,|\,f \text{ is Borel measurable on } [0,\infty) \text{ and } \int_{[0,\infty)}|f(x)|^2\,d\sigma(x)<\infty\right\}\tag{1.2}$$

with inner product given by

$$(f,g)_\sigma:=\frac{f(0)\bar{g}(0)}{A}+\int_0^\infty f(x)\bar{g}(x)\,e^{-x}\,dx.\tag{1.3}$$

Note that in (1.3), the integral is Lebesgue in view of the fact that $\hat{\sigma}$ is locally absolutely continuous with respect to Lebesgue measure on the open interval $(0,\infty)$; i.e., the functions f and g belong to the weighted Hilbert space $L^2(0,\infty;e^{-x})$ defined by

$$L^2(0,\infty;e^{-x})=\left\{f\colon(0,\infty)\to\mathbb{C}\,|\,f \text{ is Lebesgue measurable and } \int_0^\infty|f(x)|^2\,e^{-x}\,dx<\infty\right\}.$$

Since the monomials $x^n\in L^2_\sigma[0,\infty)$ $(n=0,1,2,\cdots)$, the Laguerre type polynomials, denoted in this paper by $\{R_n(x;A)|x\in[0,\infty);\,n=0,1,2,\cdots\}$, may be defined

through the Gram–Schmidt orthogonalization process; see [23, § 2.1]. For convenience, when the parameter $A>0$ is fixed, we shall write $\{R_n(x)\}$ or $\{R_n\}$ for this system of orthogonal polynomials. Alternatively, the Laguerre type polynomials may be found readily from the differential equation that they satisfy. Indeed, the Laguerre type polynomials are solutions of:

$$\begin{aligned} x^2y^{(4)}+(-2x^2+4x)y^{(3)}+(x^2-(2A+6)x)y'' \\ +((2A+2)x-2A)y'+ky=(\lambda_n+k)y, \end{aligned} \tag{1.4}$$

where $x\in(0,\infty)$, k is a fixed, nonnegative constant and

$$\lambda_n=n(n+2A+1), \qquad n=0,1,2,\cdots. \tag{1.5}$$

We note that (1.4) may be put into formally symmetric form when multiplied by e^{-x}:

$$M_k[y]=(\lambda_n+k)\,e^{-x}y,$$

where, for $x\in(0,\infty)$,

$$M_k[y](x):=(x^2\,e^{-x}y''(x))''-(((2A+2)x+2)\,e^{-x}y'(x))'+k\,e^{-x}y(x). \tag{1.6}$$

By using elementary power series techniques in (1.4), we can easily find an explicit formula for the Laguerre type polynomials. Indeed, we see that

$$R_n(x):=\sum_{j=0}^{n}\frac{(-1)^j}{(j+1)!}\binom{n}{j}((A+n+1)j+A)x^j, \qquad n=0,1,2,\cdots, \tag{1.7}$$

normalized so that $R_n(0)=A$ for all $n=0,1,2,\cdots$. These polynomials satisfy the orthogonality relation

$$\begin{aligned} (R_n,R_m)_\sigma=\int_{[0,\infty)}R_n(x)R_m(x)\,d\sigma(x)=(A+n+1)(A+n)\delta_{nm}, \\ n,m=0,1,2,\cdots, \end{aligned} \tag{1.8}$$

where δ_{nm} is the Kronecker delta function.

For general information concerning orthogonal polynomial solutions to differential equations of the form

$$\sum_{k=1}^{r}a_k(x)y^{(k)}(x)=\lambda y(x), \tag{1.9}$$

the reader is referred to the review articles [13] and [14]. Observe that, in (1.4) and (1.6), the spectral parameter λ and the degree of the polynomial solution do not appear in the coefficients on the left-hand side of the equations, a feature which is necessary for the study of the spectral properties of the differential expression (1.6). Furthermore, we note that it is a remarkable property that the Laguerre type polynomials satisfy a linear, fourth-order differential equation with this property. Certainly, it is not uncommon for orthogonal polynomials to satisfy differential equations (see, for example, [14]), but it is rare indeed that orthogonal polynomials satisfy a differential equation of the form (1.9), where the coefficients $a_k(x)$ are functions of x only. For example, only the classical orthogonal polynomials of Jacobi, Laguerre, and Hermite and the Bessel polynomials satisfy second-order differential equations of this type. In the fourth-order case, Krall [16] showed that the only differential equations of the form (1.9) with orthogonal polynomial solutions, apart from the formal squares of the known second-order equations, are the Legendre type, Laguerre type, and Jacobi type equations.

In the paper by A. M. Krall [12], the properties of the Laguerre type polynomials $\{R_n(x)\}$ are developed in detail. In particular, information is given on the three-term recurrence relation, the Rodrigues type formula, and the generating function for the polynomials. The paper [12] is also concerned with studying some of the properties of a certain self-adjoint operator generated by $M_k[\cdot]$ in the Hilbert space $L^2(0,\infty;\, e^{-x})\otimes\mathbb{C}$, which is isometrically isomorphic to $L^2_\sigma[0,\infty)$, having the Laguerre type polynomials as eigenfunctions.

The purpose of this present paper is to extend the ideas and methods in the earlier papers of Everitt, Krall, and Littlejohn [6], [7], and [12], to a study of the right-definite and left-definite spectral problems associated with the differential equation

$$M_k[y](x)=\lambda\, e^{-x}y(x) \qquad (x\in(0,\infty)).$$

The right-definite problem is studied in the Hilbert space $L^2_\sigma[0,\infty)$ and the left-definite problem in the Sobolev space $H^2_\sigma[0,\infty)$, where

$$\begin{aligned}H^2_\sigma[0,\infty)&:=\{f\colon [0,\infty)\to\mathbb{C}\,|\, f\in AC_{\text{loc}}[0,\infty);\, f'\in AC_{\text{loc}}(0,\infty);\\ &\qquad f,\,(x+1)^{1/2}f',\, xf''\in L^2(0,\infty,\, e^{-x})\}\end{aligned} \tag{1.10}$$

and the inner product is defined, for $f,\ g\in H^2_\sigma[0,\infty)$, by

$$(f,g)_H:=\int_0^\infty \{x^2\, e^{-x}f''(x)\bar{g}''(x)+((2A+2)x+2)\, e^{-x}f'(x)\bar{g}'(x)\}\,dx+k(f,g)_\sigma. \tag{1.11}$$

We are able to show that there is a self-adjoint representation of both the right-definite and left-definite problems for which, respectively, the Laguerre type polynomials $\{R_n(x)\}$ are determined as a complete set of eigenfunctions in the spaces $L^2_\sigma[0,\infty)$ and $H^2_\sigma[0,\infty)$.

Earlier work on the spectral representation of some of the classical orthogonal polynomials is given in Titchmarsh [24, Chap. IV], together with results which connect the Titchmarsh-Weyl m-coefficient theory with self-adjoint differential operators as given by Chaudhuri and Everitt [2]. The ideas and methods of Titchmarsh were extended to cover the right-definite and left-definite problems for the classical Laguerre orthogonal polynomials by Onyango-Otieno [19] and [20].

The contents of the paper are as follows. In § 2, we develop the properties of the maximal domain Δ_k in $L^2(0,\infty;\, e^{-x})$ associated with the differential expression $M_k[\cdot]$. In §§ 3 and 4, we establish the self-adjointness of the right-definite operator $T_k[\cdot]$ in the right-definite space $L^2_\sigma[0,\infty)$ and determine explicitly the spectrum $\sigma(T_k)$ of $T_k[\cdot]$. By taking advantage of the spectral properties of $T_k[\cdot]$ in $L^2_\sigma[0,\infty)$ we show, in § 5, that all self-adjoint operators generated by $M_k[\cdot]$ in $L^2(0,\infty;\, e^{-x})$ have discrete spectrums that are bounded below. Section 6 contains a proof of the density of the Laguerre type polynomials in the left-definite space $H^2_\sigma[0,\infty)$. Finally, in § 7, we present the left-definite theory for the Laguerre type orthogonal polynomials, including the definition and various properties of the self-adjoint operator $S_k[\cdot]$ in the Sobolev space $H^2_\sigma[0,\infty)$.

2. The differential expression M_k. In this section, we shall study properties of the differential expression $M_k[\cdot]$ defined in (1.6); i.e., for $x\in(0,\infty)$,

$$M_k[f](x):=(x^2\, e^{-x}f''(x))''-(((2A+2)x+2)\, e^{-x}f'(x))'+k\, e^{-x}f(x). \tag{2.1}$$

Let Δ_k denote the *maximal domain* of $M_k[\cdot]$ in $L^2(0,\infty;\, e^{-x})$; i.e.,

$$\Delta_k:=\{f\colon (0,\infty)\to\mathbb{C}\,|\, f^{(r)}\in AC_{\text{loc}}(0,\infty),\ r=0,1,2,3;\, f,\, e^xM_k[f]\in L^2(0,\infty;\, e^{-x})\}. \tag{2.2}$$

Standard techniques show that Δ_k is dense in $L^2(0, \infty; e^{-x})$; see [18, Chap. 5]. The *maximal operator* $T_{\max}[\cdot]$ generated by $M_k[\cdot]$ in $L^2(0, \infty; e^{-x})$ is defined to be:

$$T_{\max}[f](x) = e^x M_k[f](x) \qquad (x \in (0, \infty)),$$
$$\mathscr{D}(T_{\max}) = \Delta_k.$$

For f, $g \in \Delta_k$, and $[\alpha, \beta] \subset (0, \infty)$, we have *Green's formula*:

$$\int_\alpha^\beta \{e^x M_k[f](x)\bar{g}(x) - e^x \overline{M_k[g]}(x) f(x)\}\, e^{-x}\, dx = [f, g](x)|_\alpha^\beta, \tag{2.3}$$

where, for $x \in (0, \infty)$,

$$\begin{aligned} [f, g](x) := {} & \{(x^2\, e^{-x} f''(x))' - ((2A+2)x+2)\, e^{-x} f'(x)\}\bar{g}(x) - x^2\, e^{-x} f''(x)\bar{g}'(x) \\ & -\{(x^2\, e^{-x}\bar{g}''(x))' - ((2A+2)x+2)\, e^{-x}\bar{g}'(x)\} f(x) \\ & + x^2\, e^{-x} f'(x)\bar{g}''(x), \end{aligned} \tag{2.4}$$

and *Dirichlet's formula*:

$$\begin{aligned} & \int_\alpha^\beta \{x^2\, e^{-x} f''(x)\bar{g}''(x) + ((2A+2)x+2)\, e^{-x} f'(x)\bar{g}'(x) + k\, e^{-x} f(x)\bar{g}(x)\}\, dx \\ & \quad = \{-(x^2\, e^{-x} f''(x))'\bar{g}(x) + ((2A+2)x+2)\, e^{-x} f'(x)\bar{g}(x))\}|_\alpha^\beta \\ & \qquad + x^2\, e^{-x} f''(x)\bar{g}'(x)|_\alpha^\beta + \int_\alpha^\beta M_k[f](x)\bar{g}(x)\, dx. \end{aligned} \tag{2.5}$$

By Green's formula and the definition of Δ_k, note that the limits $[f, g](\infty) := \lim_{x\to\infty} [f, g](x)$ and $[f, g](0) := \lim_{x\to 0^+} [f, g](x)$ exist and are finite, for all f, $g \in \Delta_k$.

The *minimal operator* $T_{\min}[\cdot]$, generated by $M_k[\cdot]$ in $L^2(0, \infty; e^{-x})$, may be defined to be

$$T_{\min}[f](x) = e^x M_k[f](x) \qquad (x \in (0, \infty)),$$
$$\mathscr{D}(T_{\min}) = \{f \in \mathscr{D}(T_{\max}) | [f, g](\infty) = [f, g](0) \text{ for all } g \in \mathscr{D}(T_{\max})\}.$$

There is a strong similarity between the behavior of $M_k[\cdot]$ near the singular endpoint $x = 0$ and that of the Legendre type expression (see [6] and [7]) near the singular endpoints $x = \pm 1$. In fact, $M_k[\cdot]$ is limit-3 at the point $x = 0$ with the same form of Frobenius solutions as that of the Legendre type expression at $x = \pm 1$; the reader is referred to [11, pp. 396-403] for details on the Frobenius method. We shall therefore simply quote, without proof, appropriate results corresponding to Theorem 2.1 in [6], and Theorem 1.1 and Corollary 2.1 of [7], which continue to hold for f, $g \in \Delta_k$ at $x = 0$. We state these results as follows.

THEOREM 2.1. *Let f, $g \in \Delta_k$ and $a \in (0, \infty)$. Then*

(i) $\lim_{x\to 0^+} \{(x^2\, e^{-x} f''(x))' - ((2A+2)x+2)\, e^{-x} f'(x)\}$ *exists and is finite*;

(ii) $f'' \in L^2(0, a]$;

(iii) $f, f' \in AC[0, a]$; *i.e.*, $f, f' \in AC_{\mathrm{loc}}[0, \infty)$;

(iv) $\lim_{x\to 0^+} (x^2\, e^{-x} f''(x))' = 0$;

(v) $x\, e^{-x} f'' \in L^2(0, a]$;

(vi) $\lim_{x\to 0^+} x^2\, e^{-x} f''(x)\bar{g}'(x) = 0$;

(vii) $\lim_{x\to 0^+} [f, 1](x) = -2f'(0)$; $\lim_{x\to 0^+} [f, x](x) = 2f(0)$; $\lim_{x\to 0^+} [f, x^2](x) = 0$;

(viii) $\lim_{x\to 0^+} [f, g](x) = 2(f(0)\bar{g}'(0) - f'(0)\bar{g}(0))$.

Unfortunately, the methods used to establish the analogue of Theorem 2.1 for the Legendre type expression at $x = \pm 1$ do not seem to carry over in analyzing the Laguerre type expression at $x=\infty$. Recently, however, Race [21] has developed some sufficient conditions, based on ideas from [4], in order for a fourth-order differential expression to be strong limit-2 and Dirichlet at $x=\infty$. The Laguerre type differential expression satisfies Race's criteria, as he shows in [21]; we are grateful to David Race for allowing us to publish from his manuscript before publication. We can state the following theorem.

THEOREM 2.2. *Let $f, g \in \Delta_k$. Then*

(i) *The differential expression $M_k[\cdot]$ is strong limit-2 at $x=\infty$; i.e.,*

$$\lim_{x\to\infty}\{x^2 e^{-x}f''(x)\bar{g}'(x)+((2A+2)x+2)e^{-x}f'(x)\bar{g}(x)-(x^2 e^{-x}f''(x))'\bar{g}(x)\}=0.$$

(ii) *$M_k[\cdot]$ is Dirichlet at $x=\infty$; i.e., xf'', $x^{1/2}f' \in L^2(1,\infty; e^{-x})$.*

As a consequence of Theorems 2.1 and 2.2, we obtain the following simplified limiting forms of, respectively, Green's formula and Dirichlet's formula: for $f, g \in \Delta_k$,

$$\int_0^\infty \{e^x M_k[f](x)\bar{g}(x)-e^x\overline{M_k[g]}(x)f(x)\}\,e^{-x}\,dx = 2\bar{g}(0)f'(0)-2f(0)\bar{g}'(0), \tag{2.6}$$

and

$$\begin{aligned}\int_0^\infty \{x^2 e^{-x}f''(x)\bar{g}''(x)+((2A+2)x+2)e^{-x}f'(x)\bar{g}'(x)+k\,e^{-x}f(x)\bar{g}(x)\}\,dx \\ = -2f'(0)\bar{g}(0)+\int_0^\infty e^x M_k[f](x)\bar{g}(x)\,e^{-x}\,dx.\end{aligned} \tag{2.7}$$

3. A certain self-adjoint operator in $L^2(0,\infty; e^{-x})$. In this section, we find a certain self-adjoint extension of the minimal operator $T_{\min}[\cdot]$ generated by $M_k[\cdot]$ in $L^2(0,\infty; e^{-x})$. As the reader will see, this particular self-adjoint operator plays a key role in establishing the self-adjointness of the right-definite operator defined and discussed below in § 4. A characterization of all self-adjoint extensions of $T_{\min}[\cdot]$ in $L^2(0,\infty; e^{-x})$ will be given in § 5. The reader is encouraged to consult [18, Chap. 5] for details on the general theory of self-adjoint extensions of formally symmetric differential expressions.

Since $M_k[\cdot]$ is limit-2 at $x=\infty$ in $L^2(0,\infty; e^{-x})$, we note that the domain of the minimal operator $T_{\min}[\cdot]$ generated by $M_k[\cdot]$ in $L^2(0,\infty; e^{-x})$ is given by (see [18, § 18.3]):

$$\mathscr{D}(T_{\min})=\{f\in\mathscr{D}(T_{\max})\,|\,[f,g](0)=0 \text{ for all } g\in\mathscr{D}(T_{\max})\}. \tag{3.1}$$

In fact, from (3.1) and (viii) of Theorem 2.1, we see that

$$f\in\mathscr{D}(T_{\min}) \text{ if and only if } f(0)=f'(0)=0. \tag{3.2}$$

From [18, § 18.1], we see that all self-adjoint extensions of $T_{\min}[\cdot]$ can be determined by imposing on Δ_k one boundary condition at $x=0$ of the form

$$[f,g](0)=0, \qquad f\in\Delta_k,$$

where g is any function in $\Delta_k\backslash\mathscr{D}(T_{\min})$ satisfying $[g,g](0)=0$. In particular, we can take as a boundary condition $[f,1](0)=0$, or equivalently $f'(0)=0$, by using Theorem 2.1 (vii). From the theory of Naimark, we then have that the following operator in $L^2(0,\infty; e^{-x})$ is self-adjoint:

$$\begin{aligned}A_k[f](x)&=e^x M_k[f](x) \qquad (x\in(0,\infty)),\\ \mathscr{D}(A_k)&=\{f\in\Delta_k\,|\,f'(0)=0\}.\end{aligned} \tag{3.3}$$

Since $\mathcal{D}(A_k) \subset \Delta_k$ it follows, from (2.7) and the fact that the functions $x^2 e^{-x}$ and $((2A+2)x+2)\,e^{-x}$ are positive on $(0,\infty)$, that

$$(3.4)\qquad \begin{aligned}(A_k[f],f) &= \int_0^\infty M_k[f](x)\bar{f}(x)\,dx\\ &= \int_0^\infty \{x^2 e^{-x}|f''(x)|^2 + ((2A+2)x+2)\,e^{-x}|f'(x)|^2 + k\,e^{-x}|f(x)|^2\}\,dx\\ &\geqq k(f,f), \qquad f \in \mathcal{D}(A_k),\end{aligned}$$

where $(\cdot,\cdot)$ denotes the inner product in $L^2(0,\infty;\, e^{-x})$. Thus $A_k[\cdot]$ is bounded below by kI, where I is the identity operator in $L^2(0,\infty;\, e^{-x})$. Hence, if $k>0$, we see that $0 \in \rho(A_k)$, the resolvent set of $A_k[\cdot]$. Consequently, when $k>0$, the resolvent operator $R_0(A_k) = A_k^{-1}$ exists and is a bounded operator from $L^2(0,\infty;\, e^{-x})$ onto $\mathcal{D}(A_k)$. We shall assume, for the remainder of this paper, that $k>0$.

4. The right-definite self-adjoint operator in $L^2_\sigma[0,\infty)$. In this section we shall discuss the appropriate self-adjoint operator $T_k[\cdot]$ in $L^2_\sigma[0,\infty)$ generated by $M_k[\cdot]$ that has the Laguerre type polynomials as eigenfunctions and whose spectrum is given by $\{\lambda_n + k \mid n = 0,1,2,\cdots\}$.

Let T_k: $\mathcal{D}(T_k) \to L^2_\sigma[0,\infty)$ be the operator defined by

$$(4.1)\qquad \begin{aligned}T_k[f](x) &:= \begin{cases} -2Af'(0) + kf(0) & \text{if } x = 0,\\ e^x M_k[f](x) & \text{if } x \in (0,\infty),\end{cases}\\ \mathcal{D}(T_k) &= \Delta_k.\end{aligned}$$

From Theorem 2.1 (iii), we see that $\Delta_k \subset L^2_\sigma[0,\infty)$ so that $T_k[\cdot]$ does indeed map $\mathcal{D}(T_k)$ into $L^2_\sigma[0,\infty)$. Observe, from (1.4), that if $f \in C^4[0,\infty)$, then $T_k[f](x) = e^x M_k[f](x)$ for all $x \in [0,\infty)$. It is precisely this property that prompts the definition of $T_k[\cdot]$ in (4.1). Furthermore, it is easy to check that $R_n \in \Delta_k$ and $T_k[R_n](x) = (\lambda_n + k)R_n(x)$, $x \in [0,\infty)$ and $n = 0,1,2,\cdots$, where R_n is the nth Laguerre type polynomial defined in (1.7). That is to say, the Laguerre type polynomials are eigenfunctions of $T_k[\cdot]$. We first prove the following theorem.

THEOREM 4.1.

(i) *$T_k[\cdot]$ in $L^2_\sigma[0,\infty)$ is a symmetric operator.*

(ii) *$T_k[\cdot]$ is bounded below by kI, where I denotes the identity operator in $L^2_\sigma[0,\infty)$.*

Proof. Let f, $g \in \Delta_k$. Then

$$(4.2)\qquad \begin{aligned}(T_k[f],g)_\sigma &= \int_0^\infty e^x M_k[f](x)\bar{g}(x)\,e^{-x}\,dx + \frac{T_k[f](0)\bar{g}(0)}{A}\\ &= 2\bar{g}(0)f'(0) - 2\bar{g}'(0)f(0) + \left(\frac{-2Af'(0)+kf(0)}{A}\right)\bar{g}(0)\\ &\quad + \int_0^\infty e^x\overline{M_k[g]}(x)f(x)\,e^{-x}\,dx,\\ &= -2\bar{g}'(0)f(0) + \frac{kf(0)\bar{g}(0)}{A} + \int_0^\infty e^x\overline{M_k[g]}(x)f(x)\,e^{-x}\,dx\\ &= \left(\frac{-2A\bar{g}'(0)+k\bar{g}(0)}{A}\right)f(0) + \int_0^\infty e^x\overline{M_k[g]}(x)f(x)\,e^{-x}\,dx\\ &= (f, T_k[g])_\sigma,\end{aligned}$$

by (2.6) and the definition of $T_k[\cdot]$. Hence $T_k[\cdot]$ in $L^2_\sigma[0,\infty)$ is hermitian. Since $C_0^\infty[0,\infty)\subset\Delta_k$ and $C_0^\infty[0,\infty)$ is dense in $L^2_\sigma[0,\infty)$, it follows that $T_k[\cdot]$ is symmetric in $L^2_\sigma[0,\infty)$.

Moreover, it follows from Dirichlet's formula (2.7) that

$$\begin{aligned}\int_0^\infty & e^x\overline{M_k[g]}(x)f(x)\,e^{-x}\,dx\\ &=2\bar g'(0)f(0)\\ &\quad+\int_0^\infty\{x^2\,e^{-x}f''(x)\bar g''(x)+((2A+2)x+2)\,e^{-x}f'(x)\bar g'(x)+k\,e^{-x}f(x)\bar g(x)\}\,dx.\end{aligned}$$

Combining this last equality with (4.2) yields for all $f,\ g\in\Delta_k$:

$$\begin{aligned}&(T_k[f],g)_\sigma\\ &=\frac{kf(0)\bar g(0)}{A}+\int_0^\infty\{x^2\,e^{-x}f''(x)\bar g''(x)+((2A+2)x+2)\,e^{-x}f'(x)\bar g'(x)\\ &\qquad\qquad+k\,e^{-x}f(x)\bar g(x)\}\,dx.\\ &=\int_0^\infty\{x^2\,e^{-x}f''(x)\bar g''(x)+((2A+2)x+2)\,e^{-x}f'(x)\bar g'(x)\}\,dx+k(f,g)_\sigma.\end{aligned}\tag{4.3}$$

In particular, as in (3.4), we see that

$$(T_k[f],f)_\sigma\geqq k(f,f)_\sigma.$$

Hence $T_k[\cdot]$ is bounded below by kI in $L^2_\sigma[0,\infty)$. This completes the proof. □

Remarks.

(1) We shall discuss, in detail, the left-definite problem associated with $M_k[\cdot]$ in § 7. However, we point out now that the left-definite inner product $(\cdot,\cdot)_H$ defined in (1.11) coincides with the right-hand side of (4.3) above. Indeed, it is precisely this identity in (4.3) which prompts the definition of $(f,g)_H$ in (1.11).

(2) Since $T_k[R_n]=(\lambda_n+k)R_n$, $n=0,1,2,\cdots$, we see from (1.5), (1.8), (1.11), and (4.3) that

$$\begin{aligned}&(R_n,R_m)_H\\ &=\int_0^\infty\{x^2\,e^{-x}R_n''(x)R_m''(x)+((2A+2)x+2)\,e^{-x}R_n'(x)R_m'(x)\}\,dx+k(R_n,R_m)_\sigma\\ &=n(n+2A+1)(A+n+1)(A+n)\delta_{nm};\end{aligned}\tag{4.4}$$

i.e., the Laguerre type polynomials $\{R_n(x)\}$ form an orthogonal set in the weighted Sobolev space H defined by (1.10) and (1.11). We shall show that they, in fact, form a complete orthogonal set in $H^2_\sigma[0,\infty)$ in § 6.

To show that $T_k[\cdot]$ is self-adjoint in $L^2_\sigma[0,\infty)$, we shall first establish the self-adjointness of two operators T_k' and T_k'' which form a decomposition of T_k; i.e., $T_k=T_k'+T_k''$. This requires us to consider the solutions of the equation

$$M_k[y](x)=0\qquad(x\in(0,\infty))\tag{4.5}$$

which are in $L^2(0,\infty;e^{-x})$. First, we note that the deficiency index of the minimal operator $T_{\min}[\cdot]$ generated by $M_k[\cdot]$ in $L^2(0,\infty;e^{-x})$ is (1, 1); i.e., for any $\lambda\in\mathbb{C}$ with nonzero imaginary part, the equation

$$M_k[y](x)=\lambda\,e^{-x}y(x)\qquad(x\in(0,\infty))$$

has only one linearly independent solution in $L^2(0,\infty; e^{-x})$. This follows from the limit classification in $L^2(0,\infty; e^{-x})$ of the singular endpoints $x=0$ and $x=\infty$ discussed in § 3; see [18, § 17.5]. Secondly, from (2.7) and (3.2), we see that

$$(T_{\min}[f], f) \geqq k(f, f), \qquad (f \in \mathcal{D}(T_{\min})), \tag{4.6}$$

where $(\cdot,\cdot)$ denotes the inner product in $L^2(0,\infty; e^{-x})$. That is to say, $T_{\min}[\cdot]$ is bounded below by kI, where I is the identity operator on $L^2(0,\infty; e^{-x})$. Using the Cauchy-Schwarz inequality together with (4.6), we have for any $c \in \mathbb{R}$, with $c<k$:

$$(k-c)\|f\|^2 \leqq (T_{\min}[f]-cf, f) \leqq \|T_{\min}[f]-cf\|\,\|f\|,$$

where $\|\cdot\| = (\cdot,\cdot)^{1/2}$.
Hence,

$$\|T_{\min}[f]-cf\| \geqq (k-c)\|f\| \qquad (f \in \mathcal{D}(T_{\min})).$$

For $k>0$, it follows then that $c=0$ is in the domain of regularity of the minimal operator $T_{\min}[\cdot]$ (see [18, § 14.9]). Furthermore, from [18, § 14.10, Cor. 2], we can conclude that there is only one linearly independent solution $\theta(x)$ of (4.5) which belongs to $L^2(0,\infty; e^{-x})$. Clearly, $\theta \in \Delta_k$. We claim that $\theta'(0) \neq 0$. For if $\theta'(0)=0$, then $\theta \in \mathcal{D}(A_k)$, where $A_k[\cdot]$ is the operator defined in (3.3). However, this means that θ is an eigenfunction of $A_k[\cdot]$ corresponding to the eigenvalue $\lambda=0$. This contradicts the fact that $0 \in \rho(A_k)$, the resolvent set of $A_k[\cdot]$. Consequently, $\theta'(0)\neq 0$. Without loss of generality, we may assume that $\theta'(0)=1$.

Define the operator T'_k in $L^2_\sigma[0,\infty)$ by:

$$\begin{aligned} T'_k[f](x) &= \begin{cases} -2Af'(0) & \text{if } x=0, \\ e^x M_k[f](x) & \text{if } x \in (0,\infty), \end{cases} \\ \mathcal{D}(T'_k) &= \Delta_k. \end{aligned} \tag{4.7}$$

Similar to the proof of Theorem 4.1, we find that $T'_k[\cdot]$ is a symmetric operator in $L^2_\sigma[0,\infty)$. It remains to show that $T'_k[\cdot]$ is self-adjoint in $L^2_\sigma[0,\infty)$. We do this by following the analysis given in [6, § 4] which requires the following theorem (see [1, § 46]).

THEOREM 4.2. *Let A be a symmetric operator in a Hilbert space H. If the range of A is all of H, then A is self-adjoint in H.*

THEOREM 4.3. *The operator $T'_k[\cdot]$ in $L^2_\sigma[0,\infty)$ is self-adjoint.*

Proof. Let $f \in L^2_\sigma[0,\infty)$ and define g: $[0,\infty)\to\mathbb{C}$ by

$$g(x) = \frac{-f(0)}{2A}\theta(x) + [R_0(A_k)f](x), \qquad x \in [0,\infty),$$

where $R_0(A_k) = A_k^{-1}$ is the resolvent operator of A_k at the regular point $\lambda=0$. We claim that $g \in \mathcal{D}(T'_k)$ and $T_k[g](x)=f(x)$, $x\in[0,\infty)$. Since $\theta \in \Delta_k = \mathcal{D}(T'_k)$ and $R_0(A_k)f \in \mathcal{D}(A_k) \subset \mathcal{D}(T'_k)$, we see that $g \in \mathcal{D}(T'_k)$. Also, from the definition of θ and the fact that $R_0(A_k)f \in \mathcal{D}(A_k)$, we see that $g'(0) = -f(0)/2A$. Hence $T'_k[g](0)=f(0)$. Since θ is a solution of the homogeneous equation (4.5) and $R_0(A_k)$ is the inverse of $e^xM_k[\cdot]$ on $(0,\infty)$, it follows that, for all $x \in (0,\infty)$,

$$T'_k[g](x) = e^xM_k[(-f(0)/2A)\theta(x) + [R_0(A_k)f](x)] = f(x);$$

i.e., $T'_k[g](x)=f(x)$, $x \in [0,\infty)$. Hence by Theorem 4.2, $T'_k[\cdot]$ is self-adjoint in $L^2_\sigma[0,\infty)$. □

Consider now the operator T_k'' in $L_\sigma^2[0,\infty)$ defined by

$$T_k''[f](x)=\begin{cases}kf(0) & \text{if } x=0,\\ 0 & \text{if } x\in(0,\infty),\end{cases}$$

$$\mathcal{D}(T_k'')=L_\sigma^2[0,\infty).$$

It is easy to check that $T_k''[\cdot]$ is symmetric in $L_\sigma^2[0,\infty)$ and since its domain is all of $L_\sigma^2[0,\infty)$, we have, in fact, that $T_k''[\cdot]$ is self-adjoint in $L_\sigma^2[0,\infty)$. By following similar arguments in [6, § 5], we have that $T_k=T_k'+T_k''$ is self-adjoint in $L_\sigma^2[0,\infty)$.

As Theorem 4.5 below states, the spectrum $\sigma(T)$ of $T_k[\cdot]$ consists of only the point spectrum $\{\lambda_n+k\,|\,n=0,1,2,\cdots\}$. To see this, it suffices to know that the Laguerre type polynomials are complete in $L_\sigma^2[0,\infty)$ or, equivalently, that the set of polynomials $P[0,\infty)$, where

$$P[0,\infty):=\left\{\sum_{k=0}^{n} a_kx^k\,|\,a_k\in\mathbb{C},\, n=0,1,2,\cdots,x\in[0,\infty)\right\}, \tag{4.8}$$

is dense in $L_\sigma^2[0,\infty)$. For, if $P[0,\infty)$ is dense in $L_\sigma^2[0,\infty)$, then a simple argument shows that the point spectrum of $T_k[\cdot]$ is given by:

$$\sigma_p(T_k)=\{\lambda_n+k\,|\,n=0,1,2,\cdots\}.$$

Indeed, suppose $\tilde\lambda\in\sigma_p(T_k)$ and $\tilde\lambda\neq\lambda_n+k$ for any $n=0,1,2,\cdots$. Let $\tilde f$ be an eigenfunction of $T_k[\cdot]$ associated with the eigenvalue $\tilde\lambda$; in particular, note that $\tilde f\not\equiv 0$ in $L_\sigma^2[0,\infty)$. Since the eigenfunctions of a self-adjoint operator are necessarily orthogonal, we have that $(\tilde f, R_n)_\sigma=0$, $n=0,1,2,\cdots$. However, from the completeness of $\{R_n(x)\}$ in $L_\sigma^2[0,\infty)$, this forces $\tilde f\equiv 0$ in $L_\sigma^2[0,\infty)$ which is a contradiction. By appealing to a well-known result (see [22, p. 361]), we conclude that the spectrum $\sigma(T_k)$ of $T_k[\cdot]$ is the closure in $\mathbb{C}$ of the point spectrum. Since $\lim_{n\to\infty}(\lambda_n+k)=\infty$, we have

$$\sigma(T_k)=\{\lambda_n+k\,|\,n=0,1,2,\cdots\}.$$

There are many routes to take in showing that $P[0,\infty)$ is dense in $L_\sigma^2[0,\infty)$. For example, this fact follows from theorems of M. Riesz and H. Hamburger, which we state below in Theorem 4.4 (see [10, Thm. 4.2, Prob. 19, Thm. 5.2, and the remark on p. 87]). To introduce this theorem, we use the same notation that Freud [10] uses.

Suppose $\hat\mu:\mathbb{R}\to\mathbb{R}$ is a distribution; i.e., $\hat\mu$ is a monotonic, nondecreasing function with infinitely many points of increase in $\mathbb{R}$. Let μ be the regular, positive, Borel measure generated by $\hat\mu$ on the Borel subsets of $\mathbb{R}$. The nth moment of $d\mu$ is defined to be

$$\mu_n:=\int_{-\infty}^{\infty} x^n\,d\mu(x),\qquad n=0,1,2,\cdots;$$

we shall assume that these numbers exist and are finite. Of course, this implies that $P[0,\infty)\subset L_\mu^1[0,\infty)\cap L_\mu^2[0,\infty)$. In this case, we say that the moment sequence $\{\mu_n\}$ is generated or determined by $\hat\mu(x)$. We say that the moment sequence is *determinate* if, whenever it is also generated by a distribution $\hat\nu(x)$, we have $\hat\mu(x)=\hat\nu(x)+c$ at all common points of continuity, where c is a fixed constant. If $\{\mu_n\}$ is determinate, we write $d\mu\in\mathscr{C}$ and say that $\hat\mu$ is *substantially unique*. We state the following theorem.

THEOREM 4.4. *With the notation as above.*

(a) (*M. Riesz*, 1923): $P[0,\infty)$ *is dense in* $L_\mu^2[0,\infty)$ *if and only if* $d\mu/(1+x^2)\in\mathscr{C}$.

(b) (*Hamburger*, 1919): *If there exists a* $\beta > 0$ *such that*

$$\int_{-\infty}^{\infty} e^{\beta|x|}\, d\mu(x) < \infty,$$

then $d\mu \in \mathscr{C}$.

In the case of the Laguerre type polynomials, it is easy to check that $d\sigma(x)/(1+x^2)$ satisfies Hamburger's condition (b) for any $0<\beta<1$. Hence, by Riesz' condition (a), we have that $P[0,\infty)$ is dense in $L^2_\sigma[0,\infty)$.

We summarize the main results of this section.

THEOREM 4.5. *The operator* $T_k[\cdot]$, *defined in* (4.1), *is self-adjoint in* $L^2_\sigma[0,\infty)$. *The Laguerre type polynomials* $\{R_n(x)\}$ *are eigenfunctions of* $T_k[\cdot]$ *and they form a complete orthogonal set in* $L^2_\sigma[0,\infty)$. *Furthermore, the spectrum of* $T_k[\cdot]$ *is given by*

$$\sigma(T_k) = \{n(n+2A+1)+k \mid n = 0, 1, 2, \cdots\}.$$

Note. Since $T_k[R_n](0) = (\lambda_n + k)R_n(0)$, we see, from the definition of $T_k[\cdot]$, that

$$-2AR_n'(0) = \lambda_n R_n(0). \tag{4.9}$$

This is the λ-dependent boundary condition discussed in [12] and [13]. Notice that it is satisfied by the eigenfunctions of $T_k[\cdot]$ and not, in general, by each element of $\mathscr{D}(T_k)$. Hence, (4.9) is seen as a property of the Laguerre type polynomials and not as an essential element in the definition of $T_k[\cdot]$; see also [6; § 5].

5. The spectrum of self-adjoint extensions of the minimal operator generated by M_k in $L^2(0,\infty; e^{-x})$. The main result in this section is concerned with the form and the spectrum of all self-adjoint operators generated by the minimal operator $T_{\min}[\cdot]$ of $M_k[\cdot]$ in $L^2(0,\infty;\, e^{-x})$. We prove the following theorem.

THEOREM 5.1. *Let* $T[\cdot]$ *be any self-adjoint extension of the minimal operator* $T_{\min}[\cdot]$ *generated by* $M_k[\cdot]$ *in* $L^2(0,\infty;\, e^{-x})$.

(i) *Then there exists a nonzero vector* $(\alpha,\beta)\in\mathbb{R}^2$ *such that* $T[\cdot]$ *is given by*

$$\begin{gathered} T[f](x) = e^x M_k[f](x) \qquad (x\in(0,\infty)), \\ \mathscr{D}(T) = \{f\in\mathscr{D}(T_{\max}) \mid \alpha f(0)+\beta f'(0) = 0\}. \end{gathered} \tag{5.1}$$

Conversely, each operator $T[\cdot]$ *in* $L^2(0,\infty;\, e^{-x})$ *of the form* (5.1), *where* $(\alpha,\beta)\in\mathbb{R}^2\backslash\{(0,0\}$, *is self-adjoint.*

(ii) *The spectrum of T is discrete and bounded below in* $L^2(0,\infty;\, e^{-x})$.

Proof.

(i) Define $\{h_1, h_2\}\subset\Delta_k = \mathscr{D}(T_{\max})$ such that

$$h_1(x) = \begin{cases} -\frac{1}{2} & \text{for } x \text{ near } 0, \\ 0 & \text{for } x \text{ sufficiently large,} \end{cases}$$

$$h_2(x) = \begin{cases} x/2 & \text{for } x \text{ near } 0, \\ 0 & \text{for } x \text{ sufficiently large.} \end{cases}$$

Note that $[h_1,h_1](0) = [h_2,h_2](0) = 0$, $[h_1,h_2](0) = -\frac{1}{2}$, and $[h_2,h_1](0) = \frac{1}{2}$. From (3.2), it is clear that $\{h_1,h_2\}$ is linearly independent modulo $\mathscr{D}(T_{\min})$. In fact, since the deficiency index of $T_{\min}$ in $L^2(0,\infty;\, e^{-x})$ is (1, 1), the set $\{h_1,h_2\}$ forms a basis for the quotient space $\mathscr{D}(T_{\max})/\mathscr{D}(T_{\min})$. Consequently, from [18, § 18.1], every self-adjoint extension T of the minimal operator $T_{\min}[\cdot]$ generated by $M_k[\cdot]$ in $L^2(0,\infty;e^{-x})$ has the form

$$T[f](x)=e^x M_k[f](x), \qquad x\in(0,\infty),$$
$$\mathscr{D}(T)=\{f\in\mathscr{D}(T_{\max})\,|\,[f,w](x)|_0^\infty=0\},$$

where $w(x)=ah_1(x)+bh_2(x)$ satisfies

$$(5.2) \qquad [w,w](x)|_0^\infty=0,$$

and $(a,b)\in\mathbb{C}^2$ is a nonzero vector. However, since $M_k[\cdot]$ is strong limit-2 at $x=\infty$ (actually, limit-2 at $x=\infty$ is sufficient), we see that $[f,w](\infty)=\lim_{x\to\infty}[f,w](x)=0$ for all $f\in\mathscr{D}(T_{\max})$. Hence the boundary condition in the definition above for $\mathscr{D}(T)$ reduces to requiring that

$$(5.3) \qquad [f,w](0)=0,$$

while the symmetry condition (5.2) reduces to

$$(5.4) \qquad [w,w](0)=0.$$

Written out in full, (5.4) yields the requirement

$$\begin{aligned}0=[w,w](0)&=[ah_1+bh_2,\,ah_1+bh_2](0)\\&=\bar{a}b[h_2,h_1](0)+a\bar{b}[h_1,h_2](0)\\&=\tfrac{1}{2}(\bar{a}b-a\bar{b}).\end{aligned}$$

This last requirement implies, without loss of generality, that both a and b can be taken as real numbers. For the boundary condition (5.3) is homogeneous in w, and so if $a\neq 0$ we can take $a=1$, and it then follows that $b=\bar{b}$ and so b is real; similarly if $b\neq 0$ then take $b=1$, and we obtain $a=\bar{a}$, and so a is real. We now define $\alpha=b$ and $\beta=a$. Returning to the boundary condition (5.3) and using (vii) of Theorem 2.1 above, we see that

$$[f,w](0)=\bar{a}[f,h_1](0)+\bar{b}[f,h_2](0)=\alpha f(0)+\beta f'(0),$$

and we obtain the given form of the boundary condition at the endpoint 0, as required in the statement above of Theorem 5.1. This completes the proof of (i).

(ii) We shall prove that the operator $T[\cdot]$ in $L^2(0,\infty;e^{-x})$ has a discrete spectrum by relating $T[\cdot]$ to the operator $T_k[\cdot]$ in the space $L^2_\sigma[0,\infty)$. This argument is identical to the one given in [7, § 4]. Recall, from (4.6), that the minimal operator $T_{\min}[\cdot]$ is bounded below by kI in $L^2(0,\infty;e^{-x})$. Now, if a semibounded operator has equal, finite deficiency indices, then every self-adjoint extension of this operator is also semibounded (see [18, § 14]). Hence every self-adjoint extension $T[\cdot]$ of $T_{\min}[\cdot]$ is bounded below in $L^2(0,\infty;e^{-x})$.

To show that the spectrum of $T[\cdot]$ in $L^2(0,\infty;e^{-x})$ is discrete, we need only show that the essential spectrum $\sigma_e(T)=\emptyset$, the empty set. Since $T[\cdot]$ is a finite-dimensional extension of $T_{\min}[\cdot]$, we have that $\sigma_e(T)=\sigma_e(T_{\min})$ (see [18, § 14.9, Thm. 9]. Suppose then, for some real number λ, we have $\lambda\in\sigma_e(T)=\sigma_e(T_{\min})$. Then there must be some bounded, noncompact sequence $\{f_n\,|\,n=1,2,\cdots\}$ in $L^2(0,\infty;e^{-x})$ such that

$$(5.5) \qquad f_n\in\mathscr{D}(T_{\min}),\ \|f_n\|=1 \text{ and } \lim_{n\to\infty}\|T_{\min}[f_n]-\lambda f_n\|=0$$

(see [25; Thm. 7.24]); here $\|\cdot\|$ refers to the norm of an element in the space $L^2(0,\infty;e^{-x})$. Since $T_{\min}[\cdot]$ is the closure of the operator restricted to those elements of the maximal domain Δ_k having compact support in the open interval $(0, \infty)$ (see, [18, § 17]), there is no loss of generality in supposing that each f_n above has compact support in $(0, \infty)$.

Embed each f_n in $L^2_\sigma[0, \infty)$ by setting $f_n(0)=0$ for all $n=1, 2, \cdots$; by doing this we have a sequence $\{f_n\} \subset \mathscr{D}(T_k)$. Moreover, we see that

$$\|f_n\| = \|f_n\|_\sigma \qquad n=1, 2, 3 \cdots, \tag{5.6}$$

$$\|T_k[f_n] - \lambda f_n\|_\sigma = \|T_{\min}[f_n] - \lambda f_n\|. \tag{5.7}$$

It follows from (5.5), (5.6), and (5.7) that $\{f_n\}$ is bounded and noncompact in $L^2_\sigma[0, \infty)$ and

$$\lim_{n\to\infty} \|T_k[f_n] - \lambda f_n\| = 0.$$

Thus we must have $\lambda \in \sigma_e(T_k)$. However, as we showed in Theorem 4.5, the spectrum of $T_k[\cdot]$ is discrete and thus $\sigma_e(T_k) = \emptyset$.

Hence $\sigma_e(T) = \emptyset$ and therefore the spectrum of every self-adjoint extension of the minimal operator $T_{\min}[\cdot]$ generated by $M_k[\cdot]$ in $L^2(0, \infty; e^{-x})$ is discrete. □

6. The density of polynomials in the Sobolev space $H^2_\sigma[0, \infty)$. In this section, we prove that $P[0, \infty)$, the space of polynomials defined in (4.8), is dense in the Hilbert space $H^2_\sigma[0, \infty)$, defined in (1.10). We refer the reader to [7, § 5] and [9] where different proofs are given for the completeness of polynomials in the Legendre type left-definite spaces. The proof that $H^2_\sigma[0, \infty)$ is complete in the topology generated from the inner product $(\cdot, \cdot)_H$, defined in (1.11), follows from standard results in the theory of Lebesgue integration. The reader is referred to [17] for the proof of the completeness of the left-definite Sobolev spaces associated with the Legendre type expressions.

Notice that $P[0, \infty)$ and Δ_k are all linear manifolds of the Hilbert space $H^2_\sigma[0, \infty)$. In fact, from Theorem 2.1, these spaces satisfy the following inclusion

$$P[0, \infty) \subset \Delta_k \subset H^2_\sigma[0, \infty). \tag{6.1}$$

Before establishing the density of $P[0, \infty)$ in $H^2_\sigma[0, \infty)$, we note that (4.3) simplifies to

$$(T_k[f], g)_\sigma = (f, g)_H \qquad (f, g \in \Delta_k).$$

From Theorems 2.1 and 2.2, it is not too difficult to generalize this identity and establish the following (see also [21]):

$$(T_k[f], g)_\sigma = (f, g)_H, \qquad (f \in \Delta_k, g \in H^2_\sigma[0, \infty)), \tag{6.2}$$

$$(f, T_k[g])_\sigma = (f, g)_H, \qquad (f \in H^2_\sigma[0, \infty), g \in \Delta_k). \tag{6.3}$$

From (4.4), we see that the Laguerre type polynomials $\{R_n(x)\}$ are orthogonal in $H^2_\sigma[0, \infty)$. Consequently, to prove the density of $P[0, \infty)$ in $H^2_\sigma[0, \infty)$ it suffices to show, equivalently, that $\{R_n(x)\}$ forms a complete orthogonal set in $H^2_\sigma[0, \infty)$.

Let $g \in H^2_\sigma[0, \infty)$ and suppose that

$$(R_n, g)_H = 0 \qquad (n=0, 1, \cdots). \tag{6.4}$$

We shall show that $g=0$ in the space $H^2_\sigma[0, \infty)$. From (6.2), we see that (6.4) yields

$$(\lambda_n + k)(R_n, g)_\sigma = 0 \qquad (n=0, 1, \cdots), \tag{6.5}$$

where we have used the fact that

$$T_k[R_n](x) = (\lambda_n + k)R_n(x) \qquad (x \in [0, \infty), n=0, 1, \cdots).$$

Since $\lambda_n + k > 0$ $(n=0, 1, \cdots)$, we see that (6.5) simplifies to

$$(R_n, g)_\sigma = 0 \qquad (n=0, 1, \cdots). \tag{6.6}$$

However, from Theorem 4.5, the Laguerre type polynomials $\{R_n(x)\}$ form a complete orthogonal set in $L^2_\sigma[0,\infty)$. Thus it follows, from (6.6), that $g=0$ in the space $L^2_\sigma[0,\infty)$; that is to say, $g(0)=0$ and $g(x)=0$ for almost all $x\in(0,\infty)$. But since $g\in AC_{\text{loc}}[0,\infty)$, we must have $g(x)\equiv 0$ on $[0,\infty)$ and hence $g=0$ in the space $H^2_\sigma[0,\infty)$. This completes the proof of the completeness of $\{R_n(x)\}$ in $H^2_\sigma[0,\infty)$.

We summarize by the following.

THEOREM 6.1. *The Laguerre type polynomials, defined in* (1.7), *form a complete set of orthogonal polynomials in the weighted Sobolev space* $H^2_\sigma[0,\infty)$. *Equivalently, the set* $P[0,\infty)$ *of polynomials, defined in* (4.8), *is dense in* $H^2_\sigma[0,\infty)$.

7. The Laguerre type left-definite theory. In this section, we shall discuss the left-definite theory associated with the Laguerre type differential expression $M_k[\cdot]$, defined in (1.6). The reader is referred to the contributions [5], [6], [7], [8], [9], [17], [19], and [20] for further studies of left-definite theory with applications in the theory of orthogonal polynomials.

Recall, from § 4, that the self-adjoint operator $T_k[\cdot]$ is bounded below by kI, where I is the identity operator on $L^2_\sigma[0,\infty)$. Hence, if $k>0$, then $0\in\rho(T_k)$, the resolvent set of $T_k[\cdot]$. Consequently, in this case, we see that $R_0(T_k)=T_k^{-1}$ is a bounded operator from $L^2_\sigma[0,\infty)$ onto Δ_k. Furthermore, note the following inclusion between the spaces Δ_k, $H^2_\sigma[0,\infty)$ and $L^2_\sigma[0,\infty)$:

$$\Delta_k\subset H^2_\sigma[0,\infty)\subset L^2_\sigma[0,\infty). \tag{7.1}$$

Define the operator B_k: $H^2_\sigma[0,\infty)\to H^2_\sigma[0,\infty)$ by

$$B_k[f](x)=R_0(T_k)[f](x)\qquad (x\in(0,\infty)),$$
$$f\in\mathscr{D}(B_k)=H^2_\sigma[0,\infty).$$

Note, from (7.1), that $B_k[\cdot]$ does indeed map $H^2_\sigma[0,\infty)$ into $H^2_\sigma[0,\infty)$. Furthermore from (6.2) and the fact that $B_k[f]\in\Delta_k$ for all $f\in H^2_\sigma[0,\infty)$, we see that:

$$(B_k[f],g)_H=(T_k(B_k[f]),g)_\sigma=(f,g)_\sigma,\qquad f,g\in H^2_\sigma[0,\infty).$$

Similarly, from (6.3), it follows that

$$(f,B_k[g])_H=(f,g)_\sigma,\qquad f,g\in H^2_\sigma[0,\infty).$$

Consequently, $B_k[\cdot]$ is a symmetric operator in $H^2_\sigma[0,\infty)$ and, since $\mathscr{D}(B_k)=H^2_\sigma[0,\infty)$, it follows that $B_k[\cdot]$ is self-adjoint in $H^2_\sigma[0,\infty)$. Moreover, if $B_k[f]=0$ for some $f\in H^2_\sigma[0,\infty)$, then $f=T_k(B_k[f])=0$ in $H^2_\sigma[0,\infty)$; i.e., $B_k[\cdot]$ is an injective map and hence $S_k:=B_k^{-1}$ exists. Furthermore, from [1, *I*, § 41], we see that $S_k[\cdot]$ is a self-adjoint operator in $H^2_\sigma[0,\infty)$.

Now, from the equality

$$R_n=B_k(T_k[R_n])=(\lambda_n+k)B_k[R_n],$$

we see that

$$S_k[R_n]=(\lambda_n+k)R_n,\qquad n=0,1,2,\cdots.$$

That is to say, the nth Laguerre type polynomial $R_n(x)$ is an eigenfunction of $S_k[\cdot]$. Since $\lim_{n\to\infty}(\lambda_n+k)=\infty$, we see that $S_k[\cdot]$ is an unbounded self-adjoint operator in $H^2_\sigma[0,\infty)$. Of course, the general theory of self-adjoint operators in a Hilbert space says that these eigenfunctions are orthogonal in $H^2_\sigma[0,\infty)$; we remind the reader that the explicit orthogonality relation of the Laguerre type polynomials in $H^2_\sigma[0,\infty)$ is given in (4.4). From § 6, we know that the Laguerre type polynomials are complete in

$H^2_\sigma[0, \infty)$. Following the argument mutatis mutandis that is given in § 4, we deduce that the spectrum of $S_k[\cdot]$ is given by

$$\sigma(S_k) = \{\lambda_n + k \mid n = 0, 1, 2, \cdots\}.$$

Is there an identification of $S_k[\cdot]$ as a differential operator in terms of the differential expression $M_k[\cdot]$? The answer is yes; recently, it has been shown that $S_k[f](x) = e^x M_k[f](x)$ for all $f \in \mathcal{D}(S_k) \subset \Delta_k$ and $x \in (0, \infty)$. The details of this result will be reported in a future paper by Everitt and Littlejohn.

We summarize the results of this section.

THEOREM 7.1. *The operator $S_k[\cdot]$ defined above is a self-adjoint differential operator in the weighted Sobolev space $H^2_\sigma[0, \infty)$ generated by the differential expression $M_k[\cdot]$. The Laguerre type polynomials $\{R_n(x)\}$ form a complete set of eigenfunctions of $S_k[\cdot]$ in $H^2_\sigma[0, \infty)$. The spectrum of $S_k[\cdot]$ is given by*:

$$\sigma(S_k) = \{\lambda_n + k \mid n = 0, 1, 2, \cdots\}.$$

Acknowledgments. V. P. Onyango-Otieno expresses his gratitude to Professors Everitt, Krall, and Littlejohn for introducing him to the problems discussed in this paper. He is also grateful to Professor Abdus Salam of the International Centre for Theoretical Physics, the International Atomic Energy Agency, and the United Nations Educational, Scientific and Cultural Organization for kind hospitality and financial support during his stay in Trieste, Italy.

ON ORTHOGONAL POLYNOMIALS OF SOBOLEV TYPE: ALGEBRAIC PROPERTIES AND ZEROS*

M. ALFARO†, F. MARCELLÁN‡, M L. REZOLA†, AND A. RONVEAUX§

Abstract. In this paper the inner product $\langle f, g\rangle = \int_I fg\,d\mu + Mf(c)g(c) + Nf'(c)g'(c)$ is considered, where μ is a positive measure on the interval I, $c \in \mathbf{R}$ and $M, N \geqq 0$. General algebraic properties of the orthogonal polynomials associated with $\langle \cdot, \cdot \rangle$ as well as the zeros and their location are studied. In particular, the case of a symmetric measure μ is analyzed. Finally, a second-order linear differential equation and two applications are given.

Key words. orthogonal polynomials, inner product, kernels, zeros, differential equations

AMS(MOS) subject classification. 33C45

1. Introduction. Problems concerning the approximation of $C^{(k)}$ functions by polynomials, using the method of least squares, had been considered by Lewis [16], Gröbner [8], and Lesky [15]. In these papers, orthogonal polynomials associated to inner products involving derivatives appear in a natural way.

On the other hand, the study of the families of orthogonal polynomials related to inner products defined by

$$\langle f, g\rangle = \int_I fg\,d\mu + \lambda \int_I f'g'\,d\mu$$

and the properties of their zeros was begun by Althammer [1], Cohen [6], and Schäfke [22] in the case of Lebesgue measure with $I = (-1, 1)$, by Brenner [4] in the case $d\mu = e^{-x}\,dx$ with $I = (0, +\infty)$, and by Schäfke and Wolf [23] for the classical weights in the corresponding intervals I.

More recently, a group of Dutch mathematicians have considered similar problems for inner products

$$\langle f, g\rangle = \int_I fg\,d\mu + \sum_{k=0}^{n} \lambda_k f^{(k)}(0)g^{(k)}(0)$$

when $I = (0, +\infty)$ and μ is the Laguerre measure [11] or a q-discrete measure [12], as well as when μ is the Gegenbauer measure and $\langle \cdot, \cdot \rangle$ is given by

$$\langle f, g\rangle = \int_{-1}^{1} fg\,d\mu + M[f(-1)g(-1) + f(1)g(1)] + N[f'(-1)g'(-1) + f'(1)g'(1)]$$

with $I = (-1, 1)$, (see [2], [3]).

Besides, Marcellán and Ronveaux [17] have studied the most general situation when the inner product is

$$\langle f, g\rangle = \int_I fg\, d\mu + \lambda f^{(r)}(c) g^{(r)}(c),$$

where $\lambda \in \mathbf{R}^+$ and $c \in \mathbf{R}$.

Finally, results relative to zeros have been the object of a very recent work by Meijer [20] and asymptotic properties have been obtained by Marcellán and van Assche [18].

The aim of this paper is to present the most general possible treatment of the families of orthogonal polynomials associated to an inner product of type

$$\langle f, g\rangle = \int_I fg\, d\mu + Mf(c)g(c) + Nf'(c)g'(c)$$

with $c \in \mathbf{R}$ and $M, N \geqq 0$.

In § 2, we study the algebraic properties of these orthogonal polynomials. An explicit representation in terms of the orthogonal polynomials associated to μ is given, as well as a five term recurrence relation, which is based on the self-adjoint character of a certain multiplication operator in the space of the polynomials. Moreover, a relation between the corresponding kernels and an analog of the Christoffel-Darboux formula is presented.

In § 3, we obtain results related to the distribution of the zeros, showing the dependence of this distribution from the position of the point c with respect to the support of the measure μ. Estimations about the position of the greatest zero are given.

In § 4, we consider a particularly simple situation corresponding to symmetric measures. In this case we can improve the results related to the zeros.

In § 5, we expose an application for semiclassical measures, deriving a second-order linear differential equation satisfied by the new orthogonal polynomials. Finally, two particularly interesting cases are considered: one of them deals with the case of Poisson's distribution, as an example of a discrete measure, and the other one corresponds to the case of Gegenbauer measure with $c = 0$. In the latter, the mass is placed in an interior point of the support, unlike the usual location of masses in the ends of the support. This simplifies the calculations very much.

2. Algebraic properties.

2.1. Representation formulas. Let μ be a positive Borel measure on an interval (finite or infinite) $I \subset \mathbf{R}$ with infinite support such that all the moments $\int_I x^n\, d\mu$ exist. We define the following real inner product in the linear space of real polynomials $\mathcal{P}$:

$$\langle f, g\rangle = \int_I fg\, d\mu + Mf(c)g(c) + Nf'(c)g'(c),$$

where $c \in \mathbf{R}$ and $M, N \geqq 0$. This inner product cannot be associated to any positive measure on I in the standard sense [7], whenever $N > 0$.

Let $(P_n(x)) = (P_n)$ and $(Q_n(x)) = (Q_n)$ be the sequences of monic orthogonal polynomials (SMOP) with respect to μ and with the inner product $\langle \cdot, \cdot \rangle$, respectively. If we consider the representation of Q_n in terms of P_j,

$$Q_n(x) = P_n(x) + \sum_{j=0}^{n-1} \alpha_{nj} P_j(x)$$

from the orthogonality of Q_n with respect to P_j, $j=0, 1, \cdots, n-1$, it follows that

$$\alpha_{nj}=\frac{\int_I Q_nP_j\,d\mu}{\int_I P_j^2\,d\mu}=-\frac{MQ_n(c)P_j(c)+NQ'_n(c)P'_j(c)}{\|P_j\|^2} \qquad 0\leqq j\leqq n-1.$$

Then

$$Q_n(x)=P_n(x)-MQ_n(c)K_{n-1}(x, c)-NQ'_n(c)K^{(0,1)}_{n-1}(x, c), \tag{2.1}$$

where $(K_n(x, y))$ is the sequence of kernels associated to (P_n), and $K_n^{(r,s)}(x, y)$ denotes the generalized kernel

$$K_n^{(r,s)}(x, y)=\sum_{j=0}^{n}\frac{P_j^{(r)}(x)P_j^{(s)}(y)}{\|P_j\|^2}.$$

If we derive in (2.1) with respect to x and evaluating at $x=c$, the values $Q_n(c)$ and $Q'_n(c)$ can be expressed as the solutions of the system,

$$\begin{aligned} P_n(c)&=Q_n(c)[1+MK_{n-1}(c, c)]+Q'_n(c)NK^{(0,1)}_{n-1}(c, c),\\ P'_n(c)&=Q_n(c)MK^{(0,1)}_{n-1}(c, c)+Q'_n(c)[1+NK^{(1,1)}_{n-1}(c, c)], \end{aligned} \tag{2.2}$$

whose determinant:

$$\begin{aligned} D=1&+MK_{n-1}(c, c)+NK^{(1,1)}_{n-1}(c, c)\\ &+MN[K_{n-1}(c, c)K^{(1,1)}_{n-1}(c, c)-K^{(0,1)}_{n-1}(c, c)^2] \end{aligned}$$

is positive from the Cauchy-Schwartz inequality. Therefore,

$$\begin{aligned} Q_n(c)&=\frac{P_n(c)[1+NK^{(1,1)}_{n-1}(c, c)]-P'_n(c)NK^{(0,1)}_{n-1}(c, c)}{D},\\ Q'_n(c)&=\frac{-P_n(c)MK^{(0,1)}_{n-1}(c, c)+P'_n(c)[1+MK_{n-1}(c, c)]}{D}. \end{aligned} \tag{2.3}$$

Then (2.1) becomes

$$\begin{aligned} Q_n(x)=P_n(x)&-M\frac{P_n(c)[1+NK^{(1,1)}_{n-1}(c, c)]-P'_n(c)NK^{(0,1)}_{n-1}(c, c)}{D}K_{n-1}(x, c)\\ &-N\frac{-P_n(c)MK^{(0,1)}_{n-1}(c, c)+P'_n(c)[1+MK_{n-1}(c, c)]}{D}K^{(0,1)}_{n-1}(x, c). \end{aligned} \tag{2.4}$$

We need establish some auxiliary results.

LEMMA 2.1. *Let $(P_n^c(x))$ and $(P_n^{c,c}(x))$ be the* SMOP *with respect to the measures $(x-c)^2\,d\mu$ and $(x-c)^4\,d\mu$, respectively. Then*:

$$(x-c)P^c_{n-1}(x)=P_n(x)-\frac{P_n(c)}{K_{n-1}(c, c)}K_{n-1}(x, c), \tag{2.5}$$

$$P^c_{n-1}(c)=P'_n(c)-\frac{P_n(c)}{K_{n-1}(c, c)}K^{(0,1)}_{n-1}(c, c), \tag{2.6}$$

$$(x-c)P^{c,c}_{n-2}(x)=P^c_{n-1}(x)-\frac{P^c_{n-1}(c)}{K^c_{n-2}(c, c)}K^c_{n-2}(x, c), \tag{2.7}$$

$$(x-c)(y-c)K^c_{n-1}(x, y)=K_n(x, y)-\frac{K_n(x, c)K_n(c, y)}{K_n(c, c)}, \tag{2.8}$$

$$(2.9) \qquad (x-c)K^c_{n-1}(x,c)=K^{(0,1)}_n(x,c)-\frac{K^{(0,1)}_n(c,c)}{K_n(c,c)}K_n(x,c),$$

$$(2.9') \qquad K^c_{n-1}(c,c)=K^{(1,1)}_n(c,c)-\frac{[K^{(0,1)}_n(c,c)]^2}{K_n(c,c)},$$

where $(K^c_n(x,y))$ *denotes the sequence of kernels associated to* (P^c_n).

Proof. Let us consider the representation of $(x-c)P^c_{n-1}(x)$ in terms of $P_j(x)$:

$$(x-c)P^c_{n-1}(x)=P_n(x)+\sum_{j=0}^{n-1}\alpha_{n-1,j}P_j(x).$$

By using the orthogonality of the sequence (P^c_{n-1}) with respect to the measure $(x-c)^2\,d\mu$ we get:

$$\alpha_{n-1,0}=\frac{P_0(c)}{\|P_0\|^2}\int_I (x-c)P^c_{n-1}(x)\,d\mu$$

and

$$\begin{aligned}\alpha_{n-1,j}&=\frac{1}{\|P_j\|^2}\int_I (x-c)P^c_{n-1}(x)P_j(x)\,d\mu\\ &=\frac{1}{\|P_j\|^2}\left[\int_I P^c_{n-1}(x)\frac{P_j(x)-P_j(c)}{x-c}(x-c)^2\,d\mu+P_j(c)\int_I (x-c)P^c_{n-1}(x)\,d\mu\right]\\ &=\frac{P_j(c)}{\|P_j\|^2}\int_I (x-c)P^c_{n-1}(x)\,d\mu\end{aligned}$$

if $j=1,\cdots,n-1$.

Then

$$(x-c)P^c_{n-1}(x)=P_n(x)+K_{n-1}(x,c)\int_I (t-c)P^c_{n-1}(t)\,d\mu(t).$$

Evaluating at $x=c$, it follows the value of the last integral and, therefore, (2.5).

In order to prove (2.7) it suffices to consider the representation of $(x-c)P^{c,c}_{n-2}(x)$ in terms of $P^c_j(x)$ and to repeat the above argument.

If we derive (2.5) with respect to x and evaluating at $x=c$, we deduce (2.6).

Formula (2.8) can be obtained from the representation

$$(x-c)(y-c)K^c_{n-1}(x,y)=\sum_{j=0}^{n}\beta_{n-1,j}(y)P_j(x).$$

By using the reproducing property of the kernels and the orthogonality of P_n we have:

$$\beta_{n-1,0}(y)=\frac{(y-c)}{\|P_0\|^2}P_0(c)\int_I (x-c)K^c_{n-1}(x,y)\,d\mu(x)$$

and

$$\begin{aligned}\beta_{n-1,j}(y)&=\frac{(y-c)}{\|P_j\|^2}\int_I (x-c)K^c_{n-1}(x,y)P_j(x)\,d\mu(x)\\ &=\frac{(y-c)}{\|P_j\|^2}\left[\int_I K^c_{n-1}(x,y)\frac{P_j(x)-P_j(c)}{x-c}(x-c)^2\,d\mu(x)\right.\\ &\qquad\left.+P_j(c)\int_I (x-c)K^c_{n-1}(x,y)\,d\mu(x)\right]\end{aligned}$$

$$=\frac{1}{\|P_j\|^2}\left[P_j(y)-P_j(c)+(y-c)P_j(c)\int_I (x-c)K^c_{n-1}(x,y)\,d\mu(x)\right]$$

for every $j=1,\cdots,n$.

Then,

$$(x-c)(y-c)K^c_{n-1}(x,y)=K_n(x,y)-K_n(x,c)$$
$$+(y-c)K_n(x,c)\int_I (t-c)K^c_{n-1}(x,t)\,d\mu(t).$$

Now, formula (2.8) can be derived directly from the last one.

By derivation in (2.8) with respect to y and evaluating at $y=c$ we get (2.9). In a similar way, we deduce (2.9′) from (2.9). □

The above lemma allows us to represent the kernels $K_{n-1}(x,c)$ and $K^{(0,1)}_{n-1}(x,c)$ in terms of the polynomials $P_n(x)$, $P^c_{n-1}(x)$, and $P^{c,c}_{n-2}(x)$. By substitution of these values in (2.4) we obtain the following.

PROPOSITION 2.2. *Let c be such that the condition $P_n(c)P^c_{n-1}(c)\neq 0$ is satisfied for every $n\in N$. Then, the formula*

$$\begin{aligned}Q_n(x)&=(1-\alpha_n)P_n(x)+(\alpha_n-\beta_n)(x-c)P^c_{n-1}(x)\\&\quad+\beta_n(x-c)^2P^{c,c}_{n-2}(x),\end{aligned}\tag{2.10}$$

where

$$\alpha_n=1-\frac{Q_n(c)}{P_n(c)}=1-\frac{[1+NK^{(1,1)}_{n-1}(c,c)]P_n(c)-NK^{(0,1)}_{n-1}(c,c)P'_n(c)}{DP_n(c)},$$

$$\beta_n=\frac{NQ'_n(c)K^c_{n-2}(c,c)}{P^c_{n-1}(c)}$$

holds.

Remarks. (1) Since all the zeros of the polynomials $P_n(x)$ and $P^c_{n-1}(x)$ are in the interior of the interval I, we conclude that if c is not an interior point of I, then the formula (2.10) is true.

(2) The polynomials P^c_n have been identified by Kautsky and Golub (see [10]). By using methods of linear algebra they prove the fact that, if J is the Jacobi matrix associated with (P_n), a single step of the QR algorithm with the (Wilkinson) shift c corresponds to finding the Jacobi matrix associated with (P^c_n). A proof of this result by an analytic technique can be found in [5].

Let us consider the Christoffel-Darboux formula for the kernel $K_{n-1}(x,y)$ ([7, Thm. 4.5, p. 23] or [24, Thm. 3.2.2, p. 43]). For the first consequence below we evaluate at $y=c$, and for the second we derive with respect to y and evaluate at $y=c$.

$$(x-c)K_{n-1}(x,c)=\frac{1}{\|P_{n-1}\|^2}[P_n(x)P_{n-1}(c)-P_{n-1}(x)P_n(c)],$$

$$\begin{aligned}(x-c)^2K^{(0,1)}_{n-1}(x,c)&=\frac{1}{\|P_{n-1}\|^2}[P_n(x)\{P_{n-1}(c)+(x-c)P'_{n-1}(c)\}\\&\quad-P_{n-1}(x)\{P_n(c)+(x-c)P'_n(c)\}].\end{aligned}\tag{2.11}$$

Multiplying the formula (2.4) by $(x-c)^2$ and substituting (2.11) we obtain

$$(x-c)^2Q_n(x)=q_2(x,n)P_n(x)+q_1(x,n)P_{n-1}(x),\tag{2.12}$$

where

$$q_2(x, n) = (x-c)^2 - \frac{MQ_n(c)}{\|P_{n-1}\|^2} \sum_{k=0}^{1} P_{n-1}^{(k-1)}(c)(x-c)^k$$

$$-\frac{NQ_n'(c)}{\|P_{n-1}\|^2} \sum_{k=0}^{1} P_{n-1}^{(k)}(c)(x-c)^k,$$

$$q_1(x, n) = \frac{MQ_n(c)}{\|P_{n-1}\|^2} \sum_{k=0}^{1} P_n^{(k-1)}(c)(x-c)^k$$

$$+\frac{NQ_n'(c)}{\|P_{n-1}\|^2} \sum_{k=0}^{1} P_n^{(k)}(c)(x-c)^k.$$

(We denote $P_n^{(-1)}(c) = 0$.)

From (2.12), it follows that the sequence (Q_n) is strictly quasi orthogonal of order 2 with respect to the measure $(x-c)^2\, d\mu$ [19] and, therefore,

$$(x-c)^2 Q_n(x) = P_{n+2}(x) + \sum_{j=n-2}^{n+1} a_{nj} P_j(x), \tag{2.13}$$

where the numbers a_{nj} can be expressed in terms of the coefficients of the polynomials $q_2(x, n)$, $q_1(x, n)$, and the coefficients of the three term recurrence relation satisfied by the SMOP (P_n).

Now, we can obtain a recurrence relation for the orthogonal polynomials Q_n.

PROPOSITION 2.3. *The polynomials Q_n satisfy a five term recurrence relation*:

$$(x-c)^2 Q_n(x) = Q_{n+2}(x) + \sum_{j=n-2}^{n+1} \gamma_{nj} Q_j(x) \qquad n \geqq 0, \tag{2.14}$$

where $\gamma_{n,n-2} > 0$ $(n \geqq 2)$ and the convention $Q_{-1} = Q_{-2} = 0$.

Proof. Let

$$(x-c)^2 Q_n(x) = \sum_{j=0}^{n+2} \gamma_{nj} Q_j(x)$$

be the expansion of the polynomial $(x-c)^2 Q_n(x)$ with respect to the sequence (Q_n).

Obviously, $\gamma_{n,n+2} = 1$ because Q_n is monic. On the other hand, if $0 \leqq j < n-2$, $\gamma_{n,j} = 0$ from the orthogonality of the sequence (Q_n).

The remaining coefficients $\gamma_{n,j}$ can be found as follows: from the definition of the inner product, if $n-2 \leqq j \leqq n+1$

$$\gamma_{n,j} = \frac{\langle (x-c)^2 Q_n(x), Q_j(x) \rangle}{\langle Q_j, Q_j \rangle}$$

$$= \frac{1}{\langle Q_j, Q_j \rangle} \int_I (x-c)^2 Q_n(x) Q_j(x)\, d\mu(x).$$

But from (2.13),

$$(x-c)^2 Q_j(x) = \sum_{h=j-2}^{j+2} a_{jh} P_h(x) \tag{2.15}$$

with $a_{j,j+2} = 1$, and from (2.1)

$$Q_n(x) = \sum_{h=0}^{n} \beta_{nh} P_h(x),$$

where $\beta_{nn}=1$, and if $h<n$

$$\beta_{nh}=\frac{-1}{\|P_h\|^2}[MQ_n(c)P_h(c)+NQ'_n(c)P'_h(c)],$$

then,

$$\begin{aligned}\int_I (x-c)^2 Q_n(x)Q_j(x)\,d\mu(x)\\ &=a_{jn}\|P_n\|^2+\sum_{h=j-2}^{n-1}\beta_{nh}a_{jh}\|P_h\|^2\\ &=a_{jn}\|P_n\|^2-\sum_{h=j-2}^{n-1}a_{jh}[MQ_n(c)P_h(c)+NQ'_n(c)P'_h(c)].\end{aligned}$$

Also, from (2.15)

$$\sum_{h=j-2}^{j+2}a_{jh}P_h(c)=\sum_{h=j-2}^{j+2}a_{jh}P'_h(c)=0,$$

and hence

$$(2.16)\qquad \gamma_{nj}=\langle Q_j,Q_j\rangle^{-1}\left[a_{jn}\|P_n\|^2+MQ_n(c)\sum_{h=n}^{j+2}a_{jh}P_h(c)+NQ'_n(c)\sum_{h=n}^{j+2}a_{jh}P'_h(c)\right]$$

holds. Finally, from the definition of the inner product $\langle\ ,\ \rangle$

$$\langle Q_n,Q_n\rangle=\|P_n\|^2+MQ_n(c)P_n(c)+NQ'_n(c)P'_n(c).$$

So, if $j=n-2$ we get

$$\gamma_{n,n-2}=\frac{\langle Q_n,Q_n\rangle}{\langle Q_{n-2},Q_{n-2}\rangle}>0. \qquad \square$$

Remark. In the above proposition we have pointed out that

$$\langle Q_n,Q_n\rangle=\|P_n\|^2+MQ_n(c)P_n(c)+NQ'_n(c)P'_n(c).$$

An explicit expression of $\langle Q_n,Q_n\rangle$ in terms of M, N, and the polynomials P_n can be derived by using (2.3). We find, by straightforward calculations,

$$(2.17)\qquad \langle Q_n,Q_n\rangle=\|P_n\|^2\frac{\gamma_{n-1}\lambda_n+\gamma_n\lambda_{n-1}-2MNK_n^{(0,1)}(c,c)K_{n-1}^{(0,1)}(c,c)-D}{D},$$

where $\gamma_n=1+MK_n(c,c)$ and $\lambda_n=1+NK_n^{(1,1)}(c,c)$.

2.2. Kernels. We are going to derive a formula relating the kernel associated to the new polynomials Q_n with the kernels $K_n(x,c)$ and $K_{n-1}^{(0,1)}(x,c)$.

Let

$$L_n(x,y)=\sum_{h=0}^{n}\frac{Q_h(x)Q_h(y)}{\langle Q_h,Q_h\rangle}.$$

If we consider its expansion in terms of the polynomials $P_j(x)$,

$$L_n(x,y)=\sum_{j=0}^{n}\alpha_{nj}(y)P_j(x),$$

we have:

$$\begin{aligned}\alpha_{nj}(y) &= \int_I L_n(x, y)\frac{P_j(x)}{\|P_j\|^2}\,d\mu \\ &= \left\langle L_n(x, y), \frac{P_j(x)}{\|P_j\|^2}\right\rangle - ML_n(c, y)\frac{P_j(c)}{\|P_j\|^2} - NL_n^{(1,0)}(c, y)\frac{P_j'(c)}{\|P_j\|^2} \\ &= \frac{1}{\|P_j\|^2}[P_j(y) - ML_n(c, y)P_j(c) - NL_n^{(1,0)}(c, y)P_j'(c)].\end{aligned}$$

This proves that the kernels $L_n(x, y)$ and $K_n(x, y)$ satisfy the following formula:

$$\begin{aligned}L_n(x, y) = K_n(x, y) - ML_n(c, y)K_n(x, c) \\ - NL_n^{(1,0)}(c, y)K_n^{(0,1)}(x, c).\end{aligned} \tag{2.18}$$

Explicit expressions for $L_n(c, y)$ and $L_n^{(1,0)}(c, y)$ can be obtained as solutions of the system

$$\begin{aligned}K_n(c, y) &= L_n(c, y)[1 + MK_n(c, c)] + L_n^{(1,0)}(c, y)NK_n^{(1,0)}(c, c), \\ K_n^{(1,0)}(c, y) &= L_n(c, y)MK_n^{(1,0)}(c, c) \\ &\quad + L_n^{(1,0)}(c, y)[1 + NK_n^{(1,1)}(c, c)].\end{aligned} \tag{2.19}$$

Now, we obtain an analog of the Christoffel-Darboux formula for the new polynomials.

PROPOSITION 2.4. *The relation*

$$\begin{aligned}(x + y &- 2c)(x - y)L_n(x, y) \\ &= \frac{1}{\langle Q_n, Q_n\rangle}[Q_{n+2}(x)Q_n(y) - Q_{n+2}(y)Q_n(x)] \\ &+ \frac{\gamma_{n,n+1}}{\langle Q_n, Q_n\rangle}[Q_{n+1}(x)Q_n(y) - Q_{n+1}(y)Q_n(x)] \\ &+ \frac{1}{\langle Q_{n-1}, Q_{n-1}\rangle}[Q_{n+1}(x)Q_{n-1}(y) - Q_{n+1}(y)Q_{n-1}(x)]\end{aligned} \tag{2.20}$$

and its confluent form

$$\begin{aligned}2(x - c)L_n(x, x) &= \frac{1}{\langle Q_n, Q_n\rangle}[Q_{n+2}'(x)Q_n(x) - Q_{n+2}(x)Q_n'(x)] \\ &+ \frac{\gamma_{n,n+1}}{\langle Q_n, Q_n\rangle}[Q_{n+1}'(x)Q_n(x) - Q_{n+1}(x)Q_n'(x)] \\ &+ \frac{1}{\langle Q_{n-1}, Q_{n-1}\rangle}[Q_{n+1}'(x)Q_{n-1}(x) - Q_{n+1}(x)Q_{n-1}'(x)]\end{aligned} \tag{2.21}$$

hold.

Proof. Multiplying in the relation (2.14) by $Q_n(y)$ and multiplying the same relation evaluated at $x = y$ by $Q_n(x)$, we obtain after subtraction:

$$(x + y - 2c)(x - y)Q_n(x)Q_n(y) = \sum_{0\neq k=-2}^{2} \gamma_{n,n+k}[Q_{n+k}(x)Q_n(y) - Q_{n+k}(y)Q_n(x)], \tag{2.22}$$

where $\gamma_{n,n+2} = 1$.

On the other hand, the inner product $\langle\, ,\rangle$ is such that

$$\langle (x-c)^2 Q_n(x),\, Q_m(x)\rangle = \langle Q_n(x),\, (x-c)^2 Q_m(x)\rangle$$

for all $n, m \in N$. Hence, as

$$(x-c)^2 Q_{n-i}(x) = \sum_{k=i-2}^{i+2} \gamma_{n-i,n-k} Q_{n-k}(x)$$

we get

$$\gamma_{n-i,n-k}\langle Q_{n-k}, Q_{n-k}\rangle = \gamma_{n-k,n-i}\langle Q_{n-i}, Q_{n-i}\rangle, \qquad k-2 \leqq i \leqq k+2. \tag{2.23}$$

From (2.22) and (2.23), by straightforward calculations, we get (2.20).

The result in (2.21) follows immediately from (2.20). □

3. Zeros of Q_n. In this section, we always consider $N>0$. It is well known that the zeros of P_n are real, simple, and belong to $\mathring{I}$ ($\mathring{I}$ denotes the interior of the true interval of orthogonality I). But this result may be false for polynomials Q_n. In fact, the general result we can prove is the following.

PROPOSITION 3.1. *If $n \geqq 3$, the polynomial Q_n has at least $n-2$ different zeros with odd multiplicity in $\mathring{I}$.*

Proof. Let $\xi_{n1}, \cdots, \xi_{nk}$ denote all the distinct zeros of Q_n of odd multiplicity which are in $\mathring{I}$. Define $p(x) = (x-\xi_{n1})\cdots(x-\xi_{nk})$. The polynomial $(x-c)^2 p(x) Q_n(x)$ does not change sign in the interval I; hence,

$$\langle (x-c)^2 p(x) Q_n(x), 1\rangle = \int_I (x-c)^2 p(x) Q_n(x)\, d\mu(x) \neq 0.$$

Since (Q_n) is a quasi-orthogonal sequence of order 2 with respect to $(x-c)^2\, d\mu$, it follows that $\deg p(x) \geqq n-2$. □

PROPOSITION 3.2. *The zeros of the polynomial Q_n are real, simple, and at least $n-1$ of them belong to $\mathring{I}$, whenever either $c = \inf I$ or $c = \sup I$.*

Proof. Suppose $c = \sup I$. Let $\xi_{n1}, \cdots, \xi_{nk}$ denote all the zeros of Q_n in $\mathring{I}$. From Proposition 3.1, it follows that $k \geqq n-2$. Set $p(x) = (x-\xi_{n1})\cdots(x-\xi_{nk})$; then, the polynomials $p(x)Q_n(x)$ and $(x-c)p(x)Q_n(x)$ have constant but opposite signs in $\mathring{I}$.

If $Q_n'(c) = 0$, we have

$$\langle (x-c)p(x),\, Q_n(x)\rangle = \int_I (x-c)p(x)Q_n(x)\, d\mu(x) \neq 0,$$

and hence, $\deg p(x) \geqq n-1$.

Let $Q_n'(c) \neq 0$. If we suppose $k = n-2$, the following formulas hold:

$$0 = \langle (x-c)p(x),\, Q_n(x)\rangle = \int_I (x-c)p(x)Q_n(x)\, d\mu + Np(c)(Q_n'(c)$$

$$0 = \langle (p(x),\, Q_n(x)\rangle = \int_I p(x)Q_n(x)\, d\mu + Mp(c)Q_n(c) + Np'(c)Q_n'(c).$$

Hence, $p(c)Q_n'(c)$ and $p'(c)Q_n'(c)$ have opposite signs, which is a contradiction. Thus $k \geqq n-1$. As a consequence, all the zeros of $Q_n(x)$ are real and simple.

If $c = \inf I$, the proof is similar. □

Remark. We want to note that if we consider the inner product

$$\langle f, g\rangle = \int_I f(x)g(x)\, d\mu(x) + Mf(c)g(c) + Nf^{(r)}(c)g^{(r)}(c)$$

with $r \in N$, by using the above arguments, we can deduce that the polynomial Q_n associated to the new inner product has at least $n-(r+1)$ different zeros in $\mathring{I}$. Whenever either $c = \sup I$ or $c = \inf I$, then Q_n has at least $n-1$ zeros in $\mathring{I}$ and, therefore, all the zeros are real and simple (see [11]).

Note that if $c = \sup I$ and all the roots of $Q_n(x)$ are located in the interior of I, then both conditions

$$Q_n(c) > 0 \quad \text{and} \quad Q_n'(c) > 0 \tag{3.1}$$

hold. In the similar way, if $c = \inf I$ and all the roots of $Q_n(x)$ belong to $\mathring{I}$, then

$$\operatorname{sgn} Q_n(c) = (-1)^n \quad \text{and} \quad \operatorname{sgn} Q_n'(c) = (-1)^{n-1} \tag{3.2}$$

hold.

This remark allows us to easily deduce sufficient conditions to assure a zero of $Q_n(x)$ is not in $\mathring{I}$, and besides we can give some results about its location.

From now on, if $c = \sup I$ or $c = \inf I$, we shall denote the zeros of $Q_n(x)$ being ordered by increasing size: $\xi_{n1} < \cdots < \xi_{nn}$.

PROPOSITION 3.3. *The following statements hold*:

(a) *Let $c = \sup I$. If the property* (3.1) *is not true then the greatest zero of $Q_n(x)$ satisfies*

$$c \leqq \xi_{nn} < c + \frac{c - \xi_{n1}}{n-1} \quad \textit{and} \quad |\xi_{nn} - c| < |\xi_{n,n-1} - c|.$$

Moreover, if $M \neq 0$, $\xi_{nn} - c < \frac{1}{2}\sqrt{N/M}$.

(b) *Let $c = \inf I$. If the property* (3.2) *is not true then the lowest zero of $Q_n(x)$ satisfies*

$$c - \frac{\xi_{nn} - c}{n-1} < \xi_{n1} \leqq c \quad \textit{and} \quad |\xi_{n1} - c| < |\xi_{n2} - c|.$$

Moreover, if $M \neq 0$, $c - \xi_{n1} < \frac{1}{2}\sqrt{N/M}$.

Proof. It suffices to prove (a). It is easy to deduce that if (3.1) is not true, we have $c \leqq \xi_{nn}$.

Assume $c < \xi_{nn}$, then $Q_n(c) = (c - \xi_{n1}) \cdots (c - \xi_{nn}) < 0$. In this situation,

$$K_{n-1}^{(0,1)}(c, c) = \sum_{h=0}^{n-1} \frac{P_h(c) P_h'(c)}{\|P_h\|^2} > 0,$$

from (2.2) it follows $Q_n'(c) > 0$. Since

$$\frac{Q_n'(c)}{Q_n(c)} = \sum_{j=1}^{n-1} \frac{1}{c - \xi_{nj}} - \frac{1}{\xi_{nn} - c},$$

we get

$$\frac{1}{\xi_{nn} - c} > \sum_{j=1}^{n-1} \frac{1}{c - \xi_{nj}} > \frac{n-1}{c - \xi_{n1}}.$$

Hence,

$$\xi_{nn} < c + \frac{c - \xi_{n1}}{n-1} \quad \text{and} \quad |\xi_{nn} - c| < |\xi_{n,n-1} - c|.$$

Now, let us set $Q_n(x) = (\xi_{nn} - x)\varphi(x)$. Then,

$$\langle Q_n, \varphi \rangle = \int_I Q_n \varphi \, d\mu + M Q_n(c) \varphi(c) + N Q_n'(c) \varphi'(c) = 0.$$

As $Q_n(x)\varphi(x)>0$ in I, in the above formula the integral is positive and so

$$MQ_n(c)\varphi(c)+NQ_n'(c)\varphi'(c)=(\xi_{nn}-c)[M\varphi(c)^2+N\varphi'(c)^2]\\ -N\varphi(c)\varphi'(c)<0.$$

Whenever $M>0$, taking into account that $\varphi(c)<0$ and $\varphi'(c)<0$ and by using the Cauchy-Schwarz inequality, we obtain

$$\xi_{nn}-c<\frac{1}{2}\sqrt{\frac{N}{M}}. \qquad \square$$

Remark. The same results for $c=0$ and the Laguerre weight have been obtained in [13], and for some generalizations of the Laguerre weight see [20].

4. Analysis of the symmetric case. If I is a symmetric interval and the measure μ is symmetric on I (i.e., $\mu(A)=\mu(-A)$ for every $A\subset I$ measurable), it is well known [7, Thm. 4.3] that the SMOP (P_n) associated to μ satisfies $P_n(-x)=(-1)^nP_n(x)$ for all $n\in N$. As examples of this situation we have Hermite polynomials and Gegenbauer polynomials. We want to emphasize that the condition $P_n(-x)=(-1)^nP_n(x)$ for all $n\in N$ is equivalent to $K_n^{(0,1)}(0,0)=0$ for all $n\in N$.

Let us consider the condition

$$K_n^{(0,1)}(c,c)=0 \quad \text{for every } n\in N \tag{4.1}$$

is satisfied. Let us remark that

(i) $P_n(c)P_n'(c)=0$ for every $n\in N$;

(ii) $P_n(c)P_{n-1}(c)=0$ and $P_n'(c)P_{n-1}'(c)=0$ for every $n\in N$

are separately equivalent to (4.1). From (i) or (ii), it follows that c must belong to $\mathring{I}$. Furthermore there exists at most one c, which is determined by $P_1(c)=0$. Then, in general, we have

$$P_{2n-1}(c)=0 \quad \text{and} \quad P_{2n}'(c)=0 \quad \text{for every } n\in N.$$

We point out that no number c satisfies (4.1) for Jacobi polynomials with $a\neq\beta$ or for Laguerre polynomials.

Now, it is not difficult to prove the polynomials P_n are symmetric with respect to the point c is equivalent to the condition (4.1). Since translation of the centre of symmetry is trivial, in the sequel, we assume (with absolutely no loss of generality) that $c=0$.

Since the determinant D is

$$D=[1+MK_{n-1}(0,0)][1+NK_{n-1}^{(1,1)}(0,0)],$$

we achieve

$$\begin{aligned} Q_n(0)&=\frac{P_n(0)}{1+MK_{n-1}(0,0)},\\ Q_n'(0)&=\frac{P_n'(0)}{1+NK_{n-1}^{(1,1)}(0,0)}. \end{aligned} \tag{4.2}$$

Then (2.4) becomes

$$\begin{aligned} Q_{2n}(x)&=P_{2n}(x)-\frac{MP_{2n}(0)}{1+MK_{2n-1}(0,0)}K_{2n-1}(x,0),\\ Q_{2n+1}(x)&=P_{2n+1}(x)-\frac{NP_{2n+1}'(0)}{1+NK_{2n}^{(1,1)}(0,0)}K_{2n}^{(0,1)}(x,0). \end{aligned} \tag{4.3}$$

Some properties about the quantities $Q_n(0)$ and $Q'_n(0)$ can be derived directly from (4.1) and (4.2). For instance:

(a) $Q_{2n}(0) \neq 0$ and $Q_{2n-1}(0) = 0$ for every $n \in N$;

(b) $Q'_{2n}(0) = 0$ and $Q'_{2n-1}(0) \neq 0$ for every $n \in N$;

(c) sign $Q_n(0) =$ sign $P_n(0)$ and sign $Q'_n(0) =$ sign $P'_n(0)$ for every $n \in N$.

In order to obtain Proposition 2.2 we might impose $P_n(0)P'_n(0) \neq 0$ for every $n \in N$. This restriction is not necessary now. Indeed, from (2.5)

$$P_{2n}(0)K_{2n-1}(x, 0) = K_{2n-1}(0, 0)[P_{2n}(x) - xP^c_{2n-1}(x)],$$

and from (2.9), (2.6), (2.7), (2.5), and (2.9′)

$$P'_{2n+1}(0)K^{(0,1)}_{2n}(x, 0) = K^{(1,1)}_{2n}(0, 0)[P_{2n+1}(x) - x^2P^{c,c}_{2n-1}(x)].$$

By substituting these values in (4.3) we obtain the following.

PROPOSITION 4.1. *The decomposition*:

$$Q_n(x) = (1 - \alpha_n)P_n(x) + (\alpha_n - \beta_n)xP^c_{n-1}(x) + \beta_n x^2 P^{c,c}_{n-2}(x) \tag{4.4}$$

where

$$\alpha_{2n} = \frac{MK_{2n-1}(0, 0)}{1 + MK_{2n-1}(0, 0)} \qquad \beta_{2n} = 0$$

$$\alpha_{2n+1} = \frac{NK^{(1,1)}_{2n}(0, 0)}{1 + NK^{(1,1)}_{2n}(0, 0)} \qquad \beta_{2n+1} = \alpha_{2n+1}$$

holds.

Remark. It is interesting to point out that α_n and β_n are nonnegative and bounded by 1. Consequently, all the coefficients in (4.4) are nonnegative and bounded.

By substituting the values of $Q_n(0)$ and $Q'_n(0)$ (see (4.2)) in (2.12) and simplifying, we obtain:

$$x^2Q_n(x) = [x^2 - a_n]P_n(x) + b_n xP_{n-1}(x), \tag{4.5}$$

where

$$a_n = \frac{1}{\|P_{n-1}\|^2} \frac{NP'_n(0)P_{n-1}(0)}{1 + NK^{(1,1)}_{n-1}(0, 0)},$$

$$b_n = \frac{1}{\|P_{n-1}\|^2}\left[\frac{MP_n(0)^2}{1 + MK_{n-1}(0, 0)} + \frac{NP'_n(0)^2}{1 + NK^{(1,1)}_{n-1}(0, 0)}\right].$$

Note that from the above formula it follows that the polynomials Q_n are also symmetric.

To deduce the recurrence relation we shall employ the expansion of $x^2Q_n(x)$ in terms of the polynomials P_n. Using the three term recurrence formula verified by the SMOP (P_n),

$$xP_n(x) = P_{n+1}(x) + B_{n+1}P_{n-1}(x)$$

and

$$x^2Q_n(x) = P_{n+2}(x) + \sum_{j=n-2}^{n+1} a_{n,j}P_j(x),$$

we find:

$$\begin{aligned} a_{n,n+1} &= 0, \\ a_{n,n} &= B_{n+2} + B_{n+1} - a_n + b_n, \\ a_{n,n-1} &= 0, \\ a_{n,n-2} &= B_n(B_{n+1} + b_n). \end{aligned} \tag{4.6}$$

Substituting these values (2.16) we obtain the coefficients of the five term recurrence relation verified by the SMOP (Q_n). To do this, it suffices to note that if $|m-n|$ is odd,

$$P_m(0)P_n(0) = P'_m(0)P'_n(0) = 0$$

holds. Thus, by using the notations $\gamma_n = 1 + MK_n(0,0)$ and $\lambda_n = 1 + NK_n^{(1,1)}(0,0)$ we can give the following.

PROPOSITION 4.2. *The* SMOP (Q_n) *satisfies the formula*

$$x^2 Q_n(x) = Q_{n+2}(x) + \sum_{j=n-2}^{n+1} \gamma_{n,j} Q_j(x),$$

where

$$\begin{aligned} \gamma_{n,n+1} &= 0, \\ \gamma_{n,n} &= a_{n,n} + \frac{1}{\langle Q_n, Q_n\rangle}\left[\frac{MP_n(0)P_{n+2}(0)}{1+MK_{n-1}(0,0)} + \frac{NP'_n(0)P'_{n+2}(0)}{1+NK_{n-1}^{(1,1)}(0,0)}\right], \\ \gamma_{n,n-1} &= 0, \\ \gamma_{n,n-2} &= \frac{\langle Q_n, Q_n\rangle}{\langle Q_{n-2}, Q_{n-2}\rangle}, \\ \langle Q_n, Q_n\rangle &= \|P_n\|^2\left[\frac{\gamma_n}{\gamma_{n-1}} + \frac{\lambda_n}{\lambda_{n-1}} - 1\right]. \end{aligned} \tag{4.7}$$

Note that, in the symmetric case, the recurrence formula satisfied by the polynomials Q_n is

$$x^2 Q_n(x) = Q_{n+2}(x) + \gamma_{n,n}Q_n(x) + \gamma_{n,n-2}Q_{n-2}(x). \tag{4.8}$$

Moreover, the explicit expression concerning the kernels $L_n(0,y)$ and $L_n^{(1,0)}(0,y)$ is very simple. Then (2.18) becomes

$$\begin{aligned} L_n(x,y) = K_n(x,y) &- \frac{MK_n(0,y)}{1+MK_n(0,0)}K_n(x,0) \\ &- \frac{NK_n^{(1,0)}(0,y)}{1+NK_n^{(1,1)}(0,0)}K_n^{(0,1)}(x,0). \end{aligned} \tag{4.9}$$

PROPOSITION 4.3. *The kernel* $L_n(x,y)$ *associated to the the polynomials* Q_n *can be expressed, in terms of the kernels associated to the polynomials* P_n, P_n^c, *and* $P_n^{c,c}$:

$$L_n(x,y) = r_n K_n(x,y) + s_n xy K_{n-1}^c(x,y) + t_n x^2y^2 K_{n-2}^{c,c}(x,y), \tag{4.10}$$

where

$$\begin{aligned} r_n &= \frac{1}{1+MK_n(0,0)}, \\ s_n &= \frac{MK_n(0,0)}{1+MK_n(0,0)} - \frac{NK_n^{(1,1)}(0,0)}{1+NK_n^{(1,1)}(0,0)}, \\ t_n &= \frac{NK_n^{(1,1)}(0,0)}{1+NK_n^{(1,1)}(0,0)}. \end{aligned}$$

Proof. Using the formulas (2.9), the analog of (2.8) for $K_{n-2}^{c,c}(x,y)$, and (2.9') we obtain

$$K_n^{(0,1)}(x,0)K_n^{(1,0)}(0,y) = K_n^{(1,1)}(0,0)[xyK_{n-1}^c(x,y) - x^2y^2K_{n-2}^{c,c}(x,y)].$$

Then the decomposition (4.10) holds and the explicit expression of coefficients r_n, s_n, t_n is obtained. □

Remarks.

(a) The coefficients in (4.10) are bounded and besides r_n, s_n are nonnegative.

(b) If $N=0$ there is always a decomposition as (4.10). But, if $N\neq 0$ there is such a decomposition if and only if $K_n^{(0,1)}(0,0)=0$ for all $n\in N$.

Next, we shall work in the symmetric case to obtain some strong results about zeros.

PROPOSITION 4.4. *All the zeros of Q_n are real, simple and belong to $\mathring{I}$.*

Proof. By Proposition 3.1, Q_n has at least $n-2$ different zeros in $\mathring{I}$, and all of them have odd multiplicity. As, $Q_n(-x)=(-1)^n Q_n(x)$ for every $x\in I$ and $Q'_{2n-1}(0)\neq 0$ for every $n\in N$, all the zeros of Q_n are simple. Suppose ξ is a complex zero of Q_n; then $\bar{\xi}$ is also a zero of Q_n and hence $-\xi=\bar{\xi}$. Thus $\xi=ir$ with $r\in\mathbf{R}$. Let us denote ξ_{nj}, $j=1,\cdots,n-2$, the remaining zeros of Q_n. Setting $p(x)=(x-\xi_{n1})\cdots(x-\xi_{n,n-2})$ we can write $Q_n(x)=p(x)(x^2+r^2)$. Then

$$\langle p, Q_n\rangle=\int_I p^2(x)(x^2+r^2)\,d\mu(x)+Mr^2p(0)^2+Nr^2p'(0)^2>0,$$

which is a contradiction; hence all the zeros are real.

Finally, we are going to show that ξ and $-\xi$ belong to $\mathring{I}$. Indeed, as $Q_n(x)=p(x)(x^2-\xi^2)$, it follows that $\langle p, Q_n\rangle=0$. But if we suppose $\xi\notin\mathring{I}$, then

$$\langle p, Q_n\rangle=\int_I p^2(x)(x^2-\xi^2)\,d\mu(x)-Mp(0)^2\xi^2-N[p'(0)]^2\xi^2<0.$$

Therefore, $\xi\in\mathring{I}$ holds. □

It is possible as well to deduce a separation property of the zeros. In order to prove it we will use the following.

LEMMA 4.5. *Between two consecutive zeros of $P_n(x)$ there is exactly one zero of $P_{n-1}^c(x)$.* (see [20, Lemma 6.1] or [9, Prop. 1.4.9]).

Since P_n and Q_n have symmetric zeros it suffices to consider the positive zeros. Let M, N be positive, real numbers.

PROPOSITION 4.6. *The positive zeros of P_n and Q_n mutually separate each other and the greatest positive zero of Q_n is less than the greatest positive zero of P_n. Moreover, the positive zeros of Q_{2n} alternate with the positive zeros of P_{2n-1}^c and the positive zeros of Q_{2n+1} alternate with the positive zeros of $P_{2n-1}^{c,c}$.*

Proof. Let us consider $n=2m$. As in (4.4) $\beta_{2m}=0$, we may write

$$Q_{2m}(x)=(1-\alpha_{2m})P_{2m}(x)+\alpha_{2m}xP_{2m-1}^c(x). \tag{4.11}$$

We denote $(x_{2m-1,j})_1^{m-1}$, $(x_{2m,j})_1^m$, $(\xi_{2m,j})_1^m$ the systems of the positive zeros of polynomials P_{2m-1}^c, P_{2m}, and Q_{2m}, respectively, each system arranged by increasing order.

From (4.11) and Lemma 4.5 it follows that whenever $x\geqq x_{2m,m}$, $Q_{2m}(x)>0$, and so $\xi_{2m,m}<x_{2m,m}$. On the other hand, as by Lemma 4.5 $P_{2m}(x_{2m-1,m-1}^c)\leqq 0$, we have $Q_{2m}(x_{2m-1,m-1}^c)\leqq 0$ and so $x_{2m-1,m-1}^c\leqq\xi_{2m,m}$. Since the roots of P_{2m} and P_{2m-1}^c are real and simple using, once more, Lemma 4.5 we have that the sign of $P_{2m-1}^c(x)$ changes in every $x_{2m,j}$ $(j=1,\cdots,m)$ and by (4.11) the sign of $Q_{2m}(x)$ changes in $x_{2m,j}$. Therefore, in each interval $(x_{2m,j-1}, x_{2m,j})$ there exists only one root of Q_{2m}.

In a similar way, the sign of $P_{2m}(x)$ changes in the roots of $P_{2m-1}^c(x)$, and, consequently, the sign of $Q_{2m}(x)$. Hence the positive roots of Q_{2m} and P_{2m-1}^c are interlaced.

If we suppose $n=2m+1$, then $\beta_{2m+1}=\alpha_{2m+1}$ and $P_{2m+1}(x)=xP^c_{2m}(x)$. Thus

$$Q_{2m+1}(x)=(1-\alpha_{2m+1})xP^c_{2m}(x)+\alpha_{2m+1}x^2P^{c,c}_{2m-1}(x).$$

Using the above argument and taking into account that the positive zeros of P_{2m+1} coincide with the positive zeros of P^c_{2m}, the result follows. □

Remark. Note that if $M=0$, $Q_{2m}(x)=P_{2m}(x)$, and if $N=0$, $Q_{2m+1}(x)=P_{2m+1}(x)$.

5. Differential properties.

5.1. Differential equation. Let us consider the case of (P_n) being a sequence of semiclassical orthogonal polynomials (see [19]). This means that the linear functional $\mathscr{L}$ defined by

$$\int_I P\,d\mu=\langle\mathscr{L},P\rangle,\qquad P\in\mathscr{P} \tag{5.1}$$

is characterized by polynomials ϕ and ψ such that a functional equation for $\mathscr{L}$

$$D(\phi\mathscr{L})+\psi\mathscr{L}=0 \tag{5.2}$$

holds with

$$\begin{gathered}\langle\psi\mathscr{L},P\rangle=\langle\mathscr{L},\psi P\rangle,\\ \langle D(\phi\mathscr{L}),P\rangle=-\langle\phi\mathscr{L},P'\rangle\end{gathered} \tag{5.3}$$

for every $P\in\mathscr{P}$.

It is easy to construct a second-order linear differential equation for the SMOP (Q_n) using the representation (2.12), where the polynomials q_2 and q_1 are known explicitly in terms of P_n.

Let us use the structure relation (see [19]) for semiclassical orthogonal polynomials P_n of class s ($s=\max\{(\deg\psi)-1,(\deg\phi)-2\}$).

$$\phi P'_{n+1}=\sum_{k=n-s}^{n+t}\theta_{nk}P_k, \tag{5.4}$$

where $t=\deg\phi$ and θ_{nk} are constants. This relation can be writen

$$\phi P'_{n+1}=C_nP_n+D_nP_{n-1}, \tag{5.5}$$

where the polynomials $C_n=C(x,n)$ and $D_n=D(x,n)$ are computed from the three term recurrence relation for the SMOP (P_n).

The usual 3 step procedure (see [21]) now give the relations

$$(x-c)^2Q_n=q_2P_n+q_1P_{n-1}, \tag{5.6}$$

$$\begin{aligned}\phi[(x-c)^2Q_n]'&=\phi(q_2'P_n+q_1'P_{n-1})+q_2(C_nP_n+D_nP_{n-1})\\ &\quad+q_1(C_{n-1}P_{n-1}+D_{n-1}P_{n-2})\\ &=q_{2,1}P_n+q_{1,1}P_{n-1},\end{aligned} \tag{5.7}$$

$$\phi[\phi[(x-c)^2Q_n]']'=q_{2,2}P_n+q_{1,2}P_{n-1}. \tag{5.8}$$

In the computation of the polynomials $q_{i,j}$ $(i,j=1,2)$, we need again the recurrence relation of the P_n in order to eliminate P_{n-2} in terms of P_n and P_{n-1}.

The following determinant gives the expected differential equation for the sequence (Q_n):

$$\begin{vmatrix}(x-c)^2Q_n & q_2 & q_1\\ \phi[(x-c)^2Q_n]' & q_{2,1} & q_{1,1}\\ \phi\{\phi[(x-c)^2Q_n]'\}' & q_{2,2} & q_{1,2}\end{vmatrix}=0. \tag{5.9}$$

This differential equation becomes particularly simple in the symmetric case with $c=0$. The Hermite case was already treated in [17], so we study here the Gegenbauer case. Bavinck and Meijer also analyze this situation (Gegenbauer case), but with two mass points located at the endpoints of the interval (see [2]).

5.2. Applications. As a first example, we consider the inner product of Sobolev type

$$\langle f, g\rangle = \int_{-1}^{1} f(x)g(x)(1-x^2)^{\lambda-1/2}\,dx + Mf(0)g(0) + Nf'(0)g'(0) \tag{5.10}$$

with $\lambda > -\frac{1}{2}$. In this case, the point c $(c=0)$ is in the support of the measure, and the symmetric character is preserved.

It is well known that the monic Gegenbauer polynomials verify a three term recurrence relation.

$$xP_{n+1}^{(\lambda)}(x) = P_{n+2}^{(\lambda)}(x) + \frac{(n-1)(n+2\lambda)}{4(n+\lambda)(n+\lambda+1)} P_n^{(\lambda)}(x) \qquad n \geqq 0,$$

$$P_0^{(\lambda)}(x) = 1 \qquad P_1^{(\lambda)}(x) = x$$

and

$$P_{2n}^{(\lambda)}(0) = \frac{(-1)^n}{2^{2n}} \frac{(2n)!}{n!} \frac{\Gamma(n+\lambda)}{\Gamma(2n+\lambda)},$$

$$P_{2n}^{(\lambda)\prime}(0) = P_{2n}^{(\lambda)\prime\prime\prime}(0) = 0,$$

$$P_{2n+1}^{(\lambda)}(0) = P_{2n+1}^{(\lambda)\prime\prime}(0) = 0,$$

$$P_{2n+1}^{(\lambda)\prime}(0) = \frac{(2n+1)(n+\lambda)}{2n+\lambda} P_{2n}^{(\lambda)}(0),$$

$$P_{2n}^{(\lambda)\prime\prime}(0) = -4n(n+\lambda)P_{2n}^{(\lambda)}(0),$$

$$P_{2n+1}^{(\lambda)\prime\prime\prime}(0) = -\frac{4n(2n+1)(n+\lambda)(n+\lambda+1)}{2n+\lambda} P_{2n}^{(\lambda)}(0),$$

$$\|P_n^{(\lambda)}\|^2 = 2^{1-2(\lambda+n)}\pi \frac{n!\Gamma(n+2\lambda)}{(n+\lambda)[\Gamma(n+\lambda)]^2}.$$

Moreover, they satisfy a structure relation

$$(x^2-1)P_{n+1}^{(\lambda)\prime}(x) = (n+1)xP_{n+1}^{(\lambda)}(x) - \frac{(n+1)(n+2\lambda)}{2(n+\lambda)} P_n^{(\lambda)}(x) \tag{5.11}$$

(see [24, formula 4.7.27, p. 83]). Thus (4.3) becomes

$$Q_{2n}(x) = P_{2n}^{(\lambda)}(x) + M_n \frac{P_{2n-1}^{(\lambda)}(x)}{x}, \tag{5.12}$$

$$Q_{2n+1}(x) = P_{2n+1}^{(\lambda)}(x) - N_n \frac{P_{2n+1}^{(\lambda)}(x) - \dfrac{P_{2n+1}^{(\lambda)\prime}(0)}{P_{2n}^{(\lambda)}(0)} xP_{2n}^{(\lambda)}(x)}{x^2}, \tag{5.13}$$

where

$$M_n = M \frac{[P_{2n}^{(\lambda)}(0)]^2}{\|P_{2n-1}^{(\lambda)}\|^2[1+MK_{2n-1}(0,0)]},$$

$$N_n = N \frac{P_{2n+1}^{(\lambda)\prime}(0)P_{2n}^{(\lambda)}(0)}{\|P_{2n}^{(\lambda)}\|^2[1+NK_{2n}^{(1,1)}(0,0)]},$$

but,

$$P_{2n}^{(\lambda)}(x) = S_n(x^2); \qquad P_{2n+1}^{(\lambda)}(x) = xS_n^*(x^2)$$

and

$$K_{2n}^{(0,1)}(x, 0) = -\frac{P_{2n}(0)}{\|P_{2n}^{(\lambda)}\|^2}\,\frac{n(2n-1+2\lambda)}{2n+\lambda}\,xS_{n-1}^{**}(x^2)$$

(see [7, Chap. 1, § 8]). Then

$$Q_{2n}(x) = S_n(x^2) + M_nS_{n-1}^*(x^2),$$

$$Q_{2n+1}(x) = x\left[S_n^*(x^2) + N_n\frac{n(2n-1+2\lambda)}{2n+\lambda}S_{n-1}^{**}(x^2)\right].$$

The following proposition can easily be derived from the above comments and from (4.7) and (4.8).

PROPOSITION 5.1. *For the* SMOP (Q_n) *corresponding to the inner product defined by* (5.10), $Q_n(-x) = (-1)^nQ_n(x)$. *If*

$$Q_{2n}(x) = U_n(x^2) \quad \textit{and} \quad Q_{2n+1}(x) = xV_n(x^2),$$

then

(5.14) $$U_n(x) = S_n(x) + M_nS_{n-1}^*(x),$$

(5.15) $$V_n(x) = S_n^*(x) + N_n\frac{n(2n-1+2\lambda)}{2n+\lambda}S_{n-1}^{**}(x),$$

and U_n, V_n *satisfy a three term recurrence relation in the standard sense.*

Remark. In general, for a symmetric SMOP associated to a Sobolev type inner product, we can define two SMOP in the standard sense. They satisfy a decomposition in terms of (5.14) and (5.15).

PROPOSITION 5.2. *The* SMOP (Q_n) *verifies a second-order linear differential equation*

$$A(x;\, n)Q_n''(x) + B(x;\, n)Q_n'(x) + C(x;\, n)Q_n(x) = 0,$$

where A, B, C *are polynomials of degree independent of* n. *More precisely,* $\deg B(x;\, n) \leqq \deg A(x;\, n) - 1$; $\deg C(x;\, n) \leqq \deg A(x;\, n) - 2$; $\deg A(x;\, 2n) = 6$ *and* $\deg A(x;\, 2n+1) = 8$.

Proof. From (5.11) and (5.12)

$$\begin{aligned} xQ_{2n}(x) &= xP_{2n}^{(\lambda)}(x) + M_n\frac{2n-1+\lambda}{(2n-1+2\lambda)n} \\ &\quad\cdot [2nxP_{2n}^{(\lambda)}(x) - (x^2-1)P_{2n}^{(\lambda)\prime}(x)] \\ &= \left(1 + 2M_n\frac{2n-1+\lambda}{2n-1+2\lambda}\right)xP_{2n}^{(\lambda)}(x) \\ &\quad - M_n\frac{2n-1+\lambda}{n(2n-1+2\lambda)}(x^2-1)P_{2n}^{(\lambda)\prime}(x). \end{aligned}$$

On the other hand, from (5.11) and (5.13)

$$\begin{aligned} x^2Q_{2n+1}(x) &= (x^2 - N_n)P_{2n+1}^{(\lambda)}(x) - N_n\left[\frac{-P_{2n+1}^{(\lambda)\prime}(0)}{P_{2n}^{(\lambda)}(0)}xP_{2n}^{(\lambda)}(x)\right] \\ &= (x^2 - N_n)P_{2n+1}^{(\lambda)}(x) - N_n \\ &\quad\cdot [x(x^2-1)P_{2n+1}^{(\lambda)\prime}(x) - (2n+1)x^2P_{2n+1}^{(\lambda)}(x)] \\ &= ([1 + (2n+1)N_n]x^2 - N_n)P_{2n+1}^{(\lambda)}(x) - N_nx(x^2-1)P_{2n+1}^{(\lambda)\prime}(x). \end{aligned}$$

Then

$$Q_n(x) = \tilde{M}_n(x)P_n^{(\lambda)}(x) + \tilde{N}_n(x)P_n^{(\lambda)\prime}(x), \tag{5.16}$$

where

$$\tilde{M}_{2n}(x) = 1 + 2M_n \frac{2n-1+\lambda}{2n-1+2\lambda},$$

$$\tilde{M}_{2n+1}(x) = 1 + (2n+1)N_n - \frac{N_n}{x^2},$$

$$\tilde{N}_{2n}(x) = M_n \frac{2n-1+\lambda}{n(2n-1+2\lambda)} \frac{1-x^2}{x},$$

$$\tilde{N}_{2n+1}(x) = N_n \frac{1-x^2}{x}.$$

Using derivatives in (5.16),

$$\begin{aligned} Q_n'(x) = {} & \tilde{M}_n'(x)P_n^{(\lambda)}(x) + [\tilde{M}_n(x) + \tilde{N}_n'(x)]P_n^{(\lambda)\prime}(x) \\ & + \tilde{N}_n(x)P_n^{(\lambda)\prime\prime}(x). \end{aligned} \tag{5.17}$$

But, from the second-order linear differential equation satisfied by Gegenbauer polynomials (see [24, formula 4.7.5, p. 80]),

$$(x^2-1)P_n^{(\lambda)\prime\prime}(x) + (2\lambda+1)xP_n^{(\lambda)\prime}(x) - n(n+2\lambda)P_n^{(\lambda)}(x) = 0$$

formula (5.17) becomes

$$Q_n'(x) = \hat{M}_n(x)P_n^{(\lambda)}(x) + \hat{N}_n(x)P_n^{(\lambda)\prime}(x), \tag{5.18}$$

where

$$\hat{M}_n(x) = \tilde{M}_n'(x) + \frac{\tilde{N}_n(x)}{x^2-1} n(n+2\lambda),$$

$$\hat{N}_n(x) = \tilde{M}_n(x) + \tilde{N}_n'(x) - (2\lambda+1)x\frac{\tilde{N}_n(x)}{x^2-1}.$$

From (5.16) and (5.18)

$$P_n^{(\lambda)}(x) = \frac{\begin{vmatrix} Q_n(x) & \tilde{N}_n(x) \\ Q_n'(x) & \hat{N}_n(x) \end{vmatrix}}{\Delta_n}, \tag{5.19}$$

$$P_n^{(\lambda)\prime}(x) = \frac{\begin{vmatrix} \tilde{M}_n(x) & Q_n(x) \\ \hat{M}_n(x) & Q_n'(x) \end{vmatrix}}{\Delta_n}, \tag{5.20}$$

where $\Delta_n = \tilde{M}_n(x)\hat{N}_n(x) - \hat{M}_n(x)\tilde{N}_n(x)$ is a rational function.

From derivation in (5.19) and taking into account (5.20), the result follows. □

Remark. The above result should be compared with Proposition 6.1 in [14].

We consider, as a second example, an inner product of Sobolev type when μ is a discrete positive measure. More precisely, μ is a step function whose jumps are

$$d\mu(x) = \frac{e^{-a}a^x}{x!} \quad \text{at } x = 0, 1, 2, \cdots \quad \text{and} \quad a \in \boldsymbol{R}^+.$$

This corresponds to Poisson distribution in Probability Theory. The corresponding sequence $(C_n^{(a)})$ of monic orthogonal polynomials is called Charlier polynomials in the literature (see [7, p. 170]).

They can be expressed in terms of Laguerre polynomials as $C_n^{(a)}(x) = n!L_n^{(x-n)}(a)$ and satisfy a three term recurrence relation

$$C_{n+1}^{(a)}(x) = (x-n-a)C_n^{(a)}(x) - anC_{n-1}^{(a)}(x) \qquad n \geqq 0,$$
$$C_{-1}^{(a)}(x) = 0 \qquad C_0^{(a)}(x) = 1.$$

Moreover, Charlier polynomials can be characterized as the only SMOP belonging to Δ-Appell class, i.e.,

$$\Delta C_n^{(a)}(x) = nC_{n-1}^{(a)}(x) \qquad n \geqq 1,$$

where

$$\Delta p(x) = p(x+1) - p(x).$$

In this case, (2.12) becomes

$$x^2 Q_n(x) = q_2(x;\, n)C_n^{(a)}(x) + q_1(x;\, n)C_{n-1}^{(a)}(x), \tag{5.21}$$

where

$$q_2(x;\, n) = x^2 - a_n x - b_n,$$
$$q_1(x;\, n) = c_n x + d_n$$

and

$$a_n = \frac{MQ_n(0)C_{n-1}^{(a)}(0) + NQ_n'(0)C_{n-1}^{(a)\prime}(0)}{\|C_{n-1}^{(a)}\|^2},$$
$$b_n = \frac{NQ_n'(0)C_{n-1}^{(a)}(0)}{\|C_{n-1}^{(a)}\|^2},$$
$$c_n = \frac{MQ_n(0)C_n^{(a)}(0) + NQ_n'(0)C_n^{(a)\prime}(0)}{\|C_{n-1}^{(a)}\|^2},$$
$$d_n = \frac{NQ_n'(0)C_n^{(a)}(0)}{\|C_{n-1}^{(a)}\|^2} = -ab_n.$$

If in (5.21) we apply the Δ-operator and the recurrence relation for $C_n^{(a)}$, we get

$$\begin{aligned}
&(x+1)^2\Delta Q_n(x) + (2x+1)Q_n(x)\\
&\quad = q_2(x+1;\, n)nC_{n-1}^{(a)}(x) + \Delta q_2(x;\, n)C_n^{(a)}(x)\\
&\qquad + q_1(x+1;\, n)(n-1)C_{n-2}^{(a)}(x) + \Delta q_1(x;\, n)C_{n-1}^{(a)}(x)\\
&\quad = \left[\Delta q_2(x;\, n) - \frac{1}{a}q_1(x+1;\, n)\right]C_n^{(a)}(x)\\
&\qquad + \left[nq_2(x+1;\, n) + \Delta q_1(x;\, n) + \frac{1}{a}(x+1-n-a)q_1(x+1;\, n)\right]C_{n-1}^{(a)}(x).
\end{aligned}$$

Thus,

$$(x+1)^2\Delta Q_n(x) + (2x+1)Q_n(x) = A(x;\, n)C_n^{(a)}(x) + B(x;\, n)C_{n-1}^{(a)}(x) \tag{5.22}$$

with

$$A(x;\, n)=\left(2-\frac{c_n}{a}\right)x+1-a_n-\frac{1}{a}(c_n+d_n),$$

$$B(x;\, n)=\left(n+\frac{c_n}{a}\right)(x+1)^2$$
$$+\left[\frac{1}{a}\{d_n-(n+a)c_n\}-na_n\right](x+1)+c_n-d_n.$$

Then, from (5.21) and (5.22), Cramer's rule gives

$$C_n^{(a)}(x)=\frac{E_n(x)}{S_n(x)}Q_n(x)+\frac{F_n(x)}{S_n(x)}\Delta Q_n(x),$$

$$C_{n-1}^{(a)}(x)=\frac{G_n(x)}{S_n(x)}Q_n(x)+\frac{H_n(x)}{S_n(x)}\Delta Q_n(x),$$

where

$$E_n(x)=x^2B(x;\, n)-(2x+1)q_1(x;\, n),$$
$$F_n(x)=-(x+1)^2q_1(x;\, n),$$
$$S_n(x)=q_2(x;\, n)B(x;\, n)-q_1(x;\, n)A(x;\, n),$$
$$G_n(x)=(2x+1)q_2(x;\, n)-x^2A(x;\, n),$$
$$H_n(x)=(x+1)^2q_2(x;\, n).$$

Finally, using $\Delta C_n^{(a)}(x)=nC_{n-1}^{(a)}(x)$

$$\frac{E_n(x+1)}{S_n(x+1)}\Delta Q_n(x)+\left(\Delta\frac{E_n(x)}{S_n(x)}\right)Q_n(x)$$
$$+\frac{F_n(x+1)}{S_n(x+1)}\Delta^2Q_n(x)+\left(\Delta\frac{F_n(x)}{S_n(x)}\right)\Delta Q_n(x)$$
$$=n\left(\frac{G_n(x)}{S_n(x)}Q_n(x)+\frac{H_n(x)}{S_n(x)}\Delta Q_n(x)\right).$$

Therefore,

$$F_n(x+1)S_n(x)\Delta^2Q_n(x)$$
$$+([E_n(x+1)+F_n(x+1)]S_n(x)-[nH_n(x)+F_n(x)]S_n(x+1))\Delta Q_n(x)$$
$$+(E_n(x+1)S_n(x)-[E_n(x)+nG_n(x)]S_n(x+1))Q_n(x)=0.$$

In conclusion, we present the following.

PROPOSITION 5.3. *The* SMOP (Q_n) *satisfies a second-order linear difference equation*

$$U_n(x;\, n)\Delta^2Q_n(x)+V_n(x;\, n)\Delta Q_n(x)+W_n(x;\, n)Q_n=0,$$

where U, V and W are polynomials with degree independent of n. More precisely, deg $U=7$, deg $V\leqq 8$ *and* deg $W\leqq 7$.

Acknowledgments. The authors thank Professor Walter Van Assche (Katholieke Universiteit Leuven) for his useful suggestions and comments. They also wish to thank the referee who provided them with reference [10].

MULTIDIMENSIONAL q-BETA INTEGRALS*

RONALD J. EVANS†

Abstract. A multidimensional extension of a q-beta integral of Andrews and Askey is evaluated. As an application, a short new proof of an important q-Selberg integral formula is given.

Key words. q-integral, Selberg integral, beta integrals

AMS(MOS) subject classification. 33A15

1. Introduction. This paper has been motivated by Anderson's wonderfully innovative proof [2] of Selberg's multidimensional beta integral formula [17]. In § 2 (see Theorem 1), we present a new n-dimensional q-beta integral formula which reduces to that of Andrews and Askey [4, eqn. (2.2)] when $n = 1$ and that of Anderson [2, "claim"] when $q = 1$. Our proof is self-contained and in particular makes no appeal to the results of the aforementioned papers. In § 3, we apply Theorem 1 to give a surprisingly short, self-contained proof of the q-Selberg integral formula (1.8). Finally, we indicate in § 4 the modifications that can be made in § 3 to give a short proof of Kadell's extension of the q-Selberg integral formula containing the extra parameter m of Aomoto [5]; see Theorem 2. It is hoped that this method will lead to a short proof of a q-extension of the Selberg-Jack integral formula [15].

For some of the many applications and extensions of Selberg's integral, see the papers of Askey [6]-[8] and Kadell [14]-[16]. For character sum analogues of Selberg's integral, see the papers of Anderson [1], Evans [10] and van Wamelen [18].

Let

$$0<q<1, \tag{1.1}$$

and define, for complex x, α,

$$(\alpha)_\infty := \prod_{r=0}^{\infty} (1-\alpha q^r), \qquad (\alpha)_x := (\alpha)_\infty/(\alpha q^x)_\infty. \tag{1.2}$$

Define the q-gamma function

$$\Gamma_q(x) := (q)_{x-1}(1-q)^{1-x}, \qquad x \in \mathbb{C}. \tag{1.3}$$

As $q \to 1$, $\Gamma_q(x) \to \Gamma(x)$ [11, eqn. (1.10.3)]. For $\alpha, \beta \in \mathbb{C}$ and a (say) continuous function $f: \mathbb{C} \to \mathbb{C}$, define the q-integral

$$\int_\alpha^\beta f(x)\, d_qx := \int_0^\beta f(x)\, d_qx - \int_0^\alpha f(x)\, d_qx, \tag{1.4}$$

where

$$\int_0^\beta f(x)\, d_qx := (1-q) \sum_{m=0}^{\infty} f(\beta q^m)\beta q^m. \tag{1.5}$$

As $q \to 1$, $\int_\alpha^\beta f(x)\, d_qx \to \int_\alpha^\beta f(x)\, dx$ [11, p. 19]. For example, for $m > 0$,

$$\int_\alpha^\beta x^{m-1}\, d_qx = \frac{(\beta^m - \alpha^m)(1-q)}{(1-q^m)} \to \frac{\beta^m - \alpha^m}{m} \tag{1.6}$$

* Received by the editors December 17, 1990; accepted for publication (in revised form) June 21, 1991.

† Department of Mathematics 0112, University of California, San Diego, La Jolla, California 92093-0112.

as $q \to 1$. The following q-integral extension of Euler's beta function integral is essentially a version of the q-binomial theorem [11, pp. 18-19]:

$$\int_0^1 t^{a-1}(tq)_{b-1}\, d_qt = \Gamma_q(a)\Gamma_q(b)/\Gamma_q(a+b), \qquad \operatorname{Re}(a), \operatorname{Re}(b) > 0. \tag{1.7}$$

This is the case $n=1$ of the following n-dimensional q-Selberg integral formula [13, eqn. (4.18)]:

$$\begin{aligned} S_n(a, b, c) &:= \frac{1}{n!}\int_0^1 \cdots \int_0^1 \prod_{i=1}^n t_i^{a-1}(t_iq)_{b-1} \prod_{1 \leqq i<j \leqq n} \prod_{k=1-c}^{c-1} (t_i - q^k t_j)\, d_qt_1 \cdots d_qt_n \\ &= q^{ac\binom{n}{2}+2c^2\binom{n}{3}} \prod_{j=0}^{n-1} \frac{\Gamma_q(a+jc)\Gamma_q(b+jc)\Gamma_q(c+jc)}{\Gamma_q(a+b+(n-1+j)c)\Gamma_q(c)}, \end{aligned} \tag{1.8}$$

where n, c are positive integers and $\operatorname{Re}(a)$, $\operatorname{Re}(b) > 0$. This reduces to Selberg's integral formula [17] when $q \to 1$. Note that the integrand in (1.8) is symmetric in the variables t_i. It is not difficult to show that the nonsymmetric version of (1.8) originally conjectured by Askey [6, Conj. 1] is equivalent to (1.8); see Kadell [13, p. 953]. Proofs of (1.8) have been given independently by Habsieger [12] and Kadell [14].

We observe here for later use that the value of the integral in (1.8) is unchanged if the upper limits of integration are replaced by q^{-u}, when u and b are integers such that $0 \leqq u \leqq b-1$. This is because $(tq)_{b-1}$ vanishes for $t = q^{-1}, q^{-2}, \cdots, q^{-u}$. It follows that the integral in (1.8) changes only by a factor of a power of q when the variables t_i are replaced by t_iq^{-u}.

2. Extension of the Andrews–Askey q-integral.

THEOREM 1. *Let u_i, s_i be integers such that*

$$0 \leqq u_i \leqq s_i - 1, \qquad i = 0, 1, \cdots, n, \tag{2.1}$$

and let z_i, w_i be complex variables with

$$w_i = z_iq^{-u_i}, \qquad i = 0, 1, \cdots, n. \tag{2.2}$$

Then

$$\begin{aligned} L &:= \int_{t_n=w_{n-1}}^{w_n} \cdots \int_{t_2=w_1}^{w_2} \int_{t_1=w_0}^{w_1} \prod_{i=0}^n \prod_{j=1}^n \prod_{k=1}^{s_i-1} (z_i - q^k t_j) \\ &\quad \cdot \prod_{1 \leqq i<j \leqq n} (t_j - t_i)\, d_qt_1\, d_qt_2 \cdots d_qt_n \\ &= (-1)^\sigma q^\tau \frac{\Gamma_q(s_0)\Gamma_q(s_1)\cdots\Gamma_q(s_n)}{\Gamma_q(s_0+s_1+\cdots+s_n)} \prod_{0 \leqq i<j \leqq n} \prod_{k=1-s_j}^{s_i-1} (z_i - q^k z_j), \end{aligned} \tag{2.3}$$

where

$$\sigma = \sum_{i=1}^n is_i, \qquad \tau = \sum_{i=1}^n i\binom{s_i}{2}. \tag{2.4}$$

Remark 1. Suppose that all z_i are nonzero and all u_i are zero. Then the integral formula in Theorem 1 can be written in the form

$$\begin{aligned} &\int_{t_n=z_{n-1}}^{z_n} \cdots \int_{t_2=z_1}^{z_2} \int_{t_1=z_0}^{z_1} \prod_{i=0}^n \prod_{j=1}^n \left(\frac{qt_j}{z_i}\right)_{s_i-1} \\ &\quad \cdot \prod_{1 \leqq i<j \leqq n} (t_j - t_i)\, d_qt_1\, d_qt_2 \cdots d_qt_n \\ &= \frac{\Gamma_q(s_0)\Gamma_q(s_1)\cdots\Gamma_q(s_n)}{\Gamma_q(s_0+s_1+\cdots+s_n)} \prod_{0 \leqq i<j \leqq n} z_j\left(\frac{z_i}{z_j}\right)_{s_j}\left(\frac{qz_j}{z_i}\right)_{s_i-1}. \end{aligned} \tag{2.5}$$

Since (2.5) is valid for all positive integers s_i by Theorem 1, it follows by analytic continuation (cf. [3, p. 115]) that it holds for all complex s_i with

$$\operatorname{Re}(s_i) > \max_{0 \leqq j \leqq n} \frac{\log |z_j/z_i|}{|\log q|}, \qquad i = 0, 1, 2, \cdots, n.$$

If $n = 1$, (2.5) reduces to the Andrews-Askey q-integral [4, (2.2)].

Remark 2. From (2.5) and [9, Thm. 2.2], it may be deduced that the constant term of the Laurent polynomial

$$P(z_1, \cdots, z_n) := \int_0^1 \cdots \int_0^1 \prod_{1 \leqq i, j \leqq n} (qt_j z_j/z_i)_{s_i - 1} \cdot \prod_{1 \leqq i < j \leqq n} (t_j - t_i z_i/z_j) \, d_q t_1 \cdots d_q t_n$$

equals

$$\prod_{i=1}^{n} (1-q)/(1-q^{s_i + s_{i+1} + \cdots + s_n}). \tag{2.6}$$

It would be interesting to find a proof independent of [9].

Proof of Theorem 1. Assume that each z_i is an integral power of q and that the sequence $w_0, w_1, w_2, \cdots, w_n$ is monotone. It suffices to prove (2.3) under these assumptions, since both sides of (2.3) are polynomials in $z_0, \cdots, z_n$.

Consider any one of the rightmost factors in (2.3), say

$$z_\alpha - q^\gamma z_\beta, \tag{2.7}$$

with

$$0 \leqq \alpha < \beta \leqq n, \qquad 1 - s_\beta \leqq \gamma \leqq s_\alpha - 1. \tag{2.8}$$

We will show that $z_\alpha - q^\gamma z_\beta$ is also a factor of L by showing that L vanishes under the assumption

$$z_\alpha = q^\gamma z_\beta. \tag{2.9}$$

The q-integral L is a series by definition, and it suffices to show that each summand in this series vanishes. This will be accomplished if we can show

$$\prod_{k=1}^{s_\alpha - 1} (z_\alpha - q^k t) \prod_{m=1}^{s_\beta - 1} (z_\beta - q^m t) = 0 \quad \text{for all } t \in S, \tag{2.10}$$

where S is the set of integral powers of q between w_α and w_β including $\max(w_\alpha, w_\beta)$ but not $\min(w_\alpha, w_\beta)$. Define

$$A = \{z_\alpha q^{-k} : 1 \leqq k \leqq s_\alpha - 1\}, \qquad B = \{z_\beta q^{-m} : 1 \leqq m \leqq s_\beta - 1\}. \tag{2.11}$$

Since $z_\alpha = q^\gamma z_\beta$ by (2.9), there is no integral power of q lying strictly between the sets A and B on the real axis. It is thus seen that $A \cup B \supset S$, and (2.10) follows. We have now proved that L is divisible by each of the linear factors in (2.7), and hence by the polynomial

$$\prod_{0 \leqq i < j \leqq n} \prod_{k = 1 - s_j}^{s_i - 1} (z_i - q^k z_j). \tag{2.12}$$

By definition of L, if we view L as a polynomial in z_0 with leading term $C_n z_0^\nu$ (with C_n independent of z_0), then

$$\nu = n(s_0 - 1) + (s_1 + \cdots + s_n). \tag{2.13}$$

Viewing (2.12) as a polynomial in z_0, we see that it also has degree ν. Thus it remains to prove that

$$C_n=(-1)^\sigma q^\tau \frac{\Gamma_q(s_0)\cdots\Gamma_q(s_n)}{\Gamma_q(s_0+\cdots+s_n)} \prod_{1\leqq i<j\leqq n} \prod_{k=1-s_j}^{s_i-1} (z_i-q^k z_j). \tag{2.14}$$

First consider the case $n=1$. Then C_1 is the coefficient of $z_0^{s_0+s_1-1}$ in

$$\int_{t=w_0}^{w_1} \prod_{k=1}^{s_0-1} (z_0-q^k t) \prod_{m=1}^{s_1-1} (z_1-q^m t)\, d_q t, \tag{2.15}$$

so C_1 is the coefficient of $z_0^{s_0+s_1-1}$ in

$$-\prod_{m=1}^{s_1-1} (-q^m) \int_{w_1}^{w_0} t^{s_1-1} z_0^{s_0-1} (qt/z_0)_{s_0-1}\, d_q t. \tag{2.16}$$

Replace t by $z_0 t$ to see that C_1 is the constant term in the expansion in z_0 of

$$(-1)^{s_1} q^{\binom{s_1}{2}} \int_{w_1/z_0}^{q^{-u_0}} t^{s_1-1} (qt)_{s_0-1}\, d_q t. \tag{2.17}$$

The constant term in (2.17) is unchanged if the lower limit of q-integration is replaced by 0. It is further unchanged if the upper limit of q-integration is replaced by 1, since

$$(qt)_{s_0-1}=0 \quad \text{for} \quad t=q^{-i} \qquad (i=1,2,\cdots,s_0-1). \tag{2.18}$$

It now follows from (1.7) that (2.14) holds for $n=1$, so the proof of Theorem 1 is complete in the case $n=1$.

Suppose now that $n>1$ and that Theorem 1 holds with $(n-1)$ in place of n. Directly from (2.3), we see that C_n is the coefficient of $z_0^{(s_0+\cdots+s_n)-1}$ in

$$\begin{aligned}&\int_{t_n=w_{n-1}}^{w_n} \cdots \int_{t_2=w_1}^{w_2} \prod_{i=1}^{n} \prod_{j=2}^{n} \prod_{k=1}^{s_i-1} (z_i-q^k t_j) \cdot \prod_{2\leqq i<j\leqq n} (t_j-t_i)\\ &\cdot (-1)^{s_1+\cdots+s_n} q^{\binom{s_1}{2}+\cdots+\binom{s_n}{2}} \int_{t=w_1}^{w_0} t^{(s_1+\cdots+s_n)-1}\\ &\cdot \prod_{k=1}^{s_0-1} (z_0-q^k t)\, d_q t\, d_q t_2 \cdots d_q t_n.\end{aligned} \tag{2.19}$$

The inner integral on t in (2.19) may be replaced by

$$z_0^{(s_0+\cdots+s_n)-1} \int_{w_1/z_0}^{q^{-u_0}} t^{(s_1+\cdots+s_n)-1} (qt)_{s_0-1}\, d_q t, \tag{2.20}$$

and just as with (2.17), the desired coefficient is unchanged if we further replace the lower and upper limits of q-integration in (2.20) by zero and 1, respectively. Thus by (1.7), C_n is the constant term of the polynomial in z_0 obtained from (2.19) by replacing the inner integral on t by

$$\frac{\Gamma_q(s_0)\Gamma_q(s_1+\cdots+s_n)}{\Gamma_q(s_0+s_1+\cdots+s_n)}. \tag{2.21}$$

By induction on n, the proof of Theorem 1 is complete.

3. Proof of the q-Selberg integral formula. In this section we apply Theorem 1 to give a short proof of the q-Selberg integral formula (1.8). The result is true for $n=1$ by (1.7), so let $n>1$. We may assume that a and b are positive integers, as the result can be extended by analytic continuation to hold whenever Re (a), Re $(b)>0$.

Given polynomials

$$E(t)=\prod_{i=1}^{n}(t-e_i), \qquad H(t)=\prod_{i=1}^{n-1}(t-h_i) \tag{3.1}$$

with

$$0\leqq e_1\leqq h_1\leqq e_2\leqq h_2\leqq\cdots\leqq h_{n-1}\leqq e_n\leqq 1, \tag{3.2}$$

use for brevity the symbolic notation

$$\begin{aligned}\int_{E\in D_n}\{\ \}\,d_qE := \int_{e_n=0}^{1}\cdots\int_{e_2=0}^{e_3}\int_{e_1=0}^{e_2}\{\ \}\\ \cdot\prod_{1\leqq i<j\leqq n}(e_i-e_j)\,d_qe_1\,d_qe_2\cdots d_qe_n\end{aligned} \tag{3.3}$$

and

$$\begin{aligned}\int_{H\in D_{n-1}(E)}\{\ \}\,d_qH := \int_{h_{n-1}=e_{n-1}}^{e_n}\cdots\int_{h_2=e_2}^{e_3}\int_{h_1=e_1}^{e_2}\{\ \}\\ \cdot\prod_{1\leqq i<j\leqq n-1}(h_i-h_j)\,d_qh_1\,d_qh_2\cdots d_qh_{n-1}.\end{aligned} \tag{3.4}$$

Note that

$$\int_{E\in D_n}\int_{H\in D_{n-1}(E)}=\int_{H\in D_{n-1}}\int_{E\in D_n(V)}, \tag{3.5}$$

where

$$V(t)=\prod_{i=0}^{n}(t-v_i)\quad\text{with } v_0=0,\quad v_n=1,\quad v_i=qh_i\quad(1\leqq i\leqq n-1). \tag{3.6}$$

Define

$$\begin{aligned}I_n(a,b,c) := \int_{E\in D_n}\int_{H\in D_{n-1}(E)}\prod_{i=1}^{n}e_i^{a-1}(qe_i)_{b-1}\\ \cdot\prod_{i=1}^{n}\prod_{j=1}^{n-1}\prod_{k=1}^{c-1}(q^{c-1}e_i-q^kh_j)\,d_qH\,d_qE.\end{aligned} \tag{3.7}$$

If we replace n by $n-1$ in Theorem 1 and then further take $t_i=h_i$, $s_i=c$, $u_i=c-1$, $w_i=e_{i+1}$, $z_i=q^{c-1}e_{i+1}$, then Theorem 1 yields

$$\begin{aligned}\int_{H\in D_{n-1}(E)}\prod_{i=1}^{n}\prod_{j=1}^{n-1}\prod_{k=1}^{c-1}(q^{c-1}e_i-q^kh_j)\,d_qH\\ =(-1)^{\binom{n-1}{2}+c\binom{n}{2}}q^{\binom{n}{2}\binom{c}{2}}\frac{\Gamma_q(c)^n}{\Gamma_q(cn)}\\ \cdot\prod_{1\leqq i<j\leqq n}\prod_{k=1-c}^{c-1}(q^{c-1}e_i-q^{k+c-1}e_j).\end{aligned} \tag{3.8}$$

Thus, by definition of $S_n(a,b,c)$ and $I_n(a,b,c)$,

$$I_n(a,b,c)=(-1)^{\binom{n-1}{2}+c\binom{n}{2}}q^{\binom{n}{2}\binom{c}{2}+\binom{n}{2}\binom{2c-1}{2}}\frac{\Gamma_q(c)^n}{\Gamma_q(cn)}S_n(a,b,c). \tag{3.9}$$

By (3.5) and (3.6), interchange of integration in (3.7) yields

$$\begin{aligned} I_n(a,b,c) = \int_{H\in D_{n-1}} \int_{E\in D_n(V)} & (-1)^{n(a-1)} q^{-n\binom{a}{2}} \prod_{j=1}^{n}\prod_{k=1}^{a-1} (0-q^k e_j) \\ & \cdot \prod_{j=1}^{n}\prod_{k=1}^{b-1} (1-q^k e_j) \\ & \cdot q^{2\binom{n}{2}\binom{c-1}{2}} \prod_{i=1}^{n-1}\prod_{j=1}^{n}\prod_{k=1}^{c-1} (v_i - q^k e_j)\, d_qE\, d_qH. \end{aligned} \tag{3.10}$$

Apply Theorem 1 with $t_i = e_i$, $s_0 = a$, $s_n = b$, $s_i = c$ $(1 \leqq i \leqq n-1)$, $u_i = 0$, $w_i = v_i$, and $z_i = v_i$ to see that the inner integral on E equals

$$\begin{aligned} & (-1)^{\binom{n-1}{2}+c\binom{n}{2}} q^{\binom{n}{2}\binom{c}{2}+2\binom{n}{2}\binom{c-1}{2}} \\ & \cdot \frac{\Gamma_q(a)\Gamma_q(b)\Gamma_q(c)^{n-1}}{\Gamma_q(a+b+(n-1)c)} \prod_{j=1}^{n-1} v_j^{a+c-1} \prod_{j=1}^{n-1}\prod_{k=1-c}^{b-1} (1-q^k v_j) \\ & \cdot \prod_{1\leqq i<j\leqq n-1}\prod_{k=1-c}^{c-1} (v_i - q^k v_j). \end{aligned} \tag{3.11}$$

Before integrating (3.11) on H, make the change of variables $h_i \to q^{c-1}h_i$ (so $v_i \to q^c v_i$). As a result,

$$\begin{aligned} I_n(a,b,c) = & (-1)^{\binom{n-1}{2}+c\binom{n}{2}} \\ & \cdot q^{\binom{n}{2}\binom{c}{2}+2\binom{n}{2}\binom{c-1}{2}+(c-1)\binom{n}{2}+\binom{n-1}{2}\binom{2c}{2}+c(a+c-1)(n-1)} \\ & \cdot \frac{\Gamma_q(a)\Gamma_q(b)\Gamma_q(c)^{n-1}}{\Gamma_q(a+b+(n-1)c)} S_{n-1}(a+c, b+c, c). \end{aligned} \tag{3.12}$$

Comparison of (3.9) and (3.12) yields

$$\begin{aligned} S_n(a,b,c) = q^{ac(n-1)+c^2\binom{n-1}{2}} & \frac{\Gamma_q(a)\Gamma_q(b)\Gamma_q(cn)}{\Gamma_q(a+b+(n-1)c)\Gamma_q(c)} \\ & \cdot S_{n-1}(a+c, b+c, c) \end{aligned} \tag{3.13}$$

and the result follows by induction on n. □

4. Extension of the q-Selberg integral. Let $S_{n,m}(a,b,c)$ denote the extension of the q-Selberg integral $S_n(a,b,c)$ obtained by inserting the factor $t_1t_2\cdots t_m$ in the integrand in (1.8), where $0 \leqq m \leqq n$. In Theorem 2 below, we evaluate $S_{n,m}(a,b,c)$. It is not difficult to show that Theorem 2 is equivalent to the case $l=0$ of [14, Thm. 2]; see [14, eqns. (4.17), (4.19)].

THEOREM 2. *For positive integers n, c and* $\operatorname{Re}(a)$, $\operatorname{Re}(b) > 0$,

$$S_{n,m}(a,b,c) = \frac{S_n(a,b,c)T_{n,m}(a,b,c)}{\binom{n}{m}}, \tag{4.1}$$

where

$$T_{n,m}(a,b,c) := q^{c\binom{m}{2}} \prod_{i=n-m}^{n-1} \frac{(1-q^{a+ci})(1-q^{c+ci})}{(1-q^{a+b+c(n-1+i)})(1-q^{cn-ci})}. \tag{4.2}$$

Proof. We proceed as in the proof in § 3, with the following modifications. Let u be an indeterminate and let $S_n(a, b, c, u)$ be the extension of the q-Selberg integral $S_n(a, b, c)$ obtained by inserting the factor $\prod_{i=1}^n (u-t_i)$ in the integrand of (1.8). We must show that

$$\frac{S_n(a, b, c, u)}{S_n(a, b, c)} = \sum_{m=0}^{n} (-1)^m T_{n,m}(a, b, c) u^{n-m}. \tag{4.3}$$

Let $I_n(a, b, c, u)$ be the extension of $I_n(a, b, c)$ obtained by inserting the factor $q^{c(n-1)}H(u/q)$ in the integrand in (3.7). By Lagrange interpolation,

$$q^{c(n-1)}H\left(\frac{u}{q}\right) = \sum_{r=1}^{n} q^{c(n-1)}H\left(\frac{e_r}{q}\right) \prod_{i\neq r} \frac{u-e_i}{e_r-e_i}, \tag{4.4}$$

for distinct e_i. Thus, from (3.7),

$$\begin{aligned} I_n(a, b, c, u) = &\int_{E\in D_n} \sum_{r=1}^{n} \prod_{i\neq r} \frac{u-e_i}{e_r-e_i} \prod_{i=1}^{n} e_i^{a-1}(qe_i)_{b-1} \\ &\cdot \int_{H\in D_{n-1}(E)} \prod_{i=1}^{n} \prod_{j=1}^{n-1} \prod_{k=1}^{c-1+\delta(i,r)} (q^{c-1}e_i - q^k h_j)\, d_qH\, d_qE, \end{aligned} \tag{4.5}$$

where $\delta(i, r) = 1$ if $i = r$ and $\delta(i, r) = 0$ if $i \neq r$. If for each fixed r we replace n by $n-1$ in Theorem 1, and then further take $t_i = h_i$, $s_i = c + \delta(i, r)$, $u_i = c-1$, $w_i = e_{i+1}$, and $z_i = q^{c-1}e_{i+1}$, then Theorem 1 shows that the inner integral on H in (4.5) equals

$$\text{RHS (3.8) } q^{(n-1)(2c-1)} \frac{(1-q^c)}{(1-q^{cn})} \prod_{i\neq r} (q^{-c}e_r - e_i), \tag{4.6}$$

where RHS (3.8) denotes the right-hand side of (3.8). Thus

$$\begin{aligned} I_n(a, b, c, u) = &\, q^{(n-1)(2c-1)} \frac{(1-q^c)}{(1-q^{cn})} \int_{E\in D_n} \text{RHS (3.8)} \\ &\cdot \prod_{i=1}^{n} e_i^{a-1}(qe_i)_{b-1} \sum_{r=1}^{n} \prod_{i\neq r} \frac{u-e_i}{e_r-e_i} (q^{-c}e_r - e_i)\, d_qE. \end{aligned} \tag{4.7}$$

Given a polynomial $F(u)$, let $F^*(u)$ denote its q^{-c}-derivative [11, p. 22], namely

$$F^*(u) = \frac{F(u) - F(q^{-c}u)}{u - q^{-c}u}. \tag{4.8}$$

Since

$$E^*(e_r) = \prod_{i\neq r} (q^{-c}e_r - e_i), \tag{4.9}$$

the inner sum on r in (4.7) equals $E^*(u)$. Thus

$$I_n(a, b, c, u) = \text{RHS (3.9) } q^{(n-1)(2c-1)} \frac{(1-q^c)}{(1-q^{cn})} \frac{S_n^*(a, b, c, u)}{S_n(a, b, c)}. \tag{4.10}$$

After interchanging the order of integration, we obtain

$$I_n(a, b, c, u) = \text{RHS (3.12) } q^{(n-1)(2c-1)} \frac{S_{n-1}(a+c, b+c, c, uq^{-c})}{S_{n-1}(a+c, b+c, c)}. \tag{4.11}$$

Comparing (4.10) and (4.11), we arrive at the "differential equation"

$$\frac{S_n^*(a, b, c, u)}{S_n(a, b, c)} = \frac{1-q^{cn}}{1-q^c} \frac{S_{n-1}(a+c, b+c, c, uq^{-c})}{S_{n-1}(a+c, b+c, c)}. \tag{4.12}$$

By induction on n, (4.3) furnishes a solution to (4.12). Moreover, (4.3) is valid for $u=0$, by (1.8) with $a+1$ in place of a. Hence (4.3) is proved.

Acknowledgments. The author is grateful to Professors G. Anderson, G. Andrews, R. Askey, D. Bressoud, and K. Kadell for helpful correspondence.

ON REFINEMENT EQUATIONS DETERMINED BY PÓLYA FREQUENCY SEQUENCES*

T. N. T. GOODMAN† AND CHARLES A. MICCHELLI‡

Abstract. The refinement equation

$$\phi(x)=\sum_{i\in\mathbb{Z}} a_i\phi(2x-i), \qquad x\in\mathbb{R}$$

for a given sequence $\mathbf{a}=\{a_j\colon i\in\mathbb{Z}\}$ has found important application in the study of both *Stationary Subdivision Schemes* for the generation of curves and surfaces as well as the construction of *orthonormal wavelets* by means of *multiresolution analysis.* The main goal here is to study properties of the solution of this equation when the sequence $\mathbf{a}$ is a *Pólya frequency sequence.* In the case that $\operatorname{supp}\mathbf{a}:=\{k\colon a_k\neq 0, k\in\mathbb{Z}\}$ is finite the refinement equation is also considered when

$$a(z)=\sum_{j=0}^{n} a_j z^j$$

is a Hurwitz polynomial (has all zeros in the left-half plane).

1. Introduction.

The refinement equation

$$\varphi(x)=\sum_{i\in\mathbb{Z}} a_i\varphi(2x-i), \qquad x\in\mathbb{R} \tag{1.1}$$

for a given sequence $\mathbf{a}=\{a_i\colon i\in\mathbb{Z}\}$ has found important application in the study of both *Stationary Subdivision Schemes* for the generation of curves and surfaces [3] as well as the construction of *orthonormal wavelets* by means of *multiresolution analysis* [5], [11].

Our main goal here is to study properties of the solution (1.1) when the sequence $\mathbf{a}$ is a *Pólya frequency sequence.* Recall that this requires *all* the minors of the bi-infinite matrix A

$$A_{ij}=a_{j-i} \qquad i,j\in\mathbb{Z} \tag{1.2}$$

to be nonnegative, that is,

$$A\begin{pmatrix} i_1,\cdots,i_p \\ j_1,\cdots,j_p\end{pmatrix}:=\det_{k,l=1,\cdots,p} A_{i_kj_l}\geqq 0 \tag{1.3}$$

for all integers $i_1<\cdots<i_p, j_1<\cdots<j_p$.

Pólya frequency sequences have been studied by numerous authors [1], [7], [8], and a *complete* characterization of such sequences is available in terms of the symbol

$$a(z)=\sum_{i\in\mathbb{Z}} a_i z^i, \qquad z\in\mathbb{C}. \tag{1.4}$$

We will describe this later as it will be important to our analysis. Recall that the symbol of every Pólya frequency sequence (other than the trivial sequence $\{\gamma^n\colon n \in \mathbb{Z}\}$ for some $\gamma > 0$) converges in some annulus [9, p. 418]. We assume throughout that $\mathbf{a}$ is not a trivial Pólya frequency sequence.

A basic example of a solution to (1.1) comes from the theory of *spline functions.* We let χ denote the characteristic function of the interval $[0, 1]$ and define

$$M_n = \chi * \cdots * \chi, \quad n \text{ factors}, \quad n \geqq 2, \tag{1.5}$$

where $*$ signifies convolution. It is known [14] that M_n is a polynomial of degree $\leqq n-1$ on each interval $(j, j+1)$, $j \in \mathbb{Z}$, has $n-2$ continuous derivatives on $\mathbb{R}$, is zero outside of $(0, n)$, and is positive otherwise. Clearly, the Fourier transform of M_n is

$$\hat{M}_n(t) := \int_{\mathbb{R}} e^{itx} M_n(x)\,dx = \left(\frac{e^{it}-1}{it}\right)^n, \qquad t \in \mathbb{R}, \tag{1.6}$$

and so $\phi := M_n$ satisfies (1.1) with

$$m(z) = \sum_{j \in \mathbb{Z}} m_j z^j = 2^{-n+1}(1+z)^n, \qquad z \in \mathbb{C}, \tag{1.7}$$

that is,

$$M_n(x) = \sum_{j \in \mathbb{Z}} m_j M_n(2x - j), \qquad x \in \mathbb{R}. \tag{1.8}$$

This equation is central in the development of the *line average algorithm* for the fast computation of curves, cf. [4].

The function M_n also has a remarkable *variation diminishing* property. Specifically, if $S^-(f) =$ the number of sign changes of f on $\mathbb{R}$ and similarly for a sequence $\mathbf{c} = \{c_j\colon j \in \mathbb{Z}\}$, $S^-(\mathbf{c}) =$ the number of (strict) sign changes in $\mathbf{c}$ we have

$$S^-\left(\sum_{j \in \mathbb{Z}} c_j M_n(\bullet - j)\right) \leqq S^-(\mathbf{c}). \tag{1.9}$$

It is known that variation diminishing is a consequence of determinental inequalities cf. [9]. In fact, given a function φ such that

$$\Phi\begin{pmatrix} x_1, \cdots, x_p \\ i_1, \cdots, i_p \end{pmatrix} := \det_{l,j=1,\cdots,p} \varphi(x_l - i_j) \tag{1.10}$$

is nonnegative for all $x_1 < \cdots < x_p$ and integers $i_1 < \cdots < i_p$, φ is variation diminishing in the sense that for any sequence $\mathbf{c}$ of finite support

$$S^-\left(\sum_{j \in \mathbb{Z}} c_j \varphi(\bullet - j)\right) \leqq S^-(\mathbf{c}). \tag{1.11}$$

We will call any function, such that the determinants in (1.10) are nonnegative, a *ripplet.* Ripplets arise in various contexts, for instance, the B-spline with integer knots determined by a constant coefficient differential operator, whose characteristic polynomial only has real zeros is a ripplet, cf. [13]. Also, the B-spline for geometrically continuous splines studied in [6] is a ripplet.

Functions ϕ satisfying the stronger requirement

$$\Phi\begin{pmatrix} x_1, \cdots, x_p \\ y_1, \cdots, y_p \end{pmatrix} \geqq 0 \tag{1.12}$$

for all $x_1 < \cdots < x_p$ and $y_1 < \cdots < y_p$ are called *Pólya frequency functions* and have been studied extensively, cf. [9].

One useful consequence of (1.11) is the following, which has applications in computer-aided design. Given a ripplet φ with $\sum_{j\in\mathbb{Z}} \varphi(x-j)=1$, $x\in\mathbb{R}$, and a sequence $\{V_j: j\in\mathbb{Z}\}$ in $\mathbb{R}^s$, $s\geqq 2$, we may define a curve in $\mathbb{R}^s$ by

$$R(t)=\sum_{j=\mathbb{Z}} V_j\varphi(t-j), \qquad t\in\mathbb{R}. \tag{1.13}$$

The variation diminishing property (1.11) then implies that the curve R cuts any given straight line no more than the polygonal arc P, with consecutive vertices $\{V_j: j\in\mathbb{Z}\}$. This ensures that in a sense the shape of the curve R mimics that of the polygonal arc P and so the points $\{V_j: j\in\mathbb{Z}\}$ can be used to predict or control the shape of the curve R. (For further details see Goodman, "Shape preserving representatives," in *Mathematical Methods in Computer Aided Geometric Design.*)

Among other things, we will show here that any Pólya frequency sequence whose symbol can be factored as

$$a(z)=(1+z)q(z),\ q(1)=1, \qquad z\in\mathbb{C}, \tag{1.14}$$

where $q(z)\neq z^k$ for any $k\in\mathbb{Z}$ determines a ripplet solution to (1.1).

Returning to the B-spline M_n, it is known, cf. [9], that the determinants

$$M_n\begin{pmatrix} x_1, \cdots, x_p \\ i_1, \cdots, i_p \end{pmatrix} = \det_{i,l=1,\cdots,p} M_n(x_i-i_l) \tag{1.15}$$

are *strictly positive* if and only if

$$i_l<x_l<i_l+n, \qquad l=1,\cdots,p. \tag{1.16}$$

It was recently conjectured in [12] that the same result holds for the ripplet satisfying (1.1) when **a** is a finite Pólya frequency sequence $\cdots,0,a_0,\cdots,a_n,0,\cdots$. We will prove this is in fact the case even when $a(z)$ is left-half plane stable as well as delineate when the determinants appearing in (1.10) are strictly positive for the solution of (1.1) corresponding to any Pólya frequency sequence.

2. Existence of refinable ripplets. In this section we prove the existence of a unique ripplet solution to the refinement equation when **a** is a Pólya frequency sequence. Specifically, we have the following.

THEOREM 2.1. *Let $a=\{a_j: j\in\mathbb{Z}\}$ be a sequence whose symbol satisfies*:

$$a(z)=(1+z)q(z),\ q(1)=1, \tag{2.1}$$

where $q(z)=\sum_{j\in\mathbb{Z}} q_j z^i$ satisfies $q_j\geqq 0$, $j\in\mathbb{Z}$, and

$$\rho:=\max\left(\sum_{i\in\mathbb{Z}} q_{2i}, \sum_{i\in\mathbb{Z}} q_{2i+1}\right)<1. \tag{2.2}$$

Then there exists a continuous function ϕ such that

$$\varphi(x)=\sum_{j\in\mathbb{Z}} a_j\varphi(2x-j), \qquad x\in\mathbb{R}, \tag{2.3}$$

and

$$\sum_{j\in\mathbb{Z}} \varphi(x-j)=1, \qquad x\in\mathbb{R}. \tag{2.4}$$

Moreover, if a is a Pólya frequency sequence satisfying (2.1) *with $q(z)\neq z^l$ for any $l\in\mathbb{Z}$, then there is a continuous ripplet φ satisfying* (2.3) *and* (2.4), *and $\varphi(x)=0$ if $x\notin I^0$ where $I:=$ the smallest closed interval containing* $\operatorname{supp}\mathbf{a}:=\{k: k\in\mathbb{Z}, a_k>0\}$.

Remark 2.1. Our condition (2.1) means that $a(1)=2$ and $a(-1)=0$. It is important to realize that the factor $q(z)$ is also the symbol of a Pólya frequency sequence. This follows from the factorization theorem for the symbol of a Pólya frequency sequence which we now describe.

We shall write $\mathbb{Z}_+=\{j\in\mathbb{Z}: j\geqq 0\}$ and $\mathbb{R}_+=\{t\in\mathbb{R}: t\geqq 0\}$ in what follows. Moreover, for any sequence $\boldsymbol{\alpha}=\{\alpha_j: j\in\mathbb{Z}_+\}\subseteq\mathbb{R}_+$, which is summable $\sum_{j\in\mathbb{Z}_+}\alpha_j<\infty$, i.e., $\boldsymbol{\alpha}\in l^1(\mathbb{Z}_+)$ we set

$$f(z;\boldsymbol{\alpha})=\prod_{j=1}^{\infty}(1+\alpha_j z),\qquad z\in\mathbb{C}. \tag{2.5}$$

For later use we let

$$\boldsymbol{\alpha}_+=|\{j: \alpha_j>0, j\in\mathbb{Z}_+\}| \tag{2.6}$$

so that $\boldsymbol{\alpha}_+=0$ means $f(\bullet;\boldsymbol{\alpha})=1$ and $\boldsymbol{\alpha}_+<\infty$ means $f(\bullet;\boldsymbol{\alpha})$ is a polynomial with negative zeros.

The fundamental fact about Pólya frequency sequences is the following result, cf. [9, Thm. 9.5, p. 427].

THEOREM A. *A necessary and sufficient condition for* $\mathbf{a}=\{a_j: j\in\mathbb{Z}\}$ *to be a Pólya frequency sequence is that*

$$a(z)=rz^k\exp(sz+tz^{-1})\frac{f(z;\boldsymbol{\alpha})f(z^{-1};\boldsymbol{\delta})}{f(z;-\boldsymbol{\beta})f(z^{-1};-\boldsymbol{\gamma})},\qquad z\in\mathbb{C} \tag{2.7}$$

for some nonnegative $\boldsymbol{\alpha},\boldsymbol{\beta},\boldsymbol{\gamma},\boldsymbol{\delta}\in l_1(\mathbb{Z}_+)$ *as above and scalars* $r>0$, $s, t\geqq 0$ *where* k *is some integer.*

Therefore, if $a(-1)=0$, $1+z$ must be a factor and the remaining function still has the form (2.7).

Now that we know that $q(z)$ is also the symbol of a Pólya frequency sequence q we are assured by our hypothesis $q(1)=1$ that (2.2) is satisfied. This will be important in the proof of Theorem 2.1.

Let us now proceed to the proof which uses ideas from [3], where the result is proved for the case that $\mathbf{a}$ is of the finite support.

Proof of Theorem 2.1. We introduce the operator

$$(F_{\mathbf{a}}h)(x):=\sum_{k\in\mathbb{Z}}a_k h(2x-k),\qquad x\in\mathbb{R}. \tag{2.8}$$

The linear map F takes $C(\mathbb{R})$ into itself and has norm two; specifically, we have

$$\|F_{\mathbf{a}}h\|_\infty\leqq 2\|h\|_\infty,\qquad h\in C(\mathbb{R}), \tag{2.9}$$

where $\|h\|_\infty=\sup\{|h(x)|: x\in\mathbb{R}\}$.

A basic formula from [3] states that for any $\lambda\in l_1(\mathbb{Z})$, $h\in C(\mathbb{R})$

$$\sum_{k\in\mathbb{Z}}\lambda_k(F_{\mathbf{a}}h)(x-k)=\sum_{k\in\mathbb{Z}}(S_{\mathbf{a}}\lambda)_k h(2x-k),\qquad x\in\mathbb{R}, \tag{2.10}$$

where

$$(S_{\mathbf{a}}\lambda)_k=\sum_{j\in\mathbb{Z}}a_{k-2j}\lambda_j,\qquad k\in\mathbb{Z}. \tag{2.11}$$

Therefore, inductively, for any $j\in\mathbb{Z}_+$

$$\sum_{k\in\mathbb{Z}}\lambda_k(F_{\mathbf{a}}^j h)(x-k)=\sum_{k\in\mathbb{Z}}(S_{\mathbf{a}}^j\lambda)_k h(2^j x-k),\qquad x\in\mathbb{R}. \tag{2.12}$$

We choose any integer shift of the B-spline $N_n = M_n(\bullet - r)$, $r \in \mathbb{Z}$ (of degree $n \geqq 2$), and consider the sequence of functions

$$g_j = F_{\mathbf{a}}^j N_n, \qquad j \in \mathbb{Z}_+. \tag{2.13}$$

We will explain later how we choose r and n.

According to (2.12), g_j has a B-spline expansion given by

$$g_j(x) = \sum_{k \in \mathbb{Z}} (S_{\mathbf{a}}^j \delta)_k N_n(2^j x - k), \qquad x \in \mathbb{R}, \tag{2.14}$$

where

$$\delta_k := \begin{cases} 1, & k = 0 \\ 0, & k \in \mathbb{Z} \backslash \{0\}. \end{cases}$$

Let us show that g_m converges to a solution to the refinement equation (1.1). Following arguments in [3] we can show there exists a positive constant $k > 0$ such that

$$\|g_{j+1} - g_j\|_\infty \leqq k \|\Delta S_{\mathbf{a}}^j \delta\|_\infty. \tag{2.15}$$

The next step is to realize that the equation (2.1) implies that

$$\Delta S_{\mathbf{a}} = S_{\mathbf{q}} \Delta, \tag{2.16}$$

so that

$$\|\Delta S_{\mathbf{a}} \lambda\|_\infty \leqq \|S_{\mathbf{q}}\| \, \|\Delta \lambda\|_\infty = \rho \|\Delta \lambda\|_\infty, \tag{2.17}$$

where ρ is defined by (2.2); consequently we obtain

$$\|g_{j+1} - g_j\|_\infty \leqq k \rho^j, \qquad j \in \mathbb{Z}_+. \tag{2.18}$$

Since $\rho < 1$, there is a $\varphi \in C(\mathbb{R})$ such that

$$\lim_{j \to \infty} g_j(x) = \varphi(x) \tag{2.19}$$

uniformly on $\mathbb{R}$. This is the function we seek. In fact, since $g_{j+1} = F_{\mathbf{a}} g_j$ we see that φ satisfies the refinement equation (1.1).

Let us now show that the sum of integer translates of φ is one. For this purpose we return to (2.10) and note that when h is of compact support, the right-hand side of (2.10) is finite for all $x \in \mathbb{R}$ even when $\lambda \in l_\infty(\mathbb{Z})$. As for the left-hand side, we note that the mapping $F_{\mathbf{a}}$ is *nonexpansive* relative to the norm

$$|h| := \max \left\{ \sum_{l \in \mathbb{Z}} |h(x - l)| : x \in [0, 1] \right\},$$

that is,

$$|F_a h| \leqq |h|,$$

since $\sum_{l \in \mathbb{Z}} a_{k-2l} = 1$, $k \in \mathbb{Z}$. Obviously then, the left-hand side of (2.10) is also finite for all x when $\lambda \in l_\infty(\mathbb{Z})$. Thus (2.10), as well as (2.12), remain valid for $\lambda \in l_\infty(\mathbb{Z})$ and h of compact support. Thus, choosing for λ, h in (2.12) l and N_n, respectively, where $e_k = 1$, $k \in \mathbb{Z}$, we get

$$\sum_{k \in \mathbb{Z}} g_j(x - k) = \sum_{k \in \mathbb{Z}} (S_a^j e)_k N_n(2^j x - k) = \sum_{k \in \mathbb{Z}} N_n(2^j x - k) = 1, \qquad x \in \mathbb{R}.$$

This confirms the claim (2.4).

Henceforward, we assume a is a Pólya frequency sequence. It remains to verify that φ is a ripplet. As we already pointed out $g_0 = N_n$ is a ripplet. Therefore, we can see inductively, in the following way, that each g_j, $j \in \mathbb{Z}$ is a ripplet. We write

$$g_{j+1}(x-i) = \sum_{k\in\mathbb{Z}} a_k g_j(2x-2i-k) = \sum_{k\in\mathbb{Z}} a_{k-2i} g_j(2x-k), \qquad x \in \mathbb{R}. \tag{2.20}$$

Therefore, by the Cauchy-Binet formula (cf. [9, p.1])

$$\begin{aligned} G_{j+1}\begin{pmatrix} x_1, \cdots, x_s \\ i_1, \cdots, i_s \end{pmatrix} &:= \det_{l,r=1,\cdots,s} g_{j+1}(x_l - i_r) \\ &= \sum_{k_1<\cdots<k_s} A\begin{pmatrix} 2i_1, \cdots, 2i_s \\ k_1, \cdots, k_s \end{pmatrix} G_j\begin{pmatrix} 2x_1, \cdots, 2x_s \\ k_1, \cdots, k_s \end{pmatrix}. \end{aligned} \tag{2.21}$$

Since $\mathbf{a} = \{a_j : j \in \mathbb{Z}\}$ is a Pólya frequency sequence, it follows inductively that each g_j is a ripplet and hence so is φ.

For the last claim we recall that for a Pólya frequency sequence the set $\operatorname{supp} \mathbf{a} := \{k : k \in \mathbb{Z}, a_k > 0\}$ consists of a set of *consecutive integers*, cf. [9, p. 418]. Thus $\operatorname{supp} \mathbf{a} = I \cap \mathbb{Z}$ and $I = [k_-, k_+]$ where k_-, k_+ are integers, either of which may be infinite. Moreover, because of our hypothesis that $q(z) \neq z^l$ for any l we conclude that $k_+ - k_- \geqq 2$. Referring back to the iterative relation (2.20) we see that if $g_j(x) = 0$, for $x \notin I^0$, then also $g_{j+1}(x) = 0$ for $x \notin I^0$. Now, we may choose the degree of the B-spline N_n and the shift $r \in \mathbb{Z}$ so that for $j = 0$, $g_0(x) = N_n(x) = M_n(x-r)$ is zero for $x \notin I^0$, that is, $r = k_-$ and $n = k_+ - k_-$. Consequently, we conclude that $\varphi(x) = 0$, for $x \notin I^0$ as well. This completes the proof of Theorem 2.1.

3. Strict positivity of minors. In this section we develop criteria for the determinants (1.10) of the ripplet φ to be *strictly* positive. The proof is long and is distinguished by several cases. A basic ingredient is a theorem of Karlin [9, p. 428] which describes, in terms of the parameters of the factorization (2.6), when the minors of the matrix A defined by (1.2), (1.3) are strictly positive. Because we will refer to this fact several times during the course of our analysis, we begin by describing it below. For simplicity, we assume the integer k appearing in (2.6) is zero. This can always be arranged by an integer shift of $\mathbf{a}$ and φ.

THEOREM B. *Let $\mathbf{a} = \{a_j : j \in \mathbb{Z}\}$ be a Pólya frequency sequence whose symbol has the factorization* (2.6) *with $k = 0$. Then*

(a) *If $s > 0$ and $t > 0$ then the determinant* (1.3) *is always positive*;

(b) *If $s > 0$ and $t = 0$ then the determinant* (1.3) *is positive if and only if*

$$i_k < j_{k+\gamma_+} + \delta_+, \qquad k = 1, \cdots, p, \tag{3.1}$$

where equality is allowed for any k if $\gamma_+ = 0$;

(c) *If $s = 0$ and $t > 0$ then the determinant* (1.3) *is positive if and only if*

$$j_{k-\beta_+} - \alpha_+ < i_k, \qquad k = 1, \cdots, p, \tag{3.2}$$

where equality is allowed for any k, if $\beta_+ = 0$;

(d) *If $s = t = 0$ then the determinant* (1.3) *is positive if and only if*

$$j_{k-\beta_+} - \alpha_+ < i_k < j_{k+\gamma_+} + \delta_+, \qquad k = 1, \cdots, p, \tag{3.3}$$

if $\beta_+ = 0$ equality is allowed on the left-hand side of (3.3); *if $\gamma_+ = 0$ equality is allowed on the right-hand side of* (3.3).

In the equalities (3.1)-(3.3) we interpret i_k, j_k for $k < 1$ as $-\infty$, and as ∞ if $k > p$.

We use this theorem to examine when the powers of the submatrix D of A defined by

$$D_{ij} := a_{j-2i}, \qquad i, j \in \mathbb{Z} \tag{3.4}$$

are positive. It will become clear why we need this later. At this point we might note that D already appeared in the proof of Theorem 2.1, see (2.25).

Obviously,

$$D\begin{pmatrix} i_1, \cdots, i_p \\ j_1, \cdots, j_p \end{pmatrix} = A\begin{pmatrix} 2i_1, \cdots, 2i_p \\ j_1, \cdots, j_p \end{pmatrix}, \tag{3.5}$$

and so we can easily decide from Theorem B which minors of D are positive. For any $j \in \mathbb{Z}_+$ the symbol for the matrix A^j is $(a(z))^j$, and so Theorem B easily tells us which minors of A^j are positive. However, generally the minors of D^j are not minors of A^j.

Specifically, if we define the sequences $\mathbf{a}^r = \{a_i^r \colon i \in \mathbb{Z}\}$ by

$$a(z)a(z^2) \cdots a(z^{2^{r-1}}) = \sum_{i \in \mathbb{Z}} a_i^r z^i, \tag{3.6}$$

then it is straightforward to verify by induction on r that

$$D_{ij}^r = a_{j-2^r i}^r, \qquad r = 1, 2, \cdots.$$

Therefore, minors of D^r correspond to minors of the Toeplitz matrix determined by the sequence $\mathbf{a}^r$. It is apparent that the generating function of $\mathbf{a}^r$, $r \geqq 2$ does not have an expansion in the form (2.6) and so is not a Pólya frequency sequence. Nevertheless we have the following, employing the notation of Theorem A.

THEOREM 3.1. *Let* $\mathbf{a}$ *be a Pólya frequency sequence, and if* $s = t = 0$ *and* $\boldsymbol{\beta}_+ + \boldsymbol{\gamma}_+ > 0$, *then either* $p \leqq \boldsymbol{\beta}_+ + \boldsymbol{\gamma}_+$ *or* $p \leqq \boldsymbol{\alpha}_+ + \boldsymbol{\delta}_+ + \max(\boldsymbol{\beta}_+ - 1, 0) + \max(\boldsymbol{\gamma}_+ - 1, 0)$. *Then given* $r \in \mathbb{Z}_+ \backslash \{0\}$

$$D^r\begin{pmatrix} i_1, \cdots, i_p \\ j_1, \cdots, j_p \end{pmatrix} \geqq 0 \tag{3.7}$$

for $i_1 < \cdots < i_p$, $j_1 < \cdots < j_p$. *Strict inequality holds in* (3.7) *if and only if*

(a) $s > 0$ *and* $t > 0$;

or

(b) $s > 0$, $t = 0$ *and*

$$i_l \leqq 2^{-r} j_{l + r\boldsymbol{\gamma}_+} + (1 - 2^{-r})(\boldsymbol{\delta}_+ - \min(\boldsymbol{\gamma}_+, 1)), \qquad l = 1, \cdots, p; \tag{3.8}$$

or

(c) $s = 0$, $t > 0$ *and*

$$2^{-r} j_{l - r\boldsymbol{\beta}_+} + (1 - 2^{-r})(\min(\boldsymbol{\beta}_+, 1) - \boldsymbol{\alpha}_+) \leqq i_l, \qquad l = 1, \cdots, p; \tag{3.9}$$

or

(d) $s = t = 0$ *and*

$$\begin{aligned} &2^{-r} j_{l - r\boldsymbol{\beta}_+} + (1 - 2^{-r})(\min(\boldsymbol{\beta}_+, 1) - \boldsymbol{\alpha}_+) \\ &\quad \leqq i_l \leqq 2^{-r} j_{l + r\boldsymbol{\gamma}_+} + (1 - 2^{-r})(\boldsymbol{\delta}_+ - \min(\boldsymbol{\gamma}_+, 1)), \qquad l = 1, \cdots, p. \end{aligned} \tag{3.10}$$

To prove Theorem 3.1 we shall need the following.

LEMMA 3.1. *Take* $\beta, \gamma, \mu, \nu \in \mathbb{Z}_+$, $r, p \in \mathbb{Z}_+ \backslash \{0\}$, $m, n \in \mathbb{Z}$ *and* $a_i, b_i \in \mathbb{Z} \cup \{\pm\infty\}$ *with* $a_{i+1} \geqq a_1 + 1$, $b_{i+1} \geqq b_i + 1$, *for* $i \in \mathbb{Z}$. *Suppose that* $m + n \geqq 0$ *and if* $\beta + \gamma + \mu + \nu > 0$, *then* $m + n \geqq p$. *If for* $l = 1, \cdots, p$,

$$a_{l-\gamma} - n \leqq 2^{-r-1}(b_{l+\nu} - n), \tag{3.11}$$

$$2^{-r-1}(b_{l-\mu} + m) \leqq a_{l+\beta} + m, \tag{3.12}$$

then there exist $k_1 < \cdots < k_p$ *in* $\mathbb{Z}$ *such that for* $l = 1, \cdots, p$,

$$a_{l-\gamma} - n \leqq 2^{-1}(k_l - n) \leqq 2^{-r-1}(b_{l+\nu} - n), \tag{3.13}$$

$$2^{-r-1}(b_{l-\mu} + m) \leqq 2^{-1}(k_l + m) \leqq a_{l+\beta} + m. \tag{3.14}$$

Proof. This is by induction on p. We take p as in Lemma 3.1 and suppose that the result is true for all smaller values of p (a vacuous assumption if $p=1$). If $a_{1-\gamma}=b_{1-\mu}=-\infty$, then the inductive hypothesis ensures the existence of $k_2,\cdots,k_p$, satisfying (3.13) and (3.14), and k_1 can be chosen with $k_1<k_2$ to satisfy the upper bounds in (3.13), (3.14). So we may assume $a_{1-\gamma}>-\infty$ or $b_{1-\mu}>-\infty$.

Now for $l=1$, define k_l to be the smallest integer satisfying

$$a_{l-\gamma}-n\leqq 2^{-1}(k_l-n), \tag{3.15}$$

$$2^{-r-1}(b_{l-\mu}+m)\leqq 2^{-1}(k_l+m), \tag{3.16}$$

and for $l=2,\cdots,p$, define k_l to be the minimum integer satisfying (3.15), (3.16), and $k_l>k_{l-1}$. By our inductive hypothesis, (3.13), (3.14) are satisfied for $l=1,\cdots,p-1$, and so it remains only to prove

$$k_p\leqq 2^{-r}(b_{p+\nu}-n)+n, \tag{3.17}$$

$$k_p\leqq 2a_{p+\beta}+m. \tag{3.18}$$

Now suppose that for some i, $1\leqq i\leqq p-1$, $k_{i+1}\geqq k_i+2$. Then k_{i+1} is the minimum integer satisfying (3.15), (3.16) with $l=i+1$ and so, by our inductive hypothesis, k_l satisfies (3.13), (3.14) for $l=i+1,\cdots,p$, which gives (3.17) and (3.18). Thus, we may assume

$$k_{l+1}=k_l+1,\qquad l=1,\cdots,p-1. \tag{3.19}$$

Suppose that (3.18) does not hold, i.e.,

$$k_p\geqq 2a_{p+\beta}+m+1. \tag{3.20}$$

If $p\geqq 2$, then

$$k_p=k_{p-1}+1\leqq 2a_{p-1+\beta}+m+1\leqq 2a_{p+\beta}+m-1,$$

which contradicts (3.20). Suppose $p=1$, then (3.20) gives

$$k_1-1-n\geqq 2a_{1+\beta}+m-n\geqq 2a_{1-\gamma}-2n$$

since $m+n\geqq 0$. Also (3.20) gives

$$k_1-1+m\geqq 2a_{1+\beta}+2m\geqq 2^{-r}(b_{1-\mu}+m)$$

by (3.12). This contradicts the definition of k_1. Thus we have proved (3.18) and it remains to prove (3.17). Suppose that (3.17) is not true, which by (3.19) gives

$$k_1>2^{-r}(b_{p+\nu}-n)+n+1-p. \tag{3.21}$$

Then by (3.11),

$$k_1>2a_{p-\gamma}-n+1-p\geqq 2a_{1-\gamma}+p-1-n,$$

and so

$$k_1\geqq 2a_{1-\gamma}-n+1,$$

which gives

$$2^{-1}(k_1-1-n)\geqq a_{1-\gamma}-n.$$

By definition, k_1 is the smallest integer satisfying (3.16) and so

$$k_1<2^{-r}(b_{1-\mu}+m)+1-m. \tag{3.22}$$

Then

$$\begin{aligned} k_1 &\leqq 2^{-r}(b_{1-\mu}+m-1)+1-m \\ &\leqq 2^{-r}(b_{p+\nu}-p+m)+1-m \\ &= 2^{-r}(b_{p+\nu}-n)+n+1-p+(p-m-n)(1-2^{-r}). \end{aligned}$$

If $p \leqq m+n$, then this contradicts (3.21). So we may assume $\beta=\gamma=\mu=\nu=0$ and $m+n \leqq p-1$. Note that by (3.19) and (3.15),

$$\begin{aligned} k_1+p-1=k_p &\geqq 2a_p-n \\ &\geqq 2a_1+2p-2-n \\ &\geqq 2^{-r}(b_1+m)+2p-2-n-2m \\ &> k_1+2p-3-n-m \end{aligned}$$

by (3.12) and (3.22). Thus, $m+n \geqq p-1$ and it remains to consider the case $m+n=p-1$. Let

$$b_1+m-1=2^{r+1}a+t$$

for some $s, t \in \mathbb{Z}$, such that $0 \leqq t < 2^{r+1}$.

By (3.12),

$$a_1+m \geqq 2^{-r-1}(b_1+m)=s+2^{-r-1}(t+1)>s$$

and so

$$a_1+m \geqq s+1.$$

Also by (3.11),

$$2^{-r-1}(b_p-n) \geqq a_p-n \geqq a_1+p-1-n=a_1+m \geqq s+1. \tag{3.23}$$

Now by (3.22),

$$k_1 < 2s+2^{-r}(t+1)+1-m \leqq 2s+3-m$$

and so

$$k_1 \leqq 2s+2-m \leqq 2^{-r}(b_p-n)-m$$

by (3.23), which contradicts (3.21) and completes the proof of the Lemma.

Proof of Theorem 3.1. The proof of (a)-(d) is by induction on r. The case $r=1$ follows from Theorem B and (3.5). The induction step is based on the formula

$$D^{r+1}\begin{pmatrix} i_1, \cdots, i_p \\ j_1, \cdots, j_p \end{pmatrix} = \sum_{k_1<\cdots<k_p} D\begin{pmatrix} i_1, \cdots, i_p \\ k_1, \cdots, k_p \end{pmatrix} D^r\begin{pmatrix} k_1, \cdots, k_p \\ j_1, \cdots, j_p \end{pmatrix}, \tag{3.24}$$

which is a consequence of the Cauchy-Binet formula. This formula immediately establishes the nonnegativity of the minors of D^r as stated by (3.7). The proof of (a)-(d) is more involved.

To advance the induction hypothesis we must show that there is a choice of integers $k_1^0 < \cdots < k_p^0$, such that the corresponding summand in the right-hand side of (3.24) is positive. This is an easy matter for case (a) as there are no constraints on $i_1 < \cdots < i_p$ and $j_1 < \cdots < j_p$. Let's look now at (b). There are some cases we may easily handle. For instance, when $\delta_+ = \infty$ or $\gamma_+ = \infty$ there are again no conditions on $i_1 < \cdots < i_p$ and $j_1 < \cdots < j_p$, and so the induction follows immediately from (3.8). Thus, we consider only the case when $\boldsymbol{\delta}_+ < \infty$ and $\boldsymbol{\gamma}_+ < \infty$. We suppose that (3.8) is valid for r replaced by $r+1$. Our goal is to find $k_1^0 < \cdots < k_p^0$, such that

$$i_l \leqq 2^{-1} k^0_{l+\boldsymbol{\gamma}_+} + 2^{-1}(\boldsymbol{\delta}_+ - \min(\boldsymbol{\gamma}_+, 1)), \qquad l = 1, \cdots, p \tag{3.25}$$

and

$$k_l^0 \leqq 2^{-r} j_{l+r\boldsymbol{\gamma}_+} + (1 - 2^{-r})(\boldsymbol{\delta}_+ - \min(\boldsymbol{\gamma}_+, 1)), \qquad l = 1, \cdots, p. \tag{3.26}$$

The inequalities (3.25) and (3.26) insure the summand on the right-hand side of (3.11), corresponding to $k_i = k_i^0$, $i = 1, \cdots, p$, is nonzero by the induction hypothesis. As for (3.25) and (3.26) we choose

$$k_l^0 = 2i_{l-\boldsymbol{\gamma}_+} - (\boldsymbol{\delta}_+ - \min(\boldsymbol{\gamma}_+, 1)), \qquad l > \boldsymbol{\gamma}_+ \tag{3.27}$$

and *any* $k_1^0 < \cdots < k^0_{\boldsymbol{\gamma}_+}$ so that

$$k^0_{\boldsymbol{\gamma}_+} \leqq 2i_{1-\boldsymbol{\gamma}_+} - (\boldsymbol{\delta}_+ - \min(\boldsymbol{\gamma}_+, 1)). \tag{3.28}$$

For this choice, note that (3.25) is automatically satisfied. As for (3.26) we observe that the induction hypothesis implies that

$$\begin{aligned} &2i_{l-\boldsymbol{\gamma}_+} - (\boldsymbol{\delta}_+ - \min(\boldsymbol{\gamma}_+, 1)) \le 2^{-r} j_{l+r\boldsymbol{\gamma}_+} + (1 - 2^{-r})(\boldsymbol{\delta}_+ - \min(\boldsymbol{\gamma}_+, 1)), \\ &\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad l = 1, \cdots, p, \end{aligned} \tag{3.29}$$

and hence (3.26) follows for $l > \boldsymbol{\gamma}_+$. For $l \leqq \boldsymbol{\gamma}_+$ we use (3.29) for $l = 1$ to obtain

$$\begin{aligned} k_l^{sz} \leqq k^{sz}_{\boldsymbol{\gamma}_+} &\leqq 2i_{1-\boldsymbol{\gamma}_+} - (\boldsymbol{\delta}_+ - \min(\boldsymbol{\gamma}_+, 1)) \\ &\leqq 2^{-r} j_{l+r\boldsymbol{\gamma}_+} + (1 - 2^{-r})(\boldsymbol{\delta}_+ - \min(\boldsymbol{\gamma}_+, 1)) \end{aligned}$$

because obviously $j_{1+r\boldsymbol{\gamma}_+} \leqq j_{l+r\boldsymbol{\gamma}_+}$. Thus, our choice of $k_1^0, \cdots, k_p^0$ satisfies (3.25) and (3.26). Therefore, the induction has been advanced and sufficiency of (b) has been established. For the necessity of (3.8) we note that according to (3.24) and the induction hypotheses the determinant on the left-hand side of (3.24) is positive if and only if there exists $k_1^0 < \cdots < k_p^0$ satisfying the inequalities of (3.25) and (3.26). These clearly imply (3.8) for r replaced by $r+1$. The proof of (c) follows analogously and we omit the details.

The final case (d) introduces further difficulties which need some explanation. First we observe that all the quantities $\boldsymbol{\alpha}_+$, $\boldsymbol{\beta}_+$, $\boldsymbol{\gamma}_+$, and $\boldsymbol{\delta}_+$ can be assumed to be finite, otherwise (d) reduces to a previously considered case. Now, by induction, we assume

$$\begin{aligned} &2^{-r-1} j_{l-(r+1)\boldsymbol{\beta}_+} + (1 - 2^{-r-1})(\min(\boldsymbol{\beta}_+, 1) - \boldsymbol{\alpha}_+) \\ &\quad \leqq i_l \leqq 2^{-r-1} j_{l+(r+1)\boldsymbol{\gamma}_+} + (1 - 2^{-r-1}) \\ &\qquad\qquad \cdot (\boldsymbol{\delta}_+ - \min(\boldsymbol{\gamma}_+, 1)), \qquad l = 1, \cdots, p, \end{aligned} \tag{3.30}$$

and seek integers $k_1^0 < \cdots < k_p^0$, such that

$$\begin{aligned} &2^{-1} k^0_{l-\boldsymbol{\beta}_+} + 2^{-1}(\min(\boldsymbol{\beta}_+, 1) - \boldsymbol{\alpha}_+) \\ &\quad \leqq i_l \leqq 2^{-1} k^0_{l+\boldsymbol{\gamma}_+} + 2^{-1}(\boldsymbol{\delta}_+ - \min(\boldsymbol{\gamma}_+, 1), \qquad l = 1, \cdots, p, \end{aligned} \tag{3.31}$$

and

$$\begin{aligned} &2^{-r} j_{l-r\boldsymbol{\beta}_+} + (1 - 2^{-r})(\min(\boldsymbol{\beta}_+, 1) - \boldsymbol{\alpha}_+) \\ &\quad \leqq k_l^0 \leqq 2^{-r} j_{l+r\boldsymbol{\gamma}_+} + (1 - 2^{-r}) \\ &\qquad\qquad \cdot (\boldsymbol{\delta}_+ - \min(\boldsymbol{\gamma}_+, 1)), \qquad l = 1, \cdots, p. \end{aligned} \tag{3.32}$$

It will be convenient to write in the remaining part of the proof

$$m=\alpha_+-\min(\beta_+,1), \qquad n=\delta_+-\min(\gamma_+,1)$$

and to rewrite (3.30) as

$$i_{l-\gamma_+}-n\leqq 2^{-r-1}(j_{l+r\gamma_+}-n), \quad 2^{-r-1}(j_{l-r\beta_+}+m)\leqq i_{l+\beta_+}+m, \quad l=1,\cdots,p, \tag{3.33}$$

and rewrite (3.31), (3.32) as

$$i_{l-\gamma_+}-n\leqq 2^{-1}(k_l^0-n)\leqq 2^{-r-1}(j_{l+r\gamma_+}-n), \qquad l=1,\cdots,p, \tag{3.34}$$

$$2^{-r-1}(j_{l-r\beta_+}+m)\leqq 2^{-1}(k_l^0+m)\leqq i_{l+\beta_+}+m, \qquad l=1,\cdots,p. \tag{3.35}$$

If $p\geqq\beta_++\gamma_++1$, then by assumption $p\leqq m+n+\beta_++\gamma_+$, if $\beta_++\gamma_+>0$, and clearly $m+n\geqq 0$ if $\beta_+=\gamma_+=0$. So we can apply Lemma 3.1 to define $k^0_{\beta_++1}<\cdots<k^0_{p-\gamma_+}$, satisfying (3.34), (3.35) for $l=\beta_++1,\cdots,p-\gamma_+$.

If $\gamma_+<\beta_+$, we define

$$k_l^0=2i_{l-\gamma_+}-n, \qquad l=\gamma_++1,\cdots,\beta_+.$$

For $l=1,\cdots,\min(\beta_+,\gamma_+)$, we define k_l^0 as any strictly increasing sequence, satisfying the upper bounds in (3.34), (3.35) and $k_l^0<k_{l+1}^0$ for $l=\min(\beta_+,\gamma_+)$. Now for $l=\gamma_++1,\cdots,\beta_+$,

$$2^{-1}(k_l^0-n)=i_{l-\gamma_+}-n\leqq 2^{-r-1}(j_{l+r\gamma_+}-n)$$

by (3.33), and

$$\begin{aligned}2^{-1}(k_l^0+m)&=i_{l-\gamma_+}+2^{-1}(m-n)\\&\leqq i_{l+\beta_+}-\beta_+-\gamma_++m-2^{-1}(m+n)\\&\leqq i_{l+\beta_+}+m,\end{aligned}$$

since $m+n+2\beta_++2\gamma_+\geqq 0$. Thus $k_1^0,\cdots,k^0_{\beta_+}$ satisfy (3.34) and (3.35). Similarly we define k_l^0 to satisfy (3.34), (3.35) for $l>\max(p-\gamma_+,\beta_+)$. For $l=\gamma_++1,\cdots,\beta_+$, (3.34) gives

$$k^0_{l+1}\geqq 2i_{l+1-\gamma_+}-n\geqq 2i_{l-\gamma_+}+2-n=k_l^0+2.$$

Thus $k_1^0<\cdots<k^0_{\beta_++1}$, and similarly we have $k^0_{\beta_++1}<\cdots<k_p$. This advances the induction and establishes the sufficiency of (3.10). The necessity of (3.10) follows easily as in case (b), and so the proof of Theorem 3.1 is complete.

Remark 3.1. Note that, in general, part (d) of Theorem 3.1 is not true without a restriction on p. For example, take $\alpha_+=\delta_+=\beta_+=0$, $\gamma_+=1$, $p=2$, $(i_1,i_2)=(0,1)$, $(j_1,j_2)=(-1,0)$. It is easily checked that for $r=1$, (3.30) is satisfied, but (3.32) implies $k_1^0=-\frac{1}{2}$, which is impossible. Thus

$$D^2\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix}=0,$$

but for $r=2$ (3.10) is satisfied.

Before we formulate the main result of this section, we need some further facts about the function φ.

LEMMA 3.2. *Let φ be as in Theorem* 2.1. *Then*

$$\lim_{x\to\pm\infty}\varphi(x)=0 \tag{3.36}$$

and

$$\varphi(x)>0, \qquad x\in I^0, \tag{3.37}$$

where I is the smallest closed interval containing $\operatorname{supp}\mathbf{a}=\{k\colon k\in\mathbb{Z},\ a_k>0\}$.

Proof. We first prove (3.36). According to (2.3),

$$\lim_{j\to\pm\infty}\varphi(j)=0, \tag{3.38}$$

and since φ is a ripplet we also have

$$0\leqq\varphi(x)\leqq 1, \qquad x\in\mathbb{R}.$$

Suppose, also, that k is an integer such that $\varphi(k)\neq 0$. Then for $x>j+k$, $j\in\mathbb{Z}_+$ we have

$$0\leqq\Phi\begin{pmatrix} j+k & x\\ 0 & j\end{pmatrix}=\begin{vmatrix}\varphi(j+k-0) & \varphi(j+k-j)\\ \varphi(x-0) & \varphi(x-j)\end{vmatrix},$$

and hence

$$\varphi(x)\leqq\frac{\varphi(j+k)}{\varphi(k)}\varphi(x-j)\leqq\frac{\varphi(j+k)}{\varphi(k)}.$$

Thus from (3.38) we conclude that $\lim_{x\to\infty}\varphi(x)=0$. Similarly, by considering the determinant

$$\Phi\begin{pmatrix} x & j\\ j-k & 0\end{pmatrix}$$

we conclude that $\lim_{x\to-\infty}\varphi(x)=0$.

As for (3.37) we will recall that the integers for which $a_k>0$ are consecutive. Therefore, $I^0=(k_-, k_+)$ and $a_k>0$ if and only if $k=k_-,\cdots,k_+$ for some integers k_-, k_+, either of which may be infinite.

The proof of (3.37) is conveniently described by several cases. When I is a finite interval, the result appears in [12]. Here we modify the argument. First we show φ is positive on some closed interval of length one. For instance, when I is finite

$$\sum_{k_-}^{k^+}\varphi(x-j)=\sum_{j\in\mathbb{Z}}\varphi(x-j), \qquad x\in[k_-+k_+-1,\ k_-+k_++1],$$

and so the refinement equations (1.1) and (2.3) give

$$\varphi\left(\frac{x}{2}\right)\geqq\min\{a_j\colon k_-\leqq j\leqq k_+\}>0,$$

for $x\in[k_-+k_+-1,\ k_-+k_++1]$. When I is doubly infinite, we consider the sequence of functions

$$\Psi_N(x):=\sum_{-N}^{N}\varphi(x-j).$$

Clearly, Ψ_N is a nondecreasing sequence of nonnegative functions which converge pointwise to one, in view of (2.3). Hence, by Dini's theorem the convergence is uniform on any compact interval. Consequently, there is an integer p such that $\Psi_p(x)>0$ for $x\in[-1,1]$. Again the refinement equation gives

$$\varphi\left(\frac{x}{2}\right)\geqq\sum_{-p}^{p}a_j\varphi(x-j)\geqq\min\{a_j\colon |j|\leqq p\}\Psi_p(x)>0.$$

Thus, in both cases we have established the existence of a closed interval J_0 of length one on which φ is positive. Now inductively we suppose φ is positive on a closed interval J_r of length at least one. Choose any y in the interval

$$J_{r+1} := \bigcup_{j \in \operatorname{supp} \mathbf{a}} (j + J_r)/2 = \tfrac{1}{2} J_r + \tfrac{1}{2}(k_-, k_+)$$

so that $y = (x+k)/2$ for some $x \in J_r$ and $k \in \operatorname{supp} \mathbf{a}$. Then according to the refinement equation

$$\varphi(y) = \sum_{j \in \mathbb{Z}} a_j \varphi(2y - j) \geqq a_k \varphi(2y - k) = a_k \varphi(x) > 0,$$

that is, φ is positive on J_{r+1}. When $I^0 = (-\infty, \infty)$ we see that $J_1 = (-\infty, \infty)$, while in the case that $I^0 = (k_-, k_+)$ is finite, we observe that $\lim_{r \to \infty} J_r = (k_-, k_+)$, and so again in both cases we conclude φ is positive on I.

For the cases when $k_- > -\infty$, $k_+ = \infty$ or $k_- = -\infty$, $k_+ < -\infty$ we argue differently. In the first instance (the argument in the other case is the same and we omit it) we pick any $x_0 > k_-$ such that $\varphi(x_0) > 0$. Then, as above, $\varphi(y_l) > 0$, $l = k_-, k_- + 1, k_- + 2, \cdots$, where $y_l := \frac{1}{2}(x_0 + l)$ because by the refinement equation

$$\varphi(y_l) \geqq a_l \varphi(2y_l - l) = a_l \varphi(x_0) > 0.$$

Similarly, we see that φ is positive on the sequence $x_l := 2^{-l} x_0 + (1 - 2^{-l}) k_-$, $l = 0, 1, 2, \cdots$, since $x_{l+1} = \frac{1}{2}(x_l + k_-)$. Now, choose any $x \in (k_-, \infty)$. There exists an $i \in \mathbb{Z}_+$ such that

$$x_i < x < y_i.$$

Pick any k, j such that $k < 0 < j$, then

$$0 \leqq \begin{vmatrix} \varphi(x-0) & \varphi(x-j) \\ \varphi(y_i - 0) & \varphi(y_i - j) \end{vmatrix} \tag{3.39}$$

and

$$0 \leqq \begin{vmatrix} \varphi(x_i - k) & \varphi(x_i - 0) \\ \varphi(x-k) & \varphi(x-0) \end{vmatrix}. \tag{3.40}$$

We want to show $\varphi(x) > 0$. Suppose to the contrary $\varphi(x) = 0$, then from (3.39) we get $\varphi(x - j) = 0$, $j = 0, 1, 2, \cdots$, while (3.40) gives us $\varphi(x - k) = 0$, $k = -1, -2, \cdots$. But this contradicts (2.3), which says that

$$\sum_{j \in \mathbb{Z}} \varphi(x - j) = 1.$$

This establishes that $\varphi(x) > 0$ and proves the lemma.

We are now ready to state and prove the main result in this section.

THEOREM 3.2. *Let* $\mathbf{a} = \{a_j : j \in \mathbb{Z}\}$ *be a Pólya sequence whose symbol satisfies the hypothesis of Theorem* 2.1 *and has the factorization* (2.6). *Suppose that if* $s = t = 0$ *and* $\boldsymbol{\beta}_+ + \boldsymbol{\gamma}_+ > 0$, then either $p \leqq \boldsymbol{\beta}_+ + \boldsymbol{\gamma}_+$ *or* $p \leqq \boldsymbol{\alpha}_+ + \boldsymbol{\delta}_+ + \max(\boldsymbol{\beta}_+ - 1, 0) + \max(\boldsymbol{\gamma}_+ - 1, 0)$. *Then the determinant* (1.10) *is positive if and only if* $x_l - i_l \in I^0$, $l = 1, \cdots, p$. *Equivalently, the determinant* (1.10) *is positive if and only if the diagonal elements of the matrix are all positive.*

Proof. We begin the proof of this theorem by relating the parameters of the factorization (2.6) to the smallest closed interval I containing $\{k \colon k \in \mathbb{Z}, a_k > 0\}$. As before we let

$$\operatorname{supp} \mathbf{a} = \{k \colon k \in \mathbb{Z}, k_- \leqq k \leqq k_+\},$$

where k_-, k_+ are integers which may be $-\infty$, ∞, respectively. It follows directly from (2.6) that

$$k_- = \begin{cases} -\boldsymbol{\delta}_+ & \text{if } t = \boldsymbol{\gamma}_+ = 0 \\ -\infty & \text{otherwise} \end{cases} \tag{3.41}$$

and

$$k_+ = \begin{cases} \boldsymbol{\alpha}_+, & s = \boldsymbol{\beta}_+ = 0 \\ \infty & \text{otherwise.} \end{cases} \tag{3.42}$$

Next we use the refinement equation (1.1) to get

$$\begin{aligned} \varphi(x-i) &= \sum_{j\in\mathbb{Z}} a_j\varphi(2x-2i-j) = \sum_{j\in\mathbb{Z}} D_{ij}\varphi(2x-j) \\ &= \cdots = \sum_{j\in\mathbb{Z}} D^r_{ij}\varphi(2^rx-j), \qquad i\in\mathbb{Z}. \end{aligned}$$

Therefore, we obtain by the Cauchy-Binet formula

$$\Phi\begin{pmatrix} x_1, \cdots, x_p \\ i_1, \cdots, i_p \end{pmatrix} = \sum_{j_1<\cdots<j_p} D^r\begin{pmatrix} i_1, \cdots, i_p \\ j_1, \cdots, j_p \end{pmatrix} \Phi\begin{pmatrix} 2^rx_1, \cdots, 2^rx_p \\ j_1, \cdots, j_p \end{pmatrix}. \tag{3.43}$$

First, we consider the sufficiency of the conditions $x_l - i_l \in I^0$, $l = 1, \cdots, p$. The idea of the proof is to choose r sufficiently large as to approximate each x_l by a dyadic rational $2^{-r}j_{l,r}$ in such a way that the summand on the right-hand side of (3.43) corresponding to $j_{1,r} < \cdots < j_{p,r}$ is nonzero.

It is important to first note that if $2^{-r}j_{l,r}$ approximates x_l as $r\to\infty$ then the off diagonal terms of the determinant

$$\Phi\begin{pmatrix} 2^rx_1, \cdots, 2^rx_p \\ j_{1,r}, \cdots, j_{p,r} \end{pmatrix} \tag{3.44}$$

tend to zero because of (3.36) of Lemma 3.2. To insure that the diagonal terms appearing in the determinant (3.44) are positive, we pick any integer ρ such that $[\rho, \rho+1] \subseteq I$ and choose $j_{l,r} := -\rho + [2^rx_l]$. Then we see that

$$\lim_{r\to\infty} 2^{-r}j_{l,r} = x_l, \qquad l = 1, \cdots, p \tag{3.45}$$

as well as $2^rx_l - j_{l,r} \in [\rho, \rho+1] \subseteq I$, and so the diagonal terms of the determinant (3.44) are positive by (3.37) of Lemma 3.2.

To confirm that the determinant

$$D^r\begin{pmatrix} i_1, \cdots, i_p \\ j_{1,r}, \cdots, j_{p,r} \end{pmatrix} \tag{3.46}$$

is positive, we will use Theorem 3.1. It is best to verify the inequalities in four distinct cases.

Case A. The first case we consider is $k_- = -\infty$ and $k_+ = \infty$. According to (3.41) and (3.42) this occurs if one of the following four situations hold:

(i)$_1$ $\boldsymbol{\delta}_+ = \infty$, $t = 0$, $\boldsymbol{\gamma}_+ = 0$, $s > 0$ or $\boldsymbol{\beta}_+ > 0$.

(ii)$_1$ $\boldsymbol{\delta}_+ = \infty$, $t = 0$, $\boldsymbol{\gamma}_+ = 0$, $s = 0$, $\boldsymbol{\beta}_+ = 0$, and $\boldsymbol{\alpha}_+ = \infty$.

(iii)$_1$ $t > 0$ or $\boldsymbol{\gamma}_+ > 0$ and $s = 0$, $\boldsymbol{\beta}_+ = 0$, and $\boldsymbol{\alpha}_+ = \infty$.

(iv)$_1$ $t > 0$ or $\boldsymbol{\gamma}_+ > 0$ and $s > 0$ or $\boldsymbol{\beta}_+ > 0$.

In each of these cases we claim that for *r sufficiently large* the determinant (3.46) is positive. In the case (i)$_1$ we see if $s > 0$ then (3.8) implies (3.46) is positive for all r

while $s=0$ (3.10) requires only a lower bound for i_l which for r large ceases to constrain i_l as well. The other cases follow similarly.

Case B. Now, for $k_- > -\infty$ and $k_+ = \infty$ we must have one of the following:

(i)$_2$ $\boldsymbol{\delta}_+ < \infty$, $t=0$, $\boldsymbol{\gamma}_+ = 0$, $\boldsymbol{\alpha}_+ = \infty$, $s=0$, and $\boldsymbol{\beta}_+ = 0$.

(ii)$_2$ $\boldsymbol{\delta}_+ < \infty$, $t=0$, $\boldsymbol{\gamma}_+ = 0$, and $s>0$ or $\boldsymbol{\beta}_+ > 0$.

When (i)$_2$ holds, (3.10) reduces to

$$i_l \leqq 2^{-r} j_{l,r} + (1-2^{-r})\boldsymbol{\delta}_+. \tag{3.47}$$

However, by hypothesis, $0 < x_l - i_l + \boldsymbol{\delta}_+$ and so (3.47) is valid for r sufficiently large. Case (ii)$_2$ follows similarly.

Case C. When $k_- = -\infty$ and $k_+ < \infty$, which occurs if one of the following holds:

(i)$_3$ $\boldsymbol{\delta}_+ = \infty$, $t=0$, $\boldsymbol{\gamma}_+ = 0$, $\boldsymbol{\alpha}_+ < \infty$, $s=0$, and $\boldsymbol{\beta}_+ = 0$.

(ii)$_3$ $t>0$ or $\boldsymbol{\gamma}_+ > 0$ and $\boldsymbol{\alpha}_+ < \infty$, $s=0$, and $\boldsymbol{\beta}_+ = 0$.

The proof is the same.

Case D. The final case $k_- < \infty$ and $k_+ < \infty$ can occur if and only if

(i)$_4$ $\boldsymbol{\delta}_+ < \infty$, $\boldsymbol{\alpha}_+ < \infty$, $t=0$, $s=0$, $\boldsymbol{\gamma}_+ = 0$ and $\boldsymbol{\beta}_+ = 0$.

In this case inequalities (d) of Theorem 3.1 become

$$2^{-r} j_{l,r} - (1-2^{-r})\boldsymbol{\alpha}_+ \leqq i_l \leqq 2^{-r} j_{l,r} + (1-2^{-r})\boldsymbol{\delta}_+, \qquad l = 1, \cdots, r,$$

which is valid for r sufficiently large, since $-\boldsymbol{\delta}_+ < x_l - i_l < \boldsymbol{\alpha}_+$, $l = 1, 2, \cdots, p$ by hypothesis. This establishes the sufficiency of the condition that $x_l - i_l \in I^0$, $l = 1, \cdots, p$ for the positivity of lower determinants (3.43).

For the necessity, we again consider the four cases above. In Case A there is nothing to prove. In Case B if $x_\mu - i_\mu \leqq k_- = -\boldsymbol{\delta}_+$ for some μ, $1 \leqq \mu \leqq p$. Hence $\varphi(x_i - i_j) = 0$ for $i = 1, \cdots, \mu$, $j = \mu, \cdots, p$ and so the first rows of the determinant are linearly dependent. Case C is similar and we omit the details. For the last, Case D, we know $\varphi(x) = 0$ if either $x \leqq k_-$ or $x \geqq k_+$. Thus the proof here uses both the argument used in Case B and in Case C. Thus we have established the theorem.

The next result proves the conjecture made in [12].

COROLLARY 3.1. *Given* $\mathbf{a} = \{a_j : 0 \leqq j \leqq n\}$ *such that the polynomial*

$$a(z) = \sum_{j=0}^{n} a_j z^j$$

only has negative zeros, vanishes at $z = -1$, *and has the value* 2 *at* $z = 1$, *then there exists a unique solution of the refinement equation*

$$\varphi\left(\frac{x}{2}\right) = \sum_{j=0}^{n} a_j \varphi(x-j), \qquad x \in \mathbb{R}$$

such that

$$\sum_{j \in \mathbb{Z}} \varphi(x-j) = 1.$$

Moreover, the determinants

$$\Phi\begin{pmatrix} x_1, \cdots, x_p \\ i_1, \cdots, i_p \end{pmatrix} := \det_{l,j=1,\cdots,p} \varphi(x_l - i_j) \tag{3.48}$$

are nonnegative for all $x_1 < \cdots < x_p$ *and integers* $i_1 < \cdots < i_p$ *with strict positivity holding if and only if*

$$i_l < x_l < i_l + n, \qquad l = 1, \cdots, p. \tag{3.49}$$

4. Symbols which are left-half plane stable. The previous result actually holds under a much weaker hypothesis. Recall that a polynomial is called left-half plane stable if all its zeros are in the (open) left-half plane (Hurwitz polynomial).

THEOREM 4.1. *Suppose that the polynomial*

$$a(z)=\sum_{j=0}^{n} a_j z^j,$$

with real coefficients a_j, if left-half plane stable, vanishes at $z=-1$, and has the value two at $z=1$. Then all the conclusions of Corollary 3.1 *are valid.*

Proof. The proof of this result follows the pattern of Corollary 3.1 with some important differences. The existence of the function φ follows from Theorem 2.1 on noting that $a_j>0, j=0, 1, \cdots, n$ since $a(z)$ can be factored as a product of linear and quadratic factors which have positive coefficients. Hence, when we write $a(z)=(1+z)q(z)$, the polynomial $q(z)$ is also left-half plane stable and so has positive coefficients. Thus (2.2) is satisfied and Theorem 2.1 can be applied.

The main fact needed to complete the proof is a result of Kemperman [10]. We write $a(z)$ in the form

$$a(z)=d_0z^n+d_1z^{n-1}+\cdots+d_n, \qquad d_j=a_{n-j}$$

to conform with the notation of [10]. Asner [2] and Kemperman [10] proved that the Hurwitz matrix

$$H=(H_{ij}\colon i,j\in\mathbb{Z}), \qquad H_{ij}:=d_{2j-i}$$

is totally positive. In addition, Kemperman proved the following.

THEOREM C. *Let $a(z)$ be left-half plane stable. Then*

$$H\begin{pmatrix} i_1, \cdots, i_p \\ j_1, \cdots, j_p \end{pmatrix} \geqq 0$$

for any integers $i_1<\cdots<i_p$ and $j_1<\cdots<j_p$, and equality holds if and only if all the diagonal elements $d_{2j_r-i_r}$, $r=1, \cdots, p$ are positive, equivalently, that

$$0\leqq 2j_l-i_l\leqq n, \qquad l=1, \cdots, p.$$

In our notation,

$$D_{ij}=a_{j-2i}=d_{n+2i-j}=d_{2(n+i)-(n+j)}=H_{n+j,\,n+i}.$$

Thus, Kemperman's result is equivalent to saying that

$$D\begin{pmatrix} i_1, \cdots, i_p \\ j_1, \cdots, j_p \end{pmatrix} = H\begin{pmatrix} n+j_1, \cdots, n+j_p \\ n+i_1, \cdots, n+i_p \end{pmatrix} \geqq 0$$

with equality if and only if

$$0\leqq j_l-2i_l\geqq n, \qquad l=1, \cdots, p.$$

From the total positivity of D it follows, by the arguments in Theorem 2.1, that

$$\Phi\begin{pmatrix} x_1, \cdots, x_p \\ i_1, \cdots, i_p \end{pmatrix} \geqq 0 \tag{4.1}$$

for $x_1<\cdots<x_p$, $i_1<\cdots<i_p$. The methods used in the proof of Theorem 3.1, especially the case $s=t=0$, $\boldsymbol{\delta}_+=\boldsymbol{\beta}_+=\boldsymbol{\gamma}_+=0$, and $\boldsymbol{\alpha}_+=n$ implies

$$D^r\begin{pmatrix} i_1, \cdots, i_p \\ j_1, \cdots, j_p \end{pmatrix} > 0$$

if and only if $0 \leqq 2^{-r}j_l - i_l \leqq (1-2^{-r})n$, $l=1, \cdots, p$, whenever $a(z)$ is left-half plane stable. Therefore formula (3.43) can be used just as before to conclude that the determinants (3.48) are positive if and only if (3.49) holds.

As a final result we derive a fact which has applications for the study of the *planar curve*:

$$S(x) = \sum_{j \in \mathbb{Z}} \mathbf{c}_j \varphi(x-j), \qquad x \in \mathbb{R}, \tag{4.2}$$

where each $\mathbf{c}_j$, $j \in \mathbb{Z}$ is a vector in $\mathbb{R}^2$.

THEOREM 4.2. *Suppose*

$$a(z) = \sum_{j=0}^{n} a_j z^j$$

is left-half plane stable. Then the function φ of Theorem 4.1 *is $C^k(\mathbb{R})$, $0 \leqq k \leqq n-1$, if and only if $a(z)$ can be factored as*

$$a(z) = (1+z)^{k+1} q(z), \qquad q(1) = 2^{-k}. \tag{4.3}$$

Moreover, in this case

$$S^-\left(\sum_{j \in \mathbb{Z}} c_j \varphi^{(l)}(\bullet - j) \right) \leqq S^-(\Delta^l c), \qquad 0 \leqq l \leqq k, \tag{4.4}$$

where $c = \{c_j; j \in \mathbb{Z}\}$ is a sequence in $\mathbb{R}$ and ∇^l is the lth order forward difference operator defined inductively as

$$(\Delta^l c)_j = (\Delta^{l-1} c)_{j+1} - (\Delta^{l-1} c)_j, \qquad j \in \mathbb{Z}. \tag{4.5}$$

Proof. The necessity of the factorization (4.3) is a consequence of two results from [3, Cor. 6.3, 8.2] concerning a sequence a of finite support, which we state here for the convenience of the reader.

PROPOSITION A. *There exists a polynomial p of degree $\leqq k$ such that*

$$\sum_{j \in \mathbb{Z}} a_{i-2j} j^k = p(i), \qquad i \in \mathbb{Z} \tag{4.6}$$

if and only if $a^{(l)}(-1) = 0$, $l = 0, 1, \cdots, k$.

PROPOSITION B. *Let φ satisfy the refinement equation*

$$\varphi(x) = \sum_{j \in \mathbb{Z}} a_j \varphi(2x-j).$$

If $\varphi \in C^k(\mathbb{R})$ and the functions $\{\varphi(\bullet - j) : j \in \mathbb{Z}\}$ are linearly independent on $\mathbb{R}$ then (4.6) *holds for some polynomial p of degree $\leqq k$.*

To use Propositions A and B we note that Theorem 4.1 implies that the functions $\{\varphi(\bullet - j) : j \in \mathbb{Z}\}$ are linearly independent, and hence it follows that $a(z)$ can be factored as (4.3).

The converse also follows from a result from [3, Cor. 8.1]. However, let us point out that we already have enough information available in Theorem 4.1 to prove it directly.

Pick any l, $1 \leqq l \leqq k$. Then we may express $a(z)$ as

$$a(z) = 2^{-l}(1+z)^l b(z), \tag{4.7}$$

where $b(z)$ is left-half plane stable, $b(-1)=0$ and $b(1)=2$. Hence, by Theorem 4.1 there is a $\Psi \in C(\mathbb{R})$, of support in $(0, n-l)$ such that

$$\Psi(x)=\sum_{j=0}^{n-l} b_j\Psi(2x-j), \tag{4.8}$$

$$\sum_{j\in\mathbb{Z}} \Psi(x-j)=1, \qquad x\in\mathbb{R}, \tag{4.9}$$

and

$$S^-\left(\sum_{j\in\mathbb{Z}} d_j\Psi(\bullet-j)\right)\leqq S^-(d), \tag{4.10}$$

where $d=\{d_j: j\in\mathbb{Z}\}$. From (4.9) we conclude, by integrating both sides of (4.9) from zero to one, that

$$\int_{\mathbb{R}} \Psi(x)\,dx=1. \tag{4.11}$$

Using the refinement equation (4.8) for Ψ and the refinement equations (1.7), (1.8) (when $n=l$) for M_l, and the factorization (4.7), we conclude that the convolution $M_l * \Psi$ satisfies the refinement equation (1.1). This can be seen by substituting into the integral

$$(M_l * \Psi)(x)=\int_{\mathbb{R}} M_l(x-t)\Psi(t)\,dt,$$

the refinement equations for M_l, Ψ, and then by simplifying. By (4.11) we also have

$$\sum_{j\in\mathbb{Z}} (M_l * \Psi)(x-j)=1, \qquad x\in\mathbb{R},$$

and we conclude (by uniqueness) that $\varphi=M_l*\Psi$ is the function of Theorem 4.1.

By construction the B-spline satisfies the recurrence relation

$$M_l(x)=\int_0^1 M_{l-1}(x-t)\,dt$$

or equivalently $M_l'(x)=M_{l-1}(x)-M_{l-1}(x-1)$. Consequently,

$$\varphi'=M_{l-1}*(\Psi(\bullet)-\Psi(\bullet-1))$$

and therefore inductively we obtain

$$\varphi^{(l)}(x)=(\nabla^l\Psi(x-\bullet))_0,$$

where ∇ is the difference operator, $(\nabla c)_j := c_j - c_{j+1}$.

Hence it follows that

$$\sum_{j\in\mathbb{Z}} c_j\varphi^{(l)}(x-j)=\sum_{j\in\mathbb{Z}} (\Delta^l c)_j\Psi(x-j), \qquad x\in\mathbb{R},$$

and so from (4.10) we get

$$S^-\left(\sum_{j\in\mathbb{Z}} c_j\varphi^{(l)}(\bullet-j)\right)\leqq S^-(\Delta^l c),$$

which proves the theorem.

Acknowledgement. We wish to thank Allan Pinkus for bringing the paper by J. H. B. Kemperman to our attention.

WEIGHTED FOURIER TRANSFORM INEQUALITIES FOR RADIALLY DECREASING FUNCTIONS*

C. CARTON-LEBRUN† AND H. P. HEINIG‡

Abstract. Weighted norm inequalities are established for the Fourier transform of certain radially decreasing functions. For large classes of weights and indices, the involved conditions are proved to be necessary. Similar characterizations are also given for the Hankel- and K-transform of functions satisfying monotonicity conditions.

Key words. radially decreasing functions, Fourier transform, B_p-weights, Hankel transform, K-transformation

AMS(MOS) subject classifications. 42A38, 42B10

1. Introduction. Let $\hat{f}$ be the Fourier transform of f defined by

$$\hat{f}(x)=\int_{\mathbb{R}^n} e^{-2\pi i x\cdot y} f(y)\,dy, \qquad x\in\mathbb{R}^n,$$

provided the integral converges. Weighted L^p-estimates of the form

$$\|\hat{f}\|_{q,u}\leqq C\|f\|_{p,v}, \qquad 0<p,\, q<\infty, \tag{1.1}$$

where u and v are positive weight functions, have been studied in recent years with a view to characterize the weights for which (1.1) is satisfied. While much progress has been made in this direction, the complete solution is still elusive. (For a discussion of these and related questions we refer to [2], [3] and the recent work of Strömberg and Wheeden [13].)

The object of this note is to consider the Fourier transform of certain radially decreasing functions and prove weighted norm inequalities of the form (1.1). For $n\geqq 1$, $u=v$, and $q=p\geqq 1$, a complete characterization of the weight is given for which the inequality holds. Similar characterizations are given in the case of the Hankel transform which may be viewed as a generalization of the n-dimensional Fourier transform result (cf. Remark 4.2). We also consider generalizations of the Laplace transform (the K-transform) of functions satisfying certain monotonicity conditions, and characterize the weights u and v for which similar (L_v^p, L_u^q) norm estimates hold, $1<p\leqq q<\infty$. This result extends work given in [8].

Our result contrasts with previous studies, where typically monotonicity conditions on the weights are imposed to provide the characterizations (cf. [2], [5], [9]).

The plan of the paper is as follows. The next section contains the one weight characterizations involving the Fourier transform, while § 3 considers the two weighted Fourier inequalities in the index ranges $1<p\leqq q<\infty, 0<q<p<\infty$ with $p>1$ and $0<p<1<q$. If $1<p\leqq q<\infty$, then under an auxiliary condition on the range weight (which is satisfied by power weights), the results are also necessary. The final section contains the characterizations involving the Hankel- and K-transformations.

The notation and conventions used here are as follows: If $x, y \in \mathbb{R}^n$, then $x \cdot y = \sum_{i=1}^n x_i y_i$ and $|x| = (\sum_{i=1}^n x_i^2)^{1/2}$. If $x \neq 0$, we write $x = |x|x'$ where $x' \in S_{n-1}$, the unit sphere in $\mathbb{R}^n$. We also use $|S_{n-1}| = \int_{S_{n-1}} d\sigma$, with the convention $|S_0| = 2$. For $0 < p < \infty$, the conjugate index p' is defined by $1/p + 1/p' = 1$ with $p' = \infty$ if $p = 1$, and similarly for other indices. Of course $p' < 0$ if $0 < p < 1$. χ_E denotes the characteristic function of the set E and inequalities are interpreted in the sense that if the right side is finite, so is the left side and the inequality holds. A, B, C denote constants (sometimes with subscripts) which may be different at different places. Finally, we adhere to the convention that positive means nonnegative and decreasing means nonincreasing.

2. One weight characterizations. We begin with the weight characterization for the Fourier transform of positive even functions decreasing to zero on $(0, \infty)$.

THEOREM 2.1. *Let v be a positive weight function and $1 \leqq p < \infty$. Then*

$$\int_0^\infty v(1/x)x^{p-2}|\hat{f}(x)|^p\,dx \leqq C \int_0^\infty v(x)f(x)^p\,dx \tag{2.1}$$

holds for all positive even functions f decreasing to zero on $(0, \infty)$, if and only if $v \in B_p$, i.e., for each $r > 0$,

$$\int_r^\infty x^{-p}v(x)\,dx \leqq Ar^{-p}\int_0^r v(x)\,dx. \tag{2.2}$$

Proof. Since f is even, positive, and decreasing on $(0, \infty)$,

$$\begin{aligned}\hat{f}(x) &= 2\int_0^\infty \cos(2\pi xt)f(t)\,dt \\ &= 2\left[\int_0^{1/x} \cos(2\pi xt)f(t)\,dt + f(1/x)\int_{1/x}^{\xi} \cos(2\pi xt)\,dt\right].\end{aligned}$$

Here we applied the second mean value theorem. But since

$$x^{-1}f(1/x) \leqq \int_0^{1/x} f(t)\,dt,$$

it follows that

$$|\hat{f}(x)| \leqq (2 + 1/\pi)\int_0^{1/x} f(t)\,dt,$$

and therefore

$$\int_0^\infty v(x)|x^{-1}\hat{f}(1/x)|^p\,dx \leqq C\int_0^\infty v(x)\left[x^{-1}\int_0^x f(t)\,dt\right]^p dx.$$

A result of Ariño and Muckenhoupt [1, Thm. 1.7] shows that the integral on the right is dominated by the right side of (2.1) provided $v \in B_p$. This proves the sufficiency.

To prove necessity, let $f(x) = \chi_{(0,r)}(|x|)$, $r > 0$, fixed in (2.1). Then

$$\begin{aligned}C\int_0^r v(x)\,dx &\geqq \int_0^\infty v(1/x)x^{p-2}\left|2\int_0^r \cos(2\pi xt)\,dt\right|^p dx \\ &= 2^p\int_0^\infty v(x)x^{-p}\left|\int_0^r \cos(2\pi t/x)\,dt\right|^p dx \\ &\geqq 2^p\int_{2\pi r}^\infty v(x)x^{-p}\left|\int_0^r \cos(2\pi t/x)\,dt\right|^p dx.\end{aligned}$$

But since $(2\pi t/x)\leqq 1$, it follows that $\cos(2\pi t/x)\geqq \cos 1$ and hence

$$C\int_0^r v(x)\,dx \geqq (2\cos 1)^p \int_{2\pi r}^{\infty} v(x)\cdot (r/x)^p\,dx.$$

This implies (2.2).

The condition $v\in B_p$ (i.e., (2.2)) of Theorem 2.1 is equivalent to the L_v^p-boundedness of the averaging operator of positive decreasing functions [1, Thm. 1.7]. It should be noted that this L^p-boundedness property was shown by Boyd [4] (see also [10, Chap. 2, Thm. 6.6]) to be equivalent with the weight condition

$$\sup_{s>0}\frac{V(rs)}{V(s)} = o(r^p) \quad \text{as } r\to\infty, \tag{2.3}$$

where $V(s)=\int_0^s v(x)\,dx$. Therefore, we obtain the following.

COROLLARY 2.2. *Inequality* (2.1) *holds for all positive even functions decreasing to zero on* $(0,\infty)$ *if and only if* (2.3) *holds.*

Observe that with $v(x)=x^{p-2}, p>1$, Theorem 2.1 and Corollary 2.2 reduce to Theorem 82 of [14].

We now give a weighted n-dimensional characterization for the Fourier transform of certain radially decreasing functions on $\mathbb{R}^n$, $n>1$.

THEOREM 2.3. *Let* $1\leqq p<\infty$ *and* v *be a positive weight function on* $\mathbb{R}^n$. *Then*

$$\int_{\mathbb{R}^n} v(x'/|x|)|x|^{n(p-2)}|\hat{f}(x)|^p\,dx \leqq C\int_{\mathbb{R}^n} v(x)|f(x)|^p\,dx \tag{2.4}$$

holds for all positive radial functions $f(x)=f_0(|x|)$, $x\in\mathbb{R}^n$, *with* $g(t)=t^{n-1}f_0(t)$ *decreasing to zero on* $(0,\infty)$, *if and only if* $v\in B_p^*(n)$, *i.e., for each* $r>0$,

$$\int_{|x|\geqq r} |x|^{-np}v(x)\,dx \leqq Br^{-p}\int_{|x|\leqq r}|x|^{-p(n-1)}v(x)\,dx. \tag{2.5}$$

Proof (*Sufficiency*). Clearly

$$\begin{aligned}
\hat{f}(x) &= \int_{\mathbb{R}^n} f_0(|t|)\,e^{-2\pi i x\cdot t}\,dt\\
&= \int_0^\infty \rho^{n-1}\left(\int_{S_{n-1}} f_0(\rho)\,e^{-2\pi i\rho|x|(x'\cdot\omega)}\,d\sigma\right)d\rho\\
&= 2|S_{n-2}|\int_0^\infty g(\rho)\int_0^1 \cos(2\pi\rho|x|t)(1-t^2)^{(n-3)/2}\,dt\,d\rho\\
&= 2|S_{n-2}|\left(\int_0^{1/|x|}+\int_{1/|x|}^{\infty}\right)g(\rho)\int_0^1 \cos(2\pi\rho|x|t)(1-t^2)^{(n-3)/2}\,dt\,d\rho\\
&= 2|S_{n-2}|(A_1(|x|)+A_2(|x|)), \quad \text{respectively.}
\end{aligned}$$

To estimate $A_1(s)$, $s>0$, let $\psi_n(t)=\int_0^t(1-u^2)^{(n-3)/2}\,du$. Then

$$\begin{aligned}
&\int_0^1 \cos(2\pi\rho st)(1-t^2)^{(n-3)/2}\,dt\\
&\qquad = \cos(2\pi\rho s)\psi_n(1)+2\pi\rho s\int_0^1 \sin(2\pi\rho st)\psi_n(t)\,dt.
\end{aligned}$$

Therefore

$$|A_1(s)| = \left|\psi_n(1)\int_0^{1/s} g(\rho)\cos(2\pi\rho s)\,d\rho + 2\pi s\int_0^{1/s}\rho g(\rho)\int_0^1 \sin(2\pi\rho st)\psi_n(t)\,dt\,d\rho\right|$$

$$\leqq C\int_0^{1/s} g(\rho)\,d\rho.$$

On the other hand,

$$A_2(s) = \int_{1/s}^{\infty} g(\rho)\varphi_n(s\rho)\,d\rho,$$

where

$$\varphi_n(s\rho) = \int_0^1 \cos(2\pi\rho st)\cdot(1-t^2)^{(n-3)/2}\,dt.$$

By the second mean value theorem,

$$A_2(s) = g(1/s)\int_{1/s}^{\xi}\varphi_n(s\rho)\,d\rho$$

for some $\xi > 1/s$. Therefore,

$$|A_2(s)| \leqq Cs^{-1}g(1/s) \leqq C\int_0^{1/s} g(t)\,dt \tag{2.6}$$

provided we show that

$$\left|\int_{1/s}^{\xi}\varphi_n(s\rho)\,d\rho\right| \leqq C/s \tag{2.7}$$

for all $s>0$ and C independent of ξ and s.

To prove (2.7), note that, for $n \geqq 2$,

$$\int_{1/s}^{\xi}\varphi_n(s\rho)\,d\rho = \int_0^1 (1-t^2)^{(n-3)/2}\left(\int_{1/s}^{\xi}\cos(2\pi\rho st)\,d\rho\right)dt$$

$$= (1/2\pi s)\int_0^1 (1-t^2)^{(n-3)/2}[(\sin 2\pi\xi st)/t - (\sin 2\pi t)/t]\,dt$$

$$= (1/2\pi s)[T_1 - T_2], \quad \text{respectively.}$$

Clearly, $|T_2| \leqq C$.

Now, for $n \geqq 3$, a change of variable and an application of the second mean value theorem show that for any $\xi s > 1$, there exists an $\eta \in (0, 2\pi\xi s)$ such that

$$T_1 = \int_0^{2\pi\xi s}[1-(u/(2\pi\xi s))^2]^{(n-3)/2}\cdot[(\sin u)/u]\,du = \int_0^{\eta}[(\sin u)/u]\,du.$$

But since $\int_0^{\to\infty}(\sin u/u) = \pi/2$, it follows that $T_1 \leqq C$.

If $n=2$, then

$$|T_1| \leqq \left|\int_0^{1/2}\frac{\sin(2\pi\xi st)}{t(1-t^2)^{1/2}}\,dt\right| + \left|\int_{1/2}^1 \frac{\sin(2\pi\xi st)}{t(1-t^2)^{1/2}}\,dt\right|$$

Here, where the second term is clearly bounded and for the first integral, we apply the second mean value theorem to the increasing function $(1-t^2)^{-1/2}$ on $(0, 1/2)$. Thus there exists some $\lambda \in (0, 1/2)$ such that

$$\left|\int_0^{1/2} \frac{\sin(2\pi st\xi)}{t(1-t^2)^{1/2}}\,dt\right| = \left|(2/\sqrt{3})\int_\lambda^{1/2} \frac{\sin(2\pi st\xi)}{t}\,dt\right|$$

$$= \left|(2/\sqrt{3})\int_{2\pi\xi s\lambda}^{\pi\xi s} \frac{\sin u}{u}\,du\right| \leqq (4/\sqrt{3})\int_0^{\to\infty} \frac{\sin u}{u}\,du = C.$$

Therefore, (2.7) holds for all $n \geqq 2$.

From the expression of $\hat{f}(x)$ in terms of $A_i(|x|)$, $i=1,2$, we deduce, for γ to be determined later,

$$J = \int_{\mathbb{R}^n} |\hat{f}(x)|^p v(x'/|x|)|x|^\gamma\,dx$$

$$\leqq (2|S_{n-2}|)^p \int_0^\infty s^{n-1+\gamma}|A_1(s)+A_2(s)|^p V(1/s)\,ds,$$

where $V(1/s) = \int_{S_{n-1}} v(x'/s)\,d\sigma$, $s>0$.

By the estimates of $A_i(s)$, $i=1,2$, this yields

$$J \leqq C\int_0^\infty s^{n-1+\gamma}\left(\int_0^{1/s} g(\rho)\,d\rho\right)^p V(1/s)\,ds = C\int_0^\infty \left(s^{-1}\int_0^s g(\rho)\,d\rho\right)^p v_1(s)\,ds,$$

where $v_1(s) = s^{p-n-\gamma-1}V(s)$.

Applying [1, Thm. 1.7] to g and v_1, we obtain

$$J \leqq C_1 \int_0^\infty g(\rho)^p v_1(\rho)\,d\rho \tag{2.8}$$

provided that for each $r>0$,

$$\int_r^\infty s^{-p}v_1(s)\,ds \leqq C_2 r^{-p}\int_0^r v_1(s)\,ds. \tag{2.9}$$

A simple calculation shows that the integral in (2.8) is equal to $\int_{\mathbb{R}^n} v(x)|f(x)|^p\,dx$ provided $\gamma = n(p-2)$. With this γ, (2.9) is clearly equivalent to (2.5). The sufficiency part of the theorem is thus proved.

Necessity. Let $f(x) = |x|^{1-n}\chi_{(0,r)}(|x|)$ in (2.4); then we obtain

$$C\int_0^r \rho^{n-1+(1-n)p}\left(\int_{S_{n-1}} v(x'\rho)\,d\sigma\right)d\rho$$

$$= C\int_0^r \rho^{(n-1)(1-p)}V(\rho)\,d\rho = \int_{|x|\leqq r} |x|^{-p(n-1)}v(x)\,dx$$

$$\geqq \int_0^{1/(2\pi r)} \rho^{(n-1)+n(p-2)}V(1/\rho)|\hat{f}(\rho\theta)|^p\,d\rho$$

for all $\theta \in S_{n-1}$, where

$$\hat{f}(\rho\theta) = \int_0^r \left(\int_{S_{n-1}} e^{-2\pi i\rho t(\omega\cdot\theta)}\,d\sigma(\omega)\right)dt.$$

But, $0<t<r$ and $0<\rho<1/(2\pi r)$ imply $0<2\pi t\rho<1$ so that

$$\left|\int_{S_{n-1}} e^{-2\pi i\rho t(\omega\cdot\theta)}\,d\sigma(\omega)\right| = 2|S_{n-2}|\left|\int_0^1 \cos(2\pi\rho ts)(1-s^2)^{(n-3)/2}\,ds\right|$$

$$\geqq 2|S_{n-2}|(\cos 1)\int_0^1 (1-s^2)^{(n-3)/2}\,ds \equiv C>0.$$

Hence for $r>0$

$$\int_{|x|\leqq r} |x|^{-p(n-1)}v(x)\,dx \geqq C^p r^p \int_0^{1/(2\pi r)} \rho^{np-n-1}V(1/\rho)\,d\rho$$

$$= C^p r^p \int_{|x|\geqq 2\pi r} |x|^{-np}v(x)\,dx$$

which implies (2.5). This completes the proof of the theorem. □

3. The two weighted case. In this section we discuss two weighted Fourier inequalities in the index ranges

$$1<p\leqq q<\infty,\quad 0<q<p<\infty,\quad p>1 \quad\text{and}\quad 0<p<1<q.$$

PROPOSITION 3.1. *Suppose f is a positive even function decreasing to zero on* $(0,\infty)$. *Let u and v the weight functions and $V(x)=\int_0^x v(t)\,dt$, $x>0$.*

(i) *If* $1<p\leqq q<\infty$ *and*

$$A_0 := \sup_{r>0}\left(\int_0^r u(x)\,dx\right)^{1/q}\left(\int_0^r v(x)\,dx\right)^{-1/p}<\infty, \tag{3.1}$$

$$A_1 := \sup_{r>0}\left(\int_r^\infty x^{-q}u(x)\,dx\right)^{1/q}\left(\int_0^r x^{p'}V(x)^{-p'}v(x)\,dx\right)^{1/p'}<\infty, \tag{3.2}$$

then

$$\left\{\int_0^\infty u(1/x)x^{q-2}|\hat f(x)|^q\,dx\right\}^{1/q} \leqq C\left\{\int_0^\infty v(x)f(x)^p\,dx\right\}^{1/p}. \tag{3.3}$$

(ii) *If* $0<q<p<\infty, p>1$ *and* $1/r=1/q-1/p$, *then*

$$\int_0^\infty\left[\left(\int_0^t u(x)\,dx\right)^{1/p}\left(\int_0^t v(x)\,dx\right)^{-1/p}\right]^r u(t)\,dt<\infty$$

and

$$\int_0^\infty\left[\left(\int_t^\infty x^{-q}u(x)\,dx\right)^{1/q}\left(\int_0^t x^{p'}V(x)^{-p'}v(x)\,dx\right)^{1/q'}\right]^r\cdot t^{p'}V(t)^{-p'}v(t)\,dt<\infty$$

imply (3.3).

(iii) *If* $0<p\leqq q<\infty, 0<p<1$ *then* $A_0<\infty$ *and*

$$C_0 := \sup_{r>0} r\left(\int_r^\infty x^{-q}u(x)\,dx\right)^{1/q}\left(\int_0^r v(x)\,dx\right)^{-1/p}<\infty$$

imply (3.3).

Proof. The proof of Theorem 2.1 shows that

$$|\hat{f}(1/x)\cdot x^{-1}| \leqq C\left(x^{-1}\int_0^x f(t)\,dt\right), \qquad x>0,$$

so that

$$\int_0^\infty u(x)|\hat{f}(1/x)\cdot x^{-1}|^q\,dx \leqq C\left\{\int_0^\infty u(x)\left(x^{-1}\int_0^x f(t)\,dt\right)^q dx\right\}.$$

The result then follows if there are corresponding results for the two weighted averaging operator of decreasing functions. If $1<p\leqq q<\infty$ and $1<q<p<\infty, p>1$: this was given in [11, Thm. 2], and the case $0<p\leqq q<\infty$, $0<p<1$ was given in [12, Thm. 3(b)].

Our next result shows that for power weights in the range space of the operator, Proposition 3.1(i) and (iii) is sharp. In fact, with A_0, A_1 and C_0 defined as in Proposition 3.1, we have the following.

PROPOSITION 3.2. *Suppose* (3.3) *is satisfied for all positive even f decreasing to zero on* $(0,\infty)$.

(i) *If* $1<p\leqq q<\infty$, *then* $A_1<\infty$. *If, in addition,* $x^{q-2}u(1/x)\in B_q$ *i.e.*,

$$\int_r^\infty x^{-q}u(x)\,dx \geqq Cr^{-q}\int_0^r u(x)\,dx \tag{3.4}$$

then $A_0<\infty$.

(ii) *If* $0<p\leqq q<\infty$, $0<p<1$, *then* $C_0<\infty$. *If, in addition,* (3.4) *holds, then* $A_0<\infty$.

Proof. Take $f(x)=\chi_{(0,r)}(|x|)$ in (3.3), then for $0<p,\ q<\infty$,

$$\begin{aligned}
C\left(\int_0^r v(x)\,dx\right)^{1/p} &\geqq \left(\int_0^{1/(2\pi r)} u(1/x)x^{q-2}\left|\int_0^r \cos(2\pi xy)\,dy\right|^q dx\right)^{1/q}\\
&\geqq (\cos 1)r\left(\int_0^{1/(2\pi r)} u(1/x)x^{q-2}\,dx\right)^{1/q}\\
&= (\cos 1)r\left(\int_{2\pi r}^\infty u(x)x^{-q}\,dx\right)^{1/q}
\end{aligned}$$

which implies $C_0<\infty$. If (3.4) also holds, this yields at once $A_0<\infty$.

It remains to show that $A_1<\infty$ if $1<p\leqq q<\infty$. Arguing as in [12, Thm. 2], let

$$f_r(|s|)=\left(\int_{2\pi|s|}^r y^{p'}V(y)^{-p'-1}v(y)\,dy\right)^{1/p}\chi_{(0,r)}(2\pi|s|),$$

$r>0$, in (3.3). Then an interchange of order of integration shows that

$$\begin{aligned}
&C\left[\int_0^r y^{p'}V(y)^{-p'}v(y)\,dy\right]^{1/p}\\
&\quad\geqq C\left[\int_0^r y^{p'}V(y)^{-p'-1}v(y)\left(\int_0^{y/2\pi} v(x)\,dx\right)dy\right]^{1/p}\\
&\quad= C\left[\int_0^\infty v(x)f_r(|x|)^p\,dx\right]^{1/p}\\
&\quad\geqq \left\{\int_0^\infty u(x)\left|(2/x)\int_0^\infty \cos(2\pi y/x)f_r(y)\,dy\right|^q dx\right\}^{1/q}\\
&\quad\geqq 2\cos 1\left(\int_r^\infty x^{-q}u(x)\,dx\right)^{1/q}\int_0^{r/2\pi}\left[\int_{2\pi y}^{2\pi r} t^{p'}V(t)^{-p'-1}v(t)\,dt\right]^{1/p} dy.
\end{aligned}$$

Here we used the fact that $(2\pi y)/x \leqq 1$ implies $\cos(2\pi y/x) \geqq \cos 1$. On making the change of variable $2\pi y$ to y, we see that the integral on the right dominates:

$$\int_0^r y^{p'/p}\left[\int_y^r V(t)^{-p'-1}v(t)\,dt\right]^{1/p} dy$$

$$=(1/p)\int_0^r y^{p'/p}\int_y^r\left(\int_s^r V^{-p'-1}v\,d\alpha\right)^{-1/p'} V(s)^{-p'-1}v(s)\,ds\,dy$$

$$=(1/p)\int_0^r V(s)^{-p'-1}v(s)\left(\int_0^s y^{p'/p}\,dy\right)\left[\int_s^r V^{-p'-1}v\,d\alpha\right]^{-1/p'} ds$$

$$\geqq (pp')^{-1}\int_0^r V(s)^{-p'-1}v(s)\left[\int_s^\infty V^{-p'-1}v\,d\alpha\right]^{-1/p'} s^{p'}\,ds$$

$$=(1/p)(p')^{-1/p}\int_0^r V(s)^{-p'}v(s)s^{p'}\,ds.$$

The last equality was obtained under the assumption that $V(\infty)=\infty$. Thus on substituting we have shown that

$$C\left[\int_0^r y^{p'}V(y)^{-p'}v(y)\,dy\right]^{1/p}$$

$$\geqq (2\cos 1)p^{-1}(p')^{-1/p}\left(\int_{2\pi r}^\infty x^{-q}u(x)\,dx\right)^{1/q}\left(\int_0^r V(s)^{-p'}v(s)s^{p'}\,ds\right)$$

and this implies $A_1<\infty$.

Now if $V(\infty)<\infty$, replace v by $v_\varepsilon = v+\varepsilon$, $\varepsilon>0$. Then $V_\varepsilon(\infty)=\int_0^\infty v_\varepsilon\,dt=\infty$ and the above argument shows that (3.2) holds with A_1 independent of ε. Let $\varepsilon\to 0$; then the result follows from Fatou's lemma. □

Since $u(x)=|x|^\alpha$, $-1<\alpha<q-1$ satisfies (3.4) we single out the following.

COROLLARY 3.3. *The inequality* (3.3) *holds for all positive even functions, decreasing to zero on* $(0,\infty)$ *if and only if*

(i) *For* $0<p<1$, $0<p<q<\infty$,

$$r^{(\alpha+1)/q} \leqq C\left(\int_0^r v(x)\,dx\right)^{1/p}, \quad r>0, \quad -1<\alpha<q-1 \tag{3.5}$$

holds.

(ii) *For* $1<p\leqq q<\infty$, (3.5) *and*

$$\left(\int_0^r x^{p'}V(x)^{-p'}v(x)\,dx\right)^{1/p'} \leqq Cr^{1/q'-\alpha/q}, \qquad r>0,$$

hold.

4. The Hankel- and *K*-transformations. In this section we characterize weights for which the Hankel- and K-transformation of certain monotone functions is bounded on weighted Lebesgue spaces.

The Hankel transformation is defined by

$$(H_\lambda f)(x)=\int_0^\infty (xt)^{1/2}J_\lambda(xt)f(t)\,dt, \qquad \lambda>-1/2,$$

where J_λ is the Bessel function [6, p. 81(8)],

$$J_\lambda(z)=C_\lambda z^\lambda \int_0^1 (1-t^2)^{\lambda-1/2}\cos(zt)\,dt,$$

and $C_\lambda = 2^{1-\lambda}\pi^{1/2}/\Gamma(\lambda+1/2)$. Our first result in this section is the following.

THEOREM 4.1. *Let $\lambda>-1/2$, $1\leqq p<\infty$, and w be a positive weight function on $(0,\infty)$. Then*

$$\int_0^\infty w(1/s)s^{-2}|(H_\lambda h)(2\pi s)|^p\,ds \leqq C\int_0^\infty w(s)|sh(s)|^p\,ds \tag{4.1}$$

holds for all positive h with $s^{\lambda+1/2}h(s)$ decreasing to zero on $(0,\infty)$ if and only if $w_\lambda = s^{-p(\lambda-1/2)}w\in B_p^*$, i.e., for each $r>0$

$$\int_r^\infty w(s)s^{-p(\lambda+1/2)}\,ds \leqq Cr^{-p}\int_0^r w(s)\cdot s^{-p(\lambda-1/2)}\,ds. \tag{4.2}$$

Proof. Suppose $g(s)=s^{\lambda+1/2}h(s)$ is positive and decreasing to zero on $(0,\infty)$, then

$$\begin{aligned}(H_\lambda h)(2\pi s) &= C_\lambda(2\pi s)^{\lambda+1/2}\left[\int_0^{1/s}+\int_{1/s}^\infty\right]g(\rho)\int_0^1(1-t^2)^{\lambda-1/2}\cos(2\pi st\rho)\,dt\,d\rho\\ &= C'_\lambda s^{\lambda+1/2}(A_1(s)+A_2(s)).\end{aligned}$$

For $\lambda=(n-2)/2$ with $n\in\mathbb{N}$, $n\geqq 2$, the above functions A_i $(i=1,2)$ are of the same type as the A_i functions in the proof of Theorem 2.3. From the latter proof, it results that

$$A_i(s)\leqq C\int_0^{1/s} g(\rho)\,d\rho,\qquad i=1,2. \tag{4.3}$$

Noting now that all the arguments used to prove these estimates also apply if $n=2\lambda+2>1$ is not an integer, we can conclude that (4.3) holds for any $\lambda>-1/2$.

Therefore, by [1, Thm. 1.7],

$$\begin{aligned}\int_0^\infty w(s)|(H_\lambda h)(2\pi/s)|^p\,ds &\leqq C\int_0^\infty w_\lambda(s)\left[(1/s)\int_0^s t^{\lambda+1/2}h(t)\,dt\right]^p ds\\ &\leqq C'\int_0^\infty w(s)|sh(s)|^p\,ds\end{aligned}$$

provided (4.2) is satisfied.

To prove necessity, set $h(s)=s^{-(\lambda+1/2)}\chi_{(0,r)}(s)$, $r>0$, in (4.1). Then

$$\begin{aligned}&C\int_0^r w(s)s^{p(-\lambda+1/2)}\,ds\\ &\quad\geqq\int_0^\infty w(s)|(H_\lambda h)(2\pi/s)|^p\,ds\\ &\quad= C\int_0^\infty w(s)s^{-\lambda-1/2}\left|\int_0^r\int_0^1(1-y^2)^{\lambda-1/2}\cos(2\pi ty/s)\,dy\,dt\right|^p ds\\ &\quad\geqq C\int_{2\pi r}^\infty w(s)s^{-p(\lambda+1/2)}r^p(\cos 1)^p\left|\int_0^1(1-y^2)^{\lambda-1/2}\,dy\right|^p ds\\ &\quad= Cr^p\int_{2\pi r}^\infty w(s)s^{-p(\lambda+1/2)}\,ds,\end{aligned}$$

and this implies (4.2). □

Remark 4.2. Theorem 2.3 can be viewed as a corollary of Theorem 4.1. Indeed, if v is a positive weight on $\mathbb{R}^n$, $n>1$, and if w is defined by

$$w(s)=s^{n-1-(n+1)p/2}\int_{S_{n-1}} v(\theta s)\,d\sigma, \qquad s>0,$$

then v satisfies (2.5) if and only if w satisfies (4.2) with $\lambda=(n-2)/2$ (i.e., $v\in B_p^*(n)$ if and only if $w_\lambda=s^{-p(\lambda+1/2)}w\in B_p$, $\lambda=(n-2)/2$). Note also that (2.4) holds for $f(x)=f_0(|x|)$, $x\in\mathbb{R}^n$, if and only if (4.1) holds with w as above, for $h(t)=t^{(n-1)/2}f_0(t)$, $\lambda=(n-2)/2$.

Next, we consider the K-transform defined by

$$(K_\lambda f)(x)=\int_0^\infty (xy)^{1/2}k_\lambda(xy)f(y)\,dy, \qquad x>0, \quad \lambda\geqq -1/2,$$

where k_λ is the modified Bessel function of the third kind [6, Chap. X]. If $\lambda=\pm 1/2$, the K-transform reduces to the Laplace transform: $(K_{\pm 1/2}f)(x)=\sqrt{\pi/2}\int_0^\infty e^{-xt}f(t)\,dt$ and if $\lambda>-1/2$ the kernel has the representations

$$k_\lambda(x)=C_\lambda x^\lambda\int_1^\infty e^{-xt}(t^2-1)^{\lambda-1/2}\,dt=C_\lambda x^\lambda\varphi_\lambda(x),$$

$$x>0, \quad C_\lambda=2^{-\lambda}\Gamma(1/2)\cdot\Gamma(\lambda+1/2)^{-1},$$

[7, p. 958(3)], and

$$k_\lambda(x)=C_\lambda^{-1}x^{-\lambda}\int_0^\infty (1+t^2)^{-\lambda-1/2}\cos(xt)\cdot dt=C_\lambda^{-1}x^{-\lambda}\psi_\lambda(x), \qquad x>0$$

[7, p. 959(5)].

Hence we can define the K-transform for $\lambda>-1/2$ by

$$(K_\lambda f)(x)=C_\lambda x^{\lambda+1/2}\int_0^\infty y^{\lambda+1/2}f(y)\cdot\varphi_\lambda(xy)\,dy \tag{4.4}$$

and

$$(K_\lambda f)(x)=C_\lambda^{-1}x^{-\lambda+1/2}\int_0^\infty y^{-\lambda+1/2}f(y)\cdot\psi_\lambda(xy)\,dy. \tag{4.5}$$

We shall need both these representations in the next result.

THEOREM 4.3. *Let $\lambda\geqq -1/2$, $\lambda\neq 0$, $1<p\leqq q<\infty$, and u, v positive weight functions on $(0,\infty)$. Then*

$$\left(\int_0^\infty u(1/x)x^{q-2}|(K_\lambda f)(x)|^q\,dx\right)^{1/q}\leqq C\left(\int_0^\infty v(x)f(x)^p\,dx\right)^{1/p} \tag{4.6}$$

holds for all positive f, with $f(x)\cdot x^{-|\lambda|+1/2}$ decreasing to zero on $(0,\infty)$, if and only if

$$A_0^\lambda:=\sup_{r>0}\left(\int_0^r x^{q(|\lambda|-1/2)}u(x)\,dx\right)^{1/q}\left(\int_0^r v_\lambda(x)\,dx\right)^{-1/p}<\infty$$

and

$$A_1^\lambda:=\sup_{r>0}\left(\int_r^\infty x^{q(|\lambda|-3/2)}u(x)\,dx\right)^{1/q}\left(\int_0^r x^{p'}v_\lambda(x)V_\lambda(x)^{-p'}\,dx\right)^{1/p'}<\infty,$$

where $v_\lambda(x)=x^{p(|\lambda|-1/2)}v(x)$ and $V_\lambda(x)=\int_0^x v_\lambda$.

Proof. For $\lambda = -1/2$: this result is Theorem 1.12 of [8]. We assume therefore that $\lambda > -1/2$.

(i) *Sufficiency.* If $-1/2 < \lambda < 0$, then by (4.4),

$$(K_\lambda f)(x) = C_\lambda x^{\lambda+1/2}\left(\int_0^{1/x} + \int_{1/x}^{\infty}\right) y^{\lambda+1/2} f(y)\varphi_\lambda(xy)\, dy$$
$$= C_\lambda x^{\lambda+1/2}[A_1(x) + A_2(x)], \text{ respectively.}$$

Since $\varphi_\lambda(s) \leqq C$, then with $g(y) = y^{-|\lambda|+1/2} f(y)$, we obtain

$$A_1(x) \leqq C \int_0^{1/x} g(y)\, dy.$$

To estimate A_2, the second mean value theorem shows that for some $\xi > 1/x$

$$\begin{aligned} A_2(x) &= g(1/x) \int_{1/x}^{\xi} \varphi_\lambda(xy)\, dy \\ &= x^{-1} g(1/x) \int_1^{x\xi} \int_1^{\infty} e^{-st}(t^2-1)^{\lambda-1/2}\, dt\, ds \\ &= x^{-1} g(1/x) \int_1^{\infty} (t^2-1)^{\lambda-1/2}(e^{-t} - e^{-x\xi t}) t^{-1}\, dt \\ &\leqq C x^{-1} g(1/x) \\ &\leqq C \int_0^{1/x} g(y)\, dy. \end{aligned}$$

Therefore, if $-1/2 < \lambda < 0$,

$$(K_\lambda f)(x) \leqq C x^{-|\lambda|+1/2} \int_0^{1/x} g(y)\, dy. \tag{4.7}$$

If $0 < \lambda < \infty$, then, by (4.5),

$$(K_\lambda f)(x) = C_\lambda^{-1} x^{-\lambda+1/2}\left(\int_0^{1/x} + \int_{1/x}^{\infty}\right) g(y)\psi_\lambda(xy)\, dy$$
$$= C_\lambda^{-1} x^{-\lambda+1/2}[A_3(x) + A_4(x)], \text{ respectively.}$$

Since $\psi_\lambda(s) \leqq C$, $A_3(x) \leqq C \int_0^{1/x} g(y)\, dy$, again the second mean value theorem shows that for some $\xi > 1/x$,

$$A_4(x) = g(1/x) \int_{1/x}^{\xi} \psi_\lambda(xy)\, dy = x^{-1} g(1/x) \int_1^{x\xi} \psi_\lambda(s)\, ds.$$

But

$$\left|\int_1^{x\xi} \psi_\lambda(s)\, ds\right| \leqq \left|\int_0^{\infty} (1+t^2)^{-\lambda-1/2}[(\sin x\xi t)/t]\, dt\right| + \left|\int_0^{\infty} (1+t^2)^{-\lambda-1/2}[(\sin t)/t]\, dt\right|.$$

The integral on the right is clearly convergent, while the first integral is seen to be convergent if we apply the second mean value theorem to $(1+t^2)^{-\lambda-1/2}$. Therefore

$$A_4(x) \leqq C x^{-1} g(1/x) \leqq C \int_0^{1/x} g(y)\, dy,$$

and this implies that (4.7) holds also for $0<\lambda<\infty$. Now with $u_\lambda(x)=x^{q(|\lambda|-1/2)}u(x)$, (4.7) implies that

$$\left(\int_0^\infty u(x)|x^{-1}(K_\lambda f)(1/x)|^q\,dx\right)^{1/q} \leqq C\left(\int_0^\infty u_\lambda(x)\left[x^{-1}\int_0^x g(y)\,dy\right]^q dx\right)^{1/q}$$

and by [11, Thm. 2] the last integral expression is dominated by

$$\left(\int_0^\infty v_\lambda(x)g(x)^p\,dx\right)^{1/p}=\left(\int_0^\infty v(x)f(x)^p\,dx\right)^{1/p}$$

provided $A_0^\lambda<\infty$ and $A_1^\lambda<\infty$. This proves the first part of the theorem.

(ii) *Necessity.* For $-1/2<\lambda<\infty$, $\lambda\neq 0$, substitute $f(x)=x^{|\lambda|-1/2}\chi_{(0,r)}(x)$, $r>0$, in (4.6). Then from the representation (4.4) we obtain

$$\begin{aligned}
C\left(\int_0^r v_\lambda(x)\,dx\right)^{1/p} &\geqq C_\lambda\left\{\int_0^\infty u(x)\cdot x^{-q(\lambda+3/2)}\left[\int_0^r y^{\lambda+|\lambda|}\varphi_\lambda(y/x)\,dy\right]^q dx\right\}^{1/q}\\
&\geqq C_\lambda\left\{\int_0^r u(x)\cdot x^{-q(\lambda+3/2)}\left[\int_0^x y^{\lambda+|\lambda|}\varphi_\lambda(1)\,dy\right]^q dx\right\}^{1/q}\\
&=C_\lambda'\left\{\int_0^r u(x)x^{q(|\lambda|-1/2)}\,dx\right\}^{1/q}.
\end{aligned}$$

Hence $A_0^\lambda<\infty$. To prove that $A_1^\lambda<\infty$, let

$$g_r^\lambda(x)=\left(\int_x^r y^{p'}V_\lambda(y)^{-p'-1}v_\lambda(y)\,dy\right)^{1/p}$$

and substitute $f(x):=f_r^\lambda(x)=x^{|\lambda|-1/2}g_r^\lambda(x)\chi_{(0,r)}(x)$, $r>0$, in (4.6). Then for $-1/2<\lambda<\infty$, $\lambda\neq 0$, the right side of (4.6) is

$$C\left\{\int_0^r v_\lambda(x)\left(\int_x^r y^{p'}V_\lambda(y)^{-p'-1}v_\lambda(y)\,dy\right)dx\right\}^{1/p}=C\left\{\int_0^r v_\lambda(y)y^{p'}V_\lambda(y)^{-p'}\,dy\right\}^{1/p}.$$

If $-1/2<\lambda<0$, we use the representation (4.4) of the K-transform. The left side of (4.6) then has the form

$$\begin{aligned}
&C_\lambda\left\{\int_0^\infty u(x)\cdot x^{-q(\lambda+3/2)}\left|\int_0^r g_r^\lambda(y)\cdot\varphi_\lambda(y/x)\,dy\right|^q dx\right\}^{1/q}\\
&\qquad\geqq C_\lambda'\left\{\int_r^\infty u(x)\cdot x^{-q(\lambda+3/2)}\left|\int_0^r g_r^\lambda(y)\,dy\right|^q dx\right\}^{1/q}.
\end{aligned}$$

As seen in the proof of Proposition 3.2, the inner integral dominates

$$\int_0^r V_\lambda(s)^{-p'}v_\lambda(s)s^{p'}\,ds$$

whenever $V_\lambda(\infty)=\infty$ and this on substituting implies $A_1^\lambda<\infty$.

If $0<\lambda<\infty$, we substitute (4.5) in the left side of (4.6) so that it has the form

$$C_\lambda^{-1}\left\{\int_0^\infty u(x)\cdot x^{q(\lambda-3/2)}\left|\int_0^\infty g_r^\lambda(y)\psi_\lambda(y/x)\,dy\right|^q dx\right\}^{1/q}. \tag{4.8}$$

But since ψ_λ is strictly positive on $[0,\infty)$ for $0<\lambda<\infty$, there exists δ, $0<\delta<\pi/2$, such that

$$\psi_\lambda(y/x)=\int_0^\infty(1+t^2)^{-\lambda-1/2}\cos(yt/x)\,dt\geqq\int_0^\delta(1+t^2)^{-\lambda-1/2}\cos(yt/x)\,dt \tag{4.9}$$

for all $(y/x)\in[0,1]$ with δ independent of (y/x). To see this, note first that for each $\xi^*\in[0,1]$ there exists $\delta_{\xi^*}, 0<\delta_{\xi^*}<\pi/2$ such that $\int_{\delta_{\xi^*}}^{\infty}(1+t^2)^{-\lambda-1/2}\cos(\xi^* t)\,dt>0$.

Then, for $\xi^*\in[0,1]$ fixed, there exists a neighborhood V_{ξ^*} of ξ^* such that

$$\int_{\delta_{\xi^*}}^{\infty}(1+t^2)^{-\lambda-1/2}(\cos \xi t)\,dt>0$$

for all $\xi\in V_{\xi^*}$. From the covering family $\{V_{\xi^*}: \xi^*\in[0,1]\}$ of $[0,1]$, we can then extract a finite covering subfamily and define δ as the minimum of the corresponding $\delta_{\xi_j^*}, j=1,2,\cdots,N$, N finite. This δ satisfies $0<\delta<\pi/2$, which implies

$$\int_{\delta}^{\delta_{\xi_j^*}}(1+t^2)^{-\lambda-1/2}(\cos \xi t)\,dt\geqq 0$$

for each j and every $\xi\in V_{\xi_j^*}$. This shows that (4.9) holds for all $(y/x)\in[0,1]$ and, as a consequence, we can minorize (4.8) as follows:

$$\begin{aligned}&\left\{\int_r^{\infty}u(x)\cdot x^{q(\lambda-3/2)}\left[\int_0^{\infty}(1+t^2)^{-\lambda-1/2}\int_0^r\cos(yt/x)\cdot g_r^{\lambda}(y)\,dy\,dt\right]^q dx\right\}^{1/q}\\ &\quad\geqq(\cos\delta)\left(\int_0^{\delta}(1+t^2)^{-\lambda-1/2}\,dt\right)\left\{\int_r^{\infty}u(x)\cdot x^{q(\lambda-3/2)}\left[\int_0^r g_r^{\lambda}(y)\,dy\right]^q dx\right\}^{1/q}\\ &\quad\geqq C'\left\{\int_r^{\infty}u(x)\cdot x^{q(\lambda-3/2)}\,dx\right\}^{1/q}\left\{\int_0^r V_{\lambda}(s)^{-p'}v_{\lambda}(s)s^{p'}\,ds\right\},\end{aligned}$$

where the last inequality is again obtained as in the proof of Proposition 3.2, provided $V_\lambda(\infty)=\infty$. Thus again under this condition, $A_1^\lambda<\infty$.

Finally, if $V_\lambda(\infty)<\infty$, replace v_λ by $v_\lambda^\varepsilon=v_\lambda+\varepsilon$, $\varepsilon>0$. Then $V_\lambda^\varepsilon(\infty)=\int_0^\infty v_\lambda^\varepsilon\,dt=\infty$ and the above arguments show that the result holds in this case with A_1^λ independent of ε. As before, Fatou's lemma then implies the result. □

Remark 4.4. Since (4.7) holds for all $\lambda\in(-1/2,\infty)$, $\lambda\neq 0$, the sufficiency part of the theorem holds also in the index ranges $0<q<p<\infty$, $p>1$, and $0<p\leqq q<\infty$, $0<p<1$, under suitably modified weight conditions, by applying [11, Thm. 2] and [12, Thm. 3], respectively (cf. Proposition 3.1). We leave the details.

SOME TRACE THEOREMS IN ANISOTROPIC SOBOLEV SPACES*

PATRICK JOLY†

Abstract. Anisotropic Sobolev spaces are functional spaces of Sobolev's type in which different space directions have different roles. In the case of dimension 2, some new trace theorems in such spaces for very general open sets are proved. A sense is also given of the corresponding Green's formula via a generalized concept of Cauchy principal value.

Key words. Sobolev spaces, trace theorems, approximations, Green's formulas

AMS(MOS) subject classifications. 26B99, 46E35

Introduction. In the usual Sobolev spaces such as $H^m(\Omega)$ or $W^{m,p}(\Omega)$, all derivatives in all space directions play the same role. This explains why only the regularity properties of the boundary (Γ) of the domain Ω play a role for trace theorems and extension properties (see the classical references [1], [8], [10]). In some domains of physics, we encounter partial differential equations leading us to work in functional spaces in which only partial derivatives with respect to some space directions have a privileged role. This is in particular the case for paraxial approximations of the wave equation [2], [3], [5] or of the Stokes equations [9]. The simplest example is the parabolic approximation of the wave equation in two dimensions, which is written

$$\frac{1}{c}\frac{\partial^2 u}{\partial t^2}-\frac{\partial^2 u}{\partial x_2\,\partial t}-\frac{1}{2}\frac{\partial}{\partial x_1}\left(c\frac{\partial u}{\partial x_1}\right)=0. \tag{0.1}$$

The energy associated to (0.1) is

$$E(t)=\frac{1}{2}\int_\Omega\left|\frac{\partial u}{\partial t}\right|^2\frac{dx}{c}+\frac{1}{4}\int_\Omega c\left|\frac{\partial u}{\partial x_1}\right|^2 dx, \tag{0.2}$$

which leads us naturally to work in the anisotropic Sobolev space

$$H^{1,0}(\Omega)=\left\{v\in L^2(\Omega)\Big/\frac{\partial v}{\partial x_1}\in L^2(\Omega)\right\},\qquad \Omega\subset\mathbb{R}^2. \tag{0.3}$$

Trace theorems in anisotropic Sobolev spaces of type (0.3) are well known in the case where Ω is a product set [8]. The case where Ω is an arbitrary open set appears to be more delicate.

In this article, we intend to treat completely the case of the space $H^{1,0}(\Omega)$ in two dimensions (see also [7]). The outline of the paper is as follows. In § 1 we state our two main results (Theorems 1 and 2). The first is the trace theorem for $H^{1,0}(\Omega)$; the second one concerns the corresponding Green's formula. Section 2 is devoted to the detailed proof of these two theorems. In § 3 we give the extension of the previous results to the spaces $H^{s,0}(\Omega)$ and $W_p^{1,0}(\Omega)$. The interest of this paper lies rather in the results themselves, which may appear surprising compared to more classical results, than in the techniques, which remain very elementary (we use mainly some variations around Poincaré's inequality in dimension 1). In particular, the orientation of the boundary (Γ) with respect to the direction x_2 and the relative position of Ω with respect

* Received by the editors November 20, 1989; accepted for publication (in revised form) August 5, 1991.

† Institut National de Recherche en Informatique et en Automatique, Domaine de Voluceaú-Rocquencourt, BP 105, 78153 Le Chesnay Cédex, France.

to (Γ) have an influence on the result, and not the regularity of (Γ). So, even if Γ is smooth, the space $H^{1,0}(\Omega)$ does not in general satisfy the extension property.

A complete study of density, compactness, and embedding theorems is presented in the book by Besov, Il'jin, and Nicolskii [4]. An application of our results to the study of the regularity of the solutions of paraxial approximations of the wave equation can be found in [6].

1. The two main theorems in the space $H^{1,0}(\Omega)$.

1.1. Notation and definition. In what follows, Ω will denote an open set of $\mathbb{R}^2$ whose boundary $(\Gamma)=(\partial\Omega)$ is supposed to satisfy the following assumptions (see Fig. 1):

(H1) Ω is locally the epigraph of a Lipschitz function (i.e., (Γ) is locally the graph of a Lipschitz function, and Ω is locally "above" Γ);

(H2) Γ is the reunion of a finite number of:

- parts G_l in the form

$$G_l=\{(x_1,x_2):x_1=f_l(x_2),\ a_1<x_2<b_1,\ f_l \text{ is Lipschitz continuous}\},$$

- their summits $A_l=(a_l,f_l(a_l))$, $B_l=(b_l,f_l(b_l))$,
- horizontal parts H_k:

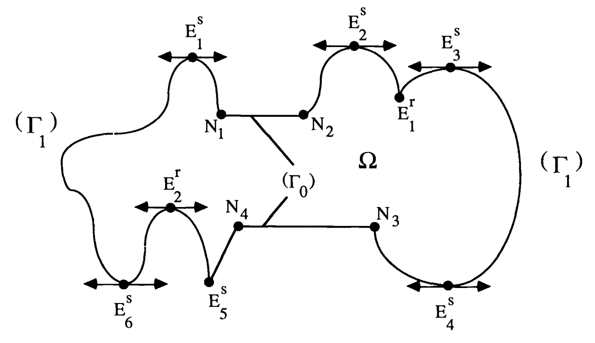
$$H_k=\{(x_1,x_2):x_2=X_k,\ c_k<x_1<d_k\}.$$

We shall note:

$$\Gamma_1=\bigcup_l \bar{G}_l,\quad \Gamma_0=\bigcup_k H_k,\quad \Gamma=\Gamma_0\cup\Gamma_1.$$

We can define the unit normal vector to Γ, outgoing with respect to Ω, almost everywhere on Γ, and we shall denote by $n(M)=(n_1(M),n_2(M))$, M belonging to Γ, the corresponding vector field. Γ_0 and Γ_1 differ by the value of the first component n_1 since

$$\text{a.e. } M\in\Gamma_0,\quad n_1(M)=0,$$
$$\text{a.e. } M\in\Gamma_1,\quad n_1(M)\neq 0.$$



- ● (N_1, N_2, N_3, N_4) : nonstrict extremal point of Γ_1
- ● $(E_1^s, E_2^s, E_3^s, E_4^s, E_5^s, E_6^s)$: strict x_2-extremal outgoing points
- ● (E_2^r, E_1^r) : strict x_2-extremal incoming points

FIG. 1. *Illustration of Hypotheses* (H1) *and* (H2).

As we shall see later, the traces will be defined only on Γ_1. We shall use in the sequel the notion of x_2-extremal point.

DEFINITION 1. A point M of Γ is a (strict) x_2-extremal point if and only if the coordinate x_2 realizes a (strict) local extremum on Γ. Such a point is said to be outgoing with respect to Ω (otherwise it is said to be incoming) if x_2 realizes at this point a local extremum in Ω, i.e., if there exists a ball $B(M, \varepsilon)$ such that

$$x_2(M) > x_2(M') \quad \forall M' \in B(M, \varepsilon),$$

or

$$x_2(M) < x_2(M') \quad \forall M' \in B(M, \varepsilon).$$

As an example, consider the case where (Γ) locally coincides with the graph of a Lipschitzian map, $x_2 = f(x_1)$, f admitting an extremum at $x_1 = 0$.

Note that the notion of x_2-extremal point makes use of the orientation of (Γ) with respect to the direction Ox_2, while the notion of an outgoing (or incoming) x_2-extremal point involves the relative position of Ω with respect to (Γ). Because of (H2), the number of strict x_2-extremal points is finite and each of them is one of the summits (A_1, B_1). We shall denote by $\{M_j, 1 \leqq j \leqq N\}$ the set of these points.
Finally, we are led to introduce a weight function $l(M)$ on Γ_1 as follows.

We shall say that a point M of Γ_1 belongs to Γ_1^* if it exists a point M^* (which is unique if it exists) of Γ such that the open segment MM^* is horizontal and included in Ω (see Fig. 3). Note that M^* may not exist if Ω is unbounded, as illustrated in Fig. 2, but that $\Gamma_1^* = \Gamma_1$ as soon as Ω is bounded. Then we introduce

$$\lambda(M) = \text{length of } MM^* = |x_1(M^*) - x_1(M)| \quad \text{for } M \text{ in } \Gamma_1^*$$

and then define the weight function $l(M)$ on Γ_1 by

$$\begin{aligned} l(M) &= \inf(\lambda(M), 1) && \text{if } M \text{ belongs to } \Gamma_1^*, \\ l(M) &= 1 && \text{if not.} \end{aligned}$$

DEFINITION 2. A function $\phi(M)$ defined on Γ_1 is said to be (Γ, x_1)-even if and only if

$$\phi(M) = \phi(M^*) \quad \text{if } M \text{ belongs to } \Gamma_1^*,$$

and (Γ, x_1)-odd if and only if

$$\begin{aligned} \phi(M) + \phi(M^*) - 0 && \text{if } M \text{ belongs to } \Gamma_1^*, \\ \phi(M) = 0 && \text{if not.} \end{aligned}$$

Of course, any function ϕ defined on Γ_1 can be uniquely decomposed as $\phi = \phi_e + \phi_o$ where ϕ_e is (Γ, x_1)-even and ϕ_0 is (Γ, x_1)-odd.

Denoting by σ a curvilinear abcissa along Γ and by $d\sigma$ the corresponding superficial measure, we introduce the following two Hilbert spaces:

$$(1.1) \qquad \begin{aligned} L^2_{\text{even}}(\Gamma_1; l|n_1|) &= \left\{\phi: \int_{\Gamma_1} |\phi|^2 l |n_1| \, d\sigma), \phi \text{ is } (\Gamma, x_1)\text{-even}\right\}, \\ L^2_{\text{odd}}(\Gamma_1; l^{-1}|n_1|) &= \left\{\phi: \int_{\Gamma_1} |\phi|^2 l^{-1} |n_1| \, d\sigma), \phi \text{ is } (\Gamma, x_1)\text{-odd}\right\} \end{aligned}$$

and the space of traces $T(\Omega, \Gamma_1)$:

$$(1.2) \qquad T(\Gamma_1, \Omega) = L^2_{\text{even}}(\Gamma_1; l|n_1|) \oplus L^2_{\text{odd}}(\Gamma_1; l^{-1}|n_1|)$$

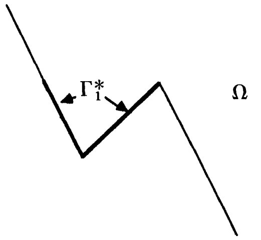


FIG. 2. *A case where* $\Gamma_1^* \neq \Gamma_1$.

equipped with the norm

$$(1.3)\qquad |\phi_e+\phi_o|^2_{T(\Omega,\Gamma_1)}=\int_{\Gamma_1}|\phi_e|^2 l|n_1|\,d\sigma+\int_{\Gamma_1}|\phi_o|^2 l^{-1}|n_1|\,d\sigma.$$

Remarks. (1) The weight function $l(M)$ is strictly positive almost everywhere on Γ_1 and vanishes only at the strict outgoing x_2-extremal points of Γ. In some sense, the singularity of the function $l(M)^{-1}$ measures the sharpness of the open set Ω in the neighborhood of such an extremal point.

(2) If Γ_1 has no strict outgoing x_2-extremal point, the space simply coincides with the space $L^2(\Gamma_1, |n_1|)$. More generally, if we exclude the neighborhoods of the points of Γ_1 whose tangent is horizontal (where the function $|n_1|$ degenerates) and the neighborhoods of the strict outgoing x_2-extremal points of Γ_1 (where $l(M)$ degenerates) the space $T(\Gamma_1, \Omega)$ simply coincides with the space $L^2(\Gamma_1)$.

(3) The space $T(\Gamma_1, \Omega)$ is intrinsically linked not to the curve Γ_1 but to the pair (Γ_1, Ω), since the function $l(M)$ depends on the outgoing x_2-extremal points of Γ_1 which themselves depend on the relative position of Γ_1 with respect to Ω.

1.2. The two main results.

THEOREM 1. *The trace mapping* $\gamma_0: D(\bar{\Omega}) \to L^2(\Gamma_1)$ *defined by* $(\gamma_0 u)(M) = u(M)$ *extends in a unique way to a linear and continuous map, which we still denote by* γ_0, *from* $H^{1,0}(\Omega)$ *onto* $T(\Gamma_1, \Omega)$. *Moreover, the application* γ_0 *is surjective from* $H^{1,0}(\Omega)$ *onto* $T(\Gamma_1, \Omega)$.

As a direct consequence of Theorem 1, we have the following corollary.

COROLLARY 1. *The space* $H^{1,0}(\Omega)$ *has the extension property if and only if* Ω *has no strict* x_2*-extremal point.*

Indeed if $\mathcal{O} = \mathbb{R}^2\text{-}\Omega$, it is clear that any strict x_2-extremal of Γ_1 that is outgoing with respect to Ω is incoming with respect to $\mathcal{O}$, and conversely. So the space $T(\Gamma_1, \Omega)$ and $T(\Gamma_1, \mathcal{O})$ coincide if and only if Γ_1 has no strict x_2-extremal point. As an example, note that the boundary of the unit square has no strict x_2-extremal point while the unit circle has two extremal points.

It is interesting to make the following comments:

- The trace of a function of $H^{1,0}(\Omega)$ is defined only on the part (Γ_1) of the boundary (Γ).

- The trace can have singularities which can be stronger than L^2-singularities the x_2-extremal points of (Γ_1). Moreover, such a singularity can be stronger at the neighborhood of a strict outgoing x^2-extremal point. However, this singularity only affects the (Γ, x_1)-odd part of the function, while the (Γ, x_1)-even part must be more regular because of the presence of the weight function l^{-1}. In some sense, this condition traduces a sort of continuity of the trace at the extremal point, due to the effect of the regularity of the original function in the x_1 direction.

Our second result will express how the classical Green's formula

$$(1.4)\qquad \int_\Omega \left(u\frac{\partial v}{\partial x_1}+\frac{\partial u}{\partial x_1}v\right)dx=\int_\Gamma uvn_1\,d\sigma\quad \forall(u,v)\in D(\bar{\Omega})^2$$

can be extended to functions in $H^{1,0}(\Omega)^2$. For this we are led to define the notion of principal value in the direction x_2 of a curvilinear integral along (Γ_1). Let us denote by $\{M_j, j\in J_o\}$ the strict outgoing x_2-extremal points of Γ_1 and by $\{M_j, j\in J_i\}$ the strict incoming x_2-extremal points of Γ_1 (which will not play any role in what follows).

For $\delta>0$ small enough and j in J_0 we denote by $\Gamma_1^j(\delta)$ the connected component of the set

$$\{M\in\Gamma_1/|x_2(M)-x_2(M_j)|<\delta\},$$

which contains M_j (see Fig. 3), and we set

$$\Gamma_1(\delta)=\bigcup_{j\in J_o}\Gamma_1^j(\delta).$$

The essential property of $\Gamma_1^j(\delta)$ is the fact that it is "x_2-symmetry with respect to M_j" in the sense that it is made of two arcs of curve whose common extremity is the point M_j and which are of equal size in the x_2-direction.

THEOREM 2. (i) *For any (ϕ,ψ) in $T(\Gamma_1,\Omega)^2$, the limit*

$$(1.5)\qquad \lim_{\delta\downarrow 0}\int_{\Gamma_1\setminus\Gamma_1(\delta)}\phi\psi n_1\,d\sigma\overset{\text{def}}{=}\text{v.p. }x_2\int_{\Gamma_1}\phi\psi n_1\,d\sigma$$

exists and the bilinear form $(\phi,\varphi)\to\text{v.p. }x_2\int_{\Gamma_1}\phi\varphi n_1\,d\sigma$ is continuous on $T(\Gamma_1,\Omega)^2$.

(ii) *We have in $H^{1,0}(\Omega)$ the following Green's formula*:

$$(1.6)\qquad \forall(u,v)\in H^{1,0}(\Omega)^2,\quad \int_\Omega\left(u\frac{\partial v}{\partial x_1}+\frac{\partial u}{\partial x_1}v\right)dx=\text{v.p. }x_2\int_{\Gamma_1}\gamma_0u\,\gamma_0v\,n_1\,d\sigma.$$

2. Proofs of the two main results.

2.1. Proof of Theorem 2. Rather than give a direct proof, we have chosen to break down our presentation into several lemmas. This has the advantage of being expository and of illustrating the importance of the notions given in § 1.1. As a preliminary result we can give a first simple result, which can be found, for instance, in [13].

PROPOSITION 1. *The map γ_{n_1}: $D(\bar{\Omega})\to L^2(\Gamma)$ defined by $\gamma_{n_1}u(M)=n_1(M)u(M)$ can be extended in a unique way to a linear and continuous mapping from $H^{1,0}(\Omega)$ in $H^{-1/2}(\Gamma)$ and we have the Green's formula*

$$(2.1)\qquad \forall(u,v)\in H^{1,0}(\Omega)\times H^1(\Omega),\quad \int_\Omega\left(\frac{\partial u}{\partial x_1}v+u\frac{\partial v}{\partial x_1}\right)dx=\langle\gamma_{n_1}u,\gamma_0u\rangle_\Gamma,$$

where $\langle\cdot,\cdot\rangle_\Gamma$ denotes the duality $H^{-1/2}(\Gamma)-H^{1/2}(\Gamma)$.

Proof. Just note that $u\in H^{1,0}(\Omega)$ implies that $(u,0)\in H(\text{div};\Omega)$ and apply the standard trace theorem in $H(\text{div};\Omega)$ (see [12]). □

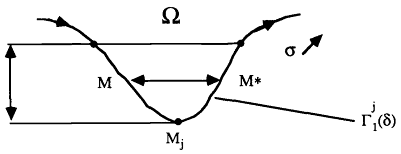

FIG. 3. *The set* $\Gamma_1^j(\delta)$.

Such a result is not completely satisfactory. Indeed, in (2.1), (u, v) have a symmetric role on the right-hand side and not on the left-hand side. Moreover, this result concerns the product $n_1 \times u$ and not u itself. In particular, as $n_1 = 0$ on Γ_0, it is clear that nothing can be said about the trace of u along Γ_0. This is not surprising since a function in $H^{1,0}(\Omega)$ can be discontinuous through a line $x_1 = \text{cste}$.

Our purpose now is to show precisely that the trace of u can be defined as a function almost everywhere (for the Lebesgue measure on Γ) defined on Γ_1 and, in order to get an optimal result, to characterize the image of this trace operator. For the sake of clarity, we shall distinguish several steps. Moreover, for the proofs, we shall use the curvilinear abcissa σ along Γ and the corresponding parametric representation

$$\sigma \to M(\sigma) = (X_1(\sigma), X_2(\sigma)),$$

and suppose that the curve Γ is oriented in such a way that, if $n(\sigma)$ denotes $n(M(\sigma))$,

$$n_1(\sigma) = -\frac{dX_2}{d\sigma}(\sigma), \qquad n_2(\sigma) = \frac{dX_1}{d\sigma}(\sigma).$$

2.1.1. The case where $n_1(\sigma)$ has a constant sign along (Γ_1).

LEMMA 1. *If $n_1(\sigma)$ has a constant sign along (Γ_1) (see Fig. 4), the trace mapping $\gamma_0 : D(\bar{\Omega}) \to L^2(\Gamma_1)$ can be uniquely extended to a linear continuous mapping from $H^{1,0}(\Omega)$ onto $L^2(\Gamma_1; |n_1|\, d\sigma)$ and we have*

$$\text{(i)} \qquad \forall (u, v) \in H^{1,0}(\Omega)^2, \qquad \int_\Omega \left(u \frac{\partial v}{\partial x_1} + \frac{\partial u}{\partial x_1} v \right) dx = \int_{\Gamma_1} \gamma_0 u \cdot \gamma_0 v n_1 \, d\sigma,$$

$$\text{(ii)} \qquad \forall u \in H^{1,0}(\Omega), \qquad \|\gamma_0 u\|_{n_1, \Gamma_1} \leqq \|u\|_{H^{1,0}(\Omega)}.$$

Proof of Lemma 1. When we take $v = u$ in the usual Green's formula, we get

$$\forall u \in D(\bar{\Omega}), \qquad \int_{\Gamma_1} |u|^2 n_1 \, d\sigma = 2 \int_\Omega u \frac{\partial u}{\partial x_1} dx.$$

Then it suffices to remark that the absolute value of the left-hand side is,if $n_1$has a constant sign, the square of the norm of $\gamma_0 u$ in $L^2(\Gamma_1; |n_1|\, d\sigma)$; we also use the Schwar z's inequality to estimate the right-hand side to obtain

$$\text{(2.2)} \qquad \forall u \in D(\bar{\Omega}), \qquad \|\gamma_0 u\|^2_{n_1, \Gamma_1} \leqq \|u\|^2_{H^{1,0}(\Omega)}.$$

Formula (ii) follows then by density and continuity. It is then easy to deduce the unique extension result and the Green's formula (i) for the same reasons.

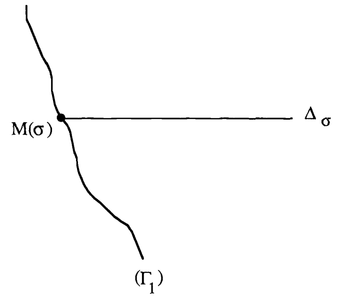

FIG. 4. *The case where n_1 has a constant sign.*

It remains to prove the surjectivity result. For this we note that, thanks to the assumption about $n_1(\sigma)$, Ω can be seen as the reunion of half lines. For instance, if $n_1(\sigma) \leqq 0$,

$$\bar{\Omega} = \bigcup_{M(\sigma)\in\Gamma_1} \bar{\Delta}_\sigma, \qquad \Delta_\sigma = \{(x_1, X_2(\sigma)), x_1 \geqq X_1(\sigma)\}.$$

Let us consider ϕ in $L^2(\Gamma_1; |n_1|\, d\sigma)$. As $|n_1(\sigma)| = |\, dX_2/d\sigma(\sigma)|$, we can write

$$\|\phi\|^2_{|n_1|,\Gamma_1} = \int_{\Gamma_1} |\phi(\sigma)|^2 \left| \frac{dX_2}{d\sigma}(\sigma) \right| d\sigma. \tag{2.3}$$

If $I_2 = \{x_2 = X_2(\sigma)/M(\sigma) \in \Gamma_1\}$, as $n_1(\sigma) \geqq 0$, the map $\sigma \to X_2(\sigma)$ is a bijection between I_2 and Σ_1, the set of the values of σ when $M(\sigma)$ describes Γ_1. Let $\Phi_\eta(x)$ be the function defined in Fig. 5.

We construct the following extension of $\phi(\sigma)$:

$$u(x_1, x_2) = \phi(\sigma)\Phi_\eta(x_1 - X_1(\sigma)) \quad \text{if } x_2 = X_2(\sigma). \tag{2.4}$$

We evaluate the integral $\int_\Omega |u|^2\, dx$ with the help of the change of variable $(x_1, \sigma) \to (x_1, x_2 = X_2(\sigma))$, whose Jacobian is equal to $|n_1(\sigma)|$. By Fubini's theorem, we have

$$\begin{aligned} \int_\Omega |u(x_1, x_2)|^2\, dx &= \int_{\Sigma_1} \left(\int_{X_1(\sigma)}^{+\infty} |\Phi_\eta(x_1 - X_1(\sigma))|^2\, dx_1 \right) |\phi(\sigma)|^2 |n_1(\sigma)|\, d\sigma \\ &= \|\Phi_\eta\|^2_{L^2} \|\phi\|^2_{|n_1|,\Gamma_1}. \end{aligned} \tag{2.5}$$

By the same approach, we obtain for $\partial u/\partial x_1$

$$\int_\Omega \left| \frac{\partial u}{\partial x_1}(x_1, x_2) \right|^2 dx = \left\| \frac{d\Phi_\eta}{dx} \right\|^2_{L^2} \|\phi\|^2_{|n_1|,\Gamma}. \tag{2.6}$$

Equations (2.5) and (2.6) show that the map $\phi \to u$ is a continuous linear extension operator from $L^2(\Gamma_1; |n_1|\, d\sigma)$ in $H^{1,0}(\Omega)^2$. □

Remark 1. Playing with the parameter η, we can localize the extension of ϕ in an arbitrary neighborhood of (Γ_1).

Figure 6 illustrates the optimality of Lemma 1.

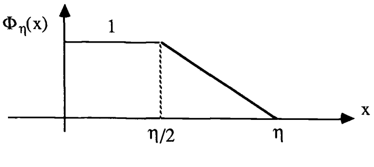

FIG. 5. *The cut-off function* Φ_η.

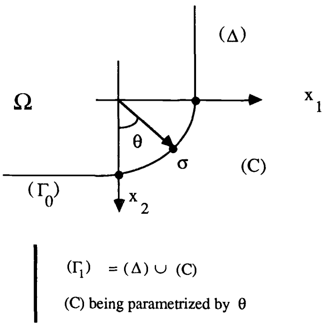

FIG. 6. *A first example.*

If (C) is parametrized by θ we easily check that $n_1(\theta)=\sin\theta$ and that

$$L^2(C;|n_1|\,d\sigma)\equiv\left\{g(\theta):\left[0,\frac{\pi}{2}\right]\to\mathbb{R}\Big/\int_0^{\pi/2}|g(\theta)|^2\sin\theta\,d\theta<+\infty\right\}.$$

Consider the function, for $\alpha>0$,

$$u_\alpha(x_1,x_2)=\Phi(x_1,x_2)\frac{1}{x_2^\alpha},$$

where Φ is a smooth function with compact support, identically equal to 1 in a neighborhood of (C). The trace of u_α can be identified to the function

$$g_\alpha(\theta)=(\sin\theta)^{-\alpha},$$

and we verify immediately that

$$u_\alpha\in H^{1,0}(\Omega)\Leftrightarrow\alpha<\tfrac{1}{2},$$
$$g_\alpha\in L^2(C,|n_1|\,d\sigma)\Leftrightarrow\alpha<\tfrac{1}{2}.$$

2.1.2. An intermediate result: Application to the case where Γ_1 has no strict x_2-extremal point. Let us establish a general result that will be useful in the sequel. For any $1\leqq j\leqq N$, we denote by $B_j(\rho)$ the ball of center M_j and radius ρ (see Fig. 7) and we set

$$\tilde{\Gamma}_{1,\rho}=\Gamma_1\cap\left[\mathbb{R}^2\Big\backslash\bigcup_{j=1}B_j(\rho)\right]. \tag{2.7}$$

We can state the following lemma.

LEMMA 2. *For any $\rho>0$ small enough, the trace operator γ_0 extends uniquely in a linear, continuous, and surjective map from $H^{1,0}(\Omega)$ in $L^2(\tilde{\Gamma}_{1,\rho};|n_1|\,d\sigma)$.*

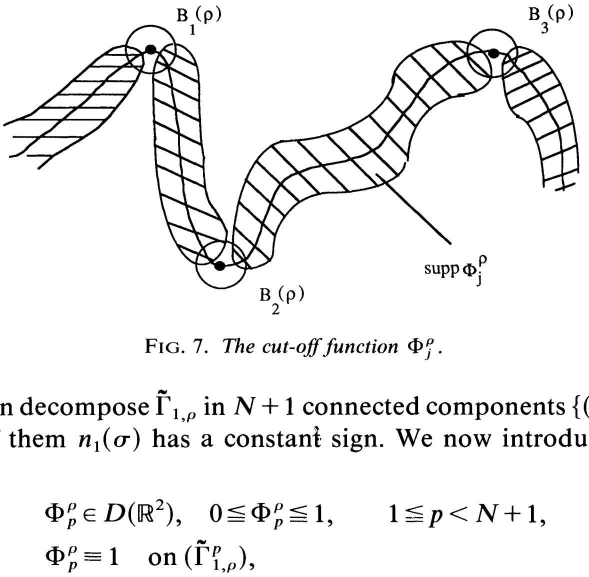

FIG. 7. *The cut-off function Φ_j^ρ.*

Proof. We can decompose $\tilde{\Gamma}_{1,\rho}$ in $N+1$ connected components $\{(\tilde{\Gamma}_{1,\rho}^p),1\leqq p\leqq N+1\}$; along each of them $n_1(\sigma)$ has a constant sign. We now introduce smooth cut-off functions:

$$\begin{aligned}&\Phi_p^\rho\in D(\mathbb{R}^2),\quad 0\leqq\Phi_p^\rho\leqq1,\qquad 1\leqq p<N+1,\\ &\Phi_p^\rho\equiv1\quad\text{on}\,(\tilde{\Gamma}_{1,\rho}^p),\\ &\operatorname{supp}\Phi_p^\rho\cap\operatorname{supp}\Phi_m^\rho=\phi\quad\text{for } p\neq m.\end{aligned}\tag{2.8}$$

On $\tilde{\Gamma}_{1,\rho}$, $\sum_{j=1}^{N+1}\Phi_\rho^p=1$, and we can write

$$\forall u\in D(\bar{\Omega}),\quad \|u\|^2_{|n_1|,\tilde{\Gamma}_{1,\rho}}=\sum_{p=1}^{N+1}\|\Phi_p^\rho u\|_{|n_1|,\tilde{\Gamma}_{1,\rho}^p} \tag{2.9}$$

We apply the Green's formula to each of the functions $\Phi^\rho_p u$:

$$\int_{\tilde\Gamma^p_{1,\rho}} |\Phi^\rho_p u|^2 |n_1|\, d\sigma = 2\left|\int_\Omega \Phi^\rho_p u \frac{\partial}{\partial x_1}(\Phi^\rho_p u)\,dx\right|$$

$$= 2\left|\int_\Omega \left(|\Phi^\rho_p|^2 u\frac{\partial u}{\partial x_1} + \Phi^\rho_p \frac{\partial \Phi^\rho_p}{\partial x_1}|u|^2\right)dx\right|.$$

After summing on p, we get

$$\int_{\tilde\Gamma_{1,\rho}} |u|^2 n_1\,d\sigma \leqq 2\sum_{p=1}^{N+1}\int_\Omega |\Phi^\rho_p|^2\left|u\frac{\partial u}{\partial x_1}\right|dx + 2\sum_{p=1}^{N+1}\int_\Omega \left|\Phi^\rho_p\frac{\partial\Phi^\rho_p}{\partial x_1}\right||u|^2\,dx.$$

So, if we introduce the constant

$$C(\rho) = \max_{1\leqq p\leqq N+1}\left(\max_{\mathbb{R}^2}\left|\frac{\partial\Phi^\rho_p}{\partial x_1}\right|\right), \tag{2.10}$$

it is easy to derive, using Young's and Cauchy-Schwarz's inequalities, the following estimate:

$$\left(\int_{\tilde\Gamma_{1,\rho}} |u|^2|n_1|\,d\sigma\right)^{1/2} \leqq (1+C(\rho))^{1/2}\|u\|_{H^{1,0}}, \tag{2.11}$$

from which the first part of the lemma follows immediately. To prove that γ_0 is surjective it is sufficient to extend locally in Ω each of the restrictions to $(\tilde\Gamma^p_{1,\rho})$ of a function ϕ in the space $L^2(\tilde\Gamma^p_{1,\rho}; |n_1|\,d\sigma)$. This is possible thanks to Remark 1. □

As a direct consequence of Lemma 2, we have the following corollary.

COROLLARY 2. *When Γ_1 has no strict x_2-extremal point, the trace mapping γ_0 is linear, continuous, and surjective from $H^{1,0}(\Omega)$ on to $L^2(\Gamma_1; |n_1|\,d\sigma)$.*

Of course, the constant $C(\rho)$ appearing in the estimate (2.11) blows up when $\rho\to 0$ as soon as $N\neq 0$; indeed, we have to keep the supports of the cut-off functions disjoint. This remark suggests that the result of Corollary 2 cannot be extended to the general case. This is confirmed by the counterexample in Fig. 8.

Consider:

$$u_\alpha(x_1,x_2) = \frac{1}{x_2^\alpha};$$

we see immediately that

$$u_\alpha \in H^{1,0}(\Omega) \Leftrightarrow \alpha < 1,$$

$$\gamma_0 u_\alpha \in L^2(\Gamma_1; |n_1|\,d\sigma) \Leftrightarrow \alpha < \tfrac{1}{2}.$$

For $\frac{1}{2}\leqq\alpha<1$, u_α belongs to $H^{1,0}(\Omega)$, whose trace on Γ_1 is not in $L^2(\Gamma_1; |n_1|\,d\sigma)$.

2.1.3. Study of the traces in a neighborhood of strict x_2-extremal points. Clearly it remains to treat the neighborhoods of the strict x_2-extremal points of (Γ). We shall

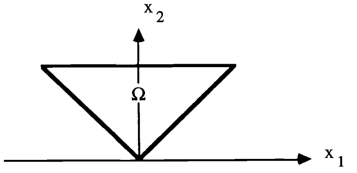

FIG. 8. *A second example.*

need some preliminary notation. Let $M_j = M(\sigma_j)$ be a strict x_2-extremal point of (Γ). As such a point is isolated, the function $\sigma \to X_2(\sigma)$ has a unique relative extremum (strict) at $\sigma = \sigma_j$. So there exists, for any $\varepsilon > 0$ small enough, a pair $\{\sigma_j^-(\varepsilon), \sigma_j^+(\varepsilon)\}$ such that, if for instance $X_2(\sigma_j)$ is minimum of $X_2(\sigma)$,

$$X_2(\sigma)\colon\ [\sigma_j^-(\varepsilon), \sigma_j] \to [X_2(\sigma_j), X_2(\sigma_j)+\varepsilon] \quad \text{is decreasing and surjective,}$$

$$X_2(\sigma)\colon\ [\sigma_j, \sigma_j^+(\varepsilon)] \to [X_2(\sigma_j), X_s(\sigma_j)+\varepsilon] \quad \text{is increasing and surjective.}$$

see Fig. 9.

Therefore, for any x_2 in $[X_2(\sigma_j), X_2(\sigma_j)+\varepsilon]$, there exists a unique pair $(\sigma_-, \sigma_+) \in [\sigma_j^-(\varepsilon), \sigma_j] \times [\sigma_j, \sigma_j^+(\varepsilon)]$, such that $X_2(\sigma^-) = X_2(\sigma^+) = x_2$. In this way we define a bijection $\sigma \to \sigma^+$ between the intervals $[\sigma_j^-(\varepsilon), \sigma_j]$ and $[\sigma_j, \sigma_j^+(\varepsilon)]$, and we can associate to σ_j the open set

$$\Omega(\sigma_j, \varepsilon) = \{]M(\sigma^-), M(\sigma^+)[/x_2 = X_2(\sigma^-) \in]X_2'(\sigma_j), X_2(\sigma_j)+\varepsilon[\}. \tag{2.12}$$

According to the notation of § 1.1, if $M(\sigma^-) = M$, $M(\sigma^+) = M^*$, and conversely. It is clear that:

$$M_j \text{ is outgoing} \Rightarrow \Omega(\sigma_j, \varepsilon) \subset \Omega,$$

$$M_j \text{ is incoming} \Rightarrow \Omega(\sigma_j, \varepsilon) \not\subset \Omega.$$

Let us note that, up to a local change the orientation of (Γ), we can assume that $X_1(\sigma^+) > X_1(\sigma^-)$ as soon as σ^- and σ^+ are related by the bijection shown in Fig. 10. By definition, $\Gamma_1^j(\varepsilon)$ is the part of (Γ) described by $M(\sigma)$ when σ varies in the interval $[\sigma_j^-(\varepsilon), \sigma_j^+(\varepsilon)]$. $\Gamma_1^j(\varepsilon)$ coincides with the "Γ_1 part" of the boundary of $\Omega(\sigma_j, \varepsilon)$.

First of all, let us note that the incoming strict x_2-extremal points do not play any role. This is due to the fact that we can move inside Ω a "horizontal" segment (i.e., parallel to the line $x_2 = 0$) of fixed length η, one of the extremities of the segment describing $\Gamma_1^j(\varepsilon)$ as illustrated in Fig. 11.

In this way, we have defined two disjoint open sets, namely, $\Omega_j^-(\varepsilon, \eta)$ and $\Omega_j^+(\varepsilon, \eta)$, included in Ω, to which we can apply the techniques of Lemmas 1 and 2. Let us define the cut-off functions ϕ_η^+ and ϕ_η^-, respectively, on $\Omega_j^-(\varepsilon, \eta)$ and $\Omega_j^+(\varepsilon, \eta)$ by

$$\phi_\eta^\pm(X_1(\sigma) \pm \xi_1, X_2(\sigma)) = \Phi_\eta(\xi_1), \qquad \xi_1 \in [0, \eta], \tag{2.13}$$

FIG. 11. *Case of an incoming x_2-extremal point.*

where Φ_η has been defined in the proof of Lemma 1. To show that the trace of a function $H^{1,0}(\Omega)$ belongs to $L^2(\Gamma_1^j(\varepsilon), |n_1|\, d\sigma)$, we apply the Green's formula (1.12) to the functions $\phi_\eta^- u$ and $\phi_\eta^+ u$ when u is smooth. To get the surjectivity result, we construct an extension of $\phi(\sigma)$ in $L^2(\Gamma_1^j(\varepsilon), |n_1|\, d\sigma)$ by constructing independently two extensions, respectively in $\Omega_j^-(\varepsilon, \eta)$ and $\Omega_j^+(\varepsilon, \eta)$, of the restrictions of $\phi(\sigma)$ to $\Gamma_1^j(\varepsilon) \cap \partial\Omega_j^-(\varepsilon, \eta)$ and $\Gamma_1^j(\varepsilon) \cap \partial\Omega_j^+(\varepsilon, \eta)$. Therefore the results stated in Lemma 2 and Corollary 2 remain valid if we replace the strict x_2-extremal points of (Γ) by the only outgoing strict x_2-extremal points of (Γ), as described in the following corollary.

COROLLARY 3. *When Γ_1 has no strict outgoing x_2-extremal point, the trace mapping γ_0 is linear, continuous, and surjective from $H^{1,0}(\Omega)$ on to $L^2(\Gamma_1; |n_1|\, d\sigma)$.*

It remains to examine what happens in a neighborhood of strict outgoing x_2-extremal points, which means to make precise the trace theorem for $H^{1,0}(\Omega(\sigma_j, \varepsilon))$. For this, we shall use the function $l(\sigma)$ defined in § 1.1. Restricting ourselves to $\Gamma_1^j(\varepsilon)$, we have

$$(2.14) \qquad l(\sigma^-) = l(\sigma^+) = |X_1(\sigma^+) - X_1(\sigma^-)| \quad \text{for } X_2(\sigma^-) = X_2(\sigma^+) = x_2.$$

We have set here $l(\sigma) = l(M(\sigma))$ and assumed that ε is small enough to ensure that

$$|X_1(\sigma^+) - X_1(\sigma^-)| < 1 \quad \forall \sigma^- \in [\sigma_j^-(\varepsilon), \sigma_j].$$

The example in Fig. 8 suggests that the subspace of $H^{1,0}(\Omega)$ of functions independent of x_1

$$(2.15) \qquad V_1 = \left\{ v \in H^{1,0}(\Omega(\sigma_j, \varepsilon)) \Big/ \frac{\partial v}{\partial x_1} = 0 \right\}$$

has a particular role. Indeed, let us use the following decomposition of $H^{1,0}(\Omega(\sigma_j, \varepsilon))$:

$$H^{1,0}(\Omega(\sigma_j, \varepsilon)) = V_1 + V_1^\perp,$$

where $V_1^\perp$ is nothing but the space of functions in $H^{1,0}$ whose mean value along each segment $[M(\sigma), M(\sigma^+)]$ is equal to zero

$$v \in V_1^\perp \Leftrightarrow \text{a.e. } x_2 = X_2(\sigma^-) = X_2(\sigma^+) \Rightarrow \int_{X_1(\sigma^-)}^{X_1(\sigma^+)} u(x_1, x_2)\, dx_1 = 0.$$

For technical reasons, we shall use another decomposition (nonorthogonal) of $H^{1,0}(\Omega(\sigma_j, \varepsilon))$:

$$(2.16) \qquad H^{1,0}(\Omega(\sigma_j, \varepsilon)) = V_1 + V_2,$$

where V_2 is defined by

$$(2.17) \qquad v \in V_2 \Leftrightarrow \text{p.p. } x_2 = X_2(\sigma^-) = X_2(\sigma^+) \Rightarrow v(M(\sigma^-)) + v(M(\sigma^+)) = 0.$$

Note that the trace of a function in V_1 is necessarily (Γ, x_1)-even while the trace of a function in V_2 is by construction (Γ, x_1)-odd.

LEMMA 3. *The trace mapping* $\gamma_0: D(\overline{\Omega(\sigma_j, \varepsilon)}) \to L^2(\Gamma_1^j(\varepsilon))$ *can be uniquely extended to a linear, continuous, and surjective map from* $H^{1,0}(\Omega(\sigma_j, \varepsilon))$ *onto* $T(\Gamma_1^j(\varepsilon), \Omega(\sigma_j, \varepsilon))$. *More precisely,* γ_0 *is linear, continuous, and surjective from* V_1 *onto* $L^2_{\text{even}}(\Gamma_1^j(\varepsilon), l|n_1|\, d\sigma)$ *and from* V_2 *onto* $L^2_{\text{odd}}(\Gamma_1^j(\varepsilon), l^{-1}|n_1|\, d\sigma)$.

Proof.

(i) *Traces of functions in* V_1. Let v be a function in V_1; its trace on $\Gamma_1^j(\varepsilon)$ is given by

$$\phi(\sigma^-) = \phi(\sigma^+) = v(x_1, x_2) \quad \text{for } x_2 = X_2(\sigma^-) = X_2(\sigma^+). \tag{2.18}$$

The norm of v in $H^{1,0}(\Omega(\sigma_j, \varepsilon))$ coincides with its L^2-norm:

$$\|v\|^2_{H^{1,0}} = \int_{X_2(\sigma_j)}^{X_2(\sigma_j)+\varepsilon} \left(\int_{X_1(\sigma^-)}^{X_1(\sigma^+)} |v(x_1, x_2)|^2\, dx_1 \right) dx_2. \tag{2.19}$$

On the other hand, we have

$$\int_{X_1(\sigma^-)}^{X_1(\sigma^+)} |v(x_1, x_2)|^2\, dx_1 = l(\sigma^-)|\phi(\sigma^-)|^2 = l(\sigma^+)|\phi(\sigma^+)|^2. \tag{2.20}$$

With the help of the two following changes of variables:

$$x_2 = X_2(\sigma^-), \qquad \sigma^- \in [\sigma_j^-(\varepsilon), \sigma_j],$$
$$x_2 = X_2(\sigma^+), \qquad \sigma^+ \in [\sigma_j, \sigma_j^+(\varepsilon)],$$

we obtain the two equalities

$$\begin{aligned} \|v\|^2_{H^{1,0}} &= \int_{\sigma_j^-(\varepsilon)}^{\sigma_j} |\phi(\sigma^-)|^2 l(\sigma^-)|n_1(\sigma^-)|\, d\sigma^-, \\ \|v\|^2_{H^{1,0}} &= \int_{\sigma_j}^{\sigma_j^+(\varepsilon)} |\phi(\sigma^+)|^2 l(\sigma^+)|n_1(\sigma^+)|\, d\sigma^+, \end{aligned} \tag{2.21}$$

which we can add to finally obtain

$$\|\phi\|^2_{l|n_1|, \Gamma_1^j(\varepsilon)} = 2\|v\|^2_{H^{1,0}}, \tag{2.22}$$

from which both the continuity and the bijectivity of γ_0 from V_1 onto $L^2_{\text{even}}(\Gamma_1^j(\varepsilon), l|n_1|\, d\sigma)$ follow immediately.

(ii) *Traces of functions in* V_2. Let v be in V_2. For almost every x_2 in $]X_2(\sigma_j), X_2(\sigma_j)+\varepsilon[$, the function $x_1 \to v(x_1, x_2)$ belongs to $H^1(]X_1(\sigma^-), X_1(\sigma^+)[)$ and satisfies, if $x_2 = X_2(\sigma^-) = X_2(\sigma^+)$,

$$v(X_1(\sigma^-), x_2) + v(X_1(\sigma^+), x_2) = 0.$$

Therefore, as $H^1 \to C^0$ in dimension 1, we know that

$$\text{p.p. } x_2 = X_2(\sigma^-) = X_2(\sigma^+),$$
$$\exists x_0 = X_0(\sigma^-) = X_0(\sigma^+) \in]X_1(\sigma^-), X_1(\sigma^+)[/ v(x_1, x_0) = 0.$$

Thus, if we set $\phi = \gamma_0 v$, we can write

$$\begin{aligned} \phi(\sigma^-) &= -\int_{X_1(\sigma^-)}^{X_0(\sigma^-)} \frac{\partial v}{\partial x_1}(x_1, X_2(\sigma^-))\, dx_1, \\ \phi(\sigma^+) &= -\int_{X_0(\sigma^+)}^{X_1(\sigma^+)} \frac{\partial v}{\partial x_1}(x_1, X_2(\sigma^+))\, dx_1. \end{aligned} \tag{2.23}$$

By the Cauchy-Schwarz inequality, using the fact that $|X_0(\sigma^-)-X_1(\sigma^-)|$ and $|X_0(\sigma^+)-X_1(\sigma^+)|$ are bounded by $l(\sigma^-)=l(\sigma^+)$, we deduce the inequalities

$$\begin{aligned}
&|\phi(\sigma^-)|^2 \leqq l(\sigma^-)\int_{X_1(\sigma^-)}^{X_1(\sigma^+)}\left|\frac{\partial v}{\partial x_1}(x_1, X_2(\sigma^-))\right|^2 dx_1,\\
&|\phi(\sigma^+)|^2 \leqq l(\sigma^+)\int_{X_1(\sigma^-)}^{X_1(\sigma^+)}\left|\frac{\partial v}{\partial x_1}(x_1, X_2(\sigma^+))\right|^2 dx_1.
\end{aligned}\tag{2.24}$$

On the other hand, using successively two change of variables,

$$\begin{aligned}
&(x_1, \sigma^-)\rightarrow(x_1, x_2)=(x_1, X_2(\sigma^-)), \qquad \sigma^-\in[\sigma_j^-(\varepsilon), \sigma_j],\\
&(x_1, \sigma^+)\rightarrow(x_1, x_2)=(x_1, X_2(\sigma^+)), \qquad \sigma^+\in[\sigma_j, \sigma_j^+(\varepsilon)],
\end{aligned}$$

with respective Jacobian $|n_1(\sigma^-)|$ and $|n_1(\sigma^+)|$, we obtain two expressions for the L^2-norm of $\partial v/\partial x_1$:

$$\begin{aligned}
\int_{\Omega(\sigma_j,\varepsilon)}\left|\frac{\partial v}{\partial x_1}\right|^2 dx &= \int_{\sigma_j^-(\varepsilon)}^{\sigma_j}\left(\int_{X_1(\sigma^-)}^{X_1(\sigma^+)}\left|\frac{\partial v}{\partial x_1}(x_1, X_2(\sigma^-))\right|^2 dx_1\right)|n_1(\sigma^-)|\,d\sigma^-\\
&= \int_{\sigma_j}^{\sigma_j^+(\varepsilon)}\left(\int_{X_1(\sigma^-)}^{X_1(\sigma^+)}\left|\frac{\partial v}{\partial x_1}(x_1, X_2(\sigma^+))\right|^2 dx_1\right)|n_1(\sigma^+)|\,d\sigma^+.
\end{aligned}\tag{2.25}$$

Consequently, from (2.24) and (2.25), we deduce

$$\begin{aligned}
&\int_{\sigma_j^-(\varepsilon)}^{\sigma_j}|\phi(\sigma^-)|^2\frac{|n_1(\sigma^-)|}{|l(\sigma^-)|}\,d\sigma^- \leqq \int_{\Omega(\sigma_j,\varepsilon)}\left|\frac{\partial v}{\partial x_1}\right|^2 dx,\\
&\int_{\sigma_j}^{\sigma_j^+(\varepsilon)}|\phi(\sigma^+)|^2\frac{|n_1(\sigma^+)|}{|l(\sigma^+)|}\,d\sigma^+ \leqq \int_{\Omega(\sigma_j,\varepsilon)}\left|\frac{\partial v}{\partial x_1}\right|^2 dx.
\end{aligned}\tag{2.26}$$

Adding these two inequalities, we obtain

$$\|\phi\|^2_{l^{-1}|n_1|,\Gamma_1^j(\varepsilon)} \leqq 2\|v\|^2_{H^{1,0}},\tag{2.27}$$

which proves the continuity of γ_0 from V_2 on to the space $L^2_{\text{odd}}(\Gamma_1^j(\varepsilon), l^{-1}|n_1|\,d\sigma)$ to consider the function v defined by (see Fig. 12)

$$\begin{aligned}
&\partial^2 v/\partial x_1^2=0 \quad \text{in } \Omega(\sigma_j, \varepsilon),\\
&v(X_1(\sigma), X_2(\sigma))=\phi(\sigma) \qquad \sigma\in[\sigma_j^-(\varepsilon), \sigma_j^+(\varepsilon)].
\end{aligned}\tag{2.28}$$

Then a simple calculation gives

$$\begin{aligned}
&\int_{\Omega(\sigma_j,\varepsilon)}|v|^2\,dx=\frac{1}{3}\int_{\Gamma_1^j(\varepsilon)}|\phi(\sigma)|^2|n_1(\sigma)|l(\sigma)\,d\sigma,\\
&\int_{\Omega(\sigma_j,\varepsilon)}\left|\frac{\partial v}{\partial x}\right|^2 dx=\int_{\Gamma_1^j(\varepsilon)}|\phi(\sigma)|^2\frac{|n_1(\sigma)|}{l(\sigma)}\,d\sigma,
\end{aligned}\tag{2.29}$$

which completes the proof of the lemma.

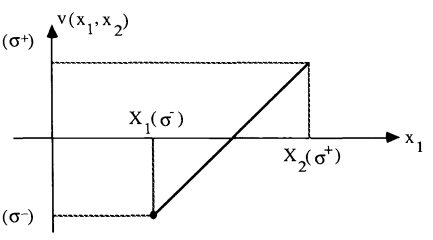

FIG. 12. *The solution of* (2.28).

Now to prove Theorem 1, the main point is to prove the estimate

$$\|\gamma_0 u\|_{T(\Gamma_1,\Omega)} \leqq C\|u\|_{H^{1,0}(\Omega)}$$

for any smooth function u. For this we proceed by localization with the help of a partition of unity. In this way we are able to write u as a finite sum of functions u_k, each of them having compact support, to which we can apply either Corollary 2 or Lemma 3. The difficulties are purely technical and we shall omit the details.

2.2. The proof of Theorem 2. To show that the limit of $\int_{\Gamma\backslash\Gamma_1(\delta)} \phi\psi n_1\, d\sigma$ exists when δ tends to zero, we first write, for $\delta < \varepsilon$,

$$\int_{\Gamma\backslash\Gamma_1(\delta)} \phi\psi n_1\, d\sigma = \int_{\Gamma\backslash\Gamma_1(\varepsilon)} \phi\psi n_1\, d\sigma + \sum_{j\in J_0} \int_{\Gamma_1^j(\varepsilon)\backslash\Gamma_1^j(\delta)} \phi\psi n_1\, d\sigma. \tag{2.30}$$

The only difficulty consists in proving that the limit

$$\lim_{\delta\searrow 0} \int_{\Gamma_1^j(\varepsilon)\backslash\Gamma_1^j(\delta)} \phi\psi n_1\, d\sigma \tag{2.31}$$

exists when j belongs to J_0. Indeed, the integral

$$\int_{\Gamma_1^j(\varepsilon)} \phi\psi n_1\, d\sigma$$

is not defined in the Lebesgue sense because of the possible singularities of ϕ and ψ near $\sigma = \sigma_j$. To overcome this difficulty we write:

$$\phi = \phi_0 + \phi_e, \qquad \psi = \psi_0 + \psi_e,$$

where $((\phi_0, \phi_e), (\psi_0, \psi_e)) \in \{L^2_{\text{odd}}(\Gamma_1^j(\varepsilon), l^{-1}|n_1|\, d\sigma) \times L^2_{\text{even}}(\Gamma_1^j(\varepsilon), l|n_1|\, d\sigma)\}^2$. We have, setting $\Gamma_1^j(\varepsilon, \delta) = \Gamma_1^j(\varepsilon)\backslash\Gamma_1^j(\delta)$,

$$\begin{aligned}\int_{\Gamma_1^j(\varepsilon,\delta)} \phi\psi n_1\, d\sigma &= \int_{\Gamma_1^j(\varepsilon,\delta)} (\phi_0(\sigma)\psi_0(\sigma) + \phi_e(\sigma)\psi_e(\sigma))\, d\sigma \\ &\quad + \int_{\Gamma_1^j(\varepsilon,\delta)} (\phi_0(\sigma)\psi_e(\sigma) + \phi_e(\sigma)\psi_0(\sigma))\, d\sigma.\end{aligned} \tag{2.32}$$

To estimate the second term of the right-hand side of (2.32), we use Cauchy–Schwarz's inequality:

$$\begin{aligned}&\int_{\Gamma_1^j(\varepsilon,\delta)} |\phi_o(\sigma)\psi_e(\sigma) + \phi_e(\sigma)\psi_o(\sigma)|\,|n_1(\sigma)|\, d\sigma \\ &\quad \leqq \|\phi_0\|_{\Gamma_1^j(\varepsilon),l^{-1}|n_1|}\|\psi_e\|_{\Gamma_1^j(\varepsilon),l|n_1|} + \|\phi_e\|_{\Gamma_1^j(\varepsilon),l|n_1|}\|\psi_0\|_{\Gamma_1^j(\varepsilon),l^{-1}|n_1|}.\end{aligned} \tag{2.33}$$

We can thus apply the dominated convergence theorem of Lebesgue and Cauchy–Schwarz's inequality to deduce

$$\begin{aligned}&\lim_{\delta\searrow 0} \int_{\Gamma_1^j(\varepsilon,\delta)} (\phi_o(\sigma)\psi_e(\sigma) + \phi_e(\sigma)\psi_o(\sigma))\, d\sigma \\ &\quad = \int_{\Gamma_1^j(\varepsilon)} (\phi_o(\sigma)\psi_e(\sigma) + \phi_e(\sigma)\psi_o(\sigma))\, d\sigma\end{aligned} \tag{2.34}$$

$$\begin{aligned}&\int_{\Gamma_1^j(\varepsilon)} (\phi_o(\sigma)\psi_e(\sigma) + \phi_e(\sigma)\psi_o(\sigma))\, d\sigma \\ &\quad \leqq \|\phi\|_{T(\Gamma_1^j(\varepsilon),\Omega(\sigma_j,\varepsilon))}\|\psi\|_{T(\Gamma_1^j(\varepsilon),\Omega(\sigma_j,\varepsilon))}\end{aligned} \tag{2.35}$$

For the first term of the right-hand side of (2.32), we remark that the function $\theta(\sigma) = \phi_o(\sigma)\psi_o(\sigma) + \phi_e(\sigma)\psi_e(\sigma)$ is (Γ, x_1)-even. Now suppose that for instance $X_2(\sigma_j)$

is a local minimum of $X_2(\sigma)$; with a suitable orientation of (Γ) we can assume that (see Fig. 13)

$$n_1(\sigma)=\frac{dX_2}{d\sigma}(\sigma)<0 \quad \text{if } \sigma\in[\sigma_j^-(\varepsilon), \sigma_j],$$

$$n_1(\sigma)=\frac{dX_2}{d\sigma}(\sigma)>0 \quad \text{if } \sigma\in[\sigma_j, \sigma_j^+(\varepsilon)].$$

We then write

$$\int_{\Gamma_1^j}\theta(\sigma)n_1(\sigma)\,d\sigma=\int_{\sigma_j^-(\varepsilon)}^{\sigma_j^-(\delta)}\theta(\sigma)n_1(\sigma)\,d\sigma+\int_{\sigma_j^+(\delta)}^{\sigma_j^+(\varepsilon)}\theta(\sigma)n_1(\sigma)\,d\sigma.$$

With the following changes of variable:

$$x_2=X_2(\sigma^-) \quad \text{if } \sigma^-\in[\sigma_j^-(\varepsilon), \sigma_j^-(\delta)],$$

$$x_2=X_2(\sigma^+) \quad \text{if } \sigma^+\in[\sigma_j^+(\delta), \sigma_j^+(\varepsilon)],$$

we obtain, taking into account the fact that the sign of $n_1(\sigma)$ changes from $[\sigma_j^-(\varepsilon), \sigma_j^-(\delta)]$ to $[\sigma_j^+(\delta), \sigma_j^+(\varepsilon)]$,

$$\int_{\Gamma_1^j(\varepsilon,\delta)}\theta(\sigma)n_1(\sigma)\,d\sigma=\int_{X_2(\sigma_j)+\delta}^{X_2(\sigma_j)+\varepsilon}[\theta(\sigma^+)-\theta(\sigma^-)]\,dx_2.$$

But, as θ is (Γ, x_1)-even, $\theta(\sigma^+)=\theta(\sigma^-)$, so that we have:

$$\forall\delta<\varepsilon, \quad \int_{\Gamma_1^j(\varepsilon,\delta)}(\phi_0(\sigma)\psi_o(\sigma)+\phi_e(\sigma)\psi_e(\sigma))\,d\sigma=0. \tag{2.36}$$

Joining this result to (2.34) shows that limit (2.31) does exist and is given by

$$\text{v.p. } x_2\int_{\Gamma_1^j(\varepsilon)}\phi(\sigma)\psi(\sigma)n_1(\sigma)\,d\sigma=\int_{\Gamma_1^j(\varepsilon)}(\phi_o(\sigma)\psi_e(\sigma)+\phi_e(\sigma)\psi_o(\sigma))\,d\sigma.$$

Moreover, the inequality (2.35) shows that the bilinear form

$$(\phi, \psi)\to\text{v.p. } x_2\int_{\Gamma_1^j(\varepsilon)}\phi(\sigma)\psi(\sigma)n_1(\sigma)\,d\sigma$$

is continuous on $T(\Gamma_1^j(\varepsilon), \Omega(\sigma_j, \varepsilon))$.

The general result is then a consequence of the equality (2.30). To obtain formula (1.14), it suffices to take the limit in Green's formula (1.12) written with a sequence

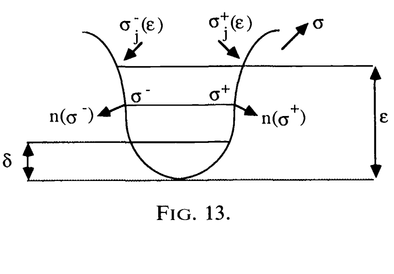

FIG. 13.

$(u_\varepsilon, v_\varepsilon)$ in $D(\bar{\Omega})^2$ converging to (u, v) in $H^{1,0}(\Omega)$ when $\varepsilon \to 0$, and to use the continuity of the bilinear forms

$$(u, v) \to \int_\Omega \left(\frac{\partial u}{\partial x_1} v + u \frac{\partial v}{\partial x_1}\right) dx,$$

$$(\phi, \psi) \to \text{v.p. } x_2 \int_{\Gamma_1} \phi(\sigma)\psi(\sigma) n_1(\sigma)\, d\sigma$$

in $H^{1,0}(\Omega)$ and $T(\Gamma_1, \Omega)$, respectively. □

3. Generalization to the spaces $W_p^{1,0}(\Omega)$ and $H^{S,0}(\Omega)$.

3.1. The trace theorem in $W_p^{1,0}(\Omega)$. For any $1 < p < +\infty$, we define the space $W_p^{1,0}(\Omega)$ by

$$W_p^{1,0}(\Omega) = \left\{ u \in L^p(\Omega) \Big/ \frac{\partial u}{\partial x_1} \in L^p(\Omega) \right\}, \tag{3.1}$$

which is a Banach space equipped with the norm

$$\|u\|_{W_p^{1,0}} = \left(\|u\|_{L^p}^p + \left\| \frac{\partial u}{\partial x_1} \right\|_{L^p}^p \right)^{1/p}. \tag{3.2}$$

With the notation and definitions of § 1, we define

$$T_p(\Gamma_1, \Omega) = L^p_{\text{odd}}(\Gamma_1; l^{1-p}|n_1|) \oplus L^p_{\text{even}}(\Gamma_1; l|n_1|) \tag{3.3}$$

where the weighted L^p-spaces $L^p_{\text{odd}}(\Gamma_1^j(\varepsilon), m)$ and $L^p_{\text{even}}(\Gamma_1^j(\varepsilon), m)$ are defined as $L^2_{\text{odd}}(\Gamma_1^j(\varepsilon), m)$ and $L^2_{\text{even}}(\Gamma_1^j(\varepsilon), m)$ (see § 1.1) by simply replacing 2 by p.

Of course, $T_p(\Gamma_1, \Omega)$ is a Banach space for the norm ($\phi = \phi_o + \phi_e$):

$$\|\phi\|_{T_p(\Gamma_1,\Omega)} = \|\phi_o\|_{L^p(\Gamma_1, l^{1-p}|n_1|)} + \|\phi_e\|_{L^p(\Gamma_1, l|n_1|)} \tag{3.4}$$

and, for ϕ in $L^p(C, m)$, $C \subset \Gamma$:

$$\|\phi\|_{L^p(C,m)} = \left(\int_C |\phi(\sigma)|^p m(\sigma)\, d\sigma \right)^{1/p}. \tag{3.5}$$

We can now state our two results in Theorems 3 and 4.

THEOREM 3. *The trace mapping $\gamma_0: D(\bar{\Omega}) \to L^p(\Gamma_1)$ can be uniquely extended to a linear, continuous and surjective map, still denoted by γ_0, from $W_p^{1,0}(\Omega)$ onto $T_p(\Gamma_1, \Omega)$.*

Proof of Theorem 3. The proof is very similar to that of Theorem 2 (§ 2). We simply point out the differences with the L^2-case.

Step 1. *Case where $n_1(\sigma)$ has a constant sign.* Take $v = |u|^{p-2}u$ in Green's formula (1.12) and use Holder's inequality instead of the Cauchy-Schwarz inequality to get the extension and continuity results. The surjectivity result can be obtained exactly as in the two-dimensional case.

Step 2. *An intermediate result.* There is no significant difference with the L^2-case.

Step 3. *The general case.* As in the L^2-case, only the strict outgoing x_2-extremal points have a role. We must study the space $W_p^{1,0}(\Omega(\sigma_j, \varepsilon))$, which we break down as follows:

$$W_p^{1,0}(\Omega(\sigma_j, \varepsilon)) = V_{1,p} + V_{2,p},$$

where $V_{1,p}$ and $V_{2,p}$ are defined as V_1 and V_2 (see § 2.1) by simply replacing 2 by p. The specific result concerning $W_p^{1,0}(\Omega)$ can be stated as in the following lemma.

LEMMA 4. *The trace mapping γ_0 extends in a unique way to a linear continuous and surjective map from $W_p^{1,0}(\Omega(\sigma_j, \varepsilon))$ onto $T_p(\Gamma_1^j(\varepsilon), \Omega(\sigma_j, \varepsilon))$. γ_0 is bijective and continuous from $V_{1,p}$ onto $L^p_{\text{even}}(\Gamma_1^j(\varepsilon), l|n_1|)$ and from $V_{2,p}$ onto $L^p_{\text{odd}}(\Gamma_1^j\varepsilon), l^{1-p}|n_1|)$.*

Proof. We only point out the differences with the proof of Lemma 3 (§ 2.1).

(i) *Traces of functions in $V_{1,p}$.* The L^p and $W_p^{1,0}$ norms of such functions coincide. With the notation of the proof of Lemma 3, we have

$$\int_\Omega |v(x_1, x_2)|^p \, dx = \int_{\sigma_j-\varepsilon}^{\sigma_j} |\phi(\sigma)|^p l(\sigma)|n_1(\sigma)| \, d\sigma$$

$$= \int_{\sigma_j}^{\sigma_j+\varepsilon} |\phi(\sigma)|^p l(\sigma)|n_1(\sigma)| \, d\sigma,$$

from which we deduce the identity

$$\|\gamma_0 v\|_{L^p(\Gamma_1^j(\varepsilon), l|n_1|)} = 2^{-1/p} \|v\|_{W_p^{1,0}};$$

from this the first part of the lemma is a direct consequence.

(ii) *Traces of functions in $V_{2,p}$.* Keeping the notation of the proof of Lemma 3, we write

$$\phi(\sigma^-) = -\int_{X_1(\sigma^-)}^{X_0(\sigma^-)} \frac{\partial v}{\partial x_1}(x_1, X_2(\sigma^-)) \, dx_1, \qquad \sigma^- \in [\sigma_j^-(\varepsilon), \sigma_j],$$

$$\phi(\sigma^+) = \int_{X_0(\sigma^+)}^{X_1(\sigma^+)} \frac{\partial v}{\partial x_1}(x_1, X_2(\sigma^+)) \, dx_1, \qquad \sigma^+ \in [\sigma_j, \sigma_j^+(\varepsilon)].$$

Using Holder's inequality we get, if $1/p + 1/q = 1$,

$$|\phi(\sigma^-)| \leqq l(\sigma^-)^{1/q} \left(\int_{X_1(\sigma^-)}^{X_1(\sigma^+)} \left| \frac{\partial v}{\partial x_1}(x_1, X_2) \right|^p d\sigma \right)^{1/p},$$

$$|\phi(\sigma^+)| \leqq l(\sigma^+)^{1/q} \left(\int_{X_1(\sigma^-)}^{X_1(\sigma^+)} \left| \frac{\partial v}{\partial x_1}(x_1, X_2) \right|^p d\sigma \right)^{1/p}.$$

Following the proof of Lemma 3, we easily get the two inequalities

$$\int_{\sigma_j^-(\varepsilon)}^{\sigma_j} |\phi(\sigma^-)|^p l(\sigma^-)^{-p/q} \, d\sigma^- \leqq \int_{\Omega(\sigma_j, \varepsilon)} \left| \frac{\partial v}{\partial x_1} \right|^p dx,$$

$$\int_{\sigma_j}^{\sigma_j^+(\varepsilon)} |\phi(\sigma^+)|^p l(\sigma^+)^{-p/q} \, d\sigma^+ \leqq \int_{\Omega(\sigma_j, \varepsilon)} \left| \frac{\partial v}{\partial x_1} \right|^p dx.$$

As $-p/q = 1 - p$, we finally get

$$\int_{\Gamma_1^j(\varepsilon)} |\phi(\sigma)|^p l(\sigma)^{1-p} \, d\sigma \leqq 2\|v\|^p_{W_0^{1,p}},$$

which proves the continuity of γ_0 from $V_{2,p}$ in $L^p_{\text{odd}}(\Gamma_1^j(\varepsilon), l^{1-p}|n_1|)$. To get the surjectivity result, we take exactly the same extension (2.28) as in the L^2-case.

Explicit calculations give

$$\int_{\Omega(\sigma_j, \varepsilon)} |v|^p \, dx = \frac{2^{-p}}{p+1} \int_{\Gamma_1^j(\varepsilon)} |\phi(\sigma)|^p l(\sigma)|n_1(\sigma)| \, d\sigma,$$

$$\int_{\Omega(\sigma_j, \varepsilon)} \left| \frac{\partial v}{\partial x_1} \right|^p dx = 2^{-p} \int_{\Gamma_1^j(\varepsilon)} |\phi(\sigma)|^p l(\sigma)|n_1(\sigma)| \, d\sigma,$$

which proves that the map $\phi \to v$ defined by (2.28) is a continuous extension operator from $L^2_{\text{odd}}(\Gamma_1^j(\varepsilon), l^{1-p}|n_1|)$ in $V_{2,p}$. This completes the proof of Lemma 4. □

From steps 1, 2, and 3, it is then easy to complete the proof of Theorem 3. □

THEOREM 4. *Let (p, q) in $[1, \infty)^2$ such that $1/p + 1/q = 1$.*

(i) *For any (ϕ, ψ) in $T_p(\Gamma_1, \Omega) \times T_q(\Gamma_1, \Omega)$ the limit*

$$(3.6) \qquad \lim_{\delta \searrow 0} \int_{\Gamma_1 \setminus \Gamma_1(\delta)} \phi\psi n_1 \, d\sigma \overset{\text{def}}{=} \text{v.p. } x_2 \int_{\Gamma_1} \phi\psi n_1 \, d\sigma$$

exists and the bilinear form $(\phi, \psi) \to \text{v.p. } x_2 \int_{\Gamma_1} \phi\psi n_1 \, d\sigma$ is continuous.

(ii) *We have the following Green's formula:*

$$(3.7) \qquad \begin{gathered} \forall (u, v) \in W_p^{1,0}(\Omega) \times W_q^{1,0}(\Omega) \\ \int_\Omega \left(u \frac{\partial v}{\partial x_1} + v \frac{\partial u}{\partial x_1} \right) dx = \text{v.p. } x_2 \int_{\Gamma_1} \gamma_0 u \gamma_0 v n_1 \, d\sigma. \end{gathered}$$

Proof of Theorem 4. This proof is very similar to that of Theorem 2. The only point is to check that the spaces $T_p(\Gamma_1, \Omega)$ and $T_q(\Gamma_1, \Omega)$ are each other's dual. To obtain this property, take for instance ϕ in $L^p(\Gamma_1^j(\varepsilon), l|n_1|)$ and ψ in $L^q(\Gamma_1^j(\varepsilon), l^{1-q}|n_1|)$ such that ϕ and ψ are zero in a neighborhood of σ_j. We can write

$$\int_{\Gamma_1^j} \phi(\sigma)\psi(\sigma)|n_1(\sigma)| \, d\sigma = \int_{\Gamma_1^j} \phi(\sigma) l(\sigma)^{1/p} |n_1(\sigma)|^{1/p} \psi(\sigma) l(\sigma)^{-1/p} |n_1(\sigma)|^{1/q} \, d\sigma.$$

By Holder's inequality, we have

$$\left|\left|\int_{\Gamma_1^j(\varepsilon)} \phi(\sigma)\psi(\sigma)n_1(\sigma) \, d\sigma\right| \leqq \left(\int_{\Gamma_1^j(\varepsilon)} |\phi(\sigma)|^p l(\sigma) |n_1(\sigma)| \, d\sigma \right)^{1/p} \cdot \left(\int_{\Gamma_1^j(\varepsilon)} |\psi(\sigma)|^q l(\sigma)^{-q/p} |n_1(\sigma)| \, d\sigma \right)^{1/q}.\right.$$

Remarking that $-q/p = 1 - q$, we get, by density,

$$(3.8) \qquad \begin{gathered} \forall (\phi, \psi) \in L^p(\Gamma_1^j(\varepsilon), l|n_1| \, d\sigma) \times L^q(\Gamma_1^j(\varepsilon), l^{1-q}|n_1| \, d\sigma), \\ \left|\left|\int_{\Gamma_1^j(\varepsilon)} \phi(\sigma)\psi(\sigma)n_1(\sigma) \, d\sigma\right| \leqq \|\phi\|_{L^p(\Gamma_1^j(\varepsilon), l|n_1|)} \|\psi\|_{L^q(\Gamma_1^j(\varepsilon), l^{1-q}|n_1|)}.\right. \end{gathered}$$

Reciprocally, it is also easy to prove that

$$(3.9) \qquad \begin{gathered} \forall (\phi, \psi) \in L^p(\Gamma_1^j(\varepsilon), l^{1-p}|n_1| \, d\sigma) \times L^q(\Gamma_1^j(\varepsilon), l|n_1| \, d\sigma), \\ \left.\int_{\Gamma_1^j(\varepsilon)} \phi(\sigma)\psi(\sigma)n_1(\sigma) \, d\sigma\right| \leqq \|\phi\|_{L^p(\Gamma_1^j(\varepsilon), l^{1-p}|n_1|)} \|\psi\|_{L^q(\Gamma_1^j(\varepsilon), l^q|n_1|)}. \end{gathered}$$

With the help of (3.10) and (3.11) it is easy to conclude as in the proof of Theorem 2. □

3.2. The trace theorem in $H^{s,0}(\Omega)$. We first define the spaces $H^{m,0}(\Omega)$, when m is an integer:

$$(3.10) \qquad H^{m,0}(\Omega) = \left\{ v \in L^2(\Omega) / \forall k \leqq m, \frac{\partial^k v}{\partial x_1^k} \in L^2(\Omega) \right\},$$

$$(3.11) \qquad \|u\|^2_{H^{m,0}} = \sum_{k=1}^{m} \left\| \frac{\partial^k v}{\partial x_1^k} \right\|^2_{L^2},$$

and the space $H^{s,0}(\Omega)$ for $s>0$, with the help of the interpolation theory (see [8]) in Hilbert spaces:

$$\theta \in]0,1[\; H^{m+\theta,0}(\Omega)=[H^{m,0}(\Omega), H^{m+1,0}(\Omega)]_\theta. \tag{3.12}$$

We define by this way a family of Hilbert spaces. If we set

$$I_2=\{x_2\in \mathbb{R}/\exists x_1 \in \mathbb{R} \text{ s.t. } (x_1,x_2)\in\Omega\},$$
$$\Omega(x_2)=\{x_1\in\mathbb{R}/(x_1,x_2)\in\Omega\} \quad \text{when } x_2\in\Omega,$$

it is not difficult to see that the space $H^{s,0}(\Omega)$ can be characterized by:

$$H^{s,0}(\Omega)=\{v\in L^2(\Omega)/v(\cdot,x_2)\in L^2(I_2;H^s(\Omega(x_2)))\} \tag{3.13}$$

and that the norm of $H^{s,0}(\Omega)$ (given by the interpolation theory) is equivalent to the norm

$$\|v\|^2_{H^{s,0}}=\int_{I_2}\|v(\cdot,x_2)\|^2_{H^s(\Omega(x_2))}\,dx_2. \tag{3.14}$$

We now define the trace spaces $T^s(\Gamma_1,\Omega)$ for $s>\frac{1}{2}$ by

$$\begin{aligned} T^s(\Gamma_1,\Omega)&=L^2_{\text{even}}(\Gamma_1, l|n_1|)\oplus L^2_{\text{odd}}(\Gamma_1, l^{1-2s}|n_1|) && \text{if } \tfrac12<s\leqq 1,\\ T^s(\Gamma_1,\Omega)&=T^1(\Gamma_1,\Omega) && \text{if } s\geqq 1,\end{aligned} \tag{3.15}$$

which we equip with its natural Hilbert-space norm.

Our precise result is given in the following theorem.

THEOREM 5. *The trace mapping γ_0 extends uniquely to a linear, continuous mapping from $H^{s,0}(\Omega)$ onto $T^s(\Gamma_1,\Omega)$ for any real $s>\frac{1}{2}$.*

Proof of Theorem 5. The case $s\geqq 1$ is trivial and so we shall treat only the case $\frac12<s<1$.

As for Theorem 3, we shall only indicate the technical differences from the proof of Theorem 1.

Step 1. *Case where $n_1(s)$ has a constant sign.* We use the notation of the proof of Theorem 1. We use the trace theorem in $H^s(\mathbb{R}^+)$,

$$|u(0)|\leqq C(s)\|u\|_{H^s(\mathbb{R}^+)},$$

to write that, if $x_2=X_2(s)\in I_2$,

$$|u(X_1(\sigma),X_2(\sigma))|^2\leqq C(s)^2\|u(\cdot,x_2)\|^2_{H^s(X_1(s),+\infty)}.$$

Integrating over x_2 in I_2 and using the change of variable $x_2=X_2(s)$, we obtain

$$\int_{\Gamma_1}|\gamma_0u(\sigma)|^2|n_1(\sigma)|\,d\sigma\leqq C(s)\|u\|^2_{H^{s,0}},$$

which gives the unique extension and continuity results. The surjectivity result is obtained exactly as in the L^2 case, thanks to interpolation arguments.

Step 2. *An intermediate result.* To obtain the equivalent of Lemma 2, we apply the previous result to each of the functions $\Phi^\rho_p u$ (see the proof of Lemma 2) for which we have

$$\int_{\Gamma_1}|\Phi^\rho_p u(\sigma)|^2|n_1(\sigma)|\,d\sigma\leqq C(s)^2\|\Phi^\rho_p u\|^2_{H^{s,0}}.$$

We have (with the same notation as in the proof of Lemma 2)

$$\|\Phi_p^\rho u\|_{L^2} \leqq C(s)\|u\|_{L^2},$$
$$\|\Phi_p^\rho u\|_{H^{1,0}} \leqq C(s)(1+C(\rho))^{1/2}\|u\|_{H^{1,0}}.$$

By interpolation we easily get

$$\|\Phi_p^\rho u\|_{H^{s,0}} \leqq C(s)(1+C(\rho))^{s/2}\|u\|_{H^{s,0}}.$$

It is then easy to see that the result of Lemma 2 can be generalized to $H^{s,0}(\Omega)$ by simply replacing $(1+C(\rho))^{s/2}$ by $C(s)(1+C(\rho))^{s/2}$.

Step 3. *General case.* The main difference with the L^2 case comes from the study of the space $H^{s,0}(\Omega(\sigma_j, \varepsilon))$. The essential of the proof is contained in the following technical lemma.

LEMMA 5. *Let* $s > \frac{1}{2}$ *and let* u *in* $H^s(0, L)$ *be such that* $u(0)+u(L)=0$; *then we have the estimate*

$$|u(0)| \leqq C(s)L^{s-1/2}\|u\|_{H^s(0,L)}.$$

Proof. Let us use a particular representation of $H^s(0, L)$. Let us introduce the self-adjoint operator A in $L^2(0, L)$ defined by:

$$D(A) = \left\{u \in H^2(0, L) \Big/ \frac{du}{dx}(0) = \frac{du}{dx}(L) = 0\right\}, \tag{3.16}$$
$$Au = -\frac{d^2u}{dx^2}.$$

It is well known (see [11], for instance) that the form-domain of A is given by

$$D(A^{1/2}) = H^1(0, L) \tag{3.17}$$

and that the spectrum of A is

$$\sigma(A) = \left\{\frac{n^2\pi^2}{L^2}, n \in \mathbb{N}\right\}.$$

The corresponding basis of eigenfunctions of A is given by

$$w_n(x) = \sqrt{\frac{2}{L}}\cos\left(\frac{n\pi x}{L}\right).$$

Of course we have, for $u = \sum_{n=0}^{+\infty} u_n w_n$ in $D(A)$,

$$\|u\|^2_{L^2(0,L)} = \sum_{n=0}^{+\infty} |u_n|^2,$$

$$\|u\|^2_{H^1(0,L)} = \sum_{n=0}^{+\infty}\left(1+\frac{n^2\pi^2}{L^2}\right)^2 |u_n|^2.$$

From the interpolation theory, we know that:

$$D(A^{s/2}) = \left\{u = \sum_{n=0}^{+\infty} u_n w_n \Big/ \sum n^{2s}|u_n|^2 < +\infty\right\}.$$

But as $D(A^{1/2}) = H^1(0, L)$ by interpolation, $D(A^{s/2}) = H^s(0, L)$ and we can write

$$\|u\|^2_{H^s(0,L)} = \sum_{n=0}^{+\infty}\left(1+\frac{n^2\pi^2}{L^2}\right)^s |u_n|^2. \tag{3.18}$$

Now, let $u(x)$ be a smooth function such that $u(0)+u(L)=0$. There exists x_0 such that $u(x_0)=0$, so that we can write

$$u(0)=u(0)-u(x_0)=\sqrt{\frac{2}{L}}\sum_{n=1}^{+\infty}\left(1-\frac{\cos n\pi x_0}{L}\right)u_n.$$

Therefore,

$$|u(0)|\leqq 2\sqrt{\frac{2}{L}}\sum_{n=1}^{+\infty}|u_n|=2\sqrt{\frac{2}{L}}\sum_{n=1}^{+\infty}\frac{L^s}{\pi^s n^s}\,\frac{\pi^s n^s u_n}{L^s}.$$

By Cauchy–Schwartz's inequality, it follows that

$$|u(0)|^2\leqq 8L^{2s-1}\left(\sum_{n=1}^{+\infty}\frac{1}{n^{2s}}\right)\left(\sum_{n=1}^{+\infty}\frac{n^{2s}\pi^{2s}u_n^2}{L^{2s}}\right),$$

which gives the lemma with $C(s)=2\sqrt{2}(\sum_{n=1}^{+\infty}1/n^{2s})^{1/2}$. □

Now we break down $H^{s,0}(\Omega(\sigma_j,\varepsilon))$ as

$$H^{s,0}(\Omega(\sigma_j,\varepsilon))=V_1^s+V_2^s,$$

$$V_1^s=\left\{u\in H^s(\Omega(\sigma_j,\varepsilon))\Big/\frac{\partial u}{\partial x_1}=0\right\},$$

$$V_2^s=\{u\in H^s(\Omega(\sigma_j,\varepsilon))/\text{p.p. } x_2=X_2(\sigma^-)=X_s(\sigma^+),$$
$$u(M(\sigma^-))+u(M(\sigma^+))=0\}.$$

As the L^2 norm and the $H^{s,0}$ norm of a function in V_1^s coincide, it is easy to see that γ_0 is an isomorphism between V_1^s and $L^2_{\text{even}}(\Gamma_1^j(\varepsilon), l|n_1|)$.

With the help of Lemma 5, it is easy to prove that γ_0 is continuous from V_2^s in $L^2_{\text{odd}}(\Gamma_1^j(\varepsilon), l^{1-2s}|n_1|)$. Finally, the surjectivity result is obtained exactly with the extension operator defined by (2.28).

The complete result is proved by localization with the help of a partition of unity. □

GLOBAL EXISTENCE OF WEAK SOLUTIONS FOR INTERFACE EQUATIONS COUPLED WITH DIFFUSION EQUATIONS*

YOSHIKAZU GIGA†, SHUN'ICHI GOTO‡, AND HITOSHI ISHII§

Abstract. A weak formulation for an interface dynamics coupled with a diffusion equation is introduced. A global-in-time weak solution is constructed for an arbitrary initial data under a periodic boundary condition. The result applies to the interface equation obtained as a certain singular limit of some reaction-diffusion systems including the activator-inhibitor model.

Key words. interface equation with diffusion equation, global existence, viscosity solution

AMS(MOS) subject classifications. 35K55, 35K57, 35K65

1. Introduction. In this paper we are concerned with interface equations coupled with diffusion equations. A typical example is formally obtained as a certain singular limit of a class of reaction diffusion systems [XYC]. Our main objective is to construct a global-in-time weak solution for the initial value problem of these interface equations.

Let $\Omega_\pm(t)$ be two disjoint open sets in $\mathbb{R}^n$ depending on time t. The complement of the union of $\Omega_+(t)$ and $\Omega_-(t)$ is called the interface and denoted by $\Gamma(t)$. To write down the equation we assume that the interface $\Gamma(t)$ is a smooth hypersurface so that $\Gamma(t)$ is the boundary of $\Omega_\pm(t)$. Let $V=V(t,x)$ denote the speed of $\Gamma(t)$ at $x\in\Gamma(t)$ in the normal direction $\vec{n}$ from $\Omega_+(t)$ to $\Omega_-(t)$. Let $\kappa(=\operatorname{div}\vec{n})$ denote ($n-1$ times) the mean curvature of $\Gamma(t)$ at $x\in\Gamma(t)$. We consider an interface equation for $\Gamma(t)$:

$$V=W(v)-c\kappa \quad \text{on } \Gamma(t) \tag{1.1}$$

coupled with a diffusion equation for $v=v(t,x)$:

$$v_t=D\Delta v+g_\pm(v), \qquad x\in\Omega_\pm(t), \quad t>0, \tag{1.2}$$

where $c\geqq 0$ and $D>0$ are constants. Here $g_\pm$ and W are given bounded continuous functions on $\mathbb{R}$. We also impose a condition that $v(t)=v(t,\cdot)$ is continuous in $\mathbb{R}^n$ with its first derivatives, i.e.,

$$v(t)=v(t,\cdot)\in C^1(\mathbb{R}^n) \quad \text{for } t>0. \tag{1.3}$$

Our goal is to construct a global solution of the initial value problem for interface equations coupled with diffusion equations—a typical example of which is (1.1)-(1.3). It is intrinsically difficult to construct a global solution $(\Omega_\pm(t), v(t))_{t\geqq 0}$ since $\Gamma(t)$ may have singularities in finite time. If v is a constant so that $g_\pm(v)=0$, (1.1)-(1.3) becomes

$$V=C-c\kappa, \tag{1.4}$$

where C is a constant. If $C=0$ and $c>0$, (1.4) becomes

$$V=-c\kappa, \tag{1.5}$$

which is called the mean curvature flow equation. Even for (1.5) Grayson [Gr] gives an example of a barbell in $\mathbb{R}^3$ with a long, thin handle that actually pinches off in finite time. To track the whole evolution of interface we interpret $\Gamma(t)$ as a level set of viscosity solution of some second order evolution equations as in [CGG]. In fact Y.-G. Chen and the first two authors [CGG] constructed a *unique* global weak solution with arbitrary initial data for a class of interface equations, including (1.4) and (1.1), where v only depends on time (see [GG1] for interface equations that the theory in [CGG] applies to). At nearly the same time, Evans and Spruck [ES1] constructed the same solution but only for (1.5). Another formulation closely related to [CGG] and [ES1] is given in [S]. We refer to [ES2] and [GG2] for further development of the theory and references. We note that the idea of using level sets of viscosity solutions for $V=C$ is also found in an unpublished paper of Barles [B].

Although the interface equation admits a global weak solution, $\Gamma(t)$ may develop an interior (Remark 2.5). We introduce a generalized formulation of (1.2)-(1.3). For technical reasons we impose a periodic boundary condition. In this paper, we construct a global weak solution of the initial value problem for (1.1)-(1.3) with arbitrary initial data $(\Gamma(0), v(0,x))$, $v(0,x)\in C^2$ under the periodic boundary condition (Theorem 4.6). (We may assume $D=1$ without loss of generality.) For this purpose, for a given v, we construct a unique global weak solution for (1.1). The basic idea is the same in [CGG], but we are forced to use results in [GGIS] since v may depend on x as well as t. We solve (1.2)-(1.3) with the above v and $\Omega_\pm(t)$ determined by (1.1) with the initial condition. If we write the solution by w, we have a mapping $v\mapsto w$. Since our weak formulation forces us to interpret the mapping $v\mapsto w$ as a multivalued mapping, we use Kakutani (-Ky Fan's) fixed point theory (see [AF]) to get a global generalized solution as a fixed point of the mapping $v\mapsto w$. Our results apply to the system (1.2), (1.3) with (1.1) replaced by more general interface equations, including anisotropic motion (cf. [Gu1], [Gu2], [C]). We do not know the uniqueness of our solutions.

Let us mention some results on (1.1)-(1.3) that are related to ours. In [XYC], X.-Y. Chen constructed a unique local smooth solution for a smooth initial data $(\Gamma(0), v(0,x))$ in $\mathbb{R}^n$ when $c>0$. When $n=1$, the curvature term in (1.1) disappears. Hilhorst, Nishiura, and Mimura [HNM] constructed a global unique solution for (1.1)-(1.3) when the interface is a point and $n=1$ under the Neumann boundary condition. Their interface is C^1 in time. After this work was completed, we learned of the recent paper of X. Chen [XC2], which extends the local existence results [XYC] to the case $c=0$. Our result seems to be a first global result even for (1.1)-(1.3) with $c>0$ or $c=0$ when $n>1$.

Interface equations and reaction-diffusion equations are closely related (see [F]). Typical examples of the system (1.1)-(1.3) are formally provided as a singular limit of reaction-diffusion equations (see [OMK] and [XYC]). We will explain it more explicitly by following [XYC]. We consider a reaction-diffusion system describing the activator-inhibitor model:

$$u_t=\varepsilon\Delta u+\frac{1}{\varepsilon}f(u,v), \qquad x\in\mathbb{R}^n, \quad t>0, \tag{1.6}$$

$$v_t=D\Delta v+g(u,v), \qquad x\in\mathbb{R}^n, \quad t>0, \tag{1.7}$$

with

$$f(u,v)=f_0(u)-v, \qquad f_0(u)=u(1-u)(u-a),$$
$$g(u,v)=u-\gamma v,$$

where $\gamma > 0$, $0 < a < 1$, and ε is a small positive parameter. The zero set of f consists of three branches

$$\begin{aligned} u &= h_-(v) \quad \text{for } u < a_-, \\ u &= h_+(v) \quad \text{for } a_+ < u, \\ u &= h_0(v) \quad \text{for } a_- < u < a_+, \end{aligned}$$

where $a_- < a_+$ and $f_0'(a_-) = f_0'(a_+) = 0$. When $\varepsilon \to 0$, it is expected that u tends to $h_\pm(v)$ in some region $\Omega_\pm(t)$ in $\mathbb{R}^n$ since $h_\pm(v)$ is a stable zero of $u_t = f(u, v)$. From (1.6), it is also expected that the interface $\Gamma(t)$ moves by (1.1) with $c = \varepsilon$. Here $W(b)$ for b, $f_0(a_-) < b < f_0(a_+)$ is the speed of the travelling wave of

$$u_t = \Delta u + f(u, b)$$

and is given by

$$W(b) = \frac{1}{\sqrt{2}}(h_+(b) + h_-(b) - h_0(b))$$

(see Aronson and Weinberger [AW]). The equation (1.7) now becomes (1.2) as $\varepsilon \to 0$ by taking $g_\pm(v) = g(h_\pm(v), v)$. For more details we refer to [OMK] and [XYC] and references therein. We note that anisotropic interface equations are also derived by a singular limit of some reaction-diffusion equation [C].

Extensive literature exists on the behavior u^ε as $\varepsilon \downarrow 0$ in (1.6) and its relation to the solutions of interface equation when v is given and the space dimension $n = 1$ (see, e.g., [FH], [BK], [CP]). Recently, some results were extended to the case $n > 1$, where the curvature effect comes in. If v is a constant and $W(v) = 0$, (1.6) is called the Allen-Cahn equation, whose relation to (1.5) with $c > 0$ is rigorously analyzed by Bronsard and Kohn [BK] and DeMottoni and Schatzman [DS]. X. Chen [XC1] extended results of [DS] and simplified the argument. After this work was completed, we learned that X. Chen [XC2] derived (1.1)-(1.3) with $c = 0$ rigorously as a singular limit of (1.6)-(1.7). There is also an argument to interpret the case $c = \varepsilon > 0$ in [XC2]. His method is an extension of his work [XC1]. All results in [BK], [DS], [XC1], [XC2] assume that the solution of the interface equation is smooth enough to get the behavior of u^ε as $\varepsilon \downarrow 0$. Very recently we learned that Evans, Soner, and Songanidis [ESS] obtained the behavior of u^ε even after singularities appear on the interface for the Allen-Cahn equation.

In § 2 we solve a general interface equation including (1.1) for a given function v globally in time under a periodic boundary condition. In § 3 we give a generalized formulation of (1.2)-(1.3). In § 4 we state our main existence results and prove them by a fixed point argument. In the Appendix, we state a stability property of the viscosity solutions used in § 4.

After this work was completed, X.-Y. Chen kindly informed us that he had found another proof for global existence for (4.1), (4.2), (4.3′) with $c > 0$ without using a fixed point argument for multivalued mappings.

2. Interface equations. We consider interface equations under periodic boundary conditions. The periodic boundary condition is important because it is often used in numerical experiments. For $\alpha_i > 0$ $(1 \leqq i \leqq n)$ let R be a rectangle in $\mathbb{R}^n$ of the form

$$R = \{(x_1, \cdots, x_n) \in \mathbb{R}^n; 0 \leqq x_i \leqq \alpha_i, 1 \leqq i \leqq n\}.$$

We identify faces $x_i = 0$ and $x_i = \alpha_i (1 \leqq i \leqq n)$ of R to obtain an n-dimensional flat torus $\mathbb{T}$. Motion of interfaces in R under periodic boundary conditions is interpreted as the motion in $\mathbb{T}$. We consider $\mathbb{T}$ rather than $\mathbb{R}^n$ for later technical convenience because $\mathbb{T}$ is compact and has no boundary.

Let $\Omega_\pm(t)$ be an open set in $\mathbb{T}$ depending on time $t \geqq 0$ such that $\Omega_+(t) \cap \Omega_-(t) = \phi$. Let $\Gamma(t)$ denote the complement of $\Omega_+(t) \cup \Omega_-(t)$ in $\mathbb{T}$. Physically speaking, $\Gamma(t)$ is called an interface bounding two phases $\Omega_\pm(t)$ of material, e.g., solid and liquid region. Suppose that $\Gamma(t)$ is a smooth hypersurface, and let $\vec{n}$ denote the unit normal vector field pointing from $\Omega_+(t)$ to $\Omega_-(t)$. Let $V = V(t, x)$ denote the speed of $\Gamma(t)$ at $x \in \Gamma(t)$ in the direction $\vec{n}$. It is convenient to extend $\vec{n}$ to a vector field (still denoted by $\vec{n}$) on a tubular neighborhood of $\Gamma(t)$ such that $\vec{n}$ is constant in the normal direction of $\Gamma(t)$. The equation for $\Gamma(t)$ that we consider here is of the form

$$\begin{aligned} V &= \xi(t, x, \vec{n}, \nabla \vec{n}) \\ &:= \eta(\vec{n}, \nabla \vec{n}) + \omega(t, x, \vec{n}) \quad \text{on } \Gamma(t), \end{aligned} \tag{2.1}$$

where η and ω are given functions and ∇ stands for the spatial gradient in $\mathbb{T}$. A typical example is

$$V = -c \operatorname{div} \vec{n} + \omega(t, x), \tag{2.2}$$

where c is a nonnegative constant and ω is independent of $\vec{n}$. Equation (2.2) is called the mean curvature flow equation if $c > 0$ and $\omega \equiv 0$. The reason we consider general (2.1) is to include anisotropic motion as in [Gu1], [Gu2].

Next, we introduce a weak formulation for (2.1) following [CGG], [GG1]. For η we set

$$\begin{aligned} F_\eta(p, X) &:= -|p|\eta(-\bar{p}, -Q_{\bar{p}}(X)), \qquad \bar{p} = p/|p|, \\ Q_{\bar{p}}(X) &= R_{\bar{p}} X R_{\bar{p}} \quad \text{with } R_{\bar{p}} = I - \bar{p} \otimes \bar{p}, \end{aligned} \tag{2.3}$$

where $p \in \mathbb{R}^n \backslash \{0\}$ and $X \in \mathbb{S}_n$, the space of $n \times n$ real symmetric matrices. We also set

$$F_\xi(t, x, p, X) := F_\eta(p, X) - \omega(t, x, -\bar{p})|p|. \tag{2.4}$$

For example, a calculation shows

$$F_\eta(p, X) = -c \operatorname{trace}((I - \bar{p} \otimes \bar{p})X) \tag{2.5}$$

if

$$\eta(\vec{n}, \nabla \vec{n}) = -c \operatorname{div} \vec{n} \tag{2.6}$$

as in (2.2). The following definition of weak solutions for (2.1) is a variant of that in [CGG], [GG1]. For the definition of (viscosity) sub- and supersolutions and viscosity solutions; see, e.g., [GGIS].

Definition 2.1. Let $\{\Omega_\pm(t)\}_{0 \leqq t < T}$ be a one parameter family of open sets in $\mathbb{T}$ such that $\Omega_+(t) \cap \Omega_-(t) = \phi$. Suppose that there is a viscosity solution $u \in C([0, T) \times \mathbb{T})$ of

$$u_t + F_\xi(t, x, \nabla u, \nabla^2 u) = 0 \quad \text{in } (0, T) \times \mathbb{T} \tag{2.7}$$

such that

$$\Omega_\pm(t) = \{x \in \mathbb{R}^n;\ u(t, x) \gtrless 0\} \quad \text{for } 0 \leqq t < T. \tag{2.8}$$

We say $\{\Omega_\pm(t)\}_{0 \leqq t < T}$ is a *weak solution* of (2.1) in $(0, T)$ with initial data $\Omega_\pm(0)$. Here F_ξ is defined by (2.3)-(2.4).

Roughly speaking, if (2.1) is parabolic (not necessarily strictly parabolic), and η grows linearly in $\nabla\vec{n}$, then we can claim the unique global existence of weak solutions for (2.1) with given initial data $\Omega_\pm(0)$, provided that η and ω are continuous. If ω is independent of x and $\mathbb{T}$ is replaced by $\mathbb{R}^n$, the unique global existence is now well known if one of $\Omega_\pm(0)$ is bounded (cf. [CGG], [GG1]). We now list our assumptions on η and ω:

$$\begin{gathered}\eta \text{ is a real valued continuous function on the vector bundle}\\ E=\{(\bar{p}, Q_{\bar{p}}(X)); \bar{p}\in S^{n-1}, X\in \mathbb{S}_n\}\\ \text{over a unit sphere } S^{n-1}.\end{gathered} \tag{2.9}$$

$$\begin{gathered}\eta(-\bar{p}, -Q_{\bar{p}}(X)) \geqq \eta(-\bar{p}, -Q_{\bar{p}}(Y)) \quad \text{for } X\geqq Y,\ \bar{p}\in S^{n-1},\\ \text{where } \mathbb{S}_n \text{ is equipped with usual ordering.}\end{gathered} \tag{2.10}$$

$$\begin{gathered}\liminf_{\rho\downarrow 0} \rho \inf_{|\bar{p}|=1} \eta\left(-\bar{p}, \frac{I-\bar{p}\otimes\bar{p}}{\rho}\right) > -\infty,\\ \limsup_{\rho\downarrow 0} \rho \sup_{|\bar{p}|=1} \eta\left(-\bar{p}, \frac{-I+\bar{p}\otimes\bar{p}}{\rho}\right) < \infty.\end{gathered} \tag{2.11}$$

(2.12) ω is continuous from $[0, T)\times\mathbb{T}\times S^{n-1}$ to $\mathbb{R}$ with a bound on $|\nabla\omega|$.

All assumptions on η are found in [GG1]; (2.10) means that $-\eta$ is degenerate elliptic and (2.11) restricts the growth of η in $\nabla\vec{n}$. The only assumption for ω is (2.12).

THEOREM 2.2. *Assume* (2.9)-(2.12) *for η and ω. Let $\Omega_\pm(0)$ be mutually disjoint open sets in $\mathbb{T}$. Then there is a unique global weak solution $\{\Omega_\pm(t)\}_{0\leqq t<T}$ of* (2.1) *in* $(0, T)$ *with initial data $\Omega_\pm(0)$.* (*The case $T=\infty$ is included.*)

The basic idea of the proof is the same as [CGG, Thms. 6.8, 7.1]; see also [GG1] for the relation between assumptions on η and F_η. The major technical difference is that the comparison theorem in [CGG] does not apply to (2.7) because F_ξ depends on x. Instead we apply [GGIS, Thm. 4.1] to get a comparison principle for (2.7). For the reader's convenience, we state a version of the comparison principle which follows from [GGIS, Thm. 4.1] and give a brief proof of Theorem 2.2.

PROPOSITION 2.3. *Assume* (2.9)-(2.12). *Let u and v be, respectively,* (*viscosity*) *sub- and supersolutions of* (2.7). *Assume that u and v are, respectively, upper and lower semicontinuous functions on* $[0, T)\times\mathbb{T}$. *If*

$$u(0,x)\leqq v(0,x) \quad \textit{on } \mathbb{T},$$

then $u(t,x)\leqq v(t,x)$ *on* $[0, T)\times\mathbb{T}$.

Proof. To apply [GGIS, Thm. 4.1] we extend u, v, and ω periodically in space variables outside R and regard (2.7) as

$$u_t + F_\xi(t, x, \nabla u, \nabla^2 u) = 0 \quad \text{in } (0, T']\times\mathbb{R}^n,$$

where T' is an arbitrary positive number less than T.

We first check assumptions of equation in [GGIS]. By (2.9)-(2.10) we know F_η satisfies all assumptions on F in [GGIS, Thm. 4.1]. Except for the boundedness of $F_\eta(p, X)$ on a bounded set in $(\mathbb{R}^n\backslash\{0\})\times\mathbb{S}_n$, the proof is found in [GG1]. This boundedness of F_η can be proved similarly to the proof of [GG1, Lemma 3.5].

By (2.12) we see ω is continuous in $[0, T']\times\mathbb{R}^n\times S^{n-1}$ with a bound on $|\nabla\omega|$ so F_ξ satisfies the uniform continuity assumption in x of [GGIS, (F8)]; there is a modulus σ (i.e., σ: $[0,\infty)\to[0,\infty)$ is continuous, nondecreasing and $\sigma(0)=0$) such that

$$|F_\xi(t,x,p,X) - F_\xi(t,y,p,X)| \leqq \sigma(|x-y|(|p|+1))$$

for x, $y \in \mathbb{R}^n$, $t \in [0, T']$, $p \in \mathbb{R}^n \backslash \{0\}$, $X \in \mathbb{S}_n$. All other assumptions on F in [GGIS, Thm. 4.1] are fulfilled since ω satisfies (2.12) and F_η satisfies all assumptions on F.

Since u and v are extended periodically and R is bounded, it is not difficult to see that u and v satisfy all the assumptions of [GGIS, Thm. 4.1].

We now apply [GGIS, Thm. 4.1] to conclude $u \leqq v$ on $[0, T'] \times \mathbb{R}^n$. Since $T' < T$ is arbitrary, the proof is complete. □

Proof of Theorem 2.2. (*Uniqueness.*) Suppose that u, $v \in C([0, T) \times \mathbb{T})$ solves (2.7) such that

$$\Omega_\pm(0) = \{x \in \mathbb{T}, u(0, x) \gtrless 0\} = \{x \in \mathbb{T}; v(0, x) \gtrless 0\}.$$

By [CGG, Lemma 7.2] there is a continuous nondecreasing function $\theta : \mathbb{R} \to \mathbb{R}$ with $\theta(0) = 0$ such that

$$u(0, x) \leqq \theta(v(0, x)).$$

Since F_ξ is geometric, i.e.,

$$(2.13) \qquad \begin{gathered} F_\xi(t, x, \lambda p, \lambda X + \sigma p \otimes p) = \lambda F_\xi(t, x, p, X) \\ \text{for } \lambda > 0,\ \sigma \in \mathbb{R},\ t \in (0, T),\ x \in \mathbb{T},\ p \in \mathbb{R}^n \backslash \{0\},\ X \in \mathbb{S}_n, \end{gathered}$$

by [CGG, Thm. 5.2] we see $\theta(v(t, x))$ also solves (2.7). From Proposition 2.3, it follows $u \leqq \theta(v)$ on $[0, T) \times \mathbb{T}$. Thus, we observe that $u > 0$ implies $v > 0$ and $v < 0$ implies $u < 0$. A parallel argument yields the converse implication so $\Omega_\pm(t)$ is determined by $\Omega_\pm(0)$ and is independent of the choice of u. This proves the uniqueness of weak solutions.

(*Existence.*) For given $\Omega_\pm(0)$, we take $u_0(x) \in C(\mathbb{T})$ such that

$$\Omega_\pm(0) = \{x \in \mathbb{T}; u_0(x) \gtrless 0\}.$$

Since (2.11) is assumed, we may apply [CGG, Prop. 6.4] to (2.7) in $[0, T'] \times \mathbb{R}^n$ with periodic initial data and find sub- and supersolutions v_-, v_+ of (2.7) on $[0, T'] \times \mathbb{R}^n$ such that

$$\begin{gathered} v_\pm(0, x) = u_0(x) \quad \text{on } \mathbb{R}^n \\ v_-(t, x) \leqq u_0(x) \leqq v_+(t, x) \quad \text{on } [0, T'] \times \mathbb{R}^n, \end{gathered}$$

where $T' < T$. The dependence of x in F_ξ is allowed in [CGG, Prop. 6.4]. A trivial modification of the argument enables us to take v_-, v_+ as functions on $[0, T'] \times \mathbb{T}$.

Existence of $v_\pm$ yields a viscosity solution $u \in C([0, T'] \times \mathbb{T})$ of (2.7) with $u(0, x) = u_0(x)$ by Perron's method and Proposition 2.3. Since $T' < T$ is arbitrary and the solution is unique, we now obtain a weak solution $\{\Omega_\pm(t)\}_{0 \leqq t < T}$ for initial data $\Omega_\pm(0)$.

Note that the scaling property (2.13) is also used to construct $v_\pm$. □

Remark 2.4. The family $\{\Omega_+(\mathrm{t})\}$ is determined by $\Omega_+(0)$ and is independent of $\Omega_-(0)$. Indeed, if u solves (2.7) with (2.8), then $\theta(u)$ solves (2.7) for continuous nondecreasing $\theta : \mathbb{R} \to \mathbb{R}$ since F_ξ is geometric. Take $\theta(\sigma) = \sigma_+ = \max(\sigma, 0)$ to observe that $u_+ = \theta(u)$ solves (2.7). By (2.8) u_+ gives a weak solution $\{\Omega'_\pm(t)\}_{0 \leqq t < T}$ with initial data $(\Omega_+(0), \phi)$. By the definition of u_+, we see $\Omega'_+(t) = \Omega_+(t)$ and $\Omega'_-(t) = \phi$. We thus observe that $\Omega_+(t)$ is determined by $\Omega_+(0)$.

Remark 2.5. The interface $\Gamma(t)$ is defined by the complement of $\Omega_+(t) \cup \Omega_-(t)$ in $\mathbb{T}$. There is a chance that $\Gamma(t)$ develops an interior even if $\Gamma(0)$ is a smooth hypersurface in $\mathbb{T}$. For example, consider the equation $V = -1$ and

$$R = \{(x_1, x_2) \in \mathbb{R}^2; 0 \leqq x_1 \leqq 2, 0 \leqq x_2 \leqq 2\}.$$

Suppose that

$$\Omega_+(0)=\{x\in\mathbb{T};\, x_1\neq 1\}, \Omega_-(0)=\phi$$

so that $\Gamma(0)=\{x_1=1\}$. Then $\Omega_+(t)=\{x\in\mathbb{T};\, 0\leqq x_1\leqq 2, |x_1\leqq 1|>t\}$ and $\Omega_-(t)=\phi$. Indeed, equation (2.7) for this example is

$$u_t+|\nabla u|=0. \tag{2.14}$$

By the definition of viscosity solutions, we can check that

$$u(t,x)=\begin{cases}0 & \text{for } |x_1-1|\leqq t,\\ x_1-1-t & \text{for } x_1-1>t\ (x\in\mathbb{R}^2),\\ 1-x_1-t & \text{for } x_1-1<-t\end{cases} \tag{2.15}$$

is a viscosity solution of (2.14) on $(0,\infty)\times\mathbb{T}$. We now observe that $\Omega_\pm(t)$ is given by (2.8) with u of (2.15).

For the mean curvature flow equation

$$V=-\operatorname{div}\vec{n},$$

we do not know whether or not $\Gamma(t)$ develops an interior if $\Gamma(0)$ is a smooth hypersurface. As pointed out in [ES1], we know $\Gamma(t)$ may develop an interior if $\Gamma(0)$ has a singularity.

3. Diffusion equations across interfaces. This section gives a generalized formulation of

$$v_t=\Delta v+g_\pm(v) \quad \text{in } Q_T^\pm=\bigcup_{0<t<T}\{t\}\times\Omega_\pm(t), \tag{3.1}$$

$$v(t):=v(t,\cdot)\in C^1(\mathbb{T}) \quad \text{for } 0<t<T, \tag{3.2}$$

where

$$Q_T^\pm=\{(t,x)\in Q_T;\, u(t,x)\gtrless 0\}, \qquad Q_T=(0,T)\times\mathbb{T} \tag{3.3}$$

with some function $u\in C(\bar{Q}_T)$. The interpretation of the equation on the interface is crucial.

We introduce a multivalued function Φ associated with continuous function $g_\pm(\sigma)$. For $(s,\sigma)\in\mathbb{R}^2$, we define a closed interval $\Phi(s,\sigma)$ such that

$$\Phi(s,\sigma)=\begin{cases}\{g_+(\sigma)\} & \text{if } s>0,\\ [\underline{g}(\sigma),\bar{g}(\sigma)] & \text{if } s=0,\\ \{g_-(\sigma)\} & \text{if } s<0,\end{cases} \tag{3.4}$$

where $\underline{g}(\sigma)=\min(g_+(\sigma),g_-(\sigma))$, $\bar{g}=\max(g_+,g_-)$. This correspondence defines a mapping $\Phi:\mathbb{R}^2\to 2^{\mathbb{R}}$. For $u,v\in C(\bar{Q}_T)$ we define a subset $G(u,v)$ such that

$$G(u,v)=\{q\in L^\infty(Q_T);\, q(z)\in\Phi(u(z),v(z)) \text{ a.e. } z\in Q_T\}, \tag{3.5}$$

where $z=(t,x)$. This correspondence defines a mapping $G: C(\bar{Q}_T)\times C(\bar{Q}_T)\to 2^{L^\infty(Q_T)}$.

DEFINITION 3.1. Suppose that $u\in C(\bar{Q}_T)$ is given and the $Q_T^\pm$ is defined by (3.3). Suppose also that $g_\pm:\mathbb{R}\to\mathbb{R}$ is continuous. We say $v\in C(\bar{Q}_T)$ is a *generalized solution* of (3.1)-(3.2) if

$$v_t-\Delta v\in G(u,v) \quad \text{in } Q_T$$

i.e., there is $q\in G(u,v)$ such that

$$v_t-\Delta v=q \quad \text{in } Q_T$$

in the distribution sense. Since $G(u,v)$ depends on u only through its signature, this definition depends only on $Q_T^\pm$ and is independent of the choice of u.

PROPOSITION 3.2. *For $u, v \in C(\bar{Q}_T)$ the set $G(u, v)$ is a nonempty, bounded convex subset of $L^\infty(Q_T)$.*

Proof. Since $\Phi(s, \sigma)$ is convex in $\mathbb{R}$,

$$\lambda q_1(z)+(1-\lambda)q_2(z) \in \Phi(u(z), v(z)) \quad \text{for a.e. } z$$

if $q_1, q_2 \in G(u, v)$ and $0<\lambda<1$. This implies that $\lambda q_1+(1-\lambda)q_2 \in G(u, v)$ so $G(u, v)$ is convex in $L^\infty(Q_T)$.

The Borel measurable function

$$\psi(s, \sigma)=\chi_{(-\infty,0)}(s)g_-(\sigma)+\chi_{[0,\infty)}(s)g_+(\sigma)$$

on $\mathbb{R}^2$ satisfies $\psi(s, \sigma) \in \Phi(s, \sigma)$ for all $s, \sigma \in \mathbb{R}$, and therefore $\psi(u, v) \in G(u, v)$.

Since $g_\pm$ is locally bounded, we see $G(u, v)$ is bounded in $L^\infty(Q_T)$. □

LEMMA 3.3. *Suppose that $u_m \to u$ in $C(\bar{Q}_T)$ and that $v_m \to v$ in $C(\bar{Q}_T)$. Suppose that $q_m \in G(u_m, v_m)$. Then there is a subsequence $\{m_j\}$ and $q \in G(u, v)$ such that $q_{m_j} \rightharpoonup q$ *-weakly in $L^\infty(Q_T)$.*

Proof. Since $g_\pm$ is continuous, $\bigcup_{m=1}^\infty G(u_m, v_m)$ is bounded in $L^\infty(Q_T)$. In particular, $\{q_m\}$ is bounded in $L^\infty(Q_T)$. By the Banach-Alaoglu theorem, $\{q_m\}$ has a *-weak convergent subsequence (still denoted $\{q_m\}$), i.e.,

$$q_m \rightharpoonup q \text{ *-weakly in } L^\infty(Q_T).$$

In particular $q_m \rightharpoonup q$ weakly in $L^2(Q_T)$ since Q_T is bounded. Applying Mazur's theorem (see, e.g., [Y]), we see that there is $\lambda_m^m, \cdots, \lambda_m^{lm} \geqq 0$ with

$$\sum_{j=m}^{l_m} \lambda_m^j=1$$

such that

$$\tilde{q}_m := \sum_{j=m}^{l_m} \lambda_m^j q_j \to q \text{ strongly in } L^2(Q_T) \quad \text{as } m \to \infty.$$

Taking a subsequence if necessary we may conclude

$$\tilde{q}_m(z) \to q(z)(m \to \infty) \quad \text{for a.e. } z. \tag{3.6}$$

We fix $z \in Q_T$ such that (3.6) and

$$q_m(z) \in \Phi(u_m(z), v_m(z)) \quad \text{for all } m \geqq 1. \tag{3.7}$$

Suppose that $u(z)=0$. By (3.4) and (3.7)

$$q_m(z) \in [\underline{g}(v_m(z)), \bar{g}(v_m(z))] \tag{3.8}$$

since $\{g_\pm(v_m(z))\}$ lies in the interval in (3.8). Since $\underline{g}$ and $\bar{g}$ are continuous and $v_m(z) \to v(z)$, for each $\varepsilon>0$ there is m_0 such that if $m \geqq m_0$, then

$$[\underline{g}(v_m(z)), \bar{g}(v_m(z))] \subset (a-\varepsilon, b+\varepsilon)$$

with

$$[a, b] := [\underline{g}(v(z)), \bar{g}(v(z))].$$

By (3.8), we now observe that

$$\tilde{q}_m(z) \in (a-\varepsilon, b+\varepsilon).$$

From (3.6) it follows that

$$q(z) \in (a-\varepsilon, b+\varepsilon).$$

Since $\varepsilon>0$ is arbitrary, this implies

$$q(z) \in [\underline{g}(v(z)), \bar{g}(v(z))]. \tag{3.9}$$

Suppose that $u(z)>0$. For sufficiently large m, say $m\geqq m_0$, we may assume $u_m(z)>0$. It follows that

$$\Phi(u_m(z), v_m(z))=\{g_+(v_m(z))\} \quad \text{for } m\geqq m_0.$$

By (3.7) we have

$$q_m(z)=g_+(v_m(z)) \quad \text{for } m\geqq m_0. \tag{3.10}$$

Since $\tilde{q}_m(z)\to q(z)$ by (3.6) and g_+ is continuous, (3.10) yields

$$q(z)=g_+(v(z)). \tag{3.11}$$

The proof for $u(z)<0$ parallels that for $u(z)>0$. By (3.9) and (3.11) we can conclude that

$$q(z)\in\Phi(u(z), (v(z)) \quad \text{a.e. } z\in Q_T,$$

which completes the proof □

COROLLARY 3.4. *The set $G(u, v)$ is weak $*$ compact in $L^\infty(Q_T)$.*

Proof. By Lemma 3.3 we see $G(u, v)$ is weak $*$ sequentially closed. Since $G(u, v)$ is bounded by Proposition 3.2 and since the predual $L^1(Q_T)$ is separable, we can drop the word "sequentially." The boundedness of $G(u, v)$ now implies that $G(u, v)$ is weak $*$ compact. □

Remark 3.5. The condition (3.2) is implicit in Definition 3.1. We will see that all generalized solutions v have the regularity property (3.2).

4. Main results. We consider a system (3.1)-(3.2), coupled with an interface equation:

$$v_t=\Delta v+g_\pm(v) \quad \text{in } Q_T^\pm=\bigcup_{0<t<T}\{t\}\times\Omega_\pm(t), \tag{4.1}$$

$$v(t)=v(t,\cdot)\in C^1(\mathbb{T}) \quad \text{for } 0<t<T, \tag{4.2}$$

$$V=\eta(\vec{n},\nabla\vec{n})+W(v)\alpha(\vec{n}) \quad \text{on } \Gamma(t)=\mathbb{T}\backslash(\Omega_+(t)\cup\Omega_-(t)), \tag{4.3}$$

with given initial data

$$v(0,x)=v_0(x) \quad \text{in } \mathbb{T}, \tag{4.4}$$

$$\Omega_\pm(t)|_{t=0}=\Omega_\pm(0). \tag{4.5}$$

Here we assume that

(4.6a) $g_\pm:\mathbb{R}\to\mathbb{R}$ is continuous and bounded,

(4.6b) η satisfies (2.9)-(2.11),

(4.6c) $W:\mathbb{R}\to\mathbb{R}$ is locally Lipschitz continuous,

(4.6d) $\alpha:S^{n-1}\to\mathbb{R}$ is continuous.

We say $(\Omega_\pm(t), v(t))$ is a *weak solution* of (4.1)-(4.5) if $\{\Omega_\pm(t)\}_{0\leqq t<T}$ is a weak solution of (4.3), (4.5) with $v\in C(\bar{Q}_T)$ and v is a generalized solution of (4.1)-(4.2) with (4.4); see Definitions 2.1 and 3.1. We now state one of our main results.

THEOREM 4.1. *Let $T>0$. Assume that $g_\pm$, η, W, α satisfy* (4.6a-d). *Suppose that $\Omega_+(0)$ and $\Omega_-(0)$ are mutually disjoint open sets in $\mathbb{T}$ and that $v_0(x)\in C^2(\mathbb{T})$. Then there exists a (global) weak solution $(\Omega_\pm(t), v(t))$ of* (4.1)-(4.5) *such that $v\in C^{1,0}(\bar{Q}_T)=\{v\in C(\bar{Q}_T);\ \nabla v\in C(\bar{Q}_T)\}$.*

Remark 4.2. We note that (4.3) includes

$$V=-c\operatorname{div}\vec{n}+W(v),\qquad c\geqq 0 \tag{4.3'}$$

as a special example. If (4.3′) replaces (4.3) in (4.1)-(4.5), then it is known that there is a unique smooth local solution. This is proved by X.-Y. Chen [XYC] for $c>0$ and by X. Chen [XC2] for $c=0$ where $\mathbb{R}^n$ replaces $\mathbb{T}$. Our result is the first global existence result ever for this special system if the space dimension $n\geqq 2$. For $n=1$ see [HNM].

We shall construct a solution using Kakutani's fixed point theory for a multivalued mapping. We take a Banach space

$$X:=C^{1,0}(\bar{Q}_T).$$

For $v\in X$ we solve (4.3), (4.5) by applying Theorem 2.2. Since v can be extended as an element of $C^{1,0}$ for $t>T$, we have a unique weak solution $\{\Omega_\pm(t)\}_{0\leqq t\leqq T}$ for (4.3), (4.5) with given $\Omega_\pm(0)$. If we set

$$\tilde{Q}_T^\pm=\bigcup_{0\leqq t\leqq T}\{t\}\times\Omega_\pm(t),$$

then we have a mapping

$$\mathcal{T}:X\to\mathcal{O},\ v\mapsto(\tilde{Q}_T^+,\tilde{Q}_T^-),$$

where $\mathcal{O}$ denotes the set of disjoint pair of open sets in $[0,T]\times\mathbb{T}$.

For $q\in L^\infty(Q_T)$, let $w=E(q)$ be the unique solution of

$$\begin{aligned} &w_t-\Delta w=q\quad\text{in } Q_T\\ &w(0,x)=v_0(x)\in C^2(\mathbb{T}).\end{aligned}\tag{4.7}$$

By the parabolic theory [LUS], E defines a continuous affine map from $L^\infty(Q_T)$ to $\bigcap_{p>1}W_p^{2,1}(Q_T)$, which is continuously embedded in X by the Sobolev inequality. Thus

$$E:L^\infty(Q_T)\to X$$

is a continuous affine operator. For u, $v\in C(\bar{Q}_T)$, we define a subset of X by

$$\mathcal{P}(u,v)=\{E(q);\ q\in G(u,v)\}.$$

This correspondence defines a mapping

$$\mathcal{P}:C(\bar{Q}_T)\times C(\bar{Q}_T)\to 2^X.$$

For given $(\tilde{Q}_T^+,\tilde{Q}_T^-)\in\mathcal{O}$, we take $u\in C(\bar{Q}_T)$ such that

$$\tilde{Q}_T^\pm=\{(t,x)\in\bar{Q}_T;\ u\gtrless 0\}.$$

Since G depends on u through its signature, we may regard the mapping $\mathcal{P}$ as

$$\mathcal{P}:\mathcal{O}\times C(\bar{Q}_T)\to 2^X.$$

For given v_0 and $\Omega_\pm(0)$, we define

$$\mathcal{S}:X\to 2^X$$

by $\mathcal{S}(v) = \mathcal{P}(\mathcal{T}(v), v)$. If $\mathcal{S}$ has a fixed point $\bar{v} \in X$, i.e.,

$$\bar{v} \in \mathcal{S}(\bar{v}),$$

we observe that $(\Omega_\pm(t), \bar{v}(t))$ is a weak solution of (4.1)-(4.5), where

$$\mathcal{T}(\bar{v}) = \bigcup_{0 \leqq t \leqq T} \{t\} \times \Omega_\pm(t).$$

We shall prove that $\mathcal{S}$ has a fixed point.

PROPOSITION 4.3. *The set $\mathcal{P}(u, v)$ is nonempty, compact and convex in $C(\bar{Q}_T)$ (and in X).*

Proof. Since E defined by (4.7) is affine and $G(u, v)$ is nonempty and convex by Proposition 3.2 we see that $\mathcal{P}(u, v)$ is convex.

We next observe that E is continuous from a bounded set of $L^\infty(\bar{Q}_T)$ (equipped with weak $*$ topology) to X. Indeed, if $q_m \rightharpoonup q$ $*$ weakly in $L^\infty(Q_T)$ then $\{E(q_m)\}$ has a weakly convergent subsequence in $W_p^{2,1}(Q_T)$ for $p > 1$. Since the inclusion

$$(4.8) \qquad W_p^{2,1}(Q_T) \to X = C^{1,0}(\bar{Q}_T) \text{ is compact if } p > n+1$$

(see, e.g., [LUS]), $E(q_m) \to w$ strongly in X by taking a subsequence. Since $w_m = E(q_m)$ satisfies

$$(\partial_t - \Delta) w_m = q_m \quad \text{in } Q_T, \qquad w_m(0, x) = v_0(x),$$

w solves

$$(\partial_t - \Delta) w = q \quad \text{in } Q_T$$

in the distribution sense with $w(0, x) = v_0(x)$. This implies $w = E(q)$. Since the limit w is independent of the choice of subsequences, we observe that

$$E(q_m) \to E(q) \quad \text{in } X.$$

This sequential continuity implies the continuity on a bounded set of $L^\infty(Q_T)$.

Since $G(u, v)$ is weak $*$ compact in $L^\infty(Q_T)$, the continuous image of $G(u, v)$ is compact. The above continuity of E implies that $\mathcal{P}(u, v)$ is compact in $C^0(\bar{Q}_T)$ as well as in X. □

Since $g_\pm$ is bounded by (4.6a), we see that

$$\bigcup_{u, v \in C(\bar{Q}_T)} G(u, v)$$

is bounded in $L^\infty(Q_T)$. Therefore, by the parabolic theory for (4.7) [LUS],

$$\mathcal{S}(v) \subset K = \{w \in W_p^{2,1}(Q_T);\ \|w\|_{W_p^{2,1}} \leqq M\}, \qquad p > 1$$

if M is taken sufficiently large. We fix $p > n+1$ so that K is compact in X by (4.8). The mapping $\mathcal{S}$ is now interpreted as

$$\mathcal{S}: X \to 2^K.$$

The graph of $\mathcal{S}$ is defined by

$$\operatorname{gr} \mathcal{S} = \{(v, w);\ w \in \mathcal{S}(v)\} \subset X \times K.$$

Since K is compact, $\operatorname{gr} \mathcal{S}$ is closed if and only if $\mathcal{S}$ is upper semicontinuous. For the definition of upper semicontinuity see [AF].

PROPOSITION 4.4. *The set $\operatorname{gr} \mathcal{S}$ is closed in $X \times K$.*

Proof. Suppose that v_m, $v \in X$, $w_m \in \mathcal{S}(v_m)$, $w \in X$ such that $v_m \to v$ in X and $w_m \to w$ in X. Our goal is to prove $w \in \mathcal{S}(v)$. By the definition of weak solutions for (4.3), there is a viscosity solution $u_m \in C(\bar{Q}_T)$ of

$$u_t + F_m(t, x, \nabla u, \nabla^2 u) = 0 \quad \text{in } Q_T$$

with

$$F_m(t, x, p, X) = F_\eta(p, X) - W(v_m(t, x))\alpha(-p/|p|)|p|$$

such that

$$\mathcal{T}(v_m) = (\{u_m(t, x) > 0\}, \{u_m(t, x) < 0\}).$$

We can arrange $u_m(0, x) = u_0(x)$ independent of m such that

$$\Omega_\pm(0) = \{x \in \mathbb{T};\ u_0(x) \gtrless 0\}.$$

Since $v_m \to v$ in X, by the stability of viscosity solutions, there is $u \in C(\bar{Q}_T)$ such that $u_m \to u$ in $C(\bar{Q}_T)$ and u solves (in the viscosity sense)

$$u_t + F(t, x, \nabla u, \nabla^2 u) = 0 \quad \text{in } Q_T$$

with $F(t, x, p, X) = F_\eta(p, X) - W(v(t, x))\alpha(-p/|p|)|p|$ (see the Theorem in the Appendix), where $u(0, x) = u_0(x)$. This implies

$$\mathcal{T}(v) = (\{u > 0\}, \{u < 0\}). \tag{4.9}$$

By the definition of $\mathcal{P}$ there is $q_m \in G(u_m, v_m)$ such that

$$\begin{aligned} &(\partial_t - \Delta)w_m = q_m \quad \text{in } Q_T, \\ &w_m(0, x) = v_0(x) \quad \text{on } \mathbb{T}. \end{aligned} \tag{4.10}$$

Applying Lemma 3.3, we may conclude that

$$q_m \rightharpoonup q \ *\text{-weakly in } L^\infty(Q_T)$$

with some $q \in G(u, v)$ by taking a subsequence if necessary. Since $w_m \to w$ in X, (4.10) implies that

$$(\partial_t - \Delta)w = q \quad \text{in } Q_T$$

in the distribution sense, and

$$w(0, x) = v_0(x).$$

This yields $w \in \mathcal{S}(v)$ by (4.9) so that the proof is now complete. □

Proof of Theorem 4.1. Since K is compact and convex, by Propositions 4.3 and 4.4 we can apply the following fixed point theorem to conclude that there is $\bar{v} \in \mathcal{S}(\bar{v}) \cap K$. By the definition of $\mathcal{S}$, we see $\bar{v}$ together with $\mathcal{T}(\bar{v})$ is a desired weak solution of (4.1)-(4.5).

KAKUTANI'S FIXED POINT THEOREM [AF, THM. 3.2.3]. *Let K be a convex compact subset of a Banach space X and $\mathcal{S}: X \to 2^K$. If $\mathcal{S}$ is upper semicontinuous and $\mathcal{S}(v)$ is a nonempty convex closed set in K for $v \in X$, then $\mathcal{S}$ has a fixed point $\bar{v} \in K \cap \mathcal{S}(\bar{v})$.*

Remark 4.5. The assumption $v_0(x) \in C^2(\mathbb{T})$ in Theorem 4.1 is weakened as $v_0(x) \in W^{2-2/p}(\mathbb{T})$, $p > n+1$ because the regularity condition on v_0 is only used to solve (4.7) in $W_p^{2,1}(\bar{Q}_T)$.

We conclude this paper by stating an existence result of a global solution on the time interval $(0, \infty)$.

THEOREM 4.6. *Assume the same hypotheses of Theorem* 4.1 *for* $g_\pm$, η, W, α, $\Omega_\pm(0)$. *Suppose that* $v_0 \in W^{2-2/p}(\mathbb{T})$ *for* $p > n+1$. *Then there exists* $\{(\Omega_\pm(t), v(t))\}_{t \geqq 0}$ *which is a weak solution of* (4.1)-(4.5) *for arbitrary* $T > 0$.

Proof. For fixed $T > 0$ by Remark 4.5 there is v_T such that $v_T \in \mathcal{S}(v_T)$. This implies

$$(\partial_t - \Delta) v_T = q_T \quad \text{in } Q_T,$$

$$v_T(0, x) = v_0(x),$$

with

$$q_T \in \bigcup_{u, v \in C(\bar{Q}_T)} G(u, v).$$

Since $g_\pm$ is bounded by (4.6a) we observe that

$$|q_T|_{L^\infty(Q_T)} \leqq M = \sup_\sigma |g_\pm(\sigma)|.$$

By the parabolic regularity theory [LUS], $\{v_T\}_{T \geqq 1}$ is bounded in $W_p^{2,1}(\bar{Q}_{t_0})(p > n+1)$ for each $t_0 > 0$. By (4.8) and a diagonal argument, there is a subsequence $\{v_{T'}\}$ and $v \in C([0, \infty) \times \mathbb{T})$ such that

$$v_{T'} \to v \text{ in } X_{t_0} = C^{1,0}(\bar{Q}_{t_0}). \tag{4.11}$$

Since $v_{T'} \in \mathcal{S}(v_{T'}) \subset X_{t_0}$ and $\operatorname{gr} \mathcal{S}$ is closed, (4.11) implies $v \in \mathcal{S}(v) \subset X_{t_0}$ where $\mathcal{S}$ depends on t_0. Since t_0 is arbitrary, this yields a desired global solution on $[0, \infty)$. □

Appendix. We shall state stability properties of viscosity solutions used in the proof of Proposition 4.4 for the reader's convenience. We use the following notation. For $h_m : L \to \mathbb{R}$, $L \subset Z$ we define

$$\lim_* h_m : \bar{L} \to \mathbb{R} \cup \{-\infty\},$$

$$\lim^* h_m : \bar{L} \to \mathbb{R} \cup \{+\infty\},$$

by

$$\left(\lim_* h_m\right)(z) = \lim_{\substack{m \to \infty \\ \varepsilon \downarrow 0}} \inf \{h_j(y), d(z, y) < \varepsilon, j \geqq m, y \in L\}$$

and

$$\lim^* h_m = -\lim_* (-h_m),$$

where Z is a metric space with metric d. If h is independent of m, we write $h_* = \lim_* h_m$, $h^* = \lim^* h_m$. We shall suppress the word "viscosity."

LEMMA. *Suppose that* $F_m : Q_T \times \mathbb{R}^n \times \mathbb{S}_n \to \mathbb{R}$ *is lower semicontinuous and that* $F = \lim_* F_m$. *Suppose that* u_m *is a subsolution of*

$$u_t + F_m(t, x, \nabla u, \nabla^2 u) = 0 \quad \textit{in } Q_T.$$

Then $u = \lim^* u_m$ *is a subsolution of*

$$u_t + F(t, x, \nabla u, \nabla^2 u) = 0 \quad \textit{in } Q_T,$$

provided that u *does not take* $+\infty$ *in* $\bar{Q}_T$.

Similar results are proved by Barles and Perthame [BP] for first-order differential equations and formulated in Ishii [I] in the general case. Since the proof is easily modified for our setting, we omit the proof. The following is a simple application of the lemma, the comparison Proposition 2.3, and construction of sub- and supersolutions.

THEOREM. *Suppose that* η, W, α *satisfy* (4.6b-d). *Suppose that* $v_m \to v$ *in* X. *We set*

$$F_m = F_\eta(p, X) - W(v_m(t, x))\alpha(-p/|p|)|p|,$$

$$F = F_\eta(p, X) - W(v(t, x))\alpha(-p/|p|)|p|,$$

where F_η *is defined by* (2.3). *Suppose that* $u_m \in C(\bar{Q}_T)$ *is a solution of*

$$u_t + F_m(t, x, \nabla u, \nabla^2 u) = 0 \quad \textit{in } Q_T \tag{1}$$

with $u_m(0, x) = u_0(x) \in C(\mathbb{T})$. *Then* $u_m \to u$ *in* $C(\bar{Q}_T)$ *for some* $u \in C(\bar{Q}_T)$ *and* u *is a solution of*

$$u_t + F(t, x, \nabla u, \nabla^2 u) = 0 \quad \textit{in } Q_T \tag{2}$$

with $u(0, x) = u_0(x)$.

Proof. Since $v_m \to v$ in $C(\bar{Q}_T)$ there are bounded sub- and supersolutions $w_\pm$ of (1) such that

$$\begin{gathered} w_\pm(0, x) = u_0(x), \\ w_-(t, x) \leqq u_0(x) \leqq w_+(t, x) \quad \text{in } Q_T \\ Q_T \end{gathered} \tag{3}$$

and that $w_\pm$ is independent of m; see [CGG, Prop. 6.4] and the proof of Theorem 2.2. By Proposition 2.3 we see that

$$w_-^* \leqq u_m \leqq w_{+*} \quad \text{in } Q_T. \tag{4}$$

Since u_m is a subsolution of

$$u_t + (F_m)_*(t, x, \nabla u, \nabla^2 u) = 0 \quad \text{in } Q_T$$

by definition, applying the lemma yields that $\bar{u} = \lim^* u_m$ is a subsolution of

$$u_t + F_*(t, x, \nabla u, \nabla^2 u) = 0 \quad \text{in } Q_T.$$

(This is the definition that $\bar{u}$ is a subsolution of (2).) Similarly $\underline{u} = \lim_* u_m$ is a supersolution of

$$u_t + F^*(t, x, \nabla u, \nabla^2 u) = 0 \quad \text{in } Q_T.$$

By (3) and (4) we observe that

$$\bar{u}(0, x) = \underline{u}(0, x) = u_0(x).$$

Applying Proposition 2.3 implies $\bar{u} = \underline{u}$ and $u = \bar{u}$ is a solution of (2). The property $\bar{u} = \underline{u}$ implies that $u_m \to u$ in $C(\bar{Q}_T)$. The proof is now complete. □

ON A NONLINEAR ELLIPTIC-PARABOLIC PARTIAL DIFFERENTIAL EQUATION SYSTEM IN A TWO-DIMENSIONAL GROUNDWATER FLOW PROBLEM*

PH. CLÉMENT†, C. J. VAN DUIJN†, AND SHUANHU LI†

Abstract. In this paper a nonlinear elliptic-parabolic system which arises in a two-dimensional groundwater flow problem is studied. Abstract results on evolution equations are employed to obtain existence and uniqueness results. Regularity and stability properties of the solution are also considered.

Key words. elliptic-parabolic system, analytic semigroups, semilinear and quasilinear evolution equations

AMS(MOS) subject classifications. 35K50, 47D05

1. Introduction.

Let $\Omega \in \mathbf{R}^2$ be a bounded domain with smooth boundary. In this paper we study the following nonlinear elliptic-parabolic system:

$$(E)\begin{cases} -\Delta v = \partial_1 u & \text{in } \Omega \times (0,\infty), \\ v = 0 & \text{on } \partial\Omega \times (0,\infty), \end{cases}$$

and

$$(P)\begin{cases} \partial_t u + \operatorname{div}\vec{F} = 0 & \text{in } \Omega \times (0,\infty), \\ \vec{F}\cdot\vec{\nu} = 0 & \text{on } \partial\Omega \times (0,\infty), \\ u(\cdot,0) = u_0(\cdot) & \text{in } \Omega. \end{cases}$$

Here we have

$$\vec{F} = \vec{q}\,u - D\cdot \operatorname{grad} u,$$
$$\vec{q} = \operatorname{curl} v,$$
$$D = (D_{ij}),$$

where $D_{ij}(q_1,q_2)$ are uniformly Lipschitz continuous functions on $\mathbf{R}^2$.

This system arises in the description of the movement of a fluid of variable density (u) through a porous medium under the influence of gravity and hydrodynamic dispersion. In §2 we set up the model and we discuss the physical background.

In a slightly different form, Problem (E), (P) was studied by Su [16] using classical partial differential equation (PDE) methods. In this paper we present an approach in the spirit of abstract evolution equations in Banach spaces. This turns out to be quite efficient because of the particular form of the problem.

We consider two cases of the model separately. In the first (approximate) case we take $D_{ij} = \delta_{ij}$ (δ_{ij} is the Kronecker symbol). Then the system can be considered as a semilinear evolution equation. Clearly, there are many results on abstract semilinear evolution equations, and these results can be well applied to partial differential equations of parabolic type; see, e.g., Friedman [7], Henry [9], Pazy [12], or von Wahl [19]. Here we choose one theorem from von Wahl [20], which fits precisely to the abstract formulation of Problem (E), (P) with constant (D). By this theorem we obtain the global existence of the solution in $L^p(\Omega)$. This is done in §3. There we also study the

*Received by the editors November 28, 1990; accepted for publication (in revised form) November 8, 1991.

† Department of Mathematics and Informatics, Delft University of Technology, the Netherlands.

regularity and asymptotic properties of the solution. We show that the solution is in fact a classical solution of $(E), (P)$, and u converges to the mean value in sup-norm as $t \to \infty$. A first draft of §3 was made by de Roo [13].

In §4, we study the full problem, i.e., D is nonconstant and velocity dependent. Then the abstract formulation leads to a quasilinear evolution equation. The abstract results on such equations are not as complete as the results on semilinear equations. Moreover the application to partial differential equations is much harder. In this paper we use the framework of quasilinear evolution equations due to Amann [2], see also Sobolevskii [15]. As a result, we obtain local existence of weak solutions in $W^{1,p}(\Omega)$. As for this moment, we are not able to obtain global existence. Because the coefficients D_{ij} are not differentiable at the origin, see (2.13), we can not expect to have classical solutions.

2. The physical background. Let $\Omega = (-L, L) \times (0, H)$, with $L, H > 0$, denote a rectangular region in the x_1, x_2 plane which is occupied by a homogeneous and isotropic porous medium. This medium is characterized by a permeability $\kappa \in (0, \infty)$ and a porosity $\phi \in (0, 1)$. It is saturated by an incompressible fluid. The fluid is characterized by a constant viscosity $\mu \in (0, \infty)$ and a variable density ρ (or a specific weight $\gamma = \rho g$, where g is the accelaration of gravity). Here the coordinate system is chosen such that the gravity is pointing in the negative x_2-direction. A typical example of this situation arises in the flow of fresh and salt groundwater in a two-dimensional vertical aquifer. In this application it is natural to assume that γ satisfies

$$0 < \gamma_f \leq \gamma(x_1, x_2, t) \leq \gamma_s \quad \forall (x_1, x_2, t) \in \Omega \times (0, \infty). \tag{2.1}$$

Here γ_f and γ_s are constants, denoting the specific weight of the fresh and the salt groundwater, respectively.

The basic equations for flow in a porous medium are the continuity equation

$$\operatorname{div} \vec{q} = 0 \quad \text{in } \Omega \times (0, \infty) \tag{2.2}$$

and the momentum balance equation (Darcy's law), see, e.g., Bear [5],

$$\frac{\mu}{\kappa} \vec{q} + \operatorname{grad} p + \gamma \vec{e}_2 \ = 0 \quad \text{in } \Omega \times (0, \infty). \tag{2.3}$$

Here we denote by the vector $\vec{q}$ the specific discharge of the fluid and by the scalar p the fluid pressure. Finally, $\vec{e}_2$ denotes the unit vector in the positive x_2-direction (i.e., pointing upwards).

In this paper we are interested in describing the distribution of the specific weight γ in the domain Ω under the action of gravity and hydrodynamic dispersion, without any other influence from outside. Therefore, we impose on the boundary $\partial\Omega$ the no-flow condition

$$\vec{q} \cdot \vec{\nu} = 0 \quad \text{on } \partial\Omega \times (0, \infty), \tag{2.4}$$

where $\vec{\nu}$ is the outward normal unit vector on $\partial\Omega$.

For a given specific weight distribution γ, (2.2)–(2.4) determine the discharge field $\vec{q}$. To obtain a single equation for this relation we can use either the pressure or, because of (2.2), the stream function. Here we use a formulation in terms of the stream function. It satisfies

$$\vec{q} = (q_1, q_2) = \operatorname{curl} \psi := (-\partial_2 \psi, \ \partial_1 \psi), \tag{2.5}$$

where ∂_i denotes the partial derivative with respect to the variable x_i for $i = 1, 2$. Note that the operator curl in (2.5) acts on a scalar function. Therefore this definition differs from the usual one. It is introduced here only for convenience.

Substituting (2.5) into Darcy's law (2.3) and taking the curl in the usual sense (i.e., curl $\vec{q} = \partial_2 q_1 - \partial_1 q_2$) gives

$$-\Delta\psi = \frac{\kappa}{\mu}\partial_1\gamma \quad \text{in } \Omega \times (0,\infty). \tag{2.6}$$

Combining (2.4) and (2.5) implies that ψ is constant on the boundary $\partial\Omega$. Without loss of generality, we take the boundary condition

$$\psi = 0 \quad \text{on } \partial\Omega \times (0,\infty). \tag{2.7}$$

The boundary value problem (2.6), (2.7) gives the stream function and thus the specific discharge, in terms of the specific weight γ. Conversely, the mass balance equation for the fluid gives the density ρ (and thus the specific weight) in terms of the fluid field $\vec{q}$. According to Bear [5], we have

$$\phi\partial_t\rho + \operatorname{div}\vec{F} = 0 \quad \text{in } \Omega \times (0,\infty), \tag{2.8}$$

where the flux $\vec{F}$ is given by

$$\vec{F} = \vec{q}\rho - D \cdot \operatorname{grad}\rho. \tag{2.9}$$

In (2.9), $D = (D_{ij})_{2\times 2}$ is the hydrodynamic dispersion matrix with $D_{ij} : \mathbf{R}^2 \to \mathbf{R}$ given by

$$D_{ij}(q_1,q_2) = \begin{cases} (\alpha_T \mid \vec{q} \mid + \tau\ \phi D_{\text{mol}})\delta_{ij} + (\alpha_L - \alpha_T)\dfrac{q_i q_j}{\mid \vec{q} \mid} & \text{if } (q_1,q_2) \neq 0, \\ \tau\phi D_{\text{mol}}\delta_{ij} & \text{if } (q_1,q_2) = 0. \end{cases} \tag{2.10}$$

Here $\alpha_L, \alpha_T, D_{\text{mol}}$ and τ are positive constants: α_L is the longitudinal and α_T is the the transversal dispersion length ($\alpha_T < \alpha_L$), D_{mol} is the molecular diffusion coefficient and the constant τ describes the tortuosity of the porous medium. Further, $|\cdot|$ denotes the Euclidean norm on $\mathbf{R}^2$ and δ_{ij} the Kronecker symbol.

In order to determine ρ (or γ) from (2.8) we have to specify boundary and initial conditions. We consider the no-flux condition

$$\vec{F} \cdot \vec{\nu} = 0 \quad \text{on } \partial\Omega \times (0,\infty), \tag{2.11}$$

and initially

$$\rho(\cdot,0) = \rho_0(\cdot) \quad \text{on } \Omega. \tag{2.12}$$

Next we rescale the equations into a dimensionless form.
Setting

$$\begin{aligned} x_1 &:= x_1/H, \\ x_2 &:= x_2/H, \\ t &:= t\frac{\kappa}{\mu}(\gamma_s - \gamma_f)/(H\phi), \\ u &:= (\gamma - \gamma_f)/(\gamma_s - \gamma_f), \\ v &:= \psi/(\frac{\kappa}{\mu}(\gamma_s - \gamma_f)H), \\ \Omega &:= (-L/H, L/H) \times (0,1), \end{aligned}$$

we find for u, v the elliptic-parabolic system

$$(E)\begin{cases} -\Delta v = \partial_1 u & \text{in } \Omega \times (0,\infty), \\ v = 0 & \text{on } \partial\Omega \times (0,\infty), \end{cases}$$

$$(P)\begin{cases} \partial_t u + \operatorname{div}\vec{F} = 0 & \text{in } \Omega \times (0,\infty), \\ \vec{F}\cdot\vec{\nu} = 0 & \text{on } \partial\Omega \times (0,\infty), \\ u(\cdot,0) = u_0(\cdot) & \text{on } \Omega. \end{cases}$$

Here we have

$$\begin{aligned} &\vec{F} = \vec{q}\,u - D\cdot\operatorname{grad} u, \\ &\vec{q} = \operatorname{curl} v, \\ &D = (D_{ij}) \end{aligned}$$

with

$$(2.13)\qquad D_{ij}(q_1,q_2) = \begin{cases} (a\mid\vec{q}\mid+m)\delta_{ij} \ + (b-a)\dfrac{q_iq_j}{\mid\vec{q}\mid} & \text{if } (q_1,q_2)\neq 0, \\ m\delta_{ij} & \text{if } (q_1,q_2) = 0, \end{cases}$$

where $a = \alpha_T/H$, $b = \alpha_L/H$ and $m = \phi D_{\mathrm{mol}T}/[\frac{\kappa}{\mu}(\gamma_s-\gamma_f)H]$.

The dispersion matrix D satisfies the following.

PROPOSITION 2.1. *Let $D = (D_{ij})$ be given by (2.13). Then*

(i) *D is uniformly positive definite on $\mathbf{R}^2$, i.e., there exists $\mu > 0$ such that*

$$\sum_{i,j=1}^{2} D_{ij}(q_1,q_2)\xi^i\xi^j \geq \mu|\xi|^2 \quad \forall\xi = (\xi^1,\xi^2), (q_1,q_2)\in\mathbf{R}^2;$$

(ii) *D_{ij} is uniformly Lipschitz continuous.*

Proof. The proof of (i) is immediate. To prove (ii) we have to show that the functions $f_{ij} : \mathbf{R}^2 \to \mathbf{R}$, defined by

$$f_{ij}(x) = \begin{cases} \dfrac{x_ix_j}{|x|} & \text{if } x\neq(0,0), \\ 0 & \text{if } x = (0,0), \end{cases}$$

are uniformly Lipschitz continuous. A straightforward computation shows that there exists a constant $L > 0$ such that

$$|\nabla f_{ij}(x)| \leq L \quad \forall x\in\mathbf{R}^2\backslash\{0\}$$

and

$$|f_{ij}(x) - f_{ij}(0)| \leq |x-0| \quad \forall x\in\mathbf{R}^2.$$

This implies the Lipschitz continuity for f_{ij} and thus for D_{ij}. □

The purpose of this paper is to study the elliptic-parabolic system $(E), (P)$. We do this in two steps. First, in §3 we consider the case, where

$$a = b = 0 \quad \text{and} \quad m = 1.$$

This situation describes the mixing of fresh and salt groundwater with dominant molecular diffusion. It implies $D_{ij} = \delta_{ij}$ which means that the problem is of semilinear type. In §4, we consider the full problem, where

$$0 < a < b < \infty \quad \text{and} \quad m > 0.$$

In this case the mixing is due to mechanical dispersion and molecular diffusion. It implies that D is velocity dependent which means that the problem is of quasilinear type.

3. The semilinear case.

3.1. The abstract setting. In this section we consider the case where the dispersion matrix D is independent of the velocity $\vec{q}$. This can be achieved by setting $a = b = 0$ in (2.13). For simplicity, we also set $m = 1$, which implies that $D_{ij} = \delta_{ij}$. Noting that $\vec{q} \cdot \vec{\nu} = 0$ on $\partial\Omega$, we arrive at the problem

$$(E)\begin{cases} -\Delta v = \partial_1 u & \text{in } \Omega \times (0,\infty), \\ v = 0 & \text{on } \partial\Omega \times (0,\infty), \end{cases}$$

$$(P')\begin{cases} \partial_t u - \Delta u + \operatorname{grad} u \cdot \operatorname{curl} v = 0 & \text{in } \Omega \times (0,\infty), \\ \dfrac{\partial u}{\partial \vec{\nu}} = 0 & \text{on } \partial\Omega \times (0,\infty), \\ u(\cdot, 0) = u_0(\cdot) & \text{in } \Omega. \end{cases}$$

Throughout this section we suppose that Ω is a bounded domain in $\mathbf{R}^2$ with smooth boundary $\partial\Omega$.

In order to formulate problem (E), (P') into an abstract form, we need to introduce some operators and Banach spaces.

Throughout this paper all vector spaces are over $\mathbf{R}$. If we use complex quantities (for example, in connection with spectral theory), it is always understood that we work with the natural complexifications (of spaces and operators). Thus by $\rho(A)$, the resolvent set of a linear operator with domain $D(A)$ and range $R(A)$, we mean always the resolvent set of its complexifications.

Let $p \in (2, \infty)$. By inverting (E) we obtain the operator (see the appendix)

$$E_p : D(E_p) = W^{1,p}(\Omega) \to W^{2,p}(\Omega) \cap W_0^{1,p}(\Omega),$$

given by

$$E_p v = (-\Delta)^{-1} \partial_1 v.$$

Then we define

$$M_p(u) = (\partial_1 E_p u)\partial_2 u - (\partial_1 u)\partial_2 E_p u - u$$

for $u \in W^{1,p}(\Omega)$. Furthermore, we define operator A_p by

$$D(A_p) = \left\{ u \in W^{2,p}(\Omega) : \frac{\partial u}{\partial \vec{\nu}} = 0 \right\},$$

$$A_p : D(A_p) \to L^p(\Omega)$$

with

$$A_p u = -\Delta u + u.$$

Observe that in the definition of A_p, due to the imbedding $W^{2,p}(\Omega) \hookrightarrow C^1(\overline{\Omega})$, the boundary condition $\partial u/\partial\vec{\nu} = 0$ is satisfied in the classical sense. By using the operators introduced above, Problem (E), (P') can be formulated as

$$(CP)\begin{cases} u' + A_p u + M_p(u) = 0 & \text{for } t \in (0,\infty), \\ u(0) = u_0. \end{cases}$$

Here u' denotes the derivative of u with respect to t.

It is known that $-A_p$ generates an analytic semigroup on $L^p(\Omega)$. We shall show that M_p is a locally Lipschitz perturbation (in an appropriate sense) of A_p. Then we can apply abstract results for proving existence of solutions of (CP).

We recall the following results.

Let $\Sigma_\omega := \{\lambda \in \mathbf{C} : \mathrm{Re}\lambda \geq \omega\}$ for $\omega \in \mathbf{R}$. Furthermore, let X be a Banach space with norm $\|\cdot\|$, and let A be a given linear operator satisfying

(A1) A is densely defined and closed;
(A2) $\Sigma_0 \subset \rho(-A)$, where $\rho(-A)$ is the resolvent set of $-A$;
(A3) There exists a constant $M > 0$, such that

$$\|(\lambda + A)^{-1}\| \leq \frac{M}{1 + |\lambda|} \quad \forall \lambda \in \Sigma_0.$$

The fractional powers A^α of A are well defined for $0 < \alpha \leq 1$, and A^α is a closed linear operator whose domain $D(A^\alpha) \supset D(A)$. In this section we denote by X_α the Banach space obtained by endowing $D(A^\alpha)$ with the graph norm of A^α. Since $0 \in \rho(A)$, A^α is invertible and the norm of X_α is equivalent to $\|u\|_\alpha := \|A^\alpha u\|$ for $u \in D(A^\alpha)$. Also, for $0 < \beta < \alpha \leq 1$, $X_\alpha \hookrightarrow X_\beta$ with continuous imbedding.

Concerning the solvability of semilinear evolution equations of the form

$$u' + Au + M(u) = 0 \tag{3.1}$$

with initial value $u(0) = \varphi$, under the assumptions (A1)–(A3), we recall the following result (see von Wahl [20]).

THEOREM 3.1. *Let $0 \leq \beta < \alpha < 1$, and let $M : X_\alpha \to X$ satisfy $M(0) = 0$ and*

$$\|M(u) - M(v)\| \leq g(\|u\|_\beta + \|v\|_\beta)[\|u - v\|_\alpha + \|u - v\|_\beta(\|u\|_\alpha + \|v\|_\alpha + 1)]$$

for some continuous function g: $\mathbf{R}^+ \to \mathbf{R}^+$ and for all u, $v \in X_\alpha$. For $\varphi \in X_\beta$, there exists a $T = T(\varphi) \in (0,\infty]$ such that

(i) *there is one and only one mapping u: $[0,T) \to X$ fulfilling*

$$u \in C([0,T), X_\beta) \cap C((0,T), X_\alpha),$$

and

$$\sup_{0<t\leq T'} \|t^{\alpha-\beta} A^\alpha u(t)\| < \infty$$

for all $0 < T' < T$;

(ii)

$$u(t) = e^{-tA}\varphi - \int_0^t e^{-(t-s)A} M(u(s))ds$$

for $t \in (0, T)$;

(iii)

$$u(0) = \varphi;$$

(iv) *if* $T < \infty$, *then*

$$\lim_{t \uparrow T} \|u(t)\|_\beta = \infty.$$

Moreover, on $(0, T)$, u *fulfills* (3.1) *in the sense that* $u \in C^1((0, T), X)$, $u(t) \in D(A)$ *for* $t \in (0, T)$ *and* $Au(\cdot) \in C((0, T), X)$.

About the solution obtained in Theorem 3.1 we also have the following (see Henry [9]).

PROPOSITION 3.2. *Under the assumptions of Theorem* 3.1, *the solution* u *satisfies*

$$u'(t) \in X_\gamma$$

for $t \in (0, T)$ *and for any* $\gamma \in (0, 1)$.

3.2. The existence results. It follows from Agmon [1] that A_p satisfies (A1)–(A3). Moreover, we have the imbedding properties (see Henry [9]):

PROPOSITION 3.3. (i) $D(A_p^\alpha) \hookrightarrow W^{1,p}(\Omega)$ *for* $\alpha \in (\frac{1}{2}, 1)$;

(ii) $D(A_p^\alpha) \hookrightarrow W^{1,\infty}(\Omega)$ *for* $\alpha \in (\frac{1}{2} + \frac{1}{p}, 1)$.

We use Theorem 3.1 to obtain the existence for (CP). In this application we take $X = L^p(\Omega)$ with norm $\|\cdot\|_p$, X_α ($\alpha \in (0, 1)$) the Banach space induced by the operator A_p and $\beta = 0$ with $\|\cdot\|_\beta = \|\cdot\|_p$.

PROPOSITION 3.4. *Let* $\alpha \in (\frac{1}{2} + \frac{1}{p}, 1)$. *Then there exists a constant* $C \geq 1$ *such that*

$$\|M_p(u) - M_p(v)\|_p \leq C[\|u - v\|_\alpha \|u\|_p + \|u - v\|_p(\|v\|_\alpha + 1)]$$

for all $u, v \in D(A_p^\alpha)$.

Proof. By the definition of M_p we have

$$\|M_p(u) - M_p(v)\|_p \leq \|u - v\|_p + \|\text{grad}\,(u - v) \cdot \text{curl}\, E_p u\|_p + \|\text{grad}\, v \cdot \text{curl}\, E_p(u - v)\|_p. \tag{3.2}$$

From the Appendix and Proposition 3.3, we obtain:

$$\|\text{curl}\, E_p u\|_p \leq C\|u\|_p \tag{3.3}$$

and

$$\|E_p u\|_{1,\infty} \leq C\|u\|_\alpha \tag{3.4}$$

for all $u \in D(A_p^\alpha)$ and for some constant $C \geq 1$. Combining (3.2), (3.3), and (3.4), the desired estimate follows. □

Combining Theorem 3.1 and Proposition 3.4, we obtain that, for every $u_0 \in L^p(\Omega)$, there exists a solution u of (CP) on some interval $[0,T)$.

According to Theorem 3.1 (iv), the global existence of the solution follows if we can show that

$$\overline{\lim_{t\uparrow T}}\|u(t)\|_p < \infty.$$

By the imbedding $W^{2,p}(\Omega) \hookrightarrow C^1(\overline{\Omega})$, we can define $u(x,t) = u(t)(x)$ pointwise on $\Omega \times (0,T)$. Further, we have the following.

PROPOSITION 3.5. *Let $u_0 \in L^p(\Omega)$ and u be the corresponding solution of (CP) on $[0,T)$ in the sense of Theorem 3.1. Let $J \in C^2(\mathbf{R},\mathbf{R}^+)$ be a convex function; then we have*

$$\int_\Omega J(u(x,t))dx \leq \int_\Omega J(u(x,s))dx$$

for any $0 < s \leq t < T$.

Proof. Note that $J(u)$ is well defined due to the imbedding $W^{2,p}(\Omega) \hookrightarrow C^1(\overline{\Omega})$.

Multiplying the differential equation in (P') by $J'(u)$ and integrating the result over Ω gives

$$\frac{d}{dt}\int_\Omega J(u)dx = \int_\Omega J'(u)\Delta u\, dx + \int_\Omega J'(u)\text{grad}\, u \cdot \text{curl}\, v\, dx$$

for $0 < t < T$. Using Green's formula we know that

$$\int_\Omega J'(u)\Delta u\, dx = -\int_\Omega J''(u)[(\partial_1 u)^2 + (\partial_2 u)^2]dx \leq 0$$

and

$$\int_\Omega J'(u)\text{grad}\, u \cdot \text{curl}\, v\, dx = \int_{\partial\Omega} J(u)\frac{\partial v}{\partial \vec{\tau}}ds = 0,$$

where $\vec{\tau}$ is the tangential unit vector along $\partial\Omega$. Therefore,

$$\frac{d}{dt}\int_\Omega J(u)dx \leq 0,$$

which implies the required inequality. □

COROLLARY 3.6. *Let $u_0 \in L^p(\Omega)$ with $p \in (2,\infty]$ and u be the solution of (CP) on $[0,T)$ in the sense of Theorem 3.1. For any $q \in [2,p]$ we have*

$$\|u(t)\|_q \leq \|u_0\|_q \tag{3.5}$$

for $t \in [0,T)$.

Proof. This estimate follows directly from Proposition 3.5 by taking $J(s) = |s|^q$ and from the fact that $u \in C([0,T),X)$ for $p < \infty$. We obtain the estimate (3.5) for $p = q = \infty$ by using a limit argument. □

Using Theorem 3.1, Proposition 3.4, and Corollary 3.6, we obtain the following existence result for (CP).

THEOREM 3.7. *Let $\alpha \in (\frac{1}{2}+\frac{1}{p},1)$ and $u_0 \in L^p(\Omega)$. Then the initial value problem (CP) has a unique global solution $u(\cdot)$, i.e.,*

$$u \in C([0,\infty),X) \cap C((0,\infty),X_\alpha),$$

$$\sup_{0<t\leq 1} \|t^{\alpha} A_p^{\alpha} u(t)\| < \infty,$$

$$u(t) = e^{-tA_p} u_0 - \int_0^t e^{-(t-s)A_p} M(u(s)) ds$$

for $t \in (0, \infty)$, *and*

$$u(0) = u_0.$$

Moreover, u fulfills the equation $u' + A_p u + M_p(u) = 0$ *on* $(0, \infty)$ *in the sense that* $u \in C^1((0, \infty), X), u(t) \in D(A_p)$ *for* $t \in (0, \infty)$ *and* $A_p u \in C((0, \infty), X)$.

3.3. Regularity and asymptotic properties. In the preceding section we obtained the solution of the abstract problem (CP). Here we consider the original system (E), (P'). Let u be the solution of (CP). Then we have

$$u(t) \in W^{2,p}(\Omega), v(t) = E_p u(t) \in W^{2,p}(\Omega) \quad \forall t \in (0, \infty).$$

By the imbedding $W^{2,p}(\Omega) \hookrightarrow C^1(\overline{\Omega})$, we can define $u(x, t) = u(t)(x)$ and $v(x, t) = E_p u(t)(x)$ for $(x, t) \in \overline{\Omega} \times (0, \infty)$. The pair (u, v) satisfies the following

THEOREM 3.8. *Let* $\theta \in (0, 1 - \frac{2}{p})$, $\partial\Omega \in C^{2+\theta}$ *and suppose* $u_0 \in L^p(\Omega)$. *Let u,v be defined as above. Then* (u, v) *is the unique classical solution of the system* (E), (P'), *which satisfies*

(i) $u(\cdot, t) \in C^{2+\theta}(\overline{\Omega})$, $\partial_t u(\cdot, t) \in C^{\theta}(\overline{\Omega})$, $\forall t \in (0, \infty)$;

(ii) $u(x, \cdot) \in C^{1+\frac{\theta}{2}}(0, \infty)$ $\forall x \in \overline{\Omega}$;

(iii) $v(\cdot, t) \in C^{2+\theta}(\overline{\Omega})$, $\forall t \in (0, \infty)$.

Proof. (i) By the imbedding $W^{2,p}(\Omega) \hookrightarrow C^{1+\theta}(\overline{\Omega})$, we have

$$u(\cdot, t), v(\cdot, t) \in C^{1+\theta}(\overline{\Omega}) \quad \forall t \in (0, \infty).$$

Using Propositions 3.2 and 3.3, we also have

$$\partial_t u(\cdot, t) \in C^{\theta}(\overline{\Omega}) \quad \forall t \in (0, \infty).$$

Let $t_0 \in (0, \infty)$ be fixed. The regularity for u and v implies that

$$F(\cdot) = -\text{grad}\, u(\cdot, t_0) \cdot \text{curl}\, v(\cdot, t_0) + u(\cdot, t_0) - \partial_t u(\cdot, t_0)$$

satisfies

$$F(\cdot) \in C^{\theta}(\overline{\Omega}).$$

Next, consider the problem

$$\begin{cases} -\Delta w + w = F & \text{in } \Omega, \\ \dfrac{\partial w}{\partial \vec{\nu}} = 0 & \text{on } \partial\Omega. \end{cases}$$

By Gilbarg and Trudinger [8] this problem has a unique solution $w \in C^{2+\theta}(\overline{\Omega})$. A standard argument gives $w(\cdot) = u(\cdot, t_0)$, hence $u(\cdot, t_0) \in C^{2+\theta}(\overline{\Omega})$.

(ii) This is a direct result of (i) and Ladyzenskaja et al. [10, Thm. 5.3].

(iii) The regularity for v is a direct result of the Dirichlet problem (E). □

Remark. If the boundary $\partial\Omega$ is smooth, then the solution is smooth in $\overline{\Omega}\times(0,\infty)$. This follows from Theorem 3.8 together with a bootstrapping argument.

Let (u, v) be the solution of (E), (P'), a straightforward computation shows

$$\overline{u} := \frac{1}{|\Omega|}\int_\Omega u(x,t)dx = \frac{1}{|\Omega|}\int_\Omega u_0(x)dx$$

for all $t \in (0,\infty)$. Here $|\Omega|$ denotes the measure of Ω.

LEMMA 3.9. *We have*

$$\lim_{t\longrightarrow\infty} \|u(\cdot,t)-\overline{u}\|_2 = 0.$$

Proof. Taking $J(s) = s^2$ in the proof of Propositon 3.5, we obtain

$$\frac{d}{dt}\|u(\cdot,t)-\overline{u}\|_2^2 \leq -(\|\partial_1 u\|_2^2 + \|\partial_2 u\|_2^2).$$

We estimate the right-hand side by Poincaré's inequality. This gives

$$\|u(\cdot,t)-\overline{u}\|_2^2 \leq K(\|\partial_1 u\|_2^2 + \|\partial_2 u\|_2^2)$$

for some constant $K > 0$. Therefore,

$$\frac{d}{dt}\|u(\cdot,t)-\overline{u}\|_2^2 \leq -\frac{1}{K}\|u(\cdot,t)-\overline{u}\|_2^2,$$

which can be integrated to yield

$$\|u(\cdot,t)-\overline{u}\|_2^2 \leq e^{-t/K}\|u_0(\cdot)-\overline{u}\|_2^2, \tag{3.6}$$

for all $t \geq 0$. □

We now consider the asymptotic behavior of the solution in the sup-norm.

THEOREM 3.10. *Let $u_0 \in L^p(\Omega)$ for any $p \in (2,\infty]$. Then*

$$\lim_{t\longrightarrow\infty} \|u(\cdot,t)-\overline{u}\|_\infty = 0.$$

Proof. We put

$$\omega = \{U \in C(\overline{\Omega}) : \exists\{t_m\}, \text{ s.t. } \lim_{m\longrightarrow\infty} t_m = \infty \text{ and } \lim_{m\longrightarrow\infty} \|u(\cdot,t_m) - U(\cdot)\|_\infty = 0\}$$

and

$$F = \{u(\cdot,t) : t \in (0,\infty)\}.$$

From Corollary 3.6 and Theorem 3.8, it follows that F is a uniformly bounded and equicontinuous subset in $C(\overline{\Omega})$. Therefore, ω is nonempty. Next we show that ω contains only one single point. Let $U \in \omega$. Then there exists a sequence $\{t_m\}$ with

$$\lim_{m\longrightarrow\infty} t_m = \infty$$

and

$$\lim_{m\longrightarrow\infty} \|u(\cdot,t_m) - U(\cdot)\|_\infty = 0.$$

This implies

$$u(x, t_m) \to U(x)$$

as $m \to \infty$, uniformly in $x \in \overline{\Omega}$.

On the other hand, we obtain from Lemma 3.9 that

$$u(x, t_m) \to \overline{u}$$

as $m \to \infty$, for almost all $x \in \Omega$. Thus

$$U(x) = \overline{u} \quad \forall x \in \overline{\Omega},$$

which completes the proof. □

4. The quasilinear case.

4.1. The abstract setting. In this section we study Problem (E), (P). As in §3, we treat this system as an abstract evolution equation in a suitably chosen Banach space. In this part we collect some results on quasilinear evolution equations.

Let $\overline{E} = (E_0, E_1)$ be a pair of Banach spaces with E_1 continuously and densely imbedded in E_0. We denote by $\mathcal{H}(\overline{E})$ the set of all $A \in \mathcal{L}(E_1, E_0)$ such that $-A$, considered as a linear operator on E_0, is the infinitesimal generator of a strongly continuous analytic semigroup on E_0. For $\theta \in (0,1)$, let E_θ be the complex interpolation space $[\overline{E}]_\theta$, and $\|\cdot\|_\theta$ be the norm on E_θ. (The notation here is different from the previous section.)

Let $T > 0$ be fixed. We assume (Q) $\beta \in (0,1), V \subset E_\beta$ is open and $A \in C^{1-}(V, \mathcal{H}(\bar{E}))$, i.e., A is locally Lipschitz continuous.

Under these assumptions, we consider the following quasilinear Cauchy problem

$$(QCP)_{(u_0)} : \begin{cases} \dot{u}(t) + A(u(t))u(t) = 0, \ 0 < t \le T, \\ u(0) = u_0, \end{cases}$$

where $u_0 \in V$.

Let $\tau \in (0, T]$; u is called a solution of $(QCP)_{(u_0)}$ on $[0, \tau]$ if the following conditions are satisfied:

(i) $u \in C([0,\tau], V) \cap C((0,\tau], E_1) \cap C^1((0,\tau], E_0)$,

(ii) $\dot{u}(t) + A(u(t))u(t) = 0, \forall t \in (0, \tau]$,

(iii) $u(0) = u_0$.

A solution u is *maximal* if there does not exist a solution of $(QCP)_{(u_0)}$ which is a proper extension of u. In this case the interval of existence is called the *maximal interval of existence.*

The following fundamental theorem can be found in Amann [2] (see also Sobolevskii [15]).

THEOREM 4.1. *Suppose that* $0 < \beta < \alpha < 1$, *and* $u_0 \in V_\alpha := E_\alpha \cap V$. *Furthermore, suppose that the assumption* (Q) *holds. Then there exists* $\tau > 0$, *such that* $(QCP)_{u_0}$ *has a unique solution* $u(\cdot)$ *on* $[0, \tau]$, *satisfying* $u \in C([0, \tau], V_\alpha)$. *Moreover, the maximal interval of existence is open in* $[0, T]$. □

4.2. Local existence. Again we put the system into an abstract form.

Let $\Omega \subset \mathbf{R}^2$ be a bounded domain with smooth boundary $\partial\Omega$. For $p \in (1, \infty)$ and $r \in (-\infty, \infty)$, we denote by $H_p^r(\Omega)$ the so-called Lebesgue spaces (see Triebel [17] or Bergh and Löfström [6]). In this section the norm on $H_p^r(\Omega)$ is denoted by $\|\cdot\|_{r,p}$.

It should be observed that $H_p^m(\Omega) = W^{m,p}(\Omega)$ for integer m. Moreover, we have the interpolation property

$$[H_{p_0}^{s_0}(\Omega), H_{p_1}^{s_1}(\Omega)]_\theta = H_p^s(\Omega) \tag{4.1}$$

for $s_0, s_1 \in \mathbf{R}$, $p_0, p_1 \in (1,\infty)$ with $\frac{1}{p} = (1-\theta)/p_0 + \theta/p_1$ and $s = (1-\theta)s_0 + \theta s_1$.

Let $a_{jk} := D_{jk} \circ Q$ and $a_j = -Q_j$ for $j, k = 1, 2$ (see Appendix). Then problem $(E), (P)$ can be formulated as

$$(QCP) \begin{cases} \partial_t u - \partial_j(a_{jk}(u)\partial_k u + a_j(u)u) = 0 & \text{in } \Omega \times (0,T], \\ \nu^j a_{jk}(u)\partial_k u + a_j(u)\nu^j u = 0 & \text{on } \partial\Omega \times (0,T], \\ u(\cdot, 0) = u_0 & \text{in } \Omega. \end{cases}$$

Here $T > 0$ and $\vec{\nu} = (\nu^1, \nu^2)$. Note that in this section the summation convention is used and the indices run from 1 to 2.

We use Theorem 4.1 to obtain the existence result for Problem (QCP). In this application we take

$$E_0 = (H_{p'}^1(\Omega))'$$

and

$$E_1 = H_p^1(\Omega),$$

where $p \in (1,\infty)$ and $\frac{1}{p} + \frac{1}{p'} = 1$. It should be observed that

$$E_\theta = [E_0, E_1]_\theta \hookrightarrow L^p(\Omega) \tag{4.2}$$

for $\theta \in [\frac{1}{2}, 1]$; see Amann [4, Thm. 3.3].

Let $\mathcal{M}(\Omega) \subset C(\overline{\Omega})^4 \times C(\overline{\Omega})^2$ be the subset whose elements $m(\cdot) = (b_{jk}(\cdot), b_j(\cdot))$ are chosen such that $(b_{jk}(\cdot))_{2\times 2}$ is uniformly positive definite on $\overline{\Omega}$. Assume we set

$$\langle f, g \rangle = \int_\Omega f(x)g(x)dx$$

for $f \in L^p(\Omega)$, $g \in L^{p'}(\Omega)$. With this notation we define

$$a(m)(v,u) = \langle \partial_j v, b_{jk}\partial_k u + b_j u \rangle$$

for $v \in H_{p'}^1(\Omega)$, $u \in H_p^1(\Omega)$, and $m \in \mathcal{M}(\Omega)$.

Furthermore, given $m \in \mathcal{M}(\Omega)$, we define the operator

$$A(m) : E_1 \to E_0$$

such that

$$\langle A(m)u, v \rangle = a(m)(v,u) \quad \forall v \in H_{p'}^1(\Omega).$$

Then we have the following generation theorem; see Amann [3] or Lunardi and Vespri [11].

THEOREM 4.2.

$$[m \to A(m)] \in C^{1-}(\mathcal{M}(\Omega), \mathcal{H}(\overline{E})).$$

For $p \in (2, \infty)$ and $r > \frac{2}{p}$, we have

$$H_p^r(\Omega) \hookrightarrow C(\overline{\Omega}), \tag{4.3}$$

Therefore, the coefficients $a_{jk}(u)$, $a_j(u)$ are defined pointwise on $\overline{\Omega}$ for each $u \in H_p^r(\Omega)$. Consequently,

$$m(u)(\cdot) := (a_{jk}(u)(\cdot), a_j(u)(\cdot))$$

is well defined on $\overline{\Omega}$. For m we also have the following.

LEMMA 4.3. *Let $p \in (2, \infty)$ and $1 \geq r > \frac{2}{p}$. Then $[u \to m(u)] : H_p^r(\Omega) \to \mathcal{M}(\Omega)$ is uniformly Lipschitz continuous.*

Proof. From the appendix we have

$$Q_i \in \mathcal{L}(H_p^r(\Omega)). \tag{4.4}$$

We combine this with imbedding (4.3) and Proposition 2.1 to obtain

$$m(u) \in \mathcal{M}(\Omega).$$

On the other hand, by Proposition 2.1, (4.3), and (4.4), there exists a constant $C > 0$ such that

$$\|a_{jk}(u) - a_{jk}(v)\|_{C(\overline{\Omega})} \leq C\|u - v\|_{r,p}$$

and

$$\|a_j(u) - a_j(v)\|_{C(\overline{\Omega})} \leq C\|u - v\|_{r,p}$$

for any $u, v \in H_p^r(\Omega)$ and for $j, k = 1, 2$. This completes the proof. □

Let us put $A(u) := A(m(u)(\cdot))$ We are now in a position to prove the main existence result.

THEOREM 4.4. *Let $p \in (2, \infty)$ and $\frac{1}{2} + \frac{1}{p} < \beta < \alpha < 1$. For every $u_0 \in E_\alpha$, there exists a $\tau > 0$ such that*

$$\begin{cases} \dot{u}(t) + A(u(t))u(t) = 0, & 0 < t \leq \tau, \\ u(0) = u_0, \end{cases}$$

has a unique solution $u(\cdot)$ on $[0, \tau]$, i.e.,

(i) $u \in C([0, \tau], E_\alpha) \cap C((0, \tau], E_1) \cap C^1((0, \tau], E_0)$,
(ii) $\dot{u}(t) + A(u(t))u(t) = 0, \forall t \in (0, \tau]$,
(iii) $u(0) = u_0$.

Proof. For $\beta = \frac{1}{2} + \frac{r}{2} \in (0, 1)$ we have

$$E_\beta \hookrightarrow [E_{\frac{1}{2}}, E_1]_r,$$

by the reiteration theorem (see Triebel [17] or Bergh and Löfström [6]). Using (4.2), we have

$$E_\beta \hookrightarrow [L^p(\Omega), H_p^1(\Omega)]_r = H_p^r(\Omega)$$

with $r \in (0, 1)$. Finally, if $1 > \beta > \frac{1}{2} + \frac{1}{p}$, then $1 > r > \frac{2}{p}$ and $H_p^r(\Omega) \hookrightarrow C(\overline{\Omega})$. From Lemma 4.3 we know $[u \to m(u)]$ is uniformly Lipschitz continuous from E_β to $\mathcal{M}(\Omega)$.

On the other hand, it follows from Theorem 4.2 that

$$[m \to A(m)] \in C^{1-}(\mathcal{M}(\Omega), \mathcal{H}(\overline{E})).$$

Hence

$$[u \to A(u)] \in C^{1-}(E_\beta, \mathcal{H}(\overline{E})).$$

The conclusion then follows directly from Theorem 4.1. □

4.3. Some properties of the weak solution. Up to now we have obtained a local solution for Problem (QCP) in $H_p^1(\Omega)$-sense. We now come back to the original system.

Let $\tau > 0$, $u_0 \in E_\alpha$ for some $\alpha \in (\frac{1}{2} + \frac{1}{p}, 1)$ and we suppose $u \in C^1((0,\tau], E_0) \cap C((0,\tau], E_1)$ is the weak solution mentioned in Theorem 4.4. By the appendix we know that $v(t) = K \circ \partial_1 u(t) \in H_p^2(\Omega)$. Using the imbedding $H_p^1(\Omega) \hookrightarrow C(\overline{\Omega})$, we can define

$$u(x,t) := u(t)(x)$$

and

$$v(x,t) := v(t)(x)$$

pointwise on $\overline{\Omega} \times (0,\tau]$. Obviously, we have

$$\partial_t u(x,t) = \dot{u}(t) \in L^p(\Omega).$$

From Theorem 4.4 we know that problem (P) is satisfied in the following sense:

$$\frac{d}{dt}\int_\Omega u(x,t) f(x) dx - \int_\Omega \vec{F}(x,t) \text{grad } f(x) dx = 0 \tag{4.5}$$

for all $f \in H_{p'}^1(\Omega)$ and $t \in (0,\tau]$. Moreover, $u(x,0) = u_0$.

As in the semilinear case we can prove the following.

THEOREM 4.5. *Let (u,v) be the weak solution of $(E), (P)$ as constructed above. Then*

$$\|u(\cdot,t)\|_p \leq \|u_0\|_p$$

for all $t \in (0,\tau]$.

Proof. Using the facts

$$u(\cdot,t) \in C(\overline{\Omega})$$

and

$$L^p(\Omega) \hookrightarrow L^{p'}(\Omega),$$

we obtain immediately that $f := p|u|^{p-1}\text{sgn } u \in H_{p'}^1(\Omega)$.

Substitution into (4.5) gives

$$\frac{d}{dt}\|u(\cdot,t)\|_p^p = \int_\Omega (u \text{ curl } v - D \cdot \text{grad } u) \cdot p(p-1)|u|^{p-2} \text{grad } u \, dx \tag{4.6}$$

Since the matrix D is positive definite,

$$-\int_\Omega (D \cdot \operatorname{grad} u) \cdot p(p-1)|u|^{p-2}\operatorname{grad} u \, dx \leq 0.$$

On the other hand, by using the Green's formula we have

$$\int_\Omega (u \operatorname{curl} v) \cdot p(p-1)|u|^{p-2}\operatorname{grad} u \, dx = 0.$$

Therefore, the conclusion follows directly from (4.6). □

Final remark. In this paper we assumed Ω to be a bounded domain of $\mathbf{R}^2$ with smooth boundary. On the other hand, the domain in the motivating problem is a rectangle. For such a domain, the same existence results will hold. This is a consequence of the fact that the generation theorems for the operators A_p in §3 and A in §4.2, as well as the proposition in Appendix also hold for such a domain (Vespri [18]).

Appendix. Here we state some results on the Laplace operator with Dirichlet boundary condition, which are related to problem (E).

Let γ denote the trace operator. It is known that the operator $-\Delta$ with Dirichlet boundary condition zero is invertible in $L^p(\Omega)$. We denote this inverse operator by

$$K := (-\Delta \mid \gamma)^{-1}.$$

Further, we introduce operator

$$Q = (Q_1, Q_2) = \operatorname{curl} K \, \partial_1.$$

Let $H^r_p(\Omega)$ be the Lebesgue spaces, with indices $-\infty < r < +\infty$, $1 < p < \infty$.

The operator Q satisfies the following.

PROPOSITION. *Let $r \in [0,1]$ and $1 < p < \infty$. Then*

$$Q_i \in \mathcal{L}(H^r_p(\Omega))$$

for $i = 1, 2$.

Proof. Let $f \in L^p(\Omega)$. We define

$$Fv = \int_\Omega f \partial_1 v \, dx$$

for $v \in W^{1,p'}_0(\Omega)$. Clearly, $F \in (W^{1,p'}_0(\Omega))'$. By the representation theorem in Simader [14, p. 91], we know that there exists $u \in W^{1,p}_0(\Omega)$ such that

$$Fv = \int_\Omega \operatorname{grad} u \cdot \operatorname{grad} v \, dx$$

for $v \in W^{1,p'}_0(\Omega)$. Moreover, there exists a constant C independent of u and f such that

$$\|u\|_{1,p} \leq C\|f\|_p.$$

Therefore,

$$Q_i \in \mathcal{L}(L^p(\Omega)).$$

On the other hand, it is well known that

$$Q_i \in \mathcal{L}(H_p^1(\Omega)).$$

By the interpolation property,

$$[H_p^{s_0}(\Omega), H_p^{s_1}(\Omega)]_\theta = H_p^s(\Omega)$$

for $\theta \in [0,1]$ and s_0, s_1, $s \in \mathbf{R}$ with $s = (1-\theta)s_0 + \theta s_1$; the conclusion follows.

Acknowledgment. The authors are very grateful to Professor H. Amann for his help during his visit in Delft.

FINAL TIME BLOWUP PROFILES FOR SEMILINEAR PARABOLIC EQUATIONS VIA CENTER MANIFOLD THEORY*

J. BEBERNES† AND S. BRICHER‡

Abstract. This paper considers the semilinear parabolic equation $u_t = \Delta u + f(u)$ in $\mathbb{R}^n \times (0, \infty)$, where $f(u) = e^u$ or $f(u) = u^p$, $p > 1$. For any initial data that is a positive, radially decreasing lower solution, and that causes the corresponding solution $u(x, t)$ to blow up at $(0, T) \in \mathbb{R}^n \times (0, \infty)$, the authors prove by using techniques from center manifold theory that the final time blowup profiles satisfy

$$u(x, T) = -2 \ln |x| + \ln |\ln |x|| + \ln 8 + o(1) \quad \text{for } f(u) = e^u,$$

$$u(x, T) = \left(\frac{8\beta^2 p |\ln |x||}{|x|^2}\right)^\beta (1 + o(1)) \quad \text{for } f(u) = u^p$$

as $|x| \to 0$.

Key words. semilinear parabolic equations, blowup, asymptotic behavior of solutions, center manifold theory

AMS(MOS) subject classifications. 35B40, 35K55, 35K57, 34C30

1. Statement of problem and results. Consider the initial-value problem

$$u_t - \Delta u = f(u), \qquad (x, t) \in \mathbb{R}^n \times (0, \infty), \tag{1.1}$$

$$u(x, 0) = \phi(x), \qquad x \in \mathbb{R}^n, \tag{1.2}$$

where

$$f(u) = e^u \quad \text{or} \quad f(u) = u^p, \quad p > 1 \tag{1.3}$$

and ϕ satisfies

$$\begin{cases} \phi \in C^2(\mathbb{R}^n; [0, \infty)) \text{ is radially symmetric,} \\ \phi = \phi(r), \qquad r = |x|, \\ \phi'(0) = 0, \phi''(0) < 0, \phi'(r) < 0 \quad \text{for } r \in (0, \infty), \\ \Delta\phi + f(\phi) \geqq 0 \text{ with } \phi \text{ not a steady-state solution.} \end{cases} \tag{1.4}$$

The following facts are well known for (1.1)-(1.2) [2], [9].

(i) There exists a unique nonnegative solution.

(ii) The solution $u(x, t)$ is radially symmetric; thus (1.1)-(1.2) is equivalent to

$$u_t = u_{rr} + \frac{n-1}{r} u_r + f(u), \qquad (0, \infty) \times \{t : t > 0\}, \tag{1.1'}$$

$$\begin{aligned} u(r, 0) &= \phi(r), \qquad r \in (0, \infty), \\ u_r(0, t) &= 0, \qquad t > 0. \end{aligned} \tag{1.2'}$$

(iii) $u(\cdot, t)$ is radially decreasing, $u_r(r, t) < 0$, and $u_t(r, t) > 0$.

We assume $\phi(x) \geqq 0$ is such that $u(x, t)$ blows up in finite time $T < \infty$; that is, $\sup_{\mathbb{R}^n} |u(x, t)| \to \infty$ as $t \to T^-$ and $\sup_{\mathbb{R}^n \times [0,\tau]} |u(x, t)| < \infty$ for all $0 < \tau < T$.

(iv) Blowup occurs only at $x=0$. Moreover; if $f(u)=e^u$, then for any $\alpha\in(0,1)$,

$$u(x,t)\leqq -\frac{1}{\alpha}\ln\left(\frac{\alpha\varepsilon|x|^2}{2}\right),$$

and if $f(u)=u^p$, then for any $\gamma\in(1,p)$,

$$u(x,t)\leqq\left(\frac{(\gamma-1)\varepsilon|x|^2}{2}\right)^{1/1-\gamma}$$

for $(x,t)\in B_R\times(0,T]$, where B_R is some ball centered at the origin and $\varepsilon>0$ is sufficiently small.

(v)

$$(1.5)\qquad \begin{aligned} &(a)\quad -\ln(T-t)\leqq u(0,t),\ t\in[0,T) &&\text{for } f(u)=e^u,\\ &(b)\quad \beta^\beta(T-t)^{-\beta}\leqq u(0,t),\ t\in[0,T) &&\text{for } f(u)=u^p \end{aligned}$$

where $\beta=1/(p-1)$.

(vi)

$$(1.6)\qquad \begin{aligned} &(a)\quad u(x,t)\leqq -\ln[\delta(T-t)],\ t\in[0,T),\ \delta>0 &&\text{for } f(u)=e^u,\\ &(b)\quad u(x,t)\leqq\left(\frac{\beta}{\delta}\right)^\beta(T-t)^{-\beta},\ t\in[0,T) &&\text{for } f(u)=u^p. \end{aligned}$$

(vii) There exists $\bar{t}<T$ such that

$$(1.7)\qquad \begin{aligned} &(a)\quad |\nabla u(x,t)|\leqq[2e^{u(0,t)}]^{1/2} &&\text{for } f(u)=e^u,\\ &(b)\quad |\nabla u(x,t)|\leqq\left[\frac{2}{p+1}(u(0,t))^{p+1}\right]^{1/2} &&\text{for } f(u)=u^p, \end{aligned}$$

where $(x,t)\in\mathbb{R}^n\times[\bar{t},T)$.

The purpose of this paper is to give a precise description of the asymptotic behavior of solutions $u(x,t)$ of (1.1)-(1.2) as the blowup time T is approached. There has been a considerable effort to resolve this problem in recent years (see [2], [9], [12]). Until very recently, the best rigorous result in this direction for the problem under consideration is the following theorem.

THEOREM 1.1. *If $u(x,t)$ is a solution of* (1.1)-(1.2) *which blows up at* $(0,T)$, *then*

$$(1.8)\qquad \begin{aligned} &(a)\quad \lim_{t\to T}[\ln(T-t)+u(x,t)]=0 &&\text{for } f(u)=e^u,\\ &(b)\quad \lim_{t\to T}u(x,t)(T-t)^\beta=\beta^\beta &&\text{for } f(u)=u^p \end{aligned}$$

uniformly for $|x|\leqq C(T-t)^{1/2}$, $C\geqq0$, *as* $t\to T^-$.

Since $u(x,t)$ blows up only at $x=0$, $u_t(x,t)\geqq0$, and $\sup_{[0,T]}u(x,t)<\infty$ for each $x\neq0$, $u(x,t)\to u_F(x)$ as $t\to T^-$ for all $x\in\mathbb{R}^n-\{0\}$. This final time solution profile $u_F(x)$ should be describable in a neighborhood of the blowup point $x=0$. This observation led Kassoy and Poland [17], [18] and Kapila [19] to formally attempt to describe $u_F(x)$ using singular perturbation techniques for $f(u)=e^u$. Dold [6] for $f(u)=e^u$ and Galaktionov [11] for $f(u)=u^p$ extended these singular perturbation ideas to predict the behavior of $u(x,t)$ near the blowup time, but their analyses are nonrigorous and formal.

Filippas and Kohn [8] are the first to have observed that a center manifold approach to such problems can be used to precisely describe, to higher-order terms, the asymptotic behavior near blowup. Bressan [4] considers (1.1) with $f(u)=e^u$ in a convex domain $\Omega\subset\mathbb{R}^n$. Given any $b\in\Omega$, he proves the existence of solutions that blow up in finite time exactly at b, and whose final profile satisfies

$$u_F(x)=u(x,T)=-2\ln|x-b|+\ln|\ln|x-b||+\ln 8+O([\ln|x-b|]^{-1/3})$$

and proves that this asymptotic behavior is stable with respect to small perturbations of initial conditions. Herrero and Velázquez [15], [16] consider the one-dimensional problem (1.1)-(1.2). Without using center manifold theory, they prove some results suggested by perturbation techniques that will be described in more detail in conjunction with our results.

In this paper, we prove the following three theorems.

THEOREM 1.2. *Let $u(x,t)$ be the solution of* (1.1)-(1.2); *then*

$$\begin{aligned}&\textit{for } f(u)=e^u,\\ &\text{(a)}\quad u(x,t)\sim\ln\left(\frac{1}{T-t}\right)+\frac{1}{4\ln(T-t)}\left(\frac{|x|^2}{T-t}-2n\right)+o\left(\frac{1}{\ln(T-t)}\right)\\ (1.9)\qquad &\textit{for } f(u)=u^p,\\ &\text{(b)}\quad (T-t)^\beta u(x,t)\sim\beta^\beta+\frac{\beta^\beta}{4p\ln(T-t)}\left(\frac{|x|^2}{T-t}-2n\right)+o\left(\frac{1}{\ln(T-t)}\right)\end{aligned}$$

uniformly on $|x|\leqq C(T-t)^{1/2}$, $C\geqq 0$, as $t\to T^-$.

For $n=1$ and $f(u)=u^p$, (1.9(b)) was first obtained by Filippas and Kohn [8], substantiating the conjecture of Galaktionov [11]. Herrero and Velázquez [15] proved both (1.9(a)) and (1.9(b)) for $n=1$. Our proof given in § 2 is influenced by that of Filippas and Kohn [8], where they utilize ideas related to a center manifold theory for infinite-dimensional dynamical systems.

THEOREM 1.3. *Let $u(x,t)$ be the solution of* (1.1)-(1.2); *then*

$$\begin{aligned}&\textit{for } f(u)=e^u,\\ &\text{(a)}\quad \lim_{t\to T}\left[u(\eta((T-t)|\ln(T-t)|)^{1/2},t)+\ln(T-t)\right]=-\ln\left(1+\frac{|\eta|^2}{4}\right)\\ (1.10)\qquad &\textit{for } f(u)=u^p,\\ &\text{(b)}\quad \lim_{t\to T}(T-t)^\beta u(\eta((T-t)|\ln(T-t)|)^{1/2},t)=\beta^\beta\left[1+\frac{|\eta|^2}{4p\beta}\right]^{-\beta}\end{aligned}$$

uniformly on compacts in η.

This result was conjectured and formally verified by Dold [6], [7] in the "ignition-kernel" variable $\eta=x/((T-t)|\ln(T-t)|)^{1/2}$ for $f(u)=e^u$ and by Galaktionov [11] for $f(u)=u^p$. Bressan [4] proved (1.10(a)) for the Cauchy-Dirichlet problem and for some initial conditions $\phi(x)$ whose corresponding solution blows up at the origin. He also showed that the same holds for all initial conditions sufficiently close to ϕ. Bressan's proof includes higher-order terms, and so for certain initial conditions, his result is an improvement of Theorem 1.3 for the case $f(u)=e^u$. This allows him to obtain a more precise estimate of the error term in the final time profile. For $n=1$, Herrero and Velázquez [15] proved (1.10(a)) and (1.10(b)). Theorem 1.3 extends their result to the multidimensional case for any ϕ satisfying (1.4), but is proven by using their techniques. For this reason, we only outline the ideas of the proof in § 3.

THEOREM 1.4. *Let $u(x, t)$ be any solution of* (1.1)-(1.2) *with initial data $\phi(x)$ satisfying* (1.4); *then*

$$\text{(1.11)}\quad \begin{aligned}&\textit{for } f(u)=e^u,\\ &\text{(a)}\quad u_F(x)=u(x,T)=-2\ln|x|+\ln|\ln|x||+\ln 8+o(1)\\ &\textit{for } f(u)=u^p,\\ &\text{(b)}\quad u_F(x)=u(x,T)=\left(\frac{8\beta^2p|\ln|x||}{|x|^2}\right)^{\beta}(1+o(1))\end{aligned}$$

as $|x|\to 0$.

By fact (iv) (see [2, p. 66]), we have the upper bounds

$$\text{(1.12)}\quad \begin{aligned}&\text{for } f(u)=e^u,\\ &\text{(a)}\quad u(x,t)\leqq -2\ln|x|+\ln|\ln|x||+C\\ &\text{for } f(u)=u^p,\\ &\text{(b)}\quad u(x,t)\leqq\left(\frac{k|\ln|x||}{|x|^2}\right)^{\beta}\end{aligned}$$

for all $(x, t)\in B_R\times(0, T]$, where k and C are constants. Theorem 1.4 gives a precise description of $u_F(x)$ in a neighborhood of the singularity $x=0$. Bressan [4] has the first rigorous result of this type provided $f(u)=e^u$ and ϕ is sufficiently spiked. Herrero and Velázquez [16] proved (1.11(b)) when $\phi\in C_b(\mathbb{R}; [0,\infty))$ and the corresponding solution $u(x, t)$ of (1.1)-(1.2) satisfies (1.10(b)). If we assume ϕ satisfies (1.4) and extend their proof to higher dimensions, we obtain (1.11(b)) provided $n\leqq 2$ or $n\geqq 3$ and $p\leqq(n+2)/(n-2)$.

Our proof uses ideas from [16], but avoids the spiked condition on ϕ for $f(u)=e^u$ and the requirement $p\leqq(n+2)/(n-2)$ when $n\geqq 3$ for $f(u)=u^p$ by making use of the upper bounds (1.12). Furthermore, it shows that for any ϕ satisfying (1.4), for which the solution $u(x, t)$ of (1.1)-(1.13) blows up in finite time, $u_F(x)$ satisfies the estimate (1.11).

In § 2, we prove Theorem 1.2 using center manifold theory. We then extend to the ignition variable grouping to obtain Theorem 1.3 in § 3. Finally, we prove Theorem 1.4 in § 4.

Throughout, we will use the following function space notation. For $1\leqq p<\infty$, let $L^p_\rho\equiv\{f\in L^p_{\text{loc}}(\mathbb{R}^n):\int_{\mathbb{R}^n}|f|^p e^{-|x|^2/4}\,dx<\infty\}$, where $\rho=e^{-|x|^2/4}$, $L^p_{\rho 0}=\{f\in L^p_\rho: f$ radially symmetric on $\mathbb{R}^n\}$, $H^m_\rho\equiv\{f\in L^2_{\text{loc}}(\mathbb{R}^n): f^{(j)}\in L^2_{\text{loc}}(\mathbb{R}^n)$, and $\int_{\mathbb{R}^n}|f^{(j)}|\,e^{-|x|^2/4}\,dx<\infty$, $j\in[0, m]\}$ is the weighted Sobolev space, and $H^m_{\rho 0}\equiv\{f\in H^m_\rho: f$ radially symmetric on $\mathbb{R}^n\}$. We will use the standard asymptotic notation $o(\cdot)$, $O(\cdot)$, $\ll$, $\sim$ when convenient.

2. Center-unstable manifold analysis of ignition models. Suppose that $u(x, t)$ is a solution of (1.1)-(1.2), which blows up at $(0, T)\in\mathbb{R}^n\times(0,\infty)$. To analyze the asymptotic behavior of $u(x, t)$, make the "hot-spot" change of variables:

$$\text{(2.1)}\qquad s=-\ln(T-t),\qquad y=\frac{x}{(T-t)^{1/2}},$$

and let

$$\text{(2.2)}\quad \begin{aligned}&\text{(a)}\quad w(y,s)=u(x,t)+\ln(T-t)\quad \text{for } f(u)=e^u,\\ &\text{(b)}\quad w(y,s)=(T-t)^{\beta}u(x,t)\qquad \text{for } f(u)=u^p.\end{aligned}$$

Then $w(y, s)$ satisfies

$$w_s = \Delta w - \tfrac{1}{2} y \cdot \nabla \omega + F(w), \qquad \mathbb{R}^n \times (s_0, \infty),\ s_0 \equiv -\ln (T) \tag{2.3}$$

or, equivalently,

$$w_s = \frac{1}{\rho} \nabla \cdot (\rho \nabla w) + F(w), \qquad \rho = e^{-|y|^2/4}, \tag{2.4}$$

where

$$\begin{aligned} &\text{(a)} \quad F(w) = e^w - 1 && \text{for } f(u) = e^u, \\ &\text{(b)} \quad F(w) = w^p - \frac{1}{p-1} w && \text{for } f(u) = u^p. \end{aligned} \tag{2.5}$$

Then $w(y, s)$ satisfies

$$\nabla w(0, s) = 0 \quad \text{for } s \geqq s_0, \tag{2.6}$$

and

$$\begin{aligned} &\text{(a)} \quad w(y, s_0) = \phi(T^{1/2} y) + \ln (T) && \text{for } f(u) = e^u, \\ &\text{(b)} \quad w(y, s_0) = T^\beta \phi(T^{1/2} y) && \text{for } f(u) = u^p. \end{aligned} \tag{2.7}$$

As a consequence of facts (v)-(vii),

$$|\nabla w| \leqq c, \tag{2.8}$$

and

$$\begin{aligned} &\text{(a)} \quad w(y, s) \leqq c,\ |w(y, s)| \leqq c(1 + |y|) && \text{for } f(u) = e^u, \\ &\text{(b)} \quad 0 < w(y, s) \leqq c && \text{for } f(u) = u^p. \end{aligned} \tag{2.9}$$

The following theorem can be found in [2] and [20].

THEOREM 2.1. *The solution $w(y, s)$ converges to $S(y)$ uniformly on compacts $|y| \leqq C$ as $s \to \infty$, where*

$$S(y) = 0 \quad \text{for } f(u) = e^u \quad \text{or} \quad S(y) = \beta^\beta \quad \text{for } f(u) = u^p. \tag{2.10}$$

This theorem gives as an immediate consequence Theorem 1.1. It gives a good description of the temporal evolution as the blowup time T is approached, but the spatial variable is stretched too much to give any information concerning the spatial variable. To get more information about u near blowup, we need to analyze more precisely how u approaches $S(y)$.

To do this, a natural first step would be to linearize about the steady-state solution $S(y)$. We set

$$v(y, s) = w(y, s) - S(y). \tag{2.11}$$

By Theorem 2.1, $\lim_{s \to \infty} v(y, s) = 0$ uniformly on compacts in $\mathbb{R}^n$. From (2.4) and (2.5), $v(y, s)$ satisfies

$$v_s = \frac{1}{\rho} \nabla \cdot (\rho \nabla v) + g(v), \tag{2.12}$$

where

$$(2.13)\qquad \begin{aligned}&\text{(a)}\quad g(v)=v+\frac{v^2}{2} &&\text{for } f(u)=e^u,\\ &\text{(b)}\quad g(v)=v+\frac{p}{2\beta^\beta}v^2 &&\text{for } f(u)=u^p,\end{aligned}$$

neglecting order three and higher terms.

Abstractly, we can write (2.12) as

$$(2.14)\qquad v'=Av+Nv,$$

where $Av=1/\rho\nabla\cdot(\rho\nabla v)+v$ and $Nv=g(v)-v$. We observe that A generates a semigroup, and the spectrum of A, $\sigma(A)$, is the point spectrum $\sigma_p(A)$.

We begin by determining the eigenvalues and eigenvectors of A. From $Av=\lambda v$, we have

$$(2.15)\qquad \Delta v-\tfrac{1}{2}y\cdot\nabla v+(1-\lambda)v=0.$$

It can be shown (see, for example, [8]) that the eigenvalues are

$$(2.16)\qquad \lambda_m=-\frac{m}{2}+1,\qquad m=0,1,2,\cdots$$

with the associated eigenfunctions being in dimension $n=1$,

$$(2.17)\qquad h_m(y)=H_m\left(\frac{y}{2}\right),$$

where H_m is the mth Hermite polynomial. The first three eigenfunctions are

$$(2.18)\qquad h_0(y)=1,\quad h_1(y)=y,\quad h_2(y)=y^2-2.$$

In higher dimensions the eigenfunctions are formed by taking products of the polynomials $\{h_m\}_{m=0}^{\infty}$. It is easy to see that the products $h_{m_1}(y_1)\cdots h_{m_n}(y_n)$ form an orthogonal basis for L^2_ρ.

Let $Z=L^2_{\rho_0}$ be the Hilbert space of radially symmetric functions in L^2_ρ with inner product $\langle f,g\rangle\equiv\int_{\mathbb{R}^n}fg\rho$, where $\rho=e^{-|y|^2/4}$.

For Z, we can ignore all odd eigenvalues and corresponding eigenfunctions due to the radial symmetry. Let

$$(2.19)\qquad \begin{aligned}Z_c&\equiv\operatorname{sp}(|y|^2-2n),\\ Z_u&\equiv\operatorname{sp}(1),\\ Z_s&\equiv\overline{Z-(Z_c\oplus Z_u)}.\end{aligned}$$

Because the linearization of (2.14) has neutral as well as stable and unstable modes, a natural tool to employ is the center manifold theory for infinite-dimensional systems [5], [14], [22]. In Z, the Hilbert space of radially symmetric functions in L^2_ρ with inner product $\langle\cdot,\cdot\rangle$, consider the given abstract problem

$$(2.14)\qquad v'=Av+Nv,$$

where $Nv=g(v)-v$ and $g(v)$ is given in (2.13). The operator A is the generator of a strongly continuous semigroup $S(s)$ and has the following spectral properties:

(1) $Z = Z_c \oplus Z_s \oplus Z_u$, where Z_c, Z_u are finite-dimensional, Z_s is closed, and all are defined in (2.19). Associated with this splitting of Z, there exist projections $\pi_s : Z \to Z_s$, $\pi_u : Z \to Z_u$, $\pi_c : Z \to Z_c$ with ker $\pi_s = Z_c \oplus Z_u = Z_{cu}$, ker $\pi_c = Z_s \oplus Z_u = Z_{su}$, and ker $\pi_u = Z_c \oplus Z_s = Z_{cs}$.

(2) Z_c and Z_u are A-invariant. If $A^0 = A|_{Z_c}$ and $A^+ = A|_{Z_u}$, then Re $\sigma_p(A^0) = 0$ and Re $\sigma_p(A^+) > 0$.

(3) If $U(s) = S(s)|_{Z_s}$, then Z_s is $U(s)$-invariant and for some $a, b > 0$,

$$\|U(s)\| \leqq a\, e^{-bs}, \qquad s \geqq 0. \tag{2.20}$$

For $v_c \in Z_c$, $v_s \in Z_s$, $v_u \in Z_u$, let $f(v_c, v_s, v_u) = \pi_c N(v_c + v_s + v_u)$, $g(v_c, v_s, v_u) = \pi_s N(v_c + v_s + v_u)$, $h(v_c, v_s, v_u) = \pi_u N(v_c + v_s + v_u)$, and $A^- = \pi_s A$. Then (2.14) can be written as

$$\begin{aligned} v_c' &= A^0 v_c + f(v_c, v_s, v_u), \\ v_s' &= A^- v_s + g(v_c, v_s, v_u), \\ v_u' &= A^+ v_u + h(v_c, v_s, v_u). \end{aligned} \tag{2.21}$$

If the nonlinear term N maps Z into Z with $N(0) = 0$ and $N'(0) = 0$, where N' is the Fréchet derivative of N so that Nv can be considered as a small perturbation, then the following theorem holds (see [5], [14], [22]).

THEOREM 2.2. (1) *System* (2.21) *has the following invariant manifolds, both of which are tangent at the origin*:

$$M_c = \{(v_c, v_s, v_u) : \|v_c\| < \delta,\ v_s = W^s(v_c),\ v_u = W^u(v_c)\},$$

the center manifold, and

$$M_{cu} = \{(v_c, v_s, v_u) : v_s = W^+(v_c, v_u),\ \|v_c\| + \|v_u\| < \delta\},$$

the center-unstable manifold.

(2) *There exists $\gamma > 0$ and $H_{cu} \in C(Z; M_{cu})$ such that for each $v_0^{cu} \in M_{cu}$ and $\varepsilon > 0$, there exists $\delta > 0$ such that $v_0 \in Z$ with $\|v_0 - v_0^{cu}\| < \delta$, and $\|v(s; v_0)\| < \varepsilon$ for large s implies $\|v(s; v_0) - v(s; H_{cu}(v_0))\| \leqq \varepsilon\, e^{-\gamma s}$, s large.*

Unfortunately, our nonlinear term does not have the required properties in any of the obvious function spaces $L^2_{\rho_0}$ or $H^m_{\rho_0}$ as observed by Filippas and Kohn in [8]. Because of this, we are unable to apply Theorem 2.2 directly. By using the properties of the known trajectory $v(y, s)$, we can avoid this difficulty and still obtain the same conclusions for $v(y, s)$ as would be given by the existence of a center-unstable manifold.

For $Z = Z_s \oplus Z_c \oplus Z_u$, we will use the following notation:

$$\begin{gathered} \pi_* = \text{projection onto } Z_* \quad \text{for } * = s, c, u, \\ P_u v = \langle v, 1 \rangle, \qquad P_c v = \langle v, |y|^2 - 2n \rangle. \end{gathered} \tag{2.22}$$

Let

$$v = v(y, s) = a(s) + b(s)(|y|^2 - 2n) + \theta, \tag{2.23}$$

where $a(s), b(s) \in \mathbb{R}$, $\theta \in Z_s$.

We claim that if v solves (2.14), then it does not decay exponentially fast. To see this, assume v decays exponentially fast, i.e., $\|v\| \leqq M e^{-\alpha s}$ for some $M, \alpha > 0$. Herrero and Velázquez [15] and Liu [21] for dimensions $n \geqq 2$ have proven that either $v \equiv 0$ or there exists an integer $m \geqq 3$, which is even by symmetry, such that

$$v = C\, e^{(1-(m/2))s} h_{m,n}(|y|) + o(e^{(1-(m/2))s}), \tag{2.24}$$

where $h_{m,n}(|y|) = \sum_{i=1}^n h_m(y_i)$ and C is some constant. If $v \equiv 0$, then for $f(u) = e^u$,

$u(x, t) = -\ln(T-t)$ and for $f(u) = u^p$, $u(x, t) = \beta^\beta(T-t)^\beta$. But this contradicts $u_r < 0$. For the other possibility, define $\bar{r} = |y|$; then $v(\bar{r}, s) = C e^{(1-(m/2))s} h_{m,n}(\bar{r}) + o(e^{(1-(m/2))s})$. Since $h_{m,n}$ has $m/2$ maxima, taking R large enough, our solution should have at least one maximum on $0 < \bar{r} < R$ for large enough s, and this is impossible because $v_{\bar{r}}(\bar{r}, s) < 0$.

The following two theorems are essentially due to Filippas and Kohn [8] and Herrero and Velázquez [15].

THEOREM 2.3. *Let $v(y, s)$ be a solution of* (2.14). *Then given any $\varepsilon > 0$, there exists $\hat{s}$ such that*

$$\begin{aligned} \dot{a} &= a + \|1\|^{-2} P_u N(\pi_u v + \pi_c v) + \varepsilon O(2), \\ \dot{b} &= \| |y|^2 - 2n \|^{-2} P_c N(\pi_u v + \pi_c v) + \varepsilon O(2) \end{aligned} \tag{2.25}$$

for $s \geqq \hat{s}$, where $O(2)$ denotes quadratic terms in a and b.

Recall that $w(y, s)$ satisfies (2.3) on $\mathbb{R}^n \times (s_0, \infty)$, is smooth (see [10]), $|w(y, s)| \leqq c(1 + |y|)$, and $|\nabla \omega| \leqq c$ on $\mathbb{R}^n \times (s_0, \infty)$. By considering the parabolic equations satisfied by the first-order spatial derivatives of $w(y, s)$, we can conclude all spatial derivatives of the same order satisfy a uniform bound in (y, s) (see [12]). Since $v = w - S$, the same is true for v. This implies v is in the Sobolev space $H^m_{\rho_0}$ for any $m \geqq 0$, where we use the convention of $H^0_{\rho_0} = L^2_{\rho_0}$. By the Lebesgue dominated convergence theorem, $v \to 0$ as $s \to \infty$ in $H^m_{\rho_0}$.

THEOREM 2.4. *Let $v(y, s)$ be a solution of* (2.14). *Then given $\varepsilon > 0$, there exists $\hat{s}$ such that*

$$\|\pi_s v\|_{H^m_{\rho_0}} \leqq \varepsilon(\|\pi_u v\|_{H^m_{\rho_0}} + \|\pi_c v\|_{H^m_{\rho_0}}) \tag{2.26}$$

for $s \geqq \hat{s}$ and any $m \geqq 0$.

The proofs of the theorems are easier than those found in [8] and [15] because we only require the stable mode to be dominated by the center and unstable components as opposed to the stable and unstable components being dominated by the center mode, which corresponds to a center manifold.

Recalling the definition of $N(\pi_u v + \pi_c v)$, we have that

$$\begin{aligned} &\text{(a)} \quad N(\pi_u v + \pi_c v) = \tfrac{1}{2}(\pi_u v + \pi_c v)^2 \qquad \text{for } f(u) = e^u, \\ &\text{(b)} \quad N(\pi_u v + \pi_c v) = \frac{p}{2\beta^\beta}(\pi_u v + \pi_c v)^2 \quad \text{for } f(u) = u^p. \end{aligned} \tag{2.27}$$

Equation (2.25) corresponds to the reduced equation for (2.14), which would determine the flow on the center-unstable manifold if it existed. Discarding $\varepsilon O(2)$ terms, using the definitions of P_u, P_c, and (2.27), we have that (2.25) reduces to the following theorem.

THEOREM 2.5. *Let $v(y, s)$ be a solution of* (2.14). *Then*

$$\left.\begin{aligned} \dot{a} &= a + \tfrac{1}{2}(a^2 + 8nb^2) \\ \dot{b} &= ab + 4b^2, \end{aligned}\right\} \quad \textit{for } f(u) = e^u, \tag{2.28a}$$

$$\left.\begin{aligned} \dot{a} &= a + \frac{p}{2\beta^\beta}(a^2 + 8nb^2) \\ \dot{b} &= \frac{p}{\beta^\beta}(ab + 4b^2) \end{aligned}\right\} \quad \textit{for } f(u) = u^p, \tag{2.28b}$$

Using Theorem 2.5, we can now obtain more information as to how $v(y, s)$ tends to zero as $s \to \infty$. By Theorem 2.1 and (2.11), we know that $\lim_{s\to\infty} v(y, s) = 0$ uniformly on compacts. This can be immediately extended to $\lim_{s\to 0} v(y, s) = 0$ in Z by observing that $v(y, s) \to 0$ pointwise as $s \to \infty$, $|v(y, s)| \leqq c(1+|y|)$ on $\mathbb{R}^n \times (s_0, \infty)$, and then applying the Lebesgue dominated convergence theorem. By the Pythagorean theorem, $\|v\|^2 \geqq \|\pi_u v\|^2 = \|a(s)\|^2 = a^2(s)\|1\|^2$, which in turn implies $a(s) \to 0$ as $s \to \infty$. Similarly, $b(s) \to 0$ as $s \to \infty$.

We now can prove the following theorem.

THEOREM 2.6. *On compacts in y,*

$$(2.29)\qquad \begin{aligned} &\text{(a)} \qquad v(y, s) \sim -\frac{1}{4s}(|y|^2 - 2n) + o\left(\frac{1}{s}\right) \qquad \textit{for } f(u) = e^u, \\ &\text{(b)} \qquad v(y, s) \sim -\frac{\beta^\beta}{4ps}(|y|^2 - 2n) + o\left(\frac{1}{s}\right) \qquad \textit{for } f(u) = u^p, \end{aligned}$$

uniformly as $s \to \infty$.

Proof. We only prove (2.29(b)) and observe that the proof of (2.29(a)) is similar. We begin by solving (2.28(b)). By a simple phase-plane analysis, we observe that $a(s) \leqq 0$ and $b(s) \leqq 0$ for all $s \geqq s_0$ since a and b decay to zero. If $a(\hat{s}) = 0$ for some $\hat{s}$, then $a(s) > 0$ for $s > \hat{s}$ unless $b(s) \equiv 0$ for $s \geqq \hat{s}$ by (2.28(b_1)). If $b(s)$ is identically zero for $s \geqq \hat{s}$, then from (2.28(b_1)) we have $\dot{a} = a + (p/2\beta^\beta)a^2$. By uniqueness we conclude $a(s) \equiv 0$ for $s \geqq \hat{s}$ since $a(s)$ decays to zero. This implies that $v(y, s) \equiv 0$ for $s \geqq \hat{s}$ by Theorem 2.4, and hence v would decay exponentially fast, which cannot happen. Thus, $a(s) < 0$ for $s \geqq s_0$. If b has a zero, then since $b \equiv 0$ solves (2.28(b_2)), we conclude by uniqueness that b must vanish identically. Thus $b(s) < 0$ for $s \geqq s_0$.

We now show that $a(s)$ does not decay exponentially fast.

If $a(s) \to 0$ exponentially fast, then $b(s) \to 0$ exponentially fast. To prove this, we assume there exists $\alpha > 0$ such that $\lim_{s\to\infty} e^{\alpha s}|a(s)| = 0$. We can express $a(s)$ as

$$a(s) = e^s\left[a(s_0)\, e^{-s_0} + \frac{p}{2\beta^\beta}\int_{s_0}^{s} e^{-\xi}(a^2(\xi) + 8nb^2(\xi))\, d\xi\right].$$

Since $a(s) \to 0$ and in fact is exponentially fast by assumption,

$$\lim_{s\to\infty}\left[a(s_0)\, e^{-s_0} + \frac{p}{2\beta^\beta}\int_{s_0}^{s} e^{-\xi}(a^2(\xi) + 8nb^2(\xi))\, d\xi\right] = 0,$$

and

$$0 = \lim_{s\to\infty} e^{\alpha s}a(s) = -\frac{4np}{\beta^\beta(1+\alpha)}\lim_{s\to\infty} e^{\alpha s}b^2(s)$$

by L'Hôpital's rule. This implies $b(s) = o(e^{-(\alpha/2)s})$. Equation (2.26) then implies $\|v\| \to 0$ exponentially fast, which is not the case. Therefore, $a(s)$ cannot decay exponentially.

Define $m(s) = b^2(s)/a(s)$. Then $m(s) < 0$ for all $s \geqq s_0$ and satisfies

$$(2.30)\qquad \dot{m} = -\frac{4np}{\beta^\beta}\, m\left(\frac{\beta^\beta}{4np} - \frac{3}{8n}a(s) - \frac{2}{n}b(s) + m\right).$$

Choose $\hat{s} > 16n^2p/\beta^\beta$ such that $|(3/8n)a(s) + (2/n)b(s)| < \beta^\beta/16n^2p$ for all $s \geqq \hat{s}$. For

$s \geqq \hat{s}$ define

$$G(s) = \sup_{\xi \geqq s} \left[\frac{3}{8n} a(\xi) + \frac{2}{n} b(\xi) \right] - \frac{\beta^\beta}{4np} + \frac{1}{s}, \tag{2.31}$$
$$F(s) = \inf_{\xi \geqq s} \left[\frac{3}{8n} a(\xi) + \frac{2}{n} b(\xi) \right] - \frac{\beta^\beta}{4np} - \frac{1}{s};$$

then $F(s) < (3/8n)a(s) + (2/n)b(s) - \beta^\beta/4np < G(s) < 0$ with F increasing, G decreasing, and both continuous for $s \geqq \hat{s}$.

We now observe that $m(s)$ has a limit at infinity. Suppose $m(\hat{s}) \geqq G(\hat{s})$, then $m(s)$ is increasing and bounded above so it has a finite limit. If $m(\hat{s}) \leqq F(\hat{s})$, then $m(s)$ is decreasing and so it has a limit, which could possibly be $-\infty$. Suppose $F(\hat{s}) < m(\hat{s}) < G(\hat{s})$. Then, either $m(s)$ remains in the funnel $(F(s), G(s))$ for all $s \geqq \hat{s}$, in which case $\lim_{s\to\infty} m(s) = -(\beta^\beta/4np)$, or $m(s)$ intersects either $F(s)$ or $G(s)$. If $m(s)$ intersects $F(s)$ or $G(s)$ at some $s^* > \hat{s}$, then $m(s)$ is either decreasing or increasing, respectively, for $s \geqq s^*$ and so it will have a limit at infinity.

Suppose $\lim_{s\to\infty} m(s) = -\infty$. Then by (2.28($\mathrm{b}_1$)), $\lim_{s\to\infty} (\dot{a}(s)/a(s)) = -\infty$. This implies that $a(s)$ decays exponentially fast, which cannot happen. Hence, $\lim_{s\to\infty} m(s)$ exists and is finite.

If $\lim_{s\to\infty} m(s) = 0$, then by (2.28($\mathrm{b}_1$)), there exists $\hat{s}$ such that $(\dot{a}(s)/a(s)) \geqq \frac{1}{2}$ for $s \geqq \hat{s}$. This implies $a(s) \leqq a(\hat{s})\, e^{1/2(s-\hat{s})}$, which is a contradiction. Therefore, $\lim_{s\to\infty} m(s) < 0$ and $b(s) = O(|a(s)|^{1/2})$ with $b \neq o(|a|^{1/2})$.

Since $\lim_{s\to\infty} (a(s)/b(s)) = 0$, there exists $\hat{s}$ such that $b(s) < a(s) < 0$ for $s \geqq \hat{s}$. By (2.28(b_2)), we have that

$$\frac{4p}{\beta^\beta} b^2(s) \leqq \dot{b}(s) \leqq \frac{5p}{\beta^\beta} b^2(s) \tag{2.32}$$

for $s \geqq \hat{s}$, which implies $b(s) = O(s^{-1})$, and so $a(s) = O(s^{-2})$. Up to order $O(s^{-3})$, (2.28(b_2)) becomes $\dot{b} = (4p/\beta^\beta)b^2$, which implies $b(s) = -(\beta^\beta/4ps) + o(s^{-1})$.

By Theorem 2.4,

$$\left\| v(y,s) + \frac{\beta^\beta}{4ps}(|y|^2 - 2n) \right\|_{H^m_{\rho_0}} \leqq \left\| \pi_u v + \pi_c v + \frac{\beta^\beta}{4ps}(|y|^2 - 2n) \right\|_{H^m_{\rho_0}} + \|\pi_s v\|_{H^m_{\rho_0}}$$
$$\leqq o(s^{-1}) + \varepsilon(\|\pi_u v\|_{H^m_{\rho_0}} + \|\pi_c v\|_{H^m_{\rho_0}}) \tag{2.33}$$
$$\leqq o(s^{-1}).$$

Therefore,

$$v(y,s) \sim -\frac{\beta^\beta}{4ps}(|y|^2 - 2n) + o(s^{-1}) \quad \text{in } H^m_{\rho_0}. \tag{2.34}$$

This can be extended to uniform convergence on compacts in y. Given the spatial dimension n, choose $m > n/2$. Then the Sobolev imbedding theorem (see [1]) implies that (2.34) holds in $C^0_{b\rho_0} = \{u \in C^0\colon u \text{ is symmetric}, \sup[\mathrm{e}^{(-|y|^2/4)}|u(y)|] < \infty\}$. On any compact set $|y| \leqq c$:

$$\sup_{|y|\leqq c} e^{-(c^2/4)} \left| v(y,s) + \frac{\beta^\beta}{4ps}(|y|^2 - 2n) \right| \leqq \sup_{|y|\leqq c} e^{-(|y|^2/4)} \left| v(y,s) + \frac{\beta^\beta}{4ps}(|y|^2 - 2n) \right|$$
$$\leqq \sup_{\mathbb{R}^n} e^{-(|y|^2/4)} \left| v(y,s) + \frac{\beta^\beta}{4ps}(|y|^2 - 2n) \right|$$
$$= o(s^{-1}),$$

which proves (2.29(b)). □

In the original variables, we can restate Theorem 2.6 as the following corollary, which is Theorem 1.2.

COROLLARY 2.7. *Let* $u(x, t)$ *be the solution of* (1.1)-(1.2), *then*

$$
\begin{aligned}
&\textit{for } f(u)=e^u,\\
&\text{(a)}\quad u(x,t)\sim \ln\left(\frac{1}{T-t}\right)+\frac{1}{4\ln(T-t)}\left(\frac{|x|^2}{T-t}-2n\right)+o\left(\frac{1}{\ln(T-t)}\right),\\
\text{(2.35)}\quad&\textit{for } f(u)=u^p,\\
&\text{(b)}\quad u(x,t)\sim\frac{1}{(T-t)^\beta}\left[\beta^\beta+\frac{\beta^\beta}{4p\ln(T-t)}\left(\frac{|x|^2}{T-t}-2n\right)+o\left(\frac{1}{\ln(T-t)}\right)\right]
\end{aligned}
$$

uniformly on $|x|\leqq C(T-t)^{1/2}$, $C\geqq 0$ *as* $t\to T^-$.

3. Extension to the ignition variable domain. We now indicate how to extend (2.29) from the hot-spot variable grouping to the ignition variable grouping first suggested by Dold [6] and independently by Galaktionov [11]. By this, we mean that we can get a spatial description of how the blowup singularity evolves not only in parabolic domains $|x|\leqq C(T-t)^{1/2}$ with vertex at $(0, T)\in\mathbb{R}^n\times(0,\infty)$, but in the larger domains $|x|\leqq C((T-t)|\ln(T-t)|)^{1/2}$, $C>0$ arbitrary.

Our procedure for doing this in the multidimensional case is due to Herrero and Velázquez ([15], § 6). We summarize their method for the case $f(u)=e^u$, along with the extension to higher dimensions. The case $f(u)=u^p$ is similar.

Let $u(x, t)$ be a solution of (1.1)-(1.2) for ϕ satisfying (1.4) and $f(u)=e^u$, which blows up at $(0, T)$. Make the change of variables:

$$
\text{(3.1)}\qquad s=-\ln(T-t),\quad y=\frac{x}{(T-t)^{1/2}},\quad \eta=\frac{x}{((T-t)|\ln(T-t)|)^{1/2}},
$$

and as before let

$$
\text{(3.2)}\qquad v(y,s)=u(x,t)+\ln(T-t).
$$

In § 2, we proved that

$$
\text{(3.3)}\qquad v(y,s)=-\frac{1}{4s}(|y|^2-2n)+o\left(\frac{1}{s}\right)
$$

in $C^0_{b\rho_0}$ or uniformly on compacts $|y|\leqq C$ as $s\to\infty$.

We now show that (3.3) actually holds on the ignition variable domain suggested by Dold.

Without loss of generality, we may assume $T=1$.

LEMMA 3.1. *For a solution* $u(x, t)$ *of* (1.1)-(1.2) *that blows up at* $T=1$,

$$
\text{(3.4)}\qquad \ln(1-t)+u(\eta((1-t)|\ln(1-t)|)^{1/2},t)\geqq-\ln\left(1+\frac{|\eta|^2}{4}\right)+o(1)
$$

uniformly for $|\eta|\leqq R$, $R>0$, *as* $t\to 1^-$.

The proof of Lemma 3.1 for dimension $n=1$ given in Herrero and Velázquez [15, Lemma 6.1] relies on expansions in terms of the Hermite polynomials. In the following proof, we are able to avoid the difficulties in extending their method to higher dimensions by making use of the semigroup associated with the heat equation in $\mathbb{R}^n$.

Proof. Let $v(y, s)$ be given by (3.2) with $T=1$; then v satisfies

$$v_s=\Delta v-\frac{y}{2}\cdot\nabla v+e^v-1$$

$$=Av+e^v-v-1.$$

From the facts of § 1, we can immediately infer that v is bounded above, $v(y, s)\to 0$ as $s\to\infty$ uniformly on compacts, and $|\nabla v(\cdot, s)|$ is bounded. Therefore, $|v(y, s)|\leqq C(1+|y|)$, and hence $\|v(\cdot, s)\|\to 0$ as $s\to\infty$.

Let α be a parameter, $0<\alpha<1$, and consider

$$\psi_\alpha(x, t)=\ln(1-\alpha)+u(x\sqrt{(1-\alpha)}, \alpha+t(1-\alpha)). \tag{3.5}$$

For any α fixed, ψ_α solves (1.1). Moreover,

$$\psi_\alpha(x, 0)=\ln(1-\alpha)+u(x\sqrt{1-\alpha}, \alpha)=\frac{1}{4\ln(1-\alpha)}(|x|^2-2n)+o\left(\frac{1}{\ln(1-\alpha)}\right)$$

as $\alpha\to 1^-$ uniformly for $|x|\leqq R$, $R>0$, by (3.3).

Now consider the function

$$F_\alpha(x, t)=-\ln(e^{-S(t)\psi_\alpha(x,0)}-t), \tag{3.6}$$

where $S(t)$ is the linear semigroup corresponding to the heat equation in the strip $\mathbb{R}^n\times[0, 1)$. It is obvious that $F_\alpha(x, 0)=\psi_\alpha(x, 0)$, and we can easily verify that

$$(F_\alpha)_t-\Delta F_\alpha-e^{F_\alpha}\leqq 0.$$

We immediately conclude $\psi_\alpha(x, t)\geqq F_\alpha(x, t)$ for fixed α whenever $x\in\mathbb{R}^n$, $0<t<1$.

Set $s_\alpha=-\ln(1-\alpha)$; then

$$\left\|S(t)\psi_\alpha(x, 0)-S(t)\left(-\frac{1}{4s_\alpha}(|x|^2-2n)\right)\right\|_{C^0_{b\rho_0}}\leqq\|S(t)\|\left\|\psi_\alpha(x, 0)+\frac{1}{4s_\alpha}(|x|^2-2n)\right\|_{C^0_{b\rho_0}}$$

$$=o\left(\frac{1}{s_\alpha}\right)$$

as $\alpha\to 1^-$. Thus

$$S(t)\psi_\alpha(x, 0)=\frac{1}{4\ln(1-\alpha)}(1-t)\left(\frac{|x|^2}{1-t}-2n\right)+o\left(\frac{1}{\ln(1-\alpha)}\right) \tag{3.7}$$

as $\alpha\to 1^-$ uniformly for $|x|\leqq R$, $R>0$.

We can write $\psi_\alpha(x, t)=\ln(1-\alpha)+u(x, \hat{t})$, where $r=x\sqrt{(1-\alpha)}$, $\hat{t}=\alpha+t(1-\alpha)$. Note that $1-\hat{t}=(1-\alpha)(1-t)$. To get a lower bound on $u(r, \hat{t})$ along sets where $r=\eta(1-\hat{t})^{1/2}|\ln(1-\hat{t})|^{1/2}$ in terms of x and t, i.e., $x=\eta(1-t)^{1/2}|\ln(1-t)(1-\alpha)|^{1/2}$, we first select $t=t(\alpha)$ by

$$1=(1-t)|\ln(1-\alpha)(1-t)| \tag{3.8}$$

so that $(1-t)\approx|\ln(1-\alpha)|^{-1}$ as $\alpha\to 1^-$. Then by (3.7) and (3.8)

$$S(t)\psi_\alpha(x, 0)=-(1-t)\frac{|\eta|^2}{4}+o(1-t)\quad\text{as } t\to 1^-,$$

uniformly on sets $|\eta|\leqq R$, $R>0$.

Using (3.6), $\psi_\alpha(x,t) \geqq F_\alpha(x,t) = -\ln(1-t) - \ln(1+(|\eta|^2/4)) + o(1)$, and thus

$$\psi_\alpha(x,t) = \ln(1-\alpha) + u(\eta(1-\hat{t})^{1/2}|\ln(1-\hat{t})|^{1/2}, \hat{t})$$
$$\geqq -\ln(1-t) - \ln\left(1+\frac{|\eta|^2}{4}\right) + o(1).$$

Therefore,

$$\ln(1-\hat{t}) + u(\eta(1-\hat{t})^{1/2}|\ln(1-\hat{t})|^{1/2}, \hat{t}) \geqq -\ln\left(1+\frac{|\eta|^2}{4}\right) + o(1)$$

as $\hat{t} \to 1^-$ uniformly on sets $|\eta| \leqq R$, $R > 0$. This proves (3.4). □

We now turn to the task of showing we have equality in (3.4).

LEMMA 3.2. *For any $R>0$ there exists $C>0$ such that*

$$|\nabla_y v(\eta\sqrt{s}, s)| \leqq \frac{C}{\sqrt{s}} \tag{3.9}$$

uniformly for $|\eta| \leqq R$ and large enough $s>0$.

The proof given in [15, Lemma 6.2] extends immediately to higher dimensions and so we do not include a proof of this lemma.

Now set

$$J = e^{-v},$$

which leads to the equation

$$J_s = \Delta J - \frac{y}{2}\cdot\nabla J + J - \frac{|\nabla J|^2}{J} - 1.$$

Since $v \to 0$ as $s \to \infty$, $J \to 1$ as $s \to \infty$.

LEMMA 3.3. *There exists $C>0$ such that*

$$\|J(\cdot, s) - 1\| \leqq \frac{C}{s} \quad \text{as } s \to \infty. \tag{3.10}$$

The proof given in [15, Lemma 6.3] uses the fact that the solution $u(x,t)$ of (1.1) is a supercaloric function. We avoid using this observation in the following proof, which allows for an immediate extension to higher dimensions.

Proof. By definition we have that

$$\|J(\cdot,s)-1\|^2 = \int_{\mathbb{R}^n} |e^{-v}-1|^2 \, e^{-(|y|^2/4)}\, dy.$$

Since $|e^{-v}-1|^2 \leqq e^{-2v} + 2e^{-v} + 1$ and $|v| \leqq C(1+|y|)$ we have

$$|e^{-v}-1|^2 \leqq k\, e^{k(1+|y|)} \in L^1_p \quad \text{for all } s \text{ and some } k>0.$$

Also, $|e^{-v}-1|^2 = O(1/s^2)$ as $s \to \infty$ pointwise in y by (3.3). The Lebesgue dominated convergence theorem gives the desired result. □

Let us write

$$G = J - 1;$$

then G solves

$$G_s = \Delta G - \frac{y}{2}\cdot\nabla G + G - \frac{|\nabla G|^2}{1+G}.$$

We set

$$L(y, s)=\frac{|\nabla G|^2}{1+G};$$

then for $s \geqq s_0$, $G(y, s)$ can be written in the form

$$\begin{aligned} G(y, s)&=\frac{e^{s-s_0}}{(4\pi(1-e^{-(s-s_0)}))^{n/2}}\int_{\mathbb{R}^n}\exp\left(-\frac{|y\,e^{-(s-s_0)/2}-\lambda|^2}{4(1-e^{-(s-s_0)})}\right)G(\lambda, s_0)\,d\lambda \\ &\quad -\int_{s_0}^{s}\int_{\mathbb{R}^n}\frac{e^{(s-\beta)}}{(4\pi(1-e^{-(s-\beta)}))^{n/2}}\exp\left(-\frac{|y\,e^{-(s-\beta)/2}-\lambda|^2}{4(1-e^{-(s-\beta)})}\right)L(\lambda, \beta)\,d\lambda\,d\beta \qquad (3.11)\\ &\equiv I_1(y, s)+I_2(y, s). \end{aligned}$$

We now indicate the estimates on I_1 and I_2 as $s\to\infty$.

LEMMA 3.4. *Let $I_1(y, s)$ be as in* (3.11); *then*

$$\lim_{s\to\infty} I_1(\eta\sqrt{s}, s)=\frac{|\eta|^2}{4} \tag{3.12}$$

uniformly on set $|\eta|\leqq C$ with $C>0$.

LEMMA 3.5. *Let $I_2(y, s)$ be as in* (3.11), *then*

$$\lim_{s\to\infty} I_2(\eta\sqrt{2}, s)=0 \tag{3.13}$$

uniformly on sets $|\eta|\leqq C$ with $C>0$.

The proofs given in [15, Lemmas 6.4, 6.5] can easily be extended to cover the multidimensional case and so we do not include the proofs of the above two lemmas.

THEOREM 3.6.

$$\lim_{t\to 1^-}[\ln(1-t)+u(\eta\sqrt{(1-t)|\ln(1-t)|}, t)]=-\ln\left(1+\frac{|\eta|^2}{4}\right) \tag{3.14}$$

uniformly on compact sets $|\eta|\leqq K$, $K>0$.

Proof. By Lemmas 3.4 and 3.5, we have that

$$\lim_{s\to\infty} G(\eta\sqrt{s}, s)=\frac{|\eta|^2}{4} \tag{3.15}$$

uniformly on compact sets $|\eta|\leqq K$. Therefore,

$$\lim_{s\to\infty} v(\eta\sqrt{s}, s)=-\ln\left(1+\frac{|\eta|^2}{4}\right)$$

uniformly on compacts. Since $v(x/\sqrt{1-t}, s)=\ln(1-t)+u(x, t)$, if

$$x=\eta\sqrt{(1-t)|\ln(1-t)|}=\eta\sqrt{1-t}\,\sqrt{s},$$

we then have the desired result. □

This is precisely Theorem 1.3 for the case $f(u)=e^u$ with the blowup time normalized to one. For the case $f(u)=u^p$, the proof proceeds in an analogous manner.

4. Final time solution profiles. We now prove Theorem 1.4, which gives us a precise description of the final time solution profile $u_F(x)$ in a neighborhood of the singularity $x=0$. Our proof follows that of Herrero and Velázquez [16].

Let $u(x, t)$ be a solution of (1.1)-(1.3) that blows up at $(0, T)\in\mathbb{R}^n\times(0,\infty)$, where ϕ satisfies (1.14). Let $\eta\neq 0$ and consider the auxiliary functions

$$\text{(4.1)}\quad \begin{aligned} &\text{(a)}\quad \psi_\alpha(x,t)=\ln(T-\alpha)+u(\lambda(\alpha)+x\sqrt{T-\alpha},\ \alpha+(T-\alpha)t) &&\text{for } f(u)=e^u,\\ &\text{(b)}\quad \psi_\alpha(x,t)=(T-\alpha)^\beta u(\lambda(\alpha)+x\sqrt{T-\alpha},\ \alpha+(T-\alpha)t) &&\text{for } f(u)=u^p,\end{aligned}$$

where

$$\text{(4.2)}\qquad \lambda(\alpha)=\sqrt{T-\alpha}\,|\ln(T-\alpha)|^{1/2}\eta,\qquad 0<\alpha<T,$$

and

$$\text{(4.3)}\qquad |x|\leqq\frac{|\eta|}{2}|\ln(T-\alpha)|^{1/2},\qquad 0<t<1.$$

We first prove the following lemma, which gives a uniform bound on the auxiliary functions (4.1) as $\alpha\to T^-$.

Lemma 4.1. *Let $m\in\mathbb{N}$ be fixed and α sufficiently close to T. Then there exists a constant M_m such that*

$$\text{(4.4)}\qquad |\psi_\alpha(x,t)|\leqq M_m$$

for $|x|\leqq m/2$, $t\in[0,1]$ uniformly as $\alpha\to T^-$.

Proof. We point out that (4.3) implies $|\lambda(\alpha)+x\sqrt{T-\alpha}|\geqq|\lambda(\alpha)|/2$. For $f(u)=u^p$, since $u_r\leqq 0$ and $u_t\geqq 0$, (4.1(b)) gives

$$\psi_\alpha(x,t)\leqq(T-\alpha)^\beta u\left(\frac{\lambda(\alpha)}{2},\ \alpha+(T-\alpha)t\right)\leqq(T-\alpha)^\beta u\left(\frac{\lambda(\alpha)}{2},\ T\right).$$

Using the upper bound (1.12(b)) and (4.2) we have that

$$\begin{aligned}\psi_\alpha(x,t)&\leqq(T-\alpha)^\beta\left(\frac{K|\ln(|\lambda(\alpha)|/2)|}{(|\lambda(\alpha)|/2)^2}\right)^\beta\\ &=\left(\frac{4K}{|\eta^2|}\left|\frac{1}{2}+\frac{1}{\ln(T-\alpha)}\left(\frac{1}{2}\ln|\ln(T-\alpha)|+\ln|\eta|-\ln 2\right)\right|\right)^\beta\leqq C\end{aligned}$$

for all $|x|\leqq|\eta|/2|\ln(T-\alpha)|^{1/2}$, $t\in[0,1]$ uniformly as $\alpha\to T^-$. Since $\psi_\alpha(x,t)\geqq 0$, the result follows.

For $f(u)=e^u$, the proof of (4.4) is more difficult since $\psi_\alpha(x,t)$ could approach $-\infty$. Since $u_r\leqq 0$ and $u_t\geqq 0$, (4.1(a)) gives

$$\psi_\alpha(x,t)\leqq\ln(T-\alpha)+u\left(\frac{\lambda(\alpha)}{2},\ T\right).$$

Using the upper bound (1.12(a)) and (4.2) we have that

$$\begin{aligned}\psi_\alpha(r,t)&\leqq\ln(T-\alpha)-2\ln\left|\frac{\lambda(\alpha)}{2}\right|+\ln\left|\ln\left|\frac{\lambda(\alpha)}{2}\right|\right|+C\\ &=\ln\left(\frac{4(t-\alpha)|\ln|\lambda(\alpha)/2||}{|\lambda(\alpha)|^2}\right)+C\\ &=\ln\left[\frac{4}{|\eta|^2}\left|\frac{1}{2}+\frac{1}{\ln(T-\alpha)}\left(\frac{1}{2}\ln|\ln(T-\alpha)|+\ln|\eta|-\ln 2\right)\right|\right]+C,\end{aligned}$$

which implies

$$\psi_\alpha(x, t) \leqq K \tag{4.5}$$

for all $|x| \leqq |\eta|/2|\ln(T-\alpha)|^{1/2}$, $t \in [0, 1]$ uniformly as $\alpha \to T^-$.

By Friedman and McLeod [9],

$$|\nabla \psi_\alpha|^2 = (T-\alpha)|\nabla u|^2 \leqq K \tag{4.6}$$

for all $|x| \leqq |\eta|/2|\ln(T-\alpha)|^{1/2}$, $t \in [0, 1]$ uniformly as $\alpha \to T^-$.

Since $u_t \geqq 0$, we can use Lemma 3.1 to obtain a lower bound for $\psi_\alpha(0, t)$.

$$\psi_\alpha(0, t) \geqq \ln(T-\alpha) + u(\lambda(\alpha), \alpha) \geqq -\ln\left(1 + \frac{|\eta|^2}{4}\right) + o(1)$$

as $\alpha \to T^-$. Therefore, for α sufficiently close to T, (4.5) gives

$$|\psi_\alpha(0, t)| \leqq K \tag{4.7}$$

for all $t \in [0, 1]$, uniformly as $\alpha \to T^-$.

Now let $m \in \mathbb{N}$ be fixed and α sufficiently close to T. For $|x| \leqq m/2$ and $t \in [0, 1]$ define $\theta_\alpha(\nu) = \psi_\alpha((1-\nu)x, t)$, $0 \leqq \nu \leqq 1$. Then

$$\psi_\alpha(x, t) - \psi_\alpha(0, t) = \theta_\alpha(1) - \theta_\alpha(0) = \int_0^1 \frac{d}{d\nu}\,\theta_\alpha(\nu)\,d\nu = -\int_0^1 \nabla\psi_\alpha((1-\nu)x, t) \cdot x\,d\nu.$$

By (4.6) and (4.7),

$$|\psi_\alpha(x, t)| \leqq K(1 + |x|) \leqq M_m$$

for some constant M_m uniformly as $\alpha \to T^-$. □

Remark. The proof for $f(u) = u^p$ given by Herrero and Velázquez [16], when extended to higher dimensions, establishes (4.4) provided $n \leqq 2$ or $n \geqq 3$ and $1 < p \leqq (n+2)/(n-2)$. This restriction is coming from an application of the results of Giga and Kohn [12] to the nonradially symmetric function $\psi_\alpha(x, t)$.

We can easily check

$$(\psi_\alpha)_t = \Delta\psi_\alpha + f(\psi_\alpha), \qquad x \in \mathbb{R}^n, \quad 0 < t < 1, \tag{4.8}$$

and, by (1.10),

$$\text{(4.9)}\quad \begin{aligned} &\text{(a)} \quad \psi_\alpha(x, 0) = -\ln\left(1 + \frac{1}{4}\left|\eta + \frac{x}{\sqrt{|\ln(T-\alpha)|}}\right|^2\right) + o(1) \qquad \text{for } f(u) = e^u, \\ &\text{(b)} \quad \psi_\alpha(x, 0) = \beta^\beta\left[1 + \frac{1}{4p\beta}\left|\eta + \frac{x}{\sqrt{|\ln(T-\alpha)|}}\right|^2\right]^{-\beta} + o(1) \quad \text{for } f(u) = u^p \end{aligned}$$

as $\alpha \to T^-$ uniformly in x for $\eta \neq 0$ fixed.

By Schauder's interior estimates all partial derivatives of ψ_α remain bounded in the set $Q_m = \{(x, t) : |x| \leqq m/3, \frac{1}{2} \leqq t \leqq 1\}$ uniformly as $\alpha \to T^-$. It follows that there exists a subsequence, also denoted by $\psi_\alpha(x, t)$, and a function $\bar{\psi}_m(x, t)$ such that

$$\psi_\alpha(x, t) \to \bar{\psi}_m(x, t) \quad \text{as } \alpha \to T^- \quad \text{uniformly on } Q_m,$$

$$(\bar{\psi}_m)_t = \Delta\bar{\psi}_m + f(\bar{\psi}_m) \quad \text{on int}\,(Q_m).$$

Repeating the construction for all m and taking a diagonal subsequence, we can conclude there exists a subsequence, again labeled $\psi_\alpha(x, t)$, and a function $\bar{\psi}(x, t)$ such that

$$\psi_\alpha(x, t) \to \bar{\psi}(x, t) \tag{4.10}$$

uniformly as $\alpha \to T^-$ on compacts of $\mathbb{R}^n \times [\frac{1}{2}, 1]$,

$$\bar{\psi}_t = \Delta\bar{\psi} + f(\bar{\psi}) \quad \text{in } \mathbb{R}^n \times (\tfrac{1}{2}, 1), \tag{4.11}$$

$$\begin{aligned} &\text{(a)} \quad \bar{\psi}(x, 0) = -\ln(1 + \tfrac{1}{4}|\eta|^2) &&\text{for } f(u) = e^u, \\ &\text{(b)} \quad \bar{\psi}(x, 0) = \beta^\beta\left[1 + \frac{1}{4p\beta}|\eta|^2\right]^{-\beta} &&\text{for } f(u) = u^p. \end{aligned} \tag{4.12}$$

It is easy to verify that $\bar{\psi}$ is given by

$$\begin{aligned} &\text{(a)} \quad \bar{\psi}(x, t) = -\ln\left((1-t) + \frac{1}{4}|\eta|^2\right) &&\text{for } f(u) = e^u \\ &\text{(b)} \quad \bar{\psi}(x, t) = \beta^\beta\left[(1-t) + \frac{1}{4p\beta}|\eta|^2\right]^{-\beta} &&\text{for } f(u) = u^p. \end{aligned} \tag{4.13}$$

From (4.10) and (4.13) we deduce that

$$\begin{aligned} &\text{(a)} \quad \psi_\alpha(0, 1) = -\ln\left(\frac{1}{4}|\eta|^2\right) + o(1) &&\text{for } f(u) = e^u, \\ &\text{(b)} \quad \psi_\alpha(0, 1) = (4p\beta^2)^\beta |\eta|^{-2\beta} + o(1) &&\text{for } f(u) = u^p, \end{aligned} \tag{4.14}$$

or recalling (4.1),

$$\begin{aligned} &\text{for } f(u) = e^u, \\ &\text{(a)} \quad \ln(T-\alpha) + u(\eta\sqrt{T-\alpha}\,|\ln(T-\alpha)|^{1/2}, T) = -\ln(\tfrac{1}{4}|\eta|^2) + o(1), \\ &\text{for } f(u) = u^p, \\ &\text{(b)} \quad (T-\alpha)^\beta u(\eta\sqrt{T-\alpha}\,|\ln(T-\alpha)|^{1/2}, T) = (4p\beta^2)^\beta|\eta|^{-2\beta} + o(1) \end{aligned} \tag{4.15}$$

as $\alpha \to T^-$.

Now set

$$y = \eta\sqrt{T-\alpha}\,|\ln(T-\alpha)|^{1/2}$$

so that

$$|\ln|y|| = \tfrac{1}{2}|\ln(T-\alpha)| + O(\ln|\ln(T-\alpha)|) \quad \text{as } \alpha \to T^-,$$

and

$$y = \eta\,\sqrt{2}\,\sqrt{T-\alpha}\,\sqrt{|\ln|y||} + O(\sqrt{T-\alpha}\,\ln|\ln|y||) \quad \text{as } \alpha \to T^-.$$

Therefore,

$$(T-\alpha) \approx \frac{|y|^2}{2|\eta|^2|\ln|y||} \quad \text{as } \alpha \to T^-.$$

Substituting this into (4.15) gives

$$u(y, T) \approx -2\ln|y| + \ln|\ln|y|| + \ln 8 \quad \text{for } f(u) = e^u,$$

$$\left(\frac{|y|^2}{2|\ln|y||}\right)^\beta u(y, T) \approx (4p\beta^2)^\beta \quad \text{for } f(u) = u^p$$

as $|y| \to 0$. Theorem 1.4 now follows immediately.

Acknowledgment. The authors express their appreciation to the referee for the many helpful comments, and, in particular, for pointing out a cleaner proof of Theorem 2.6.

EXISTENCE OF TRAVELLING WAVE SOLUTIONS FOR A BISTABLE EVOLUTIONARY ECOLOGY MODEL*

JACK D. DOCKERY† AND ROGER LUI‡

Abstract. The existence of travelling wave solutions for a density-dependent selection migration model in population genetics is proven. A single locus and two alleles are assumed. It is also assumed that the fitnesses of the heterozygotes in the population are below those of the homozygotes. The method of proof is by constructing an isolating neighborhood and computing a connection index.

Key words. population genetics, travelling waves, wave speed, connection index, isolated invariant set, homotopy

AMS(MOS) subject classifications. 35K57, 92A10

1. Introduction. During the past two decades, a considerable amount of mathematics has been done on the following nonlinear diffusion equation,

$$u_t = u_{xx} + h(u) \tag{1}$$

where $h \in C^1[0,1], h(0) = 0$ and $h(1) = 0$ [1], [10]. This equation is popular because it has numerous applications, one of which is to describe the dynamics of a certain gene frequency in a population subject to selection pressure and random migration [11]. In such an application, many simplifying assumptions had to be made in order that the situation can be modeled by (1). Some of these assumptions are more serious than others, but the most restrictive is probably the assumption that the population density remains constant throughout space and time. We would like to develop and analyze a model that does not have this requirement, and to compare our results to those of (1). We shall develop such a model in this section. The rest of the paper is devoted to proving the existence of travelling wave solutions for an important case of the model. A complete discussion of selection-migration models and the mathematics of (1) may be found in [9].

Consider a population of diploid individuals living in a one-dimensional homogeneous habitat which we assume to be the entire real line. Suppose a particular pair of chromosomes carries at one of its loci a particular gene that occurs in two forms, called alleles, which we denote by A and a. Then the population may be divided into three classes or genotypes: AA, aa, and Aa. Individuals with the first two genotypes are called homozygotes while individuals with the last genotype are called heterozygotes.

Let $\rho_1(x,t), \rho_2(x,t), \rho_3(x,t)$ be the densities of genotypes AA, Aa, and aa at point x and time t, respectively. We assume that the population mates randomly without regard to genotype, produces offspring at the rate r and that the population diffuses with a constant rate 1. Let τ_1, τ_2, τ_3 denote the death-rates of the individuals with genotypes AA, Aa, and aa, respectively, and let $n(x,t)$ denote the total population

density. Then, under the above assumptions, ρ_1, ρ_2, ρ_3 satisfy the following system of partial differential equations,

$$
(2) \qquad \begin{aligned}
\rho_{1,t} &= \rho_{1,xx} - \tau_1\rho_1 + \frac{r}{n}\left(\rho_1 + \frac{1}{2}\rho_2\right)^2, \\
\rho_{2,t} &= \rho_{2,xx} - \tau_2\rho_2 + \frac{2r}{n}\left(\rho_1 + \frac{1}{2}\rho_2\right)\left(\rho_3 + \frac{1}{2}\rho_2\right), \\
\rho_{3,t} &= \rho_{3,xx} - \tau_3\rho_3 + \frac{r}{n}\left(\rho_3 + \frac{1}{2}\rho_2\right)^2.
\end{aligned}
$$

These equations hold without any assumptions on the dependence of the birth and death rates on x, t and ρ_i.

In population genetics, the frequency of an allele is more interesting than the densities of the genotypes. Let $p(x,t) = (\rho_1 + \frac{1}{2}\rho_2)/n$ be the frequency of allele A in the population. Then a straightforward but tedious calculation yields the following equation for p,

$$
(3) \quad p_t = p_{xx} + 2\frac{p_x n_x}{n} + f(p,n)p(1-p) + \frac{1}{4}\{(\tau_2 - \tau_3)p - (\tau_2 - \tau_1)(1-p)\}\sigma.
$$

In the above equation $f(p,n) = p(\tau_2 - \tau_1) + (1-p)(\tau_3 - \tau_2)$, $\sigma = (\rho_2^2 - 4\rho_1\rho_3)/n^2$, and we have assumed that r and τ_i depend on p and n only. We can also obtain an equation for n by simply adding the equations in (2). Doing so, we obtain,

$$
(4) \qquad n_t = n_{xx} + g(p,n)n + (\tau_1 - 2\tau_2 + \tau_3)\frac{\sigma n}{4},
$$

where $g(p,n) = r - p^2\tau_1 - 2p(1-p)\tau_2 - (1-p)^2\tau_3$. The above method of deriving (3) and (4) from (2) is contained in the appendix of [1].

Equations (3) and (4) are insufficient to determine p and n; we need another equation for σ. The quantity σ measures the deviation of the population from Hardy–Weinberg equilibrium. For discrete-time models, the Hardy–Weinberg principle says that with random mating, and in the absence of factors which affect the gene frequencies, the genotype frequencies will arrive at and remain in the proportion $p^2 : 2p(1-p) : (1-p)^2$ after one generation. Such a proportion is called the Hardy–Weinberg equilibrium. Note that $\sigma = 0$ in this case. In a continuous-time model, Hardy–Weinberg equilibrium is attained only asymptotically [6]. In this paper we shall make the assumption that $\sigma = 0$. Hence we obtain the following reaction-diffusion system,

$$
(5) \qquad \begin{aligned}
p_t &= p_{xx} + 2\frac{p_x n_x}{n} + f(p,n)p(1-p), \\
n_t &= n_{xx} + g(p,n)n.
\end{aligned}
$$

It is worthwhile to see how (1) can be derived from (2) using a scaling argument. Let $v = \rho_2/n$. From (2), an equation for v can be derived which we shall not display here. Let $\epsilon = |\tau_1 - \tau_2| + |\tau_2 - \tau_3|$ and assume that it is sufficiently small. (This is called weak selection in population genetic theory.) Then by rescaling time by ϵ and space by $\sqrt{\epsilon}$, some of the terms in the equation for v will contain an ϵ in front. As a first approximation we set $\epsilon = 0$. Then the terms without ϵ in the equation for v imply that $\sigma = 0$. In other words, Hardy–Weinberg equilibrium is achieved. From (4), under the same scaling of space and time and setting $\epsilon = 0$, we obtain $g(p,n) = 0$. Suppose the birth and death rates are functions of n only. Then since $\tau_1 = \tau_2 = \tau_3 \equiv \tau$, we have $n = K$ which is the root of the equation $r(n) = \tau(n)$. For $\epsilon > 0$, we substitute $\sigma = 0$ and $n = K$ into (3) and obtain (1) where $h(p) = p(1-p)\{p(\tau_2(K) - \tau_1(K)) + (1-p)(\tau_3(K) - \tau_2(K))\}$. The above scaling argument is taken from §2.3 of [9].

By relabeling the two alleles A and a, it can always be assumed that $\tau_3 \geq \tau_1$ so that there are three cases to consider in (1), depending on whether τ_2 lies between, above or below τ_1 and τ_3. These are called the heterozygote intermediate, superior and inferior cases, respectively. In the last two cases, h has an intermediate zero between zero and 1.

The mathematical theory of (1) is very rich and well understood. One of the most intriguing properties is the existence of travelling waves. A travelling wave solution of (1) with speed θ is a nonconstant function $\tilde{u}(z)$ such that $\tilde{u}(x + \theta t)$ satisfies (1) for all x and $t > 0$. For example, in the heterozygote inferior case, if $\int_0^1 h > 0$, then there exists $\theta^* > 0$ such that a monotone travelling wave solution connecting zero to 1 exists if and only if $\theta = \theta^*$.

In this paper, we shall consider the heterozygote inferior case of (5); that is, $\tau_2(n)$ lies above $\tau_i(n)$ for $i = 1, 3$. We prove the existence of travelling wave solutions for (5) under additional assumptions on f and g. We shall discuss these assumptions in the next section. The proof of our existence theorem is based on the connection index from the Conley index theory. For the sake of completeness, we have provided a brief description of this index in §3. The computation of the connection index as well as the proof of our theorem are given in §4. To compute the connection index, we continue the original problem to a problem where the computation is much easier. In the last section, we provide a specific example and show that we can easily follow the above-mentioned continuation method numerically. In a forthcoming paper we shall prove that the travelling wave shown to exist here is stable in the case of weak selection.

2. Hypotheses and result. There are two types of hypotheses for our theorem, those that are motivated by our model ((A1) and (A2) below) and those that are necessary to complete our mathematical argument ((A3) and (A4) below). We begin by listing the hypotheses for f and g.

(A1) f and g are C^1 in p and n with $f_p > 0, f_n > 0, g_n < 0$ for $0 \leq p \leq 1$ and $n \geq 0$. Also, the relation

$$g_p(p,n) = f(p,n) \tag{6}$$

holds.

(A2) The nullclines $f = 0$ and $g = 0$ intersect at a point (p^*, n^*) in the region

$$Q \equiv \{(p,n) | 0 < p < 1 \text{ and } n > 0\} \quad \text{with } p^* < \tfrac{1}{2}.$$

(A3) Let the curve $g = 0$ intersect the line $p = 0$ at K_3 and the line $p = 1$ at K_1. We assume that $0 < K_3 < K_1$ and

$$\int_0^{p^*} f(p, K_3)p(1-p)dp < 0.$$

(A4) There exists $\alpha > 0$ such that $f(p, n^*) \geq \alpha(p - p^*)$ for $0 \leq p \leq 1$ and

$$g(0, n^*) < \frac{\min(1, \alpha)}{2}\left(\frac{1}{2} - p^*\right)^2. \tag{7}$$

From (A1) and (A2), one can determine the form of the nullclines $f(p,n) = g(p,n) = 0$. They are shown in Fig. 1.

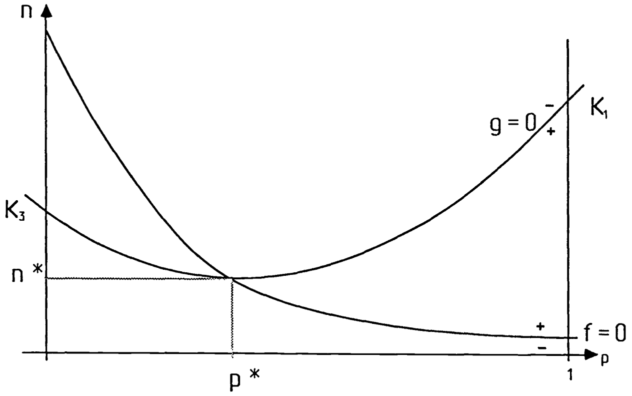

FIG. 1. *The form of the nullclines* $f = 0$ *and* $g = 0$.

We now explain how hypotheses (A1) and (A2) can be satisfied by our model.

Suppose the functions r and $\tau_i, i = 1,2,3$ depend only on n (density-dependent selection) and that they are continuously differentiable on the interval $[0, \infty)$. It is more convenient to write f and g in terms of the fitness functions η_i where $\eta_i(n) = r(n) - \tau_i(n)$. Doing so, we obtain,

$$\begin{aligned} f(p,n) &= p(\eta_1 - \eta_2) + (1-p)(\eta_2 - \eta_3), \\ g(p,n) &= p^2\eta_1 + 2p(1-p)\eta_2 + (1-p)^2\eta_3. \end{aligned} \tag{8}$$

Condition (6) is therefore satisfied. The function g represents the fitness of the entire population.

We are interested in the heterozygote inferior case of (5). A weaker condition than heterozygote inferiority is $\eta_1 + \eta_3 > 2\eta_2$ for $n \geq 0$. From (8), this is equivalent to the condition $f_p > 0$ for $n \geq 0$ in (A1).

In ecological models, it is frequently assumed that resources are scarce so that the growth rate of the population decreases with increase in population size. Thus, it is reasonable to assume that η_i is a decreasing function of n, positive near zero and negative for large n. This implies that $g_n < 0$ and that for each p, $g(p,n) = 0$ has a (unique) positive root.

Finally, from (8), the condition $f_n > 0$ for $0 \leq p \leq 1$ and $n \geq 0$ in (A1) is equivalent to $\eta_1' > \eta_2' > \eta_3'$. Such an assumption is important because it allows us to use the comparison principle on the first equation of (5). The comparison principle is not valid for (5). For an example where these inequalities and $\eta_1 + \eta_3 > 2\eta_2$ are satisfied let $\eta_i(n) = r_i(1 - (n/K_i)), i = 1,2,3$ where r_i, K_i are positive constants chosen so that $2r_2 < r_1+r_3$, $r_1/K_1+r_3/K_3 < 2(r_2/K_2)$ and $r_1/K_1 < r_2/K_2 < r_3/K_3$.

Since $f_p > 0$ and $g_n < 0$, the implicit function theorem implies that there exist functions $\tilde{n}$ and $\hat{n}$ such that $f(p, \tilde{n}(p)) = 0$ and $g(p, \hat{n}(p)) = 0$ for p in the unit interval. Since $f_n > 0$, $\tilde{n}$ is decreasing in p. We assume that the graphs of $\tilde{n}$ and $\hat{n}$ intersect at some point (p^*, n^*) where $0 < p^* < \frac{1}{2}$ and $n^* > 0$. From (6), it is easy to see that (p^*, n^*) is unique and $\hat{n}$ achieves a minimum at p^*. From (8), the function f can be written as $f(p,n) = C_1(n)(p - C_2(n))$, where $C_1(n) = \eta_1 + \eta_3 - 2\eta_2$ and $C_2(n) = (\eta_3 - \eta_2)/(\eta_1 + \eta_3 - 2\eta_2)$. Thus $p^* < \frac{1}{2}$ if and only if $\eta_3(n^*) < \eta_1(n^*)$.

Hypotheses (A1) and (A2) are not enough to prove our theorem. Two technical assumptions, (A3) and (A4), have to be added. Assumption (A3) is used only in the proof of Lemma 4.4 while (A4) is used only in the proof of Lemma 4.9. Recall the definition of $C_2(n)$ from the above paragraph. From the form of f given above, we see that the condition $f(p,n^*) \geq \alpha(p - p^*)$ is an equality and is always satisfied. Also, (7) is satisfied for sufficiently small p^* since $g(0,n^*) = \alpha(p^*)^2$. To see this, solve p^* in terms of $\eta_i(n^*)$ by writing $g(p^*,n^*) = 0$ as a quadratic equation in p^*. From the above paragraph, $p^* = C_2(n^*)$. Setting these two quantities equal, we obtain $\eta_2^2(n^*) = \eta_1(n^*)\eta_3(n^*)$ which is equivalent to $g(0,n^*) = \alpha(p^*)^2$. Finally, substituting $\eta_2(n^*) = -\sqrt{\eta_1(n^*)\eta_3(n^*)}$ into $p^* = C_2(n^*)$, we obtain

$$p^* = \frac{\sqrt{\eta_3(n^*)}}{\sqrt{\eta_1(n^*)} + \sqrt{\eta_3(n^*)}}$$

so that p^* is small if and only if $\eta_3(n^*)/\eta_1(n^*)$ is small.

It is obvious that the constant solutions of (5) in $\mathrm{cl}(Q)$ are $(0,0)$, $(1,0)$, (p^*,n^*), $(0,K_3)$ and $(1,K_1)$. If we only consider solutions that are spatially homogeneous, then (5) becomes a system of ordinary differential equations. From assumption (A1), it is easily checked that the first three solutions are unstable and the last two are stable. This type of system where there are exactly two stable equilibria is better known as a bistable system.

By a travelling wave solution of (5) with speed θ, we mean a nonconstant, bounded solution $(\tilde{p}, \tilde{n})$ such that $(\tilde{p}, \tilde{n})(x + \theta t)$ satisfies (5) for all x and $t > 0$. Equivalently, $(\tilde{p}, \tilde{n})$ satisfies the system of ordinary differential equations,

$$\begin{aligned} p'' - \theta p' + 2\frac{p'n'}{n} + f(p,n)p(1-p) &= 0, \\ n'' - \theta n' + g(p,n)n &= 0, \end{aligned} \tag{9}$$

on $\mathbf{R}$ where $' = d/dz$. As in the case of a single equation, we look for a travelling wave solution of (5) which connects the two stable equilibria $(0,K_3)$ and $(1,K_1)$; i.e., $(\tilde{p}, \tilde{n})$ satisfies the boundary conditions:

$$\lim_{z\to-\infty}(p(z),n(z))=(0,K_3),$$
$$\lim_{z\to\infty}(p(z),n(z))=(1,K_1). \tag{10}$$

Under the hypotheses (A1)–(A4) we can prove the following theorem.

THEOREM 2.1. *There exists a positive wave speed θ such that* (9) *has a solution* $(\tilde{p},\tilde{n})$ *which satisfies* (10). *Furthermore,* $\tilde{p}'>0$ *while* $\tilde{n}$ *has at most one local minimum on* $\mathbf{R}$.

The proof of Theorem 2.1 is based on the connection index theory.

3. The connection index. In this section we shall provide a cursory description of the connection index so that readers who are unfamiliar with such concepts can understand the proof of our theorem quickly. Many technical details are therefore omitted, but they can all be found in the papers [4], [5], [12]. The connection index is actually based on the Conley index [3] which we now describe.

3.1. The Conley index. Consider a flow defined by an autonomous system of differential equations on $\mathbf{R}^n$. Suppose $N\subset\mathbf{R}^n$ is compact. Let $I(N)$ denote the set of all points $x\in\mathbf{R}^n$ whose entire orbit (solution curve) through x is contained in N. If $S=I(N)$ is interior to N, then S is an isolated invariant set and N an isolating neighborhood. It is clear that a compact set N is an isolating neighborhood for S if every orbit which hits the boundary of N eventually leaves N in either forward or backward time, and if no orbit in S gets arbitrarily close to the boundary of N.

DEFINITION 1. Let S be an isolated invariant set with isolating neighborhood N. An *index pair* for S is a pair of compact sets (N_1,N_0) with $N_0\subset N_1\subset N$ such that:

(i) $\mathrm{cl}(N_1\backslash N_0)$ is an isolating neighborhood for S.

(ii) N_i is positively invariant relative to N for i=0,1, i.e., given $x\in N_i$ and $x\cdot[0,t]\subset N$, then $x\cdot[0,t]\subset N_i$.

(iii) N_0 is an exit set for N_1, i.e., if $x\in N_1$, $x\cdot[0,\infty)\not\subset N_1$, then there is a $T\geq 0$ such that $x\cdot[0,T]\subset N_1$ and $x\cdot T\in N_0$.

Given an index pair, the Conley (homotopy) index of S is defined to be the homotopy type of the pointed space N_1/N_0 obtained by collapsing N_0 to a point. This homotopy index is well defined and depends only on the invariant set S [3]. We shall denote the Conley index of S by $h(S)$.

The easiest example is when $S=\emptyset$. Then $(\emptyset,\emptyset)$ is an index pair. On collapsing the empty set to a point, a pointed one-point space is obtained. The homotopy type of this space, hence $h(\emptyset)$, is denoted by $\overline{0}$. If S is a hyperbolic rest point for the flow with a k-dimensional unstable manifold, then $h(S)=\Sigma^k$, the homotopy type of a pointed k-sphere.

An important property of the index is the sum formula. The sum of two pointed spaces (A,a) and (B,b) is defined as $A\cup B/\{a,b\}$, the pointed space obtained by taking the union of A and B and identifying the distinguished points a and b. This sum is denoted by $(A,a)\vee(B,b)$. If S_1 and S_2 are two isolated invariant sets with $S_1\cap S_2=\emptyset$, then $h(S_1\cup S_2)=h(S_1)\vee h(S_2)$. Furthermore, $\overline{0}\vee h(S)=h(S)$ for any isolated invariant set S.

The product of two pointed spaces can also be defined. If S_1 and S_2 are isolated invariant sets for the two flows $x^{'}=f(x)$ and $y^{'}=g(y)$, respectively, then $S_1\times S_2$

is an isolated invariant set for the product flow. The index of $S_1 \times S_2$ is given by $h(S_1 \times S_2) = h(S_1) \wedge h(S_2)$ where $\wedge$ is the smash product. For pointed spheres, we have $\Sigma^m \wedge \Sigma^n = \Sigma^{m+n}$ for all m and $n \geq 0$. Furthermore, $\overline{0} \wedge h(S) = \overline{0}$.

Finally, the Conley index also has the continuation property. Suppose S is an isolated invariant set with isolating neighborhood N and we continuously deform the flow so that N remains an isolating neighborhood throughout. Then the index of S before and after the deformation are the same.

3.2. The connection index. Suppose that a one-parameter family of flows on $\mathbf{R}^n$ is given by

$$x' = f(x,\theta) \tag{11}$$

where f depends continuously on $\theta \in [\theta_1, \theta_2]$. By appending the equation

$$\theta' = 0, \tag{12}$$

we obtain a flow, denoted by Φ, on $X = \mathbf{R}^n \times [\theta_1, \theta_2]$. Let S, S', and S'' be isolated invariant sets for the flow Φ and let $S(\theta)$ denote the θ slice of S.

DEFINITION 2. The triple (S, S', S'') is called a connection triple if:

(i) $S' \cup S'' \subset S$,

(ii) $S' \cap S'' = \emptyset$,

(iii) $S(\theta) = S'(\theta) \cup S''(\theta)$ for $\theta = \theta_1$ and θ_2.

A homotopy invariant index, called the connection index, can be defined for the connection triples [5]. It has many properties similar to the Conley index. We denote the connection index by $\overline{h}(S, S', S'')$ and postpone its definition together with an example to the end of this section.

Our proof of Theorem 2.1 relies on the following result in [5].

THEOREM 3.1. *Let (S, S', S'') be a connection triple for the flow Φ and suppose that $S = S' \cup S''$. Then $\overline{h}(S, S', S'') = (\Sigma^1 \wedge h(S')) \vee h(S'')$, where $h(S')$ and $h(S'')$ are the Conley indices of S' and S'' for the flow Φ, respectively.*

This theorem clearly implies that if one can prove that $\overline{h} \neq (\Sigma^1 \wedge h(S')) \vee h(S'')$ for some connection triple (S, S', S''), then there exists $\theta \in (\theta_1, \theta_2)$ such that $S(\theta) \not\subset S'(\theta) \cup S''(\theta)$. Our connection triple is constructed so that $S'(\theta)$ and $S''(\theta)$ are the rest points. Therefore there must be another orbit in $N(\theta)$ besides $S'(\theta)$ and $S''(\theta)$. From our construction of the isolating neighborhood, this orbit in $N(\theta)$ is the desired travelling wave with wave speed θ.

To show that $\overline{h} \neq (\Sigma^1 \wedge h(S')) \vee h(S'')$, we compute $\overline{h}$, $h(S')$ and $h(S'')$ via a continuation argument. The idea is similar to that of the Conley index described at the end of the previous section. We parameterize the flow Φ on X by $\lambda \in [0,1]$ and call it $\Phi(\lambda)$ where $\Phi(1) = \Phi$. Let $Y = X \times [0,1]$ with the obvious flow defined on Y and let S_0 and S_1 be isolated invariant sets for the flows $\Phi(0)$ and $\Phi(1)$, respectively. Then S_0 and S_1 are said to be related by continuation if there is an isolating neighborhood N for the flow on Y such that $S_0 = I(N(0))$ and $S_1 = I(N(1))$. ($N(\lambda)$ is the λ slice of N and is an isolating neighborhood for $\Phi(\lambda)$.) According to §3.1, $h(S_0) = h(S_1)$. Presumably, $h(S_0)$ is easier to compute than $h(S_1)$. Similarly, we can define a continuation of connection triples. Suppose S', S'', S''' are isolated invariant sets for the flow on Y such that for each λ, $(S'(\lambda), S''(\lambda), S'''(\lambda))$ is a connection triple. Then the connection triples at $\lambda = 0$ and at $\lambda = 1$ are related by continuation and have the same connection index.

We now give the definition of a connection triple (S, S', S''). The following is taken from [5].

Extend the flow (11) so that it is defined for $\theta \in [\theta_1 - \epsilon, \theta_2 + \epsilon]$ for some $\epsilon > 0$. Let U' and U'' be open neighborhoods in $\mathbf{R}^n \times [\theta_1 - \epsilon, \theta_2 + \epsilon]$ of $S'(\theta_1) \cup S'(\theta_2)$ and $S''(\theta_1) \cup S''(\theta_2)$, respectively, and choose them so that they have disjoint closures. Let ϕ be a continuous real-valued function on $\mathbf{R}^n$ which is positive on U' and negative on U'' and zero everywhere else. Append to the above given family of equations the equation $\theta' = \mu\phi(x)[\theta - (\theta_1 + \theta_2)/2]$, where μ is a small positive parameter. Let N be a compact neighborhood in $\mathbf{R}^n \times (\theta_1 - \epsilon, \theta_2 + \epsilon)$ such that $N(\theta)$ is an isolating neighborhood of $S(\theta)$ for each θ. Then there is a $\mu_0 > 0$ such that if $\mu \in (0, \mu_0)$, then N is an isolating neighborhood for the appended equation. Let h_μ be the Conley index of $I(N)$ for $\mu \in (0, \mu_0)$. Then h_μ is independent of μ and in fact depends only on the triple (S, S', S''). We define $\overline{h}(S, S', S'') = h_\mu$.

By way of example, consider the following system of equations,

$$
\begin{aligned}
u' &= v, \\
v' &= \theta v - u(1-u)(u - u^*)
\end{aligned}
$$

where $\theta > 0$ and $u^* \in \frac{1}{2}$. This is the bistable equation which has an increasing travelling wave solution connecting $(u, v) = (0,0)$ to $(1,0)$ for a positive wave speed $\theta = \theta^*$. The points $(0,0)$ and $(1,0)$ are saddles for all values of θ while $(u^*, 0)$ changes from an unstable spiral to an unstable node as θ increases, say from θ_1 near zero to $\theta_2 > \theta^*$. The phase plane diagram for the two values of θ are shown in Fig. 2 and 3 below. An isolating neighborhood is also shown where the exit set is marked. Let N denote this set cross $[\theta_1, \theta_2]$. Then N is an isolating neighborhood for the above flow and $\theta' = 0$. Let $S = I(N)$, $S' = (0,0) \times [\theta_1, \theta_2]$, and $S'' = (1,0) \times [\theta_1, \theta_2]$. Then (S, S', S'') is a connection triple according to Definition 2. To calculate its index, one can follow the recipe described in the above paragraph. An easier, though somewhat incorrect, method is the following (see §4B of [12]).

Let N_0 be a subset of N such that $(N(\theta), N_0(\theta))$ forms an index pair for $S(\theta)$. N_0 is just the exit set of N. Let $\hat{N}_0$ be N_0 together with the closure of all orbit segments in $N(\theta_1)$ and $N(\theta_2)$ which tend to $S'(\theta_1)$ and $S'(\theta_2)$ in negative time, respectively. Then $\overline{h}(S, S', S'')$ is the homotopy type of the pointed space $N/\hat{N}_0$. The reason why this is somewhat incorrect is because $S'(\theta_i) \not\subset N \backslash \hat{N}_0$, $i = 1, 2$, so that $(N, \hat{N}_0)$ is technically not an index pair according to the definition in the previous section. Therefore, we have to modify the flow near $S'(\theta_i)$ and $S''(\theta_i)$,$i = 1, 2$. It turns out that the homotopy type of N/N_0 for the modified flow is the same as the homotopy type of $N/\hat{N}_0$ as defined above.

Now the exit set at θ_i, $i = 1, 2$, consists of three disjoint parts and two of these parts are connected to the unstable manifold at $S'(\theta_i)$. (See Figs. 2 and 3.) Therefore, $\hat{N}_0$ is contractable to a point on the boundary of N, which is homotopic to the surface of a ball. Thus $N/\hat{N}_0$ is homotopy equivalent to the one-point space, or $\overline{0}$. The connection index is $\overline{0}$ for this example.

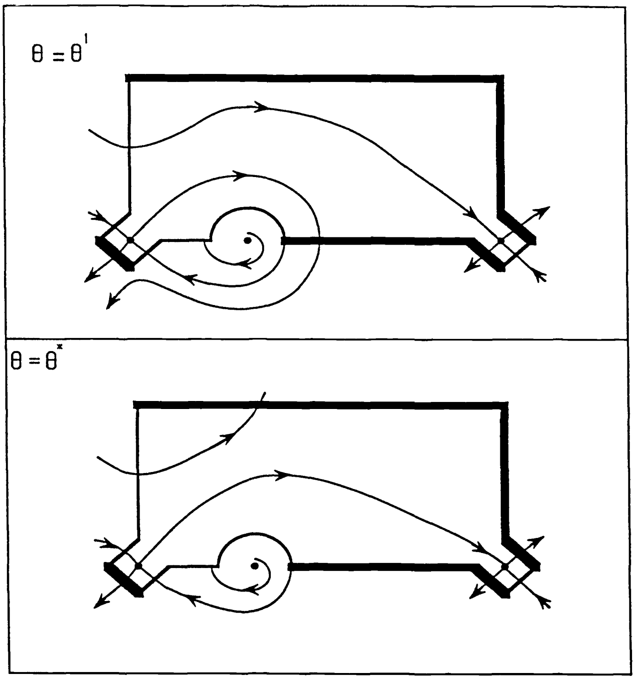

FIG. 2. *The phase planes for the bistable equation at $\theta = \theta_1$ and θ^*.*

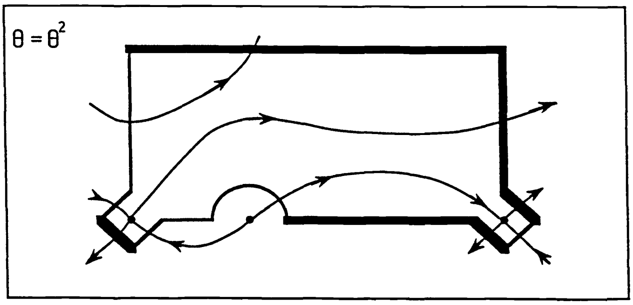

FIG. 3. *The phase plane for the bistable equation at $\theta = \theta_2$.*

4. Proof of Theorem 2.1. In this section we shall use the connection index to prove the existence of travelling waves. It is difficult to compute this index for the original model, so we continue the model to a system for which the connection index is easy to compute and then apply the continuation theorem in the previous section.

4.1. The homotopy. Let $\lambda \in [0,1]$ and consider the system,

$$\begin{aligned} p'' - \theta p' + 2\lambda \frac{p'n'}{n} + f^\lambda(p,n)p(1-p) = 0, \\ n'' - \theta n' + g^\lambda(p,n)n = 0, \end{aligned} \tag{13}$$

where $f^\lambda(p,n) = \lambda f(p,n) + (1-\lambda)(p-p^*)$ and $g^\lambda(p,n) = \lambda g(p,n) + (1-\lambda)(n^* - n)$. When $\lambda = 1$, we recover our original model and when $\lambda = 0$, (13) decouples into the

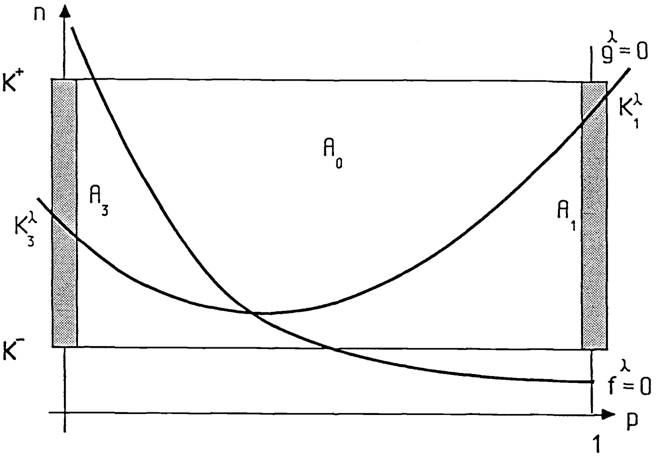

FIG. 4. *Projection of the isolating neighborhood onto the p-n plane.*

bistable equation,

$$p'' - \theta p' + p(1-p)(p-p^*) = 0 \tag{14}$$

and the Fisher equation,

$$n'' - \theta n' + n(n^* - n) = 0. \tag{15}$$

It is easy to check that except for (6), conditions (A1) to (A3) of §2 hold for f^λ and g^λ with K_i replaced by K_i^λ, $i = 1, 3$. We define K_i^λ by $g^\lambda(0, K_3^\lambda) = 0$ and $g^\lambda(1, K_1^\lambda) = 0$. The nullclines $f^\lambda = 0$ and $g^\lambda = 0$ are similar in form to the nullclines $f = 0$ and $g = 0$, respectively. In fact, $f^\lambda = 0$ lies between $f = 0$ and $p = p^*$ while $g^\lambda = 0$ lies between $g = 0$ and $n = n^*$. They intersect only at (p^*, n^*).

It is convenient to write (13) as a first order system:

$$\begin{aligned} p' &= v_1, \\ v_1' &= \theta v_1 - 2\lambda \frac{v_1 v_2}{n} - f^\lambda(p,n)p(1-p), \\ n' &= v_2, \\ v_2' &= \theta v_2 - g^\lambda(p,n)n. \end{aligned} \tag{16}$$

For each θ and λ, (16) defines a flow on $\mathbf{R}^4$. The rest points are $Y_1^\lambda = (1, 0, K_1^\lambda, 0)$, $Y^* = (p^*, 0, n^*, 0)$, $Y_3^\lambda = (0, 0, K_3^\lambda, 0)$, $(1,0,0,0)$ and $(0,0,0,0)$. A travelling wave solution of (5) corresponds to a solution of (16) which connects Y_3^1 to Y_1^1.

4.2. The isolating neighborhood. We first find a set N in $\mathbf{R}^4$, independent of θ and λ, such that it is an isolating neighborhood for the flow (16). The only rest points in N are Y_1^λ and Y_3^λ, and p is increasing along any nonconstant orbit in N.

Let K^+ and K^- be such that $0 < K^- < K_1^\lambda, K_3^\lambda < K^+$ for all $\lambda \in [0,1]$, $f = 0$ intersects $p = 0$ above K^+ and intersects $p = 1$ below K^-. Let $A_0 = \{(p,n) \mid 0 \leq p \leq 1 \text{ and } K^- \leq n \leq K^+\}$ (see Fig. 4).

If $Y = (p, v_1, n, v_2)$ is a solution of (16) with $\theta \geq \theta_0 > 0$ and $-1 \leq p(z) \leq 2$, $K^- \leq n(z) \leq K^+$ for all $z \in \mathbf{R}$, then $|v_i| \leq L$ for $i = 1, 2$. To see this, choose C such that $|g^\lambda(p,n)n| \le C$ for all $\lambda \in [0,1]$ and above values of p, n and define $L = C/\theta_0$. Suppose $v_2(z_0) > L$. Then from (16), $v_2'(z_0) > 0$ which implies that $v_2(z) > L$ for all $z \ge z_0$. Hence n is unbounded which is a contradiction. Thus, $|v_2| \le L$. A similar argument can be used to show that $|n^{2\lambda}p'|$, and hence $|p'|$, is bounded if we observe that p satisfies the equation,

$$(n^{2\lambda}p')' - \theta(n^{2\lambda}p') + f^\lambda(p,n)p(1-p)n^{2\lambda} = 0.$$

Let $N_0 = \{(p,v_1,n,v_2)|(p,n) \in A_0, 0 \le v_1 \le L \text{ and } |v_2| \le L\}$. N_0 is not an isolating neighborhood since Y_1^λ, Y_3^λ and Y^* belong to the boundary of N_0. We need to add to N_0 neighborhoods of Y_1^λ and Y_3^λ and remove a neighborhood of Y^* to obtain an isolating neighborhood.

To add a neighborhood of Y_3^λ, let $A_3 = \{(p,n) \mid |p| \le \delta, K^- \le n \le K^+\}$ where δ is independent of λ. By assumption (A1) we can choose $\delta > 0$ small enough so that $g^\lambda = 0$ intersects the boundary of A_3 only in the $|p| = \delta$ faces for all $\lambda \in [0,1]$ and A_3 lies below the curve $f = 0$ (see Fig. 4). Let $N_3 = \{(p,v_1,n,v_2) \mid (p,n) \in A_3 \text{ and } |v_i| \le L \text{ for } i = 1,2\}$. Recall that $I(N)$ is the set of all orbits of (16) that lie in N for all z.

LEMMA 4.1. $I(N_0 \cup N_3) = I(N_0)$.

Proof. We need to show that $p \ge 0$ and $v_1 \ge 0$ along any orbit in $I(N_0 \cup N_3)$ so that the orbit actually lies in $I(N_0)$.

Let $Y = (p,v_1,n,v_2)$ be an orbit in $I(N_0 \cup N_3)$. Suppose p has a negative minimum at z_0 where $v_1(z_0) = 0$ and $v_1'(z_0) \ge 0$. Since $f^\lambda(p,n) < 0$ if $p < 0$ and $n \in [K^-, K^+]$, (16) implies that $v_1'(z_0) < 0$ which is a contradiction. Therefore, $p \ge 0$.

Now suppose $v_1(z_0) < 0$. If $v_1(z) < 0$ for all $z < z_0$, then Y must tend to a rest point in N_3 as $z \to -\infty$. There is only one rest point in N_3, namely Y_3^λ. Since $p \ge 0$, we must have $p(-\infty) > p(0) \ge 0$ which contradicts the fact that $p = 0$ at Y_3^λ. Therefore, $v_1(z_1) = 0$ for some $z_1 < z_0$ and $v_1(z) < 0$ on $(z_1, z_0]$. Hence $v_1'(z_1) \le 0$. This assumption also implies that $(p,n)(z) \in A_3$ for all $z \in [z_1, z_0]$ and hence $f^\lambda(p,n) < 0$ at $z = z_1$. From (16), $v_1'(z_1) \ge 0$ and hence $v_1'(z_1) = 0$ and $p(z_1) = 0$. But then Y must lie in the invariant manifold $p \equiv 0$, $v_1 \equiv 0$ because of uniqueness which then contradicts the assumption that $v_1(z_0) < 0$. Therefore, $v_1 \ge 0$. This completes the proof of the lemma. □

We add a neighborhood of Y_1^λ in a similar manner. Let $A_1 = \{(p,n) \mid |p-1| < \delta_1, K^- \le n \le K^+\}$. We choose δ_1 independent of λ and sufficiently small so that $g^\lambda = 0$ intersects the boundary of A_1 only in the $p = 1 - \delta_1$ and $p = 1 + \delta_1$ faces (see Fig. 4). Let $N_1 = \{(p,v_1,n,v_2) \mid (p,n) \in A_1 \text{ and } |v_i| \le L \textit{ for } i = 1,2\}$. The proof of the following lemma is similar to that of Lemma 4.1 and is omitted.

LEMMA 4.2. $I(N_0 \cup N_1 \cup N_3) = I(N_0)$.

Let $\hat{N} = N_0 \cup N_1 \cup N_3$. $\hat{N}$ is still not an isolating neighborhood since Y^* is on its boundary. We need to remove a neighborhood of Y^*. To do this we first show that $v_1 > 0$ along any nonconstant orbit in $I(\hat{N})$.

LEMMA 4.3. *For any orbit $Y \in I(\hat{N})$, $n \ge n^*$ for all $z \in \mathbf{R}$.*

Proof. Suppose n has a local minimum less than n^* at say $z = 0$. Then $(p,n)(0)$ must lie in the region where $g^\lambda > 0$. From (16), $v_2'(0) < 0$ which is a contradiction. Therefore $n \ge n^*$ for all z. □

LEMMA 4.4. *Let $\theta > 0$. Then $v_1 > 0$ along any orbit in $I(\hat{N})$ except when the orbit is Y^*, Y_3^λ, or Y_1^λ.*

Proof. Suppose Y is an orbit in $I(\hat{N}) = I(N_0)$ with $v_1(z) = 0$ at say $z = 0$. Then $v_1'(0) = 0$ for otherwise Y would leave N_0 in either forward or backward time. From (16), $f^\lambda(p,n)p(1-p) = 0$ at $z = 0$. If $p(0) = 0$ or 1, then Y lies in the invariant manifold $p \equiv 0, v_1 \equiv 0$ or $p \equiv 1, v_1 \equiv 0$. In each case, a simple phase plane analysis reveals that the only orbit that lies between K^+ and K^- for all z is the rest point Y_3^λ or Y_1^λ, respectively. Thus we need only consider the case $f^\lambda(p(0), n(0)) = 0$. From Lemma 4.3, the point $(p(0), n(0))$ must lie on or above the curve $g^\lambda = 0$ which implies that $p(0) \leq p^*$. If it lies on $g^\lambda = 0$ and $v_2(0) = 0$, then $Y \equiv Y^*$. Otherwise, Y must tend to Y_3^λ as $z \to -\infty$. To see this, differentiate the equation for p to obtain $p''' + [f(p,n)]'p(1-p) = 0$ at $z = 0$. Since $p'''(0) \geq 0$, we have $n'(0) \leq 0$. If $n'(0) = 0$, then (16) implies that n has a local minimum at $z = 0$. Otherwise, $n'(0) < 0$. In both cases, since n cannot have a local maximum at a point above $g^\lambda = 0$ or a local minimum below it, we conclude that $(p,n)(-\infty) = (0, K_3^\lambda)$ and that $n' \leq 0$ for $z < 0$.

Multiply the first equation in (13) by $p' = v_1$ and integrate to obtain:

$$(17) \qquad \theta \int_{-\infty}^{0} (p')^2 dz = \int_{0}^{p(0)} f^\lambda(p, n(z^{-1}(p)))p(1-p)dp + 2\lambda \int_{-\infty}^{0} \frac{n'(p')^2}{n} dz.$$

The right side of (17) is less than $\int_0^{p^*} f^\lambda(p, K_3^\lambda)p(1-p)dp < 0$ because $n' < 0$ for $z < 0$, $f_n > 0$ and assumption (A3). This contradicts the assumption that $\theta > 0$. Therefore $v_1 > 0$ along any nonconstant orbit in $I(\hat{N})$. □

It now follows that the only orbit of (16) in $I(\hat{N})$ that hits the boundary of $\hat{N}$ is the constant solution Y^*. To see this, we may assume that the orbit Y lies entirely in N_0 because of Lemma 4.2. By our choice of L, $|v_i| < L$ along the orbit. The n-component of the orbit cannot hit the $n = K^\pm$ faces of $\partial\hat{N}$. (For example, if n has a local maximum at $z = 0$ and $n(0) = K^+$, then the last equation of (16) is contradicted.) If Y hits the boundary $p = 0$ or $p = 1$ of N_0, then $v_1 = 0$ also since Y lies in N_0. According to Lemma 4.4, $Y \equiv Y_3^\lambda$ or Y_1^λ which are in the interior of $\hat{N}$ because of the added neighborhood. Finally, if Y hits the boundary $v_1 = 0$ of N_0 and $p \neq 0$ or 1, then Lemma 4.4 implies that $Y \equiv Y^*$. Hence our assertion at the beginning of the paragraph is proved. We record it as a lemma.

LEMMA 4.5. *If $\theta \geq \theta_0 > 0$, then the only orbit of (16) in $I(\hat{N})$ which hits the boundary of $\hat{N}$ is $Y \equiv Y^*$.*

Finally, we must remove a neighborhood of Y^*. To do this, we use a result of [5] concerning the excision of a portion of an invariant set. Let S be a compact invariant set of a flow and $S_r \subset S$ an isolated set relative to S; that is, there is a compact relative neighborhood N_r of S_r in S such that $S_r = I(N_r)$. Let $A^+ = A^+(S, S_r)$ be the points on solutions in $S \backslash S_r$ that tend to S_r in forward time. Similarly, let $A^- = A^-(S, S_r)$ be those points which tend to S_r in backward time. A proof of the following lemma can be found in §4D of [5].

LEMMA 4.6. *Suppose $\tilde{N}$ is compact and $S = I(\tilde{N})$. Let $S_r \subset S$ be isolated relative to S and suppose that at least one of the sets A^+ and A^- is empty. Then for all sufficiently small neighborhoods W of S_r in $\tilde{N}$,*

$$(18) \qquad I(\tilde{N} \backslash W) \cap \partial(\tilde{N} \backslash W) = I(\tilde{N}) \cap \partial\tilde{N} \backslash (S_r \cup A^+ \cup A^-).$$

We will take $\tilde{N}$ to be $\hat{N}$ and S_r the rest point Y^*. In this case, $A^+(I(\hat{N}), Y^*)$ is the component of the stable manifold at Y^* that is contained in $I(\hat{N})$.

LEMMA 4.7. *For all $\lambda \in [0,1]$ and $\theta > 0$, $A^+(I(\hat{N}), Y^*) = \emptyset$.*

Proof. First note that if Y is a nonconstant orbit in $I(\hat{N})$, then by Lemma 4.2, $p \in [0,1]$ and by Lemma 4.4, $v_1 > 0$ for all z. Thus the only orbit in A^+ must be a heteroclinic connection from Y_3^λ to Y^*. For $\theta > 0$, there can be no such connection. The proof of this fact uses the same argument as in the second half of the proof of Lemma 4.4 and is omitted. Thus $A^+ = \emptyset$. □

The set $A^-(I(\hat{N}), Y^*)$ is nonempty since it is possible to find a connecting orbit, as for example when $\lambda = 0$, from Y^* to K_1^λ for sufficiently large θ. The unstable manifold at Y^* has dimension three and connecting orbits may be found using a shooting argument.

By Lemmas 4.6 and 4.7, for all sufficiently small neighborhoods W of Y^*, we have (18) holding. Since the λ-interval is compact, we can choose a neighborhood W so that (18) holds for all $\lambda \in [0,1]$. Finally, let $N = \hat{N} \backslash W$.

PROPOSITION 4.8. *N is an isolating neighborhood for the flow* (16) *for each $\lambda \in [0,1]$ and $\theta \geq \theta_0 > 0$.*

Proof. We must show that $I(N)$ is in the interior of N. From (18) and Lemma 4.7, we have

$$I(N) \cap \partial N = I(\hat{N}) \cap \partial \hat{N} \backslash (Y^* \cup A^-).$$

Suppose P belongs to $I(\hat{N}) \cap \partial \hat{N}$. If an orbit in $I(\hat{N})$ hits P in finite time, then by Lemma 4.5, $P = Y^*$. If P is approached by a nonconstant orbit Y in $I(\hat{N})$, then by Lemma 4.4 and the fact that the n-component of Y cannot have a local maximum (minimum) above (below) $g^\lambda = 0$, Y must connect two of the three rest points Y^*, Y_3^λ and Y_1^λ. It cannot connect Y_3^λ to Y^* because of Lemma 4.7. It cannot connect Y_3^λ and Y_1^λ since neither points are on $\partial \hat{N}$. Hence it must connect Y^* to Y_1^λ in which case $P = Y^*$. Finally, we have to consider the case when there exist orbits Y_n in $I(\hat{N})$ such that $Y_n(z_n) \rightarrow P$ as $n \rightarrow \infty$. Let $\hat{Y}_n(z) = Y_n(z_n - z)$. Then $\hat{Y}_n$ belongs to $I(\hat{N})$ and $\hat{Y}_n(0) \rightarrow P$ as $n \rightarrow \infty$. By the Arzela–Ascoli theorem, a subsequence of $\hat{Y}_n$ converges to an orbit $\hat{Y}$ in $I(\hat{N})$ where $\hat{Y}(0) = P$. From above, $P = Y^*$. Therefore, $I(N) \cap \partial N = \emptyset$ which completes the proof of the proposition. □

4.3. The proof of Theorem 2.1. We first derive a priori bounds on the wave speed θ.

LEMMA 4.9. *There exist $0 < \theta_* < \theta^*$, independent of $\lambda \in [0,1]$, such that if $(\hat{p}, \hat{n})$ is a nonconstant solution of* (13) *for some θ with $\hat{p} \in [0,1]$, $\hat{p}' > 0$, $\hat{n} \in [n^*, K^+]$, $\limsup_{z \to -\infty} \hat{p}(z) < p_1^*$ and $\liminf_{z \to \infty} \hat{p}(z) > p^*$, then $\theta \in (\theta_*, \theta^*)$. Here, p_1^* is the root of the equation $f(p, K^+) = 0$ that lies between zero and* 1.

Proof. We first show how to obtain the upper bound θ^* assuming that the lower bound θ_* has been found. Recall from the beginning of §4.2 that $\theta \geq \theta_*$ implies that $|\hat{n}'|$ is bounded independently of λ. Since $\hat{n} \geq n^*$, we can choose L_1 such that $|\hat{n}'/\hat{n}| \leq L_1$ for all z.

Consider the equation $w_t = w_{xx} + f^\lambda(w, K^+)w(1-w)$. Since

$$\int_0^1 f^\lambda(w, K^+)w(1-w)dw > 0,$$

this equation has a monotone travelling wave solution W^λ with positive wave speed

$\theta^{*,\lambda}$ such that $W^{\lambda}(-\infty)=0$ and $W^{\lambda}(\infty)=1$. Furthermore,

$$\theta^{*,\lambda}\int_{\mathbf{R}}([W^{\lambda}]')^2dz=\int_0^1 f^{\lambda}(w,K^+)w(1-w)dw.$$

This relation implies that $\theta^{*,\lambda}$ depends continuously on λ since $[W^{\lambda}]'$ depends on λ uniformly on $\mathbf{R}$. The travelling wave solution W^{λ} also has strong stability properties. Fife and McLeod showed in [10] that if the initial data w_0 satisfies the conditions $\limsup_{x\to-\infty} w_0(x)<p_1^*$ and $\liminf_{x\to\infty} w_0(x)>p_1^*$, then $w(x-\theta^{*,\lambda}t,t)$ is essentially bounded between two translates of W^{λ}.

Let $u(x,t)=\hat{p}(x+\hat{\theta}t)$ and $v(x,t)=\hat{n}(x+\hat{\theta}t)$ where $\hat{\theta}=\theta-2\lambda L_1$. From (13), $\hat{p}''-\hat{\theta}\hat{p}'+f^{\lambda}(\hat{p},\hat{n})\hat{p}(1-\hat{p})\geq 0$ so that u satisfies the inequality $u_t\leq u_{xx}+f^{\lambda}(u,v)u(1-u)$. Since $f_n>0$ and $n\leq K^+$, we have $u_t\leq u_{xx}+f^{\lambda}(u,K^+)u(1-u)$. Let w satisfy $w_t=w_{xx}+f^{\lambda}(w,K^+)w(1-w)$ with initial data $w_0=\hat{p}$. From the maximum principle, $u(x,t)=\hat{p}(x+\hat{\theta}t)\leq w(x,t)$ for all x and $t>0$. From the stability properties of W^{λ} mentioned above and our hypotheses on $\hat{p}$, there exist positive constants C,μ, and α such that

$$w(x-\theta^{*,\lambda}t,t)\leq W^{\lambda}(x-\alpha)+Ce^{-\mu t}$$

for all x and $t\geq 0$. Letting $y=x+(\hat{\theta}-\theta^{*,\lambda})t$, we have

$$\hat{p}(y)\leq W^{\lambda}(y+(\theta^{*,\lambda}-\hat{\theta})t-\alpha)+Ce^{-\mu t}.$$

If $\hat{\theta}>\theta^{*,\lambda}$, then letting $t\to\infty$ in the above inequality we obtain $\hat{p}(y)\leq 0$ for all $y\in\mathbf{R}$, which contradicts our hypotheses. Thus $\hat{\theta}\leq\theta^{*,\lambda}$. If we choose θ^* to be larger than $\max_{\lambda\in[0,1]}(\theta^{*,\lambda})+2L_1$, we obtain an upper bound for θ for all $\lambda\in[0,1]$. We now turn to finding θ_*.

Let $u=\hat{n}'/n$ and let $-\hat{\theta}=\min_z(-\theta+2\lambda u(z))$. From the definition of f^{λ}, assumption (A4), and the hypotheses of our lemma, we have

$$\hat{p}''-\hat{\theta}\hat{p}'+\beta(\hat{p}-p^*)\hat{p}(1-\hat{p})\leq 0$$

where $\beta=1-\lambda+\lambda\alpha\geq\min(1,\alpha)$. This inequality implies that $\hat{\theta}=\theta-2\lambda\min_z u(z)\geq\theta_*^{\lambda}$ where θ_*^{λ} is the wave speed of the bistable equation $w_t=w_{xx}+\beta(w-p^*)w(1-w)$. This fact may be proved using the same method we used to prove the upper bound θ^*. It is also known [2] that for the above bistable equation, θ_*^{λ} is given by $\sqrt{2\beta}(\frac{1}{2}-p^*)$. We now proceed to find the minimum of u.

If $n'\geq 0$, then $\min_z u(z)\geq 0$ so that $\theta\geq\sqrt{2\beta}(\frac{1}{2}-p^*)\geq\sqrt{2\min(1,\alpha)}(\frac{1}{2}-p^*)$. Suppose u is not monotone. Then u cannot have a local maximum. For if u achieves a local maximum at, say, $z=0$, then $(\hat{p},\hat{n})(0)$ lies below $g^{\lambda}=0$. Since $\hat{n}$ cannot have a local minimum below $g^{\lambda}=0$, $\hat{n}$ is either increasing for $z<0$ or decreasing for $z>0$. But then this would imply that either $(\hat{p},\hat{n})(-\infty)=(0,K_3^{\lambda})$ or $(\hat{p},\hat{n})(\infty)=(1,K_1^{\lambda})$ which is impossible. Therefore, we assume that $\hat{n}$ has a unique minimum at $z=0$, is decreasing on $(-\infty,0)$, is increasing on $(0,\infty)$ and the minimum of u occurs at some point $z_0<0$.

From (13), u satisfies the equation $u'=-u^2+\theta u-g^{\lambda}$ where $g^{\lambda}(z)=g^{\lambda}(\hat{p},\hat{n})(z)$. Therefore, $u(z_0)=(\theta-\sqrt{\theta^2-4g^{\lambda}(z_0)})/2$. Substituting this into the inequality $\theta-2\lambda\min_z u(z)\geq\theta_*^{\lambda}$, we obtain

$$(1-\lambda)\theta+\lambda\sqrt{\theta^2-4g^{\lambda}(z_0)}\geq\sqrt{2\beta}\left(\tfrac{1}{2}-p^*\right).$$

To estimate $g^\lambda(z_0)$, we claim that if $(p_i, n_j), i, j = 1, 2$, are four corners of a rectangle in the p-n plane where $0 < p_1 < p_2 < 1$ and $0 < n_1 < n_2 < K_3^\lambda$, then $g^\lambda(p_1, n_1) + g^\lambda(p_2, n_2) \geq g^\lambda(p_1, n_2) + g^\lambda(p_2, n_1)$. Assuming this for the moment, let $(p_2, n_2) = (\hat{p}, \hat{n})(z_0)$ and $(p_1, n_1) = (0, n^*)$. Then $g^\lambda(z_0) \geq -\lambda g(0, n^*)$ which according to (7) is greater than $-(\epsilon^2 \min(1, \alpha))(\frac{1}{2} - p^*)^2/2$ for some $0 < \epsilon < 1$. Therefore, by completing the square and rearranging the last inequality of the last paragraph, we have $\theta \geq \sqrt{2}\min(1, \alpha)(1 - \epsilon)(\frac{1}{2} - p^*) \equiv \theta_*$.

To prove our claim, let $(\tilde{p}(z), \tilde{n}(z)), 0 \leq z \leq 1$ be a line segment joining the points (p_1, n_2) to (p_2, n_1) so that $\tilde{p}' \geq 0$ and $\tilde{n}' \leq 0$. Then, since $g_{pn}^\lambda = 2\lambda f_n \geq 0$, we have,

$$
\begin{aligned}
g^\lambda(p_2, n_1) &= g^\lambda(p_1, n_2) + \int_0^1 g^\lambda(\tilde{p}(z), \tilde{n}(z))_z dz \\
&= g^\lambda(p_1, n_2) + \int_0^1 (g_p^\lambda \tilde{p}' + g_n^\lambda \tilde{n}') dz \qquad (19) \\
&\geq g^\lambda(p_1, n_2) + \int_0^1 g^\lambda(\tilde{p}(z), n_1)_z dz + \int_0^1 g^\lambda(p_2, \tilde{n}(z))_z dz, \qquad (20)
\end{aligned}
$$

which is the same as our claim. The proof of the lemma is complete. □

We are now ready to apply the connection index theory to prove Theorem 2.1. Let $X = \mathbf{R}^4 \times [\theta_*, \theta^*]$ and $Y = X \times [0, 1]$ with the obvious flow Φ defined on Y. Let N be the set defined near the end of §4.2 with $\theta_0 = \theta_*$. Then Proposition 4.8 implies that $\hat{N} = N \times [\theta_*, \theta^*] \times [0, 1]$ is an isolating neighborhood for the flow Φ. Let $S' = Y_3^\lambda \times [\theta_*, \theta^*] \times [0, 1]$, $S'' = Y_1^\lambda \times [\theta_*, \theta^*] \times [0, 1]$ and $S = I(\hat{N})$. Then S, S', S'' are isolated invariant sets for the flow Φ on Y. We claim that for each λ, $(S(\lambda), S'(\lambda), S''(\lambda))$ is a connection triple. Conditions (i) and (ii) of Definition 2 are obvious and condition (iii) follows from Lemma 4.9 above. According to §3.2, the connection index $\overline{h}(\lambda) = \overline{h}(S(\lambda), S'(\lambda), S''(\lambda))$ is independent of λ. Hence, $\overline{h}(1) = \overline{h}(0)$. When $\lambda = 0$, (16) uncouples and $(n, v_2) = (n^*, 0)$ is a saddle point for the two-dimensional flow obtained by writing (15) as a first-order system. From the example given in §3.2, $\overline{h}(0) = \Sigma^1 \wedge \overline{0} = \overline{0}$. Therefore, $\overline{h}(1) = \overline{0}$.

To compute the Conley index $h(S'(1))$, we first observe that $S'(0)$ and $S'(1)$ are related by continuation. When $\lambda = 0$, $Y_3^0 = (0, 0, n^*, 0)$ and $Y_1^0 = (1, 0, n^*, 0)$. If we write (14) as a first-order system, then $(p, v_1) = (0, 0)$ and $(1, 0)$ are both saddle points. Each has a one-dimensional unstable manifold. Hence $h(S'(1)) = h(S'(0)) = \Sigma^1 \times \Sigma^1 = \Sigma^2$, according to §3.1. Similarly, $h(S''(1)) = \Sigma^2$. Since $(\Sigma^1 \wedge h(S')) \vee h(S'') = \Sigma^3 \vee \Sigma^2 \not\simeq \overline{0} = \overline{h}(\lambda)$, Theorem 3.1 implies that there exists θ such that $I(N_\theta)$ contains a nonconstant orbit. From Lemma 4.4, this orbit must be a travelling wave solution connecting Y_3^1 to Y_1^1 with speed $\theta \in (\theta_*, \theta^*)$. Furthermore, p is increasing. Using the fact that n cannot have a maximum above the curve $g = 0$ or a minimum below the curve $g = 0$, it is easy to see that n can have at most one minimum on $\mathbf{R}$. The proof of Theorem 2.1 is complete.

5. A numerical example.

In the previous section we showed how the homotopy invariance of the connection index allowed us to ascertain the existence of a travelling wave solution for the model (5). In this section we shall show that one can follow this heteroclinic connection for a specific example using numerical continuation techniques.

Recall from the introduction that

$$f(p, n) = p(\eta_1 - \eta_2) + (1 - p)(\eta_1 - \eta_3)$$

and

$$g(p,n) = p^2\eta_1 + 2p(1-p)\eta_2 + (1-p)^2\eta_3.$$

Following [13] we assume that the fitness functions have the form:

$$\eta_i(n) = r_i(1 - n/K_i) \quad \text{for } i = 1, 2, \text{ and } 3.$$

To obtain an example of the heterozygote inferior case we use the following values of parameters:

i	1	2	3
r_i	0.6	0.7	0.8
K_i	12000	7300	8000

For the numerical computations we have found it convenient to scale n by 10^3. It is easily checked that this corresponds to scaling the K_i's by 10^{-3} in the above table. Since g is linear in n and quadratic in p one can write down explicit formula for p^* and n^*. Furthermore, it is easy to check that assumptions (A1)–(A4) are satisfied for this model with the parameters given above.

We seek a heteroclinic orbit for (16) connecting Y_3^λ at $z = -\infty$ to Y_1^λ at $z = +\infty$, where $Y_3^\lambda = (0, 0, K_3^\lambda, 0)$, $Y_1^\lambda = (1, 0, K_1^\lambda, 0)$, and

$$K_i^\lambda = K_i \frac{(1-\lambda)n^* - \lambda r_i}{(1-\lambda)K_i - \lambda r_i} \quad \text{for } i = 1 \text{ and } 3.$$

It is easy to show that for each $\theta > 0$, (16) has a two-dimensional unstable manifold and a two-dimensional stable manifold at Y_i^λ for $i = 1$ and 3. One can also write down explicit expressions for the eigenvalues as well as a set of orthonormal eigenvectors. Let $\{\phi_3^\lambda, \psi_3^\lambda\}$ denote an orthonormal bases for the tangent space to the unstable manifold at Y_3^λ and $\{\phi_1^\lambda, \psi_1^\lambda\}$ an orthonormal bases for the tangent space of the stable manifold at Y_1^λ.

The numerical method used here is similar to the method given in [7]. The approximation is based on the following equations:

$$Y' = TF^\lambda(Y, \theta) \quad \text{for } 0 < z < 1, \tag{21}$$

with the boundary conditions:

$$Y(0) = Y_3^\lambda + \epsilon_3(m_{11}\phi_3^\lambda + m_{12}\psi_3^\lambda) \quad \text{with } m_{11}^2 + m_{12}^2 = 1, \tag{22}$$

and

$$Y(1) = Y_1^\lambda + \epsilon_1(m_{21}\phi_1^\lambda + m_{22}\psi_1^\lambda) \quad \text{with } m_{21}^2 + m_{22}^2 = 1. \tag{23}$$

Here, $F^\lambda(Y, \theta)$ is the vector field on the right-hand side of (16) and T is a large positive constant.

Equation (21) is just the differential equation (16) with z scaled by T. The boundary condition (22) is the requirement that the initial value $Y(0)$ lies on the sphere of radius ϵ_3 intersect the linear approximation to the unstable manifold at

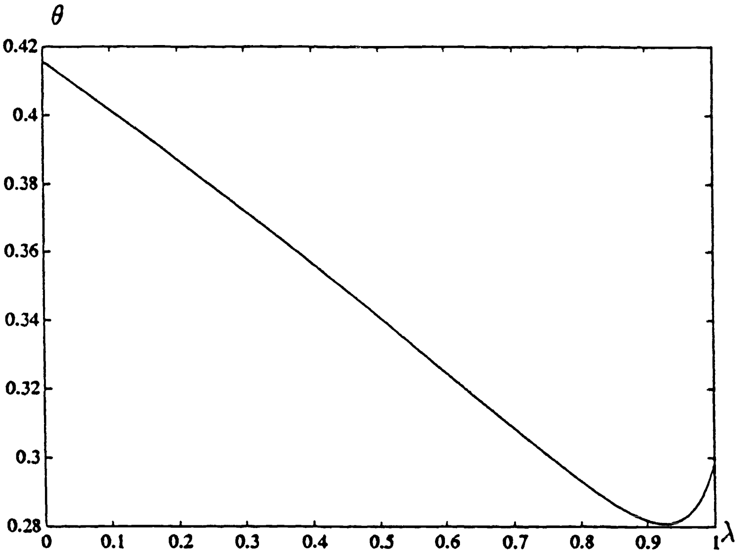

FIG. 5. *The wave speed θ versus the homotopy parameter λ.*

Y_3^λ. Likewise, (23) implies that $Y(1)$ lies on the sphere of radius ϵ_1 intersect the linear approximation to the stable manifold of Y_1^λ. The constant T is the time of travel between these two points for the original unscaled variable z. The m_{ij}'s are the projections onto the unstable and stable directions. For T large and ϵ_i's small, each solution of (20)–(22) represents an approximate heteroclinic connection.

In [7], the parameter T is fixed and the ϵ_i's are allowed to vary. Since the translate of a travelling wave is also a travelling wave, another constraint is needed to fix the phase of the solution. In [7], it was required that the L^2-norm of the difference between the derivatives of two successive approximations be at a minimum. This requirement takes the form of an integral condition. In the presence of sharp fronts, which occur for singularly perturbed equations, this condition is derived so as to economize the numerical calculations. For this model it is more economical to simply set $\epsilon_1 = \epsilon_3 \equiv \epsilon$, a fixed positive number, forego the integral constraint and allow T to be a free parameter. Along the solution branch we need to compute for each λ the solution vector Y, the wave speed θ, T and the m_{ij}'s so that the boundary conditions (21)–(22) hold.

To find a starting solution of (21) at $\lambda = 0$ we use $Y(z) = (u(z), u'(z), n^*, 0)$ where

$$u(z) = \frac{\exp(T\sqrt{2}/2(z-1/2))}{1+\exp(T\sqrt{2}/2(z-1/2))},$$

with $\theta = \sqrt{2}(1/2 - p^*)$. This is a solution of (16) at $\lambda = 0$ connecting Y_3^0 to Y_1^0. At $\lambda = 0$ we fix $T = 50$ and compute ϵ from the exact solution, thereafter holding ϵ fixed and allow T to vary. The numerical continuation is computed using the continuation program AUTO [8]. The results of this computation are shown below.

In Fig. 5 we have plotted the wave speed θ versus the homotopy parameter λ. In

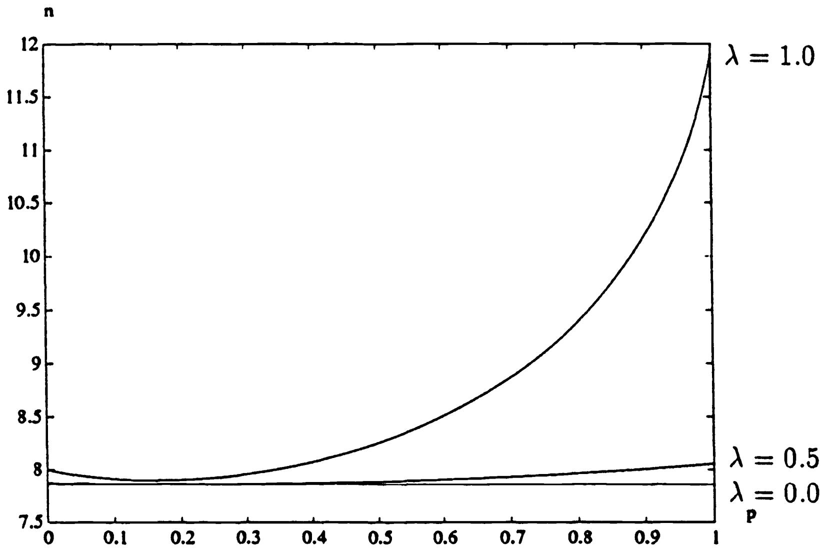

FIG. 6. *The n-component of the solution for* $\lambda = 0.0,\ 0.5,$ *and* 1.0.

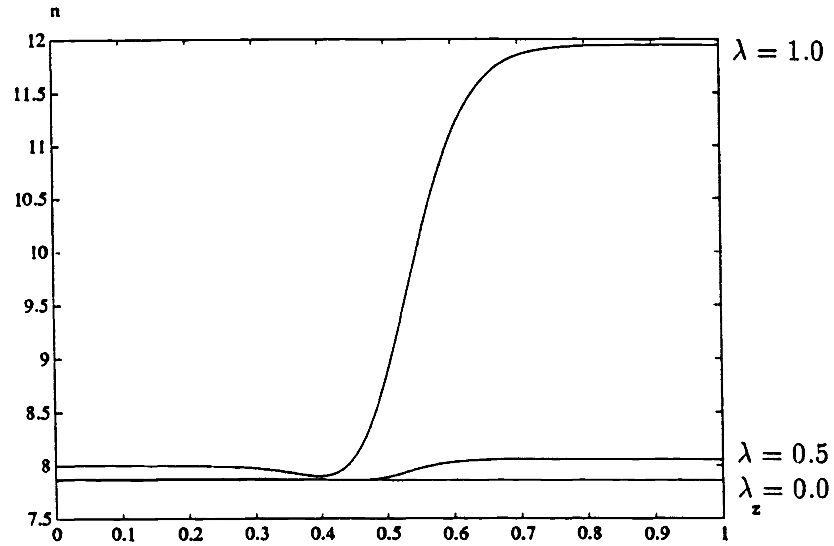

FIG. 7. *The projection onto the p-n plane of the solution for* $\lambda = 0.0,\ 0.5,$ *and* 1.0.

Fig. 6 we have plotted the n-component of the solution as a function of z for $\lambda = 0, \frac{1}{2}$, and 1. We see that n is clearly not monotone at $\lambda = 1$. In Fig. 7 we have plotted the projection of the solutions for $\lambda = 0, \frac{1}{2}$, and 1 onto the p-n phase plane.

ON THE ENERGY DECAY OF A LINEAR THERMOELASTIC BAR AND PLATE*

JONG UHN KIM†

Abstract. It is shown that the energy of a thermoelastic bar and plate decays exponentially fast. The energy method, combined with a multiplier technique and compactness property, is used.

Key words. energy decay, thermoelastic bar, thermoelastic plate

AMS(MOS) subject classifications. 35M05, 35B40

Introduction. In this paper we shall prove exponential decay of the energy of a one-dimensional linear thermoelastic bar and a linear thermoelastic plate. Since the pioneering work of Dafermos [1] on linear thermoelasticity, significant progress has been made on the mathematical aspect of thermoelasticity; see [4], [5], [8], [9], and [10], among others. Most studies focused on the existence, regularity, and asymptotic behavior of solutions to the equations of nonlinear thermoelasticity. Surprisingly, nothing has been known on exponential decay of the energy for the one-dimensional linear equations with the Dirichlet boundary condition. In the above cited works and references therein, some results on decay rate can be found. However, these are not in the form from which we can infer exponential decay. When the displacement and the temperature satisfy the Dirichlet and Neumann boundary conditions, respectively, or the other combination, Hansen [3] proved exponential decay by using nonharmonic Fourier series. But his argument does not seem to extend to the case where both the displacement and the temperature satisfy the Dirichlet boundary condition.

The purpose of the present work is to resolve this open question for the one-dimensional equations. The main results are Theorems 1.6 and 1.7 below. It is known that the energy in higher-dimensional thermoelasticity does not decay to zero under certain circumstances. There can exist nontrivial time-periodic solutions. A precise statement can be found in [1].

We shall also prove exponential decay of the energy of the linear thermoelastic plate in any space dimensions. Lagnese [6] discussed stabilization of various plate models, and showed that the energy of a linear thermoelastic plate decays exponentially fast with a certain dissipative boundary condition. We shall show that exponential decay can be achieved with the homogeneous Dirichlet boundary condition. The main results are Theorems 2.6 and 2.7.

Our main tool is the energy method, combined with a multiplier technique and compactness property. The general strategy of proof is the same for both a linear thermoelastic bar and plate. It is quite different from that of the earlier works, which also employed the energy method. Our approach is somewhat indirect in that the key estimates (1.32) and (2.32) below are established by the argument of contradiction, which fully exploits compactness property and inherent boundary regularity associated with the wave and plate equations.

1. Linear thermoelastic bar.

In this section, we let $\Omega = (0, 1)$ and consider the following initial-boundary value problem.

$$u_{tt} - au_{xx} + b\theta_x = 0 \quad \text{in } \Omega \times (0, \infty), \tag{1.1}$$

* Received by the editors November 26, 1990; accepted for publication (in revised form) November 13, 1991. This research, performed at Mathematical Sciences Research Institute, was supported in part by National Science Foundation grant DMS-8505550.

† Department of Mathematics, Virginia Polytechnic Institute, Blacksburg, Virginia 24061.

$$\theta_t - \theta_{xx} + bu_{tx} = 0 \quad \text{in } \Omega \times (0, \infty), \tag{1.2}$$

$$u = 0, \quad \theta = 0 \quad \text{at } x = 0 \text{ and } 1, \tag{1.3}$$

$$u(x, 0) = u_0(x), \quad u_t(x, 0) = u_1(x), \quad \theta(x, 0) = \theta_0(x) \quad \text{in } \Omega, \tag{1.4}$$

where $a > 0$ and $b \neq 0$ are constants, and u and θ denote the displacement and the temperature, respectively. The derivation of (1.1) and (1.2) can be found in [2].

LEMMA 1.1. *For $u_0 \in H_0^1(\Omega)$, $u_1 \in L^2(\Omega)$, and $\theta_0 \in L^2(\Omega)$, there is a unique solution (u, θ) such that*

$$u \in C([0, \infty); H_0^1(\Omega)) \cap C^1([0, \infty); L^2(\Omega)), \tag{1.5}$$

$$\theta \in C([0, \infty); L^2(\Omega)) \cap L^2(0, \infty; H_0^1(\Omega)). \tag{1.6}$$

This is a known fact. A typical proof is to construct a sequence of smooth solutions whose initial data approximate (u_0, u_1, θ_0). Then, we apply the a priori estimates derived from the identity

$$\frac{d}{dt} \int_\Omega (u_t^2 + u_x^2 + \theta^2)\, dx + 2 \int_\Omega \theta_x^2\, dx = 0 \tag{1.7}$$

to the difference between any two smooth solutions of this sequence and conclude that the sequence is strongly convergent in the function spaces in (1.5) and (1.6). We shall omit the details.

LEMMA 1.2. *For $u_0 \in H_0^1(\Omega) \cap H^2(\Omega)$, $u_1 \in H_0^1(\Omega)$, and $\theta_0 \in H_0^1(\Omega) \cap H^2(\Omega)$, there is a unique solution such that*

$$u \in C([0, \infty); H_0^1(\Omega) \cap H^2(\Omega)) \cap C^1([0, \infty); H_0^1(\Omega)), \tag{1.8}$$

$$\theta \in C([0, \infty); H_0^1(\Omega) \cap H^2(\Omega)) \cap C^1([0, \infty); L^2(\Omega)), \tag{1.9}$$

$$\theta, \theta_t \in L^2(0, \infty; H_0^1(\Omega)). \tag{1.10}$$

Proof. This can be derived from Lemma 1.1 through an equivalent problem. Suppose that $u_0 \in H_0^1(\Omega) \cap H^2(\Omega)$, $u_1 \in H_0^1(\Omega)$, and $\theta_0 \in H_0^1(\Omega) \cap H^2(\Omega)$ are given. Let (v, ϕ) be a solution of (1.1)-(1.3) and

$$v(x, 0) = v_0(x), \quad v_t(x, 0) = v_1(x), \quad \phi(x, 0) = \phi_0(x), \tag{1.11}$$

where v_0, v_1, and ϕ_0 are given by

$$v_0 = u_1, \tag{1.12}$$

$$v_1 = au_{0xx} - b\theta_{0x}, \tag{1.13}$$

$$\phi_0 = \theta_{0xx} - bu_{1x}. \tag{1.14}$$

The existence and uniqueness of (v, ϕ) follow from Lemma 1.1. Then, we set

$$u(x, t) = u_0(x) + \int_0^t v(x, s)\, ds, \tag{1.15}$$

$$\theta(x, t) = \theta_0(x) + \int_0^t \phi(x, s)\, ds. \tag{1.16}$$

It follows from the regularity conditions (1.5) and (1.6) applied to (v, ϕ) that

$$u \in C^1([0, \infty); H_0^1(\Omega)) \cap C^2([0, \infty); L^2(\Omega)), \tag{1.17}$$

$$\theta \in C^1([0, \infty); L^2(\Omega)) \cap C([0, \infty); H_0^1(\Omega)), \tag{1.18}$$

$$\theta_t \in L^2(0, \infty; H_0^1(\Omega). \tag{1.19}$$

By virtue of (1.12)-(1.14), (u, θ) defined by (1.15) and (1.16) also satisfies (1.1) and (1.2). By means of (1.17) and (1.18), we can infer from (1.1) and (1.2) that

$$u \in C([0,\infty); H_0^1(\Omega) \cap H^2(\Omega)), \tag{1.20}$$

$$\theta \in C([0,\infty); H_0^1(\Omega) \cap H^2(\Omega)). \tag{1.21}$$

The property that $\theta \in L^2(0,\infty; H_0^1(\Omega))$ follows directly from (1.7). Now the proof is complete.

For later use, we also need to consider the following initial-boundary value problem.

$$v_{tt} - av_{xx} + b\theta_{tx} = 0 \quad \text{in } \Omega \times (0,\infty), \tag{1.22}$$

$$\theta_t - \theta_{xx} + bv_x = 0 \quad \text{in } \Omega \times (0,\infty), \tag{1.23}$$

$$v = 0, \quad \theta = 0 \quad \text{at } x = 0 \text{ and } 1 \tag{1.24}$$

$$v(x,0) = v_0(x), \quad v_t(x,0) = v_1(x), \quad \theta(x,0) = \theta_0(x) \quad \textit{in } \Omega. \tag{1.25}$$

LEMMA 1.3. *For* $v_0 \in H_0^1(\Omega)$, $v_1 \in L^2(\Omega)$, *and* $\theta_0 \in H_0^1(\Omega) \cap H^2(\Omega)$, *there is a unique solution* (v, θ) *of* (1.22)-(1.25) *such that*

$$v \in C([0,\infty); H_0^1(\Omega)) \cap C^1([0,\infty); L^2(\Omega)), \tag{1.26}$$

$$\theta \in C([0,\infty): H_0^1(\Omega) \cap H^2(\Omega)) \cap C^1([0,\infty); L^2(\Omega)), \tag{1.27}$$

$$\theta, \theta_t \in L^2(0,\infty; H_0^1(\Omega)). \tag{1.28}$$

Proof. For given $v_0 \in H_0^1(\Omega)$, $v_1 \in L^2(\Omega)$, and $\theta_0 \in H_0^1(\Omega) \cap H^2(\Omega)$, we can determine $u_0 \in H_0^1(\Omega) \cap H^2(\Omega)$ uniquely from

$$au_{0xx} = v_1 + b\theta_{0x}. \tag{1.29}$$

Then, let (u, θ) be a solution in Lemma 1.2 with

$$u(x,0) = u_0, \quad u_t(x,0) = v_0, \quad \theta(x,0) = \theta_0, \tag{1.30}$$

and set $v = u_t$. Obviously, (v, θ) is a solution of (1.22)-(1.25) satisfying (1.26)-(1.28). Uniqueness follows from the identity

$$\frac{d}{dt}\int_\Omega (v_t^2 + av_x^2 + \theta_t^2)\,dx + 2\int_\Omega \theta_{tx}^2\,dx = 0. \tag{1.31}$$

LEMMA 1.4. *Let* (v, θ) *be a solution of* (1.22)-(1.25) *with* $v_0 \in H_0^1(\Omega)$, $v_1 \in L^2(\Omega)$, *and* $\theta_0 \in H_0^1(\Omega) \cap H^2(\Omega)$, *and choose any* $T > 0$. *Then, it holds that*

$$\int_0^T \int_\Omega \theta_{tx}^2\,dx\,dt \geqq M(\|v_0\|_{H_0^1(\Omega)}^2 + \|v_1\|_{L^2(\Omega)}^2 + \|\theta_0\|_{H^2(\Omega)}^2) \tag{1.32}$$

for some positive constant M independent of v_0, v_1, *and* θ_0.

Proof. Assume that (1.32) is false. Then, there are sequences $\{v_0^m\}_{m=1}^\infty \subset H_0^1(\Omega)$, $\{v_1^m\}_{m=1}^\infty \subset L^2(\Omega)$, and $\{\theta_0^m\}_{m=1}^\infty \subset H_0^1(\Omega) \cap H^2(\Omega)$ such that

$$\|v_0^m\|_{H_0^1(\Omega)}^2 + \|v_1^m\|_{L^2(\Omega)}^2 + \|\theta_0^m\|_{H^2(\Omega)}^2 = 1 \quad \text{for each } m, \tag{1.33}$$

$$\int_0^T \int_\Omega (\theta_{tx}^m)^2\,dx\,dt \to 0 \quad \text{as } m \to \infty, \tag{1.34}$$

$$v_0^m \to v_0^\infty \text{ weakly} \quad \text{in } H_0^1(\Omega) \quad \text{as } m \to \infty, \tag{1.35}$$

$$v_1^m \to v_1^\infty \text{ weakly} \quad \text{in } L^2(\Omega) \quad \text{as } m \to \infty, \tag{1.36}$$

$$\theta_0^m \to \theta_0^\infty \text{ weakly} \quad \text{in } H_0^1(\Omega) \cap H^2(\Omega) \quad \text{as } m \to \infty \tag{1.37}$$

for some $v_0^\infty \in H_0^1(\Omega)$, $v_1^\infty \in L^2(\Omega)$, and $\theta_0^\infty \in H_0^1(\Omega) \cap H^2(\Omega)$. Here (v^m, θ^m) denotes a solution of (1.22), (1.23), (1.24), and

$$v^m(x,0) = v_0^m, \quad v_t^m(x,0) = v_1^m, \quad \theta^m(x,0) = \theta_0^m. \tag{1.38}$$

Similarly, $(v^\infty, \theta^\infty)$ is a solution with

$$v^\infty(x,0) = v_0^\infty, \quad v_t^\infty(x,0) = v_1^\infty, \quad \theta^\infty(x,0) = \theta_0^\infty. \tag{1.39}$$

It follows from a priori estimates that can be deduced from (1.31), (1.35)-(1.37) that

$$v^m \to v^\infty \text{ weak * } \quad \text{in } L^\infty(0, T; H_0^1(\Omega)), \tag{1.40}$$

$$v_t^m \to v_t^\infty \text{ weak * } \quad \text{in } L^\infty(0, T; L^2(\Omega)), \tag{1.41}$$

$$\theta^m \to \theta^\infty \text{ weak * } \quad \text{in } L^\infty(0, T; H_0^1(\Omega) \cap H^2(\Omega)), \tag{1.42}$$

$$\theta_t^m \to \theta_t^\infty \text{ weak * } \quad \text{in } L^\infty(0, T; L^2(\Omega)), \tag{1.43}$$

$$\theta_t^m \to \theta_t^\infty \text{ weakly } \quad \text{in } L^2(0, T; H_0^1(\Omega)). \tag{1.44}$$

Since (1.34) implies that

$$\theta_{tx}^\infty = 0 \quad \text{in } \Omega \times (0, T) \tag{1.45}$$

and $(v^\infty, \theta^\infty)$ satisfies

$$v_{tt}^\infty - a v_{xx}^\infty + b\theta_{tx}^\infty = 0 \quad \text{in } \Omega \times (0, T), \tag{1.46}$$

$$\theta_t^\infty - \theta_{xx}^\infty + b v_x^\infty = 0 \quad \text{in } \Omega \times (0, T), \tag{1.47}$$

we find that v_x^∞ is independent of t. Since $v^\infty \in C([0, T]; H_0^1(\Omega))$, v^∞ is also independent of t. Consequently, (1.46) yields

$$v^\infty = 0 \quad \text{in } \Omega \times (0, T), \tag{1.48}$$

which, together with (1.47), implies

$$\theta^\infty = 0 \quad \text{in } \Omega \times (0, T). \tag{1.49}$$

Next, let us rewrite (1.22) and(1.23) in (v^m, θ^m):

$$v_{tt}^m - a v_{xx}^m + b\theta_{tx}^m = 0 \quad \text{in } \Omega \times (0, T), \tag{1.50}$$

$$\theta_t^m - \theta_{xx}^m + b v_x^m = 0 \quad \text{in } \Omega \times (0, T). \tag{1.51}$$

Combining (1.40)-(1.43) and (1.50), we find that for any $\varepsilon > 0$,

$$v^m \to 0 \text{ strongly } \quad \text{in } C([0, T]; H^{1-\varepsilon}(\Omega)), \tag{1.52}$$

$$v_t^m \to 0 \text{ strongly } \quad \text{in } C([0, T]; H^{-\varepsilon}(\Omega)), \tag{1.53}$$

$$\theta^m \to 0 \text{ strongly } \quad \text{in } C([0, T]; H^{2-\varepsilon}(\Omega)). \tag{1.54}$$

Since it holds that

$$\|v^m\|_{C([0, T]; H_0^1(\Omega))} + \|v_t^m\|_{C([0, T]; L^2(\Omega))} + \|\theta_{tx}^m\|_{L^2(0, T; L^2(\Omega))} \leqq M \tag{1.55}$$

for all m, where M is a constant, we obtain

$$\|v_x^m(0, t)\|_{L^2(0, T)} + \|v_x^m(1, t)\|_{L^2(0, T)} \leqq M, \tag{1.56}$$

where M is a constant independent of m. This is a well-known fact that can be proved by a multiplier technique; see [7]. Next, we multiply (1.50) by θ_x^m and integrate over $\Omega\times(0, T)$ to obtain

$$\begin{aligned}&\int_\Omega v_t^m(x, T)\theta_x^m(x, T)\,dx-\int_\Omega v_t^m(x,0)\theta_x^m(x,0)\,dx-\int_0^T\int_\Omega v_t^m\theta_{xt}^m\,dx\,dt\\ &-a\int_0^T v_x^m(1,t)\theta_x^m(1,t)\,dt+a\int_0^T v_x^m(0,t)\theta_x^m(0,t)\,dt\\ &+a\int_0^T\int_\Omega v_x^m\theta_{xx}^m\,dx\,dt+b\int_0^T\int_\Omega \theta_{xt}^m\theta_x^m\,dx\,dt=0\quad\text{for each } m.\end{aligned}\tag{1.57}$$

By virtue of (1.34), (1.53), (1.54), and (1.56), we derive from (1.57) that

$$\int_0^T\int_\Omega v_x^m\theta_{xx}^m\,dx\,dt\to 0\quad\text{as } m\to\infty.\tag{1.58}$$

Multiplying (1.51) by θ_{xx}^m and integrating over $\Omega\times(0, T)$, we get

$$\int_0^T\int_\Omega \theta_t^m\theta_{xx}^m\,dx\,dt-\int_0^T\int_\Omega(\theta_{xx}^m)^2\,dx\,dt+b\int_0^T\int_\Omega v_x^m\theta_{xx}^m\,dx\,dt=0\quad\text{for each } m.\tag{1.59}$$

On account of (1.34), (1.42), and (1.58), we have

$$\int_0^T\int_\Omega(\theta_{xx}^m)^2\,dx\,dt\to 0\quad\text{as } m\to\infty,\tag{1.60}$$

which, combined with (1.34) and (1.51), yields

$$\int_0^T\int_\Omega(v_x^m)^2\,dx\,dt\to 0\quad\text{as } m\to\infty.\tag{1.61}$$

We then multiply (1.50) by v^m, integrate over $\Omega\times(0, T)$ and use (1.34), (1.52), (1.53), and (1.61) to find that

$$\int_0^T\int_\Omega(v_t^m)^2\,dx\,dt\to 0\quad\text{as } m\to\infty.\tag{1.62}$$

Finally, we set

$$E^m(t)=\frac{1}{2}\int_\Omega\{(v_t^m)^2+a(v_x^m)^2+(\theta_t^m)^2\}\,dx.\tag{1.63}$$

Then, it follows from (1.50) and (1.51) that

$$E^m(s)-E^m(0)=-\int_0^s\int_\Omega(\theta_{xt}^m)^2\,dx\,dt,\tag{1.64}$$

from which it follows that

$$TE^m(0)-T\int_0^T\int_\Omega(\theta_{xt}^m)^2\,dx\,dt\leqq\int_0^T E^m(t)\,dt.\tag{1.65}$$

By virtue of (1.34), (1.61), and (1.62), we conclude that

$$E^m(0)\to 0\quad\text{as } m\to\infty.\tag{1.66}$$

This contradicts (1.33) because

$$\theta_t^m(x,0)=\theta_{0xx}^m-bv_{0x}^m. \tag{1.67}$$

Now the proof of (1.32) is complete.

LEMMA 1.5. *Let* (v,θ) *be a solution of* (1.22)-(1.25) *with* $v_0\in H_0^1(\Omega)$, $v_1\in L^2(\Omega)$, *and* $\theta_0\in H_0^1(\Omega)\cap H^2(\Omega)$. *Then, it holds that*

$$\begin{aligned}&\|v(t)\|_{H_0^1(\Omega)}+\|v_t(t)\|_{L^2(\Omega)}+\|\theta(t)\|_{H^2(\Omega)}\\&\quad\leqq M\exp(-\alpha t)(\|v_0\|_{H_0^1(\Omega)}+\|v_1\|_{L^2(\Omega)}+\|\theta_0\|_{H^2(\Omega)})\end{aligned} \tag{1.68}$$

for some positive constants M *and* α *independent of* v_0, v_1, *and* θ_0.

Proof. Let us define

$$E_1(t)=\int_\Omega(v_t^2+av_x^2+\theta_t^2)\,dx, \tag{1.69}$$

$$E_2(t)=\int_\Omega(v_t^2+av_x^2+\theta_{xx}^2)\,dx. \tag{1.70}$$

Then, by (1.23), there are positive constants β_1 and β_2 independent of t and (v,θ) such that

$$\beta_1E_1(t)\leqq E_2(t)\leqq\beta_2E_1(t). \tag{1.71}$$

Fix any $T>0$. Then, (1.32) and (1.71) give

$$E_1(T)-E_1(0)=-2\int_0^T\int_\Omega\theta_{xt}^2\,dx\,dt\leqq -cE_1(0) \tag{1.72}$$

for some positive constant c independent of (v,θ). Without loss of generality, we may assume $c<1$, so that

$$E_1(T)\leqq\varepsilon E_1(0)\quad\text{for } 0<\varepsilon<1. \tag{1.73}$$

This implies (1.68) by the semigroup property of solution.

THEOREM 1.6. *Let* (u,θ) *be a solution of* (1.1)-(1.4) *with* $u_0\in H_0^1(\Omega)\cap H^2(\Omega)$, $u_1\in H_0^1(\Omega)$, *and* $\theta_0\in H_0^1(\Omega)\cap H^2(\Omega)$. *Then, we have*

$$\begin{aligned}&\|u(t)\|_{H^2(\Omega)}+\|u_t(t)\|_{H_0^1(\Omega)}+\|\theta(t)\|_{H^2(\Omega)}\\&\quad\leqq M\exp(-\alpha t)(\|u_0\|_{H^2(\Omega)}+\|u_1\|_{H_0^1(\Omega)}+\|\theta_0\|_{H^2(\Omega)})\end{aligned} \tag{1.74}$$

for all $t\geqq 0$, *with some positive constants* M *and* α *independent of* u_0, u_1, *and* θ_0.

Proof. It is enough to set $v=u_t$ and use Lemma 1.5.

THEOREM 1.7. *Let* (u,θ) *be a solution of* (1.1)-(1.4) *with* $u_0\in H_0^1(\Omega)$, $u_1\in L^2(\Omega)$, *and* $\theta_0\in L^2(\Omega)$. *Then, it holds that*

$$\begin{aligned}&\|u(t)\|_{H_0^1(\Omega)}+\|u_t(t)\|_{L^2(\Omega)}+\|\theta(t)\|_{L^2(\Omega)}\\&\quad\leqq M\exp(-\alpha t)(\|u_0\|_{H_0^1(\Omega)}+\|u_1\|_{L^2(\Omega)}+\|\theta_0\|_{L^2(\Omega)})\end{aligned} \tag{1.75}$$

for all $t\geqq 0$, *with some positive constants* M *and* α *independent of* u_0, u_1, *and* θ_0.

Proof. We determine $U_0\in H_0^1(\Omega)\cap H^2(\Omega)$, $U_1\in H_0^1(\Omega)$, and $\Theta_0\in H_0^1(\Omega)\cap H^2(\Omega)$ by

$$U_1=u_0, \tag{1.76}$$

$$\Theta_{0xx}=\theta_0+bU_{1x}, \tag{1.77}$$

$$aU_{0xx}=u_1+b\Theta_{0x}. \tag{1.78}$$

Then, we denote by(U, Θ) a solution of (1.1), (1.2), (1.3), and

$$U(x,0)=U_0, \quad U_t(x,0)=U_1, \quad \Theta(x,0)=\Theta_0. \tag{1.79}$$

Then, apply Theorem 1.6 to (U, Θ). Since $u = U_t$ and $\theta = \Theta_t$, the assertion (1.75) follows.

2. Linear thermoelastic plate. Let Ω be a bounded open subset of R^n with smooth boundary $\partial\Omega$. We consider the following initial-boundary value problem.

$$u_{tt}+\Delta^2 u+\alpha\Delta\theta=0 \quad \text{in } \Omega\times(0,\infty), \tag{2.1}$$

$$\theta_t-\beta\Delta\theta+\gamma\theta-\alpha\Delta u_t=0 \quad \text{in } \Omega\times(0,\infty), \tag{2.2}$$

$$u=\frac{\partial u}{\partial \nu}=0, \quad \theta=0 \quad \text{on } \partial\Omega\times(0,\infty) \tag{2.3}$$

$$u(x,0)=u_0(x), \quad u_t(x,0)=u_1(x), \quad \theta(x,0)=\theta_0(x) \quad \text{in } \Omega, \tag{2.4}$$

where $\partial/\partial\nu$ denotes the outward normal derivative on $\partial\Omega$. Here $\alpha\neq 0$, $\beta>0$, and $\gamma\geqq 0$ are constants, and u and θ denote vertical deflection of the plate and the temperature, respectively. The derivation of (2.1) and (2.2) can be found in [6]. Our purpose is to establish exponential decay of the energy, and the argument is the same as in the previous section except some minor technical details.

LEMMA 2.1. *For* $u_0\in H_0^2(\Omega)$, $u_1\in L^2(\Omega)$, *and* $\theta_0\in L^2(\Omega)$, *there is a unique solution* (u, θ) of (2.1)-(2.4) *such that*

$$u\in C([0,\infty); H_0^2(\Omega))\cap C^1([0,\infty); L^2(\Omega)), \tag{2.5}$$

$$\theta\in C([0,\infty); L^2(\Omega))\cap L^2(0,\infty; H_0^1(\Omega)). \tag{2.6}$$

This can be proven by constructing a sequence of smooth solutions whose initial data approximate (u_0, u_1, θ_0). Then, this sequence can be shown to be strongly convergent in the function spaces in (2.5) and (2.6) by means of the identity

$$\frac{d}{dt}\int_\Omega (u_t^2+(\Delta u)^2+\theta^2)\,dx+2\int_\Omega (\beta|\nabla\theta|^2+\gamma\theta^2)\,dx=0. \tag{2.7}$$

Since this is a well-known procedure, we omit the details.

LEMMA 2.2. *For* $u_0\in H_0^2(\Omega)\cap H^4(\Omega)$, $u_1\in H_0^2(\Omega)$, *and* $\theta_0\in H_0^1(\Omega)\cap H^2(\Omega)$, *there is a unique solution* (u, θ) *of* (2.1)-(2.4) *such that*

$$u\in C([0,\infty); H_0^2(\Omega)\cap H^4(\Omega))\cap C^1([0,\infty); H_0^2(\Omega)), \tag{2.8}$$

$$\theta\in C([0,\infty); H_0^1(\Omega)\cap H^2(\Omega))\cap C^1([0,\infty); L^2(\Omega)), \tag{2.9}$$

$$\theta, \theta_t\in L^2(0,\infty; H_0^1(\Omega)). \tag{2.10}$$

Proof. This is a well-known fact. But for our purposes later, we shall derive this from Lemma 2.1 as in the proof of Lemma 1.2. Let us set

$$v_0=u_1, \tag{2.11}$$

$$v_1=-\Delta^2 u_0-\alpha\Delta\theta_0, \tag{2.12}$$

$$\varphi_0=\beta\Delta\theta_0-\gamma\theta_0+\alpha\Delta u_1, \tag{2.13}$$

and let (v, φ) be a solution of (2.1)-(2.3), and

$$v(x,0)=v_0(x), \quad v_t(x,0)=v_1(x), \quad \varphi(x,0)=\varphi_0(x) \quad \text{in } \Omega, \tag{2.14}$$

according to Lemma 2.1. Then, we set

$$u(x, t) = u_0(x) + \int_0^t v(x, s)\, ds, \tag{2.15}$$

$$\theta(x, t) = \theta_0(x) + \int_0^t \varphi(x, s)\, ds. \tag{2.16}$$

By means of the regularity conditions (2.5) and (2.6) applied to (v, φ), we find that

$$u \in C^1([0, \infty); H_0^2(\Omega)) \cap C^2([0, \infty); L^2(\Omega)), \tag{2.17}$$

$$\theta \in C^1([0, \infty); L^2(\Omega)) \cap C([0, \infty); H_0^1(\Omega)), \tag{2.18}$$

$$\theta_t \in L^2(0, \infty; H_0^1(\Omega)). \tag{2.19}$$

By virtue of (2.11)-(2.13), it is evident that (u, θ) is also a solution of (2.1)-(2.4). Then it follows from (2.2), (2.17)-(2.19) that

$$\theta \in C([0, \infty); H_0^1(\Omega) \cap H^2(\Omega)), \tag{2.20}$$

which, combined with (2.1) and (2.17), yields

$$u \in C([0, \infty); H_0^2(\Omega) \cap H^4(\Omega)). \tag{2.21}$$

The condition that $\theta \in L^2(0, \infty; H_0^1(\Omega))$ follows directly from (2.7) and the proof is complete.

We next consider the following initial-boundary value problem:

$$v_{tt} + \Delta^2 v + \alpha \Delta \theta_t = 0 \quad \text{in } \Omega \times (0, \infty), \tag{2.22}$$

$$\theta_t - \beta \Delta \theta + \gamma \theta - \alpha \Delta v = 0 \quad \text{in } \Omega \times (0, \infty), \tag{2.23}$$

$$v = \frac{\partial v}{\partial \nu} = 0, \theta = 0 \quad \text{on } \partial\Omega \times (0, \infty), \tag{2.24}$$

$$v(x, 0) = v_0(x), \quad v_t(x, 0) = v_1(x), \quad \theta(x, 0) = \theta_0(x) \quad \text{in } \Omega. \tag{2.25}$$

LEMMA 2.3. *For* $v_0 \in H_0^2(\Omega)$, $v_1 \in L^2(\Omega)$, *and* $\theta_0 \in H_0^1(\Omega) \cap H^2(\Omega)$, *there is a unique solution of* (2.22)-(2.25) *such that*

$$v \in C([0, \infty); H_0^2(\Omega)) \cap C^1([0, \infty); L^2(\Omega)), \tag{2.26}$$

$$\theta \in C([0, \infty); H_0^1(\Omega) \cap H^2(\Omega)) \cap C^1([0, \infty); L^2(\Omega)), \tag{2.27}$$

$$\theta, \theta_t \in L^2(0, \infty; H_0^1(\Omega)). \tag{2.28}$$

Proof. Let us set

$$u_1 = v_0, \tag{2.29}$$

and determine $u_0 \in H_0^2(\Omega) \cap H^4(\Omega)$ by

$$\Delta^2 u_0 = -v_1 - \alpha \Delta \theta_0. \tag{2.30}$$

We then denote by (u, θ) a solution of (2.1)-(2.4) with u_0 and u_1 determined by (2.29) and (2.30). By setting $v = u_t$, (v, θ) is a solution of (2.22)-(2.25) satisfying (2.26)-(2.28).

Uniqueness follows from the identity

$$\frac{d}{dt}\int_\Omega (v_t^2+(\Delta v)^2+\theta_t^2)\,dx+2\int_\Omega (\beta|\nabla\theta_t|^2+\gamma\theta_t^2)\,dx=0. \tag{2.31}$$

LEMMA 2.4. *Let* (v, θ) *be a solution of* (2.22)-(2.25) *with* $v_0\in H_0^2(\Omega)$, $v_1\in L^2(\Omega)$, *and* $\theta_0\in H_0^1(\Omega)\cap H^2(\Omega)$. *Choose any* $T>0$. *Then, it holds that*

$$\int_0^T\int_\Omega |\nabla\theta_t|^2\,dx\,dt \geqq M(\|v_0\|^2_{H_0^2(\Omega)}+\|v_1\|^2_{L^2(\Omega)}+\|\theta_0\|^2_{H^2(\Omega)}) \tag{2.32}$$

for some positive constant M *independent of* v_0, v_1, *and* θ_0.

Proof. The method of proof is the same as that for Lemma 1.4. Assume that (2.32) is false. Then, there are sequences $\{v_0^m\}_{m=1}^\infty\subset H_0^2(\Omega)$, $\{v_1^m\}_{m=1}^\infty\subset L^2(\Omega)$, and $\{\theta_0^m\}_{m=1}^\infty\subset H_0^1(\Omega)\cap H^2(\Omega)$ such that

$$\|v_0^m\|^2_{H_0^2(\Omega)}+\|v_1^m\|^2_{L^2(\Omega)}+\|\theta_0^m\|^2_{H^2(\Omega)}=1 \quad \text{for all } m, \tag{2.33}$$

$$\int_0^T\int_\Omega |\nabla\theta_t^m|^2\,dx\,dt\to 0 \quad \text{as } m\to\infty, \tag{2.34}$$

$$v_0^m\to v_0^\infty \text{ weakly} \quad \text{in } H_0^2(\Omega), \tag{2.35}$$

$$v_1^m\to v_1^\infty \text{ weakly} \quad \text{in } L^2(\Omega), \tag{2.36}$$

$$\theta_0^m\to\theta_0^\infty \text{ weakly} \quad \text{in } H_0^1(\Omega)\cap H^2(\Omega) \tag{2.37}$$

for some $v_0^\infty\in H_0^2(\Omega)$, $v_1^\infty\in L^2(\Omega)$, and $\theta_0^\infty\in H_0^1(\Omega)\cap H^2(\Omega)$. Here (v^m, θ^m) denotes a solution of (2.22)-(2.24), and

$$v^m(x,0)=v_0^m(x),\quad v_t^m(x,0)=v_1^m(x),\quad \theta^m(x,0)=\theta_0^m(x) \quad \text{in } \Omega. \tag{2.38}$$

Similarly, (v^∞, u^∞) stands for a solution satisfying

$$v^\infty(x,0)=v_0^\infty(x),\quad v_t^\infty(x,0)=v_1^\infty(x),\quad \theta^\infty(x,0)=\theta_0^\infty(x) \quad \text{in } \Omega. \tag{2.39}$$

By virtue of a priori estimates that can be derived from (2.31), (2.35)-(2.37), we find that

$$v^m\to v^\infty \text{ weak* } \quad \text{in } L^\infty(0, T; H_0^2(\Omega)), \tag{2.40}$$

$$v_t^m\to v_t^\infty \text{ weak* } \quad \text{in } L^\infty(0, T; L^2(\Omega)), \tag{2.41}$$

$$\theta_t^m\to\theta_t^\infty \text{ weak* in } L^\infty(0, T; L^2(\Omega)), \tag{2.42}$$

$$\theta_t^m\to\theta_t^\infty \text{ weakly} \quad \text{in } L^2(0, T; H_0^1(\Omega)). \tag{2.43}$$

In order to obtain further estimates, we rewrite (2.22) and (2.23) in (v^m, θ^m):

$$v_{tt}^m+\Delta^2 v^m+\alpha\Delta\theta_t^m=0 \quad \text{in } \Omega\times(0, T), \tag{2.44}$$

$$\theta_t^m-\beta\Delta\theta^m+\gamma\theta^m-\alpha\Delta v^m=0 \quad \text{in } \Omega\times(0, T). \tag{2.45}$$

It follows from these equations that

$$v_{tt}^m\to v_{tt}^\infty \text{ weak* } \quad \text{in } L^\infty(0, T; H^{-2}(\Omega)), \tag{2.46}$$

$$\theta^m\to\theta^\infty \text{ weak* } \quad \text{in } L^\infty(0, T; H_0^1(\Omega)\cap H^2(\Omega)). \tag{2.47}$$

Next, let $h \in (h_1, \cdots, h_n)$ be a vector field such that $h \in [C^2(\bar{\Omega})]^n$ and $h(x)$ coincide with the outward unit normal vector on $\partial\Omega$. Then, multiplying (2.44) by $h \cdot \nabla v^m$ and integrating over $\Omega \times (0, T)$, we can obtain the identity

$$\begin{aligned}\frac{1}{2}\int_0^T \int_{\partial\Omega} (\Delta v^m)^2\,dx\,dt = &\int_\Omega v^m(x, T)h \cdot \nabla v^m(x, T)\,dx - \int_\Omega v^m(x, 0)h \cdot \nabla v^m(x, 0)\,dx \\ &+ \frac{1}{2}\int_0^T \int_\Omega (\nabla \cdot h)\{(v_t^m)^2 - (\Delta v^m)^2\}\,dx\,dt \\ &+ 2\int_0^T \int_\Omega \sum_{j,k=1}^n \frac{\partial h_k}{\partial x_j}\frac{\partial^2 v^m}{\partial x_k\,\partial x_j}\Delta v^m\,dx\,dt \\ &+ \int_0^T \int_\Omega (\Delta v^m)(\Delta h) \cdot \nabla v^m\,dx\,dt \\ &- \int_0^T \int_\Omega \alpha \nabla \theta_t^m \cdot \nabla(h \cdot \nabla v^m)\,dx\,dt. \end{aligned} \tag{2.48}$$

The proof of this can be found in [7, p. 244]. On account of (2.40)-(2.43), it is easy to see that

$$\int_0^T \int_{\partial\Omega} (\Delta v^m)^2\,dx\,dt \leqq M \tag{2.49}$$

for a constant M independent of m. In the meantime, (2.34) implies that

$$\nabla \theta_t^\infty = 0 \quad \text{in } \Omega \times (0, T). \tag{2.50}$$

By the same argument as in the previous section, we can conclude that

$$v^\infty = 0 \quad \text{and} \quad \theta^\infty = 0 \quad \text{in } \Omega \times (0, T). \tag{2.51}$$

Consequently, we combine (2.40)-(2.43), (2.46), and (2.47) to find that for any $\varepsilon > 0$,

$$v^m \to 0 \text{ strongly} \quad \text{in } C([0, T]; H^{2-\varepsilon}(\Omega)), \tag{2.52}$$

$$v_t^m \to 0 \text{ strongly} \quad \text{in } C([0, T]; H^{-\varepsilon}(\Omega)), \tag{2.53}$$

$$\theta^m \to 0 \text{ strongly} \quad \text{in } C([0, T]; H^{2-\varepsilon}(\Omega)). \tag{2.54}$$

We then multiply (2.44) by θ^m, integrate over $\Omega \times (0, T)$ and use (2.49), (2.52)-(2.54) to derive that

$$\int_0^T \int_\Omega (\Delta v^m)\Delta\theta^m\,dx\,dt \to 0 \quad \text{as } m \to \infty. \tag{2.55}$$

Next, multiplying (2.45) by $\Delta\theta^m$ and integrating over $\Omega \times (0, T)$, we use (2.55) to find that

$$\int_0^T \int_\Omega (\Delta\theta^m)^2\,dx\,dt \to 0 \quad \text{as } m \to \infty. \tag{2.56}$$

By the same argument as in the proof of Lemma 1.4, we can derive from (2.34), (2.44), (2.45), (2.56) that

$$\int_0^T \int_\Omega \{(v_t^m)^2 + (\Delta v^m)^2\}\,dx\,dt \to 0 \quad \text{as } m \to \infty. \tag{2.57}$$

By means of an inequality analogous to (1.65), we arrive at

$$\|v_0^m\|^2_{H_0^2(\Omega)}+\|v_1^m\|^2_{L^2(\Omega)}+\|\theta_0^m\|^2_{H^2(\Omega)}\to 0 \quad \text{as } m\to\infty, \tag{2.58}$$

which contradicts (2.33). Now the proof is complete.

LEMMA 2.5. *Let (v,θ) be a solution of* (2.22)-(2.25) *with $v_0\in H_0^2(\Omega)$, $v_1\in L^2(\Omega)$, and $\theta_0\in H_0^1(\Omega)\cap H^2(\Omega)$. Then, it holds that*

$$\begin{aligned}&\|v(t)\|_{H_0^2(\Omega)}+\|v_t(t)\|_{L^2(\Omega)}+\|\theta(t)\|_{H^2(\Omega)}\\&\leqq M\exp(-\alpha t)(\|v_0\|_{H_0^2(\Omega)}+\|v_1\|_{L^2(\Omega)}+\|\theta_0\|_{H^2(\Omega)})\end{aligned} \tag{2.59}$$

for some positive constants M and α independent of v_0, v_1, and θ_0.

As in the proof of Lemma 1.5, (2.59) follows from (2.32). We shall omit the details of the proof. Finally, we present the main results of this section. These can be proved exactly in the same way as Theorem 1.6 and 1.7.

THEOREM 2.6. *Let (u,θ) be a solution of* (2.1)-(2.4) *with $u_0\in H_0^2(\Omega)\cap H^4(\Omega)$, $u_1\in H_0^2(\Omega)$, and $\theta_0\in H_0^1(\Omega)\cap H^2(\Omega)$. Then, it holds that*

$$\begin{aligned}&\|u(t)\|_{H^4(\Omega)}+\|u_t(t)\|_{H_0^2(\Omega)}+\|\theta(t)\|_{H^2(\Omega)}\\&\leqq M\exp(-\alpha t)(\|u_0\|_{H^4(\Omega)}+\|u_1\|_{H_0^2(\Omega)}+\|\theta_0\|_{H^2(\Omega)})\end{aligned} \tag{2.60}$$

for all $t\geqq 0$, with some positive constants M and α independent of u_0, u_1, and θ_0.

THEOREM 2.7. *Let (u,θ) be a solution of* (2.1)-(2.4) *with $u_0\in H_0^2(\Omega)$, $u_1\in L^2(\Omega)$, and $\theta_0\in L^2(\Omega)$. Then, it holds that*

$$\begin{aligned}&\|u(t)\|_{H_0^2(\Omega)}+\|u_t(t)\|_{L^2(\Omega)}+\|\theta(t)\|_{L^2(\Omega)}\\&\leqq M\exp(-\alpha t)(\|u_0\|_{H_0^2(\Omega)}+\|u_1\|_{L^2(\Omega)}+\|\theta_0\|_{L^2(\Omega)})\end{aligned} \tag{2.61}$$

for all $t\geqq 0$, with some positive constants M and α independent of u_0, u_1, and θ_0.

Acknowledgment. The author would like to acknowledge the warm hospitality of the Mathematical Sciences Research Institute in Berkeley, where this research was performed.

SOLUTIONS TO THE CUBIC SCHRÖDINGER EQUATION BY THE INVERSE SCATTERING METHOD*

AMY COHEN† AND THOMAS KAPPELER‡

Abstract. Weak solutions to the cubic Schrödinger equation are constructed by the inverse scattering method for a large class of initial data u_0 such that $(1+|x|^\alpha)u_0 \in L^1(\mathbb{R}) \cap L^2(\mathbb{R})$ and $u_0 \in H^\alpha(\mathbb{R})$ for an α with $\frac{1}{4} < \alpha < \frac{1}{2}$. These solutions are shown to evolve in $L^2(\mathbb{R}) \cap L^4(\mathbb{R})$. This construction is valid, in particular, if the initial data is the characteristic function on an interval of length not an odd multiple of $\pi/2$.

Key words. cubic Schrödinger equation, inverse scattering method

AMS(MOS) subject classification. 35Q20

1. Introduction and summary. We consider the initial value problem for the cubic Schrödinger equation

$$iu_t + \tfrac{1}{2}u_{xx} + |u|^2 u = 0 \quad \text{for } x \in \mathbb{R}, \tag{1.1}$$

$$u(x, 0) = u_0(x). \tag{1.2}$$

This initial value problem has been considered by many authors, for example [GV], [HNT1, 2], [K], [T1, 2], to cite only a few. Recently in [T2], Tsutsumi proved by functional analytic methods that for $u_0 \in L^2(\mathbb{R})$ there exists a solution $u(x, t)$ of (1.1), (1.2) evolving in $L^\infty([0, T], L^2(\mathbb{R}) \cap L^4(\mathbb{R}))$. It follows from results of Kato [K] that this solution is unique in this space.

On the other hand, Zakharov and Shabat [ZS] developed a representation theorem for smooth solutions of (1.1), (1.2) by the Marachenko-type inverse scattering method. Tanaka [Ta] used their method to construct solutions evolving in Schwartz class, provided that u_0 was of Schwartz class.

The purpose of this paper is to generalize Tanaka's results in order to construct, by the inverse scattering method, a large class of the solutions obtained by Tsutsumi [T2]. The inverse scattering representation is important because it reveals the soliton structure of the solutions and provides a method for the rigorous analysis of the long-time asymptotics of the solutions. We intend in a subsequent paper to analyze, in particular, the asymptotics of solutions evolving from box-shaped initial potentials.

In this paper a continuous map $t \to u(\cdot, t)$ from $[0, T]$ into L^2_{loc} is said to be a *weak solution* of (1.1), (1.2) if for all φ in $C^\infty([0, T] \times \mathbb{R})$, with compact support in $(0, T) \times \mathbb{R}$,

$$\int_0^\infty \int_{-\infty}^\infty u(x, t)\{i\varphi_t(x, t) + \tfrac{1}{2}\varphi_{xx}(x, t) + |u(x, t)|^2 \varphi(x, t)\}\, dx\, dt = 0, \tag{1.3}$$

and if

$$u(\cdot, t) \to u_0(\cdot) \quad \text{in } L^2_{\text{loc}}(\mathbb{R}) \quad \text{as } t \to 0^+.$$

In this paper we prove the following.

THEOREM. *Suppose there is an* α *with* $\frac{1}{4} < \alpha < \frac{1}{2}$ *such that*

$$(1+|x|^\alpha)u_0(x) \in L^1(\mathbb{R}) \cap L^2(\mathbb{R}),$$

* Received by the editors July 30, 1990; accepted for publication (in revised form) October 10, 1991.

$u_0 \in$ the Sobolev space H^α, and u_0 meets the technical assumption (2.12). *Then the inverse scattering method produces a weak solution of* (1.1), (1.2) *evolving in* $L^2(\mathbb{R}) \cap L^4(\mathbb{R})$.

Remark. It follows from the uniqueness theorem of Kato [K] that the constructed solution is unique within the space $L^2(\mathbb{R}) \cap L^4(\mathbb{R})$, and coincides with the solution constructed by Tsutsumi [T2]. In particular it follows that

$$\int_{-\infty}^{\infty} |u(x,t)|^2 \, dx$$

is preserved in time.

The method of analysis applied by Zakharov and Shabat [ZS] to (1.1), (1.2) is analogous to the inverse scattering analysis introduced by Gardner, Greene, Kruskal, and Miura [GGKM] for the Korteweg-de Vries equation. Zakharov and Shabat associate (1.1) with the scattering problem

$$i\begin{bmatrix}1 & 0\\ 0 & -1\end{bmatrix}\frac{d\vec{\psi}}{dx} - i\begin{bmatrix}0 & u\\ u^* & 0\end{bmatrix}\vec{\psi} = \zeta\vec{\psi}. \tag{1.4}$$

They showed that if $u(x,t)$ solves (1.1) and $u(\cdot,t)$ is of Schwartz class for each t, then the "scattering data" of (1.4) evolve according to certain linear first-order ordinary differential equations in t. They showed further that for $t>0$, $u(x,t)$ could be represented in terms of the scattering data at time t, and thus in terms of the initial scattering data which came from $u(x,t)$ at $t=0$. In particular,

$$u(x,t) = -B_{+1}(x,0,t),$$

where $B_{+1}(x,y,t)$ solves the Marchenko equation

$$\begin{aligned} &B_{+1}(x,y,t) + \int_0^\infty \Omega_+^*(x+y+z,t)\int_0^\infty \Omega_+(x+z+w,t)B_{+1}(x,w,t)\,dw\,dz \\ &\qquad + \Omega_+^*(x+y,t) = 0 \quad \text{for } y \geqq 0. \end{aligned} \tag{1.5}$$

The kernel $\Omega_+(s,t)$ is the sum of the inverse Fourier transform of the reflection coefficient at time t, and some linear combinations of products of the form $s^\nu e^{-2i\mathrm{Im}(\eta_j)s}$, where the η_j are the poles of the transmission coefficient.

Let us also point out that it would be possible to use the reformulation of inverse scattering due to Beals and Coifman [BC1], [BC2] in terms of the ∂-bar operator and the Riemann-Hilbert problem. While they consider the case of simple poles in the transmission coefficient, their formalism has been extended subsequently to higher order poles, cf. [SZ].

In § 2 we analyze the forward scattering theory of (1.4) for general $u = u_0 \in L^1(\mathbb{R}) \cap L^2(\mathbb{R})$, introducing the necessary added hypothesis as (2.12). The assumption (2.12) is needed to guarantee that the transmission coefficient as defined in § 2 has a finite number of poles and that none of them are on the real axis. In § 3 we discuss the time evolution of "scattering data at $t>0$." The definitions are suggested by Zakharov and Shabat [ZS] and by Tanaka [Ta]. In § 4 we solve the Marchenko equation (1.5) and begin to analyze $u(x,t) := -B_{1+}(x,0,t)$. In § 5 we treat the inverse scattering problem on the full line, and show that, under the assumption of the theorem, u evolves in $L^2 \cap L^4$. In § 6 we show that this $u(x,t)$ is a weak solution of (1.1), (1.2). In § 7 we compute the scattering data associated with a u_0 in (1.4), where u_0 is the characteristic function of an interval and analyze the solution to (1.1), (1.2) in that case.

Notational conventions. $\|\cdot\|$ denotes the norm in $L^2(\mathbb{R}^+)$; $\|\cdot\|_{\mathrm{op}}$ the operator norm on $L^2(\mathbb{R}^+)$. Other norms are noted explicitly, e.g., $\|f\|_{L^2(\mathbb{R})}$ or $\|f\|_{L^\infty(\mathbb{R}^+)}$.

$L^p(+\infty)=\{f: f\in L^p([a,\infty))$ for all finite $a\}$,

$C^b(\mathbb{R})=\{f: f$ is a bounded continuous function on $\mathbb{R}\}$,

H^{2+} is the Hardy space; $\{f\in L^2(\mathbb{R})\colon \mathscr{F}[f]$ has support in $\mathbb{R}^+\}$.

The Fourier transform $\mathscr{F}$ and its inverse $\mathscr{F}^{-1}$ are taken in the form

$$\mathscr{F}[g](\xi)=\int_{-\infty}^{\infty} g(x)\,e^{-2i\xi x}\,dx \quad\text{and}\quad \mathscr{F}^{-1}[g](x)=\frac{1}{\pi}\int_{-\infty}^{\infty} g(\xi)\,e^{+2i\xi x}\,d\xi.$$

2. The forward scattering problem. The scattering problem associated with the cubic Schrödinger equation is

$$i\begin{bmatrix}1&0\\0&-1\end{bmatrix}\frac{d\vec{\Psi}}{dx}-i\begin{bmatrix}0&u\\u^*&0\end{bmatrix}\vec{\Psi}=\zeta\vec{\Psi}, \tag{2.1}$$

where $\vec{\Psi}$ has components Ψ_1, Ψ_2, and $\zeta\in\mathbb{C}$. In general, we assume only that

$$u\in L^1(\mathbb{R})\cap L^2(\mathbb{R}). \tag{2.2}$$

The purpose of this section is to define the Jost functions and the scattering data of (2.1) and to obtain the fundamental integral equation relating them.

The Jost functions for (2.1) are the solutions $\vec{\Psi}_+$ and $\vec{\Psi}_-$ of (2.1) for $\operatorname{Im}(\zeta)>0$ such that

$$\vec{\Psi}_+(x,\zeta)\sim\begin{bmatrix}0\\1\end{bmatrix}e^{i\zeta x}\quad\text{as } x\to+\infty,\quad\text{and } \vec{\Psi}_-(x,\zeta)\sim\begin{bmatrix}1\\0\end{bmatrix}e^{-i\zeta x}\quad\text{as } x\to-\infty.$$

The existence of the Jost functions for all ζ with $\operatorname{Im}(\zeta)\geqq 0$ and their key properties are established in the Lemmas 2.1-2.7 below.

The scattering coefficients, $a_+(\xi)$ and $b_+(\xi)$, are defined for real ξ by

$$\vec{\Psi}_-(x,\xi)=a_+(\xi)\vec{\Psi}_+^{\#}(x,\xi)+b_+(\xi)\vec{\Psi}_+(x,\xi), \tag{2.3}$$

where for any 2-vector $\vec{v}$, $v^{\#}$ denotes the transpose of $[v_2^*,-v_1^*]$. Similarly, the coefficients a_- and b_- are determined by the relation

$$\vec{\Psi}_+(x,\xi)=a_-(\xi)\vec{\Psi}_-^{\#}(x,\xi)+b_-(\xi)\vec{\Psi}_-(x,\xi).$$

The formal reflection and transmission coefficients, $r_+(\xi)$ and $t_+(\xi)$, are defined by

$$r_+(\xi)=b_+(\xi)/a_+(\xi)\quad\text{and}\quad t_+(\xi)=1/a_+(\xi).$$

In Theorem 2.11 we will prove that if $u\in L^1(\mathbb{R})\cap L^2(\mathbb{R})$ and u meets (2.12), then $r_+\in L^2(\mathbb{R})\cap C^b(\mathbb{R})$ and $r_+(\xi)\to 0$ as $\xi\to\pm\infty$. This theorem will also tell how weak regularity of u gives some decay in r_+ and how decay in u gives some weak regularity in r_+. Next, the analysis of the zeros of a_+ leads to the definition of the full set of scattering data associated to u. Finally, we derive the fundamental integral equations, or Marchenko equations, which relate the Jost functions and the scattering data.

Construction of the Jost functions. For $\operatorname{Im}(\zeta)\geqq 0$, $\vec{\Psi}_+$ must satisfy the system

$$\begin{aligned} i\partial_x\Psi_{+1}(x,\zeta)-iu(x)\Psi_{+2}(x,\zeta)&=\zeta\Psi_{+1}(x,\zeta),\\ -i\partial_x\Psi_{+2}(x,\zeta)-iu^*(x)\Psi_{+1}(x,\zeta)&=\zeta\Psi_{+2}(x,\zeta), \end{aligned} \tag{2.4}$$

with the boundary conditions

$$\Psi_{+1}(x, \zeta) \sim 0 \quad \text{as } x \to +\infty,$$
$$\Psi_{+2}(x, \zeta) \sim e^{i\zeta x} \quad \text{as } x \to +\infty.$$

Similarly, $\vec{\Psi}_-$ must satisfy the system

$$\begin{aligned} i\partial_x \Psi_{-1}(x, \zeta) - iu(x)\Psi_{-2}(x, \zeta) &= \zeta \Psi_{-1}(x, \zeta), \\ -i\partial_x \Psi_{-2}(x, \zeta) - iu^*(x)\Psi_{-1}(x, \zeta) &= \zeta \Psi_{-2}(x, \zeta), \end{aligned} \tag{2.5}$$

with the boundary conditions

$$\Psi_{-1}(x, \zeta) \sim e^{i\zeta x} \quad \text{as } x \to -\infty,$$
$$\Psi_{-2}(x, \zeta) \sim 0 \quad \text{as } x \to -\infty.$$

Now write

$$m_{+j}(x, \zeta) = e^{-i\zeta x}\Psi_{+j}(x, \zeta) \quad \text{for } j = 1, 2.$$

We get

$$\begin{aligned} m_{+1}(x, \zeta) = &-\int_{y=x}^{\infty} e^{2i\zeta(y-x)}u(y)\, dy \\ &-\int_{y=x}^{\infty} u(y)\, e^{2i\zeta(y-x)} \int_{z=y}^{\infty} m_{+1}(z, \zeta)u^*(z)\, dz\, dy, \end{aligned} \tag{2.6}$$

$$m_{+2}(x, \zeta) = 1 - \int_{y=x}^{\infty} u^*(y) \int_{z=y}^{\infty} m_{+2}(z, \zeta)\, e^{2i\zeta(z-y)}u(z)\, dz\, dy. \tag{2.7}$$

Similarly, putting

$$m_{-j}(x, \zeta) = e^{i\zeta x}\Psi_{-j}(x, \zeta) \quad \text{for } j = 1, 2,$$

we get

$$m_{-1}(x, \zeta) = 1 - \int_{y=-\infty}^{x} u(y) \int_{z=-\infty}^{y} u^*(z)m_{-1}(z, \zeta)\, e^{2i\zeta(y-z)}\, dz\, dy, \tag{2.8}$$

$$\begin{aligned} m_{-2}(x, \zeta) = &-\int_{y=-\infty}^{x} u^*(y)\, e^{2i\zeta(x-y)}\, dy \\ &-\int_{y=-\infty}^{x} u^*(y)\, e^{2i\zeta(x-y)} \int_{z=-\infty}^{y} u(z)m_{-2}(z, \zeta)\, dz\, dy. \end{aligned} \tag{2.9}$$

Because (2.8) and (2.9) are similar to (2.6) and (2.7), it suffices to study (2.6) and (2.7). Here we introduce the maps T_1 and T_2, defined by the formulas

$$T_1[g](x, \zeta) = \int_{y=x}^{\infty} u(y)\, e^{2i\zeta(y-x)} \int_{z=y}^{\infty} g(z, \zeta)u^*(z)\, dx\, dy,$$

$$T_2[g](x, \zeta) = \int_{y=x}^{\infty} u^*(y) \int_{z=y}^{\infty} g(z, \zeta)\, e^{2i\zeta(z-y)}u(z)\, dz\, dy,$$

in the appropriate spaces defined below. Let

$$\mathbb{H} := \{\zeta: \operatorname{Im}(\zeta) > 0\} \quad \text{and} \quad \bar{\mathbb{H}} := \{\zeta: \operatorname{Im}(\zeta) \geqq 0\}.$$

For each real x_0 let E_{x_0} denote the space of functions $f\colon [x_0, +\infty) \times \bar{\mathbb{H}} \to \mathbb{C}$ such that

(E.1) $x \geqq x_0, f(x, \cdot)$ is continuous on $\bar{\mathbb{H}}$ and analytic on $\mathbb{H}$;

(E.2) The map $x \mapsto f(x, \cdot)$ is bounded and continuous from $[x_0, +\infty)$ into the Hardy space H^{2+};

(E.3) The map $x \mapsto f(x, \cdot)$ is bounded and continuous from $[x_0, +\infty)$ into $C^b(\bar{\mathbb{H}})$;

(E.4) The map $\zeta \mapsto f(\cdot, \zeta)$ is bounded and continuous from $\bar{\mathbb{H}}$ into $C^b([x_0, +\infty))$;

(E.5) $f(x, \xi) \to 0$ uniformly in $x \geqq x_0$ as real $\xi \to \pm\infty$.

Now (2.6) and (2.7) take the form

$$(I + T_1)[m_{+1}](x, \zeta) = -\int_{y=x}^{\infty} e^{2i\zeta(y-x)} u(y)\, dy, \tag{2.10}$$

$$(I + T_2)[m_{+2}](x, \zeta) = 1. \tag{2.11}$$

Thus, formally,

$$m_{+1} = \sum_{n=0}^{\infty} (-T_1)^n [g_1], \quad \text{where } g_1(x, \zeta) := -\int_{y=x}^{\infty} e^{2i\zeta(y-x)} u(y)\, dy,$$

and

$$m_{+2} = \sum_{n=0}^{\infty} (-T_2)^n [g_2], \quad \text{where } g_2(x, \zeta) := 1.$$

The next lemmas show that m_{+1} and m_{+2} exist in E_{x_0}. Their proofs consist of extensive, but straightforward, analysis using the definitions of m_{+1} and m_{+2}.

LEMMA 2.1. *Keep x_0 fixed. Assume that $u \in L^1(\mathbb{R}) \cap L^2(\mathbb{R})$. Then*

(i) $T_2[g_2] \in E_{x_0}$.

(ii) *If u is also in the Sobolev space $H^\alpha(\mathbb{R})$ with $0 < \alpha < \frac{1}{2}$, then*

$$|\xi|^\alpha T_2[g_2](x, \xi) \in L^2(\mathbb{R})$$

for all $x \geqq x_0$, with L^2-norms uniformly bounded for $x \geqq x_0$.

(iii) *If $x^\alpha u(x) \in L^2(\mathbb{R})$ for $0 < \alpha < \frac{1}{2}$, then*

$$T_2[g_2](x, \cdot) \in H^\alpha(\mathbb{R})$$

for all $x \geqq x_0$, with H^α-norms uniformly bounded for $x \geqq x_0$.

LEMMA 2.2. *Recall that $g_1(x, \zeta) = \int_{y=x}^{\infty} e^{2i\zeta(y-x)} u(y)\, dy$. Assume that $u \in L^1 \cap L^2$.*

(i) *For each x_0, $g_1 \in E_{x_0}$.*

(ii) *If also $u \in H^\alpha$ with $0 < \alpha < \frac{1}{2}$, then $|\xi|^\alpha g_1(x, \xi) \in L^2(-\infty < \xi < \infty)$ uniformly in $x \geqq x_0$.*

(iii) *If $|s|^\alpha u(s) \in L^2$ with $0 < \alpha < \frac{1}{2}$, then $g_1(x, \xi) \in H^\alpha$ uniformly in $x \geqq x_0$.*

LEMMA 2.3. *Assume $u \in L^1(\mathbb{R}) \cap L^2(\mathbb{R})$. Pick x_0 in $\mathbb{R}$.*

(i) *If $f \in E_{x_0}$, then $T_2 f \in E_{x_0}$.*

(ii) *If also $|\xi|^\alpha f(x, \xi) \in L^2(-\infty < \xi < \infty)$ uniformly for $x \geqq x_0$, then $|\xi|^\alpha (T_2 f)(x, \xi) \in L^2(-\infty < \xi < \infty)$ uniformly for $x \geqq x_0$.*

(iii) *If also $f(x, \cdot) \in H^\alpha(\mathbb{R})$ uniformly for $x \geqq x_0$ and $x^\alpha u(x) \in L^1(\mathbb{R})$, and $0 < \alpha < 1$, then $T_2 f(x, \cdot) \in H^\alpha(\mathbb{R})$ uniformly for $x \geqq x_0$.*

LEMMA 2.4. *Fix x_0 in $\mathbb{R}$. Assume that $u \in L^1(\mathbb{R}) \cap L^2(\mathbb{R})$.*

(i) *If $f \in E_{x_0}$, then $T_1(f) \in E_{x_0}$.*

(ii) *If also $\xi^\alpha f(x, \xi) \in L^2(\mathbb{R})$ uniformly in $x \geqq x_0$ and $0 < \alpha < \frac{1}{2}$, then $\xi^\alpha T_1(f)(x, \xi) \in L^2(\mathbb{R})$ uniformly in $x \geqq x_0$.*

(iii) *If also $f(x, \cdot) \in H^\alpha(\mathbb{R})$ uniformly in $x \geqq x_0$ and $x^\alpha u(x) \in L^1(\mathbb{R})$, then $T_1(f)(x, \cdot) \in H^\alpha(\mathbb{R})$ uniformly in $x \geqq x_0$.*

PROPOSITION 2.5. *Let $x_0 \in \mathbb{R}$. Assume that $u \in L^1(\mathbb{R}) \cap L^2(\mathbb{R})$.*

(i) *There is a function $m_{+2}(x, \zeta)$ such that*

$$m_{+2}(x, \zeta) - 1 \in E_{x_0}, \quad \textit{and}$$

$$(I + T_2)[m_{+2} - 1] = -T_2[1],$$

whence m_{+2} solves (2.7) *and* (2.11).

(ii) *If, in addition, $u \in H^\alpha(\mathbb{R})$ with $0 < \alpha < \frac{1}{2}$, then for all $n \geqq 1$,*

$$\|\xi^\alpha T_2^n[1](x, \xi)\|_{L^2(\mathbb{R})} \leqq C\sigma^{2n-2}(x)/(2n-2)!,$$

where

$$C = \|u\|_{L^1(\mathbb{R})}\|u\|_{H^\alpha(\mathbb{R})} \quad \textit{and} \quad \sigma(x) = \int_x^\infty |u(s)|\, ds.$$

Thus

$$\|\xi^\alpha T_2[m_{+2}](x, \xi)\|_{L^2(\mathbb{R}, d\xi)} \leqq \sum_1^\infty \|\xi^\alpha T_2^n[1](x, \xi)\| \leqq C\, e^{\sigma(x)}.$$

(iii) *If $u \in H^\alpha$ and $(1 + |x|^\alpha)u(x) \in L^1(\mathbb{R}) \cap L^2(\mathbb{R})$ with $0 < \alpha < \frac{1}{2}$, then*

$$\|T_2^n[1](x, \cdot)\|_{H^\alpha} \leqq 2^n K \mu^{2n-1}(x)/(2n-1)!,$$

where

$$K = \|(1 + |y|^\alpha)u(y)\|_{L^2(\mathbb{R})} \quad \textit{and} \quad \mu(x) = \int_x^\infty (1 + |s|^\alpha)|u(s)|\, ds,$$

whence

$$\|T_2[m_{+2}](x, \xi)\|_{H^\alpha} \leqq \sum_{n \geqq 1} \|T_2^n[1](x, \xi)\|_{H^\alpha} \leqq 2^{3/2} K\, e^{\mu(x)}.$$

Remark 2.6. The analogous results hold for m_{+1} and T_1. These lemmas yield the following theorem.

THEOREM 2.7. *Assume $u \in L^1(\mathbb{R}) \cap L^2(\mathbb{R})$. Consider the functions $m_{+1}(x, \zeta)$ and $m_{+2}(x, \zeta)$ defined above. For any x_0 in $\mathbb{R}$*

(i) $T_1[m_{+1}](x, \zeta) \in E_{x_0}$; $\quad T_2[m_{+2}](x, \zeta) \in E_{x_0}$.

(ii) *If, in addition, $u \in H^\alpha(\mathbb{R})$ and $0 < \alpha < \frac{1}{2}$, then for each x with $x \geqq x_0$,*

$$\xi^\alpha T_1[m_{+1}](x, \xi) \in L^2(\mathbb{R}); \qquad \xi^\alpha T_2[m_{+2}](x, \xi) \in L^2(\mathbb{R})$$

with L^2-norms uniformly bounded for $x \geqq x_0$.

(iii) *If, in addition, $u \in H^\alpha$ and $x^\alpha u(x) \in L^1(\mathbb{R}) \cap L^2(\mathbb{R})$ with $0 < \alpha < \frac{1}{2}$, then*

$$T_1[m_{+1}](x, \xi) \in H^\alpha(\mathbb{R}); \qquad T_2[m_{+2}](x, \xi) \in H^\alpha(\mathbb{R})$$

with H^α-norms uniformly bounded in $x \geqq x_0$.

Similar arguments are used to construct the left-side Jost functions $\psi_{-1}(x, \zeta)$ and $\psi_{-2}(x, \zeta)$. By analogy with E_{x_0} we define spaces $E_{x_0}^-$ on left half-lines and operators

$$T_{-1}[f](x, \zeta) := \int_{-\infty}^x u(y) \int_{-\infty}^y u^*(z) f(z, \zeta)\, e^{2i\zeta(y-z)}\, dz\, dy,$$

$$T_{-2}[f](x, \zeta) := \int_{-\infty}^x u^*(y)\, e^{2i\zeta(x-y)} \int_{-\infty}^y u(z) f(z, \zeta)\, dz\, dy.$$

We then construct the solutions m_{-1} and m_{-2} of the equations

$$(I+T_{-1})m_{-1}(x,\zeta)=1,$$

$$(I+T_{-2})m_{-2}(x,\zeta)=-\int_{-\infty}^{x} u^*(y)\, e^{2i\zeta(x-y)}\, dy.$$

This finally gives the Jost function $\psi_-(x,\zeta)$ the form

$$\psi_-(x,\zeta)=\begin{bmatrix}\psi_{-1}(x,\zeta)\\ \psi_{-2}(x,\zeta)\end{bmatrix}=e^{i\zeta x}\begin{bmatrix}m_{-1}(x,\zeta)\\ m_{-2}(x,\zeta)\end{bmatrix}.$$

COROLLARY 2.8. *The analogue of Theorem* 2.7 *holds for m_{-1} and m_{-2}.*

The scattering data, definitions, and properties. There are three components to the scattering data associated to a potential u in (1.4). The first is the *reflection coefficient* r_+, which has already been defined. The second is the set of zeros of $a_+(\zeta)$ in $\mathbb{H}$, or, equivalently, the set of *poles of the transmission coefficient* $t_+(\zeta)=1/a_+(\zeta)$. The third is the set of *normalizing chains*, which we will define below.

Since $a_+(\zeta)$ is equal to the Wronskian $W[\Psi_-,\Psi_+]$, it is continuous in $\bar{\mathbb{H}}$ and analytic in $\mathbb{H}$. Following Tanaka in § 2 of [Ta], we see that $a_+(\zeta)\to 1$ as $|\zeta|\to\infty$ in $\bar{\mathbb{H}}$, and we make the technical assumption mentioned in the Introduction, namely,

$$\text{for all real } \xi,\ a_+(\xi)\neq 0. \tag{2.12}$$

Observe that condition (2.12) is satisfied for $u\equiv 0$, just as $a_+(\xi)\equiv 1$ in this case. Note that for ξ fixed in $\mathbb{R}$, $a_+(\xi)$ is a real analytic function of Re (u) and Im (u). Therefore, for a given ξ in $\mathbb{R}$, the condition $a_+(\xi)\neq 0$ is satisfied generically. It is not likely that the stronger condition (2.12) is generic.

It follows that the set of zeros of $a_+(\zeta)$ in $\mathbb{H}$ is finite; enumerate them as

$$\zeta_1,\zeta_2,\cdots,\zeta_J.$$

By convention, $J=0$ will mean that a_+ has no zeros in $\mathbb{H}$. Let $m(j)$ denote the multiplicity of the jth zero of a_+ in $\mathbb{H}$.

The normalization chains c_j^+ and c_j^- relate the Jost functions $\Psi_+(x,\zeta_j)$ and $\Psi_-(x,\zeta_j)$. To define these chains, we give a simpler version of Tanaka's Theorem 2.3 in [Ta] and prove it by a more elementary argument.

THEOREM 2.9. *Suppose that a_+ has a zero of multiplicity $m(j)$ at ζ_j in $\mathbb{H}$. Then there are sequences*

$$c_j^+=(c_{j,0}^+,c_{j,1}^+,\cdots,c_{j,m(j)-1}^+),$$

$$c_j^-=(c_{j,0}^-,c_{j,1}^-,\cdots,c_{j,m(j)-1}^-),$$

such that

$$c_{j,0}^+\neq 0 \quad \textit{and} \quad c_{j,0}^-\neq 0,$$

and, for each k with $0\leqq k\leqq m(j)-1$,

$$\frac{1}{k!}\left(\frac{d}{d\zeta}\right)^k[\psi_-(x,\zeta)]\bigg|_{\zeta_j}=\sum_{\nu=0}^{k}\frac{1}{\nu!}c_{j,k-\nu}^+\left(\frac{d}{d\zeta}\right)^\nu[\psi_+(x,\zeta)]\bigg|_{\zeta_j}, \tag{2.13}$$

$$\frac{1}{k!}\left(\frac{d}{d\zeta}\right)^k[\psi_+(x,\zeta)]\bigg|_{\zeta_j}=\sum_{\nu=0}^{k}\frac{1}{\nu!}c_{j,k-\nu}^-\left(\frac{d}{d\zeta}\right)^\nu[\psi_-(x,\zeta)]\bigg|_{\zeta_j}. \tag{2.14}$$

Furthermore, c_j^+ is related to $\bar{c}_j$ by the relations

$$(2.15)\qquad \sum_{\lambda=\sigma}^{\tau} c^-_{j,\tau-\lambda}c^+_{j,\lambda-\sigma} = \begin{cases} 1 & \text{if } \sigma=\tau, \\ 0 & \text{if } \sigma<\tau, \end{cases}$$

whenever $0 \leqq \sigma \leqq \tau \leqq m(j)-1$.

Proof. For real ξ we have the relation

$$a_+(\xi) = W[\psi_-, \psi_+].$$

Extend ψ_+, ψ_-, and thus a_+ also, analytically to $\mathbb{H}$, obtaining

$$a_+(\zeta) = W[\psi_-(x,\zeta), \psi_+(x,\zeta)].$$

Since ζ_j is a zero of order $m(j)$ for $a_+(\zeta)$, we learn that for $0 \leqq k \leqq m(j)-1$

$$0 = \left(\frac{d}{d\zeta}\right)^k [a_+(\zeta)]\Big|_{\zeta_j},$$

whence

$$0 = \sum_{\nu=0}^{k} \binom{k}{\nu} W[\psi_-^{(\nu)}, \psi_+^{(k-\nu)}]\Big|_{\zeta_j}.$$

At $k=0$ we get, in particular,

$$0 = W[\psi_-(x,\zeta_j), \psi_+(x,\zeta_j)],$$

so each of $\psi_-(x,\zeta_j)$ and $\psi_+(x,\zeta_j)$ is a nonzero multiple of the other. Thus we can define $c_{j,0}^{\pm}$ by the relations

$$\psi_-(x,\zeta_j) = c^+_{j,0}\psi_+(x,\zeta_j) \quad \text{with } c^+_{j,0} \neq 0,$$
$$\psi_+(x,\zeta_j) = c^-_{j,0}\psi_-(x,\zeta_j) \quad \text{with } c^-_{j,0} \neq 0.$$

The proof now continues by induction. Assume that we have proved (2.13) and (2.14) for all $k=0,1,\cdots,N$, where N is less than $m(j)-1$. Now

$$0 = \left(\frac{d}{d\zeta}\right)^{N+1} [a_+(\zeta)]\Big|_{\zeta_j} = \sum_{k=0}^{N+1} \binom{N+1}{k} W[\psi_-^{(k)}, \psi_+^{(N+1-k)}]\Big|_{\zeta_j}$$
$$= W[\psi_-^{(N+1)}, \psi_+^{(0)}]|_{\zeta_j} + \sum_{k=0}^{N} \frac{(N+1)!}{k!(N+1-k)!} W[\psi_-^{(k)}, \psi_+^{(N+1-k)}]\Big|_{\zeta_j}.$$

Use the induction hypothesis to get

$$0 = W[\psi_-^{(N+1)}, \psi_+^{(0)}]|_{\zeta_j} + \sum_{k=0}^{N} \frac{(N+1)!}{k!(N+1-k)!} W\left[\sum_{\mu=0}^{k} \frac{k!}{\mu!} c^+_{j,k-\mu}\psi_+^{(\mu)}, \psi_+^{(N+1-k)}\right]\Bigg|_{\zeta_j}.$$

Treat $\mu=0$ separately from $\mu \geqq 1$.

$$0 = W[\psi_-^{(N+1)}, \psi_+^{(0)}]|_{\zeta_j} + \sum_{k=0}^{N} \frac{(N+1)!}{k!(N+1-k)!} W[k!\,c^+_{j,k}\psi_+^{(0)}, \psi_+^{(N+1-k)}]\Big|_{\zeta_j}$$
$$+ \sum_{k=0}^{N} \frac{(N+1)!}{k!(N+1-k)!} W\left[\sum_{\mu=1}^{k} \frac{k!}{\mu!} c^+_{j,k-\mu}\psi_+^{(\mu)}, \psi_+^{(N+1-k)}\right]\Bigg|_{\zeta_j}.$$

In the middle term use the linearity and skew symmetry of W to get

$$0 = W\left[\psi_-^{(N+1)} - \sum_{k=0}^{N} \frac{(N+1)!\,k!}{k!(N+1-k)!} c^+_{j,k}\psi_+^{(N+1-k)}, \psi_+^{(0)}\right]\Bigg|_{\zeta_j}$$
$$+ \sum_{k=0}^{N} \frac{(N+1)!}{k!(N+1-k)!} W\left[\sum_{\mu=1}^{k} \frac{k!}{\mu!} c^+_{j,k-\mu}\psi_+^{(\mu)}, \psi_+^{(N+1-k)}\right]\Bigg|_{\zeta_j}.$$

Suppose we could show that the second line is zero. Then there is a nonzero $\gamma_{j,N+1}$ such that

$$\psi_+^{(0)}(x,\zeta_j)=\gamma_{j,N+1}\left\{\psi_-^{(N+1)}-\sum_{k=0}^{N}\frac{(N+1)!}{(N+1-k)!}c_{j,k}^+\psi_+^{(N+1-k)}\right\}\Bigg|_{\zeta_j}.$$

Let $c_{j,N+1}^+=[(N+1)!\,\gamma_{j,N+1}]^{-1}$. Setting $n=N+1-k$, we find that

$$\frac{1}{(N+1)!}\psi_-^{(N+1)}(x,\zeta_j)=\sum_{n=0}^{N+1}\frac{1}{n!}c_{j,N+1-n}^+\psi_+^{(n)}(x,\zeta_j).$$

It remains to show that

$$0=\mathscr{S}_N:=\sum_{k=0}^{N}\frac{(N+1)!}{k!(N+1-k)!}W\left[\sum_{\mu=1}^{k}\frac{k!}{\mu!}c_{j,k-\mu}^+\psi_+^{(\mu)},\ \psi_+^{(N+1-k)}\right]\Bigg|_{\zeta_j}.$$

Now, since the $k=0$ term is vacuous,

$$\mathscr{S}_N=\sum_{k=1}^{N}\sum_{\mu=1}^{k}\frac{(N+1)!}{(N+1-k)!\,\mu!}c_{j,k-\mu}^+W[\psi_+^{(\mu)},\psi_+^{(N+1-k)}]|_{\zeta_j}.$$

Set $l=k-\mu$ for each fixed k.

$$\begin{aligned}\mathscr{S}_N&=\sum_{k=1}^{N}\sum_{l=0}^{k-1}\frac{(N+1)!}{(N+1-k)!(k-l)!}c_{j,l}^+W[\psi_+^{(k-l)},\psi_+^{(N+1-k)}]\Bigg|_{\zeta_j}\\&=(N+1)!\sum_{l=0}^{N-1}c_{j,l}^+\sum_{k=l+1}^{N}\frac{1}{(N+1-k)!(k-l)!}W[\psi_+^{(k-l)},\psi_+^{(N+1-k)}]\Bigg|_{\zeta_j}.\end{aligned}$$

Let S_l denote the sum over k.

$$S_l=\sum_{k=l+1}^{N}\frac{1}{(N+1-k)!(k-l)!}W[\psi_+^{(k-l)},\psi_+^{(N+1-k)}]\Bigg|_{\zeta_j}.$$

Note that as k runs from $l+1$ to N, $\mu:=N+1-k$ runs from $N-l$ to 1, and $\nu:=k-l$ runs from 1 to $N-l$. Thus

$$S_l=\sum_{\mu=1}^{N-l}\frac{1}{\mu!(N+1-l-\mu)!}W[\psi_+^{(N+1-l-\mu)},\psi_+^{(\mu)})]\Bigg|_{\zeta_j}$$

and

$$S_l=\sum_{\nu=1}^{\nu-l}\frac{1}{(N+1-l-\nu)!\,\nu!}W[\psi_+^{(\nu)},\psi_+^{(N-1-l-\nu)}]\Bigg|_{\zeta_j}.$$

So $S_l=-S_l$, whence $S_l=0$, and $\mathscr{S}_N=0$.

Thus (2.13) is proved for $k=N+1$ and the induction is complete. (2.14) is proved similarly, and (2.15) follows by comparing (2.13) and (2.14). □

Definition. The sequences c_j^+ and c_j^- are the normalizing chains associated to the jth pole of $T_+(\zeta)$. Because of (2.15), c_j^- is determined by c_j^+.

Properties of the reflection coefficient r_+. Since $W[\psi_-(x,\xi),\psi_+(x,\xi)]$ is independent of x for real ξ, this independence of ξ persists into the upper half plane, and

$$\begin{aligned}a_+(\zeta)&=W[\psi_-(x,\zeta),\psi_+(x,\zeta)]|_{x=0}\\&=m_{-1}(0,\zeta)m_{+2}(0,\zeta)-m_{+1}(0,\zeta)m_{-2}(0,\zeta).\end{aligned}$$

PROPOSITION 2.10. *Assume that* $u \in L^2(\mathbb{R}) \cap L^1(\mathbb{R})$.

(i) $a_+(\xi) - 1 \in C_0(\mathbb{R})$, *i.e.*, $a_+(\xi) - 1$ *is continuous form* $\mathbb{R}$ *to* $\mathbb{C}$ *and has limit* 0 *as* $\xi \to \pm\infty$; $a_+(\zeta) - 1 \in H^{2+} \cap H^{\infty+}$.

(ii) *If, in addition,* $u \in H^\alpha(\mathbb{R})$ *for* $0 < \alpha < \frac{1}{2}$, *then* $\xi^\alpha(a_+(\xi) - 1) \in L^2(\mathbb{R})$.

(iii) *If, in addition,* $|x|^\alpha u(x) \in L^2(\mathbb{R}) \cap L^1(\mathbb{R})$ *for* $0 < \alpha < \frac{1}{2}$, *then* $a_+(\xi) - 1 \in H^\alpha(\mathbb{R})$.

Proof. This can be read off from the properties of T_1, T_2, m_+, and m_-. □

Similarly, we get the expansion

$$b_+(\zeta) = m_{-1}(0, \zeta) m^*_{+1}(0, \zeta) - m_{-2}(0, \zeta) m^*_{+2}(0, \zeta),$$

and find the following result.

PROPOSITION 2.11. *Let* $u \in L^2(\mathbb{R}) \cap L^1(\mathbb{R})$. *Then*

(i) $b_+(\xi) \in L^2(\mathbb{R}) \cap C_0(\mathbb{R})$;

(ii) *If, in addition,* $u \in H^\alpha(\mathbb{R})$ *with* $0 < \alpha < \frac{1}{2}$, *then* $\xi^\alpha b_+(\xi) \in L^2(\mathbb{R})$;

(iii) *If, in addition,* $u \in H^\alpha$ *and* $x^\alpha u(x) \in L^2(\mathbb{R}) \cap L^1(\mathbb{R})$ *with* $0 < \alpha < \frac{1}{2}$, *then* $b_+(\xi) \in H^\alpha(\mathbb{R})$.

COROLLARY 2.12. *Assume* $u \in L^2(\mathbb{R}) \in L^1(\mathbb{R})$ *and* u *satisfies* (2.12). *Then*

(i) $r_+(\xi) \in L^2(\mathbb{R}) \cap C_0(\mathbb{R})$.

(ii) *If, in addition,* $u \in H^\alpha(\mathbb{R})$ *with* $0 < \alpha < \frac{1}{2}$, *then* $\xi^\alpha r_+(\xi) \in L^2(\mathbb{R})$.

(iii) *If, in addition,* $u \in H^\alpha$ *and* $x^\alpha u(x) \in L^2(\mathbb{R}) \cap L^1(\mathbb{R})$ *with* $0 < \alpha < \frac{1}{2}$, *then* $r_+(\xi) \in H^\alpha(\mathbb{R})$.

Proof. Parts (i) and (ii) follow immediately from Propositions 2.11 and 2.12 since by (2.12) $a_+(\xi)$ is bounded away from zero for ξ in $\mathbb{R}$.

By Theorem 10.2 of [LM, p. 58] we see that (iii) is equivalent to

$$r_+(\xi) \in L^2(\mathbb{R}) \quad \text{and} \quad \int_0^\infty t^{-(1+2\alpha)} \int_{-\infty}^\infty |r_+(\xi + t) - r_+(\xi)|^2 \, d\xi \, dt < \infty.$$

We already know that $r_+ \in L^2$. We also know that $a_+(\xi)$ is continuous and never zero on $\mathbb{R}$, and that $a_+(\xi) \to 1$ as $\xi \to \pm\infty$. Thus there is an M such that $|a_+(\xi)|^{-1} \leqq M$ for all real ξ. Since $b_+(\xi)$ is continuous on $\mathbb{R}$ and goes to zero as $\xi \to \pm\infty$, we may take M larger if necessary to get $|b_+(\xi)| \leqq M$ for all real ξ. Finally, because of Propositions 2.11 and 2.12, we know that

$$\int_0^\infty t^{-(1+2\alpha)} \int_{-\infty}^\infty |a_+(\xi + t) - a_+(\xi)|^2 \, d\xi \, dt < \infty$$

and

$$\int_0^\infty t^{-(1+2\alpha)} \int_{-\infty}^\infty |b_+(\xi + t) - b_+(\xi)|^2 \, d\xi \, dt < \infty.$$

Now

$$\begin{aligned} &\int_0^\infty t^{-(1+2\alpha)} \int_{-\infty}^\infty |r_+(\xi + t) - r_+(\xi)|^2 \, d\xi \, dt \\ &\leqq \int_0^\infty t^{-(1+2\alpha)} \int_{-\infty}^\infty \left| \frac{b_+(\xi + t)}{a_+(\xi + t)} - \frac{b_+(\xi)}{a_+(\xi)} \right|^2 d\xi \, dt \\ &\leqq \int_0^\infty t^{-(1+2\alpha)} \int_{-\infty}^\infty \{[1 + M^2] M^2 [|b_+(\xi + t) - b_+(\xi)|^2 + |a_+(\xi + t) - a_+(\xi)|^2] \, d\xi \, dt < \infty. \end{aligned}$$

□

3. The scattering data and Marchenko kernel for positive time. At $t = 0$ we have identified the components of the scattering data associated to (1.4), where the potential

u is the initial function u_0 in the cubic Schrödinger problem. For $t>0$ we define nominal scattering data, "nominal" because we do not assert that these objects really arise as the scattering data of any potential in $L^1(\mathbb{R})\cap L^2(\mathbb{R})$.

DEFINITIONS.

$$r(\xi,t):=r_\pm(\xi)\,e^{\pm 2i\xi^2 t}, \tag{3.1a}$$

$$\zeta_j(t):=\zeta_j \quad \text{for } 1\leqq j\leqq J, \tag{3.1b}$$

$$(c^\pm_{j,\mu}(t))_{\mu=0}^{m(j)-1}, \tag{3.1c}$$

are determined as in Tanaka's paper [Ta] by the ordinary differential equations

$$\frac{d}{dt}[c^\pm_{j,\mu}]=\pm 2i(\zeta_j^2 c^\pm_{j,\mu}+2\zeta_j c^\pm_{j,\mu-1}+c^\pm_{j,\mu-2})$$

with the conventions

$$c^\pm_{j,-1}(t)\equiv c^\pm_{j,-2}(t)\equiv 0$$

and the initial conditions

$$c^\pm_{j,\mu}(0)=c^\pm_{j,\mu}.$$

Tanaka remarks that

$$c^\pm_{j,\mu}(t)=\mathcal{P}^\pm_{j,\mu}(t)\,e^{2i\zeta_j^2 t},$$

where $\mathcal{P}^\pm_{j,\mu}(t)$ is a polynomial of degree μ in t. The ordinary differential equations (3.1c) insure that the relations (2.15) for the normalizing chains persist for $t>0$.

Now, following Tanaka [Ta], and Zakharov and Shabat [ZS], we define

$$\Omega_+(x,t):=F_+(x,t)+\sum_{j=1}^{J} f_j(x,t), \tag{3.2}$$

where

$$F_+(x,t)=\pi^{-1}\int_{-\infty}^{\infty} r_+(\xi,t)\,e^{2i\xi x}\,d\xi \tag{3.3a}$$

and

$$f_{+j}(x,t)=-2i\sum_{\mu=0}^{m(j)-1}\frac{1}{\mu!}c^+_{m(j)-1-\mu}(t)\left(\frac{d}{d\zeta}\right)^{\mu}\left[\frac{(\zeta-\zeta_j)^{m(j)}\,e^{2i\zeta x}}{a_+(\zeta)}\right]\Bigg|_{\zeta_j}. \tag{3.3b}$$

Introduce $Q^+_{j,\mu}(x)$ by the equation

$$Q^+_{j,\mu}(x)\,e^{2i\zeta_j x}=\left(\frac{d}{d\zeta}\right)^{\mu}\left[\frac{(\zeta-\zeta_j)^{m(j)}\,e^{2i\zeta x}}{a_+(\zeta)}\right]\Bigg|_{\zeta_j}.$$

Similarly, we define Ω_-, F_-, f_{-j}, and $Q^-_{j,\mu}$.

Observe that $Q^+_{j,\mu}(x)$ is a polynomial in x of degree μ, and

$$f_{+j}(x,t)=-2i\sum_{\mu=1}^{m(j)-1}\frac{1}{\mu!}\mathcal{P}^+_{j,m(j)-1-\mu}(t)\,Q^+_{j,\mu}(x)\,e^{2i\zeta_j^2 t+2i\zeta_j x}.$$

The ordinary differential equations for the normalizing chains were chosen to insure that each f_{+j} satisfied the partial diffeerential equation

$$i\omega_t-\tfrac{1}{2}\omega_{xx}=0. \tag{3.4}$$

The $f_{+j}(x,t)$ are smooth functions of x and t and decay exponentially as $x\to+\infty$ for any fixed t.

Since $r_+(\cdot, t)$ evolves in $L^2(\mathbb{R})$, so does $F_+(\cdot, t)$. Further, F_+ satisfies the initial value problem (3.4) with

$$\omega(x, 0) = F_+(x).$$

Note that (3.4) differs from the linear part of the cubic Schrödinger equation (1.1) in the sign in front of the second space derivative.

PROPOSITION 3.1. *Suppose there is an* α *with* $0 < \alpha < 1$ *such that*

$$F_+(x) \in H^\alpha(\mathbb{R}) \quad \textit{and} \quad (1+|x|^\alpha)F_+(x) \in L_2(\mathbb{R}).$$

Then for each T *with* $0 < T < \infty$,

$$\text{(a)} \qquad F_+(x, t) \in L^\infty([0, T], H^\alpha(\mathbb{R}))$$

and

$$\text{(b)} \qquad (1+|x|^\alpha)F_+(x, t) \in L^\infty([0, T], L^2(\mathbb{R})).$$

Proof. It suffices to prove that

$$\text{(i)} \qquad r_+(\xi, t) \in L^\infty([0, T], H^\alpha(\mathbb{R}))$$

and

$$\text{(ii)} \qquad (1+|x|^\alpha)r_+(\xi, t) \in L^\infty([0, T], L^2(\mathbb{R})).$$

But $r_+(\xi, t) = r_+(\xi) \exp(2i\xi^2 t)$, and thus (ii) is trivial. For (i) we must show that the H^α-norm of $r_+(\xi, t)$ is bounded uniformly in $0 \leqq t \leqq T$. Following [LM, Thm. 10.2, p. 52] the H^α-norm of $f(x)$ is equivalent to

$$\left[\|f\|^2_{L^2(\mathbb{R})} + \int_0^\infty ds\, s^{-(1+2\alpha)} \int_{\mathbb{R}} dx\, |f(x+s) - f(x)|^2\right]^{1/2}.$$

Clearly $\|r_+(\xi, t)\|_{L^2(\mathbb{R})}$ is independent of t and thus it remains to prove that

$$\int_0^\infty ds\, s^{-(1+2\alpha)} \int_{\mathbb{R}} d\xi\, |r_+(x+s, t) - r_+(\xi, t)|^2$$

is uniformly bounded for $0 \leqq t \leqq T$. Write

$$\int_0^\infty ds\, s^{-(1+2\alpha)} \int_{-\infty}^\infty d\xi\, |r_+(\xi+s) \exp(2i(\xi+s)^2 t) - r_+(\xi) \exp(2i\xi^2 t)|^2$$

$$\leqq 2 \int_0^\infty ds\, s^{-(1+2\alpha)} \int_{-\infty}^\infty |r_+(\xi+s) - r_+(\xi)|^2\, d\xi + 2 \int_0^\infty ds\, s^{-(1+2\alpha)}$$

$$\cdot \int_{-\infty}^\infty |r_+(\xi)|^2 \exp(i(\xi+s)^2 t - i\xi^2 t) - \exp(-i(\xi+s)^2 t + i\xi^2 t)|^2\, d\xi$$

$$\leqq 2C\|r_+(\cdot)\|^2_{H^\alpha} + 2 \int_0^\infty ds\, s^{-(1+2\alpha)} \int_{-\infty}^\infty |r_+(\xi)|^2 4 \sin^2((\xi+s)^2 t - \xi^2 t)\, d\xi$$

$$\leqq I_1 + I_2.$$

It remains to estimate I_2. Divide the outer integral at $s=1$.

$$I_3=2\int_1^\infty ds\, s^{-(1+2\alpha)}\int_{-\infty}^{\infty}|r_+(\xi)|^2 4\sin^2((s^2+2\xi s)t)\, d\xi$$

$$\leqq 8\|r_+\|_{L^2(\mathbb{R})}\int_1^\infty s^{-(1+2\alpha)}\, ds<\infty.$$

$$I_4=8\int_0^1 ds\, s^{-(1+2\alpha)}\int_{-\infty}^{\infty}|r_+(\xi)|^2\sin^2((s^2+2\xi s)t)\, d\xi$$

$$=8\int_{-\infty}^{\infty} d\xi\, |r_+(\xi)|^2\int_0^1 ds\, s^{-(1+2\alpha)}\sin^2((s^2+2\xi s)t)=I_5+I_6,$$

where I_5 is the piece of the outer integral where $|\xi|\leqq 1$, and I_6 is the rest.

$$I_5\leqq 8\int_{|\xi|\leqq 1} d\xi\, |r_+(\xi)|^2\int_0^1 ds\, s^{-(1+2\alpha)}(s^2+2\xi s)^2t^2$$

$$\leqq 8\int_{|\xi|\leqq 1} d\xi\, |r_+(\xi)|^2\int_0^1 ds\, s^{1-2\alpha}(s+2\xi)^2t^2<\infty$$

since $0<\alpha<1$. Now

$$I_6=8\int_{|\xi|\geqq 1} d\xi\, |r_+(\xi)|^2\int_0^1 ds\, s^{-(1+2\alpha)}\sin^2((s^2+2\xi s)^2t^2)=I_7+I_8,$$

where we have divided the integral at $s=|\xi|^{-1}$.

$$I_7=8\int_{|\xi|\geqq 1} d\xi\, |r_+(\xi)|^2\int_{1/|\xi|}^1 ds\, s^{-(1+2\alpha)}\sin^2((s^2+2\xi s)t)$$

$$\leqq 8\int_{|\xi|\geqq 1} d\xi\, |r_+(\xi)|^2\int_{1/|\xi|}^1 ds\, s^{-(1+2\alpha)}$$

$$\leqq 8\int_{|\xi|\geqq 1} d\xi\, |r_+(\xi)|^2(|\xi|^{2\alpha}-1)/2\alpha<\infty$$

since we know that $r_+(\xi)|\xi|^\alpha\in L^2(\mathbb{R})$.

$$I_8=8\int_{|\xi|\geqq 1} d\xi\, |r_+(\xi)|^2\int_0^{1/|\xi|} ds\, s^{-(1+2\alpha)}\sin^2((s^2+2\xi s)t)$$

$$\leqq 8\int_{|\xi|\geqq 1} d\xi\, |r_+(\xi)|^2\int_0^{1/|\xi|} ds\, s^{-(1+2\alpha)}s^2(s+2\xi)^2t^2.$$

Since $0\leqq s\leqq 1/|\xi|$ and $|\xi|\geqq 1$, we see that

$$I_8\leqq 8\int_{|\xi|\geqq 1} d\xi\, |r_+(\xi)|^2\int_0^{1/|\xi|} ds\, s^{1-2\alpha}(3\xi)^2t^2$$

$$\leqq 36t^2(1-\alpha)^{-1}\int_{|\xi|\geqq 1} d\xi\, |r_+(\xi)|^2|\xi|^{2\alpha}<\infty.$$

This concludes the proof of Theorem 3.1. □

4. Solution of the Marchenko equation for $t>0$. Here we obtain a function that will be shown in § 6 to be the solution to the initial value problem (1.1), (1.2), and we establish some of its properties.

We consider further the kernel $\Omega_+(x,t)$ discussed in § 3. For each real x and each nonnegative t, let F_x^t, G_{xj}^t, and Ω_x^t be the operators defined by

$$F_x^t[g](y) := \int_0^\infty F_+(x+y+z,t)g(z)\,dz,$$

$$G_{xj}^t[g](y) := \int_0^\infty f_{+j}(x+y+z,t)g(z)\,dz,$$

$$\Omega_x^t[g](y) := F_x^t[g](y) + \sum_{j=1}^J G_{xj}^t[g](y).$$

It can be shown that for each x the map $t \to \Omega_x^t$ is continuous from $[0,\infty)$ into $\mathscr{L}(L^2(\mathbb{R}^+))$ with the operator norm topology. The map $x \to \Omega_x^t$ is continuous in the strong operator topology, but not in the uniform topology. Note that $(I+\Omega_x^{t*}\Omega_x^t)^{-1}$ exists in $L^2(\mathbb{R}^+)$ with operator norm no larger than one because $\Omega_x^{t*}\Omega_x^t$ is positive and self-adjoint.

It is easy to check that the Marchenko equation

$$0 = B_+^{\#}(x,y,t) + \Omega_+(x+y,t)\begin{bmatrix}0\\1\end{bmatrix} + \int_0^\infty \Omega_+(x+y+z,t)B_+(x,z,t)\,dz \tag{4.1}$$

is equivalent to the system of equations

$$B_{+2}(x,y,t) = -\int_0^\infty \Omega_+^*(x+y+z,t)B_{+1}(x,z,t)\,dz, \tag{4.2a}$$

$$\Omega_+^*(x+y,t) = (I+\Omega_x^{t*}\Omega_x^t)[B_{+1}(x,\cdot,t)](y). \tag{4.2b}$$

Thus we get solutions to (4.1) by setting

$$B_{+1}(x,\cdot,t) = (I+\Omega_x^{t*}\Omega_x^t)^{-1}[\Omega_+^*(x+[\cdot],t)] \tag{4.3a}$$

and

$$B_{+2}(x,\cdot,t) = -\Omega_x^{t*}[B_{+1}(x,\cdot,t)]. \tag{4.3b}$$

It is easy to check that the map $(x,t) \to B_+(x,\cdot,t)$ is continuous from $\mathbb{R}\times[0,\infty)$ into $L^2(\mathbb{R})$.

DEFINITION. The function that we shall eventually prove to be the solution of our initial value problem for the cubic Schrödinger equation is

$$u(x,t) := u_+(x,t) := -\Omega_+^*(x,t) + \Omega_x^{t*}\Omega_x^t[B_+(x,\cdot,t)](0). \tag{4.4}$$

Observe that if $g \in L^2(\mathbb{R})$, then $\Omega_x^t[g](y)$ depends continuously on x, y, and t. Thus $\Omega_x^t\Omega_x^t[B_+(x,\cdot,t)](y)$ is continuous in x, y, t and can be evaluated at $y=0$.

For the rest of this section we derive some elementary properties of $u(x,t)$.

PROPOSITION 4.1. *Suppose that $u_0 \in L^1(\mathbb{R}) \cap L^2(\mathbb{R})$ and that u_0 satisfies the generic condition* (2.12). *Then the map $t \to u(x,t)$ is continuous from* $[0,\infty)$ *into* $L^2_{\text{loc}}(\mathbb{R})$.

Proof. We need to prove that for $t \geqq 0$, $u(\cdot,t) \in L^2_{\text{loc}}(\mathbb{R})$. The continuity follows from the remarks above.

It is clear from the definition of $\Omega_+(x,t)$ that $\Omega_+^*(\cdot,t) \in L^2(+\infty)$. It will suffice to show that the other term in $u(x,t)$ is bounded on all half lines $[a,\infty)$ in the x-axis. Now

$$|\Omega_x^{t*}\Omega_x^t[B_{+1}(x,\cdot,t)](0)| \leqq \int_0^\infty |\Omega_+(x+w,t)|\,|\Omega_x^t[B_{+1}(x,\cdot,t)](w)|\,dw$$

$$\leqq \|\Omega_+(\cdot,t)\|_{L^2([x,\infty))}\|\Omega_x^t\|_{op}\|B_{+1}(x,\cdot,t)\|_{L^2(\mathbb{R}^+)}.$$

Since $\|(I+\Omega_x^{t*}\Omega_x^t)^{-1}\|_{op}\leqq 1$, we conclude from (4.3a) that

$$\|B_{+1}(x,\cdot,t)\|_{L^2(\mathbb{R}^+)}\leqq\|\Omega_+(\cdot,t)\|_{L^2([x,\infty))}.$$

To control the operator norm of

$$\Omega_x^t=F_x^t-2i\sum_1^J G_{jx}^t,$$

we check that

$$\|F_x^t\|_{op}\leqq\|r_+\|_{L^\infty(\mathbb{R})}$$

and that

$$\|G_{jx}\|_{op}\leqq P(x,t)\,e^{-cx}$$

for a polynomial P and some positive c. Thus, finally, $u(\cdot,t)\in L^2_{\text{loc}}(\mathbb{R})$. □

PROPOSITION 4.2. *Suppose that* $(1+|x|^\alpha)u_0\in L^2(\mathbb{R})\cap L^1(\mathbb{R})$ *and* $u_0\in H^\alpha(\mathbb{R})$ *for some* α *with* $\frac{1}{4}<\alpha$. *Then the map* $t\to u(\cdot,t)$ *is continuous from* $[0,\infty)$ *into* $L^2(+\infty)$.

Proof. Since we know that $u(\cdot\;,t)\in L^2_{\text{loc}}$ for each t, it suffices to show that $u(\cdot,t)\in L^2([1,\infty))$. From (4.4) we have already seen that

$$|u(x,t)|\leqq|\Omega_+(x,t)|+\{\|\Omega_+(\cdot,t)\|_{L^2([x,\infty))}\}^2\|\Omega_x^t\|_{op}$$

The first term we know is in $L^2([1,\infty))$. We also know that the operator norm is bounded on $[1,\infty)$. Now, using the properties of f_{+j}, we get

$$\begin{aligned}\|\Omega_+(\cdot,t)\|^2_{L^2([x,\infty))}&\leqq\left\{\|F_+(\cdot,t)\|_{L^2([x,\infty))}+2\sum_1^J\|f_{+j}(\cdot,t)\|_{L^2([x,\infty))}\right\}^2\\&\leqq\{1+4J\}\left\{\|F_+(\cdot,t)\|^2_{L^2([x,\infty))}+\sum_1^J\|f_{+j}(\cdot,t)\|^2_{L^2([x,\infty))}\right\}\\&\leqq\{1+4J\}\left\{\|F_+(\cdot,t)\|^2_{L^2([x,\infty))}+\sum_1^J K(t)\,e^{-cx}\right\}.\end{aligned}$$

Using Proposition 3.1, we find that $\|F_+(\cdot,t)\|^2_{L^2([x,\infty))}\leqq K^2x^{-2\alpha}$. □

5. Uniqueness results. The inverse scattering method provides two candidates for the solution to the initial value problem of this paper. One is

$$u_+(x,t):=-B_{+1}(x,0,t),\tag{5.1}$$

where B_+ solves the right-side Marchenko equation

$$B_+^{\#}(x,y,t)+\begin{bmatrix}1\\0\end{bmatrix}\Omega_+(x+y,t)+\int_0^\infty\Omega_+(x+y+z,t)B_+(x,z,t)\,dz=0.\tag{5.2}$$

The other is

$$u_-(x,t):=-B^*_{-2}(x,0,t),\tag{5.3}$$

where B_- solves the left-side Marchenko equation

$$B_-^{\#}(x,y,t)+\begin{bmatrix}0\\1\end{bmatrix}\Omega_-(x+y,t)+\int_{-\infty}^0\Omega_-(x+y+z,t)B_-(x,z,t)\,dz=0.\tag{5.4}$$

In the KdV problem for $t>0$, the left-side Marchenko equation is far less tractable than the right-side equation. In the cubic Schrödinger equation problem, the two Marchenko equations are both solvable for $t>0$, provided only that

$$u_0\in L^1(\mathbb{R})\cap L^2(\mathbb{R}); \tag{5.5}$$

$a_+(\zeta)$ has no zeros on the real axis.

THEOREM 5.1. *If* u_0 *satisfies* (5.5), *then*

$$u_+(x,t)=u_-(x,t)\quad \textit{for}\, x\in\mathbb{R},\ t>0. \tag{5.6}$$

Proof. We first show that it suffices to establish the following identities:

$$a_+^{-1}(\xi)\psi_-(x,\xi,t)=\psi_+^{\#}(x,\xi,t)+r_+(\xi,t)\psi_+(x,\xi,t)\quad \text{for } x>0 \tag{5.7}$$

and

$$a_-^{-1}(\xi)\psi_+(x,\xi,t)=\psi_-^{\#}(x,\xi,t)+r_-(\xi,t)\psi_-(x,\xi,t)\quad \text{for } x<0. \tag{5.8}$$

The proof of these identities is deferred.

By construction we know that

$$L_{u_+}[\psi_+]=\zeta\psi_+, \tag{5.9}$$

$$L_{u_-}[\psi_-]=\zeta\psi_-. \tag{5.10}$$

From (5.10) with $\zeta=\xi\in\mathbb{R}$ and $x>0$, we get

$$L_{u_-}[\psi_-]=\xi\psi_-.$$

From (5.7) and verification that $L_{u_+}[\psi_+^{\#}]=\xi\psi_+^{\#}$, we get

$$\begin{aligned}L_{u_+}[\psi_-]&=L_{u_+}[a_+\psi_+^{\#}+b_+\psi_+]\\&=a_+L_{u_+}[\psi_+^{\#}]+b_+L_{u_+}[\psi_+]\\&=\xi(a_+\psi_+^{\#}+b_+\psi_+)=\xi\psi_-.\end{aligned}$$

Thus,

$$0=L_{u_-}[\psi_-]-L_{u_+}[\psi_-]=-i\begin{bmatrix}0&(u_--u_+)\\(u_--u_+)&0\end{bmatrix}\psi_-.$$

Since ψ_- cannot vanish, $u_-=u_+$ for $x>0$. By working with (5.8), we can show similarly that $u_-=u_+$ for $x<0$.

Proof of (5.7). Keep $x>0$ and $t>0$ throughout. Recall that

$$a_+(\zeta,t)=a_+(\zeta)\quad\text{and}\quad r_+(\xi,t)=r_+(\xi)\,e^{2i\xi^2t}.$$

Now (5.7) is equivalent to

$$m_-(\xi,t)/a_+(\xi)=m_+^{\#}(x,\xi,t)+r_+(\xi,t)\,e^{2i\xi x}m_+(x,\xi,t). \tag{5.11}$$

Let g_0 denote the right side of (5.11):

$$g_0(x,\xi,t):=m_+^{\#}(x,\xi,t)+r_+(\xi,t)\,e^{2i\xi x}m_+(x,\xi,t)$$

and set

$$\mathcal{G}_0(x,y,t):=\pi^{-1}\int_{-\infty}^{\infty}\left\{g_0(x,\xi,t)-\begin{bmatrix}1\\0\end{bmatrix}\right\}e^{2i\xi y}\,d\xi.$$

Thus

$$\mathcal{G}_0(x, y, t) = B_+^{\#}(x, y, t) + \begin{bmatrix} 0 \\ 1 \end{bmatrix} F_+(x+y, t) + \int_{-\infty}^{\infty} B_+(x, z, t) F_+(x+y+z, t)\, dz.$$

From the definitions and the Marchenko equation, we get

$$\begin{aligned}\mathcal{G}_0(x, y, t) &= -\begin{bmatrix} 0 \\ 1 \end{bmatrix} G_+(x+y, t) - \int_{-\infty}^{\infty} B_+(x, z, t) G_+(x+y+z, t)\, dz \\ &= -\sum_{j=1}^{J} \left\{ \begin{bmatrix} 0 \\ f_{+j}(x+y, t) \end{bmatrix} + \int_{-\infty}^{\infty} B_+(x, z, t) f_{+j}(x+y+z, t)\, dz \right\},\end{aligned}$$

where

$$f_{+j}(x, t) := -2i \sum_{\mu=0}^{m(j)-1} \frac{1}{\mu!} c^+_{m(j)-1-\mu}(t) \left(\frac{d}{d\zeta}\right)^{\mu} \left[\frac{(\zeta-\zeta_j)^{m(j)}\, e^{2i\zeta x}}{a_+(\zeta)}\right]\Bigg|_{\zeta=\zeta_j}.$$

Now keep $y > 0$, as well as $x > 0$. Recall that $B_+(x, z, t) = 0$ when $z < 0$. Let $f_{+j}^{\sim}(x, t)$ be the result of cutting off f_{+j} with the characteristic function of $\mathbb{R}^+$. Careful analysis of $f_{+j}^{\sim}$ and contour integration in the manner of Tanaka [Ta] verifies that g_0 is meromorphic in the upper half plane, with poles exactly at the ζ_j with orders $m(j)$. Introduce the new functions

$$m_0(x, \zeta, t) := a_+(\zeta) g_0(x, \zeta, t),$$
$$\psi_0(x, \zeta, t) := e^{-i\zeta x} m_0(x, \zeta, t).$$

We will show that $m_0 = m_-$; hence $\psi_0 = \psi_-$.

Since the zeros of a_+ kill off the poles of g_0, the function m_0 is holomorphic in $\mathbb{H}$. Indeed, a detailed analysis shows that

$$m_0(x, \zeta, t) - \begin{bmatrix} 1 \\ 0 \end{bmatrix} \in \text{the Hardy space } H^{2+}, \text{provided that } x > 0.$$

Setting

$$C(x, y, t) := \pi^{-1} \mathcal{F}\left[m_0(x, \cdot, t) - \begin{bmatrix} 1 \\ 0 \end{bmatrix} \right](-y) \quad \text{for } y > 0,$$

we verify that

$$m_0(x, \cdot, t) - \begin{bmatrix} 1 \\ 0 \end{bmatrix} = \int_{-\infty}^{0} C(x, y, t)\, e^{-2i\xi y}\, dy.$$

To show that $m_0 = m_-$ it suffices to show that $C = B_-$. Since the left-hand Marchenko equation (5.4) has a unique solution, it suffices to show that C satisfies (5.4).

Careful computation using the properties of a_+, b_+, and g_0 leads to

$$-m_+(x, \xi, t)/a_+(\xi) = m_0^{\#}(x, \xi, t) + r_-(\xi, t)\, e^{-2i\xi x} m_0(x, \xi, t). \tag{5.12}$$

Taking a Fourier transform and evaluating the integrals by contour integration, we get

$$\begin{aligned}&-\sum_{j=1}^{J} 2i \operatorname{Res} \frac{m_+(x, \zeta)\, e^{-2i\zeta y \cdot}}{a_+(\zeta)} \quad \text{at } \zeta_j \\ &\quad = C^{\#}(x, y, t) + \begin{bmatrix} 1 \\ 0 \end{bmatrix} \Omega_-(x, z, t) + \int_{-\infty}^{0} C(x, z, t) \Omega_-(x+y+z, t)\, dz \\ &\quad\quad - \sum_{j=1}^{J} \left\{ \begin{bmatrix} 1 \\ 0 \end{bmatrix} f_{-j}(x+y, t) + \int_{-\infty}^{0} C(x, z, t) f_{-j}(x+y+z, t)\, dz \right\}.\end{aligned}$$

We will show that the jth terms of the sums are equal in order to conclude that C solves (5.4). It turns out that it suffices to prove that

$$\frac{1}{\alpha!}\psi_+^{(\alpha)}(x, \zeta_j, t) = \sum_{\lambda=0}^{\alpha} c_{j,\alpha-\lambda}^{-}\frac{1}{\lambda!}\psi_0^{(\lambda)}(x, \zeta_j, t) \quad \text{for all } \alpha \quad \text{with } 0<\alpha<m(j)-1. \tag{5.13}$$

Here the superscripts (α) and (λ) denote orders of differentiation with respect to ζ. Because of the conditions

$$\sum_{\lambda=\sigma}^{\nu} c_{j,\nu-\lambda}^{-} c_{j,\lambda-\sigma}^{+} = \begin{cases} 1 & \text{if } \sigma=\nu, \\ 0 & \text{if } \sigma<\nu, \end{cases}$$

on the normalizing chains, (5.13) is equivalent to the identity

$$\frac{1}{\gamma!}\psi_0^{(\gamma)}(x, \zeta_j, t) = \sum_{\beta=0}^{\gamma} c_{j,\gamma-\beta}^{+}\frac{1}{\beta!}\psi_+^{(\beta)}(x, \zeta_j, t). \tag{5.14}$$

Finally, the verification of (5.14) is a straightforward argument based on (5.12).

The proof of (5.8) is similar.

PROPOSITION 5.2. *If* $u_0 \in H^\alpha(\mathbb{R})$ *and* $(1+|x|^\alpha)u_0 \in L^2(\mathbb{R}) \cap L^1(\mathbb{R})$ *for an* α *with* $\frac{1}{4}<\alpha<\frac{1}{2}$, *then the map* $t \to u(\cdot, t)$ *is continuous from* $[0, \infty)$ *into* $L^2(\mathbb{R}) \cap L^4(\mathbb{R})$.

Proof. Here we use the representation (4.4) to show that the map $t \to u(\cdot, t)$ is continuous from $[0, \infty)$ into $L^2(\mathbb{R}^+) \cap L^4(\mathbb{R}^+)$. The proof for the other half-line is similar and uses Theorem 5.1.

It follows from Proposition 3.1 that the maps $t \to F_+(\cdot, t)$ and $t \to \Omega_+(\cdot, t)$ are continuous from $[0, \infty)$ into $H^\alpha(\mathbb{R}^+)$. By the Sobolev theorem, $H^\alpha(\mathbb{R}^+)$ is continuously included in $L^2(\mathbb{R}^+) \cap L^4(\mathbb{R}^+)$, and thus $t \to \Omega_+^*(\cdot, t)$ maps $[0, \infty)$ continuously into $L^2(\mathbb{R}^+) \cap L^4(\mathbb{R}^+)$.

We already know from the proof of Proposition 4.2 that the map $t \to \Omega_+^{t*}\Omega_x^t[B_+(x, \cdot, t)](0)$ is continuous from $[0, \infty)$ into $L^2(\mathbb{R}^+)$, and we know from the proof of Proposition 4.1 that this map is continuous from $[0, \infty)$ into $L^\infty(\mathbb{R}^+)$.

6. Verification that *u* solves the problem. In this section we show that the function $u(x, t) := -B_+(x, 0, t)$ constructed in § 4 solves the cubic Schrödinger equation (1.1) in the sense that

$$\iint u(x, t)\left\{i\varphi_t + \frac{1}{2}\varphi_{xx} + |u|^2\varphi\right\} dx\, dt = 0 \quad \text{for all } \varphi \in C_0^\infty(\mathbb{R} \times [0, \infty)). \tag{6.1}$$

We already know that the initial condition (1.2) is satisfied in the sense that

$$u(\cdot, t) \to u_0(\cdot) \quad \text{in } L^2_{\text{loc}}(\mathbb{R}) \quad \text{as } t \to 0^+. \tag{6.2}$$

Return to $r_+(\xi)$, the reflection coefficient of the initial profile $u_0(x)$. From Corollary 2.12, it follows that if $u_0 \in L^1(\mathbb{R}) \cap L^2(\mathbb{R}) \cap H^\alpha(\mathbb{R})$ for $\frac{1}{4}<\alpha<\frac{1}{2}$, then $r_+ \in L^2(\mathbb{R}) \cap C_0(\mathbb{R})$ and $|\xi|^\alpha r_+(\xi) \in L^2(\mathbb{R})$. It follows further that $r_+ \in L^{3/2}(\mathbb{R})$. By cutting off and convolving with an appropriate approximate identity, we can obtain a sequence $\{r_n(\xi)\colon n \in \mathbb{N}\}$ in $C_0^\infty(\mathbb{R})$ such that

$$\|r_n\|_{L^\infty(\mathbb{R})} \leqq \|r_+\|_{L^\infty(\mathbb{R})},$$

and

$$r_n \to r_+ \quad \text{in } L^p(\mathbb{R}) \quad \text{as } n \to +\infty \quad \text{for } p=\tfrac{3}{2}, 2, \text{and } \infty.$$

Now set

$$F_n(x, t) := \pi^{-1} \int_{-\infty}^{\infty} r_n(k)\, e^{2ik^2t+2ikx}\, dk.$$

These F_n all satisfy

$$iF_t - \tfrac{1}{2}F_{xx} = 0; \tag{6.3}$$

they all evolve in $L^2(\mathbb{R})$; and at $t=0$,

$$F_n(\cdot, 0) = \mathscr{F}^{-1}[r_n] \to \mathscr{F}^{-1}[r_+] = F_+(\cdot, 0) \quad \text{in } L^2(\mathbb{R}) \quad \text{as } n \to +\infty.$$

But the initial value problem for (6.3) is well posed in $L^2(\mathbb{R})$, so we also have

$$F_n(\cdot, t) \to F_+(\cdot, t) \text{ in } L^2(\mathbb{R}) \quad \text{as } n \to \infty \quad \text{for each } t \geqq 0.$$

Finally note that

$$F_n(x, t) = \mathscr{F}^{-1}[r_n(k) \exp(4ik^2t)]$$

and that

$$\|r_n(k) \exp(4ik^2t)\|_{L^\infty(\mathbb{R})} \leqq \|r_+\|_{L^\infty(\mathbb{R})}.$$

Define kernels $\Omega_n(x, t)$ by

$$\Omega_n(x, t) = F_n(x, t) - 2i \sum_1^J f_{+j}(x, t),$$

where the $f_{+j}(x, t)$ are the functions defined in (3.3b).

We define operators on $L^2(\mathbb{R}^+)$ by

$$F^t_{n,x}[g](y) := \int_0^\infty F_n(x+y+z, t) g(z)\, dz,$$

$$\Omega^t_{n,x}[g](y) := F^t_{n,x} - 2i \sum_1^J G^t_{jx},$$

where the G^t_{jx} were defined in § 4.

Tanaka, in [Ta], has shown that smooth solutions to (1.1) are obtained by setting

$$u_n(x, t) = -B_n(x, 0, t),$$

where B_n solves

$$(I + \Omega^{t*}_{n,x}\Omega^t_{n,x})[B_n(x, \cdot, t)] = \Omega^*_n(x + \cdot, t). \tag{6.4}$$

The remainder of this section shows how these smooth solutions u_n converge to u as $n \to +\infty$.

LEMMA 6.1. *$B_n(x, \cdot, t) \to B_+(x, \cdot, t)$ in $L^2(\mathbb{R}^+)$ as $n \to +\infty$, uniformly for $x \geqq X$ and $0 \leqq t < T$ for any positive X and T.*

Proof. The proof is straightforward.

PROPOSITION 6.2. *As $n \to +\infty$, $u_n \to u$ weakly; i.e.,*

$$\iint u_n(x, t)\varphi(x, t)\, dx\, dt \to \iint u(x, t)\varphi(x, t)\, dx\, dt \quad \textit{for all } \varphi \in C_0^\infty(\mathbb{R} \times [0, \infty)).$$

Proof. This proof is also straightforward.

THEOREM 6.3. *If $u_0 \in L^1 \cap L^2 \cap H^\alpha$ for $\frac{1}{4} < \alpha$, then u is a weak solution of* (1.1), (1.2) *in $t \geqq 0$.*

Proof. Consider a ψ from $C_0^\infty(\mathbb{R}\times[0,\infty))$. Since the u_n are smooth classical solutions of (1.1) and evolve in Schwartz class $\mathcal{S}$, we get

$$0=\iint u\left\{iu_{n,t}+\frac{1}{2}u_{n,xx}+|u_n|^2u_n\right\}\varphi\,dx\,dt$$
$$=\iint u\left\{i\varphi_t+\frac{1}{2}\varphi_{xx}+|u_n|^2\varphi\right\}dz\,dt$$

for each n and each φ in $C_0^\infty(\mathbb{R}\times[0,\infty))$. In light of Proposition 6.2 we get

$$\lim_{n\to\infty}\iint u_n\left\{i\varphi_t+\frac{1}{2}\varphi_{xx}\right\}dx\,dt=\iint u\left\{i\varphi_t+\frac{1}{2}\varphi_{xx}\right\}dx\,dt.$$

It remains to show that

$$\lim_{n\to\infty}\iint u_n|u_n|^2\varphi\,dx\,dt=\iint u|u|^2\varphi\,dx\,dt. \tag{6.5}$$

Set

$$\mathcal{M}_n(x,t)=\Omega^{t*}_{n,x}\Omega^{t}_{n,x}[B_n(x,\cdot,t)](0)$$

and

$$\mathcal{M}(x,t)=\Omega^{t*}_{x}\Omega^{t}_{x}[B(x,\cdot,t)](0).$$

Thus,

$$u_n(x,t)=\mathcal{M}_n(x,t)+\Omega^*_n(x,t)$$

and

$$u(x,t)=\mathcal{M}(x,t)+\Omega^*_+(x,t).$$

To prove (6.5) it suffices to prove that

$$u_n|u_n|^2-u|u|^2\to 0\quad\text{in } L^1_{\text{loc}}(\mathbb{R}\times[0,\infty)). \tag{6.6}$$

Now

$$u_n|u_n|^2-u|u|^2=(u_n-u)|u_n|^2+u(|u_n|^2-|u|^2)$$
$$=(u_n-u)|u_n|^2+u(|u_n|-|u|)(|u_n|+|u|).$$

So,

$$|u_n|u_n|^2-u|u|^2|\leqq|u_n-u|^3+3|u_n-u|^2|u|+3|u_n-u|\,|u|^2.$$

Pick any compact interval $I=[a,b]$ in the x-axis.

$$\int_a^b|u_n|u_n|^2-u|u|^2|\,dx$$
$$\leqq\int_a^b|u_n-u|^3\,dx+3\left(\int_a^b|u_n-u|^3\,dx\right)^{2/3}\left(\int_a^b|u|^3\,dx\right)^{1/3}$$
$$+3\left(\int_a^b|u_n-u|^3\,dx\right)^{1/3}\left(\int_a^b|u|^3\,dx\right)^{2/3}.$$

It will suffice to show that $u_n-u\to 0$ in $L^3_{\text{loc}}(\mathbb{R})$ uniformly on any compact time interval $[0,T]$. Now

$$u_n-u=\Omega_n-\Omega+\mathcal{M}_n-\mathcal{M}=F_n-F+\mathcal{M}_n-\mathcal{M}.$$

We already know that $\mathcal{M}_n-\mathcal{M}\to 0$ in $L^\infty(\mathbb{R}\times[0,\infty))$. It remains to have $F_n-F\to 0$ in $L^3(\mathbb{R})$ uniformly in t. By the Hausdorff-Young inequality, we get

$$\begin{aligned}\|F_n(\cdot,t)-F_n(\cdot,t)\|_{L^3(\mathbb{R})}&=\|\mathcal{F}^{-1}[r_n(\cdot,t)-r_+(\cdot,t)]\|_{L^3(\mathbb{R})}\\&\leqq\|\{r_n(k)-r_+(k)\}\,e^{4ik^3t}\|_{L^{3/2}(\mathbb{R})}\\&=\|r_n(k)-r_+(k)\|_{L^{3/2}(\mathbb{R})}.\end{aligned}$$

We know that $r_n(k)\to r_+(k)$ in $L^{3/2}(\mathbb{R})$. Thus $F_n(\cdot,t)-F_n(\cdot,t)\to 0$ in $L^3(\mathbb{R})$ uniformly in t. □

7. Examples of initial data satisfying the general hypotheses of the existence and uniqueness theorem. In this section we consider the problem (1.1), (1.2) with initial data of the form

$$u_0(x)=\begin{cases}A & \text{when } 0<x<X,\\ 0 & \text{otherwise,}\end{cases}\tag{7.1}$$

where A is a nonzero constant and X is positive. In order to apply the general theorem we need to compute the Jost functions for u_0 as potential in (1.4), determine when the (2.12) is satisfied, and determine the regularity of u_0.

The scattering problem is

$$\begin{aligned}\psi_{1,x}-u\psi_2&=-i\zeta\psi_1,\\ \psi_{2,x}+u^*\psi_1&=i\zeta\psi_2.\end{aligned}$$

The boundary conditions determining the Jost functions $\vec{\psi}_+$ and $\vec{\psi}_-$ are

$$\begin{bmatrix}\psi_{+1}\\ \psi_{+2}\end{bmatrix}\sim\begin{bmatrix}0\\ e^{i\zeta x}\end{bmatrix}\quad\text{as } x\to+\infty;\qquad\begin{bmatrix}\psi_{-1}\\ \psi_{-2}\end{bmatrix}\sim\begin{bmatrix}e^{i\zeta x}\\ 0\end{bmatrix}\quad\text{as } x\to-\infty.$$

We now compute $\vec{\psi}_+$. It is easy to see that

$$\vec{\psi}_+(x,\zeta)=\begin{bmatrix}0\\ e^{i\zeta x}\end{bmatrix}\quad\text{throughout } X<x<+\infty.$$

In $0<x<X$, the scattering ordinary differential equations become

$$\begin{aligned}\psi_{1,x}-A\psi_2&=-i\zeta\psi_1,\\ \psi_{2,x}-A^*\psi_1&=i\zeta\psi_2,\end{aligned}$$

whence

$$\psi_2=\psi_{1,x}+i\zeta\psi_1/A$$

and

$$\psi_{1,xx}+\{|A|^2+\zeta^2\}\psi_1=0.$$

For the moment, restrict attention to $\zeta=\xi\in\mathbb{R}$. Let $\mathcal{A}=\sqrt{|A|^2+\xi^2}$. We will see that it is not necessary to resolve the sign ambiguity in the square root. Writing

$$\psi_{+1}=a_m\,e^{i\mathcal{A}x}+b_m\,e^{-i\mathcal{A}x}$$

and matching boundary conditions at $x=X$, we find that

$$\psi_{+1}(x,\xi)=A\,e^{i\xi X}(x-X)\left[\frac{\sin[\mathcal{A}(x-X)]}{\mathcal{A}(x-X)}\right]$$

and

$$\psi_{+2}(x,\xi)=e^{i\xi X}\cos[\mathcal{A}(x-X)]+\xi\,e^{i\xi X}\left[\frac{\sin[\mathcal{A}(x-X)]}{\mathcal{A}(x-X)}\right].$$

Note that both ψ_{+1} and ψ_{+2} are, in fact, functions of $\mathcal{A}^2$; therefore, both are well defined despite any sign ambiguity in $\mathcal{A}$.

Now in $x<0$, $u_0(x)\equiv 0$ and ψ_{+1}, ψ_{+2} must have the form

$$\psi_{+1}(x,\xi)=\beta\,e^{i\xi X},$$

$$\psi_{+2}(x,\xi)=\alpha\,e^{i\xi X}.$$

Matching boundary conditions at $x=0$, we find that

$$\alpha=e^{i\xi X}[\cos(\mathcal{A}X)-i\xi\sin(\mathcal{A}X)/\mathcal{A}],$$

$$\beta=-A\,e^{i\xi X}\sin(\mathcal{A}X)/\mathcal{A}.$$

Now the scattering coefficients $a_+(\xi)$ and $b_+(\xi)$ are defined by

$$\vec{\psi}_-=a_+\psi_-^{\#}+b_+\psi_+.$$

It is easy to see that

$$\psi_-(x,\xi)\equiv\begin{bmatrix}e^{-i\xi x}\\0\end{bmatrix}\quad\text{if } x<0.$$

Thus we can determine a_+ and b_+ from α and β:

$$a_+=\frac{\alpha}{|\alpha|^2+|\beta|^2};\qquad b_+=\frac{\beta}{|\alpha|^2+|\beta|^2}.$$

It also turns out to be easy to confirm that $|\alpha|^2+|\beta|^2=1$ for all real ξ. The following results are now immediate.

PROPOSITION 7.1.

(i) *The only possible real zero of $a_+(\xi)$ is $\xi=0$.*

(ii) *Unless AX is an odd multiple of $\pi/2$, $a_+(\xi)$ has no real zeros at all.*

Observe that

$$u_0(x)\in H^{\alpha}(\mathbb{R})\quad \textit{for all } \alpha\quad \textit{with } 0<\alpha<\tfrac{1}{2}$$

and

$$|x|^{\alpha}u_0\in L^2(\mathbb{R})\cap L^1(\mathbb{R})\quad \textit{for } 0\leqq\alpha.$$

Thus by the existence and uniqueness results of §§ 5 *and* 6, *we get the following.*

THEOREM 7.2. *Let u_0 be a function of the form*

$$u_0(x)=\begin{cases}A & \textit{when } 0<x<X,\\ 0 & \textit{otherwise},\end{cases}$$

where $X>0$ and $0\neq A\in\mathbb{R}$. If AX is not an odd multiple of $\pi/2$, then there is a solution of (1.1), (1.2) *in the sense of the theorem stated in the Introduction.*

GENERALIZED SOLUTIONS TO THE KORTEWEG–DE VRIES AND THE REGULARIZED LONG-WAVE EQUATIONS*

H. A. BIAGIONI[†] AND M. OBERGUGGENBERGER[‡]

Abstract. In this article generalized solutions to two model equations describing nonlinear dispersive waves are studied. The solutions are found in certain algebras of new generalized functions containing spaces of distributions. On the one hand, this allows the handling of initial data with strong singularities. On the other hand, suitable scaling allows one to introduce an infinitesimally small coefficient; thereby the authors produce generalized solutions in the sense of Colombeau to the inviscid Burgers equation.

Key words. nonlinear dispersive waves, algebras of generalized functions, singular initial data, small dispersion limit

AMS(MOS) subject classifications. 35Q20, 35D05, 46F10, 35L65

1. Introduction.

The purpose of this paper is to study generalized solutions to the Korteweg–de Vries equation

$$u_t + uu_x + u_{xxx} = 0 \tag{1}$$

as well as to the so-called regularized long-wave equation

$$u_t + u_x + uu_x - u_{xxt} = 0 \tag{2}$$

(proposed and investigated by Benjamin, Bona, and Mahony in [2]; see also [5], [6]) in the framework of generalized functions introduced by Colombeau [9], [10].

This article is the second part of a program to obtain generalized solutions to hyperbolic conservation laws by adding a viscous or dispersive term that is associated with zero; see [4].

A soliton described by the KdV equation leads to an example of a nonzero solution to (1) in the Colombeau algebra $\mathcal{G}(I\!R \times [0,\infty))$ whose restriction to $t = 0$ is zero in $\mathcal{G}(I\!R)$. This shows that we do not have uniqueness of solutions to the Cauchy problem with initial data in $\mathcal{G}(I\!R)$ for the KdV equation in the algebra $\mathcal{G}(I\!R \times [0,\infty))$. Accordingly, we define new algebras of generalized functions, denoted by $\mathcal{G}_{p,q}(\Omega)$, where $1 \leq p, q \leq \infty$ and Ω is a domain in $I\!R^n$ with the cone property, whose elements have representatives with bounds taken in terms of the L^p-norms. If $\Omega = I\!R^n$, this algebra contains the space $W^{-\infty,p}(I\!R^n)$ and it has $W^{\infty,q}(I\!R^n)$ as a subalgebra, if $q \leq p$. The algebra $\mathcal{G}_{s,g}(\overline{\Omega})$, defined in [4], is the particular case where $p = q = \infty$, if Ω has the strong local Lipschitz property.

We prove that there exists a solution to (1) in $\mathcal{G}_{\infty,2}(I\!R \times (0,\infty))$, given initial data $g \in \mathcal{G}_{2,2}(I\!R)$. Further, for every $T > 0$, there is at most one solution in $\mathcal{G}_{2,2}(I\!R \times (0,T))$ such that its partial x-derivative has a logarithmic dependence on the regularization parameter.

For equation (2) we prove existence of solutions in $\mathcal{G}_{p,q}(\mathbb{R}\times(0,T))$ for each $T>0$, provided the initial data are in $\mathcal{G}_{p,q}(\mathbb{R})$ and have moderate H^1-bounds. There is at most one solution $u \in \mathcal{G}_{p,q}(\mathbb{R}\times(0,T))$ that is of "logarithmic-type" in the following cases: $q>2$ and $\frac{1}{p}+\frac{1}{q}\geq 1$; or $1\leq q\leq 2$ and $p<\infty$; or $1\leq q\leq 2$ and $p=\infty$ (in this last case a further decay requirement has to be imposed).

We prove also existence and uniqueness of solutions to

$$u_t + uu_x + \nu u_{xxx} = 0 \tag{3}$$

in $\mathcal{G}_{\infty,2}(\mathbb{R}\times(0,\infty))$ with initial data in $\mathcal{G}_{2,2}(\mathbb{R})$, where ν is a generalized constant. As a consequence, if ν is associated with zero and the initial data have a representative with the L^2-norm bounded independently of ε, then we obtain a solution to the conservation law

$$u_t + uu_x \approx 0, \tag{4}$$

written with association, which arises in the study of shock waves in Colombeau's setting. In particular, the generalized solution to (3) with classical initial data and ν associated with zero also satisfies (4), in spite of the fact that, according to the results of Lax and Levermore [11] and Venakides [15] on zero dispersion limits, its associated distribution will generally not be a weak solution to the conservation law $v_t + (\frac{1}{2}v^2)_x = 0$. Our setting also allows us to model "infinitely narrow solitons" in the sense of Maslov et al. [12], [13], as well as some source type solutions with zero impact at positive times.

2. The space $\mathcal{G}_{p,q}(\Omega)$.

2.1. Notation. In our notation concerning spaces of functions and distributions we follow Adams [1]. Thus for $\Omega\subset\mathbb{R}^n$ open, $m\in\mathbb{Z}$, and $1\leq p\leq\infty$, $W^{m,p}(\Omega)$ is the usual Sobolev space, $W^{\infty,p}(\Omega)=\cap_m W^{m,p}(\Omega)$, $W^{-\infty,p}(\Omega)=\cup_m W^{-m,p}(\Omega)$, $H^m(\Omega)=W^{m,2}(\Omega)$. If E is a Banach space, $C^j(\Omega;E)$ denotes the space of j-times continuously differentiable functions in Ω with values in E, $C^j_B(\Omega;E)$ those functions whose derivatives are bounded, in addition. For $E=\mathbb{R}$ we simply use $C^j_B(\Omega)$.

All functions and distribution spaces are assumed to be real valued in this paper.

Let $1\leq p,q\leq\infty$ and Ω an open subset of $\mathbb{R}^n$. We set

$$\begin{aligned}
\mathcal{E}[\Omega] &= \{u:(0,\infty)\times\Omega\to\mathbb{R} \text{ such that } u(\varepsilon,x) \text{ is } C^\infty \\
&\qquad \text{in the variable } x\in\Omega, \text{ for each } \varepsilon>0\};\\
\mathcal{E}_p[\Omega] &= \{u\in\mathcal{E}[\Omega] \text{ such that } u(\varepsilon,\cdot)\in W^{\infty,p}(\Omega) \text{ for all } \varepsilon>0\};\\
\mathcal{E}_{M,p}[\Omega] &= \{u\in\mathcal{E}_p[\Omega] \text{ such that for all } \alpha\in\mathbb{N}^n \text{ there is}\\
&\qquad N\in\mathbb{N} \text{ such that}\\
&\qquad \|\partial^\alpha u(\varepsilon,\cdot)\|_p = O(\varepsilon^{-N}) \text{ as } \varepsilon\to 0\}; \qquad (5)\\
\mathcal{N}_{p,q}(\Omega) &= \{u\in\mathcal{E}_{M,p}[\Omega]\cap\mathcal{E}_q[\Omega] \text{ such that for all } \alpha\in\mathbb{N}^n\\
&\qquad \text{and } M\in\mathbb{N},\\
&\qquad \|\partial^\alpha u(\varepsilon,\cdot)\|_q = O(\varepsilon^{M}) \text{ as } \varepsilon\to 0\}, \qquad (6)
\end{aligned}$$

where $\|\cdot\|_p$ denotes the L^p-norm.

Remarks 2.2. (i) If Ω has the strong local Lipschitz property and $u\in\mathcal{E}_p[\Omega]$, then $u(\varepsilon,\cdot)\in C^\infty(\overline{\Omega})$ for every ε. In particular, the sets $\mathcal{E}_{M,\infty}[\Omega]$ and $\mathcal{N}_{\infty,\infty}(\Omega)$ are, respectively, the same as $\mathcal{E}_{M,s,g}[\overline{\Omega}]$ and $\mathcal{N}_{s,g}(\overline{\Omega})$ defined in [4].

(ii) If $\Omega = \mathbb{R}^n$, $p < \infty$, and $u \in \mathcal{E}_p[\Omega]$ then, for every $\varepsilon > 0, \lim_{|x|\to\infty} u(\varepsilon, x) = 0$.

PROPOSITION 2.3. *Let Ω have the cone property. Then*

(i) *if* $p_1 \leq p_2$, $\mathcal{E}_{M,p_1}[\Omega] \subset \mathcal{E}_{M,p_2}[\Omega]$;

(ii) $\mathcal{E}_{M,p}[\Omega]$ *is an algebra with partial derivatives;*

(iii) $\mathcal{N}_{p,q}(\Omega)$ *is an ideal in* $\mathcal{E}_{M,p}[\Omega]$ *which is invariant under partial derivatives.*

Proof. (i) We have $\mathcal{E}_{M,p_1}[\Omega] \subset \mathcal{E}_{M,\infty}[\Omega]$. Indeed, by Sobolev's imbedding theorem [1, Chap. V], we have $W^{j+m,p_1}(\Omega) \subset C^j_B(\Omega)$ for all m such that $mp_1 > n$. Thus, given $j \in \mathbb{N}$ we have, for $u \in \mathcal{E}_{M,p_1}[\Omega]$,

$$\max_{|\alpha|\leq j} ||\partial^\alpha u(\varepsilon, \cdot)||_\infty \leq c \max_{|\beta|\leq m+j} ||\partial^\beta u(\varepsilon, \cdot)||_{p_1}.$$

Thus $u \in \mathcal{E}_{M,\infty}[\Omega]$.

Given $p_2 \geq p_1$, since $L^{p_1}(\Omega) \cap L^\infty(\Omega) \subset L^{p_2}(\Omega)$, we have, if $u \in \mathcal{E}_{M,p_1}[\Omega]$ and $\alpha \in \mathbb{N}^n$, $|\alpha| \leq j$,

$$\begin{aligned} ||\partial^\alpha u(\varepsilon, \cdot)||^{p_2}_{p_2} &= \int_\Omega |\partial^\alpha u(\varepsilon, x)|^{p_2-p_1} |\partial^\alpha u(\varepsilon, x)|^{p_1} dx \\ &\leq ||\partial^\alpha u(\varepsilon, \cdot)||^{p_2-p_1}_\infty ||\partial^\alpha u(\varepsilon, \cdot)||^{p_1}_{p_1} \\ &\leq c^{p_2-p_1} \max_{|\beta|\leq m+j} ||\partial^\beta u(\varepsilon, \cdot)||^{p_2-p_1}_{p_1} ||\partial^\alpha u(\varepsilon, \cdot)||^{p_1}_{p_1} \\ &\leq c^{p_2-p_1} \max_{|\beta|\leq m+j} ||\partial^\beta u(\varepsilon, \cdot)||^{p_2}_{p_1}. \end{aligned}$$

Thus $u \in \mathcal{E}_{M,p_2}[\Omega]$. The proofs of (ii) and (iii) follow from the fact that $\mathcal{E}_{M,p}[\Omega] \subset \mathcal{E}_{M,\infty}[\Omega]$. □

DEFINITION 2.4. We define, for $1 \leq p, q \leq \infty$,

$$\mathcal{G}_{p,q}(\Omega) = \mathcal{E}_{M,p}[\Omega]/\mathcal{N}_{p,q}(\Omega).$$

If Ω has the cone property, then it is clear from Proposition 2.3 that $\mathcal{G}_{p,q}(\Omega)$ is an algebra with partial derivatives.

PROPOSITION 2.5. *For $1 \leq p_1 \leq p_2 \leq \infty$ and $1 \leq q \leq \infty$ we have that*

$$\mathcal{G}_{p_1,q}(\Omega) \subset \mathcal{G}_{p_2,q}(\Omega).$$

Proof. Consider the commutative diagram

$$\begin{tikzcd} \mathcal{E}_{M,p_1}[\Omega] \arrow[r] & \mathcal{E}_{M,p_2}[\Omega] \\ \mathcal{N}_{p_1,q}(\Omega) \arrow[u] \arrow[r] & \mathcal{N}_{p_2,q}(\Omega). \arrow[u] \end{tikzcd}$$

The result follows from the fact that $\mathcal{N}_{p_2,q}(\Omega) \cap \mathcal{E}_{M,p_1}[\Omega] = \mathcal{N}_{p_1,q}(\Omega)$. □

Remark 2.6. It is not true that $\mathcal{G}_{p_1,p_1}(\Omega) \subset \mathcal{G}_{p_2,p_2}(\Omega)$ if $p_1 < p_2$, since $\mathcal{N}_{p_2,p_2}(\Omega) \cap \mathcal{E}_{M,p_1}[\Omega] \neq \mathcal{N}_{p_1,p_1}(\Omega)$ in general. We have, though, a canonical map $\mathcal{G}_{p_1,p_1}(\Omega) \to \mathcal{G}_{p_2,p_2}(\Omega)$, which, however, is not injective.

For example, it is simple to construct an element $u \in \mathcal{E}_{M,2}[\mathbb{R}] \cap \mathcal{N}_{\infty,\infty}(\mathbb{R})$, $u \notin \mathcal{N}_{2,2}(\mathbb{R})$ as follows: let $\tilde{u} : (0,\infty) \times \mathbb{R} \to [0,1]$ be such that $\tilde{u}(\varepsilon, x) \equiv 1$ for $|x| \leq \exp(\frac{2}{\varepsilon})$, $\tilde{u}(\varepsilon, x) \equiv 0$ for $|x| \geq 1 + \exp(\frac{2}{\varepsilon})$, $\tilde{u}(\varepsilon, \cdot) \in C^\infty(\mathbb{R})$, and all derivatives of $\tilde{u}(\varepsilon, \cdot)$ are bounded independently of ε, i.e., $||\tilde{u}^{(n)}(\varepsilon, \cdot)||_\infty \leq c_n$ for all $\varepsilon > 0$. Let

$u(\varepsilon, x) = \exp(-\frac{1}{\varepsilon})\tilde{u}(\varepsilon, x)$. We have, for $p \geq 2$,

$$2\exp\left(\frac{2}{\varepsilon}\right)\exp\left(-\frac{p}{\varepsilon}\right) \leq \int_{-\infty}^{\infty} |u(\varepsilon,x)|^p dx = \exp\left(-\frac{p}{\varepsilon}\right)\int_{|x|\leq 1+\exp(2/\varepsilon)} |\tilde{u}(\varepsilon,x)|^p dx$$

$$\leq \exp\left(-\frac{p}{\varepsilon}\right)\left(2+2\exp\left(\frac{2}{\varepsilon}\right)\right) = 2\exp\left(-\frac{p}{\varepsilon}\right) + 2\exp\left(\frac{2-p}{\varepsilon}\right),$$

and, if $n \geq 1$,

$$\int_{-\infty}^{\infty} |u^{(n)}(\varepsilon,x)|^p dx = \exp\left(-\frac{p}{\varepsilon}\right)\int_{-\infty}^{\infty} |\tilde{u}^{(n)}(\varepsilon,x)|^p dx \leq 2\exp\left(-\frac{p}{\varepsilon}\right) c_n^p.$$

These inequalities show that $u \in \mathcal{E}_{M,2}[\mathbb{R}] \cap \mathcal{N}_{p,p}(\mathbb{R})$ for every $p > 2$, but $u \notin \mathcal{N}_{2,2}(\mathbb{R})$.

THEOREM 2.7. (i) *There is an imbedding of* $W^{-\infty,p}(\mathbb{R}^n)$ *into* $\mathcal{G}_{p,q}(\mathbb{R}^n)$.

(ii) *If* $q \leq p$, *this imbedding turns* $W^{\infty,q}(\mathbb{R}^n)$ *into a subalgebra of* $\mathcal{G}_{p,q}(\mathbb{R}^n)$.

Proof. (i) Fix $\rho \in \mathcal{S}(\mathbb{R}^n)$ such that $\int_{\mathbb{R}^n} x^i \rho(x)dx = 0$ for all $i \in \mathbb{N}^n$, $|i| > 0$, and $\int_{\mathbb{R}^n} \rho(x)dx = 1$. Define

$$\iota : W^{-\infty,p}(\mathbb{R}^n) \rightarrow \mathcal{E}_p[\mathbb{R}^n] \tag{7}$$

by $\iota(w)(\varepsilon,x) = (w * \rho_\varepsilon)(x)$. Let us prove first that $\iota(w) \in \mathcal{E}_{M,p}[\mathbb{R}^n]$ for all $w \in W^{-\infty,p}(\mathbb{R}^n)$. There is $m \in \mathbb{N}$ such that $w \in W^{-m,p}$, so there exist $w_\alpha \in L^p(\mathbb{R}^n)$, $|\alpha| \leq m$, such that $w = \sum_{|\alpha|\leq m} \partial^\alpha w_\alpha$. Given $\beta \in \mathbb{N}^n$, we have by Young's inequality that

$$||\partial^\beta(w * \rho_\varepsilon)||_p \leq \sum_{|\alpha|\leq m} ||w_\alpha||_p ||\partial^{\alpha+\beta}\rho_\varepsilon||_1 = \sum_{|\alpha|\leq m} ||w_\alpha||_p \frac{1}{\varepsilon^{|\alpha+\beta|}} ||\partial^{\alpha+\beta}\rho||_1.$$

On the other hand, if $\iota(w) \in \mathcal{N}_{p,q}(\mathbb{R}^n)$, then $w * \rho_\varepsilon \rightarrow 0$ in $\mathcal{D}'(\mathbb{R}^n)$ as $\varepsilon \rightarrow 0$, so $w = 0$. It follows that ι imbeds $W^{-\infty,p}(\mathbb{R}^n)$ into $\mathcal{G}_{p,q}(\mathbb{R}^n)$.

(ii) Let $f \in W^{\infty,q}(\mathbb{R}^n)$. We show that $f * \rho_\varepsilon - f \in \mathcal{N}_{p,q}(\mathbb{R}^n)$ if $q \leq p$. We have

$$||f * \rho_\varepsilon - f||_q = \left(\int_{\mathbb{R}^n} |f * \rho_\varepsilon - f|^q dx\right)^{1/q}$$

$$= \left(\int_{\mathbb{R}^n} \left|\int_{\mathbb{R}^n} [f(x-\varepsilon y) - f(x)]\rho(y)dy\right|^q dx\right)^{1/q}.$$

By Taylor's formula up to order m applied to f, and since $\int y^\alpha \rho(y)dy = 0$ for $|\alpha| \leq m$, this in turn equals

$$\left(\int_{\mathbb{R}^n} \left|\sum_{|\alpha|=m+1} \int_{\mathbb{R}^n} \frac{(-\varepsilon y)^\alpha}{m!} \int_0^1 (1-\sigma)^m \partial^\alpha f(x - \sigma\varepsilon y) d\sigma \rho(y) dy\right|^q dx\right)^{1/q}$$

$$\leq C(m,q) \max_{|\alpha|=m+1} \left(\int_{\mathbb{R}^n} \left|\int_{\mathbb{R}^n} \frac{(-\varepsilon y)^\alpha}{m!} \rho(y) \int_0^1 (1-\sigma)^m \partial^\alpha f(x-\sigma\varepsilon y) d\sigma dy\right|^q dx\right)^{1/q}.$$

By the generalized Minkowski inequality, the last expression is estimated by

$$C(m,q) \max_{|\alpha|=m+1} \int_{\mathbb{R}^n} \left(\int_{\mathbb{R}^n} \left|\frac{(\varepsilon y)^\alpha}{m!} \rho(y) \int_0^1 (1-\sigma)^m \partial^\alpha f(x-\sigma\varepsilon y) d\sigma\right|^q dx\right)^{1/q} dy$$

$$\leq \frac{\varepsilon^{m+1}}{m!} C(m,q) \max_{|\alpha|=m+1} \int_{\mathbb{R}^n} |y^\alpha \rho(y)| \left(\int_{\mathbb{R}^n} \int_0^1 |\partial^\alpha f(x-\sigma\varepsilon y)|^q d\sigma dx\right)^{1/q} dy$$

$$\leq c\varepsilon^{m+1} \int_{\mathbb{R}^n} |y|^{m+1} |\rho(y)| dy \max_{|\alpha|=m+1} ||\partial^\alpha f||_q.$$

Thus we have, for every $m \in I\!N$ and small ε that

$$\|f * \rho_\varepsilon - f\|_q \leq c\varepsilon^m.$$

The same holds for all partial derivatives of f. Hence $f * \rho_\varepsilon - f \in \mathcal{N}_{p,q}(I\!R^n)$. □

DEFINITION 2.8. Let $u \in \mathcal{G}_{p,q}(I\!R \times (0,T))$. We define the *restriction of u to $I\!R \times \{0\}$* as follows: Let $\hat{u}$ be a representative of u. By Remark 2.2(i), $\hat{u}(\varepsilon,\cdot,\cdot) \in C^\infty(I\!R \times [0,T])$ for each $\varepsilon > 0$. Since the restriction map $W^{m+1,p}(I\!R \times (0,T)) \to W^{m,p}(I\!R)$ is continuous, we have that $\hat{u}(\varepsilon,\cdot,0)$ belongs to $\mathcal{E}_{M,p}[I\!R]$. Also, $\hat{u}(\varepsilon,\cdot,0) \in \mathcal{N}_{p,q}(I\!R)$ if $\hat{u} \in \mathcal{N}_{p,q}(I\!R \times (0,T))$. Thus we may define the restriction of u to $I\!R \times \{0\}$ as the class of $\hat{u}(\varepsilon,\cdot,0)$ in $\mathcal{G}_{p,q}(I\!R)$.

DEFINITION 2.9. We say that $u \in \mathcal{G}_{p,q}(\Omega)$ *is associated with the distribution* $w \in \mathcal{D}'(\Omega)$ if there is a representative $\hat{u}$ of u such that $\hat{u}(\varepsilon,\cdot) \to w$ in $\mathcal{D}'(\Omega)$ as $\varepsilon \to 0$. Notation: $u \approx w$.

DEFINITION 2.10. We say that $u \in \mathcal{G}_{p,q}(\Omega)$ is of *r-$\sqrt[j]{\log}$-type*, $r \geq p, j \geq 1$, if it has a representative $\hat{u} \in \mathcal{E}_{M,p}[\Omega]$ such that

$$\|\hat{u}(\varepsilon,\cdot)\|_r = O(\sqrt[j]{|\log\varepsilon|}) \quad \text{as } \varepsilon \to 0. \tag{8}$$

3. Generalized solutions to the KdV equation.

THEOREM 3.1. *Let $g \in \mathcal{G}_{2,2}(I\!R)$. Then there is a solution u of* (1) *in $\mathcal{G}_{\infty,2}(I\!R \times (0,\infty))$ such that*

$$u|_{t=0} = g \tag{9}$$

and, for every $T > 0$, $u|_{I\!R\times(0,T)} \in \mathcal{G}_{2,2}(I\!R \times (0,T))$.

Proof. Let $\hat{g} \in \mathcal{E}_{M,2}[I\!R]$ be a representative of g. Since $\hat{g}(\varepsilon,\cdot) \in H^\infty(I\!R)$ for each $\varepsilon > 0$, according to the existence theory of Bona and Smith [7, Thm. 3, p. 578], there is a unique solution $\hat{u}_\varepsilon$ of (1), with initial data $\hat{g}(\varepsilon,\cdot)$, which belongs to $\bigcap_{0\leq j\leq[s/3]} C_B^j([0,\infty); H^{s-3j}(I\!R))$ for arbitrary s. Observe that for every $m \in I\!N$ there is $s \in I\!N$ large enough such that

$$\bigcap_{0\leq j\leq[s/3]} C^j([0,T]; H^{s-3j}(I\!R)) \subset H^m(I\!R \times (0,T))$$

and

$$\bigcap_{0\leq j\leq[s/3]} C_B^j([0,\infty); H^{s-3j}(I\!R)) \subset C_B^m(I\!R \times [0,\infty)).$$

It follows that the solution thus constructed belongs to $H^\infty(I\!R \times (0,T))$ for every $T > 0$ as well as to $W^{\infty,\infty}(I\!R \times (0,\infty))$; in particular, the map $\hat{u} : (\varepsilon,x,t) \mapsto \hat{u}_\varepsilon(x,t)$ belongs to $\mathcal{E}_2[I\!R \times (0,T)] \cap \mathcal{E}_\infty[I\!R \times (0,\infty)]$. It remains to show that $\hat{u} \in \mathcal{E}_{M,\infty}[I\!R \times (0,\infty)] \cap \mathcal{E}_{M,2}[I\!R \times (0,T)]$. For this, it suffices to prove that for all $k \in I\!N$ there are $c > 0$ and $\eta > 0$ such that

$$\sup_{t\geq 0} \|\partial_x^k \hat{u}(\varepsilon,\cdot,t)\|_2 \leq \frac{c}{\varepsilon^N}, \qquad 0 < \varepsilon < \eta. \tag{10}$$

In fact, if we have (10), since $\hat{u}(\varepsilon,\cdot)$ satisfies (1), we get an analogous estimate for $\partial_t \hat{u}$ and then, by successive differentiations in the equation we get, for all $\alpha \in I\!N^2$,

$$\sup_{t\geq 0} \|\partial^\alpha \hat{u}(\varepsilon,\cdot,t)\|_2 \leq \frac{c}{\varepsilon^N}, \qquad 0 < \varepsilon < \eta.$$

Accordingly, this implies an analogous estimate for $||\partial^\alpha \hat{u}(\varepsilon,\cdot)||_{L^\infty(I\!R\times(0,\infty))}$ and $||\partial^\alpha \hat{u}(\varepsilon,\cdot)||_{L^2(I\!R\times(0,T))}$. Then the class of $\hat{u}$ will be an element of $\mathcal{G}_{\infty,2}(I\!R\times(0,\infty))$, a solution to (1),(9), whose restriction to any strip belongs to $\mathcal{G}_{2,2}(I\!R\times(0,T))$.

But inequality (10) is an immediate consequence of the following lemma, and the proof is completed.

LEMMA 3.2. *For every $k \in I\!N$ there is a polynomial P_k such that*

$$(11)\qquad ||\partial_x^k \hat{u}(\varepsilon,\cdot,t)||_2 \le P_k(||\hat{g}(\varepsilon,\cdot)||_2, ||\hat{g}'(\varepsilon,\cdot)||_2, \cdots, ||\hat{g}^{(k)}(\varepsilon,\cdot)||_2).$$

Proof. In order to simplify the notation we drop the ε and the "hat" on the representatives of u and g. By Miura, Gardner, and Kruskal [14], the KdV equation has a sequence of conserved quantities

$$(12)\qquad I_k(u) = \int_{-\infty}^{\infty} [(\partial_x^k u)^2 - c_k u(\partial_x^{k-1}u)^2 + Q_k(u,\partial_x u,\cdots,\partial_x^{k-2}u)]dx,$$

$k = 0,1,\cdots$ (here $\partial_x^{-1}u = \partial_x^{-2}u \equiv 0$), and Q_k is seen as a sum of monomials $u^{a_o}(\partial_x u)^{a_1}\cdots(\partial_x^{k-2}u)^{a_{k-2}}$ such that

$$(13)\qquad \sum_{i=0}^{k-2}\left(1+\frac{i}{2}\right)a_i = k+2.$$

We will prove the assertion by induction over k. For $k=0$ it is true since $I_o(u) = \int_{-\infty}^{\infty} u^2(x,t)dx$, i.e., $d/dt\int_{-\infty}^{\infty} u^2(x,t)dx = 0$ and $||u(\cdot,t)||_2 = ||g||_2$. Assume that (11) holds for $j \le k-1$. Thus also

$$(14)\qquad ||\partial_x^j u(\cdot,t)||_\infty \le R_j(||g||_2,\cdots,||g^{(j+1)}||_2), \qquad 0 \le j \le k-2.$$

By (12) we have

$$\int_{-\infty}^{\infty}(\partial_x^k u)^2 dx = \int_{-\infty}^{\infty}[c_k u(\partial_x^{k-1}u)^2 - Q_k(u,\partial_x u,\cdots,\partial_x^{k-2}u)]dx + C,$$

where, since $(d/dt)I_k(u) = 0$, $I_k(u) = I_k(g) = C$ for all $t \ge 0$. We have, by (14) for $j=0$ and the induction hypothesis,

$$\begin{aligned}\int_{-\infty}^{\infty}|u(\partial_x^{k-1}u)^2|dx &\le ||u||_\infty ||\partial_x^{k-1}u||_2^2\\ &\le R_o(||g||_2,||g'||_2)\left(P_{k-1}(||g||_2,\cdots,||g^{(k-1)}||_2)\right)^2.\end{aligned}$$

By (13) we have that, in all monomials of Q_k, $\sum_{j=0}^{k-2} a_j \ge 2$. Thus in each monomial we may take two factors and apply Hölder's inequality to them, while the other ones are estimated by the L^∞-norm. Thus

$$\begin{aligned}\int |Q_k(u,\ldots,\partial_x^{k-2}u)|dx &\le \tilde{Q}_k(||u||_\infty,\cdots,||\partial_x^{k-2}u||_\infty,||u||_2,\cdots,||\partial_x^{k-2}u||_2)\\ &\le \tilde{\tilde{Q}}_k(||g||_2,\cdots,||g^{(k-1)}||_2)\end{aligned}$$

by induction and by (14). Thus we have proved (11). □

Remark 3.3. Theorem 3.1 establishes the existence of a representative $\hat{u} \in \mathcal{E}_{M,2}[\mathbb{R} \times (0,T)]$. Since the ideal does not enter in the proof, we might as well infer that there exists a solution in $\mathcal{G}_{2,q}(\mathbb{R} \times (0,T))$ for every $T > 0$ and $q \geq 1$, if the initial data belong to $\mathcal{G}_{2,q}(\mathbb{R})$.

THEOREM 3.3. *Let $g \in \mathcal{G}_{2,2}(\mathbb{R})$. Then, for every $T > 0$ there is at most one solution $u \in \mathcal{G}_{2,2}(\mathbb{R} \times (0,T))$ of* (1), (9) *such that $\partial_x u$ is of ∞-log-type* (*see* 2.10).

Proof. Let $u_1, u_2 \in \mathcal{G}_{2,2}(\mathbb{R} \times (0,T))$ be two solutions to (1), (9) with respective representatives $\hat{u}_1, \hat{u}_2 \in \mathcal{E}_{M,2}[\mathbb{R} \times (0,T)]$ such that $\partial_x \hat{u}_i$ satisfies (8) with $r = \infty$, $j = 1$, $i = 1,2$. There are $N \in \mathcal{N}_{2,2}(\mathbb{R} \times (0,T))$ and $n \in \mathcal{N}_{2,2}(\mathbb{R})$ such that, setting $w = \hat{u}_1 - \hat{u}_2$, $h = \frac{1}{2}(\hat{u}_1 + \hat{u}_2)$:

$$\begin{aligned} [w_t + (hw)_x + w_{xxx}](\varepsilon,x,t) &= N(\varepsilon,x,t), \\ w(\varepsilon,x,0) &= n(\varepsilon,x). \end{aligned} \tag{15}$$

By changing representatives, we may assume that $n(\varepsilon, x) \equiv 0$. For simplicity we drop the ε in our notation. Multiplying (15) by w and integrating with respect to x, we obtain

$$\int_{-\infty}^{\infty} w\, w_t\, dx + \int_{-\infty}^{\infty} (hw)_x w\, dx + \int_{-\infty}^{\infty} w_{xxx} w\, dx = \int_{-\infty}^{\infty} w\, N\, dx.$$

By Remark 2.2 (ii) we get

$$\frac{1}{2}\frac{d}{dt}\int_{-\infty}^{\infty} w^2 dx + \frac{1}{2}\int_{-\infty}^{\infty} h_x w^2 dx = \int_{-\infty}^{\infty} wN dx.$$

Integrating from zero to $t \leq T$ we have, since $w(x,0) \equiv 0$,

$$\begin{aligned} \int_{-\infty}^{\infty} w^2(x,t)dx &= 2\int_0^t \int_{-\infty}^{\infty} w(x,\tau)N(x,\tau)dx\, d\tau \\ &\quad - \int_0^t \int_{-\infty}^{\infty} h_x(x,\tau)w^2(x,\tau)dx\, d\tau \\ &\leq 2||w||_{L^2(\mathbb{R}\times(0,T))}||N||_{L^2(\mathbb{R}\times(0,T))} \\ &\quad + ||h_x||_\infty \int_0^t \int_{-\infty}^{\infty} w^2(x,\tau)dx\, d\tau. \end{aligned}$$

By Gronwall's inequality, we get

$$||w(\cdot,t)||_2^2 \leq 2||w||_{L^2(\mathbb{R}\times(0,T))}||N||_{L^2(\mathbb{R}\times(0,T))} \exp(T||h_x||_\infty).$$

Since $w \in \mathcal{E}_{M,2}[\mathbb{R} \times (0,T)]$, $N \in \mathcal{N}_{2,2}(\mathbb{R} \times (0,T))$, and h_x is of ∞-log-type, it follows that, for every $M > 0$,

$$\sup_{t\in[0,T]} ||w(\cdot,t)||_2 = O(\varepsilon^M) \ \text{ as } \ \varepsilon \to 0.$$

For the x-derivatives, we get, by differentiation of (15):

$$\partial_x^k w_t + \partial_x^{k+1}(hw) + \partial_x^{k+3} w = \partial_x^k N.$$

Multiplying the above equation by $\partial_x^k w$ and integrating with respect to x we get

$$\int_{-\infty}^{\infty} \partial_x^k w_t\, \partial_x^k w\, dx + \int_{-\infty}^{\infty} \sum_{j=0}^{k+1} \binom{k+1}{j} \partial_x^{k+1-j} h\, \partial_x^j w\, \partial_x^k w\, dx \tag{16}$$

$$+\int_{-\infty}^{\infty} \partial_x^{k+3} w \, \partial_x^k w \, dx = \int_{-\infty}^{\infty} \partial_x^k N \, \partial_x^k w \, dx.$$

The third term on the left-hand side is zero and the second one equals

$$\left(k+\frac{1}{2}\right)\int_{-\infty}^{\infty} \partial_x h (\partial_x^k w)^2 dx + \int_{-\infty}^{\infty} \sum_{j=0}^{k-1} \binom{k+1}{j} \partial_x^{k+1-j} h \, \partial_x^j w \, \partial_x^k w \, dx.$$

Then (16) becomes

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int_{-\infty}^{\infty} (\partial_x^k w)^2 dx = &-\left(k+\frac{1}{2}\right)\int_{-\infty}^{\infty} \partial_x h (\partial_x^k w)^2 dx + \int_{-\infty}^{\infty} \partial_x^k N \, \partial_x^k w \, dx \\ &-\sum_{j=0}^{k-1} \binom{k+1}{j} \int_{-\infty}^{\infty} \partial_x^{k+1-j} h \, \partial_x^j w \, \partial_x^k w \, dx.\end{aligned}$$

Then we have, by integrating from zero to t:

$$\begin{aligned}\int_{-\infty}^{\infty} (\partial_x^k w)^2 dx \le\ & 2\left(k+\frac{1}{2}\right) ||\partial_x h||_\infty \int_0^t \int_{-\infty}^{\infty} (\partial_x^k w(x,s))^2 dx\, ds \\ &+2\int_0^t \int_{-\infty}^{\infty} |\partial_x^k N(x,s) \, \partial_x^k w(x,s)| dx\, ds \\ &+2\sum_{j=0}^{k-1} \binom{k+1}{j} \int_0^t \int_{-\infty}^{\infty} |\partial_x^{k+1-j} h \, \partial_x^k w \, \partial_x^j w| dx\, ds.\end{aligned}$$

The last two terms on the right-hand side can be estimated by

$$2\left[||\partial_x^k N||_2 ||\partial_x^k w||_2 + c\sum_{j=0}^{k-1} ||\partial_x^{k+1-j} h||_\infty ||\partial_x^k w||_2 \sup_{0\le t\le T} ||\partial_x^j w(\cdot,t)||_2 \right].$$

Then, if we assume that $\sup_t ||\partial_x^j w(\cdot,t)||_2 = O(\varepsilon^M)$ for any given $M > 0$ and $0 \le j < k$, we get, since all derivatives of h and w satisfy (5),

$$\sup_{0\le t\le T} ||\partial_x^k w(\cdot,t)||_2 \le c\varepsilon^M \exp[(2k+1)||\partial_x h||_\infty T].$$

Since $\partial_x h$ is of ∞-log-type we infer that $\sup_t ||\partial_x^k w(\cdot,t)||_2 = O(\varepsilon^M)$.

For the mixed derivatives the result follows from the equation, as in the proof of Theorem 3.1. □

Remark 3.5. If $g \in \mathcal{G}_{2,2}(\mathbb{R})$ is, together with g' and g'', of 2-$\sqrt[4]{\log}$-type, then the solution $u \in \mathcal{G}_{2,2}(\mathbb{R} \times (0,T))$ to (1),(9) is such that $\partial_x u$ is of ∞-log-type. In fact, since

$$||\partial_x \hat{u}(\varepsilon,\cdot,\cdot)||_\infty \le \sup_{0\le t\le T} (||\partial_x \hat{u}(\varepsilon,\cdot,t)||_2 + ||\partial_x^2 \hat{u}(\varepsilon,\cdot,t)||_2),$$

we need a logarithmic estimate on both $||\partial_x \hat{u}(\varepsilon,\cdot,t)||_2$ and $||\partial_x^2 \hat{u}(\varepsilon,\cdot,t)||_2$. Using the conserved quantities (12) for $k = 1, 2$, we get that

$$||\partial_x u||_2^2 \le \tfrac{1}{3}(||g||_2 + ||\partial_x u||_2)||g||_2^2 + ||g'||_2^2 + \tfrac{1}{3}||g||_2^3 + \tfrac{1}{3}||g'||_2||g||_2^2$$

and

$$||\partial_x^2 u||_2^2 \le c(||u||_2 + ||\partial_x u||_2)||\partial_x u||_2^2 + c(||u||_2 + ||\partial_x u||_2)^2||u||_2^2$$
$$+||g''||_2^2 + c(||g||_2 + ||g'||_2^2)||g'||_2^2 + c(||g||_2 + ||g'||_2)^2||g||_2^2.$$

Solving the quadratic inequality for $||\partial_x u||_2$ shows that the 2-$\sqrt[4]{\log}$-type of g, g' gives a 2-$\sqrt[2]{\log}$-estimate for $\partial_x u$. This, together with the hypotheses on g'', yields the 2-log-type of $\partial_x^2 u$, and so $\partial_x u$ is of ∞-log-type.

Remark 3.6. As noted in the Introduction, the solutions to the KdV equation are not unique in the algebra $\mathcal{G}_s(\mathbb{R} \times [0,\infty))$, as defined, e.g., in Biagioni [3]. This algebra is constructed in the same way as $\mathcal{G}_{\infty,\infty}$ but the bounds are only required to hold locally. For example, the generalized function u with a representative given by

$$\hat{u}(\varepsilon, x, t) = \frac{3}{\varepsilon}\ \mathrm{sech}^2\left[\frac{1}{2\sqrt{\varepsilon}}\left(x + \frac{1}{\varepsilon} - \frac{1}{\varepsilon}t\right)\right] \tag{17}$$

is a nonzero solution to (1) which belongs to $\mathcal{G}_s(\mathbb{R}\times(0,\infty))$, but its restriction to $t = 0$ is zero in $\mathcal{G}_s(\mathbb{R})$. Indeed, (17) defines a soliton described by the KdV equation (1), where $\frac{1}{\varepsilon}$ is the amplitude and the speed of the wave. At time $t = 0$, its peak is located at $x_o = -\frac{1}{\varepsilon}$. Introducing the notation $\psi(x) = \tanh(x)$, $\varphi(x) = \mathrm{sech}^2(x) = \psi'(x)$, we check immediately that each derivative of φ is of the form $\sum a_{mn}\psi^m\varphi^n$, where $m \ge 0$ and $n \ge 1$. Thus the absolute value of any derivative of $\hat{u}(\varepsilon,\cdot,0)$ is bounded by $c\varepsilon^{-j}|\varphi[\frac{1}{2\sqrt{\varepsilon}}(x + \frac{1}{\varepsilon})]|$ for some $j \in \mathbb{N}$ and some constant c. Since

$$\left|\varphi\left(\frac{1}{2\sqrt{\varepsilon}}\left(x + \frac{1}{\varepsilon}\right)\right)\right| \le \frac{1}{\cosh[(1/2\sqrt{\varepsilon})(x + \frac{1}{\varepsilon})]} \le \frac{1}{\cosh(1/\sqrt{\varepsilon})} \le 2\exp\left(-\frac{1}{\sqrt{\varepsilon}}\right)$$

for $x \ge -\frac{1}{\varepsilon} + 2$, we have that all derivatives of $\hat{u}(\varepsilon,\cdot,0)$ are bounded from above by any positive power of ε, uniformly for x in compact sets, as $\varepsilon \to 0$. Thus $u(\cdot,0)$ is zero in $\mathcal{G}_s(\mathbb{R})$. On the other hand, $\hat{u}(\varepsilon,0,1) = \frac{3}{\varepsilon} \to \infty$ as $\varepsilon \to 0$; thus u is not equal to zero in $\mathcal{G}_s(\mathbb{R} \times [0,\infty))$. □

Our last result in this section relates the generalized solution to the classical solution, if the latter exists.

PROPOSITION 3.7. *If $g \in H^2(\mathbb{R})$, then the solution to* (1), (9) *in* $\mathcal{G}_{2,2}(\mathbb{R}\times(0,T))$ *given in Theorem* 3.1 *is associated with the classical solution* $v \in C([0,T]; H^2(\mathbb{R}))$ *given by* [7], *Corollary* 2 *of Theorem* 8.

Proof. Consider the imbedding ι given in (7); the L^2-norms of $\iota(g)(\varepsilon,\cdot)$, $\iota(g')(\varepsilon,\cdot)$ and $\iota(g'')(\varepsilon,\cdot)$ are bounded independently of ε. By Remark 3.5 and Theorem 3.4, there is a unique solution $u \in \mathcal{G}_{2,2}(\mathbb{R} \times 0, T))$ to (1), with initial data the class of $\iota(g)$ in $\mathcal{G}_{2,2}(\mathbb{R})$.

By Theorem 3 in [7], there is a unique classical solution $\hat{u}_\varepsilon$ to (1) with initial data $\iota(g)(\varepsilon,\cdot)$, which is in $C([0,T]; H^\infty(\mathbb{R}))$. Our generalized solution u has, by construction, $\hat{u}_\varepsilon$ as a representative. Since $\iota(g)(\varepsilon,\cdot) \to g$ in $H^2(\mathbb{R})$ as $\varepsilon \to 0$, it follows from the continuous dependence result in [8] for the case $s = 2$ that the net $(\hat{u}_\varepsilon)$ converges to v in $C([0,T]; H^2(\mathbb{R}))$, hence also in $\mathcal{D}'(\mathbb{R} \times (0,T))$. □

4. Generalized solutions to the regularized long-wave equation.

THEOREM 4.1. *Let $g \in \mathcal{G}_{p,q}(\mathbb{R})$ have a representative $\hat{g} \in \mathcal{E}_{M,p}[\mathbb{R}]$ satisfying*

$$||\hat{g}(\varepsilon,\cdot)||_{1,2} = \left(\int_{-\infty}^{\infty} [\hat{g}(\varepsilon,x)^2 + \hat{g}'(\varepsilon,x)^2]dx\right)^{1/2} = O(\varepsilon^{-N}) \tag{18}$$

as $\varepsilon \to 0$ for some $N \in \mathbb{N}$. Then, for each $T > 0$ there is a solution $u \in \mathcal{G}_{p,q}(\mathbb{R} \times (0,T))$ to (2), (9).

Remarks 4.2. (i) Equation (18) is always satisfied if $p \leq 2$, since then $\mathcal{E}_{M,p}[\mathbb{R}]$ is contained in $\mathcal{E}_{M,2}[\mathbb{R}]$.

(ii) The solutions constructed in Theorem 4.1 for different T are consistent, i.e., if u_T is the solution on the strip $\mathbb{R} \times (0,T)$ and $T_1 < T_2$, then $u_{T_2}|_{\mathbb{R}\times(0,T_1)} = u_{T_1}$. This will follow from the proof below.

Proof of 4.1. For ε small enough, $\hat{g}(\varepsilon,\cdot) \in C^\infty(\mathbb{R})$ satisfies the hypotheses of Theorem 1 in [2]. Thus there is $u_\varepsilon \in C^\infty_B(\mathbb{R} \times [0,T])$, which solves (2) and satisfies $u_\varepsilon(x,0) = \hat{g}(\varepsilon,x)$ for all $x \in \mathbb{R}$, and, for any $t \geq 0$,

$$\|u_\varepsilon(\cdot,t)\|_{1,2} = \|\hat{g}(\varepsilon,\cdot)\|_{1,2}. \tag{19}$$

This, together with (18), implies that, for every $r \in [2,\infty]$,

$$\|u_\varepsilon(\cdot,t)\|_r = O(\varepsilon^{-N}) \tag{20}$$

as $\varepsilon \to 0$. In particular, in the case $p \geq 2$,

$$\|u_\varepsilon(\cdot,t)\|_p = O(\varepsilon^{-N}). \tag{21}$$

We wish to show that (21) is true in the case $1 \leq p < 2$ also. A simple calculation [2, p. 58] shows that u_ε satisfies the integral equation

$$u_\varepsilon(x,t) = \hat{g}(\varepsilon,x) + \int_0^t \int_{-\infty}^\infty K(x-\xi)\left[u_\varepsilon(\xi,\tau) + \frac{1}{2}u_\varepsilon^2(\xi,\tau)\right] d\xi d\tau, \tag{22}$$

where

$$K(x) = \tfrac{1}{2}\,\mathrm{sgn}\, x\, \exp(-|x|).$$

Fixing $R > 0$ and integrating (22), we obtain

$$\begin{aligned}\left(\int_{-R}^R |u_\varepsilon(x,t)|^p dx\right)^{1/p} &\leq \left(\int_{-\infty}^\infty |\hat{g}(\varepsilon,x)|^p dx\right)^{1/p} \\ &\quad + \left(\int_{-R}^R \left|\int_0^t \int_{-\infty}^\infty K(\xi) u_\varepsilon(x-\xi,\tau) d\xi d\tau\right|^p dx\right)^{1/p} \\ &\quad + \frac{1}{2}\left(\int_{-R}^R \left|\int_0^t \int_{-\infty}^\infty K(\xi) u_\varepsilon^2(x-\xi,\tau) d\xi d\tau\right|^p dx\right)^{1/p}.\end{aligned}$$

By the generalized Minkowski inequality, this is estimated by

$$\begin{aligned}&\|\hat{g}(\varepsilon,\cdot)\|_p + \int_0^t \int_{-\infty}^\infty |K(\xi)| \left(\int_{-R-\xi}^{R-\xi} |u_\varepsilon(z,\tau)|^p dz\right)^{1/p} d\xi\, d\tau \\ &\quad + \frac{1}{2}\int_0^t \int_{-\infty}^\infty |K(\xi)| \left(\int_{-\infty}^\infty |u_\varepsilon(x-\xi,\tau)|^{2p} dx\right)^{1/p} d\xi\, d\tau \\ &\leq \|\hat{g}(\varepsilon,\cdot)\|_p + \int_0^t \int_{-\infty}^\infty |K(\xi)| d\xi \left(\int_{-R}^R |u_\varepsilon(z,\tau)|^p dz\right)^{1/p} d\tau \\ &\quad + \int_0^t \int_{-\infty}^\infty |K(\xi)| \left|\int_{-R-\xi}^{-R} |u_\varepsilon(z,\tau)|^p dz - \int_{R-\xi}^R |u_\varepsilon(z,\tau)|^p dz\right|^{1/p} d\xi\, d\tau \\ &\quad + \frac{1}{2}T \int_{-\infty}^\infty |K(\xi)| d\xi \cdot \frac{c}{\varepsilon^N}.\end{aligned}$$

(Here we have used (20), noting that $2p \geq 2$, as well as the inequality $|a+b|^{1/p} \leq |a|^{1/p} + |b|^{1/p}$.) Thus

$$\begin{aligned}\left(\int_{-R}^{R} |u_\varepsilon(x,t)|^p dx\right)^{1/p} &\leq ||\hat{g}(\varepsilon,\cdot)||_p + \int_0^t \left(\int_{-R}^{R} |u_\varepsilon(x,\tau)|^p dx\right)^{1/p} d\tau \\ &\quad + 2^{1/p} T ||u_\varepsilon||_\infty \int_{-\infty}^{\infty} |\xi|^{1/p} |K(\xi)| d\xi + \frac{1}{2} T \frac{c}{\varepsilon^N} \\ &\leq \frac{c'}{\varepsilon^N} + \int_0^t \left(\int_{-R}^{R} |u_\varepsilon(x,\tau)|^p dx\right)^{1/p} d\tau.\end{aligned}$$

By Gronwall's inequality, we obtain

$$\left(\int_{-R}^{R} |u_\varepsilon(x,t)|^p dx\right)^{1/p} \leq \frac{c'}{\varepsilon^N} \exp(T).$$

This holds uniformly in $R > 0$ and $0 \leq t \leq T$. It follows that $u_\varepsilon(\cdot,t) \in L^p(I\!R)$, and (21) holds also in the case $1 \leq p < 2$.

In order to prove (5) for the derivatives of u_ε, we differentiate (22). Thus

$$\partial_t u_\varepsilon(x,t) = [K * (u_\varepsilon + \tfrac{1}{2}u_\varepsilon^2)(\cdot,t)](x).$$

We have that $v_\varepsilon(\cdot,t) := (u_\varepsilon + \frac{1}{2}u_\varepsilon^2)(\cdot,t)$ belongs to $H^1(I\!R)$ and

$$||v_\varepsilon(\cdot,t)||_{1,2} \leq ||u_\varepsilon(\cdot,t)||_{1,2} + c||u_\varepsilon(\cdot,t)||_{1,2}^2. \tag{23}$$

Before going on, let us collect a few useful relations in a lemma.

LEMMA 4.2. *If* $u \in H^1(I\!R)$, *then*

(a) $(K * u)'(x) = u(x) + (E * u)(x)$, *where* $E(x) = -\frac{1}{2}\exp(-|x|)$;

(b) $(E * u)' = K * u$;

(c) $K * u \in H^1(I\!R)$ *and* $||K * u||_{1,2} \leq \sqrt{5}||u||_2$;

(d) $E * u \in H^1(I\!R)$ *and* $||E * u||_{1,2} \leq \sqrt{2}||u||_2$.

These assertions follow from the fact that E is a fundamental solution of $\partial_x^2 - 1$ and $\partial_x E = K$, as well as Young's inequality.

Proof. Going on with the proof of the theorem, we see from Lemma 4.3 (c) that $\partial_t u_\varepsilon(\cdot,t) \in H^1(I\!R)$ and

$$||\partial_t u_\varepsilon(\cdot,t)||_{1,2} \leq \sqrt{5}(||u_\varepsilon(\cdot,t)||_{1,2} + c||u_\varepsilon(\cdot,t)||_{1,2}^2).$$

Employing (20) with $r = p$ and $r = \infty$, we see that

$$||v_\varepsilon(\cdot,t)||_p = O(\varepsilon^{-N})$$

as $\varepsilon \to 0$, and so also

$$||\partial_t u_\varepsilon(\cdot,t)||_p = O(\varepsilon^{-N})$$

uniformly in $0 \leq t \leq T$. For the mth derivatives ($m = 2, 3, \cdots$) with respect to t, we have

$$\begin{aligned}\partial_t^m u_\varepsilon(x,t) &= [K * \partial_t^{m-1} v_\varepsilon(\cdot,t)](x) \\ &= K * \left[\partial_t^{m-1} u_\varepsilon(\cdot,t) + \sum_{k=0}^{m-2} \binom{m-2}{k} \partial_t^k u_\varepsilon \partial_t^{m-1-k} u_\varepsilon\right](x).\end{aligned} \tag{24}$$

Assuming that, for $k < m$, $\partial_t^k u_\varepsilon(\cdot,t) \in H^1(\mathbb{R})$ and $||\partial_t^k u_\varepsilon(\cdot,t)||_{1,2} \leq c\varepsilon^{-N}$, Lemma 4.3 and the fact that $H^1(\mathbb{R})$ is an algebra imply the same for $\partial_t^m u_\varepsilon(\cdot,t)$. So, if $p \geq 2$, $\partial_t^m u_\varepsilon(\cdot,t) \in L^p(\mathbb{R})$ and

$$||\partial_t^m u_\varepsilon(\cdot,t)||_p = O(\varepsilon^{-N}). \tag{25}$$

If $1 \leq p < 2$, assuming that, for $k \leq m-1$, $||\partial_t^k u_\varepsilon(\cdot,t)||_p = O(\varepsilon^{-N})$, we have from the inclusion $W^{1,p}(\mathbb{R}) \subset L^\infty(\mathbb{R})$ that $||\partial_t^\ell u_\varepsilon(\cdot,t)||_\infty = O(\varepsilon^{-N})$ for $\ell \leq m-2$. Then the L^p-norm of $\partial_t^{m-1} v_\varepsilon(\cdot,t)$ is less than or equal to

$$||\partial_t^{m-1} u_\varepsilon(\cdot,t)||_p + \sum_{k=0}^{m-2} \binom{m-2}{k} ||\partial_t^k u_\varepsilon||_\infty ||\partial_t^{m-1-k} u_\varepsilon||_p,$$

and thus we get (25) for $1 \leq p < 2$.

For the x-derivatives of u_ε we have, from (22) and Lemma 4.3 (a),

$$\partial_x u_\varepsilon(x,t) = \hat{g}'(\varepsilon,x) + \int_0^t v_\varepsilon(x,\tau)d\tau + \int_0^t (E * v_\varepsilon(\cdot,\tau))d\tau,$$

and for $m \geq 2$, again using (22) and Lemma 4.3 (b),

$$\begin{aligned} \partial_x^m u_\varepsilon(x,t) = \hat{g}^{(m)}(\varepsilon,x) + \int_0^t \partial_x^{m-1} v_\varepsilon(x,\tau)d\tau \\ + \partial_x^{m-2} u_\varepsilon(x,t) - \hat{g}^{(m-2)}(\varepsilon,x). \end{aligned} \tag{26}$$

Since $\hat{g} \in \mathcal{E}_{M,p}[\mathbb{R}]$ and $v_\varepsilon(\cdot,t) \in L^p(\mathbb{R})$, by induction as above we get $||\partial_x^m u_\varepsilon(\cdot,t)||_p = O(\varepsilon^{-N})$, uniformly in $0 \leq t \leq T$.

Let us prove (5) now for the mixed derivatives $\partial_t^n \partial_x^m u_\varepsilon$. For $n = 1$, from (26), we obtain

$$\begin{aligned} \partial_t \partial_x^m u_\varepsilon &= \partial_x^{m-1} v_\varepsilon + \partial_t \partial_x^{m-2} u_\varepsilon \\ &= \begin{cases} \partial_x^{m-1} v_\varepsilon + \partial_x^{m-3} v_\varepsilon + \ldots + \partial_x v_\varepsilon + K * v_\varepsilon & \text{if } m \text{ is even} \\ \partial_x^{m-1} v_\varepsilon + \partial_x^{m-3} v_\varepsilon + \ldots + \partial_x^2 v_\varepsilon + v_\varepsilon + E * v_\varepsilon & \text{if } m \text{ is odd.} \end{cases} \end{aligned} \tag{27}$$

Since $||\partial_x^k v_\varepsilon(\cdot,t)||_p = O(\varepsilon^{-N})$ for all k, we get the same for $||\partial_t \partial_x^m u_\varepsilon(\cdot,t)||_p$.

Noting that this implies a similar estimate for $||\partial_t \partial_x^m v_\varepsilon(\cdot,t)||_p$ as well, we can now differentiate (27) again with respect to t and obtain that

$$||\partial_t^2 \partial_x^m u_\varepsilon(\cdot,t)||_p = O(\varepsilon^{-N}),$$

and so on. This completes the proof of the estimate

$$||\partial^\alpha u_\varepsilon(\cdot,t)||_p = O(\varepsilon^{-N})$$

for every $\alpha \in \mathbb{N}^2$, uniformly in $0 \leq t \leq T$.

Since $||\partial^\alpha u_\varepsilon||_{L^p(\mathbb{R}\times(0,T))} \leq T^{1/p} \sup_{0\leq t\leq T} ||\partial^\alpha u_\varepsilon(\cdot,t)||_p$, we get $\hat{u}(\varepsilon,x,t) := u_\varepsilon(x,t)$ in $\mathcal{E}_{M,p}[\mathbb{R} \times (0,T)]$, and its class in $\mathcal{G}_{p,q}(\mathbb{R} \times (0,T))$ is a solution of (2), (9). □

THEOREM 4.3. (a) *Let* $1 \leq q \leq 2$, $g \in \mathcal{G}_{\infty,q}(\mathbb{R})$, *and* $T > 0$. *Then there exists at most one solution* $u \in \mathcal{G}_{\infty,q}(\mathbb{R} \times (0,T))$ *to* (2), (9) *which is of* ∞*-log-type and has a representative* $\hat{u}$ *such that*

$$\lim_{|x|\to\infty} \hat{u}(\varepsilon,x,t) = 0 \tag{28}$$

for every $\varepsilon > 0$ *and almost all* t, $0 \le t \le T$.

(b) *In particular, if* $1 \le q \le 2$, $1 \le p < \infty$, *and* $g \in \mathcal{G}_{p,q}(I\!R)$, *then there exists at most one solution* $u \in \mathcal{G}_{p,q}(I\!R \times (0,T))$ *to* (2), (9) *which is of* ∞*-log-type.*

(c) *If* $q > 2$, $\frac{1}{p} + \frac{1}{q} \ge 1$, *and* $g \in \mathcal{G}_{p,q}(I\!R)$, *then there exists at most one solution* $u \in \mathcal{G}_{p,q}(I\!R \times (0,T))$ *which is of* ∞*-log-type.*

Proof. We note first that (a) implies (b) since if there are two solutions to (2), (9), $u_1, u_2 \in \mathcal{G}_{p,q}(I\!R \times (0,T))$ which are of ∞-log-type, then all representatives $\hat{u}_1, \hat{u}_2 \in \mathcal{E}_{M,p}[I\!R \times (0,T)]$ satisfy (28). Thus, by (a), $\hat{u}_1 - \hat{u}_2 \in \mathcal{N}_{\infty,q}(I\!R \times (0,T))$, and so $\hat{u}_1 - \hat{u}_2 \in \mathcal{N}_{p,q}(I\!R \times (0,T))$ as well.

Also, in (c) we may assume that $\frac{1}{p} + \frac{1}{q} = 1$. Indeed, if $\frac{1}{p} + \frac{1}{q} \ge 1$ and $u \in \mathcal{G}_{p,q}$, then $u \in \mathcal{G}_{\tilde{p},q}$ for all $\tilde{p} \ge p$, in particular for $\tilde{p} = (1 - \frac{1}{q})^{-1}$.

Let $u_1, u_2 \in \mathcal{G}_{p,q}(I\!R \times (0,T))$ be two solutions of (2),(9) with respective representatives $\hat{u}_1, \hat{u}_2 \in \mathcal{E}_{M,p}[I\!R \times (0,T)]$ satisfying (28) and (8) with $r = \infty$ and $j = 1$. There are $n_1 \in \mathcal{N}_{p,q}(I\!R \times (0,T))$ and $n_2 \in \mathcal{N}_{p,q}(I\!R)$ such that, if $w = \hat{u}_1 - \hat{u}_2$,

$$\begin{aligned} \left\{w_t + w_x + \tfrac{1}{2}[(\hat{u}_1 + \hat{u}_2)w]_x - w_{xxt}\right\}(\varepsilon,x,t) &= n_1(\varepsilon,x,t), \\ w(\varepsilon,x,0) &= n_2(\varepsilon,x). \end{aligned} \tag{29}$$

By a change of representatives we can assume $n_2 \equiv 0$. Multiplying (29) by w and integrating from $-R$ to R, we obtain

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}\int_{-R}^{R}(w^2 + w_x^2)dx = &\left[w_{xt}w - \frac{1}{2}w^2 - \frac{1}{2}(\hat{u}_1 + \hat{u}_2)w^2\right]_{x=-R}^{x=R} \\ &+\frac{1}{2}\int_{-R}^{R}(\hat{u}_1 + \hat{u}_2)ww_x dx + \int_{-R}^{R} wn_1 dx. \end{aligned}$$

Thus

$$\begin{aligned} \int_{-R}^{R}(w^2 + w_x^2)dx \le 2\int_0^T &\left[w_{xt}w - \frac{1}{2}w^2 - \frac{1}{2}(\hat{u}_1 + \hat{u}_2)w^2\right]_{x=-R}^{x=R} d\tau \\ &+\int_0^t\int_{-R}^{R}(\hat{u}_1 + \hat{u}_2)w\, w_x\, dx\, d\tau \\ &+2\int_0^t\int_{-R}^{R} w\, n_1\, dx\, d\tau. \end{aligned}$$

If $\frac{1}{p} + \frac{1}{q} = 1$, then

$$\int_0^T\int_{-R}^{R}|wn_1|dx\, d\tau \le ||w||_p||n_1||_q;$$

if $p = \infty$ and $1 \le q \le 2$, since $\mathcal{N}_{p,q} \subset \mathcal{N}_{p,2}$ we have

$$\begin{aligned} \int_0^t\int_{-R}^{R}|wn_1|dx\, d\tau &\le \int_0^t\left(\int_{-R}^{R}w^2dx\right)^{1/2}\left(\int_{-\infty}^{\infty}n_1^2(x,\tau)dx\right)^{1/2}d\tau \\ &\le \int_0^t\left(1 + \int_{-R}^{R}w^2(x,\tau)dx\right)||n_1||_2 d\tau. \end{aligned}$$

We have used the estimate $\sqrt{a} \le 1 + a$ in the last inequality. We end up with

$$\int_{-R}^{R}(w^2+w_x^2)(x,t)dx \le 2\int_0^T \left[w_{xt}w - \frac{1}{2}w^2 - \frac{1}{2}(\hat{u}_1+\hat{u}_2)w^2\right]_{x=-R}^{x=R} d\tau$$
$$+\begin{cases} ||\hat{u}_1+\hat{u}_2||_\infty \int_0^t\int_{-R}^R (w^2+w_x^2)(x,\tau)d\tau + 2||w||_p||n_1||_q \\ \text{or} \\ (||\hat{u}_1+\hat{u}_2||_\infty + 2||n_1||_2)\int_0^t\int_{-R}^R(w^2+w_x^2)(x,\tau)d\tau + 2T||n_1||_2\,. \end{cases}$$

Here the first line applies to the case $\frac{1}{p}+\frac{1}{q}=1$, while the second applies to $p=\infty, 1\le q\le 2$. In any case, Gronwall's inequality gives that

$$\int_{-R}^{R}(w^2+w_x^2)(x,t)dx \le \left\{2\int_0^T \left[w_{xt} - \frac{1}{2}w^2 - \frac{1}{2}(\hat{u}_1+\hat{u}_2)w^2\right]_{x=-R}^{x=R} d\tau \right.$$
$$\left. + \begin{bmatrix} 2||w||_p||n_1||_q \\ \text{or} \\ 2T||n_1||_2 \end{bmatrix}\right\} \exp T \begin{bmatrix} ||\hat{u}_1+\hat{u}_2||_\infty \\ \text{or} \\ ||\hat{u}_1+\hat{u}_2||_\infty + 2||n_1||_2 \end{bmatrix}.$$

This estimate holds for $0\le t\le T$ and $R>0$. In particular, we may let $R\to\infty$ and obtain, since $w(\varepsilon,\cdot,t)\to 0$ as $|x|\to\infty$,

$$||w(\cdot,t)||_{1,2} \le \begin{bmatrix} 2||w||_p||n_1||_q \\ \text{or} \\ 2T||n_1||_2 \end{bmatrix} \exp(||\hat{u}_1+\hat{u}_2||_\infty + 2)T.$$

Introducing the dependence on ε again, we obtain from (8) that

$$||w(\varepsilon,\cdot,t)||_{1,2} = O(\varepsilon^M)$$

for every M, uniformly in $0\le t\le T$.

Thus it is clear that $||w(\varepsilon,\cdot,t)||_\infty = O(\varepsilon^M)$ as well. In order to go on with case (c), we want to show that actually $||w(\varepsilon,\cdot,t)||_q = O(\varepsilon^M)$ for every $M\in I\!N$. The following identity is derived similar to (22):

$$w(\varepsilon,x,t) = \int_0^t\int_{-\infty}^{\infty} K(\xi)\left[1+\frac{1}{2}(\hat{u}_1+\hat{u}_2)\right] w(\varepsilon,x-\xi,\tau)d\xi\, d\tau$$
$$-\int_0^t\int_{-\infty}^{\infty} E(x-\xi)n_1(\xi,\tau)d\xi\, d\tau. \tag{30}$$

Thus, setting $A = 1+\frac{1}{2}||\hat{u}_1(\varepsilon,\cdot)||_\infty + \frac{1}{2}||\hat{u}_2(\varepsilon,\cdot)||_\infty$,

$$\left(\int_{-R}^{R}|w(\varepsilon,x,t)|^q dx\right)^{1/q} \le A\left(\int_{-R}^{R}\left|\int_0^t\int_{-\infty}^{\infty}K(\xi)w(\varepsilon,x-\xi,\tau)d\xi d\tau\right|^q dx\right)^{1/q}$$
$$+\left(\int_{-R}^{R}\left|\int_0^t[E*n_1(\varepsilon,\cdot,\tau)](x)d\tau\right|^q dx\right)^{1/q}$$
$$\le A\int_0^t\int_{-\infty}^{\infty}\left(\int_{-R}^{R}|K(\xi)w(\varepsilon,x-\xi,\tau)|^q dx\right)^{1/q} d\xi\, d\tau$$
$$+\int_0^t ||E*n_1(\varepsilon,\cdot,\tau)||_q d\tau.$$

We have used the generalized Minkowski inequality in both terms. Now we will use Young's inequality and Hölder's inequality in the second term. The first term has already been calculated in the proof of Theorem 4.1 with u_ε instead of $w(\varepsilon,\cdot)$. Thus the last expression is estimated by

$$\begin{aligned}
&\leq A\Big(\int_0^t \Big(\int_{-R}^{R} |w(\varepsilon,x,\tau)|^q dx\Big)^{1/q} d\tau + 2^{1/q}T||w(\varepsilon,\cdot)||_\infty \int_{-\infty}^{\infty} |\xi|^{1/q}|K(\xi)|d\xi\Big) \\
&\quad + t^{1/p}||n_1(\varepsilon,\cdot)||_q \\
&\leq T^{1/p}||n_1(\varepsilon,\cdot)||_q + cT||w(\varepsilon,\cdot)||_\infty + A\int_0^t \Big(\int_{-R}^{R} |w(\varepsilon,x,\tau)|^q dx\Big)^{1/q} d\tau\ .
\end{aligned}$$

From Gronwall's inequality,

$$\Big(\int_{-R}^{R} |w(\varepsilon,x,t)|^q dx\Big)^{1/q} \leq \Big(T^{1/p}||n_1(\varepsilon,\cdot)||_q + cT||w(\varepsilon,\cdot)||_\infty\Big)\exp(AT).$$

This holds for every $R > 0$. Thus, since u_1, u_2 are of ∞-log-type, we get

$$||w(\varepsilon,\cdot,t)||_q = O(\varepsilon^M)$$

for every $M \in I\!N$.

In order to get estimates for the derivatives of w, we differentiate the integral equation (30). The t-derivatives of w satisfy:

$$\begin{aligned}
\partial_t^m w(\varepsilon,x,t) = &\int_{-\infty}^{\infty} K(x-\xi)\partial_t^{m-1}\Big[w + \frac{w}{2}(\hat{u}_1 + \hat{u}_2)\Big](\varepsilon,\xi,t)d\xi \\
&-\int_{-\infty}^{\infty} E(x-\xi)\partial_t^{m-1}n_1(\xi,t)d\xi.
\end{aligned}$$

The x-derivatives of w satisfy

$$\begin{aligned}
\partial_x w = &\int_0^t \int_{-\infty}^{\infty} E(x-\xi)\Big[w + \frac{w}{2}(\hat{u}_1 + \hat{u}_2)\Big] d\xi d\tau + \int_0^t \Big[w + \frac{w}{2}(\hat{u}_1 + \hat{u}_2)\Big] d\tau \\
&-\int_0^t \int_{-\infty}^{\infty} K(x-\xi)n_1 d\xi d\tau;
\end{aligned}$$

and, for $m \geq 2$ (using Lemma 4.3),

$$\partial_x^m w = \partial_x^{m-2}w + \int_0^t \partial_x^{m-1}\Big[w + \frac{w}{2}(\hat{u}_1 + \hat{u}_2)\Big] d\tau - \int_0^t \partial_x^{m-2} n_1 dx.$$

We now prove that $||\partial^\alpha w(\varepsilon,\cdot)||_q = O(\varepsilon^M)$ by induction, using the L^q-estimates on w, n_1, and the L^∞-estimates on $\hat{u}_1, \hat{u}_2$. □

Remark 4.5. If $g \in \mathcal{G}_{p,q}(I\!R)$ has a representative $\hat{g}$ such that

$$||\hat{g}(\varepsilon,\cdot)||_{1,2} = O(|\log\varepsilon|)$$

as $\varepsilon \to 0$, then the solution u to (2), (9), assured by Theorem 4.1, is of ∞-log-type; thus it is unique by Theorem 4.4. This follows since the representative $\hat{u}$ given in the proof of Theorem 4.1 satisfies

$$||\hat{u}(\varepsilon,\cdot)||_\infty \leq ||\hat{g}(\varepsilon,\cdot)||_{1,2}.$$

Remark 4.6. The question of uniqueness remains open in the case $q > 2$ and $\frac{1}{p} + \frac{1}{q} < 1$.

5. The equation $u_t + uu_x + \nu u_{xxx} = 0$.

PROPOSITION 5.1. *Let ν be a generalized constant with a representative $\hat{\nu}$ satisfying: there are $N \in I\!N$ and $\eta > 0$ such that*

$$\varepsilon^N \leq \hat{\nu}(\varepsilon) \leq \varepsilon^{-N}, \qquad 0 < \varepsilon < \eta. \tag{31}$$

Let $g \in \mathcal{G}_{2,2}(I\!R)$. Then there is a solution $u \in \mathcal{G}_{\infty,2}(I\!R \times (0,\infty))$ to the problem

$$\begin{cases} u_t + uu_x + \nu u_{xxx} = 0, \\ u|_{t=0} = g \end{cases} \tag{32}$$

such that $u|_{I\!R\times(0,T)} \in \mathcal{G}_{2,2}(I\!R \times (0,T))$ for every $T > 0$. Moreover, for every $T > 0$ there is at most one solution $u \in \mathcal{G}_{2,2}(I\!R \times (0,T))$ such that $\partial_x u$ is of ∞-log-type.

Proof. Let

$$\hat{h}(\varepsilon, x) = \frac{1}{\sqrt[3]{\hat{\nu}(\varepsilon)}}\hat{g}(\varepsilon, \sqrt[3]{\hat{\nu}(\varepsilon)}x),$$

where $\hat{g}$ is a representative of g. By Theorem 3.1 there is a solution $v \in \mathcal{G}_{\infty,2}(I\!R \times (0,\infty))$ to (1) with initial data $h \in \mathcal{G}_{2,2}(I\!R)$, the class of $\hat{h}$, such that $v|_{I\!R\times(0,T)} \in \mathcal{G}_{2,2}(I\!R \times (0,T))$. Set

$$\hat{u}(\varepsilon, x, t) = \sqrt[3]{\hat{\nu}(\varepsilon)}\hat{v}\left(\varepsilon, \frac{x}{\sqrt[3]{\hat{\nu}(\varepsilon)}}, t\right), \tag{33}$$

where $\hat{v} \in \mathcal{E}_{M,\infty}[I\!R \times (0,\infty)]$ is the representative of v which satisfies

$$\begin{aligned} (\hat{v}_t + \hat{v}\hat{v}_x + \hat{v}_{xxx})(\varepsilon, x, t) &= 0, \\ \hat{v}(\varepsilon, x, 0) &= \hat{h}(\varepsilon, x). \end{aligned}$$

Then

$$(\hat{u}_t + \hat{u}\hat{u}_x + \hat{\nu}\hat{u}_{xxx})(\varepsilon, x, t) = 0$$

and

$$\hat{u}(\varepsilon, x, 0) = \hat{g}(\varepsilon, x).$$

Let us prove that $\hat{u} \in \mathcal{E}_{M,\infty}[I\!R \times (0,\infty)] \cap \mathcal{E}_{M,2}[I\!R \times (0,T)]$. As we observed in the proof of Theorem 3.1, it suffices to prove (10). But that obviously holds since

$$||\partial_x^k \hat{u}(\varepsilon, \cdot, t)||_2 = (\sqrt[3]{\hat{\nu}(\varepsilon)})^{\frac{3}{2}-k}||\partial_x^k \hat{v}(\varepsilon, \cdot, t)||_2.$$

To prove uniqueness, it suffices to observe that if u solves (32) and is related to v via (33), then v is a solution of the KdV equation. Also, if $\partial_x u$ is of ∞-log-type, so is $\partial_x v$. By Theorem 3.4, v is unique; hence u is unique. □

COROLLARY 5.2. *Let ν and g be as in Proposition 5.1, and assume further that $\nu \approx 0$ and g has a representative $\hat{g}$ such that $||\hat{g}(\varepsilon, \cdot)||_2$ is bounded independently of ε. Then the solution $u \in \mathcal{G}_{\infty,2}(I\!R \times (0,\infty))$ to (32) satisfies*

$$\begin{cases} u_t + uu_x \approx 0, \\ u|_{t=0} = g. \end{cases} \tag{34}$$

Proof. Indeed, $\|\hat{u}(\varepsilon,\cdot,t)\|_2 = \|\hat{g}(\varepsilon,\cdot)\|_2$ is bounded independently of ε and t, thus $\nu u_{xxx} \approx 0$. □

Corollary 5.2 has two interesting aspects, the first one relating to results of Lax and Levermore [11] and Venakides [15] on the zero dispersion limit, the second one to the possibility of modeling what Maslov and his collaborators [12], [13] have called infinitely narrow solitons.

To discuss the first, assume that the initial data are classical, say, $g \in W^{\infty,2}(\mathbb{R})$, and let $\nu \approx 0$. By Corollary 5.2, the solution $u \in \mathcal{G}_{\infty,2}(\mathbb{R}\times(0,\infty))$ to (32) solves (34) as well. On the other hand, if g satisfies the hypotheses required in the articles of Lax and Levermore [11] or Venakides [15], the representative $\hat{u}(\varepsilon,\cdot,\cdot)$ will converge weakly to a function v which, however, will generally not solve the equation $v_t + vv_x = 0$ in the sense of distributions. Thus, in this situation our generalized solution u satisfies (4), while for its associated distribution v we will have as a rule that

$$v_t + (\tfrac{1}{2}v^2)_x \neq 0 \quad \text{in } \mathcal{D}'(\mathbb{R}\times(0,\infty)).$$

This is in contrast to the situation arising with zero viscosity limits, i.e., solutions of Burgers' equation $u_t + uu_x = \nu u_{xx}$ with $\nu \approx 0$. There the generalized solution u with classical initial data g both solves (34) and admits an associated distribution w which always satisfies $w_t + (\frac{1}{2}w^2)_x = 0$ in $\mathcal{D}'(\mathbb{R}\times(0,\infty))$; see [4]. It is clear from this discussion that solutions to (34) are not unique, although some limited uniqueness in the sense of association can be obtained in the class of zero viscosity limits [4].

Secondly, following Maslov and Omel'yanov [12], Maslov and Tsupin [13], we shall see that the notion of "infinitely narrow solitons" can be accommodated in our approach as well. To simplify the presentation, we shall take ν in (32) as the class of $\hat{\nu}(\varepsilon) = \varepsilon$. We note that for each $c \geq 0$, the function

$$\hat{u}(\varepsilon,x,t) = 3c\,\mathrm{sech}^2\left(\frac{\sqrt{c}}{2\sqrt{\varepsilon}}(x-ct)\right)$$

is a representative of a solution u in $\mathcal{G}_{\infty,2}(\mathbb{R}\times(0,\infty))$ to (32); actually, a soliton for each fixed $\varepsilon > 0$. As $\varepsilon \to 0$, the width of the soliton decreases to zero, while its amplitude remains fixed. In fact, in the sense of generalized pointvalues of elements of $\mathcal{G}_{\infty,2}(\mathbb{R}\times(0,\infty))$, we have that

$$\begin{aligned} u(x,t) &= 0 \quad \text{if } x \neq ct, \\ u(ct,t) &= 3c \end{aligned}$$

for all $x \in \mathbb{R}$ and $t \geq 0$, where the evaluation of the generalized function u at (x,t) is naturally defined as a generalized constant and the equality is understood in the corresponding sense [3, §1.5.1]. It is not difficult to check that $u \neq 0$ in $\mathcal{G}_{\infty,2}(\mathbb{R}\times(0,T))$ for every $T > 0$, while $u \approx 0$, and (4) is satisfied. In addition, the generalized function

$$\frac{1}{3\sqrt{c\varepsilon}}\hat{u}(\varepsilon,x,t)$$

is associated with the Dirac measure along the line $x = ct$. This is a special case of the asymptotic developments elaborated in the quoted articles [12], [13].

Finally, we point out that it is also possible to have solutions to (32) and (34), which are associated with the Dirac measure at $t = 0$, but associated with zero on

$t > 0$: the impact of the initial singularity is removed immediately after time $t = 0$. It is easily verified that the class u in $\mathcal{G}_{\infty,2}(I\!\!R \times (0,\infty))$ of

$$\hat{u}(\varepsilon, x, t) = \frac{\alpha^2}{48\hat{\nu}(\varepsilon)} \operatorname{sech}^2\left(\frac{\alpha}{24\hat{\nu}(\varepsilon)}(x - \frac{\alpha^2}{144\hat{\nu}(\varepsilon)}t)\right)$$

with $\nu \approx 0$ and $\alpha \in \mathbb{C}$ may serve as an example: u solves (32) and (34) with $u|_{t=0} = g \approx \alpha\delta$, and $u \approx 0$ on $I\!\!R \times (0,\infty)$, where $\delta \in \mathcal{D}'(I\!\!R)$ denotes the Dirac measure at the origin.

Acknowledgment. The authors are indebted to the referee for pointing out the connections with the results of Lax, Levermore, and Venakides in §5.

NONCONSERVATIVE PRODUCTS IN BOUNDED VARIATION FUNCTIONS*

JEAN FRANÇOIS COLOMBEAU† AND ARNAUD HEIBIG†

Abstract. There exist two definitions of products of a bounded variation function by a derivative of another bounded variation function. One of them follows from a concept of generalized functions in which arbitrary products of distributions make sense: one has only one product but its understanding involves a nonclassical concept contained in each generalized function. Another one has been recently introduced by Dal Maso, Le Floch, and Murat as a generalization of a definition of Volpert; one has a family of different products indexed by a "path ϕ"; each ϕ-product is well defined as a measure, and the scenario takes place in the familiar framework of functions of bounded variation and measures. In spite of their apparent great difference, these products are closely related: the purpose of this paper is to prove a clear correspondence between the two approaches: the path ϕ is the nonclassical ingredient inherent in the concept of generalized functions.

Key words. products of distributions, nonconservative hyperbolic equations, shock waves, generalized solutions

AMS(MOS) subject classifications. 35L65, 46F10

1. Introduction. Nonconservative shocks appear in some formulations of engineering problems; see [1]-[4], [8]-[10], [19], among other references. Since they may be viewed as problems of multiplications of distributions, a first attempt is to use the theory developed in the expository texts [3], [5]-[7], [18]. This attempt led to a numerical and physical theory of nonconservative shocks and generalized solutions of PDEs (see [3], [5], [11] and the references therein). This approach is based on a new concept of generalized functions whose construction from the classical concept of C^∞ functions is suggestive of the construction of the real number system from the rational numbers. Therefore, the price to pay is the acceptance of new objects of pure mathematics. Attempts to show how this concept of "new generalized functions" can be handled on an intuitive level in applications to physics and engineering are given in [2], [7]-[10].

Another definition of a nonconservative product was introduced in [20], [14], [15], [13], [16], [17]. The first version [14], [15] applies a definition introduced by Volpert [20]. The second version [13], [16], [17] is more general and allows various different results for the product $Y^n\delta$, according to the variant in use (note that the fact that products $Y^n\delta$ appearing in equations of physics give different results according to the context has been stressed in [3, pp. 107, 119] and [2], [5], [8], [9]). At first sight it does not involve any concept of generalized functions since it takes place in the familiar setting of bounded variation functions on the real line. However, a choice has to be made concerning the variant in use for defining any nonconservative product (this choice is called a "path" in [13], [16], [17]).

In this paper we prove that this second definition is deeply connected with the definition using generalized functions. The choice of the path in the second definition is the nonclassical ingredient contained in a new generalized function. This result is interesting since the two approaches are often presented and considered as quite different. The definition in the setting of boundary value (BV) functions and paths is

not compatible with the differential-algebraic structure of the set of generalized functions, useful for calculations: it reflects the association in $\mathcal{G}$, not the equality. This differential and integral calculus of generalized functions (and its novelty relative to the differential and integral calculus of distributions) is at the origin of most of its applications [references above]; in particular, it is at the basis of the modeling assumptions proposed in [2], [3], [5], [8] for the resolution of ambiguities. The result in this paper and its proof show that these assumptions amount to the choice of a path ϕ to define a nonconservative product according to [13], [16], [17]. Therefore, there is a clear correspondence between the two approaches, when the theory of generalized functions is restricted to the setting of bounded variation functions. In the opinion of the authors, the explicit use of generalized functions is clear and simple, and can be easily dealt with on an intuitive level. Also, the differential and integral calculus of generalized functions contains basic ingredients not yet considered in the path formulation that could perhaps be productively incorporated into the path formulation. Note that the situation looks somewhat similar when the approach of generalized functions is compared with the concept of Di Perna's measure valued solutions for systems of conservation laws [12].

2. Statement of the Theorem. The notation in the setting of BV functions is that of [13], [16], [17] (briefly recalled in this paper), and the notation in the setting of "generalized functions" is that of [8, Chap. 1] (recalled in the Appendix). The basic idea concerning the connection between the two approaches can be understood without a detailed knowledge of the definitions (§ 3).

Let $\phi:[0,1]\times\mathbb{R}^p\times\mathbb{R}^p\to\mathbb{R}^p$ be a fixed "family of paths" (a "path" for short) satisfying the assumptions (Hypothesis 1-2-3) in [13], [16], [17]: essentially the map ϕ has to be differentiable in the variable $s\in[0,1]$ and $\partial\phi/\partial s$ has to be Lipschitz. Let $u:\,]a,b[\,\to\mathbb{R}^p$ be a locally bounded Borel function. The nonconservative product $\mu=[g(u,x)(du/dx)]_\phi$ is defined in [13], [16], [17] as a real valued bounded Borel measure, for any BV function $u:\,]a,b[\,\to\mathbb{R}^p$ ($g(u,x)(du/dx)$ has to be read as $\sum_{1\leqq i\leqq p} g^i(u,x)(du^i/dx)$).

Let us look at a special case: the points of discontinuity of u. If x_0 is a point of discontinuity of u then we have by definition

$$\mu(\{x_0\})=\int_0^1 g(\phi(s;u(x_0^-),u(x_0^+)),x_0)\cdot\frac{\partial\phi}{\partial s}(s;u(x_0^-),u(x_0^+))\,ds. \tag{1}$$

The path ϕ is used inside this formula to smoothly join $u(x_0^-)$ and $u(x_0^+)$, as is made clear in Fig. 1.

In the theory of generalized functions of [3], [5]-[7], [18], the nonconservative product $g(U,x)(dU/dx)$ makes sense as a generalized function, if U is a generalized function from $]a,b[$ to $\mathbb{R}^p$ (vector valued generalized functions are of course defined as a set of components; for arbitrary $U\in\mathcal{G}(]a,b[;\mathbb{R}^p)$ some growth property on g is requested, but for the particular U considered here this restriction does not enter.) Here we shall consider only that case g is a C^∞ function; this is done only to simplify the exposition: the case of non-$C^\infty g$ can be handled as in [6, pp. 258-259].

The space $\mathcal{G}(]a,b[)$ of generalized functions from $]a,b[$ into $\mathbb{R}$ contains the space $\mathcal{D}'(]a,b[)$ of (real valued) distributions. Hence the measure $[g(u,x)(du/dx)]_\phi$ is a well-defined element of $\mathcal{G}(]a,b[)$. Any generalized function G is a class of representatives $\{R(\varepsilon,\cdot)\}_{0<\varepsilon<1}$ (see the Appendix), where the functions $R(\varepsilon,\cdot)$ are C^∞ functions. If $G\in\mathcal{G}(]a,b[)$ and if $\theta\in\mathcal{D}(]a,b[)$, the brackets $\langle G,\theta\rangle\in\mathbb{R}$ are defined as the limit—when it exists—of $\int R(\varepsilon,x)\theta(x)\,dx$ when $\varepsilon\to0$ (then it is independent on the choice

FIG. 1. *Passage from* (u, ϕ) *to* u^ε *or "How a pair* (u, ϕ) *gives a generalized function* U *(defined as the class of the family* (u^ε)*)"; the figure is drawn in the case* $p = 1$.

of a representative of G). If $G \in \mathscr{D}'(]a, b[)$, then the above $\langle G, \theta\rangle$ coincides with the classical brackets of distribution theory.

Now we are able to state our comparison theorem; note that the case of $g(u, x)(dv/dx)$ can be reduced at once to the case $u = v$. (Since we consider vector valued objects.)

THEOREM. *Let* (u, ϕ) *be a given pair* (BV *function, path*). *Then there exists a generalized function* $U \in \mathscr{G}(]a, b[)$ *such that, for every* C^∞ *function* g, *the measure* $[g(u, x)(du/dx)]_\phi \in \mathscr{D}'(]a, b[)$ *and the generalized function* $g(U, x)(dU/dx) \in \mathscr{G}(]a, b[)$ *are equal in the following sense: for every test function* $\theta \in \mathscr{D}(]a, b[)$,

$$\left\langle \left[g(u, \cdot)\frac{du}{dx}\right]_\phi, \theta \right\rangle = \left\langle g(U, \cdot)\frac{dU}{dx}, \theta \right\rangle.$$

The above equality can be considered as an equality in the sense of distributions, although $g(U) \cdot (dU/dx)$ is not a distribution. The function u is—in a sense to be made precise later—the "macroscopic aspect" of the generalized function U, while ϕ is its "microscopic aspect" on its points of discontinuity. Note that the theorem gives only a correspondence between (u, ϕ) and U; this seems to be so because an analogue of the concept of (strong) equality in $\mathscr{G}$ does not exist in the other approach: this would require a concept more precise than the pairs (u, ϕ).

The proof is somewhat technical because the set of discontinuities of an arbitrary BV function can be rather complicated. In the case of step functions, if some details are dropped the proof is quite simple and gives a clear understanding of the connection between the two frameworks. The proof of this special case is given in the next section; the complete proof is in § 4. The x-dependence of g is always dropped to simplify the notation.

3. Sketch of proof in a particular case. Let $u = (u^1, \cdots, u^p)$ be a piecewise constant function of one real variable with a discontinuity at the origin; let $\phi = (\phi^1, \cdots, \phi^p)$ be a "path." For $1 \leqq i \leqq p$, $0 < \varepsilon \leqq 1$, and $0 \leqq \xi \leqq \varepsilon$, let

$$\Psi^{i,\varepsilon}(\xi) = \phi^i\left(\frac{\xi}{\varepsilon}, u(0^-), u(0^+)\right). \tag{2}$$

Define the functions $u^{i,\varepsilon}$ by

$$(2') \qquad u^{i,\varepsilon}(x)=\begin{cases} u^i(x) & \text{if } x<0 \text{ or } x>\varepsilon, \\ \Psi^{i,\varepsilon}(x) & \text{if } 0\leqq x\leqq \varepsilon. \end{cases}$$

From definition [13], [16], [17] of a path the functions $u^{i,\varepsilon}$ are continuous. For simplicity (i.e., to avoid a regularization, as in the general proof), let us assume that the functions $u^{i,\varepsilon}$ are C^∞ functions.

Let $g=(g^i)_{1\leqq i\leqq p}$ be a C^∞ function from $\mathbb{R}^p$ to $\mathbb{R}^p$. By definition [13], [16], [17], the measure $[g(u)(du/dx)]_\phi$ is equal to $\sum_{1\leqq i\leqq p}\mu^i(\{0\})\delta$, δ the Dirac measure, where

$$(1') \qquad \mu^i(0)=\int_0^1 g^i(\phi(s,a,b))\frac{\partial\phi^i}{\partial s}(s,a,b)\,ds \quad \text{if } a=u(0^-),\, b=u(0^+).$$

By definition in the context of generalized functions, $\langle g(U)(dU/dx),\theta\rangle$ is the limit when $\varepsilon\to 0$ of

$$I=\sum_{1\leqq i\leqq p} I_\varepsilon^i, \qquad I_\varepsilon^i=\int_{-\infty}^{+\infty} g^i(u^\varepsilon(x))(u^{i\varepsilon})'(x)\theta(x)\,dx$$

if $\theta\in\mathcal{D}(\mathbb{R})$.

$$\begin{aligned} I_\varepsilon^i &= \int_0^\varepsilon g^i((\Psi^{i,\varepsilon}(x))_{1\leqq i\leqq p})\frac{d}{dx}\psi^{i,\varepsilon}(x)\theta(x)\,dx \\ &= \int_0^\varepsilon g^i\left(\phi\left(\frac{x}{\varepsilon},a,b\right)\right)\frac{\partial\phi^i}{\partial s}(s,a,b)\theta(x)\,dx \\ &= \int_0^1 g^i(\phi(s,a,b))\frac{\partial\phi^i}{\partial s}(s,a,b)\theta(\varepsilon s)\,ds. \end{aligned}$$

Thus $I_\varepsilon^i\to\mu(\{0\})\theta(0)$ when $\varepsilon\to 0$: we obtain

$$\left\langle\left[g(u)\frac{du}{dx}\right]_\phi,\theta\right\rangle.$$

Note that the construction of U is not canonical because the replacement of $[0,\varepsilon]$ by, for instance, $[-\varepsilon/2,\varepsilon/2]$ would work as well (and would produce another U). One sees very clearly that the role of the path ϕ is merely to join smoothly—by its contraction to $[0,\varepsilon]-u(0^-)$ and $u(0^+)$; this concept of path, called "microscopic profile" of the shock in [3], [9], [10] is contained in the generalized function U, but not contained in the BV function u. Different ϕ's produce different U's; the same u and ϕ may produce different U's. Thus the pairs (u,ϕ) are not generalized functions, but rather classes of generalized functions having the same macroscopic aspect u and giving the same products $[g(u)(du/dx)]_\phi$.

4. Proof of the theorem. The construction of $U=\text{class }(u^\varepsilon)_{0<\varepsilon<1}$ in $\mathcal{G}(]a,b[,\mathbb{R}^p)$ will be done in several steps:

$$\begin{tikzcd} \begin{pmatrix} u \\ \phi \end{pmatrix} \arrow[r, "\text{Step 1}"] & \begin{pmatrix} v^\varepsilon \\ \phi \end{pmatrix} \arrow[r, "\text{Step 2}"] & \tilde{v}^\varepsilon \arrow[r, "\text{Step 3}"] & \tilde{v}^\varepsilon * \rho_{h(\varepsilon)} \arrow[r, "\text{Step 4}"] & (u^\varepsilon)_{0<\varepsilon<1} \\ \text{u: BV function} & \text{v^ε: piecewise constant} & \text{$\tilde{v}^\varepsilon$: Lipschitz continuous junctions by $\psi^{i,\varepsilon}$ as in Fig. 1} & \text{regularization $\rho\in\mathcal{D}$, $\int\rho=1$, $h(\varepsilon)\to 0$ if $\varepsilon\to 0$, h suitably chosen} & \text{gives U as its class} \end{tikzcd}$$

Step 1. Given the BV function u, there is a family $(v^\varepsilon)_{0<\varepsilon<1}$ of step functions, $v^\varepsilon\to u$ in sup norm when $\varepsilon\to 0$ and $\text{TV}(v^\varepsilon)<c$ (i.e., the total variation of v^ε is less

than a constant independent of ε). Theorem 2.2 in [13] asserts that, for every test function $\theta \in \mathscr{D}(]a, b[)$,

$$\int \left[g(v^\varepsilon)\frac{dv^\varepsilon}{dx}\right]_\phi (x)\theta(x)\,dx \to \int \left[g(u)\frac{du}{dx}\right]_\phi (x)\theta(x)\,dx \tag{3}$$

when $\varepsilon \to 0$. These v^ε do not depend continuously on ε: in the Appendix we do not state such a dependence in the definition of $\mathscr{G}$. Such a dependence can be useful for other purposes (see [5]); it could be incorporated here at the price of a more complicated construction.

Step 2. We construct the continuous function $\tilde{v}^\varepsilon$ from v^ε and ϕ as described above in Fig. 1. Indeed, v^ε is piecewise constant, with a discrete set of discontinuities x_i^ε, $1 \leqq i \leqq n$, on each compact interval. In order to avoid a possible overlapping of the junctions, the segments $[x_i^\varepsilon, x_i^\varepsilon + \varepsilon]$ as in Fig. 1 are replaced by $[x_i^\varepsilon, x_i^\varepsilon + f_i^\varepsilon]$ with $0 < f_i^\varepsilon \leqq \varepsilon$ small enough. In a neighborhood of x_i^ε, we have the following:

$$\begin{cases} \tilde{v}^\varepsilon(x) = v^\varepsilon(x) & \text{if } x \leqq x_i^\varepsilon \text{ or } x \geqq x_i^\varepsilon + f_i^\varepsilon, \\ \tilde{v}^\varepsilon(x) = \phi(\lambda, v^\varepsilon(x_i^{\varepsilon-}), v^\varepsilon(x_i^{\varepsilon+})) & \text{if } x = x_i^\varepsilon + \lambda f_i^\varepsilon, \quad 0 \leqq \lambda \leqq 1. \end{cases} \tag{4}$$

Now let μ_ε be the measure $\mu_\varepsilon = [g(v^\varepsilon)(dv^\varepsilon/dx)]_\phi$ defined in [18].

Then $\mu_\varepsilon = \sum_{i \in \mathbb{N}} \mu_\varepsilon(\{x_i\})\delta_{x_i}$, where

$$\mu_\varepsilon(\{x_i\}) = \int_0^1 g(\phi(s, v^\varepsilon(x_i^-), v^\varepsilon(x_i^+)))\frac{\partial \phi}{\partial s}(s, v^\varepsilon(x_i^{\varepsilon-}), v^\varepsilon(x_i^{\varepsilon+}))\,ds.$$

An obvious change of variables and (4) give (see § 3)

$$\mu_\varepsilon(\{x_i\}) = \int_{x_i^\varepsilon}^{x_i^\varepsilon + f_i^\varepsilon} g(\tilde{v}^\varepsilon(x))\frac{d\tilde{v}^\varepsilon}{dx}(x)\,dx.$$

Therefore, if $\theta \in \mathscr{D}(]a, b[)$,

$$\int \left[g(v^\varepsilon)\frac{dv^\varepsilon}{dx}\right]_\phi (x)\theta(x)\,dx = \sum_i \theta(x_i^\varepsilon)\int_{x_i^\varepsilon}^{x_i^\varepsilon + f_i^\varepsilon} g(\tilde{v}^\varepsilon(x))\frac{d\tilde{v}^\varepsilon}{dx}(x)\,dx. \tag{5}$$

On the other hand,

$$\int g(v^\varepsilon)\frac{d\tilde{v}^\varepsilon}{dx}\theta(x)\,dx = \sum_i \int_{x_i^\varepsilon}^{x_i^\varepsilon + f_i^\varepsilon} g(\tilde{v}^\varepsilon(x))\frac{d\tilde{v}^\varepsilon}{dx}(x)\theta(x)\,dx. \tag{6}$$

The difference D of the quantities in (5) and (6) is

$$D = \sum_i \int_{x_i^\varepsilon}^{x_i^\varepsilon + f_i^\varepsilon} g(\tilde{v}^\varepsilon(x))\frac{d\tilde{v}^\varepsilon}{dx}(x)(\theta(x) - \theta(x_i^\varepsilon))\,dx.$$

Further,

$$\int_{x_i^\varepsilon}^{x_i^\varepsilon + f_i^\varepsilon} \left|\frac{d\tilde{v}^\varepsilon}{dx}\right| d\lambda = \int_0^1 \left|\frac{\partial \phi}{\partial s}(s, v^\varepsilon(x_i^{\varepsilon-}), v^\varepsilon(x_i^{\varepsilon+}))\right| ds \leqq k|v^\varepsilon(x_i^{\varepsilon-}) - v^\varepsilon(x_i^{\varepsilon+})|,$$

k independent of ε ([13, Hypothesis 2]).

Thus

$$\begin{aligned} |D| &\leqq \sum_i \int_{x_i^\varepsilon}^{x_i^\varepsilon + f_i^\varepsilon} \left| g(\tilde{v}^\varepsilon(x))\frac{d\tilde{v}^\varepsilon(x)}{dx}(\theta(x) - \theta(x_i^\varepsilon))\right| dx \\ &\leqq \|g(\tilde{v}^\varepsilon)\|_\infty \|\theta'\|_\infty \sup_i (f_i^\varepsilon) k\, \mathrm{TV}(v^\varepsilon). \end{aligned}$$

Since $(f_i^\varepsilon) \leqq \varepsilon$ and $\mathrm{TV}(v^\varepsilon) \leqq c$ one obtains

$$\int \left[g(v^\varepsilon)\frac{dv^\varepsilon}{dx}\right]_\phi (x)\theta(x)\,dx - \int g(\tilde{v}^\varepsilon(x))\frac{d\tilde{v}^\varepsilon}{dx}(x)\theta(x)\,dx \to 0 \quad \text{as } \varepsilon \to 0. \tag{7}$$

Step 3. The objective of this step is to regularize the continuous functions $\tilde{v}^{\varepsilon}$ so as to obtain C^{∞} functions.

Let $\rho \in \mathscr{D}(\mathbb{R})$, $\int \rho(x)\,dx = 1$; we set $\rho_{\varepsilon}(x) = (1/\varepsilon)\rho(x/\varepsilon)$. Let $h:]0,1] \to]0,1]$ be a decreasing function such that $h(\varepsilon) \to 0$ when $\varepsilon \to 0$. We set $\tilde{\tilde{v}}^{\varepsilon} = \tilde{v}^{\varepsilon} * \rho_{h(\varepsilon)}$. We want to prove that for a suitably chosen function h, then, for any $\theta \in \mathscr{D}(]a,b[)$ and $g \in C^{\infty}(\mathbb{R}^p, \mathbb{R}^p)$,

$$(8) \qquad \int g(\tilde{\tilde{v}}^{\varepsilon,\lambda}(x)) \frac{d\tilde{\tilde{v}}^{\varepsilon,\lambda}}{dx}(x)\theta(x)\,dx - \int g(\tilde{v}^{\varepsilon}(x)) \frac{d\tilde{v}^{\varepsilon}}{dx}(x)\theta(x)\,dx \to 0 \quad \text{as } \varepsilon \to 0.$$

Let us fix ε and set $\tilde{\tilde{v}}^{\varepsilon,\lambda} = \tilde{v}^{\varepsilon} * \rho_{\lambda}$, $\lambda > 0$. Then it is easy to prove that for fixed ε, g, and θ

$$\int g(\tilde{\tilde{v}}^{\varepsilon,\lambda}(x)) \frac{d\tilde{\tilde{v}}^{\varepsilon,\lambda}}{dx}(x)\theta(x)\,dx - \int g(\tilde{v}^{\varepsilon}(x)) \frac{d\tilde{v}^{\varepsilon}}{dx}(x)\theta(x)\,dx \to 0 \quad \text{as } \lambda \to 0.$$

Equation (8) follows (nontrivially) since we are free to make a choice of the function h (i.e., $h(\varepsilon) \to 0$ as fast as needed when $\varepsilon \to 0$); the details are left to the reader (the above limit depends on bounds of g and θ that have a countable character: for this there exists a suitable h). A similar argument has been elaborated in [12].

The conjunction of (3), (7), and (8) gives

$$(9) \qquad \int g(\tilde{\tilde{v}}^{\varepsilon}(x)) \frac{d\tilde{\tilde{v}}^{\varepsilon}}{dx}(x)\theta(x)\,dx \to \int \left[g(u)\frac{du}{dx} \right]_{\phi} (x)\theta(x)\,dx \quad \text{as } \varepsilon \to 0$$

for any $\theta \in \mathscr{D}(]a,b[)$.

Step 4. The family $(\tilde{\tilde{v}}^{\varepsilon})_{0<\varepsilon<1}$ is a family of C^{∞} functions in the x variable. In the course of the construction of this family we have lost any control on its dependence in ε. Let $\mathscr{E}_M[\,]a,b[,\mathbb{R}^p]$ be the requested reservoir of representatives for defining $\mathscr{G}(]a,b[;\mathbb{R}^p)$. A family $\{u^{\varepsilon}\}_{0<\varepsilon<1}$ of C^{∞} functions on $]a,b[$ valued in $\mathbb{R}^p$ lies in this reservoir if and only if (owing to the simplification due to the dependence on ε only) for every compact interval K in $]a,b[$ and for every $n \in \mathbb{N}$ there are $c > 0$, $\eta > 0$ and $N \in \mathbb{N}$ such that

$$\sup_{x \in K} \left\| \frac{d^n}{dx^n} u^{\varepsilon}(x) \right\| \leqq \frac{c}{\varepsilon^N} \quad \text{if } 0 < \varepsilon < \eta,$$

where $\|\ \|$ is the norm in $\mathbb{R}^p$. The family $(\tilde{\tilde{v}}^{\varepsilon})_{0<\varepsilon<1}$ does not a priori satisfy these bounds. But there is a suitable function $k:]0,1[\to]0,1[$, $k(\varepsilon) \to 0$ if $\varepsilon \to 0$, such that $u^{\varepsilon} = \tilde{\tilde{v}}^{k(\varepsilon)}$ satisfies the above bounds (k is obtained by a diagonal process since one has a countable set of requirements: countability of an exhaustive sequence of compact sets in $]a,b[$, and countability of the set of successive derivatives). Then $(u^{\varepsilon})_{0<\varepsilon<1}$ lies in the requested reservoir of representatives. Its class defines an element U of $\mathscr{G}(]a,b[;\mathbb{R}^p)$. Of course (9) holds with u^{ε} in place of $\tilde{\tilde{v}}^{\varepsilon}$. □

5. Comments. In the terminology of the concept of generalized functions in use, the weak equality in the statement of the theorem is formulated by saying that the measure $[g(u,x)(du/dx)]_{\phi}$ and the generalized function $g(U,x)(dU/dx)$ are associated; see the Appendix.

The generalized function U can—as is quite apparent from Fig. 1—be (noncanonically) considered as the pair (u, ϕ), and then, of course, the product depends only on U: the path ϕ enters into the definition of the generalized function U.

Conversely, given a generalized function U, with—to fix the idea—$U(x) = a$ if $x < 0$ and $U(x) = b$ if $x > 0$, is it possible to find a family of paths ϕ in the sense of [13], [16], [17]? In various concrete circumstances this is the case, and examples from numerical analysis and physics are shown in [3], [8]-[10], where these paths were called "the microscopic profile of the shock." In general this is impossible: U is the class of a family $(u^\varepsilon)_{0<\varepsilon<1}$ of C^∞ functions. For each u^ε the junction between the left- and right-hand side values can be assumed (at least intuitively) to take place on an interval $[\alpha(\varepsilon), \beta(\varepsilon)]$, $\alpha(\varepsilon)\to 0$, $\beta(\varepsilon)\to 0$ as $\varepsilon\to 0$. By a linear change of variable we can transform this interval into the interval [0, 1]: this gives some function ϕ^ε defined on [0, 1], which, of course, stands for the path ϕ in Fig. 1. If, when $\varepsilon\to 0$, the function ϕ^ε tends to a function ϕ, then we can say that the reverse process works: we obtain a pair (u, ϕ) from which the process in Fig. 1 gives a generalized function $U(U\approx u)$, having ϕ as a "microscopic profile." But it may happen that the ϕ^ε's vary endlessly when $\varepsilon\to 0$, or are unbounded when $\varepsilon\to 0$; even in case of a weak convergence of the ϕ^ε's to some ϕ, ϕ need not satisfy the assumptions in [13], [16], [17]. Examples have been observed in numerical tests; see [3], Figs. 6, 7 in Appendix 2 of Chapter 3, [8], [10]. Further, in [13], [16], [17] the path ϕ depends only on the left- and right-hand side values of the BV function u. This excludes step functions with time independent step values and time dependent microscopic profiles that have been observed, for example, in [1]. Also, it may happen that in the solution of a Cauchy problem (with a BV initial condition) the solution has several shocks, two of them with same left- and right-hand side values but different "microscopic profiles."

Therefore, the concept of generalized functions can be considered as more general than the concept of pairs (u, ϕ)—at least when ϕ has the properties in [13], [16], [17]. However, in the theorem of [17] a remarkable property of conservation of the path ϕ at the limit of Glimm's random choice method has been proven; then the consideration of more general objects to describe the limit is avoided. Note also that the space $\mathscr{G}$ has primarily been presented as an algebra of functions: notions of topology are exposed in [3, § 1.7], but they are not significantly used. When we restrict it to the setting of functions of bounded variation, the classical topologies in these spaces can be used; see [1], [3], [4]. Then it appears that both approaches are closely related on their common domain.

Appendix. The purpose of this Appendix is to offer a definition of the concept of the "generalized functions" we use. If Ω is an open set in $\mathbb{R}^n$, we construct the space $\mathscr{G}(\Omega)$ of (real or complex valued) generalized functions on Ω from the space $\mathscr{C}^\infty(\Omega)$ of C^∞ functions on Ω in a way that looks like the construction of the real numbers from the rational numbers (each real number is an equivalence class of (Cauchy) sequences of rational numbers). Slightly different constructions lead to slightly different spaces $\mathscr{G}(\Omega)$, but at the level of the results in this paper, there is no significant difference between them. We set

$$\mathscr{A}_q=\left\{\varphi\in\mathscr{D}(\mathbb{R}^n)\text{ such that }\int_{\mathbb{R}^n}\varphi(\lambda)\,d\lambda=1,\ \int_{\mathbb{R}^n}\lambda^i\varphi(\lambda)\,d\lambda=0\text{ if }1\leqq|i|\leqq q\right\}.$$

If $0<\varepsilon<1$, we set as usual $\varphi_\varepsilon(\lambda)=(1/\varepsilon^n)\varphi(\lambda/\varepsilon)$, and it is clear that $\varphi\in\mathscr{A}_q$ if and only if $\varphi_\varepsilon\in\mathscr{A}_q$.

Let us define our "reservoir of representatives" (i.e., the analogue of the set of all Cauchy sequences of rational numbers). This reservoir, denoted by $\mathscr{E}_M[\Omega]$, can be intuitively introduced as follows: let there be given a distribution T on $\mathbb{R}^n$; T can be viewed as a class of regularizations $T*\varphi\in\mathscr{C}^\infty(\mathbb{R}^n)$, with $\varphi\in\mathscr{D}$, φ tending to the Dirac measure δ in the sense of distributions. For a canonical regularization it is necessary to consider all possible regularizing functions φ, and, therefore, all maps $(\varphi, x)\to R(\varphi, x)(R(\varphi, x)=(T*\varphi)(x)$ in the above particular case of a distribution). $\mathscr{E}_M[\Omega]$ is the set of all maps

$$R:\mathscr{A}_0x\Omega\to\mathbb{R},\qquad(\varphi, x)\to R(\varphi, x),$$

such that:

(1) For any φ the map $R : x \to (\varphi, x)$ is a C^∞ function of the variable $x \in \Omega$;

(2) if $D = (\partial^{|k|}/\partial_{x_1}^{k_1} \cdots \partial_{x_n}^{k_n})$ is any partial derivation operator (D = identity is allowed), if $\varphi \in \mathcal{A}_0$ and K is any compact subset of Ω, then there are constants $c > 0$, $N \in \mathbb{N}$, and $0 < \eta \leqq 1$ such that

$$\sup_{x \in K} |DR(\varphi_\varepsilon, x)| \leqq \frac{c}{\varepsilon^N}$$

if $0 < \varepsilon < \eta$. Note that if $R \in \mathscr{E}_M[\Omega]$, then $DR \in \mathscr{E}_M[\Omega]$ for any D. Also, if R, $Q \in \mathscr{E}_M[\Omega]$, then $R + Q \in \mathscr{E}_M[\Omega]$ and $R.\ Q \in \mathscr{E}_M[\Omega]$: $\mathscr{E}_M[\Omega]$ is a differential algebra (partial derivatives, addition, and multiplication).

Now let us define our "set of null elements" (i.e., the analogue of all zero sequences of rational numbers). This set is denoted by $\mathcal{N}[\Omega]$ and is an ideal of the algebra $\mathscr{E}_M[\Omega]$. $\mathcal{N}[\Omega]$ is the set of all maps $R \in \mathscr{E}_M[\Omega]$ such that for all D and K as above there is $N \in \mathbb{N}$ and an increasing map $\gamma : \mathbb{N} \to \mathbb{N}$, $\gamma(q) \to +\infty$ if $q \to +\infty$, such that $\forall q \geqq N, \forall \varphi \in \mathcal{A}_q\ \exists c > 0$ and $0 < \eta \leqq 1$ such that $\sup_{x \in K} |DR(\varphi_\varepsilon, x)| \leqq c\varepsilon^{\gamma(q)}$ if $0 < \varepsilon < \eta$.

A generalized function G on Ω is an element of the quotient space $\mathscr{G}(\Omega) = \mathscr{E}_M[\Omega]/\mathcal{N}[\Omega]$, which is a differential algebra (since the operations of partial differentiation, of addition and multiplication are coherent with this quotient).

$\mathscr{C}^\infty(\Omega)$ is contained in $\mathscr{G}(\Omega)$ in the following way: to $f \in \mathscr{C}^\infty(\Omega)$ associate the "representative" $R(\varphi, x) = f(x)$. $\mathscr{D}'(\Omega)$ is contained in $\mathscr{G}(\Omega)$ in the following way: to $T \in \mathscr{D}'(\Omega)$ associate the "representative" $R(\varphi, x) = \langle T_\lambda, \varphi(\lambda - x)\rangle = (T * \varphi)(x)$. We have the inclusions $\mathscr{C}^\infty(\Omega) \subset \mathscr{D}'(\Omega) \subset \mathscr{G}(\Omega)$, and $\mathscr{C}^\infty(\Omega)$ is a subalgebra.

The origin of this somewhat unexpected construction is described in [5]. Indeed this construction relies on the classical Taylor expansion of a C^∞ function.

We state $G \approx 0$ if it has a representative R (then this works for all representatives) such that for large enough $N \in \mathbb{N}$, for any $\theta \in \mathscr{D}(\Omega)$,

$$\int R(\varphi_\varepsilon, x)\theta(x)\, dx \to 0$$

if $\varepsilon \to 0$. We state $G_1 \approx G_2$ if and only if $G_1 - G_2 \approx 0$. We say that $G \in \mathscr{G}(\Omega)$ admits $T \in \mathscr{D}'(\Omega)$ as "macroscopic aspect" or "associated distribution" if and only if $G \approx T$. The importance of this concept is due to the fact that because the ideal $\mathcal{N}[\Omega]$ is very small, the concept of equality in $\mathscr{G}(\Omega)$ is a very strong relation; the concept of association plays the role of a weaker concept of equality, however incoherent with the multiplication.

Simplified formulation. Practice often shows that the formal replacement of $R(\varphi_\varepsilon, x)$ by $R(\varepsilon, x)$ (whatever φ may be) amounts only to a simplification in notation. Also, we can rigorously consider a subalgebra $\mathscr{G}_s(\Omega)$—in which the subscript s stands for "simplified"—for which the representatives depend only on ε and x. We have the following situation [3]:

$$\begin{tikzcd}
& \mathscr{D}'(\Omega) \arrow[dr, phantom, "\subset"] & \\
\mathscr{C}^\infty(\Omega) \arrow[ur, phantom, "\subset"] \arrow[dr, phantom, "\subset"] & & \mathscr{G}(\Omega). \\
& \mathscr{G}_S(\Omega) \arrow[ur, phantom, "\subset"] &
\end{tikzcd}$$

We pay the price of simplification by a loss of the canonical inclusion of $\mathscr{D}'$ into the space $\mathscr{G}_S$ of generalized functions. In this paper we have adopted $R(\varepsilon, x)$ as a simplified notation for $R(\varphi_\varepsilon, x)$. Furthermore, the U's constructed in the proof can be considered as elements of $\mathcal{G}_S(\Omega)$. This makes no difference for the contents of this paper. Note that the simplified concept is introduced directly in [9], [10].

Acknowledgments. The authors are very much indebted to A. Y. Le Roux, M. Oberguggenberger, and D. Serre for their help during the preparation of this paper. Significant improvements in the text are due to the referee.

Note added in proof. A very simplified formulation is presented in Egorov, "On the theory of generalized functions," *Russian Math. Surveys* 5, (1990), pp. 1-49.

A UNIQUENESS RESULT CONCERNING THE IDENTIFICATION OF A COLLECTION OF CRACKS FROM FINITELY MANY ELECTROSTATIC BOUNDARY MEASUREMENTS*

KURT BRYAN† AND MICHAEL VOGELIUS‡

Abstract. The problem of identification of a collection of finitely many cracks inside a planar domain is considered. The data used for the identification consist of measurements of the electrostatic boundary potentials induced by prescribed current fluxes. It is shown that a collection of n or fewer cracks is uniquely identified by boundary measurements corresponding to $n+1$ specific current fluxes, consisting entirely of electrode pairs.

Key words. cracks, nondestructive testing, electrical impedance imaging

AMS(MOS) subject classifications. 35R30, 35J25

Introduction. In a recent paper, [1], Friedman and Vogelius proved that the presence of a single crack, and its shape and location inside a planar domain, may be determined from measurements of the steady state boundary voltage potentials corresponding to two specific boundary current fluxes. In the present paper we extend this result to any finite number of cracks. We show that voltage measurements corresponding to $n+1$ specific fluxes suffice to determine the location and shape of a collection of n (or fewer) cracks. In contrast to [1] the fluxes we use here all consist of electrode pairs—exactly the type of fluxes which were used for the computational algorithm developed in [2].

Let Ω be a simply connected domain in $\mathbb{R}^2$ with a smooth boundary. In order to describe our result in detail we need to define the notion of a collection of cracks. By a C^2-curve, σ, we understand a twice continuously differentiable map: $[0,1] \to \Omega$ with non-vanishing derivative. *A collection of cracks consists of a finite number of mutually disjoint, nonselfintersecting C^2-curves σ_k , $k = 1, \cdots, n$.* We use capital Greek letters to denote collections of cracks, e.g., $\Sigma = \{\sigma_k\}_{k=1}^n$; note that n may possibly be zero, so that Σ is empty. We shall also use the notation σ_k and Σ for the image of each of the individual curves and the union of all the images, respectively (i.e., $\Sigma = \cup_{k=1}^n \sigma_k$). Let $\gamma : \overline{\Omega} \to \mathbb{R}$ be a positive function (the known reference conductivity). Throughout this paper we assume that

$$\gamma \text{ is real-analytic on } \quad \overline{\Omega}.$$

In the following, when a function is called analytic, it shall always mean real-analytic. Quite frequently in the literature the term crack is used synonymously with an electrically insulating crack: if ϕ represents the boundary voltage, then the steady state

voltage potential satisfies

$$\begin{aligned} \nabla\cdot(\gamma\nabla v) &= 0 \quad \text{in } \Omega\setminus\Sigma,\\ \gamma\frac{\partial v}{\partial\nu} &= 0 \quad \text{on } \Sigma,\\ v &= \phi \quad \text{on } \partial\Omega. \end{aligned}$$

In this framework the inverse problem is to determine Σ from knowledge of several pairs $(\phi, \gamma\frac{\partial v}{\partial\nu}|_{\partial\Omega})$. We shall, instead of working with the potential v, opt to work with its "γ-harmonic" conjugate, u. This function is related to v by

$$(0.1) \qquad (\nabla u)^{\perp} = \gamma\nabla v,$$

where $\perp$ indicates counterclockwise rotation by $\pi/2$. Let T be a fixed point on $\partial\Omega$, in a neighborhood of which ϕ is smooth. Let τ_k be a smooth curve in $\Omega\setminus\Sigma$ connecting T to an interior point of the crack σ_k, and let s denote the unit tangent direction along τ_k, pointing from T towards σ_k. Define constants

$$c^{(k)} = -\int_{\tau_k}\gamma\frac{\partial v}{\partial\nu}ds \;+\; u(T),$$

where ν denotes the normal field $\nu = -s^{\perp}$. The "γ-harmonic" conjugate, u, solves

$$(0.2) \qquad \begin{aligned} \nabla\cdot(\gamma^{-1}\nabla u) &= 0 \quad \text{in } \Omega\setminus\Sigma,\\ u &= c^{(k)} \quad \text{on } \sigma_k \;\; k = 1,\cdots,n,\\ \gamma^{-1}\frac{\partial u}{\partial\nu} &= \frac{\partial\phi}{\partial s} = \psi \quad \text{on } \partial\Omega, \end{aligned}$$

where s denotes the counterclockwise tangent direction on $\partial\Omega$.

From (0.1) it follows immediately that knowledge of $u|_{\partial\Omega}$ leads to knowledge of $-\gamma\frac{\partial v}{\partial\nu}|_{\partial\Omega} = \frac{\partial}{\partial s}(u|_{\partial\Omega})$, and vice versa. Therefore, knowledge of pairs $(u|_{\partial\Omega}, \psi)$ is equivalent to knowledge of corresponding pairs $(\phi, \gamma\frac{\partial v}{\partial\nu}|_{\partial\Omega})$, where ϕ and ψ are related by $\psi = \frac{\partial\phi}{\partial s}$. Physically (0.2) corresponds to a collection of perfectly conducting cracks. One way to solve (0.2) is to minimize the energy

$$\frac{1}{2}\int_{\Omega}\gamma^{-1}|\nabla w|^2\,dx - \int_{\partial\Omega}\psi w\,ds$$

in the space $H^1(\Omega)\cap\{w = \text{ const on each } \sigma_k \in \Sigma\}$ (such minimization gives, modulo a single undetermined constant, exactly the values on σ_k, $k = 1,\cdots,n$ described above). This method works provided $\psi \in H^{-1/2}(\partial\Omega)$. The fluxes we shall apply here, however, correspond to single pairs of electrodes, i.e., we shall take ψ of the form $\psi = \delta_{P_0} - \delta_{P_1}$, where P_0 and P_1 are two distinct points on $\partial\Omega$. Such ψ are not in $H^{-1/2}(\partial\Omega)$—the solution, u, is, therefore, not in $H^1(\Omega)$, and it is not obtained as a minimizer of energy. Rather, u is a weak solution to (0.2); it is smooth everywhere except at P_0 and P_1 and at the endpoints of the cracks. At P_0 and P_1 the function u has singularities of the form $-\gamma(P_0)/\pi\ \log r$, $r = |x - P_0|$, and $\gamma(P_1)/\pi\ \log r$, $r = |x - P_1|$, respectively; at the endpoints of the cracks u has in general $r^{1/2}$-type singularities, cf. [1].

For our uniqueness result it is not necessary that we have solutions which attain exactly the constant values on the cracks described above—any set of constants will do. To construct the specific boundary currents, let $P_0,\cdots,P_M$ be $M+1$ different (fixed) points on $\partial\Omega$; we assume that these points are labeled in order of counterclockwise appearance, starting from P_0. In our first uniqueness result we utilize solutions to the boundary value problems

$$\begin{aligned} \nabla\cdot(\gamma^{-1}\nabla u_j) &= 0 \quad \text{in } \Omega\setminus\Sigma, \\ u_j &= \text{ constant on each } \sigma_k \in \Sigma, \\ \gamma^{-1}\frac{\partial u_j}{\partial\nu} &= \delta_{P_0} - \delta_{P_j} \quad \text{on } \partial\Omega. \end{aligned} \tag{0.3}$$

THEOREM 0.1. *Let $\Sigma = \{\sigma_k\}_{k=1}^n$ and $\tilde{\Sigma} = \{\tilde{\sigma}_k\}_{k=1}^m$ denote two collections of cracks contained in the domain Ω, with $\max(m,n)+1 \le M$. Let u_j, $j = 1,\cdots,M$ denote solutions to (0.3) and let $\tilde{u}_j$, $j = 1,\cdots,M$ denote solutions to (0.3) with Σ replaced by $\tilde{\Sigma}$. Then $u_j = \tilde{u}_j$ on $\partial\Omega\setminus\cup_{i=0}^M\{P_i\}$ for $j = 1,\cdots,M$ implies that $\Sigma = \tilde{\Sigma}$.*

Instead of prescribing fixed fluxes $\gamma^{-1}\frac{\partial u_j}{\partial\nu}|_{\partial\Omega} = \psi_j$ and measuring $u_j|_{\partial\Omega}$, we can prescibe fixed boundary voltages $w_j|_{\partial\Omega} = \phi_j$ equally well and measure $\gamma^{-1}\frac{\partial w_j}{\partial\nu}|_{\partial\Omega}$. For that purpose we utilize solutions to the following boundary value problems

$$\begin{aligned} \nabla\cdot(\gamma^{-1}\nabla w_j) &= 0 \quad \text{in } \Omega\setminus\Sigma, \\ w_j &= \text{const on each } \sigma_k \in \Sigma, \\ w_j &= 1_{\overset{\frown}{P_{j-1}P_j}} \quad \text{on } \partial\Omega, \end{aligned} \tag{0.4}$$

where $1_{\overset{\frown}{P_{j-1}P_j}}$ denotes the characteristic function of the counterclockwise curve from P_{j-1} to P_j. The function w_j is a weak solution to (0.4)—it is not in $H^1(\Omega)$, and, therefore, not obtained as a minimizer of energy. w_j has a singularity of the form $-\theta/\pi$ at P_{j-1}, $\theta = \arg(x-P_{j-1})$ and has a singularity of the form θ/π at P_j, $\theta = \arg(x-P_j)$. At the endpoints of the cracks w_j has, in general, $r^{1/2}$-type singularities.

THEOREM 0.2. *Let $\Sigma = \{\sigma_k\}_{k=1}^n$ and $\tilde{\Sigma} = \{\tilde{\sigma}_k\}_{k=1}^m$ denote two collections of cracks contained in the domain Ω, with $\max(m,n)+1 \le M$. Let w_j, $j = 1,\cdots,M$ denote solutions to (0.4) and let $\tilde{w}_j$, $j = 1,\cdots,M$ denote solutions to (0.4) with Σ replaced by $\tilde{\Sigma}$. Then $\gamma^{-1}\frac{\partial w_j}{\partial\nu} = \gamma^{-1}\frac{\partial\tilde{w}_j}{\partial\nu}$ on $\partial\Omega\setminus\cup_{i=0}^M\{P_i\}$ for $j = 1,\cdots,M$ implies that $\Sigma = \tilde{\Sigma}$.*

REMARK 0.1. As was the case with the first theorem, this second theorem also has an alternative formulation in terms of cracks that are insulating. In that case we would prescribe normal boundary fluxes $-\partial(1_{\overset{\frown}{P_{j-1}P_j}})/\partial s = \delta_{P_j} - \delta_{P_{j-1}}$ and measure the corresponding boundary voltages.

1. Preliminaries. The proof of our main results consists of a very detailed analysis of the structure of the level curves of solutions to the equation $\nabla\cdot(\gamma^{-1}\nabla u) = 0$. For that purpose we shall need two auxiliary lemmas.

LEMMA 1.1. *Let u satisfy $\nabla\cdot(\gamma^{-1}\nabla u) = 0$ in $\Omega\setminus\Sigma$ with $\gamma^{-1}\partial u/\partial\nu = \sum_j \beta_j\delta_{P_j}$ on $\partial\Omega$, and u constant on each σ_k. Let ρ be a nonempty analytic curve in Ω with $\rho\cap\Sigma = \emptyset$ along which u is constant. Then there exists an analytic curve ρ' with $\rho\subset\rho'$ such that*

$$u \text{ is constant on } \rho', \tag{1.1a}$$

$$\rho' \text{ has one endpoint on } \partial\Omega \text{ or } \sigma_k \text{ for some } k, \tag{1.1b}$$

(1.1c) *ρ' has the other endpoint on $\partial\Omega$ or σ_l for some l with $l \neq k$.*

The proof of this lemma is identical to the proof of Lemma 2.3 in [1]. We shall not repeat the the proof here. The second lemma we need concerns the existence of intersecting level curves. Some of the details of the proof of this result are not unlike those found in the proof of Lemma 2.3 in [1], but for the convenience of the reader we give a complete proof here.

LEMMA 1.2. *Let u satisfy $\nabla \cdot (\gamma^{-1}\nabla u) = 0$ in $\Omega \setminus \Sigma$ with $\gamma^{-1}\partial u/\partial\nu = \sum_j \beta_j \delta_{P_j}$ on $\partial\Omega$, and u constant on each σ_k. Let ρ be a nonempty analytic curve in Ω with $\rho \cap \Sigma = \emptyset$, along which u is constant, and assume that x^* is an interior point of ρ, where $\nabla u(x^*) = 0$. Then there exists an analytic curve ρ' which has x^* as an interior point such that*

$$\rho' \cap \rho = \{x^*\}, \tag{1.2a}$$

$$u \text{ is constant on } \rho'. \tag{1.2b}$$

Proof. Let $(r, \theta) \in [0, \epsilon] \times [0, 2\pi]$ denote polar coordinates at x^*. Since $\nabla u(x^*) = 0$ we know that $\frac{\partial}{\partial r}u(0, \theta) \equiv 0$, and by expanding in a Taylor series in r we get

$$u(x) = u(x^*) + r^N(a \sin N\theta + b \cos N\theta + rA(r, \theta))$$

for some a, b (not both zero) and some $N \geq 2$. Here we have used that u is nonconstant and satisfies $\nabla \cdot (\gamma^{-1}\nabla u) = 0$ near x^*, and we have used that γ^{-1} is analytic (the case of a constant u is trivial). We may, without loss of generality, assume that the tangent to ρ at x^* is $\{(r, 0),\ r > 0\} \cup \{(r, \pi),\ r > 0\}$. It follows that $b = 0$, i.e.,

$$u(x) = u(x^*) + ar^N(\sin N\theta + rA(r, \theta)).$$

Since u is analytic near x^*, it is well known that u as a function of (r, θ) is analytic on $[0, \epsilon] \times [0, 2\pi]$, the main point being that it is analytic at $r = 0$ and, therefore, also has an analytic extension to $[-\epsilon, \epsilon]$ for a sufficiently small ϵ (indeed the analytic extension for negative r is given by $\tilde{u}(r, \theta) = u(-r, \theta + \pi)$, $\theta + \pi$ taken modulo 2π). It follows that $A(r, \theta)$ also has an analytic extension near $r = 0$; we denote this extension by $\tilde{A}(r, \theta)$, $(r, \theta) \in [-\epsilon, \epsilon] \times [0, 2\pi]$. The function $F(r, \theta) = \sin N\theta + r\tilde{A}(r, \theta)$ satisfies

$$F(0, \pi/N) = 0 \quad \text{and} \quad \frac{\partial}{\partial\theta}F(0, \pi/N) = -N,$$

and therefore, by the implicit function theorem, it is possible to find a unique analytic function $\theta(r)$ such that $\theta(0) = \pi/N$ and $\{(r, \theta) :\ F(r, \theta) = 0\}$ coincides with $\{(r, \theta(r))\}$ in a neighborhood of $(0, \pi/N)$. The curve, ρ', given by

$$(r \cos\theta(r), r \sin\theta(r)) + x^*,$$

is an analytic curve through x^*, which satisfies $\rho' \cap \rho = x^*$ and which by its very definition is a level curve for u. □

2. Proof of Theorem 0.1. Let O be the open set enclosed by Σ and $\tilde{\Sigma}$, i.e., the set of points in $\Omega \setminus (\Sigma \cup \tilde{\Sigma})$ from which it is only possible to reach $\partial\Omega$ by crossing Σ or $\tilde{\Sigma}$. Since $\Omega \setminus (O \cup \Sigma \cup \tilde{\Sigma})$ has only one connected component, it follows from the assumptions about the boundary data (by unique continuation) that

$$u_j = \tilde{u}_j \quad \text{in } \Omega \setminus (O \cup \Sigma \cup \tilde{\Sigma}), \quad j = 1, \cdots, M. \tag{2.1}$$

If O is nonempty then ∂O consists of pieces of curves from Σ and $\tilde{\Sigma}$; on each of these pieces either u_j or $\tilde{u}_j$ is constant. Due to (2.1) it now follows that u_j is constant on each of the pieces that make up ∂O. Each function u_j therefore assumes finitely many values on ∂O (at most $m + n$). Since u_j is continuous in Ω (cf. [1]) we get that u_j is constant on each connected component of ∂O. Each connected component of O is simply connected, and it now follows, by the maximum principle, that u_j is constant in each connected component of O. This implies that u_j is constant in all of Ω—a contradiction. We thus conclude that O is empty, so that $u_j = \tilde{u}_j$ in $\Omega \setminus (\Sigma \cup \tilde{\Sigma})$; by continuity it follows that

$$u_j = \tilde{u}_j \quad \text{in } \Omega, \quad j = 1, \cdots, M. \tag{2.2}$$

Let us assume that Σ and $\tilde{\Sigma}$ are not identical. We may assume that there exists a curve ρ contained in $\tilde{\sigma}_k$ for some k with $\rho \cap \Sigma = \emptyset$. Based on (2.2) we conclude that the functions u_j are all constant on ρ. There must exist a point on ρ where $\nabla u_1 \neq 0$, since otherwise u_1 is constant in Ω (by unique continuation); the implicit function theorem asserts that ρ must be analytic near this point. By shortening, if necessary, we may assume that the entire curve ρ is analytic. Let ν be a unit normal vector field on the curve ρ and let $x_1, \cdots, x_{M-1}$ be distinct interior points on ρ. Let $\alpha_1, \cdots, \alpha_M$ denote numbers, *not all zero* , satisfying the underdetermined set of linear equations

$$\sum_{j=1}^{M} \frac{\partial u_j}{\partial \nu}(x_i)\alpha_j = 0, \qquad i = 1, \cdots, M-1.$$

Define the function

$$u(x) = \sum_{j=1}^{M} \alpha_j u_j(x) \tag{2.3}$$

for $x \in \Omega$. The curve ρ is also a level curve for u. Applying Lemma 1.1 we obtain an analytic curve ρ_0 containing ρ, which satisfies (1.1a)–(1.1c), i.e.,

$$u \text{ is constant on } \rho_0, \tag{2.4a}$$

$$\rho_0 \text{ has one endpoint on } \partial\Omega \text{ or } \sigma_k \text{ for some } k, \tag{2.4b}$$

$$\rho_0 \text{ has the other endpoint on } \partial\Omega \text{ or } \sigma_l \text{ for some } l \text{ and } l \neq k. \tag{2.4c}$$

For $x \in \rho_0$ we have $|\nabla u(x)| = |\partial u/\partial \nu(x)|$. From (2.3) it follows that $\partial u/\partial \nu(x_i) = 0$, so that $\nabla u(x_i) = 0$ for $i = 1, \cdots, M-1$. Using Lemma 1.2 we may now, for each of the critical points x_i, construct an analytic curve ρ_i such that

$$\rho_i \cap \rho_0 = \{x_i\}, \tag{2.5a}$$

(2.5b) $\qquad u \quad$ is constant on ρ_i.

Lemma 1.1 permits us to extend each of the curves ρ_i until it hits the boundary or one of the cracks in Σ; this way we obtain curves ρ_i which, in addition to (2.5a) and (2.5b), satisfy

(2.5c) $\qquad \rho_i$ has one endpoint on $\partial\Omega$ or σ_k for some k,

(2.5d) $\qquad \rho_i$ has the other endpoint on $\partial\Omega$ or σ_l for some l and $l \neq k$.

The fact that the extended curve ρ_i still only intersects ρ_0 at x_i is proven as follows. If ρ_i intersected ρ_0 at some other point x_i' then there would be some nonempty region O enclosed by ρ_0 and ρ_i with u constant on ∂O. By the maximum principle u would be constant on O, and hence it would be constant on all of Ω. This clearly contradicts the fact that $\gamma^{-1}\partial u/\partial\nu = \sum_{j=1}^{M}\alpha_j(\delta_{P_0}-\delta_{P_j})$ on $\partial\Omega$, where the P_j are distinct and at least one α_j is nonzero. Since all the curves ρ_i intersect ρ_0, the function u assumes the same constant value on $\cup_{i=0}^{M-1}\rho_i$. Note that no two of the $M-1$ curves $\rho_1, \cdots, \rho_{M-1}$ can intersect, for then we would have some nonempty region O enclosed by the M curves $\rho_0, \rho_1, \cdots, \rho_{M-1}$, with u constant on ∂O—a contradiction. For a similar reason none of the curves $\rho_0, \rho_1, \cdots, \rho_{M-1}$ can self-intersect. Between the M curves $\rho_0, \rho_1, \cdots, \rho_{M-1}$ we have a total of $2M$ endpoints. Note that no two of these curves can terminate on the same crack σ_k, for then we would have some region O bounded by these curves and the crack σ_k, with u constant on ∂O—a contradiction. There are n cracks in Σ, so it follows that there must be at least $2M-n$ points on $\partial\Omega$ at which the curves $\rho_0, \rho_1, \cdots, \rho_{M-1}$ terminate. Since the curves $\rho_1, \cdots, \rho_{M-1}$ do not intersect and each only intersect ρ_0 at one point, it is easy to see that any connected component of $\Omega \setminus \cup_{i=0}^{M-1}\rho_i$ has a part of its boundary in common with $\partial\Omega$, and that the number of connected components is exactly equal to the number of terminal points of the curves $\rho_0, \rho_1, \cdots, \rho_{M-1}$ that lie on $\partial\Omega$ (at least $2M-n$). A situation corresponding to $n=2$ and $M=4$ is schematically shown in Fig. 1.

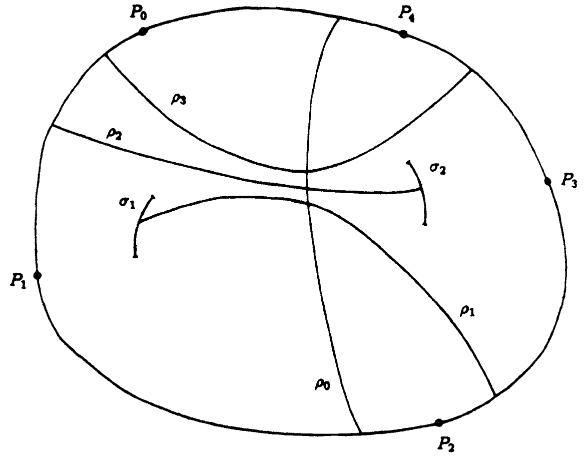

FIG. 1

The Neumann data for u has the form

$$\gamma^{-1}\frac{\partial u}{\partial\nu} = \sum_{j=0}^{M}\beta_j\delta_{P_j} \quad \text{on } \partial\Omega.$$

Let $M'+1 \leq M+1$ be the number of nonzero $\beta's$ in the above sum, i.e., $M'+1$ is the total number of sources and sinks (for u) on $\partial\Omega$. We note that none of the curves $\rho_0, \rho_1, \cdots, \rho_{M-1}$ can terminate at a source or a sink, since $|u|$ approaches ∞ there.

If $M+(M-M') > n+1$ then it follows that $2M-n = M+(M-M')-n+M' > M'+1$, and, therefore, we conclude that at least one of the connected components of $\Omega \backslash \cup_{i=0}^{M-1} \rho_i$ is bounded by a level curve for u, and a portion of $\partial\Omega$ on which the normal derivative of u vanishes. This forces u to be a constant—a contradiction. Hence we see that if $M+(M-M') > n+1$, then the assumption that Σ and $\tilde{\Sigma}$ are different is incorrect.

Since $M \geq n+1$ and $M \geq M'$ we always have that $M+(M-M') \geq n+1$. The only case we have not analyzed yet is $M+(M-M') = n+1$, or, equivalently, $M' = M = n+1$. None of the curves $\rho_0, \rho_1, \cdots, \rho_{M-1}$ can now terminate at any of the points P_j, $j = 0, \cdots, M$ (since $|u|$ approaches ∞ there). Furthermore, each of the connected components of $\Omega \backslash \cup_{i=0}^{M-1} \rho_i$ has at least one of the points P_j on its boundary. If not, the argument from the case $M+(M-M') > n+1$ leads to a contradiction. There cannot be one connected component, the boundary of which contains two or more of the points P_j because then, due to the identity $2M-n = M+1$, there would automatically have to be one connected component, the boundary of which contained none of the points P_j—a contradiction. In summary, each connected component of $\Omega \backslash \cup_{i=0}^{M-1} \rho_i$ has exactly one of the points P_j on its boundary. This means that there are exactly $M+1$ connected components and, therefore, exactly $M+1$ terminal points of the curves $\rho_0, \rho_1, \cdots, \rho_{M-1}$ on $\partial\Omega$. This leaves $2M - (M+1) = M-1 = n$ terminal points that fall on cracks—one on each crack of Σ. From the inequality $n+1 = M \geq \max(m,n)+1$ we conclude that $n \geq m$. If $n = 0$ it would follow that $m = 0$, so that both $\Sigma = \tilde{\Sigma} = \emptyset$—a contradiction. There is, therefore, at least one crack σ_{k_0} in the collection Σ. The crack σ_{k_0} is contained in the closure of one of the connected components of $\Omega \setminus \cup_{i=0}^{M-1} \rho_i$; we denote this connected component by O. Furthermore, we denote by ρ' that part of $\cup_{i=1}^{M-1} \rho_i$, which connects σ_{k_0} to ρ_0. ρ', must necessarily, due to the construction of the curves ρ_i, be an interior boundary of O. A situation corresponding to n=2 and M=3 is illustrated in Fig. 2.

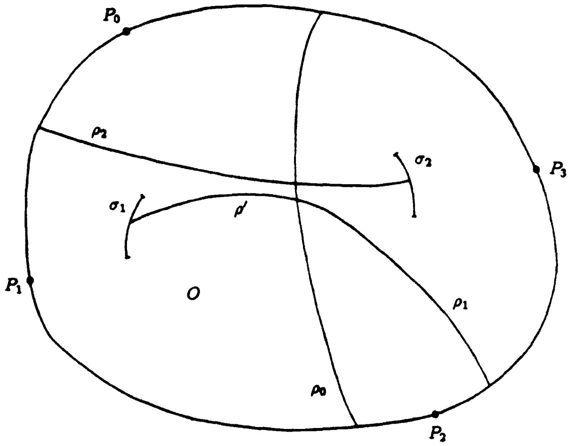

FIG. 2

Let P_{j_0} denote the point which lies on ∂O. We may, without loss of generality, assume that β_{j_0} is negative (so that P_{j_0} is a sink). Consider the maximum of u on

$\overline{O}$. This maximum must be achieved at a boundary point, and it cannot be near P_{j_0}, since u behaves like $-\beta_{j_0}\gamma(P_{j_0})/\pi \ \log r$ there. Since $\frac{\partial u}{\partial \nu}$ is zero on $\partial\Omega \setminus \cup_{j=0}^{M}\{P_j\}$ it now follows from the strong version of the maximum principle that the maximum of u on $\overline{O}$ is attained on that part of ∂O which comes from $\cup_{i=0}^{M-1}\rho_i$; in particular, the maximum is attained all along ρ'. Let x_0 be an interior point on ρ' and let $B \subset O \cup \rho'$ be a ball centered at x_0 which does not intersect Σ. The function u satisfies the elliptic equation $\nabla \cdot (\gamma^{-1}\nabla u) = 0$ in B (and is not constant), and therefore, by the maximum principle,

$$\inf_B u(x) < u(x_0) < \sup_B u(x). \tag{2.6}$$

On the other hand, $B \subset \overline{O}$ so

$$u(x_0) = \max_{\overline{O}} u(x) \geq \sup_B u(x),$$

and this immediately leads to a contradiction with (2.6). Hence we conclude that also in the case $M + (M - M') = n + 1$ we cannot have that Σ and $\tilde{\Sigma}$ are different, and this completes the proof of Theorem 0.1. □

3. Proof of Theorem 0.2. The proof of Theorem 0.2 goes entirely along the lines of the previous proof up to and including the construction of the function u and the curves ρ_i (using the equivalent of Lemmas 1.1 and 1.2 with Dirichlet boundary conditions of the form $\sum \beta_j 1_{\overset{\frown}{P_{j-1}P_j}}$). From there the proof proceeds as outlined below.

The points $P_0, \cdots, P_M$ divide the boundary $\partial\Omega$ into $M+1$ half-open curves

$$\overset{\frown}{P_0P_1} \cup \{P_0\}, \cdots, \overset{\frown}{P_{M-1}P_M} \cup \{P_{M-1}\}, \quad \text{and} \quad \overset{\frown}{P_MP_0} \cup \{P_M\}.$$

Here we have used the notation $\overset{\frown}{PQ}$ for the counterclockwise curve from P to Q, excluding the endpoints. We shall use the notation $[P,Q)$ for the counterclockwise curve from P to Q, including P: $[P,Q) = \overset{\frown}{PQ} \cup \{P\}$. The function u is constant on each of the curves $\overset{\frown}{P_0P_1}, \cdots, \overset{\frown}{P_{M-1}P_M}$, and $\overset{\frown}{P_MP_0}$ (on the last curve, u is actually zero). The curves $\rho_0, \cdots, \rho_{M-1}$ have at least $2M-n$ terminal points on the boundary of Ω, and we note that in this case the curves may very well terminate at one or more of the points $P_0, \cdots, P_M$. If $2M - n > M+1$ (i.e., $M > n+1$) it therefore follows that at least one of the curves $[P_0, P_1), \cdots, [P_{M-1}, P_M)$, and $[P_M, P_0)$ contains two terminal points of $\cup_{i=0}^{M-1}\rho_i$. Consequently, there is a connected component of $\Omega \setminus \cup_{i=0}^{M-1}\rho_i$ which as its boundary has a level curve of u—a contradiction.

We now consider the remaining case: $M = n+1$. In this case we conclude that any one of the curves $[P_0, P_1), \cdots, [P_{M-1}, P_M)$, and $[P_M, P_0)$ contains exactly one terminal point of $\cup_{i=0}^{M-1}\rho_i$. This leaves $2M - (M+1) = M - 1 = n$ terminal points of the curves $\rho_0, \cdots, \rho_{M-1}$ that fall on cracks—one on each crack of Σ. We also see that there are exactly $M+1$ connected components of $\Omega \setminus \cup_{i=0}^{M-1}\rho_i$. For each connected component, that part of the boundary which is shared with $\partial\Omega$ consists of a single curve between two adjacent terminal points of $\cup_{i=0}^{M-1}\rho_i$ (these points lie on adjacent curves $[P_{j-1}, P_j)$ and $[P_j, P_{j+1})$, indices counted modulo M+1). As in the proof of Theorem 0.1, we may argue that $n \geq 1$, so that Σ contains at least one crack σ_{k_0}. Let O denote the connected component of $\Omega \setminus \cup_{i=0}^{M-1}\rho_i$, whose closure contains σ_{k_0}, and let ρ' denote that part of $\cup_{i=0}^{M-1}\rho_i$ which connects σ_{k_0} to ρ_0. ρ' must necessarily, due to the construction of the curves ρ_i, be an interior boundary of O. The (interior) part of the boundary of O, which is shared with $\partial\Omega$, consists of a curve $\overset{\frown}{PQ}$, with $P \in [P_{j_0-1}, P_{j_0})$ and $Q \in [P_{j_0}, P_{j_0+1})$ for some j_0 (mod $M+1$). The rest of the boundary of O is a level curve for u. It is now very easy to see that u takes at most two values on ∂O. Consequently, either the minimum or the maximum of u on $\overline{O}$ is attained on ρ'. This leads to a contradiction, just as in the proof of Theorem 0.1 □

ORTHOGONAL POLYNOMIALS AND A DISCRETE BOUNDARY VALUE PROBLEM I*

RYSZARD SZWARC†

Abstract. Let $\{P_n\}_{n=0}^{\infty}$ be a system of orthogonal polynomials with respect to a measure μ on the real line. Sufficient conditions are given under which any product P_nP_m is a linear combination of P_k's with positive coefficients.

Key words. orthogonal polynomials, recurrence formula

AMS(MOS) subject classifications. 33A65, 39A70

Let us consider the following problem: we are given a probability measure μ on the real line $\mathbf{R}$ all of whose moments $\int x^{2n}d\mu(x)$ are finite. Let $\{P_n(x)\}$ be an orthonormal system in $L^2(\mathbf{R}, d\mu)$ obtained from the sequence $1, x, x^2, \cdots$ by the Gram-Schmidt procedure. We assume that the support of μ is an infinite set so that $1, x, x^2, \ldots$ are linearly independent. Clearly P_n is a polynomial of degree n which is orthogonal to all polynomials of degree less than n. It can be taken to have positive leading coefficients. The product P_nP_m is a polynomial of degree $n+m$ and it can be expressed uniquely as a linear combination of polynomials $P_0, P_1, \cdots, P_{n+m}$,

$$P_nP_m = \sum_{k=0}^{n+m} c(n, m, k)P_k$$

with real coefficients $c(n, m, k)$. Actually, if $k<|n-m|$ then $c(n, m, k)=0$. This is because

$$c(n, m, k) = \langle P_nP_m, P_k\rangle_{L^2(d\mu)} = \langle P_n, P_mP_k\rangle_{L^2(d\mu)} = \langle P_m, P_nP_k\rangle_{L^2(d\mu)}.$$

Hence if $k<|n-m|$ then either $k+m<n$ or $k+n<m$ and one of the above scalar products vanishes. Finally we get

$$P_nP_m = \sum_{k=|n-m|}^{n+m} c(n, m, k)P_k. \tag{1}$$

We ask when the coefficients $c(n, m, k)$ are nonnegative for all $n, m, k = 0, 1, 2, \cdots$. The positivity of coefficients $c(n, m, k)$ (called also the linearization coefficients) gives rise to a convolution structure on $l^1(N)$ and if some additional boundedness condition is satisfied then l^1 with this new operation resembles l^1 of the circle (see [2]).

Analogously to (1), we have

$$xP_n = \gamma_nP_{n+1} + \beta_nP_n + \alpha_nP_{n-1} \quad \text{for } n = 0, 1, 2, \cdots \tag{2}$$

(we apply the convention $\alpha_0 = \gamma_{-1} = 0$). The coefficients α_n and γ_n are strictly positive. If the measure μ is symmetric, i.e., $d\mu(x) = d\mu(-x)$, then $\beta_n = 0$. When P_n are normalized so that $\|P_n\|_{L^2(\mu)} = 1$ then we can check easily that $\alpha_{n+1} = \gamma_n$. Hence, if we put $\lambda_n = \gamma_n$ we get

$$xP_n = \lambda_nP_{n+1} + \beta_nP_n + \lambda_{n-1}P_{n-1} \quad \text{for } n = 0, 1, 2, \cdots. \tag{3}$$

Favard [4] proved that the converse is also true, i.e., any system of polynomials satisfying (3) is orthonormal with respect to a probability measure μ (not necessarily unique). In case of bounded sequences λ_n and β_n we can recover the measure μ in the following way. Consider a linear operator L on $l^2(N)$ given by

$$(4) \qquad La_n = \lambda_n a_{n+1} + \beta_n a_n + \lambda_{n-1} a_{n-1}, \qquad n = 0, 1, 2, \cdots.$$

Then L is a self-adjoint operator on $l^2(N)$. Let $dE(x)$ be the spectral resolution associated with L. Then the system $\{P_n\}$ is orthonormal with respect to the measure $d\mu(x) = d\langle E(x)\delta_0, \delta_0\rangle$.

The statement of the positivity of $c(n, m, k)$ does not require orthonormalization of the polynomials P_n. We can as well consider another normalization, i.e., let $\tilde{P}_n = \sigma_n P_n$ where σ_n is a sequence of positive numbers. The problem of positive coefficients in the product of $\tilde{P}'_n s$ is equivalent to that of $P'_n s$. Moreover, it is easy to check that the polynomials $\tilde{P}_n$ satisfy the recurrence relation of the form

$$(5) \qquad x\tilde{P}_n = \gamma_n \tilde{P}_{n+1} + \beta_n \tilde{P}_n + \alpha_n \tilde{P}_{n-1} \quad \text{for } n = 0, 1, 2, \cdots$$

and the unique relation connecting α_n, γ_n and the coefficients λ_n from (3) is $\alpha_{n+1}\gamma_n = \lambda_n^2$; the sequence of diagonal coefficients β_n remains unchanged. From this observation it follows that if polynomials $\tilde{P}_n$ satisfy (5) then after appropriate renormalization the polynomials $\bar{P}_n = c_n \tilde{P}_n$ satisfy

$$(6) \qquad x\bar{P}_n = \alpha_{n+1}\bar{P}_{n+1} + \beta_n \bar{P}_n + \gamma_{n-1}\bar{P}_{n-1}.$$

Consider the particular case of monic normalization, i.e., assume that the leading coefficient of any P_n is 1. Then the recurrence formula is

$$(7) \qquad xP_n = P_{n+1} + \beta_n P_n + \lambda_{n-1}^2 P_{n-1}.$$

In 1970 Askey proved the following theorem concerning the monic case.

THEOREM (Askey [1]). *Let P_n satisfy (6) and let the sequences λ_n and β_n be increasing ($\lambda_n \geqq 0$); then the linearization coefficients in the formula*

$$P_n P_m = \sum_{k=|n-m|}^{n+m} c(n, m, k) P_k$$

are nonnegative.

This theorem applies to the Hermite, Laguerre, and Jacobi polynomials with $\alpha + \beta \geqq 1$ (see [7]). However, it does not cover the symmetric Jacobi polynomials with $\alpha = \beta$ when $-\frac{1}{2} \leqq \alpha \leqq \frac{1}{2}$ (and, in particular, the Legendre polynomials when $\alpha = \beta = 0$). Recall that the problem of positive linearization for Jacobi polynomials was completely solved by Gaspar in [5] and [6]. In particular, $c(n, m, k)$ are positive for $\alpha \geqq \beta$ and $\alpha + \beta + 1 \geqq 0$.

The aim of this paper is to give a generalization of Askey's result so it would cover the symmetric Jacobi polynomials for $a \geqq -\frac{1}{2}$. One of the results is as follows.

THEOREM 1. *If polynomials P_n satisfy*

$$xP_n = \gamma_n P_{n+1} + \beta_n P_n + \alpha_n P_{n-1}$$

and

(i) *α_n, β_n, and $\alpha_n + \gamma_n$ are increasing sequences (γ_n, $\alpha_n \geqq 0$),*

(ii) *$\alpha_n \leqq \gamma_n$ for $n = 0, 1, 2, \cdots$,*

then $c(n, m, k) \geqq 0$ (see (1)).

It is remarkable that the assumptions on α_n's and γ_n's are separated from that on β_n.

Before giving a proof let us explain how Askey's theorem can be derived from Theorem 1. If polynomials $\tilde{P}_n$ satisfy the assumptions of Askey's theorem then after orthonormalization of $\tilde{P}_n$'s we get the system of polynomials P_n satisfying (3), i.e.,

$$xP_n=\lambda_nP_{n+1}+\beta_nP_n+\lambda_{n-1}P_{n-1} \quad \text{for } n=0,1,2,\cdots,$$

and if λ_n and β_n are increasing then putting $\alpha_n=\lambda_{n-1}$ and $\gamma_n=\lambda_n$ we can see easily that the assumptions of Theorem 1 are also satisfied.

Example. Consider the symmetric Jacobi polynomials $R_n^{(\alpha,\alpha)}$ normalized by $R_n^{\alpha,\alpha}(1)=1$. They satisfy the following recurrence formula:

$$xR_n^{(\alpha,\alpha)}=\frac{n+2\alpha+1}{2n+2\alpha+1}R_{n+1}^{(\alpha,\alpha)}+\frac{n}{2n+2\alpha+1}R_{n-1}^{(\alpha,\alpha)}.$$

In this case

$$\alpha_n=\frac{n}{2n+2\alpha+1},\quad \gamma_n=\frac{n+2\alpha+1}{2n+2\alpha+1},\quad \beta_n=0.$$

Observe that $\alpha_n+\gamma_n=1$ and α_n is increasing when $\alpha\geqq-\frac{1}{2}$. We have also $\alpha_n\leqq\gamma_n$ when $\alpha\geqq-\frac{1}{2}$.

Instead of showing Theorem 1 we will prove a more general result.

THEOREM 2. *Let polynomials P_n satisfy*

$$xP_n=\gamma_nP_{n+1}+\beta_nP_n+\alpha_nP_{n-1}$$

and let for some sequence of positive numbers σ_n polynomials $\bar{P}_n=\sigma_nP_n$ satisfy

$$x\bar{P}_n=\gamma'_n\bar{P}_{n+1}+\beta_n\bar{P}_n+\alpha'_n\bar{P}_{n-1}.$$

Assume also that

(i) $\beta_m\leqq\beta_n$ *for any* $m\leqq n$,
(ii) $\alpha_m\leqq\alpha'_n$ *for any* $m<n$,
(iii) $\alpha_m+\gamma_m\leqq\alpha'_n+\gamma'_n$ *for any* $m<n-1$,
(iv) $\alpha_m\leqq\gamma'_n$ *for any* $m\leqq n$.

Then the linearization coefficients $c(n,m,k)$ in the formula

$$P_nP_m=\sum_{k=|n-m|}^{n+m}c(n,m,k)P_k$$

are nonnegative.

Setting $\alpha'_n=\alpha_n$ and $\gamma'_n=\gamma_n$, we can easily see that Theorem 2 implies Theorem 1.

Proof. First observe that we have $\alpha_{n+1}\gamma_n=\alpha'_{n+1}\gamma'_n$. Moreover, by the remarks preceding (6) we may assume that P_n and $\bar{P}_n$ satisfy

$$xP_n=\alpha_{n+1}P_{n+1}+\beta_nP_n+\gamma_{n-1}P_{n-1},$$
$$x\bar{P}_n=\alpha'_{n+1}\bar{P}_{n+1}+\beta_n\bar{P}_n+\gamma'_{n-1}\bar{P}_{n-1}.$$

The rest of the proof will follow from the maximum principle for a discrete boundary value problem.

Let L and L' be linear operators acting on sequences $\{a_n\}_{n\in N}$ by the rule

$$La_n=\alpha_{n+1}a_{n+1}+\beta_na_n+\gamma_{n-1}a_{n-1},$$
(8)
$$L'a_n=\alpha'_{n+1}a_{n+1}+\beta'_na_n+\gamma'_{n-1}a_{n-1}.$$

Let L_m and L'_n denote the operators acting on complex functions $u(n, m)$, n, $m \in N$, as L and L' but with respect to the m- or n-variable treating the other variable as a parameter.

Let us consider the following problem: $N \times N \ni (n, m) \mapsto u(n, m) \in C$ and

$$(L'_n - L_m)u = 0, \qquad u(n, 0) \geqq 0. \tag{9}$$

THEOREM 3. *Assume that* $\alpha_n > 0$ *for* $n \geqq 1$ (*we follow the convention* $\alpha_0 = \alpha'_0 = 0$) *and*

(i) $\beta_m \leqq \beta'_n$ *for any* $m \leqq n$,

(ii) $\alpha_m \leqq \alpha'_n$ *for any* $m < n$,

(iii) $\alpha_m + \gamma_m \leqq \alpha'_n + \gamma'_n$ *for any* $m < n - 1$,

(iv) $\alpha_m \leqq \gamma'_n$ *for any* $m \leqq n$.

Then $u(n, m) \geqq 0$ *for* $m \leqq n$.

Proof. On the contrary, assume that u is negative at some points. Let $(n, m+1)$ be the lowest point in the domain $\{(s, t)\colon s \geqq t\}$ for which $u(n, m+1) < 0$. It means that $u(s, t)$ is nonnegative if $t \leqq m$. Consider the rectangular triangle with vertices $A(n, m)$, $B(n-m, 0)$ and $C(n+m, 0)$, as illustrated in Fig. 1.

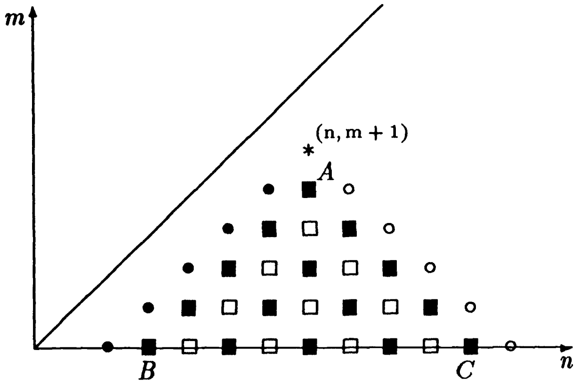

FIG. 1

All lattice points in ΔABC we divide into two subsets: Ω_1, consisting of the points (k, l) such that $k - l = n - m (\text{mod } 2)$, and the rest Ω_2. In the figure the points of Ω_1 are marked by ■ while the points of Ω_2 are marked by □. Let Ω_3 denote the lattice points connecting $(n-m-1, 0)$ and $(n, m+1)$ (except $(n, m+1)$) and Ω_4 denote those which connect $(n+m+1, 0)$ with $(n, m+1)$ (except $(n, m+1)$). The points of Ω_3 and Ω_4 are marked by ● and ○, respectively.

Assume that $(L'_n - L_m)u = 0$. Thus $\sum_{(x,y)\in\Omega_1} (L'_n - L_m)u(x, y) = 0$. If we calculate the terms $(L'_n - L_m)u(x, y) = 0$ and we sum them up we will obtain a sum of the values of the function $u(s, t)$ with some coefficients $c_{s,t}$ where (s, t) runs throughout the sets $\Omega_1 \cup \Omega_2 \cup \Omega_3 \cup \Omega_4 \cup \{(n, m+1)\}$. Namely,

$$\begin{aligned} 0 &= \sum_{(x,y)\in\Omega_1} (L'_n - L_m)u(x, y) \\ &= \sum_{i=1}^{4} \sum_{(s,t)\in\Omega_1} c_{s,t}u(s, t) + c_{n,m+1}u(n, m+1). \end{aligned}$$

It is not hard to compute the coefficients $c_{s,t}$, so we just list them below.

(i) $(s, t) \in \Omega_1$; $c_{s,t} = \beta'_s - \beta_t$.
(ii) $(s, t) \in \Omega_2$; $c_{s,t} = \alpha'_s + \gamma'_s - (\alpha_t + \gamma_t)$.
(iii) $(s, t) \in \Omega_3$; $c_{s,t} = \gamma'_s - \alpha_t$.
(iv) $(s, t) \in \Omega_4$; $c_{s,t} = \alpha'_s - \alpha_t$.
(v) $c_{n,m+1} = -\alpha_{m+1}$.

By the assumptions of the theorem all coefficients $c_{s,t}$ are nonnegative while $c_{n,m+1}$ is strictly negative. Since $u(s, t) \geqq 0$ for $(s, t) \in \Omega_1 \cup \Omega_2 \cup \Omega_3 \cup \Omega_4$ and $u(n, m+1) < 0$ then the sum we were dealing with cannot be zero. It gives a contradiction.

Let us return to the proof of Theorem 2. Let P_n and $\bar{P}_n$ satisfy (8) and $\bar{P}_n = \sigma_n P_n$ for a strictly positive sequence σ_n. If

$$P_n P_m = \sum_{k=|n-m|}^{n+m} c(n, m, k) P_k,$$

then

$$\bar{P}_n P_m = \sum_{k=|n-m|}^{n+m} \bar{c}(n, m, k) P_k,$$

where $\bar{c}(n, m, k) = c(n, m, k)\sigma_n$. Therefore in order to prove $c(n, m, k) \geqq 0$ it suffices to show that $\bar{c}(n, m, k) \geqq 0$ for $n > m$. Since

$$L'_n(\bar{P}_n P_m) = x\bar{P}_n P_m = L_m(\bar{P}_n P_m)$$

and the polynomials P_n are linearly independent then for any k the function $u(n, m) = \bar{c}(n, m, k)$ is a solution of (9). Obviously,

$$u(n, 0) = c(n, 0, k)\sigma_n = \begin{cases} \sigma_n & \text{if } n = k, \\ 0 & \text{otherwise.} \end{cases}$$

In particular, $u(n, 0) \geqq 0$. Hence by Theorem 3 we get $u(n, m) = \bar{c}(n, m, k) \geqq 0$. This completes the proof of Theorem 2.

COROLLARY. *Let polynomials P_n satisfy $xP_n = \gamma_n P_{n+1} + \beta_n P_n + \alpha_n P_{n-1}$ and let*
(i) *β_n and α_n be increasing $(\alpha_n > 0$ for $n \geqq 1$, $\alpha_0 = 0)$;*
(ii) *$\alpha_m + \gamma_m \leqq \alpha_{n+1} + \gamma_{n-1}$ for $m < n-1$;*
(iii) *$\alpha_m \leqq \gamma_n$ for $m < n$.*

Then the linearization coefficients $c(n, m, k)$ in (1) *are nonnegative.*

Proof. By remarks preceding (6) after appropriate renormalization of P_n we obtain polynomials P'_n satisfying (6). Then we get the required result by applying Theorem 2.

Example. Consider Jacobi polynomials $P_n^{(\alpha,\beta)}$. They satisfy the recurrence formula

$$xP_n^{(\alpha,\beta)} = \frac{2(n+1)(n+\alpha+\beta+1)}{(2n+\alpha+\beta+1)(2n+\alpha+\beta+2)} P_{n+1}^{(\alpha,\beta)}$$
$$+ \frac{\beta^2 - \alpha^2}{(2n+\alpha+\beta)(2n+\alpha+\beta+2)} P_n^{(\alpha,\beta)}$$
$$+ \frac{2(n+\alpha)(n+\beta)}{(2n+\alpha+\beta)(2n+\alpha+\beta+1)} P_{n-1}^{(\alpha,\beta)}.$$

Applying the corollary yields that for $\alpha \geqq \beta$ and $\alpha + \beta \geqq 0$ we get positive linearization coefficients. However, for $\alpha \geqq \beta$ and $\alpha + \beta < 0$ the sequence

$$\beta_n = \frac{\beta^2 - \alpha^2}{(2n+\alpha+\beta)(2n+\alpha+\beta+2)}$$

is decreasing and we cannot apply any of the preceding results, although we know from [5] and [6] that the condition $\alpha+\beta+1\geqq 0$ is sufficient.

In part II of this paper we will discuss the problem of positive linearization under assumption β_n is decreasing when starting from $n=1$. This is more delicate because assumptions on α_n's and γ_n's cannot be separated from those on β_n's.

ORTHOGONAL POLYNOMIALS AND A DISCRETE BOUNDARY VALUE PROBLEM II*

RYSZARD SZWARC†

Abstract. Let $\{P_n\}_{n=0}^{\infty}$ be a system of polynomials orthogonal with respect to a measure μ on the real line. Then P_n satisfy the three-term recurrence formula $xP_n = \gamma_n P_{n+1} + \beta_n P_n + \alpha_n P_{n-1}$. Conditions are given on the sequence α_n, β_n, and γ_n under which any product $P_n P_m$ is a linear combination of P_k with positive coefficients. The result is applied to the measures $d\mu(x) = (1-x^2)^{\alpha}|x|^{2\beta+1}\,dx$ and $d\mu(x) = |x|^{2\alpha+1}e^{-x^2}\,dx$, α, $\beta > -1$. As a corollary, a Gasper result is derived on the Jacobi polynomials $P_n^{(\alpha,\beta)}$ with $\alpha \geqq \beta$ and $\alpha + \beta + 1 \geqq 0$.

Key words. orthogonal polynomials, recurrence formula

AMS(MOS) subject classifications. primary 33A65, 39A70

The present paper is a continuation of our earlier work [9]. We were concerned in part I with the following question. Given a probability measure μ on the real line $\mathbb{R}$ such that all its moments are finite, let $\{P_n\}_{n=0}^{\infty}$ be a system of orthogonal polynomials obtained from the sequence of consecutive monomials $1, x, x^2, \cdots$ by the Gram-Schmidt procedure. We do not impose any special normalization upon P_n except that its leading coefficient be positive. The product $P_n P_m$ is a polynomial of degree $n+m$ and it can be expressed as

$$P_n P_m = \sum_{k=|n-m|}^{n+m} c(n, m, k) P_k \tag{1}$$

with some real coefficients $c(n, m, k)$. We are asking when $c(n, m, k)$ are nonnegative for any n, m, $k \in \mathbb{N}$. The coefficients $c(n, m, k)$ from (1) are called the *linearization coefficients* of $\{P_n\}$ and if they are nonnegative we simply say that the linearization coefficients are nonnegative.

It is well known that P_n that P_n obey a three-term recurrence formula of the form

$$xP_n = \gamma_n P_{n+1} + \beta_n P_n + \alpha_n P_{n-1}, \tag{2}$$

where α_n, γ_n are positive, except $\alpha_0 = 0$, and β_n are real. In [9, Thm. 1], we proved that if $\{\alpha_n\}$, $\{\beta_n\}$, $\{\alpha_n + \gamma_n\}$ are increasing sequences and $\gamma_n \geqq \alpha_n$, for $n = 0, 1, 2, \cdots$, then the linearization coefficients of $\{P_n\}$ are nonnegative.

Our aim now is to get rid in some way of the condition of the monotonicity of the sequence $\{\beta_n\}$. Roughly the idea consists in reducing the problem to the case $\beta_n = 0$. This can be done in the following way. Consider first polynomials P_n satisfying

$$xP_n = \gamma_n P_{n+1} + \alpha_n P_{n-1}, \qquad P_0 = 1. \tag{3}$$

Then, of course, P_{2n} are even functions while P_{2n+1} are odd ones. Equivalently, this means that the corresponding measure, which orthogonalizes $\{P_n\}$ (and which exists by the Favard theorem [5]) is symmetric with respect to zero. An easy calculation gives the following:

$$\begin{aligned} x^2 P_{2n}(x) = {} & \gamma_{2n+1}\gamma_{2n} P_{2n+2}(x) + (\alpha_{2n+1}\gamma_{2n} + \alpha_{2n}\gamma_{2n-1}) P_{2n}(x) \\ & + \alpha_{2n}\alpha_{2n-1} P_{2n-2}(x). \end{aligned} \tag{4}$$

† Mathematical Institute, University of Wroclaw, pl. Grunwaldzki 2/4, 50-384 Wroclaw, Poland.

Let us define the polynomials Q_n by

$$Q_n(y)=P_{2n}(\sqrt{y}). \tag{5}$$

Then by (4) the polynomials Q_n satisfy

$$yQ_n(y)=\gamma_{2n+1}\gamma_{2n}Q_{n+1}(x)+(\alpha_{2n+1}\gamma_{2n}+\alpha_{2n}\gamma_{2n-1})Q_n(x)+\alpha_{2n}\alpha_{2n-1}Q_{n-1}(x). \tag{6}$$

Observe that (6) is again a three-term recurrence formula. Moreover, if the polynomials P_n have nonnegative linearization coefficients, then by (5) the polynomials Q_n do as well.

We can go the other way around. Assume we are given a sequence of polynomials Q_n orthogonal with respect to a measure ν supported on $[0, +\infty)$. Instead of studying the Q_n we can examine the polynomials P_n satisfying (3) and (5) with regard to the question of nonnegative linearization coefficients. Those are easier to handle, because in (3) the coefficients β_n are missing, unlike in the recurrence formula for Q_n.

First we will sharpen Theorem 1 from [9] in case of symmetric measures.

THEOREM 1. *Let orthogonal polynomials P_n satisfy*

$$xP_n=\gamma_nP_{n+1}+\alpha_nP_{n-1}, \qquad n=0,1,2,\cdots, \tag{7}$$

where $\alpha_0=0$, α_n, $\gamma_n\geqq 0$. Assume that the sequences $\{\alpha_{2n}\}$, $\{\alpha_{2n+1}\}$, $\{\alpha_{2n}+\gamma_{2n}\}$, $\{\alpha_{2n+1}+\gamma_{2n+1}\}$ are increasing and $\alpha_n\leqq\gamma_n$ for $n=0,1,2,\cdots$. Then the linearization coefficients of P_n are nonnegative.

Proof. As in [9], Remark 1, we can renormalize P_n (i.e., multiply each P_n by a positive number σ_n) so as to satisfy

$$xP_n=\alpha_{n+1}P_{n+1}+\gamma_{n-1}P_{n-1}. \tag{8}$$

Of course, it does not affect the conclusion of the theorem, so we introduce no new symbols for the renormalized polynomials. Let μ be a symmetric probability measure that orthogonalizes the polynomials P_n. Then by (1)

$$c(n,m,k)\int P_k^2\,d\mu=\int P_nP_mP_k\,d\mu. \tag{9}$$

Hence the quantity $c(n,m,k)\int P_k^2\,d\mu$ is invariant under permutations of n, m, k. Since μ is symmetric, then $c(n,m,k)=0$ if n, m, k are all odd numbers. Thus if $c(n,m,k)\neq 0$ then one of n, m, k is an even number. By invariance, we can always assume that k is such. Collecting all of the above it suffices to show that in the formulas

$$\begin{aligned} P_{2n}P_{2m}&=\sum c(2n,2m,2k)P_{2k},\\ P_{2n+1}P_{2m+1}&=\sum c(2n+1,2m+1,2k)P_{2k}\end{aligned} \tag{10}$$

the coefficients $c(2n,2m,2k)$ and $c(2n+1,2m+1,2k)$ are nonnegative. It automatically implies that they are also nonnegative in the formula

$$P_{2n+1}P_{2m}=\sum c(2n+1,2m,2k+1)P_{2k+1}. \tag{11}$$

Let L be the linear operator acting on the sequences $\{a_n\}_{n=0}^{\infty}$ by

$$La_n=\alpha_{n+1}a_{n+1}+\gamma_{n-1}a_{n-1}. \tag{12}$$

Let L_n and L_m denote the linear operators acting on the matrices $\{u(n,m)\}_{n,m=0}^{\infty}$ as the operator L does but according to the n or m variable (cf. [9]). Fix $k\in\mathbb{N}$ and consider the matrix $u(n,m)=c(n,m,k)$. By (8) and (9) (cf. [9]) we have $(L_n-L_m)u=0$. Moreover, $u(n,0)=1$ for $n=2k$ and $u(n,0)=0$ otherwise. Hence the following maximum principle would complete the proof.

LEMMA 1. *Let the matrix $u(n, m)$, $n, m = 0, 1, 2, \cdots$ satisfy*

$$(13)\qquad \begin{gathered}(L_n - L_m)u = 0\\ u(2n, 0) \geqq 0, \quad u(2n+1, 0) = 0, \quad n = 0, 1, 2, \cdots.\end{gathered}$$

Then (under the assumptions of Theorem 1) $u(n, m) \geqq 0$ for $n \geqq m$.

For the proof of Lemma 1 we refer the reader to [9] (the proof of Theorem 3). It suffices to observe that (10) and (11) imply $u(n, m) = 0$ whenever $n + m$ is an odd number. Hence, scanning the proof of Theorem 3 from [9], we can observe that the coefficients $c_{s,t}$, which are computed there, have the property that $s + r$ is an even number.

Combining Theorem 1, (4), (5), and (6) immediately gives the following corollary.

COROLLARY 1. *Let the orthogonal polynomials $Q_n(y)$ satisfy the recurrence formula*

$$yQ_n = \tilde{\gamma}_n Q_{n+1} + \tilde{\beta}_n Q_n + \tilde{\alpha}_n Q_{n-1}.$$

Assume that there exist sequences α_n, γ_n of nonnegative numbers ($\alpha_0 = 0$) and a real constant β such that

$$(14)\qquad \tilde{\gamma}_n = \gamma_{2n+1}\gamma_{2n}, \quad \tilde{\alpha}_n = \alpha_{2n}\alpha_{2n-1}, \quad \tilde{\beta}_n = \alpha_{2n+1}\gamma_{2n} + \alpha_{2n}\gamma_{2n-1} + \beta,$$

and α_n, γ_n satisfy the assumptions of Theorem 1. Then the linearization coefficients of Q_n are nonnegative.

Before giving applications of Corollary 1 let us study the relation between orthogonal polynomials P_n and Q_n connected by (3) and (5). Let μ be a measure that orthogonalizes the polynomials P_n. Then

$$\begin{aligned}0 &= \int_{-\infty}^{+\infty} P_{2n}(x)P_{2m}(x)\,d\mu(x) = 2\int_0^{+\infty} P_{2n}(x)P_{2m}(x)\,d\mu(x)\\ &= 2\int_0^{+\infty} Q_n(y)Q_m(y)\,d\mu(\sqrt{y}).\end{aligned}$$

Hence Q_n are orthogonal with respect to the measure $d\nu(y) = 2d\mu(\sqrt{y})$, $y \geqq 0$. Note that the measure μ can be recovered back from ν by $d\mu(x) = \frac{1}{2}d\nu(x^2)$, $x \geqq 0$, and $d\mu(-x) = d\mu(x)$.

It is worthwhile to look at the polynomials R_n defined by

$$S_n(y) = \frac{1}{\sqrt{y}} P_{2n+1}(\sqrt{y}).$$

Then

$$\begin{aligned}0 &= \int_{-\infty}^{+\infty} P_{2n+1}(x)P_{2m+1}(x)\,d\mu(x)\\ &= 2\int_0^{+\infty} x^2 \frac{P_{2n+1}(x)}{x}\frac{P_{2m+1}(x)}{x}\,d\mu(x)\\ &= 2\int_0^{+\infty} S_n(y)S_m(y)y\,d\mu(\sqrt{y}).\end{aligned}$$

Hence the measure that orthogonalizes the S_n is $2y\,d\mu(\sqrt{y})$ or simply $y\,d\nu(y)$.

THEOREM 2. *Let $\{P_n\}_{n=0}^{\infty}$ be the system of polynomials orthogonal with respect to the measure $d\mu(x) = (1-x^2)^{\alpha}|x|^{2\beta+1}\,dx$, $x \in (-1, 1)$, $\alpha, \beta > -1$. If $\alpha \geqq \beta$ and $\alpha + \beta + 1 \geqq 0$, then the coefficients $c(n, m, k)$ in $P_nP_m = \sum c(n, m, k)P_k$ are nonnegative.*

Proof. It suffices to find a three-term recurrence formula for P_n so as to fulfill the assumptions of Theorem 1.

LEMMA 2. *The polynomials* $\{P_n\}_{n=0}^{\infty}$ *satisfying*

$$xP_{2n}=\frac{n+\alpha+\beta+1}{2n+\alpha+\beta+1}P_{2n+1}+\frac{n}{2n+\alpha+\beta+1}P_{2n-1}, \tag{15}$$

$$xP_{2n-1}=\frac{n+\alpha}{2n+\alpha+\beta}P_{2n}+\frac{n+\beta}{2n+\alpha+\beta}P_{2n-2} \tag{16}$$

for $n=0,1,2,\cdots$, $(P_0=1)$ *are orthogonal with respect to the measure* $d\mu(x)=(1-x^2)^{\alpha}|x|^{2\beta+1}\,dx$.

Proof of Lemma 2. Let $R_n^{(\alpha,\beta)}(y)$ denote the Jacobi polynomials normalized by $R_n^{(\alpha,\beta)}(1)=1$. Let

$$\tilde{Q}_n(y)=R_n^{(\alpha,\beta)}(2y-1). \tag{17}$$

Then $\tilde{Q}_n$ are orthogonal with respect to the measure $d\nu(y)=(1-y)^{\alpha}y^{\beta}\,dy$. By the recurrence formula for $R_n^{(\alpha,\beta)}$ (see [6, (4) p. 172] or [4, (3) and (11), p. 169]), $\tilde{Q}_n$ satisfy

$$y\tilde{Q}_n=\frac{(n+\alpha+\beta+1)(n+\alpha+1)}{(2n+\alpha+\beta+1)(2n+\alpha+\beta+2)}\tilde{Q}_{n+1}$$
$$+\frac{1}{2}\left(1+\frac{\beta^2-\alpha^2}{(2n+\alpha+\beta)(2n+\alpha+\beta+2)}\right)\tilde{Q}_n$$
$$+\frac{n(n+\beta)}{(2n+\alpha+\beta+1)(2n+\alpha+\beta)}\tilde{Q}_{n-1}.$$

Let P_n be the polynomials satisfying (13). Then by (4) and (6) the polynomials $Q_n(y)=P_{2n}(\sqrt{y})$ satisfy the same recurrence formula as $\tilde{Q}_n$ do. Indeed, in both recurrence formulas the coefficients of Q_{n+1}, Q_{n-1} *and* $\tilde{Q}_{n+1}$, $\tilde{Q}_{n-1}$ coincide. Then the coefficients of Q_n, $\tilde{Q}_n$ must also coincide because in both formulas the sum of coefficients is equal to 1 (for $\tilde{Q}_n=R_n^{(\alpha,\beta)}(1)=1$ and $Q_n(1)=P_{2n}(1)=1$ by (14)). Hence we have just proved that $Q_n=\tilde{Q}_n$. This means Q_n are orthogonal with respect to the measure $d\nu(y)=(1-y)^{\alpha}y^{\beta}\,dy$. Thus by the reasoning of Corollary 1 the polynomials P_n are orthogonal with respect to the measure $d\mu(x)=\frac{1}{2}d\nu(x^2)=(1-x^2)^{\alpha}|x|^{2\beta+1}\,dx$, as was required.

Let us return to the proof of Theorem 2. From Lemma 1 we can easily see that if $\alpha\geqq\beta$ *and* $\alpha+\beta+1\geqq0$ then the assumptions of Theorem 1 are satisfied. This completes the proof.

COROLLARY 2 (Gasper [6]). *Let* $R_n^{(\alpha,\beta)}$ *be the Jacobi polynomials normalized so that* $R_n^{(\alpha,\beta)}(1)=1$. *If* $\alpha\geqq\beta$ *and* $\alpha+\beta+1\geqq0$ *then*

$$R_n^{(\alpha,\beta)}R_m^{(\alpha,\beta)}=\sum_{k=|n-m|}^{n+m}c(n,m,k)R_k^{(\alpha,\beta)}$$

with nonnegative coefficients $c(n,m,k)$.

Proof. Let P_n be the polynomials orthogonal with respect to the measure $d\mu(x)=(1-x^2)^{\alpha}|x|^{2\beta+1}\,dx$ and satisfying (15) and (16). Then by Theorem 2 we have $P_nP_m=\sum d(n,m,k)P_k$, where $d(n,m,k)\geqq0$. From the proof of Lemma 2 we know that $P_{2n}(\sqrt{y})=R_n^{(\alpha,\beta)}(2y-1)$. Hence we get $R_n^{(\alpha,\beta)}R_m^{(\alpha,\beta)}=\sum d(2n,2m,2k)R_k^{(\alpha,\beta)}$, where $d(2n,2m,2k)\geqq0$.

COROLLARY 3. *Let $\alpha \geqq \beta$ and $\alpha+\beta+1 \geqq 0$. Then*

$$(y+1)R_n^{(\alpha,\beta+1)}R_m^{(\alpha,\beta+1)} = \sum_{k=|n-m|}^{n+m} c(n,m,k)R_k^{(\alpha,\beta)},$$

$$R_n^{(\alpha,\beta)}R_m^{(\alpha,\beta+1)} = \sum_{k=|n-m|}^{n+m} d(n,m,k)R_k^{(\alpha,\beta+1)},$$

where $c(n,m,k)$ and $d(n,m,k)$ are nonnegative coefficients.

Proof. Let P_n be the orthogonal polynomials corresponding to the measure $d\mu(x) = (1-x^2)^\alpha |x|^{2\beta+1}\,dx$. Then, as we have seen in the proof of Lemma 2, $P_{2n}(\sqrt{y}) = R_n^{(\alpha,\beta)}(2y-1)$. Let the polynomials $S_n(y)$ be defined as $S_n(y) = (1/\sqrt{y})\,P_{2n+1}(\sqrt{y})$. By the considerations following Corollary 1 we know that $S_n(y)$ are orthogonal with respect to the measure $2y\,d\mu(\sqrt{y}) = (1-y)^\alpha y^{\beta+1}\,dy$ and $S_n(1)=1$. This yields $S_n(y) = R_n^{(\alpha,\beta)}(2y-1)$. Now both required formulas coincide with (10) and (11). The latter have nonnegative coefficients if $\alpha \geqq \beta$ and $\alpha+\beta+1 \geqq 0$.

Now we turn to the so called generalized Hermite polynomials.

THEOREM 3. *Let P_n be the polynomials orthogonal with respect to the measure $d\mu(x) = |x|^{2\alpha+1} e^{-x^2}\,dx$, $\alpha > -1$. Then the P_n have nonnegative linearization coefficients.*

Proof. First we show that P_n satisfy the following recurrence formulas.

$$xP_{2n} = (n+\alpha+1)P_{2n+1} + nP_{2n-1}, \tag{18}$$

$$xP_{2n-1} = P_{2n} + P_{2n-2}. \tag{19}$$

Indeed, let P_n satisfy (18) and (19). Then

$$x^2P_{2n} = (n+\alpha+1)P_{2n+2} + (2n+\alpha+1)P_{2n} + nP_{2n-2}.$$

Hence, putting $Q_n(y) = P_{2y}(\sqrt{y})$ gives

$$yQ_n = (n+\alpha+1)Q_{n+1} + (2n+\alpha+1)Q_n + nQ_{n-1}.$$

Therefore, the polynomials Q_n coincide with the Laguerre polynomials $(-1)^n L_n^{(\alpha)}$, so they are orthogonal with respect to the measure $d\nu(y) = y^\alpha e^{-y}\,dy$. This implies that P_n are orthogonal with respect to the measure $d\mu(x) = \frac{1}{2}d\nu(x^2) = |x|^{2\alpha+1} e^{-x^2}\,dx$. Combining (18), (19) and Theorem 2 yields the conclusion.

THE GROWTH OF POLYNOMIALS BOUNDED AT EQUALLY SPACED POINTS*

DON COPPERSMITH† AND T. J. RIVLIN†

Abstract. If the absolute value of a (real) polynomial of degree d is bounded by 1 at k equally spaced points of the real line, it is of interest to know how large its absolute value on the interval spanned by the points can be. This work provides a fairly definitive answer to this question.

Key words. polynomials, comparison of norms

AMS(MOS) subject classification. 26C05

Introduction. Let $t_0 < t_1 < \cdots < t_m$ be equally spaced points on the real line. Consider the set $\mathbf{P} = P(d, m)$ of real polynomials, $p(x)$, of degree at most d such that $|p(t_i)| \leq 1$, $i = 0, \cdots, m$. Put

$$\|p\| = \|p\|_{[t_0, t_m]} = \max \{|p(x)|: t_0 \leqq x \leqq t_m\},$$

and

$$B(d, m) = \sup_{p \in P(d,m)} \|p\|. \tag{1}$$

This paper is devoted to an investigation of the behavior of $B(d, m)$. Since $B(d, m)$ is infinite for $m < d$ we suppose, henceforth, that $m \geqq d$, and consequently the "sup" in (1) may be replaced by "max". Moreover, since $B(d, m)$ is invariant under linear transformations, $s_i = at_i + b$, $(a \neq 0)$, $i = 0, \cdots, m$, we shall choose convenient sets of equally spaced points in what follows. There is a considerable literature about the properties of $B(d, m)$. Schönhage [4] showed that $B(d, m)$ is bounded if $m > d^2$. Ehlich and Zeller [1], in a brief and elegant paper, improved on Schönhage's result by showing that for $m > d^2/\sqrt{6}$, $B(d, m)$ is bounded by $(1-\rho)^{-1}$, where $\rho = d^2(d^2-1)/(6m^2)$. (In this same paper, they also showed that when the absolute value of a polynomial of degree d is bounded by one at the zeros or extrema of the Chebyshev polynomial, $T_m(x)$, its norm on $[-1, 1]$ is bounded by $(\cos(\pi d/(2m)))^{-1}$, hence certainly bounded if $m \geqq cd$, $c > 1$, a result which will motivate our approach to the problem we shall be considering.) Subsequently Ehlich and Zeller [2] showed that $B(d, m)$ remains bounded if $m > (2/\pi^2)d^2$. As counterpoint to these results, Ehlich [3], by an explicit construction involving Zolotarev polynomials, showed that if $m = o(d^2)$ as $d \to \infty$, then $B(d, m) \to \infty$ as $d \to \infty$. We wish to close the gap between the boundedness results of Schönhage and Ehlich and Zeller, and Ehlich's unboundedness result by establishing a converse to Ehlich's result. Namely, for fixed $\delta > 0$ and d and m growing subject to $m \geqq \delta d^2$, $B(d, m)$ remains bounded, with the bound depending only on δ. In fact, we show that there are positive constants a, b such that

$$B(d, m) < a\, e^{b/\delta}, \tag{2}$$

and, conversely, there are positive constants γ, β with

$$B(d, m) > \gamma\, e^{\beta/\delta},$$

$\delta = m/d^2$.

In § 1 we gather a small syllabus of elementary material to be used in establishing (2) so that the proof given in § 2 will not be excessively fragmented. Section 3 contains the construction of the polynomials that show that (2) cannot be improved upon in its dependence on δ.

1. Some preliminary information.

(i)

$$f(\varphi)=\frac{1-\cos \pi\varphi/d}{\varphi^2} \tag{3}$$

is monotonically decreasing for $0\leqq \varphi \leqq (d/2)$.

(ii) Suppose $0<j<d$, then

$$\prod_{\substack{i=0\\ i\neq j}}^{d}\left|\cos\frac{\pi i}{d}-\cos\frac{\pi j}{d}\right|=\frac{d}{2^{d-1}}. \tag{4}$$

Proof of (4). Put $\eta_i=\cos(\pi i/d)$, $i=0,\cdots,d$, and

$$\omega(x)=\prod_{i=0}^{d}(x-\eta_i)=\frac{x^2-1}{d2^{d-1}}T_d'(x),$$

where $T_d(x)$ is the Chebyshev polynomial of degree d. Then

$$\prod_{\substack{i=0\\ i\neq j}}^{d}(\eta_j-\eta_i)=\omega'(\eta_j)=\frac{(\eta_j^2-1)}{d2^{d-1}}T_d''(\eta_j)+\frac{2\eta_j}{d2^{d-1}}T_d'(\eta_j)$$

$$=(-1)^j\frac{d}{2^{d-1}},\qquad 0<j<d,$$

since $T_d'(\eta_j)=0$, $0<j<d$, $(1-x^2)T_d''(x)=xT_d'(x)-d^2T_d(x)$ and $T_d(\eta_j)=(-1)^j$. □

(iii)

$$\prod_{i=1}^{d}\sin^2\frac{\pi i}{2d}=\frac{d}{2^{2d-2}}. \tag{5}$$

Proof of (5).

$$\prod_{i=1}^{d-1}\sin^2\frac{\pi i}{2d}=\prod_{i=1}^{d-1}\left(1-\cos^2\frac{\pi i}{2d}\right).$$

But, if $U_k(x)$ is the Chebyshev polynomial of the second kind, then

$$2d=U_{2d-1}(1)=2^{2d-1}\prod_{i=1}^{2d-1}\left(1-\cos\frac{\pi i}{2d}\right)$$

$$=2^{2d-1}\prod_{i=1}^{d-1}\left(1-\cos^2\frac{\pi i}{2d}\right).$$ □

(iv) Suppose $m\leqq n$, then $B(d,n)\leqq B(d,m)$.

Proof.

$$B(d,n)=\max\{\|p\|_{[0,n]}: |p(i)|\leqq 1, i=0,1,\cdots,n\}$$

$$=|\bar{p}(x)|, 0\leqq x\leqq n.$$

Let $k, k+1, \cdots, k+m$ be chosen so that $0 \leqq k$, $k+m \leqq n$ and $k \leqq x \leqq k+m$. Then $|\bar{p}(i)| \leqq 1$, $i = k, \cdots, k+m$, and so

$$\begin{aligned} B(d, m) &= \max \{\|p\|_{[k,k+m]} : |p(i)| \leqq 1, i = k, \cdots, k+m\} \\ &\geqq \|\bar{p}\|_{[k,k+m]} = |\bar{p}(x)|. \end{aligned} \qquad \square$$

2. The upper bound. Let p be a polynomial of degree d. If $d = 0, 1$, the determination of $B(d, m)$ is trivial. If $d = 2$, Schönhage [4] gives the simple result

$$B(2, 2k+1) = 1 + \frac{1}{2k(k+1)},$$

$$B(2, 2k) = 1 + \frac{1}{2k(k+1)}.$$

With no loss of generality, we choose the $m+1$ points at which $|p|$ is bounded by 1 to be the integers $0, 1, \cdots, m$. Given d and m put $\varepsilon = m/d^2$. Suppose $d \leqq m \leqq 8d$ so that $\varepsilon \leqq 8/d$. Fix $p \in \mathbf{P}$ and $x \in [0, m]$. Select $d+1$ consecutive integers, $a_0 < a_1 < \cdots < a_d$, contained in $[0, m]$, such that $a_0 \leqq x \leqq a_d$. Then since $|p(a_i)| \leqq 1$, $i = 0, \cdots, d$, the Lagrange interpolation formula implies that $|p(x)| \leqq 2^d$. Thus

$$B(d, m) \leqq 2^d \leqq 2^{8/\varepsilon}, \qquad d \leqq m \leqq 8d. \tag{6}$$

So we shall assume that

$$m > 8d$$

in the remainder of this section. Furthermore, we assume that $\varepsilon < 1/10$ (hence $\varepsilon > 8/d$ and $d > 80$), m is divisible by 4, and d is even.

Fix $p \in \mathbf{P}$ and choose any $x \in [0, m]$. Put $M = m/4 = \varepsilon d^2/4$. Since $2M = m/2$, either the interval $[\lfloor x \rfloor, \lfloor x \rfloor + 2M]$ or the interval $[\lceil x \rceil - 2M, \lceil x \rceil]$ is contained in $[0, m]$, where $\lfloor x \rfloor$ is the greatest integer $\leqq x$, and $\lceil x \rceil$ is the least integer $\geqq x$. In either case, by a linear transformation of the argument of p, we arrive at the following setting: $x \in [M-1, M]$, $|p(i)| \leqq 1$, $i = -M, -M+1, \cdots, M-1, M$. With this setting, we obtain our bound on $B(d, m)$ by bounding $|p(x)|$, where x is chosen to be the point at which $|p(x)|$ attains its maximum.

Our plan is to choose $d+1$ integers in $[-M, M]$ in such a way that the required bound on $|p(x)|$ can be obtained from the Lagrange interpolation formula for $p(x)$ with respect to these $d+1$ integers. To this end, we next define $d+1$ *integers*, $x_j, j = 0, 1, \cdots, d$, in the interval $[-M, M]$. We would like these integers to be close to the extrema of the Chebyshev polynomial (relative to interval $[-M, M]$), $M \cos((j\pi)/d)$, $j = 0, \cdots, d$, guided by the observation made in the introduction about the efficiency of these nodes. As the Chebyshev points are bunched closely towards the endpoints of the interval, and we require distinct integers there, we will choose the x_j to be *consecutive* integers near $\pm M$. Formally, our choice is

$$x_j = \min \{M - j, \max \{-M + (d-j), \text{Round}\ (M \cos((j\pi)/d))\}\}, \qquad 0 \leqq j \leqq d,$$

where "Round" denotes rounding to the nearest integer. The following description is more useful. Define K to be the largest integer such that

$$M - K \leqq M \cos \frac{K\pi}{d}. \tag{7}$$

K is well approximated by $8/(\pi^2 \varepsilon)$. More precisely, we have the following.

LEMMA 1. *If K is the largest integer such that $M-K\leqq M\cos(K\pi/d)$, then*

$$\frac{8}{\varepsilon\pi^2}-1<K<\frac{8}{\varepsilon\pi^2}\cdot\frac{1}{1-(\pi^2/108)}<\frac{0.893}{\varepsilon}. \tag{8}$$

Moreover,

$$7<K<\frac{d}{9.7}. \tag{9}$$

Proof. Note that if $d\geqq K>d/3$, then $M\cos((K\pi)/d)<M/2$. Thus $M-K<M/2$, but $d\leqq(M/2)<K$, a contradiction which implies that $K\leqq d/3$.

(i) $M-K\leqq M\cos((K\pi)/d)$ implies

$$M-K\leqq M\left(1-\frac{\pi^2K^2}{2d^2}+\frac{\pi^4K^4}{24d^4}\right),$$

which, by the definition of M, and the inequality $K\leqq d/3$, yields

$$K\leqq\frac{8}{\varepsilon\pi^2}+\frac{\pi^2K^3}{12d^2}\leqq\frac{8}{\varepsilon\pi^2}+\frac{\pi^2d^2K}{108d^2}=\frac{8}{\varepsilon\pi^2}+\frac{\pi^2}{108}K, \tag{10}$$

from which the right-hand inequality in (8) follows.

Since $M-(K+1)>M\cos((K+1)\pi/d)>M-M(\pi^2(K+1)^2/2d^2)$, we obtain

$$\frac{M\pi^2}{2d^2}(K+1)>1,$$

and the left-hand inequality in (8) is verified.

(ii) The right-hand inequality in (9) is obtained by iteration of the first inequality in (10), recalling that $(8/\varepsilon)<d$ and beginning with

$$K^3<K\frac{d^2}{\pi^4(1-(\pi^2/108))^2}.$$

The left-hand inequality in (9) follows from (8), since $\varepsilon<1/10$. □

Thus

$$x_j=\begin{cases}M-j, & j\leqq K,\\ -M+(d-j), & (d-j)\leqq K,\\ \text{Round}\left(M\cos\frac{j\pi}{d}\right), & K<j<d-K.\end{cases} \tag{11}$$

The x_j are clearly integers. Furthermore, they are distinct since: (i) $M>2d$, (ii) $(M-K)-M\cos((K+1)\pi/d)>1$, by the definition of K, and (iii) if $K+1\leqq j\leqq d/2$, the mean-value theorem gives

$$M\cos\frac{j\pi}{d}-M\cos\frac{(j+1)\pi}{d}>1$$

(similarly for $(d/2)<j\leqq d$).

Since the x_j are integers in $[-M, M]$ we know that $|p(x_j)|\leqq 1, j=0, 1, \cdots, d$, and the Lagrange interpolation formula yields

$$\begin{aligned}|p(x)|&=\left|\sum_{j=0}^{d}p(x_j)\prod_{i\neq j}\frac{x-x_i}{x_j-x_i}\right|\\ &\leqq\sum_{j=0}^{d}|l_j(x)|,\end{aligned}$$

where

$$l_j(x)=\prod_{\substack{i\neq j\\ i=0}}^{d}\frac{x-x_i}{x_j-x_i}.$$

Our task is now reduced to bounding $|l_j(x)|$, $x\in[M-1, M]$, $j=0, 1, \cdots, d$. Since each factor $|(x-x_i)/(x_0-x_i)|\leqq 1$, we see that $|l_0(x)|\leqq 1$.

(i) *Suppose* $1\leqq j\leqq K$. We break the product

$$\prod_{\substack{i=0\\ i\pm j}}^{d}\left|\frac{x-x_i}{x_j-x_i}\right|$$

into several factors. First, note that if $i=0$,

$$\left|\frac{x-x_0}{x_j-x_0}\right|\leqq\frac{1}{j}.$$

If $1\leqq i\leqq j-1$, then

$$\prod_{i=1}^{j-1}\left|\frac{x-x_i}{x_j-x_i}\right|\leqq\prod_{i=1}^{j-1}\frac{i}{j-i}=1. \tag{12}$$

If $j+1\leqq i\leqq 2K$, then

$$\left|\frac{x-x_i}{x_j-x_i}\right|\leqq\frac{M-x_i}{x_j-x_i}=1+\frac{j}{(M-x_i)-j}\leqq 1+\frac{j}{i-j}=\frac{i}{i-j}.$$

Hence

$$\prod_{i=j+1}^{2K}\left|\frac{x-x_i}{x_j-x_i}\right|\leqq\binom{2K}{j}. \tag{13}$$

Suppose $2K<i\leqq d/2$. Then, in view of § 1 (i),

$$M\left(1-\cos\frac{\pi i}{d}\right)\geqq\frac{4Mi^2}{d^2}. \tag{14}$$

We next show that the slack in (14) more than compensates for the rounding in the x_i. Namely,

$$M-\text{Round}\left(M\cos\frac{\pi i}{d}\right)\geqq\frac{4Mi^2}{d^2}. \tag{15}$$

To establish (15) is suffices to prove

$$M\left(1-\cos\frac{\pi i}{d}-4\frac{i^2}{d^2}\right)\geqq\frac{1}{2} \tag{16}$$

because

$$\text{Round}\left(M\cos\frac{\pi i}{d}\right)-M\cos\frac{\pi i}{d}\leqq\frac{1}{2}.$$

Inequality (15) holds when $i=d/2$. Suppose $2K<i\leqq(d-2)/2$. Put

$$f(i)=\sqrt{2}\sin\frac{\pi i}{2d}-2\frac{i}{d};\qquad g(i)=\sqrt{2}\sin\frac{\pi i}{2d}+2\frac{i}{d}.$$

Then (16) may be written as

$$Mf(i)g(i)\geqq\tfrac{1}{2}. \tag{17}$$

Note that $f(t)$ is concave and nonnegative on $0 \leqq t \leqq d/2$, and $f(t)=0$ if and only if $t=0,\ d/2$. Thus

$$f(i) \geqq \min\left(f(2K+1), f\left(\frac{d-2}{2}\right)\right). \tag{18}$$

But

$$f(2K+1) > \left(\frac{\sqrt{2}\pi}{2}-2\right)\left(\frac{2K+1}{d}\right) - \frac{\sqrt{2}\pi^3}{48}\left(\frac{2K+1}{d}\right)^3 > \frac{2}{d}, \tag{19}$$

the first inequality following from the truncated power series expansion of $\sin(((2K+1)\pi)/2d)$ and the second from Lemma 1, and our assumption that $\varepsilon < 1/10$, and hence $d > 80$. Also,

$$\begin{aligned} f\left(\frac{d-2}{2}\right) &= \cos\frac{\pi}{2d} - \sin\frac{\pi}{2d} - 1 + \frac{2}{d} \\ &> \left(2-\frac{\pi}{2}\right)\frac{1}{d} - \frac{\pi^2}{8}\cdot\frac{1}{d^2} \\ &> \frac{0.413}{d}, \end{aligned}$$

so that, in view of (19), (18) yields

$$f(i) \geqq \frac{0.413}{d}. \tag{20}$$

In a similar manner, we obtain

$$g(i) > (2+\sqrt{2})\left(\frac{2K+1}{d}\right) > (2+\sqrt{2})\left(\frac{16}{\pi^2\varepsilon}-1\right)\frac{1}{d}.$$

Hence

$$\varepsilon g(i) > \frac{5.19}{d},$$

and, finally,

$$Mf(i)g(i) = \frac{\varepsilon d^2}{4} f(i)g(i) > \frac{1}{2},$$

thus establishing (16), and, therefore, (15).

Next we observe that

$$\frac{jd^2}{4M} \leqq \frac{K}{\varepsilon} < (2K)^2,$$

and so, mindful of (15), we obtain

$$\begin{aligned} \prod_{i=2K+1}^{d/2} \left|\frac{x-x_i}{x_j-x_i}\right| &\leqq \prod_{i=2K+1}^{d/2} \frac{M-x_i}{x_j-x_i} = \prod_{i=2K+1}^{d/2} \frac{M-x_i}{(M-x_i)-j} \\ &\leqq \prod_{i=2K+1}^{d/2} \frac{4Mi^2/d^2}{(4Mi^2/d^2)-j} = \prod_{i=2K+1}^{d/2} \frac{i^2}{i^2-(jd^2/4M)} \\ &< \prod_{i=2K+1}^{d/2} \frac{i^2}{(i+2K)(i-2K)} \leqq \binom{4K}{2K} < 2^{4K}. \end{aligned} \tag{21}$$

Finally, for $d/2 < i \leqq d$, we have

$$\prod_{d/2<i\leqq d}\left|\frac{x-x_i}{x_j-x_i}\right| \leqq \prod_{d/2<i\leqq d}\frac{M/2}{(M/2)-K} < \left(\frac{d}{d-K}\right)^d \tag{22}$$

$$\leqq \left(1+\frac{2K}{d}\right)^d < e^{2K},$$

where we have used $M \geqq 2d$ and $K < d/2$.

Upon putting the bounds for the various domains of i together, we find

$$|l_j(x)| \leqq \frac{1}{j} \times 1 \times \binom{2K}{j} \times 2^{4K} \times e^{2K}, \qquad 1 \leqq j \leqq K.$$

Hence

$$\sum_{j=1}^{K} |l_j(x)| \leqq 2^{4K} e^{2K} \sum_{j=1}^{K} \binom{2K}{j} < (2^6 e^2)^K. \tag{23}$$

(ii) *Suppose* $K < j \leqq d/2$. In this range of j the situation is a bit more delicate. The terms, $|l_j(x)|$, are bounded by an exponential in K times the corresponding terms when the "pure" Chebyshev points are employed. The latter are bounded by c/j^2 for some constant c, so the sum is bounded by an exponential in K. We turn to the details.

Let y_i denote the Chebyshev points:

$$y_i = M \cos\frac{\pi i}{d}, \qquad i = 0, \cdots, d.$$

The denominator of $|l_j(x)|$,

$$D_x = \prod_{\substack{i=0\\ i\neq j}}^{d} |x_i - x_j|,$$

will be related to

$$Dy = \prod_{\substack{i=0\\ i\neq j}}^{d} |y_i - y_j| = M^d \prod_{\substack{i=0\\ i\neq j}}^{d} \left|\cos\frac{\pi i}{d} - \cos\frac{\pi j}{d}\right| = 2d\left(\frac{M}{2}\right)^d, \tag{24}$$

the last equality following from (4).

The difference between D_x and D_y is due to two effects: namely, the rounding of y_i to produce x_i for $K < i < d-K$, and the replacement of y_i by consecutive integers for $0 \leqq i \leqq K$ and $d-K \leqq i \leqq d$.

If $0 \leqq i \leqq K$, then

$$\left|\frac{x_i - x_j}{y_i - y_j}\right| = \frac{M - x_j - i}{M\cos\frac{\pi i}{d} - M\cos\frac{\pi j}{d}} \geqq \frac{M - x_j - i}{M\cos\frac{\pi i}{d} - \left(x_j - \frac{1}{2}\right)}. \tag{25}$$

But by the definition of K there exists α, $K \leqq \alpha < K+1$, such that

$$M\cos\frac{\pi\alpha}{d} = M - \alpha,$$

and hence, in view of § 1 (i)

$$\frac{1-\cos\dfrac{\pi i}{d}}{i^2} \geqq \frac{1-\cos\dfrac{\pi \alpha}{d}}{\alpha^2} = \frac{1}{\alpha M}.$$

Thus, since $\alpha < K+1$,

$$M\cos\frac{\pi i}{d} \leqq M - \frac{i^2}{K+1},$$

and, in view of (25)

$$\left|\frac{x_i-x_j}{y_i-y_j}\right| > \frac{(M-x_j)-i}{(M-x_j)-\left(\dfrac{i^2}{K+1}-\dfrac{1}{2}\right)} > \frac{K+1-i}{K+\dfrac{3}{2}-\dfrac{i^2}{K+1}} \geqq \frac{1}{3}, \tag{26}$$

the last inequality holding since $(K+1-i)/(K+(3/2)-(i^2/(K+1)))$ takes its minimum when $i=K$. Inequality (26) yields

$$\prod_{i=0}^{K}\left|\frac{x_i-x_j}{y_i-y_j}\right| \geqq \left(\frac{1}{3}\right)^{K+1}. \tag{27}$$

Similarly, if $d-K \leqq i \leqq d$ we obtain

$$\prod_{i=d-K}^{d}\left|\frac{x_i-x_j}{y_i-y_j}\right| \geqq \left(\frac{1}{3}\right)^{K+1}. \tag{28}$$

If $K<i<d-K$ $(i \neq j)$ we need only worry about rounding. Now

$$\left|\frac{x_i-x_j}{y_i-y_j}\right| \geqq 1-\frac{1}{|y_i-y_j|}. \tag{29}$$

Moreover,

$$|y_i-y_j| \geqq \frac{4}{3}. \tag{30}$$

For,

$$|y_i-y_j| = |i-j|\frac{M\pi}{d}\sin\frac{\varphi\pi}{d} > \frac{M\pi}{d}\sin\frac{K\pi}{d}$$

by the mean-value theorem, $|i-j| \geqq 1$, and φ is between i and j. Thus

$$|y_i-y_j| > \frac{M\pi}{d}\left(\frac{\pi K}{d}-\frac{\pi^3K^3}{6d^3}\right) > \frac{\varepsilon\pi^2K}{4}\left(1-\frac{\pi^2}{486}\right)$$

since $K<d/9$. Inequality (30) now follows from the first inequality in (8).

We now get

$$\log\left|\frac{y_i-y_j}{x_i-x_j}\right| \leqq -\log\left(1-\frac{1}{|y_i-y_j|}\right) \leqq \frac{2}{|y_i-y_j|} = \frac{2}{2M\sin\dfrac{\pi(i+j)}{2d}\sin\dfrac{\pi(|i-j|)}{2d}},$$

where the first inequality follows from (29) and the second from (30) and the observation that (if we put $|y_i-y_j|^{-1}=x$) $f(x)=2x+\log(1-x)$ is positive for $0<x<3/4$, since $f(x)$ is concave on $[0,3/4]$, $f(0)=0$ and $f(3/4)>0$ (as $e^{3/4}>2$).

Since $j \leqq d/2$ we have

$$\frac{|\pi(i \pm j)|}{2d} \leqq \frac{3\pi}{4},$$

and for $|t| \leqq 3\pi/4$ the inequality

$$\left|\frac{\sin t}{t}\right| \geqq \frac{2\sqrt{2}}{3\pi}$$

holds. Thus

$$\log\left|\frac{y_i - y_j}{x_i - x_j}\right| \leqq \frac{2}{2M\left(\frac{2\sqrt{2}}{3\pi}\right)\frac{\pi(i+j)}{2d}\left(\frac{2\sqrt{2}}{3\pi}\right)\frac{\pi(|i-j|)}{2d}} = \frac{18}{\varepsilon(i+j)(|i-j|)}.$$

Then

$$\begin{aligned}\sum_{\substack{K<i<d-K\\ i\neq j}} \log\left|\frac{y_i - y_j}{x_i - x_j}\right| &\leqq \frac{18}{\varepsilon}\left(\sum_{i=K+1}^{j-1}\frac{1}{(i+j)(j-i)} + \sum_{i=j+1}^{d-K-1}\frac{1}{(i+j)(i-j)}\right)\\ &\leqq \frac{18}{\varepsilon}\left(\sum_{i=K+1}^{j-1}\frac{1}{j} + \sum_{i=j+1}^{\infty}\frac{1}{(i+j)(i-j)}\right)\\ &\leqq \frac{18}{\varepsilon}\left(1 + \frac{1}{2j}\sum_{i=j+1}^{\infty}\left(\frac{1}{i-j} - \frac{1}{i+j}\right)\right)\\ &= \frac{18}{\varepsilon}\left(1 + \frac{1}{2j}\sum_{h=1}^{2j}\frac{1}{h}\right)\\ &\leqq \frac{18}{\varepsilon}\left(1 + \frac{2j}{2j}\right) \leqq \frac{36}{\varepsilon},\end{aligned}$$

and so

$$\prod_{\substack{K<i<d-K\\ i\neq j}} \left|\frac{y_i - y_j}{x_i - x_j}\right| \leqq e^{36/\varepsilon}. \tag{31}$$

Thus, for $K < j \leqq d/2$ we obtain

$$\prod_{\substack{i=0\\ i\neq j}}^{d} |x_i - x_j| = D_x = D_y \times \frac{D_x}{D_y} \geqq 2d\left(\frac{M}{2}\right)^d 9^{-(K+1)}\, e^{-36/\varepsilon} \tag{32}$$

in view of (24), (27), (28), and (31).

We turn next to the numerator,

$$N_x = \prod_{\substack{i=0\\ i\neq j}}^{d} |x - x_i|.$$

N_x is bounded by

$$F_x = \prod_{\substack{i=1\\ i\neq j}}^{d} (M - x_i).$$

Next, we relate F_x to a product resembling the numerator in the pure Chebyshev case

$$F_y=\prod_{\substack{i=1\\i\neq j}}^{d}(M-y_i)=\frac{1}{M-y_j}\prod_{i=1}^{d}(M-y_i).$$

Since $j\leqq d/2$, we have

$$\sin\frac{\pi j}{2d}\geqq\frac{\sin\frac{\pi}{4}}{\frac{\pi}{4}}\frac{\pi j}{2d}=\frac{j\sqrt{2}}{d},\tag{33}$$

so that

$$F_y=\frac{1}{2M\left(\sin\frac{\pi j}{2d}\right)^2}\prod_{i=1}^{d}2M\sin^2\frac{\pi i}{2d}\leqq\frac{1}{2M\left(\frac{2j^2}{d^2}\right)}2(2d)\left(\frac{M}{2}\right)^d,\tag{34}$$

where the inequality follows from (33) and (5).

If $1\leqq i\leqq K$, then $M-x_i=i$ and $M-y_i=M(1-\cos((\pi i)/d))$. But

$$\frac{M\left(1-\cos\frac{\pi i}{d}\right)}{i^2}\geqq\frac{M\left(1-\cos\frac{\pi K}{d}\right)}{K^2}=\frac{\varepsilon d^2}{2K^2}\sin^2\frac{\pi K}{2d}$$

$$>\frac{\varepsilon d^2}{2K^2}\frac{K^2}{d^2}=\frac{\varepsilon}{2}>\frac{1}{4K}.$$

Therefore, $M-y_i>i^2/(4K)$ and

$$\prod_{i=1}^{K}\frac{M-x_i}{M-y_i}\leqq\prod_{i=1}^{K}\frac{4i}{i^2/K}=\frac{4^KK^K}{K!}<(4e)^K.\tag{35}$$

If $d-K\leqq i\leqq d$, it is easy to see that $x_i\geqq y_i$, and so

$$\prod_{i=d-K}^{d}\frac{M-x_i}{M-y_i}\leqq 1.\tag{36}$$

Lastly, suppose that $K<i<d-K$. Then

$$\frac{M-x_i}{M-y_i}=1+\frac{y_i-x_i}{M-y_i}\leqq 1+\frac{1}{M-y_i}=1+\frac{1}{2M\left(\sin\frac{\pi i}{2d}\right)^2},$$

so that

$$\log\frac{M-x_i}{M-y_i}\leqq\frac{1}{2M\left(\sin\frac{\pi i}{2d}\right)^2}\leqq\frac{1}{2M(i/d)^2}=\frac{2}{\varepsilon i^2}.$$

Thus

$$\sum_{\substack{i=K+1\\i\neq j}}^{d-K-1}\log\frac{M-x_i}{M-y_i}\leqq\sum_{i=K+1}^{d-K-1}\frac{2}{\varepsilon i^2}<\frac{2}{\varepsilon K}<\frac{\pi^2}{3}.\tag{37}$$

Hence, for $K < j \leqq d/2$ we obtain

$$\begin{aligned}\prod_{\substack{i=0\\ i\neq j}}^{d} |x-x_i| = N_x \leqq F_x = F_y \times \frac{F_x}{F_y} \\ \leqq \frac{2}{\varepsilon j^2}(2d)\left(\frac{M}{2}\right)^d (4e)^K e^{\pi^2/3},\end{aligned} \tag{38}$$

according to (34)-(37). Therefore, recalling (32), we get

$$|l_j(x)| \leqq \frac{18}{\varepsilon j^2} \exp\left(K + \frac{\pi^2}{3} + \frac{36}{\varepsilon}\right) 6^{2K}. \tag{39}$$

But

$$\sum_{j=K+1}^{d/2} \frac{1}{j^2} < \frac{1}{K},$$

so that

$$\sum_{j=K+1}^{d/2} |l_j(x)| \leqq \frac{18}{\varepsilon K} \exp\left(K + \frac{\pi^2}{3} + \frac{36}{\varepsilon}\right) 6^{2K} \leqq c_1\, e^{c_2/\varepsilon}, \tag{40}$$

where c_1, c_2 are positive constants independent of d, m, ε.

Finally, we note that if $d/2 \leqq j \leqq d$, then, by symmetry,

$$|l_j(x)| \leqq |l_{d-j}(x)|,$$

which gives

$$\sum_{j=0}^{d} |l_j(x)| \leqq 2\left(\sum_{j=0}^{K} |l_j(x)| + \sum_{j=K+1}^{d/2} |l_j(x)|\right) \leqq C_3\, e^{C_4/\varepsilon}, \tag{41}$$

where C_3, C_4 are positive constants independent of d, m, and ε. Inequality (41) was established under the assumptions that m was divisible by 4 and d was even. But if we drop these assumptions about d and m, then, since (41) holds for the greatest integer not exceeding m which is divisible by 4, and the least integer not less than d which is even, (41) is valid with appropriately chosen constants replacing C_3 and C_4, say c_3 and c_4.

We can now present our main result.

THEOREM. *If $\delta > 0$ and $n \geqq \delta\, d^2$ $(d > 0)$ there exist positive constants, a and b, independent of d, n, and δ, such that*

$$B(d, n) < a\, e^{b/\delta}. \tag{42}$$

Proof. If $m = \varepsilon d^2$, where $\varepsilon < 1/10$ and $d > 80$, then (41) gives

$$B(d, m) \leqq c_3\, e^{c_4/\varepsilon}. \tag{43}$$

Put $k = \lceil \delta d^2 \rceil$. If $\delta > 1/11$ and $d > 80$, we have

$$B(d, k) \leqq B\left(d, \left\lceil \frac{d^2}{11} \right\rceil\right) \leqq c_3\, e^{11 c_4} \tag{44}$$

in view of (43) and § 1 (iv). However, if $\delta \leqq 1/11$ and $d > 80$, we have

$$B(d, k) \leqq c_3\, e^{c_4/\delta} \leqq c_3\, e^{c_4/\delta}\, e^{11 c_4}.$$

Thus if $\delta > 0$,

$$B(d, k) \leqq c_5\, e^{c_4/\delta}$$

for $d > 80$ and c_5 a positive constant independent of d, k, and δ. Now when $1 \leqq d \leqq 80$, $B(d, d) \leqq 2^d \leqq 2^{80}$ implies that $B(d, k) \leqq 2^{80}$, since $k \geqq d$. Since $n \geqq k$, (42) now follows.

3. Lower bounds. We have exhibited an upper bound which is exponential in $d^2/m = 1/\varepsilon$. We next obtain a matching lower bound for $B(d, m)$ by constructing a polynomial of degree d whose absolute value is bounded by 1 on $m+1$ uniformly spaced points, and reaches heights exponential in d^2/m in the interior of the span of the points.

Assume that $\varepsilon < 1/10$ and $m > 8d$, so that $d > 80$. When we put $x = (m/2)(1 - \cos\theta)$,

$$Q(x) = C \prod_{j=0}^{d-1} \left(x - \frac{m}{2}\left(1 - \cos\frac{\pi(2j+1)}{2d}\right)\right) \tag{45}$$

and $\cos d\theta$ are polynomials of degree d in $\cos\theta$, having the same set of d zeros. We choose C so that

$$Q(x) = \cos d\theta, \qquad x = \frac{m}{2}(1 - \cos\theta). \tag{46}$$

Now put

$$P(x) = Q(x)\frac{K-1}{K}\prod_{j=0}^{K} \frac{x-j}{x - \frac{m}{2}\left(1 - \cos\frac{\pi(2j+1)}{2d}\right)}, \tag{47}$$

where $K = \lfloor \hat{K} \rfloor$ and $\hat{K}$ is the smallest solution of

$$\hat{K} = \frac{m}{2}\left(1 - \cos\frac{\pi(2\hat{K}+1)}{2d}\right)$$

satisfying $\hat{K} > 1$. It is easy to see that $\hat{K} < d/8$, and by methods similar to those used to establish (8) (i.e., choosing appropriate bounds for $\cos\theta$ from its power series expansion) we get the inequalities

$$1 - \frac{13\pi^2}{480} < \frac{\hat{K}}{\left(\frac{4}{\varepsilon\pi^2}\right)} < \frac{1}{1 - \frac{\pi^2}{768}},$$

so that

$$\frac{2}{\varepsilon\pi^2} < K < \frac{8}{\varepsilon\pi^2}.$$

Thus, for $1 \leqq j \leqq K$ we have

$$j \geqq \frac{m}{2}\left(1 - \cos\frac{\pi(2j+1)}{2d}\right),$$

and the factor $(K-1)/K$ in (47) has been chosen so that for $i > K$,

$$\frac{K-1}{K}(i-0) < i - \frac{m}{2}\left(1 - \cos\frac{\pi}{2d}\right).$$

Notice that $P(x)$ is of degree d and its zeros $(m/2)\,(1 - \cos(\pi(2j+1)/2d))$ are related linearly to the zeros of the Chebyshev polynomials, except near the left endpoint where they have been replaced by consecutive integers. (It is not necessary to alter those near the right endpoint.) Note the similarity to the upper bound construction.

Now $P(i)=0$, $i=0,1,\cdots,K$. For $i=K+1,\cdots,m$ we have

$$|P(i)|\leqq|Q(i)|\leqq 1.$$

since for each $j=1,\cdots,K$ the factor

$$\frac{i-j}{i-\dfrac{m}{2}\left(1-\cos\dfrac{\pi(2j+1)}{2d}\right)}$$

is bounded by 1, as is the term for $j=0$. Hence

$$|P(i)|\leqq 1,\qquad i=0,\cdots,m.$$

Let us evaluate Q and P at the point

$$\xi=\frac{m}{2}\left(1-\cos\frac{\pi}{d}\right),$$

corresponding to

$$\theta=\frac{\pi}{d}.$$

We have

$$\frac{\varepsilon\pi^2}{5}<\xi<\frac{\pi^2\varepsilon}{4}<\frac{1}{2}.$$

Then

$$Q(\xi)=\cos d\theta=\cos\pi=-1,$$

and

$$|P(\xi)|=|Q(\xi)|\frac{K-1}{K}\prod_{j=0}^{K}\frac{|\xi-j|}{\left|\xi-\dfrac{m}{2}\left(1-\cos\dfrac{\pi(2j+1)}{2d}\right)\right|}$$

$$=\frac{K-1}{K}\frac{\xi}{\xi-\dfrac{m}{2}\left(1-\cos\dfrac{\pi}{2d}\right)}\prod_{j=1}^{K}\frac{j-\xi}{\dfrac{m}{2}\left(1-\cos\dfrac{\pi(2j+1)}{2d}\right)-\xi}$$

$$\geqq\frac{K-1}{K}\prod_{j=1}^{K}\frac{j}{\dfrac{m}{2}\left(1-\cos\dfrac{\pi(2j+1)}{2d}\right)}\geqq\frac{K-1}{K}\prod_{j=1}^{K}\frac{j}{(2j+1)^2\dfrac{\pi^2\varepsilon}{16}}$$

$$=\frac{K-1}{K(2K+1)^2}\prod_{j=1}^{K}\frac{j}{(2j-1)^2\dfrac{\pi^2\varepsilon}{16}}$$

$$>\frac{1}{8K^2}\prod_{j=1}^{K}\frac{2Kj}{(2j-1)^2}>\frac{1}{8K^2}\frac{(2K)^K K!}{2^{2K}(K!)^2}=\frac{1}{8K^2}\frac{K^K}{K!}\frac{1}{2^K}$$

$$>\frac{a_1(e/2)^K}{K^{5/2}}>a_2\,e^{a_3/\varepsilon},$$

with a_2, a_3 positive and independent of d, m, and ε, and $0<a_3<1-\log 2$. Thus, if $\varepsilon<1/10$ and $\varepsilon d^2=m>8d$ we have

$$B(d, m)>a_2\, e^{a_3/\varepsilon}. \tag{48}$$

Furthermore: (i) If $m=\varepsilon d^2$, $d>80$, and $d \leqq m \leqq 8d$, then

$$B(d, m) \geqq B(d, 8d+1)>a_2\, e^{a_3/\varepsilon'}, \qquad \varepsilon'<1/10,$$

and since $\varepsilon'=\varepsilon(8d+1)/m \leqq \varepsilon(8+(1/d)) \leqq 9\varepsilon$ $(\varepsilon<1/10)$ we get

$$B(d, m)>a_2\, e^{a_3/9\varepsilon}. \tag{49}$$

(ii) If $m=\varepsilon d^2$, $d \leqq m \leqq 8d$, and $d \leqq 80$, then, since $m \leqq 8d$, there are a *finite* number of pairs d, m to consider. Let

$$a_4=\min_{d,m} \frac{B(d, m)}{e^{a_3/(m/d^2)}},$$

so that

$$B(d, m) \geqq a_4\, e^{a_3/\varepsilon}. \tag{50}$$

As a consequence of (48), (49), and (50), we have, for $\varepsilon<1/10$, $m=\varepsilon d^2$, and $d \geqq 1$,

$$B(d, m)>\alpha\, e^{\beta/\varepsilon}, \tag{51}$$

where α, β are positive and independent of ε and d.

Finally, if $\varepsilon \geqq 1/10$ put $\gamma=\min(\alpha, e^{-10\beta})$. Then we obtain, for $m=\varepsilon d^2$, $d \geqq 1$,

$$B(d, m) \geqq 1 \geqq e^{-10\beta}\, e^{\beta/\varepsilon} \geqq \gamma\, e^{\beta/\varepsilon}. \tag{52}$$

Inequalities (51) and (52) now give, for $m=\delta d^2$, $d \geqq 1$, $\delta>0$,

$$B(d, m) \geqq \gamma\, e^{\beta/\delta},$$

with γ, β positive and independent of δ and d, as we promised.

We may summarize our work as follows: $B(d, m)$ is bounded as $d \rightarrow \infty$ if and only if

$$\liminf_{d \rightarrow \infty} \frac{m}{d^2}=\delta>0. \tag{53}$$

Moreover, if (53) holds $B(d, m)<a\, e^{b/\delta}$, while for $m=\delta d^2$ we have $B(d, m)>\gamma\, e^{\beta/\delta}$, where a, b, γ, β are positive constants.

COMMUTANT LIFTING AND SIMULTANEOUS H^∞ AND L^2 SUBOPTIMIZATION*

C. FOIAS† AND A. E. FRAZHO‡

Abstract. In this paper the commutant lifting theorem is used to obtain simultaneously a suboptimal solution to the two-sided Nehari optimization problem, with respect to the L^∞ norm and the L^2 norm. For the rational Nehari case a computational procedure in terms of a minimal realization is also given.

Key words. commutant lifting theorem, H^∞ optimization, L^2 optimization, Nehari problem, minimal realization

1. Introduction. In studying subalgebras of C^*-algebras Kaftal, Larson, and Weiss [16] discovered that given any f in L^∞ and $\delta > 1$, there exists a function h in H^∞ satisfying

$$\|f+h\|_\infty \leqq \delta d_\infty \quad \text{and} \quad \|f+h\|_2 \leqq \frac{\delta d_2}{\sqrt{\delta^2-1}}, \tag{1.1}$$

where d_∞ is the distance from f to H^∞ in the L^∞ norm and d_2 is the distance from f to H^2 in the L^2 norm. In this paper, we will use the commutant lifting theorem to generalize their $H^\infty - L^2$ result to the two sided multidimensional Nehari setting. Both H^∞ and L^2 optimization have played an important role in control theory [5], [7], [11], [13], [18], [19], [20]. In fact, [7], [19], [20] develop some nice relationships between H^∞ and L^2 optimization problems arising in control theory. For this reason, we will also give explicit state space formulas to compute a solution h when f is rational, which may be useful in control theory.

To establish some notation, let $L^\infty(\mathscr{E}_1, \mathscr{E}_2)$ be the set of all strongly Lebesgue measurable functions, uniformly bounded almost everywhere on the unit circle, whose values are linear operators from $\mathscr{E}_1$ to $\mathscr{E}_2$. Throughout, we always assume that both $\mathscr{E}_1$ and $\mathscr{E}_2$ are finite-dimensional. If G is in $L^\infty(\mathscr{E}_1, \mathscr{E}_2)$, then the L^∞ norm of G is denoted by $\|G\|_\infty$, that is, $\|G\|_\infty$ is the essential supremum of $\|G(e^{it})\|$ for $0 \leqq t < 2\pi$. The L^2 norm of G is given by

$$\|G\|_2^2 = (G, G)_2 = \frac{1}{2\pi}\int_0^{2\pi} \operatorname{tr}(G(e^{it})^* G(e^{it}))\, dt = \sum_{-\infty}^{\infty} \operatorname{tr}(G_n^* G_n),$$

where tr denotes the trace and $G = \sum G_n e^{\text{int}}$ is the Fourier series expansion of G. Obviously, the set of all strongly Lebesgue measurable G satisfying $\|G\|_2 < \infty$ defines a Hilbert space. Recall that if M is any operator from $\mathscr{E}_1$ to $\mathscr{E}_2$, then

$$\|M\|_2^2 = \operatorname{tr}(M^*M) = \sum_1^n \|M\phi_i\|^2 = \operatorname{tr}(MM^*), \tag{1.2}$$

where $\{\phi_i\}_1^n$ is any orthonormal basis for $\mathscr{E}_1$. The trace of M^*M is independent of the choice of the orthonormal basis $\{\phi_i\}$. Finally, $H^\infty(\mathscr{E}_1, \mathscr{E}_2)$ is the subspace of $L^\infty(\mathscr{E}_1, \mathscr{E}_2)$ identified with the set of all uniformly bounded analytic functions in the open unit disc, whose values are operators from $\mathscr{E}_1$ to $\mathscr{E}_2$.

Throughout this paper, F is a specified function in $L^\infty(\mathscr{E}_1, \mathscr{E}_2)$ and Θ_1 is a specified $*$-inner function in $H^\infty(\mathscr{E}_1, \mathscr{F}_1)$ and Θ_2 is a specified inner function in $H^\infty(\mathscr{F}_2, \mathscr{E}_2)$. Recall that a function Θ in $H^\infty(\mathscr{E}, \mathscr{F})$ is *inner*, respectively *$*$-inner*, if $\Theta(e^{it})$ is almost everywhere an isometry, respectively, a co-isometry. Now consider the following H^∞ and, respectively, L^2 optimization problems:

$$\begin{aligned} d_\infty &= d_\infty(F) = \inf\{\|F+\Theta_2 H\Theta_1\|_\infty : H \in H^\infty(\mathscr{F}_1, \mathscr{F}_2)\}, \\ d_2 &= d_2(F) = \inf\{\|F+\Theta_2 H\Theta_1\|_2 : H \in H^\infty(\mathscr{F}_1, \mathscr{F}_2)\}, \end{aligned} \tag{1.3}$$

where d_∞ is the distance from F to $\Theta_2 H^\infty(\mathscr{F}_1, \mathscr{F}_2)\Theta_1$ in the L^∞ norm, and d_2 is the corresponding distance in the L^2 norm. These optimization problems naturally arise in control theory [7], [11]. For the sake of the reader we shall present in § 2, the N. J. Young formula for d_∞ in [23]. In most problems the same H does not minimize both d_∞ and d_2. However, in this note we will use the commutant lifting theorem to establish the following relationship between d_∞ and d_2.

THEOREM 1.1. *Let $\delta > 1$. Then there exists a function H in $H^\infty(\mathscr{F}_1, \mathscr{F}_2)$ satisfying*

$$\|F+\Theta_2 H\Theta_1\|_\infty \leqq \delta d_\infty(F) \quad \text{and} \quad \|F+\Theta_2 H\Theta_1\|_2 \leqq \frac{\delta d_2(F)}{\sqrt{\delta^2-1}}. \tag{1.4}$$

In particular, if $\delta = \sqrt{2}$, then there exists a function H in $H^\infty(\mathscr{F}_1, \mathscr{F}_2)$ satisfying

$$\|F+\Theta_2 H\Theta_1\|_\infty \leqq \sqrt{2} d_\infty \quad \text{and} \quad \|F+\Theta_2 H\Theta_1\|_2 \leqq \sqrt{2} d_2. \tag{1.5}$$

In the scalar case with $\Theta_1 = \Theta_2 = 1$, the previous theorem reduces to the following elegant result of Kaftal, Larson, and Weiss [16], which motivated much of our work.

COROLLARY 1.2. *Let $\delta > 0$ and f be any scalar valued functions in L^∞. Then there exists a function h in H^∞ satisfying* (1.1).

To prove Theorem 1.1 we will need an explicit expression for d_∞ and d_2. Because the L^2 norm defines an inner product, we can easily compute d_2 by relaying on an argument used in Wiener filtering. To this end, let $[G]_c$ be the causal part of a function G in $L^\infty(\mathscr{F}_1, \mathscr{F}_2)$, that is, if $G = \sum_{-\infty}^{\infty} G_n e^{\text{int}}$ is the Fourier series expansion of G, then

$$[G]_c = \sum_{n=0}^{\infty} G_n e^{\text{int}}.$$

We claim that

$$d_2 = d_2(F) = \|F - \Theta_2[\Theta_2^* F \Theta_1^*]_c \Theta_1\|_2. \tag{1.6}$$

By the projection theorem, it is sufficient to show that $F - \Theta_2[\Theta_2^* F\Theta_1^*]_c\Theta_1$ is orthogonal to $\Theta_2 H^\infty(\mathscr{F}_1, \mathscr{F}_2)\Theta_1$ with respect to the L^2 inner product $(\cdot, \cdot)_2$. To verify (1.6), notice that for any H in $H^\infty(\mathscr{F}_1, \mathscr{F}_2)$ we have

$$\begin{aligned} (F - \Theta_2[\Theta_2^* F\Theta_1^*]_c\Theta_1, \Theta_2 H\Theta_1)_2 &= \frac{1}{2\pi}\int_0^{2\pi} \operatorname{tr}(\Theta_1^* H^*(\Theta_2^* F - [\Theta_2^* F\Theta_1^*]_c\Theta_1))\, dt \\ &= \frac{1}{2\pi}\int_0^{2\pi} \operatorname{tr}((\Theta_2^* F - [\Theta_2^* F\Theta_1^*]_c\Theta_1)\Theta_1^* H^*)\, dt \\ &= \frac{1}{2\pi}\int_0^{2\pi} \operatorname{tr}((\Theta_2^* F\Theta_1^* - [\Theta_2^* F\Theta_1^*]_c) H^*)\, dt = 0. \end{aligned}$$

The first and third equalities follow from the fact that Θ_2 is inner and Θ_1 is $*$-inner, respectively. The second equality follows from the fact that $\operatorname{tr}(BC) = \operatorname{tr}(CB)$, where

C maps $\mathscr{E}_1$ into $\mathscr{F}_2$ and B maps $\mathscr{F}_2$ into $\mathscr{E}_1$. The above analysis shows that $F-\Theta_2[\Theta_2^*F\Theta_1^*]_c\Theta_1$ is orthogonal to $\Theta_2H^\infty(\mathscr{F}_1, \mathscr{F}_2)\Theta_1$. Therefore, by the projection theorem, (1.6) holds.

2. The computation of d_∞. In this section, following Young [23], we will use the commutant lifting theorem to show that d_∞ equals the norm of a certain intertwining operator $\Lambda(F)$. As a byproduct of this computation, we will also show that the H^∞ optimization problem in (1.3) defines a game whose value is the norm of $\Lambda(F)$. Finally, it is noted that d_∞ can also be computed by converting the H^∞ optimization problem in (1.3) to a four block problem [9]. However, for our purposes this conversion is not necessary.

Throughout, we will follow the standard notation for Hilbert spaces in [10] and [22]. For example, $L^2(\mathscr{E})$ is the Hilbert space of all square integrable Lebesgue measurable functions in $[0, 2\pi)$ with values in $\mathscr{E}$. The Hardy space $H^2(\mathscr{E})$ is the subspace of $L^2(\mathscr{E})$ identified with the set of all analytic functions in the open unit disc with values in $\mathscr{E}$, whose Fourier series coefficients are square summable. Now let $\mathscr{H}_1$ and $\mathscr{H}_2$ be the subspaces defined by

$$\mathscr{H}_1 = L^2(\mathscr{E}_1)\ominus\Theta_1^*K^2(\mathscr{F}_1) \quad \text{and} \quad \mathscr{H}_2 = L^2(\mathscr{E}_2)\ominus\Theta_2H^2(\mathscr{F}_2),$$

where $K^2(\mathscr{F})$ is the orthogonal complement of $H^2(\mathscr{F})$ in $L^2(\mathscr{F})$. Let $\Lambda(F)$ be the operator from $\mathscr{H}_1$ into $\mathscr{H}_2$, with symbol F, defined by $\Lambda(F)f = P_2M_Ff$, where f is in $\mathscr{H}_1$ and P_2 is the orthogonal projection onto $\mathscr{H}_2$. Here M_F is the multiplication operator from $L^2(\mathscr{E}_1)$ to $L^2(\mathscr{E}_2)$ defined by $(M_Fg)(e^{it}) = Fg(e^{it})$, where g is in $L^2(\mathscr{E}_1)$. We need the following useful observation.

LEMMA 2.1. *Let W be a function in $L^\infty(\mathscr{E}_1, \mathscr{E}_2)$. Then $\Lambda(W) = 0$ if and only if W admits a factorization of the form $W = \Theta_2H\Theta_1$, where H is in $H^\infty(\mathscr{F}_1, \mathscr{F}_2)$. In this case W is in $H^\infty(\mathscr{E}_1, \mathscr{E}_2)$.*

Proof. Assume that $\Lambda(W) = 0$. Then $W\mathscr{H}_1 \subseteq \Theta_2H^2(\mathscr{F}_2)$. Since $H^2(\mathscr{E}_1) \subseteq \mathscr{H}_1$, this implies that $WH^2(\mathscr{E}_1) \subseteq \Theta_2H^2(\mathscr{F}_2)$. Therefore, $W = \Theta_2R$, where R is a function in $H^\infty(\mathscr{E}_1, \mathscr{F}_2)$; see Corollary IX.2.2 in [10]. Now we have

$$\Theta_2R(L^2(\mathscr{E}_1)\ominus\Theta_1^*K^2(\mathscr{F}_1)) = W\mathscr{H}_1 \subseteq \Theta_2H^2(\mathscr{F}_2).$$

Hence R maps $L^2(\mathscr{E}_1)\ominus\Theta_1^*K^2(\mathscr{F}_1)$ into $H^2(\mathscr{F}_2)$, or equivalently, its adjoint R^* maps $K^2(\mathscr{F}_2)$ into $\Theta_1^*K^2(\mathscr{F}_1)$, that is, $R^*K^2(\mathscr{F}_2) \subseteq \Theta_1^*K^2(\mathscr{F}_1)$. As before, this readily implies that $R^* = \Theta_1^*H^*$ for some H in $H^\infty(\mathscr{F}_1, \mathscr{F}_2)$. Therefore, $W = \Theta_2H\Theta_1$. On the other hand, notice that $\Theta_1\mathscr{H}_1$ is orthogonal to $K^2(\mathscr{F}_1)$, or equivalently, $\Theta_1\mathscr{H}_1$ is contained in $H^2(\mathscr{F}_1)$. So if $W = \Theta_2H\Theta_1$, then using $\Theta_1\mathscr{H}_1 \subseteq H^2(\mathscr{F}_1)$ it follows that $\Lambda(W) = 0$. This completes the proof.

The following result is a classical application of the commutant lifting theorem (see [23]).

THEOREM 2.2. *Let F be a function in $L^\infty(\mathscr{E}_1, \mathscr{E}_2)$. Then*

$$d_\infty = \|\Lambda(F)\| = \inf\{\|F + \Theta_2H\Theta_1\|_\infty : H \in H^\infty(\mathscr{F}_1, \mathscr{F}_2)\}. \tag{2.1}$$

Moreover, there exists an optimal H_* in $H^\infty(\mathscr{F}_1, \mathscr{F}_2)$ satisfying

$$\|F + \Theta_2H_*\Theta_1\|_\infty = \|\Lambda(F)\| = d_\infty.$$

Proof. Since $\Lambda(\Theta_2H\Theta_1) = 0$ for all H in $H^\infty(\mathscr{F}_1, \mathscr{F}_2)$, we have

$$\|\Lambda(F)\| = \|\Lambda(F + \Theta_2H\Theta_1)\| = \|P_2(F + \Theta_2H\Theta_1)\,|\,\mathscr{H}_1\| \leqq \|F + \Theta_2H\Theta_1\|_\infty.$$

Therefore,

$$\|\Lambda(F)\| \leqq \inf\{\|F + \Theta_2H\Theta_1\|_\infty : H \in H^\infty(\mathscr{F}_1, \mathscr{F}_2)\}. \tag{2.2}$$

Now let V_1 and V_2 be the bilaterial shifts (multiplication by e^{it}) on $L^2(\mathscr{E}_1)$ and $L^2(\mathscr{E}_2)$, respectively. Clearly $\mathscr{H}_1$ is an invariant subspace for V_1, and $\mathscr{H}_2$ is an invariant subspace for V_2^*. Let T_1 on $\mathscr{H}_1$ be the isometry and T_2 on $\mathscr{H}_2$ be the co-isometry defined by $T_1 = V_1|\mathscr{H}_1$ and $T_2 = P_2V_2|\mathscr{H}_2$. Obviously, V_2 is an isometric lifting of T_2, that is, $P_2V_2 = T_2P_2$. Using $P_2V_2 = T_2P_2$ and $V_2M_F = M_FV_1$ it is easy to verify that $T_2\Lambda(F) = \Lambda(F)T_1$. By the commutant lifting theorem (see Theorem VII.1.2 in [10], [21], [22]), there exists an operator B mapping $L^2(\mathscr{E}_1)$ into $L^2(\mathscr{E}_2)$ satisfying $\|B\| = \|\Lambda(F)\|$ and $P_2B|\mathscr{H}_1 = \Lambda(F)$ and $V_2B = BV_1$. Since B intertwines the bilateral shifts, $B = M_G$, where G is a function in $L^\infty(\mathscr{E}_1, \mathscr{E}_2)$ and $\|G\|_\infty = \|B\|$; see [10], [22]. So there exists a G in $L^\infty(\mathscr{E}_1, \mathscr{E}_2)$ satisfying $\|G\|_\infty = \|\Lambda(F)\|$ and $\Lambda(F) = \Lambda(G)$. Notice that $\Lambda(G - F) = 0$. By Lemma 2.1, we see that $G - F = \Theta_2H_*\Theta_1$, where H_* is a function in $H^\infty(\mathscr{F}_1, \mathscr{F}_2)$. In other words, there exists a function H_* in $H^\infty(\mathscr{F}_1, \mathscr{F}_2)$ satisfying

$$\|\Lambda(F)\| = \|F + \Theta_2H_*\Theta_1\|_\infty \geqq \inf\{\|F + \Theta_2H\Theta_1\|_\infty : H \in H^\infty(\mathscr{F}_1, \mathscr{F}_2)\} \geqq \|\Lambda(F)\|.$$

The last inequality follows from (2.2). This readily gives (2.1) and completes the proof.

Remark 2.3. Ball and Helton [3] showed that the Nevanlinna-Pick problem arising in control theory defines a game. Our previous analysis can also be used to show that the two-sided Nehari problem defines a game, that is,

$$(2.3) \qquad d_\infty = \|\Lambda(F)\| = \sup_{\|g\|=1} \inf_H \|(F + \Theta_2H\Theta_1)g\| = \inf_H \sup_{\|g\|=1} \|(F + \Theta_2H\Theta_1)g\|,$$

where the supremum is taken over all unit vectors g in $H^2(\mathscr{E}_1)$ and the infimum is taken over all H in $H^\infty(\mathscr{F}_1, \mathscr{F}_2)$. Moreover, the norm of $\Lambda(F)$ is the value of the game. To prove (2.3), notice that $\|\Lambda(F)g\| = \|\Lambda(F + \Theta_2H\Theta_1)g\| \leqq \|(F + \Theta_2H\Theta_1)g\|$ gives

$$\begin{aligned}\|\Lambda(F)\| &= \sup_{\|g\|=1} \inf_H \|\Lambda(F)g\| \leqq \sup_{\|g\|=1} \inf_H \|(F + \Theta_2H\Theta_1)g\| \\ &\leqq \inf_H \sup_{\|g\|=1} \|(F + \Theta_2H\Theta_1)g\| \\ &= \inf\{\|F + \Theta_2H\Theta_1\|_\infty : H \in H^\infty(\mathscr{F}_1, \mathscr{F}_2)\} = \|\Lambda(F)\|.\end{aligned}$$

The last equality follows from the previous theorem, which is essentially a corollary of the commutant lifting theorem. Now (2.3) follows from the previous equation.

3. The central contractive intertwining lifting. In this section, we will use the central solution in the Schur representation for the commutant lifting theorem, to construct a contractive intertwining lifting that satisfies a special bound. In the next section we will use this purely geometric result to give a simple proof of Theorem 1.1.

To establish some notation, if $\mathscr{H}$ is a subspace of some Hilbert space $\mathscr{K}$, then $P_\mathscr{H}$ is the orthogonal projection onto the subspace $\mathscr{H}$. If C is a contraction ($\|C\| \leqq 1$), from $\mathscr{E}$ to $\mathscr{F}$, then D_C is the positive square root of $I - C^*C$ and $\mathscr{D}_C$ is the closed range of D_C. Throughout this paper A is a contraction from $\mathscr{H}$ into $\mathscr{H}'$ satisfying $T'A = AT$, where T is an isometry on $\mathscr{H}$, and T' is a contraction on $\mathscr{H}'$. We say that U' on $\mathscr{K}'$ is an *isometric lifting* of T' if U' is an isometry on $\mathscr{K}' \supseteq \mathscr{H}'$ and $P_{\mathscr{H}'}U' = T'P_{\mathscr{H}'}$. An operator B from $\mathscr{H}$ to $\mathscr{K}'$ is called a *contractive intertwining lifting* of A if B is a contraction satisfying $U'B = BT$ and $P_{\mathscr{H}'}B = A$. The commutant lifting theorem states that there always exists a contractive intertwining lifting B of A; see [10], [21], [22]. Furthermore, references [2], [10] provide a complete characterization of all contractive intertwining liftings B of A. This sets the stage for one of the main results of this paper.

THEOREM 3.1. *Let A be a strict contraction* ($\|A\| < 1$) *from $\mathscr{H}$ into $\mathscr{H}'$ satisfying $T'A = AT$, where T is an isometry and T' is a contraction. Let* $\mathscr{L} = \mathscr{H} \ominus T\mathscr{H} = \ker(T^*)$

be the wandering subspace determined by T. Then there exists a contractive intertwining lifting B_0 of A satisfying

$$\|B_0a\| \leqq \frac{\|Aa\|}{\sqrt{1-\|A\|^2}} \quad (\textit{for all } a \in \mathcal{L}). \tag{3.1}$$

In particular, if $\mathcal{L}$ is finite-dimensional, then this B_0 satisfies

$$\|B_0 | \mathcal{L}\|_2 \leqq \frac{\|A | \mathcal{L}\|_2}{\sqrt{1-\|A\|^2}}. \tag{3.2}$$

Proof. Since any isometric lifting U' of T' admits a reducing decomposition of the form $U' = U_1 \oplus U_m$, where U_m is the minimal isometric dilation of T' (see Remark VI.3.3 in [10]), we can assume without loss of generality that U' is the minimal isometric dilation of T'. Furthermore, because all minimal isometric dilations are unitarily equivalent, we can also assume that U' on $\mathcal{K}'$ is the Schäffer-Sz.-Nagy minimal isometric dilation of T', that is,

$$U'(h' \oplus f_0 \oplus f_1 \oplus f_2 \oplus \cdots) = T'h' \oplus D_{T'}h' \oplus f_0 \oplus f_1 \oplus f_2 \oplus \cdots,$$

where $h' \oplus (\bigoplus_0^\infty f_i)$ is in $\mathcal{K}' = \mathcal{H}' \oplus (\bigoplus_0^\infty \mathcal{D}_{T'})$; see § 3 of Chapter 6 in [10] or [22].

Now as in § 4 of Chapter XIV in [10], let ω be the unitary operator from $\mathcal{F} = \overline{D_A T \mathcal{H}}$ onto $\mathcal{F}' = \{D_{T'}Ah \oplus D_A h \colon h \in \mathcal{H}\}^-$ defined by

$$\omega D_A T h = D_{T'} A h \oplus D_A h \qquad (h \in \mathcal{H}).$$

Let P' be the orthogonal projection from $\mathcal{D}_{T'} \oplus \mathcal{D}_A$ onto $\mathcal{D}_{T'}$ and P_A the orthogonal projection from $\mathcal{D}_{T'} \oplus \mathcal{D}_A$ onto $\mathcal{D}_A$. According to equation (4.10) in Chapter XIV of [10], one contractive intertwining lifting B_0 from $\mathcal{H}$ to $\mathcal{K}'$ of A is given by

$$B_0 h = Ah \oplus \left(\bigoplus_{j=0}^{\infty} P' \omega P_{\mathcal{F}} (P_A \omega P_{\mathcal{F}})^j D_A h \right) \qquad (h \in \mathcal{H}), \tag{3.3}$$

where $P_{\mathcal{F}}$ is the orthogonal projection into $\mathcal{F}$. So using $P' = I - P_A$ and h in $\mathcal{H}$ we have

$$\begin{aligned}
\|B_0 h\|^2 &= \|Ah\|^2 + \sum_{j=0}^{\infty} \|P' \omega P_{\mathcal{F}} (P_A \omega P_{\mathcal{F}})^j D_A h\|^2 \\
&= \|Ah\|^2 + \sum_{j=0}^{\infty} (\|\omega P_{\mathcal{F}} (P_A \omega P_{\mathcal{F}})^j D_A h\|^2 - \|P_A \omega P_{\mathcal{F}} (P_A \omega P_{\mathcal{F}})^j D_A h\|^2) \\
&\leqq \|Ah\|^2 + \lim_{n \to \infty} \sum_{j=0}^{n} (\|(P_A \omega P_{\mathcal{F}})^j P_{\mathcal{F}} D_A h\|^2 - \|(P_A \omega P_{\mathcal{F}})^{j+1} D_A h\|^2) \\
&= \|Ah\|^2 + \|P_{\mathcal{F}} D_A h\|^2 - \lim_{n \to \infty} \|(P_A \omega P_{\mathcal{F}})^{n+1} D_A h\|^2 \leqq \|Ah\|^2 + \|P_{\mathcal{F}} D_A h\|^2.
\end{aligned}$$

Therefore, we obtain

$$\|B_0 h\|^2 \leqq \|Ah\|^2 + \|P_{\mathcal{F}} D_A h\|^2 \qquad (h \in \mathcal{H}). \tag{3.4}$$

(Using (3.3) and (3.4) it is easy to verify that B_0 is a contractive intertwining lifting of A.)

To complete the proof we need an explicit expression for the orthogonal projection $P_{\mathcal{F}}$. To this end, let X be the operator on $\mathcal{H}$ defined by $X = D_A T$. Since A is a strict contraction, D_A is invertible. So X is one to one. Moreover, the range of X is closed and equals $\mathcal{F}$. Therefore, X^*X is invertible. In fact, because T is an isometry,

$$X^*X = T^*(I - A^*A)T = (I - T^*A^*AT) = D_{AT}^2.$$

This, and the fact that AT is a strict contraction, clearly shows that X^*X is invertible. We claim that

$$P_{\mathcal{F}} = X(X^*X)^{-1}X^* = D_A T D_{AT}^{-2} T^* D_A. \tag{3.5}$$

To verify this notice that the operator P defined by $P = X(X^*X)^{-1}X^*$ is onto $\mathcal{F}$. Obviously, $P^2 = P$ and $P = P^*$. Therefore, $P = P_{\mathcal{F}}$ is the orthogonal projection onto $\mathcal{F}$.

Let a be in $\mathcal{L} = \ker(T^*)$. Substituting (3.5) into (3.4) and using $T^*a = 0$ we have

$$\begin{aligned} \|B_0 a\|^2 &\leqq \|Aa\|^2 + (P_{\mathcal{F}} D_A a, D_A a) = \|Aa\|^2 + (D_{AT}^{-2} T^* D_A^2 a, T^* D_A^2 a) \\ &= \|Aa\|^2 + (D_{AT}^{-2} T^* A^* A a, T^* A^* A a). \end{aligned} \tag{3.6}$$

Now notice that

$$D_{AT}^2 = I - T^*A^*AT = I - A^*T'^*T'A = I - A^*A + A^*(I - T'^*T')A \geqq D_A^2.$$

Therefore, $D_A^2 \leqq D_{AT}^2$, or equivalently, $D_{AT}^{-2} \leqq D_A^{-2}$. (Recall that if Q and R are two invertible positive operators satisfying $Q \leqq R$, then $R^{-1} \leqq Q^{-1}$.) So now (3.6) becomes

$$\begin{aligned} \|B_0 a\|^2 &\leqq \|Aa\|^2 + (D_A^{-2} T^*A^*Aa, T^*A^*Aa) \\ &\leqq \|Aa\|^2 + \frac{\|T^*A^*Aa\|^2}{1 - \|A\|^2} \leqq \|Aa\|^2 + \frac{\|A\|^2 \|Aa\|^2}{1 - \|A\|^2} = \frac{\|Aa\|^2}{1 - \|A\|^2}. \end{aligned}$$

The second inequality follows from the fact that $(1 - \|A\|^2)I \leqq D_A^2$. This proves (3.1). Finally, (3.2) follows from

$$\|B_0|\mathcal{L}\|_2^2 = \sum \|B_0 \phi_i\|^2 \leqq \sum \frac{\|A\phi_i\|^2}{1 - \|A\|^2} = \frac{\|A|\mathcal{L}\|_2^2}{1 - \|A\|^2},$$

where $\{\phi_i\}$ is an orthonormal basis for $\mathcal{L}$. This completes the proof.

Recall that U on $\mathcal{K}$ is a *unitary extension* of T on $\mathcal{H}$, if $\mathcal{H}$ is an invariant subspace for U and $T = U|\mathcal{H}$. This sets the stage for the following useful result.

COROLLARY 3.2. *Let A be a strict contraction from $\mathcal{H}$ to $\mathcal{H}'$ satisfying $T'A = AT$. Let U' on $\mathcal{K}'$ be a unitary lifting of T' and U on $\mathcal{K}$ a unitary extension of T. Then there exists a contraction Y mapping $\mathcal{K}$ into $\mathcal{K}'$ satisfying $U'Y = YU$ and $A = P_{\mathcal{H}'}Y|\mathcal{H}$, and*

$$\|Ya\| \leqq \frac{\|Aa\|}{\sqrt{1 - \|A\|^2}} \quad (\textit{for all } a \in \ker(T^*)). \tag{3.7}$$

In particular, if $\mathcal{L} = \ker T^*$ is finite-dimensional, then

$$\|Y|\mathcal{L}\|_2 \leqq \frac{\|A|\mathcal{L}\|_2}{\sqrt{1 - \|A\|^2}}. \tag{3.8}$$

Proof. By the previous theorem, there exists a contraction B_0 satisfying $U'B_0 = B_0T$ and $A = P_{\mathcal{H}'}B_0$ and (3.1). Obviously, $T^*B_0^* = B_0^*U'^*$ and U^* is an isometric lifting of T^*, that is, $P_{\mathcal{H}}U^* = T^*P_{\mathcal{H}}$. By the commutant lifting theorem, there exists a contraction Y from $\mathcal{K}$ to $\mathcal{K}'$ satisfying $U^*Y^* = Y^*U'^*$ and $P_{\mathcal{H}}Y^* = B_0^*$. The last equation implies that $B_0 = Y|\mathcal{H}$. Therefore, (3.7) follows from (3.1). Obviously, $A = P_{\mathcal{H}'}B_0 = P_{\mathcal{H}'}Y|\mathcal{H}$. This completes the proof.

4. Proof of Theorem 1.1. In this section we will use our previous analysis, based on the commutant lifting theorem, to prove Theorem 1.1. We begin with the following result, which turns out to be equivalent to Theorem 1.1.

THEOREM 4.1. *Let F be a function in $L^\infty(\mathscr{E}_1, \mathscr{E}_2)$ and assume that $\Lambda(F)$ is a strict contraction. Then there exists a function H in $H^\infty(\mathscr{F}_1, \mathscr{F}_2)$ satisfying*

$$(4.1) \qquad \|F+\Theta_2 H\Theta_1\|_\infty \leqq 1 \quad \text{and} \quad \|F+\Theta_2 H\Theta_1\|_2 \leqq \frac{d_2(F)}{\sqrt{1-d_\infty^2(F)}}.$$

Proof. Let $A=\Lambda(F)$ and $T'=T_2$ and $T=T_1$ and $U'=V_2$ and $U=V_1$, where Λ; T_1, T_2, V_1, and V_2 are all defined in § 2. According to Corollary 3.2, there exists a contraction Y mapping $\mathscr{K}=L^2(\mathscr{E}_1)$ into $\mathscr{K}'=L^2(\mathscr{E}_2)$ satisfying $V_2Y=YV_1$ and $\Lambda(F)=P_2Y|\mathscr{H}_1$, and (3.7) holds. Because Y commutes with the bilateral shifts, there exists a function G in $L^\infty(\mathscr{E}_1, \mathscr{E}_2)$ satisfying $Y=M_G$ and $\|Y\|=\|G\|_\infty$. Moreover, $\Lambda(F)=A=P_2Y|\mathscr{H}=\Lambda(G)$. So $\Lambda(G-F)=0$. By Lemma 2.1, there exists a function H in $H^\infty(\mathscr{F}_1, \mathscr{F}_2)$ satisfying $G=F+\Theta_2H\Theta_1$. Substituting this into (3.7), along with $\Theta_1^*\mathscr{F}_1=\ker T^*$, we have $\|Y\|=\|G\|_\infty=\|F+\Theta_2H\Theta_1\|_\infty \leqq 1$ and

$$\|(F+\Theta_2H\Theta_1)\Theta_1^*e\|^2=\|Y\Theta_1^*e\|^2 \leqq \frac{\|\Lambda(F)\Theta_1^*e\|^2}{1-\|A\|^2} \quad (\text{for all } e\in\mathscr{F}_1).$$

Using $\Lambda(F)\Theta_1^*e=(F\Theta_1^*-\Theta_2[\Theta_2^*F\Theta_1^*]_c)e$, along with the fact that $\|A\|=d_\infty$ and Θ_1^* is isometric, we have for $d_\infty=d_\infty(F)$ that

$$(4.2) \qquad \begin{aligned} \|G\Theta_1^*e\|^2 &= \|(F+\Theta_2H\Theta_1)\Theta_1^*e\|^2 \\ &\leqq \frac{\|(F-\Theta_2[\Theta_2^*F\Theta_1^*]_c\Theta_1)\Theta_1^*e\|^2}{1-d_\infty^2} \quad (\text{for all } e\in\mathscr{F}_1). \end{aligned}$$

Now let $G_2=F-\Theta_2[\Theta_2^*F\Theta_1^*]_c\Theta_1$ and recall that $d_2(F)=\|G_2\|_2$; see (1.6). Equation (4.2), along with the definition of the trace norm, implies that

$$(4.3) \qquad \|G\Theta_1^*\|_2^2 \leqq \frac{\|G_2\Theta_1^*\|_2^2}{1-d_\infty^2}.$$

Let $\Delta_1=I-\Theta_1^*\Theta_1$. Since Θ_1^* is isometric, $G\Delta_1=F\Delta_1=G_2\Delta_1$. In particular, this and $1-d_\infty^2 \leqq 1$ implies that

$$(4.4) \qquad \|G\Delta_1\|_2^2 \leqq \frac{\|G_2\Delta_1\|_2^2}{1-d_\infty^2}.$$

Combining this with (4.3) gives

$$(4.5) \qquad \|G\Theta_1^*\|_2^2+\|G\Delta_1\|_2^2 \leqq \frac{\|G_2\Theta_1^*\|_2^2+\|G_2\Delta_1\|_2^2}{1-d_\infty^2}.$$

Notice that because Θ_1^* is an isometry, Δ_1 is an orthogonal projection. This and the fact that the tr $(M^*M)=$ tr (MM^*) gives

$$\|G\Theta_1^*\|_2^2+\|G\Delta_1\|_2^2=\frac{1}{2\pi}\int_0^{2\pi} (\operatorname{tr}(G\Theta_1^*\Theta_1G^*)+\operatorname{tr}(G\Delta_1\Delta_1^*G^*))\,dt=\|G\|_2^2.$$

A similar calculation shows that $\|G_2\Theta_1^*\|_2^2+\|G_2\Delta_1\|_2^2=\|G_2\|_2^2$. Therefore, (4.5) becomes

$$\|G\|_2^2 \leqq \frac{\|G_2\|_2^2}{1-d_\infty^2}=\frac{d_2^2}{1-d_\infty^2}.$$

This completes the proof.

Proof of Theorem 1.1. Let F be any function in $L^\infty(\mathscr{E}_1, \mathscr{E}_2)$ and assume that $\delta > 1$. Let F_0 be the function defined by $F_0 = F/\delta\|\Lambda(F)\|$. Obviously, $\|\Lambda(F_0)\| = 1/\delta < 1$. By the previous theorem there exists a function H_0 in $H^\infty(\mathscr{F}_1, \mathscr{F}_2)$ satisfying

$$\|F_0 + \Theta_2 H_0 \Theta_1\|_\infty \leqq 1 \quad \text{and} \quad \|F_0 + \Theta_2 H_0 \Theta_1\|_2 \leqq \frac{d_2(F_0)}{\sqrt{1 - d_\infty^2(F_0)}}.$$

Using the relations $F = \delta d_\infty(F) F_0$, $d_2(F) = \delta d_\infty(F) d_2(F_0)$, $d_\infty(F_0) = 1/\delta$, and setting $H = \delta d_\infty(F) H_0$ we have

$$\|F + \Theta_2 H \Theta_1\|_\infty \leqq \delta d_\infty(F) \quad \text{and} \quad \|F + \Theta_2 H \Theta_1\|_2 \leqq \frac{\delta d_2(F)}{\sqrt{\delta^2 - 1}}.$$

This is precisely (1.4) in Theorem 1.1. The proof is now complete.

Finally, we emphasize that Theorem 1.1 is equivalent to Theorem 4.1. The previous proof shows that Theorem 1.1 is a consequence of Theorem 4.1. So to show that they are equivalent it is sufficient to show that Theorem 4.1 follows from Theorem 1.1. To this end, assume that Theorem 1.1 is true and that $\Lambda = \Lambda(F)$ is a strict contraction. Now let $\delta = 1/\|\Lambda\|$. Then, by Theorem 1.1 and $d_\infty = \|\Lambda\|$, there exists a function H in $H^\infty(\mathscr{F}_1, \mathscr{F}_2)$ satisfying

$$\|F + \Theta_2 H \Theta_1\|_\infty \leqq \delta d_\infty = 1 \quad \text{and} \quad \|F + \Theta_2 H \Theta_1\|_2 \leqq \frac{\delta d_2}{\sqrt{\delta^2 - 1}} = \frac{d_2}{\sqrt{1 - \|\Lambda\|^2}} = \frac{d_2}{\sqrt{1 - d_\infty^2}}.$$

This readily proves Theorem 4.1. Hence Theorems 1.1 and 4.1 are equivalent.

Obviously, as $\delta \to \infty$ the quantity $\delta/\sqrt{\delta^2 - 1} \to 1$. Therefore, our previous analysis shows that as $\delta \to \infty$ our solution $F + \Theta_2 H \Theta_1$ to (1.4), provided by the central intertwining lifting (3.3) in the Schur representation for the commutant lifting theorem, approaches the L^2 optimal solution $F - \Theta_2[\Theta_2^* F \Theta_1^*]_c \Theta_1$. This sort of phenomenon has also been observed in the engineering literature, where they have noticed that certain H^∞ controllers approach the optimal L^2 controller as a certain parameter approaches infinity [7], [18], [19].

5. A state space solution. State space techniques have played an important role in computing all solutions to the rational Nehari interpolation problem; see [4], [5], [10]-[14]. In this section, we will use state space techniques along with some of the results in [10], [12], to compute our solution to the Nehari version of (1.4) when F is rational, that is, given a rational F and a $\delta > 1$, we will give a state space procedure to construct a function H in $H^\infty(\mathscr{E}_1, \mathscr{E}_2)$ to satisfy

$$\|F + H\|_\infty \leqq \delta d_\infty \quad \text{and} \quad \|F + H\|_2 \leqq \frac{\delta d_2}{\sqrt{\delta^2 - 1}}. \tag{5.1}$$

Here we set $\Theta_2 = I$ and $\Theta_1 = I$ and $\mathscr{E}_1 = \mathscr{F}_1$ and $\mathscr{E}_2 = \mathscr{F}_2$. A computational formula for the general two-sided Nehari problem in (1.4) is somewhat more involved, and will be given elsewhere. In order to compute our H in (5.1), we need to compute the central solution (3.3) in the Schur representation for the commutant lifting theorem considered in the monograph [10], Chapters XIII, XIV, and in the paper [12]. Finally, it is noted that our central solution will correspond to a certain maximal entropy extension. For some nice results on maximal entropy extensions see [6], [8], and [18].

To begin, let $K^\infty(\mathscr{E}_1, \mathscr{E}_2)$ be the subspace of $L^\infty(\mathscr{E}_1, \mathscr{E}_2)$ whose Fourier series expansion contain only negative powers ($n < 0$) of e^{int}. Now let F be a rational function in $K^\infty(\mathscr{E}_1, \mathscr{E}_2)$, that is, $zF(z)$ admits a representation of the form $zF(z) = N(z)/q(z)$, where $N(z)$ is an operator valued polynomial and $q(z)$ is scalar valued polynomial with all of its zeros inside the unit circle. Let $\{A_0, B, C\}$ be a minimal realization of F; that is, A_0 is a matrix on C^n, and B maps $\mathscr{E}_1$ into C^n and C maps C^n into $\mathscr{E}_2$ and $\{A_0, B\}$ is controllable and $\{C, A_0\}$ is observable, and

$$(5.2) \qquad F(z) = C(zI - A_0)^{-1}B,$$

where $z = e^{it}$; see [5], [10], [17] for further details on realization theory. Since F is in $K^\infty(\mathscr{E}_1, \mathscr{E}_2)$, all the eigenvalues of A_0 are in the open unit disc. Notice that since $\Theta_2 = I$ and $\Theta_1 = I$, the operator $\Lambda(F)$ is now the Hankel operator mapping $H^2(\mathscr{E}_1)$ into $K^2(\mathscr{E}_2)$ defined by $\Lambda(F) = P_2 M_F | H^2(\mathscr{E}_1)$, where P_2 is now the orthogonal projection onto $K^2(\mathscr{E}_2)$. It is well known (see [5], [10], [11], [13], [14]) that this Hankel operator Λ admits a decomposition of the form $\Lambda = W_0 W_c^*$, where W_0 is the operator from C^n into $K^2(\mathscr{E}_2)$ defined by $W_0 = C(zI - A_0)^{-1}$ and W_c is the operator from C^n to $H^2(\mathscr{E}_1)$ defined by $W_c = B^*(I - zA_0^*)^{-1}$. The *controllability grammian* P and *observability grammian* Q are defined by

$$(5.3) \qquad P \triangleq W_c^* W_c = \sum_0^\infty A_0^i BB^* A_0^{*i} \quad \text{and} \quad Q \triangleq W_0^* W_0 = \sum_0^\infty A_0^{*i} C^* C A_0^i.$$

Because $\{A_0, B, C\}$ is a minimal realization, both P and Q are strictly positive matrices. Recall that P and Q can be computed by solving the following Lyapunov equations:

$$(5.4) \qquad P = A_0 P A_0^* + BB^* \quad \text{and} \quad Q = A_0^* Q A_0 + C^* C.$$

The minimal realization $\{A_0, B, C\}$, along with its controllability and observability grammians P and Q, will play a key role in our state space solution to (5.1). Finally, recall that $\|\Lambda\|^2 = d_\infty^2(F)$ equals the largest eigenvalue λ^2 of QP; see [5], [10], [11], [13], [14].

For the moment, assume that Λ is a strict contraction, or equivalently, $\lambda = d_\infty = \|\Lambda\| < 1$. According to (9.9) in Chapter XIII of [10], the set of all $F + H$ satisfying $\|F + H\|_\infty \leqq 1$, where H is in $H^\infty(\mathscr{E}_1, \mathscr{E}_2)$, is given by the following transmission type formula:

$$(5.5) \qquad (\Phi_{11} + z\Phi_{12}F_1)(\Phi_{21} + z\Phi_{22}F_1)^{-1},$$

where F_1 is an arbitrary function in the closed unit ball of $H^\infty(\mathscr{E}_1, \mathscr{E}_2)$ and $\Phi_{11}, \Phi_{12}, \Phi_{21}$, and Φ_{22} are specified functions. By consulting § 8 in Chapter XIII of [10], the central solution B_0 in (3.3) is given by (5.5), where $F_1 = 0$, that is, $B_0 = \Phi_{11}\Phi_{21}^{-1}$. Equations (1) and (8) in [12] (where our W_0 is precisely their $\hat{W}_0$) show that

$$(5.6) \qquad \Phi_{11} = W_0(I - PQ)^{-1}B \quad \text{and} \quad \Phi_{21} = W_c(I - QP)^{-1}QB + I.$$

Therefore, $F + H = \Phi_{11}\Phi_{21}^{-1}$ is precisely the Schur representation for the central solution (3.3) in the commutant lifting theorem. So, according to Theorem 4.1, along with the fact that $\|\Lambda\| < 1$, we have for $F + H = \Phi_{11}\Phi_{21}^{-1}$ that

$$(5.7) \qquad \|F + H\|_\infty \leqq 1 \quad \text{and} \quad \|F + H\|_2 \leqq \frac{d_2(F)}{\sqrt{1 - d_\infty^2(F)}}.$$

Finally, it is noted that because F is in $K^\infty(\mathscr{E}_1, \mathscr{E}_2)$ the distance $d_2(F) = \|F\|_2$.

Now let $\{A_0, B, C\}$ be a minimal realization of F, and P its controllability grammian and Q its observability grammian. Let $d_\infty^2 = \lambda^2$ be the largest eigenvalue of QP. Then the function $F_0 = F/\lambda\delta$ defines a Hankel operator $\Lambda(F_0)$ satisfying $\|\Lambda(F_0)\| = 1/\delta$. Obviously, $\{A_0, B, (1/\lambda\delta)C\}$ is a minimal realization of F_0 whose observability grammian is $Q/\lambda^2\delta^2$ and controllability grammian is P. By consulting the proof of Theorem 1.1, we see that if H_0 in $H^\infty(\mathscr{C}_1, \mathscr{C}_2)$ satisfies

$$(5.8) \qquad \|F_0+H_0\|_\infty \leqq 1 \quad \text{and} \quad \|F_0+H_0\|_2 \leqq \frac{d_2(F_0)}{\sqrt{1-d_\infty^2(F_0)}},$$

then $F+H=\lambda\delta(F_0+H_0)$ is a solution to (5.1). So by replacing Q by $Q/\lambda^2\delta^2$ and C by $(1/\lambda\delta)C$ in (5.6) and setting $\Phi_1=\lambda\delta\Phi_{11}$ and $\Phi_2=\Phi_{21}$ the previous analysis readily leads to the following method for computing a function H satisfying (5.1).

Procedure 5.1. Let F be a rational function in $K^\infty(\mathscr{C}_1, \mathscr{C}_2)$ and $\delta>1$. Compute a minimal realization $\{A_0, B, C\}$ of $F(z)$ and its corresponding controllability P and observability Q grammians. Compute $d_\infty^2=\lambda^2$, the largest eigenvalue of QP. Compute

$$(5.9) \qquad \Phi_1=\lambda^2\delta^2 W_0(\lambda^2\delta^2 I-PQ)^{-1}B \quad \text{and} \quad \Phi_2=W_c(\lambda^2\delta^2 I-QP)^{-1}QB+I.$$

Then $F+H=\Phi_1\Phi_2^{-1}$ satisfies (5.1).

The results in § 9 of Chapter XIV in [10] can also be used to give another formula to compute our function H in $H^\infty(\mathscr{C}_1, \mathscr{C}_2)$ satisfying (5.1). To see this, for the moment assume that $\|\Lambda(F)\|=d_\infty<1$. Then according to equation (9.8) in Chapter XIV of [10], the set of all $F+H$ satisfying $\|F+H\|_\infty \leqq 1$ is given by the following scattering type formula:

$$(5.10) \qquad F+H=F+\Psi_{22}+\Psi_{21}(I-F_1\Psi_{11})^{-1}F_1\Psi_{12},$$

where F_1 is an arbitrary function in the closed unit ball of $H^\infty(\mathscr{C}_1, \mathscr{C}_2)$ and $\Psi_{11}, \Psi_{12}, \Psi_{21}$, and Ψ_{22} are all specified functions. By the results in Chapter XIV of [10], the central solution B_0 in (3.3) is given by $F_1=0$, that is, $B_0=F+\Psi_{22}$. Reference [12] shows that

$$(5.11) \qquad \Psi_{22}(z)=-CP(I-zA_1)^{-1}(I-A_0^*QA_0P)^{-1}A_0^*QB,$$

where A_1 is the matrix on C^n defined by

$$(5.12) \qquad A_1=(I-A_0^*QA_0P)^{-1}A_0^*(I-QP).$$

Reference [10] also proves that all the eigenvalues of A_1 are in the open unit circle. Therefore, the central solution B_0 in (3.3) is given by $B_0=F+\Psi_{22}$. Now, proceeding exactly as above, we can use formulas (5.11) and (5.12) to obtain the following method for computing our function H satisfying (5.1).

Procedure 5.2. Let F be a rational function in $K^\infty(\mathscr{C}_1, \mathscr{C}_2)$ and $\delta>1$. Compute a minimal realization $\{A_0, B, C\}$ of $F(z)$ and its corresponding controllability P and observability grammian Q. Compute $d_\infty^2=\lambda^2$, the largest eigenvalue of QP. Compute

$$A_2=(\lambda^2\delta^2 I-A_0^*QA_0P)^{-1}A_0^*(\lambda^2\delta^2 I-QP)$$

and

$$(5.13) \qquad \Psi=-CP(I-zA_2)^{-1}(\lambda^2\delta^2 I-A_0^*QA_0P)^{-1}A_0^*QB.$$

Then $F+\Psi$ satisfies (5.1).

Finally, it is noted that if we let $\delta\to\infty$ in (5.9) or (5.13), then, as expected, our $F+H\to F$ the L^2 optimal solution.

Acknowledgment. The authors thank Allen Tannenbaum for some clarification included in §§ 1 and 2.

NONUNIFORM SAMPLING OF BANDLIMITED FUNCTIONS OF POLYNOMIAL GROWTH*

GILBERT G. WALTER†

Abstract. A version of the Shannon sampling theorem for nonuniform sampling points and signals with infinite energy is given. It is valid for signals of polynomial growth whose Fourier transform is a generalized function with compact support. It involves the theory of nonharmonic Fourier series.

Key words. sampling theorem, band limited signals, generalized functions, nonharmonic Fourier series

AMS(MOS) subject classifications. 41A05, 40G05

1. Introduction. The Shannon sampling theorem for bandlimited signals is the name given to the formula

$$f(t)=\sum_{n=-\infty}^{\infty} f(t_n)S_n(t), \qquad t\in\mathbb{R}^1, \tag{1.1}$$

where the t_n are the sampling points and the $S_n(t)$ the sampling functions. The latter have the properties that $S_n(t_k)=\delta_{nk}$, $k=0, \pm1, \cdots$. The t_n may be uniform, $t_n=nT$, and were in Shannon's original work [8]. In this case the $S_n(t)$ are given by

$$S_n(t)=\frac{\sin \sigma(t-nT)}{\sigma(t-nT)}, \qquad \sigma=\pi/T, \tag{1.2}$$

and the series (1.1) converges to $f(t)$ for $f\in L^2(\mathbb{R}^1)$ provided its Fourier transform $F(\omega)$ has support in $[-\sigma, \sigma]$.

The t_n may also be nonuniform, i.e., not equally spaced. In this case the $S_n(t)$ have a more complicated form but (1.1) still converges under the same hypotheses, provided the t_n are "close" to nT [1].

The various versions of this theorem have widespread applications. They are used whenever it is necessary to reconstitute an analog signal from sampled values or from a digital signal. This occurs, e.g., in compact disc recordings, in multiplexed signals, in optics, and in tomography. Several surveys of the literature of both the theory and applications have been given [1], [4].

Most of the results refer to finite energy (i.e., L^2) signals. Yet many signals of practical importance are not finite energy. For example, a pure musical note has infinite energy. However, it can also be recovered from its sampled values. A number of results concerning such signals have been obtained. The earliest were due to Campbell [2] and Pfaffelhuber [7]. These results were extended by several authors [3], [6], [9], [10], [5]; however, in no case did they consider nonuniform sampling, which is important for some of the applications.

In this work we shall extend the results in [9] and [10] to this case of nonuniform sampling. Our signals will be bandlimited and of at most polynomial growth on the real axis. Usually, we shall have to add another condition to obtain the needed uniqueness. In § 2, we introduce some notation and preliminary results. In § 3 we obtain a sampling theorem involving additional factors in the series. In § 4, the form

* Received by the editors August 28, 1989; accepted for publication (in revised form) September 18, 1991. This research was done while visiting the University of South Florida, Tampa, Florida 33620.

† Department of Mathematical Sciences, University of Wisconsin at Milwaukee, Box 413, Milwaukee, Wisconsin 53201.

of (1.1) is retained, but a type of summability is used rather than ordinary convergence. In § 5 the series is treated from the point of view of convergence in a class of generalized functions.

2. Background and preliminaries. An appropriate space in which to study bandlimited functions of polynomial growth (BLPG) is the space $B_r(\sigma)$, $r \geqq 0$. This space consists of those functions in $L^2((1+t^2)^{-r}) = L_r^2$ whose Fourier transforms have support on $[-\sigma, \sigma]$. Each of our BLPG functions must belong to some $B_r(\sigma)$.

In [9] it was shown that a uniform sampling theorem for $f \in B_{2N}(\sigma)$ could be given. It had the form

$$f(t) = P(t) \sin \sigma t + \sum_{n=-\infty}^{\infty} f(nT) \left[\frac{t^2+1}{(nT)^2+1}\right]^N \frac{\sin \sigma(t-nT)}{\sigma(t-nT)}, \tag{2.1}$$

where $P(t)$ is an appropriate polynomial of degree $2N-1$. This added term is necessary because of the lack of uniqueness of sampling sequences in $B_{2N}(\sigma)$. Two functions which differ by $P(t) \sin \sigma t$ will have the same sampling sequence.

2.1. Equivalence classes. In order to obtain uniqueness (and to eliminate the term $P(t) \sin \sigma t$ in (2.1)) we shall use equivalence classes of functions in $B_{2N}(\sigma)$. We denote these by $[f]$;

$$[f] := \{g \in B_{2N}(\sigma) \mid g(nT) = f(nT), n = 0, \pm 1, \cdots\},$$

with a norm defined as usual by

$$\|[f]\| = \inf_{g \in [f]} \|g\|_{-2N},$$

where $\| \quad \|_{-2N}$ denotes the norm in L_{2N}^2. The set $B'_{2N}(\sigma)$ of all such $[f]$ is a Hilbert space with this norm. Its sampling expansion has partial sums given by

$$\begin{aligned} f_m(t) &= \sum_{n=-m}^{m} g(nT) \left[\frac{t^2+1}{n^2T^2+1}\right]^N \frac{\sin \sigma(t-nT)}{\sigma(t-nT)} \\ &= \sum_{n=-m}^{m} g(nT) S_n^{\sigma,N}(t), \end{aligned} \tag{2.2}$$

where $g \in [f]$. It was shown in [9] that the partial sums of (2.1) converge in the sense of L_{2N}^2. Hence, it follows that

$$[f_m] \to [f]$$

in the norm of $B'_{2N}(\sigma)$, since

$$\begin{aligned} \|[f]-[f_m]\| &= \|[f-f_m]\| \\ &= \inf_{g \in [f-f_m]} \|g\|_{-2N} \\ &\leqq \|f(t) - P(t) \sin \sigma t - f_m(t)\|_{-2N}. \end{aligned}$$

There is exactly one element of each $[f]$ such that $f(t)/(t^2+1)^N$ is an entire function, i.e., has no singularity at $t = \pm i$. By restricting ourselves to such f we obtain an isometric copy $B_{2N}^0(\sigma)$ of $B'_{2N}(\sigma)$, which is a subspace of $B_{2N}(\sigma)$.

2.2. The space $B_{2N}^0(\sigma)$. The sampling theorem in [9] may be interpreted in $B_{2N}^0(\sigma)$ as the following.

PROPOSITION 2.1. *The sampling sequence* $\{S_n^{\sigma,N}(t)\}$ *in* (2.2) *is a complete orthogonal system in* $B_{2N}^0(\sigma)$. *Parseval's equality may be expressed as*

$$\|f\|_{-2N}^2 = \sum_{m=-\infty}^{\infty} |f(nT)|^2(n^2T^2+1)^{-2N}. \tag{2.3}$$

This follows from the orthogonality of $S_n^{\sigma,0}(t) = \sin\sigma(t-nT)/\sigma(t-nT)$ in $L^2(\mathbb{R}^1)$ and its completeness in $B_0(\sigma)$. Indeed, we have

$$\begin{aligned}\|f\|_{-2N}^2 &= \int_{-\infty}^{\infty} |f(t)|^2(t^2+1)^{-2N}\,dt\\ &= \left\|\frac{f(t)}{(t^2+1)^N}\right\|_0^2 = \sum_{n=-\infty}^{\infty}\left|\frac{f(nT)}{(n^2T^2+1)^N}\right|^2\\ &= \sum_{n=-\infty}^{\infty} |\langle f, S_n^{\sigma,N}\rangle_{-2N}|^2(n^2T^2+1)^{-2N}.\end{aligned}$$

As is $B_0(\sigma)$, the space $B_{2N}^0(\sigma)$ is a reproducing kernel Hilbert space with reproducing kernel

$$k(t,u) = (t^2+1)^N(u^2+1)^N\frac{\sin\sigma(t-u)}{\sigma(t-u)}, \tag{2.4}$$

which follows from the same sorts of considerations. This kernel may be used to find the projection of $f \in B_{2N}(\sigma)$ onto $B_{2N}^0(\sigma)$,

$$(\mathcal{P}f)(t) = \int_{-\infty}^{\infty} k(t,u)f(u)(u^2+1)^{-2N}\,du. \tag{2.5}$$

Because of the orthogonality of the $S_n^{\sigma,N}$ and the fact that

$$\langle f, S_n^{\sigma,N}\rangle_{-2N} = f(nT)(n^2T^2+1)^{-2N},$$

$(\mathcal{P}f)(t)$ is the same as $f(t)-P(t)\sin\sigma t$ in (2.1). □

The space $B_{2N}^0(\sigma)$ will be the setting for our nonuniform sampling.

2.3. Frames. If the sampling points t_n are no longer uniform, then the sequence $\{S_n^{\sigma,N}\}$ is no longer orthogonal. However, if it is close to orthogonal, it may satisfy an inequality (which is a substitute for Parseval's equality) of the form

$$0 < A\|f\|^2 \leqq \Sigma|\langle f, S_n\rangle|^2 \leqq B\|f\|^2. \tag{2.6}$$

Here f belongs to some Hilbert space H, and A and B are constant. Such sequences $\{S_n\}$ are called "frames" and share many of the properties of orthogonal sequences. In particular [11, p. 186] each $f \in H$ has an associated moment sequence $a_n = \langle g, S_n\rangle$ for some $g \in H$ such that

$$f = \sum_n a_n S_n. \tag{2.7}$$

For $B_0(\sigma)$, it is well known that

$$S_n(t) = \frac{\sin\sigma(t-t_n)}{\sigma(t-t_n)}, \qquad n = 0, \pm1, \pm2, \cdots, t_{-n} = -t_n,\ t, t_n \in \mathbb{R}, \tag{2.8}$$

is a frame provided that $|t_n - n| \leqq L < \frac{1}{4}$ for $\sigma = \pi$. (Kadec's $\frac{1}{4}$ Theorem, [11]). In fact $\{S_n\}$ is an "exact" frame, i.e., no proper subset of $\{S_n\}$ is itself a frame. In this case there is a biorthogonal sequence $\{g_n\}$ with $\{S_n\}$ such that

$$f = \Sigma\langle f, g_n\rangle S_n = \Sigma\langle f, S_n\rangle g_n \tag{2.9}$$

[11, p. 188]. In the case of $B_0(\sigma)$, we can say a little more. The series (2.7) is not the sampling series for f. Rather, it is the other series in (2.9) which gives us a sampling theorem of the form

$$f(t)=\Sigma f(t_n)g_n(t). \tag{2.10}$$

This $\{g_n\}$ may be given [11, p. 149] by the entire functions

$$g_n(t)=\frac{g(t)}{g'(t_n)(t-t_n)}, \tag{2.11}$$

where

$$g(t)=t\prod_{n=1}^{\infty}\left(1-\frac{t^2}{t_n^2}\right). \tag{2.12}$$

Each $g_n\in B_0(\pi)$, but $g(t)\notin B_0(\pi)$. Rather, it is an element of $B_1(\pi)$ just as $\sin \pi t$ is.

3. Nonuniform sampling in $B_{2N}^0(\sigma)$. We shall find a frame in $B_{2N}^0(\sigma)$ and then shall try to emulate the procedure used in $B_0(\sigma)$ to obtain a sampling theorem. We consider only the case $\sigma=\pi$, since the general case follows by a change of scale.

LEMMA 3.1. *Let $\{t_n\}_{-\infty}^{\infty}$ be a sequence of complex numbers such that*

(i) $t_n=-t_{-n}$, $n=0, \pm1, \pm2, \cdots$,

(ii) $\sup_n |\text{Re } t_n-n|<\frac{1}{4}$,

(iii) $|\text{Im } t_n|\leqq C<\infty$;

and let $\{r_n\}$ and $\{h_n\}$ be given by

$$r_n(t)=(t^2+1)^N\frac{\sin \pi(t-t_n)}{\pi(t-t_n)}, \qquad n=0, \pm1, \pm2, \cdots, t\in\mathbb{R}, \tag{3.1}$$

$$h_n(t)=(t^2+1)^N g_n(t), \qquad n=0, \pm1, \pm2, \cdots, t\in\mathbb{R}, \tag{3.2}$$

where g_n is given by (2.11). *Then $\{r_n\}$ and $\{h_n\}$ are both exact frames in $B_{2N}^0(\pi)$ and*

$$\langle r_n, h_m\rangle_{-2N}=\delta_{nm}.$$

Proof. For a sequence $\{t_n\}$ satisfying the hypothesis, the functions $\{e^{it_n\omega}\}$ constitute a frame in $L^2[-\pi,\pi]$, [11, p. 196]. Hence, the Fourier transform of $e^{it_n\omega}\chi_\pi(\omega)$, $\chi_\pi(\omega)$, the characteristic function of $[-\pi,\pi]$, given by

$$S_n(t)=\frac{\sin \pi(t-t_n)}{\pi(t-t_n)},$$

forms a frame in $B_0(\pi)$ since the Fourier transform is an isometry from $L^2(\mathbb{R})$ into itself.

Now let $f\in B_{2N}^0(\pi)$. Then

$$\langle f, r_n\rangle_{-2N}=\int\frac{f(t)}{(t^2+1)^N}S_n(t)\,dt$$
$$=\left\langle\frac{f(t)}{(t^2+1)^N}, S_n\right\rangle_0,$$

and $f(t)(t^2+1)^{-N}\in B_0(\pi)$. Hence, there are constants A and C such that

$$A\left\|\frac{f(t)}{(t^2+1)^N}\right\|_0^2\leqq\sum_n|\langle f, r_n\rangle_{-2N}|^2\leqq C\left\|\frac{f(t)}{(t^2+1)^N}\right\|_0^2 \tag{3.3}$$

by the frame inequality (2.6), since $\{S_n\}$ is a frame in $B_0(\pi)$. But we have

$$\left\|\frac{f(t)}{(t^2+1)^N}\right\|_0^2=\|f\|_{-2N}^2$$

so that $\{r_n\}$ is a frame in $B^0_{2N}(\pi)$. Similarly, since $\{S_n\}$ is exact in $B_0(\pi)$, $\{r_n\}$ is exact in $B^0_{2N}(\pi)$.

The biorthogonality of $\{h_n\}$ with $\{r_n\}$ follows similarly, as does the fact that $\{h_n\}$ is also a frame. □

COROLLARY 3.2. *Let* $f\in B^0_{2N}(\pi)t_n\in\mathbb{R}$; *then*

$$f(t)=\sum_{n=-\infty}^{\infty} f(t_n)g_n(t)\left(\frac{t^2+1}{t_n^2+1}\right)^N,\qquad t\in\mathbb{R},\tag{3.4}$$

with convergence in the sense of L_{2N}.

The proof follows from the fact that

$$\langle f, r_n\rangle_{-2N}=\frac{f(t_n)}{(t_n^2+1)^N}.$$

However, we wish to obtain a theorem similar to (2.1) for $f\in B_{2N}(\pi)$. The correction term $P(t)\sin\sigma t$ will not work in this case since it does not necessarily vanish at the sampling points. It may be replaced by $P(t)g(t)$, where $g(t)$ is given by (2.12), which does work.

COROLLARY 3.3. *Let* $f\in B_{2N}(\pi)$, $t_n\in\mathbb{R}$; *then there is a polynomial* $P(t)$ *of degree* $\leqq 2N-1$ *such that*

$$f(t)=P(t)g(t)+\sum_{n=-\infty}^{\infty} f(t_n)g_n(t)\left(\frac{t^2+1}{t_n^2+1}\right)^N,\tag{3.5}$$

where the series converges in the sense of L_{2N} *and uniformly on compact subsets of the complex plain.*

The polynomial $P(t)$ is chosen such that $f(t)-P(t)g(t)$ belongs to $B^0_{2N}(\pi)$. This will occur if

$$f^{(j)}(\pm i)=\frac{d^j}{dt^j}(P(t)g(t))\big|_{t=\pm i},\qquad j=0,1,\cdots,N-1.\tag{3.6}$$

In practical cases the sampling points t_n will be real and $f(t)$ will be known only for real values of t. In such a case $P(t)$ may be chosen by using

$$\inf_{\substack{a_0,\cdots,a_{N-1}\\ b_0,\cdots,b_{N-1}}}\int\left|f(t)-\sum_{j=0}^{N-1}(a_j-b_jt)(t^2+1)^jg(t)\right|^2(t^2+1)^{-2N}\,dt,\tag{3.7}$$

i.e., the projection of f onto the space spanned by polynomial multiples of degree $2N-1$ of $g(t)$, which belongs to $B^0_{2N}(\pi)$.

The uniform convergence of (3.5) on bounded sets follows as in § 2, by using the reproducing kernel of $B^0_{2N}(\pi)$.

4. Summability of sampling series. The results of the last section (Corollary 3.3), while generalizing the original sampling theorem, lack its elegance and simplicity. In [9], the extra factor in the series was removed by considering (C,α) summability as a substitute for ordinary convergence. In this section we shall see that a similar result holds for nonuniform sampling as well.

A series $\Sigma_{n=-\infty}^{\infty}u_n$ is said to be (C,α) summable to s if

$$\lim_{K\to\infty}\sum_{n=-K}^{K}C^\alpha_{K,n}u_n=s,\qquad C^\alpha_{K,n}=\frac{\binom{K-|n|+\alpha}{\alpha}}{\binom{K+\alpha}{\alpha}}.$$

For Fourier series the (C, α) means are given by

$$\begin{aligned}\sigma_K^\alpha(\omega) &= \sum_{n=-K}^{K} C_{K,n}^\alpha a_n e^{i\omega n}\\ &= \int_{-\pi}^{\pi} F(x)\left\{\frac{1}{2\pi}\sum_{n=-K}^{K} C_{K,n}^\alpha e^{in(\omega-x)}\right\} dx \qquad (4.1)\\ &= \int_{-\pi}^{\pi} F(x) H_K^\alpha(\omega-x)\,dx,\end{aligned}$$

where H_K^α is the kernel of (C, α) summability for Fourier series. In [9] it was shown that if supp $F \subset (-\pi, \pi)$ and if the Fourier transform $f(t) \in B_{2N}(\pi)$, then the sampling series is (C, α) summable to $f(t)$ for $\alpha > 2N$. We shall attempt to do the same for nonuniform sampling.

We shall first consider the function $e^{i\omega t}$ and show that its derivatives have uniformly convergent nonharmonic Fourier series on $-\pi+\varepsilon < \omega < \pi - \varepsilon$. Let $\varphi(\omega)$ be a $C^\infty(\mathbb{R})$ function with support on $[-\pi, \pi]$ such that $\varphi(\omega) = 1$, $|\omega| < \pi - \varepsilon$.

LEMMA 4.1. *Let $\theta_t^p(\omega) = D^p(e^{i\omega t}\varphi(\omega))$ with expansions*

$$(4.2) \qquad \theta_t^p(\omega) = \sum_{n=-\infty}^{\infty} a_n(t)\, e^{it_n\omega} = \sum_{n=-\infty}^{\infty} b_n(t)\, e^{in\omega}$$

with convergence of both series in $L^2(-\pi, \pi)$; then

$$(4.3) \qquad d_K^{\alpha,p}(t,\omega) = \sum_{n=-K}^{K} (a_n(t)\, e^{it_n\omega} - b_n(t)\, e^{in\omega}) C_{K,n}^\alpha, \qquad \alpha \geqq 0,$$

converges to zero uniformly for t on bounded sets and $|\omega| \leqq \pi - \varepsilon$ as $K \to \infty$.

For $\alpha = 0$, the proof is similar to that in [11, p. 198]. We need only prove the uniform convergence for t in addition. Using the notation there, we find that (4.3) may be given by

$$(4.4) \qquad d_K^{\alpha,p}(t,\omega) = \sum_{k=0}^{\infty} \langle \psi_k(t,\omega), (\omega^k - x^k) D_K(\omega - x)\rangle_0,$$

where $D_K(\omega)$ is the Dirichlet kernel and ψ_k the function

$$(4.5) \qquad \psi_k(t,\omega) = \sum_{n=-\infty}^{\infty} a_n(t) \frac{i^k(t_n-n)^k}{k!} e^{in\omega}.$$

Since $|t_n - n| \leqq L < \frac{1}{4}$, the norm of ψ_k in $L^2(-\pi, \pi)$,

$$\begin{aligned}\|\psi_k\|^2 &\leqq \frac{L^{2k}}{(k!)^2}\sum_{n=-\infty}^{\infty} |a_n(t)|^2 \leqq C\frac{L^{2k}}{(k!)^2}\int_{-\pi}^{\pi} |\theta_t^p(\omega)|^2\,d\omega\\ &= \frac{L^{2k}}{(k!)^2} a^2(t),\end{aligned}$$

where $a(t)$ is a continuous function of polynomial growth on $\mathbb{R}^1$. Then each of the terms in (4.4) is dominated by

$$|\langle \psi_k(t,\omega), (\omega^k - x^k) D_K(\omega - x)\rangle| \leqq C a(t) \frac{(\pi L)^k}{k!}$$

as in [11, p. 200]. From this the uniform convergence of the expression (4.3) to zero follows easily for $\alpha = 0$. For other values of α we use the fact that (C, α) summability is a regular summability method for $\alpha > 0$, i.e., all convergent series are summable to the same value. □

We now assume that $f(t)\in B_{2N}(\pi)$ and $F(\omega)$ has its support on $[-\pi+\varepsilon, \pi-\varepsilon]$. Then we may express F as

$$F(\omega)=D^{2N}G(\omega)+\sum_{j=0}^{2N-1} c_j\delta^{(j)}(\omega), \tag{4.6}$$

where $G\in L^2(-\pi, \pi)$ with support on $[-\pi+\varepsilon, \pi-\varepsilon]$ and c_j, $j=0, 1, \cdots, 2N-1$ are constant [9]. It follows that $f(t)$ may be given by

$$f(t)=\frac{1}{2\pi}(-1)^N t^{2N}\int_{-\pi}^{\pi} e^{-i\omega t}G(\omega)\,d\omega+\frac{1}{2\pi}\sum_{j=0}^{2N-1}(it)^j c_j. \tag{4.7}$$

Let us denote by $\sigma_{K,t}$ and $\sigma^*_{K,t}$ the Kth (C, α) mean of the Fourier series and of the nonharmonic Fourier series of $e^{i\omega t}\varphi(\omega)$, respectively. For $p=0$ we have by (4.3),

$$d^{\alpha,0}_K(t, \omega)=\sigma^*_{K,t}(\omega)-\sigma_{K,t}(\omega),$$

which is C^∞ and hence

$$\langle D^{2N}G, d^{\alpha,0}_K(t, \omega)\rangle=\langle G, D^{2N}d^{\alpha,0}_K(t, \omega)\rangle. \tag{4.8}$$

By the uniqueness theorems for the two types of Fourier series, we may deduce that $D^{2N}d^\alpha_K$ is their difference for $D^{2N}(e^{i\omega t}\varphi(\omega))$, i.e.,

$$d^{\alpha,2N}_K(t, \omega)=D^{2N}d^{\alpha,0}_K(t, \omega).$$

Hence, (4.8) becomes, by the lemma,

$$\begin{aligned}\langle D^{2N}G, d^{\alpha,0}_K(t, \omega)\rangle&=\langle G, d^{\alpha,2N}_K(t, \omega)\rangle\to\langle G, \theta^{2N}_t\rangle\\&=\int_{-\pi+\varepsilon}^{\pi-\varepsilon} G(\omega)D^{2N}(e^{-i\omega t}\varphi(\omega))\,d\omega\\&=(-it)^{2N}\int_{-\pi}^{\pi} G(\omega)\,e^{-i\omega t}\,d\omega \quad \text{as } K\to\infty.\end{aligned} \tag{4.9}$$

The terms $\Sigma\, c_j\delta^j$ are treated similarly. Thus we conclude that

$$\begin{aligned}&\langle F, \sigma^*_{K,t}\rangle-\langle F, \sigma_{K,t}\rangle\\&\quad=\langle F, d^{\alpha,0}_K(t, \omega)\rangle\to 0 \quad \text{as } K\to\infty.\end{aligned}$$

But $\langle F, \sigma^*_{K,t}\rangle$ and $\langle F, \sigma_{K,t}\rangle$ are, respectively, the (C, α) means of the series (1.1) and the standard sampling theorem $(t_n=n)$. Since for $\alpha>2N$ the latter converges to $f(t)$ [9], it follows that the former converges as well. We have proved the following.

THEOREM 4.2. *Let $f\in B_{2N}(\pi)$ have a Fourier transform with support in $[-\pi+\varepsilon, \pi-\varepsilon]$ and let $\alpha>2N$; let $\{t_n\}$ satisfy $t_n=-t_{-n}$ and $|t_n-n|\leqq L<\frac{1}{4}$; $t_n\in\mathbb{R}$, $n\in\mathbb{Z}$; then*

$$f(t)=\sum_{n=-\infty}^{\infty} f(t_n)g_n(t)$$

in the sense of (C, α) summability uniformly on bounded subsets of $\mathbb{R}$.

5. Convergence in the sense of generalized functions. The results in §§ 3 and 4 both require additional restrictions on $f(t)$, beyond that it be π bandlimited of polynomial growth. However, there is a sense in which (1.1) holds for all such $f(t)$. It has been shown [7], [5] that (1.1) converges in the sense of Z'_π [12], the dual of the Paley-Wiener space Z_π. This is not a contradiction since the counter example sin πt is equivalent to zero in Z'_π. (The same is true of cos πt, but its coefficients are not zero.)

In order to extend these results to nonuniform sampling points, we must first consider the nonharmonic Fourier series of distributions $F(\omega)\in D'_\pi$ (D_π is the set of $\varphi\in D(\mathbb{R})$ which vanish for $|\omega|>\pi$ with the induced topology. It is the Fourier transform of Z_π.) Since $F(\omega)$ is completely arbitrary for $|\omega|>\pi$, we take it to be zero there.

LEMMA 5.1. *Let $\{t_n\}$ be a sequence satisfying the conditions of Lemma 3.1; let $\varphi\in D_\pi$; then the nonharmonic Fourier series of φ,*

$$\varphi(\omega)\sim\sum a_n e^{it_n\omega}, \tag{5.1}$$

converges to a function $\varphi^*(\omega)$ whose restriction to $(-\pi,\pi)$ is the same as that of $\varphi(\omega)$. This convergence is in the sense of E. (The series and all its derivatives converge uniformly.)

Proof. Since $\varphi\in L^2(-\pi,\pi)$ the series (5.1) converges in the sense of $L^2(-\pi,\pi)$ to $\varphi(\omega)$ and $\{a_n\}\in l^2$. The same is true of $\varphi'(\omega)$ whose coefficients we denote by $\{a'_n\}$, with $a'_0=0$. Hence, we have

$$\varphi(\omega)=\int_{-\pi}^{\omega}\varphi'=\sum_{n\pm 0}a'_n\frac{(e^{it_n\omega}-e^{-i\pi t_n})}{it_n}$$

$$=\sum_{n\pm 0}\frac{a'_n e^{it_n\omega}}{it_n}-\sum_{n\pm 0}\frac{a'_n e^{-i\pi t_n}}{it_n}$$

in which both series converge, the latter to a constant. By using the biorthogonality of $\{G_n(\omega)\}$ and $\{e^{it_n\omega}\}$, we find that

$$a'_n=it_na_n,\qquad n\neq 0,$$

and by iterating the procedure

$$a_n^{(p)}=(it_n)^pa_n,\qquad n\neq 0. \tag{5.2}$$

Here $a_n^{(p)}$ are the coefficients of $\varphi^{(p)}$ and form a sequence in l^2. Thus $\{a_n\}$ is rapidly decreasing and the series (5.1) converges in the sense of E to some $\varphi^*(\omega)$. □

We now turn to generalized functions $F(\omega)$ with support in $[-\pi,\pi]$. We shall require that F be strongly integrable over $[-\pi,\pi]$ (see [10]). This requires that F be the pth derivative of a continuous function G in some neighborhood of π (respectively, $-\pi$) such that

$$\frac{G(\omega)}{(\omega-\pi)^{p-1}}\to 0\quad\text{as }\omega\to\pi\quad\text{(respectively, }-\pi). \tag{5.3}$$

Since F has compact support it belongs to E' and

$$\langle F,\varphi\rangle=\langle F,\varphi^*\rangle=\left\langle F,\sum_n a_n e^{it_n\omega}\right\rangle=\sum_n a_n\langle F,e^{it_n\omega}\rangle. \tag{5.4}$$

The inverse Fourier transform of such $F\in E'$ is given by

$$f(t)=\frac{1}{2\pi}\langle F,e^{it\omega}\rangle.$$

Hence, (5.4) becomes

$$\langle F,\varphi\rangle=\sum_n a_n 2\pi f(t_n). \tag{5.5}$$

But $\langle F, \varphi\rangle = 2\pi\langle f, \tilde{\varphi}\rangle$, where $\tilde{\varphi}$ is the inverse Fourier transform of φ. Also a_n is given by

$$a_n = \frac{1}{2\pi}\langle G_n, \varphi\rangle = \langle g_n, \tilde{\varphi}\rangle,$$

and (5.5) becomes

$$\langle f, \tilde{\varphi}\rangle = \langle \Sigma f(t_n) g_n, \tilde{\varphi}\rangle. \tag{5.6}$$

Thus, except for the uniqueness, we have proved the following.

THEOREM 5.2. *Let f be a π bandlimited function of polynomial growth; let $\{t_n\}$ satisfy the conditions of Lemma* 3.1; *then $f(t)$ has the sampling expansion*

$$f(t) = \Sigma f(t_n) g_n(t),$$

convergent in the sense of Z'_π. It is unique if $F(\omega)$ is strongly integrable over $[-\pi, \pi]$.

The uniqueness does not always follow since nonzero sampling series may converge to zero in Z'_π. This happens for any $f \in Z'_\pi$ such that $\langle f, \psi\rangle = 0$ for all $\psi \in Z_\pi$, e.g., $f(t) = \cos \pi t$ or $f(t) = \sin \pi t$.

If $F(\omega)$ is strongly integrable over $[-\pi, \pi]$ and $\langle F, \psi\rangle = 0$ for all $\psi \in D_\pi$, then F has support on $\pm\pi$. Such generalized functions have the form

$$\sum_{j=0}^{m} b_j \delta^{(j)}(\omega + \pi) + c_j \delta^{(j)}(\omega - \pi),$$

which are strongly integrable only if $b_j = c_j = 0$, $j = 0, 1, \cdots, m$. Thus $F \equiv 0$, and uniqueness follows. □

DISCRETE DISCRETE WAVELETS*

GILBERT G. WALTER†

Abstract. A discrete family of wavelets consisting of discrete functionals in a Sobolev space is studied. It is shown that they form a complete orthonormal system in H^{-s}, $s>\frac{1}{2}$ generated by a single "mother functional." Closed form expressions are derived in certain cases.

Key words. orthonormal basis, Sobolev spaces, generalized functions, wavelets

AMS(MOS) subject classifications. 42C10, 46F10

1. Introduction. A recurring problem in signal analysis is to approximate an analog signal by a digital signal in order to use the more versatile tools of digital signal processing. That is, a real valued function $f(t)$ on $\mathbb{R}$ must be approximated in some sense by (the generalized function)

$$f^*(t)=\sum_{k=-\infty}^{\infty} a_k\delta(t-t_k). \tag{1.1}$$

Furthermore $f(t)$ must be recoverable from $f^*(t)$. This is possible when $f(t)$ is a bandlimited function, i.e., when its Fourier transform

$$\hat{f}(w)=\int_{-\infty}^{\infty} e^{-2\pi iwt}f(t)\,dt$$

has compact support, say in the unit interval $[-\frac{1}{2},\frac{1}{2}]$. Then the sampling theorem says that if f^* is taken to be

$$f^*(t)=\sum_{k=-\infty}^{\infty} f(k)\delta(t-k),$$

$f(t)$ may be recovered by taking the projection of $f^*(t)$ into a subspace of an appropriate Sobolev space (see [6], [1]).

However, there appears to be no simple way of expanding more general functions in sequences of δ's. This is particularly true since $\delta(t-a)$ and $\delta(t-b)$ are not orthogonal for $a\neq b$ in the Sobolev space H^{-s}, for $s>\frac{1}{2}$ to which they belong. Indeed the inner product in H^{-s} is

$$\langle f,g\rangle_{-s}=\int_{-\infty}^{\infty}\hat{f}(w)\overline{\hat{g}(w)}(w^2+1)^{-s}\,dw \tag{1.2}$$

and hence

$$\begin{aligned}\langle \delta_a,\delta_b\rangle_{-s}&=\int_{-\infty}^{\infty} e^{-2\pi iaw}\,e^{2\pi ibw}(w^2+1)^{-s}\,dw\\&=\hat{h}(a-b),\end{aligned}$$

where $h(w)=(w^2+1)^{-s}$.

Fortunately there is a framework in which this expansion can be formulated. It involves the theory of wavelet expansions for the affine group.

1.1. Wavelets. The "wavelets of constant shape," or simply "wavelets," were first proposed by J. Morlet et al. [5] as a tool for analysis of seismic data. They were shown by Grossman and Morlet [3] to involve a square integrable representation of the affine group. A representation of an $L^2(\mathbb{R})$ function f was given in terms of its wavelet expansion

$$f \sim \langle h^{(u,v)}, f\rangle = \phi(u, v),$$

where $h^{(u,v)}(x) = 2^{u/2}h(2^u x - v)$ is an appropriate function in $L^2(\mathbb{R})$. This representation was in terms of integrals of $\phi(u, v)$.

A discrete version was also introduced by Grossman [2], [3] which involved the theory of frames. This was further refined by Meyer [4] who showed how to construct discrete orthognal systems of wavelets. These, in the case of the real line, were of the form

$$\varphi_{m,k}(x) = 2^{m/2}h(2^m x - k),$$

where h is a "mother function" in $L^2(\mathbb{R})$, which is continuous and piecewise linear except at half integers. He also succeeded in constructing systems in which h was in C^m and even C_0^∞.

In this work we shall emulate some aspects of his approach, but with H^{-s} spaces and with δ's instead of functions. The resulting theory is even simpler and will result in a discrete "mother functional" h of the form

$$h(x) = \sum_{k=-\infty}^{\infty} a_k \delta(2x - 1 - k).$$

For H^{-1}, h will be shown to be given by a particularly simple formula

$$h(x) = a\delta(2x-1) - b(\delta(2x) + \delta(2x-2)),$$

where a and b are constants.

2. Wavelets in H^{-s}, $s > \frac{1}{2}$. In this section we present the general theory for any real s. We shall defer detailed calculations to the next section in which we shall obtain a closed form expression for the mother functional in some cases.

2.1. Continuous wavelet expansions. The continuous wavelet expansions in H^{-s} may be easily based on those for $L^2(\mathbb{R})$ [3]. Let $g \in L^2(\mathbb{R}) \cap L^1(\mathbb{R})$ such that $\int_{-\infty}^{\infty} g = 0$. The wavelet transform of $f \in L^2$ with respect to the wavelets based on g is

$$\phi(u, v) = \int 2^{u/2}\bar{g}(2^u x - v) f(x)\, dx \tag{2.1}$$

and the representation of f is

$$f(x) = C \iint 2^{u/2} g(2^u x - v)\phi(u, v)\, du\, dv, \tag{2.2}$$

where C is constant depending only on g.

We illustrate the extension of H^{-s} for $s = 1$. Let h denote the conjugate Fourier transform of the weight $(w^2+1)^{-1}$, $h(x) = \pi e^{-2\pi|x|}$. Then for $f \in H^{-1}$, we replace (2.1) by

$$\phi(u, v) = \langle f, g^{(u,v)}\rangle_{-1} \tag{2.3}$$

where $g^{(u,v)}(x) = 2^{u/2} g(2^u x - v)$.

But $\langle f, g\rangle_{-1} = \langle f*h, g\rangle_0$ when $g \in L^2(\mathbb{R})$, and hence (2.3) becomes (2.1) with f replaced by $f*h$. Then the representation theorem gives us

$$(f*h)(x) = C \iint g^{(u,v)}(x)\phi(u, v)\, du\, dv. \tag{2.4}$$

Since h is the Green's function for $1-(D/2\pi)^2$, we may recover f by operating on both sides of (2.4) with this operator.

$$f(x) = \left[1-\left(\frac{D}{2\pi}\right)^2\right] C \iint g^{(u,v)}(x)\phi(u, v)\, du\, dv.$$

We shall not pursue this further since our main interest is in discrete rather than continuous wavelets.

2.2. Some subspaces of H^{-s}. We imitate Meyer's [4] procedure for L^2 in H^{-s} and define B_0 to be the subspace

$$B_0 = \{f \in H^{-1} | \operatorname{supp} f \subset \mathbb{Z}\}.$$

The subspace B_j is then defined to be the dilation

$$B_j = \{f \in H^{-1} | f(2^{-j}\cdot) \in B_0\}.$$

We have a characterization of B_0 given by the following.

PROPOSITION 2.1. *$f \in B_0$ if and only if*

$$f(x) = \sum_{k=-\infty}^{\infty} a_k \delta(x-k), \qquad \{a_k\} \in l^2. \tag{2.5}$$

Proof. If f has the form given, then it clearly has support on $\mathbb{Z}$ and its Fourier transform is

$$\hat{f}(w) = \sum_k a_k e^{-2\pi i w k},$$

which is periodic and in L^2_{loc}. Hence $\hat{f} \in L^2[(w^2+1)^{-s}]$ for all $s > \frac{1}{2}$, and hence $f \in B_0 \cap H^{-s}$.

If $f \in B_0$, then f is a tempered distribution in S' of order $\leqq 1$ and hence has the form of (2.5) with convergence in the sense of S'. The Fourier transform must be in $L^2(0, 1)$, and hence the Fourier coefficient sequence $\{a_k\} \in l^2$.

It should be observed that by this argument $B_0 \subset H^{-s}$ for all $s > \frac{1}{2}$. Also it follows that

$$B_0 \subset B_1 \subset \cdots \subset B_j \subset \cdots \subset H^{-s}$$

and

$$\overline{\bigcup B_j} = H^{-s}$$

since trigonometric polynomials are dense in $L^2[(w^2+1)^{-s}]$.

We define C_{j+1} to be the orthogonal complement of B_j in B_{j+1} in the sense of H^{-s}. We shall then look for an element $\varphi_j \in C_{j+1}$ whose translates

$$\varphi_{jk}(x) = \varphi_j(x - 2^{-j}k)$$

constitute an orthogonal basis of C_{j+1}. Since

$$H^{-s} = B_0 \oplus \sum_{j=1}^{\infty} \oplus C_j,$$

it follows that $\{\varphi_{jk}\}$ will be an orthonormal system in H^{-s}, which, together with a basis for B_0, will be a basis of H^{-s}.

2.3. An orthonormal basis for B_0. Let $\varphi \in B_0$, $\varphi(x) = \sum_{k=-\infty}^{\infty} a_k \delta(x-k)$; we wish to choose φ such that translates of φ are orthogonal. Then

$$\delta_{0k} = \langle \varphi, \varphi_k \rangle_{-s} = \int |\hat{\varphi}(w)|^2 \, e^{-2\pi i w k} (w^2+1)^{-s} \, dw. \tag{2.6}$$

Since by the Poisson summation formula

$$\sum_{n=-\infty}^{\infty} f(w+n) = \sum_{n=-\infty}^{\infty} \hat{f}(n) \, e^{2\pi i n w},$$

it follows for $f(w) = |\hat{\varphi}(w)|^2 (w^2+1)^{-s}$ and $\hat{f}(k) = \delta_{0k}$ (2.6) that

$$\sum_{n=-\infty}^{\infty} |\hat{\varphi}(w+n)|^2 ((w+n)^2+1)^{-s} = \sum_{k=-\infty}^{\infty} \delta_{0k} \, e^{2\pi i k w} = 1. \tag{2.7}$$

Clearly $\hat{\varphi}(w) = \sum_{k=-\infty}^{\infty} a_k \, e^{-2\pi i k w}$ is 1-periodic and hence (2.7) becomes

$$|\hat{\varphi}(w)|^2 \beta_s(w) = 1,$$

where

$$\beta_s(w) = \sum_{n=-\infty}^{\infty} ((w+n)^2+1)^{-s}.$$

Since $\beta_s(w) > 0$ for all w, it follows that one solution to (2.6) is

$$\hat{\varphi}_0(w) = \beta_s^{-1/2}(w) \tag{2.8}$$

and the general solution is

$$\hat{\varphi}(w) = \chi(w) \hat{\varphi}_0(w),$$

where $|\chi(w)| = 1$, $\chi \in L^2_{\text{loc}}$, and χ is 1-periodic.

The particular solution φ_0 may be characterized up to a constant $e^{i\lambda}$, as the one with minimum $\|x\varphi\|^2_{-s}$ among those for which this norm is finite. It clearly is for φ_0 since

$$\hat{\varphi}_0'(w) = -\tfrac{1}{2} \beta_s^{-3/2}(w) \beta_s'(w),$$

both of whose factors are continuous and periodic. Then

$$\begin{aligned} \|x\varphi\|^2_{-s} &= \int_{-\infty}^{\infty} |\hat{\varphi}'(w)|^2 (w^2+1)^{-s} \, dw \\ &= \int_{-\infty}^{\infty} |\chi'(w)|^2 |\hat{\varphi}_0(w)|^2 (w^2+1)^{-s} \, dw \\ &\quad + \int_{-\infty}^{\infty} |\chi(w)|^2 |\hat{\varphi}_0'(w)|^2 (w^2+1)^{-s} \, dw \\ &\quad + 2 \operatorname{Re} \int_{-\infty}^{\infty} \hat{\varphi}_0 \hat{\varphi}_0' \chi \overline{\chi'} (w^2+1)^{-s} \, dw. \end{aligned}$$

Since $\chi \overline{\chi'}$ is purely imaginary, this last term is zero and hence

$$\|x\varphi\|^2_{-s} \geqq \|x\varphi_0\|^2_{-s}.$$

We must still show that $\{\varphi_0(x-k)\}$ is a basis for B_0, which we do with the same argument. Indeed, let $f \in B_0$

$$\langle f, T^k\varphi_0\rangle_{-s} = 0, \qquad k = 0, \pm 1, \pm 2, \cdots,$$

where T is the shift operator $T\varphi(x) = \varphi(x-1)$. Then

$$0 = \int \frac{\hat{f}(w)\hat{\varphi}_0(w)\, e^{2\pi i w k}}{(w^2+1)^s}\, dw, \qquad k = 0, \pm 1, \cdots,$$

and by the Poisson summation formula again,

$$\hat{f}(w)\hat{\varphi}_0(w) \sum_{n=-\infty}^{\infty} \frac{1}{((w^2+n)^2+1)^s} = 0, \tag{2.9}$$

and hence $\hat{f}(w) = 0$. This shows completeness. Hence we have proved the following.

PROPOSITION 2.2. *The translates* $\{T^k\varphi_0\}$, φ_0 *given by* (2.8), *form an orthonormal basis of* B_0.

2.4. An orthonormal basis for C_1. In order to find a basis for C_1 consisting of translates of a fixed ψ, we look for $\psi \in B_1$ such that

(i) $\langle \psi, \delta_k\rangle_{-s} = 0$, $k = 0, \pm 1, \cdots$, which will ensure that ψ is orthogonal to B_0 and hence in C_1;

(ii) $\langle \psi, \psi_k\rangle_{-s} = \delta_{0k}$, the orthogonality conditon;

(iii) If $f \in B_1$ satisfies $\langle f, \delta_k\rangle_{-s} = \langle f, \psi_k\rangle_{-s} = 0$, $k = 0, \pm 1, \cdots$, then $f = 0$, the completeness condition.

These three conditions are expressed, respectively, as

$$\text{(i}'\text{)} \quad \int_{-\infty}^{\infty} \hat{\psi}(w)\, e^{i2\pi w k}(w^2+1)^{-s}\, dw = 0, \qquad k = 0, \pm 1, \cdots.$$

or by the Poisson summation formula

$$\sum_{n=-\infty}^{\infty} \hat{\psi}(w+n)((w+n)^2+1)^{-s} = 0, \ w \in \mathbb{R};$$

$$\text{(ii}'\text{)} \quad \sum_{n=-\infty}^{\infty} |\hat{\psi}(w+n)|^2((w+n)^2+1)^{-s} = 1, \ w \in \mathbb{R};$$

$$\text{(iii}'\text{)} \quad \sum_{n=-\infty}^{\infty} \hat{f}(w+n)((w+n)^2+1)^{-s} = 0, \ w \in \mathbb{R}; \quad \text{and}$$

$$\sum_{n=-\infty}^{\infty} \hat{f}(w+n)\overline{\hat{\psi}(w+n)((w+n)^2+1)^{-s}} = 0, \ w \in \mathbb{R}.$$

Since both ψ and f are in B_1, their Fourier transforms are 2-periodic. Hence we separate each of the series into its even and odd terms. The first one is

$$\sum_n \hat{\psi}(w+2n)((w+2n)^2+1)^{-s} + \sum_n \hat{\psi}(w+2n+1)((w+2n+1)^2+1)^{-s}$$
$$= \hat{\psi}(w)\sum_n ((w+2n)^2+1)^{-s} + \hat{\psi}(w+1)\sum_n ((w+2n+1)^2+1)^{-s},$$

which, if we denote $\sum_n ((w+2n)^2+1)^{-s} = A_s(w)$, becomes

$$\hat{\psi}(w)A_s(w) + \hat{\psi}(w+1)A_s(w+1) = 0. \tag{2.10}$$

Similarly (ii′) and (iii′) become

$$(2.11)\qquad |\hat{\psi}(w)|^2A_s(w)+(\hat{\psi}(w+1))^2A_s(w+1)=1,$$

$$(2.12)\qquad \hat{f}(w)A_s(w)+\hat{f}(w+1)A_s(w+1)=0,$$

and

$$(2.13)\qquad \hat{f}(w)\overline{\hat{\psi}(w)A_s(w)}+\hat{f}(w+1)\overline{\hat{\psi}(w+1)A_s(w+1)}=0.$$

We can solve (2.10) and (2.11) simultaneously for $|\hat{\psi}(w)|^2$,

$$(2.14)\qquad |\hat{\psi}(w)|^2=\frac{A_s(w+1)}{A_s(w)(A_s(w+1)+A_s(w))}.$$

Unfortunately the positive square root of (2.14) does not satisfy (2.10). In fact, if it is substituted in (2.10), the left side will be

$$\frac{A_s^{1/2}(w+1)A_s^{1/2}(w)}{(A_s(w+1)+A_s(w))^{1/2}},$$

which is positive for all w. We can get a solution by choosing the square root to be

$$(2.15)\qquad \hat{\psi}_1(w)=e^{-i\pi w}|\hat{\psi}(w)|,$$

which satisfies (2.10). However, (2.15) is not unique. We can make it unique by choosing a solution which minimizes $\|(x-\frac{1}{2})\psi(x)\|^2_{-s}$, as we did in the last section for $\|x\varphi\|_{-s}$.

In order to prove the completeness we must show that the only solution to (2.12) and (2.13) is the zero solution. This holds if the determinant of the system

$$d(w)=A_s(w)A_s(w+1)\overline{(\hat{\psi}(w+1)-\hat{\psi}(w))}\neq 0.$$

Since $A_s(w)>0$ and

$$|\hat{\psi}(w)|^2-|\hat{\psi}(w+1)|^2=\left[\frac{A_s(w+1)}{A_s(w)}-\frac{A_s(w)}{A_s(w+1)}\right]\frac{1}{(A_s(w)+A_s(w+1))}$$

by (2.14), it follows that $d(w)=0$ only at those points where $A_s(w)=A_s(w+1)$, which can easily be seen, is a set of measure zero.

Thus we have proved the following.

PROPOSITION 2.3. *There exists an orthonormal basis of C_1 in the topology of H^{-s}, $s>\frac{1}{2}$, given by translates $\{T^k\psi_1\}$, where $\hat{\psi}_1$ is given by* (2.15).

2.5. An orthonormal basis for $C_j, j>1$. Unfortunately in the case of H^{-s}, the dilation map

$$(D_a\varphi)(x)=a^{1/2}\varphi(ax)$$

is not an isometry of H^{-s} into H^{-s} even though it is a homeomorphism. Therefore, the orthonormal basis of C_1 is not necessarily mapped into an orthonormal set in C_j by the dilation operator D_2j, and we shall have to proceed differently.

We return to C_1 but modify the norm slightly to

$$(2.16)\qquad \|\varphi\|^2_{-s,\delta}=\int|\hat{\varphi}(w)|^2(w^2+\delta^2)^{-s}\,dw,\qquad \delta>0,$$

with the corresponding inner product denoted $\langle\varphi, \psi\rangle_{-s,\delta}$. This of course will change the definition of C_1, the orthogonal complement of B_0 in B_1. But B_0 and B_1 will remain the same sets.

The arguments in § 2.4 may be repeated verbatim, requiring only that we replace $A_s(w)$ by

$$A_s(w, \delta)=\sum_n ((w+2n)^2+\delta^2)^{-s}.$$

The corresponding solution to the replacements for (2.10) and (2.11) is

$$\hat{\psi}(w, \delta)=e^{-iw\pi}\left[\frac{A_s(w+1, \delta)}{A_s(w, \delta)(A_s(w+1, \delta)+A_s(w, \delta))}\right]^{1/2}. \tag{2.17}$$

Thus, we see that we again have an orthonormal basis $\{T_k\psi\}$ of the revised space $C_{1,\delta}$ with the norm given by (2.16). We shall use it to construct an orthonormal basis of C_{j+1} (original definition).

The conditions (i), (ii), and (iii) required for an orthonormal basis of C_{j+1} with the norm of H^{-s} may be translated into conditions on C_1 with a modified norm. Indeed we see that for

$$\varphi \in C_1, \qquad D_{2^j}\varphi \in C_{j+1}$$

and

$$\|D_{2^j}\varphi\|^2_{-s}=\|2^{j/2}\varphi(2^jx)\|^2_{-s}=2^{-2js}\|\varphi\|^2_{-s,2^{-j}}.$$

Since ψ, given by (2.17), has the required properties for $\delta=2^{-j}$, it follows that the system of functions given by

$$2^{j(s+\frac{1}{2})}\psi(2^jx-k, 2^{-j})=\psi_{j+1,k}(x), \quad j=0, 1, \cdots, \quad k=0, \pm 1, \cdots, \tag{2.18}$$

is an orthonormal basis of C_j. This gives us the following.

THEOREM 2.4. *Let ψ_{jk} be given by* (2.18) *for $j=1, 2, \cdots$, $k=0, \pm 1, \cdots$, and by $\psi_{0,k}=\varphi_0(x-k)$, $k=0, \pm 1, \cdots$; then $\{\psi_{jk}\}_{j=0,}^{\infty}\,{}_{k=-\infty}^{\infty}$ is a complete orthonormal basis of H^{-s} for $s>\frac{1}{2}$.*

The proof is immediate since $H^{-s}=B_0\oplus\sum_{j=1}^{\infty}\oplus C_j$.

The results for C_j, $j\geqq 1$ can be extended to nonpositive values of j and lead to the decomposition

$$H^{-s}=\{\delta\}\oplus\sum_{j=-\infty}^{\infty}\oplus C_j$$

since $\bigcap_{j=-\infty}^{\infty} B_j=\{\delta\}$, the space spanned by the δ function.

3. Explicit formulas for H^{-m}, m an integer. In some cases it is possible to sum the series arising in the last section explicitly and hence obtain closed form formulas for $A_s(w, \delta)$ and $\psi(w, \delta)$. We shall do so for integer values for s.

3.1. The case $s=1$. For $s=1$, we can sum this series defining $A_1(w, \delta)$ easily by using the fact that

$$\sum_{n=-\infty}^{\infty}\frac{1}{x+n}=\frac{\pi\cos\pi x}{\sin\pi x} \tag{3.1}$$

with symmetric partial sums being understood. This may be shown using residues or by finding the Fourier series of e^{-ixt} at $t=\pi$. Then

$$A_1(w,\delta)=\sum_n \frac{1}{(w+2n)^2+\delta^2}=\frac{i}{2\delta}\left\{\sum_n \frac{1}{w+2n+i\delta}-\sum_n \frac{1}{w+2n-i\delta}\right\}$$

$$(3.2)\qquad =\frac{\pi i}{4\delta}\;\frac{\cos \pi\left(\dfrac{w+\delta i}{2}\right)}{\sin \pi\left(\dfrac{w+\delta i}{2}\right)}-\frac{\cos \pi\left(\dfrac{w-\delta i}{2}\right)}{\sin \pi\left(\dfrac{w-\delta i}{2}\right)}$$

$$=\frac{\pi i}{2\delta}\,\frac{\sin \pi(-\delta i)}{(\cos \pi(i\delta)-\cos \pi w)}=\frac{\pi}{2\delta}\,\frac{\sinh \pi\delta}{(\cosh \pi\delta-\cos \pi w)}.$$

In order to find $\psi(w,\delta)$ we use (2.17):

$$\hat{\psi}(w,\delta)=e^{-i\pi w}\left\{\frac{A_1(w+1,\delta)}{A_1(w,\delta)(A_1(w+1,\delta)+A_1(w,\delta))}\right\}^{1/2}$$

$$(3.3)\qquad =e^{-i\pi w}\left\{\frac{2\delta/(\cosh \pi\delta+\cos \pi w)}{\dfrac{\pi \sinh \delta\pi}{\cosh \pi\delta-\cos \pi w}\left\{\dfrac{1}{\cosh \pi\delta-\cos \pi w}+\dfrac{1}{\cosh \pi\delta+\cos \pi w}\right\}}\right\}^{1/2}$$

$$=e^{-i\pi w}\left\{\frac{2\delta}{\pi \sinh \delta\pi}\,\frac{(\cosh \pi\delta-\cos \pi w)^2}{2\cosh \pi\delta}\right\}^{1/2}$$

$$=e^{-i\pi w}(\cosh \pi\delta-\cos \pi w)\sqrt{\frac{2\delta}{\pi \sinh 2\pi\delta}}.$$

Hence $\psi(x,\delta)$ may be expressed as

$$(3.4)\qquad \begin{aligned}\psi(x,\delta)&=\sqrt{\frac{2\delta}{\pi \sinh 2\pi\delta}}\left\{(\cosh \pi\delta)\delta\left(x-\frac{1}{2}\right)-\frac{1}{2}\delta(x)-\frac{1}{2}\delta(x-1)\right\}\\ &=b\left\{c\delta\left(x-\frac{1}{2}\right)-\frac{1}{2}\delta(x)-\frac{1}{2}\delta(x-1)\right\},\end{aligned}$$

where $b>0$ and $c>1$ are constants depending on δ. This is the version of "mother functional" in H^{-1}.

The orthonormal basis of B_0 in H^{-1} is given by

$$\hat{\varphi}_0(w)=\beta_1^{-1/2}(w),$$

where

$$\beta_1(w)=\sum_n ((w+n)^2+1)^{-1}=\frac{\pi \sinh 2\pi}{\cosh 2\pi-\cos 2\pi w},$$

$$\hat{\varphi}_0(w)=\left[\frac{\cosh 2\pi-\cos 2\pi w}{\pi \sinh 2\pi}\right]^{1/2}.$$

To find the inverse Fourier transform of $\hat{\varphi}_0$ we use the series expansion

$$(1-x)^{1/2}=\sum_{k=0}^{\infty}\frac{\Gamma(3/2)(-1)^k}{\Gamma(k+1)\Gamma((3/2)-k)}x^k=\sum_{k=0}^{\infty}\gamma_k x^k$$

to express $\hat{\varphi}_0$ as

$$\hat{\varphi}_0(w) = b(1 - c\cos 2w\pi)^{1/2}$$
$$= b\sum_{k=0}^{\infty} \gamma_k c^k \cos^k 2\pi w.$$

Since

$$\int_0^1 \cos^k 2\pi w\, e^{-2\pi i n w}\, dw = \begin{cases} 0, & |n| > k \\ 0, & n+k \text{ odd} \\ \dfrac{1}{2^k}\dbinom{k}{(n+k)/2}, & n+k \quad \text{even,} \end{cases}$$

it follows that the $2n$th Fourier coefficient of $\hat{\varphi}_0(w)$ is

$$c_{2n} = \int_0^1 \hat{\varphi}_0(w)\, e^{-2\pi i 2nw}\, dw = b\sum_{k=|n|}^{\infty} \gamma_{2k} c^{2k} \frac{1}{2^{2k}}\binom{2k}{n+k}$$

while the $(2n+1)$th is

$$c_{2n+1} = \int_0^1 \hat{\varphi}_0(w)\, e^{-2\pi i(2n+1)w}\, dw = b\sum_{k=|n|}^{\infty} \gamma_{2k+1} c^{2k+1}\binom{2k+1}{n+k+1}\frac{1}{2^{2k+1}}.$$

Hence the Fourier series of $\hat{\varphi}_0(w)$ is

$$\hat{\varphi}_0(w) = \sum_{n=-\infty}^{\infty} (c_{2n}\, e^{2\pi i 2nw} + c_{2n+1}\, e^{2\pi i(2n+1)w}).$$

The $\gamma_k < 0$ for $k \geqq 1$, and since all the other factors in each term of the series for c_{2n} and c_{2n+1} are positive, it follows that $c_n < 0$ for all $n \neq 0$. Thus the inverse Fourier transform of $\hat{\varphi}_0(w)$ is

$$\varphi_0(x) = \sum_{n=-\infty}^{\infty} c_n \delta(x-n), \tag{3.5}$$

where none of the terms vanish ($c_0 > 0$).

3.2. Other H^{-m}, $m > 1$. We can find expansion for $A_m(w, \delta)$, $m > 1$ in terms of $A_1(w, \delta)$ and $A_2(w, \delta)$. Indeed we note that $A_s(w, \delta)$ satisfies the recurrence relation

$$\begin{aligned} \frac{d^2}{dw^2}A_s(w,\delta) &= \frac{d^2}{dw^2}\left(\sum \frac{1}{((w+2n)^2+\delta^2)^s}\right) \\ &= s(s+1)\sum((w+2n)^2+\delta^2)^{-s-2}4(w+2n)^2 \\ &\quad -2s\sum((w+2n)^2+\delta^2)^{-s-1} \\ &= 2s(2s+1)A_{s+1}(w,\delta) - 4\delta^2 s(s+1)A_{s+2}(w,\delta). \end{aligned} \tag{3.6}$$

Hence if $A_2(w, \delta)$, in addition to $A_1(w, \delta)$, is known, we can find $A_m(w, \delta)$ for all integers > 0. To find $A_2(w, \delta)$ we use the formula

$$\sum \frac{1}{(x+n)^2} = \frac{\pi^2}{\sin^2 \pi x}, \tag{3.7}$$

which can be obtained by differentiating (3.1). Then we have

$$\begin{aligned}
A_2(w,\delta) &= \sum_n ((w+2n)^2+\delta^2)^{-2} \\
&= \frac{1}{16\delta^2}\left[\sum_n\left(\frac{i}{(w+\delta i)/2+n}\right)^2+\sum_n\left(\frac{i}{(w-\delta i)/2+n}\right)^2\right. \\
&\quad \left.+\sum\frac{2}{(n+(w/2))^2+(\delta/2)^2}\right] \\
&= \frac{-\pi^2}{16\delta^2}\left(\frac{1}{\sin^2\pi(w+\delta i)/2}+\frac{1}{\sin^2\pi(w-\delta i)/2}\right)+\frac{1}{2\delta^2}A_1(w,\delta) \qquad (3.8) \\
&= \frac{-\pi^2}{4\delta^2}\frac{(1-\cosh\pi\delta\cos\pi w)}{(\cosh\pi\delta-\cos\pi w)^2}+\frac{1}{2\delta^2}\frac{\pi}{2\delta}\frac{\sinh\pi\delta}{(\cosh\pi\delta-\cos\pi w)} \\
&= \frac{a_{21}}{\cosh\pi\delta-\cos\pi w}+\frac{a_{22}}{(\cosh\pi\delta-\cos\pi w)^2}.
\end{aligned}$$

The second derivative of $A_1(w, \delta)$ is easily calculated to be

$$\begin{aligned}
\frac{d^2}{dw^2}A_1(w,\delta) &= \frac{\pi^3\sinh\pi\delta}{2\delta}\left[\frac{\cos\pi w}{(\cosh\pi\delta-\cos\pi w)^2}-\frac{2(1-\cos^2\pi w)}{(\cosh\pi\delta-\cos\pi w)^3}\right] \\
&= \frac{C_1}{\cosh\pi\delta-\cos\pi w}+\frac{C_2}{(\cosh\pi\delta-\cos\pi w)^2}+\frac{C_3}{(\cosh\pi\delta-\cos\pi w)^3}.
\end{aligned}$$

Hence by (3.6)

$$\begin{aligned}
A_3(w,\delta) &= \frac{2s+1}{2\delta^2(s+1)}A_2(w,\delta)-\frac{1}{4\delta^2 s(s+1)}\frac{d^2}{dw^2}A_1(w,\delta) \\
&= \frac{a_{31}}{c-z}+\frac{a_{32}}{(c-z)^2}+\frac{a_{33}}{(c-z)^3},
\end{aligned}$$

where

$$c-z=(\cosh\pi\delta-\cos\pi w). \qquad (3.9)$$

The induction step is obvious, so we are able to conclude that

$$A_m(w,\delta)=\sum_{k=1}^m a_{mk}(c-z)^{-k}, \qquad (3.10)$$

where $c-z$ is given by (3.9). Clearly, we also have

$$A_m(w+1,\delta)=\sum_{k=1}^m a_{mk}(c+z)^{-k},$$

and hence

$$|\hat{\psi}(w,\delta)|^2=\frac{\sum_{k=1}^m a_{mk}(c+z)^{-k}}{\sum_{k=1}^m a_{mk}(c-z)^{-k}\{\sum_{k=1}^m a_{mk}[(c-z)^{-k}+(c+z)^{-k}]\}}.$$

The mother functional for H^{-m} will, therefore, again be as in (2.17), where now $|\hat{\psi}(w, \delta)|^2$ is a rational function in $\cos w\pi$. However, the Fourier series of $\hat{\psi}(w, \delta)$ will have an infinite number of terms except in the case of $m=1$. This Fourier series will, nevertheless, be rapidly converging. This follows from the fact that $A_m(w, \delta)>0$ on the real axis and is a holomorphic function in some neighborhood of $\mathbb{R}$ (in fact for $|\mathrm{Im}\, w| < \delta$). The reciprocal $A_m^{-1}(w, \delta)$ will also be holomorphic in some such strip and hence,

$$\frac{A_m(w+1, \delta)}{A_m(w, \delta)\{A_m(w+1)+A_m(w)\}}$$

will be holomorphic as well. Since this is also positive in $\mathbb{R}$, its square root will be holomorphic in a strip also, as will $\hat{\psi}(w, \delta))$. The Fourier coefficients c_n of $\hat{\psi}$, therefore, will behave as

$$c_n = 0(e^{-\varepsilon|n|})$$

for some $\varepsilon > 0$, which will depend on δ.

SOBOLEV CHARACTERIZATION OF SOLUTIONS OF DILATION EQUATIONS*

TIMO EIROLA†

Abstract. This work studies the smoothness of the solutions of dilation equations, which are encountered in the multiresolution analysis and iterative interpolation processes. Sharp limit of the Sobolev exponent of the solution is given as a function of the spectral radius of an associated finite-dimensional positive operator. In addition, tools are given to get good explicit upper and lower bounds for the exponent.

Key words. wavelets, iterative interpolation, positive operators

AMS(MOS) subject classifications. 39B99, 15A48, 42C15

1. Introduction.

In this paper we study the smoothness of the solutions of the dilation equation

$$\phi(x) = \sum_k h_k \phi(2x - k), \tag{1.1}$$

where h_k are given real coefficients such that $\sum_k h_k = 2$. Such equations arise in iterative interpolation processes for producing continuous curves from discrete data (see [1], [2], [5], [6]) and in multiresolution analysis and in the theory of wavelets [3], [8]. In this work we restrict ourselves to the case where only finitely many of the h_k's are nonzero (say those with $|k| \leq N$). Then [4] the condition on $\{h_k\}$ implies that (1.1) has (up to normalisation) at most one L^1 solution and if it exists it has compact support ($\subset [-N, N]$).

We use the Fourier transform:

$$\hat{f}(\omega) := \frac{1}{\sqrt{2\pi}} \int_{\mathbf{R}} e^{-i\omega x} f(x) \mathrm{d}x$$

and spaces

$$C^\alpha := \left\{ f \in C^n \mid n = \alpha - \sigma \in \mathbf{N},\ 0 \leq \sigma < 1,\ \sup_{x \neq y} \tfrac{|f^{(n)}(x) - f^{(n)}(y)|}{|x-y|^\sigma} < \infty \right\},$$

$$\mathcal{H}^s_p := \{ f \in L^p(\mathbf{R}) \mid \|f\|_{s,p} := \|[\hat{f}(\omega)(1 + |\omega|^2)^{s/2}\,]\hat{}\ \|_{L_p} < \infty\},$$

where α , $s \geq 0$. For the case $p = 2$, which is mostly considered here, set $\mathcal{H}^s := \mathcal{H}^s_2$.

Assume (1.1) has a solution $\phi \in L^1$. Then for the Fourier transform we have

$$\hat{\phi}(\omega) = p(\omega/2)\hat{\phi}(\omega/2), \tag{1.2}$$

where

$$p(\omega) := \frac{1}{2} \sum_k h_k e^{-ik\omega}. \tag{1.3}$$

*Received by the editors March 20, 1991; accepted for publication (in revised form) November 14, 1991.

†Helsinki University of Technology, Institute of Mathematics, SF-02150 Espoo, Finland (E-mail: timo.eirola@hut.fi).

Instead of (1.1) we will mainly study (1.2), which is somewhat simpler in form and has in any case a meaning since $p(0) = 1$ and p is smooth.

In iterative interpolation equation (1.2) (and (1.1)) comes from the following process (see [5], [6]).

Let initial data $u_0 \in l^2$ be given and $h = 1$. Take an interpolation scheme P which produces new values in the middle points by linear combinations:

$$(1.4) \qquad Pu\left(\left(j+\frac{1}{2}\right)h\right) = \sum_k \beta_k u((j-k)h).$$

In pure interpolation P leaves the old values $u(jh)$ unchanged, but we may consider a more general operator that also replaces the old values of u by another set of linear combinations:

$$(1.5) \qquad Pu(jh) = \sum_k \alpha_k u((j-k)h).$$

Thus P maps $l^2_h \to l^2_{h/2}$, where

$$l^2_h = \left\{ u : h\mathbf{Z} \to \mathbf{R} \mid \|u\|^2_h := h\sum_j |u(jh)|^2 < \infty \right\},$$

interpolating new values in the middle of the intervals according to (1.4) and replacing the old values by the linear combinations (1.5). Now $Pu_0 \in l^2_{1/2}$, and we may apply P again with $h = \frac{1}{2}$, i.e., consider $P^2u_0 \in l^2_{1/4}$. Repeating this gives $P^n u_0 \in l^2_{1/2^n}$—a function defined at points of the form $j/2^n$. The question is: what is $\lim_{n\to\infty} P^n u_0$? Since this is a linear process we may assume that $u_0(0) = 1$ and $u_0(j) = 0$ for $j \neq 0$ and get the general case by linear combinations of the translates of this initial data.

For $u \in l^2_h$ we use the cardinal series interpolation (see [10]) C_h to think of u as a (C^∞) function on $\mathbf{R}$:

$$C_h u(x) = \sum_j u(jh)H(x/h - j), \quad \text{where } H(x) := \frac{\sin(\pi x)}{\pi x}.$$

Since $\{H(\cdot - j)\}_{j\in\mathbf{Z}}$ is an orthonormal family, C_h is an isometry $l^2_h \to L^2(\mathbf{R})$. Set $u_n := P^n u_0 \in l^2_{2^{-n}}$ and $\phi_n(x) := C_{2^{-n}} u_n(x)$. Then

$$\begin{aligned}\hat{\phi}_n(\omega) &= 2^{-n}\sum_j u_n(2^{-n}j)e^{-i\omega j/2^n}\hat{H}(2^{-n}\omega)\\ &= \tfrac{1}{2}\textstyle\sum_k \left[\alpha_k e^{-i2k\omega/2^n} + \beta_k e^{-i(2k+1)\omega/2^n}\right] 2^{1-n}\sum_j u_{n-1}(2^{1-n}j)e^{-i\omega j/2^{n-1}}\hat{H}(\frac{\omega}{2^n})\end{aligned}$$

by using (1.4) and (1.5). By induction, this gives

$$(1.6) \qquad \hat{\phi}_n(\omega) = \hat{H}(2^{-n}\omega)\prod_{j=1}^{n} p(2^{-j}\omega),$$

where

$$(1.7) \qquad p(\omega) := \frac{1}{2}\sum_k \left[\alpha_k e^{-i2k\omega} + \beta_k e^{-i(2k+1)\omega}\right],$$

i.e., (1.3) with $h_{2k} = \alpha_k$ and $h_{2k+1} = \beta_k$. From (1.6) we get

$$\hat{\phi}_{n+1}(\omega) = p(\omega/2)\hat{\phi}_n(\omega/2).$$

Thus assuming $\{\hat{\phi}_n\}_{n\in\mathbf{N}}$ converges suitably, the limit will satisfy (1.2) and consequently (1.1). The limit of the process for general u_0 is then

$$\sum_j u_0(j)\phi(x-j).$$

These interpolation processes are used in computer graphics for generating curves and surfaces from discrete data [1], [2], [5], [6]. It also appears in the analysis of the Picard–Lindelöf iteration (waveform relaxation) for numerical solution of large systems of ordinary differential equations (see [9]). There interest lies in the $\mathcal{H}^s$-stability of the process.

Another instance where (1.1) arises is multiresolution analysis (see [3], [8]). Roughly speaking, there we look for a function ϕ such that

$$V_\phi^0 \subset V_\phi^1 := \{\, f(2\,\cdot) \mid f \in V_\phi^0\},$$

where V_ϕ^0 is the subspace (in $L^2(\mathbf{R})$, say) spanned by the translates $\{\phi(\cdot - k)\}_{k\in\mathbf{Z}}$. Then there exist h_k's such that (1.1) holds. It is a beautiful theory that such ϕ's exist, and there are conditions on h_k's which ensure that the base $\{\phi(\cdot - k)\}_{k\in\mathbf{Z}}$ is orthonormal [3], [8]. Then the functions $\psi(\cdot - k)$, where

$$\psi(x) = \sum_k (-1)^k h_{1-k}\phi(2x-k)$$

form an orthonormal basis for the orthogonal complement of V_ϕ^0 in V_ϕ^1. This ψ is called an orthonormal wavelet.

Remark. Numerical computation of the solution of (1.1) is easy (see [4]). We can apply the iteration ϕ_{n+1} = r.h.s. of (1.1) with ϕ_n, starting from an initial function with compact support, e.g., the characteristic function of an interval. If (1.1) has a continuous solution, a more economical way is to first find the values of ϕ at the integer points (of the compact support)—this is a system of linear equations after fixing one of them. Then we simply use (1.1) to get the values of ϕ at points $j + \frac{1}{2}$, after that at points $\frac{j}{2} + \frac{1}{4}$, etc. This way we directly get final values of ϕ.

In §2 we prove an abstract result that gives $s_\phi = \sup\{\, s \mid \phi \in \mathcal{H}^s\}$ as a function of the spectral radius of a finite dimensional positive operator associated to p of (1.3). The results about this operator that will be needed are proved in §3. There we also give explicit bounds for s_ϕ in terms of a couple of pointwise values of p. In §4 and 5 these tools will be applied to the symmetric iterative interpolation and to the orthormal wavelets of Daubechies [3], respectively. Both of these applications improve the known results.

The main point to the favor of the technique proposed here is that it connects the smoothness of ϕ to the spectral radius of a positive matrix, while the approach of [4] connects it to the joint spectral radius of a pair of matrices which is more difficult to estimate.

2. An abstract result for $\phi \in \mathcal{H}^s$. In this section we prove a result that allows us to compute $\sup\{\, s \mid \phi \in \mathcal{H}^s\}$ from the spectral radius of a positive operator (eventually a matrix).

Let us study the existence and smoothness of the solution of (1.1) by first taking $\phi_0(x) = H(x) := \sin \pi x/\pi x$, then iterating

$$\phi_{n+1}(x) = \sum_k h_k \phi_n(2x - k) \tag{2.1}$$

and examining in which $\mathcal{H}^s$ the sequence $\{\phi_n\}$ converges (note that $\phi_n \in \mathcal{H}^s$ for every $s \geq 0$). From (2.1) we get

$$\hat{\phi}_{n+1}(\omega) = p(\omega/2)\hat{\phi}_n(\omega/2)$$

(see (1.3)), and consequently,

$$\hat{\phi}_n(\omega) = \hat{H}(2^{-n}\omega) \prod_{j=1}^{n} p(2^{-j}\omega). \tag{2.2}$$

Remark. Comparing (1.6) and (2.2) shows that we can define the same iteration either locally on discrete data by (1.4), (1.5) or globally on continuous data by (2.1).

We will study the two terms of the right-hand side of

$$\|\phi\|_s^2 \leq C\left(\left\|\hat{\phi}\right\|_{L^2}^2 + \int_{\mathbf{R}} \left|\hat{\phi}(\omega)\right|^2 |\omega|^{2s} \mathrm{d}\omega\right) \tag{2.3}$$

separately. Fix $s \geq 0$ and put $e_n(\omega) := \left|\hat{\phi}_n(\omega) - \hat{\phi}_{n-1}(\omega)\right|^2 |\omega|^{2s}$. We want to see for how large values of s the estimate $\int_{\mathbf{R}} e_n(\omega)\mathrm{d}\omega \leq C\theta^n$ holds with some $\theta < 1$. We have $e_n(-\omega) = e_n(\omega)$ and

$$e_{n+1}(\omega) = \left|p\left(\frac{\omega}{2}\right)\right|^2 \left|\hat{\phi}_n\left(\frac{\omega}{2}\right) - \hat{\phi}_{n-1}\left(\frac{\omega}{2}\right)\right| |\omega|^{2s} = q\left(\frac{\omega}{2}\right) e_n\left(\frac{\omega}{2}\right),$$

where $q(t) := 4^s |p(t)|^2$. Since $\hat{H}(\omega) = 0$ for $|\omega| > \pi$, we have

$$\int_{-\infty}^{\infty} e_n(\omega)\mathrm{d}\omega = \int_{|\omega| \leq 2^n\pi} e_n(\omega)\mathrm{d}\omega.$$

We will study the convergence of these integrals through the operator T_q:

$$T_q u(t) := q\left(\frac{t}{2}\right) u\left(\frac{t}{2}\right) + q\left(\pi - \frac{t}{2}\right) u\left(\pi - \frac{t}{2}\right) \tag{2.4}$$

in the following way.

LEMMA 2.1. *Let $\{e_n\}$ satisfy*

$$\text{(a)} \quad e_n(-\omega) = e_n(\omega),$$

$$\text{(b)} \quad e_{n+1}(\omega) = q\left(\frac{\omega}{2}\right) e_n\left(\frac{\omega}{2}\right),$$

where q is even and 2π-periodic. Then

$$I_n := \int_{|\omega| \leq 2^n\pi} e_n(\omega)\mathrm{d}\omega = \int_0^{\pi} \kappa_n(t)\mathrm{d}t, \tag{2.5}$$

where $\kappa_1(t) = 2[e_1(t) + e_1(t-2\pi)]$ *and* $\kappa_{n+1} = T_q\kappa_n$.

Proof. From (a) the claim is trivial for $n = 1$. Assume that the lemma holds for n. Then

$$I_{n+1} = \int_{|\omega|\le 2^{n+1}\pi} e_{n+1}(\omega)\mathrm{d}\omega = \int_{|\omega|\le 2^n\pi} [e_{n+1}(\omega - 2^n\pi) + e_{n+1}(\omega + 2^n\pi)]\mathrm{d}\omega.$$

Call the last integrand $\tilde{e}_n(\omega)$. It satisfies (a) and (b) so that applying the lemma with n to $\tilde{e}_n$ gives $I_{n+1} = \int_0^\pi \tilde{\kappa}_n(t)\mathrm{d}t$, where

$$\begin{aligned}\tilde{\kappa}_1(t) &= 2[e_2(t-2\pi) + e_2(t+2\pi) + e_2(t-4\pi) + e_2(t)]\\ &= 2\left[q\left(\frac{t}{2}-\pi\right)\left[e_1\left(\pi-\frac{t}{2}\right) + e_1\left(-\pi-\frac{t}{2}\right)\right]\right.\\ &\qquad \left. + q\left(\frac{t}{2}\right)\left[e_1\left(\frac{t}{2}-2\pi\right) + e_1\left(\frac{t}{2}\right)\right]\right]\\ &= q\left(\frac{t}{2}\right)\kappa_1\left(\frac{t}{2}\right) + q\left(\pi-\frac{t}{2}\right)\kappa_1\left(\pi-\frac{t}{2}\right) = T_q\kappa_1(t),\end{aligned} \tag{2.6}$$

i.e., $I_{n+1} = \int_0^\pi T_q^{n-1}\tilde{\kappa}_1(t)\mathrm{d}t = \int_0^\pi T_q^n\kappa_1(t)\mathrm{d}t$. □

The key idea in studying the integrals $\int_{\mathbf{R}} e_n(\omega)\mathrm{d}\omega$ in terms of $\int_0^\pi \kappa_n(t)\mathrm{d}t$ lies in the fact that the positive operator T_q has better properties (see the next section) than the one that maps e_n to e_{n+1}. The best property here is that if q is in C_d—the $d+1$-dimensional space spanned by $\{\cos(jt)\}_{j=0}^d$—then T_q maps $C_d \to C_d$. Thus we end up with studying the Frobenius–Perron eigenvalue of a positive operator in a finite-dimensional space.

In the next section we will prove (Theorem 3.4 and Proposition 3.5) the following. Assume

(2.7)
(1) $q(t) = 4^s(2 + 2\cos(t))^\nu r(t)$ with r positive on $[0,\pi]$.
(2) u_0 is nonnegative and not identically zero on $[0,\pi]$ with $u_0 = O(t^{2\tilde{\nu}})$ for small $|t|$ for some $\tilde{\nu} \le \nu$.

Set $u_n := T_q^n u_0$. Then for any $\varepsilon > 0$ there exist $C, c > 0$ such that

$$c(4^s\mu - \varepsilon)^n \le \int_0^\pi u_n(t)\mathrm{d}t \le C(4^{\nu-\tilde{\nu}+s}\mu + \varepsilon)^n,$$

where μ is the spectral radius of T_r.

We apply this to the I_n's twice: for $s = 0$ and $s > 0$, corresponding to the two terms of (2.3). Naturally, we want $4^{\nu-\tilde{\nu}+s}\mu < 1$.

Since $\hat{H} = (1/\sqrt{2\pi})\chi_{[-\pi,\pi]}$ we find for $t \in [0,\pi]$,

$$\kappa_1(t) = 2[e_1(t) + e_1(t-2\pi)] = \tfrac{1}{\pi}\left[|p(\tfrac{t}{2}) - 1|^2\,|t|^{2s} + |p(\tfrac{t}{2}-\pi)|^2\,|t-2\pi|^{2s}\right].$$

Rewriting the assumptions (2.7) in terms of p we get the lower bound for the following.

THEOREM 2.2. *Assume $p(t) \ne 0$ for $t \ne \pi$. Let ν_0, ν_1 be the greatest numbers such that for $t \to 0$,*

$$p(t) = 1 + O(t^{\nu_0}), \qquad p(\pi - t) = O(t^{\nu_1}),$$

where

$$p(t) := \frac{1}{2}\sum_k h_k e^{-ikt}.$$

Let μ be the greatest eigenvalue of the positive operator T_r in $C[0,\pi]$:

$$T_r u(t) = r\left(\frac{t}{2}\right) u\left(\frac{t}{2}\right) + r\left(\pi - \frac{t}{2}\right) u\left(\pi - \frac{t}{2}\right),$$

where

$$r(t) = \frac{|p(t)|^2}{(2+2\cos(t))^{\nu_1}}.$$

If $\mu < 4^{\nu_0 - \nu_1}$, then ϕ—the (normalized) solution of the dilation equation (1.1)—satisfies

$$s_\phi := \sup\{\, s \mid \phi \in \mathcal{H}^s\} = \frac{-\log(\mu)}{\log(4)}.$$

Proof. To show the upper bound $s_\phi \le -\log(\mu)/\log(4)$, assume $\phi \ne 0$—a solution of (1.1)—is in $\mathcal{H}^s$. We have

$$\infty > \int_{-\infty}^{\infty} \left|\hat{\phi}(\omega)\right|^2 |\omega|^{2s}\, \mathrm{d}\omega \ge \int_{|\omega|\le 2^n\pi} \left|\hat{\phi}(\omega)\right|^2 |\omega|^{2s}\, \mathrm{d}\omega.$$

Denote the last integrand by $f_n(\omega)$ (independent of n). We are now in the situation of Lemma 2.1: since (1.1) implies $\hat{\phi}(\omega) = p(\omega/2)\hat{\phi}(\omega/2)$ giving further

$$f_{n+1}(\omega) = \left|p\left(\frac{\omega}{2}\right)\right|^2 \left|\hat{\phi}\left(\frac{\omega}{2}\right)\right|^2 |\omega|^{2s} = q\left(\frac{\omega}{2}\right) f_n\left(\frac{\omega}{2}\right).$$

Thus

$$\int_{|\omega|\le 2^n\pi} f_n(\omega)\mathrm{d}\omega = \int_0^{\pi} T^{n-1}\tilde{\kappa}(t)\mathrm{d}t,$$

where

$$\tilde{\kappa}(t) = 2\left[\left|\hat{\phi}(t)\right|^2 |t|^{2s} + \left|\hat{\phi}(t-2\pi)\right|^2 |t-2\pi|^{2s}\right].$$

By Proposition 3.5,

$$\int_{|\omega|\le 2^n\pi} f_n(\omega)\mathrm{d}\omega \ge c(4^s\mu - \varepsilon)^n.$$

Thus $4^s\mu \le 1$. □

Remark. Any question about weakening the assumptions of this theorem is directly forwarded to §3—can we prove something similar about T_r with weaker properties of r? The same is true if we look for $\mathcal{H}_1^s$-convergence. Also, then we come to similar situations with weaker r. Only in the case when p is already a square (a nonnegative polynomial of $\cos(t)$) can we study the $\mathcal{H}_1^s$-convergence directly by these methods (see §4). On the other hand, generalizations to other two-scale equations of type (1.1) (i.e., 2 replaced by a bigger integer) seem reachable by these techniques.

3. Some properties of T_r. Recall the definition of $T_r : C[0,\pi] \to C[0,\pi]$

$$T_r u(t) = r\left(\frac{t}{2}\right) u\left(\frac{t}{2}\right) + r\left(\pi - \frac{t}{2}\right) u\left(\pi - \frac{t}{2}\right). \tag{3.1}$$

First we prove the main convergence result of iterations with T_r when r is a positive polynomial of $\cos(t)$. Then some results for perturbed r are given. Finally, tools for getting upper and lower bounds for the spectral radius of T_r are derived. We will often write T in place of T_r.

Most of the tools used for the next result are standard in the literature on positive operators, but a suitable theorem for the present purpose was not found.

THEOREM 3.1. *Let r be a d-degree polynomial of $\cos(t)$ positive on $[0,\pi]$. Then for any nonnegative nonzero $u_0 \in C^1[0,\pi]$, the sequence $\{T_r^n u_0/\,\|T_r^n u_0\|\}$ converges to the unique positive norm-1 eigenvector of T_r. This eigenvector is a d-degree polynomial of $\cos(t)$ and corresponds to the greatest eigenvalue, which is equal to the spectral radius of T_r.*

Proof. We show first the existence of a positive eigenvector. Let C_d be the $(d+1)$-dimensional space spanned by $\{\cos(jt)\}_{j=0}^{d}$. If

$$r(t) = \sum_{j=0}^{d} \rho_j \cos(jt), \qquad u(t) = \sum_{j=0}^{d} u_j \cos(jt),$$

then

$$\begin{aligned} Tu(2t) &= \sum_{j,k=0}^{d} \rho_j u_k \left[\cos(jt)\cos(kt) + \cos(j(\pi-t))\cos(k(\pi-t))\right] \\ &= \sum_{\substack{j,k=0 \\ j+k=\text{even}}}^{d} \rho_j u_k \left[\cos((j+k)t) + \cos((j-k)t)\right], \end{aligned}$$

i.e., T maps C_d into itself. Let K, respectively, K^o be the cone of nonnegative, respectively, positive functions in $C[0,\pi]$ and K_d, K_d^o their intersections with C_d. All of these are T-invariant.

LEMMA 3.2. *If $0 \neq u \in K$, then there exists $n > 0$ such that $T^n u \in K^o$.*

Proof. u is positive at some point $t = j\pi/2^m$, $0 \leq j \leq 2^m$.

If $j < 2^{m-1}$, then Tu is positive at $j\pi/2^{m-1}$.

If $j \geq 2^{m-1}$, then Tu is positive at $(2 - j/2^{m-1})\pi$.

In either case Tu is positive at some $j\pi/2^{m-1}$. Iterating this gives that $T^m u$ is positive at zero or π. Thus $T^{m+1}u$ is positive at zero. It is also positive on some interval $[0, 2^{-m'}]$. Then $T^{m'}T^{m+1}u$ is positive on $[0,\pi]$. □

Using compactness gives further in C_d that there exists an M such that $T^M K_d \subset K_d^o$. Now the standard theory of positive operators in finite dimensions states that there exists a unique positive norm-1 eigenvector $\tilde{u}$ of T in C_d. Denote by μ the corresponding eigenvalue.

Return now to $C[0,\pi]$ and take $0 \neq u_0 \in K \cap C^1[0,\pi]$. Take n_0 such that $T^{n_0}u_0 \in K^o$. Since K is normal, a theorem of Stetsenko [7, Thm. 9.1] states that

$$\lim_{n\to\infty} \|T^n(T^{n_0}u_0)\|^{1/n} = \rho_T,$$

where ρ_T is the spectral radius of T. Since u_0 might as well have been equal to $\tilde{u}$ we have $\rho_T = \mu$. Take the sequence $\{v_n\} = \{T^n u_0/\,\|T^n u_0\|\}$. We know that $v_n \in K^o$ for $n \geq n_0$ and $\lim_{n\to\infty} \|Tv_n\| = \mu$. Set

$$\beta_n = \frac{\min_t v_n(t)/\tilde{u}(t)}{\max_\tau v_n(\tau)/\tilde{u}(\tau)}.$$

Then

$$\begin{aligned}\beta_{n+1} &= \frac{\min_t \left[r(\tfrac{t}{2})v_n(\tfrac{t}{2}) + r(\pi - \tfrac{t}{2})v_n(\pi - \tfrac{t}{2})\right]/\tilde{u}(t)}{\max_\tau \left[r(\tfrac{\tau}{2})v_n(\tfrac{\tau}{2}) + r(\pi - \tfrac{\tau}{2})v_n(\pi - \tfrac{\tau}{2})\right]/\tilde{u}(\tau)}\\ &\geq \frac{\min_t v_n(t)/\tilde{u}(t)\min_t T\tilde{u}(t)/\tilde{u}(t)}{\max_\tau v_n(\tau)/\tilde{u}(\tau)\max_\tau T\tilde{u}(\tau)/\tilde{u}(\tau)} = \beta_n.\end{aligned}$$

Thus $\{\beta_n\}$ is nondecreasing, and for $n \geq n_0$,

$$\frac{\min_t v_n(t)}{\max_\tau v_n(\tau)} \geq \beta_n \frac{\min_t \tilde{u}(t)}{\max_\tau \tilde{u}(\tau)} \geq c > 0.$$

LEMMA 3.3. *The sequence $\{v_n\}$ is bounded in $C^1[0,\pi]$.*

Proof. Set $R = \max_t |\dot{r}(t)/r(t)|$ and $a = \min_t(r(t)/r(\pi - t))$. For $n \geq n_0$,

$$\begin{aligned}\left\|\frac{\dot{v}_{n+1}}{v_{n+1}}\right\| &= \frac{1}{2}\max_t \left|\frac{\dot{r}(\tfrac{t}{2})v_n(\tfrac{t}{2}) - \dot{r}(\pi - \tfrac{t}{2})v_n(\pi - \tfrac{t}{2})}{r(\tfrac{t}{2})v_n(\tfrac{t}{2}) + r(\pi - \tfrac{t}{2})v_n(\pi - \tfrac{t}{2})}\right.\\ &\qquad\left. + \frac{r(\tfrac{t}{2})\dot{v}_n(\tfrac{t}{2}) - r(\pi - \tfrac{t}{2})\dot{v}_n(\pi - \tfrac{t}{2})}{r(\tfrac{t}{2})v_n(\tfrac{t}{2}) + r(\pi - \tfrac{t}{2})v_n(\pi - \tfrac{t}{2})}\right|\\ &\leq R + \frac{1}{1+ac}\left\|\frac{\dot{v}_n}{v_n}\right\|.\end{aligned}$$

Thus $\|\dot{v}_n/v_n\|$ and consequently $\|\dot{v}_n\|$ is bounded. □

By Lemma 3.3 there exists a convergent subsequence $\{v_{n_j}\} \to v \in K^o$ (with increasing n_j's). Write $w \succeq u$ if $w - u \in K$. Define for $u \in K^o$,

$$\varphi(u) = \max\{\lambda \mid Tu \succeq \lambda u\}. \tag{3.2}$$

φ is clearly continuous in K^o and $\varphi(Tu) \geq \varphi(u)$. We have $\varphi(u) \leq \mu$ since assuming the contrary, $u, \varepsilon > 0$ such that $Tu \succeq (\mu + \varepsilon)u$ gives

$$T^n u \succeq (\mu + \varepsilon)T^{n-1}u \succeq (\mu + \varepsilon)^n u,$$

implying $\rho_T > \mu$. Similarly,

$$u \in K^o,\ n \geq 0 \quad \Rightarrow \quad T^n u - \mu^n u \notin K^o. \tag{3.3}$$

Assume now that $Tv \neq \varphi(v)v$. Then there exists an m such that $T^m(Tv - \varphi(v)v) \in K^o$, i.e., $\varphi(T^m v) > \varphi(v)$. On the other hand,

$$\varphi(T^m v) = \lim_j \varphi(T^m v_{n_j}) \leq \lim_j \varphi(v_{n_{j+m}}) = \varphi(v).$$

Thus $Tv = \varphi(v)v$ and $\varphi(v) = \mu$.

If $v \neq \tilde{u}$, then either

(1) $v - \tilde{u} \in K \cup (-K)$ or

(2) for $w(t) := \max(\tilde{u}(t), v(t))$ holds $w \neq \tilde{u}$ and $w \neq v$.

In case (1), assume, e.g., $v - \tilde{u} \in K$. Since $\tilde{u}(t') = 1$ for some t' and

$$\mu^m(v - \tilde{u})(t') = T^m(v - \tilde{u})(t') > 0$$

for m big enough we have $v(t') > 1$, a contradiction.

In case (2), there exist m and $\varepsilon > 0$ such that

$$T^m(w - v) \succeq \varepsilon w \quad \text{and} \quad T^m(w - \tilde{u}) \succeq \varepsilon w,$$

i.e., $T^m w \succeq (\mu^m + \varepsilon)w$, a contradiction to (3.3). Thus $v = \tilde{u}$. It follows that $\tilde{u}$ is the only limit point of $\{v_n\}$. By compactness (Lemma 3.3), $\{v_n\} \to \tilde{u}$. This ends the proof of Theorem 3.1. □

Next we turn to the case where we have a zero at π:

$$r_\nu(t) = (2 + 2\cos(t))^\nu r(t).$$

THEOREM 3.4. *Let r be as in Theorem 3.1 and r_ν as above with $\nu \geq 0$. If $0 \neq u_0 \in C^1[0,\pi]$ is nonnegative and satisfies $u_0(t) = O(t^{2\nu})$, then the sequence $\{T^n_{r_\nu}u_0 / \|T^n_{r_\nu}u_0\|\}$ converges to*

$$\tilde{u}^\nu(t) = c(1 - \cos(t))^\nu \tilde{u}(t),$$

where $\tilde{u}$ is the positive eigenvector of T_r and c is such that $\|\tilde{u}^\nu\| = 1$. Moreover, $T^{n+1}_{r_\nu}u_0(t)/T^n_{r_\nu}u_0(t) \to \mu$ uniformly.

Proof. Set $u_n = T^n_{r_\nu}u_0$ and $v_n(t) := (1 - \cos(t))^{-\nu}u_n(t)$. Then $v_0 \in C^1[0,\pi]$ and

$$\begin{aligned} v_{n+1}(t) &= (1 - \cos(t))^{-\nu}\left[r_\nu\left(\frac{t}{2}\right)u_n\left(\frac{t}{2}\right) + r_\nu\left(\pi - \frac{t}{2}\right)u_n\left(\pi - \frac{t}{2}\right)\right] \\ &= \left[\frac{2(1 + \cos(t/2))(1 - \cos(t/2))}{(1 - \cos(t))}\right]^\nu \left[r\left(\frac{t}{2}\right)v_n\left(\frac{t}{2}\right) + r\left(\pi - \frac{t}{2}\right)v_n\left(\pi - \frac{t}{2}\right)\right], \end{aligned}$$

i.e., $v_{n+1} = T_r v_n$. Apply Theorem 3.1. □

For the case where u_0 does not allow full division by $(1 - \cos(t))^\nu$, the following will suffice for our present needs.

PROPOSITION 3.5. *Let $0 \neq u_0 \succeq 0$, $u_n = T^n_{r_\nu}u_0$ and μ , $\tilde{u}$ as before but $u_0(t) = O(t^{2\nu_0})$ with $\gamma := \nu - \nu_0 \geq 0$. Then for given $\varepsilon > 0$ there exist $C, c > 0$ such that*

$$c(\mu - \varepsilon)^n \leq \int_0^\pi u_n(t)\mathrm{d}t \leq C(4^\gamma\mu + \varepsilon)^n.$$

Proof. For the lower bound, take $v_0 \neq 0$ such that $u_0 \succeq v_0 \succeq 0$, and $v(t) = O(t^{2\nu})$. Then $T^n_{r_\nu}(u_0 - v_0) \succeq 0$. For given $\varepsilon > 0$ take (Theorem 3.4) n_0 such that for $n \geq n_0$ holds

$$\left|\frac{T^{n+1}_{r_\nu}v_0(t)}{T^n_{r_\nu}v_0(t)} - \mu\right| < \varepsilon$$

and $c > 0$ such that the last inequality below holds for $n \leq n_0$. Then

$$\int_0^\pi u_n(t)\mathrm{d}t \geq \int_0^\pi T^n_{r_\nu}v_0(t)\mathrm{d}t \geq c(\mu - \varepsilon)^n.$$

For the upper bound set $v_0(t) := (1 - \cos(t))^{-\nu_0}u_0(t)$ and $\hat{r} := 4^\gamma r$. Then $\hat{r} \succeq r_\gamma$ and $T_{\hat{r}}v \succeq T_{r_\gamma}v$ for every $v \succeq 0$. Thus, inductively, $T_{\hat{r}}v_0 \succeq T_{r_\gamma}v_0$, $T_{\hat{r}}(T^n_{\hat{r}}v_0) \succeq T_{\hat{r}}(T^n_{r_\gamma}v_0) \succeq T^{n+1}_{r_\gamma}v_0$, and

$$\begin{aligned} \int_0^\pi u_n(t)\mathrm{d}t &= \int_0^\pi T^n_{r_\nu}u_0(t)\mathrm{d}t = \int_0^\pi (1 - \cos(t))^{\nu_0}T^n_{r_\gamma}v_0(t)\mathrm{d}t \\ &\leq 2^{\nu_0}4^{n\gamma}\int_0^\pi T^n_r v_0(t)\mathrm{d}t \leq C(4^\gamma\mu + \varepsilon)^n. \end{aligned}$$

□

Remark. Thus far the results of this section have used the condition that r is a polynomial of $\cos(t)$ only for proving the existence of a positive eigenvector. If this is known by some other means, then any positive $r \in C^1[0,\pi]$ will do. Then, naturally, $\tilde{u}$ is not a polynomial of $\cos(t)$.

Now we make more heavy use of the fact that r is a polynomial of $\cos(t)$and turn to estimate μ. For $\theta \in [0,\pi]$, set $\eta_\theta \in K'$ (the dual cone of K): $\langle \eta_\theta, u\rangle := u(\theta)$. Then

$$T'\eta_\theta = r\left(\frac{\theta}{2}\right)\eta_{\frac{\theta}{2}} + r\left(\pi - \frac{\theta}{2}\right)\eta_{\pi-\frac{\theta}{2}}. \tag{3.4}$$

In C_d we have a better cone than K_d, namely:

$$K^d := \left\{ u \in C_d \mid u(t) = \sum_{j=0}^{d} u_j(1+\cos(t))^j(1-\cos(t))^{d-j},\ u_j \geq 0 \right\}.$$

This is smaller than K_d since $0 \neq u \in K^d$ implies $u(t) > 0$ for $t \in (0,\pi)$. It follows that the η_θ's with $\theta \in (0,\pi)$ are interior points of $(K^d)'$. We also have

$$\begin{aligned} &\text{(a)} \quad u \in K^n,\ v \in K^m \ \Rightarrow\ uv \in K^{n+m},\\ &\text{(b)} \quad n \leq m \ \Rightarrow\ K^n \subset K^m \ \text{ and } \ K^n + K^m \subset K^m. \end{aligned}$$

Property (a) is simple. From $\frac{1}{2}(1-x) + \frac{1}{2}(1+x) = 1$ we get $1 \in K^1$. Then the repeated use of (a) gives $1 \in K^n$ for all $n \geq 0$. Given $u \in K^n$, take $1 \in K^{m-n}$ and use (a) to show (b).

Naturally we also need the following.

LEMMA 3.6. *If $r \in K^d$, then $TK^d \subset K^d$.*

Proof. Set $y := \cos(t/2)$, $x := \cos(t) = 2y^2 - 1$, and let $r, u \in K^d$: $r(t) = \sum_{j=0}^{d} r_j(1+x)^j(1-x)^{d-j}$, $u(t) = \sum_{j=0}^{d} u_j(1+x)^j(1-x)^{d-j}$. Then

$$Tu(t) = \sum_{i,j=0}^{d} r_i u_j[(1+y)^{i+j}(1-y)^{2d-i-j} + (1+y)^{2d-i-j}(1-y)^{i+j}], \tag{3.5}$$

and the lemma follows after noting that for $k \leq d$,

$$\begin{aligned} &(1+y)^k(1-y)^{2d-k} + (1+y)^{2d-k}(1-y)^k \\ &\quad = (1-y^2)^k[(1+y)^{2(d-k)} + (1-y)^{2(d-k)}] \\ &\quad = \left(\tfrac{1+x}{2}\right)^k 2\textstyle\sum_{l=0}^{d-k}\binom{2d-2k}{2l}\left(\tfrac{1-x}{2}\right)^l \in K^d. \end{aligned}$$ □

From the previous proof we also see that $\tilde{u}$ is an interior point of K^d because $\tilde{u}(0)r(0) > 0 \Rightarrow \tilde{u}_0 r_0 > 0$, and the first term of (3.5) for $\tilde{u}$ gives $\tilde{u}_0 r_0 2\sum_{l=0}^{d}\binom{2d}{2l}((1-x)/2)^l$, thus introducing a positive coefficient (after multiplication with $1 \in K^{d-l}$) for each $(1-x)^{d-l}(1+x)^l$. Thus $0 \neq w \in (K^d)'$ implies $\langle w, \tilde{u}\rangle > 0$.

We base the estimates for μ on the following.

LEMMA 3.7. *If $r \in K^d$ and $0 \neq w \in (K^d)', \lambda \in \mathbf{R}$, then*

$$\begin{aligned} &\text{(a)} \quad T'w - \lambda w \in (K^d)' \ \Rightarrow\ \mu \geq \lambda,\\ &\text{(b)} \quad \lambda w - T'w \in (K^d)' \ \Rightarrow\ \mu \leq \lambda. \end{aligned}$$

Proof. (a) $0 \leq \langle T'w - \lambda w, \tilde{u}\rangle = (\mu - \lambda)\langle w, \tilde{u}\rangle$ and $\langle w, \tilde{u}\rangle > 0$. (b) is similar. □

From (3.4) we get

$$T'\eta_{2\pi/3} = r\left(\frac{2\pi}{3}\right)\eta_{2\pi/3} + r\left(\frac{\pi}{3}\right)\eta_{\pi/3}.$$

In the applications of this paper we have $r(2\pi/3) >> r(\pi/3)$ which suggests that $\eta_{2\pi/3}$ is close to the positive eigenvector of T'. Now Lemma 3.7 gives immediately $\mu \geq r(2\pi/3)$.

Note that for $u \in K^d$ and $t \in (0, \pi/2)$ we have:

$$\begin{aligned} u(t) &\leq \sum_{j=0}^{d} u_j \left(\frac{1+\cos(t)}{1+\cos(2t)}\right)^j (1+\cos(2t))^j (1-\cos(2t))^{d-j} \\ &\leq \left(\frac{1+\cos(t)}{1+\cos(2t)}\right)^d u(2t), \end{aligned} \tag{3.6}$$

and similarly $u(\pi - t) \leq ((1+\cos(t))/(1+\cos(2t)))^d u(\pi - 2t)$,

To obtain an upper bound for μ, set $w = \eta_{2\pi/3} + \alpha\eta_{\pi/3}$. Then

$$\lambda w - Tw = (\lambda - r(2\pi/3))\eta_{2\pi/3} + (\alpha\lambda - r(\pi/3))\eta_{\pi/3} - \alpha\left[r(\pi/6)\eta_{\pi/6} + r(5\pi/6)\eta_{5\pi/6}\right].$$

From (3.6) we get for any $u \in K^d$: $u(\pi/6) \leq su(\pi/3)$ and $u(5\pi/6) \leq su(2\pi/3)$, where $s = \left((2+\sqrt{3})/3\right)^d$. Thus $\lambda w - T'w \in (K^d)'$ if

$$\begin{aligned} \lambda - r\left(\frac{2\pi}{3}\right) - \alpha\ s\ r\left(\frac{5\pi}{6}\right) &=0, \\ \alpha\ \lambda - r\left(\frac{\pi}{3}\right) - \alpha\ s\ r\left(\frac{\pi}{6}\right) &=0. \end{aligned}$$

Solving these gives the following.

THEOREM 3.8. *If* $r \in K^d$ *satisfies* $r(2\pi/3) > \left((2+\sqrt{3})/3\right)^d r(\pi/6)$, *then*

$$r\left(\frac{2\pi}{3}\right) \leq \mu \leq r\left(\frac{2\pi}{3}\right)\left(1 + \frac{r(\pi/3)r(5\pi/6)}{\left(3/(2+\sqrt{3})\right)^d r(2\pi/3)^2 - r(\pi/6)r(2\pi/3)}\right).$$

4. Iterative interpolation.

Here we apply the results of §§2 and 3 to the repeated interpolation scheme (1.4) $P : l_h^2 \to l_{h/2}^2$ in the case where P is "identity on the old grid":

$$\begin{aligned} Pu(jh) &= u(jh), \\ Pu\left(\left(j+\frac{1}{2}\right)h\right) &= \sum_k \beta_k u((j-k)h). \end{aligned} \tag{4.1}$$

We restrict ourselves to odd $(2m-1)$-degree symmetric polynomial interpolation, i.e., with $\{\beta_k\}_{k=-m}^{m-1}$ such that if x is a $(2m-1)$-degree polynomial, then

$$\sum_{k=-m}^{m-1} \beta_k x(-k) = x\left(\frac{1}{2}\right). \tag{4.2}$$

The question here is: how smooth is $\lim_{n\to\infty} P^n u_0$? As noted in §1, we may take $u_0(k) = \delta_{0,k}$. From symmetry we get $\beta_{-k} = \beta_{k-1}$, and further from (1.7),

$$p(t) = \frac{1}{2}\left(1 + \sum_{j=0}^{m-1} \beta_j [e^{-it(2j+1)} + e^{it(2j+1)}]\right) = \frac{1}{2}\left(1 + \sum_{j=-m}^{m-1} \beta_j \cos((2j+1)t)\right).$$

The last sum is the interpolation of $\cos(\tau)$ at $\tau = 0$; thus it has to be $1 + O(t^{2m})$. Furthermore, repeated use of

$$\cos(nt) = 2\cos(t)\cos((n-1)t) - \cos((n-2)t)$$

gives

$$p(t) = \frac{1}{2}\left(1 + \cos(t)\sum_{j=0}^{m-1} \alpha_j \sin(t)^{2j}\right). \tag{4.2}$$

On the other hand, a standard integration formula gives

$$\cos(t)\sum_{j=0}^{m-1}(-1)^j\binom{-\frac{1}{2}}{j}\sin(t)^{2j} = 1 - 2c_m\int_0^t \sin(\tau)^{2m-1}\mathrm{d}\tau = 1 + O(t^{2m}), \tag{4.3}$$

where $c_m = 2^{1-2m}((2m-1)!/((m-1)!)^2)$. Since the polynomials of $\sin(t)$ multiplying $\cos(t)$ in (4.2) and (4.3) are of degree $2m-2$ and have $(2m-1)$-fold tangency at $t = 0$, they have to be equal. Hence

$$p(t) = 1 - c_m\int_0^t \sin(\tau)^{2m-1}\mathrm{d}\tau. \tag{4.4}$$

To apply the results of §2, it remains to divide the zero of p at π. Integration by parts yields

$$\begin{aligned} p(t) &= \frac{c_m}{m}(1+\cos(t))^m\sum_{j=0}^{m-1}\gamma_j^m(1+\cos(t))^j(1-\cos(t))^{m-1-j} \\ &= \left(\tfrac{1+\cos(t)}{2}\right)^m\textstyle\sum_{j=0}^{m-1}\binom{m-1+j}{j}\left(\tfrac{1-\cos(t)}{2}\right)^j, \end{aligned}$$

where $\gamma_j^m := \prod_{k=0}^{j}(m-k)/(m+k)$. Thus

$$\begin{aligned} r(t) &= (2+2\cos(t))^{-2m}\,|p(t)|^2 \\ &= 2^{-4m}\left(\textstyle\sum_{j=0}^{m-1}\binom{m-1+j}{j}\left(\tfrac{1-\cos(t)}{2}\right)^j\right)^2 \\ &= 2^{-2m}\frac{c_m^2}{m^2}\left[\textstyle\sum_{j=0}^{m-1}\gamma_j^m(1+\cos(t))^j(1-\cos(t))^{m-1-j}\right]^2 \\ &= 2^{-2m}\frac{c_m^2}{m^2}(1-\cos(t))^{2m-2}\left[\sum_{j=0}^{m-1}\gamma_j^m\left(\tfrac{1+\cos(t)}{1-\cos(t)}\right)^j\right]^2. \end{aligned} \tag{4.5}$$

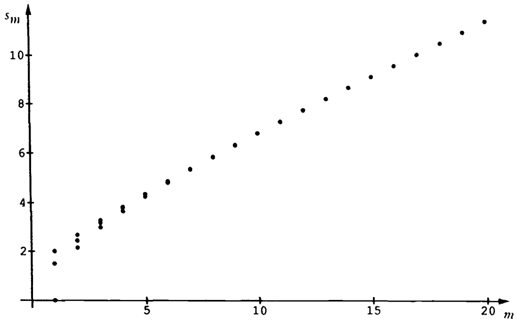

FIG. 1. *The Sobolev exponents s_m with the upper and lower bounds* (4.8).

We use the first form of (4.5) to estimate

$$r(t) \le (2+2\cos(t))^{-2m} \quad \text{for } t \in \left[0, \frac{\pi}{2}\right), \tag{4.6}$$

the third one to see that $r \in K^{2m-2}$, and the fourth to estimate for $t \in (\pi/2, \pi]$:

$$1 \le \frac{r(t)}{2^{-2m}\frac{c_m^2}{m^2}(1-\cos(t))^{2m-2}} \le \left(\frac{1-\cos(t)}{2\cos(t)}\right)^2. \tag{4.7}$$

The form of the second line of (4.5) will be used later in §5. Now $d = 2m-2$ and Theorems 2.1 and 3.8 give the following.

THEOREM 4.1. *For fixed $m \ge 1$ the iteration of $2m-1$-degree symmetric polynomial interpolation converges to a function ϕ_m for which $s_m := \sup\{s \mid \phi_m \in \mathcal{H}^s\} = -\log(\mu)/(2\log(2))$, where μ is the spectral radius of T_r in C_{2m-2}. Further, s_m satisfies* (4.8)

$$\frac{-\log\left(r(\frac{2\pi}{3})\left(1+\frac{r(\pi/3)r(5\pi/6)}{(3/(2+\sqrt{3}))^{2m-2}r(2\pi/3)^2-r(\pi/6)r(2\pi/3)}\right)\right)}{2\log(2)} \le s_m \le \frac{-\log(r(\frac{2\pi}{3}))}{2\log(2)},$$

and $r = r_m$ is given in (4.5).

To obtain asymptotics of s_m, note that $j > \sqrt{(j+1)(j-1)}$ gives

$$\frac{1}{2}\sqrt{m-\frac{1}{2}} \le c_m \le \frac{1}{\sqrt{2}}\sqrt{m-\frac{1}{2}},$$

and this together with (4.7) implies

$$\frac{1}{9}\frac{m-\frac{1}{2}}{m^2}\left(\frac{3}{4}\right)^{2m} \le r\left(\frac{2\pi}{3}\right) \le \frac{1}{2}\frac{m-\frac{1}{2}}{m^2}\left(\frac{3}{4}\right)^{2m}. \tag{4.9}$$

Furthermore, (4.6) and (4.7) give

$$\frac{r(\frac{\pi}{3})r(\frac{5\pi}{6})}{(3/(2+\sqrt{3}))^{2m-2}r(\frac{2\pi}{3})^2 - r(\frac{\pi}{6})r(\frac{2\pi}{3})} \le \frac{\frac{2m^2}{3(m-\frac{1}{2})}\left[4(7+4\sqrt{3})/81\right]^{2m-1}}{1-81m^2\left(\frac{2}{3}\right)^{4m}/((7+4\sqrt{3})(m-\frac{1}{2}))}$$

which tends to zero when $m \to \infty$; hence $\mu_m/(r_m(2\pi/3)) \to 1$. Thus, asymptotically,

$$s_m = \left(2 - \frac{\log(3)}{\log(2)}\right)m + O(\log(m)) \approx 0.415m.$$

For small values of m we can compute the eigenvalue of T_r directly giving, e.g., $s_1 = \frac{3}{2}$, $s_2 = \frac{9}{2} - (\log(5+3\sqrt{17})/2\log(2))$. For Fig. 1 we have computed the maximal eigenvalues of T_r numerically.

Cases $m = 2$ and $m = 3$ were considered also by Deslauriers and Dubuc [5]. They got $\phi_2 \in C^{2-\varepsilon}$ and $\phi_3 \in C^{2.830}$. The case where $m = 2$ is also treated in [4].

As pointed out in the Remark after Theorem 2.1, the $\mathcal{H}_1^s$-convergence can be treated by the present method (and, consequently, the C^s-convergence) when $p(t)$ is a square, which is the case in the present situation. Everything works similarly with $q(t)$ replaced by $2^s p_m(t)$ and $r(t)$ by $\rho_m(t) := (2 + 2\cos(t))^{-m} p_m(t)$ to give

$$\sigma_m := \sup\{\, s \mid \phi_m \in \mathcal{H}_1^s \} = -\log(\mu_m)/\log(2),$$

where μ_m is the spectral radius of T_{ρ_m}. Thus we get the σ_m's in this case for free.

In Table 1 we have the s_m's and σ_m's for different values of m. Note that the values of Deslauriers and Dubuc are sharp.

TABLE 1

m	s_m	σ_m
1	1.5	1.
2	2.4407	2.
3	3.1751	2.8300
4	3.7931	3.5511
5	4.3440	4.1935
6	4.8620	4.7767
7	5.3628	5.3173
8	5.8529	5.8294
9	6.3352	6.3233
10	6.8114	6.8054
11	7.2826	7.2796
12	7.7495	7.7480
13	8.2128	8.2121
14	8.6730	8.6726
15	9.1304	9.1302
16	9.5854	9.5853
17	10.038	10.038
18	10.489	10.489
19	10.938	10.938
20	11.386	11.386

An interesting property of these numbers is that $|s_m - \sigma_m|$ seems to tend to zero. This is also easy to prove from the estimates for the spectral radii. This leads us to expect that for big m the limits might be also in $\mathcal{H}_p^s$ with essentially the same s, but larger p.

5. The orthonormal wavelets of Daubechies. Here we consider solutions of (1.1) with h_k's satisfying a further condition

$$\sum_k h_{k-2i} h_{k-2j} = 2\delta_{i,j},$$

which gives orthogonality for $\phi(\cdot - k)$'s (see [3]). We skip the details and take directly the family of h_k's indexed by $m \geq 1$, which was proposed in [3]. They can be defined from

$$|p_m(t)|^2 = 1 - c_m \int_0^t \sin(\tau)^{2m-1} d\tau. \tag{5.1}$$

Meyer's book [8] contains a proof that the smoothness of ϕ grows linearly with m. Daubechies [3] shows that the growth factor is ≥ 0.1936. Here we give it exactly.

Comparing (5.1) and (4.4) shows that the p_m's here are exactly the square roots of the p_m's of §4 (note that our p equals m_0 of [3]). So it remains just to write it down, as follows.

THEOREM 5.1. *With* (5.1), *the solution* ϕ_m *of* (1.1) *satisfies*

$$s_m := \sup\{\, s \mid \phi_m \in \mathcal{H}^s \} = \frac{-\log(\mu)}{\log(4)},$$

where μ *is the spectral radius of* T_r *in the space of* $(m-1)$*-degree polynomials of* $\cos(t)$ *and*

$$r_m(t) = 2^{-2m} \textstyle\sum_{j=0}^{m-1} \binom{m-1+j}{j} \left(\frac{1-\cos(t)}{2}\right)^j .$$

Moreover, s_m has the estimates

$$(5.2) \qquad \frac{-\log\left(r(\frac{2\pi}{3})\left(1 + \frac{r(\frac{\pi}{3})r(\frac{5\pi}{6})}{(3/(2+\sqrt{3}))^{m-1} r(\frac{2\pi}{3})^2 - r(\frac{\pi}{6})r(\frac{2\pi}{3})}\right)\right)}{2\log(2)} \le s_m \le \frac{-\log(r(\frac{2\pi}{3}))}{2\log(2)} .$$

As in §4, we get, asymptotically,

$$s_m = \left(1 - \frac{\log(3)}{2\log(2)}\right) m + O(\log(m)) \approx 0.2075m.$$

Remark. We see that the asymptotics of s_m is exactly the same as the one that Daubechies [3] gives as the upper bound ever reachable by her method. Also for all m s_m here is exactly half of σ_m of §4.

Again for small values of m the eigenvalue of T_r can be computed directly. This gives, e.g., $s_1 = \frac{1}{2}$, $s_2 = 1$, $s_3 = 3 - (\log(3)/\log(2))$. For Fig. 2 we have computed the maximal eigenvalues of T_r numerically.

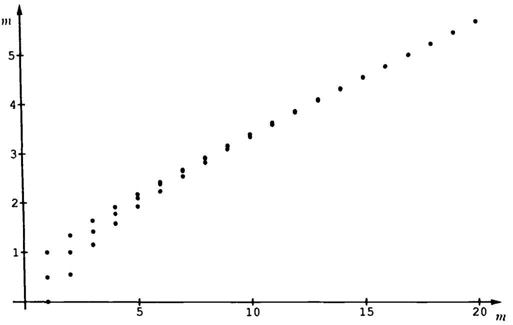

FIG. 2. *The Sobolev exponents* s_m *with the upper and lower bounds* (5.2).

In the next table we list the s_m's together with the σ_m's of Daubechies [3] and Daubechies and Lagarias [4] such that $\phi_m \in C^{\sigma_m}$.

We see that the present results practically imply (via $\mathcal{H}^s \subset C^{s'}$ for $s > s' + \frac{1}{2}$) those of [3] (cases $m \ge 5$), while the results of [4] (cases $2 \le m \le 4$) are in the gap (neither imply nor are implied by the present ones).

6. Conclusions. A positive operator technique has been shown to apply in the study of the smoothness of the solutions of some dilation equations. At present, the positive operator works well only with trigonometric polynomials. Further applicability of this technique depends most of all on possible generalisation of the results of §3.

TWO-SCALE DIFFERENCE EQUATIONS II. LOCAL REGULARITY, INFINITE PRODUCTS OF MATRICES AND FRACTALS*

INGRID DAUBECHIES‡§ AND JEFFREY C. LAGARIAS†

Abstract. This paper studies solutions of the functional equation

$$f(x)=\sum_{n=0}^{N} c_n f(kx-n),$$

where $k\geqq 2$ is an integer, and $\sum_{n=0}^{N} c_n=k$. Part I showed that equations of this type have at most one L^1-solution up to a multiplicative constant, which necessarily has compact support in $[0, N/k-1]$. This paper gives a time-domain representation for such a function $f(x)$ (if it exists) in terms of infinite products of matrices (that vary as x varies). Sufficient conditions are given on $\{c_n\}$ for a continuous nonzero L^1-solution to exist. Additional conditions sufficient to guarantee $f\in C^r$ are also given. The infinite matrix product representations is used to bound from below the degree of regularity of such an L^1-solution and to estimate the Hölder exponent of continuity of the highest-order well-defined derivative of $f(x)$. Such solutions $f(x)$ are often smoother at some points than others. For certain $f(x)$ a hierarchy of fractal sets in $\mathbb{R}$ corresponding to different Hölder exponents of continuity for $f(x)$ is described.

Key words. Hölder continuity, subdivision schemes, wavelets, infinite matrix products

1. Introduction. This is the second part of a series of two papers concerning functional equations of the type

$$f(x)=\sum_{n=0}^{N} c_n f(kx-n). \tag{1.1}$$

In Part I (Daubechies and Lagarias (1991)) we discussed existence and uniqueness of L^1-solutions. We saw that nontrivial L^1-solutions to (1.1) can only exist if $|\Sigma\, c_n|\geqq k$. If $\Sigma\, c_n=k$, then the solution, if it exists at all, is unique and furthermore it has compact support contained in $[0, N/(k-1)]$. We shall assume that $\Sigma\, c_n=k$ in this paper. Functions satisfying equations of type (1.1) arise in many contexts. Our own motivation lies in the role played by such two-scale difference equations in the construction of orthonormal bases of compactly supported wavelets (see § 6.3 in part I or Daubechies (1988)). Similar equations characterize certain nowhere differentiable functions constructed by De Rham (1956, 1957, 1959). They also play an important role in interpolating subdivision schemes with applications to computer aided design, on which an important body of work exists; papers in this subject treating 2-scale difference equations are, e.g., Dubuc (1986), Micchelli (1986), Dyn, Gregory, and Levin (1987, 1991), Deslauriers and Dubuc (1987, 1989), Micchelli and Prautzsch (1987, 1989), and Dyn and Levin (1989). All these examples satisfy $\Sigma\, c_n=k$.

For the sake of simplicity we shall usually choose $k=2$, even though all our techniques can be applied for general integer values of $k\geqq 2$. We shall also restrict ourselves to real coefficients c_n and, correspondingly, real functions f. Our analysis can, however, also be used for complex c_n, without any changes. We are thus mainly

concerned with equations of the type

$$f(x)=\sum_{n=0}^{N} c_n f(2x-n) \tag{1.2}$$

with real c_n and $\Sigma\, c_n=2$.

Not all equations of type (1.2), with $\Sigma\, c_n=2$ have a nontrivial L^1-solution. There exist several possible approaches to the study of existence and smoothness of solutions to (1.2). One approach uses the trigonometric polynomial $p(\xi)=\frac{1}{2}\sum_{n=0}^{N} c_n\, e^{in\xi}$. In particular, if $p(\xi)$ can be factored as

$$p(\xi)=[(1+e^{i\xi})/2]^{L+1}q(\xi) \tag{1.3}$$

and

$$\sup_{\xi\in\mathbb{R}} |q(\xi)|<2^{L+1-m}, \tag{1.4}$$

then there exists a nontrivial L^1-solution f to (1.2), which is, moreover, m times continuously differentiable (Daubechies (1988)). Other sufficient conditions on p guaranteeing existence and smoothness can be found in Deslauriers and Dubuc (1987, 1989). Typically these conditions all achieve regularity of f by imposing decay on its Fourier transform $\hat{f}(\xi)$. These methods work best when $p(\xi)$ is a nonnegative function, as illustrated by Deslauriers and Dubuc (1987), who obtain very sharp information about the regularity of functions f constructed via a symmetric Lagrangian interpolation scheme. For more general examples, lacking the positivity of $p(\xi)$, this analysis leads to less than optimal results (Daubechies (1988), Deslauriers and Dubuc (1989)).

In this paper we use a different technique to study the regularity of solutions of (1.2). It is essentially a "time domain" method, in the sense that it does not involve Fourier transforms at any stage. This time domain approach hinges on the fact that if f satisfies (1.2), then the values $f(x)$ can be easily calculated, recursively, for all dyadic x, i.e., all x of the type $m2^{-j}(m=\mathbb{Z}, j\in\mathbb{N})$, if the values $f(m)$ at the integers are known. Provided suitable conditions are satisfied, we can then show that there exists a continuous extension of these $f(m2^{-j})$ to all of $\mathbb{R}$, thus defining $f(x)$. In fact, an explicit formula for $f(x)$ can be expressed using an infinite product of matrices (depending on x). It is then possible to discuss the Hölder continuity, differentiability, etc., of this extension, which is the desired solution of (1.2).

We explain the matrix technique in detail in § 2. We show how to choose a "correct" initialization $\{f(m);\ m\in\mathbb{Z}\}$ for the iterative spline approximation to f, and we formulate sufficient conditions on the c_n guaranteeing that the process converges to a continuous L^1-solution of (1.2). We also compute lower bounds for the Hölder exponent of the resulting function $f(x)$. In § 3 we show how similar ideas, using the sum rules (1.5) together with some technical conditions, can be used to prove that $f\in C^L$.

The time domain method proposed here leads in many instances to sharper results than the Fourier transform methods mentioned above. One such example is the function ϕ plotted in Fig. 1(a) (or in Fig. 3(a) in Part I). Even when handled with care, the Fourier transform method only establishes that the Hölder exponent of ϕ is at least $.5-\varepsilon$ (see Daubechies (1988)). In fact ϕ is Hölder continuous with exponent $2-\ln(1+\sqrt{3})/\ln 2=.5500...$; the method presented in this paper achieves this (optimal) result. Moreover, the Fourier transform method typically only controls global regularity properties: the detailed, local analysis of the regularity of solutions to (1.2), accessible via our matrix method as explained in § 4, is wholly outside the reach of Fourier transform based techniques. Using the time domain approach we can show, e.g., that the function ϕ in Fig. 1a is almost everywhere differentiable, and that its Hölder exponent .5500... is determined by a dense set of "bad" points which has zero measure. In fact, there exists a whole hierarchy of fractal sets, all with zero measure, corresponding to the Hölder exponent between .5500... and 1. Another interesting example is the basic function associated to the dyadic interpolation scheme first studied in Dubuc (1986) and Dyn, Gregory and Levin (1987). In this case the function $p(\xi)=\sum c_n e^{in\xi}$ is positive, allowing the Fourier transform method to achieve the already optimal result $f\in C^{2-\varepsilon}$ for the global regularity of f. Our time domain method recovers this result (although by a more involved analysis than via the Fourier transform method), but it also establishes that f is almost everywhere twice differentiable, which is a result outside the reach of the Fourier transform method. A detailed discussion of these and other examples can be found in § 5.

When we developed this technique, we were unaware of related and at that time unpublished work of Micchelli and Prautzsch (1989) and Dyn and Levin (1989), to which referees drew our attention. Let us give a short overview of the situation, pointing out the overlap and the differences between our work and theirs. The two papers by Micchelli and Prautzsch (1989) and the two by Dyn and Levin (1989) (hereafter called [MP] and [DL]) are both motivated by the applications of interpolation subdivision schemes to computer aided design (see Micchelli (1986), Micchelli and Prautzsch (1987) and Dyn, Gregory, and Levin (1987, 1989)). The coefficients c_n in an interpolation subdivision scheme typically satisfy $c_{2n+n_0}=\delta_{b0}$ for some n_0, but both [MP] and [DL] are applicable to more general coefficient choices. [MP] focuses on the existence and smoothness of solutions to (1.2), whereas [DL] is more concerned with the convergence of the corresponding interpolation scheme, that is, in the language of § 4 in part I, with existence of smooth solutions *and* convergence of the cascade algorithm to these solutions. It is proved in [DL] that the cascade algorithm converges to a C^L solution only if the coefficients c_n satisfy the $L+1$ "sum rules"

$$\sum_n c_n n^l(-1)^n=0, \qquad l=0,\cdots,L. \tag{1.5}$$

Moment conditions of the type (1.5) also turn up in a different context. If the solution f to (1.2) has the property that the integer translates $f(\cdot-n)$, $n\in\mathbb{Z}$ are all independent, then the moment condition (1.5) is equivalent to saying that all the polynomials of degree at most L can be written as combinations of the $f(\cdot-n)$, and can therefore be obtained exactly by the associated subdivision scheme. See Cavaretta, Dahmen, and Micchelli (1989) for a general multivariate discussion of this aspect. Sum rules of type (1.5) are in fact satisfied by all interesting examples (wavelets as well as interpolating schemes); it is easy to check that they are equivalent to the requirement that $p(\xi)$ can be factored as in (1.3). If we are concerned with only the existence of a reasonably smooth solution to (1.2), without convergence of the cascade algorithm to this solution, then conditions (1.5) are not necessary, and [MP] do not, in fact, use them. The discussion of possible solutions $f(x)$ to (1.2) in [MP] makes use of the same matrices as our approach. In particular, for the choice $k=2$, we deal with two matrices $\mathbf{T}_0$ and $\mathbf{T}_1$, both determined by the c_n, and $f(x)$ is then given by the limit

$$\lim_{n\to\infty}[\mathbf{T}_{d_1(x)}\mathbf{T}_{d_2(x)}\cdots\mathbf{T}_{d_n(x)}\cdots]\begin{bmatrix} f(0)\\ f(1)\\ \vdots\\ f(N-1)\end{bmatrix},$$

where the index $d_j(x)$ is the jth digit in the binary expansion for x (see § 2). A very special structure of the matrices $\mathbf{T}_0, \mathbf{T}_1$ is then required for f to be a C^L-function: both matrices have to have the eigenvalues $1, \frac{1}{2}, \cdots, 2^{-L}$, and the corresponding left eigenvectors $\mathbf{e}_l^0, \mathbf{e}_l^1$ ($l = 0, \cdots, L$) have to define flags of nested subspaces with very particular properties (see § 5 in [MP] or § 2, 3 below). In our paper, we require that the sum rules (1.5) hold; as shown by examples and by [MP], they are not necessary, but they make it possible to write very explicit expressions for the eigenvectors $\mathbf{e}_l^0, \mathbf{e}_l^1$. It turns out that (1.5) forces the $\mathbf{e}_l^0, \mathbf{e}_l^1$ to satisfy many of the conditions in [MP], which explains why we have only one technical condition (as compared to the four conditions in Theorem 5.2 in [MP]). If this condition is satisfied, then a simple spline approximation argument proves that the function f is indeed L times continuously differentiable. This simple argument was partly suggested to us by one of the anonymous referees, who we would like to thank here. In an appendix we shortly sketch our original, longer approach, which does not use splines but which can be generalized to certain higher-dimensional situations where splines would be hard to use.

Another difference between our paper and [MP] is that we also exploit the structure of the matrices $\mathbf{T}_0, \mathbf{T}_1$ to study local regularity properties of f: the importance of the binary expansion of x in determining $f(x)$ means that points with different frequencies of the digits 1 or 0 in their binary expansion correspond to different local Hölder exponents for f. In fact, this feature, first observed experimentally in graphs of orthonormal wavelet bases with compact support, was one of our main motivations for undertaking this study.

2. Continuity and Hölder continuity. If f satisfies (1.2), then the values of $f(x)$ can be computed explicitly, recursively, for all dyadic rationals x, i.e., for all x of the type $m2^{-j}(m \in \mathbb{Z}, j \in \mathbb{N})$, if the values $f(m)$ at the integers m are known. If f is continuous, then the $f(m2^{-j})$ suffice to determine f everywhere; a sequence of convergent spline approximations was constructed in Theorem 4.1 in part I. However, for general c_n and for arbitrarily chosen $f(m)$ this procedure will typically diverge and not lead to a continuous function at all. The following proposition gives a necessary condition that the c_n have to satisfy and specifies restrictions on the choice of the initial values $f(m)$ for the iteration scheme.

PROPOSITION 2.1. *Assume that* $\sum_{n=0}^{N} c_n = 2$. *If f is a nontrivial continuous L^1-solution to* (1.2), *then*:

(1^0) *The* $(N-1)\times(N-1)$ *dimensional matrix* $\mathbf{M}$ *defined by*

$$\mathbf{M}_{ij} = c_{2i-j}, \qquad 1 \leqq i, j \leqq N-1$$

has 1 *as an eigenvalue.*

(2^0) *The* $(N-1)$ *dimensional vector* $(f(1), \cdots, f(N-1))$ *is a right eigenvector of* $\mathbf{M}$ *with eigenvalue* 1, *and* $f(m) = 0$ *for all* $m \leqq 0$ *and* $m \geqq N$.

Proof. By Corollary 2.2 in part I, support $(f) \subset [0, N]$. This implies that $f(m) = 0$ for $m \leqq 0$, $m \geqq N$. The other conclusions follow from Theorem 5.1 in part I. □

In what follows we shall impose that the c_n satisfy the first sum rule in (1.5); this condition is sufficient (but not necessary) for (1^0) to hold. Explicitly,

$$\sum_{n=0}^{N} (-1)^n c_n = 0 \tag{2.1}$$

or, equivalently, since $\sum_n c_n = 2$,

$$\sum_n c_{2n} = \sum_n c_{2n+1} = 1. \tag{2.2}$$

This condition is satisfied in all the practical examples discussed in part I. It also has a very simple interpretation in the cascade algorithm (see § I.4). In this algorithm, the jth level consists of $(2^j-1)N+1$ different coefficients a^j_m, which are computed from the $(j-1)$th level via

$$a^j_{2m}=\sum_k c_{2(m-k)}a^j_k, \qquad a^j_{2m+1}=\sum_k c_{2(m-k)+1}a^j_k$$

(see, e.g., Micchelli and Prautzsch (1987), Dyn, Gregory, and Levin (1989) or Daubechies (1988)). The condition (2.2) states, therefore, that the total weight of the a^{j-1}_l in the computation of a^j_m is independent of m. In the case where the cascade algorithm simplifies to an interpolation subdivision scheme, this "equal opportunity" condition is automatically satisfied, since then

$$c_{l+2n}=\delta_{n0} \quad \text{for some } l \quad (\text{see § I.4}),$$

hence

$$\sum_m = c_{2m+1+l}=\sum_n c_{n+l}-\sum_m c_{2m+l}=\sum_{n=0}^{N} c_n-1=1=\sum c_{2m+l}.$$

If the scaling factor k is an integer larger than 2, then (2.2) has to be rewritten as

$$\sum_n c_{kn}=\sum_n c_{kn+1}=\cdots=\sum c_{kn+(k-1)}=1. \tag{2.2$'$}$$

This is again an "equal opportunity" condition when looked at from the point of view of the cascade algorithm. Note that (2.2′) is equivalent to requiring that $p(\xi)=\sum_{n=0}^N c_n\, e^{in\xi}$ is divisible by $(1+e^{i\xi}+\cdots+e^{i(k-1)\xi})$.

We return to the dyadic case $(k=2)$, and we assume that (2.2) is satisfied. It immediately follows that for all j, $1\leqq j\leqq N-1$,

$$\sum_{i=1}^{N-1}\mathbf{M}_{ij}=\sum_{i=1}^{N-1}c_{2i-j}=1,$$

where $\mathbf{M}_{ij}=c_{2i-j}$ (see above, or § I.5) and where we use the convention $c_l=0$ if $l<0$ or $l>N$. Consequently, 1 is an eigenvalue of $\mathbf{M}$, with left eigenvector $(1,1,\cdots,1)$. The necessary condition in Proposition 2.1 (1^0) is therefore satisfied.

Let us assume that the eigenvalue 1 of $\mathbf{M}$ is nondegenerate. (This will be guaranteed by a technical condition below.) Then there is a unique (up to normalization) right eigenvector $\mathbf{a}$ with eigenvalue 1 for $\mathbf{M}$. This eigenvector cannot be orthogonal to the left eigenvector $(1,1,\cdots,1)$, i.e., $\sum_{i=1}^{N-1}\mathbf{a}_i\neq 0$, so that we can normalize $\mathbf{a}$ to have $\sum_{i=1}^{N-1}\mathbf{a}_i=1$. We then pick the $f(n)$ to be

$$\begin{aligned} f(n)&=\mathbf{a}_n &\quad& n=1,\cdots,N-1\\ &=0 && n\leqq 0 \quad\text{or}\quad n\geqq N. \end{aligned}$$

We define successive spline approximations f_j to f as in § I.4:

(1) $f_0(x)$ is linear on every $[n,n+1]$,
$f_0(n)=f(n)$,

(2) $f_j=V^jf_0$,

where V is the linear operator

$$(Vg)(x)=\sum_{n=0}^N c_n g(2x-n). \tag{2.3}$$

If f is continuous, then the f_j converge to f (see Theorem 4.1 in part I). A priori we have, however, no reason to expect a continuous solution to (1.2); in fact, for many choices of the c_n, even if they satisfy (2.2), f will not be continuous, and the f_j will converge to f only in some distributional sense. We shall impose further conditions on the c_n which will enable us to prove that the f_j constitute a Cauchy sequence in L^∞, which then automatically leads to continuity for f. In order to do this, we introduce a "vector" notation.

Finding solutions to (1.2) is the same as finding fixed points for the linear operator V defined in (2.3). We shall only be concerned here with functions g supported on $[0, N] = \text{support}\,(f)$. For such functions (2.3) can be rewritten in "vector" form. Define the vector valued function $\mathbf{w}\colon [0, 1] \to \mathbb{R}^N$ by

$$\mathbf{w}(x)_n = g(x+n-1), \qquad n = 1, \cdots, N. \tag{2.4}$$

Knowing the function g is equivalent to knowing $\mathbf{w}\colon [0, 1] \to \mathbb{R}^N$. Note that necessarily

$$\mathbf{w}(0)_j = \mathbf{w}(1)_{j-1} \quad \text{for } 2 \leqq j \leqq N. \tag{2.5}$$

Moreover, g is continuous if and only if $\mathbf{w}$ is continuous on $[0, 1]$ and if

$$\mathbf{w}(0)_1 = 0 = \mathbf{w}(1)_N. \tag{2.6}$$

Let us now define the linear operator $\mathbf{V}$ on vector valued functions $\mathbf{w}$ satisfying (2.5), (2.6) by

$$(\mathbf{V}\mathbf{w})(x)_n = (Vg)(x+n-1),$$

where we assume $\mathbf{w}$ and g are linked as in (2.4). Then $\mathbf{V}$ is given explicitly by

$$\mathbf{V}\mathbf{w}(x) = \begin{cases} \mathbf{T}_0\mathbf{w}(2x) & \text{if } x \leqq \frac{1}{2}, \\ \mathbf{T}_1\mathbf{w}(2x-1) & \text{if } x \geqq \frac{1}{2}, \end{cases} \tag{2.7}$$

where $\mathbf{T}_0, \mathbf{T}_1$ are the $N \times N$-matrices defined by

$$\begin{aligned} (\mathbf{T}_0)_{ij} &= c_{2i-j-1}, & 1 \leqq i, j \leqq N, \\ (\mathbf{T}_1)_{ij} &= c_{2i-j}, & 1 \leqq i, j \leqq N, \end{aligned} \tag{2.8}$$

or

$$\mathbf{T}_0 = \begin{bmatrix} c_0 & 0 & 0 & 0 & \cdots & & & 0 & 0 \\ c_2 & c_1 & c_0 & 0 & \cdots & & & 0 & 0 \\ c_4 & c_3 & c_2 & c_1 & c_0 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & & & \vdots & \vdots \\ 0 & 0 & 0 & 0 & 0 & 0 & \cdots & c_N & c_{N-1} \end{bmatrix},$$

$$\mathbf{T}_1 = \begin{bmatrix} c_1 & c_0 & 0 & 0 & \cdots & & & 0 & 0 \\ c_3 & c_2 & c_1 & c_0 & 0 & \cdots & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & & & & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & \cdots & & 0 & c_N \end{bmatrix}.$$

Note that if we strip either $\mathbf{T}_0$ of its first row and column, or $\mathbf{T}_1$ of its last row and column, then the resulting $(N-1) \times (N-1)$ matrix is exactly $\mathbf{M}$. Moreover, (2.2) implies that the N-dimensional row vector $\mathbf{e}_1 = (1, \cdots, 1)$ is a left eigenvector of both $\mathbf{T}_0$ and $\mathbf{T}_1$, with eigenvalue 1,

$$\mathbf{e}_1 \cdot \mathbf{T}_0 = \mathbf{e}_1 = \mathbf{e}_1 \cdot \mathbf{T}_1.$$

Formula (2.7) can be written more succinctly if we use binary expansions. For any $x \in [0, 1]$ we can write

$$x = \sum_{j=1}^{\infty} d_j 2^{-j}, \quad \text{where } d_j = 0 \text{ or } 1 \quad \text{for all } j.$$

We then define the action of the *shift operator* τ on x by

$$(2.9) \qquad \tau x = \sum_{j=2}^{\infty} d_j 2^{-j+1}.$$

This corresponds to shifting the decimal point in the binary expansion of x one step to the right and dropping the old first decimal. In fact,

$$\tau x = \begin{cases} 2x & \text{if } 0 \leqq x < \frac{1}{2}, \\ 2x - 1 & \text{if } \frac{1}{2} < x \leqq 1. \end{cases}$$

Note that this does not yet define τx for $x = \frac{1}{2}$; we shall come back below to what happens at $x = \frac{1}{2}$. For $x \neq \frac{1}{2}$, (2.3) can therefore be rewritten as

$$(2.10) \qquad \mathbf{V}\mathbf{w}(x) = \mathbf{T}_{d_1(x)}\mathbf{w}(\tau x),$$

where we have introduced the notation $d_j(x)$ for the jth digit in the binary expansion of x. For $x = \frac{1}{2}$ the first digit in the binary expansion (2.9) is not well defined, since we can take either $d_1 = 0$, $d_j = 1$ for $j \geqq 2$ or $d_1 = 1$, $d_j = 0$ for $j \geqq 2$. Extending (2.10) to $x = \frac{1}{2}$ leads, therefore, to two different equations, depending on which choice was made for the binary expansion of $\frac{1}{2}$,

$$\mathbf{w}(\tfrac{1}{2}) = \mathbf{T}_0\mathbf{w}(1) \quad \text{or} \quad \mathbf{w}(\tfrac{1}{2}) = \mathbf{T}_1\mathbf{w}(0).$$

For $\mathbf{w}$ satisfying the restrictions (2.5), (2.6), there is, however, no contradiction between these two equations, since $(\mathbf{T}_1)_{i,j} = (\mathbf{T}_0)_{i+1,j+1}$ for $1 \leqq i, j \leqq N-1$. Equation (2.10) therefore holds true for any $x \in [0, 1]$.

Let us apply all this to the spline functions f_j and define

$$[\mathbf{v}_j(x)]_n = f_j(x + n - 1), \qquad j \in \mathbb{N}, \quad n = 1, \cdots, N.$$

It follows that

$$\begin{aligned} \mathbf{v}_j(x) &= (\mathbf{V}^j\mathbf{v}_0)(x) \\ &= \mathbf{T}_{d_1(x)}\mathbf{T}_{d_2(x)} \cdots \mathbf{T}_{d_j(x)}\mathbf{v}_0(\tau^j x). \end{aligned}$$

Now that we have introduced all the necessary notation, we are in a position to formulate the main result of this section.

We will use the operator norm for matrices defined by $\|\mathbf{T}\| = \sup_{\mathbf{v}\neq 0} \|\mathbf{T}\mathbf{v}\| / \|\mathbf{v}\|$, where $\|\mathbf{v}\|$ is the Euclidean norm of $\mathbf{v}$, $\|\mathbf{v}\|^2 = \sum_{j=1}^{N} \mathbf{v}_j^2$.

THEOREM 2.2. *Assume that the* c_n, $n = 0, \cdots, N$ *satisfy*

$$\sum_n c_{2n} = \sum_n c_{2n+1} = 1.$$

Define the $N \times N$*-matrices* $\mathbf{T}_0$ *and* $\mathbf{T}_1$ *by*

$$(\mathbf{T}_0)_{ij} = c_{2i-j-1}, \qquad (\mathbf{T}_1)_{ij} = c_{2i-j}, \quad 1 \leqq i, j \leqq N.$$

Define E_1 *to be the* $(N-1)$*-dimensional subspace orthogonal to* $\mathbf{e}_1 = (1, \cdots, 1)$, *the common left eigenvector of* $\mathbf{T}_0, \mathbf{T}_1$ *for the eigenvalue* 1. *Assume that there exist* $\lambda < 1$ *and* $C > 0$ *such that, for all* $m \in \mathbb{N}$,

$$(2.11) \qquad \max_{d_j = 0 \text{ or } 1, j = 1, \cdots, m} \|\mathbf{T}_{d_1}\mathbf{T}_{d_2} \cdots \mathbf{T}_{d_m}|_{E_1}\| \leqq C\lambda^m.$$

Then the following hold:

(1) *The eigenvalue* 1 *is of the* $(N-1)\times(N-1)$*-dimensional matrix* $\mathbf{M}$ *defined by* $\mathbf{M}_{ij}=c_{2i-j}$, $1\leqq i, j\leqq N-1$, *is simple and there is an associated right eigenvector* $\mathbf{a}$ *with* $\sum_{i=1}^{N-1}\mathbf{a}_i=1$.

(2) *The vector-valued functions* $\mathbf{v}_j(x)$ *defined above satisfy* $\mathbf{e}_1\cdot\mathbf{v}_j(x)=1$ *for all* $j\in\mathbb{N}$, *all* $x\in[0,1]$.

(3) *The corresponding functions* f_j *converge uniformly to a continuous function* f,

$$\|f_j-f\|_{L^\infty}\leqq C2^{-j|\ln\lambda|/\ln 2}.$$

(4) *The limit function* f *is an* L^1*-solution to* (1.2); *it is normalized so that* $\int_0^N dx\, f(x)=1$, *and it is Hölder continuous,*

$$|f(x)-f(y)|\leqq C|x-y|^\alpha, \tag{2.12}$$

with $\alpha=|\ln\lambda|/\ln 2$.

Proof. (1) The constraint (2.16) automatically implies that 1 is a simple eigenvalue of $\mathbf{T}_0$ and $\mathbf{T}_1$. Indeed, if 1 were not a simple eigenvalue of, e.g., $\mathbf{T}_0$, then there would exist a right eigenvector $\mathbf{e}_1'$ for $\mathbf{T}_0$ in E_1, with eigenvalue 1 (regardless of whether the eigenvalue 1 is degenerate or not, in which last case the matrix $\mathbf{T}_0$, restricted to the invariant subspace for the eigenvalue 1, can be brought in Jordan normal form but not diagonalized). It would then immediately follow that

$$\|\mathbf{T}_0^m|_{E_1}\|\geqq\|\mathbf{T}_0^m\mathbf{e}_1'\|/\|\mathbf{e}_1'\|=1,$$

contradicting (2.11).

(2) We already know that 1 is an eigenvalue of $\mathbf{M}$ and that the $(N-1)$-dimensional vector $(1,\cdots,1)$ is a left eigenvector for this eigenvalue. Since $(\mathbf{T}_0)_{i+1,j+1}=\mathbf{M}_{ij}$, $1\leqq i,j\leqq N-1$ and $(\mathbf{T}_0)_{1j}=0$ for $j\geqq 2$, we find that any eigenvalue of $\mathbf{M}$ is an eigenvalue of $\mathbf{T}_0$, with at least the same multiplicity. Since 1 is a simple eigenvalue of $\mathbf{T}_0$, it is, therefore, also a simple eigenvalue of $\mathbf{M}$. It then follows from arguments presented above that the right eigenvector $\mathbf{a}$ for the eigenvalue 1 of $\mathbf{M}$ can be normalized so that $\sum_{n=1}^{N-1}\mathbf{a}_n=1$. As previously agreed, we then define

$$[\mathbf{v}_0(x)]_n=\mathbf{a}_{n-1}(1-x)+\mathbf{a}_n x,\qquad n=1,\cdots,N,$$

with the convention $\mathbf{a}_0=0=\mathbf{a}_N$.

(3) From the normalization of $\mathbf{a}$, it now follows that, for all $x\in[0,1]$,

$$\mathbf{e}_1\cdot\mathbf{v}_0(x)=\sum_{n=1}^{N}[\mathbf{v}_0(x)]_n=1.$$

We now prove, by induction, that the same is true for all $\mathbf{v}_j$. Suppose $\mathbf{e}_1\cdot\mathbf{v}_j(x)=1$. Then, for all $x\in[0,1]$,

$$\mathbf{e}_1\cdot\mathbf{v}_{j+1}(x)=\mathbf{e}_1\cdot\mathbf{T}_{d_1(x)}\mathbf{v}_j(\tau x)=\mathbf{e}_1\cdot\mathbf{v}_j(\tau x)=1,$$

where we have used $\mathbf{e}_1\cdot\mathbf{T}_0=\mathbf{e}_1=\mathbf{e}_1\cdot\mathbf{T}_1$.

(4) Next we show that the $\mathbf{v}_k(x)$ are uniformly bounded. Since $\mathbf{e}_1\cdot\mathbf{v}_k(x)=1$ for all k, x, it follows that $\mathbf{v}_k(x)-\mathbf{v}_l(x)\in E_1$ for all k, l, x. Hence

$$\begin{aligned}\|\mathbf{v}_{k+1}(x)-\mathbf{v}_{k(x)}\|&=\|\mathbf{T}_{d_1(x)}\cdots\mathbf{T}_{d_k(x)}[\mathbf{v}_1(\tau^k x)-\mathbf{v}_0(\tau^k x)]\|\\&\leqq C\lambda^k\sup_{y\in[0,1]}\|\mathbf{v}_1(y)-\mathbf{v}_0(y)\|.\end{aligned}$$

Consequently,

$$\begin{aligned}\|\mathbf{v}_k(x)\| &\leqq \|\mathbf{v}_0(x)\| + \sum_{j=1}^{k} \|\mathbf{v}_j(x)-\mathbf{v}_{j-1}(x)\| \\ &\leqq \sup_{y\in[0,1]} \|\mathbf{v}_0(y)\| + C(1-\lambda)^{-1} \sup_{y\in[0,1]} \|\mathbf{v}_1(y)-\mathbf{v}_0(y)\|,\end{aligned}$$

so that $\|\mathbf{v}_k(x)\|$ is bounded uniformly in k and in x.

(5) Together with $\mathbf{e}_1 \cdot \mathbf{v}_k(x)=1$, the uniform boundedness of the $\mathbf{v}_k(x)$ implies that the $\mathbf{v}_k$ constitute a Cauchy sequence in L^∞-norm. Indeed, since

$$\begin{aligned}\|\mathbf{v}_{j+k}(x)-\mathbf{v}_j(x)\| &= \|\mathbf{T}_{d_1(x)} \cdots \mathbf{T}_{d_j(x)}[\mathbf{v}_k(x)-\mathbf{v}_0(x)]\| \\ &\leqq 2C\lambda^j \sup_{l,y} \|\mathbf{v}_l(y)\|,\end{aligned}$$

we find that $\sup_{x\in[0,1]} \|\mathbf{v}_{j+k}(x)-\mathbf{v}_j(x)\|$ can be made arbitrarily small by choosing j large enough, independently of k. It follows that there exists a limit,

$$\mathbf{v}(x) = \lim_{j\to\infty} \mathbf{v}_j(x),$$

which is continuous since all the $\mathbf{v}_j$ are continuous and the convergence is uniform in x,

$$\sup_{x\in[0,1]} \|\mathbf{v}(x)-\mathbf{v}_j(x)\| \leqq C\lambda^j.$$

Since every $\mathbf{v}_j$ satisfies (2.5), (2.6), so does $\mathbf{v}$. It follows that the function f defined on $[0, N]$ by

$$f(x) = [\mathbf{v}(x-\lfloor x\rfloor)]_{\lfloor x\rfloor+1}$$

(where $\lfloor x\rfloor$ denotes the largest integer not exceeding x) is continuous, and that

$$\|f-f_j\|_{L^\infty} \leqq C\lambda^j = C2^{-j\alpha} \tag{2.13}$$

with $\alpha = |\ln \lambda|/\ln 2$.

(6) Since $f_j = Vf_{j-1}$, the limit function f satisfies $f = Vf$, i.e., f is a solution to (1.2), which is necessarily L^1 since f is bounded and compactly supported. We have, moreover, $\mathbf{e}_1 \cdot \mathbf{v}(x) = \lim_{j\to\infty} \mathbf{e}_1 \cdot \mathbf{v}_j(x) = 1$, so that

$$\int_0^N dx f(x) = \int_0^1 dx \sum_{n=1}^{N} [\mathbf{v}(x)]_n = 1.$$

(7) The Hölder continuity follows from (2.13) and standard spline results translating estimates on how well a function can be approximated by piecewise polynomials into Hölder estimates on the function itself. (See, e.g., Theorem 6.10 in Schumaker (1981), which uses approximations by piecewise constant functions rather than piecewise linear f_j; an estimate similar to (2.13) can also be proved for piecewise constant approximations to f.) For the sake of convenience, we also give a direct proof by the following short argument. Suppose that $2^{-(j+1)} \leqq y-x \leqq 2^{-j}$. Then there exists $l \in \mathbb{N}$ so that one of the two following alternatives holds: $(l-1)2^{-j} \leqq x \leqq y \leqq l2^{-j}$ or $(l-1)2^{-j} \leqq x \leqq l2^{-j} \leqq y \leqq (l+1)2^{-j}$. We shall only discuss the second case; the first one is similar. We then have

$$\begin{aligned}|f(x)-f(y)| &\leqq |f(x)-f_j(x)| + |f_j(x)-f_j(l2^{-j})| \\ &\quad + |f_j(l2^{-j})-f_j(y)| + |f_j(y)-f(y)| \\ &\leqq 2C2^{-\alpha j} + |f_j(x)-f_j(l2^{-j})| + |f_j(y)-f_j(l2^{-j})|,\end{aligned}$$

by (2.13). Because of the choice of l, there exists $k \in \mathbb{N}$ so that $x' = x - k$ and $l'2^{-j} = l2^{-j} - k$ are both in $[0, 1]$. We can, moreover, choose binary expansions for x' and $l'2^{-j}$ with coinciding first j digits (choose the expansion ending in ones for $l'2^{-j}$, and if x' is dyadic, the expansion ending in zeros for x'). It follows that

$$\begin{aligned}|f_j(x) - f_j(l2^{-j})| &\leqq \|\mathbf{v}_j(x') - \mathbf{v}_j(l'2^{-j})\| \\ &= \|\mathbf{T}_{d_1(x')} \cdots \mathbf{T}_{d_j(x')}[\mathbf{v}_0(\tau^j x') - \mathbf{v}_0(\tau^j(l'2^{-j}))]\| \\ &\leqq C\lambda^j = C2^{-j},\end{aligned}$$

where we have used (2.11), the boundedness of $\mathbf{v}_0$, and $\mathbf{v}_0(u) - \mathbf{v}_0(u') \in E_1$ for all u, u'. Similarly we can bound $|f_j(y) - f_j(l2^{-j})|$; putting it all together leads to

$$|f(x) - f(y)| \leqq C'2^{-\alpha j} \leqq C''|x - y|^{\alpha},$$

which is (2.12). □

Remarks. (1) Note that the argument in point (7) would also work, in principle, if $\lambda < \frac{1}{2}$. In that case $|f(x) - f(y)| \leqq C|x - y|^{1+\varepsilon}$ would follow, with $\varepsilon > 0$, which is only possible if $f \equiv$ constant. Since support $(f) = [0, N]$ and f is continuous, this implies $f \equiv 0$. It follows that λ in (2.11) necessarily satisfies $\lambda \geqq \frac{1}{2}$.

(2) Under the conditions of this theorem, for $0 \leqq x \leqq 1$ all infinite products $\mathbf{T}_{d_1(x)}\mathbf{T}_{d_2(x)}\mathbf{T}_{d_3(x)} \cdots$ of the matrices $\mathbf{T}_0$ and $\mathbf{T}_1$ converge to the limit matrices

$$\mathbf{T}_{d_1(x)}\mathbf{T}_{d_2(x)}\mathbf{T}_{d_3(x)} \cdots = \begin{bmatrix} f(x) & f(x) & \cdots & f(x) \\ f(x+1) & f(x+1) & \cdots & f(x+1) \\ \vdots & \vdots & & \vdots \\ f(x+N-1) & f(x+N-1) & \cdots & f(x+N-1) \end{bmatrix}.$$

Theorem 2.2 is similar to Theorem 5.1 in Micchelli and Prautzsch (1989), with the following differences. On one hand, [MP] are only interested in continuity, and technical condition (b) in their Theorem 5.1 is a little less tight than our (2.11), although both are very similar. On the other hand, they have extra conditions (a), (c), (d), which are here automatically satisfied because we have restricted ourselves to the case where the sum rule (2.2) holds.

To apply Theorem 2.2 we have to verify the technical condition (2.11). It might seem impossible to check in practice, since it involves the norms of infinitely many products of matrices. It turns out, however, that (2.11) can be reduced to a criterion that uses only a finite-time computer search. This is the constant of the next lemma.

LEMMA 2.3. *Define*

$$\lambda_m = \max_{\substack{d_j = 0 \text{ or } 1 \\ j = 1, \cdots, m}} \|\mathbf{T}_{d_1} \cdots \mathbf{T}_{d_m}|_{E_1}\|^{1/m}. \tag{2.14}$$

A necessary and sufficient condition for (2.11) *to hold is that*

$$\lambda_m < 1 \qquad \textit{for some } m \in \mathbb{N}. \tag{2.15}$$

Proof. Suppose $\lambda_m < 1$. *Write* $n = qm + r$, with q, $r \in \mathbb{N}$, $0 \leqq r < m$. Then

$$\|\mathbf{T}_{d_1} \cdots \mathbf{T}_{d_n}|_{E_1}\| \leqq \lambda_m^{mq}\lambda_r^r \leqq \max(1, \lambda_1, \cdots, \lambda_{m-1}^{m-1})\lambda_m^{-r}\lambda_m^n.$$

This implies (2.11), with $\lambda = \lambda_m < 1$, and $C = \lambda_m^{-m+1}\max(1, \cdots, \lambda_{m-1}^{m-1})$. Conversely, if (2.11) is satisfied, then $\lambda_m \leqq C^{1/m}\lambda$, hence $\lambda_m < 1$ for large enough m. □

In some examples, the smallest value m for which (2.14) holds may still be too large: up to a formidable 2^m matrix norms may have to be checked for every candidate m. In the next section, we shall see some additional tricks to simplify the search.

The technical condition (2.11) or (2.14) on $\mathbf{T}_0, \mathbf{T}_1$ can be interpreted as a "spectral" constraint. In fact, given two matrices $\mathbf{S}_0, \mathbf{S}_1$, we can define (Rota and Strang (1960), Daubechies and Lagarias (1991)) the joint spectral radius for $\mathbf{S}_0, \mathbf{S}_1$ by

$$\hat{\rho}(\mathbf{S}_0, \mathbf{S}_1) = \limsup_{m\to\infty} [\max_{\substack{d_j=0 \text{ or } 1\\ j=1,\cdots,m}} \|\mathbf{S}_{d_1}\cdots \mathbf{S}_{d_m}\|^{1/m}]. \tag{2.16}$$

In the case where the two matrices are identical, it is well known that (2.16) reduces to the spectral radius. We have the following.

LEMMA 2.4. *A necessary and sufficient condition for* (2.11) *to hold is that the joint spectral radius* $\hat{\rho}(\mathbf{T}_0|_{E_1}, \mathbf{T}_1|_{E_1}) < 1$.

Proof. We have $\hat{\rho}(\mathbf{T}_0|_{E_1}, \mathbf{T}_1|_{E_1}) = \limsup_{m\to\infty} \lambda_m$. If $\hat{\rho}(\mathbf{T}_0|_{E_1}, \mathbf{T}_1|_{E_1}) < 1$, then $\lambda_m < 1$ follows for large enough m. On the other hand, the proof of Lemma 2.3 above shows that $\lambda_m < 1$ implies $\lambda_n \leqq C^{1/n}\lambda_m$ for all $n \in \mathbb{N}$, which leads to $\hat{\rho}(\mathbf{T}_0|_{E_1}, \mathbf{T}_1|_{E_1}) < 1$. $\square$

Note that if $\hat{\rho}(\mathbf{T}_0|_{E_1}, \mathbf{T}_1|_{E_1}) = \lambda_0 < 1$, then (2.11) holds for all $\lambda > \lambda_0$, but not necessarily for $\lambda = \lambda_0$.

Remarks. (1) As noted before, the sum rule $\sum c_{2n} = \sum c_{2n+1}$ is not necessary for a continuous solution to exist. An example is the continuous function $f(x) = x/2$ for $0 \leqq x \leqq 2$, $2 - x/2$ for $2 \leqq x \leqq 4$, zero otherwise, which satisfies $f(x) = \frac{1}{2}f(2x) + f(2x-2) + \frac{1}{2}f(2x-4)$, with $\sum c_{2n} = 2$, $\sum c_{2n+1} = 0$. This example has been obtained by "stretching" an equation that does satisfy (2.1): the function $\tilde{f}(x) = f(2x)$ satisfies

$$\tilde{f}(x) = \tfrac{1}{2}\tilde{f}(2x) + \tilde{f}(2x-1) + \tfrac{1}{2}\tilde{f}(2x-2).$$

Consequently, the matrices $\mathbf{T}_0, \mathbf{T}_1$ still have many interesting properties in this case, even though they do not have a common left eigenvector for the eigenvalue 1.

(2) By the same argument as in the remark following Theorem 2.3, we necessarily have $\lambda_m \geqq \frac{1}{2}$ for any choice of $m \in \mathbb{N}$, where λ_m is as defined by (2.14).

(3) For any matrix $\mathbf{T}$ the spectral radius $\rho(\mathbf{T})$,

$$\rho(\mathbf{T}) = \max\{|\mu|;\ \mu \text{ eigenvalue of } \mathbf{T}\},$$

is given by

$$\rho(\mathbf{T}) = \lim_{l\to\infty} \|\mathbf{T}^l\|^{1/l} = \inf_l \|\mathbf{T}^l\|^{1/l}.$$

If we restrict the choices $d_1, \cdots, d_m$ in (2.11) to either all zero or all 1, it follows, therefore, that

$$\rho(\mathbf{T}_0|_{E_1}),\ \rho(\mathbf{T}_1|_{E_1}) \leqq \lambda, \tag{2.17}$$

i.e., all the other eigenvalues of $\mathbf{T}_0, \mathbf{T}_1$ (excluding 1) have absolute value smaller than $\lambda < 1$. The condition $\rho(\mathbf{T}_0|_{E1}), \rho(\mathbf{T}_1|_{E_1}) < 1$ is, however, not sufficient to ensure that (2.11) holds. An example is given by

$$N = 3; \quad c_0 = -.75, \quad c_1 = .2,$$
$$c_2 = 1.75, \quad c_3 = .8.$$

In this case the spectra of $\mathbf{T}_0, \mathbf{T}_1$ are $\{1, -.75, .95\}$ and $\{1, .8, .95\}$, respectively. We have, therefore, $\rho(\mathbf{T}_0|_{E_1}) = \rho(\mathbf{T}_1|_{E_1}) = .95$. On the other hand, the spectrum of $\mathbf{T}_0, \mathbf{T}_1$ is $\{1, .50976\cdots, -1.06226\cdots\}$, implying that $\lambda_m \geqq (1.06226\cdots)^{1/2} > 1$ for any m.

(4) Because of the special structure (2.8) of $\mathbf{T}_0, \mathbf{T}_1$, it can easily be shown that

$$\text{spectrum}\,(\mathbf{T}_0) = \{c_0\} \cup \text{spectrum}\,(\mathbf{M}),$$

$$\text{spectrum}\,(\mathbf{T}_1) = \{c_N\} \cup \text{spectrum}\,(\mathbf{M}).$$

In order for (2.11) to be satisfied, it is therefore necessary that $|c_0|, |c_N| \leqq 1$.

(5) At the end of Deslauriers and Dubuc (1989), which mainly concerns the solutions of an equation of type (1.2) corresponding to a symmetric Lagrangian interpolation scheme, a conjecture is presented concerning generalizations to other, non-Lagrangian, interpolation schemes. Translated in our present terminology, this conjecture reads as follows.

CONJECTURE 2.5. *Assume that* $\sum_n c_{2n} = \sum_n c_{2n+1} = 1$. *Define the bounded operator* $\mathbf{A}$ *on* $l^2(\mathbb{Z})$ *by* $(\mathbf{A}a)_j = \sum_l c_{2j-l}a_l$. *Then there exists a continuous nontrivial solution to* (1.2) *if* 1 *is a nondegenerate eigenvalue of* $\mathbf{A}$ *and if all the other eigenvalues of* $\mathbf{A}$ *have modulus strictly smaller than* 1.

The operator $\mathbf{A}$ does have a rather bothersome spectrum, however; we find that all the complex numbers with modulus strictly smaller than 1 are in the point spectrum of $\mathbf{A}$. For the simple case $c_0 = 1$, $c_1 = c_{-1} = \frac{1}{2}$, $c_n = 0$ for $|n| > 1$, e.g., and $\lambda \in \mathbb{C}$, $|\lambda| < 1$, the sequence a^λ defined by

$$a^\lambda_{-n} = 0, \qquad n \in \mathbb{N}$$

$$a^\lambda_1 = 0, \quad a^\lambda_2 = 1, \quad a^\lambda_{3\cdot 2^m} = -2\lambda^m, \quad a^\lambda_{4\cdot 2^m} = \lambda^m(\lambda+1),$$

$$a^\lambda_n = 0 \quad \text{if } n \geqq 5, \qquad n \neq 3 \cdot 2^m \quad \text{or} \quad 4 \cdot 2^m$$

is clearly in $l^2(\mathbb{Z})$, and satisfies $\mathbf{A}a^\lambda = \lambda a^\lambda$. It follows that the closed unit disk is part of the spectrum of $\mathbf{A}$. In practice, it may be very hard to decide whether 1 is the only element on the unit circle that is not only in the spectrum of $\mathbf{A}$, but also a true eigenvalue of $\mathbf{A}$. For this reason, this conjecture, even if true, does not seem to give an easily checkable criterion for a given set of c_n to lead to a continuous solution of (1.2).

We can prove a result analogous to Conjecture 2.5. Define, for any two matrices $\mathbf{S}_0, \mathbf{S}_1$, their "generalized spectral radius" by Daubechies and Lagarias (1991)

$$\rho(\mathbf{S}_1, \mathbf{S}_2) = \limsup_{n\to\infty} [\max_{\substack{d_j = 0, \text{or } 1 \\ j = 1, \cdots, n}} \rho(\mathbf{S}_{d_1} \cdots \mathbf{S}_{d_n})^{1/n}],$$

where $\rho(\mathbf{S})$ denotes the usual spectral radius. Berger and Wang (1991) prove that

$$\rho(\mathbf{S}_1, \mathbf{S}_2) = \hat{\rho}(\mathbf{S}_1, \mathbf{S}_2).$$

Consequently Theorem 2.2. and Lemma 2.4 give the following.

THEOREM 2.6. *Assume that the* c_n, $n = 0, \cdots, N$ *satisfy* $\sum c_{2n} = 1 = \sum c_{2n+1}$. *Then there exists a continuous nontrivial solution to* (1.2) *if* $\rho(\mathbf{T}_0|_{E_1}, \mathbf{T}_1|_{E_1}) < 1$.

It would be of interest to determine necessary and sufficient conditions on $\{c_n\}$ for the existence of a continuous solution to (2.1) having $\sum c_{2n} = 1 = \sum c_{2n+1}$.

(6) The same analysis can be done for two-scale difference equations having larger (integer) values of k. In general, there will then be k different $(N_0+1) \times (N_0+1)$-matrices $\mathbf{T}_0, \cdots, \mathbf{T}_{k-1}$, where N_0 is the largest integer strictly smaller than $N/(k-1)$. Instead of binary expansions of $x \in [0, 1]$, we take the expansion of x in base k. Otherwise, the proofs carry over without change.

3. Higher-order regularity. If L additional "sum rules" of the type (2.1) are satisfied, then techniques similar to those that proved continuity and Hölder continuity in the preceding section can be used to show that $f \in C^l$, with $l > 1$. The enlarged set of "sum rules" is

$$(3.1)\qquad \sum_{n=0}^{N} (-1)^n n^l c_n = 0 \quad \text{for } l = 0, 1, \cdots L;$$

this is equivalent to requiring that $p(\xi) = \frac{1}{2}\sum_{n=0}^{N} c_n\, e^{in\xi}$ is divisible by $(1+e^{i\xi})^{L+1}$. For $L = 0$, (3.1) reduces to (2.1). We define the vectors $\mathbf{u}_j \in \mathbb{R}^n, j = 1, \cdots, L+1$, by

$$(3.2)\qquad (\mathbf{u}_j)_k = k^{j-1}, \qquad k = 1, \cdots, N.$$

The vector $\mathbf{u}_1$ is a common left eigenvector of $\mathbf{T}_0, \mathbf{T}_1$, with eigenvalue 1. Similarly the $\mathbf{u}_j$ lead us to left eigenvectors of $\mathbf{T}_0$ and $\mathbf{T}_1$ with eigenvalue 2^{-j+1} (see below). This spectral analysis of $\mathbf{T}_0, \mathbf{T}_1$ can then be used to prove the following generalization of Theorem 2.2.

THEOREM 3.1. *Assume that the* c_n, $n = 0, \cdots, N$, *satisfy* $\sum_{n=0}^{N} c_n = 2$ *and*

$$\sum_{n=0}^{N} (-1)^n n^l c_n = 0 \quad \text{for } l = 0, 1, \cdots, L.$$

For every $m = 1, \cdots, L+1$, *define* E_m *to be the subspace of* $\mathbb{R}^N$ *orthogonal to* $U_m = \operatorname{Span}\{\mathbf{u}_1, \cdots, \mathbf{u}_m\}$ *where* $\mathbf{u}_j = (1^{j-1}, 2^{j-1}, \cdots, N^{j-1})$. *Assume that there exist* $\frac{1}{2} \leqq \lambda < 1$, $0 \leqq l \leqq L (l \in \mathbb{N})$ *and* $C > 0$ *such that, for all binary sequences* $(d_j)_{j \in \mathbb{N}}$, *and all* $m \in \mathbb{N}$,

$$(3.3)\qquad \|\mathbf{T}_{d_1} \cdots \mathbf{T}_{d_m}|_{E_{L+1}}\| \leqq C\lambda^m 2^{-ml}.$$

Then

(1) *There exists a nontrivial continuous* L^1*-solution f for the two-scale equation* (1.2) *associated with the* c_n;

(2) *This solution f is l times continuously differentiable*;

(3) *If* $\lambda > \frac{1}{2}$, *then the lth derivative* $f^{(l)}$ *of f is Hölder continuous, with exponent at least* $|\ln \lambda|/\ln 2$; *if* $\lambda = \frac{1}{2}$, *then the lth derivative* $f^{(l)}$ *of f is almost Lipschitz*: *it satisfies*

$$|f^{(l)}(x+t) - f^{(l)}(t)| \leqq C|t||\ln|t||.$$

Remarks. (1) The restriction $\lambda \leqq \frac{1}{2}$ means only that we pick the largest possible integer $l \leqq L$ for which (3.3) holds with $\lambda < 1$. If $l = L$, then we shall see below that necessarily $\lambda \geqq \frac{1}{2}$; if $l < L$ and $\lambda < \frac{1}{2}$, then we could replace l by $l+1$ and λ by 2λ, and (3.3) would hold for a larger integer l.

(2) The formulation of Theorem 3.1 implicitly assumes that $L+1 < N$. If $L+1 = N$, then $U_{L+1} = \mathbb{R}^N$, $E_{L+1} = \{0\}$, and condition (3.3) becomes meaningless. In the case $L+1 = N$, the $(N+1)$ coefficients c_n are completely determined by the N "sum rules" (3.1) and the requirement $\sum_{n=0}^{N} c_n = 2$. The characteristic determinant of the resulting system of $N+1$ linear equations is different from zero (it can be written as a positive linear combination of positive Vandermonde determinants); the unique solution to the system is $c_n = 2^{-N+1}\binom{N}{n}$, $n = 0, \cdots, N$. For $N = 2$, e.g., we find $c_0 = \frac{1}{2}$, $c_1 = 1$, $c_2 = \frac{1}{2}$. The corresponding function $f(x)$ is given by

$$f(x) = \begin{cases} x & 0 \leqq x \leqq 1, \\ 2-x & 1 \leqq x \leqq 2. \end{cases}$$

This function is Lipschitz but not C^1. This is typical of what happens for larger values of N, when $L+1 = N$: the corresponding function f is the B-spline function of degree L, which is C^{L-1}, and its $(L-1)$-th derivative is Lipschitz, but not everywhere differentiable. The points where $f^{(L-1)}$ fails to be differentiable are $0, 1, \cdots$, N, where the left and right Lth derivatives of f do not coincide. In most of what follows we shall implicitly assume $L+1<N$.

To prove Theorem 3.1, we shall need several technical lemmas. The first one shows how the $\mathbf{u}_j$ are related to left eigenvectors of $\mathbf{T}_0, \mathbf{T}_1$ with eigenvalue 2^{-j+1}.

LEMMA 3.2. *Assume that* (3.1) *holds. Let* $\mathbf{T}_0, \mathbf{T}_1$ *be defined as in* (2.8), $\mathbf{u}_j, j=1, \cdots, L+1$ *as in* (3.2). *Define* $U_j =$ *Linear span* $\{\mathbf{u}_1, \cdots, \mathbf{u}_j\}$, $j=1, \cdots, L+1$. *For all* $j=1, \cdots, L+1, 2^{-j}$ *is an eigenvalue of both* $\mathbf{T}_0, \mathbf{T}_1$. *The corresponding left eigenvectors, denoted by* $\mathbf{e}_j^0, \mathbf{e}_j^1$ *respectively, are both in* U_j. *We fix their normalization by requiring that* $\mathbf{e}_j^0-\mathbf{u}_j$, $\mathbf{e}_j^1-\mathbf{u}_j \in U_{j-1}$. *Then*

$$\mathbf{e}_j^0=\sum_{k=1}^{j}(-1)^{j-k}\binom{j-1}{k-1}\mathbf{e}_k^1 \tag{3.4}$$

or, equivalently,

$$\mathbf{e}_j^1=\sum_{k=1}^{j}\binom{j-1}{k-1}\mathbf{e}_k^0. \tag{3.5}$$

Proof. (1) Define, for $k=0, \cdots, L$,

$$C_k=\sum_n (2n)^k c_{2n}=\sum_n (2n+1)^k c_{2n+1}.$$

We then easily check from the definitions (2.8), (3.2) of $\mathbf{T}_0, \mathbf{T}_1$, and the $\mathbf{u}_j$ that

$$\mathbf{u}_j\cdot \mathbf{T}_1=2^{-j+1}\sum_{n=1}^{j}\binom{j-1}{n-1}C_{j-n}\mathbf{u}_n,$$

$$\mathbf{u}_j\cdot \mathbf{T}_0=2^{-j+1}\sum_{n=1}^{j}\binom{j-1}{n-1}\sum_{l=0}^{j-n}\binom{j-n}{l}C_l\mathbf{u}_n,$$

for $j=1, \cdots, L+1$. It follows that, for every j, $1 \leqq j \leqq L+1$, there are left eigenvectors for both $\mathbf{T}_0, \mathbf{T}_1$, with eigenvalue 2^{-j+1}, in the linear span U_j of $\{\mathbf{u}_1, \mathbf{u}_2, \cdots, \mathbf{u}_j\}$. We denote these eigenvectors by $\mathbf{e}_j^0, \mathbf{e}_j^1$, respectively. Then

$$\mathbf{e}_j^0=\sum_{n=1}^{j}a_{j,n}\mathbf{u}_n, \qquad \mathbf{e}_j^1=\sum_{n=1}^{j}b_{j,n}\mathbf{u}_n, \tag{3.6}$$

where we take $a_{j,j}=1=b_{j,j}$.

(2) From (3.6) and $\mathbf{e}_j^0\cdot \mathbf{T}_0=2^{-j+1}\mathbf{e}_j^0$, $\mathbf{e}_j^1\cdot \mathbf{T}_1=2^{-j+1}\mathbf{e}_j^1$, we derive

$$\begin{aligned} b_{j,n}&=\sum_{j=n}^{j}2^{j-j}\binom{k-1}{n-1}C_{k-n}b_{j,k},\\ a_{j,n}&=\sum_{k=m}^{j}\sum_{i=0}^{k-m}\binom{k-1}{m-1}\left(\frac{k-m}{i}\right)C_i2^{j-k}a_{j,k}. \end{aligned} \tag{3.7}$$

These equations determine $a_{j,n}, b_{j,n}$ recursively, starting from $a_{j,j}, b_{j,j}$. From (3.7) it follows that

$$a_{j,n}=\frac{(j-1)!}{(n-1)!}\alpha_{j-n}, \qquad b_{j,n}=\frac{(j-1)!}{(n-1)!}\beta_{j-n},$$

where $\alpha_0=1=\beta_0$, and the α_k, β_k satisfy the recursions

$$\beta_k=\sum_{i=0}^{k}\frac{1}{(k-i)!}C_{k-i}2^i\beta_i \tag{3.8a}$$

$$\alpha_k=\sum_{i=0}^{k}\sum_{n=i}^{k}2^i\frac{1}{(k-n)!(n-i)!}C_{k-n}\alpha_i \tag{3.8b}$$

(3) Together with $\alpha_0=1=\beta_0$, the recursions (3.8) imply that

$$\alpha_k=\sum_{i=0}^{k}(-1)^i\frac{1}{i!}\beta_{k-i} \tag{3.9}$$

or, equivalently,

$$\beta_k=\sum_{i=0}^{k}\frac{1}{i!}\alpha_{k-i}.$$

One way of checking this is to verify that if the β_i satisfy (3.8a), then the right-hand side of (3.9) satisfies (3.8b). It follows that

$$a_{j,n}=\sum_{k=n}^{j}\binom{j-1}{k-1}(-1)^{j-k}b_{k,n}.$$

This implies (3.4) and (3.5). □

Instead of the piecewise linear splines in § 2, here we shall use piecewise polynomial splines of degree $2l+1$, where l is the same as in (3.3). We shall determine the initial spline function f_0 for the iteration by fixing the values of $f_0^{(k)}(m)$, $0\leqq n\leqq N$, $0\leqq k\leqq l$. They will be defined in terms of the right eigenvectors of $\mathbf{T}_0, \mathbf{T}_1$ for the eigenvalues 1, $\frac{1}{2}, \cdots, 2^{-1}$. We first show that these eigenvalues are all simple.

LEMMA 3.3. *Assume that* (3.1) *and* (3.3) *hold. Then the* $l+1$ *eigenvalues* $1, \frac{1}{2}, \cdots, 2^{-l}$ *of* $\mathbf{T}_0, \mathbf{T}_1$ *are all simple.*

Proof. Since the e_j^0, $h=1,\cdots,L+1$, are left eigenvectors of $\mathbf{T}_0$ with eigenvalue 2^{-j+1}, there exists an appropriate basis transformation $\mathbf{B}$ such that $\mathbf{B}\mathbf{T}_0\mathbf{B}^{-1}$ has the form

$$\left(\begin{array}{cccc|ccc}
1 & 0 & \cdots & 0 & 0 & \cdots & 0\\
0 & \frac{1}{2} & & \vdots & \vdots & & \vdots\\
\vdots & & & 0 & \cdot & & \cdot\\
0 & \cdots & 0 & 2^{-L} & 0 & \cdots & 0\\
 & & \mathbf{A} & & & \mathbf{C} &
\end{array}\right),$$

where $\mathbf{A}$, $\mathbf{C}$ are $(N-L-1)\times(L+1)$- and $(N-L-1)\times(N-L-1)$-dimensional matrices, respectively. The roots of the characteristic equation for $\mathbf{T}_0$ are, therefore, $1, \frac{1}{2}, \cdots, 2^{-L}$ together with the roots of the characteristic equation for $\mathbf{C}$. It is easily checked that $\mathbf{C}=\mathbf{B}|_{E_{L+1}}\mathbf{T}_0|_{E_{L+1}}\mathbf{B}^{-1}|_{\mathbf{B}E_{L+1}}$; the spectral radius $\rho(\mathbf{C})$ of $\mathbf{C}$ can, therefore, be bounded by

$$\begin{aligned}
\rho(\mathbf{C})&=\limsup_{k\to\infty}\|\mathbf{C}^k\|^{1/k}\\
&\leqq\limsup_{k\to\infty}\left[\|\mathbf{B}\|_{E_{L+1}}\|\,\|\mathbf{T}_0^k|_{E_{L+1}}\|\,\|\mathbf{B}^{-1}|_{\mathbf{B}E_{L+1}}\|\right]^{1/k}\\
&\leqq\limsup_{k\to\infty}\left[\|\mathbf{B}|_{E_{L+1}}\|\,\|\mathbf{B}^{-1}|_{\mathbf{B}E_{L+1}}\|C\lambda^k2^{-lk}\right]^{1/k}\\
&=\lambda 2^{-l}<2^{-l}.
\end{aligned}$$

It follows that the eigenvalues $1, \frac{1}{2}, \cdots, 2^{-l}$ of $\mathbf{T}_0$ are also simple. A similar argument applies to $\mathbf{T}_1$. □

Since the eigenvalues $1, \frac{1}{2}, \cdots, 2^{-l}$ of $\mathbf{T}_0$ are also simple, it makes sense to introduce the corresponding right eigenvectors $\tilde{\mathbf{e}}_k^0$, $1\leqq k\leqq l+1$, which are uniquely determined, up to normalization. We fix their normalization by requiring

$$\mathbf{e}_k^0\cdot\tilde{\mathbf{e}}_{k'}^0=\delta_{kk'},\qquad 1\leqq k, k'\leqq l+1.$$

We similarly define right eigenvectors $\tilde{\mathbf{e}}_k^1$ of $\mathbf{T}_1$ corresponding to the eigenvalues $1, \frac{1}{2}, \cdots, 2^{-l}$, with normalization determined by

$$\mathbf{e}_k^1 \cdot \mathbf{e}_{k'}^1 = \delta_{kk'}, \qquad 1 \leqq k, k' \leqq l+1.$$

We now define the piecewise polynomial spline for f_0 of degree $2l+1$ by

$$f_0^{(k)}(n) = \begin{cases} (-1)^k k!(\tilde{\mathbf{e}}_{k+1}^0)_{n+1}, & k=0, \cdots, l, \\ & n=0, \cdots, N-1, \\ 0, & k=0, \cdots, l, \\ & n=N. \end{cases} \tag{3.10}$$

Remark. Because $(\mathbf{T}_0)_{in} = c_0 \delta_{n1}$, the vector $(1, 0, \cdots, 0)$ is a left eigenvector of $\mathbf{T}_0$ with eigenvalue c_0. It follows that $c_0 \notin \{1, \frac{1}{2}, \cdots, 2^{-l}\}$, since $c_0 = 2^{-k}$, $0 \leqq k \leqq l$ would imply the existence of two linearly independent left eigenvectors for 2^{-k}. Consequently, $(\tilde{\mathbf{e}}_{k+1}^0)_1 = (1, 0, \cdots, 0) \cdot \tilde{\mathbf{e}}_{k+1}^0 = 0$ for $0 \leqq k \leqq l$. (We can prove completely analogously that the right eigenvectors $\tilde{\mathbf{e}}_k^1$ of $\mathbf{T}_1$ satisfy $(\tilde{\mathbf{e}}_{k+1}^1)_N = 0$ for $k = 1, \cdots, l$.) For $n = 0$, (3.10), therefore, specializes to

$$f_0^{(k)}(0) = 0, \qquad k = 0, \cdots, l,$$

so that, despite appearances, there is complete symmetry between the constraints at zero and at N, the two ends of the support of f_0.

As in § 2, we again use the "folding" process that associates to a function g: $\mathbb{R} \to \mathbb{R}$, with support $[0, N]$, the vector valued function $\mathbf{w}$, $[0, 1] \to \mathbb{R}^N$ by means of

$$[\mathbf{w}(x)]_n = g(x+n-1), \qquad x \in [0, 1], \quad n = 1, \cdots, N.$$

The function g is l times continuously differentiable if and only if $\mathbf{w}$ is l times continuously differentiable on $[0, 1]$,

$$[\mathbf{w}^{(k)}(0)]_n = [\mathbf{w}^{(k)}(1)]_{n-1}, \qquad 2 \leqq n \leqq N, 0 \leqq k \leqq l, \tag{3.11}$$

$$[w^{(k)}(0)]_1 = 0 = [\mathbf{w}^{(k)}(1)]_N, \qquad 0 \leqq k \leqq l. \tag{3.12}$$

"Folding" f_0 leads to the vector valued function $\mathbf{v}_0$: $[0, 1] \to \mathbb{R}^N$, each component of which is a polynomial of degree $2l+1$; $\mathbf{v}_0$ satisfies (3.11) and (3.12). In particular, for $n = 2, \cdots, N$, $k = 0, \cdots, l$,

$$\begin{aligned} &[\mathbf{v}_0^{(k)}(0)]_n = [\mathbf{v}_0^{(k)}(1)]_{n-1} = (-1)^k k! [\tilde{\mathbf{e}}_{k+1}^0]_n, \\ &[\mathbf{v}_0^{(k)}(0)]_n = [\mathbf{v}_0^{(k)}(1)]_N = 0. \end{aligned} \tag{3.13}$$

Iterating the linear operator V defined by (2.3) on f_0 leads to a sequence f_j of piecewise polynomial splines of degree $2l+1$ and finer knot sets; their "folded" versions $\mathbf{v}_j$ can also be written as

$$\mathbf{v}_j = \mathbf{V}^j \mathbf{v}_0 \quad \text{or} \quad \mathbf{v}_j(x) = \mathbf{T}_{d_1(x)} \mathbf{T}_{d_2(x)} \cdots \mathbf{T}_{d_j(x)} \mathbf{v}_0(\tau^j x)$$

(see § 2). We now have the following lemma.

LEMMA 3.4. *For every $j \in \mathbb{N}$ and $0 \leqq k \leqq \min(2l+1, L)$,*

$$\mathbf{e}_{k+1}^0 \cdot \mathbf{v}_j(x) = (-1)^k x^k. \tag{3.14}$$

Proof. (1) We start by proving the assertion for $j=0$. By the construction of $\mathbf{v}_0$, $\mathbf{e}_k^0 \cdot \mathbf{v}_0(x) = P_k(x)$ is a polynomial on $[0,1]$ of degree $2l+1$. It is completely determined by the values of the $P_k^{(m)}(0)$, $P_k^{(m)}(1)$, $0 \leqq m \leqq l$. It, therefore, suffices to prove

$$P_k^{(m)}(0) = (-1)^k k!\,\delta_{km}, \tag{3.15}$$

$$P_k^{(m)}(1) = \begin{cases} (-1)^k \dfrac{k!}{(k-m)!} & \text{if } m \leqq k, \\ 0 & \text{if } m > k. \end{cases} \tag{3.16}$$

We have (use (3.13))

$$\begin{aligned} P_k^{(m)}(0) &= \mathbf{e}_{k+1}^0 \cdot \mathbf{v}_0^{(m)}(0) = (-1)^m m!\,\mathbf{e}_{k+1}^0 \cdot \tilde{\mathbf{e}}_{m+1}^0 \\ &= (-1)^k k!\,\delta_{km}, \end{aligned}$$

which proves (3.15), and

$$P_k^{(m)}(1) = \mathbf{e}_{k+1}^0 \cdot \mathbf{v}_0^{(m)}(1) = (-1)^m m! \sum_{n=1}^{N-1} (\mathbf{e}_{k+1}^0)_n (\tilde{\mathbf{e}}_{m+1}^0)_{n+1}. \tag{3.17}$$

Due to the special structure of $\mathbf{T}_0, \mathbf{T}_1$, we have

$$(\tilde{\mathbf{e}}_{m+1}^0)_{n+1} = (\tilde{\mathbf{e}}_{m+1}^1)_n.$$

Since $(\tilde{\mathbf{e}}_{m+1}^1)_N = 0$ (see the remark after (3.10)), (3.17) reduces to

$$P_k^{(m)}(1) = (-1)^m m!\mathbf{e}_{k+1}^0 \cdot \tilde{\mathbf{e}}_{m+1}^1,$$

which can be computed with the help of Lemma 3.2:

$$\begin{aligned} \mathbf{e}_{k+1}^0 \cdot \tilde{\mathbf{e}}_{m+1}^1 &= \sum_{r=0}^{k} (-1)^{k-r} \binom{k}{r} \mathbf{e}_{r+1}^1 \cdot \tilde{\mathbf{e}}_{m+1}^1 \\ &= \sum_{r=0}^{k} (-1)^{k-r} \binom{k}{r} \delta_{rm} \\ &= \begin{cases} 0 & \text{if } k < m, \\ (-1)^{k-m} \dbinom{k}{m} & \text{if } k \geqq m. \end{cases} \end{aligned}$$

Hence

$$P_k^{(m)}(1) = \begin{cases} (-1)^k \dfrac{k!}{(k-m)!} & \text{if } k \geqq m \\ 0 & \text{if } k < m, \end{cases}$$

which proves (3.16) and establishes (3.14) for $j=0$.

(2) For higher values of j we proceed by induction. Suppose (3.14) holds for $\mathbf{v}_j$. Then

$$\mathbf{e}_{k+1}^0 \cdot \mathbf{v}_{j+1}(x) = \mathbf{e}_{k+1}^0 \cdot \mathbf{T}_{d_1(x)} \mathbf{v}_j(\tau x). \tag{3.18}$$

If $x \leqq \frac{1}{2}$, then $d_1(x) = 0$ and (3.18) becomes

$$\begin{aligned} \mathbf{e}_{k+1}^0 \cdot \mathbf{v}_{j+1}(x) &= 2^{-k} \mathbf{e}_{k+1}^0 \cdot \mathbf{v}_j(2x) \\ &= 2^{-k}(-1)^k (2x)^k = (-1)^k x^k, \end{aligned}$$

which is (3.14) again for index $j+1$. If $x>\frac{1}{2}$, then we use Lemma 3.2 again:

$$\begin{aligned}\mathbf{e}^0_{k+1}\cdot\mathbf{v}_{j+1}(x)&=\sum_{r=0}^{k}(-1)^{k-r}\binom{k}{r}\mathbf{e}^1_{r+1}\cdot\mathbf{T}_1\mathbf{v}_j(2x-1)\\&=\sum_{r=0}^{k}(-1)^{k-r}\binom{k}{r}2^{-r}\sum_{s=0}^{r}\binom{r}{s}\mathbf{e}^0_{s+1}\cdot\mathbf{v}_j(2x-1)\\&=\sum_{s=0}^{k}(2x-1)^2\binom{k}{s}(-1)^2 2^{-s}\sum_{t=10}^{k-s}\binom{k-s}{t}(-1)^{k-s-t}2^{-t}\\&=(-2)^{-k}\sum_{s=0}^{k}\binom{k}{s}(2x-1)^s\\&=(-2)^{-k}(2x)^k=(-1)^k x^k,\end{aligned}$$

which is again (3.14). This proves the lemma. □

We need one more technical lemma before we attack the proof of Theorem 3.1.

LEMMA 3.5. *Assume that* (3.1) *and* (3.3) *hold. If* $\lambda>\frac{1}{2}$, *then there exists* $C>0$ *so that, for all binary sequences* $(d_j)_{j\in\mathbb{N}}$, *all* $m\in\mathbb{N}$, *and all* k *with* $l\leqq k\leqq L$,

$$\|\mathbf{T}_{d_1}\cdots\mathbf{T}_{d_m}|_{E_{k+1}}\|\leqq C\lambda^m 2^{-ml}. \tag{3.19}$$

If $\lambda=\frac{1}{2}$, *then* (3.19) *still holds for* $l+1\leqq k\leqq L$; *for* $k=l$, (3.19) *is replaced by the slightly weaker bound*

$$\|\mathbf{T}_{d_1}\cdots\mathbf{T}_{d_m}|_{E_{l+1}}\|\leqq Cm2^{-m(l+1)}. \tag{3.19$'$}$$

Note that we implicitly assume $l<L$; if $l=L$, then the lemma is trivial.

Proof. (1) We prove (3.19) by induction, working from high to low values of k. For $k=L$, (3.19) is (3.3), and we have nothing to prove.

(2) Because of the existence of the left eigenvectors $e^0_m, e^1_m, 1\leqq m\leqq L+1$ for $\mathbf{T}_0,\mathbf{T}_1$, with eigenvalues $1,\frac{1}{2},\cdots 2^{-L}$, and the relationships (3.4) and (3.5) between these eigenvectors, there exists an appropriate basis transformation $\mathbf{B}$ so that $(\mathbf{B}^{-1,t}\mathbf{e}^0_m)_r=\delta_{mr}$, and $\mathbf{B}E_m=\{\mathbf{w};\mathbf{w}_r=0 \text{ for } r\leqq m\}$. The matrices $\mathbf{B}\mathbf{T}_0\mathbf{B}^{-1}, \mathbf{B}\mathbf{T}_1\mathbf{B}^{-1}$ have the form

$$\mathbf{B}\mathbf{T}_0\mathbf{B}^{-1}=\left(\begin{array}{ccccc|c}1&0&\cdots&&0&\\0&\frac{1}{2}&&&\vdots&\\\vdots&\vdots&&&0&0\\0&0&\cdots&0&2^{-L}&\\\hline&&\mathbf{C}_0&&&\mathbf{A}_0\end{array}\right), \tag{3.20}$$

$$\mathbf{B}\mathbf{T}_1\mathbf{B}^{-1}=\left(\begin{array}{cccc|c}1&0&\cdots&0&\\t_{2,1}&\frac{1}{2}&&\vdots&\\\vdots&&&0&0\\t_{L+1,1}&\cdots&t_{L+1,L}&2^{-L}&\\\hline&&\mathbf{C}_1&&\mathbf{A}_1\end{array}\right). \tag{3.21}$$

The matrices $\mathbf{B}|_{E_{k+1}}\mathbf{T}_d|_{E_{k+1}}\mathbf{B}^{-1}|_{\mathbf{B}E_{k+1}}$ are then obtained by deleting the first $k+1$ rows and columns of (3.20), (3.21). Let us denote these $(N-k-1)\times(N-k-1)$-dimensional matrices by $\mathbf{S}^k_d$. It then follows that, for $l\leqq k\leqq L-1$

$$\mathbf{S}^k_d=\left(\begin{array}{c|c}2^{-k-1}&0\ \cdots\ 0\\\hline\mathbf{C}^k_d&\mathbf{S}^{k+1}_d\end{array}\right) \tag{3.22}$$

where $\mathbf{C}^k_0$, $\mathbf{C}^k_1$ are $(N-k-2)$-dimensional column vectors.

(3) Let us now assume that (3.19) holds for index $k+1 \geqq l+1$. Then

$$\begin{aligned}\|\mathbf{S}_{d_1}^{k+1} \cdots \mathbf{S}_{d_m}^{k+1}\| &\leqq \|\mathbf{B}|_{E_{k+2}}\| \, \|\mathbf{T}_{d_1} \cdots \mathbf{T}_{d_m}|_{E_{k+2}}\| \, \|\mathbf{B}^{-1}|_{\mathbf{B}E_{k+2}}\| \\ &\leqq C\|\mathbf{B}^{-1}\| \, \|\mathbf{B}\|\lambda^m 2^{-ml} \leqq C_{k+1}\lambda^m 2^{-ml}.\end{aligned}$$

From (3.22) it follows that

$$\text{(3.23)} \quad \mathbf{S}_{d_1}^k \cdots \mathbf{S}_{d_m}^k = \left(\begin{array}{c|c} 2^{-(k+1)m} & 0 \quad 0 \quad \cdots \quad 0 \\ \hline \sum\limits_{r=1}^{m} 2^{-(k+1)(m-r)}\mathbf{S}_{d_1}^{k+1} \quad \cdots \quad \mathbf{S}_{d_{r-1}}^{k+1}\mathbf{C}_{d_r}^k & \mathbf{S}_{d_1}^{k+1} \cdots \mathbf{S}_{d_m}^{k+1} \end{array}\right),$$

where

$$\begin{aligned}&\left\| \sum_{r=1}^{m} 2^{-(k+1)(m-r)}\mathbf{S}_{d_1}^{k+1} \cdots \mathbf{S}_{d_{r-1}}^{k-1}\mathbf{C}_{d_r}^k \right\| \\ &\quad \leqq C_{k+1} \sum_{r=1}^{m} 2^{-(k+1)(m-r)}(\lambda 2^{-l})^{r-1} \cdot \max(\|\mathbf{C}_0^k\|, \|\mathbf{C}_1^k\|) \\ &\quad \leqq C' 2^{-(k+1)(m-1)} \frac{(\lambda 2^{k+1-l})^m - 1}{\lambda 2^{k+1-l} - 1} \\ &\quad \leqq C''\lambda^m 2^{-lm},\end{aligned}$$

where we have assumed that $\lambda 2^{k+1-l} > 1$, i.e., $k \geqq l+1$ or $\lambda > \frac{1}{2}$. We come back below to the case $k = l+1$, $\lambda = \frac{1}{2}$.

It follows that the three pieces in (3.23) are all bounded by $C'''\lambda^m 2^{-lm}$ (since $k \geqq l+1$ and $\lambda \geqq \frac{1}{2}$). There exists, therefore, C_k (independent of m or the d_j) so that

$$\|\mathbf{S}_{d_1}^k \cdots \mathbf{S}_{d_m}^k\| \leqq C_k \lambda^m 2^{-ml}.$$

This proves the induction step if $k \geqq l+1$ or $\lambda > \frac{1}{2}$.

(4) We now treat the case $k = l+1$, $\lambda = \frac{1}{2}$. In this case we find

$$\begin{aligned}\left\| \sum_{r=1}^{m} 2^{-k(m-r)}\mathbf{S}_{d_1}^{k+1} \cdots \mathbf{S}_{d_{r-1}}^{k+1}\mathbf{C}_{d_r}^k \right\| &\leqq C_{k+1} \sum_{r=1}^{m} 2^{-(l+1)(m-r)} 2^{-(l+1)(r-1)} \\ &= C_{k+1} 2^{-(l+1)(m-1)}(m-1).\end{aligned}$$

Therefore, the three pieces in (3.23) can all be bounded by $C' 2^{-(l+1)m} m$, which proves (3.19′). □

We are now ready to attack the proof of Theorem 3.1.

Proof of Theorem 3.1. (1) As a consequence of Lemma 3.4 we have, for $0 \leqq k \leqq l$, and all $j, j' \in \mathbb{N}$,

$$\mathbf{e}_{k+1}^0 \cdot [\mathbf{v}_j(x) - \mathbf{v}_{j'}(x)] = 0,$$

hence $\mathbf{v}_j(x) - \mathbf{v}_{j'}(x) \in E_{l+1}$ for all $x \in [0, 1]$, all $j, j' \in \mathbb{N}$.

(2) It follows that

$$\begin{aligned}\|\mathbf{v}_{j+1}(x) - \mathbf{v}_j(x)\| &= \|\mathbf{T}_{d_1(x)} \cdots \mathbf{T}_{d_j(x)}[\mathbf{v}_1(\tau^j x) - \mathbf{v}_0(\tau^j x)]\| \\ &\leqq C\gamma_\lambda(j)\lambda^j 2^{-lj} \sup_{y \in [0,1]} \|\mathbf{v}_1(y) - \mathbf{v}_0(y)\|,\end{aligned}$$

where

$$\gamma_\lambda(j) = \begin{cases} 1 & \text{if } \lambda > \frac{1}{2}, \\ j & \text{if } \lambda = \frac{1}{2}. \end{cases}$$

Consequently,

$$\begin{aligned}\|\mathbf{v}_j(x)\| &\leqq \|\mathbf{v}_0(x)\| + \sum_{r=0}^{j-1} \|\mathbf{v}_{r+1}(x) - \mathbf{v}_r(x)\| \\ &\leqq C\left[1 + \sum_{r=0}^{j-1} \gamma_\lambda(r)\lambda^r 2^{-lr}\right],\end{aligned}$$

which is bounded uniformly in j and x.

(3) We now use this uniform bound to prove that the $\mathbf{v}_j$ constitute a Cauchy sequence in L^∞. We have

$$\begin{aligned}\|\mathbf{v}_{j+r}(x) - \mathbf{v}_j(x)\| &= \|\mathbf{T}_{d_1(x)} \cdots \mathbf{T}_{d_j(x)}[\mathbf{v}_r(x) - \mathbf{v}_0(x)]\| \\ &\leqq C\gamma_\lambda(j)\lambda^j 2^{-lj},\end{aligned}$$

which can be made arbitrarily small by choosing j large enough, independent of r. The $\mathbf{v}_j$ tend, therefore, to a limit $\mathbf{v}$, which satisfies

$$\|\mathbf{v}(x) - \mathbf{v}_j(x)\| \leqq C\gamma_\lambda(j)\lambda^j 2^{-lj}. \tag{3.24}$$

(4) Since all the $\mathbf{v}_j$ satisfy

$$\begin{aligned}&[\mathbf{v}_j(0)]_{n+1} = [\mathbf{v}_j(1)]_n, \qquad 1 \leqq n \leqq N-1, \\ &[\mathbf{v}_j(0)]_1 = 0 = [\mathbf{v}_j(1)]_N,\end{aligned}$$

so does $\mathbf{v}$. It follows that $\mathbf{v}$ can be "unfolded" into a continuous function f, for which (3.24) translates into

$$\|f - f_j\|_{L^\infty} \leqq C\phi_\lambda(2^{-j}), \tag{3.25}$$

where $\phi_\lambda(t) = t^{l+\alpha}$ if $\lambda > \frac{1}{2}$, $\phi_\lambda(t) = |\log_2 t| t^{l+1}$ if $\lambda = \frac{1}{2}$, with $\alpha = |\ln \lambda|/\ln 2$.

(5) Formula (3.25) tells us again how well f can be approximated by piecewise polynomials, and this can be translated into smoothness estimates on f. This result is no doubt well-known to spline experts, but we could not find in the literature a full proof of the exact result we needed. For convenience's sake, we offer the following proof "from scratch."

Note first that, by Lemma 3.4,

$$\mathbf{e}^0_{k+1} \cdot \mathbf{v}_j^{(l)}(x) = \begin{cases} 0 & \text{if } k < l, \\ (-1)^l l! & \text{if } k = 1. \end{cases}$$

It follows that $\mathbf{v}_j^{(l)}(x) - \mathbf{v}_{j'}^{(l)}(x') \in E_{l+1}$ for all j, j', all x, x'. On the other hand, the recursive definition of the $\mathbf{v}_j$ leads to

$$\mathbf{c}_j^{(l)}(x) = 2^l \mathbf{T}_{d_1(x)} \mathbf{v}_{j-1}^{(l)}(\tau x).$$

Together, these two observations imply

$$\begin{aligned}\|\mathbf{v}_{j+1}^{(l)}(x) - \mathbf{v}_j^{(l)}(x)\| &= 2^{lj} \|\mathbf{T}_{d_1(x)} \cdots \mathbf{T}_{d_j(x)}[\mathbf{v}_1^{(l)}(\tau^j x) - \mathbf{v}_0^{(l)}(\tau^j x)]\| \\ &\leqq C\lambda^j \gamma_\lambda(j) \sup_{y \in [0,1]} [\|\mathbf{v}_1^{(l)}(y)\| + \|\mathbf{v}_0^{(l)}(y)\|],\end{aligned}$$

which can be used, similarly to the argument in (2) above, to prove that the $\mathbf{v}_j^{(l)}(x)$ are bounded uniformly in j and x, and that the $\mathbf{v}_j^{(l)}$ are a Cauchy sequence in L^∞. The limit of the $\mathbf{v}_j^{(l)}$ is necessarily the lth derivative of $\mathbf{v}$. Moreover,

$$\|\mathbf{v}^{(l)}(x) - \mathbf{v}_j^{(l)}(x)\| \leqq C\lambda^j \gamma_\lambda(j),$$

uniformly in x.

The remainder of our argument is similar to (7) in the proof of Theorem 2.3. Take $x \leqq y$ in $[0, N]$ so that $2^{-(j+1)} \leqq y - x \leqq 2^{-j}$ (a slight extension of the argument can be used on a neighborhood of $[0, N]$, so that the results are also true at zero and N). Then there exists $m \in \mathbb{N}$ so that either $(m-1)2^{-j} \leqq x \leqq y \leqq m2^{-j}$ or $(m-1)2^{-j} \leqq x \leqq m2^{-j} \leqq y \leqq (m+1)2^{-j}$. We discuss the second case; the first is similar. Then

$$|f^{(l)}(x) - f^{(l)}(y)| \leqq 2C\lambda^j \gamma_\lambda(j) + |f_j^{(l)}(x) - f_j^{(l)}(m2^{-j})| + |f_j^{(l)}(y) - f_j^{(l)}(m2^{-j})|,$$

by the bound on $\mathbf{v}^{(l)} - \mathbf{v}_j^{(l)}$. There exists n so that $x' = x - n$ and $m'2^{-j} = m2^{-j} - n$ are both in $[0, 1]$; moreover, we can choose binary expansions for x' and $m'2^{-j}$ with the same j first digits. Consequently,

$$\begin{aligned} |f_j^{(l)}(x) - f_j^{(l)}(m2^{-j})| &\leqq \|\mathbf{v}_j^{(l)}(x') - \mathbf{v}_j^{(l)}(m'2^{-j})\| \\ &= 2^{lj} \|\mathbf{T}_{d_1(x)} \cdots \mathbf{T}_{d_j(x)}[\mathbf{v}_0^{(l)}(\tau^j x') - \mathbf{v}_0^{(l)}(\tau^j(m'2^{-j}))]\| \\ &\leqq C\lambda^j \gamma_\lambda(j), \end{aligned}$$

where we have used (3.3), the uniform boundedness of $\mathbf{v}_0^{(l)}(y)$, and $\mathbf{v}_0^{(l)}(y) - \mathbf{v}_0^{(l)}(y') \in E_{l+1}$ for all y, y'. A similar bound holds for $|f_j^{(l)}(y) - f_j^{(l)}(m2^{-j})|$. Putting it all together, we obtain, for $2^{-(j+1)} \leqq |x - y| \leqq 2^{-j}$,

$$|f^{(l)}(x) - f^{(l)}(y)| \leqq C'\lambda^j \gamma_\lambda(j),$$

which translates to

$$|f^{(l)}(x) - f^{(l)}(y)| \leqq C|x - y|^{|\log_2 \lambda|}$$

if $\lambda > \frac{1}{2}$, and to

$$|f^{(l)}(x) - f^{(l)}(y)| \leqq C|\log_2 |x - y|| \, |x - y|$$

if $\lambda = \frac{1}{2}$. □

Remarks. (1) If $l = L$, then we would not need Lemma 3.5, so that the assumption $\lambda \geqq \frac{1}{2}$ would never be used. The argument of (7) would work if (3.3) held for $\lambda < \frac{1}{2}$, but it would lead to a Hölder exponent α larger than 1 for $f^{(l)}$, hence to $f^{(l)} \equiv 0$. This is incompatible with the fact that f is compactly supported, except if $f \equiv 0$. It follows that for matrices $\mathbf{T}_0, \mathbf{T}_1$ constructed as in (2.8), the constant λ in (3.3) is necessarily $\geqq \frac{1}{2}$ if $l = L$.

(2) We chose f_0 so that $\mathbf{v}_0^{(k)}(0) = (-1)^k k! \tilde{\mathbf{e}}_{k+1}^0$ (see (3.13)). Since, for $x < 2^{-j}$,

$$\mathbf{v}_j^{(k)}(x) = 2^{kj} \mathbf{T}_0^j \mathbf{v}_0^{(k)}(2^j x),$$

it follows that

$$\begin{aligned} \mathbf{v}_j^{(k)}(0) &= (-1)^k k! 2^{kj} \mathbf{T}_0^j \tilde{\mathbf{e}}_{k+1}^0 \\ &= (-1)^k k! \tilde{\mathbf{e}}_{k+1}^0, \end{aligned}$$

where we have used $\mathbf{T}_0 \tilde{\mathbf{e}}_{k+1}^0 = 2^{-k} \tilde{\mathbf{e}}_{k+1}^0$. Hence the $f_j^{(k)}(n)$, $0 \leqq k \leqq l$, are independent of j. Because of the bounds (3.25), this implies also, for $0 \leqq k \leqq l$,

$$\begin{aligned} &f^{(k)}(n) = f_j^{(k)}(n) = (-1)^k k! [\tilde{\mathbf{e}}_{k+1}^0]_{n+1}, \qquad 0 \leqq n \leqq N-1, \\ &f^{(k)}(N) = 0. \end{aligned} \tag{3.26}$$

In § I.5 we had already seen that the $f^{(k)}(n)$ were linked to the right eigenvectors of $\mathbf{M}$ for the eigenvalues 2^{-k}, but it wasn't clear how to choose their normalization, explicit in (3.26). Note that $f_0^{(k)}(n) = f^{(k)}(n)$ for $0 \leqq k \leqq l$ implies that $f_j^{(k)}$ converges to $f^{(k)}$ for

$0 \leqq k \leqq l$ (see Theorem 4.2 in part I): not only do the f_j themselves converge, their derivatives up to lth order do as well.

(3) By continuity, Lemma 3.4 carries over to $\mathbf{v}(x)$: for $0 \leqq k \leqq \min(2l+1, L)$,

$$\mathbf{c}^0_{k+1} \cdot \mathbf{v}(x) = (-1)^k x^k. \tag{3.27}$$

The following lemma states that (3.27) holds for all $k \leq L$, even if $2l+1 < L$.

LEMMA 3.6. *For all* $0 \leqq k \leqq L$, $\mathbf{e}^0_{k+1} \cdot \mathbf{v}(x) = (-1)^k x^k$.

Proof. (1) If $2l+1 \geqq L$, then we have nothing to prove. We assume $2l+1 < L$ and restrict ourselves to $k > 2l+1$.

(2) We only need to prove the lemma for dyadic rationals x; by continuity it then holds for all $x \in [0, 1]$. Take, therefore, $x = n2^{-j}$. The proof works by induction on j.

(3) If $j = 0$, then only $n = 0, 1$ lead to $x \in [0, 1]$. Since $\mathbf{v}(x) = \mathbf{T}_{d_1(x)}\mathbf{v}(\tau x)$, we have $\mathbf{v}(0) = \mathbf{T}_0\mathbf{v}(0)$, $\mathbf{v}(1) = \mathbf{T}_1\mathbf{v}(1)$. Consequently,

$$\mathbf{e}^0_{k+1} \cdot \mathbf{v}(0) = \mathbf{e}^0_{k+1} \cdot \mathbf{T}_0\mathbf{v}(0) = 2^{-k}\mathbf{e}^0_{k+1} \cdot \mathbf{v}(0);$$

hence $\mathbf{e}^0_{k+1} \cdot \mathbf{v}(0) = 0$. Similarly, $\mathbf{e}^1_{k+1} \cdot \mathbf{v}(1) = 0$, which implies (use Lemma 3.2)

$$\begin{aligned} \mathbf{e}^0_{k+1} \cdot \mathbf{v}(1) &= \sum_{m=0}^{k} (-1)^{k-m} \binom{k}{m} \mathbf{e}_{m+1} \cdot \mathbf{v}(1) \\ &= (-1)^k \mathbf{e}^1_1 \cdot \mathbf{v}(1) = (-1)^k, \end{aligned}$$

where we have used (3.27) for $k = 0$. This proves $\mathbf{e}^0_{k+1} \cdot \mathbf{v}(x) = (-1)^k x^k$ for all dyadic rations $x = n2^{-j}$ with $j = 0$.

(4) Suppose that the lemma holds for all $x = n2^{-j}$, j fixed, $0 \leqq n \leqslant 2^j$. Take y of the form $r2^{-j-1}$, $r \in \mathbb{N}$, $0 \leqq r \leqq 2^{j+1}$. If $y \leqq \frac{1}{2}$, then

$$\begin{aligned} \mathbf{e}^0_{k+1} \cdot \mathbf{v}(y) &= \mathbf{e}^0_{k+1} \cdot \mathbf{T}_0\mathbf{v}(2y) \\ &= 2^{-k}\mathbf{e}^0_{k+1} \cdot \mathbf{v}(2y) = (-1)^k 2^{-k}(2y)^k \quad \text{(by induction)} \\ &= (-1)^{\mathrm{k}}\mathrm{y}^{\mathrm{k}}. \end{aligned}$$

If $y \geqq \frac{1}{2}$, then

$$\mathbf{e}^0_{k+1} \cdot \mathbf{v}(y) = \mathbf{e}^0_{k+1} \cdot \mathbf{T}_1\mathbf{v}(2y-1).$$

As in the proof of Lemma 3.4, we have

$$\mathbf{e}^0_{k+1}\mathbf{T}_1 = 2^{-k} \sum_{s=1}^{k} \binom{k}{s} (-1)^{k-s} \mathbf{e}^0_{s+1}.$$

Hence

$$\begin{aligned} \mathbf{e}^0_{k+1} \cdot \mathbf{v}(y) &= 2^{-k} \sum_{s=0}^{k} \binom{k}{s} (-1)^{k-s} (1-2y)^s \quad \text{(by induction)} \\ &= 2^{-k}(-2y)^k = (-y)^k. \end{aligned}$$

This proves the lemma. □

As in § 2, the condition (3.3) can be reduced to a condition involving only a finite number of matrix norms or interpreted as a "spectral" constraint:

$$\begin{aligned} (3.3) &\Leftrightarrow \hat{\rho}(\mathbf{T}_0|_{E_{L+1}}, \mathbf{T}_1|_{E_{L+1}}) < 2^{-l}, \\ &\Leftrightarrow \exists m \in \mathbb{N} \quad \text{so that} \\ \gamma^L_m &= \max_{\substack{d_j = 0 \text{ or } 1 \\ j = 1, \cdots, m}} \|\mathbf{T}_{d_1} \cdots \mathbf{T}_{d_m}|_{E_{L+1}}\|^{1/m} < 2^{-l}. \end{aligned} \tag{3.28}$$

If (3.28) holds for some m, then (3.3) holds with $\lambda = 2^l \gamma^L_m$.

Even the condition $\gamma_m^L < 2^{-l}$ for some $m \in \mathbb{N}$ may be hard to check in practice: for any fixed m, it is necessary to verify the norms of 2^m matrices. Some simplification may occur if the c_n are symmetric, $c_j = c_{N-j}$, but even then the number of matrices is huge if m is large. In the case of the Lagrangian interpolation scheme with dilation factor 2 and 5 nodes (see § 5), we find that $\gamma_m^1 < \frac{1}{2}$ only if $m \geqq 7$. Because the c_n are symmetric in this case, the number of matrices to check is only 2^6 instead of 2^7, but that still amounts to a large number of computations for a fairly simple example. We can reduce the number of computations significantly by some simple tricks listed in the following proposition.

PROPOSITION 3.7. *The following are all equivalent to* (3.3).

(1^0) *For some* $m \in \mathbb{N}$,

$$\gamma_m^L < 2^{-l}. \tag{3.29}$$

(2^0) *For some* $N \times N$*-matrix* $\mathbf{B}$ *with det* $\mathbf{B} \neq 0$, *and for some* $m \in \mathbb{N}$,

$$\gamma_{m;\mathbf{B}}^L < 2^{-l}, \tag{3.30}$$

where

$$\gamma_{m;\mathbf{B}}^k = \max_{\substack{d_j = 0 \text{ or } 1 \\ j = 1, \cdots, m}} \|\bar{\mathbf{T}}_{d_1} \cdots \bar{\mathbf{T}}_{d_m}|_{\mathbf{B}E_{k+1}}\|^{1/m},$$

with $\bar{\mathbf{T}}_d = \mathbf{B}\mathbf{T}_d\mathbf{B}^{-1}$.

(3^0) *There exists a finite collection of "building blocks"* $D^j, j = 1, \cdots, J$, *with* $D^j = \{d_1^j, d_2^j, \cdots, d_{k_j}^j\}$, *each* $d_n^j = 0$ *or* 1, *which is complete, in the sense that every dyadic sequence can be written as a sequence of blocks* D^j *and for which*

$$\max_{j = 1, \cdots, J} t_{D^j}^L < 2^{-l}, \tag{3.31}$$

where $t_{D^j}^m = \|\mathbf{T}_{d_1^j} \cdots \mathbf{T}_{d_{k_j}^j}|_{E_{m+1}}\|^{1/k_j}$.

Proof. (1) The proof of the equivalence (3.3)⇔(3.29) is similar to the proof of Lemma 2.3.

(2) We prove (3.29)⇔(3.30). Since

$$\|\bar{\mathbf{T}}_{d_1} \cdots \bar{\mathbf{T}}_{d_n}|_{\mathbf{B}E_{L+1}}\| \leqq \|\mathbf{B}\| \, \|\mathbf{B}^{-1}\| \, \|\mathbf{T}_{d_1} \cdots \mathbf{T}_{d_n}|_{\mathbf{B}E_{L+1}}\|,$$

we have $\gamma_{n,\mathbf{B}}^L \leqq [\|\mathbf{B}\| \, \|\mathbf{B}^{-1}\|]^{1/n} \gamma_n^L$. By the same argument used in the proof of Lemma 2.7, $\gamma_n^L \leqq C^{1/n} \gamma_m^L$ for some $C > 0$. If $\gamma_m^L < 2^{-l}$, it follows, therefore, that $\gamma_{n;\mathbf{B}}^L < 2^{-l}$ for large enough n, This proves (3.29)⇒(3.30). The converse implication is proved in the same way.

(3) The implication (3.29)⇒(3.31) is obvious: it suffices to take the 2^m "building blocks," each consisting of m entries, with every entry zero or 1.

(4) Finally, we prove (3.31)⇒(3.29), which completes the proof. Suppose (3.31) is satisfied. Define $K = \max\{k_j; j = 1, \cdots, J\}$, $C = \max\{\|\mathbf{T}_{d_1} \cdots \mathbf{T}_{d_n}|_{E_{L+1}}\|; n \leqq K, d_j = 0$ or 1 for each $j\}$. Take now any fixed sequence $(d_j)_{j \in \mathbb{N}}$, and $n \in \mathbb{N}$. The n-tuple $(d_1 \cdots d_n)$ can be written as a sequence of building blocks D^j, followed by a stretch of entries that has at most length K,

$$(d_1 \cdots d_n) = (D^{j_1} \cdots D^{j_n} \tilde{D}).$$

If $\alpha = \max t_{D_j}^L$, and $|D^j|$ denotes the number of entries in D^j, then we have, therefore,

$$\begin{aligned} \|\mathbf{T}_{d_1} \cdots \mathbf{T}_{d_m}|_{E_{L+1}}\| &\leqq 2^{-l(|D^{jm}| + \cdots + |D^{jm}|)} \alpha^{|D^{j1}| + \cdots + |D^{jm}|} C \\ &\leqq 2^{-lm} \alpha^m C 2^{lK} \alpha^{-K}, \end{aligned}$$

which amounts to (3.3). □

Note that the bounds on γ_m^L, on $\gamma_{m;\mathbf{B}}^L$, or on the $t_{D^j}^L$ all lead to lower bounds for the Hölder exponent of $f^{(L)}$, since (3.29)-(3.31) are equivalent with (3.3), with $2^l\gamma_m^L$, $2^l\gamma_{m;\mathbf{B}}^L$, or $2^l \max t_{D^j}^L$ playing the role of λ.

It is, of course, possible to combine (3.30) and (3.31) and to define $\bar{t}_{D_j}^L$ (for the matrices $\bar{\mathbf{T}}_d = \mathbf{B}\mathbf{T}_d\mathbf{B}^{-1}$). A bound on the $\bar{t}_{D_j}^L$, similar to (3.31), is again equivalent with (3.3).

Remark. The proof of Theorem 3.1 presented here relies on arguments which translate convergence rate to f by spline functions into regularity estimates for f. There exist generalizations of lattice two-scale difference equations to higher dimensions for which it does not seem possible to find appropriate spline functions playing the role of the f_j here (one such generalization is outlined in the Appendix). For this reason we present a sketch of a different proof in the Appendix, a fully detailed version which would be longer and more complicated than the proof in this section, but which does not use spline functions.

4. Local regularity and fractal sets. We assume again that the c_n, $n=0,\cdots,N$ satisfy the $L+1$ sum rules (3.2) (with $L+1<N$), as well as $\sum_{n=0}^N c_n = 2$. If (3.3) is satisfied, then Theorem 3.1 tells us that f is l times continuously differentiable, and that $f^{(l)}$ is Hölder continuous with exponent $|\ln\lambda|/\ln 2$. The proof for the uniform Hölder continuity of $f^{(l-1)}$ uses that, for any point x,

$$\|\mathbf{T}_{d_1(x)}\cdots\mathbf{T}_{d_m(x)}|_{E_{L+1}}\| \leqq 2^{-ml}\lambda^m. \tag{4.1}$$

In some cases, more accurate bounds on the left-hand side of (4.1) can be obtained for some values of x, depending on the relative frequency of the digits 0 and 1 in the binary expansion of x. This can then be used to compute local Hölder exponents, which may be larger than the uniformly valid Hölder exponents for $f^{(l-1)}$. More precisely, we have the following theorem.

THEOREM 4.2. *Assume that the c_n, $n=0,\cdots N$, satisfy the $L+1$ sum rules* (3.2), *and assume that $\sum_{n=0}^N c_n = 2$, with $L<N-1$. Assume that there exist $m\in\mathbb{N}$, and μ_0, $\mu_1<1$ such that*

$$\|\mathbf{T}_{d_1}\cdots\mathbf{T}_{d_m}|_{E_{L+1}}\| \leqq 2^{-\lambda}\mu_1^{s_m}\mu_0^{m-s_m} \tag{4.2}$$

for all possible combinations of d_j, $d_j=0$ or $1, j=1,\cdots,m$, with $s_m=\sum_{j=1}^m d_j$.

Let f be the solution f of the two-scale difference equation (1.2) *associated with the c_n, and let $f^{(l)}$ be its lth derivative, which exists and is Hölder continuous, with exponent* $\min(|\ln\mu_1|, |\ln\mu_2|)/\ln 2$, *by Theorem* 3.1. *Take $x\in[0,N]$. Assume that the decimal part of the binary expansion of x satisfies*

$$r_m(x)=\frac{1}{m}\sum_{j=1}^m d_j(x) \text{ tends to a limit } r(x) \text{ as } m\to\infty, \tag{4.3}$$

$$0<r(x)<1. \tag{4.4}$$

Then the following holds:

(1) *For all $\varepsilon>0$, there exist $\delta>0$ and $C<\infty$ such that*

$$|f^{(L)}(x)-f^{(L)}(x+t)| \leqq C|t|^{\alpha(x)-\varepsilon} \quad \text{if } |t|<\delta, \tag{4.5}$$

where $\alpha(x) = -\min\{1, [(1-r(x))|\ln\mu_0| + r(x)|\ln\mu_1|]/\ln 2\}$, *with* $r(x)=r(x-\lfloor x\rfloor)$ *as defined by* (4.4).

(2) *If* $\mu_0 \geqq \frac{1}{2} > \mu_1$ *and* $r(x) > (\ln 2 - |\ln\mu_0|)/|ln\,\mu_1| - |\ln\mu_0|)$, *or if* $\mu_1 \geqq \frac{1}{2} > \mu_0$ *and* $r(x) < (|\ln\mu_0| - \ln 2)/(|\ln\mu_0| - |\ln\mu_1|)$, *then $f^{(l)}$ is differentiable in x.*

To prove this theorem we need the following lemma.

LEMMA 4.2. *Take $x \in [0, 1]$. Assume that (4.3) and (4.4) are satisfied. Then, for all $\varepsilon > 0$, there exists an N_ε so that, for all $m \geqq N_\varepsilon$, the m first digits of the binary expansions of x and $x+t$ are identical whenever $|t| < 2^{-m(1+\varepsilon)-1}$.*

Proof. (1) Fix $\varepsilon > 0$. Choose δ small enough so that

$$[1-r(x)-\delta]^{-1} 2\delta \leqq \varepsilon \quad \text{and} \quad [r(x)-\delta]^{-1} 2\delta \leqq \varepsilon. \tag{4.6}$$

There exists N_ε so that $|r_m(x) - r(x)| \leqq \delta$ for $m \geqq N_\varepsilon$.

(2) Now choose $m \geqq N_\varepsilon$ and $0 \leqq t < 2^{-m(1+\varepsilon)-1}$. If $d_{m+1}(x) = 0$, then it follows from $t < 2^{-m-1}$ that $d_j(x) = d_j(x+t)$ for all $j \leqq m$, and we are done. Suppose that $d_{m+1}(x) = 1 = d_{m+2}(x) = \cdots = d_{m+s}(x)$, and $d_{m+s+1}(x) = 0$. Then the condition (4.6) implies an upper bound on s, since $r_{m+s}(x) \leqq r(x) + \delta$, while $r_m(x) \geqq r(x) - \delta$. Using $r_{m+s}(x) = (m+s)^{-1}[mr_m(x) + s]$ together with these restrictions leads to $s \leqq m2\delta[1-r(x)-\delta]^{-1} \leqq m\varepsilon$. Therefore, $t < 2^{-m(1+\varepsilon)-1} \leqq 2^{-(m+s)-1}$. Since $d_{m+s+1}(x) = 0$, this implies $d_j(x) = d_j(x+t)$ for all $j \leqq m+s$.

(3) The argument for $-2^{-m(1-\varepsilon)-1} < t \leqq 0$ is similar. If $d_{m+1}(x) = 1$, then $d_j(x) = d_j(x+t)$ for all $j < m$ because $|t| < 2^{-m-1}$. If $d_{m+1}(x) = 0 = d_{m+2}(x) = \cdots = d_{m+s}(x)$, and $d_{m+s+1}(x) = 1$, then $s \leqq m2\delta[r(x)-\delta]^{-1} \leqq m\varepsilon$. Hence $t > -2^{-(m+s)-1}$, which implies $d_j(x) = d_j(x+t)$ for all $j \leqq m+s$. □

We now proceed with the proof of Theorem 4.1.

Proof of Theorem 4.1. (1) Since $\mu_0, \mu_1 < 1$, (4.2) implies (3.29), hence (3.3), so that f is l times continuously differentiable. By Lemma 3.6 its "folded" version $\mathbf{v}$ satisfies

$$\mathbf{e}^0_{k+1} \cdot \mathbf{v}^{(l)}(y) = (-1)^l l! \, \delta_{lk} \quad \text{for } 0 \leqq k \leqq l,$$

which implies

$$\mathbf{v}^{(l)}(y) - \mathbf{v}^{(l)}(y') \in E_{l+1} \quad \text{for all } y, y' \in [0, 1].$$

(2) It follows from (4.2) that there exists $C > 0$ so that, for all $p \in \mathbb{N}$,

$$\|\mathbf{T}_{d_1} \cdots \mathbf{T}_{d_p}|_{E_{L+1}}\| \leqq C 2^{-lp} \mu_1^{s_p} \mu_0^{p-s_p} \tag{4.7}$$

(by the same argument as in the proof of Lemma 2.3). The same arguments used in the proof of Lemma 3.5 can then be used to derive that, for $p \geqq 1$,

$$\|\mathbf{T}_{d_1} \cdots \mathbf{T}_{d_p}|_{E_{l+1}}\| \leqq Cp 2^{-lp} \mu_1^{s_p} \mu_0^{p-s_p}, \tag{4.8}$$

where the constant C may be different from that in (4.7), and where we have introduced the extra p for the case where $\mu_1^{s_n} \mu_0^{n-s_n} = 2^{-n}$ for some n.

(3) Fix $x \in [0, N]$, such that $r(x)$ is well defined and $0 < r(x) < 1$. Note that this excludes all dyadic rationals x, since these have $r(x) = 0$ or 1, depending on which binary expansion is chosen (for dyadic rationals, there are two binary expansions). Fix $\varepsilon > 0$. There exists $\gamma > 0$ so that

$$\begin{aligned} &[(1-r(x)-\gamma/2)|\ln \mu_0| + (r(x)-\gamma/2)|\ln \mu_1|]/(1+\gamma) \\ &\qquad \geqq (1-r(x))|\ln \mu_0| + r(x)|\ln \mu_1| - \varepsilon/2 = \alpha(x) - \varepsilon/2. \end{aligned} \tag{4.9}$$

Define $\delta_1 = 2^{-N_\gamma(1+\gamma)-1}$, where N_γ is chosen as in the proof of Lemma 4.2.

(4) We have $x = n + y$, with $0 < y < 1$, $n = 0, 1, \cdots$, or $N-1$. Take $|t| < \delta = \min(\delta_1, x-n, n+1-x)$. Then $\lfloor x+t \rfloor = \lfloor x \rfloor = n$. It follows that

$$\begin{aligned} |f^{(l)}(x) - f^{(l)}(x+t)| &= |\mathbf{v}^{(l)}_{n+1}(x-n) - \mathbf{v}^{(l)}_{n+1}(x+t-n)| \\ &\leqq \|\mathbf{v}^{(l)}(y) - \mathbf{v}^{(l)}(y+t)\|. \end{aligned}$$

(5) Since $|t|<\delta$, there exist $p \geqq N_\gamma$ so that

$$2^{-(p+1)(1+\gamma)-1} \leqq |t| < 2^{-p(1+\gamma)-1}. \tag{4.10}$$

By Lemma 4.2, $d_j(y)=d_j(y+t)$ for $j \leqq p$. Hence

$$\mathbf{v}^{(l)}(y)-\mathbf{v}^{(l)}(y+t)=2^{pl}\mathbf{T}_{d_1(y)}\cdots\mathbf{T}_{d_p(y)}[\mathbf{v}^{(l)}(\tau^p y)-\mathbf{v}^{(l)}(\tau^p y+2^p t)].$$

It follows from (4.8) that

$$\|\mathbf{v}^{(l)}(y)-\mathbf{v}^{(l)}(y+t)\| \leqq 2^{pl}C2^{-pl}p\mu_1^{pr_p(y)}\mu_0^{p(1-r_p(y))}. \tag{4.11}$$

(6) From the proof of Lemma 4.2 we have

$$|r_p(y)-r(y)| \leqq \delta,$$

with $[r(y)-\delta]^{-1}2\delta \leqq \gamma$, hence $\delta \leqq r(y)\gamma/2 \leqq \gamma/2$. Substituting this in (4.11) we find

$$\begin{aligned}\|\mathbf{v}^{(l)}(y)-\mathbf{v}^{(l)}(y+t)\| &\leqq Cp\mu_1^{p[r(y)-\gamma/2]}\mu_0^{p[1-r(y)-\gamma/2]}\\ &\leqq C'p2^{-[(p+1)(1+\gamma)]\{[r(y)-\gamma/2]|\ln\mu_1|+[1-r(y)-\gamma/2]|\ln\mu_0|\}/\ln 2}\\ &\leqq C''(1+|\ln|t||)|t|^{\alpha(x)-\varepsilon/2}\\ &\leqq C'''|t|^{\alpha(x)-\varepsilon},\end{aligned}$$

where we have used (4.9). This proves the first part of the theorem.

(7) Suppose now that $\mu_0 \geqq \frac{1}{2} > \mu_1$, and that $r(x) > (\ln 2 - |\ln\mu_0|/|\ln\mu_1| - |\ln\mu_0|)$, i.e., $\mu_1^{r(x)}\mu_0^{1-r(x)} < \frac{1}{2}$. Choose γ so that

$$\mu_1^{r(x)-\gamma/2}\mu_0^{1-r(x)-\gamma/2} \leqq \tfrac{1}{2}(\tfrac{1}{2}+\mu_1^{r(x)}\mu_0^{1-r(x)}) = \lambda(x)/2 < \tfrac{1}{2}$$

and

$$2^{-2\gamma} \geqq \lambda(x).$$

Choose N_γ corresponding to γ, as in Lemma 4.2. Then, as before, for $p \geqq N_\gamma$, $|r_p(y)-r(y)| \leqq \gamma/2$; hence

$$\mu_1^{r_p(x)}\mu_0^{1-r_p(x)} \leqq \lambda(x)/2 < \tfrac{1}{2}.$$

It follows then from (4.2) that there exists $C>0$ so that, for $p \geqq N_\gamma$,

$$\|\mathbf{T}_{d_1(y)}\cdots\mathbf{T}_{d_p(y)}|_{E_{L+1}}\| \leqq 2^{-p(l+1)}\lambda(x)^p.$$

The same arguments used in the proof of Lemma 3.5 lead to

$$\|\mathbf{T}_{d_1(y)}\cdots\mathbf{T}_{d_p(y)}|_{E_{l+2}}\| \leqq C2^{-p(l+1)}\lambda(x)^p. \tag{4.12}$$

(We assume $\lambda(x) > \frac{1}{2}$; if necessary we replace $\lambda(x)$ by $\frac{1}{2}+\varepsilon$.) Since $\lambda(x)<1$, this means that the eigenvalue $2^{-(l+1)p}$ of $\mathbf{T}_{d_1(y)}\cdots\mathbf{T}_{d_p(y)}$ is simple. It follows that $\mathbf{T}_{d_1(y)}\cdots\mathbf{T}_{d_p(y)}$ has a left eigenvector $\mathbf{e}_{l+2}(p;y)$ and a right eigenvector $\tilde{\mathbf{e}}_{l+2}(p;y)$ for this eigenvalue, both uniquely determined, except for their normalization. By the structure of $\mathbf{T}_0$ and $\mathbf{T}_1$, $\mathbf{e}_{l+2}(p;y)$ is necessarily a linear combination of the $\mathbf{u}_{k+1}$, $0 \leqq k \leqq l+1$, or equivalently, of the $\mathbf{e}_{k+1}^0$, $0 \leqq k \leqq l+1$; we fix its normalization by requiring that the coefficient of $\mathbf{e}_{l+2}^0$ (which is necessarily nonzero) is equal to 1. We also fix the normalization of $\tilde{\mathbf{e}}_{l+2}(p;y)$ by the requirement

$$\mathbf{e}_{l+2}(p;y)\cdot\tilde{\mathbf{e}}_{l+2}(p;y)=1,$$

or equivalently, since $\tilde{\mathbf{e}}_{l+2}(p;y) \in E_{l+1}$, $\mathbf{e}_{l+2}^0\cdot\tilde{\mathbf{e}}_{l+2}(p;y)=1$.

(8) The vectors $\tilde{\mathbf{e}}_{l+2}(p;y)$ are uniformly bounded in p and converge to a limit as $p \to \infty$, as shown by the following argument. We have

$$\begin{aligned}&\tilde{\mathbf{e}}_{l+2}(p;y)-\tilde{\mathbf{e}}_{l+2}(p+1;y)\\ &\quad=2^{(l+1)p}\mathbf{T}_{d_1(y)}\cdots\mathbf{T}_{d_p(y)}[\tilde{\mathbf{e}}_{l+2}(p;y)-2^{l+1}\mathbf{T}_{d_{p+1}(y)}\tilde{\mathbf{e}}_{l+2}(p+1;y)].\end{aligned}$$

Since $\mathbf{e}^0_{l+2}\cdot \mathbf{T}_d = 2^{-(l+1)}\mathbf{e}^0_{l+2}+$linear combination of $\mathbf{e}^0_{k+1}, 0 \leqq k \leqq l$, we find $\mathbf{e}^0_{l+2}\cdot [\tilde{\mathbf{e}}_{l+2}(p+y) - 2^{l+1}\mathbf{T}_{d_{p+1}(y)}\tilde{\mathbf{e}}_{l+2}(p+1;y)]=0$, i.e., $\tilde{\mathbf{e}}_{l+2}(p;y) - 2^{l+1}\mathbf{T}_{d_{p+1}(y)}\tilde{\mathbf{e}}_{l+2}(p+1;y) \in E_{l+2}$. Hence, by (4.12),

$$(4.13)\qquad \|\tilde{\mathbf{e}}_{l+2}(p;y)-\tilde{\mathbf{e}}_{l+2}(p+1;y)\| \leqq C\lambda(x)^p[\|\tilde{\mathbf{e}}_{l+2}(p;y)\|+\|\tilde{\mathbf{e}}_{l+2}(p+1;y)\|],$$

which implies, for large enough p,

$$\begin{aligned}\|\tilde{\mathbf{e}}_{l+2}(p+1;y)\| &\leq [1+C\lambda(x)^p][1-C\lambda(x)^p]^{-1}\|\tilde{\mathbf{e}}_{l+2}(p;y)\|\\ &\leqq \exp[3C\lambda(x)^p]\|\tilde{\mathbf{e}}_{l+2}(p;y)\|.\end{aligned}$$

Hence, for all $p > p_0$, where p_0 is chosen large enough,

$$\|\tilde{\mathbf{e}}_{l+2}(p;y)\| \leqq \exp[3C\lambda(x)^{p_0}(1-\lambda(x))^{-1}]\|\tilde{\mathbf{e}}_{l+2}(p_0;y)\| \leqq C',$$

and, by (4.13),

$$\|\tilde{\mathbf{e}}_{l+2}(p+r;y)-\tilde{\mathbf{e}}_{l+2}(p;y)\| \leqq 2CC'\lambda(x)^p(1-\lambda(x))^{-1},$$

so that the $\tilde{\mathbf{e}}_{l+2}(p;y)$ form a Cauchy sequence in p, with limit $\tilde{\mathbf{e}}_{l+2}(y)$.

(9) Any $\mathbf{u}$ in E_{l+1} can be written as

$$\mathbf{u} = \tilde{\mathbf{e}}_{l+2}(p;y)(\mathbf{e}^0_{l+2}\cdot\mathbf{u})+\mathbf{u}',$$

where $\mathbf{u}' \in E_{l+2}$, since $\mathbf{e}^0_{l+2}\cdot\mathbf{u}'=0$ and $\|\mathbf{u}'\| \leqq C\|\mathbf{u}\|$, with C independent of p, because the $\tilde{\mathbf{e}}_{l+2}(p;y)$ are bounded uniformly in p.

Choose now $p_1 = \max(p_0, N_\gamma)$, with p_0, N_γ as in (7) and (6). For $|t| < 2^{-p_1(1+\gamma)-1}$ there exists $p \geqq p_1$ so that

$$2^{-(p+1)(1+\gamma)-1} \leqq |t| < 2^{-p(1+\gamma)-1},$$

which implies that x and $x+t$, or y and $y+t$, have the same p first digits in their binary expansion. Then

$$\mathbf{v}^{(l)}(y+t)-\mathbf{v}^{(l)}(y) = 2^{lp}\mathbf{T}_{d_1(y)}\cdots\mathbf{T}_{d_p(y)}\mathbf{u},$$

with $\mathbf{u} = \mathbf{v}^{(l)}(\tau^p y + 2^p t)-\mathbf{v}^{(l)}(\tau^p y) \in E_{l+1}$. By Lemma 3.6, $\mathbf{e}^0_{l+2}\cdot\mathbf{u} = (-1)^{l+1}(l+1)!2^p t$, so that

$$\begin{aligned}\mathbf{v}^{(l)}(y)-\mathbf{v}^{(l)}(y+t) &= 2^{lp}\mathbf{T}_{d_1(y)}\cdots\mathbf{T}_{d_p(y)}[(-1)^{l+1}(l+1)!2^p t\tilde{\mathbf{e}}_{l+2}(p;y)+\mathbf{u}']\\ &= (-1)^{l+1}(l+1)!\,t\tilde{\mathbf{e}}_{l+2}(p;y)+\mathbf{u}'',\end{aligned}$$

with $\|\mathbf{u}''\| \leqq 2^{lp}C2^{-p(l+1)}\lambda(x)^p$ by (4.12), by the p-incident bound on $\mathbf{u}$, and the boundedness of $\mathbf{v}^{(l)}$. Because $\lambda(x) \leqq 2^{-\gamma}$, it follows that,

$$(4.14)\qquad \begin{aligned}&\left\|\frac{\mathbf{v}^{(l)}(y+t)-\mathbf{v}^{(l)}(y)}{t}-(-1)^{l+1}!\tilde{\mathbf{e}}_{l+2}(y)\right\|\\ &\quad\leqq (l+1)!\,\|\tilde{\mathbf{e}}_{l+2}(p;y)-\tilde{\mathbf{e}}_{l+2}(y)\|+C2^{\gamma+2}2^{-\gamma p}.\end{aligned}$$

As $|t|\to 0, p\to\infty$, and the right-hand side of (4.14) tends to zero, so that $\mathbf{v}$ is $(l+1)$ times differentiable in y (with $(l+1)$-th derivative $(-1)^{l+1}(l+!)!\tilde{\mathbf{e}}_{l+2}(y))$. Hence, f is $(l+1)$ times differentiable in $x = \lfloor x\rfloor + y$, and the theorem is proved. □

Under the conditions of Theorem 4.1, we find that different Hölder exponents α_r correspond to the sets V_r,

$$(4.15)\qquad V_r = \{x \in [0,N];\ r(x) = r(x-\lfloor x\rfloor)=r\}.$$

These sets are fractal sets. Their Haussdorff dimension can be computed explicitly; it is given by the following theorem, conjectured in I. J. Good (1941) and proved in H. G. Eggleston (1949).

THEOREM 4.3. *For $x \in [0, 1]$, $k \in \mathbb{N}$, $k \geqq 2$, and $0 \leqq l \leqq k-1$, define $r_n(x; l, k)$ to be the number of times, divided by n, that the digit* 1 *occurs among the first n digits of the expansion of x in basis k. For any k-tuple $(r_0, r_1, \cdots, r_{k-1}) = r$ with $0 \leqq r_l \leqq 1$ for all $l \leqq k-1$ and $\sum_{l=0}^{k-1} r_l = 1$, define*

$$V_r(k) = \{x[0, 1];\ \lim_{n\to\infty} r_n(x; l, k) = r_l \text{ for } l = 0, \cdots, k-1\}.$$

Then V_r has fractal dimension δ defined by

$$k^{-\delta} = \prod_{l=0}^{k-1} r_l^{r_l}.$$

Remark. Note that the choice $r_l = k^{-1}$, $l = 0, \cdots, k-1$ leads to $\delta = 1$. This was to be expected, since in this case V_r contains all the normal numbers and, therefore, has Haussdorff dimension 1.

Specializing to $k = 2$, we find therefore that V_r, as defined by (4.15), has fractal dimension

$$\delta = \frac{r|\ln r| + (l - r)|\ln(1-r)|}{\ln 2}.$$

COROLLARY 4.4. *We assume the same conditions as in Theorem* 4.1, *with $\frac{1}{2} \leqq \mu_0, \mu_1$. Then, for any α, $\min(|\ln \mu_0|, |\ln \mu_1|) < \alpha < \max(|\ln \mu_0|, |\ln \mu_1|)$, the set S_α of $x \in [0, N]$ on which f is Hölder continuous with exponent at least α is a fractal set with Hausdorff dimension d_α, with*

$$d_\alpha = 1 \quad \text{if } \alpha \leqq \frac{|\ln \mu_0| + |\ln \mu_1|}{2 \ln 2},$$

$$d_\alpha \geqq \frac{r|\ln r| + (1-r)|\ln(1-r)|}{\ln 2} \quad \text{if } \alpha \geqq \frac{|\ln \mu_0| + |\ln \mu_1|}{2 \ln 2},$$

with

$$r = \frac{\alpha \ln 2 - |\ln \mu_0|}{|\ln \mu_1| - |\ln \mu_0|}.$$

Proof. The proof follows immediately from

$$\dim(V_r) = \frac{r|\ln r| + (1-r)|\ln(1-r)}{\ln 2}. \qquad \square$$

As announced in the introduction, we thus find a hierarchy of fractal sets S_α, with decreasing fractal dimension d_α for increasing Hölder exponents α. Similar fractal sets can be introduced if $\mu_0 < \frac{1}{2} \leqq \mu_1$ or $\mu_1 < \frac{1}{2} \leqq \mu_0$.

Remarks. (1) The different Hölder exponents, and the associated hierarchy of fractal sets do not occur as obviously if the coefficients c_n, $n = 0, \cdots, N$ are symmetric, i.e., if $c_n = c_{N-n}$, $n = 0, \cdots, N$. In this case we find indeed that

$$\mathbf{O}\mathbf{T}_0\mathbf{O}^{-1} = \mathbf{T}_1,$$

where $\mathbf{O}$ is the orthogonal matrix defined by

$$\mathbf{O}_{ij} = \delta_{N+1-i-j}.$$

We easily check that the subspaces U_l are invariant under $\mathbf{O}$,

$$\mathbf{O}\mathbf{u}_l = \sum_{n=1}^{l} \binom{l-1}{n-1} (N+1)^{l-n}(-1)^{n+1}\mathbf{u}_n.$$

It follows that the E_k are invariant under $\mathbf{O}^t = \mathbf{O}^{-1} = \mathbf{O}$. ($\mathbf{O}$ is an involution.) Consequently,

$$\mathbf{T}_1|_{V_k} = \mathbf{O}|_{V_k}\mathbf{T}_0|_{V_k}\mathbf{O}^{-1}|_{V_k}$$

for all $l = 1, \cdots, L+1$, and

$$\|\mathbf{T}_{d_1} \cdots \mathbf{T}_{d_m}|_{V_l}\| = \|\mathbf{T}_{1-d_1} \cdots \mathbf{T}_{1-d_m}|_{V_l}\|.$$

If an inequality of type (4.2) were to hold for the $\mathbf{T}_d$, this symmetry would immediately imply that the same inequality would hold if μ_0, μ_1 were both replaced by min (μ_0, μ_1). The different Hölder exponents $\alpha(x)$ then all collapse to the uniformly valid exponent $|\ln(\min(\mu_0, \mu_1))|/\ln 2 - \varepsilon$. Some fractal structure can still persist, however. An example of this is given in § 5.3.

(2) The "tricks" in Proposition 3.7 also apply here: in order to verify bounds of the type (4.2) it suffices, e.g., to check a similar bound for the matrices $\bar{\mathbf{T}}_d = \mathbf{B}\mathbf{T}_d\mathbf{B}^{-1}$, restricted to $\mathbf{B}E_{L+1}$, where $\mathbf{B}$ is any invertible matrix. A convenient choice of $\mathbf{B}$ may greatly simplify computations.

(3) In establishing local Hölder exponents and local differentiability we have restricted ourselves to x such that $r(x) = \lim_{n\to\infty} r_n(x)$ is well defined and $0 < r(x) < 1$. In fact, it is possible to handle more general x as well. In fact, Lemma 4.2 tells us that for those x for which $r(x) = \lim_{m\to\infty} r_m(x)$ exists and $0 < r(x) < 1$, there can be no "abnormally long" stretches of $0-s$ or $1-s$. If x is not of this type (it is easy to construct such x; they constitute a set of zero Lebesgue measure, however), then we need to control these stretches in some other way. We show here how this can be done when $1 > \mu_0 > \mu_1 > \frac{1}{2}$. For all $x \in [0, 1]$, $n \in \mathbb{N}$, we define

$$\omega_n^1(x) = \min\{k \in \mathbb{N};\ d_{n-k}(x) = 0\}/n.$$

Then $n\omega_n^1(x)$ is exactly the length of the stretch of digits 1 ending at n; in particular, if $d_n(x) = 0$, then $\omega_n^1(x) = 0$. A detailed analysis shows that, for $0 \leqq t < 2^{-n}$,

$$\|\mathbf{v}^{(l)}(x) - \mathbf{v}^{(l)}(x+t)\| \leqq C[\mu_1^{nr_n(x)}\mu_0^{n(1-r_n(x))} + \mu_1^{n(n_x(x)-\omega_n^1(x))+1}\mu_0^{n(1-r_n(x)+\omega_n^1(x))}].$$

For $-2^{-n} < t \leqq 0$, we find

$$\|\mathbf{v}^{(l)}(x) - \mathbf{v}^{(l)}(x+t)\| \leqq C\mu_1^{nr_n(x)}\mu_0^{n(1-r_n(x))},$$

where ω_n^1 doesn't enter because $\mu_0 > \mu_1$. Now define

$$\bar{r}(x) = \limsup_{n\to\infty} r_n(x),$$

$$\underline{r}(x) = \liminf_{n\to\infty} r_n(x),$$

$$\bar{r}^1(x) = \limsup_{n\to\infty} [r_n(x) - \omega_n^1(x)],$$

$$\underline{r}_1(x) = \liminf_{n\to\infty} [r_n(x) - \omega_n^1(x)].$$

Then it follows that, for small enough t

$$\begin{aligned} \|\mathbf{v}^{(l)}(x) - \mathbf{v}^{(l)}(x+t)\| &\leqq C|t|^{\{\underline{r}_1(x)|\ln\mu_1| + (1-\bar{r}^1(x))|\ln\mu_0|\}/\ln 2} && \text{if } t \geqq 0, \\ &\leqq C|t|^{\{\underline{r}(x)|\ln\mu_1| + \bar{r}(x)|\ln\mu_0|\}/\ln 2} && \text{if } t \leqq 0. \end{aligned}$$

This effectively defines two local Hölder exponents $\alpha_\pm(x)$, one from above and one from below. Similar bounds can be derived if $\mu_0 < \mu_1$; in this case we need to introduce $\omega_n^0(x)$, measuring the stretch of zeros preceding the digit $d_n(x)$.

The situation $\mu_0 \geqq \frac{1}{2} > \mu_1$ or $\mu_1 \geqq \frac{1}{2} > \mu_0$ is a bit more tricky, but can be dealt with in the same way. Note that if $r(x)$ is well defined, then $\bar{r}(x) = \underline{r}(x) = \bar{r}^1(x) = \underline{r}^1(x) = r(x)$.

(4) The two Hölder exponents $\alpha_\pm(x)$ introduced in the preceding remark, one from above and one from below, are particularly interesting in dyadic rational points x. For such points, we have two possible binary expansions, one ending in all zeros, the expansion "from above," which we denote by $d^+(x)$, and one ending in all ones, the expansion "from below," denoted by $d^-(x)$. For the Hölder exponent from above, we have to start from $d^+(x)$. We then have

$$\bar{r}^1(x) = \underline{r}_1(x) = 0$$

leading to $\alpha_+(x) = |\ln \mu_0|/\ln 2$. Similarly, for the Hölder exponent from below, starting from $d^-(x)$, we find

$$\bar{r}(x) = \underline{r}(x) = 1;$$

hence, $\alpha_-(x) = |\ln \mu_1|/\ln 2$.

If $\mu_0 > \frac{1}{2} > \mu_1$, we similarly find that f is left but not right differentiable in every dyadic rational point.

5. Examples. We treat three classes of examples, namely orthonormal wavelets, the de Rham function and generalizations, and the interpolation functions arising in Deslauriers and Dubuc's Lagrangian interpolation scheme or studied in detail by Dyn, Gregory, and Levin.

In many of these examples we shall use the tricks proposed in Proposition 3.7. In particular, we shall try to determine matrices $\mathbf{B}$ so that the $\mathbf{B}\mathbf{T}_d\mathbf{B}^{-1}$ are easier to study than the $\mathbf{T}_d$ themselves. If the c_n satisfy $L+1$ sum rules, then a very particular choice for $\mathbf{B}$ is the following:

$$\mathbf{B}_{ij} = \begin{cases} (i-1)!\dbinom{j-1}{i-1} & \text{for } i \leqq L+1, \\ L!\dbinom{j-i+L}{L} & \text{for } i > L+1, \end{cases}$$

where we use the standard convention that the binomial coefficient $\binom{n_1}{n_2}$ vanishes if $n_2 > n_1$. This is a triangular matrix; for $i \leqq L+1$, the ith row can be written as $\mathbf{u}_i$ – linear combination of $\mathbf{u}_k$, $k < i$. It is easy to check that the inverse matrix $\mathbf{B}^{-1}$ is again a triangular matrix, given by

$$(\mathbf{B}^{-1})_{ij} = \begin{cases} (-1)^{i+j}\dbinom{j-1}{i-1}[(j-1)!]^{-1} & \text{for } j \leqq L+1, \\ (-1)^{i+j}\dbinom{L+1}{i-j+L+1}(L!)^{-1} & \text{for } j > L+1. \end{cases}$$

Note that for $i \leqq L+1$, the ith row of $\mathbf{B}$ is a linear combination of $\mathbf{u}_1, \cdots, \mathbf{u}_i$. Because of the special choice of the first $L+1$ rows of $\mathbf{B}$, and because of the spectral properties of the $\mathbf{T}_d$, with their nested left invariant subspaces spanned by the $\{\mathbf{u}_1, \cdots, \mathbf{u}_k\}$, $k \leqq L+1$, we find, therefore, that

$$\begin{aligned} (\mathbf{B}\mathbf{T}_d\mathbf{B}^{-1})_{ij} &= 0 \qquad \text{if } i \leqq L+1, j > i, \\ &= 2^{-i+1} \quad \text{if } i = j \leqq L+1. \end{aligned}$$

This means we are in the situation described in the proofs of Lemmas 3.3, 3.5; in order to prove bounds on products of the restrictions $\mathbf{T}_d|_{E_{L+1}}$, it suffices to consider the smaller matrices obtained by deleting the first $L+1$ rows and columns of the $\mathbf{BT}_d\mathbf{B}^{-1}$. These submatrices are completely determined by $\mathbf{T}_d$ and by the last $(N-L-1)$ rows of $\mathbf{B}$ and the last $(N-L-1)$ columns of $\mathbf{B}^{-1}$. The matrix elements in these rows and columns depend only on the difference $j-i$ between column and row index. Since the $(\mathbf{T}_d)_{i,j}=c_{2i-j-1+d}$ depend only on $2i-j$, this property will, therefore, be shared by the submatrices representing $\mathbf{B}|_{E_{L+1}}\mathbf{T}_d|_{E_{L+1}}\mathbf{B}^{-1}|_{E_{L+1}}$. The entries of these submatrices will, in fact, be given exactly by the coefficients of the quotient of $\sum c_n e^{in\xi}$ by $(1+e^{i\xi})^{L+1}$. That is to say, if

$$\frac{1}{2}\sum_n c_n e^{in\xi}=\left(\frac{1+e^{i\xi}}{2}\right)^{L+1}\frac{1}{2}\sum_n q_n e^{in\xi},$$

then the last $(N-L-1)$ rows and columns of the $\mathbf{BT}_d\mathbf{B}^{-1}$ will be given by

$$(\mathbf{BT}_d\mathbf{B}^{-1})_{ij}=2^l q_{2i-j-(N-L)+d}\,.$$

This observation reduces the study to much smaller matrices, obtained by "peeling off" the sum rules; this is the analog, in our matrix notation, of the reduction from an interpolation subdivision scheme S to the "smaller" subdivision schemes $S^{(n)}$ in Dyn and Levin (1989). A similar observation can also be found in Deslauriers and Dubuc (1989).

5.A. Orthonormal wavelets with compact support. An orthonormal basis of wavelets is a family of functions generated from one single function by dilations and translations,

$$\psi_{jk}(x)=2^{-j/2}\psi(2^{-j}x-k),\qquad j,k\in\mathbb{Z}, \tag{5.1}$$

such that the resulting ψ_{jk} constitute an orthonormal basis of $L^2(\mathbb{R})$. A typical construction of such a basis involves the construction of an auxiliary function ϕ such that

$$\phi(x)=\sum c_n\phi(2x-n) \tag{5.2}$$

for some family of coefficients c_n. In order to lead to an orthonormal wavelet basis, the c_n should satisfy the condition

$$|p(\xi)|^2+|p(\xi+\pi)|^2=1, \tag{5.3}$$

where $p(\xi)=\frac{1}{2}\sum_n c_n e^{in\xi}$. If this condition is satisfied, then there exists an L^2-solution to (5.2), and the associated ψ is given by

$$\psi(x)=\sum_n(-1)^n c_{n+1}\phi(2x+n). \tag{5.4}$$

For a thorough discussion of this construction, with proofs, see Mallat (1989) and Meyer (1990). Equation (5.2) is a two-scale difference equation. If there is only a finite number of nonvanishing c_n, then (modulo some convergence conditions) ϕ has finite support, and so has ψ, by (5.4). In Daubechies (1988) the structure of finite families $\{c_n;\ n=0,\cdots,N\}$ satisfying (5.3) was analyzed. It turns out that these c_n are *always* nonsymmetric if we also require ϕ to be continuous. If this continuity requirement is dropped, then there exists one and only one symmetric solution: $c_0=c_1=1$, all other $c_n\equiv 0$, which correspond to $\phi(x)=1$ if $0\leqq x<1$, 0 otherwise, or $\psi(x)=1$ if $0\leqq x<\frac{1}{2}$, -1 if $\frac{1}{2}\leqq x<1$, zero otherwise; the ψ_{jk} then constitute the Haar basis. Apart from this example, the interesting finite families of c_n are asymmetric, and the corresponding ϕ, therefore, have local regularity properties associated with fractal sets, as described in § 4. The simplest examples are

$$(5.5)\qquad \begin{aligned} N=3, \quad c_0&=\frac{1+\sqrt{3}}{4}, \quad c_2=\frac{3-\sqrt{3}}{4},\\ c_1&=\frac{3+\sqrt{3}}{4}, \quad c_3=\frac{1-\sqrt{3}}{4},\end{aligned}$$

$$(5.6)\qquad \begin{aligned} N=5, \quad c_0&=[1+\sqrt{10}+\sqrt{5+2\sqrt{10}}]/16,\\ c_1&=[5+\sqrt{10}+3\sqrt{5+2\sqrt{10}}]/16,\\ c_2&=[10-2\sqrt{10}+2\sqrt{5+2\sqrt{10}}]/16,\\ c_3&=[10-2\sqrt{10}-2\sqrt{5+2\sqrt{10}}]/16,\\ c_4&=[5+\sqrt{10}-3\sqrt{5+2\sqrt{10}}]/16,\\ c_5&=[1+\sqrt{10}-\sqrt{5+2\sqrt{10}}]/16.\end{aligned}$$

Higher-order examples (always corresponding to odd N) cannot be written in closed form; a table with numerical values of the c_n, for N up to 19, is given in Daubechies (1988), as well as the recipe for their computation. For any N, we denote the associated solution of (1.2) by ϕ_N.

For $N=7$, we have for instance

$$(5.7)\qquad \begin{aligned} c_0&=.325803428051, & c_4&=-.264507167369,\\ c_1&=1.01094571509, & c_5&=.043616300474,\\ c_2&=.892200138247, & c_6&=.046503601071,\\ c_3&=-.039575026235, & c_7&=-.014986989330.\end{aligned}$$

(Note that these c_n are larger, by a factor $\sqrt{2}$, than the coefficients $h(n)$ in Daubechies ((1988), Table 1); the $h(n)$ are normalized by $\sum_n h(n)=\sqrt{2}$).

Let us discuss in detail what the analysis of §§ 2-4 leads to when applied to the concrete examples (5.5)-(5.7).

A. $N=3$. The c_n defined in (5.5) satisfy two "sum rules" of type (3.1), corresponding to $l=0$, 1 or $L=1$. It follows that $N-(L+1)=3-2=1$, so that $E_{L+1}=E_2$ is one-dimensional. The matrices $\mathbf{T}_0, \mathbf{T}_1$ are given by

$$\mathbf{T}_0=\begin{pmatrix} \frac{1+\sqrt{3}}{4} & 0 & 0\\ \frac{3-\sqrt{3}}{4} & \frac{3+\sqrt{3}}{4} & \frac{1+\sqrt{3}}{4}\\ 0 & \frac{1-\sqrt{3}}{4} & \frac{3-\sqrt{3}}{4}\end{pmatrix},$$

$$\mathbf{T}_1=\begin{pmatrix} \frac{3+\sqrt{3}}{4} & \frac{1+\sqrt{3}}{4} & 0\\ \frac{1-\sqrt{3}}{4} & \frac{3-\sqrt{3}}{4} & \frac{3+\sqrt{3}}{4}\\ 0 & 0 & \frac{1-\sqrt{3}}{4}\end{pmatrix}.$$

Their eigenvalues are 1, $\frac{1}{2}$, $(1+\sqrt{3})/4$ for $\mathbf{T}_0$, and $1, \frac{1}{2}, (1-\sqrt{3})/4$ for $\mathbf{T}_1$. Since $1>(1+\sqrt{3})/4>\frac{1}{2}>|(1-\sqrt{3})/4|$ we are in the situation described in Theorem 4.1, with

$\mu_0 > \frac{1}{2} > \mu_1$. Because E_{L+1} is one-dimensional, $\mathbf{T}_0|_{E_{L+1}}$ and $\mathbf{T}_1|_{E_{L+1}}$ commute and

$$\mathbf{T}_{d_1}\cdots\mathbf{T}_{d_m}|_{E_{L+1}} = \text{multiplication by } 2^{-m}\left(\frac{1+\sqrt{3}}{2}\right)^{m-s_m}\left(\frac{1-\sqrt{3}}{2}\right)^{s_m} \quad \text{on } E_2,$$

for all $m \in \mathbb{N}$. Because we have sharp bounds for the $\mathbf{T}_{d_1}\cdots\mathbf{T}_{d_m}|_{E_{L+1}}$, the lower bounds for the Hölder exponents given in Theorem 4.5 are also sharp, except for the extra ε which we always have to introduce in local Hölder exponents.

Since (3.3) is satisfied with $l=0$, $\lambda = (1+\sqrt{3})/4$, it follows from Theorem 3.1 that ϕ_3 is continuous and that ϕ_3 is Hölder continuous with exponent $1 - \ln[(1+\sqrt{3})/2]\ln 2 \cong .5500\cdots$. The following example shows that this estimate is sharp. Applying (1.2) to $x = 2^{-m}$ leads to $\phi_3(2^{-m}) = ((1+\sqrt{3})/4)^m\phi_3(1)$. The values of $\phi_3(1)$, $\phi_3(2)$ are determined by the right eigenvector of $\mathbf{T}_1$ for the eigenvalue 1, which leads to $\phi_3(1) = (1+\sqrt{3})/2$. Hence, for $x_m = 2^{-m} \to 0$,

$$|\phi_3(0) - \phi_3(x_m)| = \left(\frac{1+\sqrt{3}}{2}\right)|x_m|^{-\ln[(1+\sqrt{3})/4]/\ln 2} = \left(\frac{1+\sqrt{3}}{2}\right)|x_m|^{.5500\cdots}.$$

By Theorem 4.1, ϕ_3 is differentiable in all x such that $r(x)$ is well defined and

$$1 > r(x) > \frac{\ln\left(\dfrac{1+2\sqrt{3}}{2}\right)}{\ln\left(\dfrac{1+\sqrt{3}}{2}\right) + \left|\ln\left(\dfrac{\sqrt{3}}{2}\right)\right|} \simeq .2368\cdots.$$

In particular, ϕ_3 is differentiable in all normal numbers, since $r(x) = \frac{1}{2}$ for x normal. Consequently, ϕ_3 is differentiable almost everywhere, as announced earlier. For values of r between .2368 and zero, there exists a corresponding fractal set (see Theorem 4.3) on which ϕ_3 is Hölder continuous with a Hölder exponent, determined by r, between $.5500\cdots$ and 1.

In dyadic rationals x, we find that ϕ_3 is differentiable from below, but is only Hölder continuous from above, with exponent $.5500\cdots$ (see Remark 4 at the end of § 4). This is already illustrated by the behavior of ϕ_3 near $x=0$ (see above); it also accounts for the "jaggedness" of the graph of ϕ_3 at dyadic points (see Fig. 1).

B. $\boldsymbol{N=5}$. We now turn to the properties of ϕ_5. The corresponding c_n, given in (5.6), satisfy three sum rules of type (3.1), corresponding to $L=2$. In this case $N-(L+1) = 5-3 = 2$, i.e., $E_{L+1} = E_3$ is two-dimensional, and obtaining good estimates for $\|\mathbf{T}_{d_1}\cdots\mathbf{T}_{d_m}|_{E_{L+1}}\|$ is not as straightforward as in the previous case. Explicit computation shows that

$$(5.8)\qquad \begin{aligned} \text{spectrum}\,\mathbf{T}_0 &= \{1, \tfrac{1}{2}, \tfrac{1}{4}, (\sqrt{5+2\sqrt{10}}+\sqrt{10}+1)/16, (1-\sqrt{10})/8\} \\ &= \{1, \tfrac{1}{2}, \tfrac{1}{4}, .470467\cdots, -.270284\cdots\}, \\ \text{spectrum}\,\mathbf{T}_1 &= \{1, \tfrac{1}{2}, \tfrac{1}{4}, (1-\sqrt{10})/8, (1+\sqrt{10}-\sqrt{5+2\sqrt{10}})/16\} \\ &= \{1, \tfrac{1}{2}, \tfrac{1}{4}, -.270274\cdots, .049817\cdots\}. \end{aligned}$$

The spectral radii of both $\mathbf{T}_0|_{V_3}$ and $\mathbf{T}_1|_{V_3}$ are, therefore, strictly larger than $\frac{1}{4}$, which means that we cannot expect better than a C^1-result of ϕ_5, with some Hölder continuity for ϕ_5'. In order to obtain this much, we need to prove that (3.3) holds for $l=1$, i.e., that $\|\mathbf{T}_{d_1}\cdots\mathbf{T}_{d_m}|_{E_3}\| \leqq C2^{-m}\lambda^m$ for some $\lambda \leqq 1$. Straightforward estimates of $\|\mathbf{T}_0|_{E_3}\|$ and $\|\mathbf{T}_1|_{E_3}\|$ are much too large for our goal. To make computations easier, we apply Proposition 3.7 and work with $\mathbf{B}\mathbf{T}_0\mathbf{B}^{-1}$, $\mathbf{B}\mathbf{T}_1\mathbf{B}^{-1}$ instead, for suitably chosen $\mathbf{B}$.

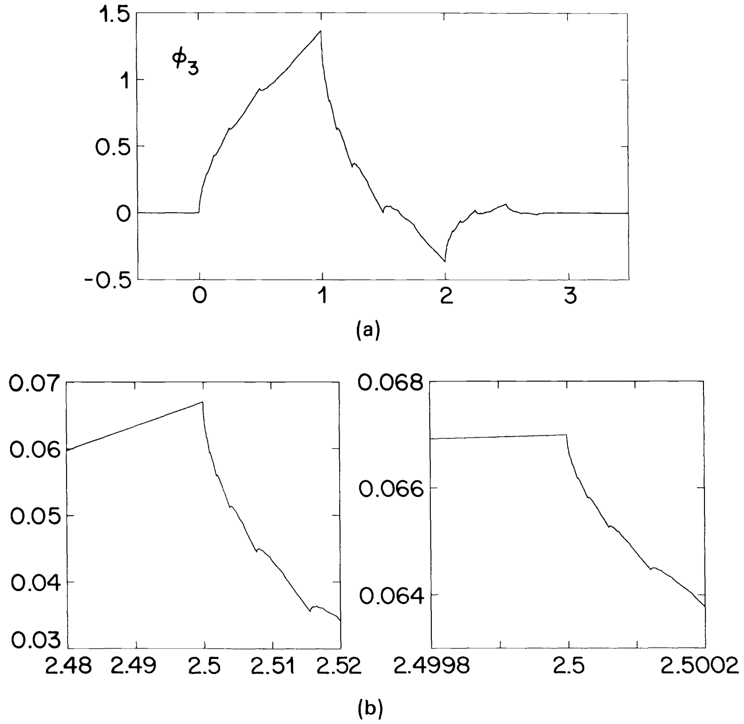

FIG. 1. (a) *The L^1-solution ϕ_3 to the two-scale difference equation $f(x)=[(1+\sqrt{3})f(2x)+(3+\sqrt{3})f(2x-1)+(3-\sqrt{3})f(2x-2)+(1-\sqrt{3})f(2x-3)]/4$. The function ϕ_3 is Hölder continuous with exponent $2-\log_2(1+\sqrt{3})=.5500\cdots$. Moreover, ϕ_3 is almost everywhere differentiable; in dyadic rational points in $[0,3[$ ϕ_3 is left but not right differentiable (see text).* (b) *Two successive blow-ups of ϕ_3 near $x=2.5$, illustrating the self-similar behavior of ϕ_3.*

As a first step, we choose $\mathbf{B}_1$ as outlined at the start of § 5, which in this case means

$$\mathbf{B}_1=\begin{pmatrix} 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 2 & 3 & 4 \\ 0 & 0 & 2 & 6 & 12 \\ 0 & 0 & 0 & 2 & 6 \\ 0 & 0 & 0 & 0 & 2 \end{pmatrix}.$$

As explained above, the matrices $\mathbf{B}_1\mathbf{T}_d\mathbf{B}_1^{-1}|_{\mathbf{B}_1E_3}(d=0$ or $1)$ are simply obtained by stripping $\mathbf{B}_1\mathbf{T}_d\mathbf{B}_d^{-1}$ of their first three columns and rows. This results in

$$\begin{aligned} \mathbf{B}_1\mathbf{T}_0\mathbf{B}_1^{-1}|_{\mathbf{B}_1E_3}&=\begin{pmatrix} .470467\cdots & 0 \\ .049817\cdots & -.270284\cdots \end{pmatrix}, \\ \mathbf{B}_1\mathbf{T}_1\mathbf{B}_1^{-1}|_{\mathbf{B}_1E_3}&=\begin{pmatrix} -.270284\cdots & .4770467\cdots \\ 0 & .049817\cdots \end{pmatrix}; \end{aligned} \tag{5.9}$$

as announced earlier, these reduced matrices can also be obtained directly from $(1+e^{i\xi})^{-3}\sum_n c_n e^{in\xi}$. The norms of these matrices are still larger than we would like them. We apply, therefore, the same trick again and multiply (5.9) on the left by $\mathbf{B}_2$, on the right by $\mathbf{B}_2^{-1}$, where $\mathbf{B}_2$ is a conveniently chosen 2×2-matrix. The choice

$$\mathbf{B}_2=\begin{pmatrix} 1 & 0 \\ .33188\cdots & 4.92450\cdots \end{pmatrix}$$

diagonalizes $\mathbf{B}_1\mathbf{T}_0\mathbf{B}_1^{-1}|_{\mathbf{B}_1E_3}$ and reduces $\mathbf{B}_1\mathbf{T}_1\mathbf{B}_1^{-1}|_{\mathbf{B}_1E_3}$ to a symmetric matrix,

$$\mathbf{B}_2(\mathbf{B}_1\mathbf{T}_0\mathbf{B}_1^{-1}|_{\mathbf{B}_1E_3})\mathbf{B}_2^{-1}=\begin{pmatrix} .470467\cdots & 0 \\ 0 & -.270284\cdots \end{pmatrix}$$

and

$$\mathbf{B}_2(\mathbf{B}_1\mathbf{T}_1\mathbf{B}_1^{-1}|_{\mathbf{B}_1E_3})\mathbf{B}_2^{-1}=\begin{pmatrix} -.238644\cdots & -.095535\cdots \\ -.095535\cdots & .018177\cdots \end{pmatrix}.$$

Consequently, the norms of these matrices are given by their spectral radii, which implies

$$\begin{aligned}\|\mathbf{B}_2(\mathbf{B}_1\mathbf{T}_1\mathbf{B}_1^{-1}|_{\mathbf{B}_1E_3})\mathbf{B}_2^{-1}\| &= \rho[\mathbf{B}_2(\mathbf{B}_1\mathbf{T}_1\mathbf{B}_1^{-1}|_{\mathbf{B}_1E_3})\mathbf{B}_2^{-1}] \\ &= \rho(\mathbf{B}_1\mathbf{T}_1\mathbf{B}_1^{-1}|_{\mathbf{B}_1E_3})=\rho(\mathbf{T}_1|_{E_3}),\end{aligned}$$

and similarly

$$\|\mathbf{B}_2(\mathbf{B}_1\mathbf{T}_0\mathbf{B}_1^{-1}|_{\mathbf{B}_1E_3})\mathbf{B}_2^{-1}\|=\rho(\mathbf{T}_0|_{E_3}).$$

It follows that, for all binary sequences d, and all m,

$$\|\mathbf{T}_{d_1}\cdots\mathbf{T}_{d_m}|_{E_3}\|\leqq C2^{-n}\mu_1^{s_n}\mu_0^{n-s_n},$$

where $s_n=\sum_{j=1}^n d_j$, and $\mu_1=[2\rho(\mathbf{T}_1|_{E_3})]=.540569\cdots$, $\mu_0=[2\rho(\mathbf{T}_0|_{E_3})]=.940934\cdots$. On the other hand, $\mu_d\geqq 2\|\mathbf{T}_d^n|_{E_3}\|^{1/n}\geqq 2\rho(\mathbf{T}_d|_{E_3})(d=0 \text{ or } 1)$. Since $\rho(\mathbf{T}_d|_{E_2})=\rho(\mathbf{T}_d|_{E_3})$ in this case (see (5.8)), the above estimates are, therefore, the sharpest possible for μ_0,μ_1.

Clearly $\frac{1}{2}<\mu_1<\mu_0<1$. It follows that ϕ_5 is continuously differentiable, and that ϕ_5' is Hölder continuous with exponent

$$|\log\mu_0|/\log 2-\varepsilon=.087833\cdots. \tag{5.10}$$

Since the sharpest estimate for μ_1 is strictly larger than $\frac{1}{2}$, ϕ_5 is nowhere twice differentiable; because $\mu_1<\mu_0$, there exists a hierarchy of fractal sets on which ϕ_5' has a larger Hölder exponent than (5.10). In particular, the Hölder exponent of ϕ_5' on the full set of normal numbers is

$$[|\log\mu_0|+|\log\mu_1|]/2\log 2-\varepsilon=.487641\cdots-\varepsilon.$$

The function ϕ_5 is plotted in Fig. 2. At first sight, we have the impression that ϕ_5 has a sharp peak at $x=1$, contradicting its differentiability at this point. Successive blowups of ϕ_5 around $x=1$ show that this peak is not really "sharp" (see Fig. 2(b)).

C. $N=7$. The c_n corresponding to ϕ_7 are given by (5.7); they satisfy (by construction; see Daubechies (1988)) four sum rules of type (3.1), corresponding to $L=3$. It follows that $E_{L+1}=E_4$ is three-dimensional. Explicit computation leads to

$$\text{spectrum } \mathbf{T}_0=\{1,\tfrac{1}{2},\tfrac{1}{4},\tfrac{1}{8},.325803\cdots,-.279620\cdots,.093804\cdots\},$$

$$\text{spectrum } \mathbf{T}_1=\{1,\tfrac{1}{2},\tfrac{1}{4},\tfrac{1}{8},-.279620\cdots,.093804\cdots,-.014986\cdots\}.$$

Since $\rho(\mathbf{T}_0|_{V_4})$, $\rho(\mathbf{T}_1|_{V_4})>\frac{1}{4}$, ϕ_7 is at most once continuously differentiable. In order to prove that ϕ_7 is indeed C^1 and to estimate the Hölder exponent of ϕ_7', we need to

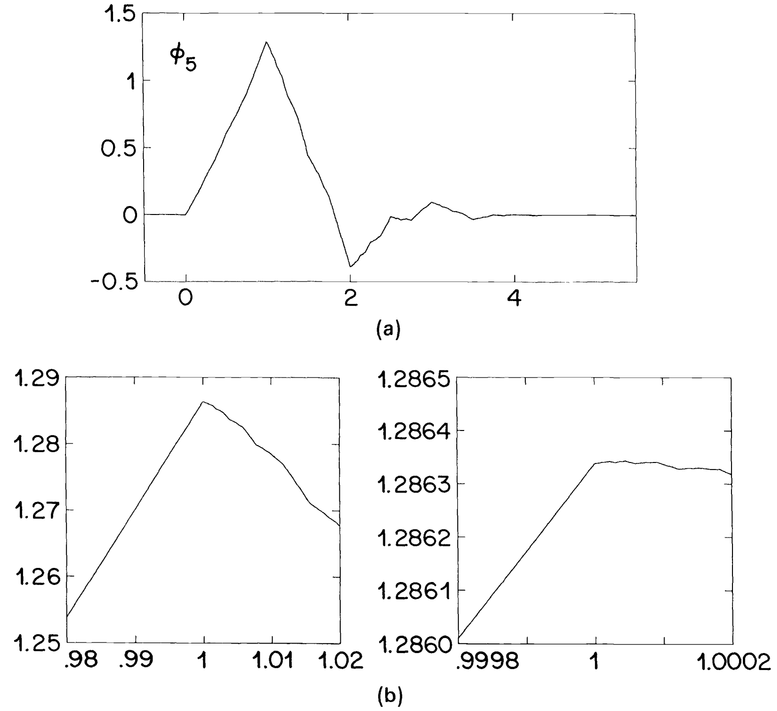

FIG. 2. (a) *The L^1-solution ϕ_5 to the two-scale difference equation $f(x)=\sum_{n=0}^{5} c_n f(2x-n)$, with c_n as given by* (5.6). *The function ϕ_5 is continuously differentiable, despite appearances.* (b) *Two blow-ups of $\phi_5(x)$ around $x=1$, showing that the peak of ϕ_5 at $x=1$ is not really "sharp." We find $\phi_5'(1)=-(\tilde{e}_2^0)_2=1.63845\cdots$.*

find bounds of the type (3.3), with $l=1$, $\lambda<1$. In order to derive such bounds, we shall again study $\|\mathbf{B}\mathbf{T}_\nu\mathbf{B}^{-1}|_{\mathbf{B}E_4}\|$ for suitably chosen, invertible $\mathbf{B}$. We choose $\mathbf{B}_1$ according to the recipe at the start of this section,

$$\mathbf{B}_1=\begin{pmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 2 & 3 & 4 & 5 & 6 \\ 0 & 0 & 2 & 6 & 12 & 20 & 30 \\ 0 & 0 & 0 & 6 & 24 & 60 & 120 \\ 0 & 0 & 0 & 0 & 6 & 24 & 60 \\ 0 & 0 & 0 & 0 & 0 & 6 & 24 \\ 0 & 0 & 0 & 0 & 0 & 0 & 6 \end{pmatrix}.$$

The restriction to $\mathbf{B}_1E_4$ of the matrices $\mathbf{B}_1\mathbf{T}_d\mathbf{B}_1^{-1}$ then simply consists of omitting the first four rows and columns, leading to

$$\mathbf{B}_1\mathbf{T}_0\mathbf{B}_1^{-1}|_{\mathbf{B}_1E_4}=\begin{pmatrix} .325803\cdots & 0 & 0 \\ .106451\cdots & -.292267\cdots & .325803 \\ 0 & -014986\cdots & .106451 \end{pmatrix},$$

$$\mathbf{B}_1\mathbf{T}_1\mathbf{B}_1^{-1}|_{\mathbf{B}_1E_4}=\begin{pmatrix} -.292267\cdots & .325803\cdots & 0 \\ -.014986\cdots & .106451\cdots & -.292267 \\ 0 & 0 & -.014986 \end{pmatrix}.$$

We recognize again the same characteristic structure as in the matrices $\mathbf{T}_d$ themselves (the ij-element depends only on $2i-j$); the entries are the coefficients of the trigonometric polynomial $2^{-4}(1+e^{i\xi})^{-4}\sum_n c_n e^{in\xi}$. The matrix

$$\mathbf{B}_2=\begin{pmatrix} 1 & 0 & 0 \\ -.144737\cdots & 0.315439\cdots & -8.125871\cdots \\ -.466989\cdots & 2.655918\cdots & -2.241310\cdots \end{pmatrix}$$

diagonalizes $\mathbf{B}_1\mathbf{T}_0\mathbf{B}_1^{-1}|_{\mathbf{B}_1E_4}$, and reduces $\mathbf{B}_1\mathbf{T}_1\mathbf{B}_1^{-1}|_{\mathbf{B}_1V_4}$ to

$$\mathbf{B}_2\mathbf{B}_1\mathbf{T}_1\mathbf{B}_1^{-1}\mathbf{B}_2^{-1}|_{\mathbf{B}_1E_4}=\begin{pmatrix} -.238104\cdots & -.034981\cdots & .126825\cdots \\ .034981\cdots & -.002306\cdots & -.004837\cdots \\ .126825\cdots & .080468\cdots & .039608\cdots \end{pmatrix}.$$

The norm of this last matrix (computed by $\|\mathbf{A}\|=[\rho(\mathbf{A}^t\mathbf{A})]^{1/2}$) is $.296060\cdots$; since $\mathbf{B}_2\mathbf{B}_1\mathbf{T}_0\mathbf{B}_1^{-1}\mathbf{B}_2^{-1}|_{\mathbf{B}_+E_4}$ is diagonal, its norm is given by the largest eigenvalue of $\mathbf{T}_0|_{E_4}$, which is $.325803\cdots$. We have thus proved that

$$\|\mathbf{T}_{d_1}\cdots\mathbf{T}_{d_m}|E_4\|\leqq C2^{-n}(.651606\cdots)^{n-s_n}(.592120\cdots)^{s_n},$$

which implies that $\phi_7\in C^1$ and that ϕ_7' is Hölder continuous with exponent

$$\frac{|\log(.651606\cdots)|}{\log 2}=.617926\cdots.$$

Since our estimate of μ_0 is sharp, this Hölder exponent is sharp as well. Since $\mu_1<\mu_0$, we again have a hierarchy of fractal sets corresponding to larger Hölder exponents. Note, however, that our estimate for μ_1 is very likely not sharp (the norm of $\mathbf{B}_2\mathbf{B}_1\mathbf{T}_1\mathbf{B}_1^{-1}\mathbf{B}_2^{-1}|_{\mathbf{B}_1E_4}$ is larger than its spectral radius, and it might be possible to sharpen this estimate by other choices of $\mathbf{B}_2$, without losing the sharp estimate on $\mathbf{T}_0$). The range of Hölder exponents might, therefore, be even larger than suggested by our estimates.

(b)

FIG. 3. (a) *The L^1-solution ϕ_7 to the two-scale difference equation $f(x)=\sum_{n=0}^7 c_nf(2x-n)$, with c_n as given in* (5.7). *The function ϕ_7 is continuously differentiable.* (b) *The derivative ϕ_7' of ϕ_7; ϕ_7' is Hölder continuous with exponent* $.6179\cdots$.

Figures 3(a) and 3(b) give plots of ϕ_7 and ϕ_7', respectively. Both plots have been realized via the cascade algorithm (see part I, § 4).

Remark. Estimates for the Hölder exponents of ϕ_3, ϕ_5, and ϕ_7 were already computed in Daubechies (1988) via a different method, involving the Fourier transform. The table below compares the estimates found here with these earlier results. With the notation $\phi \in C^{n+\alpha}$ for $\phi \in C^n$, $\phi^{(n)}$ Hölder continuous with exponent α ($\alpha \in [0, 1[$), the estimates for $n+\alpha$ compares as follows:

	best estimate in (Daubechies (1988))	as computed here
ϕ_3	$.5-\varepsilon$	$.5500\cdots$
ϕ_5	$.915\cdots-\varepsilon$	$1.0878\cdots$
ϕ_7	$1.275\cdots-\varepsilon$	$1.6179\cdots$

Our present results are significantly better; moreover, they are optimal.

5.B. The de Rham function and generalizations. The de Rham function, as defined in Part I, § 6, is the normalized L^1-solution to the two-scale difference equation

$$\phi(x)=\phi(3x)+\tfrac{1}{3}[\phi(3x-1)+\phi(3x+1)]+\tfrac{2}{3}[\phi(3x-2)+\phi(3x+2)].$$

Since the scaling factor is three instead of two, we are in a slightly different case from before. This example will illustrate, however, that our techniques can be used for all integer scaling factors k, modulo minor adaptations. In general, we have $(k-1)$-matrices $\mathbf{T}_0, \mathbf{T}_1, \cdots, \mathbf{T}_{k-1}$, with matrix elements given by

$$(\mathbf{T}_l)_{ij}=c_{ki-j-N_1-k+1,l}, \qquad 1 \leqq i, j \leqq \frac{N_2+N_1}{k-1},$$

where we assume that the index n of the c_n ranges from $-N_1$ to N_2. In this case, with $k=3$, $c_0=1$, $c_1=c_{-1}=\frac{1}{3}$, $c_2=c_{-2}=\frac{2}{3}$, we have, therefore, three 2×2 matrices,

$$\mathbf{T}_0=\begin{pmatrix}\frac{2}{3} & 0\\ \frac{1}{3} & 1\end{pmatrix} \quad \mathbf{T}_1=\begin{pmatrix}\frac{1}{3} & \frac{2}{3}\\ \frac{2}{3} & \frac{1}{3}\end{pmatrix} \quad \mathbf{T}_2=\begin{pmatrix}1 & \frac{1}{3}\\ 0 & \frac{2}{3}\end{pmatrix}$$

We have $\sum_{n=-2}^{2} c_n=3$, and the c_n satisfy one sum rule:

$$\sum c_{3n}=\sum c_{3n+1}=\sum c_{3n+2}=1. \tag{5.11}$$

The vector (1, 1) is a common left eigenvector for $\mathbf{T}_0, \mathbf{T}_1, \mathbf{T}_2$, with eigenvalue 1. The remaining eigenvalues of $\mathbf{T}_0, \mathbf{T}_1, \mathbf{T}_2$ are, respectively, $\frac{2}{3}, -\frac{1}{3}$, and $\frac{2}{3}$. For $x \in [0, 1]$ we shall now use the ternary expansion of x (since $k=3$); as in Theorem 4.3, we define

$$r_n(x, i)=\frac{1}{n}\,\#\{d_j(x)=i; j \leqq n\} \qquad i=0, 1 \text{ or } 2,$$

where $d_j(x)$ are the digits of the ternary expansion of x (each equal to zero, 1 or 2). Then

$$\mathbf{T}_{d_1(x)}\cdots\mathbf{T}_{d_n(x)}|_{E_1}=\text{multiplication by } 3^{-n}2^{n[r_n(x;0)+r_n(x;2)]}(-1)^{nr_n(x;1)}. \tag{5.12}$$

By the extension of Theorem 2.2 to scale factors $k \neq 2$, it follows that ϕ is continuous. Since

$$\|\mathbf{T}(n; d(x))|_{E_1}\| \leqq (\tfrac{2}{3})^n,$$

ϕ is Hölder continuous, with exponent $|\ln(\frac{2}{3})|\ln 3=.36907\cdots$. In fact, this example is so easy (partly due to $c_n \geqq 0$ for all n) that the Hölder continuity can be established without recourse to the matrix analysis presented in this paper; we then find that the Hölder exponent of ϕ is indeed exactly $|\ln(2\frac{2}{3})|/\ln 3$.

From (5.12) it also follows that the local Hölder exponent of ϕ at $y \in [-1, 1]$ is often larger than the uniformly valid exponent $\alpha_{\text{uniform}} = .36907 \cdots$. For $y = n + x$, $n = -1$ or 0, $x \in [0, 1]$, we find that

$$|\phi(y+t) - \phi(y)| \leqq C|t|^{\alpha(y)-\varepsilon},$$

with

$$\alpha(y) = \frac{\ln 3 - (r_0 + r_2) \ln 2}{\ln 3} = \alpha_{\text{uniform}} + r_1(x) \frac{\ln 2}{\ln 3},$$

where we have assumed that $r_1(x) = \lim_{n\to\infty} [r_n(x; 1)]$ exists. Only where $r_1(x) = 0$ is $\alpha(y) = \alpha_{\text{uniform}}$. On the other hand, there exists y such that $r_1(x) = 1$, namely $y \in [0, 2]$ of the type $3^{-j}(l + \frac{1}{2})$; in these points ϕ is Lipschitz. As usual, there exists a hierarchy of fractal sets corresponding to the Hölder exponents between and α_{uniform}; their Haussdorff dimension is given by Theorem 4.3. In particular, for the full set of normal numbers, we find

$$\alpha_{\text{normal}} = \alpha_{\text{uniform}} + \tfrac{1}{3} \frac{\ln 2}{\ln 3} = 1 - \tfrac{2}{3} \frac{\ln 2}{\ln 3} = .57938 \cdots.$$

A straightforward generalization of the de Rham function is obtained by choosing

$$c_0 = 1,\ c_1 = c_{-1} = \tfrac{1}{2} - \gamma,\ c_2 = c_{-2} = \tfrac{1}{2} + \gamma,$$

corresponding to the two-scale difference equation

$$\begin{aligned} \phi^\gamma(x) = \phi^\gamma(3x) &+ (\tfrac{1}{2} - \gamma)[\phi^\gamma(3x-1) + \phi^\gamma(3x+1)] \\ &+ (\tfrac{1}{2} + \gamma)[\phi^\gamma(3x-2) + \phi^\gamma(3x+2)]. \end{aligned}$$

In this case the matrices $\mathbf{T}_0, \mathbf{T}_1, \mathbf{T}_2$ are

$$\mathbf{T}_0 = \begin{pmatrix} \frac{1}{2}+\gamma & 0 \\ \frac{1}{2}-\gamma & 1 \end{pmatrix}, \mathbf{T}_1 = \begin{pmatrix} \frac{1}{2}-\gamma & \frac{1}{2}+\gamma \\ \frac{1}{2}+\gamma & \frac{1}{2}-\gamma \end{pmatrix}, \mathbf{T}_2 = \begin{pmatrix} 1 & \frac{1}{2}-\gamma \\ 0 & \frac{1}{2}+\gamma \end{pmatrix}.$$

We have again $\sum c_{3n} = \sum c_{3n+1} = \sum c_{3n+2} = 1$, causing $\mathbf{T}_0, \mathbf{T}_1, \mathbf{T}_2$ to have a common left eigenvector for the eigenvalue 1. The remaining eigenvalues are $\frac{1}{2} + \gamma$, -2γ, $\frac{1}{2} + \gamma$, respectively. It follows that ϕ^γ is continuous only if $|\frac{1}{2} + \gamma| < 1$ and $|2\gamma| < 1$, i.e., if $|\gamma| < \frac{1}{2}$. For $\gamma = \frac{1}{6}$, we obviously revert to the de Rham case; for $\gamma = -\frac{1}{6}$ the function ϕ^γ is piecewise linear, $\phi^{-1/6}(x) = 1 + x$ for $-1 \leqq x \leqq 0$, $1 - x$, for $0 \leqq x \leqq 1$, and zero otherwise; for $\gamma = 0$ the resulting ϕ^0 consists of a copy and its mirror image of the Cantor–Lebesgue function on $[0, 1]$.

The same analysis as before results in Hölder continuity for ϕ^γ, with exponent $\alpha_\gamma = (\min [|\ln (\frac{1}{2} + \gamma)|, |\ln (2\gamma)|])/\ln 3$. For $y = n + x$, $n = -1$ or 0, $x \in [0, 1]$, such that $r_1(x) = \lim_{n\to\infty} [r_n(x; 1)]$ exists, we find a larger local Hölder exponent

$$(5.13) \qquad \begin{aligned} \alpha_\gamma(y) &= \frac{|\ln (\frac{1}{2}+\gamma)|}{\ln 3} + r_1(x) \frac{\ln \dfrac{\frac{1}{2}+\gamma}{|2\gamma|}}{\ln 3} \quad \text{if } \tfrac{1}{2} > \gamma \geqq -\tfrac{1}{6}, \\ & \frac{|\ln |2\gamma||}{\ln 3} + [1 - r_1(x)] \frac{\ln \dfrac{|2\gamma|}{\frac{1}{2}+\gamma}}{\ln 3} \quad \text{if } -\tfrac{1}{6} \geqq \gamma > -\tfrac{1}{2}. \end{aligned}$$

For $\gamma = -\frac{1}{6}$, all these Hölder exponents (local and uniform) collapse to 1, which was to be expected since $\phi^{-1/6}$ is piecewise linear. If, for some γ and some y, $\alpha_\gamma(y)$ as given by (5.13) is larger than 1, then this means that ϕ^γ is differentiable in y. This happens, for instance, if $(\frac{1}{2}+\gamma)^2|2\gamma|<\frac{1}{27}$, and if $r_1(x)=\frac{1}{3}$. In particular, ϕ^γ is differentiable almost everywhere if $-\frac{1}{2}<\gamma<.05921689\cdots$.

Fig. 4 gives the graphs of ϕ^γ for the values $\gamma=\frac{1}{6}$ (de Rham case), $\gamma=\frac{1}{12}$, $\gamma=.05$, $\gamma=0$ and $\gamma=-\frac{1}{12}$.

5.C. Lagrangian interpolation functions and generalizations. In Deslauriers and Dubuc (1989), general symmetric Lagrangian interpolation schemes are defined, for arbitrary integer scaling factor $k>1$, and an arbitrary number of nodes. Deslauriers and Dubuc characterize the regularity of the associated "fundamental functions," which are solutions to two-scale difference equations with scaling factor k,

$$f(x)=f(kx)+\sum_{n=1}^{kN-1} c_n[f(kx-n)+f(kx+n)],$$

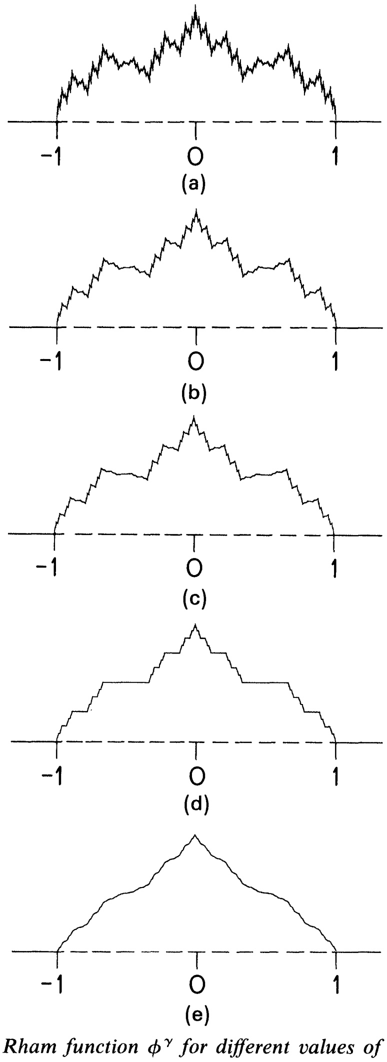

FIG. 4. *The generalized de Rham function* ϕ^γ *for different values of* γ; (a) $\gamma=\frac{1}{6}$ (*the de Rham case*), (b) $\gamma=\frac{1}{12}$, (c) $\gamma=.05$, (d) $\gamma=0$ (*characteristic function of Cantor set*), (e) $\gamma=-\frac{1}{12}$. *In the cases* (c), (d), *and* (e), ϕ^γ *is almost everywhere differentiable.*

where the c_n have the peculiarity that $c_{km} = \delta_{m0}$ (see Part I). The c_n in a Lagrangian symmetric interpolation scheme are completely determined by the requirement that $p(\xi) = k^{-1}[1 + 2\sum_{n=1}^{kN-1} c_n \cos n\xi]$ be divisible by $(1 + e^{i\xi} + \cdots + e^{i(k-1)\xi})^L$, with L as large as possible for the given N (this leads to $L = 2N$). The resulting $p(\xi)$ is positive for real ξ, which is of great help in the analysis of the regularity of f. We have indeed (see part I or Deslauriers and Dubuc (1989)) $\hat{f}(\xi) = \prod_{j=1}^{\infty} p(k^{-j}\xi)$; since $p(\xi) = ((1 - e^{ik\xi})/k(1 - e^{i\xi}))^L q(\xi)$, this leads to $\hat{f}(\xi) = ((1 - e^{i\xi})/\xi)^L \prod_{j=1}^{\infty} q(k^{-j}\xi)$. The quotient $q(\xi)$ is a trigonometric polynomial, $q(\xi) = \sum_n q_n e^{in\xi}$. The regularity of f is given by the largest λ such that $|\xi|^\lambda \hat{f}(\xi)$ is in $L^1(\mathbb{R})$; it turns out that these L^1-norms can be estimated in terms of N and the spectral radius of a finite matrix, constructed from the q_n in the same way as $\mathbf{T}_0, \mathbf{T}_1$ are constructed from the c_n (see § 7, 8 in Deslauriers and Dubuc (1989)). A similar technique was used by one of us, independently, to obtain estimates in the L^1-norm of $|\xi|^\lambda |\hat{\phi}_N(\xi)|$, where ϕ_N are the functions associated to orthonormal wavelet bases (see § 5.A). In that case, however, the function p was not positive, and it was necessary to use the Cauchy–Schwarz inequality to reduce everything to more tractable L^2-estimates, which, however, led to less sharp estimates (see the table at the end of § 5.A).

Let us see now how the present methods, which avoid Fourier transforms, perform on these interpolation functions. We shall restrict ourselves to one of the simpler examples, with $k = 2$ and $N = 2$. In this case the c_n are

$$c_0 = 1, \quad c_1 = c_{-1} = \tfrac{9}{16}, \quad c_3 = c_{-3} = -\tfrac{1}{16}. \tag{5.14}$$

We have two matrices: $\mathbf{T}_0, \mathbf{T}_1$,

$$\mathbf{T}_0 = \begin{pmatrix} -\frac{1}{16} & 0 & 0 & 0 & 0 & 0 \\ \frac{9}{16} & 0 & -\frac{1}{16} & 0 & 0 & 0 \\ \frac{9}{16} & 1 & \frac{9}{16} & 0 & -\frac{1}{16} & 0 \\ -\frac{1}{16} & 0 & \frac{9}{16} & 1 & \frac{9}{16} & 0 \\ 0 & 0 & -\frac{1}{16} & 0 & \frac{9}{16} & 1 \\ 0 & 0 & 0 & 0 & -\frac{1}{16} & 0 \end{pmatrix},$$

$$\mathbf{T}_1 = \begin{pmatrix} 0 & -\frac{1}{16} & 0 & 0 & 0 & 0 \\ 1 & \frac{9}{16} & 0 & -\frac{1}{16} & 0 & 0 \\ 0 & \frac{9}{16} & 1 & \frac{9}{16} & 0 & -\frac{1}{16} \\ 0 & -\frac{1}{16} & 0 & \frac{9}{16} & 1 & \frac{9}{16} \\ 0 & 0 & 0 & -\frac{1}{16} & 0 & \frac{9}{16} \\ 0 & 0 & 0 & 0 & 0 & -\frac{1}{16} \end{pmatrix}.$$

The c_n in (5.14) satisfy four sum rules. Because of the symmetry $c_n = c_{-n}$, we have $\mathbf{T}_1 = \mathbf{O}\mathbf{T}_0\mathbf{O}$, where $\mathbf{O}$ is the involution $\mathbf{O}_{ij} = \delta_{i+j-7}$. Consequently, $\mathbf{T}_1, \mathbf{T}_0$ have the same eigenvalues; we find

$$\text{spectrum}\,(\mathbf{T}_0) = \text{spectrum}\,(\mathbf{T}_1) = \{1, \tfrac{1}{2}, \tfrac{1}{4}, \tfrac{1}{8}, -\tfrac{1}{16}\},$$

where the root $\frac{1}{4}$ has multiplicity two in the characteristic polynomial of $\mathbf{T}_0, \mathbf{T}_1$. It follows that $\|\mathbf{T}_0|_{E_3}\| = \|\mathbf{T}_1|_{E_3}\| \geqq \frac{1}{4}$, so that the best we can hope for is a bound of type (3.3) with $l = 1$ and $\lambda = \frac{1}{2}$, corresponding to $|f'(x + t) - f'(x)| \leqq C|t|\,|\log|t||$. It turns out that the restriction of (say) $\mathbf{T}_0$ (the same will be true for $\mathbf{T}_1$) to the two-dimensional space associated with the eigenvalue $\frac{1}{4}$ can be brought to the normal Jordan form, but cannot be diagonalized. There are, therefore, only one left and one right eigenvector of $\mathbf{T}_0$ with eigenvalue $\frac{1}{4}$, and they are orthogonal. This is what causes the extra factor $|\log|t||$ in the "almost Lipschitz" bound on f'. The degeneracy of $\frac{1}{4}$ is lifted, however, as soon as $\mathbf{T}_0, \mathbf{T}_1$ are mixed: if $(d_1, \cdots, d_n)$ does not consist of only $0-s$ or only $1-s$, then the eigenvalue 4^{-n} of $\mathbf{T}_{d_1}\cdots\mathbf{T}_{d_n}$ is nondegenerate. If, however, the sequence d has a tail consisting of only $0-s$ or only $1-s$ (corresponding to a dyadic rational x), then the gap between 4^{-n} and the closest eigenvalue tends to zero as n tends to infinity, and an attempt at the construction of $\tilde{\mathbf{e}}_3(n;\, d(x))$ (see the proof of Theorem 4.1) diverges for $n\to\infty$. If f were twice continuously differentiable, then its second derivative f'' would be given by these limits $\tilde{\mathbf{e}}_3(\infty;\, d(x))$ (see § 4); the divergence of $\tilde{\mathbf{e}}_3(n;\, d(x))$ at dyadic rational x shows, therefore, that f cannot be twice differentiable at dyadic rationals.

To check that (3.3) holds for $l=1, \lambda=\frac{1}{2}$, we shall again compute estimates for $\mathbf{BT}_0\mathbf{B}^{-1}$, $\mathbf{BT}_1\mathbf{B}^{-1}$, with a conveniently chosen $\mathbf{B}$, rather than work with $\mathbf{T}_0|_{E_4}$, $\mathbf{T}_1|_{E_4}$ themselves. The existence of four sum rules suggests that we use for $\mathbf{B}_1$

$$\mathbf{B}_1=\begin{pmatrix} 1 & 1 & 1 & 1 & 1 & 1\\ 0 & 1 & 2 & 3 & 4 & 5\\ 0 & 0 & 2 & 6 & 12 & 20\\ 0 & 0 & 0 & 6 & 24 & 60\\ 0 & 0 & 0 & 0 & 6 & 24\\ 0 & 0 & 0 & 0 & 0 & 6 \end{pmatrix}. \tag{5.15}$$

The matrices $\mathbf{B}_1\mathbf{T}_0\mathbf{B}_1^{-1}|_{\mathbf{B}_1E_4}$, $\mathbf{B}_1\mathbf{T}_1\mathbf{B}_1^{-1}|_{\mathbf{B}_1E_4}$ then reduce to 2×2-matrices,

$$\mathbf{B}_1\mathbf{T}_0\mathbf{B}_1^{-1}|_{\mathbf{B}_1E_4}=\begin{pmatrix} -\frac{1}{16} & 0\\ -\frac{1}{16} & \frac{1}{4}\end{pmatrix},$$

$$\mathbf{B}_1\mathbf{T}_1\mathbf{B}_1^{-1}|_{\mathbf{B}_1E_4}=\begin{pmatrix} \frac{1}{4} & -\frac{1}{16}\\ 0 & -\frac{1}{16}\end{pmatrix}.$$

The matrix

$$\mathbf{B}_2=\begin{pmatrix} 1 & 0\\ \dfrac{\sqrt{6}}{2} & \dfrac{-5\sqrt{6}}{2}\end{pmatrix} \tag{5.16}$$

then diagonalizes $\mathbf{B}_1\mathbf{T}_0\mathbf{B}_1^{-1}|_{\mathbf{B}_1E_4}$ and reduces $\mathbf{B}_1\mathbf{T}_1\mathbf{B}_1^{-1}|_{\mathbf{B}_1E_4}$ to a symmetric matrix. It follows that, for $d=0$ or 1,

$$\begin{aligned}\|\mathbf{B}_2\mathbf{B}_1\mathbf{T}_d\mathbf{B}_1^{-1}\mathbf{B}_2^{-1}|_{\mathbf{B}_1E_4}\| &= \rho(\mathbf{B}_2\mathbf{B}_1\mathbf{T}_d\mathbf{B}_1^{-1}\mathbf{B}_2^{-1}|_{\mathbf{B}_1E_4})\\ &= \rho(\mathbf{T}_d|_{E_4})=\tfrac{1}{4}.\end{aligned}$$

This implies (3.3) with $l=1, \lambda=\frac{1}{2}$. Theorem 3.1 then implies that f is "almost" C^2, in the sense that $f\in C^1$ and that f' is Hölder continuous with exponent $1-\varepsilon$, with $\varepsilon>0$ arbitrarily small; in fact $|f'(x+t)-f'(x)|\leqq Ct|\ln|t||$ for sufficiently small t, a result which was first proved in Dubuc (1986).

Since $\mathbf{T}_1=\mathbf{OT}_0\mathbf{O}^{-1}$, where $\mathbf{O}$ is an orthogonal matrix (see above), we necessarily have $\mu_0=\mu_1$, where μ_0, μ_1 are as defined in § 4. Nevertheless, we can still improve on the estimate $\|\mathbf{T}_{d_1(x)}\cdots\mathbf{T}_{d_n(x)}|_{E_2}\|<Cn2^{-2n}$ for special, nondyadic x. Group the digits in the binary expansion of x together in pairs, $p_n(x)=d_{2n-1}(x)d_{2n}(x)$, $n=1, 2, \cdots$. Assume that the pairs 0 1, 1 0 occur with an asymptotic frequency larger than zero,

$$p(x)=\liminf_{n\to\infty}\frac{1}{n}\,\#\,\{j<n;\, p_j(x)=1\ \ 0 \text{ or } p_j(x)=0\ \ 1\}>0.$$

Then it can be shown that, for large enough n,

$$\|\mathbf{T}(n;\, d(x))|_{E_3}\|\leqq C2^{-2n}\lambda^n, \tag{5.17}$$

where $\lambda < 1$. Moreover, $\tilde{\mathbf{e}}_3(x) = \lim_{n\to\infty} \tilde{\mathbf{e}}_3(n; d(x))$ is well defined in these points x; repeating some of the arguments in § 4 shows, therefore, that f is twice differentiable in x. The estimate (5.17) is a consequence of the fact that $\mathbf{B}_2\mathbf{B}_1\mathbf{T}_0\mathbf{B}_1^{-1}\mathbf{B}_2^{-1}|_{\mathbf{B}_1 E_3}$ and $\mathbf{B}_2\mathbf{B}_1\mathbf{T}_1\mathbf{B}_1^{-1}\mathbf{B}_2^{-1}|_{\mathbf{B}_1 E_3}$ have a common left eigenvector with eigenvalue $\frac{1}{8}$, while also

$$\|\mathbf{B}_2\mathbf{B}_1\mathbf{T}_0\mathbf{T}_1\mathbf{B}_1^{-1}\mathbf{B}_2^{-1}\|_{\mathbf{B}_1 E_4}\|^{1/2} = \|\mathbf{B}_2\mathbf{B}_1\mathbf{T}_1\mathbf{T}_0\mathbf{B}_1^{-1}\mathbf{B}_2^{-1}|_{\mathbf{B}_1 E_4}\|^{1/2} = .150156 \cdots.$$

Here $\mathbf{B}_1, \mathbf{B}_2$ are the matrices defined by (5.15), (5.16), respectively. This implies

$$(5.18) \quad \|\mathbf{B}_2\mathbf{B}_1\mathbf{T}_{d_1} \cdots \mathbf{T}_{d_n}\mathbf{B}_2^{-1}|_{\mathbf{B}_1 E_4}\| \leqq C \max\,(8^{-n}, \|\mathbf{B}_2\mathbf{B}_1\mathbf{T}_{d_1} \cdots \mathbf{T}_{d_n}\mathbf{B}_1^{-1}\mathbf{B}_2^{-1}|_{\mathbf{B}_1 E_4}\|),$$

where C depends on $\mathbf{B}_1, \mathbf{B}_2$, but not on n. For large n, the right-hand side of (5.18) is bounded by

$$C[(.150156\cdots)^{p(x)}(\tfrac{1}{4})^{1-p(x)}]^n \leqq C4^{-n}(.600624\cdots)^{np(x)}.$$

Together with (5.18), this implies (5.17), with $\lambda = (.600624\cdots)^{p(x)}$.

Note that $p(x) = \frac{1}{2}$ in every normal point x. The above argument proves therefore that f is almost everywhere twice differentiable. Figure 5 gives graphs of both f and f' (both were also plotted in Dubuc (1986)). Note that f looks "smooth," but that f' again exhibits "bumps" which repeat themselves at different scales.

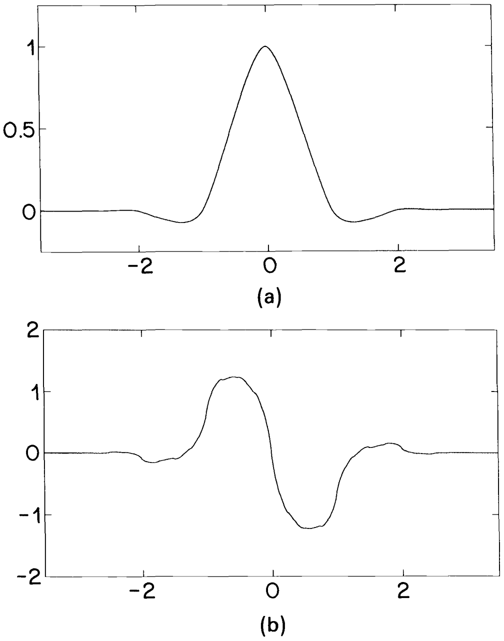

FIG. 5. (a) *The L^1-solution to the two-scale difference equation $f(x) = f(2x) + \frac{9}{16}[f(2x-1) + f(2x+1)] - \frac{1}{16}[f(2x-3) + f(2x+3)]$. Thus function is "almost" C^2 (see text).* (b) *The derivative f' of the function plotted in* (a).

The c_n in (5.14) were chosen so that, with the restrictions $c_n = c_{-n}$, $c_2 = c_{-2} = 0$, the polynomial $p(\xi) = \sum_{n=-3}^{3} c_n e^{in\xi}$ was divisible by the maximum possible number of factors $(1 + e^{i\xi})$. Other examples, still satisfying $c_n = c_{-n}$, $c_2 = c_{-2}$, $c_n = 0$ for $|n| > 3$, were mentioned in Deslauriers and Dubuc (1987). These examples satisfy fewer sum rules, ($p(\xi)$ is divisible by fewer factors $(1 + e^{i\xi})$), and the corresponding $p(\xi)$ is not positive any more. In order to evaluate the regularity of the function f, Deslauriers and Dubuc had to resort to other, less optimal techniques. They prove, e.g., that for

$c_1 = c_{-1} = \frac{1}{2} - a$, $c_3 = c_{-3} = a$, the function f is continuous if $a \in]-\frac{3}{16}, \frac{1}{16}[$. Our present technique leads to better results. For the case $a = -\frac{3}{16}$, e.g., we show that f is continuously differentiable. To do this, we shall use Proposition 3.7 again. Since the c_n satisfy only two sum rules in this case, we choose $\mathbf{B}_1$

$$\mathbf{B}_1 = \begin{pmatrix} 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 2 & 3 & 4 & 5 \\ 0 & 0 & 1 & 2 & 3 & 4 \\ 0 & 0 & 0 & 1 & 2 & 3 \\ 0 & 0 & 0 & 0 & 1 & 2 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}.$$

$\mathbf{B}_1\mathbf{T}_0\mathbf{B}_1^{-1}|_{\mathbf{B}_1 E_2}$, $\mathbf{B}_1\mathbf{T}_1\mathbf{B}_1^{-1}|_{\mathbf{B}_1 E_2}$ reduce to 4×4-matrices, with eigenvalues $\frac{3}{8}$, $-\frac{3}{16}$, and $(1 \pm i\sqrt{2})/4$. The matrices

$$\mathbf{B}_2 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 2y/9 & y & 0 & -y \\ \dfrac{5-26\sqrt{2}i}{81}z & z & \dfrac{-1+2\sqrt{2}i}{3}z & z \\ \dfrac{5+26\sqrt{2}i}{81}z' & z' & -\dfrac{1+2\sqrt{2}i}{3}z' & \end{pmatrix},$$

where y, z, z' are arbitrary complex parameters, diagonalize $\mathbf{B}_1\mathbf{T}_0\mathbf{B}_1^{-1}|_{\mathbf{B}_1 E_2}$, so that

$$\|\mathbf{B}_2\mathbf{B}_1\mathbf{T}_0\mathbf{B}_1^{-1}\mathbf{B}_2^{-1}|_{\mathbf{B}_1 E_2}\| = \rho(\mathbf{T}_0|_{E_2}) = |(1 \pm i\sqrt{2})/4| = .433012 \cdots.$$

For the choice $y = .3$, $z = .27 + .08i$, $z' = .27 - .08i$, the norm corresponding to $\mathbf{T}_1$ is

$$\|\mathbf{B}_2\mathbf{B}_1\mathbf{T}_1\mathbf{B}_1^{-1}\mathbf{B}_2^{-1}|_{\mathbf{B}_2 E_2}\| = .604342 \cdots.$$

This is still larger than $\frac{1}{2}$, and, therefore, not sufficient to show that $f \in C^1$. However, if we define

$$t_{d_1 \cdots d_m} = \|\mathbf{T}_{d_1,\mathrm{red}} \cdots \mathbf{T}_{d_m,\mathrm{red}}\|^{1/m},$$

where $\mathbf{T}_{d_{m,\mathrm{red}}} = \mathbf{B}_2\mathbf{B}_1\mathbf{T}_d\mathbf{B}_1^{-1}\mathbf{B}_2^{-2}|_{\mathbf{B}_1 E_2}$, with the parameters in $\mathbf{B}_2$ fixed as above, then we check that

$$\begin{aligned} &t_0,\ t_{10},\ t_{1100},\ t_{110100},\ t_{1101010},\ t_{11010110},\ t_{11010111}, \\ &t_{1101100},\ t_{1101101},\ t_{110111},\ t_{111000},\ t_{111001}, \\ &t_{1110100},\ t_{111010100},\ t_{1110101010},\ t_{11101010110}, \\ &t_{11101010111},\ t_{1110101100},\ t_{1110101101},\ t_{111010111}, \\ &t_{11101100},\ t_{11101101},\ t_{1110111},\ t_{111100}, \\ &t_{1111010},\ t_{11110110},\ t_{11110111},\ t_{111110} \quad \text{and} \quad t_{111111}. \end{aligned} \tag{5.19}$$

are all $<\frac{1}{2}$.

Since these groups of indices constitute a complete set of building blocks (any binary sequence can be decomposed into them), it follows that

$$\|\mathbf{T}_{d_1} \cdots \mathbf{T}_{d_m}|_{E_2}\| \leqq 2^{-m}\lambda^m$$

for some $\lambda < 1$, if m is large enough (see Proposition 3.7). Note that in order to derive (5.19) only 56 matrix norms were calculated (this includes candidates that failed, such as $t_{1101}, \cdots$), even though the longest sequences of digits has 11 elements. Checking all 2^{11} sequences of this length would have been much more cumbersome, and would, in fact, not have been sufficient in order to conclude that (3.3) holds, since some of them still lead to $t_D > \frac{1}{2}$.

From all this it follows that the function f corresponding to the two-scale difference equation with $k=2$, $c_0=1$, $c_0=c_1=\frac{11}{16}$, $c_3=c_{-3}=-\frac{3}{16}$, all other $c_n=0$, is continuously differentiable. It is plotted in Fig. 6, together with its derivative.

For general a, $c_0=1$, $c_1=c_{-1}=\frac{1}{2}-a$, $c_3=c_{-3}=a$, we find that

$$\text{spectrum } (\mathbf{T}_0) = \text{spectrum } (\mathbf{T}_1) = \left\{1, \tfrac{1}{2}, a, -2a, \frac{1 \pm \sqrt{1+16a}}{4}\right\}.$$

We conjecture that

— the associated function f is in C^1 if $-\frac{1}{4} < a < 0$,

— the associated function f is continuous if $-\frac{1}{2} < a < \frac{1}{2}$.

Appendix. In our analysis of lattice two-scale equations of the type

$$f(x) = \sum_{n=0}^{N} c_n f(2x-n), \tag{A.1}$$

the interval $[0, 1]$ and binary expansions play a special role. This is because $[0, 1]$ has the following two properties: $[0, 1]$ and its integer translates tile the real line, and $[0, 1] = \Lambda^{-1}[0, 1] \cup \Lambda^{-1}([0, 1]+1)$, where Λ is multiplication by 2. The interval $[0, 1]$ is, moreover, the unique bounded subset of $\mathbb{R}$ satisfying these two conditions. If the scale factor in (A.1) were k instead of 2, then we would define Λ to be multiplication

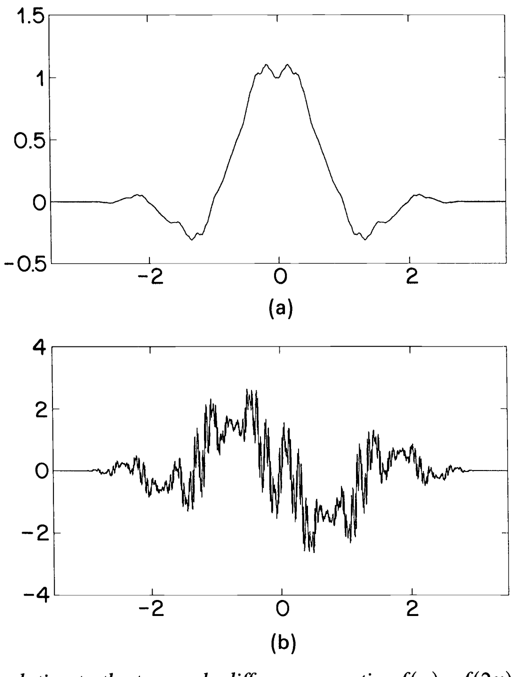

FIG. 6. (a) *The L^1-solution to the two-scale difference equation* $f(x) = f(2x) + \frac{11}{16}[f(2x-1) + f(2x+1)] - \frac{3}{16}[f(2x-3) + f(2x+3)]$. *This function is continuously differentiable* (*see text*). (b) *The derivative of the function plotted in* (a).

by k, and $[0, 1]$ would be tiled by the $\Lambda^{-1}([0,1]+m)$, $0 \leqq m \leqq k-1$, leading to k-adic expansions. All this can be generalized to higher dimensions. We can then write

$$f(x) = \sum_{n \in I} c_n f(\Lambda x - n), \tag{A.2}$$

where $x \in \mathbb{R}^n$, I is a finite subset of $\mathbb{Z}^d$, and Λ is a linear operator on $\mathbb{R}^d$ that preserves $\mathbb{Z}^d$ and has all its singular values strictly larger than 1. For $d=2$, examples of such Λ which have been proposed for applications are

$$\Lambda_0 = \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix}, \quad \Lambda_1 = \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix}, \quad \text{and } \Lambda_2 = \begin{pmatrix} 2 & 1 \\ -1 & 1 \end{pmatrix}.$$

Λ_0 is used in many two-dimensional subdivision schemes; since it consists of a simple uniform dilation, the one-dimensional approach used earlier can be transposed without any problems. The role played before by $[0, 1]$ will now be played by $[0, 1]^2$, and binary expansions still do the trick. For the matrices Λ_1 and Λ_2 the situation is more complicated. Λ_1 was first proposed by M. Vetterli (1984) for a subband coding scheme with exact reconstruction for two-dimensional images; presently, several groups are working on the corresponding orthonormal wavelet bases (Gröchenig and Madych (1992), Lawton and Resnikoff (1991)). An interpolation subdivision scheme using Λ_2 is studied in Mongeau (1990); strictly speaking, Mongeau uses

$$\Lambda_2' = \begin{pmatrix} \frac{3}{2} & \frac{\sqrt{3}}{2} \\ -\frac{\sqrt{3}}{2} & \frac{3}{2} \end{pmatrix}$$

for which the triangular lattice $\{(m+n/2, n\sqrt{3}/2);\ m, n \in \mathbb{Z}\}$, not $\mathbb{Z}^2$, is invariant. The matrix

$$\mathbf{B} = \begin{pmatrix} 1 & -\frac{1}{\sqrt{3}} \\ 0 & \frac{2}{\sqrt{3}} \end{pmatrix}$$

maps the triangular lattice to $\mathbb{Z}^2$ and can be used to translate Mongeau's results to results for lattice two-scale equations involving Λ_2; we have $\Lambda_2 = \mathbf{B}\Lambda_2'\mathbf{B}^{-1}$.

A large part of our analysis can still be carried out, even for nonuniform dilation matrices such as Λ_1 and Λ_2. Since Λ has only integer entries, and its singular values are all larger than 1, $\det \Lambda = k \in \mathbb{Z}$, with $k > 1$. The role played by $[0, 1]$ for (A.1) will now be played by the unique set Γ defined by

—the collection $\{\Gamma + n\colon n \in \mathbb{Z}^d\}$ tiles $\mathbb{R}^d$,

—Γ itself is tiled by the k elements of $\{\Lambda^{-1}(\Gamma + m);\ m \in \mathbb{Z}^d \cap \Lambda([0, 1[^d))\}$.

For both Λ_1 and Λ_2, the corresponding set Γ is a set with fractal boundary; Γ_1 is the so-called *twin dragon set.* The set Γ will be the "elementary building block" for the support of compactly supported solutions to (A.2), just like $[0, 1]$ was for (A.1). The number N of such building blocks constituting support (f) will be determined by the nonvanishing coefficients c_n in (A.2). We can then "fold" f as follows:

$$[\mathbf{v}(x)]_n = f(x + z_n), \qquad x \in \Gamma,\ z_n \in \mathbb{Z}^d, \quad n = 1, \cdots, N,$$

where $\bigcup_{n=1}^{N}(\Gamma+z_n)\supset$ support (f). Points in $\mathbb{R}^d$ can then be represented by Γ-adic expansions; in particular, for $x\in\Gamma$, we define

$$d_1(x)=\{m\in\mathbb{Z}^d\cap\Lambda([0,1[^d);\ x\in\Lambda^{-1}(\Gamma+m)\},$$
$$d_{j+1}(x)=d_j(\Lambda x-d_1(x)).$$

These expansions are unique, except for x in a set of measure zero (corresponding to the dyadic rationals in the one-dimensional case with $\Lambda=2$). We can again define a shift operator τ on Γ by

$$d_j(\tau x)=d_{j+1}(x)\qquad j=1,2,\cdots,$$

and the equation (A.2) can be rewritten in vector notation as

$$\mathbf{v}(x)=\mathbf{T}_{d_1(x)}\mathbf{v}(\tau x),$$

where the k matrices $\mathbf{T}_l$ are all determined by the coefficients c_n. We can then derive existence, continuity, smoothness, etc., of $\mathbf{v}$ (hence of f) from the spectral properties of the $\mathbf{T}_l$. A first extension to higher dimensions can be found in Mongeau (1990), extending our original approach, which did not use spline functions. It seems hard to use spline functions, which are piecewise polynomial and have to be fitted together correctly on the boundaries of the building blocks, when the building blocks have fractal boundaries as in these examples. Mongeau's work, by using appropriate powers of Λ, reduces everything to pure dilations, and thereby avoids the fractal boundaries, at the price of having to deal with much larger matrices $\mathbf{T}_d$. It is also possible to deal directly with the fractal sets by extending our original, longer, and more complicated proof without spline functions (as shown in Cohen and Daubechies (1991)). Therefore, we would like to outline here the major steps of the proofs of Theorems 2.2 and 3.1 without spline functions. For simplicity, we return for this outline to the one-dimensional case, with $\Lambda=$ multiplication by 2.

What follows is an outline of the proof of Theorem 2.1. The starting point is the equation

$$\begin{aligned}\mathbf{v}(x)&=\mathbf{T}_{d_1(x)}\cdots\mathbf{T}_{d_m(x)}\mathbf{v}(\tau^m x)\\&=\mathbf{T}(m;\,d(x))\mathbf{v}(\tau^m x).\end{aligned}$$

From $\mathbf{v}(0),\mathbf{v}(1)$ (which can be determined from the right eigenvector of $\mathbf{M}$ for the eigenvalue 1—see § I.5), we can thus derive $\mathbf{v}(x)$ for all dyadic rationals x. Existence and continuity of $\mathbf{v}$ will be proved if this definition of $\mathbf{v}$ on a dense set can be continuously extended. This is done in the following steps:

- $\mathbf{e}_1$, the common left eigenvector of $\mathbf{T}_0,\mathbf{T}_1$ for the eigenvalue 1, is a left eigenvector of every $\mathbf{T}(m;x)$, with eigenvalue 1;
- consequently, $\mathbf{e}_1\cdot\mathbf{v}(x)=1$ for every dyadic rational x;
- $\|\mathbf{v}(x)\|$ is uniformly bounded, for all dyadic rationals (this uses the condition (2.11), together with $\mathbf{v}(x)-\mathbf{v}(x')\in E_1$);
- we then use that, for small enough t,

$$\mathbf{v}(x+t)-\mathbf{v}(x)=\mathbf{T}(m;\,d(x))[\mathbf{v}(\tau^m x+2^m t)-\mathbf{v}(\tau^m x)],$$

together with (2.16), to show that the restriction of $\mathbf{v}$ to the dyadic rationals is continuous and satisfies

$$\|\mathbf{v}(x)-\mathbf{v}(y)\|\leqq C\lambda^m$$

if $|x-y|\leqq 2^{-m}$. This suffices to show that $\mathbf{v}$ has a continuous extension to all of $[0,1]$, and to prove the Hölder continuity of this extension.

In the details of the proof, we have to be careful, occasionally, because dyadic rationals have two binary extensions. This does not cause any real problem.

Next we sketch the proof of Theorem 3.1.

- Every $\mathbf{T}(m; d)$ has a left eigenvector $\mathbf{e}_k(m; d)$ for the eigenvalue $2^{-(k-1)}m$, $1 \leqq k \leqq L+1$, which can be written as $\mathbf{e}_k(m; d) = \mathbf{e}_k^0 +$ combination of $\mathbf{e}_{k'}^0$, $k' < k$. These $\mathbf{e}_k(m; d)$ are bounded uniformly in $m \in \mathbb{N}$ and $d \in \{0, 1\}^{\mathbb{N}}$. (This is a purely combinatorial fact, and we do not need (3.3) to prove it.)
- For $k \leqq l+1$, the eigenvalue $2^{-(k-1)m}$ of $\mathbf{T}(m; d)$ is simple; there exists a corresponding right eigenvector $\tilde{\mathbf{e}}_k(m; d)$, uniquely normalized by $\mathbf{e}_k(m; d) \cdot \tilde{\mathbf{e}}_k(m; d) = \mathbf{e}_k^0 \cdot \tilde{\mathbf{e}}_k(m; d) = 1$. These $\tilde{\mathbf{e}}_k(m; d)$ are bounded uniformly in m and d. (To prove this we need (3.3); the proof is analogous to (7) in the proof of Theorem 4.1.)

$$\|\mathbf{T}(m; d)|_{E_{k+1}}\| \leqq C\lambda^m 2^{-ml}, \qquad l+1 \leqq k \leqq L,$$

$$\|\mathbf{T}(m; d)|_{E_{l+1}}\| \leqq C\lambda^m 2^{-ml}\phi_\lambda(m),$$

where

$$\phi_\lambda(m) = 1 \quad \text{if } \lambda > \tfrac{1}{2}, \quad \phi_{1/2}(m) = m,$$

and

$$\|\mathbf{T}(m; d)|_{E_{k+1}}\| \leqq C2^{-mk}, \qquad 0 \leqq k \leqq l-1.$$

(Part of this is Lemma 3.5; the third bound is proved analogously.) By taking $k = 0$, we see that (3.3) implies (2.15), so that $\mathbf{v}$ can be constructed and is continuous by Theorem 2.3.

- The $\tilde{\mathbf{e}}_k(n; d)$ converge to a limit for $n \to \infty$. Moreover, if x is a dyadic rational, then $\lim_{n\to\infty} \tilde{\mathbf{e}}_k(n; d^+(x)) = \lim_{n\to\infty} \tilde{\mathbf{e}}_k(n; d^-(x))$. We can, therefore, define $\tilde{\mathbf{e}}_k(x) = \lim_{n\to\infty} \tilde{\mathbf{e}}_k(n; d(x))$ for all $x \in [0, 1]$, $l \leqq k \leqq l+1$. Finally $\tilde{\mathbf{e}}_k(x)$ is continuous in x.
- For all $x \in [0, 1]$, $k = 0, \cdots, L$,

$$\mathbf{e}_{k+1}^0 \cdot \mathbf{v}(x) = (-1)^k x^k$$

(see the proof of Lemma 3.6).

- With all these ingredients, we prove, e.g., differentiability of $\mathbf{v}$ as follows: for t small enough,

$$\begin{aligned}\mathbf{v}(x+t) - \mathbf{v}(x) &= \mathbf{T}(m; d(x))[\mathbf{v}(\tau^m x + 2^m t) - \mathbf{v}(\tau^m x)] \\ &= 2^{-m}\tilde{\mathbf{e}}_2(m; d(x))\{\mathbf{e}_2(m; d(x)) \cdot [\mathbf{v}(\tau^m x + 2^m t) - \mathbf{v}(\tau^m x)]\} \\ &\quad + \mathbf{T}(m; d(x))\mathbf{r},\end{aligned}$$

where we have used $\mathbf{e}_1(m; d(x)) \cdot [\mathbf{v}(y) - \mathbf{v}(z)] = 0$ and where $\mathbf{r} \in E_2$, $\|\mathbf{r}\|$ bounded independently of x, t, and m. Consequently,

$$\frac{\mathbf{v}(x+t) - \mathbf{v}(t)}{t} = \tilde{\mathbf{e}}_2(m; d(x)) + o(1) \to \tilde{\mathbf{e}}_2(x),$$

and $\mathbf{v}$ is differentiable in x if $l \geqq 1$.

- Higher-order differentiability is established analogously. We find

$$\frac{d^k}{dx^k}\mathbf{v}(x) = (-1)^k k!\tilde{\mathbf{e}}_k(x), \qquad j = 0, \cdots, l.$$

(There is no need to "guess" the ansatz (3.10) with this approach.)

- All these results for $\mathbf{v}$ must then be "unfolded" to state results for f; in principle, problems could occur at the integers. Since $[\tilde{\mathbf{e}}_k(0)]_1 = 0 = [\tilde{\mathbf{e}}_k(1)]_N$ and $[\tilde{\mathbf{e}}_k(0)]_{m+1} = [\tilde{\mathbf{e}}_k(1)]_m$, $m = 1, \cdots\cdots, N-1$, unfolding works without problems.

Here ends our outline of the proof without spline functions.

QUASI-CONVEX INTEGRANDS AND LOWER SEMICONTINUITY IN L^1*

IRENE FONSECA† AND STEFAN MÜLLER‡

Abstract. In this paper it is shown that, under mild continuity and growth hypotheses, if $f(x, u,.)$ is quasi-convex and if $u_n, u \in W^{1,1}$ are such that $u_n \to u$ in L^1, then

$$\int_\Omega f(x, u(x), \nabla u(x))\, dx \leqq \liminf \int_\Omega f(x, u_n(x), \nabla u_n(x))\, dx.$$

The proof relies on a blowup argument in connection with a truncation result that allows one to consider uniformly convergent sequences.

Key words. quasi-convexity, lower semicontinuity

AMS(MOS) subject classification. 49

1. Introduction. Our objective is to discuss lower semicontinuity of the functional

$$I(u) = \int_\Omega f(x, u(x), \nabla u(x))\, dx, \qquad u \in W^{1,1}(\Omega; \mathbb{R}^p),$$

where f is quasi convex in ∇u. Our result is that if

$$(1.1) \qquad u_n, u \in W^{1,1}(\Omega; \mathbb{R}^p) \quad \text{and} \quad u_n \to u \quad \text{in } L^1(\Omega; \mathbb{R}^p),$$

then

$$I(u) \leqq \liminf I(u_n),$$

provided f has linear growth in ∇u and satisfies some technical conditions. Another way to express (1.1) is to say that $u_n, u \in W^{1,1}(\Omega; \mathbb{R}^p)$ and $u_n \to u$ in $\mathcal{D}'(\Omega; \mathbb{R}^p)$, which is much less stringent than assuming, for example, weak convergence in $W^{1,1}(\Omega; \mathbb{R}^p)$. This lower semicontinuity result was obtained by Dal Maso [DM] in the scalar case $p = 1$; in the vector-valued case and for $f = f(A)$ convex, by Ball and Murat [BM] and Reshetnyak [R]; when $p > 1$ and $f = f(x, \nabla u)$ quasi-convex the problem was addressed by Fonseca [Fo] and, independently, by Kinderlehrer [K]. For the case where $f = f(x, u, a)$ and $f(x, u,.)$ is convex, Aviles and Giga [AG] obtained lower semicontinuity results.

The main new tool involved in this paper is a careful truncation technique which, together with a blowup argument, enables us to reduce to the case where the sequence u_n converges uniformly. Murat has informed us that related truncation arguments are used in the context of renormalized solutions to partial differential equations (see, e.g., [BDGM]).

The study of this problem was motivated by the analysis of variational problems for phase transitions and the related question of understanding the relaxation of functionals of the type

$$(1.2) \qquad u \to \int_\Omega f(x, u(x), \nabla u(x))\, dx$$

in spaces admitting discontinuous functions u. An important example consists of the family of singular perturbations

$$E_\varepsilon(u) := \int_\Omega W(u(x))\,dx + \varepsilon^2 \int_\Omega h^2(\nabla u(x))\,dx$$

of the nonconvex energy

$$E(u) := \int_\Omega W(u(x))\,dx,$$

where W has two potential wells at a and b. Depending on the constraints or boundary conditions imposed on the admissible functions, $E(\cdot)$ often admits infinitely many minimizers that are piecewise constant functions of bounded variation, $u \in \{a, b\}$ almost everywhere in Ω. In the search for a reasonable selection criterion the properties of the limits of sequences of minimizers for the perturbed problems (see [FT1], [G1], [G2], [KS], [Mo], [OS]) are studied. The natural notion of convergence for the functional in this context is Γ-convergence, as introduced by De Giorgi [DG] (see [At], [DM], [DD] for more recent expositions).

In the isotropic scalar case, i.e., if $u : \Omega \to \mathbb{R}$ and $h = \|\cdot\|$, using an idea of Modica and Mortola, Modica [Mo] showed that the $\Gamma(L^1)$ limit of the rescaled energies

$$J_\varepsilon(u) := \frac{1}{\varepsilon} E_\varepsilon(u)$$

is given by

$$J_0(u) = \mathscr{F}(u),$$

where

$$\mathscr{F}(u) := \inf_{\{u_n\}} \left\{ \liminf_{n\to+\infty} \int_\Omega f(x, u_n(x), \nabla u_n(x))\,dx \,\middle|\, u_n \in W^{1,1}(\Omega; \mathbb{R}),\ u_n \to u \text{ in } L^1 \right\}$$

is the relaxation in $\mathrm{BV}(\Omega; \mathbb{R})$ of (1.2) and

$$f(x, u, A) = 2\sqrt{W(u)}\, h(A). \tag{1.3}$$

Precisely, if $u \in \{a, b\}$ almost everywhere and if $\{u = a\}$ has finite perimeter in Ω, then

$$\inf_{\{u_\varepsilon\}} \{\liminf J_\varepsilon(u_\varepsilon) \,|\, u_\varepsilon \in W^{1,1}(\Omega; \mathbb{R}),\ u_\varepsilon \to u \text{ in } L^1\} = \mathscr{F}(u).$$

This result was generalized by [OS] to "anisotropic" functions h with linear growth for which h^2 is convex and the integral representation for the relaxation $\mathscr{F}(\cdot)$ was obtained by Dal Maso [DM].

In this work we consider the case were u is vectorial, and we prove lower semicontinuity of (1.2) in L^1, thus obtaining the absolutely continuous part of $\mathscr{F}(u)$ with respect to the N-dimensional Lebesgue measure.

2. Lower semicontinuity in $\mathbf{L}^1$ for quasi-convex integrands. Let $p, N \geqq 1$ and let $M^{p\times N}$ denote the vector space of all $p \times N$ real matrices. Recall that a Borel function $f : M^{p\times N} \to \mathbb{R}$ is said to be *quasi convex* if

$$f(A) \leqq \frac{1}{\operatorname{meas}(D)} \int_D f(A + \nabla\varphi(x))\,dx$$

for all $A \in M^{p\times N}$, for every domain $D \subset \mathbb{R}^N$, and for all $\varphi \in W_0^{1,\infty}(D; \mathbb{R}^p)$. If $|f(A)| \leqq C(1+\|A\|)$ we can easily show by approximation that the inequality holds for all $\varphi \in W_0^{1,1}(D; \mathbb{R}^p)$.

Let $\Omega \subset \mathbb{R}^N$ be an open, bounded domain, and let

$$f: \Omega x \mathbb{R}^p \times M^{p\times N} \to [0, +\infty).$$

We consider the following hypotheses on f:

(H1) f is continuous;

(H2) $f(x, u,.)$ is quasi convex;

(H3) There exists a nonnegative, bounded, continuous function $g: \Omega \times \mathbb{R}^p \to [0, +\infty)$, c, $C > 0$ such that

$$cg(x, u)\|A\| - C \leqq f(x, u, A) \leqq Cg(x, u)(1 + \|A\|)$$

for all $(x, u, A) \in \Omega x \mathbb{R}^p x M^{pxN}$;

(H4) For all $(x_0, u_0) \in \Omega x \mathbb{R}^p$ and for all $\varepsilon > 0$ there exists $\delta > 0$ such that $|x - x_0| + |u - u_0| < \delta$ implies that

$$f(x_0, u, A) - f(x_0, u_0, A) \geqq -\varepsilon(1 + \|A\|),$$

and

$$|f(x_0, u, A) - f(x, u, A)| \leqq \varepsilon(1 + \|A\|).$$

THEOREM 2.1. *Suppose* (H1)-(H4) *hold. If* $u_n, u \in W^{1,1}(\Omega; \mathbb{R}^p)$ *and* $u_n \to u$ *in* $L^1(\Omega; \mathbb{R}^p)$, *then*

$$\int_\Omega f(x, u(x), \nabla u(x))\,dx \leqq \liminf \int_\Omega f(x, u_n(x), \nabla u_n(x))\,dx. \tag{2.1}$$

Remark 2.2. (i) If (H2) is replaced by convexity and if the growth condition (H3) holds, then the hypothesis $(H4)_1$ presents no restriction. This fact will be examined in § 4.

(ii) Lower semicontinuity for functions of the type (1.2) follows from Theorem 2.1. Indeed, suppose that

$$f(x, u, A) = 2\sqrt{W(u)}\,h(A),$$

where h is a nonnegative quasi-convex function and

$$c\|A\| - C \leqq h(A) \leqq C(1 + \|A\|).$$

Set

$$W_M(u) := \min\{M, W(u)\} \quad \text{and} \quad f_M(u, A) := 2\sqrt{W_M(u)}\,h(A).$$

It is clear that f_M satisfies (H1)-(H4) and so, if u_n, $u \in W^{1,1}(\Omega; \mathbb{R}^p)$ are such that $u_n \to u$ in $L^1(\Omega; \mathbb{R}^p)$, then

$$\begin{aligned}\int_\Omega f_M(u(x), \nabla u(x))\,dx &\leqq \liminf \int_\Omega f_M(u_n(x), \nabla u_n(x))\,dx \\ &\leqq \liminf \int_\Omega f(u_n(x), \nabla u_n(x))\,dx.\end{aligned}$$

Letting $M \to +\infty$ and using the monotone convergence theorem, we conclude (2.1).

(iii) As we showed in (ii) the boundedness of g presents no restriction for the examples that we have in mind. This assumption becomes crucial for proving in

Proposition 2.4 that the u_n may be considered to be smooth functions, which in turn allows us to apply in $(2.14)_2$ the change of variables formula (2.3) for Lipschitz functions.

It is possible to remove in (H3) the boundedness constraint imposed on g by using a suitable generalization of the change of variables formula (2.3) for $W^{1,1}$ functions. For the sake of clarity, however, we focus attention on the case where g is bounded.

The main idea of the proof is to use a blowup argument to localize (2.1) (see 2.5) and Step 2 in the proof of Theorem 2.1) and a careful truncation technique for vector-valued functions which allows us to replace L^1 convergence by uniform convergence (see Lemmas 2.6 and Step 3 in the proof of Theorem 2.1). First we recall some auxiliary results.

PROPOSITION 2.3. *If* $f: M^{pxN} \to \mathbb{R}$ *is quasi convex and if* $|f(A)| \leqq C(1+\|A\|)$ *for all* $A \in M^{pxN}$ *and for some constant* $C>0$, *then there exists a constant* $C'=C'(C, N)$ *such that*

$$|f(A)-f(B)| \leqq C'\|A-B\|$$

for all $A, B \in M^{pxN}$.

Proof. This follows from the rank-one convexity of f. We refer the reader to Dacorogna [D, Chap. 4, Lemma 2.2] or Evans [E], for example.

PROPOSITION 2.4. (i) *If Theorem* 2.1 *holds true for* Ω *being a ball, then it holds true for all open, bounded sets* Ω.

(ii) *Let* Ω *be a ball. If* (H1) *and* (H3) *hold and if* u_n, $u \in W^{1,1}(\Omega; \mathbb{R}^p)$ *are such that* $u_n \to u$ *in* $L^1(\Omega; \mathbb{R}^p)$, *then there exist* $\tilde{u}_n \in C_0^\infty(\mathbb{R}^N; \mathbb{R}^p)$ *such that* $\|\tilde{u}_n - u\|_{L^1_{(\Omega)}} \to 0$ *and*

$$\liminf_{n\to+\infty} \int_\Omega f(x, \tilde{u}_n(x), \nabla \tilde{u}_n(x))\, dx = \liminf_{n\to+\infty} \int_\Omega f(x, u_n(x), \nabla u_n(x))\, dx.$$

Proof. The proof follows essentially the argument by Acerbi and Fusco [AF], and for completeness it is included in § 3.

PROPOSITION 2.5. *Let* $f: M^{pxN} \to \mathbb{R}$ *be a function satisfying* (H1), (H2), *and*

$$0 \leqq f(A) \leqq C(1+\|A\|), \qquad A \in M^{pxN}$$

for some $C>0$. *If* $A_0 \in M^{pxN}$ *and if* $u_n \in W^{1,1}(\Omega; \mathbb{R}^p)$ *are such that* $u_n \to 0$ *in* $L^1(\Omega; \mathbb{R}^p)$ *and* $\{\|\nabla u_n\|_{L^1}\}$ *is bounded, then*

$$\text{meas}\,(\Omega) f(A_0) \leqq \liminf \int_\Omega f(A_0 + \nabla u_n(x))\, dx.$$

Proof. See § 3.

We will also use the following results.

If $u \in W^{1,1}(\Omega; \mathbb{R}^p)$, then for almost everywhere $x_0 \in \Omega$

$$(2.2) \quad \lim_{\varepsilon\to 0} \frac{1}{\varepsilon}\left\{\frac{1}{\varepsilon^N}\int_{B(x_0,\varepsilon)} |u(x)-u(x_0)-\nabla u(x_0)(x-x_0)|^{N/(N-1)}\, dx\right\}^{(N-1)/N} = 0.$$

If $w \in W^{1,\infty}(\mathbb{R}^N; \mathbb{R})$ and $g \in L^1(\mathbb{R}^N; \mathbb{R})$, then the *change of variables formula* (or *co-area formula*) holds, namely

$$(2.3) \qquad \int_{\mathbb{R}^N} g(x)|\nabla w(x)|\, dx = \int_{-\infty}^{+\infty} \left(\int_{w^{-1}(t)} g(x)\, dH_{N-1}(x)\right) dt.$$

For details see Calderon and Zygmund [CZ], Evans and Gariepy [EG], and Ziemer [Zi]. An easy consequence of (2.3) is the following estimate on level sets of $W^{1,\infty}$ functions.

LEMMA 2.6. *Let* $v \in W^{1,\infty}_{\text{loc}}(\mathbb{R}^N; \mathbb{R}^p)$; *let* $0 < \alpha < \beta < L$, *and let* $C_0 > 0$ *be such that*

$$\int_{\{|v| \leqq L\} \cap B(0,1)} \|\nabla v(x)\| \, dx \leqq C_0.$$

Then

$$\operatorname*{ess\,inf}_{t \in (\alpha,\beta)} tH_{N-1}(\{x \in B(0,1) | \, |v(x)| = t\}) \leqq \frac{C_0}{\ln(\beta/\alpha)}.$$

Proof. Let $B := B(0,1)$, and consider a cutoff function $\varphi \in C_0^\infty(\mathbb{R}^N; \mathbb{R})$ such that $\varphi = 1$ in $B(0,1)$ and its support is contained in $B(0,2)$. Applying the co-area formula (2.3) to

$$w(x) := \varphi(x)|v(x)| \quad \text{and} \quad g(x) := \chi_{[0,L]}(|v(x)|)\chi_B(x),$$

we have

$$\begin{aligned}\int_0^L H_{N-1}(\{x \in B| \, |v(x)| = t\}) \, dt &= \int_{\{|v| \leqq L\} \cap B(0,1)} \|D|v(x)|\| \, dx \\ &\leqq \int_{\{|v| \leqq L\} \cap B(0,1)} \|\nabla v(x)\| \, dx \leqq C_0.\end{aligned}$$

And so, if

$$\operatorname*{ess\,inf}_{t \in (\alpha,\beta)} tH_{N-1}(\{x \in B| \, |v_n(x)| = t\}) = a,$$

then

$$\begin{aligned}C_0 \geqq \int_\alpha^\beta H_{N-1}(\{x \in B| \, |v_n(x)| = t\}) \, dt &\geqq \int_\alpha^\beta \frac{a}{t} \, dt \\ &= a \ln\left(\frac{\beta}{\alpha}\right).\end{aligned}$$

Thus

$$\operatorname*{ess\,inf}_{t \in (\alpha,\beta)} tH_{N-1}(\{x \in B| \, |v_n(x)| = t\}) \leqq \frac{C_0}{\ln(\beta/\alpha)}. \qquad \square$$

Proof of Theorem 2.1. In the sequel, using Proposition 2.4, we assume Ω is a ball and that $u_n \in C_0^\infty(\mathbb{R}^N; \mathbb{R}^p)$. In addition, suppose, without loss of generality, that

$$\liminf_{n \to +\infty} \int_\Omega f(x, u_n(x), \nabla u_n(x)) \, dx = \lim_{n \to +\infty} \int_\Omega f(x, u_n(x), \nabla u_n(x)) \, dx < +\infty.$$

Step 1 (localization). We first reduce the problem to verifying the pointwise inequality (2.5) below. As f is nonnegative, there exists a subsequence such that

$$f(\cdot, u_n(\cdot), \nabla u_n(\cdot)) \to \mu \quad \text{weakly} * \text{in the sense of measures},$$

where μ is a nonnegative finite measure. Using the Radon-Nikodym theorem, we can write μ as a sum of two mutually singular nonnegative measures

$$\mu = \mu_a(x)L_N + \mu_s,$$

where L_N denotes the Lebesgue measure in $\mathbb{R}^N$ and for almost everywhere $x_0 \in \Omega$

$$\mu_a(x_0) = \lim_{\varepsilon \to 0} \frac{\mu(B(x_0, \varepsilon))}{L_N(B(x_0, \varepsilon))} < +\infty. \tag{2.4}$$

We claim that

$$\mu_a(x_0) \geqq f(x_0, u(x_0), \nabla u(x_0)) \quad \text{for a.e. } x_0 \in \Omega. \tag{2.5}$$

Assuming (2.5) momentarily, consider an increasing sequence of smooth cutoff functions φ_k, with $0 \leqq \varphi_k \leqq 1$ and $\sup_k \varphi_k(x) = 1$ in Ω. We obtain

$$\begin{aligned}\lim_{n \to +\infty} \int_\Omega f(x, u_n(x), \nabla u_n(x))\, dx &\geqq \liminf_{n \to +\infty} \int_\Omega \varphi_k(x) f(x, u_n(x), \nabla u_n(x))\, dx \\ &= \int_\Omega \varphi_k(x)\, d\mu(x) \geqq \int_\Omega \varphi_k(x) \mu_a(x)\, dx \\ &\geqq \int_\Omega \varphi_k(x) f(x, u(x), \nabla u(x))\, dx.\end{aligned}$$

Letting $k \to +\infty$, the result follows now from the monotone convergence theorem. The rest of this section is dedicated to proving claim (2.5).

Step 2 (blowup). We use a blowup argument in connection with (2.2) to derive a lower bound for $\mu_a(x_0)$. Let x_0 be a Lebesgue point for $u, \nabla u$ and such that (2.2) and (2.4) hold, and consider the affine functions

$$u_0(x) := u(x_0) + \nabla u(x_0)x \quad \text{and} \quad w_0(x) := \nabla u(x_0)x.$$

We abbreviate $B := B(0, 1)$, and we consider a subdomain $B' \Subset B$. We claim that there exist sequences $r_n \to 0^+$ and $w_n \in W^{1,\infty}(\mathbb{R}^N; \mathbb{R}^p)$ such that $w_n \to w_0$ in $L^1(B; \mathbb{R}^p)$, and

$$\mu_a(x_0) \geqq \lim_{n \to +\infty} \frac{1}{\text{meas}\,(B)} \int_{B'} f(x_0 + r_n x, u(x_0) + r_n w_n(x), \nabla w_n(x))\, dx. \tag{2.6}$$

Let $\varphi \in C_0(B)$ be a cutoff function such that $0 \leqq \varphi \leqq 1$ and $\varphi(x) = 1$ if $x \in B'$. By (2.4) we have

$$\begin{aligned}\mu_a(x_0) &= \lim_{\varepsilon \to 0} \frac{1}{\varepsilon^N \text{meas}\,(B)} \mu(B(x_0, \varepsilon)) \\ &\geqq \limsup_{\varepsilon \to 0} \frac{1}{\varepsilon^N \text{meas}\,(B)} \int_{B(x_0, \varepsilon)} \varphi\left(\frac{x - x_0}{\varepsilon}\right) d\mu(x) \\ &= \limsup_{\varepsilon \to 0} \lim_{n \to +\infty} \frac{1}{\varepsilon^N \text{meas}\,(B)} \int_{B(x_0, \varepsilon)} \varphi\left(\frac{x - x_0}{\varepsilon}\right) f(x, u_n(x), \nabla u_n(x))\, dx \qquad (2.7) \\ &= \limsup_{\varepsilon \to 0} \lim_{n \to +\infty} \frac{1}{\text{meas}\,(B)} \int_B \varphi(x) f(x_0 + \varepsilon x, u_n(x_0 + \varepsilon x), \nabla u_n(x_0 + \varepsilon x))\, dx \\ &\geqq \limsup_{\varepsilon \to 0} \limsup_{n \to +\infty} \frac{1}{\text{meas}\,(B)} \int_{B'} f(x_0 + \varepsilon x, u(x_0) + \varepsilon w_{n,\varepsilon}(x), \nabla w_{n,\varepsilon}(x))\, dx,\end{aligned}$$

where

$$w_{n,\varepsilon}(x) := \frac{u_n(x_0+\varepsilon x)-u(x_0)}{\varepsilon}$$
$$= \frac{1}{\varepsilon}\,[u_n(x_0+\varepsilon x)-u_0(\varepsilon x)] + w_0(x).$$

By (2.2) and Hölder's inequality

$$\lim_{\varepsilon\to 0}\lim_{n\to+\infty}\|w_{n,\varepsilon}-w_0\|_{L^1(B)} = \lim_{\varepsilon\to 0}\frac{1}{\varepsilon}\int_B |u(x_0+\varepsilon x)-u_0(\varepsilon x)|\,dx$$
$$= \lim_{\varepsilon\to 0}\frac{1}{\varepsilon^{N+1}}\int_{B(x_0,\,\varepsilon)} |u(x)-u(x_0)-\nabla u(x_0)(x-x_0)|\,dx$$
$$=0.$$

Now (2.6) is obtained by a standard diagonalization argument. Indeed, choose a sequence $r_k\to 0$, and choose n_k such that

$$\|w_{n_k,r_k}-w_0\|_{L^1(B)} < 1/k + \lim_{n\to+\infty}\|w_{n,r_k}-w_0\|_{L^1(B)}$$

and

$$\frac{1}{\operatorname{meas}(B)}\int_{B'} f(x_0+r_kx, u(x_0)+r_kw_{n_k,r_k}(x), \nabla w_{n_k,r_k}(x))\,dx$$
$$\leqq 1/k + \limsup_{n\to+\infty}\frac{1}{\operatorname{meas}(B)}\int_{B'} f(x_0+r_kx,\, u(x_0)+r_kw_{n,r_k}(x),\, \nabla w_{n,r_k}(x))\,dx.$$

Letting

$$w_k := w_{n_k,r_k},$$

(2.6) follows from (2.7) (a further subsequence may be chosen to ensure that the limit on the right-hand side of (2.6) exists).

Step 3 (truncation). We show that the sequence w_n constructed in Step 2 can be replaced by a uniformly convergent sequence. More precisely, we claim that if $g(x_0, u(x_0))>0$, then there exists a sequence $\tilde{w}_n\in W^{1,\infty}_{\text{loc}}(\mathbb{R}^N;\mathbb{R}^p)$ such that $\|\tilde{w}_n\|_{1,1,B'}\leqq$ Const., $\tilde{w}_n\to w_0$ in $L^\infty(B;\mathbb{R}^p)$, and

$$\mu_a(x_0) \geqq \lim_n \frac{1}{\operatorname{meas}(B)}\int_{B'} f(x_0+r_nx,\, u(x_0)+r_n\tilde{w}_n(x),\, \nabla\tilde{w}_n(x))\,dx. \tag{2.8}$$

Let $0<s<t<1$, and let $\varphi_{s,t}$ be a cutoff function such that $0\leqq\varphi_{s,t}\leqq 1$, $\varphi_{s,t}(\tau)=1$ if $\tau\leqq s$, $\varphi_{s,t}(\tau)=0$ if $\tau\geqq t$, $\|\varphi'_{s,t}\|_\infty\leqq C(t-s)^{-1}$. Set

$$\phi^n_{s,t}(x) := \varphi_{s,t}(|w_n(x)-w_0(x)|)$$

and

$$w^n_{s,t}(x) := w_0(x) + \varphi_{s,t}(|w_n(x)-w_0(x)|)(w_n(x)-w_0(x)).$$

Clearly

$$\|w^n_{s,t}-w_0\|_\infty \leqq t. \tag{2.9}$$

Define

$$h_n(x,s,A) := f(x_0+r_nx,\, u(x_0)+r_ns,\, A),$$

and let $L=\|w_0\|_{L^\infty(B)}+1$. By (H3) and as $g(x_0, u(x_0))>0$, g continuous, there exists n_0 such that for all $n\geqq n_0$, $|s|\leqq L$

$$C(\|A\|+1)\geqq h_n(x, s, A)\geqq c\|A\|-C \tag{2.10}$$

for some $c, C>0$. Also

$$\begin{aligned}\int_{B'} h_n(x, w^n_{s,t}(x), \nabla w^n_{s,t}(x))\,dx &= \int_{B'\cap\{|w_n(x)-w_0(x)|\leqq s\}} h_n(x, w_n(x), \nabla w_n(x))\,dx\\ &+\int_{B'\cap\{s<|w_n(x)-w_0(x)|\leqq t\}} h_n(x, w^n_{s,t}(x), \nabla w^n_{s,t}(x))\,dx\\ &+\int_{B'\cap\{|w_n(x)-w_0(x)|>t\}} h_n(x, w_0(x), \nabla w_0(x))\,dx,\end{aligned} \tag{2.11}$$

and by (2.10) we have

$$-C\leqq h_n(x, w_0(x), \nabla w_0(x))\leqq C,$$

which implies that

$$\int_{B'\cap\{|w_n(x)-w_0(x)|>t\}} h_n(x, w_0(x), \nabla w_0(x))\,dx\leqq C\text{ meas}\,\{x\in B\,|\,|w_n(x)-w_0(x)|>t\}. \tag{2.12}$$

On the other hand, if $s<|w_n(x)-w_0(x)|<t$, then

$$\begin{aligned}\nabla w^n_{s,t}(x)&=\nabla u(x_0)+\varphi_{s,t}(|w_n(x)-w_0(x)|)(\nabla w_n(x)-\nabla u(x_0))\\ &\quad+(w_n(x)-w_0(x))\otimes\varphi'_{s,t}(|w_n(x)-w_0(x)|)\nabla|w_n(x)-w_0(x)|.\end{aligned}$$

Thus, by (2.10), we have

$$\begin{aligned}&\int_{B'\cap\{s<|w_n(x)-w_0(x)|\leqq t\}} h_n(x, w^n_{s,t}(x), \nabla w^n_{s,t}(x))\,dx\\ &\leqq C\int_{\{s<|w_n(x)-w_0(x)|\leqq t\}}(1+\|\nabla w_n(x)-\nabla u(x_0)\|)\,dx\\ &\quad+C\frac{1}{t-s}\int_{B'\cap\{s<|w_n(x)-w_0(x)|\leqq t\}}|w_n(x)-w_0(x)|\,|\nabla|w_n(x)-w_0(x)||\,dx.\end{aligned} \tag{2.13}$$

We remark that for almost all t we have

$$\lim_{s\to t-}\int_{\{s<|w_n(x)-w_0(x)|\leqq t\}}(1+\|\nabla w_n(x)-\nabla u(x_0)\|)\,dx=0, \tag{2.14a}$$

and by the change of variables formula (2.3)

$$\begin{aligned}&\lim_{s\to t-}\frac{1}{t-s}\int_{B'\cap\{s<|w_n(x)-w_0(x)|\leqq t\}}|w_n(x)-w_0(x)|\,|\nabla|w_n(x)-w_0(x)||\,dx\\ &\leqq tH_{N-1}\{x\in B'\,|\,|w_n(x)-w_0(x)|=t\}\end{aligned} \tag{2.14b}$$

for almost every t. Due to (2.10),

$$\begin{aligned}\int_{B'\cap\{|w_n(x)-w_0(x)|\leqq 1\}}|\nabla|w_n(x)-w_0(x)||\,dx&\leqq\int_{B'\cap\{|w_n(x)-w_0(x)|\leqq 1\}}(\|\nabla w_n(x)\|+C)\,dx\\ &\leqq C\int_{B'}[h_n(x, w_n(x), \nabla w_n(x))+1]\,dx\\ &\leqq\text{Const.}\end{aligned}$$

since the latter sequence is convergent. Hence, by Lemma 2.6 there exists $t_n \in [\|w_n - w_0\|_{L^1}^{1/2}, \|w_n - w_0\|_{L^1}^{1/3}]$ such that (2.14) holds (with $t = t_n$), and

$$t_n H_{N-1}\{x \in B' \,|\, |w_n(x) - w_0(x)| = t_n\} \leq \frac{\text{Const.}}{\ln \|w_n - w_0\|_{L^1}^{-1/6}}.$$

According to (2.14), choose $0 < s_n < t_n$ such that

$$\int_{\{s_n < |w_n(x) - w_0(x)| \leq t_n\}} (1 + |\nabla w_n(x) - \nabla u(x_0)|)\, dx = O(1/n),$$

$$\begin{aligned} &\frac{1}{t_n - s_n} \int_{B' \cap \{s_n < |w_n(x) - w_0(x)| \leq t_n\}} |w_n(x) - w_0(x)| \, \|\nabla |w_n(x) - w_0(x)|\, \| \, dx \\ &\quad \leq t_n H_{N-1}\{x \in \Omega \,|\, |w_n(x) - w_0(x)| = t_n\} + O(1/n), \end{aligned}$$

and set

$$\tilde{w}_n(x) := w^n_{s_n, t_n}(x).$$

By (2.9)

$$\|\tilde{w}_n - w_0\|_\infty \leq t_n \to 0,$$

and by (2.6), (2.11)-(2.14) we conclude that

$$\begin{aligned} \mu_a(x_0) &\geq \lim_n \frac{1}{\text{meas}\,(B)} \int_{B'} f(x_0 + r_n x, u(x_0) + r_n w_n(x), \nabla w_n(x))\, dx \\ &\geq \liminf_n \frac{1}{\text{meas}\,(B)} \int_{B' \cap \{|w_n(x) - w_0(x)| \leq s\}} h_n(x, w_n(x), \nabla w_n(x))\, dx \\ &\geq \liminf_n \frac{1}{\text{meas}\,(B)} \left\{ \int_{B'} h_n(x, \tilde{w}_n(x), \nabla \tilde{w}_n(x))\, dx \right. \\ &\quad \left. - O(1/n) - \frac{C}{\ln \|w_n - w_0\|_{L^1}^{-1/6}} - C \,\text{meas}\,\{x \in B \,|\, |w_n(x) - w_0(x)| > t_n\} \right\} \\ &= \liminf_n \frac{1}{\text{meas}\,(B)} \int_{B'} h_n(x, \tilde{w}_n(x), \nabla \tilde{w}_n(x))\, dx, \end{aligned}$$

since $t_n \geq \|w_n - w_0\|_{L^1}^{1/2}$, and thus

$$\text{meas}\,\{x \in B \,|\, |w_n(x) - w_0(x)| > t_n\} \leq \frac{1}{t_n} \|w_n - w_0\|_L^1 \leq \|w_n - w_0\|_{L^1}^{1/2} \to 0.$$

Finally, the bound on $\|\nabla \tilde{w}_n\|_{L^1(B')}$ follows from (2.10).

Step 4 (proof of Claim (2.5)). We want to show that

$$\mu_a(x_0) \geq f(x_0, u(x_0), \nabla u(x_0)) \quad \text{for a.e. } x_0 \in \Omega.$$

Let x_0 be a Lebesgue point for u, ∇u and such that (2.2) and (2.4) hold. If $g(x_0, u(x_0)) = 0$, then (2.5) is satisfied trivially as f is a nonnegative function. If $g(x_0, u(x_0)) > 0$ consider a subdomain $B' \Subset B$ and let $\varepsilon > 0$. By (2.8) and (H4) we have

$$\begin{aligned} \mu_a(x_0) &\geq \lim_n \frac{1}{\text{meas}\,(B)} \int_{B'} f(x_0 + r_n x, u(x_0) + r_n \tilde{w}_n(x), \nabla \tilde{w}_n(x))\, dx \\ &\geq \lim_n \frac{1}{\text{meas}\,(B)} \left\{ \int_{B'} f(x_0, u(x_0), \nabla \tilde{w}_n(x))\, dx - \varepsilon \int_{B'} (1 + \|\nabla \tilde{w}_n(x)\|)\, dx \right\}. \end{aligned}$$

By Proposition 2.5 and taking into account that $\{\nabla \tilde{w}_n\}$ is a sequence bounded in L^1, we deduce that

$$\mu_a(x_0) \geqq \frac{1}{\text{meas}\,(B)} \int_{B'} f(x_0, u(x_0), \nabla u(x_0))\, dx - \varepsilon C.$$

Letting $\varepsilon \to 0$, we conclude (2.5) given the arbitrariness of B'. □

3. Proofs of auxiliary results. In this section we prove Propositions 2.4 and 2.5.

PROPOSITION 2.4. (i) *If Theorem* 2.1 *holds true for* Ω *being a ball, it holds true for all open, bounded sets* Ω.

(ii) *Let* Ω *be a ball. If* (H1) *and* (H3) *hold and if* $u_n, u \in W^{1,1}(\Omega; \mathbb{R}^p)$ *are such that* $u_n \to u$ *in* $L^1(\Omega; \mathbb{R}^p)$, *then there exists* $\tilde{u}_n \in C_0^\infty(\mathbb{R}^N; \mathbb{R}^p)$ *such that* $\|\tilde{u}_n - u\|_{L^1_{(\Omega)}} \to 0$ *and*

$$\liminf_{n\to+\infty} \int_\Omega f(x, \tilde{u}_n(x), \nabla \tilde{u}_n(x))\, dx = \liminf_{n\to+\infty} \int_\Omega f(x, u_n(x), \nabla u_n(x))\, dx.$$

Proof. (i) As in Acerbi and Fusco [AF], we show that it suffices to prove Theorem 2.1 in the case where Ω is a ball. Indeed, if the result was true whenever the domain is a ball, for an arbitrary open set Ω and using Vitali's Covering Theorem, we can write

$$\Omega = \cup\, (a_i + \varepsilon_i B(0, 1)) \cup E,$$

where meas $(E) = 0$ and $\{a_i + \varepsilon_i B(0, 1)\}$ is a family of mutually disjoint balls. Fixing a positive integer k we have

$$\begin{aligned}\liminf_n \int_\Omega f(x, u_n(x), \nabla u_n(x))\, dx &\geqq \sum_{i=1}^k \liminf_n \int_{a_i+\varepsilon_i B(0,1)} f(x, u_n(x), \nabla u_n(x))\, dx \\ &\geqq \sum_{i=1}^k \int_{a_i+\varepsilon_i B(0,1)} f(x, u(x), \nabla u(x))\, dx.\end{aligned}$$

Letting $k \to +\infty$ and using the monotone convergence theorem, we conclude that

$$\int_\Omega f(x, u(x), \nabla u(x))\, dx \leqq \liminf \int_\Omega f(x, u_n(x), \nabla u_n(x))\, dx.$$

(ii) As in Acerbi and Fusco [AF], we remark that we can extend $u_n \in W^{1,1}(\Omega; \mathbb{R}^p)$ to $u_n^* \in W^{1,1}(\mathbb{R}^N; \mathbb{R}^p)$. Moreover, as $C_0^\infty(\mathbb{R}^N; \mathbb{R}^p)$ is dense in $W^{1,1}(\mathbb{R}^N; \mathbb{R}^p)$, there exist sequences $v_{n,k} \in C_0^\infty(\mathbb{R}^N; \mathbb{R}^p)$ such that

$$v_{n,k} \to u_n^* \quad \text{in } W^{1,1}(\mathbb{R}^N; \mathbb{R}^p) \tag{3.1}$$

as $k \to +\infty$. Moreover, we may assume that $v_{n,k}$ and $\nabla v_{n,k}$ converge to u_n and ∇u_n, respectively, almost everywhere. We claim that

$$\lim_k \int_\Omega f(x, v_{n,k}(x), \nabla v_{n,k}(x))\, dx = \int_\Omega f(x, u_n(x), \nabla u_n(x))\, dx. \tag{3.2}$$

Indeed, by (H3),

$$0 \leqq f(x, u, A) \leqq C(1 + \|A\|),$$

and thus by applying Fatou's lemma to $x \to f(x, v_{n,k}(x), \nabla v_{n,k}(x))$ and $C(1 + \|\nabla v_{n,k}(x)\|) - f(x, v_{n,k}(x), \nabla v_{n,k}(x))$ and by observing that

$$\int_\Omega (1 + \|\nabla v_{n,k}(x)\|)\, dx \to \int_\Omega (1 + \|\nabla u_n(x)\|)\, dx,$$

we have (3.2). Finally, using (3.1) and (3.2), for all n choose k_n such that

$$\|v_{n,k_n}-u_n\|_{L^1}\leqq\frac{1}{n}$$

and

$$\left|\int_\Omega f(x, v_{n,k_n}(x), \nabla v_{n,k_n}(x))\,dx-\int_\Omega f(x, u_n(x), \nabla u_n(x))\,dx\right|\leqq\frac{1}{n}.$$

It is clear that, setting

$$\tilde{u}_n := v_{n,k_n},$$

we have

$$\|\tilde{u}_n-u\|_{L^1_{(\Omega)}}\to 0$$

and

$$\lim_n\int_\Omega f(x, \tilde{u}_n(x), \nabla\tilde{u}_n(x))\,dx=\lim_n\int_\Omega f(x, u_n(x), \nabla u_n(x))\,dx. \qquad \square$$

We next prove Theorem 2.1 in the special case where $f=f(A)$ and u is an affine function. The proof presented here was obtained in Fonseca [Fo] (see Theorem 4.6 and Remark 4.16), and we are now aware of the fact that Marcellini's [Ma] proof for the case of weak convergence in $W^{1,m}$, $m>1$ is essentially the same. Yet another proof has been given by Kinderlehrer [K] who uses a subdivision of Ω in small domains in connection with the Vitali covering argument.

PROPOSITION 2.5. *Let $f: M^{pxN}\to\mathbb{R}$ be a function satisfying* (H1), (H2), *and*

$$0\leqq f(A)\leqq C(1+\|A\|)$$

for some $C>0$. If $A_0\in M^{pxN}$ and if $u_n\in W^{1,1}(\Omega;\mathbb{R}^p)$ are such that $u_n\to 0$ in $L^1(\Omega;\mathbb{R}^p)$ and $\{\|\nabla u_n\|_{L^1}\}$ is bounded, then

$$\text{meas}\,(\Omega)f(A_0)\leqq\liminf\int_\Omega f(A_0+\nabla u_n(x))\,dx.$$

Proof. The proof is taken from [Fo]. Related ideas appear in [DG] and [Ma]. We may assume without loss of generality that

$$\liminf\int_\Omega f(A_0+\nabla u_n(x))\,dx=\lim\int_\Omega f(A_0+\nabla u_n(x))\,dx)<+\infty.$$

Due to the growth condition, $\{\|\nabla u_n\|\}$ is bounded in L^1, and so there exists a subsequence and a finite measure μ in Ω such that

$$\|\nabla u_n\|\to\mu \quad \text{weakly*},$$

i.e., for every $\varphi\in C_0(\Omega)$

$$\int_\Omega \varphi(x)\|\nabla u_n(x)\|\,dx\to\int_\Omega\varphi(x)\,d\mu(x). \tag{3.3}$$

Consider an increasing sequence of subdomains Ω_k such that $\bar{\Omega}_k\Subset\Omega$ and $\Omega=\bigcup\Omega_k$. Let φ^k be a smooth cutoff function such that $0\leqq\varphi^k\leqq 1$, $\varphi^k=1$ in Ω_k, $\varphi^k=0$ in $\Omega\backslash\bar{\Omega}_{k+1}$. Setting

$$u_n^k:=\varphi^k u_n\in W_0^{1,1}(\Omega;\mathbb{R}^p),$$

as f is quasi convex, we have

$$\begin{aligned} f(A_0)\operatorname{meas}(\Omega) &\leqq \int_\Omega f(A_0+\nabla u_n^k(x))\,dx \\ &= \int_{\Omega\setminus\Omega_{k+1}} f(A_0)\,dx + \int_{\Omega_{k+1}\setminus\Omega_k} f(A_0+\nabla u_n^k(x))\,dx \\ &\quad + \int_{\Omega_k} f(A_0+\nabla u_n(x))\,dx, \end{aligned}$$

which implies that

$$f(A_0)\operatorname{meas}(\Omega_{k+1}) \leqq \int_{\Omega_{k+1}\setminus\Omega_k} f(A_0+\nabla u_n^k(x))\,dx + \int_{\Omega_k} f(A_0+\nabla u_n(x))\,dx.$$

As f is nonnegative, we deduce that

$$(3.4)\quad \int_\Omega f(A_0+\nabla u_n(x))\,dx - f(A_0)\operatorname{meas}(\Omega_{k+1}) \geqq -\int_{\Omega_{k+1}\setminus\Omega_k} f(A_0+\nabla u_n^k(x))\,dx.$$

On the other hand,

$$\begin{aligned} \int_{\Omega_{k+1}\setminus\Omega_k} f(A_0+\nabla u_n^k(x))\,dx &\leqq C\int_{\Omega_{k+1}\setminus\Omega_k} (1+\|A_0+\nabla u_n^k(x)\|)\,dx \\ &\leqq C\operatorname{meas}(\Omega_{k+1}\setminus\Omega_k) + C\int_{\Omega_{k+1}\setminus\Omega_k} \|\nabla u_n(x)\|\,dx \\ &\quad + C\int_{\Omega_{k+1}\setminus\Omega_k} |u_n(x)|\,\|\nabla\varphi^k(x)\|\,dx \\ &\leqq C\operatorname{meas}(\Omega_{k+1}\setminus\Omega_k) \\ &\quad + C\int_\Omega (\varphi_{k+1}(x)-\varphi_{k-1}(x))\|\nabla u_n(x)\|\,dx \\ &\quad + C\int_{\Omega_{k+1}\setminus\Omega_k} |u_n(x)|\,\|\nabla\varphi^k(x)\|\,dx. \end{aligned}$$

As $u_n\to 0$ in $L^1(\Omega)$, by (3.3) and (3.4) we obtain

$$\begin{aligned} &\lim_n \int_\Omega f(A_0+\nabla u_n(x))\,dx - f(A_0)\operatorname{meas}(\Omega_{k+1}) \\ &\quad \geqq -C\operatorname{meas}(\Omega_{k+1}\setminus\Omega_k) - C\int_\Omega (\varphi_{k+1}(x)-\varphi_{k-1}(x))\,d\mu(x). \end{aligned}$$

Finally, summing the above inequality for $k=2,\cdots,i$, we have

$$\begin{aligned} &(i-1)\lim_n \int_\Omega f(A_0+\nabla u_n(x))\,dx - f(A_0)\sum_{k=2}^{i}\operatorname{meas}(\Omega_{k+1}) \\ &\quad \geqq -C\sum_{k=2}^{i}\left\{\operatorname{meas}(\Omega_{k+1}\setminus\Omega_k) + \int_\Omega (\varphi_{k+1}(x)-\varphi_{k-1}(x))\,d\mu(x)\right\}. \end{aligned}$$

Dividing by $(i-1)$ we find

$$\lim_n \int_\Omega f(A_0+\nabla u_n(x))\,dx - f(A_0)\frac{1}{i-1}\sum_{k=2}^{i} \text{meas}\,(\Omega_{k+1})$$

$$\geqq -C\frac{1}{i-1}\{\text{meas}\,(\Omega_{i+1})-\text{meas}\,(\Omega_2)$$

$$+\int_\Omega (\varphi_{i+1}(x)+\varphi_i(x)+\varphi_2(x)-\varphi_1(x))\,d\mu(x)\}$$

$$\geqq -C\frac{1}{i-1}\{\text{meas}\,(\Omega)+4\mu(\Omega)\}.$$

Letting $i\to+\infty$, we conclude that

$$\lim_n \int_\Omega f(A_0+\nabla u_n(x))\,dx - f(A_0)\,\text{meas}\,(\Omega)\geqq 0. \qquad \square$$

4. Lower semicontinuity for convex integrands. Suppose that $f:\Omega x\mathbb{R}^p xM^{pxN}\to [0,+\infty)$ satisfies the hypotheses:

(H1) f is continuous;

(H2′) $f(x,u,\cdot)$ is convex;

(H3) there exists a nonnegative, bounded, continuous function $g:\Omega x\mathbb{R}^p\to [0,+\infty)$, c, $C>0$ such that

$$cg(x,u)\|A\|-C\leqq f(x,u,A)\leqq Cg(x,u)(1+\|A\|)$$

for all $(x,u,A)\in\Omega x\mathbb{R}^p xM^{pxN}$;

(H4′) for all $x_0\in\Omega x\mathbb{R}^p$ and for all $\varepsilon>0$ there exists $\delta>0$ such that $|x-x_0|<\delta$ implies that

$$|f(x_0,u,A)-f(x,u,A)|\leqq\varepsilon(1+\|A\|).$$

We obtain the following corollary of Theorem 2.1.

COROLLARY 4.1. *If the assumptions* (H1), (H2′), (H3), *and* (H4′) *hold and if* $u_n, u\in W^{1,1}(\Omega;\mathbb{R}^p)$ *are such that* $u_n\to u$ *in* $L^1(\Omega;\mathbb{R}^p)$, *then*

$$\int_\Omega f(x,u(x),\nabla u(x))\,dx\leqq\liminf\int_\Omega f(x,u_n(x),\nabla u_n(x))\,dx.$$

Clearly, in order to apply Theorem 2.1 it suffices to prove that for convex integrands with linear growth (H4′) reduces to (H4).

PROPOSITION 4.2. *If f satisfies* (H1), (H2′), *and* (H3), *then for all* $(x_0,u_0)\in\Omega x\mathbb{R}^p$ *and for all* $\varepsilon>0$ *there exists* $\delta>0$ *such that*

$$|u-u_0|<\delta \textit{ implies that } f(x_0,u,A)-f(x_0,u_0,A)\geqq-\varepsilon(1+\|A\|).$$

We introduce the recession function f^∞ given by

$$f^\infty(x,u,A):=\sup_{t>0}\frac{f(x,u,tA)-f(x,u,0)}{t}.$$

Note that, for fixed $(x,u,A)\in\Omega x\mathbb{R}^p xM^{pxN}$ and g given by $g(t):=f(x,u,tA)-f(x,u,0)$, g is a convex function with $g(0)=0$, and so

(4.1a) $\qquad t\to g(t)/t$ is increasing;

therefore,

$$\begin{aligned} f^\infty(x, u, A) &= \sup_{t>0} g(t)/t \\ &= \lim \frac{f(x, u, tA)}{t} \quad \text{as } t \to +\infty. \end{aligned} \tag{4.1b}$$

If (H1) and (H3) hold and if $f(x, u, \cdot)$ is convex, then $f^\infty(x, u, \cdot)$ is convex (and hence continuous), homogeneous of degree one, and (see, e.g., Fonseca and Rybka (FR, Lemma 2.3])

$$0 \leqq f^\infty(x, u, A) \leqq Cg(x, u)\|A\|$$

for all $(x, u, A) \in \Omega x \mathbb{R}^p x M^{pxN}$.

The proof of this result is based on the following auxiliary lemmas, where for notational convenience we omit the dependence of f on the variable x.

LEMMA 4.3. *If* (H2′) *and* (H3) *hold, then for all* $u \in \mathbb{R}^p$

$$\lim_{r\to+\infty} \sup_{\|A\|=1} \left| \frac{f(u, rA)}{r} - f^\infty(u, A) \right| = 0.$$

Proof. Fix $u \in \mathbb{R}^p$. By (H2′) and (H3) the functions

$$a \to \frac{f(u, rA)}{r}$$

are Lipschitz continuous uniformly with respect to r. By $(4.1)_2$ these functions converge to $f^\infty(u, \cdot)$ pointwise. By the Ascoli-Arzela theorem, the convergence is uniform on compact sets, and so

$$\lim_{r\to+\infty} \sup_{\|A\|=1} \left| \frac{f(u, rA)}{r} - f^\infty(u, A) \right| = 0. \qquad \square$$

LEMMA 4.4. *If* (H1), (H2′), *and* (H3) *hold, for all* $u_0 \in \mathbb{R}^p$ *and for all* $\varepsilon > 0$ *there exists* $\delta > 0$ *such that*

$$|u - u_0| < \delta \textit{ implies that } f^\infty(u, A) - f^\infty(u_0, A) \geqq -\varepsilon$$

for all matrices $A \in M^{pxN}$ *such that* $\|A\| = 1$.

Proof. Step 1. Assume that $f(u, 0) = 0$ and fix $u_0 \in \mathbb{R}^p$ and $\varepsilon > 0$. By (4.1) and by Lemma 4.3 we may choose $r_0 > 2$ such that

$$0 \leqq f^\infty(u_0, A) - \frac{f(u_0, r_0A)}{r_0} < \frac{\varepsilon}{2}$$

for every A with $\|A\| = 1$. On the other hand, as f is continuous there exists $\delta > 0$ (depending only on ε and r_0) such that

$$|u - u_0| < \delta \text{ implies } \sup_{\|A\|=1} |f(u, r_0A) - f(u_0, r_0A)| < \varepsilon.$$

By (4.1) we have

$$\begin{aligned} f^\infty(u, A) &\geqq \frac{f(u, r_0A)}{r_0} \\ &\geqq \frac{f(u_0, r_0A)}{r_0} - \frac{\varepsilon}{r_0} \\ &\geqq f^\infty(u_0, A) - \frac{\varepsilon}{2} - \frac{\varepsilon}{r_0} \\ &\geqq f^\infty(u_0, A) - \varepsilon. \end{aligned}$$

Step 2. As in the proof of the previous lemma, we set $g(u, A):=f(u, A)-f(u, 0)$, and we apply Step 1. The result follows from the fact that $f^\infty(u, A)=g^\infty(u, A)$. □

Proof of Proposition 4.2. *Step* 1. Assume that $f(u, 0)=0$, and fix $u_0\in\mathbb{R}^p$, $\varepsilon>0$. By (4.1), Lemma 4.3, and by continuity choose $r_0>2$, $\delta>0$ such that

$$0\leqq f^\infty(u_0, A)-\frac{f(u_0, r_0A)}{r_0}<\frac{\varepsilon}{2}$$

for every A with $\|A\|=1$, and

$$|u-u_0|<\delta \text{ implies } \sup_{\|A\|\leqq 1}|f(u, r_0A)-f(u_0, r_0A)|<\varepsilon.$$

Thus, if $|u-u_0|<\delta$ and if $\|A\|\leqq r_0$ we have

$$f(u, A)\geqq f(u_0, A)-\varepsilon\geqq f(u_0, A)-\varepsilon(1+\|A\|), \tag{4.2}$$

and by (4.1) if $A=rB$, $\|B\|=1$, $r>r_0$, then

$$\begin{aligned}\frac{f(u, A)}{\|A\|}=\frac{f(u, rB)}{r}&\geqq\frac{f(u, r_0B)}{r_0}\\ &\geqq\frac{f(u_0, r_0B)}{r_0}-\frac{\varepsilon}{r_0}\\ &\geqq f^\infty(u_0, B)-\frac{\varepsilon}{2}-\frac{\varepsilon}{r_0}\\ &\geqq f^\infty(u_0, B)-\varepsilon.\end{aligned}$$

Finally, as $f^\infty(u, \cdot)$ is homogeneous of degree one, by (4.1) we deduce that

$$f(u, A)\geqq f^\infty(u_0, A)-\varepsilon\|A\|\geqq f(u_0, A)-\varepsilon\|A\|,$$

which, together with (4.2), yields the result.

Step 2. In the general case we apply Step 1 to the function $g(u, A):=f(u, A)-f(u, 0)$ in order to find $\delta>0$ such that

$$|f(u, 0)-f(u_0, 0)|<\frac{\varepsilon}{2} \quad\text{and}\quad g(u, A)\geqq g(u_0, A)-\frac{\varepsilon}{2}(1+\|A\|)$$

whenever $|u-u_0|<\delta$. Hence

$$\begin{aligned}f(u, A)&\geqq f(u, 0)+f(u_0, A)-f(u_0, 0)-\frac{\varepsilon}{2}(1+\|A\|)\\ &\geqq f(u_0, A)-\frac{\varepsilon}{2}-\frac{\varepsilon}{2}(1+\|A\|)\\ &\geqq f(u_0, A)-\varepsilon(1+\|A\|).\end{aligned}$$ □

5. Concluding remarks. The integral representation for the relaxation $\mathcal{F}(\cdot)$ in $BV(\Omega)$ of

$$I(u):=\int_\Omega f(x, u(x), \nabla u(x))\,dx$$

was obtained in the scalar-valued case by Dal Maso [DM], who proved that

$$\begin{aligned}(5.1)\quad \mathcal{F}(u) = \int_\Omega f(x, u(x), \nabla u(x))\,dx + \int_{\Sigma(u)} D(x, u^-(x), u^+(x), \nu(x))\,dH_{N-1}(x)\\ + \int_\Omega f^\infty\left(x, u(x), \frac{dC(u)}{d|C(u)|}(x)\right) d|C(u)|(x),\end{aligned}$$

where H_{N-1} denotes the $N-1$-dimensional Hausdorff measure, and the distributional derivative Du of the function $u \in BV(\Omega; \mathbb{R})$ admits the decomposition into mutually singular Radon measures

$$Du = \nabla u L_N \lfloor \Omega + (u^+ - u^-)\nu H_{N-1} \lfloor \Sigma(u) + C(u).$$

Here L_N is the N-dimensional Lebesgue measure; ∇u denotes the absolutely continuous part of Du, i.e., the Radon-Nidodym derivative of Du with respect to $L_N, \Sigma(u)$ is the jump set of Du with normal ν defined for H_{N-1} almost everywhere $x \in \Omega$, and $C(u)$ is the Cantor part of the derivative (for details we refer the reader to Evans and Gariepy [EG], Federer [Fe], Ziemer [Zi]). In (5.1) f^∞ represents the *recession function* (see § 2), and $D(x, a, b, \nu)$ is given by

$$D(x, a, b, \nu) = \int_a^b f^\infty(x, s, \nu)\,ds.$$

In the isotropic vector-valued case, i.e., if $u : \Omega \to \mathbb{R}^p$ and $h = \|\cdot\|$, Baldo [B] and Fonseca and Tartar [FT1] obtained once again that the Γ-limit $J_0(\cdot)$ of

$$J_\varepsilon(u) := \int_\Omega \frac{1}{\varepsilon} W(u(x))\,dx + \varepsilon \int_\Omega h^2(\nabla u(x))\,dx$$

coincides with the relaxation

$$\mathcal{F}(u) := \inf_{\{u_n\}} \left\{ \liminf_{n \to +\infty} \int_\Omega f(x, u_n(x), \nabla u_n(x))\,dx \,\middle|\, u_n \in W^{1,1}(\Omega; \mathbb{R}^p),\ u_n \to u \text{ in } L^1 \right\},$$

where f is given by (1.3). This result confirms Gurtin's [G1], [G2] conjecture that the "preferred" solution has minimal surface energy (see also [Mo]).

In the anisotropic, vector-valued case and with u subject to the constraint curl $u = 0$, recent work by Kohn and Müller [KM] seems to indicate that the Modica and Mortola inequality

$$J_\varepsilon(u) \geqq \int_\Omega f(x, u(x), \nabla u(x))\,dx$$

with f given by (1.3) is no longer optimal. However, it is clear that

$$u \to \int_\Omega f(x, u(x), \nabla u(x))\,dx$$

still provides a lower bound for the rescaled energies $J_\varepsilon(\cdot)$. In particular, the Γ-limit must be bigger than or equal to $\mathcal{F}(u)$. The issue thus arises to find an integral representation for $\mathcal{F}(u)$ in the vector-valued case.

Fonseca and Rybka [FR] proved that, when $f(x, u, \cdot)$ is convex and if u takes only the values a and b across a plane with normal ν, then

$$\mathcal{F}(u)=\int_\Omega f(x, u(x), 0)\, dx+\int_{\Sigma(u)} K(x, a, b, \nu)\, dH_{N-1}(x),$$

where

$$K(x, a, b, \nu):=\inf\left\{\int_{Q_\nu} f^\infty(x, \xi(y), \nabla\xi(y))\, dy \,\middle|\, \xi\in\mathcal{A}\right\}$$

and

$$\mathcal{A}=\{\xi\in W^{1,1}(Q_\nu;\mathbb{R}^p)|\xi(y)=b \text{ if } y\cdot\nu=\tfrac{1}{2}, \xi(y)=a \text{ if } y.\nu=-\tfrac{1}{2}, \text{ and } \xi \text{ is periodic in the remaining } \nu_1, \cdots, \nu_{N-1} \text{ directions with period } 1\},$$

where $\{\nu_1, \cdots, \nu_{N-1}, \nu=\nu_N\}$ forms an orthonormal basis of $\mathbb{R}^N$ and Q_ν is the cube $\{y\in\mathbb{R}^N||y\cdot\nu_i|<\frac{1}{2}, i=1, \cdots, N\}$. The characterization of the surface energy density K was inspired by the work of Fonseca and Tartar [FT2].

Independently, Ambrosio and Pallara [AP] showed that $\mathcal{F}(\cdot)$ admits an integral representation with the same structure as in (5.1), and this result together with the work of Fonseca and Rybka [FR] provides a complete characterization of $\mathcal{F}(u)$, namely

$$\begin{aligned}\mathcal{F}(u)&=\int_\Omega f(x, u(x), \nabla u(x))\, dx+\int_{\Sigma(u)} K(x, u^-(x), u^+(x), \nu(x))\, dH_{N-1}(x)\\ &\quad+\int_\Omega f^\infty\left(x, u(x), \frac{dC(u)}{d|C(u)|}(x)\right) d|C(u)|(x).\end{aligned}\tag{5.2}$$

To identify the first and the third term on the right-hand side of (5.2) [AP] makes use of the lower semicontinuity results of Aviles and Giga [AG], whose proofs rely on sophisticated tools from geometric measure theory. Also, f has to satisfy linear growth condition from below, i.e.,

$$c\|A\|-C\leqq f(x, u, A)\leqq C(1+\|A\|)\tag{5.3}$$

for some $c, C>0$, preventing a situation as in (1.3). In addition, we remark that the convexity hypothesis on $f(x, u, \cdot)$ may be too restrictive. Indeed, as shown by Acerbi and Fusco [AF], Dacorogna [D], and Morrey [Mr] the $W^{1,1}$-weak lower semicontinuous envelope of the functional (1.2) is the integral of the quasi convexification of the energy density $f(x, u, \cdot)$, and so we expect quasi-convexity as a natural constitutive assumption rather than convexity. This concern is genuine as there are examples of quasi-convex functions with linear growth that are not convex (see Sverák [S] and Zhang [Zh]).

In this work we consider quasi-convex integrands, and we relax (5.3) to include degenerate lower bounds. Under these conditions we provide an analytical proof of the lower semicontinuity of (1.2) in L^1, thus obtaining the first term in the relaxation $\mathcal{F}(u)$. Our method seems to be appropriate to proving the lower semicontinuity of the third term in (5.2) corresponding to the Cantor part of the measure Du, and it might be conjectured that the representation of $\mathcal{F}(u)$ given by (5.2) is still valid for quasi-convex integrands with possibly degenerate lower bounds.

STABILITY IN OBSTACLE PROBLEMS FOR THE VON KARMAN PLATE*

E. MIERSEMANN[†] AND H. D. MITTELMANN[‡]

Abstract. The buckling beyond the critical load of a plate governed by the von Karman equations is studied. A variational inequality formulation of the problem is derived. The deflection of the plate is subject to an obstacle and the question of the stability of the state with a nontrivial contact set is considered. A stability criterion characterizing the bound through a Rayleigh quotient is proved in the general case. It is specialized to simply connected plates for which also a stress function is introduced. For a square plate numerical continuation along the variational inequality branch yields solutions whose stability is then checked through evaluation of the stability criterion. Stability bounds for both clamped and simply supported plates are obtained.

1. Introduction.

We consider a bounded domain Ω as base domain for a plate. It is assumed that the admissible deflections away from the base domain are bounded by a given obstacle and that the plate is compressed by a force $P\mathbf{K}(s)$, where $\mathbf{K}$ is a vector in the base domain acting on the boundary $\partial\Omega$ of Ω. Here, P denotes a real parameter. For $P > P_0$, where P_0 is the critical load of the free problem, the plate contacts the obstacle in a certain region. In many cases there exists a critical value $P_{\text{crit}} > P_0$ at which the deflection of the plate switches to another state. In the case of the linear theory of the plate critical loads P_{crit} were calculated in [7] for the circular plate, in [8] for the rectangular plate, in both cases for a constant obstacle.

Recently, earlier results of the authors were extended to nonconstant obstacles; see [9]. The determination of the critical load is based on a stability criterion for variational inequalities. The aim of this paper is to extend these results to the nonlinear theory of the plate governed by the von Karman equations. This nonlinear approach yields a good stability criterion from the mechanical point of view. In contrast to the above mentioned papers, variations of the displacement vector in the base domain are also considered.

In the numerical part of this paper, a rectangular plate with a constant obstacle is calculated. The results will be compared with the calculations for the linear plate problem from [8].

2. The physical background. Let $\Omega \subset \mathbf{R}^2$ be the bounded, possibly multiply connected middle surface of a thin elastic plate. We use the following notations:

$$w_{,\alpha} \equiv \frac{\partial w}{\partial x_\alpha}, \quad w_{,\alpha\beta} \equiv \frac{\partial^2 w}{\partial x_\alpha \partial x_\beta}, \quad \alpha, \beta = 1, 2.$$

D bending stiffness, $D = \dfrac{Eh^3}{12(1-\nu^2)}$,

h thickness of the plate,

E modulus of elasticity (Young's modulus),

ν Poisson ratio $(0 < \nu < \frac{1}{2})$.

By $w(x)$ and $v(x)$, $x = (x_1, x_2)$, we denote deflections perpendicular to the base domain and by $u = (u_1(x), u_2(x))$, $r = (r_1(x), r_2(x))$ displacement vectors in the base domain. The bending energy e_1 of the plate is given by (see, for example, [4, p. 50])

$$e_1 = \frac{D}{2} \int_\Omega \left[(\Delta w)^2 + 2(1-\nu)(w_{,12}^2 - w_{,11} w_{,22})\right] dx. \tag{2.1}$$

The stretching energy e_2 is, (cf. [4, p. 63])

$$e_2 = \frac{h}{2} \int_\Omega u_{\alpha\beta} \sigma_{\alpha\beta} \, dx. \tag{2.2}$$

We are using the summation convention. In (2.2), $u_{\alpha\beta}$ is the strain tensor and $\sigma_{\alpha\beta}$ the stress tensor.

According to the von Karman theory, it is assumed that

$$\sigma_{11} = \frac{E}{1-\nu^2}(u_{11} + \nu u_{22}), \quad \sigma_{22} = \frac{E}{1-\nu^2}(u_{22} + \nu u_{11}), \quad \sigma_{12} = \frac{E}{1+\nu} u_{12} \tag{2.3}$$

holds.

Instead of (2.3), we can write

$$\sigma_{\alpha\beta} = a_{\alpha\beta\gamma\sigma} u_{\gamma\sigma} \tag{2.4}$$

with

$$a_{1111} = \frac{E}{1-\nu^2}, \quad a_{1112} = 0, \quad a_{1122} = \frac{\nu E}{1-\nu^2},$$
$$a_{2212} = 0, \quad a_{2222} = \frac{E}{1-\nu^2}, \quad a_{1212} = \frac{E}{1+\nu},$$
$$a_{\alpha\beta\gamma\delta} = a_{\beta\alpha\gamma\delta}, \quad a_{\alpha\beta\gamma\sigma} = a_{\gamma\sigma\alpha\beta}.$$

Set

$$\epsilon_{\alpha\beta} = \tfrac{1}{2}(u_{\alpha,\beta} + u_{\beta,\alpha}).$$

In the nonlinear plate theory that yields the von Karman equations, it is assumed that

$$u_{\alpha\beta} = \epsilon_{\alpha\beta} + \tfrac{1}{2} w_{,\alpha} w_{,\beta} \tag{2.5}$$

holds.

The outer work is defined by

$$A = A_1 + A_2 + A_3, \tag{2.6}$$

where

$$A_1 = \sum_{i=0}^{m} \int_{S_i} u_\alpha f_\alpha^i \, dS;$$

here S_i denotes the $m+1$ disjoint curves of the boundary of Ω, and $f^i = (f_1^i, f_2^i)$ are vector fields defined on S_i.

$$A_2 = \int_\Omega u_\alpha f_\alpha \, dx,$$

where $f = (f_1, f_2)$ is a vector field defined on Ω,

$$A_3 = \int_\Omega wg \, dx;$$

here g denotes a scalar function defined on Ω.

Set $U = (u, w)$ with $u = (u_1, u_2)$, then the total energy is given by

$$e(U) = e_1(U) + e_2(U) - A(U).$$

Now, we assume that the admissible deflections w away from the base domain belong to a convex set V with $0 \in V$ and that the admissible displacements u are in a linear space $\mathcal{L}$. Replacing U by $U + \epsilon R$ with $R = (r, v - w)$, $0 < \epsilon < 1$, $r \in \mathcal{L}$, and $v \in V$, then $U + \epsilon R$ is an admissible vector in $\mathbf{R}^3$. We expand $e(U + \epsilon R)$ in powers of ϵ and obtain

$$e(U + \epsilon R) = e(U) + \epsilon e'(U)(R) + \frac{\epsilon^2}{2} e''(U)(R, R) + O(\epsilon^3). \tag{2.7}$$

Here e', e'', etc., denote (formal) Gateaux derivatives of real functionals.

Concerning the historical background of the following stability criterion, see [3, p. 257].

DEFINITION 2.1. The state U is said to be statically stable if

$$e(U + \epsilon R) > e(U)$$

holds for each fixed $R \neq 0$ and for all ϵ with $0 < \epsilon < \epsilon_0(R)$. This definition and expansion (2.7) imply a variational inequality as a necessary condition for a stable state, namely

$$e'(U)(R) \geq 0 \tag{2.8}$$

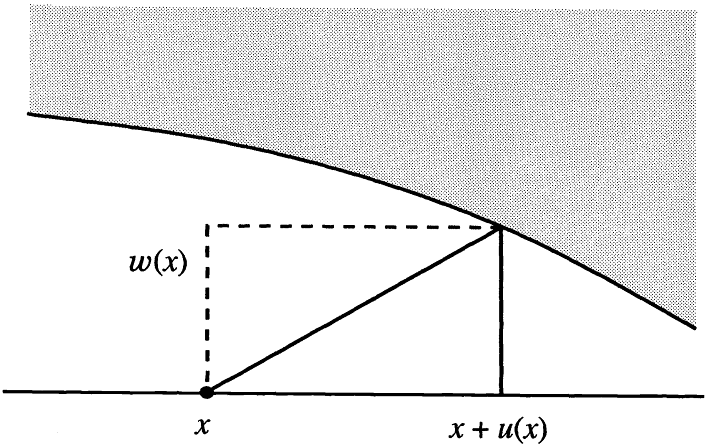

FIG. 1.1. *Plate subject to nonconstant obstacle.*

for all R.

According to the von Karman theory, the displacement vector U is given by

$$U(x) = u_1(x)\mathcal{E}_1 + u_2(x)\mathcal{E}_2 + w(x)\mathcal{E}_3,$$

where u_1, u_2, and w satisfy the system (2.11), (2.12) of §2. Here $\mathcal{E}_1$, $\mathcal{E}_2$, and $\mathcal{E}_3$ denote the basis vectors in $\mathbf{R}^3$. If one is interested in the physical problem where the displacements are restricted by an obstacle surface S given by $z = \psi(x)$, then the unilateral condition is characterized by the inequality

$$w(x) \leq \psi(x + u(x));$$

see Fig. 1.1.

This problem coincides with the problem considered in this paper only if $\psi(x) =$ const. For a nonconstant ψ, our problem may be considered merely as an approximation of the physical problem provided $u \cdot \nabla\psi$ is small.

2.1. The first Gateaux derivative. For the convenience of the reader, we derive here the first variation, see, for example, [4, p. 64]. Thus, we recall some more or less known facts. We have

$$e'(U)(R) = e_1'(U)(R) + e_2'(U)(R) - A(R).$$

The definitions of e_1 and A imply

$$e_1'(U)(R) = a(w, v - w),$$

where

$$a(w, v - w) \equiv D\int_\Omega [\Delta w \Delta(v - w) \\ + (1 - \nu)\{2w_{,12}(v - w)_{,12} - w_{,11}(v - w)_{,22} - w_{,22}(v - w)_{,11}\}]\, dx$$

and

$$A(R) = A_1(R) + A_2(R) + A_3(R)$$
$$\equiv \sum_{i=0}^{m} \int_{S_i} r_\alpha f_\alpha^i \, dS + \int_\Omega r_\alpha f_\alpha \, dx + \int_\Omega (v - w) g \, dx.$$

From (2.2) and (2.4) we obtain

$$e_2(U) = h \int_\Omega \psi(u_{\ell j}) \, dx, \tag{2.9}$$

where

$$\psi(u_{\ell j}) \equiv \tfrac{1}{2} u_{\alpha\beta} a_{\alpha\beta\gamma\sigma} u_{\gamma\sigma}.$$

The $u_{\alpha\beta}$ are defined through (2.5). Replacing U in (2.9) by $U + \epsilon R$, setting

$$u_{\alpha\beta}(\epsilon) \equiv \tfrac{1}{2}(u(\epsilon)_{\alpha,\beta} + u(\epsilon)_{\beta,\alpha}) + \tfrac{1}{2} w(\epsilon)_{,\alpha} w(\epsilon)_{,\beta} \tag{2.10}$$

with

$$u(\epsilon) = u + \epsilon r, \qquad w(\epsilon) = w + \epsilon(v - w),$$

we obtain

$$e_2'(U)(R) = h \int_\Omega \sigma_{\alpha\beta} u'_{\alpha\beta}(0) \, dx.$$

Here we have used the relation $\partial\psi/\partial u_{\ell j} = \sigma_{\ell j}$.

Using

$$u'_{\alpha\beta}(0) = \tfrac{1}{2}(r_{\alpha,\beta} + r_{\beta,\alpha}) + \tfrac{1}{2}\{w_{,\alpha}(v - w)_{,\beta} + w_{,\beta}(v - w)_{,\alpha}\}$$

and $\sigma_{\alpha\beta} = \sigma_{\beta\alpha}$, we finally arrive at

$$e_2'(U)(R) = h \int_\Omega \sigma_{\alpha\beta}\{r_{\alpha,\beta} + w_{,\alpha}(v - w)_{,\beta}\} \, dx.$$

Since w belongs to the convex set V and r to a linear space, the variational inequality splits into a coupled system of an inequality and an equation:

$$w \in V : \quad a(w, v - w) + h \int_\Omega \sigma_{\alpha\beta} w_{,\alpha}(v - w)_{,\beta} \, dx - \int_\Omega g(v - w) \, dx \geq 0 \tag{2.11}$$

for all $v \in V$;

$$h \int_\Omega \sigma_{\alpha\beta} r_{\alpha,\beta} \, dx = \sum_{i=0}^{m} \int_{S_i} f_\alpha^i r_\alpha \, dS + \int_\Omega f_\alpha r_\alpha \, dx \tag{2.12}$$

for all $r \in \mathcal{L}$. The symmetric stress tensor $\sigma_{\alpha\beta}$ and its dependence on w is given through (2.3) and (2.5).

For a given $w \in V$, (2.12) defines $\sigma_{\alpha\beta} = \sigma_{\alpha\beta}(w)$. Inserting these $\sigma_{\alpha\beta}$ into (2.11), we see that (2.11) is a nonlinear variational inequality in w and that the displacement vector u does not occur explicitly in (2.11).

For a remark concerning the existence of solutions to (2.11) or (2.12), see the next section.

Remark 2.1. If $\mathcal{L}$ is a convex set as well, with $0 \in \mathcal{L}$, then (2.12) has to be replaced by the associated variational inequality

$$h \int_\Omega \sigma_{\alpha\beta}(s_\alpha - r_\alpha)_{,\beta}\, dx \geq \sum_{j=0}^{m} \int_{S_i} f_\alpha^i (s_\alpha - r_\alpha)\, dS + \int_\Omega f_\alpha (s_\alpha - r_\alpha)\, dx \quad \text{for all } s \in \mathcal{L}.$$

2.2. The second Gateaux derivative. The second derivative of e_1 is given by (see the expansion (2.7))

$$e_1''(U)(R,R) = a(v,v),$$

where $R = (r, v)$; here we replace $v - w$ in (2.10) by v.

Since

$$e_2''(U)(R,R) = h\frac{d^2}{d\epsilon^2}\int_\Omega \psi(u_{\ell j}(\epsilon))\, dx$$

at $\epsilon = 0$, it follows that

$$\begin{aligned} h\frac{d^2}{d\epsilon^2}&\int_\Omega \psi(u_{\ell j}(\epsilon))\, dx \\ &= h\frac{d}{d\epsilon}\int_\Omega \frac{\partial\psi}{\partial u_{\ell j}} u'_{\ell j}(\epsilon)\, dx \\ &= h\int_\Omega \left\{ \frac{\partial\psi}{\partial u_{\ell j}} u''_{\ell j}(\epsilon) + \frac{\partial^2\psi}{\partial u_{\ell j}\partial u_{km}} u'_{\ell j}(\epsilon) u'_{km}(\epsilon) \right\} dx \\ &= h\int_\Omega \sigma_{\alpha\beta} v_{,\alpha} v_{,\beta}\, dx \\ &\quad + h\int_\Omega a_{\alpha\beta\gamma\delta}\left\{\epsilon_{\alpha\beta} + \frac{1}{2}[w_{,\alpha}v_{,\beta} + w_{,\beta}v_{,\alpha}]\right\}\left\{\epsilon_{\gamma\delta} + \frac{1}{2}[w_{,\gamma}v_{,\delta} + w_{,\delta}v_{,\gamma}]\right\} dx \end{aligned}$$

at $\epsilon = 0$, where $\epsilon_{\alpha\beta} = \frac{1}{2}(r_{\alpha,\beta} + r_{\beta,\alpha})$.

3. The stability criterion. Now we fix the function space under consideration. Let V be a closed convex subset of a Sobolev space H with $0 \in V$. In this paper we assume that $H = H_0^2(\Omega)$ for the clamped plate and $H = H_0^1(\Omega) \cap H^2(\Omega)$ for the simply supported plate. Then we set

$$V = \{v \in H; v(x) \leq \psi(x) \text{ on } \Omega\}.$$

Here $\psi \in C^4(\overline{\Omega})$ is given such that $\psi(x) > 0$ holds on $\overline{\Omega}$.

Let $\mathcal{L}$ be a closed linear subspace of $H^1(\Omega) \times H^1(\Omega)$.

Remark 3.1. Set

$$N_3 = \{(a + bx_2, c - bx_1); a, b, c \in \mathbf{R}\}$$

and $N \equiv \mathcal{L} \cap N_3$.

Under the assumption

$$\text{(A)} \qquad A_1(r) + A_2(r) = 0$$

for all $r \in N$, there exists for a given $w \in V$ a solution $u \in \mathcal{L}$ to (2.12) that is uniquely determined up to additive functions belonging to N. Here we have to take into account that (2.12) implies

$$h \int_{\Omega} a_{\alpha\beta\gamma\delta} \left\{ \epsilon_{\alpha\beta} + \frac{1}{2} w_{,\alpha} w_{,\beta} \right\} \eta_{\gamma\delta}\, dx = A_1(r) + A_2(r),$$

where

$$\epsilon_{\alpha\beta} = \tfrac{1}{2}(u_{\alpha,\beta} + u_{\beta,\alpha}), \qquad \eta_{\gamma\delta} = \tfrac{1}{2}(r_{\gamma,\delta} + r_{\delta,\gamma}).$$

From this it follows that

$$\int_{\Omega} a_{\alpha\beta\gamma\delta} w_{,\alpha} w_{,\beta} \eta_{\gamma\delta}\, dx = 0$$

holds for all $r \in N_3$.

The proof of the existence of solutions is based on Korn's inequality (see, for example, [1, Chap. III, §3]) for the three-dimensional case.

For existence results concerning variational inequalities of the type (2.11), see [5].

Define $\mathbf{H} = \mathcal{L} \times H$ and $\mathbf{V} = \mathcal{L} \times V$. Thus, $\mathbf{V}$ is a closed convex subset of $\mathbf{H}$.

Let $U = (u, w) \in \mathbf{V}$ be a solution of the coupled system of the variational inequality (2.11) and of the system of equations (2.12). We recall that $\sigma_{\alpha\beta}(w)$ in (2.11) is defined through (2.12).

In what follows, we are interested in whether U is stable in the sense that

$$e(W) \geq e(U)$$

holds for all $W \in \mathbf{V}$ such that $\|W - U\| < \rho$ for a sufficiently small $\rho > 0$, and equality takes place only for $W = U$. The norm on $\mathbf{H}$ is defined by

$$\|U\|^2 \equiv \|u_1\|^2_{H^1(\Omega)} + \|u_2\|^2_{H^1(\Omega)} + \|w\|^2_{H^2(\Omega)}.$$

For a given w let $\sigma_{\alpha\beta}(w)$ be the solution of (2.12) for $f^i = 0$ and $f = 0$, where $\sigma_{\alpha\beta}$ is defined through (2.3) and (2.5). By $\sigma^{(1)}_{\alpha\beta}$ we denote the solution of (2.12) for $f = 0$, where in (2.12) the $\sigma_{\alpha\beta}$ are defined through (2.3) with $u_{\alpha\beta} \equiv \epsilon_{\alpha\beta}$. That is, we set $w = 0$. Accordingly, we denote by $\sigma^{(2)}_{\alpha\beta}$ the solution with $f^i = 0$ on the right-hand side of (2.12).

Now, we replace f^i in (2.12) by $-\lambda_1 f^i$ and f by $-\lambda_2 f$ and g in (2.11) by $\lambda_3 g$ with real parameters λ_1, λ_2, and λ_3. Using this notation, we can decompose $\sigma_{\alpha\beta}$ of (2.11) as follows:

$$\sigma_{\alpha\beta} = \sigma_{\alpha\beta}(w) - \lambda_1 \sigma^{(1)}_{\alpha\beta} - \lambda_2 \sigma^{(2)}_{\alpha\beta}. \tag{3.1}$$

From the definition of the symmetric stress tensor through (2.12), we obtain ($n^{(i)}$denotes the outer unit normal at S_i)

$$\begin{aligned} \sigma_{\alpha\beta}(w)_{,\beta} &= 0 && \text{in } \Omega,\\ \sigma_{\alpha\beta}(w) n^{(i)}_{\beta} &= 0 && \text{on } S_i,\\ \sigma^{(1)}_{\alpha\beta,\beta} &= 0 && \text{in } \Omega,\\ h\sigma^{(1)}_{\alpha\beta} n^{(i)}_{\beta} &= f^i_{\alpha} && \text{on } S_i,\\ h\sigma^{(2)}_{\alpha\beta,\beta} &= f_{\alpha} && \text{in } \Omega,\\ \sigma^{(2)}_{\alpha\beta} n^{(i)}_{\beta} &= 0 && \text{on } S_i. \end{aligned} \tag{3.2}$$

For the second variation of e_2 we write

$$e_2''(U)(R,R) = e_{21}''(U)(R,R) + e_{22}''(U)(R,R),$$

where we have set

$$\begin{aligned} e_{21}''&(U)(R,R) \\ &= h\int_\Omega \sigma_{\alpha\beta}(w)v_{,\alpha}v_{,\beta}\,dx \\ &\quad + h\int_\Omega a_{\alpha\beta\gamma\delta}\left\{\epsilon_{\alpha\beta} + \frac{1}{2}[w_{,\alpha}v_{,\beta} + w_{,\beta}v_{,\alpha}]\right\}\left\{\epsilon_{\gamma\delta} + \frac{1}{2}[w_{,\gamma}v_{,\delta} + w_{,\delta}v_{,\gamma}]\right\} dx \end{aligned}$$

and

$$e_{22}''(U)(R,R) = -h\lambda_1\int_\Omega \sigma_{\alpha\beta}^{(1)}v_{,\alpha}v_{,\beta}\,dx - h\lambda_2\int_\Omega \sigma_{\alpha\beta}^{(2)}v_{,\alpha}v_{,\beta}\,dx,$$

that is, the right-hand side is independent of U.

For a given $t > 0$ we define

$$\mathbf{V}_t(U) = \{R \in \mathbf{H}; U + tR \in \mathbf{V}\}.$$

Let $R \in \mathbf{V}_t(U)$. Then $e(U+tR)$ is expanded with respect to t:

$$\begin{aligned} e(U+tR) &= e(U) + te'(U)(R) \\ &\quad + \frac{t^2}{2}\{e_1''(U)(R,R) + e_{21}''(U)(R,R) + e_{22}''(U)(R,R)\} \\ &\quad + O(t^3). \end{aligned} \tag{3.3}$$

Let U be a solution of the variational inequality (2.8), or equivalently, of the system (2.11), (2.12), where g in (2.11) is replaced by $\lambda_3 g$ and f^i in (2.12) by $-\lambda_1 f^i$ and f by $-\lambda_2 f$. That is, $w \in V$ is such that

$$\begin{aligned} a(w,v-w) &+ h\int_\Omega \sigma_{\alpha\beta}(w)w_{,\alpha}(v-w)_{,\beta}\,dx \\ &\geq \lambda_1 h\int_\Omega \sigma_{\alpha\beta}^{(1)}w_{,\alpha}(v-w)_{,\beta}\,dx + \lambda_2 h\int_\Omega \sigma_{\alpha\beta}^{(2)}w_{,\alpha}(v-w)_{,\beta}\,dx \\ &\quad + \lambda_3\int_\Omega g(v-w)\,dx \end{aligned}$$

for all $v \in V$, where $\sigma_{\alpha\beta}(w)$, $\sigma_{\alpha\beta}^{(1)}$ and $\sigma_{\alpha\beta}^{(2)}$ are defined through (3.2).

Set $\tilde{\mathbf{H}} = \tilde{\mathcal{L}} \times V$, where $\mathcal{L} = \tilde{\mathcal{L}} \oplus N$ is the orthogonal decomposition with respect to the Hilbert space norm on $H_1 \times H_1$; for notation, see Remark 3.1. Define

$$\tilde{\mathbf{V}} = \mathbf{V} \cap \tilde{\mathbf{H}}$$

and

$$\tilde{\mathbf{V}}_t = \mathbf{V}_t(U) \cap \tilde{\mathbf{H}}.$$

Set

$$e_{21}''(U)(R,R) = e_{211}''(R,R) + e_{212}''(U)(R,R),$$

where we define

$$e''_{211}(R,R) \equiv h \int_\Omega a_{\alpha\beta\gamma\sigma}\epsilon_{\alpha\beta}\epsilon_{\gamma\delta}\,dx.$$

Then, the sum

$$Q(R,R) \equiv e''_1(R,R) + e''_{211}(R,R)$$

is equivalent to the defined Hilbert space norm on $\tilde{\mathbf{H}}$.

We remark that each $W \in \tilde{\mathbf{V}}$, $W \neq U$, may be written as $U + tR$ with $t > 0$, $Q(R,R) = 1$, and $U + tR \in \tilde{\mathbf{V}}$, where $t^2 = Q(W-U, W-U)$ and $R = t^{-1}(W-U)$.

Remark 3.2.

$$Q(U)(R,R) \equiv e''_1(R,R) + e''_{21}(U)(R,R)$$

may also be used as a norm on $\tilde{\mathbf{H}}$, provided $\|U\|$ is not too large. This follows by using the inequality $2ab \leq \epsilon a^2 + \epsilon^{-1}b^2$ for all $\epsilon > 0$.

Define for a given positive constant A

$$\tilde{\mathbf{V}}_{t,A}(U) = \{R \in \tilde{\mathbf{V}}_t(U);\ Q(R,R) \leq 1 \text{ and } e'(U)(R) \leq At\}.$$

Set

$$q(U)(R,R) \equiv -e''_{212}(U)(R,R) - e''_{22}(R,R),$$

and let

$$\Lambda^{-1}_{\tilde{\mathbf{H}}} = \max_{R\in\tilde{\mathbf{H}}\setminus\{0\}} \frac{q(U)(R,R)}{Q(R,R)}.$$

The existence of a maximizer follows from Sobolev embedding theorems.

We make the following hypothesis.

(H) Let $t_n \to 0$, $t_n > 0$, and let $R_n \in \tilde{\mathbf{V}}_{t_n,A}(U)$ be a weakly convergent sequence $R_n \rightharpoonup R$. Then it follows that

$$q(U)(R,R) < 1.$$

THEOREM 3.1. *Suppose that the hypothesis* (H) *is satisfied with a constant A satisfying $2A > \Lambda^{-1}_{\tilde{\mathbf{H}}} - 1$. Then the solution U to the variational inequality $e'(U)(W - U) \geq 0$ for all $W \in \mathbf{V}$ defines a strict local minimum in the sense that there exist positive constants c and ρ such that*

$$e(W) - e(U) \geq c\|W-U\|^2$$

holds for all $W \in \tilde{\mathbf{V}}$ with $\|W - U\| < \rho$.

Proof. The result follows from the expansion

$$(3.4)\quad e(U+tR) = e(U) + te'(U)(R) + \frac{t^2}{2}[Q(R,R) - q(U)(R,R)] + O(t^3), \quad 0 < t \leq t_0.$$

If $R \in \tilde{\mathbf{V}}_t(U)$, $Q(R,R) = 1$ and $e'(U)(R) \geq At$ is satisfied for a constant A not depending on t, then (3.4) implies

$$e(U+tR) - e(U) \geq \frac{t^2}{2}[2A + 1 - \Lambda^{-1}_{\tilde{\mathbf{H}}}] + O(t^3).$$

Now, we consider those $R \in \tilde{\mathbf{V}}_t(U)$ such that $Q(R,R) = 1$ and $e'(U)(R) \leq At$. The expansion (3.4) yields that

$$e(U+tR) - e(U) \geq \frac{t^2}{2}[1 - q(U)(R,R)] + O(t^3)$$

since $e'(U)(R) \geq 0$ holds.

We pose the maximum problem

$$\begin{aligned}\mu_t(U) &\equiv \max_{R \in \tilde{\mathbf{V}}_{t,A}} q(U)(R,R) \\ &= q(U)(R_t, R_t),\end{aligned}$$

where R_t denotes a maximizer. If (H) is satisfied, then the assertion of the theorem follows.

4. A special case. To simplify the matter, we consider a simply connected plate and assume here that $\|U\|$ is small enough such that $Q(U)(R,R)$ defines a norm on $\tilde{\mathbf{H}}$; cf. Remark 3.2. Moreover, we suppose that the solution $U = (u,w)$ of the variational inequality (2.8) satisfies

$$\begin{aligned} w(x) &= \psi(x) \quad \text{on } C = \mathcal{A} \cup \partial\mathcal{A}, \\ w(x) &< \psi(x) \quad \text{on } \Omega \backslash C \end{aligned}$$

for an open set $\mathcal{A}$ with a piecewise smooth $\partial\mathcal{A}$.

We assume that $\lambda_2 = \lambda_3 = 0$ holds. Set $\lambda = \lambda_1/D$,

$$L_\lambda \psi \equiv \Delta^2 \psi - \frac{h}{D}\sigma_{\alpha\beta}(\psi)\psi_{,\alpha\beta} + \lambda h \sigma^{(1)}_{\alpha\beta}\psi_{,\alpha\beta},$$

and

$$A_1 \equiv \frac{\partial}{\partial n}(\Delta\psi - \Delta w)$$

on $\partial\mathcal{A}$; n denotes the outer unit normal on $\partial\mathcal{A}$.

As in [9, Lemma 4.3, Rem. 4.1], we prove the following.

LEMMA 4.1. *Let $L_\lambda\psi = 0$ on $\mathcal{A}$ and $A_1 > 0$ on $\partial\mathcal{A}$. Then the weak limit $R = (r,v)$ of hypothesis* (H) *of* §3 *satisfies $v = \nabla v = 0$ on $\partial\mathcal{A}$.*

Define

$$\mu^{-1} = \max_{R \in \tilde{\mathbf{H}}_0 \backslash \{0\}} \frac{Dh \int_\Omega \sigma^{(1)}_{\alpha\beta} v_{,\alpha} v_{,\beta}\, dx}{Q(U)(R,R)},$$

where

$$\tilde{\mathbf{H}}_0 = \{(r,v) \in \tilde{\mathbf{H}}; v = \nabla v = 0 \quad \text{on } \partial\mathcal{A}\}.$$

As in Theorem 3.1, we can prove the following result.

THEOREM 4.1. *Under the above assumptions, the solution $U = (u,w)$ of the variational inequality* (2.8) *defines a strict local minimum of e if $\lambda < \mu$ is satisfied.*

From the definition of μ it follows that μ is an eigenvalue of the problem: seek $R \in \tilde{\mathbf{H}}_0 \backslash \{0\}$, $R = (r,v)$ such that

$$Q(U)(R,S) = \mu h \int_\Omega \sigma^{(1)}_{\alpha\beta} v_{,\alpha} \phi_{,\beta}\, dx \tag{4.1}$$

for all $S \in \tilde{\mathbf{H}}_0 \backslash \{0\}$, $S = (s, \phi)$, where Q is defined by

$$Q(U)(R,S) \equiv a(v,\phi) + h \int_\Omega \sigma_{\alpha\beta}(w) v_{,\alpha}\phi_{,\beta}\, dx + h \int_\Omega \sigma_{\alpha\beta}(w,v)(s_{\alpha,\beta} + w_{,\alpha}\phi_{,\beta})\, dx$$

with

$$a(v,\phi) \equiv D \int_\Omega [\Delta v \Delta \phi + (1-\nu)\{2v_{,12}\phi_{,12} - v_{,11}\phi_{,22} - v_{,22}\phi_{,11}\}]\, dx.$$

The $\sigma_{\alpha\beta}(w,v)$ are defined through (2.12) with $f_\alpha \equiv 0$, $f_\alpha^{(i)} \equiv 0$, $i = 0, 1, \cdots, m$, and

$$u_{\alpha\beta} = \tfrac{1}{2}(r_{\alpha,\beta} + r_{\beta,\alpha}) + \tfrac{1}{2}(w_{,\alpha}v_{,\beta} + w_{,\beta}v_{,\alpha}).$$

$R = (r, v)$ denotes a solution of the above maximum problem for the Rayleigh quotient. This implies that the $\sigma_{\alpha\beta}$ are bilinear forms satisfying

$$\sigma_{\alpha\beta}(w,v) = \sigma_{\alpha\beta}(v,w) = \sigma_{\beta\alpha}(w,v). \tag{4.2}$$

This follows along the lines of §2.1. The definition of $\sigma_{\alpha\beta}(w)$ and $\sigma_{\alpha\beta}(w,v)$ implies that

$$\sigma_{\alpha\beta}(w + \epsilon v) = \sigma_{\alpha\beta}(w) + \epsilon\sigma_{\alpha\beta}(w,v) + \epsilon^2\sigma_{\alpha\beta}(v)$$

holds.

The equation (4.1) is equivalent to the system

$$\begin{aligned} &a(v,\phi) + h \int_\Omega \sigma_{\alpha\beta}(w) v_{,\alpha}\phi_{,\beta}\, dx + h \int_\Omega \sigma_{\alpha\beta}(w,v) w_{,\alpha}\phi_{,\beta}\, dx \\ &= \mu h \int_\Omega \sigma_{\alpha\beta}^{(1)} v_{,\alpha}\phi_{,\beta}\, dx \end{aligned} \tag{4.3}$$

and

$$\int_\Omega \sigma_{\alpha\beta}(w,v) s_{\alpha,\beta}\, dx = 0 \tag{4.4}$$

for all $s \in \mathcal{L}$, or equivalently,

$$\begin{aligned} \sigma_{\alpha\beta}(w,v)_{,\beta} &= 0 \quad \text{in } \Omega, \\ \sigma_{\alpha\beta}(w,v) n_\beta &= 0 \quad \text{on } \partial\Omega. \end{aligned} \tag{4.5}$$

Remark 4.1. In fact, the eigenvalue equation (4.3) is the linearization of the associated equation to the variational inequality (2.11) at w.

4.1. Introduction of the stress function. If the plate is simply connected, then it is well known that a stress function can be introduced and we get the von Karman equations in the nonconstrained case; see, for example, [4, p. 65] or [11, p. 109].

Let $U = (u, w) \in \mathbf{V}$ be a solution of

$$\begin{aligned} &\frac{1}{D} a(w, v - w) + \frac{h}{D} \int_\Omega \sigma_{\alpha\beta}(w) w_{,\alpha}(v - w)_{,\beta}\, dx \\ &\geq \lambda h \int_\Omega \sigma_{\alpha\beta}^{(1)} w_{,\alpha}(v - w)_{,\beta}\, dx \end{aligned} \tag{4.6}$$

for all $v \in V$, where $\sigma^{(1)}_{\alpha\beta}$, $\sigma_{\alpha\beta}(w)$ are defined in §3, and let $R = (r, v) \in \tilde{\mathbf{H}}_0$ be a solution of

$$\begin{aligned}\frac{1}{D}a(v,\phi) + \frac{h}{D}\int_\Omega \sigma_{\alpha\beta}(w)v_{,\alpha}\phi_{,\beta}\,dx + \frac{h}{D}\int_\Omega \sigma_{\alpha\beta}(w,v)w_{,\alpha}\phi_{,\beta}\,dx \\ = \mu h\int_\Omega \sigma^{(1)}_{\alpha\beta}v_{,\alpha}\phi_{,\beta}\,dx\end{aligned} \tag{4.7}$$

for all $(s,\phi) \in \tilde{\mathbf{H}}_0$.

The stress tensor $\sigma_{\alpha\beta}(w,v)$ is defined through (4.4) or (4.5). It follows from this definition that

$$\sigma_{\alpha\beta}(w,w) = 2\sigma_{\alpha\beta}(w) \tag{4.8}$$

holds.

Let $\chi \equiv \chi(w)$, $\chi \in H^2_0(\Omega)$ be the solution of

$$\Delta^2\chi = E(w^2_{,12} - w_{,11}w_{,22}). \tag{4.9}$$

χ is called a stress function. Then we have for $\sigma_{\alpha\beta} \equiv \sigma_{\alpha\beta}(w)$

$$\sigma_{11} = \chi_{,22}, \quad \sigma_{12} = -\chi_{,12}, \quad \sigma_{22} = \chi_{,11}. \tag{4.10}$$

The associated weak equation to (4.9) is given by $\chi \in H^2_0(\Omega)$;

$$\int_\Omega \Delta\chi\Delta\phi\,dx = E\int_\Omega (w_{,1}w_{,22}\phi_{,1} - w_{,1}w_{,2}\phi_{,2})\,dx$$

for all $\phi \in H^2_0(\Omega)$.

The $\sigma_{\alpha\beta}(w,v)$ in (4.7) are defined through (4.10) but with $\chi \in H^2_0(\Omega)$ given by

$$\Delta^2\chi = E(2w_{,12}v_{,12} - w_{,11}v_{,22} - w_{,22}v_{,11}), \tag{4.11}$$

or, equivalently, $\chi \in H^2_0(\Omega)$ such that

$$\int_\Omega \Delta\chi\Delta\phi\,dx = E\int_\Omega \{[w_{,1}v_{,22} + v_{,1}w_{,22}]\phi_{,1} - [w_{,1}v_{,12} + v_{,1}w_{,12}]\phi_{,2}\}\,dx$$

for all $\phi \in H^2_0(\Omega)$.

Let $\mu(\Omega\backslash C)$ be the lowest eigenvalue of (4.7) with v and ϕ defined on $\Omega\backslash C$ and $v = (\partial v/\partial n) = 0$, $\phi = (\partial\phi/\partial n) = 0$ on $\partial\mathcal{A}$ and in the case of a clamped plate on $\partial\Omega$, too. If the plate is simply supported, then the boundary conditions are $v = \phi = 0$ on $\partial\Omega$ and we have to add a free boundary condition on $\partial\Omega$; see, for example, [4, p. 54].

Let $\mu(\mathcal{A})$ be the lowest eigenvalue of (4.7) with $v, \phi \in H^2_0(\mathcal{A})$. Then, $U = (u, w)$ is stable if

$$\lambda < \min\{\mu(\Omega\backslash C), \mu(\mathcal{A})\} \equiv \mu_0$$

holds.

4.2. The rectangular plate. We take $\Omega = [0, a] \times [0, 1]$ and assume that the plate is compressed by the force $f^{(0)} = -\lambda_1 n$, n the outer unit normal. From (3.2) it follows that

$$h\sigma^{(1)}_{\alpha\beta} = \delta_{\alpha\beta},$$

where $\delta_{\alpha\beta}$ denotes Kronecker's symbol. If $v = 0$ on $\partial\Omega$, then (cf., for example, [4, p. 54])

$$a(v, v) = \frac{D}{2}\int_\Omega (\Delta v)^2\, dx - \frac{D}{2}(1 - \nu)\int_{\partial\Omega} \kappa \left(\frac{\partial v}{\partial n}\right)^2 dS.$$

Here κ denotes the curvature that is positive if $\partial\Omega$ is convex with respect to the inner normal at the boundary point under consideration. Thus, in the case of a rectangular plate, we have the variational inequality

$$\begin{aligned}&\int_\Omega \Delta w \Delta(v - w)\, dx + \frac{h}{D}\int_\Omega \sigma_{\alpha\beta}(w) w_{,\alpha}(v - w)_{,\beta}\, dx \\ &\geq \lambda \int_\Omega \nabla w \cdot \nabla(v - w)\, dx\end{aligned} \tag{4.12}$$

for all $v \in V$, where the $\sigma_{\alpha\beta}(w)$ are defined through (4.9) and (4.10).

The eigenvalue equation (4.7) reads now as

$$\Delta^2 v - \frac{h}{D}\sigma_{\alpha\beta}(w) v_{,\alpha\beta} - \frac{h}{D}\sigma_{\alpha\beta}(w, v) w_{,\alpha\beta} = -\mu\Delta v. \tag{4.13}$$

Here the $\sigma_{\alpha\beta}(w, v)$ are defined through (4.11) and (4.10). We have used the relations (4.5) and (3.2).

Further, $\mu(\mathcal{A})$ is the lowest eigenvalue of (4.13) with v defined on $\mathcal{A}$ and $v = (\partial v/\partial n) = 0$ on $\partial\mathcal{A}$, and $\mu(\Omega\backslash C)$ is the lowest eigenvalue of (4.13), where v is defined on $\Omega\backslash C$ and $v = (\partial v/\partial n) = 0$ holds on $\partial\mathcal{A}$, and $v = \Delta v = 0$ on $\partial\Omega$ for the simply supported plate or $v = (\partial v/\partial n) = 0$ on $\partial\Omega$ in the case of the clamped plate.

5. A remark concerning the unconstrained problem.

Here we consider a simply connected plate that is simply supported at the boundary $\partial\Omega$. That is, we have to describe $w = 0$ at $\partial\Omega$ for the deflections w perpendicular to the x-plane.

Let $f^i = 0$, $i = 1, 2, \cdots, m$, $f_\alpha = 0$, and $g = 0$, and set $f^0 = -\lambda_1 n$; n denotes the outer unit normal on $\partial\Omega$. A direct calculation shows that assumption (A) from §3 is satisfied.

In the absence of an obstacle, the system (2.11), (2.12) becomes

$$\Delta^2 w - \frac{h}{D}\sigma_{\alpha\beta}(w) w_{,\alpha\beta} = -\lambda\Delta w \quad \text{in } \Omega, \tag{5.1}$$

$$\Delta^2 \chi = E(w_{,12}^2 - w_{,11}w_{,22}) \quad \text{in } \Omega, \tag{5.2}$$

$$\sigma_{11} = \chi_{,22}, \quad \sigma_{12} = -\chi_{,12}, \quad \sigma_{22} = \chi_{,11}, \tag{5.3}$$

with the boundary conditions

$$\chi = \frac{\partial\chi}{\partial n} = 0 \quad \text{on } \partial\Omega, \tag{5.4}$$

$$w = 0 \quad \text{on } \partial\Omega, \tag{5.5}$$

$$Mw \equiv \frac{\partial^2 w}{\partial n^2} + \nu\kappa \frac{\partial w}{\partial n} = 0 \quad \text{on } \partial\Omega. \tag{5.6}$$

The last one is a free boundary condition; see, for example, [4, p. 54]. In the case of the clamped plate, we have to replace (5.6) by $\partial w/\partial n = 0$ on $\partial\Omega$.

Now, we are interested in the question of whether a solution of (5.1)–(5.6) is stable in the above sense. For this question concerning shells and plates, even when the first eigenvalue is not simple, see [2], [10] and the references therein.

Let λ_0 be the first eigenvalue of the linearized problem to (5.1)–(5.6), that is, of $\Delta^2 w + \lambda \Delta w = 0$ in Ω under the boundary conditions (5.5) and (5.6).

In what follows, we assume that λ_0 is a simple eigenvalue. We recall that, in the case of a simply supported plate, λ_0 is simple, and the associated eigenfunction does not change its sign in Ω provided Ω is convex; see [6].

By a well-known method, we find for the eigenvalue λ of (5.1)–(5.6) the expansion, $|\epsilon| < \epsilon_0$, ϵ_0 sufficiently small,

$$\lambda = \lambda_0 + \epsilon^2 \lambda_2 + O(\epsilon^3), \qquad w = \epsilon w_1 + \epsilon^2 w_2 + O(\epsilon^3), \tag{5.7}$$

where w_1 is an eigenfunction to the linearized problem and λ_2 is defined by

$$\lambda_2 = \frac{\frac{h}{D}\int_\Omega \sigma_{\alpha\beta}(w_1) w_{1,\alpha} w_{1,\beta}\, dx}{\int_\Omega |\nabla w_1|^2\, dx}.$$

Inserting the w from (5.7) into (4.13), we find that

$$v = w_1 + \epsilon^2 v_2 + O(\epsilon^3)$$

and

$$\mu = \lambda_0 + \epsilon^2 \mu_2 + O(\epsilon^3),$$

where μ_2 is given by

$$\mu_2 \int_\Omega |\nabla w_1|^2\, dx = \frac{h}{D}\int_\Omega \sigma_{\alpha\beta}(w_1) w_{1,\alpha} w_{1,\beta}\, dx + \frac{h}{D}\int_\Omega \sigma_{\alpha\beta}(w_1, w_1) w_{1,\alpha} w_{1,\beta}\, dx.$$

Since

$$\int_\Omega \sigma_{\alpha\beta}(w) w_{,\alpha} w_{,\beta}\, dx > 0$$

for $w \not\equiv 0$ (see, for example, [5, Lemma 7.4]) and (4.8) hold, we obtain

$$\mu_2 = \frac{\frac{3h}{D}\int_\Omega \sigma_{\alpha\beta}(w_1) w_{1,\alpha} w_{1,\beta}\, dx}{\int_\Omega |\nabla w_1|^2\, dx}$$

and thus $\lambda_2 < \mu_2$. This means the buckled state is stable, at least for small deflections.

5.1. Continuation from a stable buckled state. Let (w_s, λ_s) be a stable solution of (5.1)–(5.6). Now, we add τg to the right-hand side of (5.1), where τ is a real parameter and g is defined on Ω and sufficiently regular. We are interested in solutions $(w(\tau), \lambda(\tau))$ such that $(w(0), \lambda(0)) = (w_s, \lambda_s)$ holds.

Let $\mu(\tau)$ be the first eigenvalue to (4.13) with $w \equiv w(\tau)$, then, from §4, the stability criterion follows

$$(w(\tau), \lambda(\tau)) \text{ is stable if } \lambda(\tau) < \mu(\tau) \text{ is satisfied.}$$

We say that the stability bound is attained if and only if $\lambda(\tau) = \mu(\tau)$ holds.

6. Numerical results. For the numerical calculation we use the characterization of the eigenvalue μ_0 by the Rayleigh quotient; see §4. Set

$$B(v) = \int_\Omega |\nabla v|^2 \, dx$$

and

$$\begin{aligned} A(r, v) = &\int_\Omega (\Delta v)^2 \, dx + \frac{h}{D} \int_\Omega (\chi_{,22} v_{,1}^2 - 2\chi_{,12} v_{,1} v_{,2} + \chi_{,11} v_{,2}^2) \, dx \\ &+ \frac{h}{D} \int_\Omega \left[\frac{E}{1-\nu^2} (\tilde{\epsilon}_{11}^2 + \tilde{\epsilon}_{22}^2) + \frac{2\nu E}{1-\nu^2} \tilde{\epsilon}_{11} \tilde{\epsilon}_{22} + \frac{4E}{1+\nu} \tilde{\epsilon}_{12}^2 \right] dx, \end{aligned}$$

where

$$\tilde{\epsilon}_{\alpha\beta} = \tfrac{1}{2}(r_{\alpha,\beta} + r_{\beta,\alpha}) + \tfrac{1}{2}(w_{,\alpha} v_{,\beta} + w_{,\beta} v_{,\alpha}).$$

Then, μ_0 is given by

$$\mu_0 = \min_{\substack{(r,v) \in L \\ v \neq 0}} \frac{A(r, v)}{B(v)}, \tag{6.1}$$

where the linear space $\mathcal{L}$ contains all functions from $(H^1 \times H^1) \times H^2$ such that

$$\int_\Omega r_1 \, dx = 0, \quad \int_\Omega r_2 \, dx = 0, \quad \int_\Omega (x_2 r_1 - x_1 r_2 - r_{2,1} + r_{1,2}) \, dx = 0 \tag{6.2}$$

are satisfied for r and

$$\begin{aligned} &v = 0 \quad \text{on } \partial\Omega \quad \left(\text{and } \frac{\partial v}{\partial n} = 0 \text{ in the clamped case} \right), \\ &v = \frac{\partial v}{\partial n} = 0 \quad \text{on } \partial\mathcal{A} \end{aligned}$$

for v.

First, a continuation method has to be used to continue from the first bifurcation point λ_0 along the stable branch of solutions to the von Karman equations (5.1)–(5.5). λ_0 is given as the lowest eigenvalue of the linearized problem. Since the emphasis here is on the determination of the stability bound μ_0, a relatively simple method was used for this continuation, namely the projected relaxation method already used in [9]. Iteratively, the method was applied to (4.12) after first solving (4.9) for χ. Initially, a small multiple of the eigenfunction of the linearized problem was used as a starting guess; subsequently, the solution at a certain λ-value was used as a guess for $\lambda + \delta\lambda$. This corresponds to a zeroth-order predictor step. In general, this should be replaced by a first-order predictor as given in [9]. Also, instead of the relaxation algorithm, a projected Newton method as in §4 of [8] may be preferable. A finite-difference discretization as in [8], [9] was applied to (5.1)–(5.5); see the Appendix.

Second, the variational inequality solutions have to be tested for stability. At each computed point along this part of the branch, the eigenvalue problem (6.1), (6.2) is solved. This problem again was discretized by an analogous finite difference method. Both numerator and denominator in (6.1) are quadratic forms in the values at grid points of the variables v, r_1, and r_2. In order to make sure that the asociated matrices are symmetric, the functionals A, B were discretized, and the orthogonality conditions (6.2) were added through three additional rows and, for symmetry, also columns of the matrix associated with A, while the matrix for B had zero entries in these positions. The inverse iteration method with shift successfully applied in [8] was used to determine μ_0.

In the following we report about some computations for both the simply supported and the clamped square plate subject to a constant obstacle $\psi(x) \equiv d$. A square grid of size $\tilde{h} = 1/(n+1)$ is used, and $\delta\lambda$ is taken as 10(20) in the simply supported (clamped) case. With a bisection method λ is adjusted such that $\lambda = \mu_0(\lambda)$ holds. The physical quantities entering the problem (cf. §2) are chosen as those for a steel plate, $E = 2 \cdot 10^6$ kg/cm^2, $\nu = .25$. The obstacle has the value $d = .05$, and the thickness h of the plate has to satisfy $h < 2d$. A collection of formulae for the discrete problem is given in an appendix.

Computations for $n = 31$ yielded the stability bounds given in Table 6.1. These are the load values λ for which $\lambda = \mu_0(\lambda)$. They show that for the nonlinear theory stability holds for slightly different load values and contact sets compared to the linear theory; cf. [8]. For $w \equiv 0$ in (6.1) this reduces to the linear problem considered in [8] since the r_α are zero in the minimum. Also, formally, (6.1) reduces to this problem for $h/D \to 0$. Here this quotient is on the order of 10^{-2}. More extensive computations, also for nonconstant obstacles, will be done and presented elsewhere.

TABLE 6.1.
Stability bounds for square plate of length 1 *and thickness* $h = .025$

Boundary condition	stab. bound	% contact
simply supported	168.73	37.1
clamped	319.6	23.1

Appendix. The biharmonic operator on a square grid is approximated by the difference stencils (each has to be multiplied by $\tilde{h}^{-4}$)

$$\begin{array}{ccccc} & & 1 & & \\ & 2 & -8 & 2 & \\ 1 & -8 & 20 & -8 & 1 \\ & 2 & -8 & 2 & \\ & & 1 & & \end{array}$$

for grid points a distance of $2\tilde{h}$ or more from $\partial\Omega$. For points adjacent to $\partial\Omega$,

$$\begin{array}{ccccc} 1 & -8 & 21 & -8 & 1 \\ & 2 & -8 & 2 & \\ & & 1 & & \end{array} \qquad \begin{array}{ccc} 22 & -8 & 1 \\ -8 & 2 & \\ 1 & & \end{array}$$

are used for clamped, and

$$\begin{array}{ccccc} 1 & -8 & 19 & -8 & 1 \\ & 2 & -8 & 2 & \\ & & 1 & & \end{array} \qquad \begin{array}{ccc} 18 & -8 & 1 \\ -8 & 2 & \\ 1 & & \end{array}$$

are used for simply supported boundary conditions at $\partial\Omega$ or $\partial\mathcal{A}$. The standard five point star (multiplied by $\tilde{h}^{-2}$)

$$\begin{array}{ccc} & 1 & \\ 1 & -4 & 1 \\ & 1 & \end{array}$$

is used for the Laplace operator. Analogously, the terms $w_{,\alpha\beta}$ are approximated by the stencils (times $\tilde{h}^{-2}$)

$$\begin{array}{ccc} 1 & -2 & 1 \end{array} \qquad \begin{array}{c} 1 \\ -2 \\ 1 \end{array} \qquad \begin{array}{ccc} -\frac{1}{4} & 0 & \frac{1}{4} \\ 0 & 0 & 0 \\ \frac{1}{4} & 0 & -\frac{1}{4} \end{array}.$$

For the discretization of $B(v)$ in (6.1) the five-point star is used, which is equivalent to replacing B by

$$B_{\tilde{h}}(v) = \tilde{h}^2 \sum_{i,j=1}^{n+1} [(\delta^1_{i,j}v)^2 + (\delta^2_{i,j}v)^2],$$

where $v_{i,j} \hat{=} v(i\tilde{h}, j\tilde{h})$, $\delta^1_{i,j}v = (v_{i,j} - v_{i-1,j})/\tilde{h}$, and $v_{ij} = 0$ for $i, j = 0$, and $n+1$. Analogously,

$$\begin{aligned} \frac{1}{\tilde{h}^2} A_{\tilde{h}}(v, r) &= \sum_{i,j=1}^{n+1} (\delta^{12}_{i,j}v + \delta^{22}_{i,j}v)^2 \\ &\quad + \frac{h}{D}\left[\sum_{i,j=1}^{n+1} \tilde{\sigma}^{(i,j)}_{\alpha\beta}\delta^{\alpha}_{i,j}v\delta^{\beta}_{i,j}v + \frac{E}{1-\nu^2}\sum_{i,j=1}^{n+1}[(\tilde{e}^{(i,j)}_{11})^2 + (\tilde{e}^{(i,j)}_{22})^2]\right. \\ &\qquad \left. + \frac{2\nu E}{1-\nu^2}\sum_{i,j=1}^{n+1} \tilde{e}^{(i,j)}_{11}\tilde{e}^{(i,j)}_{22} + \frac{4E}{1+\nu}\sum_{i,j=1}^{n+1}(\tilde{e}^{(i,j)}_{12})^2\right], \end{aligned}$$

where

$$\delta^{\alpha 2} = \delta^{\alpha}(\delta^{\alpha}), \qquad \sigma_{\alpha\beta} = (-1)^{\alpha+\beta}\chi_{,\alpha\beta},$$
$$\tilde{e}^{(i,j)}_{\alpha\beta} = \tfrac{1}{2}(\delta^{\beta}_{i,j}r_{\alpha} + \delta^{\alpha}_{i,j}r_{\beta} + w^{(i,j)}_{,\alpha}\delta^{\beta}_{i,j}v + w^{(i,j)}_{,\beta}\delta^{\alpha}_{i,j}v),$$

and the summation convention is used with respect to α, β. The $\tilde{\sigma}_{\alpha\beta}$ are averages of the $\sigma_{\alpha\beta}$ in such a way that the matrix of the quadratic form $A_{\tilde{h}}$ is symmetric. The integrals in (6.2) were approximated by

$$\sum_{i,j=1}^{n+1} \tilde{h}^2 r_{1i,j}, \ \sum_{i,j=1}^{n+1} \tilde{h}^2 r_{2i,j},$$
$$\sum_{i,j=1}^{n+1} \tilde{h}^2[r_{1i,j}(j-1)\tilde{h} - r_{2i,j}(i-1)\tilde{h} - \delta^1_{i,j}r_2 + \delta^2_{i,j}r_1].$$

ON ASYMPTOTICS OF SOLUTIONS OF ELLIPTIC MIXED BOUNDARY VALUE PROBLEMS OF SECOND-ORDER IN DOMAINS WITH VANISHING EDGES*

JACEK BANASIAK†

Abstract. This paper investigates the behavior of variational solutions of second-order elliptic mixed boundary value problems (MBVP) with real coefficients in n-dimensional domains with edges near the points where the edges are vanishing. It is shown that the first coefficient involved in the decomposition of the solution into regular and singular part can be extended continuously in appropriate spaces across such points, thus showing that the standard decomposition formula holds also in such domains.

Key words. elliptic boundary value problems, nonsmooth domains

AMS(MOS) subject classification. 35J25

Introduction. In this paper we investigate the H^2-regularity of variational solutions of the second-order elliptic problem

$$Au=f \text{ in } \Omega, \quad u=\phi \text{ on } \Gamma_D, \quad Bu=\psi \text{ on } \Gamma_N, \tag{0.1}$$

where $\Omega \subset \mathbb{R}^n$ is a bounded domain with boundary Γ consisting of smooth parts Γ_D and Γ_N and a "collision submanifold" Γ_c, which can coincide with an edge of Γ. A and B are, respectively, second- and first-order differential operators defined in some neighborhood of $\bar{\Omega}$. Problem (0.1) has been investigated since the end of the 1960s, starting from the pioneering paper by Kondratiev [9]. It is known that, in general, the solutions to (0.1) have singularities due to presence of Γ_c. One of the constructive methods in dealing with such singularities is to seek a decomposition of the solution into two parts, one of which is regular, whereas the second carries all information about the singularity of solution. Such methods provided practically complete descriptions of two-dimensional problems; see, e.g., [7], [12], [1], [2]. In more dimensions certain difficulties occur. One type of decomposition formula for variational solution to (0.1), [10], specified, for example, to $A=\Delta$, $B=\partial/\partial n$, and either $\pi/2<\alpha\leqq\omega(t)\leqq\beta<\pi$ or $\pi<\gamma\leqq\omega(t)\leqq\delta<3\pi/2$ on Γ_c reads

$$u(x)=u_{\text{reg}}(x)+c_0(t)r^{\pi/2\omega(t)}\sin\frac{\pi v}{2\omega(t)}. \tag{0.2}$$

Above, $x=(r,\vartheta,t)$, $t\in\Gamma_c$, $r(x)=\operatorname{dist}(x,\Gamma_c)$, u_{reg} is a "regular" function, and c_0 is square-summable on Γ_c.

Formulas of that type are not always satisfactory since u_{reg} is usually not sufficiently regular along Γ_c due to poor regularity of c_0; see, e.g., [6]. So, instead of (0.2), the so-called "nontensor product" decomposition [13] was proposed; see, e.g., [8], [5]. Here the "regular" term is indeed regular with respect to all variables. The main disadvantage of such decomposition is that variables, tangential and transversal to Γ_c, are not explicitly separated as in (0.2), except in special cases, discussed in [13], where the authors have shown that for higher regularity of data the tensor product form exists and has required regularity properties.

* Received by the editors November 16, 1990; accepted for publication (in revised form) November 25, 1991.

† Institute of Mathematics, Technical University of Łódź, Poland.

However, as pointed out in [3], e.g., neither method deals with the case when the opening ω between Γ_D and Γ_N is equal to π in certain points of Γ_c. We shall consider this case here, calling it a "vanishing edge." The difficulty arising here is due to the fact that such a domain is not locally diffeomorphic to a dihedral angle.

Our method of dealing with this difficulty is based on a decomposition formula for variational solution u of two-dimensional problems. To use this formula, we reduce (0.1) locally to a model two-dimensional problem with parameter, thus obtaining a family of decomposition formulas, which can be "glued" together thanks to explicit expressions for coefficients of the decomposition. Thus, our technique leads us directly to formulas of type (0.2), and our main result, specified to the quoted example, is that (0.2) holds if $\pi/2<\alpha\leqq\omega(t)\leqq 3\pi/2$.

We decided to confine ourselves only to the first asymptotic in order to show in the clearest way possible the influence of the "vanishing edge" on the first step of regularization of the variational solution. Higher regularization involves a number of both technical and qualitative problems of its own, [10], [12], [3], which, added to geometrical difficulties, see (A6), creates a difficult problem, which was beyond the scope of our investigation.

1. Basic notations and definitions. Let Ω be a bounded open subset of $\mathbb{R}^n$ with the boundary $\Gamma=\Gamma_D\cup\Gamma_N\cup\Gamma_c$, where Γ_D and Γ_N are open $C^{3,1}$-submanifold in Γ such that $\Gamma_D\cap\Gamma_N=\emptyset$ and $\bar{\Gamma}_D\cap\bar{\Gamma}_N=\Gamma_c$. Γ_c is assumed to be $n-2$-dimensional, $C^{3,1}$-submanifold of Γ, and $\Gamma_c=\bigcup_{i=1}^r\Gamma_i$, $1\leqq r<\infty$. We assume that all Γ_i are closed and every point $x\in \operatorname{Int}_r\Gamma_i$ (interior relative to Γ_c) has a neighborhood in $\mathbb{R}^n$, diffeomorphic to an n-dimensional dihedral angle. Some Γ_i can be submanifolds with boundary $(bd\Gamma_i)$, and for $x\in bd\Gamma_i$ we have the $\omega(x)=\pi$. We assume that if $\Gamma_j\cap\Gamma_i\neq\emptyset$, then $\Gamma_i\cap\Gamma_j=bd\Gamma_i\cap bd\Gamma_j$.

In other words, Γ_c can be situated on the edge of the boundary, and this edge can either vanish or change itself from acute to obtuse (or reversely) in some point of the boundary.

We shall denote by ∂^i the ith partial derivative. Let A be defined on a Sobolev space $H^2(\Omega)$ by

$$Au:=-\sum_{i,j=1}^n\partial^j(a_{ij}\partial^i u)+\sum_{i=1}^n a_i\partial^i u+a_0u. \tag{1.1}$$

We assume that A is strongly elliptic with real coefficients and $a_{ij}\in C^{2,1}(\bar{\Omega})$ for $i,j=1,\cdots,n$ and $a_i\in L_\infty(\Omega)$ for $i=0,\cdots,n$. By $\vec{\nu}_A$ we denote a vector field, coinciding with the conormal field on $\bar{\Gamma}_N$ and $\vec{\mu}:=\vec{\nu}_A+b\vec{\tau}$, where $b\in C^{2,1}(\mathbb{R}_n)$ and $\vec{\tau}$ is some vector field, tangent to $\partial\bar{\Omega}_N$. We define $B:=\gamma\partial^\mu=\gamma\sum_{i=1}^n\mu_i\partial^i$.

We consider the following problem: for given $f\in L_2(\Omega)$, find u satisfying

$$\begin{cases}Au=f & \text{in } \Omega,\\ \gamma u=0 & \text{on } \partial\Omega_D,\\ Bu=0 & \text{on } \partial\Omega_N.\end{cases} \tag{1.2}$$

We can assume that (1.2) has a unique solution $u\in H^1(\Omega)$, [1], [7]. We shall investigate the behavior of u in a vicinity of Γ_c, particularly near a "vanishing edge."

2. Geometry of the problem. In the first step we perform a change of variables, which is an analogue of the "flattening" of the boundary. We shall show that the domain with "vanishing edge" is locally diffeomorphic to a domain, called a generalized dihedral angle, where the opening can vary along the edge.

First we introduce some notation. For $\xi := (\xi_1, \cdots, \xi_n) \in \mathbb{R}^n$, $\xi := (\xi_1, \xi') := (\xi_1, \xi_2, \xi'')$, and also $\xi_1^0 := (\xi_1, 0, \cdots, 0)$, $\xi_2^0 := (\xi_1, \xi_2, 0, \cdots, 0)$. $\vec{e}_i$ is a unit coordinate vector of a Cartesian system, and for any two vectors $\vec{a}$, $\vec{b}$, $\omega(\vec{a}, \vec{b})$ denotes the measure of the angle between them. Moreover, $\{\alpha_{ij}\}_{i,j=i}^n$ is the matrix of principal coefficients of A after transformation.

LEMMA 2.1. *For every $x \in \Gamma_c$ there exists an open neighborhood U_x of x and a $C^{1,1}$ diffeomorphism Φ: $U_x \to W^n$ (a unit cube) such that*

(a) $\Phi(U_x \cap \Gamma_N) = \{\xi \in W^n;\ \xi_1 = 0, \xi_2 > 0\}$;

(b) $\Phi(U_x \cap \Gamma_c) = \{\xi \in W^n;\ \xi_1 = \xi_2 = 0\}$;

(c) *For every $(0, 0, \xi'') \in W^n$ there exist $c_1 = c_1(\xi'')$, $c_2 = c_2(\xi'')$ satisfying $c_1^2 + c_2^2 = 1$ such that*

$$\Phi(U_x \cap \Gamma_D) \cap \{\xi \in \mathbb{R}^n;\ \xi'' = \text{const}\} = \{\xi \in W^n;\ c_1\xi_1 - c_2\xi_2 = 0\}.$$

We define $\omega(\xi'')$ by $\cos \omega = -c_1$ *and* $\sin \omega = c_2$:

(d) $\Phi(U_x \cap \Omega) = \{\xi \in W^n;\ 0 < \omega(\vec{e}_2, \vec{\xi}_2^0) < \omega(\xi'')\}$;

(e) $(\mathcal{J}_\Phi \vec{u})(0, \xi') = \vec{m}(\xi'') = (m_1(\xi''), m_2(\xi''), 0, \cdots, 0)$

for $\xi_2 > 0$ and $m_1 \neq 0$, where $\mathcal{J}_\Phi$ denotes the Jacobi matrix of Φ;

(f) $\bar{\alpha}_{11} = \bar{\alpha}_{22} = 1$ *and* $\bar{\alpha}_{12} = \bar{\alpha}_{21} = 0$ *for* $\xi_1 = \xi_2 = 0$.

Remark 2.2. A sketch of the proof and explicit formula for $\omega(\xi'')$ is given in the Appendix. Here we only note that if the edge of Ω vanishes at x, then $\omega(\xi'') = \pi$, where $(0, 0, \xi'') = \Phi(x)$.

3. Regularity of the solution. According to § 2, MBVP (1.2) is locally equivalent to the following problem:

$$(3.1) \qquad \begin{cases} \tilde{A}u = f & \text{in } D, \\ \tilde{B}u = -\partial_1 u + b(t)\partial_2 u = 0 & \text{on } G_N, \\ \gamma u = 0 & \text{on } G_D. \end{cases}$$

where $t := \xi''$ will hereafter denote the parameter along the edge, D is defined by Lemma 2.1(d), $G_N := \Phi(\Gamma_N)$, $G_D = \Phi(\Gamma_D)$. Moreover, $b(t) = m_2(t)/m_1(t)$ (see Lemma 2.1(e)). We put $G_c := \Phi(\Gamma_c)$. The main aim of the paper is to prove Theorem 3.1, which describes the behavior of the solution to (3.1) close to the points, where $\omega(t) = \pi$. Let $\psi(t) = \operatorname{arccot} b(t)$, $0 < \psi < \pi$, $\lambda_m(t) = (-\psi(t) + m\pi)/\omega(t)$, $m = 0, \pm 1, \cdots$, and $\bar{\xi} = (\xi_1, \xi_2)$, and $D^t = D \cap \{\xi;\ t = \text{const}\}$. Then we have the following.

THEOREM 3.1. *Let $u \in H^1(D)$ be a solution of* (3.1), *and $\vartheta(t) = \omega(t) + \psi(t)$ satisfies $\pi < \vartheta(t) \leqq 2\pi$ for $t \in G_c$. Then*

$$u(\bar{\xi}, t) = u_{\text{reg}}(\bar{\xi}, t) + c_1(t) \cdot r^{\lambda_1(t)} \sin(\lambda_1(t)\theta + \Psi(t)),$$

where

$$c_1 \in L_2(\{t \in G_c;\ \vartheta(t) \geqq k\}),$$

$$u_{\text{reg}} \in L_2(\{t \in G_c;\ k \leqq \vartheta(t) \leqq 2\pi\}, H^2(D_t))$$

for every $k > \pi$.

The proof depends on a number of lemmas and is postponed till the end of this section. We start with the following considerations. According to Lemma 2.1(e),

$$(3.2) \qquad \tilde{A}u = \Delta u + \tilde{A}_1 u + \tilde{A}_2 u + \sum_{i=1}^n \tilde{a}_i \partial^i u + \tilde{a}_0 u,$$

where $\tilde{A}_1 u = \sum_{i,j=1}^{2} \partial^i(\tilde{a}_{ij}\partial^j u)$ with $\tilde{a}_{ij}(0,0,\xi'')=0$ for $i,j=1,2$ and $\tilde{A}_2 u = \sum_{i,j\in K} \partial^i(\tilde{a}_{ij}\partial^j u)$, where

$$K=\{(i,j);\, 1\leqq i\leqq n, 3\leqq j\leqq n \text{ or } 3\leqq i\leqq n, 1\leqq j\leqq n\}.$$

Our aim is to show that if u is a H^1-solution of (3.1) (with compact support), then both $\tilde{A}_1 u$ and $\tilde{A}_2 u$ belong to $L_2(D)$. Certainly, the two last summands in (3.2) are square summable; thus, we include them in the right-hand side of the equation.

We recall that we are concentrated upon points with $\omega(t)=\pi$. Other cases have been extensively dealt with in [4], [10], [12]. We use those results without further comments.

Thanks to Lemma 2.1(a)-(d), the boundary of D near the point $\xi=(0,0,t)\in G_c$ such that $\omega(t)=\pi$ can be described by

$$\xi_1 = d\,(\xi') = \begin{cases} 0 & \text{for } \xi_2 \geqq 0,\\ \xi_2 \tan\omega(t) & \text{for } \xi_2<0,\end{cases}$$

where $\xi'=(\xi_2,t)$. We "flatten" D by

$$\zeta_1=\xi_1-d(\xi'),\qquad \zeta'=\xi'. \tag{3.3}$$

This is an invertible transformation with inverse given by

$$\xi_1=\zeta_1+d\,(\zeta'),\qquad \xi'=\zeta'. \tag{3.3'}$$

For derivatives we have the following formulas:

$$\partial^2\zeta_1=\begin{cases}0, & \xi_2>0,\\ -\tan\omega(t), & \xi_2<0,\end{cases}\qquad \partial^i\zeta_1=\begin{cases}0, & \xi_2>0,\\ -\xi_2\cdot\partial^i\omega(t)\cdot\cos^{-2}\omega(t), & \xi_2<0,\end{cases} \tag{3.4}$$

for $i\geqq 3$ and $\partial^j\zeta_i=\delta_{ij}$ for $i\geqq 2, j\geqq 1$, and $i=j=1$. Since $\partial^i\omega(t)\cdot\cos^{-2}\omega(t)$ is continuous in a neighborhood of t with $\omega(t)=\pi$, we see that $\partial^i\zeta_1$ are continuous for $i\geqq 3$ and only $\partial^2\xi_1$ suffers a jump across G_c. Thus, the transformation (3.3) is bi-Lipschitz with Jacobian equal to 1. Since $u\in H^1(D)$, (3.1) is equivalent to

$$\int_D \sum_{i,j=1}^{n} \hat{a}_{ij}\partial^i u\partial^j v\, d\xi = \int_D fv\, d\xi \tag{3.5}$$

for every $v\in H^1(D)$ such that $\gamma u=0$ on G_D, where $\hat{a}_{12}:=\tilde{a}_{12}-b$ and $\hat{a}_{21}:=\tilde{a}_{21}+b$, and $\hat{a}_{ij}:=a_{ij}$ for remaining i, j. If $\bar{u}(\zeta):=u(\xi(\zeta))$, then $\bar{u}$ satisfies the identity

$$\int_{\mathbb{R}_n^+} \sum_{i,j=1}^{n} \bar{a}_{ij}\partial^i\bar{u}\partial^j v\, d\zeta = \int_{\mathbb{R}_n^+} \bar{f}v\, d\zeta \tag{3.6}$$

for every $v\in H^1(\mathbb{R}_n^+)$ satisfying $\gamma v=0$ for $\zeta_1=0$, $\zeta_2<0$ where $\bar{a}_{ij}:=\sum_{k,l=1}^{n}\hat{a}_{kl}\partial^i\zeta_k\partial^j\zeta_l$. By (3.4) a discontinuity of $\bar{a}_{ij}$ can only appear if either i or j equals 2, and then $\bar{a}_{ij}$ suffers a jump across G_c. Therefore, each $\bar{a}_{ij}$ is Lipschitz continuous in the direction of G_c and the following lemma holds.

LEMMA 3.2. *If $\bar{u}$ is a variational solution of* (3.5) *then $\partial^k\partial^1\bar{u}\in L_2(\mathbb{R}_n^+)$ for $(k,l)\in K$.*

Proof. The proof is analogous to Nirenberg's method of differential quotients [7], if we notice that the estimates for $\partial^k\partial^1\bar{u}$ involve only bounds for $\partial^1\bar{a}_{ij}$ $i,j=1,\cdots,n$ [7, Form. (2.2.2.4)]; so, if $k\geqq 1$, $l\geqq 3$, then $\partial^k\partial^1\bar{u}\in L_2(\mathbb{R}_n^+)$ by (3.4). □

Therefore, we see that $\bar{u}$ satisfies the equation

$$\sum_{i,j=1}^{2}\bar{a}_{ij}\partial^i\partial^j\bar{u}=F=\bar{f}-\sum_{i,j\in K}\bar{a}_{ij}\partial^i\partial^j\bar{u}\quad\text{in } \mathbb{R}_n^+, \tag{3.7}$$

where, by Lemma 3.2, $F \in L_2(\mathbb{R}_n^+)$. However, (3.7) is still not satisfactory since the $\tilde{a}_{ij}$ have jumped across G_c. To overcome this difficulty, let us consider (3.7) in the variational form:

$$\int_{\mathbb{R}_n^+} \sum_{i,j=1}^{2} \tilde{a}_{ij}\partial^i \tilde{u} \partial^j \tilde{v}\, d\zeta = \int_{\mathbb{R}_n^+} Fv\, d\zeta \tag{3.8}$$

for v as in (3.6). Applying (3.3′) to the identity (3.8), we see that $u \in H^1(D)$ satisfies

$$\int_D \sum_{i,j=1}^{2} a_{ij}^* \,\partial^i u \partial^j v\, d\xi = \int_D F^* v\, d\xi \tag{3.9}$$

for v as in (3.5), where

$$a_{11}^* = \tilde{a}_{11} - 2\sum_{j=3}^{n} \tilde{a}_{1j}\partial^j d - \sum_{i,j=3}^{n} \tilde{a}_{ij}\partial^i d \partial^j d, \tag{3.10}$$

$$a_{ij}^* = \hat{a}_{ij} - \sum_{k=3}^{n} \tilde{a}_{2k}(\partial^k d) \quad \text{for } i=1, j=2 \quad \text{or} \quad i=2, j=1 \text{ (see (3.5))},$$

$$a_{22}^* = \tilde{a}_{22} \quad \text{and} \quad F^*(\xi) = F(\zeta(\xi)).$$

Thus, coefficients of (3.9) are Lipschitz continuous. Fubini's theorem, applied to (3.9), shows that for almost everywhere $t \in G_c u(\cdot, t)$ is a variational solution of the two-dimensional problem:

$$\int_{D'} \sum_{i,j=1}^{2} a_{ij}^*\partial^i u \partial^j v\, d\xi_1\, d\xi_2 = \int_{D'} F^* v\, d\xi_1\, d\xi_2, \tag{3.11}$$

where $v \in H^1(D')$, $\gamma v = 0$ on $G_D^t := G_D \cap \{\xi;\ t = \text{const}\}$. Now we have the following.

LEMMA 3.3. *Let* $r = (\xi_1^2 + \xi_2^2)^{1/2}$. *If* $u \in H^1(D)$ *satisfies* (3.1), *then* $r\partial^i\partial^j u \in L_2(D)$ *for* $i, j = 1, 2$.

Proof. The proof depends on Kondratiev's estimation for MBVP in a rectilinear angle, [9]; see also [14]. Since $u(\cdot, t)$ satisfies (3.10), we have for almost every t and $i, j = 1, 2$, [9],

$$\int_{D'} r^2 |\partial^i\partial^j u|^2\, d\xi_1\, d\xi_2 \leqq C \int_{D'} ((F^* r)^2 + (\partial^1 u)^2 + (\partial^2 u)^2 + (r^{-1}u)^2)\, d\xi_1\, d\xi_2, \tag{3.12}$$

where the constant C depends on the bound for coefficients and its first derivatives and, therefore, can be made common for all $t \in G_c$. Since $u = 0$ on Γ_D^t, we can use Hardy's inequality to estimate $(r^{-1}u)^2$. Finally, integrating (3.11) along G_c, we obtain the thesis of the lemma. □

The following proposition concerns the tangential regularity of the solution to (3.1), and although it is not used in the sequel, we give it for its own interest.

PROPOSITION 3.4. *If* u *satisfies* (3.1), *then* $\partial^i\partial^j u \in L_2(D)$ *for* $(i, j) \in K$.

Proof. We have $\partial^i\partial^j \bar{u} = \sum_{k,l=1}^{n} (\partial^k\partial^1 u)\partial^i\xi_k\partial^j\xi_l + \sum_{k=1}^{n} \partial^k u \partial^i\partial^j\xi_k$, $i, j = 1, \cdots, n$ where $\xi(\zeta)$ is defined by (3.3′). Since $(i, j) \in K$ and $u \in H^1(D)$, we see by (3.3) that the second summand is square integrable and will be omitted in the sequel. Moreover, $\partial^i\xi_k\partial^j\xi_1 \neq 0$ if and only if either $k = i$ and $l = j$ or $k = l = 1$ or we have a combination of the above conditions. Therefore, for $j \geqq 3$ $\partial^1\partial^j\bar{u} = \partial^1\partial^1 u\partial^j\xi_1 + \partial^1\partial^j u$, and since then $|\partial^j\xi_1| \leqq Mr$ for some $M \geqq 0$, we see by Lemmas 3.2 and 3.3 that $\partial^1\partial^j u \in L_2(D)$. Now let $i > 1$, $j \geqq 3$. Then $\partial^i\partial^i\bar{u} = \partial^1\partial^1 u\partial^i\xi_1\partial^j\xi_1 + \partial^i\partial^1 u\partial^j\xi_1 + \partial^1\partial^j u\partial^i\xi_1 + \partial^i\partial^j u$, and it follows that $|\partial^i\xi_1\partial^j\xi_1| \leqq Mr$. Therefore, application of Lemmas 3.2 and 3.3 and the first part of the proof gives the thesis. □

Now, from (3.2) and (3.10) we see that $a_{11}^* = 1 + \alpha$, where $|\alpha| \leqq Mr$ for some $M > 0$; thus, by Lemma 3.3, $\alpha \partial^1 \partial^1 u \in L_2(D)$. Similar considerations, applied to the remaining a_{ij}^*, show that for almost every $t \in G_c$, $u(\cdot, t)$ is an H^1-solution of the problem

$$\text{(3.13)} \qquad \begin{cases} \Delta u(\cdot, t) = \bar{\bar{F}}(\cdot, t) & \text{in } D^t, \\ B_t u = \partial^1 u(\cdot, t) + b(t)\partial^2 u = 0 & \text{on } G_N^t, \\ \gamma u(\cdot, t) = 0 & \text{on } G_D^t, \end{cases}$$

where $\bar{\bar{F}} = F^* - \sum_{i=1}^2 (a_{ii}^* - 1)\partial^i \partial^i u - (a_{12}^* + b)\partial^1\partial^2 u - (a_{21}^* - b)\partial^2 \partial^1 u \in L_2(D)$.

Therefore, we can use the two-dimensional theory developed in [1], [2], [4]. If we denote

$$\mathfrak{D}_t^1 = \{u \in H^1(D^t);\ \Delta u \in L_2(D^t),\ B_t u = 0 \text{ on } G_N^t,\ \gamma u = 0 \text{ on } G_D^t\},$$

$$\mathfrak{D}_t^2 = \mathfrak{D}_t^1 \cap H^2(D^t),$$

then, in particular, Δ is a topological isomorphism of $\mathfrak{D}_t^1$ (equipped with the graph norm) onto $L_2(D^t)$, and $\mathfrak{D}_t^2$ is a closed subspace of $\mathfrak{D}_t^1$ of finite codimension for any $\omega(t)$. Also, the image of $\mathfrak{D}_\mathrm{t}^2$ is closed in $L_2(D^t)$ since the boundary data are homogeneous. As a consequence, we see that for almost all $t \in G_c$, the solution u of (3.13) has the form

$$\text{(3.14)} \qquad u(\bar{\xi}, t) = u_r(\bar{\xi}, t) + \sum_{0<\lambda_m(t)<1} c_m(t) r^{\lambda_m(t)} \cdot \sin(\lambda(t)\theta + \psi(t)),$$

where $(r(\bar{\xi}), \theta(\bar{\xi}))$ are plane polar coordinates centered at zero and $u_r(\cdot, t) \in H^2(D^t)$. It follows, [1], that (3.14) holds for every ω and ψ. Now we can complete the proof of Theorem 3.1, focusing on the case $\omega(t) = \pi$, since the detailed considerations concerning the case where $\omega(t) \neq \pi$ can be found in [3], [10].

Proof of Theorem 3.1. In such a simple case as (3.13) it is possible to determine c_1 explicitly as in [10], [11]. We omit lengthy calculations that are similar to those in [10]. [11]. Let $w_1(\bar{\xi}, t) = w_1(r, \theta, t) = r^{-\lambda_1(t)} \times \sin(\lambda_1(t)\theta + \psi(t))$, and $\eta \in C_0^\infty(\mathbb{R}_n)$ be a function equal to 1 in the neighborhood of G_c, satisfying the adjoint boundary condition on $\bar{G}_D \cup \bar{G}_N$. Then

$$\text{(3.15)} \qquad c_1 = \frac{1}{\pi - \psi}\left(\int_{D^t} \bar{\bar{F}}\eta w_1 \, d\bar{\xi} + \int_{D^t} u\Delta(\eta w_1)\, d\bar{\xi}\right).$$

We see that the second integral, say $I_2(t)$, has no influence on regularity of c_1 since $\Delta(\eta w_1) = 0$ in a neighborhood of G_c. For the first integral, we have

$$\text{(3.16)} \qquad |I_1(t)| \leqq R(t) \|\bar{\bar{F}}(\cdot, t)\|_{L_2(D^t)} \cdot (\vartheta(t) - \pi)^{-1}$$

for a bounded R; so $c_1 \in L_2(\{t;\ \vartheta(t) \geqq k\})$ for k defined above.

Next, $u_{\mathrm{reg}}(\bar{\xi}, t) = u(\bar{\xi}, t) - c_1(t) \cdot w_1(\bar{\xi}, t)$ and since both summands on the right-hand side belong to $L_2(\{t;\ \vartheta(t) \geqq k\}, \mathfrak{D}_t^1)$, the left-hand side does also. However, $u_{\mathrm{reg}} \in \mathfrak{D}_t^2$ and norms, induced on $\mathfrak{D}_t^2$ from $H^2(D_t)$ and $\mathfrak{D}_\mathrm{t}^1$, are equivalent, [1], so $u_{\mathrm{reg}} \in L_2(\{t;\ \vartheta(t) \geqq k\}, H^2(D_t))$. □

Remark 3.6. Theorem 3.4 can serve as a tool for proving regularity results for u both in $H^s(\Omega)$, $1 < s < 2$, $s \neq 3/2$ and in weighted Sobolev spaces $H^{2,2}(\Omega, r, \varepsilon)$, [10]. However, as we saw, the first asymptotic of MBVP behaves in the same way in the neighborhood of points, where $\omega = \pi$, as it does near other points of G_c (as only $\vartheta \neq \pi$, 2π); thus, we do not go into detail.

Appendix. Here we prove Lemma 2.1 and give an explicit formula for the opening $\omega(t)$ in terms of geometrical properties of the original boundary.

Proof. We obtain Φ as a superposition of four transformations, the first of which is a modification of a normal transformation [15]. Hereafter, we adopt a convention that superscripts I, II, III, and IV will refer to successive steps of our construction. In some neighborhood of $x, \partial\Omega_N$ is a graph of $C^{3,1}$-function ϕ with outward normal given by

$$\text{(A1)} \qquad \vec{\nu} = \vec{n}/|\vec{n}|, \quad \text{where } \vec{n} = (-1, \partial^2\phi, \cdots, \partial^n\phi)$$

and $\lambda = \lambda(x) = [(\vec{\mu} \cdot \vec{\nu})(x)]^{-1/2} = [(\vec{\nu}_A \cdot \vec{\nu})(x)]^{-1/2}$ for $x \in \Gamma_c$. We define new coordinates in the following way:

$$\text{(A2)} \qquad x_1 = \phi(y_2, \cdots, y_n) - \lambda y_1 \mu_1, \quad x_i = y_i - \lambda y_1 \mu_i, \quad i = 2, \cdots, n.$$

Let $y = \Phi^{\mathrm{I}}(x)$, then $\det \mathcal{J}^{\mathrm{I}} = 1/\lambda(\vec{\mu} \cdot \vec{n}) = (\vec{\mu} \cdot \vec{\nu})/|\vec{n}|$ on Γ_c. It is easy to check that $\mathcal{J}^{\mathrm{I}}\vec{\mu} = -\lambda^{-1}\vec{e}_1$ and also that $a^{\mathrm{I}}_{11} = 1$ on $\Phi^{\mathrm{I}}(\Gamma_c)$.

Furthermore, let Γ_c be locally defined as a graph:

$$\Gamma_c = \{x \in \mathbb{R}^n;\ x_1 = \phi(\gamma(x''), x''),\ x_2 = \gamma(x'')\}.$$

It is seen that $\Gamma^{\mathrm{I}}_c = \Phi^{\mathrm{I}}(\Gamma_c \cap U_x) = \{y \in W^n;\ y_1 = 0,\ y_2 = \gamma(y'')\}$. The second transformation, Φ^{II}, will straighten Γ^{I}_c and make a^{II}_{22} equal 1 on $\Gamma^{\mathrm{II}}_c = \Phi^{\mathrm{II}}(\Gamma^{\mathrm{I}}_c)$. We define it as an inverse of

$$\text{(A3)} \qquad y_1 = z_1, \quad y_2 = z_2\beta(z'') = \gamma(z''), \quad y'' = z'' + \beta(z'')z_2,$$

where β is defined below. Let us denote by A^{I}_0 the Laplace–Beltrami operator on $y_1 = 0$ generated by A^{I} and by $\vec{\nu}_0 = \vec{n}_0/|\vec{n}_0|$, $\vec{n}_0 = (1, -\partial^3\gamma, \cdots, -\partial^n\gamma)$. Taking

$$\text{(A4)} \qquad \beta(y') = [(\vec{\nu}_{A^{\mathrm{I}}_0} \cdot \vec{\nu}_0)(y')]^{1/2}, \qquad y' \in \Gamma^{\mathrm{I}}_c,$$

we obtain $a^{\mathrm{II}} = 1$ on $\Gamma^{\mathrm{II}}_c = \{z;\ z_1 = z_2 = 0\}$, and, as defined, Φ^{II} does not change properties achieved in the first step.

In step III we perform a transformation to obtain $a^{\mathrm{III}}_{12} = a^{\mathrm{III}}_{21} = 0$ on Γ^{III}_c. We can take, for example,

$$\text{(A5)} \qquad v_1 = z_1, \quad v_2 = b(z'')z_1 + c(z'')z_2, \quad v'' = z'',$$

where $b = -a^{\mathrm{II}}_{12} \cdot [1 - (a^{\mathrm{II}}_{12})^2]^{-1/2}$ and $c = [1 - (a^{\mathrm{II}}_{12})^2]^{-1/2}$ on Γ^{II}_c. Now $\mathcal{J}^{\mathrm{III}}(-\lambda^{-1}\vec{e}_1) = -\lambda^{-1}(1, b, 0, \cdots, 0)$, and since both λ and b depend only on variables from Γ_c we see that (e) is satisfied after step (III). Clearly $a^{\mathrm{III}}_{11} = a^{\mathrm{III}}_{22} = 1$ for $v_1 = v_2 = 0$.

In the last step we straighten lines $L(v'') = \Phi^{\mathrm{III}}\Phi^{\mathrm{II}}\Phi^{\mathrm{I}}(\partial\Omega_D \cap U_x) \cap \{v;\ v'' = \text{const}\}$ by projecting them onto their tangent lines. In our case $(x \in bd\Gamma_i)$ we can assume that $L(v'')$ is locally graph of a function $v_1 = \chi(v_2, v'')$, and, consequently, define Φ^{IV} in the following way:

$$\text{(A6)} \qquad \xi_1 = \begin{cases} v_1 & \text{for } v_2 \geqq 0, \\ v_1 + v_2\partial^2\chi(0, v'') - \chi(v_2, v'') & \text{for } v_2 < 0, \end{cases}$$
$$\xi' = v'.$$

Since Γ_D is a $C^{3,1}$-manifold and $\mathcal{J}^{\mathrm{IV}} = \mathbb{I}$ along the collision submanifold, Φ^{IV} is a $C^{1,1}$-diffeomorphism, which does not change properties achieved in the first three steps. Therefore, all requirements of the lemma are satisfied by the transformation $\Phi = \Phi^{\mathrm{IV}}\Phi^{\mathrm{III}}\Phi^{\mathrm{II}}\Phi^{\mathrm{I}}$, defined in a suitable neighborhood of x. □

Now we express $\omega(\xi'')$ and $\psi(\xi'')$ in terms of quantities defined on the original boundary. It is clear, (A4), that $\cos\psi(\xi'') = -a_{12}^{\mathrm{II}}(0,0,v'')$, and furthermore $a_{12}^{\mathrm{II}} = \beta^{-1}[(a_{12}^{\mathrm{I}}, \cdots, a_{1n}^{\mathrm{I}}) \cdot \vec{n}_0]$ (where both sides are calculated along Γ_c), and since $a_{1i}^{\mathrm{I}} = -(\vec{\nu}_A \cdot \vec{m}_i)/(\vec{\nu}_A \cdot \vec{n})$ (see (A1)), we have

$$\cos\psi = (\vec{\nu}_A \cdot \vec{n})^{-1} \sum_{i=2}^{n} (\vec{\nu}_A \cdot \vec{m}_i) n_{0i} \quad \text{on } \Gamma_c. \tag{A7}$$

Let $\vec{\tau}_k := (\partial^k \phi, 0, \cdots, 0, 1, 0, \cdots 0)$, where 1 is situated on the kth place. We define $\vec{m} := \mathbb{X}(\lambda\vec{\mu}, \vec{\tau}_3, \cdots, \vec{\tau}_n)$, where $\mathbb{X}$ denotes the vector product of $n-1$ vectors in n-dimensional space. Let $\vec{\tau}_N = \mathcal{J}_\Phi^{-1}\vec{e}_2$ and denote by $\vec{\tau}_D$ the vector, tangent to G_D, lying in the plane, spanned by $\vec{\tau}_N$ and $\vec{\mu}$. It follows then, from (A5), that

$$\cos\omega = \frac{-b(\vec{n}\cdot\vec{\tau}_D) + c(\vec{m}\cdot\vec{\tau}_D)}{((\vec{n}\cdot\vec{\tau}_D)^2 + [c(\vec{m}\cdot\vec{\tau}_D) - b(\vec{n}\cdot\vec{\tau}_D)]^2)^{1/2}}.$$

ABRIKOSOV'S VORTICES IN THE CRITICAL COUPLING*

SHENG WANG† AND YISONG YANG‡

Abstract. A necessary and sufficient condition is obtained for the existence of multivortex solutions of the Bogomol'nyi system arising in the abelian Higgs theory defined on a rectangular domain and subject to a 't Hooft type periodic boundary condition. In particular, the number of vortices of a solution is confined by the size of the domain. Such solutions realize the magnetic periodic cell structure in a superconductor predicted by Abrikosov. If the periodic boundary condition is removed, the Bogomol'nyi equations on a bounded domain possess solutions with an arbitrary number of vortices, and these solutions may be used to approximate the unique finite energy solution over the full plane. Moreover, it is shown that, for any given vortex distribution in the plane, the Bogomol'nyi system has a continuous family of gauge-distinct solutions with infinite energy.

Key words. Bogomol'nyi equations, vortex-like solutions, maximum principle, sub- and supersolutions, 't Hooft periodic boundary condition, quantized magnetic flux, superconductivity, gauge transformations

1. Introduction. One of the most significant features of the classical two-dimensional abelian Higgs theory is that it allows a family of vortex-like solutions labelled by topological integers. It is known that the dimensionless Higgs self-coupling parameter, $\lambda > 0$, plays a crucial role in the model, so that, in suitably normalized units, for $\lambda < 1$, vortices attract, while, for $\lambda > 1$, repel, and the system is unstable against decay into separated vortices [10]. In fact, currently, all known finite energy solutions for $\lambda \neq 1$ are rotationally symmetric [18], [4], which can well be viewed as vortices clustered together, and it was conjectured that [11] these field configurations are the only finite energy solutions of the model modulo gauge transformations, although a verification of this statement still remains outstanding. On the other hand, for the critical choice $\lambda = 1$, the situation is entirely different. The numerical study in [10] first suggested that $\lambda = 1$ vortices do not interact, and solutions with finite separations between vortex locations should exist. This conclusion was then supported by an index theorem argument [22]. Finally, the existence of such arbitrary multivortex solutions was proved through a nonconstructive variational approach [11].

The main purpose of the present paper is to obtain the $\lambda = 1$ multivortices of the abelian Higgs theory over a periodic lattice cell realized by a 't Hooft type boundary condition and to approximate the full plane finite energy vortices of Jaffe and Taubes [11] by bounded domain solutions. The former may well be viewed as a compact version of the model. Multivortex solutions of such a nature were first explored in the pioneering work of Abrikosov [1] in the context of the Ginzburg-Landau theory [8] of low transition temperature superconductivity, where it was predicted that, under some circumstances, the magnetic flux may penetrate the sample in the form of vortex-lines with a period structure, and the total flux through a lattice cell is a quantized value proportional to the number of vortices confined. Although this prediction has been confirmed in numerous physical experiments, a mathematical verification has not been worked out in the literature yet. Earlier attempts include, for example, the work

of Odeh [17], where a prescribed flux problem was studied so that the order parameter and the magnetic field were periodic. However, his solutions do not give rise to vortex-lines and the quantized flux. We shall show in this paper that the 't Hooft periodic boundary condition [21] can naturally be used to realize Abrikosov's multivortices in the critical case $\lambda = 1$. This appears to be the first rigorous result concerning the existence of a quantized periodic lattice pattern in the classical theory of superconductivity.[1] On the other hand, the latter arises from the problem of constructing vortex solutions in the self-dual limit. Gauge field theories in two dimensions are rather different from those in three and four dimensions. It is well known that in three and four dimensions topologically nontrivial solutions (monopoles and instantons) may be found explicitly [19], [5], [23], [2], while in two dimensions, no explicit vortex-type solutions have ever been obtained. Hence it will be interesting to provide a constructive method to get such solutions. Some recent relevant numerical simulations include [7], [9], [6], [14].

The contents of the paper are as follows. In § 2, a 't Hooft type periodic boundary condition is introduced for the abelian Higgs model. Due to this boundary condition, the magnetic flux will assume a nontrivial value proportional to the total number of vortices confined in the finite rectangular region under consideration. For the critical choice $\lambda = 1$, the energy lower bound can be saturated by the solutions of the Bogomol'nyi equations [5]. These equations are then reduced to a scalar elliptic equation, coupled with a source term characterizing the locations of vortices. In § 3, we solve this elliptic equation via a monotone iteration method. Such a method may provide a useful construction of the Abrikosov solutions of the Bogomol'nyi system over a periodic lattice cell. The condition which ensures the existence of multivortices indicates that the total number of vortices or magnetic flux strength cannot be arbitrarily large, but is bounded by the size of the domain. Section 4 is a simple remark on the magnetic properties of multivortex solutions in the presence of an external field. In § 5, we solve the Bogomol'nyi system over a bounded domain subject to a natural boundary condition imposed on the observables—the amplitude of the Higgs field and the magnetic field. We shall see that solutions with arbitrarily large vortex numbers exist. Such solutions are constructed by an iterative method similar to that in § 3. Two numerical examples will be presented as an illustration. In § 6 we prove that the bounded domain solutions obtained in § 5 can be used to approximate in a global way the full plane finite energy multivortices of Jaffe and Taubes [11]. In § 7 we show that for any distribution of vortices, the Bogomol'nyi system has a continuous family of gauge-distinct solutions of infinite energy. Such an observation may be viewed as a complement to the uniqueness theorem in [11] for finite energy solutions. Section 8 is a brief summary.

2. The abelian Higgs model over a lattice cell. The energy density of the static abelian Higgs vortex model is given by the expression

$$\mathscr{E}(\phi, A) = \frac{1}{4} F_{jk}^2 + \frac{1}{2} |D_j\phi|^2 + \frac{\lambda}{8} (|\phi|^2 - 1)^2,$$

where $A = (A_1, A_2)$ is the gauge potential of the magnetic field $F_{jk} = \partial_j A_k - \partial_k A_j$, ϕ the complex scalar Higgs field, and $D_j = \partial_j - iA_j$ the gauge-covariant differentiation.

[1] However, in physical experiments, quantized periodic vortices are observed mainly in type II superconductors for which $\lambda > 1$. In such a situation there is no Bogomol'nyi reduction and the full second-order Ginzburg-Landau equations have to be considered and, thus, our method here fails.

We assume that the field configuration (ϕ, A) satisfies the following 't Hooft [21] type periodic boundary condition on the boundary of the rectangular region $\Omega = (-L_1, L_1)\times(-L_2, L_2)$ in $\mathbb{R}^2$:

$$\begin{aligned} &\phi(-L_1, x_2)\, e^{i\xi(-L_1,x_2)} = \phi(L_1, x_2)\, e^{i\xi(L_1,x_2)}, && -L_2 < x_2 < L_2,\\ &\phi(x_1, -L_2)\, e^{i\zeta(x_1,-L_2)} = \phi(x_1, L_2)\, e^{i\zeta(x_1,L_2)}, && -L_1 < x_1 < L_1, \end{aligned} \tag{2.1}$$

$$\begin{aligned} &A(-L_1, x_2) + (\nabla\xi)(-L_1, x_2) = A(L_1, x_2) + (\nabla\xi)(L_1, x_2), && -L_2 < x_2 < L_2,\\ &A(x_1, -L_2) + (\nabla\zeta)(x_1, -L_2) = A(x_1, L_2) + (\nabla\zeta)(x_1, L_2), && -L_1 < x_1 < L_1, \end{aligned} \tag{2.2}$$

where ξ and ζ are real phase change variables. The requirement that ϕ be single-valued implies in particular the relation

$$\begin{aligned} &\xi(L_1, L_2^-) - \xi(L_1, -L_2^+) + \xi(-L_1, -L_2^+) - \xi(-L_1, L_2^-)\\ &\quad + \zeta(-L_1^+, L_2) - \zeta(L_1^-, L_2) + \zeta(L_1^-, -L_2) - \zeta(-L_1^+, -L_2) + 2\pi N = 0 \end{aligned} \tag{2.3}$$

with $N \in \mathbb{Z}$. Therefore, from (2.2) and (2.3), we find the total quantized magnetic flux through Ω:

$$\Phi = \int_\Omega F_{12}\, dx = \int_{\partial\Omega} A_j\, dx_j = 2\pi N. \tag{2.4}$$

It is interesting to notice that Φ is independent of the size of Ω.

For $\lambda = 1$, using (2.4), the energy may be rewritten in the form

$$\begin{aligned} E(\phi, A) &\equiv \int_\Omega \mathscr{E}(\phi, A)\, dx\\ &= \pi|N| + \frac{1}{2}\int_\Omega dx\left\{\left|F_{12} \pm \frac{1}{2}(|\phi|^2 - 1)\right|^2 + |D_1\phi \pm iD_2\phi|^2\right\}\\ &\quad \pm \frac{1}{2}\,\mathrm{Im}\left\{\int_\Omega dx\,\{\partial_j(\varepsilon_{jk}\phi^* D_k\phi)\}\right\}, \end{aligned}$$

according to $N = \pm|N|$, where ε_{jk} is the standard skew-symmetric 2-tensor with $\varepsilon_{12} = 1$.

However, the periodic boundary condition (2.1), (2.2) implies

$$\int_\Omega dx\,\{\partial_j(\varepsilon_{jk}\phi^* D_k\phi)\} = \int_{\partial\Omega} \phi^* D_j\phi\, dx_j = 0.$$

As a consequence, there holds the energy lower bound estimate as in the $\mathbb{R}^2$ case (cf. [11]):

$$E(\phi, A) \geqq \pi|N|.$$

This lower bound is saturated if and only if (ϕ, A) is a solution of the self-dual (or anti-self-dual) Bogomol'nyi equations

$$\begin{aligned} D_1\phi \pm iD_2\phi &= 0,\\ F_{12} \pm \tfrac{1}{2}(|\phi|^2 - 1) &= 0, \end{aligned} \qquad x \in \Omega \tag{2.5}$$

subject to the periodic boundary condition (2.1), (2.2) on $\partial\Omega$.

Without loss of generality, let us consider the self-dual ($N > 0$) equations (2.5+). The solutions of the anti-self-dual system (2.5−) may be obtained by taking the "conjugate" $(\phi, A) \to (\phi^*, -A)$ of the solutions of (2.5+).

Let $Z(\phi)$ be the set of zeros of ϕ in Ω. It is convenient to view Ω as a subset of $\mathbb{C}$ and use $z=x_1+ix_2$ to denote a point in Ω. We assume that ϕ does not vanish on the boundary $\partial\Omega$. As was shown in [11], the structure of $(2.5+)_1$ allows us to conclude that $Z(\phi)$ is a finite set, say $Z(\phi)=\{z_1,\cdots,z_k\}$, and that, in a neighborhood of z_j, ϕ has the representation

$$(2.6)\qquad \phi(z)=(z-z_j)^{n_j}h_j(x_1,x_2)$$

so that n_j is a positive integer and h_j is a smooth nonvanishing scalar function. The well-known prescribed vortex problem is that, given $z_1,\cdots,z_k\in\Omega$ and $n_1,\cdots,n_k\in\mathbb{Z}_+$, find a solution of (2.5+) such that $Z(\phi)=\{z_1,\cdots,z_k\}$ and the multiplicity of the zero $z=z_j$ of ϕ is exactly n_j, $j=1,\cdots,k$. The multiplicity n_j is sometimes called the local charge or local vortex number of the solution at $z=z_j$.

For a solution pair (ϕ, A) of (2.5+), since $|\phi|^2$ is periodic, it is easy to see from the method in [11] that $|\phi|^2<1$ everywhere in the periodic cell or otherwise $|\phi|^2\equiv 1$, which means that the solution is gauge-equivalent to the trivial solution $\phi=1$, $A=0$.

3. A construction of multivortex solutions. With the notation $\partial=\frac{1}{2}(\partial_1-i\partial_2)$, $\alpha=A_1+iA_2$, $(2.5+)_1$ yields the relation

$$(3.1)\qquad \alpha=-2i\partial^*\ln\phi,\quad \text{away from } Z(\phi);$$

therefore, outside $Z(\phi)$,

$$F_{12}=-i(\partial\alpha-\partial^*\alpha^*)=-2\partial\partial^*\ln|\phi|^2=-\tfrac{1}{2}\Delta\ln|\phi|^2.$$

As a consequence of the above equation and (2.6), it is seen that $u\equiv\ln|\phi|^2$ satisfies

$$(3.2)\qquad \begin{array}{ll}\Delta u=e^u-1+4\pi\sum_{j=1}^k n_j\delta(z-z_j) & \text{in }\Omega\\ u & \text{is periodic on }\partial\Omega.\end{array}$$

Conversely, if u is a solution of (3.2), then (ϕ, A) is a smooth solution of the Bogomol'nyi system (2.5+) subject to the periodic boundary condition (2.1), (2.2), where

$$\phi(z)=\exp\frac{1}{2}(u(z)+i\theta(z))\quad\text{with } \theta(z)=2\sum_{j=1}^k n_j\arg(z-z_j),$$

and A is determined by the formula (3.1) (see [11]). Moreover, it is easily verified that, with the notation in (2.3), there holds $N=n_1+\cdots+n_k$.

Therefore, to find a solution to the prescribed vortex problem of (2.5+), it suffices to solve (3.2). In our discussion below, it is most convenient to regard (3.2) as an elliptic equation defined over a 2-torus and make no mention of the domain of the equation if there is no risk of confusion. A monotone iteration method will be adopted to construct the solution of (3.2).

The following result is useful for a background subtraction.

LEMMA 3.1. *For any smooth function f satisfying $\int f(x)\,dx=1$, there is a function u_0, which is smooth in the complement of the set $\{z_1,\cdots,z_k\}$, so that*

$$(3.3)\qquad \Delta u_0=-4\pi Nf+4\pi\sum_{j=1}^k n_j\delta(z-z_j),$$

and in a neighborhood of z_j, $u_0-\ln|z-z_j|^{2n_j}$ is smooth. Here $N=n_1+\cdots+n_k$.

For a proof of this lemma, see [3].

With the notation of Lemma 3.1, let $v=u-u_0$. From (3.2) and (3.3), it is seen that v satisfies

$$(3.4)\qquad \Delta v=e^{v+u_0}+(4\pi Nf-1).$$

Remark 3.1. Kazdan and Warner [12] have studied the (3.4)-type equations on a compact Riemannian manifold via constructing sub- and supersolutions. In their case f is a constant. In order to have larger flexibility in implementing numerical computations, we allow f to be an arbitrary function. It will be much easier to decide a solution u_0 of (3.3) when there is no restriction to f. Actually, we may just choose u_0 to be such that $u_0(z) = \ln |z - z_j|^{2n_j}$ in a neighborhood of $z = z_j, j = 1, \cdots, k$ and let $4\pi f(z) = -\Delta u_0(z) + 4\pi \sum n_j \delta(z - z_j)$. Our development below may be viewed as a specialization of that in [12].

LEMMA 3.2. *Assume $N < L_1L_2/\pi$. There are smooth functions $U \geqq V$ such that*

$$\Delta U - e^{U+u_0} - (4\pi Nf - 1) \leqq 0, \tag{3.5}$$

and

$$\Delta V - e^{V+u_0} - (4\pi Nf - 1) \geqq 0. \tag{3.6}$$

Proof. The property of u_0 implies that e^{u_0} is a smooth function and vanishes at $z_j, j = 1, \cdots, k$. It is not hard to see that

$$(\Delta - e^{u_0})U = 4\pi Nf - 1 \tag{3.7}$$

has a solution. In fact, $P \equiv \Delta - e^{u_0} - 1 : W^{2,2} \to L^2$ is bijective and $P^{-1} : L^2 \to L^2$ is compact. Hence $1 + P^{-1}$ is Fredholm of index zero due to the selfadjointness of P. Equation (3.7) may now be rewritten in the form $(1 + P^{-1})U = P^{-1}(4\pi Nf - 1)$. This equation has a solution because the only solution of $(1 + P^{-1})U = 0$ or $(\Delta - e^{u_0})U = 0$ is the trivial one $U = 0$ (the Fredholm alternatives).

Thus we have

$$\Delta U - e^{U+u_0} - (4\pi Nf - 1) \leqq \Delta U - e^{U+u_0} - (4\pi Nf - 1) + e^{u_0}(e^U - U) = 0,$$

which verifies (3.5). U is a supersolution of (3.4).

To get a subsolution of (3.4) that satisfies (3.6), we consider the equation

$$\Delta V = 4\pi Nf - \sigma, \tag{3.8}$$

where σ is a constant. In order to have a solution to (3.8), it is necessary and sufficient that the right-hand side of the equation is of zero integral mean [3]. This results in the condition

$$\sigma = 4\pi N/|\Omega| = \pi N/L_1L_2.$$

From the assumption in the lemma, we have $\sigma < 1$. There holds, due to (3.8), the equality

$$\Delta V - e^{V+u_0} - (4\pi Nf - 1) = ([1 - \sigma] - e^{V+u_0}). \tag{3.9}$$

Choose a solution V of (3.8) so that

$$\sup V \leqq \min \{\ln (1 - \sigma) - \sup u_0, 0\}.$$

Then it is seen clearly that the right-hand side of (3.9) is nonnegative. Hence (3.6) is proved.

Finally, the comparison $U \geqq V$ follows from the inequality $(\Delta - e^{u_0})(U - V) \leqq (\sigma - 1) < 0$ and the maximum principle.

LEMMA 3.3. *For $N < L_1L_2/\pi$, equation* (3.4) *has a unique solution v. This v satisfies the bounds $U \geqq v \geqq V$ and may be obtained in the limit*

$$\lim_{n \to \infty} v_n = v, \tag{3.10}$$

where $\{v_n\}$ is a monotone approximation sequence of v determined through the iterative scheme

$$\begin{aligned} &v_1 = V \quad \text{or} \quad U, \\ &(\Delta - K)v_n = e^{v_{n-1}+u_0} - Kv_{n-1} + (4\pi Nf - 1), \end{aligned} \tag{3.11}$$

with $K \geqq \sup e^{u_0+U}$. Here the limit in (3.10) *is in the space C^k for any positive integer k.*

Proof. Let us start with the assumption $v_1 = V$. We first show by induction that $v_n \leqq U$, $n = 1, 2, \cdots$. In fact, $v_1 \leqq U$ has been established in Lemma 3.2. Suppose $v_n \leqq U$ for some n. Then

$$(\Delta - K)(U - v_{n+1}) \leqq (e^{u_0+U} - K)(U - v_n) \leqq 0.$$

Thus $v_{n+1} \leqq U$ as well.

Next, we prove that

$$V = v_1 \leqq v_2 \leqq \cdots \leqq v_n \leqq \cdots \leqq U.$$

Indeed, from Lemma 3.2 we have $(\Delta - K)(v_2 - v_1) \leqq 0$. Consequently, $v_2 - v_1 \geqq 0$. By induction, if there holds $V = v_1 \leqq v_2 \leqq \cdots \leqq v_n$, then

$$\begin{aligned} (\Delta - K)(v_{n+1} - v_n) &= e^{u_0}(e^{v_n} - e^{v_{n-1}}) - K(v_n - v_{n-1}) \\ &\leqq (e^{u_0+U} - K)(v_n - v_{n-1}) \leqq 0, \end{aligned}$$

which implies $v_{n+1} - v_n \geqq 0$ as expected.

If $v_1 = U$, a similar argument shows that

$$U = v_1 \geqq v_2 \geqq \cdots \geqq v_n \geqq \cdots \geqq V.$$

Thus, in particular, we have proved that $\{v_n\}$ is bounded and convergent pointwise. By virtue of (3.11), it is seen that $\{v_n\}$ is convergent in the $W^{2,2}$ norm. A bootstrap argument then indicates that $\{v_n\}$ converges in any $W^{k,2}$ norm, hence, in any C^k norm. The limit (3.10) is the unique solution of (3.4).

The lemma is proved.

It is easy to observe that $\sigma < 1$ is also a necessary condition to ensure the solvability of (3.4). In fact, integrating both sides of (3.4), we have

$$0 = \int_\Omega e^{v+u_0}\, dx + 4\pi N - |\Omega|,$$

which implies $\sigma < 1$.

We can now state the following.

THEOREM 3.4. *For any $z_1, \cdots, z_k \in \Omega$ and positive integers $n_1, \cdots, n_k$, the system* (2.5+) *subject to the boundary condition* (2.1), (2.2) *has a smooth solution (ϕ, A) such that the zeros of ϕ are exactly $z_1, \cdots, z_k$ with respective multiplicities $n_1, \cdots, n_k$, if and only if $n_1 + \cdots + n_k = N < L_1L_2/\pi$. Moreover, up to gauge transformations, this solution is unique and can be obtained by the iteration scheme* (3.11).

Proof. The proof of existence has been obtained. To get the uniqueness part, let us assume (ϕ, A) and (ϕ', A') are two solutions of (2.5+) so that the zeros of ϕ and ϕ' are $z_1, \cdots, z_k$ with respective multiplicities $n_1, \cdots, n_k$. Consequently, $u = \ln |\phi|^2$ and $u' = \ln |\phi'|^2$ satisfy the same equation (3.2). This in turn implies $u = u'$ or $|\phi|^2 = |\phi'|^2$, namely, the difference between ϕ and ϕ' is a phase variable. Such a phase variable makes (ϕ, A) and (ϕ', A) gauge-equivalent.

Remark 3.2. If $N > 0$, we can apply the maximum principle to (3.2) in the complement of the set $\{z_1, \cdots, z_k\}$ to show that $u < 0$ everywhere, which corresponds to the property $|\phi|^2 < 1$ for a solution pair (ϕ, A) of (2.5+). In the special case where $N = 0$, the only solution of (3.2) is $u \equiv 0$, which corresponds to the trivial solution $\phi = 1$, $A = 0$ of (2.5+).

Remark 3.3. The Euler–Lagrange equations of the energy density $\mathscr{E}(\phi, A)$ in § 2 assume the form

$$\begin{aligned}\partial_k F_{jk} &= \frac{i}{2}(\phi[D_j\phi]^* - \phi^*[D_j\phi]),\\ D_k D_k \phi &= \frac{\lambda}{2}(|\phi|^2 - 1)\phi,\end{aligned} \tag{3.12}$$

which are known to be the two-dimensional Ginzburg–Landau equations. In $\mathbb{R}^2$, Jaffe and Taubes [11] showed that, when $\lambda = 1$, (2.5±) and (3.12) are equivalent systems for finite energy solutions. In our periodic case here, solutions of (2.5±) subject to (2.1), (2.2) are obviously solutions of (3.12) ($\lambda = 1$) under the same boundary condition. However, we do not know whether the two periodic systems are equivalent for $\lambda = 1$. Thus our condition for the existence of a multivortex solution only applies to the Bogomol'nyi equations (2.5±), but not to (3.12).

Remark 3.4. For a solution (ϕ, A) given in Theorem 3.4, the observables $|\phi|^2$ and F_{12} are both periodic on the lattice cell. Such a vortex structure confirms the prediction of Abrikosov on the magnetic response fashion of certain superconducting materials. Our study above has been restricted on a rectangular periodic cell. However, a general parallelogram domain does not render additional difficulties, and the same existence results hold. In this case, for an investigation of the more delicate existence problem of multivortices in the electroweak theory where the gauge group is $SU(2) \times U(1)$, see [20].

Remark 3.5. The vortex model defined by a holomorphic line bundle L over a compact Riemann surface M has been studied in the work of Noguchi [16]. It is concluded that, if the integer-valued first Chern class $c_1(L) = N \geqq 0$, then an N-vortex solution exists if and only if $N < \mathrm{Vol}\,(M)/4\pi$. Our condition in Theorem 3.4 may be interpreted in this topological spirit. The difference is that in Noguchi's solutions the gauge potentials can only be real in *local* unitary frames of L, while in our solutions, the gauge potentials are globally real, additional geometric complications are not raised, and a transparent physical meaning is contained.

4. The effect of an external field. From § 2, we see that the self-dual ($N > 0$) and anti-self-dual ($N < 0$) Bogomol'nyi vortices occupy the same energy level $E = \pi|N|$; therefore, there is a symmetry in the *vacuum* real world. The purpose of this section is to remark that such a symmetry can be broken by switching on an external field.

For simplicity, let us assume the external field is a constant magnetic field, denoted by F_{jk}^{ex}. Under the influence of such a field, the total (Gibbs) energy over the lattice cell Ω is written in the form

$$E(\phi, A) = \int_\Omega \mathscr{E}\, dx - \frac{1}{2}\int_\Omega F_{jk}F_{jk}^{\mathrm{ex}}\, dx.$$

The periodic boundary condition given in (2.1), (2.2) leads to the quantized flux (2.4). Consequently, the energy now becomes

$$E(\phi, A) = \pi(|N| - 2NF_{12}^{\mathrm{ex}}) + \frac{1}{2}\int_\Omega dx \left\{ \left| F_{12} \pm \frac{1}{2}(|\phi|^2 - 1)\right|^2 + |D_1\phi \pm iD_2\phi|^2 \right\}$$

for $N = \pm|N|$. The lower bound

$$E = \pi(|N| - 2NF_{12}^{\mathrm{ex}}) \tag{4.1}$$

is saturated by the solutions of the self-dual and anti-self-dual Bogomol'nyi equations.

First, from (4.1), we observe that, if the external field is sufficiently weak so that $|F_{12}^{\mathrm{ex}}|<\frac{1}{2}$, then the absolute energy minimizers can only have zero vortex number $N=0$. Theorem 3.4 implies that the Higgs field has no zero in Ω, and the solution is gauge-equivalent to the trivial (superconducting vacuum) solution $\phi=1$, $A=0$. Thus there is no field penetration into the lattice cell, and the magnetic screening is complete.

Next, if $|F_{12}^{\mathrm{ex}}|=\frac{1}{2}$, the energy minimum is still $E=0$, which may be attained at the vacuum solutions as well as at the N-vortex solutions satisfying $\operatorname{sgn} N=\operatorname{sgn} F_{12}^{\mathrm{ex}}$. This situation describes a transition phase between the superconducting vacuum and the onset of a coexisting normal-superconducting phase.

Finally, as the external field goes beyond the critical threshold $|F_{12}^{\mathrm{ex}}|=\frac{1}{2}$, namely, $|F_{12}^{\mathrm{ex}}|>\frac{1}{2}$, the lowest energy level is occupied by those N-vortex solutions that satisfy $\operatorname{sgn} N=\operatorname{sgn} F_{12}^{\mathrm{ex}}$ and $|N|=\max\{n\in\mathbb{Z}_+|n<L_1L_2/\pi\}$. In other words, the orientation of the vortices depends on the directon of the external field, and the vortex number should be as large as possible to achieve a maximal magnetic penetration. This is a kind of vortex-line orientation selection phenomenon under the influence of an external field, and the vacuum symmetry is thus broken.

The above discussion illustrates the celebrated Meissner effect in superconductivity theory.

5. Arbitrary number of vortices in a bounded domain. From Theorem 3.4 we see that, under the 't Hooft type periodic boundary condition given in § 2, the total magnetic flux is proportional to the number of vortices living in the lattice cell, and this number is confined by the size of the domain. In this section, we observe that, if the periodic boundary condition is removed, such a restriction will no longer exist. In other words, a bounded region may allow an arbitrary number of vortices. It is conceivable that, at the same time, we will lose the flux quantization property.

Let us consider a boundary value problem of the Bogomol'nyi system. It is natural to impose a boundary condition on the observables $|\phi|^2$ and F_{12}. Thus, for the self-dual Bogomol'nyi equations, we have the boundary value problem

$$\begin{aligned}&D_1\phi+iD_2\phi=0,\\ &F_{12}+\tfrac{1}{2}(|\phi|^2-1)=0,\qquad x\in\Omega;\\ &|\phi|^2=|\phi^0|^2,\qquad F_{12}=F_{12}^0,\quad x\in\partial\Omega,\end{aligned}\tag{5.1}$$

where $\partial\Omega$ is assumed to be sufficiently regular (Lipschitzian, say).

The equation $(5.1)_2$ implies the compatibility condition $F_{12}^0=(1-|\phi^0|^2)/2$ on $\partial\Omega$ for the boundary data. Moreover, physically, it is natural to assume the inequality

$$0<|\phi^0|\leqq 1.\tag{5.2}$$

Since the treatment of (5.1) is similar to (2.5+) and a special case of (5.1) has been studied in [24], our discussion below will be brief.

Let $z_1,\cdots,z_k$ be the zeros of ϕ (or the vortex locations of a solution (ϕ, A) of (5.1)) with respective multiplicities $n_1,\cdots,n_k\in\mathbb{Z}_+$. Then (5.1) is reduced after the substitution $u=\ln|\phi|^2$, $\bar{u}=\ln|\phi^0|^2$ into the problem

$$\begin{aligned}&\Delta u=e^u-1+4\pi\sum_{j=1}^k n_j\delta(z-z_j),\qquad x\in\Omega,\\ &u=\bar{u},\qquad x\in\partial\Omega.\end{aligned}\tag{5.3}$$

To solve (5.3), we borrow the background subtraction function u_0 from [11]:

$$u_0(z)=-\sum_{j=1}^k n_j\ln(1+|z-z_j|^{-2}).\tag{5.4}$$

Thus $v \equiv u - u_0$ will solve the modified problem

$$\begin{aligned} \Delta v &= e^{v+u_0} + (g-1), \qquad x \in \Omega, \\ v &= \bar{u} - u_0, \qquad x \in \partial\Omega, \end{aligned} \tag{5.5}$$

where

$$g(z) = 4 \sum_{j=1}^{k} n_j (1 + |z - z_j|^2)^{-2}.$$

It is easy to verify that $e^{u_0} \leqq 1$ and is smooth. The following lemma gives us a pair of super- and subsolution of (5.5) as for the problem (3.4).

LEMMA 5.1. *There exist functions $U \geqq V$ such that*

$$\Delta U - e^{U+u_0} - (g-1) \leqq 0, \qquad x \in \Omega, \tag{5.6}$$

$$\Delta V - e^{V+u_0} - (g-1) \geqq 0, \qquad x \in \Omega, \tag{5.7}$$

and $U = V = \bar{u} - u_0$, $x \in \partial\Omega$.

Proof. Let U and V be the solutions of the linear equations $\Delta U = g - 1$ and $\Delta V = g$ $(x \in \Omega)$, respectively, with $U = V = \bar{u} - u_0$ on $\partial\Omega$. Then it is self-evident that U satisfies (5.6). To see that V fulfills (5.7), it suffices to achieve the inequality $V + u_0 \leqq 0$ in $\Omega - \{z_1, \cdots, z_k\}$. First, we have $V + u_0 = \bar{u} \leqq 0$ for $x \in \partial\Omega$ due to (5.2). On the other hand, we may choose $\varepsilon > 0$ sufficiently small to make $B_\varepsilon(z_j) = \{z \mid |z - z_j| < \varepsilon\} \subset \Omega$, $j = 1, \cdots, k$, and $V + u_0 \leqq 0$ on $\partial B_\varepsilon(z_j)$, $j = 1, \cdots, k$. Since $\Delta(V + u_0) = 0$ in $\Omega_\varepsilon \equiv \Omega - \bigcup_{j=1}^{k} B_\varepsilon(z_j)$, we have, in Ω_ε, $V + u_0 \leqq 0$, by virtue of the maximum principle. Finally, letting $\varepsilon \to 0$, we reach the desired conclusion.

Using Lemma 5.1, we can find the unique solution of (5.5) in the limit $\lim_{n\to\infty} v_n = v$ as in § 3, where $\{v_n\}$ is constructed through the scheme

$$\begin{aligned} v_1 &= V \quad \text{or} \quad U, \\ (\Delta - K)v_n &= e^{v_{n-1}+u_0} - Kv_{n-1} + (g-1), \qquad x \in \Omega, \\ v_n &= \bar{u} - u_0, \qquad x \in \partial\Omega, \quad n = 2, 3, \cdots, \end{aligned} \tag{5.8}$$

whereas $K \geqq e^M$, $M = \sup_\Omega U$. Such a solution gives rise to a multivortex solution of the problem (5.1) with prescribed vortex locations $z_1, \cdots, z_k$ and local charges $n_1, \cdots, n_k$ through the construction mentioned in § 3 with $u = u_0 + v$.

In the rest of this section, we present two numerical examples of the multivortex solutions of the Bogomol'nyi system (5.1), computed using the iterative scheme (5.8). We shall see from these solutions that the flux may not be quantized as in the periodic case (see (2.4)). Rather, it depends on the locations of vortices.

In our computations shown below, we choose the domain Ω to be a lattice square: $\Omega = (-3, 3) \times (-3, 3)$. According to the conclusion of Theorem 3.4, such a region cannot allow more than two vortices if the t' Hooft type periodic boundary condition introduced in § 2 is imposed. On the other hand, from the discussion of this section, we see that if the boundary data are prescribed to the observables $|\phi|^2$ and F_{12}, then the domain may accommodate as many vortices as one pleases. We shall specify $|\phi^0| = 1$ and $F_{12}^0 = 0$ for simplicity. Such a condition represents a complete boundary magnetic screening. The numerical implementation can be described as follows.

First of all, the interval $(-3, 3)$ is discretized with 150 equidistant grid points, which results in a finite difference mesh for the square domain Ω. The scheme (5.8) is then solved through the standard five-point approximation algorithm for the boundary value problems of elliptic differential equations. As usual, the discrete approximation to v_n in (5.8), and so on, at the mesh point $(x_1(i), x_2(j))$ will be denoted by $v^n_{i,j}$. The constant K in (5.8) is chosen to be $K = 1 + e^M$ with $M = \sup U_{i,j}$. The initial $v^1_{i,j}$ is taken to be $V_{i,j}$. Here U and V are the unique solutions of the equations $\Delta U = g - 1$ and $\Delta V = g(x \in \Omega)$ with $U = V = -u_0$ on $\partial\Omega$ as in the proof of Lemma 5.1. The termination criterion of the iterative scheme (5.8) is set to be

$$|v^n - v^{n-1}| \equiv \max_{i,j} |v^n_{i,j} - v^{n-1}_{i,j}| < 10^{-3}. \tag{5.9}$$

If the accuracy (5.9) is attained at a certain step $n = k$, then the computation will halt and $v^k_{i,j}$ will be recognized as an approximation of the unique solution of (5.5) at the mesh points. Thus, a numerical solution of the boundary value problem (5.1) of the Bogomol'nyi equations is obtained.

Figures 1 and 2 present two numerical solutions with total vortex number $N = 4$.

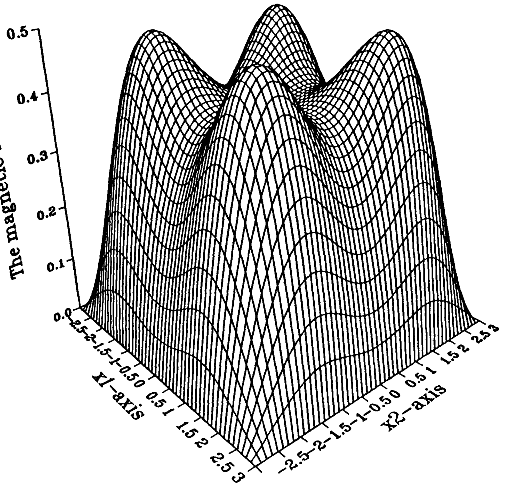

FIG. 1. *A solution of four separated vortices.*

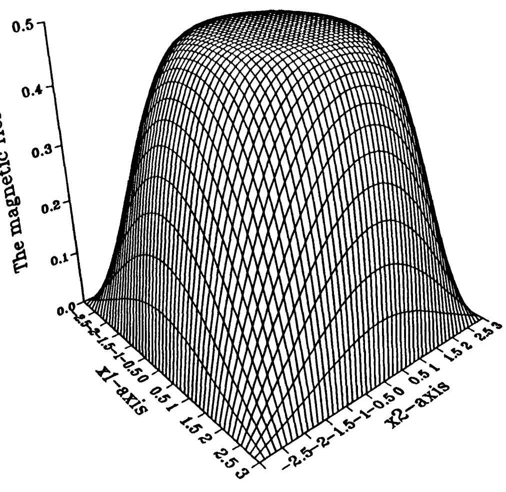

FIG. 2. *A solution of four clustered vortices.*

Figure 1 gives us the behavior of the magnetic field over Ω of a computed solution of four separated vortices located at the points $z_1 = -1.5 - 1.5i$, $z_2 = 1.5 - 1.5i$, $z_3 = 1.5 + 1.5i$, and $z_4 = -1.5 + 1.5i$, with local vortex numbers or charges satisfying $n_1 = n_2 = n_3 = n_4 = 1$. The numerical solution is obtained at $n = 27$ (27 iterations). The magnetic penetration attains its maximal value $F_{12} = 0.5$ at the centers of the vortices as expected. The total normalized flux is $\Phi/2\pi = \int_\Omega F_{12}\, dx/2\pi = 1.774$, which cannot be an integer up to numerical errors.

Figure 2 illustrates the magnetic field distribution in Ω of a numerical solution of four clustered vortices centered at $z = 0$, with the local charge $= N = 4$. In this case, the program takes 31 iterations to achieve the accuracy (5.9). The shape of the graph of F_{12} indicates that the magnetic penetration in a neighborhood of the center of these clustered vortices now gains a relatively larger average value than the separated ones. The total normalized flux for this solution is $\Phi/2\pi = 1.878$, which is greater than that of the solution of separated vortices given in Fig. 1.

Further computer experiments show that the flux depends sensitively on the locations of vortices. For example, a pair of clustered vortices centered at $z_1 = -1.5 - 1.5i$ and $z_2 = 1.5 + 1.5i$ with $n_1 = n_2 = 2$ (another four-vortex solution of (5.1)) yield a normalized flux $\Phi/2\pi = 1.580$.

Remark 5.1. If we choose

$$u_0(z) = \sum_{j=1}^{k} n_j \ln(|z - z_j|^2),$$

then $g = 0$ in (5.5), which gives us a system with a much simpler inhomogeneous term. However, in this case we lose the bound $e^{u_0} \leqq 1$. In fact, for large domains, $\sup_{\bar\Omega} e^{u_0}$ may take large values, and this in turn requires K be sufficiently large to ensure the convergence of the iterative scheme (5.8). Numerical experiments carried out on the square domain just specified indicate that the choice of u_0 according to the above simpler expression results in as much as four times the computing time needed with the choice of u_0 according to (5.4).

6. Approximating a vortex solution in the full plane. In this section, we prove that the bounded domain solutions obtained in § 5 may be used to approximate a vortex solution of the Bogomol'nyi equations on full $\mathbb{R}^2$.

Let (ϕ, A) be a finite energy solution of (2.5+) on $\mathbb{R}^2$ so that $Z(\phi) = \{z_1, \cdots, z_k\}$, the multiplicity of the zero $z = z_j$ of ϕ is $n_j \geqq 1$, $j = 1, \cdots, k$, and $n_1 + \cdots + n_k = N$. The existence and uniqueness of such a solution has been established in Jaffe and Taubes [11]. Moreover, there holds the exponential decay estimate [11]:

$$(6.1) \qquad 0 \leqq 1 - |\phi(z)|^2 \leqq C(\varepsilon) e^{-(1-\varepsilon)|z|}, \qquad z \in \mathbb{R}^2,$$

where $\varepsilon \in (0, 1)$. The function $u = \ln|\phi|^2$ is the unique solution of the equation

$$(6.2) \qquad \Delta u = e^u - 1 + 4\pi \sum_{j=1}^{k} n_j \delta(z - z_j) \quad \text{in } \mathbb{R}^2,$$

which vanishes at infinity [11].

Suppose Ω_0 is a bounded domain in $\mathbb{R}^2$ so that $Z(\phi) \subset \Omega_0$. Choose $u' \in C^\infty(\mathbb{R}^2)$ satisfying $u' = u$ in $\mathbb{R}^2 - \Omega_0$. From (6.1) and using the simple inequality $\ln(1-s) > -2s$ ($s \in (0, \frac{1}{2})$), we have

$$(6.3) \qquad -2C(\varepsilon)\, e^{-(1-\varepsilon)|z|} \leqq u(z) \leqq 0 \quad \text{for } |z| > r_\varepsilon \equiv \frac{\ln(2C(\varepsilon)+1)}{1-\varepsilon}.$$

Let $\{\Omega_n\}$: $\Omega_1 \subset \Omega_2 \subset \cdots \subset \Omega_n \subset \cdots$ be a monotone chain of bounded convex domains whose boundaries are sufficiently regular (piecewise smooth and Lipschitzian, say) and $\bigcup \Omega_n = \mathbb{R}^2$. Denote by u_n the unique solution of the boundary value problem

$$\begin{aligned} &\Delta u = e^u - 1 + 4\pi \sum_{j=1}^{k} n_j \delta(z - z_j) \quad \text{in } \Omega_n, \\ &u = 0 \quad \text{on } \partial\Omega_n, \end{aligned} \tag{6.4}$$

$n = 1, 2, \cdots$. We shall show that $u_n \to u$ as $n \to \infty$.

LEMMA 6.1. *Given $m = 1, 2, \cdots$ and $\{u_n\}_{n \geqq m}$, there holds*

$$u \leqq \cdots \leqq u_n \leqq \cdots \leqq u_m \leqq 0 \quad in\ \Omega_m.$$

Proof. It is easily observed that $u_n \leqq 0$ in Ω_n for each $n = 1, 2, \cdots$. In fact, since u_n behaves likes $n_j \ln |z - z_j|^2$ in a neighborhood of $z = z_j$, we can find an $\eta_0 > 0$ such that for any $0 < \eta < \eta_0$ we have $B_\eta(z_j) \subset \Omega_n$ and $u_n < 0$ on $\partial B_\eta(z_j)$, $j = 1, \cdots, k$. On the other hand, in $\Omega_\eta = \Omega_n - \bigcup_{j=1}^k B_\eta(z_j)$, $\Delta u_n = e^{u_n} - 1$. Hence the condition $u_n = 0$ on $\partial\Omega_n$ and the maximum principle allow us to conclude that $u_n \leqq 0$ in Ω_η, $\forall \eta < \eta_0$.

Next, we show that $u_{n+1} \leqq u_n$ in Ω_n, $n = 1, 2, \cdots$. To see this, we examine the relation $\Delta(u_{n+1} - u_n) = e^{u_{n+1}} - e^{u_n} = e^{\xi(u_{n+1}, u_n)}(u_{n+1} - u_n)$ in Ω_n. Since $(u_{n+1} - u_n)|_{\partial\Omega_n} = u_{n+1}|_{\partial\Omega_n} \leqq 0$, we conclude again from the maximum principle that $u_{n+1} \leqq u_n$ in Ω_n.

The inequality $u \leqq u_n$ in Ω_n, $n = 1, 2, \cdots$ is contained in the above proof. Thus the lemma follows.

LEMMA 6.2. *There holds the bound*

$$\|u_n - u\|_{W^{2,2}(\Omega_n)} \leqq M,$$

where $M > 0$ is a constant independent of $n = 1, 2, \cdots$.

Proof. Since Ω_n is convex, using the standard L^2-estimate in the equation

$$\begin{aligned} &\Delta(u_n - u) = e^{u_n} - e^u \quad \text{in } \Omega_n, \\ &(u_n - u) = -u' \quad \text{on } \partial\Omega_n, \end{aligned} \tag{6.5}$$

we have

$$\|u_n - u\|_{W^{2,2}(\Omega_n)} \leqq C(\|e^{u_n} - e^u\|_{L^2(\Omega_n)} + \|u'\|_{W^{2,2}(\Omega_n)} + \|u_n - u\|_{L^2(\Omega_n)}),$$

where $C > 0$ does not depend on Ω_n.

First of all, since $u' = u$ outside Ω_0, we see from (6.2), (6.3) that $u' \in W^{2,2}(\mathbb{R}^2)$. On the other hand, by virtue of Lemma 6.1, there holds $|u_n - u| \leqq |u|$. So it follows from (6.3) that $\sup_n \|u_n - u\|_{L^2(\Omega_n)}$ is finite. Finally, again from Lemma 6.1, $|e^{u_n} - e^u| \leqq |1 - e^u| = 1 - |\phi|^2$. Hence (6.1) implies that $\sup_n \|e^{u_n} - e^u\|_{L^2(\Omega_n)}$ is finite as well. This proves the lemma.

We are now ready to establish the expected convergence result. For convenience, we understand that $u_n = 0$ in $\mathbb{R}^2 - \Omega_n$. For a function f decaying sufficiently fast at infinity, we define the norm

$$|f|_\mu = \sup_{z \in \mathbb{R}^2} |e^{\mu|z|} f(z)|.$$

LEMMA 6.3. *Given $0 < \mu < 1$, there holds the limit*

$$\lim_{n \to \infty} |u_n - u|_\mu = 0. \tag{6.6}$$

Proof. From Lemma 6.2, we see that, in particular, for $m = 1, 2, \cdots$,

$$\|u_n - u\|_{W^{2,2}(\Omega_m)} \leqq M, \qquad n \geqq m. \tag{6.7}$$

Therefore $u_n - u \to$ some $w_m \in W^{2,2}(\Omega_m)$ weakly and $w_m = w_{m'}$ in Ω_m for $m' \geqq m$ due to Lemma 6.1. Set

$$w = w_m, \qquad z \in \Omega_m, \quad m = 1, 2, \cdots.$$

Then w is well defined in $\mathbb{R}^2$. We can obtain from (6.7) that $w \in W^{2,2}(\mathbb{R}^2)$. This fact implies that w decays to zero at infinity. Moreover, a simple argument applied to (6.5) leads us to conclude that w is smooth and verifies

$$\Delta w = e^{u+w} - e^u.$$

In other words, $u + w$ is also a solution of (6.2). By the uniqueness theorem in [11], we must have $w \equiv 0$.

Let $\varepsilon > 0$ be so small that $\varepsilon < 1 - \mu$. We have by (6.3) and Lemma 6.1

$$\begin{aligned} e^{\mu|z|}|u_n(z) - u(z)| &\leqq e^{\mu|z|}|u(z)| \\ &\leqq 2C(\varepsilon)\, e^{-([1-\varepsilon]-\mu)|z|}, \qquad |z| > r_\varepsilon. \end{aligned} \tag{6.8}$$

On the other hand, since $\cup\Omega_n = \mathbb{R}^2$, for any given $r > 0$ there exists $m \geqq 1$ so that $B_r = \{z \in \mathbb{R}^2 \,|\, |z| \leqq r\} \subset \Omega_m$. We have shown that $u_n \to u$ weakly in $W^{2,2}(\Omega_m)$. From the compact embedding $W^{2,2}(\Omega_m) \to C^0(\bar{\Omega}_m)$, we may conclude that $u_n \to u$ uniformly on B_r. Combining this observation with (6.8) we arrive at the expected limit (6.6).

In particular, $u_n \to u$ uniformly in $\mathbb{R}^2$.

From the sequence $\{u_n\}$ we can construct as in § 3 the corresponding solution pairs $\{(\phi^{(n)}, A^{(n)})\}$ of the Bogomol'nyi equations (2.5+) on Ω_n. It can be shown that $(\phi^{(n)}, A^{(n)}) \to (\phi, A)$ (in a suitable sense). However, since the physically interesting fields are $|\phi|^2$ and F_{12}, here we only discuss the convergence $|\phi^{(n)}|^2 \to |\phi|^2$, $F_{12}^{(n)} = \partial_1 A_2^{(n)} - \partial_2 A_1^{(n)} \to F_{12}$ in detail.

Using Lemma 6.1, we see easily that

$$\begin{aligned} 0 \leqq |\phi^{(n)}|^2 - |\phi|^2 &= e^{u_n} - e^u \\ &\leqq u_n - u. \end{aligned} \tag{6.9}$$

While from $(2.5+)_2$, which relates $\phi^{(n)}$ and ϕ to $F_{12}^{(n)}$ and F_{12}, we get

$$F_{12}^{(n)} - F_{12} = -\tfrac{1}{2}(|\phi^{(n)}|^2 - |\phi|^2). \tag{6.10}$$

As a consequence of (6.9), (6.10), we conclude that $(|\phi^{(n)}|^2, F_{12}^{(n)}) \to (|\phi|^2, F_{12})$ (as $n \to \infty$) in the same sense as the convergence for $u_n \to u$ stated in Lemma 6.3.

We summarize the results we have just obtained as follows.

THEOREM 6.4. *Let* $(\phi^{(n)}, A^{(n)})$ *be the solution of the Bogomol'yni system* (2.5+) *on* Ω_n, *obtained from the unique solution* u_n *of* (6.4), *and* (ϕ, A) *the finite energy solution of* (2.5+) *on full* $\mathbb{R}^2$ *with the same vortex distribution. Then*

$$1 \geqq |\phi^{(1)}|^2 \geqq \cdots \geqq |\phi^{(n)}|^2 \geqq \cdots \geqq |\phi|^2,$$

$$F_{12} \geqq \cdots \geqq F_{12}^{(n)} \geqq \cdots \geqq F_{12}^{(1)},$$

$||\phi^{(n)}|^2 - |\phi|^2|_\mu \to 0$, $|F_{12}^{(n)} - F_{12}|_\mu \to 0$, *and*

$$\Phi^{(n)} = \int_{\Omega_n} F_{12}^{(n)}\, dx \to \Phi = \int_{\mathbb{R}^2} F_{12}\, dx = 2\pi N$$

(*as* $n \to \infty$). *In other words, the total flux of the vortices confined in a bounded domain approaches the quantized flux of the vortex solution on* $\mathbb{R}^2$ *with larger domains giving successively better approximations.*

7. A family of infinite energy solutions. It has been shown in Jaffe and Taubes [11] that, for any vortex distribution in $\mathbb{R}^2$, the Bogomol'nyi system (2.5+) has a unique finite energy solution. The purpose of this section is to note that, when the finite energy condition is removed, such a uniqueness will no longer hold. More precisely, we state and prove the following.

THEOREM 7.1. *For any* $\{z_1, \cdots, z_k\} \subset \mathbb{R}^2$, $n_1, \cdots, n_k \in \mathbb{Z}_+$, *the Bogomol'nyi system (2.5+) has a family of gauge-distinct infinite energy solutions* $\{(\phi^{(\alpha)}, A^{(\alpha)})\}_{0<\alpha<\infty}$ *so that* $Z(\phi^{(\alpha)}) = \{z_1, \cdots, z_k\}$, *the multiplicity of the zero* $z = z_j$ *of* $\phi^{(\alpha)}$ *is* n_j, $j = 1, 2, \cdots$, *and there hold*

$$C_1\, e^{-[1/4]|z|^2}|z|^{2N+\alpha} \leqq |\phi^{(\alpha)}(z)|^2 \leqq C_2\, e^{-[1/4]|z|^2}|z|^{2N+\alpha} \quad \textit{for large } |z|, \tag{7.1}$$

where $C_1, C_2 > 0$ *are constants, which may depend on* α, *and*

$$\int_{\mathbb{R}^2} |\phi^{(\alpha)}|^2\, dx = 2\pi\alpha. \tag{7.2}$$

Proof. Choose a function $w \in C^\infty(\mathbb{R}^2)$ that verifies the property $w(z) = \ln|z|$ when $|z| \geqq 1$. Thus $f = \Delta w$ is of compact support, and

$$\int_{\mathbb{R}^2} f\, dx = \int_{|x|\leqq 2} f\, dx = \int_{|x|\leqq 2} \Delta w\, dx = \int_{|x|=2} \frac{\partial w}{\partial r}\, ds = 2\pi.$$

Consider (6.2). Introduce as before the background subtraction function

$$u_0(z) = \sum_{j=1}^{k} \ln|z - z_j|^{2n_j} + \alpha w(z) - \tfrac{1}{4}|z|^2.$$

The substitution $v = u - u_0$ leads us from (6.2) to the modified equation

$$\Delta v = K(z)\, e^v - \alpha f, \tag{7.3}$$

where

$$0 \leqq K(z) = e^{u_0(z)} = O(e^{-|z|}) \quad \text{for } |z| \to \infty.$$

Equation (7.3) has been well studied in the elegant works of Ni [15] and McOwen [13]. In particular, McOwen showed that, for any α: $0 < \alpha < \infty$, (7.3) has a smooth solution $v^{(\alpha)}$, which approaches a constant at infinity and

$$\int_{\mathbb{R}^2} K\, e^{v^{(\alpha)}}\, dx = \alpha \int_{\mathbb{R}^2} f\, dx = 2\pi\alpha.$$

From the solution $u^{(\alpha)} = u_0 + v^{(\alpha)}$ of (6.2), we can construct as in Jaffe and Taubes [11] or as in § 3 the solution pair $(\phi^{(\alpha)}, A^{(\alpha)})$ of the Bogomol'nyi equations (2.5+) so that $|\phi^{(\alpha)}|^2 = e^{u^{(\alpha)}} = e^{u_0 + v^{(\alpha)}} = K\, e^{v^{(\alpha)}}$. As a consequence, we see immediately that $|\phi^{(\alpha)}|^2$ verifies the desired decay estimate (7.1) and the space-average (7.2). Since (7.2) is invariant under the $U(1)$ gauge transformation

$$\phi \mapsto \phi\, e^{i\xi}, \qquad A \mapsto A + \nabla\xi,$$

different values of α give rise to gauge-distinct solutions. These solutions are necessarily all of infinite energy.

Remark 7.1. If the underlying domain $\mathbb{R}^2$ is replaced by an asymptotically Euclidean Riemann surface, the solutions of the curved space version of the Bogomol'nyi equations are superconducting vortices in a shell geometry or cosmic strings [25]. It is possible to modify the argument used in this section to establish a similar class of infinite energy solutions there.

8. Conclusions. In this paper we have shown that, on a lattice cell $\Omega = (-L_1, L_1) \times (-L_2, L_2)$, when a t' Hooft type periodic boundary condition is imposed, the Bogomol'nyi system arising in the abelian Higgs theory allows an arbitrarily distributed N-vortex solution, if and only if $|N| < L_1 L_2/\pi$. Such a solution exhibits the periodic structure of Abrikosov's mixed state vortices in a superconductor so that the magnetic flux can only take a quantized spectrum of values. On the other hand, when the periodic boundary condition is replaced by a boundary value condition on the observables $|\phi|^2$ and F_{12}, the system possesses a solution for any prescribed vortex locations and given total vortex number. In this case, numerical examples have shown that the flux is no longer quantized as before, but depends sensitively on the locations of vortex-lines. Such solutions can be used to approximate a finite energy full plane vortex solution in a global way, and in the large domain limit the flux approaches the quantized value related to the total vortex number. Moreover, for any prescribed vortex distribution, the Bogomol'nyi system on $\mathbb{R}^2$ has a continuous family of gauge-distinct solutions of infinite energy so that $|\phi|^2$ decays to zero exponentially fast at infinity.

EXISTENCE AND NONEXISTENCE OF SOLITARY WAVE SOLUTIONS TO HIGHER-ORDER MODEL EVOLUTION EQUATIONS*

SATYANAD KICHENASSAMY† AND PETER J. OLVER†‡

Abstract. The problem of existence of solitary wave solutions to some higher-order model evolution equations arising from water wave theory is discussed. A simple direct method for finding monotone solitary wave solutions is introduced, and by exhibiting explicit necessary and sufficient conditions, it is illustrated that a model admit exact sech^2 solitary wave solutions. Moreover, it is proven that the only fifth-order perturbations of the Korteweg–deVries equation that admit solitary wave solutions reducing to the usual one-soliton solutions in the limit are those admitting families of explicit sech^2 solutions.

Key words. solitary wave, nonlinear evolution equation, water waves, singular perturbation

1. Introduction. In the study of equations modeling wave phenomena, one of the fundamental objects of study is the traveling wave solution, meaning a solution of constant form moving with a fixed velocity. The determination of such solutions is accomplished by solving a reduced differential equation in fewer independent variables by one. In particular, the traveling wave solutions for a one-dimensional wave equation are found by solving a connection problem for an associated ordinary differential equation. Of particular interest are three types of traveling waves: the *solitary waves*, which are localized traveling waves, asymptotically zero at large distances, the *periodic waves*, and the *kink waves*, which rise or descend from one asymptotic state to another. All of these are, in the completely integrable case, solitons, coming from the inverse scattering solution to an eigenvalue problem, and dependent on a free parameter. On the other hand, the existence of these types of solutions is not dependent on integrability of the model, or the connection with an inverse scattering transform method of solution, as evidenced by the φ^4 theory; cf. [37], [38], and the examples described here. Except in the simplest instances, it is by no means obvious that such types of traveling wave solutions even exist. In addition, once existence is known, the delicacy of the connection problem to be solved makes their numerical computation rather difficult to effect in an easy, practical manner.

In this paper, we concentrate on the determination of solitary waves, whose importance for fluids came to the forefront with Scott Russell's experimental observation of solitary water waves in the Edinburgh canal [33]. Airy's premature dismissal of these solutions based on a linearized analysis of the free boundary problem necessitated the construction of suitable models exhibiting such solutions. This was accomplished, in the case of long waves over shallow water, through Boussinesq's bidirectional models and, subsequently, the celebrated Korteweg–deVries model, whose solitary wave solutions are explicit sech^2 solutions, which, moreover, have the remarkable soliton property of interacting without change of form. More recently, Amick and Toland, [4], and others, [1], [2], [19], have proved the existence of such waves for the full water wave problem. For small amplitude waves, the Korteweg–deVries solitons do a good job of modeling solitary water waves, [13]. However, the model fails to replicate such important physical phenomena as having a wave of maximal height,

originally conjectured by Stokes (cf. [1]) and the breaking of large amplitude waves. Owing to the difficulty of analyzing the water wave problem directly, the construction of suitable models is of great importance. One possible approach is to retain higher-order terms in the Boussinesq perturbation expansion, leading to fifth-order model evolution equations. One of the principal purposes of this paper is to show that there are definite difficulties with this procedure, in that for most of these higher-order models, solitary wave solutions of the appropriate form do not even exist! Indeed, this holds for almost all versions of the models derived from the water wave problem. (An alternative approach would be to employ the two-timing approach advocated by Segur, [42], and others, in which the higher-order terms in the expansion are forced evolution equations governed by the leading order Korteweg-deVries equation. However, it is hard to see how the requisite phenomena of maximal height and breaking would manifest themselves in this approach.)

The present paper is devoted to the analysis of solitary wave solutions to a general class of scalar fifth-order evolution equations; see (2.1) below. We begin by discussing the various models that are included in this class, such as the fifth-order Korteweg-deVries equations, other integrable equations, water wave models, and models from elastic media with microstructure. The third section discusses known results on explicit solitary wave solutions for certain models, numerical results, and a nonexistence result of Amick and McLeod for the critical surface tension water wave model. Next we present a simplified approach to the determination of explicit monotone traveling wave solutions, which reduces the fifth-order evolution equation to a third-order ordinary differential equation. This leads to explicit criteria for the existence of exact sech^2 solitary wave solutions, which imply that these models admit either $0, 1, 2, \infty$, or $\infty+1$ exact sech^2 solitary wave solutions. Here ∞ indicates a one-parameter family of solutions valid for a range of wave speeds, and these particular models are explicitly characterized by a pair of simple algebraic relations on the coefficients. Interestingly, even for fifth-order Korteweg-deVries models, there is the possibility of having more than one solitary wave solution for a given wave speed, leading to unusual "bound state solutions." Finally, we present a nonexistence result that says, in essence, that the only models which are perturbations of the usual Korteweg-deVries equation and that possess solitary wave solutions reducing, in the limit, to Korteweg-deVries solitons are those that have a one-parameter family of explicit sech^2 solitary waves. See Theorem 13 for a precise formulation. Our proof relies on a general method introduced by the first author [24] in a similar study of breather solutions of Klein-Gordon equations, which we outline at the end of § 3. Our result does not completely rule out all solitary wave solutions, but only those which reduce to Korteweg-deVries solitary waves in an appropriate scaling limit; nevertheless, it does demonstrate that "physically relevant" solitary wave solutions do not, in general, exist. This has some interesting implications for perturbation theories, which we discuss in the final section.

2. Higher-order model equations.

We will consider a class of fifth-order model evolution equations of the general form

$$\begin{aligned} &u_t+\mu u_{xxx}+\alpha u_{xxxxx}+\beta u u_{xxx}+\delta u_x u_{xx}+P'(u)u_x \\ &\quad =u_t+[\mu u_{xx}+\alpha u_{xxxx}+\beta u u_{xx}+\gamma u_x^2+P(u)]_x=0. \end{aligned} \tag{2.1}$$

Here α, β, γ, $\delta=2\gamma+\beta$, and μ are assumed to be constants, and $P(u)$ is an analytic function of the dependent variable. Many of these models require that P be a cubic polynomial

$$P(u)=pu+qu^2+ru^3, \tag{2.2}$$

where p, q, r are constants, although this will not be necessary for most of our analysis. (However, *only* these models will admit explicit sech^2 solitary waves.) Note that we can assume without loss of generality that $p=0$ by going to a suitable moving coordinate frame. In the models derived by perturbation expansion, the coefficients in (2.1) will depend on a small parameter, ε, in terms of which p is of order 1, q, μ are of order ε, and α, β, δ, and r of order ε^2.

The general class of equations (2.1) includes many well-known equations that have been studied at length in the literature. If the ε^2 terms are absent, the model (2.1) reduces to the well-known Korteweg-deVries equation

$$u_t+pu_x+\mu u_{xxx}+2quu_x=0, \tag{2.3}$$

which serves to model many different wave phenomena requiring a balance between dispersion and nonlinearity, [33], [46]. Also of note is the modified Korteweg-deVries equation

$$u_t+pu_x+\mu u_{xxx}+3ru^2u_x=0. \tag{2.4}$$

Both the Korteweg-deVries and modified Korteweg-deVries equations are known to be integrable via inverse scattering techniques, [33], [42], [46], the scattering operator for the Korteweg-deVries equation being the well-studied Schrödinger operator $L=D^2+v$, where the potential $v(x,t)$ is a suitable multiple of $u(x,t)$, and $D=d/dx$. In particular, their solitary wave solutions are solitons, and interact without change of form. Their speed is related to the value of the associated spectral parameter (eigenvalue). There are additional integrable models included in the class (2.1). The particular parameter values

$$\beta=\tfrac{5}{3}\kappa\alpha,\quad \delta=\tfrac{10}{3}\kappa\alpha,\quad r=\tfrac{5}{18}\kappa^2\alpha,\quad q=\tfrac{1}{2}\kappa\mu, \tag{2.5}$$

where $\kappa\neq 0$, describe a four-parameter family of integrable fifth-order Korteweg-deVries equations [33], which are soluble by the scattering problem associated with the same Schrödinger operator. (More accurately, the models given by (2.5) are linear combinations of purely fifth-order (corresponding to the parameter α) and third-order (corresponding to the parameter μ) Korteweg-deVries equations.) The Sawada-Kotera equation [41],

$$u_t+u_{xxxxx}+30uu_{xxx}+30u_xu_{xx}+180u^2u_x=0, \tag{2.6}$$

and the Kaup equation [21],

$$u_t+u_{xxxxx}+30uu_{xxx}+75u_xu_{xx}+180u^2u_x=0, \tag{2.7}$$

are also known to be integrable, being associated with the scattering problem for the third-order operator $M=D^3+vD+w$; cf. [21]. For the Sawada-Kotera equation, $v=6u$ and $w=0$, whereas for the Kaup equation $v=6u$ and $w=3u_x$. However, in contrast to the higher-order Korteweg-deVries equations, we cannot add in third-order terms to these equations without destroying their integrability.

Other models of the general form (2.1) that are (almost certainly) not integrable also arise in applications. In [34], [35] the second author proposed certain special cases of the general fifth-order model (2.3) as models for the unidirectional propagation of shallow water waves over a flat surface. (See [29] for extensions which include bottom topography.) These arose from two sources: first as the second-degree correction to the standard Korteweg-deVries model for the undirectional propagation of long waves in shallow water arising in the Boussinesq expansion for the full water wave problem. Second, using a general theory of noncanonical perturbation expansions of

Hamiltonian systems, these types of models appear as "Hamiltonian versions" of the Korteweg-deVries model, incorporating the correct first degree expansions of both the water wave Hamiltonian functional (energy) and the Hamiltonian operator. Indeed, whereas the full water wave problem admits a Hamiltonian structure due to Zakharov [50] and the Korteweg-deVries equation admits two distinct Hamiltonian structures [36], neither of these matches the perturbation expansion of Zakharov's structure. Alternatively, we can verify that the first-order perturbation expansion of the water wave energy functional is *not* conserved under the Korteweg-deVries flow. The Hamiltonian models attempt to rectify these unexpected difficulties. In the water wave models, $u(x, t)$ represents either the surface elevation or the horizontal velocity measured at a fraction $0 \leqq \theta \leqq 1$ of the undisturbed fluid depth. There are two small parameters called α, β in [34], [35], but, to avoid confusion, we denote them here by ε, which measures the ratio of wave amplitude to undisturbed fluid depth, and κ, which measures the square of the ratio of fluid depth to wave length. In the shallow water regime, ε and κ are assumed to have the same order of magnitude. The Bond number, which represents a dimensionless magnitude of surface tension, is denoted by τ. In all models, the leading order (Korteweg-deVries) terms are all the same:

$$p=1, \quad \mu=\kappa\frac{1-3\tau}{6}, \quad q=\frac{3}{4}\varepsilon, \tag{2.8}$$

representing a Korteweg-deVries equation except when the Bond number has the critical value $\tau=\frac{1}{3}$. (See below.) The models differ only in the higher-order terms, which take the following forms:

u = horizontal velocity at depth θ; second-order model

$$\alpha=\kappa^2\frac{19-30\tau-45\tau^2}{360}, \quad \beta=\kappa\varepsilon\frac{5-3\tau}{12}, \quad \delta=\kappa\varepsilon\frac{53-36\theta^2-39\tau}{24}, \quad r=0, \tag{2.9}$$

u = horizontal velocity at depth θ; Hamiltonian model

$$\begin{gathered} \alpha=-\kappa^2\frac{(5-6\theta^2-3\tau)(2-3\theta^2)}{18}, \quad \beta=\kappa\varepsilon\frac{53-66\theta^2-27\tau}{24}, \\ \delta=\kappa\varepsilon\frac{139-168\theta^2-81\tau}{24}, \quad r=-\frac{15}{32}\varepsilon^2, \end{gathered} \tag{2.10}$$

u = surface elevation; second-order model

$$\alpha=\kappa^2\frac{19-30\tau-45\tau^2}{360}, \quad \beta=\kappa\varepsilon\frac{5-6\tau}{12}, \quad \delta=\kappa\varepsilon\frac{23+15\tau}{24}, \quad r=-\frac{1}{8}\varepsilon^2, \tag{2.11}$$

u = surface elevation; Hamiltonian model

$$\alpha=0, \quad \beta=\frac{1-3\tau}{8}\kappa\varepsilon, \quad \delta=\frac{3(1-3\tau)}{8}\kappa\varepsilon, \quad r=\frac{5}{32}\varepsilon^2. \tag{2.12}$$

((2.12) corrects an error in [35, eqn. (4.28)].) It is interesting to note that none of these models is integrable, except the Hamiltonian model (2.10) for the horizontal velocity at the particular "magic depth"

$$\theta=\sqrt{\tfrac{11}{12}-\tfrac{3}{4}\tau}, \tag{2.13}$$

where the model turns out to be a fifth-order Korteweg-deVries equation. (This formula corrects a misprint in reference [35].)

The model

$$u_t+pu_x+\mu u_{xxx}+2quu_x+\alpha u_{xxxxx}=0 \tag{2.14}$$

arises in the study of water waves with surface tension in which the Bond number takes on the critical value $\tau = \frac{1}{3}$, where the Korteweg-deVries model no longer applies; cf. [18]. The particular case $p = \mu = 0$ arises in both magneto-acoustics and nonlinear transmission lines; cf. [31], [49]. The equation

$$u_t + pu_x + \mu u_{xxx} + \alpha u_{xxxxx} - uu_{xxx} - 2u_x u_{xx} = 0 \tag{2.15}$$

was proposed by Benney [6] as one possible model for the interaction of short and long waves. Third-order models of the form

$$u_t + u_x + \mu u_{xxx} + 2quu_x + \beta uu_{xxx} + \delta u_x u_{xx} + 3ru^2 u_x = 0, \tag{2.16}$$

in which $\beta = 2\delta \neq 0$, $r = 0$, were proposed by Kunin [28, § 5.3] in his study of elastic media with microstructure. Note that the Hamiltonian model (2.12) for water waves is of this type, but with $\beta = 3\delta \neq 0$, as are both second-order models (2.9), (2.11) at the particular Bond number $\tau = \frac{2}{15}\sqrt{30} - \frac{1}{3} \cong .3970$, and the Hamiltonian model (2.10) at depths $\theta^2 = \frac{2}{3}$ or $\frac{5}{6} - \frac{1}{2}\tau$. Additional models of the form (2.1) have been derived for weakly nonlinear long waves in a stratified fluid [14] and free surface waves over rotational flows [12].

Incidentally, the theory of Kodama [25] shows that all such fifth-order equations with $\alpha \neq 0$, and $P(u)$ a cubic polynomial, can be recast asymptotically into canonical form as fifth-order Korteweg-deVries equations under an appropriate change of variables. Thus, in a certain sense, all the models (2.1), (2.2) are "approximately integrable," although this remark does not imply much in the way of rigorous results for them.

Very recently Ponce [39] has proved that the initial-value problem for (2.1), (2.2) is locally well posed in any Sobolev space $H^s(\mathbb{R})$ for any $s \geqq 4$. Specifically, Ponce proves the following result.

THEOREM 1. *For any* $u_0 \in H^s(\mathbb{R})$ *with* $s \geqq 4$, *there exists a* $T > 0$ *and a unique strong solution* $u(x, t)$ *in the space* $C([0, T], H^s) \cap L^2[0, T], H^{s+2}_{\mathrm{loc}})$ *of the initial value problem* (2.1) *with* $u(x, 0) = u_0(x)$.

3. Solitary wave solutions. We now review known results concerning solitary and other traveling wave solutions to particular models of the form (2.1). We begin by discussing the known explicit solutions to these equations.

First recall that the Korteweg-deVries equation, modified Korteweg-deVries equation, and the class of fifth-order Korteweg-deVries equations (2.5) all possess explicit sech^2 solitary wave solutions for all wave speeds $c > p = P'(0)$. The amplitude of these waves is proportional to the wave speed. If $q/\mu < 0$, then the solitary wave is a wave of elevation, whereas if $q/\mu > 0$ it is a wave of depression. The Sawada-Kotera equation (2.5) also admits sech^2 solitary wave solutions for all wave speeds $c > 0$; cf. [30]. On the other hand, the Kaup equaton (2.6) has solitary wave solutions of the anomalous form

$$u(x, t) = \frac{2a^2(2\cosh 2\xi + 1)}{(\cosh 2\xi + 2)^2}, \qquad \xi = ax - 16a^5 t. \tag{3.1}$$

Again, these exist for a range of wave speeds $c = 16a^4 > 0$.

For the model (2.14) for water waves at critical surface tension, provided $\alpha\mu < 0$, Yamamoto and Takizawa [48] produced an explicit solitary wave of depression in terms of a sech^4 function:

$$u(x, t) = -\frac{105\mu^2}{338\alpha q}\operatorname{sech}^4\left[\sqrt{-\frac{\mu}{52\alpha}}\left\{x + \left(p + \frac{36\mu^2}{169\alpha}\right)t\right\}\right]. \tag{3.2}$$

This solution was also derived by Hereman et al. [15] using a more systematic procedure, and, much later, also by Huang et al. [16]. This "anomalous" solitary wave solution is quite surprising; it only appears for one particular (positive) wave speed: $c = -36\mu^2/169\alpha$. It is unclear whether this solution has any physical meaning. (Other similar "anomalous" sech^2 solitary wave solutions will be determined for many of the models (2.1), (2.2) in § 6.) Of less direct relevance to our results, but still of interest, Hunter and Scheurle [17] proved the existence of traveling waves to the model (2.7) that bifurcate from Korteweg-deVries solitons, but are no longer decreasing as $|x| \to \infty$, having small but finite amplitude oscillatory tails.

Kawahara, [22], claims to numerically establish the existence of "oscillatory solitary wave" solutions to the model (2.14), and Nagashima [31], [32], in the case $p = \mu = 0$, "establishes" their existence experimentally (!). Also, Zufiria [51], in the context of the water wave problem, while more concerned with periodic traveling wave solutions, does investigate "approximate solitary waves" for this model and concludes that they are not unique. However, Amick and McLeod [3] have, using powerful complex-analytic methods, rigorously proved that the model (2.8) does *not* possess a solitary wave of elevation for $\alpha\mu > 0$, with α sufficiently small. (Note that this result does not exclude the exact solitary wave (3.1). See also Hunter and Scheurle [18] for a less rigorous version.) It appears to be quite difficult to extend this technique to the more general models considered in this paper, especially in view of the fact that, for certain models, solitary wave solutions do exist. Amick and McLeod's result implies that Kawahara and Zufiria's numerical solutions cannot be correct, and we propose an explanation for such numerical results in § 8. Indeed, many numerical procedures for finding such waves are, in our opinion, rather suspect, as most of the nonexistence results are of the "exponentially small" variety, i.e., to all orders in ε a solitary wave can be shown to exist, but one may suspect that exponentially small terms (like $e^{-1/\varepsilon}$) prevent its final establishment. See Byatt-Smith [11], Kruskal and Segur [27], [43], and Troy [44], for other problems of this type. Numerical schemes are hard pressed indeed to discover such exponentially small errors!

In the third-order model (2.16), which includes Kunin's third order models for elastic media and some of the water wave models, the equation for solitary waves can, in certain cases, be integrated directly, and one has the intriguing phenomenon of a *wave of maximal height*, reminiscent of the Stokes phenomenon (although the maximal height waves for these models exhibit cusps rather than corners). Indeed, for the full water wave problem, Amick and Toland [4], have proved the existence of monotone solitary wave solutions of small amplitudes up to a maximal height wave with a 120° corner for the problem in the absence of surface tension. (For large values of surface tension, meaning Bond number $\tau > \frac{1}{3}$, Amick and Kirchgässner [2] and Sachs [40] have proved the existence of monotone solitary wave solutions, while very recent results of Iooss and Kirchgässner [19], and Beale [5] demonstrate the existence of solitary wave solutions with damped oscillatory tails for $0 < \tau < \frac{1}{3}$). See also the papers of Wadati, Ichigawa, and Shimizu [45], and Kawamoto [23] for other types of model equations exhibiting limiting cusp waves. It is an interesting question as to whether any of the fifth-order models exhibit such phenomena. Also, the behavior of large amplitude waves (including the possibility of breaking) in these models is not known.

Finally, we mention papers by Yamamoto and Takizawa [47], [48], and Kano and Nakayama [20], which exhibit other types of traveling wave solutions, including periodic waves and solitary sech^2 waves approaching a nonzero asymptotic value as $x \to \pm\infty$. (These can, of course, always be transformed into "genuine" solitary wave solutions, with zero asymptotic limits, to a different model of the same basic form (2.1) by subtracting a suitable constant from u.)

Our own results include the following existence and nonexistence criteria.

On the one hand, we exhibit explicit conditions for a model of the form (2.1) to possess a sech^2 solitary wave solution. First, for such solutions to exist, $P(u)$ must necessarily be a cubic polynomial, (2.2). Interestingly, the parameter space $(\alpha, \beta, \delta, \mu, p, q, r)$ splits into five regions: three of these are relatively open subregions in which there are, respectively, two, one, or no exact sech^2 solitary wave solutions. In the first and second regions, most models have such a solution for a unique, or precisely two, possible wave speeds, similar to the anomalous sech^4 solution to the model (2.8). Secondly, we prove that there are two algebraic relations that must be satisfied by the coefficients in order for the model to admit a one-parameter family of sech^2 solitary wave solutions for a range of wave speeds. This family includes the higher-order Korteweg-deVries equations, (2.4), the Sawada-Kotera equation (2.6), and the Hamiltonian water wave model (2.10) at the particular depth (2.13), but also many other (presumably nonintegrable) equations as well. This leads to the two further regions, each of codimension 2, in which there is either a one-parameter family of sech^2 solitary wave solutions, or such a family plus a single anomalous sech^2 solitary wave solution. These results reconfirm the idea that solitary waves may arise independently of the model being integrable. Also, since the Kaup equation (2.7) admits a one-parameter family of solitary wave solutions for a range of wave speeds that are not sech^2 solutions, we must exercise a bit of caution in drawing unwarranted conclusions from this result!)

On the other hand, assuming $\mu\alpha q \neq 0$, and introducing a small parameter ε representing the departure of the models from the Korteweg-deVries equation, we prove that the only models that admit solitary wave solutions that are perturbations of the corresponding Korteweg-deVries solitons, and satisfy certain analyticity conditions, are the models that satisfy these same algebraic relations. Thus the only physically relevant solitary wave solutions that can exist are always given by sech^2 functions! In outline, our nonexistence result is proved in two basic steps, similar to earlier work of the first author on the nonexistence of breather solutions to a general class of nonlinear Klein-Gordon equations, including the φ^4 equation and the double sine-Gordon equation [24]. We first establish the existence of "solitary wave tails," i.e., traveling wave solutions that decay exponentially fast at either $+\infty$ or $-\infty$, by proving the convergence of the appropriate formal power series solution. The second step in the proof is to match this solution with a formal asymptotic expansion of the solution starting with the one soliton solution of the Korteweg-deVries equation obtained by omitting the fifth-order terms in the model. We then show that, by analyzing the poles of this solution in the complex plane, the second series cannot converge to a true solution, and so we conclude that such a solitary wave solution does not exist. The details will become clearer in the subsequent discussion.

4. The equation for traveling waves. We begin by recalling the elementary method for reducing the problem of traveling wave solutions to an evolution equation such as (2.1) to a connection problem for an ordinary differential equation. A traveling wave solution is just a solution of the particular form

$$u = u(\xi) = u(x - ct), \tag{4.1}$$

where c is the wave speed and $\xi = x - ct$ is the characteristic variable. Substituting the ansatz (4.1) into (2.1), we are led to look for solutions to the fifth-order ordinary differential equation

$$\alpha u''''' + (\beta u + \mu) u''' + \delta u' u'' + [P(u) - cu]' = 0, \tag{4.2}$$

where the primes indicate derivatives with respect to ξ. Any solution $u(\xi)$ of (4.2) thus provides a traveling wave solution to the original evolution equation (2.1). The ordinary differential equation (4.2) can be integrated once, so we effectively have a fourth-order equation

$$\alpha u'''' + (\beta u + \mu)u'' + \gamma u'^2 + Q(u) = 0, \tag{4.3}$$

where

$$Q(u) = P(u) - cu - d, \tag{4.4}$$

with d being a constant of integration.

Consider the case of a localized traveling wave solution, meaning one that is asymptotically small at large distances, so $u \to 0$ as $\xi \to \pm\infty$. Note that this requires $Q(0) = 0$, which fixes the constant of integration d. As it stands, (4.3) is still invariant under the group of translations in ξ (and so could be integrated once more, [36, § 2.5]) and the discrete reflection $\xi \mapsto -\xi$. One way to get rid of this ambiguity is to assume that the wave has its crest (or trough) at $\xi_0 = 0$, and is symmetric with respect to the crest, which means that u is an even function of ξ. Thus we have a fourth-order boundary value problem on the half line $\{\xi > 0\}$, with boundary conditions

$$u'(0) = u'''(0) = 0, \quad \text{and} \quad u(\xi) \to 0, \quad \xi \to +\infty. \tag{4.5}$$

As it stands, it is by no means obvious how to solve the nonlinear connection problem (4.3), (4.5); in particular, the two boundary conditions at $\xi = 0$ define too small a target to try to aim for with a standard shooting approach. This already strongly indicates that, barring exceptional circumstances, the existence of solitary wave solutions will be rare.

5. An equation for monotone solitary waves. We introduce an effective direct method for determining explicit "monotone" (see Definition 2 below) traveling wave solutions to general one-dimensional evolution equations, reducing the fourth-order boundary value problem (4.3), (4.5) on the half line to a (singular) third-order "initial-value problem." The method could also be used to effectively compute solitary and periodic waves (when they exist) numerically, although we have not tried to implement it. (In fact, the method was originally developed by the second author in a failed attempt to prove general existence results concerning solitary wave solutions to these models!) It draws its inspiration from a paper by Kano and Nakayama [20], in which they showed the existence of explicit periodic solutions involving combinations of elliptic functions to certain particular fifth-order models by proving that a suitable polynomial solution w to the reduced equation could be determined; see also Krishnan [26], where a similar method is applied to systems of Boussinesq type. Our method is much more direct and easier to implement than that of Hereman et al. [15].

DEFINITION 2. A *monotone solitary wave solution* is a localized traveling wave solution, i.e., $u \to 0$ as $\xi \to \pm\infty$, which is monotone on the open intervals $(-\infty, \xi_0)$, (ξ_0, ∞), and symmetric about the point ξ_0. The solitary wave is a *wave of elevation* (*depression*) if u is montone increasing (decreasing) on $(-\infty, \xi_0)$, in which case $u_0 = u(\xi_0)$ is called the *crest* (*trough*). A *monotone periodic wave solution* is a traveling wave solution which is periodic in ξ, is monotone on the intervals between crests and troughs, and is symmetric about any crest or trough. A *monotone kink wave solution* is a traveling wave solution which is monotone on the entire real line and approaches limiting values at large distances, so $u \to u_1$ as $\xi \to -\infty$, and $u \to u_2$ as $\xi \to \infty$.

Rather than try to look directly for the required solution $u(\xi)$, we assume that it can be reconstructed as the solution of the simple first-order ordinary differential equation

$$u'^2 = w(u), \qquad u' \equiv \frac{du}{d\xi}, \tag{5.1}$$

where $w(u)$ is a function to be determined. Clearly, once the function $w(u)$ is known, (5.1) can be solved explicitly for $u(\xi)$ by a simple quadrature:

$$\int_a^u \frac{dv}{\sqrt{w(v)}} = \xi + k. \tag{5.2}$$

Examples of solutions that have this form are the soliton and cnoidal wave solutions of the Korteweg-deVries equation [46, § 13.12], where the function $w(u)$ is a cubic polynomial. In particular, if $u(\xi)$ is a monotone function on a given interval, the function $w(u)$ is defined implicitly by the relation (5.1).

The key is the behavior of the function $w(u)$ near its zeros. A simple zero will correspond to a crest or a trough, while a double zero will provide an asymptotic exponential tail for $u(\xi)$ near ∞ or $-\infty$. Thus, a solitary wave solution will correspond to a positive solution $w(u)$ between a double zero at $u=0$ and a simple zero at the crest or trough u_0. (See Fig. 1). Similarly, a periodic wave solution will correspond to a positive solution $w(u)$ between two consecutive simple zeros, (Fig. 2), while a kink solution has two consecutive double zeros, (Fig. 3). We thus have the following useful criterion for the existence of monotone traveling wave solutions to such models.

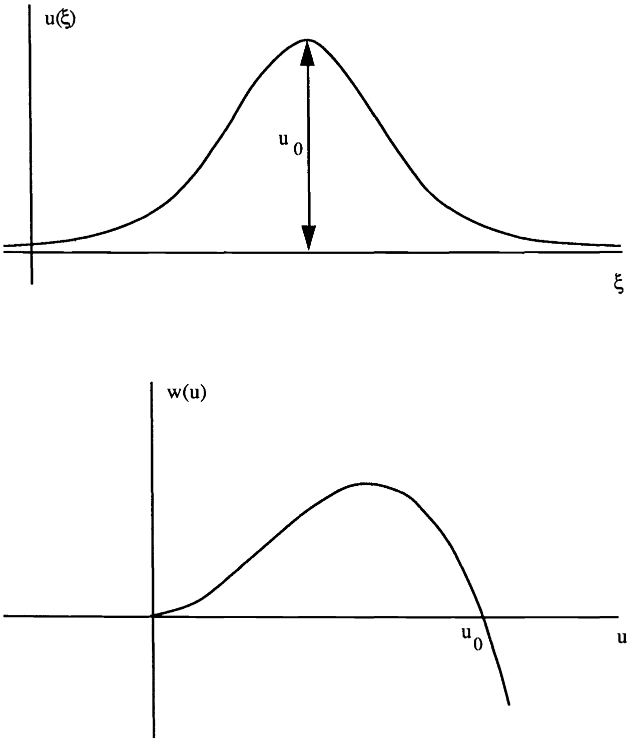

FIG. 1. *Solitary wave solution.*

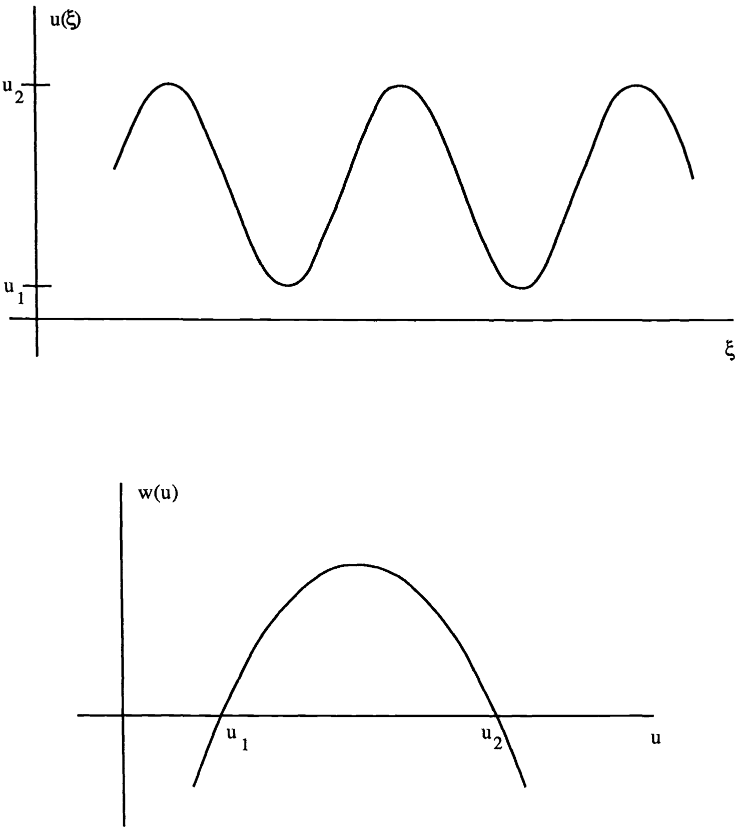

FIG. 2. *Periodic wave solution.*

PROPOSITION 3. *Let $w(u)$ be an analytic function of u, which is positive on the interval $u_0 < u < u_1$, with $w(u_0) = w(u_1) = 0$. Let $u(\xi)$ be the corresponding solution to the first-order ordinary differential equation* (5.1). *If u_0 and u_1 are simple zeros of w, then u is a monotone periodic traveling wave, oscillating between a peak u_1 and a trough u_0. If u_0 is a double zero and u_1 a simple zero of w, then u is a monotone solitary wave of elevation with peak u_1 and asymptotic value u_0 at $\pm\infty$. Conversely, if u_1 is a double zero and u_0 a simple zero of w, then u is a monotone solitary wave of depression with trough u_0 and asymptotic value u_1 at $\pm\infty$. Finally, if u_0 and u_1 are both double zeros of w, then u is a monotone kink wave with asymptotic values u_0, u_1 at $\pm\infty$* (*either going from u_0 to u_1 or the reverse by the reflectional symmetry*).

Using the ansatz (5.1), we substitute into the ordinary differential equation for the traveling wave solution $u(\xi)$, and thereby obtain an ordinary differential equation for the function $w(u)$ of order *one less* than that for u. The goal is then to determine suitable solutions $w(u)$ (if any exist) of this reduced ordinary differential equation. Differentiating our basic equation (5.1), we find that, as long as $u' \neq 0$,

$$\begin{aligned} u'^2 &= w, \\ u'' &= \tfrac{1}{2} w', \\ u'u''' &= \tfrac{1}{2} w w'', \\ u'''' &= \tfrac{1}{2} w w''' + \tfrac{1}{4} w' w'', \end{aligned}$$

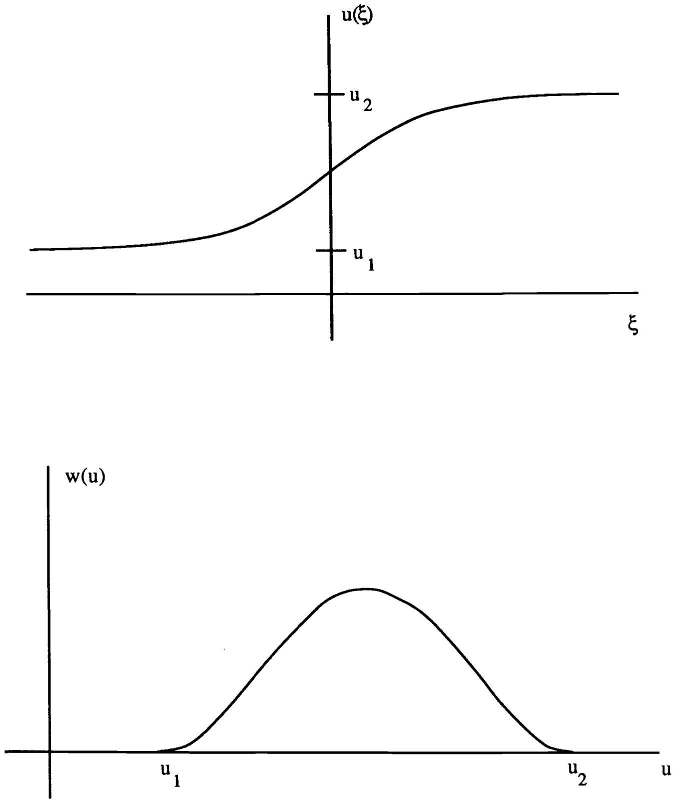

FIG. 3. *Kink wave solution.*

where the primes on w indicate derivatives with respect to u. Substituting into (4.3), we deduce that w must satisfy the third-order ordinary differential equation

$$\frac{\alpha}{4}\{2ww''' + w'w''\} + \frac{1}{2}(\beta u + \mu)w' + \gamma w + Q(u) = 0. \tag{5.3}$$

Any solution to (5.3) will implicitly determine a special traveling wave solution to the original wave equation (2.1) via the integral (5.2). In particular, for a monotone solitary wave solution to the original equation, we need to find a solution $w(u)$ to (5.3) satisfying the initial conditions

$$w(0) = w'(0) = 0, \qquad w''(0) > 0, \tag{5.4}$$

is positive, $w(u) > 0$, for u between 0 and $a \neq 0$, and

$$w(a) = 0, \quad w'(a) \neq 0, \quad w''(a) < \infty. \tag{5.5}$$

In this case a will be the amplitude (crest or trough depending on the sign) of the solitary wave.

6. Exact solitary wave solutions. In certain special cases, we can use the representation (5.1) to easily find exact sech^2 solitary wave solutions to our original evolution equation (2.1). For a solitary wave solution of the specific form

$$u(x, t) = a \operatorname{sech}^2 \lambda(x - ct), \qquad \lambda > 0, \tag{6.1}$$

the corresponding function $w(u)$ must be a cubic polynomial:

$$w(u) = 4\lambda^2\left(u^2 - \frac{1}{a}u^3\right) = \rho u^2 + \sigma u^3, \tag{6.2}$$

where

$$\rho = 4\lambda^2 > 0, \qquad \sigma = -\frac{4\lambda^2}{a} \neq 0 \tag{6.3}$$

are constants to be determined from the equation. Note that since $a = -\rho/\sigma$, we see that $\sigma < 0$ gives a wave of elevation, and $\sigma > 0$ a wave of depression. Substituting (6.2) into (5.3), we first deduce that $Q(u)$ (and hence $P(u)$) must be a cubic polynomial,

$$Q(u) = (p - c)u + qu^2 + ru^3, \tag{6.4}$$

with $Q(0) = 0$; cf. (2.2), (4.4). Moreover, the coefficients ρ and σ must satisfy three polynomial equations:

$$\alpha\rho^2 + \mu\rho + (p - c) = 0, \tag{6.5}$$

$$15\alpha\rho\sigma + 2(\beta + \gamma)\rho + 3\mu\sigma + 2q = 0, \tag{6.6}$$

$$15\alpha\sigma^2 + (3\beta + 2\gamma)\sigma + 2r = 0, \tag{6.7}$$

arising as the coefficients of the powers of u in (5.3). The fact that the solution ρ of the *indicial equation* (6.5) must be positive places certain inequality constraints on the wave speed c depending on the relative signs of the coefficients α, μ. As long as we also have a nonzero solution σ to (6.7), then (6.6) imposes a single compatibility condition on all the coefficients of the evolution equation (2.1) and the wave speed c. As we will see, this implies that there are three open regions in parameter space (coordinated by $\alpha, \beta, \gamma, \mu, p, q, r$), where the model (2.1), (2.2) has precisely 0, 1, or 2 sech^2 solitary wave solutions, for a particular value of the wave speed c.

For a special five-parameter family of models, there is actually a continuum of sech^2 solitary wave solutions for all sufficiently large wave speeds. Note that according to (6.5), ρ will depend on the wave speed c, whereas (6.7) implies that σ does not. Therefore, if the compatibility condition (6.6) is to hold for a range of wave speeds, the coefficient of ρ and the constant term must lead to the same equation for σ. We conclude that the models for which this occurs are those for which

$$(\beta + \gamma)\mu = 5q\alpha \quad \text{and} \quad 15\alpha r = \beta(\beta + \gamma). \tag{6.8}$$

In particular, the four-parameter family of integrable fifth-order Korteweg-deVries equations (2.5), and the Sawada-Kotera equation, (2.6), both satisfy these constraints. However, these do not exhaust all the models satisfying the constraints (6.8); presumably most of the others are not integrable. (Although the Kaup equation, (2.7), has a continuum of solitary wave solutions, they are not of sech^2 type, and so it is in a different class.)

For these particular models, the nature of the sech^2 solitary waves, which comes from an elementary analysis of the conditions for (6.5), (6.7) to admit real solutions ρ, σ, and the resulting signs, is of interest. Since the wave amplitude is given by the formula $a = 3\mu\rho/(2q)$, and $\rho > 0$, if $q\mu > 0$, then the solitary wave is a wave of elevation, whereas if $q\mu < 0$ it is a wave of depression, as in the Korteweg-deVries case (2.3). Substituting into (6.5), we deduce the following quadratic equation relating wave speed and amplitude:

$$c = \frac{4\alpha q^2}{9\mu^2}a^2 + \frac{2}{3}qa + p, \qquad \operatorname{sign} a = \operatorname{sign} q\mu. \tag{6.9}$$

If $\alpha\mu > 0$, then there is a unique solitary wave for each *supercritical* wave speed $c > p$. However, if α and μ have opposite signs, then besides these supercritical sech^2 solutions, there is a nonzero sech^2 solitary wave at the critical wave speed $c = p$, and *two* distinct sech^2 solitary waves for the range of *subcritical* wave speeds between p and $p - \mu^2/(4\alpha)$, reducing to a single wave of amplitude $a^* = -3\mu^2/(4\alpha q)$ at the limiting wave speed $c^* = p - \mu^2/(4\alpha)$. Figures 4 and 5 graph the different possible relationships (6.9) between wave speed and amplitude for the one-parameter family of sech^2 solutions to the models satisfying (6.8).

The elementary observation that a model of the form (2.1) can admit more than one distinct solitary wave solution for a given wave speed does not appear to be well known, even for the integrable fifth-order Korteweg-deVries models. In this particular case, this result can also be detected using the associated scattering problem as follows. The Lax pair for such an equation takes the form $L_t = [B, L]$, where L is the usual second-order Schrödinger operator, and $B = \mu B_3 + \alpha B_5 = \mu L_+^{3/2} + \alpha L_+^{5/2}$ is a linear combination of the third- and fifth-order operators giving the homogeneous third- and fifth-order Korteweg-deVries equations. The eigenvalue for the soliton is constant, and the associated norming constant has the time dependence $m(t)^2 = m(0)^2 \exp[8\mu t\eta^3 - \alpha\eta^5]$. The corresponding wave speed is then $c = (8\mu\eta^3 - \alpha\eta^5)/2\eta$. Thus, we can clearly have ranges of wave speeds for which there are two distinct sech^2 solitons traveling at the same speed. Note that the corresponding two-soliton solution for two such waves represents a bound state with two humps traveling at the same

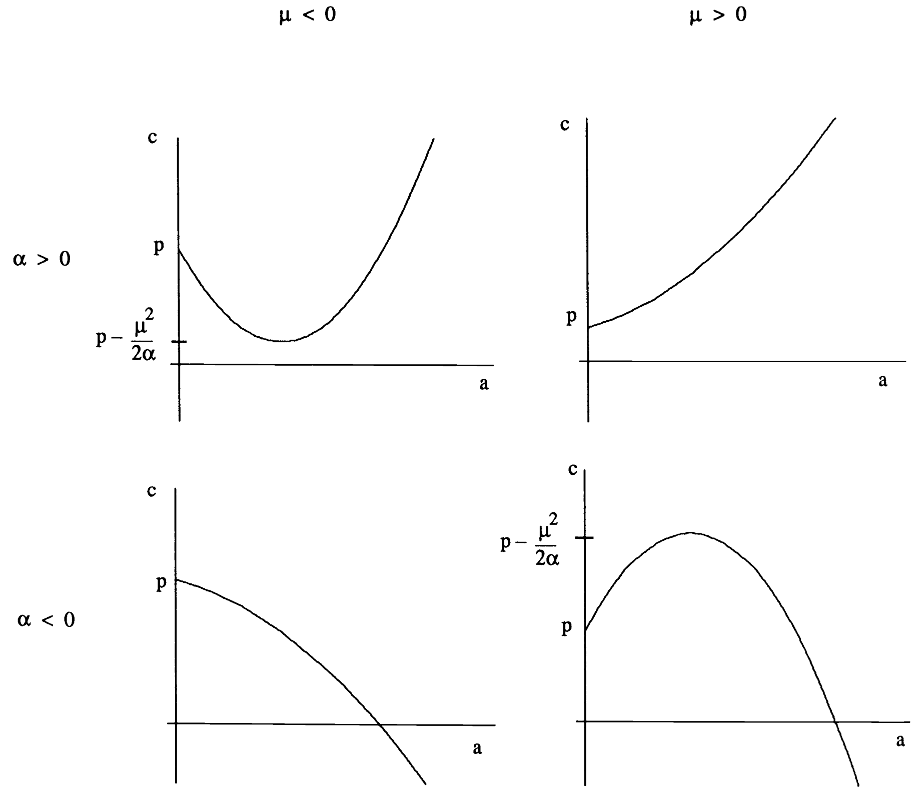

FIG. 4. *Wave speeds and amplitudes for* $q\mu > 0$.

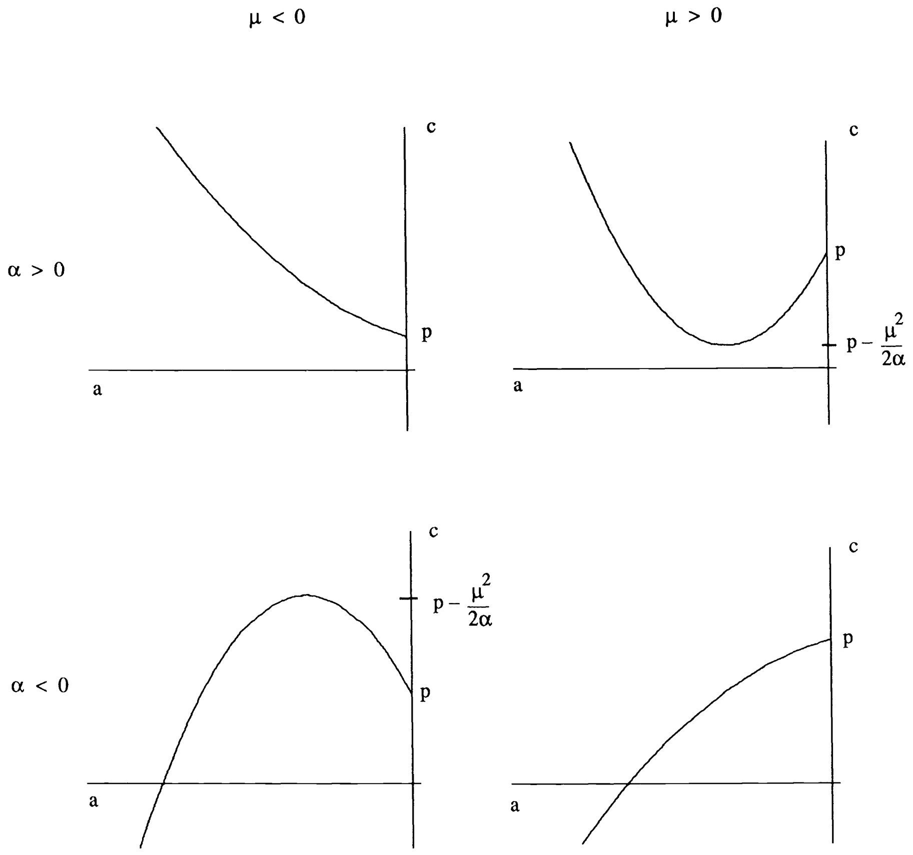

FIG. 5. *Wave speeds and amplitudes for* $q\mu < 0$.

speed. This phenomenon is reminiscent of the construction of bound states to the sine-Gordon equation, consisting of several solitons with phases having real parts with the same speed, the sine-Gordon breather being an example. However, the present property is much stronger, and its appearance for the fifth-order Korteweg-deVries equation is, we believe, a new observation. Note that similarly, we can arrange bound states for linear combinations of higher-order Korteweg-deVries equations to have any number of desired humps traveling in tandem.

Let us summarize our general results completely characterizing models admitting exact sech^2 solitary wave solutions. The different possibilities are: 0, 1, or 2 exact sech^2 solitary wave solutions, a one-parameter family of sech^2 solutions, or a one-parameter family along with a single additional exact sech^2 solution. The first three occur on relatively open subsets of parameter space, whereas the latter two occur on parts of the boundaries between these subsets.

THEOREM 4. *Consider the model evolution equation* (2.1), *assuming* $\alpha \neq 0$. *If* $P(u)$ *is not a cubic polynomial, then the model has no exact* sech^2 *solitary wave solutions. If* $P(u)$ *is given by* (2.2), *then we define*

$$\zeta = (3\beta + 2\gamma)^2 - 120\alpha r, \tag{6.10}$$

so that (6.7) *has* 0, 1, *or* 2 *real roots*

$$\sigma_1, \sigma_2 = \frac{-(3\beta + 2\gamma) \pm \sqrt{\zeta}}{30\alpha}, \tag{6.11}$$

according to whether ζ is negative, zero, or positive. If $r \neq 0$, the real roots are nonzero; if $r=0$, one root, namely $\sigma_1 = -(3\beta+2\gamma)/(15\alpha)$, is nonzero unless $\beta = -\frac{3}{2}\gamma$ also. Then the model (2.1), (2.2) *will have* 0, 1, *or* 2 *exact* sech^2 *solitary wave solutions for each nonzero real root σ_i*, which also satisfies

$$(6.12) \qquad \nu_i = 15\alpha\sigma_i + 2(\beta+\gamma) \neq 0, \qquad \rho_i = \frac{3\mu\sigma_i + 2q}{\nu_i} > 0.$$

Finally, if $(\beta+\gamma)\mu = 5q\alpha$ and $15\alpha r = \beta(\beta+\gamma)$, then the model has a one-parameter family of exact sech^2 *solitary wave solutions valid for a range of wave speeds corresponding to the first root $\sigma_1 = -2(\beta+\gamma)/(15\alpha)$. Moreover, if $\gamma \neq 0$, the second root $\sigma_2 = -\beta/(15\alpha)$ gives rise to a single additional exact* sech^2 *solitary wave solution provided ρ_2, as defined by* (6.12), *is positive.*

Example 5. The only possible water wave model which has a one-parameter family of exact sech^2 solitary wave solutions, i.e., satisfies the conditions (6.8), is the Hamiltonian model (2.10) at the particular depth (2.13). Otherwise, these models all fail to have families of sech^2 solitary wave solutions of the requisite type. However, Theorem 4 implies that many of the water wave models admit one or two anomalous sech^2 solitary wave solutions. The precise numerical values for which the different possibilities occur are rather strange; we will just summarize the results, which were deduced with the help of MATHEMATICA. First, in the case of the second-order depth model (2.9) provided $\alpha \neq 0$, i.e., except for the particular Bond number $\tau = (2\sqrt{30}-5)/15 \cong .3970$, the model admits a single exact sech^2 solitary wave solution unless $3\beta + 2\gamma = 0$, which occurs when $\tau = (73-36\theta^2)/51$. For

$$0 \leqq \tau < \frac{2\sqrt{30}-5}{15} \quad \text{or} \quad \tau > \frac{73-36\theta^2}{51}$$

the anomalous solitary wave is a wave of elevation, while for

$$\frac{2\sqrt{30}-5}{15} < \tau < \frac{73-36\theta^2}{51}$$

it is a wave of depression.

Similarly, for the second-order surface model (2.11) there are one or two exact sech^2 solitary wave solutions provided $\alpha \neq 0$, and $\zeta > 0$, which requires

$$0 \leqq \tau < \frac{4\sqrt{19866}-249}{333} \cong .9453, \qquad \tau \neq \frac{2\sqrt{30}-5}{15} \cong .3970.$$

On the range

$$\frac{\sqrt{85}+5}{30} \cong .4740 < \tau < \frac{\sqrt{23377}-91}{102} \cong .6068,$$

there are two anomalous solitary wave solutions; otherwise, there is just one. In all cases, these are waves of elevation. The Hamiltonian depth model (2.10) also admits exact solitary wave solutions for various ranges of values of the Bond number and depth, but the results are too complicated to warrant inclusion here. We are not sure of the physical significance (if any) of such exact solutions.

7. Existence of solitary wave tails. We now turn to the consideration of more general types of solitary wave solutions. We begin by proving the existence of "solitary wave tails," meaning solutions to the ordinary differential equation (4.3) for traveling waves with the correct asymptotic behavior at $+\infty$. First, let

$$Q(u)=\sum_{m=1}^{\infty} q_m u^m \tag{7.1}$$

be the power series expansion of Q at $u=0$. (Note that $Q(0)=0$ is necessary for the existence of an asymptotically decreasing solution to (4.3).) If $P(u)$ is a cubic of the form (2.2), then

$$q_1=p-c, \quad q_2=q, \quad q_3=r, \quad q_m=0, \quad m>3, \tag{7.2}$$

where c is the wave speed.

Definition 6. A *solitary wave tail* is an exponentially decreasing solution $u(\xi)$ to the equation for traveling waves with asymptotic expansion

$$u(\xi)\sim u_1\, e^{-\theta\xi}+u_2\, e^{-2\theta\xi}+u_3\, e^{-3\theta\xi}+\cdots, \tag{7.3}$$

with $\theta>0$, which converges for ξ sufficiently large.

Of course, we can also discuss solitary wave tails at $\xi=-\infty$, but these are found by using the reflectional symmetry replacing ξ by $-\xi$. We can also consider "oscillatory solitary wave tails," i.e., convergent expansions of the form (7.3) with θ complex and Re $\theta>0$. Our convergence proof will work more or less the same way in this case, but we will just concentrate on the real exponentials for simplicity.

The existence of such an expansion leads to immediate restrictions on the exponent θ and the coefficients in the model. These result from an analysis of the balance equations obtained by substituting (7.3) into (4.3), and equating terms in the various exponentials $e^{-k\theta\xi}$, $k=1,2,3,\cdots$. The first few of these are easily found.

$$e^{-\theta\xi}: \quad (\alpha\theta^4+\mu\theta^2+q_1)u_1=0, \tag{7.4}$$

$$e^{-2\theta\xi}: \quad (16\alpha\theta^4+4\mu\theta^2+q_1)u_2+[(\beta+\gamma)\theta^2+q_2]u_1^2=0, \tag{7.5}$$

$$e^{-3\theta\xi}: \quad (81\alpha\theta^4+9\mu\theta^2+q_1)u_3+[(5\beta+4\gamma)\theta^2+2q_2]u_1u_2+q_3u_1^3=0. \tag{7.6}$$

Since $u_1\neq 0$, (but is otherwise arbitrary), the first balance equation leads immediately to the *indicial equation*

$$\alpha\theta^4+\mu\theta^2+q_1=0. \tag{7.7}$$

The existence of positive real solutions θ to the indicial equation (7.7) places constraints on the coefficients α, μ, q_1 of the linearized model so that exponentially decaying solutions can exist; see Theorem 7 below. Assuming these hold, we eliminate q_1 using (7.7), and the balance equation resulting from the coefficient of $e^{-n\theta\xi}$ takes the form

$$((n^2+1)\alpha\theta^4+\mu\theta^2)u_n=\Psi_n, \tag{7.8}$$

where Ψ_n is a (complicated) polynomial involving the coefficients of the equation and the previous coefficients $u_1,\cdots,u_{n-1}$. Therefore, as long as the *nonresonance* condition

$$(n^2+1)\alpha\theta^2+\mu\neq 0, \qquad n=2,3,\cdots, \tag{7.9}$$

holds for the root θ of the indicial equation, we can solve recursively for all the coefficients u_n, $n=1,2,\cdots$, in the expansion (7.3) and thereby determine a formal solitary wave tail for the equation. Note that if α and μ have the same sign, then the nonresonance condition (7.9) automatically holds. The resonant case is quite intriguing, but we have not investigated it in any detail, and we leave it aside in what follows.

Note in particular, if $u(\xi)=a\operatorname{sech}^2\lambda\xi$, then

$$\theta=-2\lambda, \quad u_1=4a, \quad u_2=-8a, \quad u_3=12a. \tag{7.10}$$

Substituting (7.10) into the three balance equations (7.4), (7.5), (7.7), and using (7.2), (6.3), we recover our earlier three equations (6.5), (6.6), (6.7), relating the equation parameters and the solitary wave parameters a, λ. Thus, we can deduce our earlier parameter restrictions for the existence of sech^2 solitary waves by an alternative procedure based on the asymptotic expansion at ∞. However, in contrast to the earlier direct method, this does not prove that the sech^2 wave is actually a solution to (4.3), since we must also verify the higher-order balance equations. Remarkably, these are all satisfied; see § 8. This observation strongly indicates that only the first three balance equations are important for solitary waves, a fact borne out in the following section.

THEOREM 7. *Consider the model* (2.1), *and let* $Q(u)=P(u)-cu-P(0)$. *If any one of the conditions* (a) $\alpha Q'(0)<0$, (b) $\alpha\mu<0$ *and* $Q'(0)=0$, (c) $\alpha\mu<0$ *and* $4\alpha Q'(0)=\mu^2$, *or* (d) $\alpha=0$ *and* $\mu Q'(0)<0$, *then there exists a unique solitary wave tail* (7.3) *provided the nonresonance condition* (7.9) *holds. If* $0<4\alpha Q'(0)<\mu^2$ *and* $\alpha\mu<0$, *then, again provided the nonresonance condition* (7.9) *holds, there are two solitary wave tails. In all other cases there are no convergent analytic exponentially decreasing solitary wave tails.*

The conditions of Theorem 7 place restrictions on the possible wave speeds c for which there is any possibility of a solitary wave solution decaying exponentially fast to 0 at $\pm\infty$. In the case $\alpha\mu>0$, for a unique asymptotic tail, we need the usual condition that the wave speed be supercritical: $c>p=P'(0)$. (For the water wave models, this gives the standard result that the wave speed of a solitary wave (if it exists) must be larger than 1.) However, if α and μ have opposite signs, there is the possibility of *nonunique* solitary wave tails for some subcritical wave speeds $c<p$. Indeed, this corresponds precisely to what we observed in § 5 for the cases where explicit sech^2 solutions exist.

Proof of Theorem 7. Rather than work with the formal asymptotic expansion for $u(\xi)$ directly, it turns out to be simpler to employ the method introduced in § 5. We let $w(u)=u'^2$ and prove that there is a convergent power series expansion

$$w(u)=\sum_{k=2}^{\infty} w_k u^k = w_2u^2+w_3u^3+\cdots, \tag{7.11}$$

for w at $u=0$, which solves the third-order equation (5.3) with the initial conditions

$$w(0)=w'(0)=0, \qquad w''(0)=2w_2>0. \tag{7.12}$$

It is easy to express the coefficients w_k of w in terms of the coefficients u_i of u; in particular, $w_2=\theta^2$. Clearly, proving the existence of such an analytic solution w will imply that the corresponding solution $u(\xi)$ will have a convergent series expansion (7.3), which is exponentially decreasing as $\xi\to\infty$. Substituting (7.11) into (5.3), we find that the only constant term is $Q(0)$, which must necessarily vanish. The terms involving the first power of u give our by now familiar *indicial equation*

$$\alpha w_2^2+\mu w_2+q_1=0; \tag{7.13}$$

cf. (6.5), (7.7). Assuming that we have a positive solution w_2 to (7.13) (cf. the hypotheses of the theorem), we construct the corresponding power series for w recursively. The coefficient of u^m, $m\geqq 2$, in (5.3) is

$$\sum_{\substack{i+j=m+4\\ i\geqq 3, j\geqq 3}} \frac{\alpha(j-1)(j-2)}{2}[jw_{i-1}w_j+iw_iw_{j-1}]+\frac{\beta m w_m+\mu(m+1)w_{m+1}}{2}+\gamma w_m+q_m=0.$$

Extracting the terms involving w_{m+1} from the sum, we find the recurrence relation

$$w_{m+1}=-\frac{\alpha\sum_{k=3}^{m}k(k-1)(m+k-1)w_kw_{m-k+3}+2(\beta m+2\gamma)w_m+4q_m}{2(m+1)[\alpha w_2(m^2+1)+\mu]}. \tag{7.14}$$

Since $w_2=\theta^2$, the denominator does not vanish owing to the nonresonance condition (7.9), so we can continue to implement the recurrence relation (7.14), and thus construct a formal series solution to (5.3) with the prescribed initial conditions (7.12). We now need to prove convergence, which will follow from the next lemma.

LEMMA 8. *Let $w_2=\theta^2$ be a positive root to the indicial equation* (7.13). *Assume that the nonresonance condition* (7.9) *holds, and let w_m, $m\geqq 3$, satisfy the recurrence relation* (7.14). *Then there exist positive constants A and M such that*

$$|w_m|\leqq\frac{AM^{m-3}}{m^2},\qquad m\geqq 3. \tag{7.15}$$

Proof. Given the convergent power series expansion (7.1) for Q, we know that there exists a number $R>1$ such that the coefficients of the expansion satisfy the inequality

$$|q_m|\leqq R^m\quad\text{for all } m\geqq 1. \tag{7.16}$$

The nonresonance condition implies that there exists a constant $K>0$ such that the inequality

$$m^2+m\leqq 2K|\alpha w_2(m^2+1)+\mu| \tag{7.17}$$

is valid for all $m\geqq 3$. Thus, we have the following estimate on the denominator of (7.14):

$$2(m+1)|\alpha w_2(m^2+1)+\mu m|\geqq\frac{(m+1)^2m}{K}. \tag{7.18}$$

Define the following constants:

$$A=9|w_3|,\qquad M=K\max\left\{\pi^2\alpha A,\frac{2}{3}(|\beta|+|\gamma|),\frac{4R^3}{A},\frac{R}{K}\right\}. \tag{7.19}$$

A straightforward induction, starting at $m=3$, will prove the validity of (7.15). We estimate all of the terms in the numerator of (7.14) in turn. For the summation, we have

$$\begin{aligned}\sum_{k=3}^{m}k(k-1)(m+k-1)|w_k||w_{m-k+3}|&\leqq\sum_{k=3}^{m}\frac{A^2M^{m-3}k(k-1)(m+k-1)}{k^2(m-k+3)^2}\\&\leqq A^2M^{m-3}\sum_{k=3}^{m}\frac{m+k}{(m-k)^2}\\&\leqq A^2M^{m-3}\sum_{j=0}^{m-3}\frac{2m-j}{j^2}\\&\leqq\frac{\pi^2A^2mM^{m-3}}{3}\\&\leqq\frac{AmM^{m-2}}{3K\alpha}.\end{aligned}$$

For the next two terms, we find, since $m\geqq 3$,

$$\begin{aligned}2(|\beta|m+2|\gamma|)|w_m|&\leqq\frac{2A(|\beta|m+2|\gamma|)M^{m-3}}{m^2}\\&\leqq\frac{2Am(|\beta|+|\gamma|)M^{m-3}}{9}\leqq\frac{AmM^{m-2}}{3K},\end{aligned}$$

and, by (7.16),

$$4|q_m| \leqq 4R^m \leqq 4R^3 M^{m-3} \leqq \frac{AmM^{m-2}}{3K},$$

both following from the definition (7.19) of M. Substituting these three estimates and (7.18) into (7.14) easily proves the inductive step for the inequality (7.15).

8. Nonexistence of solitary waves. Having dealt with existence of explicit solitary wave solutions to particular types of the general model (2.1), we now turn our attention to a nonexistence result. We begin by explicitly introducing the small parameter ε into our model, and restrict our attention from the beginning to models in which $P(u)$ is a cubic polynomial. However, this restriction is inessential, and, coupled with the results from Theorem 4, we can deduce that only in this case is there any possibility of suitable solitary wave solutions existing. In the physical models of the form (2.1), (2.2), there is a small parameter ε, relative to which the translation coefficient p has order 1, the Korteweg-deVries terms have coefficients μ, q of order ε, and the fifth-order terms have coefficients α, β, γ (or δ), and r of order ε^2. We also assume that μ, q, and α are all nonzero, so that the model is truly fifth-order, and, moreover, reduces to a Korteweg-deVries equation when the $O(\varepsilon^2)$ terms are neglected. We are interested in the behavior of solutions in the limit $\varepsilon \to 0$, but this is rather trivial without further rescaling since all the terms except the translation will scale out, and everything will reduce to zero. Rather than this, we need to introduce a rescaling of the equation in which the fifth-order terms still have order ε^2, but the translation and Korteweg-deVries terms are of order 1, and compare these solutions in the $\varepsilon \to 0$ limit. In terms of the physical limit, then, we expect the solutions to be order ε^2 perturbations of the corresponding Korteweg-deVries solutions, which are themselves of order ε. Note that, in this limit, the velocity of a Korteweg-deVries soliton has order $c = p + O(\varepsilon^2)$.

We begin with the once-integrated equation for traveling waves (4.3), which, using (2.2), we write in the form

$$(p-c)u + \mu u'' + qu^2 + \alpha u'''' + \beta uu'' + \gamma u'^2 + ru^3 = 0. \tag{8.1}$$

Introduce the scaling

$$\xi = \varepsilon\eta, \quad u = \kappa^2 v, \quad c - p = \kappa^2 s, \tag{8.2}$$

where ε, κ are small parameters, and $s \neq 0$. Rewriting (8.1) for $v = v(\eta)$, we have

$$\varepsilon^2 \mu v'' + \kappa^2(qv^2 - sv) + \varepsilon^4 \alpha v'''' + \kappa^2\varepsilon^2(\beta vv'' + \gamma v'^2) + \kappa^4 rv^3 = 0. \tag{8.3}$$

The condition that the rescaled equation (8.3) possess solutions having the proper expansions in powers of $e^{-\eta}$ at $\eta = +\infty$ is that the rescaled indicial equation

$$s\kappa^2 = \varepsilon^2(\mu + \alpha\varepsilon^2), \tag{8.4}$$

relating the two scaling parameters, hold. This allows us to eliminate κ and rewrite the traveling wave equation in terms of the single small parameter ε:

$$\begin{aligned} &v'' - v + \frac{q}{s}v^2 + \varepsilon^2\left[\frac{\alpha}{\mu}(v'''' - v) + \frac{\alpha q}{s\mu}v^2 + \frac{1}{s}(\beta vv'' + \gamma v'^2) + \frac{\mu r}{s^2}v^3\right] \\ &\quad + \varepsilon^4\left[\frac{\alpha}{s\mu}(\beta vv'' + \gamma v'^2) + 2\frac{r\alpha}{s^2\mu}v^3\right] + \varepsilon^6\frac{\alpha^2 r}{s^2\mu^2}v^3 = 0. \end{aligned} \tag{8.5}$$

PROPOSITION 9. *There exists a formal asymptotic solution to* (8.5) *of the form*

$$v(\varepsilon, \eta) \sim v_0(\eta) + \varepsilon^2 v_1(\eta) + \varepsilon^4 v_2(\eta) + \cdots, \tag{8.6}$$

in which

$$v_0(\eta)=\frac{3s}{2q}\operatorname{sech}^2\frac{\eta}{2}, \tag{8.7}$$

and each $v_j=P_j(v_0)$ *is a polynomial in* $\operatorname{sech}^2(\eta/2)$, *with* $P_j(0)=0$.

Remark. The expansion (8.6) will formally represent the proposed solitary wave solution to the original model reducing to the Korteweg-deVries soliton, (8.7), in the limit $\varepsilon\to 0$. Thus each $v_j(\eta)$ satisfies the condition that it describe a solitary wave; in particular, it is an exponentially decreasing function of $\eta\in\mathbb{R}$. The numerically observed solitary wave solutions [22], [31], [50] can, we believe, be explained by the existence of this nonconvergent formal series. Indeed, a numerical code would be an approximation to a finite truncation of the series (8.6), which would appear to be a numerical approximation to a genuine solitary wave. But owing to the ultimate nonconvergence of the series, the numerically observed solitary wave solution cannot, in fact, be considered to approximate any actual solution to the ordinary differential equation (8.5).

Proof. Note first that (8.7) is the unique even, decaying solution to the zeroth-order equation

$$v_0''-v_0+\frac{q}{s}v_0^2=0. \tag{8.8}$$

To avoid complications in the subsequent formulae, it helps to introduce a further rescaling

$$\zeta=\frac{\eta}{2},\qquad V(\zeta)=\frac{2q}{3s}v(2\zeta), \tag{8.9}$$

in terms of which (8.5) takes the form

$$\begin{aligned}&\tfrac{1}{4}V''-V+\tfrac{3}{2}V^2+\varepsilon^2[\hat{\alpha}\{\tfrac{1}{16}V''''-V+\tfrac{3}{2}V^2\}+\hat{\beta}VV''+\hat{\gamma}V'^2+\hat{r}V^3]\\&\quad+\varepsilon^4\hat{\alpha}[\hat{\beta}VV''+\hat{\gamma}V'^2+2\hat{r}V^3]+\varepsilon^6\hat{\alpha}^2\hat{r}V^3=0,\end{aligned} \tag{8.10}$$

where

$$\hat{\alpha}=\frac{\alpha}{\mu},\quad \hat{\beta}=\frac{3\beta}{8\mu},\quad \hat{\gamma}=\frac{3\gamma}{8\mu},\quad \hat{r}=\frac{9\mu r}{4q^2}. \tag{8.11}$$

The solution $V(\xi)$ will have a formal asymptotic expansion

$$V(\zeta)\sim V_0(\zeta)+\varepsilon^2V_1(\zeta)+\varepsilon^4V_2(\zeta)+\cdots, \tag{8.12}$$

with leading term $V_0(\zeta)=\operatorname{sech}^2\zeta$.

Using the abbreviation $S(\zeta)$ for $\operatorname{sech}^2\zeta$, we group here a few formulae that are elementary, but which will be required in the sequel:

$$S'^2=4S^2(1-S),\qquad S''=4S-6S^2, \tag{8.13}$$

$$\frac{d^2}{d\zeta^2}S^m=mS^m[4m-(4m+2)S]. \tag{8.14}$$

Iterating (8.14) yields

$$\begin{aligned}\frac{d^4}{d\zeta^4}S^m&=16m^4S^m-16m(2m+1)(2m^2+2m+1)S^{m+1}\\&\quad+4m(m+1)(2m+1)(2m+3)S^{m+2}.\end{aligned} \tag{8.15}$$

Consider the particular Schrödinger operator

$$L \equiv -\frac{d^2}{d\zeta^2}+4-12S(\zeta). \tag{8.16}$$

We note that $-12S(\zeta)$ is a three-soliton potential (cf. [33]), so that the spectrum of (8.16) consists of the eigenvalues $\{-5, 0, 3\}$ and a continuous spectrum $\{\lambda \geqq 4\}$; moreover, zero is a simple eigenvalue, with eigenfunction $S'(\zeta)$, which is odd. Thus, L is invertible on even functions in L^2. Also, (8.14) implies

$$L(S^m) = mS^m[4(1-m^2)+(4m^2+2m-12)S]. \tag{8.17}$$

Together, these facts imply the following.

LEMMA 10. *The differential equation*

$$Lf = S^2P(S), \qquad P \text{ a polynomial} \tag{8.18}$$

has a unique even solution which has the form $f = SQ(S)$, where Q is a polynomial.

Now, inserting the expansion (8.12) in (8.10), each coefficient of ε^{2k} results in an equation of the form

$$\tfrac{1}{4}V_k'' - V_k + 3SV_k = F_k(\zeta),$$

or, in view of (8.16)

$$L(V_k) = -4F_k(\zeta). \tag{8.19}$$

One can see by induction that V_k must have the form $SP_k(S)$, where P_k is a polynomial. Indeed, according to Lemma 10, we need only prove that $F_k(\zeta)$ has the form $S^2R_k(S)$, where R_k is a polynomial in S. This results from the following:

(i) The remaining terms in V^2 have the form V_iV_{k-i}, $1 \leqq i \leqq k-1$, and, by the induction hypothesis, each V_i has the form $SP_i(S)$;

(ii) The coefficient of ε^{2k} in the terms ε^2V^2, ε^2V^3, ε^4V^3, and ε^6V^3 is similarly determined from $V_0, \cdots, V_{k-1}$;

(iii) V'^2 is a sum of terms of the form $P(S)'Q(S)'$, and S'^2 has S^2 as a factor by (8.13);

(iv) VV'' has S^2 as a factor by (8.13) again;

(v) (8.15) shows that $\frac{1}{16}V_{\zeta\zeta\zeta\zeta} - V$ also has the form $S^2R(S)$ if $V = SP(S)$.

Therefore, we have proved that there exists a formal series solution to (8.10) of the form

$$V(\zeta) \sim \operatorname{sech}^2 \zeta + \sum_{k=1}^{\infty} \varepsilon^k P_k(\operatorname{sech}^2 \zeta), \tag{8.20}$$

where the P_k are polynomials, $P_k(0) = 0$. This completes the proof of Proposition 9.

PROPOSITION 11. *If the expansion* (8.6) *converges to a holomorphic function in ε and* $\operatorname{sech}^2 \eta/2$ *for $\eta \to \infty$, and ε near zero, then its associated solitary wave tail is a translate of the exponentially decaying tail previously constructed in Lemma* 7.

Proof. By hypothesis, we have a convergent expansion for the tail of the form

$$v(\varepsilon, \eta) = a_1(\varepsilon)\, e^{-\eta} + a_2(\varepsilon)\, e^{-2\eta} + \cdots. \tag{8.21}$$

We must show that $a(\varepsilon) = a_1(\varepsilon)$ never vanishes so that we may replace η by $\eta + \log a(\varepsilon)$ to obtain the series

$$\tilde{v}(\varepsilon, \eta) = e^{-\eta} + b_2(\varepsilon)\, e^{-2\eta} + \cdots, \tag{8.22}$$

which can be compared to the previous form of the tail. To achieve this, we assume $a(\varepsilon_0)=0$ for some ε_0 (possibly complex). Since (8.21) must solve (8.5), the series argument from § 7 immediately shows that in this case, all the coefficients vanish at the point ε_0, $a_k(\varepsilon_0)=0$, and hence $v(\varepsilon_0, \eta)=0$ vanishes for all η. We show that this implies that every ε derivative $(\partial^n v/\partial\varepsilon^n)(\varepsilon_0, \eta)=0$ of v also vanishes at the point ε_0, for all η which, by the holomorphy assumption, ensures $v(\varepsilon, \eta)\equiv 0$, which is impossible since $v_0(\eta)\not\equiv 0$.

Note first that if $v(\varepsilon_0, \eta)$ vanishes for all η, so do all its η-derivatives; therefore, the first ε-derivative $z(\eta)=v_\varepsilon(\varepsilon_0, \eta)$ solves the linear ordinary differential equation

$$z''-z+\varepsilon_0^2\frac{\alpha}{\mu}\{z''''-z\}=0, \tag{8.23}$$

since all the nonlinear terms vanish at ε_0. Moreover, since $v(\varepsilon, \eta)$ is holomorphic, we also have that $z\to 0$ exponentially fast at infinity. But it is easy to see (e.g., by using the Fourier transform) that (8.23) has no nonzero L^2 solutions. Similarly, an easy induction proves that each derivative $z=(\partial^n v/\partial\varepsilon^n)(\varepsilon_0, \eta)$ also solves (8.23), and must, therefore, also be identically zero. This completes the proof and demonstrates the connection between our two series solutions.

Now, by analysis of the analyticity properties of the solutions to our earlier balance equations for the coefficients in the expansion (8.6) we deduce our final nonexistence result.

THEOREM 12. *Suppose* (8.5) *possesses a series solution* (8.6), *which is holomorphic, convergent on a region of the form*

$$|\varepsilon|^2<\left|\frac{\mu}{5\alpha}\right|+\kappa_0, \qquad |e^{-\eta}|<\kappa_1, \tag{8.24}$$

for $\kappa_0, \kappa_1>0$. *Then the equation necessarily satisfies the constraints* (6.8) *and thus has a one-parameter family of exact* sech^2 *solutions.*

Remark. The exact sech^2 solutions are clearly holomorphic in a region of the indicated form (8.24) provided κ_1 is chosen sufficiently small.

Proof. We begin by writing (8.5) in the more convenient form

$$\begin{aligned} &v''+\varepsilon^2\tilde{\alpha}v''''-(1+\varepsilon^2\tilde{\alpha})v \\ &\quad=-\tilde{q}(1+\varepsilon^2\tilde{\alpha})\{v^2+\varepsilon^2[\tilde{\beta}vv''+\tilde{\gamma}v'^2+(1+\varepsilon^2\tilde{\alpha})\tilde{q}\tilde{r}v^3]\}, \end{aligned} \tag{8.24$'$}$$

where

$$\tilde{\alpha}=\frac{\alpha}{\mu}, \quad \tilde{q}=\frac{q}{s}, \quad \tilde{\beta}=\frac{\beta}{q}, \quad \tilde{\gamma}=\frac{\gamma}{q}, \quad \tilde{r}=\frac{\mu r}{q^2}. \tag{8.25}$$

We substitute the expansion (8.21) into (8.24′) to compute the balance equations; cf. (7.4), (7.5), (7.6), for the coefficients a_i. The indicial equation, i.e., the terms in $e^{-\eta}$, are already balanced by design. The terms in $e^{-2\eta}$ lead to the equation

$$3(1+5\varepsilon^2\tilde{\alpha})a_2=-\tilde{q}(1+\varepsilon^2\tilde{\alpha})\{(1+5\varepsilon^2\tilde{\alpha})+\varepsilon^2(\tilde{\beta}+\tilde{\gamma}-5\tilde{\alpha})\}a_1^2. \tag{8.26}$$

Thus, a_2 will have poles at $\varepsilon^2=1/(5\tilde{\alpha})$, contradicting the hypothesis of the theorem, unless $\tilde{\beta}+\tilde{\gamma}=5\tilde{\alpha}$, which, in view of (8.25), is the same as the first condition in (6.8). Assuming this holds, and using (8.26) to solve for a_2, the remaining terms in $e^{-3\eta}$ lead to the further balance equation

$$\begin{aligned} &8(1+10\varepsilon^2\tilde{\alpha})a_3 \\ &\quad=\tfrac{2}{3}\tilde{q}^2(1+\varepsilon^2\tilde{\alpha})^2\{(1+10\varepsilon^2\tilde{\alpha})+\tfrac{1}{2}\varepsilon^2(5\tilde{\beta}+4\tilde{\gamma}-3\tilde{r}-20\tilde{\alpha})\}a_1^3. \end{aligned} \tag{8.27}$$

Thus, a_3 will have poles at $\varepsilon^2 = 1/(10\tilde{\alpha})$, unless $5\tilde{\beta}+4\tilde{\gamma}=3\tilde{r}+20\tilde{\alpha}$, which, in view of the previous condition reduces to $\tilde{\beta}=3\tilde{r}$, and, by (8.25) is the same as the second condition in (6.8); therefore, the expansion will be holomorphic in the indicated domain if and only if the conditions (6.8) hold and the equation admits exact sech^2 solutions. This completes the proof of Theorem 12.

The assumption of analyticity in Theorem 12 parallels that of [24]. It is likely that the constant $\mu/(5\alpha)$ in the domain (8.24) can be replaced by any positive constant $\varepsilon_0 > 0$, as the following argument plausibly indicates. Set, for simplicity,

$$a_1 = \frac{-6}{\tilde{q}(1+\varepsilon^2\tilde{\alpha})}.$$

Then the nth balance equation can, by a simple induction, be shown to take the form

$$(n^2-1)(1+(n^2+1)\varepsilon^2\tilde{\alpha})a_n = \frac{6n+\Phi_n}{\tilde{q}(1+\varepsilon^2\tilde{\alpha})}, \tag{8.28}$$

where each Φ_n is a rational function in ε, with poles at $\varepsilon^2 = -1/((k^2+1)\tilde{\alpha})$, for $k=2,3,\cdots,n-1$, and which vanishes identically if the sech^2 conditions (6.8) hold. In order that the expansion (8.6), and hence the a_i depend analytically on ε in some neighborhood of $\varepsilon=0$, these coefficients cannot have complex poles accumulating at $\varepsilon=0$. Thus, for n sufficiently large, each Φ_n+6n must vanish at $\varepsilon^2=-1/((n^2+1)\tilde{\alpha})$. This infinite collection of polynomial conditions seems highly unlikely in the absence of (6.8). Indeed, we can straightforwardly reduce the size of the domain (8.24) by an involved analysis of the first few of the rational functions Φ_n for n small, perhaps using MATHEMATICA, but we have not tried to implement this.

Note finally that the proof of Theorem 12 can be readily extended to include the case when $P(u)$ is an analytic function, in which case the hypotheses imply that $P(u)$ must be a cubic polynomial also. Indeed, by the above arguments, analyticity of (8.6) in a region (8.24) implies that not only the first three coefficients $p=p_1$, $q=p_2$, $r=p_3$, in the Taylor expansion of $P(u)=\sum p_n u^n$ satisfy (8.6), but, moreover, a simple induction will then show that all remaining coefficients must vanish if the poles in the general recursion relation (8.28) are to cancel, so that $p_n=0$ for $n \geqq 4$. We leave the remaining details to the reader, and conclude this section by summarizing our basic nonexistence result in a convenient unscaled form.

THEOREM 13. *Consider an evolution equation of the form*

$$u_t + [\varepsilon\mu u_{xx} + \varepsilon^2(\alpha u_{xxxx} + \beta u u_{xx} + \gamma u_x^2) + P(u,\varepsilon)]_x = 0, \tag{8.29}$$

where ε is a small parameter, α, β, γ, μ are constants, and P is an analytic function of the form

$$P(u,\varepsilon) = pu + \varepsilon q u^2 + \varepsilon^2 r u^3 + \varepsilon^2 u^4 R(u,\varepsilon), \tag{8.30}$$

where p, q, r are constants, and R is analytic. Assume $q\mu \neq 0$, so that the $O(\varepsilon)$ terms are of Korteweg-deVries type. Then the model has a solitary wave solution of the form $u=u(x-ct,\varepsilon)$ with speed $c=p+\varepsilon^2 s+\cdots$, which has a formal expansion of the form

$$u = \varepsilon\varphi_0[\sqrt{\varepsilon}(x-ct)] + \varepsilon^3\varphi_1[\sqrt{\varepsilon}(x-ct)] + \varepsilon^5\varphi_2[\sqrt{\varepsilon}(x-ct)] + \cdots, \tag{8.31}$$

which reduces to the Korteweg-deVries soliton $\varphi_0(\eta) = \{(3s)/(2q)\}\operatorname{sech}^2 \eta/2$ in the limit. Assume that the expansion (8.31) *converges to an analytic function in a complex domain of the form $|\varepsilon|^2 < |\mu/(5\alpha)| + \kappa$, $\kappa > 0$, $x-ct \gg 0$. Then, necessarily, $R=0$; so $P(u,\varepsilon)$ is a cubic polynomial in u, and the coefficients of* (8.29), (8.30) *are related by the conditions*

$$(\beta+\gamma)\mu = 5q\alpha \quad \textit{and} \quad 15\alpha r = \beta(\beta+\gamma), \tag{8.32}$$

which guarantee the existence of a one-parameter family of exact sech^2 *solitary wave solutions to the model.*

In summary, then, the models (2.1) which admit a one-parameter family of exact sech^2 solitary wave solutions are distinguished by the analyticity properties of their solutions. This result is in direct analogy with those of [24], in which the linear, sine-, and sinh-Gordon equations were distinguished among all one-dimensional Klein-Gordon equations by similar types of analyticity properties. However, our result is more revealing of the general method in that we no longer distinguish, by the smoothness properties of their solutions, just integrable equations, but rather those having particular explicit solutions. The method used here and in [24] is rather general, and is applicable to a wide variety of similar problems.

9. Conclusions and further work. We have been able to prove, under certain reasonable hypotheses, the nonexistence of solitary wave solutions to most fifth-order evolution equations that arise as models for nonlinear water waves. This is very strange, since most of the water wave models, except for the model (2.10) at the particular depth (2.13), where the Hamiltonian model is a fifth-order Korteweg-deVries equation, do not satisfy the requisite conditions (6.8) on the coefficients in the equation. Thus, by trying to do better in modeling real solitary water waves, which are known to exist [4], we, in a sense, do worse. The Korteweg-deVries model does have solitary wave (soliton) solutions that do a reasonably good job approximating solitary water waves [7], [8], [13]. But trying to get a more accurate model by retaining terms in ε^2 leaves us with *no* solitary wave solutions at all! Of course, this is not really an unequivocal problem since presumably the model does do a reasonable job approximating the solitary water waves for times on the order of $1/\varepsilon^2$ (the Kortweg-deVries model being accurate for times on the order of $1/\varepsilon$). Nevertheless, the results of this paper should give one pause in the noncritical application of naïve perturbation expansions as a means for deriving model equations.

This leads us to wonder about the following questions: what happens to initial conditions corresponding to solitary water waves as the time $t \to +\infty$? We expect that small amplitude waves decay by dispersion or radiation, whereas it is plausible that larger waves may even break. Is there a wave of maximal height? How do they behave under collision—specifically do they emerge unscathed as true solitons [33], or is there a small, but nonzero nonelastic effect, as in the BBM equation, [9]? It appears that there is a need for good numerical integration procedures to study these models in more detail. However, these must be long time accurate, and take into account exponentially small effects. For Hamiltonian models, some form of symplectic integrator [10] might be a good bet for investigating these questions. There is a lot of work remaining to be done in this direction.

Acknowledgments. It is a great pleasure to thank Jerry Bona, Stuart Hastings, Bryce McLeod, John Toland, and Bill Troy, all of whom made valuable comments on earlier attempts on this problem.

SOBOLEV SPACE METHODS FOR DUAL INTEGRAL EQUATIONS IN AXIALSYMMETRIC SCREEN PROBLEMS*

F. PENZEL[†]

Abstract. The explicit solution of some axialsymmetric scalar screen problems in Sobolev spaces is presented. The well-posedness of the boundary integral equations, which are formulated as dual integral equations, is proved. A reduction for the mixed boundary value problem to a system of singular integral equations with a symbol from the Wiener-algebra is given.

The approach of dual integral equations has a long history [*Mixed Boundary Value Problems in Potential Theory*, North-Holland, Amsterdam, 1966] whereas the new developments reviewed in [E. Meister and F. O. Speck, *Modern Wiener-Hopf methods in diffraction theory*, Proc. Conf. Dundee, 1988, in Ordinary and Partial Differential Equations, B. Sleeman and R. Jarvis, eds., 1989, pp. 130–171] make it possible to handle these equations in Sobolev spaces.

Key words. fractional integrals, potential theory, Laplace equation, Wiener–Hopf equations, dual integral equations

AMS(MOS) subject classifications. 26A33, 31B20, 35J05, 45E10, 45F10

1. Introduction.

In this paper we present the solution of certain dual integral equations by the Wiener–Hopf method. We prove the validity of the method in certain Sobolev spaces. A lot of attempts to solve dual integral equations in distributional spaces has been done before; cf. [11], [26], [28]. Some results about Fredholm properties of certain dual integral equations in L^p spaces are contained in [17]. Nevertheless, the equations considered here do not fall into this class.

During recent years the screen problems considered in [3], [24] were reformulated in Sobolev spaces of locally finite energy $H^1_{\text{loc}}(I\!R^3\backslash\Omega)$ and numerical procedures were given in [6], [7]. This enables us to understand the explicit solution formulas for the Dirichlet and Neumann problem for the Laplacian in the axialsymmetric case in a well-posed operator theoretic setting in Sobolev spaces. For this we have to define some Sobolev spaces of axialsymmetric functions and to characterize their norms by fractional integral operators (see Lemmas 2.1, 2.5, and 2.6).

These results are of independent interest. For example, Lemma 2.1 proves the strong ellipticity of the weakly singular integral operator, which is the boundary integral operator for the Dirichlet problem. This operator was extensively discussed in [27], [6], [7], [16], [29]. The hypersingular integral operator, coming up from the Neumann problem will be handled in Theorem 3.2. Discussions of this integral operator are in [27], [22].

2. Definition of function spaces and operators.

Here we use the following definition of the Fourier transform of a function f:

$$\hat{f}(x) := \int_{I\!R^n} e^{i\xi x} f(\xi) d\xi. \tag{2.1}$$

We start by defining some norms:

$$||f||_{H^s(I\!R^n)} := \left(\int_{I\!R^n} |\hat{f}(x)|^2 (1+|x|)^{2s} dx \right)^{\frac{1}{2}}. \tag{2.2}$$

* Received by the editors July 26, 1989; accepted for publication (in revised form) January 9, 1992.

[†] Fachbereich Mathematik, Technische Hochschule Darmstadt, D-6100 Darmstadt, Germany.

We recall the definition of the following Sobolev spaces that appeared in the solution of boundary value problems from [4]. $\tilde{H}^s(\Omega)$ is the closure of the set of C^∞-functions having compact support in a bounded domain Ω in the norm $||.||_{H^s(I\!R^n)}$. By $H^s(\Omega)$ we denote the closure of the set of functions that are infinitely often differentiable in $I\!R^n$, restricted to Ω in the norm

$$(2.3) \qquad ||f||_{H^s(\Omega)} := \inf_{lf} ||lf||_{H^s(I\!R^n)}.$$

$lf \in H^s(I\!R^n)$ denotes any continuation of f to $I\!R^n$. A lot of methods are available for norms and operators that are homogeneous; therefore, we introduce the following norms in $S'(I\!R^n)$:

$$(2.4) \qquad ||f||_{R^s(I\!R^n)} := \left(\int_{I\!R^n} |\hat{f}(x)|^2 |x|^{2s} dx \right)^{\frac{1}{2}}.$$

Let us define the spaces $R^s(\Omega)$ and $\tilde{R}^s(\Omega)$ analogously to the spaces $H^s(\Omega)$ and $\tilde{H}^s(\Omega)$ by using $||f||_{R^s(I\!R^n)}$ instead of $||f||_{H^s(I\!R^n)}$. Then we can prove our first result.

LEMMA 2.1. *The spaces $\tilde{R}^s(\Omega)$ and $\tilde{H}^s(\Omega)$ are the same set of $S'(I\!R^2)$-distributions for $|s| < 1$. The two norms in these spaces are equivalent. The same assertion holds for the spaces $R^s(\Omega)$ and $H^s(\Omega)$.*

Proof. First we cite from [8] that $\tilde{H}^s(\Omega)$ is a space of S'-distributions having support in Ω. It is known from the book of Gelfand and Shilov [9] that such distributions are derivatives of continuous functions. Therefore, the Fourier transform of these distributions are in C^∞ and the distributions themselves have finite $\tilde{R}^s(\Omega)$-norm for $s > -1$. $\tilde{R}^s(\Omega)$ is a closed subspace of $\tilde{H}^s(\Omega)$; therefore, we can identify the spaces as sets. Because the identity is a continuous and one-to-one mapping from $\tilde{R}^s(\Omega)$ onto $\tilde{H}^s(\Omega)$, we can conclude the stated equivalence of norms. The same holds for the spaces $R^s(\Omega)$ and $H^s(\Omega)$ because it is well known that $H^s(\Omega)$ and $\tilde{H}^{-s}(\Omega)$ are dual spaces with respect to L^2 norm. □

We introduce some Sobolev spaces of axialsymmetric distributions. We restrict ourselves to Sobolev spaces of index s satisfying $|s| < 1$. In this case Lemma 2.1 guarantees the imbedding of our spaces into the usual Sobolev spaces. Here we assume Ω to be the unit disk in $I\!R^2$. For the definition we use functions in $S((0, \infty))$ and have to recognize that they are restrictions of axialsymmetric functions from $S(I\!R^2)$, the space of rapidly decreasing functions from $C^\infty(I\!R^2)$. Here S_0 denotes the Hankel transformation of order zero:

$$(2.5) \qquad S_0 f(x) := \int_0^\infty \xi J_0(\xi x) f(\xi) d\xi.$$

By J_ν we denote the Bessel-function of order ν. If $f \in S(I\!R^2)$ is an axialsymmetric function, then it is well known [12] that the Fourier transform of f is also axialsymmetric and given by the Hankel transform of f of order zero. From now on we identify axialsymmetric functions with their restrictions to $[0, \infty)$ and vice versa. For $|s| < 1$, $\tilde{H}^s_A(\Omega)$ is the closure of the set

$$(2.6) \qquad \{f | f \in C_0^\infty([0, 1)), f^{(2k-1)}(0) = 0 \text{ for k} \in \text{N}\}$$

in the norm $||f||_{\tilde{H}^s_A(\Omega)} := (\int_0^\infty |S_0 l_0 f(x)|^2 x^{2s+1} dx)^{\frac{1}{2}}$, where $l_0 f$ is defined as the extension of f by zero to $[0, \infty)$. The functions from $C_0^\infty([0, 1))$ have to vanish in a neighbourhood of $x = 1$, but they must not vanish at $x = 0$. For $|s| < 1$ $H_A^s(\Omega)$ is defined as the closure of the set

$$\{f|f \in C^\infty([0,1]), f^{(2k-1)}(0) = 0 \text{ for k} \in \mathbb{N}\} \tag{2.7}$$

with respect to the norm $||f||_{\tilde{H}_A^s(\Omega)} := \inf_{lf}(\int_0^\infty |S_0 lf(x)|^2 x^{2s+1}dx)^{\frac{1}{2}}$, where the infimum is taken over all extensions of f on $[0,\infty)$ such that $lf \in S(\mathbb{R}^2)$. For further purposes we need the fractional integral operators defined in [24]:

$$I_{\eta,\alpha}f(x) := \frac{2x^{-2\alpha-2\eta}}{\Gamma(\alpha)}\int_0^x (x^2-u^2)^{\alpha-1}u^{2\eta+1}f(u)du, \tag{2.8}$$

$$K_{\eta,\alpha}f(x) := \frac{2x^{2\eta}}{\Gamma(\alpha)}\int_x^\infty (u^2-x^2)^{\alpha-1}u^{-2\alpha-2\eta+1}f(u)du. \tag{2.9}$$

Γ denotes Euler's Γ-function.

We give two distinct definitions of Mellin transformations:

$$Mf(s) := \int_0^\infty x^{s-1}f(x)dx \tag{2.10}$$

for a complex variable s and

$$M_{\mu,2}f(t) := Mf\left(\frac{\mu}{2}+it\right) \tag{2.11}$$

for a real parameter μ and a real variable t. We introduce weighted Hilbert-spaces:

$$L_\mu{}^2((0,\infty)) := \left\{f|\int_0^\infty |f(x)|^2x^{\mu-1}dx < \infty\right\}. \tag{2.12}$$

Remark 2.1. The space $L_2^2((0,\infty))$ can be identified with the axialsymmetric $L^2(\mathbb{R}^2)$ functions restricted to the half-axis.

We cite from [18].

LEMMA 2.2. *The Mellin transformation $M_{\mu,2}$ is an isomorphism from $L_\mu{}^2((0,\infty))$ onto $L^2(\mathbb{R})$ for all $\mu \in \mathbb{R}$.*

In the next lemma we shall describe equivalent norms in the Sobolev spaces $\tilde{H}_A^s([0,1])$ and $H_A^s([0,1])$ for $|s| < \frac{1}{2}$ by using the Mellin transformation or fractional integral operators. To abbreviate equivalence of norms, we shall use the symbol $\approx$.

LEMMA 2.3. *The following pairs of norms are equivalent in $\tilde{H}_A^s(\Omega)$, respectively, in $H_A^s(\Omega)$ for $|s| = \frac{1}{2}$:*

$$||f||_{H_A^{-\frac{1}{2}}(\Omega)} \approx \inf_{lf}\left(\int_{\mathbb{R}} \frac{|M_{3,2}(lf)(t)|^2}{(1+|t|)}dt\right)^{\frac{1}{2}}, \tag{2.13}$$

$$||f||_{H_A^{\frac{1}{2}}(\Omega)} \approx \inf_{lf}\left(\int_{\mathbb{R}} |M_{1,2}(lf)(t)|^2(1+|t|)dt\right)^{\frac{1}{2}}, \tag{2.14}$$

$$||f||_{\tilde{H}_A^{\frac{1}{2}}(\Omega)} \approx \left(\int_{\mathbb{R}} |M_{1,2}(l_0f)(t)|^2(1+|t|)dt\right)^{\frac{1}{2}}, \tag{2.15}$$

$$||f||_{\tilde{H}_A^{-\frac{1}{2}}(\Omega)} \approx \left(\int_{I\!R} \frac{|M_{3,2}(l_0 f)(t)|^2}{(1+|t|)} dt\right)^{\frac{1}{2}}. \tag{2.16}$$

Proof. Let $f \in C^\infty([0,1]), f^{(2k-1)}(0) = 0$ for $k \in I\!N$, and let $lf \in S(I\!R^2)$ be an extension of f on $(0,\infty)$. The Mellin transformations $M_{3,2}$ and $M_{1,2}$ map this type of functions on functions from $S(I\!R)$,

$$(M_{1,2}(lf))(t) = \int_0^\infty x^{-\frac{1}{2}+it}(lf)(x)dx = \int_{I\!R} e^{i\rho t}e^{\frac{1}{2}\rho}(lf)(e^\rho)d\rho. \tag{2.17}$$

The function $e^{\frac{1}{2}\rho}(lf)(e^\rho)$ is in $S(I\!R)$ because lf and all its derivatives decay exponentially at infinity:

$$e^{\frac{1}{2}\rho}(lf)(e^\rho) \leq \frac{C_k}{1+e^{k\rho}}e^{\frac{\rho}{2}} \quad \text{for } \rho \to \infty \text{ and k} \in \mathbf{N}, \tag{2.18}$$

$$e^{\frac{1}{2}\rho}(lf)(e^\rho) = (lf)(0)O(e^{\frac{\rho}{2}}) \quad \text{for } \rho \to -\infty. \tag{2.19}$$

The proof for $M_{3,2}$ is analogous.

$$\begin{aligned} {||f||^2}_{H_A^{-\frac{1}{2}}(\Omega)} &= \inf_{lf} \int_0^\infty |S_0 lf(x)|^2 dx \\ &= \inf_{lf} \int_{I\!R} \left|(MS_0 lf)\left(\frac{1}{2}+it\right)\right|^2 dt \\ &= \inf_{lf} \int_{I\!R} \left|(MJ_0)\left(\frac{1}{2}+it\right)(Mlf)\left(\frac{3}{2}-it\right)\right|^2 dt \\ &= \inf_{lf} \int_{I\!R} \left|2^{-1/2-it}\Gamma\left(\frac{1}{4}+\frac{it}{2}\right)\Gamma^{-1}\left(\frac{3}{4}-\frac{it}{2}\right)(Mlf)\left(\frac{3}{2}+it\right)\right|^2 dt. \end{aligned} \tag{2.20}$$

The third and the fourth equality can be proved with the aid of formulas from [5].

The asymptotic formula

$$\Gamma(x+iy) \sim |y|^{x-1}, \tag{2.21}$$

which holds for fixed real x and for $y \to \pm\infty$, proves the first equivalence of norms if we take the infimum over all extensions of f to $L_2^2((0,\infty))$.

To prepare the proof of the second equivalence, we use the following formula, which holds for continuously differentiable functions f, whose first derivative vanishes at $x = 0$:

$$S_0 f(x) = -\frac{1}{x}\int_0^\infty \xi J_1(\xi x)f'(\xi)d\xi. \tag{2.22}$$

This we prove by integration by parts on the left-hand side of the equation and by using the relation $(\partial/\partial\xi)((\xi/x)J_1(\xi x)) = \xi J_0(\xi x)$.

Let us assume that f is a function in $C^\infty([0,1])$, satisfying $f'(0) = 0$. Let lf be a smooth extension of f to $(0,\infty)$. Using the relation above and some properties of the

Mellin transformation, which we looked up from [5] , we get the following equation:

(2.23)

$$\begin{aligned}\int_0^\infty & |S_0lf(x)|^2x^2dx\\ &= \int_{\mathbb{R}}\left|(MS_0lf)\left(\frac{3}{2}+it\right)\right|^2dt\\ &= \int_{\mathbb{R}}\left|M\left(\frac{1}{x}\int_0^\infty \xi J_1(\xi x)(lf)'(\xi)d\xi\right)\left(\frac{3}{2}+it\right)\right|^2dt\\ &= \int_{\mathbb{R}}\left|(MJ_1)\left(\frac{1}{2}+it\right)(M(lf)')\left(\frac{3}{2}-it\right)\right|^2dt\\ &= \int_{\mathbb{R}}\left|2^{-\frac{1}{2}+it}\Gamma\left(\frac{3}{4}+\frac{it}{2}\right)\Gamma^{-1}\left(\frac{5}{4}-\frac{it}{2}\right)\left(\frac{1}{2}-it\right)(Mlf)\left(\frac{1}{2}-it\right)\right|^2dt.\end{aligned}$$

We prove the second equivalence of norms substituting t by $-t$ in the last integral, using the above given asymptotic formula for the Γ -function and taking the infimum over all extensions of f to $L_2^2((0,\infty))$. The proofs of the third and the fourth equivalence can be done analogously. We have to use functions f with compact support in $(0,1)$. □

To give an idea which functions are in the Sobolev spaces defined above, we prove a corollary of Lemmas 2.1, 2.2, and 2.3.

COROLLARY 2.1. *The following inclusions hold:*

$$L_{1,2}((0,1))\cap\left\{f\,\middle|\,\inf_{lf\in L_{1,2}(\mathbb{R}^+)}\int_{\mathbb{R}}|M_{1,2}(lf)(t)|^2(1+|t|)dt<\infty\right\}\subset H_A^{\frac{1}{2}}(\Omega),$$

$$L_{3,2}((0,1))\subset \tilde{H}_A^{-\frac{1}{2}}(\Omega). \tag{2.24}$$

Proof. Let $f\in L_{1,2}((0,1))$ have an extension $lf\in L_{1,2}(\mathbb{R}^+)$ such that

$$\int_{\mathbb{R}}|M_{1,2}(lf)(t)|^2(1+|t|)dt<\infty.$$

Then it is possible to approximate lf by functions $lf_n\in C_0^\infty(\mathbb{R}^+)$ in the $L_{1,2}(\mathbb{R}^+)$-sense. By Lemma 2.1, $M_{1,2}(lf_n)$ converges to lf in $L^2(\mathbb{R})$-sense, which implies convergence almost everywhere. If n is large enough, the integrals $\int_{\mathbb{R}}|M_{1,2}(lf_n)(t)|^2(1+|t|)dt$ must also exist; f can be approximated by functions from $C^\infty([0,1])$ in the $H_A^{\frac{1}{2}}(\Omega)$-norm. The proof of the second inclusion is analogous. We have to keep in mind that for functions $f\in L_{3,2}(\mathbb{R}^+)$ we get the estimate

$$\int_{\mathbb{R}}\frac{|M_{3,2}(f)(t)|^2}{(1+|t|)}dt\le ||M_{3,2}f||_{L^2(\mathbb{R})}^2=||f||_{L_{3,2}(\mathbb{R}^+)}^2. \tag{2.25}$$

□

Remark 2.2. The extensions lf in Corollary 2.1 can be restricted to extensions $lf\in C_0^\infty([0,b])$ for $b>1$ because these functions are a dense subset of $L_{\mu,2}(\mathbb{R}^+)$.

Given a set Ω, we denote by χ_Ω the characteristic function of Ω.

LEMMA 2.4. *The operator* $\frac{x}{2}K_{-\frac{1}{2},1}\chi_{[0,1]}$, *which maps* f *onto* $\int_x^1 f(u)du$, *is extendable to an isomorphism from* $\tilde{H}_A^{-\frac{1}{2}}(\Omega)$ *onto* $\tilde{H}_A^{\frac{1}{2}}(\Omega)$. *The inverse is given by*

$-d/dx$. The operator $\frac{x}{2}I_{0,1}\chi_{[0,1]}$, which maps f onto $\int_0^x \frac{u}{x}f(u)du$, is extendable to an isomorphism from $H_A^{-\frac{1}{2}}(\Omega)$ onto $H_A^{\frac{1}{2}}(\Omega)$. The inverse is given by $(Df)(x) := f'(x) + (f(x)/x)$.

Proof. Let $v \in C_0^\infty([0,1)), v^{(2k-1)}(0) = 0$ for k $\in$ N. We prove that $\frac{x}{2}K_{-\frac{1}{2},1}\chi_{[0,1]}$ is an isomorphism:

$$\begin{aligned} \left\|\frac{x}{2}K_{-\frac{1}{2},1}\chi_{[0,1]}v\right\|^2_{\tilde{H}_A^{\frac{1}{2}}} &= \int_{I\!R}\left|\int_0^\infty x^{-\frac{1}{2}+it}\int_x^1 (l_0v)(s)ds\,dx\right|^2 (1+|t|)dt \\ &= \int_{I\!R}\left|\int_0^\infty \frac{x^{\frac{1}{2}+it}}{\frac{1}{2}+it}(l_0v)(x)dx\right|^2 (1+|t|)dt \\ &\approx \int_{I\!R}\left|\int_0^\infty x^{\frac{1}{2}+it}(l_0v)(x)dx\right|^2 \frac{dt}{(1+|t|)} = ||v||_{\tilde{H}_A^{-\frac{1}{2}}(\Omega)}. \end{aligned} \tag{2.26}$$

The formula for the inverse follows from $-(d/dx)\int_x^1 v(s)ds = v(x)$. We shall prove that the operator $\frac{x}{2}I_{0,1}\chi_{[0,1]}$ is the adjoint operator to $\frac{x}{2}K_{-\frac{1}{2},1}\chi_{[0,1]}$. For $f \in C_0^\infty((0,1)), g \in C^\infty([0,1])$ holds:

$$\int_0^1 g(x)\frac{x}{2}(K_{-\frac{1}{2},1}f)(x)dx = \int_0^1 g(x)x\int_x^1 f(u)du\,dx = \int_0^1\int_0^x \frac{u}{x}g(u)du f(x)x\,dx, \tag{2.27}$$

which proves that the operator $\frac{x}{2}I_{0,1}\chi_{[0,1]}$ is adjoint to the operator $\frac{x}{2}K_{-\frac{1}{2},1}\chi_{[0,1]}$ with respect to the natural dual pairing between $\tilde{H}_A^{-\frac{1}{2}}(\Omega)$ and $H_A^{\frac{1}{2}}(\Omega)$. The formula for the inverse is now obvious. □

Remark 2.3. The constant functions are not in the range of the operator $\frac{x}{2}K_{-\frac{1}{2},1}\chi_{[0,1]}$, indeed they are not elements of $\tilde{H}_A^s(\Omega)$ for $s \geq \frac{1}{2}$. The operator D maps the function which is equal to one on the disk onto the function $1/|x|$, which is in $H_A^{-\frac{1}{2}}(\Omega)$. On these facts hinges the injectivity of the operators D and d/dx.

LEMMA 2.5. *The operator $x^{\frac{1}{2}}K_{\gamma,\frac{1}{2}}$ maps $L_2^2((0,1))$ one-to-one onto $\tilde{H}_A^{\frac{1}{2}}(\Omega)$ and the operator $(d/dx)x^{\frac{1}{2}}K_{\gamma,\frac{1}{2}}$ maps $L_2^2((0,1))$ one-to-one onto $\tilde{H}_A^{-\frac{1}{2}}(\Omega)$, if $\gamma > -\frac{1}{2}$.*

Proof. Let $v \in C_0^\infty((0,1))$. The function $g := x^{\frac{1}{2}}K_{\gamma,\frac{1}{2}}v$ behaves like $x^{2\gamma+\frac{1}{2}}$ at $x = 0$ and vanishes in the neighbourhood of $x = 1$. For $\gamma > -\frac{1}{2}$ the function g is in $L_1^2((0,1))$. To estimate the $\tilde{H}_A^{\frac{1}{2}}(\Omega)$ norm of g, we may use the following relation:

$$\begin{aligned} &\left\|\sqrt{1+|t|}M(g)\left(\frac{1}{2}+it\right)\right\|_{L^2(I\!R)} \\ &= \left\|\sqrt{1+|t|}\frac{\Gamma(\frac{1}{2}+\gamma+\frac{it}{2})}{\Gamma(1+\gamma+\frac{it}{2})}(Mv)(1+it)\right\|_{L^2(I\!R)} \approx ||(Mv)(1+it)||_{L^2(I\!R)}. \end{aligned} \tag{2.28}$$

This proves the equivalence of the norms $||x^{\frac{1}{2}}K_{\gamma,\frac{1}{2}}v||_{\tilde{H}_A^{\frac{1}{2}}(\Omega)}$ and $||v||_{L_2^2((0,1))}$. The mapping property of $(d/dx)x^{\frac{1}{2}}K_{\gamma,\frac{1}{2}}$ follows from Lemma 2.4. □

LEMMA 2.6. *The operator $x^{\frac{1}{2}}I_{\eta,\frac{1}{2}}$ maps $L_2^2((0,1))$ one-to-one onto $H_A^{\frac{1}{2}}(\Omega)$ and the operator $Dx^{\frac{1}{2}}I_{\eta,\frac{1}{2}}$ maps $L_2^2((0,1))$ one-to-one onto $H_A^{-\frac{1}{2}}(\Omega)$, if $\eta > -\frac{1}{2}$.*

Proof. Let $v \in C_0^\infty((0,1))$. We calculate the Mellin transform of $h(x) := x^{\frac{1}{2}} I_{\eta,\frac{1}{2}}$ $(l_0 v)(x)$; h is in $C^\infty((0,\infty))$ and vanishes in a neighbourhood of $x = 0$. From [5] we cite

$$\begin{aligned}(Mh)\left(\frac{1}{2}+it\right) &= \frac{2}{\Gamma(\frac{1}{2})}(M((x^2-1)^{-1/2}\chi_{(1,\infty)}))(-2\eta+it)(Ml_0v)(1+it)\\ &= \Gamma\left(\frac{1}{2}+\eta-i\frac{t}{2}\right)\Gamma^{-1}\left(1+\eta-i\frac{t}{2}\right)(Ml_0v)(1+it).\end{aligned} \tag{2.29}$$

This proves, that the first operator in question maps $L_2^2((0,1))$ continuously into $H_A^{1/2}(\Omega)$. Its injectivity is well known [18]. To prove surjectivity, we prove that the inverse operator is densely defined and continuous from $H_A^{\frac{1}{2}}(\Omega)$ into $L_2^2((0,1))$. For this let us assume $h_1 \in C^\infty([0,1]), h_1^{(2k-1)}(0) = 0$, if $k \in I\!N$ is given. Using some formulas from [24], we get the following result:

$$(I_{\eta,\frac{1}{2}}{}^{-1}h_1)(x) = \frac{1}{2}x^{-2\eta-1}\frac{d}{dx}x^{2+2\eta}(I_{\eta+\frac{1}{2},\frac{1}{2}}h_1)(x). \tag{2.30}$$

We extend h_1 by lh_1 to the half-axis such that the support of lh_1 is a bounded interval, say $[0, x_0]$, and obtain

(2.31)

$$\begin{aligned}&M(I_{\eta,\frac{1}{2}}{}^{-1}x^{-\frac{1}{2}}lh_1)(1+it)\\ &= \int_0^\infty x^{-2\eta-1+it}\frac{d}{dx}\frac{2}{\Gamma(\frac{1}{2})}\int_0^x \frac{u^{2\eta+\frac{3}{2}}(lh_1(u))}{\sqrt{x^2-u^2}}du\,dx\\ &= -\frac{2}{\Gamma(\frac{1}{2})}(-2\eta-1+it)\int_0^\infty x^{-2\eta-2+it}\int_0^\infty \chi_{[1,\infty)}\left(\frac{x}{u}\right)\frac{u^{2\eta+\frac{1}{2}}(lh_1(u))}{\sqrt{(\frac{x}{u})^2-1}}du\,dx\\ &= -\frac{2}{\Gamma(\frac{1}{2})}(-1-2\eta+it)M(\chi_{[1,\infty)}(x)(x^2-1)^{-\frac{1}{2}})(-1-2\eta+it)(Mlh_1)\left(\frac{1}{2}+it\right)\\ &= -(-1-2\eta+it)\Gamma\left(1+\eta-i\frac{t}{2}\right)\Gamma^{-1}\left(\frac{3}{2}+\eta-i\frac{t}{2}\right)(Mlh_1)\left(\left(\frac{1}{2}+it\right)\right).\end{aligned}$$

Here we used integration by parts and the relations

$$\left|\int_0^x \frac{u^{2\eta+\frac{3}{2}}(lh_1(u))}{\sqrt{x^2-u^2}}du\right| \le \frac{1}{x}\int_0^{x_0}\frac{u^{2\eta+\frac{3}{2}}|lh_1(u)|}{\sqrt{1-(\frac{u}{x})^2}}du = O\left(\frac{1}{x}\right) \quad \text{for x} \to \infty, \tag{2.32}$$

(2.33)

$$\left|\int_0^x \frac{u^{2\eta+\frac{3}{2}}(lh_1(u))}{\sqrt{x^2-u^2}}du\right| \le ||lh_1||_{L^\infty([0,x_0])}\int_0^1 \frac{(xt)^{2\eta+\frac{3}{2}}}{\sqrt{1-t^2}}dt = O(x^{2\eta+\frac{3}{2}}) \quad \text{for x} \to 0,$$

which ensure the existence of the integrals above and allow us to neglect the boundary terms in the second equality.

Using formulas (2.14), (2.21), we conclude the desired surjectivity of $x^{\frac{1}{2}}I_{\eta,\frac{1}{2}}$. The mapping property of the operator $Dx^{\frac{1}{2}}I_{\eta,\frac{1}{2}}$ follows from Lemma 2.4. □

Remark 2.4. The fractional integral operators $x^{\frac{1}{2}}K_{\gamma,\frac{1}{2}}, x^{-\frac{1}{2}}I_{\eta,\frac{1}{2}}$ map functions with support in $[0,1)$, respectively, $[1,\infty)$ onto functions of the same type. This property holds because their Mellin symbols, which are defined by

$$(x^{\frac{1}{2}}k_{\gamma,\frac{1}{2}})(t) := \frac{\Gamma(\frac{1}{2}+\gamma+i\frac{t}{2})}{\Gamma(1+\gamma+i\frac{t}{2})}, \qquad (x^{\frac{1}{2}}i_{\eta,\frac{1}{2}})(t) := \frac{\Gamma(\frac{1}{2}+\eta-i\frac{t}{2})}{\Gamma(1+\eta-i\frac{t}{2})}, \tag{2.34}$$

are holomorphically extendable to the lower half plane and to the upper half plane, respectively.

3. Formulation and solution of dual integral equations for the Laplacian. The Dirichlet problem for the Laplacian reads

$$\Delta u = 0 \quad \text{in } \mathbf{R}^3\backslash\overline{\Omega}, \quad \mathrm{u(x)} = \mathrm{O}\left(\frac{1}{|\mathrm{x}|}\right) \quad \text{if } |\mathrm{x}| \to \infty, \tag{3.1}$$

$$u = g \quad \text{on } \Omega, \tag{3.2}$$

where we assume g to be in $H_A^{\frac{1}{2}}(\Omega)$. In [27] the following weakly singular integral equation for the jump of the Neumann data was derived:

$$V_\Omega\left[\frac{\partial u}{\partial n}\right](x) := \frac{1}{2\pi}\int_\Omega \frac{1}{|x-y|}\left[\frac{\partial u}{\partial n}\right](y)d\Omega_y = 2g(x). \tag{3.3}$$

In [27] the invertibility of the operator $V_\Omega : \tilde{H}^{\frac{1}{2}}(\Omega) \to H^{1/2}(\Omega)$ is proved and Galerkin methods are investigated.

For the disk Ω and an axialsymmetric function g, equation (3.3) reads

$$\chi_\Omega S_0 \frac{1}{x} S_0 \left[\frac{\partial u}{\partial n}\right] = 2g, \tag{3.4}$$

where we look for $[\partial u/\partial n] \in \tilde{H}_A^{-\frac{1}{2}}(\Omega)$. To point out the relation to dual integral equations, we cite from [24] the following formal derivation of (3.4): The potential ansatz

$$u(\rho,z) = \int_0^\infty B(\xi)e^{-\xi|z|}J_0(\xi\rho)d\xi \tag{3.5}$$

leads to the dual integral equations

$$\int_0^\infty B(\xi)J_0(\xi\rho)d\xi = g(\rho), \quad 0 \le \rho \le 1; \qquad \int_0^\infty \xi B(\xi)J_0(\xi\rho)d\xi = 0, \quad \rho > 1. \tag{3.6}$$

The second equation in (3.6) gives us the information that the Hankel transform of B is supported in $[0,1]$. Using the first equation in (3.6), we end up with equation (3.4), where B denotes the Hankel transform of $[\partial u/\partial n]$.

We have to solve the Wiener–Hopf equation (3.4). This we shall do by "lifting" this equation to a Wiener–Hopf equation in $L_2^2((0,\infty))$. This method is well known for half-space problems; compare [8], [25]. The operators which map $\tilde{H}^{\frac{1}{2}}(\Omega)$ bijectively onto $L^2(\Omega)$ may be constructed by partition of unity [10]. In the axialsymmetric case this can be done more explicitly by use of the fractional integral operators introduced in §2.

THEOREM 3.1. *The explicit solution of equation* (3.4) *is given by*

$$\left[\frac{\partial u}{\partial n}\right] = -\frac{d}{dx}x^{\frac{1}{2}}K_{\frac{1}{4},\frac{1}{2}}(x^{\frac{1}{2}}I_{-\frac{1}{4},\frac{1}{2}})^{-1}2g. \tag{3.7}$$

Proof. We multiply equation (3.4) by $(x^{\frac{1}{2}}I_{-\frac{1}{4},\frac{1}{2}})^{-1}$ from the left and we use the ansatz $[\partial u/\partial n] = (-(d/dx)x^{\frac{1}{2}}K_{\frac{1}{4},\frac{1}{2}})C$ with $C \in L_2^2((0,1))$. Then we end up with an equivalent equation in $L_2^2((0,1))$:

$$(x^{\frac{1}{2}}I_{-\frac{1}{4},\frac{1}{2}})^{-1}\chi_\Omega S_0\frac{1}{x}S_0\chi_\Omega\left(\frac{d}{dx}x^{\frac{1}{2}}K_{\frac{1}{4},\frac{1}{2}}\right)C = (x^{\frac{1}{2}}I_{-\frac{1}{4},\frac{1}{2}})^{-1}2g. \tag{3.8}$$

The operator on the left-hand side of the last equation is the unit operator in $L_2^2((0,1))$. We prove this by application of the Mellin transformations, assuming $C \in C_0^\infty((0,1))$.

(3.9)

$$\begin{aligned}
&-\left(M_{1,2}S_0\frac{1}{x}S_0\frac{d}{dx}x^{\frac{1}{2}}K_{\frac{1}{4},\frac{1}{2}}C\right)(t)\\
&\quad= -(M_{1,2}J_0)(t)\left(M\left(\frac{1}{x}S_0\frac{d}{dx}x^{\frac{1}{2}}K_{\frac{1}{4},\frac{1}{2}}\right)\right)\left(\frac{3}{2}-it\right)\\
&\quad= -(MJ_0)\left(\frac{1}{2}+it\right)(MJ_0)\left(\frac{1}{2}-it\right)\left(M\left(\frac{d}{dx}x^{\frac{1}{2}}K_{\frac{1}{4},\frac{1}{2}}C\right)\right)\left(\frac{3}{2}+it\right)\\
&\quad= -\frac{\Gamma(\frac{1}{4}+i\frac{t}{2})\Gamma(\frac{1}{4}-i\frac{t}{2})}{2\Gamma(\frac{3}{4}-i\frac{t}{2})\Gamma(\frac{3}{4}+i\frac{t}{2})}\left(M\left(\frac{d}{dx}x^{\frac{1}{2}}K_{\frac{1}{4},\frac{1}{2}}C\right)\right)\left(\frac{3}{2}+it\right)\\
&\quad= \left(\frac{1}{2}+it\right)\frac{\Gamma(\frac{1}{4}+i\frac{t}{2})\Gamma(\frac{1}{4}-i\frac{t}{2})}{2\Gamma(\frac{3}{4}+i\frac{t}{2})\Gamma(\frac{3}{4}-i\frac{t}{2})}(Mx^{\frac{1}{2}}K_{\frac{1}{4},\frac{1}{2}}C)\left(\frac{1}{2}+it\right)\\
&\quad= \left(\frac{1}{4}+i\frac{t}{2}\right)\frac{\Gamma(\frac{1}{4}+i\frac{t}{2})\Gamma(\frac{1}{4}-i\frac{t}{2})}{\Gamma(\frac{5}{4}+i\frac{t}{2})\Gamma(\frac{3}{4}-i\frac{t}{2})}(MC)(1+it)\\
&\quad= \frac{\Gamma(\frac{1}{4}-i\frac{t}{2})}{\Gamma(\frac{3}{4}-i\frac{t}{2})}(MC)(1+it) = (M_{1,2}x^{\frac{1}{2}}I_{-\frac{1}{4},\frac{1}{2}}C)(t).
\end{aligned}$$

So we proved that the functions $x^{\frac{1}{2}}I_{-\frac{1}{4},\frac{1}{2}}C + S_0\frac{1}{x}S_0(d/dx)x^{\frac{1}{2}}K_{\frac{1}{4},\frac{1}{2}}C$ vanish identically on the whole half axis. □

The Neumann problem for the Laplacian reads

$$\Delta u = 0 \quad \text{in } \mathbf{R}^3 \setminus\overline{\Omega} \quad \mathrm{u(x)} = \mathrm{O}\left(\frac{1}{|\mathrm{x}|}\right) \quad \text{if } |\mathrm{x}| \to \infty, \tag{3.10}$$

$$\frac{\partial u}{\partial n} = h \quad \text{on } \Omega \tag{3.11}$$

where we assume h to be in $H_A^{-\frac{1}{2}}(\Omega)$. In [27] the following hypersingular integral equation for the jump of the Dirichlet data was analyzed:

$$D_\Omega[u](x) := \frac{1}{2\pi}\frac{\partial}{\partial n_x}\int_\Omega [u](y)\frac{\partial}{\partial n_y}\frac{1}{|x-y|}d\Omega_y = 2h(x). \tag{3.12}$$

For the disk Ω and an axialsymmetric function h this equation leads to the following Wiener–Hopf equation for $[u] \in \tilde{H}_A^{\frac{1}{2}}(\Omega)$:

$$\chi_\Omega S_0 x S_0 \chi_\Omega [u] = 2h. \tag{3.13}$$

By analogy to Theorem 3.1, which describes the solution of the Dirichlet problem, we can prove the following theorem.

THEOREM 3.2. *The explicit solution of equation* (3.13) *is given by*

$$[u] = x^{\frac{1}{2}} K_{-\frac{1}{4},\frac{1}{2}} (D x^{\frac{1}{2}} I_{\frac{1}{4},\frac{1}{2}})^{-1} 2h. \tag{3.14}$$

Proof. We multiply (3.13) by $(Dx^{\frac{1}{2}} I_{\frac{1}{4},\frac{1}{2}})^{-1}$ from the left and we use the ansatz $[u] = (x^{\frac{1}{2}} K_{-\frac{1}{4},\frac{1}{2}})d$ with $d \in L_2^2((0,1))$. Then we obtain an equivalent equation in $L_2^2((0,1))$:

$$(Dx^{\frac{1}{2}} I_{\frac{1}{4},\frac{1}{2}})^{-1} \chi_\Omega S_0 x S_0 \chi_\Omega (x^{\frac{1}{2}} K_{-\frac{1}{4},\frac{1}{2}}) d = (Dx^{\frac{1}{2}} I_{\frac{1}{4},\frac{1}{2}})^{-1} 2h. \tag{3.15}$$

The operator on the left-hand side of the last equation is the unit operator in $L_2^2((0,1))$. As in the proof of Theorem 3.1, it is sufficient to prove an identity for $d \in C_0^\infty((0,1))$:

$$\chi_\Omega S_0 x S_0 \chi_\Omega x^{\frac{1}{2}} K_{-\frac{1}{4},\frac{1}{2}} d = \chi_\Omega D x^{\frac{1}{2}} I_{\frac{1}{4},\frac{1}{2}} d. \tag{3.16}$$

To calculate the Mellin transform of $\chi_\Omega S_0 x S_0 \chi_\Omega x^{\frac{1}{2}} K_{-\frac{1}{4},\frac{1}{2}} d$ we give some comments in advance: The operator $x^{\frac{1}{2}} K_{-\frac{1}{4},\frac{1}{2}}$ maps $C_0^\infty((0,1))$ into $C_0^\infty((0,1)$; the operator $S_0 x S_0$ maps axialsymmetric functions from $S(\mathbb{R}^2)$ onto distributions from $S'(\mathbb{R}^2)$. Its Mellin symbol is derived by the use of the convolution theorem and the Fourier transform of the $S'(\mathbb{R})$ distribution $e^{3x/2} J_0(e^x)$.

$$\int_0^\infty s^{\frac{1}{2}+it} J_0(s)ds = \int_{\mathbb{R}} e^{(\frac{1}{2}+it)x} J_0(e^x)(e^x)dx = \int_{\mathbb{R}} e^{itx} J_0(e^x)(e^{3x/2})dx. \tag{3.17}$$

The function $e^{3x/2} J_0(e^x)$ grows exponentially as $x \longrightarrow +\infty$; nevertheless, it is an element of $S'(\mathbb{R})$. This follows from the equation

$$e^{3x/2} J_0(e^x) = \frac{1}{2}\left(e^{\frac{x}{2}} J_1(e^x)\right) + \frac{d}{dx}(e^{\frac{x}{2}} J_1(e^x)) \tag{3.18}$$

and the boundedness of $e^{\frac{x}{2}} J_1(e^x)$ at ±∞. Therefore, the Mellin transform $M_{3,2}$ of J_0 may be taken by holomorphic extension from the formula (1) on page 326 of [5]. We calculate the Mellin transform:

$$\begin{aligned}
&M_{3,2}(S_0 x S_0 x^{\frac{1}{2}} K_{-\frac{1}{4},\frac{1}{2}} d)(t) \\
&= (MJ_0)\left(\frac{3}{2} + it\right)(MJ_0)\left(\frac{3}{2} - it\right) M(x^{\frac{1}{2}} K_{-\frac{1}{4},\frac{1}{2}} d)\left(\frac{1}{2} + it\right) \\
&= 2\frac{\Gamma(\frac{3}{4} + i\frac{t}{2})\Gamma(\frac{3}{4} - i\frac{t}{2})}{\Gamma(\frac{1}{4} - i\frac{t}{2})\Gamma(\frac{1}{4} + i\frac{t}{2})} M(x^{\frac{1}{2}} K_{-\frac{1}{4},\frac{1}{2}} d)\left(\frac{1}{2} + it\right) \\
&= 2\frac{\Gamma(\frac{3}{4} - i\frac{t}{2})}{\Gamma(\frac{1}{4} - i\frac{t}{2})}(M(d))(1 + it).
\end{aligned} \tag{3.19}$$

Now we finish the proof:

$$
\begin{aligned}
(M_{3,2}Dx^{\frac{1}{2}}I_{\frac{1}{4},\frac{1}{2}}d)(t) &= \left(M\frac{d}{dx}x^{\frac{3}{2}}I_{\frac{1}{4},\frac{1}{2}}d\right)\left(\frac{1}{2}+it\right)\\
&= -\left(-\frac{1}{2}+it\right)(Mx^{\frac{3}{2}}I_{\frac{1}{4},\frac{1}{2}}d)\left(-\frac{1}{2}+it\right)\\
&= -\left(-\frac{1}{2}+it\right)\frac{\Gamma(\frac{3}{4}-i\frac{t}{2})}{\Gamma(\frac{5}{4}-i\frac{t}{2})}(Md)(1+it)\\
&= -\left(-\frac{1}{2}+it\right)\frac{\Gamma(\frac{3}{4}-i\frac{t}{2})}{(\frac{1}{4}-i\frac{t}{2})\Gamma(\frac{1}{4}-i\frac{t}{2})}(Md)(1+it)\\
&= 2\frac{\Gamma(\frac{3}{4}-i\frac{t}{2})}{\Gamma(\frac{1}{4}-i\frac{t}{2})}M(d)(1+it).
\end{aligned}
\tag{3.20}
$$

These formulas hold in the distributional sense. So we proved that for $d \in C_0^\infty((0,1))$ the distribution $S_0xS_0x^{\frac{1}{2}}K_{-\frac{1}{4},\frac{1}{2}}d - Dx^{\frac{1}{2}}I_{\frac{1}{4},\frac{1}{2}}d$ is equal to the null element of $S'(I\!R^2)$. □

Remark 3.1. Explicit solution formulas for the boundary value problems discussed in §3 for the Helmholtz equation are not known to the author. The methods used here to derive explicit formulas break down because of the nonhomogeneity of the Helmholtz operator. Nevertheless, in a future project we plan to use the methods developed here for investigation of numerical procedures for nonaxialsymmetric cases, for the Helmholtz equation and for time-harmonic crack problems.

4. Mixed boundary value problems. We want to formulate the Dirichlet–Neumann problem for the Laplacian here, which leads to a nontrivial system of Wiener–Hopf equations. This type of boundary value problem appears, for example, in the theory of acoustics; compare [21] and in the theory of subsonic flows, compare [13]. In Rawlins' paper the solution for the half-space case had been given explicitly. One essential step in Rawlins' paper was the derivation of the factorization of a certain matrix. For the discussion of this and related problems, [14], [20] should be consulted. In our case, we reduce the problem to the factorization of a meromorphic nonrational matrix function. This factorization is not explicitly known to us because the matrix does not fall into classes factorized in [1], [19]; therefore, we end up with the regularization of the Wiener–Hopf operator to a system of singular integral equations in $(L^2(I\!R))^2$ with a symbol from the Wiener-algebra.

The Dirichlet–Neumann problem for the Laplacian reads

$$\Delta u = 0 \quad \text{in } \mathrm{R}^3\backslash\overline{\Omega}, \quad \mathrm{u(x)} = \mathrm{O}\left(\frac{1}{\mathrm{|x|}}\right) \quad \text{if } |\mathrm{x}| \to \infty, \tag{4.1}$$

$$u(r,0^-) = g(r), \quad \frac{\partial u}{\partial n}(r,0^+) = h(r) \quad \text{for } r \in (0,1). \tag{4.2}$$

Here we assume $g \in H_A^{\frac{1}{2}}(\Omega)$ and $h \in H_A^{-\frac{1}{2}}(\Omega)$.

The ansatz

$$u(\rho,z) = \int_0^\infty \alpha(\xi)e^{-\xi z}J_0(\xi\rho)d\xi \quad \text{for } z > 0 \tag{4.3}$$

and

$$u(\rho, z) = \int_0^\infty \beta(\xi) e^{\xi z} J_0(\xi\rho) d\xi \quad \text{for } z \leq 0 \tag{4.4}$$

lead to the system of dual integral equations

$$\int_0^\infty \xi\alpha(\xi) J_0(\xi\rho) d\xi = -h(\rho), \qquad \int_0^\infty \beta(\xi) J_0(\xi\rho) d\xi = g(\rho), \quad 0 \leq \rho \leq 1, \tag{4.5}$$

and the transmission conditions imply

$$\int_0^\infty (\alpha(\xi) - \beta(\xi)) J_0(\xi\rho) d\xi = 0, \quad \int_0^\infty \xi(\alpha(\xi) + \beta(\xi)) J_0(\xi\rho) d\xi = 0, \quad \rho > 1. \tag{4.6}$$

The transmission conditions lead to the new ansatz:

$$2\alpha = S_0 \chi_\Omega a + x S_0 \chi_\Omega b, \qquad 2\beta = S_0 \chi_\Omega a - x S_0 \chi_\Omega b. \tag{4.7}$$

This ansatz for a and b reduces the mixed boundary value problem to the following system of Wiener–Hopf equations:

$$\chi_\Omega a + \chi_\Omega S_0 x S_0 \chi_\Omega b = -2h, \qquad \chi_\Omega S_0 \frac{1}{x} S_0 \chi_\Omega a - \chi_\Omega b = 2g. \tag{4.8}$$

Of course, we look for $a \in \tilde{H}_A^{-\frac{1}{2}}(\Omega)$ and for $b \in \tilde{H}_A^{\frac{1}{2}}(\Omega)$.

We "lift" this system of Wiener–Hopf equations to a system in $L_2^2((0,\infty))$: for this we introduce the substitutions

$$a = -\frac{d}{dx} x^{\frac{1}{2}} K_{\frac{1}{4},\frac{1}{2}} c, \quad b = x^{\frac{1}{2}} K_{-\frac{1}{4},\frac{1}{2}} d, \quad 2h = -D x^{\frac{1}{2}} I_{\frac{1}{4},\frac{1}{2}} u, \quad 2g = x^{\frac{1}{2}} I_{-\frac{1}{4},\frac{1}{2}} v. \tag{4.9}$$

Inserting these equations into the system above and using Theorems 3.1 and 3.2, we get the Wiener–Hopf system in $L_2^2((0,1))$ that we looked for:

$$\begin{aligned} -\chi_\Omega (D x^{\frac{1}{2}} I_{\frac{1}{4},\frac{1}{2}})^{-1} \frac{d}{dx} K_{\frac{1}{4},\frac{1}{2}} \chi_\Omega c + \chi_\Omega d &= \chi_\Omega u, \\ \chi_\Omega c - \chi_\Omega (I_{-\frac{1}{4},\frac{1}{2}})^{-1} K_{-\frac{1}{4},\frac{1}{2}} \chi_\Omega d &= \chi_\Omega v. \end{aligned} \tag{4.10}$$

An application of the Mellin transformation leads to

$$\begin{aligned} P\frac{1}{r}(t) M_{2,2} c(1+it) + P M_{2,2} d(1+it) &= P M_{2,2} u(1+it), \\ P M_{2,2} c(1+it) - P r(t) M_{2,2} d(1+it) &= P M_{2,2} v(1+it), \end{aligned} \tag{4.11}$$

where P denotes the projector onto L^2 functions that are boundary values of functions that are holomorphically extendable into the lower half plane, and r denotes the Mellin symbol of the operator $(I_{-\frac{1}{4},\frac{1}{2}})^{-1} K_{-\frac{1}{4},\frac{1}{2}}$.

$$r(t) := \frac{\Gamma(\frac{1}{4} + i\frac{t}{2})\Gamma(\frac{3}{4} - i\frac{t}{2})}{\Gamma(\frac{3}{4} + i\frac{t}{2})\Gamma(\frac{1}{4} - i\frac{t}{2})} = \frac{\sin((\frac{3}{4} + i\frac{t}{2})\pi)}{\sin((\frac{3}{4} - i\frac{t}{2})\pi)}. \tag{4.12}$$

This symbol had already been calculated by Rooney [23]. It is a meromorphic function with all its poles and zeros lying on the line $i\mathbb{R}$. A lengthy but simple calculation proves that the operator $-(Dx^{\frac{1}{2}}I_{\frac{1}{4},\frac{1}{2}})^{-1}\frac{d}{dx}x^{\frac{1}{2}}K_{\frac{1}{4},\frac{1}{2}}$ has the Mellin symbol $\frac{1}{r}$. The matrix

$$\sigma(t) := \begin{pmatrix} \frac{1}{r} & 1 \\ 1 & -r \end{pmatrix} \tag{4.13}$$

is an element of $(L^\infty(I\!R))^{2\times 2}$, having constant determinant. The limit values of r at infinity are given by:

$$\lim_{t\to\pm\infty} r(t) = \pm i. \tag{4.14}$$

It is a matrix of functions that have a finite jump at infinity. The matrix

$$\sigma_1(t) := \begin{pmatrix} 1 & \frac{1}{r} \\ -r & 1 \end{pmatrix} \tag{4.15}$$

is a dissipative matrix in the sense of [2]. Transformation of the results from [2] to the real line allows us to use Banach's fixed point principle for the solution of (4.11). We believe that it is more convenient to give a reduction to a system of singular integral equations with a matrix being continuous at infinity. If we solve this reduced equation by a numerical method, we get an approximate solution of the boundary value problem which has the same singularities like the exact solution. We state the following theorem.

THEOREM 4.1. *The solution of the axialsymmetric mixed boundary value problem* (4.1), (4.2) *is equivalent to the solution of a system of singular integral equations in* $(L^2(I\!R))^2$:

$$P\sigma_0 P u = Pf, \tag{4.16}$$

where the matrix σ_0 *is defined by*

$$\sigma_0(t) = \begin{pmatrix} -r_1(1+\frac{1}{2}(\frac{1}{r}-r)) & -\frac{r_1}{2}(\frac{1}{r}+r) \\ \frac{r_1}{2}(\frac{1}{r}+r) & -r_1(1-\frac{1}{2}(\frac{1}{r}-r)) \end{pmatrix}, \tag{4.17}$$

and r_1 *is defined by*

$$r_1(t) := \frac{\sin((\frac{1}{2}+i\frac{t}{2})\pi)}{\sin((\frac{1}{4}+i\frac{t}{2})\pi)}. \tag{4.18}$$

The matrix $\sigma_0(t)$ *converges to the identity matrix at infinity.*

Proof. We transform (4.11) equivalently by multiplying the matrix σ by the constant matrix

$$\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \tag{4.19}$$

from the right and its inverse from the left to get the new matrix σ_2, defined by

$$\begin{pmatrix} -(1+\frac{1}{2}(\frac{1}{r}-r)) & -\frac{1}{2}(\frac{1}{r}+r)) \\ -\frac{1}{2}(\frac{1}{r}+r)) & (1-\frac{1}{2}(\frac{1}{r}-r)) \end{pmatrix}. \tag{4.20}$$

The function $(r+\frac{1}{r})(t)$ vanishes exponentially for $t \to \pm\infty$. A standard method to reduce the system of singular integral equations with the matrix having a discontinuity at infinity is to fill up the discontinuities by multiplying the matrix with diagonal matrices with entries like $(t \pm i)^\alpha$. Here we multiply the matrix with meromorphic functions that have algebraic behaviour at infinity on the real axis:

$$\sigma_0(t) = \begin{pmatrix} \frac{\Gamma(\frac{3}{4}-i\frac{t}{2})}{\Gamma(\frac{1}{2}-i\frac{t}{2})} & 0 \\ 0 & -\frac{\Gamma(\frac{3}{4}-i\frac{t}{2})}{\Gamma(\frac{1}{2}-i\frac{t}{2})} \end{pmatrix} \sigma_1(t) \begin{pmatrix} \frac{\Gamma(\frac{1}{4}+i\frac{t}{2})}{\Gamma(\frac{1}{2}+i\frac{t}{2})} & 0 \\ 0 & \frac{\Gamma(\frac{1}{4}+i\frac{t}{2})}{\Gamma(\frac{1}{2}+i\frac{t}{2})} \end{pmatrix}. \tag{4.21}$$

We multiplied σ_1 from the left side with a matrix holomorphically extendable into the upper half plane, while the last matrix in the product is holomorphically extendable to the lower half plane. Both matrices have algebraic behaviour at infinity in their half planes of analyticity. By using the well-known formula

$$\Gamma(z)\Gamma(1-z) = \frac{\pi}{\sin(\pi z)}, \tag{4.22}$$

we get the representation (4.17) for σ_0. By the methods described in [15], the solution of (4.11) may be reduced to (4.16). The diagonal elements of σ_0 converge to +1, which is seen from the formula (4.14) and the following one:

$$\lim_{t\to\pm\infty} \frac{\sin(\alpha + it)}{\sin(\gamma + it)} = e^{\pm i(\alpha-\gamma)\pi}. \tag{4.23}$$

The off-diagonal elements of σ_0 vanish exponentially at infinity on the real axis, which follows from the behaviour of $r + \frac{1}{r}$ and the boundedness of r_1 at infinity. □

ENERGY INEQUALITIES FOR INTEGRO-PARTIAL DIFFERENTIAL EQUATIONS WITH RIEMANN-LIOUVILLE INTEGRALS*

YASUHIRO FUJITA†

Abstract. This paper presents energy inequalities for the integro-partial differential equations with the Riemann-Liouville integrals. These equations interpolate between the heat equation and the wave equation. This fact is reflected in the energy inequalities so that they correspond to the energy equality for the wave equation. The proofs depend on the Fourier analysis and the probability methods.

Key words. energy inequality, Mittag-Leffler distribution, fractional derivative

AMS(MOS) subject classifications. 45K05, 26A33

1. Introduction.

Let $n \geqq 1$ be an integer and $1 \leqq \alpha \leqq 2$. We study the integro-partial differential equation

$$\text{(IDE)} \qquad u(t,x)=\phi(x)+\frac{t^{\alpha/2}}{\Gamma(1+(\alpha/2))}\psi(x)+\frac{1}{\Gamma(\alpha)}\int_0^t (t-s)^{\alpha-1}\Delta u(s,x)\,ds \qquad (t>0, x\in \mathbf{R}^n),$$

where $\Gamma(x)$ is the gamma function and $\Delta=\sum_{j=1}^n (\partial/\partial x_j)^2$. The integral appeared in (IDE) is the Riemann-Liouville integral of order α defined by

$$I^\alpha f(t)=\frac{1}{\Gamma(\alpha)}\int_0^t (t-s)^{\alpha-1}f(s)\,ds.$$

The integro-partial differential equation (IDE) interpolates between the heat equation ($\alpha=1$ and $\psi\equiv 0$) and the wave equation ($\alpha=2$); (IDE) is interpreted as the integral form of the formal Cauchy problem $(\partial/\partial t)^\alpha u(t,x)=\Delta u(t,x)$. Several authors studied the qualitative properties of the solution of (IDE) [8], [9], [12], however, about the quantitative properties of it, only $L^p(\mathbf{R}^n)$-decay ($p\geqq 2$) was studied for $\psi\equiv 0$ [10].

The aim of the present paper is to derive energy inequalities for (IDE) ($1\leqq\alpha\leqq 2$). For the solution u_α of (IDE), these energy inequalities deal with the quantity

$$(1) \qquad \mathscr{E}_{m,\alpha}(t)=\|D^{\alpha/2}u_\alpha(t)\|_m^2+\|\nabla u_\alpha(t)\|_m^2$$

and its time average

$$(2) \qquad \mathscr{T}_{m,\alpha}(\lambda)=\lambda^{1/\alpha}\int_0^\infty e^{-t\lambda^{1/\alpha}}\mathscr{E}_{m,\alpha}(t)\,dt \qquad (\lambda>0).$$

Here $\|\cdot\|_m$ is the Sobolev norm of order m and $\|\nabla\phi\|_m^2=\sum_{j=1}^n\|\partial\phi/\partial x_j\|_m^2$; $D^{\alpha/2}$ is the fractional differential operator of order $\alpha/2 (1\leqq\alpha<2)$ and $D^1=(\partial/\partial t)$ (see §2). As far as we know, there exists no paper treating the quantities $\mathscr{E}_{m,\alpha}(t)$ and $\mathscr{T}_{m,\alpha}(\lambda)$ except $\alpha=2$. For $\alpha=2$, the following energy equality is widely known:

$$(3) \qquad \mathscr{E}_{m,2}(t)=\|\psi\|_m^2+\|\nabla\phi\|_m^2 \qquad (t>0).$$

The main results are as follows. In Theorem 1, we derive the energy inequality for $\mathscr{E}_{m,\alpha}(t)$ $(1\leqq\alpha<2)$. This inequality corresponds to the energy equality (3). In

Theorem 2 we treat the asymptotic behavior of $\mathscr{E}_{m,\alpha}(t)$ as $t\to\infty$ for $1\leqq\alpha<2$. In Theorem 3, we show that $\mathscr{T}_{m,\alpha}(\lambda)$ is a continuous and strictly increasing function of $\alpha\in[1,2]$. Thus the time average $\mathscr{T}_{m,\alpha}(\lambda)$ interpolates monotonically and continuously between $\mathscr{T}_{m,1}(\lambda)$ and $\mathscr{T}_{m,2}(\lambda)$.

There exist many papers about the estimates for the solutions of (Volterra) integro-partial differential equations. (Cf. [3], [4], [5], [11].) As compared with these estimates, our energy inequalities are unique in the sense that they correspond to the energy equality for the wave equation. It seems, however, to be difficult to generalize these inequalities to other equations.

The present paper is organized as follows: we state the main results in §2 and prove them in §3.

2. Main results. Let $H^\infty(\mathbf{R}^n)$ be the Fréchet space consisting of C^∞-functions ϕ such that ϕ and all its derivatives belong to $L^2(\mathbf{R}^n)$; $H^\infty(\mathbf{R}^n)$ is equipped with the sequence of norms $\{\|\cdot\|_m\}_{m=0}^\infty$ defined by

$$\|\phi\|_m=\left\{\int_{\mathbf{R}^n}(1+|\xi|^2)^m|\hat\phi(\xi)|^2\,d\xi\right\}^{1/2},$$

where $\hat\phi$ is the Fourier transform of ϕ in $L^2(\mathbf{R}^n)$:

$$\hat\phi(\xi)=\lim_{A\to\infty}\frac{1}{(2\pi)^{n/2}}\int_{\{|x|\leqq A\}}e^{-ix\cdot\xi}\phi(x)\,dx\quad\text{in } L^2(\mathbf{R}^n).$$

Throughout this paper we assume that ϕ and ψ of (IDE) belong to $H^\infty(\mathbf{R}^n)$.

Definition. The function u in $C([0,\infty)$: $H^\infty(\mathbf{R}^n))$ is said to be a solution of (IDE) if it satisfies (IDE) for every $t>0$ and $x\in\mathbf{R}^n$.

Proposition. *For* $1\leqq\alpha\leqq2$, (IDE) *has a unique solution* u_α.

Now we consider the energy inequalities for (IDE). These inequalities deal with $\mathscr{E}_{m,\alpha}(t)$ and $\mathscr{T}_{m,\alpha}(\lambda)$ defined by (1) and (2), respectively. For $1\leqq\alpha<2$, the fractional differential operator $D^{\alpha/2}$ of order $\alpha/2$ is defined by

$$D^{\alpha/2}f(t)=I^{1-(\alpha/2)}f'(t)=\frac{1}{\Gamma(1-\alpha/2)}\int_0^t(t-s)^{-\alpha/2}f'(s)\,ds.$$

For $\alpha=2$, put $D^{\alpha/2}=D^1=(\partial/\partial t)$. The following inequality for the quantity $\mathscr{E}_{m,\alpha}(t)$ corresponds to the energy equality (3).

Theorem 1. *For* $1\leqq\alpha\leqq2$, *the function* $D^{\alpha/2}u_\alpha$ *is well defined as an element of* $C([0,\infty)$: $H^\infty(\mathbf{R}^n))$. *In addition, for each integer* $m\geqq0$, *we have*

$$\mathscr{E}_{m,\alpha}(t)\leqq\|\psi\|_m^2+\|\nabla\phi\|_m^2,\qquad(t>0).\tag{4}$$

The inequality (4) *reduces to the equality for all* $\phi,\psi\in H^\infty(\mathbf{R}^n)$ *if and only if* $\alpha=2$.

Theorem 2 below treats the asymptotic behavior of $\mathscr{E}_{m,\alpha}(t)$ as $t\to\infty$ for $1\leqq\alpha<2$.

Theorem 2. *Let* $m\geqq0$ *be an integer. Suppose that there exists* $\chi\in H^\infty(\mathbf{R}^n)$ *such that* $\hat\psi(\xi)=|\xi|\hat\chi(\xi)$ almost everywhere. *Then, for each* $1\leqq\alpha<2$, *we have*

$$\lim_{t\to\infty}t^\alpha\mathscr{E}_{m,\alpha}(t)=\frac{1}{\Gamma(1-(\alpha/2))^2}(\|\chi\|_m^2+\|\phi\|_m^2).\tag{5}$$

Remark 1. As an example of ψ satisfying the assumption of Theorem 2, we give $\psi(x)=\sum_{j=1}^n a_j\partial\Psi_j/\partial x_j(x)$ for some constants a_j and $\Psi_j\in H^\infty(\mathbf{R}^n)$ $(1\leqq j\leqq n)$. In this case $\hat\chi(\xi)$ is so chosen that

$$\hat\chi(\xi)=\sum_{j=1}^n a_j\frac{i\xi_j}{|\xi|}\hat\Psi_j(\xi)\quad(\xi\neq0),\qquad=0\quad(\xi=0).$$

Clearly this χ belongs to $H^\infty(\mathbf{R}^n)$.

Next we consider the time average $\mathscr{T}_{m,\alpha}(\lambda)$. As for $\mathscr{E}_{m,\alpha}(t)$, we cannot answer whether it is a monotonic function of α because we know no method comparing $\mathscr{E}_{m,\alpha}(t)$ with $\mathscr{E}_{m,\beta}(t)$ for $1 \leqq \alpha < \beta \leqq 2$. However, as for the time average, the Laplace transforms enable us to show the following.

THEOREM 3. *Let $m \geqq 0$ be an integer and $\lambda > 0$. Unless $\phi = \psi \equiv 0$, then $\mathscr{T}_{m,\alpha}(\lambda)$ is a continuous and strictly increasing function of α. That is, $\mathscr{T}_{m,\alpha}(\lambda)$ is continuous in $\alpha \in [1, 2]$, and the following inequalities hold whenever $1 < \alpha < \beta < 2$:*

$$\mathscr{T}_{m,1}(\lambda) < \mathscr{T}_{m,\alpha}(\lambda) < \mathscr{T}_{m,\beta}(\lambda) < \mathscr{T}_{m,2}(\lambda) \equiv \|\psi\|_m^2 + \|\nabla\phi\|_m^2. \tag{6}$$

Thus, there exists a one-to-one correspondence between the two intervals $(1, 2)$ and $(\mathscr{T}_{m,1}(\lambda), \mathscr{T}_{m,2}(\lambda))$.

Theorem 3 shows that the time average $\mathscr{T}_{m,\alpha}(\lambda)$ interpolates monotonically and continuously between $\mathscr{T}_{m,1}(\lambda)$ and $\mathscr{T}_{m,2}(\lambda)$.

3. Proofs. In the following, let $Y_\alpha(t) = Y_\alpha(t, \omega)$ $(1 \leqq \alpha \leqq 2)$ be the stochastic process on a probability space $(\Omega, \mathscr{F}, \mathbf{P})$ with the Mittag-Leffler distributions of order $\alpha/2$:

$$\mathbf{E}\exp\{-sY_\alpha(t)\} = \sum_{k=0}^{\infty} \frac{(-st^{\alpha/2})^k}{\Gamma(1+(k\alpha/2))}, \qquad \operatorname{Re} s \geqq 0,\, t \geqq 0, \tag{7}$$

where $\mathbf{E}$ stands for the expectation. Then $Y_\alpha(t)$ has the continuous path with probability 1. That is, for almost all $\omega \in \Omega$, the functions $t \to Y_\alpha(t, \omega)$ are continuous for all $t \geqq 0$. These facts were proved in [1] (see also [9]). The use of the stochastic process $Y_\alpha(t)$ enables us to simplify the proofs.

Proof of Proposition. For $t \geqq 0$, put

$$U_\alpha(t, \xi) = \hat{\phi}(\xi)\mathbf{E}\cos(|\xi| Y_\alpha(t)) + \hat{\psi}(\xi)\frac{\mathbf{E}\sin(|\xi| Y_\alpha(t))}{|\xi|}. \tag{8}$$

The function $U_\alpha(t, \xi)$ is defined, except ξ belonging to a null set. Since ϕ and ψ are in $H^\infty(\mathbf{R}^n)$, their Fourier transforms $\hat{\phi}$ and $\hat{\psi}$ belong to $L^1(\mathbf{R}^n)$. Thus, $U_\alpha(t, \xi)$ also belongs to $L^1(\mathbf{R}^n)$ for each $t \geqq 0$ because we have by (7) and (8) for almost every ξ,

$$|U_\alpha(t, \xi)| \leqq |\hat{\phi}(\xi)| + |\hat{\psi}(\xi)|\mathbf{E}Y_\alpha(t) = |\hat{\phi}(\xi)| + \frac{t^{\alpha/2}}{\Gamma(1+(\alpha/2))}|\hat{\psi}(\xi)|. \tag{9}$$

Now define $u_\alpha(t, x) (t \geqq 0, x \in \mathbf{R}^n)$ by

$$u_\alpha(t, x) = \frac{1}{(2\pi)^{n/2}} \int_{\mathbf{R}^n} e^{ix\cdot\xi} U_\alpha(t, \xi)\, d\xi. \tag{10}$$

We show that u_α is a unique solution of (IDE). For each integer $m \geqq 0$, it follows from (9), (10), and Parseval's theorem that

$$\|u_\alpha(t)\|_m^2 \leqq 2\|\phi\|_m^2 + \frac{2t^\alpha}{\Gamma(1+(\alpha/2))^2}\|\psi\|_m^2.$$

Further, since $Y_\alpha(t)$ has the continuous path, we get $\|u_\alpha(t) - u_\alpha(s)\|_m \to 0$ as $|t - s| \to 0$ by (8) and the dominated convergence theorem. Thus, u_α belongs to $C([0, \infty): H^\infty(\mathbf{R}^n))$.

Next we show that u_α satisfies (IDE). By (7), we have for every $\xi \in \mathbf{R}^n$ and $t \geqq 0$,

$$\mathbf{E}\cos(|\xi| Y_\alpha(t)) = \sum_{k=0}^{\infty} \frac{(-|\xi|^2 t^\alpha)^k}{\Gamma(1+k\alpha)} \tag{11}$$

and

$$\mathbf{E}\sin(|\xi|\,Y_\alpha(t)) = |\xi|t^{\alpha/2}\sum_{k=0}^{\infty}\frac{(-|\xi|^2t^\alpha)^k}{\Gamma(1+k\alpha+(\alpha/2))}. \tag{12}$$

Thus we can rewrite (8) as

$$U_\alpha(t,\xi)=\hat{\phi}(\xi)\sum_{k=0}^{\infty}\frac{(-|\xi|^2t^\alpha)^k}{\Gamma(1+k\alpha)}+t^{\alpha/2}\hat{\psi}(\xi)\sum_{k=0}^{\infty}\frac{(-|\xi|^2t^\alpha)^k}{\Gamma(1+k\alpha+\alpha/2)}.$$

It is easy to see that $U_\alpha(\cdot,\xi)$ is a unique solution of the integral equation

$$v(t,\xi)=\hat{\phi}(\xi)+\frac{t^{\alpha/2}}{\Gamma(1+(\alpha/2))}\hat{\psi}(\xi)-\frac{|\xi|^2}{\Gamma(\alpha)}\int_0^t (t-s)^{\alpha-1}v(s,\xi)\,ds \tag{13}$$

for almost every $\xi\in\mathbf{R}^n$; therefore, the inverse Fourier transform shows that u_α defined by (10) satisfies (IDE) for every $t>0$ and $x\in\mathbf{R}^n$, so that u_α is a solution of (IDE). The uniqueness of the solution of (IDE) follows from the fact that the integral equation (13) has a unique solution for almost every $\xi\in\mathbf{R}^n$. This completes the proof of the Proposition. □

Remark 2. Let $w(=u_2)$ be the solution of the wave equation. By (8), we have $U_\alpha(t,\xi)=\mathbf{E}\hat{w}(Y_\alpha(t),\xi)$. Thus the solution u_α $(1\leqq\alpha\leqq 2)$ is expressed by

$$u_\alpha(t,x)=\mathbf{E}w(Y_\alpha(t),x).$$

This expression was given by [9] for $n=1$. Another expression was given by [12] for $\psi\equiv 0$.

Proof of Theorem 1. For each $r>0$ we remark that

$$D^{\alpha/2}[1]=0,\qquad D^{\alpha/2}[t^r]=\frac{\Gamma(1+r)}{\Gamma(1+r-(\alpha/2))}t^{r-\alpha/2}.$$

Then, we get, by (11) and (12),

$$\begin{aligned} D^{\alpha/2}[\mathbf{E}\cos(|\xi|\,Y_\alpha(t))] &= \sum_{k=1}^{\infty}\frac{(-|\xi|^2)^k}{\Gamma(1+k\alpha)}D^{\alpha/2}[t^{k\alpha}]\\ &=\sum_{k=1}^{\infty}\frac{(-|\xi|^2)^k}{\Gamma(1+(k-1)\alpha+(\alpha/2))}t^{(k-1)\alpha+(\alpha/2)}\\ &=-|\xi|\mathbf{E}\sin(|\xi|\,Y_\alpha(t)). \end{aligned}\tag{14}$$

The interchange of $D^{\alpha/2}$ and $\sum$ in (14) is permitted, since the third term of (14) converges absolutely. Similarly we get, by (11) and (12),

$$D^{\alpha/2}[\mathbf{E}\sin(|\xi|\,Y_\alpha(t))]=|\xi|\mathbf{E}\cos(|\xi|\,Y_\alpha(t)). \tag{15}$$

We have, by (8), (14), and (15),

$$D^{\alpha/2}U_\alpha(t,\xi)=-|\xi|\hat{\phi}(\xi)\mathbf{E}\sin(|\xi|\,Y_\alpha(t))+\hat{\psi}(\xi)\mathbf{E}\cos(|\xi|\,Y_\alpha(t)).$$

By (10), it is easy to see that $D^{\alpha/2}u_\alpha$ is well defined as an element of $C([0,\infty)\colon H^\infty(\mathbf{R}^n))$, and given by

$$D^{\alpha/2}u_\alpha(t,x)=\frac{1}{(2\pi)^{n/2}}\int_{\mathbf{R}^n}e^{ix\cdot\xi}D^{\alpha/2}U_\alpha(t,\xi)\,d\xi.$$

Similarly

$$\frac{\partial u_\alpha}{\partial x_j}(t,x)=\frac{1}{(2\pi)^{n/2}}\int_{\mathbf{R}^n}e^{ix\cdot\xi}i\xi_jU_\alpha(t,\xi)\,d\xi.$$

It follows from Parseval's theorem that

$$\begin{aligned}\mathscr{E}_{m,\alpha}(t) &\equiv \|D^{\alpha/2}u_\alpha(t)\|_m^2 + \|\nabla u_\alpha(t)\|_m^2 \\ &= \int_{\mathbf{R}^n} [|\xi|^2|\hat{\phi}(\xi)|^2 + |\hat{\psi}(\xi)|^2] \\ &\quad \cdot (1+|\xi|^2)^m [|\mathbf{E}\cos(|\xi|\,Y_\alpha(t))|^2 + |\mathbf{E}\sin(|\xi|\,Y_\alpha(t))|^2]\,d\xi.\end{aligned} \tag{16}$$

Since

$$\begin{aligned}&|\mathbf{E}\cos(|\xi|\,Y_\alpha(t))|^2 + |\mathbf{E}\sin(|\xi|\,Y_\alpha(t))|^2 \\ &\leqq \mathbf{E}\cos^2(|\xi|\,Y_\alpha(t)) + \mathbf{E}\sin^2(|\xi|\,Y_\alpha(t)) = 1 \qquad (t>0,\ \xi\in\mathbf{R}^n),\end{aligned} \tag{17}$$

we obtain the inequality (4). It remains to show that the inequality (4) reduces to the equality for all ϕ, $\psi \in H^\infty(\mathbf{R}^n)$ if and only if $\alpha = 2$. The "if part" is the energy equality (3). The "only if part" is proved as follows. In order that (4) reduces to the equality for all ϕ, $\psi\in H^\infty(\mathbf{R}^n)$, it is necessary that (17) reduces to the equality for all $\xi\in\mathbf{R}^n$, which is clearly equivalent to

$$\cos(|\xi|\,Y_\alpha(t)) = \mathbf{E}\cos(|\xi|\,Y_\alpha(t)), \qquad \sin(|\xi|\,Y_\alpha(t)) = \mathbf{E}\sin(|\xi|\,Y_\alpha(t)) \quad (t\geqq 0)$$

for all $\xi\in\mathbf{R}^n$ with probability 1. Thus,

$$Y_\alpha(t) = \lim_{|\xi|\to 0}\frac{\sin(|\xi|\,Y_\alpha(t))}{|\xi|} = \lim_{|\xi|\to 0}\frac{\mathbf{E}\sin(|\xi|\,Y_\alpha(t))}{|\xi|} = \mathbf{E}Y_\alpha(t) = \frac{t^{\alpha/2}}{\Gamma(1+(\alpha/2))}.$$

To complete the proof of Theorem 1, we need to show that if $Y_\alpha(t) = t^{\alpha/2}/\Gamma(1+(\alpha/2))$ $(t\geqq 0)$ $\mathbf{P}$-a.s., then $\alpha = 2$. This follows from the following lemma. This completes the proof of Theorem 1. □

LEMMA 1. *If there exists a nonrandom continuous function f on* $[0,\infty)$ *such that* $Y_\alpha(t) = f(t)$ *on* $[0,\infty)$ $\mathbf{P}$-a.s., *then* $\alpha = 2$ *and* $f(t) = t$.

Proof. By (7) and the assumption, we have

$$\sum_{k=0}^\infty \frac{(-st^{\alpha/2})^k}{\Gamma(1+(k\alpha/2))} = \mathbf{E}\exp\{-sY_\alpha(t)\} = \exp\{-sf(t)\} = \sum_{k=0}^\infty \frac{(-sf(t))^k}{k!}.$$

Thus

$$\frac{f(t)^k}{k!} = \frac{t^{k\alpha/2}}{\Gamma(1+(k\alpha/2))} \qquad (k=0,1,2,\cdots).$$

Then it is easy to see that $\alpha = 2$, so that $f(t) = t$. This completes the proof of Lemma 1. □

Proof of Theorem 2. Let $1\leqq\alpha<2$. By (11), (12), and [6, chap. 18, § 1 (21), p. 210], we have

$$\lim_{r\to\infty} r^2\,\mathbf{E}\cos(rY_\alpha(1)) = \frac{1}{\Gamma(1-\alpha)} \tag{18}$$

and

$$\lim_{r\to\infty} r\,\mathbf{E}\sin(rY_\alpha(1)) = \frac{1}{\Gamma(1-(\alpha/2))}. \tag{19}$$

For $\alpha = 1$, we interpret that $1/\Gamma(1-\alpha) = 0$. In this case the equality (18) still holds, since $r^2\,\mathbf{E}\cos(rY_1(1)) = r^2\exp\{-r^2\}$. Since $Y_\alpha(t) = t^{\alpha/2}Y_\alpha(1)$ $(t\geqq 0)$ in distribution, we have, by (16) and the assumption of Theorem 2,

$$\begin{aligned}t^\alpha\mathscr{E}_{m,\alpha}(t) &= \int_{\mathbf{R}^n} [|\hat{\chi}(\xi)|^2 + |\hat{\phi}(\xi)|^2](1+|\xi|^2)^m \\ &\quad \cdot [|\xi|^2 t^\alpha |\mathbf{E}\cos(|\xi|t^{\alpha/2}Y_\alpha(1))|^2 + |\xi|^2 t^\alpha |\mathbf{E}\sin(|\xi|t^{\alpha/2}Y_\alpha(1))|^2]\,d\xi.\end{aligned}$$

Then the desired result follows from (18), (19), and the dominated convergence theorem. This completes the proof of Theorem 2. □

To prove Theorem 3, we need a lemma, which was established in [9].

LEMMA 2. *Let $1\leqq\alpha\leqq 2$. For every bounded and continuous function $v(\cdot)$ on $[0,\infty)$, it holds that*

$$\int_0^\infty e^{-\lambda t}\mathbf{E}v(Y_\alpha(t))\,dt=\lambda^{(\alpha/2)-1}\int_0^\infty e^{-y\lambda^{\alpha/2}}v(y)\,dy \qquad (\lambda>0).$$

Proof of Theorem 3. First we show that if $1\leqq\alpha\leqq\beta\leqq 2$, then $\mathcal{T}_{m,\alpha}(\lambda)\leqq\mathcal{T}_{m,\beta}(\lambda)$ for each integer $m\geqq 0$ and $\lambda>0$. Let

$$C_\alpha(t,\xi)=\mathbf{E}\cos(|\xi|Y_\alpha(t)),\qquad S_\alpha(t,\xi)=\mathbf{E}\sin(|\xi|Y_\alpha(t)).$$

By (2) and (16), it holds that

$$\mathcal{T}_{m,\alpha}(\lambda)=\int_{\mathbf{R}^n}(1+|\xi|^2)^m[|\xi|^2|\hat{\phi}(\xi)|^2+|\hat{\psi}(\xi)|^2]A_\alpha(\lambda,\xi)\,d\xi, \tag{20}$$

where

$$A_\alpha(\lambda,\xi)=\lambda^{1/\alpha}\int_0^\infty e^{-t\lambda^{1/\alpha}}[C_\alpha^2(t,\xi)+S_\alpha^2(t,\xi)]\,dt.$$

On the other hand, using Lemma 2, we get, for every $\mu>0$ and $\xi\in\mathbf{R}^n$,

$$\int_0^\infty e^{-\mu t}C_\alpha(t,\xi)\,dt=\int_0^\infty e^{-\mu t}\quad \mathbf{E}C_\beta(Y_{2\alpha/\beta}(t),\xi)\,dt\left(=\frac{\mu^{\alpha-1}}{\mu^\alpha+|\xi|^2}\right),$$

where $Y_{2\alpha/\beta}(t)$ is the stochastic process with the Mittag-Leffler distributions of order α/β (see (7) above). The uniqueness of the Laplace transform leads to

$$C_\alpha(t,\xi)=\mathbf{E}C_\beta(Y_{2\alpha/\beta}(t),\xi).$$

Similarly we get

$$S_\alpha(t,\xi)=\mathbf{E}S_\beta(Y_{2\alpha/\beta}(t),\xi).$$

Thus, by the Cauchy-Schwarz inequality

$$A_\alpha(\lambda,\xi)$$

$$=\lambda^{1/\alpha}\int_0^\infty e^{-t\lambda^{1/\alpha}}[(\mathbf{E}C_\beta(Y_{2\alpha/\beta}(t),\xi))^2+(\mathbf{E}S_\beta(Y_{2\alpha/\beta}(t),\xi))^2]\,dt$$

(21)

$$\leqq\lambda^{1/\alpha}\int_0^\infty e^{-t\lambda^{1/\alpha}}\mathbf{E}[C_\beta^2(Y_{2\alpha/\beta}(t),\xi)+S_\beta^2(Y_{2\alpha/\beta}(t),\xi)]\,dt$$

(22)

$$=\lambda^{1/\alpha}(\lambda^{1/\alpha})^{(\alpha/\beta)-1}\int_0^\infty\exp\{-y(\lambda^{1/\alpha})^{\alpha/\beta}\}[C_\beta^2(y,\xi)+S_\beta^2(y,\xi)]\,dy$$

$$=A_\beta(\lambda,\xi),$$

so that

$$A_\alpha(\lambda,\xi)\leqq A_\beta(\lambda,\xi). \tag{23}$$

Here, in (22), we used Lemma 2. Then the inequality $\mathcal{T}_{m,\alpha}(\lambda)\leqq\mathcal{T}_{m,\beta}(\lambda)$ follows from (20) and (23).

Next, we show that if $\mathcal{T}_{m,\alpha}(\lambda)=\mathcal{T}_{m,\beta}(\lambda)$ $(\alpha \leqq \beta)$, except the trivial case $\phi=\psi\equiv 0$, then $\alpha=\beta$. Here $\lambda>0$ and $m \geqq 0$ are fixed arbitrarily. The case $\mathcal{T}_{m,\alpha}(\lambda)=\mathcal{T}_{m,\beta}(\lambda)$ occurs if and only if (21) reduces to the equality. In order that (21) reduces to the equality, it is necessary that the following equalities hold with probability 1:

$$
\begin{aligned}
C_\beta(Y_{2\alpha/\beta}(t),\xi) &= \mathbf{E}C_\beta(Y_{2\alpha/\beta}(t),\xi) \qquad (t \geqq 0,\ \xi \in \mathbf{R}^n),\\
S_\beta(Y_{2\alpha/\beta}(t),\xi) &= \mathbf{E}S_\beta(Y_{2\alpha/\beta}(t),\xi) \qquad (t \geqq 0,\ \xi \in \mathbf{R}^n).
\end{aligned}
\tag{24}
$$

Remark that

$$
\lim_{|\xi|\to 0}\frac{S_\beta(t,\xi)}{|\xi|}=\lim_{|\xi|\to 0}\frac{\mathbf{E}\sin(|\xi|\,Y_\beta(t))}{|\xi|}=\mathbf{E}\,Y_\beta(t)=\frac{t^{\beta/2}}{\Gamma(1+(\beta/2))}.
$$

Thus we have, by (24),

$$
\frac{(Y_{2\alpha/\beta}(t))^{\beta/2}}{\Gamma(1+(\beta/2))}=\mathbf{E}\frac{(Y_{2\alpha/\beta}(t))^{\beta/2}}{\Gamma(1+(\beta/2))}.
$$

By Lemma 1, we find that $2\alpha/\beta=2$, so that $\alpha=\beta$. This means that if $\alpha<\beta$, then $\mathcal{T}_{m,\alpha}(\lambda)<\mathcal{T}_{m,\beta}(\lambda)$, except the trivial case $\phi=\psi\equiv 0$.

Finally, we show that $\mathcal{T}_{m,\alpha}(\lambda)$ is continuous in $\alpha\in[1,2]$ for every $m\geqq 0$ and $\lambda>0$. For every $t \geqq 0$ and $\xi\in\mathbf{R}^n$, $C_\alpha(t,\xi)$ and $S_\alpha(t,\xi)$ are continuous in $\alpha\in[1,2]$ because the series (11) and (12) converge uniformly in $\alpha\in[1,2]$. Then the desired result follows from (20) and the dominated convergence theorem. This completes the proof of Theorem 3. □

THE GENERALIZED RIEMANN PROBLEM FOR THE MOTION OF ELASTIC STRINGS*

LI TA-TSIEN†, D. SERRE‡, AND ZHANG HAO§

Abstract. It is proven that, except in certain critical cases, the generalized Riemann problem for a nonstrictly hyperbolic system of elastic strings admits a unique local solution in the class of piecewise C^1 functions and in a neighborhood of the origin this solution possesses a structure similar to the similarity solution of the corresponding Riemann problem.

Key words. generalized Riemann problem, elastic strings, nonlinear stability

AMS(MOS) subject classifications. 35L65, 35L67, 73C50

1. Introduction.

Consider the following system for the motion of an elastic string on a plane (cf. [1]-[5])

$$\begin{aligned} &u_t - v_x = 0, \\ &v_t - \left(\frac{\hat{T}(r)}{r}u\right)_x = 0, \end{aligned} \tag{1.1}$$

where $u=(u_1, u_2)^T$, $v=(v_1, v_2)^T$ are unknown vector functions of (t, x), $r=|u|=\sqrt{u_1^2+u_2^2}$, and

$$\hat{T}(r)=\begin{cases} T(r), & r \geqq 1, \\ 0, & 0 \leqq r < 1, \end{cases} \tag{1.2}$$

in which $T(r)$ is a regular and strictly increasing function on $r \geqq 1$ and $T(1)=0$.

In this paper, for the special but important case

$$T(r)=r-1, \tag{1.3}$$

we study the generalized Riemann problem for system (1.1) and prove that, except in certain critical cases, the generalized Riemann problem admits a unique local solution in a class of piecewise continuous and piecewise smooth functions, and in a neighborhood of the origin this solution possesses a structure similar to the similarity solution of the corresponding Riemann problem. Since system (1.1) is strictly hyperbolic only for $r>1$, this shows the nonlinear stability of the solution to the Riemann problem for a system that may degenerate.

The same result can be obtained in a similar way for the motion of an elastic string on a n-dimensional space, $n \geqq 3$.

The case when $T(r)$ is a nonlinear function can be similarly treated: see [8].

2. Preliminaries.

In the domain $0 \leqq r \leqq 1$, system (1.1) simply reduces to

$$\begin{aligned} &u_t - v_x = 0, \\ &v_t = 0. \end{aligned} \tag{2.1}$$

Hence, if the initial data

$$t=0:\ u=u_0(x), \qquad v=v_0(x) \tag{2.2}$$

have a bounded C^1-norm and

$$\operatorname*{Sup}_x r_0(x)=\operatorname*{Sup}_x |u_0(x)|<1. \tag{2.3}$$

We immediately obtain the explicit solution

$$u=u_0(x)+tv_0'(x), \qquad v=v_0(x) \tag{2.4}$$

for $t>0$ suitably small. We point out that system (2.1) is not hyperbolic.

In the domain $r>1$, system (1.1) is strictly hyperbolic. There are four distinct real eigenvalues depending only on r:

$$\lambda_1=:-1<\lambda_2=:-\sqrt{\frac{r-1}{r}}<\lambda_3=:\sqrt{\frac{r-1}{r}}<\lambda_4=:1, \tag{2.5}$$

with the corresponding left eigenvectors

$$\begin{aligned} l_1&=(u,u)=(rp,rp),\\ l_2&=\left(\sqrt{\frac{r-1}{r}}\,w,\ w\right)=(\sqrt{r(r-1)}\,q,\ rq),\\ l_3&=\left(\sqrt{\frac{r-1}{r}}\,w,\ -w\right)=(\sqrt{r(r-1)}\,q,\ -rq),\\ l_4&=(u,-u)=(rp,-rp), \end{aligned} \tag{2.6}$$

and the corresponding right eigenvectors

$$\begin{aligned} r^1&=(u,u)^T=(rp,rp)^T,\\ r^2&=\left(w,\ \sqrt{\frac{r-1}{r}}\,w\right)^T=(rq,\ \sqrt{r(r-1)}\,q)^T,\\ r^3&=\left(-w,\ \sqrt{\frac{r-1}{r}}\,w\right)^T=(-rq,\ \sqrt{r(r-1)}\,q)^T,\\ r^4&=(-u,u)^T=(-rp,rp)^T, \end{aligned} \tag{2.7}$$

where

$$\begin{aligned} &u=rp, \quad p=(p_1,p_2), \quad |p|=1,\\ &w=(-u_2,u_1), \qquad q=(-p_2,p_1). \end{aligned} \tag{2.8}$$

Both the left eigenvectors and the right eigenvectors depend only on u. Moreover, all eigenvalues are linearly degenerate in the sense of P. D. Lax.

On a discontinuous curve $x=x(t)$ ($x(0)=0$), we have the Rankine-Hugoniot's conditions

$$\begin{aligned} &[u]\,dx+[v]\,dt=0,\\ &[v]\,dx+\left[\frac{\hat{T}(r)}{r}u\right]dt=0, \end{aligned} \tag{2.9}$$

where $[u]=u^+-u^-$ is the jump of u, etc.

There are several possibilities.

(1) $0<r^{\pm}\leqq 1$.

Noting (1.2), it follows from (2.9) that $x(t)\equiv 0$ and

$$v^{+}=v^{-}, \tag{2.10}$$

while u may have an arbitrary jump.

(2) $r^{\pm}\geqq 1$ (except $r^{+}=r^{-}=1$).

By means of (1.2), (1.3) we get the following.

(2a) Either

$$r^{+}=r^{-}=:r, \tag{2.11}$$

$$\frac{dx}{dt}=\pm\sqrt{\frac{r-1}{r}}, \tag{2.12}$$

$$[v]=a[p], \tag{2.13}$$

where

$$a=\begin{cases}-\sqrt{r(r-1)}, & \text{for the sign ``+'' in (2.12),}\\ \sqrt{r(r-1)} & \text{for the sign ``$-$'' in (2.12).}\end{cases} \tag{2.14}$$

In this case, $x=x(t)$ is a contact discontinuity of the second or third kind, i.e., corresponding to the second or third (transverse) characteristic family, respectively.

(2b) Or

$$p^{+}=p^{-}=:p, \tag{2.15}$$

$$\frac{dx}{dt}=\pm 1, \tag{2.16}$$

$$[v]=ap, \tag{2.17}$$

where

$$a=\begin{cases}-[r] & \text{for the sign ``+'' in (2.16),}\\ [r] & \text{for the sign ``$-$'' in (2.16),}\end{cases} \tag{2.18}$$

when $r^{\pm}>1$, $x=x(t)$ is a contact discontinuity of the first or fourth kind, i.e., corresponding to the first or fourth (longitudinal) characteristic family, respectively; while, when one of $r^{\pm}$ is equal to 1, $x=x(t)$ is only a lateral contact discontinuity, i.e., a contact discontinuity on only one side.

(3) $r^{+}>1>r^{-}>0$.

In a similar way, we get (2.15), (2.17) with

$$a=\sqrt{(r^{+}-r^{-})(r^{+}-1)} \tag{2.19}$$

and

$$\frac{dx}{dt}=-\sqrt{\frac{r^{+}-1}{r^{+}-r^{-}}}. \tag{2.20}$$

In this case $x=x(t)$ is a lateral shock of the first kind on the right side, which satisfies the P. D. Lax entropy condition

$$\lambda_1(r^{+})=-1<\frac{dx}{dt}<\lambda_2(r^{+})=-\sqrt{\frac{r^{+}-1}{r^{+}}}. \tag{2.21}$$

(4) $r^{-}>1>r^{+}>0$.

Similarly, $x = x(t)$ is a lateral shock of the fourth kind on the left side. On $x = x(t)$ we have (2.15), (2.17) with

$$a = \sqrt{(r^- - r^+)(r^- - 1)} \tag{2.22}$$

and

$$\frac{dx}{dt} = \sqrt{\frac{r^- - 1}{r^- - r^+}}. \tag{2.23}$$

Moreover, the following Lax entropy condition is satisfied:

$$\lambda_3(r^-) = \sqrt{\frac{r^- - 1}{r^-}} < \frac{dx}{dt} < \lambda_4(r^-) = 1. \tag{2.24}$$

3. The Riemann problem. In this section we recall the result (cf. [1]-[4]) on the Riemann problem for system (1.1) with the initial data

$$t = 0\colon\ U = (u, v) = \begin{cases} \hat{U}_l, & x \leqq 0, \\ \hat{U}_r, & x \geqq 0, \end{cases} \tag{3.1}$$

where $\hat{U}_l = (\hat{u}_l, \hat{v}_l)$ and $\hat{U}_r = (\hat{u}_r, \hat{v}_r)$ are constant vectors with $\hat{U}_l \neq \hat{U}_r$.

Case I. Suppose that

$$0 < \hat{r}_l = |\hat{u}_l| < 1, \qquad 0 < \hat{r}_r = |\hat{u}_r| < 1. \tag{3.2}$$

Case IA. If

$$\hat{v}_l = \hat{v}_r, \tag{3.3}$$

then the solution to Riemann problem (1.1), (3.1) is

$$U = (u, v) = \begin{cases} \hat{U}_l, & t \geqq 0, \quad x \leqq 0, \\ \hat{U}_r, & t \geqq 0, \quad x \geqq 0, \end{cases} \tag{3.4}$$

and $x = 0$ is the unique discontinuity.

Case IB. If

$$\hat{v}_l \neq \hat{v}_r, \tag{3.5}$$

then the solution to Riemann problem (1.1), (3.1) can be indicated in Fig. 1, where $\hat{U}_- = (\hat{u}_-, \hat{v}_-)$, $\hat{U}_0 = (\hat{u}_0, \hat{v}_0)$ and $\hat{U}_+ = (\hat{u}_+, \hat{v}_+)$. Moreover,

$$O\hat{A}_1\colon x = -\sqrt{\frac{\hat{r}_- - 1}{\hat{r}_- - \hat{r}_l}}\, t =: \hat{\sigma}_1 t \tag{3.6}$$

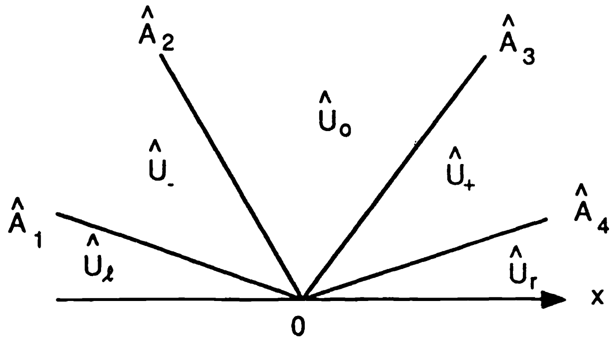

FIG. 1

is a lateral shock of the first kind on the right side, on which we have

$$\hat{p}_- = \hat{p}_l, \tag{3.7}$$

$$\hat{v}_- = \hat{v}_l + \sqrt{(\hat{r}_- - \hat{r}_l)(\hat{r}_- - 1)}\,\hat{p}_l, \tag{3.8}$$

and

$$\hat{r}_- > 1 > \hat{r}_l; \tag{3.9}$$

$$O\hat{A}_2\colon x = -\sqrt{\frac{\hat{r}_0 - 1}{\hat{r}_0}}\,t =: \hat{\sigma}_2 t \tag{3.10}$$

is a contact discontinuity of the second kind, on which we have

$$\hat{r}_0 = \hat{r}_- > 1, \tag{3.11}$$

$$\hat{v}_0 = \hat{v}_- + \sqrt{\hat{r}_0(\hat{r}_0 - 1)}\,(\hat{p}_0 - \hat{p}_-); \tag{3.12}$$

$$O\hat{A}_3\colon x = \sqrt{\frac{\hat{r}_0 - 1}{\hat{r}_0}}\,t =: \hat{\sigma}_3 t \tag{3.13}$$

is a contact discontinuity of the third kind, on which we have

$$\hat{r}_+ = \hat{r}_0 > 1, \tag{3.14}$$

$$\hat{v}_0 = \hat{v}_+ + \sqrt{\hat{r}_0(\hat{r}_0 - 1)}(\hat{p}_+ - \hat{p}_0); \tag{3.15}$$

$$O\hat{A}_4\colon x = \sqrt{\frac{\hat{r}_+ - 1}{\hat{r}_+ - \hat{r}_r}}\,t =: \hat{\sigma}_4 t \tag{3.16}$$

is a lateral shock of the fourth kind on the left side, on which we have

$$\hat{p}_+ = \hat{p}_r, \tag{3.17}$$

$$\hat{v}_+ = \hat{v}_r - \sqrt{(\hat{r}_+ - \hat{r}_r)(\hat{r}_+ - 1)}\,\hat{p}_r \tag{3.18}$$

and

$$\hat{r}_+ > 1 > \hat{r}_r. \tag{3.19}$$

In this case, system (1.1) is strictly hyperbolic only for the solution on the angular domain between $O\hat{A}_1$ and $O\hat{A}_4$.

Case II. Suppose that

$$\hat{r}_l = |\hat{u}_l| > 1, \qquad 0 < \hat{r}_r = |\hat{u}_r| < 1. \tag{3.20}$$

Case IIA. If

$$\hat{v}_l + (1 - \hat{r}_l)\hat{p}_l = \hat{v}_r, \tag{3.21}$$

then the solution to Riemann problem (1.1), (3.1) can be shown in Fig. 2, where $O\hat{A}_1$: $x = -t$ is a lateral contact discontinuity on the left side and $\hat{U}_- = (\hat{u}_-, \hat{v}_-) = (\hat{p}_l, \hat{v}_r)$.

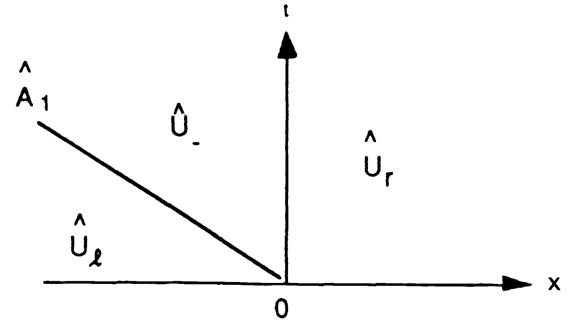

FIG. 2

In this case we have two discontinuities $x=0$ and $x=-t$; moreover, only for the solution on the left side of $O\hat{A}_1$, system (1.1) is strictly hyperbolic.

Case IIB. If

$$\hat{v}_l+(1-\hat{r}_l)\hat{p}_l\neq\hat{v}_r, \tag{3.22}$$

then the solution to the Riemann problem can be still indicated in Fig. 1. Different from Case IB, however,

$$O\hat{A}_1: \quad x=-t \tag{3.23}$$

is a contact discontinuity of first kind, on which we have (3.7),

$$\hat{v}_-=\hat{v}_l+(\hat{r}_--\hat{r}_l)\hat{p}_l \tag{3.24}$$

and

$$\hat{r}_->1. \tag{3.25}$$

In this case, system (1.1) is strictly hyperbolic only on the left side of $O\hat{A}_4$.

Case III. Suppose that

$$0<\hat{r}_l=|\hat{u}_l|<1, \qquad \hat{r}_r=|\hat{u}_r|>1. \tag{3.26}$$

In this case, the situation is completely similar to Case II.

Case IV. Suppose that

$$\hat{r}_l=|\hat{u}_l|>1, \qquad \hat{r}_r=|\hat{u}_r|>1. \tag{3.27}$$

Case IVA. If

$$\hat{v}_l+(1-\hat{r}_l)\hat{p}_l=\hat{v}_r-(1-\hat{r}_r)\hat{p}_r, \tag{3.28}$$

then the solution to the Riemann problem can be shown in Fig. 3, where $O\hat{A}_1$: $x=-t$ and $O\hat{A}_4$: $x=t$ are lateral contact discontinuities on the left side and on the right side, respectively; moreover, $\hat{U}_-=(\hat{u}_-,\hat{v}_-)=(\hat{p}_l,\hat{v}_l+(1-\hat{r}_l)\hat{p}_l)$ and $\hat{U}_+=(\hat{u}_+,\hat{v}_+)=(\hat{p}_r,\hat{v}_r-(1-\hat{r}_r)\hat{p}_r)$.

In this case we have three discontinuities $x=0$ and $x=\pm t$. System (1.1) is strictly hyperbolic only on the left side of $O\hat{A}_1$ and on the right side of $O\hat{A}_4$.

Case IVB. If

$$\hat{v}_l+(1-\hat{r}_l)\hat{p}_l\neq\hat{v}_r-(1-\hat{r}_r)\hat{p}_r, \tag{3.29}$$

then the solution to the Riemann problem can be still indicated in Fig. 1. Different from Case IB, however, not only $O\hat{A}_1$ is a contact discontinuity of the first kind, on which we have (3.7) and (3.23)-(3.25), but also

$$O\hat{A}_4: \ x=t \tag{3.30}$$

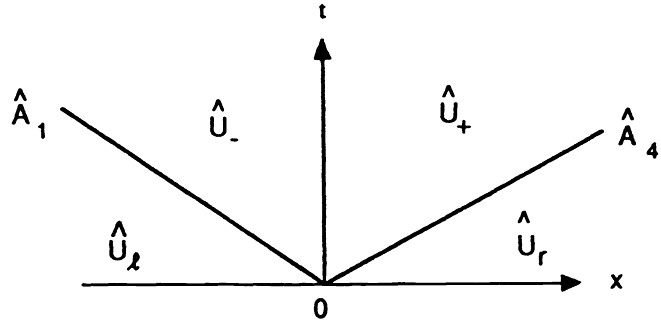

FIG. 3

is a contact discontinuity of fourth kind, on which we have (3.17),

$$\hat{v}_+ = \hat{v}_r - (\hat{r}_+ - \hat{r}_r)\hat{p}_r \tag{3.31}$$

and

$$\hat{r}_+ > 1. \tag{3.32}$$

In this case, system (1.1) is strictly hyperbolic on the whole upper plane $t \geqq 0$.

4. The generalized Riemann problem—Case I. We now consider the generalized Riemann problem for system (1.1) with the following initial data

$$t=0\colon U=(u,v)=\begin{cases} \bar{U}_l(x), & x\leqq 0, \\ \bar{U}_r(x), & x\geqq 0, \end{cases} \tag{4.1}$$

where $\bar{U}_l(x)=(\bar{u}_l(x), \bar{v}_l(x))$ and $\bar{U}_r(x)=(\bar{u}_r(x), \bar{v}_r(x))$ are regular vector functions with bounded C^1 norm, $\bar{r}_l(x)$, $\bar{r}_r(x)>0$, and $\hat{U}_l=(\hat{u}_l, \hat{v}_l) \neq \hat{U}_r=(\hat{u}_r, \hat{v}_r)$, where

$$\hat{U}_l = U_l(0), \qquad \hat{U}_r = U_r(0). \tag{4.2}$$

In this section we first study the following case.

Case I. Suppose that

$$\operatorname*{Sup}_{x\leqq 0} \bar{r}_l(x) = \operatorname*{Sup}_{x\leqq 0} |\bar{u}_l(x)| < 1, \qquad \operatorname*{Sup}_{x\geqq 0} \bar{r}_r(x) = \operatorname*{Sup}_{x\geqq 0} |\bar{u}_r(x)| < 1. \tag{4.3}$$

Case IA. If (3.3) holds, then, by means of (2.4), the solution to the generalized Riemann problem is

$$U=(u,v)=\begin{cases} (\bar{u}_l(x)+t\bar{v}_l'(x), \bar{v}_l(x)), & t\geqq 0 \text{ small}, \quad x\leqq 0, \\ (\bar{u}_r(x)+t\bar{v}_r'(x), \bar{v}_r(x)), & t\geqq 0 \text{ small}, \quad x\geqq 0. \end{cases} \tag{4.4}$$

$x=0$ is the unique discontinuity, and (4.4) possesses a structure similar to (3.4) of the corresponding Riemann problem in a neighborhood of the origin.

Case IB. If (3.5) holds, we still hope to prove that the generalized Riemann problem (1.1), (4.1) admits a unique local solution in a class of piecewise continuous and piecewise smooth functions, and in a neighborhood of the origin this solution has a structure similar to that of the corresponding Riemann problem. In other words, we want to obtain a unique local solution to the generalized Riemann problem (1.1), (4.1) as shown in Fig. 4, where

$$OA_i\colon x=x_i(t) \quad (x_i(0)=0) \quad (i=1,2,3,4) \tag{4.5}$$

are free boundaries.

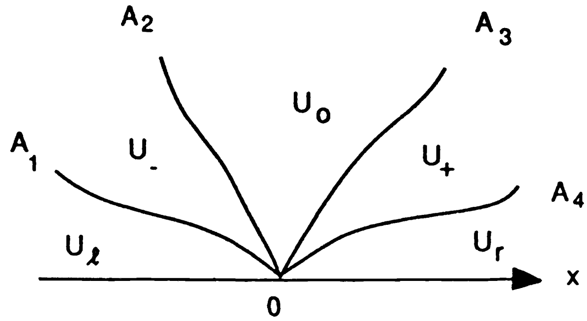

FIG. 4

By (2.4), on the domain

$$D_l(\delta)=\{(t,x)\,|\,0\leqq t\leqq \delta,\ x\leqq x_1(t)\} \tag{4.6}$$

($\delta>0$ small), the solution is known:

$$\begin{aligned} U_l(t,x)&=(u_l(t,x),\ v_l(t,x))=(r_lp_l(t,x),\ v_l(t,x))\\ &=(\bar{u}_l(x)+t\bar{v}_l'(x),\ \bar{v}_l(x)). \end{aligned} \tag{4.7}$$

Similarly, on the domain

$$D_r(\delta)=\{(t,x)|0\leqq t\leqq \delta,\ x\geqq x_4(t)\} \tag{4.8}$$

($\delta>0$ small), the solution is

$$\begin{aligned} U_r(t,x)&=(u_r(t,x),\ v_r(t,x))=(r_rp_r(t,x),\ v_r(t,x))\\ &=(\bar{u}_r(x)+t\bar{v}_r'(x),\ \bar{v}_r(x)). \end{aligned} \tag{4.9}$$

Obviously, we have

$$U_l(0,0)=\hat{U}_l,\qquad U_r(0,0)=\hat{U}_r. \tag{4.10}$$

On the domains

$$D_-(\delta)=\{(t,x)|0\leqq t\leqq \delta,\ x_1(t)\leqq x\leqq x_2(t)\}, \tag{4.11}$$

$$D_0(\delta)=\{(t,x)|0\leqq t\leqq \delta,\ x_2(t)\leqq x\leqq x_3(t)\}, \tag{4.12}$$

$$D_+(\delta)=\{(t,x)|0\leqq t\leqq \delta,\ x_3(t)\leqq x\leqq x_4(t)\} \tag{4.13}$$

($\delta>0$ small), the solution is denoted, respectively, by $U_-(t,x)=(u_-(t,x),\ v_-(t,x))=(r_-p_-(t,x),\ v_-(t,x))$, $U_0(t,x)=(u_0(t,x),\ v_0(t,x))=(r_0p_0(t,x),\ v_0(t,x))$, and $U_+(t,x)=(u_+(t,x),\ v_+(t,x))=(r_+p_+(t,x),\ v_+(t,x))$. All $U_-(t,x)$, $U_0(t,x)$, and $U_+(t,x)$ are unknown regular solutions to system (1.1); moreover,

$$U_-(0,0)=\hat{U}_-,\quad U_0(0,0)=\hat{U}_0,\quad U_+(0,0)=\hat{U}_+, \tag{4.14}$$

where $\hat{U}_-$, $\hat{U}_0$, and $\hat{U}_+$ are furnished by the solution to the corresponding Riemann problem.

Furthermore, $OA_1(x=x_1(t))$ is a lateral shock of the first kind on the right side, on which we have

$$\frac{dx_1(t)}{dt}=-\sqrt{\frac{r_--1}{r_--r_l}},\qquad x_1(0)=0, \tag{4.15}$$

$$p_-=p_l, \tag{4.16}$$

$$v_-=v_l+\sqrt{(r_--r_l)(r_--1)}\,p_l, \tag{4.17}$$

$$r_->1>r_l>0. \tag{4.18}$$

$OA_2(x=x_2(t))$ is a contact discontinuity of the second kind, on which we have

$$\frac{dx_2(t)}{dt}=-\sqrt{\frac{r_0-1}{r_0}},\qquad x_2(0)=0, \tag{4.19}$$

$$r_0=r_->1, \tag{4.20}$$

$$v_0=v_-+\sqrt{r_0(r_0-1)}(p_0-p_-). \tag{4.21}$$

$OA_3(x=x_3(t))$ is a contact discontinuity of the third kind, on which we have

$$\frac{dx_3(t)}{dt}=\sqrt{\frac{r_0-1}{r_0}},\qquad x_3(0)=0, \tag{4.22}$$

$$r_+=r_0>1, \tag{4.23}$$

$$v_0=v_++\sqrt{r_0(r_0-1)}(p_+-p_0). \tag{4.24}$$

$OA_4(x=x_4(t))$ is a lateral shock of the fourth kind on the left side, on which we have

$$\frac{dx_4(t)}{dt}=\sqrt{\frac{r_+-1}{r_4-r_r}},\qquad x_4(0)=0, \tag{4.25}$$

$$p_+=p_r, \tag{4.26}$$

$$v_+=v_r-\sqrt{(r_+-r_r)(r_+-1)}\,p_r, \tag{4.27}$$

$$r_+>1>r_r>0. \tag{4.28}$$

Noticing (4.10) and (4.14), it follows from (4.15), (4.19), (4.22), and (4.25) that

$$\frac{dx_i}{dt}(0)=\hat{\sigma}_i\qquad (i=1,2,3,4), \tag{4.29}$$

where $\hat{\sigma}_i$ $(i=1,2,3,4)$ are also furnished by the solution to the corresponding Riemann problem.

Since $U_l(t,x)$ and $U_r(t,x)$ are known, in order to get the solution we have to solve the free boundary problem (1.1) and (4.14)-(4.28) on the fan-shaped domain $D(\delta)=D_-(\delta)\cup D_0(\delta)\cup D_+(\delta)(\delta>0$ small). According to the result on the Riemann problem, by continuity system (1.1) is strictly hyperbolic on $D(\delta)$ and the inequalities in (4.18), (4.20), (4.23), and (4.28) are always satisfied for $\delta>0$ suitably small.

Let

$$L=\begin{pmatrix} l_1\\ l_2\\ l_3\\ l_4\end{pmatrix} \tag{4.30}$$

be the 4×4 matrix composed of the left eigenvectors, and denote

$$\begin{aligned} V^-&=L(\hat{u}_-)U_-=(V_1^-,V_2^-,V_3^-,V_4^-),\\ V^0&=L(\hat{u}_0)U_0=(V_1^0,V_2^0,V_3^0,V_4^0),\\ V^+&=L(\hat{u}_+)U_+=(V_1^+,V_2^+,V_3^+,V_4^+).\end{aligned} \tag{4.31}$$

Noting that $U_l(t,x)$ and $U_r(t,x)$ are known, we can verify that boundary conditions (4.16), (4.17) on $x=x_1(t)$, (4.20), (4.21) on $x=x_2(t)$, (4.23), (4.24) on $x=x_3(t)$, and (4.26), (4.27) on $x=x_4(t)$ can be rewritten, respectively, as

$$V_i^-=f_i(t,x,V_1^-)\quad (i=2,3,4)\quad \text{on } x=x_1(t), \tag{4.32}$$

$$\left.\begin{aligned} &V_1^-=f_1(V_2^-,V_3^-,V_4^-,V_1^0,V_2^0),\\ &V_i^0=g_i(V_2^-,V_3^-,V_4^-,V_1^0,V_2^0)\quad (i=3,4)\end{aligned}\right\}\quad \text{on } x=x_2(t), \tag{4.33}$$

$$\left.\begin{aligned} &V_i^0=g_i(V_3^0,\,V_4^0,\,V_1^+,\,V_2^+,\,V_3^+)\quad (i=1,2)\\ &V_4^+=h_4(V_3^0,\,V_4^0,\,V_1^+,\,V_2^+,\,V_3^+)\end{aligned}\right\} \text{on } x=x_3(t), \tag{4.34}$$

$$V_i^+=h_i(t,x,V_4^+),\quad (i=1,2,3)\quad \text{on } x=x_4(t). \tag{4.35}$$

At the point $t=x=0$, $V^-=\hat{V}^-=: l(\hat{u}_-)\hat{U}_-$, $V_0=\hat{V}^0=: l(\hat{u}_0)\hat{U}_0$, and $V^+=\hat{V}^+=: l(\hat{u}_+)\hat{U}_+$, we form the following Jacobi matrix:

$$\Theta=\frac{\partial(f_1,\cdots,f_4,g_1,\cdots,g_4,h_1,\cdots,h_4)}{\partial(V_1^-,\cdots,V_4^-,V_1^0,\cdots,V_4^0,V_1^+,\cdots,V_4^+)}. \tag{4.36}$$

Set

$$\begin{aligned}
&\tau_1^-=\frac{\lambda_1(\hat{u}_-)-\hat{\sigma}_1}{\lambda_1(\hat{u}_-)-\hat{\sigma}_2}, && \tau_i^-=\frac{\lambda_i(\hat{u}_-)-\hat{\sigma}_2}{\lambda_i(\hat{u}_-)-\hat{\sigma}_1}\quad (i=2,3,4),\\
&\tau_i^0=\frac{\lambda_i(\hat{u}_0)-\hat{\sigma}_2}{\lambda_i(\hat{u}_0)-\hat{\sigma}_3}\quad (i=1,2), && \tau_i^0=\frac{\lambda_i(\hat{u}_0)-\hat{\sigma}_3}{\lambda_i(\hat{u}_0)-\hat{\sigma}_2}\quad (i=3,4),\\
&\tau_i^+=\frac{\lambda_i(\hat{u}_+)-\hat{\sigma}_3}{\lambda_i(\hat{u}_+)-\hat{\sigma}_4}\quad (i=1,2,3), && \tau_4^+=\frac{\lambda_4(\hat{u}_+)-\hat{\sigma}_4}{\lambda_4(\hat{u}_+)-\hat{\sigma}_3}.
\end{aligned} \tag{4.37}$$

Obviously, we have

$$0\leqq \tau_i^-,\,\tau_i^0,\,\tau_i^+<1\qquad (i=1,2,3,4) \tag{4.38}$$

and

$$\tau_2^-=\tau_2^0=\tau_3^0=\tau_3^+=0. \tag{4.39}$$

Let

$$\Theta_1=\Theta\tau, \tag{4.40}$$

where

$$\tau=\operatorname{diag}(\tau_1^-,\cdots,\tau_4^-,\tau_1^0,\cdots,\tau_4^0,\tau_1^+,\cdots,\tau_4^+\}. \tag{4.41}$$

According to the result in [6], [7], if

$$\|\Theta_1\|_{\min}<1, \tag{4.42}$$

then the free boundary problem under consideration admits a unique piecewise C^1 solution on $D(\delta)$ ($\delta>0$ small), and this solution has the desired structure. Here, for an $n\times n$ matrix $A=(a_{ij})$, define

$$\|A\|=\operatorname*{Max}_{i=1,\cdots,n}\sum_{j=1}^{n}|a_{ij}| \tag{4.43}$$

and

$$\|A\|_{\min}=\operatorname{Inf}\{\|\gamma A\gamma^{-1}\|;\ \gamma=\operatorname{diag}\{\gamma_i\},\ \gamma_i\neq 0,\ i=1,\cdots,n\}. \tag{4.44}$$

Noting that at the point $t=x=0$, $V^-=\hat{V}^-$, $V^0=\hat{V}^0$, and $V^+=\hat{V}^+$, we have

$$\frac{\partial f_2}{\partial V_1^-}=\frac{\partial f_3}{\partial V_1^-}=\frac{\partial h_2}{\partial V_4^+}=\frac{\partial h_3}{\partial V_4^+}=\frac{\partial f_1}{\partial V_2^0}=\frac{\partial g_4}{\partial V_2^0}=\frac{\partial g_1}{\partial V_3^0}=\frac{\partial h_4}{\partial V_3^0}=0. \tag{4.45}$$

By dropping the row (or column) composed of null elements and the corresponding column (or row) in Θ_1, we obtain the following 6×6 matrix:

$$(4.46)\qquad \Theta_2=\begin{bmatrix} 0 & \tau_4^-\dfrac{\partial f_1}{\partial V_4^-} & \tau_1^0\dfrac{\partial f_1}{\partial V_1^0} & 0 & 0 & 0 \\ \tau_1^-\dfrac{\partial f_4}{\partial V_1^-} & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \tau_4^0\dfrac{\partial g_1}{\partial V_4^0} & \tau_1^+\dfrac{\partial g_1}{\partial V_1^+} & 0 \\ 0 & \tau_4^-\dfrac{\partial g_4}{\partial V_4^-} & \tau_1^0\dfrac{\partial g_4}{\partial V_1^0} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & \tau_4^+\dfrac{\partial h_1}{\partial V_4^+} \\ 0 & 0 & 0 & \tau_4^0\dfrac{\partial h_4}{\partial V_4^0} & \tau_1^+\dfrac{\partial h_4}{\partial V_1^+} & 0 \end{bmatrix}.$$

By definition (4.44), it is easy to see (cf. Lemma 5.4 in Chapter 2 of [6]) that (4.42) is equivalent to

$$(4.47)\qquad \|\Theta_2\|_{\min}<1.$$

Moreover, noting that all elements except a nondiagonal element are zero in the second and fifth rows, by definition (4.44), it is easy to see (cf. Lemma 5.5 in Chapter 2 of [6]) that (4.47) is equivalent to

$$(4.48)\qquad \|\Theta_3\|_{\min}<1,$$

where

$$(4.49)\qquad \Theta_3=\begin{pmatrix} \tau_1^-\tau_4^-\dfrac{\partial f_1}{\partial V_4^-}\dfrac{\partial f_4}{\partial V_1^-} & \tau_1^0\dfrac{\partial f_1}{\partial V_1^0} & 0 & 0 \\ 0 & 0 & \tau_4^0\dfrac{\partial g_1}{\partial V_4^0} & \tau_1^+\tau_4^+\dfrac{\partial g_1}{\partial V_1^+}\dfrac{\partial h_1}{\partial V_4^+} \\ \tau_1^-\tau_4^-\dfrac{\partial g_4}{\partial V_4^-}\dfrac{\partial f_4}{\partial V_1^-} & \tau_1^0\dfrac{\partial g_4}{\partial V_1^0} & 0 & 0 \\ 0 & 0 & \tau_4^0\dfrac{\partial h_4}{\partial V_4^0} & \tau_1^+\tau_4^+\dfrac{\partial h_4}{\partial V_1^+}\dfrac{\partial h_1}{\partial V_4^+} \end{pmatrix}.$$

Set

$$(4.50)\qquad e=\sqrt{\frac{\hat r_0-1}{\hat r_0}},\quad f_l=\sqrt{\frac{\hat r_0-1}{\hat r_0-\hat r_l}},\quad f_r=\sqrt{\frac{\hat r_0-1}{\hat r_0-\hat r_r}}$$

and

$$(4.51)\qquad \begin{aligned} C_\pm&=\hat p_0\cdot\hat p_\pm,\\ A_\pm&=2+(1-C_\pm)\frac{(1-e)^2}{2e}. \end{aligned}$$

By (3.9), (3.11), (3.14), and (3.19) we have

$$(4.52)\qquad 0<e<f_l<1,\qquad 0<e<f_r<1$$

and

$$|C_\pm| \leqq 1, \qquad A_\pm \geqq 2. \tag{4.53}$$

Through a direct calculation we can determine the following quantities in Θ_3:

$$\begin{aligned}
&\frac{\partial f_1}{\partial V_4^-} = -\frac{(1-C_-)(1+e)^2}{2A_- e}, \qquad \frac{\partial f_1}{\partial V_1^0} = \frac{2}{A_-},\\
&\frac{\partial g_4}{\partial V_4^-} = \frac{2C_-}{A_-}, \qquad \frac{\partial g_4}{\partial V_1^0} = -\frac{A_- - 2}{A_-},\\
&\frac{\partial g_1}{\partial V_4^0} = -\frac{A_+ - 2}{A_+}; \qquad \frac{\partial g_1}{\partial V_1^+} = \frac{2C_+}{A_+},\\
&\frac{\partial h_4}{\partial V_4^0} = \frac{2}{A_+}, \qquad \frac{\partial h_4}{\partial V_1^+} = -\frac{(1-C_+)(1+e)^2}{2A_+ e},\\
&\frac{\partial f_4}{\partial V_1^-} = -\frac{(1-f_l)^2}{(1+f_l)^2}, \qquad \frac{\partial h_1}{\partial V_4^+} = -\frac{(1-f_r)^2}{(1+f_r)^2}.
\end{aligned} \tag{4.54}$$

Hence, noticing (4.38), (4.52), and (4.53) we obtain

$$\|\Theta_3\| < 1, \tag{4.55}$$

which implies (4.48). In fact, we have

$$\begin{aligned}
\left|\tau_1^- \tau_4^- \frac{\partial f_1}{\partial V_4^-}\frac{\partial f_4}{\partial V_1^-}\right| + \left|\tau_1^0 \frac{\partial f_1}{\partial V_1^0}\right| &< \left|\frac{\partial f_1}{\partial V_4^-}\right| \left|\frac{\partial f_4}{\partial V_1^-}\right| + \left|\frac{\partial f_1}{\partial V_1^0}\right|\\
&= \frac{1}{A_-}\left[(1-C_-)\frac{(1+e)^2}{(1+f_l)^2}\frac{(1-f_l)^2}{2e} + 2\right]\\
&\leqq \frac{1}{A_-}\left[(1-C_-)\frac{(1-f_l)^2}{2} + 2\right]\\
&\leqq \frac{1}{A_-}\left[(1-C_-)\frac{(1-e)^2}{2e} + 2\right] = 1,
\end{aligned}$$

$$\begin{aligned}
\left|\tau_4^0 \frac{\partial g_1}{\partial V_4^0}\right| + \left|\tau_1^+ \tau_4^+ \frac{\partial g_1}{\partial V_1^+}\frac{\partial h_1}{\partial V_4^+}\right| &\leqq \left|\frac{\partial g_1}{\partial V_4^0}\right| + \left|\frac{\partial g_1}{\partial V_1^+}\right| \left|\frac{\partial h_1}{\partial V_4^+}\right|\\
&= \frac{1}{A_+}\left[(1-C_-)\frac{(1-e)^2}{2e} + 2|C_+|\frac{(1-f_r)^2}{(1+f_r)}\right]\\
&< \frac{1}{A_+}\left[(1-C_+)\frac{(1-e)^2}{2e} + 2\right] = 1,
\end{aligned}$$

and similarly

$$\left|\tau_1^- \tau_4^- \frac{\partial g_4}{\partial V_4^-}\frac{\partial f_4}{\partial V_1^-}\right| + \left|\tau_1^0 \frac{\partial g_4}{\partial V_1^0}\right| < 1, \qquad \left|\tau_4^0 \frac{\partial h_4}{\partial V_4^0}\right| + \left|\tau_1^+ \tau_4^+ \frac{\partial h_4}{\partial V_1^+}\frac{\partial h_1}{\partial V_4^+}\right| < 1.$$

Thus, for Case I we reach the desired conclusion mentioned in the Introduction.

5. The generalized Riemann problem—Cases IIB (IIIB) and IVB.

We now consider the following case.

Case II. Suppose that

$$\operatorname*{Inf}_{x \leqq 0} \bar{r}_l(x) = \operatorname*{Inf}_{x \leqq 0} |\bar{u}_l(x)| > 1, \qquad \operatorname*{Sup}_{x \geqq 0} \bar{r}_r(x) = \operatorname*{Sup}_{x \geqq 0} |\bar{u}_r(x)| < 1. \tag{5.1}$$

Case IIB. If (3.22) holds, we still hope to get a result similar to that in § 4. However, it is different from Case IB that in this case

$$OA_1\colon x=x_1(t)\equiv -t \tag{5.2}$$

is a given contact discontinuity of first kind, on which, instead of (4.16)-(4.18), we have

$$p_-=p_l, \tag{5.3}$$

$$v_-=v_l+(r_--r_l)p_l, \tag{5.4}$$

$$r_l,\ r_->1. \tag{5.5}$$

On the left side of OA_1 the solution $U_l(t,x)=(u_l(t,x),\ v_l(t,x))$ can be obtained by solving the Cauchy problem for system (1.1) with the initial data $\bar{U}_l(x)=(\bar{u}_l(x),\ \bar{v}_l(x))$ on $x\leqq 0$. Boundary conditions (5.3), (5.4) on OA_1 can be also rewritten in the form of (4.32), and at the point $t=x=0$, $V_1^-=\hat{V}_1^-$ we have

$$\frac{\partial f_i}{\partial V_1^-}=0 \qquad (i=2,3,4). \tag{5.6}$$

Moreover, we have

$$\tau_1^-=0. \tag{5.7}$$

Thus, the matrix Θ_3 introduced in § 4 reduces to a simpler form, in which the first column is composed of null elements; then we still have (4.55). Case III is completely similar.

Case IV. Suppose that

$$\operatorname*{Inf}_{x\leqq 0}\bar{r}_l(x)=\operatorname*{Inf}_{x\leqq 0}|\bar{u}_l(x)|>1, \qquad \operatorname*{Inf}_{x\geqq 0}\bar{r}_r(x)=\operatorname*{Inf}_{x\geqq 0}|\bar{u}_r(x)|>1. \tag{5.8}$$

Case IVB. If (3.29) holds, then it is different from Case IB that not only OA_1 is a given contact discontinuity of the first kind, on which we have (5.2)-(5.5), but also

$$OA_4\colon x=x_4(t)\equiv t \tag{5.9}$$

is a given contact discontinuity of the fourth kind, on which instead of (4.26)-(4.28) we have

$$p_+=p_r, \tag{5.10}$$

$$v_+=v_r-(r_+-r_r)p_r, \tag{5.11}$$

$$r_r,\ r_+>1. \tag{5.12}$$

On the right side of OA_4 the solution $U_r(t,x)=(u_r(t,x),\ v_r(t,x))$ can be obtained by solving the Cauchy problem for system (1.1) with the initial data $\bar{U}_r(x)=(\bar{u}_r(x),\ \bar{v}_r(x))$ on $x\geqq 0$. Boundary conditions (5.10), (5.11) on OA_4 can be still rewritten in the form of (4.35), and at the point $t=x=0$, $V_4^+=\hat{V}_4^+$ we have

$$\frac{\partial h_i}{\partial V_4^+}=0 \qquad (i=1,2,3). \tag{5.13}$$

Moreover, we have

$$\tau_4^+=0. \tag{5.14}$$

Thus, the matrix Θ_3 introduced in § 4 now reduces to a much simpler form, in which the first and fourth columns are all composed of null elements; then we still get (4.55).

The desired conclusion is then obtained also for Cases IIB (IIIB) and IVB.

6. Remarks on Cases IIA (IIIA) and IVA. In general, the preceding result is no longer true for the critical Case IIA (IIIA) and IVA, unless the initial data (4.1) satisfy certain conditions of compatibility.

We take Case IIA as an example. In this case (3.21) holds, If the generalized Riemann problem under consideration admits a unique local solution that has a structure similar to that given in Fig. 2 in a neighborhood of the origin, then the solution should be shown as in Fig. 5, where

$$OA_1\colon x=-t \tag{6.1}$$

is a lateral contact discontinuity of the first kind on the left side, while $x=0$ is another discontinuity.

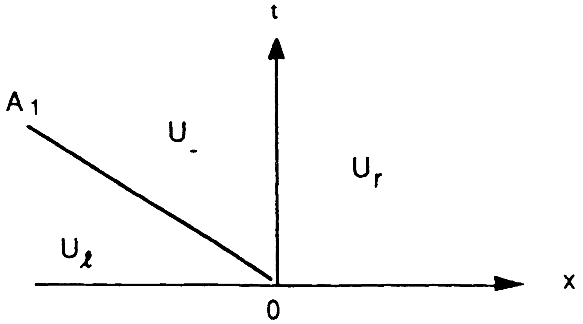

FIG. 5

On the left side of OA_1 the local solution $U_l(t, x)=(u_l(t, x),\ v_l(t, x))$ is still obtained by solving the Cauchy problem for system (1.1) with the initial data $\bar{U}_l(x)$. On the right side of the t-axis the local solution is given by (4.9). Furthermore, on the domain

$$D_-(\delta)=\{(t, x)|0\leqq t\leqq \delta,\ -t\leqq x\leqq 0\}, \tag{6.2}$$

the solution $U_-(t, x)=(u_-(t, x),\ v_-(t, x))$ should satisfy

$$r_-(t, x)=|u_-(t, x)|\leqq 1 \quad \forall (t, x)\in D_-(\delta) \tag{6.3}$$

and the following boundary conditions:

$$v_-=\bar{v}_r \quad \text{on } x=0, \tag{6.4}$$

$$\begin{matrix} u_-=p_l \\ v_-=v_l+(1-r_l)p_l \end{matrix} \quad \text{on } x=-t. \tag{6.5}$$

Then it follows from system (2.1) that on the domain $D_-(\delta)$,

$$\begin{aligned} v_-&=v_-(x)=: v_l(-x, x)+(1-r_l(-x, x))p_l(-x, x), \\ u_-&=u_-(t, x)=: p_l(-x, x)+v'_-(x)(t+x). \end{aligned} \tag{6.6}$$

Thus, in order to satisfy (6.3), certain conditions of compatibility for $\bar{U}_l(x)=(\bar{u}_l(x),\ \bar{v}_l(x))$ should be demanded. In fact, noting that

$$r_-^2(t, x)=1+2p_l(-x, x)\cdot v'_-(x)(t+x)+|v'_-(x)|^2(t+x)^2,$$

by means of system (1.1), it is easy to see that if the initial data $\bar{U}_l(x)$ satisfy the condition

$$\bar{p}_l(0)\cdot \bar{v}'_l(0)-\bar{r}'_l(0)<0, \tag{6.7}$$

then we have (6.3), provided that $\delta>0$ is suitably small.

If (6.7) does not hold, it still might be possible to construct a solution with four waves $x=x_i(t)$ $(i=1,2,3,4)$, some of which are tangent to $x=0$ at the origin. In this situation we guess that the solution to the Riemann problem may be still stable in the L^1 norm.

DIMENSIONALITY OF INVARIANT SETS FOR NONAUTONOMOUS PROCESSES*

TEPPER L. GILL† AND W. W. ZACHARY†

Abstract. The existence of global attractors and estimates of their dimensions have been investigated by various authors for a number of dissipative nonlinear partial differential equations which are either autonomous or are subject to time-periodic forcing. In the presence of more general forcing (e.g., almost periodic but not periodic), the usual estimates of the dimensionality of global attractors in terms of uniform (or global) Lyapunov exponents are not valid. This article investigates the estimation of Hausdorff and fractal dimensions of invariant sets corresponding to differential equations of the above type, subject to time-dependent forcing of a quite general class. Working in the framework of skew-product semiflows associated with these equations, the authors consider invariant sets defined in terms of global attractors of semigroups determined by these semiflows. In autonomous situations these invariant sets coincide with the usual global attractors. Upper bounds for the Hausdorff and fractal dimensions of these sets are given in terms of uniform Lyapunov exponents for a large class of dissipative nonlinear partial differential equations with time-dependent forcing terms that include the case of almost periodic functions.

Key words. global attractors, skew-product semiflows, Hausdorff and fractal dimension estimates, time dependent forcing, dissipative nonlinear partial differential equation

1. Introduction. The existence of global attractors and estimates of their Hausdorff and fractal dimensions have been investigated for numerous dissipative nonlinear partial differential equations (DNLPDE) that are either autonomous [4], [32], [9], [15] or are subject to time-periodic forcing [15]. With suitable conditions on the nonlinearities of such equations on bounded domains, it has been proved that global attractors exist and that they have finite Hausdorff and fractal dimensions. Bounds on these dimensions have been obtained in terms of uniform (or global) Lyapunov exponents (to be distinguished from the corresponding pointwise exponents [1]).

In the presence of more general forcing (e.g., almost periodic but not periodic) the usual dimension estimates of these attractors are not valid because the proofs make essential use of the fact that the solutions of the Cauchy problem for the relevant nonlinear differential equations have a semigroup structure. It is well known that solutions of equations do not have this structure when forcing terms are present that are almost periodic but not periodic, or even for periodic forcing for continuous times. The inadequacy of the customary description of global attractors in nonautonomous situations is evident from recent discussions in the literature. Thus, in the case of periodic forcing, Hale [16] and Haraux [19] have advocated the use of a different definition of global attractor than the usual one in terms of discrete semigroups.

In this article we consider the problem of estimating Hausdorff and fractal dimensions of invariant sets for DNLPDE on bounded domains of a Hilbert space subject to time-dependent nonperiodic forcing, including the case of almost periodic forcing. Our main result is that, for a large class of such equations, the types of estimates of Hausdorff and fractal dimensions of invariant sets usually made in autonomous

† Computational Science and Engineering Research Center and Department of Electrical Engineering, Howard University, Washington, DC 20059.

cases can also be carried through in this more general situation. Since the solution-maps of the Cauchy problem do not form semigroups in nonautonomous cases, we use the concept of skew-product semiflow to define appropriate invariant sets. These reduce to the usual global attractors in autonomous cases. Working in the skew-product semiflow framework associated with the given system of equations, we consider invariant sets defined in terms of global attractors of semigroups determined by these semiflows.

One of the principal conditions that we require in order to prove the results indicated above is that, for sufficiently long times, the solution-maps for the DNLPDE are invertible on the invariant set. This is true, in particular, if these maps are invertible on the whole space, and our discussion in § 4 involves a class of nonlinear wave equations and systems of such equations for which this condition is satisfied. There are cases, however, in which the semiflows are not invertible on the whole space but are, nevertheless, defined and invertible on the invariant set. In § 5 we discuss a class of reaction-diffusion equations that have this property. In the cases treated in these two sections, all the hypotheses required for the proof of our dimension estimates are satisfied.

We begin in § 2 by defining skew-product semiflows in the context of abstract DNLPDE and outlining the program that we follow in § 3 in order to obtain our results on Hausdorff and fractal dimension estimates of invariant sets for DNLPDE, and systems of such equations, with time-dependent forcing. Section 4 is devoted to the discussion of a class of nonlinear wave equations with nonlinear dissipation, and in § 5 we give a similar discussion for some reaction-diffusion equations with polynomial growth nonlinearities.

2. Skew-product semiflows. Preliminary remarks. The following discussion of skew-product semiflows is analogous to, but different from, the recent discussion by Raugel and Sell [28] in the context of the Navier–Stokes equations.

Consider a solution ψ of a DNLPDE; i.e., a continuous map from $\mathbb{R}$ to a separable Hilbert space K such that $\psi(t+s)$ represents a solution of the equation at time $t+s(t\in\mathbb{R}^+,\ s\in\mathbb{R})$, corresponding to specified initial data $\psi(s)=\phi\in K$ at time s. We assume that ψ satisfies the following nonlinear stability condition.

Assumption 2.1. For each $R>0$ there exists a positive constant $K(R)$ such that

$$\|\psi(t+s)\|_K \leqq K(R) \quad \text{for all } t\geqq 0 \quad \text{whenever } \|\phi\|_K\leqq R. \tag{2.1}$$

We will consider forcing functions $f\in C_b(\mathbb{R}, K)$, where $C_b(\mathbb{R}, K)$ denotes the Banach space of all bounded continuous functions from $\mathbb{R}$ to K. For $f\in C_b(\mathbb{R}, K)$, we define the *translate of f* by

$$f_\tau(t)\equiv(\sigma(\tau)f)(t)=f(t+\tau), \qquad \tau\in\mathbb{R}. \tag{2.2}$$

Then $f_\tau\in C_b(\mathbb{R}, K)$ and f_τ defines a (two-sided) flow on $C_b(\mathbb{R}, K)$. The *positive hull* $H^+(f)$ of $f\in C_b(\mathbb{R}, K)$ is defined as

$$H^+(f)=\text{Closure}_{C_b(\mathbb{R},K)}\{f_\tau,\ \tau\geqq 0\},$$

and the *hull* $H(f)$ as

$$H(f)=\text{Closure}_{C_b(\mathbb{R},K)}\{f_\tau,\ \tau\in\mathbb{R}\}.$$

Note that $H^+(f)$, $H(f)\subset C_b(\mathbb{R}, K)$ if $f\in C_b(\mathbb{R}, K)$. The *ω-limit set* $\omega(f)$ of $f\in C_b(\mathbb{R}, K)$ is defined by $\omega(f)=\bigcap_{\tau\geqq 0} H^+(f_\tau)$. Note that $\omega(f)$ is an invariant set in $C_b(\mathbb{R}, K)$ relative to the translation group $\{\sigma(\tau),\ \tau\in\mathbb{R}\}$.

To guarantee that $\omega(f)$ is nonempty, we restrict consideration to forcing functions for which $H(f)$ is compact. Then $\omega(f)$ is compact as well as nonempty. We list some cases for which this condition is satisfied (other examples can be found in [28]).

(1) Take $K = L^2(\Omega)$, Ω a bounded subset of $\mathbb{R}^n$, with $f \in L^2(\Omega)$ independent of $t \in \mathbb{R}$. Then $H(f) = \{f\}$.

(2) Let $f \in C_b(\mathbb{R}, K)$ be T-periodic, $f(t+T) = f(t)$ for all $t \in \mathbb{R}$. Then $H(f) = \{f_\sigma, \sigma \in [0, T)\}$.

(3) Let f be asymptotically almost periodic from $\mathbb{R}$ to K; i.e., $f = g + h$ with g almost periodic from $\mathbb{R}$ to K [18], and $\|h(t)\|_K \to 0$ as $t \to \pm\infty$.

DEFINITION 2.1. We will say that f is *admissible* if $H(f)$ is compact in $C_b(\mathbb{R}, K)$.

Given a solution ψ of a DNLPDE defined as in the second paragraph of this section, we define a two-parameter family of maps $W(t, s)$ $(t \in \mathbb{R}^+, s \in \mathbb{R})$ by

$$W(t, s)\phi = \psi(t+s), \qquad \psi(s) = \phi \in K. \tag{2.3}$$

Then we have $W(0, s)\phi = \phi (s \in \mathbb{R}, \phi \in K)$, and

$$W(t+\theta, s)\phi = W(\theta, s+t) \circ W(t, s)\phi \qquad (s \in \mathbb{R}, t, \theta \in \mathbb{R}^+), \tag{2.4}$$

where $\circ$ denotes composition. This is an example of a process in the sense of Dafermos [10].

Given a process W, we define its translate W_τ in an analogous manner to the case for functions in (2.2).

DEFINITION 2.2. Given a process W and $\tau \in \mathbb{R}$, the *τ-translate* of W is the process W_τ defined by

$$W_\tau(t, s)\phi \equiv (\sigma(\tau) W)(t, s)\phi = W(t, \tau+s)\phi, \quad t \in \mathbb{R}^+, \quad s \in \mathbb{R}. \tag{2.5}$$

DEFINITION 2.3. A process W on a Hilbert space K is called *almost periodic* if $\bigcup_{\tau \in \mathbb{R}} W_\tau(t, s)\phi$ is precompact in $C_b(\mathbb{R}, K)$ (as a function of the parameter $s \in \mathbb{R}$) for each $t \in \mathbb{R}^+$ and each $\phi \in K$.

Thus, if W is almost periodic, for any sequence $\{\sigma_n\} \subset \mathbb{R}$ there exists a subsequence $\{\sigma_{n_m}\} \subset \{\sigma_n\}$ and a map $V: \mathbb{R}^+ \times \mathbb{R} \times K \to K$ such that

$$\| W_{\sigma_{n_m}}(t, s)\phi - V(t, s)\phi \|_K \to 0 \quad \text{as } m \to +\infty \tag{2.6}$$

uniformly in $s \in \mathbb{R}$ for each $t \in \mathbb{R}^+$ and each $\phi \in K$.

DEFINITION 2.4. Let $W(t, s)\phi$ be an almost periodic process from $\mathbb{R}^+ \times \mathbb{R} \times K$ to K. The closure in $C_b(\mathbb{R}, K)$ of the set of translates of W relative to the above sense of convergence is called the *hull* of W, denoted by $H(W)$.

We will prove later that W is almost periodic if $H(f)$ is compact, and W depends on f in a Lipschitz continuous manner. See Proposition 3.1.

To define a skew-product structure, we let W denote an almost periodic process corresponding to a globally defined unique solution of a given differential equation as in (2.3), and we define the mappings

$$\pi_s(t)(\phi, V) = (V(t, s)\phi, \sigma(t) V), \quad V \in H(W), \quad \phi \in K, \quad s \in \mathbb{R}, \quad t \in \mathbb{R}^+. \tag{2.7}$$

It is easily shown formally [16, p. 44] that $\{\sigma(t), t \in \mathbb{R}\}$ is a group on $H(W)$ and that $\{\pi_s(t), t \geqq 0\}$, with s fixed in $\mathbb{R}$, is a semigroup on $K \times H(W)$. We will prove later that they are C^0 if certain conditions are satisfied. As we shall see, $\{\pi_s(t), t \geqq 0\}$ (s fixed in $\mathbb{R}$) defines a semiflow on $K \times H(W)$ if global solutions of the DNLPDE exist for each $h \in H(f)$. In addition, we will state sufficient conditions such that there exists a one-to-one correspondence between processes in $H(W)$ corresponding to a given admissible forcing function f and the distinguished almost periodic process W with a forcing function $h \in H(f)$. See equations (2.10)-(2.12) and the associated discussion.

For ordinary differential equations, it has been more conventional to define a skew-product structure in terms of translated forcing functions, rather than in terms of translated processes. Thus, consider the system of equations $u_t = f(t, u)$, where $f(\cdot, \cdot): \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}^n$. Then, under appropriate continuity conditions, we define a skew-product structure on $\mathbb{R}^n \times H(f)$ by $\tilde{\pi}_s(t)(x, f) = (u(t, s)x, \sigma(t)f)$, where $u(s, s)x = x \in \mathbb{R}^n$. For more details of this approach, we refer the reader to [16], [29], [30].

Let s be fixed in $\mathbb{R}$. A compact set A in $K \times H(W)$ is said to be an *attractor* if it is invariant under the action of $\pi_s(t)$, $\pi_s(t)A = A$ for $t \in \mathbb{R}$, and if there exists an open neighborhood U of A such that $\pi_s(t)$ B converges to A as $t \to +\infty$, where B denotes any bounded subset of U. If these properties remain true when U is replaced by the whole space $K \times H(W)$, then A is called the *maximal* or *global attractor*. At the end of the present section we will state conditions under which the global attractor is independent of s.

Given an almost periodic process W, let ${}_sA_\pi(W)$ denote a global attractor (if one exists) of the semigroup $\{\pi_s(t), t \geqq 0\}$ (s fixed in $\mathbb{R}$) and, following the discussion in [16], consider the set

$$E_s = \{\chi \in K \mid (\chi, V) \in {}_sA_\pi(W),\ V \in H(W)\}. \tag{2.8}$$

Some insight concerning the relevance of the sets E_s to the study of dynamical systems can be gleaned by considering autonomous and periodic processes. For an autonomous process, $W(t, s)$ is independent of s, and $H(W)$ consists of the single process W. We find $A_\pi(W) = E \times \{W\}$ and $\pi(t) = S(t) \times I$, where $S(t)$, I, and E denote the usual solution-map semigroup for an autonomous process, the identity map on processes, and the global attractor for $S(t)$, respectively. For T-periodic processes we have

$$H(W) = \{W_\sigma, \sigma \in [0, T)\}. \tag{2.9}$$

It is known that the set

$$A(W) = \bigcup_{\sigma \in [0, T)} W(\sigma, 0) \bigcap_{m \geqq 0} \text{Closure}_K \left(\bigcup_{n \geqq m} W(nT, 0)B_0 \right),$$

with B_0 a bounded absorbing set, corresponds to a set of the type (2.8) for T-periodic processes [16]. Thus, for autonomous and T-periodic processes, the usual global attractors correspond to sets of the form (2.8).

In the present work we will establish the following results for processes corresponding to solutions of admissible time-dependently forced DNLPDE: (a) proof of existence of sets of the type (2.8), (b) proof that these sets have finite Hausdorff and fractal dimensions, and (c) derivation of upper bounds for these dimensions in terms of uniform Lyapunov exponents. These results will be based on the idea that, for DNLPDE subject to admissible time-dependent nonperiodic forcing, the Hausdorff and fractal dimensions of sets of the form (2.8) can be estimated by consideration of the first variational equations corresponding to equations in the hull of the given equation (or system of equations). Here, an equation with forcing function h is said to belong to the hull of a given equation with forcing function f if $h \in H(f)$.

The fundamental result on the invariance of the sets (2.8) is the following.

LEMMA 2.1 (positive invariance of E_s). *Let W be an almost periodic process on K, and let ${}_sA_\pi(W)$ be a global attractor on $K \times H(W)$ relative to the semigroup $\{\pi_s(t), t \geqq 0\}$. Then, for given $s \in \mathbb{R}$, $\phi \in E_s$ implies that there exists a process $Z \in H(W)$ such that $Z(t, s)\phi \in E_s$ for all $t \geqq 0$.*

For related results, see Hale [16, p. 46] and Dafermos [10], [11]. The first of these references refers only to periodic processes. In that case the situation is simpler than for almost periodic nonperiodic processes because the hull of a periodic process has the special structure (2.9).

We can readily give examples of processes V belonging to the hull of a given almost periodic process W that are not translates of W. Examples of this phenomenon are well known in the case of uniform (Bohr) almost periodic nonperiodic functions [13], and examples of almost periodic nonperiodic processes with the desired property can be constructed in terms of such functions.

As noted in [16] and [19], under reasonable conditions we should be able to prove that, when W is almost periodic, $H(W)$ consists precisely of the set of processes in the hull of the equation (or system of equations) under consideration. Take $V \in H(W)$ with W almost periodic. Then, by Definition 2.3, there exists a sequence $\{\tau_n\} \subset \mathbb{R}$ such that $W_{\tau_n}(t, s)\phi \rightarrow_{n\rightarrow+\infty} V(t, s)\phi$ for each $t \in \mathbb{R}^+$ and each $\phi \in K$ uniformly in $s \in \mathbb{R}$. For the translated process we should have

$$W_{\tau_n}(t, s; f)\phi = W(t, s+\tau_n; f)\phi \tag{2.10}$$

$$= W(t, s; f_{\tau_n})\phi. \tag{2.11}$$

Modulo certain continuity arguments, it would then follow that V is given by

$$V(t, s) = W(t, s; h), \tag{2.12}$$

where $h = \lim_{n\rightarrow+\infty} f_{\tau_n} \in H(f)$ is the uniform limit of the f_{τ_n}. These continuity considerations will be discussed in § 3 for processes corresponding to solutions of a large class of DNLPDE. In view of Lemma 2.1 and the above considerations, it is useful to consider the maps (with s given in $\mathbb{R}$)

$$S_s(t)\phi = W(t, s; h)\phi, \qquad h \in H(f). \tag{2.13}$$

In order to prove existence of sets of the type (2.8) and to obtain estimates for their Hausdorff and fractal dimensions, we will prove the following statements, which are analogous to the corresponding program in autonomous situations but contain some additional requirements.

(1) For a distinguished almost periodic process W related to a globally defined solution of a DNLPDE (or a system of such equations) as in (2.3), $\{\sigma(t),\ t \geqq 0\}$ and $\{\pi_s(t),\ t \geqq 0,\ s \text{ fixed in } \mathbb{R}\}$ are C^0-semigroups in $H(W)$ and $K \times H(W)$, respectively.

(2) For each $t \geqq 0$ and $S \in \mathbb{R}$; $S_s(t)$ exists, is unique, and is differentiable on K for all initial data in K and for all $h \in H(f)$.

(3) Proof of the relations between $H(W)$ and $H(f)$ indicated in (2.10)-(2.12).

(4) Nonlinear stability. (See Assumption 2.1.)

(5) Existence of bounded absorbing sets.

(6) Asymptotic compactness: for all bounded sets $B \subset K$, there exists a compact set $G \subset K$ such that

$$\sup_{\chi \in B} d(W(t, s)\chi, G) \rightarrow 0 \quad \text{as } t \rightarrow +\infty \tag{2.14}$$

for each $s \in \mathbb{R}$, where, for two sets X, $Y \subset K$,

$$d(X, Y) = \sup_{\Phi \in X} \inf_{\chi \in Y} \|\Phi - \chi\|_K. \tag{2.15}$$

(7) For each $h \in H(f)$ and for $t > 0$ sufficiently large, $S_s(t)$ has an inverse on the range of $S_s(t)E_s$ that is Lipschitz continuous.

Points (1) and (3) are, of course, specific to the framework of skew-product semiflows, while the conditions in (2) and (4)-(6) require generalizations of corresponding results already known for autonomous and periodic processes. In particular, proofs are required for all $h \in H(f)$. We will see in § 3 that the validity of conditions (4)-(6) implies the existence of global attractors ${}_sA_\pi(W)$ for the semigroups $\{\pi_s(t),\ t \geqq 0\}$ (s fixed in $\mathbb{R}$).

Condition (7) is a crucial property which allows us to obtain estimates for the Hausdorff and fractal dimensions of the sets (2.8) in an analogous manner to the method used to obtain corresponding estimates in autonomous [32], [4], [7]-[9], [15] and periodic [15] processes. It can be seen to be a natural requirement by the following argument. Consider a semigroup $\{S(t),\ t \geqq 0\}$ corresponding to an autonomous process. Then, as is well known, a global attractor for this process is invariant under the action of this semigroup,

$$S(t)A = A, \qquad t \geqq 0. \tag{2.16}$$

Lemma 2.1 can be thought of as a generalization to almost periodic processes of the positive invariance condition for global attractors in the autonomous case, $S(t)A \subset A (t \geqq 0)$, which is "one-half" of the invariance condition (2.16). However, it is known for autonomous systems that the important condition required for estimates of Hausdorff and fractal dimensions of global attractors is that of negative invariance, $S(t)A \supset A(t \geqq 0)$ [24], [32]. Returning now to the consideration of almost periodic processes, we will see later that condition (7) allows us to transform the positive invariance of E_s under $S_s(t)$, as described by Lemma 2.1 and (2.13), into the negative invariance of E_s under $(S_s(t))^{-1}$.

Actually, while condition (7) only requires that $S_s(t)$ be invertible and that its inverse be Lipschitz continuous on the range of $S_s(t)$, there are a number of DNLPDE's with admissible time-dependent forcing for which these maps are invertible on the whole Hilbert space. We will discuss some equations of this type in § 4. We expect that there are many situations for which the maps $S_s(t)$ are invertible on their range even though they may not be invertible on all of K. In § 5 we will discuss a class of parabolic equations with admissible time-dependent forcing that have this property.

As a result of condition (7), it can be shown that the global attractors ${}_sA_\pi(W)$ are actually independent of s. This follows from the previously noted result that conditions (4)-(6) imply the existence of these attractors and a straightforward modification of [19, Prop. 1.10].

3. General results. In this section our results will be formulated in an abstract manner and then, in the following two sections, examples of DNLPDE's that satisfy our hypotheses will be discussed.

We first establish the continuity of the skew-product semiflow $\{\pi_s(t),\ t \geqq 0\}(s \in \mathbb{R})$ defined in (2.7). For analogous proofs in the case of ordinary differential equations, see [29], [30], [6]. Consider the formulation of § 2 in which K is a separable real Hilbert space and $W(t, s)$ a distinguished process associated as in (2.3) with a solution ψ of a given DNLPDE.

The following proposition establishes (2.10), (2.11), and related results.

PROPOSITION 3.1. *Define a distinguished process $W(t, s)$ in terms of a globally defined uniformly bounded unique solution ψ of a system of* DNLPDE'*s that satisfies* (2.1) *and, in addition, assume that ψ depends on the forcing function f in a Lipschitz-continuous manner: i.e., there exists a positive constant $c(t)$, generally depending upon t, such that for two solutions ψ_1, ψ_2 (with the same initial data) corresponding to two* *forcing terms* f_1, f_2,

$$\|\psi_1(t+s)-\psi_2(t+s)\|_K \leqq c(t) \sup_{t'\in[s,t+s]} \|f_1(t')-f_2(t')\|_K. \tag{3.1}$$

Finally, assume that the forcing functions f_1, f_2 *are admissible. Then*

(a) *For all* $\tau \in \mathbb{R}$,

$$\begin{aligned} W_\tau(t, s; f)\psi(s) &= W(t, \tau+s; f)\psi(\tau+s) \\ &= W(t, s; f_\tau)\psi(s), \end{aligned}$$

and, more generally,

(b) *Given* $V \in H(W)$, *there exists* $h \in H(f)$ *such that*

$$W(t, s; h)\psi(s) = V(t, s; f)\psi(s). \tag{3.2}$$

Conversely, given $h \in H(f)$, *there exists* $V \in H(W)$ *such that* (3.2) *holds.*

Proof. By using the existence and uniqueness of the solutions of the system of differential equations it is easy to establish (a). To prove (b), we first note that it follows from (3.1) and (a) that W is almost periodic if f is admissible. To see this, take a sequence $\{W_{\tau_n}(t, s)\phi\}$ from $\bigcup_{\tau\in\mathbb{R}} W_\tau(t, s)\phi$. Since $H(f)$ is compact in $C_b(\mathbb{R}, K)$, there exists a subsequence $\{\tau_{n_m}\} \subset \{\tau_n\}$ such that $\{f_{\tau_{n_m}}\}$ is convergent, and, therefore, Cauchy; i.e., given $\varepsilon > 0$, there exists $N \in \mathbb{N}$ such that l, $m \geqq N$ implies that

$$\|f_{\tau_{n_m}}(t') - f_{\tau_{n_l}}(t')\|_K < \frac{\varepsilon}{c(t)}$$

for all $t' \in [s, t+s]$. From (a) and (3.1) we then obtain $\|W_{\tau_{n_m}}(t, s; f)\phi - W_{\tau_{n_l}}(t, s; f)\phi\|_K < \varepsilon$ for l, $m \geqq N$ and $\varepsilon > 0$ so that $\{W_{\tau_{n_m}}(t, s; f)\phi\}$ is a Cauchy sequence and, therefore, convergent. Thus, from an arbitrary sequence in $\bigcup_\tau W_\tau(t, s; f)\phi$ we have obtained a convergent subsequence from which we infer that $\bigcup_{\tau\in\mathbb{R}} W_\tau(t, s)\phi$ is precompact in $C_b(\mathbb{R}, K)$ for each $t \in \mathbb{R}^+$, $s \in \mathbb{R}$, $\phi \in K$, and admissible f.

Take $V \in H(W)$. Then, since W is almost periodic, there exists a sequence $\{\tau_n\} \subset \mathbb{R}$ such that

$$W_{\tau_n}(t, s; f)\psi(s) \xrightarrow[n\to+\infty]{} V(t, s; f)\psi(s) \tag{3.3}$$

for each $t \in \mathbb{R}^+$ and each $\psi(s) = \phi \in K$, uniformly in $s \in \mathbb{R}$. From (a), this can be expressed as

$$W(t, s; f_{\tau_n})\psi(s) \xrightarrow[n\to+\infty]{} V(t, s; f)\psi(s).$$

To complete the proof, we obtain a relation between the convergence of translates of the forcing functions and translates of processes. Let

$$f_{\tau_n} \xrightarrow[n\to+\infty]{} h \in H(f), \tag{3.4}$$

so that, by (3.1),

$$\|\psi_1(t+s, f_{\tau_n}) - \psi_2(t+s, h)\|_K \leqq c(t) \sup_{t'\varepsilon[s,\, t+s]} \|f_{\tau_n}(t') - h(t')\|_K, \tag{3.5}$$

i.e.,

$$\lim_{n\to+\infty} W(t, s; f_{\tau_n})\psi(s) = W(t, s; h)\psi(s) \tag{3.6}$$

so that, upon comparison with (3.3),

$$W(t, s; h)\psi(s) = V(t, s; f)\psi(s).$$

Conversely, take $h \in H(f)$. Then there exists a sequence $\{\tau_n\} \subset \mathbb{R}$ such that the limit in (3.4) exists in the uniform topology. Then, from (3.6) and (a),

$$\lim_{n\to+\infty} W_{\tau_n}(t, s; f)\psi(s) = W(t, s; h)\psi(s),$$

and, using (3.5), we easily show that this result holds for each $t \in \mathbb{R}^+$ and each $\psi(s) = \phi \in K$ uniformly in $s \in \mathbb{R}$. We see that $W(t, s; h) \in H(W(t, s; f))$, and the proof is complete.

PROPOSITION 3.2. *Assume the hypotheses of Proposition* 3.1 *and further, assume that the translation group* $\{\sigma(\tau), \tau \in \mathbb{R}\}$ *defined in* (2.5) *is continuous on* $H(W)$. *Then, for each fixed* $s \in \mathbb{R}$, $\pi_s(t): K \times H(W) \to K \times H(W)$ *is jointly continuous.*

Proof. From (2.7) and (2.3) we have

$$\pi_s(t)(\phi, W) = (W(t, s; f)\phi, \sigma(t)W) = (\psi(t+s; f, \phi), W_t)$$

for $t \in \mathbb{R}^+$, $s \in \mathbb{R}$, $f \in C_b(\mathbb{R}, K)$, and $\psi(s) = \phi$. Let $\{(\phi_n, W_{\tau_n})\}$ and $\{t_n\}$ denote sequences in $K \times H(W)$ and $\mathbb{R}^+$, respectively, such that $(\phi_n, W_{\tau_n}) \to (\phi, Y)$ and $t_n \to t$ as $n \to +\infty$. We must prove that, for fixed $s \in \mathbb{R}$,

$$\pi_s(t_n)(\phi_n, W_{\tau_n}) \to \pi_s(t)(\phi, Y) \text{ as } n \to +\infty, \quad \text{i.e., } (W_{\tau_n}(t_n, s; f)\phi_n, W_{\tau_n+t_n}) \to (Y(t, s; f)\phi, Y_t)$$

or, using part (a) of Proposition 3.1,

$$(W(t_n, s; f_{\tau_n})\phi_n, W_{\tau_n+t_n}) \to (Y(t, s; f)\phi, Y_t).$$

We have $W_{\tau_n+t_n} \to Y_t$ by the continuity of the translation group (2.5) on $H(W)$, and

$$W(t_n, s; f_{\tau_n})\phi_n \to W(t, s; h)\phi, \qquad h \in H(f)$$

because of the Lipschitz condition (3.1), $\phi_n \to \phi$, and that the solutions ψ of the system of DNLPDE's are uniformly bounded for all $t \in \mathbb{R}^+$ and are uniquely determined by the initial data. The proof is concluded by noting that $W(t, s; h)\phi = Y(t, s; f)\phi$ by Proposition 3.1.

LEMMA 3.1. *Assume the hypotheses of Proposition* 3.1. *and, in addition, assume that the translation group* $\{\sigma(\tau), \tau \in \mathbb{R}\}$ *is continuous and that* $\{S_s(t), t \geqq 0\}$ *possesses a bounded absorbing set* $B_0 \subset K$; *i.e., for each* $h \in H(f)$, $W(t, s; h)\chi \subset B_0$ *whenever* $t \in \mathbb{R}^+$ *is sufficiently large, and* χ *belongs to any bounded subset of* K. *Furthermore, assume that* $\{S_s(t), t \geqq 0\}$ *is asymptotically compact*: *there exists a compact set* $G \subset K$ *that attracts all bounded subsets of* K *under* $S_s(t)$;

$$\lim_{t\to+\infty} \sup_{\psi(s)=\phi\in K} d_K(S_s(t)\psi(s), G) = 0, \tag{3.7}$$

where d_K *is defined in* (2.15). *Then, the skew-product semiflow* (2.7) *has the following properties. For fixed* $s \in \mathbb{R}$,

(a) *There exists a bounded absorbing set in* $K \times H(W)$ *for the semigroup* $\{\pi_s(t), t \geqq 0\}$;

(b) $\pi_s(t)$*-orbits of bounded sets are bounded*;

(c) $\{\pi_s(t), t \geqq 0\}$ *is asymptotically compact*: *there exists a compact set in* $K \times H(W)$ *which attracts all bounded subsets of* $K \times H(W)$.

Proof. Since f is admissible, we see that W is almost periodic as in the proof of Proposition 3.1.

(a) Let $B_1 \times B_2$ be a bounded subset of $K \times H(W)$. Then B_2 has the form

$$B_2 = \{W_{\tau_n}\} \tag{3.8}$$

for a sequence $\Lambda = \{\tau_n\} \subset \mathbb{R}$. By (2.7),

$$\pi_s(t)(\chi, V) = (V(t, s; f)\chi, \sigma(t)V)$$

for $(\chi, V) \in B_1 \times B_2$. So from $V \in B_2$ we infer from (3.8) that $V \in \bigcup_{\tau \in \Gamma} W_\tau$, where Γ denotes some subsequence of Λ. Thus,

$$\pi_s(t)(\chi, V) \in \left(\bigcup_{\tau \in \Gamma} W_\tau(t, s; f)\chi, \sigma(t) \bigcup_{\tau \in \Gamma} W_\tau \right) = \bigcup_{\tau \in \Gamma} (W(t, s; f_\tau)\chi, W_{\tau+t}), \tag{3.9}$$

where we have used Proposition 3.1 and the continuity of $\sigma(t)$ to obtain the last line. By assumption, $\{S_s(t), t \geqq 0\}$ possesses a bounded absorbing set $B_0 \subset K$. Take $\chi \in B_0$. Then a bounded absorbing set for $\{\pi_s(t), t \geqq 0\}$ is $B_0 \times \{W_\tau, \text{all } \tau \in \mathbb{R}\}$.

(b) Again take $(\chi, V) \in B_1 \times B_2$ with B_1 and B_2 as in (a). Then (3.9) holds and, by (2.1), there exists $K(R) > 0$ such that

$$\| W(t, s; f_\tau)\chi \|_K \leqq K(R) \tag{3.10}$$

for all $t \in \mathbb{R}^+$. By Proposition 3.1,

$$\begin{aligned} W_{\tau+t}(p, s; f)\chi &= W(p, s; f_{t+\tau})\chi \\ &= W(p, s+t+\tau; f)\chi \end{aligned}$$

is bounded in $C_b(\mathbb{R}, K)$ with respect to $s+t+\tau \in \mathbb{R}$ for each $p \in \mathbb{R}^+$ and each $\chi \in K$. Combination of this result with (3.10) proves assertion (b).

(c) We again use (3.9) with B_1 and B_2 as in (a) and (b). By hypothesis, there exists a compact set $Y \subset K$ which attracts all bounded subsets of K under $S_s(t)$, and, therefore, under $W(t, s; f_\tau)$ in (3.9). So, $Y \times H(W)$ attracts all bounded sets in $K \times H(W)$ under $\pi_s(t)$. Finally, $H(W)$ is compact (in $C_b(\mathbb{R}, K)$) so that $Y \times H(W)$ is compact in the product topology by Tychonoff's theorem, and the proof is complete.

We now consider the maps (2.13). Assuming that these are Fréchet differentiable on sets of type (2.8) and that the corresponding derivatives $L_s(t, \chi)$ are bounded on $L(K)$, we set up an apparatus for estimating Hausdorff and fractal dimensions of invariant sets in an analogous way to the treatment of autonomous equations [12], [7]-[9], [32], [4].

Define

$${}_s\bar{\omega}_j(t) = \sup_{\chi \in E_s} \omega_j(L_s(t, \chi)), \quad j \in \mathbb{N}, \quad t \in \mathbb{R}^+, \tag{3.11}$$

where

$$\omega_j(L_s(t, \chi)) = \alpha_1(L_s) \cdots \alpha_j(L_s) \quad \text{with}$$

$$\alpha_j(L_s(t, \chi)) = \sup_{\substack{F \subset K \\ \dim F = j}} \inf_{\substack{\eta \in F \\ \|\eta\|_K = 1}} \|L_s(t, \chi)\eta\|_K \qquad (j \in \mathbb{N}).$$

For noninteger cases we set $\omega_d(L) = (\omega_n(L))^{1-s}(\omega_{n+1}(L))^s$ for $d = n+s$, $n = \text{integer} \geqq 1, 0 < s < 1$.

Consider the composition property (2.4) for a process U corresponding to a function h in the hull of a forcing function f for a given DNLPDE:

$$\mathsf{U}(t+p, s, \chi(s); h) = \mathsf{U}(t, p+s, \mathsf{U}(p, s, \chi(s); h); h)$$

or

$$\mathsf{U}(t+p, 0, \chi(0); h_s) = \mathsf{U}(t, 0, \mathsf{U}(p, 0, \chi(0); h_s); h_{p+s})$$

using Proposition 3.2. Alternatively, in terms of the maps (2.13),

$$S_s(t+p)\chi(s) = S_{p+s}(t) \circ S_s(p)\chi(s). \tag{3.12}$$

The relations corresponding to (3.12) for the derivatives $L_s(t, \chi)$ (assuming that they exist) are

$$\begin{aligned} L_s(t+p, \chi(s)) &\equiv S_s'(t+p)(\chi(s)) \\ &= L_{p+s}(t, S_s(p)(\chi(s))) \circ L_s(p, \chi(s)). \end{aligned} \tag{3.13}$$

Corresponding to a DNLPDE, we have a first variational equation (see [32], [4], [9] for the corresponding autonomous situation). Let $\Phi(t)$ denote a solution of the latter equation subject to the initial value $\rho \in K$. Then, as is well known, we have the following relation between $L_s(t, \chi)$ and $\Phi(t)$:

$$L_s(t, \chi(s))\rho = \Phi(t), \qquad \Phi(s) = \rho \in K. \tag{3.14}$$

We assume that the corresponding equation for $\Phi(t)$ is independent of the forcing term of the original DNLPDE. This is true for a large number of DNLPDE's, and we discuss some examples in the following two sections. In such cases, L depends on the subscripts in (3.13) only through its dependence on $S_s(t)$, and we can write

$$L(t+p, \chi(s)) = L(t, S_s(p)(\chi(s))) \circ L(p, \chi(s))$$

in place of (3.13).

We now prove the important subexponential property for the quantities (3.11) for DNLPDE with time-dependent admissible forcing functions.

THEOREM 3.1. *Assume the hypotheses of Proposition* 3.2 *and, in addition, assume that the derivatives L defined in* (3.13) *exist. Then the quantities* (3.11) *satisfy the subexponential condition*

$${}_s\bar{\omega}_j(t+p) \leqq {}_s\bar{\omega}_j(t)\,{}_s\bar{\omega}_j(p); \quad t, p \in \mathbb{R}^+, \quad j \in \mathbb{N},$$

where s is a fixed real number.

Proof. From Lemma 2.1, $\phi \in E_s$ implies that, for given $s \in \mathbb{R}$, there exists a process $V \in H(W)$ such that $V(t, s)\phi \in E_s$ for all $t \geqq 0$. As in the proof of Proposition 3.1, f admissible implies that W is almost periodic, from which we infer that V is almost periodic, so that there exists a sequence $\{\tau_n\} \subset \mathbb{R}$ such that $W_{\tau_n}(t, s)\phi \to_{n \to +\infty} V(t, s)\phi$ for each $t \in \mathbb{R}^+$ and each $\phi \in K$, uniformly in $s \in \mathbb{R}$. Moreover, from Proposition 3.2, we see that $V(t, s)\phi = W(t, s; h)\phi$ with $h \in H(f)$.

Consider the maps (2.13). These satisfy (3.12), and, therefore, also (3.14), if the corresponding derivatives L exist. Thus we obtain

$$\omega_j(L_s(t+p, \phi)) \leqq \omega_j(L_{p+s}(t, S_s(p)(\phi)))\omega_j(L_s(p, \phi))$$

by [32, Cor. 1.1, p. 267]. Following our earlier argument, which centered about (3.14), we see that we can remove the subscripts on L so that

$$\omega_j(L(t+p, \phi)) \leqq \omega_j(L(t, S(p)(\phi)))\omega_j(L(p, \phi)).$$

The proof can now be completed as in the autonomous case.

We have proved that the quantities $\{{}_s\bar{\omega}_j, j \in \mathbb{N}\}$ are subexponential even though the maps (2.13) are not semigroups. This result allows one to prove that the limits

$$\lim_{t \to +\infty} ({}_s\bar{\omega}_j(t))^{1/t} \tag{3.15}$$

exist for each $s \in \mathbb{R}$, and uniform Lyapunov exponents can be defined in an analogous way to autonomous situations [7]-[9], [32]. We will discuss this in more detail at the end of the present section. Before doing this, we obtain estimates of Hausdorff and fractal dimensions of sets of the form (2.8).

Generalizations will be given of [32, Thms. 3.1-3.3, pp. 282-289] to the case of admissible time-dependent forcing.

THEOREM 3.2. *Assume the hypotheses of Proposition* 3.1 *as well as the condition of asymptotic compactness* (3.7), *and consider the maps* (2.13) *corresponding to an admissible forcing function f. In addition, assume that the derivatives L exist. Assume also that*

$$\sup_{t\in[0,1]}\ \sup_{u\in E_s} \|L(t,u)\|_{L(K)} \leqq m < +\infty$$

for some $m>0$ *as well as the condition*

$$\sup_{t\in[0,1]} \omega_d(L(t,u)) < 1 \tag{3.16}$$

for some $d>0$ *and all* $u\in E_s$ *for some fixed* $s\in\mathbb{R}$.

Finally, we assume that, for all $h\in H(f)$, *the maps* $S_s(t)$ *are Lipschitz continuous on* E_s *with inverses that exist as Lipschitz continuous surjective maps from* $S_s(t)E_s$ *onto* E_s *when* $t>0$ *is sufficiently large. Then the Hausdorff dimension of* E_s, $d_H(E_s)$, *is finite and* $d_H(E_s)\leqq d$.

Proof. By hypothesis, the derivatives L of the maps (2.13) exist. From Proposition 3.2, Lemma 3.1, and [16, Thm. 3.7.2] there exists a global attractor $A_\pi(W)$ for $\{\pi_s(t), t\geqq 0\}$ which, by the result stated at the end of § 2, is independent of s. Moreover, E_s is compact. Then, by the method of proof used in autonomous cases [12], [7]-[9], [32], [4], it follows that the set $S_s(t)E_s$ has zero Hausdorff d-measure when $t>0$ is sufficiently large:

$$\mu_H(S_s(t)E_s, d) = 0. \tag{3.17}$$

By hypothesis, for all $h\in H(f)$, $S_s(t)$ is Lipschitz-continuous on E_s with a Lipschitz-continuous inverse when $t>0$ is sufficiently large. Then, since Hausdorff measure has the property $\mu_H(FB,d)\leqq(\mathrm{Lip}\,F)^d\mu_H(B,d)$ for Lipschitz maps F on metric spaces [21], it is clear that $\mu_H(E_s,d)\leqq \mathrm{Lip}\,((S_s(t))^{-1})^d\mu_H(S_s(t)E_s,d)$ so that, using (3.17), $\mu_H(E_s,d)=0$ and $d_H(E_s)\leqq d$.

As with corresponding autonomous situations, estimates of the fractal dimension of sets of the form (2.8) proceed in a similar manner to the estimates of their Hausdorff dimension in the preceding theorem, except that more stringent hypotheses are required.

THEOREM 3.3. *Consider the same hypotheses as in Theorem* 3.2 *with the exception that condition* (3.16) *is replaced by the following condition.*

For some $d=n+s$, $n\in\mathbb{N}$ *with* $n>1$, $s\in(0,1]$, ${}_s\bar{\bar{\omega}}_j({}_s\bar{\bar{\omega}}_{n+1})^{d-j/n+1}<1$ *for* $j=1,\cdots,n$, *where* ${}_s\bar{\bar{\omega}}_j=\sup_{t\in[0,1]}{}_s\bar{\omega}_j(t)$. *Then the fractal dimension of* E_s, $d_F(E_s)$, *is finite and* $d_F(E_s)\leqq d$.

Proof. The proof is similar to that of Theorem 3.2. From the method of proof used in autonomous cases (see, e.g., [32, pp. 284-287]) we obtain a covering of the set $Y_s(t)=S_s(t)E_s$ by a minimum number $n(\varepsilon)$ of K-balls of radius $\varepsilon>0$ when $t>0$ is sufficiently large. The assertion of the theorem follows from an estimate of the capacity of the set $Y_s(t)$ when t is sufficiently large, obtained by the methods indicated above, the compactness of the set E_s, and the result that the capacity of a compact set is invariant under a mapping of the set by a Lipschitz-continuous homeomorphism with a Lipschitz-continuous inverse [27].

With the results of the preceding two theorems in hand, we can define uniform Lyapunov numbers and uniform Lyapunov exponents in an analogous manner to autonomous cases [7]-[9], [32]. Let $\Pi_{j,s}$ denote the respective limits (3.15). They exist because of the subexponential property of the quantities $\{{}_s\bar{\omega}_j\}$. We then define the quantities $\Lambda_{j,s}(j=1,\cdots,m)$ recursively by

$$\Lambda_{1,s}=\Pi_{1,s},\qquad \Lambda_{1,s}\Lambda_{2,s}=\Pi_{2,s},\cdots,\Lambda_{1,s}\cdots\Lambda_{m,s}=\Pi_{m,s}. \tag{3.18}$$

The quantities $\Lambda_{m,s}$ and

$$\mu_{m,s}=\log\Lambda_{m,s},\quad m\geqq 1 \tag{3.19}$$

will be called uniform (or global) Lyapunov numbers and exponents, respectively, for the sets E_s.

Using these exponents, we can give alternative versions of Theorems 3.2 and 3.3.

THEOREM 3.4. *Assume the hypotheses of Theorem* 3.2, *and consider the maps* (2.13) *corresponding to admissible forcing functions. If, for some* $n>1$,

$$\mu_{1,s}+\cdots+\mu_{n+1,s}<0,$$

then $\mu_{n+1,s}<0$, $\mu_{1,s}+\cdots+\mu_{n,s}/|\mu_{n+1,s}|<1$, *and*

(i) $\quad d_H(E_s)\leqq n+(\mu_{1,s}+\cdots+\mu_{n,s})_+/|\mu_{n+1,s}$,

(ii) $\quad d_F(E_s)\leqq(n+1)\max\limits_{1\leqq j\leqq n}\left(1+\dfrac{(\mu_{1,s}+\cdots+\mu_{j,s})+}{|\mu_{1,s}+\cdots+\mu_{n+1,s}|}\right)$,

where $x_+=\max(x,0)$.

The proof is analogous to that of [32, Thm. 3.3, p. 287].

As in autonomous situations, it is convenient to define auxiliary quantities (see (3.21) below) from which Lyapunov exponents and also the Hausdorff and fractal dimensions of invariant sets can be estimated. Thus, if we write the first variational equation corresponding to the mapping (3.14) in the form

$$\frac{d}{dt}\Phi(t)=F'(\psi)\Phi(t), \tag{3.20}$$

then we have, in the m-fold exterior product of the Hilbert space K,

$$\|\Phi_1(t)\Lambda\cdots\Lambda\Phi_m(t)\|_{\Lambda^m K}=\|\rho_1\Lambda\cdots\Lambda\rho_m\|_{\Lambda^m K}\exp\left(\int_0^t\operatorname{Tr}F'(S_s(p)(\phi))\circ Q_m(p)\,dp\right),$$

where $Q_m(p)=Q_m(p,\phi;\rho_1,\cdots,\rho_m)$ is the orthogonal projection onto the subspace spanned by $\Phi_1(p),\cdots,\Phi_m(p)$. We then define

$${}_sq_m=\limsup_{t\to+\infty}{}_sq_m(t) \tag{3.21}$$

with

$${}_sq_m(t)=\sup_{\chi\in E_s}\ \sup_{\substack{\rho_i\in K\\ \|\rho_i\|_K\leqq 1\\ (i=1,\cdots,m)}}\left(\frac{1}{t}\int_0^t\operatorname{Tr}F'(S_s(p)(\chi))\circ Q_m(p)\,dp\right).$$

Then, for a given DNLPDE with time-dependent forcing by admissible functions, we can obtain bounds for the uniform Lyapunov exponents in terms of the ${}_sq_j$. We will discuss this for a class of dissipative nonlinear wave equations in the following section, and for a class of reaction-diffusion equations in § 5.

4. Nonlinear wave equations with nonlinear dissipation. In this section we consider equations of the form

$$u_{tt}+\beta(u_t)-\Delta u+g(u)=f\qquad\text{on }\Omega\times[s,\infty) \tag{4.1}$$

for particular classes of polynomial nonlinearities g, admissible time-dependent forcing terms f, and nonlinear dissipation terms β for fixed $s \in \mathbb{R}$. A number of authors have considered equations of the type (4.1) with various assumptions on f, g, and β. Our results generalize investigations of autonomous [2]-[4], [15], [22], [16], [32] and time-periodic [15] forcing with linear dissipation ($\beta(u_t) = \alpha u_t$, $\alpha \in \mathbb{R}$).

We shall assume that Ω is a connected bounded open subset of $\mathbb{R}^n (n \geqq 3)$ with a smooth (at least C^2) boundary $\partial\Omega$. We consider processes W related to solutions u of (4.1) as in (2.3) and assume Dirichlet boundary conditions

$$u(x, t) = 0 \quad \text{on}\, \partial\Omega \times [s, \infty) \tag{4.2}$$

with initial conditions

$$u(x, s) = u_s(x), \quad u_t(x, s) = \tilde{u}_s(x), \quad x \in \Omega. \tag{4.3}$$

Different linear operators in (4.1) and either Neumann or periodic boundary conditions can also be considered, but we will not discuss them.

For equations of the type (4.1)-(4.3), Haraux [18], [20] proved existence and uniqueness of global solutions and existence of bounded absorbing sets in $H_0^1(\Omega) \times L^2(\Omega)$ for certain classes of nonlinearities g and dissipation terms β. However, it is clear from our discussion in § 3 that more general results are required in order to establish the dimensionality estimates in Theorems 3.2-3.4. In particular, it is necessary that the system be asymptotically compact in the sense of (3.7) or some facsimile thereof. We will establish results of this type in the present section for a class of nonlinear dissipations β.

In [19], Haraux announced asymptotic compactness results for equations of the type (4.1)-(4.3) with almost periodic forcing and weak nonlinear dissipations β whose derivatives are bounded from both above and below. We note that Haraux's result involves a concept of "uniform asymptotic compactness" that is different from our asymptotic compactness conditions (2.14) and (3.7). We will verify that (3.7) and the other hypotheses of Theorems 3.2-3.4 are satisfied for a large class of equations of the type (4.1)-(4.3). We also require the same weakness condition on β' that Haraux uses. It is recognized that this condition is excessively restrictive (see a similar remark in [19]), but this defect is common to all studies of attractors for (4.1) at the present time. We also extend our results to systems of equations analogous to (4.1)-(4.3).

We make the following assumptions concerning the nonlinearities g and β:

(4.4) g is a C^1 mapping from $V_1 \equiv H_0^1(\Omega)$ into $H \equiv L^2(\Omega)$, Fréchet differentiable with differential g', which satisfies

$$|g'(u)| \leqq C_3(1 + |u|^r) \quad \text{a.e. on } \mathbb{R} \tag{4.5}$$

with a constant $C_3 > 0$ and $r = 2$ if $n = 3$, $r = 0$ if $n \geqq 4$. Let $G(r)$ denote the following primitive of g:

$$G(r) \equiv \int_{-\infty}^{r} g(s)\, ds \quad \text{for all } r \in \mathbb{R}. \tag{4.6}$$

Then we also require that

(4.7) for all $s \in \mathbb{R}$, $G(s) \geqq \left(\frac{-\lambda_1}{2} + \omega\right)s^2 - C_4$ for $\omega > 0$, $C_4 \geqq 0$, and for all $s \in \mathbb{R}$;

(4.8) $sg(s) - G(s) \geqq \left(\frac{-\lambda_2}{2} + \delta\right)s^2 - C_5$ for $\delta > 0$, $C_5 \geqq 0$, where λ_1 denotes the smallest eigenvalue of $-\Delta$.

(4.9) β is an odd C^1 mapping from $\mathbb{R}$ to $\mathbb{R}$ which satisfies the following conditions: there exists $\alpha > 0$ and $C_1 \geqq 0$

such that

$$\beta(v)v \geqq \alpha|v|^2 - C_1 \quad \text{for all } v \in \mathbb{R}, \tag{4.10}$$

$$|\beta(v)| \leqq c(1+|v|^p) \quad \text{for all } v \in \mathbb{R} \tag{4.11}$$

with $0 \leqq p \leqq (n+2)/(n-2)$, $n \geqq 3$. Then we have the following.

THEOREM 4.1 ([20], [18]). *Assume that* (4.4), (4.5), *and* (4.7)-(4.11) *hold. Let f, u_s, $\tilde{u}_s$ be given such that (for fixed $s \in \mathbb{R}$) $f \in C_b(\mathbb{R}, H)$, $u_s \in V_1$, $\tilde{u}_s \in H$. Then the problem* (4.1)-(4.3) *has a unique solution u that satisfies $\{u, u_t\} \in C_b([s, \infty), V_1 \times H = B)$. In addition, for all $t \geqq 0$, the mapping $\{u_s, \tilde{u}_s\} \to \{u(t+s), u_t(t+s)\}$ is a homeomorphism from B onto itself. Furthermore, there exists a closed ball in B that is absorbing for* (4.1)-(4.3). *Moreover, if f is admissible, then the above results are valid if f is replaced by any $h \in H(f)$.*

The homeomorphic property of the solution-maps in Theorem 4.1 (not stated by Haraux) is associated with the properties of (4.1) under time-reversal and the fact that β is assumed to be an odd mapping. The proofs of Theorem 4.1 by Haraux use the weaker formulation of (4.5) that $0 \leqq r < \infty$ if $n = 1$ or 2 and $0 \leqq r \leqq 2$ if $n = 3$; but for the proof of Theorem 4.2 (see below) and subsequent results, we require the stronger assumption stated in (4.5).

For the proofs of the results to follow, it will be convenient to follow the customary procedure in the treatment of hyperbolic equations and write (4.1) as a system of first-order equations. Also, in order that exponential decay properties as $t - +\infty$ can be proved for solutions of the linearized equations, we decompose the dissipation term $\beta(u_t)$ into a linear part and a remainder:

$$\beta(u_t) = \gamma u_t + \tilde{\beta}(u_t), \tag{4.12}$$

and we use the renorming technique introduced by Haraux [17] and later generalized in [15] (for a short discussion see [26]). Then we have the following:

$$\psi_t + \Lambda_\varepsilon \psi + \Gamma(\psi) + D(\psi) = F, \tag{4.13}$$

where $\psi = (u, v)$, $v = u_t + \varepsilon u$, $\Gamma(\psi) = (0, g(u))$, $D(\psi) = (0, \tilde{\beta}(u_t))$, $F = (0, f)$, $\Lambda_\varepsilon = \left(\begin{smallmatrix} & \varepsilon & -1 \\ \varepsilon(\varepsilon-\gamma)-\Delta & & \gamma-\varepsilon \end{smallmatrix}\right)$, $0 < \varepsilon \leqq \varepsilon_0$ with $\varepsilon_0 = \min(\gamma/4, \lambda_1/2\gamma)$, and the initial data are expressed in the form

$$\psi(s) \equiv \psi_s = (u_s, v_s), \qquad v_s = \tilde{u}_s + \varepsilon u_s. \tag{4.14}$$

We will prove that the system (4.13), (4.14) satisfies the asymptotic compactness condition (3.7). However, we first need a result analogous to Theorem 4.1 pertaining to the domain of $-\Delta$.

THEOREM 4.2. *Assume that* (4.4), (4.5), (4.7)-(4.10) *hold and, in place of* (4.11), *assume that $\beta(v)$ has a decomposition* (4.12) *with $\tilde{\beta}$ a C^1 mapping with a Fréchet differential $\tilde{\beta}'$ such that, for some constant $C_6 > 0$,*

$$|\tilde{\beta}'(v)| \leqq C_6, \qquad v \in \mathbb{R}. \tag{4.15}$$

Let f, u_s, and $\tilde{u}_s$ be given such that (for fixed $s \in \mathbb{R}$)

$$f, f_t \in C_b(\mathbb{R}, H), \quad u_s \in H^2(\Omega) \cap H_0^1(\Omega) \equiv V_2, \quad \tilde{u}_s \in V_1. \tag{4.16}$$

Then, if

$$C_6 < \min\left(\frac{\varepsilon}{4}+\frac{\gamma}{2}, \frac{1}{8\varepsilon}\left[-1+\sqrt{1+16\varepsilon\left(\frac{\varepsilon}{4}+\frac{\gamma}{2}\right)}\right]\right), \tag{4.17}$$

the solutions of (4.1)-(4.3) *obtained in Theorem* 4.1 *satisfy* $\{u, u_t\} \in C_b([s, \infty), V_2 \times V_1)$. *Furthermore, there exists a closed ball in* $V_2 \times V_1$ *that is absorbing for* (4.13), (4.14). *Moreover, if f is admissible, the above results are also valid if f is replaced by any* $h \in H(f)$.

Proof. Except for the final assertion concerning the extension of the results to any $h \in H(f)$ when f is admissible, the proof is analogous to the proof of Theorem 2.2 in [15]; therefore, we will not give the details but will just note that the proof involves a liberal use of Young and Poincaré inequalities, combined with Gronwall estimates and the continuity of the imbedding

$$V_2 \times V_1 \hookrightarrow V_1 \times L^2. \tag{4.18}$$

The condition (4.17) results from a requirement that the positive parameters ε that occur in Young inequalities of the form

$$ab \leqq \frac{\varepsilon}{2} a^2 + (2\varepsilon)^{-1} b^2, \qquad a, b > 0$$

be chosen in such a way that we may conclude that $(u, u_t) \in C_b([s, \infty), V_2 \times V_1)$ from the appropriate Gronwall estimate. Combining this procedure with the result that $(u, u_t) \in C_b([s, \infty), B)$, which follows from Theorem 4.1, we infer the existence of a bounded absorbing set in $V_2 \times V_1$.

Now we have the following lemma.

LEMMA 4.1. *Assume the hypotheses of Theorem* 4.2 *and in addition that* $f \in C_b(\mathbb{R}, V_1)$. *Then, for all $t \in \mathbb{R}^+$ and every fixed $s \in \mathbb{R}$, the continuous mapping $U_s(t): B \to B$ defined by*

$$U_s(t) = S_s(t) - \exp(-\Lambda_\varepsilon t) \tag{4.19}$$

is uniformly compact; i.e., it satisfies the condition that, for all bounded sets $\tilde{B} \subset B$ and for all $t \in \mathbb{R}^+$, the union $\bigcup_{\tau \geqq t} U_s(\tau)\,\tilde{B}$ is contained in a compact subset of B. Moreover, if f is admissible, this result is true if f is replaced by any $h \in H(f)$.

Proof. From (4.13), (4.14) we have

$$\psi(s+t) = \Sigma_\varepsilon(t)\phi + \int_0^t \Sigma_\varepsilon(t-\sigma)(F(s+\sigma) - \Gamma(\psi(s+\sigma)) - D(\psi(s+\sigma)))\,d\sigma \tag{4.20}$$

with $\psi(s) = \phi$, where $\Sigma_\varepsilon(t) = \exp(-\Lambda_\varepsilon t)$ is the group associated with the corresponding linear equation so that, upon comparison with (4.19),

$$U_s(t+s)\phi = \int_0^t \Sigma_\varepsilon(t-\sigma)(F(s+\sigma) - \Gamma(\psi(s+\sigma)) - D(\psi(s+\sigma)))\,d\sigma. \tag{4.21}$$

We require the exponential decay of the group $\Sigma_\varepsilon(t)$ in the space $V_2 \times V_1$: $\|\Sigma_\varepsilon(t)\|_{L(V_2 \times V_1)} \leqq \exp(-(\varepsilon/2)t)$, $t \geqq 0$. This follows from the combination of an energy estimate in $V_2 \times V_1$ and a Gronwall argument as in [15]. Then we find from (4.21), (4.5), (4.15), Theorem 4.2, and the additional hypothesis that $f \in C_b(\mathbb{R}, V_1)$:

$$\begin{aligned} \|U_s(t+s)\phi\|_{V_2 \times V_1} \leqq \frac{2}{\varepsilon}\left(1 - \exp\left(-\frac{\varepsilon}{2}t\right)\right) & \\ \times \sup_{\sigma \varepsilon [0, t]} (\|f(s+\sigma)\|_{V_1} + C(R)(1 + \|u(s+\sigma)\|_{H^2(\Omega)})^\sigma & \\ + C_6 \|u_t(s+\sigma)\|_{V_1}). & \end{aligned}$$

It follows from Theorem 4.2 that, for all bounded sets $\tilde{B} \subset V_1 \times L^2(\Omega)$, $\bigcup_{\tau \geqq t} U_s(\tau)\tilde{B}$ is contained in a bounded set Y in $V_2 \times V_1$. Then, from the compactness of the imbedding (4.18), Y is compact in $V_1 \times L^2(\Omega)$, and the proof is complete.

PROPOSITION 4.1. *Assume the hypotheses of Lemma* 4.1. *Then, for given* $s \in \mathbb{R}$,

(i) $S_s(t)$ *possesses a bounded absorbing set* $B_0 \subset B$;

(ii) *For all bounded sets* $\tilde{B} \subset B$, *there exists a compact set* $G \subset B$ *such that*

$$\lim_{t \to +\infty} \sup_{\phi \in \tilde{B}} d_B(S_s(t)\phi, G) = 0, \tag{4.22}$$

where d_B *is defined as in* (2.15).

In addition, if f is admissible, (i) *and* (ii) *remain valid when f is replaced by any* $h \in H(f)$.

Proof. The proof is analogous to that of a corresponding result in [15]. (i) follows from Theorem 4.1. To prove (ii), let $\tilde{B}$ be a bounded set in B. By Lemma 4.1, there exists a compact set $G \subset B$ such that $\bigcup_{t \geqq 0} U_s(t+s)\tilde{B} \subset G$. We then establish (4.22) by using the exponential decrease with t of the linear group $\Sigma_\varepsilon(t)$.

We are now prepared to prove the continuity of the translation semigroup $\{\sigma(t), t \geqq 0\}$ relative to the system (4.1)-(4.3).

PROPOSITION 4.2. *Assume the hypotheses of Theorem* 4.1 *and, in addition, that* $f_t \in C_b(\mathbb{R}, H)$ *and that f is time-dependent admissible from* $\mathbb{R}$ *to* H. *Then the translation semigroup* $\{\sigma(t), t \geqq 0\}$ *is continuous from* $H(W)$ *to itself, where W is the almost periodic process associated as in* (2.3) *with the unique solution* $\psi(u, v)$ *of* (4.13), (4.14) *obtained in Theorem* 4.1.

Proof. Since $\psi(t+s)$ is uniformly bounded in B by Theorem 4.1, we may assume that it is contained in a B-ball:

$$\|\psi(t+s)\|_B \leqq K_1(R) \quad \text{if } \|\psi(s)\|_B \leqq R \tag{4.23}$$

for some $R > 0$. From the mean value theorem for Banach spaces, (4.5), and the well-known Sobolev imbedding theorem

$$H_0^1(\Omega) \hookrightarrow L^q(\Omega) \quad \text{if } 2 \leqq q \leqq \frac{2n}{n-2} \quad \text{with } n \geqq 3,$$

we find

$$\|\Gamma(\psi) - \Gamma(\tilde{\psi})\|_B \leqq C(R)\|\psi - \tilde{\psi}\|_B \tag{4.24}$$

with a positive constant $C(R)$, where $\tilde{\psi}$ is another solution of (4.13), (4.14) that also satisfies (4.23). Similarly, using (4.15) and the mean value theorem again, we obtain

$$\|D(\psi) - D(\tilde{\psi})\|_B \leqq 2C_6\|\psi - \tilde{\psi}\|_B. \tag{4.25}$$

Also, there exists a positive constant c such that

$$\|F(t+s+\omega) - F(t+s)\|_B \leqq c\omega$$

uniformly in s and t since $f_t \in C_b(\mathbb{R}, H)$ by hypothesis.

Since $\{\sigma(t), t \geqq 0\}$ is a semigroup, it is sufficient to prove continuity at $t = 0$. The solution ψ of (4.13), (4.14) also satisfies (4.20), and we have the following estimate for the linear group $\Sigma_\varepsilon(t)$ [15, p. 278]:

$$\|\Sigma_\varepsilon(t)\|_{L(B)} \leqq \exp\left(-\frac{\varepsilon}{2}t\right), \quad t \geqq 0, \quad 0 < \varepsilon \leqq \varepsilon_0. \tag{4.26}$$

Then, using the Schwarz inequality, we obtain (with $\omega > 0$)

$$\begin{aligned}
&\|\sigma(\omega)W(t,s)\phi - W(t,s)\phi\|_B \leqq \|\Sigma_\varepsilon(t)(\Sigma_\varepsilon(\omega)-1)\phi\|_B \\
&\quad + \int_0^t \|\Sigma_\varepsilon(t-\sigma)(\Sigma_\varepsilon(\omega)-1)(F(s+\sigma)-\Gamma(\psi(s+\sigma))-D(\psi(s+\sigma)))\|_B\, d\sigma \qquad (4.27)\\
&\quad + \int_t^{t+\omega} \|\Sigma_\varepsilon(t+\omega+\sigma)(F(s+\sigma)-\Gamma(\psi(s+\sigma))-D(\psi(s+\sigma)))\|_B\, d\sigma.
\end{aligned}$$

To estimate the first norm, we use the fact that $\Sigma_\varepsilon(t)$ is uniformly bounded in t by (4.26), so that we can approximate ϕ in the B-norm by a sequence $\{\phi_n\}$ from the domain of Λ_ε, $D(\Lambda_\varepsilon)$, which is a dense subset of B. Given $\delta > 0$, we choose $n_0 \in \mathbb{N}$ such that

$$\|\phi + \phi_n\|_B < \frac{\varepsilon}{2(\varepsilon+6)}\delta \quad \text{when } n \geqq n_0. \qquad (4.28)$$

We have the estimate

$$\|(\Sigma_\varepsilon(t)-1)\chi\|_B \leqq t\|\Lambda_\varepsilon \chi\|_B, \quad t \geqq 0, \quad \chi \in D(\Lambda_\varepsilon),$$

which is a general result for analytic semigroups (cf. [16, p. 71]). Using this result and (4.26), we obtain

$$\|\Sigma_\varepsilon(t)(\Sigma_\varepsilon(\omega)-1)\phi\|_B < \frac{\varepsilon\delta}{\varepsilon+6} + \omega\|\Lambda_\varepsilon\phi_n\|_B (n \geqq n_0, \phi_n \in D(\Lambda_\varepsilon)). \qquad (4.29)$$

Similarly, in addition to the uniform boundedness of $\Sigma_\varepsilon(t)$, we use the fact that $\Gamma(\psi(t+s))$, $D(\psi(t+s))$, and $F(t+s)$ also have this property, which follows from (4.23) and the respective hypotheses (4.5), (4.11), and $f \in C_b(\mathbb{R}, H)$. It immediately follows that the second integral in (4.27) is bounded by $C'\omega$ with C' a positive constant. Finally, to estimate the remaining integral in (4.27), we use the boundedness properties noted above to approximate $F(s+\sigma)$, $\Gamma(\psi(s+\sigma))$, and $D(\psi(s+\sigma))$ by respective sequences $\{F_n(s+\sigma)\}$, $\{\Gamma_n(s+\sigma)\}$, and $\{D_n(s+\sigma)\} \subset D(\Lambda_\varepsilon)$ to obtain a bound analogous to (4.29). By choosing n_0 large enough, we can use the same value of δ as in (4.28) for these approximations. Thus, by collecting the above results we have, with $n \geqq n_0$,

$$\begin{aligned}
&\|\sigma(\omega)W(t,s)\phi - W(t,s)\phi\|_B \\
&\quad < \delta + \omega(C' + \|\Lambda_\varepsilon\phi_n\|_B) + \omega\int_0^t \exp\left(-\frac{\varepsilon}{2}(t-\sigma)\right) \qquad (4.30)\\
&\qquad \cdot \{\|\Lambda_\varepsilon F_n(s+\sigma)\|_B + \|\Lambda_\varepsilon\Gamma_n(s+\sigma)\|_B + \|\Lambda_\varepsilon D_n(s+\sigma)\|_B\}\, d\sigma,
\end{aligned}$$

from which it follows that $\sigma(\omega)$ is continuous at $\omega = 0$ on the distinguished process W.

In order to prove that W is almost periodic, we establish an estimate of the type (3.1). Thus, consider two solutions ψ_1, ψ_2 of (4.13), (4.14) with the same initial datum ϕ, but corresponding to two distinct admissible forcing terms f_1, f_2. Then, from (4.13), (4.14), the B-positivity of $\Lambda_\varepsilon((\chi, \Lambda_\varepsilon\chi) \geqq 0, \chi \in B)$, the Lipschitz estimates (4.24), (4.25), Young's inequality, and a Gronwall estimate, we obtain the inequality

$$\begin{aligned}
&\|\psi_1(t+s) - \psi_2(t+s)\|_B \\
&\quad \leqq c^{-1}\exp\left(\frac{1}{2}\tilde{K}t\right) \sup_{\tau\in[0,t]} \|F_1(\tau+s) - F_2(\tau+s)\|_B,
\end{aligned}$$

with $\tilde{K} = c + 2C(R) + 4c\sigma$. It follows that W is almost periodic since f is admissible by hypothesis.

Take $V \in H(W)$. Then, for any sequence $\{\tau_n\} \subset \mathbb{R}$, there exists a subsequence $\{\tau_{n_m}\} \subset \{\tau_n\}$ such that $W_{\tau_{n_m}}(t, s)\phi \to_{m\to\infty} V(t, s)\phi$ uniformly in $s \in \mathbb{R}$ for all $t \in \mathbb{R}^+$ and for all $\phi \in B$. In order to show that $\sigma(\omega)$ is continuous on $V\phi$, consider the following estimate:

$$\begin{aligned}&\|\sigma(\omega)V(t, s)\phi - V(t, s)\phi\|_B\\ (4.31)\ &\leqq \|\sigma(\omega)W(t, s+\tau_{n_m})\phi - W(t, s+\tau_{n_m})\phi\|_B + \|V(t, s+\omega)\phi - W_{\tau_{n_m}}(t, s+\omega)\phi\|_B\\ &\quad + \|V(t, s)\phi - W_{\tau_{n_m}}(t, s)\phi\|_B.\end{aligned}$$

The first norm can be estimated in the same way as (4.30). Given $\eta > 0$, choose m_0 such that each of the last two norms in (4.31) is less than $\eta/2$ when $m \geqq m_0$. This can be done uniformly in $s \in \mathbb{R}$ for all $t \in \mathbb{R}^+$ and all $\phi \in H$ (see (2.6)). The assertion of the proposition follows.

This proposition, together with the result in Theorem 4.1, establishes the hypotheses of Proposition 3.1 for (4.1)-(4.3).

The first variational equation corresponding to (4.13), (4.14) has the form

$$\Phi_t(t+s) + \Lambda_\varepsilon\Phi(t+s) + \Gamma'(\psi)\Phi(t+s) + D'(\psi)\Phi(t+s) = 0, \tag{4.32}$$

$$\Phi(s) = \rho \in B, \tag{4.33}$$

where $\psi = \psi(t+s)$ is a solution of (4.13), (4.14). We see that $\Phi(t+s)$ is independent of the forcing term in (4.13) as required by one of our hypotheses in § 3.

We proceed to the proof of existence of Fréchet derivatives of the maps (2.13).

THEOREM 4.3. *Let W be a process associated in the usual way* (2.3) *with a solution ψ of* (4.13), (4.14), *assuming our hypotheses* (4.4), (4.5), (4.7)-(4.10), $f \in C_b(\mathbb{R}, .H)$, $u_s \in V_1$, $\tilde{u}_s \in H$ *and, in addition, that a decomposition* (4.12) *holds with $\tilde{\beta}$ satisfying* (4.15). *Furthermore, assume that there exists $\nu \in (0, 1]$ and, for every $R > 0$, also a positive constant $C_2 = C_2(R)$ such that*

$$\|g'(\rho) - g'(\eta)\|_{L(V_1,H)} \leqq C_2\|\rho - \eta\|_{V_1}^{\nu} \tag{4.34}$$

for all $\rho, \eta \in V_1$ with $\|\rho\|_{V_1} \leqq R$, $\|\eta\|_{V_1} \leqq R$ and, for the same value of ν, there exists $\tilde{c}_2 = \tilde{c}_2(R)$ such that

$$\|\tilde{\beta}'(u_t) - \tilde{\beta}'(\tilde{u}_t)\|_{L(H)} \leqq \tilde{c}_2\|u_t - \tilde{u}_t\|_H^{\nu} \tag{4.35}$$

for all $u_t, \tilde{u}_t \in H$ with $\|u_t\|_H \leqq R$, $\|\tilde{u}_t\|_H \leqq R$. Then Fréchet derivatives L of the maps (2.13) *exist and are defined in terms of appropriate solutions of* (4.32), (4.33) *as in* (3.14). *Moreover, if f is admissible, this result is also true when f is replaced by any $h \in H(f)$.*

The proof follows the lines of that given in Appendix B of [15] and makes use of the mean value theorem for Banach spaces, Young's inequality, and a Gronwall argument.

COROLLARY. *For all $t > 0$ and all $s \in \mathbb{R}$, the mapping $S_s(t)$ is of class $C^{1,\nu}$, where ν is the same as in* (4.34), (4.35).

We have now verified that all the hypotheses in § 3 are valid for (4.1)-(4.3). In particular, we note that condition (7) of § 2 is satisfied for this system because the maps $S_s(t)$ are Lipschitz homeomorphisms with Lipschitz-continuous inverses on the entire Hilbert space B.

We now obtain more information concerning the Hausdorff and fractal dimensions of sets of type (2.8) by deriving explicit estimates for the quantities (3.21). We note that (4.32) is of the form (3.20) with $F'(\psi) = -\Lambda_\varepsilon - \Gamma'(\psi) - D'(\psi)$. At a given time $p+s$, let $\{X_j(p+s) = (\rho_j(p+s), z_j(p+s)) \in V_1, j = 1 \cdots, m\}$ denote an orthonormal basis of B spanning an m-dimensional subspace $Q_m(p+s)B$. Then, following an argument in [32, pp. 360-364], we obtain

$$(F'(\psi)\chi_j, \chi_j)_B \leqq -\frac{\varepsilon}{4}(\|\rho_j\|_{V_1}^2 + \|z_j\|_H^2) + \frac{2(\gamma^2+C_6^2)}{\varepsilon}\|\rho_j\|_{V_\eta}^2, \tag{4.36}$$

where we have assumed that the initial data (4.14) belongs to a set of type (2.8), which, according to Theorem 4.2, is a bounded subset of $B_1 = V_2 \times V_1 = D(-\Delta) \times H_0^1(\Omega)$. Then

$$\psi(t+s) = \{u(t+s), u_t(t+s) + \varepsilon u(t+s)\}$$

belongs to a bounded subset of B_1, and $u(t+s)$ belongs to a bounded subset M of $D(-\Delta)$ for all $t \in \mathbb{R}^+$. The quantity η in (4.36) arises from the following additional assumption concerning g':

(4.37) g' is a bounded mapping from $D(-\Delta)$ to $L(V_\eta, H)$ for some $\eta \in [0, 1)$.

It follows [15] that there exists $\eta\varepsilon[0, 1)$ such that g' maps M into a bounded subset of $L(V_\eta, H)$. The constant γ in (4.36) is defined by $\gamma = \sup_{w\in D(-\Delta)} \|g'(w)\|_{L(V_\eta,H)}$. The final form of (4.36) is obtained by two applications of Young's inequality. Then, using the fact that the $\{\chi_j\}(j \in \mathbb{N})$ are orthogonal in B and a lemma in [32], we obtain the following estimates for the quantities in (3.21):

$${}_sq_m(t) \leqq \frac{-m\varepsilon}{4} + \frac{2(\gamma^2+C_6^2)}{\varepsilon}\sum_{j=1}^m \lambda_j^{\eta-1}, \tag{4.38}$$

$${}_sq_m \leqq \frac{-m\varepsilon}{4} + \frac{2(\gamma^2+C_6^2)}{\varepsilon}\sum_{j=1}^m \lambda_j^{\eta-1}, \tag{4.39}$$

where the $\{\lambda_j\}$ are eigenvalues of $-\Delta$. It follows from (3.11), (3.18), (3.19), and the above results that we obtain the following estimates for the uniform Lyapunov exponents.

THEOREM 4.4. *Assume the hypotheses of Theorem* 4.3 *as well as the additional hypothesis* (4.37). *Then*

(i) *The uniform Lyapunov exponents $\mu_{j,s}$ associated with sets of type* (2.8) *are majorized according to*

$$\mu_{1,s} + \cdots + \mu_{j,s} \leqq \frac{-m\varepsilon}{4} + \frac{2(\gamma^2+C_6^2)}{\varepsilon}\sum_{i=1}^j \lambda_i^{\eta-1}, \qquad j \in \mathbb{N}; \tag{4.40}$$

(ii) *The m-dimensional volume element is exponentially decreasing in the Hilbert space B*;

(iii) *We have the upper bounds for the Hausdorff and fractal dimensions of E_s,$d_H(E_s) \leqq m_0$, $d_F(E_s) \leqq \frac{4}{3}m_0$, where m_0 is chosen in such a way that*

$$\sum_{i=1}^{m_0} \lambda_i^{\eta-1} \leqq \frac{\varepsilon^2 m_0}{16(\gamma^2+C_6^2)}. \tag{4.41}$$

Remark 4.1. (a) Note that the bounds (4.38)-(4.40) are uniform in s. (b) There are some differences in the details of the proof of Theorem 4.4 compared with the proof of the corresponding autonomous result that we now point out. (b1) As a consequence of the fact that we include effects of weak nonlinear dissipation, the constant C_6 appears in the bounds (4.38)-(4.41). This has the consequence that the allowed values of m_0, defined to be those for which (4.41) is valid, are different from those for the corresponding linearly damped equation. (b2) The validity of (ii) follows from the estimate

$$\operatorname{Tr} F'(\psi(p+s)) \circ Q_m(p+s) \leqq \frac{-m_0\varepsilon}{4} + \frac{2(\gamma^2+C_6^2)}{\varepsilon} \sum_{j=1}^{m} \lambda_j^{\eta-1},$$

the choice of values of m_0 being those allowed by (4.41).

To conclude our discussion of the system (4.1)-(4.3), we note that the considerations of the present section can be extended to systems of equations of type (4.1). Thus, in place of that equation, we consider the system of equations

$$u_{tt} + \beta(u_t) - Au + g(u) = f, \tag{4.42}$$

obtained from (4.1) by letting u be an l-dimensional vector $u = (u_1, \cdots, u_l)$ and by replacing $-\Delta$ by $-A\Delta$ where A is a symmetric matrix, although we could also consider linear unbounded elliptic selfadjoint operators L with smooth coefficients whose inverses are compact on the Hilbert space $H = (L^2(\Omega))^l$, where Ω is a bounded domain on which we impose conditions analogous to those stated at the beginning of this section in the case of (4.1). We impose Dirichlet boundary conditions (4.2) on each component of u, although Neumann or periodic boundary conditions could also be considered. The nonlinearity $g(u)$ is of "potential type"; i.e., there exists a function $G(u_1, \cdots, u_l)$ (a generalization of the primitive (4.6)) such that $g_i(u) = (\partial/\partial u_i)G(u_1, \cdots, u_l)$ $(i = 1, \cdots, l)$. We assume that the dissipative term β has a representation analogous to (4.12) with the constant γ replaced by a positive-definite matrix. The hypotheses (4.4), (4.5), (4.7)-(4.12), (4.15), (4.16), (4.34), (4.35), and (4.37) are replaced by their obvious vector analogues. Under these conditions, we can verify all the hypotheses required for the proofs of the dimension estimates in Theorems 3.2-3.4, and analogous results to those in Theorem 4.4 can be obtained for the system (4.42). These results generalize the work of Babin and Vishik [3], [4], who proved existence and other properties of global attractors for autonomous equatons of the above type with linear dissipation.

5. Reaction-diffusion equations. In this section we consider the nonlinear PDE,

$$\psi_t - \Delta\psi + g(\psi) = f(x, t) \quad \text{in } \Omega \times [s, \infty), \tag{5.1}$$

$$\psi(x, s) = \phi(x), \quad x \in \Omega, \quad \text{some } s \in \mathbb{R}, \tag{5.2}$$

with Dirichlet boundary conditions

$$\psi(x, t) = 0, \quad x \in \partial\Omega, \quad t \geqq s, \tag{5.3}$$

where Ω denotes a connected open bounded subset of $\mathbb{R}^n$ with a smooth (at least C^2) boundary $\partial\Omega$. We consider the Hilbert space $H = L^2(\Omega)$ and set $V = H_0^1(\Omega)$. Global attractors and estimates of their dimensions for the system (5.1)-(5.3) with suitable restrictions on g have been considered previously without a time-dependent forcing term f by Babin and Vishik [2], [4], Marion [25], and Témam [32].

We assume the following conditions.

There exists a real number $p \geqq 2$ and positive constants c_1, c_2, c_3 such that

$$c_1 s^{2p} - c_3 \leqq s g(s) \leqq c_2 s^{2p} + c_3 \tag{5.4}$$

for all $s \in \mathbb{R}$. There exist positive constants C_4, C_5 such that

$$g'(s) \geqq -C_4, \tag{5.5}$$

$$g'(s) \leqq C_5(1 + s^{2p-2}) \tag{5.6}$$

for all $s \in \mathbb{R}$.

There exists a positive constant c_6 such that

$$|g(s)| \leqq c_6(1+|s|^{2p-1}) \tag{5.7}$$

for all $s \in \mathbb{R}$.

The forcing term satisfies

$$f \in C_b(\mathbb{R}, H). \tag{5.8}$$

The following result gives basic local and global existence results for (5.1)-(5.3).

THEOREM 5.1. *Assume that* (5.4)-(5.8) *hold. Then, for each* $\phi \in H$, *there exists a unique solution* ψ *of* (5.1)-(5.3) *such that* $\psi \in L^2([s, T]; V) \cap L^{2p}([s, T]; L^{2p}(\Omega))$ *for all* $T > s$ *and* $\psi \in C_b([s, \infty); H)$ *for each* $s \in \mathbb{R}$. *The mapping* $\phi \to \psi(t+s)$ *is continuous on* H. *Furthermore, if* $\phi \in V$, *then*

$$\psi \in C_b([s, T]; V) \cap L^2([s, T]; H^2(\Omega)) \quad \textit{for all } T > s.$$

Finally, if f is admissible, the above results remain valid if f is replaced by any $h \in H(f)$.

The proof relies on classical arguments [23] and is an extension of the arguments of Marion [25] and Témam [32] to cases of time-dependent forcing. We omit the details.

Remark 5.1. Hypotheses (5.4)-(5.7) are satisfied for the nonlinearities $g(s) = |s|^{p-2}s (p \geqq 4, s \in \mathbb{R})$ and $g(s) = \alpha s^3 - \beta s (\alpha, \beta > 0)$.

We now prove the existence of bounded absorbing sets for the system (5.1)-(5.3). Since the proof only differs from corresponding considerations in [32] by the inclusion of time-dependent forcing terms, many details will be omitted.

THEOREM 5.2. *Assume the hypotheses of Theorem* 5.1. *Then*

(a) *There exists a closed ball in H that is absorbing for* (5.1)-(5.3);

(b) *If, in addition to the above hypotheses,* $f \in C_b(\mathbb{R}, V)$, *then there exists a closed ball in V that is absorbing for* (5.1)-(5.3);

(c) *If we construct a process W as in* (2.3) *in terms of the unique solution of* (5.1)-(5.3) *discussed in Theorem* 5.1, *the maps* $S_s(t)\phi = W(t, s; f)\phi$, $\phi \in H$ *are uniformly compact for* $t \geqq t_0$ *with* $t_0 > 0$ *sufficiently large. Moreover, if f is admissible, the above results are valid with f replaced by any* $h \in H(f)$;

(d) *Asymptotic compactness holds; i.e., for all bounded sets* $\tilde{B} \subset H = L^2(\Omega)$, *there exists a compact set* $G \subset H$ *such that*

$$\lim_{t \to +\infty} \sup_{\phi \in \tilde{B}} d_H(S_s(t)\phi, G) = 0$$

with d_H *defined as in* (2.15). *If f is admissible, this result is true for all* $h \in H(f)$.

Proof (sketch). (a) By multiplying (5.1) by ψ and using (5.4), the Poincaré inequality for $H_0^1(\Omega)$, and Young's inequality, we obtain an energy inequality in H from which we obtain, by the standard Gronwall lemma,

$$\limsup_{t \to +\infty} \|\psi(t+s)\|_H \leqq \sqrt{\frac{2}{\lambda_1}} \sqrt{C_3|\Omega| + \frac{1}{2\lambda_1} \|f\|_H^2} \equiv R_0, \tag{5.9}$$

where λ_1 denotes the smallest eigenvalue of $-\Delta$ on Ω and $|\Omega|$ is the volume of Ω. Thus, any ball in $H = L^2(\Omega)$ centered at zero with radius $R_0' > R_0$ is an absorbing set for (5.1)-(5.3).

(b) Analogously, to obtain an absorbing ball in $H_0^1(\Omega)$, we obtain a corresponding energy inequality by multiplying (5.1) by $-\Delta\psi$ and using (5.5) and (5.3) in conjunction with Green's theorem, Young's inequality, and the Poincaré inequality [32] $\|\nabla\psi\|_H \leqq C_7(\Omega)\|\Delta\psi\|_H$ for some positive constant C_7 depending on Ω, to obtain for any $\varepsilon_1, \varepsilon_2 > 0$:

$$\frac{d}{dt} \|\nabla\psi\|_H^2 + \left(\frac{2}{C_7^2} - 2C_4 - \varepsilon_1 - \varepsilon_2\right) \|\nabla\psi\|_H^2 \leqq \varepsilon_1^{-1} \|f\|_H^2 + \varepsilon_2^{-1} \|\nabla f\|_H^2. \tag{5.10}$$

First consider the case when $C_7^{-2} > C_4$. Then, setting $\varepsilon_1 = \varepsilon_2 = \frac{1}{2}(C_7^{-2} - C_4)$, a standard Gronwall estimate yields the result

$$\limsup_{t\to+\infty} \|\nabla\psi(t+s)\|_H \leqq \sqrt{2}(C_7^{-2} - C_4)^{-1}(\|f\|_H^2 + \|\nabla f\|_H^2)^{1/2} \equiv R_1,$$

and a similar argument to the discussion following (5.9) yields the result that any ball in $H_0^1(\Omega)$ centered at zero with radius $R_1' > R_1$ is an absorbing set for (5.1)-(5.3) when $C_7^{-2} > C_4$.

For the remaining cases $C_7^{-2} \leqq C_4$, we put $\varepsilon_1 = \varepsilon_2 = C_7^{-2}$ and obtain from (5.10) by a standard Gronwall argument,

$$\begin{aligned} \|\nabla\psi(t+s)\|_H^2 \leqq{}& \exp(2C_4 t)\|\nabla\psi(s)\|_H^2 \\ &+ C_7^2(2C_4)^{-1}(\|f\|_H^2 + \|\nabla f\|_H^2)(\exp(2C_4 t) - 1). \end{aligned} \tag{5.11}$$

Then, from (5.10) and the uniform Gronwall lemma [32, p. 89], for an arbitrary fixed $r > 0$,

$$\|\nabla\psi(t+s+r)\|_H^2 \leqq \left(\frac{\kappa(r)}{r} + C_7^2(\|f\|_H^2 + \|\nabla f\|_H^2)r\right)\exp(2C_4 r) \equiv R_2^2, \tag{5.12}$$

where $\kappa(r) = \frac{1}{2}(1+\lambda_1)\|\psi(s)\|_H^2 + (\lambda_1^{-1} + 2r)(C_3|\Omega| + (2\lambda_1)^{-1}\|f\|_H^2)$. Thus, when $C_7^{-2} \leqq C_4$, (5.12) provides uniform bounds for $\|\nabla\psi(t+s)\|_H^2$ when $t+s \geqq r$ while (5.11) provides uniform bounds when $t+s \leqq r$. Any ball of $V = H_0^1(\Omega)$ centered at zero with radius $R_2' > R_2$ is absorbing for (5.1)-(5.3).

(c) The proof of the uniform compactness of the maps (2.13) now follows as in the proof of the corresponding result for the solution semigroups in autonomous cases [32, p. 86].

(d) The proof of asymptotic compactness is analogous to the corresponding proof for nonlinear wave equations in Propositions 4.1.

This completes the proof of the theorem.

The translation semigroup $\{\sigma(t), t \geqq 0\}$ is continuous relative to the system (5.1)-(5.3).

PROPOSITION 5.1. *Assume the hypotheses of Theorem* 5.1 *and, in addition, that* $f_t \in C_b(\mathbb{R}, H)$ *and that* f *is time-dependent admissible from* $\mathbb{R}$ *to* H. *Then the translation semigroup* $\{\sigma(t),\ t \geqq 0\}$ *is continuous from* $H(W)$ *to itself, where* W *is the process associated as in* (2.3) *with the unique solution* ψ *of* (5.1)-(5.3) *obtained in Theorem* 5.1.

Proof. The proof is analogous to the proof of Proposition 4.2.

This proposition, together with the result in Theorem 5.1, establishes the hypotheses of Propositon 3.1 for the system (5.1)-(5.3).

The first variational equation corresponding to (5.1)-(5.3) has the form

$$\Phi_t(t+s) - \Delta\Phi(t+s) + g'(\psi)\Phi(t+s) = 0, \tag{5.13}$$

$$\Phi(s) = \rho \in H, \tag{5.14}$$

where $\psi = \psi(t+s)$ is a solution of (5.1)-(5.3). We see that $\Phi(t+s)$ is independent of the forcing term in (5.1) as required by our hypothesis in § 3.

We now prove existence of the Fréchet derivatives of the maps (2.13) for the system of equations (5.1)-(5.3), (5.13), (5.14).

THEOREM 5.3. *Let* W *be a process associated in the usual way* (2.3) *with a solution* ψ *of* (5.1)-(5.3) *assuming the hypotheses* (5.4)-(5.8) *as well as the additional condition that there exists* $\nu \in (0, 1)$, *and for* $R > 0$ *there exists* $C_8 = C_8(R) > 0$ *such that*

$$\|g'(\chi) - g'(\tilde\chi)\|_{L(H)} \leqq C_8\|\chi - \tilde\chi\|_H^\nu \tag{5.15}$$

for every $\chi, \tilde\chi \in H$ *such that* $\|\chi\|_H \leqq R$, $\|\tilde\chi\|_H \leqq R$. *Then Fréchet derivatives* L *of the maps*

(2.13) *exist and are defined in terms of appropriate solutions of* (5.13), (5.14) *as in* (3.14). *Moreover, if in addition to satisfying* (5.8) *f is also time-dependent admissible, then these results remain valid if f is replaced by any* $h \in H(f)$.

Proof. The proof is analogous to the proof of Theorem 4.3.

COROLLARY. *For all* $t > 0$ *and all* $s \in \mathbb{R}$, *the mapping* $S_s(t)$ *is of class* $C^{1,\nu}$, *where* ν *is the same as in* (5.15).

With the exception of condition (7) of § 2, we have now verified that all the hypotheses of § 3 are valid for (5.1)-(5.3). The validity of this condition follows from the following result.

THEOREM 5.4. *Assume the hypotheses of Theorem* 5.3, *and let* E_s *denote a set of type* (2.8) *corresponding to a global attractor* ${}_s A_\pi(W)$ *for the distinguished process W. Then, for each* $s \in \mathbb{R}$ *and each* $t \in \mathbb{R}^+$, $S_s(t)$ *is invertible on the range of* $S_s(t)H$, *and the surjective map* $(S_s(t))^{-1}: S_s(t)E_s \to E_s$ *is Lipschitz continuous.*

To prove this result, we need the existence of backward extensions in t of the maps $S_s(t)$. This follows from a generalization to almost periodic processes of some results on periodic processes due to Slemrod [31], which we now discuss.

DEFINITION 5.1. Let V be an almost periodic process on a Banach space B, and consider $\eta \in B$. A function $U(\cdot, \cdot; \eta): \mathbb{R} \times \mathbb{R} \to B$ is said to be an *extension* of the process V from η if

(i) $U(\theta, s; \eta)$ is continuous in θ;

(ii) $U(t+\theta, s; \eta) = Z(t, s+\theta;\ U(\theta, s; \eta))$ for $t \in \mathbb{R}^+$, $\theta, s \in \mathbb{R}$, and some $Z \in H(V)$;

(iii) $U(0, s; \eta) = \eta$.

Then we have the following.

LEMMA 5.1. *Let V be an almost periodic process on B. Assume that the positive orbit* $0^+(s, \chi) = \bigcup_{t \geqq 0} V(t, s; \chi)$ *through* $\chi \in B$ *lies in a compact subset* $A \subseteq B$. *If* η *belongs to the* ω-*limit set* $\omega_s(\chi) = \bigcap_{\delta \geqq 0} \text{Closure}_B \bigcup_{t \geqq \delta} V(t, s; \chi)$ *of the orbit of V originating at* $(\chi, s) \in B \times \mathbb{R}$, *then V possesses an extension* $U(\theta, s; \eta)$ *from* η.

Proof. The proof is similar to that of Slemrod for periodic processes, the essential points of difference being (1) the places in Slemrod's proof where periodicity was used, and (2) the verification of condition (ii) for the extension candidate U. We will, therefore, skip some of the details. There exists a sequence $\{t_n\} \subset \mathbb{R}^+$ such that $t_n \to +\infty$ as $n \to +\infty$ with

$$V(t_n, s; \chi) \to \eta \quad \text{as } n \to +\infty. \tag{5.16}$$

Then choose $a > 0$ and pick $n_0 > 0$ sufficiently large so that $t_n \geqq 2a$ when $n \geqq n_0$. Then, following an argument similar to that of Slemrod, it can be shown that the sequence $\{V(t_n + \tau, s; \chi)\}$ is an equicontinuous family of functions of $\tau \varepsilon [-a, a]$.

From Ascoli's theorem, there exists a subsequence $\{T_m\} \subset \{t_n\}$, such that $V(T_m + \tau, s; \chi)$ converges uniformly to a continuous function of $\tau \in [-a, a]$. Call it $U(\tau, s; \eta)$. That is, we have

$$\|V(T_m + \tau, s; \chi) - U(\tau, s; \eta)\|_B \to 0 \quad \text{as } m \to +\infty \tag{5.17}$$

uniformly in τ for $\tau \in [-a, a]$, and (i) is satisfied.

For $\tau = 0$, $V(T_m, s; \chi) \to \eta$ by (5.16) so that (iii) is satisfied for all $s \in \mathbb{R}$ and it only remains to establish (ii). We have

$$\|V_{T_m}(\theta, s+\tau;\ V(\tau - T_m, s; \chi)) - V_{T_m}(\theta, s+\tau;\ U(\tau, s; \eta))\|_B \to 0$$

by continuity. But

$$V_{T_m}(\theta, s+\tau;\ V(\tau + T_m; s; \chi)) = V(\tau + T_m + \theta, s; \chi) \to U(\tau + \theta, s; \eta),$$

i.e.,

$$U(\tau+\theta, s; \eta) = \lim_{m\to+\infty} V_{T_m}(\theta, s+\tau; U(\tau, s; \eta)) = Z(\theta, s+\tau; U(\tau, s; \eta))$$

for some $Z \in H(V)$. It follows from (5.17) that $U(\tau, s; \eta) \in \omega_s(\chi)$ for all $\tau \in [-a, a]$, and hence for all $\tau \in \mathbb{R}$, and the proof is complete.

Proof of Theorem 5.4. For given $s \in \mathbb{R}$, the existence of $S_s(t)$ for each $t \geqq 0$, and each $h \in H(f)$ follows from Theorem 5.1 and its Lipschitz continuity follows from Theorem 5.3 (see the statement of the corollary to that theorem). Then, using the facts that $E_s \subset \omega_s(\phi)$ (with ϕ the same as in (2.13)) and that $S_s(t)$ possesses backward extensions in t from E_s (which follows from Lemma 5.1), we easily see by a slight generalization of the usual argument [32], [5], [14] that the injectivity of $S_s(t)$ is equivalent to the backward uniqueness property for the system (5.1)-(5.3). In fact, with our hypotheses, the proof of backward uniqueness given by Témam [32] is also valid in the present case. Thus, $(S_s(t))^{-1}$ exists on the range of $S_s(t)H$. By Theorems 5.1 and 5.2 and an argument in the proof of Theorem 3.2, there exists an s-independent global attractor $A_\pi(W)$ for the skew-product semiflow $\{\pi_s(t),\ t \geqq 0\}$ associated with the distinguished process W, and the corresponding set E_s defined by (2.8) is compact. Consider the restriction of $S_s(t)$ to E_s. Since $S_s(t)$ is continuous and E_s is compact, $S_s(t)E_s$ is a compact set. Then, by a result due to Tikonov [4, Lemma 3, p. 98], $(S_s(t))^{-1}$ is continuous as a surjective map $(S_s(t))^{-1}: S_s(t)E_s \to E_s$. From the relation $(S_s(t))^{-1} = S_{s+t}(-t)$ and (3.12), we obtain (with a fixed real number t_0) $(S_s(t))^{-1} = S_{s-t_0}(t_0) \circ (S_{s-t_0}(t+t_0))^{-1}$, from which the Lipschitz continuity of $(S_s(t))^{-1}$ follows due to the continuity of $(S_{s-t_0}(t+t_0))^{-1}$ and the Lipschitz continuity of $S_{s-t_0}(t_0)$. This completes the proof.

We now obtain additional information about the Hausdorff dimension of sets of type (2.8) by estimating the quantities (3.21). We note that (5.13) is of the form (3.20) with $F'(\psi) = \Delta - g'(\psi)$. Then, using the condition (5.5) that $g'(s)$ is bounded from below and the procedure in [32, pp. 299-301], we obtain the following estimates, which are uniform in s:

$$ {}_sq_m(t) \leqq \frac{-C_1''}{2|\Omega|^{2/n}} m^{1+2/n} + C_2''C_4^{1+n/2}|\Omega|, \tag{5.18}$$

$$ {}_sq_m \leqq \frac{-C_1''}{2|\Omega|^{2/n}} m^{1+2/n} + C_2''C_4^{1+n/2}|\Omega|, \tag{5.19}$$

where C_1'' depends only on n and the shape of Ω, and C_2'' depends only on n. If m is sufficiently large so that the right-hand side of (5.19) is negative, then the m-volume element is exponentially decaying in H and $d_H(E_s) \leqq m$. Similar estimates can be obtained for the fractal dimension of E_s by using techniques discussed in [32].

To conclude the paper, we note that the considerations of the present section can be extended to systems of equations of type (5.1). Thus, just as we generated the system of hyperbolic equations (4.42) from the single equation (4.1), we obtain the system of parabolic equations

$$\psi_t - a\Delta\psi + g(\psi) = f(x, t) \tag{5.20}$$

from (5.1) by replacing the scalar ψ by an l-dimensional vector $\psi = (\psi_1, \cdots, \psi_l)$ and by replacing Δ by $a\Delta$ where a is a positive symmetric matrix, although we could also consider certain other linear operators L as in our discussion at the end of § 4 for the dissipative nonlinear wave equations. We consider the Hilbert space $H = (L^2(\Omega))^l$, where Ω is a bounded domain on which we impose conditions analogous to those stated at the beginning of this section in the case of (5.1). We impose Dirichlet boundary conditions (5.3) on each component of ψ, although Neumann or periodic boundary conditions could also be considered. There exists a function $H(\psi_1, \cdots, \psi_l)$ such that $g_i(\psi) = (\partial/\partial\psi_i)H(\psi_1, \cdots, \psi_l)$, $i = 1, \cdots, l$; and the hypotheses (5.2), (5.4)-(5.7), (5.15), and conditions such as $f \in C_b(\mathbb{R}, V)$, $f_t \in C_b(\mathbb{R}, H)$, f is time-dependent admissible, are replaced by their obvious vector analogues. Under these conditions, we can verify all the hypotheses required for the proofs of the dimension estimates in Theorems 3.2-3.4, and analogous results to those in (5.18), (5.19) and the succeeding discussion can be obtained for the system (5.20).

Acknowledgments. We thank G. R. Sell, A. Haraux, and A. V. Babin for informative discussions and express our appreciation to A. Haraux for copies of [19], [20] and to A. V. Babin for a copy of [4]. In addition, we are particularly grateful to G. Sell for comments and suggestions concerning this work, even though we did not incorporate all of his suggestions! We thank the two referees for their constructive suggestions and remarks.

CHAOTIC DYNAMICS OF QUASI-PERIODICALLY FORCED OSCILLATORS DETECTED BY MELNIKOV'S METHOD*

KAZUYUKI YAGASAKI†

Abstract. Nonlinear oscillators that have the form of quasi-periodic perturbations of planar Hamiltonian systems with homoclinic orbits are studied. For such systems, Melnikov's method permits determination, up to the leading term, whether or not the stable and unstable manifolds of normally hyperbolic invariant tori intersect transversely. In a more general setting it is proven that such intersection results in chaotic dynamics. These chaotic orbits are characterized by a generalization of the Bernoulli shift. An example is given to illustrate the theory. The result is also compared with the results of Wiggins [1988b], Scheurle [1986], and Meyer and Sell [1989].

Key words. chaos, Melnikov method, quasi-periodically forced oscillator, Bernoulli shift

1. Introduction.

Chaotic dynamics of periodically forced oscillators have been extensively studied in the past decade (cf. Thompson and Stewart [1986] and Moon [1987]). For many cases, the chaotic dynamics result from transverse intersection between the stable and unstable manifolds of hyperbolic periodic orbits. The Smale-Birkhoff homoclinic theorem provides a mechanism for this type of chaotic dynamics, and these chaotic orbits are characterized by the Bernoulli shift. Using Melnikov's method, we can also detect such intersection in a class of periodically forced systems. See Guckenheimer and Holmes [1983] and Wiggins [1990] for details of these ideas. Using the theory of exponential dichotomies and the shadowing lemma, Palmer [1984] also described Melnikov's method and proved the Smale-Birkhoff homoclinic theorem in the context of periodic differential equations.

Recently, Wiggins [1988b] generalized Melnikov's method to a class of quasi-periodically forced systems. This version of Melnikov's method permits us to detect transverse intersection between the stable and unstable manifolds of normally hyperbolic invariant tori. His result is also applicable to systems with frequencies depending on the state variables and involves many of other versions of Melnikov's method, such as those of Holmes and Marsden [1982a], [1982b], [1983] and Wiggins and Holmes [1987]. It is also important to detect such intersection in three or more degrees of freedom Hamiltonian systems since their existence gives a mechanism for the Arnold diffusion (Arnold [1964], Lichtenberg and Lieberman [1983]). See Holmes and Marsden [1982b] and Wiggins [1988b, § 4.1] for the exposition of the Arnold diffusion in terms of the Melnikov theory.

Furthermore, Wiggins [1988b] proved a generalization of the Smale-Birkhoff homoclinic theorem: if the stable and unstable manifolds of a normally hyperbolic invariant torus intersect transversely in a torus satisfying a certain condition (see § 3), then the Bernoulli shift flow can be imbedded into the dynamics of the quasi-periodically forced system. A similar result had been obtained by Silnikov [1968]. Wiggins [1987], [1988a], [1988b], and Ide and Wiggins [1989] also applied these techniques to several types of quasi-periodically forced oscillators and obtained criteria for the existence of chaos, although their proof was not complete (see § 3).

Yagasaki [1990a], [1990b], [1991a] studied chaotic dynamics of quasi-periodically forced oscillators with weak nonlinearity. He used the averaging method and the

† Department of Mechanical Engineering, Tamagawa University, Machida, Tokyo 194, Japan.

standard Melnikov technique to show that the stable and unstable manifolds of a normally hyperbolic invariant torus intersect transversely in a torus, and then applied a generalization of Smale–Birkhoff homoclinic theorem by Wiggins [1988b] to obtain the regions in parameter space where chaos may occur. See also Yagasaki, Sakata, and Kimura [1990].

Scheurle [1986] and Meyer and Sell [1989] studied almost periodically forced systems extending the idea of Palmer [1984]. Scheurle [1986] showed that the existence of random-like solutions can be detected using a Melnikov type analysis and the shadowing lemma. Meyer and Sell [1989] used the concept of the skew product flow and generalized Melnikov's method, the shadowing lemma, and the Smale–Birkhoff homoclinic theorem to describe a mechanism for chaos in almost periodically forced systems. They showed that the chaotic behavior is also described in terms of the Bernoulli shift.

Consider nonlinear oscillators having the form of quasi-periodic perturbations of planar Hamiltonian systems:

$$\begin{aligned} &\dot{x} = JDH(x) + \varepsilon g(x, \theta), \\ &\dot{\theta} = \omega, \qquad (x, \theta) \in \mathbb{R}^2 \times T^l, \quad \omega \in \mathbb{R}^l, \end{aligned} \tag{1.1}$$

where $H(x)$ is a Hamiltonian function and $T^l = \prod_{i=1}^l S^1$ is an l-torus with $S^1 = \mathbb{R}/2\pi$ the circle of length 2π and

$$J = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}. \tag{1.2}$$

We assume that when $\varepsilon = 0$, (1.1) has a homoclinic orbit $\bar{x}_0(t)$ to a hyperbolic fixed point x_0. When ε is sufficiently small, (1.1) has a normally hyperbolic invariant torus T_ε. Using the version of Melnikov's method due to Wiggins [1988b], we can determine the behavior of the stable and unstable manifolds $W^S(T_\varepsilon)$, $W^u(T_\varepsilon)$ of the normally hyperbolic invariant torus T_ε. More precisely, we can state this result as follows. Let $M(\theta)$ be the *Melnikov function* for $\bar{x}_0(t)$, i.e.,

$$M(\theta) = \int_{-\infty}^{\infty} DH(\bar{x}_0(t)) \cdot g(\bar{x}_0(t), \omega t + \theta)\, dt. \tag{1.3}$$

If there exists a point $\theta = \theta_0 \in T^l$ such that

$$M(\theta_0) = 0, \tag{M1}$$

$$DM(\theta_0) \text{ is of rank one,} \tag{M2}$$

then $W^s(T_\varepsilon)$ and $W^u(T_\varepsilon)$ intersect transversely.

The Smale–Birkhoff homoclinic theorem guarantees the existence of chaos when the stable and unstable manifolds of a hyperbolic periodic orbit intersect transversely; however, the generalization of the Smale–Birkhoff homoclinic theorem due to Wiggins [1988b] does not always do so when the stable and unstable manifolds of a normally hyperbolic invariant torus intersect transversely. In general, there exist wide parameter regions in which conditions (M1) and (M2) are satisfied, but Wiggin's theorem does not apply (see § 7).

In this paper we obtain a more general condition for the existence of chaos in (1.1). Specifically, we prove that if there exists a point $\theta_0 \in T^l$ satisfying (M1) and

$$\sum_{j=1}^{l} \omega_j \frac{\partial}{\partial \theta_j} M(\theta_0) \neq 0, \tag{M3}$$

then there exists an invariant set on which orbits are characterized by a generalization of the Bernoulli shift. Precisely, condition (M3) is different from (M2), but their difference is very little (see § 7). Our condition is also very similar to that of Scheurle [1986] for the existence of random-like solutions in almost periodic systems. Furthermore, if (M3) holds for all points $\theta_0 \in T^l$ satisfying (M1), then we can apply the result of Meyer and Sell [1989]. See Appendix A for their results in the quasi-periodic perturbation case.

This paper is organized as follows. In §§ 2 and 3 we discuss the behavior of the stable and unstable manifolds of normally hyperbolic invariant tori in quasi-periodically forced oscillators, using Melnikov's method. In § 4 we present a generalization of the Bernoulli shift to be used to describe chaotic dynamics of quasi-periodically forced oscillators. In § 5 we study a class of diffeomorphisms instead of ordinary differential equations. This class of diffeomorphisms contains the Poincaré maps for quasi-periodically forced oscillators. We prove that if the stable and unstable manifolds of a normally hyperbolic invariant torus intersect transversely in a certain type of manifold, then there exists an invariant set on which the diffeomorphism is topologically conjugate to the generalized Bernoulli shift. In § 6 we provide a criterion for the existence of chaos in quasi-periodically forced oscillators using Melnikov's method and the result of § 5. In § 7 we give an example to illustrate our theory. Our result is also compared with the previous results of Wiggins [1988b], Scheurle [1986], and Meyer and Sell [1989].

After this paper was written, the author learned of the related work of Beigie, Leonard, and Wiggins [1991a], [1991b] and Stoffer [1988]. Their results also improved the generalization of the Smale–Birkhoff homoclinic theorem by Wiggins [1988b]. In particular, Stoffer [1988] described chaotic dynamics in general nonautonomous systems by the "extended shift map," in which the concept is similar to that of our generalized Bernoulli shift. However, in quasi-periodically forced systems, our description of chaos seems to be more suitable than theirs, since it takes a recurrence property of chaotic attractors into account. See Yagasaki [1991b] for more details.

2. Melnikov's method. In this section we briefly review Melnikov's method for quasi-periodically forced oscillators. This version of Melnikov's method is due to Wiggins [1988b]. Although we only deal here with single-degree-of-freedom systems with constant frequencies, this technique has been developed for multi-degree-of-freedom systems with nonconstant frequencies depending on the state variables. See Wiggins [1988b] for the general theory of this method.

We consider systems of the form

$$\begin{aligned} &\dot{x} = JDH(x) + \varepsilon g(x, \theta) \\ &\dot{\theta} = \omega, \qquad (x, \theta) \in \mathbb{R}^2 \times T^l, \quad \omega \in \mathbb{R}^l, \end{aligned} \tag{2.1}$$

where $T^l = \prod_{i=1}^l S^1$ is an l-torus with $S^1 = \mathbb{R}/2\pi$,

$$H : \bar{U} \to \mathbb{R}^1$$

is C^{r+1} $(r \geqq 2)$, and

$$g : \bar{U} \times T^l \to \mathbb{R}^2$$

is C^r with some open set $\bar{U} \subset \mathbb{R}^2$; J is a 2×2 matrix given by (1.2) and $0 < \varepsilon \ll 1$. For $\varepsilon = 0$, (2.1) becomes a Hamiltonian system

$$\dot{x} = JDH(x), \qquad \dot{\theta} = \omega. \tag{2.2}$$

We make the following assumption on (2.2).

(A1) The x-component of (2.2) has a homoclinic orbit $\bar{x}_0(t)$ to a hyperbolic saddle point x_0. We denote $\Gamma=\{\bar{x}_0(t)\,|\,t\in\mathbb{R}\}$.

In the full phase space $\mathbb{R}^2\times T^l$, (2.2) has a normally hyperbolic invariant l-torus

$$T_0=\{(x_0,\theta)\,|\,\theta\in T^l\}=\{x_0\}\times T^l,$$

whose $l+1$-dimensional stable and unstable manifolds $W^s(T_0)$, $W^u(T_0)$ coincide along the $l+1$-dimensional homoclinic manifold given by

$$W^s(T_0)\cap W^u(T_0)=\{(\bar{x}_0(t),\theta)\,|\,t\in\mathbb{R},\ \theta\in T^l\}=\Gamma\times T^l.$$

See Fig. 1 for the phase space of the unperturbed system.

Here "normal hyperbolicity" means that the expansive and contraction rates of the flow generated by (2.2) normal to T_0 dominate those tangent to T_0. For (2.2) this is clear since x_0 is a hyperbolic fixed point of the first equation of (2.2) so that trajectories approach T_0 exponentially fast in positive or negative time, but the flow on T_0 only indicates a rotation with the frequency vector ω. See Hirsch, Pugh, and Shub [1977] for precise definitions of normal hyperbolicity.

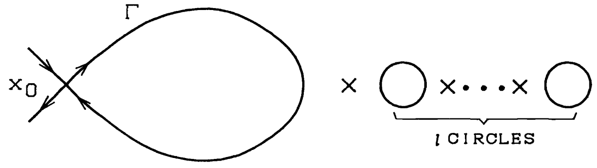

FIG. 1. *The unperturbed phase space of* (2.2).

We will reduce the study of (2.1) to that of the associated Poincaré map. We make the section to the phase space $\mathbb{R}^2\times T^l$ by fixing any element of θ, say θ_i, as follows:

$$\Sigma_i=\{(x,\theta)\in\mathbb{R}^2\times T^l\,|\,\theta_i=0\},\qquad i=1,\cdots,l.$$

Let us denote

$$\bar{\theta}^i=(\theta_1,\cdots,\theta_{i-1},\theta_{i+1},\cdots,\theta_l)\in T^{l-1}$$

and

$$\bar{\omega}^i=(\omega_1,\cdots,\omega_{i-1},\omega_{i+1},\cdots,\omega_l)\in\mathbb{R}^{l-1}.$$

The Poincaré map $P_{\varepsilon,i}:\Sigma_i\to\Sigma_i$ generated by the flow of (2.1) is given by

$$P_{\varepsilon,i}:(x(0),\bar{\theta}^i)\to\left(x\left(\frac{2\pi}{\omega_i}\right),\bar{\theta}^i+\frac{2\pi\bar{\omega}^i}{\omega_i}\right),$$

where $(x(t),\omega t+\theta)$ is a solution of (2.1). We denote the Poincaré map associated with the unperturbed system (2.2) by $P_{0,i}$.

The unperturbed Poincaré map $P_{0,i}$ has a normally hyperbolic invariant $(l-1)$-torus

$$\mathcal{T}_{0,i}=\Sigma_i\cap T_0=\{x_0\}\times T^{l-1},$$

whose l-dimensional stable and unstable manifolds $W^s(\mathcal{T}_{0,i})$, $W^u(\mathcal{T}_{0,i})$ coincide along the l-dimensional homoclinic manifold

$$W^s(\mathcal{T}_{0,i})\cap W^u(\mathcal{T}_{0,i})=\Gamma\times T^{l-1}.$$

See Fig. 2 for the phase space of the unperturbed Poincaré map $P_{0,i}:\Sigma_i\to\Sigma_i$ when $l=2$ and $i=1$. These structures of the unperturbed phase space persist for the perturbed phase space as follows.

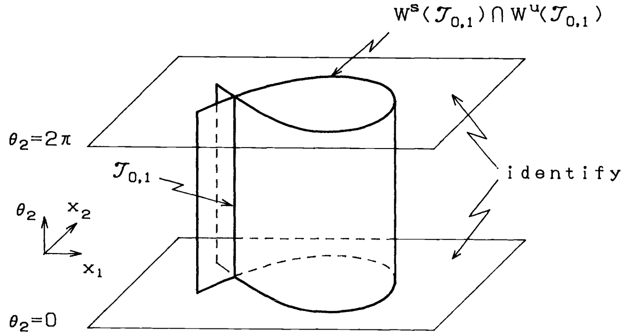

FIG. 2. *The stable and unstable manifolds for the unperturbed Poincaré map $P_{0,1}$ in the case of $l=2$.*

PROPOSITION 2.1. *For ε sufficiently small, the perturbed system* (2.1) *has a C^r normally hyperbolic invariant l-torus T_ε, whose C^r, $l+1$-dimensional local stable and unstable manifolds $W^s_{\text{loc}}(T_\varepsilon)$, $W^u_{\text{loc}}(T_\varepsilon)$ are C^r, ε-close to $W^s(T_0)$ and $W^u(T_0)$, respectively. Equivalently, the Poincaré map $P_{\varepsilon,i}$ of* (2.1) *has a C^r normally hyperbolic invariant $(l-1)$-torus $\mathcal{T}_{\varepsilon,i}$ whose C^r, l-dimensional local stable and unstable manifolds $W^s_{\text{loc}}(\mathcal{T}_{\varepsilon,i})$, $W^u_{\text{loc}}(\mathcal{T}_{\varepsilon,i})$ are C^r, ε-close to $W^s(\mathcal{T}_{0,i})$ and $W^u(\mathcal{T}_{0,i})$, respectively.*

Proof. These are immediate consequences of the invariant manifold theorem. See Hirsch, Pugh, and Shub [1977]. □

The manifolds $W^s(T_\varepsilon)$ and $W^u(T_\varepsilon)$ (or $W^s(\mathcal{T}_{\varepsilon,i})$ and $W^u(\mathcal{T}_{\varepsilon,i})$) may not coincide, but can intersect transversely. Computation of the Melnikov function provides information on the behavior of these manifolds.

In Wiggins [1988b], it was shown that the distance between $W^s(T_\varepsilon)$ and $W^u(T_\varepsilon)$ near the point

$$(x, \theta) = (\bar{x}_0(-t_0), \theta_0) \in \mathbb{R}^2 \times T^l$$

is given by

$$d(t_0, \theta_0) = \varepsilon \frac{M(\omega \tau_0 + \theta_0)}{K(t_0)} + \mathcal{O}(\varepsilon^2),$$

where

$$M(\theta) = \int_{-\infty}^{\infty} DH(\bar{x}_0(t)) \cdot g(\bar{x}_0(t), \omega t + \theta)\, dt, \tag{2.3}$$

$K(t_0)$ is a nonzero $\mathcal{O}(1)$ quantity and "$\cdot$" denotes the usual vector dot product. The function $M(\theta)$ is called the *Melnikov function*. We have the following theorem.

THEOREM 2.2. *Suppose that there exists a point $\theta = \theta_0 \in T^l$ such that*

(M1) $$M(\theta_0) = 0,$$

(M2) $$DM(\theta_0) \text{ is of rank one.}$$

Then, for $\varepsilon > 0$ sufficiently small and $t_0 \in \mathbb{R}$, $W^s(T_\varepsilon)$ and $W^u(T_\varepsilon)$ intersect transversely near the point $(\bar{x}(-t_0), \theta_0 - \omega t_0)$. Equivalently, $W^s(\mathcal{T}_{\varepsilon,i})$ and $W^u(\mathcal{T}_{\varepsilon,i})$ intersect transversely near the point

$$(x, \bar{\theta}^i) = (\bar{x}_0(-t_0), \bar{\theta}^i_0 - \bar{\omega}^i t_0) \in \Sigma_i, \tag{2.4}$$

where $\omega_i t_0 = \theta_{i0} \bmod 2\pi$.

Proof. The first part is a special case of Theorem 4.1.10 of Wiggins [1988b]. The second part is easily proved by noting that $W^s(\mathcal{T}_{\varepsilon,i}) = W^s(T_\varepsilon) \cap \Sigma_i$ and $W^u(\mathcal{T}_{\varepsilon,i}) = W^u(T_\varepsilon) \cap \Sigma_i$. □

Suppose that a point $\theta_0 \in T^l$ satisfies (M1) and (M2). Then, the local implicit function theorem (cf. Chow and Hale [1982]) implies that the zero of the Melnikov function $M(\theta)$ can be continued to an $l-1$-dimensional set in T^l. Hence, from Theorem 2.2 we see that there exists an $l-1$-dimensional manifold $\gamma_{\varepsilon,i}$ in which $W^s(\mathcal{T}_{\varepsilon,i})$ and $W^u(\mathcal{T}_{\varepsilon,i})$ intersect transversely. We refer to this manifold $\gamma_{\varepsilon,i}$ as a *transverse homoclinic manifold.*

In the next section we will discuss the structure of the transverse homoclinic manifold $\gamma_{\varepsilon,i}$ and describe how $W^s(\mathcal{T}_{\varepsilon,i})$ and $W^u(\mathcal{T}_{\varepsilon,i})$ intersect transversely, using the Melnikov function $M(\theta)$.

3. Behavior of stable and unstable manifolds. Ide and Wiggins [1989] stated that if $M(\theta)$ has a zero at $\theta = \theta_0$ and $DM(\theta)$ has rank one for all $\theta \in T^l$, then the zero θ_0 can be continued to an $(l-1)$-torus. More generally, suppose that (M2) holds at any point $\theta_0 \in T^l$ satisfying (M1). Then, using the global implicit function theorem (Chow and Hale [1982]) and modifying arguments given in Wiggins [1988b, p. 464], we can take an $(l-1)$-torus as the zero set of $M(\theta)$. We denote this torus by τ_0.

Let us fix the value of i and discuss the phase space for the Poincaré map $P_{\varepsilon,i}: \Sigma_i \to \Sigma_i$. We first consider the case in which condition

$$\text{(M2i)} \qquad \frac{\partial}{\partial \theta_i} M(\theta_0) \neq 0.$$

holds at any point $\theta_0 \in T^l$ satisfying (M1). Note that (M2i) is stronger than (M2). In this case, the global implicit function theorem implies that there exists a C^r function $h: \mathbb{R}^{l-1} \to \mathbb{R}$, such that τ_0 is given by

$$\text{(3.1)} \quad \tau_0 = \{\theta = (\theta_1, \cdots, \theta_l) \in T^l \mid \theta_i = h(\bar{s}^i),\ \theta_j = s_j \bmod 2\pi \text{ for } s_j \in \mathbb{R},\ 1 \leqq j \neq i \leqq l\}.$$

where $\bar{s}^i = (s_1, \cdots, s_{i-1}, s_{i+1}, \cdots, s_l)$. Moreover, we can assume that for each $j \neq i$, there are two integers j_1 and j_2 such that $j_1 > 0$ and

$$\text{(3.2)} \qquad h(s_1, \cdots, s_j + 2j_1\pi, \cdots, s_l) = h(s_1, \cdots, s_j, \cdots, s_l) + 2j_2\pi,$$

since τ_0 is an $(l-1)$-torus. Choose j_1 as the minimum positive one such that (3.2) holds. Then $j_2 = 0$ implies that $j_1 = 1$, since τ_0 cannot intersect itself.

Let $\gamma_{0,i}$ be the set of all points given by (2.4) with $\theta_0 \in \tau_0$, i.e.,

$$\text{(3.3)} \qquad \gamma_{0,i} = \{(\bar{x}_0(-t_0), \bar{\theta}_0^i - \bar{\omega}^i t_0) \in \Sigma_i \mid (\theta_{10}, \cdots, \theta_{l0}) \in \tau_0,\ \omega_i t_0 = \theta_{i0} \bmod 2\pi\}.$$

By Theorem 2.2. $W^s(\mathcal{T}_{\varepsilon,i})$ and $W^u(\mathcal{T}_{\varepsilon,i})$ intersect transversely in an $l-1$-dimensional manifold $\gamma_{\varepsilon,i}$ near $\gamma_{0,i}$.

DEFINITION 3.1. Consider the product space $\mathbb{R}^m \times T^l$. Let τ be an l-torus given by

$$\text{(3.4)} \quad \tau = \{(x, \theta) \in \mathbb{R}^m \times T^l \mid x = \tilde{x}(s_1, \cdots, s_l),\ \theta_j = h_j(s_j) \bmod 2\pi,\ s_j \in \mathbb{R}, j = 1, \cdots, l\},$$

where $\tilde{x}: \mathbb{R}^l \to \mathbb{R}^m$ is C^r and 2π-periodic in s_j, $j = 1, \cdots, l$, and $h_j: \mathbb{R} \to \mathbb{R}$, $j = 1, \cdots, l$, are C^r and satisfy $|h_j(2\pi) - h_j(0)| = 2n_j\pi$ for some integer n_j. Choose h_j for $j = 1, \cdots, l$ such that n_j is the minimum nonnegative one, and let $n = (n_1, \cdots, n_l)$. Then we refer to τ as a *torus of n-cycle.*

If $j_2 = 0$ for all $j \neq i$ in (3.2), then $\gamma_{0,i}$ is an $(l-1)$-torus of $(1, \cdots, 1)$-cycle. However, if $j_2 \neq 0$ for some j, then

$$\bar{x}_0(-h(s_1, \cdots, s_j + 2j_1\pi, \cdots, s_l)/\omega_i) \neq \bar{x}_0(-h(s_1, \cdots, s_j, \cdots, s_l)/\omega_i),$$

and hence $\gamma_{0,i}$ is not a torus. Since $\gamma_{\varepsilon,i}$ is ε-close to $\gamma_{0,i}$, $\gamma_{\varepsilon,i}$ is an $(l-1)$-torus of $(1, \cdots, 1)$-cycle if $j_2 = 0$ for all $j \neq i$, but $\gamma_{\varepsilon,i}$ is not a torus otherwise. These situations are shown in Fig. 3(a) and (b) for the Poincaré map $P_{\varepsilon,1}:\Sigma_1\to\Sigma_1$ when $l=2$. (Fig. 3(a) corresponds to the case of $j_2=0$ and Fig. 3(b) to the other case.) When we can take a torus as the transverse homoclinic manifold, as shown in Fig. 3(a), we call the torus a *transverse homoclinic torus.*

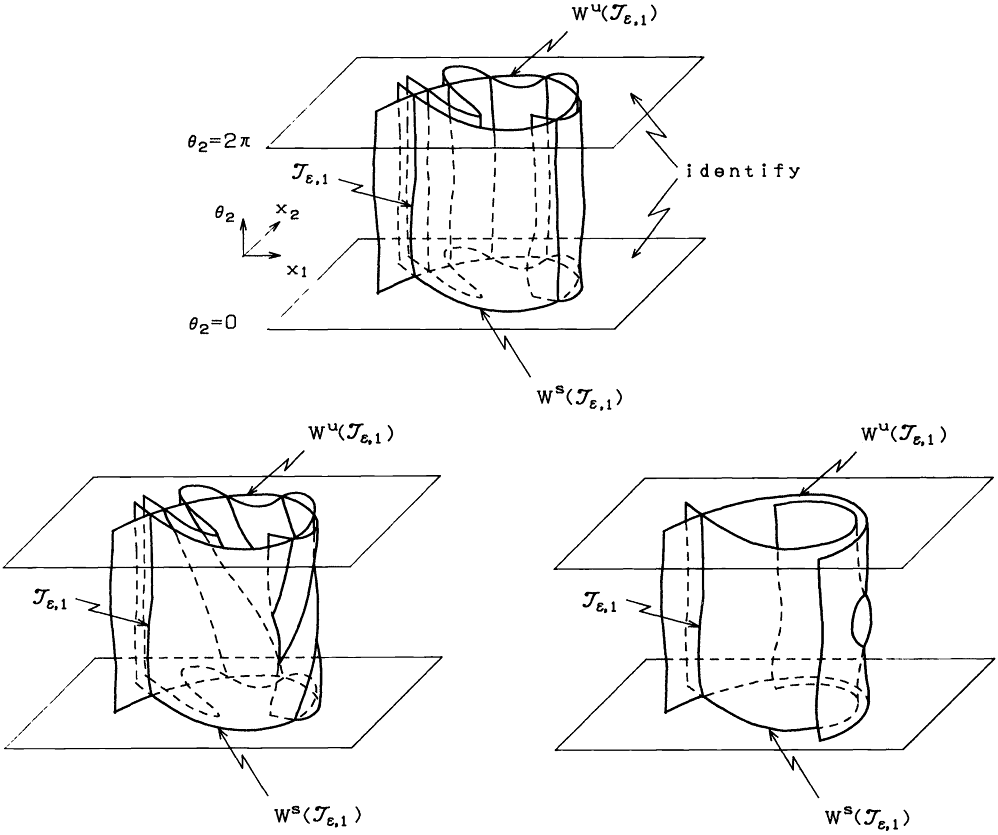
We next consider the case in which there is a point $\theta_0\in T^l$ that satisfies (M1) but does not satisfy (M2i), i.e., $M=0$ and $\partial M/\partial\theta_i=0$ at $\theta=\theta_0$. Then, in general, there is not a function h satisfying (3.1) and (3.2). Furthermore, there may exist C^r functions $h_i:\mathbb{R}^{l-1}\to\mathbb{R}$, $h_j:\mathbb{R}\to\mathbb{R}$, $0<j\neq i\leqq l$, of 2π-period in each of the arguments, such that

$$(3.5)\quad \tau_0=\{\theta=(\theta_1,\cdots,\theta_l)\in T^l\mid \theta_i=h_i(\bar{s}^i),\ \theta_j=h_j(s_j) \bmod 2\pi,\ s_j\in\mathbb{R}1\leqq j\neq i\leqq l\}.$$

From (3.3) we see that $\gamma_{\varepsilon,i}$ is an $(l-1)$-torus of $(0,\cdots,0)$-cycle since $\gamma_{\varepsilon,i}$ is ε-close to $\gamma_{0,i}$. See Fig. 3(c).

Suppose that as shown in Fig. 3(a), there exists a transverse homoclinic $(l-1)$-torus of $(1,\cdots,1)$-cycle $\tau_{\varepsilon,i}$. This is the case when the stable and unstable manifolds of normally hyperbolic invariant tori intersect transversely in a class of quasi-periodically forced oscillators with weak nonlinearity (Yagasaki [1990a], [1990b], [1991a]). In this situation, Wiggins [1988b] proved that the dynamics of the Poincaré map normal to the transverse homoclinic torus is chaotic. More precisely, we can state his result as follows.

THEOREM 3.1. *Suppose that $W^s(\mathcal{T}_{\varepsilon,i})$ and $W^u(\mathcal{T}_{\varepsilon,i})$ intersect transversely in an $(l-1)$-torus of $(1,\cdots,1)$-cycle. Then, for some $k\geqq 1$, $P^k_{\varepsilon,i}$ has an invariant Cantor set*



$W^u(\mathcal{T}_{\varepsilon,1})$
$\theta_2=2\pi$
identify
$\mathcal{T}_{\varepsilon,1}$
θ_2
x_2
x_1
$\theta_2=0$
$W^s(\mathcal{T}_{\varepsilon,1})$
$W^u(\mathcal{T}_{\varepsilon,1})$
$\mathcal{T}_{\varepsilon,1}$
$W^s(\mathcal{T}_{\varepsilon,1})$
$W^u(\mathcal{T}_{\varepsilon,1})$
$\mathcal{T}_{\varepsilon,1}$
$W^s(\mathcal{T}_{\varepsilon,1})$

FIG. 3. *Transverse intersection between the stable and unstable manifolds for the Poincaré map $P_{\varepsilon,1}$ in the case of $l=2$.* (a) *$\gamma_{\varepsilon,1}$ is a 1-torus of 1-cycle.* (b) *$\gamma_{\varepsilon,1}$ is not a torus.* (c) *$\gamma_{\varepsilon,1}$ is a 1-torus of 0-cycle.*

of $(l-1)$-tori, Ξ. Moreover, there exists a homeomorphism h taking tori in Ξ to bi-infinite sequences of N symbols such that the following diagram commutes

$$\begin{tikzcd} \Xi \arrow[r, "P^k_{\varepsilon,i}"] \arrow[d, "h"'] & \Xi \arrow[d, "h"] \\ B_N \arrow[r, "\sigma"] & B_N \end{tikzcd}$$

where B_N is the space of bi-infinite sequences of N symbols and $\sigma: B_N \to B_N$ is the shift map.

Proof. This is a special case of Theorem 3.4.1 of Wiggins [1988b]. The assumption that the transverse homoclinic torus τ is of $(1, \cdots, 1)$-cycle is essential in his result, although he did not explicitly state it. In fact, his proof requires that the transverse homoclinic torus τ can be expressed as

$$\tau = \{(x, \bar{\theta}^i) = P^{k'}_{\varepsilon,i}((0, x_2), \bar{\theta}^i_0) \mid \bar{\theta}^i_0 \in T^{l-1}\},$$

with some $x_2 \in \mathbb{R}$ and $k' > 0$ in an adequate coordinate system. This implies that τ is an $(l-1)$-torus of $(1, \cdots, 1)$-cycle. See, e.g., § 4 for the definition of the shift map σ. □

Remark 3.1. The pair (B_N, σ) is referred to as the Bernoulli shift. This is a simple dynamical system displaying stochastic behavior. If the hypothesis of Theorem 3.1 is satisfied, then the dynamics of $P^k_{\varepsilon,i}$ on Ξ is chaotic like the Bernoulli shift. See also § 4 for the Bernoulli shift.

Remark 3.2. The hypothesis of Theorem 3.1 does not always hold even if $W^s(\mathcal{T}_{\varepsilon,i})$ and $W^u(\mathcal{T}_{\varepsilon,i})$ intersect transversely, i.e., there exists a point $\theta_0 \in T^l$ satisfying (M1) and (M2). In particular, Theorem 3.1 has nothing to say about situations such as those shown in Fig. 3(b) and (c). Wiggins [1987], [1988a], [1988b] and Ide and Wiggins [1989] overlooked this fact.

Using Theorem 2.2, we obtain the following result as a corollary of Theorem 3.1.

THEOREM 3.2. *Suppose that there exists a continuous function $h(\bar{s}^i)$ of period 2π in each of the arguments such that for all $s_j \in \mathbb{R}$, $j \neq i$, (M1) and (M2) hold at $\theta_0 \in T^l$, where $\theta_{i0} = h(\bar{s}^i)$ and $\theta_{j0} = s_j \bmod 2\pi$, $j \neq i$. Then the statements of Theorem 3.1 hold.*

Proof. Suppose that the hypothesis holds. Then, the zero set of the Melnikov function $M(\theta)$ is an $(l-1)$-torus given by

$$\tau_0 = \{\theta_0 \in T^l \mid \theta_{i0} = h(\bar{s}^i),\ \theta_{j0} = s_j \bmod 2\pi \text{ for } s_j \in \mathbb{R}, 0 < j \neq i \leq l\}.$$

It follows from Theorem 2.2 that $W^s(\mathcal{T}_{\varepsilon,i})$ and $W^u(\mathcal{T}_{\varepsilon,i})$ intersect transversely near

$$\tau_{0,i} = \{(x, \bar{\theta}^i) \in \mathbb{R}^2 \times T^{l-1} \mid x = \bar{x}(-t_0),\ \omega_i t_0 = \theta_{i0},\ \theta_j = \theta_{j0} - \omega_j t_0 \bmod 2\pi \text{ for } j \neq i \text{ and } \theta_0 \in \tau_0\}.$$

We can easily show that $\tau_{0,i}$ is an $(l-1)$-torus of $(1, \cdots, 1)$-cycle. Hence, $W^s(\mathcal{T}_{\varepsilon,i})$ and $W^u(\mathcal{T}_{\varepsilon,i})$ intersect transversely in an $(l-1)$-torus $\tau_{\varepsilon,i} = \tau_{0,i} + \mathcal{O}(\varepsilon)$ of $(1, \cdots, 1)$-cycle. Applying Theorem 3.1, we obtain the desired result. □

We will give a more comprehensive criterion for the existence of chaos in quasi-periodically forced oscillators in § 6.

4. The generalized Bernoulli shift. In this section we present a generalization of the Bernoulli shift for the precise description of chaos in quasi-periodically forced oscillators. We begin with the definition of the Bernoulli shift.

Let $S_N = \{1, 2, \cdots, N\}$ for $N \geqq 2$. We define $B_N = \prod_{i=-\infty}^{\infty} S_N$, i.e., B_N is a collection of all infinite bisequences of elements of S_N. Thus, if $s \in B_N$, then $s = \{\cdots, s_{-1}, s_0, s_1, \cdots\}$ where $s_i \in S_N$, $i \in \mathbb{Z}$. Let $\sigma: B_N \to B_N$ be the *shift map* defined by $(\sigma(s))_j = s_{j+1}$.

DEFINITION 4.1. The discrete dynamical system (B_N, σ) is called the *Bernoulli shift*, or the *full shift on N symbols.*

It is clear that B_N is invariant by σ. For two sequences $s, s' \in B_N$, define the distance between them by

$$d(s, s') = \sum_{i=-\infty}^{\infty} \frac{1}{2^{|i|}} \frac{|s_i - s'_i|}{1 + |s_i - s'_i|}. \tag{4.1}$$

It is easy to show that $d(\cdot, \cdot)$ is a metric on B_N. Moreover, σ is continuous and B_N is compact. See Wiggins [1988b, § 2.2a, b], [1990, § 4.2] for the details. We also call a sequence $s \in B_N$ an *orbit in* B_N.

The Bernoulli shift contains important features of randomness. In particular, when $N = 2$, it provides a model of a completely random process, coin tossing. The shift map σ has a countable infinity of periodic orbits, an uncountable infinity of nonperiodic orbits, and a dense orbit. The Bernoulli shift is often used to describe chaotic behavior in deterministic dynamical systems. See Guckenheimer and Holmes [1983] and Wiggins [1988b] for such examples; see also Theorem 3.1.

For descriptions of chaos in some dynamical systems, it is necessary to restrict the domain of the shift map σ to a subset of B_N. This is accomplished as follows.

Let A be an $N \times N$ matrix all of whose elements are 0 or 1. The matrix A is called a *transition matrix.* We denote the set of all $N \times N$ transition matrices by M_N.

DEFINITION 4.2. For any $A \in M_N$, let $B_N(A)$ be a subset of B_N given by

$$B_N(A) = \{s \in B_N \mid (A)_{s_i s_{i+1}} = 1 \text{ for all } i\}.$$

The pair $(B_N(A), \sigma)$ is called a *subshift of finite type.* We also say that the transition matrix A is *irreducible* if there is an integer $k > 0$ such that $(A^k)_{ij} \neq 0$ for all $i, j \in S_N$.

It is easy to show that $B_N(A)$ is σ-invariant and compact with the metric (4.1). We call a sequence $s \in B_N(A)$ an *orbit in* $B_N(A)$. If A is irreducible, then for any $i, j \in S_N$ there is an orbit $s \in B_N(A)$ such that $s_0 = i$ and $(\sigma^k(s))_0 = j$ for some $k > 0$. Moreover, the subshift of finite type $(B_N(A), \sigma)$ has such properties as the Bernoulli shift (B_N, σ). For example, there exist a countable infinity of periodic orbits, an uncountable infinity of nonperiodic orbits, and a dense orbit. See Wiggins [1988b, § 2.2c] for the details.

Now we generalize the concept of the Bernoulli shift so that we can describe chaotic dynamics of quasi-periodically forced oscillators.

Let $R_\nu(\theta)$, $\theta = (\theta_1, \cdots, \theta_l) \in T^l$ be a rigid rotation through an angle ν_i in the θ_i direction for $i = 1, \cdots, l$:

$$R_\nu(\theta) = \theta + \nu, \tag{4.2}$$

where $\nu = (\nu_1, \cdots, \nu_l) \in T^l$. Let $\Theta \subset T^l$ be an l-dimensional invariant manifold for R_ν, i.e., $R_\nu(\Theta) = \Theta$. Define a set $\mathscr{B}_N(\nu)$ as follows: if $\xi \in \mathscr{B}_N(\nu)$, then $\xi = \{\cdots, \xi_{-1}, \xi_0, \xi_1, \cdots\}$ where $\xi_i = (s_i, \phi_i)$ with $s_i \in S_N$ and $\phi_i \in \Theta$, $i \in \mathbb{Z}$, such that

$$\phi_{i+1} = R_\nu(\phi_i) \tag{4.3}$$

for $i \in \mathbb{Z}$. We also denote $\xi = \{\cdots, \xi_{-1}, \xi_0, \xi_1, \cdots\} \in \mathscr{B}_N(\nu)$ with $\xi_i = (s_i, \phi_i)$ by (s, ϕ) with $s = \{\cdots, s_{-1}, s_0, s_1, \cdots\}$ and $\phi = \{\cdots, \phi_{-1}, \phi_0, \phi_1, \cdots\}$. Given the metric

$$\tilde{d}(\xi, \xi') = d(s, s') + |\phi_0 - \phi'_0|, \tag{4.4}$$

between $\xi=(s, \phi)$ and $\xi'=(s', \phi')$, $\mathscr{B}_N(\nu)$ becomes a metric space. We can identify $\xi=(s, \phi)\in\mathscr{B}_N(\nu)$ with $(s, \phi_0)\in B_N\times\Theta$, so that $\mathscr{B}_N(\nu)\cong B_N\times\Theta$. We define the shift map $\sigma_\nu: \mathscr{B}_N(\nu)\to\mathscr{B}_N(\nu)$ as

$$(\sigma_\nu(\xi))_i=\xi_{i+1}.$$

It is clear that σ_ν is continuous in $\mathscr{B}_N(\nu)$ with the metric (4.4). Moreover, $\mathscr{B}_N(\nu)$ is compact if Θ is closed. Let $\mathscr{A}=\{A(\theta)\in M_N \mid \theta\in\Theta\}$ be an l-parameter family of transition matrices. For $\theta\in\Theta$, let

$$S_N(\theta)=\{i\in S_N \mid (A(\theta))_{ij}=1 \text{ for some } j\in S_N\}$$

and

$$S'_N(\theta)=\{j\in S_N \mid (A(\theta))_{ij}=1 \text{ for some } i\in S_N\}.$$

DEFINITION 4.3. We say that $\mathscr{A}$ is *consistent with* R_ν if the two following conditions are satisfied:

(1) For any $i\in S_N$ there are $\theta, \theta'\in\Theta$ such that $i\in S_N(\theta)$ and $i\in S'_N(\theta')$;

(2) $S_N(R_\nu(\theta))=S'_N(\theta)$ for any $\theta\in\Theta$.

DEFINITION 4.4. Let $\mathscr{A}$ be consistent with R_ν, and let $\mathscr{B}_N(\mathscr{A}, \nu)$ be a subset of $\mathscr{B}_N(\nu)$ given by

$$\mathscr{B}_N(\mathscr{A}, \nu)=\{\xi=(s, \phi)\in\mathscr{B}_N(\nu) \mid (A(\phi_i))_{s_is_{i+1}}=1 \text{ for all } i\}.$$

We call the pair $(\mathscr{B}_N(\mathscr{A}, \nu), \sigma_\nu)$ the *generalized Bernoulli shift.*

It is clear that $\mathscr{B}_N(\mathscr{A}, \nu)$ is σ_ν-invariant. Let $A(\theta)$ be independent of θ, i.e., $A(\theta)=A=\text{const.}$ Then $\mathscr{B}_N(\mathscr{A}, \nu)\cong B_N(A)\times\Theta$. Moreover, if Θ is closed, then $\mathscr{B}_N(\mathscr{A}, \nu)$ is compact. However, in general, $\mathscr{B}_N(\mathscr{A}, \nu)$ may not be compact even if Θ is closed. In fact, let $l=1$ and $\Theta=S^1$, and suppose that $A(\theta)$ is not continuous but only right continuous at $\theta=\theta_0$, and for some $\varepsilon>0$ there is a pair of integers $i, j\in S_N$ such that $(A(\theta_0))_{ij}=0$ and $(A(\theta))_{ij}=1$ for $\theta\in(\theta_0-\varepsilon, \theta_0)$. Let $\xi^k=(s^k, \phi^k)$, $k=1, 2, \cdots$, be a sequence of elements of $\mathscr{B}_N(\mathscr{A}, \nu)$ such that $s_0^k=i$, $s_1^k=j$, $\theta_0-\varepsilon<\phi_0^k<\theta_0$, and $\lim_{k\to\infty}\phi_0^k=\theta_0$. Then ξ_k converges to an element $\bar{\xi}=(\bar{s}, \bar{\phi})\in\mathscr{B}_N(\nu)$ with $\bar{\phi}_0=\theta_0$, but $\bar{\xi}\notin\mathscr{B}_N(\mathscr{A}, \nu)$ since $(A(\theta_0))_{\bar{s}_0\bar{s}_1}=0$. Thus, $\mathscr{B}_N(\mathscr{A}, \nu)$ is not closed and hence not compact.

We call an element $\xi\in\mathscr{B}_N(\mathscr{A}, \nu)$ an *orbit in* $\mathscr{B}_N(\mathscr{A}, \nu)$. Let us denote

$$A^k(\theta)=A(\theta)A(R_\nu(\theta))\cdots A(R_\nu^{k-1}(\theta)), \qquad k=1, 2, \cdots.$$

DEFINITION 4.5. An l-parameter family of transition matrices

$$\mathscr{A}=\{A(\theta)\in M_N \mid \theta\in\Theta\}$$

is called *irreducible* if for $\theta\in\Theta$ there is an integer $k>0$ such that

$$(A^k(\theta))_{ij}\neq 0$$

for all $i, j\in S_N(\theta)$.

If $\mathscr{A}$ is irreducible, then for any pair $i, j\in S_N(\theta)$ and some $k>0$ there is an orbit $\xi\in\mathscr{B}_N(\mathscr{A}, \nu)$ such that $\xi_0=(i, \theta)$ and $\xi_k=(\sigma_\nu^k(\xi))_0=(j, R_\nu^k(\theta))$. In order to describe the dynamics of the generalized Bernoulli shift, the following definition will be useful.

DEFINITION 4.6. We say that a finite or infinite sequence $\{s_i\}_{i=j_1}^{j_2}$ with $s_i\in S_N$, $i=j_1, \cdots, j_2$, is *admissible* for $\mathscr{B}_N(\mathscr{A}, \nu)$ if there is a point $\theta\in\Theta$ such that

$$(A(R_\nu^i(\theta)))_{s_is_{i+1}}\neq 0, \qquad i=j_1, \cdots, j_2-1. \tag{4.5}$$

In particular, when $s\in B_N$ is admissible for $\mathscr{B}_N(\mathscr{A}, \nu)$, we call the sequence s an *admissible orbit* for $\mathscr{B}_N(\mathscr{A}, \nu)$. We also say that a finite sequence $\{\xi_i\}_{i=j_1}^{j_2}$ with $\xi_i=(s_i, \phi_i)$ is *admissible* for $\mathscr{B}_N(\mathscr{A}, \nu)$ when $\{s_i\}_{i=j_1}^{j_2}$ satisfies (4.5) and $\{\phi_i\}_{i=j_1}^{j_2}$ satisfies (4.3).

Example 4.1. Consider the case in which $S_N=\{1,2\}$, $l=1$, $\nu=1$ and $\Theta=S^1$. Let $\mathscr{A}=\{A(\theta)\in M_N\,|\,\theta\in S^1\}$ be given by

$$A(\theta)=\begin{cases}\begin{pmatrix}1&0\\0&0\end{pmatrix} & \text{for } \theta\in[0,\pi-1),\\[2mm] \begin{pmatrix}0&1\\0&0\end{pmatrix} & \text{for } \theta\in[\pi-1,\pi),\\[2mm] \begin{pmatrix}0&0\\0&1\end{pmatrix} & \text{for } \theta\in[\pi,2\pi-1),\\[2mm] \begin{pmatrix}0&0\\1&0\end{pmatrix} & \text{for } \theta\in[2\pi-1,2\pi).\end{cases}$$

It is easy to show that $\mathscr{A}$ is irreducible. We also see that there is no periodic admissible orbit. If $\xi=(s,\phi)\in\mathscr{B}_N(\mathscr{A},1)$, then $s_i=1$ or 2, depending on whether ϕ_i $(=i+\phi_0 \bmod 2\pi)\in[0,\pi)$ or not, for $i\in\mathbb{Z}$. Hence, every orbit in $\mathscr{B}_N(\mathscr{A},\nu)$ can be completely determined by the value of ϕ_0, and is trivial.

Thus, we will require the following property for $\mathscr{A}$.

Definition 4.7. An l-parameter family of transition matrices

$$\mathscr{A}=\{A(\theta)\in M_N\,|\,\theta\in\Theta\}$$

is called *nontrivial* if card $(S_N(\theta))\geqq 2$ for any $\theta\in\Theta$.

The dynamics of the generalized Bernoulli shift $(\mathscr{B}_N(\mathscr{A},\nu),\sigma_\nu)$ are similar to those of the standard Bernoulli shift (B_N,σ) if $\mathscr{A}$ is nontrivial and irreducible. The generalized Bernoulli shift $(\mathscr{B}_N(\mathscr{A},\nu),\sigma_\nu)$ may have

(1) a countable set of periodic admissible orbits,

(2) an uncountable set of nonperiodic admissible orbits,

(3) a dense admissible orbit in an adequate meaning, although this is not the case in general (see Examples 4.1 and 4.4). We present two examples.

Example 4.2. Let A be an $N\times N$ irreducible transition matrix. Then, $\mathscr{A}=\{A(\theta)=A\,|\,\theta\in\Theta\}$ is irreducible for any rigid rotation R_ν, and nontrivial since $S_N(\theta)=S_N$ for all $\theta\in\Theta$. Since $s\in B_N$ is an admissible orbit for $\mathscr{B}_N(\mathscr{A},\nu)$ if and only if $s\in B_N(A)$, there exist (1), (2), and (3), where "dense" means "dense in $B_N(A)$."

Example 4.3. Let the ith element of ν have the form $\nu_i=2\pi(p_i/q_i)$ with a pair of relatively prime integers p_i, q_i for $i=1,\cdots,l$. Then, R_ν yields a rational flow in Θ and there is an integer k such that R_ν^k is an identical map. In particular, for any $\theta\in\Theta$ there are k different points $\phi_0=\theta,\phi_1,\cdots,\phi_{k-1}\in\Theta$ with $\phi_i=R_\nu(\phi_{i-1})$, $i=1,\cdots,k-1$, and $\phi_0=R_\nu(\phi_{k-1})$. Suppose that $\mathscr{A}=\{A(\theta)\in M_N\,|\,\theta\in\Theta\}$ be irreducible and nontrivial. Let $\mathscr{B}_N^\theta(\mathscr{A},\nu)$ be a subset of $\mathscr{B}_N(\mathscr{A},\nu)$ given by

$$\mathscr{B}_N^\theta(\mathscr{A},\nu)=\{\xi\in\mathscr{B}_N(\mathscr{A},\nu)\,|\,\phi_i=\theta \text{ for some integer } i\}.$$

If $\xi=\{\xi_j\}_{j=-\infty}^{\infty}\in\mathscr{B}_N^\theta(\mathscr{A},\nu)$, then $\xi_i^k=\{\xi_{i+kj}\}_{j=-\infty}^{\infty}\in\mathscr{B}_N^{\phi_i}(\mathscr{A},k\nu)$. Since $R_{k\nu}=R_\nu^k$ is the identical map, $\mathscr{B}_N^{\phi_i}(\mathscr{A},k\nu)=B_N(A^k(\phi_i))\times\prod_{j=-\infty}^{\infty}\{\phi_i\}$. Hence, every orbit in $B_N(A^k(\phi_i))$ is also an admissible orbit for $\mathscr{B}_N^{\phi_i}(\mathscr{A}^k,k\nu)$. Since this statement holds for ϕ_i, $i=0,\cdots,k-1$, and $\mathscr{A}$ is irreducible, there exist (1), (2), and (3) for $\mathscr{B}_N^\theta(\mathscr{A},\nu)$, where "dense" means "dense in the set of all admissible orbits for $\mathscr{B}_N^\theta(\mathscr{A},\nu)$."

We present an example which can be used as a model describing the stochastic behavior in some quasi-periodically forced oscillator as shown in § 5.

Example 4.4. Let $l=1$, $\nu=3$, and $N=3$. Let $\mathscr{A}=\{A(\theta)\in M_N \mid \theta\in S^1\}$ be given by

$$A(\theta)=\begin{cases} \begin{pmatrix} 1 & 1 & 1\\ 1 & 1 & 1\\ 0 & 0 & 0\end{pmatrix} & \text{for } \theta\in\left[1-\dfrac{1}{4}\pi, 1\right],\\[2ex] \begin{pmatrix} 1 & 0 & 1\\ 1 & 0 & 1\\ 1 & 0 & 1\end{pmatrix} & \text{for } \theta\in\left[\dfrac{7}{4}\pi-3, 2\pi-3\right],\\[2ex] \begin{pmatrix} 1 & 1 & 0\\ 1 & 1 & 0\\ 1 & 1 & 0\end{pmatrix} & \text{for } \theta\in\left[\dfrac{7}{4}\pi-2, 2\pi-2\right],\\[2ex] \begin{pmatrix} 1 & 1 & 1\\ 0 & 0 & 0\\ 1 & 1 & 1\end{pmatrix} & \text{for } \theta\in\left[\dfrac{7}{4}\pi, 2\pi\right],\\[2ex] \begin{pmatrix} 1 & 1 & 1\\ 1 & 1 & 1\\ 1 & 1 & 1\end{pmatrix} & \text{for } \theta\in\left(0, 1-\dfrac{\pi}{4}\right)\cup\left(1, \dfrac{7}{4}\pi-3\right)\cup\left(2\pi-3, \dfrac{7}{4}\pi-2\right)\\ & \qquad\qquad\cup\left(2\pi-2, \dfrac{7}{4}\pi\right). \end{cases}$$

We can easily show that $\mathscr{A}$ is nontrivial and irreducible. Moreover, there is no periodic admissible orbit except $\{\cdots, 1, 1, 1, \cdots\}$.

In general, the generalized Bernoulli shift $(\mathscr{B}_N(\mathscr{A}, \nu), \sigma_\nu)$ exhibits stochastic behavior if $\mathscr{A}$ is nontrivial and irreducible, like the standard Bernoulli shift (B_n, σ): suppose that $\mathscr{A}$ is nontrivial and irreducible, and let $\theta\in\Theta$ be fixed. Then there is an integer $k>0$ such that for all $i, j\in S_N(\theta)$ there is an orbit $\xi\in\mathscr{B}_N(\mathscr{A}, \nu)$ with $\xi_0=(i, \theta)$ and $\xi_k=(j, R_\nu^k(\theta))$. Let $\bar{r}=\text{card }(S_N(\theta))\geqq 2$, and let $S_N(\theta)=\{j_r\in S_N, i=1, \cdots, \bar{r}\}$. Consider an orbit $\xi=\{s, \phi\}$ with $s_0=j_1$ and $\phi_0=\theta$. Then, even though the values of s_i and ϕ_i are known for all $i\leqq 0$, the value of s_k cannot be determined; it can be any of j_r, $r=1, \cdots, \bar{r}$. Thus, if $\mathscr{A}$ is nontrivial and irreducible, then we cannot completely predict the future $(i>0)$ for each orbit in the generalized Bernoulli shift from its past $(i\leqq 0)$, as in the Bernoulli shift.

5. Detection of chaos for diffeomorphisms. In this section we consider a C^r $(r\geqq 2)$ diffeomorphism $f:\mathbb{R}^n\times\mathbb{R}^m\times T^l\to\mathbb{R}^n\times\mathbb{R}^m\times T^l$ of the form

$$f(x, y, \theta)=(g_1(x, y, \theta), g_2(x, y, \theta), R_\nu(\theta)), \qquad (x, y, \theta)\in\mathbb{R}^n\times\mathbb{R}^m\times T^l, \tag{5.1}$$

where $g_1:\mathbb{R}^n\times\mathbb{R}^m\times T^l\to\mathbb{R}^n$, $g_2:\mathbb{R}^n\times\mathbb{R}^m\times T^l\to\mathbb{R}^m$ are C^r and $R_\nu: T^l\to T^l$ is a rigid rotation with $\nu\in T^l$ (see (4.2)). The Poincaré map $P_{\varepsilon,i}$ for (2.1) has the form (5.1) with $m=n=1$. We assume that f has a C^r normally hyperbolic invariant l-torus of $(1, \cdots, 1)$-cycle $\mathscr{T}$ with C^r, $n+l$-dimensional stable manifold $W^s(\mathscr{T})$, and $m+l$-dimensional unstable manifold $W^u(\mathscr{T})$. Furthermore, $\mathscr{T}$ is assumed to be the graph of a function $z: T^l\to\mathbb{R}^n\times\mathbb{R}^m$, i.e., $\mathscr{T}=\{(x, y, \theta)\in\mathbb{R}^n\times\mathbb{R}^m\times T^l \mid (x, y)=z(\theta), \theta\in T^l\}$. These assumptions are satisfied for $P_{\varepsilon,i}$ when ε is sufficiently small.

We begin with a lemma concerning rigid rotations.

LEMMA 5.1. *For any $\varepsilon>0$ there is an integer $k>0$ such that*

$$|R_\nu^k(\theta)-\theta|<\varepsilon \quad \text{for } \theta\in T^l. \tag{5.2}$$

Proof. If for some integers $k_1 > k_2$,

$$R_\nu^{k_1}(\theta) = R_\nu^{k_2}(\theta), \tag{5.3}$$

then we have

$$R_\nu^{k_1-k_2}(\theta) = \theta,$$

which implies (5.2) with $k = k_1 - k_2$. Let us assume that there is not a pair of integers (k_1, k_2) such that (5.3) holds. Then, for $\theta \in T^l$ fixed, $R_\nu^j(\theta)$, $j \in \mathbb{Z}$ are different from each other. The sequence $\{R_\nu^j(\theta), j \in \mathbb{Z}\}$ consists of infinitely many points and hence has an accumulation point since T^l is compact. Thus for any $\varepsilon < 0$ there are two integers $k_1 > k_2$ such that

$$|R_\nu^{k_1}(\theta) - R_\nu^{k_2}(\theta)| < \varepsilon.$$

Since R_ν is an area-preserving map, we obtain (5.2) with $k = k_1 - k_2$. □

Remark 5.1. Lemma 5.1 is a special case of Poincaré's recurrence theorem (see Abraham and Marsden [1978] or Arnold [1989]).

Remark 5.2. If the components of the frequency vector ν are incommensurable, i.e.,

$$(\kappa, \nu) \notin 2\pi\mathbb{Z} \quad \text{for } \kappa \in \mathbb{Z}^l \backslash \{0\}, \tag{5.4}$$

then we have a stronger statement; for any $\varepsilon > 0$ and θ, $\theta' \in T^l$, there is an integer $k > 0$ such that

$$|R_\nu^k(\theta) - \theta'| < \varepsilon, \tag{5.5}$$

i.e., each orbit of R_ν is dense in T^l. See § 3 of Cornfeld, Fomin, and Sinai [1982] for a proof.

From Remark 5.2, we obtain the following.

LEMMA 5.2. *Let $\Theta \subset T^l$ be an l-dimensional manifold. Then we have*

$$\bigcup_{j=0}^{\infty} R_\nu^j(\Theta) = \bigcup_{j=0}^{\infty} R_\nu^{-j}(\Theta) \equiv \tilde{\Theta}. \tag{5.6}$$

Moreover, there is an integer N_0 such that if $N \geqq N_0$, then for any integer j_0,

$$\bigcup_{j=0}^{N} R_\nu^{j+j_0}(\Theta) = \bigcup_{j=0}^{N} R_\nu^{-j+j_0}(\Theta) = \tilde{\Theta}. \tag{5.7}$$

Proof. First, let us assume that ν satisfies (5.4). It follows from Remark 5.2 that we have (5.6) with $\tilde{\Theta} = T^l$. Let $c_\varepsilon(\theta)$ be the l-dimensional cube with sides of length ε centered at θ. For $N > 0$ sufficiently large, Θ contains a cube $c_{4\pi/N}(\theta_0)$ with $\theta_0 \in \Theta$. Let N^l cubes $c_{2\pi/N}(\theta_j)$, $j = 1, \cdots, N^l$, cover T^l. From Remark 5.2 we see that there exist integers $k_j > 0$, $j = 1, \cdots, N^l$, such that

$$|R_\nu^{k_j}(\theta_0) - \theta_j| < \frac{2\pi}{N}.$$

Hence, letting $N_0 = \max k_j$, we obtain (5.7).

Next, let us assume that condition (5.4) does not hold. Then, by permuting the components of ν if necessary, ν can be written as

$$\nu = (\nu^a, \nu^b),$$

where $\nu^a = (\nu_1^a, \cdots, \nu_{l_a}^a)$ satisfies (5.4) with $\nu = \nu^a$ and $l = l_a$, and $\nu^b = (\nu_1^b, \cdots, \nu_{l_b}^b)$ has the form

$$\nu_i^b = \sum_{j=1}^{l_a} \frac{q_{ij}}{p_{ij}} \nu_j^a + 2\pi \frac{q_i}{p_i}, \qquad i = 1, \cdots, l_b,$$

with $p_{ij}, q_{ij}, p_i, q_j \in \mathbb{Z}$, and both (p_{ij}, q_{ij}) and (p_i, q_i) are relatively prime. For $\theta \in T^l$, we write $\theta = (\theta^a, \theta^b)$, where $\theta^a \in T^{l_a}$ and $\theta^b \in T^{l_b}$. Let π^a denote the projection from $T^l = T^{l_a} \times T^{l_b}$ upon T^{l_a}. Let p_0 be the least common multiple for p_i, $i = 1, \cdots, l_b$, and let

$$\Theta_r \equiv R_\nu^r(\Theta) = \left\{ (\theta^a, \theta^b) \,|\, \theta_i^b = \frac{q_{ij}}{p_{ij}}(\theta_j^a - \theta_{j0}^a) + 2\pi r \frac{q_i}{p_i} + \theta_{i0}^b, \right.$$
$$\left. \theta^a \in \pi^a(R_\nu^r(\Theta)), (\theta_0^a, \theta_0^b) \in \Theta \right\}, \qquad r \in \mathbb{Z}.$$

Since the components of ν^a are incommensurable, there is an integer N_1 such that for any $r \in \mathbb{Z}$,

$$\bigcup_{j=0}^{N_1} \pi^a(R_\nu^{jp_0}(\Theta_r)) = \bigcup_{j=0}^{N_1} \pi^a(R_\nu^{-jp_0}(\Theta_r)) = T^{l_a}.$$

On the other hand, for any j, $r \in \mathbb{Z}$,

$$R_\nu^{jp_0}(\Theta_r) = \left\{ (\theta^a, \theta^b) \,|\, \theta_i^b = \frac{q_{ij}}{p_{ij}}(\theta_j^a - \theta_{j0}^a) + 2\pi r \frac{q_i}{p_i} + \theta_{i0}^b, \right.$$
$$\left. \theta^a \in \pi^a(R_\nu^{jp_0}(\Theta_r)), (\theta_0^a, \theta_0^b) \in \Theta \right\},$$

since $2\pi p_0 q_i / p_i = 0 \bmod 2\pi$. Thus we have

$$\bar{\Theta}_r \equiv \bigcup_{j=0}^{N_1} R_\nu^{jp_0}(\Theta_r) = \left\{ (\theta^a, \theta^b) \,|\, \theta_i^b = \frac{q_{ij}}{p_{ij}}(\theta_j^a - \theta_{j0}^a) + 2\pi r \frac{q_i}{p_i} + \theta_{i0}^b, \right.$$
$$\left. \theta^a \in T^{l_a}, (\theta_0^a, \theta_0^b) \in \Theta \right\}, \qquad r = 1, \cdots, p_0 - 1.$$

It is clear that

$$\Theta_r \subset \bigcup_{j=0}^{p_0-1} \bar{\Theta}_j \quad \text{for any } r \in \mathbb{Z}.$$

Hence, we have

$$\bigcup_{j=0}^{\infty} R_\nu^j(\Theta) = \bigcup_{j=0}^{\infty} R_\nu^{-j}(\Theta) = \bigcup_{r=0}^{p_0-1} \bar{\Theta}_r,$$

and

$$\bigcup_{j=0}^{N_1(p_0-1)} R_\nu^j(\Theta) = \bigcup_{j=0}^{N_1(p_0-1)} R_\nu^{-j}(\Theta) = \bigcup_{r=0}^{p_0-1} \bar{\Theta}_r.$$

Letting $\tilde{\Theta} = \bigcup_{r=0}^{p_0-1} \bar{\Theta}_r$ and $N_0 = N_1(p_0 - 1)$, we have (5.6) and (5.7). □

We now state the main theorem of this section. Let π_θ be the projection from $\mathbb{R}^n \times \mathbb{R}^m \times T^l$ upon T^l.

THEOREM 5.3. *Suppose that $W^s(\mathcal{T})$ and $W^u(\mathcal{T})$ intersect transversely in an l-dimensional manifold γ with* $\dim \pi_\theta(\gamma)=l$. *Then there exist an integer $N\geqq 2$, an l-dimensional manifold $\tilde{\Theta}\subset T^l$, and a nontrivial and irreducible l-parameter family of transition matrices $\mathcal{A}=\{A(\theta)\in M_N \mid \theta\in\tilde{\Theta}\}$ such that for some $k\geqq 1$, f^k has an invariant set Λ on which it is topologically conjugate to the generalized Bernoulli shift $\sigma_\nu:\mathcal{B}_N(\mathcal{A},k\nu)\to\mathcal{B}_N(\mathcal{A},k\nu)$.*

Proof. The proof is similar to that of the Smale-Birkhoff homoclinic theorem (see Smale [1963] and Newhouse [1980]).

Without loss of generality, we can assume that $\mathcal{T}$ is given by

$$\mathcal{T}=\{(0,0,\theta)\in\mathbb{R}^n\times\mathbb{R}^m\times T^l \mid \theta\in T^l\},$$

and that in a neighborhood U of $\mathcal{T}$, $W^s(\mathcal{T})$ and $W^u(\mathcal{T})$ are locally straightened, i.e.,

$$W^s(\mathcal{T})\cap U=\{(x,0,\theta)\in U \mid \theta\in T^l\},$$

and

$$W^u(\mathcal{T})\cap U=\{(0,y,\theta)\in U \mid \theta\in T^l\}.$$

See Wiggins [1988b, pp. 322-325].

Let $\Theta=\pi_\theta(\gamma)$, and let

$$\tilde{\Theta}=\bigcup_{j=-\infty}^{\infty} R_\nu^j(\Theta).$$

From Lemma 5.2 we see that there is an integer N_0 such that

$$\bigcup_{j=0}^{N_0} R_\nu^j(\Theta)=\tilde{\Theta}.$$

Since $\tilde{\Theta}$ is invariant by R_ν, $\mathbb{R}^2\times\tilde{\Theta}$ is also invariant by f. Hence, we have only to consider the restriction of f on $\mathbb{R}^2\times\tilde{\Theta}$, which is denoted by $\tilde{f}$. Thus $\tilde{f}$ is a C^r diffeomorphism from $\mathbb{R}^2\times\tilde{\Theta}$ onto $\mathbb{R}^2\times\tilde{\Theta}$. It is clear that $\tilde{\mathcal{T}}=\{(x,y,\theta)\in\mathcal{T} \mid \theta\in\tilde{\Theta}\}$ is a normally hyperbolic invariant manifold for $\tilde{f}$. For $j=0,\cdots,N_0$, let

$$\Theta_j=R_\nu^j(\Theta),$$

and let

$$\gamma_j=\tilde{f}^j(\gamma).$$

Since $\lim_{p\to\infty}\tilde{f}^p\gamma\subset\tilde{\mathcal{T}}$, we can assume that γ is close to $\tilde{\mathcal{T}}$ and hence $\gamma\subset U$. Replacing γ with a subset of γ if necessary, we can assume the following:

(H1) Θ is an open, simply connected, l-dimensional submanifold of T^l, and γ is the graph of a C^r function $x_\gamma:\Theta\to\mathbb{R}^n$, i.e.,

$$\gamma=\{(x,0,\theta)\in\mathbb{R}^n\times\mathbb{R}^m\times T^l \mid x=x_\gamma(\theta),\ \theta\in\Theta\}.$$

(H2) $\gamma_i\cap\gamma_j=\phi$ for $i\neq j$.

It follows from (H1) that there are C^r functions $x_j:\Theta_j\to\mathbb{R}^n, j=0,\cdots,N_0$, such that

$$\gamma_j=\{(x,0,\theta)\in\mathbb{R}^n\times\mathbb{R}^m\times T^l \mid x=x_j(\theta),\ \theta\in\Theta_j\}.$$

We also see that for any $0<N'<N_0$ and $0\leqq j_r\leqq N_0$, $r=1,\cdots,N'$, the intersection $\bigcap_{r=1}^{N'}\Theta_{j_r}$ is a nonempty open subset of $\tilde{\Theta}$ if it is nonempty.

Let $I^s \subset \mathbb{R}^n$ be a closed n-disk such that $D^s = I^s \times \tilde{\Theta}$ is an $n+l$-dimensional manifold in $W^s(\tilde{\mathcal{T}})$, and $\tilde{\mathcal{T}}$, $\bigcup_{j=0}^{N_0} \gamma_j \subset (I^s - \partial I^s) \times \tilde{\Theta}$. For $\delta > 0$ small, $N_\delta = \{(x, y, \theta) \in \mathbb{R}^n \times \mathbb{R}^m \times T^l \mid x \in I^s, y \in [-\delta, \delta], \theta \in \Theta\}$ is a neighborhood of D^s and contains $\tilde{\mathcal{T}}$ and $\bigcup_{j=0}^{N_0} \gamma_j$. See Fig. 4. If δ is sufficiently small, then $\tilde{f}^k(N_\delta)$ accumulates along $W^u(\tilde{\mathcal{T}})$ when $k \to \infty$, as shown in Fig. 5. Hence, we can choose k large such that $N_\delta \cap \tilde{f}^k(N_\delta)$ contains $\gamma_j, j = 1, \cdots, N_0$, and has $N_0 + 2$ connected components containing $\tilde{\mathcal{T}}$ or γ_j, $j = 0, 1, \cdots, N_0$. Let us denote the connected component containing $\tilde{\mathcal{T}}$ by V_1 and those containing γ_j by V_{j+2} for $j = 0, \cdots, N_0$. See Fig. 6.

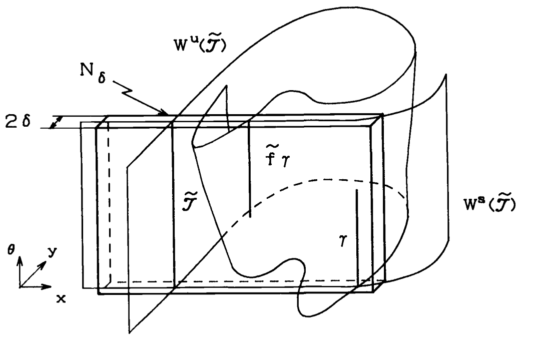


FIG. 4. *The set* N_δ.

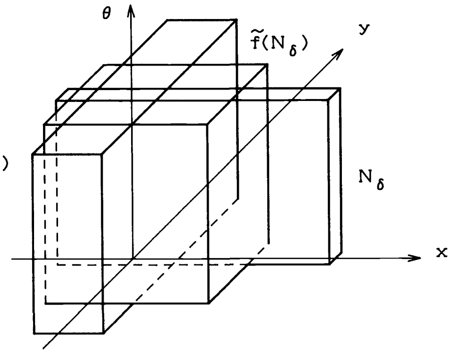

FIG. 5. N_δ, $\tilde{f}(N_\delta)$, *and* $\tilde{f}^2(N_\delta)$.

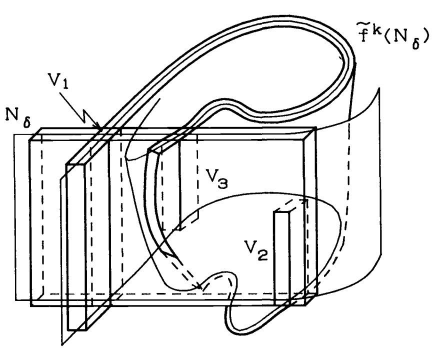

FIG. 6. *Construction of* V_i, $i = 1, 2, 3$.

Let us set $N=N_0+2$. For each $\theta\in\tilde{\Theta}$, define a $N\times N$ transition matrix $A(\theta)$ as follows: if (1) $i=j=1$, (2) $i=1$ and $\theta\in R_{k\nu}^{-1}(\Theta_{j-2})$ for $j\geqq 2$, (3) $j=1$ and $\theta\in\Theta_{i-2}$ for $i\geqq 2$, or (4) $\theta\in\Theta_{i-2}\cap R_{k\nu}^{-1}(\Theta_{j-2})$ for $i,j\geqq 2$, then

$$(A(\theta))_{ij}=1,$$

and, otherwise,

$$(A(\theta))_{ij}=0.$$

We notice that if $l=1$, $N_0=1$, $\tilde{\Theta}=S^1$, $\nu=1$, $k=3$, and $\Theta=(0,(7/4)\pi)$, then we have the one parameter family of transition matrices $\mathscr{A}$ in Example 4.4. Since

$$S_N(\theta)=\{2\leqq i\leqq N \mid \theta\in\Theta_{i-2}\}\cup\{1\}$$

and

$$S'_N(\theta)=\{2\leqq j\leqq N \mid \theta\in R_{k\nu}^{-1}(\Theta_{j-2})\}\cup\{1\},$$

we have $S_N(R_{k\nu}(\theta))=S'_N(\theta)$ and card $(S_N(\theta))\geqq 2$ for any $\theta\in\tilde{\Theta}$. Hence, the l-parameter family of transition matrices $\mathscr{A}=\{A(\theta)\in M_N \mid \theta\in\tilde{\Theta}\}$ is consistent with $R_{k\nu}$ and nontrivial. Let $S_N(\theta)=\{1,j_1,\cdots,j_{N'}\}$ for $\theta\in\tilde{\Theta}$ fixed. Since $\Theta_{j_1\cdots j_{N'}}\equiv\bigcap_{r=1}^{N'}\Theta_{j_r-2}(\ni\theta)$ is a nonempty open subset of $\tilde{\Theta}$ by (H1), it follows from Lemma 5.1 that there is an integer $K>0$ such that $R_{k\nu}^K(\theta')\in\Theta_{j_1\cdots j_{N'}}$. Thus,

$$(A^K(\theta))_{ij}\geqq(A(\theta))_{i1}(A^{K-2}(R_{k\nu}(\theta)))_{11}(A(R_{k\nu}^{K-1}(\theta)))_{1j}\geqq 1,$$

for $i,j=1,j_1,\cdots,j_{N'}$, and hence $\mathscr{A}$ is also irreducible.

Let

$$V_{i,\theta}=\{(x,y,\theta)\in\mathbb{R}^n\times\mathbb{R}^m\times T^l \mid (x,y,\theta)\in V_i\},\qquad \text{for } \theta\in\Theta_i \text{ and } i\in S_N(\theta).$$

By (H2) we can choose δ small such that $V_{i,\theta}\cap V_{j,\theta}=\phi$ for $i\neq j\in S_N(\theta)$. For any admissible sequence $\{\xi_{-j},\cdots,\xi_j\}$ for $\mathscr{B}_N(\mathscr{A},k\nu)$, let

$$V_{\xi_{-j}\cdots\xi_j}=\bigcap_{i=-j}^{j}\tilde{f}^{-ik}(V_{\xi_i}). \tag{5.8}$$

Noting (H1), we can prove that there are constants $C>0$ and $\lambda>1$ such that $V_{\xi_{-j}\cdots\xi_j}$ is an $m+n$-dimensional ball of diameter less than $C\lambda^{-j}$, as in the proof of the Smale-Birkhoff homoclinic theorem (e.g., Newhouse [1980]). Hence, for $\xi\in\mathscr{B}_N(\mathscr{A},k\nu)$, V_ξ is a single point. Let

$$\Lambda=\bigcap_{j\in\mathbb{Z}}\tilde{f}^{jk}\left(\bigcup_{i=1}^{N}V_i\right).$$

We define a map $h:\mathscr{B}_N(\mathscr{A},k\nu)\to\Lambda$ as

$$h(\xi)=V_\xi.$$

Since $V_\xi\neq V_{\xi'}$ for $\xi\neq\xi'\in\mathscr{B}_N(\mathscr{A},k\nu)$, h is a $1-1$ map of $\mathscr{B}_N(\mathscr{A},k\nu)$ onto Λ. It follows from (5.8) that h and h^{-1} are continuous when $\mathscr{B}_N(\mathscr{A},\nu)$ has the metric (4.4). Thus, h is a homeomorphism. Furthermore, $\tilde{f}^{jk}(h(\xi))\in V_{\xi_j}$ for all j, and hence

$$\tilde{f}^{jk}(\tilde{f}^k(h(\xi)))\in V_{\xi_{j+1}}=V_{(\sigma_{k\nu}(\xi))_j}.$$

Thus $\tilde{f}^k(h(\xi))=h(\sigma_{k\nu}(\xi))$ so that h conjugates $\sigma_{k\nu}$ with $\tilde{f}|_\Lambda$. This completes the proof. □

Remark 5.3. Suppose that $W^s(\mathcal{T}_{\varepsilon,i})$ and $W^u(\mathcal{T}_{\varepsilon,i})$ intersect transversely in a torus of $(1, \cdots, 1)$-cycle satisfying (H1). Then we can take $N = 2$ in Theorem 5.3. Moreover,

$$A(\theta) = A = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} \quad \text{for all } \theta \in T^l,$$

and $\mathcal{B}_2(\mathcal{A}, \nu) \cong B_2 \times T^l$. Thus, the dynamics of f on Λ can be described by the standard Bernoulli shift, as stated in Theorem 3.1.

Remark 5.4. The Smale-Birkhoff homoclinic theorem was stated in different forms in Smale [1963], Moser [1973, § 3], and Guckenheimer and Holmes [1983, § 5]. Hence, its generalization to a class of maps (5.1) can have some different versions. In Theorem 5.3 we adopted the formulation corresponding to that of Smale [1963].

6. Detection of chaos in quasi-periodically forced oscillators. We now return to the Poincaré map $P_{\varepsilon,i} : \Sigma_i \to \Sigma_i$ of the quasi-periodically forced oscillator (2.1).

Suppose that (M1) and (M2) are satisfied at $\theta_i = \omega_i t_0$, $\bar{\theta}^i = \bar{\omega}^i t_0 + \bar{\theta}_0^i \bmod 2\pi$. Then, the zero of the Melnikov function M can be continued to an $l-1$-dimensional manifold in T^l, as shown in § 2. Moreover, the stable and unstable manifolds $W^s(\mathcal{T}_{\varepsilon,i})$, $W^u(\mathcal{T}_{\varepsilon,i})$ of the normally hyperbolic invariant $(l-1)$-torus $\mathcal{T}_{\varepsilon,i}$ intersect transversely in an $l-1$-dimensional manifold $\gamma_{\varepsilon,i}$ containing a point near

$$(x, \bar{\theta}^i) = (\bar{x}_0(-t_0), \bar{\theta}_0^i) \in \Sigma_i. \tag{6.1}$$

We can denote $\gamma_{\varepsilon,i}$ by

$$\gamma_{\varepsilon,i} = \{\bar{x}_0(-t), \bar{\theta}^i) \mid t = \bar{h}_0(s), \theta_j = \bar{h}_j(s) \bmod 2\pi, s \in \tilde{U}\} + \mathcal{O}(\varepsilon), \tag{6.2}$$

where $\bar{h}_j : \tilde{U} \to \mathbb{R}$, $0 \leqq j(\neq i) \leqq l$ are C^r and satisfy $\bar{h}_0(0) = t_0$ and $\bar{h}_j(0) = \theta_{j0}$ with some neighborhood $\tilde{U}$ of 0 in $\mathbb{R}^{l-1}$. Moreover, (M1) and (M2) are satisfied at $\theta_i = \omega_i \bar{h}_0(s)$, $\theta_j = \bar{h}_j(s) + \omega_j \bar{h}_0(s) \bmod 2\pi$. Thus we have

$$\frac{\partial}{\partial t} M(\tilde{\theta}(t_0, \theta_0)) \frac{\partial}{\partial s_r} \bar{h}_0(0) + \sum_{j \neq i} \frac{\partial}{\partial \theta_j} M(\tilde{\theta}(t_0, \theta_0)) \frac{\partial}{\partial s_r} \bar{h}_j(0) = 0, \qquad r = 1, \cdots, l-1, \tag{6.3}$$

where $s = (s_1, \cdots, s_{l-1})$ and

$$\tilde{\theta}(t, \theta) = (\theta_1 + \omega_1 t, \cdots, \theta_{i-1} + \omega_{i-1} t, \omega_i t, \theta_{i+1} + \omega_{i+1} t, \cdots, \theta_l + \omega_l t).$$

From (6.2) we see that $\gamma_{\varepsilon,i}$ is tangent to $l-1$ vectors

$$t_{\varepsilon,i}^r = \left(\frac{\partial}{\partial s_r} \bar{h}_0(0) JDH(\bar{x}(-t_0)), \frac{\partial}{\partial s_r} \bar{h}_1(0), \cdots, \frac{\partial}{\partial s_r} \bar{h}_{i-1}(0), \right.$$
$$\left. \frac{\partial}{\partial s_r} \bar{h}_{i+1}(0), \cdots, \frac{\partial}{\partial s_r} \bar{h}_l(0) \right) + \mathcal{O}(\varepsilon), \qquad r = 1, \cdots, l-1,$$

at a point near (6.1). Hence, if

$$\frac{\partial}{\partial t} M(\tilde{\theta}(t_0, \theta_0)) = \sum_{j=1}^{l} \omega_j \frac{\partial}{\partial \theta_j} M(\tilde{\theta}(t_0, \theta_0)) \neq 0, \tag{6.4}$$

then $\dim \pi_\theta(\gamma_{\varepsilon,i}) = l-1$ since $DH(\bar{x}(-t_0)) \neq 0$ holds and (6.3) does not hold when $\partial \bar{h}_0(0)/\partial s_r \neq 0$ and $\partial \bar{h}_j(0)/\partial s_r = 0$ for all $j \neq i$.

Noting that (6.4) implies (M2) at $\theta = \tilde{\theta}(t_0, \theta_0)$ and applying Theorem 5.3 to the Poincaré map $P_{\varepsilon,i}$ of (2.1), we obtain the following theorem.

THEOREM 6.1. *Suppose that there exists a point $\theta_0 \in T^l$ satisfying* (M1) *and*

$$\text{(M3)} \qquad \sum_{j=1}^{l} \omega_j \frac{\partial}{\partial \theta_j} M(\theta_0) \neq 0.$$

Then for some $k \geqq 1$, $P^k_{\varepsilon,i}$ has an invariant set Λ on which it is topologically conjugate to the generalized Bernoulli shift on a finite set of symbols.

Remark 6.1. For the existence of chaotic solutions in almost periodically forced systems, Scheurle [1986] obtained conditions similar to those of Theorem 6.1, using a functional analytic method. From the proof of Theorem 5.3 we see that our result also gives a geometrical interpretation of his result, although it is limited to quasi-periodically forced systems. See Theorem A.2 of Appendix A.

7. An illustrative example. We consider a two-frequency perturbation of Duffing's equation

$$\text{(7.1)} \qquad \begin{aligned} &\dot{x} = y, \qquad \dot{y} = x - x^3 + \varepsilon(\gamma_1 \cos \theta_1 + \gamma_2 \cos \theta_2 - \delta y), \\ &\dot{\theta}_1 = \omega_1, \qquad \dot{\theta}_2 = \omega_2, \end{aligned}$$

where δ, γ_i, $\omega_i > 0$, $i = 1, 2$, and $0 < \varepsilon \ll 1$. The phase space of (7.1) is $\mathbb{R}^2 \times T^2$. See Yagasaki [1991a] for more detailed analyses. Chaotic motions near resonant tori are also described there.

When $\varepsilon = 0$, the (x, y)-component of (7.1) reduces to a planar Hamiltonian system

$$\dot{x} = y, \qquad \dot{y} = x - x^3,$$

which has a hyperbolic saddle at $(0, 0)$ and a symmetric pair of homoclinic orbits

$$\text{(7.2)} \qquad (x_\pm(t), y_\pm(t)) = \pm(\sqrt{2} \operatorname{sech} t, -\sqrt{2} \operatorname{sech} t \tanh t).$$

By substituting (7.2) into (2.3) and integrating the resulting equations, the Melnikov functions $M_\pm(t)$ for (7.2) become

$$\text{(7.3)} \qquad \begin{aligned} M_\pm(\theta_1, \theta_2) = &\pm\sqrt{2}\pi\omega_1\gamma_1 \operatorname{sech}\left(\frac{\pi\omega_1}{2}\right) \sin \theta_1 \\ &\pm\sqrt{2}\pi\omega_2\gamma_2 \operatorname{sech}\left(\frac{\pi\omega_2}{2}\right) \sin \theta_2 - \frac{4}{3}\delta. \end{aligned}$$

We see that there exists a point $(\theta_{10}, \theta_{20})$ satisfying (M1) and (M3) if

$$\text{(7.4)} \qquad \delta < \frac{3\sqrt{2}\pi}{4}\left[\omega_1\gamma_1 \operatorname{sech}\left(\frac{\pi\omega_1}{2}\right) + \omega_2\gamma_2 \operatorname{sech}\left(\frac{\pi\omega_2}{2}\right)\right].$$

By Theorem 6.1, (7.4) gives the region in parameter space $(\delta, \gamma_1, \gamma_2, \omega_1, \omega_2)$ where chaos may occur. Note that (7.4) is also the necessary condition for (M1) and (M2) to hold. Thus, in this example, transverse intersection between the stable and unstable manifolds of a normally hyperbolic invariant torus implies the existence of chaotic dynamics.

We next apply the result of Wiggins [1988b] (cf. Theorem 3.2). Suppose that

$$\text{(7.5)} \qquad \delta < \frac{3\sqrt{2}\pi}{4}\left|\omega_1\gamma_1 \operatorname{sech}\left(\frac{\pi\omega_1}{2}\right) - \omega_2\gamma_2 \operatorname{sech}\left(\frac{\pi\omega_2}{2}\right)\right|.$$

Note that if (7.5) holds, then (7.4) also holds. Moreover, let us assume that

$$\omega_1\gamma_1 \operatorname{sech}\left(\frac{\pi\omega_1}{2}\right) > \omega_2\gamma_2 \operatorname{sech}\left(\frac{\pi\omega_2}{2}\right).$$

Then

$$\frac{1}{\omega_1\gamma_1}\cosh\left(\frac{\pi\omega_1}{2}\right)\left[\frac{4\delta}{3\sqrt{2}\,\pi}+\omega_2\gamma_2\,\mathrm{sech}\left(\frac{\pi\omega_2}{2}\right)\right]<1.$$

Hence, we can define a periodic function $h_1(s)$, given by

$$h_1(s)=\sin^{-1}\left(\frac{1}{\omega_1\gamma_1}\cosh\left(\frac{\pi\omega_1}{2}\right)\left[\pm\frac{4\delta}{3\sqrt{2}\pi}-\omega_2\gamma_2\,\mathrm{sech}\left(\frac{\pi\omega_2}{2}\right)\sin s\right]\right).$$

Here the range of $\sin^{-1}$ is $[-\pi/2, \pi/2]$. We see that $h_1(s)$ satisfies the hypothesis of Theorem 3.2 when $i=1$. Similarly, if

$$\omega_1\gamma_1\,\mathrm{sech}\left(\frac{\pi\omega_1}{2}\right)<\omega_2\gamma_2\,\mathrm{sech}\left(\frac{\pi\omega_2}{2}\right),$$

then we can define a periodic function $h_2(s)$, given by

$$h_2(s)=\sin^{-1}\left(\frac{1}{\omega_2\gamma_2}\cosh\left(\frac{\pi\omega_2}{2}\right)\left[\pm\frac{4\delta}{3\sqrt{2}\pi}-\omega_1\gamma_1\,\mathrm{sech}\left(\frac{\pi\omega_1}{2}\right)\sin s\right]\right),$$

which satisfies the hypothesis of Theorem 3.2 when $i=2$.

On the other hand, let us assume that (7.4) holds but (7.5) does not. Then

$$-1<\frac{1}{\omega_i\gamma_i}\cosh\left(\frac{\pi\omega_i}{2}\right)\left[\frac{4\delta}{3\sqrt{2}\pi}-\omega_j\gamma_j\,\mathrm{sech}\left(\frac{\pi\omega_j}{2}\right)\right]<1,\qquad i=1,2,$$

where if $i=1$ then $j=2$ and otherwise $j=1$, and we set

$$a_1=\cos^{-1}\left(\frac{1}{\omega_1\gamma_1}\cosh\left(\frac{\pi\omega_1}{2}\right)\left[\frac{4\delta}{3\sqrt{2}\pi}-\omega_2\gamma_2\,\mathrm{sech}\left(\frac{\pi\omega_2}{2}\right)\right]\right),$$

where the range of $\cos^{-1}$ is $[0, \pi]$. Let

$$h_1'(s)=a_1\sin s\pm\frac{\pi}{2},$$

and let

$$h_2'(s)=\begin{cases}h_2(h_1'(s)), & s\in\left(0,\dfrac{\pi}{2}\right]\cup\left(\dfrac{3}{2}\pi,2\pi\right],\\[2ex] \pm\pi-h_2(h_1'(s)), & s\in\left(\dfrac{\pi}{2},\dfrac{3}{2}\pi\right].\end{cases}$$

Then the zero set of $M_\pm$ is given by

$$\tau_0=\{(\theta_1,\theta_2)\in T^2\mid\theta_1=h_1'(s),\ \theta_2=h_2'(s),\ s\in(0,2\pi]\}.$$

This is a special case of (3.5). Hence, we can only take a 1-torus of 0-cycle as the transverse homoclinic manifold for $P_{\varepsilon,1}$ and $P_{\varepsilon,2}$. Thus (7.5) represents a condition for the existence of chaos given by Theorem 3.2.

Figure 7 shows the regions given by (7.4) and (7.5) in $\delta-\gamma_1$ plane for fixed γ_2, ω_1, and ω_2. In this figure

$$\bar{\gamma}_1=\frac{\omega_2}{\omega_1}\gamma_2\cosh\left(\frac{\pi\omega_1}{2}\right)\mathrm{sech}\left(\frac{\pi\omega_2}{2}\right),$$

$$\bar{\delta}=\frac{3\sqrt{2}}{4}\pi\omega_2\gamma_2\,\mathrm{sech}\left(\frac{\pi\omega_2}{2}\right),$$

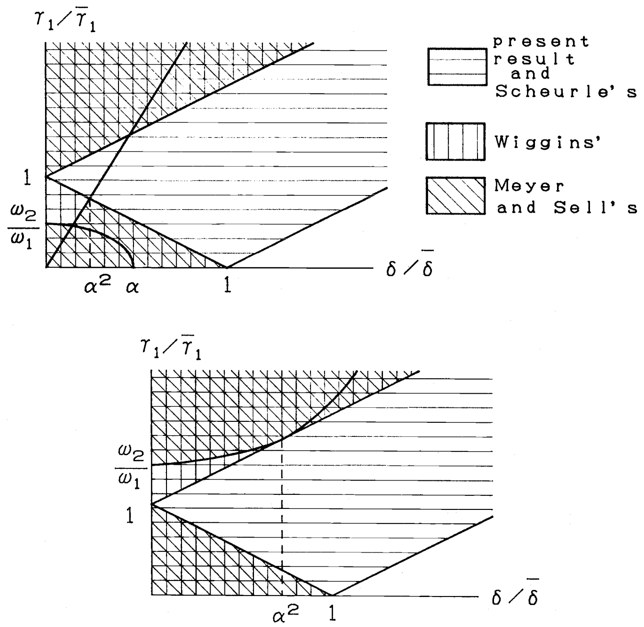

FIG. 7. *Regions in $\delta-\gamma_1$ plane for the existence of chaos in* (7.1), *with fixed γ_2, ω_1, and ω_2.* (a) $\omega_1>\omega_2$. (b) $\omega_1<\omega_2$.

and

$$\alpha=\frac{1}{\omega_1}\sqrt{|\omega_1^2-\omega_2^2|}\,.$$

We also show the regions given by the result of Scheurle [1986] and Meyer and Sell [1989] (see Appendix A). Note that Scheurle [1986] only provided a condition for the existence of random-like solutions (see Remarks A.1), although his condition gives the same regions as ours.

We close this paper with a remark on the extension of our result to a more general class of systems with frequencies depending on the state variables.

Consider systems of the form

$$\begin{aligned}&\dot{x}=JDH(x)+\varepsilon g(x,\theta),\\ &\dot{\theta}=\omega+\varepsilon G(x,\theta),\qquad (x,\theta)\in\mathbb{R}^2\times T^l,\quad \omega\in\mathbb{R}^l,\end{aligned}\tag{7.6}$$

where $G:\mathbb{R}^2\times T^l\to\mathbb{R}^l$ are C^r and $0<\varepsilon\ll 1$. We assume that condition (A1) of § 2 is satisfied, so that there exists a normally hyperbolic invariant torus $T_\varepsilon=T_0+\mathcal{O}(\varepsilon)$ whose stable and unstable manifolds $W^s(T_\varepsilon)$, $W^u(T_\varepsilon)$ are close to the unperturbed homoclinic manifold $\Gamma\times T^l$. In this case, T_ε may be subjected to phase locking.

Let us assume that the invariant torus T_ε is not subjected to phase locking. If G is independent of x, then we can show that transverse intersection between the stable and unstable manifolds of the invariant torus yields chaotic dynamics in (7.6), modifying the arguments given in § 5. It is natural to conjecture that this is the case in the general systems. However, if T_ε is subjected to phase locking, then we cannot immediately determine whether or not chaotic dynamics may occur since we do not have statements similar to those of Lemma 5.2 in general, and hence such arguments as given in § 5 do not apply. In a forthcoming paper (Yagasaki [1991b]) we will consider a perturbation of Duffing's equation with two frequencies depending on the state variables and perform the necessary analyses to detect the existence of chaos.

Appendix A. Other versions of Melnikov's method. Scheurle [1986] and Meyer and Sell [1989] extended Melnikov's method to study almost periodically forced systems. In this appendix we outline their results in the context of quasi-periodically forced oscillators.

Let Z be the zero set of the Melnikov function M, i.e.,

$$Z=\{\theta\in T^l \mid M(\theta)=0\}.$$

Suppose that Z is nonempty and

$$\text{(A.1)}\qquad \frac{d}{dt}M(\omega t+\theta)\Big|_{t=0}=\sum_{j=1}^{l}\omega_j\frac{\partial}{\partial\theta_j}M(\theta)\neq 0,$$

for all $\theta\in Z$. Then $\mathbb{R}^2\times Z$ is a global cross section for the flow of (2.1), and the Poincaré map $\Psi:\mathbb{R}^2\times Z\to\mathbb{R}^2\times Z$ is defined as follows:

$$\Psi:(x(0),\theta_0)\to(x(T),\eta(\theta_0)),$$

where $(x(t),\omega t+\theta_0)$ is a solution of (2.1),

$$\eta: Z\to Z,\qquad \theta_0\to\omega T(\theta_0)+\theta_0,$$

and $T(\theta)>0$ is the least time $t>0$ such that $\omega t+\theta\in Z$. We have the following theorem.

THEOREM A.1. *Suppose that Z is nonempty and* (A.1) *holds for all $\theta\in Z$. Then for ε sufficiently small, Ψ has an invariant set Ω. Moreover, for some integer $n\geqq 2$ and irreducible transient matrix A, $\Psi|_\Omega$ is topologically conjugate to the product map $\sigma\times\eta: B_n(A)\times Z\to B_n(A)\times Z$.*

Proof. See Meyer and Sell [1989]. □

As stated in § 2, (2.1) has a normally hyperbolic invariant l-torus T_ε near $T_0=\{x_0\}\times T^l$. Let $(x_\varepsilon^{\theta_0}(t),\theta^{\theta_0}(t))$ be an orbit on T_ε such that $\theta^0(0)=\theta_0$. Even though not every but only some zeros of M satisfy (A.1), (2.1) has random-like solutions as follows.

THEOREM A.2. *Suppose that there exists a zero $\theta=\theta_0\in T^l$ of M satisfying* (A.1). *Then, for ε sufficiently small,* (2.1) *has a solution $(\bar{x}_\varepsilon^{\theta_0}(t),\theta^{\theta_0}(t))$ with $\bar{x}_\varepsilon^{\theta_0}(t)\not\equiv x_\varepsilon^{\theta_0}(t)$ such that*

$$|\bar{x}_\varepsilon^{\theta_0}(t)-x_\varepsilon^{\theta_0}(t)|\to 0\quad\text{as } |t|\to\infty.$$

Moreover, there exist positive constants $T=T(\varepsilon)$, $\bar{T}=\bar{T}(\varepsilon)$, and $\lambda=\lambda(\varepsilon)$ such that for any interval $I_0\in\mathbb{R}$ with length λ and any sequence of real numbers $\tau_k\geqq 0$ $(k\in\mathbb{Z})$, there exists a sequence of real numbers t_k with $t_0\in I_0$ and

$$T+\tau_k\leqq t_k-t_{k-1}\leqq T+\tau_k+\lambda,$$

such that (2.1) *has a unique solution $(y_\varepsilon^{\theta_0}(t),\theta^{\theta_0}(t))$ satisfying*

$$\text{(A.2)}\qquad |y_\varepsilon^{\theta_0}(t)-\bar{x}_\varepsilon^{\theta_0}(\bar{T}+t-t_{k-1})|\leqq\varepsilon,$$

for $t\in[t_{k-1},t_k]$ and

$$\text{(A.3)}\qquad |y_\varepsilon^{\theta_0}(t)-x_\varepsilon^{\theta_0}(t)|\leqq\varepsilon,$$

for $t\in[t_{k-1}+T,t_k]$. Here we may take $\tau_l=\infty$ for some l.

Proof. The proof follows from Remark 2.9 and Theorem 2.11 of Scheurle [1986]. Note that the hypothesis of Theorem A.2 is equivalent to that of Theorem 6.1. □

Remark A.1. From the proof of Theorem 2.11 of Scheurle [1986], we can take $\bar{T}$ and T such that $\bar{x}_0(t)$ stays outside an ε-neighborhood of x_0 within an interval $I \subset [\bar{T}, \bar{T}+T]$. Hence, from (A.2) and (A.3), we see that the solution $y_\varepsilon^{\theta_0}(t)$ stays inside a neighborhood U of x_0 for some time, leaves U and then reaches U again, as $\bar{x}_\varepsilon^{\theta_0}(t)$ does. These excursions seem to occur quite randomly since $\tau_k \geqq 0$, $k \in \mathbb{Z}$, can be chosen arbitrarily. This implies that $y_\varepsilon^{\theta_0}(t)$ represents a random-like solution. Thus Theorem A.2 gives a condition for the existence of chaotic solutions. However, it has nothing to say about the existence of an invariant set on which the dynamics are characterized by Bernoulli shift or its generalization, in contrast with Theorems 3.2, 6.1, and A.1.

Now we apply Theorem A.1 to the quasi-periodically forced Duffing oscillator (7.1). Note that from Theorem A.2 we have (7.4) as a condition for the existence of chaotic solutions in (7.1).

Let

$$A_i = \frac{3\sqrt{2}\pi}{4}\,\omega_i\gamma_i \operatorname{sech}\left(\frac{\pi\omega_i}{2}\right), \qquad i = 1, 2.$$

From (7.3), the zero $(\theta_{10}, \theta_{20})$ of the Melnikov functions $M_\pm$ is given by

$$\delta = \pm A_1 \sin\theta_{10} \pm A_2 \sin\theta_{20}. \tag{A.4}$$

In this example, (A.1) becomes

$$\omega_1 A_1 \cos\theta_{10} + \omega_2 A_2 \cos\theta_{20} \neq 0.$$

Let us assume that there exists a point $(\theta_{10}, \theta_{20})$ satisfying (A.4) and

$$\omega_1 A_1 \cos\theta_{10} + \omega_2 A_2 \cos\theta_{20} = 0. \tag{A.5}$$

Then the hypothesis of Theorem A.1 does not hold, although the zero set of $M_\pm$ is nonempty. Obviously, $M_\pm$ has a zero if and only if

$$\delta \leqq A_1 + A_2.$$

From (A.4) and (A.5), we obtain

$$(\omega_1^2-\omega_2^2)A_1^2\sin^2\theta_{10} \pm 2\delta\omega_2^2 A_1 \sin\theta_{10} - \omega_1^2A_1^2 + \omega_2^2A_2^2 - \delta^2\omega_2^2 = 0, \tag{A.6a}$$

$$(\omega_2^2-\omega_1^2)A_2^2\sin^2\theta_{20} \pm 2\delta\omega_1^2 A_2 \sin\theta_{20} + \omega_1^2A_1^2 - \omega_2^2A_2^2 - \delta^2\omega_1^2 = 0. \tag{A.6b}$$

We see that (A.6) has a solution $(\theta_{10}, \theta_{20})$ if and only if

$$(\omega_1^2-\omega_2^2)(\omega_1^2A_1^2-\omega_2^2A_2^2)+\delta^2\omega_1^2\omega_2^2 \geqq 0$$

and at least one of the following conditions holds:

(i) $\delta \geqq \max\,((\omega_1^2-\omega_2^2)A_1/\omega_2^2, (\omega_2^2-\omega_1^2)A_2/\omega_1^2)$ and $|A_1-A_2| \leqq \delta \leqq A_1+A_2$,

(ii) $\delta < (\omega_1^2-\omega_2^2)A_1/\omega_2^2$ and $A_1-A_2 \leqq \delta \leqq A_1+A_2$,

(iii) $\delta < (\omega_2^2-\omega_1^2)A_2/\omega_1^2$ and $A_2-A_1 \leqq \delta \leqq A_1+A_2$.

Hence, the hypothesis of Theorem A.1 is satisfied if and only if

$$\delta^2 < \frac{\omega_2^2-\omega_1^2}{\omega_1^2\omega_2^2}(\omega_1^2A_1^2-\omega_2^2A_2^2), \tag{A.7a}$$

$$\max\,((\omega_1^2-\omega_2^2)A_1/\omega_2^2, (\omega_2^2-\omega_1^2)A_2/\omega_1^2) \leqq \delta < |A_1-A_2|, \tag{A.7b}$$

$$\delta < \min\,((\omega_1^2-\omega_2^2)A_1/\omega_2^2, A_1-A_2), \tag{A.7c}$$

or

$$\text{(A.7d)} \qquad \delta < \min\left((\omega_2^2-\omega_1^2)A_2/\omega_1^2,\ A_2-A_1\right).$$

Thus, if at least one of conditions (A.7a-d) holds, then the Poincaré map $\Psi:\mathbb{R}^2\times Z\to\mathbb{R}^2\times Z$ of (7.1) has a chaotic invariant set Ω stated in Theorem A.1. When $\delta=0$, (A.7) becomes

$$\text{(A.8a)} \qquad A_1/A_2 > \max\left(\omega_2/\omega_1, 1\right),$$

or

$$\text{(A.8b)} \qquad A_1/A_2 < \min\left(\omega_2/\omega_1, 1\right),$$

which is the same condition as given for the case of $\delta=0$ in Meyer and Sell [1989].

Acknowledgments. I would like to thank the referees for useful comments and constructive suggestions that improved this work. I also acknowledge Professor S. Wiggins for introducing me to the work of Beigie, Leonard, and Wiggins [1991a], [1991b] and Stoffer [1988].

HOMOCLINIC BIFURCATION TO A TRANSITIVE ATTRACTOR OF LORENZ TYPE, II*

CLARK ROBINSON†

Abstract. In this paper it is proven that there is a codimension two bifurcation of a double homoclinic connection of a fixed point with a resonance condition among the eigenvalues to a transitive attractor that is like that of the geometric model of the Lorenz equations. The two key parameters are the variation of the eigenvalues from resonance and the amount that the homoclinic connection is broken. Because of the need to work near resonance of two of the eigenvalues, one of the key steps in the proof is to calculate the Poincaré–Dulac map past a fixed point in this situation. Also indicated is how bifurcation is realized for a specific cubic differential equation introduced by Rychlik, which is closely related to the Lorenz equations.

Key words. attractor, Lorenz, homoclinic bifurcation

1. Statement of main theorem. In our previous paper [8], following the work of Rychlik [10], we proved that there is a homoclinic bifurcation to a transitive attractor. We also discussed the connection with the Lorenz equations and the geometric Lorenz model. In this paper, we reconsider this same theorem, improve the proof of the Poincaré–Dulac map past the fixed point, and emphasize the fact that it is a codimension two bifurcation.

As discussed in §3, both Rychlik and Shilnikov have discussed a bifurcation from a double homoclinic bifurcation to an attractor of Lorenz type, but the assumptions on the eigenvalues of the fixed point and the transversality of the stable and unstable manifolds from which they bifurcate is different than the situation considered in this paper. See [1], [11], and [10].

We start by giving the general assumptions that the parameter must satisfy at the bifurcation value, (A0)–(A5). Then, rather than give conditions that a curve of parameter values must satisfy as in the earlier paper, we describe the part of parameter space near the bifurcation value that has an attractor. This description is given in terms of two key unfolding parameters. In §3, we will verify the assumptions for the cubic equations in R^3 that Rychlik considered.

The zeroth assumption introduces the general assumptions and notation on the the symmetry about the z-axis, and the eigenvalues and eigenvectors for the fixed point at the origin. In this paper we only consider the case when the equations have a symmetry under reflection in the z-axis, $(x, y, z) \to (-x, -y, z)$. In our previous paper, we considered one type of nonsymmetric equations. The general situation for nonsymmetric equations that allows this type of bifurcation has yet to be determined. Assumptions (A1)–(A5) give the conditions at the bifurcation parameter value $\eta = \eta_0$.

(A0) We consider a C^r vector field on R^3 for $r \geq 2$, X, which depends on parameters η with a fixed point at the origin, $Q = (0, 0, 0)$, for all parameter values.

We assume that the vector field is taken to itself under the action of the reflection in the z-axis, $(x, y, z) \to (-x, -y, z)$. Further, we assume that the eigenvalues of $DX(Q)$ are all real with $\lambda_{ss}(\eta) < \lambda_s(\eta) < 0 < \lambda_u(\eta)$, and with respective eigenvectors v_{ss}, v_s, and v_u, and that $v_s = (0, 0, 1)^{tr}$ is along the axis of symmetry.

With these assumptions, there are several invariant manifolds for the fixed point at the origin. We denote the one-dimensional unstable manifold tangent to v_u by $W^u(Q, \eta)$, and the two-dimensional stable manifold tangent to v_s and v_{ss} by $W^s(Q, \eta)$. Next, there is a strong stable manifold tangent to v_{ss}, which we denote by $W^{ss}(Q, \eta)$. This latter manifold is made up of points that converge to Q at an asymptotic rate determined by the eigenvalue λ_{ss}. All of these manifolds are C^r if the vector field is C^r, and are even real analytic if the vector field is real analytic. Finally, there is a two-dimensional manifold tangent to the two most expanding directions, v_u and v_s, which we denote by $W^{us}(Q, \eta)$. This manifold is local in the stable direction but can be extended along the unstable manifold by flowing forward in time. We call this the weak unstable manifold even though it is not expanding in all directions. This manifold is at least C^1 (and C^2 with assumption (A3) on the dominance of the contraction toward $W^{us}(Q, \eta)$ given by $e^{\lambda_{ss}}$, in comparison with the greatest contraction within $W^{us}(Q, \eta)$ given by e^{λ_s}). With this notation we can make the second assumption about the existence of a homoclinic orbit. Because we are considering equations with symmetry, if one branch of $W^u(Q, \eta_0)$ is homoclinic, it follows that both sides are homoclinic. Thus within equations with symmetry it is only a codimension one condition to have a double homoclinic connection.

(A1) There is a bifurcation parameter value η_0 for which there is a *double homoclinic connection* with the unstable manifold of Q contained in the stable manifold but outside the strong stable manifold, $\Gamma \equiv W^u(Q, \eta_0) \subset W^s(Q, \eta_0) \setminus W^{ss}(Q, \eta_0)$. Also, because of the symmetry, both branches of $W^u(Q, \eta_0)$ are contained in the same component of $W^s(Q, \eta_0) \setminus W^{ss}(Q, \eta_0)$.

(A2) For η_0, the two-dimensional weak unstable manifold $W^{us}(Q, \eta_0)$ is *transverse* to the two-dimensional stable manifold $W^s(Q, \eta_0)$ along Γ. This transversality, together with the fact that $\Gamma \subset W^s(Q, \eta_0) \setminus W^{ss}(Q, \eta_0)$, implies that $W^{us}(Q, \eta_0)$ is tangent to itself at Q (when it leaves and returns to Q). Let $P_{\eta_0}(q) = T_q W^{us}(Q, \eta_0)$ for $q \in \Gamma$. If the bundle $\{P_{\eta_0}(q) : q \in \Gamma\}$ is orientable along Γ, we set $\nu = 1$, and if it is nonorientable we set $\nu = -1$. (The orientability is the same over both branches of Γ by the symmetry of the equations.)

This condition is generically satisfied and so does not add a codimension to the bifurcation.

(A3) We assume that for η_0 *the strong stable eigenvalue dominates* the other two eigenvalues in the sense that $\lambda_{ss}(\eta_0) - \lambda_s(\eta_0) + \lambda_u(\eta_0) < 0$ and $\lambda_{ss}(\eta_0) - 2\lambda_s(\eta_0) < 0$.

This is an open condition and does not add a codimension to the bifurcation. The second inequality in (A3) is what assures that the manifold $W^{us}(Q, \eta_0)$ is C^2. It is also redundant with the following resonance assumption (but sometimes we want to assume (A3), but not necessarily assume (A4)).

(A4) There is a one-to-one *resonance* between the unstable and weak stable eigenvalues for η_0: $\lambda_u(\eta_0) + \lambda_s(\eta_0) = 0$, so $1 - |\lambda_s(\eta_0)|/\lambda_u(\eta_0) = 0$.

This resonance condition is a codimension one and gives the second codimension that the bifurcation parameter must satisfy. The final assumption on the bifurcation parameter is the extent to which area is changed within the $P(q)$ directions ("within the attractor directions") during one loop around Γ.

(A5) For this assumption fix $\eta = \eta_0$. Let $\{P_{\eta_0}(q) : q \in \Gamma\}$ be the continuous bundle of planes given in (A2). Let $q(t)$ be a homoclinic orbit along one of the two branches of Γ, and let $\operatorname{div}_2(t)$ be the rate of change of area within the plane field $P_{\eta_0}(q(t))$. Define $C_{\eta_0} > 0$ by

$$\int_{-\infty}^{\infty} \operatorname{div}_2(q(t))dt \equiv \log(C_{\eta_0}).$$

We assume that the *change of area* $C_{\eta_0} < 2$. (Note, because the equations are symmetric, the integral is independent of which branch of Γ is used. Note also that if $\lambda_u(\eta_0) + \lambda_s(\eta_0) \neq 0$, then the integral would be $\pm\infty$ and $C_{\eta_0} = \infty$ or 0.)

It turns out that C_{η_0} has meaning in terms of a one-dimensional Poincaré map, f_{η_0}, from making one trip near one of the branches of Γ. We give a few definitions to explain this fact more fully and which will also be used in the final assumption and statement of the theorem. Let Σ be a fixed transversal to Γ out a short distance along the local stable manifold from Q. Points in a neighborhood V of Γ on $\Sigma \setminus W^s(Q,\eta)$ will return to Σ, defining a Poincaré map

$$F_\eta : V \setminus W^s(Q,\eta) \subset \Sigma \to \Sigma.$$

In the proof, it is shown that assumption (A3) implies that there is an invariant continuous bundle of strong stable directions over Γ, $\{E^{ss}(q) : q \in \Gamma\}$ with $E^{ss}(Q) = \langle v_{ss} \rangle$. These conditions are open so this bundle exists not only over Γ for η_0 but also over a neighborhood of Γ for nearby η. The stable manifold theory then implies that there is an invariant strong stable foliation for these nearby η. Each leaf of the strong stable manifold of a point is one-dimensional, but if we take the union of these for points on the same orbit we get two-dimensional strong stable manifolds of orbits that are transverse to Σ. Projection along the leaves of the strong stable manifolds of orbits defines a map $\pi_\eta : \Sigma \to \Sigma^1$, where Σ^1 can either be thought of as the quotient space or a one-dimensional manifold in Σ passing through Γ and transverse to the strong stable foliation. This projection can be used to define a one-dimensional map $f_\eta : V^1 \setminus \{0\} \subset \Sigma^1 \to \Sigma^1$ by $f_\eta(\pi_\eta w) = \pi_\eta F_\eta(w)$, where $V^1 = \pi_\eta(V)$. We use coordinates on Σ^1 so that zero corresponds to the point on $W^s(Q,\eta)$, and the symmetry gives $f_\eta(-u) = -f_\eta(u)$.

Let $a(\eta)$ be the signed distance, as measured in Σ^1 of the negative branch of $W^u(Q,\eta)$ from $W^s(Q,\eta)$. This is equivalent to defining

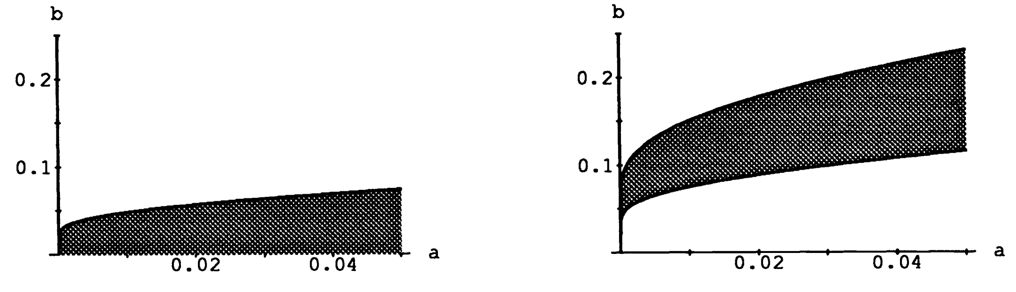
$$a(\eta) = \limsup_{u<0, u\to 0} f_\eta(u).$$

Thus the negative branch of $W^u(Q,\eta)$ intersects the positive side of Σ if $a(\eta) > 0$, and it intersects the negative side if $a(\eta) < 0$. Because of the symmetry, and the distance of the positive branch of $W^u(Q,\eta)$ from $W^s(Q,\eta)$ is -$a(\eta)$. The interval $I_\eta = [-|a(\eta)|, |a(\eta)|]$ corresponds to the interval in Σ^1 between the intersections of the two branches of $W^u(Q,\eta)$ with the transversal after projecting out the strong stable direction. With these definitions, Lemma 1 proves that $f'_{\eta_0}(0) = \nu C_{\eta_0}$. The fact that $C_{\eta_0} < 2$ means there is hope for $f_\eta([0, |a(\eta)|] \subset I_\eta$. See Lemma 2 for details.

Let $b(\eta) = 1 - |\lambda_s(\eta)/\lambda_u(\eta)|$. This quantity measures the extent to which the two eigenvalues are no longer in resonance.

Next, we discuss the relationship between the unfolding parameters $a(\eta)$ and $b(\eta)$ that must be satisfied as the homoclinic connection is broken in order for there to be an attractor. For a small neighborhood $\mathcal{N}$ of η_0 in parameter space, let

$$\mathcal{N}' = \{\eta \in \mathcal{N} : \nu a(\eta) > 0, 0 < f_\eta(a(\eta)) \leq |a(\eta)|, b(\eta) \geq 0, |f'_\eta(\pm a(\eta))| \geq 2^{1/2}\}.$$



(a) (b)

Fig. 1. *Graph of the allowable range of* $b(\eta)$ *versus* $a(\eta)$. (a) *Graph for* $C_{\eta_0} = 1.6$. (*Similar ranges are valid for* $2^{1/2} < C_{\eta_0} < 2$.) (b) *Graph for* $C_{\eta_0} = 1$. (*Similar ranges are valid for* $0 < C_{\eta_0} < 2^{1/2}$. *This is the case we prove occurs for equations* (R′) *and* (Rob).)

Lemma 2 proves that the boundary of $\mathcal{N}'$ is contained in $\partial\mathcal{N}$, γ_1, and γ_2, where the latter two are given by

$$\gamma_1 : \quad \{\eta \in \mathcal{N} : f_\eta(a(\eta)) = \nu a(\eta), b(\eta) > 0\},$$
$$\gamma_2 : \quad \begin{cases} b(\eta) = 0 & \text{if } C_{\eta_0} < 2^{1/2} \\ \{\eta \in \mathcal{N} : b(\eta) > 0, |f'_\eta(\pm a(\eta))| = 2^{1/2}\} & \text{if } C_{\eta_0} > 2^{1/2}. \end{cases}$$

The form of γ_2 when $C_{\eta_0} = 2^{1/2}$ is some combination of the two forms above. See Fig. 1. The condition related to γ_2 implies that for $\eta \in \mathcal{N}'$ $|f'_\eta(u)| > 2^{1/2}$ for all points $u \in \operatorname{interior} I_\eta$. This latter condition is what is used to imply that the attractor is transitive.

In order to insure that $\mathcal{N}' \neq \emptyset$ and $\eta_0 \in \operatorname{closure} \mathcal{N}'$, we need to make the following assumption on the ability to vary the parameters.

(A6) We assume that the parameter space for η is large enough so that $a(\eta)$ and $b(\eta)$ can vary independently for η near η_0.

Finally, we can state the main result.

THEOREM 1. *Assume that vector field in* R^3, *depending on a parameter* η *is* C^2 *and satisfies the above assumptions* (A0)–(A6). *Then, there is a neighborhood* $\mathcal{N}_0 \subset \mathcal{N}$ *in parameter space such that* $\mathcal{N}_0 \cap \mathcal{N}' \neq \emptyset$, $\eta_0 \in$ *closure* $\mathcal{N}'$, *and for* $\eta \in \mathcal{N}_0 \cap \mathcal{N}'$ *the flow for* η *has a topologically transitive attractor. The two pieces* γ_1 *and* γ_2 *of the boundary of* $\mathcal{N}_0 \cap \mathcal{N}'$ *satisfy the following equations*:

$$\gamma_1 : \log(2/C_{\eta_0}) = \limsup\{[(b(\eta)\log(1/|a(\eta)|)] : \eta \to \eta_0, \ \eta \in \gamma_1\},$$
$$\gamma_2 : \begin{cases} \liminf\{[(b(\eta)\log(1/|a(\eta)|)] : \eta \to \eta_0, \ \eta \in \gamma_2\} = \log(2^{1/2}/C_{\eta_0}) & \textit{if } C_{\eta_0} > 2^{1/2} \\ b(\eta) = 0 & \textit{if } C_{\eta_0} < 2^{1/2}. \end{cases}$$

If the value of ν *is* 1 (*respectively,* -1), *then the attractor is orientable* (*respectively, nonorientable*), *and the attractor appears for* $a(\eta)$ *positive* (*respectively, negative*), *i.e., it appears before* (*respectively, after*) *the unstable manifold crosses over the stable manifold. If the vector field is* C^3, *then the resulting one-dimensional Poincaré map* f_η *has an ergodic invariant measure with support equal to the whole interval* I_η *and which is equivalent to Lebesgue on* I_η.

2. Proof of Theorem 1. Throughout this section, we assume that the system satisfies assumptions (A0)–(A3).

The first step is to prove the existence of a $C^{1+\mu}$ for some $0 < \mu < 1$ strong stable foliation in a neighborhood of the homoclinic connection for a perturbation of the flow. (Here $C^{1+\mu}$ means that the first derivative is μ-Hölder.) The details of this argument are carried out in [8] and follow the ideas of the earlier papers [6] and [7]. The sketch of the proof is as follows. The existence of the continuous bundle of planes $\{P_{\eta_0}(q) : q \in \Gamma\}$ can be used to show the existence of a continuous strong stable bundle by using cones that are complementary to the $P_{\eta_0}(q)$. In fact, since a trajectory in a small neighborhood of Γ spends an arbitrarily large proportion of its time in a neighborhood of the fixed point where the eigenvalues give the desired estimates, it is possible to prove the existence of a $C^{1+\mu}$ strong stable bundle, E^{ss}, in a neighborhood of the homoclinic connection. These conditions are open, so for a small perturbation such a strong stable bundle persists in this open set of phase space.

Then by stable manifold theory, there is a $C^{1+\mu}$ foliation whose tangent lines are given by these strong stable bundles. See [6], which uses [3, Thm. 4.8]. A strong stable leaf or manifold at a point ζ_0 of radius r, $W^{ss}_r(\zeta_0, \eta)$ is characterized as being the points ζ within distance r such that the distance between the trajectories for ζ and ζ_0 at time t converges to zero at an exponential rate of almost $\exp(t\lambda_{ss})$.

Once we know that the strong stable manifolds form a $C^{1+\mu}$ foliation, we can form the strong stable manifolds of orbits by taking the union of the strong stable manifolds of points along an orbit:

$$W_r^{ss,\mathrm{orbit}}(\zeta_0, \eta) = \cup\{W_r^{ss}(\zeta, \eta) | \zeta = \varphi_t(\zeta_0, \eta) \text{ for } -r \le t \le r\}.$$

The tangent space to $W_r^{ss,\mathrm{orbit}}(\zeta_0, \eta)$ at ζ_0 is spanned by the strong stable bundle E^{ss} at ζ_0 and the vector field $X_\eta(\zeta_0)$. Thus, these tangent spaces are $C^{1+\mu}$ away from Q. This implies that $\pi_\eta : \Sigma \to \Sigma^1$ is $C^{1+\mu}$.

As a consequence of (A1), the value of $\nu = 1$ (respectively, $\nu = -1$) if the Poincaré map F_η preserves (respectively, reverses) the orientation of the strong stable bundle. Hence, $\nu = 1$ (respectively $\nu = -1$) if f_η preserves (respectively, reverses) the orientation within Σ^1, so f_η is increasing (respectively, decreasing). In terms of the flow, if $\nu = 1$, the "sheets within the attractor" return with either no twist or at least multiples of full twists, so the same side is up. On the other hand, if $\nu = -1$, they return with a half twist plus some multiple of full twists, so the sides are reversed.

We turn now to analyzing the Poincaré map for the flow. We need to find the lowest-order terms for f_η and f'_η in order to show that we have an invariant set and an expansion on it. In the two-dimensional case, if the flow is linearized near a saddle fixed point, then the Poincaré map past the fixed points is given by $g(u) = Cu^E$, where $E = |\lambda_s|/\lambda_u$. In our present situation, we reduce to the two-dimensional case by projecting along the strong stable foliation and use the weaker stable and unstable directions near the fixed point. This quotient space can be thought of as projection onto the invariant surface tangent to $\langle v_u, v_s\rangle$ at Q. The resulting one-dimensional Poincaré map past the fixed point has $\pm Cu^E$ as the lowest-order terms, and the following lemma makes this precise.

LEMMA 1. *Assume* (A0)–(A3) *are satisfied. Let* $E = E_\eta = |\lambda_s(\eta)|/\lambda_u(\eta) = 1 - b(\eta)$. *Let* $J \subset \Sigma^1$ *be a fixed small interval about zero. For* η *in a small neighborhood of* η_0, *the induced one-dimensional Poincaré map* $f_\eta : J \setminus \{0\} \subset \Sigma^1 \to \Sigma^1$ *has continuous derivative on* $J \setminus \{0\}$, *and* f_η *and* f'_η *have the following form:*

$$\begin{aligned} f_\eta(u) &= (-a(\eta) + \nu C_\eta |u|^E)\mathrm{sign}(u) + o(|u|^E), \\ f'_\eta(u) &= \nu E_\eta C_\eta |u|^{E-1} + o(|u|^{E-1}), \end{aligned}$$

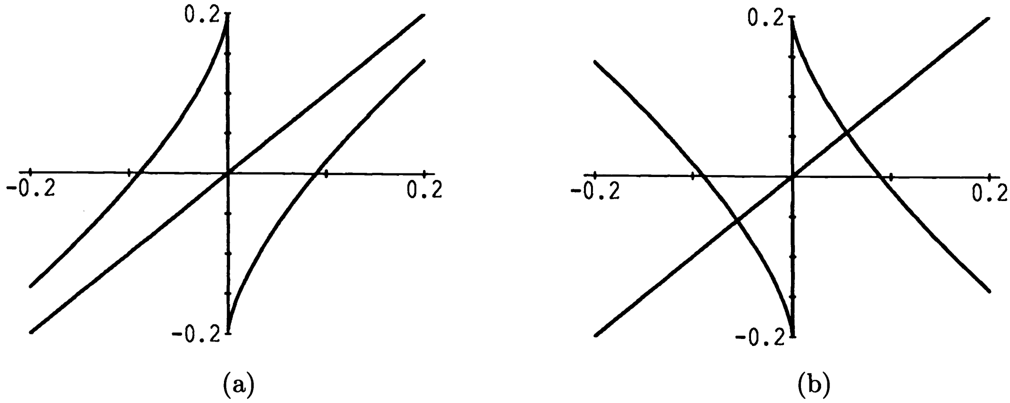


FIG. 2. *Graph of f_η.* (a) $\nu = 1$, $a(\eta) = 0.2$, $E = \frac{2}{3}$, *and* $C = 1$. (b) $\nu = -1$, $a(\eta) = -0.2$, $E = \frac{2}{3}$, *and* $C = 1$.

with $\nu = \pm 1$, depending on whether the strong stable bundle is orientable or not, $C_{\eta_0} \geq 0$ is given by the integral in (A5)*, and C_η depending continuously on η. The remainder terms uniformly go to zero when divided by the terms indicated as u goes to zero uniformly in η. See Fig.* 2*. Note that for η_0, $f_{\eta_0}(u) = \nu C_{\eta_0} u + o(|u|)$, and $f'_\eta(u) = \nu C_{\eta_0} + o(|u|^0)$ so $f'_{\eta_0}(0)$ exists and equals νC_{η_0}. Also, if $E_\eta \leq 1$ (e.g., for $\eta \in \mathcal{N}'$), then the branches of $(f_\eta^{-1})'(u)$ have Hölder extensions at $f_\eta(0\pm)$.*

Remark 1. The proof of this lemma also works in the nonsymmetric case. The delicate part of the argument about the Poincaré–Dulac map past the fixed point is the same. The part of the return map outside the neighborhood depends on the branch of the unstable manifold that is followed. Therefore, the form of the map is

$$f_\eta(u) = \begin{cases} a^+(\eta) + \nu^+ C_\eta^+ |u|^E) + o(|u|^E) & \text{for } u > 0, \\ a^-(\eta) + \nu^- C_\eta^- |u|^E) + o(|u|^E) & \text{for } u < 0, \end{cases}$$

where $a^\pm(\eta)$, $\nu^\pm$, and $C_\eta^\pm$ all depend on whether u is positive or negative.

Remark 2. There are several ways to prove this lemma under a variety of more or less restrictive hypothesis. In [8], an elementary but messy proof was given. The equations are normalized near the fixed point with coordinates u in the unstable direction, v in the strong stable direction, and z in the weaker stable direction. The variable $\rho = uv$, which is introduced, then satisfies the scalar equation

$$\dot\rho = \Lambda_\eta \rho + A_2 \rho^2 + \cdots + A_n \rho^n,$$

where $\Lambda_\eta = \lambda_u(\eta) + \lambda_s(\eta)$. It is then necessary to prove the expansion of the solution $\rho(\tau)$ with initial condition ρ_0 for a time $\tau \approx -\lambda_u^{-1} \log |\rho_0|$, which are uniformly valid for $\Lambda_\eta \geq 0$. (This value of τ is the time it takes to flow past the fixed point to a second transversal.) The method used only obtained estimates on an interval of initial conditions in state space whose length decreases as the parameter $b(\eta) = 1 - E_\eta$ goes to zero. A better proof of this general type was done earlier by Roussarie [9, Thm. F]. He obtained a higher-order expansion and showed that it was valid on an interval of uniform size as the parameter varies, although it involves $x \log(x)$ terms which go to zero slowly in the position variable x. We make further comments below about how to use his theorem to obtain our result. Finally, it is possible to prove the lemma by $C^{1+\alpha}$ linearizing within an invariant two-dimensional surface near the fixed point. Hartman showed that this was possible in two dimensions even with resonance. This proof is also valid on an interval of fixed size and is more in keeping with other arguments used in the proof of the main theorem. We give details of this proof below. We should mention that both C. Chicone and C. Pugh suggested using this approach.

Proof using Hartman's linearization. We want to prove that the one-dimensional Poincaré map is C^1. The two-dimensional Poincaré map F_η can be split into the part G_η past Q from Σ to a second transversal S, and the part H_η from S back to Σ. Since there is a bounded amount of time for the trajectory to pass from S back to Σ, H_η is C^2. All that remains to check is the form of G_η past Q. Hartman's linearization proof works by constructing two invariant C^1 foliations in the stable and unstable directions. The difficulty is that the unstable foliation can only be shown to be C^0 in the directions transverse to the leaves if we consider the flow in three dimensions. To avoid this difficulty, we show there is an invariant two-dimensional manifold $W^{us}(Q,\eta)$ in the weak stable and unstable directions, and we show that the foliations are $C^{1+\beta}$ when restricted to this two-dimensional manifold. The proof of this differentiability is very similar to the one we used above to get the existence of the strong stable foliation. The difference is that everything must be restricted to $W^{us}(Q,\eta)$ in order for the estimates to be true. The estimates for one-dimensional Poincaré map g_η is then determined using the linearization of the flow on $W^{us}(Q,\eta)$ using these two foliations. Then $f_\eta(u) = \pi_\eta H_\eta \circ G_\eta(u)$.

The limit of $f_\eta(u)$ as u approaches zero from below (zero is the point that corresponds to the stable manifold) is $a(\eta)$ because $\pi_\eta H_\eta$ takes the negative branch of the unstable manifold to $a(\eta)$.

By (A3), $\lambda_{ss}(\eta)-(2+\alpha)\lambda_s(\eta) < 0$ for small $\alpha > 0$ and η near η_0. By the invariant manifold theorem of [4], there is a $C^{2+\alpha}$ manifold $W^{us}(Q,\eta)$ tangent to the v_u and v_s directions at Q. Its tangent space E^{us} is $C^{1+\alpha}$. Thus the derivative of the time one map of the flow $D\varphi^1$ is $C^{1+\alpha}$ when restricted to $E^{us}|W^{us}(Q,\eta)$.

Turning to the invariant subbundles, if β is chosen with $0 < \beta \le \alpha$ and $\lambda_s(\eta_0) + \beta\lambda_u(\eta_0) < 0$, then there is a $C^{1+\beta}$ invariant subbundle $E^s \subset E^{us}|W^{us}(Q,\eta)$ for η near η_0. The reason this is true is that $D\varphi^{-1}$ contracts toward E^s within E^{us} by a factor of almost $\exp(\lambda_s(\eta_0) - \lambda_u(\eta_0))$. The Lipschitz constant of φ^1 is about $\exp(\lambda_u(\eta_0))$. To prove the bundle is $C^{1+\beta}$, the results of [4] say we need the product of the first of these two numbers times the $(1+\beta)$ power of the second has to be less than one, so $0 > \lambda_s(\eta_0) - \lambda_u(\eta_0) + (1+\beta)\lambda_u(\eta_0)$. Thus in a neighborhood of Q we will have the correct domination of the contraction rate.

Next, by taking $\beta > 0$ smaller so that $-\lambda_u(\eta_0) - \beta\lambda_s(\eta_0) < 0$, there is a $C^{1+\beta}$ invariant subbundle E^u of $E^{us}|W^{us}(Q,\eta)$ for η near η_0. This follows because the contraction rate toward this bundle by $D\varphi^1$ is about $\exp(-\lambda_u(\eta_0) + \lambda_s(\eta_0))$. The Lipschitz constant of φ^{-1} on $W^{us}(Q,\eta)$ is about $\exp(-\lambda_s(\eta_0))$. Again, the above estimate gives us that the product of the first of these number times $1+\beta$ times the second is less than one. This gives the stated differentiability of the bundle.

Since each of these bundles is $C^{1+\beta}$, there are two $C^{1+\beta}$ foliations tangent to them. These give coordinates on $W^{us}(Q,\eta)$ in terms of coordinates on $W^u(Q,\eta)$ and $W^s(Q,\eta)$. Since these coordinates can $C^{1+\beta}$ linearize the flow the Poincaré–Dulac map past Q in these coordinates is the same as that for the linear flow, $g_\eta(u) = Cu^E$ where $E = E(\eta) = |\lambda_s(\eta)|/\lambda_u(\eta)$. The map in the original coordinates can then be written as $k_\eta \circ g_\eta \circ h_\eta$, where k_η and h_η are the $C^{1+\beta}$ change of coordinates which vary continuously with respect to η. This shows that the remainders go to zero as u goes to zero, uniformly in η.

The connection of C_η with the integral in (A5) is discussed in [8] and uses the formula for the derivative of the Poincaré map in terms of the integral of the divergence given in [2, §28].

The comment about the branches of $(f_\eta^{-1})'(\zeta)$ follows by looking at the flow for negative time past Q. The above proof shows that the derivative of the inverse on either branch has the form

$$(f_\eta^{-1})'(\zeta) = \nu E_\eta C_\eta |\zeta - a(\eta)|^{(1/E)-1} + o(|\zeta - a(\eta)|^{(1/E)-1}),$$

which has a Hölder extension at $\zeta = a(\eta)$. □

Proof using Roussarie's expansion. To use Roussarie's result, we again need to put the equation in normal form, so we need to assume the vector field is C^∞ (or we need to keep track of some higher differentiability, which is determined by the eigenvalues). As is done in [8] and [9], by a "Sternberg differentiable linearization," there is a C^∞ change of coordinates that put the differential equations into the normal form

$$\begin{aligned} \dot v &= \lambda_{ss} v, \\ \dot u &= \lambda_u u, \\ \dot z &= z[\lambda_s + \lambda_u \alpha_2 \rho + \lambda_u \alpha_3 \rho^2 + \cdots], \end{aligned}$$

where $\rho = uz$. The proof of the differentiable linearization is valid uniformly in the parameter by using the form given by Takens in [13], as was mentioned to us by Roussarie. This also shows that the theorem is just as valid in conjugating to a normal form as given above as it is to conjugating to a linear system. All that is necessary is for the two systems to have the same C^∞ jet at the fixed point.

As in the first proof, the only part of the Poincaré map that needs to be checked is the one-dimensional map past Q. Using the normal form, this is calculated using the u and z equations. Reference [9, Thm. F] proves the form of this map to any finite order that is uniformly valid for a range of parameters near resonance. He considers the two variables u and ρ and looks at the two equations

$$\begin{aligned} \dot u &= \lambda_u u, \\ \dot \rho &= \lambda_u [b(\eta)\rho + \alpha_2 \rho^2 + \cdots], \end{aligned}$$

where $b(\eta) = [\lambda_s(\eta) + \lambda_u(\eta)]/\lambda_u(\eta)$ is as before. (He rescales time by $\lambda_u(\eta)$, which is the reason that we have factored out this term.) Next, he defines

$$\omega(b,u) = \begin{cases} \frac{u^{-b}-1}{b} & \text{for } b = b(\eta) \neq 0, \\ -\log(u) & \text{for } b(\eta) = 0. \end{cases}$$

Then he proves that the following expansion is uniformly valid in η with C^2 remainder:

$$g_\eta(u) = Cu^{1-b} + \alpha_2 u^{2-b}\omega(b,u) + \psi_\eta(u),$$

where $\psi_\eta(u)$ is C^2 and C^2 flat at $u = 0$. Remember that $E_\eta = 1 - b(\eta)$. Since $u\omega(b,u) - u\omega(0,u)$ goes to zero uniformly on a fixed interval and $u\omega(0,u) = o(u^0)$, we get the form given in the theorem. A direct calculation shows that

$$g'_\eta(u) = CEu^{E-1} + \alpha_2(1+E)u^{E-1}(u\omega) - \alpha_2 u^{E-1}u^E + \psi'_\eta(u);$$

so $f'_\eta(u)$ has the form that is given in the lemma. The other part of the proof is as is done above in the Hartman's linearization proof. □

The following lemma proves the form of the boundary of $\mathcal{N}'$.

LEMMA 2. *Assume that the systems satisfies* (A0)–(A3).

(a) *In a small neighborhood* $\mathcal{N}_0$ *of* η_0, *for the system for* $\eta \in \mathcal{N}_0$ *to have a transitive attractor with* $|f'_\eta(u)| > 2^{1/2}$ *for all* $u \in \text{interior}\, I_\eta$, *it is necessary for* $\eta \in \mathcal{N}'$. *If we assume* $\eta_0 \in \text{closure}\, \mathcal{N}'$ *so there are transitive attractors arbitrarily near* η_0, *then* (A4) *is true; so* $b(\eta_0) = 0$ *or* $E_{\eta_0} = 1$, *and* (A5) *is true in the modified sense that* $C_{\eta_0} \leq 2$.

(b) *Assume the system satisfies* (A0)–(A6). *Then, the two pieces of the boundary of the set* $\mathcal{N}'$ *are defined by*

$$\begin{aligned}
\gamma_1 :&\quad \{\eta \in \mathcal{N} : f_\eta(a(\eta)) = \nu a(\eta), b(\eta) > 0\},\\
\gamma_2 :&\quad \begin{cases} b(\eta) = 0 & \text{if } C_{\eta_0} < 2^{1/2}\\ \{\eta \in \mathcal{N} : b(\eta), |f'_\eta(\pm a(\eta))| = 2^{1/2}\} & \text{if } C_{\eta_0} > 2^{1/2}.\end{cases}
\end{aligned}$$

Further, they satisfy the following two equations:

$$\begin{aligned}
&\gamma_1 : \log(2/C_{\eta_0}) = \limsup\{[(b(\eta)\log(1/|a(\eta)|)] : \eta \to \eta_0,\ \eta \in \gamma_1\},\\
&\gamma_2 : \begin{cases} \liminf\{[(b(\eta)\log(1/|a(\eta)|)] : \eta \to \eta_0,\ \eta \in \gamma_2\} = \log(2^{1/2}/C_{\eta_0}) & \text{if } C_{\eta_0} > 2^{1/2},\\ b(\eta) = 0 & \text{if } C_{\eta_0} < 2^{1/2}.\end{cases}
\end{aligned}$$

Proof. To obtain an attracting set for the flow that contains the fixed point at the origin, f_η must preserve the interval $I_\eta = [-|a(\eta|, |a(\eta)|] \subset V^1$. For $f_\eta(u) \in I_\eta$ for small u, the form of f_η given in Lemma 1 shows that it is necessary for $\nu a(\eta) > 0$. The invariance of the interval also implies that $f_\eta(\pm a(\eta)) \in I_\eta$; so $f_\eta(a(\eta)) \leq |a(\eta)|$, i.e., that the second intersection of the unstable manifolds must lie between the first intersection of the two branches after projecting out along the strong stable foliation. (The reader can check the well-known result that if $f_\eta(I_\eta) \setminus I_\eta \neq \emptyset$, then there is horseshoe for F_η which is not an attracting set.) Also, for Q to be part of the attracting set, we need zero to be an element of the image, $f_\eta(I_\eta)$, so $0 \leq f_\eta(a(\eta))$. Also, the fact that f_η is transitive on I_η implies that $0 < f_\eta(a(\eta))$.

The condition that the absolute value of the derivative at all points of interior I_η is greater than $2^{1/2}$ certainly implies that it is greater or equal to $2^{1/2}$ at $\pm a(\eta)$. Finally, if $b(\eta) = 1 - E_\eta < 0$, then $|f'_\eta(u)| < 1$ for small u. Thus it is necessary for $b(\eta) \geq 0$. This completes the proof that it is necessary for $\eta \in \mathcal{N}'$.

If $\eta_0 \in \text{closure}\, \mathcal{N}'$, the fact that $b(\eta) \geq 0$ for $\eta \in \mathcal{N}'$ implies that $b(\eta_0) \geq 0$. To get the opposite inequality we consider the $\eta \in \mathcal{N}'$ that approach η_0 and write a for $a(\eta)$. (The reader may find it easier to just consider the case $\nu = 1$.) For these η, $\nu a > 0$; so $\nu f_\eta(\nu a) \leq \nu a$, $\nu f_\eta(\nu a) + \nu a \leq 2\nu a$, $|f_\eta(\nu a) + a| \leq 2|a|$, and

$$\frac{|f_\eta(\nu a) + a|}{|aC_\eta|} \leq \frac{2}{C_\eta}.$$

Because of the form of the lowest-order terms of f_η given in Lemma 1, taking limits as η goes to η_0,

$$\begin{aligned}
\limsup\left\{b(\eta)\log\left(\frac{1}{|a(\eta)|}\right)\right\} &= \limsup\left\{\log\left(\frac{|f_\eta(\nu a(\eta)) + a(\eta)|}{|a(\eta)C_\eta|}\right)\right\}\\
&\leq \limsup\left\{\log\left(\frac{2}{C_\eta}\right)\right\}\\
&= \log\left(\frac{2}{C_{\eta_0}}\right).
\end{aligned}$$

Since $\log(2/C_{\eta_0})$ is a constant and $\log(1/|a(\eta)|)$ goes to infinity, we also get that $b(\eta_0) \leq 0$. Combining with the inequality that $b(\eta_0) \geq 0$, we get that $b(\eta_0) = 0$. Also since $b(\eta) \geq 0$ for $\eta \in \mathcal{N}'$ and $\log(1/|a(\eta)|)$ goes to infinity, we get that $C_{\eta_0} \leq 2$. This completes the proof of part (a).

On one boundary of $\mathcal{N}'$ $f_\eta(a(\eta)) = \nu a(\eta)$ as stated for γ_1, and putting equality in the above limit as $\eta \to \eta_0$ shows that these values satisfy

$$\gamma_1: \quad \log\left(\frac{2}{C_{\eta_0}}\right) = \limsup\left\{(b(\eta)\log\left(\frac{1}{|a(\eta)|}\right) : \eta \to \eta_0, \ \eta \in \gamma_1\right\}$$

as stated.

From the form of $f'_\eta(u)$ given in Lemma 1, it follows that the smallest value of $|f'_\eta(u)|$ occurs for $u = \pm a(\eta)$. If $C_{\eta_0} > 2^{1/2}$, then the calculation below shows that the η with $|f'_\eta(a(\eta))| = 2^{1/2}$ occurs for $b(\eta) > 0$; so it forms the other boundary.

Along the η with $|f'_\eta(a(\eta))| = 2^{1/2}$, the form of the derivative given in Lemma 1 gives the following:

$$\begin{aligned}\liminf\left\{b(\eta)\log\left(\frac{1}{|a(\eta)|)}\right)\right\} &= \liminf\left\{\log E_\eta + b(\eta)\log\left(\frac{1}{|a(\eta)|}\right)\right\} \\ &= \liminf\left\{\log\left(\frac{|f'_\eta(a(\eta))|}{C_\eta}\right)\right\} \\ &= \liminf\left\{\log\left(\frac{2^{1/2}}{C_\eta}\right)\right\} \\ &= \log\left(\frac{2^{1/2}}{C_{\eta_0}}\right).\end{aligned}$$

This gives the form of γ_2 for $C_{\eta_0} > 2^{1/2}$. If $C_{\eta_0} < 2^{1/2}$, then the calculation above shows that $|f'_\eta(a(\eta))| > 2^{1/2}$; so the other boundary is given by $b(\eta) = 0$. This completes the proof of Lemma 2. □

Using Lemma 2, for $\eta \in \mathcal{N}'$, $|f_\eta(u)| > 2^{1/2}$ for $u \in$ interior I_η. This means that f_η satisfies the condition of R. Williams, which implies that f_n is locally eventually onto and so topologically transitive. See [14] and [7]. If the flow is C^3, the fact that $f_\eta^{-1}(u)$ has a Hölder extension at $f_\eta(0\pm)$ means that the the theorem of G. Keller applies, and we get the existence of an invariant measure for the interval map. See [7], which uses the results of [5].

This completes the proof of Theorem 1. □

3. Verification of assumptions for specific equations. The Lorenz equations are given by the equations

$$\text{(L)} \qquad \begin{aligned}\dot{x} &= -\sigma x + \sigma y, \\ \dot{y} &= \rho x - y - xz, \\ \dot{z} &= -\beta z + xy.\end{aligned}$$

They arise from modeling turbulence, and their numerical simulation exhibits chaotic behavior.

Later, Rychlik showed that a slight variation of the Lorenz equation could be proved to possess a transitive attractor immediately after a bifurcation from a double homoclinic connection. The equations that he considers are motivated by noting that by a change of variables the Lorenz equations, (L), can be put in the following form:

$$\text{(R)}\qquad \begin{aligned} \dot{x} &= y, \\ \dot{y} &= x - 2x^3 + \alpha y + \beta x^2 y + \delta x z, \\ \dot{z} &= -\gamma z + x^2, \end{aligned}$$

with $\beta = 0$, [10]. He then adds the $\beta x^2 y$ term, to be able to control the unstable manifold of the origin while keeping $\delta = 0$. He determines the form of the resulting two-dimensional Poincaré map, and proves that it has a $C^{1+\mu}$ strong stable foliation immediately after a homoclinic bifurcation, but not at the bifurcation value. This proof extends the type of proof in [6], where one of the approaches show how to verify that the Poincaré map had a C^1 foliation. We also remark that Rychlik considers a different bifurcation problem than the one considered in this paper and in [8]. In particular, instead of (A2), he assumes that $W^{us}(Q,\eta_0)$ and $W^s(Q,\eta_0)$ are tangent along Γ. (This is his second codimension.) With this assumption, he is able to take $\lambda_u(\eta_0) + \lambda_s(\eta_0) > 0$. Shilnikov has also considered a bifurcation from a double homoclinic connection, which is more like that of Rychlik with $\lambda_u(\eta_0) + \lambda_s(\eta_0) > 0$. He and his coauthors show there is an attractor of Lorenz type in a neighborhood. See [1] and [11].

In our previous paper we verified the assumptions for the set of equations

$$\text{(Rob)}\qquad \begin{aligned} \dot{x} &= y, \\ \dot{y} &= x - 2x^3 + \alpha y + \beta x^2 y - \nu y z, \\ \dot{z} &= -\gamma z + \delta x^2, \end{aligned}$$

with $\nu = \pm 1$. These equations can be obtained from (R) by scaling z to shift the coefficient δ from the xz term in the $\dot{y}$ equation to the x^2 term in the $\dot{z}$ equation. (This change is made because we treat a different type of perturbation problem than Rychlik.) We also change the xz term in the $\dot{y}$ equation to a yz term. Although this makes the equations farther from the Lorenz equations, they are easier to analyze.

In this paper, we return to the equations (R) but scale the equations to shift the coefficient δ to the $\dot{z}$-equation; the αy term is replaced by $-\alpha y$ so we can take $\alpha > 0$, and we allow $-\nu x z$ in the $\dot{y}$ equation with $\nu = \pm 1$:

$$\text{(R}'\text{)}\qquad \begin{aligned} \dot{x} &= y, \\ \dot{y} &= x - 2x^3 - \alpha y + \beta x^2 y - \nu x z, \\ \dot{z} &= -\gamma z + \delta x^2. \end{aligned}$$

We can now state the theorem.

THEOREM 2. *Equations* (R$'$) *satisfy assumptions* (A0)–(A6) *for correctly chosen values of the parameters* (*in particular, for some* $\alpha_0 > 2^{-\frac{1}{2}}$).

Remark 1. It is not clear that the choice of ν in the equations corresponds to the choice in assumption (A2); that is, it determines whether the one-dimensional Poincaré–Dulac map is monotonically increasing or decreasing (or the tangent space of $W^{us}(Q,\eta_0)$ is orientable or nonorientable along Γ). The difficulty is that the proof only proves transversality by an argument that uses the fact that an analytic function that is not identically zero must be nonzero in any interval.

Remark 2. It seems unlikely that any of these results, here [8] or [10], can be applied directly to the actual Lorenz equations (L). The difficulty is finding parameter values that verify both the homoclinic connection condition (A1) and the resonance condition (A4) for the same parameter values. The addition of the extra parameter β is what gives equations (R), (R$'$), or (Rob) the flexibility needed to satisfy these simultaneously.

Proof of Theorem 2. The parameters are $\eta = (\alpha, \beta, \gamma, \delta, \nu)$. The fixed point Q is always the origin. The linearization of the vector field is given by

$$DX(x,y,z) = \begin{pmatrix} 0 & 1 & 0 \\ 1 - 6x^2 + 2\beta xy - \nu z & -\alpha + \beta x^2 & -\nu x \\ 2\delta x & 0 & -\gamma \end{pmatrix}.$$

At the origin, the eigenvalues are $\lambda_{ss} = -\alpha/2 - (1 + \alpha^2/4)^{1/2}$, $\lambda_u = -\alpha/2 + (1 + \alpha^2/4)^{1/2}$, and $\lambda_s = -\gamma$. By picking the parameter $\gamma_0 = \lambda_u = -\alpha_0/2 + (1 + \alpha_0^2/4)^{1/2}$ at the bifurcation, we can insure that $\lambda_s(\eta_0) + \lambda_u(\eta_0) = 0$, giving assumption (A4).

To obtain (A3), we need the combination of all three eigenvalues less than zero: $\lambda_{ss}(\eta_0) - \lambda_s(\eta_0) + \lambda_u(\eta_0) < 0$,

$$\begin{aligned} 0 &> [-\alpha_0/2 - (1 + \alpha_0^2/4)^{1/2}] + 2[-\alpha_0/2 + (1 + \alpha_0^2/4)^{1/2}] \\ &> -3\alpha_0/2 + (1 + \alpha_0^2/4)^{1/2}, \end{aligned}$$

or

$$\alpha_0 > 2^{-1/2}.$$

Thus to obtain a C^1 foliation, it is not possible to take a small perturbation of the integrable case where $\alpha = \beta = \delta = 0$. Given the resonance condition (A4), the second inequality in (A3) follows from the first.

LEMMA 3. *For either $\nu = \pm 1$, there are parameter values $(\alpha_0^\pm, \beta_0^\pm, \gamma_0^\pm, \delta_0^\pm, \nu)$, with $\alpha_0^\pm > 1/(2^{1/2}), \beta_0^\pm > 0$, $\gamma_0^\pm = -(\alpha_0^\pm/2) + [1 + ((\alpha_0^\pm)^2/4)]^{1/2}$, and $\delta_0^\pm > 0$, but near zero, for which the equations have a homoclinic connection and an invariant continuous plane field, satisfying* (A1)–(A5).

Proof. The only difference in verifying this lemma for the equations (R$'$) and (Rob) is in the verification of (A2). We repeat the other steps because they are easy, and we give a different approach to verifying (A2).

First, taking $\alpha = \beta = \delta = 0$, we obtain a Hamiltonian system in the (x,y)-plane with energy $H = (y^2 - x^2 + x^4)/2$; therefore, the origin has a double homoclinic connection.

Now, we increase the value of α to $\alpha_0 > 1/(2)^{1/2}$, keeping $\beta = \delta = 0$, and choosing $\gamma_0 = -\alpha_0/2 + (1 + \alpha_0^2/4)^{1/2}$. The xy-plane is still invariant; so $z = 0$ along the unstable manifold. The $-\alpha y$ term in the $\dot{y}$ equation is a friction term; so the unstable manifold $W^u(Q,\eta)$ stays on the same side of $W^s(Q,\eta)$ and spirals into one of the stable fixed points. Next, increase the value of β. The term $\beta x^2 y$ in the $\dot{y}$ equation is an anti-friction term for $\beta > 0$. For large enough β, $W^u(Q,\eta)$ will cross over to the other side of $W^s(Q,\eta)$; therefore, there is a value of β' that will yield a homoclinic connection. By the symmetry of the equations, it is a double homoclinic connection.

Finally, we perturb δ to $\delta_0 > 0$, but keep the homoclinic connection. The derivative of z is given by $\dot{z} = -\gamma z + \delta x^2$; so z is positive but small along $W^u(Q,\eta)$. Thus the $-\nu xz$ term in $\dot{y}$ is a slight inward or outward push (depending on the point) along $W^u(Q,\eta)$. By adjusting the value of β' to β_0 (or adjusting α_0), we can preserve the homoclinic connection, giving (A1). The choice of α_0 and γ_0 gives (A3) and (A4).

We are left to verify (A2) and (A5). We can prove this directly for $\alpha, \beta \approx 0$. Then we use the analyticity of the manifolds to say that they cannot be identically tangent for all $\alpha_0 > 2^{-1/2}$. Thus there must be values that satisfy this inequality for which the manifold are transverse.

Before verifying (A2) for small α and β, we note more carefully the analyticity of $W^s(Q,\eta)$ and $W^{us}(Q,\eta)$. The fact that $W^s(Q,\eta)$ is analytic and varies analytically with parameters is completely standard. The proof for $W^{us}(Q,\eta)$ is not as standard. To prove that this manifold exists locally it is necessary to make an extension that is equal to the linear map outside a neighborhood of Q (or another such construction). It is not clear how to do this construction analytically. However, the tangent space of $W^{us}(Q,\eta)$ at points of $W^u(Q,\eta)$ is determined without any such extension and so depends analytically on η. By looking at $W^s(Q,\eta)$ and $W^{us}(Q,\eta)$ where they both cross $y = 0$, the angle between these two manifolds is an analytic function of η. If this is nonzero for small α, it cannot be identically equal to zero for $\alpha > 2^{-1/2}$; therefore, we can choose an $\alpha_0 > 2^{-1/2}$ for which these manifolds are transverse.

To verify the transversality given in (A2) for α and β near zero, we let $p(t)$ be the covectors that are perpendicular to $T_qW^{us}(Q)$ at points q on Γ. We write covectors as rows and vectors as columns, so that the pairing between them is just matrix multiplication. Covectors satisfy the adjoint equation to the first variation equation that is satisfied by vectors. Remember that the first variation equation for vectors is given by

$$\dot{v} = DX(q(t))v,$$

where $DX(q(t))$ is given as above, and that it is satisfied by $v(t) = X(q(t))$. The adjoint equation for covectors is obtained by differentiating the equation $C = pv$ with respect to t and obtaining $0 = \dot{p}v + pDX(q(t))v$ for all vectors v, so

$$\dot{p} = -pDX(q(t)).$$

(Note, this is the equation with p written as a row. If p^{tr} is the corresponding column vector, then we get $\dot{p}^{tr} = -[DX(q(t))]^{tr}p^{tr}$.)

We first consider $\delta = 0$, and α and β both positive but near zero and chosen so there is a homoclinic orbit. We take the parameterization of $q(t)$ with $y(0) = 0$. The equations for $\dot{p}_1$ and $\dot{p}_2$ are independent of p_3 and so can be solved independently for a solution $(\overline{p}_1(t), \overline{p}_2(t))$, that is, perpendicular in the (x,y)-plane to the homoclinic orbit. There is then a solution $\overline{p}_3(t)$ and $\overline{p}(t) = (\overline{p}_1(t), \overline{p}_2(t), \overline{p}_3(t))$, so that $(q(t), \overline{p}(t))$ lies on the unstable manifold of $(Q, 0)$ in the space of positions and covectors.

We need to determine properties of $\overline{p}_3(t)$ and $\overline{p}(t)$ as $t \to \infty$. Since $\dot{p}_3 = \nu x(t)\overline{p}_2(t) + \gamma p_3$,

$$\overline{p}_3(t) = e^{\gamma(t-t_0)}\overline{p}_3(t_0) + \nu e^{\gamma t}\int_{t_0}^{t} x(s)\overline{p}_2(s)e^{-\gamma s}\,ds.$$

As $t_0 \to -\infty$, $e^{\gamma(t-t_0)}\overline{p}_3(t_0) \to 0$ because $\overline{p}_3(t_0) \to 0$ at least at a rate of $e^{-|\lambda_{ss}||t_0|}$ (because $|\lambda_{ss}|$ is the most unstable eigenvalue for covectors) and $\gamma - |\lambda_{ss}| < 0$. Thus,

$$\overline{p}_3(t) = \nu e^{\gamma t}\int_{-\infty}^{t} x(s)\overline{p}_2(s)e^{-\gamma s}\,ds.$$

We want to show that $\overline{p}_3(t) \to \nu\infty$, as $t \to \infty$. It is easy to see that the integral converges as $t \to \infty$. For $\alpha, \beta = 0$, $x(-s) = -x(s)$, and $p_2(-s) = -p_2(s)$, so we get

$$\int_0^{\infty} x(s)\overline{p}_2(s)[e^{-\gamma s} - e^{\gamma s}]\,ds,$$

which is positive since $x(s)$ is positive and $p_2(s)$ is negative for positive s. Since this integral is positive for $\alpha, \beta = 0$, it is positive for $\alpha, \beta \approx 0$. Since it is multiplied by $\nu e^{\gamma t}$, $\bar{p}_3(t) \to \nu\infty$ as $t \to \infty$. On the other hand, $(\bar{p}_1(t), \bar{p}_2(t)) \to 0$ (as seen by the eigenvalues at $(Q,0)$). This implies that the tangent plane to $W^{us}(Q,\eta)$ limits on the (x,y)-plane and is transverse to $W^s(Q,\eta)$ for these values of η with $\delta = 0$. Transversality is an open condition and so is true for nearby small $\alpha, \beta, \delta > 0$ (for which there is a homoclinic connection), which proves (A2) for these parameter values. By analyticity, as mentioned above, we get (A2) true for some $\alpha_0 > 2^{-1/2}$.

As argued in [8], the rates of change of area near $t = \pm\infty$ show that the integral in (A5) is $-\infty$ for $\delta = 0$. Thus for small $\delta > 0$, $\log(C_{\eta_0}) << 0$; so $C_{\eta_0} << 1$. This completes the proof of Lemma 3. □

The fact that $a(\eta)$ and $b(\eta)$ can be varied independently follows because increasing β (or decreasing α) makes the manifold $W^u(Q,\eta)$ cross over $W^s(Q,\eta)$; so $a(\eta)$ varies, and varying γ makes $b(\eta)$ vary. This completes the proof of Theorem 2. □

SINGULAR PERTURBATIONS OF HOMOCLINIC ORBITS IN $\mathbb{R}^4$*

WIKTOR ECKHAUS†

Abstract. A rigorous asymptotic method is developed for the study of a class of singularly perturbed ODE's which in the limit $\varepsilon \downarrow 0$ have a homoclinic orbit. It is shown that the homoclinic orbit does not survive the perturbation and suffers an "exponentially small splitting."

Key words. singular perturbations, splitting of homoclinic orbits

AMS(MOS) subject classifications. 31A45, 31E20, 76D30

1. Introduction. In this paper we develop an asymptotic method of analysis for the "model problem" arising in the theory of water-waves in the presence of surface tension [2], given by the equation

$$\varepsilon^2 \frac{d^4 y}{dx^4} + \frac{d^2 y}{dx^2} - y + y^2 = 0, \tag{1.1}$$

and for the generalizations

$$\varepsilon^2 \frac{d^4 y}{dx^4} + \frac{d^2 y}{dx^2} - y + y^2 = \varepsilon^2 \mathcal{P}\left(y, \frac{dy}{dx}, \frac{d^2 y}{dx^2}; \varepsilon\right). \tag{1.2}$$

Here ε is a small parameter. The perturbation terms $\mathcal{P}$ will be specified in § 6.

In the limit for $\varepsilon = 0$, we find an integral

$$\left(\frac{dy}{dx}\right)^2 = y^2 - \frac{2}{3} y^3 + c, \tag{1.3}$$

and for $c = 0$ we find homoclinic orbit sketched in Fig. 1.

The solution $y(x)$ of the limit problem that corresponds to the homoclinic orbit tends to zero for $x \to \pm\infty$. In the context of water waves it is a solitary wave. In [2] this question was asked: *do there exist nontrivial solutions of the singularly perturbed model problem* (1.1) *which tend to zero for* $x \to \pm\infty$?

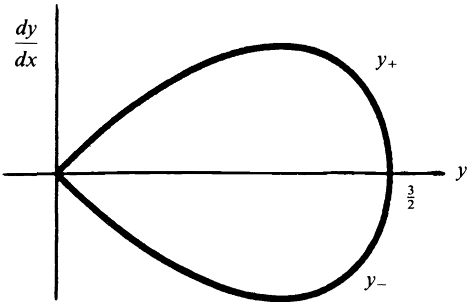

FIG. 1

* Received by the editors May 22, 1991; accepted for publication (in revised form) January 6, 1992.

† Mathematical Institute, Rijksuniversiteit Utrecht, Budapestlaan 6, Postbus 80.010, 3508 TA Utrecht, the Netherlands.

Let us briefly look at the influence of the perturbation term in (1.1) on small solution by considering the linearized equation. We then find

$$y(x) \approx e^{\omega x}, \tag{1.4}$$

$$\omega_{1.2} = \mp 1 + o(\varepsilon), \qquad \omega_{2.3} = \mp \frac{i}{\varepsilon} + o(1). \tag{1.5}$$

The perturbation thus introduces fast oscillations. The existence question can hence be rephrased as follows: *does the homoclinic orbit survive the tendency to rapid oscillations?*

In this perspective, the problem appears to be linked to the phenomenon of "exponentially small splitting of separatrices" [5], [8], which has recently drawn attention. In these publications the break-up of homoclinic orbits under influence of rapid external oscillations is studied. The mathematical analysis is highly nontrivial. This is because the quantity that we attempt to determine, the "splitting distance," is exponentially small. It is quite impressive to learn from the introduction to [5] that Poincaré already knew the phenomenon.

The nonexistence of solitary waves for the model equation (1.1) has recently been proven by Amick and McLeod [1] and by Hammersley and Mazzarino [4]. This has been done as follows.

Consider a half-orbit $y_-(x)$ that tends to zero for $x \to +\infty$, and let $x = 0$ be chosen such that $y'_-(0) = 0$. We can show that for a smooth continuation of $y_-(x)$ into a solitary wave that tends to zero for $x \to -\infty$ we need $y'''_-(0) = 0$. In [1] it has been shown that $y'''_-(0) \neq 0$. This is achieved by a rather subtle excursion into the complex plane, and no order of magnitude has been given. In [4] an ingenious combination of analysis and numerical computation is used. The results show that $y'''_-(0) \neq 0$ and indeed is exponentially small. In fact, the behaviour with ε which we shall find in § 4 if in precise agreement with the results of [4].

The original question for the model equation (1.1) has thus been settled. However, new questions arise. We list a few.

(i) For an analyst it is a challenge to establish the main result for (1.1), including the exponentially small order of magnitude estimate, without recourse to numerical computations.

(ii) What is the behaviour of the smooth continuation of $y_-(x)$ for $x < 0$?

(iii) How are we to deal with more general problems (1.2)?

In this paper we develop a method of analysis by which these questions can be answered. The organization of the paper is as follows.

In the main body of the paper we study the model equation (1.1). The problem is transformed into a second-order differential equation for the function $z(y)$, defined through

$$z(y) := \left(\frac{dy}{dx}\right)^2. \tag{1.6}$$

In § 3 formal asymptotic expansions of $z(y)$ for ε small are constructed and analysed. The proof of validity of these expansions is delayed to § 5. In § 4 we collect and discuss the main results, including the analysis of the "exponentially small splitting."

Section 5 is the mathematical backbone of the paper. We prove the validity of the formal asymptotic expansions by a contraction-mapping argument. This is a nontrivial exercise. We have made an effort to explain and motivate the various steps and tricks of the analysis in some detail. The reason is that the analysis of § 5 is not only a proof of results of § 4, but outlines a method to deal with other problems.

In § 6 we show that the analysis can be extended to large classes of perturbed model problems (1.2). On the other hand, in the companion-paper [3] we use the method of § 5 to answer question (ii), formulated above. We show there that there exist solutions $y(x)$ of (1.1) that can be called "quasi-solitary" waves. They look like solitary waves over very large distances $(-\infty, X(\varepsilon))$, or $(-X(\varepsilon), \infty)$, or $(-X(\varepsilon), X(\varepsilon))$ with $X(\varepsilon)\to\infty$ as $\varepsilon \downarrow 0$ and $y(X(\varepsilon)) = o(\varepsilon^m)$, m arbitrary positive. These solutions are approximated (with an exponentially small error) by solitary waves that have an exponentially small jump in the third derivative at $x=0$.

2. An integral and an equation for the trajectories. The perturbed problem (1.1) also has an integral. We can find it by brute force, multiplying by dy/dx and performing the integration. The perturbation term can be computed integrating by parts three times. The result is

$$\varepsilon^2\left\{\frac{dy}{dx}\frac{d^3y}{dx^3}-\frac{1}{2}\left(\frac{d^2y}{dx^2}\right)^2\right\}=-\frac{1}{2}\left(\frac{dy}{dx}\right)^2+\frac{1}{2}y^2-\frac{1}{3}y^3+c. \tag{2.1}$$

Further reduction follows by introducing y as an independent variable, using formulas such as

$$\frac{d^2y}{dx^2}=\frac{1}{2}\frac{d}{dy}\left(\frac{dy}{dx}\right)^2,\qquad \frac{d^3y}{dx^3}=\frac{1}{2}\left(\frac{dy}{dx}\right)\frac{d^2}{dy^2}\left(\frac{dy}{dx}\right)^2. \tag{2.2}$$

We finally introduce

$$\left(\frac{dy}{dx}\right)^2=z \tag{2.3}$$

and find the equation for trajectories:

$$\varepsilon^2\left\{z\frac{d^2z}{dy^2}-\frac{1}{4}\left(\frac{dz}{dy}\right)^2\right\}+z=y^2-\frac{2}{3}y^3+c. \tag{2.4}$$

One can find the integral in a more direct and elegant way by introducing y as an independent variable in (1.1). Manipulations of the type (2.2) then produce immediately

$$\frac{d}{dy}\left\{\varepsilon^2\left[z\frac{d^2z}{dy^2}-\frac{1}{4}\left(\frac{dz}{dy}\right)^2\right]+z\right\}=2(y-y^2). \tag{2.5}$$

In (2.4) we have reduced the problem from fourth- to second-order. The price is that the equation is highly nonlinear and degenerates at $z=0$. Nevertheless, the equation (2.4) will be basic in all that follows.

Remarks. The integral (2.1) also occurs in [1] and [6], but does not play a predominant role in the analysis. In [4], from (2.1) an equation equivalent to (2.4) is derived and used as a starting point of the theory. We shall comment on this further in § 3.2.

3. Formal approximations. In a search for a homoclinic orbit we put in (2.4) $c=0$. In this section we develop formal approximations for solutions of the basic equation

$$\varepsilon^2\left\{z\frac{d^2z}{dy^2}-\frac{1}{4}\left(\frac{dz}{dy}\right)^2\right\}+z=y^2\left(1-\frac{2}{3}y\right). \tag{3.1}$$

3.1. Straightforward iteration. It seems natural to look at what happens close to the unperturbed orbit

$$z_0=y^2\left(1-\frac{2}{3}y\right). \tag{3.2}$$

We introduce the transformation

$$z(y,\varepsilon)=z_0(y)+\varepsilon^2\rho_1(y,\varepsilon), \tag{3.3}$$

and obtain the equation

$$\varepsilon^2\left\{(z_0+\varepsilon^2\rho_1)\frac{d^2\rho_1}{dy^2}-\frac{1}{2}\frac{dz_0}{dy}\frac{d\rho_1}{dy}+\frac{d^2z_0}{dy^2}\rho_1-\frac{\varepsilon^2}{4}\left(\frac{d\rho_1}{dy}\right)^2\right\}+\rho_1=f_1(y) \tag{3.4}$$

with

$$f_1(y)=-z_0\frac{d^2z_0}{dy^2}+\frac{1}{4}\left(\frac{dz_0}{dy}\right)^2.$$

But now it again is natural to repeat the operation, putting

$$\begin{aligned}\rho_1(y,\varepsilon)&=z_1(y)+\varepsilon^2\rho_2(y,\varepsilon),\\ z_1(y)&=f_1(y).\end{aligned} \tag{3.5}$$

The iteration-procedure can be pursued indefinitely, leading to a formal approximation with a remainder term, in the form

$$z(y,\varepsilon)=\sum_{n=0}^{m-1}\varepsilon^{2n}z_n(y)+\varepsilon^{2m}\rho_m(y,\varepsilon). \tag{3.6}$$

Introducing the definition

$$\Phi_m=\sum_{n=0}^{m-1}\varepsilon^{2n}z_n, \tag{3.7}$$

we find a quite transparent structure:

$$z_n=-\left\{\Phi_n\frac{d^2z_{n-1}}{dy^2}-\frac{1}{2}\frac{d\Phi_{n-1}}{dy}\frac{dz_{n-1}}{dy}+\frac{d^2\Phi_{n-1}}{dy^2}z_{n-1}-\frac{1}{4}\varepsilon^{2(n-1)}\left(\frac{dz_{n-1}}{dy}\right)^2\right\}. \tag{3.8}$$

The remainder term ρ_m satisfies

$$\varepsilon^2\left\{(\Phi_m+\varepsilon^{2m}\rho_m)\frac{d^2\rho_m}{dy^2}-\frac{1}{2}\frac{d\Phi_m}{dy}\frac{d\rho_m}{dy}+\frac{d^2\Phi_m}{dy^2}\rho_m-\frac{1}{4}\varepsilon^{2m}\left(\frac{d\rho_m}{dy}\right)^2\right\}+\rho_m=f_m, \tag{3.9}$$

where f_m is defined in a formal way as z_m in (3.8).

Inspection of the formulas shows that the formal approximation Φ_m has the structure

$$\Phi_m=y^2\left[1-\frac{y}{\alpha_m(\varepsilon)}\right]g_m(y,\varepsilon), \tag{3.10}$$

where g_m is a polynomial in y without zeros on the interval $[0,\alpha_m]$. $\alpha_m(\varepsilon)$ can be computed explicitly. In the first approximations, we find

$$\alpha_m(\varepsilon)=\tfrac{3}{2}[1+\tfrac{1}{4}\varepsilon^2+\cdots]. \tag{3.11}$$

Let us now recall that $z=(dy/dx)^2$. Consider an orbit defined as a union of the curves $(dy/dx)_\pm$, given by the formal approximation

$$\left(\frac{dy}{dx}\right)_\pm=\pm y\sqrt{1-\frac{y}{\alpha_m(\varepsilon)}}\,g_m^{1/2}(y,\varepsilon). \tag{3.12}$$

It is easily verified that the corresponding solution $y(x)$ has continuous derivatives up to the fourth order (and beyond) at $y=\alpha_m(\varepsilon)$. Hence, the formal approximation Φ_m, for any m, has all the desired features of a homoclinic orbit of (1.1). This result is encouraging, but will turn out to be misleading.

3.2. Power series. It is remarkable that we can also compute a formal power series expansion for $z(y)$, which, at the same time, is an asymptotic expansion in ε. To show the structure, a small display of the algebra is needed. We abbreviate

$$Lz := \varepsilon^2\left\{z\frac{d^2z}{dy^2}-\frac{1}{4}\left(\frac{dz}{dy}\right)^2\right\}+z-y^2+\frac{2}{3}y^3 \tag{3.13}$$

and introduce

$$\tilde{\Phi}_m(y)=\alpha y^2-\beta y^3-\sum_{n=1}^{m} a_n y^{n+3}. \tag{3.14}$$

Substitution produces the following result:

$$\begin{aligned} L\tilde{\Phi}_m &= (\varepsilon^2\alpha^2+\alpha-1)y^2+\left[\frac{2}{3}-\beta(1+5\varepsilon^2\alpha)\right]y^3 \\ &\quad -y^4\sum_{n=1}^{m} a_n[1+\varepsilon^2\alpha[(n+3)(n+2)+2]]y^{n-1} \\ &\quad +\varepsilon^2y^4\left\{\frac{15}{4}\beta^2+y\beta\sum_{n=1}^{m} a_n\left[(n+3)\left(n+\frac{1}{4}\right)+6\right]y^{n-1}\right. \\ &\quad \left. +y^2\left[\sum_{n=1}^{m} a_n(n+3)\left(n+\frac{3}{2}\right)y^{n-1}\right]\left[\sum_{n=1}^{m} a_n(n+3)\left(n+\frac{5}{4}\right)y^{n-1}\right]\right\}. \end{aligned} \tag{3.15}$$

We can now determine α, β, and a_n, $n=1,\cdots,m$ by putting all coefficients of y^p, $p=2,\cdots m+3$ on the right-hand side of (3.15) equal to zero.

The first requirement is that α should be the positive root of

$$\varepsilon^2\alpha^2+\alpha-1=0. \tag{3.16}$$

This means that α^2 is the exact value of $\omega_{1,2}^2$ in (1.5). Next we find

$$\beta=\frac{2}{3}\frac{1}{1+5\varepsilon^2\alpha}, \tag{3.17}$$

$$a_1=\varepsilon^2\frac{15}{4}\beta^2\frac{1}{1+\varepsilon^2 14\alpha}. \tag{3.18}$$

Further coefficients, a_n, $n=2,\cdots,m$, can be determined recursively. A general recursion formula is of little use to us. It is sufficient to observe (from the structure of the right-hand side of (3.15)) that

$$a_n=O(\varepsilon^{2n}),\qquad a_n>0. \tag{3.19}$$

We summarize these results as follows:

$$\tilde{\Phi}_m(y)=\alpha y^2-\beta y^3-\sum_{n=1}^{m}\varepsilon^{2n}\bar{a}_n y^{n+3}, \tag{3.20}$$

$$\bar{a}_n=O(1),\qquad \bar{a}_n>0, \tag{3.21}$$

$$L\tilde{\Phi}_m=\varepsilon^{2(m+1)}y^{m+4}\sum_{p=0}^{m}\sigma_p y^p, \tag{3.22}$$

$$\sigma_p=O(1),\qquad \sigma_p>0. \tag{3.23}$$

In a final step we write

$$z = \tilde{\tilde{\Phi}}_m + \varepsilon^{2(m+2)} \tilde{\rho}_m. \tag{3.24}$$

We can easily see that for the remainder $\tilde{\rho}_m$ an equation similar to (3.9) is obtained. On the other hand, the formal approximation $\tilde{\tilde{\Phi}}_m$ is similar in structure to Φ_m, as expressed in (3.10). Working with the power-series expansion may have some advantages. This we shall see when studying the problem of splitting of the homoclinic orbit.

Remarks. In the work of Hammersley and Mazzarino [4] a formal power series of a structure similar to (3.14) (with $m = \infty$) is used as a basic step of the analysis. A recursion formula for the coefficients is given, and convergence results are derived. The authors do not recognize the asymptotic structure of the series for ε small. As already mentioned, Hammersley and Mazzarino use an ingenious combination of analysis and numerical computations. Their final results are obtained at the expense of a very impressive amount of both formula-manipulation and numerics.

4. Main results.

4.1. The solution for $z(y)$. Let us state again our basic equation

$$\varepsilon^2 \left\{ z \frac{d^2 z}{dy^2} - \frac{1}{4} \left(\frac{dz}{dy} \right)^2 \right\} + z = y^2 \left(1 - \frac{2}{3} y \right). \tag{4.1}$$

We look for solutions $z(y)$, which for $y \to 0$ behave as y^2. To this end we introduce the transformation

$$z = y^2 \bar{z} \tag{4.2}$$

and obtain for $\bar{z}$ the equation

$$\varepsilon^2 \left\{ y^2 \left[\bar{z} \frac{d^2 \bar{z}}{dy^2} - \frac{1}{4} \left(\frac{d\bar{z}}{dy} \right)^2 \right] + 3y\bar{z} \frac{d\bar{z}}{dy} \right\} + \bar{z}(1 + \varepsilon^2 \bar{z}) = 1 - \frac{2}{3} y. \tag{4.3}$$

Next we write

$$\bar{z} = \varphi_m + \varepsilon^{2m} \psi_m,$$

where φ_m is the result of formal iteration of § 3.1, or the truncated power series of § 3.2, in both cases with y^2 factored out. For the remainder ψ_m we get the equation

$$\begin{aligned} &\varepsilon^2 y^2 (\varphi_m + \varepsilon^{2m} \psi_m) \frac{d^2 \psi_m}{dy^2} \\ &\quad + \varepsilon^2 \left[-\frac{1}{2} y^2 \left(\varphi'_m + \frac{1}{2} \varepsilon^{2m} \psi'_m \right) + 3y(\varphi_m + \varepsilon^{2m} \psi_m) \right] \frac{d\psi_m}{dy} + \psi \\ &= \bar{f}_m(y) - \varepsilon^2 \{ y^2 \varphi''_m + 3y\varphi'_m + (2\varphi_m + \varepsilon^{2m} \psi_m) \} \psi_m, \end{aligned} \tag{4.4}$$

where $\bar{f}_m(y)$ is a polynomial in y. In the equation (4.4) we use both primes and d/dy to denote the derivative. The reason for this will become clear in § 5, where we shall prove (by a contraction mapping argument) the following.

RESULT. *There exists a unique solution $\psi_m(y; \varepsilon)$, which on an interval $y \in [0, y_0]$, is bounded for $\varepsilon \downarrow 0$, and the same is true for the derivative $\psi'_m(y; \varepsilon)$. y_0 is such that*

$$|\varphi_m(y; \varepsilon)| \geqq c\varepsilon^m$$

with c a constant and $m \geqq 2$.

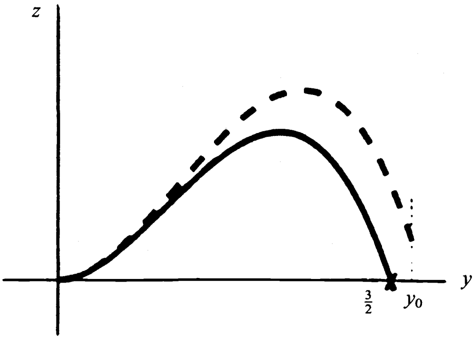

FIG. 2

Remarks. Note that m is an arbitrary integer. Hence we have the existence of a solution $z(y;\,\varepsilon)$ of the basic equation (4.1), which starts out as y^2 and ultimately gets closer to zero than any power of ε. The situation is sketched in Fig. 2.

It is further important to remark that $y_0 > 3/2$. This follows from the result (3.11).

What happens to the continuation of the solution? Obviously $z(y)$ cannot just stop at some positive value. Suppose that the function would like to turn upward and escape to large values. This could only happen at $y > y_0$. At some $z > 0$ we would have $dz/dy = 0$ and $d^2z/dy^2 \geqq 0$, and this leads to contradiction in the equation (4.1). Suppose next that $z \to 0$ as $y \to y_1 > y_0$; however, z' also tends to zero. Since z' comes from negative values, and did not pass through zero, we must still have $z'' \geqq 0$, which again gives contradiction in (4.1). The contradiction remains if we take $y_1 = +\infty$, or assume that z tends to a nonzero positive value as $y \to \infty$.

Hence the continuation of the solution $z(y)$ must reach $z = 0$ with a nonzero slope.

4.2. Splitting of the homoclinic orbit. We define two half-orbits $y_+(x), x \in (-\infty, 0]$, $y_-(x)$, $x \in [0, \infty)$ as solutions of

$$\left(\frac{dy}{dx}\right)_\pm = \pm\sqrt{z(y)}, \tag{4.5}$$

$$y_+(0) = y_-(0) = y_1(\varepsilon). \tag{4.6}$$

It is understood that

$$z(y_1) = 0. \tag{4.7}$$

We wish to investigate the regularity of the union of $y_+(x)$ and $y_-(x)$ at $x = 0$. Since the model equation is of fourth order we need continuity up to the fourth derivative. First we compute

$$\left(\frac{d^2y}{dx^2}\right)_\pm = (\pm)\frac{1}{2}\frac{1}{\sqrt{z}}\frac{dz}{dy}\left(\frac{dy}{dx}\right)_\pm = \frac{1}{2}\frac{dz}{dy}. \tag{4.8}$$

Hence

$$\left(\frac{d^2y}{dx^2}\right)_+ = \left(\frac{d^2y}{dx^2}\right)_- \quad \text{at } x = 0. \tag{4.9}$$

From the equation (1.1), it follows that fourth derivative also match continuously.

Next we compute

$$\left(\frac{d^3y}{dx^3}\right)_\pm = (\pm)\frac{1}{2}\sqrt{z}\frac{d^2z}{dy^2}. \tag{4.10}$$

We would have the continuity of the third derivative if we could show that d^2z/dy^2 is bounded as $y \to y_1$. There is, however, no reason for such assertion. In fact, in our companion paper [3, § 4], we show that

$$z(y) \approx c_1(y_1 - y) + c_2(y_1 - y)^{3/2} + \cdots \quad \text{as } y \uparrow y_1.$$

On the other hand, from (1.1) we can deduce another representation of the third derivative at $x = 0$, as follows.

First we "solve" for the second derivative and obtain

$$\left(\frac{d^2y}{dx^2}\right)_+ = -\frac{1}{\varepsilon} \int_{-\infty}^{x} \sin \frac{1}{\varepsilon}(x - \xi)[y(\xi) - y^2(\xi)]\, d\xi. \tag{4.11}$$

Next, after differentiation, we get

$$\frac{d^3y_+}{dx^3}(0) = I(\varepsilon), \tag{4.12}$$

$$I(\varepsilon) := \frac{1}{\varepsilon^2} \int_{-\infty}^{0} \cos \frac{1}{\varepsilon} \xi \cdot [y(\xi) - y^2(\xi)]\, d\xi. \tag{4.13}$$

The idea is to compute the integral along approximate trajectories, which are obtained by replacing $z(y)$ in (4.5) by its asymptotic approximations.

We define $y^{(m)}(x)$, $x < 0$ through

$$\frac{dy^{(m)}}{dx} = \sqrt{\Phi_m(y; \varepsilon)} \tag{4.14}$$

with Φ_m the asymptotic expansion defined in § 3.1. Furthermore,

$$I^{(m)}(\varepsilon) = \frac{1}{\varepsilon^2} \int_{-\infty}^{0} \cos \frac{1}{\varepsilon} \xi [y^{(m)}(\xi) - (y^{(m)}(\xi))^2]\, d\xi. \tag{4.15}$$

In the appendix, which is due to Temme, we have computed the integrals for $m = 1$ and $m = 2$, which correspond to

$$\Phi_m = \sum_{n=0}^{m-1} \varepsilon^{2n} z_n(y), \qquad m = 1, 2. \tag{4.16}$$

The results can be summarized as follows:

$$I^{(m)}(\varepsilon) = -\frac{\pi}{\varepsilon^5} c_m e^{-\pi/\varepsilon}[1 + o(1)], \tag{4.17}$$

$$c_1 = 6, \qquad c_2 \cong 3.6 c_1. \tag{4.18}$$

We see that a small correction of the trajectories does not result in a small change in the constant c_m. Before further analysis, we shall compare the results with those of Hammersley and Mazzarino [4]. Adjusting the notation of [4] to ours (ε in [4] is ε^2 here, and the quantity computed in [4] is $d^2y_-/dx^3(0)$), we find

$$I(\varepsilon) = -\Omega(\varepsilon) \frac{(1 + \varepsilon^2)^{7/4}}{\varepsilon^5} e^{-\pi/\varepsilon}. \tag{4.19}$$

The function $\Omega(\varepsilon)$ is positive. It has been computed numerically over a wide range of ε. For ε small $\Omega(\varepsilon)$ is of the order of magnitude of 10^2.

It appears that the behaviour with ε given in (4.17) is in precise agreement with (4.19). We may venture that for large m the constants c_m will settle to a definite value, but analytical determination seems beyond possibility. However, we are able to prove that for all m the integral $I^{(m)}$ is negative. This can be done using the asymptotic expansion defined by the power-series of § 3.2. The reasoning is amusing.

We recall some relevant formulas from § 3.2:

$$Lz := \varepsilon^2\left(z\frac{d^2z}{dy^2}-\frac{1}{4}\left(\frac{dz}{dy}\right)^2\right)+z-y^2+\frac{2}{3}y^3, \tag{4.20}$$

$$\tilde{\Phi}_m(y) := \alpha y^2+\beta y^3-\sum_{n=1}^{m}\varepsilon^{2n}\bar{a}_n y^{n+3}. \tag{4.21}$$

The coefficients α, β, and $\bar{a}_n$ can be determined in such way that

$$L\tilde{\Phi}_m = \varepsilon^{2(m+1)}f_m(y), \tag{4.22}$$

$$f_m(y) = y^{m+4}\sum_{p=0}^{m}\sigma_p y^p, \tag{4.23}$$

$$\sigma_p = O(1), \qquad \sigma_p > 0. \tag{4.24}$$

Let us look at $\tilde{y}^{(m)}(x)$, a solution for $x<0$ of the equation

$$\frac{d\tilde{y}^{(m)}}{dx} = \sqrt{\tilde{\Phi}^{(m)}(y^{(m)})}. \tag{4.25}$$

Because of (4.22), $\tilde{y}^{(m)}$ satisfies a perturbed model equation

$$\varepsilon^2\frac{d^4\tilde{y}^{(m)}}{dx^4}+\frac{d^2\tilde{y}^{(m)}}{dx^2} = \tilde{y}^{(m)}-[\tilde{y}^{(m)}]^2+\varepsilon^{2(m+1)}f'_m(y^{(m)}) \tag{4.26}$$

with

$$f'_m(y) = \frac{d}{dy}f_m(y). \tag{4.27}$$

Following steps analogous to (4.11), (4.12), and (4.13), we find

$$\frac{d^3\tilde{y}_+^{(m)}}{dx^3}(0) = \frac{1}{\varepsilon^2}\int_{-\infty}^{0}\cos\frac{1}{\varepsilon}\,\xi\{\tilde{y}^{(m)}-[\tilde{y}^{(m)}]^2+\varepsilon^{2(m+1)}f'_m(\tilde{y}^{(m)})\}\,d\xi. \tag{4.28}$$

However, the quantity on the left-hand side of (4.28) is zero because $\tilde{\Phi}^{(m)}$ is just a finite polynomial, and hence the second derivative which appears in (4.10) exists. We thus find

$$\begin{aligned} I^{(m)}(\varepsilon) &= -\varepsilon^{2m}\int_{-\infty}^{0}\cos\frac{1}{\varepsilon}\,\xi f'_m(\tilde{y}^{(m)}(\xi))\,d\xi \\ &= -\varepsilon^{2m}\sum_{p=0}^{m}\sigma_p(m+4+p)\int_{-\infty}^{0}\cos\frac{1}{\varepsilon}\,\xi[\tilde{y}^{(m)}(\xi)]^{m+3+p}\,d\xi. \end{aligned} \tag{4.29}$$

The next claim is that each of the integrals on the right-hand side of (4.29) is positive. This is because $\tilde{y}^{(m)}(\xi)$ is a monotone function. If we divide the interval of integration into subintervals $[-2\pi/\varepsilon, 0]$, $[-4\pi/\varepsilon, -2\pi/\varepsilon]$, etc., we get positive contributions from each subinterval. Finally, from (4.24), $\sigma_p > 0$.

Hence

$$I^{(m)}(\varepsilon) < 0 \quad \forall m.$$

5. Construction of a contraction mapping. In this section we simplify notations by dropping the subscript m.

5.1. Difficulties of the enterprise. Equation (4.4) is of the following structure:

$$\mathscr{L}(\psi)=\bar{f}(y)+\varepsilon^2 g_1(y,\psi), \tag{5.1}$$

$$\mathscr{L}=\varepsilon^2 A(y,\psi)\frac{d^2}{dy^2}+\varepsilon^2 B(y,\psi,\psi')\frac{d}{dy}+1, \tag{5.2}$$

$$A(y,\psi)=y^2(\varphi+\varepsilon^{2m}\psi), \tag{5.3}$$

$$B(y,\psi,\psi')=-\tfrac{1}{2}y^2(\varphi'+\tfrac{1}{2}\varepsilon^{2m}\psi')+3y(\varphi+\varepsilon^{2m}\psi), \tag{5.4}$$

$$g_1(y,\psi)=-\{y^2\varphi''+3y\varphi'+(2\varphi+\varepsilon^{2m}\psi)\}\psi. \tag{5.5}$$

We wish to prove the existence of a bounded solution. A standard way to proceed would be a decomposition of $\mathscr{L}$ into

$$\mathscr{L}=\mathscr{L}_1+\mathscr{L}_2 \tag{5.6}$$

such that an inverse $\mathscr{L}_1^{-1}$ could be defined and the problem reformulated into

$$\psi=\mathscr{L}_1^{-1}\{-\mathscr{L}_2(\psi)+\bar{f}+\varepsilon^2 g_1\}. \tag{5.7}$$

The right-hand side of (5.7) should define a neat mapping in some Banach space, and we should have sufficient knowledge of $\mathscr{L}_1^{-1}$ to investigate and prove contraction properties of the mapping.

In order to have sufficient control over $\mathscr{L}_1^{-1}$, we shall use for $\mathscr{L}_1$ a linear operator. This means, however, that on the right-hand side of (5.7) nonlinear terms will appear containing first and second derivatives of ψ. It turns out that the second derivative can be eliminated (integrating by parts), but the first derivative cannot be avoided. It is for this reason that we must also study the problem for the derivative ψ'. Differentiating (5.1) we find

$$\tilde{\mathscr{L}}(\psi')=\bar{f}'(y)+\varepsilon^2 g_2(y,\psi,\psi'), \tag{5.8}$$

$$\tilde{\mathscr{L}}=\varepsilon^2 A(y,\psi)\frac{d^2}{dy^2}+\varepsilon^2\tilde{B}(y,\psi,\psi')\frac{d}{dy}+1 \tag{5.9}$$

with $A(y,\psi)$ as in (5.3), and furthermore

$$\tilde{B}=5y(\varphi+\varepsilon^{2m}\psi)+\tfrac{1}{2}y^2(\varphi'+\varepsilon^{2m}\psi'), \tag{5.10}$$

$$\begin{aligned} g_2={}&-(y^2\varphi'''+5y\varphi''+5\varphi')\psi\\ &-\{5(\varphi+\varepsilon^{2m}\psi)+6y(\varphi'+\varepsilon^{2m}\psi')+y^2\varphi''-\tfrac{5}{2}\varepsilon^{2m}\psi'\}\psi'. \end{aligned} \tag{5.11}$$

Decomposing $\tilde{\mathscr{L}}$ with a linear operator we again face difficulties with nonlinear terms containing derivatives in the equivalent of (5.7). The second derivative will be eliminated by a special trick, and the first derivative will be eliminated by integration by parts. This is possible because in (5.8) we do not have a term of the structure $(d\psi'/dy)^2$.

The first task now is to define a suitable operator $\mathscr{L}_1$.

5.2. An intermezzo on "exact WKB functions." Physicists are familiar with the WKB approximation (Wentzel, Kramers, and Brillouin). In the context of equations that are of interest to us, the procedure goes as follows.

Consider a homogeneous equation

$$\varepsilon^2 a \frac{d^2\theta}{dy^2} + \varepsilon^2 b \frac{d\theta}{dy} + \theta = 0, \tag{5.12}$$

where a and b are given functions. We introduce

$$\theta = e^{1/\varepsilon Q}. \tag{5.13}$$

We get

$$aQ'^2 + \varepsilon a Q'' + \varepsilon b Q' + 1 = 0. \tag{5.14}$$

Next we introduce a formal expansion

$$Q = q_0 + \varepsilon q_1 + \varepsilon^2 q_2 + \cdots. \tag{5.15}$$

We readily find that

$$(q_0')^2 = -\frac{1}{a}, \tag{5.16}$$

$$q_1' = \frac{1}{4}\frac{a'}{a} - \frac{1}{2}\frac{b}{a}. \tag{5.17}$$

The result is more transparent if we introduce a function ν defined by

$$\nu' = -\frac{1}{2}\frac{b}{a}\nu. \tag{5.18}$$

This function appears in the well-known Liouville transformation for the equation (5.12). We find, as a formal WKB approximation,

$$\theta_0(y) = \nu(y)[a(y)]^{1/4} \exp\left\{ \mp \frac{i}{\varepsilon} \int^y \frac{d\eta}{\sqrt{a(\eta)}} \right\}. \tag{5.19}$$

If the coefficients $a(y)$, $b(y)$ are sufficiently regular, then we can prove for the linearly independent solutions of (5.12) the result

$$\theta = \theta_0\{1 + o(\varepsilon)\}. \tag{5.20}$$

This is a very nice result because it gives an approximation with a relative precision.

In our case, (5.3), (5.4), (5.10), the coefficients vanish at $y = 0$, and the proof of validity appears difficult. Additional complication arises for the values of y such that $\varphi(y)$ becomes small. However, *we shall not need any proof of validity in the approach that we shall follow now.*

Let us ask this question: *what is the differential equation that is satisfied exactly by the* WKB *approximation*? We answer that question for the linearization of $\tilde{\mathscr{L}}$. In that case we have

$$a = y^2\varphi, \tag{5.21}$$

$$b = 5y\varphi + \tfrac{1}{2}y^2\varphi', \tag{5.22}$$

and we find

$$\theta_0 = \frac{1}{y^2} \exp\left\{ \mp \frac{i}{\varepsilon} \int_y \frac{d\eta}{\eta\sqrt{\varphi}} \right\}. \tag{5.23}$$

Next a straightforward computation shows that

$$\varepsilon^2\left\{a\frac{d^2\theta_0}{dy^2}+b\frac{d\theta_0}{dy}\right\}+\theta_0=\varepsilon^2[4\varphi+y\varphi']\theta_0. \tag{5.24}$$

Hence, θ_0 *satisfies a very mildly perturbed original equation* (5.12).

It is interesting to observe that very similar results hold for the full nonlinear operator $\tilde{\mathscr{L}}$ of (5.9). In fact, everything remains true if in (5.21)-(5.24) the function φ is replaced by $\varphi+\varepsilon^{2m}\psi$. This result seems elegant; however, difficulties do arise if we attempt to use it in the construction of a contraction mapping.

We now define, for further use, the operator $\mathscr{L}_1$ explicitly:

$$\mathscr{L}_1=\varepsilon^2y^2\varphi\frac{d^2}{dy^2}+\varepsilon^2\left[5y\varphi+\frac{1}{2}y^2\varphi'\right]\frac{d}{dy}+[1+\varepsilon^2(4\varphi+y\varphi')]\cdot I. \tag{5.25}$$

The two linearly independent solutions of the homogeneous equation $\mathscr{L}_1\theta_0=0$ are given by (5.23).

Remark 1. We can perform similar analysis on the linearization of the operator $\mathscr{L}$ of the problem for ψ, given in (5.2). The equation satisfied by the corresponding WKB approximations turns out to be less tractable. However, in the decomposition of $\mathscr{L}$ we can also use $\mathscr{L}_1$. This introduces first derivatives in $\mathscr{L}_2$, which are unavoidable anyhow.

Remark 2. In the approach described above we introduce an additional perturbation such that the resulting equation is satisfied exactly by the WKB functions. This author found, to his surprise, no trace of this simple approach in the literature.

5.3. Transformation to integral equations. Let us consider an inhomogeneous problem

$$\mathscr{L}_1(\hat{\psi})=R \tag{5.26}$$

with $\mathscr{L}_1$ given by (5.25). We ask for bounded solutions on some nonempty interval $y\in[0,y_0]$, $y_0>0$.

Using the linearly independent solutions given by (5.23), we find, by elementary manipulations,

$$\hat{\psi}(y)=\frac{1}{\varepsilon^2}\cdot\left(\frac{\varepsilon}{2i}\right)\int_0^y\{\theta_0^{(1)}(\eta)\theta_0^{(2)}(y)-\theta_0^{(1)}(y)\theta_0^{(2)}(\eta)\}\eta^3\frac{1}{\sqrt{\varphi(\eta)}}R(\eta)\,d\eta. \tag{5.27}$$

To get a more explicit form we define

$$\Omega(\eta,y)=\int_y^\eta\frac{d\bar{\eta}}{\bar{\eta}\sqrt{\varphi(\bar{\eta})}} \tag{5.28}$$

and obtain

$$\hat{\psi}(y)=-\frac{1}{\varepsilon}\frac{1}{y^2}\int_0^y\sin\left[\frac{1}{\varepsilon}\Omega(\eta,y)\right]\frac{\eta}{\sqrt{\varphi(\eta)}}R(\eta)\,d\eta. \tag{5.29}$$

Let us first show that $\hat{\psi}(y)$ indeed is bounded as $y\to0$. By elementary estimate we get

$$|\hat{\psi}(y)|\leqq\frac{1}{\varepsilon}\frac{1}{y^2}\int_0^y\frac{\eta}{\sqrt{\varphi(\eta)}}d\eta\sup_{y\in[0,y_0]}|R(y)|. \tag{5.30}$$

The estimate is valid on intervals $y\in[0,y_0]$ such that $\varphi(y)\geqq0$.

From this it follows that

$$|\hat{\psi}(y)|\leqq\frac{c}{\varepsilon}\sup|R|. \tag{5.31}$$

Next we show that if R is differentiable, then $\hat{\psi}(y)$ is $O(1)$ as $\varepsilon \downarrow 0$. For this it is sufficient to observe that

$$-\frac{1}{\varepsilon}\sin\left[\frac{1}{\varepsilon}\Omega(\eta, y)\right]\cdot\frac{1}{\eta\sqrt{\varphi(\eta)}}=\frac{d}{d\eta}\cos\left[\frac{1}{\varepsilon}\Omega(\eta, y)\right]. \tag{5.32}$$

It then follows that

$$\hat{\psi}(y)=R(y)-\frac{1}{y^2}\int_0^y \cos\left[\frac{1}{\varepsilon}\Omega(\eta, y)\right]\frac{d}{d\eta}[\eta^2 R(\eta)]\,d\eta. \tag{5.33}$$

The integral on the right-hand side of (5.33) can be estimated as in (5.29) and (5.30).

Finally, if $R(\eta)$ is twice differentiable, then

$$\hat{\psi}(y)=R(y)+O(\varepsilon). \tag{5.34}$$

In fact, explicitly,

$$\hat{\psi}(y)=R(y)+\frac{\varepsilon}{y^2}\int_0^y \sin\left[\frac{1}{\varepsilon}\Omega(\eta, y)\right]\frac{d}{d\eta}\left[\eta\sqrt{\varphi}\frac{d}{d\eta}\eta^2 R\right]d\eta. \tag{5.35}$$

With these results we now turn to the problems for ψ and ψ'.

It will be convenient to have a compact notation for the integral operators that occur in the analysis. We define

$$S_1[R](y)=-\frac{1}{y^2}\int_0^y \sin\left[\frac{1}{\varepsilon}\Omega(\eta, y)\right]\frac{\eta}{\sqrt{\varphi(\eta)}}R(\eta)\,d\eta, \tag{5.36}$$

$$S_2[R](y)=-\frac{1}{y^2}\int_0^y \cos\left[\frac{1}{\varepsilon}\Omega(\eta, y)\right]\frac{\eta}{\sqrt{\varphi(\eta)}}R(\eta)\,d\eta. \tag{5.37}$$

For intervals $y\in[0, y_0]$ such that $\varphi(y)\geqq 0$ we have

$$|S_{1,2}[R]|\leqq c\ \mathrm{Sup}\,|R|. \tag{5.38}$$

Furthermore, if $R(\eta)$ is twice differentiable, then

$$\frac{1}{\varepsilon}S_1[R](y)=R(y)+O(\varepsilon). \tag{5.39}$$

5.3.1. The problem for ψ.

Starting from (5.1)-(5.5) and using the definition of $\mathscr{L}_1$ given in (5.25), we find after some arithmetic exercises that

$$\mathscr{L}_1(\psi)=\bar{f}(y)+\varepsilon^2 G(y, \psi, \psi')-\varepsilon^{2(m+1)}y^2\psi\frac{d^2\psi}{dy}, \tag{5.40}$$

where $G(y, \psi, \psi')$ is an expression of the structure

$$G=\beta_0(y)\psi+\gamma_0(y)\psi'+\varepsilon^{2m}[\beta_1(y)\psi+\gamma_1(y)\psi']\psi'. \tag{5.41}$$

The β's and γ's are polynomials in y. We shall use the symbol G generically, to denote expressions of the structure (5.41). Of course, the G's occuring in different terms have, in general, different polynomials.

Using the results the equations (5.40) is transformed to

$$\begin{aligned}\psi&=\frac{1}{\varepsilon}S_1[\bar{f}(\eta)]+\varepsilon S_1[G(\eta, \psi, \psi')]\\&\quad+\varepsilon^{2m+1}\frac{1}{y^2}\int_0^y \sin\left[\frac{1}{\varepsilon}\Omega(\eta, y)\right]\frac{\eta^3}{\sqrt{\varphi(\eta)}}\psi\frac{d^2\psi}{d\eta^2}\,d\eta.\end{aligned} \tag{5.42}$$

Integrating the last term by parts, we find it to be equal to

$$-\varepsilon^{2m+1}\frac{1}{y^2}\int_0^y \sin\left[\frac{1}{\varepsilon}\Omega(\eta, y)\right]\frac{d}{d\eta}\left[\frac{\eta^3}{\sqrt{\varphi}}\psi\right]\psi'\,d\eta$$

$$-\varepsilon^{2m}\frac{1}{y^2}\int_0^y \cos\left[\frac{1}{\varepsilon}\Omega(\eta, y)\right]\frac{\eta^2}{\varphi}\psi\psi'\,d\eta.$$

Separating out terms that are different in structure from $S_1[G]$, we obtain the following result:

$$\psi=\psi_0+\varepsilon S_1[G(\eta, \psi, \psi')]-\varepsilon^{2m}S_2\left[\frac{\eta}{\sqrt{\varphi}}\psi\psi'\right]+\frac{1}{2}\varepsilon^{2m+1}S_1\left[\frac{\eta^2}{\varphi}\varphi'\psi\psi'\right], \tag{5.43}$$

where

$$\psi_0=\frac{1}{\varepsilon}S_1[\bar{f}]=\bar{f}+O(\varepsilon). \tag{5.44}$$

The reason for separating out carefully terms of different structure lies in the fact that we want to pursue the analysis as far as possible into values of y such that $\varphi(y)$ becomes very small.

5.3.2. The problem for ψ'. We now turn to (5.8)-(5.11). The first step is to remove the nonlinearity in the term with second derivative of ψ'. This can be done by multiplying the equation by the factor

$$\frac{\varphi}{\varphi+\varepsilon^{2m}\psi}$$

and by using, whenever convenient, the identity

$$\frac{\varphi}{\varphi+\varepsilon^{2m}\psi}=1-\frac{\varepsilon^{2m}\psi}{\varphi+\varepsilon^{2m}\psi}.$$

The explicit result is

$$\begin{aligned}&\varepsilon^2y^2\varphi\frac{d^2}{dy^2}\psi'+\varepsilon^2\left(5y\varphi+\frac{1}{2}y^2\psi'\right)\frac{d\psi'}{dy}+\psi'\\ &\quad=[1-\varepsilon^{2m}\psi(\varphi+\varepsilon^{2m}\psi)^{-1}](\bar{f}'+\varepsilon^2g_2)+\varepsilon^{2m}\psi(\varphi+\varepsilon^{2m}\psi)^{-1}\psi'\\ &\quad\quad+\varepsilon^{2m+2}(\varphi+\varepsilon^{2m}\psi)^{-1}\frac{1}{2}y^2(\varphi'\psi-\varphi\psi')\frac{d\psi'}{dy}\end{aligned} \tag{5.45}$$

with g_2 given by (5.11). Next we introduce $\mathscr{L}_1$ by definition (5.25), and we use the generic notation G for terms of the structure (5.41). This produces the equation

$$\begin{aligned}\mathscr{L}_1(\psi')&=\bar{f}'+\varepsilon^2G_1(y, \psi, \psi')+\varepsilon^{2m}(\varphi+\varepsilon^{2m}\psi)^{-1}\psi G_2(y, \psi, \psi')\\ &\quad+\varepsilon^{2m+2}(\varphi+\varepsilon^{2m}\psi)^{-1}\frac{1}{4}y^2\left[2\varphi'\psi\frac{d\psi'}{dy}-\varphi\frac{d}{dy}(\psi')^2\right].\end{aligned} \tag{5.46}$$

When inverting the equation (5.46), we have to deal with the term

$$-\varepsilon^{2m+1}\frac{1}{y^2}\frac{1}{4}\int_0^y \sin\left[\frac{1}{\varepsilon}\Omega(\eta, y)\right]\frac{\eta^3}{\sqrt{\varphi}}(\varphi+\varepsilon^{2m}\psi)^{-1}\left[2\varphi'\psi\frac{d\psi'}{d\eta}-\varphi\frac{d}{d\eta}(\psi')^2\right]d\eta.$$

Integrating by parts, we find this term to be equal to

$$\begin{aligned}&-\varepsilon^{2m}S_2\left\{\frac{1}{4}\frac{\eta^2}{\sqrt{\varphi}}(\varphi+\varepsilon^{2m}\psi)^{-1}(2\varphi'\psi-\varphi\psi)\psi\right\}\\&-\varepsilon^{2m+1}S_1\left\{\frac{3}{4}\eta(\varphi+\varepsilon^{2m}\psi)^{-1}(2\varphi'\psi-\varphi\psi')\psi'\right\}\\&+\varepsilon^{2m+1}S_1\left\{\frac{1}{8}\frac{\eta^2}{\varphi}(\varphi+\varepsilon^{2m}\psi)^{-1}[2\varphi'\psi-\varphi\psi']\psi'\right\}\\&+\varepsilon^{4m+1}S_1\left\{\frac{1}{4}\eta^2(\varphi+\varepsilon^{2m}\psi)^{-2}(2\varphi'\psi-\varphi\psi')(\psi')^2\right\}.\end{aligned}$$

The expression looks very complicated. However, all that matters is the structure. We have to extend somewhat the structure defined in (5.41), and introduce for that purpose

$$\tilde{G}(y,\psi,\psi')=\sum_{l+q=1}^{l+q=3}P_{l,q}(y)(\psi)^l(\psi')^q, \tag{5.47}$$

where $P_{l,q}(y)$ are polynomials in y, which depend on ε in a regular way.

Inverting now fully the equation (5.46) and collecting terms of the same structure, we get

$$\begin{aligned}\psi'=\psi_0'&+\varepsilon S_1[\tilde{G}_1(\eta,\psi,\psi')]+\varepsilon^{2m-1}S_1[(\varphi+\varepsilon^{2m}\psi)^{-1}\tilde{G}_2(\eta,\psi,\psi')]\\&+\varepsilon^{2m}S_2[\varphi^{-1/2}(\varphi+\varepsilon^{2m}\psi)^{-1}\tilde{G}_3(\eta,\psi,\psi')]\\&+\varepsilon^{2m+1}S_1[\varphi^{-1}(\varphi+\varepsilon^{2m}\psi)^{-1}\tilde{G}_4(\eta,\psi,\psi')]\\&+\varepsilon^{4m+1}S_1[(\varphi+\varepsilon^{2m}\psi)^{-2}\tilde{G}_5(\eta,\psi,\psi')],\end{aligned} \tag{5.48}$$

where

$$\psi_0'=\frac{1}{\varepsilon}S_1[\bar{f}^1 1]=\bar{f}^1+O(\varepsilon). \tag{5.49}$$

5.4. The contraction mapping. We collect our result in the following form:

$$\psi=\psi_0+\varepsilon S_1[P_1(\eta,\psi,\psi')]+\varepsilon S_2[P_2(\eta,\psi,\psi')], \tag{5.50}$$

$$\psi'=\psi_0'+\varepsilon S_1[\tilde{P}_1(\eta,\psi,\psi')]+\varepsilon S_2[\tilde{P}_2(\eta,\psi,\psi')]. \tag{5.51}$$

The expressions for $P_{1,2}$ and $\tilde{P}_{1,2}$ are explicitly given in (5.43) and (5.48).

Let $\mathcal{T}$ be an interval $y\in[0,y_0]$, and consider pairs of functions $f, g\in C(\mathcal{T})$. We define a mapping T, with components $T^{(1)}$, $T^{(2)}$, by the following formulas:

$$\begin{aligned}T^{(1)}(f,g)&=\psi_0+\varepsilon S_1[P_1(\eta,f,g)]+\varepsilon S_2[P_2(\eta,f,g)],\\T^{(2)}(f,g)&=\psi_0'+\varepsilon S_1[\tilde{P}_1(\eta,f,g)]+\varepsilon S_2[\tilde{P}_2(\eta,f,g)].\end{aligned} \tag{5.52}$$

The operators S_1, S_2 map continuous functions into continuous functions, so we must assure that $P_{1,2}(\eta,f,g)$ and $\tilde{P}_{1,2}(\eta,f,g)$ are continuous functions. A glance at (5.48) shows that for that purpose the interval $\mathcal{T}$ must be restricted so that

$$\varphi(y)\geqq c\varepsilon^{2m-1},\quad c>0\quad \text{for } y\in\mathcal{T}. \tag{5.53}$$

We consider now T as an operator in the Banach space of pairs of continuous functions (f,g), equipped with the usual norm

$$\sup_{\mathcal{T}}|f|+\sup_{\mathcal{T}}|g|.$$

In that space we consider balls $\mathbb{B}_\varepsilon$ that are centered at the pair ψ_0, ψ_0' and have a radius $\varepsilon^{1-\mu}$, with μ positive and arbitrarily small, i.e., the radius is slightly larger than ε. We want T to map the balls into themselves. With the estimate (5.38) it follows that we must have $P_{1,2}(\eta, f, g) = O(1)$ and $\tilde{P}_{1,2}(\eta, f, g) = 0(1)$. Analysis of the different terms in (5.48) produces a further and more severe restriction on the interval $\mathcal{T}$:

$$\varphi(y) \geqq c\varepsilon^m, \quad c > 0 \quad \text{for } y \in \mathcal{T} \tag{5.54}$$

and side condition

$$m \geqq 2. \tag{5.55}$$

It is now straightforward to show that T is a contraction mapping in $\mathbb{B}_\varepsilon$, that is, for any pair of pairs $(f_1, g_1), (f_2, g_2) \in \mathbb{B}_2$ we have

$$|T^{(1,2)}(f_1, g_1) - T^{(1,2)}(f_2, g_2)| \leqq \varepsilon C\{\sup (f_1 - f_2) + \sup (g_1 - g_2)\} \tag{5.56}$$

with C a constant independent of ε.

Let us show how the analysis runs on a representative term of (5.48). We consider

$$\begin{aligned} &\varepsilon|\varepsilon^{2m} S_1[\varphi^{-1}(\varphi + \varepsilon^{2m} f_1)^{-1} \tilde{G}(\eta, f_1, g_1) - \varphi^{-1}(\varphi + \varepsilon^{2m} f_2)^{-1} \tilde{G}(\eta, f_2, g_2)]| \\ &\leqq \varepsilon \frac{\varepsilon^{2m}}{y^2} \int_0^y \frac{\eta}{\sqrt{\varphi}} \frac{(\varphi + \varepsilon^{2m} f_1)^{-1}}{\varphi} |\tilde{G}(\eta, f_1, g_1) - \tilde{G}(\eta, f_2, g_2)|\, d\eta \\ &\quad + \varepsilon \frac{\varepsilon^{2m}}{y^2} \int_0^y \frac{\eta}{\sqrt{\varphi}} \cdot \frac{1}{\varphi} |\tilde{G}(\eta, f_2, g_2)| \cdot \left| \frac{1}{\varphi + \varepsilon^{2m} f_1} - \frac{1}{\varphi + \varepsilon^{2m} f_2} \right| d\eta. \end{aligned}$$

In the first term it is sufficient to remark that $\tilde{G}(\eta, f, g)$ of the structure (5.47) is Lipschitz-continuous with respect to f and g. Hence this term is bounded by

$$\varepsilon \frac{1}{y^2} \int_0^y \frac{\eta}{\sqrt{\varphi}} d\eta \cdot \sup \frac{\varepsilon^{2m}}{(\varphi + \varepsilon^{2m} f_1)\varphi} \cdot C\{\sup |f_1 - f_2| + \sup |g_1 - g_2|\}.$$

Due to condition (5.54) it follows that

$$\sup \frac{\varepsilon^{2m}}{\varphi + \varepsilon^{2m} f_1} \cdot \frac{1}{\varphi} = O(1),$$

so that the term is finally bounded by

$$\varepsilon C\{\sup |f_1 - f_2| + \sup |g_1 - g_2|\}$$

with C a constant independent of ε.

The second term of the inequality that we study is straightforward. The term is bounded by

$$\varepsilon \frac{1}{y^2} \int_0^y \frac{\eta}{\sqrt{\varphi}} d\eta \cdot \sup \frac{\varepsilon^{4m}}{\varphi} (\varphi + \varepsilon^{2m} f_1)^{-1} (\varphi + \varepsilon^{2m} f_2)^{-1} \cdot \sup |f_1 - f_2|.$$

With the condition (5.54) we find a much stronger contraction, i.e., the term is bounded by

$$\varepsilon^{1+m} \cdot C \cdot \sup |f_2 - f_2|$$

with C independent of ε.

The reader can easily be convinced that the term we have considered is indeed representative, that is, that other terms can be analysed by a completely analogous procedure.

Having demonstrated the contraction property of the mapping T, we have proved that there exists a unique solution $\psi(y)$, $\psi'(y)$ of (5.50), (5.51) in an interval $\mathcal{T}$ limited by the condition (5.54) and that, moreover,

$$\begin{aligned} \psi &= \psi_0 + O(\varepsilon), \\ \psi' &= \psi_0' + O(\varepsilon). \end{aligned} \tag{5.57}$$

This concludes the proof of the result announced in § 4 of this paper.

6. Generalizations: perturbed model problems. Let us call the problem (1.1) a model problem and consider perturbations of it, which are of the structure

$$\varepsilon^2 \frac{d^4 y}{dx^4} + \frac{d^2 y}{dx^2} - y + y^2 = \varepsilon^2 \mathcal{P}\left(y, \frac{dy}{dx}, \frac{d^2 y}{dx^2}; \varepsilon\right). \tag{6.1}$$

More precisely, we shall look at perturbations given by

$$\mathcal{P} = X_1(y)\left(\frac{dy}{dx}\right)^2 + yX_2(y)\frac{d^2 y}{dx^2} + X_3(y)\left(\frac{dy}{dx}\right)^2 \frac{d^2 y}{dx^2} + X_4(y)\left(\frac{d^2 y}{dx^2}\right)^2, \tag{6.2}$$

where $X_{1,2,3,4}(y)$ are polynomials in y. These functions may further depend on ε, but in a regular way.

The special structure of the coefficient of the d^2y/dx^2 is motivated by the consideration that a coefficient that would not be zero at $y = 0$ could be absorbed in the left-hand side.

We shall follow in main lines the method of analysis of the proceeding sections when applied to (6.1), (6.2).

Following § 2 we introduce y as an independent variable. The perturbation term becomes

$$\mathcal{P}(y, z, z') = X_1(y)z + \frac{1}{2} yX_2(y)\frac{dz}{dy} + \frac{1}{2} X_3(y)\, z\frac{dz}{dy} + \frac{1}{4} X_4(y)\left(\frac{dz}{dy}\right)^2. \tag{6.3}$$

Instead of the integral (2.4), we shall now have, as a basic equation,

$$\varepsilon^2\left\{z\frac{d^2 z}{dy^2} - \frac{1}{4}\left(\frac{dz}{dy}\right)^2\right\} + z = y^2\left(1 - \frac{2}{3}y\right) + \varepsilon^2 \int_0^y \mathcal{P}(\eta, z, z')\, d\eta. \tag{6.4}$$

It is quite easy to convince ourselves that a straightforward iteration, starting with

$$z_0 = y^2\left(1 - \frac{2}{3}y\right),$$

produces a formal approximation of the structure

$$\Phi_m = y^2\left[1 - \frac{y}{\alpha_m(\varepsilon)}\right] g_m(y, \varepsilon) \tag{6.5}$$

with $g_m(y, \varepsilon)$ a polynomial without zeros for $y \in [1 - (y/\alpha_m(\varepsilon))]$. This can also be seen from the reformulation of the problem

$$z = y^2 \bar{z}, \tag{6.6}$$

which produces the equation

$$\varepsilon^2\left\{y^2\left[\bar{z}\frac{d^2\bar{z}}{dy^2}-\frac{1}{4}\left(\frac{d\bar{z}}{dy}\right)^2\right]+3y\bar{z}\frac{d\bar{z}}{dy}\right\}+\bar{z}(1+\varepsilon^2\bar{z}) \tag{6.7}$$
$$=\left(1-\frac{2}{3}y\right)+\varepsilon^2\frac{1}{y^2}\int_0^y \eta^2\bar{\mathscr{P}}(\eta,\bar{z},\bar{z}')\,d\eta,$$

$$\bar{\mathscr{P}}=\bar{X}_1(y)\bar{z}+\bar{X}_2(y)\bar{z}'+y\bar{X}_3(y)\bar{z}\bar{z}'+y^2\bar{X}_4(y)(\bar{z}^1)^2. \tag{6.8}$$

Clearly, the perturbation term behaves well as $y\to 0$.

We can now introduce

$$\bar{z}=\varphi_m+\varepsilon^{2m}\psi_m \tag{6.9}$$

and formulate the problem for the remainder ψ_m. This will be the equation (4.4) with additional perturbations, which are integrals over functions containing ψ and ψ'.

Suppose now that, as in the model problem, we can prove the existence of a bounded solution $\psi_m(y;\varepsilon)$ on $y\in[0,y_0]$, y_0 being such that

$$|\varphi_m(y;\varepsilon)|\geqq c\varepsilon^m.$$

Can an argument be made on the continuation of the solutions, as at the end of § 4?

Essential for the argument is the sign of the right-hand side of (6.4) in the region of continuation of solution. Let us look at the formal approximation:

$$z=z_0+\varepsilon^2z_1^{(1)}+\varepsilon^2z_1^{(2)}, \tag{6.10}$$

$$z_1^{(1)}=\frac{1}{4}\left(\frac{dz_0}{dy}\right)^2-z_0\frac{d^2z_0}{dy^2}, \tag{6.11}$$

$$z_2^{(2)}=\int_0^y \mathscr{P}(\eta,z_0,z_0')\,d\eta. \tag{6.12}$$

$z_1^{(1)}$ is positive in the ε^2 neighbourhood of $y=3/2$. It follows that the approximation is still valid for y such that $z_0+\varepsilon^2z_1^{(2)}<0$. Hence, the continuation takes place in the region where the right-hand side of (6.4) is negative, and this is sufficient for the line of reasoning as given at the end of § 4.

We now turn to the construction of a contraction mapping. The problem for ψ is not essentially changed by the addition of the perturbation integral. Crucial is the problem for ψ'. In § 5.1 we have formulated that problem by differentiating the equation for the ψ problem. However, we can also differentiate first the equation for $\bar{z}$ and introduce the formal approximation with remainder term (6.9) afterwards.

We obtain in this way the equation

$$\varepsilon^2\left\{y^2\bar{z}\frac{d^2}{dy^2}(\bar{z}')+\left(\frac{1}{2}y^2\bar{z}'+5y\bar{z}\right)\frac{d}{dy}(\bar{z}')\right\} \tag{6.13}$$
$$+(\bar{z}')+\varepsilon^2\left(5\bar{z}\bar{z}'+\frac{5}{2}y(\bar{z}')^2\right)=-\frac{2}{3}+\varepsilon^2\frac{d}{dy}\frac{1}{y^2}\int_0^y \eta^2\bar{\mathscr{P}}(\eta,\bar{z},\bar{z}')\,d\eta.$$

For any pair of continuous functions $\bar{z}$, $\bar{z}'$ the perturbation term is a continuous function of y on an interval containing the origin. Furthermore, and this is the essential point, the perturbation does not introduce any new terms with the derivatives of $\bar{z}'$. This means that the construction of § 5 can be carried out, the only complication being the bookkeeping of more perturbation terms.

We thus arrive at the conclusion that *the main results of* § 4 *hold for the perturbed problem* (6.1), (6.2).

Let us finally look briefly at perturbations that affect the fourth-order derivative. For example, let us consider

$$\varepsilon^2\left\{1+\varepsilon^2 X_0(y)\frac{d^2y}{dx^2}\right\}\frac{d^4y}{dx^2}+\frac{d^2y}{dx^2}-y+y^2=\varepsilon^2\mathcal{P}\left(y,\frac{dy}{dx},\left(\frac{d^2y}{dx}\right)^2\right), \tag{6.14}$$

where $X_0(y)$ again is a polynomial. Moving the new perturbation to the right-hand side will certainly produce severe trouble in the course of the analysis. However, we can get away with a trick similar to the one used in § 5.3.2.

Multiplying by $\{1+\varepsilon^2X_0(d^2y/dx^2)\}^{-1}$ and using, whenever convenient, the identity

$$\left(1+\varepsilon^2X_0\frac{d^2y}{dx^2}\right)^{-1}=1-\varepsilon^2X_0\frac{d^2y}{dx^2}\left\{1+\varepsilon^2X_0\frac{d^2y}{dx^2}\right\}^{-1},$$

we find

$$\varepsilon^2\frac{d^4y}{dx^4}+\frac{d^2y}{dx^2}-y+y^2=\varepsilon^2\left\{1+\varepsilon^2X_0(y)\frac{d^2y}{dx^2}\right\}^{-1}\tilde{\mathcal{P}}\left(y,\frac{dy}{dx},\frac{d^2y}{dx^2}\right), \tag{6.15}$$

where $\tilde{\mathcal{P}}$ is again an expression of the structure (6.2).

The equation (6.15) does not seem to introduce any new fundamental difficulty into the problem, and the main line of analysis of this paper can again be followed. However, bookkeeping may become extremely cumbersome, even on the level of construction of formal approximations. The most efficient way to attack the problem is probably to use (6.14) as a starting point for the construction of formal approximation and (6.15) for the purpose of constructing the proof of validity. It is beyond the ambitions of this paper to perform all the necessary calculations.

Appendix. Computation of oscillatory integrals. (By N. Temme, C. W. I., Amsterdam.) In this appendix we evaluate two integrals that occur in the analysis of § 4.2. First we consider

$$I^{(1)}(\varepsilon)=\frac{1}{\varepsilon^2}\int_{-\infty}^{0}\cos\left(\frac{1}{\varepsilon}\xi\right)[y^{(1)}(\xi)-(y^{(1)}(\xi))^2]\,d\xi, \tag{A.1}$$

where

$$y^{(1)}(x)=\frac{3}{2}\operatorname{sech}^2\left(\frac{1}{2}x\right)=\frac{3}{\cosh x+1}, \tag{A.2}$$

which is a first-order approximation of the reduced equation (1.1), that is, a symmetric solution of the equation

$$\frac{d^2y^{(1)}}{dx^2}=y^{(1)}(1-y^{(1)}),\qquad x\in\mathbb{R}. \tag{A.3}$$

Using (A.3), we can write (A.1) in the form

$$I^{(1)}(\varepsilon)=\frac{1}{\varepsilon^2}\int_{-\infty}^{0}\cos\left(\frac{1}{\varepsilon}\xi\right)\frac{d^2y^{(1)}}{d\xi^2}\,d\xi,$$

and integrating by parts we find

$$I^{(1)}(\varepsilon)=-\frac{1}{\varepsilon^4}\int_{-\infty}^{0}\cos\left(\frac{1}{\varepsilon}\xi\right)y^{(1)}(\xi)\,d\xi=-\frac{1}{2\varepsilon^4}\int_{-\infty}^{\infty}e^{i\xi/\varepsilon}y^{(1)}(\xi)\,d\xi.$$

Integrals of this type can be evaluated by using residues. Here we express the integral in terms of the Euler beta function. The substitutions $\xi = ln\, u$, $u = t/(1-t)$ yield

$$I^{(1)}(\varepsilon) = -\frac{3}{\varepsilon^4}\int_0^\infty \frac{u^{i/\varepsilon}\, du}{(u+1)^2} = -\frac{3}{\varepsilon^4}\int_0^1 t^{i/\varepsilon}(1-t)^{-i/\varepsilon}\, dt = -\frac{3}{\varepsilon^4}\frac{\Gamma(1+i/\varepsilon)\Gamma(1-i/\varepsilon)}{\Gamma(2)}.$$

Using the reflection formula of the gamma function [9],

$$\Gamma(1+z)\Gamma(1-z) = \frac{\pi z}{\sin(\pi z)},$$

we finally obtain

$$I^{(1)}(\varepsilon) = -\frac{3\pi}{\varepsilon^5 \sinh(\pi/\varepsilon)}. \tag{A.4}$$

The second integral to be evaluated is

$$I^{(2)}(\varepsilon) = \frac{1}{\varepsilon^2}\int_{-\infty}^0 \cos\left(\frac{1}{\varepsilon}\xi\right) y^{(2)}(\xi)[1-y^{(2)}(\xi)]\, d\xi \tag{A.5}$$

with

$$y^{(2)}(x) = \frac{3\lambda(1-\varepsilon^2)}{\cosh(x\sqrt{1-\varepsilon^2}) + \lambda(1-5\varepsilon^2)}, \qquad \lambda = \frac{1}{\sqrt{1+5\varepsilon^2+10\varepsilon^4}}. \tag{A.6}$$

The approximation $y^{(2)}$ is obtained by expanding the solution of the z-equation

$$\varepsilon^2\left[zz'' - \frac{1}{4}(z')^2\right] + z = y^2 - \frac{2}{3}y^3, \quad \sqrt{z} = \frac{dy}{dx}, \quad z' = \frac{dz}{dy}, \quad z'' = \frac{d^2z}{dy^2},$$

in a series $z \sim z_0 + \varepsilon^2 z_1 + \varepsilon^4 z_2 + \cdots$, which gives

$$z_0 = y^2 - \tfrac{2}{3}y^3, \qquad z_1 = \tfrac{1}{4}(z_0')^2 - z_0 z_0'' = -\tfrac{1}{3}y^2(3 - 10y + 5y^2).$$

For $y^{(2)}(x)$ we obtain the equation

$$\frac{dy^{(2)}}{dx} = \sqrt{z_0 + \varepsilon^2 z},$$

with the symmetric solution (A.6). Observe that

$$\lim_{\varepsilon \downarrow 0} y^{(2)}(x) = y^{(1)}(x).$$

For the evaluation of (A.5) we need integrals of the type

$$J_k(a,\gamma) = \int_0^\infty \frac{\cos ax}{(\cosh x + \cos\gamma)^k}\, dx = \frac{1}{2}\int_{-\infty}^\infty \frac{e^{iax}}{(\cosh x + \cos\gamma)^k}\, dx, \qquad k = 1, 2, \tag{A.7}$$

where $\gamma \in (-\pi, \pi)$, and a is a complex number in the strip $|\mathrm{Im}\, a| < k$. Let $k = 1$ and take in the second integral $x = ln\, t$; then

$$J_1(a,\gamma) = \int_0^\infty \frac{t^{ia}}{(t+e^{i\gamma})(t+e^{-i\gamma})}\, dt$$

$$= \frac{e^{i\gamma}}{2i\sin\gamma}\int_0^\infty \frac{t^{ia-1}}{t+e^{i\gamma}}\, dt - \frac{e^{-i\gamma}}{2i\sin\gamma}\int_0^\infty \frac{t^{ia-1}}{t+e^{-i\gamma}}\, dt.$$

Note that when a is real, two divergent integrals appear. However, to ensure convergence in both integrals, we temporarily assume that $-1<\operatorname{Im} a<0$. By putting $t=se^{i\gamma}$, $t=se^{-i\gamma}$, respectively, and using standard methods for complex integrals, both integrals can be combined into

$$J_1(a,\gamma)=\frac{e^{-a\gamma}-e^{a\gamma}}{2i\sin\gamma}\int_0^\infty \frac{s^{ia-1}}{s+1}\,ds,$$

which again can be expressed in terms of gamma functions. The result is

$$J_1(a,\gamma)=\frac{\pi\sinh(a\gamma)}{\sin\gamma\sinh(\pi a)},\tag{A.8}$$

derived under the condition $-1<\operatorname{Im} a<0$. Since both of these final expressions for $J_1(a,\gamma)$ and the integral representation of $J_1(a,\gamma)$ in (A.7) are analytic functions of a in the strip $|\operatorname{Im} a|<1$, we conclude that (A.8) also holds in this strip. Especially, it is valid for real values of a.

By splitting $(t+e^{i\gamma})^{-2}(t+e^{-i\gamma})^{-2}$ into partial fractions, the evaluation of $J_2(a,\gamma)$ can be done in the same manner. However, by differentiating $J_1(a,\gamma)$ of (A.7) with respect to γ, we can derive the desired result in a straightforward way; it is easily verified that the conditions for this approach are satisfied (see [9, par. 4.44]). In doing so we obtain

$$J_2(a,\gamma)=\frac{1}{\sin\gamma}\frac{\partial J_1(a,\gamma)}{\partial\gamma}=\frac{\pi}{\sinh(a\gamma)\sin^3\gamma}[a\sin\gamma\cosh(a\gamma)-\cos\gamma\sinh(a\gamma)].$$

We return to the evaluation of (A.5), and we use the integrals J_k of (A.7):

$$I^{(2)}(\varepsilon)=\frac{1}{\varepsilon^2}3\lambda\sqrt{1-\varepsilon^2}\,[J_1(a,\gamma)-3\lambda(1-\varepsilon^2)J_2(a,\gamma)],\tag{A.9}$$

where

$$a=\frac{1}{\varepsilon\sqrt{1-\varepsilon^2}}\qquad \cos\gamma=\lambda(1-5\varepsilon^2).\tag{A.10}$$

We prescribe that γ is positive and tending to zero as $\varepsilon\to0$. Furthermore, $\sin\gamma=\varepsilon\lambda\sqrt{15(1-\varepsilon^2)}$. It follows that

$$I^{(2)}(\varepsilon)=\frac{1}{\varepsilon^2}\frac{9\lambda^2\pi(1-\varepsilon^2)^{3/2}}{\sin^3\gamma\sinh(\pi a)}[\lambda\sinh(a\gamma)-a\sin\gamma\cosh(a\gamma)].\tag{A.11}$$

It is interesting to compare this result with (A.4), since we may expect that $I^{(2)}(\varepsilon)\sim I^{(1)}(\varepsilon)$ as $\varepsilon\to0$. Recalling that both a and γ depend on ε, we first consider a fixed (i.e., independent of ε). Letting $\varepsilon\to0$ (and hence $\gamma\to0$), we have

$$\frac{\lambda\sinh(a\gamma)-a\sin\gamma\cosh(a\gamma)}{\sin^3\gamma}\sim-\frac{1}{3}a^3+\frac{1}{6}a.\tag{A.12}$$

Substituting this in (A.11), we obtain

$$I^{(2)}(\varepsilon)\sim-\frac{3a^3\pi(1-\frac{1}{2}a^{-2})}{\varepsilon^2\sinh(\pi a)},\tag{A.13}$$

which indeed resembles (A.4), when $a=1/\varepsilon$, which, of course, is not allowed in (A.12). When we consider (A.11) with the true value of a given in (A.10), that is, with $a\sin\gamma=\lambda\sqrt{15}$, the representation of $I^{(2)}$ becomes

$$I^{(2)}(\varepsilon)=\frac{9\lambda^3\pi(1-\varepsilon^2)^{3/2}}{\varepsilon^2\sin^3\gamma\sinh(\pi a)}[\sinh(a\gamma)-\sqrt{15}\cosh(a\gamma)],\tag{A.14}$$

with $a\gamma \sim \sqrt{15}$ as $\varepsilon \to 0$. It follows that the ratio $I^{(2)}(\varepsilon)/I^{(1)}(\varepsilon)$ does not tend to unity when $\varepsilon \to 0$. The limit of the ratio is about 3.6.

Acknowledgments. The subject of this paper was suggested to me by Klaus Kichgässner in a casual conversation. I am grateful to him for this source of mathematical excitement and for the lengthy discussions of my work later on. After the main body of the paper was completed Klaus sent me the preprint of Amick and McLeod [1]. In an exchange of letters, Charles Amick drew my attention to the paper of Hammersley and Mazzarino [4]. I have attempted to link, whenever appropriate, certain steps of my analysis to the contents of these papers, through remarks added in the text.

I gratefully acknowledge the contribution of Nico Temme, of the C.W.I., Amsterdam, who is responsible for the analysis given in the Appendix.

UNFOLDING A POINT OF DEGENERATE HOPF BIFURCATION IN AN ENZYME-CATALYZED REACTION MODEL*

BRIAN HASSARD† AND KATIE JIANG‡

Abstract. A point of degenerate Hopf bifurcation in an enzyme-catalyzed model previously studied by Doedel [2] is rigorously analyzed by using techniques of singularity theory and interval analysis. A computation using interval analysis proves the existence of a point of degenerate Hopf bifurcation, which is a smooth function of additional parameters in the model system. Singularity theory as developed by Golubitsky and Langford [*J. Differential Equations*, 3 (1981), pp. 375-415.] and Golubitsky and Schaeffer [*Singularities and Groups in Bifurcation Theory* I, Springer-Verlag, New York, 1985.] is then used to construct universal unfoldings of the degeneracy, to completely characterize the families of small amplitude periodic solutions that arise for parameters near the degenerate values. Computations using interval analysis are employed in this proof. Excellent agreement is found between the bifurcation theoretic unfolding and (numerical) continuation results using pseudoarclength continuation.

1. Introduction. In this paper we study a mathematical model of an enzymatically active system. Enzymes are molecules that catalyze the biochemical reactions in the metabolic pathways of living organisms. The complexity of living cells is such that it is difficult to model the whole system where so many phenomena take place, including enzyme reactions and various types of transport, e.g., by diffusion, electrical migration, and convection. In the model we consider, the enzymes are physically confined in one compartment, i.e., the model is an "immobilized" enzyme system. Such models are used to study the interaction of enzyme reaction and diffusion in a well-defined context. The interaction produces oscillations.

The concentration of two chemical species in a single compartment can be modeled by a system of two ordinary differential equations that describes the change of these concentrations in the presence of an enzyme-catalyzed reaction inside the compartment with transport from an outside reservoir called the S-A system:

$$\begin{aligned}\frac{ds}{dt}&=(s_0-s)-\rho R(s,a),\\ \frac{da}{dt}&=\alpha(a_0-a)-\rho R(s,a).\end{aligned}\tag{1}$$

Here s and a denote the concentrations of the two chemical species S and A inside the compartment. S stands for "substrate" and A for "activator" though both are substrates in a reaction where they are consumed. This reaction is catalyzed by an enzyme with reaction rate proportional to

$$R(s,a)=\frac{sa}{(1+s+\kappa s^2)},\qquad \kappa>0.\tag{2}$$

The parameter ρ is a ratio of characteristic times, $\rho = \theta_T/\theta_R$, where θ_R is the characteristic time of diffusion of s from the outside reservoir into the compartment and θ_T is the characteristic time of the enzyme reaction; the terms $(s_0 - s)$ and $\alpha(a_0 - a)$ describe the transport from the outside reservoir where the concentrations are held at a constant s_0 and a_0. The parameter α represents the ratio of diffusion coefficients between the reservoir and the compartment, the parameters s_0, a_0, ρ, α, and κ are all dimensionless and positive as are the state variables s and a.

Doedel [2] used purely numerical techniques to demonstrate the birth of isolas of periodic solutions in the S-A system as the two parameters ρ and s_0 are varied. With ρ as the bifurcation parameter, his results suggest that there is a value s_0^d such that for s_0 slightly less than s_0^d, a branch of periodic solutions arises from the stationary branch in a Hopf bifurcation, and returns to the stationary branch at a second point of Hopf bifurcation. While for s_0 slightly greater than s_0^d, there is an isola (an isolated branch of periodic solutions) and no Hopf bifurcation from the stationary branch. We shall show that for $s_0 = s_0^d$, the S-A system exhibits degenerate Hopf bifurcation.

The purpose of the present paper is to analyze the birth of isolas in the S-A system by means of singularity theory and to compare the approximate bifurcation diagrams obtained from unfolding the point of degenerate Hopf bifurcation with "actual" diagrams obtained using Doedel's code AUTO [2].

The technique we apply involves first a nonlinear change of variables taking the S-A system into Poincare-Birkhoff normal form [6], followed by application of Lyapunov-Schmidt reduction as was done in [3], [5]. The degenerate Hopf bifurcation is classified using singularity theory [4], [5]. We then unfold the degeneracy with respect to the parameter s_0.

2. Location of the point of degenerate Hopf bifurcation.

2.1. Selection of s_* as bifurcation parameter. We choose to use s_*, the s-component of the stationary solution, as bifurcation parameter rather than ρ as in [2]. Then a_*, the a-component of the stationary solution, is uniquely defined by

$$a_* = a_0 + (s_* - s_0)/\alpha,$$

and the parameter ρ is replaced by

$$\rho_* = (s_0 - s_*)/R(s_*, a_*).$$

The advantage in selecting s_* as the bifurcation parameter is that the stationary solution is simple and uniquely defined as a function of s_*, whereas with ρ as the bifurcation parameter, there may be up to three distinct stationary solutions. We note that as a function of s_*, ρ_* has poles at 0 and $s_0 - \alpha a_0$. Since $a_* = a_0 + (s_* - s_0)/\alpha$, while s_* and a_* are equilibrium values of concentrations of chemical species, for physical meaning both $s_* > 0$, and $a_* > 0$; thus $s_* > \max(0, s_0 - \alpha a_0)$, which avoids the poles of ρ_*. Also, for physical reasons $\rho > 0$. Since $\kappa > 0$, $1 + s_* + \kappa s_*^2 > 0$ and $R(s_*, a_*) > 0$ for all $s_* > 0$. The inequality $\rho_* > 0$, therefore, further restricts $s_* < s_0$.

2.2. Linear stability analysis for stationary solution. The Jacboian matrix for the S-A system at the stationary solution (s_*, a_*) is

$$\left.\begin{bmatrix} -1 - \rho_* \partial R/\partial s & -\rho_* \partial R/\partial a \\ -\rho_* \partial R/\partial s & -\alpha - \rho_* \partial R/\partial a \end{bmatrix}\right|_{(s,a)=(s_*,a_*)}, \tag{3}$$

where $\partial R/\partial s = a(1 - \kappa s^2)/(1 + s + \kappa s^2)^2$ and $\partial R/\partial a = s/(1 + s + \kappa s^2)$. The linear stability of (s_*, a_*) is then determined by the real parts of the eigenvalues λ of this matrix, which satisfy the characteristic equation

$$\lambda^2 + (1 + \alpha + \rho_* \partial R/\partial s + \rho_* \partial R/\partial a)\lambda + (\alpha + \rho_* \partial R/\partial a + \alpha \rho_* \partial R/\partial s) = 0$$

We are primarily interested in the case of complex eigenvalues $\lambda = \sigma \pm i\omega$, where

$$\sigma = -\tfrac{1}{2}(1 + \alpha + \rho_* \partial R/\partial s + \rho_* \partial R/\partial a),$$
$$\omega^2 = (\alpha + \rho_* \partial R/\partial a + \alpha \rho_* \partial R/\partial s) - \sigma^2 > 0.$$

At points of Hopf bifurcation, critical values s_*^c of the bifurcation parameter must satisfy $\sigma(s_*^c, s_0) = 0$, where

$$\begin{aligned}\sigma(s_*, s_0) &= -(1 + \alpha + (s_0 - s_*)(1/a_* + (1 - \kappa s_*^2)/s_*(1 + s_* + \kappa s_*^2)))/2\\ &= (A(s_*)s_0^2 + B(s_*)s_0 + C(s_*))/D(s_*, s_0),\end{aligned}$$

where we define

$$\begin{aligned}A(s_*) &= \kappa s_*^2 - 1,\\ B(s_*) &= -3\kappa s_*^3 - (a_0\alpha\kappa + 1)s_*^2 + s_* + a_0\alpha,\\ C(s_*) &= 2\kappa s_*^4 + (1 + (a_0\alpha^2 + 2a_0\alpha)\kappa)s_*^3 + (a_0\alpha^2 + a_0\alpha)s_*^2 + a_0\alpha^2 s_*,\\ D(s_*, s_0) &= 2[(\kappa s_*^3 + s_*^2 + s_*)s_0 - \kappa s_*^4 - (a_0\alpha\kappa + 1)s_*^3 - (a_0\alpha + 1)s_*^2 - a_0\alpha s_*].\end{aligned}$$

Figures 4.5 and 4.6 of [2] suggest the existence of values (s_*^d, s_0^d) (d for degenerate) such that for s_0 slightly less than s_0^d, two distinct Hopf bifurcations occur at points $s_*^{(1)}, s_*^{(2)}$ close to s_*^d and obey $s_*^{(1)} < s_*^d < s_*^{(2)}$, that is,

$$\sigma(s_*^{(1)}(s_0), s_0) = \sigma(s_*^{(2)}(s_0), s_0) = 0,$$

and as $s_0 \to s_0^d$, the points $s_*^{(1)}(s_0)$ and $s_*^{(2)}(s_0)$ coalesce.

Assuming $\sigma(s_*, s_0)$ is smooth in a neighborhood of the supposed degenerate point (s_*^d, s_0^d), we therefore expect both $\sigma = \partial\sigma/\partial s_* = 0$ at (s_*^d, s_0^d), that is,

$$A(s_*^d)(s_0^d)^2 + B(s_*^d)s_0^d + C(s_*^d) = A'(s_*^d)(s_0^d)^2 + B'(s_*^d)s_0^d + C'(s_*^d) = 0.$$

In Lemmas 1 and 2 we shall prove the existence of such a degenerate point (s_*^d, s_0^d), and justify the smoothness assumption by showing $D(s_*^d, s_0^d) \neq 0$.

The present work depends on numerical computations of degenerate value s_*^d of the bifurcation parameter, and of various other expressions at this point. We state the numerical results in the form of lemmas. In Lemma 1, $s_*^d(500, 0.2, 0.1)$ is given to a relatively high degree of precision because there will be loss of precision in the subsequent computations leading to the coefficient a_1 in Lemma 3. For the same reason, the rectangle R_0 is chosen small: we return to this subject in the discussion.

LEMMA 1. *There is a smooth function* $s_*^d(a_0, \alpha, \kappa)$ *defined for all* (a_0, α, κ) *in the rectangle* $R_0 = \{|a_0 - 500| \leqq 10^{-14},\ |\alpha - 0.2| \leqq 10^{-16},\ |\kappa - 0.1| \leqq 10^{-16}\}$ *and obeying* $|s_*^d - 25.508771186| \leqq 10^{-9}$, *such that* $s_* = s_*^d(a_0, \alpha, \kappa)$ *is a simple zero of the polynomial equation*

$$P(s_*; a_0, \alpha, \kappa) = A'(A'C - AC')^2 - B'(A'B - AB')(A'C - AC') + C'(A'B - AB')^2 = 0.$$

Furthermore, $s_*^d(500, 0.2, 0.1)$ *is in the interval* $25.50877118629661337716 \pm 0.5 \times 10^{-20}$.

Proof. MACSYMA was used to generate analytical expressions for the coefficients of the powers of s_* in $P(s_*; a_0, \alpha, \kappa)$; see Appendix B. P is the numerator of the rational function obtained by substituting $-(A'C - AC')/(A'B - AB')$ for s_0 in the expression $A'(s_0)^2 + B's_0 + C'$. At $a_0 = 500$, $\alpha = 0.2$, $\kappa = 0.1$, in particular

$$\begin{aligned}P(s_*; 500, 0.2, 0.1) = {}&0.00004s_*^{11} - 0.0104s_*^{10} + 0.2436s_*^9 + 0.316s_*^8 - 10.78s_*^7 - 9.2s_*^6\\ &+ 178.28s_*^5 - 114s_*^4 - 3616s_*^3 - 5920s_*^2 - 480s_*,\end{aligned}$$

where each coefficient is exact.

The version of the Bairstow algorithm as implemented by Aberth in Precision BASIC (program POLY [1]) then was used to compute all zeros of $P(s_*; 500, 0.2, 0.1)$. Fixed decimal format with 20 decimal digits was specified. The program found four complex zeros and seven real zeros, including the zero $s_* = 25.50877118629661337716$ correctly rounded to 20 decimal places. Since 11 distinct zeros were found and the polynomial $P(s_*)$ is of degree 11, the zero given above is necessarily simple. Since Aberth's program, when it succeeds, gives correctly rounded results, the zero $s_*^d(500, 0.2, 0.1)$ is known to lie in the stated interval.

To show the existence of the smooth function $s_*^d(a_0, \alpha, \kappa)$, we evaluated $P'(s_*, a_0, \alpha, \kappa)$ at the ranged values $s_* = 25.508771186 \pm 10^{-9}$, $a_0 = 500 \pm 10^{-14}$, $\alpha = 0.2 \pm 10^{-16}$, and $\kappa = 0.1 \pm 10^{-16}$, and found that $P' < 0$, i.e., both ends of the interval representing P', were negative. We then evaluated $P(25.508771185;\ a_0, \alpha, \kappa)$ and $P(25.508771187;\ a_0, \alpha, \kappa)$ for the same ranged values of a_0, α, and κ, and found that P changes sign. Thus for all (a_0, α, κ) in R_0, P has a simple zero $s_*^d(a_0, \alpha, \kappa)$ obeying $|s_*^d - 25.508771186| \leqq 10^{-9}$. Smoothness of $s_*^d(a_0, \alpha, \kappa)$ follows from the implicit function theorem. □

LEMMA 2. *There is a smooth function $s_0^d(a_0, \alpha, \kappa)$ defined for all (a_0, α, κ) in R_0 and obeying $|s_0^d - 110.474757| \leqq 3 \times 10^{-6}$ such that $(s_*^d(a_0, \alpha, \kappa), s_0^d(a_0, \alpha, \kappa))$ solves the pair of equations $\sigma(s_*, s_0) = \partial\sigma/\partial s_*(s_*, s_0) = 0$. At (s_*^d, s_0^d), $\omega(s_*^d, s_0^d)$ satisfies $|\omega - 0.92965287| \leqq 9.5 \times 10^{-7}$. Furthermore, $s_0^d(500, 0.2, 0.1)$ is in the interval* $110.47475708580432554 \pm 2.9 \times 10^{-17}$.

Proof. MACSYMA was used to generate analytical expressions for $A'C - AC'$, $A'B - AB'$, $s_0^d = -(A'C - AC')/(A'B - AB')$, and D, which were then evaluated using a PBASIC program at the ranged value s_*^d stated in Lemma 1. Output from this program gave

$$-(A'C - AC') = 1.3402397625337886555 2 \times 10^6 \pm 3.0 \times 10^{-14},$$

$$A'B - AB' = 1.2131638012952059610 5 \times 10^4 \pm 3.0 \times 10^{-16},$$

$$s_0^d = 110.47475708580432554 4 \pm 2.9 \times 10^{-17},$$

$$D = -7.0240576831843718 61 \times 10^4 \pm 2.4 \times 10^{-13}.$$

In particular, $s_0^d(500, 0.2, 0.1)$ is well defined. The polynomial equation of degree 11 in Lemma 1 divided by $(A'B - AB')^2$ at s_*^d becomes

$$A'(s_*^d)(s_0^d)^2 + B'(s_*^d)s_0^d + C'(s_*^d) = 0,$$

which implies

$$AA'(s_0^d)^2 + AB's_0^d + AC' = 0.$$

By the definition of s_0^d,

$$AB's_0^d + AC' = A'Bs_0^d + A'C;$$

thus,

$$AA'(s_0^d)^2 + A'Bs_0^d + A'C = 0.$$

Since $A'(s_*^d) = 2\kappa s_*^d \neq 0$,

$$A(s_*^d)(s_0^d)^2 + B(s_*^d)s_0^d + C(s_*^d) = 0.$$

But $\sigma(s_*, s_0)$ is of the form

$$(A(s_*)s_0^2 + B(s_*)s_0 + C(s_*))/D(s_*, s_0),$$

where from above, $D(s_*^d, s_0^d) \neq 0$, so $\sigma(s_*^d, s_0^d)$ and $\partial\sigma/\partial s_*(s_*^d, s_0^d)$ are both well defined: $\sigma(s_*^d, s_0^d) = 0$ and $\partial\sigma/\partial s_*(s_*^d, s_0^d) = 0$ then follow immediately.

To show existence of the smooth function $s_0^d(a_0, \alpha, \kappa)$, we evaluated the analytical expressions for $A'C - AC'$, $A'B - AB'$, s_0^d, and D at the ranged values $s_* = 25.508771186 \pm 10^{-9}$, $a_0 = 500 \pm 10^{-14}$, $\alpha = 0.2 \pm 10^{-16}$, and $\kappa = 0.1 \pm 10^{-16}$ as in Lemma 1. We found that $A'B - AB' > 0$, so $s_0^d(a_0, \alpha, \kappa)$ is well defined and smooth for all (a_0, α, κ) in R_0. We found the ranged value $110.474757 \pm 3 \times 10^{-6}$ for s_0^d, so $|s_0^d(a_0, \alpha, \kappa) - 110.474757| \leqq 3 \times 10^{-6}$ for all (a_0, α, κ) in R_0. Also, we found $D < 0$, which implies as above that $\sigma = \partial\sigma/\partial s_* = 0$ at $(s_*^d(a_0, \alpha, \kappa), s_0^d(a_0, \alpha, \kappa))$.

The formula $\omega^2 = (1-\alpha)((s_0 - s_*)/a_*) - \alpha^2$ was derived from the equations for σ and ω^2 in § 2.2 and the condition $\sigma = 0$. A separate PBASIC program was written to evaluate this formula at the ranged values of a_0, α, s_0^d, and s_*^d given above. Output from this program gave $\omega = 0.92965287 \pm 9.5 \times 10^{-7}$. □

3. Nonlinear analysis.

3.1. Transformation to Poincaré–Birkhoff normal form. First we perform a linear change of variables such that in the new variables y_1, y_2, the Jacobian of the S-A system is in real canonical form. Define

$$P = \begin{bmatrix} 1 & 0 \\ -(1+\sigma+\rho_*\partial R/\partial s)/(\rho_*\partial R/\partial a) & \omega/(\rho_*\partial R/\partial a) \end{bmatrix}.$$

The columns of P are just $\operatorname{Re}(v)$ and $-\operatorname{Im}(v)$, where v is the eigenvector of (3) corresponding to $\lambda = \sigma + i\omega$. Let

$$\begin{bmatrix} s \\ a \end{bmatrix} = \begin{bmatrix} s_* \\ a_* \end{bmatrix} + P \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}.$$

In terms of y_1, y_2, the S-A system becomes

$$\frac{d}{dt}\begin{bmatrix} y_1 \\ y_2 \end{bmatrix} = \begin{bmatrix} f_1 \\ f_2 \end{bmatrix} = P^{-1} F\left(\begin{bmatrix} s_* \\ a_* \end{bmatrix} + P \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}; s_*, s_0\right),$$

where

$$F\left(\begin{bmatrix} s \\ a \end{bmatrix}; s_*, s_0\right) = \begin{bmatrix} s_0 - s - \rho_* R(s, a) \\ \alpha(a_0 - a) - \rho_* R(s, a) \end{bmatrix}.$$

For this new system, the Jacobian at $y_1 = y_2 = 0$ is

$$\begin{bmatrix} \sigma & -\omega \\ \omega & \sigma \end{bmatrix}.$$

It is convenient to let $z = y_1 + iy_2$, $\mu = s_* - s_*^d$, and $\nu = s_0 - s_0^d$ and write the system in the form

$$\dot{z} = (\sigma + i\omega)z + g(z, \bar{z}, \mu, \nu).$$

The derivatives of g at $z = 0$ are related to those of f at $y_1 = y_2 = 0$ by

$$\begin{aligned} g_{jk} &= (\partial/\partial z)^j (\partial/\partial \bar{z})^k g(z, \bar{z}, \mu, \nu)|_{z=\bar{z}=0} \\ &= \left(\frac{1}{2}\left(\frac{\partial}{\partial y_1} - i\frac{\partial}{\partial y_2}\right)\right)^j \left(\frac{1}{2}\left(\frac{\partial}{\partial y_1} + i\frac{\partial}{\partial y_2}\right)\right)^k (f_1(y_1, y_2, \mu, \nu) + if_2(y_1, y_2, \mu, \nu)). \end{aligned}$$

Next, we perform a nonlinear change of variables. Let

$$z=\xi+\chi_{20}\xi^2/2+\chi_{11}\xi\bar{\xi}+\chi_{02}\bar{\xi}^2/2+\chi_{30}\xi^3/6+\chi_{12}\xi^2\bar{\xi}+\chi_{03}\bar{\xi}^3/6,$$

where

$$\begin{aligned}
&\chi_{20}=g_{20}/\lambda,\\
&\chi_{11}=g_{11}/\bar{\lambda},\\
&\chi_{02}=g_{02}/(2\bar{\lambda}-\lambda),\\
&\chi_{30}=3(g_{20}\chi_{20}+g_{11}\bar{\chi}_{02}+g_{30}/3)/2\lambda,\\
&\chi_{12}=(g_{20}\chi_{02}+g_{11}(\bar{\chi}_{20}+2\chi_{11})+2g_{02}\bar{\chi}_{11}+g_{12})/2\bar{\lambda},\\
&\chi_{03}=3(g_{11}\chi_{02}+g_{02}\bar{\chi}_{20}+g_{03}/3)/(3\bar{\lambda}-\lambda).
\end{aligned}$$

In terms of new (complex) variable ξ, the S-A system assumes the Poincaré-Birkhoff (P-B) normal form

$$\dot{\xi}=(\sigma+i\omega)\xi+c(\xi,\bar{\xi}),$$

where

$$c(\xi,\bar{\xi})=c_1(\mu,\nu)\xi^2\bar{\xi}+0(\xi^4)$$

and

$$c_1(\mu,\nu)=[g_{20}g_{11}(2\lambda+\bar{\lambda})/|\lambda|^2+2|g_{11}|^2/\lambda+|g_{02}|^2/(2\lambda-\bar{\lambda})+g_{21}]/2.$$

(The coefficients χ_{20}, χ_{11}, and χ_{02} were chosen to make the quadratic terms of $c(\xi,\bar{\xi})$ vanish, and χ_{30}, χ_{12}, and χ_{03} were chosen to make the coefficients of ξ^3, $\xi\bar{\xi}^2$, and $\bar{\xi}^3$ in $c(\xi,\bar{\xi})$ all vanish. The evaluation of c_1 does not involve χ_{30}, χ_{12}, or χ_{03}.)

3.2. Lyapunov–Schmidt reduction. Letting $\xi=\xi_1+i\xi_2$ and $c_1=a_1+ib_1$, where all of ξ_1, ξ_2, a_1 and b_1 are real, the P-B normal form becomes

$$\begin{bmatrix}\dot{\xi}_1\\ \dot{\xi}_2\end{bmatrix}=\begin{bmatrix}\sigma & -\omega\\ \omega & \sigma\end{bmatrix}\begin{bmatrix}\xi_1\\ \xi_2\end{bmatrix}+\begin{bmatrix}a_1 & -b_1\\ b_1 & a_1\end{bmatrix}\begin{bmatrix}\xi_1(\xi_1^2+\xi_2^2)\\ \xi_2(\xi_1^2+\xi_2^2)\end{bmatrix}+0(\xi^4).$$

When Lyapunov-Schmidt reduction is applied to this form, the results are simple. There are periodic solutions corresponding to solutions of a bifurcation equation

$$r(u,\mu,\nu)x=0,$$

where $u=x^2$, $r(0,0,0)=0$, and the derivatives of r at $(u,\mu,\nu)=(0,0,0)$ are as follows

$$r_u(0,0,0)=-a_1,\quad r_\mu(0,0,0)=\frac{-\partial\sigma}{\partial s_*},\quad r_\nu(0,0,0)=\frac{-\partial\sigma}{\partial s_0},$$

$$r_{\mu\mu}(0,0,0)=\frac{-\partial^2\sigma}{\partial^2 s_*}.$$

The numerical evaluation of these derivatives is the subject of Lemma 3.

LEMMA 3. *For all* (a_0, α, κ) *in* R_0, *at* $(s_*, s_0) = (s^d_*(a_0, \alpha, \kappa), s^d_0(a_0, \alpha, \kappa))$ *the derivatives* $\partial\sigma/\partial s_0$ *and* $\partial^2\sigma/\partial^2 s_*$ *obey* $|\partial\sigma/\partial s_0 + 0.0305303| \leqq 2\times 10^{-6}$, $|\partial^2\sigma/\partial^2 s_* + 0.00369926| \leqq 3\times 10^{-7}$, *and the coefficient* a_1 *obeys* $|a_1 - 0.000212| \leqq 2\times 10^{-5}$. *Furthermore, for* $(a_0, \alpha, \kappa) = (500, 0.2, 0.1)$, *at* $(s_*, s_0) = (s^d_*(a_0, \alpha, \kappa), s^d_0(a_0, \alpha, \kappa))$,

$$\frac{\partial\sigma}{\partial s_0} = -0.030530330090811963\,58 \pm 1.8\times 10^{-19},$$

$$\frac{\partial^2\sigma}{\partial^2 s_*} = -0.003699263408188179\,71 \pm 1.1\times 10^{-19}$$

$$a_1 = 0.0002126442280682 \pm 2.4\times 10^{-15}.$$

Proof. Differentiating the identity

$$D(s_*, s_0)\sigma = A(s_*)s_0^2 + B(s_*)s_0 + C(s_*)$$

with respect to s_0 gives

$$D(s_*, s_0)\partial\sigma/\partial s_0 + \left(\frac{\partial D}{\partial s_0}\right)\sigma = 2s_0 A(s_*) + B(s_*).$$

At $(s_*, s_0) = (s^d_*, s^d_0)$, $\sigma(s^d_*, s^d_0) = 0$, and so

$$\frac{\partial\sigma}{\partial s_0}(s^d_*, s^d_0) = \frac{2s^d_0 A(s^d_*) + B(s^d_*)}{D(s^d_*, s^d_0)}.$$

Similarly, differentiating the identity twice with respect to s_* and using

$$\sigma(s^d_*, s^d_0) = \frac{\partial\sigma}{\partial s_*}(s^d_*, s^d_0) = 0,$$

gives the formula

$$\frac{\partial^2\sigma}{\partial^2 s_0}(s^d_*, s^d_0) = \frac{A''(s^d_*)(s^d_0)^2 + B''(s^d_*)s^d_0 + C''(s^d_*)}{D(s^d_*, s^d_0)}.$$

MACSYMA was used to generate analytical expressions for $\partial\sigma/\partial s_0$ and $\partial^2\sigma/\partial^2 s_*$ at (s^d_*, s^d_0) based upon these two formulas. An analytical formula for $a_1(0,0) = \operatorname{Re} c_1(0,0)$ was derived as follows: expressions for the partial derivatives $f^i_{jk} = \partial^2 f^i/\partial y_j \partial y_k$ and $f^i_{jkm} = \partial^3 f^i/\partial y_j \partial y_k \partial y_m$, $i, j, k, m = 1, 2$ were obtained; in terms of these derivatives,

$$\begin{aligned} g_{11} &= [f^1_{11} + i f^2_{11}]/4, \\ g_{02} &= [f^1_{11} - 2f^2_{12} + i(f^2_{11} + 2f^1_{12})]/4, \\ g_{20} &= [f^1_{11} + 2f^2_{12} + i(f^2_{11} - 2f^1_{12})]/4, \\ g_{21} &= [f^1_{111} + f^2_{112} + i(f^2_{111} - f^1_{112})]/8. \end{aligned}$$

At $(s_*, s_0) = (s^d_*, s^d_0)$, the eigenvalue $\lambda = \sigma + i\omega$ is pure imaginary, and the formula for c_1 simplifies, giving

$$c_1(0,0) = \frac{i}{2\omega_0}\left(g_{20}g_{11} - 2|g_{11}|^2 - \frac{1}{3}|g_{02}|^2\right) + \tfrac{1}{2}g_{21},$$

where $\omega_0 = (\rho_*\partial R/\partial a + \alpha\rho_*\partial R/\partial s)^{1/2}$. Then

$$\begin{aligned} a_1(0,0) = \operatorname{Re} c_1(0,0) &= \frac{1}{2\omega_0}(-\operatorname{Im}(g_{20}g_{11})) + \frac{1}{2}\operatorname{Re} g_{21} \\ &= \frac{-1}{2\omega_0}(\operatorname{Re} g_{20} \operatorname{Im} g_{11} + \operatorname{Im} g_{20} \operatorname{Re} g_{11}) + \tfrac{1}{2}\operatorname{Re} g_{21}. \end{aligned}$$

The formulas leading to a_1 are given in more detail in Appendix B.

A PBASIC program was then used to evaluate the above formulas, first for $(a_0, \alpha, \kappa) = (500, 0.2, 0.1)$ and then for all (a_0, α, κ) in R_0, as in Lemmas 1 and 2. The bounds for $\partial\sigma/\partial s_0, \partial^2\sigma/\partial^2 s_*$, and a_1 stated above were output from this program. □

3.3. Unfolding the degeneracy. From Lemmas 1, 2, and 3 we get the following.

THEOREM. *For each (a_0, α, κ) in R_0, for $s_0 = s_0^d(a_0, \alpha, \kappa)$ the* S-A *system has a degenerate Hopf bifurcation at $s_* = s_*^d(a_0, \alpha, \kappa)$. The form $-X^3 + \Lambda^2 X$ is the normal form for the degeneracy. There is a neighborhood of (s_*^d, s_0^d) such that if $s_0 < s_0^d$ in this neighborhood, there exist Hopf bifurcations at points $s_*^{(1)}, s_*^{(2)}$ obeying $s_*^{(1)} < s_*^d < s_*^{(2)}$. If $s_0 = s_0^d$, there is a degenerate Hopf bifurcation at $s_* = s_*^d$ in which two distinct families of periodic solution arise. If $s_0 > s_0^d$, then for an interval of values of s_*, there is a branch of periodic solutions, locally isolated from the stationary solution. All the local periodic solutions are unstable.*

Proof. By Lemma 3, the bifurcation equation

$$g(x, \lambda, \nu) = r(u, \lambda, \nu)x = 0$$

satisfies

$$r(0,0,0) = -\sigma = 0,$$

$$r_\lambda(0,0,0) = \frac{-\partial\sigma}{\partial s_*}(s_*^d, s_0^d) = 0, \qquad r_\nu(0,0,0) = \frac{-\partial\sigma}{\partial s_0}(s_*^d, s_0^d) > 0,$$

$$r_u(0,0,0) = -a_1(0,0) < 0, \qquad r_{\lambda\lambda}(0,0,0) = \frac{-\partial^2\sigma}{\partial s_4^2}(s_*^d, s_0^d) > 0.$$

From the solution of the recognition problem for Z_2-symmetric bifurcation problems [5, p. 257], it follows that for $\nu = 0$, the singularity at $x = 0$, $\lambda = 0$ is strongly Z_2-equivalent to the normal form $-X^3 + \lambda^2 X$. According to [5, p. 275], a universal unfolding for this normal form is

$$G(X, \Lambda, A) = R(X^2, \Lambda, A)X,$$

where $R(U, \Lambda, A) = -U^2 + \Lambda^2 + A$ and A is the unfolding parameter.

By the strong Z_2-equivalence of $g(x, \lambda, 0)$ and $G(X, \lambda, 0)$ there exist smooth functions $S_0(x, \lambda)$ and $x_0(x, \lambda)$ such that $S_0(-x, \lambda) = S_0(x, \lambda)$, $x_0(-x, \lambda) = -x_0(x, \lambda)$, $S_0(0,0) > 0$, $(\partial x_0/\partial x)(0,0) > 0$, and $G(x, \lambda, 0) = S_0(x, \lambda)g(x_0(x, \lambda), \lambda, 0)$; therefore, $S_0(x, \lambda)g(x_0(x, \lambda), \lambda, \nu)$ is an unfolding of the singularity $G(x, \lambda, 0)$, and as such, may be factored through the universal unfolding $G(X, \Lambda, A)$. That is, there exist smooth functions $S_1(x, \lambda, \nu)$, $X_1(x, \lambda, \nu)$, $\Lambda(\lambda, \nu)$, such that

$$S_0(x, \lambda)g(x_0(x, \lambda), \lambda, \nu) = S_1(x, \lambda, \nu)G(X_1(x, \lambda, \nu), \Lambda(\lambda, \nu), A(\nu)),$$

where $S_1(x, \lambda, 0) = 1$, $X_1(x, \lambda, 0) = x$, $\Lambda(\lambda, 0) = \lambda$, $A(0) = 0$, $S_1(-x, \lambda, \nu) = S_1(x, \lambda, \nu)$, and $X_1(-x, \lambda, \nu) = -X_1(x, \lambda, \nu)$. The next task is to show that the map $\nu \to A(\nu)$ is locally invertible.

Let $x_1(x, \lambda)$ denote the inverse of the map $x \to x_0(x, \lambda)$; let $X_2(x, \lambda, \nu) = X_1(x_1(x, \lambda), \lambda, \nu)$, and let $S_2(x, \lambda, \nu) = S_1(x_1(x, \lambda), \lambda, \nu)/S_0(x_1(x, \lambda), \lambda)$. Since $S_2(x, \lambda, \nu)$ is even in x and is smooth, it may be written as $S_2(x, \lambda, \nu) = S_3(u, \lambda, \nu)$, where $u = x^2$, and S_3 is smooth [5, p. 248]. Similarly, $X_2(x, \lambda, \nu)$ may be written as $X_2(x, \lambda, \nu) = \chi(x^2, \lambda, \nu)x$, where χ is smooth. Then

$$g(x, \lambda, \nu) = S_3(u, \lambda, \nu)G(\chi(u, \lambda, \nu)x, \Lambda(\lambda, \nu), A(\nu)),$$

which implies that

$$r(u, \lambda, \nu) = S(u, \lambda, \nu)R(\chi^2(u, \lambda, \nu)u, \Lambda(\lambda, \nu), A(\nu)),$$

where $S(u, \lambda, \nu) = S_3(u, \lambda, \nu)\chi(u, \lambda, \nu)$.

On taking first- and second-order partial derivatives of this equation for $r(u, \lambda, \nu)$ at $u = \lambda = \nu = 0$, algebraic equations relating partial derivatives of r, S, R, χ, Λ, and A are obtained. We find that

$$S(0,0,0) = \frac{r_{\lambda\lambda}}{2} > 0,$$

$$\chi(0,0,0) = \frac{-2r_u}{r_{\lambda\lambda}} > 0,$$

$$A_\nu(0) = \frac{2r_\nu}{r_{\lambda\lambda}} > 0,$$

so that the map $\nu \to A(\nu)$ is locally invertible; $A > 0$ corresponds to $\nu > 0$ ($s_0 > s_0^d$), $A = 0$ corresponds to $\nu = 0$ ($s_0 = s_0^d$), and $A < 0$ corresponds to $\nu < 0$ ($s_0 < s_0^d$). There are then three cases to consider.

(i) If $s_0 < s_0^d$ and $\nu = s_0 - s_0^d$ is sufficiently small, then the only small positive solutions of the bifurcation equation $g = 0$ are images under the inverse of the map $(x, \lambda) \to (\chi(x^2, \lambda, \nu)x, \Lambda(\lambda, \nu))$ of solutions of $R(X^2, \Lambda, A) = -X^2 + \Lambda^2 + A = 0$. Since $A = A(\nu) < 0$, $R(0, \Lambda, A) = 0$ has two roots $\Lambda_1 < \Lambda_2$. For $\Lambda < \Lambda_1$ and for $\Lambda > \Lambda_2$, $R(X^2, \Lambda, A) = 0$ has exactly one positive solution; but for $\Lambda_1 < \Lambda < \Lambda_2$, there are no (real) solutions. Let λ_1 and λ_2 correspond to Λ_1 and Λ_2, respectively. Then $r(0, \lambda_1, \nu) = 0$, $r_\lambda(0, \lambda_1, \nu) < 0$, $r_u(0, \lambda_1, \nu) < 0$, $r(0, \lambda_2, \nu) = 0$, $r_\lambda(0, \lambda_2, \nu) >$, $r_u(0, \lambda_2, \nu) < 0$, which shows the existence of points $s_*^{(1)} = s_*^d + \lambda_1$ and $s_*^{(2)} = s_*^d + \lambda_2$ of Hopf bifurcation.

(ii) If $s_0 = s_0^d$, then $\nu = 0$ and $A = 0$. For each $\Lambda < 0$, $X = -\Lambda$ is the unique solution of the equation $R = 0$, and for each $\Lambda > 0$, $X = \Lambda$ is the unique solution. These solutions correspond to two families of solutions of $g(x, \lambda, 0) = 0$, which meet at the point $(x, \lambda) = (0, 0)$.

(iii) If $s_0 > s_0^d$, then $\nu > 0$ and $A > 0$. The equation $R(X^2, \Lambda, A) = 0$ has just the branch of solutions $X = (\Lambda^2 + A)^{1/2}$, Λ arbitrary. Therefore, $g(x, \lambda, \nu) = 0$ has a local branch of periodic solutions, locally isolated from the stationary solution.

By Theorem 4.1 of [5, p. 360], a periodic solution of the ordinary differential equation corresponding to a small positive solution x of $g(x, \lambda, \nu) = 0$ is unstable if $g_x(x, \lambda, \nu) < 0$. By direct computation, for sufficiently small (x, λ, ν),

$$\operatorname{sgn} g_x(x, \lambda, \nu) = \operatorname{sgn} G_X(X, \Lambda, A) = \operatorname{sgn} R_U(X^2, A) = -1,$$

so all of the small periodic solutions found are necessarily unstable. □

3.4. Comparison of unfolding with numerical results from AUTO. Figures 1a and 1b are bifurcation diagrams containing curves that represent the families of periodic solutions of the S-A system for $s_0 = s_0^d - 0.01$ (curves 1 and 1′), s_0^d (curves 2 and 2′), $s_0^d + 0.01$ (curves 3 and 3′); all for $(a_0, \alpha, \kappa) = (500, 0.2, 0.1)$. The vertical axis is the peak-to-peak value

$$s_{pp} = \max_t s(t) - \min_t s(t)$$

of solutions $s(t; s_*, s_0)$, and the horizontal axis is the bifurcation parameter s_*. Curves 1, 2, and 3 were obtained by pseudoarclength continuation with Doedel's code AUTO.

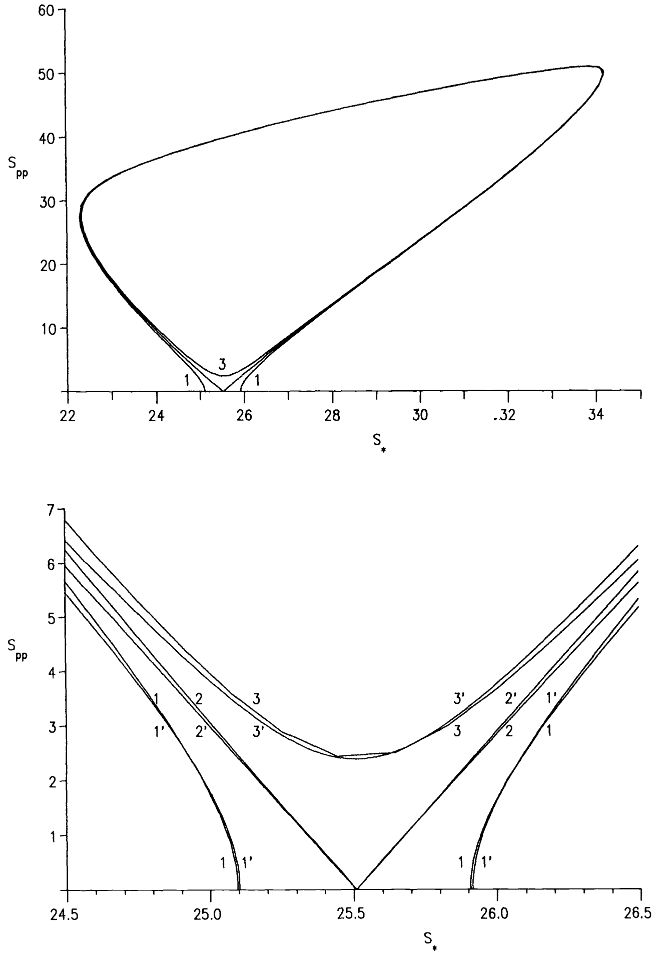

FIG. 1. *Bifurcation diagram of peak-to-peak value for s solution component versus bifurcation parameter* s_*, *for* $s_0 = s_0^d - 0.01$ (*curves* 1, 1′), $s_0 = s_0^d$ (*curves* 2, 2′), *and* $s_0 = s_0^d + 0.01$ (*curves* 3, 3′). *Curves* 1, 2, *and* 3 *are from pseudoarclength continuation* (AUTO) *Curves* 1′, 2′, *and* 3′ *are from unfolding.*

Curve 1 was computed by using AUTO to detect Hopf bifurcation from the stationary branch, and then to generate the Hopf branch by continuation from the left (smaller s_* value) bifurcation point.

Limit point continuation in the two parameters (s_*, s_0) was used to compute the left limit points (points of vertical tangency) in curves 2 and 3, starting from the solution corresponding to the left limit point in curve 1. One parameter continuation in the parameter s_* was then used to compute the other points on curves 2 and 3: since AUTO was observed to cycle when computing these curves, it was modified to stop once the value of s_* had changed direction twice. (AUTO was also modified so as to output the peak-to-peak value of s as a measure of the amplitude.)

Some angularity is visible in curves 1, 2, and 3 because discrete sets of periodic solutions are used to approximate smooth branches of solutions.

Curve 1, as computed, does not return precisely to the right point of Hopf bifurcation, so the data was "touched up" by including results of computing the branch starting from the right bifurcation point. Similarly, as computed, curve 2 does not touch the horizontal axis; rather, it approaches the axis and then jumps to the "outgoing" set of periodic solutions. This data was "touched up" by inclusion of the stationary solution for $s_* = s_*^d$.

In Fig. 1b, curves 1′, 2′, and 3′ were obtained by plotting the zero set of

$$\frac{\partial^2\sigma}{\partial^2 s_*}(s_*^d, s_0^d)\frac{(s_* - s_*^d)^2}{2} + a_1(0,0)\left(\frac{s_{pp}}{2}\right)^2 + \frac{\partial\sigma}{\partial s_0}(s_*^d, s_0^d)(s_0 - s_0^d).$$

This is a Taylor expansion of the factor $r(x^2, \lambda, \nu)$ of the bifurcation equation, retaining terms that correspond to terms in the factor $R(X^2, \Lambda, A)$ of the universal unfolding, and with x approximated by $s_{pp}/2$. The Lyapunov-Schmidt reduction approximates the periodic solutions $\xi(t)$ of the P-B form as $x\,e^{it'} + O(x^2)$, where t' is a scaled time variable. From this approximation it follows that $s_{pp} = 2x + O(x^2)$.

The agreement between the bifurcation theoretic curves 1′, 2′, 3′ and the numeric curves 1, 2, 3 is excellent. Curves 1′, 2′, and 3′ are symmetric about $s_* = s_*^d$. Curves 1, 2, and 3 are approximately symmetric, with the deviations from symmetry becoming larger further away from $(s_*, s_{pp}) = (s_*^d, 0)$. Curves 1 and 1′ each indicate Hopf bifurcations at approximately the same values $s_*^{(1)}$ and $s_*^{(2)}$. Curve 2′ consists of the two tangents to Curve 2. On curves 3 and 3′, the minimum value of s_{pp} is approximately the same. All of these features support the correctness of the values computed in Lemma 3.

4. Discussion. The main point of the present paper is to establish rigorously the existence of certain families of periodic solutions of the S-A system, both for a specific set of parameter values (a_0, α, κ) and for a nontrivial region R_0 of such values. This was accomplished by using symbolic manipulation to perform algebraic manipulations more complicated than we would normally perform by hand, and interval analysis to perform numerical computations "precisely" in the sense of Aberth's monograph [1]. We had hoped to obtain results valid for a larger region in the parameters. For $\alpha = 0.2$, and $\kappa = 0.1$, we have performed traditional numerical computations that indicate that $a_1 = 0$ for $a_0 \approx 330$, i.e., a higher-order degeneracy is present in the model. In future work, we intend to use a continuation argument to extend Lemmas 1 and 2 to a region including this degeneracy, and to construct an unfolding of this degeneracy as well. For application of a continuation argument to be practical, however, the individual overlapping regions in parameter space must be larger than the present region R_0, which means that a different type of interval arithmetic must be employed.

The loss of precision in the computed quantities as we proceed from Lemma 1 through to the theorem is normal for computations using the type of interval arithmetic implemented within PBASIC. In PBASIC, floating point centenary (base 100) arithmetic is used. An arbitrary number of centenary digits is used for the mantissa of the midpoint, but only a single digit is used for the range; this digit is a bound on the error in the last mantissa digit. Whenever the range of a computed expressions exceeds the capacity of a single centenary digit, the number of mantissa digits is decreased and subsequent computations are in reduced precision. This design economizes on storage space for intervals and on computational effort. The design works well to find individual computable numbers (such as $s_*^d(500, 0.2, 0.1)$) to "arbitrary" precision: to compensate for loss of precision during a computation, a higher degree of precision is used at the start. The design is less satisfactory when the object of a computation is to establish inequalities such as $a_1(s_*^d, s_0^d) > 0$ for all (a_0, α, κ) in R_0. In this case, compensating for loss of precision during the computation requires additional restrictions on the parameters is the reason that the region R_0 in the present work is so small.

To minimize such restrictions on the parameters, a type of interval arithmetic must be used that exhibits less loss of precision during the computation. We expect that this could be accomplished by representing both the midpoint and range of the intervals as arbitrary precision numbers.

To contrast the present work with more traditional numerical computations, we note that values for s_*^d, s_0^d, and a_1 at $(a_0, \alpha, \kappa) = (500, 0.2, 0.1)$ could have been calculated to arbitrary precision using either MACSYMA or Mathematica. By recomputing with successively higher precision arithmetic, digits that stop changing as the precision of the arithmetic is increased would be taken as "correct." This procedure for roundoff error estimation does not, however, establish true error bounds. Although relatively unsophisticated in some respects, the language PBASIC used in the present study does provide arbitrary precision *interval* arithmetic as required to make mathematically rigorous statements.

The work [3] outlines several alternate derivations of Hopf bifurcation theory, and presents formulas for bifurcation coefficients derived by application of Lyapunov-Schmidt reduction without preliminary transformation to P-B normal form. To relate our $a_1(s_*^d, s_0^d)$ to the coefficient p_{100} of [3], consider the slopes of the right and left tangent lines to curve 2 of Fig. 1 for $s_* = s_*^d$, $s_{pp} = 0$. These slopes are $\pm (-2(\partial^2\sigma/\partial s_*^2)/a_1)^{1/2}$. Based on results in [3], these same slopes are $\pm|c^1|(-2(\partial^2\sigma/\partial s_*^2)/P_{100})^{1/2}$, where c^1 the first component of the eigenvector c. (In terms of the approximate periodic solution in [3], $s_{pp} = 2\bar{x}|c^1| + 0(\bar{x}^2)$, where $\bar{x}$ is the coordinate on the kernel.) Because the geometry of curve 2 is independent of the particular derivation of bifurcation coefficients, it follows that $a_1 = p_{100}/|c^1|^2$. It should also be possible to establish this algebraically, but the geometric argument is simpler. We verified the relationship numerically. In this application, the choice of technique in deriving Hopf bifurcation seems to be a matter of taste.

Appendix A. Terms from singularity theory.

Z_2-equivalence. Let $g(x, \lambda)$ and $h(x, \lambda)$ be bifurcation problems with Z_{2-} symmetry. Then g and h are Z_2-equivalent if

$$h(x, \lambda) = S(x, \lambda) g(X(x, \lambda), \Lambda(\lambda)),$$

where the triple (S, X, Λ) is an equivalence transformation (i.e., S is nonzero and positive and (X, Λ): $(x, \lambda) \rightarrow (X(x, \lambda), \Lambda(\lambda))$ is a local diffeomorphism that preserves the orientation of x and λ; that is, $X_x(x, \lambda) > 0$ and $\Lambda'(\lambda) > 0$) such that X is odd in x and S is even in x. If this relation holds with $\Lambda(\lambda) = \lambda$, then g and h are strongly Z_2-equivalent.

Factors through. Let $G(x, \lambda, \alpha)$ and $H(x, \lambda, \beta)$ be unfolding of a germ g. We say that H factors through G if there exist smooth mappings S, X, Λ, and A such that

$$H(x, \lambda, \beta) = S(x, \lambda, \beta) G(X(x, \lambda, \beta), \Lambda(\lambda, \beta), A(\beta)),$$

where for $\beta = 0$ the following hold: $S(x, \lambda, 0) = 1$, $X(x, \lambda, 0) = x$, $\Lambda(\lambda, 0) = \lambda$, and $A(0) = 0$.

Unfolding. Let g be in $\varepsilon_{x,\lambda}$ [5, p. 56]; a k-parameter unfolding of g is a germ $G \in \varepsilon_{x,\lambda,\alpha}$, where $\alpha = (\alpha_1, \cdots, \alpha_k) \in R^k$, such that for $\alpha = 0$, $G(x, \lambda, 0) = g(x, \lambda)$. Here G is a germ in all variables: x, λ, $\alpha_1, \cdots \alpha_k$. Thus G is defined and C^∞ on a neighborhood of zero in R^{k+2}.

Universal unfolding, codimension. An unfolding G of g is versal if every other unfolding of g factors through G. A versal unfolding of g depending on the minimum number of parameters possible is called universal. The minimum number is called the codimension of g.

Appendix B: formulas. The polynomial $P(s;\, a_0, \alpha, \kappa)$ is given by the expression

$$\begin{aligned}
P(s;\, a_0, \alpha, \kappa) = {} & 4\kappa^5 s^{11} + (-16a_0\alpha^2\kappa^5 - 8a_0\alpha\kappa^5 + 8\kappa^4)s^{10} \\
& + (-2a_0^2\alpha^4\kappa^5 - 2a_0^2\alpha^3\kappa^5 + 4a_0^2\alpha^2\kappa^5 - 16a_0\alpha^2\kappa^4 - 8a_0\alpha\kappa^4 \\
& \quad - 4\kappa^4 + 4\kappa^3)s^9 + (48a_0\alpha^2\kappa^4 + 24a_0\alpha\kappa^4 - 20\kappa^3)s^8 \\
& + (16a_0^2\alpha^4\kappa^4 + 16a_0^2\alpha^3\kappa^4 - 20a_0^2\alpha^2\kappa^4 + 80a_0\alpha^2\kappa^3 + 40a_0\alpha\kappa^3 \\
& \quad - 20\kappa^3 - 20\kappa^2)s^7 + (8a_0^2\alpha^4\kappa^3 + 8a_0^2\alpha^3\kappa^3 - 4a_0^2\alpha^2\kappa^3 \\
& \quad + 16a_0\alpha^2\kappa^3 + 8a_0\alpha\kappa^3 + 16a_0\alpha^2\kappa^2 + 8a_0\alpha\kappa^2 - 32\kappa^2 - 4\kappa)s^6 \\
& + (-28a_0^2\alpha^4\kappa^3 - 28a_0^2\alpha^3\kappa^3 + 28a_0^2\alpha^2\kappa^3 - 48a_0\alpha^2\kappa^2 - 24a_0\alpha\kappa^2 \\
& \quad - 12\kappa^2 - 8\kappa)s^5 + (-32a_0^2\alpha^4\kappa^2 - 32a_0^2\alpha^3\kappa^2 + 8a_0^2\alpha^2\kappa^2 \\
& \quad - 48a_0\alpha^2\kappa^2 - 24a_0\alpha\kappa^2 - 16a_0\alpha^2\kappa - 8a_0\alpha\kappa - 4\kappa)s^4 \\
& + (-16a_0^2\alpha^4\kappa^2 - 16a_0^2\alpha^3\kappa^2 - 12a_0^2\alpha^2\kappa^2 - 8a_0^2\alpha^4\kappa - 8a_0^2\alpha^3\kappa \\
& \quad - 16a_0\alpha^2\kappa - 8a_0\alpha\kappa)s^3 + (-8a_0^2\alpha^4\kappa - 8a_0^2\alpha^3\kappa - 4a_0^2\alpha^2\kappa)s^2 \\
& + (-2a_0^2\alpha^4\kappa - 2a_0^2\alpha^3\kappa)s.
\end{aligned}$$

The formula for the coefficient a_1 is as follows: at $(s, s_0) = (s_*^d, s_0^d)$, form

$$\begin{aligned}
a_* &= a_0 + (1/\alpha)(s - s_0), \\
R &= sa_*/(1 + s + \kappa s^2), \\
R_s &= a_*(1 - \kappa s^2)/(1 + s + \kappa s^2)^2, \\
R_a &= s/(1 + s + \kappa s^2), \\
\rho_* &= (s_0 - s)/R, \\
\omega_0 &= (\alpha + \rho_* R_a + \alpha\rho_* R_s)^{1/2}, \\
\partial s/\partial y_1 &= 1, \\
\partial a/\partial y_1 &= -(1 + \rho_* R_s)/(\rho_* R_a), \\
\partial a/\partial y_2 &= \omega_0/(\rho_* R_a), \\
p_3 &= \rho_* R_a/\omega_0, \\
p_4 &= (1 + \rho_* R_s)/\omega_0, \\
p &= p_3 + p_4, \\
R_{sa} &= (1 - \kappa s^2)/(1 + s + \kappa s^2)^2, \\
R_{ss} &= a_*(-2 - 6\kappa s + 2\kappa^2 s^3)/(1 + s + \kappa s^2)^3, \\
R_{sss} &= a_*(6 - 6\kappa + 24\kappa s + 36\kappa^2 s^2 - 6\kappa^3 s^4)/(1 + s + \kappa s^2)^4, \text{ and} \\
R_{ssa} &= R_{ss}/a_*.
\end{aligned}$$

The partial derivatives of f are then given by the formulas

$$
\begin{aligned}
&f_{111}=(-\rho_*)(R_{ss}(\partial s/\partial y_1)^2+2R_{sa}(\partial a/\partial y_1)(\partial s/\partial y_1)),\\
&f_{112}=(-\rho_*)R_{sa}(\partial a/\partial y_2)(\partial s/\partial y_1),\\
&f_{211}=pf_{111},\\
&f_{212}=pf_{112},\\
&f_{1111}=(-\rho_*)(R_{sss}(\partial s/\partial y_1)^3+3R_{ssa}(\partial a/\partial y_1)(\partial s/\partial y_1)^2),\\
&f_{1112}=(-\rho_*)R_{ssa}(\partial a/\partial y_2)(\partial s/\partial y_1)^2,\\
&f_{2111}=pf_{1111}, \text{ and}\\
&f_{2112}=pf_{1112}.
\end{aligned}
$$

The coefficient a_1 is then given by

$$a_1=-\frac{1}{2\omega_0}(\operatorname{Re} g_{20} \operatorname{Im} g_{11}+\operatorname{Im} g_{20} \operatorname{Re} g_{11})+\frac{1}{2} \operatorname{Re} g_{21},$$

where

$$
\begin{aligned}
&\operatorname{Re} g_{11}=f_{111}/4,\\
&\operatorname{Im} g_{11}=f_{211}/4,\\
&\operatorname{Re} g_{20}=(f_{111}+2f_{212})/4,\\
&\operatorname{Im} g_{20}=(f_{211}-2f_{112})/4, \text{ and}\\
&\operatorname{Re} g_{21}=(f_{1111}+f_{2112})/8.
\end{aligned}
$$

SOME PROPERTIES OF THE FIRST EIGENVALUE OF THE LAPLACE OPERATOR ON THE SPHERICAL BANDS IN S^2*

CHAO-LIANG SHEN† AND CHUNG-TSUN SHIEH†

Abstract. On the unit sphere in the three-dimensional Euclidean space, among all spherical bands with a given area $2\pi A$, the spherical band which is symmetric to the equator has the largest first Dirichlet eigenvalue.

Key words. first eigenvalue, Laplace operator, spherical bands

AMS(MOS) subject classifications. 35B05, 35P99

1. Introduction. In this paper the subject under investigation is the first eigenvalue of the vibrating membrane equation with Dirichlet boundary condition over those spherical bands with parallel boundary circles on the unit sphere S^2 in $\mathbb{R}^3$. We prove that among all spherical bands with a given area $2\pi A$, where $0<A<2$, the one which is symmetric to the equator has the largest eigenvalue. We also find a monotonicity property of the first eigenvalue when the spherical bands move on the unit sphere. These results are stated and proved in Theorem 1 of the next section.

2. Main results. We express points on the unit sphere S^2 by the Euler coordinate (θ, φ), where $0 \leqq \theta \leqq 2\pi$, $0 \leqq \varphi \leqq \pi$. For $0 \leqq \xi < \eta \leqq \pi$, $0<A<2$, if the *spherical band* bounded by $\varphi = \xi$ and $\varphi = \eta$ has area $2\pi A$, then η can be expressed in terms of ξ and A as follows:

$$\eta = \cos^{-1}(\cos \xi - A).$$

We denote this η by $f(\xi, A)$, or $f(\xi)$ if A is fixed. From now on we shall fix A.

Let Δ_{S^2} denote the Laplace operator on S^2. For $0 \leqq \xi < \pi$, let $B(\xi)$ denote the spherical band on S^2 with area $2\pi A$ and bounded by $\varphi = \xi$ and $\varphi = f(\xi)$. Let $\lambda_1(\xi)$ denote the first eigenvalue of the following eigenvalue problem:

$$\begin{aligned} &\Delta_{S^2} u + \lambda u = 0 \quad \text{in } B(\xi), \\ (1) \qquad & u = 0 \quad \text{on } \partial B(\xi), \end{aligned}$$

where $\partial B(\xi) = \{(\theta, \varphi)\colon 0 \leqq \theta \leqq 2\pi,\ \varphi = \xi \text{ or } f(\xi)\}$ denotes the boundary of $B(\xi)$, and

$$\Delta_{S^2} u(\theta, \varphi) = \frac{1}{\sin \varphi}\left[\frac{\partial}{\partial \varphi}(\sin \varphi u_\varphi) + \frac{\partial}{\partial \theta}\left(\frac{1}{\sin \varphi} u_\theta\right)\right].$$

Since $B(\xi)$ is rotationally symmetric in θ-variable, and the first eigenvalue of (1) is nondegenerate, we see that the first eigenfunction u_1 of (1) is independent of the variable θ, and $(\lambda_1(\xi), u_1)$ is the first eigenpair of the following eigenvalue problem:

$$\begin{aligned} &[\sin \varphi v'(\varphi)]' + \lambda \sin \varphi v(\varphi) = 0, \qquad \xi < \varphi < f(\xi), \\ (2) \qquad & v(\xi) = v(f(\xi)) = 0. \end{aligned}$$

Recall that $f(\xi)=\cos^{-1}(\cos\xi-A)$, where A is fixed, $0<A<2$. For $\xi\leqq\varphi\leqq f(\xi)$, introducing the new variable

$$a=a(\varphi)=\int_\xi^\varphi \sin t\,dt,$$

and letting

$$w(a)=v(\varphi),$$

(2) can be written as follows:

$$\begin{aligned}&\{[1-(\cos\xi-a)^2]w'(a)\}'+\lambda w(a)=0, \qquad 0<a<A,\\ &w(0)=w(A)=0.\end{aligned}\tag{3}$$

We shall use the notation $\lambda_1(\xi)$ to denote the first eigenvalue of (3) and $w(\xi,a)$ to denote the positive first eigenfunction of (3) that is *normalized*, i.e., $\int_0^A w^2(\xi,a)\,da=1$. Then it follows from the results in § 2.6, Chapter VI of [2] that $\lambda_1(\xi)$ is continuous on the interval $[0,\pi-\cos^{-1}(1-A)]$. Furthermore, by [1, Lemma 3.15], both $w(\xi,a)$ and $dw(\xi,a)/da$ are real analytic in ξ; hence the function $\lambda_1(\xi)$ is real analytic in ξ. Now we present our main results in the following theorem.

THEOREM 1. *As a function of* ξ *on the interval* $[0,\pi-\cos^{-1}(1-A)]$, *the first eigenvalue* $\lambda_1(\xi)$ *of* (1) *attains its maximum at* $\xi=\cos^{-1}(A/2)$, *i.e., when* $B(\xi)$ *is the spherical band symmetric to the equator. Furthermore, the function* $\lambda_1(\xi)$ *is monotonically increasing on* $0\leqq\xi\leqq\cos^{-1}(A/2)$.

Proof. By the equatorical symmetry of the spherical bands $B(\xi)$ and $B(\pi-\cos^{-1}(\cos\xi-A))$, we have $\lambda_1(\xi)=\lambda_1(\pi-\cos^{-1}(\cos\xi-A))$. Thus $\lambda_1'(\cos^{-1}(A/2))=0$, where $\lambda_1'(\xi)=d\lambda_1(\xi)/d\xi$. For the proof of Theorem 1 we need to compute $\lambda_1'(\xi)$. Let $w'(\xi,a)$ denote $dw(\xi,a)/da$, and recall that $\int_0^A w^2(\xi,a)\,da=1$.

By using $w(\xi+\Delta\xi,a)$ (respectively, $w(\xi,a)$) as a testing function to estimate $\lambda_1(\xi)$ (respectively, $\lambda_1(\xi+\Delta\xi)$), it follows from the Rayleigh quotient of (3) and the minimum principle that we have the following inequalities:

$$\int_0^A [1-(\cos\xi-a)^2][w'(\xi+\Delta\xi,a)]^2\,da\geqq\lambda_1(\xi),\tag{4}$$

$$\int_0^A [1-(\cos(\xi+\Delta\xi)-a)^2][w'(\xi,a)]^2\,da\geqq\lambda_1(\xi+\Delta\xi).\tag{5}$$

By (3)-(5), we have the following inequalities:

$$\begin{aligned}&\int_0^A\{[1-(\cos(\xi+\Delta\xi)-a)^2]-[1-(\cos\xi-a)^2]\}[w'(\xi+\Delta\xi,a)]^2\,da\\ &\leqq\lambda_1(\xi+\Delta\xi)-\lambda_1(\xi)\\ &\leqq\int_0^A\{[1-(\cos(\xi+\Delta\xi)-a)^2]-[1-(\cos\xi-a)^2]\}[w'(\xi,a)]^2\,da.\end{aligned}\tag{6}$$

The inequalities in (6) imply

$$\begin{aligned}&2[(\sin\xi)\Delta\xi]\int_0^A(\cos\xi-a)[w'(\xi+\Delta\xi,a)]^2\,da+o(\Delta\xi)\\ &\leqq\lambda_1(\xi+\Delta\xi)-\lambda_1(\xi)\\ &\leqq 2[(\sin\xi)\Delta\xi]\int_0^A(\cos\xi-a)[w'(\xi,a)]^2\,da+o(\Delta\xi).\end{aligned}\tag{7}$$

By (7) and [1, Lemma 3.15] we have

$$\lambda_1'(\xi)=2\sin\xi\int_0^A(\cos\xi-a)[w'(\xi,a)]^2\,da. \tag{8}$$

Thus

$$\lambda_1'\left(\cos^{-1}\left(\frac{A}{2}\right)\right)=2\sin\left(\cos^{-1}\left(\frac{A}{2}\right)\right)\int_0^A\left(\frac{A}{2}-a\right)\left[w'\left(\cos^{-1}\left(\frac{A}{2}\right),a\right)\right]^2da=0,$$

which implies

$$\int_0^A\frac{A}{2}\left[w'\left(\cos^{-1}\left(\frac{A}{2}\right),a\right)\right]^2da=\int_0^A a\left[w'\left(\cos^{-1}\left(\frac{A}{2}\right),a\right)\right]^2da. \tag{9}$$

Let

$$H(\xi)=\int_0^A[1-(\cos\xi-a)^2]\left[w'\left(\cos^{-1}\left(\frac{A}{2}\right),a\right)\right]^2da.$$

Then by the assumption $\int_0^A[w(\cos^{-1}(A/2),a)]^2\,da=1$, we have $H(\cos^{-1}(A/2))=\lambda_1(\cos^{-1}(A/2))$ and

$$\lambda_1(\xi)\leqq H(\xi),\qquad 0\leqq\xi\leqq\cos^{-1}\left(\frac{A}{2}\right). \tag{10}$$

We also have

$$H'(\xi)=2\sin\xi\int_0^A(\cos\xi-a)\left[w'\left(\cos^{-1}\left(\frac{A}{2}\right),a\right)\right]^2da. \tag{11}$$

By (9) and (11), for $0\leqq\xi\leqq\cos^{-1}(A/2)$, we have

$$H'(\xi)\geqq 0 \tag{12}$$

since $\cos\xi\geqq A/2$. By (10) and (12), we have

$$\lambda_1(\xi)\leqq H\left(\cos^{-1}\left(\frac{A}{2}\right)\right)=\lambda_1\left(\cos^{-1}\left(\frac{A}{2}\right)\right).$$

This proves the first part of Theorem 1.

To prove the second part of Theorem 1, by the result of the first part and the fact that $\lambda_1(0)$ is the minimum of $\lambda_1(\xi)$ (see [3]), it is sufficient to prove that $\lambda_1(\xi)$ does not have any critical point in the open interval $0<\xi<\cos^{-1}(A/2)$. We prove it by contradiction. Assume $0<\xi_0<\cos^{-1}(A/2)$ such that

$$\lambda_1'(\xi_0)=2\sin\xi_0\int_0^A(\cos\xi_0-a)[w'(\xi_0,a)]^2\,da=0. \tag{13}$$

Since $0<A<2$, $\cos\xi$ is strictly decreasing in the interval $0\leqq\xi\leqq\cos^{-1}(A/2)$. Thus by (13) we have

$$\int_0^A(\cos\xi-a)[w'(\xi_0,a)]^2\,da\leqq 0 \tag{14}$$

for $\xi_0\leqq\xi\leqq\cos^{-1}(A/2)$, where the equality holds only when $\xi=\xi_0$. Define

$$H_0(\xi)=\int_0^A[1-(\cos\xi-a)^2][w'(\xi_0,a)]^2\,da.$$

Then it follows from (14) that $H_0(\xi)$ is strictly decreasing in the interval $[\xi_0, \cos^{-1}(A/2)]$, i.e., $H_0(\xi_0) > H_0(\cos^{-1}(A/2))$ if $\xi_0 \neq \cos^{-1}(A/2)$. But, as $H_0(\xi_0) = \lambda_1(\xi_0)$, $H_0(\cos^{-1}(A/2)) \geqq \lambda_1(\cos^{-1}(A/2))$, we have $\lambda_1(\xi_0) > \lambda_1(\cos^{-1}(A/2))$, which is absurd. Thus $\lambda_1(\xi)$ is strictly increasing in the interval $(0, \cos^{-1}(A/2))$. The proof of Theorem 1 is complete. □

The proof of Theorem 1 generalizes to certain surfaces of revolution. Let $f(x)$ be a smooth strictly increasing function on the interval $[0, \infty)$. Suppose $f'(0) = 0$. Let S_f denote the surface obtained by revolving f with respect to the y-axis. Let A be a fixed positive number. For each $\xi \geqq 0$, define $F(\xi, A)$ by the identity

$$\int_{\xi}^{F(\xi,A)} x\sqrt{1+[f'(x)]^2}\,dx = A,$$

and let $S_f(\xi)$ denote the band on S_f bounded by $x = \xi$ and $x = F(\xi, A)$. Let $\mu_1(\xi)$ denote the first Dirichlet eigenvalue of the Laplace operator on the surface $S_f(\xi)$. Then the proof of Theorem 1 can be generalized to show that $\mu_1(\xi)$ is an increasing function of ξ. We leave the proof to the reader.

SUPERRESOLUTION VIA SPARSITY CONSTRAINTS*

DAVID L. DONOHO[†]

Abstract. Consider the problem of recovering a measure μ supported on a lattice of span Δ, when measurements are only available concerning the Fourier Transform $\hat{\mu}(\omega)$ at frequencies $|\omega| \leq \Omega$. If Ω is much smaller than the Nyquist frequency π/Δ and the measurements are noisy, then, in general, stable recovery of μ is impossible. In this paper it is shown that if, in addition, we know that the measure μ satisfies certain sparsity constraints, then stable recovery is possible. Say that a set has *Rayleigh index* less than or equal to R if in any interval of length $4\pi/\Omega \cdot R$ there are at most R elements. Indeed, if the (unknown) support of μ is known, a priori, to have *Rayleigh index* at most R, then stable recovery is possible with a stability coefficient that grows at most like Δ^{-2R-1} as $\Delta \to 0$. This result validates certain practical efforts, in spectroscopy, seismic prospecting, and astronomy, to provide superresolution by imposing support limitations in reconstruction. The results amount to inequalities for interpolation of entire functions of exponential type from values at special point sets which are irregular, yet internally balanced, uniformly discrete, and of uniform density 1.

Key words. inverse problems, spectroscopy, diffraction-limited imaging, Rayleigh criterion, Nyquist rate, superresolution, nonlinear recovery, entire functions of exponential type, interpolation, balayage

1. Introduction.

Let $\mu = \sum_{k=-\infty}^{\infty} \alpha_k \delta_{k\Delta}$ be a signed measure supported on the lattice $\{k\Delta\}_{k=-\infty}^{\infty}$, with signed mass α_k attached to the point $k\Delta$. We think of the lattice span Δ as a small number $\Delta \ll 1$. The measure μ may be interpreted as a caricature of certain scientifically interesting objects: for example, a polarized spectrum in a spectroscopy problem; or, in exploration seismology and in medical ultrasound, as the sequence of reflectivities of a layered medium with layers of constant width Δ.

Suppose we obtain noisy measurements on μ in the frequency domain, with frequency cutoff Ω:

$$y(\omega) = \hat{\mu}(\omega) + z(\omega), \qquad |\omega| \leq \Omega. \tag{1}$$

Here $\hat{\mu}(\omega) = \int_{-\infty}^{\infty} e^{-i\omega t} d\mu(t) = \sum_{-\infty}^{\infty} \alpha_k e^{-i\omega k\Delta}$ is the Fourier transform of μ, and $z(\omega)$ represents noise. Our objective is to recover μ (or, equivalently, the coefficients α_k) from the data (1).

To make the phrase "recovery of μ" precise, we adapt some notions from the theory of *optimal recovery* (compare Micchelli and Rivlin [21]). We suppose first of all that the noise z can be any function in $L_2[-\Omega, \Omega]$ satisfying $||z||_{L_2[-\Omega,\Omega]} \leq \epsilon$. Let $\tilde{\mu} = \tilde{\mu}(y)$ be a method of recovery. We measure the recovery error with respect to the quadratic "Wiener" norm $||\tilde{\mu}(y) - \mu||_2$, where, for a discrete signed measure ν, we define $||\nu||_2 \equiv (\sum_{t\in\mathrm{supp}(\nu)} |\nu(\{t\})|^2)^{1/2}$. We record our a priori information about μ by saying that $\mu \in \mathcal{M}$, where $\mathcal{M}$ is a class of measures. For example, if our prior information is that μ is a lattice measure, i.e., a member of the set $\mathcal{L}(\Delta) = \{\mu : \mu = \sum_{k=-\infty}^{\infty} \alpha_k \delta_{k\Delta}\}$, then we set $\mathcal{M} = \mathcal{L}(\Delta)$. In general, we measure

[†] Department of Statistics, Stanford University, Stanford, California 94305-4065.

the difficulty of recovery with a priori information $\mathcal{M}$ by the minimax error over $\mathcal{M}$:

$$E^*(\epsilon; \mathcal{M}, \Omega) = \inf_{\tilde{\mu}} \sup_{\mu \in \mathcal{M}} \sup_{||z||_{L_2[-\Omega,\Omega]} \leq \epsilon} ||\tilde{\mu}(y) - \mu||_2.$$

In particular, we say that stable recovery of μ is possible, with a priori information $\mathcal{M}$, if

$$E^*(\epsilon; \mathcal{M}, \Omega) \leq \text{Const} \cdot \epsilon,$$

which indicates the stability property

$$\text{Error} \leq \text{Constant} \cdot \text{Noise Level}.$$

1.1. The stability threshold $\Omega \geq \pi/\Delta$. π/Δ is the usual Nyquist frequency for samples taken on the lattice $\{k\Delta\}_{k=-\infty}^{\infty}$. This frequency pops up in our problem: if the frequency cutoff Ω exceeds π/Δ then stable recovery of μ is possible. Indeed, motivated by the Fourier inversion formula

$$\alpha_k = \frac{\Delta}{2\pi} \int_{-\pi/\Delta}^{\pi/\Delta} e^{i\omega k\Delta} \hat{\mu}(\omega) d\omega \tag{2}$$

one is led immediately to the rule

$$\tilde{\alpha}_k = \frac{\Delta}{2\pi} \int_{-\pi/\Delta}^{\pi/\Delta} e^{i\omega k\Delta} y(\omega) d\omega. \tag{3}$$

Parseval's relation implies that the reconstruction formula $\tilde{\mu} = \sum_{k=-\infty}^{\infty} \tilde{\alpha}_k \delta_{k\Delta}$ has error

$$||\tilde{\mu}(y) - \mu||_2^2 = \frac{\Delta}{2\pi} \int_{-\pi/\Delta}^{\pi/\Delta} |z(\omega)|^2 d\omega \leq \frac{\Delta}{2\pi} \epsilon^2.$$

Consequently, if $\mathcal{M} = \mathcal{L}(\Delta)$ we get

$$E^*(\epsilon; \mathcal{M}, \Omega) \leq \sqrt{\frac{\Delta}{2\pi}} \cdot \epsilon,$$

and an extra argument shows that in fact equality holds. Hence, in the case $\Omega \geq \pi/\Delta$, stable recovery is possible, and in fact optimal recovery requires only the simplest of linear reconstruction formulas.

The case $\Omega \ll \pi/\Delta$ is more interesting. In this case data on $\hat{\mu}(\omega)$ are not available on the whole range [−Nyquist, Nyquist], and formulas like (3) are not immediately applicable. Indeed, formula (3) suggests that, if $\Omega < \pi/\Delta$, reconstruction will require some sort of process of *extrapolation* of the noisy measurements inside $[-\Omega, \Omega]$ to produce quasi measurements over the whole of the fundamental interval $[-\pi/\Delta, \pi/\Delta]$.

However, such extrapolation is evidently impossible in the absence of special prior information. Indeed, if μ can be any lattice measure, then (α_k) can be any square summable sequence. We could therefore let $\hat{\mu}(\omega)$ be a nonzero function, periodic of period $2\pi/\Delta$, belonging to L^2 on the fundamental interval $(-\pi/\Delta, \pi/\Delta)$, and vanishing on $[-\Omega, \Omega]$. The sequence (α_k) obtained from (2) would give a nonzero lattice measure μ whose transform agrees, over the low frequency band $|\omega| \leq \Omega$, with the zero measure. Even at noise level $\epsilon = 0$, our observations could not distinguish this μ from the zero measure, nor from its sign-reversal $-\mu$. Consequently, if $\Omega < \pi/\Delta$,

$$\begin{aligned} E^*(\epsilon, \mathcal{L}(\Delta), \Omega) &\geq \sup\{\|\mu - \tilde{\mu}\|_2 : \mu, \tilde{\mu} \in \mathcal{L}(\Delta), \hat{\mu}(\omega) = \hat{\tilde{\mu}}(\omega), |\omega| \leq \Omega\} \\ &\geq \sup\{\|\mu\|_2 : \mu \in \mathcal{L}(\Delta), \hat{\mu}(\omega) = 0, |\omega| \leq \Omega\} \\ &= +\infty. \end{aligned}$$

Stable recovery is not possible under the condition $\Omega < \pi/\Delta$ if all we know a priori is the lattice constraint $\mu \in \mathcal{L}(\Delta)$.

1.2. The Rayleigh threshold $\Omega \geq \pi/\Delta$. A mathematically equivalent reformulation of our problem occurs in the theory of optics. The frequency-domain data (1) are equivalent to the spatial-domain data

$$(4) \qquad Y(t) = (K_\Omega \star \mu)(t) + Z(t), \qquad t \in (-\infty, \infty),$$

where $K_\Omega(t)$ is the sinc-Kernel $\hat{\sin}(\Omega t)/(\pi t)$ and $\star$ denotes convolution; and Z is a bandlimited noise with Fourier transform

$$\hat{Z}(\omega) = \begin{cases} z(\omega) & |\omega| \leq \Omega \\ 0 & \text{else.} \end{cases}$$

Hence, one observes not the measure μ directly, but instead a noisy version which is blurred by convolution with the kernel K_Ω. In this form, Y is a noisy diffraction-limited image of μ, a superposition of point-sources.

The study of diffraction-limited imaging for such superpositions of point sources goes back a long way. Lord Rayleigh studied it, and formulated a "resolution limit" [28, pp. 33–35]: if a measure μ consists of two point sources of equal strength separated by a distance Δ, a visual inspection of the $Y(t)$ curve will suggest the presence of two point sources provided $\Delta \geq 1.22\pi/\Omega$ and of one point source provided that $\Delta < 1.22\pi/\Omega$. Rayleigh's constant 1.22 is rather arbitrary, and Rayleigh's argument could, with minor modifications, yield instead the constant 1.0. This replacement would lead to the criterion: *pointlike sources separated by at least Δ can be resolved into separate sources, using data diffraction-limited by K_Ω, provided $\pi/\Delta \leq \Omega$.*

This modified Rayleigh limit coincides with the threshold $\pi/\Delta \leq \Omega$ for stable recovery mentioned earlier. In this sense, if we *were* able to recover stably the lattice measure μ from data satisfying $\Omega \ll \pi/\Delta$, we would have exceeded Rayleigh's resolution limit. Therefore, the problem of stably recovering μ from noisy data with parameters in the range $\Omega \ll \pi/\Delta$ below the Rayleigh threshold may be called the problem of *superresolution.*

1.3. Empirical superresolution via sparsity. Despite the mathematical fact that stable recovery of the class $\mathcal{L}(\Delta)$ is impossible when the data satisfy $\Omega \ll \pi/\Delta$, there has been considerable effort to develop superresolving algorithms for specific problems. The idea is essentially that additional a priori information about the support of the measure μ should be exploited in the recovery process.

1. Högbom [11] and others, working in radio astronomy, have developed the method CLEAN, which involves finding a small set of delta-functions $\tilde{\mu} = \sum \alpha_k \delta_{t_k}$ such that $K \star \tilde{\mu}$ (where K is a sinc-like kernel) nearly reproduces the original measurements. As Schwarz [27] says, "... some extra information about the brightness distribution must be used. The CLEAN method is designed for the case that the brightness distribution contains only a few sources at well-separated, small regions, i.e., *the brightness distribution is essentially empty.*"

2. Papoulis and Chamzas [23] have proposed a nonlinear iterative method which assumes implicitly that the underlying measure is sparse, attempts to identify adaptively the regions where coefficients might be nonzero, and recover an object supported only in those regions. They describe an application in medical ultrasound [24]. They point out that the Rayleigh limit is exceeded, in some examples, by their method, and that the actual limit of resolution depends on noise and signal in some yet-to-be determined fashion.

3. Working in seismic prospecting, Levy and Fullagar [15], Santosa and Symes [26], and Walker and Ulrych [33] describe methods which attempt to exploit the fact that the underlying object is a "sparse spike train" to recover wideband data from measurements over a limited frequency range. The Levy–Fullagar and Santosa–Symes work exploits special support properties of l_1-norm penalized reconstruction—namely, that for large values of the multiplier attached to the penalty, the algorithm tends to employ very few nonzero elements in the reconstruction. Walker and Ulrych exploit a method based on low-order autoregressive extrapolation of the Fourier data away from the measured frequency band. The low-order autoregressive model for the Fourier transform may be justified by an assumption that few elements in the spatial domain representation of the object are nonzero. Wang [34] recently introduced a method which constrains the reconstruction so that in any segment of a certain length there are only a few nonzero elements.

4. Working in Fourier transform spectroscopy, Kawata, Minami, and Minami [14], [20] and Mammone [18], also exploit parsimony. Kawata et al. use low-order autoregressive extrapolation away from the measured frequency band, and Mammone uses parametric linear programming to get reconstructions which nearly reproduce the data with minimal numbers of nonzero elements. In later work Minami, Kawata, and Minami refined their technique by using the singular value decomposition to improve the choice of order in autoregressive extrapolation.

5. Working in NMR spectroscopy, Barkhuisen et al. [1] use autoregressive extrapolation, combined with singular value decomposition (LPSVD); Newman [22] proposes the use of l_1-norm penalized reconstruction. Tang and Norris [29] and Mazzeo et al. [19] divide the signal into segments and treat individual segments by sparsity-enhancing methods (e.g., LPSVD) mentioned above.

All these researchers seek to recover wideband objects from narrow-band data; all proceed by in some way imposing sparsity limitations on the recovered object; and all have achieved successes in certain computational experiments. Implicitly or explicitly, these successes amount to a claim that a certain sparsity of the unknown object enables recovery.

At first glance, the computational work just mentioned seems to conflict with the Rayleigh and stability criteria developed above. In fact there is no conflict, since the Rayleigh and the stability criteria do not seek to describe the impact of sparsity.

1.4. Theoretical results. We now develop theory that sheds light on the possibilities, and difficulties, of superresolution via sparsity constraints. We will show that, if the support of μ, though unknown, is known to be sufficiently sparse, then even in the case $\Omega \ll \pi/\Delta$, stable recovery is possible. On the other hand, the quantitative degree of stability might be disappointingly poor if we must recover objects that possess a high degree of complexity.

We do not exhibit a practical method for achieving stable recovery, but instead exhibit inequalities which show that, in the sense of the theory of optimal recovery, the object admits of stable reconstruction. Any stable reconstruction scheme is necessarily highly nonlinear. It would be interesting to know whether stability of the kind we establish below holds for the nonlinear methods [1], [11], [14], [15], [20], [22], [26], [33], [24] mentioned above.

Before developing stability results, we discuss uniqueness. Let S be a discrete set. Following Beurling [3], we define the upper uniform density

$$u.u.d.(S) = \lim_{r\to\infty} r^{-1} \sup_t \#(S \cap [t, t+r))$$

and the lower uniform density

$$l.u.d.(S) = \lim_{r\to\infty} r^{-1} \inf_t \#(S \cap [t, t+r)).$$

Both limits exist.

THEOREM 1.1. (a) *Let* $\mathcal{M}_{<1}(\Delta)$ *denote the class of finite signed lattice measures* $\mu \in \mathcal{L}(\Delta)$ *which have density* $u.u.d.(\mathrm{supp}(\mu)) < 1$. *If* $\Omega \geq 2\pi$, μ *is uniquely characterized among* $\mathcal{M}_{<1}(\Delta)$ *by the transform* $\hat{\mu}(\omega)$, $|\omega| \leq \Omega$.

(b) *Let* S_1 *and* S_2 *be any two disjoint sets with* $l.u.d.(S_i) > 1$, $i = 1, 2$. *Let* μ_1 *be any finite signed measure supported on* S_1. *There exists* μ_2 *with support* S_2 *such that* $\hat{\mu}_1(\omega) = \hat{\mu}_2(\omega)$ *for* $|\omega| \leq \pi$, *yet* $\mu_1 \neq \mu_2$.

(c) *There exist disjoint equispaced sets* S_i, *with* $l.u.d.(S_i) = u.u.d.(S_i) = 1$, $i = 1, 2$, *and measures* μ_i *supported in the* S_i, *such that* $\hat{\mu}_1(\omega) = \hat{\mu}_2(\omega)$ *for* $|\omega| \leq 2\pi - \delta$, $\delta > 0$, *yet* $\mu_1 \neq \mu_2$.

The proof, which relies on Beurling's theory of interpolation and balayage [3], [2], is given in §7.

We conclude that $u.u.d. < 1$ and $\Omega \geq 2\pi$ ensures uniqueness; $l.u.d. > 1$ and $\Omega \leq \pi$ ensures nonuniqueness; and $l.u.d. = u.u.d. = 1$ and $\Omega \in (\pi, 2\pi)$ may, in some cases, lead to nonuniqueness. Hence in searching for stability results, we confine attention to the case $u.u.d. < 1$ and $\Omega \geq 2\pi$.

By rescaling, this pair of conditions is equivalent to the single condition $u.u.d. < \Omega/2\pi$. Now compare this uniqueness condition with the modified Rayleigh criterion $\Delta > \pi/\Omega$. For a typical nonsparsely supported measure $\mu \in \mathcal{L}(\Delta)$, $u.u.d.(\mathrm{supp}(\mu)) = \Delta^{-1}$; hence Rayleigh's criterion is comparable to $u.u.d. < \Omega/\pi$. Our uniqueness criterion therefore demands exactly twice the frequency-domain measurement band (or half the spatial domain density) as the Rayleigh criterion. Our stability estimates will demand at least four times as much as the Rayleigh criterion.

We now return to the scaling convention $u.u.d. < 1$.

DEFINITION 1. Let S be a discrete set of upper uniform density less than one. The *Rayleigh index* of S is

$$R^*(S) = \min\left\{R : R \geq \sup_t \#(S \cap [t, t+R))\right\}.$$

The class of lattice measures μ with $(\alpha_k) \in l_1$ and Rayleigh index $R^*(\mathrm{supp}(\mu)) \leq R$ will be denoted $\mathcal{S}(R, \Delta)$.

The Rayleigh index measures, for sets which have on average, no more than one element per unit cell, the maximum number that can be clustered very closely together. We aim to show that the clustering of many elements together in one cell makes superresolution difficult; we will see that the degree of clustering, as measured by the Rayleigh index, enters directly into our bounds on the stability coefficient.

DEFINITION 2. The *modulus of continuity* for the recovery of measures in $\mathcal{S}(R,\Delta)$ is

$$\Lambda(\epsilon;\mathcal{S}(R,\Delta),\Omega) = \sup\{||\mu_1-\mu_2||_2 : \mu_i \in \mathcal{S}(R,\Delta),\\ ||\hat{\mu}_1-\hat{\mu}_2||_{L_2[-\Omega,\Omega]} \leq \epsilon\}.$$

This modulus of continuity measures the extent to which two lattice measures, both satisfying the sparsity condition $R^*(\text{supp}(\mu_i)) \leq R$, can differ, if the bandlimited data $\{\hat{\mu}_i(\omega), |\omega| \leq \Omega\}$ differ by at most ϵ in L_2-norm. Its relevance comes from the following.

LEMMA 1.2.

$$E^*(\epsilon,\mathcal{S}(R,\Delta),\Omega) \leq \Lambda(2\epsilon,\mathcal{S}(R,\Delta),\Omega). \tag{5}$$

The proof is given in §7. (For arguments relating a modulus of continuity to a minimax error in other contexts, see [21], [25], [30], [31], [6].)

Our main result bounds the modulus of continuity directly.

THEOREM 1.3. *Let* $\Omega > 4\pi$.

$$\Lambda(\epsilon,\mathcal{S}(R,\Delta),\Omega) \leq \Delta^{-2R-1} \cdot \beta(R,\Omega) \cdot \epsilon, \qquad \epsilon > 0. \tag{6}$$

β *is a positive finite constant defined below.*

The raw materials on which this result depends are developed in the body of the paper, §§2–6 below. They are assembled to give a formal proof in §7.

The following lower bound shows that our upper bound is nearly sharp. It is proved in §7 below.

THEOREM 1.4. *Let* $\Delta_0 \in (0,1)$. *If* $\Delta < \Delta_0$ *then*

$$\Lambda(\epsilon,\mathcal{S}(R,\Delta),\Omega) \geq \Delta^{-2R+1} \cdot b(R,\Omega,\Delta_0) \cdot \epsilon, \qquad \epsilon > 0. \tag{7}$$

$b(R,\Omega,\Delta_0)$ *is a positive finite constant defined below.*

1.5. Interpretation of the theory. To interpret these results, we introduce some terminology. We speak of the stability coefficient as the *noise amplification* factor in the relation

Reconstruction Error = Noise Amplification · Noise in Data.

We speak of the ratio Ω/Δ as the *superresolution factor.* Our results indicate that *noise amplification increases polynomially with the superresolution factor.* Hence, to achieve reconstructions with a fixed degree of reconstruction error requires data of increasingly low noise level as the superresolution factor increases. Moreover, the rate at which the noise requirement imposes itself is directly tied to the Rayleigh index, and hence it may be extremely difficult to recover an object with a high degree of clumping or irregularity.

Hence superresolution is possible if the object is known to contain, on average, less than one pointlike event per cell of size $4\pi/\Omega$; but this may require extremely precise data, particularly if we cannot rule out the possibility that a few cells contain many more than one pointlike event. These relations, rather than the Rayleigh criterion, determine the ultimate limits of resolution.

2. Balanced (R, Δ)-sets.

DEFINITION 3. A *balanced* (R, Δ)*-set* is a countable set of points $\{t_k\}$ on the real line which may be obtained from the union of two bilateral sequences $(u_i)_{i=-\infty}^{\infty}$ and $(v_i)_{i=-\infty}^{\infty}$ satisfying these conditions:

$$\begin{array}{lrll}
(8) & \text{(Internal Symmetry)} & u_i = i + \delta_i, & i \in \mathbf{Z}, \\
 & & v_i = i - \delta_i, & i \in \mathbf{Z}, \\
(9) & \text{(Uniform Density)} & |\delta_i| \le R, & i \in \mathbf{Z}, \\
(10) & \text{(Uniform Discreteness)} & |t_k - t_l| \ge \Delta, & k \ne l, \\
(11) & \text{(Unicity)} & u_i \ne u_j, & i \ne j.
\end{array}$$

We note that no assumption is made that $v_i \ne v_j$ for $i \ne j$. Nor is there an assumption that $u_i \ne v_j$ for every i, j. Consequently, the multiplicity

$$m_k = \#\{i : u_i = t_k\} + \#\{i : v_i = t_k\}$$

may be greater than 1, in fact, as large as $2R + 2$. Also, no assumption is made that the points t_k belong to a lattice, although this is not excluded, either.

These four conditions describe a set which is allowed to be locally irregular, yet must be globally regular. A long interval, of length N, say, contains roughly $2 \cdot N$ elements of the set $\{t_k\}$, counting with multiplicities m_k. The internal symmetry condition is also important; it implies that even though the points are not equispaced, they may be arranged in pairs whose centers of gravity are equispaced.

Obviously, balanced (R, Δ)-sets are quite special, and do not occur "naturally"; our interest is in sets which can be "filled out," by the addition of new elements, to become balanced (R, Δ)-sets.

DEFINITION 4. $\{s_k\}$ is a pre-(R, Δ)-set if it is a subsequence of the (u_i) sequence associated to an (R, Δ)-set. A measure μ is an (R, Δ)-measure if its support $\{s_k\}$ is a pre-(R, Δ)-set.

We prove the following in §8.

LEMMA 2.1. *The measures in* $\mathcal{S}(R, \Delta)$ *are all* (R, Δ)*-measures.*

(Elizabeth Gassiat, of Université de Paris-Sud, has shown the author in personal correspondence that the above lemma may be improved, with this conclusion: *the measures in* $\mathcal{S}(R, \Delta)$ *are all* $(R/2, \Delta)$ *measures.* Her work, which is used further below, answers a question raised in the preprint of this article. Her argument is given in [10].)

Our introduction of balanced (R, Δ)-sets is geared to the development of certain interpolation schemes based on entire functions. Entire functions with real zeros have zeros which are roughly equispaced (compare [5], [12], [13]) and possess a certain symmetry (compare the discussion of Lindelöf's theorem in [13]). The conditions (8)–(11) serve to guarantee that there is an entire function of exponential type 2π with $\{t_k\}$ as its set of zeros. We prove the following in §8.

LEMMA 2.2. *Let* $\{t_k\}$ *be a balanced* (R, Δ)*-set. Define*

$$G_n(t) = \frac{\Pi_{-n}^{n}(t - u_i)(t - v_i)}{\Pi_{-n}^{n}(t - i)^2} \sin^2(\pi t).$$

Then (G_n) *is a sequence of entire functions of exponential type* 2π*, uniformly bounded on the real axis. This sequence converges uniformly on compacts to a limit function* G*,* *entire of exponential type 2π. The $\{t_k\}$ are the zeros of the function G; the multiplicity of t_k is m_k.*

The representation as a limit of the sequence (G_n) seems nonstandard; we use it for the purpose of bounding $||G||_\infty$ and related quantities. We record now several important bounds, all of which only involve the parameters R and Δ rather than the detailed properties of the set $\{t_k\}$. The proofs are given in §8.

LEMMA 2.3. *Let $\{t_k\}$ be a balanced (R, Δ)-set. Then*

$$\sup_t |G(t)| \leq A_1(R)$$

where $A_1(R)$ is defined below.

LEMMA 2.4. *Let $\{t_k\}$ be a balanced (R, Δ)-set. Let G have a zero at t_0 of multiplicity m_0. Then*

$$\sup_{|t-t_0|\leq 1} \frac{|G(t)|}{|t-t_0|^{m_0}} \leq A_2(R)$$

where $A_2(R)$ is defined below.

LEMMA 2.5. *Let $\{t_k\}$ be a balanced (R, Δ)-set. Let G have a zero of multiplicity m_k at t_k. Let*

$$g_k = \lim_{t\to t_k} G(t)/(t-t_k)^{m_k}.$$

Then

$$g_k \geq A_3(R)\Delta^{2R+1},$$

where $A_3(R)$ is a strictly positive constant defined below.

These bounds on the entire function G, although stated as lemmas, are in fact the "hard analysis" on which our main result depends; in succeeding sections we reduce the question of superresolution to these inequalities by the use of "soft analysis."

3. Superresolution for (R, Δ)-sets. Let $B_q(\Omega)$, $1 \leq q \leq \infty$, denote the space of entire functions of exponential type Ω belonging to L_q on the real axis [4], [5], [16], [17]. For a sigma-finite signed measure ν, define

$$||\nu||_{p,\Omega} = \sup\left\{\int f d\nu : f \in B_q(\Omega), ||f||_q \leq 1\right\}$$

where $1/p + 1/q = 1$ as usual. In the case where $p = 2$, Parseval's relation implies that

$$||\nu||_{2,\Omega}^2 = \frac{1}{2\pi}||\hat{\nu}||_{L_2[-\Omega,\Omega]}^2.$$

Also, for ν a discrete measure, let

$$||\nu||_p = \left(\sum_{t\in\text{supp}(\nu)} |\nu(\{t\})|^p\right)^{1/p}.$$

Thus, for example, the case where $p = 1$ gives the total variation norm of ν.

We call any inequality of the form

$$||\nu||_p \leq C_p(R,\Delta,\Omega)||\nu||_{p,\Omega}, \tag{12}$$

when valid for all finite signed (R,Δ)-measures ν, a *superresolution inequality.* Besides the case $p = 2$, the main case of interest to us is the case $p = 1$, or

$$\text{Variation}(\nu) \leq C_1(R,\Delta,\Omega)||\nu||_{1,\Omega}.$$

The rationale for calling (12) a superresolution inequality is that, ordinarily, bounds on the norms $||\nu||_p$ would seem to require knowledge of the transform $\hat{\nu}(\omega)$ at all frequencies up to the Nyquist π/Δ; but the norm $||\nu||_{p,\Omega}$ involves only knowledge of frequencies in the smaller band, since, by Parseval, we have

$$\int_{-\infty}^{\infty} f(t)d\nu(t) = \frac{1}{2\pi}\int_{-\Omega}^{\Omega} \hat{f}(\omega)\hat{\nu}(\omega)d\omega$$

for $f \in B_q(\Omega)$, $1 \leq q < \infty$.

4. Duality with interpolation. Consider the following interpolation problem for the sequence $(u_i)_{i=-\infty}^{\infty}$ associated with a balanced (R,Δ)-set. *Given constants* $(c_i)_{i=-\infty}^{\infty}$, $(c_i) \in l_q$, *find a function* $f \in B_q(\Omega)$ *satisfying*

$$f(u_i) = c_i, \qquad i \in \mathbf{Z}. \tag{13}$$

Suppose that for *every* sequence $(c_i) \in l_q$, and *every* (u_i) associated to a balanced (R,Δ)-set, we have a solution to (13) satisfying

$$||f||_{L_q} \leq K_q(R,\Delta,\Omega)||c||_{l_q}, \tag{14}$$

where K_q does not depend on the details of the (u_i), but only on the parameters R and Δ. We claim that then, if p and q are conjugate indices $1/p + 1/q = 1$,

$$K_q(R,\Delta,\Omega) \geq C_p(R,\Delta,\Omega). \tag{15}$$

This expresses a certain duality between the superresolution inequality (12) and the interpolation problem (13).

To prove (15), let ν be any (R,Δ)-measure. Then, by definition, $\text{supp}(\nu) \subset \{u_i\}$ for some sequence $(u_i)_{i=-\infty}^{\infty}$ associated with a balanced (R,Δ)-set. Let $(c_i)_{i=-\infty}^{\infty}$ be aligned with $(\nu\{u_i\})$ in the usual sense that

$$c_i = \lambda\,\text{sgn}(\nu\{u_i\})\,|\nu\{u_i\}|^{p-1},$$

with the scalar λ chosen to make $||c||_{l_q} = 1$. Then

$$\begin{aligned}\sum_{i=-\infty}^{\infty} c_i\nu\{u_i\} &= \left(\sum |\nu\{u_i\}|^p\right)^{1/p}\\ &= ||\nu||_p,\end{aligned}$$

as $\text{supp}(\nu) \subset \{u_i\}$. Now, if f solves the interpolation problem (13), we have

$$\int f d\nu = \sum_{i=-\infty}^{\infty} c_i\nu\{u_i\} = ||\nu||_p,$$

and as $f \in B_q(\Omega)$,

$$\int f d\nu \leq ||f||_{L_q} ||\nu||_{p,\Omega}.$$

Thus, $||\nu||_p \leq ||f||_{L_q} ||\nu||_{p,\Omega}$, and so by (14),

$$||\nu||_p \leq K_q(R, \Delta, \Omega) ||\nu||_{p,\Omega}.$$

Relation (15) follows.

As a result of (15) we now turn our attention to problems of interpolation in $B_q(\Omega)$.

5. Pointwise bounds on interpolation. As indicated in §2, a balanced (R, Δ)-set generates a function G, entire of exponential type 2π. By convention, G has a zero of multiplicity m_k at t_k; defining as before

$$g_k = \lim_{t \to t_k} G(t)/(t - t_k)^{m_k}, \tag{16}$$

the function

$$\xi_k(t) = \frac{G(t)}{g_k \cdot (t - t_k)^{m_k}} \tag{17}$$

satisfies formally

$$\xi_k(t_l) = \begin{cases} 1, & k = l, \\ 0, & k \neq l. \end{cases} \tag{18}$$

Actually, ξ_k is a well-defined entire function of type 2π which belongs to L_2 on the real axis. Therefore, formally, the "Lagrange interpolation series"

$$f = \sum_k d_k \xi_k \tag{19}$$

gives a solution of the interpolation problem

$$f(t_k) = d_k, \qquad k \in \mathbf{Z}. \tag{20}$$

However, regularity conditions would be needed on (ξ_k) in order to be sure that such sums converge and define elements of $B_q(\Omega)$. (For discussion of Lagrange interpolation for sets where the corresponding function G has only simple zeros ($m_k \equiv 1$), see [3], [35].)

Regularity is easier to establish if we mollify the ξ_k. We record, without proof, the following essentially obvious technical fact.

LEMMA 5.1. *Let $\eta > 0$. There exists a smooth function $h(x)$ satisfying*

(a) *$\hat{h}(\omega)$ is a smooth function supported in $(-\eta, \eta)$;*

(b) *$h \geq 0$;*

(c) *$h(0) = 1$;*

(d) *$h(x) \leq C(\eta)/(1 + x^2)$ for some positive finite constant $C(\eta)$ and all x.*

The mollified functions $\tilde{\xi}_k = \xi_k(t) h(t - t_k)$ again formally satisfy the Lagrange interpolation conditions

$$\tilde{\xi}_k(t_l) = \begin{cases} 1, & k = l, \\ 0, & k \neq l. \end{cases}$$

However, they also have good decay at ∞, and so belong to $B_1(2\pi + \eta)$.

The interpolation problem (20) at the (t_k) is somewhat more general than the problem (13) at the (u_i), so it is convenient to work with a subsequence of the $(\tilde{\xi}_k)$. By (11), each u_i occurs exactly once in the set $\{t_k\}$. Hence, a one-one mapping $k(i)$ exists so that $t_{k(i)} = u_i$. Define the function

$$\psi_i = \tilde{\xi}_{k(i)} = \xi_{k(i)} \cdot h(\cdot - t_{k(i)}).$$

Then $(\psi_i)_{i=-\infty}^{\infty}$ is a sequence of functions in $B_1(2\pi+\eta)$, satisfying the formal Lagrange interpolation conditions

$$\psi_i(u_j) = \begin{cases} 1, & i = j, \\ 0, & i \neq j. \end{cases}$$

Let $\phi(t) = (1 + t^2)^{-1}$ and $\phi_i(t) = \phi(t - i)$. It turns out that the functions ψ_i are effectively not worse behaved than ϕ_i.

THEOREM 5.2.

$$|\psi_i(t)| \leq A\phi_i(t), \qquad t \in (-\infty, \infty)$$

where

$$A(R, \Delta, \eta) = \Delta^{-2R-1}\alpha(R, \eta)$$

and $\alpha(R, \eta)$ is a positive, finite constant specified below.

The theorem follows from earlier estimates on G and g_k, on the mollifier h. To see how, put for short $k = k(i)$. Property (d) of the mollifier h gives $h(\cdot - u_i)/\phi(\cdot - u_i) \leq C(\eta)$. Hence

$$\sup_t \frac{|\psi_i(t)|}{|\phi(t - u_i)|} \leq C(\eta) \sup_t \frac{|G(t)|}{g_k|t - t_k|^{m_k}}.$$

Now

$$\begin{aligned} \sup_t \frac{|G(t)|}{g_k|t - t_k|^{m_k}} &\leq g_k^{-1} \max \left[\sup_t |G(t)|, \sup_{|t-t_k|\leq 1} \frac{|G(t)|}{|t - t_k|^{m_k}} \right] \\ &\leq \Delta^{-2R-1} A_3(R)^{-1} \max[A_1(R), A_2(R)] \\ &= A_5(R)\Delta^{-2R-1}, \end{aligned}$$

say. It follows that

$$|\psi_i| \leq C(\eta) A_5(R) \Delta^{-2R-1} \phi(\cdot - u_i).$$

Note that, by (9), $|u_i - i| \leq R$. Simple algebra gives the following lemma.

LEMMA 5.3. *If $|\delta| \leq R$,*

$$\phi(t \pm \delta) \leq A_4(R)\phi(t), \qquad t \in (-\infty, \infty)$$

where

$$A_4(R) = (R + 1)^2.$$

It follows that $\phi(\cdot - u_i) \leq A_4(R)\phi(\cdot - i)$. Hence

$$|\psi_i| \leq \alpha(R, \eta)\Delta^{-2R-1}\phi_i,$$

say, where

$$\alpha(R, \eta) = C(\eta) \cdot A_5(R) \cdot A_4(R).$$

This completes the proof of Theorem 5.2.

6. Operator norms for interpolation. Let $\mathcal{I}(c) = \sum_{i=-\infty}^{\infty} c_i \psi_i$ denote the Lagrange interpolation operator formally "solving" the interpolation problem (13). We now show that this operator is a bounded linear operator from l_q into $L_q(\mathbf{R})$, and so $\mathcal{I}$ rigorously solves the interpolation problem.

LEMMA 6.1. (1,1)-Boundedness. *Suppose that* $|\psi_i| \le A\phi_i$, $i \in \mathbf{Z}$. *Then*

$$\left\| \sum_i c_i \psi_i \right\|_{L_1(\mathbf{R})} \le A \cdot \pi \cdot \|c\|_{l_1}.$$

Proof.

$$\begin{aligned}\left\| \sum_i c_i \psi_i \right\|_{L_1(\mathbf{R})} &\le \sum_i |c_i| \, \|\psi_i\|_{L_1(\mathbf{R})} \\ &\le \sum_i |c_i| \cdot \sup_i \|\psi_i\|_{L_1(\mathbf{R})} \\ &\le \|c\|_{l_1} A \|\phi\|_{L_1(\mathbf{R})}.\end{aligned}$$

The result follows from $\|\phi\|_{L_1(\mathbf{R})} = \int_{-\infty}^{\infty} (1+t^2)^{-1} dt = \pi$.

LEMMA 6.2. (∞,∞)-Boundedness. *Suppose that* $|\psi_i| \le A\phi_i$, $i \in \mathbf{Z}$. *Then*

$$\left\| \sum_i c_i \psi_i \right\|_{L_\infty(\mathbf{R})} \le A \left(\frac{2\pi}{1 - e^{-2\pi}} \right) \|c\|_{l_\infty}.$$

Proof. Using positivity of ϕ,

$$\begin{aligned}\left\| \sum_i c_i \psi_i \right\|_{L_\infty(\mathbf{R})} &\le \sup_t \sum_i |c_i| \, |\psi_i(t)| \\ &\le A \sup_t \sum_i |c_i| \, \phi_i(t) \\ &\le A \|c\|_{l_\infty} \sup_t \sum_i \phi_i(t).\end{aligned}$$

Using the Poisson summation formula [35, p. 105], the formula $\hat{\phi}(\lambda) = \pi e^{-|\lambda|}$, and the relation $|\hat{\phi}_i(\omega)| = \hat{\phi}(\omega)$,

$$\begin{aligned}\sum_i \phi_i(t) &= \sum_j \hat{\phi}_i(2\pi j) \\ &\le \sum_j |\hat{\phi}_i(2\pi j)| = \sum_j \hat{\phi}(2\pi j) \\ &\le 2 \sum_0^{\infty} \pi e^{-2\pi j} = \frac{2\pi}{1 - e^{-2\pi}}.\end{aligned}$$

These lemmas combine to prove that the operator $\mathcal{I}(c) = \sum_i c_i \psi_i$ gives a bounded mapping from l_q into $L_q(\mathbf{R})$ for each $q \in [1, \infty]$. Indeed, with $\theta = 1/q$ we get, from the Riesz–Thorin Interpolation theorem [36, p. 95],

$$\left\| \sum_i c_i \psi_i \right\|_{L_q(\mathbf{R})} \le (A\pi)^\theta \left(A \frac{2\pi}{1 - e^{-2\pi}} \right)^{1-\theta} \|c\|_{l_q}.$$

Combining these bounds with Theorem 5.2 gives the following theorem.

THEOREM 6.3. *Let $\Omega > 2\pi + \eta$. Then for each $q \in [1, \infty]$ the interpolation problem* (13) *has a solution in $B_q(\Omega)$ satisfying the interpolation inequality* (14) *with*

$$K_q(R, \Delta, \Omega) = \Delta^{-2R-1}\kappa(R, \Omega),$$

where

$$\kappa(R, \Omega) = \frac{2\pi}{1 - e^{-2\pi}} \cdot \alpha(R, \eta).$$

7. Proofs for §1.

7.1. Main result. Suppose that μ_1, μ_2 are lattice measures with support of Rayleigh index $\leq R$. For a set A, let $A/2$ denote the dilation $\{t : (2t) \in A\}$. Define the measure ν by

$$\nu(A) = (\mu_1 - \mu_2)\left(\frac{A}{2}\right).$$

Note that ν is supported in the lattice of span $\Delta' = 2\Delta$, and that

$$\begin{aligned} u.u.d.(\mathrm{supp}(\nu)) &= \tfrac{1}{2}\, u.u.d.(\mathrm{supp}(\mu_1) \cup \mathrm{supp}(\mu_2)) \\ &\leq \tfrac{1}{2}\left(u.u.d.(\mathrm{supp}(\mu_1)) + u.u.d.(\mathrm{supp}(\mu_2))\right) < 1. \end{aligned}$$

Moreover, $R^*(\mathrm{supp}(\nu)) \leq R^*(\mathrm{supp}(\mu_1)) + R^*(\mathrm{supp}(\mu_2))$. Hence, $\nu \in \mathcal{S}(2R, \Delta')$. Applying E. Gassiat's improvement of Lemma 2.1, we conclude that ν is an (R, Δ')-measure.

Applying the superresolution inequality (12), the interpolation inequality (14), and Theorem 6.3, we have for any $\Omega' > 2\pi$,

$$\begin{aligned} ||\nu||_2 &\leq C_2(R, \Delta', \Omega')||\nu||_{2,\Omega'} \\ &\leq K_2(R, \Delta', \Omega')||\nu||_{2,\Omega'} \\ &\leq (\Delta')^{-2R-1}\, \kappa(R, \Omega')||\nu||_{2,\Omega'}. \end{aligned}$$

Now we observe that $||\nu||_2 = ||\mu_1 - \mu_2||_2$. Also $\hat{\nu}(\omega) = (\hat{\mu}_1 - \hat{\mu}_2)(2\omega)$. Hence, making the particular choice $\Omega' = \Omega/2$ we have

$$\begin{aligned} ||\nu||_{2,\Omega'} &= \sqrt{2}||\mu_1 - \mu_2||_{2,\Omega} \\ &= \frac{1}{\sqrt{\pi}}||\hat{\mu}_1 - \hat{\mu}_2||_{L_2[-\Omega,\Omega]}. \end{aligned}$$

Upon combining these relations, (6) follows once we set

$$\beta(R, \Omega) = 2^{-2R-1} \cdot \kappa(R, \Omega/2)/\sqrt{\pi}.$$

Remark. If we used Lemma 2.1, rather than Gassiat's improvement, the argument above would give a proof of a result like Theorem 1.3, only with a factor Δ^{-4R-1} rather than Δ^{-2R-1}. This was the result given in the preprint of this article.

7.2. Proof of Theorem 1.1. Part a. Let $\mu_1 \neq \mu_2$ be two distinct measures, and s be a point of $S = \mathrm{supp}(\mu_1) \cup \mathrm{supp}(\mu_2)$ such that $d \equiv \mu_1\{s\} - \mu_2\{s\} \neq 0$. As the μ_i are lattice measures, S is a *separated* set: any two distinct elements of S differ by at least some strictly positive amount. Moreover, $u.u.d.(S) < 2$. Hence by Theorem 1 of Beurling [3], for all sufficiently small $\delta > 0$, there exists a function in $B_\infty(2\pi - \delta)$ solving the interpolation problem

$$f(t) = \begin{cases} 0, & t \in S\backslash\{s\}, \\ \mathrm{sgn}(d), & t = s. \end{cases}$$

Pick a mollifier $h \in B_1(\delta)$ satisfying (i) $h \geq 0$, (ii) $h(0) = 1$. Set

$$\psi(t) = f(t)\, h(t - s).$$

Then, by construction,

$$\int \psi\, d(\mu_1 - \mu_2) = |\mu_1\{s\} - \mu_2\{s\}| > 0.$$

On the other hand, as $\psi \in B_1(2\pi)$, $\hat{\psi}(\omega)$ exists, and by Parseval,

$$\int \psi\, d(\mu_1 - \mu_2) = \frac{1}{2\pi} \int_{-2\pi}^{2\pi} \hat{\psi}(\omega)(\hat{\mu}_1(\omega) - \hat{\mu}_2(\omega)) d\omega.$$

As the integrand of the right side is continuous and as the integral on the left side is strictly positive, we conclude that

$$\hat{\mu}_1(\omega) \neq \hat{\mu}_2(\omega) \quad \text{for some } \omega \in [-2\pi, 2\pi].$$

Part b. This is an application of Beurling's theory of balayage [2]. Say that S *admits balayage* if the restriction to $[-\Omega, \Omega]$ of any Fourier transform of a finite signed measure ν supported in $\mathbf{R}$ can be represented as the restriction to $[-\Omega, \Omega]$ of the Fourier transform of a finite signed measure ν' supported entirely in S, and if the ratio $||\nu'||_1/||\nu||_1$ is bounded above independently of ν. Beurling shows that a necessary and sufficient condition for S to admit balayage is $l.u.d.(S) > \pi/\Omega$; see Theorem 5 [2, p. 346].

To apply this, simply set $\nu = \mu_1$ and $S = S_2$. By assumption, $l.u.d.(S_2) > 1 > \pi/\Omega$ and so we may perform balayage. Let $\mu_2 = \nu'$ be the result. The measure μ_2 is supported on S_2, which by assumption is disjoint from S_1, and yet $\hat{\mu}_1(\omega) = \hat{\mu}_2(\omega)$ for $|\omega| \leq \pi$.

Part c. Let $\Delta = \frac{1}{2}$ and let $f(\omega)$ be a nonzero, smooth function, periodic of period 4π, vanishing on $[-2\pi + \delta, 2\pi - \delta]$, and satisfying the Hermitian symmetry $f(-\omega) = \overline{f}(\omega)$. Set

$$\alpha_k = \frac{\Delta}{2\pi} \int_{-\pi/\Delta}^{\pi/\Delta} e^{i\omega k\Delta} f(\omega) d\omega$$

and define

$$\mu_1 = \sum_{k \text{ odd}} \alpha_k \delta_{k\Delta}$$

and

$$\mu_2 = -\sum_{k \text{ even}} \alpha_k \delta_{k\Delta}.$$

This defines a pair of finite signed measures; the first supported at the half-integers; the second at the integers. These measures have Fourier transforms and

$$(\hat{\mu}_1(\omega) - \hat{\mu}_2(\omega)) = f(\omega) = 0, \qquad |\omega| \leq 2\pi - \delta$$

and so the two measures, although supported disjointly, have Fourier transforms which agree throughout the band $|\omega| \leq 2\pi - \delta$. In addition, note that $l.u.d.(\text{supp}(\mu_i)) = u.u.d.(\text{supp}(\mu_i)) = 1$.

7.3. Proof of Lemma 1.2. In this proof, let $N(y, \epsilon) = N(y, \epsilon; R, \Delta, \Omega) = \{\nu : ||\hat{\nu} - y||_{L_2[-\Omega,\Omega]} \leq \epsilon, \nu \in \mathcal{S}(R, \Delta)\}$ denote the set of all lattice measures with Rayleigh index R which are within an ϵ-distance of y. This set contains μ by assumption. Hence it is nonempty. Consider any "feasible reconstruction" rule $\tilde{\mu}(y)$, i.e., any rule with

$$\tilde{\mu}(y) \in N(y, \epsilon).$$

Such a rule selects, from among all measures which could have generated the data, one which satisfies the assumed sparsity. (It is possible to select from the set $N(y, \epsilon)$ so that $\tilde{\mu}(y)$ is a measurable function of y in the topology generated from $L_2[-\Omega, \Omega]$-norm balls.)

The triangle inequality implies that any such $\tilde{\mu}$ formally has

$$||\hat{\mu} - \hat{\tilde{\mu}}(y)||_{L_2[-\Omega,\Omega]} \leq ||\hat{\mu} - y||_{L_2[-\Omega,\Omega]} + ||y - \hat{\tilde{\mu}}(y)||_{L_2[-\Omega,\Omega]} \leq 2 \cdot \epsilon.$$

Hence, by definition of Λ,

$$||\mu - \tilde{\mu}(y)||_2 \leq \Lambda(2 \cdot \epsilon).$$

The lemma follows.

Remark. The idea of "feasible reconstruction," i.e., of selecting any reconstruction matching known constraints on signal and noise, while of practical value in other contexts [32] is not necessarily practical here, because "projection" onto the set of sparse objects is not a contraction, and so certifiably convergent iterative algorithms are lacking, notwithstanding [23].

7.4. Proof of Theorem 1.4. We make a simple computation. Let $\nu_{r,h} = \sum_{k=0}^{r} (-1)^k C(r,k) \delta_{kh}$, where $C(r,k)$ is the standard combinatorial factor

$$C(r,k) = \frac{r!}{k!(r-k)!}.$$

Then $||\nu_{r,h}||_2 = (\sum_{k=0}^{r} C(r,k)^2)^{1/2}$ independent of h. On the other hand, we recognize that $\nu_{r,h} \star f = D_h^r f$, where D_h^r is the rth-order finite difference operator of span h. From the fact that

$$h^{-r} D_h^r f \rightarrow_{L_2(\mathbf{R})} f^{(r)} \quad \text{as } h \rightarrow 0,$$

for every smooth f of compact support, we get

$$h^{-2r}\int_{-\Omega}^{\Omega}|\hat{\nu}_{r,h}(\omega)|^2 d\omega \to \int_{-\Omega}^{\Omega}\omega^{2r}d\omega = \frac{\Omega^{2r+1}}{r+1/2}.$$

Hence, as $h \to 0$,

$$||\nu_{r,h}||_{2,\Omega} \sim h^r \frac{\Omega^{r+1/2}}{\sqrt{\pi\,(2r+1)}}. \tag{21}$$

Let now

$$\mu_1 = \eta \sum_{\substack{k \text{ odd} \\ 0<k<2R}} C(2R-1,k)\delta_{k\Delta}$$

and

$$\mu_2 = \eta \sum_{\substack{k \text{ even} \\ 0\le k<2R}} C(2R-1,k)\delta_{k\Delta}.$$

Then the μ_i belong to $\mathcal{S}(R,\Delta)$ and $\mu_2-\mu_1 = \eta\,\nu_{2R-1,\Delta}$. Hence if we choose η so that $||\mu_1-\mu_2||_{2,\Omega} = \epsilon$, then

$$\Lambda(\epsilon) \ge ||\mu_1-\mu_2||_2. \tag{22}$$

Now, evidently,

$$||\mu_1-\mu_2||_2 = \frac{||\nu_{2R-1,\Delta}||_2}{||\nu_{2R-1,\Delta}||_{2,\Omega}}\,||\mu_1-\mu_2||_{2,\Omega}.$$

Define

$$b(R,\Omega,\Delta_0) = \inf_{\Delta<\Delta_0}\frac{||\nu_{2R-1,\Delta}||_2}{||\nu_{2R-1,\Delta}||_{2,\Omega}}\,\Delta^{2R-1}.$$

By (21), $b(R,\Omega,\Delta_0) > 0$ and, as $\Delta_0 \to 0$,

$$b(R,\Omega,\Delta_0) \to \frac{\Omega^{2R-1/2}}{\sqrt{\pi\,(4R-1)}}.$$

Hence if $\Delta < \Delta_0$,

$$||\mu_1-\mu_2||_2 \ge \Delta^{-2R+1}\,b(R,\Omega,\Delta_0)\,||\mu_1-\mu_2||_{2,\Omega}$$

and so, by (22) the theorem follows.

8. Proofs for §2.

8.1. Proof of Lemma 2.1. Let $S = \mathrm{supp}(\mu) = \{s_k\}$. Partition the line into intervals $I_m = [mR+\frac{1}{2},(m+1)R+\frac{1}{2})$, $m = \cdots,-1,0,1,\cdots$. In I_m there are by assumption $r_m \le R$ elements of S. We pair up these elements of $S\cap I_m$ with integer elements of I_m from right to left (say). For an integer i paired with an element $s \in S$ in this way, set $u_i = s$. Some integer elements of I_m may remain unpaired after this step; we simply set u_i to be the closest element of the lattice $\{k\Delta\}$ to i which has not been previously assigned to a u_i and which does belong to I_m. In this way we get a bilateral sequence $(u_i)_{i=-\infty}^{\infty}$.

Defining $v_i = 2i - u_i$, gives (8). Since for $i \in I_m$, $u_i \in I_m$, we have $|u_i - i| \leq R$, hence (9). Now any two distinct points in $\{u_i\} \cup \{v_i\}$ are separated by at least the lattice span Δ, hence (10). Also, by our pairing convention, we never assign a u_i to a value which has been previously assigned. Thus all four properties (8)–(11) are verified.

8.2. Proof of Lemma 2.2. If $f \in B_\infty(\Omega)$ has a zero at t_0, then $g(t) = f(t)(t - s_0)/(t - t_0)$ is again in $B_\infty(\Omega)$. Compare, for example, [35, pp. 126–129]. Now, $\sin^2(\pi t) \in B_\infty(2\pi)$; hence, we have $G_n \in B_\infty(2\pi)$ for all $n \geq 1$. Moreover, as $\sin^2(\pi z)$ has only real zeros, $G_n(z)$ has only real zeros.

We show that $\{G_n\}$ forms a Normal Family. Indeed, by the Theorem on page 47 of Koosis [13], an entire function of exponential type with only real zeros satisfies, for $\Im(z) > 0$

$$\log|f(z)| = A_+\Im(z) + \frac{1}{\pi}\int_{-\infty}^{\infty} \frac{\Im(z)}{|z-t|^2} \log|f(t)|dt, \tag{23}$$

where

$$A_+ = \limsup_{y\to\infty} \frac{\log|f(iy)|}{y}.$$

A parallel relation, employing

$$A_- = \limsup_{y\to-\infty} \frac{\log|f(iy)|}{|y|},$$

holds in $\Im(z) < 0$. We note that for $f = G_n$, $A_+ = A_- = 2\pi$. Indeed, $G_n(z) = Q_n(z)\sin^2(\pi z)$, where Q_n is a rational function of degree (n, n) which satisfies

$$Q_n(z) \to 1 \quad \text{as } |z| \to \infty$$

because the numerator and denominator polynomials both have coefficient 1 on the highest order term z^n. Moreover,

$$\frac{1}{\pi}\int_{-\infty}^{\infty} \frac{|\Im(z)|}{|z-t|^2} dt = 1$$

for each nonreal z, and so the second term on the right side of (23) is never larger than $\log||f||_{L_\infty(\mathbf{R})}$. Combining these facts we have

$$\log|G_n(z)| \leq 2\pi|z| + \log||G_n||_{L_\infty(\mathbf{R})}. \tag{24}$$

The proof of Lemma 2.3 below shows that $||G_n||_{L_\infty(\mathbf{R})} \leq A_1(R)$ for all n. Hence (24) shows that $\{G_n(z)\}$ is uniformly bounded in each bounded region of the complex plane. Hence, $\{G_n\}$ is a normal family of entire functions. By Montel's theorem, an entire function G exists as a cluster point of $\{G_n\}$; it must obey, because of (24),

$$\log|G(z)| \leq 2\pi|z| + \log A_1(R)$$

and so G must be entire of exponential type 2π. However, a calculation based on the definition of G_n shows that for each fixed t, $G_n(t)$ converges to a definite limit as $n \to \infty$ so there can only be one cluster point of G_n, and hence the sequence actually has G as a proper limit. The limit function G must satisfy the same relation (23) as the G_n, so G has only real zeros. The following lemma allows us to see that these zeros are at the points t_k and have the same multiplicity as the m_k.

LEMMA 8.1.

$$(n!)^4 \cdot \frac{\sin^2(\pi t)}{\prod_{i=-n}^{n}(t-i)^2} \to \pi^2 \quad \textit{as } n \to \infty$$

uniformly on compact sets of t in $(-\infty, \infty)$.

8.3. Proof of Lemma 2.3. We now arrive at the key estimates. It is enough to show that for large n, $||G_n||_\infty \leq A_1(R)$, as G is the limit of the G_n. We may assume, without loss of generality, that $t \in [-\frac{1}{2}, \frac{1}{2}]$ and $n \gg R$.

$$|G_n(t)| = \frac{\prod_{i=-n}^{n} |i+\delta_i - t|\,|i-\delta_i-t|}{\prod_{i=-n}^{n} |i-t|^2} \sin^2(\pi t).$$

Now, for $|i| > R$, the inequality of the Arithmetic-Geometric mean gives

$$|i+\delta_i-t|\,|i-\delta_i-t| \leq |i-t|^2.$$

On the other hand, for $|i| \leq R$,

$$|i+\delta_i-t|\,|i-\delta_i-t| \leq (2R+1)^2.$$

We also note that

$$\sup_{t\in[-1/2,1/2]} \prod_{\substack{|i|\leq R \\ i\neq 0}} |t-i|^{-2} = \prod_{i=1}^{R} |i^2 - 1/4|^{-2}.$$

Combining these estimates,

$$\begin{aligned}
|G_n(t)| &\leq \frac{\prod_{i=-R}^{R} |i+\delta_i-t|\,|i-\delta_i-t|}{\prod_{i=-R}^{R} |i-t|^2} \sin^2(\pi t) \\
&\leq ((2R+1)^2)^{2R+1} \sup_{t\in[-1/2,1/2]} \prod_{\substack{|i|\leq R \\ i\neq 0}} |t-i|^{-2} \sup_t \frac{\sin^2(\pi t)}{t^2} \\
&= ((2R+1)^2)^{2R+1} \prod_{i=1}^{R} |i^2-1/4|^{-2}\, \pi^2 \\
&= A_1(R).
\end{aligned}$$

8.4. Proof of Lemma 2.4. Without loss of generality, let $k = 0$, let $t_0 \in [-\frac{1}{2}, \frac{1}{2})$ and let $i_0 = i_0(t)$ denote an integer closest to t. Let $a_i = 1$ if $u_i \neq t_0$, and zero otherwise; and let $b_i = 1$ if $v_i \neq t_0$, and zero otherwise. Pick $n \gg 2R$.

$$\frac{|G_n(t)|}{|t - t_0|^{m_0}} = \frac{\prod_{i=-n}^{n} |i + \delta_i - t|^{a_i} \, |i - \delta_i - t|^{b_i}}{\prod_{i=-n}^{n} |i - t|^2} \sin^2(\pi t).$$

Note that if $|i| > 2R$ then necessarily $a_i = b_i = 1$. We again have

$$|i + \delta_i - t| \, |i - \delta_i - t| \leq |i - t|^2 \quad \text{for } |i| > 2R,$$

and so

$$\frac{|G_n(t)|}{|t - t_0|^{m_0}} \leq \frac{\prod_{|i| \leq 2R} |i + \delta_i - t|^{a_i} \, |i - \delta_i - t|^{b_i}}{\prod_{\substack{|i| \leq 2R \\ i \neq i_0}} |t - i|^{-2}} \cdot \frac{\sin^2(\pi t)}{|t - i_0|^2}.$$

Now

$$\sup_{t \in [-1/2, 1/2]} \prod_{\substack{|i| \leq 2R \\ i \neq i_0}} |t - i|^{-2} \leq \prod_{i=1}^{2R-1} |i^2 - 1/4|^{-2}$$

and also,

$$|i + \delta_i - t|^{a_i} \, |i - \delta_i - t|^{b_i} \leq (3R + 1)^2 \quad \text{for } |i| \leq 2R.$$

Hence

$$\begin{aligned} \frac{|G_n(t)|}{|t - t_0|^{m_0}} &\leq ((3R + 1)^2)^{4R+1} \prod_{i=1}^{2R-1} |i^2 - 1/4|^{-2} \, \pi^2 \\ &= A_2(R). \end{aligned}$$

8.5. Proof of Lemma 2.5. Without loss of generality, let $k = 0$, and suppose that $|t_0| \leq \frac{1}{2}$. Set

$$G_n(t) = \prod_{-n}^{n} (t - u_i)(t - v_i) \, H_n(t).$$

By Lemma 8.1, $(n!)^4 H_n(t_0) \to \pi^2$ as $n \to \infty$. Let n be so large that $(n!)^4 H_n(t_0) \geq \pi^2/2$. Then set $x_i = |u_i - t_0|$ and $y_i = |v_i - t_0|$. Define a_i and b_i as in the previous section. The convention $0^0 = 1$ will simplify notation below.

Now

$$|g_{0,n}| = |H_n(t_0)| \cdot \prod_{-n}^{n} x_i^{a_i} y_i^{b_i}$$

and so, by our choice of n,

$$|g_{0,n}| \geq \frac{\pi^2}{2} \cdot \frac{\prod_{-n}^{n} x_i^{a_i} y_i^{b_i}}{\prod_{i=1}^{n} i^4}. \tag{25}$$

We need two estimates. First, for a constant $E_0(R)$,

$$\prod_{i=-R}^{R} x_i^{a_i} y_i^{b_i} \geq E_0(R)\, \Delta^{2R+1}. \tag{26}$$

To see this, note that at most $2R+2$ of the x_i and y_i can be less than $\frac{1}{2}$. Indeed, if $i \neq 0$ at most one member of each pair (u_i, v_i) can be in the interval $[-1,1]$; and if $|i| > R$, neither member of a pair can be in the interval. On the other hand, by hypothesis, at least one of the (x_i) or (y_i) must be zero, as t_0 belongs to $\{u_i\} \cup \{v_i\}$. Therefore, the product on the left side of (26) contains at most $2R+1$ terms of size less than $\frac{1}{2}$. Such terms, by (10), must be at least Δ in size. Hence,

$$\prod_{i=-R}^{R} x_i^{a_i} y_i^{b_i} \geq \Delta^{2R+1} \left(\frac{1}{2}\right)^{2R+1}. \tag{27}$$

Thus (26) holds, with $E_0(R) = 2^{-2R-1}$. (Much larger values for E_0 may established with more effort.)

Our second estimate concerns the terms omitted by (26). We wish to show that

$$\prod_{R+1}^{n} \frac{x_i^{a_i} y_i^{b_i} x_{-i}^{a_{-i}} y_{-i}^{b_{-i}}}{i^4} \geq E_1(R) > 0. \tag{28}$$

The key point is that for $|i| > R$, $a_i = b_i = 1$. Now

$$\begin{aligned}
\frac{x_i y_i x_{-i} y_{-i}}{i^4} &= \frac{|i+\delta_i - t_0|\,|i-\delta_i-t_0|\,|-i+\delta_{-i}-t_0|\,|-i-\delta_{-i}-t_0|}{i^4} \\
&= \frac{|(i-t_0)^2 - \delta_i^2|\,|(-i-t_0)^2-\delta_{-i}^2|}{i^4} \\
&= \left|\left(1-\frac{t_0}{i}\right)^2 - \left(\frac{\delta_i}{i}\right)^2\right| \left|\left(1+\frac{t_0}{i}\right)^2 - \left(\frac{\delta_{-i}}{i}\right)^2\right| \\
&\geq \left|\left(1-\frac{1}{2i}\right)^2 - \left(\frac{R}{i}\right)^2\right| \left|\left(1+\frac{1}{2i}\right)^2 - \left(\frac{R}{i}\right)^2\right| \\
&= e_i,
\end{aligned}$$

say (the inequality step is justified by additional calculations, which we omit). Now $e_i \geq [((2R+1)/(2R+2))^2 - (R/(R+1))^2]^2 > 0$. A little algebra shows that for $i > 2R$, $e_i > (1-(2R/i)^2)$. Hence, defining

$$E_1(R) = \prod_{i=R+1}^{\infty} e_i,$$

we have

$$E_1(R) \geq \prod_{i=R+1}^{2R} e_i \cdot \prod_{i=2R+1}^{\infty} \left(1 - \left(\frac{2R}{i}\right)^2\right) > 0,$$

and (28) holds. Again, this is only a very crude estimate; much larger values of $E_1(R)$ can be established.

Combining the inequalities (25), (26), and (28), we have

$$|g_{0,n}| \geq \Delta^{2R+1} \cdot \frac{\pi^2}{2} \cdot E_0(R) \cdot E_1(R) \cdot (R!)^{-4},$$

which, by a limiting process, yields the sought-for inequality

$$|g_0| \geq \Delta^{2R+1} \cdot A_3(R)$$

with the (very crude) value

$$A_3(R) = \frac{\pi^2}{2} \cdot E_0(R) \cdot E_1(R) \cdot (R!)^{-4}.$$

9. Discussion.

A few final remarks may clarify issues raised by the above.

9.1. The optimal exponent.

Theorems 1.3 and 1.4 together suggest that for a certain exponent $e(R)$ we have, for $\Omega > \Omega_0$, and all small Δ

$$E^*(\epsilon, R, \Delta, \Omega) \asymp \Delta^{-e(R)} \cdot \text{Const}(R, \Omega) \cdot \epsilon.$$

If such a relation holds, we must have, by Theorems 1.3 and 1.4,

$$2R - 1 \leq e(R) \leq 2R + 1.$$

What is the value of $e(R)$?

9.2. Relation to other work.

A number of papers treat the problem of recovering a signal from data which are missing information about a whole band of frequencies, by exploiting support limitations: compare results in [26], [7], [8], [25].

The closest result in those papers to the present one may be stated as follows [8, §6]. Suppose that (x_t) is a discrete-time signal, and that we have noisy information $\hat{y}(\omega) = \hat{x}(\omega) + \hat{z}(\omega)$ about the Fourier transform of x; only now the *high* frequencies $|\omega| \in [\frac{\pi}{m}, \pi]$ are observed, m an integer greater than 1. Then, despite the missing information about the *low* frequency band $[-\frac{\pi}{m}, \frac{\pi}{m}]$, we can stably recover (x_t)—provided that in every interval of length m, a fraction less than $1/\pi$ of the samples are nonzero.

The present paper covers the complementary case, where information for the *low* frequency interval $[-\frac{\pi}{m}, \frac{\pi}{m}]$ would be observed, and information for the *high* frequency band $|\omega| \in [\frac{\pi}{m}, \pi]$ would be missing. For stable recovery of (x_t), Theorem 1.4 would require that for each interval of length $4mR$, fewer than R samples are nonzero.

This considerably more restrictive sparsity condition expresses the fact that the problem of missing *high* frequencies is much more ill-posed than the problem of missing *low* frequencies.

In another direction, one might compare the interpolation results developed here with other work on interpolation of entire functions. Both in Boas [4] and in Duffin and Schaeffer [9] there is discussion of sets which are uniformly discrete and of uniform density 1, so that conditions (9) and (10) hold. However, the internal symmetry condition (8) seems different from earlier work and figures significantly in the key Lemmas 2.3, 2.4, and 2.5. It would be interesting to know whether this internal symmetry condition is in some sense necessary.

9.3. Removing the lattice constraint. We consider it plausible that a more general family of superresolution inequalities holds, in which the lattice constraint $\mu \in \mathcal{L}(\Delta)$ is removed. Such an inequality would be of the form

$$||\nu||_{p,\lambda\Omega} \leq A_p(\lambda, \Omega, R)||\nu||_{p,\Omega},$$

where $\lambda > 1$ is the superresolution factor, and the inequality is suppposed valid for all finite signed measures ν with support of Rayleigh index R. Such an inequality would express superresolution by the fact that the norm on a larger frequency band would be controlled by the norm on a smaller frequency band. For comparison, if $\mu \in \mathcal{L}(\Delta)$, and $\lambda\Omega = \pi/\Delta$, then

$$||\nu||_{2,\lambda\Omega}^2 = \frac{1}{2\pi}||\nu_2||_2^2,$$

so we get the inequality proved in this paper as a special case. Evidently λ plays the role of Δ^{-1}; it seems plausible that the stability coefficient A_p would grow with λ like $\lambda^{e(R)}$, where $e(R)$ is the optimal exponent in the lattice case.

HALFWAY POINTS*

W. A. BEYER† AND BLAIR SWARTZ‡

This paper is dedicated to R. S. Varga.

Abstract. As a half space moving perpendicularly to its border crosses a given density distribution, it may be stopped when it contains exactly half of the total mass of the distribution. Any point in common with the boundaries of all such stopped half spaces is called a "halfway point" for the distribution. One may regard it as a multidimensional extension of the "median" of one-dimensional distributions. A context in which such points arise is discussed, and some characteristics of distributions that have halfway points are considered.

Key words. moment center, center of volume, median

AMS(MOS) subject classification. 28A75

Introduction. Suppose two-dimensional cakes come in various shapes and mass distributions. Suppose we buy only those cakes such that there is a unique point on the cake (that we shall call the cake's *halfway point*) such that a sufficiently long knife cutting through that point divides the cake into two pieces of equal mass, independent of the orientation of the cake. What kinds of shapes and mass distributions of cakes are we limited to buying? What about n-dimensional cakes?

This problem was suggested by work concerning interface reconstruction in computational hydrodynamics and edge reconstruction in image enhancement [8]. We outline these contexts—a more complete statement is given in §1 below and in [8]. Suppose we are given a characteristic function $c(x)$ of an open subset Ω of the plane (say), with the boundary of Ω being sufficiently regular. Blur $c(x)$ using a convolution with a scaled measure distribution function ρ (of total mass one) as in (1.4) below. Call the blurred function $\bar{c}(x)$—it depends on the scale h, on the function ρ, on Ω, and on the location z of the origin for ρ. If the scale h is sufficiently small and z is inside ρ's support (here assumed compact), then $\bar{c}(x)$ will be 1 inside Ω and zero outside, except that there will be a narrow strip containing Ω's boundary on which $\bar{c}$ assumes values strictly between zero and 1. This is the reason that $\bar{c}$ is called a blurring of c.

The paper [8] analyzes three algorithms for approximately reconstructing the boundary of Ω from discrete data about its blurred image. When the scale is small (relative to the boundary's curvature), and when the data are taken at a comparable scale, then algorithms designed to recover linear boundaries exactly will have "second-order" accuracy for curved boundaries (assuming the algorithms also have a certain stability property [8]). Such accuracy is useful for efficient interface reconstruction in numerical hydrodynamics when it involves the "volume fractions" of computational cells in two-dimensional calculations. (Second-order accuracy is even more important for three space dimensions.) And the "sub-pixel-size" accuracy associated with the

†T Division, MS B284, University of California, Los Alamos National Laboratory, Los Alamos, New Mexico 87545.

second-order accurate reconstruction of curved "edges" would also be useful in (two-dimensional) image processing.

Thus, the creation of second-order accurate algorithms depends on understanding the details of the behavior of the blurring of linear boundaries. It turns out that if the point z in the blurring (1.4) is the halfway point of the function ρ, then the blurring has the property that, for the case of an unblurred linear boundary with an arbitrary orientation, x lies exactly on the unblurred boundary if and only if $\bar{c}(x)$ has the value $\frac{1}{2}$. This is the property of the halfway point that gives it significance for us. But we may also regard it as locating a "central" point of the distribution—in particular, as a multidimensional extension of the "median" of one-dimensional distributions. Also, suppose a solid convex body, of uniform density, has a halfway point and displaces twice its weight when fully immersed in a fluid. Then, if allowed to float in the fluid, the sea-level plane will contain the halfway point. Indeed, the body's "surface of buoyancy" as it is called in naval architecture (i.e., the envelope of all *candidates* for the sea-level plane) reduces to the halfway point.

In §2 we explore some characteristics of mass distributions that have halfway points—cf. Propositions A and B there.

1. The blurring of boundaries; cumulative distributions. Motivation for this note arose in the following context. The plane is decomposed into two regions, Ω_0 and Ω_1, separated by their common boundary β. We assume that β has bounded curvature, does not cross itself, and consists of one component only. Associate with this setup the color function (essentially, characteristic function) c, defined by

$$c(x) := \begin{cases} 0, & x \text{ in } \Omega_0, \\ 1, & x \text{ in } \Omega_1, \\ \frac{1}{2}, & x \text{ in } \beta. \end{cases} \tag{1.1}$$

In particular, and somewhat artificially, β is the inverse image of $\frac{1}{2}$ under the map c. The following example of a scaled blurring of c is used in computational fluid dynamics (see, e.g., references in [8]). Let $S(x,h)$ be the square of area h^2, centered on the point x, and with sides parallel to the coordinate axes. Associate with c and S the "average color" function

$$\bar{c}(x) := \iint_{S(x,h)} c(\xi)\, dA(\xi)/h^2, \qquad x \text{ in } \mathbb{R}^2. \tag{1.2}$$

For h sufficiently small (relative to β's curvature), the set $\bar{c}^{-1}(\frac{1}{2})$ is one-dimensional and approximates β. Given a uniform mesh of points $X_i := (i_1h, i_2h)$ of grid-size h—the same h as in S—we can and do consider the use of meshpoint values $\bar{c}(X_i)$ (sometimes called "volume fractions") in approximately reconstructing β. For example, [8] discusses local approximate reconstruction using the locations of a few adjacent "gray" values of the average color $(\bar{c} \in (0,1))$. Reconstruction that is "first-order accurate" in the blurring's "scale" h (i.e., has $O(h)$ accuracy as $h \to 0$) is relatively easy, since the Hausdorff distance from β to the set of gray meshpoints does not exceed $h/\sqrt{2}$. But for $O(h^2)$ accuracy, the localized algorithm must essentially reproduce linear boundaries. To do this it is important to know how the local averaging smears the boundaries of half spaces.

Observe that the level curves of the average color function $\bar{c}_L$, of the color function c_L associated with the $h \times h$ square $S(x,h)$ and the two half planes bounded by a common line L (with unit normal ν pointing into Ω_1), are lines parallel to L. Moreover, $\bar{c}_L(x)$ is only a function $f_\nu(\sigma)$ of the (signed) *scaled* distance $\sigma := s/h$ from x to L, with s, say, as measured along ν. Ambiguity is removed by choosing $s > 0$ in Ω_1. With this and no matter how L is oriented, (1) f_ν is strictly monotone increasing where it is neither zero nor 1; (2) the symmetry of the square S means that $f_\nu = \frac{1}{2}$ exactly when $\sigma = 0$, i.e.,

$$L = \bar{c}_L^{-1}(\tfrac{1}{2}) \quad \text{for arbitrary lines } L; \tag{1.3}$$

and (3) the graph of f_ν is symmetric under reflection through the point $(0, \frac{1}{2})$. f_ν has been called the *cumulative distribution function for ν-normal lines* (with respect to the unit square centered on the origin)—cf. [8], where it is also expressed more analytically.

The blurring (1.2) is a special case of the following. Assume we are given a probability density ρ defined on the plane. Let ρ_z be its translate to an "origin" z, i.e., $\rho_z(x) := \rho(x + z)$. Redefine the "average color" of a color function c to be the scaled convolution

$$\bar{c}(x) := \iint_{\text{plane}} \rho_z\bigl((\xi - x)/h\bigr)\, c(\xi)\, dA(\xi)/h^2\,; \tag{1.4}$$

it bears the origin z and the scale h as parameters.

Consider what needs to be imposed on ρ so that, for arbitrary lines L, the property (1.3) of the associated $\bar{c}_L$ holds true. To fix ideas, suppose ρ were the characteristic function of an equilateral triangle T of unit area. Is there some z so that (1.3) holds? There is for fixed L—it is any z on the line $\hat{L}$ parallel to L that contains half of the area of T on one side and half on the other. But if (1.3) is to be independent of L, then the envelope of such lines must reduce to a point, x_0, that we would then label the *point that divides ρ in half*, or, *the halfway point for ρ* (the phrase "ρ's center of mass" having been preempted by $\iint \xi\, \rho(\xi)\, dA$, and "midpoint" being less dynamic). To see that T has no halfway point, it suffices to observe that, while the three altitudes each bisect T and intersect $\frac{2}{3}$ of the way down an altitude from its corresponding vertex, the corresponding relative distance to the line that both bisects T and is parallel to a side of T is $\sqrt{2}/2$. A fixed affine map taking T onto a given general triangle maps these altitudes onto medians and bisecting lines onto bisecting lines (since its Jacobian is independent of location). It follows that no triangle has a characteristic function that has a halfway point. (That is to say, the envelope of the bisecting lines is a curve, not a point. See, e.g., [2], [3], [4, §253, p. 382], [5, p. 190], or [6, Ex. 3, p. 232].)

For what densities do halfway points exist? In terms of polar coordinates centered on ρ's halfway point, the quantity

$$\int_\alpha^{\alpha+\pi} \int_0^\infty r\, \rho(r, \theta)\, dr\, d\theta$$

must be constant (namely, $\frac{1}{2}$). Differentiating it, we see that x_0 divides ρ in half if and only if (in these same polar coordinates and for all θ) $\int_0^\infty r\, \rho(r, \theta)\, dr = \int_0^\infty r\, \rho(r, \pi + \theta)\, dr$. In particular, a halfway point for ρ, if it exists, need not coincide with ρ's center of mass. The following statements are justified in the next section. An equivalent characterization of a halfway point for ρ (should it exist) is that opposite sectors, bounded by two lines through it, have the same mass. ρ has at most one halfway point.

If ρ is symmetric under reflection through a point x_0, (i.e., if $\rho(x_0 + x) = \rho(x_0 - x)$ for all x), then x_0 divides ρ in half. On the other hand, if ρ is nonzero only on an open set S and has a halfway point x_0 with respect to which S is star-shaped, and if $\rho(x_0 + x) = \rho(x_0 - x)$ when $x_0 - x$ and $x_0 + x$ are both in S (for example, if, on the S-part of each line through x_0, ρ were constant), then both S and ρ are symmetric under reflection through x_0. In particular, x_0 is the halfway point for the (normalized) characteristic function χ_K of a bounded open convex set K if and only if K is symmetric under reflection through x_0.

For $L = L_\nu$ to coincide with the associated $\bar{c}_L^{-1}(\frac{1}{2})$ (and not be just a proper subset), we must also assume, with z being ρ's halfway point, that ρ_z's associated *cumulative distribution function for* ν*-normal lines* [8], namely,

$$f_\nu(\sigma) := \int_{-\sigma}^{\infty} \int_{-\infty}^{\infty} \rho(z + s\nu + t\omega)\, dt\, ds, \quad \omega \cdot \nu = 0, \quad \|\omega\| = \|\nu\| = 1, \tag{1.5}$$

is strictly monotone at $(0, \frac{1}{2})$; indeed, it is useful to impose a wider extension of this—see (2.3) ff. below. And recall that ν points into Ω_1, i.e., towards that side of the line L where $c = 1$, so that $\bar{c}_L(x) = f_\nu(\sigma)$, with $h\sigma$, the signed distance from the line to x as measured along ν, being negative for x in Ω_0 and nonnegative, otherwise.

Examples of probability densities having halfway points include (1) the (normalized) characteristic functions of parallelograms or ellipses; (2) normalized, azimuthally symmetric densities (which are functions only of r in polar coordinates centered on some point, i.e., functions called "radial functions" in recent literature concerning scattered data approximation); and (3) the following two structures: Suppose two circular discs each have mass one and uniform but different densities. Interchange a sector $0 \leq \theta < \alpha$ of one disc with a similar sector of the other, matching up (former) centers and bounding radii, this last as far as is possible. For either of the new structures, its halfway point—namely, the discs' former centers—is not its center of mass.

It is worth noting that, for distributions over *one* space dimension, halfway points *always* exist—they are called "medians" of the distribution. Recall that, as in more dimensions, they needn't coincide with the distribution's mean, but that for one space dimension they needn't be unique.

2. Halfway points in n dimensions. Let g, a nonnegative integrable function on n-dimensional Euclidean space $\mathbb{R}^n$, be not identically zero and sufficiently smooth—we take this to mean that (a) the support of g (i.e., the closure of the set on which g is nonzero) is the closure of its nonempty interior, and (b) the amount of $r^{n-1}g$ on half lines, namely,

$$G(x, \nu) := \int_0^\infty r^{n-1} g(x + r\nu)\, dr,$$

is, for each x in $\mathbb{R}^n$, an integrable function on the unit sphere $\|\nu\| = 1$ in $\mathbb{R}^n$.

We shall say that *the point x_0 in a k-dimensional hyperplane $H_k \subseteq \mathbb{R}^n$ divides g in half on H_k* means that *for any $(k-1)$-dimensional hyperplane $H_{k-1} \subset H_k$ through x_0, the amount of g in H_k on either side of H_{k-1} is the same; more precisely,*

$$\int_{H^+(H_{k-1})} g(x)\, d^k x = \int_{H^-(H_{k-1})} g(x)\, d^k x,$$

where the $H^\pm(H_{k-1})$ are the sides of H_k with respect to H_{k-1}. Such a point will be called *a halfway point for g on H_k*. With this, we have the following.

PROPOSITION A. (1) *Suppose $G(x_0, \cdot)$ is continuous on the unit sphere. Then if for some k, $1 \leq k \leq n$, x_0 is a halfway point for the function $\|x - x_0\|^{n-k} g(x)$ on every k-dimensional hyperplane in $\mathbb{R}^n$ containing x_0, then this is so for all such k.* (2) *If x_0 is a halfway point for g on $\mathbb{R}^n$, $G(x_0, \cdot)$ is continuous on the unit sphere, and H is any $(n-1)$-dimensional hyperplane through x_0, then x_0 is the center of mass of the H-section of g, i.e., of the density distribution $g|_H$.* (3) *A halfway point for g on $\mathbb{R}^n$ is unique for $n > 1$.* (4) *If g is symmetric under reflection through a point x_0, then x_0 divides g in half.* (5) *If g is nonzero only on an open set S and has a halfway point x_0 with respect to which S is star-shaped, and if $g(x_0 + x) = g(x_0 - x)$ when $x_0 - x$ and $x_0 + x$ are both in S, then both S and g are symmetric under reflection through x_0. In particular, x_0 is the halfway point for the characteristic function χ_K of a bounded open convex set K if and only if K is symmetric under reflection through x_0.*

For these results we need a lemma and its corollary.

LEMMA. *That x_0 divides g in half on a k-dimensional hyperplane H_k $(k > 1)$ is equivalent to the following. Let $S_1 \neq S_2$ be $(k-1)$-dimensional hyperplanes in H_k and through x_0. Then the amount of g between opposing sectors (bounded by S_1, S_2, and their intersection) is the same.*

Proof. Sufficiency is clear. (Let the two hyperplanes coalesce.) For necessity, identify four regions in H_k, $X_{\pm\mp}$, by the signs of $\lambda_i - \lambda_i(x_0)$ for two appropriate linear functionals λ_i (i.e., such that S_i is the null space in H_k of $\lambda_i - \lambda_i(x_0)$); and let the four numbers $g_{\pm\mp}$ be the amount of g in $X_{\pm\mp}$. Then, the difference between the two relations,

$$g_{++} + g_{+-} = g_{--} + g_{-+} \quad \text{and} \quad g_{+-} + g_{--} = g_{-+} + g_{++},$$

yields the desired relation $g_{++} = g_{--}$. □

In this Lemma, let $S_1 \cap S_2 =: H_{k-2}$ be fixed, and let S_1 approach $S_2 =: H_{k-1}$. Then we are led to the following.

COROLLARY. *If x_0 divides g in half on H_k, some $k \geq 2$, and $G(x_0, \cdot)$ is continuous, then for all $H_{k-2} \subset H_{k-1}$ both containing x_0,*

$$\int_{H^+(H_{k-2})} \|x - x_0\| \, g(x) \, d^{k-1}x = \int_{H^-(H_{k-2})} \|x - x_0\| \, g(x) \, d^{k-1}x.$$

Proof. Let $S_1 \neq S_2 = H_{k-1}$ be $(k-1)$-dimensional hyperplanes in H_k, each containing x_0, with $S_1 \cap S_2 = H_{k-2}$. Let $W^{\pm}$ be the opposite sectors of the regions bounded by S_1 and S_2 with interior angle ϕ. Then from the Lemma,

$$\int_{W^-} g(x) \, d^k x = \int_{W^+} g(x) \, d^k x.$$

Recall from, e.g., Sommerfeld [7, pp. 227–228] that the volume element in k-dimensional spherical coordinates, namely (for $r > 0$, $-\pi < \theta_1 < \pi$, and $0 < \theta_i < \pi$ when $i > 1$),

$$d^k x = \sin^{k-2}\theta_{k-1} \sin^{k-3}\theta_{k-2} \cdots \sin\theta_2 \, r^{k-1} \, dr \, d\theta_1 \cdots d\theta_{k-1} \tag{2.1}$$

satisfies $d^k x = \sin^{k-2}\theta_{k-1} \, (r \, d^{k-1}x) \, d\theta_{k-1}$. Place the origin at x_0, and place the polar axis normal to H_{k-1} and oriented so that all points in $W^{\pm}$ satisfy $\theta_{k-1} = \pi/2 \pm \psi_{\pm}$, some $\psi_\pm \in [0,\phi]$. Let $C^\pm(\psi)$ be the cone with vertex x_0 that is defined by $\theta_{k-1} =$ constant $= \pi/2 \pm \psi$. By Fubini's theorem,

$$\int_{\pi/2-\phi}^{\pi/2} \left[\int_{W^-\cap C^-(\pi/2-\theta_{k-1})} g(x,\theta_{k-1})\, r\, d^{k-1}x \right] \sin^{k-2}\theta_{k-1}\, d\theta_{k-1}$$
$$= \int_{\pi/2}^{\pi/2+\phi} \left[\int_{W^+\cap C^+(\theta_{k-1}-\pi/2)} g(x,\theta_{k-1})\, r\, d^{k-1}x \right] \sin^{k-2}\theta_{k-1}\, d\theta_{k-1}.$$

The conclusion of the Corollary is obtained by letting $\phi \to 0$ and by using the mean value theorem for integrals, which may be done by the continuity of $G(x_0, \cdot)$. □

To prove (1) in Proposition A, we suppose that for some k, $1 \le k \le n$, x_0 is a halfway point for $\|x - x_0\|^{n-k} g(x)$ on all k-dimensional hyperplanes H_k containing x_0. If $k > 1$, apply the Corollary successively to the functions

$$\|x-x_0\|^{n-k} g(x)\big|_{H_k}, \quad \|x-x_0\|^{n-k+1} g(x)\big|_{H_{k-1}}, \cdots, \|x-x_0\|^{n-2} g(x)\big|_{H_2}.$$

Thus, x_0 is a halfway point for the restriction of $\|x-x_0\|^{n-1} g(x)$ to any line L through x_0, so that $G(x_0,-\nu) = G(x_0,\nu)$ for all ν on the unit sphere. Placing the origin for spherical coordinates at x_0 with the polar axis normal to a given but arbitrary $(n-1)$-dimensional hyperplane containing x_0, we see that x_0 is a halfway point for g on $\mathbb{R}^n$. We may now replace k by n in this argument to complete the proof of (1).

To prove (2) in Proposition A, restrict g to the $(n-1)$-dimensional hyperplane H, and let n-dimensional spherical coordinates be centered on x_0 with polar axis normal to H, so that a line L in H through x_0 is determined by fixing $0 < \theta_1, \cdots, \theta_{n-2} < \pi$ and $\theta_{n-1} = \pi/2$. Then, taking $k = 1$ in part (1), the amount of $r^{n-1} g\big|_L$ on either side of the origin is the same: $\int_{r>0} r^{n-1} g(r,\cdot)\big|_L\, dr = \int_{r<0} r^{n-1} g(r,\cdot)\big|_L\, dr$. It follows that the component of the center of mass of $g\big|_H$ along any unit vector u parallel to H vanishes, since it is proportional to $\int_H g\big|_H r\cos\alpha\, dx^{n-1}$, i.e., (using (2.1) with $k = n-1$), to

$$\int_0^\pi \cdots \int_0^\pi \int_0^\pi \int_0^\infty \big(g(r,\cdot,\pi/2) - g(-r,\cdot,\pi/2)\big)\, r\cos\alpha$$
$$r^{n-2}\sin^{n-3}\theta_{n-2}\sin^{n-4}\theta_{n-3}\cdots\sin\theta_2\, dr\, d\theta_1\cdots d\theta_{n-2},$$

in both of which α, the angle (in $\mathbb{R}^n$) between u and the radius vector, is independent of r.

To prove (3) in Proposition A, suppose $n > 1$ and that $x_0 \ne x_1$ are both halfway points determining a line L; and let x not lie on L. We want to show $g(x) = 0$; for then, x being arbitrary, g would be zero or concentrated on L, cases we do not allow. For this, let $H(0)$ and $H(1)$ be two parallel $(n-1)$-dimensional hyperplanes with (a) x strictly between them, and (b) x_0 in $H(0)$ and x_1 in $H(1)$. Then, the amount of g on the side of $H(0)$ not containing x_1 is the amount of g on the side of $H(1)$ not containing x_0. Hence, the amount of g between $H(0)$ and $H(1)$ is zero. Since x lies strictly between these two hyperplanes, $g(x) = 0$.

The proof of (4) in Proposition A is clear.

To prove (5) in Proposition A, choose a line L through x_0; and let $x_0 - w$ and $x_0 + z$ be the endpoints of the open line segment $L \cap S$, choosing $\|w\| \le \|z\|$. Then, with $a(y)$ the amount of the function $\|x - x_0\|^{n-1} g(x_0 + x)$ between x_0 and $x_0 + y$

on L, $a(w) = a(-w)$. But, since x_0 is the halfway point for g, $a(z) = a(-w)$. So, since $x_0 + w$ and $x_0 + z$ lie on the same side of x_0, the amount of g between $x_0 + w$ and $x_0 + z$ is zero. Since S is star-shaped with respect to x_0, this amount would be positive if $\|w\| < \|z\|$. So, $\|w\| = \|z\|$; and, as L was arbitrary, the boundary of S is symmetric under reflection through x_0. As S is star-shaped with respect to x_0, S itself has the same symmetry. Hence, so does g. It remains to show that if, instead, $S = K$ is bounded, open and convex, and if $g := \chi_K / \int_{\mathbb{R}^n} \chi_K$ has halfway point x_0, then $x_0 \in K$ (for then K is star-shaped with respect to x_0). But if $x_0 \notin K$, then there is an $(n-1)$-dimensional hyperplane H with $x_0 \in H$, but with K completely on one side of H—say, the side in the direction of H's unit normal vector ν. But, then, the "cumulative distribution function f_ν for ν-normal hyperplanes" associated with the density $\rho := g$ ((2.3) below, with $z := 0$) satisfies (a) $f_\nu(0) = \frac{1}{2}$ and (b) $f_\nu(\sigma) = 1$ for $\sigma > 0$. But this contradicts the continuity of f_ν, so $x_0 \in K$ after all. □

In Proposition A, (1) fails to characterize halfway points in some easy cases—for example, $G(x_0, \cdot)$ fails to be continuous for the open, azimuthally symmetric, two-dimensional "butterfly" $\{(r,\theta) : 0 < |r| < 1,\ 0 < \theta < \alpha_0 < \pi/2\}$ or its partly open, unsymmetric sibling, $\{(r,\theta) : 0 < r < 1;\ 0 \le \theta < \alpha_0 \text{ or } \pi < \theta \le \pi + \alpha_0\}$. It might prove amusing to explore the extent that (1) (and the definition of halfway point) could be weakened to: $(\hat{1})$ *If for some k, $1 \le k \le n$, x_0 is a halfway point for the function $\|x - x_0\|^{n-k} g(x)$ on almost every k-dimensional hyperplane in $\mathbb{R}^n$ containing x_0, then this is so for all such k.*

Remark. The conclusion of (2) in Proposition A—namely, that a distribution's halfway point in $\mathbb{R}^n$ is also the center of mass of every $(n-1)$-dimensional (hyper)plane section containing it—is also a consequence of the first of a sequence of results in the hydrostatics of floating bodies. This connection goes as follows (here in three dimensions but with no loss in generality): Suppose one is given a body B (say, a convex body) along with a prescribed fraction γ in $(0,1)$. Let E be the envelope of those planes that divide B into two parts having relative volume γ and $1-\gamma$. (If the body B had specific gravity γ and were floating in some orientation, then its sea-level plane section would be tangent to E independent of that orientation.) The result of particular interest in this context states that *the point of tangency of each of the dividing planes to their envelope E is the (two-dimensional) center of mass of the corresponding plane section of B.* This result is the simplest of a sequence of conclusions concerning the orientation and stability of the equilibrium positions for floating bodies; a sequence generally attributed (by Bouasse [4], Appell [1, §651, p. 196ff], Greenhill [5, p. 160], and Lamb [6, pp. 227ff]) to Bouguer (1746) in part and to Dupin (1814)—although Bouasse [4, §220, p. 324] attributes this particular result instead to Lacroix, one of the early (1797) calculus textbook writers. All justify the result in much the same way that our Lemma and its Corollary were proved (but no author clearly states the hypotheses he assumes). The typical argument goes as follows. Two nearby planes of the type mentioned intersect in a line L; the amount of B in each of the two narrow sectors between the planes on either side of L must be the same, but this is also closely approximated by the product of the small angle between the planes with the plane section's first moment in either of the directions orthogonal to L. Let the two planes and the lines L converge. Then the limiting line contains the section's center of mass along with the limiting plane's point of tangency to the envelope.

A similar argument indicates that the result should extend to higher dimensions and to the division by hyperplanes of relatively general mass distributions into two parts having fixed but not necessarily equal masses. (L, then, is an $(n-2)$-dimensional hyperplane.) We see no difficulties with such extensions in the case of interest here—namely, when the entire envelope reduces to a point. But there do exist counterexamples in more general situations—see, e.g., Beyer and Swartz [2, Ex. 10.3].

To complete this Remark we reconsider part (2) of Proposition A in our three-dimensional context. So we suppose above that $B \subset \mathbb{R}^3$ has a halfway point x_0. Then, taking $\gamma = \frac{1}{2}$, the envelope E reduces to x_0. Thus the result above implies, as desired, that every plane section of B containing x_0 has center of mass x_0.

In the context of boundary reconstruction in n dimensions, the average color of a color function c is the analog of the scaled convolution (1.4):

$$\bar{c}(x) := \int_{\mathbb{R}^n} \rho_z\big((\xi - x)/h\big)\, c(\xi)\, d\xi^n/h^n; \tag{2.2}$$

it again bears the "origin" z (of the given probability distribution ρ) and the "scale" h as parameters. With the z the halfway point for ρ (=: g above) assumed to exist, we would also like to ensure that each $(n-1)$-dimensional hyperplane boundary H *coincides* with the inverse image $\bar{c}_H^{-1}(\frac{1}{2})$ under the average coloring $\bar{c}_H$ of $\mathbb{R}^n$ associated with H, and is not just a proper subset of that inverse image. For this, define, for each unit vector ν (regarded as the normal for an associated $(n-1)$-dimensional hyperplane $H(\nu)$ through the origin), the *cumulative distribution function f_ν of ρ for ν-normal hyperplanes,* namely,

$$f_\nu(\sigma) := \int_{-\sigma}^{\infty} \int_{H(\nu)} \rho(z + s\nu + x_{n-1})\, d^{n-1}x_{n-1}\, ds. \tag{2.3}$$

Then, $H = \bar{c}_H^{-1}(\frac{1}{2})$ for all H if and only if each f_ν is strictly increasing on a neighborhood of $f_\nu^{-1}(\frac{1}{2})$; that is to say, there exists no pair of distinct $(n-1)$-dimensional ν-normal hyperplanes that separate the support of ρ into two pieces of mass $\frac{1}{2}$. In fact, [8] imposes a further restriction on ρ that ensures the even more desirable property that each $df_\nu/d\sigma$ is bounded away from zero where f_ν is bounded away from both zero and one: *If, for some ν and some $\sigma_0 \neq 0$, $\int_{H(\nu)} \rho(z + \sigma_0\nu + x_{n-1})\, dx^{n-1} = 0$, then ρ vanishes on the whole open half space on the side of $H(\nu) + \sigma_0\nu$ away from ρ's halfway point z.*

Two examples of cumulative distributions f_ν (2.3) associated with particular probability densities ρ in n dimensions are presented in [8]. The first is the construction of the univariate nth degree polynomial spline that is the cumulative distribution associated with a (mass one) union of interiorly disjoint tetrahedra (simplices)—of course, such objects need not have halfway points. The second involves the determination of the azimuthally symmetric probability density ρ on the n-ball (of diameter one) whose cumulative distribution function is linear where it is neither constantly zero nor constantly one.

The analog $H = \bar{c}_H^{-1}(\frac{1}{2})$ of (1.3) has led us to the notion of a halfway point for the probability distribution ρ occurring in the scaled blurring (2.2), i.e., to a generalized "median" whose existence imposes a sort of symmetry restriction on ρ. Other properties of the blurring can lead to other sorts of restrictions. For example, the cumulative distribution function f_ν for ν-normal hyperplanes (2.3) specifies the behavior of the average color as the moving density distribution crosses the boundary of a half space from its black (0) side to white (1) side. We could ask that identical behavior be obtained if black is interchanged with white and we cross in the opposite direction. That is to say, we could insist that

$$\text{(2.4)} \qquad \text{for each normal } \nu, \qquad f_{-\nu}(\sigma) = f_\nu(\sigma) \quad \text{for all } \sigma.$$

This is equivalent (using the consequence $f_{-\nu}(\sigma) = 1 - f_\nu(-\sigma)$ of invoking a *probability* density ρ) to insisting that the graph of f_ν be symmetric under reflection through $(0, \frac{1}{2})$:

$$\text{(2.5)} \qquad \text{for each normal } \nu, \qquad \tfrac{1}{2} - f_\nu(-\sigma) = f_\nu(\sigma) - \tfrac{1}{2} \quad \text{for all } \sigma.$$

In particular, this insists that, for each ν, $f_\nu(0) = \frac{1}{2}$; i.e., that the associated density ρ have a halfway point. But (2.5) must restrict ρ even more, since, for either structure constructed at the end of §1, the associated f_ν does not satisfy (2.5) except for ν normal to the line that cuts the structure into two mirror images.

And, indeed, (2.5) is equivalent to ρ being almost everywhere symmetric under reflection through its halfway point.

PROPOSITION B. *Let ρ be a probability density on $\mathbb{R}^n$. Then ρ's cumulative distribution function f_ν (defined by (2.3) with $z = 0$) is symmetric under reflection through $(0, \frac{1}{2})$ for all unit vectors ν—i.e., (2.5) holds—if and only if ρ is symmetric under reflection through the origin almost everywhere. Either condition means that the origin is ρ's halfway point.*

Proof. Such symmetry for ρ is clearly sufficient. On the other hand, suppose that f_ν (2.3) (with $z = 0$) satisfies (2.5). Then the cumulative distribution function $f_\nu^{(R)}$ for the "reflected" density

$$\rho^{(R)}(x) := \rho(-x)$$

is the same as f_ν:

$$\begin{aligned} f_\nu^{(R)}(\sigma) &= \int_{-\sigma}^{\infty} \int_{H(\nu)} \rho^{(R)}(s\nu + x_{n-1})\, d^{n-1}x_{n-1}\, ds \\ &= \int_{-\infty}^{\sigma} \int_{H(\nu)} \rho(t\nu - x_{n-1})\, d^{n-1}x_{n-1}\, dt = 1 - f_\nu(-\sigma) = f_\nu(\sigma) \end{aligned}$$

(the last using (2.5)). Differentiating, now, the amount of $\Delta := \rho^{(R)} - \rho$ on any $(n-1)$-dimensional hyperplane is zero. In other words, the Radon transform of Δ is zero. But it now follows—from a nice argument described to us by L. Shepp—that the n-dimensional Fourier transform $\hat{\Delta}$ of Δ is zero. For with $-\infty < \sigma < \infty$, and since $\|\nu\| = 1$ with ν normal to $H(\nu)$,

$$\begin{aligned} (2\pi)^{n/2}\, (\hat{\Delta})(\sigma\nu) :&= \int_{-\infty}^{\infty} \int_{H(\nu)} e^{i\sigma\nu\cdot(s\nu + x_{n-1})}\, \Delta(s\nu + x_{n-1})\, d^{n-1}x_{n-1}\, ds \\ &= \int_{-\infty}^{\infty} e^{i\sigma s} \left(\int_{H(\nu)} \Delta(s\nu + x_{n-1})\, d^{n-1}x_{n-1} \right) ds. \end{aligned}$$

But the inner integral is the Radon transform of Δ at (s, ν). Thus $\hat{\Delta} = 0$; so $\Delta = 0$ almost everywhere. □

ROTATION INVARIANT SEPARABLE FUNCTIONS ARE GAUSSIAN*

PL. KANNAPPAN[†] AND P. K. SAHOO[‡]

Abstract. In digital image analysis, edge detection, line detection, texture classification, and so forth are basic to image understanding and interpretation. Since a typical image is void of predetermined directions of edge, line, or texture, rotation invariant filters are important for their detection. In designing such filters the concept of rotation invariant separable function is often used. Here it is shown that every rotation invariant separable real valued function of two variables is either Gaussian or identically zero. This justifies the use of Gaussian filters in image processing. Furthermore, while deriving this result, the authors obtained the general solutions of two functional equations considered by Swiatak in 1975. Swiatak found the solutions when one of the unknown functions is continuous at zero. No regularity assumptions were made and all the general solutions that contain the solution obtained in [*Aequationes Math.*, 12 (1975), pp. 39–64] were determined.

Key words. Gaussian function, separable function, functional equation

AMS(MOS) subject classifications. 39B40, 82A15, 68U10

1. Introduction. Let R be the set of reals and $\mathbf{R}_+ = \{x \in \mathbf{R} \mid x > 0\}$ be the set of positive reals. Let $\Omega = \{\theta \in \mathbf{R} \mid \theta \neq n\pi/2,\, n = 0, 1, 2, 3, 4, \cdots\}$. A function $f : \mathbf{R}^n \to \mathbf{R}$ is said to be *Gaussian* if and only if

$$f(x_1, x_2, \cdots, x_n) = k\, e^{A(x_1^2 + x_2^2 + \cdots + x_n^2)}, \qquad (x_1, x_2, \cdots, x_n) \in \mathbf{R}^n, \tag{1.1}$$

where k is a real nonzero constant and $A : \mathbf{R} \to \mathbf{R}$ is a function satisfying

$$A(u+v) = A(u) + A(v) \tag{1.2}$$

for all $u, v \in \mathbf{R}$. In the literature, A is often referred to as an *additive* function. The probability density function of a normal distribution is an example of a Gaussian function. A function $G : \mathbf{R}^2 \to \mathbf{R}$ is said to be *separable* if there exist functions $g, h : \mathbf{R} \to \mathbf{R}$ such that

$$G(x, y) = g(x)\, h(y) \tag{1.3}$$

for all $x, y \in \mathbf{R}$. A function $G : \mathbf{R}^2 \to \mathbf{R}$ is said to be *rotation invariant* if

$$G(x, y) = G(x_\theta, y_\theta) \quad \text{for all } \theta \in \Omega, \tag{1.4}$$

where

$$\begin{pmatrix} x_\theta \\ y_\theta \end{pmatrix} = \begin{pmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix}.$$

*Received by the editors June 12, 1991; accepted for publication (in revised form) January 21, 1992. This work was supported by grants from the College of Arts and Sciences of the University of Louisville and the Natural Sciences and Engineering Research Council of Canada.

[‡] Department of Mathematics, University of Louisville, Louisville, Kentucky 40292.

If a function $G : \mathbf{R}^2 \to \mathbf{R}$ is rotation invariant and separable then

$$g(x)\,h(y) = k(x_\theta)\,l(y_\theta) \quad \text{for all } x, y \in \mathbf{R} \quad \text{and} \quad \text{for all } \theta \in \Omega, \tag{1.5}$$

where g, h, k, $l : \mathbf{R} \to \mathbf{R}$. The introduction of functions k and l is just to give a general aspect to the functional equation. It is not imposed by separability. In digital image processing edge detection, line detection, texture classification, and so forth are basic to the problems of image understanding and interpretation. Since a typical image does not have predetermined directions of edge, line, or texture, rotation invariant filters are used for their detection. In designing of such filters (see [2]) the concept of rotation invariant separable function is used. Also, in many problems in optics and quantum mechanics we encounter such functions. For instance, two independent particles in quantum mechanics whose wavefunction is a product of function of individual coordinates is also a product when expressed in the center of mass and relative coordinates. In this paper we show that rotation invariant, separable functions satisfy the functional equations (FE) and its analogue considered in §2 are either Gaussian or zero function. In [4], the authors study bifactorizable quantum wave functions. While proving if two quantum systems are prepared independently and if their center of mass is found to be in a pure state, then each of the component systems is also in a pure state, which in the coordinate representation is a Gaussian wave function, the authors of [4] come across the functional equation (FE). They established their result assuming the functions are infinitely differentiable. We establish this result without assuming any regularity conditions on the unknown functions. Our approach is from the functional equation point of view and it is simple, direct, and interesting.

2. Auxiliary results. We give the motivation for considering the functional equation (FE) in the next section. In this section we determine the most general solution of the functional equations (FE), (GFE), (SE), and (GSE). Since the identically zero function is always a solution of our functional equations, we consider nontrivial (that is, not identically zero) solutions. First we prove the following theorem concerning the equation (FE). We require the following theorem to establish our main result.

THEOREM 1. *Let f, $g : \mathbf{R} \to \mathbf{R}$ satisfy the functional equation*

$$f(x+y) = f(x)\,f(y)\,g(xy), \qquad x,\ y \in \mathbf{R}, \tag{FE}$$

where f and g are not identically zero functions. Then the general solution of (FE) *is given by*

$$\left.\begin{aligned} f(x) &= c\,e^{\frac{1}{2}A_1(x^2)+A_2(x)} \\ g(x) &= \frac{1}{c}\,e^{A_1(x)} \end{aligned}\right\} \qquad x \in \mathbf{R}, \tag{2.1}$$

where $A_i : \mathbf{R} \to \mathbf{R}$ $(i = 1, 2)$ are additive functions and c is an arbitrary nonzero real constant.

Proof. If there exists a real number x_o such that $f(x_o) = 0$, then replacing x by $x - x_o$ and y by x_o in (FE), we obtain

$$f(x) = f(x - x_o)\,f(x_o)\,g((x - x_o)\,x_o) = 0$$

for all $x \in \mathbf{R}$. But f is not identically zero, and hence f is nowhere zero. If $g(x_o) = 0$ at some $x_o \in \mathbf{R}$, then from (FE) with $y = 1$, we get

$$f(x_o + 1) = f(x_o)\,f(1)\,g(x_o) = 0. \tag{2.2}$$

But f is nowhere zero, and hence g is also nowhere zero.

From (FE), we obtain

$$\begin{aligned} f(x+y+z) &= f((x+y)+z) \\ &= f(x+y)\,f(z)\,g((x+y)z) \\ &= f(x)\,f(y)\,f(z)\,g(xy)\,g((x+y)z). \end{aligned}$$

Similarly,

$$f(x+(y+z)) = f(x)\,f(y)\,f(z)\,g(yz)\,g(x(y+z))$$

and

$$f(y+(x+z)) = f(x)\,f(y)\,f(z)\,g(xz)\,g(y(x+z)).$$

Thus from the above equations, we get

$$g(xy)\,g((x+y)z) = g(yz)\,g(x(y+z)) = g(xz)\,g(y(x+z)) \tag{2.3}$$

for all $x, y, z \in \mathbf{R}$. Now we restrict f and g to $\mathbf{R}_+$ (positive reals). It is easy to see that (FE) and (2.3) hold for $x, y, z \in \mathbf{R}_+$. For u, v, $w \in \mathbf{R}_+$, let

$$x = \sqrt{\frac{u\,w}{v}}, \qquad y = \sqrt{\frac{u\,v}{w}}, \qquad z = \sqrt{\frac{v\,w}{u}}. \tag{2.4}$$

Then (2.3) becomes

$$g(u)\,g(v+w) = g(v)\,g(u+w) = g(w)\,g(u+v).$$

Since g is nowhere zero, we rewrite the above equation as

$$\frac{g(v+w)}{g(v)} = \frac{g(u+w)}{g(u)}$$

for all u, v, $w \in \mathbf{R}_+$. Hence for fixed $w \in \mathbf{R}_+$, we get $g(u+w)/g(u) =$ constant for $u \in \mathbf{R}_+$. So we have

$$g(u+w) = g(u)\,h(w), \qquad u,\ v \in \mathbf{R}_+, \tag{2.5}$$

where $h : \mathbf{R}_+ \to \mathbf{R}$. The left side of (2.5) is symmetric in u and w. Using the symmetry of the left side of (2.5), we obtain

$$g(u)\,h(w) = g(w)\,h(u), \qquad u,\ v \in \mathbf{R}_+. \tag{2.6}$$

Letting $w = w_o$ in (2.6), we get

$$h(u) = c\,g(u), \tag{2.7}$$

where $c := h(w_o)/g(w_o)$ is a nonzero real constant. Now (2.7) in (2.5) yields

$$g(u+w) = c\,g(u)\,g(w), \qquad u,\ v \in \mathbf{R}_+. \tag{2.8}$$

Hence (see [1, Thm. 5, p. 29])

$$g(x) = \frac{1}{c}\,e^{A_1(x)}, \qquad x > 0, \tag{2.9}$$

where $A_1 : \mathbf{R} \to \mathbf{R}$ is an additive function.

Inserting (2.9) into (FE), we obtain

$$f(x+y) = f(x)\, f(y)\, \frac{1}{c}\, e^{A_1(xy)}, \qquad x,\, y \in \mathbf{R}_+. \tag{2.10}$$

Define

$$F(x) := \frac{1}{c}\, e^{-\frac{1}{2} A_1(x^2)}\, f(x), \qquad x \in \mathbf{R}_+. \tag{2.11}$$

Then (2.10) and (2.11) yield

$$F(x+y) = F(x)\, F(y), \qquad x, y \in \mathbf{R}_+. \tag{2.12}$$

Hence (see [1, Thm. 5, p. 29])

$$F(x) = e^{A_2(x)}, \qquad x \in \mathbf{R}_+, \tag{2.13}$$

where $A_2 : \mathbf{R} \to \mathbf{R}$ is an additive function. Now from (2.11) and (2.13) we obtain

$$f(x) = c\, e^{\frac{1}{2} A_1(x^2) + A_2(x)}, \qquad x > 0. \tag{2.14}$$

Thus we have shown that f and g have the asserted form (2.1) if $x > 0$. Next we show (2.1) is also the asserted form of f and g for $x \leq 0$.

Let $x < 0$ and choose $y > 0$ such that $x + y > 0$. Then from (FE) and (2.14) we get

$$g(xy)\, f(x) = e^{\frac{1}{2} A_1(x^2) + A_2(x) + A_1(xy)} \tag{2.15}$$

for all $x < 0$ and $x + y > 0$. Now for $x < 0$, choose $z > 0$ such that $x + z > 0$. From (2.3), we have

$$g(xy)\, g(xz + yz) = g(xz)\, g(xy + yz),$$

and since $xz + yz > 0$ and $xy + yz > 0$, using (2.9) in the above equation, we get

$$g(xy)\, e^{-A_1(xy)} = g(xz)\, e^{-A_1(xz)}, \tag{2.16}$$

for all $x < 0$ and $y > -x,\ \ z > -x$. From (2.16), we see that

$$g(xy)\, e^{-A_1(xy)} = r(x),$$

where $r(x)$ is a nowhere zero function of x. Thus

$$g(xy) = r(x)\, e^{A_1(xy)} \tag{2.17}$$

holds for all $x < 0$ and $x + y > 0$. Inserting (2.17) into (2.15), we get

$$f(x) = \frac{1}{r(x)}\, e^{\frac{1}{2} A_1(x^2) + A_2(x)}, \qquad x < 0. \tag{2.18}$$

Next let us choose $x < 0$ and $y < 0$. Using (FE), (2.9), and (2.18), we obtain

$$r(x+y) = r(x)\, r(y)\, c \tag{2.19}$$

for all x, $y < 0$.

Let $f(0) = b$ (a nonzero constant). With $y = 1$, (FE) gives

$$f(x+1) = f(1)\, f(x)\, g(x), \qquad x \in \mathbf{R}. \tag{2.20}$$

Letting $x = -1$ in (2.20) and using (2.18) and (2.14), we get

$$g(-1) = \frac{1}{c}\, b\, r(-1)\, e^{A_1(-1)}. \tag{2.21}$$

Substituting $y = -\frac{1}{x}$ in (FE) for $x > 1$, we get

$$f\left(x - \frac{1}{x}\right) = f(x)\, f\left(-\frac{1}{x}\right)\, g(-1). \tag{2.22}$$

Using (2.14) and (2.18) in (2.22), we obtain

$$g(-1) = r\left(-\frac{1}{x}\right)\, e^{A_1(-1)} \tag{2.23}$$

for all $x > 1$. From (2.21) and (2.23), we see that

$$r(y) = d \qquad \text{(constant)} \tag{2.24}$$

for $-1 < y < 0$. Now we choose x, y in the interval $]-1, 0[$ with $x + y < 0$ and $x + y > -1$. Then (2.19) yields

$$d = \frac{1}{c}.$$

For $x < 0$ and $y \in]-1, 0[$, we obtain from (2.19) and (2.24)

$$r(x+y) = r(x) \tag{2.25}$$

for all $x < 0$ and all $y \in]-1, 0[$. Hence $r(x)$ is a constant function. Again using (2.19), we see that

$$r(x) = \frac{1}{c} \quad \text{for } x < 0. \tag{2.26}$$

Now using (2.26) in (2.18), we get

$$f(x) = c\, e^{\frac{1}{2} A_1(x^2) + A_2(x)}, \qquad x < 0. \tag{2.27}$$

From (2.20), (2.14), and (2.27), we get

$$g(x) = \frac{1}{c}\, e^{A_1(x)}, \qquad x < 0. \tag{2.28}$$

Hence f and g have the form (2.1) for $x < 0$. Now $y = -x$ in (FE) yields $b = c$, that is, $f(0) = c$. This completes the proof of the theorem.

Now a few remarks are in order.

Remark 2. First the solution of (FE) is obtained without assuming any regularity condition whatsoever on f or g. Furthermore, this solution is obtained without using the substitutions $x = 0$ or $y = 0$.

Remark 3. If we assume some regularity condition on f, say f is measurable, or continuous or continuous at a point, say, at zero, then we obtain as in [6], $f(x) = c e^{\frac{1}{2} a x^2 + b x}$ and $g(x) = \frac{1}{c} e^{a x}$. The measurability or continuity on f implies (use (2.20)) the same of g, and (2.18) and (2.12) yield continuous additive functions A_1 and A_2. As for continuity at zero of f, as in [6], we can show that f is continuous everywhere.

Our next remark is the following. We can easily obtain the general solutions of the functional equation

$$\text{(GFE)} \qquad f_1(x+y) = f_2(x)\, f_3(y)\, g(xy), \qquad x,\, y \in \mathbf{R},$$

where f_1, f_2, f_3, g are not identically zero by reducing it to (FE).

COROLLARY 4. *The general nontrivial solution of* (GRE), *where* f_1, f_2, f_3, g : $\mathbf{R} \to \mathbf{R}$ *is given by*

$$\left.\begin{aligned} f_1(x) &= a\, b\, c\, e^{\frac{1}{2} A_1(x^2) + A_2(x)} \\ f_2(x) &= \frac{1}{a} f_1(x) \\ f_3(x) &= \frac{1}{b} f_1(x) \\ g(x) &= \frac{1}{c} e^{A_1(x)} \end{aligned}\right\} \qquad x \in \mathbf{R},$$

where $A_i : \mathbf{R} \to \mathbf{R}$ $(i = 1, 2)$ *are additive functions and* a, b, c *are arbitrary nonzero real constants.*

Proof. The assumption that either f_2 or f_3 is zero at some point would imply f_1 is identically zero. Suppose $g(x_o) = 0$. Then (GFE) first gives $f_1(x_o + 1) = 0$ and then with $x = x_o + 1$, $y = 0$ gives $g(0) = 0$. This would imply f_1 is identically zero. So, all f_1, f_2, f_3, and g are nowhere zero. The reduction of (GRE) to (FE) can be accomplished as follows. By substituting into (GFE), first $y = 0$ and then $x = 0$, we have $f_1(x) = a\, f_2(x)$ and $f_1(y) = b\, f_3(x)$ so that (GFE) becomes

$$\frac{1}{a\,b} f_1(x+y) = \frac{1}{a\,b} f_1(x)\, \frac{1}{a\,b} f_1(y)\, g(xy),$$

which is the functional equation (FE).

Next we prove the following corollary to establish another result in [6]. Again we make no regularity assumptions on the unknown functions. Again, as before we solve it by reducing it to (FE).

COROLLARY 5. *Let* f, $g : \mathbf{R} \to \mathbf{R}$ *satisfy the functional equation*

$$\text{(SE)} \qquad f(x-y) = f(x)\, f(y)\, g(xy) \qquad (x, y \in \mathbf{R}),$$

where f *and* g *are not identically zero. Then the general solution of* (SE) *is given by*

$$\text{(2.29)} \qquad \left.\begin{aligned} f(x) &= c\, e^{\frac{1}{2} A_1(x^2)} \\ g(x) &= \frac{1}{c} e^{A_1(-x)} \end{aligned}\right\} \qquad x \in \mathbf{R},$$

where $A_1 : \mathbf{R} \to \mathbf{R}$ *is an additive function and* c *is a nonzero real constant.*

Proof. It is easy to verify that (2.29) satisfies (SE). We assume f and g are nowhere zero. Then interchanging x with y in (SE), we get

$$f(x-y) = f(x)\,f(y)\,g(xy) = f(y-x) \tag{2.30}$$

for all x, $y \in \mathbf{R}$. Thus f is an even function in $\mathbf{R}$. Replacing y by $-y$ in (SE), we get

$$f(x+y) = f(x)\,f(y)\,g(-xy) \tag{2.31}$$

for all $x\,y \in \mathbf{R}$, which is the same as (FE). Hence from Theorem 1, we get

$$f(x) = c\,e^{\frac{1}{2}A_1(x^2)+A_2(x)} \tag{2.32}$$

and

$$g(x) = \frac{1}{c}\,e^{A_1(-x)}. \tag{2.33}$$

Since f is even, (2.32) yields $A_2 \equiv 0$. Thus (2.32) and (2.33) yield (2.29). This completes the proof.

Remark 4. Note (2.31) is a special case of (GFE). Use Corollary 4 to obtain (2.29).

Finally (FE) can be used to solve another functional equation

$$f_1(x-y) = f_2(x)\,f_3(y)\,g(xy), \qquad x,\, y \in \mathbf{R}, \tag{GSE}$$

where f_1, f_2, f_3, and g are not identically zero functions. We will use this equation in the main theorem in the next section.

COROLLARY 6. *Let* f_1, f_2, f_3, $g : \mathbf{R} \to \mathbf{R}$ *satisfy the functional equation* (GSE). *Then the general nontrivial solution of* (GSE) *is given by*

$$\left.\begin{aligned} f_1(x) &= a\,b\,c\,e^{\frac{1}{2}A_1(x^2)+A_2(x)} \\ f_2(x) &= \frac{1}{a}\,f_1(x) \\ f_3(x) &= \frac{1}{b}\,f_1(-x) \\ g(x) &= \frac{1}{c}\,e^{A_1(-x)} \end{aligned}\right\} \qquad x \in \mathbf{R},$$

where $A_i : \mathbf{R} \to \mathbf{R}$ $(i = 1, 2)$ *are additive functions and* a, b, c *are arbitrary nonzero real constants.*

Proof. As before we can show that none of f_1, f_2, f_3, g is anywhere zero. Putting $y = 0$ in (GSE) and then $x = 0$, we obtain $f_1(x) = a\,f_2(x)$ and $f_1(y) = b\,f_3(-y)$ so that (GSE) can be rewritten as

$$\frac{1}{a\,b}\,f_1(x-y) = \frac{1}{a\,b}\,f_1(x)\,\frac{1}{a\,b}\,f_1(-y)\,g(xy).$$

Now changing y to $-y$ in the above equation, we see that it reduces to (FE) (also to (GFE) and then use Corollary 4).

3. The main result. We prove our main result by first deriving the equation (FE).

THEOREM 7. *If $G : \mathbf{R}^2 \to \mathbf{R}$ is rotation invariant separable function, then G is either identically zero or Gaussian.*

Proof. If G is the zero function, it is obviously rotation invariant and separable. So, we assume G is not identically zero. Suppose $G(x_o, y_o) = 0$. Then by using separability and rotation invariance, we can show that $G(x, y) = 0$ for all x, $y \in \mathbf{R}$. The separability condition (1.3) gives $g(x_o)\,k(y_o) = 0$. Assume $g(x_o) = 0$. Then again (1.3) gives $G(x_o, y) = 0$ for all y. Given any (x_1, y_1), it is possible to find a suitable (x_o, y) or a rotation of it, so that (x_1, y_1) is obtained as the image of (x_o, y) by a suitable rotation. Hence, $G(x_1, y_1) = 0$. So, G is nowhere zero. Then from (1.5) we obtain

$$k(\mu x + \nu y)\, l(-\nu x + \mu y) = g(x)\, h(y) \quad \text{for all } x, y \in \mathbf{R} \tag{3.1}$$

for all (μ, ν) not equal to $(0,1)$, $(1,0)$, $(0,-1)$, $(-1,0)$, where $\mu = \cos\theta$ and $\nu = \sin\theta$. Since G is nowhere zero we conclude that k, l, g, h are also nowhere zero. Letting $x = 0$ in (3.1) we get

$$h(y) = a\, k(\nu y)\, l(\mu y), \tag{3.2}$$

where a is a nonzero constant. Similarly, letting $y = 0$ in (3.1) we get

$$g(x) = b\, k(\mu x)\, l(-\nu x), \tag{3.3}$$

where b is a nonzero constant. Using (3.2) and (3.3) in (3.1), we obtain

$$k(\mu x + \nu y)\, l(-\nu x + \mu y) = a\, b\, k(\mu x)\, l(-\nu x)\, k(\nu y)\, l(\mu y),$$

which is

$$\frac{k(\mu x + \nu y)}{k(\mu x)\, k(\nu y)} = a\, b\, \frac{l(-\nu x)\, l(\mu y)}{l(-\nu x + \mu y)}. \tag{3.4}$$

Replacing x by $\frac{1}{\mu}\, x$ and y by $\frac{1}{\nu}\, y$ in (3.4), we get

$$\frac{k(x + y)}{k(x)\, k(y)} = a\, b\, \frac{l(-\frac{\nu}{\mu}\, x)\, l(\frac{\mu}{\nu}\, y)}{l(-\frac{\nu}{\mu}\, x + \frac{\mu}{\nu}\, y)}. \tag{3.5}$$

Letting $\frac{\mu}{\nu} = x$ any nonzero real (recall $\frac{\mu}{\nu} = \cot\theta$, it is possible to choose $\frac{\mu}{\nu} = x$, any nonzero real) in (3.5), we see that the right side of (3.5) is a function of xy. Hence we have

$$k(x + y) = k(x)\, k(y)\, \phi(xy) \tag{3.6}$$

for all x, $y \in \mathbf{R}$ with $x \neq 0$. By Theorem 1 and Remark 2, we obtain

$$\begin{aligned} k(x) &= c\, e^{\frac{1}{2}\, A_1(x^2) + A_2(x)}, \\ \phi(x) &= \frac{1}{c}\, e^{A_1(x)}. \end{aligned} \tag{3.7}$$

Letting $(\mu, \nu) = (\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}})$ in (3.5), we get

$$\frac{k(x + y)}{k(x)\, k(y)} = a\, b\, \frac{l(-x)\, l(y)}{l(-x + y)}. \tag{3.8}$$

Using (3.7) in (3.8), we see that

$$l(-x+y) = a\,b\,c\,l(-x)\,l(y)\,e^{-A_1(xy)}.$$

Thus, by Corollary 6 (could use Corollary 4 and Corollary 5), we have

$$l(x) = \frac{1}{a\,b\,c}\,e^{\frac{1}{2}A_1(x^2)+A_3(x)}. \tag{3.9}$$

Using (3.7), (3.9), (1.4), (1.5), and (3.1), we obtain

$$G(x,y) = k(\mu x+\nu y)\,l(-\nu x+\mu y) = \frac{1}{a\,b}\,e^{\frac{1}{2}A_1(x^2+y^2)+A_2(\mu x+\nu y)+A_3(-\nu x+\mu y)}. \tag{3.10}$$

Since G is rotation invariant for all $\theta \in \Omega$, G in (3.10) remains the same for different choices of (μ,ν). By choosing $(\mu,\nu) = (\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}})$, we get

$$G(x,y) = \frac{1}{a\,b}\exp\left(\frac{1}{2}A_1(x^2+y^2) + A_2\left(\frac{x+y}{\sqrt{2}}\right) + A_3\left(\frac{-x+y}{\sqrt{2}}\right)\right). \tag{3.11}$$

Similarly, choosing $(\mu,\nu) = (-\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}})$, we see that (3.10) becomes

$$G(x,y) = \frac{1}{a\,b}\exp\left(\frac{1}{2}A_1(x^2+y^2) + A_2\left(\frac{-x-y}{\sqrt{2}}\right) + A_3\left(\frac{x-y}{\sqrt{2}}\right)\right). \tag{3.12}$$

Hence from (3.11) and (3.12), we obtain

$$A_2\left(\frac{x+y}{\sqrt{2}}\right) = A_3\left(\frac{x-y}{\sqrt{2}}\right) \tag{3.13}$$

for all x, $y \in \mathbf{R}$. Now from (3.11) we have

$$G(x,y) = \frac{1}{a\,b}\,e^{\frac{1}{2}A_1(x^2+y^2)}.$$

This completes the proof of the theorem.

We conclude this paper with the following remark. A function $G : \mathbf{R}^2 \to \mathbf{R}$ is circularly symmetric if $G(x,y) = f(\sqrt{x^2+y^2})$ for some real valued function f. It was shown in [5] that circularly symmetric separable functions are Gaussian. Circularly symmetric functions are precisely rotation invariant; and not the converse. In harmonic analysis, such functions are generally called radial functions [3]. Thus our Theorem 7 can also be deduced from [5]. However, here we accomplished our task by solving a quite different and interesting functional equation (FE) and the related ones considered by others in different contexts [4], [6]. Furthermore, this approach allows us to study linear transformation invariant separable functions. For similar results, refer to [7], [8].

Acknowledgments. We are thankful to the referee for suggestions that improved the presentation of this paper.

GLOBAL LINEAR INDEPENDENCE AND FINITELY SUPPORTED DUAL BASIS*

KANG ZHAO†

Abstract. Relating the global linear independence of an arbitrary locally finite family of functions to the basic fact that a linear map is onto if and only if its adjoint is 1-1, it is shown that any locally finite and globally linearly independent family of functions has a dual basis consisting of finitely supported linear functionals.

Key words. global linear independence, locally finite, finitely supported dual basis

AMS(MOS) subject classifications. 41A05, 41A15, 41A63

1. Introduction. Call the (indexed) family Φ of distributions on $\mathbb{R}^s$ *locally finite* in case, for any *test function*, i.e., any compactly supported C^∞-function f, $\langle \varphi, f\rangle = 0$ for all but finitely many $\varphi \in \Phi$. For such a locally finite family, the sum

$$\Phi c := \sum_{\varphi\in\Phi} \varphi c(\varphi) \tag{1.1}$$

is a well-defined distribution, regardless of what the coefficient "sequence" $c \in \mathbf{C}^\Phi$ might be, if we define the sum *pointwise*, i.e., set

$$\langle \Phi c, f\rangle := \left\langle \sum_{\varphi\in\Phi} \varphi c(\varphi), f \right\rangle := \sum_{\varphi\in\Phi} c(\varphi)\langle\varphi, f\rangle.$$

We assume that no confusion will arise from the use of the symbol Φ for both the indexed family and the linear map (1.1) naturally associated with it. Call such a locally finite family Φ *globally linearly independent* in case $\Phi c = 0$ implies that $c = 0$. In such a case, there is a *dual basis* for Φ, i.e., a corresponding collection $(\lambda_\varphi)_{\varphi\in\Phi}$ of linear functionals on $\operatorname{ran}\Phi$, given by the rule that

$$\langle \lambda_\varphi, \Phi c\rangle = c(\varphi).$$

Therefore $(\lambda_\varphi)_{\varphi\in\Phi}$ satisfies that

$$\forall\, \psi \in \Phi, \quad \langle \lambda_\varphi, \psi\rangle = \delta_\varphi(\psi) := \begin{cases} 1 & \text{if } \psi = \varphi; \\ 0 & \text{otherwise.} \end{cases} \tag{1.2}$$

Recently, Ben-Artzi and Ron [BR] published the surprising and useful result that if Φ is locally finite, then the elements of this dual basis are *local*, in the sense that, for each $\varphi \in \Phi$, there exists a ball $B = B_\varphi$ (of finite radius) so that $\langle \Phi c, f\rangle = 0$ for all f with $\operatorname{supp} f \subset B$ implies that $c(\varphi) = 0$.

It is the purpose of this paper to show that this result is a direct consequence of the basic fact that the adjoint of a linear map is 1-1 if and only if the map itself is onto. By this fact, the above-mentioned result of [BR] is improved and generalized to the case that Φ is a locally finite family of functions defined on *any* domain X. Their result is recovered by considering distributions as functions on the collection of test functions.

2. The results. In linear algebra, an infinite subset of a linear space is called algebraically linearly independent if any finite subset of it is linearly independent. In approximation theory, a locally finite family Φ of functions defined on $\mathbb{R}^s$ is called globally linearly independent if

$$\sum_{\varphi\in\Phi} \varphi c(\varphi) = 0 \quad \Longrightarrow \quad c = 0.$$

In other words, the (indexed) family Φ is globally linearly independent if and only if the corresponding *map* $\Phi : c \mapsto \sum_{\varphi\in\Phi} \varphi c(\varphi)$ is 1-1. In this section, we derive a condition equivalent to global linear independence of Φ, which gives a geometric meaning to the global linear independence of Φ. We rely on the following basic fact.

PROPOSITION 2.1 ([T, p. 52]). *Let U and V be two linear spaces, with duals U' and V', respectively, and let $M : U \to V$ be a linear map. Then M is onto if and only if the adjoint $M' : V' \to U' : \lambda \mapsto \lambda M$ of M is 1-1.*

Let $\mathbb{F}$ be a field. Denote by $\mathbb{F}^X$ the linear space of all functions from X to $\mathbb{F}$ and by $\mathbb{F}_0^X$ the subspace of $\mathbb{F}^X$ of all finitely supported functions. Here, we say that $g \in \mathbb{F}^X$ is *finitely supported* if the *support* of g, i.e., the set

$$\operatorname{supp} g := \{x \in X : g(x) \neq 0\}$$

is finite. We want to *stress* that we make no assumptions concerning the domain X. In particular, the case that Φ is a collection of distributions in $\mathcal{D}'(\mathbb{R}^s)$ is covered because, for this case, X is the space of all test functions.

If X is finite, then $\mathbb{F}^X$ is known to be its own dual space. For arbitrary X, the following is well known.

PROPOSITION 2.2. *For any domain X, $\mathbb{F}^X$ represents the (algebraic) dual of $\mathbb{F}_0^X$ with respect to the natural pairing $\mathbb{F}_0^X \times \mathbb{F}^X \to \mathbb{F} : (\lambda, g) \mapsto \sum_{x\in X} \lambda(x)g(x)$.*

Let Φ be a *locally finite* family in $\mathbb{F}^X$, i.e., only finitely many entries of Φ are nonzero at any particular $x \in X$. Then the corresponding linear map Φ is well defined. If we think of it as a matrix, its rows indexed by $x \in X$ and its columns indexed by $\varphi \in \Phi$, then its "transposed" is the "matrix" $\Psi := (\varphi(x))_{\varphi\in\Phi;x\in X}$, with its rows indexed by $\varphi \in \Phi$ and its columns indexed by $x \in X$. We cannot hope to apply this "matrix" to an arbitrary $g \in \mathbb{F}^X$. But we can apply it to any $g \in \mathbb{F}_0^X$, since, for any such g,

$$\#\{\varphi \in \Phi : \operatorname{supp}\varphi \cap \operatorname{supp} g \neq \emptyset\} < \infty.$$

Therefore,

$$\Psi : \mathbb{F}_0^X \to \mathbb{F}_0^\Phi : g \mapsto \sum_{x\in\operatorname{supp} g} \Phi_x g(x)$$

is a well-defined linear map, where

$$\Phi_x : \Phi \to \mathbb{F} : \varphi \mapsto \varphi(x)$$

is the "x-column" of Ψ; hence

$$\Psi g : \varphi \mapsto \sum_{x \in \operatorname{supp} g} \varphi(x) g(x).$$

For any $c \in \mathbb{F}^{\Phi}$ and any $g \in \mathbb{F}_0^X$,

$$\langle \Psi' c, g\rangle = \langle c, \Psi g\rangle = \sum_{\varphi \in \Phi} c(\varphi) \left(\sum_{x \in \operatorname{supp} g} \varphi(x) g(x) \right) = \sum_{x \in \operatorname{supp} g} \sum_{\varphi \in \Phi} \varphi(x) c(\varphi)\, g(x).$$

This proves that

$$\Psi' : \mathbb{F}^{\Phi} \to \mathbb{F}^X : c \mapsto \Phi c.$$

Consequently, by Proposition 2.1, Φ is 1-1 if and only if Ψ is onto. Now note that, since Φ is locally finite, $\operatorname{ran} \Psi = \operatorname{span} \Phi_X$, with

$$\Phi_X := \{\Phi_x : x \in X\}.$$

Thus we obtain the following geometric description of the global linear independence of Φ.

THEOREM 2.3. *A locally finite family Φ in $\mathbb{F}^X$ is globally linearly independent if and only if*

$$\operatorname{span} \Phi_X = \mathbb{F}_0^{\Phi},$$

with $\Phi_X = \{\Phi_x : x \in X\}$ and $\Phi_x : \Phi \to \mathbb{F} : \varphi \mapsto \varphi(x)$.

Since $\mathbb{F}_0^{\Phi}$ contains, in particular, the "unit sequence" δ_φ (defined in (1.2)), the following corollary is immediate.

COROLLARY 2.4. *If the locally finite family Φ in $\mathbb{F}^X$ is globally linearly independent, then, for each $\varphi \in \Phi$, there exists $h_\varphi \in \mathbb{F}_0^X$ so that*

$$\sum_{x \in X} h_\varphi(x) \psi(x) = \delta_\varphi(\psi), \qquad \psi \in \Phi.$$

This shows that the dual basis $(\lambda_\varphi)_{\varphi \in \Phi}$ for Φ is *finitely supported* in the sense that each λ_φ has a representation in the form

$$\lambda_\varphi : \operatorname{ran} \Phi \to \mathbb{F} : g \mapsto \sum_{x \in X} h_\varphi(x) g(x)$$

for some *finitely supported* h_φ.

THEOREM 2.5 [BR]. *Let Φ be a collection of distributions in $\mathcal{D}'(\mathbb{R}^s)$. If Φ is locally finite and globally linearly independent, then the elements of its dual basis are local.*

Proof. The local finiteness of the family Φ of distributions implies that it is also locally finite as a family of functions on the set X of all test functions. Therefore, with this choice for X, for each $\varphi \in \Phi$, we can find $h_\varphi \in \mathbb{F}_0^{\Phi}$ so that $\sum_{x \in X} h_\varphi(x) \psi(x) = \delta_\varphi(\psi)$. It follows that

$$B := \cup_{x \in \operatorname{supp} h_\varphi} \operatorname{supp} x$$

is a bounded set. Also, if $\langle \Phi c, f\rangle = 0$ for all f with $\operatorname{supp} f \subset B$, then, in particular, $\langle \Phi c, x\rangle = 0$ for all $x \in \operatorname{supp} h_\varphi$; therefore,

$$0 = \sum_{x \in X} h_\varphi(x) \langle \Phi c, x\rangle = c(\varphi). \qquad \square$$

In the following, we compare the global linear independence with the algebraic linear independence of Φ geometrically. By Theorem 2.3, a locally finite Φ is globally linearly dependent if and only if $\operatorname{span}\Phi_X$ is a proper subspace of $\mathbb{F}_0^\Phi$. We claim that if Φ is algebraically linearly independent, then $\operatorname{span}\Phi_X$ cannot be too *small.*

Equip $\mathbb{F}^\Phi$ with the topology of pointwise convergence as follows. For each $\varphi \in \Phi$, let

$$p_\varphi(c) := |c(\varphi)| \quad \forall\, c \in \mathbb{F}^\Phi.$$

It is clear that $\{p_\varphi : \varphi \in \Phi\}$ is a separating family of seminorms on the linear space $\mathbb{F}^\Phi$. By [R, Thm. 1.37], this family produces a locally convex linear topology for $\mathbb{F}^\Phi$. With this topology, for $c_k \in \mathbb{F}^\Phi$, c_k converges to $c \in \mathbb{F}^\Phi$ as $k \to \infty$ if and only if for each $\varphi \in \Phi$,

$$\lim_{k\to\infty} c_k(\varphi) = c(\varphi).$$

We can verify that $\mathbb{F}_0^\Phi$ is the topological dual of $\mathbb{F}^\Phi$. Furthermore, $\mathbb{F}_0^\Phi$ is a dense subspace of $\mathbb{F}^\Phi$. Thus, $\mathbb{F}_0^\Phi$ is its own topological dual.

PROPOSITION 2.6. *A locally finite $\Phi \subset \mathbb{F}^X$ is algebraically linearly independent if and only if* $\operatorname{span}\Phi_X$ *is dense in* $\mathbb{F}_0^\Phi$.

Proof. The span of Φ_X is not dense in $\mathbb{F}_0^\Phi$ if and only if there exists a nontrivial continuous linear functional $\lambda \in (\mathbb{F}_0^\Phi)^* = \mathbb{F}_0^\Phi$, which vanishes on $\operatorname{span}\Phi_X$, i.e., if and only if

$$\sum_{\varphi \in \operatorname{supp}\lambda} \varphi(x)\lambda(\varphi) = 0 \quad \forall\, x \in X,$$

for some $\lambda \in \mathbb{F}_0^\Phi$, and this holds if and only if Φ is (algebraically) linearly dependent. □

LOCALIZED GALERKIN ESTIMATES FOR BOUNDARY INTEGRAL EQUATIONS ON LIPSCHITZ DOMAINS*

V. ADOLFSSON†, M. GOLDBERG‡, B. JAWERTH§, AND H. LENNERSTAD¶

Abstract. The Galerkin method is studied for solving the boundary integral equations associated with the Laplace operator on nonsmooth domains. Convergence is established with a condition on the meshsize, which involves the local curvature on certain approximating domains. Error estimates are also proved, and the results are generalized to systems of equations.

Key words. Galerkin methods, nonsmooth, Lipschitz, double layer potential, systems of equations

1. Introduction. The Dirichlet and Neumann problems for the Laplace operator in a Lipschitz domain $\Omega \subset \mathbb{R}^n$ are of fundamental interest, both from a theoretical and applied point of view. It is well known that these boundary value problems can be solved by using the boundary integral method, involving the appropriate layer potentials. The basic facts concerning this approach are contained in the papers by Dahlberg [D], Jerison and Kenig [JK], Verchota [V], and Dahlberg and Kenig [DK].

To be able to use the boundary integral method on Lipschitz domains numerically, we must first study the solvability properties of discretized versions of the layer potentials in nonsmooth domains. The study of the theoretical foundation for such a numerical implementation was initiated by Dahlberg and Verchota [DV]. They established the convergence of the Galerkin method for solving the integral equations associated with layer potentials of the Laplace operator on Lipschitz domains. In particular, they proved the optimal L^p-solvability of the Galerkin procedure for the Neumann and Dirichlet problems in Lipschitz domains. A first step in their approach is to approximate the domain Ω by appropriate smooth domains Ω_h, $h > 0$, so that, among other things, the Ω_h's have uniformly bounded Lipschitz constant as $h \to 0$. On each Ω_h it is then required that there is a finite-dimensional subset X_h of the bounded functions on $\partial\Omega_h$ satisfying certain quite general, but technical, conditions. The L^p convergence of the Galerkin procedure is then proved under the condition that $\lim_{h\to 0} \rho(h)\kappa(h) = 0$, where $\rho(h)$ corresponds to a uniform meshsize on $\partial\Omega_h$, and κ_h denotes the maximum curvature of $\partial\Omega_h$. So, roughly speaking, the meshsize is determined by the maximum curvature of the approximating domains. (More detail and precise conditions will be presented below.)

The main purpose of this paper is to extend this result in the following respects.

(1) We will show that we may allow variable meshsize and still obtain the convergence of the Galerkin method. The product of the meshsize and a measure of the local curvature on Ω_h is required to go to zero uniformly.

(2) Let E_h be the error between the solution of the boundary integral equation and the solution of the corresponding discretized equation. We shall prove that we have the error estimate

$$\|E_h\|_{L^p} \le ch\,\|\nabla f\|_{L^p}\,, \qquad 2-\epsilon_M < p < \infty,$$

as long as f is in the Sobolev space L^p_1.

(3) We will also establish corresponding results for certain systems of equations. In particular, we will consider the Dirichlet problem in elastostatics, Stokes' system of hydrostatics, and the boundary value problem modeling the stresses exerted on a body inserted in a Stokes flow.

In the interest of brevity we shall only consider in detail the Dirichlet problem for an unbounded domain $\Omega = \{(x,y) : x \in \mathbb{R}^{n-1},\ y > \Phi(x)\}$, where $\Phi : \mathbb{R}^{n-1} \to \mathbb{R}$ is a Lipschitz function with Lipschitz constant M. Such a domain is usually called a Lipschitz graph domain. The Neumann problem and the bounded case require some minor modifications for which we refer to [DK].

A brief outline of the content of this paper is as follows.

In §2 we write down the precise conditions that the finite element spaces must satisfy. We also make some related, simple observations. In particular, we show that if the domain Ω is sufficiently nice, then we may, at least theoretically, work directly with Ω and avoid the approximating domains Ω_h.

In §3 we give the criteria that the approximating spaces Ω_h must satisfy and establish the convergence of the Galerkin procedure. We assume that we are given approximating domains Ω_h, $h > 0$, and a finite element space X_h on each of these. We then show the invertibility of $\Pi_h A_h$ on X_h, uniformly in $h > 0$, and the convergence in the L^p-norm of the approximate solutions $f_h \in X_h$, solving $\Pi_h A_h f_h = \Pi_h g$, to the solution f of $Af = g$.

The conditions that the finite element spaces X_h, $h > 0$ have to satisfy are not entirely simple. In §4 we discuss a simple and efficient way to construct them.

For the Galerkin method to be of any real practical use, we need some error estimates. This is the subject of §5. As we mentioned above, we prove that if the function and its first derivatives are in L^p, i.e., $f \in L^p_1$, and if the meshsize is $\mathcal{O}(h)$, then the rate of convergence of the approximate solutions f_h to the exact solution f is at least $\mathcal{O}(h)$.

In §6 we discuss systems of equations in Lipschitz domains and the modifications of the scalar case necessary to use the Galerkin method for systems.

2. Finite element spaces.

Let us start by reviewing the boundary integral method in the case of the Dirichlet problem in a nonsmooth domain Ω. Let $\Phi : \mathbb{R}^{n-1} \to \mathbb{R}$ be a Lipschitz function with Lipschitz constant M, and let $\Omega = \{(x,y) : x \in \mathbb{R}^{n-1}, y > \Phi(x)\}$. For f defined on $\partial\Omega$, and $P \in \Omega$, the double layer potential of f is defined by

$$\mathcal{D}f(P) = \mathcal{D}_\Omega f(P) = \frac{1}{\omega_n}\int_{\partial\Omega} f(Q)\frac{\langle P-Q, n(Q)\rangle}{|P-Q|^n}\,d\sigma, \tag{2.1}$$

where $d\sigma$ denotes the surface measure of $\partial\Omega$, ω_n is the surface area of the unit sphere, and $n(Q)$ the inward unit normal to $\partial\Omega$. By formally allowing $P \in \partial\Omega$ in the definition of $\mathcal{D}f$, we obtain a principal value operator that we denote by T_Ω or just T. In local coordinates, the kernel of T is

$$k(x,y) = \frac{1}{\omega_n} \frac{\Phi(x) - \Phi(y) - \nabla\Phi(y) \cdot (x-y)}{(|x-y|^2 + (\Phi(x) - \Phi(y))^2)^{n/2}}. \tag{2.2}$$

The boundary values of $\mathcal{D}f$ from the interior of Ω are given by $Af = (\frac{1}{2}I + T)f$. The boundary integral method uses $\mathcal{D}(A^{-1}g)$ to solve the Dirichlet problem in Ω with boundary values g.

To apply this method two basic facts must be established. First we need to prove the boundedness of A. In the case of Lipschitz domains, this follows from the L^p boundedness of the Cauchy integral on Lipschitz curves, cf. [CMM] and [C], and the method of rotations. We thus have

$$\|Af\|_p \leq C_p \|f\|_p \tag{2.3}$$

for $1 < p < \infty$. We must then prove the invertibility of A. In the case of smooth domains it is easy to see that $A = \frac{1}{2}I + T$ with T compact, which means that the invertibility follows from Fredholm theory. In the case of general Lipschitz domains, T is not compact and Fredholm theory does not apply. Instead, the invertibility follows as a consequence of certain Rellich type identities and estimates using these identities. It follows that there exists an $\epsilon_M > 0$, depending only on the Lipschitz constant M, such that A is invertible on $L^p(\partial\Omega)$ for $2 - \epsilon_M < p < \infty$, and

$$\|Af\|_p \geq c_p \|f\|_p \tag{2.4}$$

for this range of p (see [DK]).

To discuss a discretized version of this and the Galerkin procedure we need certain finite element function spaces X. We shall assume that the space X satisfies the following conditions.

(1) $X \subset L^\infty(\partial\Omega)$, X closed under uniform convergence.

(2) There are pairwise disjoint sets $E_j \subset \partial\Omega$ whose union equals $\partial\Omega$, points $P_j \in E_j$, and positive numbers ρ_j, K, c_0, and ϵ_0 such that each point in $\partial\Omega$ lies in at most K of the sets $B_j = B(P_j, \rho_j) \cap \partial\Omega$, $\rho_j > \epsilon_0$,

$$E_j \subset B_j, \tag{2.5}$$

and

$$\|f\|_{L^\infty(E_j)} \leq \frac{c_0}{\sigma(B_j)} \sup \left| \int_{\partial\Omega} fw \, d\sigma \right|, \tag{2.6}$$

where the supremum is taken over all $w \in X$ with $\|w\|_\infty \leq 1$ and w supported in B_j. Here, $B(P,r)$ denotes the ball in $\mathbb{R}^n$ with center P and radius r.

(3) All constant vectors belong to X.

We shall call such an X a localized space with variable scale. We say that the covering $\{B_j\}$ has the finite intersection property, and we will sometimes refer to (2.6) as the localization property.

The conditions on X imply the existence of a projection operator Π.

PROPOSITION 2.1. *With X and $\partial\Omega$, set $X^p = L^p(\partial\Omega) \cap X$. Then X^p is a closed subspace of $L^p(\partial\Omega)$ for $p \in [1,\infty]$. If Π denotes the L^2 projection onto X^2, then Π has a bounded extension $\Pi : L^p(\partial\Omega) \to X^p$ with $\|\Pi f\|_p \le C\,\|f\|_p$, $1 \le p \le \infty$, with C independent of f.*

Proof. The localization property implies that if $f \in X$, then for $x \in E_j$

$$|f(x)| \le \frac{c_0}{\sigma(B_j)} \int_{B_j} |f|\, d\sigma \le C\rho_j^{-(n-1)/p}\, \|f\|_{L^p(B_j)} \le C\epsilon_0^{-(n-1)/p}\, \|f\|_{L^p(B_j)}\,.$$

From this estimate it follows that if a sequence in X^p converges in the L^p sense, it also converges in the maximum norm. X is closed under uniform convergence, so X^p is a closed subspace of $L^p(\partial\Omega)$. Similarly, if $f \in L^p(\partial\Omega) \cap L^2(\partial\Omega)$ and $w \in X$, supported on B_j, satisfies $\|w\|_\infty \le 1$, then for $x \in E_j$

$$|\Pi f(x)| \le \frac{c_0}{\sigma(B_j)} \left| \int w \Pi f\, d\sigma \right| = \frac{c_0}{\sigma(B_j)} \left| \int w f\, d\sigma \right| \le C\rho_j^{-(n-1)/p}\, \|f\|_{L^p(B_j)}\,.$$

Using the variable scale localization property, we now have that

$$\begin{aligned} \int |\Pi f|^p\, d\sigma &= \sum \int_{E_j} |\Pi f|^p\, d\sigma \le C \sum \rho_j^{n-1}\, \|\Pi f\|^p_{L^\infty(E_j)} \\ &\le C \sum \int_{B_j} |f|^p\, d\sigma \le C \int |f|^p\, d\sigma. \end{aligned}$$

This is the step where we use the finite intersection property of the B_j's. The proof is complete. □

When the domain is sufficiently smooth and bounded, then, as we have remarked earlier, the operator T is compact (cf. [FJR]). Hence, the following elementary observation proves the solvability of the Galerkin equations for a family of finite element spaces X_h, $h > 0$, and corresponding projections Π_h, on such domains. Note, however, that we obtain no estimates on the norms involved.

PROPOSITION 2.2. *Let $A = \frac{1}{2}I + T$, as before, and suppose that Ω is Lipschitz. Suppose $T : L^2(\partial\Omega) \to L^2(\partial\Omega)$ is compact. Let X_h, $h > 0$ be a family of closed subspaces of $L^2(\partial\Omega)$, and let Π_h be orthogonal projections of $L^2(\partial\Omega)$ onto X_h. Further, suppose $\|\Pi_h f - f\|_2 \longrightarrow 0$ as $h \longrightarrow 0$ for $f \in L^2(\partial\Omega)$. Then, there exist $h_0, c_0 > 0$ such that if $0 < h \le h_0$,*

$$\|\Pi_h A \Pi_h f\|_2 \ge c_0\, \|\Pi_h f\|_2 \quad \textit{for } f \in L^2(\partial\Omega), \tag{2.7}$$

and $\Pi_h A : X_h \to X_h$ is invertible.

Proof. Suppose this is not so. Then, there is a sequence $f_k \in L^2(\partial\Omega)$ and $\{h_k\}$, $h_k \longrightarrow 0^+$, with $\|\Pi_{h_k} f_k\|_2 = 1$, and

$$\|\Pi_{h_k} A \Pi_{h_k} f_k\|_2 \le \frac{1}{k}. \tag{2.8}$$

Without loss of generality, by compactness, $T\Pi_{h_k} f_k \longrightarrow g \in L^2(\partial\Omega)$. Now, $\Pi_{h_k} A \Pi_{h_k} f = \frac{1}{2}\Pi_{h_k} f_k + \Pi_{h_k} T \Pi_{h_k} f_k$. Since $T\Pi_{h_k} f_k \longrightarrow g$, using our hypothesis, $\Pi_{h_k} T \Pi_{h_k} f_k \longrightarrow g$, and using (2.8), $\frac{1}{2}\Pi_{h_k} f_k \longrightarrow -g$, so $\Pi_{h_k} f_k \longrightarrow -2g$. Note that $g \not\equiv 0$ since $\|\Pi_{h_k} f_k\|_2 = 1$. Since $T\Pi_{h_k} f_k \longrightarrow g$, and $\Pi_{h_k} f_k \longrightarrow -2g$, and T is bounded, we obtain $-2Tg = g$.

This implies $Ag = 0$, i.e., $g \equiv 0$ since A is one to one. This is impossible and (2.7) thus follows.

The inequality (2.7) shows that $\Pi_h A : X_h \to X_h$ is one to one and has closed range. To show that $\Pi_h A$ is onto, suppose $\langle \Pi_h A g, \phi \rangle = 0$ for all $g \in X_h$, for some $\phi \in X_h$. Taking $g = \Pi_h A^* \phi$, and noting that $\phi = \Pi_h \phi$, we obtain $\Pi_h A^* \Pi_h \phi = 0$. Applying the same proof we used to prove (2.7) to A^* and T^*, we obtain $\phi \equiv 0$. This finishes the proof of Proposition 2.2. □

For general Lipschitz domains this result is of little help, since T is not necessarily compact and also because we do not get much information about h_0 and c_0. It is still an open problem as to whether there is an analogous result for Lipschitz domains which would allow us to establish the invertibility with interesting spaces X_h directly on the boundary of the domain.

Following the approach of Dahlberg and Verchota [DV], we shall approximate the Lipschitz domain Ω with smooth domains and prove a uniform invertibility result. This essentially involves quantifying the compactness of T on each of these domains in a suitable way.

Let us fix a domain Ω and a finite element space X on $\partial\Omega$ that is localized with variable scale. We shall say that an operator T satisfies the local approximation property with constant δ if there are $\phi_j \in X$ such that

$$\sum_j \int_{B_j} |Tf - \phi_j|^p \, d\sigma \leq \delta \, \|f\|_p^p \quad \text{if } f \in L^p(\partial\Omega). \tag{2.9}$$

Observe that the existence of *some* δ in (2.9) follows immediately from the boundedness of T and the finite intersection property of the covering $\{B_j\}$, simply by taking $\phi_j \equiv 0$.

Remark 2.3. The local approximation property is closely connected with compactness. Suppose that for each $h > 0$ we are given a decomposition $\partial\Omega = \cup_j B(P_j, \rho(h)) \cap \partial\Omega$ of balls with a uniform size $\rho(h)$ and uniformly bounded overlap. Assume further that the size tends to zero with h, $\lim_{h\to 0} \rho(h) = 0$. Then it is an easy consequence of the Fréchet–Kolmogorov characterization of compact operators on L^p that T is compact if and only if

$$\int_{|x|>R} |Tf(x)|^p \, dx \to 0 \quad \text{as } R \to \infty$$

uniformly in $f \in L^p$, and there are constants c_j such that

$$\sum_j \int_{B(P_j,\rho(h))\cap\partial\Omega} |Tf - c_j|^p \, d\sigma \to 0 \quad \text{as } h \to 0$$

uniformly in $f \in L^p$.

LEMMA 2.4. *Suppose that $\Omega = \{(x,y) : y > \Phi(x)\}$ is a Lipschitz domain with Lipschitz constant M, and that X is a localized space of variable size. Then, for each p, $2 - \epsilon_M < p < \infty$ there is a δ_0 with the following property: if the operator $T = T_\Omega$ satisfies the local approximation property with constant $\delta < \delta_0$, then*

$$\|\Pi A \Pi f\|_p \geq C \, \|\Pi f\|_p \quad \textit{for } f \in L^p(\partial\Omega).$$

Here C and δ_0 only depend on p, the Lipschitz constant M, and the parameters K and c_0 in the definition of X.

Proof. We let $g = \Pi A f$ and write

$$Af = Af - Tf + \phi_j + Tf - \phi_j. \tag{2.10}$$

Now, $Af - Tf + \phi_j = \frac{1}{2}f + \phi_j \in X$; so, by (2.6), for $x \in E_j$,

$$\begin{aligned} |(Af - Tf + \phi_j)(x)| &\le \frac{c_0}{\sigma(B_j)} \sup_w \left| \int_{\partial\Omega} (Af - Tf + \phi_j) w \, d\sigma \right| \\ &\le cg^*(x) + c \left(\int_{B_j} |Tf - \phi_j|^p \frac{1}{\sigma(B_j)} \right)^{1/p}, \end{aligned}$$

where g^* is the Hardy–Littlewood maximal function of g. Hence,

$$\int_{E_j} |Af - Tf + \phi_j|^p \, d\sigma \le c \int_{E_j} (g^*(x))^p + c \int_{B_j} |Tf - \phi_j|^p,$$

and thus, from (2.10),

$$\int_{\partial\Omega} |Af|^p \le c \int_{\partial\Omega} |g|^p + c \sum_j \int_{B_j} |Tf - \phi_j|^p.$$

Now, from (2.4) and (2.9), we obtain

$$(2.11) \qquad (c_p^p - c\delta) \, \|f\|_p^p \le c \, \|g\|_p^p .$$

Thus, if δ is sufficiently small, i.e., so that $c_p^p - c\delta > 0$, we obtain the desired conclusion. □

Remark 2.5. The localization property (2.6) can be replaced, here and also below, by weaker conditions. For instance, let us consider Lemma 2.4 in the special case $p = 2$ and assume a priori that Π is the (bounded) projection of L^2 on X. By a slight modification of the proof above, we may establish the lemma in this special case, assuming instead that

$$(2.12) \qquad \|f\|_{L^2(E_j)} \le c_0 \sup \left| \int_{\partial\Omega} f w \, d\sigma \right|,$$

where the supremum is taken over all $w \in X$ with $\|w\|_2 \le 1$ and w supported in B_j. Suppose, for example, that X is the closure of the linear span of the (real) functions $\{\Phi_j\}$. Then the following is a sufficient condition for (2.12) to hold:

$$(2.13) \qquad \cup_{E_i \cap \operatorname{supp} \Phi_j \ne \emptyset} \operatorname{supp} \Phi_j \subset B_i.$$

To see this, let $f = \sum_j \lambda_i \Phi_i$. Clearly,

$$\|f\|_{L^2(E_j)} \le \left(\int_{\partial\Omega} \left| \sum_{\operatorname{supp} \Phi_i \cap E_j \ne \emptyset} \lambda_i \Phi_i \right|^2 d\sigma \right)^{1/2} = \sup \left| \int_{\partial\Omega} f w \, d\sigma \right|,$$

since $\operatorname{supp} \sum_{\operatorname{supp} \Phi_i \cap E_j \ne \emptyset} \lambda_i \Phi_i \subset B_j$.

3. The Galerkin method on Lipschitz domains. We will next prove the solvability of the Galerkin equation, i.e., show that $\Pi A : X^p \to X^p$ is invertible. In order to prove this, we first recall the following standard continuation lemma (see [DV] or [DK1]).

LEMMA 3.1. *Let Y be a Banach space and suppose $S_t : Y \to Y$ are bounded linear operators for $0 \le t \le 1$. Suppose, furthermore, that there are positive constants c and C such that the following properties hold.*

(i) *For all $t \in [0,1]$, and all $f \in Y$, $\|S_t f\| \ge c\|f\|$.*
(ii) *For all $t, s \in [0,1]$, $\|S_s - S_t\| \le C|s-t|$.*
(iii) *The operator S_0 is invertible on Y.*

Then S_1 is invertible on Y.

Let $A_t = \frac{1}{2}I + T_t$, $0 \le t \le 1$, where the kernel of T_t is given by (2.2) with Φ changed to $t\Phi$. If T_t satisfies the local approximation property with a sufficiently small δ_0, uniformly in t, then the Continuation Lemma applied to ΠA_t, combined with Lemma 2.4, immediately yields the invertibility of ΠA. (By an abuse of notation, we consider A_t acting on functions defined on $\partial\Omega$.) Next we shall give a condition on Ω that guarantees this uniform approximation property.

Let the surface $\partial\Omega = \{(x,y) : y = \Phi(x)\}$ be given by the graph of the smooth function $\Phi : \mathbb{R}^{n-1} \to \mathbb{R}$. For a point $P = (x, \Phi(x))$ on the surface and $\rho > 0$, we define the function κ by

$$\kappa(P,\rho) = \sup_{|x-y|<\rho} \max_{i,j} \left| \frac{\partial^2 \Phi(y)}{\partial y_i \partial y_j} \right|.$$

The function κ is a measure of the maximal curvature near P. This is clear if we recall that the curvature in a direction $\xi \in \mathbb{R}^{n-1}$, $|\xi| = 1$, is given by

$$k(x,\xi) = \frac{D_{\xi\xi}\Phi(x)}{(1 + (D_\xi \Phi(x))^2)^{3/2}},$$

where $D_\xi \Phi$ is the directional derivative of the function Φ in the direction ξ and $D_{\xi\xi}\Phi(x) = \langle \xi, \nabla_2 \Phi \xi \rangle$ with $\nabla_2 \Phi =$ the Hessian of Φ.

THEOREM 3.2. *Suppose that $\Omega = \{(x,y) : y > \Phi(x)\}$ is a smooth domain and that X is a localized space of variable size. For each p, $2 - \epsilon_M < p < \infty$ there is a $\delta_0 > 0$ and a $\gamma > 2$ with the property that if $\sup_j \kappa(P_j, \gamma\rho_j)\gamma\rho_j < \delta_0$, then $\Pi A : X^p \to X^p$ is invertible. In particular, for every $g \in L^p(\partial\Omega)$ there is a unique $f \in X \cap L^p(\partial\Omega)$, such that*

$$\int_{\partial\Omega} Af\, w\, d\sigma = \int_{\partial\Omega} gw\, d\sigma \tag{3.1}$$

for all $w \in X$ with compact support. Here γ and δ_0 only depend on p, the Lipschitz constant M of the function Φ, and the parameters K and c_0 in the definition of X.

Proof. We claim that for every j there is a constant c_j such that for $\gamma > 2$,

$$|Tf(P) - Tf(P_j)| \le c\left(\kappa(P_j, \gamma\rho_j)\gamma\rho_j + \frac{1}{\gamma}\right) f^*(P), \qquad P \in B_j, \tag{3.2}$$

where the constant $c = c(M)$.

This is easy to show. We write $f = a_j + b_j$, where $a_j = f$ on $B(P_j, \gamma\rho_j) \cap \partial\Omega$, and $a_j = 0$ elsewhere, and let $b_j = f - a_j$. Then, by using Taylor's expansion to second order,

$$|Ta_j(P)| \le \kappa(P_j, \gamma\rho_j) \int_{B(P_j,\gamma\rho_j)\cap\partial\Omega} \frac{1}{|P-Q|^{n-2}} |f(Q)|\, d\sigma \le c\kappa(P_j, \gamma\rho_j)\gamma\rho_j f^*(P).$$

The last inequality follows from the standard fact that if q is a nonnegative, radial, decreasing function, then for a function h we have $\int qh \leq h^*(0) \int q$. We now let $c_j = Tb_j$. Using this fact again, we see that

$$|Tb_j(P) - Tb_j(P_j)| \leq c\rho_j \int_{B(P_j,\gamma\rho_j)^c \cap \partial\Omega} \frac{1}{|P_j - Q|^n} |f(Q)|\, d\sigma \leq \frac{c}{\gamma} f^*(P).$$

This proves the claim.

Note that the operators $T = T_t$, $0 \leq t < 1$, satisfy the same inequality (3.2). Hence, the uniform local approximation property, and the theorem, immediately follow by picking γ sufficiently large. □

As in [DV] we approximate a given Lipschitz domain $\Omega = \{(x,y) : y > \Phi(x)\}$ by certain smooth domains Ω_h. These domains must satisfy the following conditions.

(1) $\Omega_h = \{(x,y) : x \in \mathbb{R}^{n-1},\ y > \Phi_h(x)\}$ for some Lipschitz functions Φ_h with a uniform Lipschitz constant M.

(2) dist $\{\partial\Omega_h, \partial\Omega\} \leq Ch$.

(3) $\kappa(h) \leq C(1/h)$, where $\kappa(h)$ denotes the least upper bound of the absolute values of the curvatures of $\partial\Omega_h$.

(4) The mapping $F_h : \partial\Omega \longrightarrow \partial\Omega_h$ defined by $F_h((x, \Phi(x)) = (x, \Phi_h(x))$ is a Lipschitz diffeomorphism such that the Lipschitz constants of F_h and its inverse G_h are uniformly bounded in h.

(5) The mapping $h \longrightarrow \Phi_h(x)$, $0 < h < 1$, is continuous almost everywhere in x, and

$$\lim_{h \downarrow 0} \frac{\Phi_h(x) - \Phi(x)}{h} \text{ exists a.e. in } x.$$

(6) $|F_h(P) - P| \leq Ch$ for all $P \in \partial\Omega$.

(7) The Jacobian of F_h converges almost everywhere to 1.

Note that these conditions are not independent, and that the conditions are satisfied by the following standard regularization. Let $\eta \in C_0^\infty(\mathbb{R}^{n-1})$ be radial, with $\int \eta\, dx = 1$. Set $\eta_h = (1/h^{n-1})\eta(x/h)$ for $h > 0$. Let $\Phi_h(x) = \eta_h * \Phi(x)$ with corresponding domains $\Omega_h = \{(x,y) : y > \Phi_h(x)\}$. Note that the second derivatives of Φ_h (differentiate η_h with one partial, Φ with the second) are bounded by c/h. Φ_h are Lipschitz, with Lipschitz constant bounded by M, and the others of the seven conditions on $\partial\Omega_h$ are satisfied.

Given the domain $\Omega = \{(x,y) : y > \Phi(x)\}$, we let Ω_h, $h > 0$, be such approximating domains, and for each h we let X_h be a finite element space on Ω_h that is localized with variable size, with the constants K, and c_0 independent of h.

If $\rho_{j,h}$ denotes the ρ_j's corresponding to X_h, we let $\rho_h = \max_j \rho_{j,h}$. Suppose now that $\rho_h \longrightarrow 0$ as $h \longrightarrow 0$. Then it is an easy consequence of the localization property that for $q \in L^p(\partial\Omega)$,

$$\left\| \Pi_h(q \circ F_h^{-1}) - q \circ F_h^{-1} \right\|_p \longrightarrow 0 \quad \text{as } h \longrightarrow 0. \tag{3.3}$$

Let A be the operator giving the interior boundary values of the double layer potential on Ω, and A_h the corresponding operators for Ω_h. As a consequence of the conditions on the Ω_h's we also have

$$\left\| Af - A_h(f \circ F_h^{-1}) \circ F_h \right\|_p \longrightarrow 0 \quad \text{as } h \longrightarrow 0. \tag{3.4}$$

The proof of this is similar to that in [DV, Lemma 2.4], so we only give a very brief outline. By a change of variables, $A_h(f \circ F_h^{-1}) \circ F_h = T_hf(P) + \frac{1}{2}f(P)$, where

$$T_hf(P) = T_hf(P) = \frac{1}{\omega_n}\int_{\partial\Omega} \frac{\langle F_h(P) - F_h(Q), n_h(Q)\rangle}{|F_h(P) - F_h(Q)|^n} J_h(Q)f(Q)\,d\sigma. \tag{3.5}$$

Here $n_h(Q)$ is the unit inward normal to $\partial\Omega_h$ at the point $F_h(Q)$, and J_h is the determinant of the Jacobian of F_h. So we need to show T_hf converges to Tf in $L^p(\partial\Omega)$. This is a rather straightforward exercise about singular integrals, using properties of $\partial\Omega_h$. We add and subtract 1 from $n_h(Q)J_h(Q)$. The difference converges to zero in $L^p(\partial\Omega)$ using uniform boundedness of T_h in $L^p(\partial\Omega)$. For the other term, we estimate the difference of this new singular integral and Tf, truncated on a ball of radius rh around x, by looking at the parts close to P, distance at most rh, far away from P, distance at least Rh, and in the middle. The near part has a factor of r coming out, and the far part a factor of $1/R$. For the middle part we use condition (5), satisfied by the approximating domains, to see that it is bounded uniformly by an L^p function and converges pointwise to zero. Letting h go to zero, to estimate the limsup in terms of r and $1/R$, and then letting r go to zero and R go to ∞, finishes the proof of (3.4).

These observations and Theorem 3.2 easily yield the next result. We shall assume that $\Omega = \{(x,y) : y > \Phi(x)\}$ is a Lipschitz domain, and that Φ has Lipschitz constant M. We let $\Omega_h = \{(x,y) : y > \Phi_h(x)\}$, $h > 0$ be approximating domains as defined above, and for each $h > 0$ we let X_h be a finite element space on Ω_h that is localized with variable size, with the constants L, K, and c_0 independent of h.

THEOREM 3.3. *Suppose that* $\lim_{h\to 0}\rho_h = 0$. *Then, given* p, $2 - \epsilon_M < p < \infty$, *there are* $h_0 > 0$ *and* $\gamma > 1$ *with the property that if*

$$\lim_{h\to 0}\kappa_h = \lim_{h\to 0}\sup_j \kappa(P_{j,h}, \gamma\rho_{j,h})\gamma\rho_{j,h} = 0.$$

Then for every $g \in L^p(\partial\Omega)$ *there is a unique* $f_h \in X_h \cap L^p(\partial\Omega_h)$, *for* $h < h_0$, *such that*

$$\int_{\partial\Omega_h} A_hf_h\, w\, d\sigma = \int_{\partial\Omega_h} g_h w\, d\sigma \tag{3.6}$$

for all $w \in X$ *with compact support. Here* $g_h(P) = g(F_h^{-1}(P))$. *Moreover, if* $f \in L^p(\partial\Omega)$ *is defined by* $Af = g$, *then* $f_h \circ F_h$ *converges to* f *in* $L^p(\partial\Omega)$.

Proof. The proof is immediate. Of course, (3.6) follows directly from Theorem 3.2; in fact, it follows that the Π_hA_h's are uniformly invertible. To finish the proof, it remains to show that $f_h \circ F_h$ converge to f in $L^p(\partial\Omega)$, where $Af = g$.

We have $\Pi_hA_hf_h = \Pi_hg_h$, and, since we have assumed that c_0 does not depend on h, the projections Π_h are uniformly bounded. Hence,

$$\begin{aligned}
&\left\|\Pi_hA_hf_h - \Pi_hA_h\Pi_h(f\circ F_h^{-1})\right\|_p = \left\|\Pi_hg_h - \Pi_hA_h\Pi_h(f\circ F_h^{-1})\right\|_p \\
&\qquad \le C\left\|g_h - A_h\Pi_h(f\circ F_h^{-1})\right\|_p = C\left\|g\circ F_h^{-1} - A_h\Pi_h(f\circ F_h^{-1})\right\|_p \\
&\qquad \le C\left\|g - A_h\Pi_h(f\circ F_h^{-1})\circ F_h\right\|_p = C\left\|Af - A_h\Pi_h(f\circ F_h^{-1})\circ F_h\right\|_p.
\end{aligned} \tag{3.7}$$

Now, using (3.3) and the fact that the A_h's are uniformly bounded on $L^p(\partial\Omega_h)$, as well as the uniform invertibility of the F_h, we obtain from (3.7) that

$$\left\|\Pi_hA_hf_h - \Pi_hA_h\Pi_h(f\circ F_h^{-1})\right\|_p \le C\left\|Af - A_h(f\circ F_h^{-1})\circ F_h\right\|_p + o(1). \tag{3.8}$$

Using (3.4) and the uniform invertibility of the $\Pi_h A_h$, (3.8) yields that

$$\left\| f_h - \Pi_h(f \circ F_h^{-1}) \right\|_p \longrightarrow 0. \tag{3.9}$$

Using (3.3) once more, and composing on the right with F_h, we finally get that

$$\| f_h \circ F_h - f \|_p \longrightarrow 0,$$

which establishes the theorem. □

4. An example of a localized space. In this section we shall describe a simple construction of a localized space of variable size on a given smooth domain.

We start in $\mathbb{R}^{n-1}$ and assume that $\Phi : \mathbb{R}^{n-1} \to \mathbb{R}$ is a smooth function with Lipschitz constant M and with $\kappa = \sup_x \max_{i,j} |\partial^2\Phi(x)/\partial x_i \partial x_j| < \infty$. For each cube $Q \subset \mathbb{R}^{n-1}$, we let

$$K(Q) = \ell(Q) \sup_{y \in Q} \max_{i,j} \left| \frac{\partial^2 \Phi(y)}{\partial y_i \partial y_j} \right|.$$

Fix $\epsilon > 0$ and a $\gamma \geq 1$. For each $x \in \mathbb{R}^{n-1}$, we let $Q(x)$ be the largest dyadic cube Q containing x such that $K(\gamma Q) \leq \epsilon$. Here γQ is the cube with the same center as Q, but with sidelength γ as long. Note that there is always such a nonempty finite cube $Q(x)$, and, in fact, $\inf_x \ell(Q(x)) \geq \epsilon_0 > 0$ since $\kappa < \infty$. There are only countably many different such cubes; let us call them Q_i. These cubes have the following properties:

(i) $\mathbb{R}^{n-1} = \cup_i Q_i$;
(ii) The cubes Q_i are pairwise disjoint (modulo sets of measure zero);
(iii) $\ell(Q_i) \geq \epsilon_0$;
(iv) $K(\gamma Q_i) \leq \epsilon$;
(v) For any fixed $\beta \leq \gamma/4$, the cubes βQ_i have bounded overlap.

Of these, only v requires some explanation. Let Q_i and Q_j be two distinct cubes in this cover such that $\frac{\gamma}{4}Q_i \cap \frac{\gamma}{4}Q_j \neq \emptyset$. We claim that Q_i and Q_j must be of approximately the same size. This would clearly prove v.

Let us assume for instance that Q_j is much smaller than Q_i, $\ell(Q_j)/\ell(Q_i) \leq \frac{1}{8}$, say. Simple geometric considerations then show that Q_j is contained in a dyadic cube $\tilde{Q}_j$ with $\ell(\tilde{Q}_j) = 2\ell(Q_j)$ and such that $\gamma\tilde{Q}_j \subset \gamma Q_i$. This implies that $K(\tilde{Q}_j) \leq K(Q_i) \leq \epsilon$, which contradicts the maximality of Q_j.

Now, given the smooth domain $\Omega = \{(x, y) : x \in \mathbb{R}^{n-1}, \Phi(x) > y\}$ with $\kappa < \infty$, we let G_0 be the projection of $\partial\Omega$ on $\mathbb{R}^{n-1}$, and F_0 its inverse so that

$$G_0((x, \Phi(x))) = x, \qquad F_0(x) = (x, \Phi(x)).$$

For any Q_i in the covering of $\mathbb{R}^{n-1}$ that is obtained by our construction, define $E_i = F_0(Q_i)$, $P_j = F_0(x_j)$, where x_j is the center of Q_j, and define ρ_j to be the radius of the ball (in $\mathbb{R}^{n-1}$) inscribed in βQ_j. We can take any $\beta > \delta\sqrt{M^2+1}$ to satisfy $E_i \subset B_i(P_i, \rho_i)$, where δ is a constant depending only on the dimension $n-1$. Note that each $(x, \Phi(x)) \in \partial\Omega$ lies in only finitely many of the $B(P_i, \rho_i)$. Indeed, $(x, \Phi(x)) \in B(P_i, \rho_i)$ implies $x \in G_0(B(P_i, \rho_i))$. But $G_0(B(P_i, \rho_i)) \subset \beta Q_i$, and x is in at most K of these, as noted in our construction.

To satisfy conditions 1, 2, and 3 for a localized variable scale space X, we can, for example, choose X to be the space of polynomials defined on $\mathbb{R}^{n-1}$, of total degree less than or equal to 1 on each Q. See also [Li]. There are many other choices as well. For instance, we can use certain functions satisfying a refinement relation, and, in particular, each of the functions Φ yielding the compactly supported wavelets of Daubechies [Da]. More specifically, let Φ be a compactly supported function defined on $\mathbb{R}$. For $I = [2^{-\nu}k, 2^{-\nu}(k+1)]$ we let $\Phi_I = 2^{\nu/2}\Phi(2^\nu x - k)$. Φ_I is thus supported on $I + 2 - \nu \operatorname{supp} \Phi$. We let $\mathcal{D}_\nu$ denote the set of dyadic intervals with sidelength 2^ν, and $\mathcal{D}$ the union of the $\mathcal{D}_\nu$'s. We assume that Φ satisfies a refinement condition,

$$\Phi(x) = \sum_j c_k \Phi(2x - k).$$

Let S_ν be the span of the functions Φ_I, $I \in \mathcal{D}_\nu$. We also assume that for some integer $r > 0$, S_ν contains the polynomials of degree $< r$. In particular, the Φ_I's form a partition of unity when the length of I is fixed. Finally, for J an interval in $\mathbb{R}$, we let Λ_J denote the set of all j for which $\Phi(\cdot - j)$ is not identically zero on J. We assume that for all $J \in \mathcal{D}$, the functions $\Phi(\cdot - j)$, $j \in \Lambda_J$, are linearly independent over J (i.e., local linear independence). From these assumptions, it follows that if $\Phi_I = \sum_J c_J \Phi_J$, where $\ell(J) < \ell(I)$, then the support of each Φ_J is contained in the support of Φ_I.

Returning to the S_ν's, we see from the refinement property that they form an increasing chain of linear spaces. Each S_ν is associated to a uniform partition of $\mathbb{R}$ into dyadic intervals of length $2^{-\nu}$. Note that even if we have a nonuniform partition of $\mathbb{R}$ into dyadic intervals, with a lower bound on permissible lengths, there is a natural linear space V arising from Φ associated with this partition. The functions of V still retain local linear independence, and further refinements of this partition generate superspaces of V. We will illustrate this association starting with S_0 and perform one subdivision of one of the cubes. The process of associating natural spaces for further subdivisions is analogous. The final space V obtained, which corresponds to a nonuniform partition, will thus be shown to arise in a natural way.

So, let I_0 be a dyadic interval of length 1. We subdivide I_0 into two intervals, J_1 and J_2, of length $\frac{1}{2}$. Let $I_1, I_2, \cdots, I_m$ be the finite number of intervals such that the support of each of $\Phi_{I_1}, \Phi_{I_2}, \cdots, \Phi_{I_m}$ has nonempty intersection with I_0. From the refinement condition, each Φ_{I_k} has a decomposition in terms of intervals of length $\frac{1}{2}$, and for $|I| = 1$, Φ_I has a decomposition containing Φ_{J_1} or Φ_{J_2} only if I is one of $I_1, I_2, \cdots, I_m$. For any I_k such that Φ_{I_k} has Φ_{J_1} or Φ_{J_2} in its decomposition, let $\Phi^*_{I_k}$ be the function obtained by discarding Φ_{J_1} and Φ_{J_2} from the decomposition and summing the other functions. Replace Φ_{I_k} by $\Phi^*_{I_k}$ in S_0 and also adjoin Φ_{J_1} and Φ_{J_2}. The new linear space is the one we choose for the new partition.

In this context, let us make a remark concerning orthogonality. Suppose that the functions Φ_I, $|I| = 1$, in addition, form an orthonormal set in $L^2(\mathbb{R})$. (This is the case for the Φ that yields the compactly supported wavelets.) Then the above construction leads to three mutually orthogonal sets of functions: the functions Φ_I in S_0 that do not contain the Φ_{J_1} or Φ_{J_2}, and, hence, are not changed, the functions Φ_{J_1} and Φ_{J_2}, and, finally, the $\Phi^*_{I_k}$'s. Clearly, the functions in each of the first two sets are also pairwise orthogonal. If we thus want orthogonality also for the functions corresponding to the nonuniform partition, there only remains to orthogonalize the functions $\Phi^*_{I_k}$, which of course can be done in a standard manner.

Using tensor products, it is possible to obtain spaces adapted to nonuniform dyadic decompositions in higher dimensions.

Suppose now that we consider a Lipschitz domain $\Omega = \{(x, y) : x \in \mathbb{R}^{n-1}, \Phi(x) > y\}$ and the corresponding approximating domains $\Omega_h = \{(x, y) : x \in \mathbb{R}^{n-1}, \Phi_h(x) > y\}$. Let us consider a discrete sequence of these, $\Omega^n = \Omega_{2^{-n}}$, $n \geq 0$. It is easy to arrange that the dyadic cube mesh constructed at one level is a refinement of the dyadic cube mesh for the previous level. To see this, we start with the first level, corresponding to $n = 0$, and carry out the construction of the dyadic mesh described above with $K(Q) = K_0(Q)$, defined with respect to Φ_1. This gives us the collection $\{Q_i^0\}$. On the next level, $j = 1$, we only consider dyadic cubes which are subcubes of the dyadic cubes in $\{Q_i^0\}$. In fact, to ensure that the sidelengths of the cubes in $\{Q_i^n\} \longrightarrow 0$ as $n \longrightarrow \infty$, we also restrict the sidelengths of the cubes we consider. For each $x \in \mathbb{R}^{n-1}$, we let $Q(x)$ be the largest dyadic cube Q, contained in some Q_i^0 and containing x, with $\ell(Q) \leq \frac{1}{2}$ and such that $K_1(\gamma Q) \leq \epsilon$. Here $K_1(Q)$ is defined with respect to $\Phi_{1/2}$. As before, this yields the collection $\{Q_i^1\}$. Proceeding by induction gives us the dyadic meshes $\{Q_i^n\}$, $n \geq 0$.

5. An error estimate. In this section we prove error estimates for the Galerkin procedure of the previous sections. The proof we shall give is similar to that of Lin [Li], where the solvability of the Galerkin equations for functions $f \in L_1^p$ is established. In that work p is assumed to lie between $2-\epsilon$ and $2+\epsilon$, and more involved approximation spaces are used.

Consider, as before, the Lipschitz graph case and the corresponding smooth approximating domains satisfying the seven conditions above. On each $\partial\Omega_h$ we assume that we have a function space X_h, localized of variable scale with parameters K and c_0 independent of h. If, under the hypotheses of Theorem 3.3, the function f defined by $Af = g$ has gradient in L^p, then we have the following estimate of the rate of convergence of the approximate solutions to f.

THEOREM 5.1. *Suppose the hypotheses of Theorem* 3.3 *are satisfied, and, in addition, that* $\rho_h = \max_j \rho_{j,h} = \mathcal{O}(h)$. *For each* $2 - \epsilon_M < p < \infty$ *and* $g \in L^p(\partial\Omega)$, *let* f *and* f_h *denote the unique solutions in* $L^p(\partial\Omega)$ *and in* $X_h \cap L_1^p(\partial\Omega_h)$ *of* $Af = g$ *and* $\Pi_h A_h f_h = \Pi_h g_h$, *respectively. Then*

$$\|f - f_h \circ F_h\|_{L^p(\partial\Omega)} \leq Ch \|\nabla f\|_{L^p(\partial\Omega)} \quad \text{for all } f \in L_1^p(\partial\Omega).$$

Before entering into the details of the proof, we shall give a brief outline and state some lemmas which we need.

The idea is simple. We know that $\|f - f_h \circ F_h^{-1}\|_{L^p(\partial\Omega)} \to 0$ as $h \to 0^+$. The main obstacle in obtaining an estimate for the rate of convergence is that $\nabla\Phi_h \to \nabla\Phi$ almost everywhere, but not uniformly, and, as a consequence it is not immediate that $\|Tf - T_h(f \circ F_h^{-1})\|_{L^p(\partial\Omega)} \longrightarrow 0$ as $h \to 0$. However, $\Phi_h \to \Phi$ uniformly; so, exploiting the smoothness of the function $f \in L_1^p(\partial\Omega)$, we can use Green's theorem to move the derivatives from Φ and Φ_h to f and f_h, or, rather, to

$$f(y, \Phi(y)) \frac{x_i - y_i}{(|x-y|^2 + (\Phi(x) - \Phi(y))^2)^{n/2}}$$

and

$$f(y, \Phi(y)) \frac{x_i - y_i}{(|x-y|^2 + (\Phi_h(x) - \Phi_h(y))^2)^{n/2}}.$$

This yields an estimate $\|Tf - T_h(f \circ F_h^{-1})\|_{L^p(\partial\Omega)} = \mathcal{O}(h)$, which is what we need.

We shall use the following two lemmas.

LEMMA 5.2. *Suppose* $\rho_h = \mathcal{O}(h)$. *For* $2 - \epsilon_M < p < \infty$,

$$\|\Pi_h q \circ F_h^{-1} - q \circ F_h^{-1}\|_{L^p(\partial\Omega_h)} \leq Ch \|\nabla q\|_{L^p(\partial\Omega)} \quad \text{for all } q \in L_1^p(\partial\Omega).$$

Proof. Take $x_0 \in E_{j,h}$. The localization property gives

$$\begin{aligned}&\left\|\Pi_h q \circ F_h^{-1} - q \circ F_h^{-1}(x_0)\right\|_{L^\infty(E_{j,h})}\\&\qquad\leq \sup_w \frac{1}{\sigma(B_{j,h})}\left|\int_{B_{j,h}}(q\circ F_h^{-1}(t) - q \circ F_h^{-1}(x_0))w(t)\,dt\right|,\end{aligned}$$

where the supremum is taken over $w \in X_h$ with $\|w\|_\infty \leq 1$ and support in $B_{j,h} = B(P_j, \rho_{j,h}) \cap \partial\Omega_h$. It is easy to estimate the right-hand side by $C|\nabla q|^*(x_0) \max_j \rho_{j,h} \leq Ch|\nabla q|^*(x_0)$, from which the proposition follows. □

The second lemma ultimately depends on the boundedness of the Cauchy integral on Lipschitz curves [CMM], [C]; cf. [Li] and the references therein.

LEMMA 5.3 (Lin [Li]). *Let*

$$T_\epsilon(y) = \int_{|x-y|>\epsilon} \frac{(f(x) - f(y))g(x)\prod_k(\Psi_i(x) - \Psi_i(y))}{(|x-y|^2 + (\Phi(x) - \Phi(y))^2)^{(n+k)/2}}\,dx.$$

Suppose that $\|\nabla\Phi\|\infty \leq M$ *and that* $k \geq 2$ *is an even integer. Then*

$$\left\|\sup_{\epsilon>0}|T_\epsilon(y)|\right\|_{L^r(\mathbb{R}^{n-1})} \leq C(M)\prod_k \|\nabla\Psi_i\|_{L^\infty(\mathbb{R}^{n-1})}\,\|\nabla f\|_{L^p(\mathbb{R}^{n-1})}\,\|g\|_{L^q(\mathbb{R}^{n-1})},$$

where $\frac{1}{r} = \frac{1}{q} + \frac{1}{p}, 1 < p \leq \infty, 1 < q \leq \infty, 1 < r < \infty$.

Proof of Theorem 5.1. We have

$$\begin{aligned}&\|f - f_h \circ F_h\|_{L^p(\partial\Omega)}\\&\qquad\leq c\left\|f\circ F_h^{-1} - \Pi_h(f\circ F_h^{-1})\right\|_{L^p(\partial\Omega_h)} + \left\|\Pi_h(f\circ F_h^{-1}) - f_h\right\|_{L^p(\partial\Omega_h)}.\end{aligned}$$

Hence, by Lemma 5.2 it is sufficient to estimate $\left\|\Pi_h(f\circ F_h^{-1}) - f_h\right\|_{L^p(\partial\Omega_h)}$. By the uniform invertibility of $\Pi_h A_h$, we see that

$$\begin{aligned}&\left\|f_h - \Pi_h(f\circ F_h^{-1})\right\|_{L^p(\partial\Omega_h)} \leq \|(\Pi_h A_h)^{-1}\|\,\left\|\Pi_h A_h f_h - \Pi_h A_h \Pi_h(f\circ F_h^{-1})\right\|_{L^p(\partial\Omega_h)}\\&\quad\leq C\left\|\Pi_h g_h - \Pi_h A_h \Pi_h(f\circ F_h^{-1})\right\|_{L^p(\partial\Omega_h)} \leq C\left\|g_h - A_h\Pi_h(f\circ F_h^{-1})\right\|_{L^p(\partial\Omega_h)}\\&\quad\leq C\left\|g\circ F_h^{-1} - A_h\Pi_h(f\circ F_h^{-1})\right\|_{L^p(\partial\Omega_h)} \leq C\left\|g - A_h\Pi_h(f\circ F_h^{-1})\circ F_h\right\|_{L^p(\partial\Omega)}\\&\quad= C\left\|Af - A_h\Pi_h(f\circ F_h^{-1})\circ F_h\right\|_{L^p(\partial\Omega)}.\end{aligned}$$

Adding and subtracting $A_h(f\circ F_h^{-1})\circ F_h$ and using the triangle inequality shows that this is less than

$$\begin{aligned}&C\big(\left\|Af - A_h(f\circ F_h^{-1})\circ F_h\right\|_{L^p(\partial\Omega)}\\&\quad+\left\|A_h(f\circ F_h^{-1})\circ F_h - A_h\Pi_h(f\circ F_h^{-1})\circ F_h\right\|_{L^p(\partial\Omega)}\big)\\&\qquad\leq C\big(\left\|Tf - T_h(f\circ F_h^{-1})\circ F_h\right\|_{L^p(\partial\Omega)} + \|A_h\|\,\left\|f\circ F_h^{-1} - \Pi_h(f\circ F_h^{-1})\right\|_{L^p(\partial\Omega)}\big).\end{aligned}$$

Applying Lemma 5.2, there only remains to estimate the first term of the right-hand side.

Let $P = (x, \Phi(x))$ and $F(x) = f(x, \Phi(x))$. Since $T1 = T_h 1 = \frac{1}{2}$, we have $Tf(P) - T_h(f \circ F_h^{-1})(F_h(P)) = \lim_{\epsilon \to 0} \tilde{I}^\epsilon(P)$ with

$$\tilde{I}^\epsilon(P) = \frac{1}{\omega_n} \int_{\mathbb{R}^{n-1} \setminus \tilde{B}(y,\epsilon)} (F(y) - F(x)) \left(\frac{(x-y) \cdot \nabla\Phi(y) - (\Phi(x) - \Phi(y))}{(|x-y|^2 + (\Phi(x) - \Phi(y))^2)^{n/2}} \right. \\ \left. - \frac{(x-y) \cdot \nabla\Phi_h(y) - (\Phi_h(x) - \Phi_h(y))}{(|x-y|^2 + (\Phi_h(x) - \Phi_h(y))^2)^{n/2}} \right) dy.$$

Here $\tilde{B}(x,\epsilon) = \{y \in \mathbb{R}^{n-1} : (y, \Phi(y)) \in B(P,\epsilon) \cap \partial\Omega\}$ is the perpendicular projection of $B(P,\epsilon) \cap \partial\Omega$ on $\mathbb{R}^{n-1}$. Let $I^\epsilon(x)$ be defined as $\tilde{I}^\epsilon(P)$, but with $\tilde{B}(y,\epsilon)$ replaced by a regular ball $b(y,\epsilon) = \{y \in \mathbb{R}^{n-1} : |x-y| \le \epsilon\}$ in $\mathbb{R}^{n-1}$. Since Φ is Lipschitz, each $\tilde{B}(y,\epsilon)$ is enclosed between two regular balls of comparable size, $b(y, \epsilon/(1+M^2)^{1/2}) \subset \tilde{B}(y,\epsilon) \subset b(y,\epsilon)$, and, as a consequence, it easy to see that $\lim_{\epsilon \to 0}(\tilde{I}^\epsilon - I^\epsilon) = 0$ in L^p. Hence, $Tf(P) - T_h(f \circ F_h^{-1})(F_h(P)) = \lim_{\epsilon \to 0} I^\epsilon(x)$. In the remainder of the proof we shall estimate I^ϵ.

Let $L(x,y) = (|y-x|^2 + (\Phi(y) - \Phi(x))^2)^{n/2}$ and denote by $L_h(x,y)$ the corresponding entity for Φ_h. Then, dividing into gradient and nongradient parts, and adding and subtracting the quantities $(F(y) - F(x))(\Phi(x) - \Phi(y))/L(x,y)$ and $(F(y) - F(x))((x-y) \cdot \nabla\Phi_h(y))/L(x,y)$, respectively, we get the decomposition $I_\epsilon(x) = I_1^\epsilon(x) + I_2^\epsilon(x) + I_3^\epsilon(x) + I_4^\epsilon(x) + J^\epsilon(x)$, where

$$I_1^\epsilon(x) = \int_{|y-x| \ge \epsilon} (F(y) - F(x)) \frac{\Phi(y) - \Phi_h(y)}{L(x,y)}\, dy,$$

$$I_2^\epsilon(x) = -\int_{|y-x| \ge \epsilon} (F(y) - F(x)) \frac{\Phi(x) - \Phi_h(x)}{L(x,y)}\, dy,$$

$$I_3^\epsilon(x) = \int_{|y-x| \ge \epsilon} (F(y) - F(x))(\Phi_h(x) - \Phi_h(y)) \left(\frac{1}{L(x,y)} - \frac{1}{L_h(x,y)} \right) dy,$$

$$I_4^\epsilon(x) = \int_{|y-x| \ge \epsilon} (F(y) - F(x))(x-y) \cdot \nabla\Phi_h(y) \left(\frac{1}{L(x,y)} - \frac{1}{L_h(x,y)} \right) dy,$$

and

$$J^\epsilon(x) = -\int_{|y-x| \ge \epsilon} (F(y) - F(x))(x-y) \cdot \nabla(\Phi(y) - \Phi_h(y)) \frac{1}{L(x,y)}\, dy.$$

Using Green's formula, we move the derivative away from $\nabla(\Phi(y) - \Phi_h(y))$ in $J^\epsilon(x)$. In this way, we see that $J^\epsilon(x) = I_5^\epsilon(x) + I_6^\epsilon(x) + I_7^\epsilon(x) + I_8^\epsilon(x)$, where

$$I_5^\epsilon(x) = \int_{|y-x| = \epsilon} \frac{F(y) - F(x)}{L(x,y)} (\Phi(y) - \Phi_h(y))|y-x|\, d\sigma(y),$$

$$I_6^\epsilon(x) = -\int_{|y-x| \ge \epsilon} \frac{\nabla F(y) \cdot (x-y))}{L(x,y)} (\Phi(y) - \Phi_h(y))\, dy,$$

$$I_7^\epsilon(x) = \int_{|y-x| \ge \epsilon} \frac{n(F(y) - F(x))(\Phi(x) - \Phi(y))^2}{L(x,y)^{1+2/n}} (\Phi(y) - \Phi_h(y))\, dy,$$

and

$$I_8^\epsilon(x) = -\int_{|y-x| \ge \epsilon} \frac{n(F(y) - F(x))\nabla\Phi(y) \cdot (x-y)}{L(y,x)^{1+2/n}} (\Phi(x) - \Phi(y))(\Phi(y) - \Phi_h(y))\, dy.$$

Our basic decomposition of I^ϵ is $I^\epsilon = \sum_{k=1}^{8} I_k^\epsilon$.

We estimate the boundary integral $I_5^\epsilon(x)$ first. Clearly,

$$|I_5^\epsilon(x)| \leq C \|\Phi - \Phi_h\|_{L^\infty} \int_{|\omega|=1} |\nabla F(x + \epsilon\omega)| \, d\omega.$$

Hence, by Minkowski's inequality and a change of variable,

$$\|I_5^\epsilon\|_p \leq C \|\Phi - \Phi_h\|_{L^\infty} \|\nabla F\|_p .$$

The estimates for the remaining integrals will follow from Lemma 5.2. For I_1^ϵ and I_2^ϵ a direct application of the lemma with $k = 2$, $r = p$, and $q = \infty$ yields

$$\|I_i^\epsilon\|_p \leq \left\|\sup_{\epsilon>0} |I^{\epsilon_i}|\right\|_p \leq C(M) \|\Phi - \Phi_h\|_\infty \|\nabla F\|_p , \qquad i = 1, 2.$$

To estimate I_6^ϵ, we write the integrand as

$$\frac{\sum_i \frac{\partial F}{\partial x_i}(y)(x_i - y_i)(\Phi(y) - \Phi_h(y)) \times \left(|x - y|^2 + (\Phi(x) - \Phi(y))^2\right)}{\left(|x - y|^2 + (\Phi(x) - \Phi(y))^2\right)^{n/2+1}} .$$

Now, Lemma 5.2 with $k = 2$, $r = q = 2$, and $p = \infty$ readily gives

$$\|I_6^\epsilon\|_p \leq C(M) \|\Phi - \Phi_h\|_\infty \|\nabla F\|_p .$$

In a similar way, we get

$$\|I_i^\epsilon\|_p \leq C(M) \|\Phi - \Phi_h\|_\infty \|\nabla F\|_p , \qquad i = 7, 8.$$

There remains to estimate I_3^ϵ and I_4^ϵ. We let $H(q) = H_{xy}(q) = (|y - x|^2 + q^2)^{-n/2}$, $q \in \mathbb{R}$ so that $H'(q) = -nq(|y - x|^2 + q^2)^{-n/2-1}$. We also define $\Psi_t(x) = \Phi_h(x) + t(\Phi(x) - \Phi_h(x))$. Then

$$\begin{aligned}\frac{1}{L} - \frac{1}{L_h} &= H(\Phi(x) - \Phi(y)) - H(\Phi_h(x) - \Phi_h(y)) \\ &= -n\big(\Phi(x) - \Phi_h(x) - (\Phi(y) - \Phi_h(y)\big) \int_0^1 \frac{\Psi_t(x) - \Psi_t(y)}{L_{\Psi_t}^{1+2/n}} \, dt,\end{aligned}$$

where $L_{\Psi_t} = (|x - y|^2 + (\Psi_t(x) - \Psi_t(y))^2)^{n/2}$. Hence, by Fubini's theorem,

$$\begin{aligned}&I_3^\epsilon(x) \\ &= -n \int_0^1 \int_{|y-x|\geq\epsilon} (F(y) - F(x))(\Phi_h(x) - \Phi_h(y))(\Phi(x) - \Phi_h(x)) \frac{\Psi_t(x) - \Psi_t(y)}{L_{\Psi_t}^{1+2/n}} \, dydt \\ &+ n \int_0^1 \int_{|y-x|\geq\epsilon} (F(y) - F(x))(\Phi_h(x) - \Phi_h(y))(\Phi(y) - \Phi_h(y)) \frac{\Psi_t(x) - \Psi_t(y)}{L_{\Psi_t}^{1+2/n}} \, dydt \\ &= I_3' + I_3''.\end{aligned}$$

Another use of Lemma 5.2 shows that

$$\begin{aligned}\|I_3'\|_p \leq & n\,\|\Phi - \Phi_h\|_\infty \int_0^1 \left\| \sup_{\epsilon>0} \left| \int_{|y-x|\geq\epsilon} (F(y) - F(x))(\Phi_h(x) - \Phi_h(y)) \right.\right. \\ & \left.\left. \times \frac{\Psi_t(x) - \Psi_t(y)}{(|x-y|^2 + (\Psi_t(x) - \Psi_t(y)))^{n/2+1}}\, dy \right|\right\|_p dt \\ \leq & n\,\|\Phi - \Phi_h\|_\infty \int_0^1 C(M)\,\|\nabla\Phi\|_\infty\,\|\nabla F\|_p\,\|1\|_\infty\, dt \\ \leq & C(M)\,\|\Phi - \Phi_h\|_\infty\,\|\nabla F\|_p,\end{aligned}$$

where C(M) only depends on M, since the Lipschitz constant of Ψ_t is less than $3M$.

Similar arguments give the same kind of estimates for I_3'' and I_4^ϵ.

Summing up, we have thus proved that

$$\left\|f_h - \Pi_h(f \circ F_h^{-1})\right\|_{L^p(\partial\Omega_h)} \leq C \left\|\lim_{\epsilon\to 0} I^\epsilon\right\|_p \leq C\,\|\Phi - \Phi_h\|_\infty\,\|\nabla F\|_p,$$

which is the desired inequality. □

6. Systems of equations. In this section we shall discuss certain systems of elliptic equations on a Lipschitz domain $\Omega \subset \mathbb{R}^n$, $n \geq 3$. For simplicity, we shall still assume that $\Omega = \{(x,y) : y = \Phi(x)\}$ for some Lipschitz function Φ. We shall concentrate on the discretized version of the Dirichlet problem for the Lamé systems of linearized elastostatics with $L^2(\partial\Omega)$ data. For the detailed treatment of the continuous case, and background and references, we refer to [DKV] and [FKV].

Let the function $\vec{g} = (g_1, \cdots, g_n) \in L^2(\partial\Omega)$ be given. The Dirichlet problem for the Lamé system is to find a function $\vec{u}$ that solves

$$\mu\Delta\vec{u} + (\lambda + \mu)\nabla(\operatorname{div}\vec{u}) = \vec{0} \tag{6.1}$$

with boundary values $\vec{u}|_{\partial\Omega} = \vec{g}$. Here λ and μ are constants, the so-called Lamé moduli, which satisfy

$$\mu > 0, \qquad \lambda > -2\mu/n.$$

The Kelvin matrix Γ of fundamental solutions of (6.1) is given by

$$\Gamma_{ij}(x) = \frac{A}{\omega_n(n-2)}\frac{\delta_{ij}}{|x|^{n-2}} + \frac{B}{\omega_n}\frac{x_i x_j}{|x|^n} \tag{6.2}$$

where

$$A = \frac{1}{2}\left(\frac{1}{\mu} + \frac{1}{2\mu+\lambda}\right), \qquad B = A = \frac{1}{2}\left(\frac{1}{\mu} - \frac{1}{2\mu+\lambda}\right).$$

To discuss the boundary integral method, we first need the analog of the layer potentials. Corresponding to the single layer potential, we have

$$\mathcal{S}\vec{f}(P) = \int_{\partial\Omega} \Gamma(P-Q)\vec{f}(Q)\, d\sigma(Q). \tag{6.3}$$

There are, in fact, infinitely many conormal derivatives and corresponding double layer potentials associated with the Lamé system in a natural way. Following [DKV], we consider

$$\frac{\partial}{\partial\rho}\vec{u} = \left(\lambda + \frac{2\mu^2}{3\mu+\lambda}\right)(\operatorname{div}\vec{u})N + \mu(\nabla\vec{u})N + \left(\mu - \frac{2\mu^2}{3\mu+\lambda}\right)(\nabla\vec{u}^T)N, \tag{6.4}$$

where N denotes the outward normal. The associated double layer potential is

$$\mathcal{D}\vec{f}(P)=\int_{\partial\Omega}\left(\frac{\partial}{\partial\rho}\Gamma(P-Q)\right)^{T}\vec{f}(Q)\,d\sigma(Q).$$

We let $\mathcal{A}$ denote the operator corresponding to the boundary values of this double layer potential. By formally allowing $P\in\partial\Omega$ in the definition of $\mathcal{D}$, we obtain, as in the scalar case, a principal value operator T that satisfies

$$\mathcal{A}\vec{f}(P)=\tfrac{1}{2}\vec{f}(P)+T\vec{f}(P).$$

The conormal derivative defined by (6.4) has the advantage that the operator T is compact for bounded, smooth surfaces. More specifically, the kernel of T is a sum of terms with kernels of the form

$$\frac{(P-Q)_i(P-Q)_j}{|P-Q|^2}\frac{\langle P-Q,N_Q\rangle}{|P-Q|^n}$$

and

$$\frac{\langle P-Q,N_Q\rangle}{|P-Q|^n}\delta_{ij}.$$

Furthermore, the analog of the norm inequality (2.4) is true for $p=2$ (see [DKV]). As a consequence, the Galerkin procedure of Dahlberg and Verchota and the results above extend, in a straightforward way, to the Dirichlet problem for the Lamé system.

From an application point of view, the so-called traction problem is perhaps more interesting. This problem is the analog of the Neumann problem with the (co)normal derivative defined by

$$\frac{\partial}{\partial\nu}\vec{u}=\lambda(\operatorname{div}\vec{u})N+\mu(\nabla\vec{u}+\nabla\vec{u}^{T})N. \tag{6.5}$$

The boundary values of the corresponding double layer potential can be written $\tilde{A}\vec{f}=\frac{1}{2}\vec{f}+\tilde{T}\vec{f}$. However, in this case the operator $\tilde{T}$ is not compact on smooth boundaries, and the Dahlberg–Verchota procedure does not apply, at least not in a trivial way.

There are many other examples of systems of equations to which the theory applies. One such example is the Stokes system of linear hydrostatics:

$$\begin{cases}\Delta u=\nabla p,\\ \nabla\cdot u=0.\end{cases}$$

We define the conormal derivative

$$\frac{\partial}{\partial\rho}\vec{u}=(\nabla\vec{u}+\nabla\vec{u}^{T})N-Np. \tag{6.6}$$

Again the boundary values of the associated double layer potential equals

$$A\vec{f}=\tfrac{1}{2}\vec{f}+T\vec{f}. \tag{6.7}$$

The operator T is of essentially the same type as before; in particular, it is compact on smooth bounded domains. Also, the norm inequality that replaces (2.4) is proved in [DKV] (cf. also [FKV]). This means that the analog of the above results for the Galerkin method procedure and the Dirichlet problem are true. In addition, the Neumann problem associated with this conormal derivative (cf. [DKV]), which results in the so-called slip condition, can be discretized. Let

$$B\vec{f}=-\tfrac{1}{2}\vec{f}+T^{*}\vec{f},$$

where T^* is the adjoint of the operator in (6.7). A typical example is the following result (cf. Theorem 3.3).

THEOREM 6.1. *Suppose that* $\lim_{h\to 0}\rho_h = 0$. *Then there are* $h_0 > 0$ *and* $\gamma > 1$ *with the property that if*

$$\lim_{h\to 0}\kappa_h = \lim_{h\to 0}\sup_j \kappa(P_{j,h}, \gamma\rho_{j,h})\gamma\rho_{j,h} = 0,$$

then for every $\vec{g} \in L^2(\partial\Omega)$ *there is a unique* $\vec{f_h} \in X_h \cap L^2(\partial\Omega_h)$ *for* $h < h_0$, *such that*

$$\int_{\partial\Omega_h} B_h \vec{f_h}\, w\, d\sigma = \int_{\partial\Omega_h} \vec{g}_h \vec{w}\, d\sigma \tag{6.8}$$

for all $\vec{w} = (w_1, \dots, w_n)$, $w_i \in X$, *with compact support. Here* $\vec{g}_h(P) = \vec{g}(F_h^{-1}(P))$. *Moreover, if* $\vec{f} \in L^2(\partial\Omega)$ *is defined by* $B\vec{f} = \vec{g}$, *then* $\vec{f_h} \circ F_h$ *converges to* $\vec{f}$ *in* $L^2(\partial\Omega)$.

Another interesting example is provided by the system

$$\frac{1}{2}f_i(y) = \tilde{f}_i(y) + \frac{3}{4\pi}\int_{\partial\Omega} \frac{y_i - x_i}{|y-x|^5}\langle y - x, n(y)\rangle \langle y - x, \vec{f}(x)\rangle dS_x, \qquad i = 1, 2, 3.$$

This system describes the stress $\vec{f}$ in a Stokes flow after a body of shape $\Omega \subset \mathbb{R}^3$ has been inserted in a Stokes flow with stress $\tilde{f}$ (cf. [BL]); n denotes the inward normal. In this case, the kernel K has the form

$$K_{i,j} = \frac{\langle x - y, n(y)\rangle}{|x-y|^5}(x_i - y_j)(x_j - y_i),$$

which obviously is compact on bounded, smooth domains.

The boundedness of the operator $\frac{1}{2} + K$ and its inverse with respect to the appropriate subspace of $L^2(\partial\Omega)$ follow from Theorem 4.6 in [DKV]. The Galerkin procedure with variable meshsize thus applies for this system as well.

Acknowledgment. This paper grew out of a problem posed to us by Björn E. J. Dahlberg, and arising in a natural way in [DV]. We have also had several useful discussions with Dahlberg.

MATHEMATICAL ANALYSIS OF MISCIBLE DISPLACEMENT IN POROUS MEDIUM*

PIERRE FABRIE† AND MICHEL LANGLAIS‡

Abstract. When modeling miscible fluid displacement in porous medium [*Stud. Math. Appl.*, 17 (1986)], [*Mathematical and Computational Method in Seismic Exploration and Reservoir Modeling*, SIAM, pp. 108-127] variation with temperature of such physically relevant parameters as viscosity and thermal conductivity needs to be considered [Goyeau, thesis, Université Bordeaux I, 1988]. The dependence of dispersion with velocity is also important when modeling pollution problems. In so doing, one is led to a system of a nonlinear parabolic equation coupled with a Darcy or a Darcy-Forchheimer type equation; natural boundary conditions are supplemented.

A mathematical analysis of such a problem is performed in a cylindrical domain corresponding to a reservoir. A notion of weak solutions is introduced for the two unknown functions: temperature and velocity. The existence of at least one such solution is proved. This is achieved upon introducing a positive time-lag in the nonlinearities featuring in the energy equation. It leads to a decoupling of the system into a pair of linear problems having at least one solution. A uniform bound for the approximate temperature is derived using a maximum principle from which further energy estimates leading to a compactness property follow. Next, using a local Meyers lemma, a compactness property is derived for the approximate velocity.

The existence of a weak solution is obtained upon letting the time-lag go to zero. Some extra properties of the solution, when more or less restrictive conditions are added, are given.

This paper refers to [*J. Differential Equations*, 90 (1991), pp. 186-202] for a mathematical theory of related stationary problem. See also [*Stud. Math. Appl.*, 17 (1986)] for a comprehensive modeling of this type of displacement.

1. Introduction.

For an incompressible but dilatable fluid, the main system frequently used reads

—mass conservation law

$$\varepsilon\frac{\partial\rho}{\partial t}+\nabla\cdot\rho\mathbf{V}=0;$$

—energy conservation law

$$(\rho c)^*\frac{\partial T}{\partial t}+(\rho c)_f\mathbf{V}\cdot\nabla T-\nabla\cdot[(\lambda^*(T)+D(\mathbf{V}))\cdot\nabla T]=0;$$

—momentum equation (taking either forms)

—Darcy's law

$$\text{(i)}\qquad \mu(T)\mathbf{V}+K\cdot(\nabla p+\rho g)=0;$$

—Darcy-Forchheimer's law

$$\text{(ii)}\qquad \frac{\rho}{\varepsilon}\frac{\partial\mathbf{V}}{\partial t}+\mu(T)K^{-1}\mathbf{V}+c_j\rho\sigma(\mathbf{V})+\nabla p+\rho\mathbf{g}=0;$$

the underlying constitutive equations are first

$$\rho = \rho_0(1 - \beta(T - T_0))$$

(this constitutive law expresses that the fluid is incompressible $(\partial\rho/\partial p) = 0$ but dilatable $\rho = \rho(T)$) and next

$$\mu(T) = \lambda_0 e^{\gamma(T-T_0)}, \qquad D_{ij}(\mathbf{V}) = \alpha_L|\mathbf{V}|^{-1}V_iV_j + \alpha_T|\mathbf{V}|^{-1}(|\mathbf{V}|^2\delta_{ij} - V_iV_j).$$

In these relations ε stands for porosity, ρ for density, $\mathbf{V}$ the filtration velocity, p the pressure, and T the temperature. We, respectively, denote by $(\rho c)_f$ and $(\rho c)_s$ the fluid and solid heat capacity, so that the equivalent heat capacity of the medium is given by $(\rho c)_* = \varepsilon(\rho c)_f + (1-\varepsilon)(\rho c)_s$. Next $\lambda^*(T)$ is the thermal conductivity of the medium, D the dispersion tensor, $\mu(T)$ the fluid viscosity, and K the permeability. According to the generalized Boussinesq assumption, the fluid density variation is neglected everywhere in all of the previous equations, except in the term $\rho\mathbf{g}$.

The Darcy model is the one most frequently used. But for large velocities, the Darcy-Forchheimer model is more realistic: see [12]; in this case, for isotropic flow $\boldsymbol{\sigma}(\mathbf{V})$ may take the following form:

$$\boldsymbol{\sigma}(\mathbf{V}) = k^{-1/2}|\mathbf{V}|\mathbf{V},$$

where k is the intrinsic permeability and $K = kId$. For more general flows we may take the ith component of $\boldsymbol{\sigma}(\mathbf{V})$ to be

$$\frac{1}{|\mathbf{V}|}\sigma_{ijkl}V_jV_kV_l.$$

As an example, $\boldsymbol{\sigma}(\mathbf{V}) = J(\mathbf{V})\mathbf{V}$ with

$$J_{ij}(\mathbf{V}) = \alpha|\mathbf{V}|\delta_{ij} - \beta\frac{V_iV_j}{|\mathbf{V}|}(1-\delta_{ij}), \qquad \beta > 0, \quad \alpha > 0.$$

So the dimensionless final problem that is to be analyzed here takes the following form:

—isovolume flow

(1) $$\nabla \cdot \mathbf{V} = 0;$$

—energy equation

(2) $$\frac{\partial\theta}{\partial t} + \mathbf{V}\cdot\nabla\theta - \nabla\cdot[(\lambda(\theta) + D(\mathbf{V}))\nabla\theta] = 0;$$

—momentum equation

—Darcy's law

(3a) $$\mu(\theta)\mathbf{V} + K(\nabla p - Ra^*\beta(\theta)\mathbf{e}_z) = 0;$$

—Darcy-Forchheimer's law

(3b) $$\varepsilon^{-1}DaP_r^{-1}\frac{\partial\mathbf{V}}{\partial t} + K^{-1}\mu(\theta)\mathbf{V} + c_jDa^{1/2}P_r^{-1}\boldsymbol{\sigma}(\mathbf{V}) + \nabla p - Ra^*\beta(\theta)\mathbf{e}_z = 0,$$

where $Ra^* = RaDa$ is the filtration Rayleigh number, Pr the Prandtl number, and Da the Darcy number. Further, $\lambda(\theta)$, $\mu(\theta)$, and $\beta(\theta)$ are dimensionless thermal conductivity, viscosity, and density.

In a cylindrical aquifer $\Omega =]0, H[\times]R_i, R_e[\times]0, 2\pi[$, having height H, external radius R_e, crossed by an injection well of radius R_i, the thermal and hydrodynamical boundary conditions are

$$-(\lambda(\theta)+D(\mathbf{V}))\cdot\nabla\theta\cdot\boldsymbol{\eta}=0 \quad \text{for } z=0 \quad \text{and} \quad z=H, \tag{4}$$

where $\boldsymbol{\eta}$ is the unique outward normal vector to $\partial\Omega$

$$-(\lambda(\theta)+D(\mathbf{V}))\cdot\nabla\theta\cdot\boldsymbol{\eta}+g_i(\theta-h_i)=0 \quad \text{for } r=R_i, \tag{5}$$

$$-(\lambda(\theta)+D(\mathbf{V}))\cdot\nabla\theta\cdot\boldsymbol{\eta}=0 \quad \text{for } r=R_e, \tag{6}$$

$$\mathbf{V}\cdot\boldsymbol{\eta}=0 \quad \text{for } z=0 \quad \text{and} \quad z=H, \tag{7}$$

$$\mathbf{V}\cdot\boldsymbol{\eta}=g_j \quad \text{for } r=R_j \quad j=i \text{ or } e, \tag{8}$$

with

$$\int_{r=R_i} g_i\,d\sigma_i+\int_{r=R_e} g_e\,d\sigma_e=0. \tag{9}$$

2. Assumptions, notations, and weak formulation.

2.1. Assumptions and notations.

Σ_j is the subset of the boundary $\partial\Omega$ defined by

$$\Sigma_j=\{(z, R_j, \zeta), 0<z<H, 0\leqq\zeta<2\pi\}, \quad j=i \quad \text{or} \quad e.$$

Throughout this work, the data will satisfy the following conditions:

$$h_i\in L^\infty(\Sigma_i), \quad g_j\in L^\infty(\Sigma_j), \quad j=i \quad \text{or} \quad e, \tag{A1}$$

(A2) there exists $m_i>0$, $M_i>0$ such that

$$-M_i\leqq g_i\leqq -m_i \quad \text{a.e.,}$$

$$0\leqq g_e \quad \text{a.e.,}$$

$$\int_{\Sigma_i} g_i\,d\sigma_i+\int_{\Sigma_e} g_e\,d\sigma_e=0.$$

The tensors λ, D, and $\boldsymbol{\sigma}$ are continuous on their respective domains. The functions μ and β are continuous over $\mathbb{R}$.

Furthermore, we assume that

$$\begin{aligned}&\forall(a,b)\in\mathbb{R}^2, \quad \exists\alpha_1>0, \quad \forall c\in]a,b[, \quad \alpha_1\leqq\mu(c).\\ \text{(A3)}\quad&\forall(a,b)\in\mathbb{R}^2, \quad \exists\alpha_2>0, \quad \forall c\in]a,b[, \quad \forall\boldsymbol{\zeta}\in\mathbb{R}^3, \quad \alpha_2|\boldsymbol{\zeta}|^2\leqq\lambda(c)\cdot\boldsymbol{\zeta}\cdot\boldsymbol{\zeta},\\ &\exists\alpha_3>0, \quad \forall\boldsymbol{\zeta}\in\mathbb{R}^3, \quad \alpha_3|\boldsymbol{\zeta}|^2\leqq K^{-1}\cdot\boldsymbol{\zeta}\cdot\boldsymbol{\zeta},\end{aligned}$$

$$\forall\mathbf{V}\in\mathbb{R}^3, \quad \forall\boldsymbol{\zeta}\in\mathbb{R}^3, \quad D(\mathbf{V})\cdot\boldsymbol{\zeta}\cdot\boldsymbol{\zeta}\geqq 0, \tag{A4}$$

$$\exists(\alpha_4,\alpha_5)\in\mathbb{R}_+^2, \quad \forall\mathbf{V}\in\mathbb{R}^3, \quad |D(\mathbf{V})|\leqq\alpha_4+\alpha_5|\mathbf{V}|, \tag{A5}$$

$$\begin{aligned}\text{(A6)}\quad&\exists\sigma_1>0, \quad \forall\mathbf{V},\mathbf{U}\in\mathbb{R}^3\times\mathbb{R}^3, \quad (\boldsymbol{\sigma}(\mathbf{U})-\boldsymbol{\sigma}(\mathbf{V}))\cdot(\mathbf{U}-\mathbf{V})\geqq\sigma_1|\mathbf{U}-\mathbf{V}|^3,\\ &\exists\sigma_2>0, \quad \forall\mathbf{V},\mathbf{U}\in\mathbb{R}^3\times\mathbb{R}^3, \quad |\boldsymbol{\sigma}(\mathbf{U})-\boldsymbol{\sigma}(\mathbf{V})|\leqq\sigma_2(|\mathbf{U}|+|\mathbf{V}|)(|\mathbf{U}-\mathbf{V}|).\end{aligned}$$

2.2. Weak formulation.

We first introduce the closure in $L_p(\Omega)$ of the smooth and divergence free functions vanishing on $\partial\Omega$, which we denote $\mathbb{H}_p$.

We begin with the Darcy model.

Assuming (A1), $\cdots$, (A5) to hold, a weak solution for problems (1) to (9) is a triplet $(\theta, \mathbf{V}, p)$ such that for all positive t,

$$\begin{aligned}&\theta\in L^\infty(\mathbb{R}_+\times\Omega)\cap L^2((0,t); H^1(\Omega)),\\ &\mathbf{V}\in L^\infty(\mathbb{R}_+; \mathbb{H}_2),\\ &p\in L^\infty(\mathbb{R}_+; H^1(\Omega)/\mathbb{R}),\end{aligned}$$

verifying for any test function φ lying in $L^2((0, t); W^{1,\infty}(\Omega))$,

$$\begin{aligned}&\int_0^t \left\langle \frac{\partial \theta}{\partial t}, \varphi \right\rangle d\tau + \int_0^t \int_\Omega (\lambda(\theta) + D(\mathbf{V})) \cdot \nabla\theta \cdot \nabla\varphi \, d\omega \, d\tau \\ &+\frac{1}{2}\int_0^t \int_\Omega ((\mathbf{V}\cdot\nabla\theta)\varphi - (\mathbf{V}\cdot\nabla\varphi)\theta) \, d\omega \, d\tau + \frac{1}{2}\int_0^t \int_{\Sigma_i} g_i\theta\varphi \, d\sigma_i \, d\tau \\ &+\frac{1}{2}\int_0^t \int_{\Sigma_e} \theta g_e \varphi \, d\sigma_e \, d\tau - \int_0^t \int_{\Sigma_i} g_i(\theta - h_i)\varphi \, d\sigma_i \, d\tau = 0,\end{aligned} \tag{10}$$

and verifying for any test function lying in $H^1(\Omega)$,

$$\begin{aligned}&\int_\Omega \mu^{-1}(\theta)K\cdot(\nabla p - Ra^*\beta(\theta)\mathbf{e}_z)\cdot\nabla\psi \, d\omega + \int_{\Sigma_i} g_i\psi \, d\sigma_i \\ &\quad + \int_{\Sigma_e} g_e\psi \, d\sigma_e = 0 \quad \text{a.e. in } (0, t);\end{aligned} \tag{11a}$$

the velocity is then given by

$$\mathbf{V} = -\mu^{-1}(\theta)K\cdot(\nabla p - Ra^*\beta(\theta)\mathbf{e}_z). \tag{12}$$

Next we consider the Darcy–Forchheimer model.

The only two modifications are in the momentum equation. The velocity function is given by $\mathbf{V} = \mathbf{U} + \mathbf{Z}$, where $\mathbf{Z}$ is a solution to

$$\begin{aligned}&\nabla\cdot\mathbf{Z} = 0,\\ &\mathbf{Z}\cdot\boldsymbol{\eta} = 0 \quad \text{for } z = 0 \quad \text{and} \quad H,\\ &\mathbf{Z}\cdot\boldsymbol{\eta} = g_j, \quad r = R_j, \quad j = i, e\end{aligned}$$

and seek $\mathbf{U}$ in $L^3((0, t), \mathbb{H}_3)$, satisfying, for each test function $\mathbf{W}$ lying in $L^3((0, t), \mathbb{H}_3)$,

$$\begin{aligned}&\int_0^t \int_\Omega \frac{\partial \mathbf{U}}{\partial t}\mathbf{W} \, d\omega \, d\tau + \int_0^t \int_\Omega (\mu(\theta)K^{-1}\cdot(\mathbf{U}+\mathbf{Z}) \\ &\qquad + c_j Da^{1/2}P_r^{-1}\boldsymbol{\sigma}(\mathbf{U}+\mathbf{Z})\cdot\mathbf{W}) \, d\omega \, d\tau \\ &- Ra^* \int_0^t \int_\Omega \beta(\theta)\mathbf{W}\cdot\mathbf{e}_z \, d\omega \, d\tau = 0.\end{aligned} \tag{11b}$$

Note that here we first compute $\mathbf{V}$; the pressure p appears by using a De Rahm type theorem.

3. Main results.

3.1. Existence of a weak solution. The main result of this work is the following.

THEOREM 1. *Under the assumptions* (A1), $\cdots$, (A5) *for each* θ_0, *in* $L^\infty(\Omega)$, *there is at least one weak solution in the Darcy model such that* $\theta(0) = \theta_0$.

Under the assumption (A1), $\cdots$, (A6) *for each* $(\theta_0, \mathbf{U}_0)$ *in* $L^\infty(\Omega)\times\mathbb{H}_2$, *there is at least one weak solution in the Darcy–Forchheimer model such that* $(\theta(0), \mathbf{U}(0)) = (\theta_0, \mathbf{U}_0)$.

We supply the proof in § 4; it will be a consequence of the following theorem.

THEOREM 2. *Under the assumptions* (A1), $\cdots$, (A4), (A6), *and* (A7),

$$\exists\alpha_6 \in \mathbb{R}_+ \quad \forall\mathbf{V}\in\mathbb{R}^3, \quad |D(\mathbf{V})| \leqq \alpha_6, \tag{A7}$$

there is at least one solution satisfying the following estimates.

There exist positive constants k_l and positive continuous functions f_l independent of D as long as it satisfies (A4), *but depending on the data h_i, g_i, g_e, and θ_0 or (θ_0, U_0) such that*

$$|\theta|_{L^\infty(\mathbb{R}_+\times\Omega)} \leqq k_1, \tag{13}$$

$$\int_0^t |\nabla\theta(\tau)|^2_{L^2(\Omega)}\, d\tau \leqq f_1(t), \tag{14}$$

$$|\mathbf{V}|_{L^\infty(\mathbb{R}_+;\mathbb{H}_2)} \leqq k_2. \tag{15}$$

Moreover, there exists q greater than 2 depending only on k_1 such that for the Darcy model

$$|\mathbf{V}|_{L^\infty(\mathbb{R}_+;\mathbb{H}_q)} \leqq k_3, \tag{16}$$

while for the Darcy-Forchheimer model,

$$\int_0^t |\nabla\mathbf{V}(\tau)|^3_{\mathbb{H}_3}\, d\tau \leqq f_2(t).$$

3.2. Uniqueness results.

THEOREM 3. *Assuming λ, D, μ to be constant and β Lipschitz continuous, then the weak solution is unique (for either models).*

The sketch of the proof follows from Gronwall's inequality as in [4], to which we refer for further details.

Now we give, for the Darcy model, uniqueness theorems assuming some regularity on the data and the solution. We are not actually able to prove that weak solutions have such regularity properties.

THEOREM 4. *Suppose that λ, μ, β, D are Lipschitz continuous. Assume there exist two weak solutions $(\theta_l, \mathbf{V}_l, p_l)_{l=1,2}$ for the Darcy model verifying*

$$\theta_l \in L^2((0,t);\ W^{1,\infty}(\Omega)) \cap L^\infty(\mathbb{R}_+\times\Omega),$$
$$p_l \in L^\infty((0,t);\ W^{1,\infty}(\Omega));$$

then $\theta_1(0) = \theta_2(0)$ imply $\theta_1 = \theta_2$, $p_1 = p_2$, and $\mathbf{V}_1 = \mathbf{V}_2$.

Remark. In fact, we have the following continuous dependence: for two weak solutions $(\theta_l, p_l)_{l=1,2}$ verifying

$$\theta_l \in L^2((0,t);\ W^{1,\infty}(\Omega))$$
$$p_l \in L^\infty((0,t);\ W^{1,\infty}(\Omega)),$$

there exists a nonnegative function $f(t)$ in $L^1_{\text{loc}}(\mathbb{R}_+)$ such that

$$|\theta_1(t) - \theta_2(t)|_{L^2(\Omega)} \leqq c_0 \exp\left(\int_0^t f(\tau)\, d\tau\right) |\theta_1(0) - \theta_2(0)|_{L^2(\Omega)}.$$

THEOREM 5. *Assuming D satisfies* (A7), *suppose, moreover, that λ, μ, β are Lipschitz continuous and there exists a solution (θ_1, p_1) verifying*

$$\theta_1 \in L^2((0,t);\quad W^{1,\infty}(\Omega)) \cap L^\infty((0,t)\times\Omega),$$
$$p_1 \in L^\infty((0,t);\quad W^{1,\infty}(\Omega));$$

then for the Darcy model any weak solution $(\theta, \mathbf{V}, p)$ satisfying $\theta(0) = \theta_1(0)$ is equal to $(\theta_1, \mathbf{V}_1, p_1)$.

3.3. Remark on the large time behavior for the Darcy model. If D satisfies (A7), and if the boundary data h_i is constant on Σ_i, then we have

$$\lim_{t\to\infty} |\theta(t)-h_i|_{L^2(\Omega)}=0, \qquad \lim_{t\to\infty} |V(t)-V_\infty|_{\mathbb{H}_2}=0,$$

where V_∞ is the solution of (11), (12) with $\theta=h_i$.

4. Proof of the main results; Theorems 1 and 2. We supply a detailed proof of Theorem 1 for the Darcy model, which turns out to be less regular than the Darcy-Forchheimer one. For this case, in order to get some smoothness properties for the velocity, it is convenient to choose both pressure and temperature as main unknowns.

The proof for the Darcy-Forchheimer model follows the same lines and is sketched in § 4.3.

4.1. Preliminary results. We first prove Theorem 2. The proof goes through several steps. We use a kind of linearization process by introducing a positive delay which uncoupled the system. This is similar in spirit to the fractional step method in [16]. A similar idea, called retarded mollification, is used in [2]. This idea is also known as the method of Rothe, and it is used in [13] for quasilinear parabolic equations. We next derive a priori estimates for the approximate solutions and pass to the limit upon letting the delay go to zero.

4.1.1. Approximate solution. Let h be a small positive number.

For any measurable function $f:\mathbb{R}\times\Omega\to\mathbb{R}$, set $\tau_h f:\mathbb{R}\times\Omega\to\mathbb{R}$ as $\tau_h f(t,x)=f(t-h,x)$.

Next we introduce the following scheme.

Define first

$$\theta_h(t,x)=\theta_0(x); \quad t\in[-h,0], \quad x\in\Omega;$$

then, assuming θ_h to be known on the interval $[kh,(k+1)h]$, $k\in\mathbb{N}$, compute p_h verifying

$$p_h\in L^\infty([kh,(k+1)h];\, H^1(\Omega)/\mathbb{R})$$

such that for any test function ψ belonging to $H^1(\Omega)/\mathbb{R}$

$$\int_\Omega \mu(\theta_h)^{-1}K\cdot(\nabla p_h - Ra^*\beta(\theta_h)\mathbf{e}_z)\cdot\nabla\psi\,d\omega+\int_{\Sigma_i} g_i\psi\,d\sigma_i+\int_{\Sigma_e} g_e\psi\,d\sigma_e=0, \tag{17}$$

set $\mathbf{V}_h$ as

$$\mathbf{V}_h\in L^\infty([kh,(k+1)h];\,\mathbb{H}_2),$$
$$\mathbf{V}_h=\mu(\theta_h)^{-1}K\cdot(\nabla p_h-Ra^*\beta(\theta_h)\mathbf{e}_z);$$

then define θ_h on the interval $[(k+1)h,(k+2)h]$ verifying

$$\theta_h\in L^\infty([(k+1)h,(k+2)h];\,L^\infty(\Omega))\cap L^2([(k+1)h,(k+2)h];\,H^1(\Omega))$$

and such that for any test function φ belonging to $L^2_{\text{loc}}(\mathbb{R}_+;\,H^1(\Omega))$,

$$\begin{aligned}
&\int_{(k+1)h}^{(k+2)h}\left\langle\frac{\partial\theta_h}{\partial t},\varphi\right\rangle d\tau+\int_{(k+1)h}^{(k+2)h}\int_\Omega(\lambda(\tau_h\theta_h)+D(\tau_h\mathbf{V}_h))\cdot\nabla\theta_h\cdot\nabla\varphi\,d\omega\,d\tau\\
&\quad+\frac{1}{2}\int_{(k+1)h}^{(k+2)h}\int_\Omega(\tau_h\mathbf{V}_h\cdot\nabla\theta_h\varphi-\tau_h\mathbf{V}_h\cdot\nabla\varphi\theta_h)\,d\omega\,d\tau\\
&\quad-\int_{(k+1)h}^{(k+2)h}\int_{\Sigma_i}g_i(\theta-h_i)\varphi\,d\sigma_i\,d\tau\\
&\quad+\frac{1}{2}\int_{(k+1)h}^{(k+2)h}\int_{\Sigma_i}g_i\theta_h\varphi\,d\sigma_i\,d\tau+\frac{1}{2}\int_{(k+1)h}^{(k+2)h}\int_{\Sigma_e}g_e\theta_h\varphi\,d\sigma_e\,d\tau=0,
\end{aligned}\tag{18}$$

where $\theta_h((k+1)h,x)$ is known from the previous step.

LEMMA 1. *The algorithm is consistent and gives a global solution* $(\theta_h, p_h, \mathbf{V}_h)$, *satisfying*

$$\theta_h \in L^\infty(\mathbb{R}_+\times\Omega)\cap L^2_{\text{loc}}(\mathbb{R}_+; H^1(\Omega)),$$
$$\mathbf{V}_h \in L^\infty(\mathbb{R}_+; \mathbb{H}_2),$$
$$p_h \in L^\infty(\mathbb{R}_+; H^1(\Omega)/\mathbb{R});$$

furthermore, there exist constants k_l *and a positive and continuous function* f_1 *independent of* D *as long as it satisfies* (A4), *but depending on the data* h_i, g_i, g_e, θ_0 *such that*

$$|\theta_h|_{L^\infty(\mathbb{R}_+\times\Omega)} \leqq k_1, \tag{19}$$

$$\int_0^t |\nabla\theta_h|^2_{L^2(\Omega)}\,d\tau \leqq f_1(t), \tag{20}$$

$$|\mathbf{V}_h|_{L^\infty(\mathbb{R}_+;\mathbb{H}_2)} \leqq k_2, \tag{21}$$

$$|p_h|_{L^\infty(\mathbb{R}_+;H^1(\Omega)/\mathbb{R})} \leqq k_3. \tag{22}$$

Moreover, there exists a positive and continuous function f_2 *depending on* k_1, f_1, k_2, k_3, g_i, g_e, *and* α_6 (*see* (A7)) *such that*

$$\int_0^t \left|\frac{\partial\theta_h}{\partial t}\right|^2_{(H^1(\Omega)')} d\tau \leqq f_2(t). \tag{23}$$

The lengthy proof of this statement is postponed until § 7.

4.1.2. Regularity results for the velocity. Let $(\theta_n)_{n\geqq 0}$ be a sequence of bounded function over Ω. Define $\mathbf{V}_n$ as the solution of the Darcy equation with data θ_n,

$$\mathbf{V}_n = \mu(\theta_n)^{-1}K\cdot(\nabla\pi_n - Ra^*\beta(\theta_n)\mathbf{e}_z), \tag{24}$$

where π_n is the unique solution in $H^1(\Omega)/\mathbb{R}$ to

$$\nabla\cdot(\mu(\theta_n)^{-1}K\cdot(\nabla\pi_n - Ra^*\beta(\theta_n)\mathbf{e}_z)) = 0, \tag{25}$$

$$\begin{aligned}&\mu(\theta_n)^{-1}K\cdot(\nabla\pi_n - Ra^*\beta(\theta_n)\mathbf{e}_z)\cdot\boldsymbol{\eta} = 0 \quad \text{on } \partial\Omega\backslash\Sigma_i\cup\Sigma_e,\\ &\mu(\theta_n)^{-1}K\cdot(\nabla\pi_n - Ra^*\beta(\theta_n)\mathbf{e}_z)\cdot\boldsymbol{\eta} = g_j \quad \text{on } \Sigma_j \quad j=i \quad \text{or} \quad e.\end{aligned} \tag{26}$$

We are going to prove the following.

LEMMA 2. *Assume the previous sequence* $(\theta_n)_{n\geqq 0}$ *is bounded in* $L^\infty(\Omega)$ *by a constant* M *and converges strongly to some function* θ *in* $L^2(\Omega)$; *then there exists* q *greater than two, depending only on* M *such that* $(\mathbf{V}_n)_{n\geqq 0}$ *converges strongly to* $\mathbf{V}$ *in* $L^q(\Omega)$, *where* $\mathbf{V}$ *is the unique solution of the Darcy equation with data* θ.

Proof. Let G be the unique solution in $H^1(\Omega)/\mathbb{R}$ of the variational problem.

For any test function φ belonging to $H^1(\Omega)/\mathbb{R}$,

$$\int_\Omega \nabla G\cdot\nabla\varphi\,d\omega = \int_{\Sigma_i} g_i\varphi\,d\sigma_i + \int_{\Sigma_e} g_e\varphi\,d\sigma_e,$$

where g_j are as in (A2).

According to Lions-Magenes [9], G belongs to $W^{1,p}(\Omega)$ for any p greater than 1. Thus (25), (26) become

$$\int_\Omega \mu(\theta_n)^{-1}\mathbf{K}\cdot\nabla\pi_n\cdot\nabla\varphi\,d\omega = \int_\Omega (Ra^*\mu(\theta_n)^{-1}\beta(\theta_n)\mathbf{e}_z + \nabla G)\cdot\nabla\varphi\,d\omega. \tag{27}$$

Let $\hat{G}$ be a function of $W^{1,p}(\mathbb{R}^3)$ with compact support whose restriction to Ω coincides with G. Consider, then, $\tilde{\theta}_n$ the extension by zero of θ_n to $\hat{\Omega}$, where $\hat{\Omega}$ is an open domain in $\mathbb{R}^3$ containing $\bar{\Omega}$ and supp $\hat{G}$.

Consider the variational problem.

For each φ of $H^1(\hat{\Omega})/\mathbb{R}$.

$$\int_{\hat{\Omega}} \mu(\tilde{\theta}_n)^{-1} K \cdot \nabla \tilde{\pi}_n \cdot \nabla \varphi \, d\omega = \int_{\Omega} (Ra^* \mu(\tilde{\theta}_n)^{-1} \beta(\tilde{\theta}_n) \mathbf{e}_z + \nabla \hat{G}) \cdot \nabla \varphi \, d\omega. \tag{28}$$

By local Meyers regularity theorem [1], [10] there exists p_0 greater than 2, depending only on the ellipticity constant of $\mu(\tilde{\theta}_n)^{-1}K$ and on $|\mu(\tilde{\theta}_n)^{-1}K|_{L^\infty(\mathbb{R}^3)}$ such that $\tilde{\pi}_n$ belongs to $W^{1,p}_{\text{loc}}(\hat{\Omega})$.

The equation (28) being in divergence form on both sides and the boundary conditions being natural ones, π_n coincides with $\tilde{\pi}_{n|\Omega}$.

Remark. When θ_n does not belong to $\mathscr{C}^0(\bar{\Omega})$, we cannot make sure that π_n belongs to $W^{1,p}(\Omega)$ for any p.

Let π be the solution of the Darcy equation with data θ; taking the difference of the equation for π_n and π, we obtain

$$\begin{aligned} |\nabla(\pi_n - \pi)|_{L^2(\Omega)} &\leqq \alpha_0 |(\mu(\theta_n)^{-1} - \mu(\theta)^{-1}) \nabla \pi|_{L^2(\Omega)} \\ &\quad + \alpha_1 |\beta(\theta_n)\mu(\theta_n)^{-1} - \beta(\theta)\mu(\theta)^{-1}|_{L^2(\Omega)} \end{aligned} \tag{29}$$

for some constant α_0, α_1 independent of n.

By assumption and the Lebesgue dominated convergence theorem, we have that $(\theta_n, \mu(\theta_n), \beta(\theta_n))_{n\geqq 0}$ converges strongly for each finite q to $(\theta, \mu(\theta), \beta(\theta))$.

Choose then q such that $(1/q)+(1/p_0)=\frac{1}{2}$; then from (29) π_n converges to π strongly in $H^1(\Omega)/\mathbb{R}$.

Furthermore, $(\nabla \pi_n)_{n\geqq 0}$ is bounded in $L^{p_0}(\Omega)$; so for each small positive ε, $(\pi_n)_n$ converges to π, strongly in $W^{1,p_0-\varepsilon}(\Omega)/\mathbb{R}$.

By definition of $(\mathbf{V}_n)_{n\geqq 0}$, $(\mathbf{V}_n)_{n\geqq 0}$ is strongly converging to $\mathbf{V}$ in $L^q(\Omega)$ for each q satisfying $2 \leqq q < p_0$.

4.1.3. End of the proof of Theorem 2. When D is bounded, we have built a family of functions $(\theta_h, \mathbf{V}_h, \pi_h)$, verifying the uniform estimates of Lemma 1, solutions of the following.

For any test function φ in $H^1(\Omega)$,

$$\begin{aligned} &\left\langle \frac{\partial \theta_h}{\partial t}, \varphi \right\rangle + \int_\Omega (\lambda(\tau_h \theta_h) + D(\tau_h \mathbf{V}_h)) \cdot \nabla \theta_h \cdot \nabla \varphi \, dx \\ &\quad + \int_\Omega \tau_h \mathbf{V}_h \cdot \nabla \varphi \theta_h \, dx + \int_{\Sigma_i} g_i h_i \varphi \, d\sigma_i \\ &\quad + \int_{\Sigma_e} g_e \theta_h \varphi \, d\sigma_e = 0 \quad \text{a.e. in } (0, t); \end{aligned} \tag{30}$$

for any test function ψ in $H^1(\Omega)$,

$$\begin{aligned} &\int_\Omega \mu(\theta_h)^{-1} K \cdot (\nabla p_h - Ra^* \beta(\theta_h) \mathbf{e}_z) \cdot \nabla \psi \, d\omega \\ &\quad + \int_{\Sigma_i} g_i \psi \, d\sigma_i + \int_{\Sigma_e} g_e \psi \, d\sigma_e = 0 \quad \text{a.e. in } (0, t). \end{aligned} \tag{31}$$

Upon extracting a sequence, we may assume that

$$\begin{array}{lll} \theta_h \to \theta & \text{in } L^\infty((0,t)\times\Omega) & \text{weak star,} \\ \theta_h \to \theta & \text{in } L^2((0,t)\times\Omega) & \text{weakly,} \\ p_h \to p & \text{in } L^\infty((0,t);\, H^1(\Omega)/\mathbb{R}) & \text{weak star,} \\ \dfrac{\partial \theta_h}{\partial t} \to \dfrac{\partial \theta}{\partial t} & \text{in } L^2((0,T);\, H^1(\Omega)') & \text{weakly;} \end{array}$$

using Aubin's lemma,

$$\begin{array}{lll} \theta_h \to \theta & \text{in } L^2((0,t)\times\Omega) & \text{strongly and a.e.,} \\ \theta_h \to \theta & \text{in } L^p((0,t)\times\Omega) & \text{strongly for each finite } p; \end{array}$$

then, according to Lemma 2 there exist r and q greater than two such that

$$\begin{array}{lll} p_h \to p & \text{in } L^r(0,t);\, W^{1,r}(\Omega)/\mathbb{R}) & \text{strongly,} \\ \mathbf{V}_h \to \mathbf{V} & \text{in } \mathbb{L}^q((0,t);\, \mathbb{H}_q) & \text{strongly.} \end{array}$$

Noting that translations are strongly continuous in $L^p(0, T)$ for each finite p, we show that $(\theta, \mathbf{V}, \pi)$ is a solution of the problem satisfying $\theta(0) = \theta_0$.

This completes the proof of Theorem 2.

4.2. Proof of Theorem 1. We approximate a general D satisfying (A4), (A5) by a sequence of bounded operator D^l defined in the following way:

$$D^l_{ij}(\mathbf{V}) = \operatorname{Min}\,(l,\, D_{ij}(\mathbf{V})).$$

Now by Theorem 2 for each l there exists a triplet $(\theta_l, \mathbf{V}_l, \pi_l)$ verifying the following.

For each test function φ in $H^1(\Omega)$.

$$\begin{aligned} &\left\langle \frac{\partial \theta_l}{\partial t}, \varphi \right\rangle + \int_\Omega (\lambda(\theta_l) + D^l(\mathbf{V}_l)) \cdot \nabla \theta_l \cdot \nabla \varphi \, d\omega \\ &\quad + \int_\Omega \mathbf{V}_l \cdot \nabla \varphi \theta_l \, d\omega + \int_{\Sigma_i} g_i h_i \varphi \, d\sigma_i \qquad (32) \\ &\quad + \int_{\Sigma_e} g_e \theta_l \varphi \, d\sigma_e = 0 \quad \text{a.e. in } (0,t); \end{aligned}$$

for each test function ψ in $H^1(\Omega)$,

$$\begin{aligned} &\int_\Omega \mu(\theta_l)^{-1} K \cdot (\nabla \pi_l - Ra^* \beta(\theta_l) \mathbf{e}_z) \cdot \nabla \psi \, d\omega \qquad (33) \\ &\quad + \int_{\Sigma_i} g_i \psi \, d\sigma_i + \int_{\Sigma_e} g_e \psi \, d\sigma_e = 0 \quad \text{a.e. in } (0,t). \end{aligned}$$

The sequence $(\theta_l, \mathbf{V}_l, \pi_l)$ satisfies uniformly the estimates (19), (20), (21), (22) of Lemma 1 because each D^l satisfies the assumption (A4).

The estimate on $(\partial\theta_l/\partial t)$ in $L^2((0,t);\,(H^1(\Omega))')$ may not be uniform; so we are to prove a weaker uniform estimate, namely:

There exists a positive function f, independent of l such that

$$\left| \frac{\partial \theta_l}{\partial t} \right|_{L^2((0,t);(H^3(\Omega))')} \leqq f(t). \qquad (34)$$

Toward this end we remark that $D^l(\mathbf{V}_l)\nabla\theta_l$ is uniformly bounded in $\mathbb{L}^2((0, t); L^1(\Omega))$; so from (32) and by the previous estimates it follows that the sequence $(\partial\theta_l/\partial t)_{l\geqq 0}$ is uniformly bounded in $L^2((0, t); H^3(\Omega)')$.

Then we can apply again Aubin's lemma and conclude as in Theorem 2 to the convergence of a subsequence $(\theta_{l_r}, \mathbf{V}_{l_r}, \pi_{l_r})$ toward a weak solution of the original problem.

Remark. We also obtain that $\partial\theta/\partial t$ belongs to $L^2((0, t); W^{-1,1}(\Omega))$.

4.3. Main estimates for the Darcy–Forchheimer model. Let again $\mathbf{Z}$ be a function of $\mathbb{H}_3$ such that

$$\nabla\cdot\mathbf{Z}=0,$$

$$\mathbf{Z}\cdot\boldsymbol{\eta}=0 \quad \text{for } z=0 \quad \text{and} \quad z=H,$$

$$\mathbf{Z}\cdot\boldsymbol{\eta}=g_j \quad \text{for } r=R_j \quad j=i \text{ or } e.$$

Next take $\mathbf{U}=\mathbf{V}-\mathbf{Z}$; $\mathbf{U}$ verify $\mathbf{U}\cdot\boldsymbol{\eta}=0$ on $\partial\Omega$.

Now, as in the Darcy model we introduce the following scheme.

Define first

$$\theta_h(t, x)=\theta_0(x), \qquad t\in[-h, 0],$$

$$\mathbf{U}_h(t, x)=\mathbf{U}_0(x), \qquad t=0;$$

then assuming θ_h to be known on the interval $[kh, (k+1)h]$, $k\in\mathbb{N}$, compute $\mathbf{U}_h$ verifying

$$\mathbf{U}_h\in L^\infty([kh, (k+1)h]; \mathbb{H}_2)\cap L^3([kh, (k+1)h]; \mathbb{H}_3)$$

such that for any test function $\mathbf{W}$ in $L^3_{\text{loc}}(\mathbb{R}^+; \mathbb{H}_3)$,

$$\begin{aligned}
\varepsilon^{-1}DaP_r^{-1}&\int_{kh}^{(k+1)h}\int_\Omega \frac{\partial\mathbf{U}_h}{\partial t}\cdot\mathbf{W}\,d\omega\,d\tau\\
&+\int_{kh}^{(k+1)h}\int_\Omega K^{-1}\mu(\theta_h)(\mathbf{U}_h+\mathbf{Z})\cdot\mathbf{W}\,d\omega\,d\tau\\
&+c_jDa^{1/2}P_r^{-1}\int_{kh}^{(k+1)h}\int_\Omega \sigma(\mathbf{U}_h+\mathbf{Z})\cdot\mathbf{W}\,d\omega\,d\tau\\
&-Ra^*\int_{kh}^{(k+1)/h}\int_\Omega \beta(\theta_h)e_z\mathbf{W}\,d\omega\,d\tau=0,
\end{aligned}$$

where $U_h(kh, x)$ is known from the previous step.

Set $p_h\in L^{3/2}([kh, (k+1)h]; W^{1,3/2}(\Omega)/\mathbb{R})$ such that for any test function ψ belonging to $W^{1,3/2}(\Omega)/\mathbb{R}$,

$$\begin{aligned}
\int_\Omega \nabla p_h\cdot\nabla\psi\,d\omega = &-\int_\Omega K^{-1}\mu(\theta)(\mathbf{U}_h+\mathbf{Z})\nabla\psi\,d\omega\\
&-c_jDa^{1/2}P_r^{-1}\int_\Omega \boldsymbol{\sigma}(\mathbf{U}_h+\mathbf{Z})\mathbf{W}\,d\omega\,d\tau\\
&+Ra^*\int_\Omega \beta(\theta)e_z\cdot\nabla\psi\,d\omega.
\end{aligned}$$

Then define θ_h on the interval $[(k+1)h, (k+2)h]$ verifying

$$\theta_h\in L^\infty([(k+1)h, (k+2)h]; L^\infty(\Omega))\cap L^2([(k+1)h, (k+2)h]; H^1(\Omega))$$

and such that for any test function φ belonging to $L^2_{\text{loc}}(\mathbb{R}_+;\, H^1(\Omega))$,

$$
\begin{aligned}
&\int_{(k+1)h}^{(k+2)h}\left\langle\frac{\partial\theta_h}{\partial t},\varphi\right\rangle d\tau+\int_{(k+1)h}^{(k+2)h}\int_\Omega(\lambda(\tau_h\theta_h)+D(\tau_h\mathbf{V}_h))\cdot\nabla\theta_h\cdot\nabla\varphi\,d\omega\,d\tau\\
&+\frac{1}{2}\int_{(k+1)h}^{(k+2)h}\int_\Omega(\tau_h\mathbf{V}_h\cdot\nabla\theta_h\varphi-\tau_h\mathbf{V}_h\cdot\nabla\varphi\theta h)\,d\omega\,d\tau\\
&-\int_{(k+1)h}^{(k+2)h}\int_{\Sigma_i}g_i(\theta-h_i)\varphi\,d\sigma_i\,d\tau\\
&+\frac{1}{2}\int_{(k+1)h}^{(k+2)h}\int_{\Sigma_i}g_i\theta_h\varphi\,d\sigma_i\,d\tau+\frac{1}{2}\int_{(k+1)h}^{(k+2)h}\int_{\Sigma_e}g_e\theta_h\varphi\,d\sigma_e\,d\tau=0.
\end{aligned}\tag{18}
$$

LEMMA 3. *The algorithm is consistent and gives a global solution* $(\theta_h, p_h, \mathbf{U}_h)$ *satisfying*

$$
\begin{aligned}
&\theta_h\in L^\infty(\mathbb{R}_+\times\Omega)\cap L^2_{\text{loc}}(\mathbb{R}_+;\, H^1(\Omega)),\\
&\mathbf{U}_h\in L^3_{\text{loc}}(\mathbb{R}_+;\, \mathbb{H}_3)\cap L^\infty(\mathbb{R}_+;\, \mathbb{H}_2),\\
&p_h\in L^{3/2}_{\text{loc}}(\mathbb{R}_+;\, W^{1,3/2}_{\text{loc}}(\Omega)/\mathbb{R});
\end{aligned}
$$

furthermore, there exist constants k_l and positive and continuous functions f_l independent of D as long as it satisfies (A4), *but depending on the data h_i, g_i, g_e, θ_0, U_0 such that*

$$|\theta_h|_{L^\infty(\mathbb{R}_+\times\Omega)}\leqq k_1,$$

$$\int_0^t|\nabla\theta_h|_{L^2(\Omega)}\,d\tau\leqq f_1(t),$$

$$|\mathbf{U}_h|_{L^\infty(\mathbb{R}^+;\mathbb{H}_2)}\leqq k_2,$$

$$\int_0^t|\mathbf{U}_h|^3_{\mathbb{H}_3}\,d\tau\leqq f_2(t),$$

$$\int_0^t|\nabla p_h|^{3/2}_{L^{3/2}(\Omega)}\,d\tau\leqq f_3(t),$$

$$\int_0^t\left|\frac{\partial\mathbf{U}_h}{\partial t}\right|^{3/2}_{\mathbb{H}_{3/2}}d\tau\leqq f_4(t).$$

Moreover, there exists a positive and continuous function f_5 depending on k_1, f_1, k_2, f_2, g_i, g_e, and α_6 (see A7) *such that*

$$\int_0^t\left|\frac{\partial\theta_h}{\partial t}\right|^2_{H^1(\Omega)'}d\tau\leqq f_5(t).$$

The existence of a global solution u_h is a classical consequence of the hypothesis (A6); *the estimate of U_h obtained by taking $W=\mathbf{U}_h$ as a test function is the Darcy-Forchheimer equation, using Young's inequalities.*

5. Uniqueness results.

5.1. Proof of Theorem 4. Let $(\theta_l, \mathbf{V}_l, p_l)$ be two weak solutions corresponding to the same data $(h_i, g_i, g_e, \theta_0)$, $l=1$, or 2.

Set $\theta=\theta_2-\theta_1$, $p=p_2-p_1$, $\mathbf{V}=\mathbf{V}_2-\mathbf{V}_1$.

Taking the difference of the equations for θ_1 and θ_2, we get, after straightforward computations,

$$\begin{aligned}
&\left\langle \frac{\partial\theta}{\partial t}, \varphi \right\rangle_{W^{-1,1}(\Omega), W^{1,\infty}(\Omega)} + \int_\Omega (\lambda(\theta_2)+D(\mathbf{V}_2)) \cdot \nabla\theta \cdot \nabla\varphi \, d\omega \\
&\quad -\frac{1}{2}\int_{\Sigma_i} g_i\theta\varphi \, d\sigma_i + \frac{1}{2}\int_{\Sigma_e} g_e\theta\varphi \, d\sigma_e + \frac{1}{2}\int_\Omega (\mathbf{V}_2 \cdot \nabla\theta\varphi - \mathbf{V}_2 \cdot \nabla\varphi\theta) \, d\omega \\
(35) \qquad &\quad = -\int_\Omega (\lambda(\theta_2)+D(\mathbf{V}_2)) - (\lambda(\theta_1)+D(\mathbf{V}_1)) \cdot \nabla\theta_1 \cdot \nabla\varphi \, d\omega \\
&\quad -\frac{1}{2}\int_\Omega (\mathbf{V} \cdot \nabla\theta_1\varphi - \mathbf{V} \cdot \nabla\varphi\theta_1) \, d\omega.
\end{aligned}$$

We may now take $\varphi = \theta$ as θ belongs to $L^2((0, t); W^{1,\infty}(\Omega)) \cap L^\infty(\mathbb{R}_+ \times \Omega)$ to get the following energy inequality:

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}|\theta|^2_{L^2(\Omega)} + c_0|\nabla\theta|^2_{\mathbb{L}^2(\Omega)} - \frac{1}{2}\int_{\Sigma_i} g_i\theta^2 \, d\sigma_i + \frac{1}{2}\int_{\Sigma_e} g_e\theta^2 \, d\sigma_e \\
(36) \qquad &\quad \leqq \int_\Omega (c_1|\theta_2-\theta_1| + c_2|\mathbf{V}_2-\mathbf{V}_1|)|\nabla\theta_1||\nabla\theta| \, d\omega \\
&\quad + \int_\Omega |\mathbf{V}|(|\mathbf{V}\theta_1||\theta| + |\nabla\theta||\theta_1|) \, d\omega.
\end{aligned}$$

Using Hölder inequalities, we get

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}|\theta|^2_{L^2(\Omega)} + c_0|\nabla\theta|^2_{\mathbb{L}^2(\Omega)} - \frac{1}{2}\int_{\Sigma_i} g_i\theta^2 \, d\sigma_i + \frac{1}{2}\int_{\Sigma_e} g_e\theta^2 \, d\sigma_\epsilon \\
(37) \qquad &\quad \leqq \frac{c_0}{4}|\nabla\theta|^2_{\mathbb{L}^2(\Omega)} + c_3|\theta|^2_{L^2(\Omega)}|\nabla\theta_1|^2_{\mathbb{L}^\infty(\Omega)} + c_4|\mathbf{V}|^2_{\mathbb{H}_2}|\nabla\theta_1|^2_{\mathbb{L}^\infty(\Omega)} \\
&\quad + |\mathbf{V}|_{\mathbb{H}_2}|\theta|^2_{L^2(\Omega)}|\nabla\theta_1|^2_{\mathbb{L}^\infty(\Omega)} + \frac{c_0}{4}|\nabla\theta|^2_{\mathbb{L}^2(\Omega)} + c_5|\theta_1|^2_{L^\infty(\Omega)}|\mathbf{V}|^2_{\mathbb{H}_2}.
\end{aligned}$$

So there exists a function f_1 belonging to $L^1(0, t)$ such that

$$\begin{aligned}
(38) \qquad &\frac{1}{2}\frac{d}{dt}|\theta|^2_{L^2(\Omega)} + \frac{c_0}{2}|\nabla\theta|^2_{\mathbb{L}^2(\Omega)} - \frac{1}{2}\int_{\Sigma_i} g_i\theta^2 \, d\sigma_i + \frac{1}{2}\int_{\Sigma_e} g_e\theta^2 \, d\sigma_e \\
&\quad \leqq f_1(t)(|\theta|^2_{L^2(\Omega)} + |\mathbf{V}|^2_{\mathbb{H}_2}).
\end{aligned}$$

To obtain an estimate on the velocity $\mathbf{V} = \mathbf{V}_2 - \mathbf{V}_1$, we first prove a bound for the pressure gradient $\nabla p = \nabla p_2 - \nabla p_1$.

Taking the difference of the equations for p_2 and p_1, we get, after some calculations,

$$\begin{aligned}
\int_\Omega \mu(\theta_2)^{-1}K \cdot \nabla p \cdot \nabla\psi \, d\omega &= \int_\Omega (\mu(\theta_2)^{-1} - \mu(\theta_1)^{-1})K \cdot \nabla p_1 \cdot \nabla\psi \, d\omega \\
&\quad + Ra^* \int_\Omega (\beta(\theta_2)\mu(\theta_2)^{-1} - \beta(\theta_1)\mu(\theta_1)^{-1})\mathbf{e}_z \cdot \nabla\psi \, d\omega.
\end{aligned}$$

By taking $\psi = p$, we find

$$c_6|\nabla p|^2_{L^2(\Omega)} \leqq c_7|\nabla p_1|_{\mathbb{L}^\infty(\Omega)}|\theta|_{L^2(\Omega)}|\nabla p|_{\mathbb{L}^2(\Omega)} + c_8|\theta|_{L^2(\Omega)}|\nabla p|_{\mathbb{L}^2(\Omega)}.$$

So there exists a function f_2 belonging to $L^\infty(0, t)$ such that

$$(39) \qquad |\nabla p|_{\mathbb{L}^2(\Omega)} \leqq f_2(t)|\theta|_{L^2(\Omega)}.$$

According to the Darcy law, we get

$$\mathbf{V} = -\mu(\theta_2)^{-1} K \nabla p - (\mu(\theta_2)^{-1} - \mu(\theta_1)^{-1}) K \nabla p_1 \\ + Ra^*(\mu(\theta_2)^{-1}\beta(\theta_2) - \mu(\theta_1)^{-1}\beta(\theta_1))\mathbf{e}_z.$$

So we have for some functions f_3 or f_4 belonging $L^\infty(0, t)$,

(40) $$|\mathbf{V}|_{\mathbb{H}_2} \leqq f_3(t) |\nabla p|_{L^2(\Omega)} + f_4(t) |\theta|_{L^2(\Omega)}.$$

So according to the inequality (39), there exists a function f_5 in $L^\infty(0, t)$,

(41) $$|\mathbf{V}|_{\mathbb{H}_2} \leqq f_5(t) |\theta|_{L^2(\Omega)}.$$

By taking this last inequality in the energy equation (38), we prove the existence of a function f in $L^1(0, t)$ such that

$$\frac{d}{dt}|\theta|^2_{L^2(\Omega)} + c_0 |\nabla\theta|^2_{L^2(\Omega)} - \int_{\Sigma_i} g_i \theta^2 \, d\sigma_i + \int_{\Sigma_e} g_e \theta^2 \, d\sigma_e \leqq f(t)(|\theta|^2_{L^2(\Omega)}).$$

According to the assumption (A2), we derive, by using the Gronwall lemma, the uniqueness of a solution.

5.2. Proof of Theorem 5. When D satisfies (A7), the equality (35) has the form

$$\left\langle \frac{\partial\theta}{\partial t}, \varphi \right\rangle_{W^{-1,1}(\Omega), W^{1,\infty}(\Omega)} + \int_\Omega (\lambda(\theta_2) + D(\mathbf{V}_2)) \cdot \nabla\theta \cdot \nabla\varphi \, d\omega \\ -\frac{1}{2}\int_{\Sigma_i} g_i \theta\varphi \, d\sigma_i + \frac{1}{2}\int_{\Sigma_e} g_e \theta\varphi \, d\sigma_e + \frac{1}{2}\int_\Omega (\mathbf{V}_2 \nabla\theta\varphi - \mathbf{V}_2 \nabla\varphi\theta) \, d\omega \\ = -\int_\Omega (\lambda(\theta_2) - \lambda(\theta_1) + D(\mathbf{V}_2) - D(\mathbf{V}_1)) \cdot \nabla\theta_1 \cdot \nabla\varphi \, d\omega \\ -\frac{1}{2}\int_\Omega ((\mathbf{V} \cdot \nabla\theta_1)\varphi - (\mathbf{V} \cdot \nabla\varphi)\theta_1) \, d\omega.$$

Assuming only that θ_1 belongs to $L^2((0, t), W^{1,\infty}(\Omega))$, this equality remains valid for any test function in $L^2((0, t), H^1(\Omega))$, and by taking $\varphi = \theta$ we get the inequality (38).

The bound for $\mathbf{V}$ follows the same lines as in Theorem 4, and uniqueness is deduced by using Gronwall's lemma.

6. Proof of the large time behavior.

When D satisfies (A7), we may use Theorem 2 in § 4.1. This implies that $\partial\theta/\partial t$ belongs to $L^2((0, t), H^1(\Omega)')$. When h_i is constant, the function $T = \theta - h_i$ satisfies the following equation.

For any test function in $H^1(\Omega)$,

$$\left\langle \frac{\partial T}{\partial t}, \varphi \right\rangle + \int_\Omega (\lambda(\theta) + D(\mathbf{V})) \cdot \nabla T \cdot \nabla\varphi \, d\omega \\ + \int_\Omega (\mathbf{V} \cdot \nabla T)\varphi - \mathbf{V} \cdot \nabla\varphi T \, d\omega - \int_{\Sigma_i} g_i T\varphi \, d\sigma_i = 0.$$

Then taking $\varphi = T$ in the above equation, we get the following inequality:

$$\frac{1}{2}\frac{d}{dt}|T|^2_{L^2(\Omega)} + c_0 |\nabla T|^2_{\mathbb{L}^2(\Omega)} + m_i \int_{\Sigma_i} |T|^2 \, d\sigma_i \leqq 0.$$

Because the two-dimensional Lebesgue measure of Σ_i is positive, Poincaré's inequality gives

$$\frac{d}{dt}|T|^2_{L^2(\Omega)}+\beta|T|^2_{L^2(\Omega)}\leqq 0 \quad \text{for some constant } \beta>0,$$

and, therefore,

$$\lim_{t\to\infty}|T(t)|_{L^2(\Omega)}=0.$$

7. Proof of Lemma 1. The equations we are to solve are linear equations. We omit the index h, which is a fixed positive number throughout this section.

We introduce the bilinear and continuous mapping $\alpha_2(\cdot,\cdot)$ defined on $H^1(\Omega)\times H^1(\Omega)$ by

$$a_2(p,\psi)=\int_\Omega \frac{K}{\mu(\theta)}\nabla p\cdot\nabla\psi\,d\omega.$$

Next $b_2(\theta,\psi)$ is the bilinear and continuous mapping defined on $L^2(\Omega)\times H^1(\Omega)$ by

$$b_2(\theta,\psi)=\int_\Omega \frac{K}{\mu(\theta)}\beta(\theta)\mathbf{e}_z\cdot\nabla\psi\,d\omega.$$

7.1. Solving the Darcy equation.

LEMMA 4. *Assume* (A3) *holds. Let* $\theta\in L^\infty(\mathbb{R}_+;L^\infty(\Omega))$; *there exists a unique p such that*

$$p\in L^\infty(\mathbb{R}_+;H^1(\Omega)/\mathbb{R})$$

and a solution of

$$a_2(p,\psi)+b_2(\theta,\psi)+\int_{\Sigma_1}g_1\psi\,d\sigma_2+\int_{\Sigma_2}g_2\psi\,d\sigma_2=0 \quad \forall\psi\in H^1(\Omega). \tag{42}$$

Furthermore, there is a constant c_0 *depending only on* g_i, g_e, α_1, *and* $|\theta|_{L^\infty(\mathbb{R}_+\times\Omega)}$ *such that* $|\nabla p|_{L^2(\Omega)}\leqq c_0$.

Proof. Because θ is fixed, a_2 is coercive on $H^1(\Omega)/\mathbb{R}$ while b_2 is linear. Hence, existence and uniqueness follows from the Lax-Milgram theorem once we have checked that

$$b_2(\theta,1)+\int_{\Sigma_i}g_i\cdot 1\,d\sigma_i+\int_{\Sigma_e}g_e\cdot 1\,d\sigma_e=0 \qquad \text{(A2)}.$$

Assume now that $\theta\in L^2_{\text{loc}}(\mathbb{R}_+;H^1(\Omega))\cap L^\infty(\mathbb{R}_+;L^\infty(\Omega))$. Then p verifies

$$\nabla\cdot\left(\frac{K}{\mu(\theta)}\cdot\nabla p\right)=Ra^*\nabla\cdot K\cdot\left(\frac{\beta(\theta)}{\mu(\theta)}\mathbf{e}_z\right) \quad \text{in } \mathscr{D}'(\Omega). \tag{43}$$

Now that θ is lying in $L^2_{\text{loc}}(\mathbb{R}^+;H^1(\Omega))\cap L^\infty(\mathbb{R}^+;L^\infty(\Omega))$, the right-hand side of (43) belongs to $L^2_{\text{loc}}(\mathbb{R}^+;L^2(\Omega))$; hence we may define

$$\left(\frac{K}{\mu(\theta)}\nabla p\right)\cdot\boldsymbol{\eta}$$

as the normal trace on $\partial\Omega$ of an $L^2(\Omega)$ function having a square integrable divergence.

We may now use Green's formula to get

$$\left(\frac{K}{\mu(\theta)}\nabla p\right)\cdot \boldsymbol{\eta} = Ra^* \frac{\beta(\theta)}{\mu(\theta)} K\mathbf{e}_z \cdot \boldsymbol{\eta} \quad \text{on } z=0 \quad \text{and} \quad z=H,$$

$$(44)\qquad \begin{aligned} \left(\frac{K}{\mu(\theta)}\nabla p\right)\cdot \boldsymbol{\eta} &= Ra^* \frac{\beta(\theta)}{\mu(\theta)} K\mathbf{e}_z \cdot \boldsymbol{\eta} + g_i; \qquad r = R_i,\\ \left(\frac{K}{\mu(\theta)}\nabla p\right)\cdot \boldsymbol{\eta} &= Ra^* \frac{\beta(\theta)}{\mu(\theta)} K\mathbf{e}_z \cdot \boldsymbol{\eta} + g_e, \qquad r = R_e. \end{aligned}$$

Remark. When K is a diagonal tensor, (44) reduces to

$$(45)\qquad \begin{aligned} \left(\frac{1}{\mu(\theta)} k\nabla p\right)\cdot \boldsymbol{\eta} &= g_i \quad \text{on } r = R_i,\\ \left(\frac{1}{\mu(\theta)} k\nabla p\right)\cdot \boldsymbol{\eta} &= g_e \quad \text{on } r = R_e. \end{aligned}$$

Remark. θ is not smooth enough to make sure that $(K\cdot \nabla p)$ has a normal trace.

7.2. Solving the energy equation. Take $\mathbf{V}$ in $\mathbb{L}^\infty(\mathbb{R}^+; \mathbb{H}_2)$ with $\operatorname{div}\mathbf{V}=0$.
Choose (θ, φ) in $L^\infty(\mathbb{R}_+; L^\infty(\Omega)) \cap L^2_{\text{loc}}(\mathbb{R}_+; H^1(\Omega))$.
We then have

$$\int_\Omega (\mathbf{V}\cdot\nabla\theta)\varphi\, d\omega = -\int_\Omega (\mathbf{V}\cdot\nabla\varphi)\theta + \langle \theta\varphi, \mathbf{V}\cdot\boldsymbol{\eta}\rangle_{H^{1/2}(\partial\Omega), H^{-1/2}(\partial\Omega)}$$

because any element of $H^1(\Omega)\cap L^\infty(\Omega)$ has a trace in $L^\infty(\partial\Omega)\cap H^{1/2}(\partial\Omega)$, which is actually an algebra.

In particular, we may write

$$\int_\Omega (\mathbf{V}\cdot\nabla\theta)\varphi\, d\omega = \frac{1}{2}\left[\int_\Omega (\mathbf{V}\cdot\nabla\theta)\varphi - (\mathbf{V}\cdot\nabla\varphi)\theta\, d\omega\right] + \frac{1}{2}\langle \theta\varphi, \mathbf{V}\cdot\boldsymbol{\eta}\rangle_{H^{1/2}(\partial\Omega), H^{-1/2}(\partial\Omega)}.$$

For our problem, this reads

$$(46)\qquad \int_\Omega (\mathbf{V}\cdot\nabla\theta)\varphi\, d\omega = \frac{1}{2}\left[\int_\Omega (\mathbf{V}\cdot\nabla\theta)\varphi - (\mathbf{V}\cdot\nabla\varphi)\theta\, d\omega\right] + \frac{1}{2}\int_{\Sigma_i} \theta\varphi g_i\, d\sigma_i + \frac{1}{2}\int_{\Sigma_e} \theta\varphi g_e\, d\sigma_e.$$

The variational formulation of the energy equation is now

$$(47)\qquad \begin{aligned} &\left\langle \frac{\partial\theta}{\partial t}, \varphi\right\rangle + \int_\Omega \lambda(\theta)\nabla\theta\nabla\varphi\, dx + \int_\Omega D(\mathbf{V})\nabla\theta\nabla\varphi\, dx\\ &+\frac{1}{2}\int_\Omega [(\mathbf{V}\cdot\nabla\theta)\varphi - (\mathbf{V}\cdot\nabla\varphi)\theta]\, dx\\ &-\int_\Omega g_i(\theta - h_i)\varphi\, d\sigma_i + \frac{1}{2}\int_{\Sigma_e} g_e\theta\,\varphi\, d\sigma_e + \frac{1}{2}\int_{\Sigma_i} g_i\theta\varphi\, d\sigma_i = 0. \end{aligned}$$

This equation possesses at least one solution in the setting of § 2.2. To see this, we may approximate **V** by smooth functions, use Galerkin's type techniques, and pass to the limit. We omit this lengthy process. (See also [6] and [8].)

7.3. First estimates in $H^1(\Omega)$. Taking $\varphi=\theta$ in (47), which is possible because $D(\mathbf{V})$ is bounded, yields

$$\frac{1}{2}\frac{d}{dt}|\theta|^2_{L^2(\Omega)}+\int_\Omega(\lambda(\theta)\cdot\nabla\theta)\cdot\nabla\theta\,dx+\int_\Omega(D(\mathbf{V})\cdot\nabla\theta)\cdot\nabla\theta\,dx$$
$$-\int_{\Sigma_i}g_i(\theta-h_i)\theta\,d\sigma_i+\frac{1}{2}\int_{\Sigma_i}g_i\theta^2\,d\sigma_i+\frac{1}{2}\int_{\Sigma_e}g_e\theta^2\,d\sigma_e=0.$$

Thus

$$\frac{1}{2}\frac{d}{dt}|\theta|^2_{L^2(\Omega)}+\alpha_1|\nabla\theta|^2_{\mathbb{L}^2(\Omega)}-\frac{1}{2}\int_{\Sigma_i}g_i\theta^2\,d\sigma_i+\frac{1}{2}\int_{\Sigma_e}g_e\theta^2\,d\sigma_e$$
$$\leqq\int_{\Sigma_i}|g_ih_i||\theta|\,d\sigma_i.$$

Hence, using assumption (A2), we have

$$\frac{1}{2}\frac{d}{dt}|\theta|^2_{L^2(\Omega)}+\alpha_1|\nabla\theta|^2_{\mathbb{L}^2(\Omega)}+\frac{1}{2}m_1\int_{\Sigma_i}\theta^2\,d\sigma_i\leqq\int_{\Sigma_i}|g_ih_i||\theta|\,d\sigma_i. \tag{48}$$

Using Young's inequality on the right-hand side of (48), we find a constant c_1 depending only on m_i such that

$$\frac{1}{2}\frac{d}{dt}|\theta|^2_{L^2(\Omega)}+\alpha_1|\nabla\theta|^2_{\mathbb{L}^2(\Omega)}+\frac{1}{4}m_i\int_{\Sigma_i}\theta^2\,d\sigma_i\leqq c_1\int_{\Sigma_i}g_i^2h_i^2\,d\sigma_i.$$

Therefore, there exists a constant c_2 depending only on $(|g_i|_{L^\infty(\Sigma_i)},|h_i|_{L^2(\Sigma_i)},m_i)$ such that

$$|\theta(t)|^2_{L^2(\Omega)}+2\alpha_1\int_0^t|\nabla\theta(\tau)|^2_{\mathbb{L}^2(\Omega)}\,d\tau\leqq|\theta(0)|^2_{L^2(\Omega)}+c_2t. \tag{49}$$

We may conclude that for each t, θ lies in a bounded set of

$$L^\infty(0,t;L^2(\Omega))\cap L^2(0,t;H^1(\Omega)).$$

7.4. Uniform estimates in L^∞.

LEMMA 5. *Assume θ_0 and h_i are bounded. Then*

$$|\theta|_{L^\infty((0,t)\times\Omega)}\leqq\operatorname{Max}(|\theta_0|_{L^\infty(\Omega)},|h_i|_{L^\infty(\Sigma_i)}).$$

Proof. Take $\nu=\operatorname{Max}(|\theta_0|_{L^\infty(\Omega)},|h_i|_{L^\infty(\Sigma_i)})$. Let $T=\theta+\nu$; T is a solution of

$$\begin{aligned}&\left\langle\frac{\partial T}{\partial t},\varphi\right\rangle+\int_\Omega(\lambda(\theta)+D(\mathbf{V}))\nabla T\nabla\varphi\,dx+\frac{1}{2}\int_\Omega(\mathbf{V}\cdot\nabla T)\varphi-(\mathbf{V}\cdot\nabla\varphi)(T-\nu)\,dx\\&-\int_{\Sigma_i}g_i(T-\nu-h_i)\varphi\,d\sigma_i+\frac{1}{2}\int_{\Sigma_i}g_i(T-\nu)\varphi\,d\sigma_i+\frac{1}{2}\int_{\Sigma_e}g_e(T-\nu)\varphi\,d\sigma_e.\end{aligned}\tag{50}$$

Green's formula yields

$$+\frac{1}{2}\int_\Omega\mathbf{V}\cdot\nabla\varphi\nu\,dx=+\frac{1}{2}\int_{\partial\Omega}\nu\varphi\,\mathbf{V}\cdot\boldsymbol{\eta}\,d\sigma$$
$$=+\frac{1}{2}\int_{\Sigma_i}\nu\cdot\varphi g_i\,d\sigma_i+\frac{1}{2}\int_{\Sigma_e}\nu\cdot\varphi g_e\,d\sigma_e.$$

Thus we have

$$
\begin{aligned}
&\left\langle\frac{\partial T}{\partial t}, \varphi\right\rangle+\int_\Omega(\lambda(T)+D(\mathbf{V}))\cdot\nabla T\cdot\nabla\varphi\,dx\\
(51)\qquad&+\frac{1}{2}\int_\Omega(\mathbf{V}\cdot\nabla T)\varphi-(\mathbf{V}\cdot\nabla\varphi)T\,dx\\
&-\int_{\Sigma_i}g_iT\varphi\,d\sigma_i+\int_{\Sigma_i}g_i(\nu+h_i)\varphi\,d\sigma_i.
\end{aligned}
$$

Taking $\varphi=-T^-$ in this relation and writing $T=T^+-T^-$, we find, after some calculations,

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}|T^-|^2_{L^2(\Omega)}+\alpha_1|\nabla T^-|^2_{L^2(\Omega)}+m_1\int_{\Sigma_i}|T^-|^2\,d\sigma_i\\
(52)\qquad&=+\int_{\Sigma_i}g_i(\nu+h_i)T^-\,d\sigma_i.
\end{aligned}
$$

We know that

$$-m_i\leqq g_i\leqq -m_i<0,\qquad -\nu-h_i<0.$$

It follows that the left-hand side of (52) is nonpositive; this implies that $T^-=0$. In a similar fashion, setting $T=\theta-\nu$ we show that $T^+=0$. Lemma 7.2 is proved.

7.5. Estimates on $\partial\theta/\partial t$. In this subsection we rewrite

$$\frac{1}{2}\int_\Omega(\mathbf{V}\cdot\nabla\theta\varphi-\mathbf{V}\cdot\nabla\varphi\theta)\,dx$$

as

$$-\int_\Omega(\mathbf{V}\cdot\nabla\varphi)\theta\,dx+\frac{1}{2}\int_{\Sigma_i}g_i\theta\varphi\,d\sigma_i+\frac{1}{2}\int_{\Sigma_e}g_e\theta\varphi\,d\sigma_e.$$

Hence θ is a solution of

$$
\begin{aligned}
&\left\langle\frac{\partial\theta}{\partial t}, \varphi\right\rangle+\int_\Omega(\lambda(\theta)+D(\mathbf{V}))\nabla\theta\cdot\nabla\varphi\,dx-\int_\Omega\mathbf{V}\cdot\nabla\varphi\theta\,dx\\
(53)\qquad&-\int_{\Sigma_i}g_i(\theta-h_i)\varphi\,d\sigma_i+\int_{\Sigma_i}g_i\theta\varphi\,d\sigma_1+\int_{\Sigma_e}g_e\theta\varphi\,d\sigma_e=0.
\end{aligned}
$$

Because θ is bounded, we get

$$
\begin{aligned}
\left|\left\langle\frac{\partial\theta}{\partial t}, \varphi\right\rangle\right|\leqq&\{|\lambda(\theta)|_{L^\infty(\Omega)}|\nabla\theta|_{L^2(\Omega)}+|D(\mathbf{V})|_{L^\infty(\Omega)}|\nabla\theta|_{L^2(\Omega)}+|\mathbf{V}|_{\mathbb{H}_2}|\theta|_{L^\infty}\}|\nabla\varphi|_{L^2(\Omega)}\\
&+|g_1|_{L^\infty(\Sigma_i)}|h_1|_{L^2(\Sigma_i)}|\varphi|_{L^2(\Sigma_i)}+|g_2|_{L^\infty(\Sigma_e)}|\theta|_{L^2(\Sigma_e)}|\varphi|_{L^2(\Sigma_e)}.
\end{aligned}
$$

Therefore, there is a function $f(t)$ depending only on

$$(k_1, k_2, |g_i|_{L^\infty(\Sigma_i)}, |g_e|_{L^\infty(\Sigma_e)}, |\mathbf{V}|_{\mathbb{H}_2}, |D(\mathbf{V})|_{L^\infty(\Omega)})$$

such that

$$(54)\qquad\left|\frac{\partial\theta}{\partial t}\right|_{L^2(0,t;(H^1(\Omega))')}\leqq f(t).$$

This completes the proof of Lemma 1.

ONE-DIMENSIONAL THERMOELASTIC CONTACT WITH A STRESS-DEPENDENT RADIATION CONDITION*

KEVIN T. ANDREWS†, ANDRO MIKELIĆ‡, PETER SHI†,
MEIR SHILLOR†, AND STEVE WRIGHT†

Abstract. A one-dimensional quasistatic thermoelastic contact problem with a stress-dependent boundary condition is considered. The problem models the evolution of the temperature and the displacement of a long thin elastic rod that may come into contact with a rigid obstacle. The mathematical problem is reduced to solving a nonlocal heat equation with a nonlinear and nonlocal boundary condition. This boundary condition contains a heat exchange coefficient that depends on the pressure when there is contact with the obstacle and on the size of the gap when there is no contact. The local existence of a strong solution to the problem and local dependence on the initial-boundary data are proved. In addition, the uniqueness of the solution is established. The proof rests on an abstract result dealing with perturbations of monotone operators, as well as some a priori estimates which permit an application of Schauder's fixed point theorem.

Key words. thermoelastic contact, nonlinear heat transfer coefficient, nonlinear perturbations, monotone operators, nonlinear boundary conditions, Signorini's condition

1. Introduction.

Thermoelastic problems with contact arise naturally in many industrial processes, particularly in the manufacture of such items as castings, mouldings, pistons, thermostats, etc. In these situations two or more elastic materials are forced into contact with each other as a result of thermal expansion. Predicting the behavior of thermoelastically contacting bodies in such situations is of considerable applied importance. In ball bearings, for example, in cases where the ball and the casing are made of different materials, thermal expansion or contraction may cause the bearing either to lock up or to chatter. There is a considerable engineering literature that deals with such problems. For example, Srinivasan and France [SF] report on erratic performance of duplex heat exchange tubes in experimental breeder reactors and suggest that this may be due to the presence of multiple steady states. Richmond and Huang [RH] have suggested that the growth of a sinusoidal perturbation in an otherwise uniform contact pressure between a solidifying casting and the mould may be responsible for experimentally observed waviness in nominally plane cast surfaces. Barber [Ba2] has shown that such behavior may result from the instability of the thermoelastic contact.

In spite of the obvious applied importance of the subject, there are relatively few theoretical results about general problems of thermoelastic contact. Until recently the existing mathematical models make various restrictive assumptions about how the process behaves. A general variational inequality model was derived in Duvaut and Lions [DL], where evolution problems with unilateral conditions were considered, but it assumes that there is no loss of contact. Duvaut [Du] considered only the static problem with Signorini's contact condition and a smoothed stress-dependent radiation condition.

‡Department of Physics, Ruder Bošković Institute, 41001 Zagreb, Yugoslavia.

More recently, the one-dimensional quasistatic problem of thermoelastic contact was considered in a series of papers by Gilbert, Shi, and Shillor [GSS], Shi and Shillor [SS1], [SS2], and Shi, Shillor, and Zou [SSZ]. The problem was formulated as a fully coupled variational inequality in [GSS], and the existence of a strong solution was established. A reformulation of the problem in [SS1] led to a decoupled heat equation with a nonlinear and nonlocal source term. The uniqueness of the solution was proved as well as the fact that the solution converges to a steady state. In both of the papers [GSS], [SS1] the Dirichlet condition was assumed for the temperature at the contacting edge. The more realistic heat exchange condition was considered in [SS2], where the existence of a solution was obtained from an abstract result involving perturbations of monotone operators. The model there was somewhat restrictive in that the heat exchange coefficient k was assumed to be a constant.

It is known from the work of Barber and his collaborators, [Ba1], [Ba2], [BDC], [BZ] as well as [CD], that the heat exchange between the contacting edge and the wall seems to depend in a complicated way on the distance of the edge from the obstacle and on the contact pressure. Thus it seems reasonable that a general model for the process would assume that the heat exchange coefficient k depends on the distance of the edge from the obstacle when there is no contact, and on the contact pressure otherwise. In the latter case it is also assumed that there is a thin heat-resisting layer at the edge and that the resistance to the heat conduction decreases when the magnitude of the contact pressure increases. In this paper we consider such a general model. Some numerical simulations for problems with constant and nonconstant k can be found in [SSZ].

We now describe the remaining sections of this paper. The modelling of k is presented in §2, where the precise mathematical problem is described. Decoupling leads to a heat equation with a contact dependent source term. This section also contains a statement of our main result, Theorem 2.1, which guarantees the local existence of a strong solution to the problem and the local dependence on the initial-boundary data. The theorem also asserts that any solution to the problem is unique. The remaining sections of the paper are devoted to constructing a proof of this theorem. In §3 we prove an abstract result, Theorem 3.1, concerning variational inequalities associated with nonlinear perturbations of monotone operators in Banach spaces. This theorem is used in §4 to solve an auxiliary problem. Finally, the results of §4, together with Schauder's fixed point theorem, are used in §5 to prove Theorem 2.1.

2. The model.

The problem under consideration models a homogeneous elastic rod that is held fixed at one edge. It is free to expand or contract at the other edge as a result of the evolution of its temperature and stress field, but the expansion is limited by the existence of an obstacle, say a rigid wall, which blocks any further expansion once the rod comes into contact with it. We assume that the accelerations in the system are negligible, and thus the problem may be described as quasistatic.

The physical setting is depicted in Fig. 1. We denote the temperature by $\theta = \theta(x,t)$, the displacement by $u = u(x,t)$, and the stress by $\sigma = \sigma(x,t)$, all in nondimensional form. The thermoelastic problem for such a system may be posed (see, e.g., Carlson [Ca] or Day [Da]) as follows: find a pair $\{\theta, u\}$ such that

$$\theta_{xx} = \theta_t + au_{xt} \quad \text{for } 0 < x < 1 \quad \text{and} \quad 0 < t < T, \tag{2.1}$$

$$u_{xx} = a\theta_x \quad \text{for } 0 < x < 1 \quad \text{and} \quad 0 < t < T. \tag{2.2}$$

Here (1.1) and (1.2) are the energy and the elasticity equations, respectively. The *coupling constant* a is related to the physical properties of the material (see [Da],

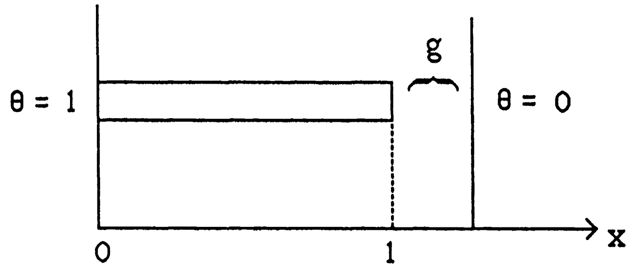

FIG. 1

[SS1], or [GSS]) and is typically a small positive number. We shall assume throughout that $0 < a < 1$. To complete the model, we prescribe the initial condition $\theta(x, 0) = \varphi$ together with the following boundary conditions. At the left edge ($x = 0$) we assume that the temperature is prescribed in the form $\theta = m(t)$ and that the rod is held fixed there, i.e., $u = 0$. At the right edge ($x = 1$) we assume the radiation condition $-\theta_x = k\theta$, which is discussed below. For the displacement at that edge we assume the Signorini contact condition

$$u \leq g, \quad \sigma \leq 0, \quad \text{and} \quad (u - g)\sigma = 0, \tag{2.3}$$

where g is the initial gap between the wall and the free edge. This condition implies that the expansion of the free edge is restricted by the obstacle, i.e., $u \leq g$, and the stress is compressive, i.e., $\sigma \leq 0$. Consequently, if contact occurs, then $u = g$, but if the edge is free then $\sigma = 0$. In one space dimension we have that $\sigma(x, t) = u_x(x, t) - a\theta(x, t)$ (see [Da]). Therefore, the condition may be written in terms of the displacement and temperature as

$$u \leq g, \quad u_x \leq a\theta, \quad \text{and} \quad (u - g)(u_x - a\theta) = 0. \tag{2.4}$$

We turn next to the modelling of the radiation condition, more precisely to k. As was mentioned above, we would like it to depend on the actual gap $g - u$, when there is no contact, and on the pressure σ when contact occurs. It turns out that the natural argument for k is $\eta = g - u + \sigma$. Indeed, in the absence of contact, $\sigma = 0$ and $\eta = g - u > 0$. Thus η measures the distance of the edge from the wall. On the other hand, when contact occurs, $u = g$ and, therefore, $\eta = \sigma \leq 0$, and now η measures the contact pressure. Therefore, we propose the following form for the heat exchange coefficient:

$$k = k(g - u + \sigma) = k(g - u + u_x - a\theta). \tag{2.5}$$

Here $k = k(\eta)$ is a prescribed function of its argument. In this paper we will consider only smooth nonnegative functions k. Primicerio [Pr] has suggested that in some applications it may be appropriate to take k to be a piecewise constant function

$$k(\eta) = \begin{cases} k_0, & \eta \leq 0, \\ k_1, & \eta > 0. \end{cases}$$

Some numerical simulations were performed in [SSZ] using such a choice of k. A more complicated condition (the so-called "imperfect contact" condition) was proposed in Barber [Ba1] (see also [CD]).

We now describe the spaces in which we expect to find solutions. Let $\Omega_T = (0,1) \times (0,T)$ for some $T > 0$. From the form of (2.1) and (2.2) it is natural to seek a solution θ, which lies in the Sobolev space $W_2^{2,1}(\Omega_T)$, which consists of all $L^2(\Omega_T)$-summable functions that possess generalized $L^2(\Omega_T)$-summable second-order space and first-order time derivatives. The norm of this Hilbert space is given by

$$\| \theta \|^2_{W_2^{2,1}(\Omega_T)} = \int_{\Omega_T} (\theta_t^2 + \theta_x^2 + \theta_{xx}^2 + \theta^2)\, dx\, dt. \tag{2.6}$$

Similarly, we seek for u a function that lies in the Sobolev space

$$X = \{u \in H^1(\Omega_T);\ u_{xx}, u_{xt} \in L^2(\Omega_T),\ u(0,t) = 0,\ 0 < t < T\}, \tag{2.7}$$

whose norm is given by

$$\| u \|^2_X = \int_{\Omega_T} (u_t^2 + u_x^2 + u_{xx}^2 + u_{xt}^2) dx\, dt. \tag{2.8}$$

For θ as above, it is known (see, e.g., [LM, p.9]) that the boundary functions $\theta(0,\cdot)$ and $\theta(1,\cdot)$ lie in $H^{3/4}(0,T)$, $\theta_x(1,t)$ in $H^{1/4}(0,T)$, and $\theta(x,0)$ in $H^1(0,1)$. These facts imply that the initial-boundary data must have the degree of regularity described below. The only properties of these fractional Sobolev spaces that we shall need are that they are Hilbert spaces and that they satisfy compact imbedding theorems. For a full treatment of these spaces, we refer the interested reader to [LM]. The definitions of any unexplained spaces or notation may be found in [LSU], but we mention one item in particular here since the notation may be unfamiliar to some. The Banach space $W^1_\infty(R)$ consists of all essentially bounded functions defined on R having a generalized derivative that is also essentially bounded; the norm of this space is the sum of the essential suprema of the function and its derivative.

We can now give a complete description of the initial-boundary value problem that we will consider in this paper.

Given φ in $H^1(0,1)$, m in $H^1(0,T)$, and a nonnegative k in $W^1_\infty(R)$, find θ in $W^{2,1}(\Omega_T)$ and u in X such that

$$\theta_{xx} = \theta_t + au_{xt} \quad \text{in } \Omega_T, \tag{2.9}$$
$$u_{xx} = a\theta_x \quad \text{in } \Omega_T, \tag{2.10}$$
$$\theta(0,t) = m(t), \qquad 0 < t < T, \tag{2.11}$$
$$\theta(x,0) = \varphi(x), \qquad 0 < x < 1, \tag{2.12}$$
$$-\theta_x(1,t) = k\theta(1,t), \qquad 0 < t < T, \tag{2.13}$$
$$u(0,t) = 0, \qquad 0 < t < T, \tag{2.14}$$
$$u(1,t) \le g, \qquad 0 < t < T, \tag{2.15}$$
$$u_x(1,t) \le a\theta(1,t), \qquad 0 < t < T, \tag{2.16}$$
$$[u(1,t) - g][u_x(1,t) - a\theta(1,t)] = 0, \qquad 0 < t < T, \tag{2.17}$$

where $k = k(g - u + u_x - a\theta)$ is given by (2.5). Of course, to find a solution with the desired degree of regularity the data must be compatible, i.e., $\varphi(0) = m(0)$.

It turns out, as was shown in [SS1], [SS2], that the problem (2.9)–(2.17) decouples and can be formulated equivalently in terms of the temperature only. It is this problem that we will solve here. The reformulation is obtained by performing a number of integrations with respect to x, using the boundary conditions. We refer the interested reader to [SS2] for the details. Once the temperature is found, the displacement is given by

$$u(x,t) = a\int_0^x \theta(\xi,t)\,d\xi - x\max\left\{a\int_0^1 \theta(\xi,t)\,d\xi - g, 0\right\}. \tag{2.18}$$

In particular, the displacement of the right edge is

$$u(1,t) = \min\left\{a\int_0^1 \theta(\xi,t)d\xi, g\right\}. \tag{2.19}$$

Also $\sigma(x,t) = \sigma(t)$, as can be seen from (2.10) upon recalling that $\sigma = u_x - a\theta$. It was shown in [SS1], [SS2] that

$$\sigma(t) = \min\left\{g - a\int_0^1 \theta(\xi,t)d\xi, 0\right\}. \tag{2.20}$$

We turn next to consider k and its argument. Using (2.19) and (2.20) we have

$$\begin{aligned}\eta = g - u - \sigma &= g - \min\left\{a\int_0^1 \theta(\xi,t)d\xi, g\right\} + \min\left\{g - a\int_0^1 \theta(\xi,t)d\xi, 0\right\}\\ &= g - a\int_0^1 \theta(\xi,t)d\xi.\end{aligned} \tag{2.21}$$

It is interesting to note that k has a nonlocal argument. We can now state our main result.

THEOREM 2.1. *Given φ in $H^1(0,1)$ and m in $H^1(0,T)$ and a nonnegative k in $W^1_\infty(R)$, there exists a $T_0 \le T$ and a θ in $W_2^{2,1}(\Omega_{T_0})$ which satisfies the conditions*

$$\begin{aligned}(1+a^2)\theta_t - \theta_{xx} &= a\frac{d}{dt}\max\left\{a\int_0^1 \theta(\xi,t)d\xi - g, 0\right\} \quad \text{in } \Omega_{T_0},\\ \theta(0,t) &= m(t) \qquad 0 < t < T_0,\\ -\theta_x(1,t) &= k\left(g - a\int_0^1 \theta(\xi,t)d\xi\right)\theta(1,t) \qquad 0 < t < T_0,\\ \theta(x,0) &= \varphi(x) \qquad 0 < x < 1,\end{aligned} \tag{2.22}$$

provided $0 < a < 1$ and φ and m satisfy the compatibility condition $\varphi(0) = m(0)$. Moreover, if $\varphi_n \to \varphi$ in $H^1(0,1)$ and $m_n \to m$ in $H^1(0,T_0)$, and θ_n and θ are the corresponding solutions, then $\theta_n \to \theta$ in $L^2(\Omega_{T_0})$. Finally, for any T_0, if the solution to (2.22) exists, then it is unique.

As previously indicated, the constant a is typically close to zero, and hence it is possible to satisfy the hypothesis of the theorem. It is shown in [SS2] that if θ satisfies the conditions of Theorem 2.1 and if u is given by (2.18), then the pair $\{\theta, u\}$ solves the problem (2.9)–(2.17). The proof of Theorem 2.1 is given in §5.

3. An abstract existence theorem. In this section we prove an abstract existence result that is used in the proof of Theorem 2.1. The result is of some independent interest and is similar in flavor to results described in Chapter 10 of [BC] in that Fan's lemma plays a key role.

Let Y be a Banach space with dual Y^*, and let K be a convex subset of Y. Let ρ denote a proper convex functional on K, and let κ be a topology on K that is stronger than the norm topology and such that ρ is lower semicontinuous in the κ-topology and ρ-bounded and κ-closed subsets of K are norm compact. We denote the duality pairing between Y and Y^* by $\langle \cdot, \cdot \rangle$. Let Z be a subspace of Y^*. Let A and B be two operators (not necessarily linear) mapping K into Y^* so that the following conditions hold:

(A1) The operators A and B are κ-to-weak* continuous; the range of B is in Z;

(A2) The operator A is monotone, i.e., for any $u, v \in K$ with $u \neq v$ we have that

$$\langle Au - Av, u - v \rangle > 0; \tag{3.1}$$

(A3) There exists a function $F : Z \to R$ and constants $\beta \geq 0, \lambda > 0$ and $\gamma \geq 0$ so that

(i) For each $y^* \in Z$ there is a $y_0 \in K$ such that

$$\langle Ay_0, y - y_0 \rangle \geq \langle y^*, y - y_0 \rangle \quad \forall y \in K, \tag{3.2}$$

and

$$\rho(y_0) \leq F(y^*) + \beta; \tag{3.3}$$

(ii) For each $y \in K$ we have that

$$F(By) \leq \lambda \rho(y) + \gamma; \tag{3.4}$$

(iii) for each $y^* \in Z$ there exists a constant $c_{y^*} \geq 0$ such that

$$F(y^* + w^*) \leq F(w^*) + c_{y^*} \quad \forall w^* \in Z. \tag{3.5}$$

We can now state our abstract existence result.

THEOREM 3.1. *Assume that $\lambda < 1$. Under the assumptions* (A1)–(A3) *we have that for every y^* in Z there exists a $y_0 \in K$ such that*

$$\langle Ay_0 - By_0, y - y_0 \rangle \geq \langle y^*, y - y_0 \rangle \quad \forall y \in K. \tag{3.6}$$

Proof. It suffices to establish the existence of y_0 when $y^* = 0$ since the general case may be reduced to this by replacing A by $A - y^*$. In this reduction we use part (iii) of assumption (A3), and this is the only place where this condition is used in the proof.

Since $\lambda < 1$ and ρ is proper, we can choose $\delta > (\beta + \gamma)/(1 - \lambda) \geq 0$ so that the convex set K_δ, defined by

$$K_\delta = \{ y \in K : \rho(y) \leq \delta \}, \tag{3.7}$$

is nonempty. Notice that the hypotheses imply that K_δ is norm compact. Consider the problem of finding y_1 in K_δ so that

$$\langle Ay_1 - By_1, y - y_1 \rangle \geq 0 \quad \forall y \in K_\delta. \tag{3.8}$$

For each $y \in K_\delta$ we define

$$K(y) = \{ w \in K_\delta : \langle Aw - Bw, y - w \rangle \geq 0 \}.$$

The existence of y_1 in (3.8) is thus equivalent to the assertion that $\bigcap_{y\in K_\delta} K(y) \neq \emptyset$. To establish this latter fact we use Fan's lemma [BC, p. 208]. Note that, for each y, $K(y)$ is nonempty since $y \in K(y)$. Next we show that each $K(y)$ is κ-closed and hence norm compact. Note that κ is first countable since it is stronger than the norm topology. Hence we may check closure using sequences. Let $\{w_n\}$ be a sequence in $K(y)$ that converges in κ and hence in norm to an element w (necessarily in K_δ). Since A and B are κ-to-weak* continuous, it follows that

$$Aw_n - Bw_n \rightarrow Aw - Bw \quad \text{weak* in } Y^*,$$

and hence

$$\begin{aligned} 0 \leq \langle Aw_n - Bw_n, y - w_n\rangle =& \langle Aw_n - Bw_n, y - w\rangle + \langle Aw_n - Bw_n, w - w_n\rangle \\ \rightarrow& \langle Aw - Bw, y - w\rangle. \end{aligned}, \tag{3.9}$$

This shows that each $K(y)$ is κ-closed. It remains to be shown that for each finite subset $\{y_1, \cdots, y_n\}$ of K_δ we have that

$$co\{y_1, \cdots, y_n\} \subset \bigcup_{i=1}^{n} K(y_i).$$

Assume, by way of contradiction, that there exists an element $y = \sum_{i=1}^n \lambda_i y_i$ (with $\lambda_i \geq 0$ and $\sum_{i=1}^n \lambda_i = 1$) so that $y \notin K(y_i)$ for each i, i.e.,

$$\langle Ay - By, y_i - y\rangle < 0.$$

But then

$$0 = \langle Ay - By, y - y\rangle = \sum_{i=1}^{n} \lambda_i \langle Ay - By, y_i - y\rangle < 0,$$

a contradiction. Since all conditions of Fan's lemma are satisfied, we have that $\bigcap_{y\in K_\delta} K(y)$ is nonempty. Let y_1 be any point in the intersection. Then by (A3) there is a $y_0 \in K$ so that

$$\langle Ay_0, y - y_0\rangle \geq \langle By_1, y - y_0\rangle \quad \forall y \in K, \tag{3.10}$$

$$\rho(y_0) \leq F(By_1) + \beta, \tag{3.11}$$

$$F(By_1) \leq \lambda\rho(y_1) + \gamma. \tag{3.12}$$

Now (3.11) and (3.12) imply that

$$\rho(y_0) - \beta \leq \lambda\rho(y_1) + \gamma,$$

and hence

$$\rho(y_0) \leq \lambda\rho(y_1) + \gamma + \beta \leq (\lambda)\delta + (1 - \lambda)\delta = \delta,$$

by the choice of δ above. Thus $y_0 \in K_\delta$, and so

$$\langle Ay_1 - By_1, y_0 - y_1\rangle \geq 0. \tag{3.13}$$

On the other hand, substituting $y = y_1$ in (3.10) yields

$$\langle Ay_0 - By_1, y_1 - y_0\rangle \geq 0. \tag{3.14}$$

Combining (3.13) and (3.14) gives

$$\langle Ay_0 - Ay_1, y_1 - y_0\rangle \geq 0$$

or

$$\langle Ay_0 - Ay_1, y_0 - y_1\rangle \leq 0. \tag{3.15}$$

Hence, by condition (A2), we have that $y_0 = y_1$. Consequently, (3.10) may be written as

$$\langle Ay_0 - By_0, y - y_0\rangle \geq 0 \quad \forall y \in K,$$

which is the desired result for $y^* = 0$.

4. A priori estimates and an auxiliary result. In this section we will see how the abstract existence theorem of §3 may be applied to prove the existence of a solution to an auxiliary problem. We seek a solution θ, which lies in the space $W_2^{2,1}(\Omega_T)$. The convex set K will thus be a subset of this space. In order to construct the space Y and the convex functional ρ of the theorem, we need an estimate on the size of solutions to the initial-boundary value problem. This estimate is furnished by Lemma 4.2. This lemma also contains a second estimate, which we will use in §5 to complete the proof of Theorem 2.1. In order to derive this second estimate we need a preliminary lemma, Lemma 4.1, which allows us to control the size of $\theta(1,\cdot)$ in a particular manner. To motivate this result, we recall that there exists a constant c so that $\|\theta(1,\cdot)\|^2_{L^6(0,T)} \leq c\|\theta\|_{W_2^{2,1}(\Omega_T)}$ for all θ in $W_2^{2,1}(\Omega_T)$. However, in general, this constant depends upon T . The purpose of the next lemma is to show that the dependence upon T may be concentrated in the initial-boundary data.

LEMMA 4.1. *Let θ be in $H^1(\Omega_T)$, and suppose that $\theta(0,t) = m(t)$ and $\theta(x,0) = \varphi(x)$ are in $L^\infty(0,T)$ and $L^\infty(0,1)$, respectively. Then*

$$\|\theta(1,\cdot)\|^2_{L^6(0,T)}$$
$$\leq c\Big(\|\theta_t\|^2_{L^2(\Omega_T)} + \|\theta_x\|^2_{L^2(\Omega_T)} + (1+T^2)\,\|\varphi\|^2_{L^\infty(0,1)} + \left(1+T^{1/3}+T\right)\|m\|^2_{L^\infty(0,T)}\Big),$$

where c is a constant that is independent of θ and T.

Proof. We suppose first that $m(t) = 0$. Then by integrating the equality

$$\theta^6(1,t) = 3\theta^3(1,t)\int_0^1 \theta^2(x,t)\theta_x(x,t)dx$$

over [0,T] and then repeatedly using the Cauchy–Schwarz inequality, we obtain

$$\int_0^T \theta^6(1,t)dt$$
$$\leq 3\int_0^T \theta^3(1,t)\int_0^1 |\theta^2(x,t)\theta_x(x,t)|dx\,dt$$
$$\leq 3\left(\int_0^T \theta^6(1,t)dt\right)^{1/2}\left(\int_0^T\left(\int_0^1 |\theta^2(x,t)\theta_x(x,t)|dx\right)^2 dt\right)^{1/2}$$
$$\leq 3\left(\int_0^T \theta^6(1,t)dt\right)^{1/2}\left(\int_0^T\left(\int_0^1 \theta^4(x,t)dx\right)\left(\int_0^1 \theta_x^2(x,t)dx\right)dt\right)^{1/2}$$
$$\leq 3\left(\int_0^T \theta^6(1,t)dt\right)^{1/2}\operatorname*{ess\,sup}_{0<t<T}\left(\int_0^1 \theta^4(x,t)dx\right)^{1/2}\left(\int_0^T\int_0^1 \theta_x^2(x,t)dx\,dt\right)^{1/2}.$$

It follows that

(4.1)
$$\left(\int_0^T \theta^6(1,t)dt\right)^{1/3} \le 3^{2/3} \operatorname*{ess\,sup}_{0<t<T} \left(\int_0^1 \theta^4(x,t)dx\right)^{1/3} \left(\int_0^T \int_0^1 \theta_x^2(x,t)dx\,dt\right)^{1/3}.$$

We now release the assumption that $\theta(0,t)=0$ and apply (4.1) to $\theta - m(t)$ to obtain

(4.2)
$$\begin{aligned} &\|\theta(1,\cdot)\|^2_{L^6(0,T)} \\ &\le 2\left(\|\theta(1,\cdot)-m\|^2_{L^6(0,T)} + \|m\|^2_{L^6(0,T)}\right) \\ &\le c\left(\operatorname*{ess\,sup}_{0<t<T} \|\theta(\cdot,t)-m(t)\|^{4/3}_{L^4(0,1)}\|\theta_x\|^{2/3}_{L^2(\Omega_T)} + \|m\|^2_{L^6(0,T)}\right) \\ &\le c\left(\left(\operatorname*{ess\,sup}_{0<t<T} \|\theta(\cdot,t)\|^{4/3}_{L^4(0,1)} + \|m\|^{4/3}_{L^\infty(0,T)}\right)\|\theta_x\|^{2/3}_{L^2(\Omega_T)} + \|m\|^2_{L^6(0,T)}\right) \\ &\le c\left(\operatorname*{ess\,sup}_{0<t<T} \|\theta(\cdot,t)\|^{4/3}_{L^4(0,1)}\|\theta_x\|^{2/3}_{L^2(\Omega_T)} + \|m\|^2_{L^\infty(0,T)} + \|\theta_x\|^2_{L^2(\Omega_T)} + \|m\|^2_{L^6(0,T)}\right). \end{aligned}$$

Here c denotes a constant that is independent of θ and T but that changes from line to line. We now estimate $\operatorname{ess\,sup}_{0<t<T} \|\theta(\cdot,t)\|^{4/3}_{L^4(0,1)}$ by assuming first that $\theta(x,0)=0$ and then applying the Cauchy–Schwarz inequality to the equality

$$\int_0^1 \theta^4(x,t)dx = 2\int_0^1 \theta^2(x,t)\left(\int_0^t \theta(x,s)\theta_s(x,s)ds\right)dx$$

as before to obtain

$$\begin{aligned} &\int_0^1 \theta^4(x,t)dx \\ &\quad\le 2\left(\int_0^1 \theta^4(x,t)dx\right)^{1/2}\left(\int_0^1\left(\int_0^t \theta(x,s)\theta_s(x,s)ds\right)^2 dx\right)^{1/2} \\ &\quad\le 2\left(\int_0^1 \theta^4(x,t)dx\right)^{1/2}\left(\int_0^1\left(\int_0^t \theta^2(x,s)ds\right)\left(\int_0^t \theta_s^2(x,s)ds\right)dx\right)^{1/2} \\ &\quad\le 2\left(\int_0^1 \theta^4(x,t)dx\right)^{1/2} \operatorname*{ess\,sup}_{0<x<1}\left(\int_0^t \theta^2(x,s)ds\right)^{1/2}\left(\int_0^1\int_0^t \theta_s^2(x,s)ds\,dx\right)^{1/2}. \end{aligned}$$

It follows that

(4.3)
$$\begin{aligned} &\operatorname*{ess\,sup}_{0<t<T}\|\theta(\cdot,t)\|^{4/3}_{L^4(0,1)} \\ &\quad\le 2^{1/3} \operatorname*{ess\,sup}_{0<x<1}\left(\int_0^T \theta^2(x,s)ds\right)^{1/3}\left(\int_0^1\int_0^T \theta_s^2(x,s)ds\,dx\right)^{1/3}. \end{aligned}$$

Again we release the assumption that $\theta(x,0)=0$ and apply (4.3) to $\theta-\varphi$ to obtain

$$
\begin{aligned}
&\operatorname*{ess\,sup}_{0<t<T}\|\theta(\cdot,t)\|^{4/3}_{L^4(0,1)}\\
&\quad\le c\left(\operatorname*{ess\,sup}_{0<t<T}\|\theta(\cdot,t)-\varphi\|^{4/3}_{L^4(0,1)}+\|\varphi\|^{4/3}_{L^4(0,1)}\right)\\
&\quad\le c\left(\operatorname*{ess\,sup}_{0<x<1}\|\theta(x,\cdot)-\varphi\|^{2/3}_{L^2(0,T)}\|\theta_t\|^{2/3}_{L^2(\Omega_T)}+\|\varphi\|^{4/3}_{L^4(0,1)}\right)\\
&\quad\le c\left(\operatorname*{ess\,sup}_{0<x<1}\|\theta(x,\cdot)\|^{2/3}_{L^2(0,T)}\|\theta_t\|^{2/3}_{L^2(\Omega_T)}+T^{2/3}\|\varphi\|^{2/3}_{L^\infty(0,1)}\|\theta_t\|^{2/3}_{L^2(\Omega_T)}+\|\varphi\|^{4/3}_{L^4(0,1)}\right).
\end{aligned}
\tag{4.4}
$$

Using the result (4.4) in (4.2) and then using Young's inequality, we have that

$$
\begin{aligned}
&\|\theta(1,\cdot)\|^2_{L^6(0,T)}\\
&\quad\le c\Bigg(\operatorname*{ess\,sup}_{0<x<1}\|\theta(x,\cdot)\|^{2/3}_{L^2(0,T)}\|\theta_t\|^{2/3}_{L^2(\Omega_T)}\|\theta_x\|^{2/3}_{L^2(\Omega_T)}\\
&\qquad\quad+T^{2/3}\|\varphi\|^{2/3}_{L^\infty(0,1)}\|\theta_t\|^{2/3}_{L^2(\Omega_T)}\|\theta_x\|^{2/3}_{L^2(\Omega_T)}\\
&\qquad\quad+\|\varphi\|^{4/3}_{L^4(0,1)}\|\theta_x\|^{2/3}_{L^2(\Omega_T)}+\|m\|^2_{L^\infty(0,T)}+\|\theta_x\|^2_{L^2(\Omega_T)}+\|m\|^2_{L^6(0,T)}\Bigg)\\
&\quad\le c\Bigg(\operatorname*{ess\,sup}_{0<x<1}\|\theta(x,\cdot)\|^2_{L^2(0,T)}+\|\theta_t\|^2_{L^2(\Omega_T)}+\|\theta_x\|^2_{L^2(\Omega_T)}\\
&\qquad\quad+(1+T^2)\|\varphi\|^2_{L^\infty(0,1)}+\left(1+T^{1/3}\right)\|m\|^2_{L^\infty(0,T)}\Bigg)\\
&\quad\le c\Bigg(\|\theta_t\|^2_{L^2(\Omega_T)}+\|\theta_x\|^2_{L^2(\Omega_T)}+(1+T^2)\|\varphi\|^2_{L^\infty(0,1)}+\left(1+T^{1/3}+T\right)\|m\|^2_{L^\infty(0,T)}\Bigg).
\end{aligned}
$$

This is the desired result.

LEMMA 4.2. *Let f be in $L^2(\Omega_T)$, φ in $H^1(0,1)$, m in $H^1(0,T)$, and let k in $W^1_\infty(R)$ be nonnegative. Suppose θ in $W^{2,1}_2(\Omega_T)$ satisfies the following conditions*:

$$(1+a^2)\theta_t-\theta_{xx}=f\quad in\ \Omega_T,\tag{4.5}$$

$$\theta(x,0)=\varphi(x),\qquad 0<x<1,\tag{4.6}$$

$$\theta(0,t)=m(t),\qquad 0<t<T,\tag{4.7}$$

$$k(t)\theta(1,t)+\theta_x(1,t)=0,\qquad 0<t<T.\tag{4.8}$$

Then

$$
\begin{aligned}
&\frac{3(1+a^2)^2}{4}\|\theta_t\|^2_{L^2(\Omega_T)}+\|\theta_{xx}\|^2_{L^2(\Omega_T)}+\frac{(1+a^2)}{T}(1-4T\|k'\|_{L^\infty(R)})\|\theta_x\|^2_{L^2(\Omega_T)}\\
&\quad\le 3\|f\|^2_{L^2(\Omega_T)}+c\Big(\|m\|^2_{H^1(0,T)}+\|\varphi\|^2_{H^1(0,1)}\Big),
\end{aligned}
\tag{4.9}
$$

where $c=c(a,T,\|k\|_{W^1_\infty(R)})$ is a constant that depends only on a, T, and $\|k\|_{W^1_\infty(R)}$. If instead of (4.8) *we assume that*

$$k(\eta)\theta(1,t)+\theta_x(1,t)=0,\tag{4.10}$$

where $\eta = g - a\int_0^1 \xi(x,t)dx$ and ξ is in $W^{2,1}(\Omega_T)$, then we have

$$\begin{aligned}(4.11)\qquad &(a(1+a^2)^2 - cT^{1/6}\|\xi_t\|_{L^2(\Omega_T)})\|\theta_t\|^2_{L^2(\Omega_T)} + \|\theta_{xx}\|^2_{L^2(\Omega_T)}\\ &+\left(\frac{(1+a^2)}{T} - cT^{1/6}\|\xi_t\|_{L^2(\Omega_T)}\right)\|\theta_x\|^2_{L^2(\Omega_T)}\\ &+(1+a^2)\sup_{0\le\tau\le T}\|\theta_x(\cdot,\tau)\|^2_{L^2(0,1)}\\ &\le \frac{(1+a^2)^2}{a^2}\|f\|^2_{L^2(\Omega_T)} + C\Big(\|m\|^2_{H^1(0,T)} + \|\varphi\|^2_{H^1(0,1)}\Big)\\ &+cT^{1/6}\|\xi_t\|_{L^2(\Omega_T)}\Big((1+T^2)\,\|\varphi\|^2_{L^\infty(0,1)} + \left(1+T^{1/3}+T\right)\|m\|^2_{L^\infty(0,T)}\Big),\end{aligned}$$

where $c = c(a, \|k'\|_{L^\infty(R)})$ is a constant that depends only on a and $\|k'\|_{L^\infty(R)}$, and $C = C(a, T, \|k\|_{W^1_\infty(R)})$ is a constant that depends only on a, T, and $\|k\|_{W^1_\infty(R)}$. Moreover, for fixed a and $\|k\|_{W^1_\infty(R)}$, C is an increasing function of T.

Proof. We first establish the result under the additional assumptions that θ_{xt} and θ_{tt} exist as elements of $L^2(\Omega_T)$. Notice that θ must satisfy

$$(1+a^2)(\theta - m)_t - \theta_{xx} = f - (1+a^2)m' \quad \text{in } \Omega_T.$$

Now squaring both sides of the above and integrating over $\Omega_\tau = (0,1)\times(0,\tau)$ yields

$$\begin{aligned}(4.12)\qquad &(1+a^2)^2\|\theta_t\|^2_{L^2(\Omega_\tau)} - 2(1+a^2)\int_{\Omega_\tau}(\theta-m)_t\theta_{xx} + \|\theta_{xx}\|^2_{L^2(\Omega_\tau)}\\ &= \|f\|^2_{L^2(\Omega_\tau)} - 2(1+a^2)\int_{\Omega_\tau} m'f + 2(1+a^2)^2\int_{\Omega_\tau} m'\theta_t.\end{aligned}$$

The two integrals on the right in (4.12) are easily estimated by Cauchy's inequality with ϵ:

$$(4.13)\qquad \left|-2(1+a^2)\int_{\Omega_\tau} m'f\right| \le 2(1+a^2)^2\|m'\|^2_{L^2(0,\tau)} + \frac{1}{2}\|f\|^2_{L^2(\Omega_\tau)},$$

$$(4.14)\qquad \left|2(1+a^2)^2\int_{\Omega_\tau} m'\theta_t\right| \le 4(1+a^2)^2\|m'\|^2_{L^2(0,\tau)} + \frac{(1+a^2)^2}{4}\|\theta_t\|^2_{L^2(\Omega_\tau)}.$$

Applying integration by parts to the integral on the left of (4.10) and using the boundary conditions, we obtain

$$\begin{aligned}-2(1+a^2)\int_0^\tau\int_0^1 (\theta-m)_t\theta_{xx}dx\,dt &= 2(1+a^2)\int_0^\tau\int_0^1 \theta_x\theta_{xt}dx\,dt\\ &\quad - 2(1+a^2)\int_0^\tau \theta_x(x,t)(\theta-m)_t(x,t)\Big|_0^1 dt\\ (4.15)\qquad &= (1+a^2)\|\theta_x(\cdot,\tau)\|^2_{L^2(0,1)} - (1+a^2)\|\varphi'\|^2_{L^2(0,1)}\\ &\quad - 2(1+a^2)\int_0^\tau k(t)m'(t)\theta(1,t)dt\\ &\quad + 2(1+a^2)\int_0^\tau k(t)\theta(1,t)\theta_t(1,t)dt.\end{aligned}$$

We now estimate the two integrals on the right. The first integral in (4.15) may be estimated directly by Cauchy's inequality with ϵ:

$$\begin{aligned}&\left|2(1+a^2)\int_0^\tau m'(t)k(t)\theta(1,t)dt\right|\\ &\leq 2T(1+a^2)\int_0^\tau (m')^2(t)k(t)dt+\frac{(1+a^2)}{2T}\int_0^\tau k(t)\theta^2(1,t)dt\\ &\leq c\|m\|^2_{H^1(0,\tau)}+\frac{(1+a^2)}{2T}\int_0^\tau k(t)\theta^2(1,t)dt.\end{aligned}\tag{4.16}$$

Here c denotes a constant that depends only on a and $\|k\|_{W^1_\infty(R)}$, and from this point until the end of the proof we will use c to designate such a constant. Applying integration by parts to the second integral in (4.15) yields

$$\begin{aligned}2(1+a^2)\int_0^\tau k(t)\theta(1,t)\theta_t(1,t)dt&=(1+a^2)k(\tau)\theta^2(1,\tau)-(1+a^2)k(0)\varphi^2(0)\\ &\quad-(1+a^2)\int_0^\tau k'(t)\theta^2(1,t)dt.\end{aligned}\tag{4.17}$$

Using the results of (4.13)–(4.17) in (4.12) and rearranging terms leads to

$$\begin{aligned}&\left(\frac{3(1+a^2)^2}{4}\right)\|\theta_t\|^2_{L^2(\Omega_\tau)}+\|\theta_{xx}\|^2_{L^2(\Omega_\tau)}\\ &\quad+(1+a^2)\|\theta_x(\cdot,\tau)\|^2_{L^2(0,1)}+(1+a^2)k(\tau)\theta^2(1,\tau)\\ &\leq\frac{3}{2}\|f\|^2_{L^2(\Omega_\tau)}+c\Big(\|m\|^2_{H^1(0,\tau)}+\|\varphi\|^2_{H^1(0,1)}\Big)\\ &\quad+(1+a^2)\int_0^\tau k'(t)\theta^2(1,t)dt+\frac{(1+a^2)}{2T}\int_0^\tau k(t)\theta^2(1,t)dt.\end{aligned}\tag{4.18}$$

In particular, we have that

$$\begin{aligned}&(1+a^2)\|\theta_x(\cdot,\tau)\|^2_{L^2(0,1)}+(1+a^2)k(\tau)\theta^2(1,\tau)\\ &\leq\frac{3}{2}\|f\|^2_{L^2(\Omega_\tau)}+c\Big(\|m\|^2_{H^1(0,\tau)}+\|\varphi\|^2_{H^1(0,1)}\Big)\\ &\quad+(1+a^2)\int_0^\tau k'(t)\theta^2(1,t)dt+\frac{(1+a^2)}{2T}\int_0^\tau k(t)\theta^2(1,t)dt.\end{aligned}\tag{4.19}$$

Integrating (4.19) with respect to τ over the interval [0,T] and then combining terms yields

$$\begin{aligned}&(1+a^2)\|\theta_x\|^2_{L^2(\Omega_T)}+\frac{(1+a^2)}{2}\int_0^T k(\tau)\theta^2(1,\tau)d\tau\\ &\leq\left(\frac{3}{2}\right)T\|f\|^2_{L^2(\Omega_T)}+c\Big(\|m\|^2_{H^1(0,T)}+\|\varphi\|^2_{H^1(0,1)}\Big)\\ &\quad+(1+a^2)T\|k'\|_{L^\infty(R)}\int_0^T\theta^2(1,t)dt.\end{aligned}\tag{4.20}$$

Using (4.18) with τ=T and (4.20) together we obtain

$$\begin{aligned}\left(\frac{3(1+a^2)^2}{4}\right)\|\theta_t\|^2_{L^2(\Omega_T)} + \|\theta_{xx}\|^2_{L^2(\Omega_T)} + \frac{(1+a^2)}{T}\|\theta_x\|^2_{L^2(\Omega_T)} \\ \le 3\|f\|^2_{L^2(\Omega_T)} + c\Big(\|m\|^2_{H^1(0,T)} + \|\varphi\|^2_{H^1(0,1)}\Big) \\ + 2(1+a^2)\|k'\|_{L^\infty(R)}\int_0^T \theta^2(1,t)dt.\end{aligned} \tag{4.21}$$

Using the elementary estimate $\|\theta(1,\cdot)\|^2_{L^2(0,T)} \le 2\|m\|^2_{L^2(0,T)} + 2\|\theta_x\|^2_{L^2(\Omega_T)}$ in (4.17) and rearranging terms yields the first result.

To obtain the second result, we proceed in a similar way using appropriate choices of ϵ in (4.13) and (4.14) to obtain the estimate

$$\begin{aligned}a(1+a^2)^2\|\theta_t\|^2_{L^2(\Omega_\tau)} + \|\theta_{xx}\|^2_{L^2(\Omega_\tau)} + \frac{(1+a^2)}{T}\|\theta_x\|^2_{L^2(\Omega_\tau)} + (1+a^2)\|\theta_x(\cdot,\tau)\|^2_{L^2(0,1)} \\ \le \frac{(1+a^2)^2}{2a^2}\|f\|^2_{L^2(\Omega_\tau)} + C\Big(\|m\|^2_{H^1(0,\tau)} + \|\varphi\|^2_{H^1(0,1)}\Big) \\ + 2a(1+a^2)\int_0^\tau \left|k'(\eta)\Big(\int_0^1 \xi_t(x,t)dx\Big)\theta^2(1,t)\right|dt.\end{aligned} \tag{4.22}$$

Here $C = C(a,T,\|k\|_{W^1_\infty(R)})$ is a constant that depends only on a, T, and $\|k\|_{W^1_\infty(R)}$, and we will use C to designate such a constant from this point on until the end of the proof. It is also easy to check that, for fixed a and $\|k\|_{W^1_\infty(R)}$, that C is an increasing function of T. It will be apparent in the next section why we wish the coefficients of $\|\theta_t\|^2_{L^2(\Omega_\tau)}$ and $\|f\|^2_{L^2(\Omega_\tau)}$ to take on the above form. We now proceed to estimate the last integral on the right. Using the multi-Hölder inequality and then Lemma 4.1, we obtain

$$\begin{aligned}&\int_0^\tau \left|k'(\eta)\Big(\int_0^1 \xi_t(x,t)dx\Big)\theta^2(1,t)\right|dt \\ &\le \|k'(\eta)\|_{L^6(0,\tau)}\|\xi_t\|_{L^2(\Omega_\tau)}\|\theta(1,\cdot)\|^2_{L^6(0,\tau)} \\ &\le c\tau^{1/6}\|\xi_t\|_{L^2(\Omega_\tau)}\Bigg(\|\theta_t\|^2_{L^2(\Omega_\tau)} + \|\theta_x\|^2_{L^2(\Omega_\tau)} + (1+\tau^2)\,\|\varphi\|^2_{L^\infty(0,1)} \\ &\qquad + \left(1+\tau^{1/3}+\tau\right)\|m\|^2_{L^\infty(0,\tau)}\Bigg).\end{aligned}$$

Here c is a constant that depends only on $\|k'\|_{L^\infty(R)}$. Using this estimate in (4.22) and taking appropriate suprema over all τ in $[0,T]$ leads to

$$\begin{aligned}&a(1+a^2)^2\|\theta_t\|^2_{L^2(\Omega_T)} + \|\theta_{xx}\|^2_{L^2(\Omega_T)} + (1+a^2)\sup_{0\le\tau\le T}\|\theta_x(\cdot,\tau)\|^2_{L^2(0,1)} \\ &\quad + \frac{(1+a^2)}{T}\|\theta_x\|^2_{L^2(\Omega_\tau)} \\ &\le \frac{(1+a^2)^2}{a^2}\|f\|^2_{L^2(\Omega_T)} + C\Big(\|m\|^2_{H^1(0,T)} + \|\varphi\|^2_{H^1(0,1)}\Big) \\ &\quad + cT^{1/6}\|\xi_t\|_{L^2(\Omega_T)}\Big(\|\theta_t\|^2_{L^2(\Omega_T)} + \|\theta_x\|^2_{L^2(\Omega_T)} + (1+T^2)\,\|\varphi\|^2_{L^\infty(0,1)} \\ &\qquad + \left(1+T^{1/3}+T\right)\|m\|^2_{L^\infty(0,\tau)}\Big).\end{aligned}$$

Here c depends upon a as well as $\|k'\|_{L^\infty(R)}$. Rearranging the terms yields (4.11).

To obtain the estimate (4.9) for a general θ we apply the forward averaging operator $(1/h)\int_t^{t+h}(\cdot)d\tau$ to both sides of (4.9)–(4.13) to obtain

$$(4.23) \qquad (1+a^2)(\theta_h)_t - (\theta_h)_{xx} = f_h \quad \text{in } \Omega_{T-h},$$

$$(4.24) \qquad \theta_h(x,0) = \varphi_h(x), \qquad 0 < x < 1,$$

$$(4.25) \qquad \theta_h(0,t) = m_h(t), \qquad 0 < t < T-h,$$

$$(4.26) \qquad (k(t)\theta(1,t))_h + (\theta_h)_x(1,t) = 0, \qquad 0 < t < T-h,$$

where in each case the subscripted variable is the forward average of its unsubscripted counterpart. Note that in (4.26) we may replace $(k(t)\theta(1,t))_h$ by $k(t)\theta_h(1,t)$ and still have the right-hand side converge to zero in the norm of $H^1(0,T)$ since $(k(t)\theta(1,t))_h - k(t)\theta_h(1,t)$ converges to zero in $H^1(0,T)$ as h tends to zero. Since θ_h possesses the additional smoothness properties assumed at the start of the proof, we may apply the previous manipulations to (4.23)–(4.26), and then let h tend to zero to obtain the result. The same technique may be applied to produce (4.11).

The following auxiliary result is a generalization of the main result of [SS2], which treats the case when k is a constant.

THEOREM 4.3. *Let m, φ, and k be as in Lemma 4.2. Then there exists a unique θ in $W_2^{2,1}(\Omega_T)$, which satisfies the conditions*

$$\begin{aligned} (1+a^2)\theta_t - \theta_{xx} &= a\frac{d}{dt}\max\left\{a\int_0^1 \theta(\xi,t)d\xi - g, 0\right\} \quad \text{in } \Omega_T,\\ \theta(x,0) &= \varphi(x), \qquad 0<x<1,\\ \theta(0,t) &= m(t), \qquad 0<t<T,\\ k(t)\theta(1,t) + \theta_x(1,t) &= 0, \qquad 0<t<T. \end{aligned}$$

Proof. We establish the result by applying Theorem 3.1 and begin by defining the various items found in the assumptions of that theorem. We suppose first that k satisfies $k_{\min} = \inf k > 0$. Let

$$\begin{aligned} K &= \left\{(\theta, \theta(1,t)) : \theta \in W_2^{2,1}(\Omega_T),\ \theta(x,0) = \varphi(x),\ \theta(0,t) = m(t)\right\},\\ Y &= L^2(\Omega_T) \oplus L^2(0,T),\\ Z &= L^2(\Omega_T) \oplus 0,\\ \kappa &= \text{ the norm topology of } W_2^{2,1}(\Omega_T), \end{aligned}$$

and

$$\rho(\theta) = \left(\frac{3(1+a^2)^2}{4}\|\theta_t\|^2_{L^2(\Omega_T)} + \|\theta_{xx}\|^2_{L^2(\Omega_T)} + \frac{(1+a^2)}{T}(1 - 4T\|k'\|_{L^\infty(R)})\|\theta_x\|^2_{L^2(\Omega_T)}\right)^{1/2}.$$

We shall identify elements of K with their first components. Note that, for T sufficiently small, ρ is a proper convex functional on K and ρ-bounded subsets of K are Y-compact since ρ-bounded subsets of K are $W_2^{2,1}(\Omega_T)$-norm bounded. Define the operators A, B from K into Y^* by

$$A\theta = \Big((1+a^2)\theta_t - \theta_{xx}, (\theta_x + k(t)\theta)(1,t)\Big)$$

and

$$B\theta = \left(a\frac{d}{dt}\max\left(a\int_0^1 \theta(x,t)dx \;-g,0\right),0\right).$$

We now verify that the hypotheses of Theorem 3.1 are satisfied.

(A1) The operator A is easily seen to be κ-to-weak* continuous since if $\theta_n \to \theta$ in $W_2^{2,1}(\Omega_T)$, then $(\theta_n)_t \to \theta_t$ and $(\theta_n)_{xx} \to \theta_{xx}$ in $L^2(\Omega_T)$, while $\theta_n(1,\cdot) \to \theta(1,\cdot)$ in $L^\infty(0,T)$ and $(\theta_n)_x(1,\cdot) \to \theta_x(1,\cdot)$ in $L^2(0,T)$. The continuity of the operator B has already been demonstrated in [SS2], and its range is obviously in Z.

(A2) To show that A is monotone suppose that θ_1, θ_2 are in K and that $\langle A\theta_1 - A\theta_2, \theta_1 - \theta_2\rangle \leq 0$. Let $z = \theta_1 - \theta_2$. Then

$$\begin{aligned}\langle A\theta_1 - A\theta_2, \theta_1 - \theta_2\rangle &= \int_{\Omega_T} \left[(1+a^2)(\theta_1-\theta_2)_t - (\theta_1-\theta_2)_{xx}\right](\theta_1-\theta_2)\\ &\quad + \int_0^T \left[(\theta_1-\theta_2)_x(1,t) + k(t)(\theta_1(1,t)-\theta_2(1,t))\right](\theta_1-\theta_2)(1,t)dt\\ &= \left(\frac{1}{2}\right)(1+a^2)\|z(\cdot,T)\|^2_{L^2(0,1)} - \int_0^T z_x(1,t)z(1,t)dt\\ &\quad + \|z_x\|^2_{L^2(\Omega_T)} + \int_0^T z_x(1,t)z(1,t)dt + \int_0^T k(t)z^2(1,t)dt\\ &\leq 0.\end{aligned}$$

It follows that $z = 0$ and hence $\langle A\theta_1 - A\theta_2, \theta_1 - \theta_2\rangle > 0$ if $\theta_1 \neq \theta_2$.

(A3) Define $F : Z \to R$ by $F\big((f,0)\big) = \sqrt{3}\|f\|_{L^2(0,T)}$, and let

$$\beta = \left(c\|m\|^2_{H^1(0,T)} + c\|\varphi\|^2_{H^1(0,1)}\right)^{1/2},$$

$$\lambda = \frac{2a^2}{(1+a^2)},$$

and

$$\gamma = 0.$$

Here c is the constant of (4.9). Then the following conditions are satisfied.

(i) The inequalities (3.2) and (3.3) hold since for every pair $(f,0)$ in Z there exists a θ in $W_2^{2,1}(\Omega_T)$ satisfying the standard initial-boundary value problem (4.5)–(4.8) [LM, p. 33], and hence the a priori estimate (4.9).

(ii) The inequality (3.4) holds since

$$\|B\theta\|^2_Z \leq a^4\|\theta_t\|^2_{L^2(0,T)} \leq \frac{4a^4}{3(1+a^2)^2}\rho^2(\theta).$$

(iii) The inequality (3.4) holds simply with $c_{y^*} = \|y^*\|$.

Finally, note that $\lambda < 1$ since $a < 1$. This completes the verification of the hypotheses of Theorem 3.1. Consequently, we obtain, if T satisfies $1 - 4T\|k'\|_{L^\infty} > 0$, a function θ in K that satisfies $\langle A\theta - B\theta, \xi - \theta\rangle \geq 0$ for all ξ in K. If we now put $\xi = \theta \pm \psi$, where ψ is in $C^\infty(\Omega_T)$, with $\psi(x,0) = \psi(0,t) = 0$, then it follows that $\langle A\theta - B\theta, \psi\rangle = 0$ for all such ψ. Hence $A\theta = B\theta$, i.e., θ satisfies all the conclusions of the theorem.

To obtain a solution for a general T we appeal to a standard continuation argument. Choose $T_0 > 0$ so that $1 - 4T_0\|k'\|_{L^\infty(R)} > 0$, and then choose n so that

$nT_0 > T > (n-1)T_0$. Let $T_i = iT_0$ for $i = 0, 1, \cdots n-1$, and let $T_n = T$. Then the preceding argument shows that for each i there is a function θ_{i+1} defined on $\Omega_i = (0,1) \times (T_i, T_{i+1})$ and satisfying the conditions

$$\begin{gathered}
(1+a^2)(\theta_{i+1})_t - (\theta_{i+1})_{xx} = a\frac{d}{dt}\max\left\{a\int_0^1 \theta_{i+1}(\xi,t)d\xi - g, 0\right\} \quad \text{in } \Omega_i, \\
\theta_{i+1}(x,T_i) = \theta_i(x,T_i), \qquad 0 < x < 1, \\
\theta_{i+1}(0,t) = m(t), \qquad T_i < t < T_{i+1}, \\
k(t)\theta_{i+1}(1,t) + (\theta_{i+1})_x(1,t) = 0, \qquad T_i < t < T_{i+1}.
\end{gathered}$$

If we now define θ on Ω_T by $\theta(x,t) = \theta_{i+1}(x,t)$ for (x,t) in $(0,1) \times (T_i, T_{i+1})$, then θ is in $W_2^{2,1}(\Omega_T)$ and satisfies the conclusions of the theorem.

Finally, to obtain a solution for a general $k \geq 0$, let $k_n = k + (1/n)$, and let θ_n be the corresponding solution. We have already seen that if f_n is the first component of $B\theta_n$, then $\|f_n\|_{L^2(\Omega_T)} \leq a^2\|(\theta_n)_t\|_{L^2(\Omega_T)}$. Hence the estimate (4.9) shows that

$$\begin{aligned}
\left(\frac{3(1+a^2)^2}{4} - 3a^4\right) &\|(\theta_n)_t\|^2_{L^2(\Omega_T)} + \|(\theta_n)_{xx}\|^2_{L^2(\Omega_T)} \\
&+ \frac{(1+a^2)}{T}(1 - 4T\|k'\|_{L^\infty(R)})\|(\theta_n)_x\|^2_{L^2(\Omega_T)} \\
&\leq c\left(\|m\|^2_{H^1(0,T)} + \|\varphi\|^2_{H^1(0,1)}\right).
\end{aligned}$$

Note that $3(1+a^2)^2/4 - 3a^4 > 0$ since $a < 1$. Consequently, if $1 - 4T\|k'\|_{L^\infty(R)} > 0$, then an expression equivalent to the $W_2^{2,1}(\Omega_T)$ norm of the θ_n's may be bounded by the initial and boundary data. Hence the θ_n's form a relatively weakly compact set in $W_2^{2,1}(\Omega_T)$, and any weak cluster point θ of the set will satisfy $\theta_x(1,t) = k(t)\theta(1,t)$, and will, therefore, satisfy the conclusion of the theorem. To obtain a solution for a general T we can again use a standard continuation argument. This completes the proof of existence. Because uniqueness may be established using the kinds of manipulations that are found in the next section, we postpone further mention of the proof until then.

5. Existence, uniqueness, and stability.

To complete the proof of the existence of a solution to (2.22) we now prepare to employ Schauder's fixed point theorem. We suppose first that $k_{\min} = \inf k > 0$. For each ξ in $W_2^{2,1}(\Omega_T)$, define $\theta = S\xi$ in $W_2^{2,1}(\Omega_T)$ as a solution to the initial-boundary value problem

$$(1+a^2)\theta_t - \theta_{xx} = a\frac{d}{dt}\max\left\{a\int_0^1 \theta(x,t)dx - g, 0\right\} \quad \text{in } \Omega_T, \tag{5.1}$$

$$\theta(x,0) = \varphi(x), \qquad 0 < x < 1, \tag{5.2}$$

$$\theta(0,t) = m(t), \qquad 0 < t < T, \tag{5.3}$$

$$k\left(g - a\int_0^1 \xi(x,t)dx\right)\theta(1,t) + \theta_x(1,t) = 0, \qquad 0 < t < T. \tag{5.4}$$

Note that the existence of such a θ is guaranteed by Theorem 4.3. Now since

$$\left\|a\frac{d}{dt}\max\left\{a\int_0^1 \theta(x,t)dx - g, 0\right\}\right\|^2_{L^2(0,T)} \leq a^4\|\theta_t\|^2_{L^2(0,T)},$$

the estimate (4.11) implies that

$$\begin{aligned}(5.5)\qquad &(a(1-a)(1+a^2)^2 - cT^{1/6}\|\xi_t\|_{L^2(\Omega_T)})\|\theta_t\|^2_{L^2(\Omega_T)} + \|\theta_{xx}\|^2_{L^2(\Omega_T)} \\ &\quad + \left(\frac{(1+a^2)}{T} - cT^{1/6}\|\xi_t\|_{L^2(\Omega_T)}\right)\|\theta_x\|^2_{L^2(\Omega_T)} \\ &\quad + (1+a^2)\sup_{0\le\tau\le T}\|\theta_x(\cdot,\tau)\|^2_{L^2(0,1)} \\ &\le C\Big(\|m\|^2_{H^1(0,T)} + \|\varphi\|^2_{H^1(0,1)}\Big) \\ &\quad + cT^{1/6}\|\xi_t\|_{L^2(\Omega_T)}\Big(\left(1+T^2\right)\|\varphi\|^2_{L^\infty(0,1)} + \left(1+T^{1/3}+T\right)\|m\|^2_{L^\infty(0,T)}\Big),\end{aligned}$$

where $c = c(a, \|k'\|_{L^\infty(R)})$ is a constant that depends only on a and $\|k'\|_{L^\infty(R)}$, and $C = C(a,T,\|k\|_{W^1_\infty(R)})$ is a constant that depends only on a, T, and $\|k\|_{W^1_\infty(R)}$. We now choose T_0 so that

$$cT_0^{1/6}\left(\frac{2}{a(1-a)(1+a^2)^2}\right)^{1/2}\Big(\left(1+T^2\right)\|\varphi\|^2_{L^\infty(0,1)} + \left(1+T^{1/3}+T\right)\|m\|^2_{L^\infty(0,T)}\Big) < \frac{1}{2},$$

and then choose $M > 1$ so that $M > 2C(a,T,\|k\|_{W^1_\infty(R)})(\|m\|^2_{H^1(0,T)} + \|\varphi\|^2_{H^1(0,1)})$. Note that any smaller value for T_0 will satisfy the above inequality. Consequently, we may choose $0 < T_0 \le \min(1,T)$ so that the following additional conditions hold:

$$a(1-a)(1+a^2)^2 - cT_0^{1/6}\left(\frac{2M}{a(1-a)(1+a^2)^2}\right)^{1/2} > \frac{a(1-a)(1+a^2)^2}{2},$$

$$\frac{(1+a^2)}{T_0} - cT_0^{1/2}\left(\frac{2M}{a(1-a)(1+a^2)^2}\right)^{1/2} > (1+a^2).$$

We now define

$$\begin{aligned}K = \Big\{\xi \in W_2^{2,1}(\Omega_T) :\ &\xi(x,0) = \varphi(x), \xi(0,t) = m(t), \\ &\frac{a(1-a)(1+a^2)^2}{2}\|\xi_t\|^2_{L^2(\Omega_{T_0})} + \|\xi_{xx}\|^2_{L^2(\Omega_{T_0})} + (1+a^2)\|\xi_x\|^2_{L^2(\Omega_{T_0})} \le M\Big\}.\end{aligned}$$

Then, recalling that C is an increasing function of T, (5.5) shows that S maps K into K. Note that K is compact when regarded as a subset of $L^2(\Omega_{T_0})$ since it is bounded in $W_2^{2,1}(\Omega_{T_0})$, and $W_2^{2,1}(\Omega_{T_0})$ embeds compactly into $L^2(\Omega_{T_0})$ [LSU, p. 74]. We now need only show that S is well defined, i.e., that the solution to (5.1)–(5.4) is unique, and that if ξ_n and ξ are in K and $\xi_n \to \xi$ in $L^2(\Omega_{T_0})$, then $S\xi_n \to S\xi$ in $L^2(\Omega_{T_0})$. Since the proofs of these two statements require essentially the same manipulations, we content ourselves with presenting a proof of the latter. Toward this end, let $\theta_n = S\xi_n, \theta = S\xi$, and $w_n = \int_0^t(\theta - \theta_n)$. Note that w_n must satisfy the conditions

$$\begin{aligned}(5.6)\qquad (1+a^2)(w_n)_t - (w_n)_{xx} &= f(\theta,\theta_n), \\ (w_n)(x,0) &= 0, \\ (w_n)(0,t) &= 0, \\ -(w_n)_x(1,t) &= \int_0^t (k_n)(w_n)_s(1,s)ds + \int_0^t (k_n - k_0)\theta(1,s)ds,\end{aligned}$$

where

$$f(\theta,\theta_n)=a\max\left\{a\int_0^1\theta(x,t)dx-g,0\right\}-a\max\left\{a\int_0^1\theta_n(x,t)dx-g,0\right\},$$

$$k_n=k(\eta_n)=k\left(g-a\int_0^1\xi_n(x,s)dx\right),$$

$$k_0=k(\eta)=k\left(g-a\int_0^1\xi(x,s)dx\right).$$

Note that, for each τ satisfying $0<\tau<T$, we have that

$$\|f(\theta,\theta_n)\|^2_{L^2(\Omega_\tau)}\le a^4\|w_t\|^2_{L^2(\Omega_\tau)}.$$

Squaring both sides of (5.6) and integrating over Ω_τ, we obtain

$$\begin{aligned}(1+a^2)^2\|(w_n)_t\|^2_{L^2(\Omega_\tau)}-2(1+a^2)\int_{\Omega_\tau}(w_n)_t(w_n)_{xx}\,dx\,dt+\|(w_n)_{xx}\|^2_{L^2(\Omega_\tau)}&\\ =\|f(\theta,\theta_n)\|^2_{L^2(\Omega_\tau)}&\\ \le a^4\|(w_n)_t\|^2_{L^2(\Omega_\tau)}.&\end{aligned}\tag{5.7}$$

We now proceed, as in Lemma 4.1, to apply integration by parts to the integral on the left of (5.7) and thus obtain

$$\begin{aligned}-2(1+a^2)\int_{\Omega_\tau}(w_n)_t(w_n)_{xx}\,dx\,dt&=(1+a^2)\|(w_n)_x(\cdot,\tau)\|^2_{L^2(0,1)}\\ &\quad+2(1+a^2)\int_0^\tau(w_n)_t(1,t)\int_0^t(k_n)(w_n)_s(1,s)\,ds\,dt\\ &\quad+2(1+a^2)\int_0^\tau(w_n)_t(1,t)\int_0^t(k_n-k_0)\theta(1,s)\,ds\,dt.\end{aligned}\tag{5.8}$$

Applying integration by parts twice to the first integral on the right in (5.8) yields

$$\begin{aligned}&\int_0^\tau(w_n)_s(1,t)\int_0^t(k_n)(w_n)_t(1,s)ds\,dt\\ &\quad=w(1,\tau)\int_0^\tau(k_n)(w_n)_s(1,s)\,ds\\ &\qquad-\int_0^\tau(w_n)(1,t)(k_n)(w_n)_t(1,t)\,dt\\ &\quad=\frac{1}{2}w_n^2(1,\tau)k_n(\tau)\\ &\qquad+aw_n(1,\tau)\int_0^\tau k'(\eta_n)\left(\int_0^1(\xi_n)_s(x,s)dx\right)w_n(1,s)\,ds\\ &\qquad-\frac{1}{2}a\int_0^\tau k'(\eta_n)\left(\int_0^1(\xi_n)_s(x,s)dx\right)w_n^2(1,s)\,ds,\end{aligned}\tag{5.9}$$

where the prime denotes differentiation with respect to the argument. Applying a single integration by parts to the second integral in (5.8) yields

$$\begin{aligned}\int_0^\tau(w_n)_t(1,t)\int_0^t(k_n-k_0)\theta(1,s)ds\,dt&=w_n(1,\tau)\int_0^\tau(k_n-k_0)\theta(1,s)ds\\ &\quad-\int_0^\tau(w_n)(1,t)(k_n-k_0)\theta(1,t)dt.\end{aligned}\tag{5.10}$$

Using the results of (5.8)–(5.10) in (5.7) and rearranging terms, we obtain

$$\begin{aligned}(1+2a^2)\|(w_n)_t\|^2_{L^2(\Omega_\tau)} &+ (1+a^2)\|(w_n)_x(\cdot,\tau)\|^2_{L^2(0,1)}\\ &+ \|(w_n)_{xx}\|^2_{L^2(\Omega_\tau)} + (1+a^2)w_n^2(1,\tau)k_n(\tau)\\ &\leq -2a(1+a^2)w_n(1,\tau)\int_0^\tau k'(\eta_n)\left(\int_0^1(\xi_n)_s(x,s)\,dx\right)w_n(1,s)ds\\ &+ a(1+a^2)\int_0^\tau k'(\eta_n)\left(\int_0^1(\xi_n)_s(x,s)dx\right)w_n^2(1,s)\,ds\\ &- 2(1+a^2)w_n(1,\tau)\int_0^t(k_n-k_0)\theta(1,s)ds\\ &+ 2(1+a^2)\int_0^\tau(w_n)(1,t)(k_n-k_0)\theta(1,t)dt.\end{aligned}\tag{5.11}$$

We now estimate the four integrals on the right in (5.11). The first integral may be estimated using the Cauchy–Schwarz inequality and then Cauchy's inequality with ϵ:

$$\begin{aligned}&\left|2a(1+a^2)w_n(1,\tau)\int_0^\tau k'(\eta_n)\left(\int_0^1(\xi_n)_s(x,s)dx\right)w_n(1,s)ds\right|\\ &\quad\leq 2a(1+a^2)|w_n(1,\tau)|\ \|k'\|_{L^\infty(R)}\|(\xi_n)_s\|_{L^2(\Omega_\tau)}\|w_n(1,\cdot)\|_{L^2(0,\tau)}\\ &\quad\leq \frac{(1+a^2)}{4}w_n^2(1,\tau)k_n(\tau)\\ &\qquad+ 4a^2(1+a^2)k_n(\tau)^{-1}\|k'\|^2_{L^\infty(R)}\|(\xi_n)_s\|^2_{L^2(\Omega_\tau)}\|w_n(1,\cdot)\|^2_{L^2(0,\tau)}.\end{aligned}\tag{5.12}$$

The second integral may be estimated using the Cauchy–Schwarz inequality and then Cauchy's inequality with ϵ:

$$\begin{aligned}&a(1+a^2)\int_0^\tau\left|k'(\eta_n)\left(\int_0^1(\xi_n)_s(x,t)dx\right)w_n^2(1,t)\right|dt\\ &\leq a(1+a^2)\|k'\|_{L^\infty(R)}\|(\xi_n)_t\|_{L^2(\Omega_\tau)}\|(w_n)(1,\cdot)\|_{L^\infty(0,\tau)}\|(w_n)(1,\cdot)\|_{L^2(0,\tau)}\\ &\leq k_{\min}\frac{(1+a^2)}{4}\|(w_n)(1,\cdot)\|^2_{L^\infty(0,\tau)}\\ &\quad+ k_{\min}^{-1}a^2(1+a^2)\|k'\|^2_{L^\infty(R)}\|(\xi_n)_s\|^2_{L^2(\Omega_\tau)}\|(w_n)(1,\cdot)\|^2_{L^2(0,\tau)}\end{aligned}\tag{5.13}$$

The last two integrals are easily estimated using Cauchy's inequality with ϵ:
(5.14)

$$\begin{aligned}\left|2(1+a^2)w_n(1,\tau)\int_0^\tau(k_n-k_0)\theta(1,s)ds\right| &\leq \frac{(1+a^2)}{4}w_n^2(1,\tau)k_n(\tau)\\ &\quad+ 4(1+a^2)k_n(\tau)^{-1}\int_0^\tau(k_n-k_0)^2\theta^2(1,s)ds,\\ \left|2(1+a^2)\int_0^\tau(w_n)(1,t)(k_n-k_0)\theta(1,t)dt\right| &\leq (1+a^2)\int_0^\tau(w_n)^2(1,t)dt\\ &\quad+ (1+a^2)\int_0^\tau(k_n-k_0)^2\theta^2(1,t)dt.\end{aligned}$$

Using the results of (5.12)–(5.14) in (5.11) and rearranging terms we have that

$$\begin{aligned}(1+2a^2)\|(w_n)_t\|^2_{L^2(\Omega_\tau)} &+ (1+a^2)\|(w_n)_x(\cdot,\tau)\|^2_{L^2(0,1)} \\ &+ \|(w_n)_{xx}\|^2_{L^2(\Omega_\tau)} + \frac{(1+a^2)}{2} w_n^2(1,\tau)k_n(\tau) \\ &\le k_{\min}\frac{(1+a^2)}{4}\|(w_n)(1,\cdot)\|^2_{L^\infty(0,\tau)} \\ &+ (1+a^2)\left(5a^2k_{\min}^{-1}\|k'\|^2_{L^\infty(R)}\|(\xi_n)_t\|^2_{L^2(\Omega_\tau)}+1\right)\|(w_n)(1,\cdot)\|^2_{L^2(0,\tau)} \\ &+ 4(1+a^2)(k_{\min}^{-1}+1)\int_0^\tau (k_n-k_0)^2\theta^2(1,s)ds.\end{aligned} \tag{5.15}$$

In particular, we have that

$$\begin{aligned}&\frac{(1+a^2)}{2} w_n^2(1,\tau)k_n(\tau) \\ &\le k_{\min}\frac{(1+a^2)}{4}\|(w_n)(1,\cdot)\|^2_{L^\infty(0,\tau)} \\ &\quad + (1+a^2)\left(5a^2k_{\min}^{-1}\|k'\|^2_{L^\infty(R)}\|(\xi_n)_s\|^2_{L^2(\Omega_\tau)}+1\right)\|(w_n)(1,\cdot)\|^2_{L^2(0,\tau)} \\ &\quad + 4(1+a^2)(k_{\min}^{-1}+1)\int_0^\tau (k_n-k_0)^2\theta^2(1,s)ds \\ &\le k_{\min}\frac{(1+a^2)}{4}\|(w_n)(1,\cdot)\|^2_{L^\infty(0,\nu)} \\ &\quad + (1+a^2)\left(5a^2k_{\min}^{-1}\|k'\|^2_{L^\infty(R)}\|(\xi_n)_s\|^2_{L^2(\Omega_\nu)}+1\right)\|(w_n)(1,\cdot)\|^2_{L^2(0,\nu)} \\ &\quad + 4(1+a^2)(k_{\min}^{-1}+1)\int_0^\nu (k_n-k_0)^2\theta^2(1,s)\,ds\end{aligned} \tag{5.16}$$

for any ν satisfying $\tau \le \nu \le T_0$. It follows that

$$\begin{aligned}&k_{\min}\frac{(1+a^2)}{2}\|(w_n)(1,\cdot)\|^2_{L^\infty(0,\nu)} \\ &\le k_{\min}\frac{(1+a^2)}{4}\|(w_n)(1,\cdot)\|^2_{L^\infty(0,\nu)} \\ &\quad + (1+a^2)\left(5a^2k_{\min}^{-1}\|k'\|^2_{L^\infty(R)}\|(\xi_n)_s\|^2_{L^2(\Omega_\nu)}+1\right)\|(w_n)(1,\cdot)\|^2_{L^2(0,\nu)} \\ &\quad + 4(1+a^2)(k_{\min}^{-1}+1)\int_0^\nu (k_n-k_0)^2\theta^2(1,s)ds,\end{aligned} \tag{5.17}$$

and hence

$$\begin{aligned}(w_n)^2(1,\nu) \le &\left(20a^2k_{\min}^{-2}\|k'\|^2_{L^\infty(R)}\|(\xi_n)_s\|^2_{L^2(\Omega_\nu)}+4k_{\min}^{-1}\right)\|(w_n)(1,\cdot)\|^2_{L^2(0,\nu)} \\ &+ 16k_{\min}^{-1}(k_{\min}^{-1}+1)\int_0^\nu (k_n-k_0)^2\theta^2(1,s)ds.\end{aligned} \tag{5.18}$$

Consequently, by Gronwall's inequality [LSU, p.94], we have that
(5.19)

$$\begin{aligned}\int_0^{T_0} w_n^2(1,\tau)d\tau \le &\exp\left(\int_0^{T_0}\left(20a^2k_{\min}^{-2}\|k'\|^2_{L^\infty(R)}\|(\xi_n)_s\|^2_{L^2(\Omega_\tau)}+4k_{\min}^{-1}\right)d\tau\right) \\ &\times 16k_{\min}^{-1}(k_{\min}^{-1}+1)\left(\int_0^{T_0}\int_0^\tau (k_n-k_0)^2\theta^2(1,s)\,ds\,d\tau\right).\end{aligned}$$

Now

$$|k_n - k_0| \leq a\|k'\|_{L^\infty(R)} \int_0^1 |(\xi_n - \xi)(x,s)|dx, \tag{5.20}$$

and, consequently, (5.19) shows that as $\xi_n \to \xi$ in $L^2(\Omega_{T_0})$ we have that $w_n(1,\cdot) \to 0$ in $L^2(0,T_0)$. Using this fact in (5.17) and then (5.15), we obtain that $(w_n)_t = \theta - \theta_n \to 0$ in $L^2(\Omega_{T_0})$. Consequently, the operator S is continuous when K is viewed with the $L^2(\Omega_{T_0})$-topology and so by Schauder's theorem S must have a fixed point $\theta = S\theta$. This fixed point satisfies all the requirements of the problem (2.22) on Ω_{T_0}. To obtain a solution for a general $k \geq 0$, let $k_n = k + (1/n)$, and let θ_n be the corresponding solution in K. Then the θ_n's form a relatively weakly compact set in $W_2^{2,1}(\Omega_{T_0})$, and any weak cluster point θ of the set will satisfy $\theta_x(1,t) = k(\eta)\theta(1,t)$, and will therefore satisfy the conclusion of the theorem on Ω_{T_0}. This concludes the proof of the existence of a local solution to (2.22).

To show uniqueness of the solution let θ and ξ be two solutions to (2.22) corresponding to the same initial-boundary data, and let $w = \int_0^t(\theta - \xi)$. If we repeat the same manipulations as in (5.6)–(5.11), then we obtain

$$\begin{aligned}
&(1+2a^2)\|w_t\|^2_{L^2(\Omega_\tau)} + (1+a^2)\|w_x(\cdot,\tau)\|^2_{L^2(0,1)} + \|w_{xx}\|^2_{L^2(\Omega_\tau)} + (1+a^2)w^2(1,\tau)k_1(\tau)\\
&\quad \leq -2a(1+a^2)w(1,\tau)\int_0^\tau k'(\eta_\xi)\left(\int_0^1 (\xi)_s(x,s)dx\right)w(1,s)ds\\
&\quad + a(1+a^2)\int_0^\tau k'(\eta_\xi)\left(\int_0^1 (\xi)_s(x,s)dx\right)w^2(1,s)ds\\
&\quad - 2(1+a^2)w(1,\tau)\int_0^t (k_1 - k_0)\theta(1,s)ds\\
&\quad + 2(1+a^2)\int_0^\tau w(1,t)(k_1-k_0)\theta(1,t)dt,
\end{aligned} \tag{5.21}$$

where

$$k_1 = k(\eta_\xi) = k\left(g - a\int_0^1 \xi(x,s)dx\right) \quad \text{and} \quad k_0 = k(\eta_\theta) = k\left(g - a\int_0^1 \theta(x,s)dx\right).$$

We now estimate the four integrals on the right in ways different from what was done in (5.12)–(5.14). The first and second integrals are estimated simply by using the Cauchy–Schwarz inequality:

$$\begin{aligned}
&\left|2a(1+a^2)w(1,\tau)\int_0^\tau k'(\eta_\xi)\left(\int_0^1 \xi_s(x,s)dx\right)w(1,s)ds\right|\\
&\quad \leq 2a(1+a^2)\sup_{0\leq s\leq \tau}|w^2(1,s)|\ \|k'\|_{L^2(R)}\|\xi_s\|_{L^2(\Omega_\tau)}\\
&\quad \leq 2a(1+a^2)\tau^{1/2}\sup_{0\leq s\leq \tau}|w^2(1,s)|\ \|k'\|_{L^\infty(R)}\|\xi_s\|_{L^2(\Omega_\tau)},\\
&a(1+a^2)\int_0^\tau \left|k'(\eta_\xi)\left(\int_0^1 \xi_s(x,t)dx\right)w^2(1,t)\right|dt\\
&\quad \leq a(1+a^2)\tau\sup_{0\leq s\leq \tau}|w^2(1,s)|\ \|k'\|_{L^\infty(R)}\|\xi_s\|_{L^2(\Omega_\tau)}.
\end{aligned} \tag{5.22}$$

The last two integrals are easily estimated using the Cauchy's inequality with ϵ:

(5.23)

$$\begin{aligned}\left|2(1+a^2)w(1,\tau)\int_0^\tau (k_1-k_0)\theta(1,s)ds\right| \leq &\frac{(1+a^2)}{4}w^2(1,\tau)\\ &+4(1+a^2)\int_0^\tau (k_1-k_0)^2\theta^2(1,s)ds,\\ \left|2(1+a^2)\int_0^\tau w(1,t)(k_1-k_0)\theta(1,t)dt\right| \leq &(1+a^2)\int_0^\tau w^2(1,t)dt\\ &+(1+a^2)\int_0^\tau (k_1-k_0)^2\theta^2(1,t)dt.\end{aligned}$$

Using these facts in (5.21), we have that

$$\begin{aligned}&(1+2a^2)\|w_t\|^2_{L^2(\Omega_\tau)}+(1+a^2)\|w_x(\cdot,\tau)\|^2_{L^2(0,1)}+\|w_{xx}\|^2_{L^2(\Omega_\tau)}\\ &\quad+(1+a^2)w^2(1,\tau)k_1(\tau)\\ &\quad\leq (3a\|k'\|_{L^\infty(R)}\|\xi_s\|_{L^2(\Omega_\tau)}+\tau^{1/2})(1+a^2)\tau^{1/2}\sup_{0\leq s\leq\tau}|w^2(1,s)|\\ &\quad+\frac{(1+a^2)}{4}w^2(1,\tau)\\ &\quad+5(1+a^2)\int_0^\tau (k_1-k_0)^2\theta^2(1,s)ds.\end{aligned}\tag{5.24}$$

Now, using the fact that $\|w_x(\cdot,\tau)\|^2_{L^2(0,1)}\geq w^2(1,\tau)$, we have that

$$\begin{aligned}&(1+2a^2)\|w_t\|^2_{L^2(\Omega_\tau)}+\frac{(1+a^2)}{2}\|w_x(\cdot,\tau)\|^2_{L^2(0,1)}\\ &\quad\leq (3a\|k'\|_{L^\infty(R)}\|\xi_s\|_{L^2(\Omega_\tau)}+\tau^{1/2})(1+a^2)\tau^{1/2}\sup_{0\leq s\leq\tau}|w^2(1,s)|\\ &\quad+5(1+a^2)\int_0^\tau (k_1-k_0)^2\theta^2(1,s)ds\\ &\quad\leq (3a\|k'\|_{L^\infty(R)}\|\xi_s\|_{L^2(\Omega_\tau)}+\nu^{1/2})(1+a^2)\nu^{1/2}\sup_{0\leq s\leq\nu}|w^2(1,s)|\\ &\quad+5(1+a^2)\int_0^\nu (k_1-k_0)^2\theta^2(1,s)ds\end{aligned}\tag{5.25}$$

for any ν satisfying $\tau\leq\nu\leq T$. In particular, we have that

$$\begin{aligned}&(1+a^2)/2\sup\nolimits_{0\leq\tau\leq\nu}\|w_x(\cdot,\tau)\|^2_{L^2(0,1)}\\ &\quad\leq (3a\|k'\|_{L^\infty(R)}\|\xi_s\|_{L^2(\Omega_\tau)}+\nu^{1/2})(1+a^2)\nu^{1/2}\sup_{0\leq s\leq\nu}|w^2(1,s)|\\ &\quad+5(1+a^2)\int_0^\nu (k_1-k_0)^2\theta^2(1,s)ds.\end{aligned}\tag{5.26}$$

Using (5.25) and (5.26) and rearranging terms yields

(5.27)

$$\begin{aligned}&(1+2a^2)\|w_t\|^2_{L^2(\Omega_\nu)}\\ &\quad+\left(\frac{(1+a^2)}{2}-2(3a\|k'\|_{L^\infty(R)}\|\xi_s\|_{L^2(\Omega_\nu)}+\nu^{1/2})(1+a^2)\nu^{1/2}\right)\sup_{0\leq\tau\leq\nu}\|w_x(\cdot,\tau)\|^2_{L^2(0,1)}\\ &\leq 10(1+a^2)\int_0^\nu (k_1-k_0)^2\theta^2(1,s)ds.\end{aligned}$$

Now, for all ν sufficiently small, we have that

$$\frac{(1+a^2)}{2} - 2(3a\|k'\|_{L^\infty(R)}\|\xi_s\|_{L^2(\Omega_\nu)} + \nu^{1/2})(1+a^2)\nu^{1/2} > 0.$$

Consequently, we have that

$$\begin{aligned} \|w(\cdot,\nu)\|^2_{L^2(0,1)} &\leq (1+a^2)^2\|w_t\|^2_{L^2(\Omega_\nu)} \\ &\leq 10(1+a^2)\int_0^\nu (k_1-k_0)^2\theta^2(1,s)ds \\ &\leq 10(1+a^2)\|\theta(1,\cdot)\|^2_{L^\infty(0,\nu)}\|k'\|^2_{L^\infty(R)}\int_0^\nu\int_0^1 w^2(x,s)\,dx\,ds \end{aligned} \tag{5.28}$$

for all ν less than some T_0. Hence Gronwall's inequality shows that $w=0$, i.e., $\theta=\xi$ on the rectangle $(0,1)\times(0,T_0)$. We may now use a continuation argument to extend the result to all of Ω_T. A similar, but more complicated argument, establishes that if $\varphi_n \to \varphi$ in $H^1(0,1)$ and $m_n \to m$ in $H^1(0,T)$ and if θ_n and θ are the corresponding solutions in $W_2^{2,1}(\Omega_T)$, then $\theta_n \to \theta$ in $L^2(\Omega_{T_0})$ for some T_0 less than T.

A DEGENERATE STEFAN-LIKE PROBLEM WITH JOULE'S HEATING*

XIANGSHENG XU†

Abstract. This paper studies the system $(\partial/\partial t)\alpha(u)-\operatorname{div} a(\nabla u)\ni\sigma(u)|\nabla\varphi|^2$, $\operatorname{div}(\sigma(u)\nabla\varphi)=0$ in a bounded domain of $\mathbb{R}^N$ coupled with initial and boundary conditions. Here, α is a maximal monotone graph in $\mathbb{R}$, a a monotone mapping from $\mathbb{R}^N$ to $\mathbb{R}^N$, and σ a positive function on $\mathbb{R}$ with the limit of $\sigma(s)$ as $|s|\to\infty$ being zero. In the generality considered here, the problem may not always have a solution in the sense of distributions. Under certain assumptions on the data, an existence assertion is established for the problem that incorporates the new phenomena involved and, at the same time, retains the main feature of a classical weak solution.

1. Introduction. Let Ω be a bounded domain in $\mathbb{R}^N$ with smooth boundary $\partial\Omega$ and T a positive number. Consider the following initial-boundary value problem:

$$\frac{\partial}{\partial t}v-\operatorname{div} a(\nabla u)=\sigma(u)|\nabla\varphi|^2 \quad \text{in } Q_T\equiv\Omega\times(0,T), \tag{1.1a}$$

$$\operatorname{div}(\sigma(u)\nabla\varphi)=0 \quad \text{in } Q_T, \tag{1.1b}$$

$$a(\nabla u)\cdot\nu+f(x,t,u)=0 \quad \text{in } S_T\equiv\partial\Omega\times(0,T), \tag{1.1c}$$

$$\varphi=\varphi_0 \quad \text{in } S_T, \tag{1.1d}$$

$$v=v_0 \quad \text{in } \Omega\times\{0\}, \tag{1.1e}$$

$$v\in\alpha(u) \quad \text{a.e. on } Q_T. \tag{1.1f}$$

Here, α is a maximal monotone graph in $\mathbb{R}$, ν denotes the outward normal to $\partial\Omega$, ∇ (respectively, div) is the gradient (respectively, divergence) in the spatial variable $x\in\mathbb{R}^N$, a is a monotone mapping from $\mathbb{R}^N$ to $\mathbb{R}^N$, and σ is a continuous function on $\mathbb{R}$.

A special case of (1.1) is proposed in [SSX] as a model for the combined processes of heat conduction and electrical conduction in a conductor, which may undergo a change of phase due to the heat generated by the electric current, the so-called Joule heating. An example situation is the process of resistance spot-welding of thin steel sheets [A]. In this case, u is the temperature of the conductor, v the enthalpy density, φ the electrical potential, and $\sigma(u)$ the electrical conductivity. Equations (1.1a) and (1.1f) amount to the employment of the "enthalpy formulation" for the Stefan problem to describe the melting of the conductor as a result of Joule's heating, while equation (1.1b) represents the current conservation. We refer the reader to [SSX] for a detailed discussion on the physical justification of this model.

Mathematical problems related to the combined heat and current flow were considered recently in a number of papers under the title of "the thermistor problem." However, most of the studies only focus on the stationary case; see, e.g., [C2], [C3], [CP], [HRS], [X3], [CF1], [CF2], [CH], [AX], where the effect of various

assumptions on σ and different boundary conditions on the existence of a solution and regularity properties of the solution is investigated. The time-dependent case was first considered in [C1] for $N=2$. This restriction on the space dimension was later eliminated in [SSX]. However, in both papers it is assumed, among other things, that

$$M_1 \leqq \sigma(s) \leqq M_2 \quad \text{for all } s,$$

where M_1, M_2 are two positive constants. This condition is very crucial to the existence of a classical weak solution. In [X2] σ is only assumed to be positive, but the boundary conditions are linear and no phase change is allowed in the conductor, i.e., $\alpha(s)=s$. In this paper we shall further relax most of the assumptions in [SSX] and [X2], which leads to new mathematical difficulties. Let us make some remarks on the new mathematical aspects of (1.1). For this we need to state our precise assumptions on the data involved first. We shall assume the following:

(A1) The vector field $a(x)=(a_1(x), \cdots, a_N(x))^T$ is continuous on $\mathbb{R}^N$, and satisfies the growth condition

$$|a(x)| \leqq K|x| \quad \text{for } |x| \text{ sufficiently large,} \quad \text{some } K>0.$$

Moreover, $a(x)$ is strongly coercive monotone, i.e.,

$$(a(x)-a(y))\cdot(x-y) \geqq c_0|x-y|^2 \quad \text{for all } x, y \in \mathbb{R}^N$$

for some $c_0>0$.

(A2) The function $f(x, t, \xi)$ is continuous over $\overline{S_T} \times \mathbb{R}$, and satisfies the growth condition

$$|f(x, t, \xi)| \leqq K_0 + K_1|\xi|,$$

where K_0, K_1 are positive constants. Moreover, $\xi \to f(x, t, \xi)$ is monotone at the origin for all $(x, t) \in S_T$, i.e., $f(x, t, \xi)$ sign $\xi \geqq 0$.

(A3) $\sigma(s)$ is continuous on $\mathbb{R}$, and satisfies

$$0 < \sigma(s) \leqq M \quad \text{for all } s \in \mathbb{R}$$

for some $M>0$. Furthermore, $\lim_{|s|\to\infty} \sigma(s)=0$.

(A4) $\alpha(s)$ is given by

$$\alpha(s)=\begin{cases} \alpha_1(s) & \text{if } s>0, \\ [-1, 0] & \text{if } s=0, \\ \alpha_2(s)-1 & \text{if } s<0, \end{cases}$$

where α_1 and α_2 are two known functions that are continuously differentiable on their respective domains, with $\alpha_1(0+)=\alpha_2(0-)=0$. Moreover, for each $\varepsilon>0$ there exist two positive numbers c_1 and c_2 such that

$$c_1 \leqq \alpha'(s) \leqq c_2 \quad \text{for all } s \in \mathbb{R}\backslash(-\varepsilon, \varepsilon).$$

(A5) $\varphi_0 \in L^\infty(0, T; L^\infty(\partial\Omega))$ and there is a function $\overline{\varphi_0}$ in $L^\infty(0, T; W^{1,\infty}(\Omega))$ such that

$$\overline{\varphi_0} = \varphi_0 \quad \text{in } L^\infty(S_T).$$

The initial value v_0 belongs to $L^2(\Omega)$.

Assumption (A4) says that the melting temperature of the conductor is zero. Assumption (A3) arises in the case of metallic conduction; see [C1].

Under these assumptions we see that there are three different types of degeneracy involved in our problem. First, $\alpha'(s)$ may oscillate wildly near zero in the sense that $\alpha'(s)$ may be unbounded above and $\alpha'(s)$ may not be bounded away from zero as $s \to 0$. We mention in passing that results concerning the existence of a solution and regularity properties of the solution for a one-dimensional Stefan-like problem with this feature are established in [X1]. Also, in the references cited there we may find descriptions of several heat conduction phase change processes that give rise to this type of degeneracy in α. Second, (1.1b) does not contain a term involving $(\partial/\partial t)\varphi$. Third, $\sigma(s)$ does not stay away from zero as $|s| \to \infty$. As it is observed in [X2], this condition prevents us from obtaining a solution of (1.1) via the classical weak formulation as it is done in [SSX]. Let us expand on this point a little bit more. In order for us to view the system in the sense of distributions, we should know that φ belongs to $L^2(0, T; W^{1,2}(\Omega))$. This information would be implied by the boundedness of the temperature, which in turn depends upon the regularity of φ. Existing results on the regularity of weak solutions to degenerate parabolic equations of type (1.1a) indicate that there is a gap between the regularity of φ obtained from assuming u is bounded and that needed to yield the boundedness of u. This gap does not seem to be of a technical nature. As a result, the classical notion of a weak solution [SSX] is not appropriate in analyzing (1.1). We conclude that the solution to (1.1) may display new phenomena that cannot be incorporated into the classical notion of a weak solution. It turns out that we are able to employ the notion of a capacity solution developed in [X2] to study (1.1). This notion of a solution is based upon the following observation. Equation (1.1b) degenerates only at points where u is infinity. For each $m > 0$, (1.1b) is uniformly elliptic on the set $E_m \equiv \{(x, t) \in Q_T : |u(x, t)| \leqq m\}$. Thus it is reasonable to expect that $\nabla\varphi$ exists as a vector-valued function on E_m for each m in a certain sense. That is to say, $\nabla\varphi$ in the sense of distributions may not belong to any L^p-space with $p \geqq 1$. Somehow, $\nabla\varphi$ still exists almost everywhere on Q_T as a function. Then we may view $\sigma(u)\nabla\varphi$ as a product of two functions in Q_T. In this way we hope to avoid the above-mentioned gap in our problem. To make our above statements precise, we have the following definition.

Definition. By a capacity solution of (1.1), we mean a quadruplet (u, φ, v, g) such that

(i) $u \in L^2(0, T; W^{1,2}(\Omega))$, $\varphi \in L^\infty(Q_T)$, $v \in L^2(Q_T)$, and $g \in [L^2(0, T; L^2(\Omega))]^N$;

(ii) $v \in \alpha(u)$ almost everywhere on Q_T;

(iii) u, φ, v, g satisfy

$$\begin{aligned}(1.2)\qquad &-\int_{Q_T} v\eta_t + \int_{Q_T} a(\nabla u)\nabla\eta\,dx\,dt + \int_0^T \int_{\partial\Omega} f(x, t, u)\eta\,ds\,dt \\ &= -\int_{Q_T} (\varphi - \overline{\varphi_0})g\nabla\eta\,dx\,dt + \int_{Q_T} g\nabla\overline{\varphi_0}\eta\,dx\,dt + \int_\Omega v_0(x)\eta(x, 0)\,dx\end{aligned}$$

for all $\eta \in H^1(0, T; W^{1,2}(\Omega))$ such that $\eta(x, T) \equiv 0$, and

$$(1.3)\qquad \int_{Q_T} g\nabla\psi\,dx\,dt = 0 \quad \text{for all } \psi \in L^2(0, T; W_0^{1,2}(\Omega));$$

(iv) For each positive integer m and each function θ in $\mathscr{A} \equiv \{b \in C^1(\mathbb{R}): b'(s) \geqq 0$ on $\mathbb{R}$, $b(s) = 0$ on $(-\infty, 0]$, and $b(s) = 1$ on $[1, \infty)\}$ there hold

$$(1.4)\qquad F_\theta^{(m)}\varphi \in L^2(0, T; W^{1,2}(\Omega)),$$

$$F_\theta^{(m)}\varphi = \varphi_0 \quad \text{in } L^2(0, T; L^2(\partial\Omega)), \tag{1.5}$$

$$F_\theta^{(m)}g = \sigma(u)(\nabla(F_\theta^{(m)}\varphi) - \varphi\nabla F_\theta^{(m)}), \tag{1.6}$$

where $F_\theta^{(m)} \equiv 1 - \theta((1/m)|u|)$.

LEMMA 1.1. *Let* (A1)-(A5) *be satisfied. Assume that* (u, φ, v, g) *is a capacity solution of* (1.1). *If* $|u| \leqq M$ *almost everywhere on* Q_T *for some* $M > 0$, *then* $\nabla\varphi \in L^2(0, T; W^{1,2}(\Omega))$, $g = \sigma(u)\nabla\varphi$, *and* (u, φ, v) *is a classical weak solution of* (1.1).

Remark. A classical weak solution of (1.1) can be defined in an obvious way; see, e.g., [SSX]. The proof of this lemma is similar to that given in [X2]. Thus the notion of a capacity solution is a suitable generalization of that of a classical weak solution. If (u, φ, v) is a classical weak solution, then we deduce from (1.3) that for any $\eta \in L^2(0, T; W^{1,2}(\Omega)) \cap L^\infty(Q_T)$,

$$\begin{aligned}\int_{Q_T} \sigma(u)|\nabla\varphi|^2\eta \, dx\, dt &= \int_{Q_T} \sigma(u)\nabla\varphi(\nabla(\varphi - \bar{\varphi}_0)\eta + \nabla\bar{\varphi}_0\eta)\, dx\, dt \\ &= -\int_{Q_T} \sigma(u)\nabla\varphi(\varphi - \bar{\varphi}_0)\nabla\eta\, dx\, dt + \int_{Q_T} \sigma(u)\nabla\varphi\nabla\bar{\varphi}_0\eta\, dx\, dt.\end{aligned} \tag{1.7}$$

Now let (u, φ, v, g) be a capacity solution of (1.1). For each positive integer k, let $E_k = \{(x, t) \in Q_T: |u(x, t)| \leqq k\}$. By the proof of Lemma 1.1 in [X2], we may select a θ from $\mathscr{A}$ and an m so that

$$F_\theta^{(m)}\varphi = \varphi \quad \text{a.e. on } E_k. \tag{1.8}$$

Since $F_\theta^{(m)}\varphi \in L^2(0, T; W^{1,2}(\Omega))$, we may calculate $\nabla(F_\theta^{(m)}(x, t)\varphi(x, t))$ for almost every $(x, t) \in Q_T$ in the sense of Lemma A.2 in [KS, p. 50]. In view of (1.8), it is natural for us to define

$$\nabla\varphi(x, t) = \nabla(F_\theta^{(m)}(x, t)\varphi(x, t)) \quad \text{for } (x, t) \in E_k. \tag{1.9}$$

Since $Q_T \backslash \bigcup_{k=1}^\infty E_k$ is of measure zero, we may evaluate $\nabla\varphi(x, t)$ through (1.9) for almost every $(x, t) \in Q_T$. Thus we say that $\nabla\varphi(x, t)$ exists almost everywhere on Q_T. Clearly, $\nabla\varphi$ so obtained is a measurable function, and it belongs to $[L^2(E_k)]^N$ for each k. Also, we easily obtain from (1.6) that

$$g = \sigma(u)\nabla\varphi \quad \text{a.e. on } Q_T.$$

We may conclude that the difference between a capacity solution and a classical weak solution is that in the classical weak solution the gradient of φ is evaluated in the sense of distributions, while in the capacity solution the same gradient is calculated in the almost everywhere sense. However, in a capacity solution, $\nabla\varphi$ in the sense of distributions may not belong to any L^p-space with $p \geqq 1$. Thus (1.7) only holds for those $\eta \in L^2(0, T; W^{1,2}(\Omega)) \cap L^\infty(Q_T)$ such that $(\varphi - \bar{\varphi}_0)\eta \in L^2(0, T; W_0^{1,2}(\Omega))$. It is easy to see that if $\eta \in L^2(0, T; W^{1,2}(\Omega))$ is such that $\eta = 0$ almost everywhere on $Q_T \backslash E_k$ for some k, then $\eta\varphi \in L^2(0, T; W^{1,2}(\Omega))$. Also, in a capacity solution, the trace $\varphi|_{S_T}$ may not make sense, and thus (1.5) is used to describe the boundary condition for φ. Moreover, the product $\sigma(u)\nabla\varphi$ is taken as a product of two functions in Q_T. Thus through the use of (1.4)-(1.6) we have successfully avoided all possible ambiguity in our problem caused by the degeneracy and at the same time probably retained the best possible regularity information on the solution under the circumstances.

The main result of this paper is that under (A1)-(A5) there is a capacity solution to (1.1).

A capacity solution to (1.1) is constructed as a limit of a sequence of classical weak solutions of the regularized problems. In § 2 we consider the regularized stationary problem, while § 3 is devoted to the study of the regularized time-dependent problem. The results in §§ 2 and 3 are used in § 4 to prove our main existence theorem.

The letter c will be used to denote the generic constant. When distinction among different constants is needed, we add a subscript i to c with $i \in \{0, 1, 2, \cdots\}$.

2. The stationary problem. In this section we consider the following stationary problem:

$$\alpha(u) - \operatorname{div} a(\nabla u) = \sigma(u)|\nabla\varphi|^2 + H(x) \quad \text{in } \Omega, \tag{2.1a}$$

$$\operatorname{div}(\sigma(u)\nabla\varphi) = 0 \quad \text{in } \Omega, \tag{2.1b}$$

$$a(\nabla u) \cdot \nu + f(x, u) = 0 \quad \text{in } \partial\Omega, \tag{2.1c}$$

$$\varphi = \varphi_0 \quad \text{in } \partial\Omega. \tag{2.1d}$$

With respect to the data involved we assume the following.

(B1) α is Lipschitz continuous and strongly coercive monotone, i.e.,

$$C_1|s_1 - s_2|^2 \geqq (\alpha(s_1) - \alpha(s_2))(s_1 - s_2) \geqq C_0|s_1 - s_2|^2 \quad \text{for all } s_1, s_2 \in \mathbb{R},$$

where C_0, C_1 are two positive constants.

(B2) $\sigma(s)$ is continuous and satisfies

$$C_2 \leqq \sigma(s) \leqq C_3 \quad \text{for all } s \in \mathbb{R},$$

where C_2, C_3 are two positive constants with $C_2 \leqq C_3$.

(B3) a is given as in § 1. The function $f(x, \xi)$ satisfies (A2) with (x, t) replaced by x, while the function $H(x)$ belongs to $L^2(\Omega)$. Also, $\varphi_0 \in L^2(\partial\Omega)$, and there is a function $\overline{\varphi_0}$ in $W^{1,\infty}(\Omega)$ such that $\overline{\varphi_0} = \varphi_0$ in $L^2(\partial\Omega)$.

A weak solution to (2.1) is defined as a pair (u, φ) such that

$$u, \varphi \in W^{1,2}(\Omega), \tag{2.2}$$

$$\varphi = \varphi_0 \quad \text{in } L^2(\partial\Omega), \tag{2.3}$$

$$\begin{aligned} &\int_\Omega (\alpha(u)\psi + a(\nabla u)\nabla\psi)\,dx + \int_{\partial\Omega} f(x, u)\psi\,ds \\ &= \int_\Omega (\sigma(u)|\nabla\varphi|^2 + H(x))\psi(x)\,dx \end{aligned} \tag{2.4}$$

for every $\psi(x) \in W^{1,2}(\Omega) \cap L^\infty(\Omega)$, and

$$\int \sigma(u)\nabla\varphi\nabla\eta(x)\,dx = 0 \quad \text{for every } \eta \in W_0^{1,2}(\Omega). \tag{2.5}$$

We immediately have the following.

LEMMA 2.1. *If* (u, φ) *is a weak solution of* (2.1), *then* (2.4) *is equivalent to the following*:

$$\begin{aligned} &\int_\Omega (\alpha(u)\psi + a(\nabla u)\nabla\psi)\,dx + \int_{\partial\Omega} f(x, u)\psi\,ds \\ &= -\int_\Omega \sigma(u)\nabla\varphi\nabla\psi(\varphi - \overline{\varphi_0})\,dx + \int_\Omega \sigma(u)\nabla\varphi\nabla\overline{\varphi_0}\psi\,dx + \int_\Omega H(x)\psi\,dx \end{aligned} \tag{2.6}$$

for every $\psi \in W^{1,2}(\Omega)$.

The proof is similar to that of [HRS, Lemma 1], and we shall omit it here.

LEMMA 2.2. *Under the assumptions* (B1)-(B3) *there is a weak solution to* (2.1).

Proof. We follow the approach adopted in [X3]. For each positive integer k define

$$P_k(x)=\begin{cases} k & \text{if } |x|^2>k, \\ |x|^2 & \text{if } |x|^2\leqq k. \end{cases} \tag{2.7}$$

By an argument similar to that used in the proof of Lemma 2.1 in [X3], we obtain that for each k there exists at least one vector-valued function $u_k=(u_1^{(k)}, u_2^{(k)})\in W^{1,2}(\Omega)\times\{v\in W^{1,2}(\Omega)\colon v|_{\partial\Omega}=\varphi_0\}$ such that

$$\begin{aligned}\int_\Omega (\alpha(u_1^{(k)})\psi(x)+a(\nabla u_1^{(k)})\nabla\psi)\,dx+\int_{\partial\Omega} f(x, u_1^{(k)})\psi(x)\,ds \\ =\int_\Omega (\sigma(u_1^{(k)})P_k(\nabla u_2^{(k)})+H(x))\psi\,dx\end{aligned} \tag{2.8}$$

for all $\varphi\in W^{1,2}(\Omega)$, and

$$\int_\Omega \sigma(u_1^{(k)})\nabla u_2^{(k)}\nabla\eta(x)\,dx=0 \quad \text{for all } \eta\in W_0^{1,2}(\Omega). \tag{2.9}$$

We infer from (2.9) that

$$\sup_\Omega |u_2^{(k)}|\leqq c, \tag{2.10}$$

$$\int_\Omega |\nabla u_2^{(k)}|^2\,dx\leqq c \qquad (k=1,2,\cdots). \tag{2.11}$$

We infer from the proof of Lemma 2.1 in [X3] that we can set $\psi=(u_1^{(k)})^-$, $(u_1^{(k)})^+$ successively in (2.8) to obtain

$$\|u_1^{(k)}\|_{W^{1,2}(\Omega)}\leqq c \qquad (k=1,2,\cdots). \tag{2.12}$$

In view of (2.10), (2.11), and (2.12), we may select a subsequence of $\{k\}$, still denoted by $\{k\}$, so that

$$u_1^{(k)}\to u_1 \quad \text{strongly in } L^2(\Omega) \quad \text{and weakly in } W^{1,2}(\Omega), \tag{2.13}$$

$$u_2^{(k)}\to u_2 \quad \text{strongly in } L^2(\Omega) \quad \text{and weakly in } W^{1,2}(\Omega). \tag{2.14}$$

Setting $\eta=u_2^{(k)}-u_2$ in (2.9) and using (2.14) in the resulting equation yields

$$u_2^{(k)}\to u_2 \quad \text{strongly in } W^{1,2}(\Omega). \tag{2.15}$$

It follows from (2.13) and a result in [M, p.76] that

$$u_1^{(k)}\to u_1 \quad \text{strongly in } L^2(\partial\Omega).$$

We still need to show that

$$\nabla u_1^{(k)}\to\nabla u_1 \quad \text{a.e. on } \Omega. \tag{2.16}$$

For this purpose, fix $\varepsilon, \delta>0$ and define

$$\beta_\varepsilon(s)=\begin{cases} \varepsilon & \text{if } s\geqq\varepsilon, \\ s & \text{if } -\varepsilon<s<\varepsilon, \\ -\varepsilon & \text{if } s\leqq-\varepsilon. \end{cases}$$

According to Egoroff's theorem, there exists a measurable set $E_\delta \subset \Omega$ such that $L^N(\Omega\backslash E_\delta) \leqq \delta$ and $u_1^{(k)} \to u_1$ uniformly on E_δ. Thus if we choose k so large that $|u_1^{(k)} - u_1| \leqq \varepsilon/2$ on E_δ, we may calculate using (2.8) and [B3] that

$$\int_{E_\delta} |\nabla u_1^{(k)} - \nabla u_1|^2 \, dx \leqq c_0 \int_\Omega (a(\nabla u_1^{(k)}) - a(\nabla u_1)) \nabla \beta_\varepsilon(u_1^{(k)} - u_1) \, dx$$

$$= c_0 \bigg(\int_\Omega (\sigma(u_1^{(k)}) P_k(\nabla u_2^{(k)}) + H(x)) \beta_\varepsilon(u_1^{(k)} - u_1) \, dx$$

$$- \int_{\partial\Omega} f(x, u_1^{(k)}) \beta_\varepsilon(u_1^{(k)} - u_1) \, ds - \int_\Omega \alpha(u_1^{(k)}) \beta_\varepsilon(u_1^{(k)} - u_1) \, dx$$

$$- \int_\Omega a(\nabla u_1) \nabla \beta_\varepsilon(u_1^{(k)} - u_1) \, dx \bigg).$$

Now $\beta_\varepsilon(u_1^{(k)} - u_1)$ goes to zero strongly in $L^2(\Omega)$ and weakly in $W^{1,2}(\Omega)$. Also, $P_k(\nabla u_2^{(k)})$ converges strongly to $|\nabla u_2|^2$ in $L^1(\Omega)$ due to (2.15). Consequently,

$$\limsup_{k\to\infty} \int_{E_\delta} |\nabla u_1^{(k)} - \nabla u_1|^2 \, dx \leqq 0.$$

Hence, passing if need be to a further subsequence, we deduce $\nabla u_1^{(k)} \to \nabla u_1$ almost everywhere on E_δ. This is true for each $\delta > 0$, and so (2.16) holds. By (B3), we conclude

$$a(\nabla u_1^{(k)}) \to a(\nabla u_1) \quad \text{weakly in } [L^2(\Omega)]^N.$$

Now we can pass to the limit in (2.8) and (2.9). This completes the proof of the lemma.

Remark. The proof peresented here can easily be modified to cover the case considered in [HRS].

3. The time-dependent problem. In this section we assume that (B1), (B2), (A1), (A2), and (A5) hold. Consider the following problem:

$$\frac{\partial}{\partial t} \alpha(u) - \operatorname{div} a(\nabla u) = \sigma(u) |\nabla \varphi|^2 \quad \text{in } Q_T, \tag{3.1a}$$

$$\operatorname{div}(\sigma(u) \nabla \varphi) = 0 \quad \text{in } Q_T, \tag{3.1b}$$

$$a(\nabla u) \cdot \nu + f(x, t, u) = 0 \quad \text{in } S_T, \tag{3.1c}$$

$$\varphi = \varphi_0 \quad \text{in } S_T, \tag{3.1d}$$

$$\alpha(u) = v_0 \quad \text{in } \Omega \times \{0\}. \tag{3.1e}$$

By a weak solution to (3.1) we mean a pair (u, φ) such that

$$\begin{gathered} u, \varphi \in L^2(0, T; W^{1,2}(\Omega)), \\ \varphi = \varphi_0 \quad \text{in } L^2(0, T; L^2(\partial\Omega)), \end{gathered} \tag{3.2}$$

$$\begin{aligned} &- \int_{Q_T} \alpha(u) \psi_t \, dx \, dt + \int_{Q_T} a(\nabla u) \nabla \psi \, dx \, dt + \int_0^T \int_{\partial\Omega} f(x, t, u) \psi \, ds \, dt \\ &= \int_\Omega v_0 \psi(x, 0) \, dx + \int_{Q_T} \sigma(u) |\nabla \varphi|^2 \psi \, dx \, dt \end{aligned} \tag{3.3}$$

for all $\psi \in H^1(0, T; W^{1,2}(\Omega)) \cap L^\infty(Q_T)$ such that $\psi(x, T) \equiv 0$, and

$$\int_{Q_T} \sigma(u)\nabla\varphi\nabla\eta \, dx \, dt = 0 \tag{3.4}$$

for all $\eta \in L^2(0, T; W_0^{1,2}(\Omega))$.

Let $U = W^{1,2}(\Omega)$ and U^* be the topological dual of U. Define an operator $A: L^2(0, T; U) \to L^2(0, T; U^*)$ by

$$(A(u), v) = \int_{Q_T} a(\nabla u)\nabla v \, dx \, dt + \int_0^T \int_{\partial\Omega} f(x, t, u)v \, ds \, dt, \qquad u, v \in L^2(0, T; U).$$

In view of (A1) and (A2), A is well defined. Let $B(u, v)$ be the operator from $L^2(0, T; U) \times L^2(0, T; U) \cap L^\infty(Q_T)$ to $L^2(0, T; U^*)$ defined by

$$(B(u, v), w) = -\int_{Q_T} \sigma(u)\nabla v(v - \overline{\varphi_0})\nabla w \, dx \, dt + \int_{Q_T} \sigma(u)\nabla v \nabla\overline{\varphi_0} w \, dx \, dt,$$

$$u, w \in L^2(0, T; U), \qquad v \in L^2(0, T; U) \cap L^\infty(Q_T).$$

By [B2] and [A5], $B(u, v)$ is also well defined.

LEMMA 3.1. *If the pair* (u, φ) *is a weak solution of* (3.1), *then* (3.3) *is equivalent to the following*:

$$\frac{\partial}{\partial t}\alpha(u) \in L^2(0, T; U^*), \tag{3.5}$$

$$\frac{\partial}{\partial t}\alpha(u) + A(u) = B(u, \varphi) \quad \text{in } L^2(0, T; U^*). \tag{3.6}$$

For $\psi \in L^2(0, T; U) \cap L^\infty(Q_T)$ we calculate, with the aid of (3.4), that

$$\begin{aligned} \int_{Q_T} \sigma(u)|\nabla\varphi|^2\psi \, dx \, dt &= \int_{Q_T} \sigma(u)\nabla\varphi(\nabla(\varphi - \overline{\varphi_0})\psi + \nabla\overline{\varphi_0}\psi) \, dx \, dt \\ &= -\int_{Q_T} \sigma(u)\nabla\varphi(\varphi - \overline{\varphi_0})\nabla\psi \, dx \, dt \\ &\quad + \int_{Q_T} \sigma(u)\nabla\varphi\nabla\overline{\varphi_0}\psi \, dx \, dt. \end{aligned} \tag{3.7}$$

The lemma can easily be inferrred from using (3.7) in (3.3).

LEMMA 3.2. *Let* (B1), (B2), (A1), *and* (A5) *be satisfied. Assume that* $\alpha^{-1}(v_0) \in W^{1,2}(\Omega)$. *Then there is a weak solution to* (3.1).

Proof. Let k be a positive integer and $\delta = T/k$. Set

$$u_0^{(k)} = \alpha^{-1}(v_0).$$

By Lemma 2.2, we may define a set of k pairs $(u_1^{(k)}, \varphi_1^{(k)}), \cdots, (u_k^{(k)}, \varphi_k^{(k)})$ via the following iteration formula:

$$\frac{\alpha(u_j^{(k)}) - \alpha(u_{j-1}^{(k)})}{\delta} - \operatorname{div} a(\nabla u_j^{(k)}) = \sigma(u_j^{(k)})|\nabla\varphi_j^{(k)}|^2 \quad \text{in } \Omega, \tag{3.8}$$

$$\operatorname{div}(\sigma(u_j^{(k)})\nabla\varphi_j^{(k)}) = 0 \quad \text{in } \Omega, \tag{3.9}$$

$$a(\nabla u_j^{(k)})\nu + f(x, j\delta, u_j^{(k)}) = 0 \quad \text{in } \partial\Omega, \tag{3.10}$$

$$\varphi_j^{(k)} = \frac{1}{\delta}\int_{(j-1)\delta}^{j\delta} \varphi_0(x, t) \, dt \quad \text{on } \partial\Omega, \quad j = 1, 2, \cdots, k. \tag{3.11}$$

Subsequently, set

$$u^{(k)}(x,t)=\begin{cases} u_0^{(k)} & \text{if } t\leqq 0 \\ u_j^{(k)}(x) & \text{if } (j-1)\delta<t\leqq j\delta \end{cases} \quad (j=1,\cdots,k),$$

$$\varphi^{(k)}(x,t)=\begin{cases} \varphi_1^{(k)}(x) & \text{if } t\leqq \delta \\ \varphi_j^{(k)}(x) & \text{if } (j-1)\delta<\leqq j\delta \end{cases} \quad (j=2,\cdots,k).$$

Invoking the weak formulation of problem (3.8)-(3.11), we obtain

$$\text{(3.12)} \qquad \int_{Q_T} \sigma(u^{(k)})\nabla\varphi^{(k)}\nabla\xi\,dx\,dt=0$$

for all $\xi\in L^2(0,T;\, W_0^{1,2}(\Omega))$. We infer from the weak maximum principle that

$$\text{(3.13)} \qquad \sup_{Q_T}|\varphi^{(k)}|\leqq c \qquad (k=1,2,\cdots).$$

Set

$$\overline{\varphi_{0k}}(x,t)=\frac{1}{\delta}\int_{(j-1)\delta}^{j\delta}\overline{\varphi_0}(x,\tau)\,d\tau \quad \text{if } (j-1)\delta<t\leqq j\delta \qquad (j=1,2,\cdots,k).$$

Let $\xi=\varphi^{(k)}-\overline{\varphi_{0k}}$ in (3.12) to obtain

$$\text{(3.14)} \qquad \int_{Q_T}|\nabla\varphi^{(k)}|^2\,dx\,dt\leqq c \qquad (k=1,2,\cdots).$$

Now set

$$J(s)=\int_0^s \alpha^{-1}(\tau)\,d\tau.$$

Without loss of generality, we assume $\alpha(0)=0$. Then the functional $G: L^2(\Omega)\to[0,\infty]$ defined by

$$G(f)=\begin{cases} \int_\Omega J(f)\,dx & \text{if } J(f)\in L^1(\Omega), \\ +\infty & \text{otherwise} \end{cases}$$

is lower semicontinuous on $L^2(\Omega)$.

Now we wish to show that

$$\text{(3.15)} \qquad \sup_{0\leqq t\leqq T}\int_\Omega |u^{(k)}(x,t)|^2\,dx+\int_{Q_T}|\nabla u^{(k)}|^2\,dx\,dt\leqq c \qquad (k=1,2,\cdots).$$

This estimate can easily be inferred from § 4 of [SSX]. We only point out that in our situation there exist two positive numbers c_1, c_2 such that

$$|\alpha^{-1}(s)|\geqq c_1|s|, \qquad |\alpha(s)|\geqq c_2|s| \quad \text{for all } s\in\mathbb{R}.$$

Subsequently,

$$\begin{aligned} G(\alpha(u^{(k)}(x,t)))&=\int_\Omega\int_0^{\alpha(u^{(k)}(x,\tau))}\alpha^{-1}(s)\,ds\,dx \\ &=\int_\Omega\left|\int_0^{\alpha(u^{(k)}(x,t))}\alpha^{-1}(s)\,ds\right|dx\geqq c\int_\Omega|u^{(k)}(x,t)|^2\,dx. \end{aligned}$$

Now define $v^{(k)}$ by

$$v^{(k)}(x,t)=\frac{t-(j-1)\delta}{\delta}\,\alpha(u_j^{(k)})+\frac{j\delta-t}{\delta}\,\alpha(u_{j-1}^{(k)})$$

if $(j-1)\delta < t \leqq j\delta, j=1,\cdots,k$ for $k=1,2,\cdots$. We may infer from Lemma 3.1, (3.8), and (3.9) that

$$\begin{aligned}&\left(\frac{\partial}{\partial t}v^{(k)},\xi\right)+\int_{Q_T}a(\nabla u^{(k)})\nabla\xi\,dx\,dt+\int_0^T\int_{\partial\Omega}f(x,t,u^{(k)})\xi\,ds\,dt\\ &\quad=-\int_{Q_T}\sigma(u^{(k)})\nabla\varphi^{(k)}(\phi^{(k)}-\overline{\varphi_{0k}})\nabla\xi\,dx\,dt\\ &\qquad+\int_{Q_T}\sigma(u^{(k)})\nabla\varphi^{(k)}\nabla\overline{\varphi_{0k}}\xi\,dx\,dt\quad\text{for all }\xi\in L^2(0,T;W^{1,2}(\Omega)),\end{aligned}\tag{3.16}$$

where $(\cdot,\cdot)$ denotes the duality pairing between $L^2(0,T;U^*)$ and $L^2(0,T;W^{1,2}(\Omega))$. Since α is Lipschitz continuous, we derive from (3.15) that

$$\sup_{0\leqq t\leqq T}\int_\Omega|v^{(k)}(x,t)|^2\,dx+\int_0^T\int_\Omega|\nabla v^{(k)}|^2\,dx\,dt\leqq c,\qquad(k=1,\cdots),$$

where c may depend on $\|\nabla\alpha^{-1}(v_0)\|_{L^2(\Omega)}$. This, together with (3.16), (3.13), and (3.14) implies that

$$\left\|\frac{\partial}{\partial t}v^{(k)}\right\|_{L^2(0,T;U^*)}\leqq c\qquad(k=1,\cdots).$$

By Lions-Aubin's theorem, $\{v^{(k)}\}$ is precompact in $L^2(Q_T)$. We estimate

$$\begin{aligned}\int_{Q_T}(v^{(k)}-\alpha(u^{(k)}))^2\,dx\,dt&=\frac{1}{3}\int_{Q_T}(\alpha(u^{(k)}(x,t))-\alpha(u^{(k)}(x,t-\delta)))^2\,dx\,dt\\ &\leqq c\int_{Q_T}(u^{(k)}(x,t)-u^{(k)}(x,t-\delta))^2\,dx\,dt.\end{aligned}\tag{3.17}$$

Using $u_j^{(k)}-u_{j-1}^{(k)}$ as a test function in (3.8), after a sequence of calculations we get

$$c_0\int_0^T\int_\Omega(u^{(k)}(x,t)-u^{(k)}(x,t-\delta))^2\,dx\,dt\leqq c_1\delta^{1/2}\to0\quad\text{as }k\to\infty.$$

This, together with (3.17) implies that $\{\alpha(u^{(k)})\}$ is precompact in $L^2(Q_T)$. Consequently, $\{u^{(k)}\}$ is also precompact in $L^2(0,T;L^2(\Omega))$ due to (B1). Now we can select a subsequence of $\{k\}$, still denoted by $\{k\}$, such that

$$\begin{aligned}u^{(k)}\to u\text{ strongly }&\text{ in }L^2(0,T;L^2(\Omega))\quad\text{and}\\ &\text{weakly in }L^2(0,T;W^{1,2}(\Omega)),\end{aligned}\tag{3.18}$$

$$a(\nabla u^{(k)})\to L(x,t)\quad\text{weakly in }[L^2(Q_T)]^N,\tag{3.19}$$

$$\varphi^{(k)}\to\varphi\quad\text{weakly in }L^2(0,T;W^{1,2}(\Omega)).\tag{3.20}$$

By (3.18) and the trace theorem [CDK], we obtain

$$u^{(k)}\to u\quad\text{strongly in }L^2(0,T;L^2(\partial\Omega)).\tag{3.21}$$

From the definition of $\{\overline{\varphi_{0k}}\}$, we see that

$$\varphi^{(k)}-\overline{\varphi_{0k}}\in L^2(0,T;\ W_0^{1,2}(\Omega))\quad\text{for each } k,$$
$$\overline{\varphi_{0k}}\to\overline{\varphi_0}\quad\text{strongly in } L^2(0,T;\ W^{1,2}(\Omega)).$$

Set $\xi=\varphi^{(k)}-\overline{\varphi_{0k}}-\varphi+\overline{\varphi_0}$ in (3.12) to get

$$\int_{Q_T}\sigma(u^{(k)})\nabla\varphi^{(k)}\nabla(\varphi^{(k)}-\varphi)\,dx\,dt=\int_{Q_T}\sigma(u^{(k)})\nabla\varphi^{(k)}\nabla(\overline{\varphi_{0k}}-\overline{\varphi_0})\,dx\,dt$$

from whence follows

$$\lim_{k\to\infty}\int_{Q_T}|\nabla(\varphi^{(k)}-\varphi)|^2\,dx\,dt=0. \tag{3.22}$$

Note that $(\partial/\partial t)v^{(k)}\to(\partial/\partial t)\alpha(u)$ weakly in $L^2(0,T;\ U^*)$ because of (3.17). We can take $k\to\infty$ in (3.16) to obtain

$$\begin{aligned}&\frac{\partial}{\partial t}\alpha(u)\in L^2(0,T;\ U^*),\\ &\frac{\partial}{\partial t}\alpha(u)+\tilde{A}(u)=B(u,\varphi)\quad\text{in } L^2(0,T;\ U^*),\end{aligned} \tag{3.23}$$

where $B(u,\varphi)$ is given as in Lemma 3.1, and $\tilde{A}(u)\in L^2(0,T;\ U^*)$ is given by

$$(\tilde{A}(u),v)=\int_{Q_T}L\nabla v\,dx\,dt+\int_0^T\int_{\partial\Omega}f(x,t,u)v\,dS\,dt,$$
$$v\in L^2(0,T;\ W^{1,2}(\Omega)).$$

Before we continue, let us cite the following lemma.

LEMMA 3.3. *Let α be a Lipschitz continuous and strongly coercive monotone function on $\mathbb{R}$ and β a Lipschitz continuous function on $\mathbb{R}$ with $\alpha(0)=\beta(0)=0$. Assume that $u\in L^2(0,T;\ W^{1,2}(\Omega))$ and that $(\partial/\partial t)\alpha(u)\in L^2(0,T;\ U^*)$. Then the function $t\to\int_\Omega\int_0^{\alpha(u(x,t))}\beta(\alpha^{-1}(s))\,ds\,dx$ is absolutely continuous on $(0,T)$, and*

$$\frac{d}{dt}\int_\Omega\int_0^{\alpha(u(x,t))}\beta(\alpha^{-1}(s))\,ds\,dx=\left(\frac{\partial}{\partial t}\alpha(u),\beta(u)\right)\qquad\textit{for a.e. } t\in(0,T),$$

where $(\cdot,\cdot)$ denotes the duality pairing between U^* and $W^{1,2}(\Omega)$.

Remark. This lemma is a consequence of Theorem 17 in [BR1], the chain rule, and the fact that $(v,u)=\int_\Omega vu\,dx$ for $u\in W^{1,2}(\Omega)$, $v\in L^\infty(\Omega)\cap U^*$. It is worth pointing out that if v only belongs to $L^1(\Omega)\cap U^*$ the question of whether $(v,u)=\int_\Omega vu\,dx$ is first, raised by Brézis in [BR2], remains open.

Return to the proof of Lemma 3.2. We derive from (3.23) and Lemma 3.3 that

$$\begin{aligned}&\int_\Omega\int_0^{\alpha(u(x,T))}\alpha^{-1}(s)\,ds\,dx-\int_\Omega\int_0^{v_0(x)}\alpha^{-1}(s)\,ds\,dx\\ &\quad+\int_{Q_T}L\nabla u\,dx\,dt+\int_0^T\int_{\partial\Omega}f(x,t,u)u\,dS\,dt\\ &=-\int_{Q_T}\sigma(u)\nabla\varphi(\varphi-\overline{\varphi_0})\nabla u\,dx\,dt+\int_{Q_T}\sigma(u)\nabla\varphi\nabla\overline{\varphi_0}u\,dx\,dt.\end{aligned} \tag{3.24}$$

Here we would like to point out that $\alpha(u)\in C([0,T];L^2(\Omega))$, and thus the first term in (3.24) makes sense. We have

$$
\begin{aligned}
&G(\alpha(u^{(k)}(x,T)))-G(v_0)+\int_{Q_T} a(\nabla u^{(k)})\nabla u^{(k)}\,dx\,dt\\
&\quad+\int_0^T\int_{\partial\Omega} f_k(x,t,u^{(k)})u^{(k)}\,ds\,dt\\
&\quad=-\int_{Q_T}\sigma(u^{(k)})\nabla\varphi^{(k)}(\varphi^{(k)}-\overline{\varphi_0})\nabla u^{(k)}\,dx\,dt\\
&\quad\quad+\int_{Q_T}\sigma(u^{(k)})\nabla\varphi^{(k)}\nabla\overline{\varphi_0}u^{(k)}\,dx\,dt.
\end{aligned}
\tag{3.25}
$$

Remember that $v^{(k)}(x,t)\rightarrow\alpha(u(x,t))$ strongly in $L^2(\Omega)$ for almost every $t\in(0,T]$. Also, $\{(\partial/\partial t)v^{(k)}\}$ is bounded in $L^2(0,T;U^*)$. We easily see that $\alpha(u),v^{(k)}\in C([0,T];L^2(\Omega))$ for each k and

$$
v^{(k)}(x,t)\rightarrow\alpha(u(x,t))\quad\text{weakly in } L^2(\Omega)\quad\text{for each } t \text{ in } [0,T].
$$

In particular, we have

$$
v^{(k)}(x,T)=\alpha(u^{(k)}(x,T))\rightarrow\alpha(u(x,T))\quad\text{weakly in } L^2(\Omega).
$$

Consequently,

$$
\liminf_{k\rightarrow\infty} G(\alpha(u^{(k)}(x,T)))\geqq G(\alpha(u(x,T))).
$$

We easily deduce from (3.22) that

$$
\varphi^{(k)}\rightarrow\varphi\quad\text{strongly in } L^p(Q_T)\quad\text{for each } p\geqq 1.
$$

Thus letting $k\rightarrow\infty$ in (3.25) yields

$$
\begin{aligned}
\limsup_{k\rightarrow\infty}\int_{Q_T} a(\nabla u^{(k)})\nabla u^{(k)}\,dx\,dt&\leqq G(v_0)-G(\alpha(u(x,T)))-\int_0^T\int_{\partial\Omega} f(x,t,u)u\,dS\,dt\\
&\quad-\int_{Q_T}\sigma(u)\nabla\varphi(\varphi-\overline{\varphi_0})\nabla u\,dx\,dt\\
&\quad+\int_{Q_T}\sigma(u)\nabla\varphi\nabla\overline{\varphi_0}u\,dx\,dt\\
&=\int_{Q_T} L\nabla u\,dx\,dt.
\end{aligned}
$$

The last step is due to (3.24).

We estimate from (A1) that

$$
\begin{aligned}
\int_{Q_T}|\nabla u^{(k)}-\nabla u|^2\,dx\,dt&\leqq c\int_{Q_T}(a(\nabla u^{(k)})-a(\nabla u))(\nabla u^{(k)}-\nabla u)\,dx\,dt\\
&=c\left[\int_{Q_T} a(\nabla u^{(k)})\nabla u^{(k)}\,dx\,dt-\int_{Q_T} a(\nabla u^{(k)})\nabla u\,dx\,dt\right.\\
&\quad\left.-\int_{Q_T} a(\nabla u)(\nabla u^{(k)}-\nabla u)\,dx\,dt\right].
\end{aligned}
$$

This implies that

$$\lim_{k\to\infty}\int_{Q_T}|\nabla u^{(k)}-\nabla u|^2\,dx\,dt=0.$$

We immediately obtain, with the aid of (A1) and (3.19), that

$$L=a(\nabla u)\quad \text{a.e. on } Q_T.$$

This completes the proof of Lemma 3.2.

Remark. The arguments presented here can be used to simplify the proof in [SSX].

4. Proof of the main result. Let $J(s)$ be a nonnegative function on $\mathbb{R}$ belonging to $C_0^\infty(\mathbb{R})$ and having the following properties:

(i) $J(s)=0$ if $|s|\geqq 1$; and

(ii) $\int_{\mathbb{R}} J(s)\,ds=1$.

We derive from (A4) that $\alpha^{-1}(s)$ is uniformly continuous on $\mathbb{R}$. Thus the sequence $\{\tilde{\alpha}_k(s)\}$ defined by

$$\tilde{\alpha}_k(s)=\frac{1}{k}\int_{\mathbb{R}} J(k(s-\tau))\alpha^{-1}(\tau)\,d\tau\qquad (k=1,2,\cdots)$$

converges to $\alpha^{-1}(s)$ uniformly on $\mathbb{R}$ as $k\to\infty$. For each k, denote by $\alpha_k(s)$ the inverse of $\tilde{\alpha}_k(s)+(1/k)s-\tilde{\alpha}_k(0)$. Then α_k is Lipschitz continuous and strongly coercive monotone for each fixed k. Now fix a k, and consider the following problem:

$$\frac{\partial}{\partial t}\alpha_k(u)-\operatorname{div} a(\nabla u)=\sigma_k(u)|\nabla\varphi|^2\quad\text{in } Q_T, \tag{4.1}$$

$$\operatorname{div}(\sigma_k(u)\nabla\varphi)=0\quad\text{in } Q_T, \tag{4.2}$$

$$\begin{aligned} a(\nabla u)\cdot\nu+f(x,t,u)&=0\quad\text{in } S_T,\\ \varphi&=\varphi_0\quad\text{in } S_T, \qquad (4.3)\\ \alpha_k(u)&=v_0\quad\text{in } \Omega\times\{0\}, \end{aligned}$$

where $\sigma_k(s)=\sigma(s)+(1/k)$. Without loss of generality, assume $\alpha_k^{-1}(v_0)\in W^{1,2}(\Omega)$ for each k. By Lemma 3.2, for each k there is a pair (u_k,φ_k) such that

$$\varphi_k\in L^\infty(Q_T)\cap L^2(0,T;W^{1,2}(\Omega)),\qquad u_k\in L^2(0,T;W^{1,2}(\Omega)), \tag{4.4}$$

$$\frac{\partial}{\partial t}v_k+A(u_k)=B(u_k,\varphi_k)\quad\text{in } L^2(0,T;U^*), \tag{4.5}$$

$$\int_{Q_T}\sigma_k(u_k)\nabla\varphi_k\nabla\psi\,dx\,dt=0\quad\text{for all } \psi\in L^2(0,T;W_0^{1,2}(\Omega)), \tag{4.6}$$

$$\varphi_k=\varphi_0\quad\text{in } L^2(0,T;L^2(\partial\Omega)), \tag{4.7}$$

$$\alpha_k(u_k)=v_0\quad\text{in } C([0,T);L^2(\Omega)), \tag{4.8}$$

where $v_k=\alpha_k(u_k)$.

Now we proceed to derive a priori estimates on the sequence $\{(u_k,\varphi_k)\}$. Set $\psi=\varphi_k-\overline{\varphi_0}$ in (4.6) to obtain

$$\int_{Q_T}\sigma_k(u_k)|\nabla\varphi_k|^2\,dx\,dt\leqq c\qquad (k=1,2,\cdots). \tag{4.9}$$

By the weak maximum principle,

$$\sup_{Q_T} |\varphi_k| \leqq c \qquad (k=1,2,\cdots). \tag{4.10}$$

We wish to show that

$$\sup_{0\leqq t\leqq T} \int_\Omega u_k^2(x,t)\,dx + \int_{Q_T} |\nabla u_k|^2\,dx\,dt \leqq c \qquad (k=1,2,\cdots). \tag{4.11}$$

For this purpose, fix a positive number M. For each k let s_k be the solution of the following equation:

$$\alpha_k(s) = M. \tag{4.12}$$

By [A4], there is a positive number M_0 so that

$$\liminf_{k\to\infty} s_k > M_0. \tag{4.13}$$

Use $(v_k - M)^+$ as a test function in (4.5) to get

$$\begin{aligned} &\frac{1}{2}\int_\Omega [(v_k(x,T)-M)^+]^2\,dx - \frac{1}{2}\int_\Omega [(v_0-M)^+]^2\,dx \\ &\quad + \int_{(u_k\geqq s_k)} a(\nabla u_k)\alpha_k'(u_k)\nabla u_k\,dx\,dt + \int_0^T \int_{\partial\Omega} f(x,t,u_k)(v_k-M)^+\,ds\,dt \\ &= -\int_{\{u_k\geqq s_k\}} \sigma_k(u_k)\nabla\varphi_k(\varphi_k-\overline{\varphi_0})\alpha_k'(u_k)\nabla u_k\,dx\,dt \\ &\quad + \int_{Q_T} \sigma_k(u_k)\nabla\varphi_k\nabla\overline{\varphi_0}(v_k-M)^+\,dx\,dt. \end{aligned} \tag{4.14}$$

Without loss of generality, assume $a(0)=0$. According to (A4) and (4.3), there exist two positive numbers M_1 and M_2 such that

$$M_1 \leqq \alpha_k'(u_k) \leqq M_2 \quad \text{a.e. on } \{u_k \geqq s_k\} \tag{4.15}$$

at least for k sufficiently large. Also, the term $\int_0^T \int_{\partial\Omega} f(x,t,u_k)(v_k-M)^+\,dS\,dt$ is nonnegative due to (A2). Consequently, we deduce from (4.9), (4.10), and (4.14) that

$$\begin{aligned} &\int_\Omega [(v_k(x,T)-M)^+]^2\,dx + c\int_{\{u_k\geqq s_k\}} |\nabla u_k|^2\,dx\,dt \\ &\leqq c_1 + c_2 \int_{Q_T} [(v_k-M)^+]^2\,dx\,dt. \end{aligned} \tag{4.16}$$

It is not difficult to see from the proof of (4.16) that

$$\frac{1}{2}\int_\Omega [(v_k(x,t)-M)^+]^2\,dx \leqq c_1 + c_2 \int_0^t \int_\Omega [(v_k-M)^+]^2\,dx\,dt$$

for all $t\in(0,T]$.

An application of Gronwall's inequality yields

$$\sup_{0\leqq t\leqq T} \int_\Omega [(v_k(x,t)-M)^+]^2\,dx \leqq c \qquad (k=1,2,\cdots). \tag{4.17}$$

In a similar fashion, we can find a positive number M_3 so that

$$\sup_{0\leqq t\leqq T}\int_\Omega [(v_k(x,t)+M_3)^-]^2\,dx\leqq c \qquad (k=1,2,\cdots). \tag{4.18}$$

Combining (4.17) and (4.18) yields

$$\sup_{0\leqq t\leqq T}\int_\Omega v_k^2(x,t)\,dx\leqq c \qquad (k=1,2,\cdots). \tag{4.19}$$

This, together with [A4], implies

$$\sup_{0\leqq t\leqq T}\int_\Omega u_k^2(x,t)\,dx\leqq c \qquad (k=1,2,\cdots). \tag{4.20}$$

Use u_k as a test function in (4.5), and keep in mind Lemma 3.3, to get

$$\begin{aligned}&\int_\Omega\int_0^{v_k(x,T)}\alpha_k^{-1}(s)\,ds\,dx-\int_\Omega\int_0^{v_0(x)}\alpha_k^{-1}(s)\,ds\,dx+c\int_{Q_T}|\nabla u_k|^2\,dx\,dt\\ &\leqq-\int_{Q_T}\sigma_k(u_k)\nabla\varphi_k(\varphi_k-\overline{\varphi_0})\nabla u_k\,dx\,dt+\int_{Q_T}\sigma_k(u_k)\nabla\varphi_k\nabla\overline{\varphi_0}u_k\,dx\,dt.\end{aligned} \tag{4.21}$$

Since $\alpha_k(0)=0$, the term $\int_0^{v_k(x,T)}\alpha_k^{-1}(s)\,ds=\int_0^{\alpha_k(u_k(x,T))}\alpha_k^{-1}(s)\,ds$ is nonnegative. Also, recall that $\alpha_k^{-1}(s)\to\alpha^{-1}(s)$ uniformly on $\mathbb{R}$ as $k\to\infty$. We have

$$\int_\Omega\int_0^{v_0(x)}\alpha_k^{-1}(s)\,ds\,dx\to\int_\Omega\int_0^{v_0(x)}\alpha^{-1}(s)\,ds\,dx,$$

which is finite by our assumption. We estimate from (4.21), using (4.20), (4.9), and (4.10) that

$$\int_{Q_T}|\nabla u_k|^2\,dx\,dt\leqq c \qquad (k=1,2,\cdots).$$

This completes the proof of (4.11).

It follows from (4.11) and (4.5) that $\{(\partial/\partial t)v_k\}$ is bounded in $L^2(0,T;U^*)$. This, together with (4.19), implies that $\{v_k\}$ is precompact in $L^2(0,T;U^*)$ (see [S]). Thus we may select a subsequence of $\{k\}$, still denoted by $\{k\}$, so that

$$u_k\to u \quad \text{weakly in } L^2(0,T;W^{1,2}(\Omega)), \tag{4.22}$$

$$a(\nabla u_k)\to L \quad \text{weakly in } [L^2(Q_T)]^N, \tag{4.23}$$

$$v_k\to v \quad \text{weakly in } L^2(Q_T) \quad \text{and strongly in } L^2(0,T;U^*), \tag{4.24}$$

$$\sigma_k(v_k)\nabla\varphi_k\to g \quad \text{weakly in } [L^2(Q_T)]^N, \tag{4.25}$$

$$\varphi_k\to\varphi \quad \text{weakly* in } L^\infty(Q_T). \tag{4.26}$$

By (4.22) and (4.24), we have

$$\int_{Q_T}(v_k-v)(u_k-u)\,dx\,dt=\int_0^T(v_k-v,u_k-u)\,dt\to 0 \quad \text{as } k\to\infty,$$

where $(\cdot,\cdot)$ denoted the duality pairing between U^* and $W^{1,2}(\Omega)$.

Consequently,

$$\begin{aligned}\int_{Q_T}&(\alpha_k(u_k)-\alpha_k(u))(u_k-u)\,dx\,dt\\&=\int_{Q_T}(\alpha_k(u_k)-v)(u_k-u)\,dx\,dt\\&\quad+\int_{Q_T}(v-\alpha_k(u))(u_k-u)\,dx\,dt\to 0\quad\text{as } k\to\infty.\end{aligned}$$

Hence, passing if need be to a further subsequence, we deduce

$$0\leqq(\alpha_k(u_k)-\alpha_k(u))(u_k-u)\to 0\quad\text{a.e. on } Q_T. \tag{4.27}$$

Since $\alpha^{-1}(s)$ is a single-valued function, we can derive from (4.27) that

$$u_k\to u\quad\text{a.e. on } Q_T. \tag{4.28}$$

In view of (A4) and (4.28), we have that $v_ku_k\to vu$ almost everywhere on Q_T. By (4.27), $\int_{Q_T} v_ku_k\,dx\,dt\to\int_{Q_T} vu\,dx\,dt$. Then a result of [X4] asserts that $\{v_ku_k\}$ is uniformly integrable. This, together with (A4), implies that $\{u_k^2\}$ is uniformly integrable. We may appeal to Vitali's theorem to conclude that

$$u_k\to u\quad\text{strongly in } L^2(0,T;L^2(\Omega)). \tag{4.29}$$

Now we are in a position to invoke the trace theorem [CDK] to get

$$u_k\to u\quad\text{strongly in } L^2(0,T;L^2(\partial\Omega)). \tag{4.30}$$

We wish to modify the proof presented in [X2, § 3] so that we can establish

$$\varphi_k\to\varphi\quad\text{a.e. on } Q_T. \tag{4.31}$$

For each k let

$$\psi_k=\varphi_k-\overline{\varphi_0}\quad\text{and}\quad\psi=\varphi-\overline{\varphi_0}.$$

Then ψ_k is a solution of the problem

$$-\operatorname{div}(\sigma_k(u_k)\nabla\psi_k)=\operatorname{div}(\sigma_k(u_k)\nabla\overline{\varphi_0})\quad\text{in } Q_T,$$

$$\psi_k=0\quad\text{in } S_T.$$

For $\theta\in\mathscr{A}$, where $\mathscr{A}$ is defined in § 1, and $m\in\{1,2,\cdots\}$, let

$$\phi_k^{(m)}=1-\theta\left(\frac{1}{m}|u_k|\right),\qquad \phi^{(m)}=1-\theta\left(\frac{1}{m}|u|\right)\equiv F_\theta^{(m)}.$$

By the proof presented in [X2, § 3], there hold

$$0\leqq\phi_k^{(m)}\leqq 1,\qquad 0\leqq\phi^{(m)}\leqq 1,$$

$$\int_{Q_T}|\nabla\phi_k^{(m)}|^2\,dx\,dt\leqq\frac{c}{m^2},$$

$$\int_{Q_T}|\nabla\phi^{(m)}|^2\,dx\,dt\leqq\frac{c}{m^2}\qquad(m=1,2,\cdots),$$

and for each fixed m

$$\phi_k^{(m)}\to\phi^{(m)}\quad\text{strongly in } L^2(Q_T)\ \text{ and weakly in } L^2(0,T;W^{1,2}(\Omega)),$$

$$\psi_k\phi_k^{(m)}\to\psi\phi^{(m)}\quad\text{weakly in } L^2(0,T;W_0^{1,2}(\Omega)).$$

Now we are in a position to establish

$$(4.32)\quad \limsup_{k\to\infty}\int_{Q_T}\sigma_k(u_k)|\nabla(\psi_k\phi_k^{(m)}-\psi\phi^{(m)})|^2\,dx\,dt\leqq\frac{c}{m}\qquad(m=1,2,\cdots).$$

To this end, we calculate, for $\chi\in L^2(0,T;W_0^{1,2}(\Omega))$, that

$$\begin{aligned}\int_{Q_T}\sigma_k(u_k)\nabla(\psi_k\phi_k^{(m)})\nabla\chi\,dx\,dt=&-\int_{Q_T}\sigma_k(u_k)\nabla\overline{\varphi_0}\nabla(\chi\phi_k^{(m)})\,dx\,dt\\&-\int_{Q_T}\sigma_k(u_k)\chi\nabla\psi_k\nabla\phi_k^{(m)}\,dx\,dt\\&+\int_{Q_T}\sigma_k(u_k)\psi_k\nabla\phi_k^{(m)}\nabla\chi\,dx\,dt.\end{aligned}$$

Note that $\psi_k\phi_k^{(m)},\psi\phi^{(m)}\in L^2(0,T;W_0^{1,2}(\Omega))$. Set $\chi=\psi_k\phi_k^{(m)}-\psi\phi^{(m)}$ in the above equation to obtain

$$\begin{aligned}&\int_{Q_T}\sigma_k(u_k)\nabla(\psi_k\phi_k^{(m)})\nabla(\psi_k\phi_k^{(m)}-\psi\phi^{(m)})\,dx\,dt\\&=-\int_{Q_T}\sigma_k(u_k)\nabla\overline{\varphi_0}\nabla[(\psi_k\phi_k^{(m)}-\psi\phi^{(m)})\phi_k^{(m)}]\,dx\,dt\\&\quad-\int_{Q_T}\sigma_k(u_k)(\psi_k\phi_k^{(m)}-\psi\phi^{(m)})\nabla\psi_k\nabla\phi_k^{(m)}\,dx\,dt\\&\quad+\int_{Q_T}\sigma_k(u_k)\psi_k\nabla\phi_k^{(m)}\nabla(\psi_k\phi_k^{(m)}-\psi\phi^{(m)})\,dx\,dt\\&\equiv I_1+I_2+I_3.\end{aligned}$$

Each term on the right-hand side is estimated below:

$$\begin{aligned}I_1=&-\int_{Q_T}\sigma_k(u_k)\nabla\overline{\varphi_0}\nabla\phi_k^{(m)}(\psi_k\phi_k^{(m)}-\psi\phi^{(m)})\,dx\,dt\\&-\int_{Q_T}\sigma_k(u_k)\nabla\overline{\varphi_0}\phi_k^{(m)}\nabla(\psi_k\phi_k^{(m)}-\psi\phi^{(m)})\,dx\,dt\\\leqq&\, c\|\nabla\overline{\varphi_0}\|_{L^2(Q_T)}\|\nabla\phi_k^{(m)}\|_{L^2(Q_T)}\\&-\int_{Q_T}\sigma_k(u_k)\nabla\overline{\varphi_0}\phi_k^{(m)}\nabla(\psi_k\phi_k^{(m)}-\psi\phi^{(m)})\,dx\,dt\\\leqq&\frac{c_1}{m}-\int_{Q_T}\sigma_k(u_k)\nabla\overline{\varphi_0}\phi_k^{(m)}\nabla(\psi_k\phi_k^{(m)}-\psi\phi^{(m)})\,dx\,dt\\\to&\frac{c_1}{m}\quad\text{as } k\to\infty.\end{aligned}$$

I_2 and I_3 can be estimated in the same manner as in [X2, § 3]:

$$\begin{aligned}|I_2|\leqq&\, c\|\sigma_k(u_k)\nabla\psi_k\|_{L^2(Q_T)}\|\nabla\phi_k^{(m)}\|_{L^2(Q_T)}\leqq\frac{c_1}{m},\\|I_3|\leqq&\frac{c}{m}+c_1\frac{1}{m^2}+\frac{c_2}{m}\|\sigma_k(u_k)\nabla(\psi\phi^{(m)})\|_{L^2(Q_T)}\\&\to\frac{c}{m}+c_1\frac{1}{m^2}+\frac{c_2}{m}\|\sigma(u)\nabla(\psi\phi^{(m)})\|_{L^2(Q_T)}\quad\text{as } k\to\infty\leqq\frac{c_3}{m}.\end{aligned}$$

We are ready to estimate

$$\limsup_{k\to\infty}\int_{Q_T}\sigma_k(u_k)|\nabla(\psi_k\phi_k^{(m)}-\psi\phi^{(m)})|^2\,dx\,dt$$

$$\leqq\limsup_{k\to\infty}\int_{Q_T}\sigma_k(u_k)\nabla(\psi_k\phi_k^{(m)})\nabla(\psi_k\phi_k^{(m)}-\psi\phi^{(m)})\,dx\,dt$$

$$+\lim_{k\to\infty}-\int_{Q_T}\sigma_k(u_k)\nabla(\psi\phi^{(m)})\nabla(\psi_k\phi_k^{(m)}-\psi\phi^{(m)})\,dx\,dt\leqq\frac{c}{m}.$$

This completes the proof of (4.32).

Choose a bounded domain D in $\mathbb{R}^N$ so that

$$D\supset\bar{\Omega}.$$

We extend each u_k to belong to $L^2(0, T;\ W_0^{1,2}(D))$ in such a manner that there still hold

$$u_k\to u\quad\text{strongly in } L^2(0, T;\ L^2(D)),$$

$$u_k\to u\quad\text{weakly in } L^2(0, T;\ W_0^{1,2}(D)).$$

A careful examination of the proofs of the extension theorems in [AD] clearly indicates that such an extension is possible. We extend each ψ_k to be identically zero outside Q_T. Clearly, we still have $\psi_k\in L^2(0, T;\ W_0^{1,2}(D))$ for each k, and (4.32) still holds with Q_T replaced by $DX(0, T)$.

Whenever $E\subset DX(0, T)$, $1\leqq p<\infty$, define

$$X_p(E)=\inf\left\{\int_{DX(0,T)}|\nabla v|^p\,dx\,dt\colon v\in L^p(0, T;\ W_0^{1,p}(D)),\ v\geqq 1\quad\text{a.e. on } E\right\}.$$

We easily verify that X_p is an outer measure over $DX(0, T)$; see [X2, Lemma 2.1]. We can also prove, as in [X2, Lemma 2.2], the following lemma.

LEMMA 4.1. *Assume that the sequence* $\{f_k\}$ *is bounded in* $L^2(0, T;\ W_0^{1,2}(D))$ *and precompact in* $L^2(0, T;\ L^2(D))$. *Then there exist a subsequence* $\{f_{k_j}\}\subset\{f_k\}$ *and a function* $f\in L^2(0, T;\ W_0^{1,2}(D))$ *such that for each* $1\leqq p<2$ *and each* $\delta>0$, *there exists a set* $E_\delta\subset DX(0, T)$ *with*

$$f_{k_j}\to f\quad\textit{uniformly on } E_\delta\quad\textit{and}\quad X_p(DX(0, T)\backslash E_\delta)\leqq\delta.$$

Once we have Lemma 4.1 and (4.32), we can appeal to the proof presented in [X2, § 3] to conclude that

$$\psi_k\to\psi\quad\text{a.e. on } DX(0, T).$$

This completes the proof of (4.31).

Remark. Here we do not have estimates of the type

$$d_{u,\varepsilon}(h)=\frac{1}{h^\varepsilon}\left(\int_0^{T-h}\int_D(u(x, t+h)-u(x, t))^2\,dx\,dt\right)^{1/2}\leqq c$$

for all $h\in(0, T)$ and some $\varepsilon>0$

for u_n. If we examine the proof of Lemmas 2.1 and 2.2 in [X2], the only purpose such estimates serve is to guarantee that a bounded sequence in $L^2(0, T;\ W_0^{1,2}(D))$ is precompact in $L^2(Q_T)$. Here we already know that $[u_k\}$ is precompact in $L^2(Q_T)$. Thus we may ignore the term $d_{u,\alpha}(h)$ and claim that Lemmas 2.1 and 2.2 in [X2] remain true even when $\varepsilon=0$. However, we are no longer able to use the method employed in [X2, § 2] to prove

$$\nabla u_k \to \nabla u \quad \text{a.e. on } Q_T.$$

For this, we need to adopt a different analysis here. We calculate, using Lemma 3.3, that

$$\begin{aligned}\int_0^T \left(\frac{\partial}{\partial t} v_k, u_k\right) dt &= \int_\Omega \int_0^{v_k(x,T)} \alpha_k^{-1}(s)\, ds\, dx - \int_\Omega \int_0^{v_0(x)} \alpha_k^{-1}(s)\, ds\, dx \\ &= \int_\Omega \int_0^{v_k(x,T)} (\alpha_k^{-1}(s)-\alpha^{-1}(s))\, ds\, dx \\ &\quad - \int_\Omega \int_0^{v_0(x)} (\alpha_k^{-1}(s)-\alpha^{-1}(s))\, ds\, dx \\ &\quad + \int_\Omega \int_0^{v_k(x,T)} \alpha^{-1}(s)\, ds\, dx - \int_\Omega \int_0^{v_0(x)} \alpha^{-1}(s)\, ds\, dx.\end{aligned} \tag{4.33}$$

Recall that $\alpha_k^{-1} \to \alpha^{-1}$ uniformly on $\mathbb{R}$ as $k\to\infty$. Thus the first two terms on the right-hand side of (4.33) converge to zero as $k\to\infty$. Since $\{(\partial/\partial t)v_k\}$ is bounded in $L^2(0, T;\ U^*)$, it is not difficult for us to verify that

$$v_k \in C([0, T];\ L^2(\Omega)),$$
$$v_k(\cdot, t)\to v(\cdot, t) \quad \text{weakly in } L^2(\Omega) \quad \text{for all } t\in[0, T].$$

We deduce from (4.33) that

$$\begin{aligned}\liminf_{k\to\infty} \int_0^T \left(\frac{\partial}{\partial t} v_k, u_k\right) dt &\geqq \int_\Omega \int_0^{v(x,T)} \alpha^{-1}(s)\, ds\, dx \\ &\quad - \int_\Omega \int_0^{v_0(x)} \alpha^{-1}(s)\, ds\, dx.\end{aligned} \tag{4.34}$$

We may take $k\to\infty$ in (4.5) to get

$$\frac{\partial}{\partial t} v + \tilde{A}(u) = \tilde{B}(u, \varphi) \quad \text{in } L^2(0, T;\ U^*), \tag{4.35}$$

where $\tilde{A}(u)$ is given by

$$\begin{aligned}\int_0^T (\tilde{A}(u), v)\, dt = \int_0^T \int_\Omega L\nabla v\, dx\, dt + \int_0^T \int_{\partial\Omega} f(x, t, u) v\, ds\, dt \\ \text{for each } v\in L^2(0, T;\ W^{1,2}(\Omega)),\end{aligned} \tag{4.36}$$

and $\tilde{B}(u, \varphi)$ is defined by

$$\begin{aligned}\int_0^T (\tilde{B}(u, \varphi), v)\, dt = -\int_{Q_T} (\varphi - \overline{\varphi_0}) g \nabla v\, dx\, dt + \int_{Q_T} g\nabla \overline{\varphi_0} v\, dx\, dt \\ \text{for each } v\in L^2(0, T;\ W^{1,2}(\Omega)).\end{aligned} \tag{4.37}$$

A result of [BCS] asserts that

$$v\in\alpha(u) \quad \text{a.e. on } Q_T.$$

Moreover, we have that $(\partial/\partial t)v\in L^2(0, T;\ U^*)$ and that

$$\int_0^T \left(\frac{\partial}{\partial t} v, u\right) dt = \int_\Omega \int_0^{v(x,T)} \alpha^{-1}(s)\, ds\, dx - \int_\Omega \int_0^{v_0(x)} \alpha^{-1}(s)\, ds\, dx. \tag{4.38}$$

Now we use u_k as a test function in (4.5) to get

$$
\begin{aligned}
\int_{Q_T} a(\nabla u_k)\nabla u_k\,dx\,dt = &-\int_0^T \left(\frac{\partial}{\partial t} v_k, u_k\right) dt - \int_0^T \int_{\partial\Omega} f(x,t,u_k)u_k\,ds\,dt \\
&-\int_{Q_T} \sigma_k(u_k)\nabla\varphi_k(\varphi_k - \overline{\varphi_0})\nabla u_k\,dx\,dt \qquad (4.39)\\
&+\int_{Q_T} \sigma_k(u_k)\nabla\varphi_k\nabla\overline{\varphi_0}u_k\,dx\,dt.
\end{aligned}
$$

Pick a θ from $\mathscr{A}$ so that $\theta(s)=0$ on $(-\infty, \frac{1}{2})$. For each m let

$$p(m) = \sup_{|s|\geqq m/2} \sigma(s).$$

We estimate

$$
\begin{aligned}
&\left|\int_{Q_T} \sigma_k(u_k)\nabla\left(\varphi_k\theta\left(\frac{1}{m}|u_k|\right)\right)(\varphi_k - \overline{\varphi_0})\nabla(u_k-u)\,dx\,dt\right| \\
&\leqq \left|\int_{Q_T} \sigma_k(u_k)\theta\left(\frac{1}{m}|u_k|\right)\nabla\varphi_k(\varphi_k - \overline{\varphi_0})\nabla(u_k-u)\,dx\,dt\right| \\
&\quad+\left|\int_{Q_T} \sigma_k(u_k)\varphi_k\nabla\left(\theta\left(\frac{1}{m}|u_k|\right)\right)(\varphi_k - \overline{\varphi_0})\nabla(u_k-u)\,dx\,dt\right| \qquad (4.40)\\
&\leqq\left(\int_{Q_T}\left[\sigma_k(u_k)\theta\left(\frac{1}{m}|u_k|\right)(\varphi_k-\overline{\varphi_0})\right]^2|\nabla\varphi_k|^2\,dx\,dt\right)^{1/2}\|\nabla(u_k-u)\|_{L^2(Q_T)}+\frac{c}{m} \\
&\leqq c_1\sqrt{p(m)+1/k}+\frac{c}{m}.
\end{aligned}
$$

We have that

$$
\begin{aligned}
&\limsup_{k\to\infty}\left|\int_{Q_T} \sigma_k(u_k)\nabla(\varphi_k\phi_k^{(m)})(\varphi_k - \overline{\varphi_0})\nabla(u_k-u)\,dx\,dt\right| \\
&\leqq \limsup_{k\to\infty}\left|\int_{Q_T} \sigma_k(u_k)\nabla(\psi_k\phi_k^{(m)})(\varphi_k - \overline{\varphi_0})\nabla(u_k-u)\,dx\,dt\right| \qquad (4.41)\\
&\quad+\limsup_{k\to\infty}\left|\int_{Q_T} \sigma_k(u_k)\nabla(\bar{\varphi}_0\phi_k^{(m)})(\varphi_k - \overline{\varphi_0})\nabla(u_k-u)\,dx\,dt\right. \\
&\equiv J_1+J_2.
\end{aligned}
$$

Note that $\{\sigma_k(u_k)(\varphi_k-\bar{\varphi})\}$ converges strongly in $L^2(Q_T)$ due to (4.31). Consequently,

$$
\begin{aligned}
J_2 \leqq &\lim_{k\to\infty}\left|\int_{Q_T} \sigma_k(u_k)\phi_k^{(m)}\nabla\overline{\varphi_0}(\varphi_k - \overline{\varphi_0})\nabla(u_k-u)\,dx\,dt\right| \\
&+\limsup_{k\to\infty}\left|\int_{Q_T} \sigma_k(u_k)\overline{\varphi_0}\nabla\phi_k^{(m)}(\varphi_k - \overline{\varphi_0})\nabla(u_k-u)\,dx\,dt\right| \\
&\leqq \limsup_{k\to\infty} c\|\nabla\phi_k^{(m)}\|_{L^2(Q_T)}\|\nabla(u_k-u)\|_{L^2(Q_T)} \leqq \frac{c_1}{m}.
\end{aligned}
$$

To estimate J_1, we use (4.32) to obtain

$$J_1 \leqq \limsup_{k\to\infty} \left| \int_{Q_T} \sigma_k(u_k)\nabla(\psi_k\phi_k^{(m)} - \psi\phi^{(m)})(\varphi_k - \overline{\varphi_0})\nabla(u_k - u)\, dx\, dt \right|$$

$$+ \lim_{k\to\infty} \left| \int_{Q_T} \sigma_k(u_k)\nabla(\psi\phi^{(m)})(\varphi_k - \overline{\varphi_0})\nabla(u_k - u)\, dx\, dt \right| \leqq \frac{c}{\sqrt{m}}.$$

We conclude that

$$\limsup_{k\to\infty} \left| \int_{Q_T} \sigma_k(u_k)\nabla(\varphi_k\phi_k^{(m)})(\varphi_k - \overline{\varphi_0})\nabla(u_k - u)\, dx\, dt \right| \leqq \frac{c}{\sqrt{m}}. \tag{4.42}$$

We derive from (4.40) and (4.42) that

$$\begin{aligned} &\limsup_{k\to\infty} - \int_{Q_T} \sigma_k(u_k)\nabla\varphi_k(\varphi_k - \overline{\varphi_0})\nabla u_k\, dx\, dt \\ &\leqq - \int_{Q_T} g(\varphi - \overline{\varphi_0})\nabla u\, dx\, dt \\ &\quad + \limsup_{k\to\infty} - \int_{Q_T} \sigma_k(u_k)\nabla\left(\varphi_k\phi_k^{(m)} + \varphi_k\theta\left(\frac{1}{m}|u_k|\right)\right) \\ &\quad \cdot(\varphi_k - \overline{\varphi_0})\nabla(u_k - u)\, dx\, dt \\ &\leqq - \int_{Q_T} g(\varphi - \overline{\varphi_0})\nabla u\, dx\, dt + c\left(\frac{1}{m} + \frac{1}{\sqrt{m}} + \sqrt{p(m)}\right). \end{aligned} \tag{4.43}$$

By (A3), $\lim_{m\to\infty} p(m) = 0$. Thus we have from (4.43) that

$$\limsup_{k\to\infty} - \int_{Q_T} \sigma_k(u_k)\nabla\varphi_k(\varphi_k - \overline{\varphi_0})\nabla u_k\, dx\, dt \leqq - \int_{Q_T} g(\varphi - \overline{\varphi_0})\nabla u\, dx\, dt. \tag{4.44}$$

Letting $k \to \infty$ in (4.39) and taking into account (4.34), (4.31), (4.30), and (4.44) yields

$$\begin{aligned} \limsup_{k\to\infty} \int_{Q_T} a(\nabla u_k)\nabla u_k\, dx\, dt \leqq &- \int_\Omega \int_0^{v(x,T)} \alpha^{-1}(s)\, ds\, dx + \int_\Omega \int_0^{v_0(x)} \alpha^{-1}(s)\, ds\, dx \\ &- \int_0^T \int_{\partial\Omega} f(x, t, u)u\, ds\, dt \\ &- \int_{Q_T} g(\varphi - \overline{\varphi_0})\nabla u\, dx\, dt + \int_{Q_T} g\nabla\overline{\varphi_0}u\, dx\, dt. \end{aligned}$$

This, together with (4.35) and (4.38), implies

$$\limsup_{k\to\infty} \int_{Q_T} a(\nabla u_k)\nabla u_k\, dx\, dt \leqq \int_{Q_T} L\nabla u\, dx\, dt$$

whence follows

$$\lim_{k\to\infty} \int_{Q_T} |\nabla u_k - \nabla u|^2\, dx\, dt = 0.$$

Consequently,

$$L = a(\nabla u) \quad \text{a.e. } Q_T.$$

Equation (1.2) is a consequence of (4.35). Taking $k \to \infty$ in (4.6) yields (1.3). Equations (1.4), (1.5), and (1.6) can be obtained in the same manner as in [X2]. This completes the proof of our main theorem.

A FREE BOUNDARY PROBLEM ARISING IN ELECTROPHOTOGRAPHY: SOLUTIONS WITH CONNECTED TONER REGION*

BEI HU† AND LIHE WANG‡

Abstract. A free boundary problem that arises in the development of a photocopy is studied. The electric potential $-u$ satisfies the equation $\Delta u = 1$ in the toner region and $\Delta u = 0$ elsewhere. It is shown that $C^{1+\alpha}$ smoothness of the free boundary would imply the $C^{2+\alpha}$ smoothness of the solution up to both sides of the free boundary. Using this fact, the existence of a solution with connected it is proven that toner region with $\frac{\partial u}{\partial n} = 0$ on the free boundary when the electrical charge length is "small."

Key words. free boundary problems, electrophotography, photocopy, elliptic estimates

AMS(MOS) subject classifications. 35B45, 35R05, 35R35

1. Introduction.

One of the steps in the photocopying process is the development of the electrical image into a visible image. A positively charged toner is brushed on to the electrical image, and a visible dark image is therefore produced. This process is modeled as a nonstandard free boundary problem. (See [2], [3] for more details.)

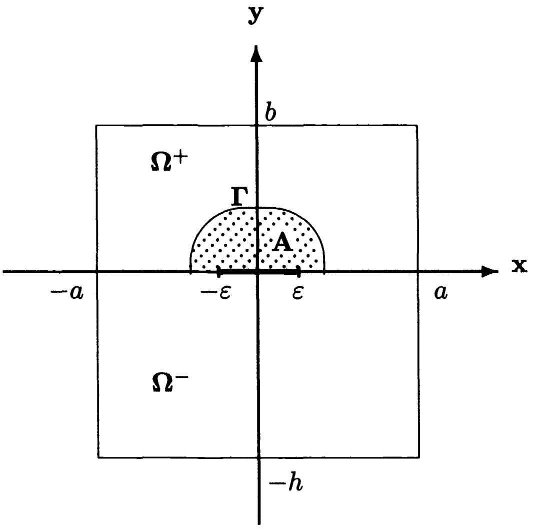

FIG. 1

We set (see Fig. 1)

$$\Omega^+ = \{(x,y);\ |x| < a, 0 < y < b\},$$
$$\Omega^- = \{(x,y);\ |x| < a, -h < y < 0\},$$

$$I = \{(x,0);\ |x| < \varepsilon\},$$
$$J = \{(x,0);\ |x| < a\},$$
$$\Omega = \{(x,y);\ |x| < a, -h < y < b\} = \Omega^+ \cup J \cup \Omega^-.$$

The problem is formulated as follows. Find the pair (u, A) such that

$$\Delta u = 1 \quad \text{in } A, \tag{1.1}$$
$$\Delta u = 0 \quad \text{in } \Omega \setminus \overline{A}, \tag{1.2}$$
$$u \in C^1(\overline{\Omega} \setminus \overline{I}), \tag{1.3}$$
$$u_y(x, 0+) - u_y(x, 0-) = -\sigma \quad \text{in } I, \tag{1.4}$$

and u satisfies the free boundary condition

$$\frac{\partial u}{\partial n} = 0 \quad \text{on } \Gamma, \tag{1.5}$$

where $\Gamma = \partial A \cap \Omega^+$ and $\frac{\partial}{\partial n}$ is the outward normal to A, and also the boundary conditions:

$$u(x, -h) = 0 \qquad -a < x < a, \tag{1.6}$$
$$u(x, b) = M \qquad -a < x < a, \tag{1.7}$$
$$u_x(\pm a, y) = 0 \qquad -h < y < b. \tag{1.8}$$

Here $-u$ is the electrical potential. The jump condition (1.4) on the interval I represents a negative surface charge, and positively charged toner is expected to be attracted to cover the interval I. The domain A is the toner region, and $(\Omega^+ \setminus A)$ is the air region. The condition (1.5) indicates that there is no force to attract or repel the toner on the interface between the toner and air, and, therefore, the toner region reaches its equilibrium. This should be the case when the image is fully developed. Mathematically, the toner region A is a nonempty region where $\Delta u = 1$.

a, b, h, M, σ in (1.1)–(1.8) are positive constants, and it is reasonable to assume that (see [3])

$$M < \sigma h, \qquad b \geq h. \tag{1.9}$$

When $a - \varepsilon$ is small, the problem reduces to a variational inequality; it is proved in [3] that in this case the problem has a unique solution.

When ε is small, it is proved in [3] that the problem is no longer a variational inequality and there are infinitely many solutions with two symmetric components, it is not clear, however, whether such solutions are physical.

The toner is expected to cover the entire interval I, where a black dot should develop. A connected toner region over the interval I will serve such a purpose. It is shown in [3] that there exists a "ε^m-approximate" solution for which the toner set consists of a single component. The tool used there is the topological fixed point theorem. In order to use a topological fixed point theorem, the system (1.1)–(1.4) is solved with the boundary condition (1.6)–(1.8) for each given Γ, and then a new Γ is obtained, roughly speaking, by solving (1.5). The difficulty for finding a real solution with one connected toner region is that the corresponding u will have $\nabla u = 0$ at the point $\Gamma \cap \{x = 0\}$, which makes it very difficult to solve the dynamical system (1.5) for the new $\Gamma = \{(x,y);\ x = x(t),\ y = y(t)\}$. In [3], a $W^{2,p}$ estimate is employed for the Partial Differential Equation (PDE) solution; however, for this dynamical system coupled with the solution of the PDE, it is clear that more regularity is required on the solution of the PDE to use a fixed point theorem.

Here we prove that if ε is small, the problem has a solution with one connected toner region. In §2, we prove an elliptic estimate that is of independent interest. Using the elliptic estimate, we prove in §3 the existence result.

Recently, this problem has been formulated in [6] as an optimization problem. The solution of the optimization problem is an approximate solution of (1.1)–(1.8) in some sense.

2. Elliptic estimate. In this section, we shall establish that $C^{1+\alpha}$ smoothness of the free boundary would imply the $C^{2+\alpha}$ smoothness of the solution up to both sides of the free boundary. Suppose that Γ is given by $y = g(x)$ for $-2 < x < 2$ with $g(0) = 0$. Let $B(s)$ denote the ball of radius s centered at (0,0). Suppose that

$$\Delta u = \theta \chi_E \quad \text{for } (x,y) \in B(2), \quad (0 < \theta \leq 1), \tag{2.1}$$

where χ_E is the characteristic function of E and $E = \{y > g(x)\}$.

THEOREM 2.1. *Suppose that*

$$\sup_{B(2)} |u(x,y)| \leq L, \tag{2.2}$$

and

$$\|g\|_{C^{1+\alpha}(-2,2)} \leq K, \tag{2.3}$$

where $0 < \alpha < 1$. *Then*

$$\|u\|_{C^{2+\alpha}(\overline{E} \cap B(1))} \leq C, \tag{2.4}$$

$$\|u\|_{C^{2+\alpha}((\overline{B(1) \setminus E}))} \leq C, \tag{2.5}$$

where the constant C depends only on L, K, and α.

Remark. The proof below will actually show that the conclusion is also true in n dimensions.

The proof uses harmonic polynomials to approximate the derivatives. Such a technique was used in Caffarelli and Friedman [1]. (See also [4]). It is worth mentioning that because of the discontinuous right-hand side, the space L^1 seems to be the right choice (cf. Lemma 2.4).

We shall divide the proof into several lemmas.

LEMMA 2.2. *If*

$$\Delta u = f \quad \text{in } B(s), \tag{2.6}$$

$$u = 0 \quad \text{on } \partial B(s); \tag{2.7}$$

where $0 < s \leq 1$, *then*

$$\int_{B(s)} |u| \leq \frac{1}{4} \int_{B(s)} |f|. \tag{2.8}$$

Proof.

$$u(x,y) = \int_{B(s)} G(x-\xi, y-\eta) f(\xi,\eta) d\xi d\eta, \tag{2.9}$$

where G is the Green function on $B(s)$. Therefore,

$$\begin{aligned}\int_{B(s)} |u(x,y)|dx\,dy &\le \int_{B(s)} \left(\int_{B(s)} |G(x-\xi, y-\eta)|dx\,dy \right) |f(\xi,\eta)|d\xi d\eta \\ &= \int_{B(s)} \frac{1}{4}(s^2-\xi^2-\eta^2)|f(\xi,\eta)|d\xi d\eta \\ &\le \frac{1}{4}\int_{B(s)} |f(\xi,\eta)|d\xi d\eta. \end{aligned}$$ □

LEMMA 2.3. *Suppose that for some $s \in [\frac{3}{4}, 1]$, we have*

$$\Delta v = 0 \quad \textit{in } B(s) \tag{2.10}$$

$$\int_{\partial B(s)} |v|d\sigma \le L. \tag{2.11}$$

Then there exists a constant C_L depending only on L such that

$$|v(x,y) - P_2[v](x,y)| \le C_L r^3 \quad \textit{for } r = \sqrt{x^2+y^2} \le \tfrac{1}{2}\ , \tag{2.12}$$

where $P_2[v](x,y)$ is the second order polynomial of the Taylor series of v at $(0,0)$.

Proof. Using (2.11) and Poisson formula we conclude that

$$\|D^3 v\|_{L^\infty(B(1/2))} \le C_L, \tag{2.13}$$

from which the lemma follows. □

We now fix L and α. Then we take C_L as in Lemma 2.3, and select a number λ satisfying

$$0 < \lambda \le \frac{1}{2}, \qquad C_L \lambda^{1-\alpha} \le \frac{1}{2\pi}. \tag{2.14}$$

For such a fixed λ, we take ε_0 such that

$$\varepsilon_0 \le \lambda^{4+\alpha}. \tag{2.15}$$

Using the scaling $\overline{u}(x,y) = u(\delta x, \delta y)$ $(\delta = (\varepsilon_0/K)^{1/\alpha})$ if necessary, we may assume without loss of generality that

$$[g']_{C^\alpha(-2,2)} \le \varepsilon_0. \tag{2.16}$$

LEMMA 2.4. *Let the assumptions of Theorem 2.1 be in force, and let (2.16) hold. Then there exists a constant C such that for any $Q \in \Gamma \cap B(1)$, there exists P_Q*

$$\left\| u - \left(P_Q + \frac{\theta}{2}\left((\langle (x,y) - Q, \mathbf{n}_Q \rangle^+ \right)^2 \right) \right\|_{L^1(B_Q(r))} \le Cr^{4+\alpha} \quad \textit{for } 0 < r < \lambda, \tag{2.17}$$

where P_Q is a harmonic polynomial of second degree, and $\mathbf{n}_Q$ is the normal of Γ at Q in the direction of y-axis.

Proof. We may assume without loss of generality that

$$Q = (0,0), \quad g(0) = 0, \quad g'(0) = 0.$$

Then

$$|g(x)| \le \frac{\varepsilon_0}{1+\alpha}|x|^{1+\alpha} \le \varepsilon_0 |x|^{1+\alpha}. \tag{2.18}$$

Set

$$w_1(x,y) = u(x,y) - \frac{\theta}{2}(y^+)^2, \tag{2.19}$$

and define v_1 by

$$\Delta v_1 = 0 \quad \text{in } B(1), \tag{2.20}$$
$$v_1 = w_1 \quad \text{on } \partial B(1). \tag{2.21}$$

Then

$$\Delta(w_1 - v_1) = 0 \quad \text{in } B(1) \setminus \{|y| \ge \varepsilon_0 |x|\}, \tag{2.22}$$
$$|\Delta(w_1 - v_1)| \le 1 \quad \text{in } B(1). \tag{2.23}$$

Therefore, by Lemma 2.2 and (2.15),

$$\|w_1 - v_1\|_{L^1(B(1))} \le \tfrac{1}{4}\text{meas}(B(1) \cap \{|y| \le \varepsilon_0|x|\}) \le \tfrac{1}{2}\varepsilon_0 \le \tfrac{1}{2}\lambda^{4+\alpha}. \tag{2.24}$$

Clearly,

$$\int_{\partial B(1)} |v_1| = \int_{\partial B(1)} |w_1| \le L; \tag{2.25}$$

therefore, by Lemma 2.3,

$$\begin{aligned} &|v_1(x,y) - P_2[v_1](x,y)| \le C_L r^3 \le C_L \lambda^{1-\alpha}\lambda^{2+\alpha} \le \frac{1}{2\pi}\lambda^{2+\alpha} \\ &\quad \text{for } r = \sqrt{x^2+y^2} \le \lambda, \end{aligned} \tag{2.26}$$

which implies

$$\|v_1 - P_2[v_1]\|_{L^1(B(\lambda))} \le \frac{1}{2\pi}\lambda^{2+\alpha}\pi\lambda^2 \le \frac{1}{2}\lambda^{4+\alpha}. \tag{2.27}$$

The inequalities (2.24) and (2.27) imply

$$\|w_1 - P_2[v_1]\|_{L^1(B(\lambda))} \le \lambda^{4+\alpha}. \tag{2.28}$$

Next, define

$$w_2(x,y) = \frac{(w_1 - P_2[v_1])(\lambda x, \lambda y)}{\lambda^{2+\alpha}}, \tag{2.29}$$

and observe that, by (2.28),

$$\|w_2\|_{L^1(B(1))} = \frac{1}{\lambda^{4+\alpha}}\|w_1 - P_2[v_1]\|_{L^1(B(\lambda))} \le 1. \tag{2.30}$$

It follows that there exists $s_0 \in [\frac{3}{4}, 1]$ such that

$$\int_{\partial B(s_0)} |w_2| \le 4 \le L. \tag{2.31}$$

Now, define v_2 by

$$\Delta v_2 = 0 \quad \text{in } B(s_0), \tag{2.32}$$

$$v_2 = w_2 \quad \text{on } \partial B(s_0). \tag{2.33}$$

Then

$$\Delta(w_2 - v_2) = 0 \quad \text{in } B(s_0) \setminus \{|y| \geq \varepsilon_0 \lambda^\alpha |x|\}, \tag{2.34}$$

$$|\Delta(w_2 - v_2)| \leq \frac{1}{\lambda^\alpha} \quad \text{in } B(s_0). \tag{2.35}$$

Therefore, by Lemma 2.2 and (2.15),

$$\|w_2 - v_2\|_{L^1(B(s_0))} \leq \frac{1}{4} \int_{(B(s_0) \cap \{|y| \leq \varepsilon_0 \lambda^\alpha |x|\})} \frac{1}{\lambda^\alpha} \leq \frac{1}{2}\varepsilon_0 \leq \frac{1}{2}\lambda^{4+\alpha}. \tag{2.36}$$

Clearly by Lemma 2.3, using (2.31),

$$\begin{aligned} &|v_2(x,y) - P_2[v_2](x,y)| \leq C_L r^3 \leq C_L \lambda^{1-\alpha}\lambda^{2+\alpha} \leq \frac{1}{2\pi}\lambda^{2+\alpha} \\ &\text{for } r = \sqrt{x^2+y^2} \leq \lambda, \end{aligned} \tag{2.37}$$

and, therefore,

$$\|v_2 - P_2[v_2]\|_{L^1(B(\lambda))} \leq \frac{1}{2\pi}\lambda^{2+\alpha}\pi\lambda^2 \leq \frac{1}{2}\lambda^{4+\alpha}. \tag{2.38}$$

The inequalities (2.36) and (2.38) imply

$$\|w_2 - P_2[v_2]\|_{L^1(B(\lambda))} \leq \lambda^{4+\alpha}. \tag{2.39}$$

Now we inductively define

$$w_n(x,y) = \frac{(w_{n-1} - P_2[v_{n-1}])(\lambda x, \lambda y)}{\lambda^{2+\alpha}}. \tag{2.40}$$

Notice that whenever we scale the domain by λ, we get one more $1/\lambda^\alpha$ factor on the right-hand side of the equation; but that is compensated by the fact that we get one more factor of λ^α for the domain at the same time. Hence we obtain

$$\|w_n - P_2[v_n]\|_{L^1(B(\lambda))} \leq \lambda^{4+\alpha}, \tag{2.41}$$

where $P_2[v_n]$ is a harmonic polynomial of the second degree. It follows from (2.40) and (2.41) that

$$\|w_1 - P_n\|_{L^1(B(\lambda^n))} \leq C(\lambda^n)^{4+\alpha}, \tag{2.42}$$

where $C = 1/\lambda^2$, and

$$P_n = \sum_{k=1}^{n} P_2[v_k]\left(\frac{x}{\lambda^{k-1}}, \frac{y}{\lambda^{k-1}}\right)(\lambda^{k-1})^{2+\alpha}. \tag{2.43}$$

It is obvious that all coefficients of the harmonic polynomials $P_2[v_k]$ are bounded with the bounds depending only on L. If we set

$$P = \lim_{n\to\infty} P_n = \sum_{k=1}^{\infty} P_2[v_k]\left(\frac{x}{\lambda^{k-1}}, \frac{y}{\lambda^{k-1}}\right)(\lambda^{k-1})^{2+\alpha}, \tag{2.44}$$

then (assuming that $\lambda^\alpha \leq \frac{1}{2}$)

$$|\text{0th order coefficients of } (P - P_n)| \leq C \sum_{k=n}^{\infty} (\lambda^{2+\alpha})^k \leq 2C(\lambda^{2+\alpha})^n, \tag{2.45}$$

$$|\text{1st order coefficients of } (P - P_n)| \leq C \sum_{k=n}^{\infty} (\lambda^{1+\alpha})^k \leq 2C(\lambda^{1+\alpha})^n, \tag{2.46}$$

$$|\text{2nd order coefficients of } (P - P_n)| \leq C \sum_{k=n}^{\infty} (\lambda^{\alpha})^k \leq 2C(\lambda^{\alpha})^n. \tag{2.47}$$

So

$$\begin{aligned} &\|P - P_n\|_{L^1(B(\lambda^n))} \\ &\leq C\left[(\lambda^{2+\alpha})^n(\lambda^n)^2 + (\lambda^{1+\alpha})^n\lambda^n(\lambda^n)^2 + (\lambda^\alpha)^n(\lambda^n)^2(\lambda^n)^2\right] \\ &\leq C(\lambda^n)^{4+\alpha}. \end{aligned} \tag{2.48}$$

For each $0 < r < \lambda$, choose n so that $\lambda^{n+1} < r \leq \lambda^n$. Then by (2.48) and (2.41), we obtain

$$\|w_1 - P\|_{L^1(B(r)} \leq Cr^{4+\alpha} \quad \text{for } 0 < r < \lambda, \tag{2.49}$$

where P is a harmonic polynomial of second degree. □

Next, for any point $Q \in B(1)$, take $\pi(Q) \in \Gamma$ such that

$$d(Q, \pi(Q)) = \inf\{|Q - S|;\ S \in \Gamma\}. \tag{2.50}$$

Although Γ is not C^2 and, therefore, $\pi(Q)$ need not be uniquely determined by Q, the map $\pi : B(1) \to \Gamma$ is well defined by axiom of choice.

LEMMA 2.5. *Let the assumptions of Theorem* 2.1 *be in force, and let* (2.16) *hold. Then there exists a constant C such that for any $Q \in B(1)$, there exists P_Q*

$$\left\| u - \left(P_Q + \frac{\theta}{2}\left(\langle (x,y) - \pi(Q), \mathbf{n}_{\pi(Q)}\rangle^+\right)^2\right)\right\|_{L^1(B_Q(r))} \leq Cr^{4+\alpha} \quad \textit{for } 0 < r < \lambda\ , \tag{2.51}$$

where P_Q is a harmonic polynomial of second degree, and $\mathbf{n}_{\pi(Q)}$ is the normal of Γ at $\pi(Q)$ in the direction of y-axis.

Proof. We may assume without loss of generality that

$$\pi(Q) = (0,0), \quad g(0) = 0, \quad g'(0) = 0.$$

Set

$$w(x,y) = u(x,y) - \frac{\theta}{2}(y^+)^2, \tag{2.52}$$

and

$$G = \{x;\ \Delta w(x) \neq 0\}. \tag{2.53}$$

Then it is clear that

$$|G \cap B_Q(r)| \leq \varepsilon_0 r^{2+\alpha} \quad \text{for } 0 < r < 1, \tag{2.54}$$

where $B_Q(r)$ is a ball of radius r centered at Q. Now the remainder of the proof is the same as Lemma 2.4, where we shall use (2.54) instead of Lemma 2.2. □

Lemmas 2.4 and 2.5 give the equalities

$$u(Q) = P_Q(Q), \tag{2.55}$$

$$Du(Q) = DP_Q(Q), \tag{2.56}$$

and if $Q \notin \Gamma$,

$$D^2u(Q) = D^2P_Q(Q) + \frac{\theta}{2} D^2 \left((\langle (x,y) - \pi(Q), \mathbf{n}_{\pi(Q)} \rangle^+)^2 \right|_{(x,y)=Q}, \tag{2.57}$$

which implies that $\|u\|_{W^{2,\infty}(B(1))} \leq C$.

Lemma 2.6. *For any $Q_1, Q_2 \in B(1)$, there holds*

$$\begin{aligned} &\left| P_{Q_1}(x,y) - P_{Q_2}(x,y) + \frac{\theta}{2} \left((\langle (x,y) - \pi(Q_1), \mathbf{n}_{\pi(Q_1)} \rangle^+ \right)^2 \right. \\ &\left. - \frac{\theta}{2} \left((\langle (x,y) - \pi(Q_2), \mathbf{n}_{\pi(Q_2)} \rangle^+ \right)^2 \right| \leq Cr^{2+\alpha} \quad \textit{for} \quad \left| (x,y) - \frac{Q_1+Q_2}{2} \right| \leq \frac{r}{2}, \end{aligned} \tag{2.58}$$

where $r = 3|Q_1 - Q_2|$.

Proof. Let $d_i = d(Q_i, \pi(Q_i))$ for $i = 1, 2$. Without loss of generality, we assume that $d_1 \geq d_2$.

Case 1. $d_2 \geq 2r$.

In this case the balls $B_{Q_1}(r)$ and $B_{Q_2}(r)$ do not intersect and $B_{\frac{1}{2}(Q_1+Q_2)}(r)$ does not intersect Γ. Hence

$$\Delta \left(P_{Q_1} - P_{Q_2} + q \right) = 0 \quad \text{in } B_{\frac{1}{2}(Q_1+Q_2)}(r), \tag{2.59}$$

where

$$q(x,y) = \frac{\theta}{2} \left((\langle (x,y) - \pi(Q_1), \mathbf{n}_{\pi(Q_1)} \rangle^+ \right)^2 - \frac{\theta}{2} \left((\langle (x,y) - \pi(Q_2), \mathbf{n}_{\pi(Q_2)} \rangle^+ \right)^2 .$$

It follows that

$$\|P_{Q_1} - P_{Q_2} + q\|_{L^1(\partial B_{\frac{1}{2}(Q_1+Q_2)}(s_r))} \leq \frac{Cr^{4+\alpha}}{r/4} \leq Cr^{3+\alpha} \tag{2.60}$$

for some $s_r \in \left(\frac{3}{4}r, r\right]$. Now by the Poisson formula

$$\begin{aligned} &\|P_{Q_1} - P_{Q_2} + q\|_{L^\infty(B_{\frac{1}{2}(Q_1+Q_2)}(r/2))} \\ &\leq \frac{C}{r/4} \|P_{Q_1} - P_{Q_2} + q\|_{L^1(\partial B_{\frac{1}{2}(Q_1+Q_2)}(s_r))} \\ &\leq Cr^{2+\alpha}. \end{aligned} \tag{2.61}$$

Case 2. $d_2 < 2r$.

In this case,

$$d_1 = |Q_1 - \pi(Q_1)| \leq |Q_1 - \pi(Q_2)| \leq |Q_1 - Q_2| + d_2 \leq 5r$$

so that

$$|\pi(Q_1) - \pi(Q_2)| \leq d_1 + |Q_1 - Q_2| + d_2 \leq 5r + 3r + 2r = 10r. \tag{2.62}$$

Therefore,

$$\left|\langle \pi(Q_1)-\pi(Q_2), \mathbf{n}_{\pi(Q_2)}\rangle\right| \le Cr^{1+\alpha},$$

$$|\mathbf{n}_{\pi(Q_1)}-\mathbf{n}_{\pi(Q_2)}| = \left|\left[\frac{(-g',1)}{\sqrt{1+(g')^2}}\right]_{\pi(Q_1)}^{\pi(Q_2)}\right| \le Cr^{\alpha}. \tag{2.63}$$

This in turn implies

$$\begin{aligned} |q(x,y)| &\le Cr\left|\langle (x,y)-\pi(Q_1), \mathbf{n}_{\pi(Q_1)}\rangle^+ - \langle (x,y)-\pi(Q_2), \mathbf{n}_{\pi(Q_2)}\rangle^+\right| \\ &\le Cr\left|\langle (x,y)-\pi(Q_1), \mathbf{n}_{\pi(Q_1)}-\mathbf{n}_{\pi(Q_2)}\rangle\right| \\ &\quad +Cr\left|\langle \pi(Q_1)-\pi(Q_2), \mathbf{n}_{\pi(Q_2)}\rangle\right| \\ &\le Cr^{2+\alpha} \end{aligned} \tag{2.64}$$

for $(x,y)\in B(r)$. Similar to the proof of Case 1 from (2.59) to (2.61), we can now estimate $P_{Q_1}-P_{Q_2}$ (which is harmonic). Since the error term q is controlled by (2.64), the proof goes through. □

Proof of Theorem 2.1. Take $Q_1, Q_2 \in B(1)\setminus E$ (in which $\Delta u = 0$). Notice that in this case the second term of (2.57) is zero for both $Q = Q_1$ and $Q = Q_2$; therefore, by Lemma 2.6 and (2.55)–(2.57),

$$\begin{aligned} &\big|\big(u(Q_1)+Du(Q_1)\cdot(X-Q_1)+\tfrac{1}{2}(X-Q_1)^T D^2u(Q_1)(X-Q_1)\big) \\ &\quad -\big(u(Q_2)+Du(Q_2)\cdot(X-Q_2)+\tfrac{1}{2}(X-Q_2)^T D^2u(Q_2)(X-Q_2)\big)\big| \\ &\le C|Q_1-Q_2|^{2+\alpha} \end{aligned} \tag{2.65}$$

for all X with $\left|X-\frac{1}{2}(Q_1+Q_2)\right| \le 3r$. This implies that

$$\|u\|_{C^{2+\alpha}((\overline{B(1)\setminus E}))} \le C.$$

The estimates on $\overline{E}\cap B(1)$ is obtained by considering $-\left(u-\frac{\theta}{4}(x^2+y^2)\right)$. □

3. Existence of a solution with connected toner region. We shall always assume (1.9). Let $\alpha\in(0,1)$ be fixed.

THEOREM 3.1. *The free boundary problem* (1.1)–(1.8) *has a solution* (u, A) *with a connected toner region* A *such that*

$$\Gamma = \partial A \cap \Omega^+ \in C^{1+\alpha}, \tag{3.1}$$

provided ε *is small enough.*

Suppose that u_ε satisfy (1.1)–(1.4) and (1.6)–(1.8). Set

$$\widetilde{u}_\varepsilon(x,y) = \frac{1}{\varepsilon}\left[u_\varepsilon(\varepsilon x, \varepsilon y) - u_\varepsilon(0,0)\right]. \tag{3.2}$$

Then

$$\Delta\widetilde{u}_\varepsilon = \begin{cases} \varepsilon & \text{for } (x,y)\in \frac{1}{\varepsilon}A_\varepsilon \equiv \widetilde{A}_\varepsilon, \\ 0 & \text{for } (x,y)\notin \widetilde{A}_\varepsilon \cup \{(x,0); |x|\le 1\}\ , \end{cases}$$

where A_ε is the region in which $\Delta u_\varepsilon = 1$.

It has been proved in [3, §8] that for any compact $F \subset R^2$

$$\|\widetilde{u}_\varepsilon - \widetilde{v}\|_{W^{2,p}(F)} \le C_{F,p}\,(\text{meas}(A_\varepsilon) + \varepsilon^p)^{1/p} \tag{3.3}$$

for any $p > 2$, where

$$\widetilde{v}(x,y) = -\frac{\sigma}{2\pi}\int_{-1}^{1} \log\sqrt{(x-\xi)^2 + y^2}d\xi + \frac{My}{b+h} - \frac{\sigma}{\pi}. \tag{3.4}$$

The equation $\frac{\partial \widetilde{v}}{\partial n} = 0$ gives the level curves of the harmonic conjugate $z(x,y)$ of $\widetilde{v}$, where

$$\begin{aligned} z(x,y) = \frac{\sigma}{4\pi}\Big\{ & y\log\frac{(1-x)^2+y^2}{(1+x)^2+y^2} - 2(1-x)\arctan\frac{1-x}{y} \\ & + 2(1+x)\arctan\frac{1+x}{y}\Big\} - \frac{M}{b+h}x. \end{aligned} \tag{3.5}$$

There is only one of these curves, $y = \varphi_0(x)$, that passes through y axis. $\varphi_0(x)$ is analytic and it is shown in [3] that

$$\begin{aligned} &\varphi_0(0) = y_0, \qquad \varphi_0'(0) = 0, \\ &\varphi_0'(x) < 0 \quad \text{for } 0 < x \le \bar{x}_0, \\ &\varphi_0''(x) < 0 \quad \text{for } 0 \le x \le \bar{x}_0, \end{aligned} \tag{3.6}$$

where

$$y_0 = \cot\left(\frac{\pi}{\sigma}\frac{M}{b+h}\right), \qquad \bar{x}_0 = \frac{b+h}{M}\frac{\sigma}{2} > 1. \tag{3.7}$$

It is clear that

$$\frac{\partial \widetilde{v}}{\partial n} = 0 \quad \text{on } y = \varphi_0(x). \tag{3.8}$$

We set

$$\begin{aligned} X = \Big\{ & \gamma(x);\quad \gamma \in C^{1+\alpha}[0, \bar{x}_0 + l],\quad \gamma'(0) = 0, \quad \gamma(\bar{x}_0 + l) \le 0, \\ & \gamma(x) \ge \sqrt{\mu^2 - (x-1)^2}, \quad \tfrac{1}{2}y_0 \le \gamma(x) \le \tfrac{3}{2}y_0 \quad \text{for } 0 \le x \le \mu, \\ & \gamma(x) \ge c_0 > 0 \quad \text{for } \mu \le x \le 1, \qquad \|\gamma\|_{C^{1+\alpha}[0,\bar{x}_0+l]} \le K\Big\}, \end{aligned} \tag{3.9}$$

where l, μ, and c_0 are fixed small positive constants, and K is to be determined later.

For each $\gamma \in X$, we extend it to an even function on the interval $[-\bar{x}_0 - l, \bar{x}_0 + l]$ by letting $\gamma(-x) = \gamma(x)$. Denote by $\widetilde{A}_\gamma$ the connected component of the area enclosed by γ and x axis which contains $\{(0,y),\ 0 < y < \gamma(0)\}$. Next, define w by

$$\Delta w = \chi_{\widetilde{A}_\gamma} \quad \text{in } R_{2N}, \tag{3.10}$$

$$w = 0 \quad \text{on } \partial R_{2N}, \tag{3.11}$$

where $R_{2N} = \{|x| < 2N,\ |y| < 2N\}$ $(N/2 > 3y_0/2)$ and $\chi_{\widetilde{A}_\gamma}$ is the characteristic function of $\widetilde{A}_\gamma$.

By $W^{2,p}$ estimates and Sobolev's embedding theorem,

$$\|w\|_{C^{1+\alpha}(R_{2N})} \leq C. \tag{3.12}$$

Here and below we shall use C to denote constants independent of K and C_K to denote the constants depending on K.

Let $V = ([0,1] \times [c_0, N]) \cup \left(([1, \bar{x}_0 + l] \times [0, N]) \setminus \{(x-1)^2 + y^2 < \mu^2\}\right)$. Then by Theorem 2.1,

$$\|w\|_{W^{2,\infty}(R_N \cap V)} \leq C_K. \tag{3.13}$$

Now let u_γ be the solution of (1.1)–(1.4) and (1.6)–(1.8) with $A = \varepsilon \widetilde{A}_\gamma$, and let

$$\widetilde{u}_{\gamma,\varepsilon}(x,y) = \frac{1}{\varepsilon}\left[u_\gamma(\varepsilon x, \varepsilon y) - u_\varepsilon(0,0)\right],$$

and observe that

$$\Delta\left(\widetilde{u}_{\gamma,\varepsilon} - \widetilde{v} - \varepsilon w\right) = 0 \quad \text{in } R_{2N}. \tag{3.14}$$

Therefore, by (3.12) and (3.3) (with $\widetilde{u}_\varepsilon = \widetilde{u}_{\gamma,\varepsilon}$ in (3.3)), we can apply the Schauder's interior estimates to obtain

$$\|\widetilde{u}_{\gamma,\varepsilon} - \widetilde{v} - \varepsilon w\|_{C^3(R_N)} \leq C\varepsilon + C\varepsilon^{2/p}, \tag{3.15}$$

where the constant is independent of K.

By symmetry,

$$\frac{\partial}{\partial x}\left(\widetilde{u}_{\gamma,\varepsilon} - \widetilde{v} - \varepsilon w\right) = 0 \quad \text{on } x = 0, \tag{3.16}$$

and so by (3.15),

$$\frac{\partial}{\partial x}\left(\widetilde{u}_{\gamma,\varepsilon} - \widetilde{v} - \varepsilon w\right) \leq (C\varepsilon + C\varepsilon^{2/p})x \quad \text{for } (x,y) \in R_N. \tag{3.17}$$

Using (3.13) and $\frac{\partial w}{\partial x}(0,y) = 0$ (by symmetry), we get

$$\frac{\partial w}{\partial x} = \frac{\partial w}{\partial x}(x,y) - \frac{\partial w}{\partial x}(0,y) \leq C_K x \quad \text{for } (x,y) \in V. \tag{3.18}$$

Clearly,

$$\widetilde{v}_x = \frac{\sigma}{4\pi}\log\frac{(1-x)^2 + y^2}{(1+x)^2 + y^2} \leq -c_1 x < 0 \quad \text{for } (x,y) \in V. \tag{3.19}$$

It follows that

$$\frac{\partial}{\partial x}\widetilde{u}_{\gamma,\varepsilon} \leq \left(C\varepsilon + C\varepsilon^{2/p} + C_K\varepsilon - c_1\right)x \leq -\frac{1}{2}c_1 x \quad \text{in } V, \tag{3.20}$$

provided $0 < \varepsilon \leq \varepsilon_K$ and ε_K is small enough (depending on K).

Write

$$\widetilde{u}_{\gamma,\varepsilon} \equiv \widetilde{v} + \varepsilon w + \varepsilon^{2/p}\widetilde{w}, \tag{3.21}$$

where $\|\widetilde{w}\|_{C^3(R_N)} \le C$ by (3.15), and

$$\|w_x(\cdot,\gamma(\cdot))\|_{C^{1+\alpha}} \le C_K, \qquad \|w_y(x,\gamma(x))\|_{C^{1+\alpha}} \le C_K,$$

by Theorem 2.1.

Let $w^* = \varepsilon^{1-1/p}w + \varepsilon^{1/p}\widetilde{w}$; then

$$\widetilde{u}_{\gamma,\varepsilon} \equiv \widetilde{v} + \varepsilon^{1/p}w^*. \tag{3.22}$$

If $0 < \varepsilon < \varepsilon_K$ and ε_K is small enough, then

$$\|\zeta_1\|_{C^{1+\alpha}} \le 1, \qquad \|\zeta_2\|_{C^{1+\alpha}} \le 1, \tag{3.23}$$

where $\zeta_1(x) = w^*_x(x,\gamma(x))$ and $\zeta_2(x) = w^*_y(x,\gamma(x))$.

Differentiating (3.19) in x, we obtain

$$\widetilde{v}_{yy} = -\widetilde{v}_{xx} = \frac{\sigma}{4\pi}\left(\frac{2(1-x)}{(1-x)^2+y^2} + \frac{2(1+x)}{(1+x)^2+y^2}\right). \tag{3.24}$$

Therefore,

$$\widetilde{v}_{yy}(0,y) = \frac{\sigma}{\pi}\frac{1}{y^2}. \tag{3.25}$$

It follows that (using also (3.22) and (3.13)),

$$\frac{\partial^2\widetilde{u}_{\gamma,\varepsilon}}{\partial y^2}(0,y) \ge \frac{1}{2}\frac{\sigma}{\pi}\frac{1}{y^2} > 0 \quad \text{in } V, \tag{3.26}$$

provided ε_K is small enough.

Therefore, the equation

$$\frac{\partial\widetilde{u}_{\gamma,\varepsilon}}{\partial y}(0,y) = 0, \qquad \frac{1}{2}y_0 \le y \le \frac{3}{2}y_0 \tag{3.27}$$

has a unique solution $y = y_\gamma$, provided ε_K is small enough. It is obvious that y_γ depends continuously on the $C^{1+\alpha}$ norm of γ.

Now we take $\tau > 0$ and define $\eta = T\gamma$ to be the solution of the ordinary differential equation (ODE)

$$\eta(0) = y_\gamma, \tag{3.28}$$

$$\eta'(x) = \frac{\dfrac{\widetilde{v}_y(x,\eta(x)) - \widetilde{v}_y(x,y_\gamma)}{x+\tau} + \varepsilon^{1/p}\dfrac{\zeta_2(x)-\zeta_2(0)}{x+\tau}}{\dfrac{\widetilde{v}_x(x,\eta(x))}{x} + \varepsilon^{1/p}\left(\dfrac{\zeta_1(x)}{x}\right) * \rho_\tau(x)}, \tag{3.29}$$

where $\rho_\tau(x)$ is a C^∞ mollifier (see [5, Chap. 7]) and the convolution is defined after extending the definition of $\zeta_1(x)/x$ to be $\zeta_1(\overline{x}_0 + l)/(\overline{x}_0 + l)$ for $x > \overline{x}_0 + l$ and $\lim_{x\to 0+}(\zeta_1(x)/x)$ for $x < 0$.

We write the right-hand side of (3.29) as $f_1(x,y)/f_2(x,y)$, where $y = \eta(x)$. Then by analyticity of $\widetilde{v}$, noticing also that $\widetilde{v}_{xy}(0,y) \equiv 0$, we get

$$\left\|\frac{\partial f_2}{\partial y}\right\|_{L^\infty(V)} = \left\|\frac{1}{x}\widetilde{v}_{xy}\right\|_{L^\infty(V)} \le C. \tag{3.30}$$

LEMMA 3.2.

$$\left[\frac{\zeta_1(x)}{x}\right]_{C^\alpha[0,\bar{x}_0+l]} \le 3. \tag{3.31}$$

Proof. Suppose that $0 < x_1 < x_2$. If $x_2 - x_1 \ge x_1$. Then $x_2 = x_2 - x_1 + x_1 \le 2(x_2 - x_1)$. So by (3.23),

$$\begin{aligned}\left|\frac{\zeta_1(x_1)}{x_1} - \frac{\zeta_1(x_2)}{x_2}\right| &\le \left|\frac{\zeta_1(x_1)}{x_1} - \zeta_1'(0)\right| + \left|\frac{\zeta_1(x_2)}{x_2} - \zeta_1'(0)\right| \\ &\le {x_1}^\alpha + {x_2}^\alpha \ \le\ (1+2^\alpha)|x_1 - x_2|^\alpha.\end{aligned}$$

Now we consider the case $x_2 - x_1 < x_1$. Clearly,

$$\zeta_1(x_2) = \zeta_1(x_1) + \zeta_1'(x_1)(x_2 - x_1) + r, \qquad |r| \le |x_2 - x_1|^{1+\alpha}.$$

Therefore,

$$\begin{aligned}\left|\frac{\zeta_1(x_1)}{x_1} - \frac{\zeta_1(x_2)}{x_2}\right| &\le \left|\frac{(x_1 - x_2)\zeta_1(x_1) + x_1\zeta_1'(x_1)(x_2 - x_1)}{x_1x_2}\right| + \frac{|x_2 - x_1|^{1+\alpha}}{x_2} \\ &\le \frac{|x_1 - x_2|}{x_1x_2}|\zeta_1(x_1) - x_1\zeta_1'(x_1)| + \frac{|x_2 - x_1|^{1+\alpha}}{x_2} \\ &\le \frac{|x_1 - x_2|}{x_1x_2}|x_1|^{1+\alpha} + \frac{|x_2 - x_1|^{1+\alpha}}{x_2} \qquad (\text{since } \zeta_1(0) = 0) \\ &\le 2|x_1 - x_2|^\alpha.\end{aligned}$$

□

Since $\widetilde{v}_x(0,y) = 0$, Lemma 3.2 and the analyticity of $\widetilde{v}$ imply that

$$\sup_V |f_2(x,y)| + \sup_{x_1 \ne x_2;\ (x_1,y),(x_2,y)\in V} \frac{|f_2(x_1,y) - f_2(x_2,y)|}{|x_1 - x_2|^\alpha} \le C. \tag{3.32}$$

By (3.19), we have

$$f_2(x,y) \le -\tfrac{1}{2}c_1 < 0, \tag{3.33}$$

provided ε_K is small enough.

Using the analyticity of $\widetilde{v}$, $\widetilde{v}_{yx}(0,y) \equiv 0$, $\zeta_2'(0) = 0$ and an argument similar to Lemma 3.2 for $(\zeta_2(x) - \zeta_2(0))/(x + \tau)$, we conclude

$$\sup_{x\ne y;\ (x_1,y),(x_2,y)\in V} \frac{|f_1(x_1,y) - f_1(x_2,y)|}{|x_1 - x_2|^\alpha} \le C, \tag{3.34}$$

and

$$\sup_{0\le t\le x} |f_1(t,\eta(t))| \le C \sup_{0<t\le x} \frac{|\eta(t) - \eta(0)|}{t}, \tag{3.35}$$

where the constant C is independent of τ, and also

$$\left|\frac{\partial f_1}{\partial y}\right| = \left|\frac{\widetilde{v}_{yy}(x,y)}{x+\tau}\right| \le \frac{C}{x+\tau}. \tag{3.36}$$

Therefore, for each $\tau > 0$, the ODE (3.28), (3.29) is uniquely solvable. It is obvious that for each $\tau > 0$, $\eta \in C^{1+\alpha}$. Next, we shall derive $C^{1+\alpha}$ estimates independent of τ. From now on we shall assume that

$$\text{for the solution } \eta(x), \text{ we have } (x, \eta(x)) \in V. \tag{3.37}$$

What we need to prove is actually the estimates near $x = 0$.

LEMMA 3.3.

$$\lim_{x\to 0} \frac{-x\widetilde{v}_{yy}}{\widetilde{v}_x} = 1. \tag{3.38}$$

Proof.

$$\lim_{x\to 0} \frac{-x\widetilde{v}_{yy}}{\widetilde{v}_x} = \lim_{x\to 0} \frac{-\widetilde{v}_{yy}}{\widetilde{v}_x/x} = \lim_{x\to 0} \frac{-\widetilde{v}_{yy}}{\widetilde{v}_{xx}} = 1.$$ □

The convergence is uniform by the analyticity of $\widetilde{v}$. Thus there exists some small $\mu > 0$ such that

$$\frac{-x\widetilde{v}_{yy}}{\widetilde{v}_x} > 0 \quad \text{for } 0 \le x \le \mu,\ \frac{1}{2}y_0 \le y \le \frac{3}{2}y_0,$$

which implies

$$\frac{(f_1)_y(x,y)}{f_2(x,\eta(x))} = \frac{\dfrac{\widetilde{v}_{yy}(x,y)}{x+\tau}}{f_2(x,\eta(x))} < 0 \quad \text{for } 0 \le x \le \mu,\ \frac{1}{2}y_0 \le y \le \frac{3}{2}y_0. \tag{3.39}$$

Let $\lambda(x) = \eta(x) - \eta(0)$; then

$$\begin{aligned} \lambda'(x) &= \frac{f_1(x,\eta(x))}{f_2(x,\eta(x))} \\ &= \frac{f_1(x,\eta(x)) - f_1(x,\eta(0)) + \varepsilon^{1/p}\dfrac{\zeta_2(x)-\zeta_2(0)}{x+\tau}}{f_2(x,\eta(x))} \\ &\equiv q_1(x)\lambda(x) + q_2(x)\ , \end{aligned} \tag{3.40}$$

where $q_1(x) = (f_1)_y(x,y)/f_2(x,\eta(x)) < 0$ by (3.39), and it is also clear that $q_1(x) \ge -\frac{C}{x+\tau}$.

By the definition of ζ_2 we have $\zeta_2'(0) = 0$; therefore,

$$|q_2(x)| \le C\varepsilon^{1/p}\left|\frac{\zeta_2(x)-\zeta_2(0)}{x+\tau}\right| \le C^* x^\alpha, \tag{3.41}$$

where the constant is independent of K, τ. It follows by comparison (we use $q_1(x) < 0$ here) that

$$|\lambda(x)| \le \int_0^x |q_2(\xi)|d\xi \le C^* x^{1+\alpha}. \tag{3.42}$$

This inequality, together with (3.35), implies that

$$|\eta'(x)| = |\lambda'(x)| \le C^* x^\alpha. \tag{3.43}$$

It follows that

$$\|\eta'\|_{L^\infty[0,\bar{x}_0+l]} \le C^*. \tag{3.44}$$

Next, take $a > 0$, and consider $\widetilde{\lambda}(x) = \eta(x+a) - \eta(x)$ for $x > 0$. Clearly,

$$\begin{aligned}
&\widetilde{\lambda}'(x) \\
&\quad = \frac{f_1(x+a,\eta(x+a))}{f_2(x+a,\eta(x+a))} - \frac{f_1(x,\eta(x))}{f_2(x,\eta(x))} \\
&\quad = \frac{f_1(x+a,\eta(x+a)) - f_1(x+a,\eta(x)) + f_1(x+a,\eta(x)) - f_1(x,\eta(x))}{f_2(x+a,\eta(x+a))} \\
&\qquad + \frac{f_1(x,\eta(x))[f_2(x,\eta(x)) - f_2(x+a,\eta(x+a))]}{f_2(x,\eta(x))f_2(x+a,\eta(x+a))} \\
&\quad \equiv I_1 + I_2.
\end{aligned} \tag{3.45}$$

We estimate I_i, $i = 1,2$ separately. First by (3.32), (3.33), (3.35), and (3.44),

$$|I_2| \le C^* a^\alpha. \tag{3.46}$$

Next, letting

$$I_1 \equiv J_1 + J_2, \tag{3.47}$$

where by (3.34), (3.33),

$$|J_2| = \left| \frac{f_1(x+a,\eta(x)) - f_1(x,\eta(x))}{f_2(x+a,\eta(x+a))} \right| \le C^* a^\alpha. \tag{3.48}$$

Moreover,

$$\begin{aligned}
J_1 &= \frac{f_1(x+a,\eta(x+a)) - f_1(x+a,\eta(x))}{f_2(x+a,\eta(x+a))} \\
&\equiv q(x+a)(\eta(x+a) - \eta(x)) \ ,
\end{aligned} \tag{3.49}$$

where by (3.33), (3.36),

$$|q(x+a)| \le \frac{C^*}{x+a+\tau}. \tag{3.50}$$

By (3.43),

$$|\eta(x+a) - \eta(x)| \le \int_x^{x+a} |\eta'(\xi)| d\xi \le C^*(x+a)^\alpha a \le C^*(x+a)a^\alpha. \tag{3.51}$$

Therefore, (3.49)–(3.51) imply

$$|J_1| \le C^* a^\alpha. \tag{3.52}$$

Combining (3.46)–(3.52), we obtain

$$|\eta'(x+a) - \eta'(x)| = |\widetilde{\lambda}'(x)| \le C^* a^\alpha. \tag{3.53}$$

This proves that if $\varepsilon \in (0, \varepsilon_K)$, then

$$\|\eta\|_{C^{1+\alpha}[0,\bar{x}_0+l]} \le C^{**}, \tag{3.54}$$

where the constant C^{**} is independent of K and τ.

We now choose $K = C^{**}$. Since the curve $\eta = T\gamma$ goes to $y = \varphi_0(x)$ uniformly as $\varepsilon \to 0$, it is easy to choose the remaining constants in the definition of X (as in [3]) so that T maps X into itself.

Obviously T is a continuous map from X to X (using $C^{1+\alpha}$ norm topology). For each $\tau > 0$, the image of T is contained in a bounded set of $C^{1+\beta}$ for any $\beta \in (\alpha, 1)$. Therefore, the closure of the image of T is compact. Hence T has a fixed point, by Schauder's fixed point theorem (see [5]). It is obvious that all the estimates of this section apply to the fixed point $\eta = T\eta$, where the estimates are independent of τ; therefore, we can take a subsequence and pass the limit as $\tau \to 0$ to obtain a solution (u, A) with one connected toner region. This proves Theorem 3.1.

Acknowledgment. We would like to thank the referee for many helpful comments. The referee assisted in revising the exposition. This work was partially carried out while both authors were visiting Institute for Mathematics and Applications at the University of Minnesota. For its hospitality, the authors would like to express their gratitude.

CONSTRUCTION OF APPROXIMATE INERTIAL MANIFOLDS USING WAVELETS*

OLIVIER GOUBET†

Abstract. In this work, approximate inertial manifolds are constructed for a class of dissipative evolution equations. The innovation is that these manifolds are defined as graphs on orthonormal wavelet bases.

Key words. dissipative nonlinear parabolic equations, approximate inertial manifolds, wavelets

AMS(MOS) subject classifications. 35A35, 35K60, 42C15

1. Introduction. Our aim in this article is to construct approximations of inertial manifolds for dissipative evolution equations by utilization of wavelets. In this way we make the connection between two recent theories: the theory of inertial manifolds that has emerged from the study of dynamical systems and the theory of orthonormal wavelet bases.

First let us have an overview of the inertial manifolds theory that relates to the large time study of dissipative evolution equations.

Let us consider a nonlinear PDE that is dissipative; it means that there exists a *global attractor* for the associated dynamical system, i.e., a compact set that is invariant by the flow of the solutions, and that attracts all the orbits when $t \to +\infty$. Nevertheless, the convergence of the orbits towards the attractor can be arbitrarily slow, and this one can have a complex structure, and even be a fractal (see [18]).

New mathematical tools have been introduced by Foias, Sell, and Temam [7]: the inertial manifolds (IM), which are smooth finite-dimensional manifolds, positively invariant by the flow of the solutions, and which attract all the trajectories with exponential speed. From the physics point of view, IMs model the interaction laws between small and large structures of a turbulent flow, and represent its permanent regime; actually on an IM small eddies are slaved by large ones, and there are similar results, after a transient time, for a trajectory that is not on the IM (see [5], [7]). Nevertheless, until now the existence of IM necessitates a very restrictive property, the spectral gap condition (see [18]).

Hence came the approximate inertial manifolds (AIM). They are smooth finite-dimensional manifolds that attract all the orbits into a thin neighborhood, in a finite time, and with exponential speed. AIMs provide good substitutes for IMs when no existence result for IM is available; moreover, because their equations are rather simple, they make the implementation of numerical algorithms easier (see [3], [4], [5], [19]).

The theory of AIMs, which first developed in the spectral case, has begun to extend beyond. Some nonlinear algorithms have been established for finite elements (see [14]) and finite differences (see [20]). The purpose of this paper, following a suggestion by Temam, is to construct approximate inertial manifolds using the newly developed concept of orthonormal bases of wavelets.

The improvement featured by wavelets with respect to spectral bases (here the trigonometrical system), is to combine good localization properties in space variable,

† Laboratoire d'Analyse Numérique, Université de Paris-Sud, 91405 Orsay Cedex, France.

and good localization properties in frequencies (see [13]). Hence by constructing AIMs using wavelets we hope to obtain laws for the slaving of small eddies and high frequencies by large eddies and low frequencies. In this paper we are interested in the space periodic case, and we consider the periodic version of orthonormal wavelet bases of Daubechies, Lemarié, and Meyer (see [2], [11], [12]) as described in [13]. However, wavelets are flexible tools that can be adapted to other domains than the n-dimensional torus (see [10]), and allow us to consider the construction of AIMs in general domains where little information on the spectral bases is available.

Nevertheless, in this paper, for the sake of clarity, we will focus particularly on the one-dimensional spline wavelet bases of [11], referring the reader to the Appendix for multidimensional results and for other wavelet bases.

The paper is organized as follows. In § 2 we briefly recall some results about spline wavelets in the one-dimensional periodic case. In § 3 we give, for the sake of completeness, a proof of a result announced in [13] saying that, if spline wavelets are sufficiently regular, then they provide an unconditional basis for periodic Sobolev spaces. In § 4, we describe a class of nonlinear parabolic PDEs, that includes, for instance, the two-dimensional Navier–Stokes equations, written in the stream function formulation (in order to avoid the difficult problem of the treatment by wavelets of the incompressibility condition), and the Kuramoto–Sivashinsky equation. In § 5 we show how the wavelet expansion of a function can be used to construct several AIMs for the class of evolution equation described above. The method follows [21]; first we define the *induced trajectories*, tools that allow us to estimate the distance, for different topologies, between the orbits and the space spanned by the first k wavelets, ordered in the natural way. These estimates, which hold for large time, are then compared to the ones obtained in the spectral case, for spaces that have the same dimension. The result is that the wavelets provide a flat AIM that provide the same order of approximation as the one obtained using spectral bases. Then we give two examples of nontrivial (nonflat) AIMs that approximate the attractor with higher order than the flat one; once again we match the accuracy obtained in the spectral case. Finally in the Appendix we extend the results of § 3 to the constructions of [2] and of [12] and to the multidimensional case.

Notation. Let $\mathscr{Z}$ (respectively, $\mathscr{R}$, $\mathscr{C}$) be the set of integers (respectively, of real numbers, of complex numbers).

Let $\Pi=\mathscr{R}/\mathscr{Z}$ be the one-dimensional torus. We denote by $C^N(\Pi)$ the space of N times continuously differentiable functions on Π and by $H^s(\Pi)$ the usual periodic Sobolev space.

We denote by $\dot{H}^s(\Pi)$ the space of functions u in $H^s(\Pi)$ such that

$$\int_\Pi u(x)\,dx=0.$$

$\dot{H}^s(\Pi)$ is a Hilbert space when endowed with the scalar product

$$(u,v)_s=\sum_{k\in\mathscr{Z}}|k|^{2s}\hat{u}(k)\overline{\hat{v}(k)},$$

where

$$\hat{u}(k)=\int_\Pi u(x)\,e^{-2i\pi kx}\,dx.$$

Let $|u|_s$ be the corresponding norm,

$$|u|_s=(u,u)_s^{1/2}.$$

When $s=0$ we write $H^0(\Pi)=L^2(\Pi)$.

In the following we will denote by C a constant that only depends on the regularity N of the wavelet, and in § 5 on the data of the equation.

2. Spline wavelet bases of $\dot{L}^2(\Pi)$. We consider the finite-dimensional space $V_j = \{v \in C^N(\Pi);\ v$ is a piecewise polynomial function of degree less than or equal to $N+1$, with nodes at $k/2^j;\ 0 \leqq k < 2^j\}$. Then we have the embeddings

$$V_0 \subset \cdots \subset V_j \subset V_{j+1} \subset \cdots L^2(\Pi).$$

We define

$$W_j = V_{j+1} \cap (V_j)^\perp, \tag{2.1}$$

then we have

$$\dot{L}^2(\Pi) = \bigoplus_{j=0}^{+\infty} W_j, \tag{2.2}$$

the sum being orthogonal.

Let us introduce what are the periodic wavelet bases associated to the W_j's. We first recall the original construction on $\mathscr{R}$; from [11] (see also [1], [13]) we know that, for each integer N, there exists a function ψ_N satisfying

(i)

$$\psi_N \in C^N(\mathscr{R}), \tag{2.3}$$

ψ_N being a piecewise polynomial function of degree less than or equal to $N+1$ with nodes at the half integers.

(ii)

$$\exists \varepsilon_N > 0/ \quad \text{for } m \leqq N+1, \qquad \left| \frac{\partial^m}{\partial x^m} \psi_N(x) \right| \leqq C e^{-\varepsilon_N |x|}. \tag{2.4}$$

(iii) If $m \leqq N+1$

$$\int_{\mathscr{R}} x^m \psi_N(x)\, dx = 0. \tag{2.5}$$

The wavelets, that are derived from ψ_N by a translation and a dilation as below, satisfy

(iv) The family $\{2^{j/2}\psi_N(2^j x - k)\}_{j,k \in \mathscr{Z}}$ is an orthonormal basis of

$$L^2(\mathscr{R}). \tag{2.6}$$

Remark 1. Formula (2.4) shows the exponential decay of the wavelet $2^{j/2}\psi_N(2^j x - k)$ for x away from $(k+\frac{1}{2})/2^j$. Formulae (2.3) and (2.5) describe the localization in frequencies of the wavelet $2^{j/2}\psi_N(2^j x - k)$ around an annulus of radii $C_1 2^j, C_2 2^j$; actually (2.5) means that $|\hat{\psi}_N(\xi)| = O(|\xi|^{N+1})$ when $|\xi| \to 0$, and $|\hat{\psi}_N(\xi)| = O(|\xi|^{-N-1})$ when $|\xi| \to \infty$.

Remark 2. Throughout this paper we shall omit the subscript N on ψ_N.

Then following [13] we define the periodic wavelets as

$$\psi_{j,k}(x) = 2^{j/2} \sum_{l \in \mathscr{Z}} \psi(2^j x + 2^j l - k). \tag{2.7}$$

This periodization transfers to periodic wavelets the localization in frequencies (see Lemma 2 below), and does not deteriorate the localization in space variable too much. Then we have

$$\text{The family } \{\psi_{j,k}\}_{1 \leqq k \leqq 2^j} \text{ is an orthonormal basis of } W_j, \tag{2.8}$$

$$\text{The family } \{\psi_{j,k}\}_{0 \leqq j \leqq +\infty; 1 \leqq k \leqq 2^j} \text{ is an orthonormal basis of } \dot{L}^2(\Pi). \tag{2.9}$$

3. Preliminary results.

3.1. Bernstein inequalities.

PROPOSITION 1. *There exists $C > 0$ such that for any v in V_j*

$$|v|_{N+1} \leqq C 2^{j(N+1)} |v|_0. \tag{3.1}$$

Proof. Let b_N be the Nth fundamental B-spline, defined from the characteristic function χ of $[-\frac{1}{2}, \frac{1}{2}]$ by

$$b_N = \underbrace{\chi * \cdots\cdots * \chi}_{N+1 \text{ times}}. \tag{3.2}$$

For v in V_j,

$$v = \sum_{k=1}^{2^j} \alpha_{j,k} 2^{j/2} b_N(2^j x - k). \tag{3.3}$$

It is well known that

$$c_1 \left(\sum_{k=1}^{2^j} |\alpha_{j,k}|^2 \right) \leqq |v|_0^2 \leqq c_2 \left(\sum_{k=1}^{2^j} |\alpha_{j,k}|^2 \right), \tag{3.4}$$

for some constants c_1, c_2 depending on N.

On the other hand, we have

$$|v|_{N+1}^2 = \sum_{1 \leqq k, p \leqq 2^j} 4^{j(N+1)} \alpha_{j,k} \alpha_{j,p} m_{j,k,p}, \tag{3.5}$$

where

$$m_{j,k,p} = 2^j \int_\Pi \frac{\partial^{N+1}}{\partial x^{N+1}} b_N(2^j x - k) \frac{\partial^{N+1}}{\partial x^{N+1}} b_N(2^j x - p)\, dx. \tag{3.6}$$

We observe that either $m_{j,k,p} = 0$ if $|k - p| > N + 1$ or

$$|m_{j,k,p}| \leqq \left\| \frac{\partial^{N+1}}{\partial x^{N+1}} b_N \right\|_{L^1(\mathscr{R})} \left\| \frac{\partial^{N+1}}{\partial x^{N+1}} b_N \right\|_{L^\infty(\mathscr{R})}. \tag{3.7}$$

It follows

$$|v|_{N+1}^2 \leqq C 4^{j(N+1)} \sum_{|k-p| \leqq N+1} |\alpha_{j,k}| |\alpha_{j,p}|. \tag{3.8}$$

Using

$$\sum_{|k-p| \leqq N+1} |\alpha_{j,k}| |\alpha_{j,p}| \leqq C \sum_{k=1}^{2^j} |\alpha_{j,k}|^2, \tag{3.9}$$

we infer the result from (3.4) and (3.8).

Remark 3. We recall that C is a constant that depends on N, but which is independent of j.

LEMMA 1. *Let r, s, t be real numbers, $r \leqq s \leqq t$. Then for any u in $\dot{H}^t(\Pi)$*

$$|u|_s \leqq |u|_r^{(t-s)/(t-r)} |u|_t^{(s-r)/(t-r)}. \tag{3.10}$$

Proof. This is just a particular case of the interpolation inequality (see [18] and the references therein).

COROLLARY 1. *Let s belong to $[0, N+1]$; then for any v in V_j*

$$|v|_s \leqq C2^{js}|v|_0. \tag{3.11}$$

Proof. Thanks to (3.10),

$$|v|_s \leqq |v|_0^{1-s/(N+1)}|v|_{N+1}^{s/(N+1)}. \tag{3.12}$$

We infer from (3.1) and (3.12)

$$|v|_s \leqq C^{s/(N+1)}2^{js}|v|_0. \tag{3.13}$$

COROLLARY 2. *Let s belong to $[-N-1, 0]$; then for any v in V_j*

$$|v|_0 \leqq C2^{-js}|v|_s. \tag{3.14}$$

Proof. Thanks to (3.10), we have

$$|v|_0 \leqq |v|_s^{(N+1)/(N+1-s)}|v|_{N+1}^{-s/(N+1-s)}. \tag{3.15}$$

Using (3.1)

$$|v|_0 \leqq C^{-s/(N+1-s)}2^{-js(N+1)/(N+1-s)}|v|_0^{-s/(N+1-s)}|v|_s^{(N+1)/(N+1-s)}. \tag{3.16}$$

To conclude we take the $\{(N+1-s)/(N+1)\}$th power of inequality (3.16).

3.2. Poincaré inequalities.

LEMMA 2. *Let f be in $L^1(R)$. Let $g(x)=\sum_{l\in\mathscr{Z}} f(x+l)\in L^1(\Pi)$. Then*

$$\hat{g}(k)=\hat{f}(k). \tag{3.17}$$

(*The left-hand side of the equality represents the* kth *Fourier coefficient of g, the right-hand side denotes the value at the point k of the Fourier transform of f*).

Proof. Thanks to Fubini's theorem,

$$\int_\Pi g(x)\, e^{-2i\pi kx}\, dx = \sum_{l\in\mathscr{Z}} \int_l^{l+1} f(x)\, e^{-2i\pi(k-l)x}\, dx \tag{3.18}$$

provides the result.

PROPOSITION 2. *There exists $C>0$ such that for any w in W_j*

$$|w|_{-N-1} \leqq C2^{-j(N+1)}|w|_0. \tag{3.19}$$

Proof. Let $w\in W_j$; we write

$$w=\sum_{k=1}^{2^j} \alpha_{j,k}\psi_{j,k}. \tag{3.20}$$

We easily infer from (2.7) and (3.17)

$$\hat{\psi}_{j,k}(l)=\frac{1}{2^{j/2}}\,\hat{\psi}\left(\frac{l}{2^j}\right)\exp\left(-2i\pi\frac{kl}{2^j}\right). \tag{3.21}$$

We set

$$m\left(\frac{l}{2^j}\right)=2^{-j/2}\sum_{k=1}^{2^j}\alpha_{j,k}\exp\left(-2i\pi\frac{kl}{2^j}\right). \tag{3.22}$$

This yields

$$\hat{w}(l)=m\left(\frac{l}{2^j}\right)\hat{\psi}\left(\frac{l}{2^j}\right). \tag{3.23}$$

Then, thanks to Parseval's identity,

$$|w|_0^2=\sum_{l\in\mathscr{Z}}|\hat{w}(l)|^2, \tag{3.24}$$

we obtain

$$|w|_0^2=\sum_{l\in\mathscr{Z}}\left|m\left(\frac{l}{2^j}\right)\right|^2\left|\hat{\psi}\left(\frac{l}{2^j}\right)\right|^2, \tag{3.25}$$

we write

$$|w|_0^2=\sum_{k=1-2^{j-1}}^{2^{j-1}}\sum_{l\in\mathscr{Z}}\left|m\left(\frac{k}{2^j}+l\right)\right|^2\left|\hat{\psi}\left(\frac{k}{2^j}+l\right)\right|^2. \tag{3.26}$$

Observing that m is a one-periodic function, we obtain

$$|w|_0^2=\sum_{k=1-2^{j-1}}^{2^{j-1}}\left|m\left(\frac{k}{2^j}\right)\right|^2\left(\sum_{l\in\mathscr{Z}}\left|\hat{\psi}\left(\frac{k}{2^j}+l\right)\right|^2\right). \tag{3.27}$$

Now we need the following.

LEMMA 3. *Let f be in $L^1(\mathscr{R})\cap L^2(\mathscr{R})$ such that $|\hat{f}(z)|\leq C(1+|z|)^{-\alpha}$ with $\alpha>\frac{1}{2}$, and such that the family $\{f(x+l)\}_{l\in\mathscr{Z}}$ is an orthonormal family in $L^2(\mathscr{R})$. Then, for each z in Π*

$$\sum_{l\in\mathscr{Z}}|\hat{f}(z+l)|^2=1. \tag{3.28}$$

Proof. We prove that the Fourier coefficients of the one-periodic function

$$1-\sum_{l\in\mathscr{Z}}|\hat{f}(z+l)|^2$$

are equal to zero.

Lemma 2 yields

$$\int_\Pi\left(\sum_{l\in\mathscr{Z}}|\hat{f}(z+l)|^2\right)e^{-2i\pi kz}\,dz=\int_{\mathscr{R}}|\hat{f}(z)|^2\,e^{-2i\pi kz}\,dz. \tag{3.29}$$

The result follows, using Plancherel's theorem

$$\int_{\mathscr{R}}|\hat{f}(z)|^2\,e^{-2i\pi kz}\,dz=\int_{\mathscr{R}}f(x)f(x-k)\,dx. \tag{3.30}$$

Then, we apply Lemma 3 to (3.27) to obtain

$$|w|_0^2=\sum_{k=1-2^{j-1}}^{2^{j-1}}\left|m\left(\frac{k}{2^j}\right)\right|^2. \tag{3.31}$$

On the other hand, by the same computations as above

$$|w|_{-N-1}^2=\frac{1}{4^{j(N+1)}}\sum_{k=1-2^{j-1}}^{2^{j-1}}\left|m\left(\frac{k}{2^j}\right)\right|^2\left(\sum_{l\in\mathscr{Z}}\left(l+\frac{k}{2^j}\right)^{-2N-2}\left|\hat{\psi}\left(l+\frac{k}{2^j}\right)\right|^2\right). \tag{3.32}$$

Using (3.31), we observe that it is sufficient to show that there exists $C>0$ such that

$$\sum_{l\in\mathscr{Z}}\left|\left(l+\frac{k}{2^j}\right)\right|^{-2N-2}\left|\hat{\psi}\left(l+\frac{k}{2^j}\right)\right|^2\leq C<+\infty \tag{3.33}$$

to conclude the proof of Proposition 2.

Actually, we write

$$\sum_{l\in\mathscr{X}}\left|\left(l+\frac{k}{2^j}\right)\right|^{-2N-2}\left|\hat{\psi}\left(l+\frac{k}{2^j}\right)\right|^2 = \sum_{l\in\mathscr{X}^*}\left|\left(l+\frac{k}{2^j}\right)\right|^{-2N-2}\left|\hat{\psi}\left(l+\frac{k}{2^j}\right)\right|^2+\left|\frac{k}{2^j}\right|^{-2N-2}\left|\hat{\psi}\left(\frac{k}{2^j}\right)\right|^2, \tag{3.34}$$

and we majorize independently the two terms involved in the right-hand side of equality (3.34).

We first observe that for $l\in\mathscr{X}^*$, for $|k|\leqq 2^{j-1}$, we have

$$\left|\frac{k}{2^j}+l\right|^{-2N-2}\leqq 4^{N+1}.$$

Then, using Lemma 3, we obtain

$$\sum_{l\in\mathscr{X}^*}\left(\frac{k}{2^j}+l\right)^{-2N-2}\left|\hat{\psi}\left(l+\frac{k}{2^j}\right)\right|^2\leqq 4^{N+1}\sum_{l\in\mathscr{X}^*}\left|\hat{\psi}\left(l+\frac{k}{2^j}\right)\right|^2\leqq 4^{N+1}. \tag{3.35}$$

Now we prove

$$\left(\frac{k}{2^j}\right)^{-2N-2}\left|\hat{\psi}\left(\frac{k}{2^j}\right)\right|^2\leqq C, \tag{3.36}$$

that is a consequence of (2.5) that implies $|\hat{\psi}(\xi)|=O(|\xi|^{N+1})$ when $\xi\to 0$. This fact concludes the proof of Proposition 2.

Then we also have the following.

COROLLARY 3. *Let s belong to* $[-N-1,0]$; *then for any w in* W_j

$$|w|_s\leqq C2^{js}|w|_0. \tag{3.37}$$

COROLLARY 4. *Let s belong to* $[0,N+1]$; *then for any w in* W_j

$$|w|_0\leqq C2^{-js}|w|_s. \tag{3.38}$$

Proof. We prove (3.37) and (3.38) as we established (3.11) and (3.14), using (3.19) instead of (3.1).

3.3. Conclusion. We summarize §§ 3.1 and 3.2 by the following.

PROPOSITION 3. *There exist* $C_1, C_2>0$ *such that, for each s in* $[-N-1,N+1]$, *for any* w_j *in* W_j, *setting*

$$w_j=\sum_{k=1}^{2^j}\gamma_{j,k}\psi_{j,k},$$

we have

$$C_1|w_j|_s\leqq 2^{js}\left(\sum_{k=1}^{2^j}\gamma_{j,k}^2\right)^{1/2}\leqq C_2|w_j|_s. \tag{3.39}$$

We also have

$$|w_j|_0=\left(\sum_{k=1}^{2^j}\gamma_{j,k}^2\right)^{1/2}. \tag{3.40}$$

Proof. First we observe that (3.40) is a rewriting of (2.8). On the other hand, for w_j as above, for $s>0$,

$$2^{js}\left(\sum_{k=1}^{2^j}\gamma_{j,k}^2\right)^{1/2}\leqq C_2|w_j|_s$$

is established using (3.38) and (3.40). The proofs of the other inequalities are similar using Corollaries 1, 2, 3, and 4.

The following theorem includes the main result of this section.

THEOREM 1. *Let s be in $(-N-1, N+1)$; let u be in $\dot{H}^s(\Pi)$. We set*

$$\gamma_{j,k}=\langle u, \psi_{j,k}\rangle_{\dot{H}^s(\Pi),\dot{H}^{-s}(\Pi)}, \qquad w_j=\sum_{k=1}^{2^j}\gamma_{j,k}\psi_{j,k}.$$

Then, $u=\sum_{j=0}^{+\infty} w_j$, where the sum is unconditionally convergent in $\dot{H}^s(\Pi)$.

Actually, there exist $C_1(s)$, $C_2(s)>0$ such that

$$C_1(s)|u|_s^2 \leqq \sum_{j=0}^{+\infty} |w_j|_s^2 \leqq C_2(s)|u|_s^2. \tag{3.41}$$

Proof. We first prove (3.41) for u regular, such that $u=\sum_{j=0}^{+\infty} w_j$ holds in $\dot{L}^2(\Pi)$, for instance.

Then we conclude by noticing that if $u_n \to u$ in $\dot{H}^s(\Pi)$, then, thanks to Proposition 3, $w_{j,n}\to w_j$ in $\dot{H}^s(\Pi)$ ($w_{j,n}$ defined from u_n in the obvious way).

Now we follow step by step the proof of Theorem 8 [13, Chap. 2]. We write

$$|u|_s^2=\sum_{j=0}^{+\infty}|w_j|_s^2+2\sum_{j<l}(w_j, w_l)_s. \tag{3.42}$$

Choosing ε such that $|s|<N-\varepsilon$, we obtain

$$|(w_j, w_l)_s| \leqq |w_j|_{s+\varepsilon}|w_l|_{s-\varepsilon}, \tag{3.43}$$

and thanks to (3.39)

$$|(w_j, w_l)_s| \leqq C2^{-\varepsilon(l-j)}|w_j|_s|w_l|_s. \tag{3.44}$$

Therefore,

$$\begin{aligned}2\sum_{j<l}|(w_j, w_l)_s| &\leqq C\sum_{j=0}^{+\infty}\left(\sum_{l\neq j}2^{-\varepsilon|l-j|}\right)|w_j|_s^2\\ &\leqq \frac{C}{2^\varepsilon-1}\sum_{j=0}^{+\infty}|w_j|_s^2.\end{aligned} \tag{3.45}$$

This yields

$$|u|_s^2 \leqq C(s)\sum_{j=0}^{+\infty}|w_j|_s^2. \tag{3.46}$$

On the other hand, setting

$$u_J=\sum_{j=0}^{J}4^{js}w_j, \tag{3.47}$$

we have

$$(u, u_J)_0=\sum_{j=0}^{J}4^{js}|w_j|_0^2. \tag{3.48}$$

Thanks to (3.39), we obtain

$$\sum_{j=0}^{J}4^{js}|w_j|_0^2 \geqq C\sum_{j=0}^{J}|w_j|_s^2. \tag{3.49}$$

Then we infer from (3.48), (3.49)

$$\sum_{j=0}^{J} |w_j|_s^2 \leqq C|u|_s |u_J|_{-s}. \tag{3.50}$$

Using the first part of the proof, we obtain

$$|u_J|_{-s}^2 \leqq C(s) \sum_{j=0}^{J} |4^{js} w_j|_{-s}^2. \tag{3.51}$$

This yields, using (3.39),

$$|u_J|_{-s}^2 \leqq C(s) \sum_{j=0}^{J} |w_j|_s^2. \tag{3.52}$$

We then infer from (3.50) and (3.52)

$$\left(\sum_{j=0}^{J} |w_j|_s^2\right)^{1/2} \leqq C(s)|u|_s. \tag{3.53}$$

We let $J \to +\infty$ to end the proof.

We summarize Proposition 3 and Theorem 1 by the following.

COROLLARY 5. *For each s in $(-N-1, N+1)$, there exist $C_1(s), C_2(s) > 0$ such that, if*

$$u = \sum_{j=0}^{+\infty} \sum_{k=1}^{2^j} \gamma_{j,k}\psi_{j,k} \in \dot{H}^s(\Pi),$$

then

$$C_1(s)|u|_s^2 \leqq \sum_{j,k} 4^{js}|\gamma_{j,k}|^2 \leqq C_2(s)|u|_s^2. \tag{3.54}$$

In other words, if $|s| < N+1$, the family $\{\psi_{j,k}\}_{0 \leqq j \leqq +\infty; 1 \leqq k \leqq 2^j}$ is an unconditional basis for $\dot{H}^s(\Pi)$. (For equivalent definitions of an unconditional basis in Hilbert spaces, see, for instance, [10]; see also [13] and the references therein.)

4. A class of evolution equations. Let H be a Hilbert space whose elements are periodic functions. Actually we assume that there exists an integer p such that either

$$H = \dot{H}^p(\Pi^n)$$

or H is a closed subspace of $\dot{H}^p(\Pi^n)$ endowed with its natural topology. The class of evolution equations we shall consider has the form

$$\frac{du}{dt} + \nu Au + Ru + B(u, u) = f, \tag{4.1}$$

where $\nu > 0$, A is the unbounded operator $(-\Delta)^m$ acting on H, whose domain is

$$D(A) = \{u \in H;\ Au \in H\},$$

R is a bounded linear operator from $D(A^{1/2})$ into H, B is a bilinear operator from $D(A^{1/2}) \times D(A^{1/2})$ into $D(A^{-1/2})$, f is in H, and the unknown u maps $\mathcal{R}_+$ into H.

We will consider the initial value problem consisting of (4.1) and of initial condition

$$u(0) = u_0 \in H. \tag{4.2}$$

As usual we denote by $|\cdot|$ and by $(\cdot,\cdot)$, respectively, the norm and the scalar product on H. We set $V=D(A^{1/2})$, $\|\cdot\|$ being the norm on V, and $((\cdot,\cdot))$ being the corresponding scalar product.

We assume that there exists $\alpha, C>0$ such that for any $v\in V$ we have

$$(\nu Au+Ru,u)\geqq\alpha\|u\|^2, \tag{4.3}$$

$$|Ru|\leqq C\|u\|. \tag{4.4}$$

Moreover, we assume that the following properties involving B hold: setting

$$B(u)=B(u,u),\qquad b(u,v,w)=\langle B(u,v),w\rangle_{V',V},$$

for $u, v, w\in V$, we have

$$b(u,v,v)=0, \tag{4.5}$$

and there exists $C_b>0$ such that for any u, v, w in V

$$|b(u,v,w)|\leqq C_b|u|^{1/2}\|u\|^{1/2}\|v\|\,|w|^{1/2}\|w\|^{1/2}. \tag{4.6}$$

We also assume that there exists $C_B>0$ such that for any u, v in $D(A)$

$$|B(u,v)|\leqq C_B|u|^{1/2}|Au|^{1/2}\|v\|, \tag{4.7}$$

$$|B(u,v)|\leqq C_B|u|^{1/2}\|u\|^{1/2}\|v\|^{1/2}|Av|^{1/2}, \tag{4.8}$$

$$|B(u,v)|\leqq C_B\|u\|\,\|v\|\left(1+\mathrm{Log}\left(\frac{|Au|^2}{\lambda_1\|u\|^2}\right)\right)^{1/2}, \tag{4.9}$$

where λ_1 is the smallest eigenvalue of A.

Under these assumptions we recall without proofs the following results that are classical for this class of evolution equations.

THEOREM 2 (Well-posed problem). *There exists a unique solution u of* (4.1) *and* (4.2) *belonging to*

$$C(0,+\infty;H)\cap L^2(0,T;D(A^{1/2}))\quad(\textit{for each } T>0).$$

Moreover, if $u_0\in V$, then

$$u\in C(0,+\infty;V)\cap L^2(0,T;D(A))\quad(\textit{for each } T>0).$$

Proof. See [18] and the references therein.

THEOREM 3 (Dissipativity and absorbing sets). *Let us consider initial data u_0 in* (4.2) *satisfying*

$$|u_0|\leqq R_0.$$

Then there exists a time t_0 that depends on u_0 through R_0, and on the data $\nu, \lambda_1, |f|$ of the equation such that for $t\geqq t_0$

$$|u(t)|\leqq M_0,\qquad \|u(t)\|\leqq M_1, \tag{4.10}$$

where M_0, M_1 are independent of u_0, but dependent on the other data.

Proof. This is related to the existence of an absorbing set in H and V for the dynamical system (4.1); actually $t_0=C_1\log(R_0)+C_2$ is the entrance time in these absorbing sets; see Chapter III, § 2.2, in [18].

THEOREM 4 (Time analyticity). *Let u_0 belong to V; then there exists a domain of $\mathscr{C}$ containing*

$$\begin{aligned}\Gamma(\|u_0\|)=\{\zeta\in\mathscr{C}, \operatorname{Re}\zeta>0,\\ |\operatorname{Im}\zeta|\leqq T_0 \text{ if } \operatorname{Re}\zeta\geqq T_0,\\ |\operatorname{Im}\zeta|\leqq\operatorname{Re}\zeta \text{ if } \operatorname{Re}\zeta\leqq T_0\},\end{aligned}$$

where u can be extended to an analytic map into $D(A)$; here T_0 depends on $\lambda_1, |f|, \|u_0\|, \nu$.

Proof. See [5], [9], [17].

Remark 4. We will use Theorem 4 in the following form: let u_0 belong to H, for $t\geqq t_0$ (t_0 as in Theorem 3), u can be extended to an analytic map from

$$\begin{aligned}\Gamma=\{\zeta\in\mathscr{C}, \operatorname{Re}\zeta>t_0,\\ |\operatorname{Im}\zeta|\leqq T_0 \text{ if } \operatorname{Re}\zeta\geqq t_0+T_0,\\ |\operatorname{Im}\zeta|\leqq\operatorname{Re}\zeta-t_0 \text{ if } \operatorname{Re}\zeta\leqq t_0+T_0\}\end{aligned}$$

into $D(A)$, with T_0 that depends on $\nu, \lambda_1, |f|$ but which is independent of u_0.

We also recall from the proof of Theorem 4 (see [17], for instance) that for $\zeta\in\Gamma$,

$$\|u(\zeta)\|\leqq 2(1+M_1), \tag{4.11}$$

M_1 being as in Theorem 3.

Let us briefly describe two examples of equations satisfying these hypotheses.

Example 1. The stream function formulation of the two-dimensional Navier-Stokes equations.

The usual velocity-pressure formulation of the two-dimensional Navier-Stokes equations reads (see [22]),

$$\frac{\partial u}{\partial t}-\nu\Delta u+(u.\nabla u)+\nabla P=F, \tag{4.12}$$

$$\operatorname{div} u=0, \tag{4.13}$$

where $u=\{u_1, u_2\}$ is the velocity vector, P the pressure; the driving force F is given. These equations are supplemented by space-periodic boundary conditions on Π^2.

Nevertheless, we do not want to address in this paper the difficult question of the treatment by wavelets of the incompressibility condition (4.13). Therefore we rather consider the stream function formulation of the Navier-Stokes equation that reads, setting $u=\operatorname{curl}\Psi$

$$-\frac{\partial\Delta\Psi}{\partial t}+\nu\Delta^2\Psi+\frac{\partial}{\partial x_2}\left(\Delta\Psi\frac{\partial\Psi}{\partial x_1}\right)-\frac{\partial}{\partial x_1}\left(\Delta\Psi\frac{\partial\Psi}{\partial x_2}\right)=\operatorname{curl} F, \tag{4.14}$$

where the unknown Ψ maps $\mathscr{R}_+$ into $\dot{H}^1(\Pi^2)$.

The equation (4.14) has the form (4.1) with $H=\dot{H}^1(\Pi^2), A=-\Delta, D(A)=\dot{H}^3(\Pi^2), R=0$,

$$(B(\Psi_1,\Psi_2),\Psi_3)=\iint_{\Pi^2}\Delta\Psi_1\left(\frac{\partial\Psi_2}{\partial x_2}\frac{\partial\Psi_3}{\partial x_1}-\frac{\partial\Psi_3}{\partial x_2}\frac{\partial\Psi_2}{\partial x_1}\right)dx_1\,dx_2$$

for any Ψ_1, Ψ_2, Ψ_3 in V, and f is defined by

$$(f,\Psi)=\iint_{\Pi^2}F\cdot\operatorname{curl}\Psi\,dx_1\,dx_2.$$

Since the application

$$\operatorname{curl}: \dot{H}^{s+1}(\Pi) \to \{v \in (\dot{H}^s(\Pi))^2; \operatorname{div} v = 0\}$$

$$\Psi \mapsto \left\{\frac{\partial \Psi}{\partial x_2}, -\frac{\partial \Psi}{\partial x_1}\right\}$$

is an isomorphism, all the assumptions (4.3)-(4.9) are satisfied, and are easily derived from similar results that hold for the velocity-pressure formulation of the Navier-Stokes equations (see [18]).

Example 2. The Kuramoto-Sivashinsky equation. This equation reads

$$\frac{\partial v}{\partial t}+\frac{\partial^4 v}{\partial x^4}+\frac{\partial^2 v}{\partial x^2}+v\frac{\partial v}{\partial x}=0, \tag{4.15}$$

where the unknown v maps $\mathscr{R}_+$ into $\dot{L}^2(\Pi)$.

We use the translation method of [15], [16], [18] to transform (4.15) into an equation that has the form (4.1), with assumptions (4.3)-(4.9) satisfied; actually, the difficulty is to prove (4.3), and hence Theorem 3. Following the method of the references above, we restrict ourselves to the case where v is an odd function on $\Pi = [\frac{-1}{2}, \frac{1}{2}]$. Hence

$$H = \{w \in \dot{L}^2(\Pi); \ w \text{ is odd}\},$$

$$A = \frac{\partial^4}{\partial x^4}, \qquad D(A) = \dot{H}^4(\Pi) \cap H.$$

We then set

$$v = u + \phi,$$

where ϕ is an appropriate function in $D(A)$. The new equation for u reads

$$\begin{gathered}\frac{\partial u}{\partial t}+\frac{\partial^4 u}{\partial x^4}+\frac{\partial^2 u}{\partial x^2}+u\frac{\partial \phi}{\partial x}+\phi\frac{\partial u}{\partial x}+u\frac{\partial u}{\partial x}=g(\phi),\\ g(\phi)=-\frac{\partial^4 \phi}{\partial x^4}-\frac{\partial^2 \phi}{\partial x^2}-\phi\frac{\partial \phi}{\partial x}.\end{gathered} \tag{4.16}$$

This equation has the form (4.1), with $\nu = 1$, A as above, $f = g(\phi)$, while $B(u) = u(\partial u/\partial x)$, and

$$R(u) = \frac{\partial^2 u}{\partial x^2} + u\frac{\partial \phi}{\partial x} + \phi\frac{\partial u}{\partial x}.$$

The choice of ϕ such that (4.3) holds is one of the main tasks in [15] and [16]. On the other hand, using Sobolev embeddings and Agmon inequality (see [18]), we easily check that for $u, v \in V$

$$|B(u, v)| \leqq |u|_{L^\infty}\left|\frac{\partial v}{\partial x}\right| \leqq |u|^{1/2}\|u\|^{1/2}|v|^{1/2}\|v\|^{1/2}.$$

This implies (4.6)-(4.9). Finally we observe that (4.5) is not satisfied, but instead we have

$$b(u, u, u) = 0$$

for any $u \in V$. This induces some slight changes in the proofs of Theorem 2 and 3 that still hold (see [18]).

5. Approximate inertial manifolds. Let us consider the dynamical system defined by (4.1). First we recall what is an approximate inertial manifold (AIM).

DEFINITION. A smooth finite-dimensional manifold $\mathcal{M}$ is an AIM of order η (in H) for (4.1) if for any trajectory $u(t)$ there exists t_1 that depends on $|u_0|$ (as in Theorem 3), such that for $t \geqq t_1$

$$\operatorname{dist}_H (u(t), \mathcal{M}) \leqq \eta.$$

Remark 5. Therefore the global attractor is imbedded into an η-neighborhood (in H) of $\mathcal{M}$.

Remark 6. For equivalent definitions of AIMs, and for construction of sequences of AIMs for several dissipative equations, see [3], [4], [5], [21].

Let us describe briefly the aim of this section. We are looking for AIMs defined as graphs of mappings

$$\Phi : PV \rightarrow (\mathrm{Id} - P) V,$$

where P is a suitable linear projector that has finite rank.

The innovation of our work is that, instead of considering a projector onto an eigenspace of A (see the references above), we choose P as the projector onto the space spanned by a finite number of wavelets. As we will see in the next section, it is important to take the wavelets in the natural order, i.e., to consider the functions of W_j before the functions of W_{j+1}. In other words, we choose P as the projector onto a low frequencies wavelet space.

Remark 7. For instance, for Example 1, since $H = \dot{H}^1(\Pi^2)$, we shall use the two-dimensional wavelets derived from the one-dimensional ones by tensor products (see the Appendix). For Example 2, we have to choose wavelets that are odd, since $H = \{v \in \dot{L}^2(\Pi);\ v \text{ is odd}\}$. For that purpose, we proceed as in [13, § VI.11]. We know that the function ψ_N defined in § 2 satisfies

$$\psi_N(1-x) = (-1)^{N+1}\psi_N(x). \tag{5.1}$$

Therefore, N being fixed, a basis for H is given by considering all functions

$$\tilde{\psi}_{j,k}(x) = \frac{1}{\sqrt{2}}\left(\psi_{j,k}\left(x - \tfrac{1}{2}\right) + (-1)^N \psi_{j,k^*}\left(x - \tfrac{1}{2}\right)\right), \tag{5.2}$$

such that $k + k^* = 0[2^j]$, for all $j > 0$ (we recall that $\psi_{j,k}(x)$ is defined in (2.7)). Of course this construction applies to wavelets that enjoy symmetries, as the Littlewood-Paley ones (see [13]).

5.1. Induced trajectories lying in the flat manifold. In the following, for the sake of clarity, we will assume that $n = 1$ and that $H = \dot{H}^p(\Pi)$. The reader could check that only minor changes are needed to extend the results of the next sections to, for instance, the cases described in Examples 1 and 2.

Let V_j (j being fixed in this section) be the flat manifold associated with the (linear) Galerkin approximation of (4.1), (4.2) by periodic piecewise polynomial functions. Being provided $m + p \leqq N + 1$ such that $V_j \subset V$ holds, we define P_j as the orthogonal projector in H onto V_j; let $Q_j = \mathrm{Id}_H - P_j$. We also define $P_{1,j}$ as the orthogonal projector in V onto V_j, and $Q_{1,j} = \mathrm{Id}_V - P_{1,j}$.

Remark 8. In the following we shall omit the subscript j on P_j, Q_j, $P_{1,j}$, and $Q_{1,j}$.

Following the methods developed in [21] we call induced trajectories (lying in the flat manifold) associated with $u(t)$ solution of (4.1), (4.2) the trajectories $y(t)$, $y_1(t)$ defined by

$$y(t) = Pu(t), \qquad y_1(t) = P_1 u(t). \tag{5.3}$$

We also set

$$z(t) = Qu(t), \qquad z_1(t) = Q_1 u(t). \tag{5.4}$$

Remark 9. In contrast with the spectral case we no longer have $y = y_1$.

We recall from the results of § 3 the following proposition.

PROPOSITION 4. *For $p + m < N + 1$, there exists $c > 0$ such that for any z in QV,*

$$|z| \leqq \frac{c}{2^{jm}} \|z\|. \tag{5.5}$$

Proof. For the sake of clarity, and although this is not necessary, we first prove the result for $p = 0$, an then consider the case $p \neq 0$.

First let us assume $p = 0$. We then have $H = \dot{L}^2(\Pi)$, and

$$QH = V_j^{\perp} = \bigoplus_{l \geqq j} W_l,$$

with the notation of §§ 2 and 3. For z in QV, we write

$$z = \sum_{l=j}^{+\infty} \sum_{k=1}^{2^j} \gamma_{l,k} \psi_{l,k},$$

such that

$$|z|^2 = \sum_{l,k} |\gamma_{l,k}|^2.$$

On the other hand, thanks to Corollary 5, we have for $m < N + 1$

$$c(p) \sum_{l,k} 2^{lm} |\gamma_{l,k}|^2 \leqq \|z\|^2.$$

Therefore the two last inequalities yield (5.5).

Let us consider the general case $p \neq 0$. z belongs to QV means that there exists u in $\dot{H}^{m+p}(\Pi)$ such that $z = u - Pu$. Since Pu belongs to $\dot{H}^{N+1}(\Pi)$, we have to assume $m + p \leqq N + 1$ to have $z \in \dot{H}^{m+p}(\Pi)$. Hence

$$(z \in QV) \Leftrightarrow (z \in \dot{H}^{p+m}(\Pi) \quad \text{and} \quad \langle (-\Delta)^p z, \psi_{l,k} \rangle_{\dot{H}^{m-p}, \dot{H}^{p-m}} = 0 \text{ for } l < j).$$

Then we write

$$(-\Delta)^p z = \sum_{l=j}^{+\infty} \sum_{k=1}^{2^l} \gamma_{l,k} \psi_{l,k}, \tag{5.6}$$

this equality holding in $\dot{H}^{m-p}(\Pi)$; moreover, thanks to Corollary 5

$$\sum_{l=j}^{+\infty} \sum_{k=1}^{2^l} |\gamma_{l,k}|^2 4^{l(m-p)} \leqq c(m-p) |(\Delta)^p z|^2_{m-p}. \tag{5.7}$$

We then observe that

$$|(-\Delta)^p z|_{m-p} = |z|_{p+m} = \|z\|, \tag{5.8}$$

which yields

$$C 4^{jm} \sum_{l=j}^{+\infty} \sum_{k=1}^{2^l} 4^{-lp} |\gamma_{l,k}|^2 \leqq \|z\|^2. \tag{5.9}$$

On the other hand, computing the norm in $\dot{H}^{-p}(\Pi)$ of $|(-\Delta)^p z|$, we obtain, thanks to Corollary 5,

$$|z|^2 \leqq C \sum_{l=j}^{+\infty} \sum_{k=1}^{2^l} 4^{-lp} |\gamma_{l,k}|^2. \tag{5.10}$$

Therefore, (5.9) and (5.10) yield (5.5).

We would like to check this kind of inequality for z_1 in $Q_1 V$. For this purpose we need more regularity on the wavelets $\psi_{j,k}$'s.

PROPOSITION 5. *For $2m+p<N+1$, there exists $c>0$ such that for any z_1 in $Q_1 V$*

$$|z_1| \leqq \frac{c}{2^{jm}} \|z_1\|. \tag{5.11}$$

Proof. First we observe that

$$(z_1 \in Q_1 V) \Leftrightarrow (z_1 \in \dot{H}^{p+m}(\Pi) \quad \text{and} \quad \langle (-\Delta)^{p+m} z_1, \psi_{l,k} \rangle_{\dot{H}^{-m-p}, \dot{H}^{p+m}} = 0 \text{ for } l<j).$$

Then we write

$$(-\Delta)^{m+p} z_1 = \sum_{l=j}^{+\infty} \sum_{k=1}^{2^l} \gamma_{l,k} \psi_{l,k}. \tag{5.12}$$

We then apply the method of the proof of Proposition 4 to derive (5.11). The assumption $2m+p<N+1$ comes from the fact that we apply Corollary 5 to estimate the $\dot{H}^{-2m-p}(\Pi)$ norm of $(-\Delta)^{p+m} z_1$ to obtain $|z_1|$.

5.2. Behavior of small eddies.

THEOREM 5. *For $2m+p<N+1$, both $z(t)$, $z_1(t)$ satisfy, for t large enough as in Theorem 3, the following inequalities*:

$$|z(t)|, |z_1(t)|, |z'(t)|, |z_1'(t)| \leqq c \frac{\sqrt{j}}{4^{jm}}, \tag{5.13}$$

$$\|z(t)\|, \|z_1(t)\| \leqq c \frac{\sqrt{j}}{2^{jm}}. \tag{5.14}$$

We reinterpret these inequalities saying that the flat manifold V_j associated to splines of order N is an approximate inertial manifold of order $\sqrt{j}/4^{jm}$ in H and of order $\sqrt{j}/2^{jm}$ in V.

Remark 10. Here we set $z' = dz/dt$, $z_1' = dz_1/dt$.

Remark 11. We match here the accuracy established in the spectral case. For instance, let us consider Example 1, the Navier-Stokes equations. In [5] (see also [21]), it has been proven that if $\tilde{P}_j$ is the orthogonal projector onto the space spanned by the first $(2^j)^2$ (here the dimension space is $n=2$) eigenvectors of A; $\tilde{Q}_j = Id - \tilde{P}_j$; then we have, for t large enough,

$$|\tilde{Q}_j u(t)| \leqq c\delta L^{1/2},$$

$$\|\tilde{Q}_j u(t)\| \leqq c\delta^{1/2} L^{1/2},$$

where $\delta = c/4^{jm}$, L being a logarithmic correction of δ. Here we obtain analogous results, considering a wavelet space that has the same dimension. Therefore, for equations of type (4.1), we can say that wavelets provide a flat AIM that has the same order of approximation as the one obtained using the eigenvectors of A.

Proof of Theorem 5. We take the scalar product in H of (4.1) with z_1; using (4.5) and

$$(Au, z_1) = ((u, z_1)) = \|z_1\|^2, \tag{5.15}$$

we obtain

$$\nu\|z_1\|^2 = (f, z_1) - \left(\frac{du}{dt}, z_1\right) - (Ru, z_1) - b(z_1, y_1, z_1) - b(y_1, y_1, z_1). \tag{5.16}$$

Then (4.9) yields

$$|b(y_1, y_1, z_1)| \leqq C_B\|y_1\|^2\left(1 + \operatorname{Log}\left(\frac{|Ay_1|^2}{\lambda_1\|y_1\|^2}\right)\right)^{1/2}|z_1|. \tag{5.17}$$

Thanks to (3.1), we have

$$\left(1 + \operatorname{Log}\left(\frac{|Ay_1|^2}{\lambda_1\|y_1\|^2}\right)\right)^{1/2} \leqq c\sqrt{j}. \tag{5.18}$$

Hence

$$|b(y_1, y_1, z_1)| \leqq C\sqrt{j}\|y_1\|^2|z_1|. \tag{5.19}$$

On the other hand, we use (4.6) to obtain

$$|b(z_1, y_1, z_1)| \leqq C\|y_1\|\,\|z_1\|\,|z_1|. \tag{5.20}$$

Then we infer from (5.16), (5.19), and (5.20)

$$\nu\|z_1\|^2 \leqq \left(|f| + \left|\frac{du}{dt}\right| + |Ru| + C\sqrt{j}\|y_1\|^2 + C\|y_1\|\,\|z_1\|\right)|z_1|. \tag{5.21}$$

We observe that for t large enough as in Theorem 3 we have both

$$\|y_1\|, \|z_1\| \leqq \|u\| \leqq M_1, \tag{5.22}$$

and that for t large enough as in Theorem 4

$$\left|\frac{du}{dt}\right| \leqq C, \tag{5.23}$$

that is a consequence of the Cauchy formula applied to u in a ball included in Γ, and of (4.11). On the other hand, we derive from (4.4) and (5.22) that $|\mathrm{Ru}| \leqq C$.

We use these facts to obtain

$$\|z_1\|^2 \leqq C\sqrt{j}|z_1|, \tag{5.24}$$

holding for t large enough as above, where C depends on N and on the data ν, λ_1, $|f|$ of the equation, but is independent of j. Then Proposition 5 yields

$$\|z_1\| \leqq C\frac{\sqrt{j}}{2^{jm}}, \tag{5.25}$$

$$|z_1| \leqq C\frac{\sqrt{j}}{4^{jm}}. \tag{5.26}$$

Now we estimate $|z|$ and $\|z\|$; we observe that $z = Qz_1$ and that therefore

$$|z| \leqq |z_1| \leqq C\frac{\sqrt{j}}{4^{jm}} \tag{5.27}$$

holds; but moreover we have the following.

PROPOSITION 6. *For $m+p<N+1$, Q, which is an orthogonal projector in H, maps continuously V into itself, and its norm as a linear operator acting in V is bounded independently of j.*

Proof. For $v \in V$, the following inequalities hold in $\dot{H}^{m-p}(\Pi)$

$$(-\Delta)^p v = \sum_{l=0}^{+\infty} \sum_{k=0}^{2^l} \gamma_{l,k} \psi_{l,k}, \tag{5.28}$$

$$(-\Delta)^p Qv = \sum_{l=j}^{+\infty} \sum_{k=0}^{2^l} \gamma_{l,k} \psi_{l,k}. \tag{5.29}$$

Thanks to Corollary 5 we have

$$\begin{aligned} |(-\Delta)^p Qv|_{m-p} = \|Qv\| &\leqq \frac{1}{c_1(m-p)^{1/2}} \left(\sum_{l=j}^{+\infty} \sum_{k=0}^{2^l} 4^{l(m-p)} |\gamma_{l,k}|^2 \right)^{1/2} \\ &\leqq \frac{1}{c_1(m-p)^{1/2}} \left(\sum_{l=0}^{+\infty} \sum_{k=0}^{2^l} 4^{l(m-p)} |\gamma_{l,k}|^2 \right)^{1/2} \\ &\leqq \left(\frac{c_2(m-p)}{c_1(m-p)} \right)^{1/2} \|v\|, \end{aligned} \tag{5.30}$$

where $c_1(m-p)$, $c_2(m-p)$ are as in Corollary 5.

We apply this result to $z = Qz_1$ to obtain

$$\|z\| \leqq C \frac{\sqrt{j}}{2^{jm}}. \tag{5.31}$$

To end the proof of Theorem 5, it remains to estimate $|z'|$ and $|z_1'|$. For this purpose we observe that z and z_1 are analytic in time in the same domain as u, and then we use Cauchy's formula to get the estimates on z' and z_1' from these on z and z_1. For the reader's convenience we give a complete proof below.

First we need to introduce some notation. Let H_c, V_c, V_c^j, and $D(A^s)_c$ be the complexifications of H, V, V_j, and $D(A^s)$. We recall that if $u_1 + iu_2$ is a typical element of H_c, then we have

$$A(u_1 + iu_2) = Au_1 + iAu_2,$$

$$(u_1 + iu_2, v_1 + iv_2) = (u_1, v_1) + (u_2, v_2) + i[(u_2, v_1) - (u_1, v_2)],$$

and that the multiplication by a complex constant is performed in the natural manner.

We observe that the family $\{\psi_{l,k}\}_{0 \leqq l < j; 1 \leqq k \leqq 2^j}$ is an orthonormal basis of V_c^j in $\dot{L}^2(\Pi)_c$ and that moreover we have the following.

LEMMA 4. The family

$$\{\psi_{l,k}\}_{0 \leqq l < +\infty; 1 \leqq k \leqq 2^l} \text{ is an orthonormal basis of } \dot{L}^2(\Pi)_c, \tag{5.32}$$

and for $(m+p)|s| < N+1$ the family

$$\{\psi_{l,k}\}_{0 \leqq l < +\infty; 1 \leqq k \leqq 2^l} \text{ is an unconditional basis of } D(A^{s/2})_c. \tag{5.33}$$

Proof. The proof is straightforward and left as an exercise to the reader.

Now we observe that y_1 and z_1 can be extended as time analytic functions in the same domain as u. Let Y_1, Z_1, and U be the extensions of y_1, z_1, and u. Then U satisfies, for $\zeta \in \Gamma$,

$$\frac{\partial U}{\partial \zeta} + \nu AU + RU + B(U) = f. \tag{5.34}$$

Taking the scalar product in H_c of (5.34) with Z_1 we obtain

$$\begin{aligned}\nu\|Z_1\|^2 \leqq \left(\left|\frac{\partial U}{\partial \zeta}\right| + |RU|\right)|Z_1| + |b(Y_1, Y_1, Z_1)| \\ + |b(Y_1, Z_1, Z_1)| + |b(Z_1, Y_1, Z_1)| \\ + |b(Z_1, Z_1, Z_1)| + |f||Z_1|.\end{aligned} \tag{5.35}$$

Easy computations yield

$$|b(Z_1, Z_1, Z_1)| \leqq |Z_1| \, \|Z_1\|^2, \tag{5.36}$$

$$|b(Z_1, Y_1, Z_1)| \leqq C|Z_1| \, \|Z_1\| \, \|Y_1\|, \tag{5.37}$$

where C is an absolute constant.

Using (3.1) on Re (Y_1) and Im (Y_1) we obtain

$$|b(Y_1, Y_1, Z_1)| \leqq C\|Y_1\|^2 \sqrt{j}|Z_1|, \tag{5.38}$$

$$|b(Y_1, Z_1, Z_1)| \leqq C\|Y_1\| \, \|Z_1\| \sqrt{j}|Z_1|, \tag{5.39}$$

where C depends on N.

For ζ such that $|\text{Im } \zeta| \leqq T_0/2$ and Re $\zeta \geqq t_0 + 2T_0$ (with t_0 and T_0 as in Remark 4), we apply Cauchy's formula on a ball B centered at ζ, of radius $T_0/2$, to obtain

$$\left|\frac{\partial U}{\partial \zeta}(\zeta)\right| \leq C \sup_{\eta \in B} |U(\eta)|, \tag{5.40}$$

and we infer from (4.11)

$$\left|\frac{\partial U}{\partial \zeta}\right| \leqq C, \tag{5.41}$$

where C depends on the data of the equation through M_1.

We also use (4.11) to majorize $\|Y_1\|$, $\|Z_1\|$, and $|RU|$ (thanks to (4.4)) by $2(1+M_1)$, for ζ as above.

All these facts yield

$$\|Z_1\|^2 \leqq C\sqrt{j}|Z_1|. \tag{5.42}$$

On the other hand, we observe that Lemma 4 provides analogous forms of Poincaré inequalities (5.5) and (5.11) for Z and Z_1. We also infer from Lemma 4 that the orthogonal projector in H_c onto the orthogonal complement of V_c^j is continuous as a linear operator mapping V_c into itself, the corresponding norm being bounded independently of j.

We apply these remarks to (5.42) to obtain, by the same computations as above,

$$|Z|, |Z_1| \leqq C\frac{\sqrt{j}}{4^{jm}}, \tag{5.43}$$

$$\|Z\|, \|Z_1\| \leqq C\frac{\sqrt{j}}{2^{jm}}, \tag{5.44}$$

for ζ belonging to a strip thinner than Γ, for example

$$\left\{\text{Re } \zeta \geqq t_0 + 2T_0, |\text{Im } \zeta| \leqq \frac{T_0}{2}\right\}.$$

To end the proof of Theorem 5, we apply Cauchy's formula on a ball B centered at $t \geqq t_0 + 3T_0$, of radius $T_0/2$ to obtain

$$\left|\frac{dz}{dt}(t)\right| \leqq C \sup_{\eta \in B} |Z(\eta)|, \tag{5.45}$$

where C depends on the data of the equation through M_1. We then infer from (5.43) and (5.45)

$$\left|\frac{dz}{dt}\right| \leqq C \frac{\sqrt{j}}{4^{jm}}. \tag{5.46}$$

An analogous result for z_1' concludes the proof.

5.3. Two nonflat approximate inertial manifolds. Following the methods developed in [21] we provide below two examples of (nonflat) approximate inertial manifolds of higher order than the flat one.

First let us consider the (nonlinear) mapping $\Phi_1 \colon PV \to QV$ defined as follows: for each y in PV, there exists a unique $\Phi_1(y)$ in QV such that

$$\nu((\Phi_1(y), \tilde{z})) = (f - \nu Ay - Ry - B(y), \tilde{z}), \tag{5.47}$$

for any $\tilde{z}$ in QV. Φ_1 is well defined, thanks to a straightforward consequence of the Riesz representation theorem.

Remark 12. Let us notice that the term $(Ay, \tilde{z})$ does not vanish. Actually, unlike the spectral case y and $\tilde{z}$ are orthogonal in H, not in V. This point can be also observed in the nonlinear algorithms described in [14].

Let $\mathcal{M}_1$ be the graph of Φ_1; then we have the following.

PROPOSITION 7. *$\mathcal{M}_1$ is an approximate inertial manifold for* (4.1) *of order $j/8^{jm}$ in H and of order $j/4^{jm}$ in V.*

Remark 13. We match here the accuracy established in the spectral case (see [5], [21]) in the sense of Remark 11.

Proof. We plan to estimate the gap between the trajectory $u(t)$ and its induced trajectory lying in $\mathcal{M}_1$, $y(t) + \Phi_1(y(t))$, where $y(t) = Pu(t)$ as above. We set

$$\chi_1(t) = \Phi_1(y(t)) - z(t). \tag{5.48}$$

We rewrite (5.47) as

$$\nu QA\Phi_1(y) + \nu QAy + QRy + QB(y) = Qf. \tag{5.49}$$

Hence χ_1 satisfies

$$\nu QA\chi_1 + Q(B(y) - B(u)) = \frac{dz}{dt} + Rz. \tag{5.50}$$

We take the scalar product in H of (5.50) with χ_1 to obtain

$$\nu \|\chi_1\|^2 \leqq |b(y, z, \chi_1)| + |b(z, y, \chi_1)| + |b(z, z, \chi_1)| + \left|\frac{dz}{dt}\right| |\chi_1| + |Rz|\,|\chi_1|. \tag{5.51}$$

On the other hand, (4.9) yields

$$|b(y, z, \chi_1)| \leqq C_B \|y\|\,\|z\| \left(1 + \operatorname{Log}\left(\frac{|Ay|^2}{\lambda_1 \|y\|^2}\right)\right)^{1/2} |\chi_1|. \tag{5.52}$$

We infer from (4.10) and (5.30)

$$\|y\| \leqq C\|u\| \leqq CM_1, \tag{5.53}$$

and from (5.14)

$$\|z\| \leqq C\frac{\sqrt{j}}{2^{jm}},$$

these estimates holding for t large enough as in Theorem 5.

We apply (5.5) to obtain

$$|\chi_1| \leqq \frac{C}{2^{jm}} \|\chi_1\|, \tag{5.54}$$

and (3.1) to get

$$\left(1+\operatorname{Log}\left(\frac{|Ay|^2}{\lambda_1\|y\|^2}\right)\right)^{1/2} \leqq C\sqrt{j}. \tag{5.55}$$

Then we finally obtain

$$|b(y, z, \chi_1)| \leqq C\frac{j}{4^{jm}} \|\chi_1\|. \tag{5.56}$$

We also have, using (4.6),

$$|b(z, y, \chi_1)| \leqq C_b|z|^{1/2}\|z\|^{1/2}\|y\| \, |\chi_1|^{1/2}\|\chi_1\|^{1/2}. \tag{5.57}$$

We then infer from (5.13), (5.14), (5.53), (5.54), and (5.57)

$$|b(z, y, \chi_1)| \leqq C\frac{\sqrt{j}}{4^{jm}} \|\chi_1\|, \tag{5.58}$$

for t large enough as above.

Using (4.5) and (4.6) we obtain

$$|b(z, z, \chi_1)| \leqq C_b|z| \, \|z\| \, \|\chi_1\|, \tag{5.59}$$

as well, and thanks to (5.13) and (5.14), we have

$$|b(z, z, \chi_1)| \leqq C\frac{j}{8^{jm}} \|\chi_1\|. \tag{5.60}$$

We also have, thanks to (4.4),

$$|(Rz, \chi_1)| \leqq C\|z\| \, |\chi_1|, \tag{5.61}$$

and thanks to (5.14) and (5.54)

$$|(Rz, \chi_1)| \leqq C\frac{\sqrt{j}}{4^{jm}} \|\chi_1\|. \tag{5.62}$$

Using (5.13) to estimate $|dz/dt|$ we finally obtain

$$\|\chi_1\|^2 \leqq \left[C_1\frac{j}{4^{jm}} + C_2\frac{\sqrt{j}}{4^{jm}} + C_3\frac{j}{8^{jm}} + C_4\frac{\sqrt{j}}{8^{jm}}\right] \|\chi_1\|. \tag{5.63}$$

This yields

$$\|\chi_1\| \leqq C\frac{j}{4^{jm}}, \tag{5.64}$$

and thanks to (5.54),

$$|\chi_1| \leqq C\frac{j}{8^{jm}}, \tag{5.65}$$

holding for t large enough as above.

Now we define $\mathcal{M}_2$ as the graph of the mapping $\Phi_2: PV \to QV$ defined by induction from Φ_1 by:

$$\begin{aligned}\nu((\Phi_2(y), \tilde{z})) = (\nu QA\Phi_1(y) - QR\Phi_1(y) - QB(y, \Phi_1(y))\\ -QB(\Phi_1(y), y), \tilde{z}) \quad \text{for any } \tilde{z} \text{ in } QV.\end{aligned} \tag{5.66}$$

Existence and uniqueness of $\Phi_2(y)$ are consequences of the Riesz representation theorem. We have the following proposition.

PROPOSITION 8. *$\mathcal{M}_2$ is an approximate inertial manifold for* (4.1) *of order* $(j)^{3/2}/16^{jm}$ *in H and of order* $(j)^{3/2}/8^{jm}$ *in V.*

Remark 14. We match here the accuracy established in the spectral case (see [21]) in the sense of Remark 11.

Proof. Setting

$$\chi_2 = \Phi_2(y) - z, \tag{5.67}$$

and using (5.49) we rewrite (5.66) as

$$\begin{aligned}\nu QA\Phi_2(y) + \nu QAy + QB(y) + QRy + QR\Phi_1(y)\\ +QB(y, \Phi_1(y)) + QB(\Phi_1(y), y) = Qf.\end{aligned} \tag{5.68}$$

Hence

$$\nu QA\chi_2 + QR\chi_1 + QB(y, \chi_1) + QB(\chi_1, y) = \frac{dz}{dt} + QB(z), \tag{5.69}$$

where χ_1 is defined as above. We take the scalar product in H of (5.69) with χ_2 to obtain

$$\begin{aligned}\nu\|\chi_2\|^2 \leqq |R\chi_1||\chi_2| + |b(y, \chi_1, \chi_2)| + |b(\chi_1, y, \chi_2)|\\ +|b(z, z, \chi_2)| + \left|\frac{dz}{dt}\right| |\chi_2|.\end{aligned} \tag{5.70}$$

As usual, thanks to (4.9), we obtain

$$|b(y, \chi_1, \chi_2)| \leqq C_B\|y\| \, \|\chi_1\|\left(1 + \operatorname{Log}\left(\frac{|Ay|^2}{\lambda_1\|y\|^2}\right)\right)^{1/2} |\chi_2|. \tag{5.71}$$

From previous estimates (5.53), (5.55), and (5.64) we obtain, for t large enough as above,

$$|b(y, \chi_1, \chi_2)| \leqq C\frac{(j)^{3/2}}{4^{jm}} |\chi_2|, \tag{5.72}$$

and thanks to (5.5)

$$|b(y, \chi_1, \chi_2)| \leqq C\frac{(j)^{3/2}}{8^{jm}} \|\chi_2\|. \tag{5.73}$$

On the other hand, using (4.6)

$$|b(\chi_1, y, \chi_2)| \leqq C_b|\chi_1|^{1/2}\|\chi_1\|^{1/2}\|y\| \, |\chi_2|^{1/2}\|\chi_2\|^{1/2}. \tag{5.74}$$

We infer from (5.5), (5.53), (5.64), and (5.65)

$$(5.75)\qquad \begin{aligned}|b(\chi_1, y, \chi_2)| &\leqq C\frac{j}{(4\sqrt{2})^{jm}}\frac{1}{(\sqrt{2})^{jm}}\|\chi_2\| \\ &\leqq C\frac{j}{8^{jm}}\|\chi_2\|.\end{aligned}$$

By similar computations, using (4.5), (4.6), (5.13), and (5.14)

$$(5.76)\qquad |b(z, z, \chi_2)| \leqq C_b|z|\,\|z\|\,\|\chi_2\| \leqq C\frac{j}{8^{jm}}\|\chi_2\|.$$

We have as well, using (4.4), (5.5), (5.13), and (5.64)

$$(5.77)\qquad |R\chi_1|\,|\chi_2| + \left|\frac{dz}{dt}\right|\,|\chi_2| \leqq C\frac{\sqrt{j}}{8^{jm}}\|\chi_2\|.$$

We summarize (5.70), (5.73), (5.75), (5.76), and (5.77) by

$$(5.78)\qquad \|\chi_2\|^2 \leqq C\frac{(j)^{3/2}}{8^{jm}}\|\chi_2\|,$$

holding for t large enough as above. The Poincaré inequality (5.5) ends the proof.

Appendix. In this Appendix we want first to present a proof of Theorem 1 for the multidimensional periodic wavelet bases built from the one-dimensional ones by tensor products. For the sake of simplicity we present this result for the two-dimensional case. The reader could check that it can be extended without difficulties to the d-dimensional case, $d > 2$.

After that we will end the paper by explaining in a few words how to prove Theorem 1, considering two other important examples of wavelet bases.

In both cases we just have to prove analogous results to Propositions 1 and 2.

We recall from [11], [13] that, for each $N > 0$, there exists a function φ_N satisfying (i) and (ii) such that

$$(A.1)\qquad \int_R \varphi_N(x)\,dx \neq 0,$$

and that, setting

$$(A.2)\qquad \varphi_{j,k}(x) = 2^{j/2}\sum_{l\in\mathscr{Z}} \varphi_N(2^j x + 2^j l - k),$$

the family

$$(A.3)\qquad \{\varphi_{j,k}\}_{1\leqq k\leqq 2^j} \text{ is an orthonormal basis of } V_j.$$

(We dropped for convenience the subscript N on the $\varphi_{j,k}$'s.)

Let us introduce some notation. $H^s(\Pi^2)$ will be the usual periodic Sobolev space on the two-dimensional torus. $\dot{H}^s(\Pi^2)$ will be the set of functions u in $H^s(\Pi^2)$ such that

$$\iint_{\Pi^2} u(x)\,dx_1\,dx_2 = 0.$$

$\dot{H}^s(\Pi^2)$ is a Hilbert space when endowed with the scalar product

$$((u, v))_s = \sum_{k\in\mathscr{Z}^2} |k|^{2s}\hat{u}(k)\overline{\hat{v}(k)},$$

where

$$|k|=(k\cdot k)^{1/2},\ k\cdot l=k_1l_1+k_2l_2,$$

$$\hat{u}(k)=\int\int_{\Pi^2} u(x)\, e^{-2i\pi k\cdot x}\, dx.$$

We denote the corresponding norm

$$\|u\|_s=((u,u))_s^{1/2}.$$

Then let $\mathscr{V}_j$ be the space of functions $v\in L^2(\Pi^2)=H^0(\Pi^2)$ such that both

$$x_1\mapsto v(x_1,x_2), \qquad x_2\mapsto v(x_1,x_2),$$

belong to V_j (i.e., $\mathscr{V}_j=V_j\otimes V_j$). For $\alpha=(\alpha_1,\alpha_2)$ in $\mathscr{A}_j=\{1,\cdots,2^j\}^2$, we set

$$\varphi_\alpha(x)=\varphi_{j,\alpha_1}(x_1)\varphi_{j,\alpha_2}(x_2). \tag{A.4}$$

Then we observe that the family $\{\varphi_\alpha\}_{\alpha\in\mathscr{A}_j}$ is an orthonormal basis of $\mathscr{V}_j$.

Now we are ready to claim the following.

PROPOSITION A.1. *There exists $C>0$ such that for any v in $\mathscr{V}_j$*

$$\|v\|_{N+1}\leqq C2^{j(N+1)}\|v\|_0. \tag{A.5}$$

Remark A.1. As above, C is a constant that depends only on N.

Proof. We use the convexity of the function $\lambda\mapsto\lambda^{N+1}$ to write

$$\begin{aligned}\|u\|_{N+1}^2&=\sum_{k\in\mathscr{Z}^2}(k_1^2+k_1^2)^{N+1}|\hat{u}(k)|^2\\&\leqq 2^N\sum_{k\in\mathscr{Z}^2}(k_1^{2N+2}+k_2^{2N+2})|\hat{u}(k)|^2\\&\leqq 2^N[\|(\partial_1)^{N+1}u\|_0^2+\|(\partial_2)^{N+1}u\|_0^2],\end{aligned} \tag{A.6}$$

setting $(\partial_i)^{N+1}u=\partial^{N+1}u/\partial x_i^{N+1}$; $i=1,2$.

On the other hand, we write for

$$v=\sum_{\alpha\in\mathscr{A}_j}\lambda_\alpha\varphi_\alpha \quad \text{in } \mathscr{V}_j, \tag{A.7}$$

$$\|(\partial_1)^{N+1}v\|_0^2=\sum_{\alpha,\alpha'\in\mathscr{A}_j}\lambda_\alpha\lambda_{\alpha'}(((\partial_1)^{N+1}\varphi_\alpha,(\partial_1)^{N+1}\varphi_{\alpha'}))_0. \tag{A.8}$$

Thanks to Fubini's theorem

$$\begin{aligned}(((\partial_1)^{N+1}\varphi_\alpha,(\partial_1)^{N+1}\varphi_{\alpha'}))_0=&\left(\int_\Pi \varphi_{\alpha_1}^{(N+1)}(x_1)\varphi_{\alpha_1'}^{(N+1)}(x_1)\,dx_1\right)\\&\cdot\left(\int_\Pi \varphi_{\alpha_2}(x_2)\varphi_{\alpha_2'}(x_2)\,dx_2\right),\end{aligned} \tag{A.9}$$

where we set

$$\varphi_{\alpha_1}^{(N+1)}(x_1)=\frac{\partial^{N+1}}{\partial x_1^{N+1}}\varphi_{\alpha_1}(x_1),$$

and where we dropped the subscript j on the φ_{j,α_i}'s to write φ_{α_i}; $i=1,2$.

Using $\int_\Pi \varphi_{\alpha_2}(x_2)\varphi_{\alpha_2'}(x_2)\,dx_2=0$ if $\alpha_2\neq\alpha_2'$ (cf. (A.3)), we obtain

$$\|(\partial_1)^{N+1}v\|_0^2=\sum_{\alpha_2=1}^{2^j}\int_\Pi\left(\sum_{\alpha_1=1}^{2^j}\lambda_\alpha\varphi_{\alpha_1}^{(N+1)}(x_1)\right)^2dx_1. \tag{A.10}$$

We then apply (3.1) to the function $x_1\mapsto\sum_{\alpha_1=1}^{2^j}\lambda_\alpha\varphi_{\alpha_1}^{(N+1)}(x_1)$

$$\int_\Pi\left(\sum_{\alpha_1=1}^{2^j}\lambda_\alpha\varphi_{\alpha_1}^{(N+1)}(x_1)\right)^2dx_1\leqq C4^{j(N+1)}\int_\Pi\left(\sum_{\alpha_1=1}^{2^j}\lambda_\alpha\varphi_{\alpha_1}(x_1)\right)^2dx_1. \tag{A.11}$$

(A.3) yields

$$\int_\Pi\left(\sum_{\alpha_1=1}^{2^j}\lambda_\alpha\varphi_{\alpha_1}(x_1)\right)^2dx_1=\sum_{\alpha_1=1}^{2^j}\lambda_\alpha^2, \tag{A.12}$$

therefore

$$\|(\partial_1)^{N+1}v\|_0^2\leqq C4^{j(N+1)}\left(\sum_{\alpha\in\mathscr{A}_j}\lambda_\alpha^2\right). \tag{A.13}$$

To conclude we recall that the family $\{\varphi_\alpha\}_{\alpha\in\mathscr{A}_j}$ is an orthonormal basis of $\mathscr{V}_j$, then using (A.6), (A.13), and that (A.13) holds for $\|(\partial_2)^{N+1}v\|_0^2$ as well, we obtain

$$\|v\|_{N+1}^2\leqq C4^{j(N+1)}\|v\|_0^2.$$

Now we set

$$\mathscr{W}_j=\mathscr{V}_{j+1}\cap(\mathscr{V}_j)^\perp. \tag{A.14}$$

$\mathscr{W}_j$ can be viewed as the direct sum of three of its subspaces, namely

$$V_j\otimes W_j,\quad W_j\otimes V_j,\quad W_j\otimes W_j.$$

We observe that the family $\{\varphi_{\alpha_1}(x_1)\psi_{\alpha_2}(x_2)\}_{\alpha\in\mathscr{A}_j}$ is an orthonormal basis of

$$V_j\otimes W_j. \tag{A.15}$$

(We dropped the subscript j on ψ_{j,α_2} to write ψ_{α_2}.) We claim the following.

PROPOSITION A.2. *There exists $C>0$ such that for any w in $\mathscr{W}_j$*

$$\|w\|_{-N-1}\leqq C2^{-j(N+1)}\|w\|_0. \tag{A.16}$$

Proof. For w in $\mathscr{W}_j$ we write $w=w_1+w_2+w_3$, where

$$w_1\in V_j\otimes W_j,\quad w_2\in W_j\otimes V_j,\quad w_3\in W_j\otimes W_j.$$

We observe that

$$\|w\|_0^2=\|w_1\|_0^2+\|w_2\|_0^2+\|w_3\|_0^2, \tag{A.17}$$

$$\|w\|_{-N-1}^2\leqq 3(\|w_1\|_{-N-1}^2+\|w_2\|_{-N-1}^2+\|w_3\|_{-N-1}^2). \tag{A.18}$$

It follows that it is sufficient to check (A.16) on both w_1, w_2, w_3. Because the proofs are similar we present below only the proof for w_1.

Let

$$w_1=\sum_{\alpha\in\mathscr{A}_j}\lambda_\alpha\varphi_{\alpha_1}(x_1)\psi_{\alpha_2}(x_2). \tag{A.19}$$

Using (2.7), (3.17), and (A.2) easy computations yield

$$\hat{w}_1(l)=\left(\frac{1}{2^j}\sum_{\alpha\in\mathscr{A}_j}\lambda_\alpha e^{-2i\pi\alpha\cdot l/2^j}\right)\hat{\varphi}\left(\frac{l_1}{2^j}\right)\hat{\psi}\left(\frac{l_2}{2^j}\right). \tag{A.20}$$

Hence

$$\|w_1\|_0^2=\sum_{l\in\mathscr{Z}^2}\left|m\left(\frac{l}{2^j}\right)\right|^2\left|\hat{\varphi}\left(\frac{l_1}{2^j}\right)\right|^2\left|\hat{\psi}\left(\frac{l_2}{2^j}\right)\right|^2, \tag{A.21}$$

setting

$$m\left(\frac{l}{2^j}\right)=\frac{1}{2^j}\sum_{\alpha\in\mathcal{A}_j}\lambda_\alpha\, e^{-2i\pi(l\cdot\alpha/2^j)}. \tag{A.22}$$

m is a $\mathcal{Z}^2$-periodic function. Using this fact, we obtain

$$\|w_1\|_0^2=\sum_{k\in\Gamma}\left|m\left(\frac{k}{2^j}\right)\right|^2\left(\sum_{l_1\in\mathcal{Z}}\left|\hat{\varphi}\left(\frac{k_1}{2^j}+l_1\right)\right|^2\right)\left(\sum_{l_2\in\mathcal{Z}}\left|\hat{\psi}\left(\frac{k_2}{2^j}+l_2\right)\right|^2\right), \tag{A.23}$$

where $\Gamma=\{k\in\mathcal{Z}^2/1-2^{j-1}\leqq k_i\leqq 2^{j-1}, i=1,2\}$.

Thanks to Lemma 3

$$\|w_1\|_0^2=\sum_{k\in\Gamma}\left|m\left(\frac{k}{2^j}\right)\right|^2. \tag{A.24}$$

On the other hand, we write

$$4^{j(N+1)}\|w_1\|_{-N-1}^2=\sum_{l\in\mathcal{Z}_*^2}|\hat{w}_1(l)|^2\left|\frac{l}{2^j}\right|^{-2N-2}. \tag{A.25}$$

By the same computations as above, we obtain

$$\begin{aligned}4^{j(N+1)}\|w_1\|_{-N-1}^2=\sum_{k\in\Gamma}&\left|m\left(\frac{k}{2^j}\right)\right|^2\\ &\cdot\left(\sum_{l\in\mathcal{Z}^2}\left|\frac{k}{2^j}+l\right|^{-2N-2}\left|\hat{\varphi}\left(\frac{k_1}{2^j}+l_1\right)\right|^2\left|\hat{\psi}\left(\frac{k_2}{2^j}+l_2\right)\right|^2\right).\end{aligned} \tag{A.26}$$

We infer from (A.24) and (A.26) that to prove (A.16) for w_1 it is sufficient to majorize the function

$$\left[-\frac{1}{2},\frac{1}{2}\right]^2\to\mathcal{R}_+,\qquad z\mapsto\sum_{l\in\mathcal{Z}^2}|z+l|^{-2N-2}|\hat{\varphi}(z_1+l_1)|^2|\hat{\psi}(z_2+l_2)|^2.$$

Observing that $|z+l|^{-2N-2}\leqq 4^{N+1}$ for z in $[-\frac{1}{2},\frac{1}{2}]^2$ and $l\neq 0$ we obtain

$$\begin{aligned}&\sum_{l\neq 0}|z+l|^{-2N-2}|\hat{\varphi}(z_1+l_1)|^2|\hat{\psi}(z_2+l_2)|^2\\ &\leqq 4^{N+1}\left(\sum_{l_1\in\mathcal{Z}}|\hat{\varphi}(z_1+l_1)|^2\right)\left(\sum_{l_2\in\mathcal{Z}}|\hat{\psi}(z_2+l_2)|^2\right).\end{aligned} \tag{A.27}$$

We then apply Lemma 3 to obtain

$$\sum_{l\neq 0}|z+l|^{-2N-2}|\hat{\varphi}(z_1+l_1)|^2|\hat{\psi}(z_2+l_2)|^2\leqq 4^{N+1}. \tag{A.28}$$

Now we have to majorize

$$|z|^{-2N-2}|\hat{\varphi}(z_1)|^2|\hat{\psi}(z_2)|^2.$$

We infer from (2.5) and (A.1) that

$$|\hat{\varphi}(z_1)|^2=0(1),\qquad |\hat{\psi}(z_2)|^2=0(|z_2|^{2N+2}),$$

when $|z|\to 0$. This fact ends the proof.

Let us recall some results about Daubechies' compactly supported wavelets. (See [2], [13].)

For all $n\geqq 1$, there exist a couple of functions ψ_n, φ_n such that

$$\psi_n,\ \varphi_n\in C^n(\mathcal{R}), \tag{A.29}$$

$$\int x^m\psi_n(x)\,dx=0\quad\text{if } m\leqq n, \tag{A.30}$$

$$\psi_n,\ \varphi_n \text{ are compactly supported.} \tag{A.31}$$

(Actually there exist two constants $c_1, c_2 > 0$ such that the width of their support belongs to $[c_1 n, c_2 n]$.)

(A.32) The family $\{2^{j/2}\psi_n(2^j x - k)\}_{j,k\in\mathscr{Z}}$ is an orthonormal basis of $L^2(\mathscr{R})$.

(A.33) If we denote by $\tilde{W}_j$ the space spanned by the functions $\psi_n(2^j x - k)$; $k \in \mathscr{Z}$, then the family $\{2^{j/2}\varphi_n(2^j x - k)\}_{k\in\mathscr{Z}}$ is an orthonormal basis of $\bigoplus_{l<j} \tilde{W}_l$.

Now we are able to define the periodic Daubechies wavelet bases and to prove Theorem 1 in this case, provided n is large enough with respect to s. Actually, we just have to replace b_N by φ_n in the proof of Proposition 1 and ψ_N by ψ_n in the proof of Proposition 2. The multidimensional results follow.

We now recall the Littlewood-Paley wavelet basis (see [12], [13]). There exist a couple of functions φ, ψ belonging to the Schwartz class $\mathscr{S}(\mathscr{R})$ satisfying, respectively, (A.1), (A.30), for each integer m, (A.32) and (A.33). Moreover, $\hat{\varphi}$ and $\hat{\psi}$ are compactly supported. Then, with the same notation as above, for w in W_j

$$\hat{w}(l) = m(l/2^j)\hat{\psi}(l/2^j), \tag{A.34}$$

where m is a one-periodic function. This yields, for each s in $\mathscr{R}$,

$$\begin{aligned} |w|_s^2 &= \sum_{l\in\mathscr{Z}} |\hat{w}(l)|^2|l|^{2s} \\ &= \sum_{a2^j \leqq l \leqq b2^j} |\hat{w}(l)|^2|l|^{2s}, \end{aligned} \tag{A.35}$$

where a and b are independent of j. This fact yields to Proposition 1 and Proposition 2. We then deduce that the periodic Littlewood-Paley wavelets provide an unconditional basis for all Sobolev spaces $\dot{H}^s(\Pi)$. The multidimensional results follow.

HOMOGENIZATION AND TWO-SCALE CONVERGENCE*

GRÉGOIRE ALLAIRE†

Abstract. Following an idea of G. Nguetseng, the author defines a notion of "two-scale" convergence, which is aimed at a better description of sequences of oscillating functions. Bounded sequences in $L^2(\Omega)$ are proven to be relatively compact with respect to this new type of convergence. A corrector-type theorem (i.e., which permits, in some cases, replacing a sequence by its "two-scale" limit, up to a strongly convergent remainder in $L^2(\Omega)$) is also established. These results are especially useful for the homogenization of partial differential equations with periodically oscillating coefficients. In particular, a new method for proving the convergence of homogenization processes is proposed, which is an alternative to the so-called energy method of Tartar. The power and simplicity of the two-scale convergence method is demonstrated on several examples, including the homogenization of both linear and nonlinear second-order elliptic equations.

Key words. homogenization, two-scale convergence, periodic

AMS(MOS) subject classification. 35B40

Introduction. This paper is devoted to the homogenization of partial differential equations with periodically oscillating coefficients. This type of equation models various physical problems arising in media with a periodic structure. Quite often the size of the period is small compared to the size of a sample of the medium, and, denoting their ratio by ε, an asymptotic analysis, as $\varepsilon \to 0$, is required: namely, starting from a microscopic description of a problem, we seek a macroscopic, or averaged, description. From a mathematical point of view, we have a family of partial differential operators L_ε (with coefficients oscillating with period ε), and a family of solutions u_ε which, for a given domain Ω and source term f, satisfy

$$L_\varepsilon u_\varepsilon = f \quad \text{in } \Omega, \tag{0.1}$$

complemented by appropriate boundary conditions. Assuming that the sequence u_ε converges, in some sense, to a limit u, we look for a so-called homogenized operator $\bar{L}$ such that u is a solution of

$$\bar{L}u = f \quad \text{in } \Omega. \tag{0.2}$$

Passing from (0.1) to (0.2) is the homogenization process. (There is a vast body of literature on that topic; see [10], [40] for an introduction, and additional references.) Although homogenization is not restricted to the case of periodically oscillating operators (cf. the Γ-convergence of DeGiorgi [16], [17], the H-convergence of Tartar [42], [34], or the G-convergence of Spagnolo [41], [49]), we restrict our attention to that particular case. This allows the use of the well-known two-scale asymptotic expansion method [7], [10], [27], [40] in order to find the precise form of the homogenized operator $\bar{L}$. The key to that method is to postulate the following ansatz for u_ε:

$$u_\varepsilon(x) = u_0\left(x, \frac{x}{\varepsilon}\right) + \varepsilon u_1\left(x, \frac{x}{\varepsilon}\right) + \varepsilon^2 u_2\left(x, \frac{x}{\varepsilon}\right) + \cdots, \tag{0.3}$$

* Received by the editors November 5, 1991; accepted for publication (in revised form) February 24, 1992.

† Commissariat à l'Energie Atomique, Laboratoire d'Etudes Thermiques des Réacteurs, Service d'Etudes des Réacteurs et de Mathématiques Appliquées, Département de Mécanique et Technologie, Centre d'Etudes Nucléaires de Saclay, F-91191 Gif sur Yvette, Cédex, France.

where each term $u_i(x, y)$ is periodic in y. Then, inserting (0.3) in (0.1) and identifying powers of ε leads to a cascade of equations for each term u_i. In general, averaging with respect to y that for u_0 gives (0.2), and the precise form of $\bar{L}$ is computed with the help of a so-called cell equation in the unit period (see [10], [40] for details). This method is very simple and powerful, but unfortunately is formal since, a priori, the ansatz (0.3) does not hold true. Thus, the two-scale asymptotic expansion method is used only to guess the form of the homogenized operator $\bar{L}$, and other arguments are needed to prove the convergence of the sequence u_ε to u. To this end, the more general and powerful method is the so-called energy method of Tartar [42]. Loosely speaking, it amounts to multiplying equation (0.1) by special test functions (built with the solutions of the cell equation), and passing to the limit as $\varepsilon \to 0$. Although products of weakly convergent sequences are involved, we can actually pass to the limit thanks to some "compensated compactness" phenomenon due to the particular choice of test functions.

Despite its frequent success in the homogenization of many different types of equations, this way of proceeding is not entirely satisfactory. It involves two different steps, the formal derivation of the cell and homogenized equation, and the energy method, which have very little in common. In some cases, it is difficult to work out the energy method (the construction of adequate test functions could be especially tricky). The energy method does not take full advantage of the periodic structure of the problem (in particular, it uses very little information gained with the two-scale asymptotic expansion). The latter point is not surprising since the energy method was not conceived by Tartar for periodic problems, but rather in the more general (and more difficult) context of H-convergence. Thus, there is room for a more efficient homogenization method, dedicated to partial differential equations with periodically oscillating coefficients. The purpose of the present paper is to provide such a method that we call two-scale convergence method.

This new method relies on the following theorem, which was first proved by Nguetseng [36].

THEOREM 0.1. *Let u_ε be a bounded sequence in $L^2(\Omega)$ (Ω being an open set of $\mathbb{R}^N$). There exists a subsequence, still denoted by u_ε, and a function $u_0(x, y) \in L^2(\Omega \times Y)$ ($Y = (0\,; 1)^N$ is the unit cube) such that*

$$\lim_{\varepsilon \to 0} \int_\Omega u_\varepsilon(x) \psi\left(x, \frac{x}{\varepsilon}\right) dx = \int_\Omega \int_Y u_0(x, y) \psi(x, y)\, dx\, dy \tag{0.4}$$

for any smooth function $\psi(x, y)$, which is Y-periodic in y. Such a sequence u_ε is said to two-scale converge to $u_0(x, y)$.

We provide a simple proof of Theorem 0.1 along with a new corrector result.

THEOREM 0.2. *Let u_ε be a sequence that two-scale converges to $u_0(x, y)$. Then, u_ε weakly converges in $L^2(\Omega)$ to $u(x) = \int_Y u_0(x, y)\, dy$, and we have*

$$\lim_{\varepsilon \to 0} \|u_\varepsilon\|_{L^2(\Omega)} \geqq \|u_0\|_{L^2(\Omega \times Y)} \geqq \|u\|_{L^2(\Omega)}. \tag{0.5}$$

Furthermore, if equality is achieved in the left part of (0.5), *namely,*

$$\lim_{\varepsilon \to 0} \|u_\varepsilon\|_{L^2(\Omega)} = \|u_0\|_{L^2(\Omega \times Y)}, \tag{0.6}$$

and if $u_0(x, y)$ is smooth, then we have

$$\lim_{\varepsilon \to 0} \left\| u_\varepsilon(x) - u_0\left(x, \frac{x}{\varepsilon}\right) \right\|_{L^2(\Omega)} = 0. \tag{0.7}$$

Loosely speaking, Theorem 0.1 is a rigorous justification of the first term in the ansatz (0.3), while Theorem 0.2 gives the condition of a strong convergence to zero of the difference between u_ε and its ansatz. We are now equipped to explain the two-scale convergence method. We multiply equation (0.1) by a test function of the type $\psi(x, x/\varepsilon)$, where $\psi(x, y)$ is a smooth function, Y-periodic in y. After some integration by parts, we pass to the two-scale limit with the help of Theorem 0.1. In the limit, we read off a variational formulation for $u_0(x, y)$. The corresponding partial differential equation is called the two-scale homogenized problem. It is usually of the same type as the original problem (0.1), but it involves two variables x and y. Thus, averaging with respect to y leads to the homogenized problem (0.2). Eventually, so-called corrector results (i.e., strong or pointwise convergences) can be obtained by the application of Theorem 0.2.

We emphasize that the two-scale convergence method is self-contained, i.e., in a single process we find the homogenized equation and we prove convergence. This is in contrast with the former "usual" homogenization process (as described above) which is divided in two steps: first, find the homogenized and cell equations by means of asymptotic expansions; second, prove convergence with the energy method. Another interesting feature of the two-scale convergence method is the introduction of the two-scale homogenized problem. It turns out that it is a well-posed system of equations, which are a combination of the usual homogenized and cell equations. Indeed, if it is expected that the periodic oscillations in the operator L_ε generate only the same type of oscillations in the solution u_ε, the sequence u_ε is completely characterized by its two-scale limit $u_0(x, y)$. Thus, starting from a well-posed problem for u_ε, we should obtain in the limit a well-posed problem of the same type for u_0. However, this is not always the case for the usual macroscopic homogenized equation (the solution of which is $u(x) = \int_Y u_0(x, y)\, dy$). When averaging the two-scale homogenized problem with respect to y, its "nice" form can disappear, and, rather, we could obtain integro-differential terms (corresponding to memory effects), nonlocal terms, or nonexplicit equations. There are many such examples in the literature (see [5], [29], [32], [46], where "classical" methods are used, and [2], [3], [37], where two-scale convergence is applied). In these cases, the two-scale homogenized problem explains and simplifies the complicated form of the macroscopic limit equation, thanks to the additional microscopic variable y, which plays the role of a hidden variable.

Since Theorem 0.1 proves the existence of the first term in the ansatz (0.3), the two-scale convergence method appears as the mathematically rigorous version of the, intuitive and formal, two-scale asymptotic expansion method [7], [10], [27], [40]. The key of the success for such a method is to consider only periodic homogenization problems. This amounts to restricting the class of possible oscillations of the solutions to purely periodic ones. Working with the relatively small class of periodic oscillations allows us to obtain the representation formula (0.4) for weak limits of solutions. For general types of oscillations, a result like (0.4) seems to be out of reach (the main obstacle being how to choose the test functions). On the other hand, periodic homogenization can be cast into the framework of quasi-periodic, or almost-periodic (in the sense of Besicovitch) homogenization (see, e.g., [28], [38]), since periodic functions are a very special subclass of quasi-, or almost-, periodic functions. In this case, test functions can also be written $\psi(x, x/\varepsilon)$, where $\psi(x, y)$ is quasi-, or almost-, periodic in y. However, we do not know if Theorem 0.1 can be generalized to such test functions or if a new convergence method can thus be obtained.

The paper is organized as follows. Section 1 is devoted to the proof of Theorems 0.1 and 0.2, and other related results. In § 2, we show precisely how the two-scale convergence method works on the homogenization of linear second-order elliptic equations (this is the favorite model problem in homogenization; see, e.g., Chapter 1 in [10]). We do this in a fixed domain Ω, but also in a periodically perforated domain Ω_ε (a porous medium), obtained by removing from Ω infinitely many small holes of size ε (their number is of order ε^{-N}), which support a Neumann boundary condition. Two-scale convergence is particularly well adapted to the latter case, and we recover previous results (see [13], [1], [4]) without using any extension techniques. Section 3 generalizes § 2 to the nonlinear case. In the periodic setting, we give a new proof of the Γ-convergence of convex energies (see [31], [16], [17]), and we revisit the homogenization of monotone operators [42]. On the contrary of §§ 2 and 3, § 4 deals with an example of homogenization where typical two-scale phenomena appear. We consider a linear elliptic second-order equation with periodic coefficients taking only two values 1 and ε^2. It models a diffusion process in a medium made of two highly heterogeneous materials. It turns out that the limit diffusion process is of a very special type: the usual homogenized problem is not an explicit partial differential equation. Finally, § 5 is devoted to the proof of a technical lemma used in § 1; more generally, we investigate under which regularity assumptions on a Y-periodic function $\psi(x, y)$ the following convergence holds true:

$$\lim_{\varepsilon\to 0}\int_\Omega \left|\psi\left(x,\frac{x}{\varepsilon}\right)\right| dx=\int_\Omega\int_Y |\psi(x,y)|\,dx\,dy. \tag{0.8}$$

It is easily seen that continuous functions satisfy (0.8). We prove that (0.8) still holds true for functions of $L^1[\Omega; C_\#(Y)]$ or $L^1_\#[Y; C(\bar{\Omega})]$, which are continuous in only one variable, x or y. However, we cannot decrease the regularity of $\psi(x, y)$ too much. Indeed, we construct a counterexample to (0.8) for a function $\psi(x, y)$ of $C[\Omega; L^1_\#(Y)]$, which is not continuous in x for any value of y, but merely continuous in x in the "$L^1(Y)$-mean."

1. Two-scale convergence.

Let us begin this section with a few notations. Throughout this paper Ω is an open set of $\mathbb{R}^N (N \geqq 1)$, and $Y=[0; 1]^N$ is the closed unit cube. As usual, $L^2(\Omega)$ is the Sobolev space of real-valued functions that are measurable and square summable in Ω with respect to the Lebesgue measure. We denote by $C^\infty_\#(Y)$ the space of infinitely differentiable functions in $\mathbb{R}^N$ that are periodic of period Y. Then, $L^2_\#(Y)$ (respectively, $H^1_\#(Y)$) is the completion for the norm of $L^2(Y)$ (respectively, $H^1(Y)$) of $C^\infty_\#(Y)$. Remark that $L^2_\#(Y)$ actually coincides with the space of functions in $L^2(Y)$ extended by Y-periodicity to the whole of $\mathbb{R}^N$.

Let us consider a sequence of functions u_ε in $L^2(\Omega)$ (ε is a sequence of strictly positive numbers which goes to zero). Following the lead of Nguetseng [36], we introduce the following.

Definition 1.1. A sequence of functions u_ε in $L^2(\Omega)$ is said to *two-scale converge* to a limit $u_0(x, y)$ belonging to $L^2(\Omega\times Y)$ if, for any function $\psi(x, y)$ in $D[\Omega; C^\infty_\#(Y)]$, we have

$$\lim_{\varepsilon\to 0}\int_\Omega u_\varepsilon(x)\psi\left(x,\frac{x}{\varepsilon}\right) dx=\int_\Omega\int_Y u_0(x,y)\psi(x,y)\,dx\,dy. \tag{1.1}$$

This new notion of "two-scale convergence" makes sense because of the next compactness theorem.

Theorem 1.2. *From each bounded sequence u_ε in $L^2(\Omega)$, we can extract a subsequence, and there exists a limit $u_0(x, y)\in L^2(\Omega\times Y)$ such that this subsequence two-scale converges to u_0.*

To establish Theorem 1.2, we need the following lemma, the proof of which may be found in § 5.

LEMMA 1.3. *Let $\psi(x, y)$ be a function in $L^2[\Omega; C_\#(Y)]$, i.e., measurable and square summable in $x \in \Omega$, with values in the Banach space of continuous functions, Y-periodic in y. Then, for any positive value of ε, $\psi(x, x/\varepsilon)$ is a measurable function on Ω, and we have*

$$(1.2)\qquad \left\| \psi\left(x, \frac{x}{\varepsilon}\right) \right\|_{L^2(\Omega)} \leqq \|\psi(x, y)\|_{L^2[\Omega;\, C_\#(Y)]} \equiv \left[\int_\Omega \operatorname*{Sup}_{y \in Y} |\psi(x, y)|^2 \, dx \right]^{1/2}$$

and

$$(1.3)\qquad \lim_{\varepsilon \to 0} \int_\Omega \psi\left(x, \frac{x}{\varepsilon}\right)^2 dx = \int_\Omega \int_Y \psi(x, y)^2 \, dx \, dy.$$

DEFINITION 1.4. A function $\psi(x, y)$, Y-periodic in y, and satisfying (1.3), is called an "admissible" test function.

It is well known (and easy to prove) that a continuous function $\psi(x, y)$ on $\Omega \times Y$, Y-periodic in y, satisfies (1.3). However, the situation is not so clear if the regularity of ψ is weakened: in particular, the measurability of $\psi(x, x/\varepsilon)$ is not obvious. To our knowledge, the minimal regularity hypothesis (if any) making of $\psi(x, y)$ an "admissible" test function is not known. In order that the right-hand side of (1.3) makes sense, $\psi(x, y)$ must at least belong to $L^2(\Omega \times Y)$ (in addition to being Y-periodic in y). But, as we shall see in § 5, this is not enough for (1.3) to hold (a counterexample is provided in Proposition 5.8). Loosely speaking, $\psi(x, y)$ turns out to be an "admissible" test function if it is continuous in one of its arguments (as is the case when ψ belongs to $L^2[\Omega; C_\#(Y)]$). For more details, see § 5, which is devoted to the proof of Lemma 1.3 and to the investigation of other regularity assumptions making of ψ an "admissible" test function.

Proof of Theorem 1.2. Let u_ε be a bounded sequence in $L^2(\Omega)$: there exists a positive constant C such that

$$\|u_\varepsilon\|_{L^2(\Omega)} \leqq C.$$

For any function $\psi(x, y) \in L^2[\Omega; C_\#(Y)]$, according to Lemma 1.3, $\psi(x, x/\varepsilon)$ belongs to $L^2(\Omega)$, and the Schwarz inequality yields

$$(1.4)\qquad \left| \int_\Omega u_\varepsilon(x) \psi\left(x, \frac{x}{\varepsilon}\right) dx \right| \leqq C \left\| \psi\left(x, \frac{x}{\varepsilon}\right) \right\|_{L^2(\Omega)} \leqq C \|\psi(x, y)\|_{L^2[\Omega; C_\#(Y)]}.$$

Thus, for fixed ε, the left-hand side of (1.4) turns out to be a bounded linear form on $L^2[\Omega; C_\#(Y)]$. The dual space of $L^2[\Omega; C_\#(Y)]$ can be identified with $L^2[\Omega; M_\#(Y)]$, where $M_\#(Y)$ is the space of Y-periodic Radon measures on Y. By virtue of the Riesz representation theorem, there exists a unique function $\mu_\varepsilon \in L^2[\Omega; M_\#(Y)]$ such that

$$(1.5)\qquad \langle \mu_\varepsilon, \psi \rangle = \int_\Omega u_\varepsilon(x) \psi\left(x, \frac{x}{\varepsilon}\right) dx,$$

where the brackets in the left-hand side of (1.5) denotes the duality product between $L^2[\Omega; C_\#(Y)]$ and its dual. Furthermore, in view of (1.4), the sequence μ_ε is bounded in $L^2[\Omega; M_\#(Y)]$. Since the space $L^2[\Omega; C_\#(Y)]$ is separable (i.e., contains a dense countable family), from any bounded sequence of its dual we can extract a subsequence that converges for the weak* topology. Thus, there exists $\mu_0 \in L^2[\Omega; M_\#(Y)]$ such that, up to a subsequence, and for any $\psi \in L^2[\Omega; C_\#(Y)]$,

$$(1.6)\qquad \langle \mu_\varepsilon, \psi \rangle \to \langle \mu_0, \psi \rangle.$$

By combining (1.5) and (1.6) we obtain, up to a subsequence, and for any $\psi \in L^2[\Omega; C_{\#}(Y)]$,

$$\lim_{\varepsilon \to 0} \int_\Omega u_\varepsilon(x) \psi\left(x, \frac{x}{\varepsilon}\right) dx = \langle \mu_0, \psi \rangle. \tag{1.7}$$

From Lemma 1.3 we know that

$$\lim_{\varepsilon \to 0} \left\| \psi\left(x, \frac{x}{\varepsilon}\right) \right\|_{L^2(\Omega)} = \|\psi(x, y)\|_{L^2(\Omega \times Y)}. \tag{1.8}$$

Now, passing to the limit in the first two terms of (1.4) with the help of (1.7) and (1.8), we deduce

$$|\langle \mu_0, \psi \rangle| \leqq C \|\psi\|_{L^2(\Omega \times Y)}.$$

By density of $L^2[\Omega; C_{\#}(Y)]$ in $L^2(\Omega \times Y)$, and by the Riesz representation theorem, μ_0 is identified with a function $u_0 \in L^2(\Omega \times Y)$, i.e.,

$$\langle \mu_0, \psi \rangle = \int_\Omega \int_Y u_0(x, y) \psi(x, y)\, dx\, dy. \tag{1.9}$$

Equalities (1.7) and (1.9) are the desired result. □

Remark 1.5. In the proof of Theorem 1.2, we considered test functions $\psi(x, y)$ in $L^2[\Omega; C_{\#}(Y)]$. Other choices of space of test functions are actually possible. For example, in the case where Ω is bounded, we could have replaced $L^2[\Omega; C_{\#}(Y)]$ by $C[\bar{\Omega}; \mathrm{C}_{\#}\ (\mathrm{Y})]$, or by $L^2_{\#}[Y; C(\bar{\Omega})]$. The main ingredients of the proof would not be affected by this change. All these spaces have in common that they are separable Banach spaces, which is the required property in order to extract a weakly * convergent subsequence from any bounded sequence in their dual. In any case the two-scale limit $u_0(x, y)$ is always the same, whatever the chosen space of test functions (see Remark 1.11).

Before developing further the theory, let us give a few examples of two-scale limits.

(*) For any smooth function $a(x, y)$, being Y-periodic in y, the associated sequence $a_\varepsilon(x) = a(x, x/\varepsilon)$ two-scale converges to $a(x, y)$.

(**) Any sequence u_ε that converges strongly in $L^2(\Omega)$ to a limit $u(x)$, two-scale converges to the same limit $u(x)$.

(***) Any sequence u_ε that admits an asymptotic expansion of the type $u_\varepsilon(x) = u_0(x, x/\varepsilon) + \varepsilon u_1(x, x/\varepsilon) + \varepsilon^2 u_2(x, x/\varepsilon) + \cdots$, where the functions $u_i(x, y)$ are smooth and Y-periodic in y, two-scale converges to the first term of the expansion, namely, $u_0(x, y)$.

In view of the third example we already have a flavour of the main interest of two-scale convergence: even if the above asymptotic expansion does not hold (or is unknown), it is permited to rigorously justify the existence of its first term $u_0(x, y)$. This is very helpful in homogenization theory, where such asymptotic expansions are frequently used in a heuristical way (see [10], [40]). This remark is the key of our two-scale convergence method, as explained in §§ 2, 3, and 4.

The next proposition establishes a link between two-scale and weak L^2-convergences.

PROPOSITION 1.6. *Let u_ε be a sequence of functions in $L^2(\Omega)$, which two-scale converges to a limit $u_0(x, y) \in L^2(\Omega \times Y)$. Then u_ε converges also to $u(x) = \int_Y u_0(x, y)\, dy$ in $L^2(\Omega)$ weakly. Furthermore, we have*

$$\lim_{\varepsilon \to 0} \|u_\varepsilon\|_{L^2(\Omega)} \geqq \|u_0\|_{L^2(\Omega \times Y)} \geqq \|u\|_{L^2(\Omega)}. \tag{1.10}$$

Proof. By taking test functions $\psi(x)$, which depends only on x, in (1.1), we immediately obtain that u_ε weakly converges to $u(x)=\int_Y u_0(x,y)\,dy$ in $L^2(\Omega)$. To obtain (1.10), for $\psi(x,y)\in L^2[\Omega;\, C_\#(Y)]$, we compute

$$\int_\Omega \left[u_\varepsilon(x)-\psi\left(x,\frac{x}{\varepsilon}\right)\right]^2 dx=\int_\Omega u_\varepsilon(x)^2\,dx+\int_\Omega \psi\left(x,\frac{x}{\varepsilon}\right)^2 dx$$

$$-2\int_\Omega u_\varepsilon(x)\psi\left(x,\frac{x}{\varepsilon}\right) dx \geqq 0.$$

Passing to the limit as $\varepsilon\to 0$ yields

$$\lim_{\varepsilon\to 0}\int_\Omega u_\varepsilon(x)^2\,dx \geqq 2\int_\Omega\int_Y u_0(x,y)\psi(x,y)\,dx\,dy-\int_\Omega\int_Y \psi(x,y)^2\,dx\,dy.$$

Then, using a sequence of smooth functions that converges strongly to u_0 in $L^2(\Omega\times Y)$ leads to

$$\lim_{\varepsilon\to 0}\int_\Omega u_\varepsilon(x)^2\,dx\geqq\int_\Omega\int_Y u_0(x,y)^2\,dx\,dy.$$

On the other hand, the Cauchy–Schwarz inequality in Y gives the other inequality in (1.10). □

Remark 1.7. From Proposition 1.6, we see that, for a given bounded sequence in $L^2(\Omega)$, there is more information in its two-scale limit u_0 than in its weak L^2 limit u: u_0 contains some knowledge on the periodic oscillations of u_ε, while u is just the average (with respect to y) of u_0. However, let us emphasize that the two-scale limit captures only the oscillations that are in resonance with those of the test functions $\psi(x, x/\varepsilon)$. Contrary to the example (*) above, the sequence defined by $b_\varepsilon(x)=a(x, x/\varepsilon^2)$ (where $a(x,y)$ is a smooth function, Y-periodic in y) has the same two-scale limit and weak L^2 limit, namely, $\int_Y a(x,y)\,dy$. (This is a consequence of the difference of orders in the speed of oscillations for b_ε and the test functions $\psi(x, x/\varepsilon)$.) In this example, no oscillations are captured because the two-scale limit depends only on the variable x. Remark also here that the independence of the two-scale limit on the "fast" variable y does not imply strong convergence of the sequence in $L^2(\Omega)$.

We claim that there is more information in the two-scale limit of a sequence than in its weak L^2 limit. But does this supplementary knowledge yield some kind of strong convergence? This question is precisely answered by the following theorem.

THEOREM 1.8. *Let u_ε be a sequence of functions in $L^2(\Omega)$ that two-scale converges to a limit $u_0(x,y)\in L^2(\Omega\times Y)$. Assume that*

$$\lim_{\varepsilon\to 0}\|u_\varepsilon\|_{L^2(\Omega)}=\|u_0\|_{L^2(\Omega\times Y)}. \tag{1.11}$$

Then, for any sequence v_ε that two-scale converges to a limit $v_0(x,y)\in L^2(\Omega\times Y)$, we have

$$u_\varepsilon(x)v_\varepsilon(x)\rightharpoonup\int_Y u_0(x,y)v_0(x,y)\,dy \quad \text{in } D'(\Omega). \tag{1.12}$$

Furthermore, if $u_0(x,y)$ belongs to $L^2[\Omega;\, C_\#(Y)]$, we have

$$\lim_{\varepsilon\to 0}\left\|u_\varepsilon(x)-u_0\left(x,\frac{x}{\varepsilon}\right)\right\|_{L^2(\Omega)}=0. \tag{1.13}$$

Remark 1.9. The condition (1.11) can be interpreted as "u_0 contains all the oscillations of the sequence u_ε." Indeed, (1.11) always takes place for a sequence $\psi(x, x/\varepsilon)$, with $\psi(x,y)\in L^2[\Omega;\, C_\#(Y)]$ or, more generally, being an "admissible" test function in the sense of Definition 1.4. The result (1.12) can be defined as a *strong* two-scale convergence for the sequence u_ε; remarkably, it allows to pass to the limit in some product of two weak convergences in $L^2(\Omega)$.

Remark 1.10. As already pointed out before, for a given ε, the function $u_0(x, x/\varepsilon)$ need not be measurable in Ω, if $u_0(x, y)$ merely belongs to $L^2(\Omega\times Y)$. Thus, in order for (1.13) to make sense, some regularity on u_0 is required; more precisely, we restrict ourselves to functions $u_0(x, y)$ in $L^2[\Omega;\ C_\#(Y)]$ (more generally, $u_0(x, y)$ could be any "admissible" test function; see § 5 for details). However, we could wonder if all two-scale limits automatically are "admissible" test functions. Unfortunately, this is not true, and Lemma 1.13 below shows that any function in $L^2(\Omega\times Y)$ is attained as a two-scale limit. In view of the counterexample of Proposition 5.8, it is clear that, in general, a function of $L^2(\Omega\times Y)$ is not "admissible" in the sense of Definition 1.4. Thus, we cannot avoid an assumption on the regularity of u_0 in order to state (1.13).

Finally, we claim that, in the vocabulary of homogenization, (1.13) is a corrector-type result. Indeed, the sequence u_ε is approximated by its two-scale limit $u_0(x, x/\varepsilon)$ up to a strongly convergent reminder in $L^2(\Omega)$. Thus, the weak L^2-convergence of u_ε to its weak limit u is improved by (1.13), and the precise corrector is $u_0(x, x/\varepsilon)-u(x)$.

Proof of Theorem 1.8. Let $\psi_n(x, y)$ be a sequence of smooth functions in $L^2[\Omega;\ C_\#(Y)]$ that converges strongly to $u_0(x, y)$ in $L^2(\Omega\times Y)$. By definition of two-scale convergence for u_ε, and using Lemma 1.3 and assumption (1.11), we obtain

$$\lim_{\varepsilon\to 0}\int_\Omega\left[u_\varepsilon(x)-\psi_n\left(x,\frac{x}{\varepsilon}\right)\right]^2 dx=\int_\Omega\int_Y[u_0(x,y)-\psi_n(x,y)]^2\,dx\,dy. \tag{1.14}$$

Passing to the limit as n goes to infinity, (1.14) yields

$$\lim_{n\to\infty}\lim_{\varepsilon\to 0}\int_\Omega\left[u_\varepsilon(x)-\psi_n\left(x,\frac{x}{\varepsilon}\right)\right]^2 dx=0. \tag{1.15}$$

Let v_ε be a sequence that two-scale converges to a limit $v_0(x, y)$. For any $\phi(x)\in D(\Omega)$, we have

$$\begin{aligned}\int_\Omega\phi(x)u_\varepsilon(x)v_\varepsilon(x)\,dx&=\int_\Omega\phi(x)\psi_n\left(x,\frac{x}{\varepsilon}\right)v_\varepsilon(x)\,dx\\&\quad+\int_\Omega\phi(x)\left[u_\varepsilon(x)-\psi_n\left(x,\frac{x}{\varepsilon}\right)\right]v_\varepsilon(x)\,dx.\end{aligned}$$

Passing to the limit as ε goes to zero (and having in mind that v_ε is a bounded sequence in $L^2(\Omega)$) yields

$$\begin{aligned}&\left|\lim_{\varepsilon\to 0}\int_\Omega\phi(x)u_\varepsilon(x)v_\varepsilon(x)\,dx-\int_\Omega\int_Y\phi(x)\psi_n(x,y)v_0(x,y)\,dx\,dy\right|\\&\quad\leqq C\lim_{\varepsilon\to 0}\left\|u_\varepsilon(x)-\psi_n\left(x,\frac{x}{\varepsilon}\right)\right\|_{L^2(\Omega)}.\end{aligned}$$

Next, passing to the limit when n goes to infinity and using (1.15) leads to (1.12), i.e.,

$$\lim_{\varepsilon\to 0}\int_\Omega\phi(x)u_\varepsilon(x)v_\varepsilon(x)\,dx=\int_\Omega\int_Y\phi(x)u_0(x,y)v_0(x,y)\,dx\,dy.$$

Furthermore, if $u_0(x, y)$ is smooth, say $u_0\in L^2[\Omega;\ C_\#(Y)]$, then (1.14) applies directly with u_0 instead of ψ_n, and it is nothing but (1.13). □

Remark 1.11. As a consequence of Theorem 1.8, we can enlarge the class of test functions $\psi(x, y)$ used in the definition of two-scale convergence. In Definition 1.1, a sequence u_ε two-scale converges to a limit u_0 if

$$(1.16) \qquad \lim_{\varepsilon \to 0} \int_\Omega u_\varepsilon(x)\psi\left(x, \frac{x}{\varepsilon}\right) dx = \int_\Omega \int_Y u_0(x, y)\psi(x, y)\, dx\, dy$$

for any smooth test function ψ, namely, for $\psi(x, y) \in D[\Omega; C_\#^\infty(Y)]$. The class of test functions has already been considerably enlarged since the compactness Theorem 1.2 is proved for any $\psi(x, y) \in L^2[\Omega; C_\#(Y)]$. In view of Theorem 1.8, the validity of (1.16) is extended to all "admissible" test functions ψ in the sense of Definition 1.4. Indeed, an admissible test function satisfies hypothesis (1.11) in Theorem 1.8, and thus the sequence $\psi(x, x/\varepsilon)$ two-scale converges strongly to $\psi(x, y)$. Retrospectively, the choice of the space $L^2[\Omega; C_\#(Y)]$ in the proof of Theorem 1.2 appears to be purely technical: other choices would have led to the same two-scale limit.

Remark 1.12. Let us conclude this section by some bibliographical comments. As already said, the notion of two-scale convergence and the proof of the compactness Theorem 1.2 go back to Nguetseng [36]. Here we present a new proof of Theorem 1.2, which is simpler than the original one (note in passing that our proof has some similarities with that of Ball [8] for the existence of Young measures). Proposition 1.6 and Theorem 1.8 (concerning corrector results) are new. Recently, a generalization of two-scale convergence to Young measures has been introduced by E [19] in order to handle homogenization of nonlinear hyperbolic conservation laws (see Remark 3.8). Various authors have also developed ideas similar to two-scale convergence: Arbogast, Douglas, and Hornung [6] defined a so-called dilation operator for homogenization problems in porous media, while Mascarenhas [32] introduced a kind of two-scale Γ-convergence in the study of some memory effects in homogenization. All these works can be embedded in the general setting of two-scale convergence.

Now that the basic tools of the two-scale convergence method have been established, we give a few complementary results before explaining how it can be applied to the homogenization of partial differential equations with periodically oscillating coefficients. We first prove that two-scale limits have no extra regularity, as announced in Remark 1.10.

LEMMA 1.13. *Any function $u_0(x, y)$ in $L^2(\Omega \times Y)$ is attained as a two-scale limit.*

Proof. For any function $u_0(x, y) \in L^2(\Omega \times Y)$, we shall construct a bounded sequence u_ε in $L^2(\Omega)$ that two-scale converges to u_0. Let $u_n(x, y)$ be a sequence of smooth, Y-periodic in y functions that converge strongly to u_0 in $L^2(\Omega \times Y)$. Let $[\psi_k(x, y)]_{1 \leqq k \leqq \infty}$ be a dense family of smooth, Y-periodic in y functions in $L^2(\Omega \times Y)$, normalized such that $\|\psi_k\|_{L^2(\Omega \times Y)} = 1$. Obviously, for fixed n, the sequence $u_n(x, x/\varepsilon)$ two-scale converges to $u_n(x, y)$, i.e., for any $\delta > 0$, and for any smooth $\psi(x, y)$, there exists $\varepsilon_0(n, \delta, \psi) > 0$ such that $\varepsilon < \varepsilon_0$ implies

$$\left| \int_\Omega u_n\left(x, \frac{x}{\varepsilon}\right) \psi\left(x, \frac{x}{\varepsilon}\right) dx - \int_\Omega \int_Y u_n(x, y)\psi(x, y)\, dx\, dy \right| \leqq \delta.$$

Now, we extract a diagonal sequence; namely, fixing $\delta_n = \|u_n - u_0\|_{L^2(\Omega \times Y)}$, there exists a sequence of positive numbers $\varepsilon(n)$, which goes to zero as $n \to \infty$ such that

$$\left| \int_\Omega u_n\left(x, \frac{x}{\varepsilon(n)}\right)^2 dx - \int_\Omega \int_Y u_n(x, y)^2\, dx\, dy \right| \leqq \delta_n$$

$$(1.17) \quad \left| \int_\Omega u_n\left(x, \frac{x}{\varepsilon(n)}\right) \psi_k\left(x, \frac{x}{\varepsilon(n)}\right) dx - \int_\Omega \int_Y u_n(x, y)\psi_k(x, y)\, dx\, dy \right| \leqq \delta_n$$

for $1 \leqq k \leqq n$.

Defining the diagonal sequence $u_{\varepsilon(n)}(x) \equiv u_n(x, x/\varepsilon(n))$, and recalling that δ_n is a sequence of positive numbers that goes to zero, it is clear from the first line of (1.17) that the sequence $u_{\varepsilon(n)}$ is bounded in $L^2(\Omega)$. By density of the family $[\psi_k(x, y)]_{1 \leqq k \leqq \infty}$ in $L^2(\Omega \times Y)$, the second line implies that $u_{\varepsilon(n)}$ two-scale converges to u_0. □

So far we have only considered bounded sequences in $L^2(\Omega)$. The next proposition investigates some cases where we have additional bounds on sequences of derivatives.

PROPOSITION 1.14.

(i) *Let u_ε be a bounded sequence in $H^1(\Omega)$ that converges weakly to a limit u in $H^1(\Omega)$. Then, u_ε two-scale converges to $u(x)$, and there exists a function $u_1(x, y)$ in $L^2[\Omega; H^1_\#(Y)/\mathbb{R}]$ such that, up to a subsequence, ∇u_ε two-scale converges to $\nabla_x u(x) + \nabla_y u_1(x, y)$.*

(ii) *Let u_ε and $\varepsilon \nabla u_\varepsilon$ be two bounded sequences in $L^2(\Omega)$. Then, there exists a function $u_0(x, y)$ in $L^2[\Omega; H^1_\#(Y)]$ such that, up to a subsequence, u_ε and $\varepsilon \nabla u_\varepsilon$ two-scale converge to $u_0(x, y)$ and to $\nabla_y u_0(x, y)$, respectively.*

(iii) *Let u_ε be a divergence-free bounded sequence in $[L^2(\Omega)]^N$, which two-scale converges to $u_0(x, y)$ in $[L^2(\Omega \times Y)]^N$. Then, the two-scale limit satisfies* $\operatorname{div}_y u_0(x, y) = 0$ *and* $\int_Y \operatorname{div}_x u_0(x, y)\, dy = 0$.

Proof.

(i) Since u_ε (respectively, ∇u_ε) is bounded in $L^2(\Omega)$ (respectively, $[L^2(\Omega)]^N$), up to a subsequence, it two-scale converges to a limit $u_0(x, y) \in L^2(\Omega \times Y)$ (respectively, $\chi_0(x, y) \in [L^2(\Omega \times Y)]^N$). Thus for any $\psi(x, y) \in D[\Omega; C^\infty_\#(Y)]$ and any $\Psi(x, y) \in D[\Omega; C^\infty_\#(Y)]^N$, we have

$$(1.18) \quad \begin{aligned} &\lim_{\varepsilon \to 0} \int_\Omega u_\varepsilon(x) \psi\left(x, \frac{x}{\varepsilon}\right) dx = \int_\Omega \int_Y u_0(x, y) \psi(x, y)\, dx\, dy, \\ &\lim_{\varepsilon \to 0} \int_\Omega \nabla u_\varepsilon(x) \cdot \Psi\left(x, \frac{x}{\varepsilon}\right) dx = \int_\Omega \int_Y \chi_0(x, y) \cdot \Psi(x, y)\, dx\, dy. \end{aligned}$$

By integration by parts, we have

$$\varepsilon \int_\Omega \nabla u_\varepsilon(x) \cdot \Psi\left(x, \frac{x}{\varepsilon}\right) dx = -\int_\Omega u_\varepsilon(x) \left[\operatorname{div}_y \Psi\left(x, \frac{x}{\varepsilon}\right) + \varepsilon \operatorname{div}_x \Psi\left(x, \frac{x}{\varepsilon}\right)\right] dx.$$

Passing to the limit in both terms with the help of (1.18) leads to

$$0 = -\int_\Omega \int_Y u_0(x, y) \operatorname{div}_y \Psi(x, y)\, dx\, dy.$$

This implies that $u_0(x, y)$ does not depend on y. Since the average of u_0 is u, we deduce that for any subsequence the two-scale limit reduces to the weak L^2 limit u. Thus, the entire sequence u_ε two-scale converges to $u(x)$. Next, in (1.18) we choose a function Ψ such that $\operatorname{div}_y \Psi(x, y) = 0$. Integrating by parts we obtain

$$\begin{aligned} \lim_{\varepsilon \to 0} \int_\Omega u_\varepsilon(x) \operatorname{div}_x \Psi\left(x, \frac{x}{\varepsilon}\right) dx &= -\int_\Omega \int_Y \chi_0(x, y) \cdot \Psi(x, y)\, dx\, dy \\ &= \int_\Omega \int_Y u(x) \operatorname{div}_x \Psi(x, y)\, dx\, dy. \end{aligned}$$

Thus, for any function $\Psi(x, y) \in D[\Omega; C^\infty_\#(Y)]^N$ with $\operatorname{div}_y \Psi(x, y) = 0$, we have

$$\int_\Omega \int_Y [\chi_0(x, y) - \nabla u(x)] \cdot \Psi(x, y)\, dx\, dy = 0. \tag{1.19}$$

Recall that the orthogonal of divergence-free functions are exactly the gradients (see, if necessary, [43] or [47]). This well-known result can be very easily proved in the present context by means of Fourier analysis in Y. Thus, we deduce from (1.19) that there exists a unique function $u_1(x, y)$ in $L^2[\Omega; H^1_\#(Y)/\mathbb{R}]$ such that

$$\chi_0(x, y) = \nabla u(x) + \nabla_y u_1(x, y).$$

(ii) Since u_ε (respectively, $\varepsilon \nabla u_\varepsilon$) is bounded in $L^2(\Omega)$ (respectively, $[L^2(\Omega)]^N$), up to a subsequence, it two-scale converges to a limit $u_0(x, y) \in L^2(\Omega \times Y)$ (respectively, $\chi_0(x, y) \in [L^2(\Omega \times Y)]^N$). Thus for any $\psi(x, y) \in D[\Omega; C^\infty_\#(Y)]$ and any $\Psi(x, y) \in D[\Omega; C^\infty_\#(Y)]^N$, we have

$$\tag{1.20} \begin{aligned} &\lim_{\varepsilon \to 0} \int_\Omega u_\varepsilon(x) \psi\left(x, \frac{x}{\varepsilon}\right) dx = \int_\Omega \int_Y u_0(x, y) \psi(x, y)\, dx\, dy, \\ &\lim_{\varepsilon \to 0} \int_\Omega \varepsilon \nabla u_\varepsilon(x) \cdot \Psi\left(x, \frac{x}{\varepsilon}\right) dx = \int_\Omega \int_Y \chi_0(x, y) \cdot \Psi(x, y)\, dx\, dy. \end{aligned}$$

Integrating by parts in (1.20), we obtain

$$\begin{aligned} \lim_{\varepsilon \to 0} \int_\Omega u_\varepsilon(x) \left[\operatorname{div}_y \Psi\left(x, \frac{x}{\varepsilon}\right) + \varepsilon \operatorname{div}_x \Psi\left(x, \frac{x}{\varepsilon}\right)\right] dx &= -\int_\Omega \int_Y \chi_0(x, y) \cdot \Psi(x, y)\, dx\, dy \\ &= \int_\Omega \int_Y u_0(x, y) \operatorname{div}_y \Psi(x, y)\, dx\, dy. \end{aligned}$$

Disintegrating by parts leads to $\chi_0(x, y) = \nabla_y u_0(x, y)$.

The proof of part (iii) is similar to the previous ones, and is left to the reader. □

Two-scale convergence is not limited to bounded sequences in $L^2(\Omega)$. Our main result, Theorem 1.2, is easily generalized to bounded sequences in $L^p(\Omega)$, with $1 < p \leqq +\infty$. Remark that the case $p = +\infty$ is included, while $p = 1$ is excluded (this is similar to what happens for weak convergence).

COROLLARY 1.15. *Let u_ε be a bounded sequence in $L^p(\Omega)$, with $1 < p \leqq +\infty$. There exists a function $u_0(x, y)$ in $L^p(\Omega \times Y)$ such that, up to a subsequence, u_ε two-scale converges to u_0, i.e., for any function $\psi(x, y) \in D[\Omega; C^\infty_\#(Y)]$, we have*

$$\lim_{\varepsilon \to 0} \int_\Omega u_\varepsilon(x) \psi\left(x, \frac{x}{\varepsilon}\right) dx = \int_\Omega \int_Y u_0(x, y) \psi(x, y)\, dx\, dy.$$

(*The proof is exactly the same as that of Theorem* 1.2.)

Of course, two-scale convergence is also easily generalized to n-scale convergence, with n any finite integer greater than two. This is a very helpful tool for what is called reiterated homogenization (see [10, Chap. 1, § 8]).

COROLLARY 1.16. *Let u_ε be a bounded sequence in $L^2(\Omega)$. There exists a function $u_0(x, y_1, \cdots, y_{n-1})$ in $L^2(\Omega \times Y^{n-1})$ such that, up to a subsequence, u_ε n-scale converges to u_0, i.e., for any function $\psi(x, y_1, \cdots, y_{n-1}) \in D[\Omega; C^\infty_\#(Y^{n-1})]$, we have*

$$\begin{aligned} &\lim_{\varepsilon \to 0} \int_\Omega u_\varepsilon(x) \psi\left(x, \frac{x}{\varepsilon}, \cdots, \frac{x}{\varepsilon^{n-1}}\right) dx \\ &\quad = \int_\Omega \int_{Y^{n-1}} u_0(x, y_1, \cdots, y_{n-1}) \psi(x, y_1, \cdots, y_{n-1})\, dx\, dy_1 \cdots dy_{n-1}. \end{aligned}$$

Remark 1.17. In the present paper, the test functions $\psi(x, y)$ are always assumed to be Y-periodic in y. Other choices for the period are possible. For a same sequence u_ε different two-scale limits can arise according to the period chosen for the test functions $y \to \psi(x, y)$, but they are related by a straightforward change of variables.

2. Homogenization of linear second-order elliptic equations. In this section we show how two-scale convergence can be used for the homogenization of linear second-order elliptic equations with periodically oscillating coefficients. We first revisit this favorite model problem of homogenization (see, e.g., [10, Chap. 1, § 6] in a fixed domain Ω, and later on we consider the case of perforated domains Ω_ε (see [13]). Besides recovering previous well-known results from a new point of view, we establish a new form of the limit problem, that we call the two-scale homogenized problem, and which is simply a combination of the usual homogenized problem and the cell problem (see [10], [40] for an introduction to the topic).

Let Ω be a bounded open set of $\mathbb{R}^N$. Let f be a given function in $L^2(\Omega)$. We consider the following linear second-order elliptic equation

$$(2.1) \qquad \begin{aligned} -\operatorname{div}\left(A\left(x, \frac{x}{\varepsilon}\right)\nabla u_\varepsilon\right) &= f \quad \text{in } \Omega, \\ u_\varepsilon &= 0 \quad \text{on } \partial\Omega, \end{aligned}$$

where $A(x, y)$ is a matrix defined on $\Omega \times Y$, Y-periodic in y, such that there exists two positive constants $0 < \alpha \leqq \beta$ satisfying

$$(2.2) \qquad \alpha|\xi|^2 \leqq \sum_{i,j=1}^{N} A_{ij}(x, y)\xi_i\xi_j \leqq \beta|\xi|^2 \quad \text{for any } \xi \in \mathbb{R}^N.$$

Assumption (2.2) implies that the matrix $A(x, y)$ belongs to $[L^\infty(\Omega \times Y)]^{N^2}$, but it doesn't ensure that the function $x \to A(x, x/\varepsilon)$ is measurable, nor that it converges to its average $\int_Y A(x, y)\, dy$ in any suitable topology (see the counterexample of Proposition 5.8). Thus, we also require that $A_{ij}(x, y)$ is an "admissible" test function in the sense of Definition 1.4, namely, $A_{ij}(x, x/\varepsilon)$ is measurable and satisfies

$$(2.3) \qquad \lim_{\varepsilon \to 0} \int_\Omega A_{ij}\left(x, \frac{x}{\varepsilon}\right)^2 dx = \int_\Omega \int_Y A_{ij}(x, y)^2\, dx\, dy.$$

Assumption (2.3) is the weakest possible, but is rather vague. More precise, but also more restrictive, assumptions include, e.g., $A(x, y) \in L^\infty[\Omega; C_\#(Y)]^{N^2}$, $A(x, y) \in L^\infty_\#[Y; C(\bar{\Omega})]^{N^2}$, or $A(x, y) \in C[\Omega; L^\infty_\#(Y)]^{N^2}$ (the latter is the usual assumption in [10]). Under assumptions (2.2), (2.3), equation (2.1) admits a unique solution u_ε in $H^1_0(\Omega)$, which satisfies the a priori estimate

$$(2.4) \qquad \|u_\varepsilon\|_{H^1_0(\Omega)} \leqq C\|f\|_{L^2(\Omega)},$$

where C is a positive constant that depends only on Ω and α, and not on ε. Thus, there exists $u \in H^1_0(\Omega)$ such that, up to a subsequence, u_ε converges weakly to u in $H^1_0(\Omega)$. The homogenization of (2.1) amounts to find a "homogenized" equation that admits the limit u as its unique solution.

Let us briefly recall the usual process of homogenization. In a first step, two-scale asymptotic expansions are used in order to obtain formally the homogenized equation (see, e.g., [10], [40]). In a second step, the convergence of the sequence u_ε to the solution u of the homogenized equation is proved (usually by means of the so-called energy method of Tartar [42]).

The results of the first (heuristic) step are summarized in the following.

DEFINITION 2.1. The homogenized problem is defined as

$$(2.5)\qquad \begin{aligned} -\operatorname{div}[A^*(x)\nabla u(x)]&=f \quad \text{in } \Omega,\\ u&=0 \quad \text{on } \partial\Omega, \end{aligned}$$

where the entries of the matrix A^* are given by

$$(2.6)\qquad A^*_{ij}(x)=\int_Y A(x,y)[\nabla_y w_i(x,y)+e_i]\cdot[\nabla_y w_j(x,y)+e_j]\,dy$$

and, for $1\leqq i\leqq N$, w_i is the solution of the so-called cell problem

$$(2.7)\qquad \begin{aligned} -\operatorname{div}_y[A(x,y)[\nabla_y w_i(x,y)+e_i]]&=0 \quad \text{in } Y,\\ y\to w_i(x,y) &\quad Y\text{-periodic.} \end{aligned}$$

As a result of the second step, we have the following theorem [10, Chap. I, Thm. 6.1].

THEOREM 2.2. *The sequence u_ε of solutions of* (2.1) *converges weakly in $H_0^1(\Omega)$ to the unique solution u of* (2.5).

We are going to recover this last result with the help of two-scale convergence, but we also propose an alternative formulation of the limit problem by introducing the *two-scale homogenized problem*, which is a combination of the usual homogenized equation (2.5) and of the cell equation (2.7).

THEOREM 2.3. *The sequence u_ε of solutions of* (2.1) *converges weakly to $u(x)$ in $H_0^1(\Omega)$, and the sequence ∇u_ε two-scale converges to $\nabla u(x)+\nabla_y u_1(x,y)$, where (u,u_1) is the unique solution in $H_0^1(\Omega)\times L^2[\Omega;H^1_\#(Y)/\mathbb{R}]$ of the following two-scale homogenized system*:

$$(2.8)\qquad \begin{aligned} -\operatorname{div}_y[A(x,y)[\nabla u(x)+\nabla_y u_1(x,y)]]&=0 \quad \text{in } \Omega\times Y,\\ -\operatorname{div}_x\left[\int_Y A(x,y)[\nabla u(x)+\nabla_y u_1(x,y)]\,dy\right]&=f \quad \text{in } \Omega,\\ u(x)&=0 \quad \text{on } \partial\Omega,\\ y\to u_1(x,y) &\quad Y\text{-periodic.} \end{aligned}$$

Furthermore, (2.8) *is equivalent to the usual homogenized and cell equations* (2.5)–(2.7) *through the relation*

$$(2.9)\qquad u_1(x,y)=\sum_{i=1}^{N}\frac{\partial u}{\partial x_i}(x)w_i(x,y).$$

Remark 2.4. The two-scale homogenized problem (2.8) is a system of two equations, two unknowns (u and u_1), where the two space variables x and y (i.e., the macroscopic and microscopic scales) are mixed. Although (2.8) seems to be complicated, it is a well-posed system of equations (cf. its variationial formulation (2.11) below), which is easily shown to have a unique solution. Remark that, here, the two equations of (2.8) can be decoupled in (2.5)–(2.7) (homogenized and cell equations) which are also two well-posed problems. However, we emphasize that this situation is very peculiar to the simple second-order elliptic equation (2.1). For many other types of problems, this decoupling is not possible, or leads to very complicated forms of the homogenized equation, including integro-differential operators and nonexplicit equations. Thus, the homogenized equation does not always belong to a class for which an existence and uniqueness theory is easily available, as opposed to the two-scale homogenized system, which is, in most cases, of the same type as the original problem, but with twice the variables (x and y) and unknowns (u and u_1). The supplementary, microscopic, variable and unknown play the role of "hidden" variables in the vocabulary of mechanics (as remarked by Sanchez-Palencia [40]). Although their presence doubles the size of the limit problem, it greatly simplifies its structure (which could be useful for numerical purposes, too), while eliminating them introduces "strange" effects (like memory or nonlocal effects) in the usual homogenized problem. In short, both formulations ("usual" or two-scale) of the homogenized problem have their pros and cons, and none should be eliminated without second thoughts. Particularly striking examples of the above discussion may be found in § 4, in [2] (a convection-diffusion problem), or in [3] (unsteady Stokes flows in porous media).

Remark 2.5. As stated earlier, the two-scale homogenized problem (2.8) is equivalent to the homogenized system (2.5) and the cell problem (2.7), which are obtained by two-scale asymptotic expansions. This equivalence holds without any assumptions on the symmetry of the matrix A. Recall that, if A is not symmetric, the test functions used in the energy method are not the solutions of (2.7), but that of the dual cell problem (i.e., (2.7), where A is replaced by its transpose ${}^tA$).

Proof of Theorem 2.3. Thanks to the a priori estimate (2.4), there exists a limit u such that, up to a subsequence, u_ε converges weakly to u in $H_0^1(\Omega)$. As a consequence of Proposition 1.14, there exists $u_1(x, y) \in L^2[\Omega; H^1_\#(Y)/\mathbb{R}]$ such that, up to another subsequence, ∇u_ε two-scale converges to $\nabla_x u(x) + \nabla_y u_1(x, y)$. In view of these limits, u_ε is expected to behave as $u(x) + \varepsilon u_1(x, x/\varepsilon)$. This suggests multiplying (2.1) by a test function $\phi(x) + \varepsilon\phi_1(x, x/\varepsilon)$, with $\phi(x) \in D(\Omega)$ and $\phi_1(x, y) \in D[\Omega; C^\infty_\#(Y)]$. This yields

$$\begin{aligned} &\int_\Omega A\left(x, \frac{x}{\varepsilon}\right)\nabla u_\varepsilon\left[\nabla\phi(x) + \nabla_y\phi_1\left(x, \frac{x}{\varepsilon}\right) + \varepsilon\nabla_x\phi_1\left(x, \frac{x}{\varepsilon}\right)\right] dx \\ (2.10) \qquad &= \int_\Omega f(x)\left[\phi(x) + \varepsilon\phi_1\left(x, \frac{x}{\varepsilon}\right)\right] dx. \end{aligned}$$

If the matrix $A(x, y)$ is smooth, then the function ${}^tA(x, x/\varepsilon)[\nabla\phi(x) + \nabla_y\phi_1(x, x/\varepsilon)]$ can be considered as a test function in Theorem 1.2, and we pass to the two-scale limit in (2.10). Even if $A(x, y)$ is not smooth, at least, by assumption (2.3), the function ${}^tA(x, x/\varepsilon)[\nabla\phi(x) + \nabla_y\phi_1(x, x/\varepsilon)]$ two-scale converges *strongly* to its limit ${}^tA(x, y)$ $[\nabla\phi(x) + \nabla_y\phi_1(x, y)]$ (i.e., condition (1.11) is satisfied in Theorem 1.8). Thus, using Theorem 1.8, we can still pass to the two-scale limit in (2.10):

$$\begin{aligned} (2.11) \qquad &\int_\Omega\int_Y A(x, y)[\nabla u(x) + \nabla_y u_1(x, y)] \cdot [\nabla\phi(x) + \nabla_y\phi_1(x, y)]\, dx\, dy \\ &= \int_\Omega f(x)\phi(x)\, dx. \end{aligned}$$

By density, (2.11) holds true for any (ϕ, ϕ_1) in $H_0^1(\Omega) \times L^2[\Omega; H^1_\#(Y)/\mathbb{R}]$. An easy integration by parts shows that (2.11) is a variational formulation associated to (2.8). Endowing the Hilbert space $H_0^1(\Omega) \times L^2[\Omega; H^1_\#(Y)/\mathbb{R}]$ with the norm $\|\nabla u(x)\|_{L^2(\Omega)} +$ $\|\nabla_y u_1(x, y)\|_{L^2(\Omega\times Y)}$, we check the conditions of the Lax-Milgram lemma in (2.11). Let us focus on the coercivity in $H_0^1(\Omega) \times L^2[\Omega; H^1_\#(Y)/\mathbb{R}]$ of the bilinear form defined by the left-hand side of (2.11):

$$\begin{aligned} &\int_\Omega\int_Y A(x, y)[\nabla\phi(x) + \nabla_y\phi_1(x, y)] \cdot [\nabla\phi(x) + \nabla_y\phi_1(x, y)]\, dx\, dy \\ &\geqq \alpha \int_\Omega\int_Y |\nabla\phi(x) + \nabla_y\phi_1(x, y)|^2\, dx\, dy \\ &= \alpha\int_\Omega |\nabla\phi(x)|^2\, dx + \alpha\int_\Omega\int_Y |\nabla_y\phi_1(x, y)|^2\, dx\, dy. \end{aligned}$$

Thus, by application of the Lax-Milgram lemma, there exists a unique solution of the two-scale homogenized problem (2.8). Consequently, the entire sequences u_ε and ∇u_ε converge to $u(x)$ and $\nabla u(x)+\nabla_y u_1(x,y)$. At this point, we could content ourselves with (2.8) as a homogenized problem, since its variational formulation (2.11) appears very naturally by application of two-scale convergence. However, it is usually preferable, from a physical or numerical point of view, to eliminate the microscopic variable y (one doesn't want to solve the small scale structure). This is an easy algebra exercise (left to the reader) to average (2.8) with respect to y, and to obtain the equivalent system (2.5)-(2.7), along with formula (2.6) for the homogenized matrix A^*. □

Corrector results are easily obtained with the two-scale convergence method. The next theorem rigorously justifies the two first terms in the usual asymptotic expansion of the solution u_ε (see [10]).

THEOREM 2.6. *Assume that $\nabla_y u_1(x,y)$ is an "admissible" test function in the sense of Definition* 1.4. *Then, the sequence $[\nabla u_\varepsilon(x)-\nabla u(x)-\nabla_y u_1(x, x/\varepsilon)]$ converges strongly to zero in $[L^2(\Omega)]^N$. In particular, if $u_1, \nabla_x u_1$, and $\nabla_y u_1$ are "admissible," then we have*

$$\left[u_\varepsilon(x)-u(x)-\varepsilon u_1\left(x,\frac{x}{\varepsilon}\right)\right]\to 0 \quad \textit{in } H^1(\Omega) \textit{ strongly.}$$

Proof. Let us first remark that the assumption on u_1, being an "admissible" test function, is satisfied as soon as the matrix A is smooth, say $A(x,y)\in C[\Omega; L^\infty_\#(Y)]^{N^2}$, by standard regularity results for the solutions $w_i(x,y)$ of the cell problem (2.7).

Now, using this assumption, we can write

$$\begin{aligned}
&\int_\Omega A\left(x,\frac{x}{\varepsilon}\right)\left[\nabla u_\varepsilon(x)-\nabla u(x)-\nabla_y u_1\left(x,\frac{x}{\varepsilon}\right)\right]^2 dx\\
&=\int_\Omega f(x)u_\varepsilon(x)\,dx+\int_\Omega A\left(x,\frac{x}{\varepsilon}\right)\left[\nabla u(x)+\nabla_y u_1\left(x,\frac{x}{\varepsilon}\right)\right]^2 dx \qquad (2.12)\\
&\quad-\int_\Omega (A+{}^tA)\left(x,\frac{x}{\varepsilon}\right)\nabla u_\varepsilon(x)\cdot\left[\nabla u(x)+\nabla_y u_1\left(x,\frac{x}{\varepsilon}\right)\right]dx.
\end{aligned}$$

Using the coercivity condition (2.2) and passing to the two-scale limit in the right-hand side of (2.12) yields

$$\begin{aligned}
&\alpha\lim_{\varepsilon\to 0}\left\|\nabla u_\varepsilon(x)-\nabla u(x)-\nabla_y u_1\left(x,\frac{x}{\varepsilon}\right)\right\|^2_{L^2(\Omega)} \qquad (2.13)\\
&\leqq\int_\Omega f(x)u(x)\,dx-\int_\Omega\int_Y A(x,y)[\nabla u(x)+\nabla_y u_1(x,y)]^2\,dx\,dy.
\end{aligned}$$

In view of (2.8), the right-hand side of (2.13) is equal to zero, which is the desired result. □

Two-scale convergence can also handle homogenization problems in perforated domains, without requiring any extension lemmas or similar technical ingredients. Let us define a sequence Ω_ε of periodically perforated subdomains of a bounded open set Ω in $\mathbb{R}^N$. The period of Ω_ε is εY^*, where Y^* is a subset of the unit cube $Y=(0;1)^N$, which is called the solid or material part (by opposition to the hole, or void part, $Y-Y^*$). We assume that the material domain E^*, obtained by Y-periodicity from Y^*, is a smooth connected open set in $\mathbb{R}^N$ (remark that no assumptions are made on the void domain $\mathbb{R}^N - E^*$; thus, the holes $Y - Y^*$ may be connected or isolated). Denoting by $\chi(y)$ the characteristic function of E^* (a Y-periodic function), Ω_ε is defined as

$$\Omega_\varepsilon = \left\{ x \in \Omega \Big/ \chi\left(\frac{x}{\varepsilon}\right) = 1 \right\}. \tag{2.14}$$

We consider a linear second-order elliptic equation in Ω_ε,

$$\begin{aligned} -\operatorname{div}\left(A\left(x, \frac{x}{\varepsilon}\right)\nabla u_\varepsilon\right) + u_\varepsilon = f \quad & \text{in } \Omega_\varepsilon, \\ \frac{\partial u_\varepsilon}{\partial v_{A_\varepsilon}} = \left[A\left(x, \frac{x}{\varepsilon}\right)\nabla u_\varepsilon\right] \cdot n = 0 \quad & \text{on } \partial\Omega_\varepsilon - \partial\Omega, \\ u_\varepsilon = 0 \quad & \text{on } \partial\Omega \cap \partial\Omega_\varepsilon, \end{aligned} \tag{2.15}$$

where the matrix A satisfies the same assumptions (2.2), (2.3) as before. From (2.15), we easily deduce the a priori estimates

$$\|u_\varepsilon\|_{L^2(\Omega_\varepsilon)} \leqq C \quad \text{and} \quad \|\nabla u_\varepsilon\|_{L^2(\Omega_\varepsilon)} \leqq C, \tag{2.16}$$

where C is a constant which does not depend on ε. The main difficulty in homogenization in perforated domains is to establish that the sequence u_ε admits a limit u in $H^1(\Omega)$. From (2.16) we cannot extract a convergent subsequence by weak compactness in a given Sobolev space, since each u_ε is defined in a different space $H^1(\Omega_\varepsilon)$, which varies with ε.

Nevertheless, this problem has first been solved by Cioranescu and Saint Jean Paulin [13] in the case of domains perforated with isolated holes (i.e., $Y - Y^*$ is strictly included in Y), while the general case is treated in [1] and [4]. The main result of these three papers is the following theorem.

THEOREM 2.7. *The sequence u_ε of solutions of* (2.15) *"converges" to a limit u, which is the unique solution in $H_0^1(\Omega)$ of the homogenized problem*

$$\begin{aligned} -\operatorname{div}[A^*\nabla u] + \theta u = \theta f \quad & \textit{in } \Omega, \\ u = 0 \quad & \textit{on } \partial\Omega, \end{aligned} \tag{2.17}$$

where θ is the volume fraction of material (i.e., $\theta = \int_Y \chi(y)\,dy = |Y^*|$), and the entries of the matrix A^* are given by

$$A_{ij}^*(x) = \int_{Y^*} A(x, y)[\nabla_y w_i(x, y) + e_i] \cdot [\nabla_y w_j(x, y) + e_j]\,dy, \tag{2.18}$$

and, for $1 \leqq i \leqq N$, w_i is the solution of the cell problem

$$\begin{aligned} -\operatorname{div}_y (A(x, y)[\nabla_y w_i(x, y) + e_i]) = 0 \quad & \textit{in } Y^*, \\ A(x, y)[\nabla_y w_i(x, y) + e_i] \cdot n = 0 \quad & \textit{on } \partial Y^* - \partial Y, \\ y \to w_i(x, y) \quad & Y\textit{-periodic}. \end{aligned} \tag{2.19}$$

Remark 2.8. The convergence of the sequence u_ε is intentionally very "vague" in Theorem 2.7. In view of the a priori estimates (2.16), there is no clear notion of convergence for u_ε, which is defined on a varying set Ω_ε. In the literature this difficulty has been overcome in two different ways. In [13] and [1], an extension of u_ε to the whole domain Ω is constructed, and this extension is proved to converge weakly in $H^1(\Omega)$ to the homogenized limit u. In [4], no sophisticated extensions are used, but a version of the Rellich theorem in perforated domains is established (loosely speaking, the embedding of $H^1(\Omega_\varepsilon)$ in $L^2(\Omega_\varepsilon)$ is compact, uniformly in ε), which allows us to prove that u_ε converges to u in the sense that $\|u_\varepsilon - u\|_{L^2(\Omega)_\varepsilon}$ goes to zero. All these references use classical methods of homogenization (the energy method of Tartar in [13] and [4], and the Γ-convergence of De Giorgi in [1]).

In the next theorem we recover the results of Theorem 2.7, using two-scale convergence. As in [4], we do not use any sophisticated extensions (apart from the trivial extension by zero in the holes $\Omega - \Omega_\varepsilon$), and we give a new interpretation of the "vague" convergence mentioned above.

THEOREM 2.9. *Denote by* $\tilde{}$ *the extension by zero in the domain* $\Omega - \Omega_\varepsilon$. *The sequences* $\tilde{u}_\varepsilon$ *and* $\tilde{\nabla u_\varepsilon}$ *two-scale converge to* $u(x)\chi(y)$ *and* $\chi(y)[\nabla u(x) + \nabla_y u_1(x, y)]$, *respectively, where* (u, u_1) *is the unique solution in* $H_0^1(\Omega) \times L^2[\Omega; H^1_\#(Y^*)/\mathbb{R}]$ *of the following two-scale homogenized system*;

$$\begin{aligned} -\operatorname{div}_y (A(x, y)[\nabla u(x) + \nabla_y u_1(x, y)]) = 0 \quad &\text{in } \Omega \times Y^*, \\ -\operatorname{div}_x \left[\int_{Y^*} A(x, y)[\nabla u(x) + \nabla_y u_1(x, y)]\, dy\right] + \theta u(x) = \theta f(x) \quad &\text{in } \Omega, \\ u(x) = 0 \quad &\text{on } \partial\Omega, \\ y \to u_1(x, y) \quad &Y\text{-periodic} \\ (A(x, y)[\nabla u(x) + \nabla_y u_1(x, y)]) \cdot n = 0 \quad &\text{on } \partial Y^* - \partial Y. \end{aligned} \tag{2.20}$$

Furthermore, (2.20) *is equivalent to the usual homogenized and cell equations* (2.17)-(2.19) *through the relation*

$$u_1(x, y) = \sum_{i=1}^N \frac{\partial u}{\partial x_i}(x) w_i(x, y). \tag{2.21}$$

Proof. In view of (2.16), the two sequences $\tilde{u}_\varepsilon$ and $\tilde{\nabla u_\varepsilon}$ are bounded in $L^2(\Omega)$, and by application of Theorem 1.2 they two-scale converge, up to a subsequence, to $u_0(x, y)$ and $\xi_0(x, y)$, respectively. Since, by definition, $\tilde{u}_\varepsilon$ and $\tilde{\nabla u_\varepsilon}$ are equal to zero in Ω-Ω_ε, their two-scale limit $u_0(x, y)$ and $\xi_0(x, y)$ are also equal to zero if $y \in Y - Y^*$. In order to find the precise form of u_0 and ξ_0 in $\Omega \times Y^*$, we argue as in Proposition 1.14(i). Let $\psi(x, y) \in D[\Omega; C^\infty_\#(Y)]$ and $\Psi(x, y) \in D[\Omega; C^\infty_\#(Y)]^N$ be two functions, equal to zero if $y \in Y - Y^*$ (hence, they belong to $D(\Omega_\varepsilon)$ and $[D(\Omega_\varepsilon)]^N$). We have

$$\begin{aligned} \lim_{\varepsilon \to 0} \int_{\Omega_\varepsilon} u_\varepsilon(x) \psi\left(x, \frac{x}{\varepsilon}\right) dx &= \int_\Omega \int_{Y^*} u_0(x, y) \psi(x, y)\, dx\, dy, \\ \lim_{\varepsilon \to 0} \int_{\Omega_\varepsilon} \nabla u_\varepsilon(x) \cdot \Psi\left(x, \frac{x}{\varepsilon}\right) dx &= \int_\Omega \int_{Y^*} \xi_0(x, y) \cdot \Psi(x, y)\, dx\, dy. \end{aligned} \tag{2.22}$$

By integration by parts, we obtain

$$\varepsilon \int_{\Omega_\varepsilon} \nabla u_\varepsilon(x) \cdot \Psi\left(x, \frac{x}{\varepsilon}\right) dx = -\int_{\Omega_\varepsilon} u_\varepsilon(x) \left[\operatorname{div}_y \Psi\left(x, \frac{x}{\varepsilon}\right) + \varepsilon \operatorname{div}_x \Psi\left(x, \frac{x}{\varepsilon}\right)\right] dx.$$

Passing to the limit in both terms with the help of (2.22) leads to

$$0 = -\int_\Omega \int_{Y^*} u_0(x, y) \operatorname{div}_y \Psi(x, y)\, dx\, dy.$$

This implies that $u_0(x, y)$ does not depend on y in Y^*, i.e., there exists $u(x) \in L^2(\Omega)$ such that

$$u_0(x, y) = u(x)\chi(y).$$

Now, we add to the previous assumptions on $\Psi(x, y)$ the condition $\operatorname{div}_y \Psi(x, y) = 0$. Integrating by parts in Ω_ε gives

$$\int_{\Omega_\varepsilon} \nabla u_\varepsilon(x) \cdot \Psi\left(x, \frac{x}{\varepsilon}\right) dx = -\int_{\Omega_\varepsilon} u_\varepsilon(x) \operatorname{div}_x \Psi\left(x, \frac{x}{\varepsilon}\right) dx. \tag{2.23}$$

Passing to the two-scale limit yields

$$\int_\Omega \int_{Y^*} \xi_0(x, y) \cdot \Psi(x, y)\, dx\, dy = -\int_\Omega \int_{Y^*} u(x) \operatorname{div}_x \Psi(x, y)\, dx\, dy. \tag{2.24}$$

By using Lemma 2.10 below, the right-hand side of (2.24) becomes $\int_\Omega u(x) \operatorname{div}_x \theta(x)\, dx$, while the left-hand side is a linear continuous form in $\theta(x) \in [L^2(\Omega)]^N$. This implies that $u(x) \in H_0^1(\Omega)$. Then, integrating by parts in (2.24) shows that, for any function $\Psi(x, y) \in L^2[\Omega; L^2_\#(Y^*)]^N$ with $\operatorname{div}_y \Psi(x, y) = 0$ and $\Psi(x, y) \cdot n_y = 0$ on $\partial Y^* - \partial Y$, we have

$$\int_\Omega \int_{Y^*} [\xi_0(x, y) - \nabla u(x)] \cdot \Psi(x, y)\, dx\, dy = 0. \tag{2.25}$$

Since the orthogonal of divergence-free functions is exactly the gradients, we deduce from (2.25) that there exists a function $u_1(x, y)$ in $L^2[\Omega; H^1_\#(Y^*)/\mathbb{R}]$ such that $\xi_0(x, y) = \chi(y)[\nabla u(x) + \nabla_y u_1(x, y)]$.

We are now in the position of finding the homogenized equations satisfied by u and u_1. Let us multiply the original equation (2.15) by the test function $\phi(x) + \varepsilon\phi_1(x, x/\varepsilon)$, where $\phi \in D(\Omega)$ and $\phi_1 \in D[\Omega; C^\infty_\#(Y)]$. Integrating by parts and passing to the two-scale limit yields

$$\begin{aligned}\int_\Omega \int_{Y^*} A(x, y)[\nabla u(x) + \nabla_y u_1(x, y)] \cdot [\nabla\phi(x) + \nabla_y \phi_1(x, y)]\, dx\, dy + \theta \int_\Omega u\phi\, dx \\ = \theta \int_\Omega f\phi\, dx.\end{aligned} \tag{2.26}$$

By density, (2.26) holds true for any (ϕ, ϕ_1) in $H_0^1(\Omega) \times L^2[\Omega; H^1_\#(Y^*)/\mathbb{R}]$. An easy integration by parts shows that (2.26) is a variational formulation associated to (2.20). It remains to prove existence and uniqueness in (2.26), and, as in Theorem 2.3, the main point is to show the coercivity of the left-hand side of (2.26). Indeed, it is an easy exercise (left to the reader) to check that $\|\nabla u(x) + \nabla_y u_1(x, y)\|_{L^2(\Omega \times Y^*)}$ is a norm for the Hilbert space $H_0^1(\Omega) \times L^2[\Omega; H^1_\#(Y^*)/\mathbb{R}]$. Remark, however, that this result relies heavily on the assumption on Y^* (namely, the Y-periodic set E^*, with period Y^*, is connected), and even fails if Y^* is strictly included in the unit cell Y. Remark also that here, to the contrary of the situation in Theorem 2.3, the above norm is not equal to $\|\nabla u(x)\|_{L^2(\Omega)} + \|\nabla_y u_1(x, y)\|_{L^2(\Omega \times Y^*)}$. □

LEMMA 2.10. *For any function $\theta(x) \in [L^2(\Omega)]^N$ there exists $\Psi(x, y) \in L^2[\Omega; H^1_\#(Y^*)]^N$ such that*

$$\begin{aligned} &\operatorname{div}_y \Psi(x, y) = 0 \quad \textit{in } Y^*, \\ &\Psi(x, y) = 0 \quad \textit{on } \partial Y^* - \partial Y, \\ &\int_{Y^*} \Psi(x, y)\, dy = \theta(x), \\ &\|\Psi(x, y)\|_{L^2(\Omega;\, H^1_\#(Y^*))^N} \leqq C \|\theta(x)\|_{L^2(\Omega)^N}. \end{aligned} \tag{2.27}$$

Proof. For $1 \leqq i \leqq N$, consider the following Stokes problem:

$$\begin{aligned} \nabla p_i - \Delta v_i = e_i &\quad \text{in } Y^*, \\ \operatorname{div} v_i = 0 &\quad \text{in } Y^*, \\ v_i = 0 &\quad \text{on } \partial Y^* - \partial Y, \\ p_i, v_i &\quad Y\text{-periodic}, \end{aligned}$$

which admits a unique, nonzero solution (p_i, v_i) in $[L^2_\#(Y^*)/\mathbb{R}] \times [H^1_\#(Y^*)]^N$ since we have assumed that E^* (the Y-periodic set obtained from Y^*) is smooth and connected. Denote by A the constant, symmetric, positive definite matrix $(\int_{Y^*} \nabla v_i \cdot \nabla v_j)_{1 \leqq i,j \leqq N}$. Then, for any $\theta(x) \in [L^2(\Omega)]^N$, the function Ψ defined by

$$\Psi(x, y) = \sum_{i=1}^{N} \langle A^{-1}\theta(x), e_i \rangle v_i(y)$$

is easily seen to satisfy all the properties (2.27) since $\int_{Y^*} \nabla v_i \cdot \nabla v_j = \int_{Y^*} v_i \cdot e_j$. □

3. Homogenization of nonlinear operators. In this section we show how two-scale convergence can handle nonlinear homogenization problems. Again, we revisit two well-known model problems in nonlinear homogenization: first, the Γ-convergence of oscillating convex integral functionals, and second, the H-convergence (also known as G-convergence) of oscillating monotone operators. We begin this section by recovering some previous results of De Giorgi, and Marcellini [31], concerning Γ-convergence of convex functionals. Then we recover other results of Tartar [42], about H-convergence of monotone operators, and finally we conclude by giving a few references where generalizations of the two-scale convergence method are applied to the homogenization of nonlinear hyperbolic conservation laws, and nonlinear equations admitting viscosity solutions (see Remark 3.8).

Let Ω be a bounded open set in $\mathbb{R}^N$ and $f(x)$ a given function on Ω. We consider a family of functionals

$$I_\varepsilon(v) = \int_\Omega \left[W\left(\frac{x}{\varepsilon}, \nabla v(x)\right) - f(x)v(x) \right] dx, \tag{3.1}$$

where $v(x)$ is a vector-valued function from Ω into $\mathbb{R}^n$, and the scalar energy $W(y, \lambda)$ satisfies, for some $p > 1$,

$$\begin{aligned} &\text{(i)} && \text{for any } \lambda, \text{ the function } y \to W(y, \lambda) \text{ is measurable and } Y\text{-periodic}, \\ &\text{(ii)} && \text{a.e. in } y, \text{ the function } \lambda \to W(y, \lambda) \text{ is strictly convex and } C^1 \text{ in } \mathbb{R}^{nN}, \\ &\text{(iii)} && 0 \leqq c|\lambda|^p \leqq W(y, \lambda) \leqq C[1 + \lambda|^p] \text{ a.e. in } y, \text{ with } 0 < c < C, \\ &\text{(iv)} && \left| \frac{\partial W}{\partial \lambda}(y, \lambda) \right| \leqq C[1 + |\lambda|^{p-1}] \text{ a.e. in } y. \end{aligned} \tag{3.2}$$

(Actually, assumption (iv) is easily seen to be a consequence of (ii) and (iii), as remarked by Francfort [24].) We also assume that $f(x) \in [L^{p'}(\Omega)]^n$ with $(1/p) + (1/p') = 1$. Since $W(y, \lambda)$ is convex in λ, for fixed ε, there exists a unique $u_\varepsilon(x) \in [W_0^{1,p}(\Omega)]^n$ that achieved the minimum of the functional $I_\varepsilon(v)$ on $[W_0^{1,p}(\Omega)]^n$, i.e.,

$$I_\varepsilon(u_\varepsilon) = \operatorname*{Inf}_{v \in [W_0^{1,p}(\Omega)]^n} \int_\Omega \left[W\left(\frac{x}{\varepsilon}, \nabla v(x)\right) - f(x)v(x) \right] dx. \tag{3.3}$$

The homogenization of the functionals $I_\varepsilon(v)$ amounts to finding an "homogenized" functional $\bar{I}(v)$ such that the sequence of minimizers u_ε converges to a limit u, which is precisely the minimizer of $\bar{I}(v)$. This problem has been solved by Marcellini [31]. His result is the following.

THEOREM 3.1. *There exist a functional $\bar{I}$ and a function u such that*

$$\begin{aligned} &u_\varepsilon \rightharpoonup u \quad \textit{weakly in } [W_0^{1,p}(\Omega)]^n,\\ (3.4)\qquad &I_\varepsilon(u_\varepsilon) \to \bar{I}(u),\\ &\bar{I}(u) = \operatorname*{Inf}_{v\in[W_0^{1,p}(\Omega)]^n} \bar{I}(v). \end{aligned}$$

Furthermore, $\bar{I}$ is given by

$$\bar{I}(v) = \int_\Omega [\bar{W}(\nabla v(x)) - f(x)v(x)]\,dx, \tag{3.5}$$

where the energy $\bar{W}$ is defined by

$$\bar{W}(\lambda) = \operatorname*{Inf}_{w\in[W_\#^{1,p}(Y)]^n} \int_Y W(y, \lambda + \nabla w(y))\,dy. \tag{3.6}$$

Remark 3.2. By definition, $\bar{I}$ is the homogenized functional, and the sequence I_ε is said to Γ-converge to $\bar{I}$. (For more details about the Γ-convergence of De Giorgi, see [16], [17].) In addition, it is easy to see that the energy $\bar{W}$ is also convex and C^1, and satisfies the same growth conditions as W. We emphasize that Theorem 3.1 is restricted to convex energies; the situation is completely different in the nonconvex case (see [12], [33]).

We are going to recover Theorem 3.1 using two-scale convergence, and without any tools form the theory of Γ-convergence.

THEOREM 3.3. *There exists a function $u(x)$ such that the sequence u_ε of solutions of* (3.3) *converges weakly to u in $[W_0^{1,p}(\Omega)]^n$. There also exists a function $u_1(x, y) \in L^p[\Omega; W_\#^{1,p}(Y)]^n$ such that the sequence ∇u_ε two-scale converges to $\nabla_x u(x) + \nabla_y u_1(x, y)$. Furthermore, the homogenized energy is also characterized as*

$$\bar{I}(u) = I(u, u_1) = \operatorname*{Inf}_{\substack{v\in[W_0^{1,p}(\Omega)]^n\\ v_1\in L^p[\Omega;\, W_\#^{1,p}(Y)/\mathbb{R}]^n}} I(v, v_1), \tag{3.7}$$

where $I(v, v_1)$ is the two-scale homogenized functional defined by

$$I(v, v_1) = \int_\Omega \int_Y [W[y, \nabla v(x) + \nabla_y v_1(x, y)] - f(x)v(x)]\,dx\,dy. \tag{3.8}$$

Remark 3.4. Theorem 3.3 furnishes a new characterization of the homogenized problem, which turns out to be a double minimization over two different spaces of functions of two variables x and y. In the quadratic case, this characterization was also proposed by Lions (see his "averaging principle" in the calculus of variations [30, § 5, Chap. 1]). Theorem 3.1 is easily deduced from Theorem 3.3 by averaging the two-scale homogenized functional $I(v, v_1)$ with respect to y to recover the usual homogenized functional $\bar{I}(v)$. The difference between $\bar{I}(v)$ and $I(v, v_1)$ corresponds exactly to the difference in the linear case between the usual and two-scale homogenized problems (see Remark 2.4).

Proof of Theorem 3.3. In view of the growth condition (3.2)(iii) for the energy W, the sequence of minimizers u_ε is bounded in $[W_0^{1,p}(\Omega)]^n$. Thus, there exists a function u such that, up to a subsequence, u_ε converges weakly to u in $[W_0^{1,p}(\Omega)]^n$.

Applying Proposition 1.14 and Corollary 1.15, there also exists a function $u_1(x,y)\in L^p[\Omega;\ W^{1,p}_{\#}(Y)/\mathbb{R}]^n$ such that, up to another subsequence, ∇u_ε two-scale converges to $\nabla_x u(x)+\nabla_y u_1(x,y)$.

In a first step we give a lower bound for $I_\varepsilon(u_\varepsilon)$. Since $W(\cdot,\lambda)$ is convex and differentiable, we have

$$W(\cdot,\lambda)\geqq W(\cdot,\mu)+\left\langle\frac{\partial W}{\partial\lambda}(\cdot,\mu),\lambda-\mu\right\rangle. \tag{3.9}$$

By specifying (3.9), we obtain

$$W\left[\frac{x}{\varepsilon},\nabla u_\varepsilon(x)\right]\geqq W\left[\frac{x}{\varepsilon},\mu\left(x,\frac{x}{\varepsilon}\right)\right]+\left\langle\frac{\partial W}{\partial\lambda}\left[\frac{x}{\varepsilon},\mu\left(x,\frac{x}{\varepsilon}\right)\right],\nabla u_\varepsilon(x)-\mu\left(x,\frac{x}{\varepsilon}\right)\right\rangle. \tag{3.10}$$

For a smooth function $\mu(x,y)\in D[\Omega;\ C^\infty_{\#}(Y)]^n$, we can integrate (3.10) on Ω, and then pass to the two-scale limit in the right-hand side. This leads to

$$\begin{aligned}\lim_{\varepsilon\to0} I_\varepsilon[u_\varepsilon(x)]\geqq&\int_\Omega\int_Y\Big(W[y,\mu(x,y)]-f(x)u(x)\Big)\,dx\,dy\\ &+\int_\Omega\int_Y\left\langle\frac{\partial W}{\partial\lambda}[y,\mu(x,y)],\nabla_x u(x)+\nabla_y u_1(x,y)-\mu(x,y)\right\rangle dx\,dy.\end{aligned} \tag{3.11}$$

Now, we apply (3.11) to a sequence of smooth functions $\mu(x,y)$, Y-periodic in y, which converges to $\nabla_x u(x)+\nabla_y u_1(x,y)$ strongly in $[L^p(\Omega\times Y)]^{nN}$. In view of the growth conditions (3.2)(iii) and (iv) on W and $\partial W/\partial\lambda$, we can pass to the limit in (3.11) and obtain

$$\begin{aligned}\lim_{\varepsilon\to0} I_\varepsilon[u_\varepsilon(x)]&\geqq\int_\Omega\int_Y[W[y,\nabla_x u(x)+\nabla_y u_1(x,y)]-f(x)u(x)]\,dx\,dy\\ &=I(u,u_1).\end{aligned} \tag{3.12}$$

Now, in a second step we establish an upper bound for $I_\varepsilon(u_\varepsilon)$. For $\phi(x)\in[D(\Omega)]^n$ and $\phi_1(x,y)\in D[\Omega;\ C^\infty_{\#}(Y)]^n$, since u_ε is the minimizer, we have

$$I_\varepsilon[u_\varepsilon(x)]\leqq I_\varepsilon\left[\phi(x)+\varepsilon\phi_1\left(x,\frac{x}{\varepsilon}\right)\right]. \tag{3.13}$$

Passing to the two-scale limit in the right-hand side of (3.13) yields

$$\begin{aligned}\lim_{\varepsilon\to0} I_\varepsilon[u_\varepsilon(x)]&\leqq\int_\Omega\int_Y[W[y,\nabla_x\phi(x)+\nabla_y\phi_1(x,y)]-f(x)\phi(x)]\,dx\,dy\\ &=I(\phi,\phi_1).\end{aligned} \tag{3.14}$$

The functional $I(\phi,\phi_1)$ is called the two-scale homogenized functional. By density, we deduce from (3.14) that

$$\lim_{\varepsilon\to0} I_\varepsilon[u_\varepsilon(x)]\leqq \operatorname*{Inf}_{\substack{v\in[W^{1,p}_0(\Omega)]^n\\ v_1\in L^p[\Omega;\,W^{1,p}_{\#}(Y)/\mathbb{R}]^n}} I(v,v_1). \tag{3.15}$$

Combining (3.12) and (3.15) yields

$$\lim_{\varepsilon\to0} I_\varepsilon[u_\varepsilon(x)]=I(u,u_1)=\operatorname*{Inf}_{\substack{v\in[W^{1,p}_0(\Omega)]^n\\ v_1\in L^p[\Omega;\,W^{1,p}_{\#}(Y)/\mathbb{R}]^n}} I(v,v_1). \tag{3.16}$$

Since $W(\cdot, \lambda)$ is a strictly convex energy, there exists a unique minimizer (u, u_1) of (3.16). Thus, the entire sequence u_ε converges weakly to u in $[W_0^{1,p}(\Omega)]^n$, and the entire sequence ∇u_ε two-scale converges to $\nabla_x u(x) + \nabla_y u_1(x, y)$. □

So far, we have considered minimization problems. Instead, we could have solved the corresponding nonlinear Euler equations, satisfied by the minimizers. More generally, we could consider nonlinear second-order elliptic equations, which may not correspond to any energy minimization. Indeed, we are going to generalize Theorem 3.3 to the case of monotone operators, thus recovering previous results of Tartar [42].

Define an operator $a(y, \lambda)$ from $Y \times \mathbb{R}^{nN}$ in $\mathbb{R}^{nN}$ as follows:

$$\text{(3.17)}\quad \begin{array}{ll} \text{(i)} & \text{for any } \lambda, \text{ the function } y \to a(y, \lambda) \text{ is measurable and } Y\text{-periodic,} \\ \text{(ii)} & \text{a.e. in } y, \text{ the function } \lambda \to a(y, \lambda) \text{ is continuous,} \\ \text{(iii)} & 0 \leqq c|\lambda|^p \leqq a(y, \lambda) \cdot \lambda, \text{ for } 0 < c, \text{ and } p > 1, \\ \text{(iv)} & |a(y, \lambda)| \leqq C[1 + |\lambda|^{p-1}], \text{ for } 0 < C. \end{array}$$

Furthermore, the operator a is strictly monotone, i.e.,

$$\text{(3.18)}\qquad [a(y, \lambda) - a(y, \mu)] \cdot (\lambda - \mu) > 0 \quad \text{for any } \lambda \neq \mu.$$

For $f(x) \in [L^{p'}(\Omega)]^n$ (with $(1/p) + (1/p') = 1$), we consider the equation

$$\text{(3.19)}\qquad \begin{aligned} -\operatorname{div} a\left(\frac{x}{\varepsilon}, \nabla u_\varepsilon\right) &= f \quad \text{in } \Omega, \\ u_\varepsilon &= 0 \quad \text{on } \partial\Omega, \end{aligned}$$

which admits a unique solution u_ε in $[W_0^{1,p}(\Omega)]^n$.

THEOREM 3.5. *The sequence u_ε of solutions of* (3.19) *converges weakly to a function $u(x)$ in $[W_0^{1,p}(\Omega)]^n$, and the sequence ∇u_ε two-scale converges to $\nabla_x u(x) + \nabla_y u_1(x, y)$, where (u, u_1) is the unique solution in $[W_0^{1,p}(\Omega)]^n \times L^p[\Omega; W_\#^{1,p}(Y)/\mathbb{R}]^n$ of the homogenized problem*

$$\text{(3.20)}\qquad \begin{aligned} -\operatorname{div}_x \left[\int_Y a[y, \nabla u(x) + \nabla_y u_1(x, y)]\, dy\right] &= f \quad \textit{in } \Omega \\ -\operatorname{div}_y a[y, \nabla u(x) + \nabla_y u_1(x, y)] &= 0 \quad \textit{in } Y \\ u &= 0 \quad \textit{on } \partial\Omega \\ y \to u_1(x, y) &\quad Y\text{-periodic.} \end{aligned}$$

Proof. From the growth conditions (3.17), we easily obtain a priori estimates on u_ε, which is bounded in $[W_0^{1,p}(\Omega)]^n$, and $g_\varepsilon = a(x/\varepsilon, \nabla u_\varepsilon)$, which is bounded in $[L^{p'}(\Omega)]^{nN}$. Thus, up to a subsequence, u_ε converges weakly to a limit u in $[W_0^{1,p}(\Omega)]^n$, while ∇u_ε and g_ε two-scale converge to $\nabla u(x) + \nabla_y u_1(x, y)$ and $g_0(x, y)$, respectively. Since $f + \operatorname{div} g_\varepsilon = 0$, arguing as in Proposition 1.14, it is not difficult to check that the two-scale limit g_0 satisfies

$$\text{(3.21)}\qquad \begin{aligned} \operatorname{div}_y g_0(x, y) &= 0 \\ f(x) + \operatorname{div}_x \left[\int_Y g_0(x, y)\, dy\right] &= 0. \end{aligned}$$

The problem is to identify g_0 in terms of a, u, and u_1. To this end, for any positive number t, and any functions ϕ, $\phi_1 \in D[\Omega; C_\#^\infty(Y)]^n$, we introduce a test function defined by

$$\mu_\varepsilon(x) = \nabla\left[u(x) + \varepsilon\phi_1\left(x, \frac{x}{\varepsilon}\right)\right] + t\phi\left(x, \frac{x}{\varepsilon}\right),$$

which two-scale converges to a limit $\mu_0(x,y)=\nabla u(x)+\nabla_y\phi_1(x,y)+t\phi(x,y)$. The monotonicity property (3.18) yields

$$\int_\Omega \left[g_\varepsilon - a\left(\frac{x}{\varepsilon},\mu_\varepsilon\right)\right]\cdot(\nabla u_\varepsilon-\mu_\varepsilon)\,dx \geqq 0,$$

or, equivalently,

$$\int_\Omega \left[-\operatorname{div} g_\varepsilon\cdot u_\varepsilon - a\left(\frac{x}{\varepsilon},\mu_\varepsilon\right)\cdot\nabla u_\varepsilon - g_\varepsilon\cdot\mu_\varepsilon + a\left(\frac{x}{\varepsilon},\mu_\varepsilon\right)\cdot\mu_\varepsilon\right]dx \geqq 0. \tag{3.22}$$

Using (3.19) in the first term of (3.22), and passing to the two-scale limit in all the other terms leads to

$$\int_\Omega\int_Y \left[f\cdot u - a(y,\mu_0)\cdot[\nabla u(x)+\nabla_y u_1(x,y)] - g_0\cdot\mu_0 + a(y,\mu_0)\cdot\mu_0\right]dx\,dy \geqq 0. \tag{3.23}$$

In view of the growth conditions (3.17) on the operator a, we can pass to the limit in (3.23) when considering a sequence of functions $\phi_1(x,y)$ that converges strongly to $u_1(x,y)$ in $[L^p(\Omega;\ W^{1,p}_{\#}(Y))]^n$. Thus, replacing μ_0 by $\nabla u(x)+\nabla_y u_1(x,y)+t\phi(x,y)$ and integrating by parts, (3.23) becomes

$$\begin{aligned}&\int_\Omega\left[f(x)+\operatorname{div}\left(\int_Y g_0(x,y)\,dy\right)\right]\cdot u(x)\,dx+\int_\Omega\int_Y \operatorname{div}_y g_0(x,y)\cdot u_1(x,y)\,dx\,dy\\&+\int_\Omega\int_Y [a[y,\nabla u(x)+\nabla_y u_1(x,y)+t\phi(x,y)]-g_0(x,y)]t\phi(x,y)\,dx\,dy\geqq 0.\end{aligned}\tag{3.24}$$

Thanks to (3.21), the first two terms of (3.24) are equal to zero. Then, dividing by $t>0$, and passing to the limit, as t goes to zero, gives for any function $\phi(x,y)$,

$$\int_\Omega\int_Y [a[y,\nabla u(x)+\nabla_y u_1(x,y)]-g_0(x,y)]\phi(x,y)\,dx\,dy\geqq 0.$$

Thus, we conclude that $g_0(x,y)=a[y,\nabla u(x)+\nabla_y u_1(x,y)]$. Combined with (3.21) it implies that (u,u_1) is a solution of the homogenized system (3.20). Since the operator a is strictly monotone, system (3.20) has a unique solution, and the entire sequence u_ε converges. □

In the case $p=2$, and under the further assumption that the operator a is uniformly monotone, i.e., there exists a positive constant c such that

$$[a(y,\lambda)-a(y,\mu)]\cdot(\lambda-\mu)\geqq c|\lambda-\mu|^2 \quad \text{for any } \lambda,\ \mu, \tag{3.25}$$

we obtain a corrector result similar to Theorem 2.6 in the linear case.

THEOREM 3.6. *Assume that the function $u_1(x,y)$ is smooth. Then, the sequence $u_\varepsilon(x)-u(x)-\varepsilon u_1(x,x/\varepsilon)$ converges strongly to zero in $H^1(\Omega)$.*

Remark 3.7. Corrector results for monotone operators in the general framework of H-convergence have been obtained by Murat [35] (see also [15] in the periodic case). By lack of smoothness for $\nabla u(x)$, the corrector in [35] is not explicit. Here, on the contrary, the corrector is explicitly given as $\nabla_y u_1(x,x/\varepsilon)$. However, we still have to assume that $u_1(x,y)$ is smooth in order to state Theorem 3.6 (more precisely, $\nabla_y u_1(x,x/\varepsilon)$ is required to be, at least, an admissible test function in the sense of Definition 1.4).

Proof of Theorem 3.6. Since $u_1(x, y)$ is assumed to be smooth, we consider the function

$$\mu_\varepsilon(x)=\nabla\left[u(x)+\varepsilon u_1\left(x,\frac{x}{\varepsilon}\right)\right],$$

which two-scale converges to $\mu_0(x, y)=\nabla u(x)+\nabla_y u_1(x, y)$. The monotonicity property (3.25) yields

$$\int_\Omega\left[g_\varepsilon-a\left(\frac{x}{\varepsilon},\mu_\varepsilon\right)\right]\cdot(\nabla u_\varepsilon-\mu_\varepsilon)\,dx\geqq c\int_\Omega|\nabla u_\varepsilon-\mu_\varepsilon|^2\,dx. \tag{3.26}$$

As in the proof of Theorem 3.5, the left-hand side of (3.26) goes to zero, which implies that the sequence $\nabla[u_\varepsilon(x)-u(x)-\varepsilon u_1(x, x/\varepsilon)]$ converges to zero in $[L^2(\Omega)]^N$. □

Remark 3.8. In the literature, homogenization has also been applied to other types of nonlinear equations. A first example is given by certain fully nonlinear, first- or second-order, partial differential equation, which fall within the scope of the theory of viscosity solutions (see the review paper of Crandall, Ishii, and Lions [14]). The key point of the viscosity solutions theory is that it provides a maximum principle that permits comparison between solutions. Based on this fact is the so-called "perturbed test function" method of Evans [22], [23], which provides very elegant proof of convergence for the homogenization of such equations. A perturbed test function is a function of the type $\phi(x)+\varepsilon^i\phi_1(x, x/\varepsilon)$ $(i=1, 2$, depending on the order of the equation), which is, thus very similar to that of the two-scale convergence method. Indeed, the perturbed test function method appears, a posteriori, as the ad hoc version of two-scale convergence in the context of viscosity solutions of nonlinear equations.

A second example is nonlinear hyperbolic conservation laws. To handle homogenization of such equations, E [19] introduced so-called two-scale Young measures, which are a combination of the usual Young measures (introduced for PDEs by Tartar [45]) with two-scale convergence. Combined with DiPerna's method for reducing measure-valued solutions of conservation laws to Dirac masses [18], it allows us to rigorously homogenize nonlinear transport equations, and nonlinear hyperbolic equations with oscillating forcing terms [19], [20]. In the case of linear hyperbolic equations, two-scale convergence has also been applied by Amirat, Hamdache, and Ziani [5] and Hou and Xin [26].

4. Homogenization of a diffusion process in highly heterogeneous media. In § 2 we studied the homogenization of a second-order elliptic equation with varying coefficients $A(x, x/\varepsilon)$. This can be regarded as a stationary diffusion process in a medium made of two materials, if $A(x, x/\varepsilon)$ takes only two different values (of the same order of magnitude). The present section is also devoted to the homogenization of a diffusion process, but the main novelty with respect to § 2 is the high heterogeneity of the two materials: namely, ε being the microscale, the ratio of their diffusion coefficients is taken of order ε^2 (this precise scaling corresponds to an equipartition of the energy in both materials, see Remark 4.9). As we shall see, it changes completely the form of the homogenized problem, which is genuinely of "two-scale" type (see 4.6)). In particular, the elimination of the microscale in the homogenized system does not yield a partial differential equation (see (4.9)).

Let us turn to a brief description of the geometry of the heterogeneous medium. We consider two materials, periodically distributed in a domain Ω (a bounded open set in $\mathbb{R}^N$), with period εY (ε is a small positive number, and $Y=(0\,;1)^N$ is the unit cube). The unit period Y is divided in two complementary parts Y_1 and Y_2, which are occupied by material 1 and material 2, respectively. Let $\chi_1(y)$ (respectively, $\chi_2(y)$)

be the characteristic function of Y_1 (respectively, Y_2), extended by Y-periodicity to the whole $\mathbb{R}^N$. They satisfy

$$\chi_1(y)+\chi_2(y)=1 \quad \text{in } Y.$$

The domain Ω is thus divided in two subdomains Ω_ε^1 and Ω_ε^2 (occupied by materials 1 and 2, respectively), which are defined by

$$\Omega_\varepsilon^1=\left\{x\in\Omega/\chi_1\left(\frac{x}{\varepsilon}\right)=1\right\} \quad \text{and} \quad \Omega_\varepsilon^2=\left\{x\in\Omega/\chi_2\left(\frac{x}{\varepsilon}\right)=1\right\}.$$

We make the fundamental assumption that, in the heterogeneous domain Ω, material 1 is the "matrix," while material 2 can be either "inclusions" or another matrix (like interconnected fibers). More precisely, denoting by E_1 the subset of $\mathbb{R}^N$ obtained by Y-periodicity from Y_1, we assume that E_1 is smooth and connected. On the contrary, no such assumptions are made on E_2 (the Y-periodic set built with Y_2).

Let μ_1 and μ_2 be two positive constants. We define the varying diffusion coefficient μ_ε of the heterogeneous medium Ω by

$$\mu_\varepsilon(x)=\mu_1\chi_1\left(\frac{x}{\varepsilon}\right)+\varepsilon^2\mu_2\chi_2\left(\frac{x}{\varepsilon}\right). \tag{4.1}$$

For a given source term f and positive constant α, we consider the following diffusion process for a scalar u_ε

$$\begin{aligned} -\operatorname{div}[\mu_\varepsilon\nabla u_\varepsilon]+\alpha u_\varepsilon&=f \quad \text{in } \Omega,\\ u_\varepsilon&=0 \quad \text{on } \partial\Omega. \end{aligned} \tag{4.2}$$

We implicitly assume in (4.2) the usual transmission condition at the interface of the two materials, namely, u_ε and $\mu_\varepsilon\partial u_\varepsilon/\partial n$ are continuous through $\partial\Omega_\varepsilon^1\cap\partial\Omega_\varepsilon^2$.

Remark 4.1. We emphasize the particular scaling of the coefficients defined in (4.2): the order of magnitude of μ_ε is 1 in material 1 (the "matrix"), and ε^2 in material 2 (the "inclusions" or the "fibers"). This explains why such a medium is called "highly" heterogeneous. (For a motivation of the precise scaling, see Remark 4.9 below.) Problem (4.2) is a simplified version of a system studied by Arbogast, Douglas, and Hornung [6], which models single phase flow in fractured porous media. Its homogenization leads to the so-called double porosity model. In their context, u_ε is the fluid pressure, and μ_ε is the permeability that is much larger in the network of fractures Ω_ε^1 than in the porous rocks Ω_ε^2. Problem (4.2) can also be interpreted as the heat equation. Then, u_ε is the temperature, and μ_ε is the thermal diffusion. (Thus, material 1 is a good conductor, while material 2 is a poor one.) Under additional assumptions on the geometry and the regularity of the source term, problem (4.2) has been studied by Panasenko [39] with the help of the maximum principle (that we do not use here).

Assuming $f\in L^2(\Omega)$, it is well known that there exists a unique solution of (4.2) in $H_0^1(\Omega)$. Multiplying (4.2) by u_ε and integrating by parts leads to

$$\int_\Omega \mu_\varepsilon|\nabla u_\varepsilon|^2+\alpha\int_\Omega u_\varepsilon^2=\int_\Omega fu_\varepsilon. \tag{4.3}$$

Then, if α is strictly positive, the solution u_ε is easily seen to satisfy the a priori estimates

$$\begin{aligned} \|u_\varepsilon\|_{L^2(\Omega)}&\leqq C,\\ \|\nabla u_\varepsilon\|_{L^2(\Omega_\varepsilon^1)}&\leqq C,\\ \|\nabla u_\varepsilon\|_{L^2(\Omega_\varepsilon^2)}&\leqq\frac{C}{\varepsilon}, \end{aligned} \tag{4.4}$$

where C is a positive constant which does not depend on ε.

Remark 4.2. The a priori estimates (4.4) are easily deduced from (4.3) when $\alpha > 0$. Actually they hold true even when $\alpha = 0$, but with a new ingredient, namely, a Poincaré-type inequality. Under the additional assumption that Y_1 is connected in Y, there exists a constant C, which does not depend on ε, and such that, for any $v \in H_0^1(\Omega)$,

$$\|v\|_{L^2(\Omega)} \leqq C[\|\nabla v\|_{L^2(\Omega_\varepsilon^1)} + \varepsilon \|\nabla v\|_{L^2(\Omega_\varepsilon^2)}]. \tag{4.5}$$

Obviously the Poincaré-type inequality (4.5), applied to u_ε, implies (4.4) even for $\alpha = 0$. The proof of (4.5) is rather technical and out of the scope of the present paper. The interested reader is referred to Lemma 3.4 in [4] for a similar proof. Thus, this is only for simplicity that a zero-order term has been introduced in (4.2).

Before stating the main result of the present section, let us define the Hilbert space $H_{0\#}^1(Y_2)$ made of functions of $H_\#^1(Y_2)$, which vanishes on the interface $\partial Y_1 \cap \partial Y_2$.

THEOREM 4.3. *The sequence u_ε of solutions of* (4.2) *two-scale converges to a limit $u(x) + \chi_2(y)v(x, y)$, where (u, v) is the unique solution in $H_0^1(\Omega) \times L^2[\Omega; H_{0\#}^1(Y_2)]$ of the homogenized problem*

$$\begin{aligned} -\mu_1 \operatorname{div}_x [A^*\nabla_x u(x)] + \alpha u(x) &= f(x) - \alpha \int_{Y_2} v(x, y)\, dy \quad \textit{in } \Omega, \\ -\mu_2 \Delta_{yy} v(x, y) + \alpha v(x, y) &= f(x) - \alpha u(x) \quad \textit{in } Y_2, \\ u &= 0 \quad \textit{on } \partial\Omega, \\ v(x, y) &= 0 \quad \textit{on } \partial Y_1 \cap \partial Y_2, \\ y &\to v(x, y) \quad Y\textit{-periodic}, \end{aligned} \tag{4.6}$$

where the entries of the constant matrix A^* are given by

$$A_{ij}^* = \int_{Y_1} [\nabla_y w_i(y) + e_i] \cdot [\nabla_y w_j(y) + e_j]\, dy, \tag{4.7}$$

and, for $1 \leqq i \leqq N$, $w_i(y)$ is the solution of the cell problem

$$\begin{aligned} -\operatorname{div}_y [\nabla_y w_i + e_i] &= 0 \quad \textit{in } Y_1, \\ [\nabla_y w_i + e_i] \cdot n &= 0 \quad \textit{on } \partial Y_1 \cap \partial Y_2, \\ y &\to w_i(y) \quad Y\textit{-periodic.} \end{aligned}$$

Thanks to a separation of variables, the homogenized system (4.6) can be simplified. Denoting by $U(x)$ the weak limit in $L^2(\Omega)$ of the sequence u_ε, we obtain an equation for U. (Let us note in passing that $U(x)$ is not equal to $u(x)$, but rather to $u(x) + \int_{Y_2} v(x, y)\, dy$.)

PROPOSITION 4.4. *Let $w(y)$ be the unique solution in $H_{0\#}^1(Y_2)$ of*

$$\begin{aligned} -\mu_2 \Delta_{yy} w(y) + \alpha w(y) &= 1 \quad \textit{in } Y_2, \\ w(y) &= 0 \quad \textit{on } \partial Y_1 \cap \partial Y_2, \\ y &\to w(y) \quad Y\textit{-periodic.} \end{aligned}$$

Then, $v(x, y) = w(y)[f(x) - \alpha u(x)]$, and $u(x)$ is the unique solution in $H_0^1(\Omega)$ of

$$\begin{aligned} -\mu_1 \operatorname{div}_x [A^*\nabla_x u(x)] + \alpha \left(1 - \alpha \int_{Y_2} w(y)\, dy\right) u(x) &= \left(1 - \alpha \int_{Y_2} w(y)\, dy\right) f(x) \quad \textit{in } \Omega \\ u &= 0 \quad \textit{on } \partial\Omega. \end{aligned} \tag{4.8}$$

Denoting by L^{-1} *the solution operator of* (4.8) *from* $H^{-1}(\Omega)$ *to* $H_0^1(\Omega)$ (*i.e.*, $u(x) = L^{-1}f(x)$), $U(x)$ *can be written as*

$$U(x) = L^{-1}f(x) + \left[\int_{Y_2} w(y)\,dy\right] f(x). \tag{4.9}$$

Remark 4.5. In view of (4.9), $U(x)$ is the solution of a very special diffusion process for which no simple partial differential equation can be found. Of course, if the source term $f(x)$ is smooth, we can apply the operator L to (4.9) and obtain the equation

$$L[U(x)] = f(x) + \left[\int_{Y_2} w(y)\,dy\right] L[f(x)]. \tag{4.10}$$

But (4.10) is only formal, since, a priori, the solution $U(x)$ does not satisfy the required Dirichlet boundary condition. Thus, it seems preferable to write $U(x)$ as the sum of two terms, which are solutions of a more standard problem (4.6). The homogenized problem (4.6) is a system of two coupled equations, one "macroscopic" (in Ω) and the other one "microscopic" (in Y_2): $u(x)$ is the contribution coming from material 1 in Ω_ε^1, and $v(x, y)$ is the additional contribution from material 2 in Ω_ε^2. This is definitely a "two-scale" phenomenon, since in the limit as $\varepsilon \to 0$ (4.6) keeps track of the two different materials on two different scales. This phenomenon allowed Arbogast, Douglas, and Hornung [6] to recover the so-called double porosity model in porous media flows.

The two-scale convergence of u_ε towards $u(x) + \chi_2(y)v(x, y)$ can be improved with the following corrector result.

PROPOSITION 4.6. *Assume that* $v(x, y)$ *is smooth* (*namely, that it is an admissible test function in the sense of Definition* 1.4). *Then we have*

$$\left[u_\varepsilon(x) - u(x) - \chi_2\left(\frac{x}{\varepsilon}\right) v\left(x, \frac{x}{\varepsilon}\right)\right] \to 0 \quad \text{in } L^2(\Omega) \text{ strongly.} \tag{4.11}$$

For the proof of Theorem 4.3 we need the following.

LEMMA 4.7. *There exist functions* $u(x) \in H_0^1(\Omega)$, $v(x, y) \in L^2[\Omega; H_{0\#}^1(Y_2)]$, *and* $u_1(x, y) \in L^2[\Omega; H_\#^1(Y_1)/\mathbb{R}]$ *such that, up to a subsequence,*

$$\begin{pmatrix} u_\varepsilon \\ \chi_1(x/\varepsilon)\nabla u_\varepsilon \\ \varepsilon\chi_2(x/\varepsilon)\nabla u_\varepsilon \end{pmatrix} \text{ two-scale converge to } \begin{pmatrix} u(x) + \chi_2(y)v(x, y) \\ \chi_1(y)[\nabla u(x) + \nabla_y u_1(x, y)] \\ \chi_2(y)\nabla_y v(x, y) \end{pmatrix}. \tag{4.12}$$

Proof. In view of the a priori estimates (4.4), the three sequences in (4.12) admit two-scale limits. Arguing as in Theorem 2.9, it is easily seen that there exist $u(x) \in H_0^1(\Omega)$ and $u_1(x, y) \in L^2[\Omega; H_\#^1(Y_1)/\mathbb{R}]$ such that $\chi_1(x/\varepsilon)u_\varepsilon$ and $\chi_1(x/\varepsilon)\nabla u_\varepsilon$ two-scale converge to $\chi_1(y)u(x)$ and $\chi_1(y)[\nabla u(x) + \nabla_y u_1(x, y)]$. On the other hand, it follows from Proposition 1.14 that there exists a function $u_0(x, y) \in L^2[\Omega; H_\#^1(Y_2)]$ such that $\chi_2(x/\varepsilon)u_\varepsilon$ and $\varepsilon\chi_2(x/\varepsilon)\nabla u_\varepsilon$ two-scale converge to $\chi_2(y)u_0(x, y)$ and $\chi_2(y)\nabla_y u_0(x, y)$. It remains to find the relationship between $u(x)$ and $u_0(x, y)$.

Consider the sequence $\varepsilon\nabla u_\varepsilon$ in the whole domain Ω. For any function $\phi(x, y) \in D[\Omega; C_\#^\infty(Y)]^N$, we know from the above results that

$$\lim_{\varepsilon\to 0} \int_\Omega \varepsilon\nabla u_\varepsilon(x) \cdot \phi\left(x, \frac{x}{\varepsilon}\right) dx = \int_\Omega \int_Y \chi_2(y)\nabla_y u_0(x, y) \cdot \phi(x, y)\,dx\,dy. \tag{4.13}$$

By integration by parts, the left-hand side of (4.13) is also equal to

$$\lim_{\varepsilon\to 0} -\int_\Omega u_\varepsilon(x)\left[\operatorname{div}_y \phi\left(x,\frac{x}{\varepsilon}\right)+\varepsilon \operatorname{div}_x \phi\left(x,\frac{x}{\varepsilon}\right)\right] dx$$

$$= -\int_\Omega\int_Y [\chi_1(y)u(x)+\chi_2(y)u_0(x,y)] \operatorname{div}_y \phi(x,y)\, dx\, dy.$$

By equality between the two limits, we obtain that $u_0(x,y)=u(x)$ on $\partial Y_1 \cap \partial Y_2$. Thus, there exists $v(x,y)\in L^2[\Omega; H^1_{0\#}(Y_2)]$ such that $u_0(x,y)=u(x)+v(x,y)$. □

Proof of Theorem 4.3. In view of the two-scale limit of the sequence u_ε, we multiply (4.2) by a test function of the form $\phi(x)+\varepsilon\phi_1(x,x/\varepsilon)+\psi(x,x/\varepsilon)$, where $\phi(x)\in D(\Omega)$, $\phi_1(x,y)\in D[\Omega; C^\infty_\#(Y)]$, and $\psi(x,y)\in D[\Omega; C^\infty_\#(Y)]$ with $\psi(x,y)=0$ for $y\in Y_1$. Integrating by parts and passing to the two-scale limit yields

$$\begin{aligned}&\int_\Omega\int_{Y_1} \mu_1[\nabla u(x)+\nabla_y u_1(x,y)]\cdot[\nabla\phi(x)+\nabla_y\phi_1(x,y)]\, dx\, dy\\ &\quad+\int_\Omega\int_{Y_2}\mu_2\nabla_y v(x,y)\cdot\nabla_y\psi(x,y)\, dx\, dy\\ &\quad+\alpha\int_\Omega\int_Y [u(x)+\chi_2(y)v(x,y)]\cdot[\phi(x)+\chi_2(y)\psi(x,y)]\, dx\, dy\\ &=\int_\Omega\int_Y f(x)[\phi(x)+\chi_2(y)\psi(x,y)]\, dx\, dy.\end{aligned}\tag{4.14}$$

By density (4.14) holds true for any $(\phi,\phi_1,\psi)\in H^1_0(\Omega)\times L^2[\Omega; H^1_\#(Y_1)/\mathbb{R}]\times L^2[\Omega; H^1_{0\#}(Y_2)]$. Its left-hand side is easily seen to be coercive on the above functional space; thus (4.14) admits a unique solution (u,u_1,v). Another integration by parts shows that (4.14) is a variational formulation of the following two-scale homogenized system for u, u_1, and v:

$$\begin{aligned}-\mu_1\operatorname{div}_x\left[\int_{Y_1}[\nabla_x u(x)+\nabla_y u_1(x,y)]\, dy\right]+\alpha u(x)&=f(x)-\alpha\int_{Y_2}v(x,y)\, dy \quad \text{in } \Omega,\\ -\operatorname{div}_y[\nabla_x u(x)+\nabla_y u_1(x,y)]&=0 \quad \text{in } Y_1,\\ -\mu_2\Delta_{yy}v(x,y)+\alpha v(x,y)&=f(x)-\alpha u(x) \quad \text{in } Y_2,\\ u&=0 \quad \text{on } \partial\Omega,\\ [\nabla_x u(x)+\nabla_y u_1(x,y)]\cdot n_y&=0 \quad \text{on } \partial Y_1\cap\partial Y_2,\\ y\to u_1(x,y)&\quad Y\text{-periodic},\\ v(x,y)&=0 \quad \text{on } \partial Y_1\cap\partial Y_2,\\ y\to v(x,y)&\quad Y\text{-periodic}.\end{aligned}\tag{4.15}$$

In (4.15), the equation in u_1 can be decoupled from the two other ones, as we did in Theorem 2.9. Then, introducing the matrix A^* defined in (4.7), (4.8), the elimination of u_1 leads to system (4.6). □

Proof of Proposition 4.6. Recall the energy equation (4.3):

$$\int_\Omega \mu_\varepsilon|\nabla u_\varepsilon|^2+\alpha\int_\Omega u_\varepsilon^2=\int_\Omega f u_\varepsilon.\tag{4.3}$$

Passing to the limit in the right-hand side of (4.3), and using the variational formulation (4.14) yields

$$\begin{aligned}
&\lim_{\varepsilon\to 0}\int_\Omega \mu_\varepsilon|\nabla u_\varepsilon|^2+\alpha\int_\Omega u_\varepsilon^2\\
(4.16)\qquad &=\int_\Omega\int_{Y_1}\mu_1|\nabla u(x)+\nabla_y u_1(x,y)|^2\,dx\,dy\\
&\quad+\int_\Omega\int_{Y_2}\mu_2|\nabla_y v(x,y)|^2\,dx\,dy+\alpha\int_\Omega\int_Y[u(x)+\chi_2(y)v(x,y)]^2\,dx\,dy.
\end{aligned}$$

By application of Proposition 1.6, the limit of each term in the left-hand side of (4.16) is larger than the corresponding two-scale limit in the right-hand side. Thus equality holds for each contribution. In particular, if $\alpha>0$, we have

$$(4.17)\qquad \lim_{\varepsilon\to 0}\int_\Omega u_\varepsilon^2=\int_\Omega\int_Y[u(x)+\chi_2(y)v(x,y)]^2\,dx\,dy.$$

In view of (4.17) and Theorem 1.8, we obtain the desired result (4.11). The result holds true also for $\alpha=0$: first we obtain a corrector result for the gradients $\chi_1(x/\varepsilon)\nabla u_\varepsilon$ and $\varepsilon\chi_2(x/\varepsilon)\nabla u_\varepsilon$, second we use again the Poincaré-type inequality (4.5) to deduce (4.11). □

Remark 4.8. Similarly to the scalar equation (4.2), we could consider a Stokes problem in a domain filled with two fluids having a highly heterogeneous viscosity μ_ε (still defined by (4.1))

$$(4.18)\qquad \begin{aligned}
\nabla p_\varepsilon-\operatorname{div}[\mu_\varepsilon\nabla u_\varepsilon]&=f\quad\text{in }\Omega,\\
\operatorname{div}u_\varepsilon&=0\quad\text{in }\Omega,\\
u_\varepsilon&=0\quad\text{on }\partial\Omega,
\end{aligned}$$

with the usual transmission condition at the interface: u_ε and $p_\varepsilon n-\mu_\varepsilon\partial u_\varepsilon/\partial n$ are continuous through $\partial\Omega_\varepsilon^1\cap\partial\Omega_\varepsilon^2$ (u_ε and p_ε are the velocity and pressure of the fluids). Assuming that Y_2 is a "bubble" strictly included in the period Y, (4.18) can be regarded as a model for bubbly fluids, where the viscosity is much smaller in the bubble than in the surrounding fluid. Because of its simplicity, this model is very academic since the size, the shape, and the periodic arrangement of the bubbles are kept fixed. Nevertheless, in view of Theorem 4.3, the homogenization of (4.18) could be interesting to derive averaged equations for bubbly fluids. Unfortunately, it turns out that the homogenized system can be drastically simplified in the Stokes case. Drawing upon the ideas of [44], Theorem 4.3 can be generalized to the Stokes equation (4.18), and a homogenized system similar to (4.6) is obtained:

$$(4.19)\qquad \begin{aligned}
\nabla p(x)-\mu_1\operatorname{div}_x[A^*\nabla_x u(x)]&=f(x)\quad\text{in }\Omega,\\
\operatorname{div}u(x)&=0\quad\text{in }\Omega,\\
\nabla_y q(x,y)-\mu_2\Delta_{yy}v(x,y)&=f(x)-\nabla p(x)\quad\text{in }Y_2,\\
\operatorname{div}_y v(x,y)&=0\quad\text{in }Y_2,\\
u&=0\quad\text{on }\partial\Omega,\\
v(x,y)&=0\quad\text{on }\partial Y_2,
\end{aligned}$$

where A^* is a given positive fourth-order tensor. Since we assumed that the bubble Y_2 does not touch the faces of Y, they are no periodic boundary condition for $q(x, y)$ and $v(x, y)$. Thus, the unique solution of (4.19) satisfies $v = 0$ and $q = y \cdot [f(x) - \nabla p(x)]$. As the weak limit in $[L^2(\Omega)]^N$ of the sequence u_ε is $u(x) + \int_{Y_2} v(x, y)\, dy$, it coincides with $u(x)$. Thus the homogenized problem can be reduced to the Stokes equation for $u(x)$. In other words, there are no contributions from the bubbles in the limit, and thus no interesting phenomena due to the bubbles appear in the homogenized Stokes equations.

Remark 4.9. We have chosen a very special scaling of the diffusion coefficients in (4.2): the order of magnitude of μ_ε is 1 in material 1, and ε^2 in material 2. Indeed, we could more generally consider a scaling ε^k in material 2, with k any positive real number. Let us motivate our choice of the scaling $k = 2$, and to make things easier, we assume that there is no zero-order term in (4.2), i.e., $\alpha = 0$. Then, it turns out that the value $k = 2$ is the only one (apart from zero) that insures a balance between the energies in material 1 and 2 is the only one (apart from zero) that insures a balance between the energies in material 1 and 2, i.e., as ε goes to zero, both terms $\int_{\Omega_\varepsilon^1} \mu_\varepsilon |\nabla u_\varepsilon|^2$ and $\int_{\Omega_\varepsilon^2} \mu_\varepsilon |\nabla u_\varepsilon|^2$ have the same order of magnitude. Thus, for $k = 2$, the limit problem will exhibit a coupling between material 1 and 2. On the contrary, for $k < 2$ the energy is much larger in material 1 than in 2, and in the limit no contributions from material 2 remains (material 2 behaves as a perfect conductor on the microscopic level). For $k > 2$ the energy is much smaller in material 1 than in 2, and in the limit no contributions from material 1 remains (actually, material 2 is a very poor conductor on the microscopic level, but since the source term is of order one its energy goes to infinity).

In other words, our scaling is the only one which makes of material 1 (respectively, 2) a good conductor on the macroscopic (respectively, microscopic) level, yielding an asymptotic (as ε goes to zero) equipartition of the energies stored in materials 1 and 2.

5. On convergence results for periodically oscillating functions. This section is devoted to the proof of Lemma 1.3, and more generally to the convergence of periodically oscillating functions $\psi(x, x/\varepsilon)$. Although in § 1 the convergence of the sequence $\psi(x, x/\varepsilon)$ was studied in $L^2(\Omega)$, for the sake of clarity we recast Lemma 1.3 and Definition 1.4 in the framework of $L^1(\Omega)$. More precisely, we consider functions of two variables $\psi(x, y)$ ($x \in \Omega$ open set in $\mathbb{R}^N$, $y \in Y$ the unit cube of $\mathbb{R}^N$), periodic of period Y in y, and we investigate the weak convergence of the sequence $\psi(x, x/\varepsilon)$ in $L^1(\Omega)$, as $\varepsilon \to 0$. Recall the analogue of Definition 1.4 obtained by replacing L^2 by L^1.

DEFINITION 5.1. A function $\psi(x, y) \in L^1(\Omega \times Y)$, Y-periodic in y, is called an "admissible" test function if and only if

$$\lim_{\varepsilon \to 0} \int_\Omega \left| \psi\left(x, \frac{x}{\varepsilon}\right) \right| dx = \int_\Omega \int_Y |\psi(x, y)|\, dx\, dy. \tag{5.1}$$

The purpose of this section is to investigate under which assumptions a function $\psi(x, y)$ is admissible in the sense of Definition 5.1. It is easily seen that continuous functions on $\Omega \times Y$ are admissible. However, when less smoothness is assumed on $\psi(x, y)$, the verification of (5.1) is not obvious (first of all, the measurability of $\psi(x, x/\varepsilon)$ is not always clear). In the sequel we propose several regularity assumptions for $\psi(x, y)$ to be admissible (see Lemma 5.2, Corollary 5.4, and Lemma 5.5). They all involve the continuity of ψ in, at least, one of the variables x or y. We emphasize that it is definitely not a necessary condition for (5.1). However, to our knowledge this is the only way to obtain, in general, the measurability of $\psi(x, x/\varepsilon)$, by asserting that $\psi(x, y)$ is a

Caratheodory-type function (for a precise definition, see, e.g., Definition 1.2 of Chapter VIII in [21]). We also emphasize that this question of measurability is not purely technical and futile, but is very much linked to possible counterexamples to (5.1). We actually exhibit a counterexample to (5.1), which clearly indicates that the regularity of $\psi(x, y)$ cannot be decreased too much, even if $\psi(x, x/\varepsilon)$ is measurable (see Proposition 5.8).

Our first and main result is the L^1 equivalent of Lemma 1.3, which we recall for the reader's convenience.

LEMMA 5.2. *Let $\psi(x, y) \in L^1[\Omega; C_\#(Y)]$. Then, for any positive value of ε, $\psi(x, x/\varepsilon)$ is a measurable function on Ω such that*

$$\left\| \psi\left(x, \frac{x}{\varepsilon}\right) \right\|_{L^1(\Omega)} \leqq \|\psi(x, y)\|_{L^1[\Omega; C_\#(Y)]}, \tag{5.2}$$

and $\psi(x, y)$ is an "admissible" test function, i.e., satisfies (5.1).

By definition, $L^1[\Omega; C_\#(Y)]$ is the space of functions, measurable and summable in $x \in \Omega$, with values in the Banach space of continuous functions, Y-periodic in y. More precisely, $L^1[\Omega; C_\#(Y)]$ is a space of *classes* of functions (two functions belong to the same class if they are equal almost everywhere in Ω); however, for simplicity we shall not distinguish a class or any of its representatives. The above definition of $L^1[\Omega; C_\#(Y)]$ is not very explicit, but we also have the following characterization, which implies, in particular, that any function of $L^1[\Omega; C_\#(Y)]$ is of Caratheodory type, i.e., satisfies (i) and (ii).

LEMMA 5.3. *A function $\psi(x, y)$ belongs to $L^1[\Omega; C_\#(Y)]$ if and only if there exists a subset E (independent of y) of measure zero in Ω such that*

(i) *For any $x \in \Omega - E$, the function $y \to \psi(x, y)$ is continuous and Y-periodic*;

(ii) *For any $y \in Y$, the function $x \to \psi(x, y)$ is measurable on Ω*;

(iii) *The function $x \to \operatorname{Sup}_{y \in Y} |\psi(x, y)|$ has a finite $L^1(\Omega)$-norm.*

Proof. We simply sketch the proof that relies on the equivalence between strong and weak measurability for functions with values in a separable Banach space. Recall the following result of functional analysis (see [11, Prop. 10, Chap. IV.5], or Petti's theorem [48, Chap. V]): let $f(x)$ be a function defined on Ω with values in a separable Banach space E, and let ϕ_n be a weak $*$ dense, countable, family of functions in the unit ball of the dual E' of E; the function f is measurable if and only if all the real-valued functions $x \to \langle \phi_n(x), f(x) \rangle_{E', E}$ are measurable.

Applying this result with $E = C_\#(Y)$, and ϕ_n the family of Dirac masses at rational points of Y, yields the result. □

Proof of Lemma 5.2. From Lemma 5.3, we know that $\psi(x, y)$ is a Caratheodory-type function, and this establishes the measurability of $\psi(x, x/\varepsilon)$. Then, inequality (5.2) is a consequence of the definition of the norm $\|\psi(x, y)\|_{L^1[\Omega; C_\#(Y)]} = \int_\Omega \operatorname{Sup}_{y \in Y} |\psi(x, y)|\, dx$. Let us check that $\psi(x, y)$ satisfies (5.1).

For any integer n, we introduce a paving of the unit cube Y made of n^N small cubes Y_i of size n^{-1}. The main properties of this paving are

$$Y = \bigcup_{i=1}^{n^N} Y_i, \quad |Y_i| = \frac{1}{n^N}, \quad |Y_i \cap Y_j| = 0 \quad \text{if } i \neq j. \tag{5.3}$$

Let $\chi_i(y)$ be the characteristic function of the set Y_i extended by Y-periodicity to $\mathbb{R}^N$, and let y_i be a point in Y_i. We approximate any function $\psi(x, y)$ in $L^1[\Omega; C_\#(Y)]$ by a step function in y defined by

$$\psi_n(x,y)=\sum_{i=1}^{n^N}\psi(x,y_i)\chi_i(y). \tag{5.4}$$

We first prove (5.1) for ψ_n, and then show that passing to the limit as n goes to infinity yields the result for ψ. Thanks to Lemma 5.3 the function $x\to\psi(x,y_i)$ belongs to $L^1(\Omega)$, while $\chi_i(x/\varepsilon)$ is in $L^\infty(\Omega)$. Due to the periodicity of χ_i, a well-known result on oscillating functions leads to

$$\lim_{\varepsilon\to 0}\int_\Omega \psi(x,y_i)\chi_i\left(\frac{x}{\varepsilon}\right)dx=\int_\Omega \psi(x,y_i)\,dx\,|Y_i|. \tag{5.5}$$

Summing equalities (5.5) for $i\in[1,\cdots,n^N]$ leads to (5.1) for ψ_n.

It remains to pass to the limit in n. Let us first prove that ψ_n converges to ψ in the strong topology of $L^1[\Omega;\, C_\#(Y)]$. Define

$$\delta_n(x)=\operatorname*{Sup}_{y\in Y}|\psi_n(x,y)-\psi(x,y)|. \tag{5.6}$$

The function $y\to[\psi_n(x,y)\text{-}\psi(x,y)]$ is piecewise continuous in Y almost everywhere in x. Thus, in (5.6) the supremum over $y\in Y$ can be replaced by the supremum over $y\in Y\cap\mathbb{Q}$. This implies that δ_n, being the supremum of a countable family of measurable functions, is measurable, too (see if necessary [11, Chap. IV.5, Thm. 2]). On the other hand, as a result of the continuity in y of ψ, we have

$$\lim_{n\to+\infty}\delta_n(x)=0 \quad \text{a.e. in } \Omega.$$

Furthermore,

$$0\leqq\delta_n(x)\leqq 2\operatorname*{Sup}_{y\in Y}|\psi(x,y)|\in L^1(\Omega).$$

By application of the Lebesgue theorem of dominated convergence, the sequence δ_n strongly converges to zero in $L^1(\Omega)$. Thus ψ_n strongly converges to ψ in $L^1[\Omega;\, C_\#(Y)]$.

Let us estimate the difference

$$\begin{aligned}\left|\int_\Omega\psi\left(x,\frac{x}{\varepsilon}\right)dx-\int_\Omega\int_Y\psi(x,y)\,dx\,dy\right| &\leqq \left|\int_\Omega\psi\left(x,\frac{x}{\varepsilon}\right)dx-\int_\Omega\psi_n\left(x,\frac{x}{\varepsilon}\right)dx\right|\\ &\quad+\left|\int_\Omega\psi_n\left(x,\frac{x}{\varepsilon}\right)dx-\int_\Omega\int_Y\psi_n(x,y)\,dx\,dy\right|\\ &\quad+\left|\int_\Omega\int_Y\psi(x,y)\,dx\,dy-\int_\Omega\int_Y\psi_n(x,y)\,dx\,dy\right|.\end{aligned} \tag{5.7}$$

The first term in the right-hand side of (5.7) is bounded by

$$\int_\Omega\left|\psi\left(x,\frac{x}{\varepsilon}\right)-\psi_n\left(x,\frac{x}{\varepsilon}\right)\right|dx\leqq\int_\Omega\operatorname*{Sup}_{y\in Y}|\psi(x,y)-\psi_n(x,y)|\,dx=\|\psi_n-\psi\|_{L^1[\Omega;C_\#(Y)]}.$$

For fixed n we pass to the limit in (5.7) as $\varepsilon\to 0$:

$$\lim_{\varepsilon\to 0}\left|\int_\Omega\psi\left(x,\frac{x}{\varepsilon}\right)dx-\int_\Omega\int_Y\psi(x,y)\,dx\,dy\right|\leqq 2\|\psi_n-\psi\|_{L^1[\Omega;C_\#(Y)]}. \tag{5.8}$$

Then, we pass to the limit in (5.8) as $n\to\infty$, and we obtain (5.1). □

Reversing the role of x and y (namely, assuming continuity in x and measurability in y), the same proof as that of Lemma 5.2 works also for the following corollary.

COROLLARY 5.4. *Assume that Ω is a bounded open set (its closure $\bar{\Omega}$ is thus compact). Let $\psi(y,x)$ be a function in $L^1_\#[Y; C(\bar{\Omega})]$, i.e., measurable, summable, and Y-periodic in y, with values in the Banach space of continuous functions in $\bar{\Omega}$. Then, for any positive value of ε, $\psi(x/\varepsilon, x)$ is a measurable function on Ω such that*

$$(5.9) \qquad \left\| \psi\left(\frac{x}{\varepsilon}, x\right) \right\|_{L^1(\Omega)} \leqq C(\Omega) \| \psi(y,x) \|_{L^1_\#[Y; C(\bar{\Omega})]},$$

and $\psi(y,x)$ is an "admissible" test function, i.e., $\lim_{\varepsilon\to 0} \int_\Omega |\psi(x/\varepsilon, x)|\, dx = \int_\Omega \int_Y |\psi(y,x)|\, dx\, dy$.

In the literature (see, e.g., [10]) the favorite assumption on $\psi(x,y)$, ensuring it is an admissible test function, is $\psi(x,y) \in C_c[\Omega; L^\infty_\#(Y)]$ (i.e., continuous with compact support in Ω, with values in the Banach space of measurable, essentially bounded, and Y-periodic functions in Y). The next two lemmas are concerned with this situation.

LEMMA 5.5. *Let $\psi(x,y)$ be a function such that there exist a subset $E \subset Y$, of measure zero, independent of x, and a compact subset $K \subset \Omega$ independent of y, satisfying*

(i) *For any $y \in Y - E$, the function $x \to \psi(x,y)$ is continuous, with compact support K;*

(ii) *For any $x \in \Omega$, the function $y \to \psi(x,y)$ is Y-periodic and measurable on Y;*

(iii) *The function $x \to \psi(x,y)$ is continuous on K, uniformly with respect to $y \in Y - E$.*

Then, for any positive value of ε, $\psi(x, x/\varepsilon)$ is a measurable function on Ω, and $\psi(x,y)$ is an admissible test function in the sense of Definition 5.1, *i.e., satisfies*

$$(5.1) \qquad \lim_{\varepsilon\to 0} \int_\Omega \left| \psi\left(x, \frac{x}{\varepsilon}\right) \right| dx = \int_\Omega \int_Y |\psi(x,y)|\, dx\, dy.$$

Before proving Lemma 5.5, let us remark that any function satisfying (i)-(iii) obviously belongs to $C_c[\Omega; L^\infty_\#(Y)]$. The converse is more subtle. Indeed, since $\psi(x,y)$ is an element of $C_c[\Omega; L^\infty_\#(Y)]$, for each $x \in \Omega$, its value $y \to \psi(x,y)$ is a class of functions in $L^\infty_\#(Y)$: picking up a representative for each x and collecting them gives a "representative" of $\psi(x,y)$ in $C_c[\Omega; L^\infty_\#(Y)]$.

LEMMA 5.6. *Let $\psi(x,y)$ be a function in $C_c[\Omega; L^\infty_\#(Y)]$. Then, there exists a "representative" of $\psi(x,y)$ for which properties* (i)-(iii) *in Lemma* 5.5 *hold.*

Proof. Let $\psi(x,y) \in C_c[\Omega; L^\infty_\#(Y)]$. By definition, for any value of $x \in \Omega$, the function $y \to \psi(x,y)$ is measurable on Y, Y-periodic, and there exists a subset $E(x)$ of measure zero in Y such that $\psi(x,y)$ is bounded on $Y - E(x)$. The continuity of $x \to \psi(x,y)$ from Ω in $L^\infty_\#(Y)$ is equivalent to

$$(5.10) \qquad \lim_{\eta\to 0} \operatorname*{Sup}_{y \in Y - [E(x) \cup E(x+\eta)]} |\psi(x+\eta, y) - \psi(x,y)| = 0 \quad \text{for any } x \in \Omega.$$

We emphasize that, a priori, the exceptional set $E(x)$, where the function $y \to \psi(x,y)$ is not defined, depends on x. Nevertheless, thanks to the continuity of $\psi(x,y)$ with respect to the x variable, we are going to exhibit a "representative" of $\psi(x,y)$ for which $E(x)$ is included in a fixed set E of measure zero.

Let $K \subset \Omega$ be the compact support of $x \to \psi(x,y)$. Let $(K_i)_{i=1}^n$ be a sequence of partitions of K (i.e., $\bigcup_{i=1}^n K_i = K$ and $|K_i \cap K_j| = 0$ if $i \neq j$) such that $\lim_{n\to+\infty} \operatorname{Sup}_{1\leqq i\leqq n} \operatorname{diam}(K_i) = 0$. Let $\chi_i(x)$ be the characteristic function of K_i, and x_i a point in K_i. Define the step function $\psi_n(x,y)$ by

$$\psi_n(x,y) = \sum_{i=1}^n \psi(x_i, y) \chi_i(x).$$

By definition of the partitions $(K_i)_{i=1}^n$, and continuity of $x \to \psi(x, y)$ from Ω in $L^\infty_\#(Y)$, we have

$$\lim_{n\to+\infty} \operatorname{Sup}_{x\in K} \|\psi(x, y)-\psi_n(x, y)\|_{L^\infty_\#(Y)}. \tag{5.11}$$

In view of its definition, $\psi_n(x, y)$ is defined and bounded on $\Omega\times(Y-E_n)$, where E_n is a set of measure zero that does not depend on x. Then, the set $E=\bigcup_{n=1}^\infty E_n$ is also of measure zero and does not depend on x. From (5.11) it is easily deduced that $\psi_n(x, y)$ converges pointwise in $\Omega\times(Y-E)$ to a limit $\tilde{\psi}(x, y)$ that is continuous in $x\in\Omega$ uniformly with respect to $y\in Y-E$. As announced, $\tilde{\psi}$ is a "representative" of $\psi(x, y)$, which has the desired properties (i)-(iii). □

Proof of Lemma 5.5. Properties (i) and (ii) imply that $\psi(x, y)$ is a Caratheodory-type function, and thus $\psi(x, x/\varepsilon)$ is measurable on Ω. Using the approximating sequence of step functions $\psi_n(x, y)$ introduced in the proof of Lemma 5.6, and arguing as in Lemma 5.2, leads to (5.1) for ψ. □

In the three previous results, the function $\psi(x, y)$ is assumed to be continuous in, at least, one variable x or y. Of course, it is not a necessary assumption that ψ be an "admissible" test function. For example, if a separation of variables holds, namely, ψ is the product of two functions, each depending on only one variable, we have the following well-known result (for a proof, see, e.g., [9]).

LEMMA 5.7. *Assume that Ω is a bounded open set. Let $\phi_1(x)\in L^p(\Omega)$ and $\phi_2(y)\in L^{p'}_\#(Y)$ with $(1/p)+(1/p')=1$ and $1\leqq p\leqq+\infty$. (In case $p=1$ and $p'=+\infty$, the set Ω can be unbounded.) Then, for any positive value of ε, $\phi_1(x)\phi_2(x/\varepsilon)$ is a measurable function on Ω, and $\phi_1(x)\phi_2(y)$ is an "admissible" test function in the sense of Definition* 5.1.

In general the regularity of ψ cannot be weakened too much: even if $\psi(x, x/\varepsilon)$ is measurable, the function $\psi(x, y)$ may be not "admissible" in the sense of Definition 5.1. Following an idea of Gérard and Murat [25], we are able to construct a counterexample to (5.1) with $\psi(x, y)\in C[\bar{\Omega}; L^1_\#(Y)]$.

PROPOSITION 5.8. *Let $\bar{\Omega}=Y=[0; 1]$. There exists $v(x, y)\in C([0, 1]; L^1_\#[0, 1])$, which is not an "admissible" test function, namely,*

$$\lim_{n\to+\infty} \int_0^1 |v(x, nx)|\,dx \neq \int_0^1\int_0^1 |v(x, y)|\,dx\,dy. \tag{5.12}$$

Remark 5.9. In general, a function $\psi(x, y)\in C[\bar{\Omega}; L^1_\#(Y)]$ is not of Caratheodory type, i.e., is not continuous in x almost everywhere in Y. Thus, the measurability of $\psi(x, x/\varepsilon)$ is usually not guaranteed.

Proof of Proposition 5.8. Let us fix $\bar{\Omega}=Y=[0; 1]$. In the square $[0; 1]^2$, we are going to construct an increasing sequence of measurable subset E_n, which converges to a set E. The desired function $v(x, y)$ will be defined as the characteristic function of E extended by $[0; 1]$-periodicity in y.

For each integer n, we consider the n lines defined in the plane by

$$y=nx-p \quad \text{with}\, p\in\{0, 1, 2, \cdots, n-1\}.$$

Then, we define the set D_n made of all the points (x, y) in $[0; 1]^2$ that are at a distance less than αn^{-3} of one of the lines $y=nx-p$ for $p=0, 1, \cdots, n-1$ (the distance is the usual Euclidean distance, and α is a small strictly positive number). The set D_n is made of n strips of width $2\alpha n^{-3}$ and length of order 1. Next, we define the measurable set $E_n=\bigcup_{p=1}^n D_p$. The sequence E_n is increasing in $[0; 1]^2$, and thus converges to a measurable limit set E. We have a bound on its measure

$$|E| \leqq \sum_{n=1}^{\infty} |D_n| \leqq 4\alpha \sum_{n=1}^{\infty} \frac{1}{n^2}. \tag{5.13}$$

Let $v(x, y)$ be the characteristic function of E extended by $[0; 1]$-periodicity in y. For sufficiently small α, we deduce from (5.13) that $\int_{[0;1]^2} v(x, y)\, dx\, dy = |E| < 1$. Meanwhile, we obviously have $v(x, nx) = 1$ for $x \in [0; 1]$. Thus, the sequence $\int_{[0;1]} v(x, nx)\, dx$ cannot converge to the average of v. To complete the proof it remains to show that $v(x, y)$ belongs to $C([0, 1]; L^1_{\#}[0, 1])$, i.e., for any $x \in [0; 1]$,

$$\lim_{\varepsilon \to 0} \int_{[0;1]} |v(x+\varepsilon, y) - v(x, y)|\, dy = 0. \tag{5.14}$$

(By definition of E, $v(x, y)$ is measurable in $[0; 1]^2$ and is easily seen to be also measurable, at fixed x, in y.) Let $E(x)$ (respectively, $D_n(x)$) be the section of E (respectively, D_n) at fixed abcissa x, i.e.,

$$E(x) = \{y \in [0; 1]/(x, y) \in E\},$$
$$D_n(x) = \{y \in [0; 1]/(x, y) \in D_n\}.$$

Then

$$\int_{[0;1]} |v(x+\varepsilon, y) - v(x, y)|\, dy = |E(x) \cap ([0; 1] - E(x+\varepsilon))| + |E(x+\varepsilon) \cap ([0; 1] - E(x))|.$$

Since $E(x) = \bigcup_{n=1}^{\infty} D_n(x)$, we have

$$|E(x) \cap ([0; 1] - E(x+\varepsilon))| \leqq \sum_{n=1}^{\infty} |D_n(x) \cap ([0; 1] - D_n(x+\varepsilon))|.$$

It is easily seen that $|D_n(x) \cap ([0; 1] - D_n(x+\varepsilon))|$ is constant when x varies in $[0; 1]$. Thus

$$\int_{[0;1]} |v(x+\varepsilon, y) - v(x, y)|\, dy \leqq 2 \sum_{n=1}^{\infty} |D_n(x) \cap ([0; 1] - D_n(x+\varepsilon))|. \tag{5.15}$$

Let us fix $\varepsilon > 0$. Recall that D_n is made of n strips of width $2\alpha n^{-3}$. Denote by l_n (respectively, L_n) the length of the intersection of one strip with the x-axis (respectively, y-axis). It is easily seen that l_n is of order n^{-3}, while L_n is of order n^{-2}. Both points (x, y) and $(x+\varepsilon, y)$ lie in the same strip of D_n if n is smaller than $\varepsilon^{-1/3}$. This suggests to cut the sum in (5.15) in two parts, the first one being

$$\sum_{n=\varepsilon^{-1/3}}^{\infty} |D_n(x) \cap ([0; 1] - D_n(x+\varepsilon))| \leqq \sum_{n=\varepsilon^{-1/3}}^{\infty} |D_n(x)|, \tag{5.16}$$

while the second one is

$$\sum_{n=1}^{\varepsilon^{-1/3}} |D_n(x) \cap ([0; 1] - D_n(x+\varepsilon))|. \tag{5.17}$$

Since $|D_n(x)| = L_n$ is of order n^{-2}, (5.16) is bounded by

$$\sum_{n=\varepsilon^{-1/3}}^{\infty} |D_n(x)| \leqq C \sum_{n=\varepsilon^{-1/3}}^{\infty} \frac{1}{n^2} \leqq C\varepsilon^{1/3}.$$

On the other hand, an easy calculation shows that, for any value of n, $|D_n(x) \cap ([0;1]-D_n(x+\varepsilon))|$ is bounded by $C\varepsilon n$. Thus, (5.17) is bounded by

$$\sum_{n=1}^{\varepsilon^{-1/3}} |D_n(x) \cap ([0;1]-D_n(x+\varepsilon))| \leqq C \sum_{n=1}^{\varepsilon^{-1/3}} \varepsilon n \leqq C\varepsilon^{1/3}.$$

This leads to

$$\int_{[0;1]} |v(x+\varepsilon, y) - v(x, y)| \, dy \leqq C\varepsilon^{1/3},$$

where C is a constant independent of ε. Letting $\varepsilon \to 0$ yields (5.14). □

Acknowledgment. The author wishes to thank F. Murat for stimulating discussions on the topic.

ENERGY MOMENTS IN TIME AND FREQUENCY FOR TWO-SCALE DIFFERENCE EQUATION SOLUTIONS AND WAVELETS*

LARS F. VILLEMOES†

Abstract. This paper indicates how to find energy moments in direct and Fourier space of a solution to the functional equation $u(x) = \sum_{k=0}^{N-1} 2c_k u(2x-k)$ and shows that the Sobolev regularity of u is determined by the spectral radius of a matrix defined from the coefficients (c_k). The results are applied to compactly supported orthonormal wavelets.

Key words. two-scale difference equations, wavelets, Sobolev regularity

AMS(MOS) subject classifications. 39B32, 42C15, 94A11

1. Introduction.

A two-scale difference equation is a functional equation of the type

$$u(x) = \sum_{k=0}^{N-1} 2c_k u(2x-k), \tag{1.1}$$

where $c_0, c_1, \ldots, c_{N-1}$ are given complex numbers. Such equations arise in many contexts where the concept of changing scale is employed, such as the construction of orthonormal and biorthogonal bases of compactly supported wavelets derived from a multiresolution analysis [D1], [M], [C], [VH], [S], subdivision schemes for computer aided design [CDM], [D], [DD], and subband or pyramid based coding of speech and images [BA], [CMQW], [Ma], [Ri].

In all such applications it is important to control the properties of the solution u from the choice of the coefficients (c_k). We will focus here on the concentration in time and frequency as well as the regularity (smoothness) of u. More specifically, we will explain (in §§6–7) how to find the energy moments in time and frequency,

$$\int_{-\infty}^{+\infty} x^n |u(x)|^2 \, dx \quad \text{and} \quad \int_{-\infty}^{+\infty} \xi^n |\hat{u}(\xi)|^2 \, d\xi, \qquad n = 0, 1, 2, \ldots,$$

when these exist. ($\hat{u}$ denotes the Fourier transform of u.) The number of existing moments in frequency is closely related to Sobolev regularity, and in §9 we present an exact criterion for u to be in the Sobolev space $H^s(\mathbb{R})$ (meaning that $(1+\xi^2)^{s/2}\hat{u} \in L^2(\mathbb{R})$). This optimal regularity estimate relies on the calculation of the spectral radius of a matrix defined from the coefficients (c_k). We describe how this approach actually unifies and improves the Fourier transformation based Hölder regularity estimation methods presented in [D1] and [C]. Finally, §10 is devoted to the study of compactly supported orthonormal wavelets. All results of the paper, except for those of the last

section, have straightforward generalizations to the case where the dilation factor 2 in (1.1) is replaced by any integer $M \geq 2$. For a discussion of more general two-scale difference equations and the history of the subject, we refer to [DL1].

Many of the sharpest results of this paper depend on a technical condition, described in §5, which in some sense requires (c_k) to be nondegenerate. We refer to [C] for a more detailed description of the corresponding degenerate case. A central result which does not depend on the condition of §5, however, is the exact criterion for u to be square integrable, formulated in §4. The role played by *sum rules* is explained in §8, and we show here that maximal Sobolev regularity for a given number of coefficients N is obtained when u is a basic spline.

The starting point of the paper is an existence and uniqueness theorem defining the compactly supported distribution solution to (1.1) that we consider here.

2. The compactly supported solution φ. Assume that u is a compactly supported distribution solving (1.1). Then necessarily,

$$2\mathrm{supp}(u) \subset \mathrm{supp}(u) + [0, N-1],$$

and therefore

$$\mathrm{supp}(u) \subset [0, N-1].$$

The Fourier transform $\hat{u}$ of u can be extended to an entire function, and with the definition

$$m_0(\xi) = \sum_{k=0}^{N-1} c_k e^{-ik\xi}, \tag{2.1}$$

we can write (1.1) in the equivalent form,

$$\hat{u}(2\xi) = m_0(\xi)\hat{u}(\xi). \tag{2.2}$$

Hence, if $\hat{u}(0) \neq 0$, we must have $\sum c_k = m_0(0) = 1$. This is essentially the only interesting case, since a zero of $\hat{u}$ must be of finite order if $u \neq 0$. Thus, solutions to (2.2) with $\hat{u}(0) = 0$ are just finite order derivatives of solutions of the first kind. Now fix the normalization of u to $\hat{u}(0) = 1$. By iterating (2.2) we get

$$\hat{u}(\xi) = \prod_{j=1}^{+\infty} m_0(2^{-j}\xi),$$

where the infinite product must converge uniformly on every compact subset of $\mathbb{C}$. This shows the uniqueness statement of the following.

THEOREM 2.1. *Let $c_0, \ldots, c_{N-1} \in \mathbb{C}$ with $\sum c_k = 1$. Then there is a unique compactly supported distribution solution $u = \varphi$ to* (1.1) *with $\hat{u}(0) = 1$. The support of φ is contained in $[0, N-1]$, and*

$$\hat{\varphi}(\xi) = \prod_{j=1}^{+\infty} m_0(2^{-j}\xi).$$

Proof. By the discussion above and the obvious formal result $\hat{\varphi}(2\xi) = m_0(\xi)\hat{\varphi}(\xi)$, we only have to prove that the infinite product converges to the Fourier transform of a compactly supported distribution. This is a result of Deslauriers and Dubuc [DD], presented with a different proof in [DL1]. For completeness, we sketch the main ideas of both proofs.

Define the distributions u_n, $n = 1, 2, \dots$, by

$$\hat{u}_n(\xi) = \prod_{j=1}^{n} m_0(2^{-j}\xi).$$

Since $m_0(0) = 1$, we have $|m_0(\xi) - 1| \le C|\xi|$ for some positive constant C. This ensures that $\hat{u}_n$ converges uniformly on every compact subset of $\mathbb{C}$ towards an entire function F as $n \to +\infty$. In particular we have, for all n,

$$\sup_{|\xi|\le 2} |\hat{u}_n(\xi)| \le M < +\infty.$$

Using this together with the easy estimate that for some $R \ge 0$ and $B \ge 1$,

$$|m_0(\xi)| \le B e^{R|\mathrm{Im}\,\xi|},$$

we can then prove the fundamental estimate,

$$|\hat{u}_n(\xi)| \le M(1 + |\xi|)^{\log_2 B} e^{R|\mathrm{Im}\,\xi|}, \tag{2.3}$$

by considering the cases $2^m \le |\xi| \le 2^{m+1}$, $m = 1, 2, \dots$, and $|\xi| \le 2$ separately. Letting $n \to +\infty$, we see that the same inequality holds for $F(\xi)$, so by the Paley–Wiener theorem for distributions [R, p. 183], this function is the Fourier transform of a compactly supported distribution φ.

Alternatively, we could have observed that for each n, u_n is a linear combination of Dirac masses supported in $[0, N-1]$. Using (2.3) for real ξ then provides a uniform majorization of polynomial growth, sufficient to ensure the convergence of u_n towards φ in the sense of tempered distributions. □

From this point on, we will always assume $\sum c_k = 1$, define m_0 from (2.1), and let φ denote the solution described in Theorem 2.1. Note that in the case $N = 1$, this solution is just the Dirac mass at $x = 0$.

Example 2.2. (The Haar solution.) Let $N = 2$ and $(c_0, c_1) = (\frac{1}{2}, \frac{1}{2})$. Then $\varphi = \mathbf{1}_{[0,1]}$, the characteristic function of the interval $[0, 1]$. Indeed, except for $x = \frac{1}{2}$,

$$\varphi(x) = \varphi(2x) + \varphi(2x - 1),$$

and φ is integrable with $\int \varphi = \hat{\varphi}(0) = 1$. We call this φ the Haar solution, since the corresponding orthonormal wavelet (see §10) is the well-known Haar function [H].

3. Two useful operators. Let $C(\mathbb{T})$ be the space of 2π-periodic, complex continuous functions on $\mathbb{R}$. Define the linear operators A and A' on $C(\mathbb{T})$ as follows:

$$\begin{aligned} Af(\xi) &= \left|m_0\left(\frac{\xi}{2}\right)\right|^2 f\left(\frac{\xi}{2}\right) + \left|m_0\left(\frac{\xi}{2} + \pi\right)\right|^2 f\left(\frac{\xi}{2} + \pi\right), \\ A'f(\xi) &= 2|m_0(\xi)|^2 f(2\xi). \end{aligned}$$

Here A' is the transpose of A in the following sense.

LEMMA 3.1. *For all $f, g \in C(\mathbb{T})$, we have*

$$\int_{-\pi}^{\pi} Af(\xi)g(\xi)\,d\xi = \int_{-\pi}^{\pi} f(\xi)A'g(\xi)\,d\xi.$$

Proof. Change variable $\xi \to \xi/2$ in the right-hand side integral and use periodicity. □

We can write

$$2|m_0(\xi)|^2 = \sum_{k=1-N}^{N-1} a_0(k)e^{-ik\xi},$$
$$\text{with } a_0(k) = 2(c * \check{\bar{c}})(k) = \sum_l 2c_l\overline{c_{l-k}}.$$

Therefore, A leaves the following space of trigonometric polynomials invariant:

$$S_N = \left\{ P \in C(\mathbb{T}) \mid P(\xi) = \sum_{k=2-N}^{N-2} p(k)e^{-ik\xi}, \quad p(k) \in \mathbb{C} \right\}.$$

(For N=1, define $S_1 = S_2$.) If we assume $c_0c_{N-1} \neq 0$, then $A(S_k) \subset S_k$ exactly when $k \in \{N, N+1\}$, so S_N is the smallest nontrivial space of symmetrically truncated Fourier series which is invariant for A. By identifying the elements of S_N with their coefficients $p \in \mathbb{C}^{2N-3}$, the action of $A : S_N \to S_N$ can be described by a $(2N-3) \times (2N-3)$-matrix with entries $A_{kl} = a_0(2k-l)$, that is,

$$Ap(k) = (a_0 * p)(2k) = \sum_{l=2-N}^{N-2} a_0(2k-l)p(l), \qquad k \in \{2-N, \dots, N-2\}.$$

In the language of signal processing, A is an operator of filtering (convolution with a_0), followed by subsampling by a factor 2. If $|m_0(\xi)|^2 + |m_0(\xi+\pi)|^2 = 1$, this operator belongs the class of transition operators analyzed in [CR].

Remark 3.2. Assume the coefficients (c_k) are real. Then $m_0(-\xi) = \overline{m_0(\xi)}$, and A commutes with the parity operator

$$J : P(\xi) \mapsto P(-\xi).$$

Thus the action of A on a symmetric vector

$$(p(N-2), \dots, p(1), p(0), p(1), \dots, p(N-2))^\top \in \mathbb{C}^{2N-3}$$

can be represented by a $(N-1) \times (N-1)$-matrix A^s acting on

$$(p(0), p(1), \dots, p(N-2))^\top \in \mathbb{C}^{N-1}.$$

Using indices $\{0, 1, \dots, N-2\}$ for the entries of A^s, we find

$$A^s_{kl} = \begin{cases} A_{kl}, & l = 0, \\ A_{kl} + A_{k,-l}, & l > 0. \end{cases}$$

Similarly, the action of A on antisymmetric vectors can be described by a square matrix A^a of dimension $(N-2)$ with entries

$$A^a_{kl} = A_{kl} - A_{k,-l}, \qquad k, l \in \{1, \dots, N-2\}.$$

Also, any eigenvector of A can be chosen to be either symmetric or antisymmetric, and this reduces an eigenvalue problem for A to two problems of dimension $N-1$ and $N-2$, respectively.

Even in the general case of complex coefficients c_k, another kind of reduction in dimension can be obtained from the observation that $|m_0|^2$ is real: the action of A on conjugate symmetric vectors, $(p(-k) = \overline{p(k)})$, can be described by a $(2N-3)\times(2N-3)$-matrix with *real* entries.

Eigenvectors of A corresponding to *real* eigenvalues can be chosen conjugate symmetric, so for problems involving only the real part of the spectrum of A, we can reduce the $2N-3$ dimensions to $2N-3$ real ones.

4. A characterization of the case $\varphi \in L^2(\mathbb{R})$. Before we can define the energy moments in time and frequency of φ

$$\int_{-\infty}^{+\infty} x^n |\varphi(x)|^2 \, dx \quad \text{and} \quad \int_{-\infty}^{+\infty} \xi^n |\hat{\varphi}(\xi)|^2 \, d\xi,$$

we must at least have $\varphi \in L^2(\mathbb{R})$, i.e., that φ can be represented by a measurable function with

$$\|\varphi\|_2^2 = \int_{-\infty}^{+\infty} |\varphi(x)|^2 \, dx < +\infty.$$

If this is the case, all moments in time are well defined since φ has compact support. We postpone the discussion of the existence of moments in frequency to §9.

Assume $\varphi \in L^2(\mathbb{R})$. Then we can define a trigonometric polynomial $P_0 \in S_N$ by its coefficients

$$p_0(k) = \int_{-\infty}^{+\infty} \varphi(x)\overline{\varphi(x-k)} \, dx.$$

In fact, using Plancherel's theorem, we find that for almost every ξ:

$$P_0(\xi) = \sum_{k\in\mathbb{Z}} |\hat{\varphi}(\xi + 2\pi k)|^2.$$

Even better, this infinite sum converges uniformly and unconditionally towards P_0 on $[-\pi, \pi]$, because $x\varphi(x)$ is square integrable [M, p. 29].Observe that P_0 is real and nonnegative, with

$$P_0(0) \geq |\hat{\varphi}(0)|^2 = 1 > 0,$$

and a simple use of $\hat{\varphi}(2\xi) = m_0(\xi)\hat{\varphi}(\xi)$ yields

$$\begin{aligned} P_0(2\xi) &= \sum_{k\in\mathbb{Z}} |m_0(\xi + \pi k)|^2 |\hat{\varphi}(\xi + \pi k)|^2, \\ &= |m_0(\xi)|^2 P_0(\xi) + |m_0(\xi + \pi)|^2 P_0(\xi + \pi), \end{aligned}$$

that is, $AP_0 = P_0$. It turns out that the existence of such a trigonometric polynomial also implies $\varphi \in L^2(\mathbb{R})$:

THEOREM 4.1. *We have $\varphi \in L^2(\mathbb{R})$ if and only if there exists a real nonnegative trigonometric polynomial $P \in S_N$ satisfying $P(0) > 0$ and $AP = P$.*

Proof. We have seen above that if $\varphi \in L^2(\mathbb{R})$, then $P = P_0$ is a trigonometric polynomial with the desired properties.

Conversely, assume we have a P as described, and normalize P to satisfy

$$P(0) = 1.$$

Define for every $n = 0, 1, \ldots,$

$$g_n(\xi) = P(2^{-n}\xi)\left(\prod_{j=1}^{n} |m_0(2^{-j}\xi)|^2\right) \mathbf{1}_{[-\pi,\pi]}(2^{-n}\xi),$$

where $\mathbf{1}_\Omega$ denotes the characteristic function of a set Ω, and we set the product equal to one when $n = 0$. As $n \to +\infty$, g_n converges pointwise to $|\hat{\varphi}|^2$, and as a consequence of Lemma 3.1,

$$\begin{aligned}\int_{-\infty}^{+\infty} g_n(\xi)\, d\xi &= \int_{-\pi}^{\pi} P(\xi) \prod_{j=0}^{n-1} 2|m_0(2^j\xi)|^2\, d\xi,\\ &= \int_{-\pi}^{\pi} P(\xi)(A')^n(1)(\xi)\, d\xi = \int_{-\pi}^{\pi} A^n P(\xi)\, d\xi,\\ &= \int_{-\pi}^{\pi} P(\xi)\, d\xi = 2\pi p(0).\end{aligned}$$

Hence, by Fatou's lemma and Plancherel's theorem, $\|\varphi\|_2^2 \le p(0) < +\infty$. □

The proof of Theorem 4.1 shows that

$$\|\varphi\|_2^2 \le \inf\{p(0) \mid P \in S_N, P \ge 0, AP = P, P(0) = 1\}.$$

Admit for the moment the following result, which is a special case ($n = 0$) of Theorem 7.1.

LEMMA 4.2. *If $\varphi \in L^2(\mathbb{R})$, then $P_0(0) = 1$.*

Then the next corollary is obvious from the fact that $p_0(0) = \|\varphi\|_2^2$.

COROLLARY 4.3. *If $\varphi \in L^2(\mathbb{R})$, then*

$$\|\varphi\|_2^2 = \min\{p(0) \mid P \in S_N, P \ge 0, AP = P, P(0) = 1\}.$$

To illustrate the use of Theorem 4.1 and Corollary 4.3, let us consider a simple example, which follows.

Example 4.4. Consider the case of $N = 3$ coefficients. We will apply Theorem 4.1 to decide which choices lead to $\varphi \in L^2$. Evaluating $AP = P$ at $\xi = 0$ yields

$$|m_0(\pi)|^2 P(\pi) = 0.$$

If $P \in S_3$, $P \ge 0$, and $P(\pi) = 0$, then $P(\xi)$ must be a positive multiple of $\cos^2 \xi/2$. Evaluating $AP = P$ at $\xi = \pi/2$ now gives $m_0(\pi/2) = m_0(-\pi/2) = 0$ and this fixes

$$m_0(\xi) = \frac{1 + e^{-2i\xi}}{2}.$$

Hence, φ is just a dilation of the Haar solution of Example 2.2: $\varphi = \frac{1}{2}\mathbf{1}_{[0,2]} \in L^2$.

If $P(\pi) \neq 0$ we must have $m_0(\pi) = 0$. A parametrization of all the possible choices of coefficients in this case is given by

$$(c_0, c_1, c_2) = \left(\frac{1+re^{i\theta}}{4}, \frac{1}{2}, \frac{1-re^{i\theta}}{4}\right)$$

with $r \geq 0$ and $-\pi \leq \theta < \pi$. The 3×3-matrix representing A has $\lambda = 1$ as eigenvalue for all r, θ and we find that necessarily,

$$p = t\left(\frac{1-r^2+2ir\sin\theta}{4-4ir\sin\theta}, 1, \frac{1-r^2-2ir\sin\theta}{4+4ir\sin\theta}\right)^{\mathsf{T}}.$$

Here $P \geq 0$ implies $t = p(0) = (1/2\pi)\int_{-\pi}^{\pi} P(\xi)\,d\xi \geq 0$ and since we have

$$P(0) = \sum p(k) = t\frac{3-r^2}{2+2r^2\sin^2\theta},$$

we see that $P(0) > 0$ only if $r < \sqrt{3}$. Conversely, it turns out that $P \geq 0$ if $r < \sqrt{3}$. (It suffices to show that $2|p(1)| \leq p(0)$.)

To conclude we have shown that $\varphi \in L^2$ if and only if

$$(c_0, c_1, c_2) \in \left\{\left(\frac{1+z}{4}, \frac{1}{2}, \frac{1-z}{4}\right) \mid |z| < \sqrt{3}\right\} \cup \left\{\left(\frac{1}{2}, 0, \frac{1}{2}\right)\right\}.$$

In the first case, Corollary 4.3 gives the result

$$\int_{-\infty}^{+\infty} |\varphi(x)|^2\,dx = \frac{2+2(\operatorname{Im} z)^2}{3-|z|^2}.$$

5. The Riesz basis property. If $(e_k)_{k\in\mathbb{Z}}$ is a sequence of vectors in a Hilbert space H, such that the collection of finite linear combinations $\sum \alpha_k e_k$ are dense in H, and there exist constants $C_1 > 0$, $C_2 < +\infty$, such that for all these finite sums,

$$C_1 \sum |\alpha_k|^2 \leq \left\|\sum \alpha_k e_k\right\|_H^2 \leq C_2 \sum |\alpha_k|^2,$$

then $(e_k)_{k\in\mathbb{Z}}$ is called a *Riesz basis* for H.

A case where many results of the following sections get sharper, and pathologies in the convergence of subdivision schemes involving the coefficients (c_k) are avoided [C], is when φ has the *Riesz basis property*.

DEFINITION 5.1. We say that φ has the *Riesz basis property*, if $\varphi \in L^2(\mathbb{R})$ and the sequence of functions $\varphi(x-k)$, $k \in \mathbb{Z}$ forms a Riesz basis for the closure of its linear span in $L^2(\mathbb{R})$.

If $\varphi \in L^2$, it turns out that φ has the Riesz basis property if and only if there exist constants $C_1 > 0$, $C_2 < +\infty$, such that

$$C_1 \leq \sum_{k\in\mathbb{Z}} |\hat{\varphi}(\xi + 2\pi k)|^2 \leq C_2.$$

To prove this, use Plancherel's theorem (or see [M, p. 27]). We recognize the sum as $P_0(\xi)$ from §4. Since P_0 is continuous and 2π-periodic the condition above is equivalent to

$$\forall \xi : P_0(\xi) > 0.$$

Cohen [C] and Lawton [L1], [L2] have characterized this situation in different ways. We present some of the results in Theorem 5.3, but first a definition follows.

Definition 5.2. We say that m_0 satisfies *Cohen's criterion* if there is a compact set $K \in \mathbb{R}$ containing a neighborhood of $\xi = 0$ and equal to a finite union of closed intervals, such that

(1) For all but a finite number of $\xi \in [-\pi, \pi]$, there is a unique $\eta \in K$ with $\eta - \xi \in 2\pi\mathbb{Z}$.

(2) $m_0(\xi) \neq 0$ for $\xi \in \bigcup_{j=1}^{+\infty} 2^{-j}K$.

Observe that if m_0 does not vanish on $[-\pi/2, \pi/2]$ then Cohen's criterion is trivially satisfied with $K = [-\pi, \pi]$. If m_0 satisfies Cohen's criterion, we have

$$\hat{\varphi}(\xi) \neq 0 \quad \text{for } \xi \in K,$$

and if $\varphi \in L^2$, this clearly implies $P_0 > 0$. Conversely, if $P_0 > 0$, it is possible to use the uniform convergence on $[-\pi, \pi]$ of the sum defining P_0 to construct a K as in Definition 5.2. This is how to see the equivalence (1) $\Leftrightarrow$ (2) in the following.

Theorem 5.3. *The following three statements are equivalent:*

(1) *φ has the Riesz basis property.*

(2) *$\varphi \in L^2(\mathbb{R})$ and m_0 satisfies Cohen's criterion.*

(3) *Up to scalar multiplication there is a unique solution $P \in S_N$ to $AP = P$, and this solution can be chosen to be strictly positive.*

Proof. We prove only (1) $\Leftrightarrow$ (3) here. By Theorem 4.1 condition (3) implies that $\varphi \in L^2$, and since $AP_0 = P_0$, the unicity statement insures that P_0 is strictly positive. This shows that (3) implies (1).

Conversely, assume (1). Then $P = P_0$ is a strictly positive solution to $AP = P$. If $P(\xi) = \sum p(k)e^{-ik\xi}$ is another solution we find using Lemma 3.1:

$$\begin{aligned}
2\pi p(k) &= \int_{-\pi}^{\pi} P(\xi)e^{ik\xi}\,d\xi = \int_{-\pi}^{\pi} A^j P(\xi)e^{ik\xi}\,d\xi \\
&= \int_{-\pi}^{\pi} P(\xi)(A')^j(e^{ik\cdot})(\xi)\frac{\sum|\hat{\varphi}(\xi + 2\pi k)|^2}{P_0(\xi)}\,d\xi \\
&= \int_{-\infty}^{+\infty} \frac{P(\xi)}{P_0(\xi)}\left(\prod_{l=0}^{j-1} 2|m_0(2^l\xi)|^2\right) e^{ik2^j\xi}|\hat{\varphi}(\xi)|^2\,d\xi \\
&= \int_{-\infty}^{+\infty} \frac{P(2^{-j}\eta)}{P_0(2^{-j}\eta)}|\hat{\varphi}(\eta)|^2 e^{ik\eta}\,d\eta, \qquad (\eta = 2^j\xi).
\end{aligned}$$

This holds for every $j = 1, 2, \ldots$. The last integrand is dominated by $M|\hat{\varphi}|^2$ with $M = \sup_\xi(|P(\xi)|/P_0(\xi))$ which is finite since P_0 attains a strictly positive minimum on $[-\pi, \pi]$. Letting $j \to +\infty$, we conclude that P is a scalar multiple of P_0. □

Example 5.4. If $m_0(\xi) = (1 + e^{-3i\xi})/2$, it turns out that the eigenspace E_1 of $A : S_4 \to S_4$ corresponding to the eigenvalue $\lambda = 1$ is spanned by the functions

$$\{1, \quad (\tfrac{1}{2} + \cos\xi)^2\}.$$

By Theorem 4.1, $\varphi \in L^2$, and we find $\|\varphi\|_2^2 = \min[\frac{1}{3}, 1] = \frac{1}{3}$ from Corollary 4.3, but since $\dim(E_1) = 2$, Theorem 5.3(3) shows that φ does not have the Riesz basis property. In fact, $\varphi = \frac{1}{3}1_{[0,3]}$ and $P_0(\xi) = (\frac{1}{3} + \frac{2}{3}\cos\xi)^2$.

Even if the eigenspace E_1 is one-dimensional, we cannot be sure to be in the Riesz basis case. To see this, consider $m_0(\xi) = (1 + e^{-2i\xi})/2$. Then $\dim(E_1) = 1$ and $P_0(\xi) = \cos^2(\xi/2)$. Again φ is square integrable, but does not have the Riesz basis property since $P_0(\pi) = 0$.

6. Calculating moments in time. Assume $\varphi \in L^2$. For $n = 1, 2, \ldots$, and $k \in \mathbb{Z}$, we can then define the moments in time

$$q_n(k) = \int_{-\infty}^{+\infty} x^n \varphi\left(x + \frac{k}{2}\right) \overline{\varphi\left(x - \frac{k}{2}\right)} \, dx, \tag{6.1}$$

and as a discrete analogue, generalizing a_0 of §3,

$$a_n(k) = 2 \sum_{l \in \mathbb{Z}} \left(l - \frac{k}{2}\right)^n c_l \overline{c_{l-k}}. \tag{6.2}$$

By definition both q_n and a_n are conjugate symmetric, $q_n(k) = 0$ for $|k| > N - 2$, and $a_n(k) = 0$ for $|k| > N - 1$. In §4 we related $q_0 = p_0$ to a_0. In Proposition 6.1, we will generalize these relations to the cases $n = 1, 2, \ldots$ as well. Once q_n is found, we obtain as a special case the energy moment in time,

$$q_n(0) = \int_{-\infty}^{+\infty} x^n |\varphi(x)|^2 \, dx.$$

The extra information contained in $q_n(k)$ for $k \neq 0$ will be needed in §10, were we consider wavelets associated to φ.

In analogy with the definition of A we can define operators $A_0, A_1, A_2, \ldots$, acting on $S_N \simeq \mathbb{C}^{2N-3}$ by

$$A_n q(k) = \sum_l a_n(2k - l) q(l). \tag{6.3}$$

Because of the definition of a_n, these operators have the same symmetry properties as A in Remark 3.2.

PROPOSITION 6.1. *Assume $\varphi \in L^2(\mathbb{R})$, then*

$$q_n = 2^{-n} \sum_{p=0}^{n} \binom{n}{p} A_p q_{n-p} \quad \textit{for } n = 0, 1, 2, \ldots. \tag{6.4}$$

If φ has the Riesz basis property, then the q_n are uniquely determined by (6.4) *and the requirement $\sum_k q_0(k) = 1$.*

Proof. By inserting $\varphi(x) = \sum_k 2c_k \varphi(2x - k)$ into (6.1) we find

$$\begin{aligned}
q_n(k) &= \sum_{l,m} 4 c_l \overline{c_m} \int x^n \varphi(2x + k - l) \overline{\varphi(2x - k - m)} \, dx \\
&= 2^{-n} \sum_{l,m} 2 c_l \overline{c_m} \int \left(y + \frac{l+m}{2}\right)^n \varphi\left(y + k + \frac{m-l}{2}\right) \overline{\varphi\left(y - k + \frac{l-m}{2}\right)} \, dy \\
&\qquad \left(\text{where } y = 2x - \frac{l+m}{2}\right) \\
&= 2^{-n} \sum_{l,m} 2 c_l \overline{c_m} \sum_{p=0}^{n} \binom{n}{p} \left(\frac{l+m}{2}\right)^p q_{n-p}(2k - m - l) \\
&= 2^{-n} \sum_{p=0}^{n} \binom{n}{p} \sum_s \left(\sum_p (l - s/2)^p c_l \overline{c_{l-s}}\right) q_{n-p}(2k - s) \qquad (s = l - m) \\
&= 2^{-n} \sum_{p=0}^{n} \binom{n}{p} A_p q_{n-p}(k),
\end{aligned}$$

which shows (6.4).

Now, assume in addition that φ has the Riesz basis property. Then from Theorem 5.3(3) and Lemma 4.2 we know that $q_0 = p_0$ is uniquely defined by $Aq_0 = q_0$ and $\sum_k q_0(k) = 1$. To find $q_1, q_2, \dots$, we rearrange the terms of (6.4) to get

$$(I - 2^{-n}A)q_n = 2^{-n}\sum_{p=1}^{n}\binom{n}{p}A_p q_{n-p}.$$

If $I - 2^{-n}A$ is invertible, then q_n is uniquely determined from $q_{n-1}, q_{n-2}, \dots, q_0$. This fixes all q_n by iteration, if we can show that the spectral radius $\rho(A)$ of $A : S_N \to S_N$ is less than 2. We will show that $\rho(A) = 1$.

Let $P \in S_N$ be a strictly positive trigonometric polynomial with $AP = P$ (furnished by Theorem 5.3(3)), and equip S_N with the following weighted supremum norm:

$$\|X\|_P = \sup_{\xi\in[-\pi,\pi]} \frac{|X(\xi)|}{P(\xi)}.$$

Let us try to estimate $\|AX\|_P$. For all ξ, we have

$$\begin{aligned}\frac{|AX(2\xi)|}{P(2\xi)} &\leq \frac{|m_0(\xi)|^2P(\xi)}{P(2\xi)}\frac{|X(\xi)|}{P(\xi)} + \frac{|m_0(\xi+\pi)|^2P(\xi+\pi)}{P(2\xi)}\frac{|X(\xi+\pi)|}{P(\xi+\pi)}\\ &\leq \frac{AP(2\xi)}{P(2\xi)}\|X\|_P = \|X\|_P.\end{aligned}$$

Hence, $\|AX\|_P \leq \|X\|_P$ and $\rho(A) \leq \|A\|_P \leq 1$. To see that equality holds, use $X = P$. □

7. Calculating moments in frequency. For each $s \in \mathbb{R}$, define the Sobolev space $H^s(\mathbb{R})$ to be the space of tempered distributions u such that $(1+\xi^2)^{s/2}\hat{u} \in L^2(\mathbb{R})$. Given $n \in \mathbb{N}_0$, assume $\varphi \in H^{n/2}$ and define

$$p_n(k) = \frac{1}{2\pi}\int_{-\infty}^{+\infty} \xi^n|\hat{\varphi}(\xi)|^2 e^{ik\xi}\,d\xi. \tag{7.1}$$

Note that since $\hat{\varphi}$ is continuous, $\varphi \in H^{n/2}$ is exactly the condition ensuring that the integral in (7.1) is absolutely convergent. In other words, we ensure that the moment in frequency

$$p_n(0) = \frac{1}{2\pi}\int_{-\infty}^{+\infty} \xi^n|\hat{\varphi}(\xi)|^2\,d\xi,$$

exists.

The definition of p_n is consistent with §4 in the case $n = 0$, and p_n is conjugate symmetric, $p_n(-k) = \overline{p_n(k)}$. For even $n = 2m$, the mth derivative of φ is in L^2 and

$$p_{2m}(k) = \int_{-\infty}^{+\infty} \varphi^{(m)}(x)\overline{\varphi^{(m)}(x-k)}\,dx.$$

Define Φ_n by

$$\hat{\Phi}_n(\xi) = \xi^n|\hat{\varphi}(\xi)|^2. \tag{7.2}$$

If $\varphi \in H^{n/2}$, then $\hat{\Phi}_n$ is integrable so Φ_n itself is continuous and by definition

$$p_n(k) = \Phi_n(k).$$

Since $\Phi_n = (-i)^n\varphi^{(n)} * \check{\overline{\varphi}}$, the support of Φ_n is contained in $[1-N, N-1]$, and by continuity $p_n(k) = 0$ for $|k| > N-2$. Thus $P_n(\xi) = \sum_k p_n(k)e^{-ik\xi}$ defines an element of S_N.

THEOREM 7.1. *Let $n \in \mathbb{N}_0$. If $\varphi \in H^{n/2}$, then*

$$Ap_n = 2^{-n}p_n, \tag{7.3}$$

$$\sum_k k^l p_n(k) = \begin{cases} 0, & l = 0, 1, \ldots, n-1, \\ i^n n!, & l = n. \end{cases} \tag{7.4}$$

Furthermore, p_n is the only solution to (7.3)–(7.4) if φ has the Riesz basis property.

Proof. Observe that $\hat{\Phi}_n(2\xi) = 2^n|m_0(\xi)|^2\hat{\Phi}_n(\xi)$ and for almost every ξ,

$$P_n(\xi) = \sum_{k\in\mathbb{Z}} \hat{\Phi}_n(\xi + 2\pi k).$$

Generalizing the result for P_0 in §4, we obtain

$$P_n(2\xi) = 2^n\big(|m_0(\xi)|^2 P_n(\xi) + |m_0(\xi+\pi)|^2 P_n(\xi+\pi)\big),$$

which is equivalent to (7.3).

To show (7.4) consider the Riemann sums

$$I_n^l(j) = 2^{-j}\sum_k (2^{-j}k)^l \Phi_n(2^{-j}k)$$

for $l = 0, 1, \ldots, n$ and $j \in \mathbb{N}_0$. For $j = 0$ we have

$$I_n^l(0) = \sum_k k^l p_n(k),$$

and since Φ_n is continuous with compact support,

$$I_n^l(j) \to \int_{-\infty}^{+\infty} x^l \Phi_n(x)\,dx \quad \text{for } j \to +\infty.$$

If $a_0(k)$ are the Fourier coefficients of $2|m_0|^2$ as in §3 we have

$$\Phi_n(x) = 2^n \sum_k a_0(k)\Phi_n(2x - k).$$

Inserting this into the definition of I_n^l yields

$$I_n^l(j+1) = 2^{n-l} I_n^l(j) + \sum_{r=0}^{l-1} \gamma(r, j, l, n) I_n^r(j). \tag{7.5}$$

The exact expression for γ is of no importance here. From the inclusion $H^{s'} \subset H^s$ for $s' \geq s$ we see that (7.5) holds with n replaced by any $n' = 0, 1, \ldots, n$. If $n \geq 1$ we have in particular $I_1^0(j+1) = 2I_1^0(j)$ and since the sequence $I_1^0(j)$ converges for $j \to +\infty$ it must be identically zero. By induction, using a similar argument, we obtain in fact

$$I_n^l(j) = 0 \quad \text{for } 0 \leq l < n, \quad j = 0, 1, \ldots.$$

The special case $j = 0$ proves the homogeneous part of (7.4).

For $l = n$ the last term of (7.5) now disappears so $I_n^n(j)$ is independent of j. We thus find

$$\begin{aligned}\sum_k k^n p_n(k) &= I_n^n(0) = \lim_{j\to+\infty} I_n^n(j)\\ &= \int_{-\infty}^{+\infty} x^n \Phi_n(x)\,dx = i^n \hat{\Phi}^{(n)}(0)\\ &= i^n n!\end{aligned}$$

and this concludes the proof of the first part of the theorem.

If φ has the Riesz basis property, then P_0 is a strictly positive trigonometric polynomial and we have just seen that $P_0(0) = 1$. As shown in the case $n = 0$ in the proof of Theorem 5.3, a solution p to $Ap = 2^{-n}p$ must satisfy

$$p(k) = \frac{1}{2\pi}\int_{-\infty}^{+\infty} \frac{2^{nj}P(2^{-j}\xi)}{P_0(2^{-j}\xi)}|\hat{\varphi}(\xi)|^2 e^{ik\xi}\,d\xi, \tag{7.6}$$

where $P(\xi) = \sum_k p(k)e^{-ik\xi}$. If p satisfies (7.4) we can write

$$P(\xi) = \left(2\sin\frac{\xi}{2}\right)^n e^{i\xi/2}R(\xi),$$

for some trigonometric polynomial R with $R(0) = 1$. Inserting this into (7.6) we see that as $j \to \infty$, the integrand converges pointwise towards $\xi^n|\hat{\varphi}(\xi)|^2 e^{ik\xi}$ dominated by $C|\xi|^n|\hat{\varphi}(\xi)|^2$ where $C = \sup(|R(\xi)|/P_0(\xi))$. By the assumption $\varphi \in H^{n/2}$, Lebesgue's dominated convergence theorem allows us to conclude that $p(k) = p_n(k)$, thereby showing the last statement of Theorem 7.1. □

Remark. A different proof of Theorem 7.1 has been indicated by Beylkin [B], in the special case where φ is the scaling function of a multiresolution analysis (see §10). Assuming sufficient regularity of φ, we have

$$p_n(k) = i^n \int_{-\infty}^{+\infty} \varphi(x)\overline{\varphi^{(n)}(x-k)}\,dx.$$

Therefore the coefficients $p_n(k)$ arise naturally when the representation of the operator d^n/dx^n in a basis of orthonormal wavelets is sought, for use in the fast numerical algorithm of [BCR].

8. Sum rules. In this section we will describe some simplifications that occur in the analysis of φ when m_0 has a zero at $\xi = \pi$. As we will see in Proposition 8.3, such a zero exists if φ has the Riesz basis property.

DEFINITION 8.1. We say (c_k) satisfies M *sum rules* if $m_0(\xi) = \sum_k c_k e^{-ik\xi}$ has a zero of order at least M at $\xi = \pi$. Equivalently,

$$\sum_{k=0}^{N-1}(-1)^k k^n c_k = 0 \quad \text{for } n = 0, 1, \ldots, M-1.$$

Observe that if (c_k) satisfies M sum rules we have the factorization

$$m_0(\xi) = \left(\frac{1+e^{-i\xi}}{2}\right)^M \tilde{m}_0(\xi) \tag{8.1}$$

$$\text{with } \tilde{m}_0(\xi) = \sum_{k=0}^{N-M-1} \tilde{c}_k e^{-ik\xi}.$$

Clearly, we can have at most $N-1$ sum rules. Combining Theorem 2.1 with Example 2.2, we see that the factorization (8.1) corresponds to an M-fold convolution with the Haar solution, that is,

$$\varphi = \mathbf{1}_{[0,1]}^{*M} * \widetilde{\varphi}, \tag{8.2}$$

where $\widetilde{\varphi}$ is defined from $\widetilde{m}_0$.

A convolution with $\mathbf{1}_{[0,1]}$ has a very precise effect on the regularity of compactly supported distributions. We describe this in terms of Sobolev regularity in Lemma 8.2, but note that essentially the same proof applies to show the result in terms of Hölder regularity (C^α spaces). This observation could have simplified the higher regularity estimates of [DL2].

LEMMA 8.2. *If $s \in \mathbb{R}$ and u is a compactly supported distribution, then*

$$u \in H^s(\mathbb{R}) \Leftrightarrow \mathbf{1}_{[0,1]} * u \in H^{s+1}(\mathbb{R}).$$

Proof. Define $v = \mathbf{1}_{[0,1]} * u$. If τ_h denotes the operator of translation with h and δ_h is the Dirac mass at $x = h$ we have

$$v' = \mathbf{1}_{[0,1]}{}' * u = (\delta_0 - \delta_1) * u = u - \tau_1 u. \tag{8.3}$$

If $u \in H^s$, we see that $\hat{v}(\xi) = ((1 - e^{-i\xi})/i\xi)\hat{u}(\xi)$, and since the first factor is dominated by $2(1+\xi^2)^{-1/2}$, it follows that $v \in H^{s+1}$. (Note that the boundedness of the support of u is not necessary here.)

Conversely, if $v \in H^{s+1}$ we have $v' \in H^s$ and we will obtain $u \in H^s$ by telescoping (8.3). Indeed we can write for every $n = 1, 2, \ldots,$

$$u - \tau_n u = \sum_{k=0}^{n-1} \tau_k v' \in H^s.$$

For n large enough the supports of u and $\tau_n u$ are disjoint and we can choose a smooth compactly supported test function η, such that $\eta = 1$ on $\mathrm{supp}(u)$ and $\eta = 0$ on $\mathrm{supp}(\tau_n u)$. Since H^s is stable under multiplication by test functions [R, p.199], we conclude that $u = \eta(u - \tau_n u) \in H^s$. □

Since the Dirac mass δ_0 is in H^t if and only if $t < -\frac{1}{2}$, a simple consequence of Lemma 8.2 is that

$$\mathbf{1}_{[0,1]}^{*M} \in H^s \Leftrightarrow s < M - \tfrac{1}{2}. \tag{8.4}$$

In particular, $\varphi = \mathbf{1}_{[0,1]}^{*M}$ is a two-scale difference equation solution with $\varphi \in H^{N-2}$. This can also be seen directly, since φ is a basic spline.

We now turn to the general Riesz basis case. Assume $\varphi \in L^2$ has the Riesz basis property, then P_0 from §4 is strictly positive and

$$P_0(2\xi) = |m_0(\xi)|^2 P_0(\xi) + |m_0(\xi+\pi)|^2 P_0(\xi+\pi).$$

Evaluating at $\xi = 0$ we obtain $m_0(\pi) = 0$, hence (c_k) satisfies one sum rule. With $M = 1$ (8.1)–(8.2) become

$$m_0(\xi) = \left(\frac{1+e^{-i\xi}}{2}\right)\widetilde{m}_0(\xi), \qquad \varphi = \mathbf{1}_{[0,1]} * \widetilde{\varphi}.$$

Now if $\varphi \in H^1$, Lemma 8.2 gives $\widetilde{\varphi} \in L^2$. Since $\widetilde{m}_0$ obviously satisfies Cohen's criterion, $\widetilde{\varphi}$ will have the Riesz basis property (Theorem 5.3). Therefore $(\widetilde{c}_k)$ satisfies one sum rule as well, and (c_k) satisfies two.

By induction, we have shown the following.

PROPOSITION 8.3. *Let $m \in \mathbb{N}_0$. If $\varphi \in H^m(\mathbb{R})$ and φ has the Riesz basis property, then (c_k) satisfies $m+1$ sum rules.*

This proposition shows that in the Riesz basis case, φ cannot belong to H^{N-1} and the only possible $\varphi \in H^{N-2}$ is given by

$$\varphi = \mathbf{1}_{[0,1]}^{*(N-1)}, \qquad m_0(\xi) = \left(\frac{1+e^{-i\xi}}{2}\right)^{N-1}. \tag{8.5}$$

It turns out that this maximal regularity property of the spline solution does not depend on the Riesz basis assumption.

PROPOSITION 8.4. *If $\varphi \in H^{N-2}(\mathbb{R})$, we are in the case* (8.5).

Proof. For $N=1$ we have necessarily $\varphi = \delta_0$ and for $N=2$ the proposition follows from Example 4.4.

Assume therefore $N \geq 3$ and $\varphi \in H^{N-2}$. By downward induction on N we only have to show that (c_k) satisfies one sum rule.

Define the vectors $p_0, p_1, \ldots, p_{2N-4} \in \mathbb{C}^{2N-3}$ as in §7, and let W be the orthogonal complement of the linear span V of $p_1, p_2, \ldots, p_{2N-4}$. From Theorem 7.1 we know that

$$Ap_n = 2^{-n}p_n.$$

Thus, the dimension of V must be $2N-4$ and it follows that W is one-dimensional. If v is left eigenvector for the matrix (A_{kl}) corresponding to the eigenvalue $\lambda = 1$, we must have $v \in W$. On the other hand we have from (7.4) that $(1,1,\ldots,1) \in W$. Since $\dim(W) = 1$, we conclude that v is proportional to $(1,1,\ldots,1)$, hence

$$\sum_k A_{kl} = \sum_k a_0(2k-l) = 1,$$

which implies $|m_0(\pi)|^2 = 0$. □

Assume φ is m times continuously differentiable: $\varphi \in C^m$. Then φ is also in H^m, and Proposition 8.4 gives the lower bound $N \geq m+2$ for the number of coefficients defining φ. In fact, since $\mathbf{1}_{[0,1]}^{*(m+1)}$ is not of class C^m, we have even $N \geq m+3$. This result is well known [DL1], but in the critical case $N = m+3$, there are many different φ of class C^m. In contrast to this, Proposition 8.4 characterizes the spline solution (8.5) as the optimal choice with respect to Sobolev regularity for a given number of coefficients N.

The next lemma describes how the existence of sum rules can reduce the dimension of an eigenvalue problem for A.

LEMMA 8.5. *Let $m_0(\xi) = ((1+e^{-i\xi})/2)\widetilde{m}_0(\xi)$ and define $\widetilde{A}$ from $\widetilde{m}_0$. If $\widetilde{P} \in S_{N-1}$ is an eigenfunction for $\widetilde{A}$ corresponding to the eigenvalue λ and*

$$P(\xi) = \sin^2\left(\frac{\xi}{2}\right)\widetilde{P}(\xi),$$

then $P \in S_N$ is an eigenfunction for A corresponding to the eigenvalue $\lambda/4$.

Proof. Since $\sin\xi = 2\sin(\xi/2)\cos(\xi/2)$, we have

$$\begin{aligned} AP(2\xi) =& \cos^2\left(\frac{\xi}{2}\right)|\widetilde{m}_0(\xi)|^2\sin^2\left(\frac{\xi}{2}\right)\widetilde{P}(\xi) \\ &+ \sin^2\left(\frac{\xi}{2}\right)|\widetilde{m}_0(\xi+\pi)|^2\cos^2\left(\frac{\xi}{2}\right)\widetilde{P}(\xi+\pi) \\ =& \frac{1}{4}\sin^2(\xi)\widetilde{A}\widetilde{P}(2\xi) = \frac{\lambda}{4}P(2\xi). \end{aligned}$$

□

In parallel to this observation we see directly from the definition of Φ_n in §7, that if (c_k) satisfies M sum rules and $\varphi \in H^{n/2}$, then

$$P_n(\xi) = \left(4\sin^2\frac{\xi}{2}\right)^M \widetilde{P}_{n-2M}(\xi)$$

as long as $(n/2) \geq M$ and $\widetilde{P}_{n-2M} \in S_{N-M}$ is defined from $\widetilde{\varphi}$.

In fact, in the presence of M sum rules, any eigenfunction $P \in S_N$ for A corresponding to an eigenvalue $\lambda = 2^{-n}$ where $n < 2M$, must have a zero of order at least n at $\xi = 0$. To see this, let l be the order of the zero of P at $\xi = 0$. Expanding $AP = 2^{-n}P$ in Taylor series around $\xi = 0$ yields

$$(2^{l-n} - 1)\xi^l = \mathrm{o}(\xi^l) + \mathrm{o}(\xi^n).$$

Hence, if $l < n$, dividing by ξ^l leads to a contradicton. By Proposition 8.3, a consequence of this observation is that the homogeneous part of the condition (7.4) is superfluous when φ has the Riesz basis property.

9. Optimal Sobolev regularity estimates. For $m = 0, 1, \ldots$, we can obtain a criterion for $\varphi \in H^m(\mathbb{R})$, generalizing Theorem 4.1, just from the observation that P_{2m} is nonnegative.

THEOREM 9.1. *For $m \in \mathbb{N}_0$ we have $\varphi \in H^m(\mathbb{R})$ if and only if there exists a nonnegative trigonometric polynomial $P \in S_N$, such that $AP = 4^{-m}P$ and*

$$\sum_k k^l p(k) = \begin{cases} 0, & l = 0, 1, \ldots, 2m-1, \\ (-1)^m(2m)!, & l = 2m, \end{cases}$$

Moreover, the minimum over all such P of the central coefficient $p(0)$ equals the moment in frequency $(1/2\pi)\int \xi^{2m}|\hat{\varphi}(\xi)|^2\,d\xi$.

Proof. If $\varphi \in H^m$, then $P = P_{2m}$ will do: the eigenfunction property and corresponding normalizations follow from Theorem 7.1, and since we see from (7.2) that $\hat{\Phi}_{2m} \geq 0$, the nonnegativeness of $P(\xi) = \sum_k \hat{\Phi}_{2m}(\xi + 2\pi k)$ is clear as well.

Conversely, assume P satisfies the stated conditions. Define for $n = 1, 2 \ldots,$

$$g_n(\xi) = 4^{mn}P(2^{-n}\xi)\left(\prod_{j=1}^{n}|m_0(2^{-j}\xi)|^2\right)\mathbf{1}_{[-\pi,\pi]}(2^{-n}\xi).$$

As $n \to +\infty$, g_n converges pointwise to $\xi^{2m}|\hat{\varphi}|^2$, because of the normalization of P. Using Lemma 3.1 as in the proof of Theorem 4.1, we find that the integral of g_n equals $2\pi p(0)$ for all n. Since the g_n are nonnegative, we deduce from Fatou's lemma that

$$\frac{1}{2\pi}\int_{-\infty}^{+\infty} \xi^{2m}|\hat{\varphi}(\xi)|^2\,d\xi \leq p(0) < +\infty.$$

By the continuity of $\hat{\varphi}$, this shows that $\varphi \in H^m$.

Finally, since the above integral by definition is equal to $p_{2m}(0)$, the last statement of the theorem is evident. □

If φ has the Riesz basis property, much simpler regularity criteria can be formulated. First, the H^m-criterion of Theorem 9.1 becomes inferior to a simple combination of Proposition 8.3, Lemma 8.2, and the L^2-criterion Theorem 4.1, but we can do even better: we can find an optimal Sobolev regularity estimate s_0, in the sense that $\varphi \in H^s$ if and only if $s < s_0$, by calculating the spectral radius of a certain matrix. This optimal estimate is described in Theorem 9.5. It relies on two results: Lemma 9.2 and Lemma 9.3, which we state and prove first.

In the following, we use the supremum norm on S_N, $\|P\|_\infty = \sup_\xi |P(\xi)|$. Let $\rho(A)$ be the spectral radius of the operator $A : S_N \to S_N$ defined from m_0 as in §3. Since S_N is finite-dimensional, this radius equals the maximum modulus of the set of eigenvalues of A. The first lemma relates $\rho(A)$ and the operator norm $\|A^n\|$ to

$$\sigma_n = \int_{-\pi}^{\pi} \prod_{j=0}^{n-1} 2|m_0(2^j\xi)|^2 \, d\xi. \tag{9.1}$$

LEMMA 9.2. *There is an* $r > 0$ *such that*

$$\forall n \in \mathbb{N}: \quad r\rho(A)^n \le \sigma_n \le 2\pi \|A^n\|.$$

Proof. To show the upper bound on σ_n, observe that

$$\sigma_n = \int_{-\pi}^{\pi} (A')^n(1)(\xi)\, d\xi = \int_{-\pi}^{\pi} A^n(1)(\xi)\, d\xi \le 2\pi \|A^n\| \|1\|_\infty,$$

where we have applied Lemma 3.1 with $f = g = 1$.

Now, let λ be an eigenvalue of A with $|\lambda| = \rho(A)$, let $P \in S_N$ be a corresponding eigenfunction, and consider

$$\gamma_n = \int_{-\pi}^{\pi} P(\xi) \left(\prod_{j=0}^{n-1} 2|m_0(2^j\xi)|^2 \right) \overline{P(2^n\xi)}\, d\xi.$$

By trivial estimates we get

$$|\gamma_n| \le \|P\|_\infty^2 \sigma_n.$$

On the other hand, Lemma 3.1 gives

$$\gamma_n = \int_{-\pi}^{\pi} P(\xi)\overline{(A')^n P(\xi)}\, d\xi = \int_{-\pi}^{\pi} A^n P(\xi)\overline{P(\xi)}\, d\xi = \lambda^n \int_{-\pi}^{\pi} |P(\xi)|^2\, d\xi.$$

Thus, the lower bound on σ_n follows with $r = \|P\|_\infty^{-2} \int_{-\pi}^{\pi} |P(\xi)|^2\, d\xi$. □

The second lemma explains why we consider the sequence σ_n of (9.1).

LEMMA 9.3. *Let* $t > 0$ *and assume that* m_0 *satisfies Cohen's criterion* (*Definition* 5.2). *Then*

$$\varphi \in H^{-t}(\mathbb{R}) \Leftrightarrow \sum_{n=1}^{+\infty} \sigma_n 4^{-tn} < +\infty.$$

Proof. Let $R > 0$ be arbitrary but fixed; we will choose this parameter later. By the continuity of $\hat{\varphi}$, we have

$$\varphi \in H^{-t} \Leftrightarrow \int_{|\xi|>R} |\xi|^{-2t} |\hat{\varphi}(\xi)|^2\, d\xi < +\infty.$$

With the dyadic decomposition $\{|\xi| > R\} = \bigcup_{n=1}^{+\infty} \Omega_n$, where

$$\Omega_n = \{\xi \in \mathbb{R} \mid 2^{n-1}R < |\xi| \leq 2^n R\},$$

we obtain, by simple estimations of $|\xi|^{-2t}$ on each Ω_n,

$$\varphi \in H^{-t} \Leftrightarrow \sum_{n=1}^{+\infty} 4^{-tn} \int_{\Omega_n} |\hat{\varphi}(\xi)|^2 \, d\xi < +\infty.$$

Next, with $I_n = \int_{-2^n R}^{2^n R} |\hat{\varphi}(\xi)|^2 \, d\xi$, we find for each $k = 2, 3, \ldots,$

$$\begin{aligned}\sum_{n=1}^{k} 4^{-tn} \int_{\Omega_n} |\hat{\varphi}(\xi)|^2 \, d\xi &= \sum_{n=1}^{k} 4^{-tn}(I_n - I_{n-1}) \\ &= 4^{-tk} I_k - 4^{-t} I_0 + (1 - 4^{-t}) \sum_{n=1}^{k-1} 4^{-tn} I_n.\end{aligned}$$

Using the fact that $t > 0$, we can thus replace $\int_{\Omega_n} |\hat{\varphi}(\xi)|^2 \, d\xi$ with I_n:

$$\varphi \in H^{-t} \Leftrightarrow \sum_{n=1}^{+\infty} I_n 4^{-tn} < +\infty.$$

To complete the proof of the lemma, we now only have to show that I_n is equivalent to σ_n for $n \longrightarrow +\infty$.

By a change of variable, we can write

$$I_n = \int_{-R}^{R} \left(\prod_{j=0}^{n-1} 2|m_0(2^j \xi)|^2 \right) |\hat{\varphi}(\xi)|^2 \, d\xi.$$

Let K be the compact set of Cohen's criterion. Then $|\hat{\varphi}|^2$ attains a positive minimum $m > 0$ on K. If we choose R equal to a multiple p of π and large enough to have $K \subset [-R, R]$ it follows, with M equal to the maximum of $|\hat{\varphi}|^2$ on $[-R, R]$, that $m\sigma_n \leq I_n \leq pM\sigma_n$. □

Remark 9.4. Note that the convergence of the series in Lemma 9.3 implies $\varphi \in H^{-t}$ even when m_0 does not satisfy Cohen's criterion. (Choose $p = 1$ in the last part of the proof.) However, the condition cannot be removed from the lemma.

Consider the case $N = 3$ with $(c_0, c_1, c_2) = (1, -1, 1)$. Here it turns out that $\rho(A) = 4$, so by Lemma 9.2 we have

$$\sum_{n=1}^{+\infty} \sigma_n 4^{-n} = +\infty.$$

On the other hand, by multiplying $m_0(\xi)$ with $(1 + e^{-i\xi})/2$, we arrive at the first case of Example 5.4. Hence, the result of a convolution of φ with $\mathbf{1}_{[0,1]}$ is an L^2- function. By Lemma 8.2, this is equivalent to $\varphi \in H^{-1}$.

We are now ready to prove the main result of this section.

THEOREM 9.5. *Assume* $m_0(\xi) = ((1+e^{-i\xi})/2)^M \widetilde{m}_0(\xi)$ *where* $\widetilde{m}_0$ *satisfies Cohen's criterion and* $\widetilde{m}_0(\pi) \neq 0$. *If* $\widetilde{A}$ *is defined from* $\widetilde{m}_0$ *and* $s_0 = M - \log_4 \rho(\widetilde{A})$, *then*

$$\varphi \in H^s(\mathbb{R}) \Leftrightarrow s < s_0.$$

Proof. We have $\varphi = \mathbf{1}_{[0,1]}^{*M} * \widetilde{\varphi}$, as in (8.2), and repeated use of Lemma 8.2 gives

$$\varphi \in H^s \Leftrightarrow \widetilde{\varphi} \in H^{s-M}.$$

Recall the spectral radius formula [R, p. 235]

$$\rho(\widetilde{A}) = \lim_{n\to+\infty} \|\widetilde{A}^n\|^{1/n} = \inf_{n\in\mathbb{N}} \|\widetilde{A}^n\|^{1/n}.$$

Since $\widetilde{A}P(0) \geq P(0)$ for all nonnegative $P \in S_{N-M}$, we have $\|\widetilde{A}^n\| \geq 1$ for all n. As a first application of the spectral radius formula, we conclude that

$$\rho(\widetilde{A}) \geq 1.$$

Assume $s < s_0$. With $t = M - s$ we then have $t > \log_4 \rho(\widetilde{A}) \geq 0$, and we have to show that $\widetilde{\varphi} \in H^{-t}$. By Lemmas 9.2 and 9.3 it suffices to show that the power series $\sum_{n=1}^{+\infty} \|\widetilde{A}^n\|(4^{-t})^n$ converges. But this follows from

$$4^{-t} \limsup_{n\to+\infty} \|\widetilde{A}^n\|^{1/n} = 4^{-t}\rho(\widetilde{A}) < 1.$$

Next, we have to show that $\varphi \notin H^{s_0}$. Equivalently, that $\widetilde{\varphi} \notin H^{-t_0}$ where $t_0 = M - s_0 = \log_4 \rho(\widetilde{A})$. Since $\widetilde{\varphi} \in L^2$ would contradict the assumption $\widetilde{m}_0(\pi) \neq 0$, (by Theorem 5.3(2) and Proposition 8.3), we only have to consider the case $t_0 > 0$: from Lemma 9.2 we see that

$$\sum_{n=1}^{+\infty} \sigma_n 4^{-t_0 n} \geq r \sum_{n=1}^{+\infty} \rho(\widetilde{A})^n \rho(\widetilde{A})^{-n} = +\infty.$$

The desired conclusion then follows from Lemma 9.3. □

Example 9.6. Consider the case

$$(c_0, c_1, c_2) = \left(\frac{1+z}{4}, \frac{1}{2}, \frac{1-z}{4}\right), \qquad z \in \mathbb{C}.$$

From Example 4.4 we know that $\varphi \in L^2$ if and only if $|z| < \sqrt{3}$. Using the notation of Theorem 9.5 and excluding the case $z = 0$, we have $M = 1$ and

$$\widetilde{m}_0(\xi) = \frac{1+z}{2} + \frac{1-z}{2}e^{-i\xi}.$$

Since $\widetilde{m}_0$ can at most have one zero in $[-\pi, \pi[$, it is not hard to see that Cohen's criterion is satisfied for all z. The operator $\widetilde{A}$ is given by the 1×1-matrix $(1 + |z|^2)$; hence Theorem 9.5 gives $\varphi \in H^s \Leftrightarrow s < s_0$, where

$$s_0 = 1 - \log_4(1 + |z|^2), \qquad z \neq 0.$$

For $z = 0$ we are in the case $M = 2$ of (8.4), so $s_0 = \frac{3}{2}$. That is, the regularity exhibits a jump from $1 - \epsilon$ in the neighborhood of $z = 0$ for $z \neq 0$ to $\frac{3}{2} - \epsilon$ when $z = 0$.

The result is in agreement with Example 4.4, since $s_0 > 0$ if and only if $|z| < \sqrt{3}$. What is not captured by Theorem 9.5 is the degenerate case $c = (\frac{1}{2}, 0, \frac{1}{2})$ where we know that $\varphi \in L^2$ but φ does not have the Riesz basis property (Example 5.4). Here, Theorem 9.5 would only give the result $s < 0 \Rightarrow \varphi \in H^s$. □

The following estimations of $\rho(A)$ will be useful in order to compare the performance of Theorem 9.5 with other regularity estimates.

PROPOSITION 9.7. *Define for every $n \in \mathbb{N}$*

$$K_n = \left(\sup_{\xi \in [-\pi,\pi]} \prod_{j=0}^{n-1} |m_0(2^j \xi)|^2 \right)^{1/n}.$$

Then we have $\limsup_{n\to+\infty} K_n \le \rho(A) \le 2 \inf_{n\in\mathbb{N}} K_n$.

Proof. By induction we find

$$A^n P(\xi) = \sum_{k=0}^{2^n-1} \left(\prod_{j=1}^{n} |m_0(2^{-j}(\xi + 2\pi k))|^2 \right) P(2^{-n}(\xi + 2\pi k)).$$

Using the triangle inequality and testing $P = 1$ leads then to the result

$$\|A^n\| = \sup_\xi \left(\sum_{k=0}^{2^n-1} \prod_{j=1}^{n} |m_0(2^{-j}(\xi + 2\pi k))|^2 \right).$$

Simple estimates of the right-hand side give

$$K_n \le \|A^n\|^{1/n} \le 2K_n,$$

and the desired result follows from the spectral radius formula. □

Remark 9.8. Inserting $\xi = 2\pi/3$ into the definition of K_n gives the lower bound $K_{2n} \ge |m_0(2\pi/3)m_0(-2\pi/3)|$. ($\xi_0 = 2\pi/3$ is periodic of period 2 for $\xi \mapsto 2\xi$ modulo 2π.) Therefore we get

$$\rho(A) \ge \limsup_{n\to+\infty} K_n \ge \left| m_0\left(\frac{2\pi}{3}\right) m_0\left(-\frac{2\pi}{3}\right) \right|,$$

as a simple consequence of Proposition 9.7

Relation to Hölder regularity estimates. In the appendix of [D1] a method is developed to estimate the regularity of φ from the spectral radius of $\widetilde{A}$. Using the terminology of Theorem 9.5, the result is that

$$\alpha < s_0 - \tfrac{1}{2} \Rightarrow \varphi \in C^\alpha(\mathbb{R}). \tag{9.2}$$

Here we define C^α in the following way: if $\alpha = k + \beta$ with $k \in \mathbb{N}_0$ and $0 \le \beta < 1$, then $f \in C^\alpha$ if f is of class C^k and $f^{(k)}$ is uniformly Hölder continuous with exponent β.

The result (9.2) is also a corollary of Theorem 9.5 and the well-known inclusion

$$H^s(\mathbb{R}) \subset C^\alpha(\mathbb{R}) \quad \text{for } s > \alpha + \tfrac{1}{2}.$$

If C_0^α denotes the space of compactly supported C^α functions, we have an inclusion in the opposite direction [Hö, p. 242],

$$C_0^\alpha(\mathbb{R}) \subset H^s(\mathbb{R}) \quad \text{for } s < \alpha.$$

Therefore, the following Hölder estimates of accuracy $\frac{1}{2}$ hold.

COROLLARY 9.9. *With notation and assumptions as in Theorem* 9.5 *then* $\varphi \in C^\alpha(\mathbb{R})$ *if* $s_0 > \alpha + \frac{1}{2}$ *and* $\varphi \notin C^\alpha(\mathbb{R})$ *if* $s_0 < \alpha$.

Let $\widetilde{K}_n$ be defined from $\widetilde{m}_0$ as in Proposition 9.7. Since $s_0 = M - \log_4 \rho(\widetilde{A})$, we get, for every $n \in \mathbb{N}$,

$$\alpha < M - \log_4 \widetilde{K}_n \Rightarrow \varphi \in C^\alpha(\mathbb{R}). \tag{9.3}$$

This is also obtained in [D1], but as a consequence of the stronger result about the decay of the Fourier transform of φ,

$$|\hat{\varphi}(\xi)| \leq C(1+|\xi|)^{-M+\log_4 \widetilde{K}_n}.$$

Cohen has refined this regularity estimation method starting from the observation that $\widetilde{K}_n$ converges to $\widetilde{K} = \inf_n \widetilde{K}_n$ as $n \to +\infty$. (A consequence of $\widetilde{K}_{n+m}^{n+m} \leq \widetilde{K}_n^n \widetilde{K}_m^m$.) Then (9.3) still holds with $\widetilde{K}_n$ replaced by $\widetilde{K}$ and it is shown in [C], under the technical assumption $|\widetilde{m}_0(\pi)| \geq 1$, that

$$\alpha > M + \tfrac{1}{2} - \log_4 \widetilde{K} \Rightarrow \varphi \notin C^\alpha(\mathbb{R}).$$

In other words, if $\alpha_0 = \sup\{\alpha \mid \varphi \in C^\alpha\}$ and we put $b = \log_4 \widetilde{K}$, then α_0 lies in the interval $[M - b - 1, M - b + \frac{1}{2}]$.

Here we can immediately remove the technical assumption and improve by $\frac{1}{2}$ the upper bound by observing that Proposition 9.7 implies $M - b - \frac{1}{2} \leq s_0 \leq M - b$. Thus we get from Corollary 9.9

$$\alpha_0 \in [M - b - 1, M - b].$$

Finally, we should note that optimal estimates of Hölder regularity have been obtained by Daubechies and Lagarias in [DL2] without making use of the Fourier transform. However, their criteria get very complex as N increases. For purposes where an accuracy of $\frac{1}{2}$ in the estimation of α_0 is sufficient, Corollary 9.9 offers a substantially easier alternative.

10. Application to orthonormal wavelets.

Throughout this section we will assume that

$$|m_0(\xi)|^2 + |m_0(\xi+\pi)|^2 = 1 \tag{10.1}$$

and that m_0 satisfies Cohen's criterion (Definition 5.2). Then $P = 1$ will be the unique solution to $AP = P$ with $P(0) = 1$, so φ is square integrable and the integer translates of φ constitute an orthonormal basis for the closure of their linear span. In this case φ is the scaling function of a multiresolution analysis of $L^2(\mathbb{R})$ [M], [C], and we can associate a compactly supported wavelet ψ to this scaling function as follows:

$$\frac{1}{2}\psi\left(\frac{x}{2}\right) = \sum_k d_k \varphi(x-k), \tag{10.2}$$

$$\text{where} \quad d_k = (-1)^{1-k}\overline{c_{1-k}}. \tag{10.3}$$

If we define $m_1(\xi) = \sum_k d_k e^{-ik\xi}$, then (10.2)–(10.3) can also be written in the form

$$\hat{\psi}(2\xi) = m_1(\xi)\hat{\varphi}(\xi), \tag{10.4}$$

$$\text{with } m_1(\xi) = e^{-i\xi}\,\overline{m_0(\xi+\pi)}. \tag{10.5}$$

Modulo integer translation and multiplication by complex constants of modulus one, ψ is the unique compactly supported L^2-function of unit norm in the span of $\{\varphi(2x-k)\}_{k\in\mathbb{Z}}$, which is orthogonal to all $\varphi(x-k)$. The set of functions

$$\psi_{jk}(x) = 2^{j/2}\psi(2^j x - k), \qquad j, k \in \mathbb{Z}$$

then defines an orthonormal basis for $L^2(\mathbb{R})$ consisting of compactly supported wavelets [M].

Moments in time. Let us try to apply the results of §6 to find the moment $\int x|\psi(x)|^2\,dx$, i.e., the center of gravity of the squared modulus of the wavelet.

First we define, in analogy with (6.2)–(6.3),

$$b_n(k) = 2\sum_l \left(l - \frac{k}{2}\right)^n d_l \overline{d_{l-k}},$$
$$B_n q(k) = \sum_l b_n(2k-l)q(l).$$

Then by mimicking the proof of Proposition 6.1 we get

$$\int_{-\infty}^{+\infty} x|\psi(x)|^2\,dx = \left(\frac{1}{2}B_0 q_1 + \frac{1}{2}B_1 q_0\right)(0).$$

From (10.1) and the definition of (d_k) it follows that

$$a_0(k) + b_0(k) = 2\delta_{0k},$$
$$a_1(0) + b_1(0) = 1.$$

(Here δ is the Kronecker delta.) Using all this together with Proposition 6.1 for $n = 1$, we obtain

$$\begin{aligned}\int_{-\infty}^{+\infty} x|\psi(x)|^2\,dx &= \left(q_1 - \frac{1}{2}A_0 q_1 + \frac{1}{2}B_1 q_0\right)(0)\\ &= \left(\frac{1}{2}A_1 q_0 + \frac{1}{2}B_1 q_0\right)(0) = \frac{1}{2}(a_1(0) + b_1(0)) \qquad (Q_0 = P_0 = 1)\\ &= \frac{1}{2}.\end{aligned}$$

Hence, we have shown the following amusing result.

PROPOSITION 10.1. *If the orthonormal wavelet ψ is defined from* (10.2) *then*

$$\int_{-\infty}^{+\infty} x|\psi(x)|^2\,dx = \frac{1}{2}.$$

Remark 10.2. This proposition is easily generalized to $\int x|\psi(x)|^2\,dx \in \frac{1}{2} + \mathbb{Z}$ for all orthonormal wavelets which are obtained from a multiresolution analysis and have a reasonable decay at infinity. □

Turning to the second moment in time of ψ, things become more complicated. However, using

$$\int_{-\infty}^{+\infty} x^2|\psi(x)|^2\,dx = \left(\frac{1}{4}B_0 q_2 + \frac{1}{2}B_1 q_1 + \frac{1}{4}B_2 q_0\right)(0)$$

together with simple relations between b_n and a_n for $n = 1, 2$ and Proposition 6.1, we arrive at the formula

$$\begin{aligned}(\Delta x)^2 &= \int_{-\infty}^{+\infty} \left(x - \frac{1}{2}\right)^2 |\psi(x)|^2\, dx \\ &= \frac{1}{2} q_2(0) + \frac{1}{2} a_2(0) + \sum_k a_1(2k+1) q_1(-2k-1).\end{aligned} \tag{10.6}$$

Here $q_2(0)$ and $q_1(2k+1)$ can be found from Proposition 6.1.

The above method was applied in [DV] to choose wavelets with the minimum root mean square duration in time Δx from classes of wavelets with equal $|\hat{\psi}|$.

Moments in frequency and regularity. We have a simple relation between the moments in frequency of φ and ψ. In particular, the regularity of ψ is exactly the same as for φ.

PROPOSITION 10.3. *Define φ and ψ as above. Then*

(1) $\forall s \geq 0$: $\psi \in H^s(\mathbb{R}) \Leftrightarrow \varphi \in H^s(\mathbb{R})$

(2) *Let $n \in \mathbb{N}_0$. If $\psi \in H^{\frac{n}{2}}(\mathbb{R})$, then*

$$\int_{-\infty}^{+\infty} \xi^n |\hat{\psi}(\xi)|^2\, d\xi = (2^{1+n} - 1) \int_{-\infty}^{+\infty} \xi^n |\hat{\varphi}(\xi)|^2\, d\xi. \tag{10.7}$$

Proof. The key ingredient in the proof is the relation

$$|\hat{\psi}(\xi)|^2 = \left|\hat{\varphi}\left(\frac{\xi}{2}\right)\right|^2 - |\hat{\varphi}(\xi)|^2, \tag{10.8}$$

which follows from (10.1) and (10.4)–(10.5). Iterating this result, we obtain for every $k \in \mathbb{N}$:

$$\sum_{j=1}^{k} |\hat{\psi}(2^j \xi)|^2 = |\hat{\varphi}(\xi)|^2 - |\hat{\varphi}(2^k \xi)|^2.$$

The integral of the last term tends to zero as $k \to \infty$, and since the terms of the sum are nonnegative we have pointwise convergence for almost every ξ in

$$\sum_{j=1}^{+\infty} |\hat{\psi}(2^j \xi)|^2 = |\hat{\varphi}(\xi)|^2.$$

By the monotone convergence theorem it follows that

$$\begin{aligned}\int_{-\infty}^{+\infty} |\xi|^{2s} |\hat{\varphi}(\xi)|^2\, d\xi &= \sum_{j=1}^{+\infty} \int_{-\infty}^{+\infty} |\xi|^{2s} |\hat{\psi}(2^j \xi)|^2\, d\xi \\ &= \sum_{j=1}^{+\infty} 2^{-j(2s+1)} \int_{-\infty}^{+\infty} |\xi|^{2s} |\hat{\psi}(\xi)|^2\, d\xi \\ &= (2^{2s+1} - 1)^{-1} \int_{-\infty}^{+\infty} |\xi|^{2s} |\hat{\psi}(\xi)|^2\, d\xi.\end{aligned}$$

This clearly proves (1), and the result (2) is now an easy consequence of (10.8), since (1) guarantees that both integrals in (10.7) are well defined. □

Remark 10.4. The statement (1) about the regularity of ψ could also have been obtained simply by observing from (10.2) that ψ is a finite linear combination of half integer translates of $\varphi(2x)$. Then a slight generalization of the telescoping argument of the proof of Lemma 8.2 would do. Moreover, this approach would also work when (10.1) does not hold, i.e., when we are dealing with compactly supported biorthogonal wavelets as in [VH], [C].

Example 10.5. If m_0 is a solution to (10.1) with M sum rules, i.e.,

$$m_0(\xi) = \left(\frac{1+e^{-i\xi}}{2}\right)^M \widetilde{m}_0(\xi),$$

then $|\widetilde{m}_0|^2$ must be of the form [D1]

$$|\widetilde{m}_0(\xi)|^2 = \sum_{k=0}^{M-1} \binom{M-1+k}{k} \sin^{2k}\left(\frac{\xi}{2}\right) + \sin^{2M}\left(\frac{\xi}{2}\right) R(\xi), \tag{10.9}$$

where R is a real valued trigonometric polynomial satisfying $R(\xi) + R(\xi+\pi) = 0$:

$$R(\xi) = \sum_{k=1}^{K} \{\alpha_k \cos(2k-1)\xi + \beta_k \sin(2k-1)\xi\}.$$

Conversely, if R is chosen such that the right-hand side of (10.9) is nonnegative, we can find a trigonometric polynomial $\widetilde{m}_0$ solving (10.9), thanks to a lemma of Riesz. (This factorization method is well known in signal analysis [P, p. 231].) The resulting number of coefficients N is equal to $2(M+K)$ if either $\alpha_K \neq 0$ or $\beta_K \neq 0$, and equal to $2M$ if $R = 0$.

Assume R is chosen such that $\widetilde{m}_0$ verifies Cohen's criterion. From Proposition 8.3 we know that $\varphi \in H^m$ implies $M \geq m+1$ and therefore $N \geq 2M \geq 2m+2$.

As a first example, consider the case $M = 2$ and $R = 0$ of (10.9):

$$|\widetilde{m}_0(\xi)|^2 = 1 + 2\sin^2\left(\frac{\xi}{2}\right) = 2 - \cos\xi.$$

Then we have simply $\widetilde{A} = (4)$, so the Sobolev regularity given by Theorem 9.5 is $s_0 = 2 - \log_4 4 = 1$, meaning that

$$\varphi \in H^s \Leftrightarrow s < 1.$$

Clearly, we cannot obtain a better Sobolev regularity for any scaling function φ defined from $N = 4$ coefficients, because if we had $\varphi \in H^1$, the two necessary sum rules would fix $R = 0$. This stands in contrast to the behaviour of the Hölder regularity examined in [D2], where it is shown that the best possible Hölder coefficient is obtained for a choice with $M = 1$ and $R \neq 0$.

For $N = 6$ and $R = 0$ the Sobolev regularity is $s_0 = 3 - \log_4 9 \approx 1.4150$, and numerical experiments suggest that this cannot be improved by allowing $R \neq 0$. Cohen has shown in [C] (using the method described here in Remark 9.8 together with an estimation of $\widetilde{K}_4$) that the regularity of the family (10.9) with $R = 0$ is roughly $N/10$

for large N. Most of the $N/2$ sum rules could therefore very well be unnecessary, and the problem of finding the solution with the highest regularity for a given number of coefficients N is still open. However, if we accept the measure of regularity to be in the Sobolev sense, Theorem 9.5 provides a simpler cost function for this optimization problem than the methods of [DL2].

As mentioned in the previous section, Daubechies developed a spectral radius based regularity estimation method. She applied this to the family (10.9) with $R = 0$, and listed the resulting Hölder regularity estimates for $M = 2, 3, \ldots, 10$ in a table [D1, p. 984]. In fact, adding $\frac{1}{2}$ to the values of this table, we arrive at the corresponding exact Sobolev regularity estimates s_0 of Theorem 9.5. In particular, Corollary 9.9 asserts that the optimal Hölder estimates lies in closed intervals of length $\frac{1}{2}$ with left end points equal to the values of this table.

Acknowledgments. Part of this work was done during a stay at the Department of Mathematics of the Royal Institute of Technology in Stockholm. The author wishes to express his thanks for their warm hospitality. A grant from the Nordic Council of Ministers made the stay possible and is also gratefully acknowledged.

After the completion of this work, the author has learned that part of the results presented here have also been derived by T. Eirola [E].

SIMPLE REGULARITY CRITERIA FOR SUBDIVISION SCHEMES*

OLIVIER RIOUL†

Abstract. Convergent subdivision schemes arise in several fields of applied mathematics (computer-aided geometric design, fractals, compactly supported wavelets) and signal processing (multiresolution decomposition, filter banks). In this paper, a polynomial description is used to study the existence and Hölder regularity of limit functions of binary subdivision schemes. Sharp regularity estimates are derived; they are optimal in most cases. They can easily be implemented on a computer, and simulations show that the exact regularity order is accurately determined after a few iterations. Connection is made to regularity estimates of solutions to two-scale difference equations as derived by Daubechies and Lagarias, and other known Fourier-based estimates. The former are often optimal, while the latter are optimal only for a subclass of symmetric limit functions.

1. Introduction.

This paper focuses on the behavior of real-valued discrete sequences u_n $(n \in \mathbf{Z})$ of finite length under repeated action of an operator $\mathcal{G}$ defined as

$$u_n \xrightarrow{\mathcal{G}} v_n = \sum_{k\in\mathbf{Z}} u_k\, g_{n-2k}. \tag{1.1}$$

The fixed sequence g_n that parameterizes $\mathcal{G}$ is called the subdivision *mask* [14], [15]. It plays a central role in the following. Starting from the initial "impulse" sequence

$$\delta_n = \begin{cases} 1 & \text{if } n = 0, \\ 0 & \text{otherwise,} \end{cases}$$

a *binary subdivision scheme* [14], [15], [17] (in one dimension) is an infinite collection of sequences g_n^j $(j \in \mathbf{N})$, defined by iteration as shown.

$$\begin{aligned} g_n^1 &= \mathcal{G}\{\delta_n\} = g_n, \\ g_n^2 &= \mathcal{G}\{g_n^1\}, \\ &\ \vdots \\ g_n^{j+1} &= \mathcal{G}\{g_n^j\}. \qquad (1.2) \\ &\ \vdots \end{aligned}$$

The g_n^j's are fully determined given the mask g_n. Of course other initial sequences can be considered. In addition, this scheme is said to be *interpolatory* [10]–[15] if it satisfies the extra condition $g_{2n} = \delta_n$, which means that all points g_n^j at some level j are carried unchanged to the next level: $g_{2n}^{j+1} = g_n^j$. In this paper we regard interpolatory subvision schemes as a special case to which general results will apply. However, we restrict ourselves to *binary* subdivision schemes, even though the results

FIG. 1. *A binary subdivision scheme converging to a limit function (after* [6]*). The discrete sequences* g_n^j *are plotted as "pulses" against* $n2^{-j}$ *for* $j = 1, 2, 3,$ *and* 6*. At each iteration step the up-scaling operator* (1.1) *is applied, which approximatively doubles the number of coefficients while preserving a global shape. When* $j \to \infty$*, these discrete curves converge to a "nice-looking," regular limit function, compactly supported on* $[0, 13]$.

of this paper easily extend to more general subdivision schemes, for which the number 2 in (1.1) is replaced by any integer $p \geq 2$ [8], [9].

Subdivision schemes arise in several fields of applied mathematics and signal processing. They have been used for curve fitting and to generate fractal or smooth curves and surfaces numerically [10]–[15], [17]. They also play an important role in wavelet theory [1], [3]–[7], [20]–[23], a newly born theory in functional analysis closely related to filter bank theory in signal processing [20], [18], [21], [22]. In all of these applications, the convergence of (1.2) to a function of a continuous variable $\varphi(x)$ as j indefinitely increases is important. It is also important to control several properties of the limit function $\varphi(x)$ from the choice of the mask g_n. For example, whether limit functions $\varphi(x)$ are regular (smooth) or not may be relevant for image coding applications using wavelets [1], [20], and this has motivated the work presented here.

The aim of this paper is to find necessary and sufficient conditions on the mask g_n for the existence and Hölder regularity of the limit function $\varphi(x)$. Figure 1 shows that $\varphi(x)$ can be thought of as a limit of discrete curves g_n^j plotted against $n2^{-j}$. (We then say that the sequences g_n^j "converge" to $\varphi(x)$ as $j \to \infty$.) In addition, we shall often be in the case of *uniform* convergence. Intuitively, this means that the discrete curves g_n^j converge "as a whole" to the limit curve $\varphi(x)$. Section 3 discusses several possible definitions for both types of convergence.

This paper is organized as follows. First, §2 describes binary subdivision schemes

(1.2) using the convenient polynomial notation. Then, various definitions of convergence are discussed (§3), and a basic necessary condition for the existence of a limit function is derived (§4). We show how the values of a limit function can be computed exactly on a computer (§5). The relation between the values of g_n^j and those of $\varphi(x)$ leads us to define "stable" subdivision schemes, to which the results of this paper fully apply (§6). Fortunately, almost all limit functions are stable.

To tackle the regularity problem, we characterize regularity of limit functions in terms of discrete sequences. Continuity is connected to uniform convergence and a necessary and sufficient condition for uniform convergence is derived in §7. Hölder regularity $\dot{C}^\alpha$ $(0 < \alpha \leq 1)$ is expressed by a similar property of the g_n^j's (§8). Finite differences of the g_n^j's play the role of derivatives and N-times continuously differentiable limit functions are, therefore, characterized by uniform convergence of finite differences (§9).

From these equivalences a full characterization of Hölder regularity $\dot{C}^r$ (for all $r > 0$) naturally emerges in terms of discrete sequences (§10). The main result of this paper is an easily implemented, optimal regularity estimate derived in §11. This estimate is then compared to other related work [3]–[12], [23]. A sharp upper bound for Hölder regularity is also derived in §13.

As a general rule, the first parts of the theorems derived in this paper show that a given property of the g_n^j's implies the corresponding regularity property of the limit function $\varphi(x)$. The second parts prove the converse implication, which is useful for proving optimality of regularity estimates and generally assumes the stability condition.

The purpose of this paper is close to the one of Daubechies and Lagarias in [8], [9]. They studied the existence, uniqueness, and regularity of solutions to "two-scale difference equations." We shall see in §5 that the limit function $\varphi(x)$ associated to mask g_n indeed satisfies the following two-scale difference equation.

$$\varphi(x) = \sum_k g_k \, \varphi(2x - k).$$

Although it can be shown [9] that a solution to this equation is not necessarily the limit function of the subdivision scheme with mask g_n, both approaches are closely related. In fact, the study of regularity of solutions to two-scale difference equations can be reduced, after suitable transformation [2], to that of limit functions $\varphi(x)$ of a binary subdivision scheme. However, the contents, formulation, and proofs of this paper differ notably from [8], [9]; Daubechies and Lagarias derive conditions for the existence of $\mathbf{L}^1$-solutions to two-scale difference equations and estimate global and local regularity of solutions that are, in fact, limit functions. This paper concentrates on the determination of *optimal* estimates for global regularity of limit functions, with interpretation in terms of discrete sequences and comparison with Fourier-based techniques. (Local regularity may also be investigated using the methods of this paper [19].)

It was pointed out to the author by one of the referees that the framework of this paper is very close to that of Dyn and Levin [14], [15]. I learned that several results were derived independently in [14], [15] for the study of C^N limit functions (see §§7 and 9).

2. Polynomial notation. Subdivision schemes have been mostly described using matrices or Fourier transforms [6], [8]–[11]. Throughout this paper we often use the polynomial description

$$U(X) = \sum_{n=0}^{L-1} u_n X^n$$

of any causal sequence u_n of length L ($u_n = 0$ for $n < 0$ and $n \geq L$). Since sequences of finite length can always be made causal by shifting, we assume all sequences causal in the following. This notation was adopted in [14], [15], which uses Laurent polynomials for noncausal sequences.

In polynomial notation, the up-scaling operator (1.1) reads

$$U(X) \xrightarrow{\mathcal{G}} V(X) = G(X)\, U(X^2), \tag{2.1}$$

which shows that it can be seen as resulting from two operations.

1. Change X to X^2 in $U(X)$, i.e., insert zeros between every two samples of u_n.
2. Multiply by $G(X)$, i.e., convolve the result with the mask g_n.

In other words, the operator (1.1), (2.1) "smooths" u_n at twice its rate, and (2.1) can be seen as a discrete version of a dilation by two: $f(x) \to f(x/2)$.

Iterating (2.1) gives the polynomial $G^j(X)$, associated to the sequence g_n^j (1.2).

$$G^j(X) = G(X)\, G(X^2)\, G(X^4) \cdots G(X^{2^{j-1}}). \tag{2.2}$$

This equation fully describes binary subdivision schemes in terms of polynomials (see §4 when the initial sequence is not δ_n). It can be rewritten in recursive form in two ways.

$$G^{j+1}(X) = G(X)\, G^j(X^2), \quad \text{i.e.,}\ g_n^{j+1} = \sum_k g_k^j\, g_{n-2k}, \tag{2.3}$$

$$G^{j+1}(X) = G^j(X)\, G(X^{2^j}), \quad \text{i.e.,}\ g_n^{j+1} = \sum_k g_k\, g_{n-2^j k}^j. \tag{2.4}$$

Both are useful in the sequel. Equation (2.3) is simply a rewriting of definition (1.2), while (2.4) links binary subdivision schemes to two-scale difference equations (see §5). We shall also consider (2.2) for polynomials other than $G(X)$. Given any polynomial $U(X)$, $U^j(X)$ (with a superscript index j) is

$$U^j(X) = U(X)\, U(X^2)\, U(X^4) \cdots U(X^{2^{j-1}}). \tag{2.5}$$

In this paper we use l^1 and l^∞-norms of discrete sequences in terms of polynomials,

$$\|U(X)\|_\infty = \max_k |u_k|,$$
$$\|U(X)\|_1 = \sum_k |u_k|,$$

and the following well-known inequality:

$$\|U(X)\, V(X)\|_\infty \leq \|V(X)\|_1 \|U(X)\|_\infty. \tag{2.6}$$

For polynomials with real coefficients, the following useful inequality holds whenever $V(X)$ has no roots *on* the unit circle.

$$\|U(X)\|_\infty \leq c_V\, \|U(X)\, V(X)\|_\infty, \tag{2.7}$$

where c_V is a constant depending only on $V(X)$.

Proof. This is trivially true for infinite sequences when the roots of $V(X)$ lie outside the unit circle; the constant c_V is then the converging l^1-norm of the Laurent series coefficients of $1/V(X)$, which is analytic in the complex-domain region $|X| \leq 1$. Here, since v_n is a sequence of finite length L, the index reversal $n \leftrightarrow L-1-n$ in v_n transforms roots of $V(X)$ inside the unit circle into roots outside the unit circle. Hence (2.7) holds when $V(X)$ has no roots *on* the unit circle. □

3. Definition of convergent subdivision schemes. Various definitions of convergent binary subdivision schemes have been proposed in the literature [6], [10]–[15], [17]. In this paper we restrict ourselves to pointwise or uniform convergence. It is easy to define a limit function in the case of interpolatory subdivision schemes as defined in the introduction: Since for such schemes one has $g_n^{j+1} = g_n^j$, the function $\varphi(x)$ can always be defined on dyadic rationals by

$$\varphi(n2^{-j}) = g_n^j. \tag{3.1}$$

For example, determining a continuous limit function amounts to finding a continuous extension of (3.1) to the real axis [11], [12].

The situation is more complex for general subdivision schemes since the values of g_n^j are not necessarily preserved as j increases. In order to "converge" to a limit function, the sequence g_n^j must be somehow interpolated. The idea is that the resulting sequence of functions of the continuous variable x, indexed by j, converges (pointwise or uniformly) to a limit function $\varphi(x)$ under some conditions on the mask g_n.

In [6], Daubechies chose to interpolate the sequence g_n^j by stepwise constant functions: she defined $\varphi(x)$ as the limit of $\varphi^j(x) = g^j_{\lfloor 2^j x + 1/2 \rfloor}$ as $j \to \infty$. Other kinds of interpolation are possible and yield similar results. Among possible choices are $g^j_{\lfloor 2^j x \rfloor}$, $g^j_{\lceil 2^j x \rceil}$, and the continuous linear interpolation function $\varphi^j_{\mathcal{L}}(x)$ obtained by connecting the points g_n^j by segments as in Figs. 2 and 3. All such interpolation functions $\varphi^j(x)$ agree at the "knots" $n2^{-j}$, i.e., $\varphi^j(n2^{-j}) = g_n^j$. In this paper we use a stronger definition that gives some flexibility on the way the subdivision scheme is interpolated.

DEFINITION 3.1. A binary subdivision scheme g_n^j (1.2) converges (pointwise) to a limit function $\varphi(x)$ if, for any sequence of integers n_j satisfying

$$|n_j 2^{-j} - x| \leq c\,2^{-j} \tag{3.2}$$

(where c is a constant independent of j), we have

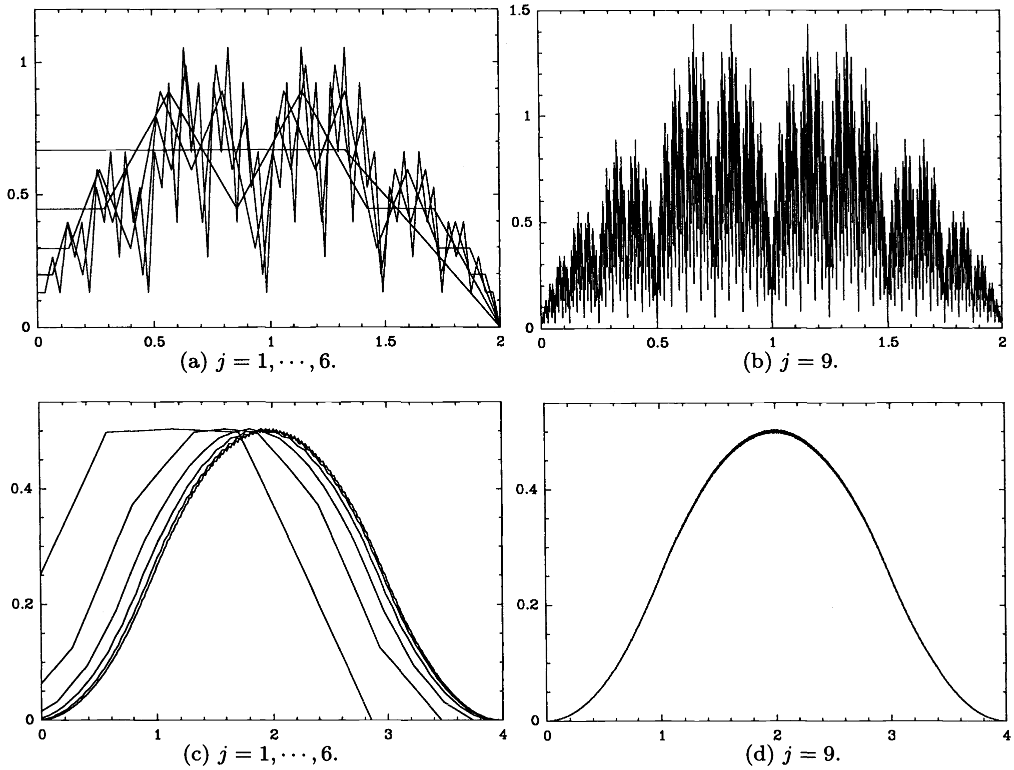
$$\varphi(x) = \lim_{j \to \infty} g^j_{n_j}. \tag{3.3}$$

The convergence is, moreover, *uniform* if

$$\sup_x |\varphi(x) - g^j_{n_j}| \to 0 \quad \text{as } j \to \infty. \tag{3.4}$$

Note that the sequence n_j depends on x, hence $g^j_{n_j}$ can be regarded as a function of x. The flexibility comes from the arbitrary choice of n_j satisfying (3.2)[1]. In particular,

[1] It seems natural to impose the more general condition $n_j 2^{-j} \to x$ as $j \to \infty$ in place of (3.2). But then $n_j - 2^j x$ is allowed to increase indefinitely as $j \to \infty$, and the resulting definition becomes too strong for deriving some of the results of this paper.



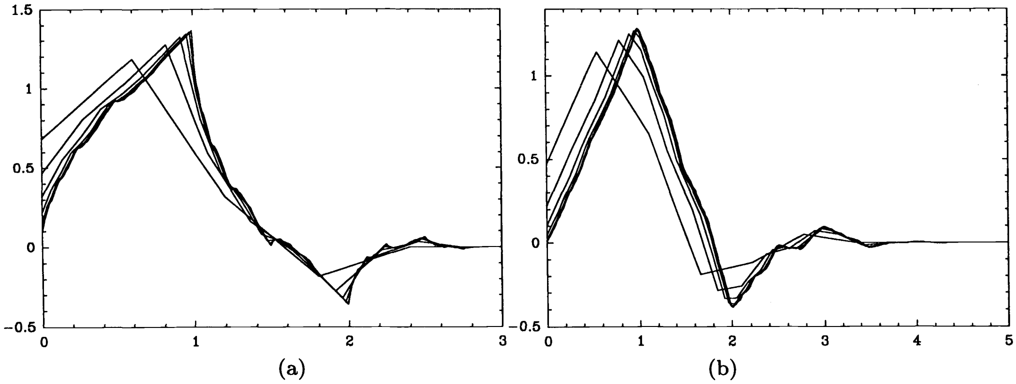
(a) $j = 1, \cdots, 6$.

(b) $j = 9$.

(c) $j = 1, \cdots, 6$.

(d) $j = 9$.

FIG. 2. *Two examples of diverging dyadic up-scaling schemes. Figures* (a), (c) *show six plots of the discrete sequences g^j_n ($j = 1, \cdots, 6$), represented with values joined by segments and plotted against $n2^{-j}$. Figures* (b), (d) *show the obtained curve after* 9 *iterations.* (a), (b) $g_0 = g_1 = g_2 = \frac{2}{3}$, $g_n = 0$ *elsewhere. Here* $G(-1) = \frac{2}{3} \neq 0$. *Note that up-scaling follows a fractal law.* (c), (d) $g_0 = g_4 = 0.5$, $g_1 = g_3 = 0.99$, $g_2 = 1$, $g_n = 0$ *elsewhere, renormalized such that* $G(1) = 2$. *Here* $G(-1) \approx 0.01$ *is so small that divergence is not obvious at the level of the figure. Divergence is here due to oscillations that occur in the graph of g^j_n. Although very small, these oscillations are so rapid that they preclude convergence.*



(a)

(b)

FIG. 3. *Two examples of converging dyadic up-scaling schemes (after* [6]). *The g^j_n's are plotted against $n2^{-j}$ for $j = 1, \cdots, 6$, with coefficients joined by segments, so that the behavior of the "slopes" can be observed.* (a) *The limit function is* $\dot{C}^{0.5500\cdots}$ *and not* C^1; *therefore, slopes are allowed to increase indefinitely near the peaks of the limit function.* (b) *The limit function is* $\dot{C}^{1.0878\cdots}$; *therefore,* C^1. *Slopes are constrained to be bounded, especially near the apparent "peaks" of the limit function.*

the above "stepwise interpolation" examples are recovered by letting $n_j = \lfloor 2^j x + \frac{1}{2} \rfloor$, $\lfloor 2^j x \rfloor$, $\lceil 2^j x \rceil$, respectively.

Convergence of the linear interpolations $\varphi^j_{\mathcal{L}}(x)$ of the g^j_n is also implied by Definition 3.1. This comes from the inequality $|\varphi^j_{\mathcal{L}}(x) - g^j_{n_j}| \leq |g^j_{n_j+1} - g^j_{n_j}|$, which holds for $n_j = \lfloor 2^j x \rfloor$ because $\varphi^j_{\mathcal{L}}$ is monotonous on each interval $[n2^{-j},\ (n+1)2^{-j}]$. From (3.3) this clearly implies $|\varphi^j_{\mathcal{L}}(x) - g^j_{n_j}| \to 0$; hence $|\varphi(x) - \varphi^j_{\mathcal{L}}(x)| \to 0$. Convergence of smoother interpolation functions such as splines are similarly implied by Definition 3.1.

Still another definition of convergence was proposed in [14], [15] by Dyn and Levin. For example, uniform convergence is expressed as the existence of a continuous function $\varphi(x)$ such that $\sup_n |g^j_n - \varphi(n2^{-j})| \to 0$ as $j \to \infty$. Note that this is implied by the uniform convergence of the linear interpolations $\varphi^j_{\mathcal{L}}(x)$; since the $\varphi^j_{\mathcal{L}}(x)$'s are continuous, their uniform limit is continuous and we have $\sup_n |g^j_n - \varphi(n2^{-j})| = \sup_n |\varphi^j(n2^{-j}) - \varphi(n2^{-j})|$, which $\to 0$ as $j \to \infty$.

Therefore, Definition 3.1 implies all the others. In fact, §7 shows that all definitions of uniform convergence presented in this section are equivalent. Since the results of this paper are mostly based on uniform convergence, they remain valid for various frameworks used in other works (in particular [6], [14]).

It is possible, however, to find examples for which *pointwise* convergence holds for one definition and not for another. Consider, for example, $G(X) = X$ for which $g^j_n = 1$ if $n = 2^j - 1$ and zero otherwise. Here pointwise convergence of stepwise—or linear—interpolations holds and we easily find that the limit exists and is $\varphi(x) \equiv 0$. (This is a typical example of a pointwise, nonuniform convergence to a continuous function.) But convergence does not hold for all x in the sense of Definition 3.1 because the scheme diverges for $x = 1$ (take $n_j = 2^j - 1$). Therefore, Definition 3.1 forbids "sharp discontinuities" about which $|g^j_{n_j+1} - g^j_{n_j}|$ does not tend to zero as $j \to \infty$.

The choice $G(X) = 1 + X$ behaves similarly. For $x \neq 0$ and $x \neq 1$, the scheme converges to a limit function equal to 1 for $0 < x < 1$, and zero for $x < 0$ or $x > 1$; however, depending on the choice of the definition of pointwise convergence, it either converges or diverges for $x = 0$ and $x = 1$.

4. Basic properties. Several basic properties and simplifications for the study of convergent binary subdivision schemes follow easily from the description (1.2), (2.2). First note that all functions considered in this paper are compactly supported because the mask g_n is of finite length L. In fact, we easily find that the length of g^j_n is $(2^j - 1)(L - 1) + 1$ by estimating the polynomial degree of (2.2). Therefore, $\varphi(x)$, if it exists, has compact support $[0,\ L - 1]$. This property makes many technical proofs easier.

Second, we can restrict the initial sequence in (1.2) to δ_n. For an arbitrary initial sequence of finite length h_n, (2.2) is simply multiplied by $H(X^{2^j})$:

$$H^j(X) = G^j(X)\, H(X^{2^j}). \tag{4.1}$$

The iterated sequence is, therefore, $h^j_n = \sum_k h_k\, g^j_{n-2^j k}$. From Definition 3.1, the limit function becomes $\psi(x) = \sum_k h_k \varphi(x - k)$ instead of $\varphi(x)$. Moreover, since both functions are compactly supported, $\varphi(x)$ itself can be written as $\varphi(x) = \sum_k (h^{-1})_k \psi(x - k)$, where $(h^{-1})_n$ is the convolutional inverse of h_n, i.e., $\sum_k (h^{-1})_k h_{n-k} = \delta_n$. The convergence and regularity properties of $\varphi(x)$ and $\psi(x)$ are, therefore, the same, and we can restrict ourselves to the study of the g_n^j's and $\varphi(x)$.[2]

In order that $\varphi(x)$ is well defined or does not vanish for all x, the iterated sequences g_n^j should neither diverge nor tend to zero as $j \to \infty$. The following proposition shows that this requires some basic conditions to be fulfilled by mask g_n.

PROPOSITION 4.1. If $\varphi(x) \neq 0$ exists for some $x \in \mathbf{R}$, then

$$\sum_k g_{2k} = \sum_k g_{2k+1} = 1, \quad \text{i.e., } G(1) = 2 \text{ and } G(-1) = 0. \tag{4.2}$$

Proof. The key point is to consider the even and odd-indexed sequences g_{2n}^j and g_{2n+1}^j separately. Let $y = x/2$ and $n_j = n_j(y)$ be a sequence of integers satisfying (3.2) for y. On one hand, from Definition 3.1, the common limit of $g_{2n_j}^j$ and $g_{2n_j+1}^j$ as $j \to \infty$ is $\varphi(2y) = \varphi(x)$. But from (2.3) we also have

$$g_{2n}^j = \sum_k g_{2k}\, g_{n-k}^{j-1},$$

$$g_{2n+1}^j = \sum_k g_{2k+1}\, g_{n-k}^{j-1}.$$

Letting $n = n_j$ and applying Definition 3.1 to the right-hand sides of these equations, we obtain that their respective limits as $j \to \infty$ are $(\sum_k g_{2k})\varphi(2y)$ and $(\sum_k g_{2k+1})\varphi(2y)$. By identification we therefore have

$$\varphi(2y) = \left(\sum_k g_{2k}\right)\varphi(2y) = \left(\sum_k g_{2k+1}\right)\varphi(2y).$$

Dividing the members of this equality by $\varphi(2y) \neq 0$ gives (4.2). □

Condition (4.2) may be interpreted as follows. On one hand, $G(1) = 2$ is just a normalization condition that ensures that the order of magnitude of g_n^j is preserved when $j \to \infty$. On the other hand, the fact that $G(X)$ must have at least one zero at $X = -1$ is a "local" requirement. For example, it ensures that the g_n^j's, for large j, do not rapidly oscillate in n between two different limits, $(\sum_k g_{2k})\varphi(2y)$ and $(\sum_k g_{2k+1})\varphi(2y)$. Figure 2 illustrates this phenomenon on a particular example (see also [20]).

Note that (4.2) is not sufficient to ensure convergence. As an example, consider $G(X) = 1 + X^3$. Here $G^j(X)$ is a polynomial in X^3; therefore, g_n^j vanishes for $n \neq 3k$ ($k \in \mathbf{Z}$), whereas $g_{3k}^j = 1$. It, therefore, cannot converge to a limit function. (Section 7 gives a necessary and sufficient condition for uniform convergence.)

5. Exact computation of limit functions.

Assume that the limit function $\varphi(x)$ of a binary subdivision scheme g_n^j exists for all $x \in \mathbf{R}$. This section derives a simple, easily implementable method for computing the *exact* values of $\varphi(x)$ at dyadic rationals $x = n2^{-j}$, $n \in \mathbf{Z}$, with a finite number of operations. The starting point is the *two-scale difference equation* [8], [9] satisfied by $\varphi(x)$:

$$\varphi(x) = \sum_k g_k\, \varphi(2x - k). \tag{5.1}$$

[2] Note that this restriction works only for initial sequences of *finite* length. If, e.g., $h_n = 1$ for all $n \in \mathbf{Z}$, then using the definition $h_n^{j+1} = \mathcal{G}\{h_n^j\}$ and Proposition 4.1, it easily follows by induction on j that $h_n^j \equiv 1$. Hence $\psi(x) = \sum_k \varphi(x - k) \equiv 1$ is C^∞, whatever the regularity order of $\varphi(x)$.

This equation, which was mentioned in the introduction, is easily derived by using (2.4) for $n = n_j$ (3.2) and applying Definition 3.1.

Now, let

$$\Phi^j(X) = \sum_n \varphi(n2^{-j})X^n \tag{5.2}$$

be the polynomial associated to the sequence $\varphi(n2^{-j})$. Taking $x = n2^{-j-1}$ in the two-scale difference equation yields $\varphi(n2^{-j-1}) = \sum_k g_k\, \varphi(2^{-j}(n - 2^j k))$, i.e., $\Phi^{j+1}(X) = \Phi^j(X)G(X^{2^j})$. By iteration we have

$$\Phi^j(X) = \Phi(X)G^j(X), \tag{5.3}$$

where

$$\Phi(X) = \Phi^0(X) = \sum_n \varphi(n)X^n. \tag{5.4}$$

Equation (5.3) is very useful, since it links the values of the iterated sequences g_n^j to the ones of the limit function $\varphi(n2^{-j})$. The latter are simply obtained from the g_n^j's by convolving them with the sequence $\varphi(n)$, provided that the $\varphi(n)$'s can be predetermined.

There are several methods for precomputing $\varphi(n)$, which is, by definition, the limit of $g_{n2^j}^j$ as $j \to \infty$. First note that we have, from (2.4),

$$g_{n2^{j+1}}^{j+1} = \sum_k g_k\, g_{(2n-k)2^j}^j = \mathcal{G}^*\{g_{n2^j}^j\},$$

where $\mathcal{G}^*$ is the following transposed operator [6], [18] of $\mathcal{G}$ (1.1):

$$u_n \xrightarrow{\mathcal{G}^*} v_n = \sum_{k\in\mathbf{Z}} g_k\, u_{2n-k}. \tag{5.5}$$

Therefore, $\varphi(n)$ can be determined as the limit of $(\mathcal{G}^*)^j\{\delta_n\}$ as $j \to \infty$.

Another method stems from the resulting equality

$$\varphi(n) = \mathcal{G}^*\{\varphi(n)\}. \tag{5.6}$$

The sequence $\varphi(n)$, $n = 0, \cdots, L-1$ (where L is the length of the mask g_n), is here determined, up to normalization, as the eigenvector of the operator $\mathcal{G}^*$ associated to the eigenvalue 1. To obtain a normalization for $\varphi(n)$, rewrite (5.5) under polynomial form

$$V(X^2) = (U(X)G(X) + U(-X)G(-X))/2. \tag{5.7}$$

Since we have, by Proposition 4.1, $G(1) = 2$, and $G(-1) = 0$, it follows that $\mathcal{G}^*$ preserves the sum of sequences; hence $\sum_n \varphi(n) = \sum_n g_{n2^j}^j = \sum_n g_{2n} = 1$, i.e.,

$$\Phi(1) = 1. \tag{5.8}$$

6. Stability. There is an exceptional class of limit functions $\varphi(x)$ for which the regularity estimates derived in this paper will not always be optimal. Optimality, as well as some other results of this paper, will be proven only in the case of "stability," in the sense of the following definition.

DEFINITION 6.1. A binary subdivision scheme converging to a nonzero limit function (or its limit function $\varphi(x) \not\equiv 0$) is *stable* if no root of $\Phi(X)$ (5.4) lies on the unit circle, i.e.,

$$\sum_n \varphi(n)\, e^{in\omega} \neq 0 \quad \text{for all } \omega \in \mathbf{R}.$$

The terminology "stable" comes from (2.6), (2.7) written for $V(X) = \Phi(X)$,

$$c_1 \,\|U(X)\|_\infty \leq \|U(X)\Phi(X)\|_\infty \leq c_2 \,\|U(X)\|_\infty,$$

which means that the filter of impulse response $\varphi(n)$ and its inverse are numerically stable for finite length sequences. The stability condition slightly restricts the choice of the scaling sequence g_n. For example, if the mask length is $L = 4$, "unstable" $\varphi(x)$'s are such that $g_0 = g_3$ and $g_1 = g_2$. All (real-valued) limit functions are stable for lengths up to 3. Note that an interpolatory subdivision scheme is always stable since it has the property that $\varphi(n/2) = g_n$ (see (3.1) for $j = 1$); hence $\Phi(X) \equiv 1$.

In fact, in the rest of this paper, stability can be replaced by the even weaker condition that there exists $x \in \mathbf{R}$ such that

$$\sum_n \varphi(n + x)\, e^{in\omega} \neq 0 \quad \text{for all } \omega \in \mathbf{R} \tag{6.1}$$

(a similar, but stronger stability condition appears in [15]). Condition (6.1) comes from (5.3) where n is replaced by $n + x$, for any fixed number x. That is,

$$\Phi_x^j(X) = \Phi_x(X) G^j(X)$$

where

$$\Phi_x^j(X) = \sum_n \varphi((n + x)2^{-j}) X^n$$

and $\Phi_x(X) = \Phi_x^0(X)$.

Although almost all convergent subdivision schemes are stable, it is easy to construct unstable ones (even with definition (6.1)). As in the preceding section we have the following generalization of (5.6), (5.7).

$$\Phi_x(X^2) = (\Phi_{2x}(X)G(X) + \Phi_{2x}(-X)G(-X))/2.$$

Therefore, any polynomial mask $G(X)$ divisible by $(X^2 - e^{i\omega})$, $\omega \neq 0$, yields unstability since we have $\Phi_x(e^{i\omega}) = 0$.

I conjecture that the converse holds, i.e., stability (in the weak form (6.1)) is equivalent to the condition that $G(X)$ has no pair of opposite zeros $(e^{i\omega/2},\ e^{i(\omega/2+\pi)})$ on the unit circle. If this conjecture is true, then the regularity estimates presented below will be optimal under the simple condition above on the mask coefficients g_n, which is easy to check. When this condition is not satisfied, it is possible to apply a trick as shown at the end of §9 which allows one to consider another, *stable* binary subdivision scheme which has the same regularity properties.

7. Continuous limit functions. The framework of uniform convergence (3.4) is shown to be very convenient in the sequel, and the following theorem shows that all stable continuous limit functions are obtained by uniform convergence. We shall then derive a necessary and sufficient condition for uniform convergence in all cases.

THEOREM 7.1. *Assume that a binary subdivision scheme converges pointwise to a limit function $\varphi(x)$ for all $x \in \mathbf{R}$. If the convergence is uniform, then $\varphi(x)$ is continuous. The converse is true if $\varphi(x)$ is stable.*

Proof. ($\Rightarrow$) In §3 we have seen that uniform convergence (3.4) implies uniform convergence of linear interpolations $\varphi^j_{\mathcal{L}}(x)$ of the g^j_n's to $\varphi(x)$. Since this is a uniformly convergent sequence of compactly supported continuous functions, $\varphi(x)$ is continuous.

($\Leftarrow$) We have

$$\sup_x |\varphi(x) - g^j_{n_j}| \leq \sup_x |\varphi(x) - \varphi(n_j 2^{-j})| + \sup_{n_j} |\varphi(n_j 2^{-j}) - g^j_{n_j}|$$

where n_j is a sequence of integers satisfying (3.2). Since $\varphi(x)$ is compactly supported and continuous, it is uniformly continuous. Therefore $\sup_x |\varphi(x) - \varphi(n_j 2^{-j})| \to 0$. The other term can be written $\sup_n |\varphi(n2^{-j}) - g^j_n| = \|\Phi^j(X) - G^j(X)\|_\infty$. From (5.3) we have $\Phi(X)(\Phi^j(X) - G^j(X)) = (\Phi(X) - 1)\Phi^j(X)$. Since (5.8) holds, $X - 1$ divides $\Phi(X) - 1$ and we can write, using (2.6), $\|\Phi(X)(\Phi^j(X) - G^j(X))\|_\infty \leq c\,\|(X-1)\,\Phi^j(X)\|_\infty$. The latter norm is $\sup_n |\varphi(n2^{-j}) - \varphi((n-1)2^{-j})|$, which tends to zero as $j \to \infty$ because $\varphi(x)$ is uniformly continuous. Now we can use (2.7) with $V(X) = \Phi(X)$ since $\Phi(X)$ is stable. This yields $\|\Phi^j(X) - G^j(X)\| \to 0$ as $j \to \infty$, which ends the proof. □

It is an open problem to find a limit function $\varphi(x)$ for which the convergence is not uniform (in the sense of Definition 3.1). That would imply that $\varphi(x)$ is unstable or discontinuous.

We now derive a necessary and sufficient condition for uniform convergence of a binary subdivision scheme g^j_n to a (continuous) limit function $\varphi(x)$. (By Theorem 7.1, this also gives a necessary and sufficient condition for the continuity of a stable limit function.) We need the following lemma, which will also be useful for deriving an optimal regularity estimate in §11.

LEMMA 7.2. *Assume $G(-1) = 0$ and let $F(X) = G(X)/(1+X)$. The sequence of the first-order differences of g^j_n,*

$$d^j_n = g^j_n - g^j_{n-1},$$

follows a binary subdivision scheme with polynomial mask $F(X)$ and initial sequence's polynomial $1 - X$.

In addition, for any fixed positive integer i, we have

$$\max_n |g^j_{n+1} - g^j_n| \leq c \left(\max_{0 \leq n \leq 2^i - 1} \sum_k |f^i_{n-2^i k}| \right)^{j/i}, \tag{7.1}$$

where f_n is the mask associated to the polynomial $F(X)$ and c is a constant independent of j.

Proof. Let $D^j(X) = (1-X)G^j(X)$ be the polynomial associated to d^j_n. We have

$$\begin{aligned} D^j(X) &= (1-X)(1+X)(1+X^2)\cdots(1+X^{2^{j-1}})\,F^j(X) \\ &= (1-X^{2^j})F^j(X), \end{aligned}$$

which shows, by (4.1), that d_n^j follows the announced subdivision scheme.

Using (2.2) in the above equation, we can write $D^{i+\ell}(X) = F^i(X)\, D^\ell(X^{2^i})$, which also reads $d_n^{i+\ell} = \sum_k f_{n-2^ik}^i d_k^\ell$. Majorating yields

$$\|D^{i+\ell}(X)\|_\infty \le \left(\max_n \sum_k |f_{n-2^ik}^i|\right) \|D^\ell(X)\|_\infty,$$

which, by iteration for $j = \ell + ni$, $0 \le \ell \le i-1$, gives (7.1) where c depends only on the fixed integers i and ℓ. □

THEOREM 7.3. *A binary subdivision scheme g_n^j converges uniformly to a (continuous) limit function if and only if $G(1) = 2$, $G(-1) = 0$ and*

$$\max_n |g_{n+1}^j - g_n^j| \to 0 \quad \text{as } j \to \infty. \tag{7.2}$$

Moreover, there exists $\alpha > 0$ such that

$$\max_n |g_{n+1}^j - g_n^j| \le c\, 2^{-j\alpha}. \tag{7.3}$$

Proof. (⇒) immediately results from Proposition 4.1 and the inequality

$$\max_n |g_{n+1}^j - g_n^j| \le \sup_x |\varphi(x) - g_{n_j+1}^j| + \sup_x |\varphi(x) - g_{n_j}^j|.$$

(⇐) We first prove that (7.3) is implied by conditions $G(1) = 2$, $G(-1) = 0$ and (7.2). First note that from the first part of Lemma 7.2 we have $(1-X)G^j(X) = (1-X^{2^j})F^j(X)$, i.e., $g_n^j - g_{n-1}^j = f_n^j - f_{n-2^j}^j$. Write

$$\begin{aligned} f_n^j &= (f_n^j - f_{n-2^j}^j) + (f_{n-2^j}^j - f_{n-2\cdot 2^j}^j) + \cdots \\ &= (g_n^j - g_{n-1}^j) + (g_{n-2^j}^j - g_{n-2^j-1}^j) + \cdots. \end{aligned}$$

The number of terms in the sums is bounded by L because the length of f_n^j is bounded by 2^jL. From (7.2) each term tends to zero uniformly with respect to n; hence so does f_n^j. Therefore, there exists a (sufficiently large) index i such that $\max_n |f_n^i| \le \varepsilon_i < 1/L$. Now since the number of terms in the sum in (7.1) is bounded by L, the second part of Lemma 7.2 gives (7.3) with $\alpha = -\log_2(L\varepsilon_i)/i > 0$.

To prove the converse part of the theorem, consider $\sup_{n_j} |g_{n_{j+1}}^{j+1} - g_{n_j}^j|$, where n_j satisfies (3.2). This equals $\sup_{n_j} |g_{2n_j+m_j}^{j+1} - g_{n_j}^j|$, where $m_j = n_{j+1} - 2n_j$ is a bounded integer. Now, from (2.3) we can write $g_{2n+m}^{j+1} = \sum_k g_{2k+m}\, g_{n-k}^j$. Therefore, the sequence $g_{2n+m}^{j+1} - g_n^j$ is a convolved version of g_n^j; its associated polynomial can be written in the form $U_m(X)G^j(X)$. But from (4.2), we have $\sum_k g_{2k+m} = 1$ (for all m), and, therefore, $U_m(1) = 0$. Using (2.6), it follows that

$$\sup_{n_j} |g_{2n_j+m_j}^{j+1} - g_{n_j}^j| = \|U_{m_j}(X)G^j(X)\|_\infty \le c'\, \|(1-X)G^j(X)\|_\infty,$$

where c' is a constant (independent of j since m_j is bounded). From (7.3) the latter norm is bounded by $c\,c'\,2^{-j\alpha}$. We, therefore, end up with $\sup_{n_j} |g_{n_{j+1}}^{j+1} - g_{n_j}^j| \le cc'\,2^{-j\alpha}$. Iterating this inequality, we obtain, for any $\ell > 0$,

$$\sup_{n_j} |g_{n_{j+\ell}}^{j+\ell} - g_{n_j}^j| \le c\,c'\,(2^{-(j+\ell-1)\alpha} + \cdots + 2^{-(j+1)\alpha} + 2^{-j\alpha}) \le c''\,2^{-j\alpha}, \tag{7.4}$$

which shows that the sequence of functions $g^j_{n_j(x)}$ is a uniform Cauchy sequence, which converges uniformly to a continuous limit function $\varphi(x)$. □

This theorem has several interesting consequences. First, we shall see in §8 that (7.3), in fact, implies that $\varphi(x)$ is Lipschitz of order α, which is stronger than continuity.[3] Therefore, by Theorem 7.1, a continuous stable limit function is automatically Lipschitz of order α for some $\alpha > 0$.

Second, note that the necessary and sufficient condition is quite weak and intuitive: it is sufficient that the differences $g^j_{n+1} - g^j_n \to 0$ uniformly as $j \to \infty$ to obtain a continuous limit function.[4] In fact, we easily find that (7.2) holds for any definition of uniform convergence presented in §3.1. (For example, any uniformly convergent sequence of interpolating functions $\varphi^j(x)$ of the g^j_n's such that $g^j_n = \varphi^j(n2^{-j})$ clearly gives (7.2).) Since we have seen that Definition 3.1 for uniform convergence implies the others, it follows that *all* these definitions of uniform convergence are equivalent.

In particular, some results derived in this paper have been derived in the framework of Dyn and Levin [14], [15] as well. The necessary and sufficient condition (7.2) appears in [14] for interpolatory subdivision schemes and was first derived in [15, Thm. 3.2] for general binary subdivision schemes—using the (apparently) weaker definition mentioned in §3.1—in a slightly different but equivalent form, namely, $\max_n |f^j_n| \to 0$ as $j \to \infty$. Theorem 7.3 was included here in order that this paper be self-contained, since some material presented in this section is also useful in the sequel.

8. Lipschitz limit functions. In this section we want to characterize Lipschitz limit functions. Recall that $\varphi(x)$ is said to be *Lipschitz of order* α $(0 < \alpha \leq 1)$, $\varphi(x) \in \dot{C}^\alpha$, if we have for all x and $h \in \mathbf{R}$,

$$(8.1) \qquad |\varphi(x+h) - \varphi(x)| \leq c\,|h|^\alpha,$$

where c is a constant. Here, $\varphi(x)$ is compactly supported, and (8.1) needs to be satisfied only for small h's. Since the spaces $\dot{C}^\alpha$, for $0 < \alpha \leq 1$, interpolate between C^0 and C^1, a $\dot{C}^\alpha$-function will be said to be *regular of order* α. There is a slight irritation in that C^1 and $\dot{C}^1$ do not coincide; for example, a linear spline function is $\dot{C}^1$ but not differentiable at its knots.

THEOREM 8.1. *If* $G(1) = 2$, $G(-1) = 0$, *and*

$$(8.2) \qquad \max_n |g^j_{n+1} - g^j_n| \leq c\,2^{-j\alpha}$$

for some $0 < \alpha \leq 1$, *then the binary subdivision scheme converges uniformly to a* $\dot{C}^\alpha$ *limit function. The converse is true if* $\varphi(x)$ *is stable.*

In addition, the more regular the limit, the faster the convergence to this limit:

$$(8.3) \qquad \sup_x |\varphi(x) - g^j_{n_j}| \leq c\,2^{-j\alpha}$$

for any sequence n_j *of integers satisfying* (3.2).

Proof. (⇒) Let us first prove (8.3). Since (8.2) holds, we are in the framework of Theorem 7.3, and (7.4) holds. Letting $\ell \to \infty$ in (7.4) gives (8.3).

[3] Using the same proof as the one of Theorem 7.3, we can show that when (3.2) is replaced by $n_j 2^{-j} \to x$ as $j \to \infty$, uniform convergence requires (7.3) for $\alpha = 1$, which corresponds to almost continuously differentiable functions.

[4] In contrast, the *slopes* $(g^j_{n+1} - g^j_n)/(2^{-j})$ may indefinitely increase (see next section).

We now prove that $\varphi(x)$ is $\dot{C}^\alpha$. Let $n_j = n_j(x)$ satisfy (3.2) (for all $x \in \mathbf{R}$) and consider the inequality

$$\begin{aligned}\sup_x |\varphi(x+h) - \varphi(x)| &\le \sup_x |\varphi(x+h) - g^j_{n_j(x+h)}| \\ &\quad + \sup_x |g^j_{n_j(x+h)} - g^j_{n_j(x)}| + \sup_x |g^j_{n_j(x)} - \varphi(x)|.\end{aligned}$$

By (8.3), the first and third terms in the right-hand side of this inequality are bounded by $c2^{-j\alpha}$. Assume, for example, that $|h| < 1$. If $h > 0$, choose $n_j(x) = \lfloor x2^j \rfloor$, otherwise choose $n_j(x) = \lceil x2^j \rceil$. A simple calculation yields $|n_j(x+h) - n_j(x)| \le |n_j(h)| + \varepsilon$, where $\varepsilon = 0$ or ± 1. Now, let j be such that $2^{-j} \le |h| < 2^{-j+1}$. This gives $|n_j(h)| = 1$; hence we find, from (8.2), that $\sup_x |g^j_{n_j(x+h)} - g^j_{n_j(x)}| \le c2^{-j\alpha}$. Putting all inequalities together yields $\sup_x |\varphi(x+h) - \varphi(x)| \le c'2^{-j\alpha} \le c|h|^\alpha$, i.e., $\varphi(x)$ is $\dot{C}^\alpha$.

($\Leftarrow$) $G(1) = 2$, $G(-1) = 0$ result from Proposition 4.1. Since $\varphi(x)$ is $\dot{C}^\alpha$, we have $|\varphi((n+1)2^{-j}) - \varphi(n2^{-j})| \le c2^{-j\alpha}$, i.e.,

$$\|(1-X)\Phi^j(X)\|_\infty = \|\Phi(X)(1-X)G^j(X)\|_\infty \le c2^{-j\alpha}$$

(the first equality comes from (5.3)). Because $\varphi(x)$ is stable, we can apply (2.7) to obtain the inequality $\|(1-X)G^j(X)\|_\infty \le c'\,2^{-j\alpha}$, which is (8.2). □

This theorem provides an intuitive interpretation of regularity of order $0 \le \alpha < 1$ for binary subdivision schemes: regularity $\dot{C}^\alpha$ holds if and only if the absolute values of the "slopes" $(g^j_{n+1} - g^j_n)/2^{-j}$ of the discrete curves g^j_n's (see next section) grow less than $2^{j(1-\alpha)}$ when j indefinitely increases. For example, if the slopes of g^j_n are always bounded for all j's, then $\varphi(x)$ is $\dot{C}^1$. On the contrary, less regularity allows slopes to increase indefinitely and the resulting limit function, although continuous, may present a "fractal" structure as shown in Fig. 3. Note that in this case, (8.3) means that uniform convergence of the curves g^j_n is slower as slopes increase faster.

As an example, consider the convergence of binary subdivision schemes in the case of positive masks $g_n > 0$, $n = 0, \cdots, L-1$, as studied by Micchelli and Prautzsch in [17]. They found that

$$\sup_{0 \le n-m \le L-2} |g^j_m - g^j_n| \le c\,(1 - \min g_n)^j;$$

hence any binary subdivision scheme with positive mask uniformly converges to a continuous function [17]. Theorem 8.1 immediately applies to show that the limit function is, in fact, $\dot{C}^\alpha$, where $\alpha = -\log_2(1 - \min g_n)$.

Since we have a characterization of regularity for stable $\varphi(x)$'s, it is easy to find a condition on g_n that states an exact regularity order $0 < \alpha < 1$.

COROLLARY 8.2. *Let g_n be a stable binary subdivision scheme such that $G(1) = 2$ and $G(-1) = 0$. If, for $0 < \alpha < 1$,*

$$\max_n |g^j_{n+1} - g^j_n| \text{ decreases as } 2^{-j\alpha} \quad \text{when } j \to \infty, \tag{8.4}$$

then the limit function $\varphi(x)$ is $\dot{C}^\alpha$ but is not $\dot{C}^{\alpha+\varepsilon}$, for any $\varepsilon > 0$.

Proof. This is an immediate consequence of Theorem 8.1. If $\varphi(x)$ were $\dot{C}^{\alpha+\varepsilon}$ (with $\varepsilon > 0$ small enough so that $\alpha + \varepsilon < 1$), we would have $|g^j_{n+1} - g^j_n| \le c2^{-j(\alpha+\varepsilon)}$, which contradicts (8.4). □

Note that Corollary 8.2 does not hold if $\alpha = 1$, since $|g^j_{n+1} - g^j_n|$ cannot decrease faster than 2^{-j} as $j \to \infty$ when $\varphi(x)$ is more regular than C^1 (see §10). Otherwise, intuitively the derivative of $\varphi(x)$ would vanish identically, which would imply $\varphi(x) = 0$ since $\varphi(x)$ is compactly supported.

9. Continuously differentiable limit functions. In this section, we study the derivatives of the limit function $\varphi(x)$. We start by defining finite differences of the g^j_n's, which will be shown to converge to the derivatives of $\varphi(x)$. The first finite difference is

$$\Delta g^j_n = (g^j_n - g^j_{n-1})/2^{-j}, \quad \text{i.e.,} \ \Delta G^j(X) = 2^j(1-X)G^j(X). \tag{9.1}$$

In other words, the Δg^j_n's are the *slopes* of the "discrete curve" g^j_n plotted against $n2^{-j}$ (see Figs. 2 and 3). Finite differences $\Delta^k g^j_n$ of order k are simply obtained by applying k times the difference operator Δ:

$$\Delta^k G^j(X) = 2^{jk}(1-X)^k G^j(X). \tag{9.2}$$

In order to study finite differences $\Delta^k g^j_n$ similarly, as for the g^j_n's, it is convenient to express them as binary subdivision schemes as well, associated to masks other than g_n. The following lemma shows that this is possible when $G(X)$ has enough zeros at $X = -1$.

LEMMA 9.1. *Assume $G(X)$ has at least k zeros at $X = -1$ and define $G_k(X)$ by*

$$G(X) = \left(\frac{1+X}{2}\right)^k G_k(X). \tag{9.3}$$

Then the finite differences $\Delta^k g^j_n$'s follow a binary subdivision scheme with the initial sequence's polynomial $(1-X)^k$ and polynomial mask $G_k(X)$.

Proof. This is an immediate generalization of the first part of Lemma 7.2. From (9.2), (9.3), we have

$$\Delta^k G^j(X) = 2^{jk}(1-X)^k \prod_{i=0}^{j-1} \left(\frac{1+X^{2^i}}{2}\right)^k G^j_k(X),$$

where $G^j_k(X) = (G_k)^j(X)$ is defined by (2.5). Using the identity $(1-Y)(1+Y) = 1 - Y^2$ for $Y = X, X^2, X^4, \cdots$, we obtain

$$\Delta^k G^j(X) = G^j_k(X)(1 - X^{2^j})^k, \tag{9.4}$$

which from (4.1) proves the lemma. □

Using the preceding sections we can extend the results of §7 to higher-order regularity C^N (N-times continuously differentiable functions).

THEOREM 9.2. *If the sequence of the Nth-order finite differences $\Delta^N g^j_{n_j}$ (where n_j satisfies (3.2)) uniformly converges as $j \to \infty$, then $\varphi(x)$ is C^N. The converse is true if $\varphi(x)$ is stable.*

In addition, $\Delta^k g^j_{n_j}$ (where n_j satisfies (3.2)) converges uniformly to $\varphi^{(k)}(x)$, the kth-order derivative of $\varphi(x)$, for $k = 0, \cdots, N$, and $G(X)$ has at least $N+1$ zeros at $X = -1$.

Proof. ($\Rightarrow$) Let us first prove uniform convergence of the kth-order finite differences ($k = 0, \cdots, N$) by backward induction on k. We show that if $\Delta^{k+1} g^j_n$ converges uniformly to some (continuous) function $h(x)$, then $\Delta^k g_n^j$ converges uniformly to the primitive of $h(x)$ defined by

$$H(x) = \int_{-\infty}^{x} h(u)\, du.$$

For simplicity we assume $k = 0$, the proof being identical for $k > 0$.

First we prove that $H(x)$ is compactly supported. The functions $\Delta g^j_{\lfloor x2^j \rfloor}$ are all Riemann-integrable and converge uniformly to the function $h(x)$ of compact support $[0; L-1]$ (where L is the length of g_n); therefore,

$$\int_0^{L-1} \Delta g^j_{\lfloor x2^j \rfloor}\, dx = \sum_n 2^{-j} \Delta g_n^j \text{ tends to } \int_0^{L-1} h(u)\, du \quad \text{as } j \to \infty.$$

But since $\Delta G^j(1) = 0$ (see (9.4)), these integrals vanish, which shows that $H(x)$ is compactly supported.

Now, since $H(x)$ is C^1 and has compact support, it is uniformly continuously differentiable and, therefore, $\sup_x |\Delta g^j_{n_j} - \big(H(n_j 2^{-j}) - H((n_j - 1)2^{-j})\big)/2^{-j}|$ tends to zero as $j \to \infty$, where n_j are integers satisfying (3.2). This can be written

$$\|2^j(1-X)(G^j(X) - \Psi^j(X))\|_\infty \to 0,$$

where $\Psi^j(X)$ is the polynomial associated to the sequence $H(n2^{-j})$. But for any polynomial $U(X)$, we have

$$\|U(X)\|_\infty \le \sum_k |u_k - u_{k-1}| \le d\, \|(1-X)U(X)\|_\infty,$$

where d is the degree of the polynomial $U(X)$. Applying this to $U(X) = G^j(X) - \Psi^j(X)$ of degree $(L-1)(2^j - 1)$, we obtain $\sup_{n_j} |g^j_{n_j} - H(n_j 2^{-j})| = \|G^j(X) - \Psi^j(X)\|_\infty \le (L-1)\|2^j(1-X)(G^j(X) - \Psi^j(X))\|_\infty$, which tends to zero; therefore, g_n^j converges uniformly to $\varphi(x) = H(x)$, and $h(x)$ is the derivative of $\varphi(x)$. By induction it follows that the kth-order finite differences converge uniformly to the kth-order derivatives of $\varphi(x)$ for $0 \le k \le N$.

In particular, the continuous uniform limit of $\Delta^N g_n^j$ is $\varphi^{(N)}(x) \in C^0$. Therefore, $\varphi(x)$ is C^N. The property that $G(X)$ has at least $N+1$ zeros at $X = -1$ follows easily by forward induction on the derivative order k as a consequence of Proposition 4.1 and Lemma 9.1.

($\Leftarrow$) We prove uniform convergence of the kth-order finite differences to the kth-order derivative of $\varphi(x)$ ($k = 0, \cdots, N$), from the assumption that $\varphi(x)$ is stable and C^N, by forward induction on k. For $k = 0$, this is true by Theorem 7.1. It remains to prove that this implies $\sup_x |\varphi^{(k)}(x) - \Delta^k g^j_{n_j}| \to 0$ for $k = 1, \cdots, N$, where n_j satisfies (3.2). For simplicity, assume $k = 1$. The proof is identical for larger k's when one replaces Δ by Δ^k. Define $\Delta\Phi^j(X) = 2^j(1-X)\Phi^j(X)$, where $\Phi^j(X)$ is defined by (5.2), i.e., $\Delta\varphi(n_j 2^{-j}) = 2^j(\varphi(n_j 2^{-j}) - \varphi((n_j - 1)2^{-j}))$. We have

$$\begin{aligned} \sup_x |\varphi'(x) - \Delta g^j_{n_j}| &\le \sup_x |\varphi'(x) - \varphi'(n_j 2^{-j})| \\ &\quad + \sup_x |\varphi'(n_j 2^{-j}) - \Delta\varphi(n_j 2^{-j})| \\ &\quad + \sup_x |\Delta\varphi(n_j 2^{-j}) - \Delta g^j_{n_j}|. \end{aligned} \tag{9.5}$$

The first term in the right-hand side of (9.5) tends to zero as $j \to \infty$ because $\varphi'(x)$ is continuous and compactly supported, hence uniformly continuous. The second term also tends to zero because $\varphi(x)$ is uniformly continuously differentiable on a compact support. Note that this implies

$$\sup_{n_j} |\Delta\varphi(n_j 2^{-j}) - \Delta\varphi((n_j - 1)2^{-j})| = \|(1 - X)\Delta\Phi^j(X)\|_\infty \to 0. \tag{9.6}$$

The third term in the right-hand side of (9.5) can be written as $\|\Delta\Phi^j(X) - \Delta G^j(X)\|_\infty$. But from (5.3) we have $\Phi(X)(\Delta\Phi^j(X) - \Delta G^j(X)) = (\Phi(X) - 1)\Delta\Phi^j(X)$. Since $\Phi(1) = 1$ (5.8), $X - 1$ divides $\Phi(X) - 1$ and we can write, using the norm inequality (2.6), $\|\Phi(X)(\Delta\Phi^j(X) - \Delta G^j(X))\|_\infty \leq c\,\|(X - 1)\Delta\Phi^j(X)\|_\infty$, which tends to zero by (9.6). Now we can use (2.7) with $V(X) = \Phi(X)$ because $\varphi(x)$ is stable. This yields $\|\Delta\Phi^j(X) - \Delta G^j(X)\|_\infty \to 0$ as $j \to \infty$, which ends the proof. □

The direct part of this theorem already appeared in [14], [15]. The converse part also appeared in [14], [15] for interpolatory subdivision schemes (we have seen in §6 that interpolatory subdivision schemes are stable.)

This theorem is useful because it allows us to estimate the regularity of the derivatives of a stable limit function $\varphi(x)$ the same way as for $\varphi(x)$ itself: if $G(X)$ has enough zeros at $X = -1$, the finite differences of the g_n^j's, which converge to the derivatives of $\varphi(x)$, all follow binary subdivision schemes.

Theorem 9.2 also provides an *upper bound* for regularity. Since it is necessary that $G(X)$ has $N + 1$ zeros at $X = -1$ to obtain C^N stable limit functions $\varphi(x)$, the regularity order of $\varphi(x)$ is always bounded by the number of zeros at $X = -1$ in $G(X)$. We shall see that this upper bound may be attained.

However, it is important to note that imposing zeros at $X = -1$ in $G(X)$ does *not* ensure any regularity in general. It does not even ensure convergence, as in the example $G(X) = (1 + X^3)^{N+1}$, which has $N + 1$ zeros at $X = -1$, although g_n^j does not converge for the same reason as for the choice $G(X) = 1 + X^3$ treated in §4. (Section 13 derives a sharp upper bound for regularity.)

Finally, note that the number of zeros of $G(X)$ at $X = -1$ is an upper bound for regularity only for *stable* limit functions. This upper bound may be exceeded for unstable limit functions, as shown in the following example [2], for which the converse part of Theorem 9.2 fails—as well as many other "optimality" results given in the rest of this paper.

Consider the polynomial mask $G(X) = 2^{-N}(1 + X)(1 + X^2)^N$. Setting $U_j(X) = 1 + X + X^2 + \cdots + X^{2^j - 1}$ and applying (2.6) several times give

$$\begin{aligned} \|(1 - X)G^j(X)\|_\infty &\leq 2^{-jN}\|(1 - X^{2^j})\|_1 \|(U_j(X^2))^N\|_\infty \\ &\leq 2^{-jN+1}\|U_j(X)\|_1^{N-1}\|U_j(X)\|_\infty \\ &\leq 2^{-j+1}; \end{aligned}$$

therefore, by Theorem 8.1 the limit function $\varphi(x)$ exists and is $\dot{C}^1$, hence continuous. Theorem 9.2 cannot improve this regularity order since $G(X)$ has only one zero at $X = -1$. However, $\varphi(x)$ is unstable since $1 + X^2$ divides $G(X)$ (see §6), so we might expect higher regularity for $\varphi(x)$.

Now consider another mask $\tilde{G}(X) = 2^{-N}(1 + X)^{N+1}$. It is easy to see that the subdivision scheme $\tilde{g}_n^j$ converges to a $\dot{C}^N$ limit function $\tilde{\varphi}(x)$, i.e., the $(N-1)$th derivative of $\tilde{\varphi}(x)$, for which the mask polynomial is $\tilde{G}_{N-1}(X) = (1+X)^2/2$, is $\dot{C}^1$. This comes from Theorems 8.1 and 9.2 since we have $\|(1 - X)\tilde{G}_{N-1}^j\| \leq$

$2^{-j}\|(1-X^{2^j})\|_1\|U_j(X)\|_\infty \le 2^{-j+1}$. Now, since the two masks are related by $(1+X)^N G(X) = (1+X^2)^N \tilde{G}(X)$, we have by iteration $(1+X)^N G^j(X) = (1+X^{2^j})^N \tilde{G}^j(X)$, i.e.,

$$\sum_{k=0}^{N} \binom{N}{k} g^j_{n-k} = \sum_{k=0}^{N} \binom{N}{k} \tilde{g}^j_{n-2^j k}.$$

Letting $n = n_j$ and $j \to \infty$ gives, by Definition 3.1,

$$\varphi(x) = 2^{-N} \sum_{k=0}^{N} \binom{N}{k} \tilde{\varphi}(x-k),$$

which proves that $\varphi(x)$ is $\dot{C}^N$, hence C^{N-1}, even though $G(X)$ has only one zero at $X=-1$.

This example shows that an unstable binary subdivision scheme may converge to an arbitrary regular limit function while *all* finite differences diverge. Note that since $\tilde{\varphi}(x)$ can also be expressed as a sum of integer translates of $\varphi(x)$ (see the beginning of §4.1), both functions have the same regularity order. It is easy to check that the regularity estimate $\dot{C}^N$ is optimal for $\tilde{\varphi}(x)$ (which is, in fact, the B-spline of degree N [15]); hence it is also optimal for $\varphi(x)$.

Therefore, the argument used in this example has led to an optimal regularity estimate for an *unstable* limit function, while the rest of this paper derives regularity estimates that are optimal for all *stable* limit functions. This example can be easily generalized to the case where unstability is due to the fact that $G(X)$ is divisible by $X^2 - e^{i\omega}$ (see §6). Note that if the conjecture mentioned in §6 is true, then this methods works for arbitrary unstable limit functions (in the sense of (6.1)).

10. Determining the exact Hölder regularity order. Recall the definition of Hölder regularity. The limit function $\varphi(x)$ is regular of order $r = N + \alpha$ $(0 < \alpha \le 1)$, $\varphi(x) \in \dot{C}^r$, if it is C^N and its Nth derivative $\varphi^{(N)}(x)$ is Lipschitz of order α, $\varphi^{(N)}(x) \in \dot{C}^\alpha$, as defined earlier by (8.1). Hölder spaces $\dot{C}^r$ generalize the spaces C^N of N-times continuously differentiable functions. As already mentioned in the case $N=1$, $\dot{C}^N$ contains functions that are not C^N, such as spline functions of degree N. In fact "$\varphi(x)$ is $\dot{C}^N$" can be thought of as "$\varphi(x)$ is almost C^N," since if $\varphi(x)$ is $\dot{C}^{N+\varepsilon}$, for some $\varepsilon > 0$, then $\varphi(x)$ is truly C^N. Other spaces, based on the Fourier transform of $\varphi(x)$, are sometimes used to define a regularity order $r \in R$ as well. They will be considered later in §17.

Using the results of the preceding sections, we can extend the characterization of Lipschitz limit functions $\dot{C}^\alpha$ $(0 < \alpha \le 1)$, derived in §8, to any Hölder regularity order $r > 0$.

THEOREM 10.1. *If $G(1) = 2$, $G(X)$ has at least $N+1$ zeros at $X=-1$ and*

$$\max_n |\Delta^N g^j_{n+1} - \Delta^N g^j_n| \le c\,2^{-j\alpha} \tag{10.1}$$

for some $\alpha > 0$, then $\varphi(x)$ is $\dot{C}^{N+\alpha}$. The converse is true whenever $\varphi(x)$ is stable. Moreover, (10.1) *implies $\alpha \le 1$ (if $\varphi(x) \not\equiv 0$), and*

$$\max_n |\Delta^N g^j_{n+1} - \Delta^N g^j_n| = \|(1-X)\Delta^N G^j(X)\|_\infty \tag{10.2}$$

can be replaced in (10.1) *by any of the following:*

$$\max_n |(g^j_N)_{n+1} - (g^j_N)_n| = \|(1-X)G^j_N(X)\|_\infty, \tag{10.3}$$

$$\max_n |(f_N^j)_n| = \|F_N^j(X)\|_\infty, \tag{10.4}$$

$$\max_{0\le n\le 2^j-1} \sum_k |(f_N^j)_{n+2^jk}|, \tag{10.5}$$

where we have set $G(X) = 2^{-N}(1+X)^N G_N(X) = 2^{-N}(1+X)^{N+1}F_N(X)$. *The iterated polynomials* $G_N^j(X)$, $F_N^j(X)$, *corresponding to the sequences* $(g_N^j)_n$, $(f_N^j)_n$, *are defined by* (2.5).

Proof. ($\Rightarrow$) Assume for the moment that $\alpha \le 1$. Since (10.1) implies, by Theorem 8.1, that $\Delta^N g_n^j$ converges uniformly to a $\dot{C}^\alpha$ function, it follows from Theorem 9.2 that all finite differences $\Delta^k g_n^j$ converge uniformly to $\varphi^{(k)}(x)$, for $k = 0, \cdots, N$. Hence $\varphi(x)$ is $\dot{C}^{N+\alpha}$.

($\Leftarrow$) If $\varphi(x)$ is stable and C^N, then by Theorem 9.2, $\Delta^N g_n^j$ converges uniformly to $\varphi^{(N)}(x) \in \dot{C}^\alpha$. Using (5.3) and the stability of $\varphi(x)$ we have $\|(1-X)\Delta^N G^j(X)\|_\infty \le c\,\|(1-X)\Delta^N\Phi^j(X)\|_\infty$, where $\Delta^N\Phi^j(X) = 2^{jN}(1-X)^N\Phi^j(X)$ corresponds to the coefficients $\Delta^N\varphi(n2^{-j})$. Now, we have

$$\begin{aligned}|\Delta^N\varphi(x) - \Delta^N\varphi(x-2^{-j})| &= 2^j\left|\int_{x-2^{-j}}^{x} (\Delta^{N-1}\varphi'(y) - \Delta^{N-1}\varphi'(y-2^{-j}))\,dy\right| \\ &\le \max_x |\Delta^{N-1}\varphi'(x) - \Delta^{N-1}\varphi'(x-2^{-j})|.\end{aligned}$$

By backward induction on N, it follows that

$$\|(1-X)\Delta^N\Phi^j(X)\|_\infty \le \max_x |\varphi^{(N)}(x) - \varphi^{(N)}(x-2^{-j})| \le c2^{-j\alpha},$$

which proves (10.1).

We now prove that (10.2)–(10.5) are "equivalent" in the following sense. Two sequences u_j and v_j are equivalent if there exist two constants c_1 and c_2, independent of j, such that $c_1v_j \le u_j \le c_2v_j$. From Lemma 9.1, we then have $\Delta^N G^j(X) = (1-X^{2^j})^N G_N^j(X)$. Hence, using the norm inequality (2.6), $\|(1-X)\Delta^N G^j(X)\|_\infty \le 2^N\|(1-X)G_N^j(X)\|_\infty$. Now, since the degree of $(1-X)G_N^j(X)$ is less than 2^jL, where L is the length of the sequence $(g_N)_n$, we also have

$$\begin{aligned}\|(1-X)G_N^j(X)\|_\infty &= \|(1-X^{2^jL})^N(1-X)G_N^j(X)\|_\infty \\ &= \|\left(\frac{1-X^{2^jL}}{1-X^{2^j}}\right)^N (1-X)\Delta^N G^j(X)\|_\infty \\ &\le c_N\,\|(1-X)\Delta^N G^j(X)\|_\infty.\end{aligned}$$

This proves that (10.2) and (10.3) are equivalent. The proof of (10.3)$\Leftrightarrow$(10.4) is very similar, based on the relation $(1-X)G_N^j(X) = (1-X^{2^j})F_N^j(X)$, which comes from Lemma 9.1. The equivalence (10.4)$\Leftrightarrow$(10.5) is obvious.

We finally show that (10.1) implies $\alpha \le 1$. Since $G(1) = 2$, we have $F_N(1) = F_N^j(1) = 1$; therefore, $\|F_N^j(X)\|_\infty \ge 2^{-j}\|F_N^j(X)\|_1 \ge 2^{-j}|F_N^j(1)| = 2^{-j}$, which shows, from (10.1) written with (10.4), that $\alpha \le 1$. □

The "equivalent" sequences (10.2)–(10.5) allow useful flexibility in the formulation of Theorem 10.1. As in §8, the following corollary immediately results from Theorem 10.1.

COROLLARY 10.2. *Let g_n be a stable binary subdivision scheme such that $G(1) = 2$ and $G(X)$ has at least $N+1$ zeros at $X = -1$. If, for $0 < \alpha < 1$,*

$$\max_n |\Delta^N g^j_{n+1} - \Delta^N g^j_n| \quad \text{decreases as } 2^{-j\alpha} \quad \text{when } j \to \infty, \tag{10.6}$$

then the limit function $\varphi(x)$ is $\dot{C}^{N+\alpha}$, but is not $\dot{C}^{N+\alpha+\varepsilon}$, for any $\varepsilon > 0$.

This does not hold for $\alpha = 1$, since by Theorem 10.1, (10.1) implies $\alpha \leq 1$. Of course, in (10.6) we can choose either (10.2), (10.3), (10.4), or (10.5).

Note that the characterization (10.1), or the criterion (10.6), depends on the choice of N. Theorem 10.1 (or Corollary 10.2) therefore allows us to check whether the exact regularity order r (that is, the number such that $\varphi(x)$ is $\dot{C}^r$ but not $\dot{C}^{r+\varepsilon}$, for any $\varepsilon > 0$) falls in the range $N \leq r < N+1$.

Assume, for example, that (10.6) is tested for some $N = N_0$ larger than the *unknown* exact regularity order r. This test necessarily fails, which only ensures that $\varphi(x)$ is not $\dot{C}^{N_0}$. On the other hand, if the value of N is too small, i.e., $N = N_1 < r-1$, then necessarily (10.6) is satisfied with $\alpha = 1$. This shows that $\varphi(x)$ is $\dot{C}^{N_1+1}$, but does not tell whether $\varphi(x)$ is actually more regular or not. In both cases (under or overestimated N's), the criterion (10.6) has to be checked all over again for other values of N to determine r. It is only when it turns out that $N < r \leq N+1$ that the criterion is really optimal and provides $N + \alpha = r$; therefore, the exact regularity order cannot be determined in general unless all possible values of N are tried.

However, if (10.1) can be extended to *negative* values of α, then the exact regularity order r is determined even if N is "too large," i.e., $N+1 \geq r$. That is, even if the criterion (10.1) for regularity order $r > N$ fails, it could be used to characterize lower regularity orders $0 < r \leq N$. In particular, if we use all of the zeros at $X = -1$ in $G(X)$ (i.e., if $G(X)$ has no more than $N+1$ such zeros), then the characterization (10.1), extended to any $\alpha \leq 1$, necessarily provides the exact regularity order r. This extension is provided by the following theorem.

THEOREM 10.3. *Theorem 10.1 and Corollary 10.2 hold for $-N < \alpha \leq 1$, with the following slight restriction. If (10.1) holds for $\alpha = -n$, $n = 0, 1, \cdots, N-1$, then $\varphi(x)$ is only "almost" $\dot{C}^{N-n}$, i.e., its $(N-n-1)$th derivative satisfies*

$$|\varphi^{(N-n-1)}(x+h) - \varphi^{(N-n-1)}(x)| \leq c.|h|| \log |h|| \quad \text{for all } x,\ h \in \mathbf{R}. \tag{10.7}$$

This theorem will be proven if we can simultaneously increase α and decrease N by 1 in (10.1). We, therefore, need the following lemma.

LEMMA 10.4. *Assume that $G(1) = 2$, $G(-1) = 0$, and that $G(X)$ has at least $N+1$ zeros at $X = -1$. The condition*

$$\max_n |\Delta^{N-1} g^j_{n+1} - \Delta^{N-1} g^j_n| \leq c\, 2^{-j(\alpha+1)} \tag{10.8}$$

implies (10.1). The converse implication holds for $\alpha < 0$ only. When $\alpha = 0$, (10.1) implies

$$\max_n |\Delta^{N-1} g^j_{n+1} - \Delta^{N-1} g^j_n| \leq c j 2^{-j}. \tag{10.9}$$

Proof. ($\Rightarrow$) We have

$$2^{-j} \max_n |\Delta^N g^j_n - \Delta^N g^j_{n-1}| = \max_n |\Delta^{N-1} g^j_n - 2\Delta^{N-1} g^j_{n-1} + \Delta^{N-1} g^j_{n-2}|$$

$$\leq \max_n(|\Delta^{N-1}g^j_n - \Delta^{N-1}g^j_{n-1}| \\ +|\Delta^{N-1}g^j_{n-1} - \Delta^{N-1}g^j_{n-2}|);$$

therefore, (10.8) clearly implies (10.1).

($\Leftarrow$) Condition (10.8) implies $1+\alpha \leq 1$ by Theorem 10.1. We, therefore, assume $\alpha \leq 0$ to prove the converse implication. Rewrite (10.1) and (10.8) using (10.4), knowing that $F^j_{N-1}(X) = 2^{-j}F^j_N(X)(1-X^{2^j})/(1-X)$ by Lemma 9.1. We, therefore, have to prove that (10.1), that is, $\|F^j_N(X)\|_\infty \leq c2^{-j\alpha}$ implies (10.8), that is $\|F^j_N(X)(1-X^{2^j})/(1-X)\|_\infty \leq c2^{-j\alpha}$. There is a problem at $X=1$; we, therefore, subtract $F^j_N(1) = F_N(1) = 1$ to $F^j_N(X)$ as shown:

$$\left\|F^j_N(X)\frac{1-X^{2^j}}{1-X}\right\|_\infty \leq \left\|(F^j_N(X)-1)\frac{1-X^{2^j}}{1-X}\right\|_\infty + \left\|\frac{1-X^{2^j}}{1-X}\right\|_\infty .$$

The second term in the right-hand side equals 1. Denote the first one by $\|H^j(X)\|_\infty$. From (2.3) written for $F_N(X)$, we have $F^j_N(X) - 1 = (F^{j-1}_N(X^2)-1) + (F_N(X) - 1)F^{j-1}_N(X^2)$. But since $F_N(1) = 1$, $X-1$ divides $F_N(X)-1$; therefore, $H^j(X) = H^{j-1}(X^2)(1+X) + (X^{2^j}-1)F^{j-1}_N(X^2)(F_N(X)-1)/(X-1)$ and

$$\|H^j(X)\|_\infty \leq \|H^{j-1}(X)\|_\infty + c2^{-(j-1)\alpha}.$$

By induction on j, for $\alpha < 0$, $\|H^j(X)\|_\infty \leq c'2^{-j\alpha}$ follows, which implies (10.8). When $\alpha = 0$, we have $\|H^j(X)\|_\infty \leq c'j$, which implies (10.9). □

Proof of Theorem 10.3. If α is not a negative integer, the generalization of Theorem 10.1 to $-N < \alpha \leq 0$ follows from several applications of Lemma 10.4. When $\alpha = -n$, $n = 0,\cdots,N-1$, by n successive applications of Lemma 10.4, (10.1) implies $\max_n |\Delta^{N-n}g^j_{n+1} - \Delta^{N-n}g^j_n| \leq c$. Applying Lemma 10.4 again, we only obtain $|\Delta^{N-n-1}g^j_{n+1} - \Delta^{N-n-1}g^j_n| \leq cj2^{-j}$. By Theorem 10.1, this implies that $\varphi(x)$ is $\dot{C}^{N-n-\varepsilon}$ (for any $\varepsilon > 0$), but we have a little more: mimicking the proof of the direct part of Theorem 8.1, we have $|\varphi^{(N-n-1)}(x+h) - \varphi^{(N-n-1)}(x)| \leq cj2^{-j}$ for $2^{-j} \leq |h| < 2^{-j+1}$, which gives (10.7). □

11. A practical, optimal Hölder regularity estimate.

Theorem 10.3 already provides an optimal regularity criterion (10.1) (with $-N < \alpha \leq 1$). However, it is not implementable on a computer as written since it needs to be verified for all j's and the order of magnitude of the constant c in (10.1) is unknown. The aim of this section is to transform this criterion into an easily implementable estimate [19] for Hölder regularity, computable with a finite number of operations.

The following theorem assumes some properties and notation we have already met:

- $G(1) = 2$;
- $G(X)$ has at least $N+1$ zeros at $X=-1$;
- $F_N(X)$ (corresponding to the sequence $(f_N)_n$) is, as defined in Theorem 10.1, $G(X)$ "without its $N+1$ zeros at $X=-1$," i.e.,

$$G(X) = \left(\frac{1+X}{2}\right)^N (1+X)\,F_N(X).$$

It generates iterated polynomials $F^j_N(X)$ and sequences $(f^j_N)_n$ by (2.5).

THEOREM 11.1. *With the above notation and assumptions, define the Hölder regularity estimate* $N+\alpha_N^j$ *by*

$$2^{-j\alpha_N^j}=\max_{0\le n\le 2^j-1}\sum_k |(f_N^j)_{n+2^jk}| \tag{11.1}$$

and let $\alpha_N=\sup_j \alpha_N^j$. *The sequence* α_N^j *converges to* $\alpha_N\le 1$ *as* $j\to\infty$. *If there exists* j *such that* $N+\alpha_N^j>0$, *then* $\varphi(x)$ *is* $\dot C^{N+\alpha_N^j}$ *(almost* $\dot C^{N+\alpha_N^j}$ *if* $\alpha_N^j\in -\mathbf{N}$, *see (10.7)); therefore,* $\varphi(x)$ *is* $\dot C^{N+\alpha_N-\varepsilon}$ *for any* $\varepsilon>0$.

In addition, if $\varphi(x)$ *is stable, then the regularity estimate is optimal: If* $\alpha_N\ne 1$, *or if* $\alpha_N=1$, *and* $G(X)$ *has no more than* $N+1$ *zeros at* $X=-1$, *then* $\varphi(x)$ *is* $\dot C^{N+\alpha_N-\varepsilon}$, *but is not* $\dot C^{N+\alpha_N+\varepsilon}$ *for any* $\varepsilon>0$. *Moreover, the rate of convergence of the estimates* $N+\alpha_N^j$ *to the exact regularity order* $N+\alpha_N$ *is given by*

$$0\le \alpha_N-\alpha_N^j\le c/j. \tag{11.2}$$

Proof. From (11.1) and Theorem 10.3 rewritten with (10.5), we have $\alpha_N^j\le 1$ for all j; hence $\alpha_N\le 1$. Now, using the relation $F_N^{i+j}(X)=F_N^j(X)F_N^j(X^{2^j})$ or the matrix formulation (12.1) given in the next section, we easily find that $2^{-(i+j)\alpha_N^{i+j}}\le 2^{-i\alpha_N^i}2^{-j\alpha_N^j}$, i.e.,

$$\alpha_N^{i+j}\ge\frac{i\alpha_N^i+j\alpha_N^j}{i+j}.$$

The following proof of convergence of the α_N^j is due to Cohen [3], [4]: Let $\varepsilon>0$ be an arbitrary small number and J such that $\alpha_N^J\ge\alpha^N-\varepsilon$. For any j, write $j=nJ+i$, $0\le i\le J-1$. Applying the inequality above several times, we find $\alpha_N^j\ge((j-i)\alpha_N^J+i\alpha_N^i)/j$; hence, when j is large enough, $\alpha_N^j\ge\alpha_N-2\varepsilon$, which proves that $\alpha_N^j\to\alpha_N$ as $j\to\infty$.

We now prove the announced regularity order for $\varphi(x)$. Let $G_N(X)=(1+X)F_N(X)$ be as in Theorem 10.1. By Lemma 7.2 applied to $G_N(X)$, we immediately obtain (10.1), written with (10.3) and $\alpha=\alpha_N^i$; therefore, Theorem 10.3 applies with $\alpha=\alpha_N^i$, for any i such that $\alpha_N^i>-N$. The limit function is thus $\dot C^{N+\alpha_N^i}$ (with the restriction (10.7)), and, therefore, $\varphi(x)$ is $\dot C^{N+\alpha_N-\varepsilon}$ for any $\varepsilon>0$.

Now assume that $\varphi(x)$ is stable. From (11.1), the condition (10.1), rewritten with (10.5) is satisfied only when $\alpha\le\liminf_{j\to\infty}\alpha_N^j=\alpha_N$. Now if $\varphi(x)$ were $\dot C^{N+\alpha_N+\varepsilon}$, where $\alpha_N<1$ and $\varepsilon>0$, by Theorem 10.1 (10.1) would hold with $\alpha=\alpha_N+\varepsilon$, which contradicts $\alpha\le\alpha_N$; therefore, if $\varphi(x)$ is stable, $\alpha_N<1$ implies that $\varphi(x)$ is not $\dot C^{N+\alpha_N+\varepsilon}$ for any $\varepsilon>0$. In addition, $\varphi(x)$ cannot be $N+1+\varepsilon$ if $G(X)$ has no more than $N+1$ zeros at $X=-1$ because of Theorem 9.2.

We finally prove (11.2). When $\varphi(x)$ is stable and $\dot C^{N+\alpha_N-\varepsilon}$, by Theorem 10.3, (10.1), written with (10.5), holds for $\alpha=\alpha_N-\varepsilon$. By definition of α_N^j (11.1), we thus have $2^{-j\alpha_N^j}\le c2^{-j(\alpha_N-\varepsilon)}$ for any $\varepsilon>0$, which implies (11.2). □

Of course, we can replace (10.5) in (11.1) by any other equivalent sequence (10.2), (10.3), (10.4). We would still obtain a sequence $N+\beta_N^j$, which converges to the optimal regularity order $N+\alpha_N$, however, $\varphi(x)$ may not be regular of order $N+\beta_N^j$ for any fixed j because β_N^j may be greater than α_N.

Let us make precise the practical outcomes of Theorem 11.1. For a given number of iterations j, and a given N, the computation of $N+\alpha_N^j$—with a finite number of

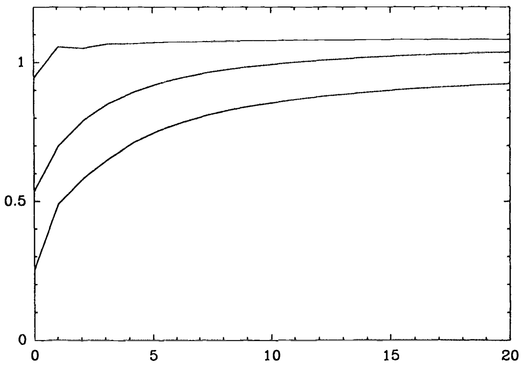


FIG. 4. *Program output of regularity estimates* $N+\alpha_N^j$ (11.1) ($N=0,\ 1,\ 2$) *for* $j=1$ *to* 20 *iterations. The corresponding limit function is the Daubechies "minimum phase" wavelet of length* 5 (*see* §14), *whose exact regularity order is* $r=1.0878\cdots$. *For* $N=0$, *the estimate is bounded by* 1 *and, therefore, does not converge to* r. *For* $N=2$, *the estimate converges fairly rapidly to* r. *After* 20 *iterations we find* $2+a_2^{20}=1.0831\cdots$.

operations—by (11.1) gives a Hölder regularity estimate for $\varphi(x)$ in all cases. Since $\lim_j \alpha_N^j = \sup_j \alpha_N^j$, the estimate is improved when the number of iterations j increases.

Figure 4 shows that N must be chosen large enough because the estimate $N+\alpha_N^j$ is bounded by $N+1$, whereas the exact regularity order of $\varphi(x)$ might be greater than $N+1$. If N is too small, $N+\alpha_N^j$, in fact, necessarily converges to $N+1$. It is therefore recommended that N should be chosen maximal (i.e., such that $G(X)$ has exactly $N+1$ zeros at $X=-1$). In this case Theorem 11.1 ensures that the regularity estimates $N+\alpha_N^j$ converge to $N+\alpha_N$, which, provided that $\varphi(x)$ is stable, gives the exact regularity order of $\varphi(x)$. In practice, Fig. 4 shows that the convergence rate of the estimates α_N^j is fairly high. When the scaling sequence length L is not too large (e.g., $L\le 10$), the exact regularity order is numerically estimated to two decimal places after a few dozen iterations. However, it can be shown [19] that the computational load of an implementation of (11.1) is increasing exponentially with j (increasing j by one roughly doubles the number of operations required to compute (11.1)).

Note that from Theorem 9.2, finite differences $\Delta^k g_n^j$ converge uniformly to the derivatives of a stable limit function $\varphi(x)$ whenever these derivatives exist.

Theorem 11.1 is the main result of this paper. It permits us to estimate sharply Hölder regularity in most cases of interest. (See §9 for the derivation of the optimal regularity estimate on a particular example of an unstable limit function.) The remainder of this paper connects this result to related work on regularity estimates, and illustrates it with examples.

12. Relation to Daubechies and Lagarias estimates. In a recent paper [9], Daubechies and Lagarias determined sharp conditions for Hölder regularity based on matrix products. Although the approach in [9] relies on two-scale difference equations (5.1) rather than on limit functions (3.3), the above results, which were derived independently, are closely related to what can be found in [9]. In fact, (11.1) reads, in matrix notation,

$$2^{-j\alpha_N^j} = \max_{\varepsilon_i=0 \text{ or } 1} \left\| \prod_{i=0}^{j-1} \mathbf{F}_N^{\varepsilon_i} \right\|_1 , \tag{12.1}$$

where the matrices F_N^0 and F_N^1 of size $(L-1)\times(L-1)$ (where L is the length of the sequence $(f_N)_n$) are defined as

$$\mathbf{F}_N^0 = \begin{pmatrix} (f_N)_0 & 0 & 0 & 0 & \cdots \\ (f_N)_2 & (f_N)_1 & (f_N)_0 & 0 & \cdots \\ (f_N)_4 & (f_N)_3 & (f_N)_2 & (f_N)_1 & \cdots \\ (f_N)_6 & (f_N)_5 & (f_N)_4 & (f_N)_3 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix}, \tag{12.2}$$

$$\mathbf{F}_N^1 = \begin{pmatrix} (f_N)_1 & (f_N)_0 & 0 & 0 & \cdots \\ (f_N)_3 & (f_N)_2 & (f_N)_1 & (f_N)_0 & \cdots \\ (f_N)_5 & (f_N)_4 & (f_N)_3 & (f_N)_2 & \cdots \\ (f_N)_7 & (f_N)_6 & (f_N)_5 & (f_N)_4 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix}, \tag{12.3}$$

and $\|\mathbf{A}\|_1$ denotes the l^1-norm of a square matrix $\mathbf{A} = ((a_{i,j}))$, i.e.,

$$\|\mathbf{A}\|_1 = \max_i \sum_j |a_{i,j}|.$$

Formulation (12.1) can be proved as follows. Consider the operators of polynomial "biphase decomposition [22]" $\mathbf{D}^\varepsilon$ ($\varepsilon = 0$ or 1), defined by the relation $U(X) = U^0(X^2) + XU^1(X^2)$, where $U^\varepsilon(X) = \mathbf{D}^\varepsilon\{U(X)\}$. Clearly $\mathbf{F}_N^\varepsilon$, seen as an operator acting on polynomials of degree $\leq L-2$, transforms $U(X)$ into $\mathbf{D}^\varepsilon\{F_N(X)U(X)\}$. Applying j times the identity $\mathbf{D}^\varepsilon\{U(X)V(X^2)\} = \mathbf{D}^\varepsilon\{U(X)\}V(X)$ gives the polynomial associated to the sequence $(f_N^j)_{n+2^jk}$ (where $n = \varepsilon_0\varepsilon_1\cdots\varepsilon_{j-1}$ in base 2) as

$$\left(\prod_{i=0}^{j-1}\mathbf{D}^{\varepsilon_i}\right)\{F_N^j(X)\} = \prod_{i=0}^{j-1}(\mathbf{F}^{\varepsilon_i}\{1\}),$$

where the polynomial 1 corresponds to the vector $(1\ 0\ 0\ \cdots\ 0)^t$. Therefore, $(f_N^j)_{n+2^jk}$, seen as a vector indexed by k, is equal to the first column of the matrix product in (12.1). To obtain the other columns, replace the initial polynomial 1 by X^m. This amounts to shifting the value of n in $(f_N^j)_{n+2^jk}$, hence changing the values of the ε_i. But since (11.1) involves the maximum over the values of n, the l^1-norm of the first column of the matrix product can be replaced by the l^1-norm of the whole matrix product, which gives (12.1).

Using (12.1) in place of (11.1) in Theorem 11.1, we easily recover the results on global Hölder regularity derived in [9]. Formulation (12.1) and that used in [9] differ only by some minor details: Daubechies and Lagarias use l^2-norms rather than l^1-norms, and the matrices they consider are a bit larger than (12.2), (12.3) because they correspond to $G(X) = 2^{-N}(1+X)^{N+1}F_N(X)$ rather than $F_N(X)$. Although regularity estimates are not proved to be optimal in general in [9], Daubechies and Lagarias prove optimality for several examples, such as those of §14.

Working with matrices is useful when we want to find optimal regularity estimates "by hand" [9], without implementing (11.1). Unfortunately, it seems difficult to derive a general method for determining the optimal regularity by matrix manipulation. As a result, unlike an implementation of (11.1) on a computer, each example has to be investigated separately and requires fastidious treatment. We here recall for completeness the basic method used in [9].

THEOREM 12.1 (Daubechies and Lagarias [9]). *The following method often provides a sharp Hölder regularity estimate for a limit function* $\varphi(x)$:

- *Compute the eigenvalues of* $\mathbf{F}_N^0$ *and* $\mathbf{F}_N^1$ *and let* ρ^0, ρ^1 *be their respective spectral radii (largest moduli of eigenvalues).*
- *Assume, for example, that* $\rho^0 > \rho^1$. *Compute matrix* $\mathbf{B}$, *whose columns are proportional to the eigenvectors of* $\mathbf{F}_N^0$. *The norm of the diagonal matrix* $\mathbf{B}^{-1}\mathbf{F}_N^0\mathbf{B}$ *is therefore* ρ^0.
- *Parameterize* $\mathbf{B}$ *by* $L-1$ *numbers, one for each column. If we can find a parameterization of* $\mathbf{B}$ *such that*

$$\|\mathbf{B}^{-1}\mathbf{F}_N^1\mathbf{B}\| \leq \rho^0, \tag{12.4}$$

where $\|\cdot\|$ *is any matrix norm, then* $\varphi(x)$ *is regular of order* $N - \log_2 \rho^0$ *(and this Hölder regularity estimate is moreover optimal if* $\varphi(x)$ *is stable).*

Proof. First, specifying $\varepsilon_i = 0$ for all i in (12.1) gives $2^{-j\alpha_N^j} \geq \|(\mathbf{F}_N^0)^j\|$. Let λ be an eigenvalue of $\mathbf{F}_N^0$ and v an associated nonzero eigenvector. We have, on one hand, $\|(\mathbf{F}_N^0)^j v\| \leq \|(\mathbf{F}_N^0)^j\| \cdot \|v\|$, and on the other hand, $\|(\mathbf{F}_N^0)^j v\| = |\lambda|^j \|v\|$. It follows that $(\rho^0)^j = \sup |\lambda|^j \leq \|(\mathbf{F}_N^0)^j\| \leq 2^{-j\alpha_N^j}$. Now, with the change of basis $\mathbf{B}$, we have

$$2^{-j\alpha_N^j} = \max_{\varepsilon_i} \left\| \mathbf{B} \left(\prod_{i=0}^{j-1} \mathbf{B}^{-1}\mathbf{F}_N^{\varepsilon_i}\mathbf{B} \right) \mathbf{B}^{-1} \right\| \leq c \max_{\varepsilon_i} \prod_{i=0}^{j-1} \|\mathbf{B}^{-1}\mathbf{F}_N^{\varepsilon_i}\mathbf{B}\| .$$

But we have $\|\mathbf{B}^{-1}\mathbf{F}_N^0\mathbf{B}\| = \rho^0$ and (12.4); therefore, $2^{-j\alpha_N^j} \leq c\,(\rho^0)^j$ follows. We, therefore, have proved that $(\rho^0)^j \leq 2^{-j\alpha_N^j} \leq c\,(\rho^0)^j$, which implies $\alpha^N = \lim_j \alpha_N^j = -\log_2 \rho^0$. The theorem therefore follows from Theorem 11.1. □

Note that this method is only optimal if (12.4) is met for at least one matrix norm, otherwise the obtained estimate, $N - \log_2 \|\mathbf{B}^{-1}\mathbf{F}_N^1\mathbf{B}\|$, is suboptimal. Whether (12.4) holds for a large class of masks g_n is an open problem [9].

13. A sharp upper bound for regularity. So far we have seen two types of Hölder regularity estimates: One is optimal in (almost) all cases (§11), but many iterations, performed on a computer, are necessary to determine the regularity order accurately. The other (§12) requires the calculation of two spectral radii of matrices, but is sometimes suboptimal. Based on the latter, it is nevertheless possible to obtain a (possibly sharp) *upper bound* for regularity of stable limit functions that only requires the computation of one spectral radius and gives the exact regularity order whenever condition (12.4) is satisfied:

Specifying $\varepsilon_i = 0$ or $\varepsilon_i = 1$ for all i in (12.1) gives $2^{-j\alpha_N^j} \geq \max(\|(\mathbf{F}_N^0)^j\|, \|(\mathbf{F}_N^1)^j\|)$. We have seen that this is greater than $\max((\rho^0)^j, (\rho^1)^j)$; therefore, an upper bound for the Hölder regularity is $N - \log_2 \max(\rho^0, \rho^1)$. By Theorem 12.1, this upper bound is attained for stable limit functions if (12.4) holds.

The computation of this upper bound can be simplified to the search of the spectral radius of only one matrix $\mathbf{F}_N$, defined as the common submatrix of $\mathbf{F}_N^0$ and $\mathbf{F}_N^1$.

$$\mathbf{F}_N^0 = \left(\begin{array}{c|c} (f_N)_0 & 0 \;\cdots\; 0 \\ \hline (f_N)_2 & \\ (f_N)_4 & \mathbf{F}_N \\ \vdots & \end{array} \right) \quad \text{and} \quad \mathbf{F}_N^1 = \left(\begin{array}{c|c} & \vdots \\ \mathbf{F}_N & (f_N)_{L-3} \\ & (f_N)_{L-2} \\ \hline 0 \;\cdots\; 0 & (f_N)_{L-1} \end{array} \right).$$

We have

$$N - \log_2 \max(\rho^0, \rho^1) = N - \log_2 \max(|(f_N)_0|, |(f_N)_{L-1}|, \rho(\mathbf{F}_N)), \tag{13.1}$$

where $\rho(\mathbf{F}_N)$ is the spectral radius of $\mathbf{F}_N$. Therefore the regularity order of a stable limit function is at most (13.1).

A similar upper bound can be computed using the inequality

$$2^{-j\alpha_N^j} \geq \max\left(\sum_k |(f_N^j)_{2^j k}|, \sum_k |(f_N^j)_{2^j k-1}|\right),$$

which yields a fast implementation [19]: the computational load is here linear in j (compare with §11). When $j \to \infty$, this gives an upper bound which may be greater than (13.1) but is still sharp. This result and Theorem 11.1 can be used to compute sharp lower and upper bounds for the Hölder regularity of $\varphi(x)$. Table 1 provides values of these bounds for the examples presented in the next section.

14. Examples: Daubechies orthonormal wavelets. A family of orthonormal wavelets with compact support has been constructed by Daubechies in [6]. The construction is based on binary subdivision schemes. The "mother wavelet" is defined as the limit function $\psi(x)$ of the scheme (1.2) with initial sequence $h_n = (-1)^n g_{L-1-n}$ (where L is the mask length). She showed that the regular functions $2^{-j/2}\psi(2^{-j}x - k)$, defined for all integers j and k, form an orthonormal basis of $\mathbf{L}^2(\mathbf{R})$ if L is even and

$$G(X)\tilde{G}(X) - G(-X)\tilde{G}(-X) = 4X^{L-1}, \tag{14.1}$$

where $\tilde{G}(X)$ is the polynomial associated to the sequence g_{L-1-n}. In [6], $G(X)$ is, moreover, required to have as many zeros at $X = -1$ as possible. This results in several possible solutions for $G(X)$ that have exactly $N + 1 = L/2$ zeros at $X = -1$ [6], [7].

Examples of $G(X)$ in [6] have all zeros outside the unit circle ("minimum phase" choice in the signal processing terminology, since X corresponds to a delay). In [9], the optimal regularities of "minimum phase" Daubechies wavelets $\psi(x)$ for $L = 4$, 6, and 8 are obtained using the method described in the preceding section. It turns out that (12.4) holds for these lengths; therefore, the upper bound (13.1) is attained and actually equals $N - \log_2 |(f_N)_0|$. The estimated regularity of Daubechies "minimum phase" wavelets derived in [6] is, therefore, $-\log_2 |g_0|$ in this case. It can easily be checked that the convergent binary subdivision schemes involved are stable; hence this estimate is optimal. This can be checked directly [9] from Theorem 10.3 by noting that the first "slope" of $\Delta^N g_n^j$ is $|2g_0|^j = 2^{j(1-\alpha)}$, where $\alpha = -\log_2 |g_0|$. Table 1 lists these optimal regularities (for $L \leq 8$), the corresponding outputs of a program implementing (11.1), and upper bounds derived in §13.

There are other solutions g_n, derived for $L \geq 8$ in [7], which, unlike "minimum phase solutions," are close to being symmetric. Table 1 shows that the regularity estimates for these wavelets, based on Theorem 11.1, are lower than those of "minimum phase" wavelets. This will be justified in §17.

15. "Strictly linear phase" symmetric limit functions. In this section we apply the above results to a subclass of scaling sequences that is often encountered. This section is also a prerequisite for comparing Hölder regularity estimates to those determined using Fourier techniques (§17). The subclass considered here consists of

TABLE 1

Some regularity estimates for two types of Daubechies orthonormal wavelets: Minimum phase wavelets [6] *and "more symmetric" ones* [7] (*for mask lengths* $L \geq 8$). *The upper bound fcr Hölder regularity in the right-most column is obtained by adding* $\frac{1}{2}$ *to the optimal Sobolev regularity estimate, derived in* [6, *Appendix*] (*see* §17). *These two apply to all Daubechies wavelets that differ only by their phase. The numbers* r_{20} *are the Hölder regularity estimates* (11.1) *obtained by computer program after* $j = 20$ *iterations. Note that more symmetry decreases regularity in general. For minimum phase wavelets, these estimates converge rapidly to the optimal Hölder regularity estimates* r_∞ *derived in* [9] *by using the method described in* §12. *The upper bounds for both types of wavelets are obtained from* §13. *They are sharper than the "Sobolev" upper bound and in fact give optimal Hölder regularity estimates in the "minimum phase" case for lengths* $L \leq 8$.

L	Optimal Sobolev regularity estimate	More symmetric wavelets		Minimum phase wavelets			Upper bound
		r_{20}	Upper bound	r_{20}	r_∞	Upper bound

scaling sequences for which either $G(X)$ or $G(X)/(1+X)$ is "strictly linear phase," in the following sense.

DEFINITION 15.1. *A polynomial* $U(X)$ (*or its associated sequence* u_n *of finite length* L) *is* strictly linear phase *if it is symmetric,* $u_n = u_{L-1-n}$, *and if the trigonometric polynomial* $U(e^{i\omega})e^{-i(L-1)\omega/2}$ *does not change sign for any* $w \in R$.

Note that symmetry of u_n implies $U(e^{i\omega})e^{-i(L-1)\omega/2} \in \mathbf{R}$. This condition is called "linear phase" in signal processing [22]. The above definition requires more, namely that no discontinuities of the phase due to a change of sign in $U(e^{i\omega})e^{-i(L-1)\omega/2}$ occur. Therefore, complex zeros of the symmetric polynomial U(X) occur in pairs $(z, 1/\bar{z})$ not only for $|z| \neq 1$, but also *on* the unit circle. That is, roots on the unit circle have even order. It follows that $U(X)$ has an even number of roots, hence L is odd.

If $G(X)$ or $G(X)/(1+X)$ is strictly linear phase, then for N odd (even, respectively), the sequence $(f_N)_n$ in (11.1) is also strictly linear phase. The following theorem shows that in this case, the determination of the exact regularity order of a (stable) limit function $\varphi(x)$ only requires the computation of the spectral radius of one matrix. This is to be compared with §§12 and 13, where it is shown that two matrices are involved in the general case, and the computation of one matrix's spectral radius only provides an upper bound for regularity.

The following regularity estimate has been derived independently, by other means, and on particular examples of strictly linear phase scaling sequences, in [6] and [10] (see §§16 and 17).

THEOREM 15.2. *Assume* $G(1) = 2$, $G(X)$ *has at least* $N+1$ *zeros at* $X = -1$: $G(X) = 2^{-N}(1+X)^{N+1}F_N(X)$, *and* $F_N(X)$ *is strictly linear phase. Define* $(\hat{f}_N)_n = (f_N)_{((L-1)/2)\pm n}$ (*where* L *is the length of* $(f_N)_n$) *and the* $(L-1)/2 \times (L-1)/2$ *matrix*

$\hat{\mathbf{F}}_N$ obtained by "folding" the following $(L-1)/2 \times (L-2)$ matrix

$$\begin{pmatrix} \cdots & (\hat{f}_N)_3 & (\hat{f}_N)_2 & (\hat{f}_N)_1 & (\hat{f}_N)_0 & (\hat{f}_N)_1 & (\hat{f}_N)_2 & (\hat{f}_N)_3 & \cdots \\ \cdots & (\hat{f}_N)_1 & (\hat{f}_N)_0 & (\hat{f}_N)_1 & (\hat{f}_N)_2 & (\hat{f}_N)_3 & (\hat{f}_N)_4 & (\hat{f}_N)_5 & \cdots \\ \cdots & (\hat{f}_N)_1 & (\hat{f}_N)_2 & (\hat{f}_N)_3 & (\hat{f}_N)_4 & (\hat{f}_N)_5 & (\hat{f}_N)_6 & (\hat{f}_N)_7 & \cdots \\ & & & & \vdots & & & & \end{pmatrix}$$

around its middle column, i.e.,

$$\hat{\mathbf{F}}_N = \begin{pmatrix} (\hat{f}_N)_0 & 2(\hat{f}_N)_1 & 2(\hat{f}_N)_2 & \cdots \\ (\hat{f}_N)_2 & (\hat{f}_N)_1 + (\hat{f}_N)_3 & (\hat{f}_N)_0 + (\hat{f}_N)_4 & \cdots \\ (\hat{f}_N)_4 & (\hat{f}_N)_3 + (\hat{f}_N)_5 & (\hat{f}_N)_2 + (\hat{f}_N)_6 & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix}. \tag{15.1}$$

Let ρ be its spectral radius. One has $\rho \geq \frac{1}{2}$. If $\rho < 2^N$, then the limit function $\varphi(x)$ is $\dot{C}^{N-\log_2 \rho}$ (almost $\dot{C}^{N-\log_2 \rho}$ in the sense of (10.7) if $\rho \geq 1$ is an integer power of two). In addition, if $\varphi(x)$ is stable, and if either $\rho > \frac{1}{2}$ or $\rho = \frac{1}{2}$ and $G(X)$ has no more than $N+1$ zeros at $X = -1$, then the estimate is optimal: $\varphi(x)$ is not $\dot{C}^{N-\log_2 \rho+\varepsilon}$ for any $\varepsilon > 0$.

Proof. Define $(\hat{f}^j_N)_n = (f^j_N)_{(2^{j-1}-2^{-1})(L-1)+n}$. This noncausal, symmetric sequence is strictly linear phase. We first prove that $\|F^j_N(X)\|_\infty = \max_n |(\hat{f}^j_N)_n| = |(\hat{f}^j_N)_0|$. Using Fourier coefficients, we have $(\hat{f}^j_N)_n = \frac{1}{2\pi}\int_0^{2\pi} \hat{F}^j_N(e^{i\omega})e^{in\omega}\, d\omega$, where $\hat{F}^j_N(e^{i\omega}) = \sum_n (\hat{f}^j_N)_n e^{in\omega} = \pm|\hat{F}^j_N(e^{i\omega})|$. Hence

$$\max_n |(\hat{f}^j_N)_n| \leq \frac{1}{2\pi}\int_0^{2\pi} |\hat{F}^j_N(e^{i\omega})|\, d\omega = |(\hat{f}^j_N)_0|.$$

The theorem, therefore, results from Theorem 10.3 if we prove that $|(\hat{f}^j_N)_0|$ is equivalent to ρ^j as $j \to \infty$. From (2.4) written for $F_N(X)$, we have, for$0 \leq m \leq 2^j - 1$, $(f^{j+1}_N)_{2^{j+1}n+m+2^j} = \sum_k (f_N)_{k+1}(f^j_N)_{2^j(2n-k)+m}$. This means, in matrix notation,

$$((f^{j+1}_N)_{2^{j+1}n+m+2^j})_n = \mathbf{F}^1_N((f^j_N)_{2^j n+m})_n,$$

where $\mathbf{F}^1_N$ is defined by (12.3). Let $m = 2^j - (L-1)/2$ (for sufficiently large j's to ensure $m \geq 0$). The above equation is then rewritten, in terms of the $(\hat{f}^j_N)_n$, as $((\hat{f}^{j+1}_N)_{2^{j+1}(n-(L-3)/2)})_n = \mathbf{F}^1_N((\hat{f}^j_N)_{2^j(n-(L-3)/2)})_n$ By symmetry, this equation can be restricted to $n = 0, \cdots, (L-3)/2$, in which case the action of $\mathbf{F}^1_N$ is exactly that of $\hat{\mathbf{F}}_N$. It follows by induction on j that $|(\hat{f}^j_N)_0|$ is equivalent to $\|(\hat{\mathbf{F}}_N)^j\|_\infty$, hence to ρ^j, when $j \to \infty$. □

16. Examples: Deslauriers and Dubuc interpolatory schemes. Deslauriers and Dubuc [10]–[12] studied the regularity of limit functions of a special family of interpolatory subdivision schemes based on Lagrangian interpolation. Recall that for interpolatory schemes the iterated points g^j_n are carried unchanged at each iteration. Here, we simply insert between $g^j_n = g^{j+1}_{2n}$ and $g^j_{n+1} = g^{j+1}_{2n+2}$ the value g^{j+1}_{2n+1} of the Lagrangian polynomial interpolation of the K consecutive values $g^j_{n+1-K/2}, \cdots,$ $g^j_n, g^j_{n+1}, \cdots, g^j_{n+K/2}$, where K is even. This corresponds to a mask g_n of length

TABLE 2

Optimal Hölder regularity estimates r of interpolatory subdivision schemes of Deslauriers and Dubuc [10], [11], [12] *for several Lagrangian interpolation orders K corresponding to mask lengths $L = 2K - 1$ (see* §16). *These estimates are also optimal in the "Fourier sense," and the numbers $(r-1)/2$ give the optimal Sobolev regularity estimates listed in Table* 1 *(see* §17).

K	L	r	K	L	r
2	3	1.	12	23	4.7767
4	7	2.	14	27	5.3173
6	11	2.8300	16	31	5.8294
8	15	3.5511	18	35	6.3233
10	19	4.1935	20	39	6.8054

$L = 2K - 1$, which reads (when made causal by shifting)

$$\left\{ \begin{array}{l} g_{2n} = \delta_{n-K/2}, \\ g_{2n+1} = L_n(\frac{K-1}{2}), \end{array} \right. \tag{16.1}$$

where $L_n(X)$ is the Lagrangian polynomial $L_n(X) = \prod_{k\neq n}(X-k)/(n-k)$ associated to the interpolation points $k = 0, \cdots, K-1$.

Shensa has shown [21] that $G(X)$ of length $L = 2K - 1$ is exactly $G(X) = G_W(X)\tilde{G}_W(X)$, where $G_W(X)$ is the polynomial mask of Daubechies wavelets of compact support $[0,\ K-1]$ (see §14—this fact will be useful in §17). From §14 it follows that $G(X)$ has exactly K zeros at $X = -1$. Moreover, it is strictly linear phase because $G(e^{i\omega}) = G_W(e^{i\omega})\tilde{G}_W(e^{i\omega}) = |G_W(e^{i\omega})|^2 e^{i(K-1)\omega}$. Thus Theorem 15.2 applies with $N = K - 1$. Moreover, since all interpolatory subdivision schemes are stable (§6), Theorem 15.2 will provide the *exact* regularity order of $\varphi(x)$.

The matrices $\hat{\mathbf{F}}^{K-1}$ (15.1) needed by Theorem 15.2 can be easily determined using the formula

$$(f_{K-1})_n = c \left(\begin{array}{c} K-2 \\ n \end{array} \right)^{-1} \sum_{i=0}^{n} (-1)^i \left(\begin{array}{c} K-1 \\ i \end{array} \right)^2, \qquad n = 0, \cdots, K-2,$$

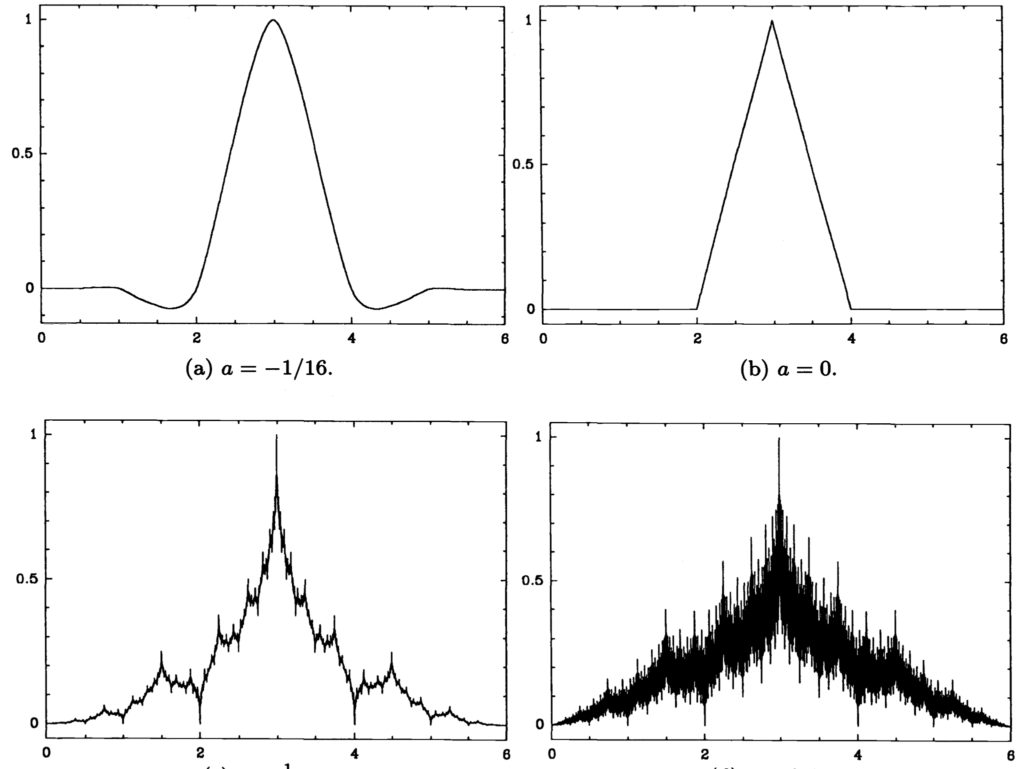
which results from (16.1) after some calculation. Determination of their spectral radii yields to the optimal regularities listed in Table 2. For $L = 7$ (i.e., $K = 4$), using 4 zeros at $X = -1$ in $G(X)$, we find that the limit function is almost $\dot{C}^2$ in the sense of (10.7), which was first proven by Dubuc in [12]. However, when only 2 zeros at $X = -1$ in $G(X)$ are used ($N = 1$), we find that the spectral radius of Theorem 15.2 is $\rho = \frac{1}{2}$, hence the limit function is in fact $\dot{C}^2$.

In [10], Deslauriers and Dubuc extended the study of the previous subdivision scheme for $L = 7$ (i.e., $K = 4$) to the following interpolatory mask (here defined for $n = -3, \cdots, 3$):

$$g_0 = 1, \quad g_{\pm 1} = 1/2 - a, \quad g_{\pm 3} = a, \quad g_n = 0 \quad \text{elsewhere},$$

where $a \in R$. The case $a = -1/16$ corresponds to the previous example, for which the limit function is $\dot{C}^2$.

The simplicity and usefulness of Theorem 15.2 is well illustrated through this example. The mask g_n is easily seen to be strictly linear phase for $-1/16 \leq a \leq \frac{1}{2}$; therefore, Theorem 15.2 applies in this case. (For other values of a we have to use more general theorems such as Theorem 11.1.) Now, for $a \neq -1/16$, $G(X)$ has exactly



(a) $a = -1/16$.

(b) $a = 0$.

(c) $a = \frac{1}{4}$.

(d) $a = 0.4$.

FIG. 5. *Plots of Deslauriers and Dubuc limit functions corresponding to* $g_0 = 1$, $g_{\pm 1} = 0.5 - a$, $g_{\pm 3} = a$, *and* $g_n = 0$ *elsewhere. The successive values of* a *are* $a = -1/16$ *(regularity order* 2*),* $a = 0$ *(regularity order* 1*),* $a = \frac{1}{4}$ *(regularity order* $\log_2(\sqrt{5} - 1) = 0.305\cdots$*) and* $a = 0.4$ *(regularity order* $0.104\cdots$*).*

two zeros at $X = -1$, and we can, therefore, apply Theorem 15.2 with $N = 1$. We have $(\hat{f}_1)_0 = 1 + 4a$, $(\hat{f}_1)_{\pm 1} = -4a$, and $(\hat{f}_1)_{\pm 2} = 2a$; hence

$$\hat{\mathbf{F}}_1 = \begin{pmatrix} 1 + 4a & -8a \\ 2a & -4a \end{pmatrix}.$$

Its spectral radius is $\rho = (1 + \sqrt{1 + 16a})/2$. From Theorem 15.2, the exact regularity order of $\varphi(x)$ is $r = 2 - \log_2(1 + \sqrt{1 + 16a})$, which decreases from 2 to zero when a increases from $-1/16$ to $\frac{1}{2}$. Figure 5 illustrates this through several examples corresponding to various values of a.

17. Comparison with Fourier-based regularity estimates. This paper has developed a direct approach based on the definition of Hölder regularity. But several other approaches for estimating regularity based on the Fourier transform $\hat{\varphi}(\omega)$ of the (compactly supported) limit function $\varphi(x)$ have also been considered [3]–[5], [10], [11], [23]. Note that we have easy access to $\hat{\varphi}(\omega)$ from mask g_n by [3]–[6]

$$\hat{\varphi}(\omega) = \lim_{j \to \infty} G^j(e^{i\omega}). \tag{17.1}$$

The idea is here to estimate the decay of $\hat{\varphi}(\omega)$ as $|\omega| \to \infty$. To do this, several functional spaces (other than $\dot{C}^r$) can be used to interpolate the spaces C^N of N-times continuously differentiable functions. We generally consider one of the following spaces: $\mathbf{H}_1^r$, $\mathbf{H}_2^r$, $\mathbf{H}_\infty^r$, defined by the conditions $|\omega|^r\hat{\varphi}(\omega) \in \mathbf{L}^1, \mathbf{L}^2, \mathbf{L}^\infty$, respectively. (The spaces $\mathbf{H}_2^r$ are the Sobolev spaces of order r.) Estimations of the parameter r for these spaces ensure some Hölder regularity, since we have, for any $\varepsilon > 0$,

$$\mathbf{H}_\infty^{r+1+2\varepsilon} \subset \mathbf{H}_2^{r+1/2+\varepsilon} \subset \mathbf{H}_1^r \subset \dot{C}^r. \tag{17.2}$$

(These inclusions are easily proven. The second one uses the Cauchy–Schwarz inequality and [11] contains a proof of the last one.)

In [6], Daubechies has derived an estimate for $\varphi(x) \in \dot{C}^{r-\varepsilon}$ based on $\mathbf{H}_\infty^{r+1}$. This estimate is easily recovered from the results derived in this this paper. We have, using the notation of Theorem 10.1,

$$\|F_N^j(X)\|_\infty = \max_n |(f_N^j)_n| \le \frac{1}{2\pi}\int_0^{2\pi} |F_N^j(e^{i\omega})|\,d\omega \le \max_{\omega\in\mathbf{R}} |F_N^j(e^{i\omega})|.$$

Define the number β^j such that $2^{-j\beta^j} = \max_{\omega\in\mathbf{R}} |F_N^j(e^{i\omega})|$. Then, by Theorem 10.3 and 11.1, $\varphi(x)$ is $\dot{C}^{N+\beta-\varepsilon}$, where $\beta = \limsup_{j\to\infty}\beta_j$. Cohen [3], [4] has shown that the sequence β^j actually converges to β (the proof is the same as in Theorem 11.1) and that, under some weak conditions on $G(X)$, the optimal regularity order r based on $\mathbf{H}_1^r$ lies between $N+\beta-\varepsilon$ and $N+1+\beta+\varepsilon$. In the case of Daubechies orthonormal wavelets (§14), Cohen and Daubechies [3]–[5] found that β is equivalent to $(\frac{1}{2} - \frac{1}{4}\log_2 3)L \approx 0.10376L$ as $L \to \infty$. It follows (from the following theorem) that the optimal Hölder regularity order of Daubechies orthonormal wavelets is also asymptotically equivalent to $(0.10376\cdots)L$ as $L \to \infty$. However, for small values of L ($L \le 20$), the estimates derived in this paper, listed in Table 1, are much sharper than the asymptotic result of Cohen and Daubechies.

Daubechies has also derived [6, Appendix] other regularity estimates for the special case of her orthonormal wavelets described in §14. It turns out that her estimates are optimal for the Sobolev spaces $\mathbf{H}_2^r$. This is due to Theorem 15.2 and the property, already mentioned in §14, that the polynomial mask $G(X)$ of a Daubechies wavelet is such that $G(X)\tilde{G}(X)$ is the polynomial mask of a Deslauriers and Dubuc interpolatory scheme [21]. We have $G(e^{i\omega})\tilde{G}(e^{i\omega}) = |G(e^{i\omega})|^2$; therefore, from (17.1) the Fourier transform of the limit function of a Deslauriers and Dubuc scheme is $|\hat{\varphi}(\omega)|^2$, where $\hat{\varphi}(\omega)$ is the Fourier transform of the limit function corresponding to the wavelet. The following theorem shows that since the Deslauriers and Dubuc limit functions are strictly linear phase, their optimal Hölder regularity estimates r, provided by Theorem 15.2 and listed in Table 2, are also optimal for the spaces $\mathbf{H}_1^r$. This implies $\varphi(x) \in \mathbf{H}_2^{r/2}$; therefore, $\varphi(x) \in \dot{C}^{(r-1)/2-\varepsilon}$, which is optimal for spaces $\mathbf{H}_2^{r/2}$. This regularity order is exactly the one derived by Daubechies in [6]. Table 1 lists these optimal Sobolev regularity orders for several lengths.

The above discussion shows that if $G(X)\tilde{G}(X)$ is strictly linear phase, then Theorem 15.2 applied on $G(X)\tilde{G}(X)$ provides the optimal Sobolev regularity of the limit function corresponding to the polynomial mask $G(X)$. This result has been derived independently by Daubechies and Cohen [5] using the Littlewood–Paley theory. Recently, Villemoes [23] has shown that this holds more generally under the weak conditions on $G(X)$ of Cohen [3].

But are these "Fourier-optimal" estimates optimal for Hölder regularity? The following theorem shows that the answer is *no*. The basic reason for this is that the exact Hölder regularity order of $\varphi(x)$ depends on the *phase* of $\hat{\varphi}(\omega)$, i.e., on the phase of $G(e^{i\omega})$ by (17.1), whereas Fourier-based regularity estimates only depend on the *modulus* of $\hat{\varphi}(\omega)$ (or $G(e^{i\omega})$). This theorem also shows that in the framework of §15 (the "strictly linear phase" case), optimal Fourier-based estimates are, in fact, also optimal for Hölder regularity. This is natural since the strictly linear phase case corresponds to limit functions that can be made zero-phase by shifting, i.e., $\hat{\varphi}(\omega) \geq 0$.

THEOREM 17.1. *For strictly linear phase masks, optimal regularity estimates based on* $\mathbf{H}_1^r$ *are also optimal for Hölder regularity.*

Optimal regularity estimates based on $\mathbf{H}_2^r$ *are not optimal for Hölder regularity in general. Nonetheless, they are off by* $\frac{1}{2}$ *at most compared to optimal Hölder regularity estimates.*

Proof. We first prove optimality in the strictly linear phase case. From (17.1), the framework of §15 can easily be reduced to the case $\hat{\varphi}(\omega) \geq 0$. Optimality for spaces $\mathbf{H}_1^r$ and $\dot{C}^r$ coincide if we prove that in this case $\varphi(x) \in \dot{C}^\alpha$ implies $\varphi(x) \in \mathbf{H}_1^{\alpha-\varepsilon}$, for any $\varepsilon > 0$. We may restrict to $0 < \alpha \leq 1$, otherwise just consider a derivative of $\varphi(x)$. The integral $I(w) = \int \sin(\omega h/2)|h|^{-1-\alpha+\varepsilon}\,dh$ absolutely converges for $0 < \alpha \leq 1$; making a change of variable yields $I(w) = |w|^{\alpha-\varepsilon} I(1)$; therefore,

$$\begin{aligned}\int \hat{\varphi}(\omega)|w|^{\alpha-\varepsilon}\,dw &= c \iint \hat{\varphi}(\omega)\sin(\omega h/2)|h|^{-1-\alpha+\varepsilon}\,dh d\omega \\ &= c \int (\varphi(h/2) - \varphi(-h/2))|h|^{-1-\alpha+\varepsilon}\,dh\end{aligned}$$

absolutely converges because $\varphi(x)$ is compactly supported and $\dot{C}^\alpha$. This proves that $\varphi(x) \in \mathbf{H}_1^{\alpha-\varepsilon}$.

Table 1 shows that regularity orders of Daubechies orthonormal wavelets that are optimal for Sobolev spaces $\mathbf{H}_2^r$ are not optimal for Hölder regularity.

The fact that optimal Fourier-based estimates are greater than or equal to $r - \frac{1}{2}$, where r is the exact Hölder regularity estimate, results from the well-known inclusion $\dot{C}^r \subset \mathbf{H}_2^{r-\varepsilon}$, which holds for compactly supported functions [16]. □

Trivial extensions of this theorem can be derived for other "Fourier-based" spaces, using inclusions like (17.2).

Note that Table 1 shows that the Hölder regularity estimates of "more symmetric" wavelets are numerically found to be less than those of minimum phase wavelets (the ones that are "nonsymmetric" the most). That is, more symmetry (for the same modulus of $G(e^{i\omega})$) decreases regularity. In addition, both regularity estimates are greater than the optimal Sobolev regularity order that constitutes a lower-bound for the exact Hölder regularity order. In fact, Theorem 17.1 shows that this lower bound is attained for strictly linear phase masks.

Acknowledgments. I would like to thank Pierre Duhamel and Thierry Blu of Centre National d'Études des Télécommunications, Paris, for fruitful discussions and for carefully reading the manuscript, Ingrid Daubechies of AT&T Bell Labs for letting me use her unpublished material [7], [9] and for pointing out the results of Albert Cohen [3]–[5]; and Lars F. Villemoes of the Technical University of Denmark for suggesting reference [16], which led to an improvement of Theorem 17.1.

I am also grateful to the anonymous referees for pointing out several deficiencies, which led to §3, and for suggesting the references of Dyn and Levin.

BIFURCATIONS OF NONLINEAR OSCILLATIONS AND FREQUENCY ENTRAINMENT NEAR RESONANCE*

CARMEN CHICONE[†]

Abstract. A unified approach to the Poincaré–Andronov global center bifurcation and the subharmonic Melnikov bifurcation theory is developed using S. P. Diliberto's integration of the variational equations of a two-dimensional system of autonomous ordinary differential equations and a Lyapunov–Schmidt reduction to the implicit function theorem. In addition, the subharmonic Melnikov function is generalized to the case of subharmonic bifurcation from an unperturbed system whose free oscillation is a limit cycle. Thus, results on frequency entrainment are obtained when an external periodic excitation is in resonance with the frequency of the limit cycle. The theory is applied to the subharmonic bifurcations of two coupled van der Pol oscillators running in resonance.

Key words. limit cycles, center bifurcations, subharmonics, Melnikov method, forced oscillations, frequency entrainment

1. Introduction.

The subject of this paper is the theory of frequency entrainment for driven nonlinear oscillators when the period of the self-sustained free oscillation is nearly resonance with a periodic external excitation. Our main purpose is to demonstrate a mathematical theorem that is useful in determining the number and position of the subharmonics produced by such an external excitation. Our result is closely related to two well-known theorems: the Poincaré–Andronov theorem on the global center bifurcation [1], [2], [3], [6], and the Melnikov theorem on the global bifurcation of subharmonics from an integrable system [21], [31], [42], [43]. In fact, our theorem can be considered as a generalization of Melnikov's method to cover the case of self-sustained oscillations.

In order to explain the main result, consider a forced oscillation problem of the following type:

$$\dot{x} = \mathbf{f}(x) + \epsilon \mathbf{g}(x,t), \quad x \in \mathbb{R}^2, \quad \epsilon \in \mathbb{R},$$

where the unperturbed system

$$\dot{x} = \mathbf{f}(x)$$

with flow $t \mapsto \phi_t$ has a limit cycle Γ of period T as a self-sustained oscillation; the external excitation is periodic of period η, i.e.,

$$\mathbf{g}(x, t+\eta) = \mathbf{g}(x,t),$$

and the period of the external excitation is in resonance with the period of Γ, i.e., there are relatively prime positive integers m and n such that $nT = m\eta$. We are interested in the periodic solutions of the forced system of period $m\eta$, the subharmonics of order m. For this, we look for a curve $\epsilon \mapsto \sigma(\epsilon)$ in the phase plane such that $\sigma(0) \in \Gamma$ and, for sufficiently small ϵ, such that the point $\sigma(\epsilon)$ is the initial value for a subharmonic of order m. When there is such a curve of initial conditions for a family of subharmonics,

we say $\sigma(0)$ is a subharmonic branch point on Γ. Our main result gives a real valued function $\xi \mapsto \mathcal{C}(\xi)$, for ξ a coordinate on Γ, such that the simple zeros of $\mathcal{C}$ are the subharmonic branch points. The formula for this function is expressed in terms of Euclidean geometrical quantities that we denote as follows: $\|\ \|$ denotes the Euclidean norm, $<, >$ the Euclidean inner product, κ the scalar curvature, div the divergence of a vector field, curl the curl of a vector field, and $\wedge$ the wedge product of two vectors. In fact, the bifurcation function $\mathcal{C}$ is defined by

$$\mathcal{C}(\xi) := [(1-\beta)\mathcal{N} + \alpha\mathcal{M}]\,(m\eta, \xi),$$

where

$$\begin{aligned}
\beta(t) := \beta(t,\xi) &:= \exp\left(\int_0^t \operatorname{div} \mathbf{f}(\phi_s(\xi))\,ds\right),\\
\alpha(t) := \alpha(t,\xi) &:= \int_0^t \left\{\frac{1}{\|\mathbf{f}\|^2}\left[2\kappa\|\mathbf{f}\| - \operatorname{curl}\mathbf{f}\right]\right\}(\phi_\tau(\xi))\beta(\tau)\,d\tau,\\
\mathcal{N}(t,\xi) &:= \int_0^t \left\{\frac{1}{\|\mathbf{f}\|^2}\langle \mathbf{f},\mathbf{g}\rangle - \frac{\alpha(s)}{\beta(s)}\mathbf{f}\wedge\mathbf{g}\right\}(\phi_s(\xi))\,ds,\\
\mathcal{M}(t,\xi) &:= \int_0^t \left\{\frac{1}{\beta(s)}\mathbf{f}\wedge\mathbf{g}\right\}(\phi_s(\xi))\,ds.
\end{aligned}$$

Our main theorem, the limit cycle subharmonic bifurcation theorem, states: *If either $\beta(m\eta,\xi) \neq 1$ or $\alpha(m\eta,\xi) \neq 0$ and if ξ is a simple zero of $\mathcal{C}$, then ξ is a subharmonic branch point.*

If the periodic trajectory Γ of the unperturbed system is not a limit cycle, but rather a periodic trajectory of period T contained in a one parameter family of periodic trajectories of the unperturbed system, then the appropriate bifurcation function is the subharmonic Melnikov function given by $\mathcal{M}$. In order to show that $\mathcal{C}$ reduces to $\mathcal{M}$ in this case, consider a Poincaré section Σ for the unperturbed system that is orthogonal to Γ at a point $\xi_0 \in \Sigma$, and define both the Poincaré return map and the transition time function on Σ. In §2 we will show the derivative of the return map, evaluated at the coordinate on Σ corresponding to ξ_0, is $\beta(T,\xi_0)$, while the derivative of the transition time function is $\alpha(T,\xi_0)$. Thus, for example, if Γ is a member of a one parameter family of periodic orbits, then Γ is not hyperbolic, equivalently, $\beta(nT,\xi) \equiv 1$, and $\mathcal{C}$ reduces to the usual subharmonic Melnikov function. Moreover, in this case, the appropriate nondegeneracy condition of the theorem, $\alpha(m\eta,\xi) \neq 0$, reduces to the condition that the period function for the one parameter family of periodic trajectories of the unperturbed system has a nonzero derivative at Γ; this is the usual nondegeneracy condition for the subharmonic Melnikov theory; cf. [15], [21], [43]. For further results related to period functions, see [4], [9], [11], [12], [14], [16], [17], [33], and [40].

As a typical application, consider two weakly coupled van der Pol oscillators of the form

$$\begin{aligned}
\dot{u} &= v,\\
\dot{v} &= -u + \delta(1-u^2)v,\\
\dot{x} &= \tau y,\\
\dot{y} &= \tau(-x + \delta(1-x^2)y) + \epsilon u,
\end{aligned}$$

where $\delta > 0$, ϵ is a small parameter, and $\tau > 0$ is a rational number. We view the second oscillator as a driven oscillator where the periodic forcing function, $t \mapsto u(t)$,

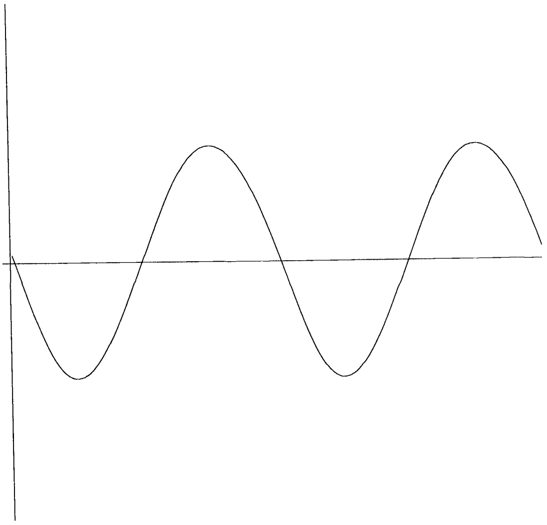

FIG. 1. *Computer generated graph of C vs ξ for weakly coupled van der Pol oscillators* $\dot{u} = v$, $\dot{v} = -u + 0.1(1 - u^2)v$, $\dot{x} = 0.5y$, $\dot{y} = 0.5(-x + 0.1(1 - x^2)y) + \epsilon u$ *with* $2 : 1$ *resonance.*

is the output of the first oscillator. Since τ is rational, the frequency of the free oscillation of the second oscillator is in resonance with the frequency of the external excitation. We ask for the periodic response of the second oscillator when $\epsilon \neq 0$. For background material on forced oscillation problems we refer to [2], [15], [18], [27], [30], [22], [23], [25], [32], [34], [41] for classic treatments and to [21], [26], [36], [42], [43] for some of the latest results. As a typical calculation we fix $\delta = 0.1$ and $\tau = 0.5$. For this example the period of the free oscillation of the second oscillator is twice the period of the "external" force, a $2 : 1$ resonance. A numerical approximation to the graph of $C(\xi)$ is shown in Fig. 1. The graph indicates the existence of four simple zeros of C over one period of the free oscillation and, applying our theorem, we expect, for $|\epsilon|$, sufficiently small, four subharmonics of order two, i.e., four periodic solutions of the forced second oscillator each with period twice the period of the self-sustained oscillation of the first oscillator. Of course, in view of the topology of the circle, two of these subharmonics are stable and two of them are unstable, with the subharmonics corresponding to consecutive zeros of C having opposite stability.

Our treatment of the bifurcation theory of nonlinear oscillations is based on the geometric quadrature of the homogeneous variational equations of a two-dimensional differential system given by Diliberto [20] and a Lyapunov–Schmidt reduction to the implicit function theorem. Using this foundation, we are able to offer a unified approach to the bifurcation theory for plane vector fields that includes the Poincaré–Andronov center bifurcation theorem and the usual subharmonic Melnikov theorem. Since an exposition of these results requires only a minimum of additional effort, we do not offer the most efficient proof of our main result. Rather, we take a slightly longer route to our theorem that allows us to give new proofs of these other classic results. In addition to the unification provided by our implicit function theorem approach to the bifurcation theory, we obtain smooth curves of bifurcating periodic solutions. Thus, the precise positions of the bifurcating solutions can be computed and, perhaps, continued to further global bifurcations. Also, we mention that our method yields proofs of the bifurcation theorems that do not require reduction to a normal form or a change to action angle variables.

The plan of the paper is as follows. In §2 we give a proof of Diliberto's theorem and obtain the geometric interpretation of the functions α and β in terms of the Poincaré map and the transition time function. We also define the functions $\mathcal{N}$ and $\mathcal{M}$ in their natural context as constituents of the solution of a certain inhomogeneous variational equation. In §3 we prove the Poincaré–Andronov center bifurcation theorem. In §4 we prove the subharmonic Melnikov theorem, our main result, the limit cycle subharmonic bifurcation theorem, and we prove some theorems on bifurcation of subharmonics from degenerate families. Also, we connect our theory with the classical perturbation theory for linear systems. In the final section, §5, we give additional applications of the theory.

2. Diliberto's theorem. The fundamental result on which this paper is based is the theorem of Diliberto [20] on the integration of the homogeneous variational equations of a plane autonomous differential equation in terms of geometric quantities along a given trajectory of the system. Here we let $\mathbf{X} = (X_1, X_2)$ denote a smooth plane vector field with flow ϕ_t. The geometric quantities are the curvature, the curl, and the divergence given by

$$\kappa = \|\mathbf{X}\|^{-3}\left(X_1\dot{X}_2 - X_2\dot{X}_1\right), \quad \operatorname{curl}\mathbf{X} = \frac{\partial X_2}{\partial x_1} - \frac{\partial X_1}{\partial x_2}, \quad \operatorname{div}\mathbf{X} = \frac{\partial X_1}{\partial x_1} + \frac{\partial X_2}{\partial x_2},$$

where $\|\mathbf{X}\| = \sqrt{\langle \mathbf{X}, \mathbf{X}\rangle}$ denotes the Euclidean norm. It will also be convenient to define the orthogonal vector field $\mathbf{X}^\perp := (-X_2, X_1)$ as well as the vector field $\mathbf{u}_{\mathbf{X}^\perp}$ parallel to $\mathbf{X}^\perp$ given by

$$\mathbf{u}_{\mathbf{X}^\perp}(p) := \frac{1}{\|\mathbf{X}(p)\|^2}\mathbf{X}^\perp(p).$$

The normalization is chosen so that $\langle \mathbf{X}^\perp, \mathbf{u}_{\mathbf{X}^\perp}\rangle = 1$. Finally, we introduce the wedge product of two vector fields $\mathbf{X} = (X_1, X_2)$ and $\mathbf{Y} = (X_1, X_2)$ to be $\mathbf{X} \wedge \mathbf{Y} = X_1Y_2 - X_2Y_1$. In the course of our discussion we make use of the formula

$$\mathbf{X} \wedge \mathbf{Y} = \left\langle \mathbf{X}^\perp, \mathbf{Y}\right\rangle.$$

It allows for a choice between two geometric interpretations of the same quantity, namely, the area given by the wedge product and the projection given by the inner product. This choice is rather arbitrary, but is often made according to tradition.

THEOREM 2.1 (Diliberto's theorem). *If* $\mathbf{X}(p) \neq 0$, *then the linear variational equation along the integral curve* $t \mapsto \phi_t(p)$,

$$\dot{\mathbf{V}} = D\mathbf{X}(\phi_t(p))\mathbf{V},$$

has a fundamental matrix solution $\Phi(t)$, *satisfying* $\det(\Phi(0)) = 1$, *given by*

$$\Phi(t) := [\mathbf{X}(\phi_t(p)), \mathbf{V}(t)],$$

where

$$\mathbf{V}(t) := \alpha(t)\mathbf{X}(\phi_t(p)) + \beta(t)\mathbf{u}_{\mathbf{X}^\perp}(\phi_t(p))$$

and

$$\beta(t) := \beta(t, \mathbf{X}, p) := \exp\left(\int_0^t \operatorname{div}\, \mathbf{X}(\phi_s(p))\, ds\right),$$

$$\alpha(t) := \alpha(t, \mathbf{X}, p) := \int_0^t \left\{\frac{1}{\|\mathbf{X}\|^2}\left[2\kappa\|\mathbf{X}\| - \operatorname{curl}\,\mathbf{X}\right]\right\}(\phi_\tau(p))\beta(\tau)\, d\tau.$$

Moreover, the inverse of this fundamental matrix (partitioned by rows) is given by

$$\Phi^{-1}(t) = \frac{1}{\beta(t)} \begin{bmatrix} -\mathbf{V}^{\perp}(t) \\ \mathbf{X}^{\perp}(\phi_t(p)) \end{bmatrix}.$$

Proof. Define $\gamma(t) := \phi_t(p)$. Since $\mathbf{X}(p) \neq 0$, the function $t \mapsto \mathbf{X}(\gamma(t))$ is a nontrivial solution of the linear variational equation. Next, define

$$\mathbf{P}(t) := \frac{1}{\|\mathbf{X}(\gamma(t))\|} \left[\mathbf{X}(\gamma(t)), \mathbf{X}^{\perp}(\gamma(t))\right]$$

(partitioned by columns) and use the coordinate transformation $\mathbf{U} = \mathbf{P}^{-1}\mathbf{V}$ on the linear variational equation $\dot{\mathbf{V}} = D\mathbf{X}(\gamma(t))\mathbf{V}$ to obtain $\dot{\mathbf{U}} = \mathbf{A}\mathbf{U}$, where

$$\mathbf{A} := \mathbf{P}^{-1}(D\mathbf{X}(\gamma(t)))\mathbf{P} - \mathbf{P}^{-1}\dot{\mathbf{P}}.$$

A somewhat tedious calculation shows the matrix $\mathbf{A}$ is given by

$$\mathbf{A} = \begin{bmatrix} \|\mathbf{X}\|^{-1}\frac{d}{dt}\|\mathbf{X}\| & 2\|\mathbf{X}\|^{-2}(X_1\dot{X}_2 - X_2\dot{X}_1) - \operatorname{curl}\mathbf{X} \\ 0 & -\|\mathbf{X}\|^{-1}\frac{d}{dt}\|\mathbf{X}\| + \operatorname{div}\mathbf{X} \end{bmatrix}$$
$$= \begin{bmatrix} \frac{d}{dt}\ln\|\mathbf{X}\| & 2\|\mathbf{X}\|\kappa - \operatorname{curl}\mathbf{X} \\ 0 & -\frac{d}{dt}\ln\|\mathbf{X}\| + \operatorname{div}\mathbf{X} \end{bmatrix}.$$

Since this system is in triangular form, we can find a simple representation for the general solution of $\dot{\mathbf{U}} = \mathbf{A}\mathbf{U}$. In fact, if we use $\mathbf{e}_1 := (1, 0)$ and $\mathbf{e}_2 := (0, 1)$, then

$$\mathbf{U}(t) = \frac{\|\mathbf{X}(\gamma(t))\|}{\|\mathbf{X}(p)\|}\left\{U_1(0) + U_2(0)\|\mathbf{X}(p)\|^2\alpha(t)\right\}\mathbf{e}_1 + \frac{U_2(0)\|\mathbf{X}(p)\|}{\|\mathbf{X}(\gamma(t))\|}\beta(t)\mathbf{e}_2,$$

where $\mathbf{U} = (U_1, U_2)$. Finally, if we choose the initial conditions so that one solution has initial condition $\mathbf{U}(0) = \|\mathbf{X}(p)\|\mathbf{e}_1$, and a second solution satisfies the initial condition $\|\mathbf{X}(p)\|\mathbf{U}(0) = \mathbf{e}_2$, then we obtain two linearly independent solutions. These solutions form the columns of a fundamental matrix $\tilde{\Phi}$ for $\dot{\mathbf{U}} = \mathbf{A}\mathbf{U}$, while the fundamental matrix in the statement of the theorem is just $\Phi = \mathbf{P}\tilde{\Phi}$. A simple calculation shows that $\det(\Phi(0)) = 1$. The statement about the inverse of the fundamental matrix $\Phi(t)$ is a straightforward deduction, and its proof is omitted. □

Remark. It should be noted that the constant 2 multiplying the curvature in the theorem was omitted in the formulas in Diliberto's original paper.

Diliberto's theorem contains all the important information about the solutions of the linear variational equation along the trajectories of the plane vector field $\mathbf{X}$. We will use the theorem to derive several corollaries that illustrate the importance of the result. The first few of these corollaries can be taken to give the *geometric* meaning of the two functions α and β that are defined in the statement of the theorem. For this we introduce some basic definitions. Let p and q be points in $\mathbb{R}^2$ on the trajectory $t \mapsto \phi_t(p)$ of $\mathbf{X}$ with $q = \phi_T(p)$. We consider two sections for the flow of $\mathbf{X}$, Σ at p, and Δ at q, given by plane curves $s \mapsto \sigma(s)$ and $s \mapsto \delta(s)$ with $\sigma(\xi) = p$. Moreover, we let $\mathbf{Y}$ denote the tangent vector field of σ and $\mathbf{Z}$ the tangent vector field of δ. We use $\widetilde{\mathbf{h}} : \Sigma \to \Delta$ to denote the *transition map.* It assigns to a point $r \in \Sigma$ the point where the trajectory of $\mathbf{X}$ starting from r first meets Δ. We use $\widetilde{T} : \Sigma \to \mathbb{R}$ to denote the *transition time function* that assigns to $r \in \Sigma$ the minimum positive time required for the transition. There will be an open interval $\mathcal{I} \subset \mathbb{R}$ such that for $s \in \mathcal{I}$ both $\widetilde{\mathbf{h}}$ and $\widetilde{T}$ are defined on $\sigma(\mathcal{I})$. We define $\mathcal{J} := \delta^{-1} \circ \widetilde{\mathbf{h}} \circ \sigma(\mathcal{I})$. Then, we can express the transition map and the transition time function in the local coordinates on the two sections defined by the functions σ and δ. It is convenient to give these representations names. In fact, we define the *scalar transition map* $h : \mathcal{I} \to \mathcal{J}$ by the formula

$$h := \delta^{-1} \circ \widetilde{\mathbf{h}} \circ \sigma,$$

and the *scalar transition time function* $T : \mathcal{I} \to \mathbb{R}$ by

$$T := \widetilde{T} \circ \sigma.$$

When we write $\widetilde{\mathbf{h}}'(p)$, we understand this to be the derivative $h'(\xi)$, and when we write $\widetilde{T}'(p)$ we understand this to be the derivative $T'(\xi)$. Finally, we specify two special cases. If p is a periodic point of $\mathbf{X}$, we can take $\Sigma = \Delta$. In this case, the transition map is called the *return map* or the *Poincaré map* on the *Poincaré section* Σ. If, in addition, p is contained in a one parameter family of periodic trajectories of $\mathbf{X}$, we say p is in a *period annulus with* (*Poincaré*) *section* Σ. In this case, the corresponding transition time function is called the *period function.*

The next theorem identifies the functions α and β in Diliberto's theorem geometrically and, in particular, provides formulas for the derivative of the return map and the period function.

THEOREM 2.2. *Let* $\mathbf{X}$ *be a plane vector field with flow* ϕ_t, Σ *a section for the flow at* $p \in \mathbb{R}^2$, *and* Δ *a section for the flow at* $q = \phi_T(p)$. *Also, let* $s \mapsto \sigma(s)$ *be a local coordinate function for* Σ *with tangent vector field* $\mathbf{Y}$ *such that* $\sigma(\xi) = p$, *and let* $s \mapsto \delta(s)$ *be a local coordinate function for* Δ *with tangent vector field* $\mathbf{Z}$. *If* $\widetilde{\mathbf{h}}$ *is the transition map and* $\widetilde{T}$ *is the transition time function, then*

$$\widetilde{\mathbf{h}}'(p) = \frac{\mathbf{X} \wedge \mathbf{Y}(p)}{\mathbf{X} \wedge \mathbf{Z}(\widetilde{\mathbf{h}}(p))}\beta(\widetilde{T}(p), \mathbf{X}, p)$$

and

$$\widetilde{T}'(p) = \frac{\langle \mathbf{Z}, \mathbf{X}\rangle}{\|\mathbf{X}\|^2}(\widetilde{\mathbf{h}}(p))\widetilde{\mathbf{h}}'(p) - \frac{\langle \mathbf{Y}, \mathbf{X}\rangle}{\|\mathbf{X}\|^2}(p) - \mathbf{X} \wedge \mathbf{Y}(p)\alpha(\widetilde{T}(p), \mathbf{X}, p).$$

In particular, if p *is a periodic point of* $\mathbf{X}$, *the derivative of the return map is given by*

$$\widetilde{\mathbf{h}}'(p) = \frac{\mathbf{X} \wedge \mathbf{Y}(p)}{\mathbf{X} \wedge \mathbf{Y}(\widetilde{\mathbf{h}}(p))}\beta(\widetilde{T}(p), \mathbf{X}, p),$$

and, in addition, if p *is contained in a period annulus, the derivative of the period function is given by*

$$\widetilde{T}'(p) = -\mathbf{X} \wedge \mathbf{Y}(p)\alpha(\widetilde{T}(p), \mathbf{X}, p).$$

Proof. By the definition of the transition map and the transition time function we have

$$\widetilde{\mathbf{h}}(\sigma(s)) = \phi_{\widetilde{T}(\sigma(s))}(\sigma(s)),$$

or, in local coordinates,

$$\delta(h(s)) = \phi_{T(s)}(\sigma(s)).$$

After differentiating both sides of the last equation and evaluating at $s = \xi$, we obtain the following formula for the derivative of the transition map:

$$h'(\xi)\mathbf{Z}(q) = \frac{d}{ds}\phi_{T(s)}(\sigma(s))\bigg|_{s=\xi} = D\phi_{T(\xi)}(p)\mathbf{Y}(p) + T'(\xi)\mathbf{X}(q).$$

We will apply Diliberto's theorem to obtain the required formulas. For this, observe that the function $t \mapsto \mathbf{V}(t)$, giving the second column of the Diliberto fundamental matrix of the linear variational equations along the trajectory $t \mapsto \phi_t(p)$ of $\mathbf{X}$, is the unique solution of the following linear variational initial value problem:

$$\dot{\mathbf{V}} = D\mathbf{X}(\phi_t(p))\mathbf{V}, \qquad \mathbf{V}(0) = \mathbf{u}_{\mathbf{X}^\perp}(p),$$

whose solution evaluated at $T(\xi)$ is

$$\mathbf{V}(T(\xi)) = \alpha(T(\xi), \mathbf{X}, p)\mathbf{X}(q) + \beta(T(\xi), \mathbf{X}, p)\mathbf{u}_{\mathbf{X}^\perp}(q).$$

Since $t \mapsto D\phi_t(p)\mathbf{u}_{\mathbf{X}^\perp}(p)$ is a solution of the same initial value problem, we have

$$D\phi_t(p)\mathbf{u}_{\mathbf{X}^\perp}(p) = \mathbf{V}(t),$$

and, of course, we also have

$$D\phi_t(p)\mathbf{X}(p) = \mathbf{X}(\phi_t(p)).$$

Moreover, there are real numbers a, b, c, and d such that

$$\mathbf{Y}(p) = a\mathbf{X}(p) + b\mathbf{u}_{\mathbf{X}^\perp}(p), \qquad \mathbf{Z}(q) = c\mathbf{X}(q) + d\mathbf{u}_{\mathbf{X}^\perp}(q).$$

In fact, these numbers can be expressed in terms of the given vectors as follows:

$$\begin{aligned} a &= \frac{\langle \mathbf{Y}, \mathbf{X}\rangle}{||\mathbf{X}||^2}(p), \qquad & b &= \mathbf{X} \wedge \mathbf{Y}(p), \\ c &= \frac{\langle \mathbf{Z}, \mathbf{X}\rangle}{||\mathbf{X}||^2}(q), \qquad & d &= \mathbf{X} \wedge \mathbf{Z}(q). \end{aligned}$$

Now, we compute

$$D\phi_t(p)\mathbf{Y}(p) = a\mathbf{X}(\phi_t(p)) + b\mathbf{V}(t),$$

and, after the obvious substitutions into the formula for $h'(\xi)$, we obtain

$$(ch'(\xi) - T'(\xi) - a - b\alpha)\,\mathbf{X}(q) + (dh'(\xi) - b\beta)\,\mathbf{u}_{\mathbf{X}^\perp}(q) = 0.$$

The first part of the theorem follows immediately from the last equality and the linear independence of $\mathbf{X}(q)$ and $\mathbf{u}_{\mathbf{X}^\perp}(q)$.

From the definition of the return map we can assume $\Sigma = \Delta, q = \widetilde{\mathbf{h}}(p)$, and $\mathbf{Y} = \mathbf{Z}$. The derivative of the return map in the statement of the theorem is obtained by specializing the formula,

$$h'(\xi) = \frac{b}{d}\beta,$$

just derived for the derivative of the transition map.

For the derivative of the period function we have the same specialization and, in addition, the fact that p lies in a period annulus. The periodicity of p implies $p = q$ and, in turn, $a = c$, while the membership of p in a period annulus implies $\widetilde{\mathbf{h}}'(p) = 1$. Hence, in this case, $ch'(\xi) - a = 0$ and the formula obtained for the derivative of the transition time function reduces to the required formula for the period function,

$$T'(\xi) = -b\alpha. \qquad \square$$

For the majority of situations encountered in practice, when dealing with a spiral flow in the plane, a horizontal line segment can be chosen as a Poincaré section. In this case, the representation of the derivative of the return map and of the period function given in the last theorem takes a particularly simple form. If the horizontal line segment is an interval of the line with equation $y = k$, then, for example, the vector field $\mathbf{Y}$ may be taken to be the unit vector in the (positive) horizontal direction. If X_2 denotes the second component of the vector field $\mathbf{X}$, then, with $\gamma(t) := \phi_t(x, k)$, the representation of the derivative of the return map is

$$h'(x) = \frac{X_2(x,k)}{X_2(h(x),k)} \exp\left(\int_0^{T(x)} \operatorname{div}\mathbf{X}(\gamma(t))\,dt\right),$$

while the representation of the derivative of the period function is

$$T'(x) = X_2(x,k) \int_0^{T(x)} \left\{\frac{1}{\|\mathbf{X}\|^2}\left[2\kappa\|\mathbf{X}\| - \operatorname{curl}\mathbf{X}\right]\right\}(\gamma(\tau)) \exp\left(\int_0^{\tau} \operatorname{div}\mathbf{X}(\gamma(t))\,dt\right) d\tau.$$

These cases are often encountered in the applications.

The geometric identification of the function β is now clear. In fact, generally, if we consider a trajectory $t \mapsto \phi_t(p)$ of $\mathbf{X}$ and two sections Σ at p and Δ at $\phi_\tau(p)$, then $\beta(\tau, \mathbf{X}, p)$ is just the normalized derivative of the transition map. The normalization coefficient is the quotient of the two wedge products given in the theorem. The geometric identification of the function α is more complicated in the general case. But, if the two sections are orthogonal to the trajectory through p, then $\alpha(\tau, \mathbf{X}, p)$ is just the derivative of the transition time function normalized by the multiplicative factor $-\mathbf{X} \wedge \mathbf{Y}(p)$.

The next lemma gives an explicit formula for the solution of the inhomogeneous linear variational equations along a trajectory of $\mathbf{X}$; this formula will be needed in the perturbation theory that will be developed later.

LEMMA 2.3 (variation lemma). *Let* $\mathbf{X} = (X_1, X_2)$ *and* $\mathbf{b} = (b_1, b_2)$ *denote smooth plane vector fields, and let* ϕ_t *denote the flow of* $\mathbf{X}$. *If* $p \in \mathbb{R}^2$ *and* $\mathbf{X}(p) \neq 0$, *then the solution,* $t \mapsto \mathbf{W}(t)$, *of the initial value problem*

$$\dot{\mathbf{W}} = D\mathbf{X}(\phi_t(p))\mathbf{W} + \mathbf{b}(\phi_t(p)), \qquad \mathbf{W}(0) = 0$$

is given by

$$\mathbf{W}(t) = [\mathcal{N}(t) + \alpha(t)\mathcal{M}(t)]\,\mathbf{X}(\phi_t(p)) + [\beta(t)\mathcal{M}(t)]\,\mathbf{u}_{\mathbf{X}^\perp}(\phi_t(p)),$$

where

$$\mathcal{N}(t) := \mathcal{N}(t, \mathbf{X}, \mathbf{b}, p) := \int_0^t \left\{ \frac{1}{||\mathbf{X}||^2} \langle \mathbf{X}, \mathbf{b} \rangle - \frac{\alpha(s)}{\beta(s)} \mathbf{X} \wedge \mathbf{b} \right\} (\phi_s(p))\, ds,$$
$$\mathcal{M}(t) := \mathcal{M}(t, \mathbf{X}, \mathbf{b}, p) := \int_0^t \left\{ \frac{1}{\beta(s)} \mathbf{X} \wedge \mathbf{b} \right\} (\phi_s(p))\, ds,$$

and α, β are defined in the statement of Diliberto's theorem. In addition, if m is a positive integer, p is a point in a period annulus of $\mathbf{X}$ with local section Σ given at p by the integral curve $s \mapsto \sigma(s)$ of $\mathbf{X}^\perp$ such that $\sigma(\xi) = p$, and if T denotes the scalar period function defined on Σ, then

$$\alpha(mT(\xi)) = -\frac{m}{||\mathbf{X}(p)||^2} T'(\xi), \qquad \beta(mT(\xi)) = 1$$

and

$$W(mT(\xi)) = \left[\mathcal{N}(mT(\xi)) - \frac{m}{||\mathbf{X}(p)||^2} T'(\xi) \mathcal{M}(mT(\xi)) \right] \mathbf{X}(p) + \mathcal{M}(mT(\xi)) \mathbf{u}_{\mathbf{X}^\perp}(p).$$

Proof. Using variation of parameters, we have

$$\mathbf{W}(t) = \Phi(t) \int_0^t \Phi^{-1}(s) \mathbf{b}(s)\, ds,$$

where Φ is the Diliberto fundamental matrix. To evaluate this formula for $\mathbf{W}$ we first observe that

$$-\mathbf{V}^\perp(t) = \left\{ -\alpha(t) \mathbf{X}^\perp + \beta(t) \frac{1}{||\mathbf{X}||^2} \mathbf{X} \right\} (\phi_t(p)).$$

Then, using the formulas for the Diliberto fundamental matrix and its inverse given in Diliberto's theorem, we compute

$$\int_0^t \Phi^{-1}(s) \mathbf{b}(\phi_s(p))\, ds = \begin{bmatrix} \mathcal{N}(t) \\ \mathcal{M}(t) \end{bmatrix}.$$

The first statement of the lemma is now immediate.

For the second part of the lemma, we assume p is a periodic point of $\mathbf{X}$ and the coordinate for the section at p is given by the integral curve $s \mapsto \sigma(s)$ of $\mathbf{X}^\perp$ with $\sigma(\xi) = p$. Then, since p belongs to a period annulus, the return map is the identity on Σ, and we conclude from the formula for the return map obtained above that

$$\beta(mT(\xi)) = 1.$$

Moreover, using this fact, together with a straightforward change of variables in the integral representation of $\alpha(mT(\xi))$, or, using the formula for $\widetilde{T}'$, we find

$$\alpha(mT(\xi)) = m\alpha(T(\xi)).$$

Thus, in view of the formula for the derivative of the period function given in the previous theorem,

$$\alpha(mT(\xi)) = -\frac{m}{||\mathbf{X}(p)||^2}T'(\xi).$$

After substitution of these identities into the formula for $\mathbf{W}(t)$ and a simple rearrangement of the terms, the final equality in the statement of the lemma is proved. □

3. The Poincaré–Andronov theorem. In order to state the main result of this section, we consider a plane vector field $(x, y) \mapsto \mathbf{X}(x, y, \epsilon)$ depending on the real small parameter ϵ. In case the phase portrait of the unperturbed system $\mathbf{X}_0(x, y) := \mathbf{X}(x, y, 0)$ contains a period annulus $\mathcal{A}$, we seek to determine if there is a periodic trajectory Γ contained in $\mathcal{A}$ and a continuous family Γ_ϵ of periodic trajectories of $(x, y) \mapsto \mathbf{X}(x, y, \epsilon)$ such that $\Gamma_0 = \Gamma$.

For this bifurcation problem it is convenient to consider the differential equation corresponding to the vector field $(x, y) \mapsto \mathbf{X}(x, y, \epsilon)$ in the form

$$\dot{x} = P(x, y) + \epsilon p(x, y) + O(\epsilon^2), \qquad \dot{y} = Q(x, y) + \epsilon q(x, y) + O(\epsilon^2).$$

Also, we let ϕ_t^ϵ denote the flow of $\mathbf{X}$. We can always arrange the coordinates so that a certain horizontal line segment $\Sigma : y = y_0$ is transverse to the flow of $\mathbf{X}_0$ in $\mathcal{A}$. Then, there is some $\epsilon_0 > 0$ such that $(x, y) \mapsto \mathbf{X}(x, y, \epsilon)$ is transverse to Σ, for all ϵ satisfying $|\epsilon| < \epsilon_0$. We assume Γ is one of the periodic trajectories in $\mathcal{A}$ transverse to Σ, and let ξ denote the usual distance coordinate along Σ. Then, both the scalar transition time function $(\xi, \epsilon) \mapsto T(\xi, \epsilon)$ and the scalar Poincaré return map $(\xi, \epsilon) \mapsto h(\xi, \epsilon)$ are defined on Σ. It is convenient in the analysis to define $\mathbf{X}_0^\perp$ to be the vector field with components $(-Q, P)$ and $\mathbf{H}(\xi, \epsilon)$ to be the vector $(d(\xi, \epsilon), 0)$, where d is the *displacement function* defined by $d(\xi, \epsilon) := h(\xi, \epsilon) - \xi$. We also define the *normalized displacement function* F by

$$F(\xi, \epsilon) = \mathbf{X}_0^\perp(\xi, y_0) \cdot \mathbf{H}(\xi, \epsilon) = -Q(\xi, y_0)d(\xi, \epsilon).$$

There are two basic facts: $F(\xi, \epsilon) = 0$ if and only if the trajectory of $(x, y) \mapsto \mathbf{X}(x, y, \epsilon)$ through (ξ, y_0) is periodic and $F(\xi, 0) \equiv 0$. If there is an $\epsilon_* > 0$ and a continuous function $\beta : (-\epsilon_*, \epsilon_*) \to \Sigma$ such that $F(\beta(\epsilon), \epsilon) \equiv 0$, then, for each ϵ in the domain of β, there is a periodic trajectory Γ_ϵ of the vector field $(x, y) \to \mathbf{X}(x, y, \epsilon)$ passing through the point $(\beta(\epsilon), y_0)$. In this case, we say *a continuous family of periodic trajectories of* $\mathbf{X}$ *emerges from the periodic trajectory* Γ_0.

The next result provides a means to identify the periodic trajectories in a period annulus of the unperturbed system from which a family of limit cycles emerges. It is a version of the theorem given in [1] and is the basic bifurcation theorem in this context. Our approach to the proof of this theorem is somewhat different from the development of the same result in [1]. For example, in [1, §32], the vector field family in which the bifurcation occurs is assumed to be analytic and, in [1, §33], a first integral must be constructed for the unperturbed conservative system. Here, we prove the result by analyzing an appropriate variational equation directly. The theorem has two main components: a reduction and an identification. Here, reduction refers to reducing the problem of the existence of a family of limit cycles to an application of the implicit function theorem, and identification refers to the identification of the appropriate partial derivatives in terms of the components of the vector field $\mathbf{X}$.

THEOREM 3.1. *Let $(x,y) \mapsto \mathbf{X}(x,y,\epsilon)$ denote a vector field with flow $t \mapsto \phi_t^\epsilon$ and corresponding differential equation*

$$\dot{x} = P(x,y) + \epsilon p(x,y) + O(\epsilon^2), \qquad \dot{y} = Q(x,y) + \epsilon q(x,y) + O(\epsilon^2)$$

such that the corresponding unperturbed vector field $\mathbf{X}_0$ given by $(x,y) \to \mathbf{X}(x,y,0)$ has a period annulus with Poincaré section $\Sigma \subset \{(x,y) : y = y_0\}$.

(i) *Reduction. If there is a point $\xi_0 \in \Sigma$ such that the corresponding normalized displacement function F satisfies $F_\epsilon(\xi_0,0) = 0$ and $F_{\xi\epsilon}(\xi_0,0) \neq 0$, then there is a periodic trajectory Γ of $\mathbf{X}_0$ meeting Σ at ξ_0 and a continuous family, Γ_ϵ, of periodic trajectories of $\mathbf{X}$ emerging from Γ. Moreover, for sufficiently small $\epsilon \neq 0$, the periodic trajectory Γ_ϵ is a limit cycle of the vector field $(x,y) \to \mathbf{X}(x,y,\epsilon)$. In fact, if $\epsilon F_{\xi\epsilon}(\xi_0,0)/Q(\xi_0,y_0) > 0$, then Γ_ϵ is asymptotically stable. If $\epsilon F_{\xi\epsilon}(\xi_0,0)/Q(\xi_0,y_0) < 0$, then Γ_ϵ is asymptotically unstable.*

(ii) *Identification. The partial derivative of the normalized displacement function with respect to the bifurcation parameter is given by*

$$F_\epsilon(\xi,0) = \int_0^{T(\xi,0)} (Pq - Qp)\,(\gamma(t)) \exp\left(-\int_0^t \operatorname{div} \mathbf{X}_0(\gamma(s))\,ds\right) dt,$$

where $\gamma(t) := \phi_t^0(\xi, y_0)$ is the integral curve corresponding to the periodic trajectory Γ through (ξ, y_0). In addition, if $F_\epsilon(\xi_0,0) = 0$ for some $\xi_0 \in \Sigma$, then

$$\begin{aligned} F_{\xi\epsilon}(\xi_0,0) = -Q(\xi_0,y_0)\Bigg\{ & \operatorname{div} \mathbf{X}_0(\xi_0,y_0) T_\epsilon(\xi_0,0) \\ & + \int_0^{T(\xi_0,0)} \operatorname{div}(p,q)(\gamma(t))\,dt \\ & + \int_0^{T(\xi_0,0)} \frac{d}{d\epsilon} \operatorname{div} \mathbf{X}_0(\phi_t^\epsilon(\xi_0,y_0))\bigg|_{\epsilon=0} dt \Bigg\}. \end{aligned}$$

(iii) *If $\mathbf{X}_0$ is Hamiltonian* $(\operatorname{div} \mathbf{X}_0 \equiv 0)$, *then for $\xi \in \Sigma$,*

$$F_\epsilon(\xi,0) = \int_0^{T(\xi,0)} (Pq - Qp)(\gamma(t))\,dt = -\int_\Omega \operatorname{div}(p,q)\,dxdy.$$

If, in addition, $F(\xi_0,0) = 0$, then

$$F_{\xi\epsilon}(\xi_0,0) = -Q(\xi_0,y_0) \int_0^{T(\xi_0,0)} \operatorname{div}(p,q)(\gamma(t))\,dt.$$

Proof. Since $F(\xi,0) \equiv 0$,

$$F(\xi,\epsilon) = \epsilon\,(F_\epsilon(\xi,0) + O(\epsilon)) := \epsilon G(\xi,\epsilon).$$

But then, from the hypotheses,

$$G(\xi_0,0) = F_\epsilon(\xi_0,0) = 0 \quad \text{and} \quad G_\xi(\xi_0,0) = F_{\xi\epsilon}(\xi_0,0) \neq 0.$$

The implicit function theorem applied to G implies the existence of the required function $\epsilon \mapsto \beta(\epsilon)$. For the stability of the perturbed limit cycles, just note that the displacement has the form

$$d(\xi,\epsilon) = \epsilon d_\epsilon(\xi,0) + O(\epsilon^2).$$

Thus, for sufficiently small ϵ, if $\epsilon d_{\epsilon\xi}(\xi_0, 0) < 0$, then $\xi \mapsto d(\xi, \epsilon)$ crosses the horizontal line segment Σ with negative slope as ξ increases through ξ_0. It is then immediate from the definition of the displacement that Γ_ϵ is a stable limit cycle. By the same argument, the limit cycle will be unstable when $\epsilon d_{\epsilon\xi}(\xi_0, 0) < 0$. But,

$$\epsilon d_{\epsilon\xi}(\xi_0, 0) = -\epsilon \frac{F_{\epsilon\xi}(\xi_0, 0)}{Q(\xi_0, y_0)},$$

and therefore the statement of the theorem follows.

For the computation of the partial derivative $F_\epsilon(\xi, 0)$, we have

$$F_\epsilon(\xi, 0) = \mathbf{X}_0^\perp(\xi, y_0) \cdot \mathbf{H}_\epsilon(\xi, 0)$$

with $\mathbf{H}_\epsilon(\xi, 0) = (h_\epsilon(\xi, 0), 0)$. Thus, we must compute h_ϵ. For this, consider the integral curve $(x(t, \xi, \epsilon), y(t, \xi, \epsilon))$ of $(x, y) \mapsto \mathbf{X}(x, y, \epsilon)$ starting at the point (ξ, y_0), and let $T(\xi, \epsilon)$ denote the time of first return of this solution to Σ. Clearly, we have

$$x(T(\xi, \epsilon), \xi, \epsilon) = h(\xi, \epsilon), \qquad y(T(\xi, \epsilon), \xi, \epsilon) = y_0,$$

and, after differentiation with respect to ϵ and an evaluation at $\epsilon = 0$, we obtain

$$\begin{aligned} &\dot{x}(T(\xi, 0), \xi, 0)T_\epsilon(\xi, 0) + x_\epsilon(T(\xi, 0), \xi, 0) = h_\epsilon(\xi, 0), \\ &\dot{y}(T(\xi, 0), \xi, 0)T_\epsilon(\xi, 0) + y_\epsilon(T(\xi, 0), \xi, 0) = 0. \end{aligned}$$

Define

$$\mathbf{W}(t) := (x_\epsilon(t, \xi, 0), y_\epsilon(t, \xi, 0)),$$

and then, using the abbreviations $T := T(\xi, 0)$, $T_\epsilon := T_\epsilon(\xi, 0)$, and $\mathbf{H}_\epsilon := \mathbf{H}_\epsilon(\xi, 0)$, we have

$$T_\epsilon \mathbf{X}_0(\gamma(T)) + \mathbf{W}(T) = \mathbf{H}_\epsilon = T_\epsilon \mathbf{X}_0(\xi, y_0) + \mathbf{W}(T).$$

Consequently,

$$F_\epsilon(\xi, 0) = \mathbf{X}_0^\perp(\xi, y_0) \cdot \mathbf{W}(T).$$

In order to compute $\mathbf{W}$ we will solve an appropriate variational initial value problem. Since

$$x(0, \xi, \epsilon) = \xi, \qquad y(0, \xi, \epsilon) = y_0,$$

we have

$$x_\epsilon(0, \xi, \epsilon) = 0, \qquad y_\epsilon(0, \xi, \epsilon) = 0.$$

Thus, it is easy to see that $\mathbf{W}$ is the solution of the the following initial value problem:

$$\dot{\mathbf{W}} = D\mathbf{X}_0(\gamma(t))\mathbf{W} + \mathbf{b}(t), \qquad \mathbf{W}(0) = 0,$$

where $\mathbf{b}(t) = (p(\gamma(t)), q(\gamma(t)))$. An application of the second part of the variation lemma with $m = 1$ implies

$$F_\epsilon(\xi, 0) = \mathbf{X}_0^\perp(\xi, y_0) \cdot \mathbf{W}(T) = \mathcal{M}(T, \mathbf{X}, \mathbf{b}, \gamma(0)).$$

Thus

$$F_\epsilon(\xi,0)=\int_0^T (Pq-Qp)\,(\gamma(t))\exp\left(-\int_0^t \operatorname{div}\mathbf{X}_0(\gamma(\tau))\,d\tau\right)dt$$

as required.

To obtain the representation for $F_{\xi\epsilon}(\xi,0)$ under the hypothesis that $F_\epsilon(\xi_0,0)=0$, we do not compute the mixed partial derivative directly from the representation just obtained for $F_\epsilon(\xi,0)$. Rather, we return to the definition of F and compute the partial derivatives from the formula

$$F(\xi,\epsilon)=\mathbf{X}_0^\perp(\xi,y_0)\cdot\mathbf{H}(\xi,\epsilon).$$

Since $\mathbf{X}_0^\perp$ does not depend on ϵ, we have

$$F_{\xi\epsilon}(\xi,0)=\mathbf{X}_0^\perp\cdot\mathbf{H}_{\xi\epsilon}+\mathbf{X}_{0\xi}^\perp\cdot\mathbf{H}_\epsilon(\xi,0).$$

But, by hypothesis, $\mathbf{H}_\epsilon(\xi_0,0)=0$. So the required derivative is given by

$$F_{\xi\epsilon}(\xi_0,0)=\mathbf{X}_0^\perp(\xi_0,y_0)\cdot\mathbf{H}_{\xi\epsilon}(\xi_0,0).$$

To compute the partial derivatives of $\mathbf{H}$ we use the previously given representation of the scalar return map. In the present case, this takes the form

$$h_\xi(\xi,\epsilon)=\frac{X_2(\xi,y_0,\epsilon)}{X_2(h(\xi,\epsilon),y_0,\epsilon)}\exp\left(\int_0^{T(\xi,\epsilon)}\operatorname{div}\mathbf{X}(\phi_t^\epsilon(\xi,y_0),\epsilon)\,dt\right).$$

Since

$$\mathbf{H}_{\xi\epsilon}(\xi_0,0)=(h_{\epsilon\xi}(\xi_0,0),0),$$

we need only calculate $h_{\epsilon\xi}$. First, using the hypotheses, $h(\xi,0)=\xi$ and $h_\epsilon(\xi,0)=0$, it is easy to verify that the derivative of the first factor of $h_\xi(\xi,\epsilon)$ with respect to ϵ vanishes at $\epsilon=0$, and the value of this factor at $(\xi_0,0)$ is unity. Thus, the required derivative is given by

$$h_{\epsilon\xi}(\xi_0,0)=\exp\left(\int_0^T\operatorname{div}\mathbf{X}_0(\gamma(t))\,dt\right)\left\{\operatorname{div}\mathbf{X}_0(\xi_0,y_0)T_\epsilon(\xi_0,0)\right.$$
$$\left.+\int_0^{T(\xi_0,0)}\frac{d}{d\epsilon}\operatorname{div}\mathbf{X}(\phi_t^\epsilon(\xi_0,y_0),\epsilon)\Big|_{\epsilon=0}dt\right\}.$$

Since the characteristic exponent of Γ vanishes, the exponential term is unity. We also have

$$\frac{d}{d\epsilon}\operatorname{div}\mathbf{X}(\phi_t^\epsilon(\xi_0,y_0),\epsilon)\Big|_{\epsilon=0}=\operatorname{div}(p,q)(\phi_t^0(\xi_0,y_0))+\frac{d}{d\epsilon}\operatorname{div}\mathbf{X}_0(\phi_t^\epsilon(\xi_0,y_0))\Big|_{\epsilon=0},$$

and it follows that

$$h_{\epsilon\xi}(\xi_0,0)=\operatorname{div}\mathbf{X}_0(\xi_0,y_0)T_\epsilon(\xi_0,0)+\int_0^{T(\xi_0,0)}\operatorname{div}(p,q)(\gamma(t))\,dt$$
$$+\int_0^{T(\xi_0,0)}\frac{d}{d\epsilon}\operatorname{div}\mathbf{X}_0(\phi_t^\epsilon(\xi_0,y_0))\Big|_{\epsilon=0}dt$$

as required.

The proof of (iii) is just an application of Green's theorem. □

There is a large literature on the applications of the theorem. In most of these applications the most difficult problem is the computation of the integral for $F_\epsilon(\xi, 0)$ and the determination of its simple zeros. Some examples of such computations can be found in the references [1], [5], [7], [8], [10], [13], [19], [21], [27], [28], [29], [35], [37], [39], [43], [44]. A classic, but very simple application, can be made for the van der Pol oscillator with small damping. For this we have the system

$$\dot{x} = y, \qquad \dot{y} = -x + \epsilon(1 - x^2)y.$$

Here the unperturbed system is linear, and the period annulus fills the entire punctured plane. The positive x-axis is a Poincaré section and, using the theorem, we compute

$$\begin{aligned} F_\epsilon(\xi, 0) &= \int_0^{2\pi} (1 - x^2)y^2 \, dt \\ &= \int_0^{2\pi} (1 - \xi^2 \cos^2 t)\xi^2 \sin^2 t \, dt \\ &= -\frac{\pi}{4}\xi^2(\xi^2 - 4). \end{aligned}$$

The bifurcation function has a unique simple zero at $\xi = 2$, and

$$\epsilon \frac{F_{\epsilon\xi}(2, 0)}{Q(2, 0)} = 2\epsilon\pi.$$

Thus, there is a continuous family of limit cycles emerging from the periodic trajectory $x(t) = 2\cos t \;\; y(t) = -2\sin t$ of the unperturbed system such that the family consists of stable limit cycles for $\epsilon > 0$ and unstable limit cycles for $\epsilon < 0$.

4. Subharmonic bifurcation theory.

In this section we consider bifurcation to periodic solutions in the family E_ϵ of planar differential equations

$$\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x}) + \epsilon \mathbf{G}(\mathbf{x}, t, \epsilon), \quad \mathbf{x} \in \mathbb{R}^2, \quad \epsilon \in \mathbb{R},$$

where both $\mathbf{f}$ and $\mathbf{G}$ are smooth functions; $\mathbf{G}$ is an η-periodic function, i.e.,

$$\mathbf{G}(\mathbf{x}, t + \eta, \epsilon) = \mathbf{G}(\mathbf{x}, t, \epsilon)$$

for all $\mathbf{x}$, t, and ϵ, and where $\mathbf{G}$ has the form

$$\mathbf{G}(\mathbf{x}, t, \epsilon) = \mathbf{g}(\mathbf{x}, t) + \epsilon \mathbf{g}_R(\mathbf{x}, t, \epsilon)$$

with both $\mathbf{g}$ and $\mathbf{g}_R$ smooth functions of the indicated variables. We are interested in the bifurcation of periodic orbits from periodic trajectories Γ of the unperturbed system E_0 as $|\epsilon|$ increases from zero. For this we make one further assumption. The period of Γ is in $m : n$ *resonance* with the period of the forcing function $\mathbf{G}$, i.e., there are relatively prime positive integers m and n such that the period of Γ is $m\eta/n$. At the end of this section we show how to relax this assumption in the presence of a "detuning."

The idea of the bifurcation theory is to find the periodic trajectories as fixed points of the *parameterized Poincaré map* $\mathbf{P} : \mathbb{R}^2 \times \mathbb{R} \to \mathbb{R}^2$ given by $(\xi, \epsilon) \mapsto \mathbf{x}(m\eta, \xi, \epsilon)$, where $t \mapsto \mathbf{x}(t, \xi, \epsilon)$ is the solution of E_ϵ satisfying the initial condition $\mathbf{x}(0, \xi, \epsilon) = \xi$. In this interpretation, ξ is in the section $\Sigma = \mathbb{R}^2 \times 0$ for the flow considered on the manifold diffeomorphic to $\mathbb{R}^2 \times S^1$ obtained by identification of the time modulo $m\eta$. The basic property of the Poincaré map is that, for fixed ϵ, a solution of E_ϵ that starts at a fixed point of the function $\xi \mapsto \mathbf{P}(\xi, \epsilon)$ is a periodic solution of E_ϵ. For example, suppose $\mathbf{P}(\xi_0, \epsilon) = \xi_0$ and $\mathbf{x}(t, \xi_0, \epsilon)$ satisfies $\mathbf{x}(0, \xi_0, \epsilon) = \xi_0$. If we define $\mathbf{y}(t) := \mathbf{x}(t + m\eta, \xi_0, \epsilon)$, then

$$\begin{aligned} \dot{\mathbf{y}} &= \mathbf{f}(\mathbf{y}) + \epsilon \mathbf{G}(\mathbf{y}, t + m\eta, \epsilon) \\ &= \mathbf{f}(\mathbf{y}) + \epsilon \mathbf{G}(\mathbf{y}, t, \epsilon). \end{aligned}$$

Thus, $\mathbf{y}$ is a solution of E_ϵ with the initial condition $\mathbf{y}(0) = \mathbf{x}(m\eta, \xi_0, \epsilon) = \xi_0$ and, by uniqueness of the solutions of E_ϵ, we have $\mathbf{x}(t, \xi_0, \epsilon) = \mathbf{y}(t, \xi_0, \epsilon)$. It follows that $\mathbf{x}$ is a periodic function of its first variable. Also, if $\mathbf{x}$ is not a constant solution of E_ϵ, the minimum period of $\mathbf{x}$ must be $m\eta/k$ for some positive integer k.

The Poincaré map is easy to compute on the resonant orbit Γ. Since, for the flow ϕ_t of the unperturbed system, we have

$$\phi_{m\eta}(\xi) = \phi_{n(m\eta/n)}(\xi) = \xi;$$

the function $\xi \mapsto \mathbf{P}(\xi, 0)$ is the identity on Γ. We wish to find conditions on the functions $\mathbf{f}$ and $\mathbf{G}$ such that, for sufficiently small $\epsilon \neq 0$, some of these fixed points remain. In order to state the bifurcation theorems that provide these conditions, we will need a few more definitions. We identify $\Sigma = \mathbb{R}^2 \times 0$ with $\mathbb{R}^2$ and, for $\xi \in \Sigma$, we define the *displacement function* $\delta(\xi, \epsilon) := \mathbf{P}(\xi, \epsilon) - \xi$ together with its *radial projection* $\rho(\xi, \epsilon) := \langle \delta(\xi, \epsilon), \mathbf{f}^\perp(\xi) \rangle$ and its *tangential projection* $\tau(\xi, \epsilon) := \langle \delta(\xi, \epsilon), \mathbf{f}(\xi) \rangle$, where $\langle , \rangle$ denotes the usual inner product on $\mathbb{R}^2$. For Γ a periodic trajectory of the unperturbed system whose period is in resonance with the external periodic force $\mathbf{G}$, we say $\xi \in \Gamma$ is a *subharmonic branch point* if there is an $\epsilon_0 > 0$ and a curve, $\epsilon \mapsto \sigma(\epsilon)$, defined for $|\epsilon| < \epsilon_0$, with image in the section Σ, such that $\sigma(0) = \xi$ and $\delta(\sigma(\epsilon), \epsilon) \equiv 0$. Of course, if $\delta(\sigma(\epsilon), \epsilon) = 0$, then $\sigma(\epsilon) \in \Sigma$ is the initial value for a periodic solution of E_ϵ. When the unperturbed periodic solution Γ is in $m : 1$ resonance with the forcing, the resonance is called *subharmonic of order m* and the perturbed periodic solutions are called subharmonics. Subharmonic resonance of order one is also called *harmonic.* This is the reason for the use of the term "subharmonic" in the definition of subharmonic branch points. However, the bifurcating solutions at a subharmonic branch point may not be, in the strict sense of the term, subharmonics. For example, if $n \neq 1$, a $1 : n$ resonance is called *ultraharmonic* and an $m : n$ resonance is called *ultrasubharmonic.* See [43, pp. 73–78] for a geometric view of these solutions.

As in the Poincaré–Andronov theorem, the bifurcation analysis for subharmonic branch points consists of two main steps: reduction and identification. Here, reduction refers to reducing the problem of the existence of a curve of subharmonics bifurcating from Γ to an application of the implicit function theorem, i.e., to the nonvanishing of a certain partial derivative, while identification refers to finding an explicit formula for this derivative in terms of the functions $\mathbf{f}$ and $\mathbf{G}$. For this we will use throughout the functions defined in §2 and given by

$$\beta(t) := \beta(t, \xi) := \exp\left(\int_0^t \operatorname{div} \mathbf{f}(\phi_s(\xi))\, ds \right),$$

$$\alpha(t) := \alpha(t, \xi) := \int_0^t \left\{ \frac{1}{\|\mathbf{f}\|^2} \left[2\kappa \|\mathbf{f}\| - \operatorname{curl} \mathbf{f} \right] \right\} (\phi_\tau(\xi)) \beta(\tau)\, d\tau,$$

$$\mathcal{N}(\xi) := \int_0^{m\eta} \left\{ \frac{1}{\|\mathbf{f}\|^2} \langle \mathbf{f}, \mathbf{g} \rangle - \frac{\alpha(s)}{\beta(s)} \mathbf{f} \wedge \mathbf{g} \right\} (\phi_s(\xi))\, ds,$$
$$\mathcal{M}(\xi) := \int_0^{m\eta} \left\{ \frac{1}{\beta(s)} \mathbf{f} \wedge \mathbf{g} \right\} (\phi_s(\xi))\, ds.$$

Also, we will compute several times the derivatives of functions of the two variables ξ and ϵ. We will use the convention that derivatives indicated by D, for functions with range in $\mathbb{R}^2$, or by d, for functions with range in $\mathbb{R}$, refer to the derivative with respect to the space variable ξ, while derivatives indicated by a subscripted variable refer to the partial derivative with respect to that variable.

To begin the analysis, we expand the displacement function into its perturbation series

$$\begin{aligned}\delta(\xi, \epsilon) &= \mathbf{P}(\xi, 0) - \xi + \mathbf{P}_\epsilon(\xi, 0)\epsilon + O(\epsilon^2) \\ &= \mathbf{x}(m\eta, \xi, 0) - \xi + \mathbf{x}_\epsilon(m\eta, \xi, 0)\epsilon + O(\epsilon^2),\end{aligned}$$

and we recall that, by the variation lemma, the first-order term of the perturbation series is given by

$$\mathbf{x}_\epsilon = (\mathcal{N} + \alpha\mathcal{M})\mathbf{f} + \beta\mathcal{M}\mathbf{u}_{\mathbf{f}^\perp}.$$

For ξ on the resonant orbit Γ, $\delta(\xi, 0) \equiv 0$, and, consequently,

$$D\delta(\xi, 0)(\mathbf{f}(\xi)) = \frac{d}{dt}\mathbf{P}(\phi_t(\xi), 0)\Big|_{t=0} - \mathbf{f}(\xi) = 0.$$

Thus, $\xi \mapsto D\delta(\xi, 0)$ is not invertible and we cannot use the implicit function theorem directly. However, we can use various forms of the Lyapunov–Schmidt reduction depending on how degenerate the curve Γ is as part of the zero set of the function $\xi \to \delta(\xi, 0)$.

The most degenerate case is the classical case when the unperturbed system is linear and $\delta(\xi, 0) \equiv 0$. Actually, this degeneracy is equivalent to assuming Γ is contained in an isochronous period annulus; cf. [13]. In this case, we have the following proposition.

PROPOSITION 4.1. *Let* $\mathbf{P}$ *denote the parameterized Poincaré map for the system* E_ϵ,

$$\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x}) + \epsilon\mathbf{G}(\mathbf{x}, t, \epsilon), \quad \mathbf{x} \in \mathbb{R}^2, \quad \epsilon \in \mathbb{R},$$

where $\mathbf{G}$ *is* η*-periodic of the form*

$$\mathbf{G}(\mathbf{x}, t, \epsilon) = \mathbf{g}(\mathbf{x}, t) + \epsilon\mathbf{g}_R(x, t, \epsilon),$$

and assume that Γ *is a periodic solution of the unperturbed system that belongs to an isochronous period annulus.*

Reduction. If there are positive integers m and n such that the period of Γ *is equal to* $m\eta/n$ *and if the function* $\xi \mapsto \mathbf{P}_\epsilon(\xi, 0)$ *has a simple zero at* ξ_0, *i.e.,*

$$\mathbf{P}_\epsilon(\xi_0, 0) = 0 \quad \textit{and} \quad \det(D\mathbf{P}_\epsilon(\xi_0, 0)) \neq 0,$$

then ξ_0 *is a subharmonic branch point.*

Identification. The bifurcation function $\xi \mapsto \mathbf{P}_\epsilon(\xi,0)$ *is given by*

$$\mathbf{P}_\epsilon(\xi,0) = \left[\mathcal{N}\mathbf{f} + \frac{1}{||\mathbf{f}||^2}\mathcal{M}\mathbf{f}^\perp\right](\xi).$$

Moreover, in case the unperturbed system is linear with $\mathbf{f}(x_1,x_2) = (\omega x_2, -\omega x_1)$ *and if* $2\pi n/\omega = m\eta$, *then the bifurcation function is given by*

$$\mathbf{P}_\epsilon(\xi,0) = \frac{1}{||\xi||^2}\left(\xi_1 I_2(\xi) + \xi_2 I_1(\xi),\ \xi_2 I_2(\xi) - \xi_1 I_1(\xi)\right),$$

where

$$I_1(\xi) := \int_0^{2\pi n/\omega} x_2 g_1(\mathbf{x},t) - x_1 g_2(\mathbf{x},t)\,dt, \quad I_2(\xi) := \int_0^{2\pi n/\omega} x_1 g_1(\mathbf{x},t) + x_2 g_2(\mathbf{x},t)\,dt.$$

Proof. By the hypotheses, the displacement function, $\delta(\xi,\epsilon) := \mathbf{P}(\xi,\epsilon) - \xi$, for the perturbed system can be represented in the form

$$\delta(\xi,\epsilon) = \epsilon\left[\mathbf{P}_\epsilon(\xi,0) + O(\epsilon)\right].$$

Therefore, the implicit function theorem can be applied to determine when there is an implicit solution of the equation $\mathbf{P}_\epsilon(\xi,0) + O(\epsilon) = 0$ at some point $(\xi_0, 0)$. This proves the reduction statement of the proposition. For the identification we simply observe that Γ is not hyperbolic and that the period function on the period annulus is constant. Then, using the results of §2, we have $\beta(m\eta,\xi) \equiv 1$ and $\alpha(m\eta,\xi) \equiv 0$ for $\xi \in \Gamma$. Thus, from the formula for $\mathbf{x}_\epsilon$ given above, we obtain the desired result.

In case the unperturbed vector field $\mathbf{f}$ is linear, with $\mathbf{f}(x_1,x_2) = (\omega x_2, -\omega x_1)$, the punctured phase plane of the unperturbed system is filled by periodic trajectories, each of which lies on a circle centered at the origin, and the hypotheses of the proposition hold. If, in addition, we assume the period of the external excitation is in resonance with the linear system, i.e., there are positive integers m and n such that $2\pi n/\omega = m\eta$, then the formula for $\mathbf{x}_\epsilon(m\eta,\xi,0)$ reduces to

$$\frac{1}{\omega^2||\xi||^2}\left[\left(\int_0^{m\eta}\langle \mathbf{f}(\mathbf{x}), \mathbf{g}(\mathbf{x},t)\rangle\,dt\right)\mathbf{f}(\xi) + \left(\omega\int_0^{m\eta}\mathbf{f}(\mathbf{x}) \wedge \mathbf{g}(\mathbf{x},t)\,dt\right)\xi\right],$$

where, in components, $\xi = (\xi_1, \xi_2)$ and

$$\mathbf{x}(t) := (x_1(t), x_2(t)) = (\xi_1\cos(\omega t) + \xi_2\sin(\omega t),\ -\xi_1\sin(\omega t) + \xi_2\cos(\omega t)).$$

Moreover, if the components of the external excitation are given by

$$\mathbf{g}(\mathbf{x},t) := (g_1(\mathbf{x},t), g_2(\mathbf{x},t)),$$

and we define

$$I_1(\xi) := \int_0^{2\pi n/\omega} x_2 g_1(\mathbf{x},t) - x_1 g_2(\mathbf{x},t)\,dt, \quad I_2(\xi) := \int_0^{2\pi n/\omega} x_1 g_1(\mathbf{x},t) + x_2 g_2(\mathbf{x},t)\,dt,$$

we then have

$$\mathbf{x}_\epsilon(m\eta,\xi,0) = \frac{1}{||\xi||^2}\left(\xi_1 I_2(\xi) + \xi_2 I_1(\xi),\ \xi_2 I_2(\xi) - \xi_1 I_1(\xi)\right)$$

as required. □

For computational purposes, it is convenient to define $\mathcal{I}(\xi) := (I_1(\xi), I_2(\xi))$, and to observe that

$$\mathbf{P}_\epsilon(\xi, 0) = \begin{pmatrix} \xi_2 & \xi_1 \\ -\xi_1 & \xi_2 \end{pmatrix} \begin{pmatrix} I_1(\xi) \\ I_2(\xi) \end{pmatrix}.$$

Then, the existence of a simple zero of $\mathbf{P}_\epsilon(\xi, 0)$ is easily seen to be equivalent to the existence of a simple zero of $\mathcal{I}$. A final special case, where we take $\omega = 1$ and $g_1(\mathbf{x}, t) \equiv 0$, results in the identification

$$\mathbf{P}_\epsilon(\xi, 0) = \left(-\int_0^{2\pi n} g_2(\mathbf{x}(t), t)\sin t\,dt,\ \int_0^{2\pi n} g_2(\mathbf{x}(t), t)\cos t\,dt\right).$$

Here, the components of $\mathbf{P}_\epsilon(\xi, 0)$ are given by the same formulas obtained from the classical perturbation series methods. See [27, XII, §2] for a version of the classic approach to these formulas and for the computations, using the same formulas, showing the existence of a unique stable harmonic solution of the forced van der Pol oscillator,

$$\begin{aligned} \dot{x} &= y, \\ \dot{y} &= -x + \epsilon(1 - x^2)y + \epsilon a \sin t. \end{aligned}$$

When $\xi \to \delta(\xi, 0)$ is not identically zero on some neighborhood of Γ, the bifurcation theory must deal with the zero order terms of the perturbation expansion of the displacement function. The least degenerate case occurs when the kernel $\mathcal{K}$ of the map $D\delta(\xi, 0) : \mathbb{R}^2 \to \mathbb{R}^2$ is one-dimensional. We have already shown $\mathbf{f}(\xi) \in \mathcal{K}$. Thus, this nondegeneracy condition will be satisfied when $\mathbf{f}^\perp(\xi) \notin \mathcal{K}$. It turns out that this nondegeneracy condition is equivalent to having one of the following: either Γ is hyperbolic or, at $\xi \in \Gamma$, the transit time map on a section in the phase plane orthogonal to Γ has a nonzero derivative along the section at ξ. The second possibility is the only way to have nondegeneracy when Γ is in a period annulus. In this case, the transit time reduces to the period function. Of course, if the period function has a zero derivative "at Γ" on a section transverse to Γ, then this derivative will be zero on every such section. When the derivative of the period function vanishes in this way, Γ is called *critical.* However, it is worth noting that the vanishing of the derivative of the transit time along a section intersecting a limit cycle depends on the choice of section.

For the next theorem we assume that the unperturbed system $\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x})$ has flow ϕ_t and a noncritical periodic trajectory Γ given by $t \mapsto \phi_t(p)$ that lies in a period annulus $\mathcal{A} \subset \Sigma$. We let $T : \mathcal{A} \to \mathbb{R}$ denote the *period function* for the unperturbed system on the period annulus $\mathcal{A}$; it assigns to each $\xi \in \mathcal{A} \subset \Sigma$ the minimum period of the periodic trajectory of the unperturbed system passing through ξ. Also, the *subharmonic Melnikov function* is defined for $\xi \in \mathcal{A}$, in terms of the radial projection of the displacement function ρ, by

$$M(\xi) := \rho_\epsilon(\xi, 0).$$

THEOREM 4.2 (subharmonic bifurcation theorem). *Let E_ϵ denote the parameterized family of differential equations*

$$\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x}) + \epsilon\mathbf{g}(\mathbf{x}, t) + \epsilon^2\mathbf{g}_R(\mathbf{x}, t, \epsilon), \quad \mathbf{x} \in \mathbb{R}^2, \quad \epsilon \in \mathbb{R},$$

such that E_0 has flow $t \mapsto \phi_t$, a period annulus $\mathcal{A}$, and a periodic trajectory $\Gamma \subset \mathcal{A}$ that is in resonance with the η-periodic external force $\mathbf{G}(x,t,\epsilon) := \mathbf{g}(\mathbf{x},t) + \epsilon\mathbf{g}_R(\mathbf{x},t,\epsilon)$, i.e., there are relatively prime natural numbers m and n such that the period of Γ is $m\eta/n$.

(i) *Reduction. If Γ is not critical and $\xi \in \Gamma$ is a simple zero of the subharmonic Melnikov function, i.e., $dT(\mathbf{f}^\perp)(\xi) \neq 0$, $M(\xi) = 0$ and $dM(\mathbf{f})(\xi) \neq 0$, then ξ is a subharmonic branch point.*

(ii) *Identification. The directional derivative of the period function T in the direction $\mathbf{f}^\perp(\xi)$ is given by*

$$dT(\mathbf{f}^\perp)(\xi) = \\ -\|\mathbf{f}(\xi)\|^2 \int_0^{T(\xi)} \left\{ \frac{1}{\|\mathbf{f}\|^2} [2\kappa\|\mathbf{f}\| - \operatorname{curl}\mathbf{f}] \right\} (\phi_s(\xi)) \exp\left(\int_0^s \operatorname{div}\mathbf{f}(\phi_t(\xi))\,dt \right) ds,$$

and the subharmonic Melnikov function is given by

$$M(\xi) = \mathcal{M}(m\eta, \mathbf{f}, \mathbf{g}, \xi) = \int_0^{m\eta} \exp\left\{ -\int_0^t \operatorname{div}\ \mathbf{f}(\phi_s(\xi))\,ds \right\} \mathbf{f}(\phi_t(\xi)) \wedge \mathbf{g}(\phi_t(\xi), t)\,dt.$$

Proof. We have

$$\delta(\xi,\epsilon) = \mathbf{P}(\xi,0) - \xi + \mathbf{P}_\epsilon(\xi,0)\epsilon + O(\epsilon^2).$$

For ξ on the resonant orbit Γ, $\delta(\xi,0) \equiv 0$, and, as we have seen,

$$D\delta(\xi,0)(\mathbf{f}(\xi)) = \frac{d}{dt}\mathbf{P}(\phi_t(\xi),0)\Big|_{t=0} - \mathbf{f}(\xi) = 0.$$

Thus, $\xi \mapsto D\delta(\xi,0)$ is not invertible, and we cannot use the implicit function theorem directly. However, the Lyapunov–Schmidt reduction can be employed. First, we apply the implicit function theorem to the tangential projection τ. For this, let $\xi \in \Gamma$, and compute the directional derivative of $\xi \mapsto \tau(\xi,0)$ in the direction $\mathbf{f}^\perp$ to obtain

$$d\tau(\xi,0)(\mathbf{f}^\perp(\xi)) = \left\langle D\delta(\xi,0)\mathbf{f}^\perp(\xi), \mathbf{f}(\xi) \right\rangle + \left\langle \delta(\xi,0), D\mathbf{f}(\xi)\mathbf{f}^\perp(\xi) \right\rangle.$$

Since $\delta(\xi,0) \equiv 0$ on Γ, the formula for this derivative reduces to

$$d\tau(\xi,0)(\mathbf{f}^\perp(\xi)) = \left\langle D\delta(\xi,0)\mathbf{f}^\perp(\xi), \mathbf{f}(\xi) \right\rangle.$$

In order to compute $D\delta(\xi,0)\mathbf{f}^\perp(\xi)$, recall

$$DP(\xi,0)\mathbf{f}^\perp(\xi) = D\phi_{m\eta}(\xi)\mathbf{f}^\perp(\xi),$$

and let $\mathbf{V}$ be as defined in Diliberto's theorem. Since both

$$t \mapsto D\phi_t(\xi)\frac{1}{\|\mathbf{f}(\xi)\|^2}\mathbf{f}^\perp(\xi) \quad \text{and} \quad t \mapsto \mathbf{V}(t,\mathbf{f},\xi)$$

are solutions of the homogeneous variational equation for the unperturbed system $\dot{x} = \mathbf{f}(x)$ along the trajectory $t \mapsto \phi_t(\xi)$ satisfying the same initial condition, the two functions are equal, and we have

$$D\phi_{m\eta}(\xi)\mathbf{f}^\perp(\xi) = \|\mathbf{f}(\xi)\|^2\mathbf{V}(m\eta) = \|\mathbf{f}(\xi)\|^2 \left\{ \alpha(m\eta)\mathbf{f}(\xi) + \frac{\beta(m\eta)}{\|\mathbf{f}(\xi)\|^2}\mathbf{f}^\perp(\xi) \right\}.$$

In view of the representation of the period function given in the variation lemma and the nonhyperbolicity of Γ, this formula can be expressed more concisely as

$$D\phi_{m\eta}(\xi)\mathbf{f}^{\perp}(\xi) = -\left[m\, dT(\mathbf{f}^{\perp})(\xi)\right]\mathbf{f}(\xi) + \mathbf{f}^{\perp}(\xi),$$

and, in turn, we have a simple expression for the directional derivative of δ :

$$D\delta(\xi,0)\mathbf{f}^{\perp}(\xi) = (D\mathbf{P}(\xi,0) - I)\mathbf{f}^{\perp}(\xi) = -\left[m\, dT(\xi)(\mathbf{f}^{\perp}(\xi))\right]\mathbf{f}(\xi).$$

Taking the inner product with $\mathbf{f}(\xi)$, we find the required directional derivative of τ to be

$$d\tau(\xi,0)(\mathbf{f}^{\perp}(\xi)) = -m\,||\mathbf{f}(\xi)||^2\, dT(\xi)(\mathbf{f}^{\perp}(\xi)) \neq 0.$$

Now, by an application of the implicit function theorem to the function τ, we conclude that there is a smooth two-dimensional surface $\mathcal{S}$ in the (ξ,ϵ)-space passing through the curve $\Gamma \times 0$ such that τ vanishes on $\mathcal{S}$. Since, in addition, for $\xi \in \Gamma$ we have

$$d\tau(\xi,0)\mathbf{f}(\xi) = \langle (D\mathbf{P}(\xi,0) - I)\mathbf{f}(\xi), \mathbf{f}(\xi)\rangle \equiv 0,$$

$\mathcal{S}$ is transverse to the section Σ and $\Gamma \subset \mathcal{S}$.

To complete the reduction we restrict our attention to the manifold $\mathcal{S}$. To be more precise, we consider a neighborhood of the point $(\xi_0,0)$ on Γ. There is a local coordinate chart (U,φ_U) on $\mathcal{S}$ such that U is a product neighborhood in $\mathbb{R}\times\mathbb{R}$ and $\varphi_U : U \to \mathcal{S} \subset \mathbb{R}^2 \times \mathbb{R}$ is a smooth function that can be taken to have the form

$$\varphi_U(\theta,\epsilon) = (\varphi(\theta,\epsilon),\epsilon).$$

Here the image of the function $\theta \mapsto \varphi(\theta,0)$ is contained in Γ, and $\varphi(0,0) = \xi_0$. Now, we can view the restriction of the radial projection ρ to $\mathcal{S}$, $\rho_{\mathcal{S}}$, as the function defined by

$$\rho_{\mathcal{S}}(\theta,\epsilon) = \rho(\varphi_U(\theta,\epsilon)).$$

Since $\rho_{\mathcal{S}}(\theta,0) = \rho(\varphi(\theta,0),0) \equiv 0$, the restriction of ρ, represented locally by its Taylor polynomial with remainder, has the form

$$\rho_{\mathcal{S}}(\theta,\epsilon) = \rho_1(\theta)\epsilon + O(\epsilon^2)$$

on a product neighborhood of the origin in the (θ,ϵ)-space. The first-order Taylor coefficient is given by

$$\rho_1(\theta) = \frac{\partial\rho_{\mathcal{S}}}{\partial\epsilon}(\theta,0) = d\rho(\varphi(\theta,0),0)(\varphi_\epsilon(\theta,0)) + \rho_\epsilon(\varphi(\theta,0),0).$$

But, for $\xi \in \Gamma$, a computation similar to the computation made above for $d\tau$ shows

$$d\rho(\xi,0)(\mathbf{f}^{\perp}(\xi)) = d\rho(\xi,0)(\mathbf{f}(\xi)) = 0.$$

Thus, $d\rho(\xi,0) = 0$ and

$$\rho_1(\theta) = \rho_\epsilon(\varphi(\theta,0),0) = M(\varphi(\theta,0)).$$

The hypothesis $M(\xi_0) = 0$, but $dM(\xi_0)(f(\xi_0)) \neq 0$ implies $\rho_1(0) = 0$ and $\rho_1'(0) \neq 0$. Thus, there is an $\epsilon_0 > 0$ and a smooth function σ_0 defined for $|\epsilon| < \epsilon_0$, with range in the θ-space, such that $\rho_S(\sigma_0(\epsilon), \epsilon) \equiv 0$. If we define $\sigma(\epsilon) := (\varphi(\sigma_0(\epsilon), \epsilon), \epsilon)$, then

$$\rho(\sigma(\epsilon), \epsilon) \equiv \tau(\sigma(\epsilon), \epsilon) \equiv 0,$$

and we have $\delta(\sigma(\epsilon), \epsilon) \equiv 0$ as required to prove the reduction.

For the identification, the derivative of the period function can be computed directly from the variation lemma. In fact,

$$dT(\mathbf{f}^{\perp})(\xi) = -||\mathbf{f}(\xi)||^2 \alpha(T(\xi), \mathbf{f}, \xi).$$

The proof will be complete when we identify the Melnikov function. To do this, we compute $\rho_\epsilon(\xi, 0)$ as follows:

$$\begin{aligned} \rho_\epsilon(\xi, 0) &= \left\langle \delta_\epsilon(\xi, 0), \mathbf{f}^{\perp}(\xi) \right\rangle \\ &= \left\langle \mathbf{P}_\epsilon(\xi, 0), \mathbf{f}^{\perp}(\xi) \right\rangle \\ &= \left\langle \mathbf{x}_\epsilon(m\eta, \xi, 0), \mathbf{f}^{\perp}(\xi) \right\rangle. \end{aligned}$$

But, $\mathbf{x}_\epsilon(t, \xi, 0)$ is the solution of the variational initial value problem

$$\dot{\mathbf{W}} = D\mathbf{f}(\phi_t(\xi))\mathbf{W} + \mathbf{g}(\phi_t(\xi), t), \qquad \mathbf{W}(0) = 0.$$

By the variation lemma, this solution is given by

$$\mathbf{x}_\epsilon(m\eta, \xi, 0) = \beta(\xi)\mathcal{M}(\xi)\mathbf{u}_{\mathbf{f}^{\perp}}(\xi) \qquad (\text{mod } \mathbf{f}).$$

Using the fact that $\beta(\xi) \equiv 1$ and substitution of this expression into the formula for $\rho_\epsilon(\xi, 0)$ we obtain the desired result. □

When Γ is hyperbolic, the result is similar to the last theorem, but the formulas for the partial derivatives of the perturbation series are more complicated. In order to state our bifurcation theorem in this context, we again consider the system E_ϵ given by

$$\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x}) + \epsilon \mathbf{G}(\mathbf{x}, t, \epsilon), \quad \mathbf{x} \in \mathbb{R}^2, \quad \epsilon \in \mathbb{R},$$

where the external excitation G is periodic of period η in its second variable. We assume the unperturbed system, $\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x})$, has a limit cycle Γ whose period is in resonance with the period of the forcing function. In fact, we assume the period of Γ is $m\eta/n$ for m and n relatively prime positive integers.

Before stating our theorem, we pause to recall a trivial but important fact. If the limit cycle of the unperturbed system is hyperbolic, it is structurally stable in the class of plane vector fields. When we consider the forced oscillator on the manifold $\mathbb{R}^2 \times S^1$, the three-dimensional system of differential equations has, for $\epsilon = 0$, a normally hyperbolic torus corresponding to the limit cycle. The flow on this torus will be periodic or quasiperiodic depending on whether or not the resonance condition is satisfied. But, in either case, the orbits corresponding to the limit cycle will no longer be structurally stable; the stability of the limit cycle has been "transferred to the torus." In the resonant case, if we consider the appropriate iterate of the Poincaré map, we will have the Poincaré map reduced to the identity on the torus. Thus, it is natural to ask if any of the fixed points of the Poincaré map, corresponding to the points on the limit cycle, survive after perturbation as fixed points or higher order periodic points of the Poincaré map, i.e., if any periodic solutions survive as harmonic or subharmonic solutions of the forced oscillator.

For our bifurcation result, the definitions of the Poincaré section Σ, the parameterized Poincaré map $\mathbf{P}$ and the displacement function δ remain unchanged. We consider $\mathbf{f}$ and $\mathbf{G}$ fixed, with

$$\mathbf{G}(\mathbf{x}, t, \epsilon) = \mathbf{g}(\mathbf{x}, t) + \epsilon \mathbf{g}_R(\mathbf{x}, t, \epsilon),$$

and, for notational convenience, when we refer to the functions α, β, $\mathcal{M}$, and $\mathcal{N}$ with the single argument ξ, we understand that the remaining arguments are fixed at $t = m\eta$, $\mathbf{f}$, and $\mathbf{g}$. In order to obtain our bifurcation result, a correction term must be added to the subharmonic Melnikov function. In fact, the new function we require is defined by

$$\mathcal{C}(\xi) := [(1-\beta)\mathcal{N} + \alpha\mathcal{M}]\,(\xi).$$

We call $\mathcal{C}$ the *subharmonic bifurcation function.* The next theorem applies either when Γ is hyperbolic or when, at the bifurcation point, the derivative of the transit time does not vanish.

THEOREM 4.3 (limit cycle subharmonic bifurcation theorem). *Let E_ϵ denote the parameterized family of differential equations*

$$\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x}) + \epsilon \mathbf{g}(\mathbf{x}, t) + \epsilon^2 \mathbf{g}_R(\mathbf{x}, t, \epsilon), \quad \mathbf{x} \in \mathbb{R}^2, \quad \epsilon \in \mathbb{R},$$

such that E_0 has a limit cycle Γ whose period is in resonance with the η-periodic external force $\mathbf{G}(x, t, \epsilon) := g(x, t) + \epsilon \mathbf{g}_R(x, t, \epsilon)$, i.e., there are relatively prime natural numbers m and n such that the period of Γ is $m\eta/n$. If Γ is hyperbolic and $\xi \in \Gamma$ is a simple zero of the subharmonic bifurcation function $\mathcal{C}$, i.e., $\mathcal{C}(\xi) = 0$ and $d\mathcal{C}(\mathbf{f})(\xi) \neq 0$, then ξ is a subharmonic branch point. Also, if $\xi \in \Gamma$ is a simple zero of the subharmonic bifurcation function and if $\alpha(\xi) \neq 0$, then ξ is a subharmonic branch point.

Proof. With the projections ρ and τ defined exactly as before and with $\xi \in \Gamma$, we have

$$\begin{aligned}
d\tau(\xi,0)(\mathbf{f}(\xi)) &= \langle (D\mathbf{P}(\xi,0) - I)\mathbf{f}(\xi), \mathbf{f}(\xi)\rangle = 0,\\
d\rho(\xi,0)(\mathbf{f}(\xi)) &= \left\langle (D\mathbf{P}(\xi,0) - I)\mathbf{f}(\xi), \mathbf{f}^{\perp}(\xi)\right\rangle = 0,\\
d\tau(\xi,0)(\mathbf{f}^{\perp}(\xi)) &= \left\langle ||\mathbf{f}||^2 \left\{\alpha\mathbf{f} + \frac{\beta}{||\mathbf{f}||^2}\mathbf{f}^{\perp}\right\} - \mathbf{f}^{\perp}, \mathbf{f}\right\rangle(\xi) = \left[||\mathbf{f}||^4\alpha\right](\xi),\\
d\rho(\xi,0)(\mathbf{f}^{\perp}(\xi)) &= \left\langle ||\mathbf{f}||^2 \left\{\alpha\mathbf{f} + \frac{\beta}{||\mathbf{f}||^2}\mathbf{f}^{\perp}\right\} - \mathbf{f}^{\perp}, \mathbf{f}^{\perp}\right\rangle(\xi) = \left[||\mathbf{f}||^2(\beta - 1)\right](\xi).
\end{aligned}$$

Thus, there are two choices. If Γ is hyperbolic, then $\beta \neq 1$, and we can apply the implicit function theorem to the radial projection to obtain a manifold $\mathcal{S}$ transverse to Σ such that ρ is identically zero on $\mathcal{S}$ and such that $\Gamma \subset \mathcal{S}$. If, on the other hand, $\alpha(\xi) \neq 0$, there is a manifold $\mathcal{S}$, defined locally in a neighborhood U of $(\xi, 0)$, such that τ is identically zero on $\mathcal{S}$, $\mathcal{S}$ is transverse to $\Sigma \cap U$, and $\Gamma \cap U \subset \mathcal{S}$. In both cases, the local coordinates are given by

$$(\theta, \epsilon) \mapsto (\varphi(\theta, \epsilon), \epsilon)$$

with $\varphi(\theta, 0) = \xi$. Thus, in the hyperbolic case we can restrict τ to $\mathcal{S}$ and obtain the representation

$$\tau_{\mathcal{S}}(\theta, \epsilon) := \tau_1(\theta)\epsilon + O(\epsilon^2),$$

while in case $\alpha(\xi) \neq 0$, we restrict the projection ρ to $\mathcal{S}$ to obtain

$$\rho_{\mathcal{S}}(\theta, \epsilon) = \rho_1(\theta)\epsilon + O(\epsilon^2).$$

The reduction portion of the theorem is the content of the following propositions. In the hyperbolic case, a simple zero of $\theta \to \tau_1(\theta)$ is a subharmonic branch point, while in the case $\alpha(\xi) \neq 0$, a simple zero of $\theta \to \rho_1(\theta)$ is a subharmonic branch point.

We will complete the proof by identification of the functions τ_1 and ρ_1. For this, note that

$$\begin{aligned}\tau_1(\theta) = \frac{\partial \tau_{\mathcal{S}}}{\partial \epsilon}(\theta, 0) &= d\tau(\varphi(\theta,0),0)(\varphi_\epsilon(\theta,0)) + \tau_\epsilon(\varphi(\theta,0),0)\\ &= d\tau(\xi,0)(\varphi_\epsilon(\theta,0)) + \tau_\epsilon(\xi,0)\end{aligned}$$

and

$$\begin{aligned}\rho_1(\theta) = \frac{\partial \rho_{\mathcal{S}}}{\partial \epsilon}(\theta, 0) &= d\rho(\varphi(\theta,0),0)(\varphi_\epsilon(\theta,0)) + \rho_\epsilon(\varphi(\theta,0),0)\\ &= d\rho(\xi,0)(\varphi_\epsilon(\theta,0)) + \rho_\epsilon(\xi,0).\end{aligned}$$

As in the last computation of the previous theorem, using the variation lemma and remembering that $\beta(\xi)$ may not be unity, we find

$$\tau_\epsilon(\xi,0) = ||\mathbf{f}||^2(\mathcal{N} + \alpha\mathcal{M})(\xi), \qquad \rho_\epsilon(\xi,0) = (\beta\mathcal{M})\,(\xi).$$

To compute the other terms we observe that $\varphi(\theta,\epsilon) \in \Sigma$. Hence, the vector field φ_ϵ can be expressed as a linear combination of $\mathbf{f}$ and $\mathbf{f}^\perp$ evaluated at $\varphi(\theta,\epsilon)$. In fact, there are scalars a and b (perhaps different in the two cases) such that

$$\varphi_\epsilon(\theta,0) = a\mathbf{f}(\xi) + b\mathbf{f}^\perp(\xi).$$

Moreover, since both $d\tau(\xi,0)\mathbf{f}(\xi) = 0$ and $d\rho(\xi,0)\mathbf{f}(\xi) = 0$, we have

$$d\tau(\xi,0)\varphi_\epsilon(\theta,0) = b||\mathbf{f}||^4\alpha(\xi), \qquad d\rho(\xi,0)\varphi_\epsilon(\theta,0) = \left[b(\beta-1)||\mathbf{f}||^2\right](\xi).$$

Now, after substitution, we obtain

$$\tau_1(\theta) = \left[b||\mathbf{f}||^4\alpha + ||\mathbf{f}||^2(\mathcal{N} + \alpha\mathcal{M})\right](\xi), \qquad \rho_1(\theta) = \left[b(\beta-1)||\mathbf{f}||^2 + \beta\mathcal{M}\right](\xi),$$

and it suffices, in each case, to compute b. For this, we recall that on $\mathcal{S}$, in the hyperbolic case,

$$\rho(\varphi(\theta,\epsilon),\epsilon) \equiv 0.$$

So

$$d\rho(\varphi(\theta,0),0)(\varphi_\epsilon(\theta,0)) + \rho_\epsilon(\varphi(\theta,0),0) = 0,$$

and we have

$$b\, d\rho(\xi,0)\mathbf{f}^\perp(\xi) = -\rho_\epsilon(\xi,0).$$

Thus, we can solve for b to obtain

$$b = \frac{\beta \mathcal{M}}{||\mathbf{f}||^2(1-\beta)},$$

and, after substitution into the last formula for τ_1, we compute

$$\tau_1(\theta) = \frac{||\mathbf{f}||^2}{1-\beta}\left[(1-\beta)\mathcal{N} + \alpha\mathcal{M}\right](\theta).$$

In case $\alpha(\xi) \neq 0$, the proof is similar. We find

$$b = -\frac{\tau_\epsilon(\xi, 0)}{||\mathbf{f}(\xi)||^4\alpha(\xi)}$$

and

$$\rho_1(\theta) = \frac{1}{\alpha}\left[(1-\beta)\mathcal{N} + \alpha\mathcal{M}\right](\theta)$$

as required. □

We have just considered subharmonic bifurcation from periodic trajectories of our unperturbed system in the most degenerate case, when the unperturbed system has an isochronous center, and in the least degenerate case, when the kernel of the space derivative of the displacement function at the unperturbed periodic orbit Γ is one-dimensional. A bifurcation theory for the cases of intermediate degeneracy can be carried out quite generally using our methods. However, since computation of the higher-order derivatives that appear in the analysis increase in complexity, we are content to illustrate the analysis in the least degenerate of the remaining cases. For this, it should now be clear that there are two possibilities depending on whether or not Γ is a limit cycle. If Γ is not a limit cycle, it belongs to a period annulus. This means $\beta(\xi) \equiv 1$ for ξ in this period annulus, and the degenerate case is $\alpha(\xi) \equiv 0$ but $d\alpha(\xi)\mathbf{f}^\perp(\xi) \neq 0$ for $\xi \in \Gamma$, i.e., the derivative of the period function vanishes on Γ but its second derivative does not vanish. This case has been treated by different methods when the unperturbed system is Hamiltonian in [38] and in a more abstract setting in [24]. In case Γ is a nonhyperbolic limit cycle, say for $\xi \in \Gamma$, $\beta(\xi) \equiv 1$ but $d\beta(\xi)\mathbf{f}^\perp(\xi) \neq 0$, we already know the bifurcation is not degenerate at a point $\xi \in \Gamma$ where $\alpha(\xi) \neq 0$. So the bifurcation is degenerate when this is not the case, i.e., when Γ is a nonhyperbolic limit cycle of multiplicity 2 (cf. [1, p. 272]), which contains points where the derivative of the transit time map on orthogonal sections vanishes. For these cases there is the possibility that more than one family of subharmonics is found near a subharmonic branch point. We will say $\xi \in \Gamma$ is a *subharmonic branch point with n-branches* if there is an $\epsilon_0 > 0$ and distinct (germs of) curves (at $\epsilon = 0$), $\epsilon \mapsto \sigma_k(\epsilon)$; $k = 1, \cdots, n$, each defined either for $\epsilon_0 < \epsilon \leq 0$ or $0 \leq \epsilon < \epsilon_0$, and each with image in the section Σ, such that $\sigma_k(0) = \xi$ and $\delta(\sigma_k(\epsilon), \epsilon) \equiv 0$. The next theorem gives the result for the case of the period annulus.

THEOREM 4.4 (order 2 subharmonic bifurcation theorem). *Let E_ϵ denote the parameterized family of differential equations*

$$\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x}) + \epsilon\mathbf{g}(\mathbf{x}, t) + \epsilon^2\mathbf{g}_R(\mathbf{x}, t, \epsilon), \quad \mathbf{x} \in \mathbb{R}^2, \quad \epsilon \in \mathbb{R},$$

such that E_0 has a period annulus $\mathcal{A}$ and a periodic trajectory $\Gamma \subset \mathcal{A}$ that is in resonance with the η-periodic external force $\mathbf{G}$, i.e., there are relatively prime natural *numbers m and n such that the period of Γ is $m\eta/n$. If Γ is critical ($\alpha(\xi) \equiv 0$) and if $\xi \in \Gamma$ is a simple zero of the subharmonic Melnikov function, such that*

$$\mathcal{N}(\xi) d\alpha(\xi) \mathbf{f}^{\perp}(\xi) \neq 0,$$

then ξ is a subharmonic branch point with two branches. Moreover, these two branches exist only in the direction of ϵ such that

$$\epsilon \mathcal{N}(\xi) d\alpha(\xi) \mathbf{f}^{\perp}(\xi) < 0.$$

Proof. Fix $\xi \in \Gamma$; let $t \to \phi_t$ denote the flow of $\dot{x} = \mathbf{f}(x)$; let $s \to \psi_s$ denote the flow of $\dot{x} = \mathbf{f}^{\perp}(x)$, and consider the local coordinates defined at $(\xi, 0)$ by the transformation

$$(s, t, \epsilon) \to (\psi_s(\phi_t(\xi)), \epsilon).$$

In these coordinates we have

$$\tau_{\mathrm{loc}}(s, t, \epsilon) := \tau(\psi_s(\phi_t(\xi)), \epsilon).$$

However, for notational convenience, we will write τ for τ_{loc}. Using this convention, we see immediately that $\tau(0, t, 0) \equiv 0$. Also, since

$$\tau_s(s, t, 0) = ||\mathbf{f}(\psi_s(\phi_t(\xi)))||^4 \alpha(\psi_s(\phi_t(\xi))),$$

we have

$$\tau_s(0, t, 0) = ||\mathbf{f}(\phi_t(\xi))||^4 \alpha(\phi_t(\xi)) \equiv 0,$$

and, for each $t \in \mathbb{R}$, we compute

$$\tau_{ss}(0, t, 0) = ||\mathbf{f}(\phi_t(\xi))||^4 d\alpha(\phi_t(\xi)) \mathbf{f}^{\perp}(\phi_t(\xi)) \neq 0.$$

By an application of the (Weierstrass) preparation theorem,

$$\tau(s, t, \epsilon) = \left(a(t, \epsilon) + b(t, \epsilon)s + s^2\right) u(s, t, \epsilon)$$

for functions a, b, and u, of the indicated variables, which satisfy

$$a(t, 0) \equiv 0, \quad b(t, 0) \equiv 0, \quad u(0, t, 0) \neq 0.$$

In particular, there are functions $t \to a_1(t)$ and $t \to b_1(t)$ such that

$$a(t, \epsilon) = a_1(t)\epsilon + O(\epsilon^2), \qquad b(t, \epsilon) = b_1(t)\epsilon + O(\epsilon^2),$$

and we have $\tau(s(t, \epsilon), t, \epsilon) \equiv 0$ for $s(t, \epsilon)$ denoting one of the two roots

$$\frac{-b(t, \epsilon) \pm \sqrt{-4a_1(t)\epsilon + O(\epsilon^2)}}{2}$$

of the Weierstrass polynomial. Now, if $a_1(0) \neq 0$, there is a branched surface $\mathcal{S}$ with exactly two branches along Γ in the direction of ϵ such that $a_1(0)\epsilon < 0$. In fact, for each root there is a locally defined "surface" given by

$$(t, \epsilon) \to (s(t, \epsilon), t, \epsilon)$$

that contains Γ and is such that $\tau(s(t,\epsilon),t,\epsilon)\equiv 0$.

To identify the quantity $a_1(0)$, we first compute

$$\tau_\epsilon(0,0,0)=a_\epsilon(0,0)u(0,0,0)=a_1(0)u(0,0,0).$$

But, in addition, we know that

$$\tau_\epsilon(0,0,0)=\tau_\epsilon(\xi,0)=\left[(\mathcal{N}+\alpha\mathcal{M})||\mathbf{f}||^2\right](\xi)=||\mathbf{f}(\xi)||^2\mathcal{N}(\xi)$$

and

$$||\mathbf{f}(\xi)||^4 d\alpha(\xi)\mathbf{f}^\perp(\xi)=\tau_{ss}(0,0,0)=2u(0,0,0).$$

Thus, after substitution, we obtain

$$a_1(0)=\frac{2\mathcal{N}(\xi)}{||\mathbf{f}(\xi)||^2 d\alpha(\xi)\mathbf{f}^\perp(\xi)},$$

and we see there will be a real branched surface with two branches provided

$$\epsilon\mathcal{N}(\xi)d\alpha(\xi)\mathbf{f}^\perp(\xi)<0.$$

Next, as before, we consider the restriction of the projection ρ to $\mathcal{S}$. However, here there is a slight difference from our previous arguments because the function s is not necessarily smooth at $\epsilon=0$. To overcome this difficulty we must incorporate the Puiseux series for our expansion of s in powers of ϵ. In the quadratic case this is quite simple. In fact, under our hypothesis that $a_1(0)\neq 0$, there exists a function $(t,\zeta)\to s^*(t,\zeta)$, analytic at $(0,0)$, such that

$$s(t,\epsilon)=s^*(t,\sqrt{\epsilon}).$$

When we restrict the projection ρ to the corresponding branch of $\mathcal{S}$, we have a function $(t,\zeta)\to\rho^*(t,\zeta)$, analytic at $(0,0)$, defined by

$$\rho^*(t,\zeta):=\rho_{\mathrm{loc}}(s^*(t,\zeta),t,\zeta^2)$$

with

$$\rho_{\mathcal{S}}(t,\epsilon)=\rho^*(t,\sqrt{\epsilon}).$$

Now, using the definition of ρ,

$$\rho_{\mathrm{loc}}(s,t,\epsilon):=\rho\left(\psi_s\left(\phi_t(\xi)\right),\epsilon\right),$$

but henceforth writing ρ for ρ_{loc}, we obtain from previous computations, $\rho(0,t,0)\equiv 0$, and

$$\rho_s(s,t,0)=d\rho(s,t,0)\mathbf{f}^\perp(s,t)=-||\mathbf{f}(s,t)||^2(1-\beta(s,t))\equiv 0.$$

A calculation using these facts and the chain rule yields $\rho^*_\zeta(t,0)\equiv 0$ and

$$\rho^*_{\zeta\zeta}(t,0)=2\rho_\epsilon(0,t,0)=2\beta\left(\phi_t(\xi)\right)\mathcal{M}\left(\phi_t(\xi)\right).$$

Thus, we have the representation

$$\rho^*(t,\zeta)=\rho_2(t)\zeta^2+O(\zeta^3)$$

with $\rho_2(t) = \mathcal{M}(\phi_t(\xi))$, and we see that if ξ is a simple zero of the Melnikov function, then $t = 0$ is a simple zero of ρ_2, and the implicit function theorem applies to show the existence of a curve $\zeta \to \sigma(\zeta)$, analytic at $\zeta = 0$, and such that $\rho^*(\sigma(\zeta), \zeta) \equiv 0$. It follows that

$$\rho_S(\sigma(\sqrt{\epsilon}), \epsilon) = \rho^*\left(\sigma(\sqrt{\epsilon}), \sqrt{\epsilon}\right) \equiv 0,$$

and, therefore, $t = \sigma(\sqrt{\epsilon})$, i.e.,

$$\epsilon \to \psi_{s(\sigma(\sqrt{\epsilon}),\epsilon)}\left(\phi_{\sigma(\sqrt{\epsilon})}(\xi)\right)$$

is the desired branch of subharmonics at $\xi \in \Gamma$. □

THEOREM 4.5 (order 2 limit cycle subharmonic bifurcation theorem). *Let E_ϵ denote the parameterized family of differential equations*

$$\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x}) + \epsilon\mathbf{g}(\mathbf{x}, t) + \epsilon^2\mathbf{g}_R(\mathbf{x}, t, \epsilon), \quad \mathbf{x} \in \mathbb{R}^2, \quad \epsilon \in \mathbb{R},$$

such that E_0 has a periodic trajectory $\Gamma \subset \mathcal{A}$ that is in resonance with the η-periodic external force **G**, *i.e., there are relatively prime natural numbers m and n such that the period of Γ is $m\eta/n$. If $\xi \in \Gamma$ is such that following three conditions are satisfied:* (i) $\alpha(\xi) = 0$ *and* $\beta(\xi) = 1$, (ii) *either* $\mathcal{M}(\xi)d\beta(\xi)\mathbf{f}^{\perp}(\xi) \neq 0$ *or* $\mathcal{N}(\xi)d\alpha(\xi)\mathbf{f}^{\perp}(\xi) \neq 0$, *and* (iii) $\xi \in \Gamma$ *is a simple zero of the bifurcation function*

$$\mathcal{D} := \mathcal{N}(\xi)d\beta(\xi)\mathbf{f}^{\perp}(\xi) - \mathcal{M}(\xi)d\alpha(\xi)\mathbf{f}^{\perp}(\xi),$$

then ξ is a subharmonic branch point with two branches. Moreover, these two branches exist, in case $\mathcal{M}(\xi)d\beta(\xi)\mathbf{f}^{\perp}(\xi) \neq 0$, only in the direction of ϵ such that

$$\epsilon\mathcal{M}(\xi)d\beta(\xi)\mathbf{f}^{\perp}(\xi) < 0$$

and, in case $\mathcal{N}(\xi)d\alpha(\xi)\mathbf{f}^{\perp}(\xi) \neq 0$, only in the direction of ϵ such that

$$\epsilon\mathcal{N}(\xi)d\alpha(\xi)\mathbf{f}^{\perp}(\xi) < 0.$$

Proof. The proof of this theorem follows exactly the same logic as the proof of the last theorem with only a few complications. The preparation theorem is applied in turn to both projections ρ and τ, but the proof in both cases is the same. Also, using the notation developed in the proof of the last theorem, we must deal with the fact that neither $\rho_{ss}(0,0,0)$ nor $\tau_{ss}(0,0,0)$ must vanish. For example, in the computation of $\tau^*_{\zeta\zeta}$ we obtain

$$\tau^*_{\zeta\zeta}(0,0) = \tau_{ss}(0,0,0)[s^*_\zeta(0,0)]^2 + 2\tau_\epsilon(0,0,0).$$

So, we must compute $s^*_\zeta(0,0)$. However, using the quadratic formula and the definition of s^* it is clear that

$$[s^*_\zeta(0,0)]^2 = -a_1(0),$$

with the quantity $a_1(0)$ computable as before. Thus, by similar, but slightly more complicated computations, the theorem can be proved by computation of the bifurcation derivatives in terms of α, β, $\mathcal{M}$, and $\mathcal{N}$. □

We end this section with an important remark on detuning. For this, consider a parametrized family of differential equations E_ϵ given by

$$\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x}) + \epsilon\mathbf{G}(\mathbf{x}, t, \epsilon), \quad \mathbf{x} \in \mathbb{R}^2, \quad \epsilon \in \mathbb{R},$$

where E_0 has a periodic trajectory Γ. Up to now we have assumed that the period η of the excitation $t \to \mathbf{G}(\mathbf{x}, t, \epsilon)$ is in resonance with the period of Γ. However, this condition can easily be relaxed in our analysis. In fact, we can assume merely that the period of the excitation is given by an expression of the form $\eta + k\epsilon + O(\epsilon^2)$. In this situation the parameter $k \in \mathbb{R}$ is called a *detuning.* When detuning is introduced, we retain our resonance assumption that the period of Γ is equal to $m\eta/n$ and simply reformulate the analysis in terms of an appropriate Poincaré map, namely,

$$\mathbf{P}(\xi, \epsilon) = \mathbf{x}(m\eta + mk\epsilon + O(\epsilon^2), \xi, \epsilon),$$

where $\mathbf{x}(t, \xi, \epsilon)$ is the solution of E_ϵ with $\mathbf{x}(0, \xi, \epsilon) = \xi$. Clearly, all the derivatives of $\mathbf{P}$ with respect to the space variable ξ reduce to previously computed expressions when evaluated at $\epsilon = 0$. On the other hand, we have

$$\begin{aligned}\mathbf{P}_\epsilon(\xi, 0) &= \dot{\mathbf{x}}(m\eta, \xi, 0)mk + \mathbf{x}_\epsilon(m\eta, \xi, 0)\\ &= mk\mathbf{f}(\xi) + [(\mathcal{N} + \alpha\mathcal{M})\mathbf{f} + \beta\mathcal{M}\mathbf{u}_{\mathbf{f}^\perp}](\xi)\\ &= \left[((mk + \mathcal{N}) + \alpha\mathcal{M})\mathbf{f} + \frac{1}{||\mathbf{f}||^2}\beta\mathcal{M}\mathbf{f}^\perp\right](\xi).\end{aligned}$$

Thus, all previous statements of theorems and formulas for derivatives remain valid in the case of a detuning when we replace each occurrence of $\mathcal{N}$ with $mk + \mathcal{N}$.

5. Examples. As a first example to illustrate the use of the limit cycle subharmonic bifurcation theorem, we consider the nonlinear system given by

$$\dot{x} = -y + x(1 - x^2 - y^2) + \epsilon g_1(x, y, t), \qquad \dot{y} = x + y(1 - x^2 - y^2) + \epsilon g_2(x, y, t),$$

where $G(x, y, t) := (g_1(x, y, t), g_2(x, y, t))$ is t-periodic of period $\eta := 2\pi n/m$ for some relatively prime positive integers n and m. Also, we denote the associated vector field of the unperturbed system by $\mathbf{X}$. This vector field is chosen to have a simple representation in polar coordinates,

$$\dot{r} = r(1 - r^2), \qquad \dot{\theta} = 1,$$

and a unique hyperbolic limit cycle Γ of period 2π on the unit circle. In fact the integral curve of $\mathbf{X}$ corresponding to Γ and starting at $\xi := (\xi_1, \xi_2)$ with $|\xi| = 1$ is given by

$$x(t) = \xi_1 \cos t - \xi_2 \sin t, \qquad y(t) = \xi_1 \sin t + \xi_2 \cos t.$$

For this example, we compute $\alpha(t) \equiv 0$ on Γ. Thus, the bifurcation function is

$$\mathcal{C}(\xi) = [(1 - \beta)\mathcal{N}](\xi) = (1 - e^{-2m\eta}) \int_0^{m\eta} xg_2(x, y, t) - yg_1(x, y, t)\, dt.$$

If we specify the forcing function, we can now determine the existence of subharmonic branch points. For example, if

$$g_1(t) = a\cos t + b\sin t, \qquad g_2(t) = c\cos t + d\sin t,$$

we compute

$$\mathcal{C}(\xi) = n\pi\left(1 - e^{-4n\pi}\right)\left((c-b)\xi_1 - (a+d)\xi_2\right),$$

and we see there are generically two subharmonic branch points at the intersection of the unit circle with the line $(c-b)\xi_1 - (a+d)\xi_2 = 0$. For an example where the excitation depends on the space variables, we take

$$g_1(x,y,t) = ax\cos\frac{t}{2}, \qquad g_2(x,y,t) = by\sin\frac{t}{2}$$

and compute, taking $n = 1$,

$$\mathcal{C}(\xi) = \frac{8}{15}(b-a)\left(1 - e^{-4\pi}\right)(\xi_1 - \xi_2)(\xi_1 + \xi_2).$$

Thus, there are four subharmonic branch points corresponding to the intersections of the lines

$$\xi_1 - \xi_2 = 0, \qquad \xi_1 + \xi_2 = 0$$

with the unit circle.

In the above example we are able to give a complete mathematical analysis of the subharmonic response of a system whose free oscillation is a limit cycle when the system is subjected to a resonant periodic external excitation. We are not able at present to give a similar rigorous mathematical analysis for a model equation that arises from a physical problem. However, we have been successful in applying the theory using numerical experiments. To illustrate this, we consider the example mentioned in the introduction of a forced van der Pol oscillator. In fact, we consider the system

$$\begin{aligned}
\dot{u} &= v,\\
\dot{v} &= -u + \delta(1-u^2)v,\\
\dot{x} &= \tau y,\\
\dot{y} &= \tau(-x + \delta(1-x^2)y) + \epsilon u,
\end{aligned}$$

where τ, δ, and ϵ are real parameters. Here, we view

$$\dot{x} = \tau y, \qquad \dot{y} = \tau(-x + \delta(1-x^2)y)$$

as the unperturbed system. It has, for $\delta > 0$ and $\tau > 0$, a stable limit cycle as its free oscillation. If, in addition, τ is a rational number and $\epsilon \neq 0$, then the xy-system is perturbed by a periodic external stimulus provided by the periodic output $t \mapsto u(t)$ of the uv-system, a second van der Pol oscillator running in resonance. To find the number and the positions of the subharmonic branch points where, for sufficiently small ϵ, families of subharmonic solutions of the perturbed oscillator emerge, we must find the simple zeros of the subharmonic bifurcation function $\mathcal{C}$ along the unperturbed limit cycle. Here, we are restricted by the lack of explicit analytic expressions for the solutions of the unperturbed system near its stable limit cycle. Thus, we have resorted to numerical experiments in order to suggest the actual subharmonic response. The graph of the bifurcation function $\mathcal{C}$ can be computed numerically to obtain the subharmonic branch points for various choices of the parameters. A typical graph of this type is depicted in Fig. 1 of the introduction.

Our final example is an application of the order 2 limit cycle subharmonic bifurcation theorem. For this, consider the system E_ϵ given by

$$\dot{x} = y - x(1 - x^2 - y^2)^2 - \epsilon \cos t, \qquad \dot{y} = -x - y(1 - x^2 - y^2)^2 + \epsilon \sin t,$$

which has the form

$$\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x}) + \epsilon \mathbf{g}(t).$$

Here, the unperturbed system has a (semistable) multiplicity 2 limit cycle Γ on the unit circle. The corresponding integral curve of E_0 starting at $\xi := (\xi_1, \xi_2)$ is

$$x(t) = \xi_1 \cos t + \xi_2 \sin t, \qquad y(t) = -\xi_1 \sin t + \xi_2 \cos t.$$

To apply the theorem, we define $r := \sqrt{x^2 + y^2}$, and compute

$$\begin{aligned} \operatorname{div} \mathbf{f}(x,y) &= -2(r^2 - 1)(3r^2 - 1), \\ \operatorname{curl} \mathbf{f}(x,y) &= -2, \\ 2\kappa ||\mathbf{f}||(x,y) &= -2\frac{2 - 6r^4 + 8r^6 - 3r^8}{2 - 4r^2 + 6r^4 - 4r^6 + r^8}. \end{aligned}$$

Then, for $\xi \in \Gamma$, we can compute

$$\begin{aligned} \alpha(t,\xi) &\equiv 0, \qquad & d\alpha(\xi)\mathbf{f}^\perp(\xi) &= 0, \\ \beta(\xi) &= 1, \qquad & d\beta(\xi)\mathbf{f}^\perp(\xi) &= -16\pi. \end{aligned}$$

For example, we have $\mathbf{f}^\perp(\xi) = \xi$, and, for any $\zeta \in \mathbb{R}^2$,

$$\beta(\zeta) = \exp\left(\int_0^{2\pi} -2(r^2 - 1)(3r^2 - 1)\, dt\right).$$

Thus,

$$d\beta(\xi)\mathbf{f}^\perp(\xi) = d\beta(\xi)\xi = \frac{d}{ds}\beta((1+s)\xi)\bigg|_{s=0}.$$

After the obvious computation, we find

$$d\beta(\xi)\mathbf{f}^\perp(\xi) = -8\int_0^{2\pi} \frac{dr}{ds}\bigg|_{s=0} dt.$$

But, since

$$\dot{r} = -r^2(1 - r^2)^2,$$

we can easily find the variational equation for r_s on Γ to be

$$\dot{r}_s = 0.$$

Also, since $r(0,s) = ||(1+s)\xi||$, we have $r_s(0,0) = 1$. This means $dr/ds \equiv 1$, and, in turn,

$$d\beta(\xi)\mathbf{f}^\perp(\xi) = -16\pi.$$

Next, we find

$$\mathcal{M}(\xi) = \int_0^{2\pi} y \sin t - x \cos t \, dt = -2\pi \xi_1.$$

Thus, the only zeros of $\mathcal{M}(\xi) = 0$ are on the line $\xi_1 = 0$. In particular, for $\zeta = (\pm 1, 0)$,

$$\mathcal{M}(\zeta) d\beta(\zeta) \mathbf{f}^{\perp}(\zeta) \neq 0.$$

We also have

$$\mathcal{D}(\xi) = -16\pi \mathcal{N}(\zeta) = 16\pi \int_0^{2\pi} (y \cos t + x \sin t)\, dt = 32\pi^2 \xi_2.$$

Thus, $\mathcal{D}$ has a simple zero along Γ at ζ, and, by the theorem, there will be two branches of harmonics at the subharmonic branch point ζ. At $\zeta = (-1, 0)$ these harmonics exist for sufficiently small $\epsilon < 0$, while at $(1, 0)$ they exist for sufficiently small $\epsilon > 0$.

LIMIT CYCLES IN A CUBIC SYSTEM WITH A CUSP*

WANG XIAN† AND ROBERT E. KOOIJ‡

Abstract. This paper studies the number of limit cycles in a cubic system with a cusp. By using new results concerning systems of Liénard type, the question of relative position and the maximum number of limit cycles for this system is solved completely.

Key words. cubic system, limit cycles, Liénard system

AMS(MOS) subject classifications. 34C, 58F

1. Introduction. In this paper we give a global analysis of a planar cubic system that arises in the study of three-dimensional viscous flow structures near a plane wall. In [3] Bakker developed a classification strategy to classify two-dimensional viscous flow structures near a plane wall in a systematic way. The investigation of three-dimensional flows is taken up by Bakker and de Winkel [4] and Kooij and Bakker [10]. The classification strategy relies to a great extent on the qualitative theory of differential equations and bifurcation theory. The flow is assumed to be steady, viscous, incompressible, and it satisfies no-slip boundary conditions on the wall. The topology of such a flow is studied on the basis of local solutions of the Navier–Stokes equations. The streamline pattern is represented by the trajectories of a three-dimensional system

$$(*)\qquad \frac{dx}{dt}=\dot{x}=u, \qquad \frac{dy}{dt}=\dot{y}=v, \qquad \frac{dz}{dt}=\dot{z}=w,$$

where t is real time, and u, v, w denote the velocity components in a cartesian reference system. The wall is represented by $z=0$. The local solutions are obtained by performing Taylor expansions of the velocity vector field.

The main objective of the classification strategy developed by Bakker [3] is to give a unified description of all topologically different flow patterns that will arise near a singularity of system $(*)$.

The dynamical behavior of the wall shear stress vector, defined by $\tau=\mu(\partial u/\partial z)_{z=0}$ in the x-direction and $\sigma=\mu(\partial v/\partial z)_{z=0}$ in the y-direction, where μ is the dynamical viscosity of the fluid, is governed by the equation $dy/dx=\lim_{z\to 0}(v(x,y,z)/u(x,y,z))$. The solution curves of this equation are referred to as skin friction lines.

For the type of singularity that is studied by Kooij and Bakker [10], the equation that describes the skin friction lines is equivalent with the following system:

$$\dot{x}=y+ax^2+x^3, \qquad \dot{y}=\lambda x^2-x^3.$$

In this paper we present a qualitative study of this cubic system.

2. Some definitions and theorems concerning Liénard systems. First we shall quote some results from [13]-[15], [17].

Consider the system

$$(1)\qquad \dot{x}=\varphi(y)-F(x), \qquad \dot{y}=-g(x),$$

* Received by the editors July 10, 1991; accepted for publication (in revised form) March 11, 1992.

† Department of Mathematics, Nanjing University, Nanjing, People's Republic of China.

‡ Faculty of Technical Mathematics and Informatics, Delft University of Technology, Delft, the Netherlands.

with $F(x)=\int_0^x f(s)\,ds$, where

$$f(x), g(x)\in C^1_{(\gamma_1,\gamma_2)}, \quad -\infty\leqq\gamma_1<0<\gamma_2\leqq\infty, \quad \varphi(y)\in C^1_{\mathbb{R}}.$$

In (1), $g(x)$ and $\varphi(y)$ may have several zeros, that is, (1) may have several singular points.

Definition 1 [13]. A set of singular points of (1) is called an unstable (stable) singular point system with index +1 if the sum of the indices of the singular points is +1 and there exists a bounded region D, containing this set of singular points, such that from every point on the boundary ∂D only positive (negative) semitrajectories of (1) are leaving D.

Definition 2 [13]. A set of singular points of (1) is called an unstable (stable) singular point-cycle system with index +1 if the sum of the indices of the singular points is +1 and there exists at least one limit cycle or separatrix cycle containing one or several of these singular points in its interior and there exists a bounded region D, containing the set of singular points, such that from every point on the boundary ∂D only positive (negative) semitrajectories of (1) are leaving D.

Theorem 1 [13]. *Consider the special case of system* (1):

$$(2)\qquad \dot{x}=\varphi(y)-E(x), \qquad \dot{y}=-g(x)=-g_0(x)-g_e(x),$$

where $g_0(x)$ and $g_e(x)$ are the odd part and the even part of $g(x)$, respectively. Suppose (2) *satisfies*

(1) $E(0)=0, E(-x)=E(x), y\varphi(y)>0$ $(y\neq 0)$, *and $\varphi(y)$ increasing for $y\in\mathbb{R}$*;

(2) $g(0)=0, xg(x)>0$ for $x\notin[a,0]$ $(\gamma_1<a\leqq 0)$ *and $g_e(x)>0$.*

Then (2) *does not have closed orbits that intersect with $x=a$ and $x=0$ simultaneously.*

Theorem 2 [14]. *Suppose that system* (1) *satisfies*

(1) $y\varphi(y)>0$ $(y\neq 0)$ *and $\varphi(y)$ is increasing for $y\in\mathbb{R}$, and there exist x_0, x_1, Δ, with $0<x_0<x_1<\gamma_2, 0<\Delta\leqq x_1$, such that $F(0)=F(x_1)=0, f(x)<0$ for $x<x_0, f(x)>0$ for $x>x_0$, $g(0)=g(\Delta)=0, xg(x)>0$ $(x\neq 0,\Delta)$*;

(2) *The system of equations*

$$F(u)=F(v), \quad \frac{g(u)}{f(u)}=\frac{g(v)}{f(v)}, \quad \gamma_1<u<0, \quad x_1<v<\gamma_2,$$

has at most one solution;

(3) *The function $f(x)/g(x)$ is increasing for $x\in(x_1,\gamma_2)$.*

Then (1) *has at most one limit cycle, and if it exists it has a negative characteristic exponent.*

Corollary. *If system* (1) *satisfies condition* (1) *in Theorem* 2 *and the function $g(x)/f(x)$ is decreasing for $\gamma_1<x<0$ and $x_1<x<\gamma_2$, then* (1) *has at most one limit cycle, and if it exists it has a negative characteristic exponent.*

Theorem 3 [15]. *Suppose that system* (1) *satisfies*

(1) $y\varphi(y)>0(y\neq 0)$, *$\varphi(y)$ is increasing for $y\in\mathbb{R}$, and there exist $\Delta, x_1, \bar{x}_1, \bar{x}_2, x_2$, with $\gamma_1<x_1<\bar{x}_1<0<\bar{x}_2<x_2<\gamma_2$, $0<\Delta\leqq x_2$, such that $F(x_1)=F(0)=F(x_2)=0, f(x)<0$ for $x\in(\bar{x}_1,\bar{x}_2), f(x)>0$ for $x\notin(\bar{x}_1,\bar{x}_2)$, $g(0)=g(\Delta)=0, xg(x)>0(x\neq 0,\Delta)$*;

(2) $G(x_1)\geqq G(x_2)$, *where $G(x)=\int_0^x g(s)ds$*;

(3) *The system of equations*

$$F(u)=F(v), \quad \frac{g(u)}{f(u)}=\frac{g(v)}{f(v)}, \quad \bar{x}_1<u<0, \quad x_2<v<\gamma_2,$$

has at most one solution;

(4) *The function $f(x)/g(x)$ is increasing for $x \in (x_2, \gamma_2)$.*

Then (1) *has at most one limit cycle, and if it exists it has a negative characteristic exponent.*

Remark. If in system (1) $\varphi(y)=y$, then the last condition of Theorem 3 may be weakened into

(4′) The function $f(x)F(x)/g(x)$ is increasing for (x_2, γ_2).

THEOREM 4 [17]. *Consider the system*

$$\dot{x}=y, \qquad \dot{y}=-g(x)-f(x)y. \tag{3}$$

Suppose there exist $\gamma_1 < c_1 \leqq b_1 < a_1 < 0 < a_2 < b_2 \leqq c_2 < \gamma_2$, such that

(1) *$xg(x)<0$ for $x \in (a_2, b_2) \cup (c_1, a_1)$, $xg(x)>0$ for $x \in (c_2, \gamma_2) \cup (\gamma_1, c_1)$,*

(2) *$f(x) \leqq 0$ for $x \in (b_1, b_2)$, $f(x) \geqq 0$ for $x \notin (b_1, b_2)$,*

(3) *$F(a_2)=F(c_2)$, $F(c_1)=F(a_1)$,*

(4) *The functions $f(x)$, $g(x)/(x-c_2)$ and $(x-c_2)(f(x)/g(x))$ are increasing for $x \in (c_2, \gamma_2)$, the functions $f(x)$, $g(x)/(x-c_1)$ and $(x-c_1)(f(x)/g(x))$ are decreasing for $x \in (\gamma_1, c_1)$.*

Then (3) *has at most two limit cycles surrounding all singular points.*

Remark. It follows from the proof of Theorem 4 that it still can be applied as $c_2=b_2=a_2=0$ or $c_1=b_1=a_1=0$.

3. Some properties of a cubic system with a cusp. The cubic system given in [10] reads

$$\dot{x}=y+ax^2+x^3, \qquad \dot{y}=\lambda x^2-x^3. \tag{4}$$

We can confine ourselves to the case $a>0$ because for $a=0$ it is easy to see that (4) has no closed orbits and for $a<0$ the transformation $(x, y, a, \lambda) \to (-x, -y, -a, -\lambda)$ can be applied to retain system (4) with $a>0$.

For $\lambda \neq 0$, (4) has two singularities, $O(0,0)$ and $A(\lambda, -a\lambda^2-\lambda^3)$, where O is a cusp and A is an antisaddle. A cusp is a nonhyperbolic singularity whose local topology is determined by two tangent separatrices, a stable and an unstable one. By an antisaddle, we mean a node, a focus, or a center. For $\lambda=0$, O and A collapse to form an unstable nilpotent focus ($a<\sqrt{2}$) or a nilpotent point with an elliptic sector ($a \geqq \sqrt{2}$), as can be seen from the classification scheme for nilpotent singularities in Andronov [2].

By comparing the trajectories of (4) for $\lambda=0$, $a<\sqrt{2}$, with the trajectories of the system $\dot{x}=y+ax^2$, $\dot{y}=-x^3$ (which form a family of closed curves), it can be proved that O is globally unstable for $\lambda=0$, $a<\sqrt{2}$; see Appendix A.

It is easy to check that A is a stable (unstable) elementary antisaddle if $\lambda(2a+3\lambda)<0(>0)$ and that for $2a+3\lambda=0$ A is a stable first-order weak focus.

The qualitative behavior of system (4) at infinity is as given in Fig. 1, as can be confirmed by using several blowups; see [6]. In fact, it can be shown that for all values

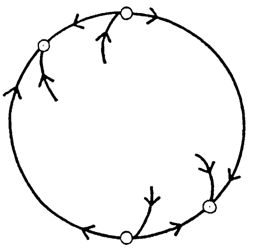

FIG. 1. *Behavior at infinity of system* (4).

of a and λ, the Poincaré equator is attracting. The blowups are described in detail in Appendix B.

The translation of A to the origin and a rescaling of time, $t=-\tau$, reduces (4) to the following Liénard system:

$$\frac{dx}{d\tau}=y-F(x), \qquad \frac{dy}{d\tau}=-g(x), \tag{5}$$

with

$$\begin{aligned}
F(x)&=\lambda(2a+3\lambda)x+(a+3\lambda)x^2+x^3,\\
f(x)&=(x+\lambda)(3x+2a+3\lambda),\\
g(x)&=x(x+\lambda)^2,\\
G(x)&=\frac{x^2}{12}(3x^2+8\lambda x+6\lambda^2).
\end{aligned}$$

4. Statement of the main result. In the following we will call a limit cycle that does not intersect the line $x+\lambda=0$ (in system (5)) small, and a limit cycle that does intersect the line $x+\lambda=0$ (in system (5)) large.

The main result of this paper is the following.

THEOREM 5. (i) *For $\lambda \geqq 0$ system* (5) *has no closed orbits.* (ii) *For fixed $\lambda<0$ there exist $a_1=a_1(\lambda)$, $a_2=a_2(\lambda)$, and $a_3=a_3(\lambda)$ with $-\lambda<a_3\leqq a_2\leqq a_1$ and $-\frac{4}{3}\lambda\leqq a_1<-\frac{3}{2}\lambda$, such that*

(a) *For $a\geqq -\frac{3}{2}\lambda$ system* (5) *has no small limit cycle and exactly one large limit cycle, and it has a negative characteristic exponent*;

(b) *For $a_1<a<-\frac{3}{2}\lambda (a=a_1)$ system* (5) *has exactly one large limit cycle and exactly one small limit cycle* (*one cusploop*); *the small limit cycle has a positive characteristic exponent*; *the large limit cycle is stable*;

(c) *For $a_2<a<a_1$ $(a=a_2)$ system* (5) *has two large limit cycles* (*a unique semistable large limit cycle*) *and no small limit cycles*;

(d) *For $a_3<a<a_2$ system* (5) *has no small limit cycles and the number of large limit cycles is two, one* (*in which case the limit cycle is semistable*), *or zero*;

(e) *For $a_3<a$ $(a=a_3)$ system* (5) *has no closed orbits* (*a unique semistable large limit cycle*).

By a cusploop, we mean a homoclinic orbit that consists of a cusp and its two separatrices that connect. The theorem will be proved completely by six lemmas.

First, let us define the roots of $F(x)=0$ and $f(x)=0$:

$$x_1=-\frac{a+3\lambda+\sqrt{(a-3\lambda)(a+\lambda)}}{2}, \quad x_0=0, \quad x_2=-\frac{a+3\lambda-\sqrt{(a-3\lambda)(a+\lambda)}}{2}$$

and

$$\bar{x}_1=-\tfrac{2}{3}a-\lambda<-\lambda=\bar{x}_2,$$

respectively. The roots of $g(x)$ are $x=0$ and $x=-\lambda$.

LEMMA 1. *For $\lambda\geqq 0$ system* (5) *has no closed orbits.*

Proof. We first consider the case $\lambda=0$; at this time (5) has only one singular point $O(0,0)$ and $xg(x)>0$ $(x\neq 0)$. Since

$$F(u)=F(v), \quad G(u)=G(v), \quad -\infty<u<0, \quad 0<v<\infty,$$

i.e.,

$$u^2+uv+v^2+a(u+v)=0, \quad (u^2+v^2)(u+v)=0, \quad -\infty<u<0, \quad 0<v<\infty$$

does not have a solution, (5) has no closed orbit by Rychkov's theorem [11].

For $\lambda>0$, if $0<a\leqq 3\lambda$, then $F(x)=0$ has no real roots except $x=0$; thus $g(x)F(x)>0$ for $x\in\mathbb{R}\backslash\{0,\lambda\}$. Notice that

$$\mu(x,y)=\tfrac{1}{2}y^2+G(x)=C$$

represents a family of closed curves, and so from

$$\frac{d\mu}{d\tau}=-g(x)F(x)\leqq 0,$$

we know at once that (5) has no closed orbits.

In order to discuss the case $a>3\lambda$, we consider the equivalent system of (5),

$$(6)\qquad \frac{dx}{d\tau}=y,\qquad \frac{dy}{d\tau}=-g(x)-f(x)y.$$

System (6) has two singular points, $B(-\lambda,0)$ and $O(0,0)$. Since at this time $x_1<x_2<\bar{x}_2=-\lambda$, thus $f(x)>0$ for $-\lambda<x<\infty$, it follows that (6) has no closed trajectory surrounding O alone.

Next we consider the system

$$(7)\qquad \frac{dx}{d\tau}=y,\qquad \frac{dy}{d\tau}=-x(x+\lambda)^2-2(a+3\lambda)xy$$

and the equivalent system

$$(8)\qquad \frac{dx}{d\tau}=y-(a+3\lambda)x^2,\qquad \frac{dy}{d\tau}=-x(x^2+\lambda^2)-2\lambda x^2.$$

From Theorem 1 we know that (8) does not have a trajectory intersecting with $x=-\lambda$ and $x=0$ simultaneously; therefore, (7) has no closed trajectory surrounding B, O. Furthermore, we can prove that (8) has no limit cycles surrounding O alone, by using a Dulac function $B(y)=\exp(-(2(a+3\lambda)/\lambda^2)y)$.

Because for (8) O is a stable first-order weak focus, as can be proved using [5, form. 3.4.11], it follows that singular point system B, O of (7) is stable.

Suppose that (6) has a closed trajectory surrounding B, O; then from

$$\begin{aligned}\left.\frac{dy}{dx}\right|_{(6)}&=-\frac{x(x+\lambda)^2}{y}-2(a+3\lambda)x-[3x^2+\lambda(2a+3\lambda)]\\&<-\frac{x(x+\lambda)^2}{y}-2(a+3\lambda)x=\left.\frac{dy}{dx}\right|_{(7)},\end{aligned}$$

it would follow that (7) has at least one limit cycle, but this contradicts the result proved above. Hence (6), that is (5), has no closed trajectory. This completes the proof of Lemma 1.

Next we will discuss the case $\lambda<0$.

LEMMA 2. *For* $0<a\leqq-\lambda$ *system* (5) *has no closed orbits. For* $-\lambda<a<-\frac{4}{3}\lambda$ *system* (5) *has no small limit cycle.*

Proof. The proof of the first statement is the same as for the case $\lambda>0$, $0<a\leqq 3\lambda$ above. After simplifying and by putting $\xi=u+v$, $\eta=uv$, the system of equations

$$(9)\qquad F(u)=F(v),\quad G(u)=G(v),\quad -\infty<u<0,\quad 0<v<-\lambda$$

can be changed into

$$(10)\qquad \begin{aligned}\eta&=\xi^2+(a+3\lambda)\xi+\lambda(2a+3\lambda)=H_1(\xi),\qquad \eta<0,\\ \eta&=\frac{\xi(3\xi^2+8\lambda\xi+6\lambda^2)}{2(3\xi+4\lambda)}=H_2(\xi),\qquad 0<\xi<-\lambda.\end{aligned}$$

The solutions of $H_1(\xi)=H_2(\xi)$ are $\xi_{12}=-a-2\lambda\pm\sqrt{a(3a+4\lambda)/3}$ and $\xi_0=-2\lambda$. Obviously, the numbers ξ_{12} are complex for $3a+4\lambda<0$, and because $\xi_0>-\lambda$, (10) and hence (9) have no solution. The second statement of the lemma follows from Rychkov's theorem [11].

LEMMA 3. *For $a\geqq-\frac{3}{2}\lambda$ system* (5) *has no small limit cycle.*

Proof. If $P(x,y)=y-F(x)$ and $Q(x)=-g(x)$, then for $B(y)=\exp(-(3/\lambda)y)$ we have $\operatorname{div}(BP,BQ)=(B/\lambda)(x+\lambda)(3x^2-\lambda(2a+3\lambda))$. By Dulac's criterion, for $\lambda(2a+3\lambda)<0$, system (5) has no closed orbits that do not intersect $x+\lambda=0$.

LEMMA 4. *For $a<-\frac{3}{2}\lambda$ system* (5) *has at most one small limit cycle, and if it exists it has a positive characteristic exponent.*

Proof. By the change of variables, $t=-\tau$, $y\to-y$, system (5) converts into the system

$$(5')\qquad \frac{dx}{dt}=y-F_1(x),\qquad \frac{dy}{dt}=-g(x),$$

where $F_1(x)=-F(x)$, $f_1(x)=-f(x)$.

It is easy to see that $0<\bar{x}_1<x_1<-\lambda=\bar{x}_2<x_2$, $F_1(0)=F_1(x_1)=0$, $f_1(x)<0$ for $x<\bar{x}_1$, and $f_1(x)>0$ for $x>\bar{x}_1$, $xg(x)>0$ $(x\neq0)$ for $x\in(-\infty,-\lambda)$.

An elementary calculation shows that

$$\frac{d}{dx}\left(\frac{g(x)}{f_1(x)}\right)=-\frac{(x+\lambda)^2}{f_1^2(x)}H(x),$$

with $H(x)=3x^2+2(2a+3\lambda)x+\lambda(2a+3\lambda)$.

The discriminant D of $H(x)$ satisfies $D=8a(2a+3\lambda)<0$, and, therefore, (d/dx)-$(g(x)/f_1(x))<0$ certainly holds for $x\in(-\infty,0)\cup(x_1,-\lambda)$.

The result follows from the corollary of Theorem 2 and the observation that we have used the transformation $t=-\tau$.

LEMMA 5. *For $a\geqq-\frac{3}{2}\lambda$ system* (5) *has exactly one large limit cycle, and if it exists it has a negative characteristic exponent.*

Proof. For $a\geqq-\frac{3}{2}\lambda$, (5) has no closed trajectory surrounding O alone by Lemma 3. It follows that the singular point system O, $A'(-\lambda,-a\lambda^2-\lambda^3)$ is unstable. Notice that for system (5) the singular points at infinity are repelling; so (5) has at least one large stable limit cycle. We will prove the uniqueness of this large limit cycle by using Theorem 3. It is easy to see that $x_1<\bar{x}_1<0<\bar{x}_2=\lambda<x_2$, where $f(x)<0$ for $x\in(\bar{x}_1,\bar{x}_2)$ and $f(x)>0$ for $x\notin(\bar{x}_1,\bar{x}_2)$, and, therefore, condition (1) of Theorem 3 is satisfied; see Fig. 2.

An elementary calculation shows that

$$G(x_1)-G(x_2)=\frac{(a+\lambda)(3a^2+4a\lambda-3\lambda^2)\sqrt{(a+\lambda)(a-3\lambda)}}{12}.$$

The region $S=\{(\lambda,a)\,|\,\lambda(2a+3\lambda)<0,\ a>0\}$ can be divided into

$$S_1=\left\{(\lambda,a)\,\middle|\,-\frac{3a}{2+\sqrt{13}}\leqq\lambda<0,\ a>0\right\}$$

and

$$S_2=\left\{(\lambda,a)\,\middle|\,-\frac{2}{3}a<\lambda\leqq-\frac{3a}{2+\sqrt{13}},\ a>0\right\}.$$

Obviously, for $S_1(S_2)$ the inequality $G(x_1)-G(x_2)\geqq0(\leqq0)$ holds, and, therefore, condition (2) of Theorem 3 holds for S_1.

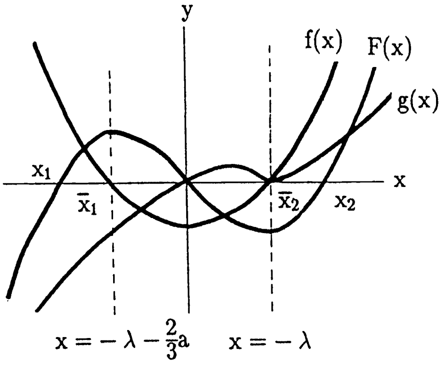

FIG 2. *Relative positions of $f(x)$, $F(x)$, and $g(x)$.*

After simplifying and by putting $\xi = u+v$, $\eta = uv$, the system of equations

$$F(u)=F(v), \quad \frac{f(u)}{g(u)}=\frac{f(v)}{g(v)}, \quad \bar{x}_1<u<0, \quad x_2<v<\infty$$

can be reduced to

$$\eta=\xi^2+(a+3\lambda)\xi+\lambda(2a+3\lambda)=H_1(\xi),$$
$$\eta=-\tfrac{1}{3}(2a+3\lambda)(\xi+\lambda)=H_2(\xi), \qquad \eta<0.$$

It is easy to check that the functions $H_1(\xi)$ and $H_2(\xi)$ have exactly one intersection point with $\eta<0$; see Fig. 3. Therefore, condition (3) of Theorem 3 is also fulfilled.

An elementary calculation shows that

$$\frac{d}{dx}\left(\frac{f(x)F(x)}{g(x)}\right)=\frac{q(x)}{(x+\lambda)^2},$$

where $q(x)=6x^3+(5a+21\lambda)x^2+2\lambda(5a+12\lambda)x-\lambda(a-3\lambda)(2a+3\lambda)$. The numbers $\hat{x}_1=-\lambda$ and $\hat{x}_2=-(5a+12\lambda)/9$ satisfy $q'(\hat{x}_1)=q'(\hat{x}_2)=0$. Furthermore, $\hat{x}_1-\hat{x}_2=(5a+3\lambda)/9>0$ and $q(-\lambda)=-2a\lambda(a+\lambda)>0$. It follows that $q(x)>0$ for $x>x_2>\bar{x}_2=\hat{x}_1$; hence

$$\frac{d}{dx}\left(\frac{f(x)F(x)}{g(x)}\right)>0 \quad \text{for } x\in(x_2,\infty),$$

i.e., condition (4') of Theorem 3 is also fulfilled.

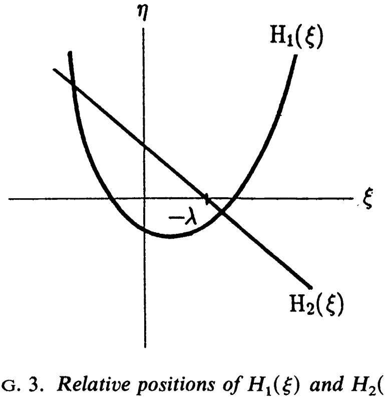

FIG. 3. *Relative positions of $H_1(\xi)$ and $H_2(\xi)$.*

For the region S_1 all conditions of Theorem 3 are satisfied and the lemma is proved. To prove the lemma for region S_2, we will reflect system (5) with respect to the y-axis, yielding

$$\frac{dx}{d\tau}=y-\bar{F}(x), \qquad \frac{dy}{d\tau}=-\bar{g}(x), \tag{11}$$

with $\bar{F}(x)=-F(-x)$ and $\bar{g}(x)=-g(-x)$.

It is easy to see that for system (11) $\bar{G}(x_1)\geqq\bar{G}(x_2)$ in the region S_2. The other conditions of Theorem 3 are also satisfied for system (11), as can be shown in a similar way as above. The lemma is completely proved.

LEMMA 6. *For $-\lambda<a<-\frac{3}{2}\lambda$ system* (4) *has at most two large limit cycles.*

Proof. By a change of variables $t=-\tau$, $y\to-y$, system (4) changes into the system

$$\frac{dx}{d\tau}=y-ax^2-x^3, \qquad \frac{dy}{d\tau}=-x^2(x-\lambda). \tag{4'}$$

Consider the equivalent system of (4'):

$$\frac{dx}{d\tau}=y, \qquad \frac{dy}{d\tau}=-x^2(x-\lambda)-(2ax+3x^2)y. \tag{12}$$

Let $F(x)=x^2(x+a), f(x)=x(2a+3x), g(x)=x^2(x-\lambda)$.

The roots of $F(x)=0$ are $x_1=-a<x_2=0$. The roots of $f(x)=0$ are $\alpha=-\frac{2}{3}a<\beta=0$. The roots of $g(x)=0$ are $c=\lambda<d=0$. For $-\lambda<a<-\frac{3}{2}\lambda$, we have $\frac{3}{2}\lambda<x_1<\lambda$ and $\lambda<\alpha<\frac{2}{3}\lambda$.

Notice that the first three conditions of Theorem 4 are fulfilled with

$$\gamma_1=-\infty, \quad c_1=\lambda, \quad b_1=\alpha, \quad a_2=b_2=c_2=0, \quad \gamma_2=\infty$$

and where a_1 satisfies $F(a_1)=F(\lambda)$ and $b_1<a_1<0$; see Fig. 4.

In the interval $(0,\infty), f'(x)=6x+2a>0, (g(x)/x)'=2x-\lambda>0,$

$$\left(\frac{xf(x)}{g(x)}\right)'=-\frac{2a+3\lambda}{(x-\lambda)^2}>0,$$

so the functions $f(x), g(x)/x$ and $(xf(x))/g(x)$ are increasing for $x\in(0,\infty)$. In the interval $(-\infty,\lambda), f'(x)=6x+2a<3\lambda+(2a+3\lambda)<0, (g(x)/(x-\lambda))'=2x<0,$ $(((x-\lambda)f(x))/g(x))'=-2a/x^2<0$, so the functions $f(x), g(x)/(x-\lambda)$ and $((x-\lambda)f(x))/g(x)$ are decreasing for $x\in(-\infty,\lambda)$. Therefore, from Theorem 4 and its remark,

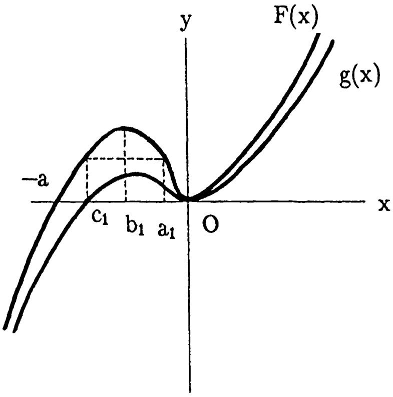

FIG 4. *Relative positions of $F(x)$ and $g(x)$.*

it follows that (12) has at most two large limit cycles surrounding the two singular points O, A. The lemma is completely proved.

Proof of Theorem 5. In the region $K=\{(x,y)\,|\,-\infty<x<-2\lambda, |y|<\infty\}$ system (5), considered as a vector field X_a, is a so-called semicomplete family (mod $x=0$) of rotated vector fields with respect to the parameter "a" because in the region K the following assertions hold except on $x=0$:

—The derivative of the angle between X_0 and X_a with respect to a is strictly negative for $x\neq 0$,

—$\tan\theta\to\pm\infty$ as $a\to\pm\infty$, where θ is the angle of the vector field.

From this we can deduce, see Perko [11], that attracting (repelling) limit cycles expand (shrink) monotonically as a decreases. As a varies, limit cycles appear or disappear in a singular point, in a separatrix cycle or in a semistable limit cycle. It follows from Lemmas 2–4 that there must exist a unique $a_1=a_1(\lambda)$ with $-\frac{4}{3}\lambda\leqq a_1<-\frac{3}{2}\lambda$, such that $(5)_{a=a_1}$ has a cusploop Γ. It is easy to see that Γ is unstable from the inside. We conjecture that when the cusploop Γ exists, it is surrounded by a large stable limit cycle, and hence Γ is also unstable from the outside. However, we were not able to exclude the possibility that for some λ the cusploop is semistable, i.e., $a_2(\lambda)=a_1(\lambda)$.

Thus O, A' form an unstable singular point system ($a\geqq-\frac{3}{2}\lambda$), an unstable singular point-cycle system ($a_1\leqq a<-\frac{3}{2}\lambda$) or O, A' form a stable singular point system ($a<a_1$). The remaining conclusions of Theorem 5 can be deduced at once from Lemmas 2–6.

Remark. Because the parameter a rotates the vector field in the region K only, we were not able to prove the uniqueness of the semistable limit cycle bifurcation set. We conjecture that this bifurcation set is unique (i.e., $a_2=a_3$ in Theorem 5). If it could be shown that (5) has no limit cycles intersecting $x+2\lambda=0$, then the conjecture is proved.

5. Concluding remarks. In this section we give the bifurcation diagram (Fig. 5) and the corresponding phase portraits (Fig. 6) for system (4), using the conjectures stated above. The bifurcation sets in Fig. 5 correspond to Hopf-bifurcation (H), the cusploop (CL), and a semistable limit cycle (SS). The results follow directly from Theorem 5. Notice that in order to transform (4) to (5), the transformation $\tau=-t$ has been used.

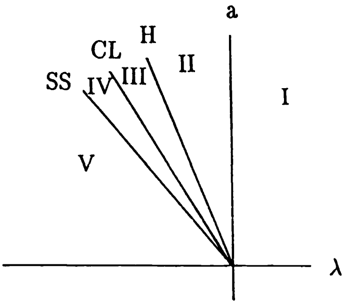

FIG. 5. *The bifurcation diagram.*

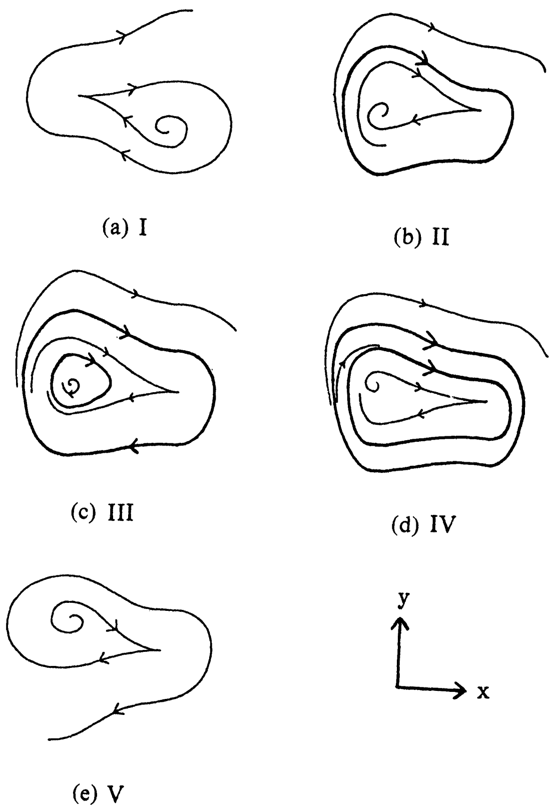
If in system (4), a and λ are taken to be small parameters, then (4) can be considered a partial unfolding of a nilpotent focus of codimension 4. We call it a focus of codimension 4, copying some arguments in [8], since normal form theory (see [12]) together with the Tarski–Seidenberg decision theorem (see Appendix [1]) show that



(a) I

(b) II

(c) III

(d) IV

(e) V

FIG. 6. *Phase portraits of system* (4).

this singularity lies on a semialgebraic set of codimension 4. We do not know whether there exists a theorem that asserts that 4 parameters suffice to fully describe a versal unfolding of such a singularity. We conjecture that the following system is a versal unfolding of the nilpotent focus of codimension 4:

$$\dot{x} = y + \mu_1 x + \mu_2 x^2 + x^3, \qquad \dot{y} = \mu_3 x + \lambda x^2 - x^3. \tag{13}$$

Using Theorem 5 and the well-known results concerning the Takens-Bogdanov system, describing the unfolding of a cusp of codimension 2, it follows that system (13) can have three limit cycles and that the distribution of limit cycles as given in Fig. 7 is realizable. Obviously, system (13) can be brought into the equivalent form

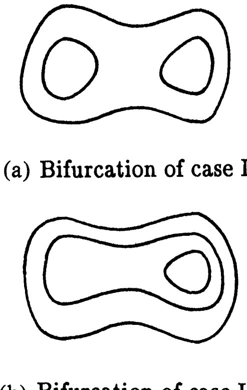
$$\dot{x} = y, \qquad \dot{y} = \lambda_1 x + \lambda_2 x^2 - x^3 + (\nu_1 + \nu_2 x + x^2) y. \tag{14}$$

In [7] Dumortier, Roussarie, and Sotomayor have studied system (14) with ν_2 fixed $(0 < \nu_2 < 2\sqrt{2})$ and considered this system as a versal unfolding of the nilpotent focus of codimension 3. Dangelmeyer and Guckenheimer [5] also obtained some results for system (14).

Appendix A. System (4) with $\lambda = 0$. For $\lambda = 0$ system (4) reduces to

$$\frac{dx}{dt} = y + ax^2 + x^3, \qquad \frac{dy}{dt} = -x^3. \tag{A1}$$

For $a^2 < 2$ the origin $O(0, 0)$ of system (A1) is a nilpotent focus. We will show that it is globally unstable.



(a) Bifurcation of case III

(b) Bifurcation of case IV

FIG. 7. *Limit cycles for system* (14).

Consider the following system:

$$\text{(A2)}\qquad \frac{dx}{dt}=y+ax^2=P(x,y),\qquad \frac{dy}{dt}=-x^3=Q(x).$$

It is obvious that the trajectories of (A2) form a family of closed curves because $P(-x,y)=P(x,y)$, and $Q(-x)=-Q(x)$.

The first integral of (A2) reads

$$V(x,y)=\frac{1}{4}\log(x^4+2ax^2y+2y^2)+\frac{a}{2\omega}\tan^{-1}\left(\frac{ax^2+2y}{\omega x^2}\right)=C,$$

with $\omega=\sqrt{2-a^2}$ and $a^2<2$.

The derivative of $V(x,y)$ along trajectories of (A1) satisfies

$$\left.\frac{dV}{dt}\right|_{(\mathrm{A1})}=\frac{\partial V}{\partial x}(y+ax^2+x^3)-\frac{\partial V}{\partial y}x^3=\frac{x^6}{x^4+2ax^2y+2y^2}\geqq 0\quad \text{for } a^2<2.$$

It follows that the origin $O(0,0)$ of (A1) is globally unstable for $a^2<2$.

Appendix B. Singularities at infinity of system (4). System (4) reads

$$\text{(B1)}\qquad \dot{x}=y+ax^2+x^3,\qquad \dot{y}=\lambda x^2-x^3.$$

It is easy to check that (B1) has no singularity at the end of the x-axis. Therefore, it suffices to use the Poincaré transformation $z=1/y$, $v=x/y$, $dt/d\tau=z^2$, to study the singularities at infinity. System (B1) reduces to

$$\text{(B2)}\qquad \frac{dz}{d\tau}=-\lambda z^2v^2+zv^3,\qquad \frac{dv}{d\tau}=z^2+azv^2+v^3-\lambda zv^3+v^4.$$

The singularities of (B2) on $z=0$ are $I_1(0,0)$ and $I_2(0,-1)$.

First let us study $I_1(0,0)$.

Using a polar blowup, $z=r\cos\varphi$, $v=r\sin\varphi$, $-\pi\leqq\varphi\leqq\pi$, system (B2) changes into

$$\text{(B3)}\qquad \begin{aligned}\dot{r}&=r\cos^2\varphi\sin\varphi+r^2(a\cos\varphi\sin^3\varphi+\sin^4\varphi)+r^3(-\lambda\cos\varphi\sin^2\varphi+\sin^3\varphi),\\ \dot{\varphi}&=\cos^3\varphi+r(a\cos^2\varphi\sin^2\varphi+\cos\varphi\sin^3\varphi).\end{aligned}$$

The singularities of system (B3) on $r=0$ are $A_1(0,-(\pi/2))$ and $A_2(0,\pi/2)$.

Linearization of (B3) near A_1, with $\varphi = -(\pi/2) + \xi$, yields

$$\dot{r} = r^2 - r^3 - r\xi^2 - ar^2\xi - \lambda r^3\xi, \qquad \dot{\xi} = \xi^3 + ar\xi^2 - r\xi. \tag{B4}$$

If in (B4) we make the change of variables $(r, t) \to (-r, -t)$, then we obtain the linearization of (B4) near A_2 (with $\varphi = (\pi/2) + \xi$).

So, in order to study the topological character of A_1 and A_2, it suffices to study the phase portrait of (B4) near the origin both for $r < 0$ and for $r > 0$.

A second blowup, $r = \eta \cos\theta$, $\xi = \eta \sin\theta$, with $-(\pi/2) \leqq \theta \leqq \pi/2$, changes (B4) into

$$\begin{aligned}\dot{\eta} &= \eta(\cos^3\theta - \cos\theta\sin^2\theta) + \eta^2(-\cos^2\theta - a\cos^3\theta\sin\theta + a\cos\theta\sin^3\theta + \sin^4\theta)\\ &\quad -\lambda\eta^3\cos^4\theta\sin\theta,\\ \dot{\theta} &= -2\cos^2\theta\sin\theta + \eta(\cos^3\theta\sin\theta + 2a\cos^2\theta\sin^2\theta + 2\cos\theta\sin^3\theta)\\ &\quad +\lambda\eta^2\cos^3\theta\sin^2\theta.\end{aligned} \tag{B5}$$

The singularities of (B5) on $\eta = 0$ are $C_1(0, -(\pi/2))$, $C_2(0, 0)$, and $C_3(0, \pi/2)$.

Linearization of (B5) near C_1, with $\theta = -(\pi/2) + \delta$, yields

$$\begin{aligned}\dot{\eta} &= \eta^2 - \eta\delta - a\eta^2\delta - \eta^2\delta^2 + \eta\delta^3 + a\eta^2\delta^3 + \lambda\eta^3\delta^4,\\ \dot{\delta} &= -2\eta\delta + 2\delta^2 + 2a\eta\delta^2 - \eta\delta^3 + \lambda\eta^2\delta^3.\end{aligned} \tag{B6}$$

Near C_2 system (B5) has a linear part $\dot{\eta} = \eta$, $\dot{\theta} = -2\theta$, and it follows that C_2 is a hyperbolic saddle.

If in (B6) we make the change of variables $(\delta, a, \lambda) \to (-\delta, -a, -\lambda)$, we obtain the linearization of (B6) near C_3 (with $\theta = (\pi/2) + \delta$).

A third blowup, $\eta = \rho\cos\mu$, $\delta = \rho\sin\mu$, with $0 \leqq \mu \leqq \pi$, changes (B6) into a system with four singularities on $\rho = 0$; $D_1(0, 0)$, $D_2(0, \pi/4)$, $D_3(0, \pi/2)$, and $D_4(0, \pi)$. We do not give the complete system after the blowup, just the linearization near D_i, $i = 1, 2, 3, 4$, with $\mu = \mu_0 + \sigma$:

$$\begin{aligned}&D_1: &&\dot{\rho} = \rho + o(|\rho, \sigma|), &&\dot{\sigma} = -3\sigma + o(|\rho, \sigma|),\\ &D_3: &&\dot{\rho} = 2\rho + o(|\rho, \sigma|), &&\dot{\sigma} = -3\sigma + o(|\rho, \sigma|),\\ &D_4: &&\dot{\rho} = -\rho + o(|\rho, \sigma|), &&\dot{\sigma} = 3\sigma + o(|\rho, \sigma|),\end{aligned}$$

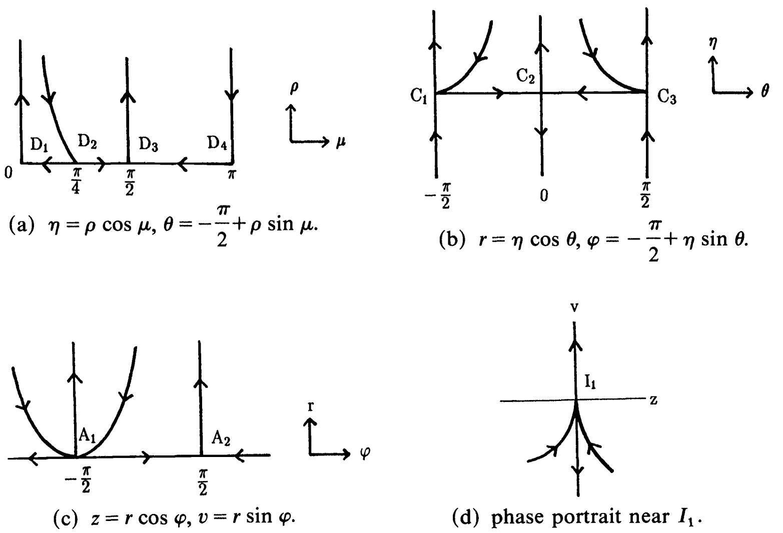
$$\begin{aligned}D_2:\quad &\dot{\rho} = \frac{a}{4}\rho^2 + \frac{\rho\sigma}{\sqrt{2}} - \frac{1}{4\sqrt{2}}\rho^3 + \frac{3}{2}a\rho^2\sigma + 3\sqrt{2}\,\rho\sigma^2 + o(|\rho, \sigma|^3),\\ &\dot{\sigma} = \frac{3}{4}a\rho + \frac{3\sigma}{\sqrt{2}} - \frac{1}{4\sqrt{2}}\rho^2 + \frac{\lambda - a}{8}\rho^3 - \frac{3}{4\sqrt{2}}\rho^2\sigma - \frac{3}{2}a\rho\sigma^2 - \frac{3\sigma^3}{\sqrt{2}} + o(|\rho, \sigma|^3).\end{aligned} \tag{B7}$$

Obviously, D_1, D_3, and D_4 are hyperbolic saddles. D_2 is a semihyperbolic saddle, as can be seen after transforming

$$\omega = \frac{3\sigma}{\sqrt{2}} + \frac{3}{4}a\rho - \frac{1}{4\sqrt{2}}\rho^2$$

in system (B7):

$$\dot{\rho} = -\frac{1}{6\sqrt{2}}\rho^3 + \omega O(|\rho, \omega|) + o(|p|^3), \qquad \dot{\omega} = \frac{3\omega}{\sqrt{2}} + o(|\rho, \omega|).$$



(a) $\eta = \rho \cos \mu$, $\theta = -\frac{\pi}{2} + \rho \sin \mu$.

(b) $r = \eta \cos \theta$, $\varphi = -\frac{\pi}{2} + \eta \sin \theta$.

(c) $z = r \cos \varphi$, $v = r \sin \varphi$.

(d) phase portrait near I_1.

FIG. B1

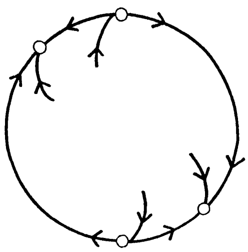


FIG. B2

After three blowups we have obtained only isolated singularities that are hyperbolic or semihyperbolic, so we can determine the topological character of I_1 in system (B2). Notice that the topological character of I_1 is independent of a and λ.

In Fig. B1 the blow-down for the singularity I_1 is sketched. After linearization of system (B1) near I_2 (take $v = -1 + w$), the linear part of (B2) becomes $z' = -z$, $w' = (a + \lambda)z - w$. It follows that I_2 is a stable improper node, independent of a and λ.

In Fig. B2 the topological behavior of system (B1) near infinity is sketched. The Poincaré equator is attracting for all values of a and λ.

ELIMINATING THE GENERICITY CONDITIONS IN THE SKEW TOEPLITZ OPERATOR ALGORITHM FOR H^{∞}-OPTIMIZATION*

CAIXING GU†

Abstract. In this paper the genericity conditions are eliminated in the skew Toeplitz operator algorithm for H^{∞}-optimization of [*Oper. Theory: Adv. Appl.*, 49 (1988), pp. 21-43], [*Systems Control Lett.*, 11 (1988), pp. 259-264]. This paper gives an explicit formula for a class of weighted sensitivity minimization problems.

Key words. H^{∞}-optimization, skew Toeplitz, Hankel operator, weighted sensitivity

AMS(MOS) subject classifications. 47A20, 93B35, 93C05

1. Introduction. It is well known now that a number of problems in control engineering can be reduced to certain generalized interpolation problems in H^{∞} [1]. Namely, let $w, m \in H^{\infty}$ with w rational and m nonconstant inner. Then the H^{∞}-optimal weighted sensitivity problem amounts to the computation of

$$\rho_0 = \inf \|w - mq\|_{\infty}, \qquad q \in H^{\infty},$$

and find the corresponding q_{opt} that reaches the bound.

This problem has been studied from an operator point of view in a number of papers (see [1]-[4] and the reference therein). Particularly, in [1], [3], [4] Bercovici, Foias, Tannenbaum, and Zames introduced the skew Toeplitz operators and developed several algorithms for the computation of ρ_0 and q_{opt}. The point of this paper is to eliminate the genericity conditions in the algorithm given in [4] (see also [2, § XII]).

To be more precise, recall that ρ_0 is the norm of a certain operator (which is equivalent to the Hankel operator [1]). q_{opt} can be computed from the corresponding singular vector. Namely, $S: H^2 \to H^2$ denotes the unilateral shift (all of our Hardy spaces will be defined on the unit disc D in the standard way) and $P_H: H^2 \to H^2 \ominus mH^2 = H$ denotes the orthogonal projection. Let $T = S(m) = P_H S | H$, then $\rho_0 = \|W(T)\|$: here $W(T) = P_H M_W | H$, M_w is the multiplication operator by w. In [1]-[4], under some specified genericity conditions an algorithm is given to compute ρ_0 and q_{opt} by reducing the problem to the noninvertibility of an $n \times n$ matrix; here $n := \max\{\text{degree } p, \text{degree } q\}$ for relatively prime polynomials p and q such that $w = p/q$. This paper eliminates those genericity conditions, and also reduces the computation of ρ_0 to the noninvertibility of an $(n+l) \times (n+l)$ matrix (see Theorem 3). So the algorithm is now complete (see § 4 for the algorithm).

2. Some basic facts and equalities. Throughout this paper, for a linear bounded operator A on a complex Hilbert space K, we denote its spectrum by $\sigma(A)$, its essential spectrum by $\sigma_e(A)$, and its essential norm by $\|A\|_e$. Recall that the essential spectrum and essential norm are, respectively, the spectrum and norm in the Calkin algebraic (i.e., the quotient of the space of all operators modulo the compact operators). In this

section we present some facts from [2, § XII, 3] that are essential for our work. Let

$$\begin{aligned} T_\rho &= q(T)(\rho^2 - W(T)W(T)^*)q(T)^* \\ &= \rho^2 q(T)q(T)^* - p(T)p(T)^* \\ &= \sum_{0,0}^{n,n} C_{jk}T^jT^{*k}, \end{aligned}$$

where

$$C_{jk} = \rho^2 q_j\bar{q}_k - p_j\bar{p}_k \tag{2.1}$$

and p_j, respectively, q_j are coefficients for z^j in p, respectively, q.

It is clear that T_ρ is not invertible if and only if $\rho^2 I - W(T)W(T)^*$ is not invertible, or equivalently, $\rho^2 \in \sigma(W(T)W(T)^*)$. If $\rho > \|W(T)\|_e$, then the noninvertibility of T_ρ is equivalent to ρ^2 being an eigenvalue of $W(T)W(T)^*$; the largest such $\rho > 0$ is equal to $\inf \|w - mq\|_\infty$, $q \in H^\infty$.

By dropping ρ, we are thus lead to the following problem: given a skew Toeplitz operator [1],

$$T_\rho = \sum_{0,0}^{n,n} C_{jk}T^jT^{*k}$$

with the property that $0 \in \sigma(T_\rho)$ if and only if zero is an eigenvalue of T_ρ (which is equivalent to $\{z, C(z) = 0\} \cap \{z \in \partial D, z \in \sigma(T)\} = \phi$. Here by [8], [9], $\sigma(T) = \{$zeros of m in D and essential singularities of m on $\partial D)$, determine if $0 \in \sigma(T_\rho)$ or not. If $0 \in \sigma(T_\rho)$, find a nonzero y in H such that $T_\rho y = 0$.

Now recall that the unilateral shift on H^2 is the minimal isometric dilation of $T = S(m)$ [5], [6]. This implies that

$$T_\rho = P_H \sum_{0,0}^{n,n} C_{jk}S^jS^{*k} \,|\, H. \tag{2.2}$$

In particular, $T_\rho y = 0$ for some y in H if and only if

$$\sum_{0,0}^{n,n} C_{jk}S^jS^{*k}y = mg \tag{2.3}$$

for some $g \in H^2$. If y_j is the coefficient of z^j in the power series expansion of y, then

$$\begin{aligned} S^jS^{*k}y &= S^j[z^{-k}(y - y_0 - zy, \cdots, -z^{k-1}y_{k-1})] \\ &= z^{j-k}(y - y_0 - zy, \cdots, -z^{k-1}y_{k-1}). \end{aligned} \tag{2.3a}$$

Now let $C(z)$, respectively $C_i(z)$ (for $0 \leqq i < n$) be the polynomials of degree less than or equal to $2n$, respectively, $2n-1$ defined by

$$\begin{aligned} C(z) &= \sum_{0,0}^{n,n} C_{jk}z^{n+j-k} = \sum_{j=0}^{2n} a_jz^j, \\ C_i(z) &= \sum_{i<k\leqq n, 0 \leqq j \leqq n} C_{jk}z^{n+j-k+i} = \sum_{j=1}^{2n-1} a_{ij}z^j, \end{aligned} \tag{2.3b}$$

where C_{jk} is given by (2.1). We notice that for $i \leqq j < n$, we have

$$a_{ij} = a_{j-i}. \tag{2.3c}$$

Substituting (2.3a) into (2.3) and using the definition of $C(z)$ and $C_i(z)$'s, we conclude that $T_\rho y = 0$ if and only if

$$(2.4)\qquad C(z)y(z) - \sum_{i=0}^{n-1} C_i(z)y_i = z^n m(z)q(z)$$

for some $g \in H^2$.

Now we can state the genericity conditions assumed in [4] (see also [2, § XII]).

$$(\mathrm{A})\qquad C(z) \neq 0 \quad \text{for all } z \in \sigma(T) \cup \{0\}.$$

Under the assumption (A), since

$$C(T) = \beta\Pi(T - z_0 I),$$

where $\beta \neq 0$ and z_0 runs over the zeros of $C(z)$ (thus z_0 is not in $\sigma(T)$ so each $T - z_0 I$ is invertible), we deduce that $C(T)$ is invertible. Obviously $C(T)^{-1}$ commutes with T. By Sarason's theorem [10] (see also [2, § IX, 7.4]) there exists $C^{(-1)}$ in H^∞ such that $C^{(-1)}(T) = C(T)^{-1}$. Moreover, using the fact that $(C^{(-1)}C)(T) = I$, we see that there exists an h_1 in H^∞ satisfying

$$(2.5)\qquad C^{(-1)}C = 1 + mh_1.$$

By multiplying (2.4) by $C^{(-1)}$, we obtain

$$(2.6)\qquad y(z) - \sum_{i=0}^{n-1} (C^{(-1)}C_i)(z)y_i = m(z)[z^n C^{(-1)}g(z) - h_1(z)y(z)] = m(z)h(z),$$

where $h(z) \in H^2$.

Applying P_H to the previous equation gives

$$(2.7)\qquad y = \sum_{i=0}^{n-1} y_i P_H C^{(-1)} C_i = \sum_{i=0}^{n-1} y_i \chi_i,$$

where using $P_H C^{(-1)}(S) = C(T)^{-1} P_H$ (see [2] for the definition of $C^{(-1)}(S)$) then

$$(2.7\mathrm{a})\qquad \chi_i = P_H C^{(-1)} C_i = C(T)^{-1} P_H C_i \quad (\text{for } 0 \leqq i < n)$$

does not depend on the particular choice of $C^{(-1)}$ and is obviously in H. Substituting (2.7) into (2.4) produces

$$(2.8)\qquad \sum_{i=0}^{n-1} y_i (C P_H C^{(-1)} C_i - C_i)(z) = z^n m(z) g(z) \qquad (z \in D).$$

Using in addition the lifting property $P_H C(S) P_H = P_H C(S)$, we have $P_H C P_H C^{(-1)} C_i - C_i = P_H C C^{(-1)} C_1 - C_i = (P_H - I)C_i$ in mH^2 $(0 \leqq i < n)$. So by (2.7a) and (2.8) there exists a sequence of functions g_i in H^2 such that

$$(2.9)\qquad C\chi_i - C_i = mg_i \quad (\text{for } 0 \leqq i < n),$$

$$(2.10)\qquad \sum_{i=0}^{n-1} y_i g_i(z) = z^n g(z) \qquad (z \in D).$$

3. Main results. First we will eliminate the condition $C(0) \neq 0$ in A. Namely, we assume $C(z)$ has a zero at zero of order k $(k \leqq n)$ and

$$(\mathrm{A1})\qquad \{z, C(z) = 0\} \cap \sigma(T) = \phi.$$

Let us introduce some notations. For $\alpha \in D$, $f \in H^2$, let $f = \sum_{i=0}^{\infty} f_i (z - \alpha)^i$ be the power series expansion of f at α. Define $\Pi_s(\alpha): H^2 \to H^2$ by

$$\Pi_s(\alpha) f = \sum_{i=0}^{s-1} f_i (z - \alpha)^i = [f_0 \cdots f_{s-1}].$$

It is clear from the definition that for $f, h \in H^2$,

$$\Pi_s(\alpha)f\cdot h = [f_0h_0, f_1h_0+f_0h_1, \cdots] \tag{3.0}$$
$$= \begin{bmatrix} f_0 & & & 0 \\ f_1 & \ddots & & \\ \vdots & \ddots & \ddots & \\ f_{s-1} & \cdots & f_1 & f_0 \end{bmatrix} \begin{bmatrix} h_0 \\ \vdots \\ h_{s-1} \end{bmatrix}.$$

Let $\Pi_n(0)g_i(z) = [g_{i0}, g_{i1}, \cdots, g_{in+1}]$ and $\Pi_n(0)\chi_i(z) = [\chi_{i,0}, \chi_{i,1}, \cdots, \chi_{i,n-1}]$. Notice that under the assumption (A1) all equalities in § 2 are valid. Applying $\Pi_n(0)$ to (2.10) and (2.7), respectively, we get

$$\sum_{i=0}^{n-1} y_i g_{ij} = 0 \qquad (0 \leqq j < n), \tag{3.0a}$$

$$\sum_{i=0}^{n-1} y_i \chi_{ij} = y_j \qquad (0 \leqq j < n). \tag{3.0b}$$

It seems that we get $2n$-equations for n-unknown $[y_0, \cdots, y_{n-1}]$. Soon we will see that some equations are redundant.

Notice by (2.3b, c) that the first n coefficients of polynomials $C_i(z)$ are

$$\Pi_n(0)C_i(z) = \sum_{j=i}^{n-1} a_{ij}z^j = z^i \sum_{j=0}^{n-1-i} a_j z^j \tag{3.1}$$
$$= [0 \cdots 0, a_0, \cdots, a_{n-1-i}] \qquad (0 \leqq i < n).$$

THEOREM 1. *Under the assumption* (A1) *if* $T_\rho y = 0$ *for some nonzero function* y *in* H, *then* y *is given by* (2.7), *where* $[y_0, \cdots, y_{n-1}]$ *is a nonzero solution of*

$$\sum_{i=0}^{n-1} y_i g_{ij} = 0 \qquad (k \leqq j < n) \tag{3.2a}$$

and

$$\sum_{i=0}^{n-1} y_i \chi_{ij} = y_j \qquad (n-k \leqq j < n), \tag{3.2b}$$

or, equivalently,

$$\begin{bmatrix} G_{n-k} \\ H_k \end{bmatrix} [y_0, \cdots, y_{n-1}]' = 0, \tag{3.2}$$

where $[y_0 \cdots y_{n-1}]'$ *is the transpose of vector* $[y_0 \cdots y_{n-1}]$ *and*

$$G_{n-k} = \begin{bmatrix} g_{0k} & \cdots & g_{n-1,k} \\ \vdots & & \vdots \\ g_{0,n-1} & \cdots & g_{n-1,n-1} \end{bmatrix}_{(n-k)\times n},$$

$$H_k = \begin{bmatrix} \chi_{0k} & \cdots & \chi_{n-1,k} \\ \vdots & & \vdots \\ \chi_{0,n-1} & \cdots & \chi_{n-1,n-1} \end{bmatrix} - \begin{bmatrix} 0 & \cdots & 1 & \cdots & 0 \\ \vdots & & \vdots & \ddots & \\ 0 & \cdots & 0 & 1 & \\ \vdots & & \vdots & & \ddots \\ 0 & \cdots & 0 & \cdots & 1 \end{bmatrix}.$$

Conversely, if $[r_0, \cdots, r_{n-1}]$ *is a nonzero solution of* (3.2), *then the function* y *given by* (2.7) *with* $y_i = r_i$ $(0 \leqq i < n)$ *is a nonzero function in* H *satisfying* $T_\rho y = 0$ *and has its first* n *Taylor coefficients given by* $y_i = r_i$ $(0 \leqq i < n)$.

Proof. From the above analysis, it follows that if y is nonzero in H such that $T_\rho y=0$, then y is given by (2.7), and $[y_0,\cdots,y_{n-1}]$ is nonzero satisfying (3.0a) and (3.0b); hence (3.2a) and (3.2b).

Conversely, let $y=\sum r_i\chi_i$. Observe that (A1) implies $a_0=a_1=\cdots=a_{k-1}=0$. By (3.1), $C(z)=z^kd(z)$, $C_i(z)=z^kd_i(z)$ $(0\leqq i<n)$, where $d(z)$, $d_i(z)$ are polynomials. Therefore, (2.9) becomes

$$z^k(d(z)\chi_i-d_i(z))=mg_i \qquad (0\leqq i<n).$$

Thus

$$g_{ij}=0 \quad \text{for } 0\leqq i<n, \quad 0\leqq j\leqq k-1. \tag{3.2c}$$

Hence (3.2a) is equivalent to (3.0a). So by (2.10) and (2.9) we have

$$C(z)y(z)-\sum_{i=0}^{n-1} r_iC_i(z)=\sum_{i=0}^{n-1} r_i(C\chi_i-C_i)=\sum_{i=0}^{n-1} r_img_i=z^nmg. \tag{3.2d}$$

Since (2.4) holds if and only if $T_\rho y=0$, it suffices to prove that the first n Taylor coefficients of y, namely, $y_0, y_1,\cdots,y_{n-1}$ coincide with $r_0, r_1,\cdots,r_{n-1}$. Applying $\Pi_n(0)$ to (3.2d) yields

$$\Pi_n(0)C(z)y(z)-\sum_{i=0}^{n-1} r_i\Pi_n(0)C_i(z)=0.$$

Notice that

$$\sum r_i\Pi_n(0)C_i(z)=\sum_{i=0}^{n-1} r_i[0\cdots 0, a_0,\cdots,a_{n-1-i}]$$
$$=A[r_0,\cdots,r_{n-1}]'$$

where

$$A=\begin{bmatrix} a_0 & & & 0\\ a_1 & \ddots & & \\ \vdots & \ddots & \ddots & \\ a_{n-1} & \cdots & a_1 & a_0\end{bmatrix}.$$

By (3.0) and (3.1) we obtain

$$A[y_0-r_0,\cdots,y_{n-1}-r_{n-1}]'=0. \tag{3.2e}$$

By (A1), $a_0=a_i=\cdots=a_{k-1}=0$ but $a_k\neq 0$. So by (3.2e), $y_i=r_i$ $(0\leqq i<n-k)$. But $y_i=r_i$ $(n-k\leqq i<n)$ is exactly (3.2b). Thus $y_i=r_i$ $(0\leqq i<n)$. This also shows that $y=0$ if and only if $[y_0,\cdots,y_{n-1}]=0$; therefore, y is nonzero. □

Remark 2. For $k=0$, Theorem 1 reduces to Proposition 3 in [2, § XII, 3]. For the $k>n$ we have $C(z)\equiv 0$ (see § 4 below). Of course in this case, Assumption (A1) is not satisfied, but we can nevertheless characterize ker T_ρ. Namely, now by (2.4) $T_\rho y=0$, $y\in H$, if and only if

$$\sum_{i=0}^{n-1} y_iC_i(z)=z^nm(z)g(z)$$

for some $g(z)\in H^2$. By (3.1), $C_i(z)=z^nd_i(z)$ $(0\leqq i<n)$, where $d_i(z)$ are polynomials of degree at most $n-1$. So we have

$$\sum_{i=0}^{n-1} y_id_i(z)=m(z)g(z). \tag{3.2f}$$

Now let $l(z)=\sum_{i=0}^{n-1} y_id_i(z)$. There are two situations.

(i) If $m(z)$ is a Blaschke product of degree at most $n-1$, namely,

$$m(z)=\prod_{i=1}^{s}\left(\frac{z-\alpha_i}{1-\bar{\alpha}_i z}\right)^{l_i}, \qquad l_1+\cdots+l_s \leqq n-1,$$

then y_i satisfying (3.2f) for some $g\in H^2$ if and only if y_i is a solution of the system

$$\text{(3.2g)} \qquad l^{(j)}(\alpha_i)=0 \qquad 1\leqq i\leqq s, \qquad 0\leqq j<l_i,$$

where $l^{(j)}(\alpha_i)$ means the jth derivative of $l(z)$ evaluated at α_i.

(ii) If $m(z)$ is not a Blaschke product of degree at most $n-1$, namely, either $m(z)$ has a singular part or $m(z)$ has more than $n-1$ roots in D; then (3.2f) is valid for some $g\in H^2$ if and only if $\sum y_i d_i(z)\equiv 0$, i.e.,

$$\text{(3.2h)} \qquad \sum_{i=0}^{n-1} a_{i,j+n}y_i=0 \qquad 0\leqq j<n,$$

where $a_{i,j+n}$ is given by (2.3c).

Notice that in both cases we do not assume $m(0)\neq 0$. Let us denote by Y_1 (respectively, Y_2) the set

$$\text{(3.2i)} \qquad \begin{aligned} Y_1 \text{ (respectively, } Y_2) = \{y\neq 0,\ Y\in H,\ y(z) &\text{ has its first} \\ n\text{-Taylor coefficients } &y_0,\cdots,y_{n-1} \\ \text{satisfying (3.2g)(respectively, (3.2h))}&\}. \end{aligned}$$

From the above discussion, we see that

$$\text{(3.2j)} \qquad \ker T_\rho := \{y\neq 0, y\in H, T_\rho y=0\} = Y_1 \text{ (respectively, } Y_2).$$

Next we consider another nongeneric case, namely, we make the assumption (A2):

$$\text{(A2)} \qquad C(0)\neq 0, \qquad \{z, C(z)=0\}\cap\{\sigma(T)\}=\{\alpha\}.$$

(Recall that by § 2, $\alpha\in D$.)

We need the following facts (for detail see [2, § X.1]).

LEMMA 3. *Let $m(z)$ be an inner function in H^∞ such that*

$$m(z)=\prod_{i=0}^{k}\left(\frac{z-\alpha_i}{1-\bar{\alpha}_i z}\right)^{l_i} m_1(z)=m_0(z)m_1(z), \quad \textit{and} \quad (m_0(z),m_1(z))=1.$$

Let

$$\sigma_{ij}=\left[\frac{(z-\alpha_i)^{l_i-j-1}}{(1-\bar{\alpha}_i z)^{l_i}}\right]\prod_{\substack{s=0\\ s\neq i}}^{k}\left(\frac{z-\alpha_s}{1-\bar{\alpha}_s z}\right)^{l_s} \qquad 0\leqq i\leqq k, \quad 0\leqq j<l_i.$$

Then

$$H(m)=H(m_1)\oplus m_1H(m_0)=H(m_1)\oplus m_i\left\{\sum_{ij} C_{ij}\sigma_{ij},\ C_{ij}\in\mathbb{C}\right\}.$$

Now assume (A2) holds. Let $m(z)=(z-\alpha)/(1-\bar{\alpha}z)^l m_1(z)$, with $m_1(\alpha)\neq 0$ by virtue of (A2), $l\geqq 1$. Let

$$\sigma_j=(z-\alpha)^{l-j-1} \qquad 0\leqq j<l.$$

By Lemma 3.2,

$$H=H(m)=H(m_1)\oplus\left\{\sum_{j=0}^{l-1}\beta_j\frac{m_1}{(1-\bar{\alpha}z)^l}\sigma_j,\ \beta_j\in\mathbb{C}\right\}=H_1\oplus H_0.$$

Let P_{H_i} be the corresponding projection P_{H_i}: $H^2\to H_i$, $i=0,1$.

Let y in H such that $T_\rho y = 0$. The idea is to decompose y into

$$y = P_{H_1}y + P_{H_0}y = P_{H_1}y + \frac{m_1(z)}{(1-\bar{\alpha}z)^l}\sum_{j=0}^{l-1}\beta_j\sigma_j, \tag{3.3}$$

and for $P_{H_1}y$ to apply the techniques in § 2. By (2.4), we have

$$C(z)y(z) - \sum_{i=0}^{n-1} C_i(z)y_i = z^n m_1(z)\left(\frac{z-\alpha}{1-\bar{\alpha}z}\right)^l g(z). \tag{3.4}$$

Since $\sigma(S(m_1)) = \{$zeros of m_1 in D and essential singularities of m_1 on $\partial D\}$, we have $\{z, C(z)=0\} \cap \sigma(S(m_1)) = \phi$ by virtue of (A2). Thus as for (2.5), there exists $C^{(-1)} \in H^\infty$ such that

$$C^{(-1)}C = 1 + m_1h_1. \tag{3.5}$$

Hence

$$\begin{aligned} y(z) - \sum_{i=0}^{n-1} C^{(-1)}C_iy_i &= m_1(z)\left[z^n\left(\frac{z-\alpha}{1-\bar{\alpha}z}\right)^l C^{(-1)}g(z) - h_1(z)y(z)\right] \\ &= m_1(z)h(z). \end{aligned} \tag{3.6}$$

Applying P_{H_1} to the previous equation yields

$$P_{H_1}y(z) = \sum_{i=0}^{n-1} y_iP_{H_1}(C^{(-1)}C_i)(z) = \sum_{i=0}^{n-1} y_i\chi_i, \tag{3.7a}$$

where $\chi_i \in H_1 = H(m_1)$. Substituting (3.7a) into (3.3), we obtain

$$y = \sum_{i=0}^{n-1} y_i\chi_i + \frac{m_1(z)}{(1-\bar{\alpha}z)^l}\sum_{j=0}^{l-1}\beta_j\sigma_j. \tag{3.7}$$

Substituting (3.7) into (3.4) and multiplying both sides by $(1-\bar{\alpha}z)^l$ gives

$$\begin{aligned} &m_1C(z)\left(\sum_{j=0}^{l-1}\beta_j\sigma_j\right) + (1-\bar{\sigma}z)^l\sum_{i=0}^{n-1}(C\chi_i - C_i)(z) \\ &= z^n(z-\alpha)^l m_1(z)g(z) \end{aligned} \tag{3.8}$$

as for (2.9), we have that there exists $g_i \in H^2$ such that

$$C\chi_i - C_i = m_1(z)g_i(z) \qquad (0 \leqq i < n). \tag{3.9}$$

Therefore, by combining (3.8) and (3.9), we have

$$C(z)\sum_{j=0}^{l-1}\beta_j\sigma_j + (1-\bar{\alpha}z)^l\sum_{i=0}^{n-1}y_ig_i = z^n(z-\alpha)^lg(z). \tag{3.10}$$

Let us define $\Pi_l(\alpha)C(z) = [a_0(\alpha), \cdots, a_{l-1}(\alpha)]$ and introduce the matrices $A(\alpha, l\times l, C(z))$ and $M(\alpha, s\times l, f_0, \cdots, f_{s-1})$, where $f_0, \cdots, f_{s-1} \in H^2$,

$$A(\alpha, l\times l, C(z)) = \begin{bmatrix} a_0(\alpha) & & 0 \\ a_1(\alpha) & \ddots & \\ \vdots & \ddots & \ddots \\ a_{l-1}(\alpha) & a_1(\alpha) & a_0(\alpha) \end{bmatrix},$$

$$M(\sigma, l\times s, f_0, \cdots, f_{s-1}) = \begin{bmatrix} \Pi_l(\alpha)f_0 \\ \Pi_l(\alpha)f_{s-1} \end{bmatrix}'.$$

Let $A=A(0, n\times n, C(\cdot))$, $N=M(0, n\times l, \sigma_0, \cdots, \sigma_{l-1})$, and

$$M=M(0, n\times n, (1-\bar{\alpha}z)^l g_0, \cdots, (1-\bar{\alpha}z)^l g_{n-1}).$$

Applying $\Pi_n(0)$ to (3.10) gives

$$\sum_{j=0}^{l-1} \beta_j A[\Pi_n(0)\sigma_j]' + M[y_0, \cdots, y_{n-1}]' = 0.$$

Observe that $\sum_{j=0}^{l-1} \beta_j[\Pi_n(0)\sigma_j]' = N[\beta_0, \cdots, \beta_{l-1}]'$; hence

$$AN[\beta_0, \cdots, \beta_{l-1}]' + M[y_0, \cdots, y_{n-1}]' = 0,$$

that is,

$$[AN, M][\beta_0, \cdots, \beta_{l-1}, y_0, \cdots, y_{n-1}]' = 0. \tag{3.10a}$$

Let $A_\alpha = A(\alpha, l\times l, C(z))$, $N_\alpha = M(\alpha, l\times l, \sigma_0, \cdots, \sigma_{l-1})$, $M_\alpha = M(\alpha, l\times n, (1-\bar{\alpha}z)^l g_0, \cdots, (1-\bar{\alpha}z)^l g_{n-1})$. Similarly, applying $\Pi_l(\alpha)$ to (3.10) produces

$$[A_\alpha N_\alpha, M_\alpha][\beta_0, \cdots, \beta_{l-1}, y_0, \cdots, y_{n-1}]' = 0. \tag{3.10b}$$

Finally, we get the singular system for the skew Toeplitz operator T_ρ,

$$\begin{bmatrix} AN & M \\ A_\alpha N_\alpha & M_\alpha \end{bmatrix} [\beta_0, \cdots, \beta_{l-1}, y_0, \cdots, y_{n-1}]' = 0. \tag{3.11}$$

Remark 4. For the more general case, namely,

$$C(0)\neq 0, \qquad \{z, C(z)=0\}\cap \sigma(T) = \{\alpha_0, \cdots, \alpha_k\},$$

let $m(z)$, σ_{ij} be as in Lemma 2. Let $B(z)=\prod_{i=0}^{k}(1-\bar{\alpha}_i z)^{l_i}$ and $\gamma_{ij}=B(z)\sigma_{ij}$. Obviously, γ_{ij} are polynomials. Reindex γ_{ij} to be $\gamma_0, \cdots, \gamma_{l-1}$; here $l=\sum_{i=0}^{k} l_i$. Let

$$N = M(0, n\times l, \gamma_0, \cdots, \gamma_{l-1}),$$
$$M = M(0, n\times n, B(z)g_0, \cdots, B(z)g_{n-1}),$$
$$N_i = M(\alpha_i, l_i\times l, \gamma_0, \cdots, \gamma_{l-1}),$$
$$M_i = M(\alpha_i, l_i\times n, B(z)g_0, \cdots, B(z)g_{n-1}),$$
$$A_i = A(\alpha_i, l_i\times l_i, C(z)) \qquad (0\leqq i\leqq k).$$

Then, similar to (3.11), we get the $(n+l)\times(n+l)$ matrix of the following form

$$\begin{bmatrix} AN & M \\ A_0N_0 & M_0 \\ \vdots & \vdots \\ A_iN_i & M_i \\ \vdots & \vdots \\ A_kN_k & M_k \end{bmatrix}.$$

For simplicity we shall present the details only for the case when assumption (A2) is valid. Then we are able to present our second theorem.

THEOREM 5. *Under the assumption* (*A*2), *if* $T_\rho y=0$ *for some nonzero function in* H, *then* y *is given by* (3.7), *where* $[\beta_0, \cdots, \beta_{l-1}, y_0, \cdots, y_{n-1}]$ *is a nonzero solution of* (3.11). *Conversely, if* $[\theta_0, \cdots, \theta_{l-1}, \delta_0, \cdots, \delta_{n-1}]$ *is a nonzero solution of* (3.11), *then the function* y *given by* (3.7) *with* $y_i=\delta_i$ $(0\leqq i<n)$ *and* $\beta_j=\theta_j$ $(0\leqq j<l)$ *is a nonzero function in* H *satisfying* $T_\rho y=0$ *and has its first n-Taylor coefficient given by* $y_i=\delta_i$ $(0\leqq i<n)$ (*hence the* β_j*'s in* (3.3) *equal the given* θ_j $(0\leqq j<l)$).

Proof. The first part easily follows from the above discussion. Conversely, if $[\theta_0, \cdots, \theta_{l-1}, \delta_0, \cdots, \delta_{n-1}]$ satisfying (3.11), then (3.10) and (3.8) with β_j and y_k replaced by θ_j and δ_k, respectively, $(0 \leqq j \leqq l-1, 0 \leqq k \leqq n-1)$ are valid with some $g \in H^2$. Introducing

$$y = \sum_{i=0}^{n-1} \delta_i \chi_i + \frac{m_1(z)}{(1-\bar{\alpha}z)^l} \sum_{j=0}^{l-1} \theta_j \alpha_j \tag{3.12}$$

yields

$$\begin{aligned} C(z)y(z) - \sum_{i=0}^{n-1} \delta_i C_i(z) &= z^n \left(\frac{z-\alpha}{1-\bar{\alpha}z}\right)^l m_1(z) g(z) \\ &= z^n m(z) g(z). \end{aligned} \tag{3.12a}$$

Again, like in the proof of Theorem 1, applying $\Pi_n(0)$ to (3.12) we obtain

$$A[y_0 - \delta_0, \cdots, y_{n-1} - \delta_{n-1}]' = 0,$$

but this time by (A2) $a_0 \neq 0$; this implies that A is invertible, hence $y_i = \delta_i$ $(0 \leqq i < n)$. Therefore, $P_{H_1} y = \sum_{i=0}^{n-1} y_i \chi_i = \sum_{i=0}^{n-1} \delta_i y_i$. This in turn shows y is given by (3.3) with $\beta_i = \theta_j$ $(0 \leqq j < l)$, and thus by (3.4), (3.12) implies $T_\rho y = 0$. By (3.7) and the fact that $H = H_1 \oplus H_0$, it is clear that y is a nonzero function in H if and only if $[\beta_0, \cdots, \beta_{l-1}, y_0, \cdots, y_{n-1}]$ is nonzero. This completes the proof. □

Following [3], [4] we shall call the systems (3.2) and (3.11) the singular systems associated to the skew Toeplitz operator T_ρ. Notice that in the more general case when we assume only $C(0) \neq 0$, the system (3.11) must be replaced with that given in the Remark 4.

4. The computation of singular systems. In the singular system (3.11) the matrices N and N_α are easy to compute. In order to complete the algorithm, we have to find the functions g_i $(0 \leqq i < n)$. To illustrate the idea clearly, we introduce the following properties:

(B1). $C(z)$ has a zero at 0 of order k $(k \leqq n)$, and other zeros of $C(z)$ are simple;

(B2). The zeros of $C(z)$ are simple, different from zero.

Condition (B2) is one of the genericity conditions in [3], [4]; the simplicity of the zeros is only a technical simplification there as well as here (see Remark 8 below). Also we notice that $C^\#(z) := z^{2n} C(1/\bar{z}) = C(z)$ since in (2.3b) $C_{jk} = \bar{C}_{kj}$ by (2.1); we have that under the condition (B2), $C(z)$ has $2n$ zeros $z_1, \cdots, z_p, z_{p+1}, \cdots, z_{2n-p}, 1/\bar{z}_1, \cdots, 1/\bar{z}_p$, $|z_i| < 1$ $(1 \leqq i \leqq p)$, and $|z_i| = 1$ $(p+1 \leqq i \leqq 2n-p)$. Under the condition (B1), notice that $C(z)$ is of degree $2n-k$, in addition to zero; $C(z)$ has $2n-2k$ zeros $z_1, \cdots, z_p, z_{p+1}, \cdots, z_{2n-2k-p}, 1/\bar{z}, \cdots, 1/\bar{z}_p$, $|z_i| < 1$ $(1 \leqq i \leqq p)$, and $|z_i| = 1$ $(p+1 \leqq i \leqq 2n-2k-p)$ (see [3], [4] for details).

PROPOSITION 6 (see [3], [2, § XII.3]). *Under the assumptions* (A2) *and* (B2), *the polynomials g_i (of degree at most $2n-1$) $(0 \leqq i < n)$ in* (3.9) *and in* (3.11) *are uniquely determined by the following $2n$ interpolation conditions*:

$$\begin{aligned} g_i(z_s) &= -\frac{C_i(z_s)}{m_1(z_s)} \qquad \begin{pmatrix} 0 \leqq i < n \\ 1 \leqq s \leqq 2n-p \end{pmatrix}, \\ g_i(1/\bar{z}_s) &= -\overline{m_1(z_s)} C_i\left(\frac{1}{\bar{z}_s}\right) \qquad \begin{pmatrix} 0 \leqq i < n \\ 1 \leqq s \leqq p \end{pmatrix}. \end{aligned} \tag{4.1}$$

For the next proposition, we need $\Pi_k(0) m(z) = [m_0 \cdots m_{k-1}]$.

PROPOSITION 7. *Under the assumptions* (A1) *and* (B1), *the polynomials* g_i (*of degree at most* $2n-1$) $(0\leqq i<n)$ *in* (2.9) *and in* (3.2) *are uniquely determined by the following* $2n$ *interpolation conditions*:

$$g_{ij}=0 \qquad (0\leqq i<n,\quad 0\leqq j<k), \tag{4.1a}$$

$$g_{ij}=-\sum_{s}^{2n-1-j}\bar{m}_s a_{i,j+s} \qquad (0\leqq i<n,\quad 2n-k\leqq j\leqq 2n-1), \tag{4.1b}$$

$$\begin{aligned} g_i(z_s)&=-\frac{C_i(z_s)}{m(z_s)} && (0\leqq i<n,\quad 1\leqq s\leqq 2n-2k-p),\\ g_i\left(\frac{1}{\bar{z}_s}\right)&=-\overline{m(z_s)}C_i\left(\frac{1}{\bar{z}_s}\right) && (0\leqq i<n,\quad 1\leqq s\leqq p). \end{aligned} \tag{4.1c}$$

Proof. (4.1a) is from (3.2c). For $z=e^{it}$, by multiplying (2.9) with $\bar{m}(e^{it})$, we get

$$g_i=C\bar{m}\chi_i-\bar{m}C_i \qquad (0\leqq i<n),$$

where $\bar{m}\chi_i\in K_0^2$ is the orthogonal of H^2 in L^2, since $\chi_i\in H=H(m)$. Also, since $C^{\#}(z)=z^{2n}\overline{C(1/\bar{z})}=C(z)=\sum_{j=0}^{2n}a_jz^j$, we have $a_{2n-i}=\bar{a}_i$ $(0\leqq i<n)$; so by (A1), $a_i=0$ $(0\leqq i<k)$ implies $a_{2n-i}=0$ $(0\leqq i<k)$. Thus $C(z)$ is a polynomial of degree $2n-k$. Since $C_i(z)$ is of degree at most $2n-1$, the coefficients of e^{imt} in the Fourier expansion of g_i are all zero for $m\geqq 2n$, and they come from $-\bar{m}C_i(e^{it})$ for $2n-k\leqq m\leqq 2n-1$. By direct computation we have (4.1b). For (4.1c) see [3] and Proposition 3.4 in [2, § XII.3]. The proof is complete. □

Remark 8. The assumption of simplicity for the zeros of $C(z)$ is not essential. Indeed, for instance if z_1 is a zero of multiplicity 2, then from (2.9) $C\chi_i-C_i=mg_i$ we have also that $C'\chi_i'+C\chi_i'-C_i'=m'g_i+mg_i'$, and thus we obtain the two interpolation conditions for g_i at $z=z_1$, namely,

$$g_i(z_1)=-\frac{C_i(z_1)}{m(z_1)}$$

and

$$\begin{aligned} g_i'(z_i)&=[-C_i'(z_1)-m'(z_1)C_i(z_1)]\frac{1}{m(z_1)}\\ &=-\left[-C_i'(z_1)-C_i(z_1)\frac{m'(z_1)}{m(z_1)}\right]\frac{1}{m(z_1)}, \end{aligned}$$

and similarly other two interpolation conditions for g_i at $1/\bar{z}_1$. The general case is handled in a similar way. For details see [3].

Also, by combining the techniques of Theorems 1 and 5, we can handle the most general case. This is the case when

$$\{z,\ C(z)=0\}\cap\sigma(T)=\{0,\alpha_1,\cdots,\alpha_s\}.$$

Remark 9. We would like to mention here a method for constructing $C^{(-1)}(z)$ and $h_1(z)$ in (2.5). More precisely, let $z_1\cdots z_p$ $(p\leqq 2n)$ denote the roots of C. Then

$$C^{(-1)}(z)=\frac{1-\chi(z)m(z)}{C(z)}, \qquad h_1(z)=-\chi(z),$$

where $\chi(z)$ is a polynomial obeying the following interpolation conditions

$$1-\chi(z_i)m(z_i)=0, \qquad 1\leqq i\leqq p.$$

Thus $P_{H(m)}C^{(-1)}(z)C_i(z)=P_H(1-\chi(z)m(z))C_i(z)/C(z)$ $(0\leqq i<n)$. For details see [1] and the references therein.

5. The algorithm. We can now summarize the above discussion and present the computational algorithm for H^∞ optimization.

First compute $\|W\|_\infty=\max\{|W(z)|, z\in D\}$ and $\|W\|_e=\max\{|W(z)|, z\in\sigma_e(T)=\sigma(T)\cap\partial D\}$. Then for any ρ such that $\|W\|_\infty\geqq\rho>\|W\|_e$, compute the zeros of the polynomial $C(z)$. ($C(z)$ is given by (2.3b) and (2.1), hence depending on ρ.)

Case 1. If (A) holds, then compute the Lagrange polynomials $g_0,\cdots,g_{n-1}$ determined by (3.14c) with $k=0$ and by Remark 8, and define (3.2) with $k=0$ accordingly. Retain ρ if (3.2) with $k=0$ has a nonzero solution, that is, if the $n\times n$ matrix $G_n=[g_{ij}]$ is singular. Denote the largest such ρ by ρ_1.

Case 2. If (A1) holds, then compute the $g_0,\cdots,g_{n-1}$ by (3.14a, b, c) and by Remark 8, compute $C^{(-1)}$ and $P_HC^{(-1)}C_i$ $(0\leqq i<n)$ by Remark 8, and hence get the system (3.2). Retain ρ if (3.2) has a nonzero solution. Denote the largest such ρ by ρ_2.

Case 3. If (A2) holds, then obtain $g_0,\cdots,g_{n-1}$ by (4.1) and Remark 8. Compute (3.11) accordingly. Retain ρ if the $(n+l)\times(n+l)$ matrix

$$\begin{bmatrix} AN & M \\ A_\alpha N_\alpha & M_\alpha \end{bmatrix}$$

is singular. Denote the largest such ρ by ρ_3.

Case 4. In all other cases, use Remarks 8 and 9, and adjust accordingly the computations from the previous cases. The largest ρ obtained is denoted by ρ_4.

If none of ρ_i $(1\leqq i\leqq 4)$ exists, then

$$\rho_0=\inf\{\|w-mq\|_\infty\, q\in H^\infty\}=\|w\|_e.$$

If some ρ_i exists, then $\rho_0=\max_{1\leqq i\leqq 4}\rho_i>\|w\|_e$. In this case, we also have [2], [10] q_{opt} is unique.

$$q_{\text{opt}}=\frac{(W(T)-w(z))x(z)}{m(z)x(z)},$$

where $x(z)=W(T)^*y(z)$ and $y(z)$ is any function in H corresponding to the singular value ρ_0, namely, $y(z)$ is given by (2.7) or (3.7) accordingly.

Next we will apply the algorithm to explicitly solve the weighted sensitivity minimization problem for the weight of the form

$$W(z)=\frac{\alpha z+\beta}{\gamma z+\delta},\qquad \alpha\delta-\beta\gamma\neq 0.$$

For background material and similar results by using different methods, see [3], [4], [5]-[7], [11].

$$\begin{aligned} T\rho&=(\gamma T+\delta)(\bar\gamma T^*+\bar\delta)-\frac{1}{\rho^2}(\alpha T+\beta)(\bar\alpha T^*+\bar\beta)\\ &=A+BT+\bar BT^*+CTT^*,\end{aligned}$$

where

$$A=|\delta|^2-\left(\frac{1}{\rho^2}\right)|\beta|^2,\quad B:=\left(\gamma\bar\delta-\left(\frac{1}{\rho^2}\right)\alpha\bar\beta\right),\quad C:=\left(|\gamma|^2-\left(\frac{1}{\rho^2}\right)|\alpha|^2\right).$$

$C(z)=Bz^2+Fz+\bar B$, where $F=A+C$, $C_0(z)=\bar B+Cz$. The zeros of $C(z)$ are $z_1, z_2=(-F\pm\sqrt{F^2-4|B|^2})/2B$. We always assume $|z_1|\leqq|z_2|$. Then $z_2=1/\bar z_1$ if $z_1\neq 0$.

Case 1. (A) holds. If $z_1 \neq z_2$ (that is, if $|F| \neq 2|B|$), then the system (3.2) with $k=0$, $n=1$ has nonzero solution if and only if

$$0 = g_0(0) = \frac{z_2}{z_1 - z_1}\frac{C_0(z_1)}{m(z_1)} + \frac{z_1}{z_2 - z_1}\overline{m(z_1)}C_0(z_2)$$
$$= -\frac{\bar{B}}{B(z_1 - z_2)m(z_1)(1 - |m(z_1)|^2)}\left(\frac{A-C}{2} + \frac{\sqrt{F^2 - 4|B|^2}}{2}\frac{1 + |m(z_1)|^2}{1 - |m(z_1)|^2}\right).$$

If $|F| = 2|B|$, then $z_1 = z_2 = -\text{sign}\,(F)(|B|/B)$, where

$$\text{sign}\, F = \begin{cases} 1 & F > 0, \\ -1 & F < 0. \end{cases}$$

Then the system (3.2) with $k=0$, $n=1$ has a nonzero solution if and only if

$$0 = g_0(0) = g_0(z_1) - g_0'(z_1)z_1$$
$$= -\frac{1}{m(z_1)}\left(C_0(z_1) - Cz_1 + C_0(z_1)z_1\frac{m'(z_1)}{m(z_1)}\right)$$
$$= -\frac{|B|^2}{B^2 m(z_1)}\left(B + (C - (\text{sign}\, F)|B|)\frac{m'(x_1)}{m(z_1)}\right)$$

Case 2. (A1) holds, i.e., $B=0$, $m(0) \neq 0$; hence $C(z) = Fz$, $C_0(z) = Cz = (C/F)C(z)$. So $\chi_0(z) = P_H C^{(-1)}(z)C_0(z) = (C/F)P_H C^{(-1)}(z)C(z) = (C/F)P_H 1 = (C/F)(1 - m(z)\overline{m(0)})$. The system (3.2) reduces to

$$y_0\left(\frac{C}{F}(1 - |\overline{m(0)}|^2) - 1\right) = 0,$$

or, equivalently, (for $y_0 \neq 0$)

$$A + C|m(0)|^2 = 0.$$

If $m(0) \neq 0$; $B=0$, $F=0$, i.e., $C(z) \equiv 0$ (for instance, for $w(z) = (\alpha z + \beta)/(z + \bar{\alpha}/\bar{\beta})$). If $\rho^2 = |\beta^2|$, then $C(z) \equiv 0$. For $w = \alpha z$, if $\rho^2 = |\alpha|^2$, then $C(z) \equiv 0$). Then by $F = A + C = 0$, $T_\rho = A(I - TT^*)$, and $T_\rho y = 0$ for $y \neq 0$ if and only if $(I - TT^*)y = 0$ (since $A = B = 0$ implies $\alpha\delta = \beta\gamma$). We know by [9] that $(I - TT^*) = u_* \otimes u_*$ is a rank one operator, where $u_* = (1 - m(z)\overline{m(0)})$. Therefore, ker T_ρ is the orthogonal of one-dimension space $\{cu_*, c \in \mathbb{C}\}$ in $H(m)$, which is always nonempty when dim $H(m)$ is greater than one.

Case 3. (A2) holds, i.e., $C(z) = Bz^2 + Fz + \bar{B} = B(z - z_1)(z - z_2)$, $0 \leqq |z_1| < 1$, $m(z) = ((z - z_1)/(1 - \bar{z}_1 z))^l m_1(z)$, with $m_1(z_i) \neq 0$ $(i = 1, 2)$. Then we have

$$\sigma_i = (z - z_i)^{l-i-1} \quad 0 \leqq i < l, \qquad A(0, 1 \times 1, C(z)) = \bar{B},$$
$$N = M(0, 1 \times h, \alpha_0, \cdots, \alpha_{i-1}) = [(-z_1)^{l-1}, \cdots, 1],$$

$$A_{z_1} = A(z_1, l \times l, C(z)) = \begin{bmatrix} 0 & & & & 0 \\ 2Bz_1 + Fz_1 & \ddots & & & \\ \bar{B} & \ddots & \ddots & & \\ \vdots & \ddots & \ddots & \ddots & \\ 0 & \cdots & B & 2Bz_1 + Fz_1 & 0 \end{bmatrix},$$

$$N_{z_1} = M(z_1, l \times l, \alpha_0, \cdots, \alpha_{l-1}) = \begin{bmatrix} & 0 & \cdots & 1 \\ & \vdots & 1 & \\ & \vdots & \cdot^{\cdot^{\cdot}} & \\ & 1 & 0 & \\ 1 & & & \end{bmatrix},$$

$$M=M(0,1\times 1,(1-\bar z_1 z)^l g_0(z))=g_0(0),$$

$$M_{z_1}=M(z_1,l\times 1,(1-\bar z_1 z)^l g_0(z))=\begin{bmatrix}(1-|z_1|^2)^l g_0(z_1)\\ * \\ \vdots \\ * \end{bmatrix},$$

where $g_0(z)$ is a polynomial of degree 1 given by (3.13); in particular, $g_0(z_1)=-C_0(z_1)/m_1(z_1)$. Therefore, the $(1\times l)\times(1\times l)$ matrix in system (3.11) is

$$\begin{bmatrix} B(-z_1)^{l-1} & ,\cdots, & & \bar B & g_0(0) \\ 0 & ,\cdots, & & 0 & (1-|z_1|^2)^l g_0(z_1) \\ \vdots & & & 2Bz_1+Fz_1 & * \\ \vdots & & \cdot^{\cdot^{\cdot}} & B & * \\ \vdots & & \cdot^{\cdot^{\cdot}} \quad \cdot^{\cdot^{\cdot}} & & \vdots \\ 0 & 2Bz_1+Fz_1 & B & 0 & * \end{bmatrix},$$

whose determinant equals to $\pm(1-|z_1|^2)^l z_1^{l-1}B(2Bz_1+Fz_1)^{l-1}g_0(z_1)$.

Notice by $0<|z_1|<1$, $2Bz_1+Fz_1\neq 0$ (since $2B+F=0$ implies $z_1=z_2$ but $|z_2|=|1/z_1|>1$); hence the system (3.11) has a nonzero solution if and only if $g_0(z_1)=0$, i.e., $C_0(z_1)=0$. So $z_1=-\bar B/C$, but

$$z_1=\frac{-F+\sqrt{F^2-4|B|^2}}{2B}\quad\text{when } F>0,\qquad z_1=\frac{-F-\sqrt{F^2-4|B|^2}}{2B}\quad\text{when } F<0.$$

In both cases we have $AC=|B|^2$, which is true if and only if

$$|\alpha\delta|^2=|\beta\gamma|^2=\bar\alpha\bar\delta\beta\gamma+\overline{\bar\alpha\bar\delta\beta\gamma}.$$

By simple algebraic manipulation, we obtain $\alpha\delta=\beta\gamma$. This is a contradiction.

Case 4. $B=0$, $F\neq 0$, $m(z)=z^l m_1(z)$ with $l\geqq 1$ and $m_1(0)\neq 0$. Then $C(z)=Fz$, $C_0(z)=Cz$ as in Case 2. For this case we have not written down an explicit singular system. As we mentioned in Remark 9, we have to invoke the techniques of Cases 2 and Case 3. The following shows how to do this in principle for the general weight.

Let y be such that $T_\rho y=0$. Observe that (3.7), (3.9), and (3.10) are still valid, namely, we have

$$(*)\qquad y=y_0\chi_0(z)+m_1(z)\sum_{j=0}^{l-1}\beta_j z^{l-j-1},$$

$$(**)\qquad Fz\sum_{j=0}^{l-1}\beta_j z^{l-j-1}+y_0 g_0(z)=z^{l+1}g(z)$$

for some $g(z)\in H^2$, where, by (3.9) and (3.14a, b), $g_0(z)$ is a polynomial of degree 1, $g_0(0)=0$, $g_0'(0)=-\overline{m_1(0)}\cdot C$. Therefore, by $(*)$ and $(**)$, $\beta_j=0$ $(0\leqq j\leqq l-2)$ and

$$F\beta_{l-1}+y_0 g_0'(0)=0,\qquad m_1(0)\beta_{l-1}+y_0(\chi_0(0)-1)=0,$$

where by (3.5) $C^{(-1)}(z)C(z)=1+m_1(z)h_1(z)$. So

$$\chi_0(z)=P_{H(m_1)}C^{(-1)}(z)C_0(z)=\frac{C}{F}P_{H(m_1)}1=\frac{C}{F}(1-m(z)\overline{m(0)}).$$

The above linear equation for (β_{l-1}, y_0) has a nonzero solution if and only if

$$\begin{vmatrix} F & g_0'(0) \\ m_1(0) & \chi_0(0)-1 \end{vmatrix} = A = 0,$$

which plus $B=0$ leads to $\alpha\delta = \gamma\beta$. This is again a contradiction.

In conclusion *for the weight of the form* $w(z)=(\partial z+\beta)/(\gamma z+\delta)$ *in Cases* 3 *and* 4, ker $T_\rho = \{0\}$.

Remark 10. In Case 4 there is a simpler way to show ker $T_\rho = 0$. Recall from [9] that $I - TT^* = 1 \otimes 1$, where 1 is the function with constant value 1; thus $T_\rho = A + CTT^* = A + C(I - 1\otimes 1)$, and for $y \neq 0$, $T_\rho y = 0$ if and only if

$$Fy(z) = C(1\otimes 1)\cdot y(z) = C(y(z), 1)\cdot 1.$$

So by $F \neq 0$, $(y(z), 1) \neq 0$, and $F(y(z), 1) = (Fy(z), 1) = C(y(z), 1)(1, 1)$, i.e., $F = C$, that is again $A = 0$, which is impossible as in Case 4.

ON THE ASYMPTOTICS OF THE JACOBI FUNCTION AND ITS ZEROS*

R. WONG† AND Q.-Q. WANG†

Abstract. Explicit and realistic error bounds are constructed for a one-term and a two-term asymptotic approximation of the Jacobi function $\varphi_\mu^{(\alpha,\beta)}(t)$ as $\mu \to \infty$, uniformly for $t \in (0, \infty)$. A similar result is obtained for the zeros $t_{\mu,k}$ of this function as $\mu \to \infty$, which holds uniformly with respect to unbounded k. Exponentially decaying error bounds are also given for asymptotic approximations of $\varphi_\mu^{(\alpha,\beta)}(t)$ as $t \to \infty$ and of $t_{\mu,k}$ as $k \to \infty$, which are uniform for $\mu \geqq \delta > 0$.

Key words. Jacobi function, uniform asymptotic approximations, error bounds, zeros

AMS(MOS) subject classifications. 33A30, 41A60

1. Introduction. Let α, β, and μ be real numbers with $\mu > 0$ and $\alpha \neq -1, -2, \cdots$. The Jacobi function is defined by

$$(1.1) \qquad \varphi_\mu^{(\alpha,\beta)}(t) = {}_2F_1[\tfrac{1}{2}(\alpha+\beta+1-i\mu), \tfrac{1}{2}(\alpha+\beta+1+i\mu);\ \alpha+1;\ -\sinh^2 t]$$

for $t > 0$, where ${}_2F_1(a, b; c; z)$ is the Gaussian hypergeometric function. This function plays an important role in the interactions of special functions and group theory, and for an excellent survey of this topic, we refer to Koornwinder [7].

The Jacobi polynomial $P_n^{(\alpha,\beta)}(x)$ can also be expressed in terms of the hypergeometric function [12, p. 63]

$$(1.2) \qquad \frac{\Gamma(\alpha+1)\Gamma(n+1)}{\Gamma(\alpha+n+1)} P_n^{(\alpha,\beta)}(x) = {}_2F_1\left[-n, n+\alpha+\beta+1;\ \alpha+1; \frac{1}{2}(1-x)\right],$$

and this formula furnishes the extension of the polynomial $P_n^{(\alpha,\beta)}(x)$ to arbitrary values of the degree n. From (1.1) and (1.2), it is evident that

$$(1.3) \qquad \varphi_\mu^{(\alpha,\beta)}(t) = \frac{\Gamma(\alpha+1)\Gamma(\frac{1}{2}(i\mu-\alpha-\beta+1))}{\Gamma(\frac{1}{2}(i\mu+\alpha-\beta+1))} P^{(\alpha,\beta)}_{\frac{1}{2}(i\mu-\alpha-\beta-1)}(\cosh 2t),$$

and for this reason, $\varphi_\mu^{(\alpha,\beta)}(t)$ is called the Jacobi function. This function is also related to the Legendre function [8, (12.05), p. 170]

$$(1.4) \qquad \begin{aligned} P_n^{-m}(z) &= 2^{-m}(z-1)^{m/2}(z+1)^{m/2} \\ &\quad \cdot {}_2F_1(m-n, m+n+1;\ m+1;\ \tfrac{1}{2}-\tfrac{1}{2}z)/\Gamma(\alpha+1), \end{aligned}$$

and the relationship is

$$(1.5) \qquad (\sinh t)^\alpha(\cosh t)^\alpha \varphi_{2\mu}^{(\alpha,\alpha)}(t) = \Gamma(\alpha+1)P^{-\alpha}_{-\frac{1}{2}+i\mu}(\cosh 2t).$$

Recently, asymptotic approximations, complete with error bounds, have been obtained for the Jacobi polynomial $P_n^{(\alpha,\beta)}(\cos\theta)$ as $n \to \infty$, which are uniformly valid for $0 \leqq \theta \leqq \pi/2$; see [4] and [2]. Corresponding results for the Legendre function $P_n^{-m}(\cosh z)$ as $n \to +\infty$, which are uniformly valid for $0 < z < \infty$, can also be found in [8, p. 466] and [10]. The purpose of this paper is to present similar results for the Jacobi function $\varphi_\mu^{(\alpha,\beta)}(t)$ as $\mu \to +\infty$, which is uniform with respect to t in $(0, \infty)$, and

† Department of Applied Mathematics, University of Manitoba, Winnipeg, Manitoba, Canada, R3T 2N2.

to use these results to obtain asymptotic approximations for the zeros $t_{\mu,k}$ of this function as $\mu\to\infty$, uniformly with respect to k. Asymptotic expansions of $\varphi_\mu^{(\alpha,\beta)}(t)$ have been given previously by Triméche [13] and Fitouhi and Hamza [3] using differential equation theory. Based on an integral representation of the Jacobi function, Schindler [9] (in the case when $\alpha=\beta$) and Stanton and Tomas [11] have derived asymptotic expansions of $\varphi_\mu^{(\alpha,\beta)}(t)$ as $t\to 0$, which is, in a sense, uniform with respect to μt. However, no error bounds were constructed for these expansions, and no study of the asymptotic behavior of the zeros $t_{\mu,k}$ was made in these investigations. In the present paper, we shall also use the differential equation approach, and our work relies heavily on the results of Olver [8, Chap. 12]. For completeness, we also include an asymptotic approximation of $\varphi_\mu^{(\alpha,\beta)}(t)$ as $t\to\infty$, which is uniform in $\mu\geqq\delta>0$, and a corresponding result for $t_{\mu,k}$ as $k\to\infty$. The problems studied in this paper have been suggested by R. A. Askey.

2. Differential equations. It is known that the Jacobi function $\varphi_\mu^{(\alpha,\beta)}(t)$ is the unique even C^∞-function on **R** which satisfies

$$\begin{aligned} &v''(t)+[(2\alpha+1)\coth t+(2\beta+1)\tanh t]v'(t)\\ &+[\mu^2+(\alpha+\beta+1)^2]v(t)=0 \end{aligned} \tag{2.1}$$

and $v(0)=1$; see [7, p. 2]. If we set

$$u(t)=(\sinh t)^{\alpha+\frac{1}{2}}(\cosh t)^{\beta+\frac{1}{2}}\varphi_\mu^{(\alpha,\beta)}(t), \tag{2.2}$$

then it is easily verified that

$$u''(t)+\left\{\mu^2+\frac{\frac{1}{4}-\alpha^2}{\sinh^2 t}-\frac{\frac{1}{4}-\beta^2}{\cosh^2 t}\right\}u(t)=0. \tag{2.3}$$

When $\alpha>-\frac{1}{2}$, we also have $u(0)=0$.

To apply the asymptotic theory of Olver [8, pp. 438-440], we shall restrict ourselves to the case $\alpha\geqq 0$ and introduce the new variables

$$\begin{aligned} &(-\zeta)^{\frac{1}{2}}=t, \qquad \zeta<0,\\ &W(\zeta)=(-\zeta)^{\frac{1}{4}}u(t). \end{aligned} \tag{2.4}$$

The transformed equation is given by

$$\frac{d^2W}{d\zeta^2}=\left\{\frac{\mu^2}{4\zeta}+\frac{\alpha^2-1}{4\zeta^2}+\frac{\psi(\zeta)}{\zeta}\right\}W(\zeta), \qquad \zeta<0, \tag{2.5}$$

where

$$\psi(\zeta)=\frac{1}{4}\left\{\frac{\frac{1}{4}-\alpha^2}{\zeta}+\left[\frac{\frac{1}{4}-\alpha^2}{\sinh^2(-\zeta)^{\frac{1}{2}}}-\frac{\frac{1}{4}-\beta^2}{\cosh^2(-\zeta)^{\frac{1}{2}}}\right]\right\}. \tag{2.6}$$

Note that $\psi(\zeta)$ is analytic at $\zeta=0$.

3. Asymptotic expansion. For negative ζ, Theorem 4.1 in [8, p. 444] gives two asymptotic solutions to (2.5), one involving the Bessel function $J_\alpha(\mu\sqrt{-\zeta})$ and the other involving $Y_\alpha(\mu\sqrt{-\zeta})$. To identify the function $(-\zeta)^{\frac{1}{4}}u(t)$ in (2.4) with one of these two solutions or a linear combination of them, we note that from (2.2) and (2.4) we have

$$(-\zeta)^{\frac{1}{4}}u(t)\sim(-\zeta)^{(\alpha+1)/2} \tag{3.1}$$

as $\zeta \to 0^-$. Since $J_\alpha(x) \sim (x/2)^\alpha/\Gamma(\alpha+1)$ for x near zero, it can be shown, as in [8, pp. 464 and 466], that

$$\begin{aligned}(3.2)\qquad &(\sinh t)^{\alpha+\frac{1}{2}}(\cosh t)^{\beta+\frac{1}{2}}\varphi_\mu^{(\alpha,\beta)}(t)\\ &= \frac{2^\alpha\Gamma(\alpha+1)}{\mu^\alpha}t^{-\frac{1}{2}}\left\{tJ_\alpha(\mu t)\sum_{s=0}^{n}\frac{A_s(-t^2)}{\mu^{2s}}\right.\\ &\qquad \left.-\frac{t^2}{\mu}J_{\alpha+1}(\mu t)\sum_{s=0}^{n-1}\frac{B_s(-t^2)}{\mu^{2s}}+\varepsilon_{2n+1,1}(\mu,-t^2)\right\}\end{aligned}$$

for $t>0$, where the coefficients $A_s(\zeta)$ and $B_s(\zeta)$ are analytic functions in a region containing $\zeta=0$, and are determined by the recursive formulas

$$(3.3)\qquad B_s(\zeta) = -A_s'(\zeta)+\frac{1}{(-\zeta)^{\frac{1}{2}}}\int_\zeta^0\left\{\psi(v)A_s(v)-\left(\alpha+\frac{1}{2}\right)A_s'(v)\right\}\frac{dv}{(-v)^{\frac{1}{2}}},$$

$$(3.4)\qquad A_{s+1}(\zeta) = \alpha B_s(\zeta)-\zeta B_s'(\zeta)+\int\psi(\zeta)B_s(\zeta)\,d\zeta,$$

with $A_0(\zeta)=1$. The remainder in (3.2) satisfies the estimate

$$\begin{aligned}(3.5)\qquad |\varepsilon_{2n+1,1}(\mu,\zeta)| &\leqq \lambda_3(\alpha)(-\zeta)^{\frac{1}{4}}E_\alpha^{-1}(\mu\sqrt{-\zeta})M_\alpha(\mu\sqrt{-\zeta})\\ &\quad\cdot\exp\left\{\frac{\lambda_2(\alpha)}{\mu}\mathcal{V}_{\zeta,0}(\sqrt{-\zeta}\,B_0)\right\}\frac{\mathcal{V}_{\zeta,0}(\sqrt{-\zeta}\,B_n)}{\mu^{2n+1}},\end{aligned}$$

where the modulus function $M_\alpha(x)$ and the weight function $E_\alpha(x)$ are defined in [8, Chap. 12, § 1.3], $E_\alpha^{-1}(x)=1/E_\alpha(x)$ and $\mathcal{V}_{a,b}(f)$ denotes the total variation of a function $f(x)$ on an interval (a, b). The constants $\lambda_2(\alpha)$ and $\lambda_3(\alpha)$ in (3.5) are given in [8, p. 443]. It is not easy to estimate or compute these constants; some properties and values of these constants can be found in the above mentioned reference.

Note that for each n, expansion (3.2) gives $(2n+1)$ terms, i.e., we always have an odd number of terms. By using the same argument as in [8, Chap. 12], it is possible to derive an expansion that yields an even number of terms, and the result is

$$\begin{aligned}(3.6)\qquad &(\sinh t)^{\alpha+\frac{1}{2}}(\cosh t)^{\beta+\frac{1}{2}}\varphi_\mu^{(\alpha,\beta)}(t)\\ &= \frac{2^\alpha\Gamma(\alpha+1)}{\mu^\alpha}t^{-\frac{1}{2}}\left\{tJ_\alpha(\mu t)\sum_{s=0}^{n-1}\frac{A_s(-t^2)}{\mu^{2s}}\right.\\ &\qquad \left.-\frac{t^2}{\mu}J_{\alpha+1}(\mu t)\sum_{s=0}^{n-1}\frac{B_s(-t^2)}{\mu^{2s}}+\varepsilon_{2n,1}(\mu,-t^2)\right\},\end{aligned}$$

where

$$\begin{aligned}(3.7)\qquad |\varepsilon_{2n,1}(\mu,-t^2)| &\leqq \bar\lambda_3(\alpha)tE_\alpha^{-1}(\mu t)M_\alpha(\mu t)\\ &\quad\cdot\exp\left\{\frac{\lambda_2(\alpha)}{\mu}\mathcal{V}_{0,t}(tB_0)\right\}\frac{\mathcal{V}_{0,t}(A_n)}{\mu^{2n}}\end{aligned}$$

and

$$(3.8)\qquad \bar\lambda_3(\alpha) = \sup_{x\in(0,\infty)}\{\pi xE_\alpha(x)M_\alpha(x)|J_{\alpha+1}(x)|\}.$$

The leading coefficients can be calculated explicitly. For convenience, we put

$$(3.9)\qquad A=\tfrac{1}{4}-\alpha^2,\qquad B=\tfrac{1}{4}-\beta^2.$$

Since $A_0(\zeta)=1$, it follows from (3.3) and (2.6) that

$$B_0(-t^2)=\frac{1}{2t}\int_0^t\{A(-s^{-2}+\operatorname{csch}^2 s)-B\operatorname{sech}^2 s\}\,ds;$$

accordingly,

$$B_0(-t^2)=\frac{1}{2t}\{A(t^{-1}-\coth t)-B\tanh t\}. \tag{3.10}$$

From (3.4), we also have

$$\begin{aligned}A_1(-t^2)=&\tfrac{1}{2}(\alpha+\tfrac{1}{2})t^{-1}\{A(t^{-1}-\coth t)-B\tanh t\}\\&+\tfrac{1}{4}\{A(t^{-2}-\operatorname{csch}^2 t)+B\operatorname{sech}^2 t\}\\&-\tfrac{1}{4}\{A^2(\tfrac{1}{2}t^{-2}-t^{-1}\coth t+\tfrac{1}{2}\operatorname{csch}^2 t)\\&\quad-ABt^{-1}\tanh t-\tfrac{1}{2}B^2\operatorname{sech}^2 t\}+C,\end{aligned} \tag{3.11}$$

where

$$C=\frac{\alpha}{2}\left(\frac{1}{3}A+B\right)-\frac{1}{8}(A^2+2AB+B^2) \tag{3.12}$$

is chosen so that $A_1(0)=0$, a condition needed in deriving (3.2).

4. Estimates for $\mathcal{V}_{0,t}(tB_0)$ and $\mathcal{V}_{0,t}(A_1)$. In order for the error bounds in (3.5) and (3.7) to be of any practical use, the total variations $\mathcal{V}_{0,t}(tB_n)$ and $\mathcal{V}_{0,t}(A_n)$ should be estimated. Here we illustrate only the cases involving B_0 and A_1. First we recall the property

$$\mathcal{V}_{a,b}(f)=\int_a^b|f'(t)|\,dt, \tag{4.1}$$

and observe the relation

$$\mathcal{V}_{\zeta,0}\{\sqrt{-\zeta}\,B_n(\zeta)\}=\mathcal{V}_{0,t}\{tB_n(-t^2)\}.$$

From (3.10), we have

$$\{tB_0(-t^2)\}'=\tfrac{1}{2}\{A(-t^{-2}+\operatorname{csch}^2 t)-B\operatorname{sech}^2 t\}.$$

Since $-t^{-2}+\operatorname{csch}^2 t$ is always negative, it follows from (4.1) that

$$\mathcal{V}_{0,t}(tB_0)\leqq\tfrac{1}{2}\{|A|(\coth t-t^{-1})+|B|\tanh t\}. \tag{4.2}$$

Consequently,

$$\mathcal{V}_{0,t}(tB_0)\leqq\mathcal{V}_{0,\infty}(tB_0)=\tfrac{1}{2}(|A|+|B|). \tag{4.3}$$

On the other hand, since both $t^{-1}\coth t-t^{-2}$ and $t^{-1}\tanh t$ are decreasing in the interval $0<t<\infty$, we have $0\leqq t^{-1}\coth t-t^{-2}\leqq\frac{1}{3}$ and $0\leqq t^{-1}\tanh t\leqq 1$. Hence (4.2) also gives

$$\mathcal{V}_{0,t}(tB_0)\leqq\frac{t}{6}(|A|+3|B|). \tag{4.4}$$

For large values of t, the bound in (4.3) is preferable since it is independent of t. For small values of t, (4.4) is a better estimate since the bound on the right-hand side decreases to zero with t.

Similarly, (3.11) (or (3.4) and (3.10)) gives

$$\{A_1(-t^2)\}' = \tfrac{1}{2}(\tfrac{1}{2}+\alpha)AT_1(t) + \tfrac{1}{4}\{2(\tfrac{1}{2}+\alpha)B - AB\}T_2(t) + \tfrac{1}{4}AT_3(t) + \tfrac{1}{4}A^2T_4(t) + \tfrac{1}{4}(2B+B^2)T_5(t),$$

where

$$T_1(t) = -2t^{-3} + t^{-2}\coth t + t^{-1}\operatorname{csch}^2 t,$$

$$T_2(t) = t^{-2}\tanh t - t^{-1}\operatorname{sech}^2 t,$$

$$T_3(t) = -2t^{-3} + 2\coth t\operatorname{csch}^2 t,$$

$$T_4(t) = t^{-3} - t^{-2}\coth t - t^{-1}\operatorname{csch}^2 t + \coth t\operatorname{csch}^2 \mathrm{t},$$

$$T_5(t) = -\tanh t\operatorname{sech}^2 t.$$

We now show that for each $i = 1, \cdots, 5$, the sign of $T_i(t)$ remains the same for $t \in (0, \infty)$. Clearly, $T_1(t)$ can be written as

$$T_1(t) = \frac{(-2\sinh^2 t + t\sinh t\cosh t + t^2)4}{4t^3\sinh^2 t},$$

and the numerator here is equal to

$$-2(e^{2t} - 2 + e^{-2t}) + t(e^{2t} - e^{-2t}) + (2t)^2.$$

By expanding e^{2t} and e^{-2t} into Maclaurin series and regrouping terms with equal exponents of t, it can be easily verified that this numerator has the power series expansion

$$\sum_{n=2}^{\infty} \frac{-4+2n}{(2n)!}(2t)^{2n},$$

from which it follows immediately that

$$T_1(t) > 0, \qquad t > 0.$$

In a similar manner, it can be proven that for $t > 0$,

$$T_2(t) > 0, \quad T_3(t) < 0, \quad T_4(t) < 0, \quad T_5(t) < 0.$$

Hence

$$\int_0^t |T_1(t)|\,dt = t^{-2} - t^{-1}\coth t + \tfrac{1}{3} \leqq \tfrac{1}{3},$$

$$\int_0^t |T_2(t)|\,dt = -t^{-1}\tanh t + 1 \leqq 1,$$

$$\int_0^t |T_3(t)|\,dt = -t^{-2} + \operatorname{csch}^2 t + \tfrac{1}{3} \leqq \tfrac{1}{3}, \tag{4.5}$$

$$\int_0^t |T_4(t)|\,dt = \tfrac{1}{2}t^{-2} - t^{-1}\coth t + \tfrac{1}{2}\operatorname{csch}^2 t + \tfrac{1}{2} \leqq \tfrac{1}{2},$$

$$\int_0^t |T_5(t)|\,dt = -\tfrac{1}{2}\operatorname{sech}^2 t + \tfrac{1}{2} \leqq \tfrac{1}{2}.$$

From (4.1), it follows that

$$\begin{aligned}\mathscr{V}_{0,t}(A_1) \leqq {} & \tfrac{1}{2}\left|\tfrac{1}{2}+\alpha\right||A|\{t^{-2}-t^{-1}\coth t+\tfrac{1}{3}\} \\ & +\tfrac{1}{4}|2(\tfrac{1}{2}+\alpha)B-AB|\{-t^{-1}\tanh t+1\} \\ & +\tfrac{1}{4}|A|\{-t^{-2}+\operatorname{csch}^2 t+\tfrac{1}{3}\} \\ & +\tfrac{1}{4}A^2\{\tfrac{1}{2}t^{-2}-t^{-1}\coth t+\tfrac{1}{2}\operatorname{csch}^2 t+\tfrac{1}{2}\} \\ & +\tfrac{1}{4}|2B+B^2|\{-\tfrac{1}{2}\operatorname{sech}^2 t+\tfrac{1}{2}\},\end{aligned} \tag{4.6}$$

and

$$\begin{aligned}\mathscr{V}_{0,t}(A_1) & \leqq \mathscr{V}_{0,\infty}(A_1) \\ & =\tfrac{1}{6}(\tfrac{1}{2}+\alpha)|A|+\tfrac{1}{12}|A|+\tfrac{1}{8}A^2 \\ & \quad +\tfrac{1}{4}|2(\tfrac{1}{2}+\alpha)B-AB|+\tfrac{1}{8}|2B+B^2|.\end{aligned} \tag{4.7}$$

It can also be shown that

$$\mathscr{V}_{0,t}(A_1) \leqq t^2 V(\alpha, \beta), \tag{4.8}$$

where

$$\begin{aligned}V(\alpha,\beta)= {} & \tfrac{1}{90}(\tfrac{1}{2}+\alpha)|A|+\tfrac{1}{12}|2(\tfrac{1}{2}+\alpha)B-AB| \\ & +\tfrac{1}{60}|A|+\tfrac{1}{72}A^2+\tfrac{1}{8}|2B+B^2|.\end{aligned} \tag{4.9}$$

To do this, we return to (4.5) and put

$$X_i(t)=\frac{1}{t^2}\int_0^t |T_i(t)|\,dt, \qquad i=1,\cdots,5.$$

By expressing the hyperbolic functions in terms of the exponential function, it can easily be shown that

$$\begin{aligned}X_1'(t)=\frac{t^{-5}}{(e^t-e^{-t})^2}\biggl\{ & -4(e^{2t}-2+e^{-2t})+3t(e^{2t}-e^{-2t}) \\ & +4t^2-\frac{2}{3}t^2(e^{2t}-2+e^{-2t})\biggr\}.\end{aligned}$$

We now apply the argument in § 4 used to show the signs of $T_i(t)$. This leads to a Maclaurin series expansion with all negative coefficients for the quantity inside the above curly bracket. Thus, $X_1(t)$ is a decreasing function in $(0,\infty)$. In a similar manner, it can be verified that for each $i=1,\cdots,5$, $X_i(t)$ is a nonnegative decreasing function in $(0,\infty)$. Furthermore, as $t\to 0^+$, we have

$$X_1(t)\to\tfrac{1}{45}, \qquad X_2(t)\to\tfrac{1}{3}, \qquad X_3(t)\to\tfrac{1}{15},$$

$$X_4(t)=X_1(t)+\tfrac{1}{2}X_3(t)\to\tfrac{1}{18}, \qquad X_5(t)\to\tfrac{1}{2}.$$

From (4.6), it follows that (4.8) is proved.

5. Zeros. The uniform expansions (3.2) and (3.6) can be used to determine the zeros of the Jacobi function $\varphi_\mu^{(\alpha,\beta)}(t)$, and the main tool in this regard is the following result stated in Hethcote [6].

THEOREM A. *In the interval* $[a-\rho, a+\rho]$, *suppose* $f(t)=g(t)+\varepsilon(t)$, *where* $f(t)$ *is continuous*, $g(t)$ *is differentiable*, $g(a)=0$, $m=\min|g'(t)|>0$, *and*

$$E=\max|\varepsilon(t)|<\min\{|g(a-\rho)|, |g(a+\rho)|\}. \tag{5.1}$$

Then there exists a zero c *of* $f(t)$ *in the interval such that* $|c-a|\leqq E/m$.

In (3.2) we now take $n=0$. This gives

$$\begin{aligned}&(\sinh t)^{\alpha+\frac{1}{2}}(\cosh t)^{\beta+\frac{1}{2}}\varphi_\mu^{(\alpha,\beta)}(t)\\ &\quad=\frac{2^\alpha\Gamma(\alpha+1)}{\mu^\alpha}\, t^{\frac{1}{2}}\{J_\alpha(\mu t)+t^{-1}\varepsilon_{1,1}(\mu, -t^2)\}.\end{aligned} \tag{5.2}$$

In terms of the phase function $\theta_\alpha(x)$ defined by

$$\begin{aligned}\theta_\alpha(x)&=-\tfrac{1}{4}\pi, \qquad 0<x\leqq X_\alpha,\\ \theta_\alpha(x)&=\tan^{-1}\left\{\frac{Y_\alpha(x)}{J_\alpha(x)}\right\}, \qquad x\geqq X_\alpha,\end{aligned} \tag{5.3}$$

where X_α denotes the smallest positive root of the equation $J_\alpha(x)+Y_\alpha(x)=0$ and the branch of the inverse tangent is chosen to make $\theta_\alpha(x)$ continuous, the Bessel function can be expressed as

$$J_\alpha(x)=E_\alpha^{-1}(x)M_\alpha(x)\cos\theta_\alpha(x). \tag{5.4}$$

It is known that

$$\theta_\alpha'(x)=\frac{2}{\pi x M_\alpha^2(x)}, \qquad x>X_\alpha, \tag{5.5}$$

and

$$\theta_\alpha(j_{\alpha,s})=(s-\tfrac{1}{2})\pi, \qquad \theta_\alpha(y_{\alpha,s})=(s-1)\pi, \tag{5.6}$$

where $j_{\alpha,s}$ and $y_{\alpha,s}$ are the sth positive zero of $J_\alpha(x)$ and $Y_\alpha(x)$; see [8, p. 437]. To apply the above theorem to (5.2), we take

$$\begin{aligned}f(t)=&\frac{\mu^\alpha}{2^\alpha\Gamma(\alpha+1)}\, t^{-\frac{1}{2}}(\sinh t)^{\alpha+\frac{1}{2}}(\cosh t)^{\beta+\frac{1}{2}}\\ &\cdot E_\alpha(\mu t)M_\alpha^{-1}(\mu t)\varphi_\mu^{(\alpha,\beta)}(t),\end{aligned} \tag{5.7}$$

$$g(t)=\cos\theta_\alpha(\mu t), \tag{5.8}$$

$$\varepsilon(t)=t^{-1}E_\alpha(\mu t)M_\alpha^{-1}(\mu t)\varepsilon_{1,1}(\mu, -t^2). \tag{5.9}$$

From (3.5) with $(-\zeta)^{\frac{1}{2}}=t$ (see (2.4)), it follows that

$$|\varepsilon(t)|\leqq\lambda_3(\alpha)\exp\left\{\frac{\lambda_2(\alpha)}{\mu}\mathcal{V}_{0,t}[tB_0(-t^2)]\right\}\frac{\mathcal{V}_{0,t}[tB_0(-t^2)]}{\mu}, \tag{5.10}$$

which, coupled with (4.3), yields

$$|\varepsilon(t)|\leqq\frac{\lambda_3(\alpha)(|A|+|B|)}{2\mu}\exp\left\{\frac{\lambda_2(\alpha)(|A|+|B|)}{2\mu}\right\}. \tag{5.11}$$

In view of (4.4), the estimate (5.10) also gives

$$|\varepsilon(t)|\leqq\lambda_3(\alpha)\exp\left\{\frac{\lambda_2(\alpha)(|A|+|B|)}{2\mu}\right\}\frac{(|A|+3|B|)}{6}\frac{t}{\mu}. \tag{5.12}$$

Differentiation and use of (5.5) give

$$g'(t) = -\frac{2\mu \sin \theta_\alpha(\mu t)}{\pi \mu t M_\alpha^2(\mu t)}, \qquad \mu t > X_\alpha. \tag{5.13}$$

Since $\lambda_2(\alpha) \geqq \pi x M_\alpha^2(x)$ (see [8, p. 443]), we have

$$|g'(t)| \geqq \frac{2\mu |\sin \theta_\alpha(\mu t)|}{\lambda_2(\alpha)}, \qquad \mu t \geqq X_\alpha. \tag{5.14}$$

According to (5.6), the sth zero of $g(t)$ is $a_s = j_{\alpha,s}/\mu$ and $\sin \theta_\alpha(j_{\alpha,s}) = \pm 1$. We now choose $\rho_s = \mu^{-\frac{3}{2}}$ with μ being sufficiently large so that

$$|\sin \theta_\alpha(\mu t)| \geqq |\sin \theta_\alpha(j_{\alpha,s} \pm \mu^{-\frac{1}{2}})| \geqq \tfrac{1}{2} \tag{5.15}$$

for $a_s - \rho_s \leqq t \leqq a_s + \rho_s$. (Note that by (5.5), $\theta_\alpha(x)$ is an increasing function for $x > X_\alpha$.) Coupling (5.14) and (5.15) gives

$$m = \min |g'(t)| \geqq \frac{\mu}{\lambda_2(\alpha)} > 0, \tag{5.16}$$

the minimum being taken over the interval $[a_s - \rho_s, a_s + \rho_s]$. To verify that condition (5.1) holds, we observe from (5.11) that

$$E = \max |\varepsilon(t)| \leqq \frac{e\lambda_3(\alpha)(|A| + |B|)}{2\mu}, \tag{5.17}$$

if we choose

$$\mu \geqq \tfrac{1}{2}\lambda_2(\alpha)(|A| + |B|). \tag{5.18}$$

From (5.12), we also have

$$E = \max |\varepsilon(t)| \leqq \frac{e\lambda_3(\alpha)(|A| + 3|B|)}{6\mu}\left(\frac{j_{\alpha,s}}{\mu} + \mu^{-\frac{3}{2}}\right),$$

which of course implies

$$E \leqq 0.5473 \lambda_3(\alpha)(|A| + 3|B|)\frac{j_{\alpha,s}}{\mu^2}, \tag{5.19}$$

if (5.18) holds and $\mu \geqq 4$. Here we have made use of the fact that $j_{\alpha,s} \geqq j_{0,1} = 2.40482$ for $\alpha \geqq 0$ and $s \geqq 1$.

On the other hand, since $g(a_s) = 0$ by (5.6), we have

$$g(a_s \pm \rho_s) = \pm g'(\xi_\pm)\rho_s,$$

where $a_s < \xi_+ < a_s + \rho_s$ and $a_s - \rho_s < \xi_- < a_s$. From (5.14) and (5.15) it follows that

$$|g(a_s \pm \rho_s)| \geqq \frac{1}{\lambda_2(\alpha)} \mu^{-\frac{1}{2}}. \tag{5.20}$$

Thus, in view of (5.17), condition (5.1) holds if

$$\mu^{\frac{1}{2}} \geq \frac{e}{2} \lambda_2(\alpha)\lambda_3(\alpha)(|A| + |B|). \tag{5.21}$$

By Theorem A, (5.16), and (5.21), the Jacobi function $\varphi_\mu^{(\alpha,\beta)}(t)$ has a zero $t_{\mu,s}$ satisfying

$$\left| t_{\mu,s} - \frac{j_{\alpha,s}}{\mu} \right| \leqq \frac{e\lambda_2(\alpha)\lambda_3(\alpha)(|A| + |B|)}{2\mu^2}, \tag{5.22}$$

if (5.18) and the second inequality in (5.15) hold. On the other hand, from (5.16) and (5.19), we also have

$$(5.23)\qquad \left|t_{\mu,s}-\frac{j_{\alpha,s}}{\mu}\right| \leqq 0.5473\lambda_2(\alpha)\lambda_3(\alpha)(|A|+3|B|)\frac{j_{\alpha,s}}{\mu^3},$$

if, in addition, (5.21) holds.

Note that since X_α is a zero of $J_\alpha(x)+Y_\alpha(x)$, from (4.3) in [8, p. 443] we have $\lambda_3(\alpha) \geqq \pi X_\alpha M_\alpha^2(X_\alpha)/\sqrt{2}$. Furthermore, since $xM_\alpha^2(x) \geqq 2/\pi$ if $\alpha \geqq \frac{1}{2}$ (see [15, pp. 446 and 447]), it follows that $\lambda_3(\alpha) \geqq \sqrt{2}$. From the integral representation of $J_\alpha^2(x)+Y_\alpha^2(x)$ in [15, p. 444], it is readily seen that $M_\alpha^2(x)$ is an increasing function of α. If $0 \leqq \alpha \leqq \frac{1}{2}$, then $xM_\alpha^2(x)$ is also an increasing function of x; see [15, p. 446]. Since X_α is increasing in α (see [15, p. 508]), $X_\alpha M_\alpha^2(X_\alpha) \geqq X_\alpha M_0^2(X_\alpha) \geqq X_0 M_0^2(X_0)$. Using $X_0 = 0.23$ (see [8, p. 438]), the last quantity is easily computed to be greater or equal to 0.93. Consequently, in both cases, $0 \leqq \alpha \leqq \frac{1}{2}$ and $\alpha \geqq \frac{1}{2}$, we have $\lambda_3(\alpha) \geqq e^{-1}$. Thus, condition (5.18) is included in condition (5.21) for $\mu \geqq 1$.

The condition in the second inequality of (5.15) can also be made more explicit. In view of (5.6), the Mean Value Theorem gives

$$(5.24)\qquad \sin\theta_\alpha(j_{\alpha,s}+\mu^{-\frac{1}{2}}) = \pm 1 + \cos\theta_\alpha(j_{\alpha,s}+\xi)\theta'_\alpha(j_{\alpha,s}+\xi)\mu^{-\frac{1}{2}}$$

for some $0<\xi<\mu^{-\frac{1}{2}}$. Since $j_{\alpha,s}+\xi > X_\alpha$ and $xM_\alpha^2(x) \geqq 2/\pi$ if $\alpha \geqq \frac{1}{2}$, we have, from (5.5), $|\theta'_\alpha(j_{\alpha,s}+\xi)| \leqq 1$ if $\alpha \geqq \frac{1}{2}$. For $0 \leqq \alpha \leqq \frac{1}{2}$, we can repeat an earlier argument (in the previous paragraph) to show that $xM_\alpha^2(x) \geqq X_0 M_\alpha^2(X_0) \geqq 0.93$ for all $x \geqq X_\alpha$. Thus from (5.5) we have $|\theta'_\alpha(j_{\alpha,s}+\xi)| \leqq 0.685$ if $0 \leqq \alpha \leqq \frac{1}{2}$. In both cases, we conclude

$$(5.25)\qquad |\sin\theta_\alpha(j_{\alpha,s}+\mu^{-\frac{1}{2}})| \geqq 1-\mu^{-\frac{1}{2}}.$$

Therefore, (5.15) holds if $\mu^{1/2} \geqq 2$. Summarizing the above results gives the following theorem.

THEOREM 1. *If* $\mu^{\frac{1}{2}} \geqq \max\{2, e\lambda_2(\alpha)\lambda_3(\alpha)(|A|+|B|)/2\}$, *then the zeros* $t_{\mu,s}$ *of the Jacobi function* $\varphi_\mu^{(\alpha,\beta)}$ *satisfy the uniform asymptotic estimates* (5.22) *and* (5.23).

Note that both results (5.22) and (5.23) are needed, since the quantity $j_{\alpha,s}/\mu$ may tend to zero or infinity.

To show that the error estimates in (5.22) and (5.23) are of the correct order, we recall a result given in [8, p. 453, Ex. 7.2], which states that the sth negative zero of the solution in (4.05) of that reference is given by

$$(5.26)\qquad \zeta = -\eta_s + \frac{2\eta_s B_0(-\eta_s)}{\mu^2} + \eta_s^{\frac{1}{2}} O(\mu^{-3}), \qquad \mu \to \infty,$$

uniformly with respect to unbounded s, where $\eta_s = j_{\alpha,s}^2/\mu^2$. Since $t=(-\zeta)^{\frac{1}{2}}$ by (2.4), it is readily seen that

$$(5.27)\qquad \begin{aligned} t_{\mu,s} = \gamma_s - \frac{\gamma_s B_0(-\gamma_s^2)}{\mu^2} &+ \gamma_s B_0^2(-\gamma_s^2) O(\mu^{-4}) \\ &+ B_0(-\gamma_s^2) O(\mu^{-5}) + O(\mu^{-3}), \qquad \mu \to \infty, \end{aligned}$$

uniformly with respect to s, where $\gamma_s = j_{\alpha,s}/\mu$. By the argument used for (4.4), it is easily shown that

$$(5.28)\qquad |B_0(-t^2)| \leqq \tfrac{1}{6}(|A|+3|B|).$$

Hence (5.27) gives

$$(5.29)\qquad t_{\mu,s} = \gamma_s - \frac{\gamma_s B_0(-\gamma_s^2)}{\mu^2} + \gamma_s O(\mu^{-4}) + O(\mu^{-3}).$$

Using the same argument as for (4.3), we also have from (3.10),

$$|tB_0(-t^2)| \leqq \tfrac{1}{2}(|A|+|B|), \qquad t>0. \tag{5.30}$$

In view of (5.28) and (5.30), it is now clear from the second term in (5.29) that the error estimates for the one-term approximation (5.22), (5.23) are of the right asymptotic order.

By using similar arguments as above, error bounds have been constructed for the two-term expansion (5.29). The details are, however, much more complicated, and can be found in [14]. For this case, use has also been made of the results (4.7) and (4.8).

6. Large-*t* behavior. Turning our attention to the asymptotic behavior of $\varphi_\mu^{(\alpha,\beta)}(t)$ as $t \to \infty$, we first recall the following Liouville-Green approximation. Let $f(t)$ be a real, positive, twice continuously differentiable function on a finite or infinite interval (a_1, a_2), and let $g(t)$ be a continuous real or complex function on (a_1, a_2). Theorem 2.2 in [8, p. 196] states that the differential equation

$$\frac{d^2u}{dt^2}+\{f(t)-g(t)\}u=0 \tag{6.1}$$

has two linearly independent, twice continuously differentiable solutions

$$u_1(t)=f^{-\frac{1}{4}}(t)\exp\left\{i\int f^{\frac{1}{2}}(t)\,dt\right\}\{1+\varepsilon_1(t)\}, \tag{6.2}$$

$$u_2(t)=f^{-\frac{1}{4}}(t)\exp\left\{-i\int f^{\frac{1}{2}}(t)\,dt\right\}\{1+\varepsilon_2(t)\}, \tag{6.3}$$

such that

$$|\varepsilon_j(t)| \leqq \exp\{\mathcal{V}_{a,t}(F)\}-1, \qquad j=1,2, \tag{6.4}$$

where a is an arbitrary point in the closure of (a_1, a_2), and

$$F(t)=\int\left\{\frac{1}{f^{\frac{1}{4}}}\frac{d^2}{dt^2}\left(\frac{1}{f^{\frac{1}{4}}}\right)-\frac{g}{f^{\frac{1}{2}}}\right\}dt. \tag{6.5}$$

To apply this result to (2.3), we take $a=\infty$, $f(t)=\mu^2$, and

$$g(t)=-\frac{\frac{1}{4}-\alpha^2}{\sinh^2 t}+\frac{\frac{1}{4}-\beta^2}{\cosh^2 t},$$

and get the two linearly independent solutions

$$u_1(t)=\mu^{-\frac{1}{2}}\,e^{i\mu t}\{1+\varepsilon_1(t)\}, \tag{6.6}$$

$$u_2(t)=\mu^{-\frac{1}{2}}\,e^{-i\mu t}\{1+\varepsilon_2(t)\}, \tag{6.7}$$

with $|\varepsilon_j(t)| \leqq \exp\{\mathcal{V}_{t,\infty}(F)\}-1$. By (6.5),

$$F(t)=\frac{1}{\mu}\int\left\{\frac{\frac{1}{4}-\alpha^2}{\sinh^2 t}-\frac{\frac{1}{4}-\beta^2}{\cosh^2 t}\right\}dt,$$

from which it follows that

$$\begin{aligned}\int_t^\infty |F'(t)|\,dt &\leqq \frac{1}{\mu}\left\{|A|\int_t^\infty \operatorname{csch}^2 t\,dt+|B|\int_t^\infty \operatorname{sech}^2 t\,dt\right\}\\ &\leqq \frac{1}{\mu}\{|A|(\coth t-1)+|B|(1-\tanh t)\}.\end{aligned}$$

Simple estimation gives

$$\mathscr{V}_{t,\infty}(F) \leqq \frac{1}{\mu}\{4|A|\, e^{-2t}+2|B|\, e^{-2t}\}$$

for $t \geqq \frac{1}{2}$. Thus the error terms in (6.6) and (6.7) satisfy

$$|\varepsilon_j(t)| \leqq \exp\left\{\frac{1}{\mu}(4|A|+2|B|)\, e^{-2t}\right\}-1, \qquad j=1,2, \tag{6.8}$$

for $t \geqq \frac{1}{2}$. The general solution $\tilde{u}(t)$ of (2.3) is a linear combination of the two solutions $u_1(t)$ and $u_2(t)$ given in (6.6) and (6.7). Hence

$$\tilde{u}(t)=\frac{1}{\mu^{\frac{1}{2}}}\{c_1\, e^{i\mu t}+c_2\, e^{-i\mu t}+\tilde{\varepsilon}(t)\}, \tag{6.9}$$

where c_1 and c_2 are arbitrary constants and $\tilde{\varepsilon}(t)$ satisfies

$$|\tilde{\varepsilon}(t)| \leqq (|c_1|+|c_2|)\left\{\exp\left[\frac{1}{\mu}(4|A|+2|B|)\, e^{-2t}\right]-1\right\} \tag{6.10}$$

for $t \geqq \frac{1}{2}$. Note that $\tilde{\varepsilon}(t)=O(e^{-2t})$ as $t \to \infty$. Consequently,

$$\tilde{u}(t)=\frac{1}{\mu^{\frac{1}{2}}}\{c_1\, e^{i\mu t}+c_2\, e^{-i\mu t}+O(e^{-2t})\} \tag{6.11}$$

as $t \to \infty$. Let $u(t)$ be the function defined by (2.2), i.e.,

$$u(t)=(\sinh t)^{\alpha+\frac{1}{2}}(\cosh t)^{\beta+\frac{1}{2}}\varphi_\mu^{(\alpha,\beta)}(t). \tag{6.12}$$

From (1.1) and the connection formula (10.16) in [8, p. 167], it can be shown that

$$u(t)=\Gamma(\alpha+1)\{\Lambda(\mu)\, e^{i\mu t}+\overline{\Lambda(\mu)}\, e^{-i\mu t}+O(e^{-2t})\} \tag{6.13}$$

as $t \to \infty$, where

$$\Lambda_\mu \equiv \Lambda_{\alpha,\beta}(\mu) \equiv \frac{\Gamma(i\mu)2^{-i\mu}}{\Gamma[\frac{1}{2}(\alpha+\beta+1+i\mu)]\Gamma[\frac{1}{2}(\alpha-\beta+1+i\mu)]} \tag{6.14}$$

and the bar in (6.13) denotes the complex conjugate; cf. [7, eqns. (2.17) and (2.18)]. Comparing (6.11) and (6.13), we conclude that $u(t)=\tilde{u}(t)$ if we choose

$$c_1=\Gamma(\alpha+1)\mu^{\frac{1}{2}}\Lambda(\mu), \qquad c_2=\Gamma(\alpha+1)\mu^{\frac{1}{2}}\overline{\Lambda(\mu)},$$

and, consequently, we obtain from (6.6) and (6.7).

$$u(t)=2\Gamma(\alpha+1)|\Lambda(\mu)|\{\cos(\mu t+\theta_\mu)+\varepsilon^*(t)\}, \tag{6.15}$$

where $\theta_\mu=\theta_\mu(\alpha,\beta)$ denotes the argument of $\Lambda(\mu)$, i.e.,

$$\Lambda(\mu)=|\Lambda(\mu)|\, e^{i\theta_\mu}$$

and

$$|\varepsilon^*(t)| \leqq \exp\left\{\frac{1}{\mu}(4|A|+2|B|)\, e^{-2t}\right\}-1. \tag{6.16}$$

Note that the error term $\varepsilon^*(t)$ is exponentially decaying in t. Indeed, we have

$$\varepsilon^*(t)=O(e^{-2t}) \tag{6.17}$$

as $t \to \infty$. Direct computation from (6.14) shows that $\theta_\mu(\frac{1}{2},\frac{1}{2})=\theta_\mu(\frac{1}{2},-\frac{1}{2})=-\pi/2$ and $\theta_\mu(-\frac{1}{2},\frac{1}{2})=\theta(-\frac{1}{2},-\frac{1}{2})=0$.

To derive an asymptotic formula for the zeros $t_{\mu,s}$ for large values of s, we will make use of the following corollary of Theorem A stated in [5].

THEOREM B. *In the interval* $[n\pi - \psi - \rho, n\pi - \psi + \rho]$, *where* $\rho < \pi/2$, *suppose* $f(t) = \sin(t+\psi) + \varepsilon(t)$, $f(t)$ *is continuous, and* $E = \max|\varepsilon(t)| < \sin\rho$. *Then there exists a zero* c *of* $f(t)$ *in the interval such that* $|c - (n\pi - \psi)| \leqq E\rho \csc\rho$.

To apply this result, we rewrite (6.15) in the form

$$u(t) = 2\Gamma(\alpha+1)|\Lambda(\mu)|\left\{\sin\left(\mu t + \theta_\mu + \frac{\pi}{2}\right) + \varepsilon^*(t)\right\}, \tag{6.18}$$

and we take $\psi = \theta_\mu + \pi/2$ and $\rho = \pi/4$. For t satisfying $s\pi - \theta_\mu - \frac{3}{4}\pi \leqq \mu t \leqq s\pi - \theta_\mu - \pi/4$, we have from (6.16),

$$|\varepsilon^*(t)| \leqq \exp\left\{\frac{1}{\mu}(4|A|+2|B|)\, e^{-2(s\pi - \theta_\mu - \frac{3}{4}\pi)/\mu}\right\} - 1. \tag{6.19}$$

Note that if $A = B = 0$, then $\varepsilon^*(t) = 0$; cf. [7, eqn. (2.11)]. Since $2 > 1/\ln(1+1/\sqrt{2})$, to have the right-hand side of (6.19) bounded by $\sin(\pi/4) = 1/\sqrt{2}$, we require

$$\left(s\pi - \theta_\mu - \frac{3}{4}\pi\right) \geqq \frac{\mu}{2}\ln\left\{\frac{2}{\mu}(4|A|+2|B|)\right\}. \tag{6.20}$$

Furthermore, since $e^x - 1 \leqq xe^x$, coupling (6.19) and (6.20) gives

$$E = \max|\varepsilon^*(t)| \leqq 1.7072(4|A|+2|B|)\, e^{-2(s\pi - \theta_\mu - \frac{3}{4}\pi)/\mu}\frac{1}{\mu}. \tag{6.21}$$

From Theorem B, it follows that $u(t)$ has a zero $t_{\mu,s}$ such that

$$\left|t_{\mu,s} - \left(s\pi - \theta_\mu - \frac{\pi}{2}\right)\frac{1}{\mu}\right| \leqq 1.8963(4|A|+2|B|)\, e^{-2(s\pi - \theta_\mu - \frac{3}{4}\pi)/\mu}\frac{1}{\mu^2}. \tag{6.22}$$

for all integers s satisfying (6.20). In particular, we have

$$t_{\mu,s} = \left(s\pi - \theta_\mu - \frac{\pi}{2}\right)\frac{1}{\mu} + O(e^{-2\pi s/\mu}) \tag{6.23}$$

as $s \to \infty$. Note that (6.23) agrees with the exact results: $t_{\mu,s} = s\pi/\mu$ when $\alpha = \beta = \frac{1}{2}$, and $t_{\mu,s} = (s - \frac{1}{2})\pi/\mu$ when $\alpha = \beta = -\frac{1}{2}$.

Acknowledgments. The authors would like to thank the referees for a careful reading of this paper and several helpful suggestions, and they are also grateful to one of the referees for pointing out an error in an earlier version.
